0.1 Software version information for external equipment

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SW_NAME_0	V/O	0…FFh	0…255	1	-
SW version information part for 0 byte (Bit 0…15)					
SW_NAME_1	V/O	0…FFh	0…255	1	-
SW version information part for 1 byte (Bit 0…15)					
SW_NAME_2	V/O	0…FFh	0…255	1	-
SW version information part for 2 byte (Bit 0…15)					
SW_NAME_3	V/O	0…FFh	0…255	1	-
SW version information part for 3 byte (Bit 0…15)					
SW_NAME_4	V/O	0…FFh	0…255	1	-
SW version information part for 4 byte (Bit 0…15)					
SW_NAME_5	V/O	0…FFh	0…255	1	-
SW version information part for 5 byte (Bit 0…15)					

Input data:

FUNCTION DESCRIPTION:

General information:

In order to show software version information at external monitoring equipment (ex, VMU), version name values are defined. These values are prepared for A2L files of VMU. A2L file is modified as ASAP formation for SAM2000 values and 6 bytes can express the software information.

Software name can be composed of 6 byte and every one byte means one name of SW_NAME_x

Example) 670G30 = 36, 37, 30, 47, 33, 30 [hex] : SW_NAME_x

Formula section:

Activation: once at reset

0.2 End-Of-Line Trimming of analog MAF Signal Input

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MAF_TRIM	V/S	0…1H	0…1	1	-
flag to indicate a performed MAF Trimming					
STATE_MAF_TRIM	V/S	00H FFH	'Trim done' 'Trim not done'	1	-
Status Information for MAF Trimming from ECU Production Line (copied from address 6000h…6001h)					
V_MAF_TRIM	V/S	0…3FFH	0…4.995	0.00488	V
voltage of MAF signal input measured with C_V_MAF_TRIM_NOM input					
FAC_MAF_TRIM	V/O/S	0…FFH	0.9…1.1	0.00078	-
stored MAF Trimming Factor from ECU Production Line as ratio between measured and nominal voltage					

Input data:

FUNCTION DESCRIPTION:

General information:

In order to compensate the Voltage Tolerance of the ECU internal Reference Voltage Supply which is used to evaluate the MAF Sensor Signal Input, a Trimming Value is determined during the ECU Production Process at the Manufacturing End-of-Line Test.

A nominal Trimming Voltage C_V_MAF_TRIM_NOM (typically 4.000 V) is applied from an external Precision Device to the ECU MAF Signal Input and then measured inside the ECU.

The MAF-Signal Voltage inside the ECU is measured 10 times and then averaged. The averaged Value is stored in the non-volatile Memory and used to calculate the Trimming Value as Ratio between the measured Voltage and the nominal Voltage.

The Trimming Value is limited to +/- 10 % (FAC_MAF_TRIM = 0.9 … 1.1).

Measured Values which are outside the allowed tolerance window indicate a too high ECU Hardware Tolerance or a wrongly adjusted nominal Voltage and reject the ECU from the Production Line for Rework.

The Trimming Value is determined **only once in the ECU Lifetime** during the VXI Test. As the Trimming Value is unique to the ECU hardware, **it is never overwritten or erased**.

For Testing Purpose it is possible to switch from the trimmed value to the init value by a calibration constant. The trimmed value remains in the memory, but the read-out correction value is then changed to the initialization values.

Memory Address	**Description**
6000…6001 h	Trimming Status Information: 00FF h = Trimming Value available 0000 h = no Trimming Value available
6002…6003 h	V_MAF_TRIM Range: 0…3FF hex = 0…4.995 phys
6004…6005 h	Complement of V_MAF_TRIM

Application conditions:

Initialisation: the Initialization is performed only when no Trimming was done before or the Trimming has been reset by LC_RST_MAF_TRIM for testing.

If LV_MAF_TRIM = 0 from NVMY *(no Trimming Values available)*

then

if STATE_MAF_TRIM = 00 h *(read from Address 6000h…6001h)*
(to check if MAF Trimming was done at ECU Production Line)

and MAF Trimming Value from Address 6002h…6005h is valid

then V_MAF_TRIM = saved value from Address 6002h…6005h

FAC_MAF_TRIM = V_MAF_TRIM / C_V_MAF_TRIM_NOM
(calculation of Trimming Factor from saved Trimming Value)

LV_MAF_TRIM = 1 *(to indicate that Trimming is available)*

else V_MAF_TRIM = C_V_MAF_TRIM_NOM

FAC_MAF_TRIM = 1 *(to apply neutral init values)*

else *(Trimming Values are available)*

FAC_MAF_TRIM = FAC_MAF_TRIM from NVMY

V_MAF_TRIM = V_MAF_TRIM from NVMY

Recurrence: 1 sec

Activation: always active

Deactivation: no Deactivation

Formula section:

Reset of the Trimming Values for Testing Purpose:

If LC_RST_MAF_TRIM = 1 *(Reset of Trimming Value requested)*

then V_MAF_TRIM = C_V_MAF_TRIM_NOM *(to apply neutral init values)*

FAC_MAF_TRIM = 1 *(to apply neutral init values)*

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_V_MAF_TRIM_NOM	1	0…3FFH	0…4.995	0.00488	V
nominal Voltage from external device for MAF Signal Trimming					
LC_RST_MAF_TRIM	1	0…1H	0…1	1	-
for testing purpose the Trimming can be reset to init values					

0.3 Determination and Storage of ECU Reset Status

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ECU_RST_STATUS_SW_1	V/O/S	0…FFFFh	0…65535	1	-
ECU SW Reset Status (Bit 0…15)					
ECU_RST_STATUS_SW_1_HB	V/O/S	0…FFh	0…255	1	-
ECU SW Reset Status (Bit 8…15)					
ECU_RST_STATUS_SW_1_LB	V/O/S	0…FFh	0…255	1	-
ECU SW Reset Status (Bit 0…7)					
ECU_RST_STATUS_SW_2	V/O/S	0…FFFFh	0…65535	1	-
ECU SW Reset Status (Bit 16…31)					
ECU_RST_STATUS_SW_2_HB	V/O/S	0…FFh	0…255	1	-
ECU SW Reset Status (Bit 24…31)					
ECU_RST_STATUS_SW_2_LB	V/O/S	0…FFh	0…255	1	-
ECU SW Reset Status (Bit 16…23)					
ECU_RST_STATUS_HW	V/O/S	0…FFFFh	0…65535	1	-
ECU HW Reset Status (Bit 0…15)					
ECU_RST_STATUS_HW_HB	V/O/S	0…FFh	0…255	1	-
ECU HW Reset Status (Bit 8…15)					
ECU_RST_STATUS_HW_LB	V/O/S	0…FFh	0…255	1	-
ECU HW Reset Status (Bit 0…7)					

Input data:

BIOS_RST_GET_STATUS	BIOS_RST_IS_STATUS_VALID		

FUNCTION DESCRIPTION:

General information:

In order to support the root-cause identification after a non-power-on ECU Reset, the available background information from I/O Software is read out and stored to the non-volatile memory. The stored information is only written or overwritten by unexpected resets.

The BIOS driver for the Reset provides a basic interface BIOS_RST_GET_STATUS which describes the status of processor reset unit and cause of ECU reset, if one occurs.

There are two groups of possible reset causes:
- SW-caused resets (described by ECU_RST_STATUS_SW_1/2)
- HW-caused resets (described by ECU_RST_STATUS_HW)

Formula section:

Activation: once after any Reset

Deactivation: 1. when ECU is reset through KWP service request, ECU RESET

2. when Reprogramming Session gets started

If BIOS_RST_IS_STATUS_VALID *(to determine non-power-on Reset)*

then write data from BIOS_RST_GET_STATUS

into ECU_RST_STATUS_SW_1
and ECU_RST_STATUS_SW_2
and ECU_RST_STATUS_HW

SW Reset Status

Bit	Description	Value '1'	Value '0'
31	Machine check reset status	Reset has occurred	Reset has not occurred
30	Alignment reset status	Reset has occurred	Reset has not occurred

0.4 Siemens Logistic Information – Description

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
sam_name_ecu[8]	O	0...FFh	0...255	1	-
SAM name of ECU-SW					
sam_name[8]	O	0...FFh	0...255	1	-
SAM name of calibration					
NC_KWP_IO_RSCOTSN[10]	O	0...FFh	0...255	1	-
RepairShopCode or TesterSerialNumber					
NC_KWP_IO_PD[4]	O	0...FFh	0...255	1	-
Software ProgrammingDate					
NC_KWP_IO_CRSCOTSN[10]	O	0...FFh	0...255	1	-
Calibration RepairShopCode or TesterSerialNumber					
NC_KWP_IO_CPD[4]	O	0...FFh	0...255	1	-
Calibration ProgrammingDate					

0.5 Customer Logistic Information configuration

0.5.1 Customer logistic information fied

0.5.1.1 Calibration reprogramming history data

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CAL_PROG_TESTER_NR_HIS_i[10]	O	0...FFH	0...255	1	-
Repair shop code or tester serial number used for calibration reprogramming					
CAL_PROG_DATE_HIS_i[4]	O	0...FFH	0...255	1	-
Calibration programming date (Format: YYYY/MM/DD)					
CAL_NAME_HIS_i[8]	O	0...FFH	0...255	1	-
ECU calibration identifier					

Input data:

NC_KWP_IO_CRSCOTSN[10]	NC_KWP_IO_CPD[4]	sam_name[8]	

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_ NR _PROG_HIS	-	0...255H	0...255	1	[-]
Size of reprogramming history memory					

0.5.2 Local configuration data:

Data	Value	
NC_NR_PROG_HIS	10	Size of reprogramming history memory

PHYSICAL IMPLEMENTATION

-

FUNCTION DESCRIPTION:

Any time the calibration data is programmed via KWP2000 service, the following data are stored in the logistic area of the Siemens Boot SW:

Description	Variables located in ASW logistic area (ALIF_SI and ALIF_CU)	Variables located in Siemens Boot Block (SBLIF_CU)
Tester serial Number or Repair shop code	NC_KWP_IO_CRSCOTSN	CAL_PROG_TESTER_NR_HIS_i
Calibration programming Date	NC_KWP_IO_CPD	CAL_PROG_DATE_HIS_i
ECU Calibration Identifier	sam_name	CAL_NAME_HIS_i

Application conditions:

Initialisation: at programming of SIEMENS Boot Block: all variables = 0xFFh

Recurrence: -

Activation: by KWP2000 service STRBLI with RELI 01h

Formula section:

The following action must be done **BEFORE** StartRoutineByLocalID service to erase data:

If (CAL_NAME_HIS_[NC_NR_PROG_HIS – 1][0..7] = 0xFF) /* Last entry for calibration reprogramming history not yet filled

and (SW_NAME_HIS_[NC_NR_PROG_HIS – 1][0..7] = 0xFF) /* Last entry for software reprogramming history not yet filled

Then Search next free entry (=x) in Calibration reprogramming history starting at 0

Copy actual data to position x in history:

CAL_PROG_TESTER_NR_HIS_x = NC_KWP_IO_CRSCOTSN

CAL_PROG_DATE_HIS_x = NC_KWP_IO_CPD

CAL_NAME_HIS_x = sam_name

Endif

0.5.2.1 Software reprogramming history data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SW_PROG_TESTER_NR_HIS_i[10]	O	0...FFH	0...255	1	-
Repair shop code or tester serial number used for SW reprogramming					
SW_PROG_DATE_HIS_i[4]	O	0...FFH	0...255	1	-
Software programming date (Format: YYYY/MM/DD)					
SW_NAME_HIS_i[8]	O	0...FFH	0...255	1	-
ECU Software identifier					

Input data:

NC_KWP_IO_RSCOTSN	NC_KWP_IO_PD	sam_name_ecu	

PHYSICAL IMPLEMENTATION

-

FUNCTION DESCRIPTION:

Any time the software is programmed via KWP2000 service, the following data are stored in the logistic area of the Siemens Boot SW:

0.5.2.2 Locked by timer information for immobilizer

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
BF_LOCKED_BY_TIMER[32]	O	0...FFh	0...255	1	-
Bitfield, that indicates number of times entered state LOCKED_BY_TIMER					

Application conditions:

Initialisation: at programming of SIEMENS Boot Block: all entries = 0xFFh

Formula section:

For more information see immobilizer specification.

0.6 Erasement of adaptation values

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_VB_OFF	V	0...1H	0...1	1	-
Battery disconnected.					
LV_VB_OFF_ACT	V/O	0...1H	0...1	1	-
Filtered battery disconnected information bit.					

Input data:

General information:

The adaptation values can be erased in several ways:

- via KW2000-protocol
- after battery disconnection detected
- with application system by calibration

The adaptation values can be erased in SAM2000 by the calibration constant LC_AD_CLR (all adaptation values) or by the calibrations LC_AD_CLR_xxx (individual adaptation values).

The Reset is effective immediately and only at the transition from LC_AD_CLR(_xxx)= 0 to 1.

Note : additionally to the erasement of adpatation values, an erasement of the failure memory can be performed. More informatino available in chapter A.

Application recurrence: once after system reset.

0.6.1 Erasement after battery disconnection

A hardware with one bit-memory characteristic is provided which detects at system start up if the ECU or the battery was disconnected since the last housekeeping phase.

If a disconnection is configured and detected, and erasement of non volatile memory is configured the adaptation values will be reset like described below.

Formula section:

Detection of battery-off :

If CONF_FMY_RST = 1
or CONF_AD_RST > 0
then LV_VB_OFF_ACT = LV_VB_OFF *(One-Bit Memory is set)*
else LV_VB_OFF_ACT = 0 *(reset One-Bit Memory)*

Remark : The flag LV_VB_OFF is set to 1 if the battery has been disconnected since the last driving cycle : LV_VB_OFF = LV_IM_VB_OFF

Erasement of failure memory:

If LV_VB_OFF = 1
then **If** CONF_FMY_RST = 0 **then** the failure memory is **not** reset
If CONF_FMY_RST = 1 **then** the failure memory is reset

Erasement of adaptative values from the memory :

If LV_VB_OFF = 1
then **If** CONF_AD_RST = 0 **then** the adaptation values are **not** reset
If CONF_AD_RST = 1 **then all** the adaptation values are reset
If CONF_AD_RST = 2 **then** only **some** adaptation values are reset. See details in the table below.

Remark : After the first power latch phase after battery disconnection, it takes at least 50 ms until the One-Bit Memory is reset.

0.7 Control of data saving in Non Volatile Memory

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_RD_AR_NVMY	O	0...1H	0...1	1	-
Flag indicating Block restored has already been read NC_MAX_RD_AR_NVMY times					

General information:

The saving of datas to the Non Volatile Memory is only allowed at the end of Power latch before ECU switch off. The area for saved data is made of several blocks. At the end of the Power latch data are stored from RAM to the next free block of NVMY. A reset before end of Powerlatch prevents this saving and the last valid block is read out again at next initalisation. If same block of Reset values is already read out for NC_MAX_RD_NVMY times, the flag LV_ERR_RD_AR_NVMY is set.

Application conditions:

Initialisation: *(no Initialisation, because Activation during reset Phase)*

Recurrence: once per Reset

Activation: at Reset

Formula section:

If block n is valid, but this block has been read already NC_MAX_RD_AR_NVMY times
then LV_ERR_RD_AR_NVMY = 1
else LV_ERR_RD_AR_NVMY = 0
endif

NC_MAX_RD_AR_NVMY = 1

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_MAX_RD_AR_NVMY	-	0..10H	0...16	1	-
number of read outs of NVMY datas already read by previous store					

0.8 CPU Load Measurement

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CPU_LOAD	O/V	0...400H	0..100	0.0977	%
CPU load above measurement level					
CPU_LOAD_MAX	O/V	0...400H	0..100	0.0977	%
Maximum detected CPU load above measurement level					
CPU_LOAD_MAX_TOT_DC	O/V/S	0...400H	0..100	0.0977	%
Former / current driving cycle maximum CPU_LOAD					
CPU_LOAD_TSK_PER_MIN_SAVE	O/V/S	0...FFFFFFFFH	0...4294967295	1	Ticks
Saved Minimum Time between 2 Instances of TASK_BG_MES					
CPU_LOAD_TSK_PER_MIN	O/V	0...FFFFFFFFH	0... 4294967295	1	Ticks
Minimum Time between 2 Instances of TASK_BG_MES					
CPU_LOAD_TSK_PER	O/V	0...FFFFFFFFH	0... 4294967295	1	Ticks
Time between 2 Instances of TASK_BG_MES					
CPU_LOAD_TSK_PER_CTR	O/V	0...FFFFH	0..65535	1	-
Counter of TASK_BG_MES Instances					

FUNCTION DESCRIPTION:

General information:

The CPU load is defined as the processor activity above the background level.

The variable CPU_LOAD_MAX represents the maximum detected CPU load value. The calibration flag LC_CPU_LOAD_MAX_RST can be used in order to reset this variable.

The variable CPU_LOAD_MAX_TOT_DC represents the maximum CPU load value over several driving cycles since ECU programming.

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

CPU_LOAD_MAX_TOT_DC = 0

- otherwise: restored from non-volantile memory

Formula section:

IF CPU_LOAD_MAX > CPU_LOAD_MAX_TOT_DC

THEN CPU_LOAD_MAX_TOT_DC = CPU_LOAD_MAX

ENDIF

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CPU_LOAD_SES_T_BEGIN		0..FFFFH	[0…65535]	1	-
Beginning of measurement session					
C_CPU_LOAD_SES_T_END		0..FFFFH	[0…65535]	1	-
End of measurement session					
C_CPU_LOAD_PER		0..FFFFH	[0…65535	1	-
Time between 2 measurement sessions					
C_CPU_LOAD_TSK_MES_DLY		0...FFFFH	0...65535	1	-
Calibration for acting on measurement task period					
LC_CPU_LOAD_TSK_PER_MIN_UPD		0..1	0..1	-	-
Flag for authorizing update of variable CPU_LOAD_TSK_PER_MIN_SAVE with CPU_LOAD_TSK_PER_MIN					
LC_CPU_LOAD_TSK_PER_MIN_RST		0..1	0..1	-	-
Flag for reset of variable CPU_LOAD_TSK_PER_MIN					
LC_CPU_LOAD_MAX_RST		0..1	0..1	-	-
Flag for reset of variable CPU_LOAD_MAX					

0.9 Stack size monitoring of Ercosek 4.1

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
E_OS_STATE_STACK	V	0000H 0001H 0002H 0100H 0200H 0404H	STACK_OK USTACK_OVFL USTACK_NFULL ESTACK_OVFL ESTACK_NFULL OSTACK_OVFL	1	[-]
Stack status					
E_OS_USED_USER_STACK	V	0...FFFFFFFFH	0...17179869180	4	[Byte]
User stack consumption					
E_OS_USED_SYS_STACK	V	0...FFFFFFFFH	0...17179869180	4	[Byte]
System/Ercosek stack consumption					
E_OS_USED_USER_STACK_MAX	V/S	0...FFFFFFFFH	0...17179869180	4	[Byte]
Maximum user stack consumption (stored at shutdown)					
E_OS_USED_SYS_STACK_MAX	V/S	0...FFFFFFFFH	0...17179869180	4	[Byte]
Maximum system/Ercosek stack consumption (stored at shutdown)					

FUNCTION DESCRIPTION:

General information:

The stack monitor of Ercosek operating system is called to gain information about the stack consumption. The maximum values are stored at ECU shutdown to track the stack consumption over several driving cycles.

The calculations are done, when no other task is pending (background task).

The following variables are provided by the Ercosek operating system:

E_OS_STATE_STACK:

- STACK_OK: Stack consumption of user and system stack in normal ranges (0..75 %)
- USTACK_OVFL, ESTACK_OVFL: Overflow of user or Ercosek stack (> 100 %). This is extremely dangerous and therefore prompt actions to reach 75 % have to be taken.
- USTACK_NFULL, ESTACK_NFULL: User or Ercosek stack is nearly full (75..100 %). Actions to fulfill the requirement of max. 75 % have to be taken.

E_OS_USED_USER_STACK: Used user stack size in byte.

E_OS_USED_SYS_STACK: Used system/Ercosek stack size in byte.

Application conditions:

Initialisation: -

Recurrence: background

Activation: at every engine state

Deactivation: -

Formula section:

If E_OS_USED_USER_STACK > E_OS_USED_USER_STACK_MAX(n-1)
Then E_OS_USED_USER_STACK_MAX = E_OS_USED_USER_STACK

If E_OS_USED_SYS_STACK > E_OS_USED_SYS_STACK_MAX(n-1)
Then E_OS_USED_SYS_STACK_MAX = E_OS_USED_SYS_STACK

1 General

Table of Contents

Index

1.1 General

1.1.1 Application of the system for natural aspirateded system

1.1.1.1 Engine

Description	HMC Theta PI Engine Facelift
No. of cylinders	4
Displacement	1.8l, 2.0l, 2.4l
Charge cycle	DOHC 4 valves/cylinder
Valve Timing	continuously variable intake and exhaust
Intake Manifold	2-Step variable
Intake Port	Variable Charge Motion Flap
Emission Classification	S-ULEV, ULEV-LEVII, EU4, K-LEV, GEN, Leaded

1.1.1.2 Vehicle

Description	NF Facelift MY 2008 and others
Transmission	M5, A5
Power steering	Pressure Feedback via Pressure Switch or Pressure Transducer
Air conditioner	Pressure Feedback via Pressure Switch or Pressure Transducer
Cooling Fan	Relay Type or PWM type
Generator Load Signal	PWM Type

1.1.2 Application of the system for turbo charged system

1.1.2.1 Engine

Description	HMC Theta PI Turbo Engine
No. of cylinders	4
Displacement	2.0l
Charge cycle	DOHC 4 valves/cylinder
Valve Timing	continuously variable intake and exhaust
Emission Classification	ULEV-LEVII, EU4, K-LEV, GEN

1.1.2.2 Vehicle

Description	BK MY 2008 and others
Transmission	M5, A5
Power steering	Pressure Feedback via Pressure Switch or Pressure Transducer
Air conditioner	Pressure Feedback via Pressure Switch or Pressure Transducer
Cooling Fan	Relay Type or PWM type
Generator Load Signal	PWM Type

1.2 System Performance for C-Sample (preliminary)

* Manifold Absolute Pressure Sensor with TIA Acquisition
* Pressure upstream of throttle acqusition (TCI variant)
* Ambient pressure acquisition (integrated in ECU) (for TCI variant)
* Mass Air Flow Acquisition with Backflow-Compensation (alternative to MAP Input via configuration switch) and TIA Acquisition inside MAF Sensor
  (additionally MAF input instead of PUT-Sensor for Calibration purpose possible)
* Ignition (Single Ignition Coil)
* TCO Acquisition
* TOIL Acquisition
* Heated Oxygen Sensor; Linear upstream for S-ULEV
  Binary ZrO2 upstream for all other markets ;binary ZrO2 downstream
* Exhaust wastegate (variable PWM control) turbo charger bypass (TCI variant)
* Recirculation valve (on/off connected to vacuum MAP)–intake compressor bypass (TCI variant)
* Adaptive Lambda Control
* Evaporative Emission Control
* Adaptive Idle Control
* Throttle Position Sensor (non ETC-variant)
* Electronic Throttle Control by PWM H-bridge with 2-channel Throttle Position Sensors (ETC-variant)
* Pedal value Sensor 2 channel (ETC variant)
* Air Conditioner Compressor Control (Relay type)
* OBD-II Diagnosis and Emergency Operation
* Storage of Adaptation data and Failure Memory data in Flash Memory
* CAN Connection to other Vehicle Control Units*** (TCU; TCS; MSR; ESP)
* CAN Connection to Application System

*** **Remark**: The CAN specification is common for all HMC Projects with SV EMS

1.3 Basic System Definitions

1.3.1 Allocation of CRK / CAM angles

CRK disk:
The falling edge of the first tooth after the gap is 114 °CRK before the ignition TDC of the first or the fourth cylinder.

CAM disk:
The electrical falling edge of the Intake CAM signal is positioned at tooth #114 (564°CRK absolute), the electrical rising edge of the Intake CAM signal is located at tooth #54 (204°CRK abs.).
The distinction between tooth #1 and #61 is done depending on the Intake CAM signal level during the gap:
- Intake CAM signal level = high during the gap, then tooth #61;
- Intake CAM signal level = low during the gap, then tooth #1.

The electrical falling edge of the Exhaust CAM signal is positioned at tooth #75 (336°CRK abs.), the electrical rising edge of the Exhaust CAM signal is located at tooth #15 (696°CRK abs.)

A "true power-on" logic of the CAM-Sensor is mandatory for this setup.

The firing order is stored as follows: 1 - 3 - 4 - 2 .

The injection valves are controlled according to the firing order.

An angle at start of injection of 0° means: The injection valve begins to open at the previous ignition TDC of this cylinder. A negative SOI means that the injection will start between the previous TDC of this cylinder and the next TDC of this cylinder.

1.3.2 Cylinder numbering

In the software the cylinders are numbered logically with 0...3, whereas in the ECU-hardware they are numbered 1...4.

If in the specification a cylinder-specific-variable is mentioned with ...[CYL] then always the logic value is ment.

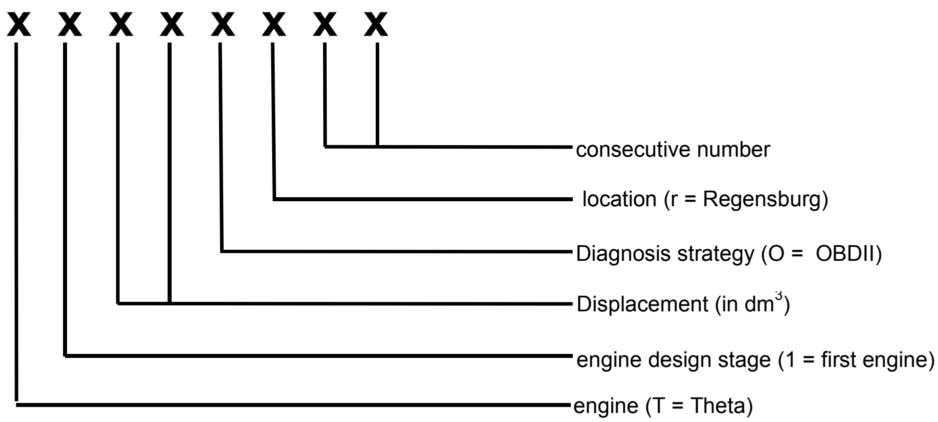
The firing order of the engine follows continuously from logic 0 to logic 3, whereas the physical firing order is 1 - 3 - 4 - 2.

The relation between logical and physical cylinder numbers is as follows:

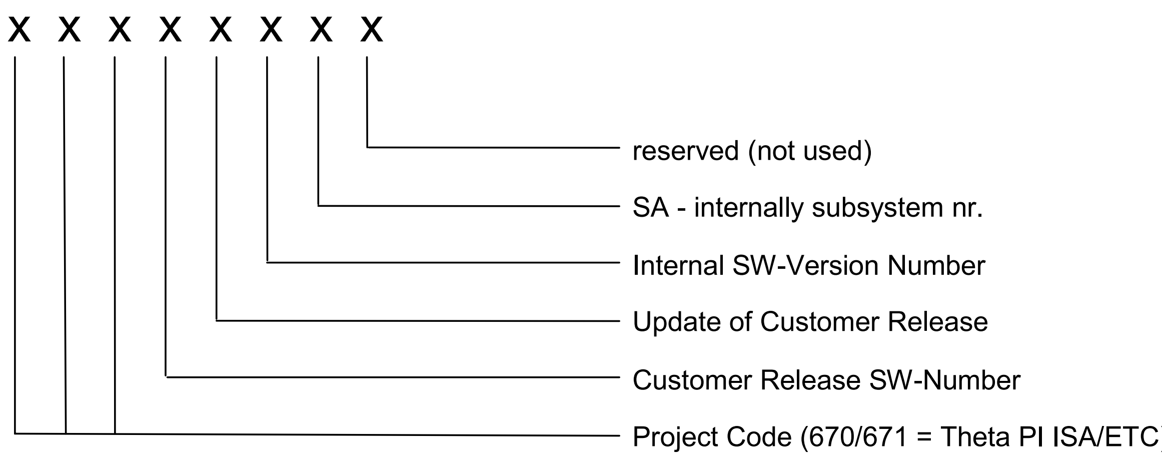
SW-Logic	HW-Logic	Physical
0	1	1
1	2	3
2	3	4
3	4	2

1.3.3 Nomenclature of Program and Data Updates

The data update is described as follows:



The program update is described as follows:



1.4 PIN-reservation of the connector (C-sample)

1.5 List of Configuration Data

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ACTIVE_CRK_EDGE	1	0...1H	0...1	1	-
Active crankshaft edge definition - used in the s/w, but not in the spec					
NC_CBK_NR	1	0...2H	0...2	1	-
Remark : not used in the s/w - for spec interface only					
NC_CYC_TOOTH_NR	1	0...FFH	0...255	1	tooth
Number of crankshaft teeth per engine cycle including the missing teeth in the reference gap					
NC_FAC_MAF_INT	1	0...FFFFH	0...892,4	0,0136	ms
Factor for unit adaptation					
NC_FRQ_ASW	1	0...FFFFFFFFH	1...4295e6	1	Hz
Applicative software frequency (Remark : not used in the s/w - for spec interface only)					
NC_FRQ_ECU	1	0...FFFFFFFFH	1...4295e6	1	Hz
ECU processor real frequency					
NC_KNKS_CH1	1	0...FFH	0...255	1	-
Initialization value for the analogue channel of knock sensor					
NC_KNKS_CONF	1	0...FFH	0...255	1	-
Configuration : knock sensor number = f(cylinder number)					
NC_NR_TOOTH_TDC_REF	1	0..FFFF	0..65535	1	tooth
Number of teeth between first tooth and TDC synchro					
NC_T_BAS_FRQ_DIV	1	0...FFH	0...255	1	-
Divisor for calculation of timer frequency for basic time measurements					
NC_T_SEG_LOW_N	1				
Maximum segment duration for low engine speed range.					
NC_T_SEG_MAX	1				
Maximum segment duration for engine stalling detection.					
NC_T_TOOTH_MAX	1				
Maximum duration of normal tooth.					
NC_T_TOOTH_MIN	1				
Minimum duration of normal tooth.					
T1_FREQ	1				
Timer frequency					
T8_FREQ	1				
Timer frequency					
NC_TIPO_MIN	1				
Value of TIPO_MIN (minimum injection time for injection update)					
NC_TOOTH_GRD_MAX	1	0...1000H	0...16	0.0039	-
Maximum tooth gradient for valid or invalid tooth duration.					
NC_TOOTH_GRD_MAX_GAP	1	0...1000H	0...16	0.0039	-
Maximum tooth gradient for valid or invalid crankshaft gap detection.					
NC_TOOTH_GRD_MIN	1	0...1000H	0...16	0.0039	-
Minimum tooth gradient for valid or invalid tooth detection.					
NC_TOOTH_GRD_MIN_GAP	1	0...1000H	0...16	0.0039	-
Minimum tooth gradient for valid or invalid crankshaft gap detection.					
NC_USE_EXT_ADJ	1	0...1H	0...1	1	-
Configuration Constant, 1 = Service tool intervention enabled, 0 = Service tool intervention inhibited					
NC_LAM_SWI	1	0...1H	0...1	1	-
NC_SEG_TOOTH_RR	1	1H...FFH	0...255	1	-
Number of wheel speed signal teeth to build one segment, typical value = 4					
NC_MAX_T_AST_FIRST_EOL_FDOUT	1	0H...FFFFH	0...6553.5	0.1	sec
Maximum misfire detection inhibition time after first engine run					

Input data:

NC_CPPWM_CPS_BOL	NC_TD_LIM	NC_IGBT_CUT_OFF_T	NC_CYL_NR
NC_INI_CTR_DEAC	NC_KEY_OFF_NR	NC_KEY_ON_NR	NC_KNKWB_INI
NC_KNKWE_INI	NC_FAC_MAF_INT_100	NC_CPPWM_CPS_TOL	NC_PSD_DLY
NC_N_DIF_MIN_CRLC	NC_FAST_TRAN_SYN_ENG_IG K_OFF_PWL	NC_NR_TOOTH_GAP_TDC	NC_KEY_OFF_THR
NC_N_MIN	NC_T_SEG_FRQ	NC_LOW_N	NC_N_MAX

Remark : in some cases, the physical and hexadecimal limits don't appear because they are not explicit in the s/w. Only the value is used.

General information:

To satisfy the spec interface (data defined and used), the following convention is applied :

- if a NC value is used as an INPUT in a function, it is defined as a CONFIGURATION DATA in the present spec "List of Configuration Data", and its value is also affected in the present spec.

- if a NC value is defined in a function (in the field " CONFIGURATION DATA), then it is called as an INPUT in the present spec "List of Configuration Data", and its value is affected in this present spec (even if its value is already affected in the function)

Description:

Name	Value

NC_PSD_DLY	2

1.6 AIRT Aggregate general:

Target / Objectives of the function:

The goal of the AIRT is:

_ to realize the acquisition of the sensor voltage

_ to compute:

. the air ambient temperature TAM (ie: outside the intake manifold)
. the three air temperatures TIA_THR, TIA_IM and TIA_CYL (i.e.: inside the intake system) taking into account:
. External EGR version (or not)
. CHRG version (or not)
. One or several air temperature sensors at different locations on the intake system

_ to perform the diagnosis of the TIA sensor(s).

Requirements:

TIA sensor electrical diagnosis (OBD1)

TAM sensor (via CAN) out of range diagnosis (OBD1): via Project specific solutions
TIA and TAM sensor plausibility diagnoses (OBDII)

Physical background of the function:

The AIRT uses basically 2 Physical / Mathematical laws:

_ *The heat transfer law for the mix of two gas:*

Between fresh air and burned gases coming from EGR (we suppose that the isobaric heat capacities are the same for air and EGR gases).

$$m_{egr}C_p\left(T_{egr}-T\right)=m_{air}C_p\left(T-T_{air}\right)\Rightarrow T=T_{egr}\times ratio\_egr+T_{air}\times\left(1-ratio\_egr\right)$$

To estimate the air temperature, we use the following law :

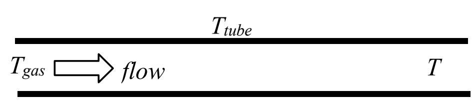
_ *The Reynolds law:*

It describes the heat transfers of a gas flowing into a tube. For gases at moderate temperature, the change of temperature between the final gas temperature and the initial one follows the law:

$$T-T_{gas}=\frac{K\left(L,D\right)\left[T_{tube}-T_{gas}\right]}{flow^{0.2}}$$

Where: K depends on the length of the tube (L) and its diameter (D).

flow is the mass flow of gas.



Overview picture:

General remark concerning all Signal Flow Diagrams presented below:

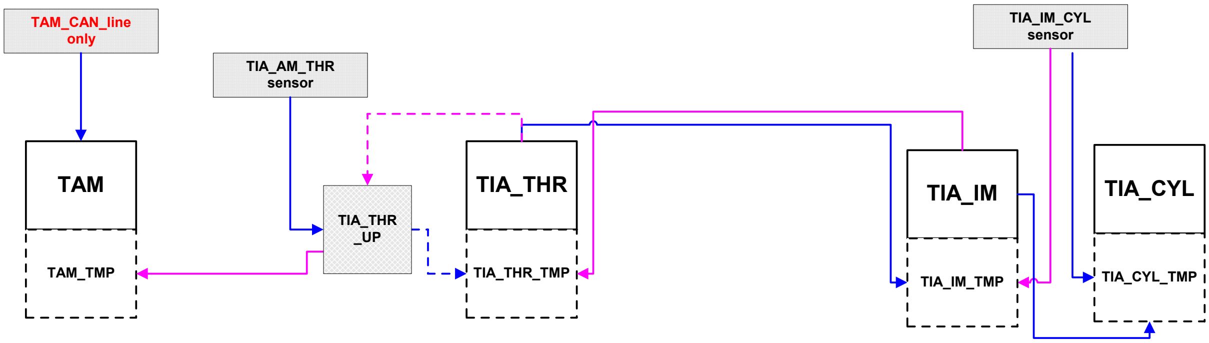
. in blue ink: DIRECT data flow / in pink ink: REVERSE data flow

. “TIA_x_TMP” is the main variable for TIA_x calculation:

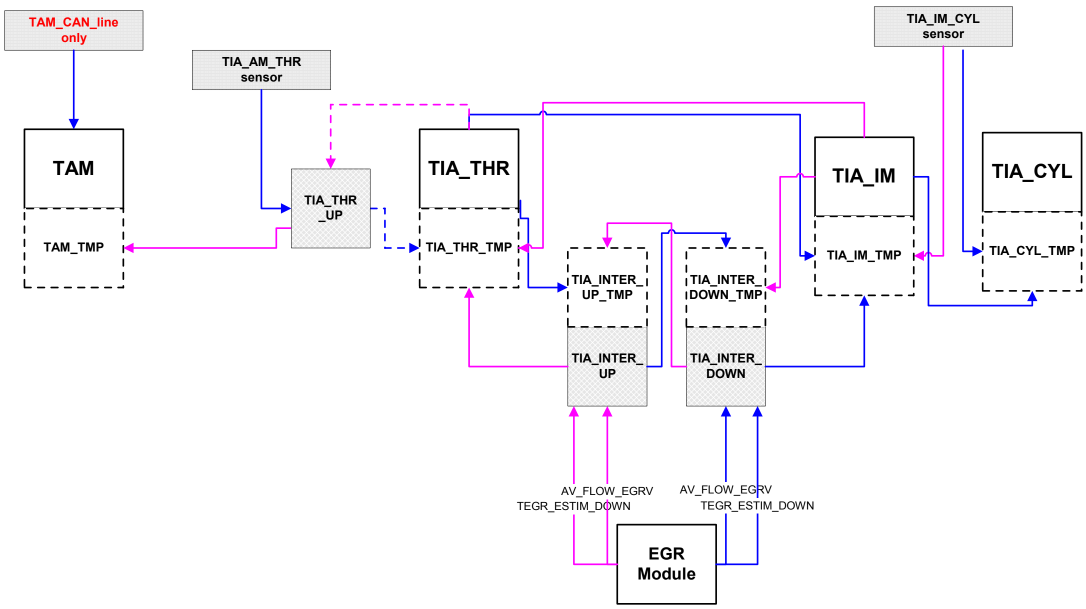
example: TIA_THR_TMP is the main input for TIA_THR calculation.

. EGR module [respectively CHRG module] are defined in EGRC Aggregate [respectively CHRG Aggregate]

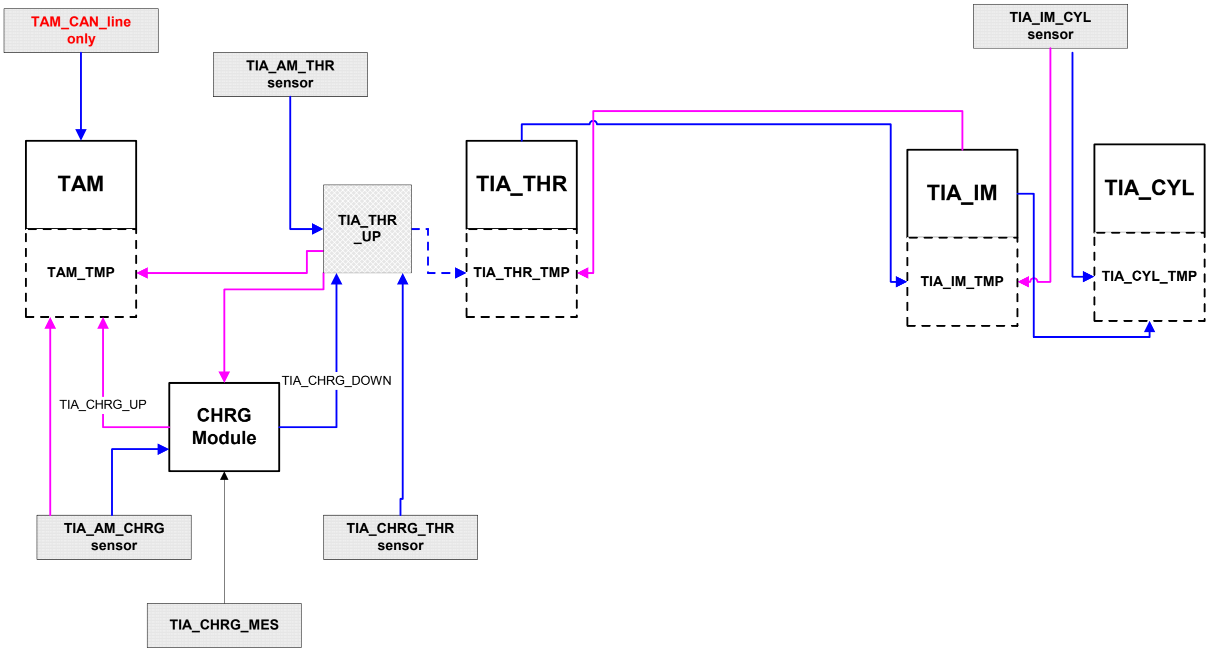
- Signal Flow Diagram for version: No CHRG + No External EGR (+ 2 possible TIA sensors positions)



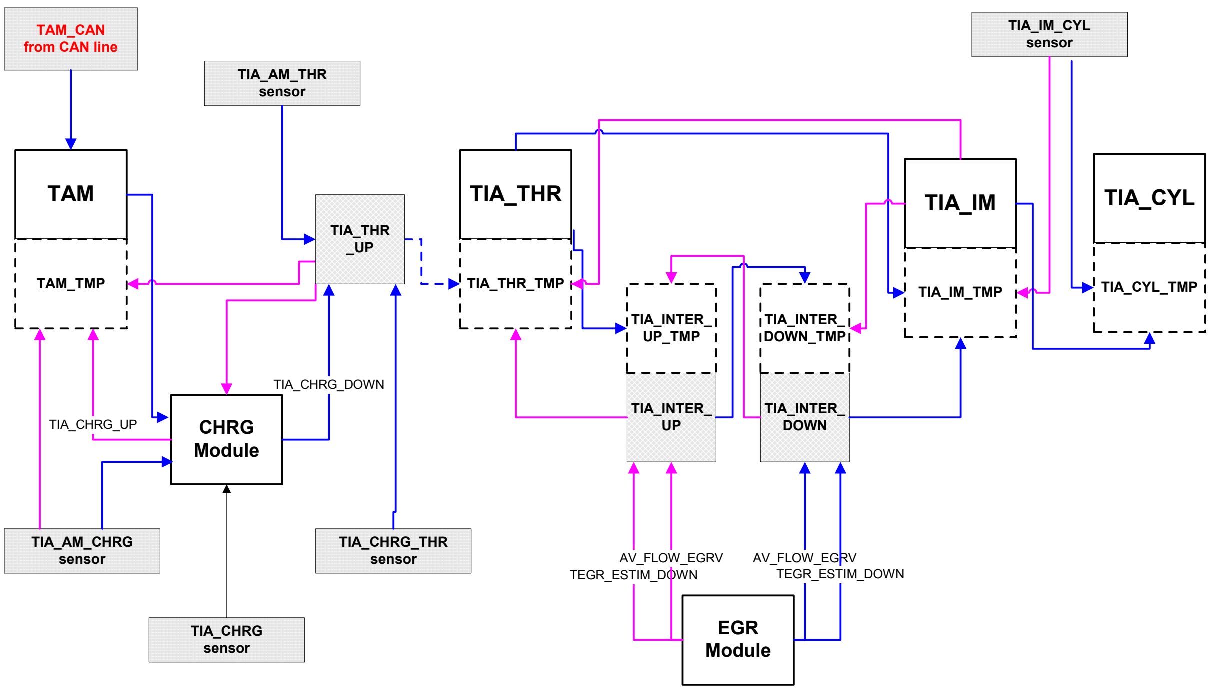
- Signal Flow Diagram for version: No CHRG + External EGR (+ 2 possible TIA sensors positions)



- Signal Flow Diagram for version: CHRG + No External EGR (+ 5 possible TIA sensors positions)



- Signal Flow Diagram for version: CHRG + External EGR (+ 5 possible TIA sensors positions)



1.7 General information

Target

The goal of the EGPR is to calculate the actual valid exhaust pressure in the exhaust manifold.

There is an increase of the pressure in the exhaust pipe in comparison to the ambient pressure. The increase of the pressure is higher with increasing mass flow in the exhaust pipe. The cylinder mass air flow is direct proportional to the exhaust mass flow. Therefore the pressure increase in the exhaust pipe is a function of the engine mass flow.

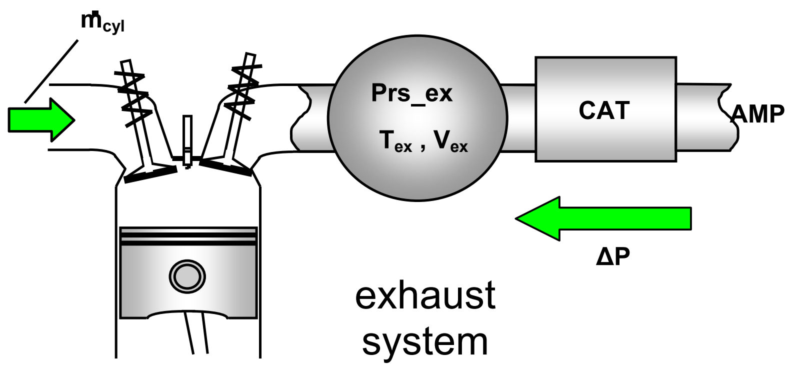
Dependence of IMM on reliable measurement signals

To reach always λ = 1, i.e. in steady state/ transient, cold/warm engine operating, a precise load signal is required. The IMM strongly depends on reliable measurement signals, for two main reasons:

_ In systems equipped with an air-mass flow sensor (HFM) during steady state engine operation, the measured air-mass flow signal (MAF) usually equals the air-mass flow into the cylinder, which is the base for injection time calculation. This is not true during transient engine operation, because of the filling characteristic of the manifold. The HFM is mounted in front of the intake manifold which behaves during transient as a mass storage system. To avoid λ deviations, the dynamic behaviour (in steady state and transient engine operating) of the intake manifold is calculated via the “IMM”.

_ Systems equipped with a manifold pressure (MAP) sensor do not have problems with the filling dynamics of the intake manifold. Due to the fact that the air-mass flow is not directly measured but only calculated out of the air density, therefore it strongly depends on the knowledge of the air-temperature in the cylinder. Any deviations from the temperatures valid during the calibration of the engine have to be compensated.

Overview



List /short description of the containing function

-Exhaust gas pressure determination

- The EGPR is based on an increase of the pressure in the exhaust pipe in comparison to the ambient pressure. This increase is proportional to the engine flow:

$$\dot{m}_{eng} = \dot{m}_{cyl} + \dot{m}_{ff\_sp} \qquad \textbf{(1)}$$

- The exhaust pressure is calculated as :

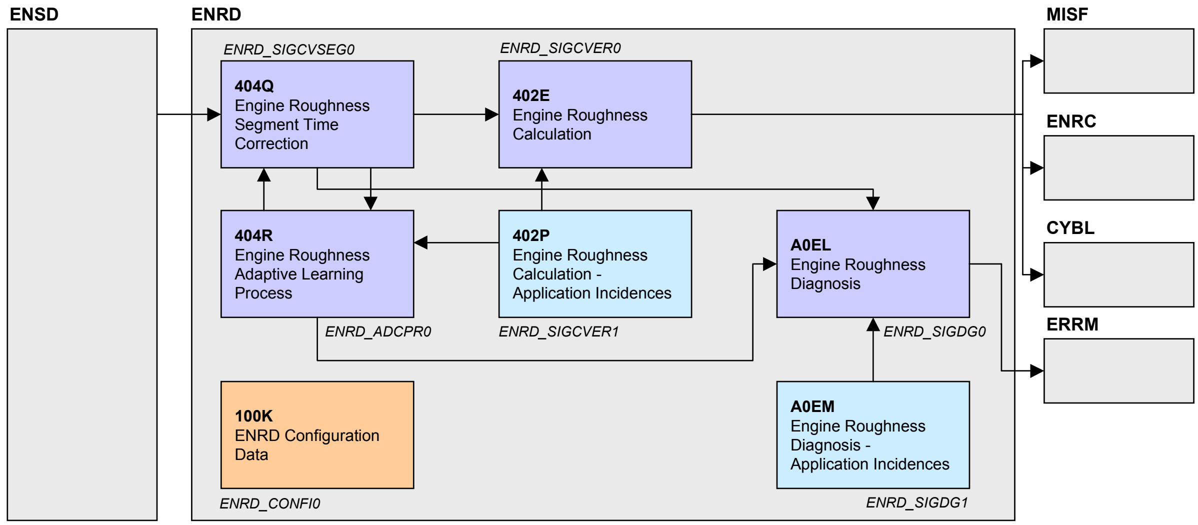
$$p_{ex} = amp + \Delta \cdot f\left(\dot{m}_{eng}\right) \qquad \textbf{(2)}$$

1.8 ENRD General

1.8.1 General description

The goal of the ENRD is to provide an engine roughness information to functions linked to combustion process like misfire monitoring, engine roughness control and cylinder balancing.

1.8.2 Architecture Overview



1.8.3 Description of the containing functions

1.8.3.1.1 404Q Engine roughness segment time correction

Segment times coming from ENSD are managed and corrected according adaptive learning values obtained in 404R module.

1.8.3.1.2 402P Engine roughness calculation - Application Incidences

Application specific requirements, fade-out requests are handled to act on the generic function core. (Template module, modified by the project according its integration environment)

1.8.3.1.3 402E Engine roughness calculation

Engine roughness indexes calculation is grounded on corrected segment time samples provided by 404Q module.

1.8.3.1.4 404R Engine roughness adaptive learning process

Engine roughness adaptive learning process provides adaptive values to 404Q module, to minimise noises produced by flywheel mechanical tolerances.

This module also consumes fade-out requests coming from 402P module.

1.8.3.1.5 A0EM Engine roughness diagnosis - Application Incidences

Application specific requirements, fade-out requests are handled to act on the generic engine roughness diagnosis function. (Template module, modified by the project according its integration environment)

1.8.3.1.6 A0EL Engine roughness diagnosis

This modules provides two diagnosis :

A diagnosis for the ER segment acquisition (thin synchronisation default criterion).

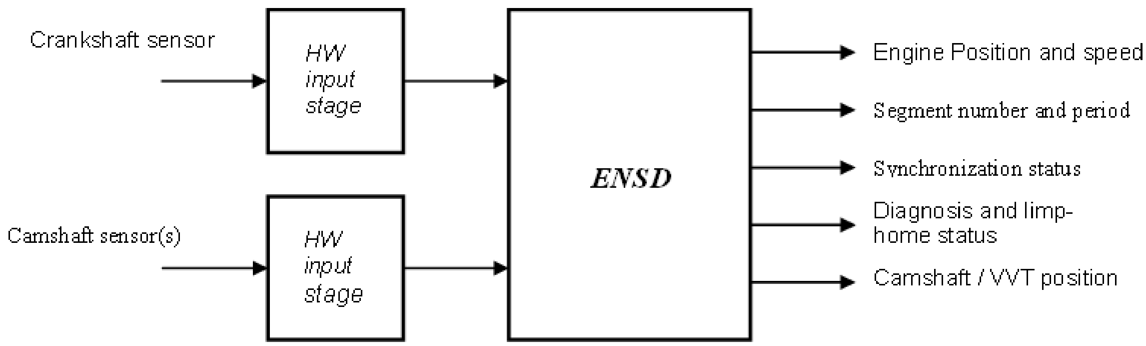
A check range diagnosis for the ER adaptive values obtained by the 404R module.

1.8.3.1.7 100K ENRD Configuration data

This module defines ENRD configuration data used during software integration & compilation. These configuration options defines mainly data and buffer size according the number of cylinders. This module is not attached to a software task.

1.9 ENSD General

1.9.1 General Description



Up to 4 camshaft sensors are supported.

The ENSD aggregate calculates all output data which depend on crankshaft and camshaft sensor information. This includes:

- engine position
- engine speed
- engine speed gradient
- segment number and period
- synchronization status
- diagnosis and limp-home flags
- camshaft / VVT position feedback
- min./max. engine position for pre-injection

At engine start, three synchronization modes are activated:

1) Crankshaft (self-)synchronization:

   The purpose of this synchronization mode is to identify the crankshaft position (0...360° CRK). The crankshaft position is clearly identified at the reference gap of the crankshaft target wheel.

2) Camshaft (self-)synchronization:

   The purpose of this synchronization mode is to identify the camshaft position (0..720° CRK). The camshaft position is clearly identified as soon as an unambigous camshaft edge pattern is found.

3) Camshaft/crankshaft synchronization:

   The purpose of this synchronization mode is to identify the engine position (0..720° CRK). The engine position is clearly identified as soon as an unambigous crankshaft to camshaft position is found.

Injection / Ignition can be enabled as soon as

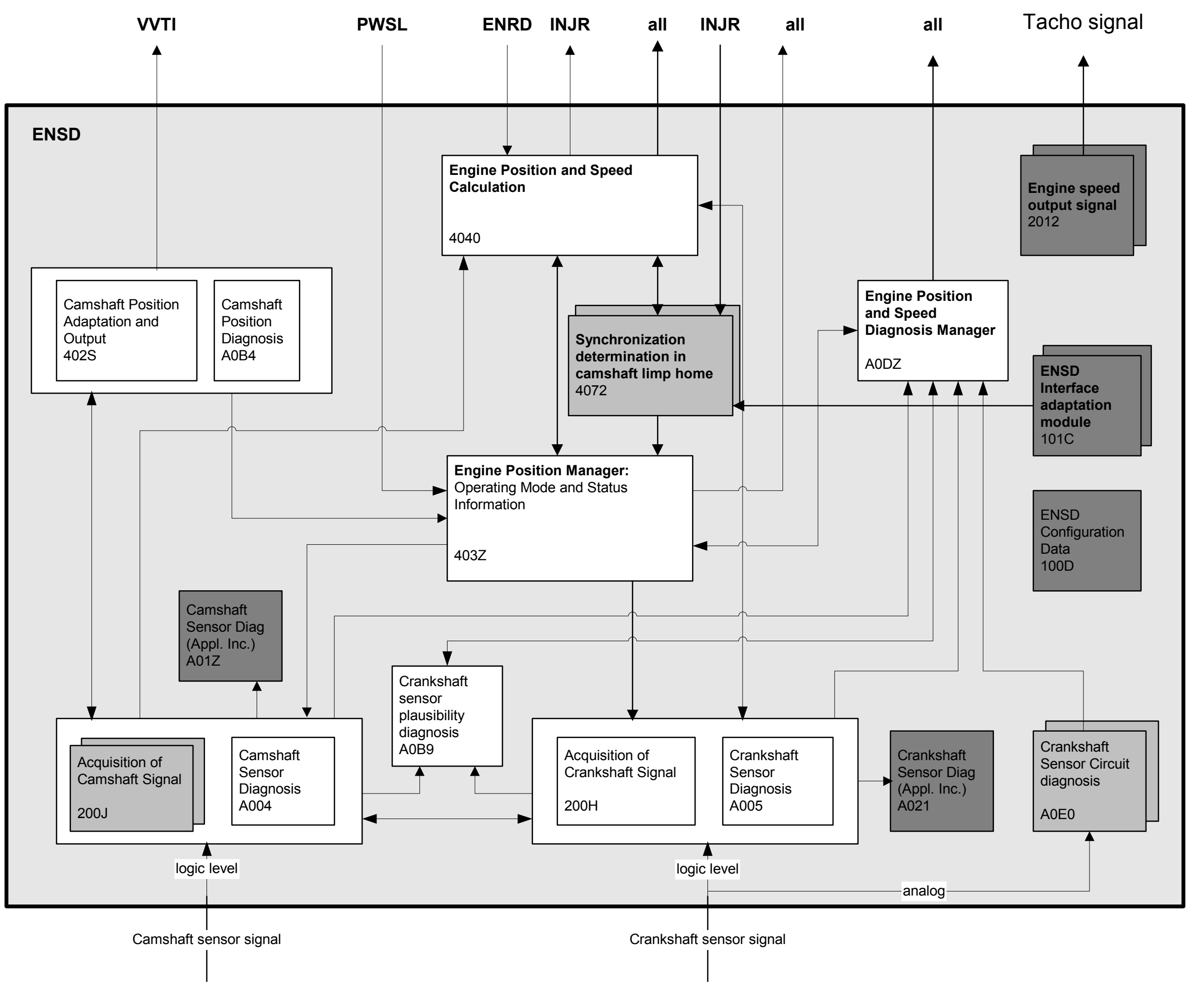
- engine position is identified (MPI engines)

- engine position is validated (DI / DS engines)

A corresponding status information (LV_SYN_ENG / LV_SYN_VLD) is produced and sent to the other aggregates.

1.9.2 Overview

The following figure shows the functional breakdown of the ENSD aggregate:



The light shaded blocs represent modules which are choosen in function of the actual system configuration (Hook modules).

The dark shaded blocs represent modules which have to be modified by the project („templates“ – Hook modules)

1.9.3 Short description of the containing functions

200H: Acquisition of crankshaft signal

Crankshaft synchronization, reference gap detection and crankshaft tooth validation. Measurements of tooth periods and segment periods

200J: Acquisition of camshaft signal

cam/crk synchronization (engine position offset determination), camshaft self-synchronization and engine position determination before engine synchronization (for pre-injection).

403Z: Engine position manager

Selection of operating modes (normal mode, camshaft or crankshaft limp-home mode) and generation of synchronization status information.

4040: Engine position and speed calculation

Calculation of engine position, speed, speed gradient, fast engine speed, segment period and number.

4072: Synchronization determination in camshaft limp-home

Engine synchronization determination in camshaft camshaft limp-home by specific injection pattern management

402S: Camshaft adaptation and position output

Camshaft edge position adaptation and camshaft position feedback for VVT-controller.

A0DZ: Engine position and speed diagnosis manager

Generation of diagnosis information and diagnosis inhibition flags.

A004: Camshaft sensor diagnosis

Camshaft segment period diagnosis and camshaft ratio check.

A0B4: Camshaft position diagnosis

Diagnosis of camshaft to crankshaft reference position.

A005: Crankshaft sensor diagnosis

Crankshaft tooth number and tooth period diagnosis.

A0B9: Crankshaft sensor plausibility diagnosis

Failure detection if crankshaft synchronization cannot be achieved, if camshaft signal is missing and if camshaft signal not valid for engine synchronization.

A021: Crankshaft sensor circuit diagnosis

Detection of open circuit and short circuit for magnetic crankshaft position sensor.

1.10 ERRM General

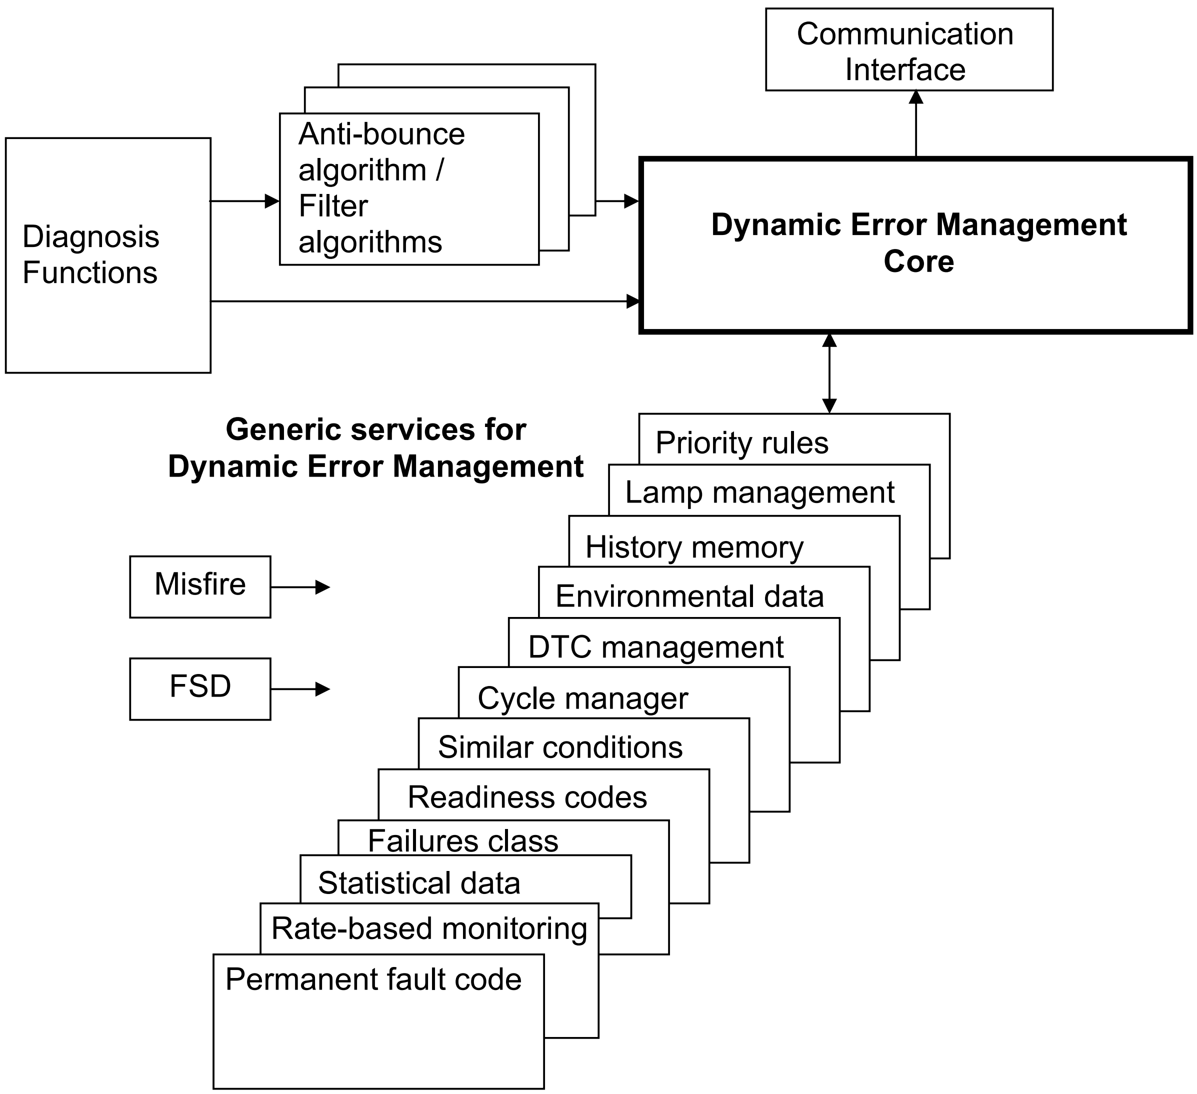
1.10.1 Target / Objectives of ERRM function

The purpose of the Error Management is :

- to collect, store and provide diagnostics information for repair and inspection programs
- to inform the driver via dashboard lamps from malfunctions which could affect emissions compliance with regulations (CARB for US market / EOBD for European market).

1.10.2 Architecture Overview

Principle of the dynamic error management is to receive diagnoses results (filtered or not by anti-bounce, muliti-condition, or statistical algorithms). These results are managed as diagnoses failures, according **CARB** and **EOBD** standards.



1.10.3 Description of the containing functions

- Dynamic Error Management core

The dynamic error management core manages different failures states thanks to the fault detection performed by the diagnoses : detected, present, temporary, pending, disappeared and confirmed. All failures are detected without any limitation on quantity. On the contrary, the number of present failures able to be stored into dynamic memory is limited. Management of this limitation is performed thanks to priority rules mecanism.
When a failure is stored into dynamic memory, the related environment data is stored, the lamp management may force lamp illumination (MIL, WAL,...), and DTCs management is done until failure is deleted. When deleted, failures are stored into history memory.

- History memory

History memory permits to trace historic of deleted failures. Some specific information are stored for each deleted failure. Only the more pertinent data linked to failure shall be stored.

- Debounce algorithm

The debounce algorithms is in charge of detected failures filtering according several available and predefined filters.

- Multi-conditions debounce algorithm

Debounce algorithm able to filter failures according a conditions per symptoms based algorithm.

- Cycle manager

Cycle manager computes driving cycle and warm-up cycle according to engine states and engine coolant temperature. Cycle manager permits to evaluate failure states.

- Failures class

Each failure can be configured to obtain a specific behaviour : emission relevant or not, can illuminate MIL or not ... This module contain to all the predefined behaviours each failure can be associated with. It permits to symplify greatly tuning of diagnosis by decreasing quantity of calibrations.

- DTC management

DTC management permits to catch some data when a failure becomes present and to generate a code identifier, called DTC. It permits to identify default of the function.

- Communication interface

This module allow to access failure memory data related to error management such as freeze frame, stored DTCs, readiness codes.

- Priority rules

This module manages dynamic memory size limitation. It defines criteria, called priority rules, to store or not a new failure into this dynamic memory.

- Environmental data

This module describes the structure of the freeze frame and its management : storage and delete.

- Similar conditions

Similar conditions are additional conditions based on engine and load status to erase a failure in memory (for Misfire and Fuel system failure only).

- Lamp management

Lamp management module can manage illumination of several warning lamps (MIL and other warning lamps) including pre-drive check.

- Readiness codes

Readiness codes allow to know if a diagnosis has been performed or not.

- Rate-based monitoring

Rate-base monitoring functionality : monitoring performances under real world conditions. Performs statistics calculation on diagnoses.

- Statistical data

Statistical data allows monitoring and storage of statistical data on error management data flow.

- Permanent fault code

This module manages the permanent fault codes into a new dedicated dynamic memory.

1.11 EXTC General

The aggregate EXTC –EXhaust system Temperature Control- concerns the component overheating prevention and catalyst heating.

1.11.1 Components overheating prevention functions

There are 3 measures to reduce the temperature in the exhaust line. With high temperature first *ignition retardation* shell be inhibited, because it causes high exhaust temperature due to worse combustion efficiency (used for catalyst heating). The 2nd measure is the enrichment of the air/fuel mixture, what makes the temperature decrease. The 3rd measure is the reduction of the indicated torque. With high catalyst temperature especially after a time with enriched mixture it is necessary to inhibit fuel cutoff in pull phase. This function is located in Appl. Inc. and can be modified by project in "Overheating prevention (Appl. Inc.)". In the figure below the overheating prevention interfaces are marked gray.

1.11.1.1 Minimum ignition limitation

The inhibition of late ignition angles is realized via limitation of the minimum ignition difference to reference ignition - IGA_DIF_MIN_TEG. In general this value does not limit the ignition itself, but reduces the torque reserve! For steady state environment this corresponds to an ignition advance. Dynamic torque reduction via ignition retardation below IGA_MIN_TEG is allowed!

For direct limitation of the ignition the value IGA_DIF_MIN_TEG_BAS has to limit IGA_DIF_MIN. This function has to be done by the project in "(TQM) Minimum ignition angle".

According specification: "IGA_MIN limitation for exhaust gas temperature protection"

1.11.1.2 Enrichment of air-fuel mixture

With richer mixture the exhaust temperature can be lowered. For catalyst overheating prevention there is an I–controller. The number of temperatures which are to be controlled and their location can be specified in Appl. Inc. and configuration. It is recommended to use for controlling static catalyst temperatures to realize a better control response. For turbine overheating prevention -if existent- there is a P-I--controller. The lambda-interface is LAMB_OHP and concerns the minimum of LAMB_COP (for catalyst prevention) and LAMB_TUR_OHP (for turbine prevention).

According specification: "Overheating prevention (Appl. Inc.)"; "Catalyst overheating prevention"; "Turbocharger overheating prevention"

1.11.1.3 Torque reduction

The reduction of the indicated torque shell normally not become effective – depends on catalyst design. The function can be activated if the Lambda-setpoint is on bottom limit and the temperature is still high.

According specification: "Torque based overheating prevention"; "Torque based turbine overheating prevention"

1.11.2 Catalyst heating functions

With EXTC you can impact on several setpoints to optimize them for quick light off of the catalyst and for minimum emissions. Catalyst heating can be activated for after start catalyst heating and for catalyst heating in low load to avoid temperatures below the catalyst working temperature.

The parameters for catalyst heating are:

- TQ_ADD_CH - torque reserve (results in air mass flow and ignition)
- LAMB_CH - air-fuel-mixture
- N_SP_IS_CH - idle speed setpoint
- FUP_RES_H_SP_CH - fuel pressure setpoint – only relevant HPDI engines
- CAM_SP_IVVT_CH_IN/EX - camshaft setpoints (for variable valve timing)
- SOI_1_MPLH_CH - start of 1st injection during MPLH *-only AGGR-Vers. 2*
- EOI_2_MPLH_CH - end of 2nd injection during MPLH *-only AGGR-Vers. 2*
- FAC_MFF_SP_1_MPLH_CH - Split up factor for MPLH *-only AGGR-Vers. 2*

These setpoints are inputs for other aggregates and are used if catalyst heating is active. Some of them are inputs in application incidences of other aggregates and can be used in different ways. The catalyst heating interfaces are marked black.

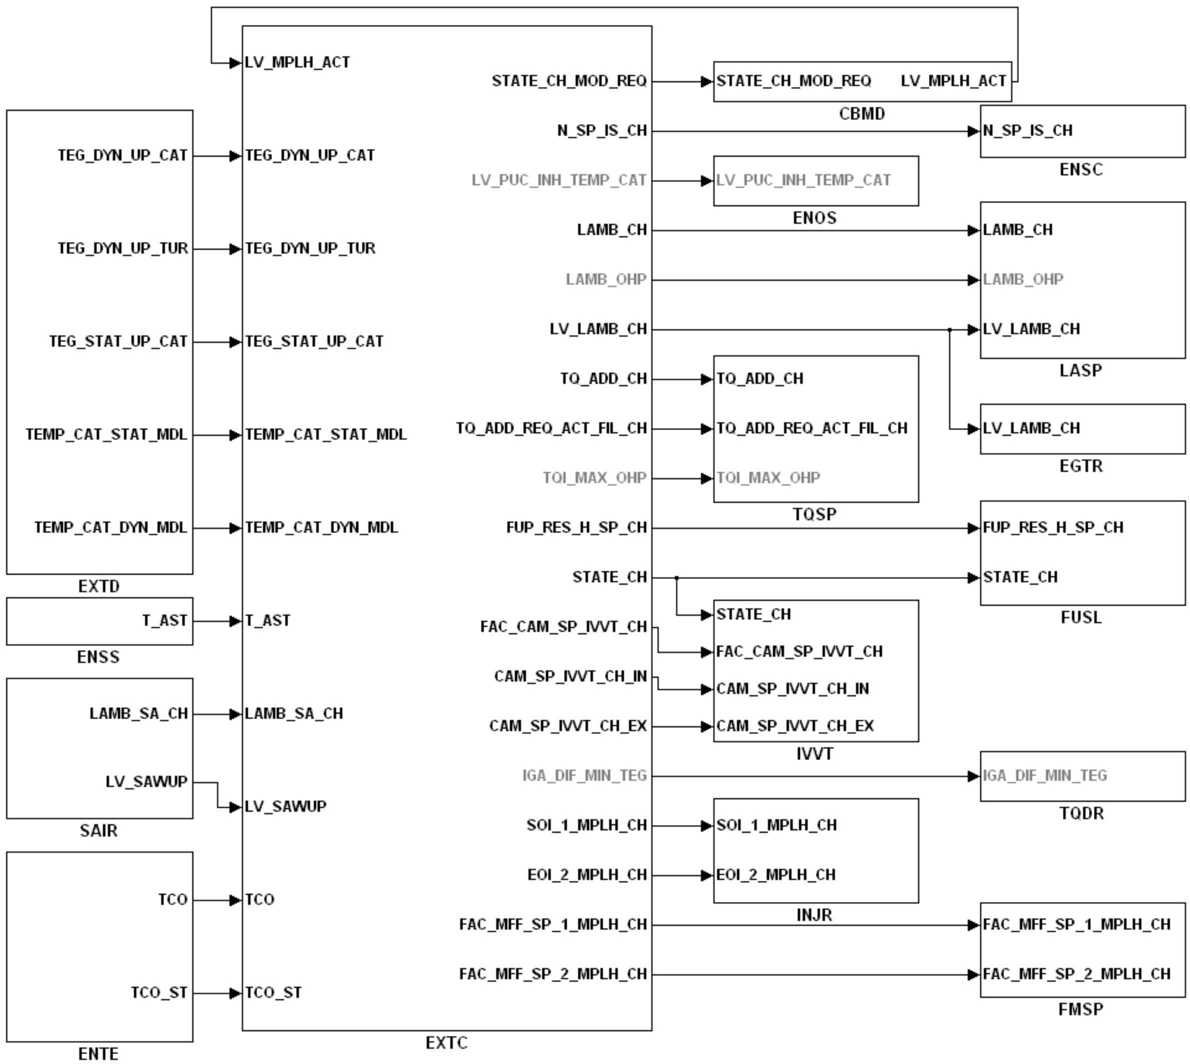


Figure: Main aggregate interfaces

1.12 EXTD General

EXTD (EXhaust system Temperature Determination) is the aggregate where all necessary temperatures in the exhaust line are determined. These temperatures are used for different purposes in different other functionalities:

1. Component overheating prevention: Turbine and Catalyst overheating prevention
2. Lambda sensor heater management
3. Catalyst efficiency diagnosis

Additionally EXTD is responsible for the dew point detection (or dew point passed detection) which is used for the full activation of the lambda sensor heater.

In general there are two ways to determine the temperatures in the exhaust line:

1. Measurement of the exhaust gas temperature
2. Model of the exhaust temperature dependent on the engine operating conditions

The model is always necessary to have a back up information in case of sensor damage and the sensor damage has also to be detected.

So EXTD can be split up in 4 parts:

1. Exhaust gas temperature sensor acquisition
2. Exhaust gas temperature sensor diagnosis
3. Exhaust gas temperature model
4. Dew point detection

1.12.1 Exhaust gas temperature sensor acquisition

Three specifications belong to this part:

1. **EXTD infrastructure requirement specification (IRS)**: Specifies all information concerning the hardware of the ECU and how often the sensor information is updated. If no sensor is available in the system (NC_TEG_SENS_TYP = No Sensor) this specification is skipped.
2. **Exhaust gas temperature sensors (Appl. Inc.)**: Project specific part to inhibit the sensor acquisition for different cases e.g.: If the sensor is only available for certain configurations: Turbo / non Turbo; US market / European market. If no sensor is available in the system (NC_TEG_SENS_TYP = No Sensor) this specification is skipped.
3. **Exhaust gas temperature sensors**: Deals with the sensor information acquisition which can be the raw value of the ADC converter or a PWM value in case of a sensor type with external evaluation control unit which communicated with the ECU by PWM information. Conversion of the raw value in a "raw" exhaust gas temperature and filtering of this "raw" exhaust gas temperature. If no sensor is available in the system (NC_TEG_SENS_TYP = No Sensor) TEG_MES is initialized by zero within this specification.

1.12.2 Exhaust gas temperature sensor diagnosis

This part consists out of two specifications:

1. **Exhaust gas temperature sensor diagnosis (Appl. Inc.)**: Project specific part where the conditions for the activation of the different diagnosis are specified and also the anti bounce behaviour of the different diagnosis are specified. If no sensor is available in the system (NC_TEG_SENS_TYP = No Sensor) this specification is skipped.

2. **Exhaust gas temperature sensor diagnosis**: 4 different types of diagnosis are carried out here: electrical diagnosis, cold start diagnosis, increment diagnosis and gradient diagnosis. If no sensor is available in the system (NC_TEG_SENS_TYP = No Sensor) the global error flag LV_ERR_TEG_MES is initialized by zero.

1.12.3 Exhaust gas temperature model

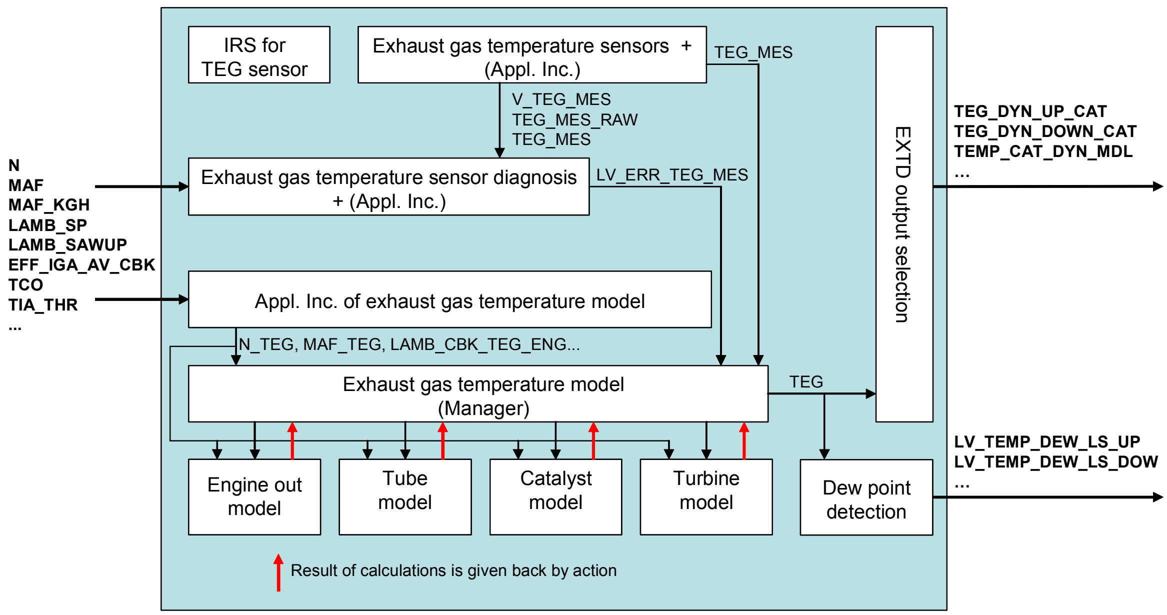
This part is the most important and also the biggest part of EXTD with the following 7 specifications:

1. **Exhaust gas temperature model (Appl. Inc.)**: In this project specific part almost all inputs of the exhaust gas temperature model are generated out of the available system information. E.g.: The engine speed for the exhaust gas temperature model N_TEG is generated out of the system variable N. This is done to deal with different customer request (e.g.: to have a filtered engine speed as input for the exhaust gas temperature model). Additionally several customer specific corrections (e.g.: TEG_ENG_OUT_ADD_CUS) for different purposes (e.g.: VVL and MPLH corrections) can be generated here.
2. **Exhaust gas temperature model**: This module is the manager of the exhaust gas temperature model. All component models (Engine out- / Tube- / Turbine- and Catalyst exhaust gas temperature model) are coordinated here. This means the manager calls the different component models in the right order with the correct update rate and writes the result calculated in the component model in the right position of the arrays (TEG_DYN_MDL, TEG, LV_TEMP_DEW_MDL...). It handles also at which position the sensor information is used instead of the model based value. There is only one calibration data in the specification LC_TEG_MDL_SENS_ENA which has to be set to one if the sensor information shall be used (if no sensor error detected). So for calibration this specification is not important.
3. **Engine out exhaust gas temperature model**: In this module all engine operating point dependencies (e.g.: engine speed, load, ignition angle ...) are used to determine the first temperature which is effective engine out exhaust gas temperature. Additional the engine out exhaust gas humidity is determined here.
4. **Tube exhaust gas temperature model**: This model part is used to simulate the cooling down of the exhaust gas and the influence on the dynamic of the exhaust gas temperature by the influence of the heat capacity of an exhaust pipe like the exhaust manifold and by the external conditions like ambient temperature and vehicle speed.
5. **Turbine exhaust gas temperature model**: This model part is used to simulate the cooling down of the exhaust gas due to the turbine power and the influence on the dynamic of the exhaust gas temperature by the influence of the heat capacity of the turbine housing and by the external conditions like ambient temperature and vehicle speed.
6. **Catalyst exhaust gas temperature model**: This model part is used to simulate the catalyst temperature and it's dynamic. Therefore the exothermic reactions are considered to calculate the increased temperature in the catalyst and also ambient temperature and vehicle speed are again used to calculate the exhaust gas temperature downstream catalyst.
7. **EXTD Output selection**: At the end of the calculation all exhaust gas temperatures are available in the array TEG[NC_NR_TEG_MDL] but the output of the aggregate are values with a certain naming (e.g.: TEG_DYN_UP_CAT). For each value with a certain naming a value out of TEG has to be selected. This mapping is done in this module.

1.12.4 Dew point detection

The dew point detection is a project specific specification because there are several strategies for this functionality. All information's out of the exhaust gas temperature model, like modelled tube wall temperatures and the internal dew point flags for each position in the exhaust line LV_TEMP_DEW_MDL[NC_NR_TEG_MDL], can be used to determine the "dew point passed flag" LV_TEMP_DEW_LS_UP/DOWN for the upstream and downstream sensor. But also mass air flow integral can be used to set the dew point flag. Of course also combinations out of these information's are possible.

Module overview:



1.12.5 Introduction

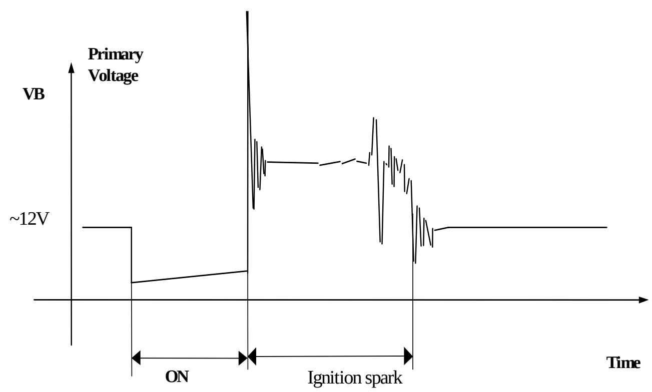
This document is the Aggregate Integration Document of the IGRE Aggregate. Its aim is to describe the integration constraints of this aggregate with the others. It aims with interfaces (imported and exported), architecture, and configuration. This document covers all versions of the IGRE aggregate.

1.12.6 Purpose

The IGRE Aggregate defines the calculation of the dwell time, the ignition realization and the ignition diagnosis functions.

Basically the ignition command function has to fulfill two main tasks; to ensure that there is enough energy in the ignition coil and to start the combustion at the requested ignition angle. Knowing the desired ignition advance, engine speed and several other parameters, this aggregate determines the correct timing for switching ON and OFF the power stage in order to bring the ignition coil to the necessary primary current value. The time during ON state (load phase) of the switch is often improperly called Dwell time (with reference to the dwell ratio in breaker systems).

At the end of this Dwell time the ignition stage is switched OFF and the ignition spark is created. The OFF event corresponds to the advance ignition angle (IGA_IGC).



The ignition command functions and the linked diagnostic functions are regrouped in the ignition realisation aggregate.

1.12.7 Function Description

This function sets the angular position of the dwell time turn on in order to have the time to set up the necessary current in the ignition coil.

The strategy is based on a priority of the ignition angle. If dwell time priority is requested the minimum dwell time is equal to maximum dwell time.

The strategy respects ignition coils with dual and single outputs. This function could be used independently of the number of cylinders (x) and the geometry of the crankshaft target wheel.

All of the functions described in this section operate over the entire engine speed range.

- Realization of minimum 1 ignition spark per cycle
- Realization of a number of multiple spark

- Physical limits of the ignition angle +60°CRK / -35,625°CRK
- In case of an acceleration of ±10 000 RPM/s the ignition spark output tolerance depending on engine speed.

1.13 IGSP General

1.13.1 General description

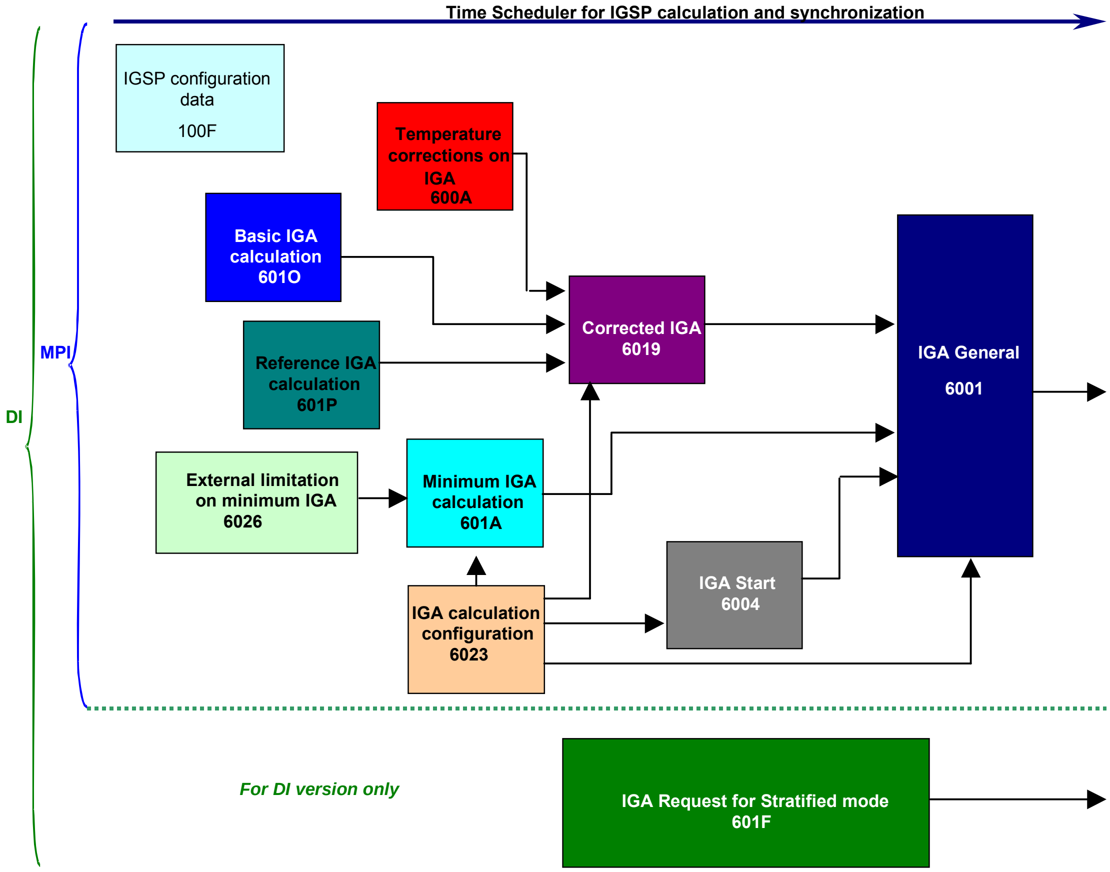
The IGSP Aggregate defines the calculation of the ignition angles to be applied on an engine with a TQ based EMS.

The Ignition functionality of an engine management system can be organised in two different parts. A first part is the determination of the ignition angle itself, and a second one is the realisation of this ignition angle with the management of the charge and the discharge of coils. This document is the “over head” for the first part, “Ignition Angle Calculation / Ignition Angle Setpoint”. The information of this function will thus been send to the coil for the proper application on the spark of the mandatory determined ignition angle.

The goal of this aggregate is to calculate the 3 ignition angles (BAS, REF and MIN) that describe the limits of engine behaviour and capacities and then to co-ordinate this basic structural angle with the ignition angle request from the Torque manager to produce the requested torque in the requested period, with the limitation to the engine possibilities. The ignition angle hence calculated will be provided to the second part in order to be realised as best by the ignition coil.

The Ignition structure gets an ignition angle request from torque structure (named IGA_DIF_TQ_REQ) which is the transformation in term of ignition angle of the setpoint for TQ. It provides representative ignition angles to the other functionality. With this information, the torque structure can interpret and define which ignition angle has to be realised. Then the ignition angle choice between TQ requests and engine possibilities with IGA is done to produce the best fitted (in term of TQ production and engine limits respect) ignition angle that will be applied to each cylinder.

1.13.2 Architecture Overview



1.13.3 Description of the containing functions

<u>Ignition angle calculation structure</u>

The calculation of the ignition angle to be applied is done by various functional calculations steps represented by the modules here listed:

- *IGSP Configuration data*
  Here are defined – by each project – the configurations values to be used for IGSP aggregate

- *IGA_BAS calculation*
  For the calculation of the basic ignition angle depending on the engine configuration Homogenous or Lean Burn and cylinder bank specific.

- *Reference IGA calculation*
  Here the reference ignition for best torque production is computed.

- *Temperature correction on ignition angle*
  Here the temperature corrections on IGA_BAS and IGA_REF are computed.

- *External limitation on minimum ignition angle*
  Some external limitations can be admitted on the minimum ignition in some particular engine running area.
  Each projects have to provide their specific considerations for this function.

- *Configuration of IGA calculation*
  Here are defined – by each project - the name of external corrections that will be applied to ignition

- *Minimum ignition angle*
  This module defines the minimum possible ignition angle for combustion stability.

- *Corrected IGA*
  Here the corrections on IGA_BAS and IGA_REF are performed: gathering and calculation of all corrections on the ignition angles.

- *Basic ignition angle at start*
  This module enables a specific management of IGA during start phase.

- *Ignition angle general*
  This block manages all the ignition requests – regarding torque request and engine capacities – and defines the IGA to be applied at the coil.

In case of switch to stratified mode only the module hereafter is calculated in the software.

- *IGA Request for stratified mode*
  This module co-ordinates the calculation of the ignition angle IGA_AV_S[x] which is applied to each different cylinder of the engine in Stratified combustion mode. This value is directly related and fitted for one particular cylinder (*cylinder x*).

1.14 General information

1.14.1 Target

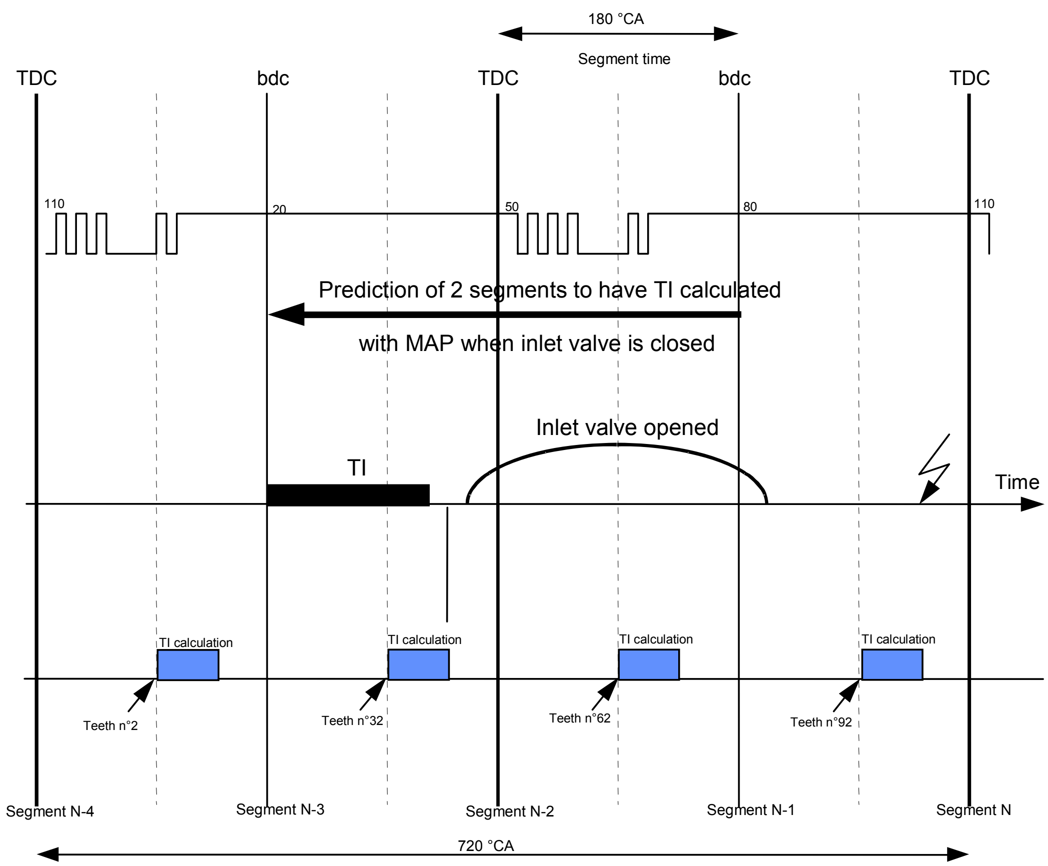
The purpose of the "**In**take **Sy**stem" (INSY) is to coordinate the air flow controlling components and to predict the air mass flow behavior. Needed is the prediction, as the injection time is calculated based on the real mass-flow, which is present in the cylinder for the considered combustion cycle. However, the injection time is calculated before the closure of the intake valves, and parameters like MAP or MAF are still not known.

All this modeling aims to evaluate, at the moment of the injection time calculation, the conditions in pressure and flow which are present at the closure of the intake valves for the concerned combustion cycle. Therefore, the predicted pressure is calculated. This predicted pressure is the estimation of the pressure value at the moment of the injection.

⇒ Calculation of MAF_THR, MAF_CYL and MAP in order to calculate MAP_PRED and MAF.

1.14.2 Scheme

Example for a 4 cylinder engine:



1.14.3 Dependence of IMM on reliable measurement signals

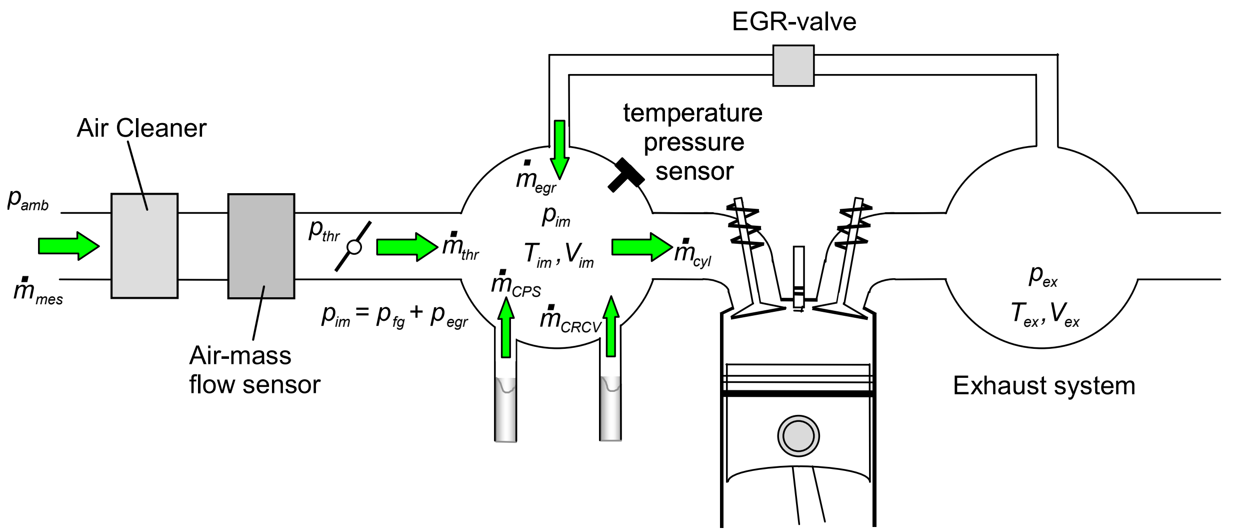
To reach always λ = 1, i.e. in steady state / transient, cold / warm engine operating a precise load signal is required. The IMM strongly depends on reliable measurement signals, for two main reasons:

In **systems equipped with an air-mass flow sensor (HFM)** during steady state engine operation, the measured air-mass flow signal (MAF_KGH) usually equals the air-mass flow into the cylinder, which is the base for injection time calculation. This is not true during transient engine operation, because of the filling characteristic of the manifold. The air-mass flow sensor is mounted in front of the intake manifold, which behaves during transient as a mass storage system. To avoid λ deviations, the dynamic behavior (in steady state and transient engine operating) of the intake manifold is calculated via the “INSY”.

Systems equipped with a manifold pressure (MAP) sensor do not have problems with the filling dynamics of the intake manifold. Because the air-mass flow is not directly measured but only calculated out of the air density, **it strongly depends on the knowledge of the air-temperature in the manifold**. Any deviations from the temperatures valid during the calibration of the engine have to be compensated.

1.15 Physical background

1.15.1 Scheme of the system used



Variables used:

p_{AMP}	AMP	Ambient pressure
p_{thr}	PUT	Pressure up stream the throttle
$\dot{m}_{THR}$	MAF_THR	Air-mass flow at the throttle
$\dot{m}_{CYL}$	MAF_CYL	Air-mass flow into the cylinder
$\dot{m}_{EGR}$	MAF_EGR	Exhaust air-mass flow
$\dot{m}_{CPS}$	FLOW_CPS	Air-mass flow through the canister purge solenoid
$\dot{m}_{CRCV}$	FLOW_CRCV	crank case air flow
T_{im}	TIA	Intake air temperature
V_{im}	VOL_IM	Volume of the intake manifold
p_{ex}	PRS_EX	Pressure in exhaust system
T_{ex}	TEG_EGR	Temperature of the exhaust side of EGR valve

1.15.2 Physical/ mathematical laws used in the intake manifold model

- The IMM is based on the **conservation of mass** over the intake manifold. Assuming that the air is an ideal gas this gives the basic equation:

$$\frac{\partial}{\partial t}\left(\frac{p_{im}V_{im}}{R_{air}T_{im}}\right) = \dot{m}_{in} - \dot{m}_{out} \qquad (3)$$

The inflowing air-mass flow is the sum of the throttle air-mass flow, the exhaust gas recirculation, the flow through the canister purge solenoid (CPS) and the crank case air flow (CRCV) $\dot{m}_{in} = \dot{m}_{thr} + \dot{m}_{egr} + \dot{m}_{cps} + \dot{m}_{crcv}$. The outflow is the air-mass flow into the cylinder.

Under the assumption that T_{im} and V_{im} *are* not time dependent (or at least quasi stationary) the **overall pressure change** can be modeled as:

$$\frac{\partial}{\partial t}p_{im} = \frac{R_{air}T_{im}}{V_{im}}\left(\dot{m}_{THR} + \dot{m}_{EGR} + \dot{m}_{CPS} + \dot{m}_{CRCV} - \dot{m}_{CYL}\right) \qquad (4)$$

- **The air-mass flow through the throttle** can be described with the flow of ideal gas through throttle. Throttling will be taken into account with the reduced area A_{red}

$$\dot{m}_{thr} = A_{red}\cdot\sqrt{\frac{2\cdot\chi}{\chi-1}\cdot\frac{1}{R_{air}\cdot T_{im}}}\cdot p_{thr}\cdot\Psi \qquad (5)$$

With

$$\Psi = \begin{cases} \sqrt{\left(\frac{p_{im}}{p_{thr}}\right)^{\frac{2}{\chi}} - \left(\frac{p_{im}}{p_{thr}}\right)^{\frac{\chi+1}{\chi}}} & \text{for undercritical pressure ratio } \left(\frac{p_{im}}{p_{thr}} > 0.53\right) \\ \Psi_{critical} = 0.2588 & \text{for overcritical pressure ratio } \left(\frac{p_{im}}{p_{thr}} < 0.53\right) \end{cases} \qquad (6)$$

The reduced area of the throttle A_{red} is a function of the throttle position TPS. The critical pressure ratio is the pressure ratio where sonic speed is reached at the throttle

$$\left.\frac{p_{im}}{p_{thr}}\right|_{critical} = \left(\frac{2}{\chi+1}\right)^{\frac{\chi}{\chi-1}} \approx 0.53 \qquad (7)$$

- The **flow into the cylinder** is modeled via the (linearized) volumetric efficiency

$$\dot{m}_{cyl} = \eta_{slop} \cdot p_{fg} + \eta_{slop} \cdot p_{EGR} - \eta_{ofs} \cdot \frac{p_{fg}}{p_{im}} - \eta_{ofs} \cdot \frac{p_{EGR}}{p_{im}} \tag{8}$$

where p_{fg} means the fresh gas partial pressure in the manifold (if no EGR available, it is the same as the manifold pressure). The volumetric efficiency is the suction air of the engine. It mainly depends on the engine speed, the exhaust gas pressure and engine hardware (e.g. variable valve timing, port flap position, variable intake manifold).

- The **intake manifold pressure** p_{im} is calculated by integration of eq. (2) with a trapezoidal algorithm

$$p_{im}^{N} = p_{im}^{N-1} + \frac{\Delta t^{N}}{2} \cdot \left(\dot{p}_{im}^{N-1} + \dot{p}_{im}^{N}\right) \tag{9}$$

- Similar to (2) the model for the exhaust **gas partial pressure** in the manifold can be derived (mass balance for exhaust gas)

$$\frac{\partial}{\partial t} p_{EGR} = \frac{R_{EGR} T_{im}}{V_{im}} \left(\dot{m}_{EGR} - \dot{m}_{cyl}^{EGR}\right) \tag{10}$$

To simplify differences between R_{air} and R_{EGR} at T_{im} are neglected (strictly, this is only valid for $\lambda = 1$).

- The **flow at the exhaust gas recirculation valve** can be modeled similar to that at the throttle

$$\dot{m}_{thr}^{EGR} = A_{red}^{EGR} \cdot \sqrt{\frac{2 \cdot \chi}{\chi - 1} \cdot \frac{1}{R_{air} \cdot T_{im}}} \cdot p_{ex} \cdot \Psi^{EGR} \tag{11}$$

with

$$\Psi^{EGR} = \begin{cases} \sqrt{\left(\frac{p_{im}}{p_{ex}}\right)^{\frac{2}{\chi}} - \left(\frac{p_{im}}{p_{ex}}\right)^{\frac{\chi+1}{\chi}}} & \textit{for}\ \text{undercritical}\ \textit{pressure ratio} \\ \Psi_{critical} = 0.2588 & \textit{for overcritical pressure ratio} \end{cases} \tag{12}$$

and p_{ex} meaning the pressure at the upstream side of the EGR valve (exhaust gas pressure).

The air-mass flow of exhaust gas into the cylinder can be calculated based on

$$\dot{m}_{cyl} = \dot{m}_{cyl}^{fg} + \dot{m}_{cyl}^{EGR} = \eta_{slop} \cdot p_{im} - \eta_{ofs} = \eta_{slop} \cdot (p_{fg} + p_{EGR}) - \eta_{ofs} \cdot \frac{(p_{fg} + p_{EGR})}{p_{im}} \tag{13}$$

as

$$\dot{m}_{cyl}^{EGR} = \eta_{slop} \cdot p_{EGR} - \eta_{ofs} \cdot \frac{p_{EGR}}{p_{im}} \tag{14}$$

The exhaust gas partial pressure is integrated with a rectangular algorithm

$$p_{EGR}^{N} = p_{EGR}^{N-1} + \Delta t^{N} \cdot \dot{p}_{EGR}^{N} \tag{15}$$

With the intake manifold pressure p_{im}^{N} (calculated with (2) - (7)) and the exhaust gas partial pressure p_{EGR}^{N} (calculated with (8) – (13)) it is possible to calculate the **fresh gas partial pressure**

$$p_{fg} = p_{im}^{N} - p_{EGR}^{N} \tag{16}$$

and then the fresh gas mass flow into the cylinder.

$$\dot{m}_{cyl,fg} = \eta_{slop} \cdot p_{fg} - \eta_{ofs} \cdot \frac{p_{fg}}{p_{im}} \tag{17}$$

In systems without EGR, the fresh-gas partial pressure equals the intake manifold pressure

$$p_{fg} = p_{im}^{N} \tag{18}$$

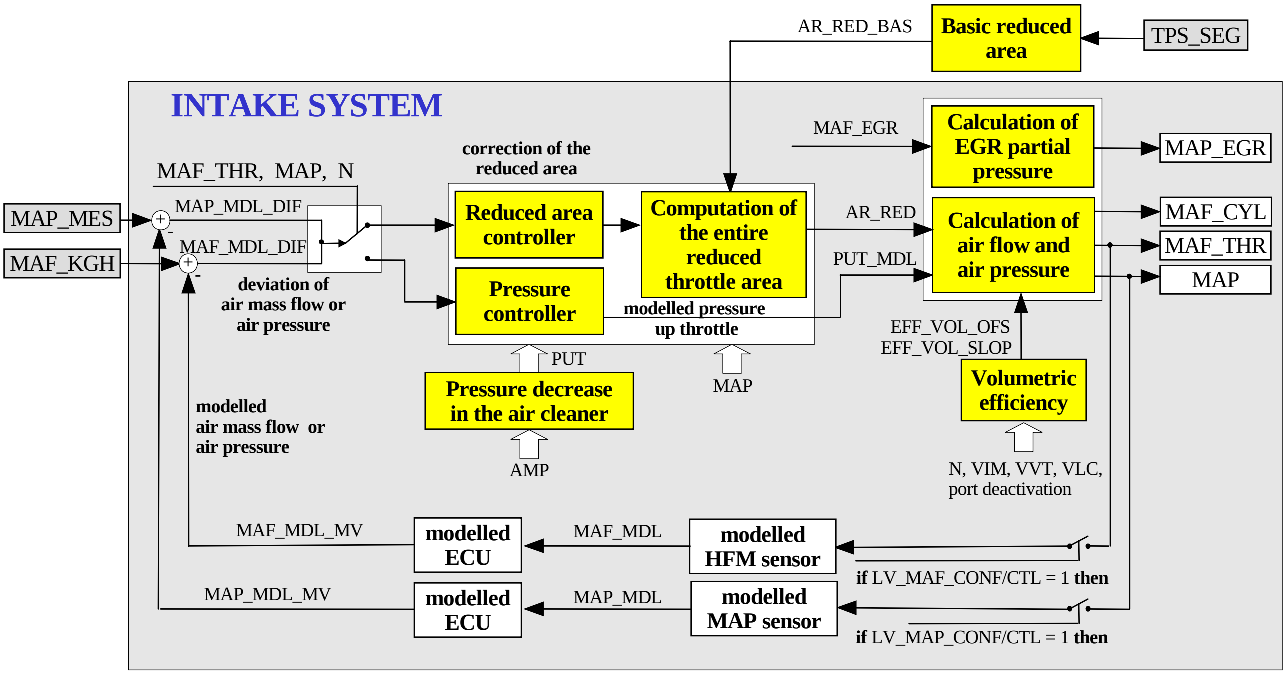
- Due to injection-timing constraints, it is necessary **to predict the pressure in the intake manifold** (usually about 2 segments in advance). The prediction ensures, that the air-mass flow used for the injection timing calculation is as close as possible to the pressure at closing the respective inlet valve. The prediction is done by extrapolation of the actual pressure with the mean value of the last two pressure gradients multiplied by a calibratable constant C

$$p_{fg}^{pred} = p_{fg} + \frac{(\dot{p}^{N} + \dot{p}^{N-1})}{2} \cdot C \cdot \Delta t^{N} \tag{19}$$

With the predicted pressure the (predicted) air flow into the cylinder (at closing the intake valve) is

$$\dot{m}_{cyl,fg}^{pred} = \eta_{slop} \cdot p_{fg}^{pred} - \eta_{ofs} \tag{20}$$

1.15.3 Algorithm for the complete Intake Manifold System



The complete calculation algorithm for the Intake manifold system is subdivided into six major separate modules:

- application incidence for project specific adaptation
- calculation of the air/EGR partial pressures and air mass flows
- INSY-controller with reduced area controller and pressure up throttle controller
- ambient pressure adaptation with ambient pressure learning
- reduced area adaptation
- calculation of the pressure decrease in the air filter
- volumetric efficiency calculation
- basic reduced area calculation

In addition, there are modules that strictly do not belong to the IMM, but usually are handled with the IMM:

- data acquisition for MAF values
- data acquisition for MAP values

The tuning of the complete IMM is therefore consequently also subdivided into the tuning of the separate depicted modules.

1.16 Measurement Set-up

1.16.1 Required sensor equipment

The following sensors are required for a calibration of the IMM:

- Pressure sensor in the intake manifold
- Linear lambda sensor
- Air-mass flow sensor and / or a fuel-consumption measuring device
- Barometer in the test-cell
- Coolant temperature sensor
- Intake air temperature sensor
- Pressure sensor between air filter and throttle
- Pressure sensor in the exhaust system (if EGR is configured)
- Pressure sensor just in front of the EGR-valve (if EGR is configured)
- Temperature sensor in front of the EGR-valve (if EGR is configured)

1.16.2 Recommendations on sensor equipment

It is recommended to use **calibrated** sensors. At least the HFM and all pressure sensors shall be calibrated. The HFM sensor should be calibrated completely mounted on the air-filter module on the flow-bench (required time: about ½ day). The resulting table should be used instead of the table in the ECU.

If possible, a pulsation compensated HFM sensor should be used. If the data acquisition is capable of measuring external analogue channels, it is not necessary to use the system HFM (i.e. the airflow sensor can be of any type). If no pulsation compensated HFM is used, it is important to mount the sensor at a location where no pulsation effects occur. E.g. an oil barrel, mounted **upstream** of the air-cleaner can be used as a low pass filter (do not mount it downstream of the throttle, the barrel will be damaged). If the airflow sensor is mounted upstream of the barrel, this ensures that no pulsation effects will occur. It is recommended to mount an air-intake in front of the sensor.

1.16.3 Data acquisition system

If the data is acquired with a calibration system, it should be capable of measuring external analogue channels. In addition, it should be possible to convert those measured voltages into physical units by interpolation with tables (not only linear functions).

It should be possible to export measured data into tables either in ASCII or Excel file format.

1.16.4 Test bench

<u>Duration of tests on engine dyno:</u> 2 days

<u>Duration of tests on chassis dyno:</u> 1 week

<u>Duration of tests on climatic chamber:</u> 1-2 weeks

<u>Duration of tests on altitude bench:</u> 1 week

For the calibration of the intake manifold model at normal engine operation temperature, there are no special requirements for the test bench.

If the IMM has to be calibrated during warm-up (temperature dependency) at the engine dyno it would be helpful if the coolant (and the intake air) can be adjusted to any desired temperature (e.g. use heat exchanger in coolant circuit).

If the dyno is equipped with an ACS (Automatic Calibration System), all steady state measurements can be done very fast (and unattended) using the ACS.

1.17 Calibration Method

1.17.1 Calibration preparation

The following points have to be done or checked before beginning with the calibration:

- Pulsation compensated air-mass flow sensor is used
- HFM is mounted at a position where no pulsation takes place
- Calibration of the air-mass flow sensor was done with complete air-cleaner module and resulting conversion table is used for conversion of voltage to air-mass flow
- Adaptation of the throttle position sensor stabilized
- Intake manifold has no leakage (especially required for MAF system)
- Throttle — and if used Idle speed actuator — should be nominal for principal calibration
- Run-in phase of the engine is finished
- All sensors (especially HFM and MAP) are calibrated and signals have been checked.

For a calibration of the temperature correction of the volumetric efficiency in addition the data acquisition system has to be prepared so that it can be started directly before starting the engine. Otherwise, data at low temperatures will be lost.

1.17.2 Points to be checked during the engine run

The following points have to be checked during the engine run:

- Engine is operating at nominal temperature (about 90°C)
- System intake air has desired value (usually about 25 °C)

1.17.3 Interfering functions

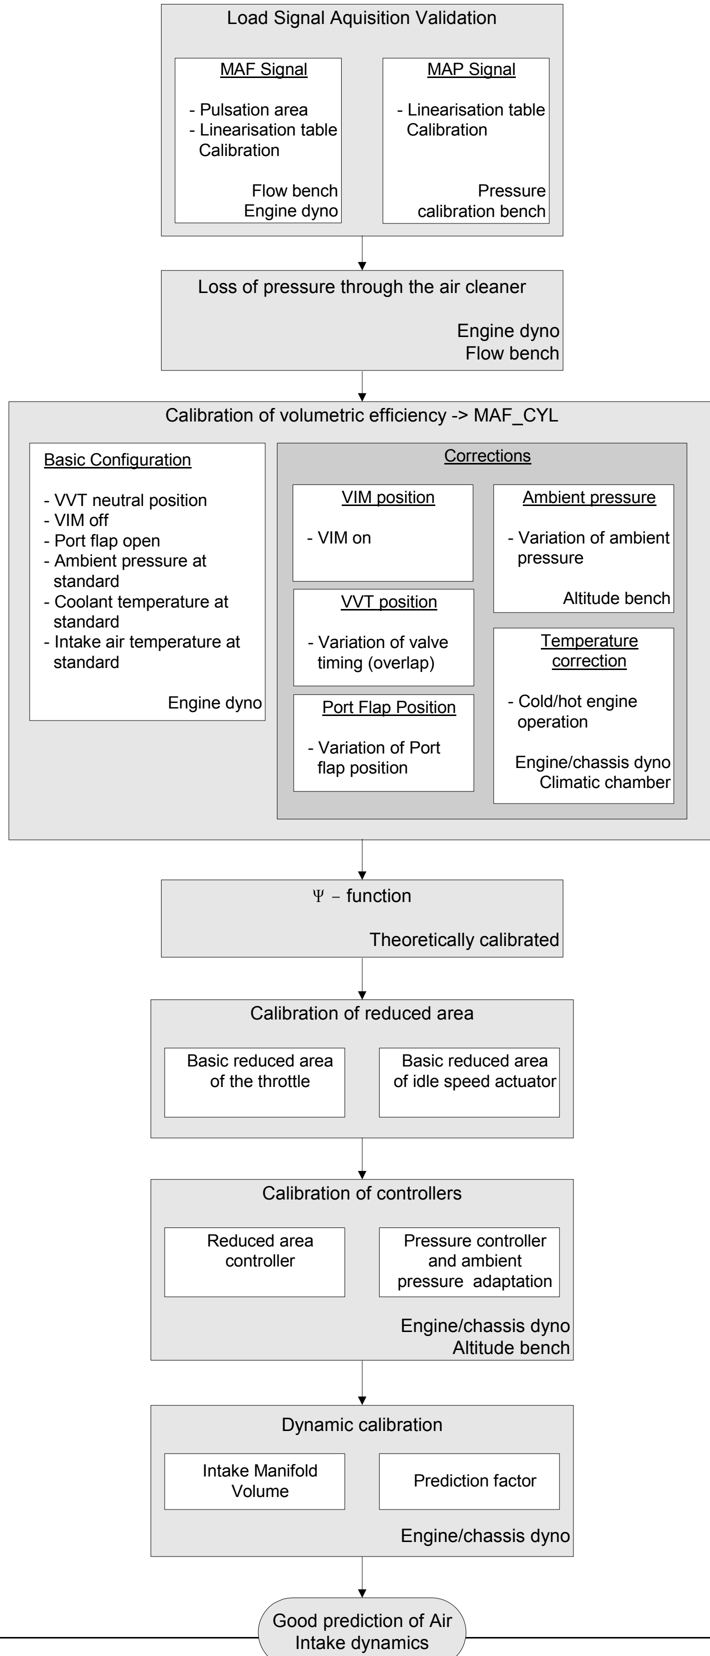
None

1.17.4 Test sequence

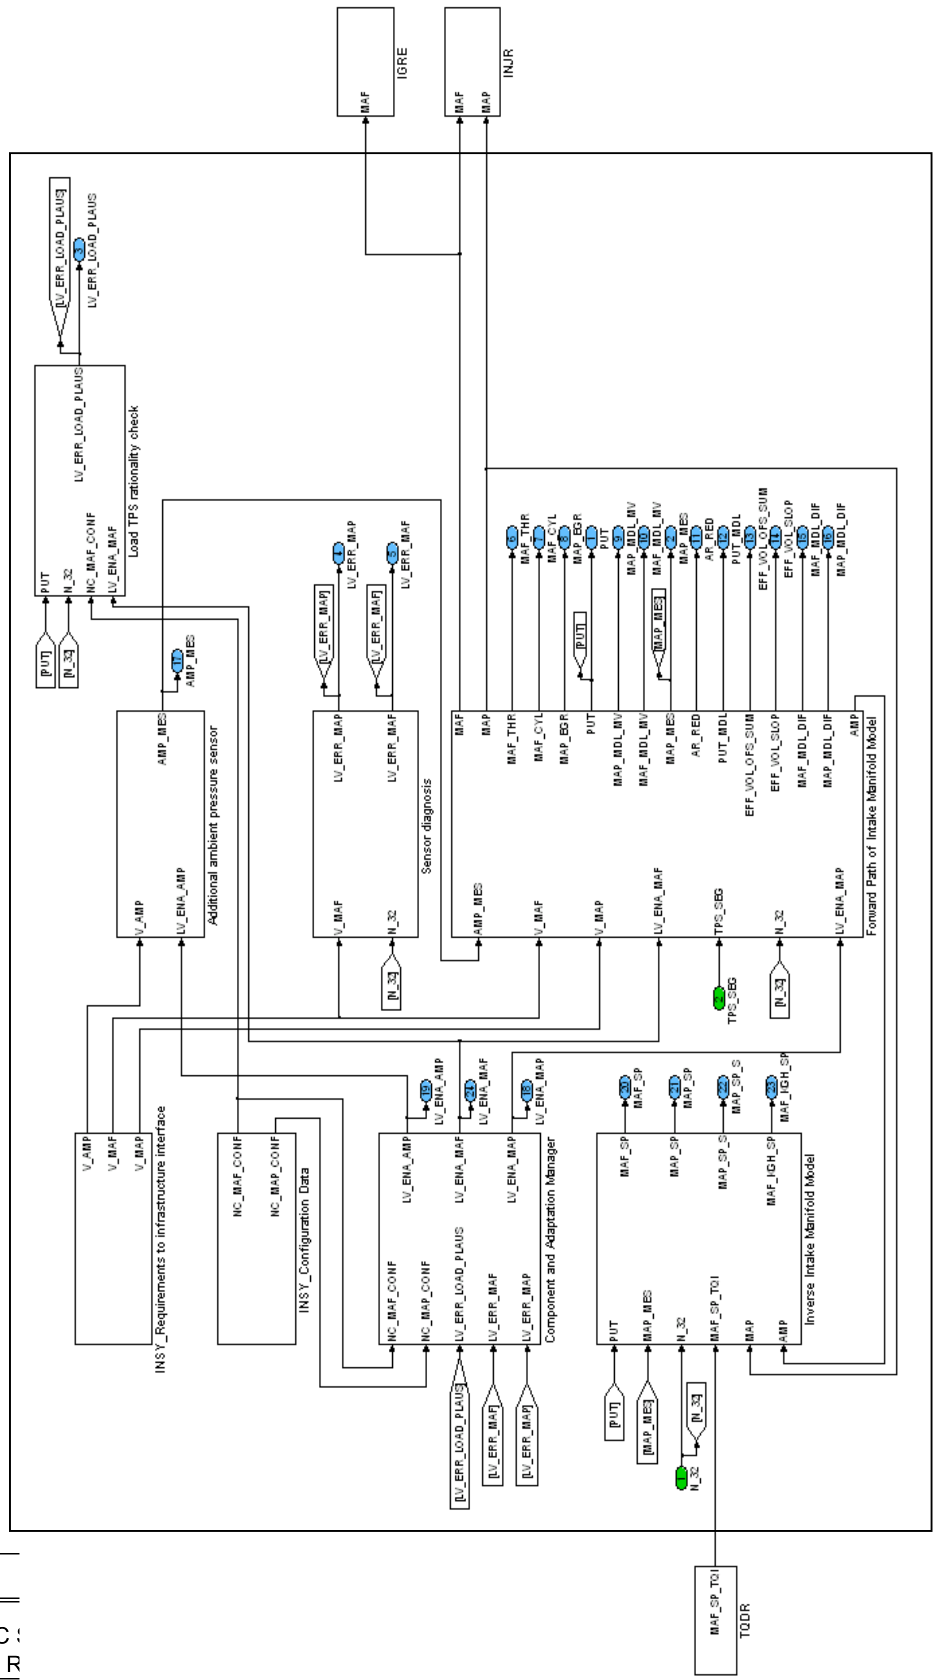
The steady state and transient calibrations are done on the engine test bench. The temperature corrections of the volumetric efficiency have to be done on a climatic chamber. Afterwards the steady state and transient calibrations have to be checked on a chassis dyno. Altitude corrections and pressure adaptation have to be calibrated either on an altitude test bench and/or on an altitude trip.

1.17.5 Calibration flow chart

general specification



1.17.6 Architecture Overview



1.18 MISF General

1.18.1 General description

The goal of the MISF is execute a misfire monitoring according legal requirements (conditions, engine area, errors & symptoms handling...) and provide to the ERRM aggregate following CARB misfire legal informations to manage the MIL and corresponding error Pcodes

- **CARB A misfire failure criterion:**

  Risk of catalyst damage, monitoring interval over 200 crankshaft during the driving cycle.

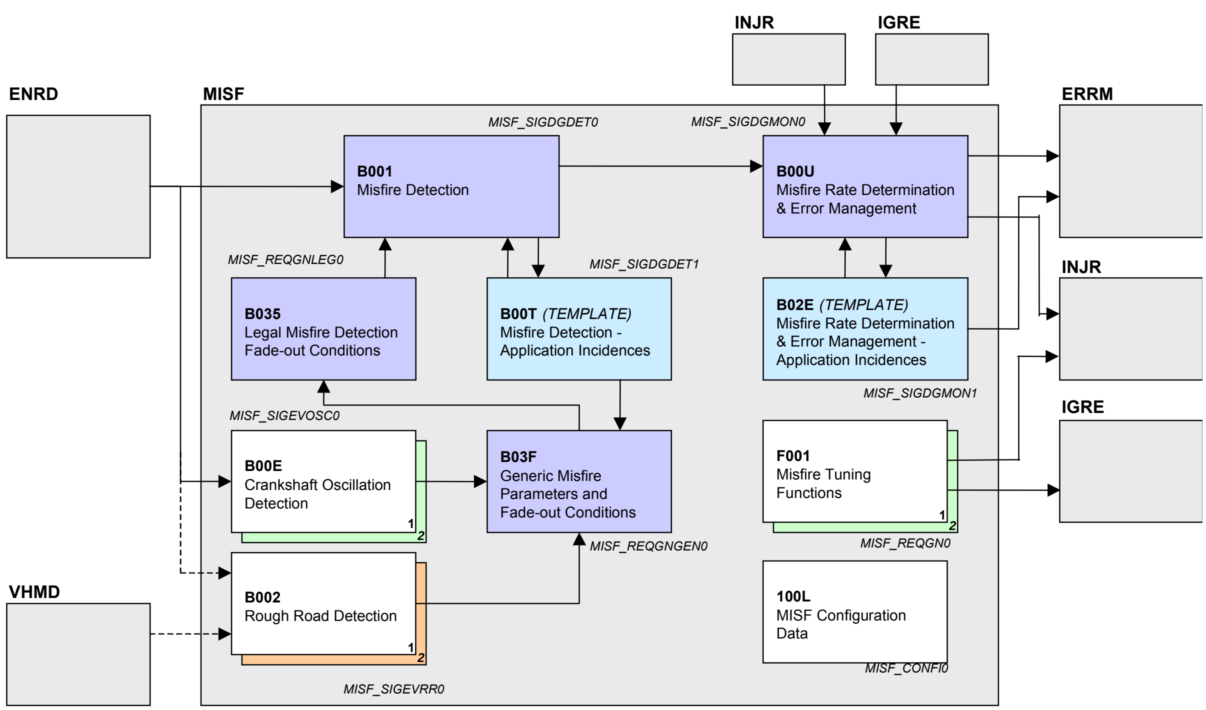
- **CARB B1 misfire failure criterion:**

  Emission increase, monitoring interval over the first 1000 crankshaft revolutions of the driving cycle.

- **CARB B4 misfire failure criterion:**

  Emission increase, monitoring interval over 1000 crankshaft revolutions. For error detection, misfire must be take place for 4 monitoring intervals (consecutive or not).

1.18.2 Architecture Overview



1.18.3 Description of the containing functions

1.18.3.1.1 B00E - Crankshaft oscillation detection

The crankshaft oscillation detection module uses engine roughness components to identify drivetrain oscillations than could cause wrong misfire detections in a defined engine operating area. If such oscillation occurs, this module triggers a fade-out.

1.18.3.1.2 B002 - Rough road detection

The rough road detection module uses informations coming from wheel speed sensor(s) or from ABS module (via harness or CAN) to identify transmission oscillations than could cause wrong misfire detections in a defined engine operating area. If such oscillation occurs, this module triggers a fade-out.

1.18.3.1.3 B03F - Generic misfire parameters & fade-out conditions

This module provides parameters needed for the misfire detection process (data delayed, data stacks, and zero load line...). It also managed all generic misfire fade-out conditions linked to the misfire detection method.

1.18.3.1.4 B035 - Legal misfire detection fade-out conditions

This module manages all legal misfire fade-out conditions defined in legal texts (US & EC).

1.18.3.1.5 B00T - Misfire detection - Application incidences

This module defines specific corrections for detection thresholds, application specific fade-out with standardised outputs to the generic modules.

1.18.3.1.6 B001 - Misfire detection

Detection core function based on engine roughness index provided by ENRD.

1.18.3.1.7 B00T - Misfire detection - Application incidences

Some functionality for calibration ease can be launched after detection.

1.18.3.1.8 B02E - Misfire rate determination & error management - Application Incidences

This module defines application specific fade-out & informations with standardised outputs to the generic misfire rate determination module. Diagnosis conditions are defined in this module.

Must be executed before B00U module.

1.18.3.1.9 B00U - Misfire rate determination & error management

This module defines the Misfire criterions according legal texts description *(MIS_A = misfire damage catalyst criterion, MIS_B1 = misfire emission criterion at engine warm-up & MIS_B4 = misfire emission criterion)* and identify the cylinders in failures

1.18.3.1.10 B02E - Misfire rate determination & error management - Application Incidences

This module defines misfire errors according the type chosen by NC_TREAT_DIAG_MIS: errors defined per misfire criterions or errors defined per cylinder.

Failures like Misfire with low fuel tank level, Multiple cylinder misfire, Random cylinder misfire are also managed in this module.

Must be executed after B00U module.

1.18.3.1.11 F001 - Misfire Tuning Functions

This module allows to generate misfire patterns (continuous or pseudo random) via injection and/or ignition shut-off interfaces.

general specification

This module is optionnal and can be integrated during validation and calibration stages. It is strongly recommended to remove this functionally on serial product software (integration choice via NC_USE_MIS_GEN compilation switch).

1.19 VVTI General

Objectives

The goal of the VVTI is to phase the opening period of the inlet and/or exhaust valves with regard to the crankschaft. In other words, it is possible to change the closing point of the inlet valves and/or the closing point of the exhaust valves.

This system provides the adjustment of a camshaft to a desired phasing ~ to a desired valve timing. The desired camshaft position is further called setpoint. The setpoint can be any position in the available adjustment range. Every project has to implement its determination of the setpoint as a function of the engine operating state. The setpoint can be adapted to the control algorithm slightly and the controller sets the camshaft to this setpoint.

Principle

The camshaft phasing is realised by means of an actuator that works with the engine oil. The actuator has two chambers that can be filled and emptied by the oil. Filling one chamber and emptying the second one leads to a change of the camshaft phasing. If the oil flow into and out of the chambers is stopped the actuator holds its position, i.e. the camshaft does not move (no additional movement to the basic rotary movement). The oil flow is controlled by means of a solenoid proportional oil control valve. The solenoid is energised with a duty cycle signal from 0 to 100 %. The piston of the valve is pressed against the solenoid by a string. If 0 % energisation is applied the valve piston is in the passive stop position. The oil flow causes that the actuator moves towards and remains in the actuator passive stop position. If 100 % energisation is applied the actuator moves towards and remains in the actuator active stop position. If an energisation is applied, in which the valve piston closes both chambers or opens both in the same level, the actuator holds its position. Such energisation is called holding energisation. It is approximately from 30 to 60 % duty cycle depending especially on the voltage and solenoid temperature.

The IVVT system is an optional part of the engine. Its implementation has many benefit impacts on the engine performance. The system allows to phase the opening period of the valves continuously in the adjustment range of the actuator. Influences of IVVT on the engine processes and how IVVT can improve the engine performance is briefly described in following paragraphs.

There are two physical effects regarding the gas flow in the engine manifold. The first one is the inertia of the gas flowing in a pipe (ram effect) and the second one is the wave effect.

The gas in the inlet pipe is accelerated during the induction stroke. The pressure in the combustion chamber rises at the end of the induction phase because the piston already moves towards the top dead centre. The kinetic energy of the flowing gas acts against the combustion chamber pressure and helps to improve the volumetric efficiency. The ram effect is very strong at high engine speeds. The inlet valve timing is to phase towards retard. The inlet valve timing is to phase towards advanced at low engine speeds in order to minimise the backflow due to the increased combustion chamber pressure.

The piston moving towards the bottom dead centre during the induction stroke creates a low pressure wave (compared with the mean inlet pressure) running away from the combustion chamber. It propagates with the velocity of sound in the pipe. This wave is reflected at the open end of the pipe (manifold collector) as a high pressure wave running towards the combustion chamber. If this high pressure wave reaches the inlet valve short before its closing, improvement of the volumetric efficiency can be obtained. The time of the wave arrival depends on the pipe length and time available, i.e., engine speed. The velocity of sound changes slightly with the air temperature.

These two effects are superposed. It is possible to increase the maximum torque at low speed and to keep the power output without increasing engine displacement by means of the infinitely variable inlet valve timing.

There are similar effects on the exhaust side. The gas flowing in a pipe tends to create vacuum if there is not enough gas supply from the combustion chamber, also "an anti-ram effect". High pressure waves are produced during the exhaust period. They are reflected as low pressure waves. It is possible to reduce the amount of the residual gases, and thus to manage more space for the fresh air. The phasing of the exhaust valve timing can contribute to improvement of the volumetric efficiency too. The high gas temperatures and high pressures, especially amplitudes, in the exhaust system make these effects very sensitive to changes of the engine load and speed.

The situation at full load has been described above. The IVVT system can improve the engine performance at part load too. The means is the internal exhaust gas recirculation. That is an intentional extension of the amount of the residual gases in the combustion chamber. Higher portion of the residual gases improves the thermodynamic efficiency of the cycle because of changed properties of the working fluids. Further, it is necessary to increase the inlet pressure in order to have the same power output (~ the same volumetric efficiency) at higher portion of the residual gases. This decreases the pumping losses in part load. It leads to the reduction of the fuel consumption. Higher portion of the residual gases dilutes the air-fuel mixture. The maximum combustion temperature is lowered and this reduces the production of oxides of nitrogen.

Higher portions of the residual gases are obtained by moving inlet towards advanced and exhaust towards retard. The exhaust gases flows into the inlet port at the opening of the inlet valve because the combustion chamber pressure is higher than the inlet system one. This leads to a decrease of the combustion chamber pressure, and thus, there can be a backflow of the exhaust gases from the exhaust port. The exhaust gases in the inlet port are then inducted into the combustion chamber during the main induction period.

The extension of the amount of the residual gases is limited. The ignition properties of the mixture get worse. It leads to higher engine roughness. The driver must not feel it especially in idle. The combustion duration becomes longer which acts against the fuel efficiency improvement. It is obvious that the ignition angle has to be fitted. On the other hand the IVVT system allows to decrease the engine roughness in idle in comparison with an engine with fixed timing. The fixed timing is a compromise for the maximum power output, maximum torque and idle stability. The variable timing can have the minimum valve overlap smaller, and thus less residual gases in idle and therefore better idle stability.

There are further effects of the IVVT system on the engine performance. It is possible to reduce the fuel film creation on the inlet port walls by means of the backflow of the hot gases from the combustion chamber. It can reduce the production of unburned hydrocarbons during the warm-up phase. The catalyst light-off steps and the catalyst overheating protection can be supported by IVVT. The variable valve timing influences the flow field within the combustion chamber which is a part of the combustion process in the gasoline direct injection engines.

Description

The IVVT system can be in active or inactive state. The inactive one is characterised by permanent low level energisation (~0-15 % PWM) of the solenoid valve. The active state means that the camshaft position is controlled to a desired setpoint. It is the normal prevailing state. The system is inactive when the engine is stopped. The following steps are done before reaching the active state: check min/max oil temperature and min/max battery voltage (continuously done), wait for enough oil pressure after the engine start, wait for the end of the reference position adaptation, active state is reached. If there is a failure the IVVT system is inactivated. In some cases the system remains partly active (some camshafts are active, some are inactive) in order to enable bank balancing (see bellow).

The reference position adaptation is done by the ENSD aggregate when enabled by the IVVT function. The aim of the adaptation is to eliminate inaccuracies of the camshaft position acquisition. The primary camshaft position from ENSD in its coordinate system is recalculated into an IVVT camshaft position. This position is related to the gas-exchange top dead centre.

The setpoint is calculated dependent on the engine operating state (combustion mode, load, speed, coolant temperature, etc.). The inlet setpoint can be prioritised to the exhaust one at low oil pressure. It means that the exhaust setpoint is kept untill inlet reaches its desired position and then the map exhaust setpoint is handed over.

The setpoint is worked up in order to facilitate the position control. The main operations are: limitation to the possible adjustment range and setpoint close to the reference position equals the reference position. If the setpoint is in the reference position for a longer time the reference position adaptation is enabled.

The camshaft position control is based on a superposition of the holding energisation and time limited low or high level energisations. Generally, the holding energisation is applied. The controller calculates an energisation duration and its level dependent on the setpoint course and the camshaft deviation from the setpoint. The holding energisation is replaced by the calculated level for the calculated time. This is realised at camshaft edges where the camshaft position is acquired.

The controller consists of a Pre-control and P-control. The Pre-control manages part of the setpoint change and reacts to setpoint changes quickly. The delay and the adjustment speed dependent on the engine speed and oil temperature are the Pre-control parameters. The P-control manages the residual part of the setpoint change and disturbances.

The primary holding duty cycle is a feed-forward control (map dependent on the battery voltage and modelled solenoid temperature). A correction is usually needed for every individual engine due to tolerances. This is realised by means of two adaptations (one of them is a kind of I-control) which evaluate the camshaft deviation and drift at steady setpoint conditions.

There is a balancing of the camshaft positions in the individual banks of a 2-bank system. Unequal adjustment speeds or a failure in one bank can cause different positions in the individual banks. An interbank controller calculates individual setpoints so that the differences between the banks are minimal.

There are some diagnoses in the IVVT system. The electrical failures "short circuit to plus", "short circuit to ground" and "open circuit" can be detected. A chain/belt jump is monitored. There is a diagnosis for the detection of a persistent camshaft deviation and/or slow responsing actuator. The system can be tested by means of a short trip test (special setpoint course) at EOL test or as a garage test.

The IVVT system influences the gas-exchange process, especially the amount of the residual gases. The ignition angle has to be corrected. Ignition angle corrections (one for the basic and one for the reference ignition angle) are outputs from the VVTI aggregate.

There is an important question how the engine reacts on an IVVT failure. It is possible to test it by means of a special algorithm. The operating point dependent setpoint is used in the diagnoses. The controller works with a special setpoint, e.g. a constant for a blocked actuator. The engine behavior, especially the emission production, can be observed.

A multi-segment camshaft target wheel can be used. It is not necessary to use all edges for the camshaft position control especially at high engine speeds. There can be harmful effects on the controll if the time between edges is shorter than the system delay. Additionally, there is a huge runtime demand if many edges are used. It is possible to strech the setpoint calcualtion to every n-th engine revolution (dependent on the engine speed) for runtime saving.

Flowchart

For the sake of clearness the basic flowchart (architecture) of the VVTI aggregate presented here is simplified. Only the main signals are shown. Further, names of some quantities were shortened. Following substitions were done: "x" = "IVVT_IN(_EX)" and "z" = "IN(_EX)".

Aggregate functions

This aggregate version consists of the following functions:

- VVT State - Valve timing data are defined here. Camshaft position is calculated. IVVT system state is determined.
- VVT SP (setpoint) - Calculation of camshaft position setpoint as a function of engine state.
- VVT Control - Camshaft position control including feed-forward control, feed-back control and adaptations.
- VVT Interface BSW - Realisation of control signals. Ouput signal diagnosis information is acquired.
- VVT LIH (limp home) manager - Manages IVVT system state in case of a failure.
- VVT OBDI - Output signal diagnosis.
- VVT OBDII - Crankshaft to camshaft mechanics violation diagnosis (chain/belt jump). Camshaft position deviation diagnosis (actuator jammed, actuator slow responsing). Rate based monitoring interface.
- VVT EOL test - IVVT short trip (prescribed setpoint course is evaluated).
- VVT Ignition corr (correction) - Ignition angle correction as a function of a camshaft position not in reference position.

1.20 AIRT Configuration Data:

Input data:

NC_TIA_CONF	NC_TAM_CAN_USE	NC_TAM_CLC_BOL	NC_TAM_CLC_TOL

1.20.1 Local configuration data:

Here are listed the configuration data, which are internally (and only internally) used in AIRT.

Data	Value
NC_TAM_CLC_BOL (non calibreatable value)	-35°C (typical value for lower limit of TAM)
NC_TAM_CLC_TOL (non calibreatable value)	50°C (typical value for upper limit of TAM)
NC_DIAG_INTM_DYN_USE	1

1.20.2 Global configuration data:

Here are listed the configuration data, which can be used by other Aggregates.

Data	Value
NC_TIA_CONF (compile switch)	10 (one TIA Sensor in Intake Manifold)
NC_TAM_CAN_USE (compile switch)	1 (ambient Temperature via CAN available)

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_DIAG_INTM_DYN_USE	1	0H...1H	0...1	1	-
Choice to use the Intermittent and Stuck Signal Diagnosis (=1) else (=0)					

1.21 VVTI Configuration Data

Input data:

NC_NR_CBK_IVVT	NLC_IVVT_IN	NLC_IVVT_EX	NC_CAM_MDL_BUF_IVVT

General information:

The following describes the general rules for determination of the configuration data and their values.

1.21.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	Value	Description
NC_NR_CBK_IVVT	1	Number of camshafts cylinder banks
NLC_IVVT_IN	1	inlet phasing present
NLC_IVVT_EX	1	exhaust: no phasing

1.21.2 Local Configuration Data

used only in the VVTI aggregate :

Data	Value	Description
NC_CAM_MDL_BUF_IVVT	50	buffer size for modelling camshaft position

1.22 EGPR Configuration Data

General information:

The constant NC_xxx_CONF describes whether a system is equipped with additional functionality or not.

The following describes the general rules for determination of the configuration data:

1.22.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	Value
NC_PRS_EX_MES_CONF	0

1.22.2 Local configuration data

Here are listed the configuration data, which are used only in the EGPR aggregate.

Data	Value
NC_EF_CONF	0

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_PRS_EX_MES_CONF	1	0H...01H	0...1	1	-
System configuration flag (compiler) if an exhaust gas presure iis available (= 1) or not (= 0)					
NC_EF_CONF	1	0...1H	0...1	1	-
System configuration (compiler) flag to indicate if a system with exhaust flap is available (= 1) or not (= 0)					

1.23 EGRC configuration data

General information:

The constant NC_EGR_CONF describes whether a system is equipped with external Exhaust Gas Recirculation or not. NC_EGR_CONF is set to:

- 0, if external EGR is not available
- 1, if external EGR is available

Formula section:

NC_EGR_CONF = 0

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_EGR_CONF	1	0...1H	0...1	1	-
System configuration (compiler) flag to indicate whether external EGR is available (= 1) or not (= 0)					

1.24 FMSP Configuration Data

The following document describes the general rules for definition of the configuration data for FMSP Aggregate.

Input data:

NC_IN_REF	NC_LAMB_REF

General information:

The following document describes the general rules for definition of the configuration data for FMSP Aggregate

1.24.1 Global configuration data

Here are listed the configuration data, which are not only used in the modules of the FMSP aggregate.

Data	Value
NC_DUI_CONF	**0**: single injection
NC_USE_FQ	**1**: FQ is used
NC_WF_MFF_BAS	**0** : TI-based wallfilm compensation
NC_IN_REF	**00000000** (Pattern for allocation of physical cylinders to exhaust bank)
NC_LAMB_REF	**00000000** (Pattern for allocation of physical cylinders to intake bank)

1.24.2 Local configuration data

Here are listed the configuration data, which are used only in the FMSP aggregate.

Data	Value

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_DUI_CONF	1	0H 1H	single ínjection double ínjection	1	-
System flag to distinguish between Single- and Double Injection					
NC_USE_FQ	1	0H 1H	FQ is not used FQ is used	1	-
Configuration switch to indicate the usage of the generic fuel quality adaptation					
NC_WF_MFF_BAS	1	0H 1H	TI-based wallfilm compensation MFF-based wallfilm compensation	1	-
Configuration switch to indicate the usage of MFF- or TI based wallfilm compensation					

1.25 INJR Configuration Data

The following document describes the general rules for definition of the configuration data for INJR Aggregate.

Input data:

NC_CYL_NR			

General information:

The following document describes the general rules for definition of the configuration data for INJR Aggregate

1.25.1 Global configuration data

Here are listed the configuration data, which are not only used in the modules of the INJR aggregate.

Data	Value
NC_INJ_CONF	0: MPI
NC_NR_SYM_IV	Constant, which defines the available symptoms for injection valve diagnostic. ATIC 39: (SYM_SCB + SYM_SCG +SYM_OC) =7H

1.25.2 Local configuration data

Here are listed the configuration data, which are used only in the INJR aggregate.

Data	Value
NC_EOI_LIM	**End of phasing range relatet to NC_REF_EOI_LIM 540 °CRK (MPI-Engine)** **NC_REF_EOI_LIM = -360°CRK, defined in I/O SW, assigned to REF_EOI_LIM)** **(Refers to 30706C01 and 02)**
NC_INJ_INH_SWI_IV_SHIFT_NR	Constant which defines how many bits are used for the shut off sequence. **8 (Cf. 7018 Module)**
NC_USE_TI_EXT_ADJ	0

Data	Value
#if (NC_INJ_CONF = 0)	
NC_ECU_SAMPLE_FAST	**1ms (Specified fastest task recurrency)**
NC_EOI_CST_CYC_ST_ENA	Compiler switch to decide start strategy: cycle counter dependent : NC_EOI_CST_CYC_ST_ENA = 0 (Refers to 30706C02)
#elseif (NC_INJ_CONF = 1)	
NC_VBOOST_STAGE	Boost divisor bridge ratio for ATIC 21 HPDI Driver (Refers to 30402G01)
#endif	

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_INJ_CONF	1	0H 1H	MPI HPDI	1	-
Injection Mode					
NC_ECU_SAMPLE_FAST	1	-	1 ... 10	-	ms
Specified fastest task recurrency, recommendation 1ms					
NC_INJ_INH_SWI_IV_SHIFT_NR	1	3 ... 10 H	3 ... 16	1	-
Constant which defines how many bits are used for the shut off sequence					
NC_EOI_LIM	1	0 ... 780H	0 ... 720	0.375	°CRK
End of phasing range relatet to NC_REF_EOI_LIM					
NC_NR_SYM_IV	1	1..FH	1..15	1	-
Available symptoms for injection valve diagnostic					
NC_USET_ADJ	1	0 ... 1 H	0 ... 1	1	-
Compiler switch to enable external TI adjustment caused by service tool					
#if (NC_INJ_CONF = 0)					
NC_EOI_CST_CYC_ST_ENA	1	0 ... 1 H	0 ... 1	1	-
Compiler switch to decide start strategy: cycle counter dependent (1) or TCO dependent start (0)					
#elseif (NC_INJ_CONF = 1)					
NC_VBOOST_STAGE	1	0...1000H	0..25.6	0.00625	-
Boost divisor bridge ratio for ATIC 21 HPDI Driver					
#endif					

1.26 IGSP Configuration Data

Input data:

NC_INJ_CONF	NC_N_IGA_UPD_RATE	NC_CBK_EX_NR	NLC_USE_IGA_DUI_S
NC_IGSP_VERS			

General information:

The following document describes the general rules for definition of the configuration data for Ignition Angle Calculation Aggregate

1.26.1 Global configuration data

Data	Value
NC_INJ_CONF	MPI
NC_CBK_EX_NR	1

NC_INJ_CONF is used to integrate in the IGSP aggregate calculation and variables related to Stratified DI engines

NC_CBK_EX_NR is used to calculate the Mean Values of Ignition for determination of Ignition Efficiencies for Exhaust treatment

1.26.2 Local configuration data

Here are listed the configuration data, which are used only in the IGSP aggregate.

Data	Value
NC_IGSP_VERS	02
NC_N_IGA_UPD_RATE	8160rpm
NLC_USE_IGA_DUI_S	0

1.26.2.1 Cylinder bank definition for Ignition Angle definition

Due to the special needs of an engine with multiple cylinder banks each project have to defined the cylinders related to one cylinder bank for Ignition Angle calculation.

Normally, the cylinder bank definition for Ignition Angle corresponds to the one for Injection calculation.

_i represents the cylinder bank, defined in the table here after that will be used for Ignition Angle Calculation
_x designated the current cylinder

Firing order	1	3	4	2
Cylinder number _x	0	1	2	3
Cylinder bank _i (*IGA_BAS_i, …*)	1	1	1	1

1.27 IGRE Configuration Data

Input data:

NC_IGN_DIAG_TYP	NC_TD_LIM_MIN	NC_TD_LIM_MAX	NC_MPL_T_MAX
NC_MAX_IGN_MPL_NR	NC_IGC_DLY	NC_MPL_IGN_CRK_MAX	NC_IGC_CONF

General information :

The following describes the general rules for determination of the configuration data

1.27.1 Local configuration data

Here are listed the configuration data, which are used only in the IGRE aggregate.

Data	Value
NC_IGN_DIAG_TYP	ATM46
NC_TD_LIM_MIN	20 us
NC_TD_LIM_MAX	22.5 ms
NC_MAX_IGN_MPL_NR	7
NC_IGC_DLY	16
NC_MPL_T_MAX	60 ms
NC_MPL_IGN_CRK_MAX	12 °CRK)
NC_IGC_CONF	Full static

1.28 MISF Configuration Data

Input data:

NLC_USE_ER_STND_MIS	NLC_TREAT_DIAG_MIS	NLC_USE_MIS_GEN	SEG_NR_ER
NLC_USE_CRK_OSC_MIS	NC_SIZE_THD_ER_BUF	NC_CBK_EX_NR_MISF[NC_CYL_NR]	NC_CYL_NR
NLC_CONF_ER_MV	NLC_ENA_SCDN_NEW		

General information :

The following describes the general rules for determination of the configuration data

1.28.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	Value
NLC_TREAT_DIAG_MIS	1
NLC_USE_CRK_OSC_MIS	1

1.28.2 Local configuration data

Here are listed the configuration data, which are used only in the MISF aggregate.

Data	Value
NC_MISF_VERS	1
NLC_USE_ER_STND_MIS	0
NC_SIZE_THD_ER_BUF	5
NC_CONF_RR_MIS	OTHER (Project Specific : 2KB00201,xxx)
NLC_USE_MIS_GEN	1
NC_CBK_EX_NR_MISF[NC_CYL_NR]	*see table below*
NLC_ENA_SCDN_NEW	1
NLC_CONF_ER_MV	0

Exhaust Configuration:

All cylinders are located on exhaust cylinder bank 0

SEG_NR_ER	0	1	2	3
NC_CBK_EX_NR_MISF	0	0	0	0

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_MISF_VERS	1	00H...FFH	0...255	1	-
MISF aggregate version					
NC_CONF_RR_MIS	1	0...FFH	0...255	1	-
Configuration of rough road detection module (None, WSS via Harness, CAN, Other)					

1.29 ENRD Configuration Data

Input data:

NC_CYL_NR	NC_SEG_DLY_ER_MES	NLC_CONF_GAIN_ADD_ER	NC_SIZE_SEG_T_COR_BUF

General information :

The following describes the general rules for determination of the configuration data

1.29.1 Local configuration data

Here are listed the configuration data, which are used only in the ENRD aggregate.

Data	**Value**
NC_ENRD_VERS	01
NC_SIZE_SEG_T_COR_BUF	9
NC_SEG_DLY_ER_MES	1
NLC_CONF_GAIN_ADD_ER	**1**

Default configurations:

NC_CYL_NR	NC_SIZE_SEG_T_COR_BUF

1.31 EXTC Configuration Data

General information:

This module describes the configuration data that is defined in the aggregate EXTC and its setting (not calibratable) for this software release.

Description:

With NC_NR_COP_CTL it is possible to choose 1 or 2 COP-controller. In the module Overheating prevention (Appl. Inc.) it is choosen which temperature shell be used for activation (via TEMP_COP_ACT) and which for controlling (via TEMP_COP_CTL) of the temperature controlller for catalyst overheating prevention. For controlling static temperatures and for activation dynamic temperatures are used.

The catalyst overheating prevention is independent from aggregate versions.

Local configuration data:

Data	Value
NC_NR_COP_CTL	2 – two COP-controller, 1. controls exhaust temperature before catalyst, 2. controls temperature in catalyst

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_COP_CTL	1	1...2H	1...2	1	[-]
Number of temperature-controllers for catalyst overheating prevention					

1.32 ENSD Configuration Data

Input data:

NC_CYL_NR	NC_NR_EDGE_CAM_IN	NC_NR_EDGE_CAM_EX	NC_N_MAX
NC_N_MIN	NLC_CAM_IN	NLC_CAM_EX	NC_NR_CAM_CBK
NC_OFS_TDC0_REF_CRK	NC_PSN_SEG_TDC_REF	NC_PRI_LIH_CAM_IN	NC_PRI_LIH_CAM_CBK

NC_CRK_WIN_SEG_LEN	18°CRK

edge index z	1	2
NC_PSN_EDGE_z_CAM_IN_1	564	204
NC_PSN_EDGE_z_CAM_EX_1	336	696

To be defined by project with information from customer. Remember: edge #1 is the first falling edge after TDC0, positions are given for VVT passive.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CRK_SENS_TYP	1	0H 1H	ACPS MCPS	1	-
Crankshaft sensor technology					
NC_CAM_WHEEL_TYP	1	0H 1H	Single-tooth Multi-teeth	1	-
Camshaft target wheel type					
NC_CAM_SENS_TYP	1	0H 1H 2H	MCAM ACAM ACAM TPO	1	-
Camshaft sensor technology					
NC_NR_CONF_CAM	1	1H ... 2H	1 ... 2	1	-
Number of camshaft target wheel configurations					
NLC_ESS	1	0H 1H	not present present	1	-
Engine speed (Tacho) hardware output controlled by basic SW present					

1.33 ENSD interface adaptation module

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TCO_CMN	V/O	0...FFH	-50...205	1	[°C]
Coolant temperature (ENSD internal)					
VB_CMN	V/O	0...FFH	0...28.8	1.13E-01	[V]
Battery voltage (ENSD internal)					

Input data:

TCO	VB	NC_CAM_LIH_SWI	

FUNCTION DESCRIPTION:

General information:

The aim is to get a common definition for coolant temperature and battery voltage inside ENSD aggregate whatever their definition is in the rest of software.

Description:

TCO_CMN and VB_CMN are stubbed

Application conditions:

Initialisation: none

Recurrence: at reset

Activation: *NC_CAM_LIH_SWI ≠ “INJ”*

Deactivation: NC_CAM_LIH_SWI = “INJ”

Formula section:

TCO_CMN = 0
VB_CMN = 0

Remark: As this module is only a stub, TCO and VB are not used.

1.34 ENTE Configuration data

Input data:

NLC_TCO_2_CONF			

FUNCTION DESCRIPTION:

General information:

The logical constants NC(NLC)_xxx_CONF are necessary to adapt the Aggregate to a given system environment. The values describe either the variant of a used system component, or a vehicle component is available or not.

With use of the logical constant **NLC_ECT_CONF** the availability of an electronically controlled thermostat within the system is determined. In case of a vehicle configuration with an ECT, the component control and diagnosis is included within the aggregate version. (refer: ENTE A.I.D.)

With use of the logical constant **NLC_TCO_2_CONF** the availability of a coolant temperature sensor at radiator outlet is determined. In case of a vehicle configuration with a TCO_2 sensor, the sensor signal acquisition and diagnosis is included within the aggregate version. (refer: ENTE A.I.D.)

The configuration constant **NC_ECF_CONF** allows to determine the wanted fan control strategy. In principal it is possible to choose between a RLY- or a PWM-control architecture. A RLY/PWM fan control strategy in parallel is also existing. In this case the aggregate architecture allows switching either the control of RLY-fan(s) or the control of PWM–fan(s) during ECU runtime depending on the setting of a corresponding configuration bit. The control of both variants (RLY- and PWM-fan(s)) at the same time is not allowed and not supported within the aggregate.

Independent on the chosen fan control strategy (PWM/RLY), the configuration constant **NC_ECF_NR** describes the number of available cooling fans (hardware components) at the vehicle. In case of a PWM-fan configuration, the number of available PWM cooling fans at the vehicle is always equal to the number of PWM fan output stages provided by the ECU hardware.

Because one or more RLY-switch(es) may control only one cooling fan (hardware component) in case of a RLY-fan configuration, the number of RLY-switch(es) per cooling fan can be different. With use of the configuration constant **NC_ECF_RLY_NR**, the number of RLY output stages per cooling fan are determined.

With the configuration constant NC_NR_TCO_SENS the number of available coolant temperature sensors is determined, which provide the sensor voltage values to calculate TCO, TCO_2, TCO_n.

The following describes the general rules for determination of the configuration data.

1.34.1 Local configuration data

Here are listed the configuration data, which are used only in the ENTE aggregate.

Data	Value
NLC_ECT_CONF	[0] Electronically controlled thermostat (ECT) is not available
NLC_TCO_2_CONF	[0] Coolant temperature sensor at radiator outlet is not available
NC_ECF_CONF	[2] Control of RLY- or PWM-fan(s) requested (RLY or PWM fan(s))
NC_ECF_NR	[1] Number of available cooling fans (hardware components) at the vehicle
NC_ECF_RLY_NR	[2] Number of RLY output stages per cooling fan (hardware components)
NC_NR_TCO_SENS	[1] Number of available coolant temperature sensors (hardware components) at the vehicle

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NLC_ECT_CONF	1	0...1H	0...1	1	-
System configuration flag (compiler) if an electronic controlled thermostat is available (=1) or not (=0)					
NC_ECF_CONF	1	0...3H	0...3	1	-
System configuration switch for cooling fan control strategy (RLY || PWM || RLY and PWM)					
NC_ECF_NR	1	1...FFH	1...255	1	-
Number of available cooling fans (hardware components) at the vehicle					
NC_ECF_RLY_NR	1	0...FFH	0...255	1	-
Number of RLY output stages per cooling fan (hardware components)					
NLC_TCO_2_CONF	1	0...1H	0...1	1	-
System configuration flag (compiler) if a coolant temperature sensor at radiator outlet is available (=1) or not (=0)					
NC_NR_TCO_SENS	1	1...FFH	1...255	1	-
Number of available coolant temperature sensors (hardware components) at the vehicle					

1.35 INSY Configuration Data

FUNCTION DESCRIPTION:

General information:

The constant NC_xxx_CONF describes whether a system is equipped with additional functionality or not.

NC_MAF_FAC_CYL is used as conversion factor between maf (kg/h) and maf (mg/stk) based on the cylinder number.

The variable NC_CBK_IN_NR defines the number of intake cylinder lines.

1.35.1 Global configuration data:

Data	Value
NC_ETC_CONF	1 *(ETC version)*
NC_AMP_CONF	1 *(with AMP-sensor)*
NC_CBK_IN_NR	1 *(one intake cylinder line)*
NC_MAF_FAC_CYL	8333.3 (4 cylinder engine)

1.35.2 Local configuration data:

Data	Value
NC_CRCV_CONF	0
NC_MAF_CONF	1 *(allow MAF-controll)*
NC_MAP_CONF	1 *(allow MAP-controll)*
NC_NR_STATE_ACR	2 (system with one additional actuator (VIM))
NC_NR_LEN_CAM_EX	6 = six break points for considering exhaust cam adjustment
NC_NR_LEN_CAM_IN	8 = eight break points for considering intake cam adjustment
NC_NR_N_EFF_VOL_BAS	16 = sixteen N breakpoints
NC_NR_MAP_SAMPLE_ACQ	4 = last four samples within one segment used for V_MAP_MV calulation
NC_NR_SP_REQ_CAM_OFS_AD	8 (8 inlet/exhaust camshaft positions are available for adaptation purposes)
NC_NR_OPP_CAM_OFS_AD	1 (camshaft-offset adaptation is done at one engine speed operating point)
NC_NR_MAP_OPP_CAM_OFS_AD	1 (camshaft-offset adaptation is done at one MAP_MES operating point)
NLC_CAM_OFS_AD	1 (camshaft offset adaptation functionality is activated)
NC_NR_LEN_IP_TIA_IM_STND	4 (calculation of TIA_IM_STND at 4 engine speed and MAF break points)
NC_EFF_VOL_ACR_COR_CONF	2 (VIM and Port correction of EFF_VOL done in basic volumetric efficiency structure and in additional maps)
NC_PUT_CONF	1 = sensor always used

Data	Value
NLC_CAM_OFS_AD_EXT_REQ	0 = No external activation of Camshaft-offset adaptation functionality.

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_AMP_CONF	-	0...2H	0...2	1	[-]
System configuration flag (compiler) if an ambient pressure sensor is available (= 1) or not (= 0)					
NC_CRCV_CONF	-	0...1H	0...1	1	[-]
System configuration (compiler) flag to indicate if Crank case ventilation flow is considered (=1) or not(=0)					
NC_ETC_CONF	-	0...1H	0...1	1	[-]
System configuration (compiler) flag to indicate if a system with ETC is available (= 1) or not (= 0)					
NC_MAF_CONF	-	0...2H	0...2	1	[-]
System configuration flag (compiler) if an air-flow sensor is available (= 1) or not (= 0)

NC_PUT_CONF	1	0...2H	0...2	1	[-]
Pressure upstream throttle sensor configuration					
NLC_CAM_OFS_AD_EXT_REQ	1	0...1H	0...1	1	[-]
System configuration flag to indicate whether Camshaft-offset adaptation can be externally activated(=1 for e.g. through end-of-line test) or not(=0)					

1.36 CHRG Configuration Data

General information:

Every constant NC_xxx_CONF describes whether a system is equipped with additional functionality or not.

- Sensor-Configuration

For all sensors (NC_xxx_CONF) following possibilities are available:

0 = NO_SENSOR: sensor is not available, value never used
1 = SENSOR_ALWAYS_USED: sensor is always available and value is used
2 = SENSOR_SWITCHABLE: sensor-evaluation can be switched "on / off "during runtime (by LC_switch)

For information it's possible to show the usage later usage of the configuration: (TB) only for engine-testbench, (SER) also for series-production

- Variant-Selection

some NC-switches can be used to select between spec-versions, some can be used as normal compiler-switches (e.g. to select sensor-values for evaluation)

Type: C = Compilerswitch (NC-name usable within CHRG-Software-modules)

D = Spec-selection for different versions for DOKU

(NC-name only information, not usable)

Also a combination compilerswitch + Spec-Variant-selection "C/D" is allowed.

HINT:

M266 has 2 engine-variants: turbocharger and selfinduced system, each with a different sensor- and HW configurations. In order to have the same software for both variants, the sensor-configuration can be selected by LC_TCHA_CONF at power-up of the ECU.

Application conditions:

Initialisation: at ECU reset

Recurrence: none

1.36.1 Global configuration data

Here the configuration data are listed, which can be used in other aggregates :

Data	Value
NC_CHRG_CONF	1 = turbocharger
LC_TCHA_CONF	1 = turbocharger 0 = selfinduced engine (via data bin)

1.36.2 Local configuration data

Here the configuration data are listed, which are used only in the CHRG aggregate.

1.36.3 Turbine speed sensor (N_TCHA)

NC_N_TCHA_CONF	C/D	turbo charger speed sensor (TB) 0 = NO_SENSOR

1.36.4 Wastegate (WG) - location: exhaust path

Data	Type	Value
NC_PRS_WG_ACR_CONF	C/D	wastegate-actuator pressure sensor (TB) 0 = NO_SENSOR

1.36.5 Recirculation-system (RCL) - location: intake path

NC_PSN_RCL_CTL	C/D	recirculation-actuator position-control: 1 = PSN_RCL_DIG_CTL: digital control (ON/OFF)
NC_RCL_UP_ICO	C	position of recirculation pipe inlet 1 = upstream intercooler
NC_PSN_RCL_CONF	C/D	recirculation-actuator position sensor 0 = NO_SENSOR

1.36.6 general switches

NC_MAF_RNG_H_CHRG	C/D	Switch whether old/low or new/high MAF_KGH range is used 0 = USE_LOW_MAF_KGH_RANGE
NC_BOOST_MNG_CHRG	C/D	Switch whether Dynamic boost manager is supported 0 = DYNAMIC_BOOST MANAGER_NOT_SUPPORTED
NC_NR_TCHA	C	Number of turbo chargers in the system 1 = one turbo charger - Mono turbo system

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_TCHA_CONF	1	0...1H	0...1	1	-
System configuration flag for turbo charged engine (=1), for naturally aspirated engine (=0)					

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_CHRG_CONF	1	0h..2h	0..2	1	-
Charger configuration					
NC_PSN_WG_CONF	1	0h..2h	0..2	1	-
Wastegate position sensor configuration					
NC_PSN_RCL_CONF	1	0h..2h	0..2	1	-
Recirculation actuator position sensor configuration					
NC_TIA_CHA_UP_CONF	1	0h..2h	0..2	1	-
Intake temperature upstream charger sensor configuration					
NC_TIA_CHA_DOWN_CONF	1	0h..2h	0..2	1	-
Intake temperature downstream charger sensor configuration					
NC_TEG_TUR_UP_CONF	1	0h..2h	0..2	1	-
Exhaust gas temperature upstream turbine sensor configuration					
NC_N_TCHA_CONF	1	0h..2h	0..2	1	-
Turbo charger speed sensor configuration					
NC_MAF_RCL_CONF	1	0h..2h	0..2	1	-
Recirculation air mass flow sensor configuration					
NC_PRS_WG_ACR_CONF	1	0h..2h	0..2	1	-
Wastegate actuator pressure configuration					
NC_PSN_WG_CTL	1	0h..1h	0..1	1	-
Wastegate position control configuration					
NC_RCL_UP_ICO	1	0h..1h	0..1	1	-
position of recirculation pipe inlet					
NC_PSN_WG_MDL	1	0h..1h	0..1	1	-
wastegate position model type					
NC_PRS_WG_ACR_MDL	1	0h..1h	0..1	1	-
wastegate actuator pressure model type					
NC_PSN_RCL_CTL	1	0h..2h	0..2	1	-
recirculation actuator position control					
NC_PRS_CHA_UP_CONF	1	0h..2h	0..2	1	-
Pressure upstream charger sensor configuration					
NC_MAF_RNG_H_CHRG	1	0h..1h	0..1	1	-
Switch whether old/low or new/high MAF_KGH range is used					
NC_BOOST_MNG_CHRG	1	0h..1h	0..1	1	-
Switch whether Dynamic boost manager is supported					
NC_NR_TCHA	1	0h..2h	0..2	1	-
Number of turbo chargers					
NC_TYP_SENS_TEG_TUR_UP	1	0h..1h	0..1	1	-
Type of exhaust gas temperature sensor (0 – analog voltage output, 1 – PWM output)					

1.37 TQDR Configuration Data

Input data:

NC_CYC_ADD_ACT			

General information :

The following describes the general rules for determination of the configuration data

1.37.1 Local configuration data

Here are listed the configuration data, which are used only in the TQDR aggregate.

Data	Value
NC_CYC_ADD_ACT	1

1.38 ERRM Configuration Data

Input data:

NC_ABC_CONF_FCT_DIAG_XX	NC_NR_DTC_FMT	NC_ERR_DTC_CONF
NC_NR_ENVD_CUS_SET_CMN	NC_MIL_CHK_TYP	NC_NR_ENVD_CUS_CMN
NC_NR_ENVD_PREV	NC_NR_ENVD_CUS_SET_SPC	NC_NR_ENVD_OBD
NC_NR_FRF_SET	NC_NR_ERR_DYN	NC_NR_ERR_HIS
NC_NR_WIN_SCDN	NC_NR_HIS	NC_NR_SYM_XX
NC_ENVD_CUS_CMN_UPD	NC_ERR_DTC_REQ_CUS	NC_ERR_DTC_REQ_OBD
NC_NR_ERR_INTM	NLC_ABC_INI_DC_END_DIAG	NC_NR_LAMP
NC_ERR_PRI_H	NLC_INC_ERR_PRI	NLC_OLD_ERR_PRI
NLC_OBD_FRF_PND	NLC_FMY_CONV_FOR_FRF	NC_NR_DIAG_RBM
NLC_BENCH_MODE	NC_LDP_1_DTC_TABLE_SIZE	NLC_MIL_ACT_REQ
NC_LDP_2_DTC_MIS_TABLE_SIZE	NC_LDP_2_DTC_TABLE_SIZE	NC_NR_ERR_PERM
NLC_OBD_DSL	NC_NR_DIAG_SYM_RBM	

General information :

The following describes the general rules for determination of the configuration data

1.38.1 Global configuration data

Data	Value	
	Typical values are listed below	
NLC_OBD_RBM_ENA	1	Rate base monitoring functionality present or not : 0 : Rate base monitoring disabled **1 : Rate base monitoring enabled**
NLC_ENA_SCDN_NEW	1	Old or new Similar conditions functionality used: 0: old SCDN functionality used 1: new SCDN functionality used
NLC_ENA_SCDN	1	Similar conditions present or not : 0 : Similar conditions disable, acceptable for Europe applications. 1 : Similar conditions enable, for US applications
NLC_CAN_LAMP_ACT	0	Warning lamps interface type 0: warning lamps hardwired to ECU 1: warning lamps status sended to CAN inter-system
NC_ERR_DET_UPD	01h	Configuration for all diagnoses : 00h: no sporadic error detection 01h: sporadic error detection 02h: sporadic error detection with extended information
NLC_ENA_MULTI_CDN	1	Activation/deactivation of multi-condition debounce algorithm 0 : Multi-condition debounce algorithm unused 1 : Multi-condition debounce algorithm used
NLC_OBD_READY_CAL	0	Activation/deactivation of calibratable readiness classes : 0 : readiness classes are not calibratable 1 : readiness classes are calibratable
NLC_ENA_SYM_DIAG_AD	0	Activation/deactivation of adaptations modules for symptom based diagnostics : 0 : adaptation not required 1 : adaptation used to connect symptom based diagnostics
NLC_ENA_RBM_DIAG_AD	0	Activation/deactivation of adaptations modules for symptom based diagnostics with rate-based monitoring (always <= NC_NR_DIAG_RBM) 0 : adaptation not required 1 : adaptation used to connect symptom based diagnostics to rate-based monitoring

1.38.2 Local configuration data

Here are listed the configuration data, which are used only in the ERRM aggregate.

Data	Value	
	Typical values are listed below	
NC_NR_ERR_DYN	10	Dynamic memory size, quantity of failures
NLC_OLD_ERR_PRI	1	Failure chronological priority order 0: priority to new failures **1: priority to old failures**
NLC_INC_ERR_PRI	1	Set this bit to 0 to disable increased failure priority **Set this bit to 1 to enable increased failure priority**
NC_ERR_PRI_H	6	failure priority level linked to NLC_INC_ERR_PRI
NC_NR_ENVD_OBD	33	Size of OBD environmental data, quantity of data byte
NC_NR_ENVD_CUS_CMN	0	Size of common environmental data, quantity of data byte
NC_NR_ENVD_CUS_SET_CMN	12	Size of environmental data set, quantity of data byte
NC_NR_ENVD_CUS_SET_SPC	4	Size of specific environmental data set, quantity of data byte
NC_NR_FRF_SET	1	Quantity of environmental data sets, quantity of sets
NC_NR_ENVD_PREV	2	Number of different failure instances xx using prestored freeze frame **00h:**No prestored freeze frame functiunality used **01h...FFh:**Quantity of failure instances XX using prestored freeze frame.
NC_ ENVD_CUS_CMN_UPD	1	Way to update environmental data 0: no update at failure status change **1: update at failure status change (same as obd)**
NC_NR_WIN_SCDN	xx	Quantity of diagnosis using similar conditions, quantity of diagnosis *For exact number see Chapter "Similar conditions (Appl. Inc.)" 5WB02U01.yyy*
NC_NR_ERR_HIS	10	Size of history memory. quantity of failures
NC_NR_HIS	22	Size of data stored for a single failure in history memory, quantity of data bytes
NC_ERR_DTC_REQ_OBD	0	Type of obd/carb DTCs returned by api **0 : detailed for each symptom** 1 : limited to the global failure
NC_ERR_DTC_REQ_CUS	0	Type of customer DTCs returned by api **0 : detailed for each symptom** 1 : limited to the global failure

Data	Value	
	Typical values are listed below	
NC_ERR_DTC_CONF	0	Selection of DTCs displaying strategies for ERR_DTC_IDX : 0 : One unique DTC which corresponds to the first symptom detected (ERR_SYM_MEM_IDX). The DTC is encoded according OBD J2012.1 : One unique global DTC whatever the symptom detected. The DTC is encoded according OBD J2012. 2 : One unique DTC which corresponds to the first symptom detected (ERR_SYM_MEM_IDX). The DTC is encoded according customer specific format. 3 : One unique global DTC whatever the symptom detected. The DTC is encoded according customer specific format. 4 : One unique DTC which corresponds to the last symptom detected (ERR_SYM_LST_IDX). The DTC is encoded according OBD J2012. 5 : One unique DTC which corresponds to the last symptom detected (ERR_SYM_LST_IDX). The DTC is encoded according customer specific format.
NC_NR_DTC_FMT	0	Selection of 6 or 10 DTCs configurations Defines 1 or 2 different DTC identifiers per symptom. Defintion with 1 DTC permits DTC usage in common for OBD and customer. 0 : a single DTC per symptom (a single one for OBD and cutomer) 1 : 2 DTCs defined per symptom (one for OBD, one for cutomer)

Data	Value	
	Typical values are listed below	
NC_MIL_CHK_TYP	3h	Pre-drive check strategy on stalling event : Bit0=0 : Disable pre-drive check after “stalling event/engine start” **Bit0=1 : Enable pre-drive check after “stalling event/engine start”** Display readiness status during pre-drive check (MIL blinking) : Bit1=0 : disable readiness status display during pre-drive check **Bit1=1 : enable readiness status display during pre-drive check**
NLC_OBD_FRF_PND	0	Defines the eobd/carb freeze frame strategy the following ways : **0 : eobd/carb freeze frame data of mode 2 will be returned after confirmed failure detection** 1 : eobd/carb freeze frame data of mode 2 will be returned after confirmed/emission relevant failure If confirmed in memory, after pending/emission relevant detection If not confirmed in memory.
NC_NR_DIAG_RBM	xx	Instance number (1...255) of monitors with real in-use performances tracked by the Rate-Based monitoring functionality. *For exact number see chapter* "Rate base monitoring (Appl. Inc.)" 5WB045xx.yyy
NC_NR_SYM_XX	 03h 07h	Configuration to define available symptom for each diagnosis XX : This constant is used in the multicondition filtering algorithm. 03h: SYM_0 & SYM_1 available 07h: SYM_0...SYM_2 available Please take note that this configuration shall be mentioned in “table of failure” module for each diagnosis
NC_ABC_CONF_FCT_DIAG_XX	 00h 03h 0Bh 0Eh 10h 13h	Configuration depends on each diagnosis XX behaviour : 00h: Standard configuration STD 03h: Standard configuration STD_INI with initialisation(only this config is available for multicondition) 0Bh: memory configuration MEM 0Eh: memory configuration MEM_INI 10h: decrement calibration configuration DEC_CAL 13h: statistical configuration STC Please take note that this configuration shall be mentioned in “table of failure” module for each diagnosis
NLC_ABC_INI_DC_END_DIAG	01h	Configuration for all diagnoses : 00h: diagnosis init managed at transition LV_IGK 0→1 01h: end of diagnosis init managed at transition LV_DC 1→0 (only this configuration is available for multicondition filtering)
NC_NR_ERR_INTM	10	Maximum number of diagnosis instances to be listed in ERRM_INTM_DIAG_INST[NC_NR_ERRM_INTM] array
NLC_BENCH_MODE	1	Configuration for all diagnoses, to allow/forbid the bench mode activation. The maximum CPU optimisation is reached when NLC_BENCH_MODE =0. 0 : bench mode can’t be activated whatever LC_ABC_BENCH value 1 : bench mode activation is possible when LC_ABC_BENCH = 1
NLC_FMY_CONV_FOR_FRF	1	Conversion of data before storage in the specific freeze frame 0: Data are not converted before the storage in the specific freeze frame 1: Store the converted data in the specific freeze frame

Data	Value	
	Typical values are listed below	
NC_LDP_2_DTC_MIS_TABLE_SIZE	6	Size of LDP_2_ID_ERR_DTC_MIS_SIZE axis (= NC_CYL_NR + 2)
NC_LDP_2_DTC_TABLE_SIZE	6	Size of LDP_2_ID_ERR_DTC_XX_SIZE axis (= 6 - NC_NR_DTC_FMT)
NC_LDP_1_DTC_TABLE_SIZE	1	Size of LDP_1_ID_ERR_DTC_XX_SIZE axis (= 1 + NC_NR_DTC_FMT)
NC_NR_LAMP	1	Number of warning lamps
NLC_MIL_ACT_REQ	1	External MIL request is taken or not into account for DIST_ACT_MIL and T_ACT_MIL calculations. 0 : External MIL request not taken into account 1 : External MIL request taken into account
NC_NR_ERR_PERM	4	Maximum number of failure defined in permanent failure memory structure (CARB required minimum value : 4)
NLC_OBD_DSL	0	Selection of engine type : gasoline (0) or diesel (1)
NC_NR_DIAG_SYM_RBM	0	Instance number of monitor designed for symptom based error management and connected to rate-based monitoring (Typical value : 0)

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NLC_ENA_SCDN	1	0...1H	0...1	1	[-]
Boolean to indicate if similar conditions functionality is present (1) or not (0)					
NLC_ENA_SCDN_NEW	1	0...1H	0...1	1	[-]
Boolean to indicate if new similar conditions functionality is used (1) or not (0)					
NC_ERR_DET_UPD	1	0...2H	0...2	1	[-]
Activation of sporadic errors storage and visualisation (0: disabled, 1: enabled)					
NLC_OBD_RBM_ENA	1	0...1H	0...1	1	[-]
Rate-based monitoring functionality present or not (0: Rate-based monitoring disabled, 1: Rate-based monitoring enabled)					
NLC_CAN_LAMP_ACT	1	0...1H	0...1	1	[-]
Selection of the strategy to drive warning lamps (0: wire, 1: CAN)					
NLC_OBD_READY_CAL	1	0...1H	0...1	1	[-]
Activation/deactivation of calibratable readiness classes					
NLC_ENA_SYM_DIAG_AD	1	0...1H	0...1	1	[-]
Activation/deactivation of adaptations modules for symptom based diagnostics connection					
NLC_ENA_MULTI_CDN	1	0...1H	0...1	1	[-]
Activation/deactivation of multi-condition debounce algorithm (0: disabled, 1: enabled)					
NLC_ENA_RBM_DIAG_AD	1	0...1H	0...1	1	[-]
Activation/deactivation of adaptations modules for symptom based diagnostics with rate-based monitoring (always <= NC_NR_DIAG_RBM)					

1.39 EGCP Configuration Data

Input data:

NC_LSHPWM_BOL_LSH_DOWN	NC_LSHPWM_TOL_LSH_DOWN	NC_LSHPWM_BOL_LSH_UP	NC_LSHPWM_TOL_LSH_UP
NC_R_REF_LS_DOWN	NC_VLS_DOWN_CUR_PUMP_REF	NC_FAC_R_REF_LS_DOWN	NC_VLS_UP_CUR_PUMP_REF
NC_FAC_R_REF_LS_UP	NC_R_REF_LS_UP		

General information :

The following describes the general rules for determination of the configuration data

1.39.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	**Value**
NC_CBK_EX_NR	1
NC_STATE_LSL_UP_IF	0
NC_STATE_VLS_UP_SIG_ACQ	0
NLC_LSH_RLY_EFP	0
NC_FRQ_LSHPWM_UP	-10
NC_FRQ_LSHPWM_DOWN	7,6
NC_FAC_R_REF_LS_UP	0.118316 (=5.62/47.5)
NC_R_REF_LS_UP	5620
NC_VLS_UP_CUR_PUMP_REF	4.82
NC_FAC_R_REF_LS_DOWN	0.118316 (=5.62/47.5)
NC_R_REF_LS_DOWN	5620
NC_VLS_DOWN_CUR_PUMP_REF	4.82

1.39.2 Local configuration data

Here are listed the configuration data, which are used only in the EGCP aggregate.

Data	**Value**
NC_LSHPWM_BOL_LSH_DOWN	1 %
NC_LSHPWM_TOL_LSH_DOWN	99 %
NC_LSHPWM_BOL_LSH_UP	1 %
NC_LSHPWM_TOL_LSH_UP	99 %

To be defined by project with information from customer.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CBK_EX_NR	1	1...4H	1...4	1	-
Number of exhaust cylinder banks					
NC_STATE_VLS_UP_SIG_ACQ	1	0...7H	0...7	1	-
Configuration switch for optional signal acquisition					
NLC_LSH_RLY_EFP	1	0...1H	0...1	1	-
Configuration switch to indicate whether lambda sensor heater is connected to EFP or main relay					
NC_STATE_LSL_UP_IF	1	0...7H	0...7	1	-
Interface to lambda sensor linear upstream					
NC_FRQ_LSHPWM_UP	1	0...FFFFH	0...4095.9375	0.0625	Hz
PWM frequency for the upstream oxygen sensor heater					
NC_FRQ_LSHPWM_DOWN	1	0...FFFFH	0... 4095.9375	0.0625	Hz
PWM frequency for the downstream oxygen sensor heater					

Notes:

- *The configuration switch NC_STATE_VLS_UP_SIG_ACQ denotes whether signal filtering shall be applied to the linear lambda sensor's raw signal provided by the BSW prior to further signal processing. If signal filtering shall be applied NC_STATE_VLS_UP_SIG_ACQ shall be set to 1. If not or if binary upstream sensor is used NC_STATE_VLS_UP_SIG_ACQ shall be set to 0.*

- *The PWM frequency for the oxygen sensor heater must be adjusted to values larger than 5Hz, i.e.* NC_FRQ_LSHPWM_UP >= 5Hz and NC_FRQ_LSHPWM_DOWN >= 5Hz. *Usually no values larger than 100 Hz are applied, the exact value has to be derived from the corresponding sensor specification.*

1.40 Variant and Version Coding

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CONF_TCU	V/O/S	0...0FH	0...15	1	-

FUNCTION DESCRIPTION:

General information:

In order to minimize the necessary amount of different ECU variants by different equipment in the vehicles under mass production conditions, it is necessary to build a structure into the ECU software that allows to select different control algorithm and access to different calibration data maps and constants by setting of configuration bytes.

It is possible to change the variants during the development process by SAM 2000 whereas the versions could be selected by KW 2000 (SAM-Dias or service tester) at the end of line-programming or at the service. The underlined variant respectively version is the default one.

Remark: A change of a version or variant will only be valid after system reset (that means when the power latch phase has expired).
This applies also to the outputs CONF_xxx and CONF_xxx_CAN.

Exception: CONF_CRU is learnt after Key-On without Powerlatch, it is effective immediately.

1.40.1 Variant coding

Oxygen sensor configuration :

CONF_LAM = C_CONF_LAM

C_CONF_LAM = 0 Open loop

C_CONF_LAM = 1 Lambda control

Vehicle speed acquisition :

C_CONF_VS = GEAR_BOX Vehicle speed signal from gear box (non-OBD II variant)

C_CONF_VS = ABS Vehicle speed signal from inductive wheel speed sensor or from ABS control unit (OBD II variant)

C_CONF_VS = TCU_CAN Vehicle speed signal from TCU via CAN (non-OBD II variant)

C_CONF_VS = 0	CONF_VS = GEAR_BOX	Vehicle speed signal from gear box
C_CONF_VS = 1	CONF_VS = ABS	Vehicle speed signal from ABS control unit
	CONF_VS = WHEEL	Vehicle speed signal from inductive wheel sensor
	CONF_VS = LEARNING	Vehicle speed signal learning currently active
C_CONF_VS = 2	CONF_VS = TCU_CAN	Vehicle speed signal from TCU via CAN

Immobilizer :

CONF_IMOB = C_CONF_IMOB

C_CONF_IMOB = 0 Passive

C_CONF_IMOB = 1 Active

Once the CONF_IMOB has been set for an ECU, it can be reset only by the service tester (not anymore by SAM2000).

Evaporative system :

C_CONF_CP = 0 Passive

C_CONF_CP = 1 Active with open loop lambda control

C_CONF_CP = 2 Active with closed loop lambda control

	CONF_LAM = 0	CONF_LAM = 1
C_CONF_CP = 0	CONF_CP = 0 (passive)	CONF_CP = 0 (passive)
C_CONF_CP = 1	CONF_CP = 1 (open loop)	CONF_CP = 1 (open loop)
C_CONF_CP = 2	CONF_CP = 1 (open loop)	CONF_CP = 2 (closed loop)

Evaporative system diagnosis :

C_CONF_DIAGCP = 0 Passive

C_CONF_DIAGCP = 1 Active : single run per driving cycle

C_CONF_DIAGCP = 2 Active : continuous run

	CONF_CP = 0	CONF_CP = 1	CONF_CP = 2
C_CONF_DIAGCP = 0 passive	CONF_DIAGCP = 0 passive	CONF_DIAGCP = 0 passive	CONF_DIAGCP = 0 passive
C_CONF_DIAGCP = 1 single run	CONF_DIAGCP = 0 passive	CONF_DIAGCP = 0 Passive	CONF_DIAGCP = 1 active
C_CONF_DIAGCP = 2 continuous	CONF_DIAGCP = 0 passive	CONF_DIAGCP = 0 Passive	CONF_DIAGCP = 2 active

Fuel tank level acquisition for EVAP-diagnosis

CONF_DIAGCP_VOL = C_CONF_DIAGCP_VOL

C_CONF_DIAGCP_VOL = 0 fuel tank level estimation by DTP signal gradient

C_CONF_DIAGCP_VOL = 1 fuel tank level acquisition by single fuel gauge

C_CONF_DIAGCP_VOL = 2 fuel tank level acquisition by dual fuel gauge

Failure management and MIL Handling Information:

CONF_MIL_FMY = C_CONF_MIL_FMY

CONF_MIL_FMY = 0	no MIL, Failure Memory Management OBD-I
CONF_MIL_FMY = 1	MIL treatment OBD-I, Failure Memory Management OBD-I
CONF_MIL_FMY = 2	MIL treatment OBD-II, Failure Memory Management OBD-II *Exception :* *MIL is turned on in first driving cycle for comprehensive components (CARB_COMP_MIL)*
CONF_MIL_FMY = 3	MIL treatment OBD-II, Failure Memory Management OBD-II
CONF_MIL_FMY = 4	MIL treatment E-OBD, Failure Memory Management E-OBD
CONF_MIL_FMY = 5	MIL treatment KOBD, Failure Memory Management KOBD

Variable valve timing (only exhaust camshaft)

CONF_CAM_VVT_EX = C_CONF_CAM_VVT_EX

C_CONF_CAM_VVT_EX = 0	exhaust camshaft without adjustment
C_CONF_CAM_VVT_EX = 1	exhaust camshaft with adjustment

Erasement of adaptative values :

CONF_AD_RST = C_CONF_AD_RST

C_CONF_AD_RST = 0	the adaptation values are **not** reset
C_CONF_AD_RST = 1	**all** the adaptation values are reset
C_CONF_AD_RST = 2	only **some** adapt. values are reset. See details in chap. 0

Erasement of failure memory :

CONF_FMY_RST = C_CONF_FMY_RST

C_CONF_FMY_RST = 0	then the failure memory is **not** reset in case of Battery has been disconnected since last driving cycle (LV_VB_OFF=1)
C_CONF_FMY_RST = 1	then the failure memory is reset in case of Battery has been disconnected since last driving cycle (LV_VB_OFF=1)

Status of selection of fan control method:

CONF_CFA = C_CONF_CFA

C_CONF_CFA = 0	controlled by RLY_CFA_HIGH/LOW
C_CONF_CFA = 1	controlled by CFAPWM

Acquisition of AC pressure:

CONF_ACP = C_CONF_ACP

C_CONF_ACP = 0	PRS_ACC from Triple Switch
C_CONF_ACP = 1	ACP from A/C Pressure Transducer

Acquisition of Power steering pressure:

CONF_PSTE = C_CONF_PSTE

C_CONF_PSTE = 0	Pressure Switch
C_CONF_PSTE = 1	Pressure from Pressure Transducer

Acquisition of TOIL:

CONF_TOIL_MDL = C_CONF_TOIL_MDL

C_CONF_TOIL_MDL = 0	TOIL from oil temperature sensor (if error free)
C_CONF_TOIL_MDL = 1	TOIL calculated from Toil model for Fuel system diagnosis
C_CONF_TOIL_MDL = 2	TOIL calculated from Toil model (TOIL_MDL)

Acquisition of Cruise Signal: (only available for ETC Configuration)

if	CONF_CRU = 0		Non-Cruise Vehicle or Cruise not yet learnt
then	**if**	LV_CRU_MAIN_SWI = 1	Cruise Control Main Switch after filtering
	then	CONF_CRU = 1	Cruise Control function learnt

Rermarks:

- LV_CRU_MAIN_SWI is calculated each 10 msec, therefore CONF_CRU is also calculated with 10 msec recurrence. Once CONF_CRU is learnt, it is effective immediately w/o PWL.
- CONF_CRU can be reset from 1 to 0 by KWP2000 service (see Keyword Spec).

Acquisition of GEN_LOAD:

CONF_GEN_LOAD = C_CONF_GEN_LOAD

C_CONF_GEN_LOAD = 0	GEN_LOAD is not available from alternator.
C_CONF_GEN_LOAD = 1	GEN_LOAD is available from alternator.

Catalyst efficiency diagnosis :

CONF_CAT_EFF = C_CONF_CAT_EFF

C_CONF_CAT_EFF = 0	Passive
C_CONF_CAT_EFF = 1	Active

Status of Variable Intake Manifold:

CONF_VIM = C_CONF_VIM

C_CONF_VIM = 0 no variable Intake Manifold available

C_CONF_VIM = 1 variable Intake Manifold available without position feedback

C_CONF_VIM = 2 variable Intake Manifold available with position feedback

Support for KOBD specific requirement:

CONF_KOBD = C_CONF_KOBD

C_CONF_KOBD = 0 Not support for KOBD specific requirement

C_CONF_KOBD = 1 Support for KOBD specific requirement

Status of Slow ASR Request Availability from TCS Control Unit:
(only available for ETC Configuration)

CONF_ASR_SLOW = C_CONF_ASR_SLOW

C_CONF_ASR_SLOW = 0 Slow Torque Request from TCS Control Unit not available

C_CONF_ASR_SLOW = 1 Slow Torque Request from TCS Control Unit available

Status of Port Flap:

CONF_PORT = C_CONF_PORT

C_CONF_PORT = 0 no Port Flap (TCI)

C_CONF_PORT = 1 Port Flap (Facelift, SULEV)

System Load Sensor:

CONF_MAF = C_CONF_MAF

C_CONF_MAF = 0 A MAP-Sensor is used as Load Sensor

C_CONF_MAF = 1 A MAF-Sensor is used as Load Sensor

Model Year information for VIN coding with sample ECU :

The main purpose of this configuration data is to avoid VIN failure message during J1699 test with sample ECU during development period.
With this year information, VIN code is to be automatically created.
Of course, this function is disabled at production SW.

CONF_YEAR = C_CONF_YEAR ⇒ Just write a model year.

TCU Learning:

CONF_TCU_LEARN = C_CONF_TCU_LEARN

C_CONF_TCU_LEARN = 0 no TCU learning via CAN

C_CONF_TCU_LEARN = 1 TCU learning via CAN activated

Status of Battery Sensor type (only for ETC versions):

CONF_BAT_LIN = C_CONF_BAT_LIN

Remark:

CONF_BAT_LIN = 0 (Battery Sensor sending Signal via Analog Inputs)

CONF_BAT_LIN = 1 (Communication with SEMI-Smart Battery Sensor via LIN BUS)

CONF_BAT_LIN = 2 (Communication with Smart Battery Sensor via LIN BUS)

Hint: As the Temperature Input of Analog BEM Sensor is same as OIL Temperature Sensor it is not possible to choose CONF_TOIL_MDL = 0 and CONF_BAT_LIN = 0, If this configuration is choosen, then CONF_BAT is set to = 0

Status of Battery Management (only for ETC versions):

If (CONF_TOIL_MDL = 0 and CONF_BAT_LIN = 0)

Same input PIN is used for TOIL-Sensor and analog TBAT-Sensor

Then CONF_BAT = 0

Else CONF_BAT = C_CONF_BAT

Remark:

CONF_BAT = 0 (no Battery Management)

CONF_BAT = 1 (Battery Management)

Status of Passenger Compartment digital input (only for ETC versions):

IF CONF_BAT = 0

Then CONF_PC_FAN = 0

Else CONF_PC_FAN = C_CONF_PC_FAN

Endif

C_CONF_PC_FAN = 0 (No Passenger Comp. Blower switch Input)

C_CONF_PC_FAN = 1 (Passenger Comp. Blower switch information via Analog Input)

C_CONF_PC_FAN = 2 (Passenger Comp. Blower switch information via CAN message)

Status of Engine torque limitation(slow path) from TCU

CONF_ETL_TCU = C_CONF_ETL_TCU

C_CONF_ETL_TCU = 0 (No slow intervention)

C_CONF_ETL_TCU = 1 (Intervention with TQI_GS_SLOW_REQ)

C_CONF_ETL_TCU = 2 (Proportion of fast signal TQI_GS_REQ is used)

1.40.2 Version Learning

Update rate : 1000ms

1.40.2.1 Gearbox Type

The presence of an automatic gearbox is learnt depending if there is a signal from the TCU_TYPE from TCU on the CAN-bus. With C_CONF_TCU_LEARN = 0 also a learnt TCU can be reset from CONF_TCU = 00H or 0AH to CONF_TCU = 0FH.

The learning strategy includes the following items:
- A virgin ECU is configured to MT.
- If the configuration of the ECU is MT then the ECU monitors the CAN concerning the related messages during 10s after key on.
- At a learnt ECU the normal CAN-timeout-diagnosis is active.
- It is possible to set back an already learnt TCU by diagnosis tool.

Remark:
It is necessary to have a different calibration of some maps depending on AT- or MT-gearbox-type. Due to the setting of the gearbox-type some maps are existing double. The maps for the AT are signed with '_AT' at the end of the map. If CONF_TCU = 0Fh (MT) then the map without '_AT' is choosen and vice versa. In the specification a double existing map is listed once but marked with (_AT) at the end of the map.

At the moment separated maps for CVT are not available.

```
If      LV_TEACH_CAN_FINISHED = 0
Then If     CONF_TCU_LEARN = 1
     Then If     CONF_TCU = 0Fh (MT/initial value)
          Then If     LV_TCU1_CAN_VLD = 1
               Then             If     TCU_TYPE = 01h
                    Then CONF_TCU = 00h        Automatic transmission (Step shift)
                    Else If     TCU_TYPE = 02h
                         Then CONF_TCU =  0Ah    Automatic transmission (CVT)
                         Else CONF_TCU = 0Fh (MT/initial value)Manual transmission
                         Endif
                    Endif
               Endif (no valid TCU1 message on CAN)
          Endif  (already learnt)
     Else   (no TCU learning)
            CONF_TCU = 0Fh (MT/initial value)Manual transmission
            LV_AT = 0
     Endif
     If     T_TEACH_CONF < 10
     Then   Increment T_TEACH_CONF by 1
     Else   LV_TEACH_CAN_FINISHED = 1
Else (no more teaching after end of teach time)
Endif
```

If CONF_TCU = 00h or CONF_TCU = 0Ah

then LV_AT = 1

else LV_AT = 0

Restart TCU learning:

TCU learning can be restartet using KWP2000 Service IOCtlByLocalId. After this Service call the following actions will be done:

CONF_TCU = 0Fh (MT/ initial value)

LV_AT = 0

LV_TEACH_CAN_FINISHED = 0

T_TEACH_CONF = 0

1.40.2.2 Traction Control system

The presence of a TCS is learnt depending if there is a signal from the TCS on the CAN-bus.

The learning strategy includes the following items:

- A virgin ECU is configured to "no TCS" (CONF_TCS = 0).
- If the configuration of the ECU is "no TCS" (CONF_TCS = 0) then the ECU monitors the CAN concerning the related messages during 10s after key on.
- It is possible to set back an already learnt TCS by diagnosis tool.

If LV_TEACH_CAN_FINISHED = 0

Then If CONF_TCS = 0

  Then If LV_TCS1_CAN_VLD = 1

    Then CONF_TCS = 1

    Endif

  Endif

Else no more teaching after end of teach time

Endif

Restart TCS learning:

TCS learning can be restartet using KWP2000 Service IOCtlByLocalId. After this Service call the following actions will be done:

CONF_TCS = 0

LV_TEACH_CAN_FINISHED = 0

T_TEACH_CONF = 0

1.40.2.3 Acquisition of the ambient air temperature

For turbo charged engines there are two possibilities to recieve TAM in formation: From the CAN-bus or from an analog sensor value.

The learning strategy for turbo charged engines (LC_TCHA_CONF = 1) includes the following items:

- A virgin ECU is configured to CONF_TAM = 0 (no sensor value available).
- The ECU monitors the CAN concerning the related messages during a certain time (C_T_TAM_LEARN) after reset. If the respective CAN messages were received CONF_TAM is set to 1 (TAM via CAN available).
- If the respective CAN messages were not received it is assumed that an analog signal is available and CONF_TAM is set to 2.
- It is possible to set back an already learnt TAM signal by diagnosis tool.

For non charged engines (LC_TCHA_CONF = 0) CONF_TAM is always set to 0.

CONF_TAM = 0: no TAM sensor available or not yet learnt
CONF_TAM = 1: TAM via CAN (only for LC_TCHA_CONF = 1)
CONF_TAM = 2: TAM via analog sensor signal (only for LC_TCHA_CONF = 1)

Initialization: - at first power up or non-volatile memory lost:
CONF_TAM = 0
- otherwise: restored from non-volatile memory
- at reset: T_TAM_LEARN = C_T_TAM_LEARN

Recurrence: 1000ms

Formula section:

```
If    CONF_TAM = 0
      And LC_TCHA_CONF = 1
      And LV_ERR_CAN_BUS_OFF = 0
Then        If     T_TAM_LEARN <> 0
            Then   T_TAM_LEARN = T_TAM_LEARN – 1
                   If     LV_TAM_CAN_FIRST_VLD = 1
                   Then   CONF_TAM = 1
                          T_TAM_LEARN = 0
                   Endif
            Else   CONF_TAM = 2
            Endif
Else        If     LC_TCHA_CONF = 0
            Then   CONF_TAM = 0
            Endif
Endif
```

1.40.2.4 Air Condition Control

The presence of an air condition control is learnt depending if there is once the signal for "air condition control selected" recognized. In order to prevent signal disturbance being interpreted as ACIN, the LV_IM_ACIN has to be present during 3 following recurrences.

<u>Application conditions:</u>

Initialisation: at reset:

CONF_ACC: restored from NVMY; 0 in case of 1st power up or NVMY lost

CTR_ACC_LEARN = 0

Recurrence: *1000 ms*

ACTION_INFR_GetLvImAcin(OUT < *lv_im_acin* >***)***

If CONF_ACC = 0 *(no air condition control present)*

then **if** LV_IM_ACIN = 1 *(ACIN selected by dashboard switch)*

or LV_IM_ACIN_CAN = 1 *(ACIN selected by CAN input)_* **then**

$CTR\_ACC\_LEARN_{(n)} = CTR\_ACC\_LEARN_{(n-1)} + 1$

if CTR_ACC_LEARN = 3 *(ACIN signal present during 3 sec)*

then CONF_ACC = 1 *(air condition control present /learnt)*

endif

else CTR_ACC_LEARN = 0 *(reset ACIN learning counter)*

endif

1.40.2.5 Vehicle Speed Input

For non-OBD II-variants the vehicle speed input is coming only from the gearbox. In this case CONF_VS = 0, as the variant-coding is C_CONF_VS = 0 (see chapter “Variant coding”).
For OBD II-variants (C_CONF_VS = 1) it is possible to obtain the input for the vehicle speed from an inductive wheel speed sensor or from ABS. The ECU is able to distinguish the two inputs by comparing the two different signals and to <u>learn</u> the actual configuration.

<u>Learning strategy:</u>

The learning is performed only once for virgin ECU and C_CONF_VS = 1 and CONF_VS ≠ 1 or 2 hex. During learning CONF_VS is 3, that means the learning is active and the result of the learning is not known yet.

One of the configurations (ABS or inductive wheel speed sensor) is considered as learned, if during C_T_VS_MIN_LEARN seconds VS_ABS or VS_WHEEL_INDU is greater than C_VS_MIN_LEARN and the VS-change is smaller than C_VS_DIF_MAX_LEARN. If the conditions are fullfilled for both inputs at the same time the ABS-variant is learned (as the signal coming from ABS is considered more stable):

If LV_CDN_VB_MIN_DIAG = 1

then a timer is started for C_T_VS_MIN_LEARN seconds

If (VS_WHEEL_INDU > C_VS_MIN_LEARN

and $|VS\_WHEEL\_INDU_n - VS\_WHEEL\_INDU_{n-1}| < C\_VS\_DIF\_MAX\_LEARN)$

then CONF_VS = 2 (Vehicle speed signal acquisition from inductive sensor)

If (VS_ABS > C_VS_MIN_LEARN

and $|VS\_ABS_n - VS\_ABS_{n-1}| < C\_VS\_DIF\_MAX\_LEARN)$

then CONF_VS = 1 (Vehicle speed signal acquisition from ABS)

Vehicle speed during learning:

During learning (CONF_VS = 3) the vehicle speed is determined as follows :

a). if VS_ABS = 0 and VS_WHEEL_INDU = 0 then VS = 0

b). if VS_ABS > 0 and VS_WHEEL_INDU = 0 then VS = VS_ABS

c). if VS_ABS = 0 and VS_WHEEL_INDU > 0 then VS = VS_WHEEL_INDU

d). if VS_ABS > 0 and VS_WHEEL_INDU > 0 then VS = VS_ABS
(as the signal coming from ABS-input is considered more stable)

Remark:

The learned configuration is stored in non-volatile memory.
It is possible to change the variant by SAM 2000 and therefore a new learning is performed after next engine start. This happens also after an erasement of the learned configuration via KW 2000 (SAM-S or service tester) at the end of line-programming or at the service.

1.40.2.6 Acquisition of the aircon control unit configuration

The presence of a external control unit is learnt depending if there is a signal from the FATC on the CAN-bus.

The learning strategy includes the following items:
- A virgin ECU is configured to CONF_ACC_FATC = 0
- The ECU monitors the CAN concerning the related messages during a certain time (C_T_ACC_FATC_LEARN) after reset. If the respective CAN messages were received CONF_ACC_FATC is set to 1 (ACC message via CAN available).
- If the respective CAN messages were not received it is assumed that no presence of FATC
- It is possible to set back an already learnt FATC configuration by diagnosis tool.

Initialization: - at first power up or non-volatile memory lost:
CONF_ACC_FATC = 0
- otherwise: restored from non-volatile memory
- at reset: T_ACC_FATC_LEARN = C_T_ACC_FATC_LEARN

Recurrence: 1000ms

Formula section:

```
If      CONF_ACC_FATC = 0
    And NC_ETC_CONF = 1
    And LV_ERR_CAN_BUS_OFF = 0
Then    If      T_ACC_FATC_LEARN ≠ 0
        Then    T_ACC_FATC_LEARN = T_ACC_FATC_LEARN – 1
                If      LV_ACC_FATC_CAN_FIRST_VLD = 1
                        Or      LC_ACC_FATC = 1
                Then    CONF_ACC_FATC = 1
                        T_ACC_FATC_LEARN = 0
                Endif
        Endif
Endif
```

1.41 Adjustments via serial communication line

1.41.1 Idle speed CO-trim

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MFF_CO_IS	V/S/O	8000...7FFFH	-694.510597 ...694.489403	0,021194	Mg/stk
MFF correction for idle speed CO-adjustment					

Input data:

LV_IS	VS	TCO	LV_ERR_MAF
LV_ERR_VS	LV_ERR_TCO	LV_ERR_TPS	LV_ERR_ISA_i
LV_ERR_IV[NC_CYL_NR]	LV_ERR_MAP		

FUNCTION DESCRIPTION:

General information:

For the idle speed CO-trim, the diagnostic tester is using the KWP2000-protocol service Input Output Control By Local Identifier (IOCBLI). With its Input Output Control Parameter Short Term Adjustment (STA), the CO-trim is adjusted stepwise, that means each time the button “up” or “down” is pressed on the tester, the CO-trim value MFF_CO_IS is incremented or decremented by one step. If the CO-trim is correct, the value is stored if the service Long Term Adjustment (LTA) is performed. Temporary changes can be reset by the service Return Control To ECU (RCTECU).

1.41.1.1 Temporary change of MFF_CO_IS

The CO-trim value MFF_CO_IS is changed temporarily using the KWP2000 service IOCBLI-STA. If ignition is switched off, the changes are reset.

Application conditions:

The Adjustment can be performed if the following conditions are fullfilled:

If LV_IS = 1
and VS = 0
and TCO > C_TCO_MIN_CO_IS
and LV_ERR_TCO = 0
and LV_ERR_TPS = 0
and LV_ERR_MAF = 0
and LV_ERR_MAP = 0
and LV_ERR_ISA_i = 0
and LV_ERR_IV[NC_CYL_NR] = 0
and LV_ERR_VS = 0

If this service is performed, MFF_CO_IS is incremented or decremented by one step, depending on the control option byte of this service.
The condition LV_ERR_ISA_i is only for ISA system.

1.41.1.2 Long term storage of MFF_CO_IS

The CO-trim value MFF_CO_IS is stored in the flash memory using the KWP2000 service IOCBLI-LTA.

1.41.1.3 Reset changes of MFF_CO_IS to previous MFF_CO_IS

The CO-trim value MFF_CO_IS is reset to the MFF_CO_IS value which was permanently stored in the ECU, using the KWP2000 service IOCBLI-RCTECU.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TCO_MIN_CO_IS	1	0...FEH	-48...142.5	0.75	°C
Coolant temperature threshold for idle speed CO-adjustment.					

1.41.2 Nominal idle speed adjustment

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_SP_IS_ADJ_ASA	V/S	0...FFH	0...255	1	Rpm
Tuning correction for nominal idle speed					

Input data:

LV_IS	TCO	N_SP_IS	

FUNCTION DESCRIPTION:

Application conditions:

The Adjustment can be performed

If LV_IS = 1
and TCO > C_TCO_MIN_N_ASA

1.41.2.1 Idle speed-trim via Diagnostic tester

For the idle speed-trim, the diagnostic tester is using the KWP2000-protocol service Input Output Control By Local Identifier (IOCBLI). With its Input Output Control Parameter Short Term Adjustment (STA), the idle speed-trim is adjusted stepwise, that means each time the button “up” or “down” is pressed on the tester, the idle speed-trim value is incremented or decremented by one step. If the idle speed is correct, the value N_SP_IS_ADJ_ASA is stored if the service Long Term Adjustment (LTA) is performed. Temporary changes can be reset by the service Return Control To ECU (RCTECU).

1.41.2.2 Temporary change of N_SP_IS_ADJ_ASA

The idle speed-trim value N_SP_IS_ADJ_ASA is changed temporarily using the KWP2000 service IOCBLI-STA. If ignition is switched off, the changes are reset.

Application conditions:

LV_IS= 1

If this service is performed, N_SP_IS_ADJ_ASA is incremented or decremented with NC_N_SP_IS_ADJ_ASA by one step, depending on the direction of the correction (+/-) of this service but it is possible only to higher nominal idle speed values. A decrementation is possible down to the original uncorrected N_SP_IS.

1.41.2.3 Long term storage of N_SP_IS_ADJ_ASA

The idle speed-trim value N_SP_IS_ADJ_ASA is stored in the flash memory using the KWP2000 service IOCBLI-LTA.

1.41.2.4 Reset changes of N_SP_IS_ADJ_ASA to previous N_SP_IS_ADJ_ASA

The idle speed value N_SP_IS_ADJ_ASA is reset to the N_SP_IS_ADJ_ASA value which was permanently stored in the ECU, using the KWP2000 service IOCBLI-RCTECU.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TCO_MIN_N_ASA	1	0...FEH	-48...142.5	0.75	°C
Coolant temperature threshold for nominal idle speed correction.					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_N_SP_IS_ADJ_ASA	1	0...FFH	0...255	1	Rpm
Tuning correction for nominal idle speed - Non adjustable					

Applicative values:

NC_N_SP_IS_ADJ_ASA = 1

Flag to activate the Recirculation Valve Actuator test					
LV_ACT_RCL_EXT_ADJ	V/O	0...1H	0...1	1	-
Recirculation valve external Adjustment request by Service Tool					

Input data:

LV_ST_END	LV_IGK	LV_ES	LV_IS
ECU_STATE			

General information:

The test of the actuators is divided into several groups with different conditions. The adjustments are done via KWP2000 protocol by the service InputOutputControlByLocalIdentifier. For more detailed informations refer to KWP2000-specification. During test with engine stop, starting of the engine is possible only after ignition key off (ECU_STATE = ENG_LOCK)

1.42.1 Engine Lock

As long as any actuator test is activated the engine is locked (ECU_STATE = ENG_LOCK) with following exceptions (Actuator test allowed at LV_IS = 1)

- Injectors (INH_IV_x)
- O2 Heater Front (LSH_UP)
- O2 Heater Rear (LSH_DOWN)
- Variable Intake Manifold Switch (VIM)
- Recirculation valve (RCL)

1.42.2 On/Off Outputs

1.42.2.1 Actuator test is performed only with stopped engine

Conditions for activation: LV_IGK = 1
and LV_ES = 1

The component is switched on and off for each 1 sec

- Malfunction indicator lamp (MIL): on/off each 1 sec
- Fuel pump relay (EFP): on/off each 1 sec
- A/C compressor relay (ACC): on/off each 1 sec
- Imobilizer malfunction indicator light (IMOB_MIL) on/off each 1 sec
- Shut off valve (SOV) open/close each 1 sec
- Main relay (MAIN): on/off each 1 sec

(all other tests are switched off before testing main relay)

only for ETC version:

- Adaptive Cruise Control Main Lamp on/off each 1 sec
- Adaptive Cruise Control Set Lamp on/off each 1 sec

The component is switched on and off for each 5 sec

- CFA relay low speed (RLY_FAN_L) on/off each 5 sec
- CFA relay high speed (RLY_FAN_H) on/off each 5 sec

The component is permanently switched on/off by request

- Shut off valve (SOV): action 00H permanently open
  action FFH permanently closed

1.42.2.2 Actuator test activation at idle or stopped engine

Conditions for Activation: LV_IGK = 1
and LV_IS = 1 **or** LV_ES = 1

The component is switched on and off for each 1 sec

- Variable Intake Manifold Switch (VIM) on/off each 1 sec

only for TCI version:

- Recirculation Valve (RCL) on/off each 1 sec

1.42.3 PWM outputs

1.42.3.1 Actuator test activation only at stopped engine

Conditions for activation: LV_IGK = 1
and LV_ES = 1

- Oil control valve (OCV) Intake side 0%/100% each 0,5 sec
  If IOL-ID 24h is send from service tool,
  then On/Off definition On: STATE_ACR_TEST_IVVT = 1h
  Off: STATE _ACR_TEST_IVVT = 0h

- Oil control valve (OCV) Exhaust side 0%/100% each 0,5 sec
  If IOL-ID 80h is send from service tool,
  then On/Off definition On: STATE_ACR_TEST_IVVT = 3h
  Off: STATE _ACR_TEST_IVVT = 0h

- Canister purge solenoid (CPS) : on/off each 1 sec
  On/Off definition : On: CPPWM_EXT_ADJ = C_MAX_PWM_CPS
  Off: CPPWM_EXT_ADJ = C_MIN_PWM_CPS

- Port Flap (VCM): on/off each 1 sec
  On/Off definition : On: PORT_SP_EXT_ADJ = 1 (close)
  Off: PORT_SP_EXT_ADJ = 0 (open)

- Cooling Fan (CFA) on/off each 1 sec
  On/Off definition: On: CFA_PWM_EXT_ADJ = C_MAX_PWM_CFA
  Off: CFA_PWM_EXT_ADJ = C_MIN_PWM_CFA

- ETC Motor (MTC) (**only for ETC version**) on/off each 1 sec
  On/Off definition : On: TPS_EXT_ADJ = C_MAX_ACR_MTC
  Off: TPS_EXT_ADJ = C_MIN_ACR_MTC

- Idle speed actuator (ISA): (**only for ISA version**) on/off each 1 sec
  On/Off definition : On: OPG_ISA_EXT_ADJ = C_MAX_PWM_ISA
  Off: OPG_ISA_EXT_ADJ = C_MIN_PWM_ISA

- Wastegate (WG) (**only for TCI version**) on/off each 1sec
  On/Off definition : On: PWM_WG_EXT_ADJ = C_MAX_PWM_WG
  Off: PWM_WG_EXT_ADJ = C_MIN_PWM_WG

1.42.3.2 Actuator test activation only after Start

Conditions for activation: LV_IGK= 1
and LV_ST_END = 1

- O2 Heater Front (LSH_UP) on/off each 1 sec
  On/Off definition:
  On: LSHPWM_EXT_LS_UP [NC_CBK_EX_NR] = C_MAX_PWM_LSH_UP
  Off: LSHPWM_EXT_LS_UP [NC_CBK_EX_NR] = C_MIN_PWM_LSH_UP

- O2 Heater Rear (LSH_DOWN) on/off each 1 sec
  On/Off definition:
  On: LSHPWM_EXT_LS_DOWN [NC_CBK_EX_NR] = C_MAX_PWM_LSH_DOWN
  Off: LSHPWM_EXT_LS_DOWN [NC_CBK_EX_NR] = C_MIN_PWM_LSH_DOWN

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_MIN_PWM_CPS	1	0...FFH	0...99,609	0,391	%
CPS low value (= OFF state) for Actuator test					
C_MAX_PWM_CPS	1	0...FFH	0...99,609	0,391	%

ETC Position high value (= ON state) for Actuator test					
C_MIN_PWM_ISA	1	0...FFH	0...99.609	0.391	%
ISA low value (= OFF state) for Actuator test					
C_MAX_PWM_ISA	1	0...FFH	0...99.609	0.391	%
ISA high value (= ON state) for Actuator test					
C_MIN_PWM_WG	1	0...FFFFH	0...99.9984	1.5258e-3	%
Wastegate low value (= OFF state) for Actuator test					
C_MAX_PWM_WG	1	0...FFFFH	0...99.9984	1.5258e-3	%
Wastegate high value (=ON state) for Actuator test					

1.42.4 Injectors

Conditions for activation: LV_IGK = 1

and LV_IS = 1

Each several injector can be selected for a test. After activation of the test, the corresponding injector is disabled, until the test is stopped.

- **If** IOL 39h is recieved from service tool **then** switch On/OFF log. Injector 0 (phys: IVCyl 1)
- **If** IOL 3Ah **then** log Injector 3 (phys: IV Cyl 2)
- **If** IOL 3Bh **then** log.Injector 1 (phys: IV Cyl 3)
- **If** IOL 3Ch **then** log.Injector 2 (phys: IV Cyl 4)

INH_IV_EXT_ADJ = x x x x 0 0 1 0 BIN

- logical cylinder 0 enabled
- logical cylinder 1 disabled
- logical cylinder 2 disabled
- logical cylinder 3 disabled

1.42.5 Ignition

Each ignition coil can be separately selected for Actuator Test. When Actuator Test is activated, a spark is generated with normal Dwell Time every second.

Application conditions :

Initialization : LV_IGC_x_EXT_ADJ = IGC_x_EXT_ADJ = 0

Activation : LV_IGK = 1

and LV_ES = 1

Deactivation : LV_IGK = 0

or LV_ES = 0

If conditions for activation are fullfilled and Ignition Actuator test is activated via KW2000, then LV_IGC_x_EXT_ADJ is set to 1 and IGC_x_EXT_ADJ is toggling with 1 Hz frequency and 50% PWM ratio (trigger point to generate ignition pulse), else both LV_IGC_x_EXT_ADJ and IGC_x_EXT_ADJ are set to 0.

If IOL 31h is send by service tool, **then** activate test for IGC_0_EXT_ADJ (phys: IGC Cyl 1)

If IOL 32h **then** IGC_3_EXT_ADJ (phys: IGC Cyl 2)

If IOL 33h **then** IGC_1_EXT_ADJ (phys: IGC Cyl 3)

If IOL 34h **then** IGC_2_EXT_ADJ (phys: IGC Cyl 4)

1.43 Initialization of variables from non implemented functions

1.45 INTC - Introduction

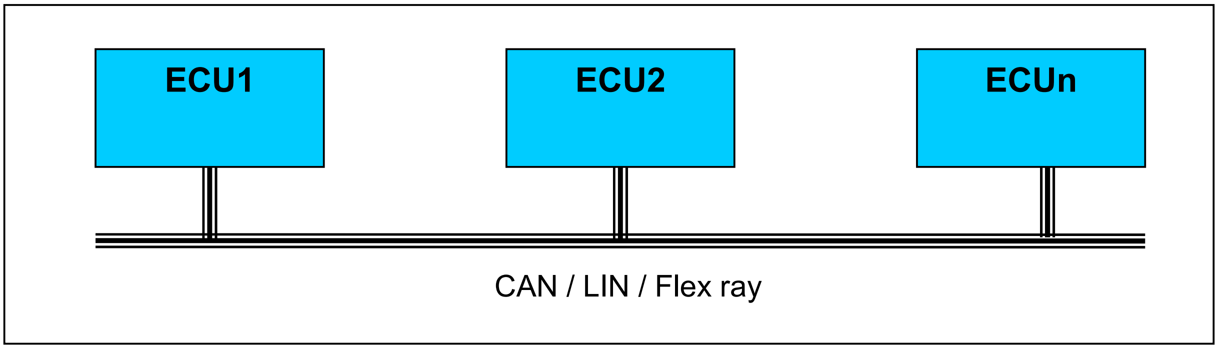
FUNCTION DESCRIPTION:

General information:

Intersystem communication stands for the communication across different control units (ECU) for various applications. The exchange of application data takes place in the form of messages. Data links like CAN, LIN or FlexRay are used for this communication purpose.

This document provides the brief introduction of these datalink layer protocols.

Signal flow diagram:



Description:

LIN
LIN stands for Local Interconnect Network.
LIN is a single wire bus system.
LIN network is a single master system with a maximum of 15 slave nodes.
LIN was designed to link switches, actuators and sensors in to a sub-bus that connects to the main bus, usually via a CAN.
LIN implementation is based on common UART/SCI interface hardware.
LIN is an inexpensive, low speed (from 1 to 20KiloBitsPerSecond), serial multiplexing protocol.

Most of the times the LIN master node implementation is done in the ECU. The LIN master node implementation in an ECU involves three different layers

- Application software
- LIN data link layer
- Low level Asynchronous (ASY) driver

The LIN master node functionality is explained in the below mentioned specification.
LIN: Master Node Data Link Layer
LIN: Master Node Data Link Layer (Appl. Inc.)

Normative reference for LIN

This implementation and the description of LIN data link layer is based on :
LIN Specification Package Revision 2.0 LIN Consortium 2003.

2.1 Analog Inputs

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VP_MAF_CAL	O	0...3FFH	0...4.9951	5 / 1024	Volt
Mass Air Flow sensor for Calibration purpose raw acquisition.					
VB_BAS	O	0...3FFH	0... 4.9951	5 /1024	Volt
Battery voltage raw acquisition.					
V_IGK_BAS	O	0...3FFH	0...4.9951	5 / 1024	Volt
Battery voltage raw acquisition.					
VCC_SENS_SUB_DIAG_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage supply for DTP, APT, PORT Poti, VIM Poti, MAP 2 and PSTE_AN					
FTL_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Main Fuel tank level sensor raw acquisition					
TOIL_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Oil temperature sensor raw acquisition.					
V_DTP	V/O	0...03FFH	0...4.9951	5 / 1024	Volt
Differential fuel tank pressure sensor raw acquisition.					
ACP_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Air conditioning pressure transducer voltage raw acquisition.					
MWSS_DIAG_BAS	O	0...3FFH	0...4.9951	5 / 1024	Volt
Magnetic wheel speed signal sensor raw acquisition.					
V_TECU	O	0...3FFH	0...4.9951	5 / 1024	Volt
ECU/PCU hardware temperature sensor voltage					
VCC_TPS_DIAG_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage supply for throttle position sensor 1/2 raw acquisition					
VCC_PVS1_DIAG_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage supply for pedal value sensor 1 raw acquisition					
VCC_PVS2_DIAG_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage supply for pedal value sensor 2 and MAP1 raw acquisition					
PSP_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Power steering pressure transducer voltage raw acquisition.					
V_VIM	V/O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage value for position feedback sensor at VIM					
PORT_FB_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage value for position feedback Sensor Port Flap					
CRU_BAS	V/O	0...03FFH	0...4.9951	5 / 1024	Volt
Cruise switch signal					
TPS_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Throttle Position Sensor raw acquisition					
VP_TAM	V/O	0...03FFH	0...4.9951	5 / 1024	Volt
Ambient Temperature Sensor Raw Aquisition					
FTL_BAS_SUB	O	0...03FFH	0...4.9951	5 / 1024	Volt
Sub fuel tank level sensor raw acquisition					
TBAT_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Battery temperature sensor raw acquisition.					
CUR_BAT_BAS	O	0...03FFH	0...4.9951	5 / 1024	Volt
Battery Sensor Charging Current Raw Aquisition					
V_PC_FAN	O	0...03FFH	0...4.9951	5 / 1024	Volt
Voltage value from Passenger compartment blower switch

FUNCTION DESCRIPTION:

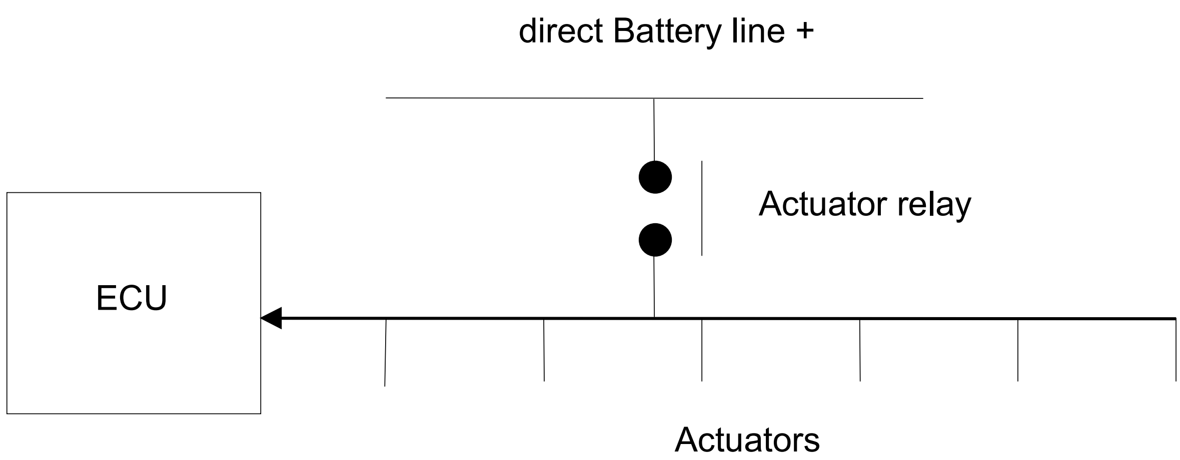
General information:

The acquisition of the raw values is performed every 1 ms with the resolution of 10 bits.



Application conditions:

Activation: at reset

Initialization: VB_MES = VB_BAS.

Recurrence : 10 ms

System Description:

The range of VB_BAS and VB_MES depends to the voltage divider (means 0 - 5V at ADC) at the input of the µC. The input is the ADC-value of the V_EL-Pin.

Formula section:

$$VB\_MES = (1/NC\_VB\_SAMPLE\_NR) * \sum_{n=1}^{NC\_VB\_SAMPLE\_NR} VB\_BAS_n$$

NC_VB_SAMPLE_NR = 2^n ; 1 =< n =< 6 (NC_VB_SAMPLE_NR is initialized with 8)

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_VB_SAMPLE_NR	1	0...40H	0...64	1	-
number of acquisition for filtering					

2.3 Acquisition of raw after key battery voltage

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_IGK_MES	O	0...3FFH	0...4,9951	0,0049	V
Computed ignition key voltage					

Input data:

V_IGK_BAS			

FUNCTION DESCRIPTION:

General information:

The acquisition of the raw values is performed every 1 ms with the resolution of 10 bits.
V_IGK_BAS is the same ADC-value which is used in Key on/Key off detection.

Application conditions:

Activation: at reset

Initialization: V_IGK_MES = V_IGK_BAS

Recurrence : 10 ms

Formula section:

$$V\_IGK\_MES = (1/NC\_V\_IGK\_SAMPLE\_NR) * \sum_{n=1}^{NC\_V\_IGK\_SAMPLE\_NR} V\_IGK\_BAS_n$$

NC_V_IGK_SAMPLE_NR = 2^n ; 1 =< n =< 6 (NC_V_IGK_SAMPLE_NR is initialized with 8)

Configuration data:

Name	DIM	Hex. limits	Phys. limits	Resol.	Unit
NC_V_IGK_SAMPLE_NR	1	0...40H	0...64	1	-
number of acquisition for filtering					

2.4 BIOS Knock function

Input data:

KNKS_CMF_FIL_x	KNKS_CMD_INT_x	KNKS_CMD_GAIN_x	KNKS_CMD_CONF_x
KNKWB_x	KNKWE_x		

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNKS_x	O	0 ... FFFFH	0 ... 4.99992	$7.63*10^{-5}$	V
Knock noise raw signal for cylinder x					

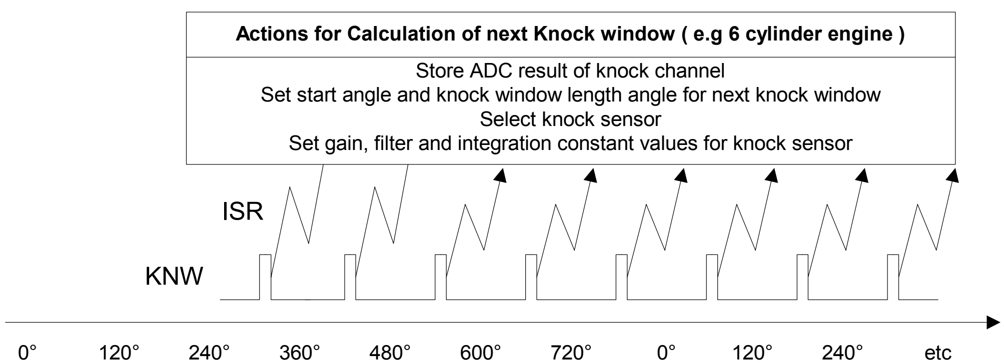
General information:

Activation : at every engine state except engine stop; calculate KNKS_CMD_CONF_x, KNKWB_x, KNKWE_x, KNKS_CMD_FIL_x, KNKS_CMD_INT_X AND KNKS_GAIN_x.
Deactivation : T_KNK_DISABLE

Initialization : calculate KNKS_CMD_CONF_x, KNKWB_x, KNKWE_x, KNKS_CMD_FIL_x, KNKS_CMD_INT_X AND KNKS_GAIN_x T_KNK_INIT
Update rate : every segment recalculate KNKWB_x, KNKWE_x, KNKS_CMD_FIL_x, KNKS_CMD_INT_x and KNKS_GAIN_x

The knock detection is performed for cylinder-individually defined measurement windows since knock-typical oscillations only occur for certain crankshaft angles. For the time of the knock window the knock signal is integrated. At the end of the knock window the integrated signal is sampled and converted to the digital value KNKSx.

The knock window for cylinder x+1 is reprogrammed at the end of the knock window for cylinder x. The parameters KNKS_CMD_FIL_x, KNKS_CMD_INT_x, KNKS_CMD_GAIN_x, KNKS_CMD_CONF_x, KNKWB and KNKWE have to be stable at this time. The knock channel adc is configured for triggering on the end of the knock window. The end of conversion generates an interrupt in which the parameters for the next knock window are set. The following picture illustrates this.



The knock function may be activated by T_KNK_INIT or T_KNK_ENABLE and deactivated by T_KNK_DISABLE.

2.5 Logic Inputs

2.5.1 Basic software

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_IM_ACIN	-	0...01H	0...1	1	-
Air Condition selected.					
LV_IM_ACCIN	-	0...01H	0...1	1	-
Air Condition requested.					
LV_IM_PRS_ACC	-	0...01H	0...1	1	-
Pressure switch for Air Condition circuit.					
LV_IM_VB_OFF	-	0...01H	0...1	1	-
Battery disconnected detection.					
LV_IM_CS_PN	O	0...01H	0...1	1	-
Clutch switch					
LV_PIN_BLS	O	0...01H	0...1	1	-
Brake light switch					
LV_PIN_BTS	O	0...01H	0...1	1	-
Brake test switch					
LV_IM_PSTE	-	0...01H	0...1	1	-
Power Steering Switch					
LV_IM_HDLP	-	0...1H	0...1	1	-
Head Lamp switch					

FUNCTION DESCRIPTION:

List of logic Inputs

Name	Port - Channel	Logic state	Remarks
LV_IM_ACIN	MDA30	Positive Logic	
LV_IM_ACCIN	MDA31	Positive Logic	
L_IM_PRS_ACC	A_AN52/PQA0	Positive Logic

2.5.2 Applicative software

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DRI	V/O	0...01H	0...1	1	-
Boolean for DRIVE or REVERSE engaged.					
LV_ACIN	V/O	0...01H	0...1	1	-
Air condition selected.					
LV_ACCIN	V/O	0...01H	0...1	1	-
Air condition requested.					
LV_PRS_ACC	V/O	0...01H	0...1	1	-
Pressure switch for Air Condition circuit.					
LV_PSTE	V	0...01H	0...1	1	-
Pressure switch for power steering circuit.					
LV_HDLP	V/O	0...01H	0...1	1	-
Head Lamp switch					

Input data:

CONF_ACC	LV_IM_PRS_ACC	LV_IM_ACIN	TAR_GC
PSP	CONF_TCU	LV_IM_ACCIN	CONF_PSTE
LV_IM_PSTE	LV_IM_HDLP	CONF_BAT	
LV_IM_ACCIN_CAN			

2.5.2.1 Air-condition system :

```
If      CONF_ACC = 1
then
        if      CONF_ACC_FATC = 0
        then    LV_ACIN = LV_IM_ACIN
        else    LV_ACIN = LV_IM_ACIN_CAN
        endif

if  CONF_ACC_FATC = 0              then    LV_ACCIN = LV_IM_ACCIN
        else    if      LC_TQ_LOSS_ACC_CLULESS = 0
                then    LV_ACCIN = LV_IM_ACCIN_CAN
                else    if      TQ_LOSS_ACC_CAN < C_TQ_LOSS_ACCIN_CAN
                        then            LV_ACCIN = 1
                        else            LV_ACCIN = 0
                        endif
                endif
        endif

    LV_PRS_ACC = LV_IM_PRS_ACC
```

else LV_ACIN = 0
and LV_ACCIN = 0
and LV_PRS_ACC = 0

2.5.2.2 Automatic gear-box system :

If CONF_TCU = 1
and TAR_GC > 0
then LV_DRI = 1
else LV_DRI = 0

Remark: For detailed information refer to CAN - Specification.

2.5.2.3 Power steering system :

If CONF_PSTE = 0
then LV_PSTE = LV_IM_PSTE

2.5.2.4 Battery and Energy Management

If CONF_BAT = 1
then LV_HDLP = LV_IM_HDLP
endif

Calibration data:

At least one missing tooth has been simulated					

Input data:

N_32	LV_ACT_CRK	NC_CYL_NR	NC_NR_GAP

FUNCTION DESCRIPTION:

2.6.1 Crankshaft Synchronization

General information:

The crankshaft signal is generated by the crankshaft sensor in conjunction with the crankshaft target wheel. The target wheel has a theoretical number of NC_NR_TOOTH (typically 60) teeth, and NC_NR_TOOTH_GAP missing teeth (typically 2) forming the reference gap (“60-2”). The crankshaft sensor converts the mechanical shape into an electrical signal.

Magnetic Crankshaft Position Sensors (MCPS) deliver an AC signal with an amplitude depending primarily on crankshaft speed, and sensor air gap. The signal is shaped into a rectangular signal by the ECU input circuitry. Each edge of that signal represents a tooth or a gap of the target wheel. Only signal edges generated from teeth will be processed by software (active signal edge definition). These may be falling or rising edges, depending on sensor polarity.

Active Crankshaft Position Sensors (ACPS) switch an open collector output on and off with every tooth or gap passing. Connecting the sensor output to a pull-up resistor inside the ECU generates a signal with rectangular shape. Each edge of that signal represents a tooth or a gap of the target wheel. Only falling signal edges will be processed by software (active signal edge definition), because they are faster. Design and installation of the sensor must ensure that falling signal edges are generated from teeth.

The corresponding configuration data is NC_ACT_CRK_EDGE.

The choice is taken in a way not to use the unprecise signal edge generated in the crankshaft reference gap.

It may be 0 (falling) or 1 (rising) with MCPS, depending on sensor polarity.

With ACPS it should always be 0, because the falling edge is faster due to the sensor’s open collector interface. The unprecise signal edge in the reference gap is avoided by choosing the correct installation of the sensor relativ to the target wheel motion direction.

Application conditions:

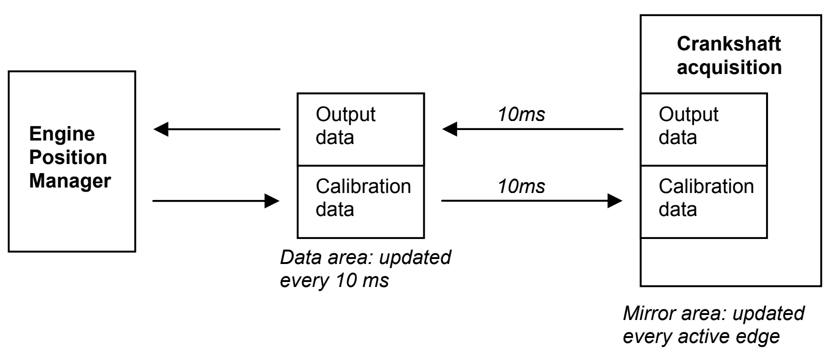
Recurrence:

For set of the RAM as flags, a mirror area is defined which contains a copy of the output and calibration data in the basic software area (see figure below).

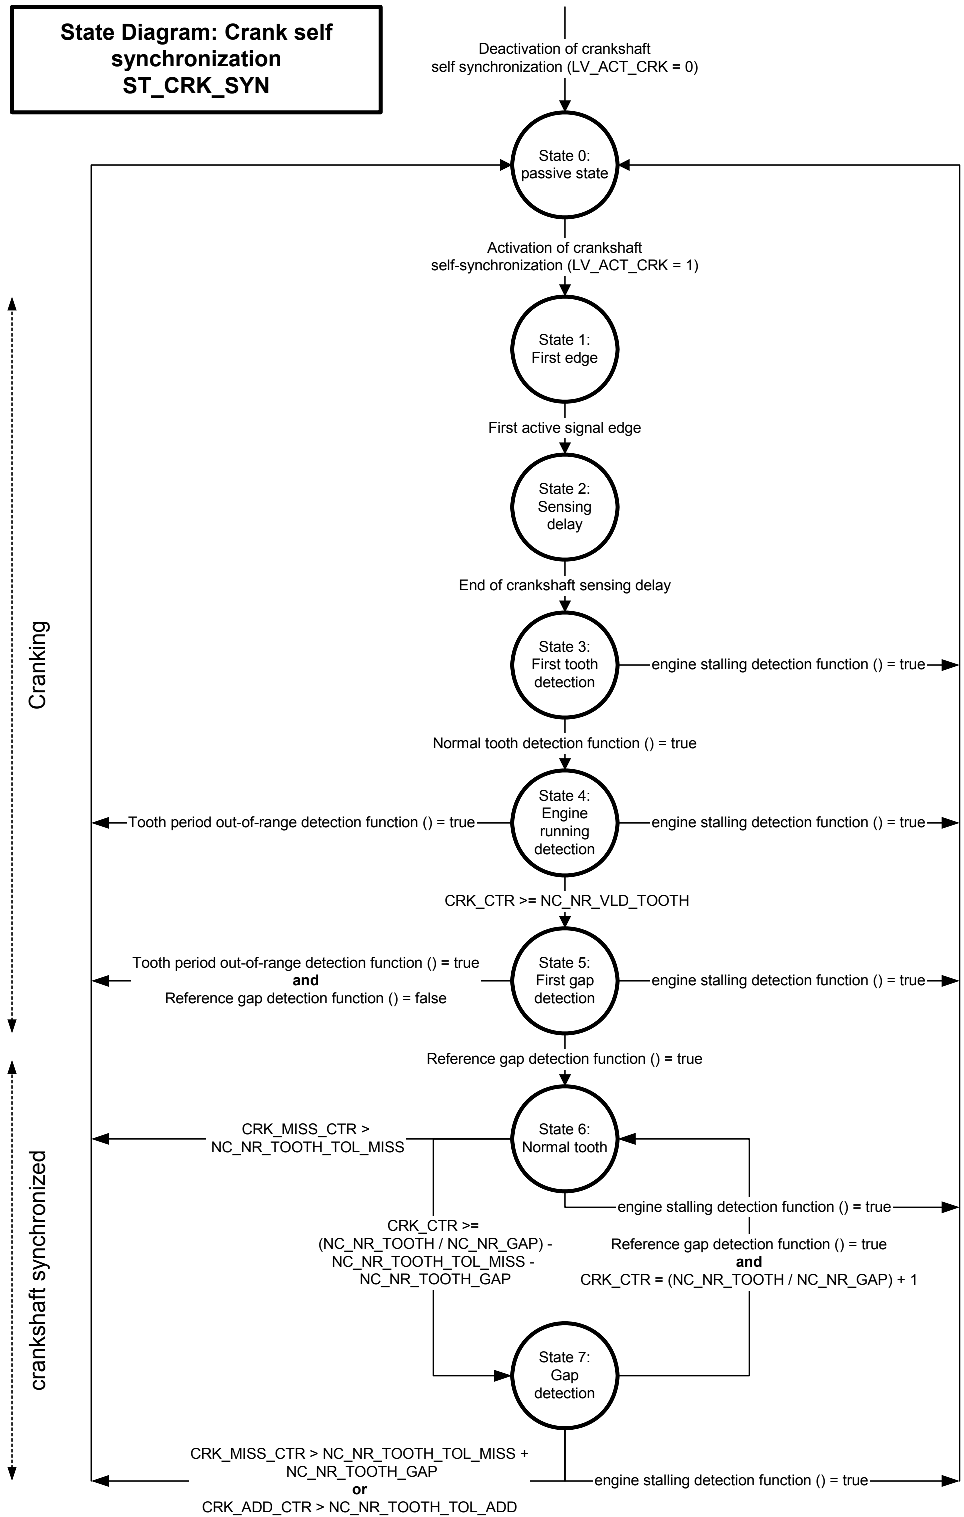
The mirror area of the output data is updated by the lower layer at every active signal edge.

The mirror area of the calibration data is updated by the upper layer each 10ms.

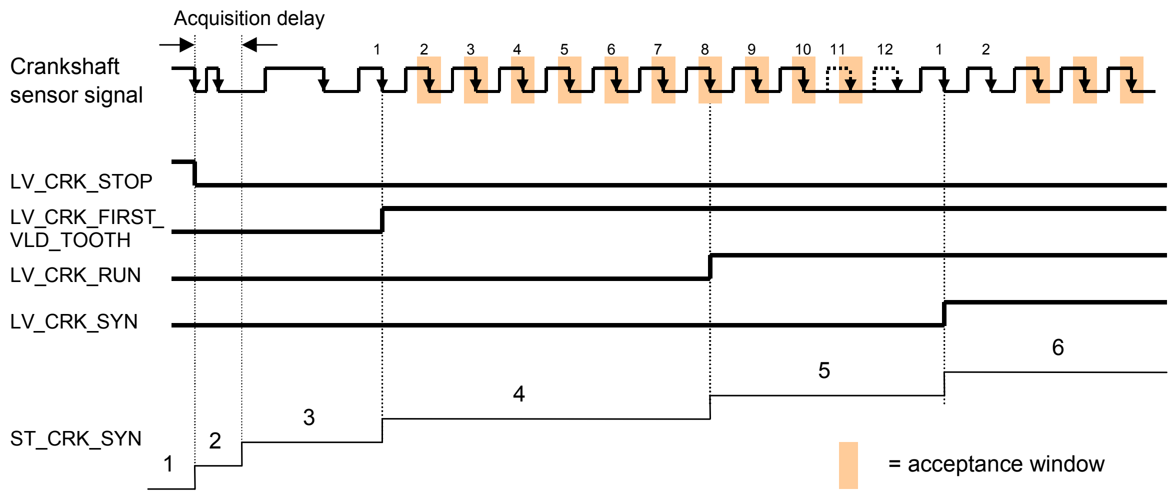
The output data is copied from the mirror area every 10 ms



State Flow Diagram:



Timing Diagram (example):



Formula section:

State 0: Crankshaft passive state

Input condition :

From state 4,5:	Tooth period out-of-range detection function () = true

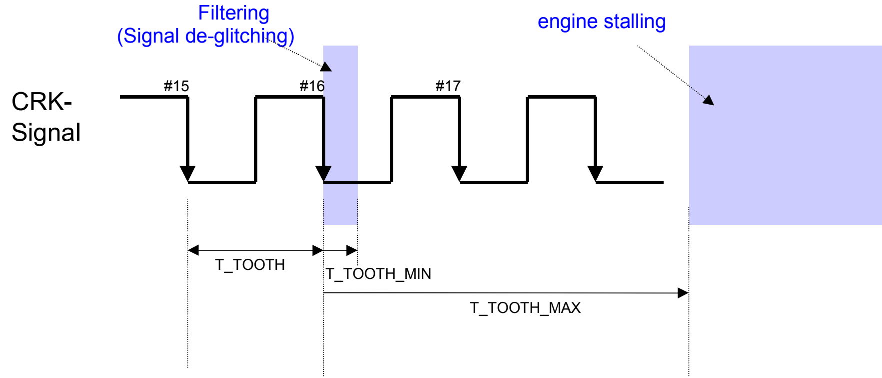
	Then	LV_LOST_SYN_CRK = 1
	Endif	

2.6.2 Definition of the sub function task

2.6.2.1 Normal tooth detection function ()

General information:

The purpose of this function is to validate the tooth period of a normal tooth. The function returns false when the tooth period is too small (Signal edges detected before a delay time of T_TOOTH_MIN are not valid).



Formula section:

$$T\_TOOTH\_MIN = \frac{60}{NC\_NR\_TOOTH * NC\_N\_MAX}$$

If	T_TOOTH => T_TOOTH_MIN
Then	return (true)
Else	return (false)
Endif	

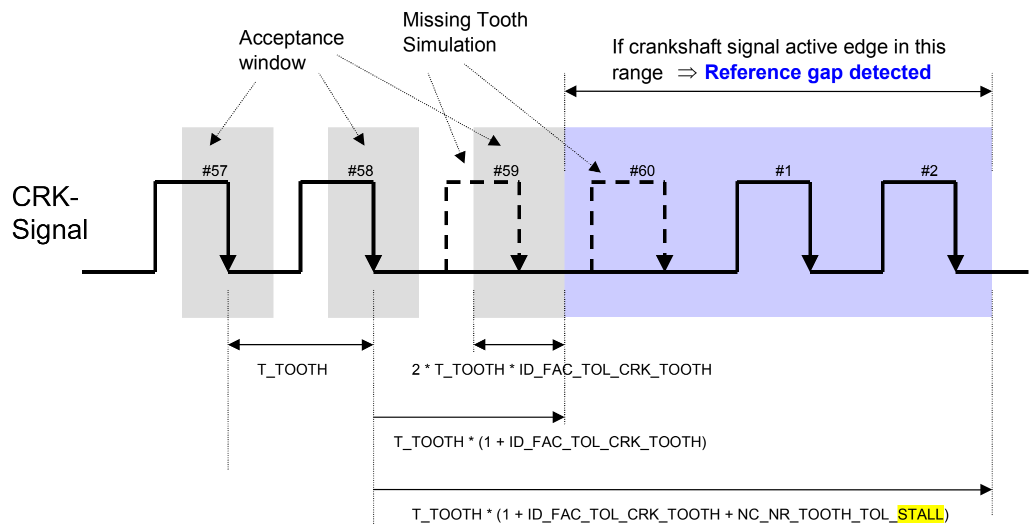
2.6.2.2 Reference gap detection function ()

General information:

The purpose of this function is to detect a reference gap.

A reference gap is detected if no signal edge was detected inside the crankshaft acceptance window and at least 1 (after synchronization) or NC_NR_TOOTH_GAP (first gap detection) teeth have been completely simulated.

The follow figure shows the reference gap detection after synchronization:



Formula section:

If LV_CRK_SYN = 1

Then **If** Number of simulated missing teeth in gap position >=1

Then **If** (NC_NR_TOOTH / NC_NR_GAP) – CRK_MISS_CTR <=

CRK_CTR <=

(NC_NR_TOOTH / NC_NR_GAP) + CRK_ADD_CTR

Then (*correct tooth counter)*

CRK_CTR = CRK_CTR + CRK_MISS_CTR – CRK_ADD_CTR

return (true)

Else return (false)

Endif

Else **If** Number of simulated missing teeth in gap position >=

NC_NR_TOOTH_GAP

Then return (true)

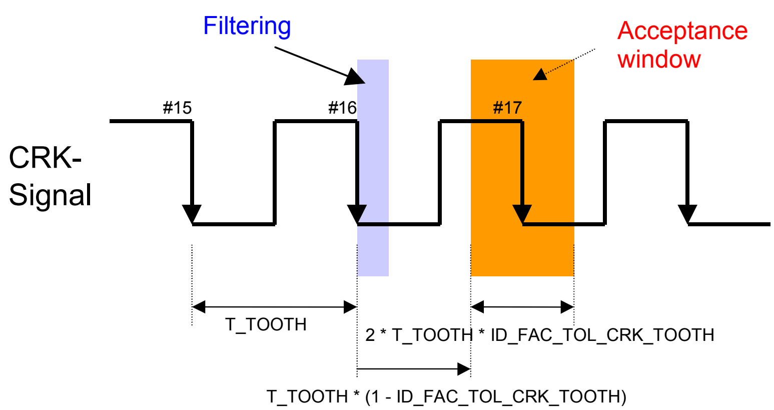
Endif

Endif

2.6.2.3 Tooth period out-of-range detection function ()

General information:

The purpose of this function is to check if the tooth period is within a defined window area. The function returns true if the tooth period is outside the acceptance window.



Formula section:

Before first reference gap:

If T_TOOTH n-1 * (1 – ID_FAC_TOL_CRK_TOOTH) ≤ T_TOOTH n ≤ T_TOOTH n-1 * (1 + ID_FAC_TOL_CRK_TOOTH)

Then return (false)

Else return (true)

After first reference gap:

If T_TOOTH n-1 * (1 – ID_FAC_TOL_CRK_TOOTH) ≤ T_TOOTH n

Then return (false)

Else return (true)

Remark: If T_TOOTH > T_TOOTH n-1 * (1 + ID_FAC_TOL_CRK_TOOTH) after first reference gap, then a tooth is simulated (see below "Missing Tooth Simulation Function").

The acceptance window is disabled

- on the first and second crankshaft signal edge after a reference gap detection
- on the first and second crankshaft signal edge after simulation of a missing tooth

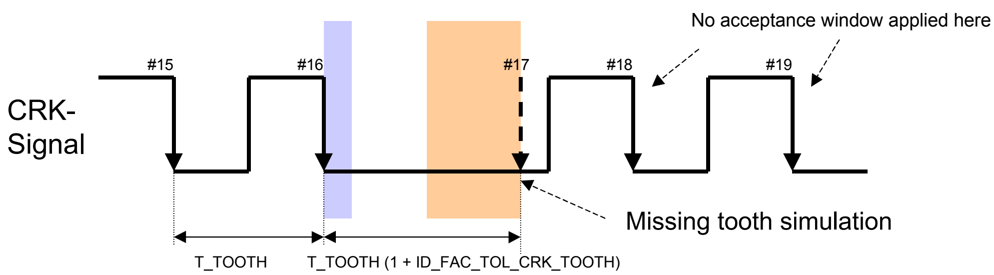
2.6.2.4 Missing Tooth Simulation Function ()

General information:

Simulate a tooth with tooth period T_TOOTH n-1 (last measured tooth period).

All measurements shall be based on the simulated tooth not on real edges.

Simulation starts at the last (real or simulated) signal edge if no signal edge is detected inside the acceptance window defined by ID_FAC_TOL_CRK_TOOTH.



Formula section:

Increment CRK_CTR.

Increment CRK_MISS_CTR.

LV_CRK_MISS_TOOTH = 1

2.6.2.5 Missing Tooth Simulation in Gap Position Function ()

General information:

Simulate a tooth with tooth period T_TOOTH n-1 (last measured tooth period).

Simulation starts at the last (real or simulated) signal edge if no signal edge is detected inside the acceptance window defined by ID_FAC_TOL_CRK_TOOTH.

Simulation stops when a edge is detected after the first simulated missing tooth.

All measurements shall be based on the simulated tooth not on real edges.

Formula section:

Increment CRK_CTR.

If number of simulated teeth < NC_NR_TOOTH_GAP

And

Missing tooth simulation stopped

Then Increment CRK_MISS_CTR

High acceleration during reference gap: only one tooth could be simulated

Endif

If number of simulated teeth > NC_NR_TOOTH_GAP

Then Increment CRK_ADD_CTR

High deceleration during reference gap: more than NC_NR_TOOTH_GAP teeth simulated

Endif

2.6.2.6 Engine stalling detection function ()

General information:

Engine stalling is detected when the number of consecutive simulated teeth exceeds NC_NR_TOOTH_STALL or when the tooth period is greater than T_TOOTH_MAX.

Formula section:

$$T\_TOOTH\_MAX = \frac{60}{NC\_NR\_TOOTH * NC\_N\_MIN}$$

If more than NC_NR_TOOTH_ STALL consecutive teeth are simulated

Or

T_TOOTH (1 + ID_FAC_TOL_CRK_TOOTH) >= T_TOOTH_MAX

Then return (true)

Else return (false)

Endif

2.6.3 Requirements to infrastructure

2.6.3.1 Crankshaft Tooth Time Measurement (T_TOOTH)

General information:

System request accuracy <= 4 us

The crankshaft tooth period T_TOOTH is the measured time between two consecutive valid active crankshaft signal edges (falling or rising according to configuration).

If a missing tooth is simulated, T_TOOTH represents the time period between the last two real valid signal edges. T_TOOTH keeps the latest value until a new measured value is available.

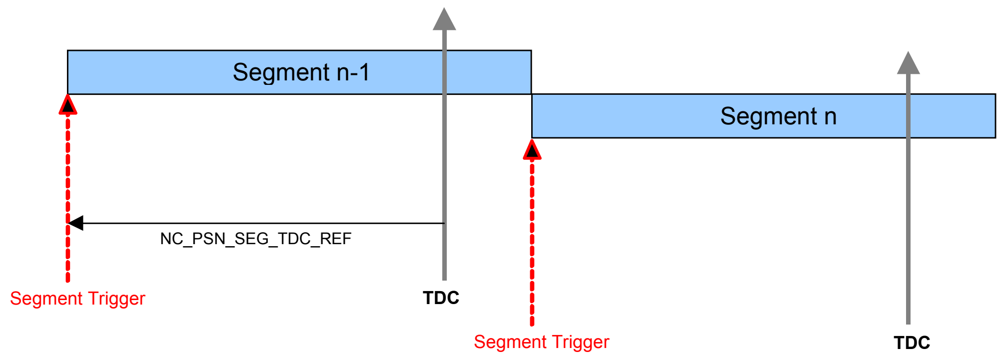
2.6.3.2 Segment Period Measurement (T_SEG_ENSD) and Trigger Generation

General information:

System request accuracy <= 1 us

At Segment event, a trigger is defined and a control signal is generated to trigger execution of segment synchronous tasks.

The corresponding time intervals T_SEG_ENSD are measured between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC.



Application conditions:

Initialisation:	T_SEG_ENSD is set to the maximum value
Recurrence :	before synchronization: once (when LV_CRK_RUN is set) after synchronization: NC_PSN_SEG_TDC_REF degrees before each TDC (segment trigger)
Activation :	LV_CRK_RUN = 1
Deactivation :	LV_CRK_STOP = 1

Formula section:

Before synchronization, one segment time is output at the moment when crankshaft rotation is validated. The first segment period is calculated from the most recent tooth period:

T_SEG_ENSD = (2 * T_TOOTH * NC_NR_TOOTH) / NC_CYL_NR

The same calculation applies to the first segment after synchronization.

After synchronization:

T_SEG_ENSD = time interval between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC

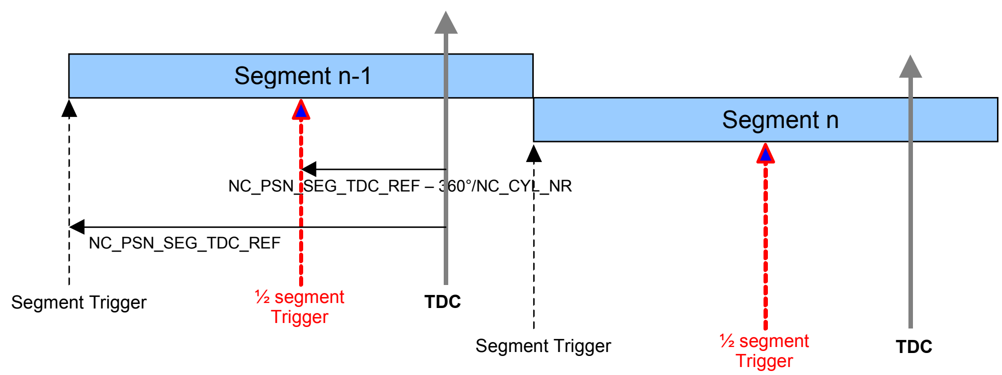
2.6.3.3 Half-Segment Period Measurement (T_SEG_HALF_ENSD) and Trigger Generation

General information:

System request accuracy <= 1 us

At the half of a segment (in the middle of two segment events) a half-segment event is generated and an half-segment trigger is defined and send to the ASW if the engine speed is lower than a threshold defined by NC_N_SEG_HALF_END.

This function provides a output value for the half-segment period. This measured time is send to the ASW.



Application conditions:

Initialisation: T_SEG_HALF_ENSD is set to the maximum value

Recurrence : before synchronization: once (when LV_CRK_RUN is set)
after synchronization:

NC_PSN_SEG_TDC_REF degrees before each TDC (segment trigger)

and

NC_PSN_SEG_TDC_REF – 360° CRK / NC_CYL_NR degrees before each TDC (half-segment trigger) **if** T_SEG_HALF_ENSD >= 60 / (NC_CYL_NR * NC_N_SEG_HALF_END)

Activation : LV_CRK_RUN = 1

Deactivation : LV_CRK_STOP = 1

Formula section:

The first half segment period is calculated from the most recent tooth period:

T_SEG_HALF_ENSD = (T_TOOTH * NC_NR_TOOTH) / NC_CYL_NR

After synchronization:

T_SEG_HALF_ENSD = time elapsed between

- a segment event and a half-segment event or
- a half-segment event and a segment event

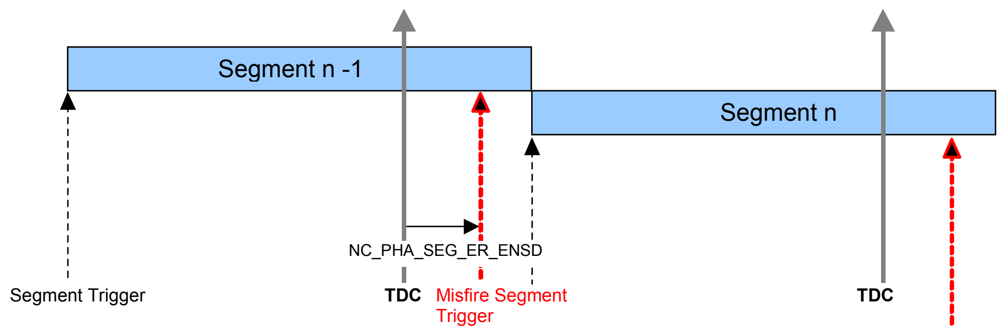
2.6.3.4 Misfire Segment Period Measurement (T_SEG_ER)

General information:

System request accuracy <= 1 us

The function provides output values for the misfire segment period.

The misfire segment period T_SEG_ER corresponds to the TDC period, measured at the tooth events, which are closest to NC_PHA_SEG_ER_ENSD after each TDC.



Application conditions:

Initialisation: T_SEG_ER is set to the maximum value

Recurrence : every misfire segment

Formula section:

T_SEG_ER = time interval between misfire segment tooth events.

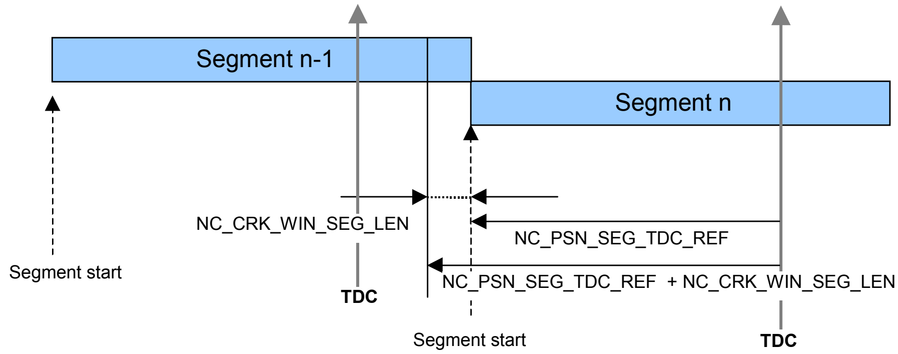
2.6.3.5 Crankshaft tooth window measurement (T_CRK_WIN_ENSD)

General information:

System request accuracy <= 1 us

The time interval elapsed between tooth events located between NC_CRK_WIN_SEG_LEN degrees before the end of each segment and the segment trigger is measured and send to the ASW segment synchronous

It provides and measures the time of the last NC_CRK_WIN_SEG_LEN teeth period before segment event.



Application conditions:

Initialisation: T_CRK_WIN_ENSD is set to the maximum value

Recurrence : every segment

Activation : LV_CRK_SYN = 1

Deactivation : LV_CRK_STOP = 1

Formula section:

If LV_CRK_SYN is set to 1 between NC_CRK_WIN_SEG_LEN degrees before the end of the segment and the segment trigger event

Then /* Recalculation from last available tooth period */

T_CRK_WIN = (T_TOOTH * NC_NR_TOOTH) / (360°CRK / NC_CRK_WIN_SEG_LEN)

Else /* Normal calculation */

T_CRK_WIN_ENSD = time interval between tooth events located between NC_CRK_WIN_SEG_LEN degrees before the end of each segment and the segment triger

Endif

2.6.3.6 ID_FAC_TOL_CRK_TOOTH calculation

General information:

ID_FAC_TOL_CRK_TOOTH[0rpm] is used until crankshaft synchronization (i.e. until first gap is detected, LV_CRK_SYN is set).

Then after crankshaft synchronization, ID_FAC_TOL_CRK_TOOTH is calculated depending on engine speed value (N_32).

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit

2.6.4 System requirements to sensor signal

2.6.4.1 General

With both sensor technologies, there is an angular offset between the mechanical reference (usually the trailing edge of a tooth) and the timing reference of the sensor (zero crossing of the MCPS signal, output switching of the ACPS) for an active edge. This offset will further on be referred to as phase angle. The phase angle depends strongly on sensor tolerances, installation tolerances (air gap), and operating conditions (speed, temperature).

The tolerances given in the following paragraphs refer to the angular position of the crankshaft target wheel when an active signal edge is recognized by the input port of the µP, or to the rotation angle between such events, respectively.

2.6.4.2 Relative phase angle tolerances

The usual synchronization algorithms can accept ±3% tolerance of the target wheel rotation angle between consecutive active signal edges.

e.g. for a "60-2" target wheel, this is 6° (18°) ±0.2°

The sensor/target wheel combination has to fulfill this requirement at all operating conditions.

The permissible accumulation of tooth angle tolerances over a TDC segment is ±0.25% of the angle for one TDC segment (720°/ NC_CYL_NR) at segment reference conditions.

e.g. for four-cylinder engines 180° ±0.45°

e.g. for six-cylinder engines 120° ±0.3°

Segment reference conditions are: 2000rpm, 80°C.

Please note that for engines with more than 8 cylinders, this requirement is more stringent than the requirement for consecutive signal edges.

2.6.4.3 Relative phase angle stability

The angle for one TDC period measured under segment reference conditions must not have a drift > 0.045° versus speed variation from 2000 rpm...7000 rpm and temperature variation within the complete range. This requirement has to be fulfilled for all tolerances and all possible displacements of the target wheel relative to the sensor (air gap, radial run-out, crankshaft flexion, bearing clearance...).

In case of MCPS sensors, phase angle stability must be measured with the ECU hardware stage.

2.6.4.4 Repeatability

Two different definitions of repeatability are functionally equal. The choice depends on the sensor test bench and measurement equipment.

1. Phase angle repeatability

(mechanical edge to signal edge for the same tooth) ±0.025°

2. Interval repeatability

(signal edge to signal edge for the same pair of teeth) ±0.05°

In both cases the repeatability is determined from the maximum and minimum value out of a large number of measurements under constant conditions.

2.6.5 Hardware and HAL requirements

2.6.5.1 EMI

Any signal disturbance must be suppressed as far as possible. Supplemental trigger events must not be generated due to such disturbance, particularly not at the slow zero crossing in the reference gap.

2.6.5.2 Phase shift repeatability

At constant operating conditions, the phase shift introduced by the input circuitry must be constant within ±0.1 µs

Import actions:

ACTION_ENSD_*GetDigCAMINLevel* (IN <STATE_CAM_IN>)
ACTION_ENSD_*GetDigCAMEXLevel* (IN <STATE_CAM_EX>)

General information:

This specification applies for cam/crk configurations with:

- up to 4 camshaft sensors
- active camshaft sensors (ACAM) with TPO or without TPO
- magnetic camshaft sensors (MCAM)
- halfmoon or pin-type camshaft target wheels
- one reference gaps per engine revolution (NC_NR_GAP = 1)

The active camshaft signal edge(s) for synchronization can be selected by configuration data NC_ACT_CAM_EDGE_SYN:

- NC_ACT_CAM_EDGE_SYN = 1 or 2: no level detection is performed, only camshaft edges (falling or rising) are evaluated. This configuration shall be selected when a ACAM non – TPO or a MCAM sensor is used.
- NC_ACT_CAM_EDGE_SYN = 3: level detection at engine start, falling and rising camshaft edges are evaluated. This configuration should be selected when a ACAM TPO sensor is used.

A diagnostic output is delivered to allow detection of camshaft signal failure.

The signal is used for:

1. Self synchronization of all camshafts : timing validation of the active edges of the signal in correspondance with its theoretic position (used for VVT controler, for detection of crankshaft signal failure, and for limp-home in case of crankshaft signal failure).
2. Camshaft / crankshaft synchronization of the selected camshaft : determination of the offset for the engine position calculation
3. Engine position interface for pre-injection (with the selected camshaft used for cam/crank synchronization)

These three functions are described with three states diagrams.

Application conditions:

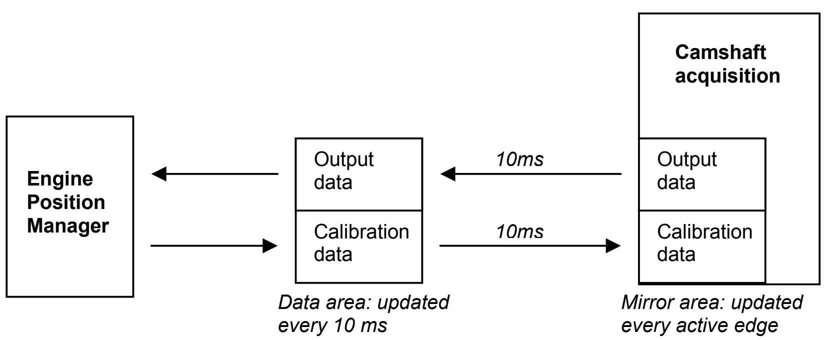
Recurrence:

For set of the RAM as flags, a mirror area is defined which contains a copy of the output and calibration data in the basic software area (see figure below).

The mirror area of the output data is updated by the lower layer at every active signal edge.

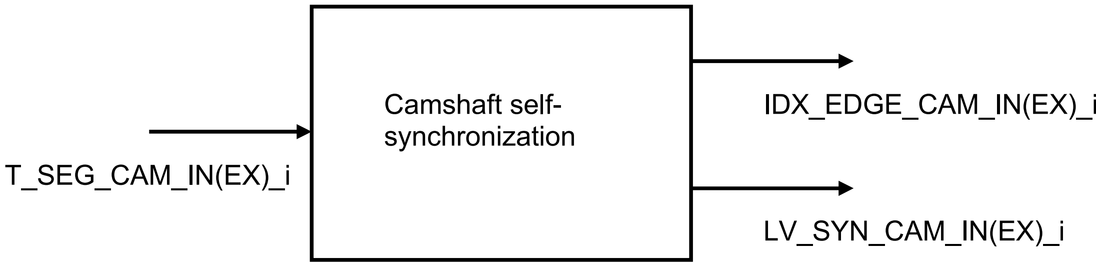
The mirror area of the calibration data is updated by the upper layer each 10ms.

The output data is copied from the mirror area every 10 ms



2.7.1 Camshaft Self Synchronization

General information:



Self-synchronization is performed on every available camshaft sensor. It's purpose is to determine the current camshaft signal index IDX_EDGE_CAM_IN(EX)_i based on measured camshaft segment periods T_SEG_CAM_IN(EX)_i (see requirements to infrastructure).

Note that there are two lists of possible camshaft signal indexes:

- For self-synchronization (described in this chapter)
- For cam/crk synchronization and engine position determination for pre-injection

Application conditions:

Recurrence: every camshaft signal edge (falling and rising)

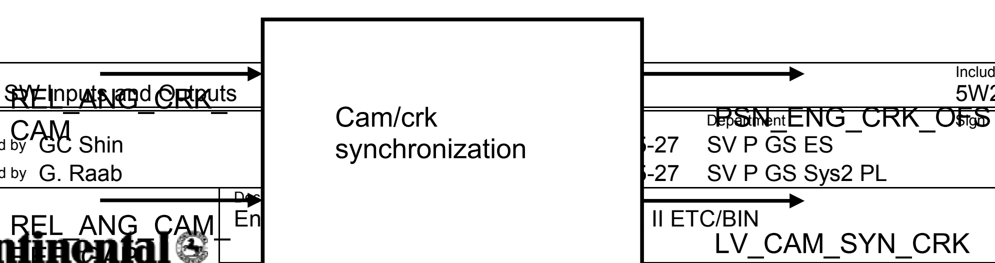
2.7.2 Camshaft/Crankshaft Synchronization

<u>General information:</u>



Cam/crk-synchronization is performed on the camshaft sensor which is selected for synchronization by the engine position manager. It's purpose is to determine the engine position offset PSN_ENG_CRK_OFS based on measured angular distances REL_ANG_CRK_CAM and REL_ANG_CAM_REF_GAP (see requirements to infrastructure).

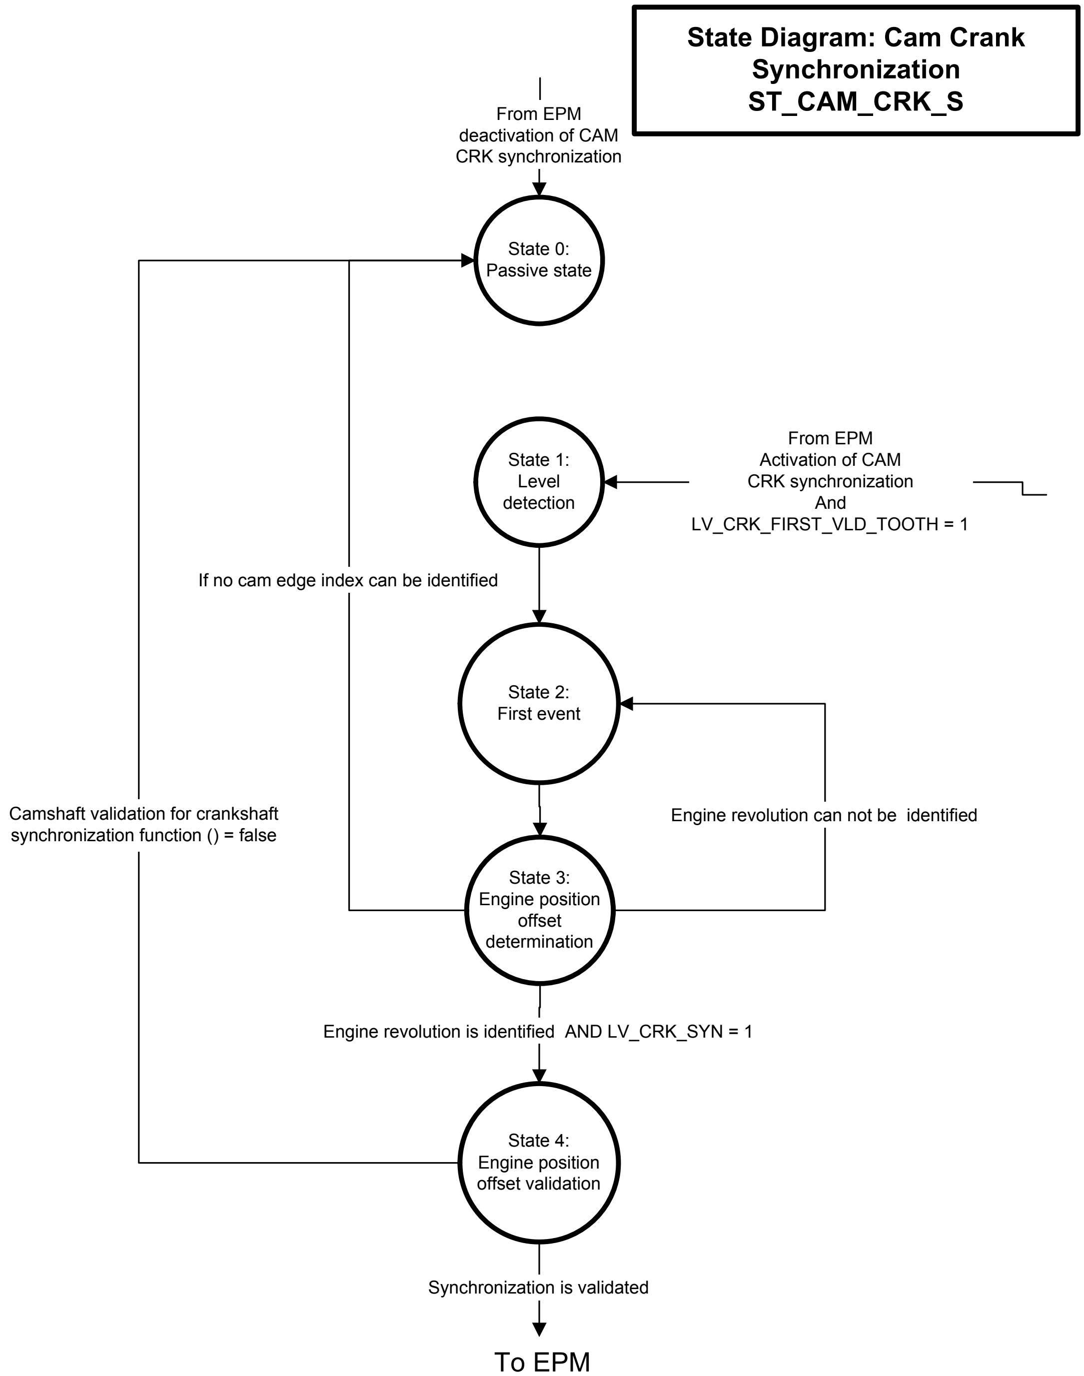
The engine position offset is

- 360° or 720° for NC_NR_GAP = 1

Note that there are two lists of possible camshaft signal indexes:

- For self-synchronization
- For cam/crk synchronization and engine position determination for pre-injection (described in this chapter)

Signal flow diagram:



Application conditions:

Recurrence: every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1

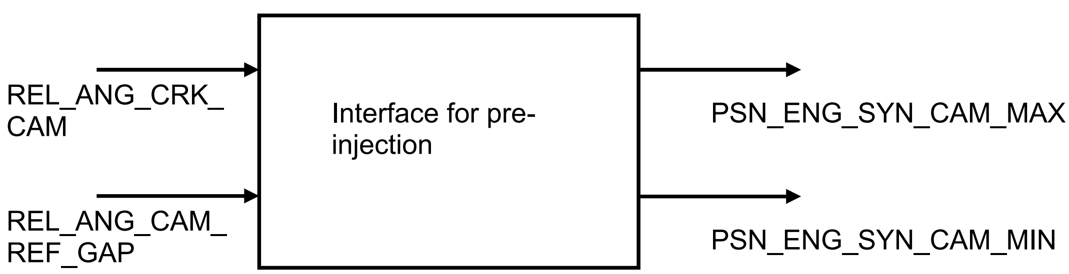
2.7.3 Engine Position Interface for Pre-Injection

<u>General information:</u>



For rapid start of port-injection engines it is useful to start injection before synchronization on crankshaft signal is achieved. An approximative information about engine position is necessary for phasing the injection in a way to avoid emissions increase.

For this purpose, a minimum and the maximum engine position is determined according to the actual possible camshaft signal edge indexes found by camshaft signal acquisition for crankshaft synchronization. The minimum and the maximum position will converge gradually during the synchronization process.

Application conditions:

Recurrence:	every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1
	every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2
	every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

2.7.4.1 Time out detection function ()

General information:

Time-out is detected when the segment period exceeds NC_T_SEG_MAX_CAM_IN(EX).
Time out detection is used for engine stalling detection during crankshaft limp-home.

Formula section:

If T_SEG_CAM_IN(EX)_i <= NC_T_SEG_MAX_CAM_IN(EX)

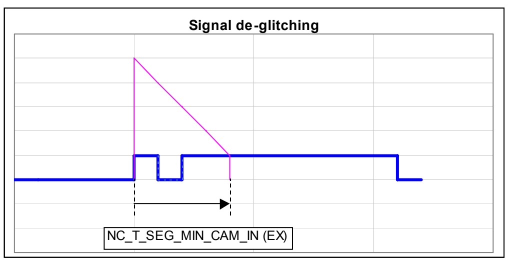
Then return (true)

Else return(false)

Endif

2.7.4.2 Signal de-glitching ()

Any signal edge detected before a delay time NC_T_SEG_MIN_CAM_IN respectively NC_T_SEG_MIN_CAM_EX following the previous signal edge will not produce any output.



Formula section:

If a glitch occurs during the delay NC_T_SEG_MIN_CAM_IN(EX)

Then Return (true)

Else Return (false)

Endif

2.7.4.3 Camshaft segment ratio calculation function ()

General information:

The computation of the ratio will be compared to the theoric ratio.

Application conditions:

Recurrence : every camshaft active edge.

Measured ratio :

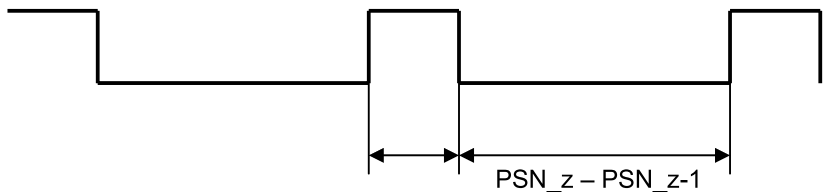
RATIO_PER_CAM_IN(EX)_i =

T_SEG_CAM_IN(EX)_i_n / T_SEG_CAM_IN(EX)_i_{n-1}

Theoric ratio : for all remaining indexes z

RATIO_PSN_EDGE_z_CAM_IN(EX)_i =

(NC_PSN_EDGE_z_CAM_IN(EX)_i - NC_PSN_EDGE_(z-1)_CAM_IN(EX)_i) /
(NC_PSN_EDGE_(z-1)_CAM_IN(EX)_i - NC_PSN_EDGE_(z-2)_CAM_IN(EX)_i)



2.7.4.4 Camshaft edge recognition ()

General information:

The algorithm has to determine the index of the actual signal edge corresponding to the position of the camshaft by checking the measured ratio and the theoric ratio.

Application conditions:

Recurrence: every camshaft active edge.

Formula section:

For all remaining indexes z:

If RATIO_PSN_EDGE_z_CAM_IN(EX)_i * ID_FAC_CAM_IN(EX) > RATIO_PER_CAM_IN(EX)_i > RATIO_PSN_EDGE_z_CAM_IN(EX)_i / ID_FAC_CAM_IN(EX)

Then keep index z in the table

Else eliminate index z from the table

Endif

2.7.4.5 Camshaft edge index determination function ()

General information:

This function determines the possible camshaft signal indexes and returns the engine position offset (0° or 360°) when index is identified.

The range of the local variables alpha and beta is:

Alpha: -720° CRK to +720° CRK

Beta: 0° CRK to +720° CRK

Limit: 0° CRK to +720° CRK

Application conditions:

Recurrence: every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1

every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2

every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Formula section:

Calculate theoretical angular distance between two successive active camshaft edges:

If NC_ACT_CAM_EDGE_SYN = 3

Then F*alling and rising camshaft edges*

PSN_CAM_CAM = NC_PSN_EDGE_z_CAM_IN(EX)_i –

NC_PSN_EDGE_z-1_CAM_IN(EX)_i

Else *Only Falling or only rising camshaft edges*

PSN_CAM_CAM = NC_PSN_EDGE_z_CAM_IN(EX)_i –

NC_PSN_EDGE_z-2_CAM_IN(EX)_i = 720° CRK

Endif

Tests (depending on actual event and history) are done for each index z of the possible indexes table. If the test is false then the corresponding index is eliminated.

The following table shows the actions to perform in function of the current (n) and last event (n-1).

The event is a detection of Camshaft edge (CAM) or a detection of reference gap (GAP).

Tests are done with the current value of REL_ANG_CRK_CAM.

The EPM initialize PSN_ENG_CRK with 360° - NC_OFS_TDC0_REF_CRK (engine revolution 1)

Event (n)	CAM	CAM	GAP	GAP	CAM	GAP
Event (n-1)	None	CAM	None	CAM	GAP	GAP
Action / Test	Action 1 Test 1	Action 1 Test 2	Tests 3	Test 4	Action 1 Test 5	Test 3

Action 1:

This action should be done before the test.

If NC_ACT_CAM_EDGE_SYN = 3

Then Increment indexes in the list of possible camshaft signal index by 1 modulo 2.

Else (no operation)

Endif

Test 1:

Beta = PSN_CAM_CAM
+ CAM_DYW_SYN_IN(EX)

If Beta < 0°

Then Beta = Beta + 720°

Endif

Keep all indexes for which the following condition is true :

REL_ANG_CRK_CAM < Beta

Test 2:

Alpha = PSN_CAM_CAM - CAM_DYW_SYN_IN(EX)

Beta = PSN_CAM_CAM + CAM_DYW_SYN_IN(EX)

If Beta < 0°

Then Alpha = Alpha + 720°
Beta = Beta + 720°

Endif

If Alpha < 0°

Then (no operation)

Endif

Keep all indexes for which the following condition is true:

Alpha < REL_ANG_CRK_CAM < Beta

Test 3:

Test 3A:

Beta = 360° - NC_OFS_TDC0_REF_CRK - NC_PSN_EDGE_z_CAM_IN(EX)_i
+ CAM_DYW_CRK_SYN_ADC_IN(EX)

If Beta < 0°

Then Beta = Beta + 720°

Endif

If REL_ANG_CRK_CAM < Beta < Limit

Then PSN_ENG_CRK_OFS_TMP=0

Endif

Test 3B:

Beta = 720° - NC_OFS_TDC0_REF_CRK - NC_PSN_EDGE_z_CAM_IN(EX)_i
+ CAM_DYW_CRK_SYN_ADC_IN(EX)

If Beta < 0°

Then Beta = Beta + 720°

Endif

If **REL_ANG_CRK_CAM** < Beta < Limit

Then PSN_ENG_CRK_OFS_TMP= 360

Endif

Limit = Maximum angle between two active camshaft edges:

NC_ACT_CAM_EDGE_SYN = 3 and half-moon target wheel:

Limit = 360° CRK

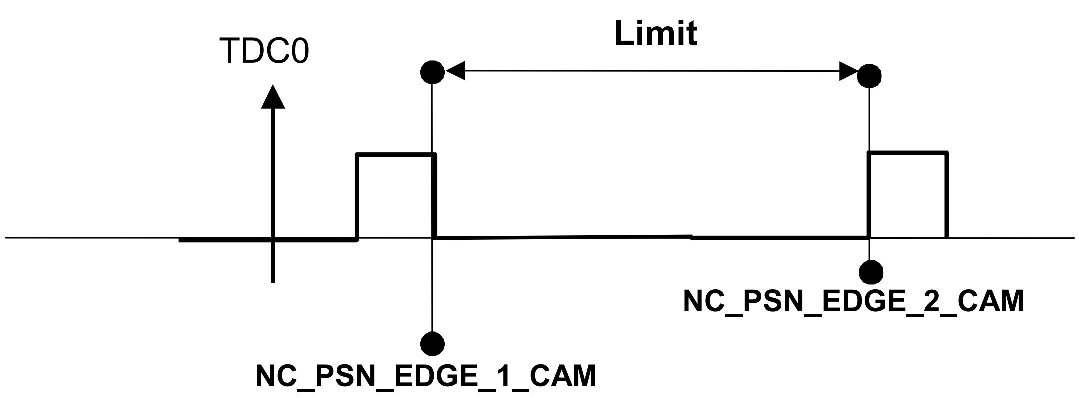
NC_ACT_CAM_EDGE_SYN = 3 and pin-type target wheel:

360° CRK < Limit < 720° CRK

NC_ACT_CAM_EDGE_SYN = 1 or 2 (non-TPO sensors):

Limit = 720° CRK

For example: pin-type target wheel, NC_ACT_CAM_EDGE_SYN=3:



If **Test 3A** And **Test 3B** are true

Or

NC_CAM_SENS_TYP = 0 (MCAM sensor)

Then The engine revolution can not be identified

*(comment: identical camshaft signal level on two successive reference gaps **and** measured ang. distance < theoretical ang. distance between camshaft edge #z and reference gap **or** MCAM sensor)*

Else **if** **Test 3A** And **Test 3B** are false

Then Index z should be eliminated

*(comment: different camshaft signal level on two successive reference gaps **and** measured ang. distance > theoretical ang. distance between camshaft edge #z and reference gap)*

Else PSN_ENG_CRK_OFS = PSN_ENG_CRK_OFS_TMP

The engine revolution is identified

*(comment: different camshaft signal level on two successive reference gaps **and** measured ang. distance < theoretical ang. distance between camshaft edge #z and reference gap **or** identical camshaft signal level on two successive reference gaps **and** measured ang. distance > theoretical ang. distance between camshaft edge #z and reference gap)*

Endif

Endif

Test 4:

Engine revolution identified
Else Index z should be eliminated
Endif

Endif

2.7.4.6 Camshaft validation for crankshaft synchronization function ()

General information:

The purpose of this function is to check the angular distance between cam/crk events. The function returns false is the active camshaft signal edge z is outside the defined tolerance window.

Application conditions:

Recurrence: every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1

every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2

every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Formula section:

Calculate theoretical angular distance between two successive active camshaft edges:

If NC_ACT_CAM_EDGE_SYN = 3
Then F*alling and rising camshaft edges*
PSN_CAM_CAM = NC_PSN_EDGE_z_CAM_IN(EX)_i –
NC_PSN_EDGE_z-1_CAM_IN(EX)_i
Else *Only Falling or only rising camshaft edges*

PSN_CAM_CAM = NC_PSN_EDGE_z_CAM_IN(EX)_i –

NC_PSN_EDGE_z-2_CAM_IN(EX)_i = 720° CRK

Endif

The following table shows the actions to perform in function of the current (n) and last event (n-1).

The event is a detection of Camshaft edge (CAM) or a detection of reference gap (GAP).

Tests are done with the current value of REL_ANG_CRK_CAM.

Endif

2.7.5 Requirements to Infrastructure

2.7.5.1 Acquisition and pre-filtering

General information:

The Cam acquisition will be available for every active edge of the signal. A pre-filtering is used in order to remove the glitch.

Application conditions:

Recurrence: every active edge

Formula section:

System request accuracy <= 4 us

Activation of Signal de-glitching function () at each active edge.

Calculation of camshaft tooth period: The camshaft tooth period T_SEG_CAM_IN(EX)_i is the time between two consecutive camshaft signal edges.

2.7.5.2 Relative cam crank angle position

General information:

The purpose of this function is to provide a measurement for

- the angular distance between the first valid crankshaft teeth and the first active camshaft edge
- the angular distance between two consecutive valid active camshaft signal edges

Only active camshaft signal edges shall be processed. The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Application conditions:

Recurrence: every crankshaft or camshaft active edge

Formula section:

```
If      LV_CRK_FIRST_VLD TOOTH = 0
Then    REL_ANG_CRK_CAM = 0
Else    If      active cam edge
        Then    REL_ANG_CRK_CAM = 0
        Else    If      active crank edge or after missing tooth simulation
                Then    REL_ANG_CRK_CAM = REL_ANG_CRK_CAM +
                                360°crk /NC_NR_TOOTH
                Else    REL_ANG_CRK_CAM n is frozen
                Endif
        Endif
Endif
```

2.7.5.3 Relative cam angle position from reference gap

General information:

The purpose of this function is to provide a measurement for

- the angular distance between a crankshaft reference gap and a active camshaft signal edge

This counter will be reset at every reference gap.

Application conditions:

Recurrence: every crankshaft active edge

Formula section:

```
If      LV_CRK_SYN = 0
Then    REL_ANG_CAM_REF_GAP = 0
Else    if      Reference Gap is detected
        Then    REL_ANG_CAM_REF_GAP = 0
        Else    if      crank active edge
                Then    REL_ANG_CAM_REF_GAP = REL_ANG_CAM_REF_GAP +
                                360°crk /NC_NR_TOOTH
                Else    REL_ANG_CAM_REF_GAP is frozen
                Endif
        Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_NR_EDGE_MIN_VLD_CAM_IN	1	0...FFH	0...255	1	-
Number of intake camshaft signal edges for valid position output

2.8 IVVT Output - Requirements to Infrastructure

Export actions:

ACTION_INFR_SetHoldIvvt(IN <Ivvt>, IN <Ivvthpwm>, IN <Frq_Ivvthpwm>)
This action sets a holding pulse width modulation energisation for the camshaft Ivvt.
ACTION_INFR_StartPulseIvvt(IN <Ivvt>, IN <Ivvtpwm>, IN <Frq_Ivvtpwm>, IN <T_Ivvtpwm>)
This action starts a time limited pulse width modulation energisation for the camshaft Ivvt.
ACTION_INFR_StopPulseIvvt(IN <Ivvt>)
This action stops the time limited pulse width modulation energisation for the camshaft Ivvt.

Description for actions:

ACTION_INFR_SetHoldIvvt(<Ivvt>, <Ivvthpwm>, <Frq_Ivvthpwm>)
This action sets a holding pulse width modulation energisation for the camshaft Ivvt.
Default SYNCHRONIZATION option when calling this Action is ASYNCHRONOUS.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Ivvt	IN	0H 1H 2H 3H	IVVT_IN_1 IVVT_EX_1 IVVT_IN_2 IVVT_EX_2	1	-
Camshaft specification for setting energisation					
Ivvthpwm	IN	0...FFFFH	0...99.99847	0.001526	%
Holding pulse width modulation					
Frq_Ivvthpwm	IN	32H...1F4H	50...500	1	Hz
Frequency of holding pulse width modulation					

ACTION_INFR_StartPulseIvvt(<Ivvt>, <Ivvtpwm>, <Frq_Ivvtpwm>, <T_Ivvtpwm>)
This action starts a time limited pulse width modulation energisation for the camshaft Ivvt.
Default SYNCHRONIZATION option when calling this Action is ASYNCHRONOUS.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Ivvt	IN	0H 1H 2H 3H	IVVT_IN_1 IVVT_EX_1 IVVT_IN_2 IVVT_EX_2	1	-
Camshaft specification for setting energisation					
Ivvtpwm	IN	0...FFFFH	0...99.99847	0.001526	%
Pulse width modulation for adjustment energisation					
Frq_Ivvtpwm	IN	32H...1F4H	50...500	1	Hz
Frequency of pulse width modulation for adjustment energisation					
T_Ivvtpwm	IN	0...FFFFFFFFH	0...17179.87	4e-6	s
Duration of adjustment energisation					

ACTION_INFR_StopPulseIvvt(<Ivvt>)
This action stops the time limited pulse width modulation energisation for the camshaft Ivvt.
Default SYNCHRONIZATION option when calling this Action is ASYNCHRONOUS.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Ivvt	IN	0H 1H 2H 3H	IVVT_IN_1 IVVT_EX_1 IVVT_IN_2 IVVT_EX_2	1	-
Camshaft specification for setting energisation					

FUNCTION DESCRIPTION:

General information:

The IVVT control consists of the merging of the holding pulse width modulation energisation and time limited low or high level adjustment pulses. The holding energisation is a system parameter, which is adapted slightly due to e.g. tolerances. It can be the low level energisation in some special cases. The adjustment energisations are calculated by the controller and lead to camshaft movement. Some solenoid valve energisation cases are shown in figure "Solenoid valve energisation".

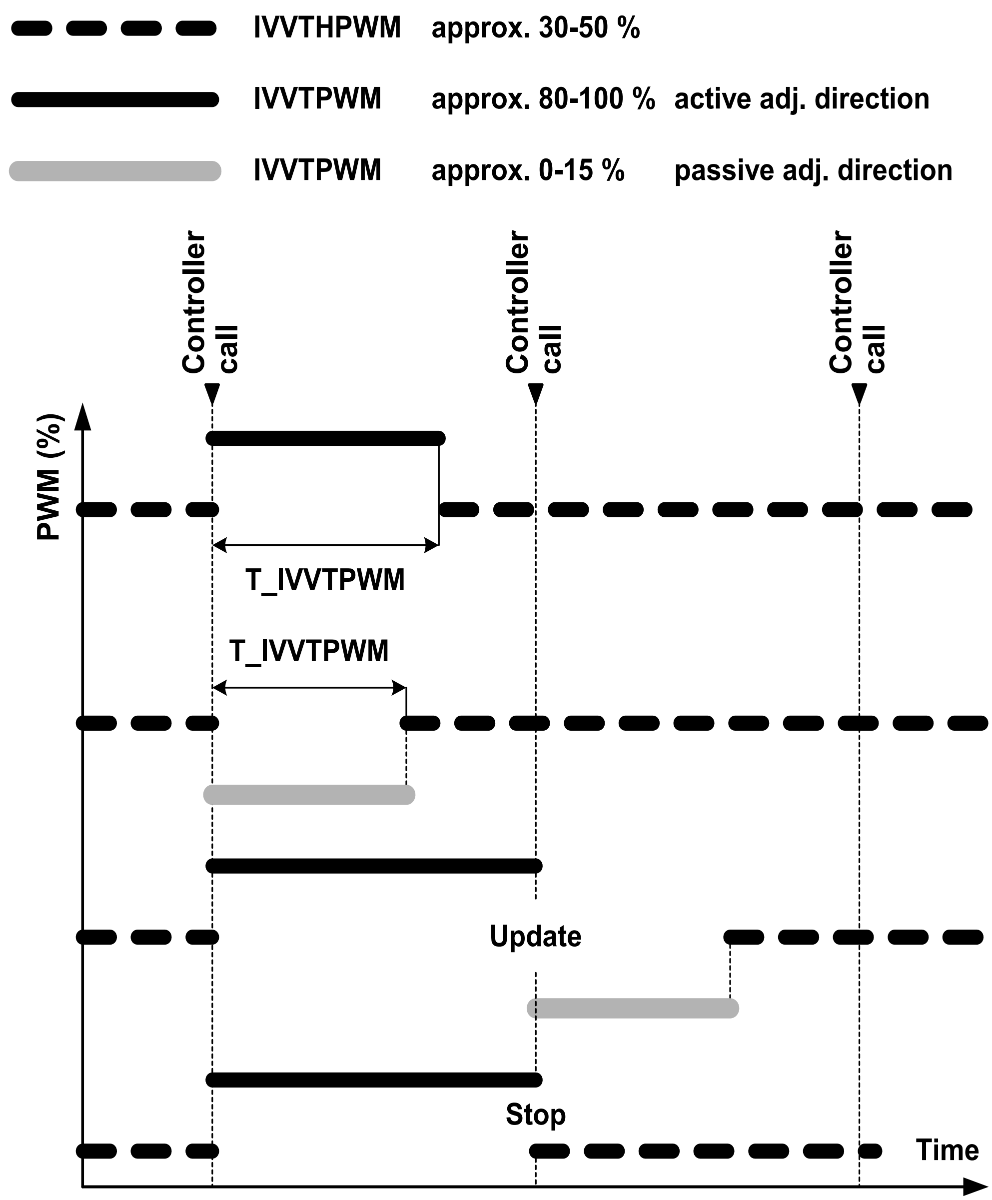

Figure: "Solenoid valve energisation".

Requirements for ACTION_INFR_SetHoldIvvt:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Ivvt	1	-	-	-	Set energisation for related camshaft: IVVT_IN_1, IVVT_IN_2, IVVT_EX_1, IVVT_EX_2
Ivvthpwm	0.025	-	-	-	If FFFFH is set then real output has to be 100 %
Frq_Ivvthpwm	1	-	-	-	

Requirements for ACTION_INFR_StartPulseIvvt:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Ivvt	1	-	-	-	Set energisation for related camshaft: IVVT_IN_1, IVVT_IN_2, IVVT_EX_1, IVVT_EX_2
Ivvtpwm	0.025	-	-	-	If FFFFH is set then real output has to be 100 %
Frq_Ivvtpwm	1	-	-	-	
T_Ivvtpwm	1e-4	-	-	-	

Requirements for ACTION_INFR_StopPulseIvvt:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Ivvt	1	-	-	-	Set energisation for related camshaft: IVVT_IN_1, IVVT_IN_2, IVVT_EX_1, IVVT_EX_2

Diagnosis: -

Coincidence requirements:

ACTION_INFR_SetHoldIvvt starts the holding energisation.

ACTION_INFR_StartPulseIvvt starts a time limited adjustment energisation. This energisation replaces the holding energisation.

If the adjustment energisation is over or is stopped by ACTION_INFR_StopPulseIvvt the holding energisation starts again.

An active adjustment energisation can be updated by a new one without a switch to the holding energisation. The update means a start of a new adjustment energisation.

There is no effect if ACTION_INFR_StopPulseIvvt is called and there is currently no active adjustment energisation.

2.9 Acquisition of vehicle speed

Output data:

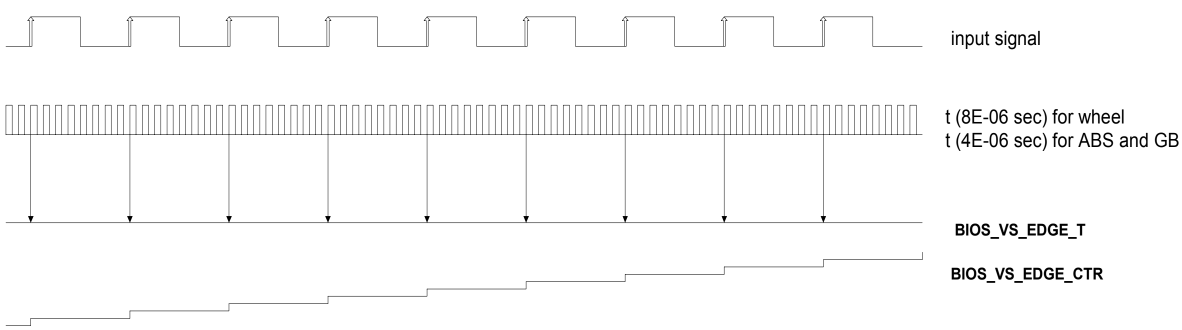
Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
BIOS_VS_EDGE_CTR	O	0 ... FFFFH	0 ... 65565	1	-
Vehicle speed sensor tooth counter (free running counter)					
BIOS_VS_EDGE_T	O	0 ... FFFFH	0 … 1,718 E10	4	µs
timestamp of last tooth (free running timer)					

FUNCTION DESCRIPTION:

General information:

The signal from wheel sensor or ABS control unit or gearbox sensor (high and low) is recorded by incrementation of the free running edge counter BIOS_VS_EDGE_CTR with one digit at every change from low to high. The value is stored as BIOS_VS_EDGE_CTR in a free running counter too.

Signal flow diagram:



2.9.1 Segment period acquisition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_T_MES_0_RR_BAS	V/O	0...FFFFH	RES_ECU_ SEG_T_MES_RR	LIM_PHY_ECU_ SEG_T_MES_RR	s
Actual segment time measurement from the wheel speed signal – BSW acquisition					
SEG_T_MES_1_RR_BAS	V/O	0...FFFFH	RES_ECU_ SEG_T_MES_RR	LIM_PHY_ECU_ SEG_T_MES_RR	s
Previous segment time measurement from the wheel speed signal – BSW acquisition					

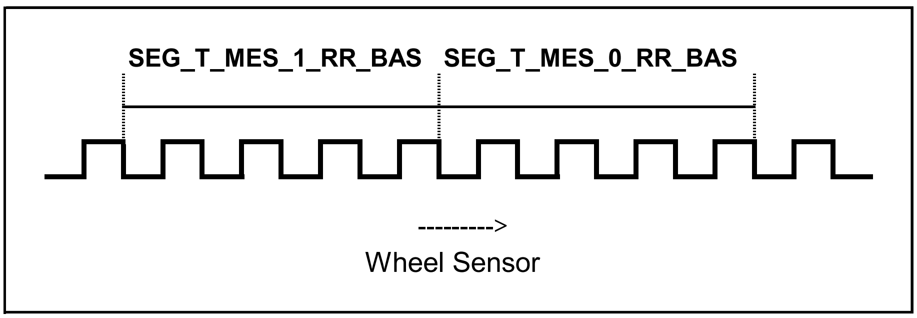
Input data:

NC_T_BAS_FRQ_DIV	NC_FRQ_ECU		

General information:

SEG_T_MES_0_RR_BAS and SEG_T_MES_0_RR_BAS are the Basic s/w acquisitions of wheel speed signal. More informations are available in chapter B, "Rough Road detection".

Description:



Remark : SEG_T_MES_1_RR is the segment period preceding SEG_T_MES_0_RR.

2.9.1.1 Definition of output variable depending on ECU and ASW frequency

As the function is used with different ECU and ASW quartz frequencies, the output resolution and the physical limits are defined as variables.

The resolution of the output data depending on the quartz frequency is defined as:

RES_ECU_SEG_T_MES_RR = NC_T_BAS_FRQ_DIV / NC_FRQ_ECU

The HEX-limits don’t change.

The physical limits are :

LIM_PHY_ECU_SEG_T_MES_RR = LIM_HEX (dec) * RES_ECU_SEG_T_MES_RR

2.10 Acquisition of electronically controlled cooling fan signal

General information:

The configuration constant NC_ECF_CONF allows to determine the wanted fan control strategy. In principal it is possible to choose between a RLY- or a PWM-control architecture. A RLY/PWM fan control strategy in parallel is also existing. In this case the aggregate architecture allows to switch either the control of RLY-fan(s) or the control of PWM–fan(s) during ECU runtime depending on the setting of the configuration bit CONF_CFA. The control of both variants (RLY- and PWM-fan(s)) in parallel at the same time is not allowed.

The following fan control architecture is adjusted:

NC_ECF_CONF = 2 ➔ control of cooling fan(s) by Relay(s) **or** PWM(s)
(CONF_CFA = 0 for RLY- control)
(CONF_CFA = 1 for PWM- control)

The configuration bit CONF_CFA is representing the activated control algorithm. Either the functions for RLY-fan(s) or the functions for PWM-fan(s) are activated. Both control functions are never activated in at the same time.

For each fan stage as well as each PWM value, a signal at the ECU output stage has to be generated by the infrastructure to guarantee the link between the calculated signal to the available cooling fan(s) (hardware component) at the vehicle.

2.10.1 Acquisition of cooling fan signal (RLY version)

Input data:

LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_NR]	NC_ECF_RLY_NR	NC_ECF_NR	

FUNCTION DESCRIPTION:

General information:

In case of a enabled RLY-fan control strategy (refer chapter: “ENTE Configuration data”), a Boolean is calculated (LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_NR) to switch on / off the requested cooling fan stage(s). For each fan stage a signal at the ECU output has to be generated by the infrastructure to guarantee the link between the calculated signal to the available cooling fan(s) (hardware component) at the vehicle.

Name	Frequency	Notes
LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_NR] (LV_RYL_FAN_L) (LV_RYL_FAN_H)	40 ms	Logical signal to switch on / off the requested cooling fan stage(s)

Application conditions:

Activation: at every engine operating state

Deactivation: -

(see: “ENTE scheduler”)

Formula section:

In case of a RLY/PWM-fan configuration (NC_ECF_CONF=2), when the RLY output stage(s) for the control of the cooling fan(s) at the vehicle are activated, the PWM output stage(s) are permanent disabled (no PWM output) to prevent an unwanted fan control behaviour.

2.10.2 Acquisition of cooling fan signal (PWM version)

Input data:

ECFPWM[NC_ECF_NR]	NC_ECF_NR		

FUNCTION DESCRIPTION:

General information:

In case of an enabled PWM-fan control strategy (refer chapter: “ENTE Configuration data), a pulse width modulated value is calculated (ECFPWM[NC_ECF_NR]) to control the requested cooling fan(s). For each PWM value, a signal at the ECU output stage has to be generated by the infrastructure to guarantee the link between the calculated signal to the available cooling fan(s) (hardware component) at the vehicle.

PWM output name	Frequency	Updating of duty cycle	Range of duty cycle
ECFPWM[NC_ECF_NR] (CFAPWM_CFA)	300 Hz	200 ms	0 -100%

Application conditions:

Activation: at every engine operating state

Deactivation: -

(see: “ENTE scheduler”)

Formula section:

In case of a RLY/PWM-fan configuration (NC_ECF_CONF=2), when the PWM output stage(s) for the control of the cooling fan(s) at the vehicle are activated, the RLY output stage(s) are permanent disabled (no RLY output) to prevent an unwanted fan control behaviour.

2.11 Acquisition of throttle position

2.11.1 Definition of TPSPWM

Output data:

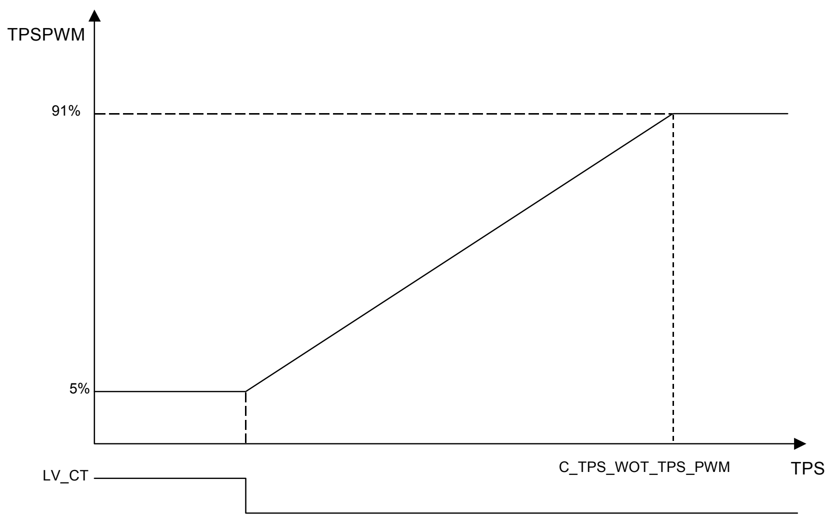
Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TPSPWM	V/O	0...FFFFH	0...100	1,53E-3	%
Relative throttle angle distributed to TCU					

Input data:

TPS	C_TPS_IS_OUT	LV_ERR_TPS	LV_ERR_TPS_PLAUS
LV_CT			

If LV_ERR_TPS = 1
or LV_ERR_TPS_PLAUS = 1
then TPSPWM = 3% *(Error Identifier)*
else **if** LV_CT = 1
then TPSPWM = 5%
else **if** TPS > C_TPS_WOT_TPS_PWM
then TPSPWM = 91%
else TPSPWM =

$$\frac{91\% - 5\%}{C\_TPS\_WOT\_TPSPWM - C\_TPS\_IS\_OUT} * (TPS - C\_TPS\_IS\_OUT) + 5\%$$



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TPS_WOT_TPSPWM	1	0...FFH	0...119,5	0,47	°TPS
Throttle angle which corresponds with 91% TPSPWM					

2.12 Acquisition of fuel tank level voltage

2.12.1 Basic software

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_FTL	V/O	0...FFH	0...4,985	0.0195	Volt
Main Fuel tank level voltage measured					
V_FTL_SUB	V/O	0...FFH	0...4,985	0.0195	Volt
Sub Fuel tank level voltage measured					

Input data:

FTL_BAS	FTL_BAS_SUB	CONF_DIAGCP_VOL	

FUNCTION DESCRIPTION:

General information:

The raw value of fuel tank level voltage (FTL_BAS) is measured by continuous conversion (10 bits) every **0.1 sec**.

The sub value of fuel tank level voltage (FTL_BAS_SUB) is measured by continuous conversion (10 bits) every **0.1 sec**, only if dual FTL sensor is available.

The corresponding value of the first measurement after hardware reset is used for initialisation.

Formula section:

```
If        CONF_DIAGCP_VOL = 0                     (no FTL sensor)
then            V_FTL       = 0
          and   V_FTL_SUB   = 0

else if   CONF_DIAGCP_VOL = 1                     (single FTL sensor)
then            V_FTL       = FTL_BAS / 4         (8 bits)
          and   V_FTL_SUB   = 0

else if   CONF_DIAGCP_VOL = 2                     (dual FTL sensor)
                V_FTL       = FTL_BAS / 4         (8 bits) : main FTL
          and   V_FTL_SUB   = FTL_BAS_SUB / 4     (8 bits) : sub FTL
endif
```

2.13 Input system event : Key off recognition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_KEY_OFF	V/O	0...1H	0...1	1	No
Key off flag					

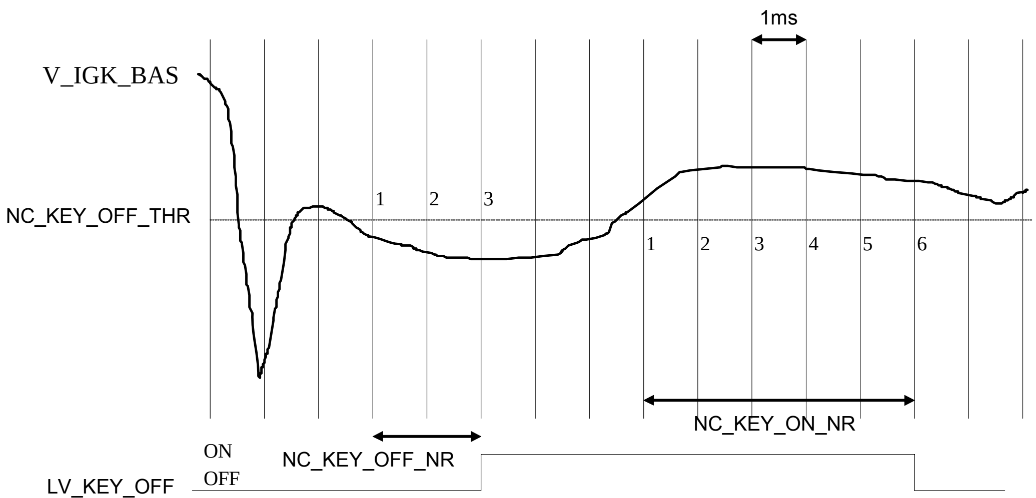
Input data:

V_IGK_BAS			

FUNCTION DESCRIPTION:

General information:

According to the battery voltage raw value (V_IGK_BAS) after ignition key, the ignition key OFF recognition is performed.



See on Analogic Acquisition Sampling chapter the recurrence of V_IGK_BAS acquisition.

Application conditions:

Activation: at reset

Initialization: LV_KEY_OFF = first valid value **after** RESET

Recurrency: 1ms

Formula section:

Ignition key ON recognised :

If V_IGK_BAS **>** NC_KEY_OFF_THR

for more than NC_KEY_ON_NR number of successive samples (* 1 msec.)

then LV_KEY_OFF **= 0** (ON)

End IF

Ignition key OFF recognised :

If V_IGK_BAS **<** NC_KEY_OFF_THR

for more than NC_KEY_OFF_NR number of successive samples (* 1 msec.)

then LV_KEY_OFF **= 1** (OFF)

End IF

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_KEY_OFF_THR	1	0...3FFH	0...NC_V_IGK_MAX	NC_V_IGK_MAX / 1024	V
Threshold for key off detection (typical value : 142 = 4 Volts)					
NC_KEY_OFF_NR	1	0...FFH	0...255	1	No
Samples filter for key off detection (typical value : 3)					
NC_KEY_ON_NR	1	0...FFH	0...255	1	No
Samples filter for key on detection (typical value : 6)					

2.14 Logic Outputs

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ACC_MAIN_LAMP	-	0...1H	0...1	1	-
Cruise control main lamp signal from ECU					
ACC_SET_LAMP	-	0...1H	0...1	1	-
Cruise control activ lamp signal from ECU					
LV_RLY_MAIN	V	0...01H	0...1	1	-
Main relay activation					

Input data:

LV_EXT_ADJ_ACC_MAIN_LAMP	LV_CRU_MAIN_SWI	LV_CRU_ACT	LV_CMD_RCL_OPEN
LV_ACT_EXT_ADJ_ACC_MAIN_LAMP	LV_EXT_ADJ_MIL	LV_MIL	LC_TCHA_CONF
LV_EXT_ADJ_ACC_SET_LAMP	LV_VIM_SP	ENG_STATE	LV_ACT_EXT_ADJ_MIL
LV_ACT_EXT_ADJ_ACC_SET_LAMP	NC_ETC_CONF		

FUNCTION DESCRIPTION:

List of logic Outputs:

Name	Port – Channel	Logic state
ACC_MAIN_LAMP	MPWM1	positive
ACC_SET_LAMP	MPWM3	positive
LV_RLY_MAIN	MPIO32B5	negative
LV_VIM_SP	A_TPUCH6	negative
LV_CMD_RCL_OPEN	A_TPUCH12	positive
LV_RLY_ST	SGPIOC6	negative

2.14.1 Cruise main lamp activation (NC_ETC_CONF = 1)

Initialisation: At EEProm Error or LV_IGK=0 to 1 then ACC_MAIN_LAMP = 0

if LV_EXT_ADJ_ACC_MAIN_LAMP = 1

then ACC_MAIN_LAMP = LV_ACT_EXT_ADJ_ACC_MAIN_LAMP

else if LV_CRU_MAIN_SWI = 1

then ACC_MAIN_LAMP = 1

else ACC_MAIN_LAMP = 0

2.14.2 Cruise set lamp activation (NC_ETC_CONF = 1)

if LV_EXT_ADJ_ACC_SET_LAMP = 1

then ACC_SET_LAMP = LV_ACT_EXT_ADJ_ACC_SET_LAMP

else if LV_CRU_ACT = 1

then ACC_SET_LAMP = 1

else ACC_SET_LAMP = 0

2.14.3 MIL activation

if ENG_STATE = ES

and LV_EXT_ADJ_MIL = 1

then MIL output is switched according to LV_ACT_EXT_ADJ_MIL

else MIL output is switched according to LV_MIL

2.14.4 Main relay activation

The main relay is controlled by ECU and the LV_RLY_MAIN shows the status of main relay from ECU output channel.

2.14.5 VIM activation

if LV_VIM_SP = 1

then activate VIM output with 99.4 % duty @ 20 Hz (=diagnosis pulse time 0.30ms)

else deactivate VIM output with 1% duty @ 20 Hz (=diagnosis pulse time 0.50ms)

2.14.6 RCL (Bypass valve) activation (LC_TCHA_CONF = 1)

If LV_CMD_RCL_OPEN = 1

then activate RCL output (open RCL valve)

else deactivate RCL output (close RCL valve)

2.14.7 Starter Relay activation

Initialisation: according to Spec: 5W901501.00X " In Reset ECU output is pulled to ground" (i.e. LV_RLY_ST = 1)

If LV_RLY_ST = 1

then output switched to GND (as negative logic)

else output switched to VB (as negative logic)

2.15 PWM Outputs and Inputs

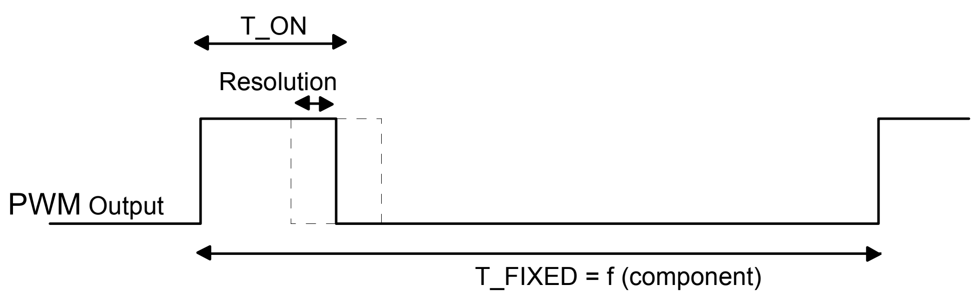
Input data:

CPPWM_CPS	LSHPWM_UP[NC_CBK_EX_NR]	LSHPWM_DOWN[NC_CBK_EX_NR]	IVVTPWM_IN_i
IVVTPWM_EX_i	TPSPWM	CFAPWM_CFA	ISAPWM_ISA
PWM_WG	LV_SOV	PORTPWM	FRQ_PORTPWM
GEN_LOAD	MTCPWM	ALTPWM	CONF_BAT

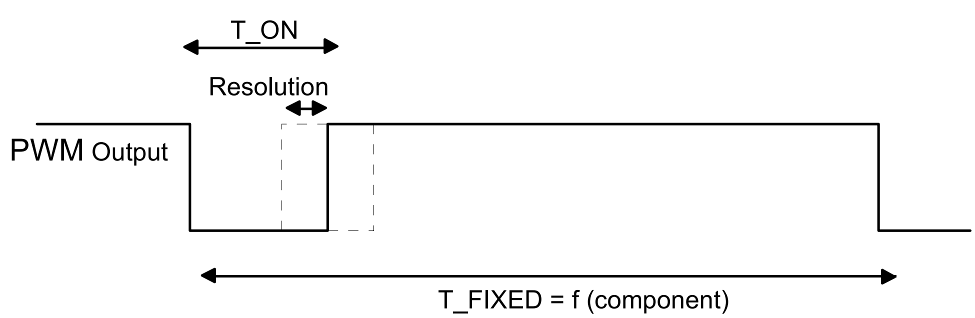
FUNCTION DESCRIPTION:

2.15.1 PWM management principle :

“ Positive “ PWM : Duty cycle = T_ON / T_FIXED



“ Negative “ PWM : Duty cycle = T_ON / T_FIXED



In case of PWM input signal, the PWM value is automatically calculated by basic software.

2.15.2 List of PWM Outputs:

PWM Output Name	Frequency (Hz)	Attached Component	Updating of Duty Cycle (ms)	Range of Duty Cycle (%)	PWM State	Remarks
CPPWM_CPS	16		20	0...99,9	negative	
LSHPWM_UP	10	Zirconium NTK	1000	2,3...97,3	negative	binary
	30			4...96		linear
LSHPWM_DOWN	7,6	Zirconium NTK	1000	2,3...97,3	negative

Latest possible EOI relatet to EOI_LIM					
TRL_LV_ADD_PULSE_x	-	0 ... 1H	0 ... 1	1	-
Switch to enable additional injection pulse at homogeneous mode, single injection mode (injection update at transient operation)					

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TRL_LV_INH_INJ_x	-	0 ... 1H	0 ... 1	1	-
Flag that indicates if cylinder shut off is active or not					
TRL_SOI_MAX	-	0 ... 780H	0 ... 720	0.375	°CRK
Earliest possible SOI					
TRL_TI_ADD_DLY	-	8000 ... 7FFFH	-131.07 ... 131.03	0.004	ms
Injector dead time correction, homogeneous mode 1. pulse					
TRL_TI_ADD_PULSE_MIN	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Minimum injection time for additive injection pulse					
TRL_FAC_ADD_PULSE	-	0 ... FFH	0 ... 0.996094	0.0039	-
Weighting factor for injection time update at transient conditions (additive pulse)					
TRL_TRIG_INJ_UPD	-	-	-	-	-
Trigger for update of calculated injection data					
TRL_TRIG_INJ_UPD_x	-	-	-	-	-
Trigger for update of calculated injection data, cylinder individual					
TRL_NC_EOI_LIM	-	0 ... 780H	0 ... 720	0.375	°CRK
End of phasing range relatet to NC_REF_EOI_LIM					
NC_CYL_NR	-	3...8H	3...8	1	-
Number of cylinders					

Note: The prefix TRL to a data xxx (e.g. TI_1_x) indicates a I/O SW function interface for that data. In the following specification only the data labels (e.g. TI_1_x) is used to describe the required functionality.

General information:

The I/O software is responsible for opening and closing the injectors in all injection modes according to the inputs supplied. It is is applicable for HPDI and MPI engines with 3 to 8 cylinders (logical cylinder numbers 0, 1, 2, ...). It must work in an engine speed range from 30 to 8200 rpm.

Two injection pulses per cylinder and working cycle (720 °crk) should be handled.

2.16.1.1 Reference point and injection phase

The fuel can be injected over a range of 720 °CRK. The cylinder individual zero position of this range is defined via the constants NC_REF_EOI_LIM (defined in I/O SW) and NC_EOI_LIM (import data) with reference to the ignition TDC of cylinder 0, see figure below.

Related to tdc cylinder 0:

EOI_LIM_x = NC_REF_EOI_LIM + NC_EOI_LIM - x * (720 / NC_CYL_NR)

SOI_LIM_x = EOI_LIM_x + 720 °CRK

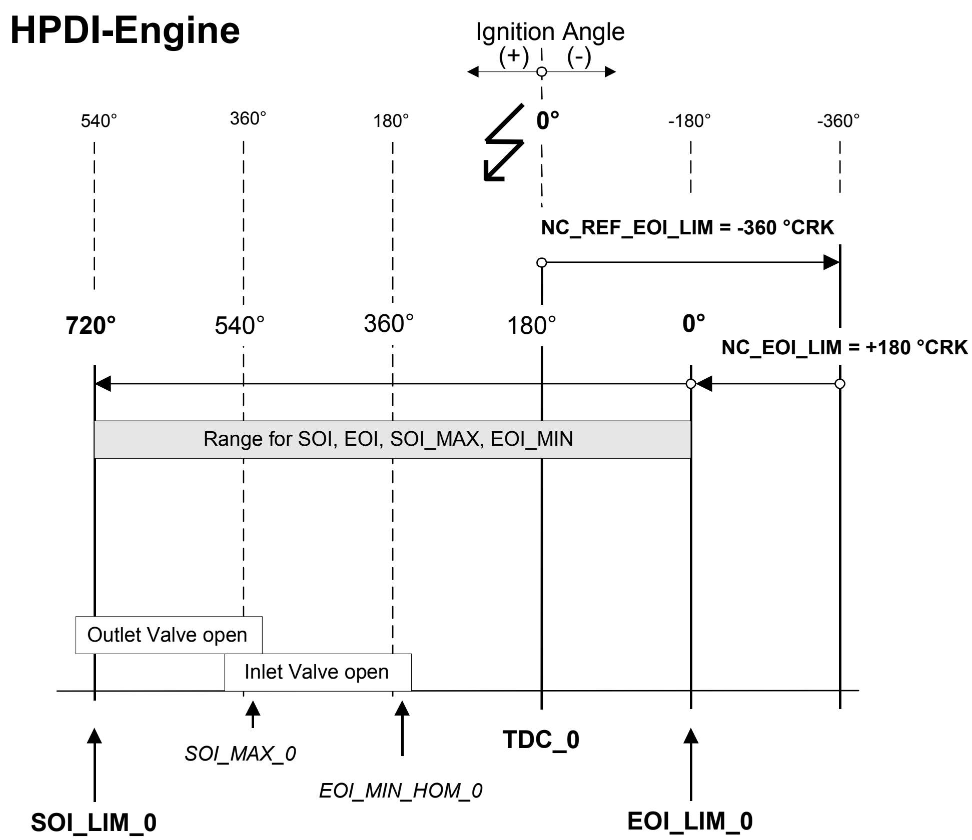

Figure 1: Example for reference point and injection phase, HPDI engine

Definition of the non calibrateable constants HPDI:

NC_REF_EOI_LIM = -360°CRK

NC_EOI_LIM = 180 °CRK

Definition of the non calibrateable constants MPI:

NC_REF_EOI_LIM = -360°CRK

NC_EOI_LIM = 540 °CRK

2.16.1.2 Calculation of Start of Injection SOI

The start of injection angles SOI_1_x, SOI_2_x, SOI_POST_INJ_x are calculated using the end of injection angles EOI_1_x, EOI_2_x, EOI_POST_INJ_x and the cylinder specific injection times TI_1_x, TI_2_x, TI_POST_INJ_x.

EOI_1_x, EOI_2_x and EOI_POST_INJ_x are counted in degrees with reference to EOI_LIM_x.

The latest engine speed information is used for the transformation between time and angle.

2.16.1.3 Injection and Calculation Updates

Injection is started at the angle SOI_1_x, SOI_2_x and SOI_POST_INJ_x, respectively.

As soon as the trigger TRIG_INJ_UPD / TRIG_INJ_UPD_x is set, the input data are updated (once per segment).

The trigger TRIG_INJ_UPD / TRIG_INJ_UPD_x is set every time EOI_LIM_x is reached.

Every injection starts earliest at SOI_MAX_x and ends latest at EOI_HOM_x.

Between different injection modes it will be switched with interface INJ_MOD_GLOBAL. It switches all cylinders at same time to a new injection mode. The INJ_MOD_x interface is able to switch between single and double injection mode for a single selected logical cylinder x. These rules will be excepted by pre injection mode, which changes automatically the cylinder individual pre injection mode to sequential mode with single injection cylinder individual. – for detail look at chapter 2.16.2.1 Pre injection.

The following injection modes are valid for interface INJ_MOD_GLOBAL:

1. Injection disable mode
2. Sequential injection mode with single injection
3. Sequential injection mode with double injection
4. Pre injection mode

The following injection modes are valid for interface INJ_MOD_x:

2. Sequential injection mode with single injection
3. Sequential injection mode with double injection

2.16.1.3.1 Single Injection

⇒ If the calculation is updated before the injector is opened and the new SOI_1_x has already passed, the injection is started at once and will be continued for TI_1_x.

(see Figure 2, Injection Update 1)

⇒ If the calculation is updated while the injector is open and LV_ADD_PULSE_x = 1, the injection time should be increased if

$TI\_1\_x_{n+1} > TI\_1\_x_{n}$

and should be decreased if

$TI\_1\_x_{n+1} < TI\_1\_x_{n}$

If the new TI of the pulse has already elapsed the injection should be stopped immediately.

(see Figure 2, Injection Update 2)

⇒ If the calculation is updated after the previous calculated fuel amount is already injected (the injector is already closed) an additional injection pulse should be performed immediately after the injection update. But only

IF
LV_ADD_PULSE_x = 1
AND
$(TI\_1\_x_{n+2} - TI\_1\_x_{n+1}) * FAC\_ADD\_PULSE + TI\_ADD\_DLY > TI\_ADD\_PULSE\_MIN$
AND
NC_T_MIN_INJ_INH has elapsed after the actual EOI_1_x
THEN
$TI\_x_{add.\ Puls} = (TI\_1\_x_{n+2} - TI\_1\_x_{n+1}) * FAC\_ADD\_PULSE + TI\_ADD\_DLY$
ELSE
Additional injection pulse is not performed
ENDIF

Remark: $TI\_1\_x_{n+1}$ is the actual performed injection time.

(see Figure 2, Injection Update 3)

⇒ If the calculation is updated while the additional pulse is performed the injection time should be increased if

$TI\_x_{add.\ Puls} < (TI\_1\_x_{n+3} - TI\_1\_x_{n+2}) * FAC\_ADD\_PULSE + TI\_ADD\_DLY$

The additional pulse should be stopped immediately at EOI_MIN.

The injection time should be decreased if

$TI\_x_{add.\ Puls} > (TI\_1\_x_{n+3} - TI\_1\_x_{n+2}) * FAC\_ADD\_PULSE + TI\_ADD\_DLY$

If the new TI of the pulse has already elapsed the injection should be stopped immediately.

(see Figure 2, Injection Update 4)

Note: In stratified mode LV_ADD_PULSE_x is always zero.Therefore neither in/decrease of the injection time nor the additional pulse is performed. In homogeneous mode LV_ADD_PULSE_x can be set by the application system.

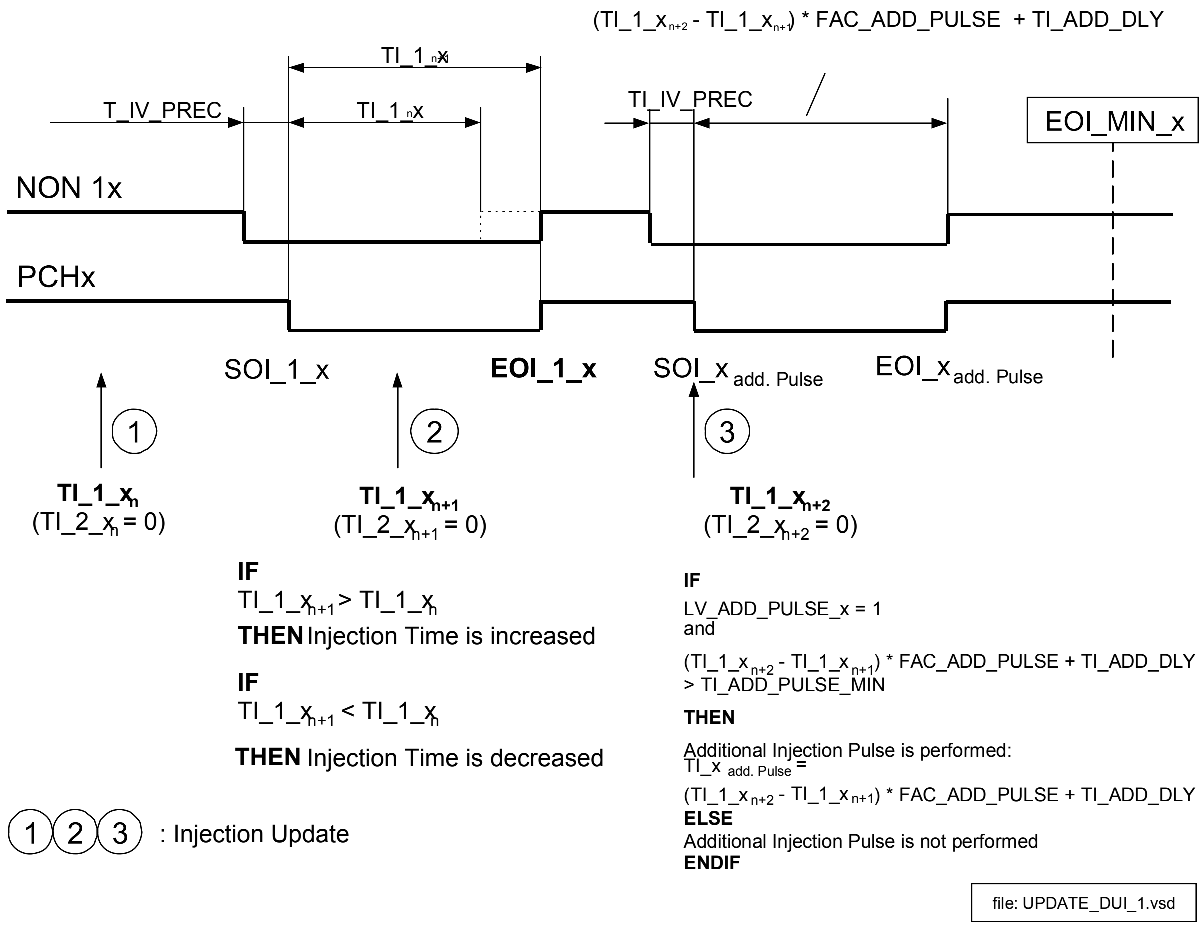

Figure 2: Injection update at single injection (HPDI Engine).
(Please Note: TRL_TI_PLS_1 = TI_1_x + T_IV_PREC for HPDI engine
TRL_TI_PLS_1 = TI_1_x for MPI engine)

2.16.1.3.2 Double Injection

⇒ If the calculation is updated befor the injector is opened for the first pulse and the new SOI_1_x has already passed, the injection is started at once and will be continued for TI_1_x.

(see Figure 3, Injection Update 1)

⇒ If the calculation is updated while the injector is open and LV_ADD_PULSE_x = 1, for the first pulse the injection time should be increased if

$TI\_1\_x_{n+1} > TI\_1\_x_{n}$

and should be decreased if

$TI\_1\_x_{n+1} < TI\_1\_x_{n}$

If the new TI of the pulse has already elapsed the injection should be stopped immediately.

(see Figure 3, Injection Update 2)

⇒ If the calculation is updated after the first pulse is performed (the injector is already closed) the second injection pulse should be performed with EOI_2_x $_{n+2}$.
But only

IF
LV_ADD_PULSE_x = 1
THEN
FAC_ADD_PULSE_CLC_x = FAC_ADD_PULSE
(means a pulse update of the preceding pulse is performed)
ELSE
FAC_ADD_PULSE_CLC_x = 0
(means a pulse update of the preceding pulse is not performed)
ENDIF

IF
(TI_1_x $_{n+2}$ – TI_1_x $_{n+1}$) * FAC_ADD_PULSE_CLC_x + TI_2_x > TI_ADD_PULSE_MIN
AND
NC_T_MIN_INJ_INH has elapsed after the actual EOI_1_x
THEN
TI_2_x = (TI_1_x $_{n+2}$ – TI_1_x $_{n+1}$) * FAC_ADD_PULSE_CLC_x + TI_2_x
ELSE
Second injection pulse is not performed
ENDIF

(see Figure 3, Injection Update 3)

If the new SOI_2_x has already passed, the injection is started at once and will be continued for TI_2_x.

The second pulse should be stopped immediately at EOI_MIN.

⇒ If the calculation is updated while the injector is open for the second pulse the injection time should be increased if
TI_2_x < (TI_1_x $_{n+3}$ – TI_1_x $_{n+1}$) * FAC_ADD_PULSE_CLC_x + TI_2_x

The second pulse should be stopped immediately at EOI_MIN.

The injection time should be decreased if
TI_2_x > (TI_1_x $_{n+3}$ – TI_1_x $_{n+1}$) * FAC_ADD_PULSE_CLC_x + TI_2_x

If the new TI of the pulse has already elapsed the injection should be stopped immediately.

(see Figure 3, Injection Update 4)

Note: In stratified mode LV_ADD_PULSE_x is always zero. In homogeneous mode LV_ADD_PULSE_x can be set by the application system.

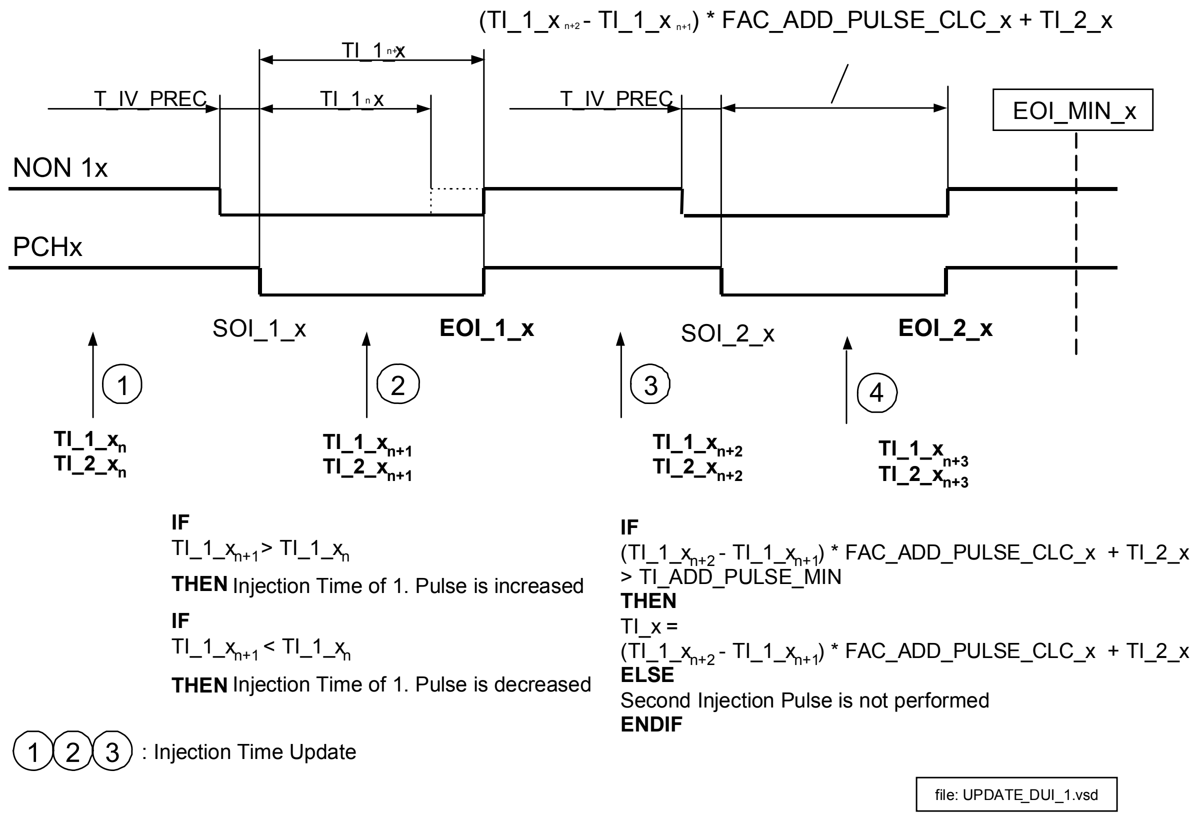

Figure 3: Injection update at double injection (HPDI Engine).
(Please Note: TRL_TI_PLS_1 = TI_1_x + T_IV_PREC for HPDI engine
TRL_TI_PLS_1 = TI_1_x for MPI engine
TRL_TI_PLS_2 = TI_2_x + T_IV_PREC for HPDI engine
TRL_TI_PLS_2 = TI_2_x for MPI engine)

Application hint:

Minimum off-time between two injections NC_T_MIN_INJ_INH is 0.1 ms. For diagnosis the minimum off-time between two injections has to be 0.25 ms).

2.16.1.4 Priorities for timing of injection

If the different requirements for the injection can not all be fulfilled simultaneously, the priorities are defined as:

1. The injection shall not start before the beginning of the injection phase (SOI_LIM).
2. The injection shall not proceed beyond the end of the injection phase (EOI_LIM).

3. The injection shall not start until the minimum delay NC_T_MIN_INJ_INH has passed after a previous injection.
4. The actual injection time shall be as close as possible to the desired injection time.
5. The actual end of injection shall be as close as possible to the desired end of injection.

2.16.1.5 Deactivation of cylinders

All cylinders can be deactivated independently. The information is contained in the variable LV_INH_IV_x which is input for this functionality. The variable is checked at every SOI_x.

If LV_INH_IV_x = 1 the injection is not performed.

At EOI_LIM_x, the deactivation status of the cylinder during the previous injection phase (0 ... 720 °CRK) is indicated at the output interface by the variable INJ_StateOfPrevInj_x.

INJ_StateOfPrevInj_x = 1 .... logical cylinder x was injected

INJ_StateOfPrevInj_x = 0 .... logical cylinder x was not injected

In case of double injection: If the first injection is deactivated by LV_INH_IV_x then the second injection is not performed.

2.16.1.6 Information about actual performed SOI, EOI and TI at the Output Interface

After an Injection was performed, the (cylinder individual) SOI, EOI and TI of that injection is indicated at the output interface as:

SOI_1_MES_x ... actual performed SOI of the first injection pulse (estimated)

EOI_1_MES_x ... actual performed EOI of the first injection pulse (estimated)

SOI_2_MES_x ... actual performed SOI of the second injection pulse (estimated)

EOI_2_MES_x ... actual performed EOI of the second injection pulse (estimated)

TI_1_MES_x ... actual performed injection time of the first injection pulse

TI_2_MES_x ... actual performed injection time of the second injection pulse

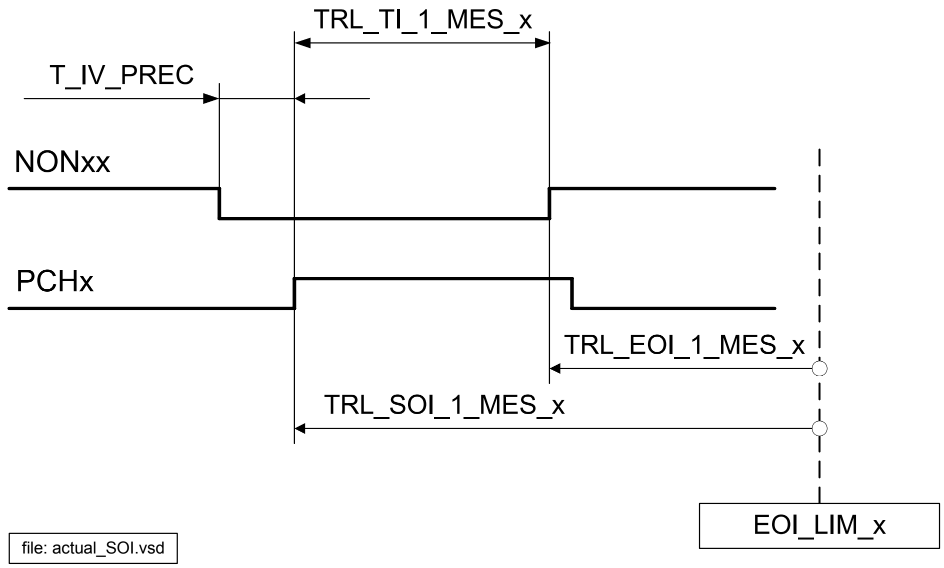

Figure 3: Actual performed SOI and EOI for the first injection pulse, example for HPDI-Engines.

(SOI is defined by the engine rotation position of the rising edge of the current controller signal PCHx. EOI is defined by the engine rotation position of the rising edge of the current controller signal NONxx.)

2.16.1.7 Dynamic angular error of SOI and EOI under transient engine operation

The maximum angular error under transient engine operation is defined as follows:

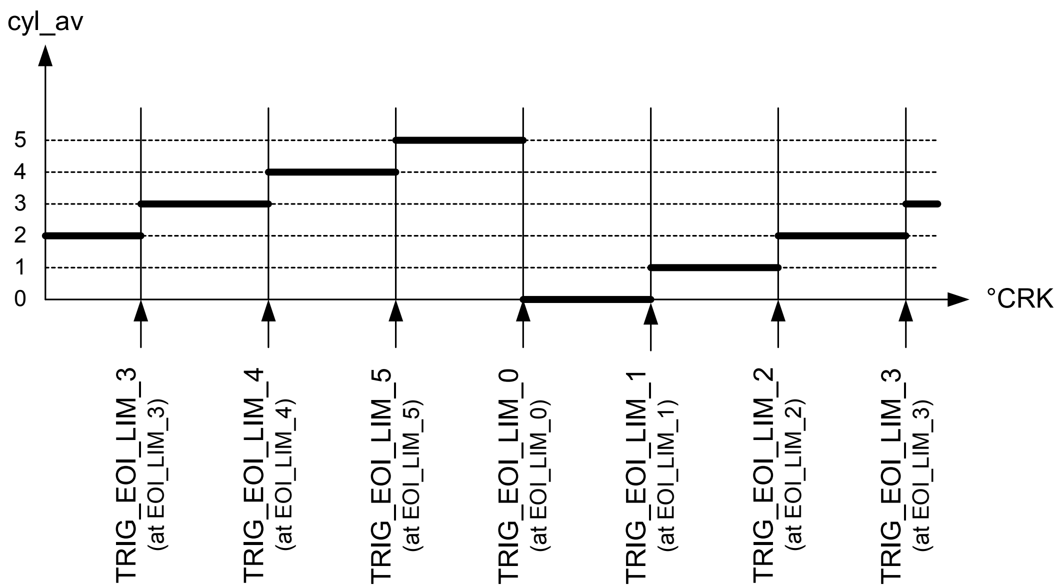
Maximum angular error = f(N, Gradient of N)

The error is measured assuming the engine speed is constant and begins to accelerate or decelerate at a constant rate. A positive error is defined if the actual angular is smaller than expected (acceleration error) while a negative error is defined if the actual angular is bigger than expected (deceleration error).

2.16.1.8 Indication of the actual number of TRIG_EOI_LIM_x

2.16.1.9 At every EOI_LIM_x a trigger TRIG_EOI_LIM_x is required.

2.16.1.10 The actual number of the TRIG_EOI_LIM_x is indicated by the parameter CYL_AV, see figure below.



File: cyl_av.vsd

2.16.1.11 Diagnosis for ATIC21 and ATIC 39

This section describes the requirements needed for the diagnosis of the injectors and injector driver.

Output data: (Diagnosis)

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TRL_LV_SCG_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual short cut to ground information					
TRL_LV_SCB_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual short cut to battery information					
TRL_LV_OC_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual open circuit information					
TRL_LV_SCG_VLD_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual information if diagnosis is valid or not (short cut to ground information)					
TRL_LV_SCB_VLD_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual information if diagnosis is valid or not (short cut to battery information)					
TRL_LV_OC_VLD_IV_x	O	0 ... 1H	0 ... 1	1	-
Cylinder individual information if diagnosis is valid or not (open circuit information)					

2.16.1.11.1 Recurrence of the output data every 10 ms

⇒ Error informations are gathered (or-ed symptom specific) until read out by the application software ASW.

At the moment when ASW is reading data from I/O software, the I/O software data will be reset. (It is possibel to have more than one electrical failure symtom reported to ASW.)

⇒ The cylinder specific variable LV_SCG_VLD_IV_x, LV_SCB_VLD_IV_x, LV_OC_VLD_IV_x are set to one (valid) if new diagnosis data from hardware are available.

⇒ If more the one error symptom is detected during the 10 ms readout period, the priority of the errors reported is:

1. short cut to battery (scb)
2. short cut to ground (scg)
3. open curcuit (oc)

⇒ SCB will shut off the device and the error will be kept by the device until a “off-slope” occurs.

⇒ SCG, OC: read out of the device erases error status and the device is not shut off.

Application hint:

The minimum injection time TI_MIN has to be calibrated to ensure proper diagnosis (for diagnosis the minimum injection time is 0.4 ms and the minimum off-time between two injections is 0.25 ms).

Configuration data: (chapter 1.1)

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_T_MIN_INJ_INH	1	0 ... 64H	0.1... 0.5	0.004	ms
Minimum off time between two injection pulses					
NC_REF_EOI_LIM	1	FC40 ... 0 H	-360 ... 0	0.375	°CRK
Offset of the EOI_LIM reference point after TDC					

2.16.2 Additional Requirements for MPI engines

2.16.2.1 Pre injection

Input data: (Pre injection)

TRL_EOI_PRE_INJ [NC_CYL_NR]	TRL_TI_PRE_INJ [NC_CYL_NR]	TRL_EOI_MIN_PRE_INJ

Detailed input data definition (Pre injection):

TRL_EOI_PRE_INJ [NC_CYL_NR]	-	0 ... 780H	0 ... 720	0.375	°CRK
End of injection for preinjection					
TRL_TI_PRE_INJ [NC_CYL_NR]	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Pre injection time					
TRL_EOI_MIN_PRE_INJ	-	0 ... 780H	0 ... 720	0.375	°CRK
Latest end of injection angle for pre injection					

FUNCTION DESCRIPTION:

The aim is to **pre-synchronise** and start the engine as fast as possible. The experience has shown, that when the engines was switched off, it will stop in the most of the cases at the same specific engine positions. This information is used together with the information of relative engine positions PSN_ENG_SYN_MIN and PSN_ENG_SYN_MAX to pre-synchronise the engine. In the case that the difference of PSN_ENG_SYN_MIN and PSN_ENG_SYN_MAX is lower than the threshold PSN_DIF_ENG_SYN_THD then the pre injection will be enabled in the ASW.

Injection phasing for preinjection:

The cylinder individual end-of-preinjection-angle EOI_PRE_INJ [NC_CYL_NR] is calculated in the ASW and send to the IO SW. All angles are related to engine position. In addition to that, the angle EOI_MIN_PRE_INJ is used to look for the first cylinder and for the first fuel injection.

The start of injection angles for pre injection are calculated using the end of injection angles EOI_PRE_INJ [NC_CYL_NR] and the injection times TI_PRE_INJ [NC_CYL_NR] analog to chapter “Calculation of Start of Injection SOI”.

The preinjection is carried out by the IO SW in the case that the injection mode is set to pre injection.

In the case that the injection mode sequential is selected, then the fuel injection will start in sequential mode directly (this occurs when crankshaft synchronisation is detected by the ASW). The IO SW is using the standard data set for injection (TI_1_x, ...).

Actualisation of the engine position during the pre synchronisation phase

During the pre synchronisation phase it is possible, that the actual engine position can jump due to hardware events i.e. CAM edge or CRK GAP. The IO- injection – SW has to react on such changing engine positions and check if any already started injections can be finished successfully at the latest possible angle EOI_MIN_PRE_INJ. See the four cases in figure 4.

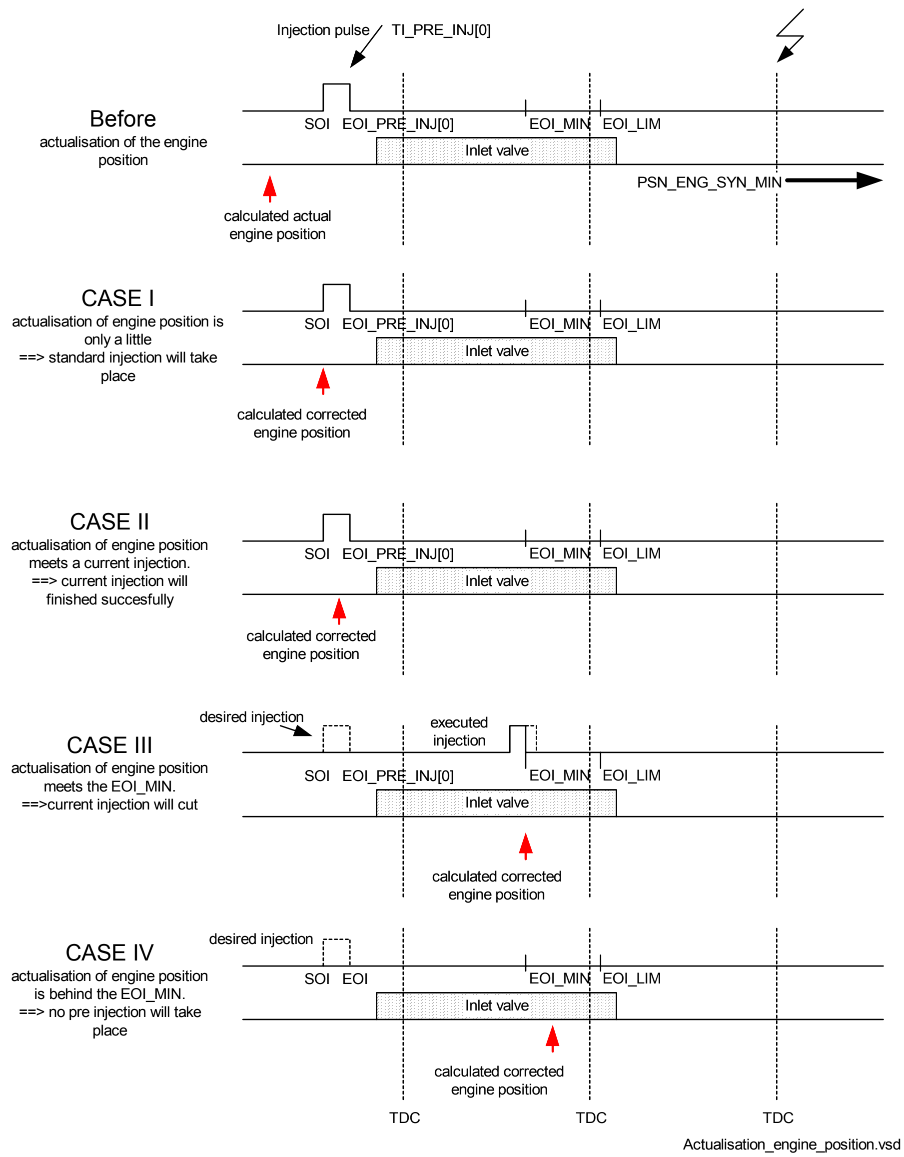


Figure 4: Injection behaviour at engine position actualisation

Formula section:

IF Injection mode pre injection is selected

THEN

the following actions has to be executed:

- First injection TI_PRE_INJ [NC_CYL_NR] will be applied with the phasing of EOI_PRE_INJ[NC_CYL_NR].
- As basis for the EOI calculation the angles are referenced to engine position.
- The latest allowed end of injection for the first pulse is EOI_MIN_PRE_INJ.
- All cylinders will be checked if TI_PRE_INJ [0] can be finished until EOI_MIN_PRE_INJ. Then choose the **earliest** cylinder, who's individual pulse position is before EOI_MIN_PRE_INJ, For this check it is assumed that the engine speed will not change during the injection.
- The following cylinders do not need the check of EOI_PRE_INJ because their pulse positions will be later.
- They are performed with TI_PRE_INJ [1 ... NC_CYL_NR –1] and EOI_PRE_INJ [1 ... NC_CYL_NR –1] in their logical order.
- For each of the NC_CYL_NR preinjections:
    - it is executed immediately if it's start of injection SOI is already past **or** it will be started at it's determined SOI,
    - it will be cut off at EOI_MIN_PRE_INJ at latest.
- After each injection the INJ_MOD_x is changed by the IO-SW to sequential mode with single injection cylinder individual.
- If an engine position actualisation occurs due to a position jump then the four following cases has to be checked corresponding to figure 1:

Case I: Injection was not started up to now.
Start with pre-injection at planned reference position.
Stop injection at EOI_MIN_PRE_INJ position or earlier.

Case II: Injection has been started.
Stop injection at EOI_MIN_PRE_INJ position or earlier.

Case III: Injection should be started during singular step.
Start injection immediately and cut at EOI_MIN_PRE_INJ or earlier.

Case IV: Injection happened during singular step.

Start injection immediately and stop at EOI_MIN_PRE_INJ or earlier.
If the actualised position is behind the EOI_MIN_PRE_INJ, skip the pre-injection and continue with standard sequential injection, i.e. pre-injection on this cylinder is missing!

ENDIF

IF the injection mode sequential is selected,

THEN

the fuel injection will start in sequential mode directly (this occurs when crankshaft synchronisation is detected by the ASW). The IO SW is using the standard data set for injection (TI_1_x, ...).

ENDIF

2.16.3 Additional Requirements for HPDI engines

2.16.3.1 Injection pulse lock mechanism for ATIC 21 driver

For the ATIC 21 driver a lock mechanism is needed to prevent overlapped pulses on the two injectors, which are connected to the same high side driver. After start of a pulse sequence on one of the two injectors the other injection driver has to be locked for injection pulse generation. The lock mechanism has to be switched to the other injector, if one of the following conditions occurs:

- Immediately after finishing the latest possible pulse of the current unlocked injector plus minimum off-time between to injections (NC_T_MIN_INJ_INH)
- Immediately after reaching the EOI_MIN of the latest pulse for the current selected cylinder, independent from having carried out or having finished the pulse under consideration of NC_T_MIN_INJ_INH

After the cylinders are switched the previous cylinder has to be locked – no injection pulses for the previous cylinder are allowed anymore.

2.16.3.2 Post Pulses (Injection after ignition TDC, e.g. for catalyst heating)

Input data: (Post Pulses)

TRL_EOI_POST_INJ_x	TRL_TI_POST_INJ_x	TRL_LV _POST_INJ_CH_x	TRL_EOI_MIN_POST _x
TRL_SOI_MAX_POST_x			

Detailed input data definition (Post Pulses):

TRL_EOI_POST_INJ_x	-	0 ... 780H	0 ... 720	0.375	°CRK
End of the post injection					
TRL_TI_POST_INJ_x	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Injection time of the post injection					
TRL_LV _POST_INJ_CH_x	-	0 ... 1H	0 ... 1	1	-
Logical variable for enabling post injection					
TRL_EOI_MIN_POST _x	-	0 ... 780H	0 ... 720	0.375	°CRK
Latest possible EOI for post injection relatet to EOI_LIM					
TRL_SOI_MAX_POST_x	-	0 ... 780H	0 ... 720	0.375	°CRK
Earliest possible SOI for post injection related to EOI_LIM					

Post pulses are performed if LV_POST_INJ_x = 1 with the injection time TI_POST_INJ_x and with the end of injection EOI_POST_INJ_x.

LV_POST_INJ_x is checked at every TRIG_INJ_UPD_x and every EOI of the pulse before start of injection of a post pulse (SOI_POST_INJ_x).

Post pulses are not started before SOI_MAX_POST_x and are stopped immediately at EOI_MIN_POST_x.

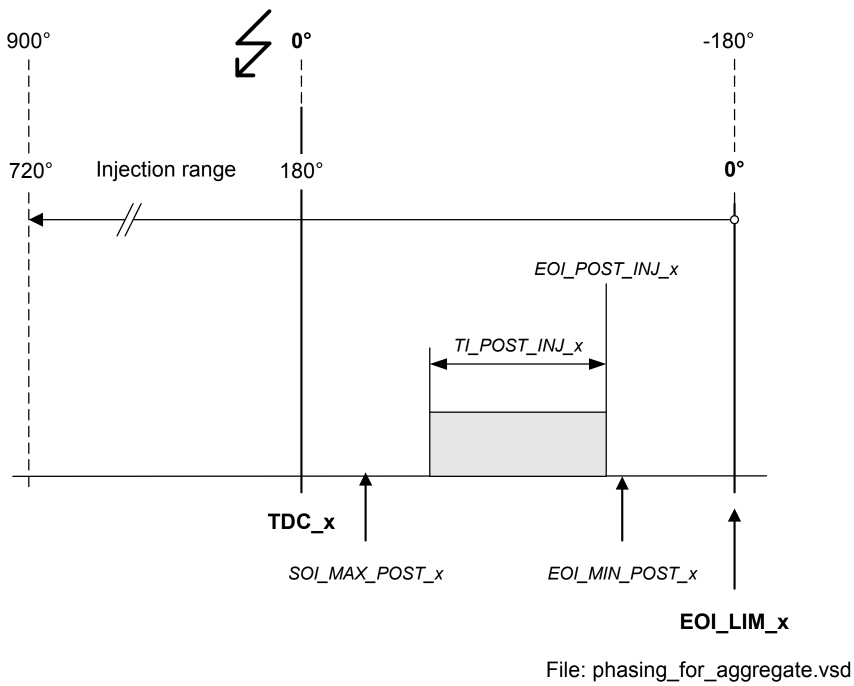

Figure 4: Phasing of post pulses

2.16.3.3 Injector current control (ATIC 21)

Output data: (Injector current control)

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TRL_VBOOST_BAS	O	0 ... 3FFH	0 ... 4.999	5/1023	V
Boost voltage					

Input data: (Injector current control)

TRL_T_IV_PREC	TRL_T_HLD_IVP	TRL_T_END_IVP	

Detailed input data definition (Injector current control):

TRL_T_IV_PREC	-	0...2FFH	0...3	0.004	ms
Injector current precharge time					
TRL_T_HLD_IVP	-	0...7H	0.192..0.416	0.032	ms
Injector current Peak Hold Time					
TRL_T_END_IVP	-	0..1FH	0..0.062	0.002	ms
Injector current Fast Decrease Time					

The specification refers to the injector driver ATIC 21 in combination with solenoid injectors. The current to control the injector is variable and can be influenced via the application software. The current profile is described by

- the **"Precharge Time" T_IV_PREC**, necessary to limit the energy which comes from the DC/DC-Converter (ECU integrated) and is needed during the "Peak Hold Time".
- the **"Peak Hold Time" T_HLD_IVP** (or boost phase) to guarantee a safe opening of the injector up to a defined fuel pressure,
- the **"Fast Decrease Time" T_END_IVP**, which enables a fast reduction of the energy stored in solenoid coil down to the level of the Hold Current. This guarantees almost a constant injector closing time (for a certain fuel pressure) down to very short injection times (~ 0.4 ms) and therefore a better Linerar Flow Range,
- the **"Hold Phase"** with a constant current, high enough to keep the injector open,

see Figure 5.

The boost voltage is the voltage from the DC/DC-Converter which is active at the injector from start of injection until the injector current reaches its peak value, see figure 5.

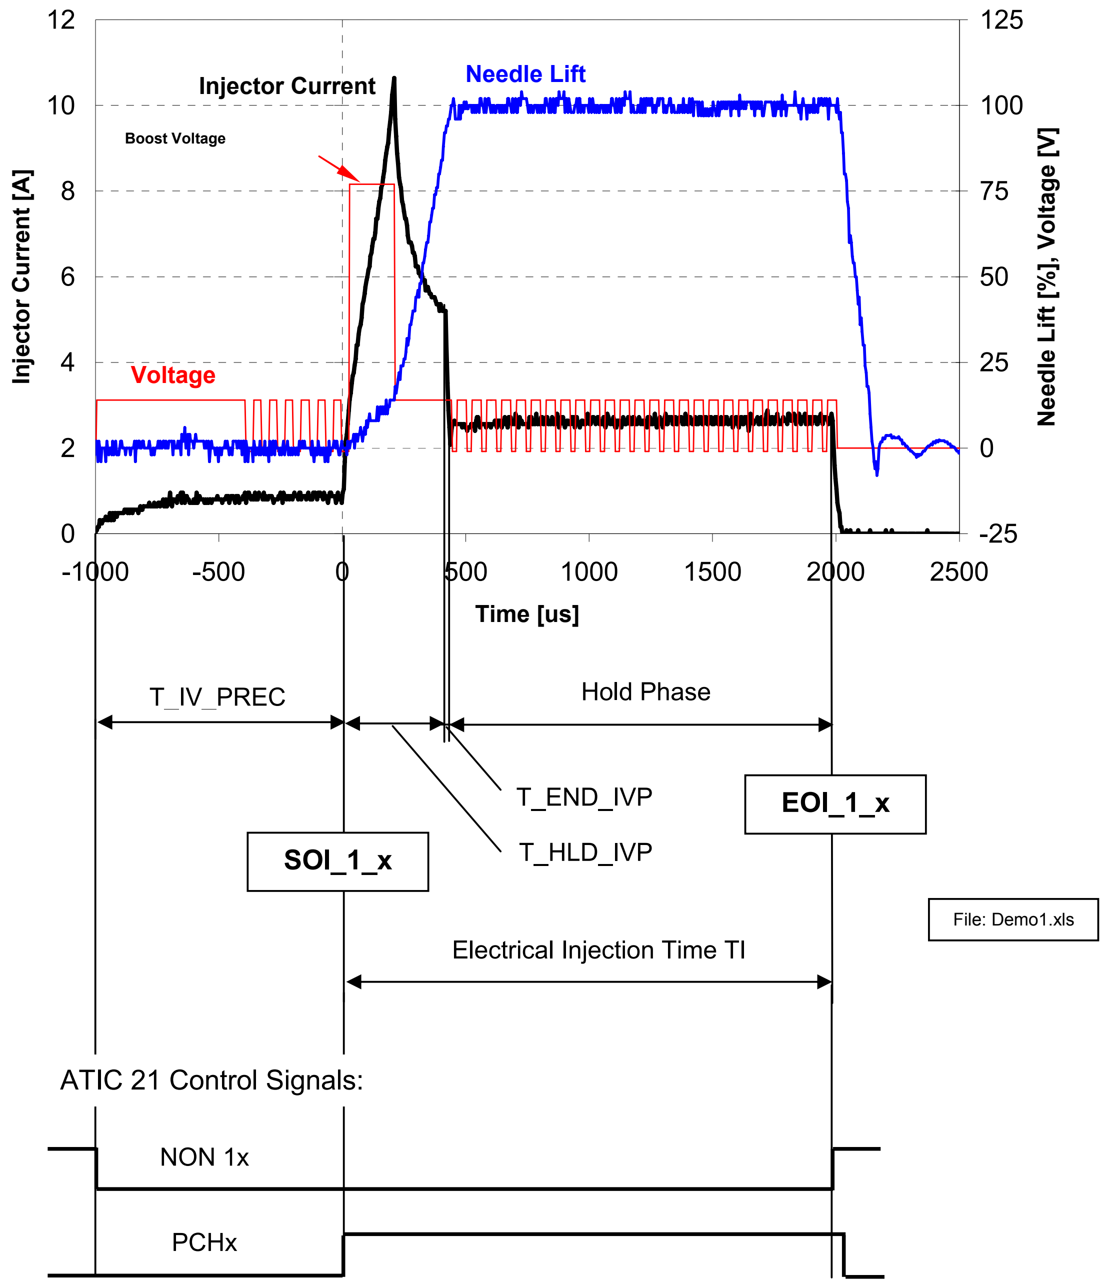

Figure 5: Current, voltage and needle lift at the injector

2.17 Spark Advance and Dwell Output

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TD_FAC_MAX	O/V	1...FFH	1/128...255/128	1/128	-
Maximal dwell time control					
TD_FAC_MIN	O/V	1...FFH	1/128...255/128	1/128	-
Minimal dwell time control					

Input data:

LV_ ERR_CAM	VB	LV_ST	N_32
LDPM_N_32_1_IGRE	LV_SYN_ENG	NC_CYL_NR	

Import actions:

ACTION_INFR_SetIgnCtl(IN <>)

FUNCTION DESCRIPTION:

This function sets the angular position of the dwell time turn on in order to have the time to set up the necessary current in the ignition coil.

The strategy is based on a priority of the ignition angle. If dwell time priority is requested the minimum dwell time is equal to maximum dwell time.

The strategy respects ignition coils with dual and single outputs. This function could be used independently of the number of cylinders (n) and the geometry of the crankshaft target wheel.

This function could be used for homogeneous combustion mode and for stratified combustion mode. The calculation of the spark advance is in both cases the same.

All of the functions described in this section operate over the entire engine speed range.

This specification includes two mode following the IGRE version: PI or PI + DI

Application conditions:

Initialisation: at reset

Activation: LV_SYN_ENG = 1 Engine synchronised

2.17.1 Minimum / Maximum dwell time calculation

FUNCTION DESCRIPTION:

The two values are calculated independently of all environment factors. The aim is to have a larger window at start and low engine speed to obtain a better flexibility to apply the requested ignition angle.

These 2 values are expressed in term of min/max factor to be applied to the nominal dwell time and transferred to the Basic SW

The cylinder individual nominal Dwell Time to be applied requested by ASW function is defined in TD_IGC[x] taking into account the combustion mode switch

Application conditions:

Initialisation: TD_FAC_MIN = TD_FAC_MAX = 1 *at reset*

Recurrence: 10 ms

Formula section:

If LV_ST = 1

Then *(Start mode)*

If VB > C_TD_VB_MAX

Then TD_FAC_MAX = 1

TD_FAC_MIN = Min[C_TD_FAC_ST_MIN , 1]

Else TD_FAC_MAX = Max[C_TD_FAC_ST_MAX , 1]

TD_FAC_MIN = Min[C_TD_FAC_ST_MIN , 1]

Else *(run mode)*

If VB > C_TD_VB_MAX

Then TD_FAC_MAX = 1

TD_FAC_MIN = Min[IP_TD_FAC_MIN , 1]

Else TD_FAC_MAX = Max[IP_TD_FAC_MAX , 1]

TD_FAC_MIN = Min[IP_TD_FAC_MIN , 1]

Endif

In every case: TD_IGC[x] * TD_FAC_MAX <= NC_TD_LIM_MAX

TD_IGC[x] * TD_FAC_MIN >= NC_TD_LIM_MIN

NC_TD_LIM_MIN is defined for dwell time protection in case of advance ignition changes during the dwell time application. If the dwell time is equal to this minimal limit value, the advance ignition could be not guaranteed

NC_TD_LIM_MAX is defined for the maximum dwell time in case of advance ignition changes during the dwell time application. If the dwell time is equal to this maximal limit value, the advance ignition could be not guaranteed

Note: In any case, TD_FAC_MIN has to be smaller than 1 and TD_FAC_MAX greater than one to be sure to respect the requested dwell and avoid inconsistencies
care has to be taken with the setting of NC_TD_LIM_MAX in order to avoid Dwell Time / coil charging recovery:
Dwell time can start at the earliest at 288°CRK before the TDC.
NC_TD_LIM_MAX should be tuned in consequence to respect coil charging time no recovery and coil capacity

2.17.2 Half static of full static

Recurrence: engine stop to engine run

Formula section:

Following NC_IGC_CONF = Half or full, the ignition is half static controlled or full static controlled

ACTION_INFR_SetIgnCtl(NC_IGC_CONF)

2.17.3 Limp home without cam signal

Recurrence: engine stop to engine run

Formula section:

In case of CAM failure, the cylinder in combustion cannot be unequivocally identified. Engine phasing might be wrong. In such a case, a limp home mode function on Ignition is provided in order to have the possibility to drive the engine. Nevertheless, in this case, since the right cylinder phasing is not known, Ignition coil have to be driven in Half-Static mode to be sure to execute at least an ignition on the cylinder in combustion.

Decision to use such Limp Home functionality will depend on the setting of LC_IGC_LIH_CONF. If LC_IGC_LIH_CONF = 0, no Limp Home is provided in CAM failure and Ignition is stopped. If LC_IGC_LIH_CONF = 1, then Half-Static Ignition mode is done in case of CAM failure

If LV_ERR_CAM is active, the ignition coil control will be executed in half-static ignition-coil control mode if selected by the settings of LC_IGC_LIH_CONF

In such a case (*half-static mode activation in CAM failure*) the same Ignition and Dwell Time will be applied to the 2 Crank synchronous cylinders (*eg. on a 4 cyl engine, cyl. 1 and 4 and cyl. 2 and 3 will be fed with the same Ignition and Dwell Time*)

The limp home function could be applied only if the number of cylinders is even (2, 4, 6, ...)

If NC_IGC_CONF = full

Then **If** LV_ERR_CAM = 1 And LC_IGC_LIH_CONF = 1

Then **ACTION_INFR_SetIgnCtl**(HALF_STATIC)

Else **ACTION_INFR_SetIgnCtl**(FULL_STATIC)

EndIf

Else **ACTION_INFR_SetIgnCtl**(HALF_STATIC)

EndIf

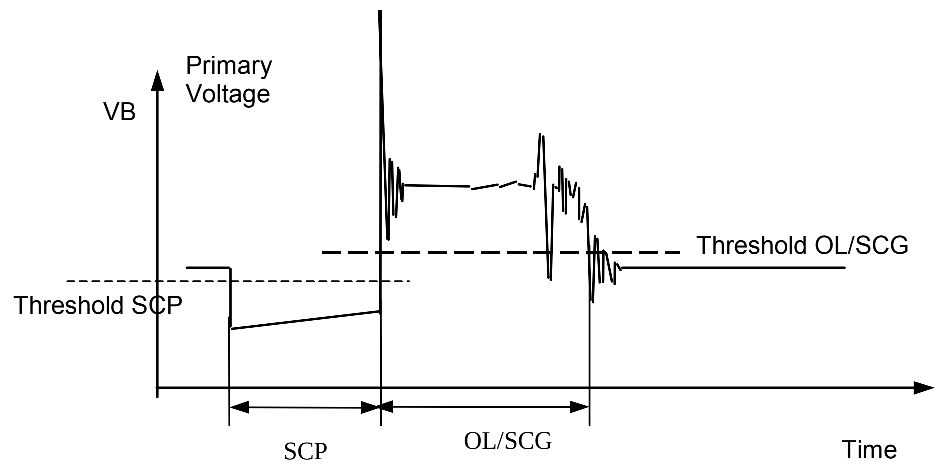
2.18 Ignition output diagnosis (for ATM 46 / Combined "ASIC")

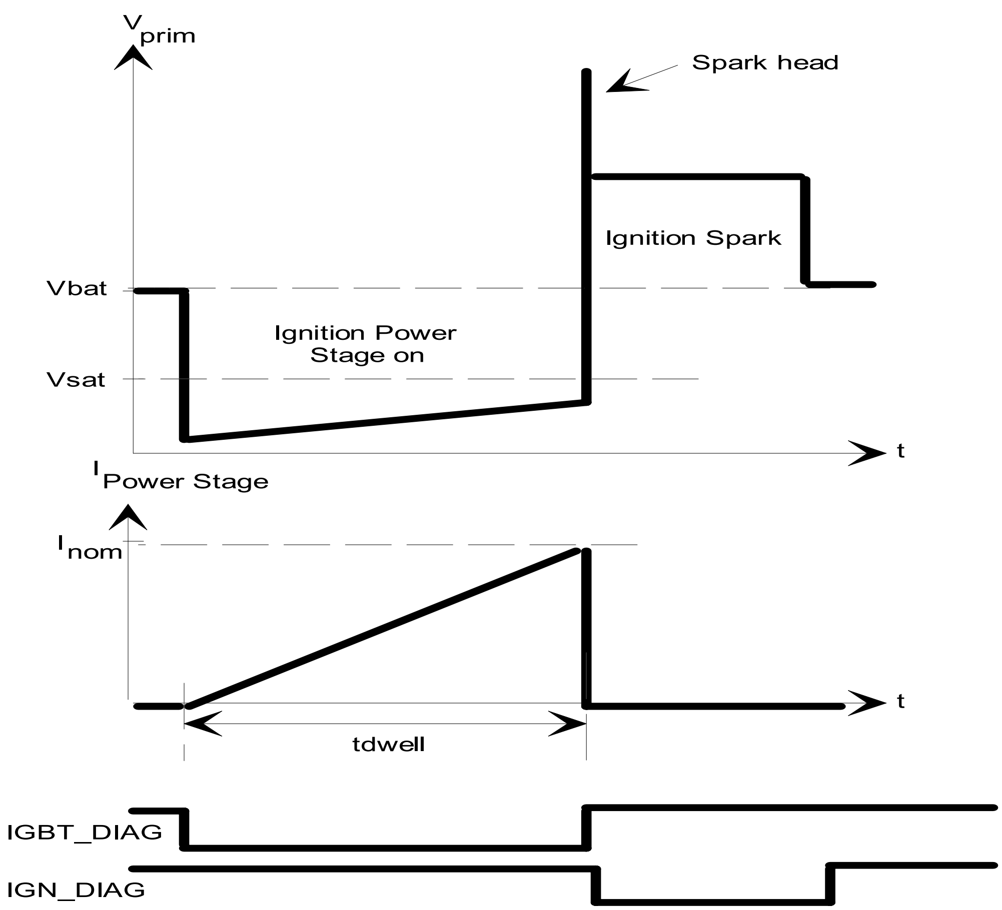
Each ATM46 could analyze 4 ignition coils. If diagnostics for more the than 4 coils are necessary, a parallel ATM46 has to be used.

The diagnosis is based on ignition coil primary over voltage measurement.

The input signal of the ATM 46 is the IGBT collector voltage.

In case of an ignition system with single output coils, the function does not work in camshaft limp home mode.





2.18.1 IGBT Protection (with “ATM46” / Combined “ASIC”)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SCP_IGC[NC_CYL_NR]	O/V	0...1H	0...1	1	-
Diagnostic of primary short circuit to battery (cylinder selected)					

Input data:

LV_SYN_ENG	NC_CYL_NR	SEG_NR	LV_CDN_DIAG_IGC_SCP[NC_CYL_NR]

Import actions:

ACTION_INFR_GetIgnScpDiagAtm46Atic71(IN <>,OUT<>)

FUNCTION DESCRIPTION:

The aim of the present function is to protect the ignition power stage against short circuit to battery (SCP).

The purpose of ignition power stage diagnostic is to detect a short circuit to battery voltage condition (SCP). At each Dwell Time On event, the ignition power stage is switched on. In normal condition, the current increase in the ignition power stage is limited by the inductance of the ignition coil solenoid.
In case of a short circuit to battery, the coil external device does not limit the current in the ignition power stage. In this situation the current is only limited by the current capability of the ignition power stage. This power dissipation would destroy the power stage. From the Dwell Time ON event in SCP condition, the IGBT’s can withstand this overload current only for a very short time (*750µs for IGBT without shunt*). So, it is necessary to switch off this IGBT transistor for safety and protection reasons by software (*IGBT deactivation by switching off the charging command in SW*) in case of an overload condition and after a certain time delay has elapsed (NC_INI_CTR_DEAC). This time delay is necessary in order to filter parasitic spikes. On the other hand this time delay must not exceed the maximum rating of the IGBT’s.

For ignition power stage diagnostic, the voltage across the ignition power stage is compared to a fixed threshold voltage. This threshold voltage is chosen to be higher than the maximum saturation voltage of the ignition power stage during a dwell time in normal operation. If there is no short to battery voltage condition, the voltage across the ignition power stage drops below this fixed threshold voltage at each dwell time. In case of a short to battery voltage failure, this voltage is not (or only for a short time) passed. A micro controller monitoring the ignition power stage diagnostic output is able to detect this fault.

This ignition power stage diagnostic circuit is designed for an engine management system including four ignition power stages. This four diagnostic information can be evaluated at one output by having a logic OR function of them.

After each deactivation from this protection function, the cut off IGBT will be reactivated again in the next ignition cycle

The function could be used for ignition systems with single-output coils and double-output coils. The IGBT protection function is cylinder selectively deactivated in case of single-output coil and linked dual cylinders for ½ static coils.

Application conditions:

Activation: *LV_SYN_ENG = 1*

Formula section:

Initialization: at reset
LV_SCP_IGC[x] = 0

Update rate: segment

System description:

The ATM46 is used to generate a signal evaluated by the SW for overload condition detection.

To perform the IGBT protection and SCP diagnostic, the BSW provides one functional service (BSW driver – one driver for one ATM46 protection and SCP diagnostic line)

As only one IGBT diagnosis output signal from the "ATM 46" exists (all channels are linked by a wired "OR") and only one BSW functional service (*this BSW functional service used is described in the following paragraph*) is used in connection to this diagnosis output signal line, the function is limited to non-overlapping dwell time pulses. In case of overlapping Dwell Time, the last TD ON event that occurs will re-trigger the call of this function and thus be considered for diagnosis purpose.

Formula section:

ACTION_INFR_GetIgnScpDiagAtm46Atic71(SEG_NR -2,LV_SCP_IGC[SEG_NR-2])

2.18.1.1 Ignition Actuator Tests Diagnosis

Formula section:

Initialization: LV_SCP_IGC[x] = 0 at reset

System description:

For ignition coil actuator tests purpose, the SCP diagnostic function has to be enabled and activated upon the tests requests

The same case and comments (see before) apply here also.

Formula section:

For x = 0 to NC_CYL_NR – 1
 If LV_CDN_DIAG_IGC_SCP[x] = 1
 Then **ACTION_INFR_GetIgnScpDiagAtm46Atic71**(x,LV_SCP_IGC[x])
 EndIf
EndFor

Input data:

LV_SYN_ENG	N_32	MAF	NC_CYL_NR

Import actions:

ACTION_INFR_GetIgnScgDiagAtm46Atic71 (IN <>,IN<>,OUT<>,OUT<>)

Description:

This ignition diagnosis function evaluates the primary over voltage duration **V_DUR_IGC[x]** provided after the ignition coil cut off.

The aim of this spark burning diagnostic function is to measure the spark duration by detecting the presence of a spark on an ignition plug. The over-voltage at the primary coil of an ignition solenoid is equal to the voltage across the spark gap of the ignition plug divided by the transmission ratio of the ignition solenoid and superimposed on the battery voltage. The time where the voltage at the primary coil of the ignition solenoid is higher than a battery voltage dependent threshold voltage (V_{BD_TH}) gives the spark duration.

In the moment, when the ignition power stage (IGBT) is switched OFF *(ie. at TD OFF event occurrence)*, the voltage V_C at the collector of the IGBT rises, due to self-induction, and ignition occurs. As long as the ignition spark is burning, the voltage is well exceeding the battery voltage.

By means of a hardware defined threshold (V_{BD_TH}; typical value: V_{Bat} + 3V) the burn condition is detected and a matching signal is generated, *eg. Here by the combined ASIC ATM46*. This signal is used to measure the overall burning duration.

The Ignition Burning diagnostic signal IGN_DIAG is generated by this combined ASIC. This time for the burning spark IGN_DIAG is calculated via the duration of the diagnostic signal staying above the threshold of V_{BD_TH}.

This ATM46 ignition diagnostic circuit is designed for an engine management system including up to 4 ignition coils/solenoids. This four diagnostic information are then evaluated on one output by applying a logic NOR function on them. The output signal IGN_DIAG of the ignition diagnostic circuit is processed by the µP.

Due to combustion chamber turbulence the spark of an ignition plug is not stable. The result is an unstable primary voltage at the ignition solenoid. Therefore a filter in the output signal IGN_DIAG is necessary to prevent the µP from high frequency inputs.

The ignition coil primary over voltage on the ignition output is roughly equal to the voltage across the spark gap divided by the ignition coil transformation ratio, superimposed on the battery voltage.

The Burn Time measurement is used today only for Spark / Combustion Diagnosis Purpose. It is a rough measurement of the effective Burn Time.

Application conditions:

Activation: LV_SYN_ENG = 1

Initialisation: LV_OL_IGC[x] = 0

LV_SCG_IGC[x] = 0

at reset

V_DUR_IGC[x] = 0

Recurrence: segment

Formula section:

ACTION_INFR_GetIgnScgDiagAtm46Atic71(SEG_NR-2,ID_V_DUR_IGC_MIN, V_DUR_IGC[SEG_NR-2], LV_SCG_IGC[SEG_NR-2])
LV_OL_IGC[SEG_NR-2] = LV_SCG_IGC[SEG_NR-2]

Calibration data:

Minimum duration of the Burntime to detect ignition errors					

2.19 Fuel consumption signal output FCO

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FCO	V/O	0...FFFFH	0...8388,6	0,128	µl
Fuel consumption quantity for fuel consumption signal output.					
FCO_NR	-	0...5H	0...5	1	1/10msec
Number of pulses for fuel consumption determination.					

Input data:

FCO_SUM			

FUNCTION DESCRIPTION:

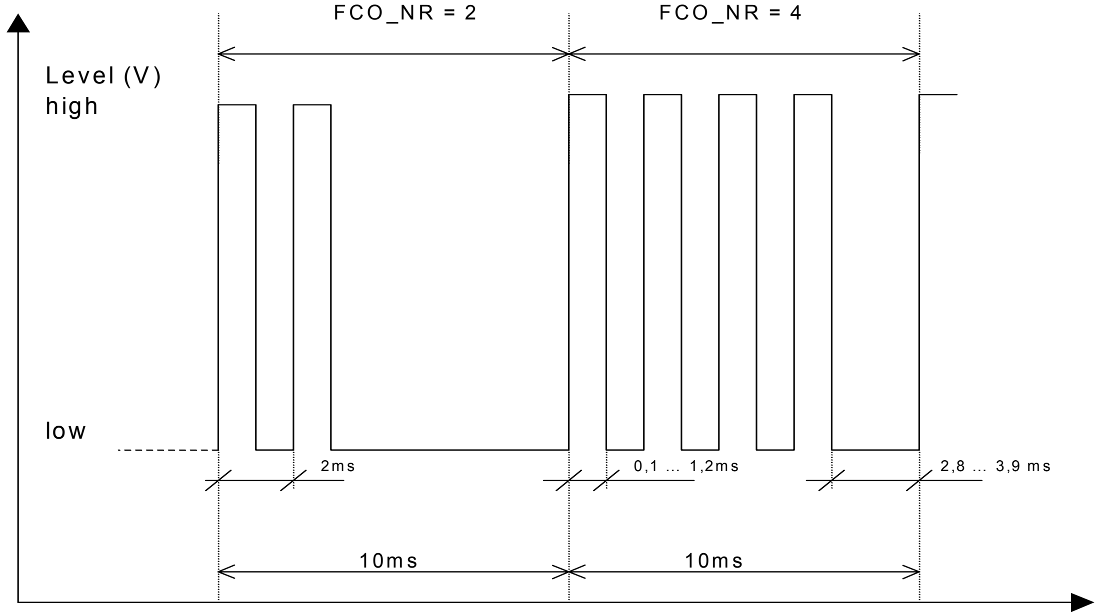
General information:

Application recurrence **: 10 ms**

The ECU generates a fuel consumption output signal (FCO) to be dispatched to other ECUs (Transmission Control Unit, Dashboard ...).

The information about the actual fuel consumption is passed to the other ECUs every 10 ms via a pulse code. Each pulse represents a fuel quantity of 80 µl. The pulse is active at level „high“. The high phase can last between 0,1 and 1,2 msec.
The period of one pulse lasts 2 ms. For each 10 ms duration the maximum possible number of pulses FCO_NR is 5.
As soon as all injectors are switched off (PUC..) the level of the signal is set to „low“.

The remaining injection quantity, which is not covered by the current pulses (during the 10 ms), is memorized for the following calculation.



Initialisation :

The output signal is set to “low” at key on after ECU initialisation.

The signal is deactivated when the house keeping phase has elapsed.

Formula section:

$$FCO = (FCO\_SUM_{n} - FCO\_SUM_{n-1})$$

$$FCO\_NR = FCO / 80\ \mu l$$

FCO_NR is limited to $0 \leq FCO\_NR \leq 5$.
The remaining fuel quantity is memorized for the next calculation (n+1).

2.19.1.1 Engine speed signal output ESS

2.19.1.1.1 Basic software

FUNCTION DESCRIPTION:

General information:

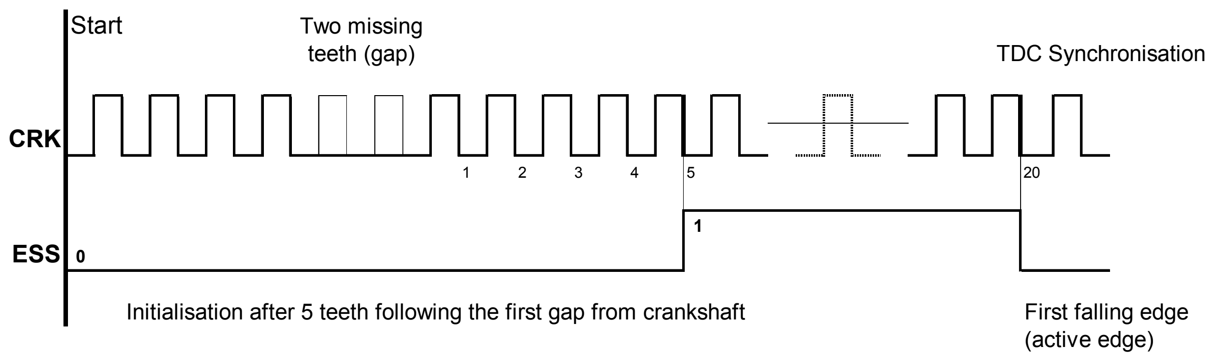
This specification is applicable for a 4 cylinders engine.

The ECU generates an engine speed signal (ESS) to be dispatched to other ECUs (Transmission Control Unit, Dashboard ...)

This output is only activated when the engine is running and the signal is representative of engine speed. It is performed with a fixed logic state ratio and a variable frequency proportional to the engine speed.

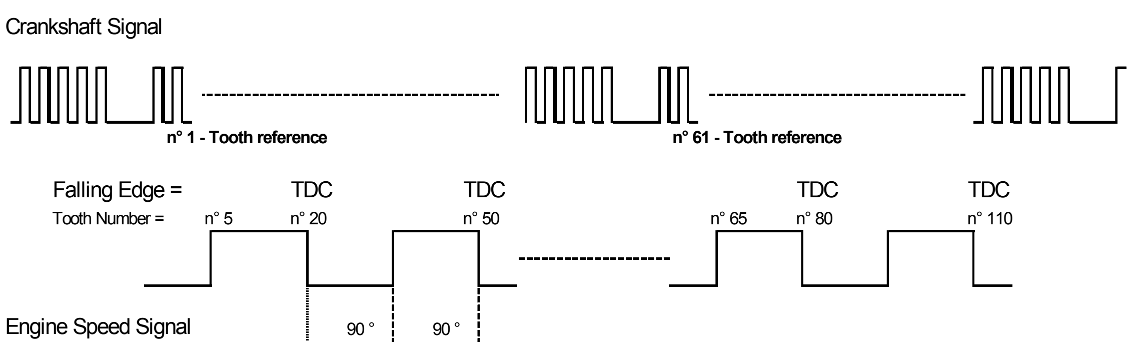
Initialisation :

The output signal is initialised with a low logic state (0).



Formula section:

The active edge on the engine speed signal is the falling edge, corresponding to the TDC location.



2.20 Acquisition of Air conditioning Pressure Signal

2.20.1 Air conditioning Pressure Voltage Signal

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_ACP_MES	V/O	0...3FFH	0...4,995	4.88e-3	V
Air conditioning Pressure Voltage Signal (before electrical Diagnosis)					

Input data:

ACP_BAS			

FUNCTION DESCRIPTION:

General information:

The raw value for air conditioning pressure voltage signal (ACP_BAS) is measured by continuous conversion (10 bits) every 10 msec.

The value of the numeric conversion is adapted to take into account of the electronic component drift. The result of this adaptation must be linearized according to the pressure sensor response.

The corresponding value of the first measurement after hardware reset is used for initialization.

Formula section:

The voltage from the air conditioning pressure voltage signal is converted to the measured AC pressure V_ACP_MES.

$$V\_ACP\_MES = (1/10) * \sum_{n=1}^{n=10} ACP\_BAS_n$$

2.20.2 Supply Voltage signal for Air conditioning Pressure Tranducer

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VCC_SENS_SUB_MES	V/O	0...7FFH	0...9.9951	4.88e-3	V
Supply voltage to calculate ACP_RATIO					

Input data:

VCC_SENS_SUB_BAS			

FUNCTION DESCRIPTION:

General information:

The raw value for APT supply voltage signal (VCC_SENS_SUB_BAS) is measured by continuous conversion (10 bits) every 10 msec.

Formula section:

The voltage signal is converted to the VCC_SENS_SUB_MES.

VCC_SENS_SUB_BAS delivered from HW is half of the real supply voltage.

$$VCC\_SENS\_SUB\_MES = [\,(1/10) * \sum_{n=1}^{n=10} VCC\_SENS\_SUB\_BAS_n\,] * 2$$

2.21 Get SLV VVT Electric Diagnosis Result - Requirements to Infrastructure

</table>

FUNCTION DESCRIPTION:

General information:

This Action returns the result of the electric diagnosis of the VVT solenoid control valve power stage dedicated to the camshaft given by the parameter Vvt.

- The device readout is performed autonomous by the Infrastructure each 10 ms.
- The error informations are gathered in the Infrastructure (or-ed symptom, camshaft specific) until the Application reads out the information by calling ACTION_INFR_GetElDiagSlvVvt().
- After having read out the information by calling ACTION_INFR_GetElDiagSlvVvt(), the data inside the Infrastructure are reset. Resetting of Cdn_Diag avoids unambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagSlvVvt(): Reset Cdn_Diag indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_INFR_GetElDiagSlvVvt:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Vvt	1	1	1		Return parameters Err_Diag and Cdn_Diag

					belonging to electrical diagnosis of related camshaft: VVT_IN_1, VVT_IN_2, VVT_EX_1, VVT_EX_2
Cdn_Diag	-	-	<bit coded>	Err_Diag	Diagnosis condition for each symptom **Bit 0:** diagnosis condition for symptom SCP (SYM_0) **Bit 1:** diagnosis condition for symptom SCG (SYM_1) **Bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled.
Err_Diag	-	-	<bit coded>	Cdn_Diag	Bit coded result of each symptom (SYM_0=SCP, SYM_1=SCG, SYM_2=OC) **0H** = NO_SYM **1H** = SYM_0 **2H** = SYM_1 **4H** = SYM_2 The relevant bit is set, if the error has beed detected.

Diagnosis: ACTION_INFR_GetElDiagSlvVvt() returns the electric diagnosis

Coincidence requirements: No coincidence requirements to other events

2.22 Acquisition of Oil Temperature

2.22.1 Basic Software

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TOIL_MES	V/O	0...C8H	-40...160	1	°C
Oil temperature signal measured value					
V_TOIL	V/O	0...FFH	0...4.9805	5 / 256	Volt
Oil temperature voltage raw value (8 bits).					

Input data:

TOIL_BAS			

FUNCTION DESCRIPTION:

General information:

This function is applicable with a NTC type of sensor.

The raw value of the oil temperature (TOIL_BAS) is measured by continuous conversion (10 bits) every 1 msec.

The value of the numeric conversion is adapted to take into account of the electronic component drift. The result of this adaptation must be linearized according to the temperature sensor response.

The corresponding value of the first measurement after hardware reset is used for initialization.

Formula section:

The voltage from the oil temperature sensor is converted to the measured oil temperature TOIL_MES using the map IP_TOIL__V_TOIL.

V_TOIL ← TOIL_BAS / 4 (8 bits)

TOIL_MES = IP_TOIL__V_TOIL

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_TOIL__V_TOIL	16	0...C8H	-40...160	1	°C
LDP_V_TOIL__IP_TOIL	16	0...3FFH	0...5	0,0049	V

Voltage of pedal value sensor 2					

Input data:

V_PVS_1_BAS	V_PVS_2_BAS		

FUNCTION DESCRIPTION:

General information:

The Signal Acquisition and Conversion is done in the Basic Software.

A Filtering to reduce noise is done in the Application Software, refer to the Subchapter "PVS Variables" in the Chapter "System Variables".

Application conditions:

Activation: allways

Deactivation: -

Initialisation: at reset

V_PVS_1 = V_PVS_1_BAS

V_PVS_2 = V_PVS_2_BAS

Update Rate: 10 ms

Formula section:

V_PVS_1 = V_PVS_1_BAS

V_PVS_2 = V_PVS_2_BAS

2.24 INSY Requirements Infrastructure Interface

Overview

Those actions read out the dedicated digitalized voltages.

The sensor values retrieved by the actions have to be valid at reset.

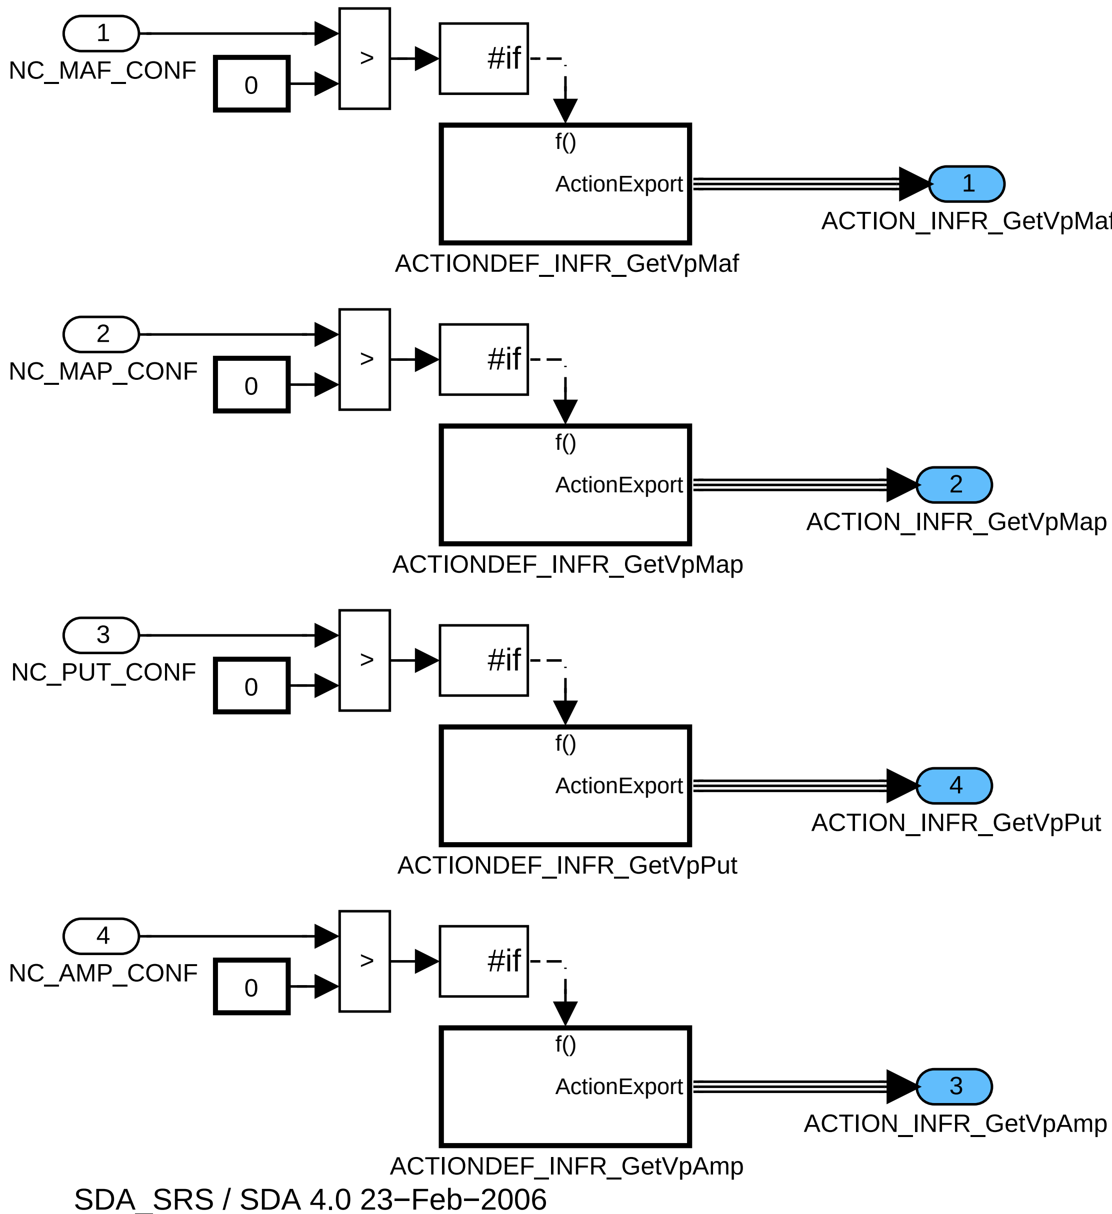

Figure 1 INSY_IFINF0

Input data:

NC_MAF_CONF	NC_MAP_CONF	NC_PUT_CONF	NC_AMP_CONF

Export actions:

ACTION_INFR_GetVpAmp(OUT <VP_AMP>)
This action returns the digitalized voltage of ambient pressure data acquisition.
ACTION_INFR_GetVpMaf(OUT <VP_MAF>)
This action returns the digitalized voltage of mass air flow data acquisition.
ACTION_INFR_GetVpMap(OUT <VP_MAP>)
This action returns the digitalized voltage of manifold air pressure data acquisition.
ACTION_INFR_GetVpPut(OUT <VP_PUT>)
This action returns the digitalized voltage of pressure upstream throttle data acquisition.

Description for Actions

ACTION_INFR_GetVpAmp(OUT <VP_AMP>)

This action returns the digitalized voltage of ambient pressure data acquisition. The digitalization is done autonomous by the Infrastructure.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
VP_AMP	OUT	0...7FFFH	0...4.999847	1.52588 E-4	V
This parameter returns the digitalized voltage					

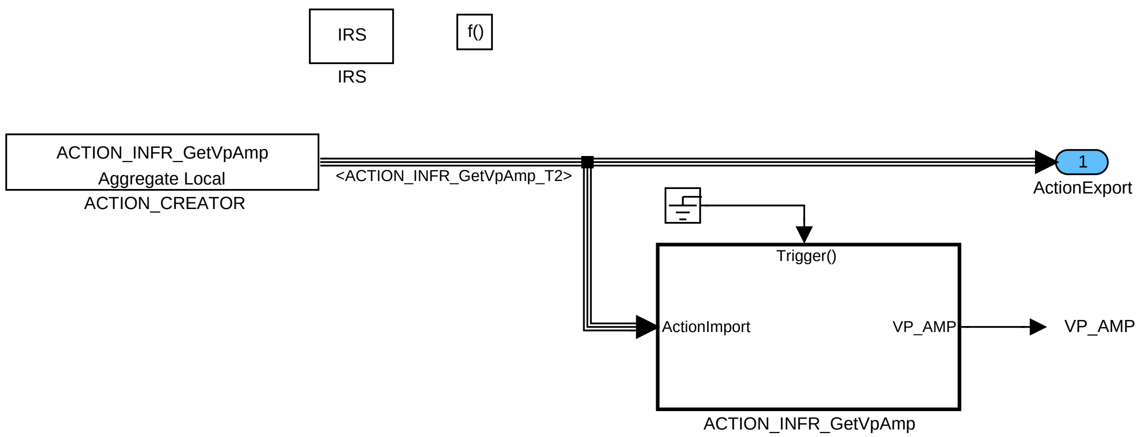

Figure 2 INSY_IFINF0/ ACTIONDEF_INFR_GetVpAmp

ACTION_INFR_GetVpMaf(OUT <VP_MAF>)

This action returns the digitalized voltage of mass air flow data acquisition. The digitalization is done autonomous by the Infrastructure.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
VP_MAF	OUT	0...7FFFH	0...4.999847	1.52588 E-4	V
This parameter returns the digitalized voltage					

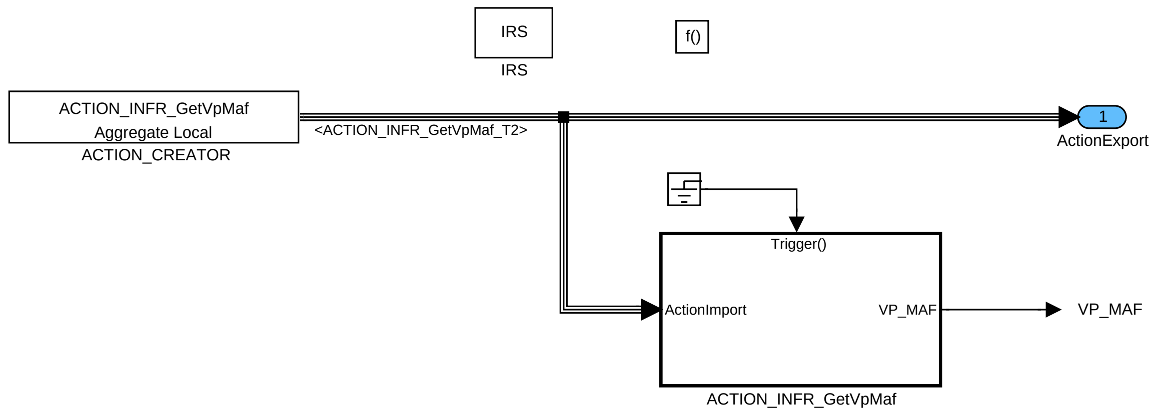

Figure 3 INSY_IFINF0/ ACTIONDEF_INFR_GetVpMaf

ACTION_INFR_GetVpMap(OUT <VP_MAP>)					
This action returns the digitalized voltage of manifold air pressure data acquisition. The digitalization is done autonomous by the Infrastructure.					
Parameter	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
VP_MAP	OUT	0...7FFFH	0...4.999847	1.52588 E-4	V
This parameter returns the digitalized voltage					

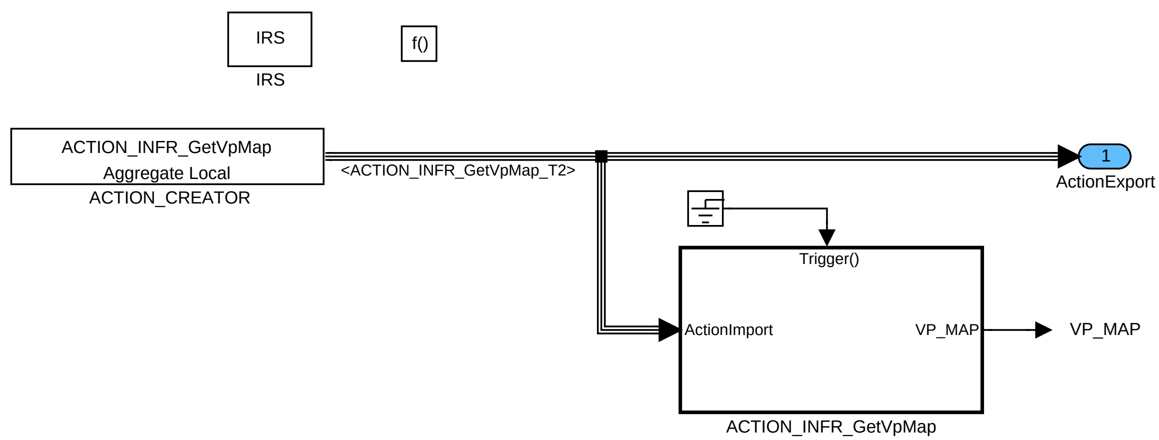

Figure 4 INSY_IFINF0/ ACTIONDEF_INFR_GetVpMap

ACTION_INFR_GetVpPut(OUT <VP_PUT>)					
This action returns the digitalized voltage of pressure upstream throttle data acquisition. The digitalization is done autonomous by the Infrastructure.					
Parameter	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
VP_PUT	OUT	0...7FFFH	0...4.99984741	1.52588 E-4	V
This parameter returns the digitalized voltage					

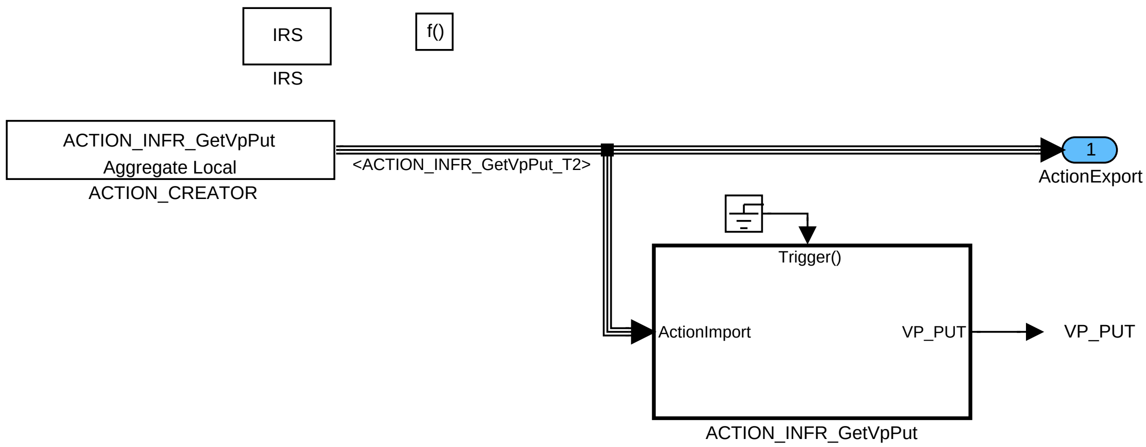

Figure 5 INSY_IFINF0/ ACTIONDEF_INFR_GetVpPut

Function Description

2.24.1 Requirements for ACTION_INFR_GetVpMaf:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
VP_MAF		< 1% of reference supply voltage for sensor	ADC: 10 bit value: 15 bit	Not relevant	VP_MAF is converted into a MAF signal. To receive a certain absolute MAF precision, the given precision of VP_MAF is needed.

Diagnosis: A diagnosis is performed based on the returned signal elsewhere

Coincidence requirements: The sensor value retrieved by the action has to be valid at reset.

When calling the Action, the returned voltage is not older than 1ms.

2.24.2 Requirements for ACTION_INFR_GetVpMap:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
VP_MAP		< 1% of reference supply voltage for sensor	ADC: 10 bit value: 15 bit	Not relevant	VP_MAP is converted into a MAP signal. To receive a certain absolute MAP precision, the given precision of VP_MAP is needed.

Diagnosis: A diagnosis is performed based on the returned signal elsewhere

Coincidence requirements: The sensor value retrieved by the action has to be valid at reset.

When calling the Action, the returned voltage is not older than 1ms.

2.24.3 Requirements for ACTION_INFR_GetVpPut:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
VP_PUT		< 1% of reference supply voltage for sensor	ADC: 10 bit value: 15 bit	Not relevant	VP_PUT is converted into a PUT signal. To receive a certain absolute PUT precision, the given precision of VP_PUT is needed.

Diagnosis: A diagnosis is performed based on the returned signal elsewhere

Coincidence requirements: The sensor value retrieved by the action has to be valid at reset.

When calling the Action, the returned voltage is not older than 1ms.

2.24.4 Requirements for ACTION_INFR_GetVpAmp:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
VP_AMP		< 1% of reference supply voltage for sensor	ADC: 10 bit value: 15 bit	Not relevant	VP_AMP is converted into a AMP signal. To receive a certain absolute AMP precision, the given precision of VP_AMP is needed.

Diagnosis: A diagnosis is performed based on the returned signal elsewhere

Coincidence requirements: The sensor value retrieved by the action has to be valid at reset.

When calling the Action, the returned voltage is not older than 100ms.

2.25 Acquisition of sensor voltages within INSY

Overview

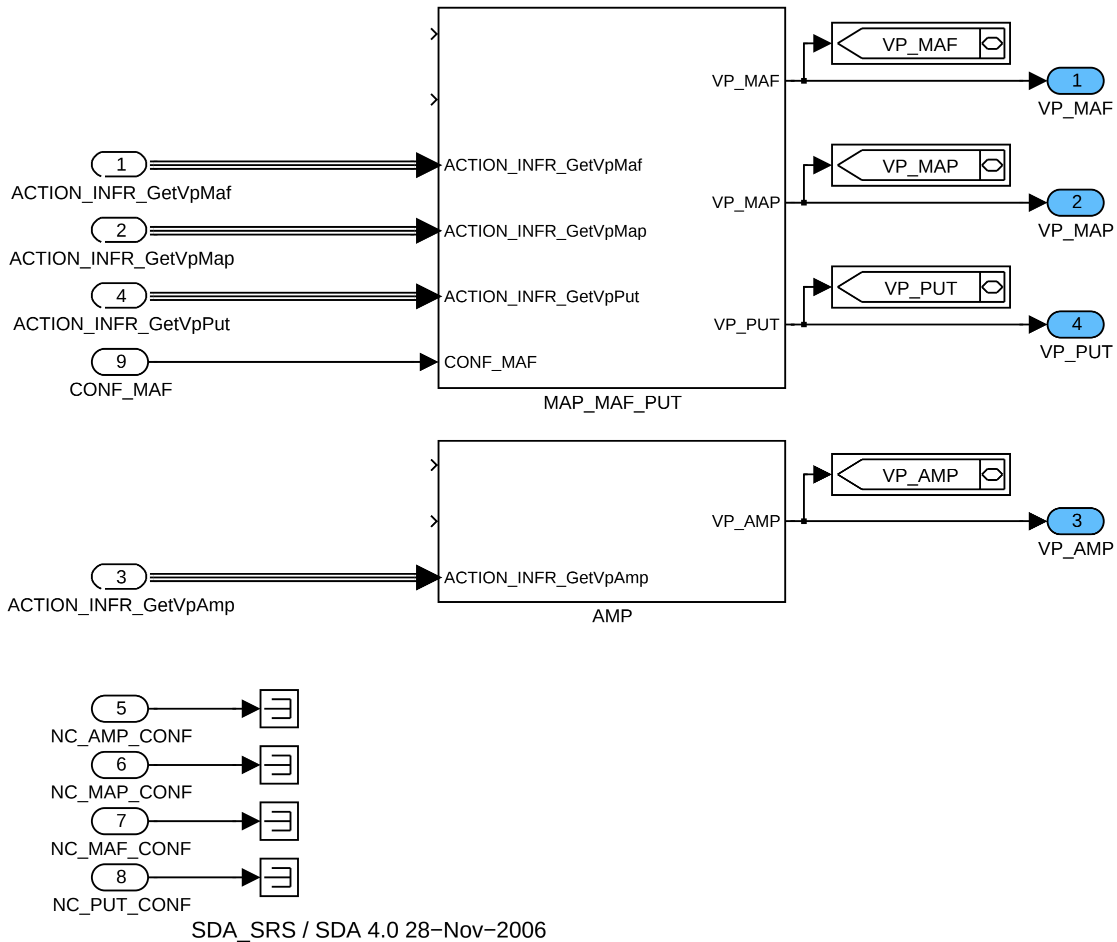

Figure 6 INSY_SIGCVSENS0

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VP_MAF	O/V	0...7FFFH	0...4.99984741	1.52588E-4	V
Mass air flow sensor raw acquisition.					
VP_MAP	O/V	0...7FFFH	0...4.99984741	1.52588E-4	V
Voltage of the intake manifold pressure sensor (for diagnosis)					
VP_AMP	O/V	0...7FFFH	0...4.99984741	1.52588E-4	V
measured sensor voltage at ECU input pin for AMP					
VP_PUT	O/V	0...7FFFH	0...4.99984741	1.52588E-4	V
Pressure upstream throttle sensor voltage					

Input data:

NC_AMP_CONF	NC_MAP_CONF	NC_MAF_CONF	NC_PUT_CONF
CONF_MAF			

Import actions:

ACTION_INFR_GetVpAmp(OUT <VP_AMP>)
This action returns the digitalized voltage of ambient pressure data acquisition
ACTION_INFR_GetVpMaf(OUT <VP_MAF>)
This action returns the digitalized voltage of mass air flow data acquisition
ACTION_INFR_GetVpMap(OUT <VP_MAP>)
This action returns the digitalized voltage of manifold air pressure data acquisition
ACTION_INFR_GetVpPut(OUT <VP_PUT>)
This action returns the digitalized voltage of pressure upstream throttle data acquisition

2.25.1 Mass air flow, Manifold air pressure and Pressure upstream throttle raw acquisitions

The purpose of this module is to make a first level of filtering of raw acquisition mass air flow and / or raw acquisition of manifold air pressure and / or raw acquisition of pressure upstream throttle.

Function Description

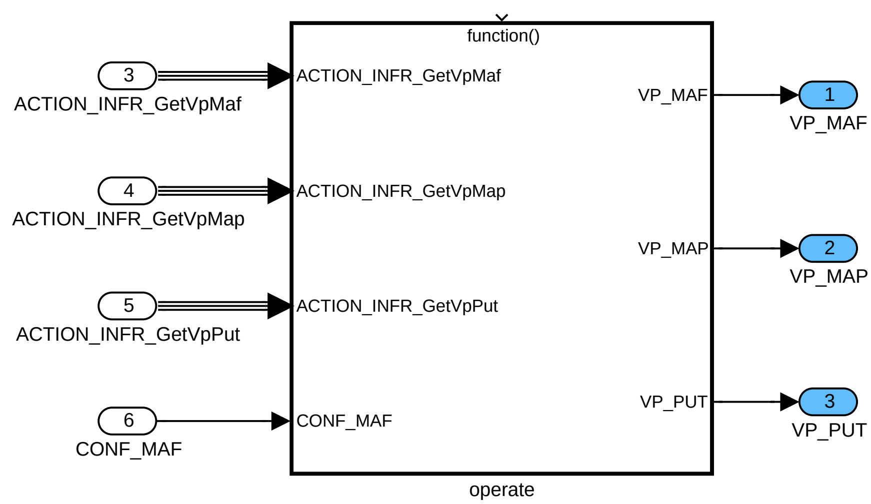

Figure 7 INSY_SIGCVSENS0/ MAP_MAF_PUT

2.25.1.1 Initialization at reset and operate_1ms:

Filtering of raw values is done in infrastructure. The values are returned by the action ACTION_INFR_GetVpMaf, ACTION_INFR_GetVpMap and ACTION_INFR_GetVpPut.

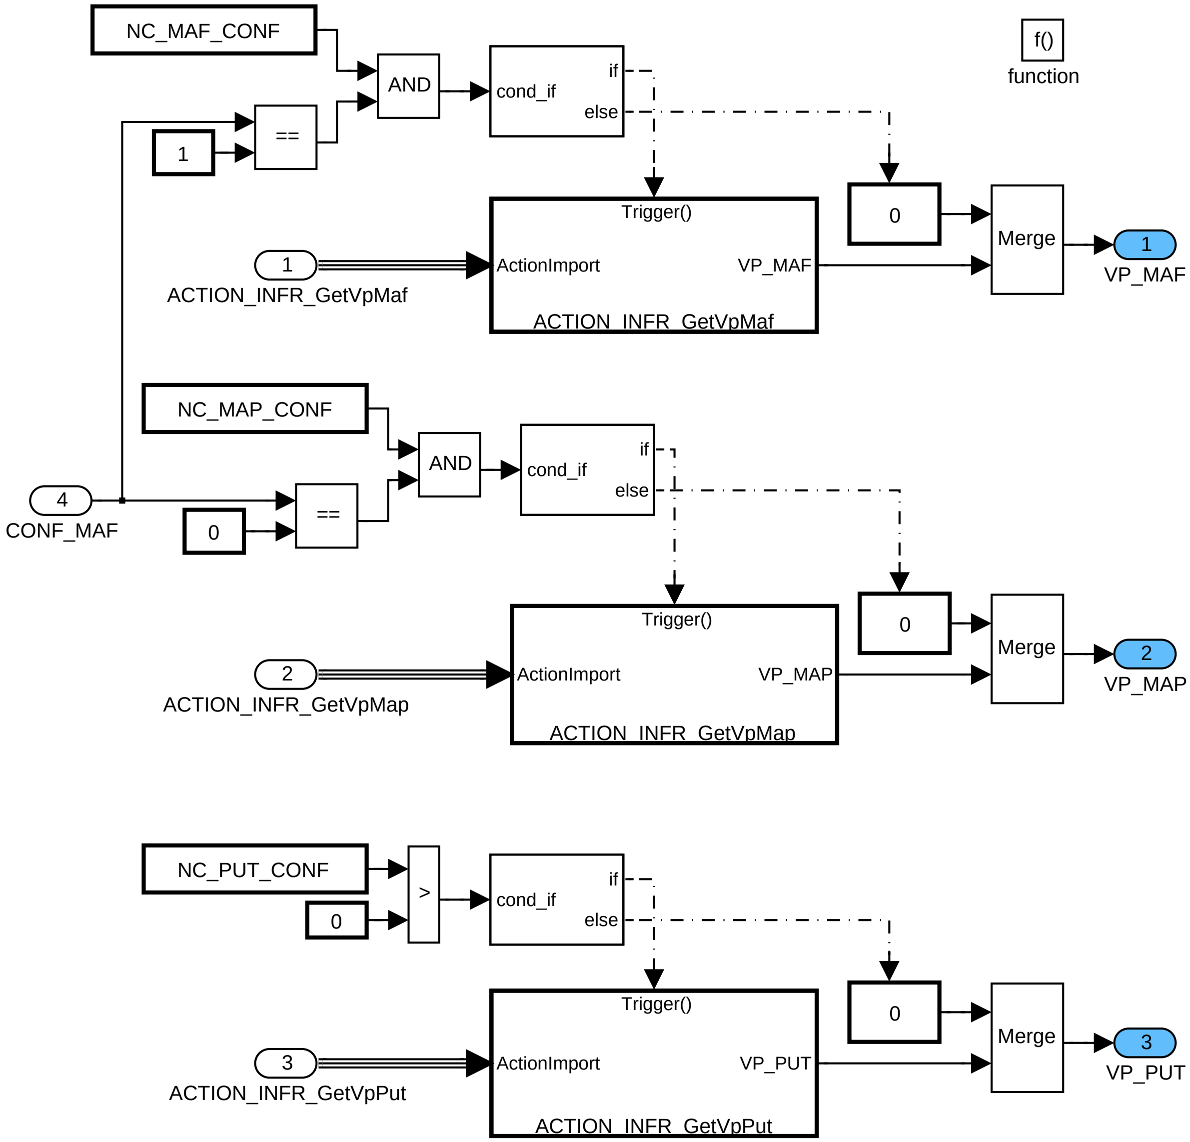

Figure 8 INSY_SIGCVSENS0/ MAP_MAF_PUT/ operate

2.25.2 Ambient pressure raw acquisition

The purpose of this module is to make a first level of filtering of raw acquisition of ambient pressure.

Function Description

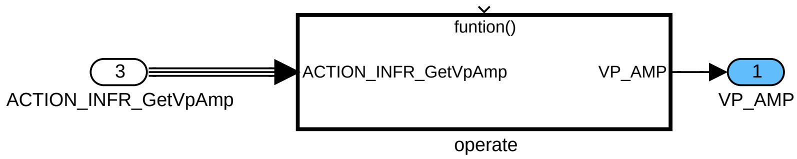

Figure 9 INSY_SIGCVSENS0/ AMP

2.25.2.1 Initialization at reset and operate_100ms:

Filtering of raw values is done in infrastructure. The value is returned by the action ACTION_INFR_GetVpAmp.

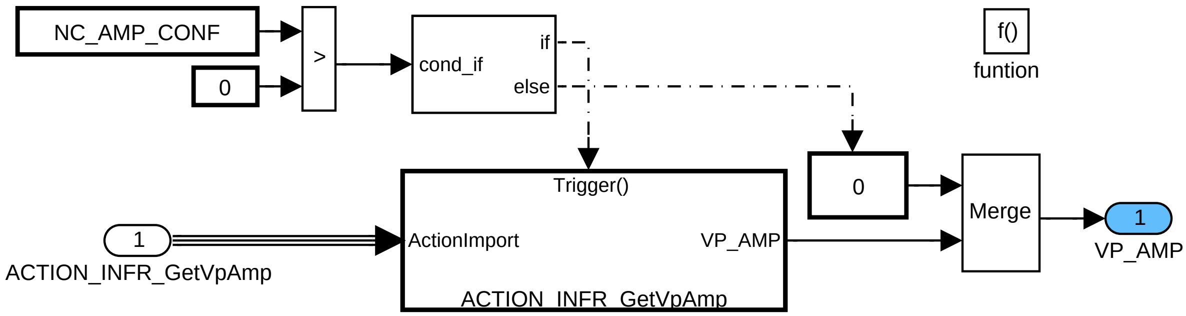

Figure 10 INSY_SIGCVSENS0/ AMP/ operate

2.26 THRO - Requirements for infrastructur (ETC)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_TPS_1_BAS	V/O	0h ... 3FFh	0 ... 4.9951	0.0049	V
Raw value throttle position sensor 1 (not amplified)					
V_TPS_GAIN_1	V/O	0h ... 3FFh	0 ... 4.9951	0.0049	V
Dummy value for throttle position sensor 1 (amplified)					
V_TPS_2_BAS	V/O	0h ... 3FFh	0 ... 4.9951	0.0049	V
Raw value throttle position sensor 2 (not amplified)					

Input data:

MTCPWM	LV_PRDR_ACT		

FUNCTION DESCRIPTION:

General information:

This module describes the interfaces to the basic software (BSW) and the time behaviour between throttle position signal aquisition, digital position controller calculation and the PWM output generation (power stage).

2.26.1 Throttle position signal aquisition

Description:

The two throttle position sensor signals are determined every millisecond. V_TPS_1_BAS and V_TPS_2_BAS are converted in the standard queue.

Name	Aquisition recurrence	Acquisition precision	Notes
V_TPS_1_BAS	1 ms	10 bit	Raw value of TPS 1
V_TPS_2_BAS	1 ms	10 bit	Raw value of TPS 2

Application conditions:

Initialisation: *at reset:*

V_TPS_x_BAS = 0 V

V_TPS_GAIN_1 = 5 V *{ Is intialisied but isn't determined in DC ! }*

Recurrence: 1 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

Raw signal processing: -

2.26.2 PWM output generation

Description:

The power at the H–bridge outputs is managed by a PWM signal and the current direction is adjusted by a direction request (a second power stage input pin) with a update rate of 2 ms.

Name	Frequency (Hz)	Updating of duty cycle	Range of duty cycle	Init.	Notes
MTCPWM	1000	2 ms	-100 % ... 99.997 %	0 %	Output position controller

Application conditions:

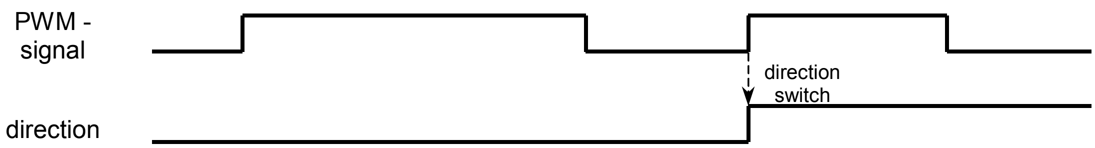
Initialisation: *at reset inactive, currentless*

Recurrence: 2 ms

Activation: at every engine operating state

Deactivation: -

Note: The direction of the H-bridge can be inverted only synchronised to the PWM:



2.26.3 Time behaviour

General information:

This chapter describes the time behaviour between throttle position signal aquisition, digital position controller calculation and the PWM output generation (power stage).
The aim is to synchronise the TPS aquisition with the controller calculation and the PWM output generation for minimal time delay.

Description:

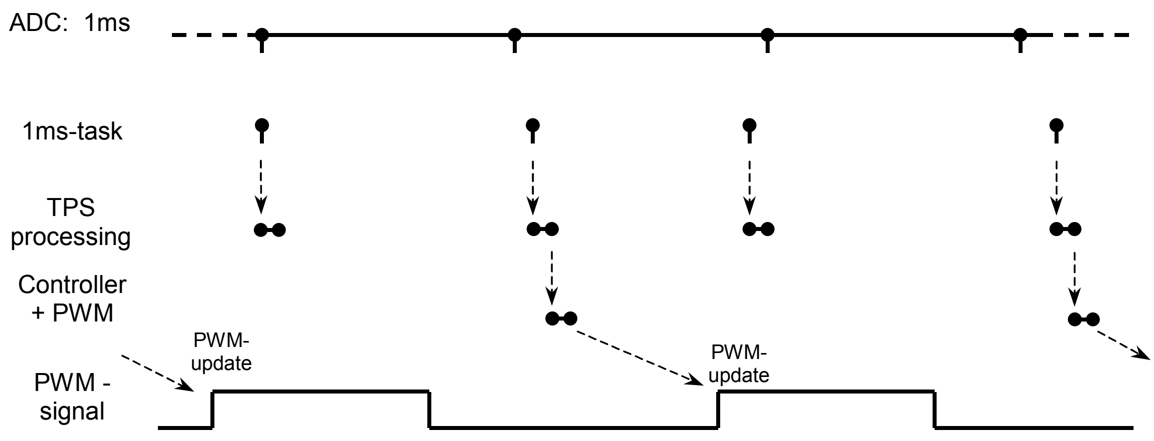
The TPS signal determination and the digital position controller are calculated in the 1 ms ASW task. The AD conversion process (after every ms) and the PWM generation are executed asynchronously to the 1 ms ASW task. The maximum time delay between AD conversion and PWM generation depend on time jitter between:

- AD conversion and TPS signal determination ($0 \leq T_1 \leq 1$ ms)
- Position controller calculation and PWM update ($0 \leq T_2 \leq 1$ / frequency)

The maximum time delay is the summation of T_1 and T_2 !

($0 \leq T_{delay} \leq 3$ ms for a frequency of 500 Hz, $0 \leq T_{delay} \leq 2$ ms for a frequency of 1000 Hz)

Signal flow diagram:



2.26.4 Power stage activation

General information:

The ETC power stage is equipped with two disable lines to switch-on or off. Disable line one is connected with the main controller and disable line two with the monitoring unit, both processor units are able to switch-off the power stage. (To the activation of the power stage both disable lines have to be enable.)

Description:

The BSW provides a rountine to switch on or off the power stage via disable line.

Application conditions:

Initialisation: *at reset:*

{ Consider requirements of Monitoring Concept (Level 3 – PREDRIVE check) }

if LV_PRDR_ACT == 0

then *{ disable power stages }*

CALL BSW routine to disable H-bridge via disable line

else *{ enable power stages }*

CALL BSW routine to enable H-bridge via disable line

endif

Recurrence: -

Activation: *at every engine operating state*

Deactivation: -

2.26.5 Power stage error detection

General information:

The power stage (H – bridge IC) for electronical throttle control is equipped with internal diagnosis functions. The following errors can be indicated but can not be distinguished by the software per power stage status flag line.

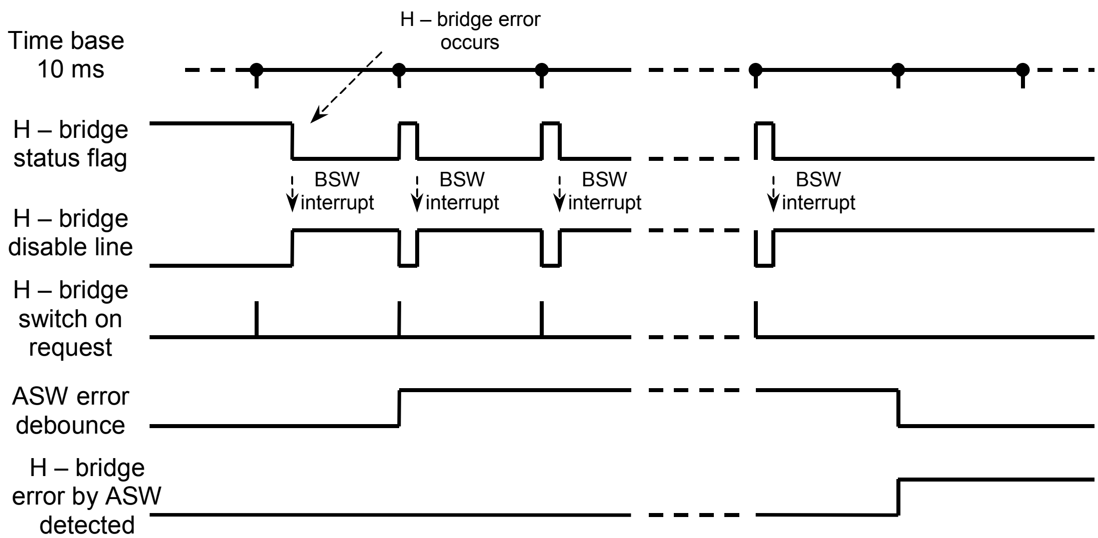
- Undervoltage / Overcurrent / Overtemperature / H-bridge hardware disable

Description:

The following error detection are done by BSW and ASW if an error occurs. In the case of errors, the status flag line of the power stage changes his logical level and triggers an BSW interrupt. The interrupt set a mark for the ASW “ power stage diagnosis “ and switch-off the power stage. The ASW reads and resets the mark, starts the error debounce and switch-on the power stage. The error detection is started newly.

After the error debounce, an error is set and the power stage is switched off by the ASW. The respective ASW functions are executed in a time base of 10 ms.

Signal flow diagram:



2.27 ETC Monitoring ECM2 - Requirements to BSW

2.27.1 Requirements concerning ‘Monitoring of engine speed using a software timer’

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_SEG_SW	O	0 ... FFFFFFFFH	0 ... 2.6844e8	1	µs
segment time determined by means of a software timer					

FUNCTION DESCRIPTION:

General information:

The segment time T_SEG_SW is generated by a software timer solution in the BSW. The software timer is triggered by crankshaft segments and produces time stamps for the trigger events. The maximum delay between event and time stamp must be less than 300 µs (split into an invariable part of 50 µs and a variable part of 250µs). From the time stamps the signal T_SEG_SW is determined; its resolution is 1 µs.

The segment time T_SEG_SW is necessary to generate an engine speed signal that is independent from N_32 (generated from T_SEG). It is used in the module ‚Monitoring of engine speed using a software timer‘ of the aggregate ECM2.

Note: Since for the event <Engine Stop> the engine speed N_32 is set to zero in the function level (and T_SEG is set to its maximum value, respectively), the segment time T_SEG_SW has to be set to its maximum value for <Engine Stop> as well. However, this action must not be triggered using the variable LV_ES=0, but must be initialized by the BSW trigger that is set when the BSW is recognizing the event <Engine Stop>.

Application conditions:

Initialisation: max. value

at 1. initialization after <Power On> and

at transition BSW event <Engine Running> ⇒ <Engine Stop>

Recurrence: segment - synchronous

Activation: during every engine state

Deactivation: -

2.27.2 Requirements for pedal value signals and throttle position sensor signals

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_PVS_1_BAS	O	0...3FFH	0 ... 4.995117	0.004888	V
Voltage PVS channel 1					
V_PVS_2_BAS	O	0...3FFH	0 ... 4.995117	0.004888	V
Voltage PVS channel 2					
V_TPS_1_BAS	O	0...3FFH	0 ... 4.995117	0.004888	V
Voltage TPS channel 1					
V_TPS_2_BAS	O	0...3FFH	0 ... 4.995117	0.004888	V
Voltage TPS channel 2					

FUNCTION DESCRIPTION:

General information:

The pedal value signals, channel 1 and 2, as well as the throttle position signals, channel 1 and 2, are monitored in the *Process Monitoring*, see "Monitoring of pedal value signals" and "Monitoring or mass air flow signals". The according modules are running with a recurrence of 40ms, see "Process Monitoring". To define the scope of the *Process Monitoring* as wide as possible, the voltages should be a direct output of the ADCs.

Note: Here only the requirements regarding the *Process Monitoring* are given. No functional aspects of the functionalities primarily processing these signals are listed here. Therefore especially the recurrence may occure with a higher frequency, but the range and resolution have to be the same.

Application conditions:

Recurrence: 40ms

Activation: for conditions see 'Application Incidences and configuration of Process Monitoring'

2.28 Exhaust gas composition – Requirements to I/O BSW

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VLS_UP_RAW[NC_CBK_EX_NR]	O/V	0...3FFH	0...4.995	0.0049	Volt
Raw value of upstream m oxygen sensor voltage					
VLS_DOWN[NC_CBK_EX_NR]	O/V	0...3FFH	0...4.995	0.0049	Volt
Downstream oxygen sensor voltage					
LV_LSH_SCP_LSH_UP[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					
LV_LSH_SCG_LSH_UP[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					
LV_LSH_OC_LSH_UP[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					
LV_LSH_SCP_LSH_DOWN[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					
LV_LSH_SCG_LSH_DOWN[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					
LV_LSH_OC_LSH_DOWN[NC_CBK_EX_NR]	O	0...1H	0...1	1	-
Logical value for Hardware-based LSH error detection					

Input data:

NC_CBK_EX_NR	LV_R_IT_REQ_LS_UP[NC_CBK_EX_NR]	LV_R_IT_REQ_LS_DOWN[NC_CBK_EX_NR]	NC_STATE_VLS_UP_SIG_ACQ
NC_STATE_LSL_UP_IF			

FUNCTION DESCRIPTION:

General information:

Name	Acquisition recurrence	Acquisition precision	Notes
VLS_UP_RAW[i]	10ms	10bit	NC_STATE_VLS_UP_SIG_ACQ = 0
	1ms	10bit	NC_STATE_VLS_UP_SIG_ACQ = 1
VLS_DOWN[i]	10ms	10bit	-

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

If the lambda sensor signal shall be filtered prior to further processing NC_STATE_VLS_UP_SIG_ACQ has to be set to 1, otherwise to 0.

Description:

Voltages of lambda sensors offered by Basic SW are transformed to application system specific variables.

The error detection is effected via the ECU hardware.
Error informations are gathered (or-ed symptom specific) until read out by the application software ASW.

At the moment when ASW is reading data from I/O software, the I/O software data will be reset. (It is possibel to have more than one electrical failure symtom reported to ASW.)

The variables LV_LSH_SCP/SCG/OC_LSH_UP/DOWN[i] are set to one (valid) if new diagnosis data from hardware are available.

If more than one error symptom is detected during the readout period, the priority of the errors reported is:

4. short cut to battery (scp)
5. short cut to ground (scg)
6. open curcuit (ol)

⇒ SCP will shut off the device and the error will be kept by the device until a "off-slope" occurs.

⇒ SCG, OL: read out of the device erases error status and the device is not shut off.

Application conditions:

Activation:	at every engine operating state	
Deactivation:	-	
Update rate:		
VLS_UP_RAW[i]:	10 ms for NC_STATE_VLS_UP_SIG_ACQ = 0	
	1 ms for NC_STATE_VLS_UP_SIG_ACQ = 1	
VLS_DOWN[i] :	10 ms	
Initialization:	at reset:	VLS_UP_RAW[i] = 0
		VLS_DOWN[i]= 0

Formula section:

 # If NC_STATE_LSL_UP_IF = 0 *% Masking shall only be done for binary sensor*
 # then **If** LV_R_IT_REQ_LS_UP[i] = 0
then *acquire* VLS_UP_RAW[i]
else $VLS\_UP\_RAW[i]_N = VLS\_UP\_RAW[i]_{N-1}$
endif
 # else *acquire* VLS_UP_RAW[i]
 # endif

If LV_R_IT_REQ_LS_DOWN[i] = 0

then *acquire* VLS_DOWN[i]

else $VLS\_DOWN[i]_{N} = VLS\_DOWN[i]_{N-1}$

endif

2.29 ENTE – Requirements to infrastructure interface

Input data:

NC_NR_TCO_SENS			

Export actions:

ACTION_INFR_GetVpTco (OUT <>)
This action provides the digitized voltage value of the available coolant temperature sensors in an array.

Description for actions:

ACTION_INFR_GetVpTco (OUT <>)					
This action provides the digitized voltage value of the available coolant temperature sensors in an array delivered from the infrastructure. The AD conversion is performed autonomously by the infrastructure. When the action is called the gathered information will be provided to the application software level. The dimension of the parameter *Vp_tco_sens* is given by configuration input NC_NR_TCO_SENS. The index range is 0 … NC_NR_TCO_SENS-1.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Vp_tco_sens [NC_NR_TCO_SENS]	OUT	0...7FFFH	0...4.999847412	1.53E-04	V
Coolant temperature sensor voltage value					

FUNCTION DESCRIPTION:

General information:

The following action is used for the acquisition of the digitized voltage value of the adressed coolant temperature sensor in an array. The action delivers the coolant temperature sensor voltage value to the application software level from the standard AD converter queue.

- NC_NR_TCO_SENS is valid from 1...255.

  The voltage belonging to the first sensor is returned in Vp_tco_sens[0].

  The voltage belonging to the *n* sensor is returned in Vp_tco_sens[n-1].
- The AD conversion is performed autonomously by the infrastructure, the returned value is not older than 10 ms.
- The voltage value is gathered in the infrastructure until the application reads out the information by calling the action, old values are replaced by new values.

Requirements for ACTION_INFR_GetVpTco:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Vp_tco_sens [NC_NR_TCO_SENS]			10 Bit	The following coinicidence requirement has to be fulfilled in case of NC_NR_TCO_SENS > 1: Vp_tco_sens[k] is digitized at point in time t_k. For the returned array the maximum allowed time periode $\| t_k - t_i \|$ must less than 10ms.	No comment

Diagnosis: no electrical diagnosis done here

Coincidence requirements: When calling this action, all returned voltages must be within the last 100 ms.

2.30 ENSD - Requirements to infrastructure interface

Export actions:

ACTION_ENSD_GetDigCAMINLevel (OUT <STATE_CAM_IN>)
This action reads whether the intake camshaft signal is high or low
ACTION_ENSD_GetDigCAMEXLevel (OUT <STATE_CAM_EX>)
This action reads whether the exhaust camshaft signal is high or low

FUNCTION DESCRIPTION:

General information:

The minimum and maximum engine positions are determined according to the actual possible camshaft signal edge indexes found by the camshaft signal acquisition for crankshaft synchronisation. In the presence of both intake and exhaust camshaft signals the engine position is known with better precision. This is done by initialising the minimum and maximum engine positions based on the combinations of the intake and exhaust camshaft signals. And for this the state of the camshaft signals (HIGH or LOW) are required.

Activation: CONF_CAM_VVT_EX = 1

Deactivation: LV_CRK_SYN = 1

Description for actions:

ACTION_ENSD_GetDigCAMINLevel (OUT<STATE_CAM_IN>)					
This action reads whether the intake camshaft signal is high or low					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
STATE_CAM_IN	OUT	0H 1H	LOW HIGH	1	-
State variable indicating intake camshaft signal is high or low					
ACTION_ENSD_GetDigCAMEXLevel (OUT <STATE_CAM_EX>)					
This action reads whether the exhaust camshaft signal is high or low					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
STATE_CAM_EX	OUT	0H 1H	LOW HIGH	1	-
State variable indicating exhaust camshaft signal is high or low					

2.30.1 Detailed description for Action: ACTION_ENSD_GetDigCAMINLevel

Requirements for ACTION_ENSD_GetDigCAMINLevel:

Data acquisition					
Parameter	Absolute precision	Relaitve precision	Resolution	Coincidence with parameter	Comment
STATE_CAM_IN	Not relevant	Not relevant	1	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here
Coincidence requirements: Every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

2.30.2 Detailed description for Action: ACTION_ENSD_GetDigCAMEXLevel

Requirements for ACTION_ENSD_GetDigCAMEXLevel:

Data acquisition					
Parameter	Absolute precision	Relaitve precision	Resolution	Coincidence with parameter	Comment
STATE_CAM_EX	Not relevant	Not relevant	1	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here
Coincidence requirements: Every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

2.31 ENSS - Requirements to infrastructure interface

Output data:

Input data:

Export actions:

ACTION_INFR_EONVStartTimer ( )
Start the timer of the PIC
ACTION_INFR_EONVStopTimer ( )
Stop the timer of the PIC
ACTION_INFR_EONVResetTimer ( )
Reset the basic timer of the PIC
ACTION_INFR_EONVWarmReset ( )
Reset PIC micro controller
ACTION_INFR_EONVCompleteReset( )
Reset PIC micro controller and clear all data
ACTION_INFR_EONVReadTimer (IN<Lv_cmd>**, OUT<**T_es> **)**
Engine Off timer is read in from PIC

FUNCTION DESCRIPTION:

General information:

The Engine off timer function is deployed to two separate processors – the main microcontroller and an external 8-bit microcontroller. The two controllers are linked via a dedicated SPI (serial peripheral interface) bus.

Within the main microcontroller, the BIOS driver EMUSPI (emulated SPI) is used to control communication with the 8-bit microcontroller. Consult the specification "BIOS SW Specification EMUSPI" (bemuspi.doc), which is maintained by the software team, for more information. The application software interfaces with the IO software through the TRL (transformation layer) via the TRL EMUSPI interface. Consult the specification "TRL SW Specification EMUSPI" (temuspi.doc), which is also maintained by the software team, for more information.

Description:

The raw engine off duration, t_es, is produced from a basic timer that is capable of running while the main CPU is powered-off. The basic timer is deployed on the external 8-bit microcontroller and can be started, stopped, and reset upon request from the application.

Application conditions:

Recurrence: Upon request.

Activation: Upon request.

Deactivation: Upon request

Description for actions:

The general mechanism for reading values is to invoke an interface to read the values from the external microcontroller into the EMUSPI shift register, and then invoke another interface to read the values from the EMUSPI shift register into the variable. These interfaces are called upon request from the application software; however, the timing constraints given in the specifications (bemuspi.doc and temuspi.doc) must be respected.

--- Interfaces involved in getting data ---
Note: * Interface need to be called two times consecutively with Lv_cmd = 0 and Lv_cmd =1, respectively. Minimum recurrence of these consecutive calls is 5ms. Any other interfaces must not be called between these two calls.

ACTION_INFR_EONVStartTimer ( )
This action start the basic timer inside PIC

ACTION_INFR_EONVStopTimer ( )
This action stop the basic timer inside PIC

ACTION_INFR_EONVResetTimer ( )
Reset the basic timer

ACTION_INFR_EONVWarmReset ( )
Reset PIC controller

ACTION_INFR_EONVCompleteReset( )
Reset the PIC controller and all data are clear

***ACTION_INFR_EONVReadTimer (** Lv_cmd**,** T_es**)**					
The engine of timer is read in over the PIC controller					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Lv_cmd	IN	0..1H	0..1	1	-
T_es	OUT	0...FFFFFFH	0...16777216	1	sec

Information for ACTION_INFR_EONV_ReadTimer:

T_es = Data shifted right by 8

Diagnosis: no diagnosis

2.32 AIRT Temperature Sensor(s): Infrastructure Requirement

Overview

FUNCTION DESCRIPTION:

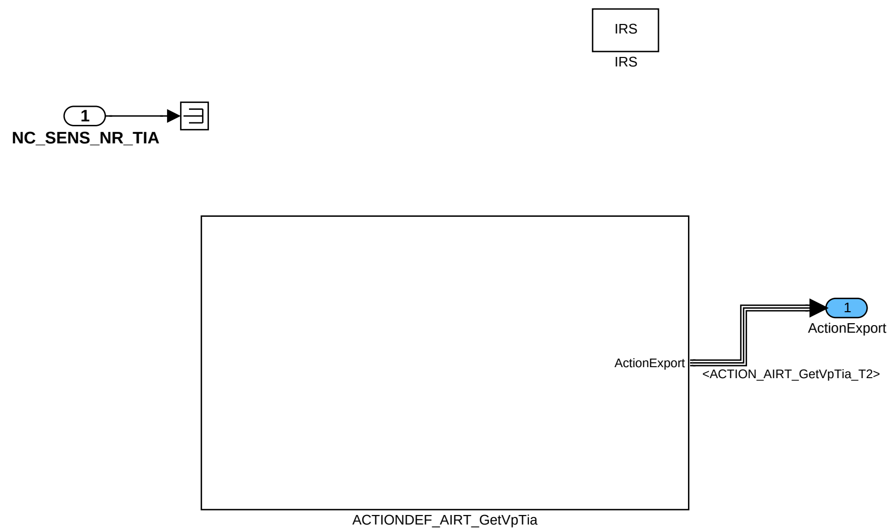
The sensor value retrieved by the action has to be valid at reset

This function is applicable with a NTC type sensor.

The data of the ACTION call have the following meaning.

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
CtrTiaSens	**1**			**VpTia is the digitalised voltage of the sensor with the index CtrTiaSens**	
VpTia	**Not relevant**	**< 1% of reference supply voltage for sensor**	**ADC: 10bit** **Value: 15bit**	**Recurrence 100ms**	

(*) Depending on the Project, one or several TIA sensors can be used. See Specification "**Air Temperature Sensor(s) Configuration - 30404X01"** where the Sensors Configuration is defined from NC_TIA_CONF value.



SDA_SRS / SDA 3.1 31−Mar−2004

Figure 11 AIRT_IFINF0

Input data:

NC_SENS_NR_TIA

Export actions:

ACTION_AIRT_GetVpTia(IN <CtrTiaSens>, OUT <VpTia>)
Action to read the sensor voltage of the different intake air temperature sensors (NC_SENS_NR_TIA sensors)

Description for Actions

ACTION_AIRT_GetVpTia(IN <CtrTiaSens>, OUT <VpTia>)

The input <CtrTiaSens> gives the basic software the information which of the NC_SENS_NR_TIA sensor has to be provided to the application software.
Action to read the sensor voltage of intake air temperature sensors (NC_SENS_NR_TIA sensors)

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
CtrTiaSens	IN	0...3H	1...4	1	-
Array index of TIA sensor					
VpTia	OUT	0...7FFFH	0...4.999847	1.52588 E-4	V
voltage of the intake air temperature sensor					

2.33 CHRG - Requirements to Infrastructure Interface

2.33.1 Analog inputs from hardware to ECU

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VP_N_TCHA	V/O	0...7FFFH	0... 4.999847	1.5259E-4	V
Turbo charger speed sensor raw signal					

FUNCTION DESCRIPTION:

General information:

Name	Acquisition recurrence	Acquisition precision	Initialization at ECU reset	Notes (Initialization with values which stand for a critical engine operation)
VP_N_TCHA	10 ms	10 bit	4.999847	

Diagnosis capabilities:

Electrical diagnosis will be done by using converted values within the Application.

Consistency requirements regarding AD convertion:

2.33.2 Get EL_RCL_ACR electrical diagonis result - Requirements to Infrastructure

Input data:

Export actions:

ACTION_INFR_GetElDiagEl_rcl_acr(OUT <Cdn_diag>, OUT<Err_diag>**)**
This action reads the failure and condition information for a symptom of the RCL_ACR power stage

Description for actions:

ACTION_INFR_GetElDiagEl_rcl_acr(OUT <Cdn_diag>, OUT<Err_diag>**)** This action reads the failure and condition information for a symptom of the RCL_ACR power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

Cdn_diag	OUT	0 ... 7H	0 ... 7	1	-
Diagnosis condition for symptom: Bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled Bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled Bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled					
Err_diag	OUT	0H 1H 2H 4H	NO_SYM SYM_0 SYM_1 SYM_2	1	-
Raw value of error symptom. The relevant bit is set, if the error has beed detected.					

FUNCTION DESCRIPTION:

General information:

This Action returns the result of the electrical diagnosis of the RCL_ACR power stage.

_ The device readout is performed autonomous by the Infrastructure each 10ms.
_ The error informations are gathered in the Infrastructure (or-ed symptom, cylinder specific) until the Application reads out the information by calling ACTION_INFR_GetElDiagEl_rcl_acr().
_ After having read out the information by calling ACTION_INFR_GetElDiagEl_rcl_acr(), the data inside the Infrastructure are reset. Resetting of *Cdn_diag* avoids unambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagEl_rcl_acr(): Reset *Cdn_diag* indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_AGGR_Command:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag	-	-	<bit coded>	Err_diag	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag	-	-	<bit coded>	Cdn_diag	Bitcoded result of each symptom (SYM_0=SCP, SYM_1=SCG, SYM_2=OC) **0h** = NO_SYM **1h** = SYM_0 **2h** = SYM_1 **4h** = SYM_2 The relevant bit is set, if the error has beed detected.

Diagnosis: ACTION_INFR_GetElDiagEl_rcl_acr returns the electric diagnosis

Coincidence requirements: no coincidence requirements to other events

2.33.3 Get WG electrical diagonis result - Requirements to Infrastructure

Input data:

Export actions:

ACTION_INFR_GetElDiagWg(OUT <Cdn_diag>, OUT<Err_diag>**)**
This action reads the failure and condition information for a symptom of the WG power stage

Description for actions:

ACTION_INFR_GetElDiagWg(OUT <Cdn_diag>, OUT<Err_diag>**)**					
This action reads the failure and condition information for a symptom of the WG power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cdn_diag	OUT	0 ... 7H	0 ... 7	1	-
Diagnosis condition for symptom: Bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled Bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled Bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled					
Err_diag	OUT	0H 1H 2H 4H	NO_SYM SYM_0 SYM_1 SYM_2	1	-
Raw value of error symptom. The relevant bit is set, if the error has beed detected.					

FUNCTION DESCRIPTION:

General information:

This Action returns the result of the electrical diagnosis of the wastegate (Wg) power stage.

_ The device readout is performed autonomous by the Infrastructure each 10ms.
_ The error informations are gathered in the Infrastructure (or-ed symptom, cylinder specific) until the Application reads out the information by calling ACTION_INFR_GetElDiagWg().
_ After having read out the information by calling ACTION_INFR_GetElDiagWg(), the data inside the Infrastructure are reset. Resetting of *Cdn_diag* avoids unambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagWg(): Reset *Cdn_diag* indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_AGGR_Command:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Cdn_diag	-	-	<bit coded>	Err_diag	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag	-	-	<bit coded>	Cdn_diag	Bitcoded result of each symptom (SYM_0=SCP, SYM_1=SCG, SYM_2=OC) **0h** = NO_SYM **1h** = SYM_0 **2h** = SYM_1 **4h** = SYM_2 The relevant bit is set, if the error has beed detected.

Diagnosis: ACTION_INFR_GetElDiagWg returns the electric diagnosis

Coincidence requirements: no coincidence requirements to other events

2.33.4 Digital Outputs from ECU to hardware

Output data:

Name	Frequency	Notes
#if NC_PSN_RCL_CTL = 1 **#then**		
LV_CMD_RCL_OPEN	-	Control signal for the digital recirculation actuator 1 = open, 0 = close
#end		

Input data:

LV_CMD_RCL_OPEN	NC_PSN_RCL_CTL		

2.33.5 Pulse width modulation Outputs from ECU to hardware

Output data:

PWM output name	Frequency	Updating of duty cycle	Range of duty cycle
#if NC_PSN_RCL_CTL = 2 **#then**			
PWM_RCL	30 Hz	10 ms	0 -100%
#end			
PWM_WG	30 Hz	10 ms	0 -100%
after ECU-reset PWM_WG-frequency is switched to C_PWM_WG_FRQ (see 30404A01.xxx)			

Input data:

PWM_RCL	PWM_WG	NC_PSN_RCL_CTL	

2.34 IGRE – Requirements to infrastucture interface

Input data:

NC_MPL_T_MAX	NC_MPL_IGN_CRK_MAX	NC_INI_CTR_DEAC	NC_IGBT_CUT_OFF_T

Detailed input data definition:

Name	Hex. limits	Phys. limits	Resol.	Unit
NC_MPL_T_MAX	0...FFFFH	0...262.14	0.004	ms
Maximum time duration of multiple spark (normal value 60ms)				
NC_MPL_IGN_CRK_MAX	0...FFH	0...95.625	0.375	°CRK
Maximum ignition angle after TDC to start TD_MPL (normal value 12 to 18°CRK)				
NC_INI_CTR_DEAC	0...FFFFH	0...262.14	0.004ms	ms
Time delay after IGBT response before switching OFF the IGBT – typical value 600µs				
NC_IGBT_CUT_OFF_T	0...FFFFH	0...262.14	0.004ms	ms
Inhibition of "IGBT protection cut off function"				

Export actions:

ACTION_INFR_SetIgnEnable(IN <Cyl>, IN <Inh_igc>)
Enables (inh_igc=1) or disables (inh_igc=0) the ignition for cylinder Cyl.
ACTION_INFR_SetIgnAngle(IN <Cyl>, IN <Iga_igc>)
Sets the ignition angle to apply for cylinder Cyl
ACTION_INFR_SetIgnDwell(IN <Cyl>, IN<Td_fac_min>, IN <Td_igc>, IN <Td_fac_max>)
Sets the dwell time duration and the factors for maximal and minimum dwell time for cylinder Cyl
ACTION_INFR_SetIgcDwellTest(IN <Cyl>, IN <Td_igc>)
Sets the dwell time duration for cylinder Cyl and activate coil charging accordingly
ACTION_INFR_SetIgnMplDwell(IN <Td_mpl>)
Sets dwell time for multiple spark
ACTION_INFR_SetIgnMplDly(IN <Td_mpl_dly>)
Sets the dwell time interruption in multiple sparks
ACTION_INFR_SetIgnMplNr(IN <Ign_mpl_nr>)
Sets the number of ignition sparks in multiple spark
ACTION_INFR_SetIgnCtl(IN <Ign_ctl_mod>)
Sets the ignition in full static or half static mode
ACTION_INFR_GetIgnScpDiagAtm46Atic71(IN <Cyl>, OUT<Diag_scp>)
Gets the diagnosis output for SCP detection
ACTION_INFR_GetIgnScgDiagAtm46Atic71(IN <Cyl>, IN <Min_burn_time>, OUT <V_dur_igc>, OUT<Diag_scg>)
Gets the diagnosis output for SCG or OL detection and the burn time duration

Description for actions:

ACTION_INFR_ SetIgnEnable(IN <Cyl>, IN <Inh_igc>)					
Enables (inh_igc=1) or disables (inh_igc=0) the ignition for cylinder Cyl.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number affected by the inhibition of ignition system					
Inh_igc	IN	0 ... 1	0 ... 1	1	1
Flag indicating inhibition of ignition system					

ACTION_INFR_SetIgnAngle(IN <Cyl>, IN <Iga_igc>)					
Sets the ignition angle to apply for cylinder Cyl					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the ignition angle is applied					
Iga_igc	IN	0 ... FF	-35.625 ... 60	0.375	°CRK
Ignition angle to be applied on cylinder Cyl					

ACTION_INFR_SetIgnDwell(IN <Cyl>, In <Td_fac_min>, IN <Td_igc>, IN <Td_fac_max>)					
Sets the dwell time duration and the factors for maximal and minimum dwell time					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the dwell time is set					
Td_fac_min	IN	1 ... FF	1/128 ... 255/128	1/128	-
Factor to calculate minimum dwell time					
Td_igc	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Dwell time duration					
Td_fac_max	IN	1 ... FF	1/128 ... 255/128	1/128	-
Factor to calculate maximum dwell time					

ACTION_INFR_SetIgcDwellTest(IN <Cyl>, IN <Td_igc>)					
Sets the dwell time duration for cylinder Cyl and activate coil charging accordingly					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the dwell time is set					
Td_igc	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Dwell time duration					

ACTION_INFR_SetIgnMplDwell (IN <Td_mpl>)					
Sets dwell time for multiple spark					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Td_mpl	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Dwell time for multiple spark					

ACTION_INFR_SetIgnMplDly (IN <Td_mpl_dly>)					
Sets the dwell time interruption in multiple sparks					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Td_mpl_dly	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Dwell time interruption					

ACTION_INFR_SetIgnMplNr(IN <Ign_mpl_nr>)					
Sets the number of ignition sparks in multiple spark					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Ign_mpl_nr	IN	0 ... FF	0 ... 255	1	-
Number of ignition sparks					

ACTION_INFR_SetIgnCtl(IN <Ign_ctl_mod>)					
Sets the ignition in full static or half static mode					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Ign_ctl_mod	IN	1 ... 2	1 HALF_STATIC 2 FULL_STATIC		
Control mode for ignition are : HALF_STATIC or FULL_STATIC					

ACTION_INFR_GetIgnScpDiagAtm46Atic71(IN <Cyl>, OUT<Diag_scp>)					
Gets the diagnosis output for SCP detection					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the diagnosis for SCP is get					
Diag_scp	OUT	0 ... 1	0 ... 1	1	-
Diagnostic of primary short circuit to battery					

ACTION_INFR_GetIgnScgDiagAtm46Atic71(IN <Cyl>, IN <min_burn_time>, OUT <V_dur_igc>, OUT<Diag_scg>)					
Gets the diagnosis output for SCG or OL detection and the burn time duration					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the diagnosis for SCG or OL is get					
Min_burn_time	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Minimum duration for burn time to detect ignition errors					
V_dur_igc	OUT	0 ... FFFF	0 ... 262.14	0.004	ms
Burn time duration for diagnosis validation					
Diag_scg	OUT	0 ... 1	0 ... 1	1	-
Diagnostic for primary short circuit to ground or open load					

FUNCTION DESCRIPTION:

General information:

Requirements for ACTION_INFR_ SetIgnEnable:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Inh_igc	1	-	1		0: ignition inhibited 1 : ignition enabled

Coincidence requirements:

The decision to inhibit an ignition stage is taken for each output before the turn on at TD_ON[x]. This means that no Disable / cut off can be set on a coil while charging.

Management of Ignition Cut-Off: Enable / Disable mode of Ignition Power stages

For normal Dwell Time and coil charging management:

a. No Ignition cut is allowed on a currently charging coil, *ie.* no Disable Command of a power stage is considered after the TD_ON event
   Nevertheless, if the Disable request still be present, it will be applied on the next coming to fire cylinder
b. Enable command request coming to a power stage in Disable mode will be only performed if TD_IGC[x] time to IGA_IGC point can be respected/realised.

In other case, this Enable request will be performed only on the next engine cycle (720°CRK or 360°CRK depending of the Ignition Coil mode - full or half static) if it still be present

c. No Re-Enable command can - neither will - be done on a power stage which is yet already in Enable mode

In Multiple Spark phase:

d. As for the nominal phase, no Ignition-Cut can be allowed on a currently charging coil even in Multiple Spark phase, *ie.* no Disable Command of power stage is considered after during the TD_MPL charge: if one TD_MPL is on the way, no Ignition cut is possible.
See dwell comments
The Disable request could be done/happened anywhere but it will only be executed, can only occur and be taken into account only at the end of the charging of this TD_MPL

Requirements for ACTION INFR SetIgnAngle:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Iga_igc	0.375°CRK		0.375°CRK		

Diagnosis:

Coincidence requirements:

Requirements for ACTION INFR SetIgnDwell:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Td_fac_min			1/128		
Td_igc			0.004ms		
Td_fac_max			1/128		

Diagnosis:

Coincidence requirements:

The normal request dwell time to be programmed and applied for charging the ignition coil is and has to be TD_IGC[x]
The coil starts charging with the target of achieving TD_IGC[x] at the IGA_IGC[x] angle. An update occuring for the Ignition Spark Angle will be taken into account as long as TD_MIN is not reached.
This Ignition Spark Angle change obtained when reaching TD_MIN will be taken into account and respected by a corresponding change of the coil charging time (the Dwell Time).
But, such a change of the Dwell Time to be thus and then applied can only be processed within the limits defined by TD MIN and TD MAX limits excursion range (*see drawing here after*)

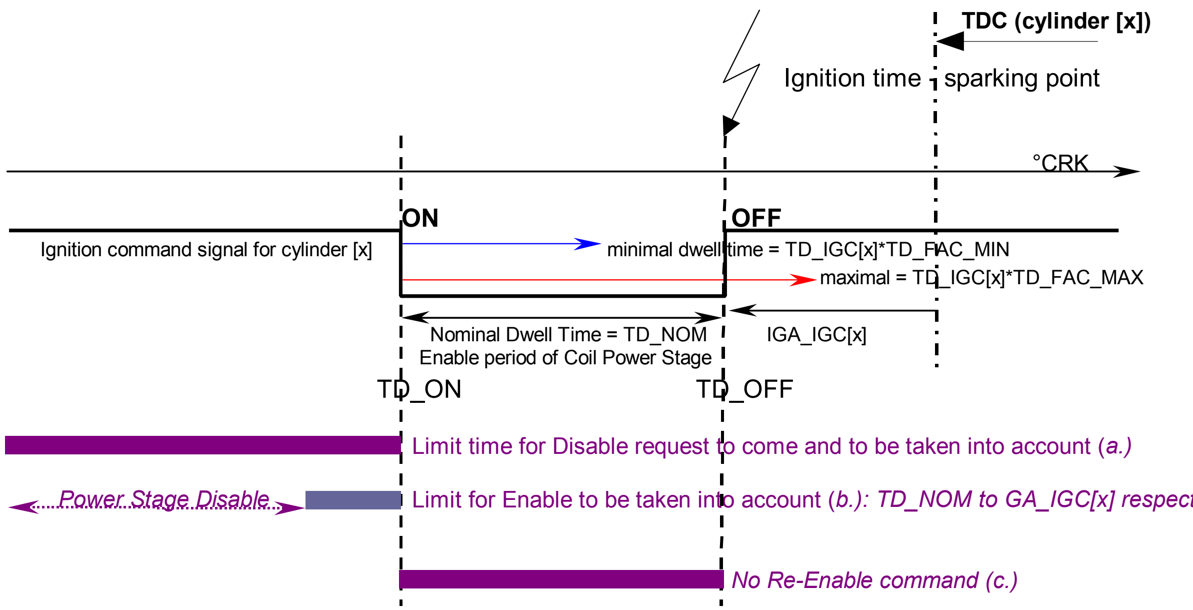
For the definition and calculation of those TD MIN and TD MAX:

TD MAX = TD_IGC[x] * TD_FAC_MAX but in any cases TD MAX <= NC_TD_LIM_MAX

*TD MAX = min(TD_IGC[x] * TD_FAC_MAX , NC_TD_LIM_MAX)*

TD MIN = TD_IGC[x] * TD_FAC_MIN but in any cases TD MIN >= NC_TD_LIM_MIN

*TD MIN = max(TD_IGC[x] * TD_FAC_MIN, NC_TD_LIM_MIN)*



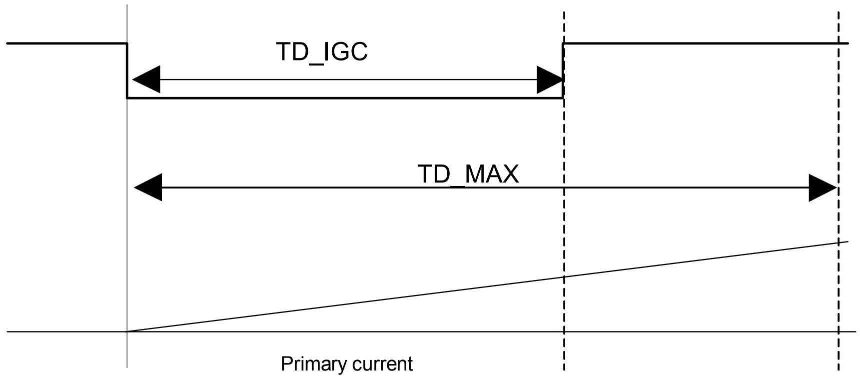
Calculations after starting the dwell time output at TD_ON

For the ignition time there are three main requests for the dwell time output.

1. A minimum dwell time TD_IGC[x] * TD_FAC_MIN has to be guaranteed to ensure ignition.
2. The dwell time has to be limited by a maximum dwell time which is defined as a TD_IGC[x] * TD_FAC_MAX.

   To prevent all cases of big negative engine speed gradients which could destroy the ignition system, by too long conduction between conduction angle calculation and spark, a timer limits the resulting conduction time (ignition power stage protection against high current).

   The ignition output is turned off immediately at TD_IGC[x] * TD_FAC_MAX (IGA_IGC[x] could not be respected).
3. In these limits (TD_IGC[x] * TD_FAC_MIN, TD_IGC[x] * TD_FAC_MAX) we have an absolute ignition angle priority.



Requirements for ACTION_INFR_SetIgcDwellTest:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Td_igc			0.004ms		

Diagnosis:

Coincidence requirements:

The normal request dwell time to be programmed and applied for charging the ignition coil is and has to be TD_IGC[x]
On Actuator test request activation, the coil starts charging with the target of achieving TD_IGC[x]

The coils start charging upon actuator test request pattern with the dwell time defined.

The pulse is generated once and immediately after calling the action. The Dwell time could not be updated during the pulse generation, excepting if it is set to 0. in this case, the current pulse should be stopped immediately.

Detection of SCP failure must be enabled

When a pulse is active on a cylinder no pulse could be generated on an other cylinder connected on the same ignition driver (ATIC71 or ATM46).

Requirements for ACTION_INFR_SetIgnMplDwell

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Td_mpl			0.004ms		

Diagnosis:

Coincidence requirements:

The value TD_MPL determines the conduction time of the ignition coil and the time delay TD_MPL_DLY specifies a time-out when the ignition coil is turned on for the next spark.

The number of successive sparks is defined as IGN_MPL_NR and checked at every TD_OFF.

The absolute duration of multiple sparks is limited to a maximum time defined as NC_MPL_T_MAX.

The maximum ignition angle to start a TD_MPL is defined as NC_MPL_IGN_CRK_MAX after TDC.

Requirements for ACTION_INFR_GetIgnScpDiagAtm46Atic71:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Diag_scp			1		

Diagnosis:

Coincidence requirements:

1. A Dwell Time Pulse is considered as a main or a multiple dwell pulse. Thus there is no distinction in the treatment of “Dwell Time On Events” from main and multiple pulses.
2. Consequently, there is no distinction in the treatment of “Spark Events” from main and/or multiple Dwell Time pulses.
3. A “Dwell Time On Event” defines the start time of coil charging. The resolution and precision of this time is defined by the corresponding ignition channel
4. A “Spark Event” or “Dwell Time Off Event” defines the end time of coil charging. The resolution and precision of this time is defined by the corresponding ignition channel.

Each time a “Dwell Time On Event” occurs, the time during which the IGBT_DIAG Pin indicates a SCP condition has to be integrated within a time window (*defined below*). If this integrated time inside this window exceeds NC_INI_DEAC_CTR, the cylinder that has produced the most recent Dwell Time On event must be switch off as fast as possible for the current ignition cycle. The time window begins at any “Dwell Time On Event” and ends if either one of the following criteria is met:

cr.a) another “Dwell Time On Event” from any Cylinder occurs. This restarts the time window and thus the integration of the time for which IGBT_DIAG indicates SCP conditions cr.b) a “Spark Event” of the same Cylinder that started charging the coil occurs. “Spark Events” of any other Cylinder are ignored.

cr.c) the integrated time for which the IGBT_DIAG pin indicates a SCP condition exceeds NC_INI_DEAC_CTR

cr.d) the time period back to the most recent “Dwell Time On Event” exceeds NC_IGBT_CUT_OFF_T.

Note that: * in case of overlapping of dwell time periods no short circuit detection can be guaranty due to HW design and limitation.

* If Dwell Time periods are overlapping, only the most recent one that has the latest started a coil charging (*last and most recent TD ON event, whatever it is*) will trigger the activation of this protection (BSW service) function. Hence, the last occurring TD ON event will define the coil to be considered by this function and thus diagnosed and protected (cut off if needed, when SCP failure appears)

With overlapping Dwell Time periods, there is thus a risk to do not diagnose (and switch off) the correct IGBT in real failure conditions

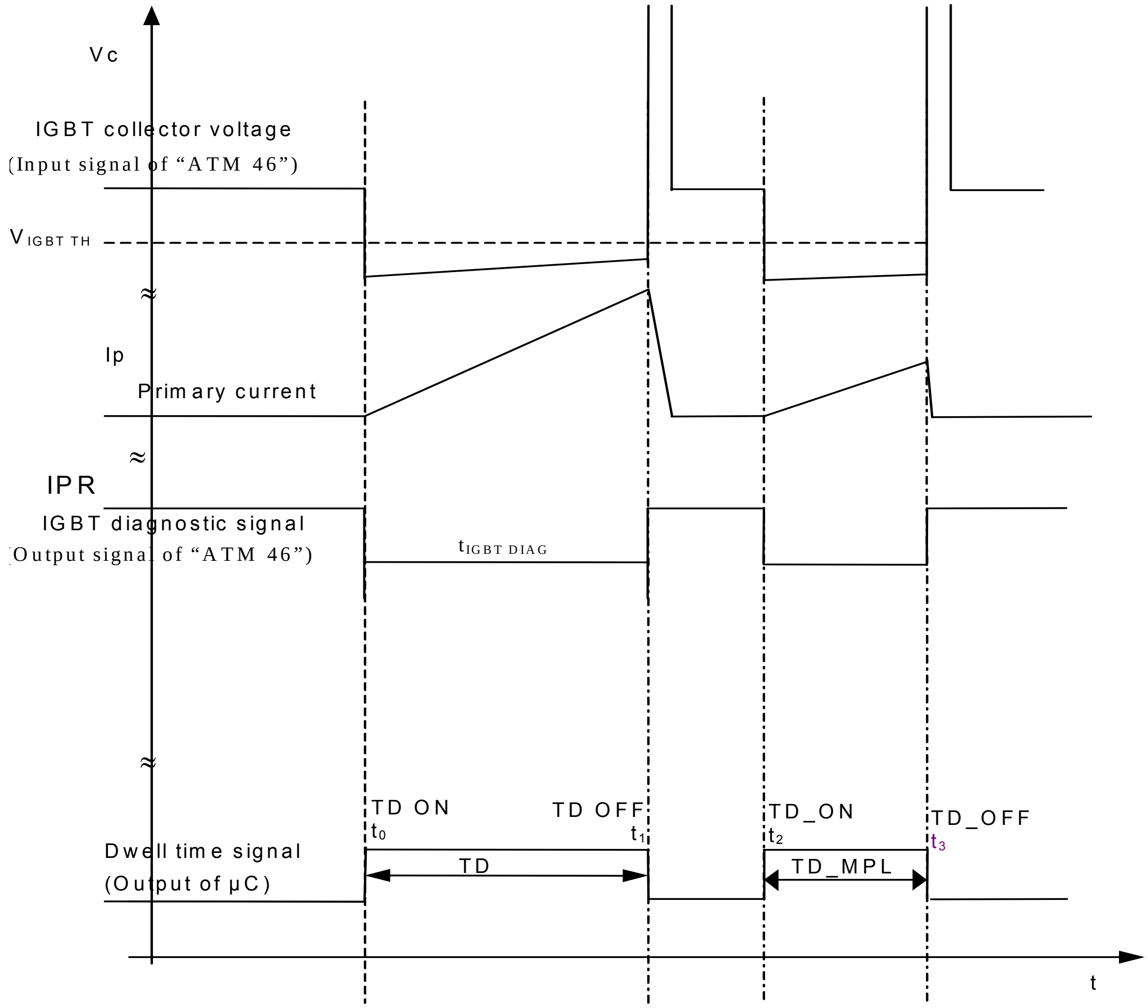
Dwell Times overlapping conditions may occur, in normal running, with too long settings of Dwell time in half and full static ignition modes.

Dwell Times overlapping conditions will occur, in Ignition Limp Home running (*ie. ½ static mode usage for coils charging*).

One ATM 46 could handle only 4 ignition coils. If there are more than 4 ignition coils 2 ASIC have to be used. To reduce the possibility of overlapping we have to use them in a crossed order.

Timing diagram:

Normal Condition:

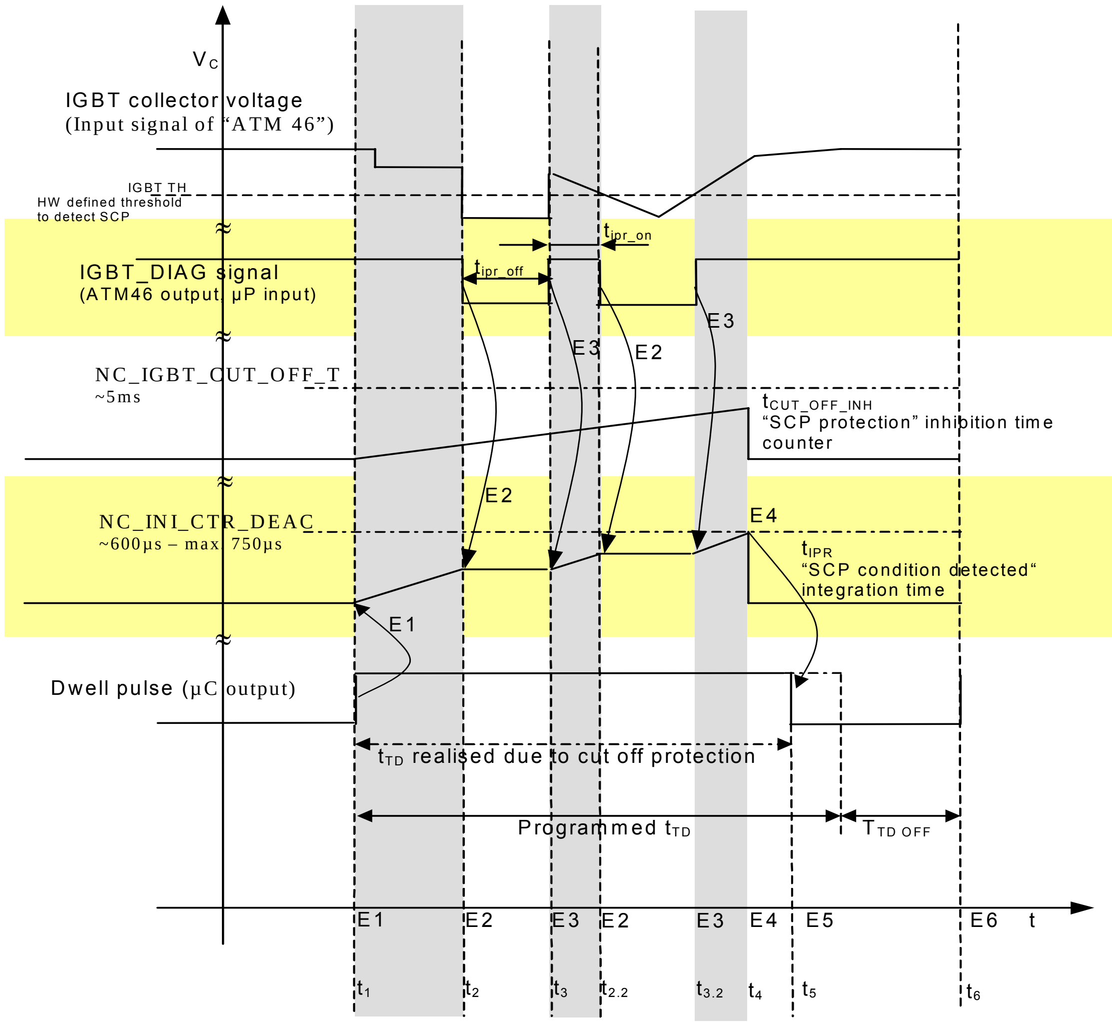


V_{IGBT_TH} is the threshold voltage of the failure detection of IGBT protection. It is fixed by the component ("ATM 46") at ≈3V.

The input signal of the "ATM 46" is the IGBT collector voltage.

The output signal of "ATM 46" is low as long as the battery voltage is less than the threshold of $V_{IGBT\ TH}$ if no failure is detected.

Cut Off Condition and integration of SCP condition for Dwell pulse:



A dwell pulse is considered as a main or multiple dwell pulse, no distinctions are done as both can be critics in case of SCP failure.

When the collector voltage is higher than the threshold (V_{IGBT_TH}), it indicates a SCP condition on IGBT. In this case, the IGBT_DIAG signal from the ASIC is high (in SCP level).

a) Events and Actions definition

E1: Dwell Time On Event – Start the charging of the coil
When this event occurs at t_1:
- Clear the SCP pulse periods measured up to now (*ie. the "SCP condition detected" integration time*)
– start / enable to integrate the time for which the IGBT_DIAG Pin indicates a SCP condition

E2: IGBT output without SCP condition (t_2) or transition to No SCP ($t_{2.2}$ - *SCP disappears*)
When E2 occurs, the *"SCP condition detected" integration time* is stopped (*no or no more SCP conditions seen*)

E3: IGBT output in SCP conditions (t_3) or transition to SCP ($t_{3.2}$ - *SCP occurs again*)
When E3 occurs, the *"SCP condition detected" integration time* is started or re-started (*SCP conditions seen or re-seen again*)

E4: Cut Event from the IGBT SCP Protection function

E4 will not occur in normal condition when the coil encounters no SCP conditions (no or too short E3 is met, only E2)

t_{IPR} designates the *“SCP condition detected“ integration time* acquired (*see after*)
t_{IPR} is permanently checked when this protection function is active

IGBT Cut Off in case of SCP detection validated:

If t_{IPR} > NC_INI_CTR_DEAC

And $(t_4 – t_1)$ < NC_IBGT_CUT_OFF_T

Then Switch off the ignition channel that has produced the most recent Dwell Time On Event (*most recent or latest E1 event*) as fast as possible

Dwell Time applied in this case will be “t_{TD} realized due to cut off protection” function and not the “Programmed t_{TD}”

Else No action on ignition channel

EndIf

E5: Spark Event at the cutting of Ignition Coil charging

E5 occurs at t_5. E5 / t_5 can be either:
- the normal “*Programmed t_{TD}*” if this SCP protection function has not been reached (no E4) or
- the Coil charging Time corresponding to *“t_{TD} realized due to cut off protection”* function if this SCP protection function has been reached (at E4)

When E5 occurs: the *“SCP condition detected“ integration time* (t_{IPR}) is stopped

E6: Identical to Dwell On Event E1 for the next following coil coming to charging mode on the same ASIC diagnostic line

b) Times definition

t_{ipr_on} = time period that indicates a SCP conditions (*ie. V_C > IGBT_TH, the IGBT_DIAG signal from the ASIC indicates the SCP*). During this time, the *“SCP condition detected” integration time* – t_{IPR} – is enabled.

t_{ipr_off} = time period where no SCP conditions exist (*ie. V_C < IGBT_TH*). This can happen also in between IGBT SCP diagnosis pulses detection

t_{TD} = time period of any dwell pulse. It correspond normally to the programmed Dwell Time period for charging the Ignition coil. Here, it can be shortened (*cut off of the Coil Charging*) by the IGBT SCP protection function.

$t_{TD\ OFF}$ =time period between any successive dwell pulses

$t_{CUT\_OFF\_INH}$ = For the Ignition Coil under SCP Protection diagnostic, the “Cut Off” functionality is deactivated after a time longer than
$t_{CUT\_OFF\_INH}$ > NC_IGBT_CUT_OFF_T
If such a time out occurs, the dwell time is not interrupted cause it corresponds to case where IGBT handles over a situation with a high gradient of battery tension and not a short circuit to battery

t_{IPR} = *“SCP condition detected“ integration time* acquired
This Pulse Measurement Method has to be active – which is equivalent to: the IGBT_DIAG input to the µP at SCP level has to be measured – between t_0 and either criteria cr.a), cr.b), cr.c) or cr.d) is met **whichever** comes first.

*The minimum length of IGBT_DIAG pulses to be detected should be as short as possible (minimal requirement: 8µs = 2*4µs)*

Warning: due different HW and/or µP architecture and implementation constraint limitations

1. Every events E1 to E6 must be processed within a Maximum tolerable time delay smaller than 50µs
2. The Dwell Time and Dwell Charging period succession should be limited to:
   $100µs \le t_{TD} \le 60ms$ and $100µs \le t_{TD\ OFF}$
3. Event E4 = "Switch off the ignition channel that has produced the most recent Dwell Time On Event" should only occur within 50µs after SCP detection confirmation
4. IGBT_DIAG pulses shorter than 50µs have a risk of not being processed

Requirements for ACTION_INFR_GetIgnScgDiagAtm46Atic71:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Min_burn_time			0.004ms		
V_dur_igc			0.004ms		
Diag_scg			1		

Diagnosis:

Coincidence requirements:

For the Spark Burn Time Duration measurement, the functionality is:

- To ensure a correct measurement in case of spark blow out, only the Active Level of Burn Time measurement signal from the ATM46 (IGN_DIAG) is integrated in the time window defined by two consecutive main spark events on the same ASIC
- Active Level of Burn Time measurement signal can be "High" or "Low" depending on HW configuration
- Minimum length of Active Level pulses to be detected is 50µs and Minimum inter-space between Active Level pulses to be detected is 50µs. Consequently, IGN_DIAG pulses shorter than 50µs have a risk of not being processed.

Sparking events from multiple spark pulses do not restart the time window for measurement. Indeed, the Burning effect that can be created by any Multiple spark pulses is *de facto* integrated and cumulated with the Burning Duration from the preceding Main Spark pulse.

At the end of the time measurement window started by cylinder[x], the measured burning duration is read out and written into the variable V_DUR_IGC[x] for the corresponding logical cylinder [x]. The time for Burn Time measurement is then cleared and prepared for the next measurement.

Consider that only one IGN_DIAG signal exists (*this IGN_DIAG signal represents a wired "OR" of all the presents coils channels*) which will limit the measurement range.

In Limp Home and ½ static modes, 2 main spark events – on one ATM46 diagnostic signal line – occur at the same time. This means that the time windows for measurement of (*at least*) two cylinders overlap. In such cases, due to the "OR" wiring on the signal information, only the cylinder on which the most recent main spark event (*TD OFF*) is produced will define and will be identified for the time window measurement.
Therefore, the reported burning duration in the interface variable V_DUR_IGC[x] may not correspond to right real burning cylinder [x] in case of Limp Home mode and ½ static coils.

Each ATM46 could analyze 4 ignition coils. If diagnostics for more the than 4 coils are necessary, a parallel ATM46 have to be used.

General Information

For the Acquisition of Battery Temperature and Battery Current there are two possible Sensors. The Analog Sensor (CONF_BAT_LIN = 0) send the raw values for Battery Sensor (Current and Temperature) via Analog INPUT. These signals are measured by continuous conversion (10bits) every 10msec.
The Battery Sensor is a Hall Effect Sensor with a NTC Temperature element. The Hall sensor provides a voltage Signal, which is directly proportional to the current, which is going in or out of the battery. According to the characteristic line of the Sensor small voltages shows a negative current (Battery is discharged) while high Voltage shows positive current (Battery is charged)

The Semi Smart Battery Sensor (CONF_BAT_LIN = 1) send the signals via LIN BUS communication. The Temperature Signal is already based on a model, which gives the Fluid temperature inside the battery

To take into consideration the current losses of the battery, the Self discharging current is subtract from the measured current.

general specification

The Analog Temperature Sensor measures the Temperature at the Sensor location. As the Actual Battery Temperature increased quicker than the Battery fluid temperature a Low Pass Filter is used. The Initial value is calculated depending on Engine off time, calculated value at engine stop and Sensor value at start.

For Battery Management it is necessary to know the Battery voltage with higher resolution. This can be done either with Battery Sensor via LIN BUS communication or via Analog Input signal from VB_MES.

Application Conditions

Initialization: RST, NVMRES, NVMINI, NVMSTO
Recurrence: 10MS
Activation: CONF_BAT==1
Deactivation: if activation not true

3.3 AGGR adaptation: MISF

3.3.1 Rough road acquisition adaptation (contents of B002)

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
T_SEG_RR_0	O/V	0H...FFFFH	0...262140	4	µs
Actual segment time measurement from the wheel speed signal.					
T_SEG_RR_1	O/V	0H...FFFFH	0...262140	4	µs
Previous segment time measurement from the wheel speed signal.					

Input data:

BIOS_VS_EDGE_CTR	BIOS_VS_EDGE_T		

Application conditions:

Initialisation : all other outputs and local variables are set to 0 at ECU-reset and at function deactivation

Recurrence : 10 msec of rough road event task

Activation : After VS signal learning is finished

Formula section:

Segment period acquisition

The function uses consecutive segment times for calculation of a wheel speed gradient. The segments are built with a minimum number of NC_SEG_TOOTH_RR edges and afterwards normalized to a length of 4 teeth.

If BIOS_VS_EDGE_CTR - TMP_BIOS_VS_EDGE_CTR_OLD >= NC_SEG_TOOTH_RR
then *// If condition reversed, Then and else position interchanged*

(calculation of T_SEG_RR_0)

T_SEG_RR_1=T_SEG_RR_0

$$T\_SEG\_RR\_0 = \frac{(BIOS\_VS\_EDGE\_T - TMP\_BIOS\_VS\_EDGE\_T\_OLD)*4}{BIOS\_VS\_EDGE\_CTR - TMP\_BIOS\_VS\_EDGE\_CTR\_OLD}$$

TMP_BIOS_VS_EDGE_T_OLD=BIOS_VS_EDGE_T

TMP_BIOS_VS_EDGE_CTR_OLD=BIOS_VS_EDGE_CTR

else (no seg.period acquisition)

No Action

T_SEG_RR_1 is the segment period preceding T_SEG_RR_0. TMP_BIOS_VS_EDGE_T_OLD & TMP_BIOS_VS_EDGE_CTR_OLD are temporary local variables .

Configuration data:

Name	Dim	Hex. Limits	Phys. Limits	Resol.	Unit

4.1 ECU state

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ECU_STATE	O/V	0H 1H 2H 3H 4H 5H	ENG_STOP RUN_ENG SYN_ENG_IGK_ON SYN_ENG_IGK_OFF PWL ENG_LOCK	-	-
Information on ECU state					

Input data:

LV_IGK	LV_ES	LV_MU_INH_PWL_TRAN_ES_EL	

FUNCTION DESCRIPTION:

General information:

The function ECU-state manages detection of the operating states of the ECU and transitions between them referring to the main inputs key detection and crankshaft synchronization.

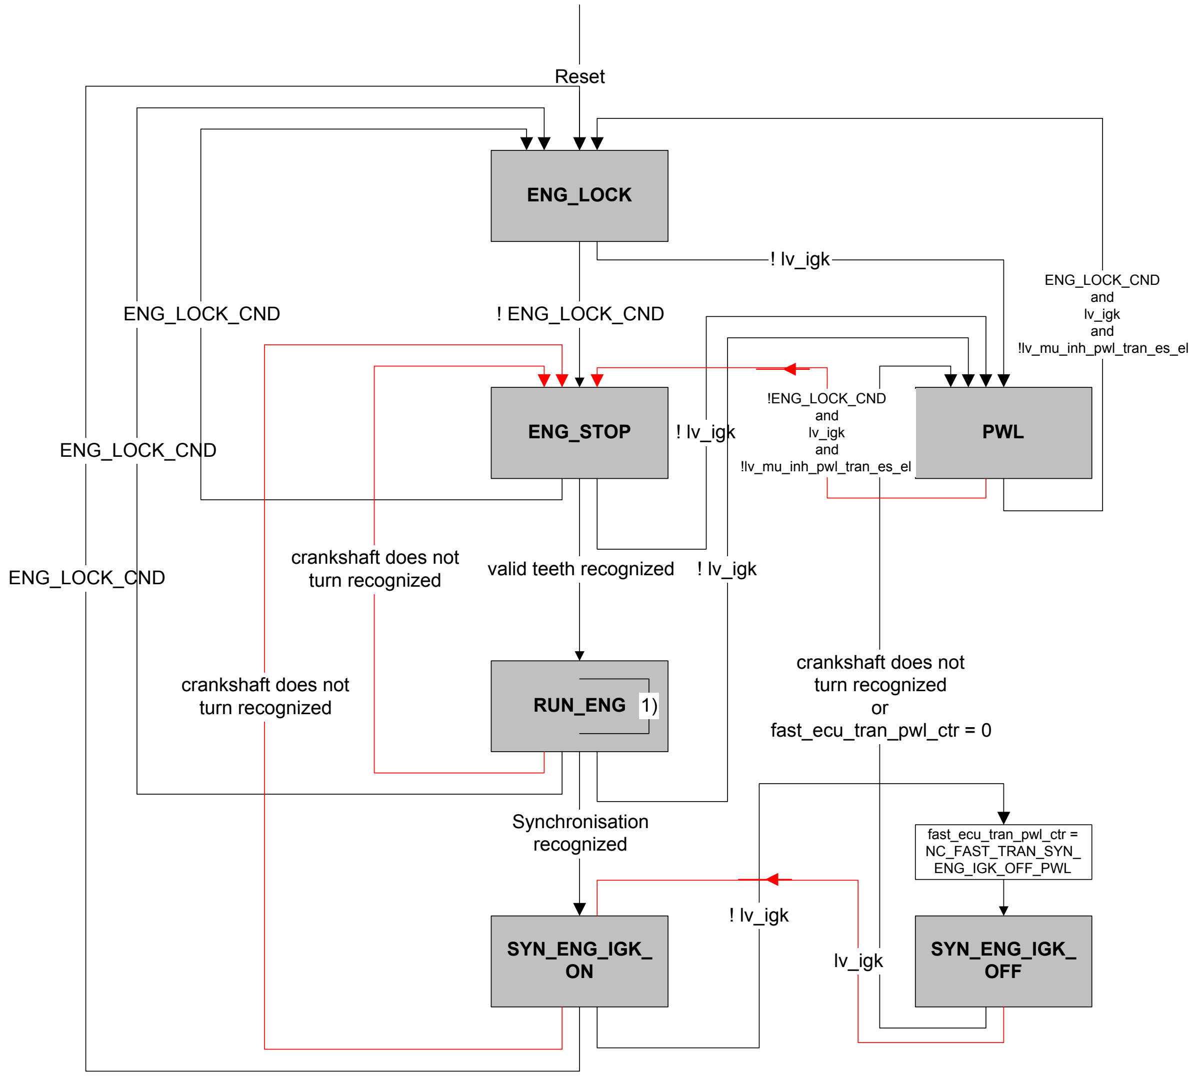
The ECU-state offers system events corresponding to those transitions that can be used by other functions (e. g. ignition function that asks for ignition reset on the transition engine running to engine stop).

Those actions are described in the specification chapter of the corresponding functions.

An important value to determine the ECU-state is the value ENG_LOCK_CDN. Here are stored bit-wise conditions which prevent leaving the ECU-state ENG_LOCK. If anyone of those bits becomes 1, the ECU-state will become ENG_LOCK. These conditions are:

- cross check of software and calibration data reference

ECU-State
Activation: every engine state Deactivation: - Initialisation: ECU_STATE = ENG_LOCK Update rate: 10ms



1) Transition ENG_STOP -> RUN_ENG -> SYN_ENG_IGK_ON in one cycle if Synchronisation recognized (by BSW)

4.1.1 ENGINE LOCK (ENG_LOCK)

This state is dedicated to a special operating state where all essential outputs are inhibited.

An interface for project specific activities on this state (ENG_LOCK) does exist.

The ECU state is initialized with this state after reset.

4.1.1.1 ENGINE LOCK => POWERLATCH (PWL)

IF LV_IGK = 0
THEN offer an interface for project specific activities on this state transition
ECU_STATE = PWL
ENDIF

4.1.1.2 ENGINE LOCK => ENGINE STOP (ENG_STOP)

IF LV_IGK **AND** (ENG_LOCK_CDN = 0)
THEN offer an interface for project specific activities on this
state transition,
ECU_STATE = ENG_STOP
ENDIF

4.1.2 ENGINE STOP

The crankshaft does not turn

An interface for project specific activities on this state (ENG_STOP) does exist.

4.1.2.1 ENGINE STOP => POWERLATCH

IF LV_IGK = 0
THEN offer an interface for project specific activities
ECU_STATE = PWL
ENDIF

4.1.2.2 ENGINE STOP => ENGINE LOCK

IF (ENG_LOCK_CDN ≠ 0) **AND** (LV_IGK)
THEN offer an interface for project specific activities,
ECU_STATE = ENG_LOCK
ENDIF

4.1.2.3 ENGINE STOP => ENGINE STOP

IF LV_ES **AND** (LV_IGK) **AND** (ENG_LOCK_CDN = 0)

THEN offer an interface for project specific activities

ENDIF

4.1.2.4 ENGINE STOP => RUNNING ENGINE (RUN_ENG)

IF (STATE_CRK_SYNC < BIOS_CRK_VLD_TEETH)
AND (LV_IGK) **AND** (ENG_LOCK_CDN = 0)

THEN offer an interface for project specific activities

ECU_STATE = RUN_ENG

ENDIF

4.1.2.5 ENGINE STOP => SYNCHRONOUS ENGINE IGNITION KEY ON (SYN_ENG_IGK_ON)

IF LV_SYN_ENG **AND** LV_RUN_ENG

THEN offer an interface for project specific activities for transition of state RUN_ENG,

offer a second interface for project specific activities on the state transition in state SYN_ENG_IGK_ON.

ECU_STATE = SYN_ENG_IGK_ON

ENDIF

4.1.3 RUNNING ENGINE (RUN_ENG)

This state corresponds to a turning engine without synchronization on crankshaft.

An interface for project specific activities on this state (RUN_ENG) does exist.

4.1.3.1 RUNNING ENGINE => POWERLATCH

IF LV_IGK = 0

THEN offer an interface for project specific activities on this state transition.

ECU_STATE = PWL

ENDIF

4.1.3.2 RUNNING ENGINE => ENGINE LOCK

IF ENG_LOCK_CDN ≠ 0

THEN offer an interface for projekt specific activities,

ECU_STATE = ENG_LOCK

ENDIF

4.1.3.3 RUNNING ENGINE => ENGINE STOP

IF STATE_CRK_SYNC = BIOS_EPO_CRK_PAS

THEN offer an interface for project specific activities,

ECU_STATE = ENG_STOP

FUNCTION DESCRIPTION:

General information:

The nominal idle speed in the engine operating state Idle (LV_IS) depends on the additional loads, coolant temperature TCO and cranking coolant temperature TCO_ST. It is initialized with the table corresponding to the conditions at the initialization (additional loads).

The input value LV_DLY_N_SP_IS (output from module Converter Torque) is derived from LV_DRI including a tuneable delay time. If drive is engaged the converter torque is build up after a short delay time (about 400 ms) if the change in engine speed setpoint for drive engaged also is delayed the new setpoint can be adjusted more stable.

Following corrections can be done:
- Nominal Idle speed increase for fast Catalyst Heating : If Catalyst Heating function is active, nominal idle speed offset depends on coolant temperatue (TCO), ambient pressure (AMP), time after Start (T_AST), and gearbox (A/T, M/T)
- Nominal idle speed increase in case of vehicle rolling (VS > 0) : separate correction for A/T and M/T
- Nominal idle speed increase in case of high transmission oil temperature for A/T vehicle
- Nominal Idle speed increase in case of low Battery Voltage : correction in Drive for low Vehicle speed or for M/T vehicle (always active)

In general the transition from a nominal idle speed to another is performed with an adjustable change limitation IP_N_SP_LGRD.

Exception: no change limitation is applied during catalyst heating activation – see below

else N_SP_IS_9 = 0

endif

Electrical load compensation N_SP_IS_GEN_LOAD

Activation : All engine operating state

If CONF_GEN_LOAD = 0
or TCO <= C_TCO_MIN_N_SP_IS_GEN_LOAD
or LV_ERR_GEN_LOAD = 1
then N_SP_IS_GEN_LOAD = 0
else N_SP_IS_GEN_LOAD is calculated as below description after time delay C_T_DLY_N_SP_IS_GEN_LOAD:

The N_SP_IS_GEN_LOAD is performed with an adjustable change limitation C_N_SP_LGRD_IS_GEN_LOAD.

If LV_ERR_GEN_LOAD is set to 1, the N_SP_IS_GEN_LOAD is initialized to C_N_SP_IS_GEN_LOAD_INI with an adjustable change limitation C_N_SP_LGRD_IS_GEN_LOAD.

If GEN_LOAD_MMV_FIL > C_GEN_LOAD_N_SP_IS_GEN_LOAD_ACT
then T_DLY_DEC_N_SP_IS_GEN_LOAD is initialized to C_T_DLY_DEC_N_SP_IS_GEN_LOAD
  If LV_DRI = 0
  then T_DLY_INC_N_SP_IS_GEN_LOAD_DRI is initialized to C_T_DLY_INC_N_SP_IS_GEN_LOAD_DRI
    and T_DLY_INC_N_SP_IS_GEN_LOAD is decreased by 10ms step.
  else T_DLY_INC_N_SP_IS_GEN_LOAD is initialized to C_T_DLY_INC_N_SP_IS_GEN_LOAD
    and T_DLY_INC_N_SP_IS_GEN_LOAD_DRI is decreased by 10ms step.
  endif
  if T_DLY_INC_N_SP_IS_GEN_LOAD = 0
    or T_DLY_INC_N_SP_IS_GEN_LOAD_DRI = 0
  then $N\_SP\_IS\_GEN\_LOAD_n = N\_SP\_IS\_GEN\_LOAD_{n-1}$ + ID_N_SP_IS_INC_GEN_LOAD_MMV_FIL
    and T_DLY_INC_N_SP_IS_GEN_LOAD = C_T_DLY_INC_N_SP_IS_GEN_LOAD
    and T_DLY_INC_N_SP_IS_GEN_LOAD_DRI = C_T_DLY_INC_N_SP_IS_GEN_LOAD_DRI
  endif
else **If** GEN_LOAD_MMV_FIL <= C_GEN_LOAD_N_SP_IS_GEN_LOAD_ACT – C_GEN_LOAD_HYS
  then T_DLY_INC_N_SP_IS_GEN_LOAD is initialized to C_T_DLY_N_SP_IS_GEN_LOAD
    and T_DLY_INC_N_SP_IS_GEN_LOAD_DRI is initialized to

C_T_DLY_N_SP_IS_GEN_LOAD_DRI

and T_DLY_DEC_N_SP_IS_GEN_LOAD is decreased by 10ms step.

endif

if T_DLY_DEC_N_SP_IS_GEN_LOAD = 0

then $N\_SP\_IS\_GEN\_LOAD_n = N\_SP\_IS\_GEN\_LOAD_{n-1}$ - ID_N_SP_IS_DEC_GEN_LOAD_MMV_FIL

and T_DLY_DEC_N_SP_IS_GEN_LOAD = C_T_ DLY_DEC_N_SP_IS_GEN_LOAD

endif

endif

N_SP_IS_GEN_LOAD is limited for each engine condition as below (depending on M/T or A/T):

	Minimum	Maximum
LV_DLY_N_SP_IS = 0 **and** LV_ACIN = 0	IP_N_SP_IS_MT(_AT)	IP_N_SP_IS_MT(_AT) + C_N_SP_IS_GEN_LOAD_MAX
LV_DLY_N_SP_IS = 0 **and** LV_ACIN = 1	IP_ACIN_N_SP_IS_MT(_AT)	IP_ACIN_N_SP_IS_MT(_AT) + C_ACIN_N_SP_IS_GEN_LOAD_MAX
LV_DLY_N_SP_IS = 1 **and** LV_ACIN = 0	IP_DRI_N_SP_IS	IP_DRI_N_SP_IS + C_DRI_N_SP_IS_GEN_LOAD_MAX
LV_DLY_N_SP_IS = 1 **and** LV_ACIN = 1	IP_DRI_ACIN_N_SP_IS	IP_DRI_ACIN_N_SP_IS + C_DRI_ACIN_N_SP_IS_GEN_LOAD_MAX

When T_DLY_DEC_N_SP_IS_GEN_LOAD is reached to 0, if N_SP_IS_GEN_LOAD is not changed compared to previous value after reaching its minimum value, then CTR_N_SP_IS_ GEN_LOAD_INI is increased by 1 step.

If CTR_N_SP_IS_GEN_LOAD_INI is higher than C_CTR_N_SP_IS_GEN_LOAD_INI, N_SP_IS_GEN_LOAD is set to C_N_SP_IS_GEN_LOAD_INI.
(In this case, N_SP_IS_GEN_LOAD could be lower than its minimum value.)

End of line test idle N_SP_IS_EOL

Activation : Only under EOL test request

EOL (End of line) test should be done at high enough rpm to prevent engine stall and to increase passing rate at production line. IVVT EOL needs high oil pressure to activate IVVT contoller and this can be realized only at high rpm.

If EOL_STATE_DIAGCP = 1h (EOL_ACT)

then N_SP_IS_EOL = C_N_SP_IS_EOL_DIAGCP

else **if** LV_TRIP_ACT_IVVT_IN = 1 **or** LV_TRIP_ACT_IVVT_EX = 1

then N_SP_IS_EOL = C_N_SP_IS_EOL_IVVT

else N_SP_IS_EOL = 0 [rpm]

endif

endif

Offset due to atmospheric pressure

In order to assure manifold vacuum for brake performance in all atmospheric conditions e.g. at high altitude, it is possible to calibrate an offset to the target engine idle speed dependant on atmospheric pressure. This offset may be positive or negative. It is added to the final coordinated idle speed setpoint.

Due to the fact that this offset is applied in all conditions, care must be taken to ensure that all engine functional requirements are fufilled even with the offset applied.

N_SP_IS_OFS_AMP = IP_N_SP_IS_OFS_AMP(AMP)

Final value

For driving off assistance, the following offset, which is determined in the module “Driving off assistance”, has to be considered:
And also IVVT short circuit to ground error must be considered for engine stall prevention purpose.

If LV_DRI = 0

N_SP_IS_SLV_IVVT_SCG = IP_N_SP_IS_SLV_IVVT_SCG__TCO

else N_SP_IS_SLV_IVVT_SCG = IP_N_SP_IS_SLV_IVVT_SCG_DRV__TCO

Input data:

N	N_SP_IS	LV_CT	C_N_MAX_IDLE_CALC

FUNCTION DESCRIPTION:

General information:

When speed is falling with high negative gradients at the actual engine speed N with N_DIF < 0 (overspeed), an interception function should be active to prevent transient effects round the idle speed setpoint N_SP_IS. These transient effects are normally caused by high integral part values, which may result from activating the idle speed controller at high speed deviations. In order to prevent such situations, a corrected setpoint N_SP_IS_COR is calculated, which intercepts speed when falling into idle range and which leads to small deviations in speed from the (corrected) setpoint and so to small controller outputs. This interception function is only active in case of overspeed.

If this function is activated (LC_N_SP_IS_COR_CALC = 1), the N_DIF_COR calculation, which is described in the following chapter, will be done by the equation N_DIF_COR = N_SP_IS_COR – N. So, N_DIF_COR will not be calculated by N_DIF-N_DIF_MMV·C_N_DIF_FAC in this case! This means, N_DIF_COR will then not include the DT_1-filtering! See also chapter "Engine speed deviations N_DIF, N_DIF_MMV, N_DIF_COR", "N_DIF_COR calculation".

The calculation of N_SP_IS_COR is depending on the actual value N, figure 1.

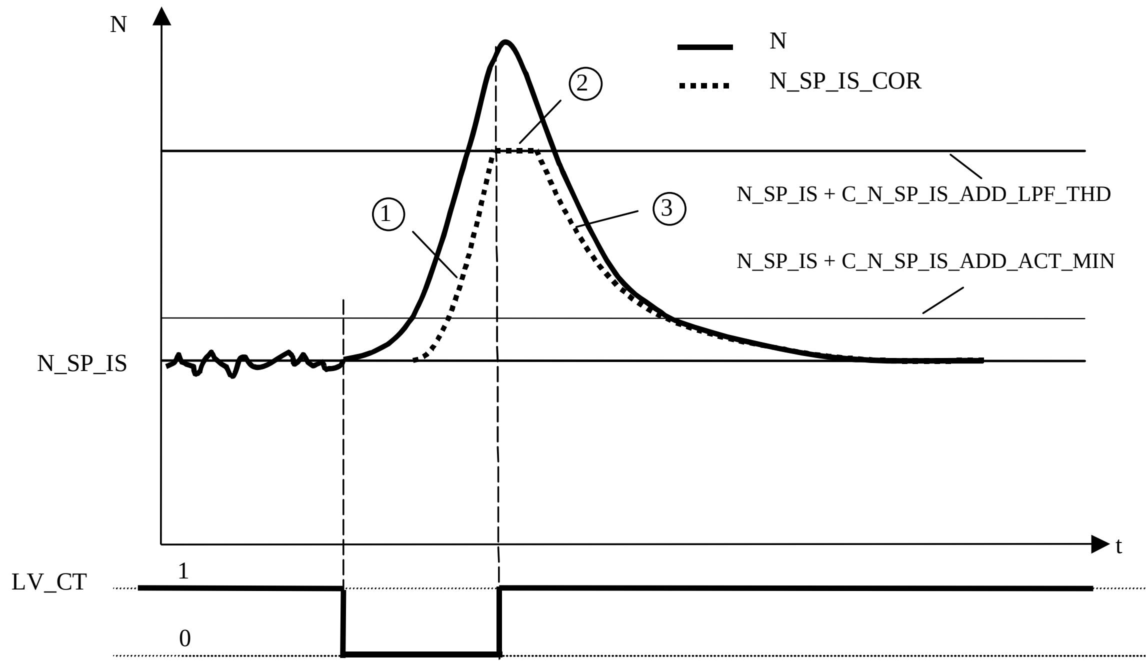

Figure 1: *Calculation of N_SP_IS_COR, part I*

If the driver hits the gas pedal (LV_CT=0) **OR** speed is above the threshold N_SP_IS + C_N_SP_IS_ADD_LPF_THD **AND** speed is above the offset N_SP_IS + C_N_SP_IS_ADD_ACT_MIN, the corrected idle speed setpoint N_SP_IS_COR is calculated as a part of the actual speed, case 1 in figure 1:

IF **[** N > N_SP_IS + C_N_SP_IS_ADD_ACT_MIN **]** **AND** **[{** LV_CT = 0 **}** **OR**
{ N_SP_IS + C_N_SP_IS_ADD_LPF_THD < N_SP_IS_COR_2 **}]**
THEN
N_SP_IS_COR = min { C_FAC_N_SP_IS_COR, 1 } · N,
with 0 <= C_FAC_N_SP_IS_COR <= 1
ENDIF;

(1)

If N_SP_IS_COR reaches N_SP_IS + C_N_SP_IS_ADD_LPF_THD or becomes greater, this upper limit value is held, case 2 in figure 1. When the driver releases the gas pedal (LV_CT=1) and speed is falling again, a low pass filter is activated in case

N_SP_IS_COR_2=C_FAC_N_SP_IS_COR · N = N_SP_IS + C_N_SP_IS_ADD_LPF_THD, (2)

i.e. N reaches

$$N = \frac{N\_SP\_IS + C\_N\_SP\_IS\_ADD\_LPF\_THD}{C\_FAC\_N\_SP\_IS\_COR} \quad (3)$$

Then the corrected setpoint N_SP_IS_COR is lead on an e-function down to the setpoint N_SP_IS. If in this situation the driver hits the gas pedal, N_SP_IS_COR is calculated by eq.(1) again.

The following picture 2 shows a special situation.

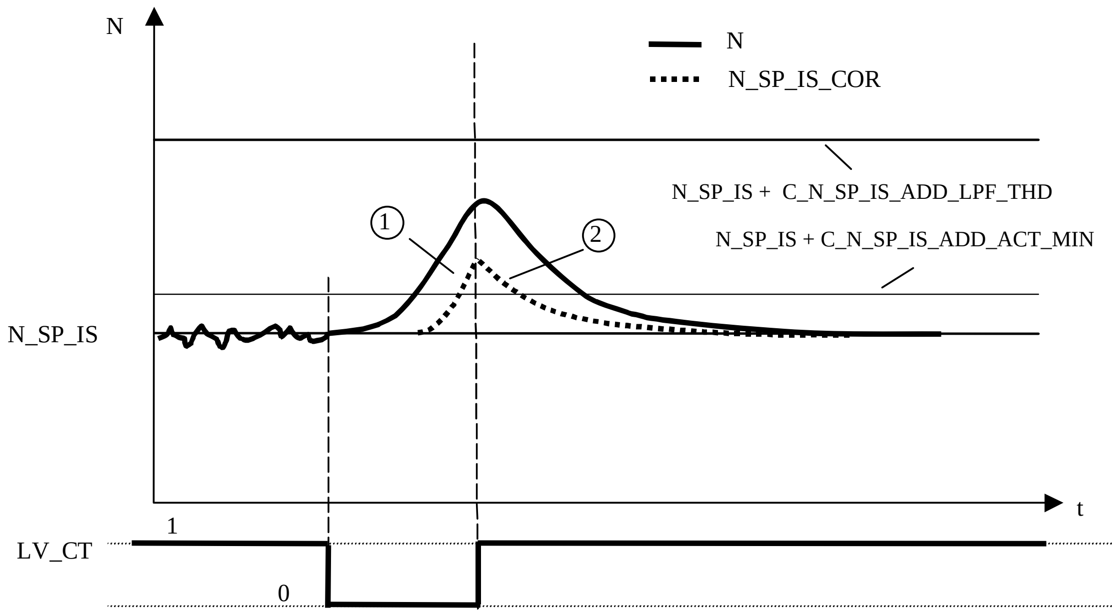

***Figure 2:** Calculation of N_SP_IS_COR, part II*

When the driver releases the gas pedal in the range

N_SP_IS + C_N_SP_IS_ADD_ACT_MIN <= N_SP_IS_COR <= N_SP_IS + C_N_SP_IS_ADD_LPF_THD

again, then the low pass filter starts from the last value N_SP_IS_COR.

Application conditions:

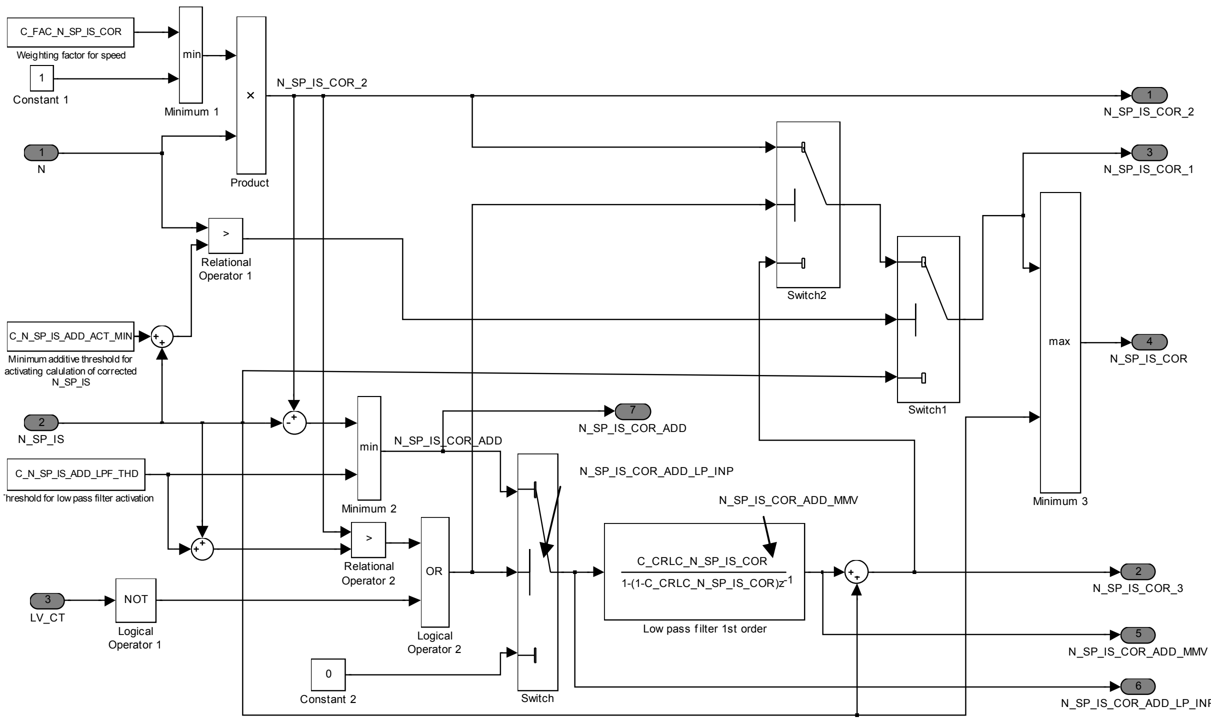
Activation: **(** LC_N_SP_IS_COR_CALC = 1 **) AND (** N <= C_N_MAX_IDLE_CALC **)**

Deactivation: **(** LC_N_SP_IS_COR_CALC = 0 **) OR (** N > C_N_MAX_IDLE_CALC **)**

$N\_SP\_IS\_COR_k = N\_SP\_IS\_COR_{k-1}$

Initialization: N_SP_IS_COR = N_SP_IS, N_SP_IS_COR_GRD = 0 at reset

Update rate: 10 ms



Formula section:

Figure 3: *Structure calculation of N_SP_IS_COR*

Initialization

N_SP_IS_COR_2 = **min {** C_FAC_N_SP_IS_COR, 1 **}** * N

N_SP_IS_COR_ADD = **min {**N_SP_IS_COR_2 - N_SP_IS, C_N_SP_IS_COR_LPF_THD**}**

Initialization low pass filter

IF **(**LV_CT = 0**) OR (**N_SP_IS + C_N_SP_IS_ADD_LPF_THD < N_SP_IS_COR_2**)**

THEN N_SP_IS_COR_ADD_LP_INP = N_SP_IS_COR_ADD;

ELSE N_SP_IS_COR_ADD_LP_INP = 0;

Low pass filter

$$N\_SP\_IS\_COR\_ADD\_MMV_k = N\_SP\_IS\_COR\_ADD\_MMV_{k-1} + C\_CRLC\_N\_SP\_IS\_COR \cdot (N\_SP\_IS\_COR\_ADD\_LP\_INP_k - N\_SP\_IS\_COR\_ADD\_MMV_{k-1});$$

Determination N_SP_IS_COR

IF **[** N > N_SP_IS + C_N_SP_IS_ADD_ACT_MIN **]**

IF **{** LV_CT = 0 **}** **OR**

{ N_SP_IS + C_N_SP_IS_ADD_LPF_THD < N_SP_IS_COR_2 **}**

THEN N_SP_IS_COR_1 = N_SP_IS_COR_2;

ELSE N_SP_IS_COR_1 = N_SP_IS_COR_3 =

N_SP_IS + N_SP_IS_COR_ADD_MMV$_k$;

ELSE N_SP_IS_COR_1 = N_SP_IS;

ENDIF;

N_SP_IS_COR = **max [** N_SP_IS_COR_1, N_SP_IS **]**;

Determination of N_SP_IS_COR gradient :

N_SP_IS_COR gradient is used to correct engine speed gradient used as input of Idle speed P-D controller. It is N_SP_IS_COR variation over 100 msec. :

N_SP_IS_COR_GRD = (N_SP_IS_COR$_{(n)}$ – N_SP_IS_COR$_{(n-10)}$) / 0.1

N_DIF_3	V/O	8000...7FFFH	-32768...32767	1	rpm
Engine speed deviation 3 N_SP_IS-N					

Input data:

N	N_SP_IS	N_SP_IS_COR	LV_IS
LC_N_SP_IS_COR_CALC	C_N_MAX_IDLE_CALC		

FUNCTION DESCRIPTION:

General information:

Application conditions:

Activation: N <= C_N_MAX_IDLE_CALC

Deactivation: N > C_N_MAX_IDLE_CALC

$N\_DIF_k = N\_DIF_{k-1}$

$N\_DIF\_COR_k = N\_DIF\_COR_{k-1}$

$N\_DIF\_3_k = N\_DIF\_3_{k-1}$

Initialization:

N_DIF	= 0	at reset
N_DIF_MMV	= 0	at reset
N_DIF_COR	= 0	at reset

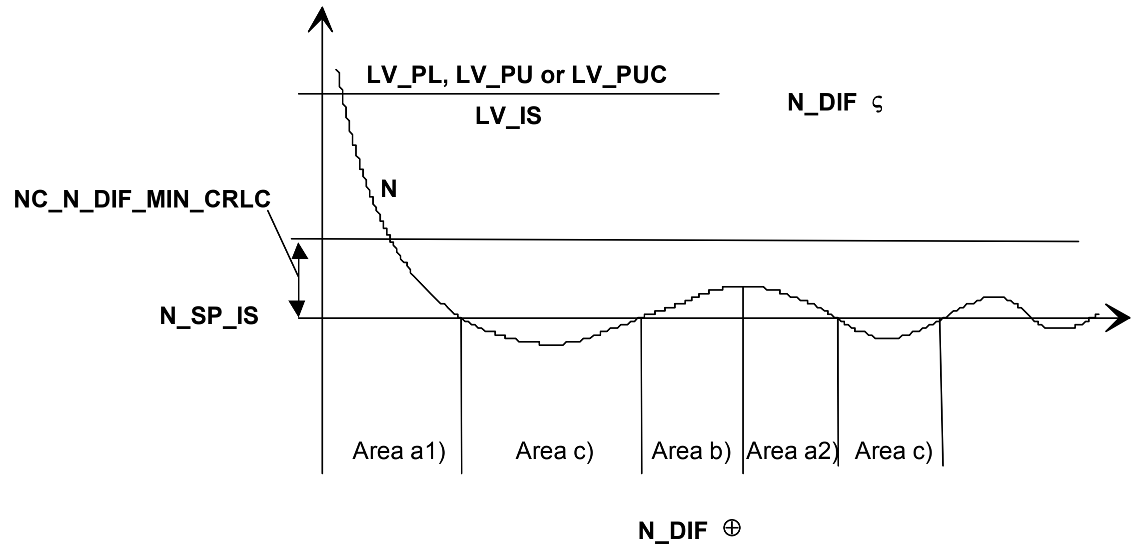
Update rate: 10 ms

Formula section:

N_DIF calculation:

The deviation N_DIF from the nominal idle speed is defined as:

N_DIF = N_SP_IS - N



N_DIF_MMV calculation:

After entry in Idle (LV_IS=1), N_DIF_MMV is set to N_DIF taking into account the limits defined below. Then the moving mean value is determined:

N_DIF_MMV (n) = N_DIF_MMV (n-1) + (N_DIF - N_DIF_MMV(n-1)) * N_DIF_CRLC

The correlation constant C_N_DIF_CRLC may assume 3 discrete values:

a1) Decreasing engine speed above nominal idle speed after entry in Idle (LV_IS=1) and conditions b.) and c.) not previously met (or N_DIF < NC_N_DIF_MIN_CRLC):

(N_DIF (n-3) < N_DIF (n) and N_DIF (n) < 0)

N_DIF_CRLC = **C_N_DIF_CRLC** (per adjustment)

a2) Decreasing engine speed above nominal idle speed

and N_DIF > **NC_N_DIF_MIN_CRLC**

and condition b.) previously fulfilled

N_DIF_CRLC = 1

b) Increasing engine speed above nominal idle speed

((N_DIF (n-3) >= N_DIF (n) and N_DIF (n) < 0)

N_DIF_CRLC = 1

c) Engine speed below nominal idle speed after entry at idle and is still below idle speed

(N_DIF (n) >= 0)

N_DIF_CRLC = 0

Limits of N_DIF_MMV:

C_N_DIF_MIN_MMV <= N_DIF_MMV <= 0

Description:

N_DIF_COR calculation:

N_DIF_COR is relevant for the idle controller (idle-charge actuator and ignition timing):

IF **{** LC_N_SP_IS_COR_CALC = 0 **}** `% this variable is calibratible in`
`% "Engine Speed Setpoint Calculation"`

N_DIF_COR = N_DIF - N_DIF_MMV * C_N_DIF_FAC

ELSE

N_DIF_COR = N_SP_IS_COR – N;

ENDIF;

Calibration data:

4.2.4 Start End Engine Speed

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_MAX_TOL_ST	V / O	0 ... FF H	0 ... 8160	32	rpm
Top level end of start engine speed					

Input data:

TCO	C_N_MAX_IDLE_CALC		

General information:

Application conditions:

Activation: N <= C_N_MAX_IDLE_CALC

Deactivation: N > C_N_MAX_IDLE_CALC

$N\_MAX\_TOL\_ST_k = N\_MAX\_TOL\_ST_{k-1}$

Initialization: N_MAX_TOL_ST = IP_N_MAX_TOL_ST at reset

Update rate: 1 s

Formula section:

N_MAX_TOL_ST = IP_N_MAX_TOL_ST

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_N_MAX_TOL_ST	9	0...FF H	0...8160	32	rpm
LDPM_TCO_9	9	0...FE H	-48 ...142.5	0.75	°C
Top level end of start engine speed					

4.2.5 Engine speed deviation N_DIF_ST

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_DIF_ST	V / O	8000 ... 7FFF H	-32768 ... 32767	1	rpm
Engine speed deviation N_MAX_TOL_ST - N					

Input data:

N	N_MAX_TOL_ST	C_N_MAX_IDLE_CALC	

General information:

The engine speed deviation N_DIF_ST is used as an input variable in module “Torque control at start” for calculation TQ_ST.

Description:

Application conditions:

Activation: N <= C_N_MAX_IDLE_CALC

Deactivation: N > C_N_MAX_IDLE_CALC

$N\_DIF\_ST_{k} = N\_DIF\_ST_{k-1}$

Initialization: N_DIF_ST = conversion(N_MAX_TOL_ST) at reset

Update rate: 10 ms

Formula section:

N_DIF_ST = {conversion(N_MAX_TOL_ST)} - N

conversion means shift from 32 rpm to 1 rpm resolution

4.2.6 Engine speed setpoint ratio

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_SP_IS_RATIO	V / O	0...FFFFH	0... 7,999	122E-6	-
Ratio actual engine speed versus engine speed setpoint at idle

Maximum time of engine speed increasing activation after activation of the function					
LC_N_INC_TCU_REQ	1	0...1H	0 ... 1	1	-
logical constant to allow engine speed incrasing request					

FUNCTION DESCRIPTION:

General information:

The engine speed setpoint request for AT is calculated in this module, after plausibility check of N_SP_IS_TCU = engine speed setpoint request from TCU.
Monitoring is done in "Transmission control unit diagnosis".

Application conditions:

Initialisation: at reset or N = 0 or LV_IGK = 0-> 1

LV_N_INC_TCU_ACT = 0
LV_T_MAX_N_INC_ACT_NOT_PLAUS = 0
N_INC_OLD = 0

Recurrence: 10ms

Activation:

Enable conditions

LV_AT = 1

Activation of the timer T_MAX_N_INC_ACT

Recurrence: 10 ms

If LV_N_INC_TCU_ACT = 1
Then T_MAX_N_INC_ACT incremented until FFFF H
Else T_MAX_N_INC_ACT is initialized with 0

Maximum Requested GS Intervention Time

Maximum requested time for the engine speed controller to be active. If this time is exceeded the request is set as not plausible.

If T_MAX_N_INC_ACT > C_T_MAX_N_INC_NOT_PLAUS
Then LV_T_MAX_N_INC_ACT_NOT_PLAUS = 1
Endif

Save engine speed at LV_N_INC_TCU_REQ set

If LV_N_INC_TCU_REQ = 0 -> 1
Then N_INC_OLD = N
Endif

Check of the activation condition of the rpm controller

If LC_N_INC_TCU_REQ = 1
and VS > C_VS_MIN_N_INC_TCU_ACT
and N_SP_IS_TCU > C_N_SP_IS_TCU_MIN

FUNCTION DESCRIPTION:

General information:

Several conditions can activate an engine speed limit. The actual engine speed limit is calculated as minimal selection of all requests.

Several conditions can activate an engine speed limit:

a1) Engine speed limit for stopped vehicle :

a2) Engine speed limit for highest gear ratio in A/T or M/T-vehicle:

a3) Engine speed limit in case of vehicle speed signal error

a4) Engine speed limit in case of throttle position signal error, mass air flow sensor error or in case of engine speed limitation required by monitoring concept

a5) Engine speed limitation for vehicle speed limitation:

a6) Engine speed limitation in case of CRK error with limp-home activated

a7) Engine speed limitation in case of CAM error with limp-home activated

a8) Engine speed limitation in case of CAM chain ONE_TOOTH_OFF

a9) Engine speed limitation in case of PVS limp-home activated

a10) Engine speed limitation in case of gearbox in neutral

a11) Engine speed limitation in case of too high engine oil temperature

a12) Engine speed limitation in case of sustained engine speed limiter driving

Time recurrence: 100 ms

Initialization (at engine start):

N_MAX_THD	=	NC_N_REF_MAX
N_MAX_NEUTRAL	=	NC_N_REF_MAX
N_MAX_TOIL	=	NC_N_REF_MAX
LV_N_MAX_TOIL	=	0
LV_N_MAX_VS_0	=	0
LV_N_MAX_GR	=	0
LV_N_MAX_VS_ERR	=	0
LV_VS_MAX	=	0

T_N_MAX_VS_0_1	=	0
T_N_MAX_VS_0_2	=	0
LV_N_MAX_PVS_LIH	=	0
LV_N_MAX_RED_ACT	=	0
N_MAX_BAS	=	C_N_MAX
CTR_N_MAX	=	0

Formula section:

a1) Engine speed limit for stopped vehicle :

In order to prevent the catalyst system from over-heating, it is detected if the engine speed stays high with vehicle stopped during a pre-defined time.

if VS = 0
and LV_CT = 0
and LV_DRI = 0
and TCO > C_TCO_N_MAX_VS_0
and **(** N_32 > C_N_MAX_VS_0 **or** LV_N_MAX_VS_0 = 1 **)** [1])
and LV_ERR_CRK = 0
and LV_ERR_CAM_IN_i = 0
and LV_ERR_TCO = 0
and LV_ERR_TCO_STUCK = 0
and LV_ERR_TCO_GRD = 0
and LV_ERR_TCO_PLAUS = 0
and LV_ERR_VS = 0
and LV_ERR_MWSS = 0
then increment T_N_MAX_VS_0_1 (Do NOT reset value if saturation is reached)
if T_N_MAX_VS_0_1 > C_T_N_MAX_VS_0
then LV_N_MAX_VS_0 = 1
and increment T_N_MAX_VS_0_2 (Do NOT reset value if saturation is reached)
and N_MAX_VS_0 = IP_N_MAX_VS_0
else LV_N_MAX_VS_0 = 0
and reset T_N_MAX_VS_0 _1, reset T_N_MAX_VS_0_2
and N_MAX_VS_0 = NC_N_REF_MAX

[1]) This special condition permits to check the N threshold only for activation of LV_N_MAX_VS_0. Once LV_N_MAX_VS_0 is set, the N condition must not be checked anymore.

a2) Engine speed limit for highest gear ratio in A/T or M/T-vehicle:

With highest gear an engine speed limitation can be activated to protect the cardan joints.

```
if      LV_ERR_VS = 0
  and   LV_ERR_MWSS = 0
  and   {     ( LV_AT = 0   and   GR_MT >= C_GR_MT )
        or    ( LV_AT = 1   and   GR_AT >= C_GR_AT ) }
then    N_MAX_GR          = C_N_MAX_GR
  and   LV_N_MAX_GR       = 1
else    N_MAX_GR          = NC_N_REF_MAX
  and   LV_N_MAX_GR       = 0
```

a3) Engine speed limit in case of vehicle speed signal error

```
if      ( LV_ERR_VS = 1    or    LV_ERR_MWSS = 1 )
and     { (LV_AT = 1  and   GR_AT >= C_GR_AT )
        or    LV_AT = 0 }
then    N_MAX_VS_ERR = C_N_MAX_VS_ERR
        and   LV_N_MAX_VS_ERR = 1
else    N_MAX_VS_ERR = NC_N_REF_MAX
        LV_N_MAX_VS_ERR = 0
```

a4) Engine speed limitation request by the ETC limp home management or Monitoring Concept

```
if      STATE_N_LIM_ETC_REQ = N_LIM_CON or LV_N_LIM_REQ_MON = 1
then    N_MAX_ETC_LIH = C_N_MAX_ETC_LIH
else    if    STATE_N_LIM_ETC_REQ = N_LIM_PVS
        then  N_MAX_ETC_LIH = IP_N_MAX_ETC_LIH (PV_AV)
        else  N_MAX_ETC_LIH     = NC_N_REF_MAX
        endif
endif
```

a5) Engine speed limitation for vehicle speed limitation:

In case of vehicle speed limitation the engine speed limitation will be activated.

VS_LIM = max**{** VS, (VS_MAX/32) **}**
(to avoid division by zero and to ensure no overflow of VS_RATIO)

VS_RATIO = VS_MAX / VS_LIM

N_MAX_VS_MAX = N * VS_RATIO

if VS_RATIO <= 1.0
then LV_VS_MAX = 1
else LV_VS_MAX = 0
endif

a6) Engine speed limitation in case of CRK error with limp-home activated

if LV_ACT_LIH_CRK_CAM_IN_1 = 1

then N_MAX_CRK_LIH = C_N_MAX_CRK_LIH

else N_MAX_CRK_LIH = NC_N_REF_MAX

a7) Engine speed limitation in case of CRK error with limp-home activated

if LV_LIH_ERR_CAM = 1

then N_MAX_CAM_LIH = C_N_MAX_CAM_LIH

else N_MAX_CAM_LIH = NC_N_REF_MAX

a8) Engine speed limitation in case of CAM chain ONE_TOOTH_OFF

if LV_ERR_TOOTH_OFF_IN[NC_NR_CAM_CBK] = 1

then N_MAX_ONE_TOOTH_OFF = C_N_MAX_ONE_TOOTH_OFF

else N_MAX_ONE_TOOTH_OFF = NC_N_REF_MAX

endIf

a9) Engine speed limitation in case of PVS limp-home activated

if LV_ACT_PVS_LIH = 1

then N_MAX_PVS_LIH = C_N_MAX_PVS_LIH

LV_N_MAX_PVS_LIH = 1

else N_MAX_PVS_LIH = NC_N_REF_MAX

LV_N_MAX_PVS_LIH = 0

endIf

a10) Engine speed limitation in case of gearbox in neutral

if	LV_AT = 1 **and** LV_DRI = 0
then	N_MAX_NEUTRAL = C_N_MAX_NEUTRAL_AT
elseif	LV_AT = 0 **and** GEAR = 0
then	N_MAX_NEUTRAL = C_N_MAX_NEUTRAL_MT
else	N_MAX_NEUTRAL = NC_N_REF_MAX

a11) Engine speed limitation in case of too high engine oil temperature

if	TOIL ≥ C_TOIL_THD_N_MAX **and** LV_N_MAX_TOIL = 0	
then	LV_N_MAX_TOIL = 1(keep 1 until below 'else' conditions are fulfilled.)	
else	**if**	TOIL < C_TOIL_THD_N_MAX – C_TOIL_HYS_N_MAX
	and	LV_N_MAX_TOIL = 1
	then	LV_N_MAX_TOIL = 0

If	LV_N_MAX_TOIL = 1	
then	**if** LV_AT = 0	
	then	N_MAX_TOIL = IP_N_MAX_TOIL_MT
	else	N_MAX_TOIL = IP_N_MAX_TOIL_AT
else	N_MAX_TOIL = NC_N_REF_MAX	

a12) Engine speed limitation in case of sustained engine speed limiter driving

- *A counter counts up when the engine speed limit is above the threshold*
- *When the counter reaches a threshold the engine speed limit is ramped down*
- *The counter is decremented when the engine limiter is not active*
- *When the counter reaches zero, the higher engine speed limit is allowed again*

if	N_32 > C_N_MAX_RED **and** LV_N_MAX_RED_ACT = 0	
then	CTR_N_MAX = CTR_N_MAX$_{(n-1)}$ + C_CTR_N_MAX_INC	
else		
	if	LV_N_MAX = 0 **and** N_32 <= C_N_MAX_RED
	then	CTR_N_MAX = CTR_N_MAX$_{(n-1)}$ - C_CTR_N_MAX_DEC
		CTR_N_MAX = max(0,CTR_N_MAX) *counter may not go below zero*
	endif	
endif		

Flip Flop construction for LV_N_MAX_RED_ACT

```
if      CTR_N_MAX >= C_CTR_N_MAX_THD
then    LV_N_MAX_RED_ACT = 1
else
        if      CTR_N_MAX = 0
        then    LV_N_MAX_RED_ACT = 0
        endif
endif
```

Selection of raw engine speed limit

```
if      LV_N_MAX_RED_ACT = 1
then    N_MAX_RAW = C_N_MAX_RED
else    N_MAX_RAW = C_N_MAX
endif
```

Gradient limitation of threshold

N_MAX_BAS = N_MAX_RAW (resolution change and gradient limitation)

N_MAX_BAS is gradient limited with C_N_MAX_LGRD in both direction

b) Selection of the currently active engine speed limit N_MAX_THD:

The lowest active engine speed limitation is selected as input for the controller:

```
N_MAX_THD   = MAX {   C_N_MAX_THD_MIN,
                      MIN (  N_MAX_VS_0,
                             N_MAX_GR,
                             N_MAX_VS_ERR,
                             N_MAX_ETC_LIH,
                             N_MAX_VS_MAX,
                             N_MAX_CRK_LIH,
                             N_MAX_CAM_LIH,
                             N_MAX_ONE_TOOTH_OFF,
                             N_MAX_PVS_LIH,
                             N_MAX_NEUTRAL,
                             N_MAX_TOIL
                             N_MAX_BAS        )     }
```

General Information

This module is calculated segment synchronously or two segment synchronously.

The air mass flow MAF_KGH is determined depending on the presence of an air mass flow meter in the system.

- If no air mass flow meter is present, the intake manifold model based MAF_THR is copied to MAF_KGH.

- In a MAF controlled system the measured air mass flow is copied to MAF_KGH.

MAF_DIF is the increase of MAF over the previous segment. In case of two-segment synchronous operation it is half the increase since the previous calculation.

In the case of rapidly falling load, the transition to (LV_PUC) can be accelerated in order to avoid an engine speed run-up, which is undesirable. To trigger this function (see the following chapters: ignition, ignition angle correction for trailing throttle) some load conditions have to be fulfilled.

Hint: The calculation of this module is done synchronously to multiples of a segment.

conversion table for MAF value					

4.6.1 INSY_SIGCVMAF0.

General information:

The raw value for MAF is measured by continous conversion every 1 ms. The raw values (8 bit) are converted by a table ID_MAF_TAB (size: 256 words) into values with the unit [kg/h] and summed up in alternating two buffers, MAF_SUM and MAF_SUM_1. The number of values is counted in MAF_CTR or MAF_CTR_1.

Depending on the logical value LV_MAF_SEG one of the two buffers — MAF_SUM or MAF_SUM_1 — and the respective counter — MAF_CTR or MAF_CTR_1 — are selected for writing, the contents of the other buffer (counter) is used for diagnosis and calculations.

After having read out one buffer — MAF_SUM or MAF_SUM_1 — the buffer has to be cleared as well as the corresponding counter — MAF_CTR or MAF_CTR_1.

A two-buffer-system is used to avoid incorrect MAF calculation. The buffers alternate with each change of segment, i. e. LV_MAF_SEG is toggled each segment always on fixed tooth event before setting crankshaft trigger.

Application Condition

Activation: At every engine state

Deactivation: -

Initialization: After HW reset, the buffers - MAF_SUM and MAF_SUM_1 - and the corresponding counters - MAF_CTR and MAF_CTR_1 - have to be cleared and the pointer has to be initialized with the address of ID_MAF_TAB.

LV_MAF_SEG=0

Calculation recurrence:

Segment synchronous: Calculation of MAF_KGH_MES_BAS

1 ms: Calculation of MAF_SUM and MAF_SUM_1

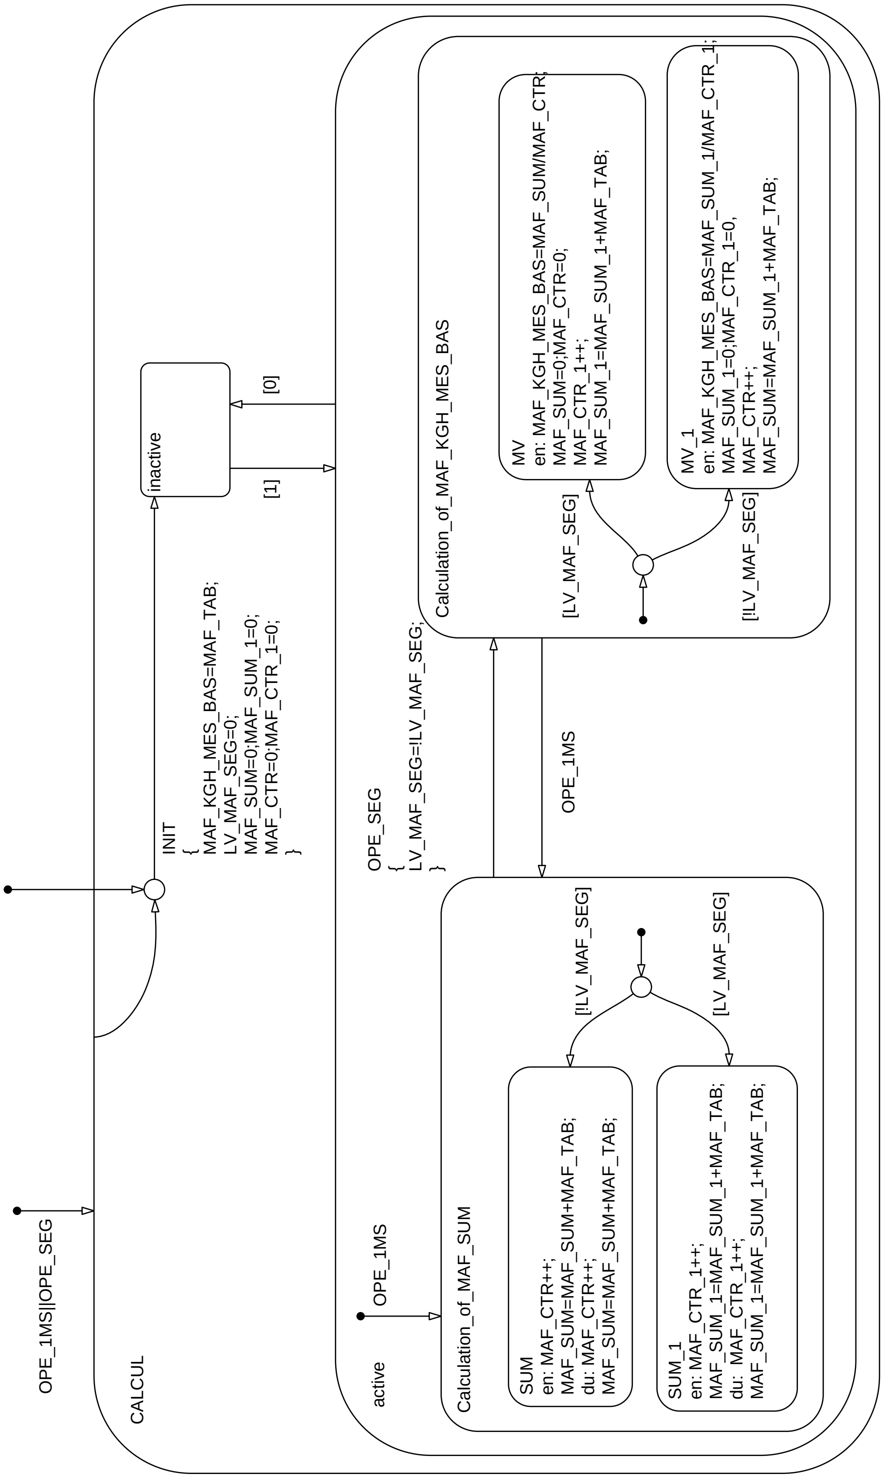

Figure 7 INSY_SIGCVMAF0/ operate/ CALC_MAF_SUM_MAF_KGH_MES_BAS/ CALC_MAF_KGH

Acquisition of mass air flow difference

General information:

For correction of oscillating MAF, the system needs the mass air flow differential that exists through a segment. To obtain this, the maximum and the minimum value - MAF_MAX and MAF_MIN - of MAF, converted by the table ID_MAF_TAB, during the actual segment will be stored in order to calculated the difference (module 30401E01).

Application Condition

Activation:	At every engine state
Deactivation:	-
Initialization:	At reset MAF_MAX=MAF_MAX_intern=0000h MAF_MIN=MAF_MIN_intern=0FFFFh
Calculation recurrence:	1ms If the engine is running on a fixed tooth each segment.

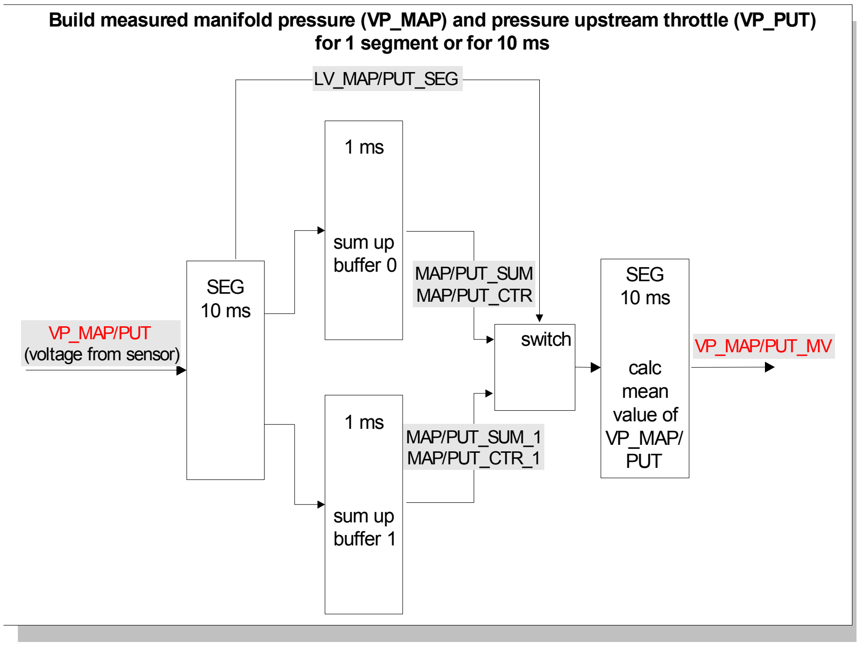
General Information

This module includes the signal conversion of the sensor voltage into the measured pressure signal for all air pressure sensors. Also a pressure adjustment between all the used pressure sensors is done at engine standing before start.



The raw value (voltage) for MAP/PUT is measured by continuous conversion every 1ms. The values (10 bit) are summed up in two alternating buffers, MAP/PUT_SUM or MAP/PUT_SUM_1. The numbers of values are counted in comparable buffers MAP/PUT_CTR or MAP/PUT_CTR_1. This mechanism is necessary to synchronize the measurement and the calculation of MAP/PUT_MES (build mean value with a standardized range)
Depending on the logical variable LV_MAP/PUT_SEG one of the two buffers MAP/PUT_SUM or MAP/PUT_SUM_1 and the respective counter MAP/PUT_CTR or MAP/PUT_CTR_1 are selected for writing, the contents of the other buffer (counter) is used for calculations and diagnosis (after this buffer and the corresponding counter have been read they are cleared).
After having read out one buffer MAP/PUT_SUM or MAP/PUT_SUM_1 the buffer has to be cleared as well as the corresponding counter MAP/PUT_CTR or MAP/PUT_CTR_1.
A twobuffersystem is used to avoid incorrect MAP/PUT calculation.

Note: It must be made sure by SW that the 1ms task is called before the reset.

4.7.2.2.1.1.1 Calculation of VP_MAP_MV if LV_MAP_SAMPLE_DYN = 1:

It is possible for transient operating points only to use the last defined number (= NC_NR_MAP_SAMPLE_ACQ) of samples. Through this the pressure change is included more quickly and the dynamics of the intake manifold model increases.

This mechanism is activated only at transient engine operation. The controlbit LV_MAP_SAMPLE_DYN is set in the Appl.Inc.

4.8.1 General information:

The model mean value MAP_MDL_MV has to be calculated. The sensor behaviour and the data-acquisition of the ECU is integrated in the model to minimize the deviations under transient engine operating. In the case of a bad sensor signal (LV_MAP_CTL=0) this value will be used as substitution for the measured manifold pressure sensor value.

Function Description

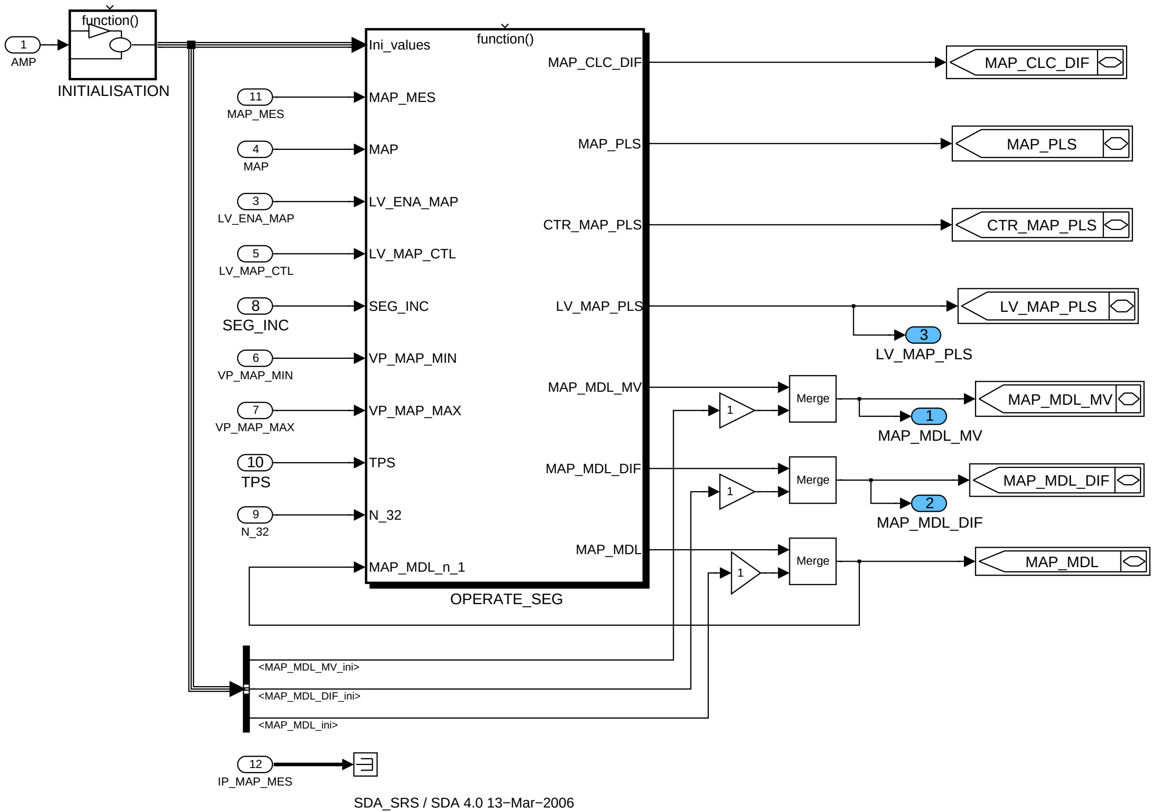

Figure 52 INSY_MDLADMAP0

4.8.1.1 Initialization:

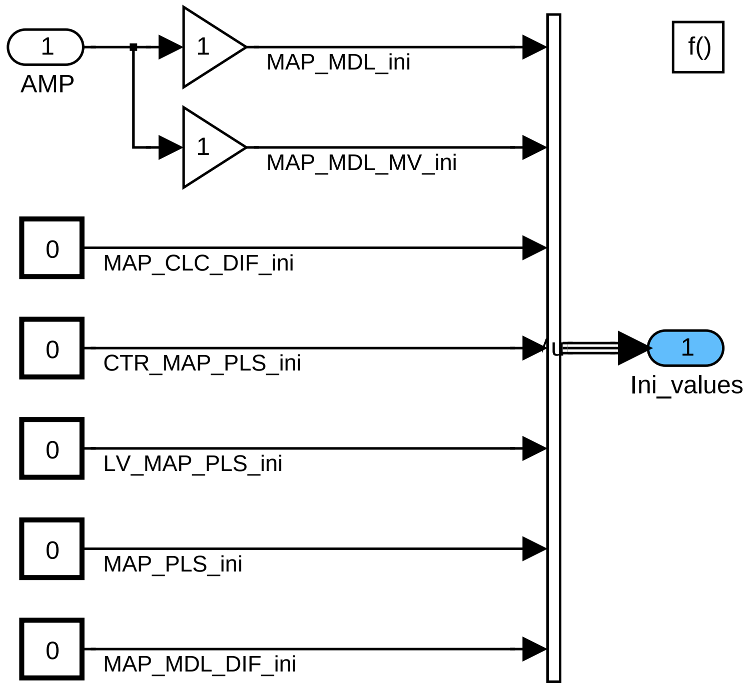

Figure 53 INSY_MDLADMAP0/ INITIALISATION

4.8.1.2 Calculation of model deviation MAP_MDL_DIF

The deviation between the model manifold pressure and the measured manifold pressure will be calculated only if the sensor is diagnosed as properly working.

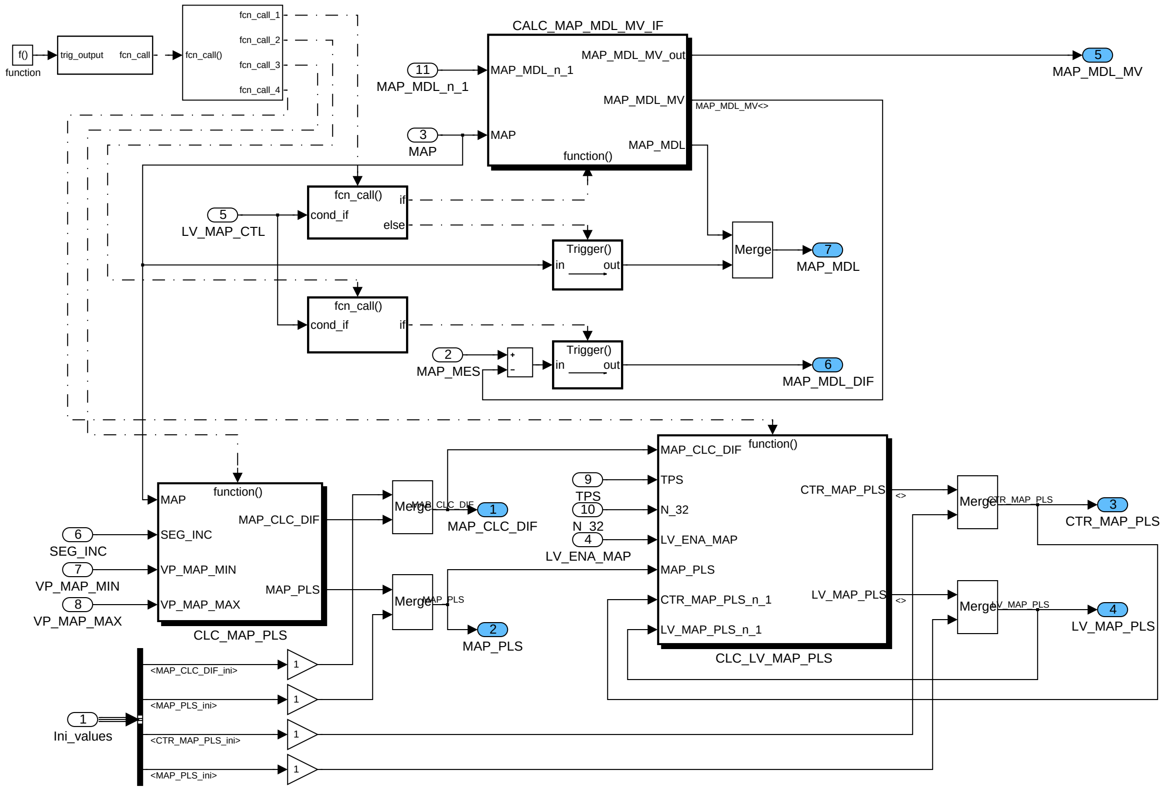

Figure 54 INSY_MDLADMAP0/ OPERATE_SEG

Calculation of model manifold pressure mean value MAP_MDL_MV

The scanning of the manifold pressure by the ECU is described by the mean value between the two previous segments. This calculation only takes place if the sensor is properly working.

4.9.1 INSY_MDLADMAF0

MAF_KGH_MES is equivalent to MAF_KGH_MES_BAS corrected by the factor MAF_KGH_MES_FAC.

The air-mass MAF_MES in [mg/stroke] is calculated from the measured air-mass flow MAF_KGH_MES and engine speed N. NC_MAF_FAC_CYL is inversely proportional to the number of cylinders, so the output MAF_MES depends on the number of cylinders.

Maximum and minimum air mass values are determined via a segment, from which results the differential air mass value. The values MAF_MAX and MAF_MIN are the maximum and minimum air mass flow values in [kg/h], they are converted in [mg/stroke] via the engine speed and the number of cylinders.

The model mean value MAF_MDL_MV has to be calculated. The sensor behavior and the data-acquisition of the ECU are integrated in the model to minimize the deviations under transient engine operating. In the case of a bad sensor signal (LV_MAF_CTL = 0) this value will be used as substitution for the measured air-mass flow value.

Function Description

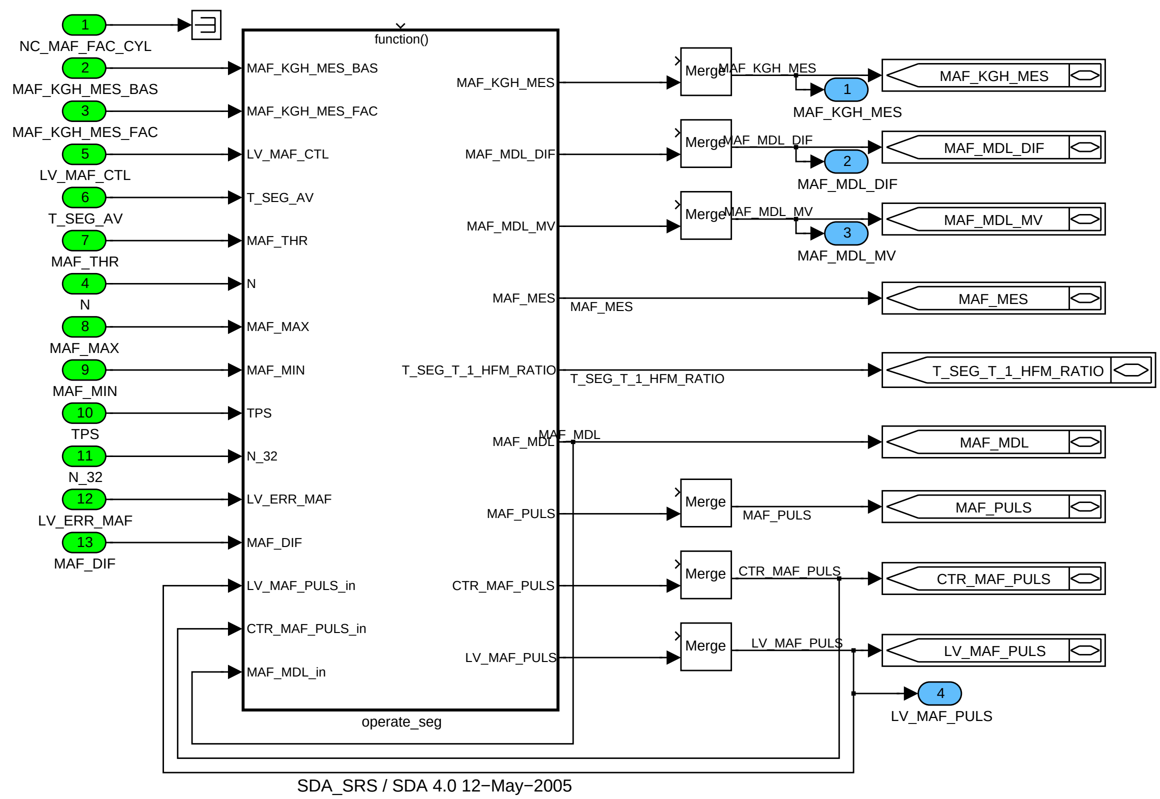

Figure 59 INSY_MDLADMAF0

4.9.1.1 INSY_MDLADMAF0/OPERATE_SEG

MAF_KGH_MES and MAF_MES are calculated seperately before the intake manifold model. The remaining calculations are done after the intake manifold model.

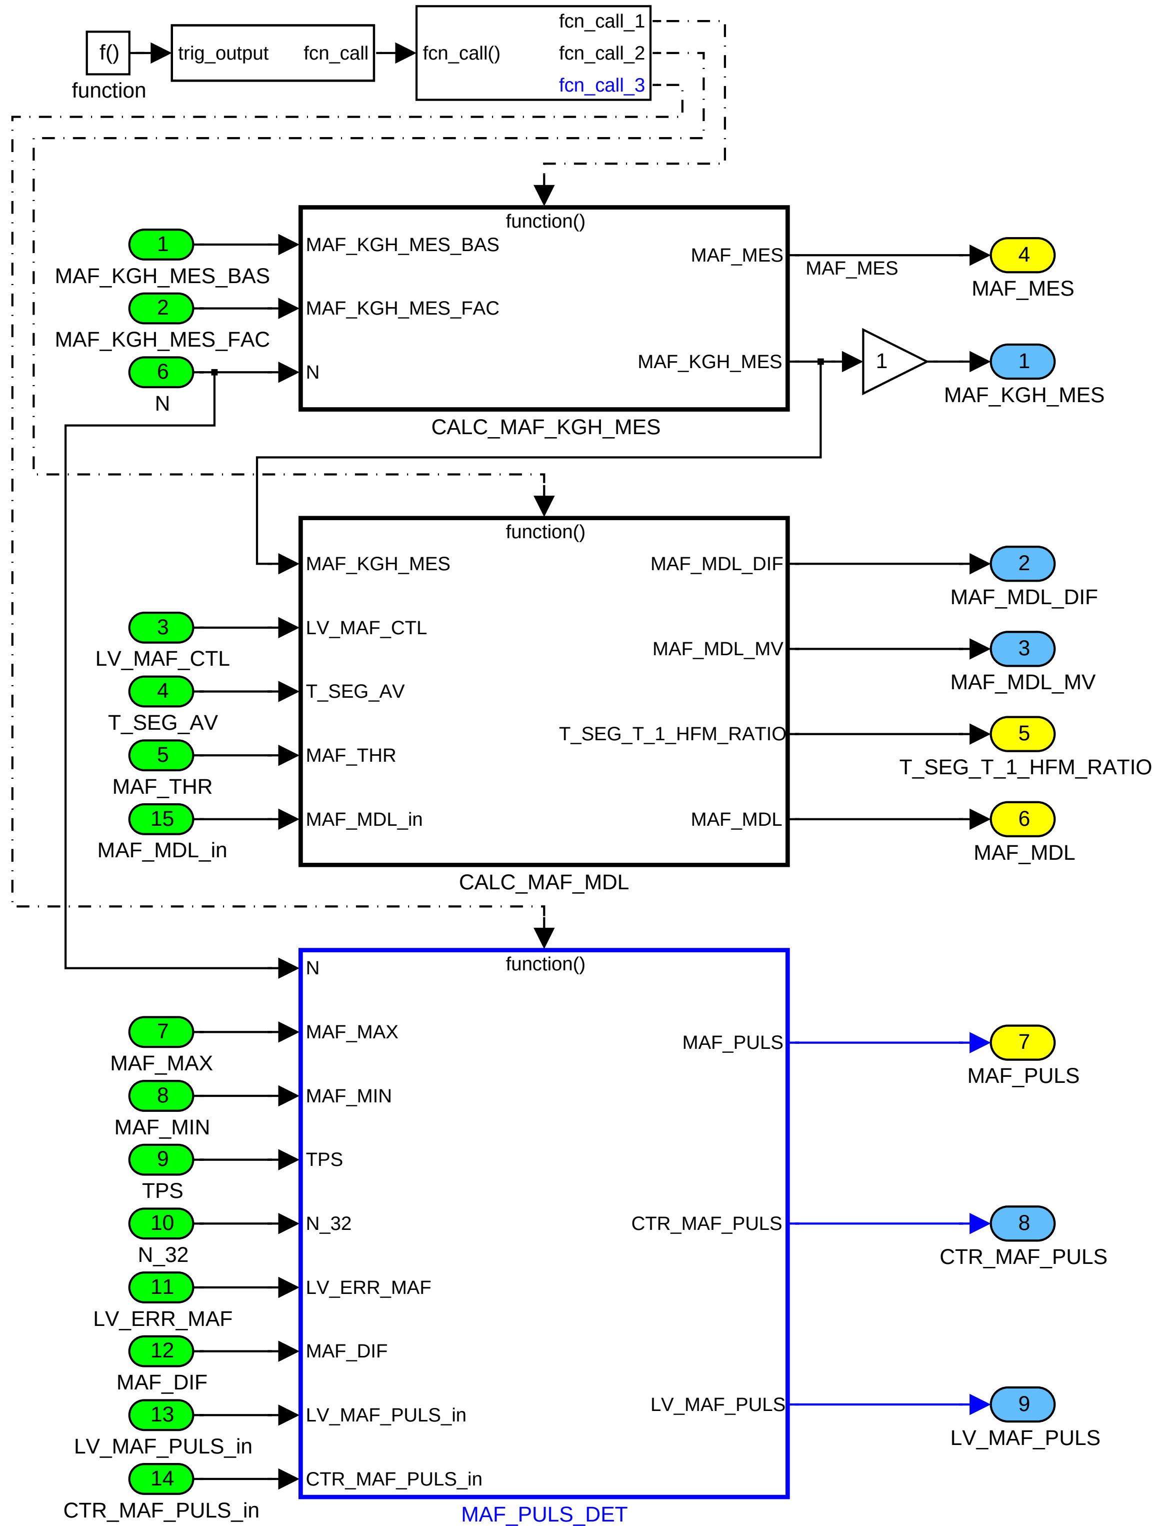

Figure 60 INSY_MDLADMAF0/ operate_seg

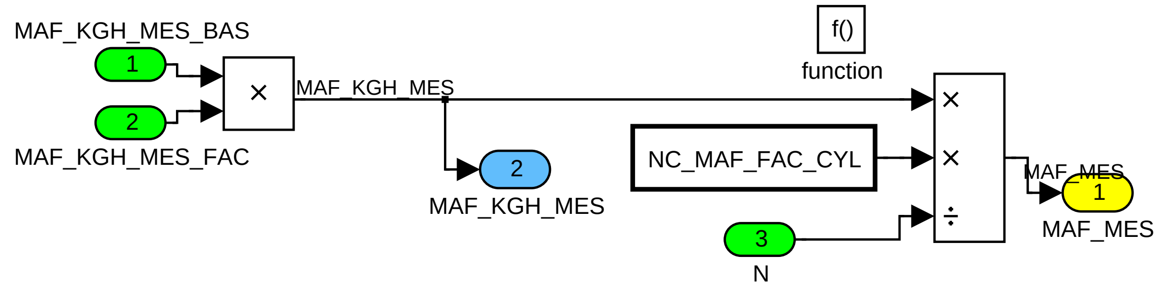

Figure 61 INSY_MDLADMAF0/ operate_seg/ CALC_MAF_KGH_MES

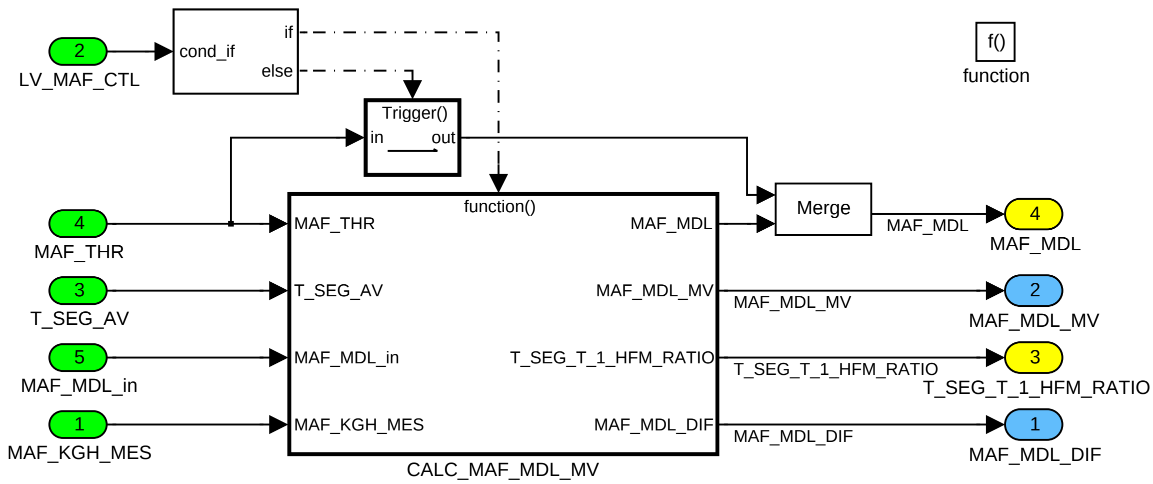

Figure 62 INSY_MDLADMAF0/ operate_seg/ CALC_MAF_MDL

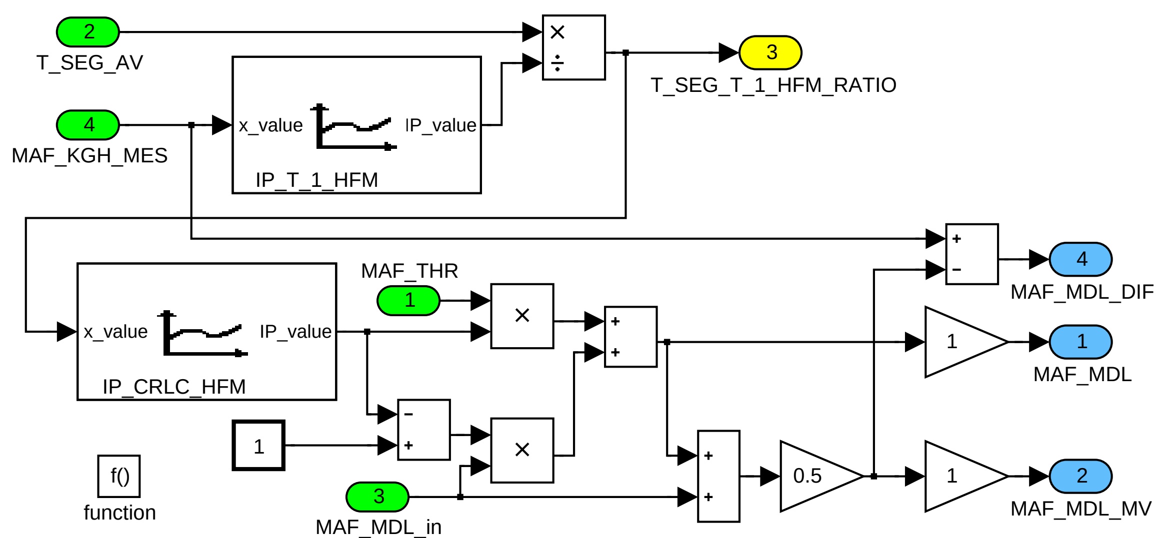

Figure 63 INSY_MDLADMAF0/ operate_seg/ CALC_MAF_MDL/ CALC_MAF_MDL_MV

INSY_MDLADMAF0/OPERATE_SEG/MAF_PULS_DET

If the difference of maximum and minimum air mass flow during a segment MAF_PULS is greater than a threshold MAF_PULS_MAX LV_CTR_SET_MAF_PLS is set. If MAF_PULS is smaller than MAF_PULS_MAX minus a hysteresis LV_CTR_RST_MAF_PLS is set. When any of these bit toggles then the counter CTR_MAF_PULS is initialized with C_CTR_MAF_PULS; otherwise CTR_MAF_PULS is decreased. If LV_CTR_SET_MAF_PLS has been set for C_CTR_MAF_PULS consecutive cycles, then MAF pulsation is detected (LV_MAF_PULS = 1). If LV_CTR_RST_MAF_PLS has been set for C_CTR_MAF_PULS consecutive cycles, then no MAF pulsation is detected (LV_MAF_PULS = 0).

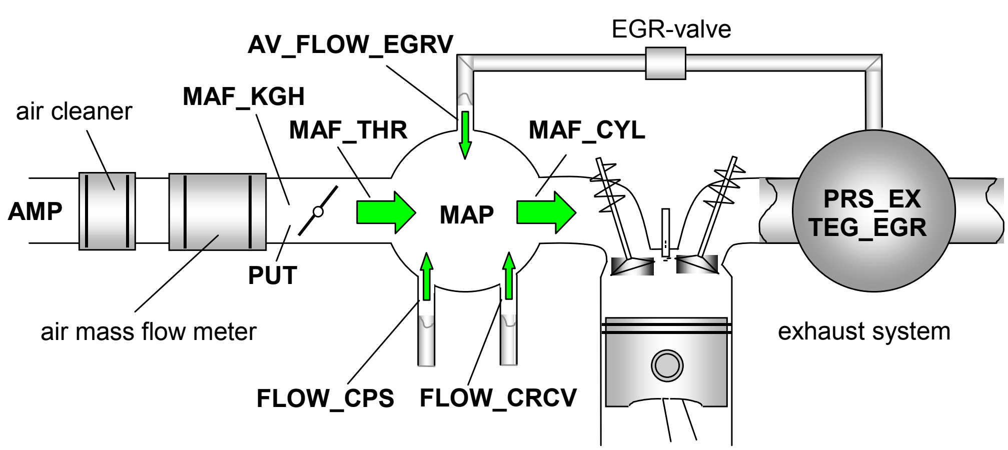
General Information



The intake manifold model calculates the air mass flow at the throttle, the air mass flow into the cylinder and the pressure in the intake manifold. In case of exhaust gas recirculation (NC_EGR_CONF = 1) the exhaust gas flow will be considered. If the system is not equipped with an EGR then some of the calculations need not to be done (reduction of calculation time).

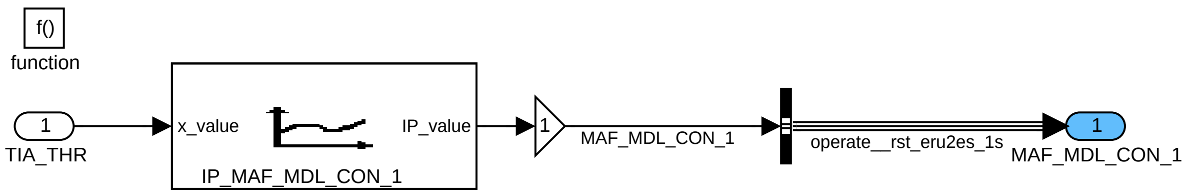

Figure 68:
Path: INSY_DTSYSIMM0/operate__1S

4.10.3 Calculation of Constants

During one loop some variables are used twice or more. These constants are prepaed at the beginning of the calculation process. The intake air temperature is scanned once a second and for the multiplication converted into the unit [°Kelvin].
The variable RA_VOL_IM represents the specific gas constant of air (RA = 287 [J/(kgK)]) devided by the intake manifold volume (m3]). Due to the influence of engine speed and load change it is defined as a map and not as a single constant.
Note: RA_VOL_IM and MAF_MDL_CON_0 have to be calculated at reset for the first time. Then the calculations run synchronously to multiples of a segment.

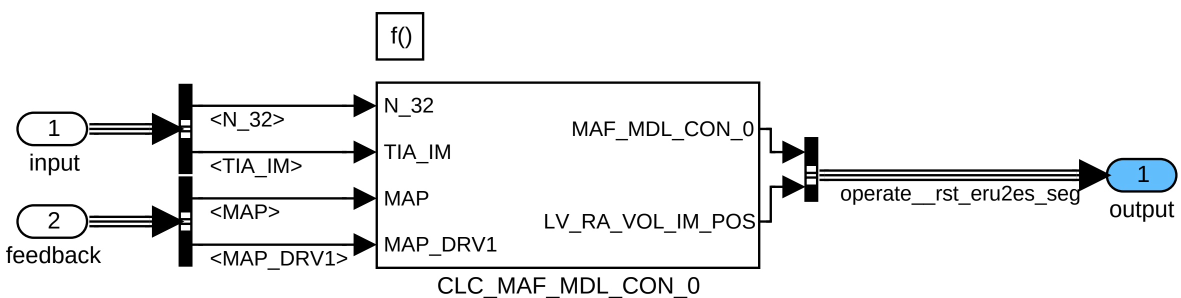

Figure 69:
Path: INSY_DTSYSIMM0/operate__RST_ERU2ES_SEG

4.10.3.1 Calculation of MAF_MDL_CON_0 and RA_VOL_IM:

4.10.4.1 Calculation of MAP_ESTIM:

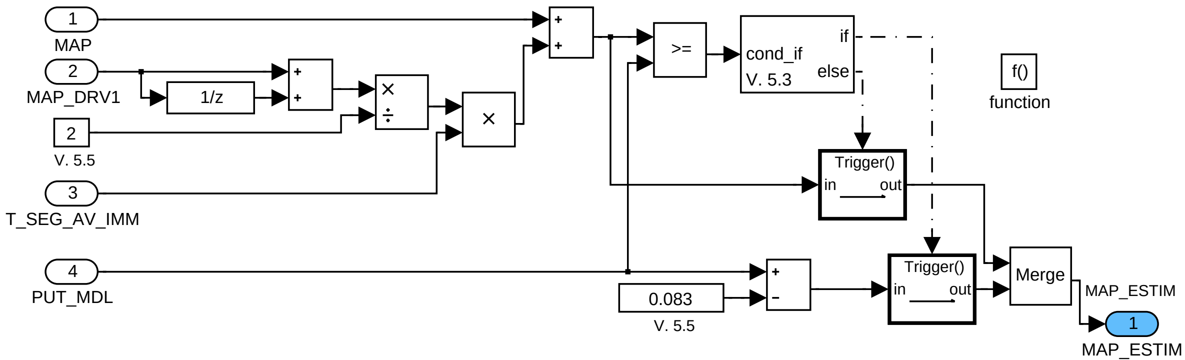

Figure 74:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_MAP_ESTIM

4.10.4.2 Estimation of the pressure quotient of PQ_ESTIM:

For the calculation of the manifold air pressure the slope MAF_FAC_SLOP and the offset MAF_FAC_OFS of the linearized air-flow function are necessary. An estimation of the future pressure quotient is done. It is necessary to make a estimation for the pressure quotient at the throttle. MAF_FAC_SLOP and MAF_FAC_OFS are read out of two interpolation table.
Slope MAF_FAC_SLOP and offset MAF_FAC_OFS of the throttle equation are read synchronously to multiples of a segment from the tables ID_MAF_FAC_OFS and ID_MAF_FAC_SLOP. The two maps have the same list of data points (LDPM_PQ_ESTIM_1_INSY).

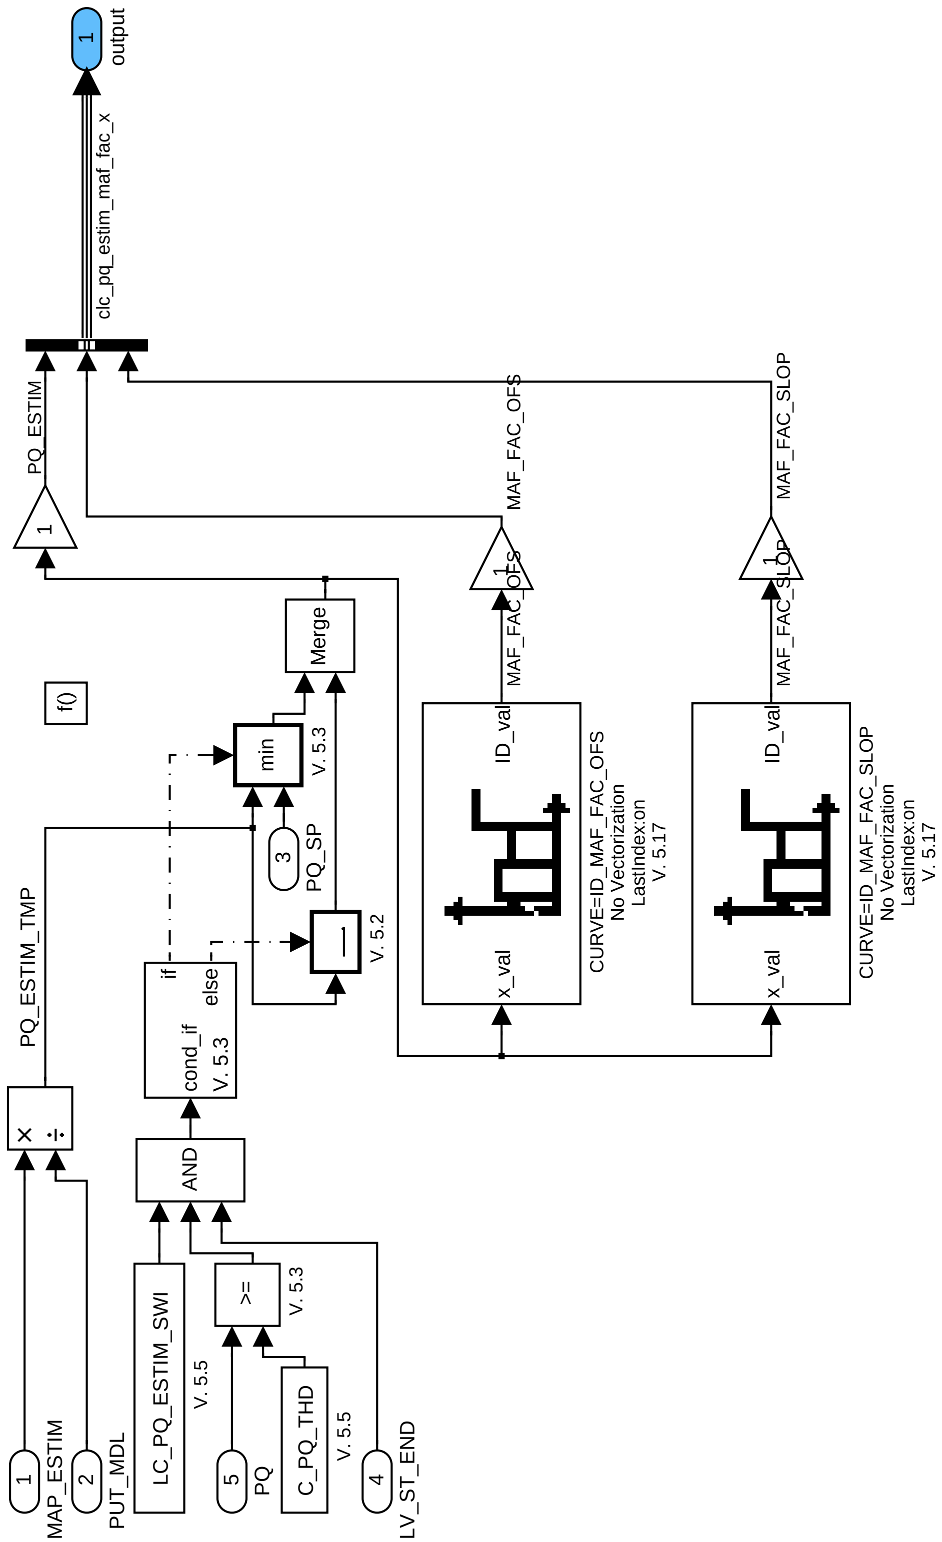

Figure 75:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PQ_ESTIM_MAF_FAC_X

4.10.4.3 Calculation of the manifold pressure MAP

The term of the air flow calculation at the throttle depending on the intake air temperature is stored in the map IP_MAF_MDL_CON_1. This interpolation can be done in the time schedule (once a second).
Note: MAF_MDL_CON_1 has to be calculated at reset for the first time.

Path: INSY_DTSYSIMM0/operate__SEG/CLC_MAP_CLC/CLC_PQ

4.10.4.4 Calculation of MAP_EGR, MAP_EGR_DRV1, MAP_FG, and MAP_EGR_RATIO

Most parts of this chapter have only to calculated if NC_EGR_CONF = 1. As the total pressure in the manifold is known, it is possible to calculate the mass flow at the EGR valve and therefore the residual gas pressure in the intake manifold. With the residual gas pressure and the total manifold pressure the fresh gas partial pressure can be calculated.

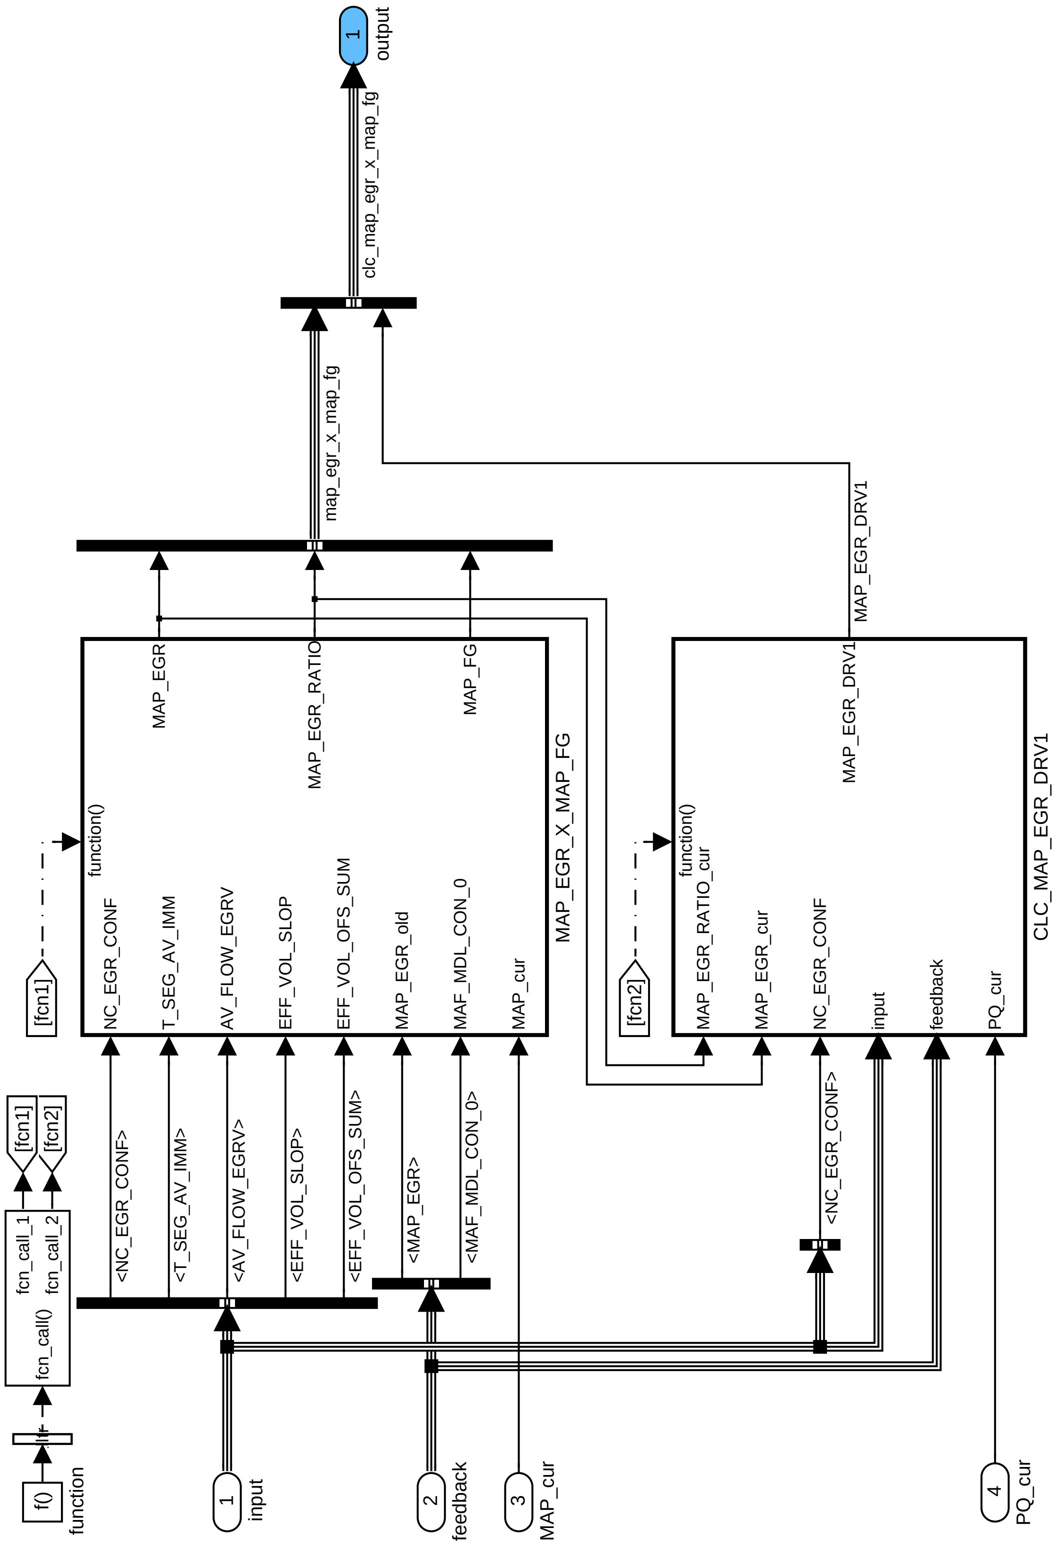

Figure 90:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_MAP_EGR_X_MAP_FG

4.10.4.4.1 Calculation of MAP_EGR_X_MAP_FG

4.10.4.5 Calculation of the throttle and cylinder air flows

With the new manifold pressure it is possible to calculate the actual gas flows into and out of the manifold. Further for the next step the change of manifold pressure is calculated. The complete gas flow into the cylinder is:

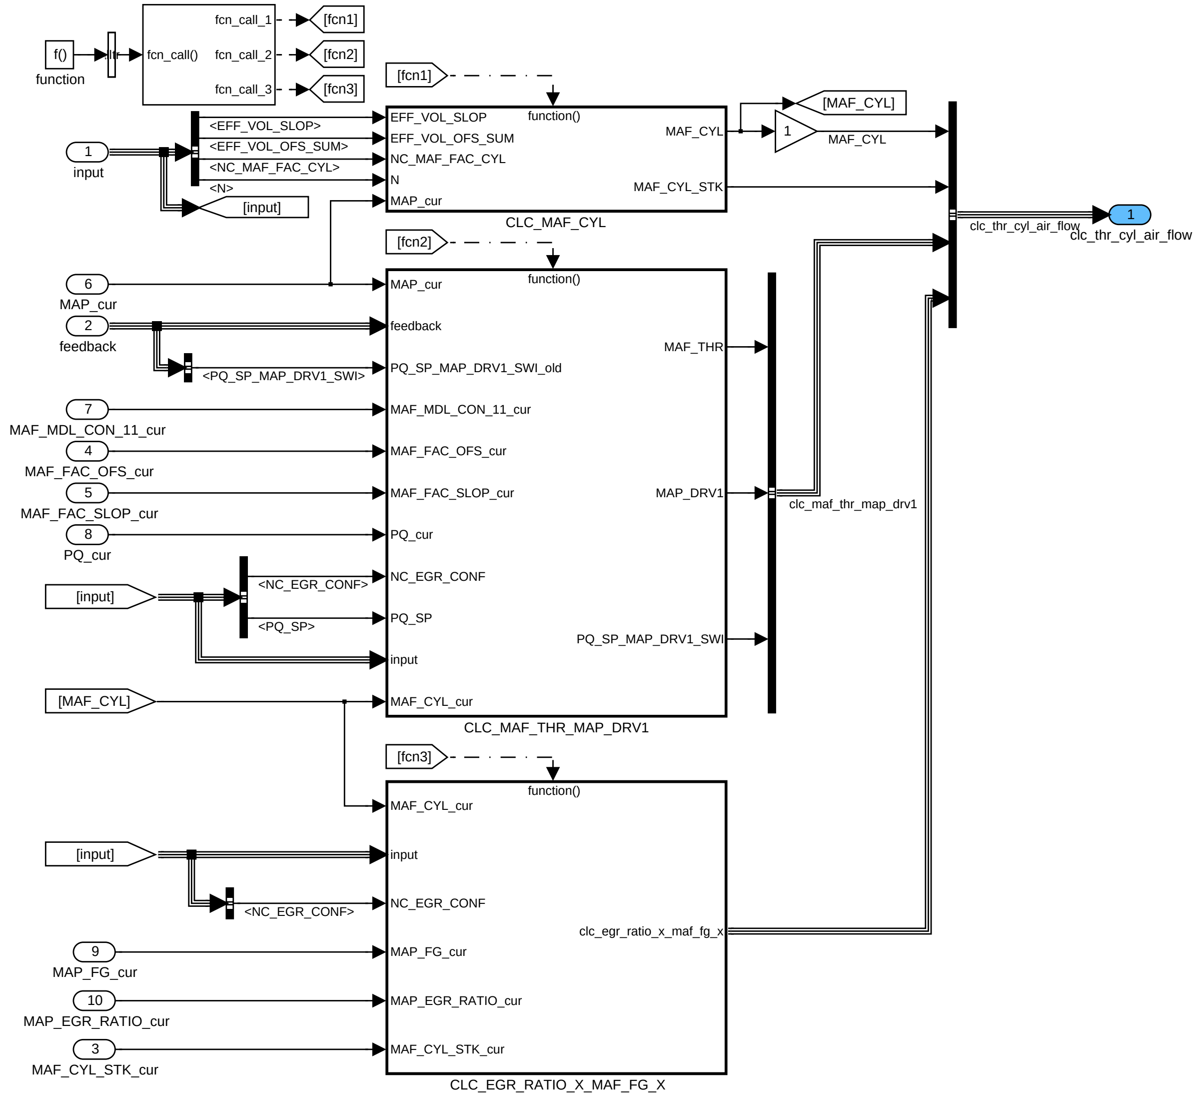

Figure 95:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_THR_CYL_AIR_FLOW

4.10.4.5.1 Calculation of MAF_CYL

For taking into account pumping losses of the engine the segment synchronous variable MAF_CYL_STK is needed (in module TQ_LOSS).

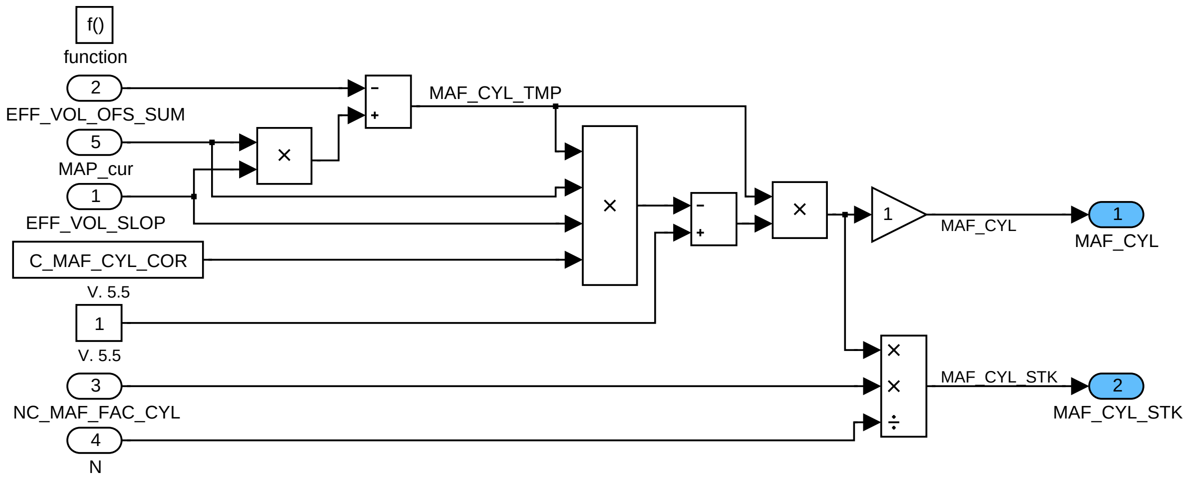

Figure 96:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_THR_CYL_AIR_FLOW/CLC_MAF_CYL

4.10.4.5.2 Calculation of MAF_THR and MAP_DRV1

The air-flow at the throttle and the pressure change in the manifold are calculated as:

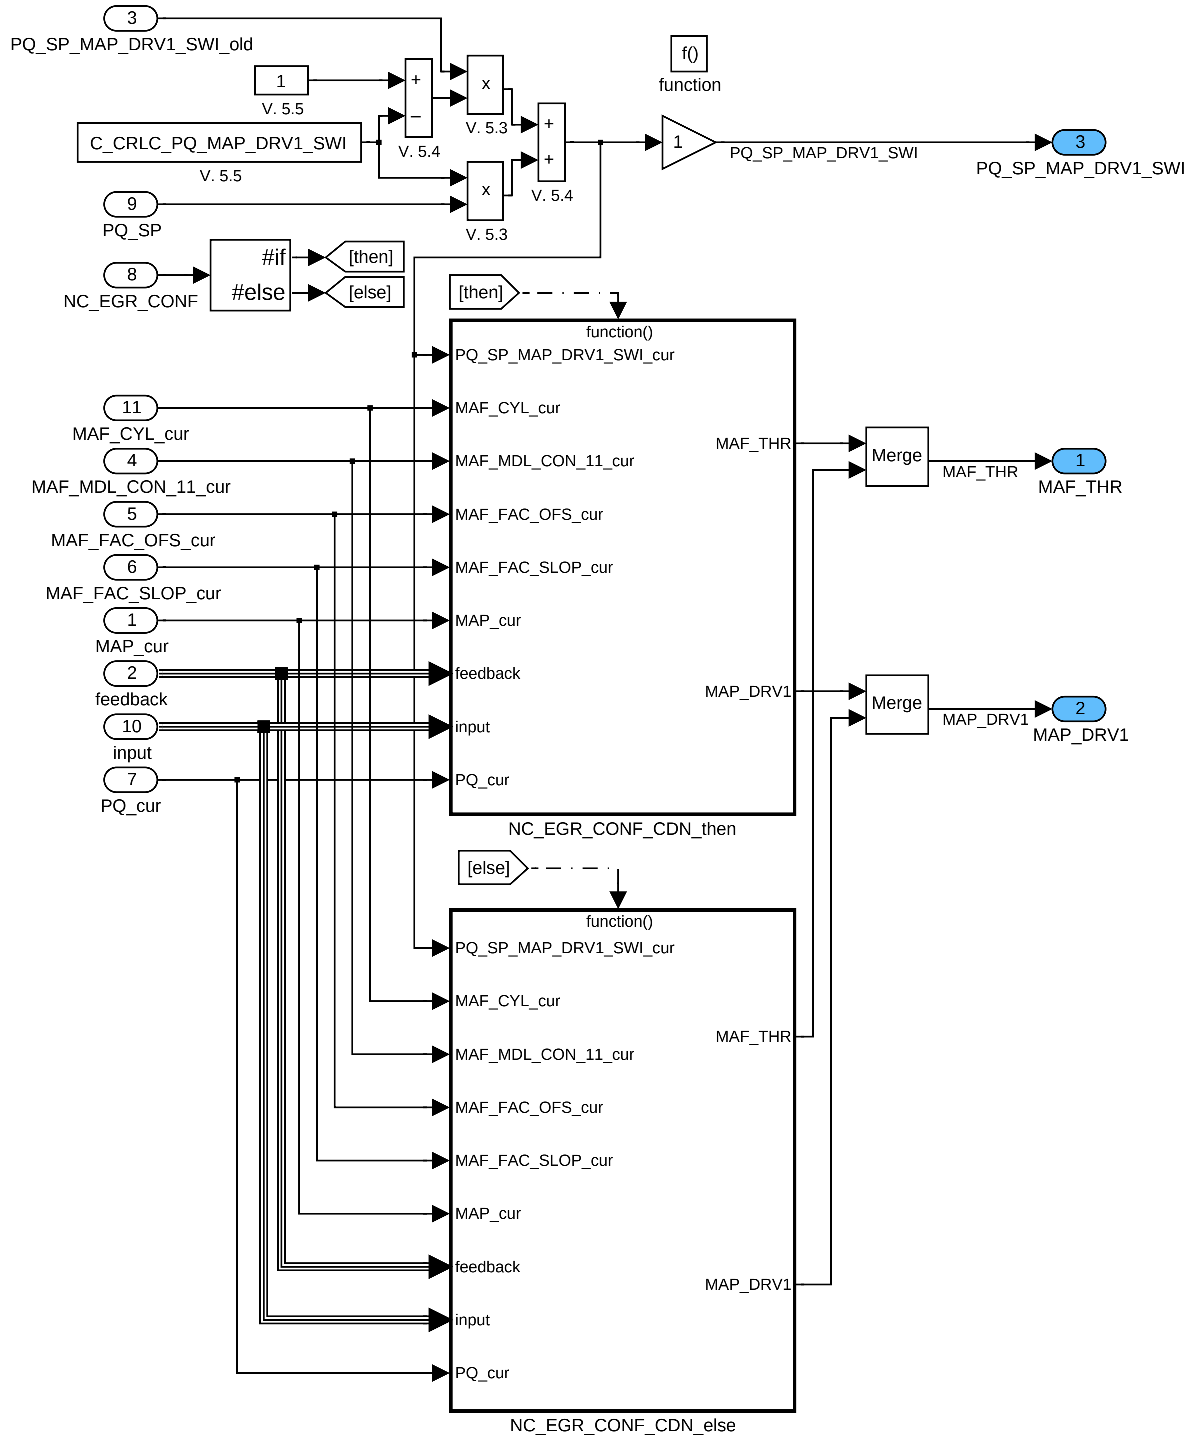

Figure 97:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_THR_CYL_AIR_FLOW/CLC_MAF_THR_MAP_DRV1

4.10.4.5.2.1 Calculation of MAF_THR and MAP_DRV1 - then branch

For systems with EGR.

4.10.4.6 Pressure predictions and the cylinder air mass prediction

The change of pressure in the actual and previous segment is known. So it is possible to predict the manifold air pressure for a various number of segments. The number of segments for the prediction (prediction horizon) is a function of engine speed.

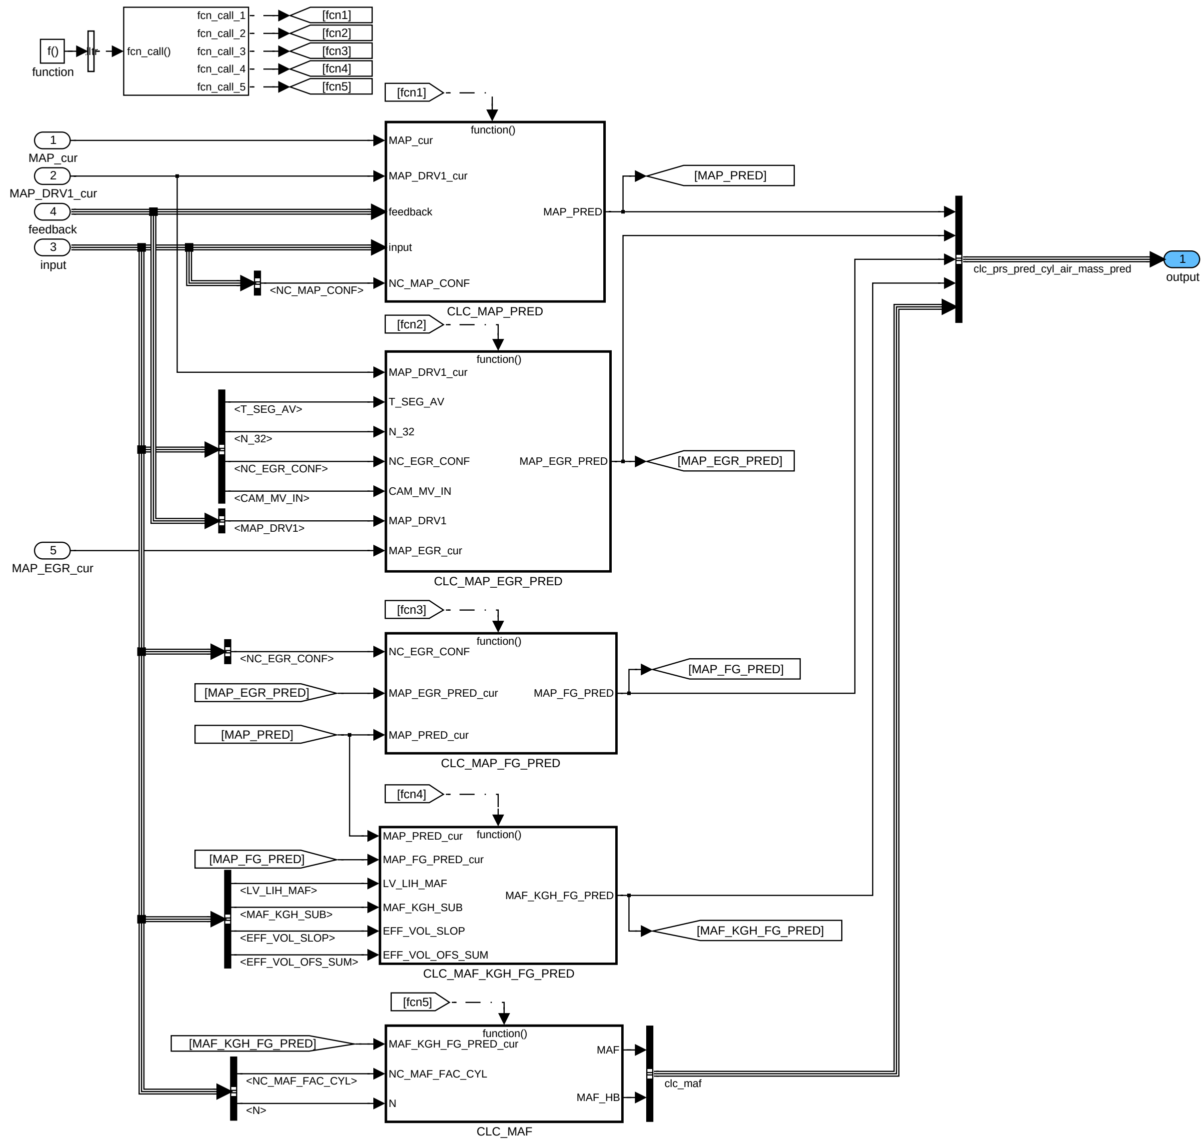

Figure 114:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED

4.10.4.6.1 Calculation of MAP_PRED

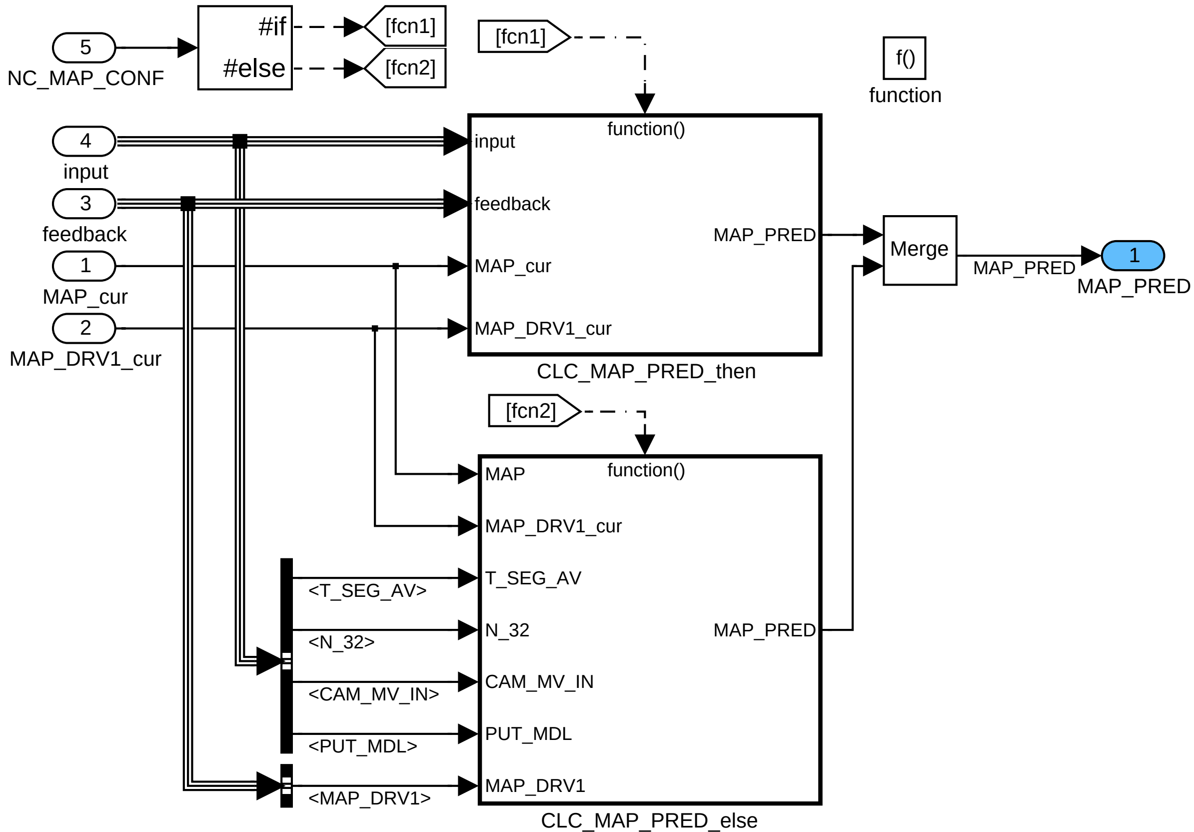

Figure 115:

Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAP_PRED/CLC_MAP_PRED_else

4.10.4.6.2 Calculation of MAP_EGR_PRED

The predicted residual gas partial pressure in the manifold is given by:

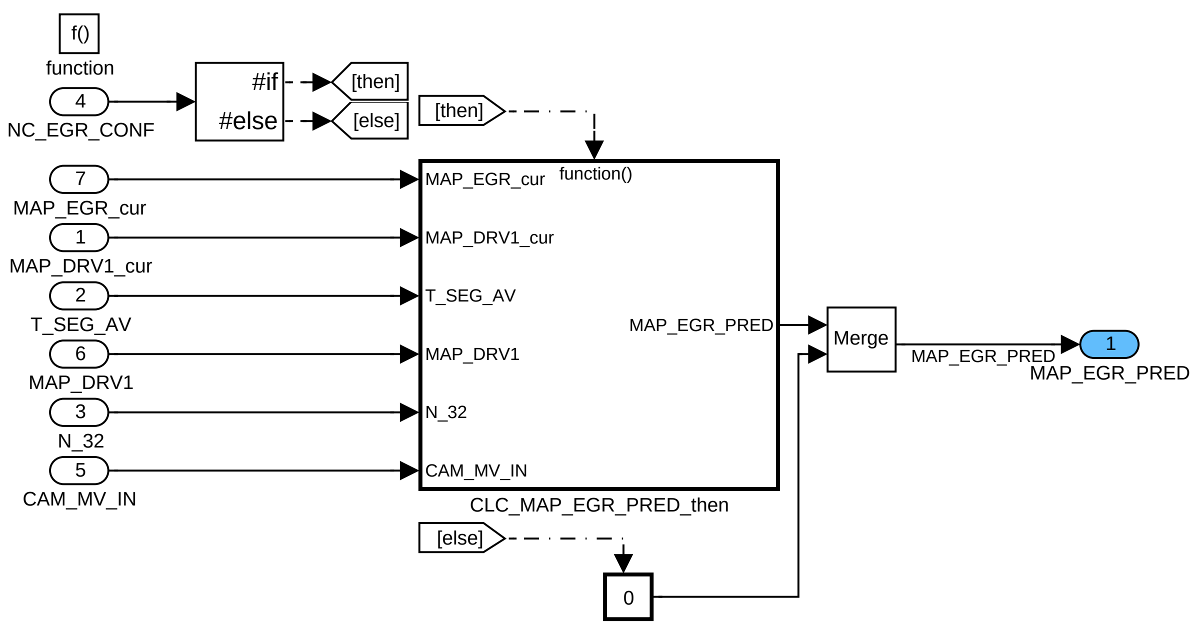

Figure 120:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAP_EGR_PRED

4.10.4.6.2.1 Calculation of MAP_EGR_PRED - then branch

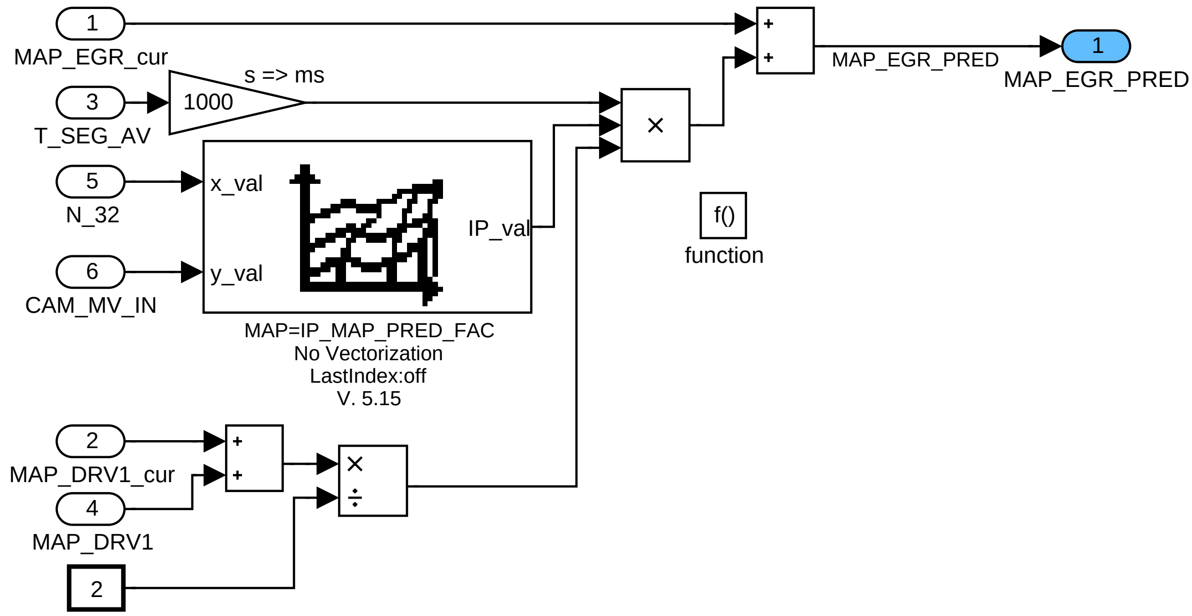

Figure 121:
Path:
INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAP_EGR_PRED/CLC_MAP_EGR_PRED_then

4.10.4.6.3 Calculation of MAP_FG_PRED

With the predicted manifold pressure and the residual gas pressure it is possible to calculate the fresh air partial pressure and the predicted mass of fresh air into the cylinder. In case of a TPS error non ETC systems use the measured mass air flow as an substitute for the air mass flow model value.
The predicted fresh gas partial pressure in the manifold is given by:

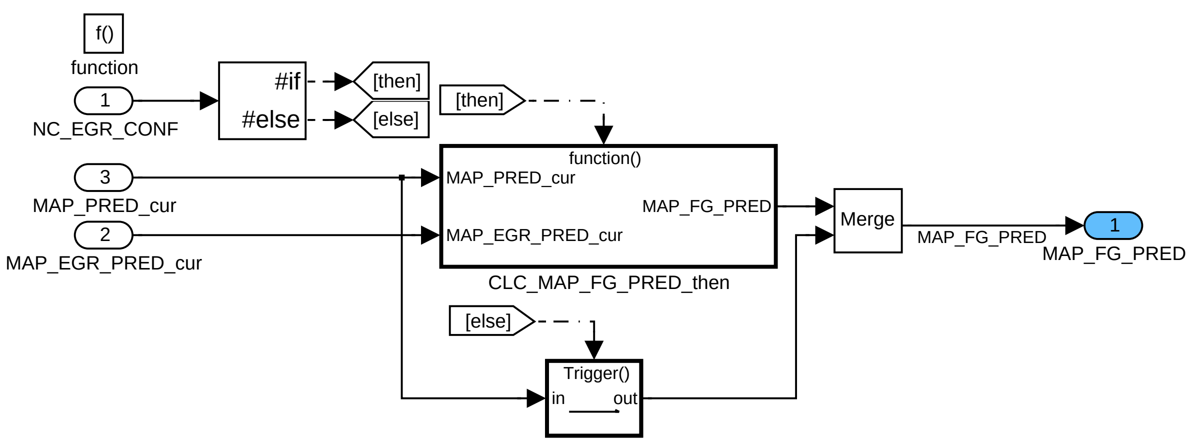

Figure 122:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAP_FG_PRED

4.10.4.6.3.1 Calculation of MAP_FG_PRED - then branch

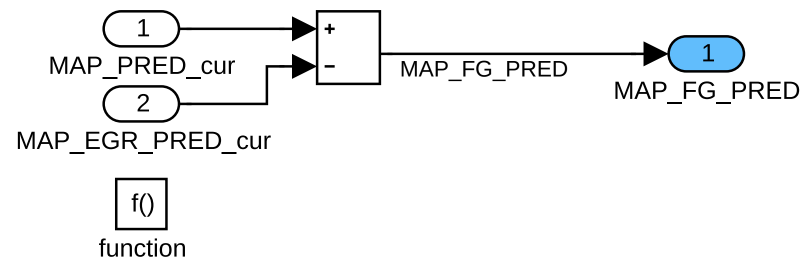

Figure 123:
Path:
INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAP_FG_PRED/CLC_MAP_FG_PRED_then

4.10.4.6.4 Calculation of MAF_KGH_FG_PRED:

It is necessary to consider two different errors (they are defined in the Intake Manifold Model Appl. Inc.) because if one of these errors occurs then we have to calculate the predicted fresh gas out of the manifold in the following way (using a map or using the measured value).

The predicted fresh gas mass flow out of the manifold is given by:

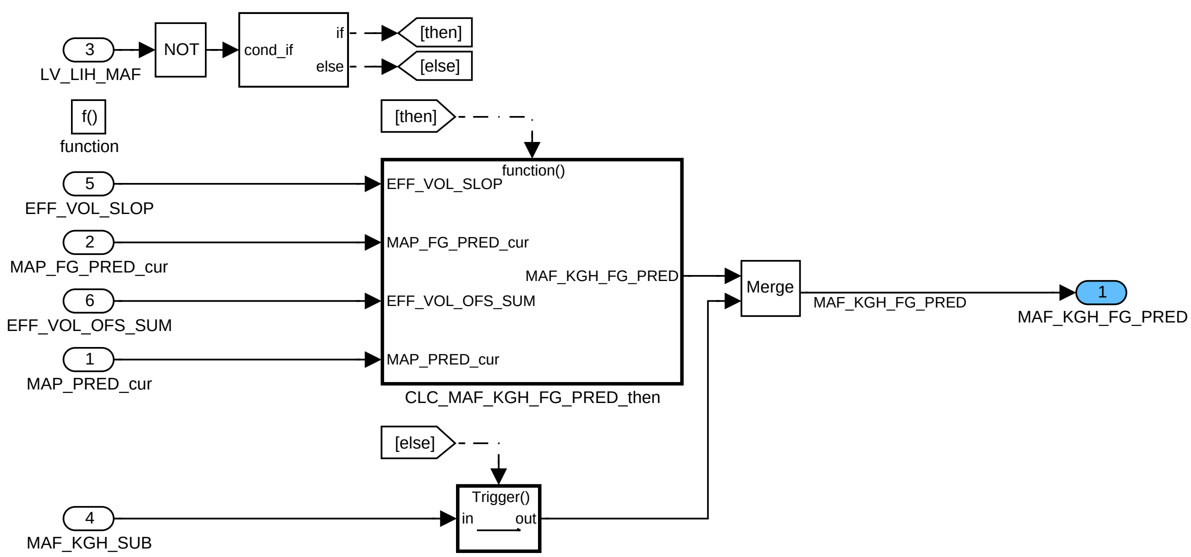

Figure 124:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAF_KGH_FG_PRED

4.10.4.6.4.1 Calculation of MAF_KGH_FG_PRED - then branch:

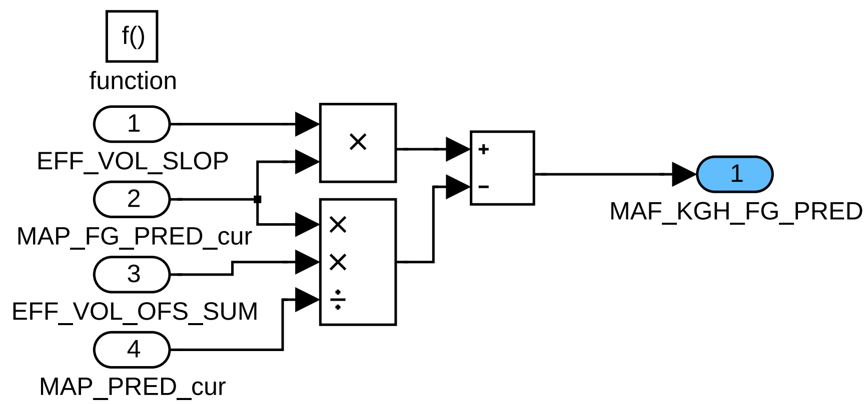

Figure 125:
Path:
INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAF_KGH_FG_PRED/CLC_MAF_KGH_FG_PRED_then

4.10.4.6.5 Calculation of MAF:

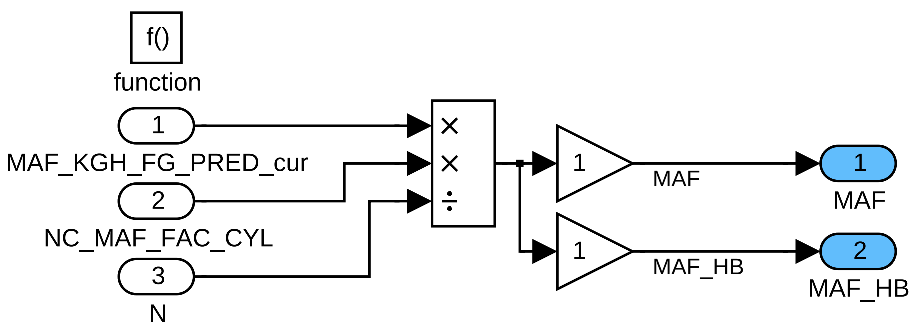

Figure 126:
Path: INSY_DTSYSIMM0/operate__SEG/CLC_PRS_PRED_CYL_AIR_MASS_PRED/CLC_MAF

FUNCTION DESCRIPTION:

General information:

The configuration of the system is done with the non-calibratable constants. Those constants are also used as compiler switches in some cases.

Application conditions:

Initialization: The initialization at reset is split up:

- part 1: only "Setting of sensor configuration" (chapter 1.1.1)
- part 2: all other "initialization at reset" - tasks

Activation:	at every engine state
Deactivation:	-
Calculation recurrence:	10 ms
Segment synchronous	1.1.3 TPS error handling. To adjust STATE_TPS_DIAG (10 ms) to LV_LIH_MAF (segment synchronous) just "If-Then-Else" loop No.:(2) (Definition of LV_LIH_MAF) is calculated every 10 ms. 1.1.5 ISA opening limitation in case of suspected TPS Ratio failure LV_TPS_GRD_CTL_STOP calculation

4.11.1 Adjustment of Intake System

4.11.1.1 System load sensor (MAF/MAP-System)

Via CONF_MAF it is possible to switch between MAF- and MAP controlled System. The MAF, MAP or AMP sensor can switched off via the variables LV_MAF_SWI, LV_MAP_SWI and LV_AMP_SWI.

Additionally the MAF signal can be calculated via second Input (alternative to PUT-Sensor Input for Non-Turbo versions). This is determined only for Calibration Purpose.

Initialization: At Reset – Setting of Sensor configuration (Initialization at reset – part 1)

If CONF_MAF = 1

Then LV_MAP_SWI = 0

LV_MAF_SWI = 1

Else LV_MAP_SWI = 1

LV_MAF_SWI = 0

Endif

If LC_TCHA_CONF = 1

Then LV_AMP_SWI = 1

LV_PUT_SWI = 1

LV_MAF_CAL_SWI = 0

Else LV_AMP_SWI = 0

LV_PUT_SWI = 0

LV_MAF_CAL_SWI = 1

Endif

The correction value MAF_KGH_MES_FAC is included to correct the MAF_KGH_MES (measured air-mass flow) in case of strong pulsation. As the engine speed where pulsation occurs is depending on air temperature (air velocity change), a corrected engine speed is used to interpolate IP_MAF_KGH_MES_FAC. Offset engine speed is typically positive for high air temperature and negative for low air temperature.

Furthermore a Trimming Factor is applied to compensate EMS MAF Signal Input Circuit Tolerance. The Trimming Factor is determined at the EMS Production Line and then stored in the non-volatile Memory. The Trimming Factor is corrected by an additional Compensation Factor depending on VP_MAF to compensate the non-linear MAF Linearization Characteristic.

Initialization at reset: MAF_KGH_MES_FAC = 1

Segment synchronuos update:

N_MAF_MES_FAC = N + IP_N_MAF_MES_FAC_OFS (TIA)

<u>Remark</u> : if the result of N + IP_N_MAF_MES_FAC_OFS (TIA) is below 0 or above 8160 (min. / max. limits of engine speed), then N_MAF_MES_FAC is set to 0 or 8160 accordingly.

MAF_KGH_MES_FAC = IP_MAF_KGH_MES_FAC (N_MAF_MES_FAC, TPS_SEG)
* (1 + IP_FAC_MAF_TRIM_COR * (1 - FAC_MAF_TRIM))

4.11.1.2 Closed Crank case ventilation

No <u>additional</u> CRCV flow is considered (NC_CRCV_CONF = 0)

Initialization at reset: FLOW_CRCV = 0

4.11.1.3 TPS error handling

In Case of a TPS error there is a special handling of the MAF signal in the Intake Manifold Model for non-ETC systems.

In case of a non-ETC system a double error has to be detected, an error present on the TPS acquisition and an error present on the MAF sensor (both are coming from OBDI diagnosis).

If an ETC-System is used, some related variables must be defined as dummy to satisfy the corresponding interfaces.

Initialization at reset: LV_LIH_MAF = 0
MAF_KGH_SUB = 0
MAF_MES_FIL = 0

For ETC-System (NC_ETC_CONF = 1):
Initialization at reset : LV_LIH_MAF_TMP = 0

Endif(3)

4.11.1.4 Correction of the basic reduced throttle area

FAC_AR_RED_MAF is a correction factor for the calculation of AR_RED_BAS(forward path) and AR_RED_SP_MMV(inverse path).

Initialization at reset: FAC_AR_RED_MAF = 1

Formula section:

FAC_AR_RED_MAF = IP_FAC_AR_RED_THR_COR (N_32, TPS_SEG)

4.11.1.5 ISA opening limitation in case of suspected TPS Ratio failure : OPG_SP_LIM_ISA

In order to avoid unexpected high Idle Speed Actuator opening in case of too high TPS signal, ISA opening is limited via OPG_SP_LIM_ISA if TPS input is suspected to be unplausible : that means high negative reduced area controller or high negative MAP_MDL_DIF.

***Initialization* :**

#If NC_ETC_CONF = 1

Then OPG_SP_LIM_ISA =0 (never changed)

#Else OPG_SP_LIM_ISA = 99.9985%

#Endif

Formula section:

#If NC_ETC_CONF = 0

#Then

If(1) (LV_MAP_SWI =1

And MAP_MES_BAS - MAP < IP_MAP_MDL_DIF_OPG_LIM_ISA)

Or

(LV_MAF_SWI =1

And MAF_MDL_DIF < IP_MAF_MDL_DIF_OPG_LIM_ISA)

Else(1) CYCNR_OPG_LIM_ISA = 0

Endif(1)

If(2) AR_RED_DIF_REL < C_AR_RED_DIF_REL_OPG_LIM_ISA

Or (CYCNR_OPG_LIM_ISA >= C_CYCNR_OPG_LIM_ISA)

Then(2)

If(3) N > N_SP_IS

Then(3) OPG_SP_LIM_ISA = IP_OPG_SP_LIM_ISA (TPS_AV, TCO)

Else(3) OPG_SP_LIM_ISA = 99,9985%

Endif(3)

Else(2) OPG_SP_LIM_ISA = 99,9985%

Endif(2)

#Endif

4.11.2 Check for MAP-Sensor-failure in case of a Load-TPS-plaus error

For MAP-Systems it is assumed that the Load-sensor is faulty if a Load-TPS-error is detected and Lambda is out of range.

If a MAP-Failure is detected (LV_INH_MAP_CTL = 1) the IMM-controller, reduced area adaptation and AMP- adaptation is stopped and reset for this DC. Also LV_MAP_CTL is set to 0 to not use MAP_MES for MAF-calculation.

Initialisation at reset: LV_INH_MAP_CTL = 0

LAMB_CTL_SUM_INH_MAP_i = 0

LAMB_CTL_SUM_INH_MAP_MMV_i = 0

Recurrence: 10 ms

Formula section:

LAMB_CTL_SUM_INH_MAP_i = FAC_LAM_LIM_i+ FAC_LAM_AD_OUT_i+
FAC_MFF_ADD_LAM_AD_OUT_i

LAMB_CTL_SUM_INH_MAP_MMV_i = (LAMB_CTL_SUM_INH_MAP_MMV_i(N-1)
* (1 – C_CRLC_LAMB_CTL_SUM_INH_MAP))
+ (LAMB_CTL_SUM_INH_MAP_i *
C_CRLC_LAMB_CTL_SUM_INH_MAP)

If LV_MAP_SWI = 1
And LV_ERR_LOAD_TPS_PLAUS = 1
And (LAMB_CTL_SUM_INH_MAP_MMV_i > C_LAMB_CTL_INH_MAP_MAX
Or LAMB_CTL_SUM_INH_MAP_MMV_i < C_LAMB_CTL_INH_MAP_MIN**)**
Then LV_INH_MAP_CTL = 1
Endif

4.11.3 Check for IMM closed loop condition

If LV_MAF_MAP_REQ = 0 and no MAP-sensor error is detected, the adjustment of the Model is done with the MAP-sensor. If LV_MAF_MAP_REQ = 1 and no pulsation takes place and no mass air flow sensor error is detected, the adjustment of the model is done with the mass air flow meter. If the sensor is faulty, the model is working as a throttle / engine-speed system without adjustment (open loop).

To stop or to reset to “0” the adaptation or the controller values of the ambient pressure or the reduced area a cross lock matrix is used. This matrix describes all errors and their implications.

Initialisation at reset: LV_MAF_CTL = 0
LV_MAP_CTL = 0

Formula section:

Recurrence: 10 ms

Coordination between MAF- and MAP-controlled:

If(1) CONF_MAF = 1
Then(1) LV_MAP_CTL = 0
If(2) ERR_SYM_MAF_SCG_OC = 0
And ERR_SYM_MAF_SCP = 0
And LV_MAF_PULS = 0
Then(2) LV_MAF_CTL = 1 *(MAF-control)*
Else(2) LV_MAF_CTL = 0 *(α-/N-control)*
Endif(2)
Else(1) LV_MAF_CTL = 0
If(3) LV_ERR_MAP = 0

And ERR_SYM_EL_MAP = 0

And LV_ERR_LOAD_PLAUS = 0

And LV_ERR_MAP_PLAUS_DIAG = 0

And LV_INH_MAP_CTL = 0

Then(3) LV_MAP_CTL = 1 *(MAP-control)*

Else(3) LV_MAP_CTL = 0 *(α-/N-control)*

Endif(3)

Endif(1)

4.11.4 Check for Volumetric Efficiency Calculation

Explanation: FAC_VIM_TMP is always calculated segment synchronous (with FAC_VIM_TMP = FAC_VIM). If a calculation for the camshaft offset adaptation is required it is possible that FAC_VIM_TMP is calculated additionally with a recurrence of 20 ms (with FAC_VIM_TMP = (FAC_VIM or FAC_VIM_REQ_CAM_OFS_AD)).

4.11.4.1 Calculation of variables for Camshaft Offset Adaptation – Seg. Syn. & 20ms

Application conditions:

Activation: **If** multi segment synchronous

Then recurrence multiples of a segment

Endif

#If [(NLC_IVVT_IN = 1) **or** (NLC_IVVT_EX = 1)]

#Then

If (LV_CAM_SP_ADJ_CAM_OFS_AD = 1 **and**
LV_EFF_VOL_CLC_CAM_OFS_AD = 0 **and**
STATE_CAM_OFS_AD = 3)

Then recurrence every 20 ms

Endif

#Endif

Deactivation: -

Initialization: -

Recurrence: The calculation is done synchronously to **multiples of a segment or in 20ms recurrency**

Formula section:

FAC_VIM_TMP = FAC_VIM

FAC_PORT_DEAC_MV_TMP = FAC_PORT_DEAC

4.11.4.2 Calculation of variables for Camshaft Offset Adaptation – 20ms

Application conditions:

Activation: **#If** [(NLC_IVVT_IN = 1) **or** (NLC_IVVT_EX = 1) **and** (LV_EFF_VOL_CLC_CAM_OFS_AD = 1)]

#Then

every 20 ms

#Endif

Formula section:

FAC_VIM_TMP = FAC_VIM_REQ_CAM_OFS_AD

4.11.4.3 Calculation of variables for Camshaft Offset Adaptation – interface to basic volumetric efficiency

The Camshaft-offset adaptation functionality is used to learn the inlet and exhaust camshaft error and other errors leading to a wrong calculation of the real air-mass flow into the cylinder. The result of this adaptation(CAM_OFS_IVVT_IN and CAM_OFS_IVVT_EX) is an offset to the inlet and exhaust position which is used as an input for the basic volumetric efficiency calculation.

Application conditions:

Activation: LC_EFF_VOL_INP_CAM_OFS_INH = 0

And STATE_CAM_OFS_AD = 5 -> 0

And LV_DET_VLD_RES_CAM_OFS_AD[1] = 1

And LV_CAM_OFS_AD_END = 0

Deactivation: -

Initialization: - at first ECU power up and non-volantile memory lost:

CAM_OFS_IVVT_IN(EX)_1 = 0

LV_CAM_OFS_AD_END = 0

CAM_OFS_IVVT_IN(EX)_1_PREV = 0

- otherwise: restored from non-volantile memory

at reset: CAM_OFS_IVVT_IN(EX)_TMP = 0

Recurrence: 20ms

Formula section:

If |CAM_OFS_IVVT_IN[1]| > C_CAM_OFS_MIN

or |CAM_OFS_IVVT_EX[1]| > C_CAM_OFS_MIN

Endif
```

4.11.4.4 Selection of STATE_ACR_EFF_VOL_CLC for the Basic Volumetric Efficiency Calculation

Application conditions:

Activation: **if** multi segment synchronous

then recurrence multiples of a segment

endif

#if [(NLC_IVVT_IN = 1) **or** (NLC_IVVT_EX = 1)]

#then

if (LV_EFF_VOL_CLC_CAM_OFS_AD = 1)

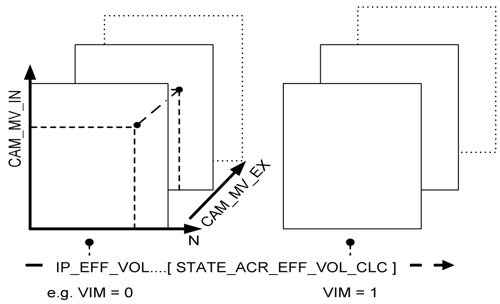
then recurrence every 20 ms

endif

#endif

General information:

With the index STATE_ACR_EFF_VOL_CLC can be switched between different sets of volumetric efficiency maps, depending on the project-configuration (set in the INSY Configuration data).
Example: influence of actuators VIM.



Formula section:

If (FAC_VIM_TMP < C_FAC_VIM_MIN_EFF_VOL_CLC)

Then STATE_ACR_EFF_VOL_CLC = 0

Else STATE_ACR_EFF_VOL_CLC = 1

Endif

4.11.5 Speeded up MAP-acquisition

When the systems runs MAP-controlled (LV_MAP_CTL = 1), it is possible to speed up the load acquisition during transient operating conditions.

At reset: LV_MAP_SAMPLE_DYN = 0

4.11.6 Coordination AMP substitude value for INSY

For naturally aspirated engines:

At reset: AMP_SUB = C_AMP_INI

4.11.7 Cross lock matrix definition

All possible errors and their implications are defined in the cross lock matrix. The output of this matrix results in the settings of the logical variables to stop or to reset to “0” the adaptation or the controller values of the ambient pressure and/or the reduced area.

cross lock matrix ⇒		
	LV_AMP_AD_RST/_STOP	= 0 / 1
	LV_PUT_CTL_STOP	= 0 / 1
	LV_AR_RED_AD_RST/_STOP	= 0 / 1
	LV_AR_RED_CTL_STOP	= 0 / 1

If (LV_ERR_LOAD_TPS_PLAUS = 1 **And** LV_MAF_SWI = 1)
Or LV_INH_MAP_CTL = 1
Or [NC_ETC_CONF == 0 **And** (LV_ERR_TPS_DET = 1 **Or** LV_ERR_ISA_i = 1)]
Then LV_AMP_AD_STOP = 1
LV_AMP_AD_RST = 1
LV_AR_RED_AD_STOP = 1
LV_AR_RED_AD_RST = 1
Else **If** LV_ERR_TPS = 1
Or LV_ERR_LOAD_TPS_PLAUS = 1
Or LV_ERR_LOAD_TPS_PLAUS_FAST = 1
Or (OPG_SP_LIM_ISA < 99,9985% **And** NC_ETC_CONF = 0)
Then LV_AMP_AD_STOP = 1
Else LV_AMP_AD_STOP = 0
Endif
LV_AMP_AD_RST = 0
LV_AR_RED_AD_STOP = 0
LV_AR_RED_AD_RST = 0
Endif

<u>*Determination of LV_TPS_GRD_CTL_STOP*</u> *:*

Target of this flag is to indicate that Reduced Area / Ambient Pressure controllers must be stopped due to transient conditions (high throttle position gradient) during a pre-defined number of cycles.

Following calculation is segment synchronous:

If (TPS_GRD > C_TPS_GRD_CTL_STOP_MAX **And** LV_TPS_GRD_UP =1)
Or (TPS_GRD > C_TPS_GRD_CTL_STOP_MIN **And** LV_TPS_GRD_UP = 0)

```
Then        LV_TPS_GRD_CTL_STOP = 1
            CYC_TPS_GRD_CTL_STOP = C_CYC_TPS_GRD_CTL_STOP
Else        If     LV_TPS_GRD_CTL_STOP = 1
            Then   If     CYC_TPS_GRD_CTL_STOP = 0
                   Then   LV_TPS_GRD_CTL_STOP = 0
                   Else   CYC_TPS_GRD_CTL_STOP = CYC_TPS_GRD_CTL_STOP - 1
                   Endif
            Endif
Endif
```

Conditions to stop Reduced Area / Ambient Pressure controllers :

```
If          LV_TPS_GRD_CTL_STOP = 1
            Or (LV_ERR_LOAD_TPS_PLAUS = 1 And LV_MAF_SWI = 1)
            Or [NC_ETC_CONF == 0 And (LV_ERR_TPS_DET = 1 Or LV_ERR_ISA_i = 1)]
            Or T_AST < ID_T_AST_INSY_CTL_DEAC
Then        LV_AR_RED_CTL_STOP = 1
            LV_PUT_CTL_STOP = 1
Else        LV_AR_RED_CTL_STOP = 0
            LV_PUT_CTL_STOP = 0
Endif
```

4.11.8 Calculation of the relevant segment time and segment counter

Application conditions:

Activation:	multi segment synchronous
Deactivation:	-
Initialization:	SEG_INC = 1
Calculation recurrence:	The calculation is done -depending on the activation condition synchronously to **multiples of a segment**.

General information:

If INSY - depending on the engine speed - is not activated every segment, the segment time T_SEG_AV and the increment of the segment counter have to be adapted.

Formula section:

If (STATE_CLC_SEG_INSY = INSY_SEG_HALF)

Then T_SEG_AV_IMM = T_SEG_HALF_AV

SEG_INC_N = 1 *(only used by modules running segment / double segment synchronous)*

Else **If** ($STATE\_CLC\_RED_N$ <> $STATE\_CLC\_RED_{N-1}$)

Then SEG_INC = (STATE_CLC_RED and NC_STATE_CLC_RED_MASK_1) /NC_STATE_CLC_RED_SEG_1

Else SEG_INC_N = SEG_INC_{N-1} (remains unchanged)

T_SEG_AV_IMM = T_SEG_AV * SEG_INC

Endif

Endif

4.11.9 Flag to inhibit the adaptation of AMP with open throttle (PQ >= C_PQ_AMP_AD)

The ambient pressure adaptation could be inhibited under certain conditions; no such conditions are yet defined, so

Initialization at reset: LV_INH_AMP_AD = 0 (never changed)

4.11.10 Flag to inhibit the adaptation of the additive correction of the reduced area at the throttle

In order to inhibit the adaptation of the reduced area at the throttle a flag is defined that will be set each time the AMP adaptatio is learning during a period of time.

If LV_END_AMP_AD = 1 **And** LV_INH_AMP_AD = 0

Then LV_INH_AR_RED_AD = 0

Else LV_INH_AR_RED_AD = 1

Endif

4.11.11 Variables for fleet monitoring

- Monitoring of MAF:

Activation: LV_IGK = 1 and LV_ST_END = 1

Deactivation: -

Initialization: *at first ECU powver up and non-volatile memory lost:*

MAF_MIN_TOT_DC = FFFFH (1,389E+03 mg/stk)

MAF_MAX_TOT_DC = 0H (0 mg/stk)

-otherwise: restore from non-volatile memory

Calculation recurrence: The calculation is done synchronously to **multiples of a segment**.

Formula section:

If MAF < MAF_MIN_TOT_DC
Then MAF_MIN_TOT_DC = MAF
Endif
If MAF > MAF_MAX_TOT_DC
Then MAF_MAX_TOT_DC = MAF
Endif

4.11.12 - Monitoring of MAP:

Initialisation: - at first ECU power up and non-volantile memory lost:

Then PUT_MDL_DIF_MMV_REL_MIN_TOT_DC = PUT_MDL_DIF_MMV_REL

Endif

4.11.20 Calculation of MAF- Signal for Calibration Purpose

General information:

The calculation of the MAF Signal for calibration purpose is done same way as the MAF Signal for System. The factor for MAF trimming value is not included, as no Trimming will be done for this input.

Activation: LV_MAF_CAL_SWI = 1

Deactivation: LV_MAF_CAL_SWI = 0

Initialization: After HW reset, the buffers - MAF_SUM_CAL and MAF_SUM_1_CAL - and the corresponding counters - MAF_CTR_CAL and MAF_CTR_1_CAL - have to be cleared and the pointer has to be initialized with the address of ID_MAF_TAB.

LV_MAF_SEG_CAL=0

Calculation recurrence:

Segment synchr: Calculation of MAF_KGH_MES_BAS_CAL

1ms Calculation of MAF_SUM_CAL and MAF_SUM_1_CAL

Formula section:

if LV_MAF_SEG_CAL = 0

then MAF_CTR_CAL = MAF_CTR_CAL + 1

MAF_SUM_CAL = MAF_SUM_CAL + ID_MAF_TAB(VP_MAF_CAL)

else **if** LV_MAF_SEG_CAL == 1

then MAF_CTR_1_CAL = MAF_CTR_1_CAL + 1

MAF_SUM_1_CAL = MAF_SUM_1_CAL + ID_MAF_TAB(VP_MAF_CAL),

endif

endif

Calculation of MAF_KGH_MES_BAS_CAL:

Calculation recurrence: If the engine is running on a fixed tooth each segment.

LV_MAF_SEG_CAL = ! LV_MAF_SEG_CAL

if LV_MAF_SEG_CAL = 1

and MAF_CTR_CAL > 0

then

$$\mathrm{MAF\_KGH\_MES\_BAS\_CAL} = \frac{\mathrm{MAF\_SUM\_CAL}}{2 * \mathrm{MAF\_CTR\_CAL}}$$

MAF_SUM_CAL = MAF_CTR_CAL = 0

else

if (LV_MAF_SEG_CAL == 0)

and (MAF_CTR_1_CAL > 0)

then

$$\mathrm{MAF\_KGH\_MES\_BAS\_CAL} = \frac{\mathrm{MAF\_SUM\_1\_CAL}}{2 * \mathrm{MAF\_CTR\_1\_CAL}}$$

```
            MAF_SUM_1_CAL = MAF_CTR_1_CAL = 0
        endif
endif
```

If the selected counter is zero MAF_KGH_MES_BAS_CAL stay unchanged.

Calculation of MAF_KGH_MES_CAL and MAF_MES_CAL:

MAF_KGH_MES_CAL = MAF_KGH_MES_BAS_CAL * IP_MAF_KGH_MES_FAC

MAF_MES_CAL = MAF_KGH_MES_CAL / N * NC_MAF_FAC_CYL

4.11.21 Interface to other functions:

4.12.1 INSY_M405W

General information:

This module calculates the maximum possible air mass flow that is available to the Engine Management system.

The maximum possible air-mass flow into the cylinder will be reached with wide open throttle (i.e. MAP = PUT). For the calculation it is assumed, that at open throttle there will be no EGR-ratio active.

Application Condition

Activation: At every engine state

Deactivation: -

Initialization: -

Recurrence: 40 ms

Application Condition

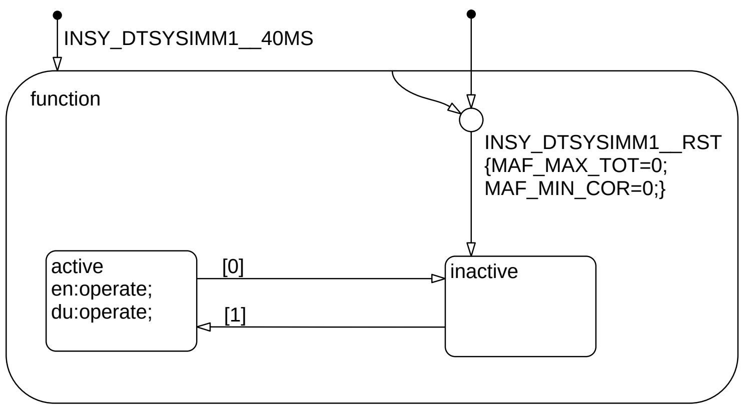

Figure 127 INSY_M405W/ APP_CDN/ Chart

Function Description

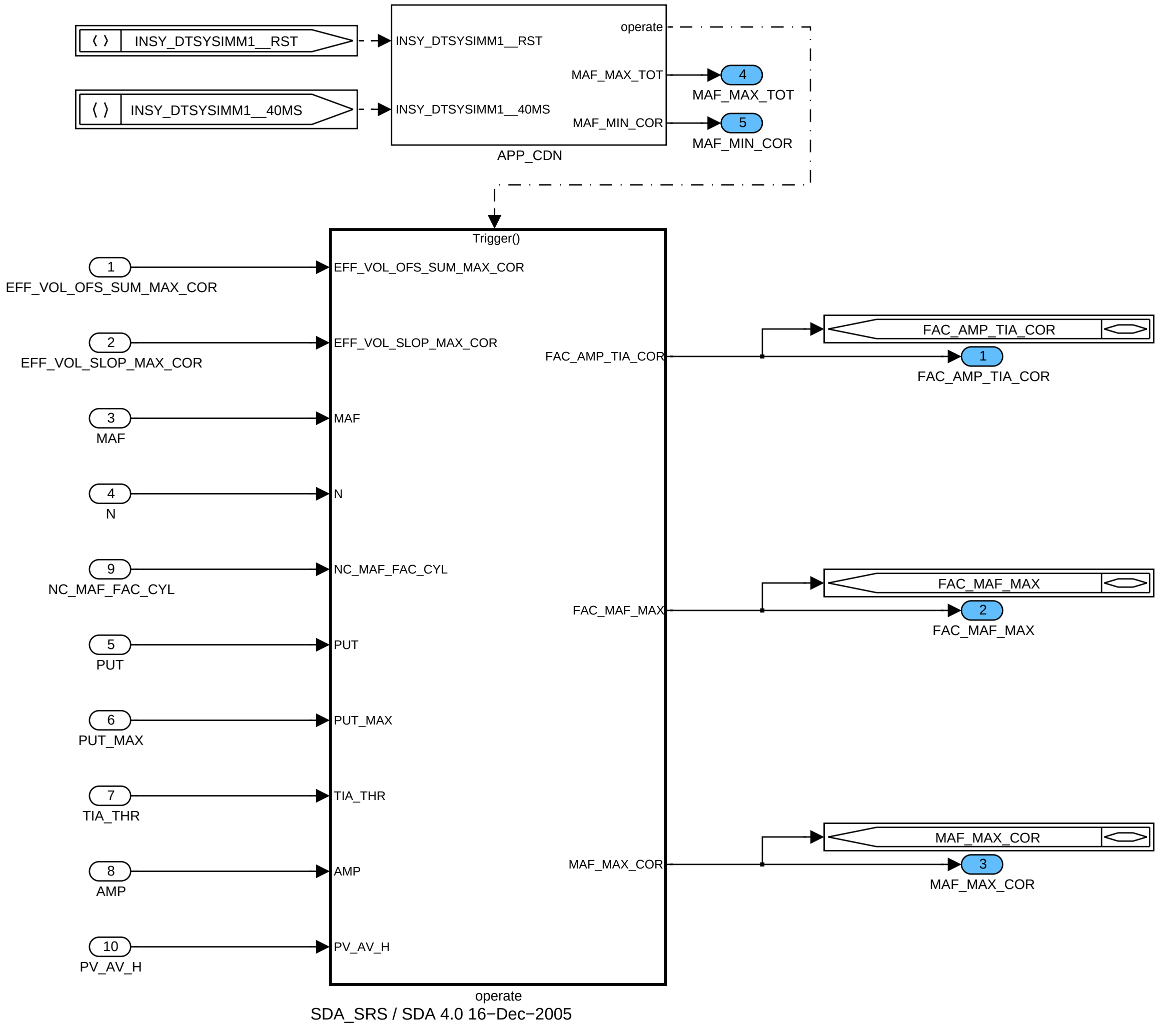

Figure 128 INSY_M405W

4.12.1.1 Calculation of maximum possible mass air flow and the ratio between actual and maximum mass air flow

The maximum air mass flow going into the cylinder at the current engine speed will be reached with wide open throttle. To calculate this air mass, the manifold pressure is assumed to be equal to the pressure up throttle PUT.

It is possible to switch between two algorithms:

If LC_MAF_MAX_SWI = 0 the calculation is done with a full load map. The standard value from this map is corrected with a factor depending on ambient pressure and intake air temperature. For naturally aspirated engines this factor is proportional to the ambient pressure divided by the intake air teperature in Kelvin. For charged engines an alternative calculation with two interpolation maps can be activated with LC_FAC_AMP_TIA_COR_SWI = 0.

If LC_MAF_MAX_SWI = 1 the calculation is done with a maximum slope and offset and transformed into the air mass MAF_MAX_COR [mg/stk] by dividing by the engine speed and applying the factor NC_MAF_FAC_CYL (depending on the number of cylinders).

4.13.1 INSY_REQCOMAFIN0

For calatyst enrichment function and for plausibility checks of lambda sensor diangosis functions air mass flow integrals during and out of trailing throttle fuel cut-off phase must be calculated.

Function Description

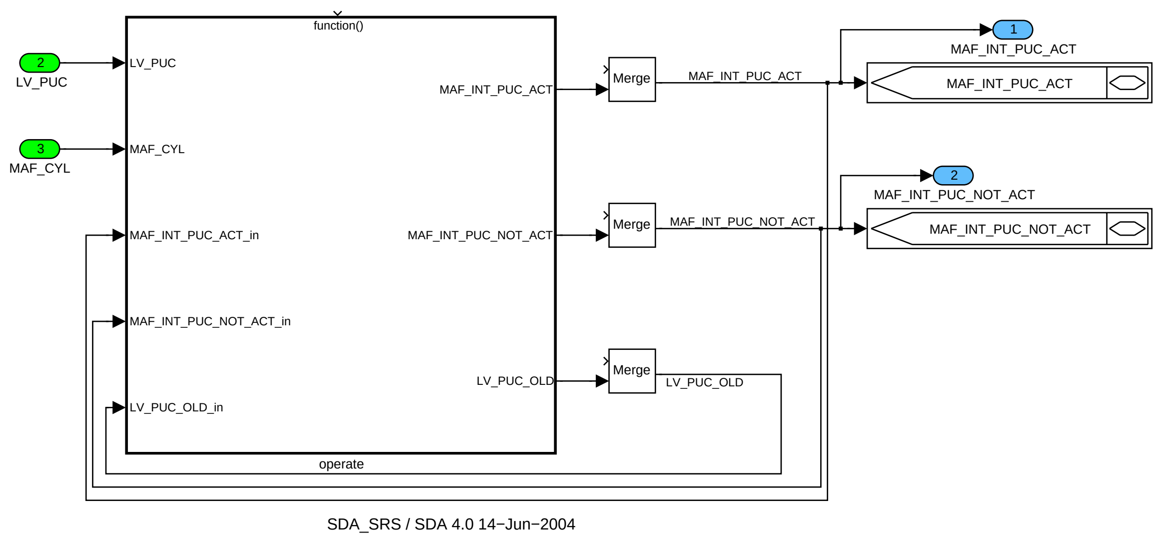

Figure 132 INSY_REQCOMAFIN0

4.13.1.1 operate

During trailing throttle fuel cut-off phase (LV_PUC = 1) the air mass flow integral MAF_INT_PUC_ACT is calculated. The integral is reset to 0 at the rising edge of LV_PUC.

Out of trailing throttle fuel cut-off phase the integral MAF_INT_PUC_NOT_ACT is calculated. It is reset to 0 at the falling edge of LV_PUC.

General Information

The strategy of the closed loop control depends on the available sensors:

- If only a mass air flow sensor is available the loop will be controlled with MAF (LV_MAF_CTL = 1).

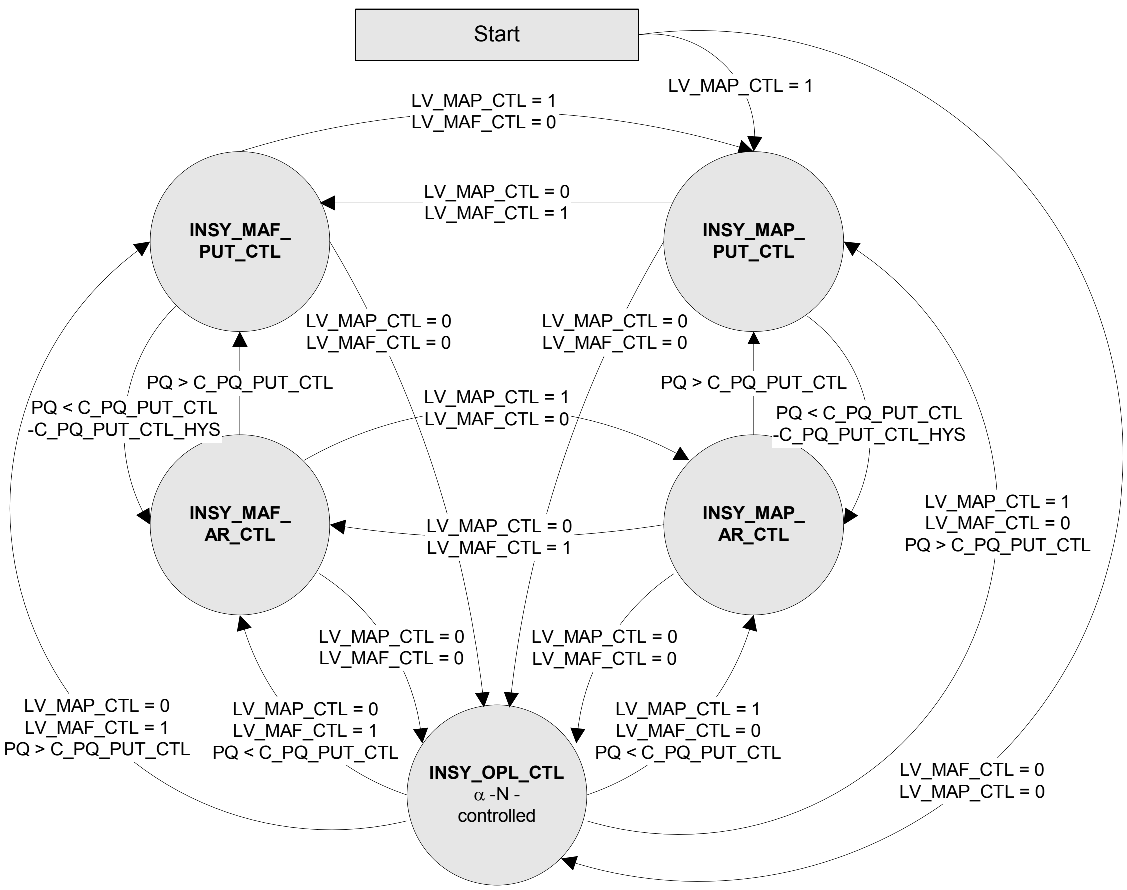
- If only a manifold pressure sensor is available the loop will be controlled with MAP (LV_MAP_CTL = 1).

- If both sensors are available the control depends on the pressure ratio at the throttle PQ. If PQ is smaller than the calibratable threshold C_PQ_MAF_CTL_MAX, considering a hysteresis C_PQ_MAF_CTL_MAX_HYS, the control will be done with the mass air flow. If the mass air flow sensor gives no reasonable signal (LV_MAF_CTL = 0) then the loop will be controlled with MAP (LV_MAP_CTL = 1). If PQ is greater than the calibratable threshold C_PQ_MAF_CTL_MAX the control will be done with MAP, except the MAP sensor gives no reasonable signal (LV_MAP_CTL = 0). Then the loop will be controlled with MAF (LV_MAF_CTL = 1).

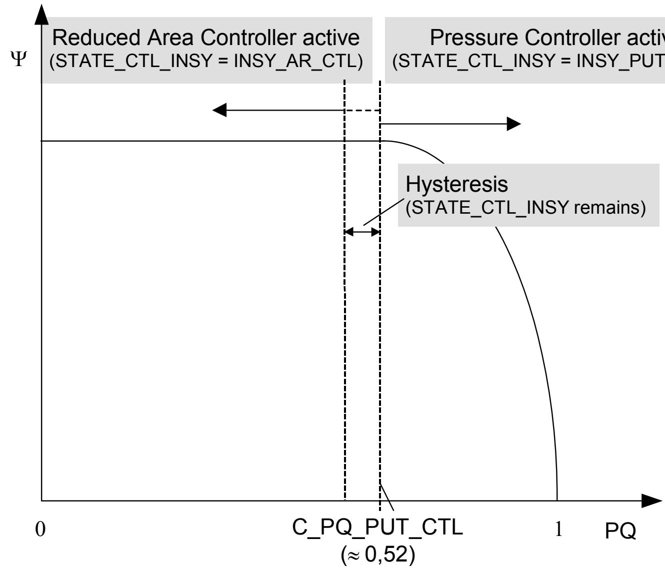
- If there is no reasonable signal for the closed loop control (LV_MAP_CTL = 0 and LV_MAF_CTL = 0) the system will be N controlled.

As long as the pressure ratio at the throttle d s not reach the calibratable threshold C_PQ_PUT_CTL, considering a hysteresis C_PQ_PUT_CTL_HYS, the deviations between intake manifold model values and measurement values are minimized with a PI controller adapting the reduced area (STATE_CTL_INSY = INSY_xx_AR_CTL). If the pressure ratio exceeds C_PQ_PUT_CTL the deviations are minimized with a PI controller adapting the modeled pressure upstream throttle PUT_MDL (STATE_CTL_INSY = INSY_xx_PUT_CTL).

In the state INSY_xx_AR_CTL the correction AR_RED_DIF_REL is calculated out of the model deviation MAF_MDL_DIF or MAP_MDL_DIF. If the manifold pressure sensor and the mass air flow sensor are defect the model g s into open loop INSY_CTL_OPL and AR_RED_DIF_x are identical to zero.



Picture 1: Control strategy, STATE_CTL_INSY transitions for different sensor configurations (Remark: This diagram is meant as an illustration only, in case of any doubt the written transition conditions are valid)



Picture 2: Working range of Reduced Area Controller and Pressure Controller

The reduced area controller can be stopped or reset to 0 by LV_AR_RED_CTL_STOP / RST. Correspondingly the controller for the pressure upstream the throttle can be stopped or reset to 0 by LV_PUT_CTL_STOP / RST.

4.14.2 Recurrence: Segment synchronous

The segment synchronous tasks are activated multisegment synchronously, i. e. every half segment, every segment or every other segment according to the Administration of calculation optimization.

Function description

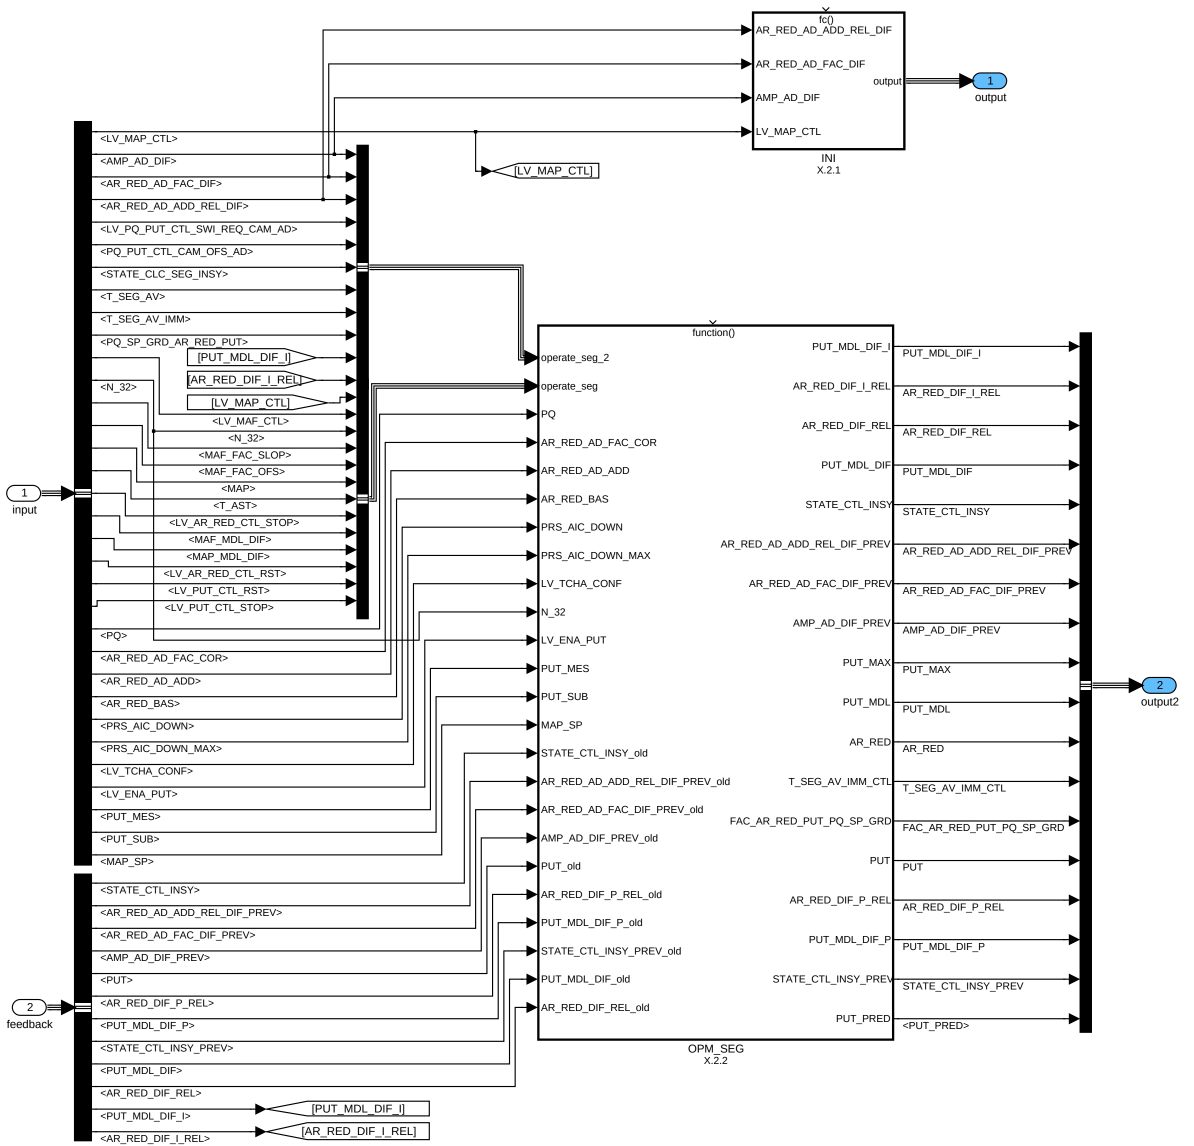

Figure 140:
Path: INSY_M404T/operate_SEG

4.14.2.1 Initialization (SEG - task):

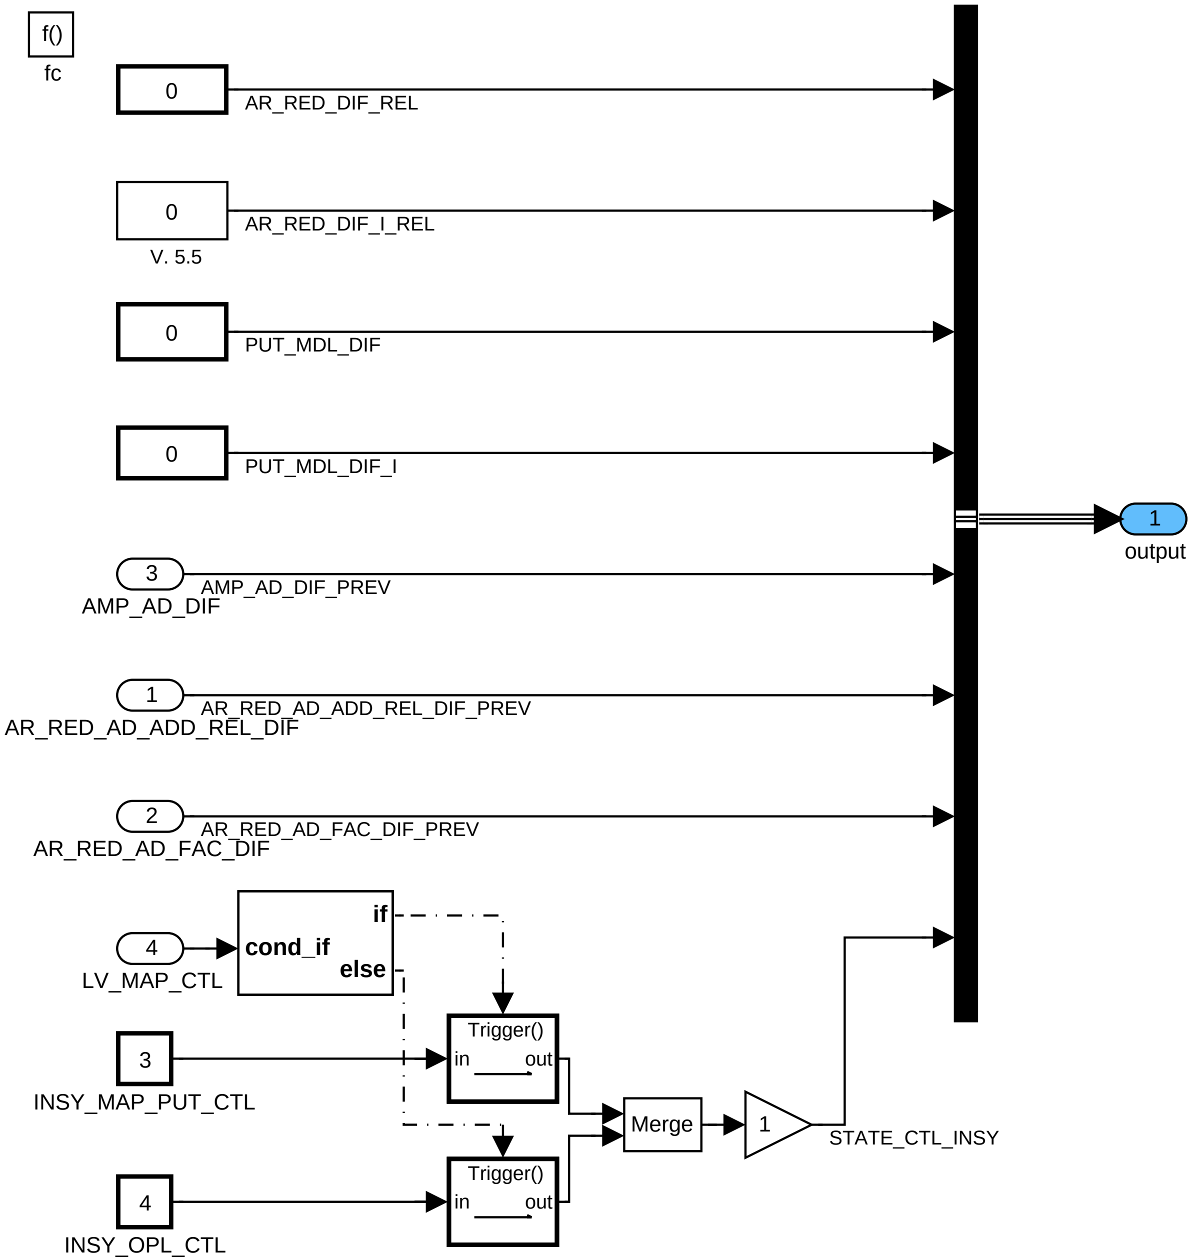

Figure 141:
Path: INSY_M404T/operate_SEG/INI

4.14.2.2 Overview over all possible states of intake manifold model adaptation:

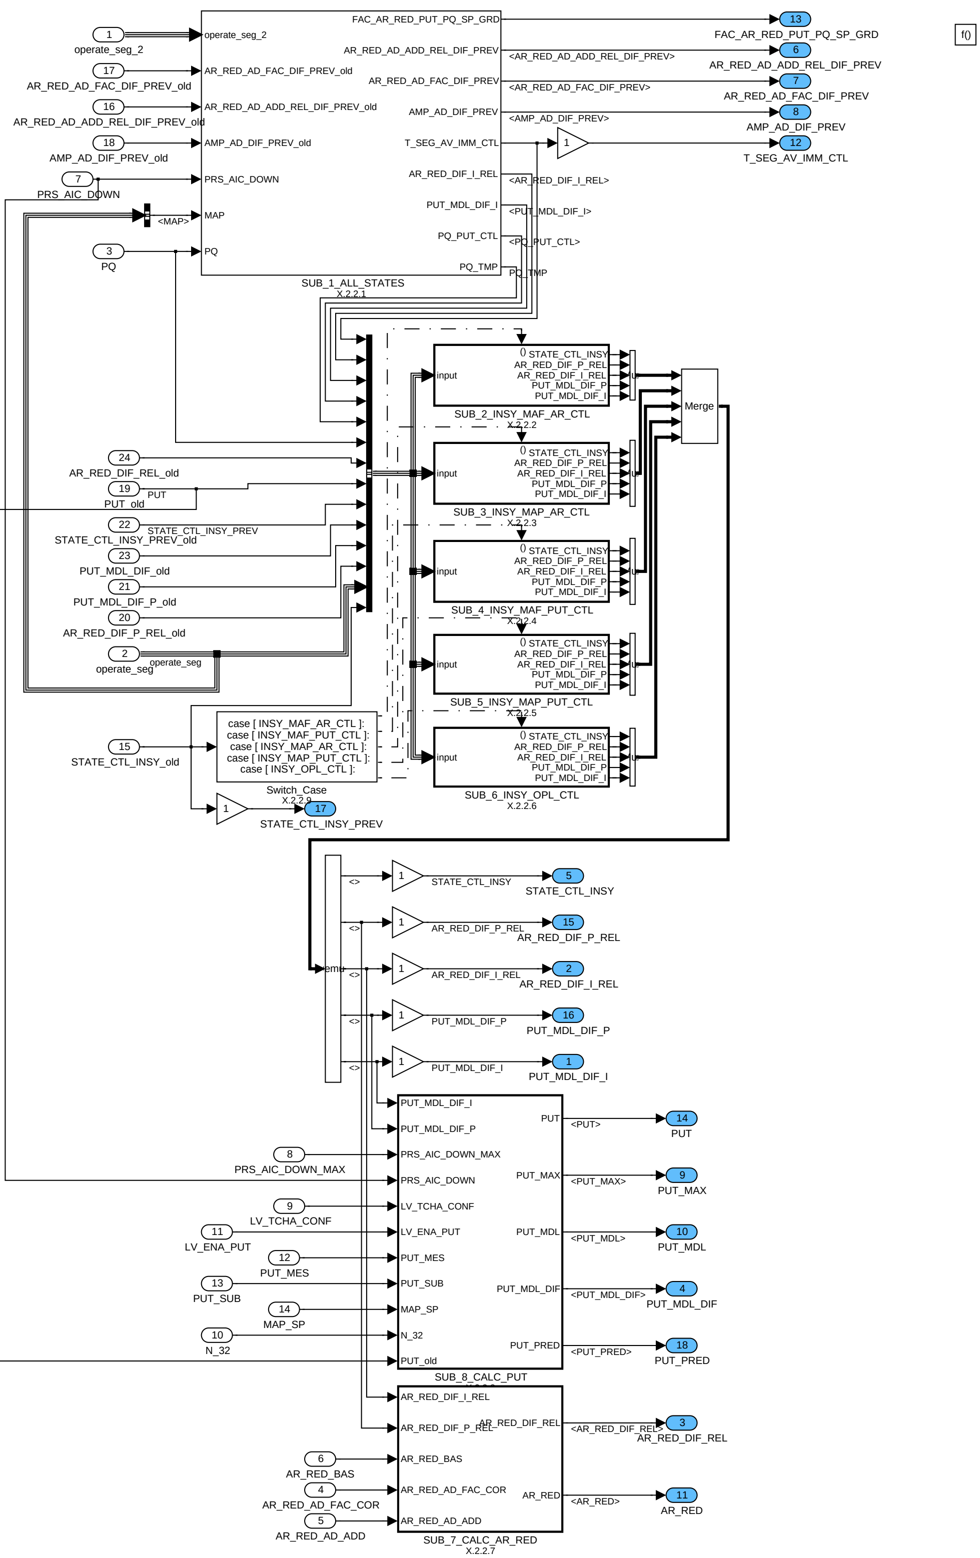

Figure 142:
Path: INSY_M404T/operate_SEG/OPM_SEG

4.14.2.2.1 SUB_1: Calculation of values which are used in all states (previous calculations):

When an reduced area adaptation has been performed, i.e. when a new AR_RED_AD_ADD or AR_RED_AD_FAC has been calculated by the Reduced Area Adaptation module, the reduced area controller output and its integral part are corrected with the learned adaptation values differences in order to get a continuous AR_RED. If an execution of the Reduced Area Adaptation module performs no adaptation, i.e. delivers no significant AR_RED_AD_ADD_REL_DIF or AR_RED_AD_FAC_DIF respectively, the Adaptation module sets AR_RED_AD_ADD_REL_DIF or AR_RED_AD_FAC_DIF to 0.
The variables with the ending PREV are defined to synchronize the different recurrences of the reduced area adaptation and the INSY-controller.

With the map IP_FAC_AR_RED_PUT_PQ_SP_GRD the I shares of the controller can be ramped down to zero depending on the rate of change of PQ_SP.

When an ambient pressure adaptation has been performed, i.e. when a new AMP_AD_DIF has been calculated by the Ambient Pressure Adaptation module, the pressure controller output and its integral part are corrected with the learned ambient pressure values in order to get a continuous PUT_MDL. If an execution of the Ambient Pressure Adaptation module performs no adaptation, i.e. delivers no significant AMP_AD_DIF, it sets AMP_AD_DIF = 0.

If a request from CAM_OFS_AD is valid, PQ_PUT_CTL has to be calculated in a different way.

The segment time for the INSY controller is chosen here, normal or double segment time are possible. As the INSY controller will not be calculated with half segment then the internal segment time has to be the normal segment time T_SEG_AV in case of INSY_SEG_HALF.

PQ_TMP is built for internal use.

4.14.2.2.2 SUB_2: MAF sensor based intake manifold model adjustment via reduced area (INSY_MAF_AR_CTL):

4.14.2.2.2.1 SUB_21: MAF sensor based intake manifold model adjustment via reduced area (INSY_MAF_AR_CTL)

The Reduced Area controller works based on the air-mass flow deviation MAF_MDL_DIF. The Pressure Controller is switched off. PUT_MDL_DIF_I and PUT_MDL_DIF_P are not calculated as long as the Reduced Area controller is active. PUT_MDL_DIF_P is ramped down to 0

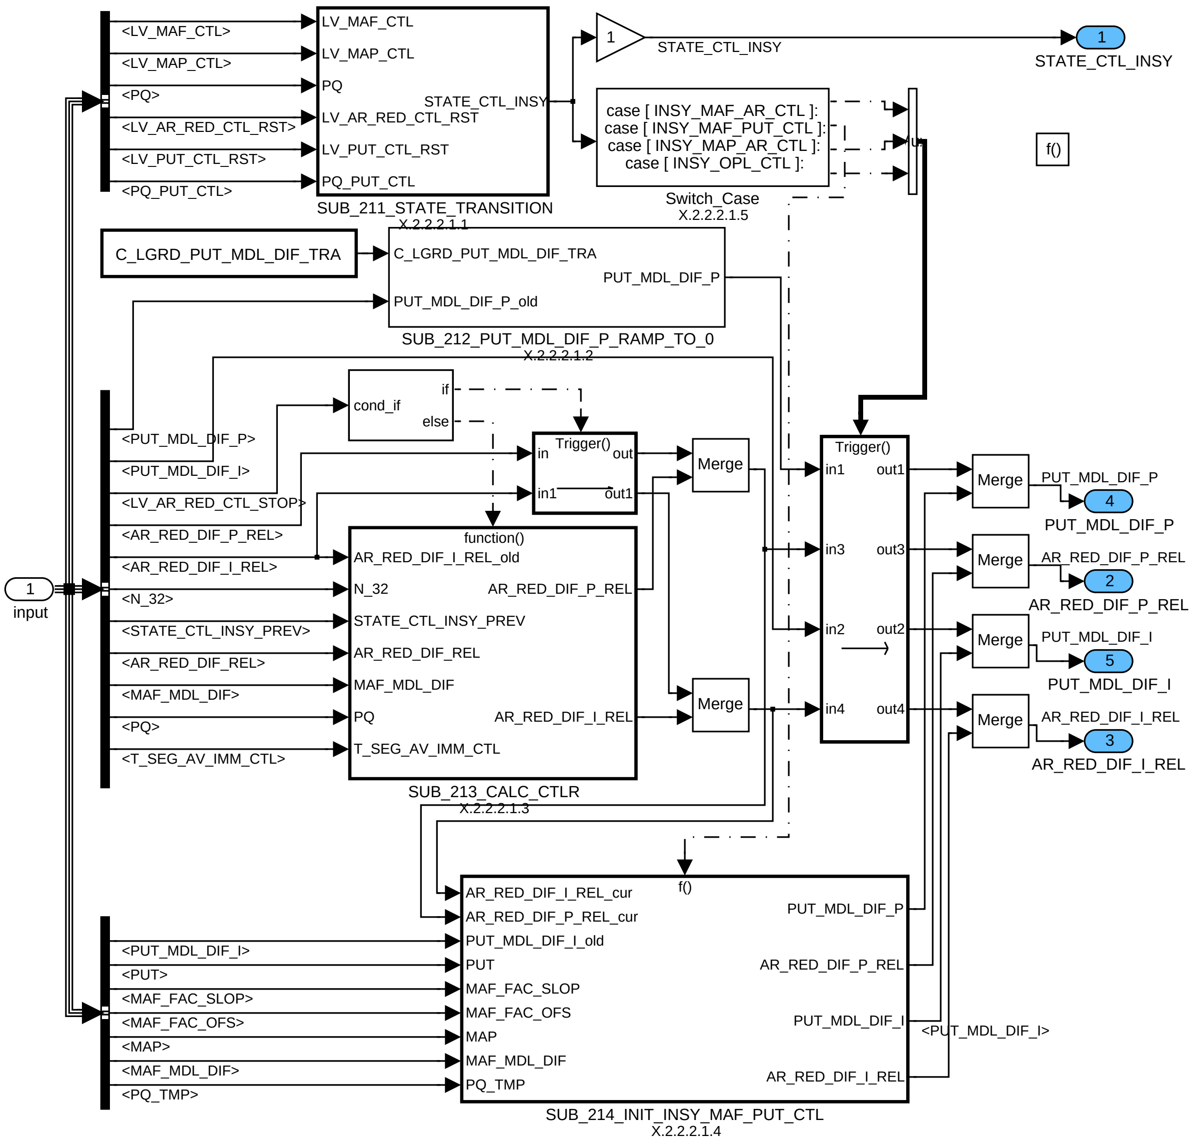

Figure 144:

4.14.2.2.2.1.1 SUB_211: Check if a state transition is requested:

The INSY controller can be deactivated (switched to open loop) by the logical variables LV_AR_RED_CTL_RST and LV_PUT_CTL_RST.

From INSY_MAF_AR_CTL a switch over to INSY_OPL_CTL, INSY_MAF_PUT_CTL and INSY_MAP_AR_CTL is possible. If a switch to INSY_MAP_PUT_CTL is required, which can happen if C_PQ_PUT_CTL is close to C_PQ_MAF_CTL_MAX, the system is switched over to INSY_MAF_PUT_CTL first. The switch to INSY_MAP_PUT_CTL is performed at the next execution cycle of the INSY controller. To avoid an unsteady controller output signal when switching over to the pressure controller, its integral part is accordingly initialized.

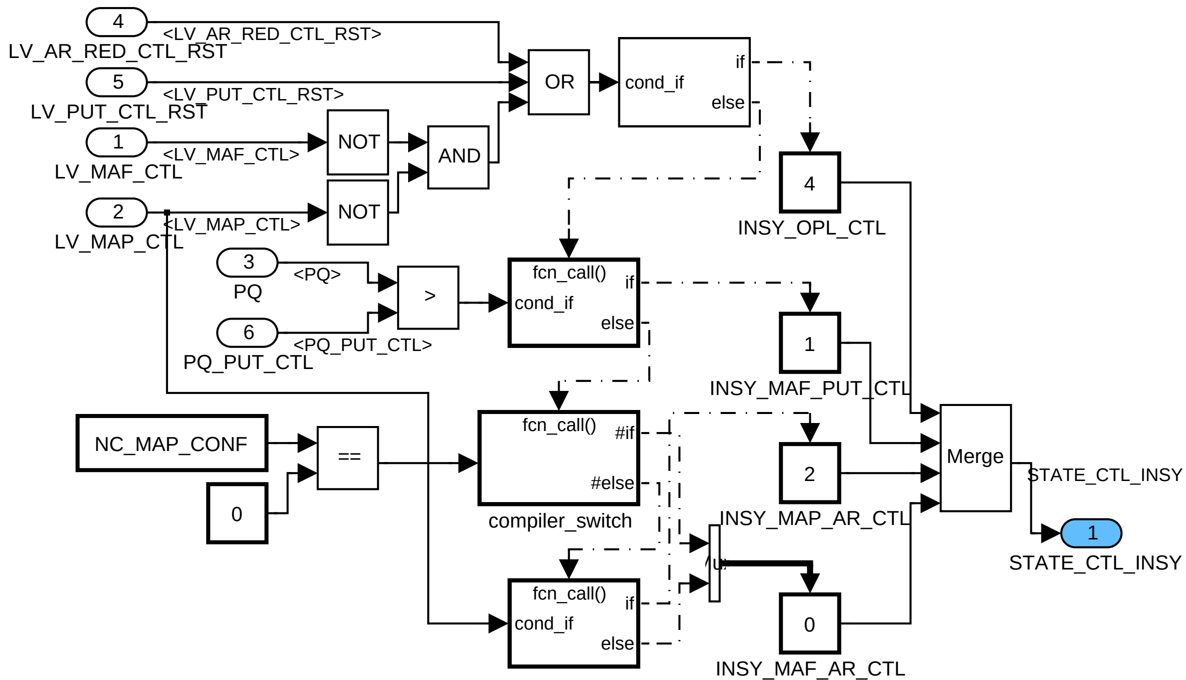

Figure 145:

4.14.2.2.7 SUB_7: Calculation of the reduced area controller output AR_RED_DIF_REL:

Reduced area controller output AR_RED_DIF_REL is calculated. The final reduced area AR_RED includes basic reduced area AR_RED_BAS based on TPS, the controller output AR_RED_DIF_REL and the adaptive corrections.

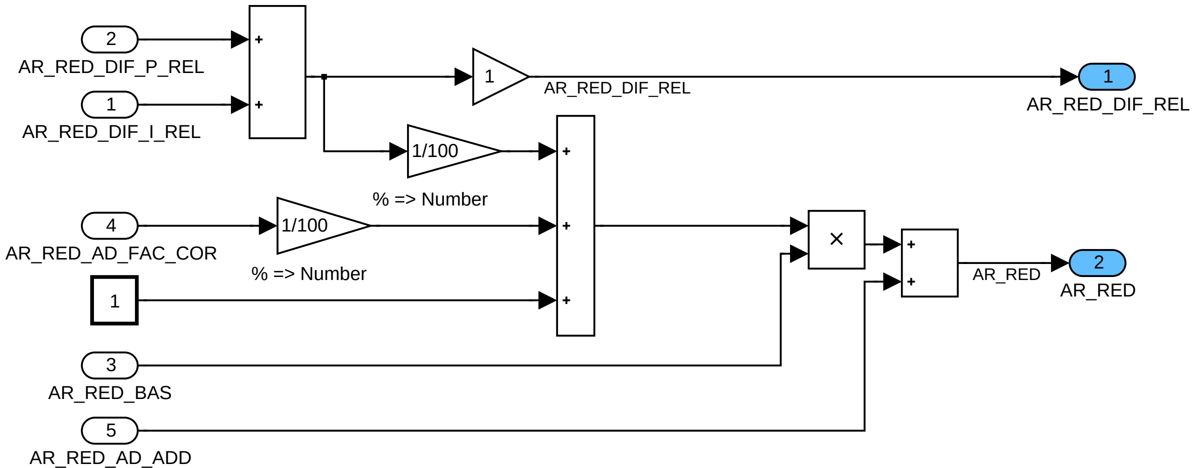

Figure 177:
Path: INSY_M404T/operate_SEG/OPM_SEG/SUB_7_CALC_AR_RED

4.14.2.2.8 SUB_8: Calculation of the pressure upstream throttle:

For engines with turbocharger or supercharger the pressure upstream throttle PUT is equal to a pressure upstream throttle substitute value if a PUT sensor value is not available or defective. If a PUT sensor is available and o.k. then the measured PUT value is used.

For engines without charger PUT is equal to the pressure downstream air cleaner PRS_AIC_DOWN.

The P- and I-share of the pressure controller are summed up to PUT_MDL_DIF.

For turbocharged engines and engines without charger PUT and PUT_MDL_DIF are summed up to PUT_MDL, for supercharged engines PUT_MDL_DIF is not taken into consideration.

Weighting function for decreasing multiplicative learning controller value during PQ>C_PQ_AMP_CTL					

General Information

General information:
At certain operating points depending on engine speed and the pressure ratio a learning algorithm for the adaptation values of the throttle area is implemented. In a brand new ECU the adaptation values AR_RED_AD_ADD and AR_RED_AD_FAC are initialized to 0.
Additional the adaptation can be stopped or reset to 0 by logical variables.

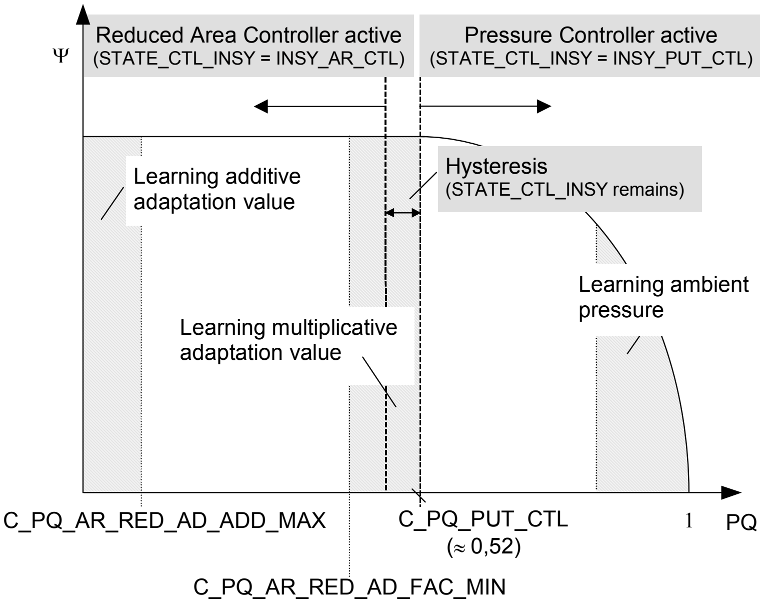

Figure 1: Learning of reduced area adaptation constants

When the adaptation from the throttle is done than the moving mean value (AR_RED_AD_ADD_MMV) has to be set as null.

Reduced area adaptation learning:

In order to compensate serial production tolerances an adaptive correction of the reduced area is learned. The additive and multiplicative adaptation corrections AR_RED_AD_ADD and AR_RED_AD_FAC are used in calculating the reduced area of the throttle AR_RED.

For calculation of the new adaptation value the filtered integral part of the controller is used.

The additive value AR_RED_AD_ADD (offset in air-mass flow through blow-by) is only learned at closed throttle and if the engine speed is inside a calibratable range.

The adaptation is only allowed, when LV_ENA_AR_RED_AD has been set by the Component and Adaptation Manager module. This flag also considers that the reduced area adaptation is inhibited if the MAF/MAP-TPS plausibility check detects implausibilities between the MAF/MAP and the TPS signal (LV_ERR_RATIO_CHK = 1). Additionally, the adaptation is enforced when the I part of the reduced area controller is out of range (in idle) in order to make the LoadTPS ratio check more sensitive. In case of the AMP adaptation is not learned the reduced area adaptation will be inhibited.(LV_INH_AR_RED_AD).

If the actual and the last learned value of AR_RED_AD_ADD differ, then the integral part AR_RED_DIF_I_REL of the INSY controller is corrected.

The learned values are limited to calibratable minimum and maximum values.

When the conditions of the reduced area adaptation are confirmed (LV_ACT_AR_RED_AD_ADD = 1) the first calculation from the additive value will be not perform before the process of a whole interval of calculation is done (2000ms). The verification of the conditions of activation takes place every 1000ms.

The multiplicative value (e.g. HFM value influenced by humidity) is only learned in a calibratable range of PQ near 0.52 (transition from overcritical to undercritical flow through the throttle) and if in addition the engine speed is inside a specified range.

Application Conditions

4.15.4.2.2 Coordination of reduced-area adaptation request for CAM_OFS_AD functionality - 1000ms

The bit LV_AR_RED_AD_ADD_REQ_CAM_TMP is used to indicate the status of the adaptation request by the CAM_OFS_AD functionality. Before the adaptation is then actually carried out, the results of the NORMAL Reduced-area adaptation(that is used by the other INSY modules) are saved in temporary variables. When the adaptation for the CAM_OFS_AD functionality has been completed, the results of the previous NORMAL adaptation cycle(saved in the temporary variables) are copied back into the corresponding variables.

4.15.4.4 Adaptation speed request recognition

The adaptation of the reduced throttle area can be performed at two different speed levels, depending on the flag LV_TPS_AD_REQ, indicating a throttle adaptation request. If the throttle adaptation is requested (LV_TPS_AD_REQ = 1), the adaptation speed will be increased for a calibratable number of cycles (counter CTR_AR_RED_AD_ADD_FAST).
In the post-operating phase of the ECU, the counter CTR_AR_RED_AD_ADD_FAST is saved in the non-volatile RAM of the ECU. To detect that the fast adaptation of additive reduced area has been learnt, a flag is defined in order to fix the order to make the several adaptations and to prevent the multiplicative adaptation from taking place before the additive adaptation. It must be noted that the fast adaptation is not used when STATE_AR_RED_AD_ADD = ACTIVE_FOR_CAM_OFS_AD.
It is important to ensure, that AR_RED_AD_ADD_REL_DIF is set to 0 when no AR_RED_AD_ADD adaptation is performed!. When the counter CTR_AR_RED_ADD_FAST decreases to zero (only at the first time), the calculation of AR_RED_AD_ADD_REL_DIF will be switched over to the c fficient C_AR_RED_AD_COR_CRLC and at the same time the moving mean value AR_RED_AD_ADD_MMV will take the value from AR_RED_AD_ADD.

4.15.4.5 Calculation of the moving mean value from the adaptation of the throttle

/*This chapter is only calculated in the power latch phase i.e. transition to PWL, called before adaptation values are stored in NVMY*/
The calculation of the moving mean value is only executed if at least one new adaptation value AR_RED_AD_ADD has been calculated in the current DC (LV_ACT_AR_RED_AD_ADD = 1). Otherwise the moving mean value stored in the EPROM remains unchanged. It has to be taken into account that in this case one has to abdicate the using of the congregating filter.
The averaging constant CRLC_AR_RED_AD_ADD_MMV to calculate the mean value depends on the adaptation demand AR_RED_AD_ADD_DIF from a driving cycle. Therefore the value AR_RED_AD_ADD_MMV in case of natural changes (pollution) will follow very fast the value AR_RED_AD_ADD (leakage) and in case of fast changes the value of the adaptation will be followed slowly.This adaptation is learned if at least once the adaptation of the ambient pressure at open throttle is learned
In case of erasing the adaptation values it is necessary to put the values from AR_RED_AD_ADD_MMV and from AR_RED_AD_ADD to zero and the counter CTR_AR_RED_AD_ADD_FAST has to be initialized with the value of the c fficient C_CTR_AR_RED_AD_ADD_FAST. It must be noted here that this erase-function is specific for each project.

4.16.1 INSY_ADCPRAMP0

General information:

Usually the ambient pressure is not measured with a dedicated sensor. When the engine is not running, then typically after 1-3 seconds the pressure in the manifold becomes equal to the ambient pressure of the environment. If a manifold pressure sensor is available (LV_ENA_MAP = 1) AMP_AD can be initialized with the measured MAP then.

Additionally the adaptation of the ambient pressure can be stopped by logical variables.

If the pressure ratio at the throttle exceeds the calibratable threshold C_PQ_AMP_AD and the engine speed is inside a calibratable range then the ambient pressure AMP_AD is learned (**Figure Learning of ambient pressure**).

Under the engine-state PUC a correction of the ambient pressure is made by a comparison between the measured air-mass flow and the calculated air-mass flow at the throttle.

For a configuration with charger an ambient pressure sensor is needed.

Function Description

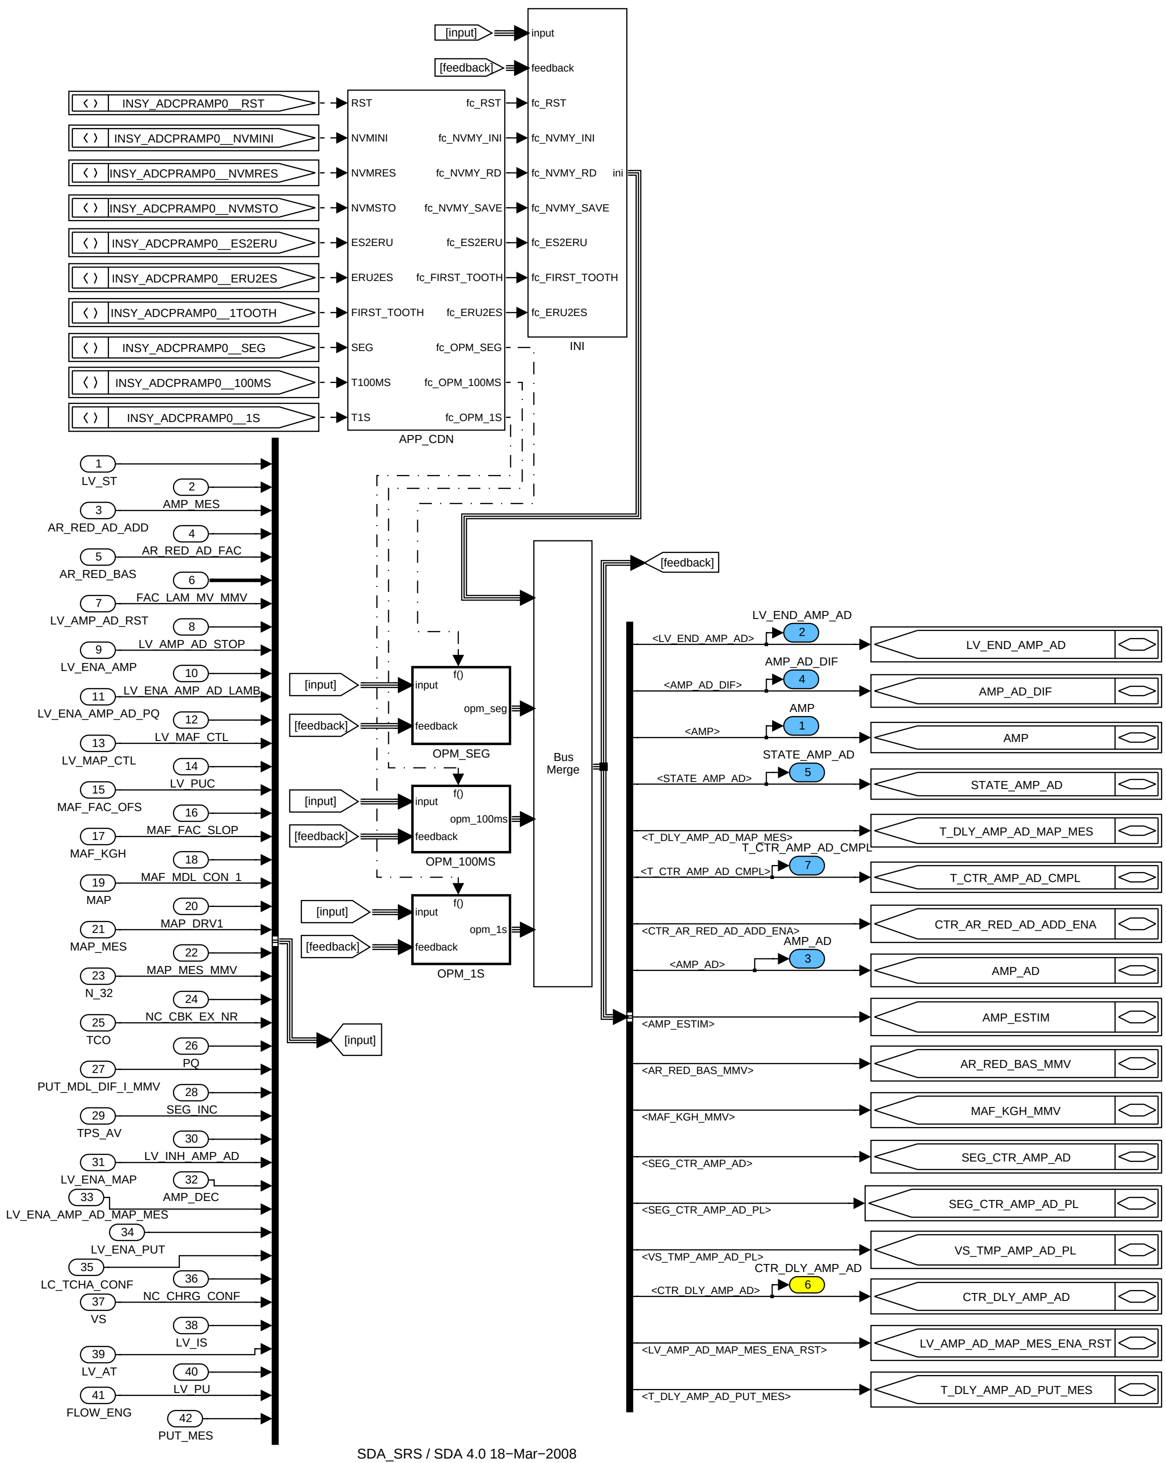

Figure 212 INSY_ADCPRAMP0

4.16.1.1 Bus merge of function:

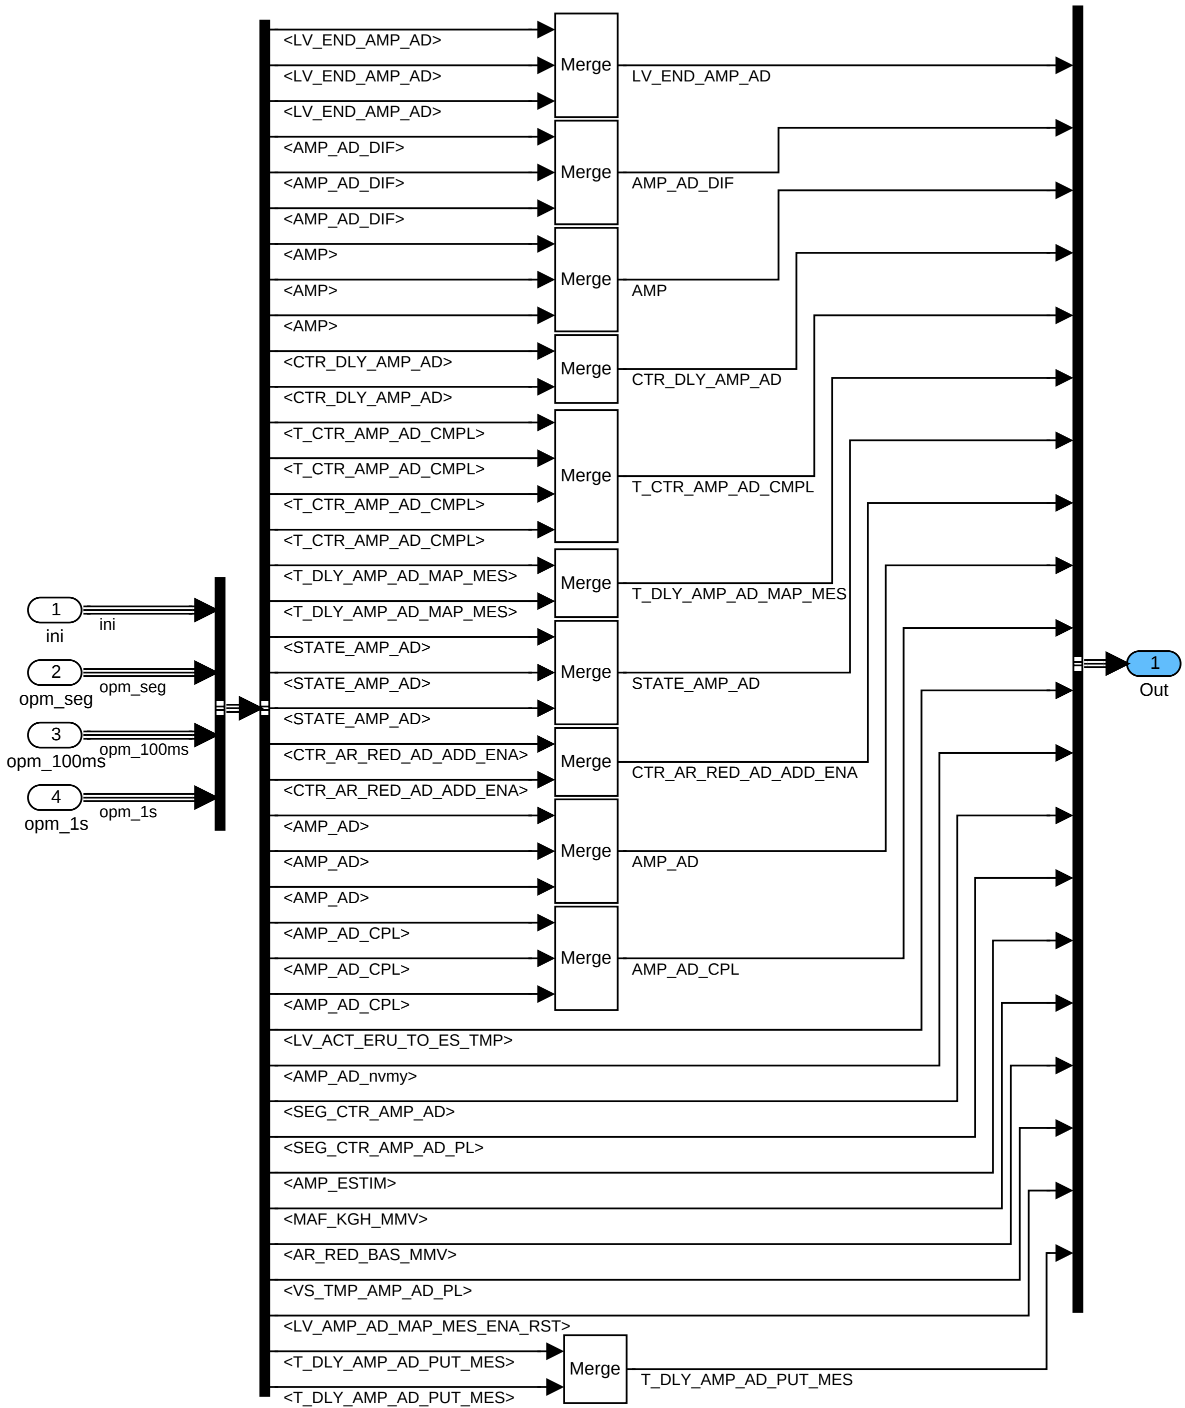

Figure 213 INSY_ADCPRAMP0/ BusMerge

4.16.1.2 Initialization of ambient pressure AMP_AD if no ambient pressure sensor is available

Initialization of ambient pressure AMP_AD if no ambient pressure sensor is available

Usually the ambient pressure is not measured with a dedicated sensor (LV_ENA_AMP = 0).

The adapted ambient pressure AMP_AD is initialized with its value stored in the none volatile memory. In case of a checksum error, AMP_AD is initialized with C_AMP_INI. During the initialization of the ECU, MAP and AMP are initialized with this AMP_AD. If the system is equipped with a properly working manifold pressure sensor, AMP_AD is overwritten during the detection of the first valid tooth (see Figure Initialization path for ambient pressure variable AMP).

The measurement of the ambient pressure AMP is done with the manifold pressure sensor. It must therefore be ensured that during the ambient pressure data acquisition the engine is not running. For this purpose, the first valid tooth will be the trigger i.e. the motor is nearly standing. If this tooth is detected, the current buffer content is used for sensor diagnosis and for calculating MAP_MES. If MAP_MES is validated by the sensor diagnosis, AMP and AMP_AD are set to MAP_MES.

Information to detect the first ambient pressure adaptation within the engine run must be stored in the memory area that is not cleared by the RAM test. This ensures that measurement of ambient pressure with the MAP-sensor will not be allowed in case of ECU-resets, resynchronization during running engine or during a restart with not finished pressure equalization.

Initialization at first valid tooth if MAP sensor available and no AMP sensor available:

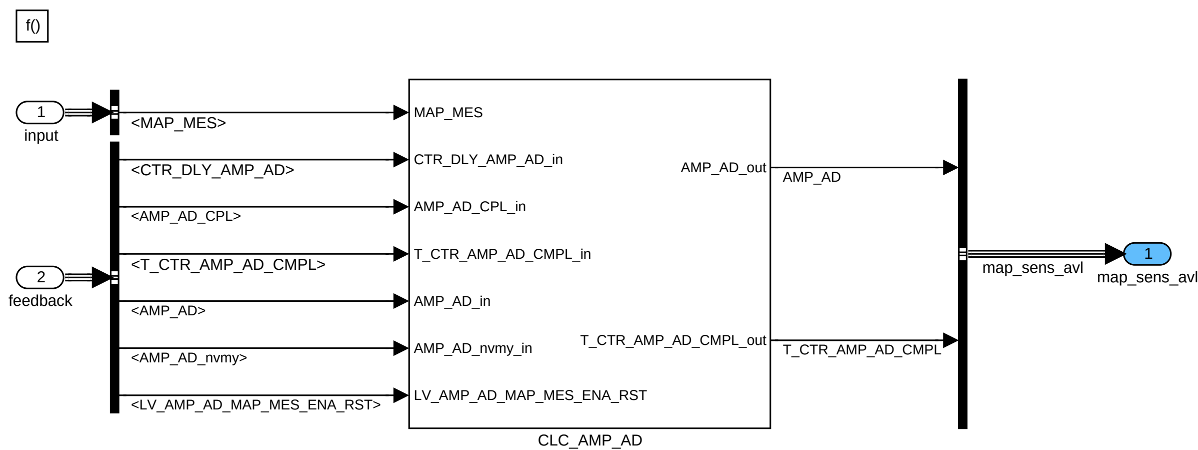

Figure 222 INSY_ADCPRAMP0/ INI/ FIRST_TOOTH/ CLC_1/ MAP_SENS_AVL

Initialization at first valid tooth if MAP sensor available and no AMP sensor available:

When the engine is not running, after a certain time (typically after 1 3 seconds) when the pressure in the intake manifold is equal to the ambient pressure or no warm reset was detected then AMP and AMP_AD are initialized with the measured MAP. If a warm reset was detected then AMP_AD is initialized with the so far adapted AMP value. At a cold reset with MAP_MES out of his plausible range, AMP_AD is initialized with the AMP_AD value read out from non volatile memory.

A warm reset can be detected by comparing the AMP_AD value with a calculated complementary value of AMP_AD.

4.16.1.3 Learning of ambient pressure at full load (takeover of MAP_MES) – recurrence 100ms:

If the System is equipped with a MAP sensor, the adaptation of the Ambient pressure can be done at full load using the load sensor signal. Adaptation is only allowed, when the enable bit LV_ENA_AMP_MAP_MES has been set by the Component and Adaptation Manager module. This enable flag takes into account the inhibition of Pressure learning if the load/throttle position rationality check detects implausibilities (LV_ERR_RATIO_CHK =1). The adaptation is only performed if the throttle opening is above a calibratable angle.

Ambient pressure should only be learned when a stable system is reached (e.g. no adaptation during short tip-in). Therefore a counter T_DLY_AMP_AD_MAP_MES is initialized with C_T_DLY_AMP_AD_MAP_MES at the transition from (TPS_AV > IP_TPS_AMP_AD_MAP_MES_MIN) to (TPS_AV <= IP_TPS_AMP_AD_MAP_MES_MIN) and then decreased by 100 ms every calculation call until it reaches zero. Adaptation is only allowed if this counter has reached zero. If one of the conditions are not fulfilled T_DLY_AMP_AD_MAP_MES is set back to C_T_DLY_AMP_AD_MAP_MES.

If T_DLY_AMP_AD_MAP_MES reaches zero, then the measured manifold pressure MAP_MES will be stored. With this stored value – regardless of whether the conditions are fulfilled or not – AMP_AD_DIF will be calculated. This is done till PUT is within a calibratable range around the stored manifold pressure.

Are the conditions of this algorithm fulfilled then the ambient pressure adaptation via model will be stopped and the ambient pressure will be adapted using the measured manifold pressure.

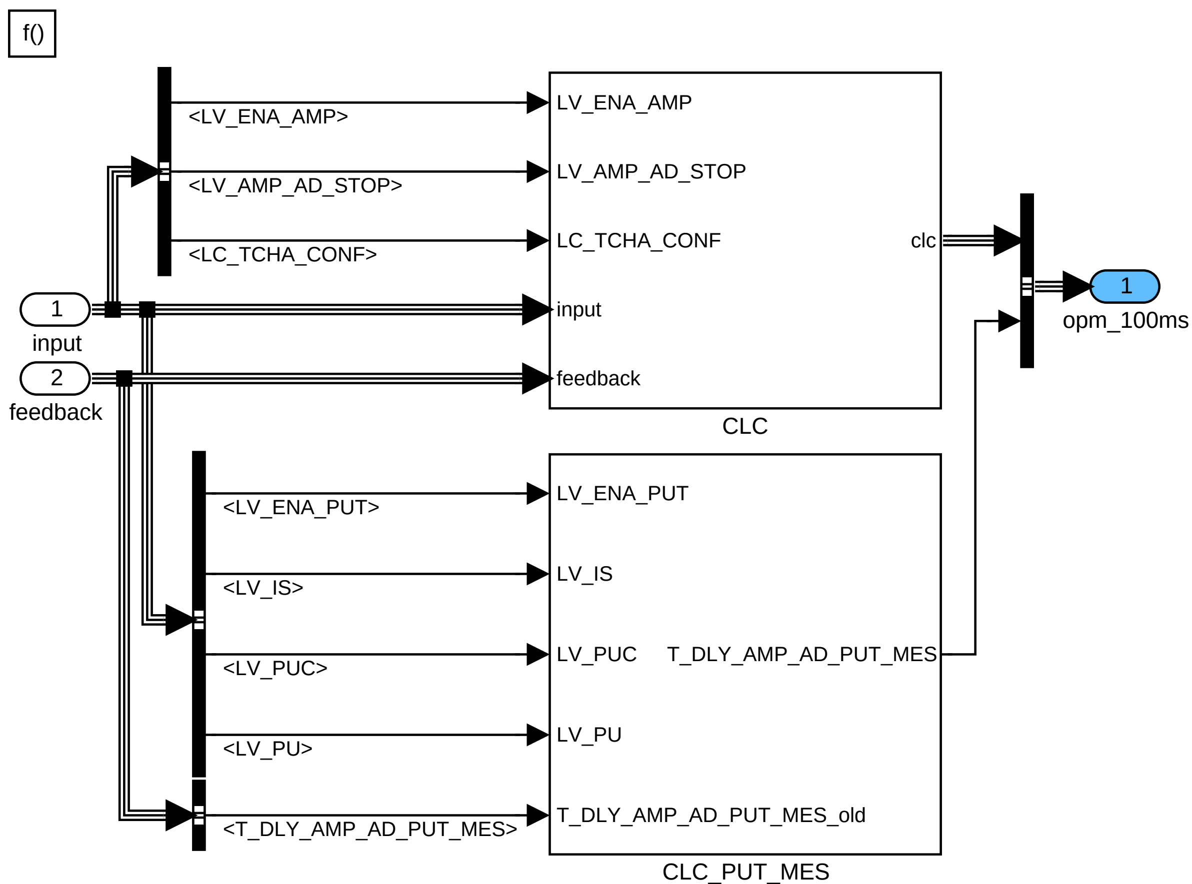

Figure 231 INSY_ADCPRAMP0/ OPM_100MS

Activation of learning of ambient pressure at full-load (takeover of MAP_MES):

Checking whether a stable system at full load is reached for ambient pressure learning via MAP_MES:

Learning of ambient pressure via the measured MAP value should only be done after a stable system at full load is reached. To ensure stable conditions TPS_AV must be higher than a threshold (IP_TPS_AMP_AD_MAP_MES_MIN) for a certain time

(C_T_DLY_AMP_AD_MAP_MES_MIN). Only after reaching this stable system at full load, STATE_AMP_AD is set to 3 (AMP_AD_VIA_MAP_MES).

Pressure loss through the air cleaner					

General Information

General information:
With increasing air mass flow through the air cleaner there is a drop of pressure in the air cleaner in comparison to the ambient pressure.

The calculation is done depending on the activation condition synchronously to multiples of segment.

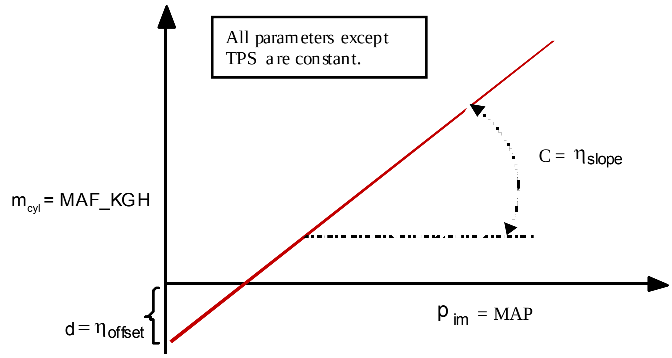
FUNCTION DESCRIPTION:

General information:

At a given engine speed N, the air-mass flow is modelled as a linear function (volumetric efficiency) depending on the manifold pressure MAP. The influence of the engine specific actuators is modelled as variations of the slope and offset. This approach ensures a basically linear model.



With the index STATE_ACR_EFF_VOL_CLC (built in the Appl.Inc.), it can be switched between different sets of volumetric efficiency maps, depending on the project-configuration (see INSY Configuration data).
Example: influence of actuators VIM, PORT, VVL etc., or others like SECONDARY-AIR.

No interpolation between these different IP-set [x] and IP-set [y] will be done.

Calibration data:

intermediate array (defined in the same way like a map), contains temporary offset/slope of the cylinder air-mass flow; IP_EFF_VOL_RAM has to be placed in RAM; not visible in application-system!! LDPM_CAM_MV_EX_INSY can be calibrated normally					

4.18.1 Standard EFF_VOL calculation (Seg-Syn.), using camshaft position mean value

Recurrence: multiples of a segment

Activation: **if** (STATE_CLC_RED **and** NC_STATE_CLC_RED_CLC_DEAC) = 0
(masking = bitwise AND!)

Formula:

#if (NLC_IVVT_IN = 1)
#then CAM_MV_IN_1 = $CAM\_MV\_IN_k$ + CAM_OFS_IVVT_IN_1
#else CAM_MV_IN_1 = C_CAM_INI_IN
#endif

#if (NLC_IVVT_EX = 1)
#then CAM_MV_EX_1 = $CAM\_MV\_EX_k$ + CAM_OFS_IVVT_EX_1
#else CAM_MV_EX_1 = C_CAM_INI_EX
#endif

subfunction-CALL: Calculate EFF_VOL_SLOP/OFS_BAS – Chapter 1.3
with input values: N_TMP = N
CAM_MV_IN_TMP = CAM_MV_IN_1
CAM_MV_EX_TMP = CAM_MV_EX_1

# Result: EFF_VOL_SLOP_BAS = EFF_VOL_SLOP_BAS_TMP
EFF_VOL_OFS_BAS = EFF_VOL_OFS_BAS_TMP

4.18.2 EFF_VOL-REQ-calculation for CAM_OFS-adaptation (20ms), when requested

Recurrence: *every 20 ms*

Activation: LV_EFF_VOL_CLC_CAM_OFS_AD = 1

Formula:

for i = 0 **to** 2 **FOR-loop below to be completed within one recurrence**

#if (NLC_IVVT_IN = 1)
#then CAM_MV_IN_2 = CAM_MV_IN_REQ_CAM_OFS_AD[i]
#else CAM_MV_IN_2 = 0hex
#endif

#if (NLC_IVVT_EX = 1)
#then CAM_MV_EX_2 = CAM_MV_EX_REQ_CAM_OFS_AD[i]
#else CAM_MV_EX_2 = 0hex
#endif

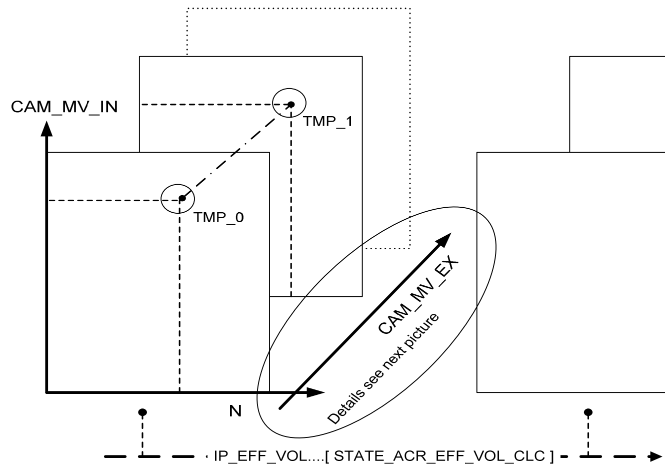
subfunction-CALL: Calculate EFF_VOL_SLOP/OFS_BAS – Chapter 1.3
with input values: N_TMP = N_REQ_CAM_OFS_AD
CAM_MV_IN_TMP = CAM_MV_IN_2
CAM_MV_EX_TMP = CAM_MV_EX_2

#Result: EFF_VOL_SLOP_BAS_REQ_CAM_OFS_AD[i] = EFF_VOL_SLOP_BAS_TMP
EFF_VOL_OFS_BAS_REQ_CAM_OFS_AD[i] = EFF_VOL_OFS_BAS_TMP

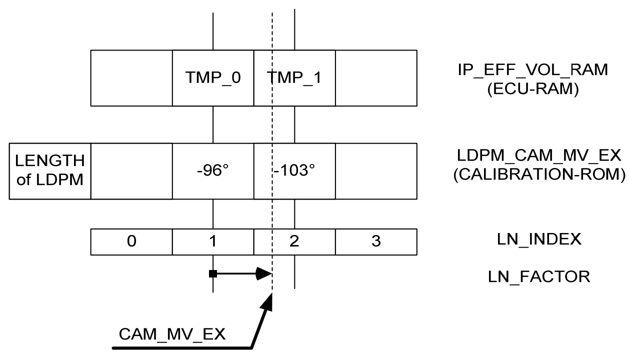
endfor

4.18.3 Main algorithm for the Basic Volumetric Efficiency - slope and offset

This subfunction is called twice with different input-parameters (see chapters above):
Param1 = N_TMP, Param2 = CAM_MV_IN_TMP, Param3 = CAM_MV_EX_TMP



Picture 1: overview of interpolation with 3 dimensions, and configurable sets of these 3D-maps



Picture 2: interpolation of 3rd dimension, with the help of standard library-routines

Example: input: CAM_MV_EX = -101.5°
output: LN_INDEX = 1
LN_FACTOR = (-101.5°-(-96°)) / (-103°-(-96°)) = 0.7857

LN_INDEX array-position [0...FF] of LDPM-search (range: 0...NC_NR_LEN_CAM_EX-1)
LN_FACTOR physical distance [0..0.9999][0..FFFF] between 2 interpolation-fields
in case of direct hit of the online-value CAM_MV_EX with the calibrated LDP-value, the internal variable LN_FACTOR is set to 0.

Note: The Hex. limits and Phys. limits of LDPM_CAM_MV_EX run against each other -> calibration of LDPM_CAM_MV_EX has to be done in ascending order for the Hex. limits.

Hint for better readability
"STATE_ACR" is used in following text equivalent to "STATE_ACR_EFF_VOL_CLC"

Formula section:

1. index-search for CAM_MV_EX-interpolation

* do LDPM-search of IP_EFF_VOL_RAM (CAM_MV_EX_TMP)

* save internal results to be used below:
  IDX_CAM_EX = LN_INDEX
  DELTA_CAM_EX_TMP = LN_FACTOR

2. Read out corresponding IP..., depending on STATE_ACR and CAM_MV_EX

TMP_0_OFS = IP_EFF_VOL_OFS_2 [STATE_ACR][IDX_CAM_EX]
(N_TMP, CAM_MV_IN_TMP)

TMP_0_SLOP = IP_EFF_VOL_SLOP_2 [STATE_ACR][IDX_CAM_EX]
(N_TMP, CAM_MV_IN_TMP)

if(1) *"no direct hit of LDPM" (DELTA_CAM_EX_TMP ≠ 0)*

then(1) *interpolation between 2 map-results:*

TMP_1_OFS = IP_EFF_VOL_OFS_2 [STATE_ACR][IDX_CAM_EX + 1]
(N_TMP, CAM_MV_IN_TMP)

TMP_1_SLOP = IP_EFF_VOL_SLOP_2 [STATE_ACR][IDX_CAM_EX + 1]
(N_TMP, CAM_MV_IN_TMP)

3. Store both interpolation-results into 2 fields of dummy-map (located in ECU-RAM)

offset:

IP_EFF_VOL_RAM [IDX_CAM_EX] = TMP_0_OFS

IP_EFF_VOL_RAM [IDX_CAM_EX + 1] = TMP_1_OFS

EFF_VOL_OFS_BAS_TMP = IP_EFF_VOL_RAM

Do interpolation with calculated index IDX_CAM_EX and DELTA_CAM_EX_TMP (from LDPM-search in(1.)) !

slope:

IP_EFF_VOL_RAM [IDX_CAM_EX] = TMP_0_SLOP

IP_EFF_VOL_RAM [IDX_CAM_EX + 1] = TMP_1_SLOP

EFF_VOL_SLOP_BAS_TMP = IP_EFF_VOL_RAM

Do interpolation with calculated index IDX_CAM_EX and DELTA_CAM_EX_TMP (from LDPM-search in(1.)) !

else(1) *"direct hit of LDP" : no additional interpolation necessary*

offset:

EFF_VOL_OFS_BAS_TMP = TMP_0_OFS

slope:

EFF_VOL_SLOP_BAS_TMP = TMP_0_SLOP

endif(1)

4.19 Calculation of VIM influence for volumetric efficiency

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
EFF_VOL_SLOP_VIM_COR	V/O	8000...7FFFH	-6.029...6.029	1.84e-4	kg/(hPa*h)

Filtered value of VIM_AV					
VIM_SP_FIL	V/O	0...FFH	0...0.996	0.0039	-
Filtered value of VIM_SP					

Input data:

PQ	LV_VIM_SP	VIM_AV	CONF_VIM
LV_ERR_VIM_FB_EL		N	VO

FUNCTION DESCRIPTION:

General information:

The influence of the switching intake manifold is taken into account via the correction coefficients EFF_VOL_SLOP_VIM_COR and EFF_VOL_OFS_VIM_COR.

In case of available VIM position feedback signal (CONF_VIM = 2), this measured signal VIM_AV is filtered and the correction of gas flow is based on this information VIM_AV_FIL.
If no feedback signal available (CONF_VIM = 1) or the diagnosis detects an error on the feedback signal (LV_ERR_VIM_FB_EL = 1), then the correction of gas flow is calculated via the filtered VIM setpoint VIM_SP_FIL.

The basic maps for the determination of the influence are depending on engine speed and valve overlap. The correction for slope/ offset of the volumetric efficiency is calculated with the filtered activation value of VIM.

Application conditions:

Initialisation: at reset

EFF_VOL_SLOP_VIM_COR = 0 kg(hPa * h) (0H)

EFF_VOL_OFS_VIM_COR = 0 kg/h (0H)

FAC_VIM = 0 (0H)

Recurrence: segment synchronous

Activation: at every engine state

Deactivation: none

4.20 Calculation of PORT influence for volumetric efficiency

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
EFF_VOL_SLOP_PORT_COR	V/O	8000...7FFFH	-6.0301...6.0299	0.184e-3	kg/(hPa*h)
PORT influence for slope of volumetric efficiency					
EFF_VOL_OFS_PORT_COR	V/O	8000...7FFFH	-1024...1023.969	0.03125	kg/h
PORT influence for offset of volumetric efficiency					

Input data:

N	VO	FAC_PORT_DEAC	CONF_PORT

FUNCTION DESCRIPTION:

General information:

The influence of Port Flap for the volumetric efficiency is taken into account via the correction coefficients EFF_VOL_SLOPE_PORT_COR and EFF_VOL_OFS_PORT_COR.

The basic maps for the determination of the influence are depending on engine speed and valve overlap. The correction for slope/ offset of the volumetric efficiency is weighted with the actual value of the Port flap position.

Application conditions:

Initialisation: EFF_VOL_SLOP_PORT_COR = 0 kg(hPa * h) (0H)

EFF_VOL_OFS_PORT_COR = 0 kg/h (0H)

Recurrence: segment synchronous

Activation: CONF_PORT = 1

Deactivation:

Formula section:

EFF_VOL_SLOP_PORT_COR = FAC_PORT_DEAC * IP_EFF_VOL_SLOP_PORT

EFF_VOL_OFS_PORT_COR = FAC_PORT_DEAC * IP_EFF_VOL_OFS_PORT

Calibration data:

4.21.1 General information:

Volumetric efficiency adaption

In systems with both MAF and MAP sensor one of measured values MAF_KGH and MAP_MES delivered by these load sensors is always used in the INSY controller to tune the model of the throttle flow. The present module uses the other load sensor to adapt the volumetric efficiency of the engine.

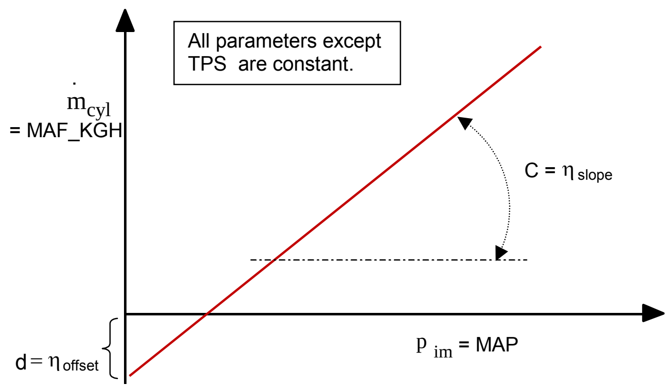
At a given engine speed N the air-mass flow is modeled as a linear function (volumetric efficiency) depending on the manifold pressure MAP.

Variations of the slope and offset model the influence of the engine specific actuators. The total volumetric efficiency can be build out of a basic value and a lot of engine specific corrections (e.g. VIM or port flap influences). Corrective values of these slope and offset EFF_VOL_SLOP_DIF and EFF_VOL_OFS_DIF are calculated here. EFF_VOL_OFS_DIF is calculated at low MAP, EFF_VOL_SLOP_DIF at high MAP.

Calculation of final volumetric efficency

general specification

At a given engine speed N the air-mass flow is modeled as a linear function (volumetric efficiency) depending on the manifold pressure MAP.



Variations of the slope and offset model the influence of the engine specific actuators. This approach ensures a basically linear model.

The total volumetric efficiency can be build out of a basic value and a lot of engine specific corrections (e.g. VIM or port flap influences). Both the basic efficiency and all the engine specific influences are calculated in the corresponding external modules. This module only coordinates all the corrections and calculates the final volumetric efficiency. The complete structure is depicted below.

Function Description

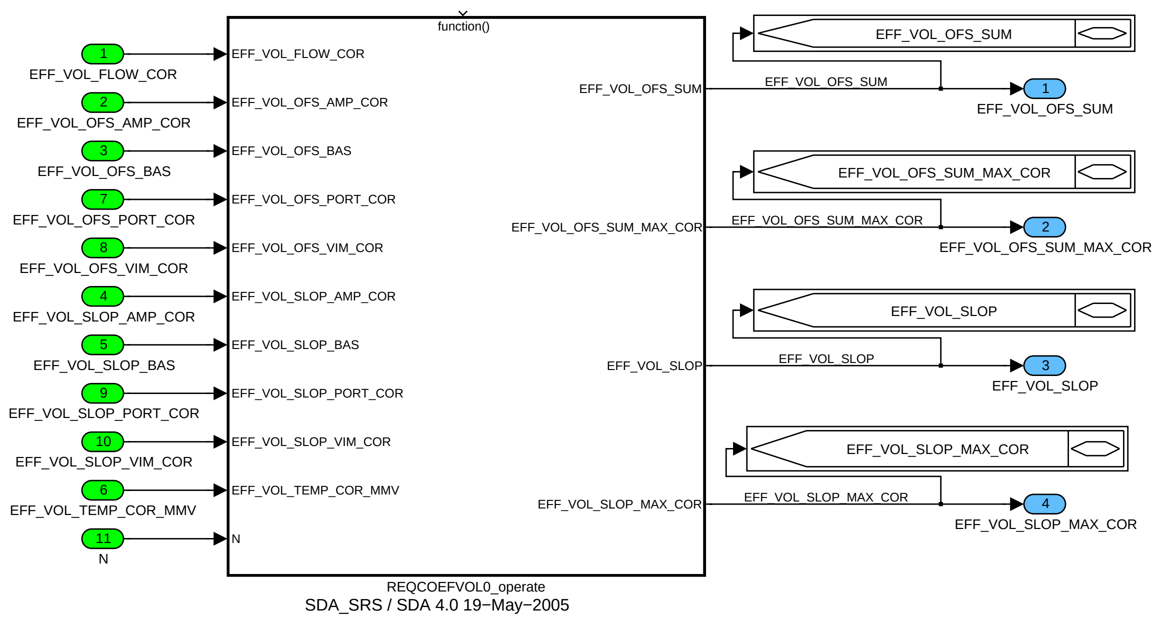


Figure 303 INSY_M403R

4.21.1.1 Calculation of final volumetric efficiency

4.23.1 General Information

Target of the temperature correction function is, to compensate the temperature influences onto the volumetric efficiency calculation. The air-mass flow into the cylinder is the product of the volume flow and the density of the air $\dot{m} = A \cdot w \cdot \rho(T) = \dot{V} \cdot \rho(T)$, where the density depends on the air-temperature. At low temperatures the air-density is much higher than at standard temperatures, therefore the air flowing into the cylinder at the same manifold pressure will increase. The basic volumetric efficiency usually is calibrated at standard temperatures of about 25 °C for intake air and about 90 °C for coolant temperature. To take into account the change in density with temperature, the volumetric efficiency has to be corrected.

Especially at speed-density systems, this temperature correction is essential, because the density of the air and therefore the air-mass flow strongly depend on the air temperature. This means all deviations from the temperatures at which the volumetric efficiency was calibrated will lead to a wrong air-mass flow value into the cylinder (e.g. wrong MAF value at cold starts without temperature corrections for a MAP system).

At systems equipped with an HFM sensor, the temperature correction is not as essential as for speed-density systems. Nevertheless, it is used to consider the heating of the air due to heat transfer from the warm intake duct to the air.The compensation function is capable of taking into account deviations of coolant temperature and intake air temperature separately

$$EFF\_VOL\_COR = \frac{273 + C\_TCYL\_STND}{273 + C\_TCYL\_STND + IP\_EFF\_TCO\_FAC \cdot (TCO - C\_TCO\_STND) + IP\_EFF\_TIA\_IM\_FAC \cdot (TIA\_IM - C\_TIA\_STND)}$$

Application Condition

Activation:	At every engine state
Deactivation:	-
Initialization:	*at reset and engine running to stopped engine*
	EFF_VOL_TEMP_COR=EFF_VOL_TEMP_COR_MMV=1
Calculation recurrence:	The calculation is done depending on the activation condition- synchronously to **multiples of a segment**

Application Condition

Function Description

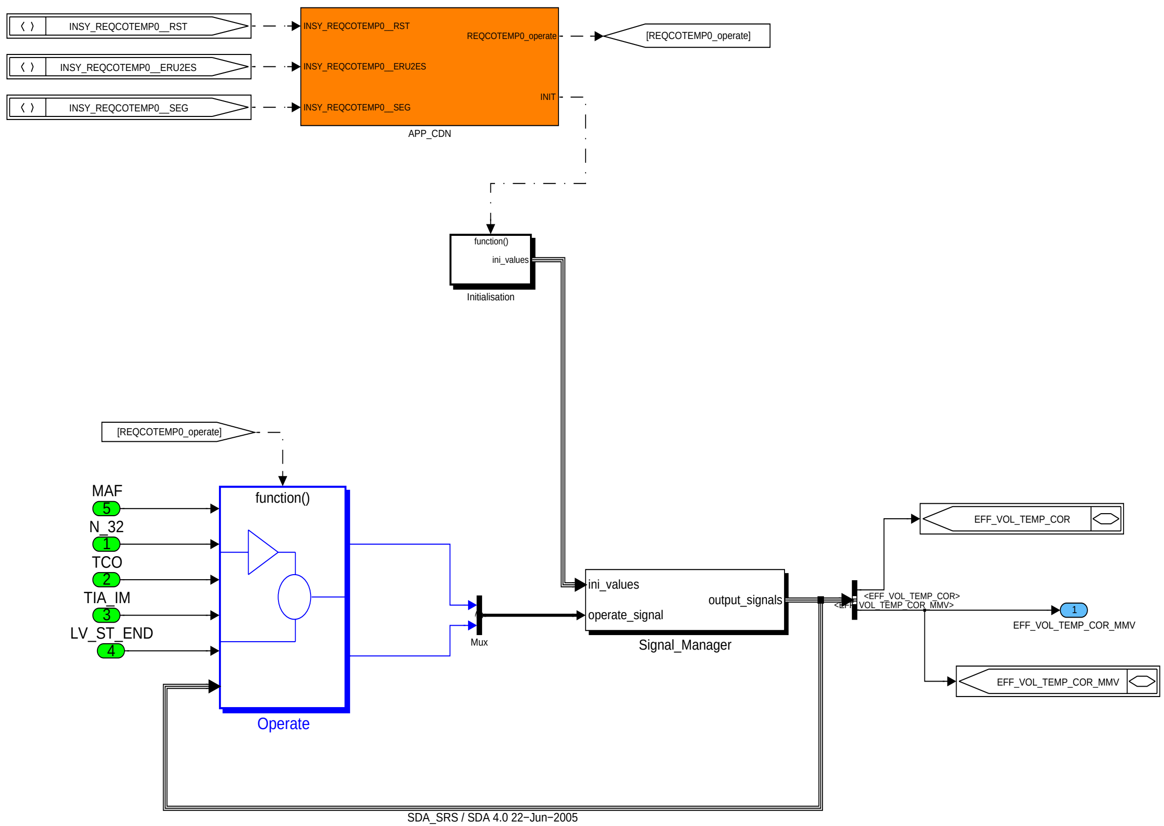

Figure 308 INSY_REQCOTEMP0

4.23.1.1 Initialization

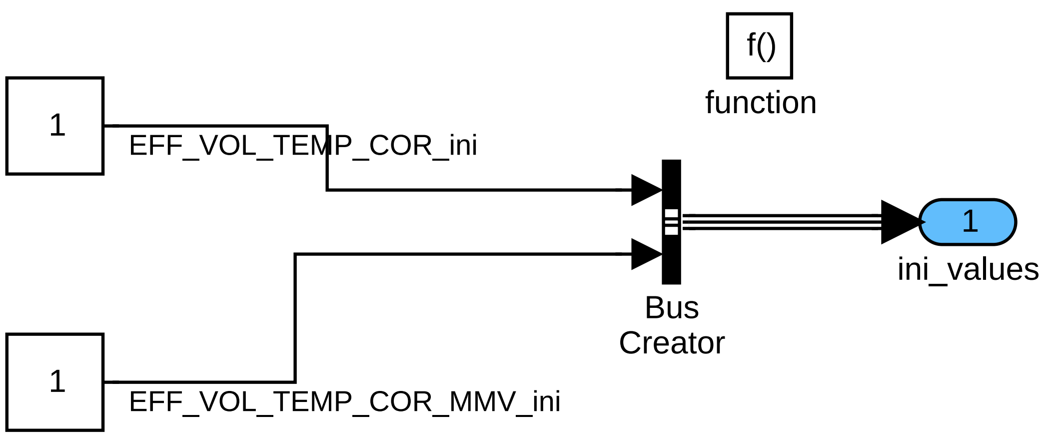

Figure 309 INSY_REQCOTEMP0/ Initialisation

Description:

The temperature correction factor EFF_VOL_TEMP_COR is the ratio between air temperature in the cylinder for standard conditions TCYL compared to air temperature in the cylinder for current TCO, TIA_IM and operating point. TCO and TIA_IM are compared to standard conditions and weighted by operating point.

General Information

general specification

Target of this correction function is, to consider the influence of cam phasing and exhaust gas back pressure on volumetric efficiency.

While the load exchange process with opening of the intake valves a back flow of burnt load from the combustion chamber to the intake manifold occurs. Beside engine speed, the amount of this back flow depends on the ratio between the exhaust gas back pressure and the intake manifold pressure and on the valve opening timing. This leads to a reduction of the volumetric efficiency.

Description:
The mass flow from the combustion chamber to the intake manifold or the exhaust pipe depends at any given engine speed on the one hand on the ratio between exhaust gas back pressure and intake-manifold pressure and on the other hand on the valve timing.

The number of engine speed breakpoints of the maps IP_EFF_VOL_PRS_EX_COR_1 and IP_EFF_VOL_VO_COR_1 are defined by NC_NR_N_EFF_VOL_BAS (defined in INSY configuration data). The same breakpoints are used for the basic volumetric efficiency maps (IP_EFF_VOL_OFS/SLOP).

Hint for calibration data: Dimension N = NC_NR_N_EFF_VOL_BAS for LDPM_N_3_INSY

With the index STATE_ACR_EFF_VOL_CLC (built in the Appl. Inc.) it can be switched between different maps. Between how many maps it can be switched depends on the number of actuators (project configuration) which are influencing EFF_VOL (e.g. VIM, PORT, etc.) (like in the basic volumetric efficiency).

Application Conditions:

Activation:	always
Deactivation:	-
Initialization:	At a reset of the ECU or at the transition from engine running to stopped engine the following values are initialized PQ_MAP_PRS_EX=1
Calculation recurrence:	The calculation is done –depending on the activation condition- synchronously to **multiples of a segment**

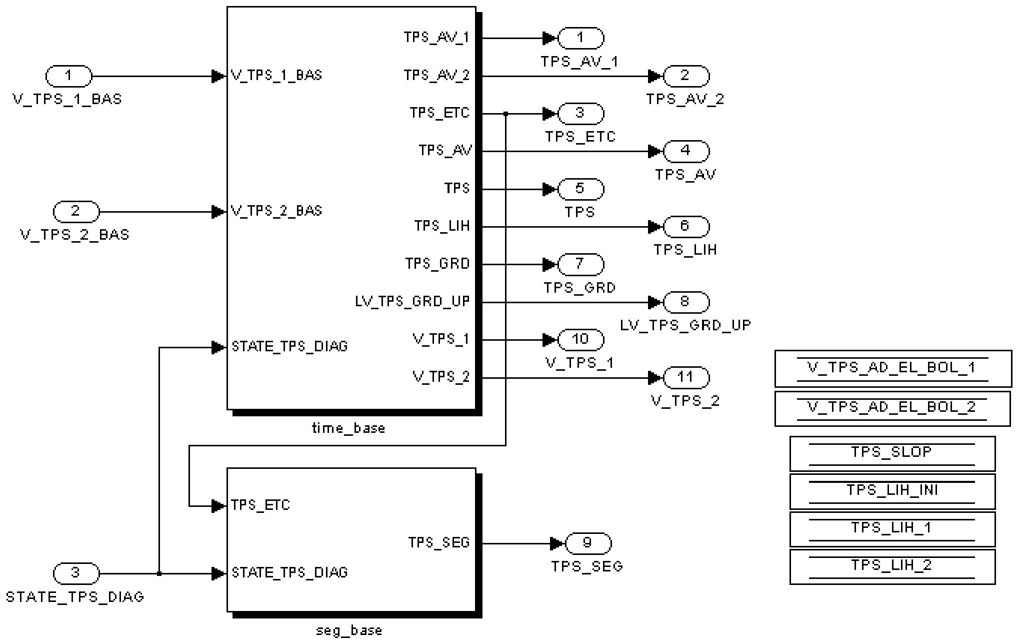
4.25 Determination of the Throttle Position

General Information:

The throttle position is determined by a two-channel sensor system. Both of the supply voltage channels delivers inverse dispersing voltage signals. With the help of the determined adaptation values, the TPS-Position is standardized using the standard slope of the throttle position sensors.
V_TPS_1 has to be increasing and V_TPS_2 has to be decreasing with rising throttle.



A Plausibility Unit monitors both sensor signals, as well as the corresponding supply voltage and from them establishes the system state of the TPS-Position Acquisition (Undisturbed, Disturbed, TPS-Position not recognizable). From the voltage value of both TPS-Channels, the existing TPS-Position for the channels is determined, taking into consideration, the adaptation value for the lower stop. Based on the determined state of the system, the resulting TPS-Position is determined by the individual values. In case of a disturbance of the position acquisition, the selection of the position is conducted from one of the two DK-Channels- respectively- by a complete collapse, or the Shutdown of the TPS_control and with it the Limp Home.

Output data:

Name	V/S	Hex. limits	Phys. limits	Resol.	Unit
TPS_ETC	V/O	C000h...3FFFh	-119.51...119.5	0.0073	°TPS

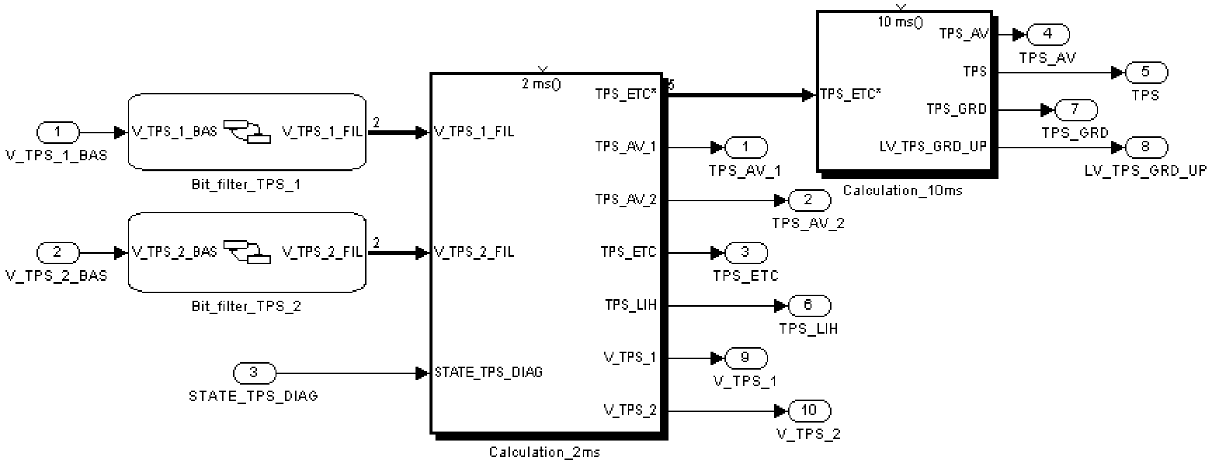
4.25.1 Time synchronous throttle valve position

Description:

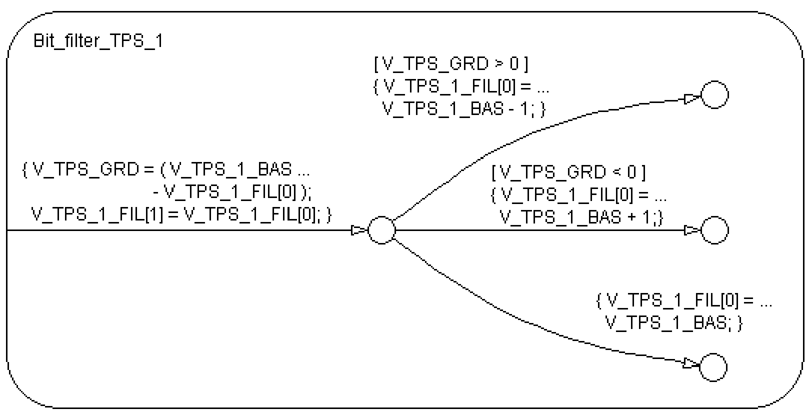
The time synchronous throttle position value TPS_ETC is needed as input for the electronic throttle control. The calculation of TPS_ETC is carried out every 2 ms.



4.25.1.1 TPS signal filter

Description:

The AD values of the throttle position sensors have a resolution of 10 bit (1024 increments) according to the AD converter. The smallest signification bit, one increment, is the fault of the AD conversion process and this bit can alternate from conversion to conversion. To compensate this fault a bit filter is used, see below.



Bit filter, general functionality (throttle position sensor 1)

Application conditions:

Initialisation: v_tps_x_fil[0] = v_tps_x_fil[1] = 0;

Recurrence: 1 ms

Activation: at every operating state

Formula section:

{ bit filter for TPS 1}
v_tps_grd_1 = V_TPS_1_BAS – v_tps_1_fil[0];

v_tps_1_fil[1] = v_tps_1_fil[0];

if v_tps_grd_1 > 0

then v_tps_1_fil[0] = V_TPS_1_BAS – 1

else **if** v_tps_grd_1 < 0

then v_tps_1_fil[0] = V_TPS_1_BAS + 1

else v_tps_1_fil[0] = V_TPS_1_BAS

endif

{ bit filter for TPS 2 }
v_tps_grd_2 = V_TPS_2_BAS – v_tps_2_fil[0];

v_tps_2_fil[1] = v_tps_2_fil[0];

if v_tps_grd_2 > 0

then v_tps_2_fil[0] = V_TPS_2_BAS – 1

else **if** v_tps_grd_2 < 0

then v_tps_2_fil[0] = V_TPS_2_BAS + 1

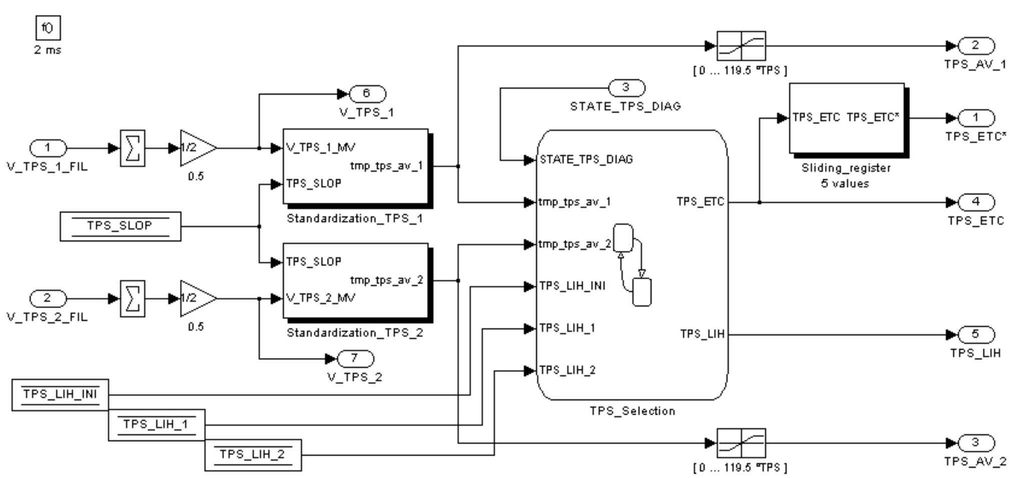
else v_tps_2_fil[0] = V_TPS_2_BAS

endif

4.25.1.2 Standardization of the TPS-Voltage

Description:

With the help of the determined adaptation values, the TPS-Position is standardized using the standard slope TPS_SLOP of the throttle position sensors.



Application conditions:

Initialisation: TPS_AV_x = C_TPS_MAX

Recurrence: 2 ms

Activation: at every operating state

Formula section:

{ The values ..._mv are meant to be local variables with a resolution 0,00244 V instead of 0,00488 V for V_TPS_x. These values are introduced to do the calculation below with higher resolution. }

V_TPS_x = v_tps_x_mv = 0.5 * (v_tps_x_fil[0] + v_tps_x_fil[1])

{ We introduce logical variables tmp_tps_av_x with physical limits of -119.51 ... 119.5 °TPS which are also needed in the section " Selection of throttle control value TPS_ETC " . }

actual value TPS 1 *{ Calculation with a higher resolution than V_TPS_1 }*

tmp_tps_av_1 = (v_tps_1_mv – V_TPS_AD_EL_BOL_1) * TPS_SLOP

actual value TPS 2 *{ Calculation with a higher resolution than V_TPS_2 }*

tmp_tps_av_2 = (V_TPS_AD_EL_BOL_2 – v_tps_2_mv) * TPS_SLOP

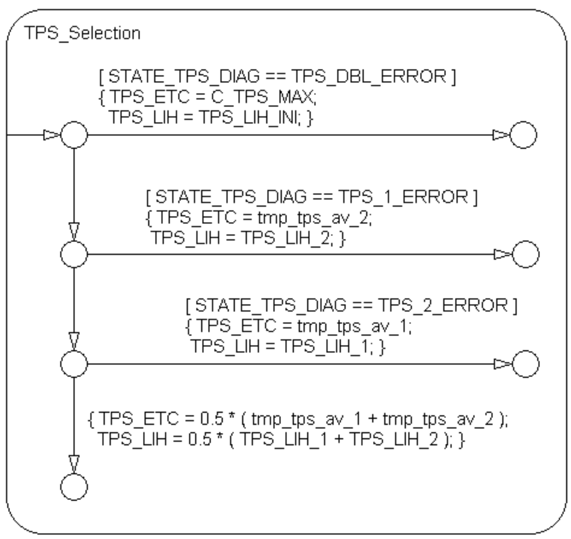
{ The actual values are limited to values greater than zero }

TPS_AV_x = MAX(tmp_tps_av_x, 0)

4.25.1.3 Selection of throttle control value TPS_ETC

Description:

The selection of electronic throttle control value TPS_ETC and the limp home position TPS_LIH depends on the status of TPS diagnosis.



Application conditions:

Initialisation: TPS_LIH = TPS_LIH_INI
TPS_ETC = C_TPS_MAX

Recurrence: 2 ms

Activation: at every operating state

Formula section:

```
{ TPS1 & TPS2 erroneous }
if    STATE_TPS_DIAG == TPS_DBL_ERROR
then        TPS_ETC = C_TPS_MAX
            TPS_LIH  = TPS_LIH_INI
{ TPS 1 erroneous }
else  if    STATE_TPS_DIAG == TPS_1_ERROR
      then        TPS_ETC = tmp_tps_av_2
                  TPS_LIH = TPS_LIH_2
      { TPS 2 erroneous }
      else  if    STATE_TPS_DIAG == TPS_2_ERROR
            then  TPS_ETC = tmp_tps_av_1
                  TPS_LIH = TPS_LIH_1
            { TPS1 & TPS2 errorfree, no TPS plausibility error }
            else  TPS_ETC = 0.5 * ( tmp_tps_av_1 + tmp_tps_av_2 )
                  TPS_LIH = 0.5 * ( TPS_LIH_1 + TPS_LIH_2 )
            endif
         endif
endif
```

4.25.1.4 Calculation of throttle position value TPS_AV/TPS

Description:

The TPS_ETC values are written into a buffer with 5 values, all 10 ms the mean value TPS_AV is calculated. TPS is the throttle position value TPS_AV with low resolution.

Application conditions:

Initialisation: TPS_AV = TPS = TPS_ETC(k-n) = C_TPS_MAX

Recurrence: 10ms

Activation: at every operating state

Formula section:

```
TPS_AV  = 0.2 * [ TPS_ETC(k) + TPS_ETC(k-1) + TPS_ETC(k-2) ...
                + TPS_ETC(k-3) + TPS_ETC(k-4) ]
TPS     = TPS_AV
```

4.25.1.5 Calculation of throttle position gradient: (TPS_GRD)

Description:

The gradient is calculated as (absolute value of) difference from the actual throttle value and the throttle value k - 4 (that is the throttle value which was actual 40ms before).

Application conditions:

Initialisation: TPS_GRD = 0

LV_TPS_GRD_UP = 0

Recurrence: 10ms

Activation: at every operating state

Formula section:

TPS_GRD = | [TPS_AV(k) – TPS_AV(k-4)] * 25 |

The throttle gradient direction is calculated as follows

If [TPS_AV(k) – TPS_AV(k-4)] < 0

then LV_TPS_GRD_UP = 0 (negative throttle gradient)

else LV_TPS_GRD_UP = 1 (positive throttle gradient)

endif

4.25.2 Segment synchronous throttle valve position: (TPS_SEG)

Description:

The segment synchronous throttle valve position TPS_SEG is needed as input for the intake manifold model. The current throttle valve position TPS_ETC is copied in TPS_SEG to every segment interrupt, in case of TPS double error, TPS_SEG ist set to TPS_LIH_INI.

Application conditions:

Initialisation: TPS_SEG = TPS_LIH_INI

Recurrence: segment synchronous

Activation: at every operating state

Formula section:

{ TPS1 & TPS2 erroneous }

if STATE_TPS_DIAG == TPS_DBL_ERROR

then TPS_SEG = TPS_LIH_INI

else TPS_SEG = TPS_ETC

endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

General Information

There are several optional components that are not mandatory for every system configuration. These are mainly sensors, but components like charger and EGR are optional as well. The mandatory air path functions are designed to work both with or without and with several combinations of these optional components. Some optional components can be switched on/off if they are present (e.g. EGR), other cannot be switched off if they are present (e.g. charger).

general specification

In dependence of the presence and recognized malfunction of the components several adaptations related to these components can be allowed or inhibited.
The function of the present Component and Adaptation Manager module is:
- to collect configuration information (information about the presence of components in the system),
- to collect error state information (information about malfunction of existing components),
- to enable or disable the usage of these components,
- to allow or inhibit adaptations related to these components.

4.27 Vehicle Speed Variables

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VS	V/O	0...FFH	0...255	1	km/h
vehicle speed					
VS_MAX	O	0...FFH	0...255	1	km/h
Maximum vehicle speed.					
VS_FAC	O	0 … 1FFFFFFFH	0 … 0,582542	1,736109 *10E-8	m
Factor to calculate vehicle speed in km/h from signal pulses					
LV_VS_RUN	V/O	0...1H	0...1	1	-
Boolean for running vehicle					
VS_WORD	V/O	0...FFFFH	0...511.992	0.0078125	km/h
Vehicle speed (16 bits)					
VS_MAX_DC	V/O	0...FFH	0...255	1	km/h
Maximum vehicle speed during current driving cycle					

Input data:

VS_SENS_XX	CONF_VS	VS_TCU_CAN	

FUNCTION DESCRIPTION:

General information:

Running vehicle is detected if vehicle speed VS >= C_VS_MIN_RUN.

Activation : at every engine operating state

Deactivation : -

Initialization : VS = 0

LV_VS_RUN = 0

VS_MAX_DC = 0

Update rate : 10ms

With the configuration byte CONF_VS, different possibilities of vehicle speed acquisition are available (gear box, inductive wheel speed sensor, ABS control unit, TCU via CAN).

The following variables are automatically adjusted according to CONF_VS:

- VS_MAX : maximum vehicle speed
- VS_FAC : factor to make the conversion from pulse to distance(m)

Filtering function:

To prevent for sudden VS signal jumps, a function is used to filter implausible changes of the vehicle speed signal. If the difference between 2 following values is grater than a calibratable constant, the previous value is kept.

If more than 5 following values have been determined as implausible the latest value is used.

Formula section:

VS_MIN, VS_MAX, VS_FAC calculation:

```
If      CONF_VS = "GEAR_BOX" (0 hex)
then    VS_MAX  =  C_VS_MAX_GB
        VS_FAC  =  C_VS_FAC_GB
else    VS_FAC = C_VS_FAC_ABS_WHEEL
        if      CONF_VS = "TCU_CAN" (4 hex)
        then    VS_MAX = C_VS_MAX_TCU_CAN
        else    VS_MAX =  C_VS_MAX_ABS_WHEEL
        endif
endif
```

The calculation is performed once after system reset.

VS calculation :

```
If      CONF_VS = "WHEEL"
then    VS = VS_SENS_WHEEL
else    if      CONF_VS = "TCU_CAN"
        then    VS = VS_TCU_CAN
        else    VS = VS_SENS_ABS_GB
        endif
endif
```

VS_MAX_DC calculation:

```
If      VS > VS_MAX_DC
then    VS_MAX_DC = VS
endif
```

VS_WORD calculation (high resolution – 16 bits) :

```
If      CONF_VS = "WHEEL"
then    VS = VS_SENS_WHEEL
else    if      CONF_VS = "TCU_CAN"
        then    VS = VS_TCU_CAN
        else    VS = VS_SENS_ABS_GB
        endif
endif
```

VS Filter:

If $| VS_{(n)} – VS_{(n-1)} | > C\_VS\_DIF\_MAX\_FIL$
and CTR_VS_FIL < 5
then $VS = VS_{(n-1)}$ *(previous value is kept)*
and CTR_VS_FIL = CTR_VS_FIL + 1
else $VS = VS_{(n)}$
and CTR_VS_FIL = 0

The Filter can be enabled by setting LC_VS_FIL_ENA = 1

LV_VS_RUN calculation :

If VS >= C_VS_MIN_RUN
then LV_VS_RUN = 1
else LV_VS_RUN = 0
endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_MIN_RUN	1	0...FFH	0...255	1	km/h
vehicle speed threshold for running vehicle detection					
C_VS_MAX_GB	1	0...FFH	0...255	1	km/h
Maximum Vehicle speed if CONF_VS = "GEAR_BOX"					
C_VS_MAX_ABS_WHEEL	1	0...FFH	0...255	1	km/h
Maximum Vehicle speed if CONF_VS = "ABS" or "WHEEL"					
C_VS_MAX_TCU_CAN	1	0...FFH	0...255	1	km/h
Maximum Vehicle speed if CONF_VS = "TCU_CAN"					
C_VS_FAC_GB	1	0 … 1FFFFFFH	0 … 0,582542	1,736109 *10E-8	m
Vehicle distance pulse if CONF_VS = "GEAR_BOX"					
C_VS_FAC_ABS_WHEEL	1	0 … 1FFFFFFH	0 … 0,582542	1,736109 *10E-8	m
Vehicle distance per pulse CONF_VS = "ABS" or "WHEEL"					
C_VS_DIF_MAX_FIL	1	0 … FFH	0 … 255	1	km/h
Filtering threshold for VS changes					
LC_VS_FIL_ENA	1	0 … 1H	0 … 1	1	-
Activation constant for VS filtering function					

4.27.1 Internal vehicle speed signal

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VS_SENS_XX	V/O	0 ... FFFFH	0...1023,984375	0,015625	km/h
vehicle speed calculated from corresponding input signal					
VS_SENS_GRD_XX	V	8000 ... 7FFFH	-256 ... 255,9921875	0,0078125	km/h / 10ms
Vehicle speed gradient calculated from VS_SENS_XX					
VS_EDGE_CTR_AV_XX	V	0 ... FFFFh	0 ... 65565	1	-
actual value of vehicle speed tooth counter (free running counter)					
VS_EDGE_T_AV_XX	V	0 ... FFFFFFFFh	0 ... 17179869	0,004	ms
actual timestamp of last tooth (free running timer)					
LV_VST	V	0 ... 1H	0 ... 1	1	-
boolean for stopped vehicle					

Input data:

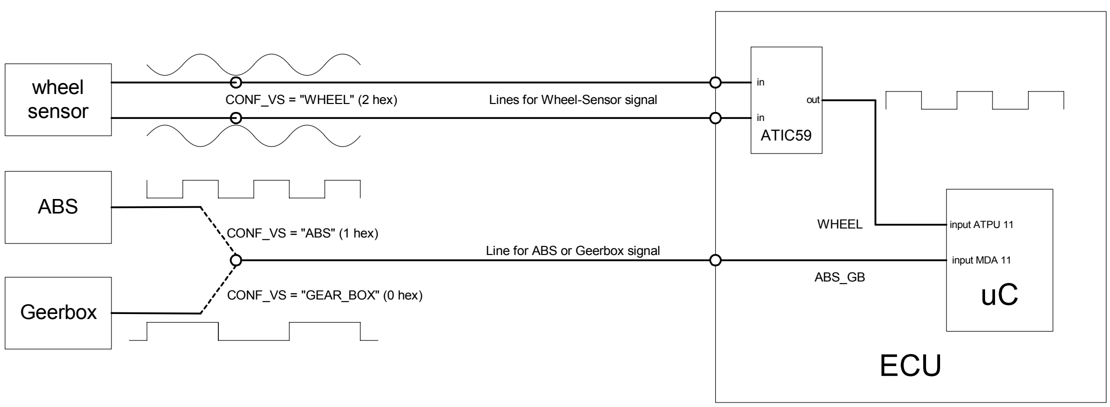
BIOS_VS_EDGE_CTR	BIOS_VS_EDGE_T	VS_FAC	

FUNCTION DESCRIPTION:

General information:

The source of the signal for the VS acquisition is defined by CONF_VS. The ECU has two different input lines: one for the signal from the inductive wheel speed sensor and one as common line for signal from ABS control unit or gear box sensor.
The data processing for each input line is done separately.

The two different input lines can be distinguished by the suffix XX:
with XX= "ABS_GB" for input from ABS contol unit or gear box sensor
"WHEEL" for input from inductive wheel speed sensor



Every 10 ms, VS_EDGE_CTR_AV_XX and VS_EDGE_T_AV_XX are updated based on BIOS_VS_EDGE_CTR and BIOS_VS_EDGE_T.

The edge counter is checked every 10ms and if new edge is detected ,

⇒ The logical variable for stopped vehicle LV_VST is set to 0.

⇒ If ($VS\_EDGE\_CTR\_AV\_XX_{n}$ - $VS\_EDGE\_CTR\_AV\_XX_{n-x}$) > C_VS_EDGE_SUM_MIN a new vehicle speed calculation is performed. VS_SENS_XX as well as VS_SENS_GRD_XX are calculated as described in formula section.

If no new edge counter is detected during the time C_T_VST_XX,
⇒ The logical variable for stopped vehicle LV_VST is set to 1.
⇒ VS_SENS_XX as well as VS_SENS_GRD_XX are set to 0.

Application conditions:

Activation : at every engine operating state

Deactivation : -

Initialization : VS_SENS_XX = 0
VS_SENS_GRD_XX = 0

LV_VST = 1

Update rate : 10ms

Formula section:

$$VS\_SENS\_XX = VS\_FAC * (VS\_EDGE\_CTR\_AV\_XX_{n} - VS\_EDGE\_CTR\_AV\_XX_{n-x}) / (VS\_EDGE\_T\_AV\_XX_{n} - VS\_EDGE\_T\_AV\_XX_{n-x})$$

$$VS\_SENS\_GRD\_XX = (VS\_SENS\_XX_{n} – VS\_SENS\_XX_{n-x}) / (VS\_EDGE\_T\_AV\_XX_{n} - VS\_EDGE\_T\_AV\_XX_{n-x})$$

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_T_VST_GB	1	1 … FFH	10 … 2550	10	ms
Time delay for detection of vehicle stop in case C_CONF_VS =0					
C_T_VST_ABS_WHEEL	1	1 … FFH	10 … 2550	10	ms
Time delay for detection of vehicle stop in case C_CONF_VS = 1					
C_VS_EDGE_SUM_MIN	1	1 … FFH	1 … 255	1	-
minimum number of wheel segments for evaluation of vehicle speed					

4.27.2 Vehicle speed state VS_STATE_CFA

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VS_STATE_CFA	V/O	0...2H	0...2	1	-
Vehicle speed state for cooling fans.					

Input data:

VS	LV_ACCIN	LV_ERR_VS	LV_ERR_MWSS

FUNCTION DESCRIPTION:

General information:

The fans are controlled according to the vehicle speed. For this purpose, a vehicle speed state is determined. The vehicle speed thresholds are different if the air conditioner is selected or not.

Formula section:

Initialization:

At ECU initialization, VS_STATE_CFA is set to 0.

Calculation :

* LV_ACCIN = 0

If (VS_STATE_CFA = 0 **and** VS **>** C_VS_2_CFA)

then VS_STATE_CFA **= 1**

If (VS_STATE_CFA = 1 **and** VS **<** C_VS_2_CFA - C_VS_HYS_1_CFA)

then VS_STATE_CFA **= 0**

* LV_ACCIN = 1

If (VS_STATE_CFA = 0 **and** VS **>** C_VS_1_CFA)

then VS_STATE_CFA **= 1**

If (VS_STATE_CFA = 1 **and** VS **<** C_VS_1_CFA - C_VS_HYS_1_CFA)

then VS_STATE_CFA **= 0**

* Independently of LV_ACCIN

If (VS_STATE_CFA = 1 **and** VS **>** C_VS_3_CFA)

then VS_STATE_CFA **= 2**

If (VS_STATE_CFA = 2 **and** VS **<** C_VS_3_CFA - C_VS_HYS_2_CFA)

then VS_STATE_CFA **= 1**

Remark : C_VS_1_CFA **<** C_VS_2_CFA **<** C_VS_3_CFA

Limp Home :

If LV_ERR_VS **=** 1 *(Error currently present on vehicle speed sensor)*

or LV_ERR_MWSS = 1 *(Error currently present on MWS-sensor)*

then VS_STATE_CFA **=** 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_1_CFA	1	0...FFH	0...255	1	km/h
Vehicle speed threshold for fans management.					
C_VS_2_CFA	1	0...FFH	0...255	1	km/h
Vehicle speed threshold for fans management.					
C_VS_3_CFA	1	0...FFH	0...255	1	km/h
Vehicle speed threshold for fans management.					
C_VS_HYS_1_CFA	1	0...FFH	0...255	1	km/h
Vehicle speed hysteresis for VS_STATE_CFA transition 1 -> 0.					
C_VS_HYS_2_CFA	1	0...FFH	0...255	1	km/h
Vehicle speed hysteresis for VS_STATE_CFA transition 2 -> 1.					

4.28 Vehicle Speed (Appl. Inc.)

4.28.1 Variables for fleet monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VS_MAX_TOT_DC	V/O/S	0...FFH	0...255	1	km/h
Former / current driving cycle maximum vehicle speed					

Input data:

VS	LV_IGK	ERR_SYM_VS	

Description:

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

VS_MAX_TOT_DC = 0H

- otherwise: restored from non-volantile memory

Recurrence: *10 ms*

Activation: *LV_IGK = 1*

Deactivation: -

Formula section:

If ERR_SYM_VS = 0

Then If VS > VS_MAX_TOT_DC

Then VS_MAX_TOT_DC = VS

Endif

Endif

4.29 Mileage counter

4.29.1 Distance accumulator

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DIST	S/O/V	0...FFFFFFFFH	0...429496729,5	0,1	km
Distance accumulator [0,1 km]					
DIST_TMP	-	0...FFFFFFFFH	0...38177,487	8,88889E-06	m
Internal distance counter					
DIST_DC	O/V	0...FFFFFFFFH	0...429496729,5	0,1	km
Distance at current driving cycle					

Input data:

CONF_VS	VS_EDGE_CTR_AV_XX	VS_FAC	

FUNCTION DESCRIPTION:

General information:

This Function is to accumulate the covered distance since the first vehicle start in resolution of 100m for EOBD purpose.

Application conditions:

Activation : at every engine operating state

and if the VS signal is determinate (CONF_VS **is not** "LEARNING")

Deactivation : -

Initialization : at the first power on: DIST = 0

*at transition LV_IGK 0->*1 *or reset*: DIST_DC = 0

Update rate : 1s

In dependence of the configuration byte CONF_VS the pulse counter VS_EDGE_CTR_AV_XX is used for distance calculation.

With XX = 'ABS_GB' if ABS control unit or gear box sensor is used

'WHEEL' if inductive wheel speed sensor is used.

Formula section:

$$DIST\_TMP_{(n)} = DIST\_TMP_{(n-1)} + (VS\_FAC/512 * (VS\_EDGE\_CTR\_AV\_XX_{(n)} - VS\_EDGE\_CTR\_AV\_XX_{(n-1)}))$$

If DIST_TMP >= 100m

then DIST = DIST + 0,1 km

DIST_DC = DIST_DC + 0,1 km

DIST_TMP = DIST_TMP –100m

EndIf

4.29.2 Distance for fuel consuption rate

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DIST_FCO	O/V	0...FFFFFFH	0...16777.215	0,001	km
Distance for fuel consumption rate [0,001 km]					

Application conditions:

Initialisation: At ECU reset :

DIST_FCO = 0

Recurrence: 1s

Activation: at every engine operating state

and if the VS signal is determinate (CONF_VS **is not** “LEARNING”)

Deactivation: -

Formula section:

If $DIST\_FCO_{(n-1)}$ < 0xFFFFFF

Then $DIST\_FCO_{(n)} = DIST\_FCO_{(n-1)} + (DIST\_TMP_{(n)} – DIST\_TMP_{(n-1)}) * 0.001$

Else $DIST\_FCO_{(n)} = DIST\_FCO_{(n-1)}$

EndIf

Remark : After calculating difference of DIST_TMP, the distance which is smaller than 1m should be kept and added to next DIST_FCO(n+1) calculation.

4.29.3 Distance at last time failure meory cleared

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DIST_FMY	-/S	0...FFFFFFFFH	0...4294967295	1	km
Distance at last time failure memory cleared					

FUNCTION DESCRIPTION:

General information:

Purpose of this strategy is to memorize the distance of the last time the failure memory was cleared.

Application conditions:

Initialisation: on failure memory clear service received

DIST_FMY = DIST

Recurrence: -

Activation: -

Deactivation: -

4.30 Battery voltage VB

4.30.1 Computation of VB

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VB	V/O	0...FFH	0...26	0.102	V
Relay - battery voltage					
V_IGK	V/O	0...FFH	0...26	0.102	V
Key - battery voltage					

Input data:

VB_MES	V_IGK_MES	LV_ERR_VB_OC	

FUNCTION DESCRIPTION:

General information:

The battery voltage (V_IGK_MES and VB_MES (10 bit)) is measured up to 30V, 28V or 26V (means 0-5V at ADC), depending on the project-specific solution, but the range of VB (8 bit) remains 0-26 V. For the computation of VB in hex the correction factor NC_FAC_VB_RATIO is necessary; its value depends on the project-specific battery voltage range. NC_FAC_VB_RATIO is definded in the "List of Configuration Datas". The following table shows how NC_FAC_VB_RATIO is formed.

Measured battery voltage range (for example)	NC_FAC_VB_RATIO
0 ..... 26 V	26V / 26V
0 .. 28,8 V	28,8V / 26V
0 ..... 30 V	30V / 26V

Application conditions:

Activation: at reset

Initialisation: VB = 0

V_IGK = 0

Recurrence: 10 ms

Formula section:

HEX calculation:

VB = (VB_MES / 4) * NC_FAC_VB_RATIO

V_IGK = (V_IGK_MES / 4) * NC_FAC_VB_RATIO

VB relay:

If LV_ERR_VB_OC = 1
Then VB = V_IGK
Else **If** VB_MES <= 26 Volt
Then VB = (VB_MES / 4) * NC_FAC_VB_RATIO
Else VB = 26 Volt (FF hex)
Endif
Endif

VB key:

If V_IGK_MES <= 26 Volt
Then V_IGK = (V_IGK_MES / 4) * NC_FAC_VB_RATIO
Else V_IGK = 26 Volt (FF hex)
Endif

4.30.2 Secured battery voltage computation

Output data:

Name	V/S	Hex. limits	Phys. limits	Resol.	Unit
VB_SECU	V	0...FFH	0...26	0,102	V
Battery Voltage secured for dwell computation					

Input data:

VB			

Description:

A secured battery voltage value is a mix of VB and V_IGK values which provides a safer battery voltage for functions especially in case of VB - relay wire to the ECU disconnection.

The securate battery voltage value can be used for exemple for dwell computation in order to protect ignition coil and ECU ignition output stage against too long dwell time.

VB_SECU = MAX(VB, V_IGK - NC_VB_SECU)

with VB_SECU - NC_VB_SECU satured to zero

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_VB_SECU	1	0...FFH	0...26	0,102	V
Battery voltage offset (typical value = 1,02V)					
NC_FAC_VB_RATIO	1	0..FFH	0 ... 1,9922	0,0078125	-
Factor to adapt the HEX-range to the range of 0 to 26 V					

4.30.3 Battery voltage ranges

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_VB_JUMP	V/O	0...1H	0...1	1	-
Logical value for detected overvoltage (jump start)					
LV_CDN_VB_OBD1	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for OBD diagnosis					
LV_CDN_VB_OBD2	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for OBD-II diagnosis					
LV_CDN_VB_MIN_DIAG	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for remaining diagnosis					
LV_CDN_VB_CAN_DIAG	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for CAN diagnosis					

Input data:

VB	LV_IGK	C_VB_MIN_CAN_DIAG	

FUNCTION DESCRIPTION:

General information:

Depending on VB there is a detection:

- Jump start
- Valid range for OBD1 diagnosis
- Valid range for OBD2 diagnosis
- Valid range for CAN diagnosis
- Valid range for remaining customer diagnosis

Application conditions:

Initialisation: all 0

Recurrence: 10ms

Activation: at reset

4.30.3.1 Detection of overvoltage (Jump start)

Description:

The bit LV_VB_JUMP is used by functions which must not run when overvoltage is detected for example secondary air injection to prevent damages to the components.

Formula section:

Jump start detection:

If VB > C_VB_MIN_JUMP
Then LV_VB_JUMP = 1
Else LV_VB_JUMP = 0
Endif

4.30.3.2 Battery voltage valid for OBD diagnosis

Description:

Depending of OBD1/OBD2 there is a different flag for the valid VB range

Formula section:

Valid range for OBD1 diagnosis:

If VB > C_VB_MIN_OBD1 **and** VB < C_VB_MAX_OBD1
Then LV_CDN_VB_OBD1 = 1
Else LV_CDN_VB_OBD1 = 0
Endif

Valid range for OBD2 diagnosis:

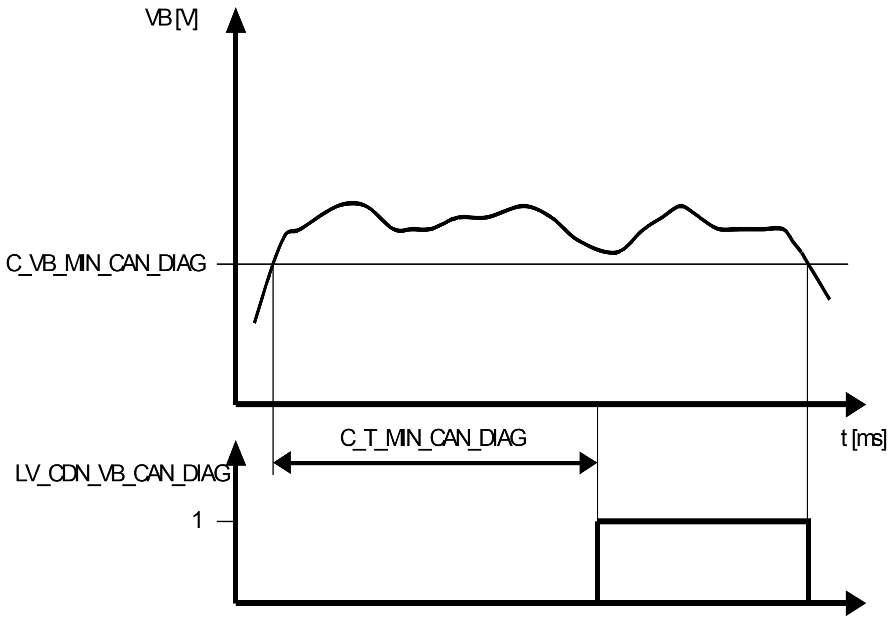
If VB > C_VB_MIN_OBD2 **and** VB < C_VB_MAX_OBD2
Then LV_CDN_VB_OBD2 = 1
Else LV_CDN_VB_OBD2 = 0
Endif

4.30.3.3 Minimum battery voltage detection for CAN diagnosis

Description:

Due to low battery voltage CAN messages can be mutilated. So CAN timeout diagnosis is only done if battery voltage is valid for a minimum duration time.

Signal flow diagram:



Formula section:

Valid range for CAN diagnosis:

If LV_IGK = 1 **and**

VB > C_VB_MIN_CAN_DIAG **for**

time > C_T_MIN_CAN_DIAG

(timer always started at every transition VB > C_VB_CAN_DIAG)

Then LV_CDN_VB_CAN_DIAG = 1

Else LV_CDN_VB_CAN_DIAG = 0

Endif

4.30.3.4 Minimum Battery Voltage Detection for non OBD Diagnosis

Description:

The remaining diagnosis functions which are not covered by the above mentioned conditions are disabled below a separate threshold, which should be lower as OBD1/2 and CAN.

Formula section:

Valid range for non OBD diagnosis:

If VB < C_VB_MIN_DIAG **or**
VB > C_VB_MAX_DIAG **or**
LV_IGK = 0
Then LV_CDN_VB_MIN_DIAG = 0
Else LV_CDN_VB_MIN_DIAG = 1
Endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VB_MIN_JUMP	1	0...FFH	0...26	0.102	V
VB -threshold for maximum permissible battery voltage					
C_VB_MIN_OBD1	1	0...FFH	0...26	0.102	V
VB –threshold for minimum permissible battery voltage for OBD diagnosis					
C_VB_MAX_OBD1	1	0...FFH	0...26	0.102	V
VB -threshold for maximum permissible battery voltage for OBD diagnosis					
C_VB_MIN_OBD2	1	0...FFH	0...26	0.102	V
VB -threshold for minimum permissible battery voltage for OBD2 diagnosis					
C_VB_MAX_OBD2	1	0...FFH	0...26	0.102	V
VB -threshold for maximum permissible battery voltage for OBD2 diagnosis					
C_VB_MIN_DIAG	1	0...FFH	0...26	0,102	V
Battery voltage threshold for low voltage detection for remaining diagnosis					
C_VB_MAX_DIAG	1	0...FFH	0...26	0,102	V
Battery voltage threshold for high voltage detection for remaining diagnosis					
C_T_MIN_CAN_DIAG	1	0...FFH	0...2550	0.01	s
VB-Time-condition for CAN diagnosis					

4.30.4 Moving average value for battery voltage

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VB_MMV	V/O	0...FFH	0...26	0.102	V
Moving mean value of battery voltage VB					

Input data:

VB			

A moving average value VB_MMV is used in the chapter “Engine speed setpoint calculation” to define a minimum N_SP_IS in dependance of the battery voltage:

Application conditions:

Activation: *at reset*

Initialization: VB_MMV = 14 V

Recurrence: 10 ms

Formula section:

$VB\_MMV_k = VB\_MMV_{k-1} + (VB_k - VB\_MMV_{k-1}) \cdot C\_CRLC\_VB.$

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CRLC_VB	1	0...FFH	0...0.996	0.0039	-
Low pass filter correlation constant for VB_MMV					

4.31 TIA_THR_UP, TIA_TMP and TAM temperatures

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TIA_TMP	V/O	0...FEH	-48...142.5	0.75	[°C]
Interface value of Air temperature used as an input for mappings					
TIA_THR_UP	V/O	0...FEH	-48...142.5	0.75	[°C]
Air interface temperature up throttle					
TAM	V/O/S	0...FEH	-48...142.5	0.75	[°C]
Ambient temperature					
TAM_ST	V/O	0...FEH	-48...142.5	0.75	[°C]
Ambient air temperature at Start					
T_TAM1	V	0...FFH	0...255	1	[s]
First timer for TAM model					
T_TAM2	V	0...FFH	0...255	1	[s]
Second timer for TAM model					
TAM_MDL	V	0...FEH	-48...142.5	0.75	[°C]
Modeled ambient temperature					
LV_TAM_VLD_DIAGCP	V/O	0...1H	0...1	1	-
Flag to indicate that TAM is valid for EVAP mon. : TAM_MDL updated at least one time since engine Start					
T_TAM_VLD_DIAGCP	V	0...FFFFH	0...65535	1	Sec.
Timer to reset LV_TAM_VLD_DIAGCP if no TAM_MDL learning take place (to ensure regular TAM_MDL update)					

Input data:

TIA[NC_SENS_NR_TIA]	LV_ERR_TAM_CAN	VS	LV_ST_END
ERR_SYM_TAM_CAN	TIA_CHRG_UP	TIA_CHRG_DOWN	NC_IDX_TIA_IM_CYL
NC_IDX_TIA_CHRG_THR	NC_TIA_CONF	NC_IDX_TIA_AM_CHRG	CONF_TAM
NC_SENS_NR_TIA	LV_ERR_ORNG_TAM	LV_ERR_PLAUS_TAM	ERR_SYM_ORNG_TAM
LV_TAM_CAN_FIRST_VLD	STATE_ENG	ERR_SYM_PLAUS_TAM	TAM_MES_MMV
ERR_SYM_EL_TAM	MAF_KGH	CONF_MAF	LV_T_ES_NOT_PLAUS
T_ES	TIA_THR		

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TAM_INI_MIN	1	0...FEH	-48...142.5	0.75	[°C]
TAM value at initialization cnnot be lower than C_TAM_INI_MIN					
C_TAM_AS	1	0...FEH	-48...142.5	0.75	[°C]
Application system calibration for TAM					
C_TAM_OFS	1	0...FEH	0...190.5	0.75	[°C]
Temperature offset between TAM_TMP and TAM					
C_T_TAM1	1	0...FFH	0...255	1	[s]
Time threshold to correct TAM					
C_T_TAM2	1	0...FFH	0...255	1	[s]
Time threshold vehicle speed conditon can be violated without reset of timer					
C_VS_TAM_MIN	1	0...FFH	0...255	1	[km/h]
Minimum vehicle speed to calculate TAM					
LC_ERR_TAM_CAN_AS	1	0...1H	0...1	1	[-]
Application system switch for TAM subsitute formula validation: default value = 0					
LC_TAM_AS	1	0...1H	0...1	1	[-]
Application system value for TAM: TAM = C_TAM_AS if LC_TAM_AS = 1					
C_MAF_KGH_TAM_MIN	O/V	0... FFFFH	0... 2047.969	0.03125	[kg/h]
Minimum air-mass flow to calculate TAM					
C_T_ES_TEMP_MIN	1	0... FFFFH	0...6.5535E+4	1	min
Minimum necessary engine shut off time duration (cold start condition reached)					

C_T_TAM_VLD_DIAGCP	1	0... FFFFH	0...65535	1	Sec
Time interval to reset LV_TAM_VLD_DIAGCP					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_TAM_CLC_BOL	-	0...FEH	-48...142.5	0.75	[°C]
Lower limit of TAM: typical value = -35°C					
NC_TAM_CLC_TOL	-	0...FEH	-48...142.5	0.75	[°C]
Upper limit of TAM: typical value = 50°C					

4.31.1 General Information [Version for : NC_CHRG_CONF <> 0 And NC_TIA_CONF = 10,11,12,13,21,22,23,24,30]

TIA_TMP:

TIA_TMP is defined as one of the TIA sensor values. In case of one TIA sensor only, then TIA_TMP equals this only sensor value. It will be used as a reference input for calibration tables.

TIA_THR_UP:

TIA_THR_UP is an interface variable. Its purpose is to link this specification to the “TIA_THR, TIA_IM, TIA_CYL calculation” specification. Indeed, TIA_THR_UP is used for TIA_THR and/or for TAM calculation.

TAM:

The ambient temperature TAM can be measured by a sensor (CONF_TAM = 2) **or** can be delivered via the CAN (CONF_TAM = 1) **or** determined from a model based on the temporary variable TAM_TMP. TAM_TMP is defined below.

Basically the algorithm of the model consists of two timers T_TAM1 and T_TAM2. Timer T_TAM1 represents the time the vehicle speed exceeds the threshold C_VS_TAM_MIN. When that conditon is fullfilled for a defined time (T_TAM1 > C_T_TAM1) a new TAM value is calculated based on TAM_TMP and a constant temperature offset C_TAM_OFS.

T_TAM2 is the timer that counts the time the vehicle speed condition is violated. It is permissible to violate the vehicle speed conditon for a certain time (T_TAM2 < C_T_TAM2) without a reset of timer T_TAM1.

The resulting TAM value is limited to a range between NC_TAM_CLC_BOL and NC_TAM_CLC_TOL.

LV_TAM_VLD_DIAGCP / T_TAM_VLD_DIAGCP:

To ensure accurate EVAP monitoring result, accurate TAM_MDL must be calculated. Flag LV_TAM_VLS_DIAGCP shall indicate that TAM_MDL was updated since engine start or within the last C_T_TAM_VLD_DIAGCP seconds. Flag LV_TAM_VLD_DIAGCP is reseted every C_T_TAM_VLD_DIAGCP seconds if no TAM_MDL take place (due to MAF_KGH condition to learn TAM_MDL, it can happen that TAM_MDL is not updated during long down-hill driving -> need to disable EVAP monitoring until next TAM_MDL update by reseting LV_TAM_VLD_DIAGCP).

TAM_ST:

Ambient temperature at start TAM_ST

Application Conditions:

Initialization: **At** Reset

- TIA_TMP:

NC_TIA_CONF	10	11, 22, 23, 30
TIA_TMP	TIA[NC_IDX_TIA_IM_CYL]	TIA[NC_IDX_TIA_AM_CHRG]

NC_TIA_CONF	13, 21	12, 24
TIA_TMP	TIA[NC_IDX_TIA_CHRG_THR]	TIA_CHRG_DOWN

- TIA_THR_UP and TAM_TMP:

TAM_TMP = TIA_THR_UP = TIA_TMP

- TAM:

If T_ES > C_T_ES_TEMP_MIN **and** LV_T_ES_NOT_PLAUS = 0
Then TAM = TIA_TMP
Else **If** there is no previously TAM value saved in the NVMY
Or the EEPROM does not work
Then TAM = 20.25°C
Else TAM = TAM saved in NVMY
Endif
TAM = Max[min(TAM; TIA_TMP), C_TAM_INI_MIN]
Endif

- TAM_ST = TAM
- TAM_MDL = TAM
- LV_TAM_VLD_DIAGCP = 0
- T_TAM_VLD_DIAGCP = 0

Recurrence: **see below**

Activation: At every Engine States

Deactivation: -

Formula section:

4.31.2 TIA_TMP definition:

Recurrence: **100 ms**

The aim of the table here below is to define the values of TIA_TMP depending on the Hardware Configuration (see NC_TIA_CONF definition in Chapter Sensor(s) Configuration).

NC_TIA_CONF	10	11, 22, 23, 30
TIA_TMP	TIA[NC_IDX_TIA_IM_CYL]	TIA[NC_IDX_TIA_AM_CHRG]

NC_TIA_CONF	13, 21	12, 24
TIA_TMP	TIA[NC_IDX_TIA_CHRG_THR]	TIA_CHRG_DOWN

eg: for NC_TIA_CONF = 23: TIA_TMP = TIA[NC_IDX_TIA_AM_CHRG]

4.31.3 TIA_THR_UP definition:

Recurrence: **100 ms**

In the same way, the table here below defines the value of TIA_THR_UP, depending on the configuration of the load sensor – either for MAF (CONF_MAF = 1) or MAP sensor (CONF_MAF = 0).

	CONF_MAF = 1	CONF_MAF = 0
TIA_THR_UP	TIA_TMP	TIA_THR

eg: for NC_TIA_CONF = 23: TIA_THR_UP = TIA_CHRG_DOWN

(note: TIA_THR_UP is not defined for NC_TIA_CONF = 10 as it is not used.)

4.31.4 TAM_TMP definition:

Recurrence: **1 s**

	CONF_TAM <> 0 **And** LV_ERR_TAM = 0 **And** LC_ERR_TAM_CAN_AS = 0	CONF_TAM = 0 **Or** LV_ERR_TAM = 1 **OR** LC_ERR_TAM_CAN_AS = 1	
NC_TIA_CONF	**-**	**10,** 12, 13, 21, 24	11, 22, 23, 30
TAM_TMP	(Not Calculated)	**TIA_CHRG_UP**	TIA[NC_IDX_TIA_AM_CHRG]

4.31.5 TAM_MDL,LV_TAM_VLD_DIAGCP and T_TAM_VLD_DIAGCP calculation:

Recurrence: **1 s**

```

4.31.6 TAM calculation:

Recurrence: **1 s**

- There are 3 possibilities to calculate TAM: from the CAN, from an analog sensor value or from a model (then use of TAM sustitute formula)
- It is also possible to fix TAM by the mean of an application system calibration (if LC_TAM_AS=1).
- LC_ERR_TAM_CAN_AS can be set to 1 to easier software validation (otherwise, it must always be set to 0).

If LC_TAM_AS = 0

Then

If CONF_TAM = 0 *(no TAM sensor available or learnt)*

Or LV_ERR_TAM = 1

Or LC_ERR_TAM_CAN_AS = 1

Then TAM = TAM_MDL

Else

If ERR_SYM_ORGN_TAM <> 0

Or ERR_SYM_EL_TAM <> 0

Or ERR_SYM_TAM_CAN <> 0

Or ERR_SYM_PLAUS_TAM <> 0

Or (CONF_TAM = 1 **And** LV_TAM_CAN_FIRST_VLD = 0)

Then $TAM_{(n)} = TAM_{(n-1)}$

Else TAM = TAM_MES_MMV

Endif

Endif

Else TAM = C_TAM_AS

Endif

4.31.7 TAM_ST:

If STATE_ENG = "ES"
Then TAM_ST = TAM
Endif *(TAM_ST value remains unchaged out of ES)*

LV_ERR_TIA_IM	LV_ES	NC_NR_TCO_SENS	T_ES

Import actions:

ACTION_INFR_GetVpTco (OUT <>)

FUNCTION DESCRIPTION:

General information:

The coolant temperature raw sensor voltage is measured with use of an A/D converter by the ECU hardware. The software then is generating a modified sensor signal (VP_TCO[0]), which is requested by the application software for further execution.

The modified sensor signal (VP_TCO[0]) is converted into a measured temperature value (TCO_MES) with use of a one-dimension interpolation table (IP_TCO_MES).

Application conditions:

See separate chapters:

4.33.1 Coolant temperature gradient monitoring

FUNCTION DESCRIPTION:

General information:

The measured coolant temperature (TCO_MES) is monitored for not plausible gradients. It is checked if the temperature difference between the old and the new measured coolant temperature (TCO_MES) exceeds the permissible gradient C_TCO_MES_GRD_MAX. In this case the old measured value remains unchanged. If the temperature difference between the measured coolant temperature values is exceeding the permissible gradient again during the next measurement, the new measured value is transferred into the working memory. A measured value can be inhibited only if the gradient exceeded for one time (recurrence).

The monitoring of the coolant temperature gradient does not lead to failure entries. The only purpose is to extract implausible measured values (noise).

Application conditions:

Initialisation at Reset:

FOR k = 0 to NC_NR_TCO_SENS -1
    ACTION_INFR_GetVpTco(VP_TCO[k])
END FOR

// all sensor values are imported and provided as output

$TCO\_MES_{(n)} = TCO\_MES_{(n-1)}$ = IP_TCO_MES

// acquisition of the main coolant temperature measurement signal

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

// all sensor values are imported and provided as output

FOR k = 0 to NC_NR_TCO_SENS - 1

ACTION_INFR_GetVpTco(VP_TCO[k])

END FOR

// VP_TCO[0] is used as input signal for the interpolation table IP_TCO_MES

TCO_MES = IP_TCO_MES

// acquisition of the main coolant temperature measurement signal

If $| TCO\_MES_{(n-1)} - TCO\_MES_{(n)} |$ > C_TCO_MES_GRD_MAX

then $TCO\_MES_{(n)} = TCO\_MES_{(n-1)}$ (only one time!)

else $TCO\_MES_{(n)} = TCO\_MES_{(n)}$

endif

4.33.2 Coolant temperature acquisition

FUNCTION DESCRIPTION:

General information:

The actualisation of the coolant temperature value (TCO) is only executed, if no coolant temperature error / preliminary error is detected. In case of a detected error, the TCO value will be set to the calculated coolant temperature substitute value (TCO_SUB).

The initialisation of the coolant temperature value (TCO) is only performed once per engine run as long as the engine operating state “Engine stop” is active. If the engine stalls and in this case the engine operating state is changing to “Engine stop” again, a new initialization of the coolant temperature will not be done. Power latch must always be finished before a new initialization process is performed as long as no ECU reset occurs. An ECU reset is handled like the beginning of a new engine run and an initialization of the TCO value is also done in this case for at least one recurrence.

Application conditions:

Initialisation at Reset:

LV_CDN_INI_TCO = 1

TCO = TCO_MES

Initialisation at Engine stop to Engine run (ES_to_ERU):

LV_CDN_INI_TCO = 0

Activation: at every engine operating state

Deactivation: -

LV_PU	TCO	TCO_ST	LV_ERR_TCO
TAM	MAF_KGH	TIA_ST	T_AST
LV_ERR_TCO_STUCK_RNG	IP_TCO_INI_TIA_IM	TIA_IM	

FUNCTION DESCRIPTION:

General information:

The coolant temperature substitute model (TCO_SUB) is initialized with the coolant temperature at engine start (TCO_ST) and an offset value (IP_TCO_SUB_INI_OFS) as soon as the system event “Engine stop” to “Engine run” is detected. The substitute model increment values are dependent on the actual engine performance (equivalent to mass air flow MAF_KGH). To take the smaller incrementation values at higher coolant temperatures into consideration, the increment values are weighted. TCO_SUB calculation shall be divided into two modes (fast/slow) depending on coolant temperature and intake air temperature.

During “Idle speed” and “Pull fuel cutoff” phases the calculation of the coolant temperature substitute value remains activated.

A delay time after engine start to activate the incrementation of the temperature substitute value is incremented, to simulate the warm up of the real coolant temperature very efficient.

In case of a coolant temperature acquisition failure (LV_ERR_TCO = 1), the coolant temperature substitute value is reinitialized with the latest valid coolant temperature value. In this case the model incrementation starts from the initialization value on.

Application conditions:

Initialisation at Engine stop to Engine run (ES_to_ERU):

T_DLY_TCO_SUB_ST = 0

T_DLY_TCO_SUB = 0

$TCO\_SUB_{(n)} = TCO\_SUB_{(n-1)}$ = TCO_ST + IP_TCO_SUB_INI_OFS

LV_CDN_ENA_TCO_SUB = 1

Initialisation at Exit start (EXIT_ST):

If TIA_ST > C_TCO_ST_MIN_TCO_SUB

And abs(TCO_ST - TIA_ST) < C_DIF_TCO_TIA_ST_MIN_TCO_SUB

Then LV_TCO_SUB_INC_FAST = 1

Else LV_TCO_SUB_INC_FAST = 0

Initialisation at Engine run to Engine stop (ERU_to_ES):

LV_CDN_ENA_TCO_SUB = 0

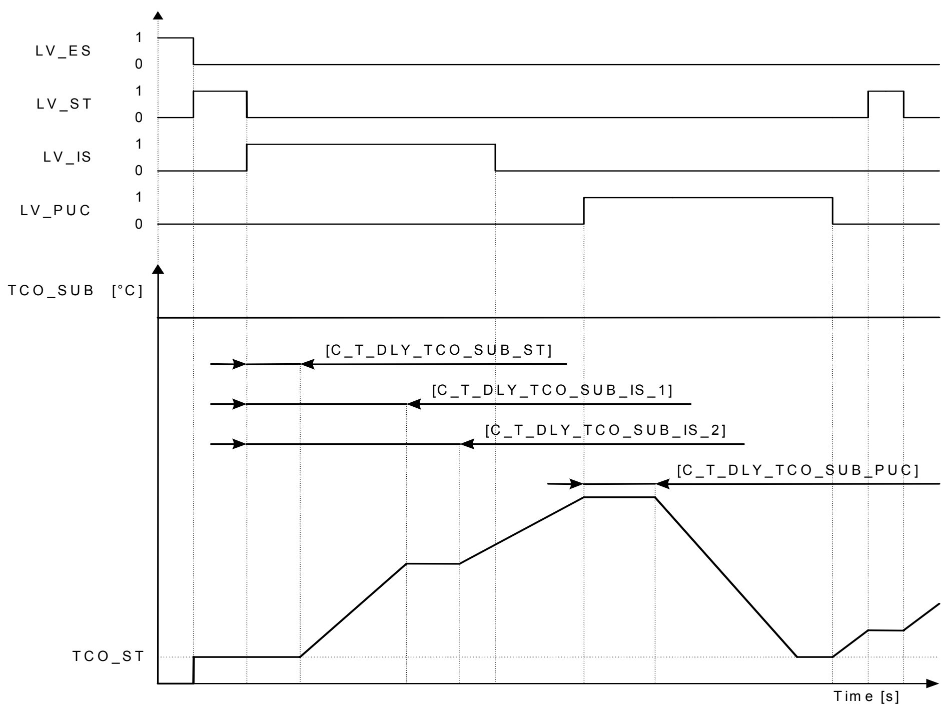
Recurrence: 1000 ms

(100ms for TCO sub re-initialisastion at TCO error detection)

Activation: LV_CDN_ENA_TCO_SUB = 1

Deactivation: LV_CDN_ENA_TCO_SUB = 0

Signal flow diagram:



Formula section:

Calculation of the substitute model increment value during “Engine start”:

If LV_ST = 1

then TCO_SUB_INC = 0

Switching of LV_TCO_SUB_INC_FAST:

If LV_TCO_SUB_INC_FAST = 1 // Fast TCO_SUB increment

Then **If** TCO_SUB > C_MAX_TCO_SUB_FAST_INC

Then LV_TCO_SUB_INC_FAST = 0 // Slow TCO_SUB increment

∗ Remark: LV_TCO_SUB_INC_FAST may not be switched from "FAST" to "SLOW" by setting of C_MAX_TCO_SUB_FAST_INC to be maximum value.

Determination of temporary model inc./dec. value and factor according to starting condition:

If LV_TCO_SUB_INC_FAST = 1

Then TCO_SUB_INC_TMP = IP_TCO_SUB_INC_FAST (MAF_KGH)

FAC_TCO_SUB_INC_TMP = IP_FAC_TCO_SUB_INC_FAST (MAF_KGH ,TCO_SUB)

TCO_SUB_DEC_TMP = IP_TCO_SUB_DEC_FAST (MAF_KGH)

Else TCO_SUB_INC_TMP = IP_TCO_SUB_INC_SLOW (MAF_KGH)

FAC_TCO_SUB_INC_TMP = IP_FAC_TCO_SUB_INC_SLOW (MAF_KGH,TCO_SUB)

TCO_SUB_DEC_TMP = IP_TCO_SUB_DEC_SLOW (MAF_KGH)

Calculation of the substitute model increment value during “PL” or “PU”:

If LV_PL = 1 **or** LV_PU = 1

then TCO_SUB_INC = TCO_SUB_INC_TMP

* FAC_TCO_SUB_INC_TMP

* FAC_TCO_SUB_COR

Calculation of the substitute model increment value during “PUC”:

If Transition: LV_PUC = 0 -> LV_PUC = 1

then T_DLY_TCO_SUB = 0

if LV_PUC = 1

then **if** T_DLY_TCO_SUB < C_T_DLY_TCO_SUB_PUC

then TCO_SUB_INC = 0

else TCO_SUB_INC = -**(** TCO_SUB_DEC_TMP **)**

***** FAC_TCO_SUB_INC_TMP

T_DLY_TCO_SUB = T_DLY_TCO_SUB + 1 s

Calculation of the substitute model increment value during "Idle speed":

```
If      Transition:    LV_IS = 0 -> LV_IS = 1
then    T_DLY_TCO_SUB = 0
if      LV_IS = 1
then    if      T_DLY_TCO_SUB < C_T_DLY_TCO_SUB_IS_1
          or    T_DLY_TCO_SUB > C_T_DLY_TCO_SUB_IS_2
        then    TCO_SUB_INC  =    TCO_SUB_INC_TMP
                                  * FAC_TCO_SUB_INC_TMP
                                  * FAC_TCO_SUB_COR
        else    TCO_SUB_INC  = 0
        T_DLY_TCO_SUB = T_DLY_TCO_SUB + 1 s
```

Calculation of the coolant temperature substitute model value:

```
If      LV_ERR_TCO = 0
then    FAC_TCO_SUB_COR = 1
else    FAC_TCO_SUB_COR = C_FAC_TCO_SUB_COR
endif

If      T_DLY_TCO_SUB_ST < C_T_DLY_TCO_SUB_ST
then    if      Transition: LV_ERR_TCO_STUCK_RNG  = 0 --> 1
        then  TCO_SUB = IP_TCO_INI_TIA_IM
        else   TCO_SUB(n) = TCO_SUB(n-1)
                T_DLY_TCO_SUB_ST = T_DLY_TCO_SUB_ST + 1 s
        endif
else    if      Transition: LV_ERR_TCO = 0 --> 1
        then  TCO_SUB(n) = TCO(n-1) (re-initialization of TCO_SUB with last plausible TCO value)
                (This is done as 100msec task)
        endif
        TCO_SUB(n) = TCO_SUB(n-1) + TCO_SUB_INC

endif
```

4.36.1 Definition of TIA

FUNCTION DESCRIPTION:

General information:

Basically the HMC Theta projects uses the TIA sensor located in the manifold pressure sensor (named “TIA_IM_CYL”). However it is possible, for vehicle types equipped with a mass air flow sensor (MAF), to switch to a TIA sensor position located at the MAF (upstream the throttle body). By CONF_MAF the system switches between MAF position (CONF_MAF = 1) and MAP position (CONF_MAF = 0).

Application conditions:

Initialisation: at reset or transition LV_IGK = 0 → 1

TIA = TIA_TMP

Recurrence: 100 ms (note: TIA_IM is calculated every 100 ms)

Activation: every engine state

Deactivation:

Formula section:

If CONF_MAF = 0 *(system with MAP sensor - TIA sensor located at MAP sensor)*

Then TIA = TIA_IM

Elseif CONF_MAF = 1 *(system with MAF sensor - TIA sensor located at MAF sensor)*

Then TIA = TIA_THR

4.36.2 Definition of TIA_ST

FUNCTION DESCRIPTION:

General information:

AIRT produces TIA_TMP as reference for intake air temperature from sensor. Also TIA_ST will be defined equal to TIA_TMP.

Application conditions:

Initialisation: at reset and LV_IGK = 0→1

TIA_ST = TIA_TMP

Recurrence: 100 ms (note: TIA_TMP is calculated every 100 ms)

Activation: every engine state

Deactivation:

Formula section:

TIA_ST = TIA_TMPevery 100 ms as long as LV_ES = 1.

4.36.3 Definition of LV_ERR_TIA

FUNCTION DESCRIPTION:

General information:

LV_ERR_TIA is defined as the currently general error in HMC Theta project. LV_ERR_TIA will be defined equal to LV_ERR_TIA_IM (for systems equipped with a MAP sensor – combined TMAP sensor, located in the intake manifold) or equal to LV_ERR_TIA_THR (for systems equipped with a MAF sensor – temperature value coming from MAF sensor, located upstream the throttle).

Application conditions:

Initialisation:

Recurrence: 100 ms

(note: LV_ERR_TIA_IM is calculated every 100 ms)

Activation: *every engine state*

Deactivation:

Formula section:

If CONF_MAF = 0 *(system with MAP sensor - TIA sensor located in the intake manifold)*

Then LV_ERR_TIA = LV_ERR_TIA_IM

Elseif CONF_MAF = 1 *(system with MAF sensor - TIA sensor located upstream the throttle)*

Then LV_ERR_TIA = LV_ERR_TIA_THR

4.36.4 Definition of LV_END_DIAG_TIA

FUNCTION DESCRIPTION:

General information:

LV_END_DIAG_TIA is defined equal to LV_END_DIAG_EL_TIA[NC_IDX_TIA_IM_CYL].

Application conditions:

Initialisation:

Recurrence: 1000 ms

(note: LV_END_DIAG_EL_TIA[NC_IDX_TIA_IM_CYL] is calculated every 100 ms)

Activation: every engine state

Deactivation:

Formula section:

LV_END_DIAG_TIA = LV_END_DIAG_EL_TIA[NC_IDX_TIA_IM_CYL]

4.36.5 Calculation of TAM_MES and TAM_MES_MMV

FUNCTION DESCRIPTION:

General information:

For turbocharged (TCI) version the ambient temperature (TAM) is measured by an analog temperature sensor or is available via CAN message.

Application conditions:

Initialisation: at reset TAM_MES = TAM_MES_MMV = TAM
(Important: TAM has to be initialised previously!)

Recurrence: 100 ms

Activation: *every engine state*

Formula section:

If CONF_TAM = 0 *(no TAM sensor available or learned)*

Then TAM_MES = -48°C

Elseif CONF_TAM = 1 *(TAM value via CAN)*

Then TAM_MES = TAM_CAN

Else *(CONF_TAM = 2 TAM value via analog sensor)*

TAM_MES = IP_TAM_MES (VP_TAM)

End

If $TAM\_MES_{(n)} <= TAM\_MES\_MMV_{(n-1)}$

Then TAM_MES_MMV = TAM_MES

Else

$$TAM\_MES\_MMV_{(n)} = TAM\_MES\_MMV_{(n-1)} + (TAM\_MES - TAM\_MES\_MMV_{(n-1)}) * IP\_CRLC\_TAM\_MES(VS, MAF\_CYL)$$

Endif

4.37 Calculation of the basic reduced area

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
AR_RED_BAS	O/V	0...FFFFH	0...58.592855	8.9407E-4	cm²
Basic reduced opening area					

Input data:

FAC_AR_RED_MAF	TPS_SEG	LV_AT	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_AR_RED_THR_AT	16	0...FFFFH	0...58.592855	8.9407E-4	cm²
LDPM_TPS_SEG_IP_AR_RED_THR	16	0...3FFFH	0...119.5	0.00729415	°TPS
Reduced Area at the throttle for A/T					
IP_AR_RED_THR_MT	16	0...FFFFH	0...58.592855	8.9407E-4	cm²
LDPM_TPS_SEG_IP_AR_RED_THR	16	0...3FFFH	0...119.5	0.00729415	°TPS
Reduced Area at the throttle for M/T					

In this the effective opening area for the air – mass flow into the take manifold is calculated. The reduced opening area of the throttle depend on its actual opening angle (segment synchronous TPS_SEG)

Application Condition

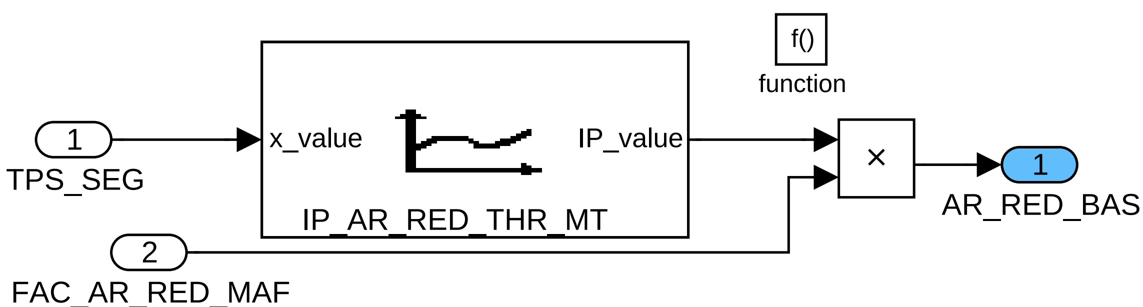

Figure 339 INSY_MDLADARRED0/ Calc_AR_RED/ CALC_AR_RED_MT

4.38 AIRT Air Temperature Sensor(s) Configuration:

4.38.1 General:

The configuration of the hardware definition is done with the Non-Calibratable constants NC_TIA_CONF which is here also used as Compiler Switch.

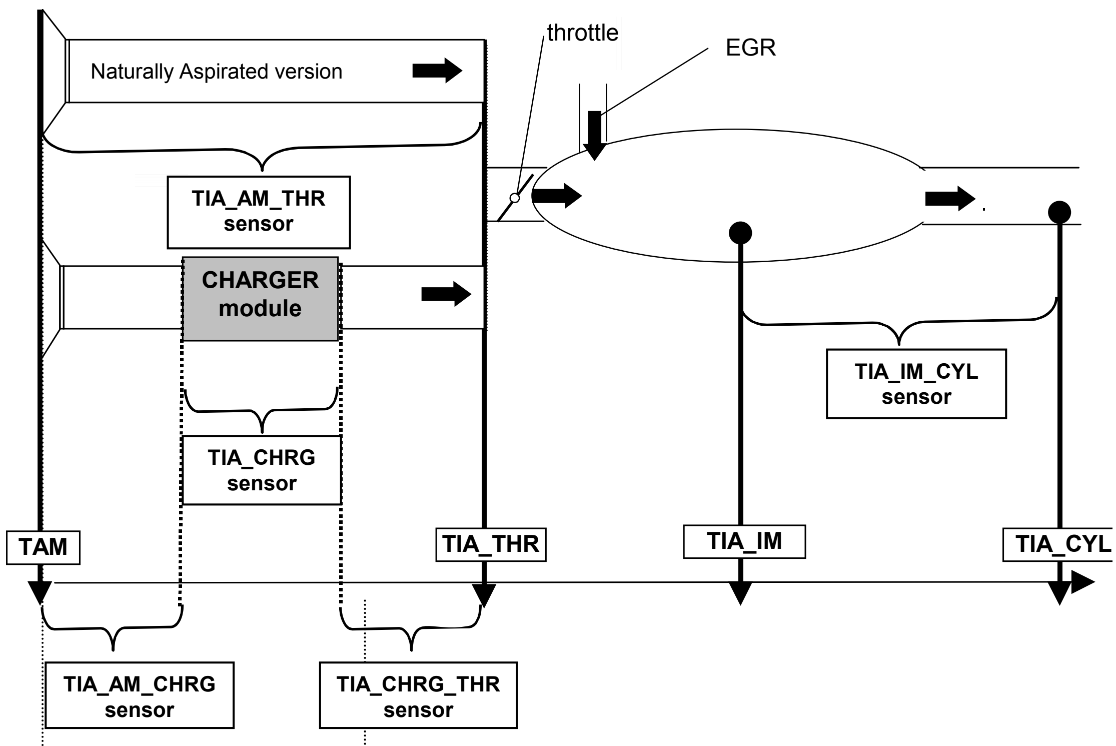
Hypothesis: At least one TIA system sensor is used in the complete intake system (ie: AIRT + CHRG Aggregates).

4.38.2 Air Temperature Sensor Configuration Variables:

FUNCTION DESCRIPTION:

General information:

Definition of the possible positions for the TIA sensor(s):
The drawing above describes the 5 **possible** positions inside the Intake System for the TIA sensors:



- *Whatever version (CHRG or No CHRG):*

TIA_IM_CYL sensor is located:
. After the Throttle in case of no EGR version
. After the EGR Inlet in case of EGR version

- *In case of No CHRG version **only**:*

TIA_AM_THR sensor is located before the Throttle (ie: located in the Intake System only; TIA_AM_THR cannot be an Ambiant temperature sensor)

- *In case of CHRG version **only**:*

_ TIA_AM_CHRG sensor is located in the intake system before the Charger Module **or** can be an Ambiant Temperature sensor.
_ TIA_CHRG_THR sensor is located between the Charger Module and the Throttle

remark: TIA_CHRG sensor, located inside the CHRG Module, is defined in the CHRG Aggregate.

Application conditions:

Activation: at all Engine States

Deactivation: -

Initialization: **at** Reset / initialized with the values of the table below

Recurrence: **no** (the outputs are just calculated once)

Formula section:

4.38.2.1 NC_TIA_CONF definition:

Depending on the number of TIA sensors and of their location(s), NC_TIA_CONF has to be set with the value given in the Table below.

NC_TIA_CONF defines the TIA sensor(s) Intake System hardware

Engine version	Possible Sensors	1					2					3
Naturally aspirated only	TIA_AM_THR sensor	-	-	-	-	Av.	Av.	-	-	-	-	-
Charged only	TIA_AM_CHRG sensor	-	Av.	-	-	-	-	-	Av.	Av.	-	Av.
Charged only	TIA_CHRG_THR sensor	-	-	-	Av.	-	-	Av.	Av.	-	-	Av.
Naturally asp. or Charged	TIA_IM_CYL sensor	Av.	-	-	-	-	Av.	Av.	-	Av.	Av.	Av.
Charged only	*TIA_CHRG sensor*	-	-	Av.	-	-	-	-	-	-	Av.	-
	NC_TIA_CONF	**10**	**11**	**12**	**13**	**14**	**20**	**21**	**22**	**23**	**24**	**30**
	NC_SENS_NR_TIA	**1**	**1**	**0 (*)**	**1**	**1**	**2**	**2**	**2**	**2**	**1 (*)**	**3**
	NC_IDX_TIA_AM_THR	0	0	0	0	**1**	**1**	0	0	0	0	0
	NC_IDX_TIA_AM_CHRG	0	**1**	0	0	0	0	0	**1**	**1**	0	**1**
	NC_IDX_TIA_CHRG_THR	0	0	0	**1**	0	0	**1**	**2**	0	0	**2**
	NC_IDX_TIA_IM_CYL	**1**	0	0	0	0	**2**	**2**	0	**2**	**1**	**3**

eg: if the 2 sensors TIA_AM_THR and TIA_IM_CYL are available (notation “Av.” In the Table for “Available”) then NC_TIA_CONF has to be set to = 20

Remark1:
the first digit of NC_TIA_CONF fixes the number of sensor ie:
. definition with **1** sensor for **1**0 ≤ NC_TIA_CONF ≤ **1**4
. definition with **2** sensor for **2**0 ≤ NC_TIA_CONF ≤ **2**4
. definition with **3** sensor for NC_TIA_CONF = **3**0
Remark2:
NC_TIA_CONF is the only value which has to be set by the Application Engineer.

4.38.2.2 NC_SENS_NR_TIA Definition:

See same Table above.

From NC_TIA_CONF is automatically defined the number of sensors used **for the AIRT. The eventual sensor from the Charger Module is excluded (*).**

eg: . for NC_TIA_CONF = 20 then NC_SENS_NR_TIA = 2
. for NC_TIA_CONF = 24 then NC_SENS_NR_TIA = 1

4.38.2.3 NC_IDX_TIA_[AM_THR ,IM_CYL, AM_CHRG, CHRG_THR] definitions:

Explanation with an example with the variable TIA_MES and for NC_TIA_CONF = 20:

_ On the Application Tool:

The value of TIA_MES:

- for the sensor TIA_AM_THR will be displayed as: TIA_MES[NC_IDX_TIA_AM_THR]
- for the sensor TIA_IM_CYL will be displayed as: TIA_MES[NC_IDX_TIA_IM_CYL]

_ For software coding:

It is necessary to define the correspondance between the Index (NC_IDX) and the physical position of the sensor (function of NC_TIA_CONF). A value from 0 to 3 is allocated to each index (See same Table above).

- NC_IDX_TIA_AM_THR = 1
- NC_IDX_TIA_IM_CYL = 2

which means:

- TIA_MES[1] corresponds to the temperature value from the sensor TIA_AM_THR
- TIA_MES[2] corresponds to the temperature value from the sensor TIA_IM_CYL

in the same way for every variable “VARIABLE”:

- VARIABLE[1] is relative to sensor TIA_AM_THR
- VARIABLE[2] is relative to sensor TIA_IM_CYL

Remark: When a sensor is not available then the corresponding index value is set to 0.
Eg: for NC_TIA_CONF = 20 then NC_IDX_TIA_AM_CHRG = 0

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_TIA_CONF	1	0...28H	0...40	1	[-]
TIA sensor(s) intake system hardware definition (compile switch)					
NC_SENS_NR_TIA	1	0...3H	0...3	1	[-]
Number of TIA sensors for AIRT Aggregate only (ie: excluding CHRG Aggregate)					
NC_IDX_TIA_AM_THR	1	0...3H	0...3	1	[-]
Index value corresponding to TIA_AM_THR temperature					
NC_IDX_TIA_AM_CHRG	1	0...3H	0...3	1	[-]
Index value corresponding to TIA_AM_CHRG temperature					
NC_IDX_TIA_CHRG_THR	1	0...3H	0...3	1	[-]
Index value corresponding to TIA_CHRG_THR temperature					
NC_IDX_TIA_IM_CYL	1	0...3H	0...3	1	[-]
Index value corresponding to TIA_IM_CYL temperature					

Important:

- NC_TIA_CONF has to be set by the Project

- NC_SENS_NR_TIA, NC_IDX_TIA_[AM_THR, AM_CHRG, CHRG_THR, IM_CYL] values are automatically configurated from NC_TIA_CONF (ie: no manual intervention from the Project is needed).

4.38.3 TAM via CAN Configuration: NC_TAM_CAN_USE

FUNCTION DESCRIPTION:

General information:

If NC_TAM_CAN_USE is set to 1 then the value delivered via the TAM_CAN Line is assigned to TAM. In case of an error on the CAN Line a model is used.
Else (ie: NC_TAM_CAN_USE = 0) then TAM will be calculated from a model based on a TIA sensor value.

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_TAM_CAN_USE	1	0...1H	0...1	1	[-]
TAM is computed from to the value delivered by the TAM_CAN Line: 1 = Yes / 0 = No					

4.39 TIA_THR, TIA_IM and TIA_CYL

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TIA_CYL	O/V	0...FEH	-48...142.5	0.75	°C

4.39.1 General :

Version for NC_EGR_CONF = 0 and for systems with different TIA sensor locations

Objective is to estimate the air temperature at the throttle (TIA_THR), in the manifold (TIA_IM) and before the inlet valve (TIA_CYL) taking into account the different hardware configuration – depending on the load sensor (in case of MAP sensor it is located in the intake manifold, in case of MAF sensor the location is upstream the throttle).

Model is based on the following hypothesis:

The flow from the Canister Purge is neglected: also, MAF_THR will be used (and not MAF_CYL).

To estimate the air temperature, we use the following law :

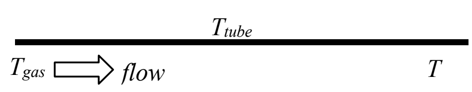
The Reynolds law:

It describes the heat transfers of a gas flowing into a tube. For gases at moderate temperature, the change of temperature between the final gas temperature and the initial one follows the law:

$$T - T_{gas} = \frac{K(L,D)\left[T_{tube} - T_{gas}\right]}{flow^{0.2}}$$

Where: K depends on the length of the tube (L) and its diameter (D).

flow is the mass flow of gas.



It is very difficult to define properly the temperature of the tube for all the configurations but we can approach this law using two mappings. One is depending on MAF_THR and N_32, the second one on TIA_TMP and TCO.

Air flow transients management:

The temperature dynamic is lower than the flow one (MAF_THR). To take into account the geometry differences (L and D) between the different sections, we will apply differents filtering factors (C_CRLC_TIA_THR, C_CRLC_TIA_IM and C_CRLC_TIA_CYL) on the temperatures values.

Three other temperature variables („temporary" variables) are created to avoid too many redundancies in the specification

. TIA_THR_TMP: used to calculate TIA_THR

. TIA_IM_TMP: used to calculate TIA_IM

. TIA_CYL_TMP: used to calculate TIA_CYL

Model for temperature calculation will differ depending on:

_ how many TIA sensors are used

_ their respective location(s) on the intake system – depending on load sensor configuration, it differs between positioning upstream the throttle (in case of MAF sensor) and in the intake manifold (in case of MAP sensor),

Definition of TIA_IM calculation point position:

4.41.1 General

NC_SENS_NR_TIA has been defined depending on the TIA hardware definition (NC_TIA_CONF value).

The **Air temperature Variables** have to be determined for the NC_SENS_NR_TIA sensor(s) (See “Loop For m = 1 to NC_SENS_NR_TIA” below).

FUNCTION DESCRIPTION:

General information:

Version valid for : NC_CHRG_CONF <> 0
And (NC_TIA_CONF = 10,13 And NC_TAM_CAN_USE = 1
Or NC_TIA_CONF = 22,23)

Two basic informations are needed from AIRT Aggregate to compute the charger intake air temperatures models:
_ an intake air temperature information at the throttle (or downstream the throttle) and
_ an ambient air temperature information (TAM_CAN **or/and** the information from the sensor situated closed to the air filter case – called "TIA_AM_CHRG" in AIRT)
remark: configurations set with NC_TIA_CONF = 12, 24 (TIA sensor "TIA_CHRG" inside the CHRG Aggregate) are not covered as no TIA diagnosis is available inside CHRG Aggregate currently.

The aim of this module is to define:
_ the relative value (ie: °C) of the temperatures:
. downstream the air cleaner casing
. upstream / downstream the charger
. upstream / downstream the recirculation actuator
and the relevant substitute values in case of unvalid TAM value
_ the absolute value (ie: Kelvin) of the temperature upstream charger
_ finally, the temperature interfaces with AIRT Aggregate.

4.42.1 Intake air temperatures in CHRG:

Description:

Application conditions:

Initialisation: At ECU Reset

TEMP_COLD, TEMP_HOT, FAC_TIA_COR_TEMP: using formula section

// In case of TAM failure, TAM substitute value (model value calculated in AIRT Agg.) can be underestimated in case of the vehicle is not started for a long period of time. This leads to a underestimation of TIA_ABSV_CHA_UP and of the charger speed N_CHA. Also, in case of TAM failure, TIA_ABSV_CHA_UP is approached by TIA_THR (as TIA is always higher than TAM). In this way, we insure that the charger is always adequately protected from overspeed.

4.42.2 Intake air temperature interfaces between CHRG and AIRT:

Description:

Application conditions:

Initialisation: **At** Reset

TIA_CHRG_UP = TIA_CHRG_DOWN = TIA_THR

Recurrence: **100 ms**

Activation: for all Engine States

Deactivation: -

Formula section:

Remark: Every calculation input must be in [°C]

TIA_CHRG_UP:

#If NC_TIA_CONF = **10** Or **13**
#Then **If** LC_TCHA_CONF = 0
Or (LC_TCHA_CONF =1 **And** LC_TIA_CHRG_UP_CLC = 0)
Then TIA_CHRG_UP = TIA_THR
Else TIA_CHRG_UP = TAM_CHA_SUB
Endif
#Endif *(TIA_CHRG_UP not needed for AIRT: TIA_CHRG_UP keeps init value)*

TIA_CHRG_DOWN :

(TIA_CHRG_DOWN not needed for AIRT: TIA_CHRG_UP keeps init value)

4.43.1 FUNCTION PART: CHRG_SIGCVNTCHA0

Function Description

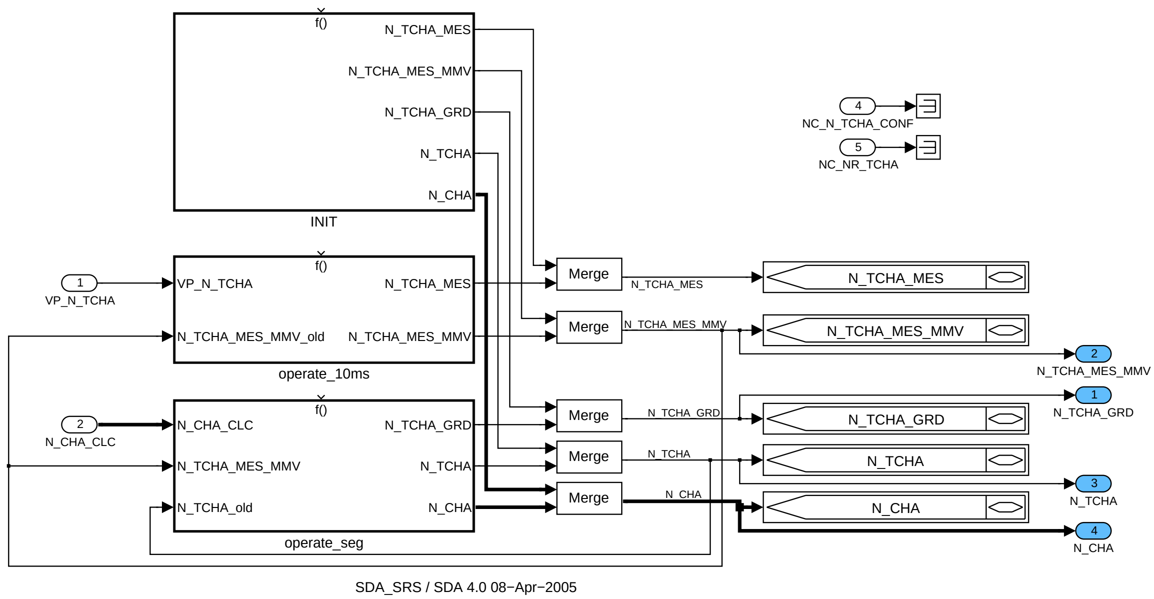

Figure 353 CHRG_SIGCVNTCHA0

4.43.1.1 SUBFUNCTION: INIT

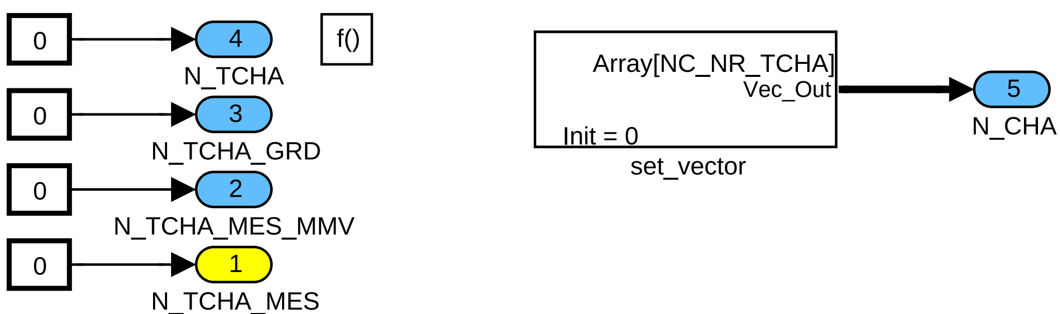

Figure 354 CHRG_SIGCVNTCHA0/ INIT

4.43.1.2 CHRG_SIGCVNTCHA0/OPERATE_10MS

Turbo Charger Rotational Speed (measured value)

This function calculates the measured turbo charger speed.

The module Turbo charger rational speed used the voltage of a turbo charger rational speed sensor. To avoid usage of signal noise and in case of short signal interruption the last value is used. To know if the last value is valid or not valid, the algorithm calculates the present step of the turbo charger sensor signal and compares it with the possible positve or negative deviations. Due to the fact of oscillations, for the value N_TCHA_MES_MMV a moving mean value calculation is used.

4.43.1.3 CHRG_SIGCVNTCHA0/OPERATE_SEG

Turbo charger rotational speed – interface values

N_TCHA is the interface, which should be used by other modules. Via LC_N_CHA_CLC_ACT is selected, whether the model based charger speed N_CHA_CLC or the measured and filtered turbocharger speed N_TCHA_MES_MMV is used. Afterwards the gradient of the turbo charger speed over the segment time is calculated

4.44.1 CHRG_MDLADMAFRC0

General information:

The objective is to determine the air mass flow through the Recirculation actuator.

The air mass flow is function of the pressure upstream the recirculation actuator and this pressure is defined according the position of the recirculation actuator (see NC_RCL_UP_ICO value).

A digital actuator, depending on its design, can show a true digital or a pseudo-continuous behaviour. Both possibilities are taken into account.

4.45.1 CHRG_MDLADPRCAC0

Description:

PRS_EPC_RCL_UP_ACT consists of modeling the pressure variation due to:

- leakage in the complete vacuum system (vacuum reservoir, connecting hoses and vacuum valve). PRS_EPC_RCL_UP_ACT will increase [or decrease] slowly depending on the pressure difference between the Manifold and PRS_EPC_RCL_UP_ACT.

- EPC activation: each activation of the RCL valve leads to vacuum consumption (independently of the effective opening of the RCL valve).

The Electro pneumatic converter (EPC) is connected to three pressures:

- the outlet pressure downstream EPC:

EPC: PRS_EPC_RCL_DOWN

- the 2 inlet pressures upstream EPC:

PRS_EPC_RCL_UP_PAS and PRS_EPC_RCL_UP_ACT defined as follows:

. PRS_EPC_RCL_DOWN equal PRS_EPC_RCL_UP_PAS when EPC is passive,

. PRS_EPC_RCL_DOWN equal PRS_EPC_RCL_UP_ACT when EPC is active.

Hardware configuration:

. PRS_EPC_RCL_UP_PAS is configurable: it can be connected to the ambiance (AMP) or to the pressure upstream the throttle (PRS_CHRG_DOWN) or to the pressure downstream the charger (PRS_CHA_DOWN) or to manifold pressure (MAP).

. PRS_EPC_RCL_UP_ACT must be connected to Manifold (Vacuum) (MAP)

The RCL valve can be activated by the mean of vacuum pressure (PRS_EPC_RCL_DOWN). When the EPC is passive (no activated) ambient pressure or overpressure (according to hardware definition) is applied on the RCL valve: The RCL valve remains closed. When the EPC is activated the vacuum pressure is applied on the RCL valve. The source of vacuum is the pressure from the Intake Manifold. If this vacuum pressure decreases sufficiently (example: in Idle state) the Vacuum Valve opens and the vacuum pressure spreads in the Vacuum reservoir. The Vacuum valve closes as soon as the pressure increases in the Manifold. In this way, the Vacuum pressure is stored in the Vacuum Reservoir and the valve can be activated even if the pressure in the Manifold increased in the mean time.

4.46.1 CHRG_MDLADICO0

The pressure loss in the intercooler is defined as a function of:

_ the flow passing through the Intercooler (MAF_ICO) (1^{st} order)

_ ambiant air temperature (TAM) (2nd order)

The cooling fluid temperature reference can be fixed by the mean of the switch LC_TEMP_ICO_COOL.

Square root of exhaust gas temperature upstream turbine in Kelvin					

4.47.1 General information

The function is calculated if LC_TCHA_CONF and LV_IGK are both equal one.

The exhaust gas temperature is filtered and its square root is calculated. The filter works only for decreasing exhaust gas temperature, negative changes smaller than C_TEG_TUR_UP_FIL_HYS are ignored.

4.49 ECU temperature TECU

4.49.1 ECU Temperature

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TECU	V/O	0...FE H	-48...142.5	0.75	°C
ECU/PCU hardware temperature					
TECU_MAX	V/O/S	0...FE H	-48...142.5	0.75	°C
Maximum measured ECU/PCU hardware temperature					

Input data:

V_TECU			

FUNCTION DESCRIPTION:

General information:

TECU represents the ECU/PCU internal temperature from ECU/PCU hardware.

TECU_MAX represents the max. measured ECU/PCU internal temperature since last programming.

Application conditions:

Recurrence: 1000 ms.

Initialisation: TECU = -48 °C (0H)

First Initialisation: TECU_MAX = -48 °C (0H)

Initialisation (after reset): TECU_MAX = TECU_MAX from previous driving cycle.

Formula section:

TECU = IP_TECU__V_TECU

If TECU > TECU_MAX

then TECU_MAX = TECU

Calibration data:

LV_BLS	LV_BTS	LV_ERR_PVS_RATIO_PRED	C_CTR_MAX_PVS_MOVE

FUNCTION DESCRIPTION:

General information:

The accelerator pedal value is determined by means of a two-channel system (PVS: pedal value sensor).

The gradient of the raw values is limited. The values are filtered and normalized to a range between 0 and 99,9%.

The calculation of the pedal value depends on the error state. Normally the pedal value is calculated by channel 1. In case of a disturbed PVS-signal, a selection of one of both PVS-channels and a limitation is done, or the output is set to 0%.

Since it is a two-channel system, the letter ‘X’ is used for either channel 1 or channel 2, in order to simplify the description.

General Application condition:

Activation: always

Deactivation: -

Initialization: for additional conditions see ‘Appl. Incidences of PVS Determination’. Initialization shall be done according to the project philosophy.

V_PVS_1/2$_{(K-1)}$_INI= 5V

V_PVS_FIL_1/2$_{(K-1)}$_INI = 0V

LV_ERR_PVS_SUB$_{(K)}$ = 0

CTR_PVS_THD_IS_L_1 = C_CTR_MAX_PVS_MOVE

CTR_IDLE = C_CTR_MAX_PVS_IS_DET

LV_PVS_THD_IS_H_INI = 1

PV_AV_1/2_H = 0

PV_AV_H = 0

PV_AV = 0

PV_AV_SEL = 0

LV_PV_AV_SEL_NULL = 0

Recurrence: every 10 ms

Signal flow diagram:

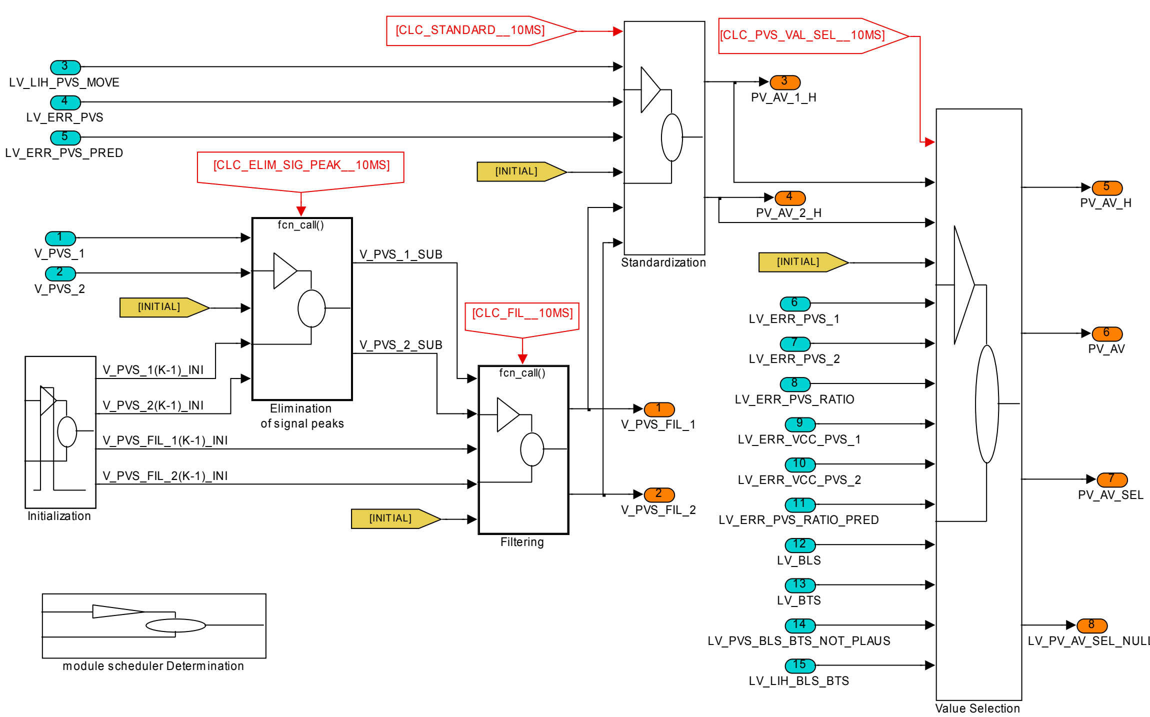

Figure 1: Determination of PVS

Description:

The module “Determination of accelerator pedal value (PVS)” is executed at function call CLC_PVS_SIG_CONV__10MS and initialized at CLC_PVS_SIG_CONV__RST.
Each function part is calculated according to the corresponding function call, which are organized in the module scheduler as shown below.

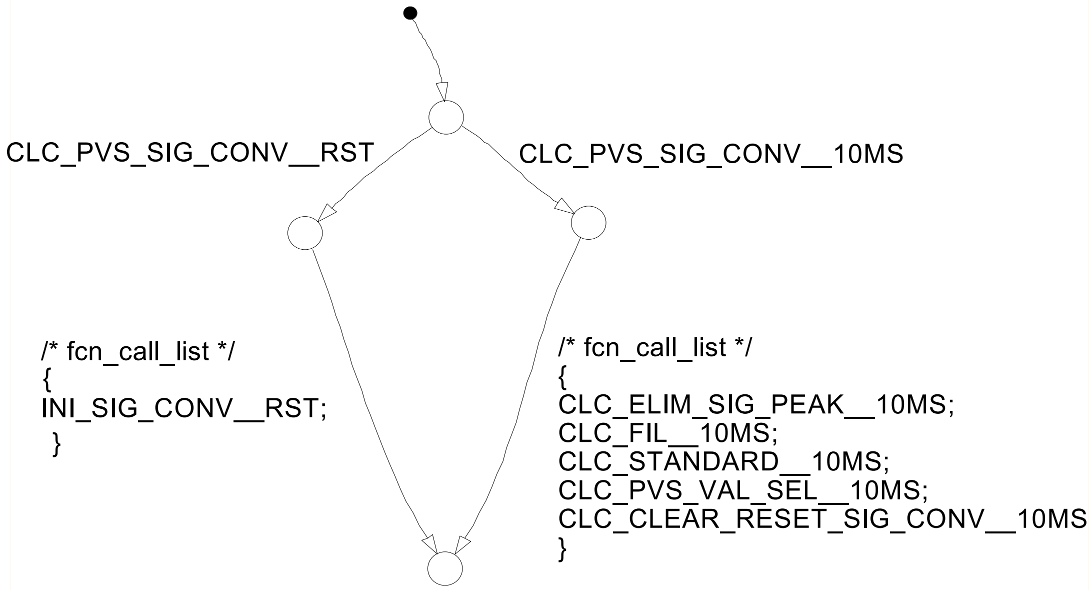

Figure 2: module scheduler Determination

Calculation order:

At initialization (CLC_PVS_SIG_CONV__RST):

1.	INI_SIG_CONV__RST	=>	INITIALIZATION

Calculation regular:

1.	CLC_ELIM_SIG_PEAK__10MS	=>	Elimination of Signal Peaks
2.	CLC_FIL__10MS	=>	Filtration
3.	CLC_STANDARD__10MS	=>	Standardization
4.	CLC_PVS_VAL_SEL	=>	Value Selection
5.	CLC_CLEAR_RESET_SIG_CONV	=>	INITIALIZATION

Initialization:

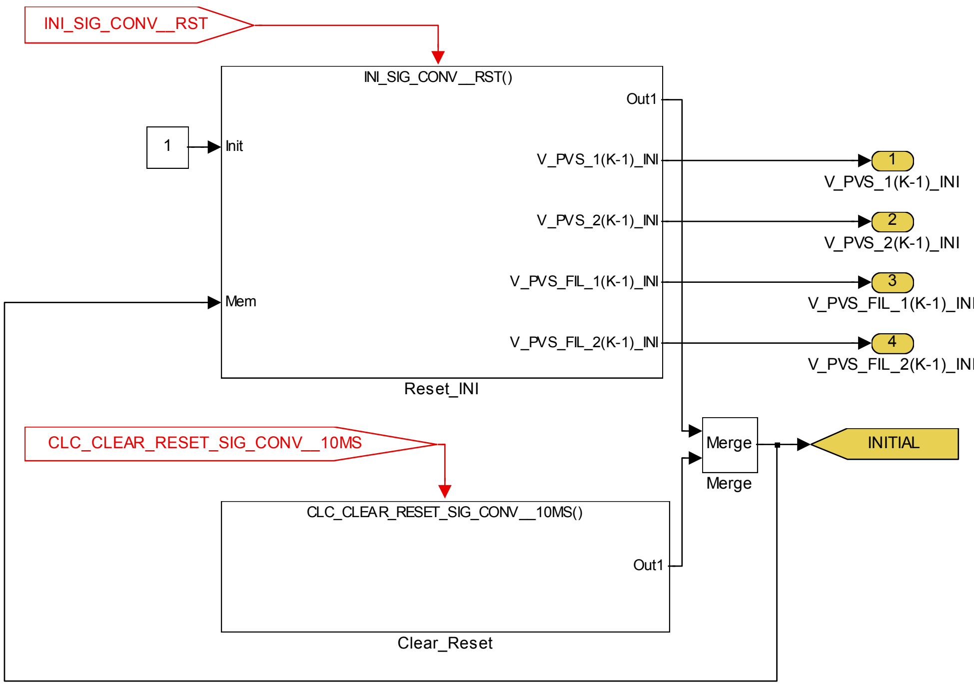

Figure 3: Initialization

At function call **INI_SIG_CONV__RST** initialization is done and “INITIAL” is set **active**.
It is set to **passive** again at the end of the next regular calculation cycle at function call **CLC_CLEAR_RESET_SIG_CONV__10MS**.

4.50.1 Elimination of signal peaks

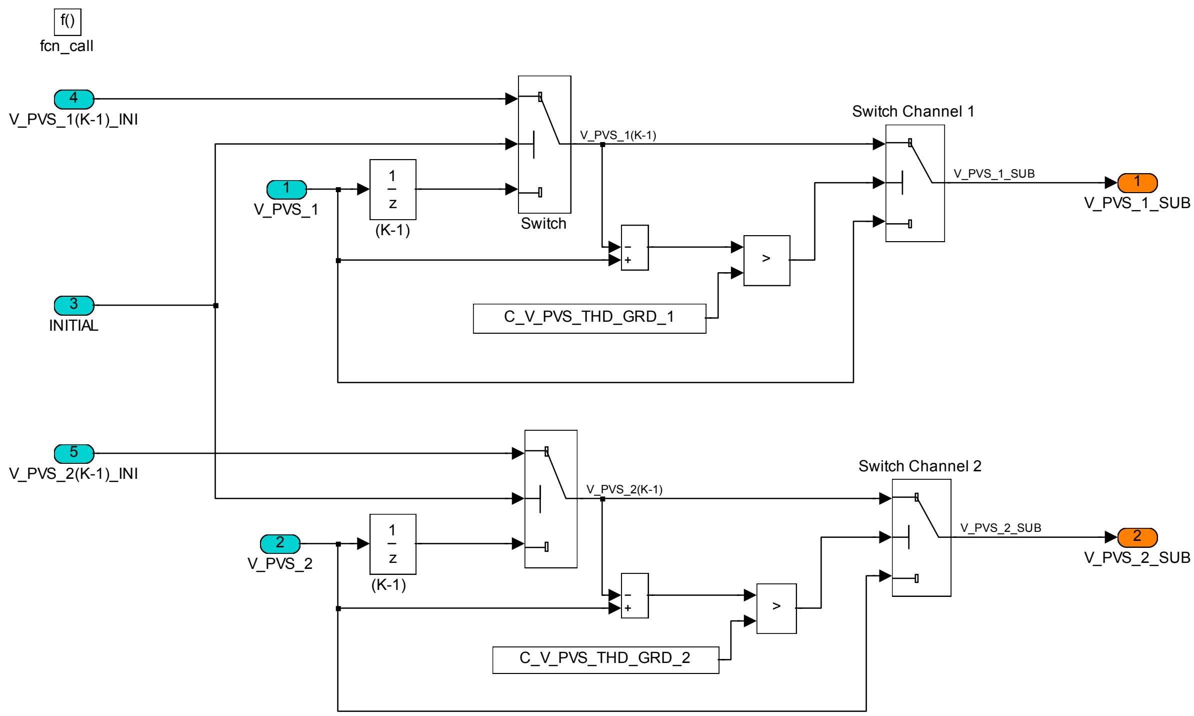

Figure 4: Elimination of signal peaks

Description:

To avoid surge voltage, the gradients of the PVS-signals are limited. If the positive signal gradient of channel X is larger than C_V_PVS_THD_GRD_X, the last value will be kept for one sampling period.

Formula section

Switch Channel 1:

IF $V\_PVS\_1_{(K)} - V\_PVS\_1_{(K-1)} > C\_V\_PVS\_THD\_GRD\_1$

{intermediate results are limited to pos. values}

THEN $V\_PVS\_1\_SUB = V\_PVS\_1_{(K-1)}$

ELSE $V\_PVS\_1\_SUB = V\_PVS\_1_{(K)}$

Switch Channel 2:

IF $V\_PVS\_2_{(K)} - V\_PVS\_2_{(K-1)} > C\_V\_PVS\_THD\_GRD\_2$

{intermediate results are limited to pos. values}

THEN $V\_PVS\_2\_SUB = V\_PVS\_2_{(K-1)}$

ELSE $V\_PVS\_2\_SUB = V\_PVS\_2_{(K)}$

4.50.2 Filtering of the PVS-Values

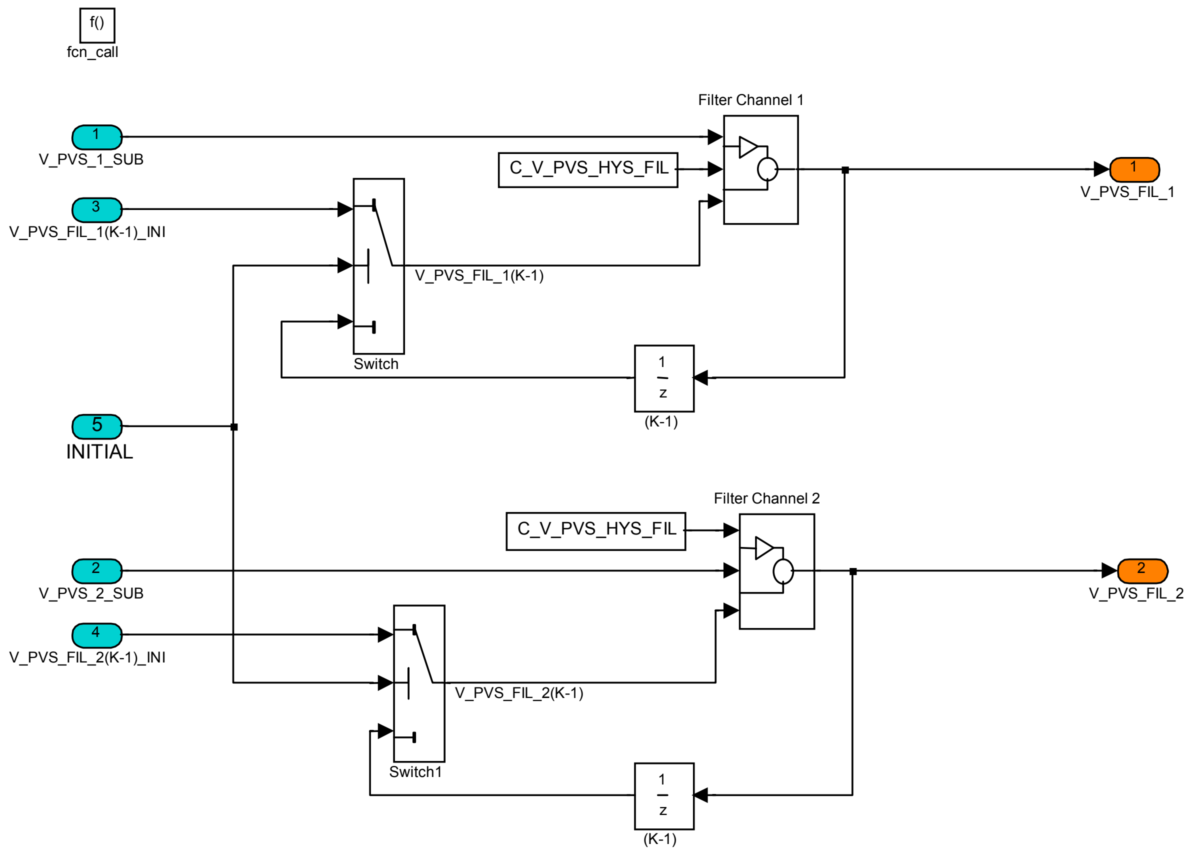

Figure 5: Filtering

Description:

To maintain a stabile driver demand, the PVS-Voltage values need to be filtered.
To avoid a detoriation of the signal accuracy, an asymmetrical filter is used.
The hysteresis C_V_PVS_HYS_FIL is used for both PVS-signals. For increasing signal voltage V_PVS_FIL_X = V_PVS_X_SUB – C_V_PVS_HYS_FIL.
This means a continuously increasing without big incremental steps.
For decreasing signal voltage V_PVS_FIL_X follows the raw value.

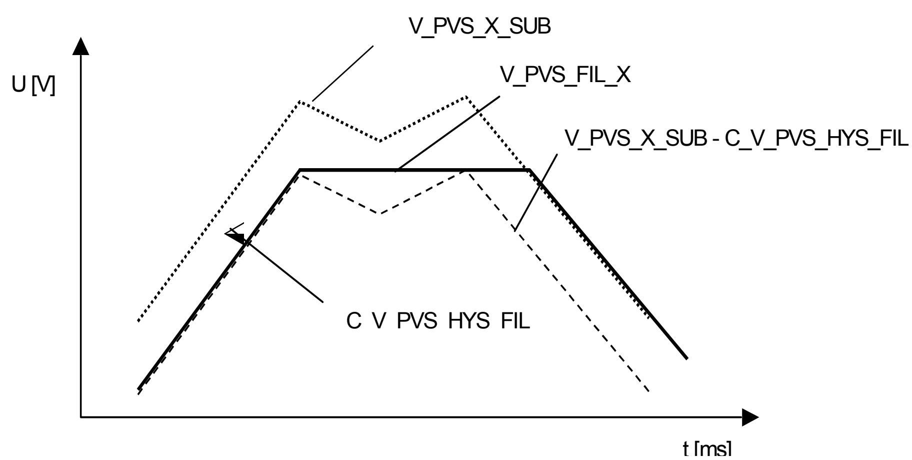

Figure 6: asymmetrical filter

Formula section:

Filter 'Channel_1':

IF V_PVS_FIL_1$_{(K-1)}$ < (V_PVS_1_SUB - C_V_PVS_HYS_FIL)
THEN V_PVS_FIL_1 = V_PVS_1_SUB - C_V_PVS_HYS_FIL
ELSE
  IF V_PVS_FIL_1$_{(K-1)}$ > V_PVS_1_SUB
  THEN V_PVS_FIL_1=V_PVS_1_SUB
  ELSE V_PVS_FIL_1=V_PVS_FIL_1$_{(K-1)}$
  ENDIF
ENDIF

Filter 'Channel_2':

IF V_PVS_FIL_2$_{(K-1)}$ < (V_PVS_2_SUB - C_V_PVS_HYS_FIL)
THEN V_PVS_FIL_2 = V_PVS_2_SUB - C_V_PVS_HYS_FIL
ELSE
  IF V_PVS_FIL_2$_{(K-1)}$ > V_PVS_2_SUB
  THEN V_PVS_FIL_2=V_PVS_2_SUB
  ELSE V_PVS_FIL_2=V_PVS_FIL_2$_{(K-1)}$
  ENDIF
ENDIF

4.50.3 Standardization of PVS

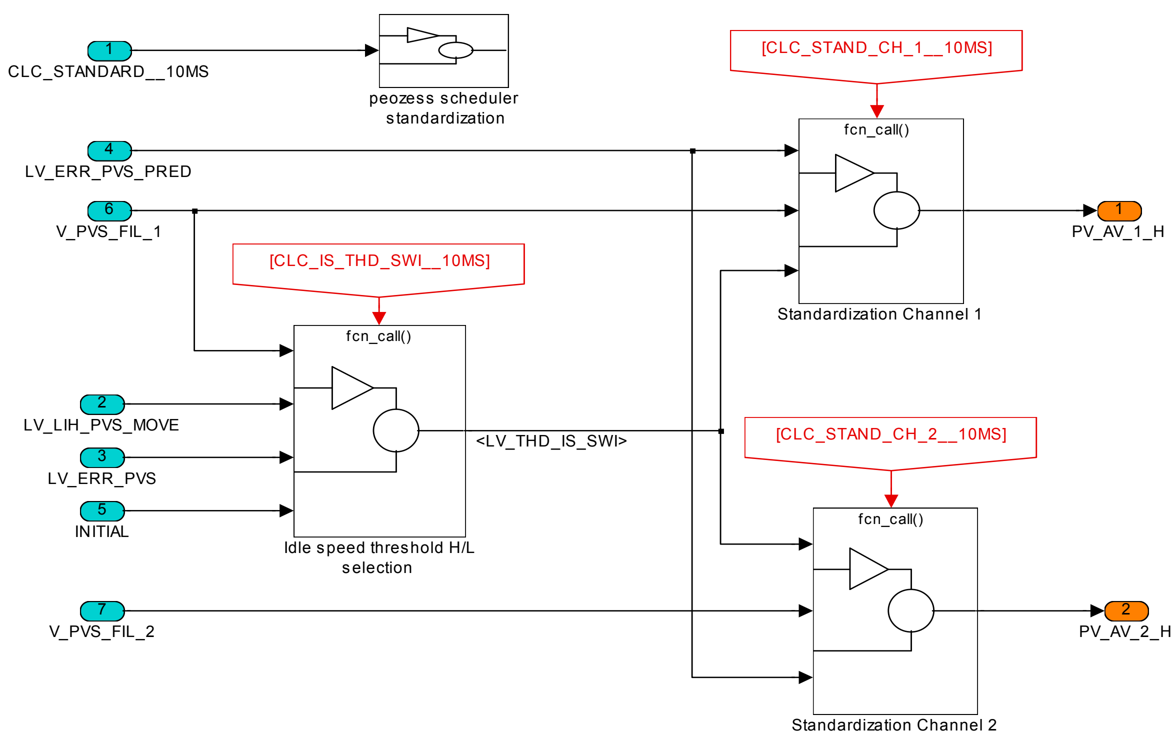

Figure 7: Standardization of PVS

Description:

The sensor voltages are normalized to a range between 0 and 99,9% (pedal value). The calculation is done with high or low thresholds for idle speed recognition depending on PVS error state and Initialization (idle speed threshold H/L selection).

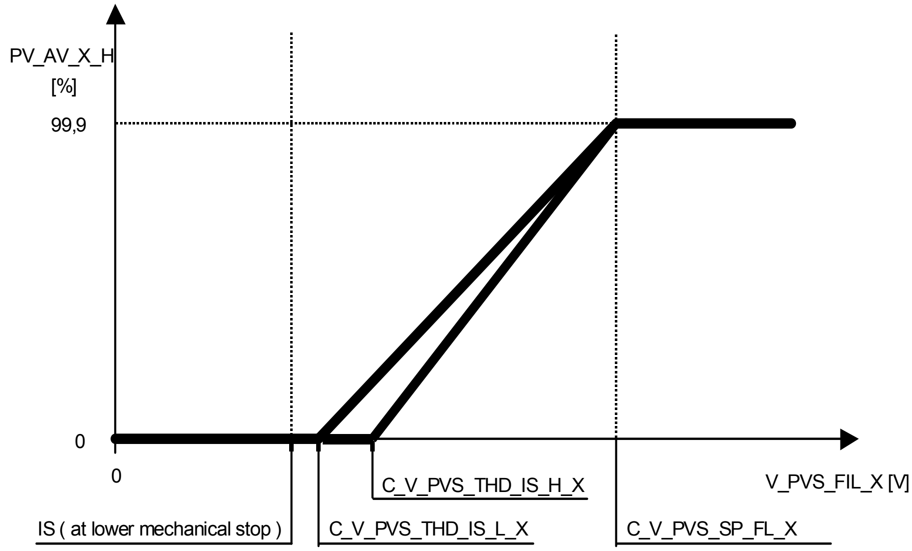

Figure 8: Standardization with high or low IS-threshold

Calculation order:

1. CLC_IS_THD_SWI__10MS => idle speed threshold H/L selection
2. CLC_STAND_CH_1__10MS => Standardization Channel 1
3. CLC_STAND_CH_2__10MS => Standardization Channel 2

4.50.3.1 idle speed threshold H/L selection

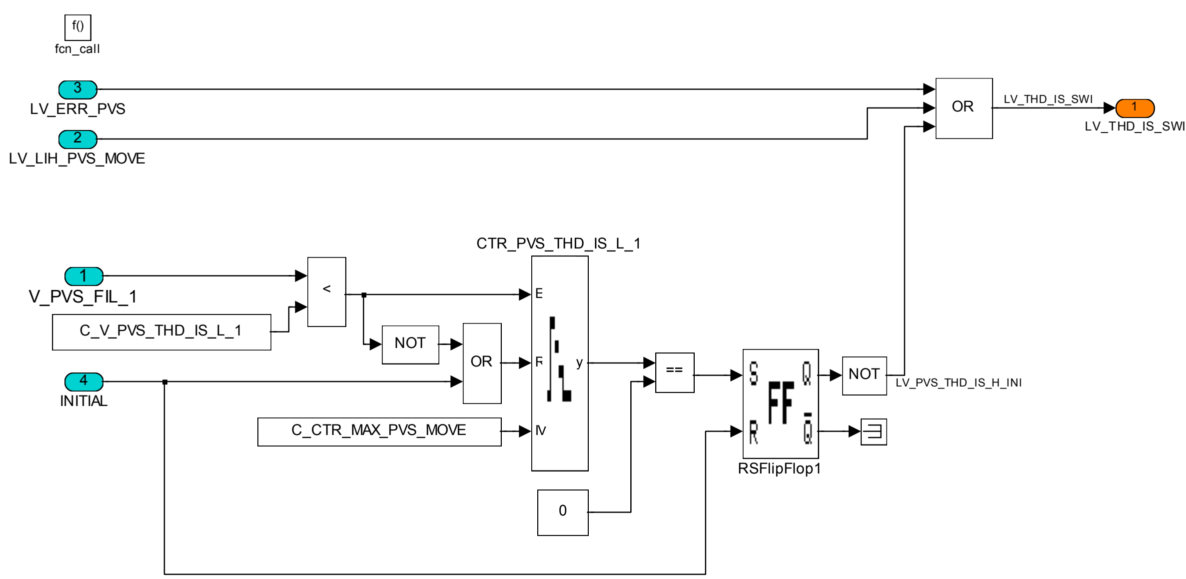

Figure 9: idle speed threshold H/L selection

Description:

The calculation of the pedal values with high idle speed thresholds is done (LV_THD_IS_SWI = 1), if

- a PVS error has been detected LV_ERR_PVS = 1, or
- or a Move error is recognized LV_LIH_PVS_MOVE = 1, or
- as long as V_PVS_FIL_1 has not been below C_V_PVS_THD_IS_L_1 for C_CTR_MAX_PVS_MOVE after initialization LV_PVS_THD_IS_H_INI = 1

Otherwize (LV_SWI_IS_THD = 0) the low thresholds are used.

For functionality it is essentially that the recognition time is the same as in the Move Check (Diagnosis of PVS), therefore C_CTR_MAX_PVS_MOVE is used here, too. It is defined in PVS Diagnosis.

Formula section:

```
IF          NOT V_PVS_FIL_1 < C_V_PVS_THD_IS_L_1                         OR
            at Initialization
THEN        CTR_PVS_THD_IS_L_1(K) = C_CTR_MAX_PVS_MOVE
ELSE
    IF      CTR_PVS_THD_IS_L_1(K) >0                                     AND
            V_PVS_FIL_1 < C_V_PVS_THD_IS_L_1
    THEN    CTR_PVS_THD_IS_L_1(K) = CTR_PVS_THD_IS_L_1(K-1) – [ update rate]
    ENDIF
ENDIF

IF          CTR_PVS_THD_IS_L_1(K) = 0
THEN        LV_PVS_THD_IS_H_INI = 0
ENDIF
{ at Initialization LV_PVS_THD_IS_H_INI = 1}

IF          LV_ERR_PVS = 1                                               OR
            LV_LIH_PVS_MOVE = 1                                          OR
            LV_PVS_THD_IS_H_INI = 1
THEN        LV_THD_IS_SWI = 1
ELSE        LV_THD_IS_SWI = 0
ENDIF
```

4.50.3.2 Standardization Channel 1

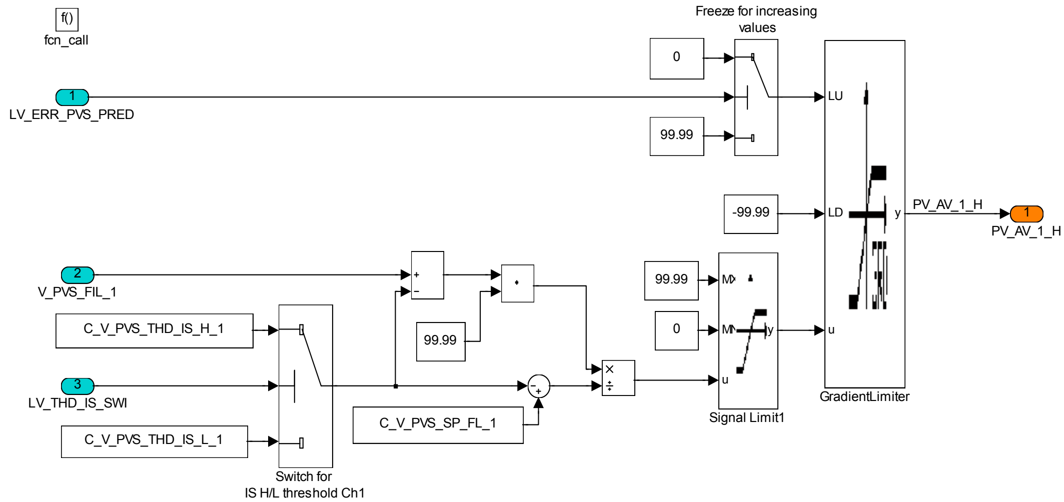

Figure 10: Standardization Channel 1

Description:

If an error is predicted but not debounced yet (LV_ERR_PVS_PRED), PV_AV_1_H will be frozen for $PV\_AV\_1\_H_{(K)} > PV\_AV\_1\_H_{(K-1)}$.

Depending on LV_THD_IS_SWI the high or low thresholds for idle speed recognition are selected for calculation.

If LV_THD_IS_SWI = 0:

$$PV\_AV\_1\_H = \frac{(V\_PVS\_FIL\_1 - C\_V\_PVS\_THD\_IS\_L\_1) \cdot 99{,}9\%}{C\_V\_PVS\_SP\_FL\_1 - C\_V\_PVS\_THD\_IS\_L\_1}$$

If LV_THD_IS_SWI = 1:

$$PV\_AV\_1\_H = \frac{(V\_PVS\_FIL\_1 - C\_V\_PVS\_THD\_IS\_H\_1) \cdot 99{,}9\%}{C\_V\_PVS\_SP\_FL\_1 - C\_V\_PVS\_THD\_IS\_H\_1}$$

4.50.3.3 Standardization Channel 2

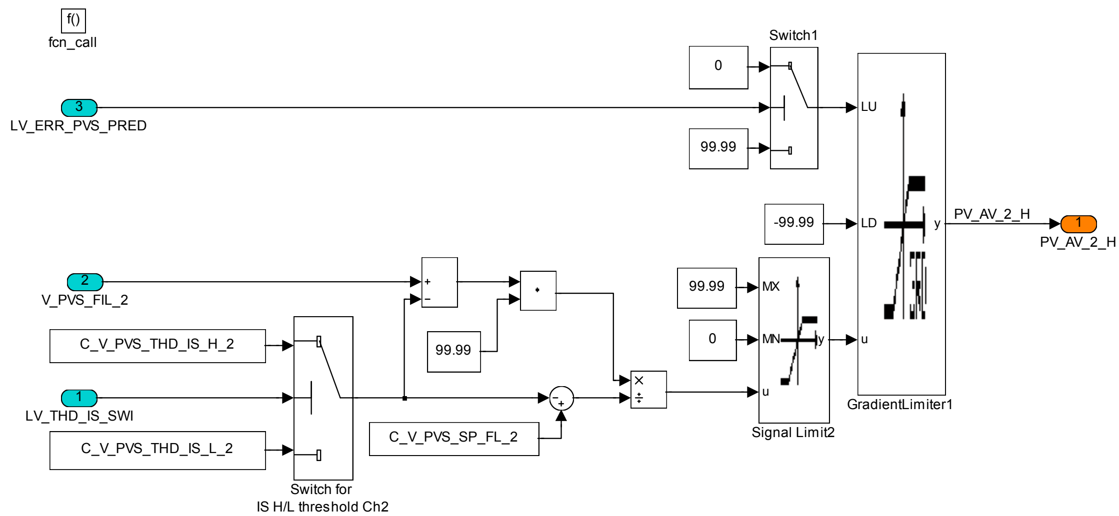

Figure 11: Standardization Channel 2

Description:

If an error is predicted but not debounced yet (LV_ERR_PVS_PRED), PV_AV_2_H will be frozen for $PV\_AV\_2\_H_{(K)} > PV\_AV\_2\_H_{(K-1)}$.

Depending on LV_THD_IS_SWI the high or low thresholds for idle speed recognition are selected for calculation.

If LV_THD_IS_SWI = 0:

$$PV\_AV\_2\_H = \frac{(V\_PVS\_FIL\_2 - C\_V\_PVS\_THD\_IS\_L\_2) \cdot 99{,}9\%}{C\_V\_PVS\_SP\_FL\_2 - C\_V\_PVS\_THD\_IS\_L\_2}$$

If LV_THD_IS_SWI = 1:

$$PV\_AV\_2\_H = \frac{(V\_PVS\_FIL\_2 - C\_V\_PVS\_THD\_IS\_H\_2) \cdot 99{,}9\%}{C\_V\_PVS\_SP\_FL\_2 - C\_V\_PVS\_THD\_IS\_H\_2}$$

.

4.50.4 Value Selection

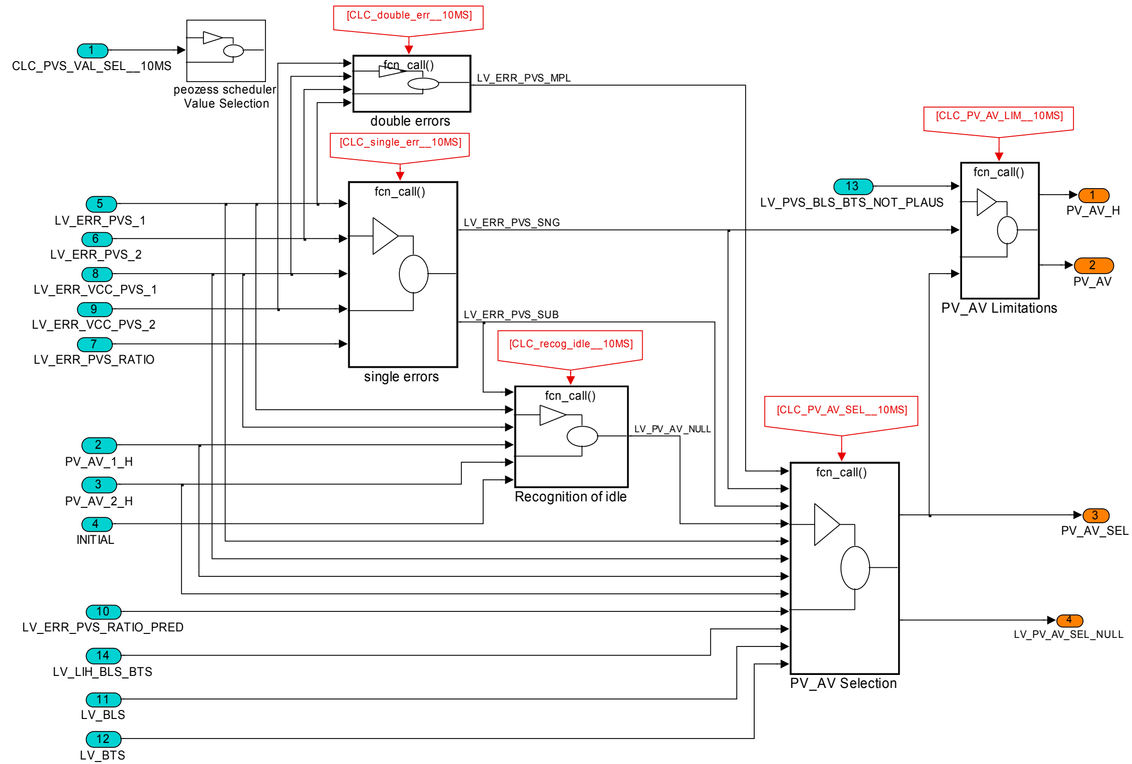

Figure 12: Value Selection

Description:

Depending on PVS error state the final pedal value (PV_AV_H) is calculated. A channel selection and a limitation is done based on PVS diagnosis and brake information.

Calculation order:

1.	CLC_single_err__10MS	=>	single errors
2.	CLC_double_err__10MS	=>	double errors
3.	CLC_recog_idle__10MS	=>	Recognition of idle
4.	CLC_PV_AV_SEL__10MS	=>	PV_AV Selection
5.	CLC_PV_AV_LIM__10MS	=>	PV_AV Limitation

4.50.4.1 single errors

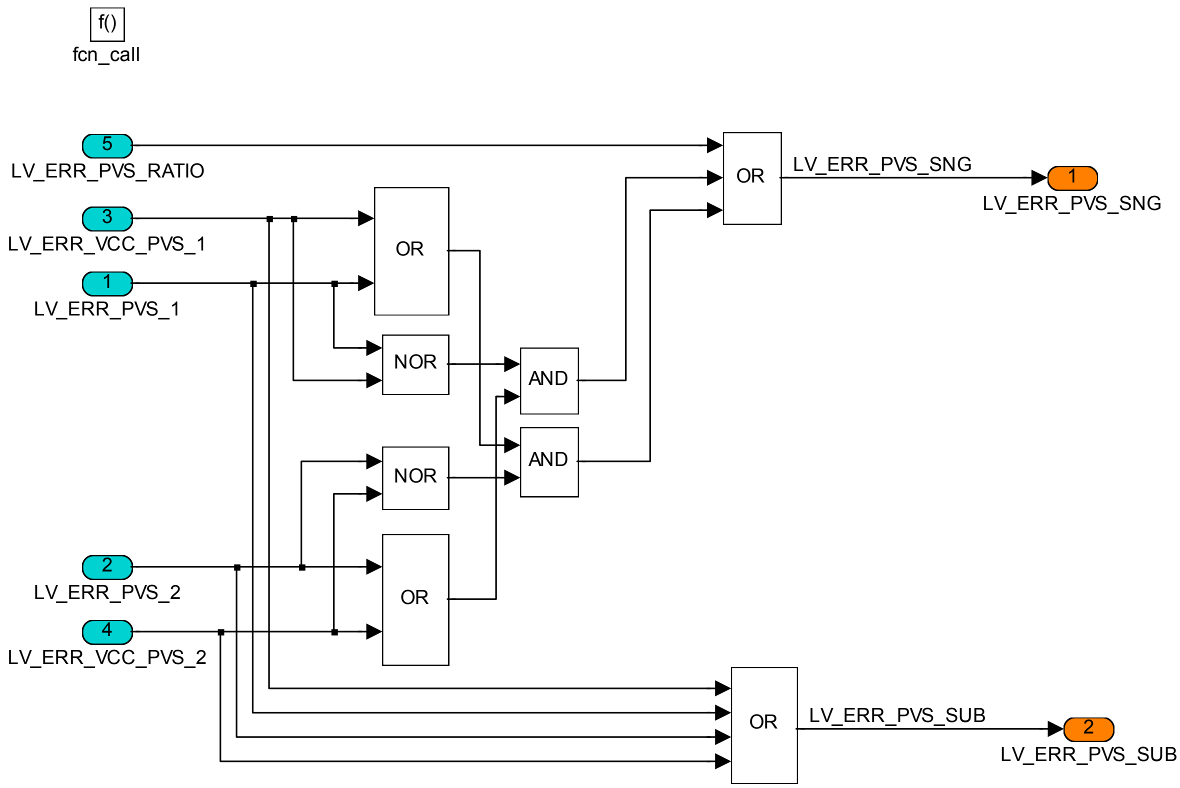

Figure 13: single errors

Formula section:

IF	LV_ERR_PVS_RATIO == 1	**OR**
	{ (LV_ERR_PVS_1==1 or LV_ERR_VCC_PVS_1==1) **and** NOT(LV_ERR_PVS_2==1 or LV_ERR_VCC_PVS_2==1) **}**	**OR**
	{ (LV_ERR_PVS_2==1 or LV_ERR_VCC_PVS_2==1) **and** NOT(LV_ERR_PVS_1==1 or LV_ERR_VCC_PVS_1==1) **}**	
THEN	LV_ERR_PVS_SNG = 1 (only fault on one channel)	
ELSE	LV_ERR_PVS_SNG = 0	
ENDIF		

IF	LV_ERR_PVS_1==1	**OR**
	LV_ERR_VCC_PVS_1==1	**OR**
	LV_ERR_PVS_2==1	**OR**
	LV_ERR_VCC_PVS_2==1	**OR**
THEN	LV_ERR_PVS_SUB = 1 (at least one error is detected)	
ELSE	LV_ERR_PVS_SUB = 0	
ENDIF		

4.50.4.2 double errors

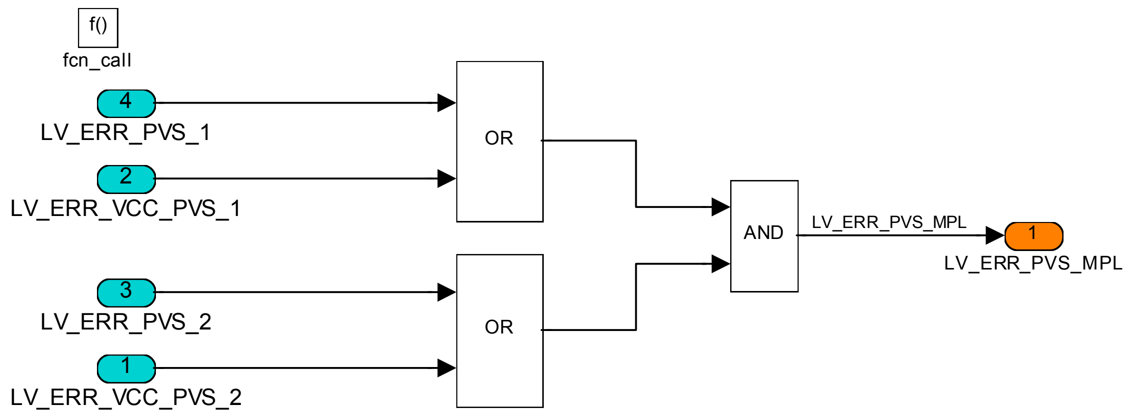

Figure 14: double errors

Formula section:

If	(LV_ERR_PVS_1 == 1 **or** LV_ERR_VCC_PVS_1 == 1)
and	(LV_ERR_PVS_2 == 1 **or** LV_ERR_VCC_PVS_2 == 1)
then	LV_ERR_PVS_MPL = 1 (both channels faulty)
else	LV_ERR_PVS_MPL = 0

4.50.4.3 Recognition of idle

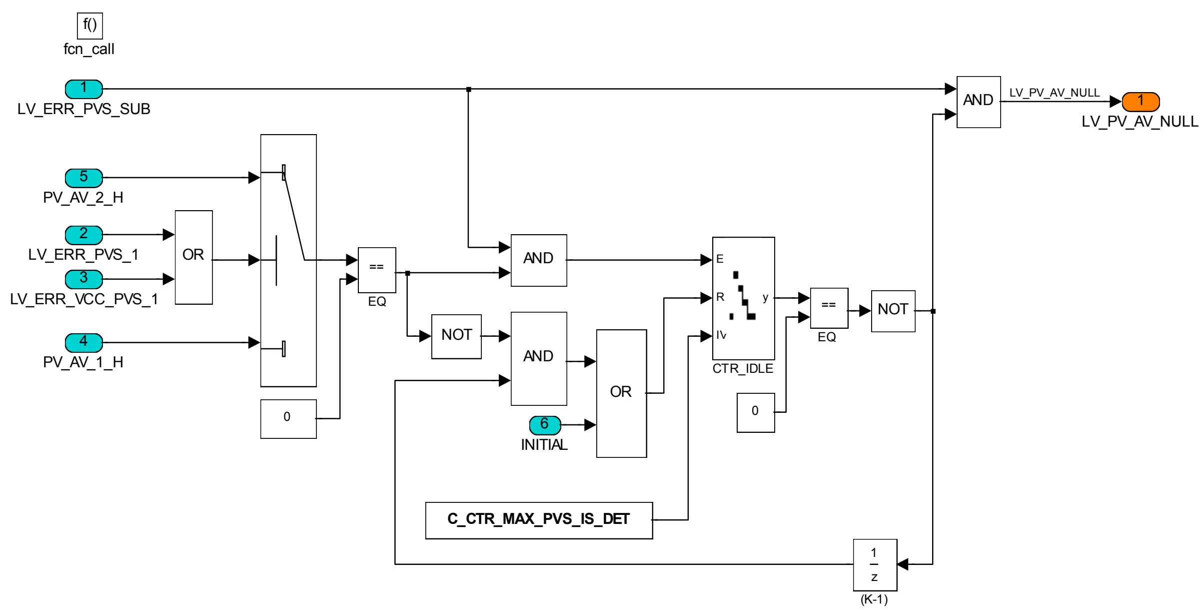

Figure 15: Recognition of PV_AV_X_H at idle

Description:

If channel x is recognized as faulty, the pedal value PV_AV_SEL will be set to 0% directly. The other channel can be selected as the leading channel if driver demand has been recognized as idle (PV_AV_y_H = 0 %) for C_CTR_MAX_PVS_IS_DET * update rate without interruption. As long as this condition is not fulfilled, PV_AV_SEL remains set to 0 % (LV_PV_AV_NULL = 1).

4.50.4.4 PV_AV Selection

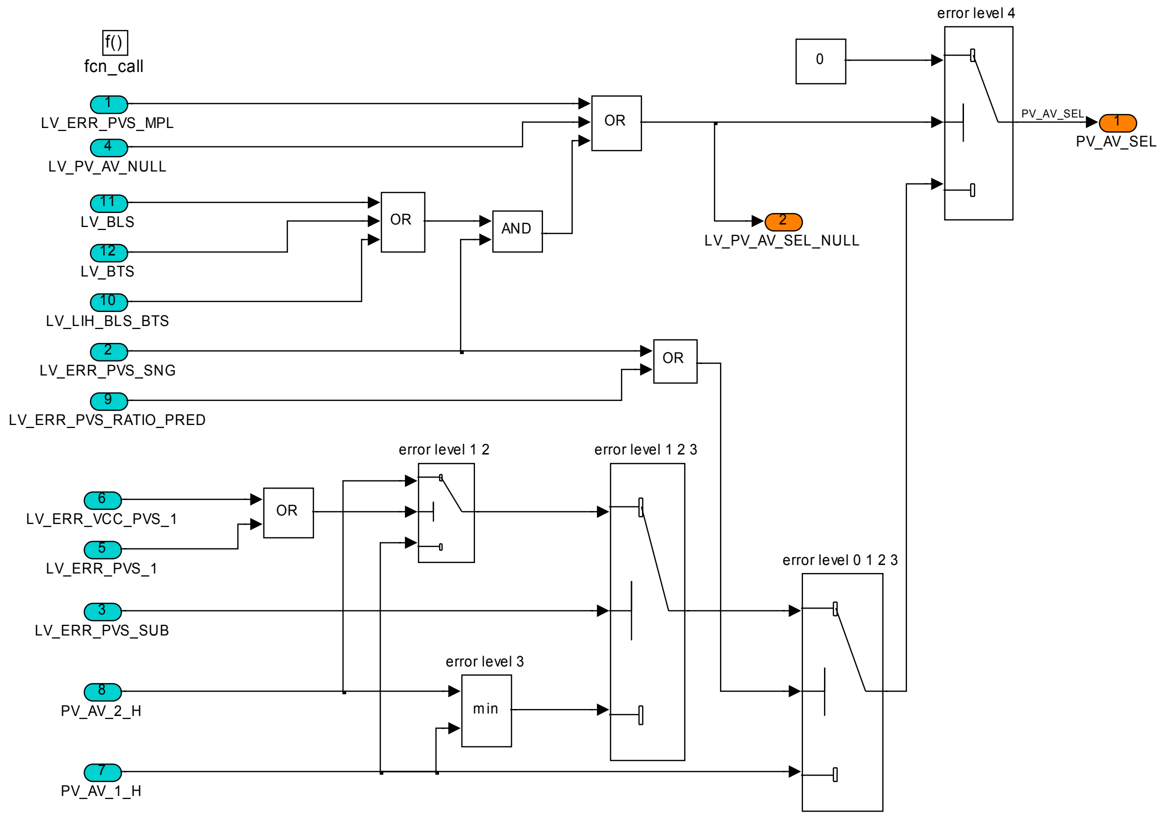

Figure 16: PV_AV Selection

Description:

The pedal value is selected depending on the PVS error state (error level) as follows:

Error level	Error bits		Error handling
0	 **and** **and**	LV_ERR_PVS_1/2 = 0 LV_ERR_VCC_PVS_1/2 = 0 LV_ERR_PVS_RATIO = 0	PV_AV_SEL= PV_AV_1_H no error: → Channel 1 is leading
1	 **and**	(LV_ERR_PVS_1=1 or LV_ERR_VCC_PVS_1=1) (LV_ERR_PVS_2=0 and LV_ERR_VCC_PVS_2=0)	PV_AV_SEL = PV_AV_2_H error on channel 1: → switch to channel 2
2	 **and**	(LV_ERR_PVS_2=1 or LV_ERR_VCC_PVS_2=1) (LV_ERR_PVS_1=0 and LV_ERR_VCC_PVS_1=0)	PV_AV _SEL = PV_AV_1_H error on channel 2: → switch to channel 1
3	 **or** **and** **and** **and** **and**	(LV_ERR_PVS_RATIO = 1 LV_ERR_PVS_RATIO_PRED = 1) LV_ERR_PVS_1 = 0 LV_ERR_PVS_2 = 0 LV_ERR_VCC_PVS_1 = 0 LV_ERR_VCC_PVS_2 = 0	PV_AV_SEL = min (PV_AV_1_H, PV_AV_2_H) ratio error: → min selection
4	 **and**	(LV_ERR_PVS_1=1 or LV_ERR_VCC_PVS_1=1) (LV_ERR_PVS_2=1 or LV_ERR_VCC_PVS_2=1)	PV_AV _SEL = 0 errors on both channels: → pedal value is set to 0%

Additionally to PVS double error (Error Level 4), PV_AV_SEL can be set to 0 % at following conditions:

– A ORNG- or VCC-error on channel x has been detected and the condition for channel switch is not fulfilled , LV_PV_AV_NULL = 1

– As in Error Level 1,2 and 3 only a one-driver demand is available, the break is used as redundant driver demand.
  If LV_ERR_PVS_SNG = 1 (any SRC-, VCC- or Ratio-error is set) and
  - a break detection (LV_BLS = 1 or LV_BTS = 1) **or**
  - a break-error LV_LIH_BLS_BTS = 1

  is present, PV_AV_SEL is set to 0 %.

4.50.4.5 PV_AV Limitations

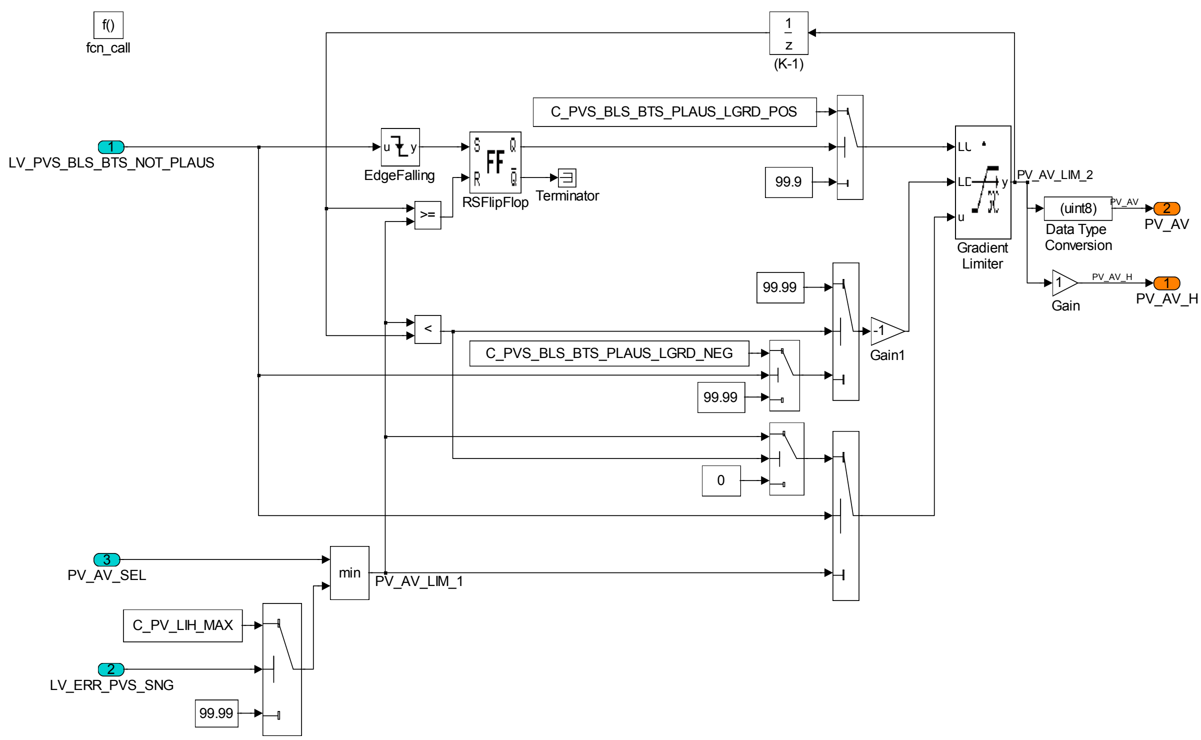

Figure 17: PV_AV Limitations

Description:

Limitations due to error level 1,2 or 3:

If LV_ERR_PVS_SNG = 1 (means only fault on one channel and/or Ratio-error) the absolute value of PV_AV_H is limited to C_PV_LIH_MAX.

Limitations due to plausibility PVS / brake

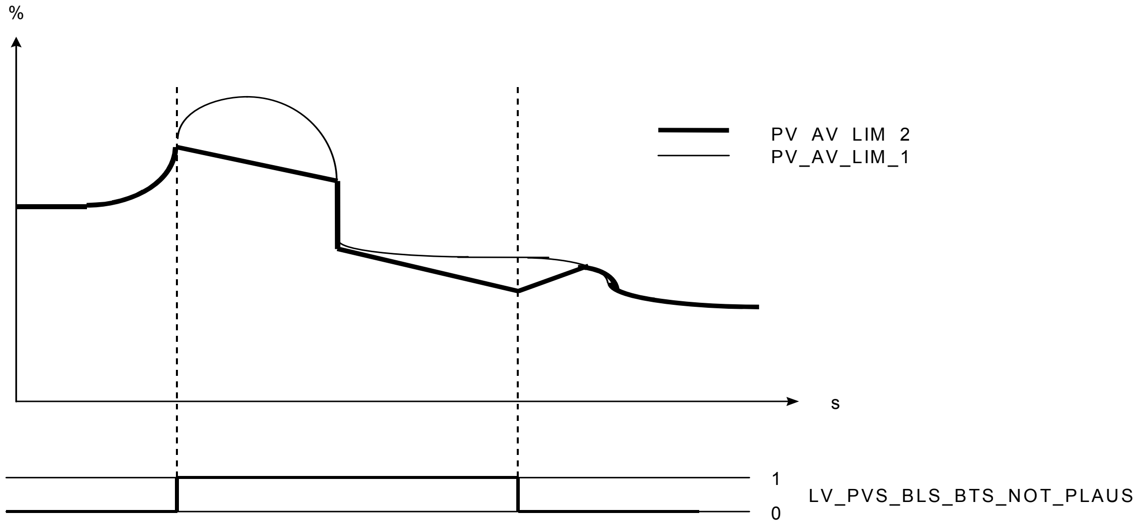

Figure 18: ramp

If an implausible state of brake and gas-pedal (LV_PVS_BLS_BTS_NOT_PLAUS=1) is recognized, the pedal value (PV_AV_LIM_2) will be decreased with C_PVS_BLS_BTS_PLAUS_LGRD_NEG by limiter. To avoid that PV_AV_LIM_2 may exceed PV_AV_LIM_1, PV_AV_LIM_2 is bound to PV_AV_LIM_1 if it drops quickly (faster than decreasing by ramp shown in Figure 18 ramp). After PVS_BLS_BTS_NOT_PLAUS = 0, PV_AV_LIM_2 will be increased with C_PVS_BLS_BTS_PLAUS_LGRD_POS by limiter up to PV_AV_LIM_1.

Calibration data:

4.51 Determination of accelerator pedal value (Appl. Inc.)

4.51.1 Application Incidences

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_LIH_BLS_BTS	O/V	0 ... 1H	0 ... 1	1	-
limp home flag for error on BRAKE or CAN					

Input data:

LV_ERR_BLS_BTS			

General Information:

The application incidences describe several value- and bit-settings used as Inputs in ‘Determination of accelerator pedal value (PVS)’

Application conditions:

Activation: same than module ‘Determination of accelerator pedal value (PVS)’

Deactivation: same than module ‘Determination of accelerator pedal value (PVS)’

Initialization: LV_LIH_BLS_BTS = 0

Recurrence: same than module ‘Determination of accelerator pedal value (PVS)’

General Description:

The application incidences are executed at function call CLC_PVS_DETERM_ APPL_INC__10MS and initialized at CLC_PVS_SIG_CONV_APPL_INC__RST.

4.51.1.1 Initialization conditions

Description:

The Initialization conditions for the modules
- Determination of accelerator pedal value
- Determinations of accelerator pedal value (Appl. Inc.)

are commonly defined here

Initialization is done at following conditions

- at reset
- at transition from LV_IGK == 0 to 1
- at clearing the failure memory

Formula section:

If LV_ERR_BLS_BTS = 1

THEN LV_LIH_BLS_BTS = 1

ELSE LV_LIH_BLS_BTS = 0

4.52 Inverse accelerator pedal value (PV_CRU)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PV_CRU	O/V	0...FFH	0...99.6	0.3906	%
Inverse accelerator pedal					

Input data:

FAC_TQ_REQ	N	LV_CRU_ACT	FAC_TQ_REQ_DRIV
FAC_TQ_REQ_CRU			

FUNCTION DESCRIPTION:

General information:

During the cruise control function active, this inverse pedal value is calculated and this information could be used instead of PV_AV to TPS_SP_MDL_MAX calculation and auto transmission control.

The IP_PV_CRU is just inverted table of IP_FAC_TQ_REQ_DRIV.

General Application condition:

Activation: *always*

Deactivation: -

Initialization: PV_CRU = PV_AV

Recurrence: every 10 ms

Formula section:

If LV_CRU_ACT = 0
or FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU
Then PV_CRU = PV_AV
Else PV_CRU = IP_PV_CRU__FAC_TQ_REQ__N

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_PV_CRU	12*12	0...FFH	0...99.6	0.3906	%
LDP_FAC_TQ_REQ__PV_CRU	12	0 ... FFFFH	0 ... 1.999969	3.052E-5	-
LDP_N__PV_CRU	12	0 ... 1FE0H	0 ... 8160	1	rpm
Inverse Pedal value map					

4.53 Definition of PV_AV_CAN

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PV_AV_CAN	V/O	00...FFH	0...99.6	0,3906	%
PV_AV distributed via CAN.					

Input data:

PV_AV	LV_ERR_PVS_1	LV_ERR_VCC_PVS_1	LV_ERR_PVS_2
LV_ERR_VCC_PVS_2	PV_CRU	LV_CRU_ACT	LV_CRU_OVER_ACT
LV_MTC_CUR_OFF_REQ	LV_OFF_MTC_MON		

FUNCTION DESCRIPTION:

General information:

The PV-value is distributed to other control units via CAN.

If the EMS-ECU recognises that the accelerator pedal is not activated, then the value 00H is carried over on the CAN. If the EMS-ECU detects that the accelerator pedal is fully activated, then FEH is carried over on the CAN bus. In case of a PV-error is detected at both PV channels (PV_AV_1 and PV_AV_2) then the identifier FFH is distributed as an error identifier.

If ETC limphome is active and the throttle body is switched of (LV_MTC_CUR_OFF_REQ = 1) or ETC powerstage is disabled due to a monitoring error, PV_AV_CAN is set to FFH.

For cruise controlled driving, PV_AV_CAN is set to PV_CRU.

Formula section:

If ((LV_ERR_PVS_1 = 1 **or**
LV_ERR_VCC_PVS_1 = 1)
and (LV_ERR_PVS_2 = 1 **or**
LV_ERR_VCC_PVS_2 = 1))
or LV_MTC_CUR_OFF_REQ = 1
or LV_OFF_MTC_MON = 1

then PV_AV_CAN = FFH
else **if** (LV_CRU_ACT = 1 **and** LV_CRU_OVER_ACT = 0)
then PV_AV_CAN = PV_CRU
else **If** PV_AV > FE H
then PV_AV_CAN = FE H
else PV_AV_CAN = PV_AV

4.54 Variables for fleet monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PV_AV_MAX_TOT_DC	O/V/S	0...FFH	0...99.6	0.3906	%
Former / current driving cycle maximum accel. pedal position					
PV_AV_GRD	O/V	0...FFH	0...255	1	%/100ms
Pedal value gradient					
PV_AV_GRD_MAX_TOT_DC	O/V/S	0...FFH	0...255	1	%/100ms
Former / current driving cycle maximum gradient of accel. pedal position					

Input data:

PV_AV	LV_ES		

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

PV_AV_MAX_TOT_DC = 0

PV_AV_GRD_MAX_TOT_DC = 0

- otherwise: restored from non-volantile memory

- at LV_IGK 0->1 and reset:

PV_AV_GRD = 0

Recurrence: 10 ms

Activation: LV_ES = 0

Deactivation: -

Formula section:

If PV_AV > PV_AV_MAX_TOT_DC

Then PV_AV_MAX_TOT_DC = PV_AV

Endif

If $PV\_AV_{(n)} > PV\_AV_{(n-1)}$ \\ only for acceleration

Then $PV\_AV\_GRD = (PV\_AV_{(n)} – PV\_AV_{(n-1)}) * 10$

Else PV_AV_GRD = 0

Endif

If PV_AV_GRD > PV_AV_GRD_MAX_TOT_DC

Then PV_AV_GRD_MAX_TOT_DC = PV_AV_GRD

Endif

4.55 Definition of PV_GRD

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PV_GRD	V/O	FC00...3FFH	-100...99.902	0.0976	% / 40ms
Pedal value gradient					

Input data:

PV_AV			

Application conditions:

Initialisation: PV_GRD = 0

Recurrence: 10 ms

Activation: LV_ES = 0

Deactivation: -

FUNCTION DESCRIPTION:

General information:

The PV_GRD value shows the gradient of the accelerator pedal. It can have positive or negative values

Formula section:

$PV\_GRD = PV\_AV_{(n)} - PV\_AV_{(n-4)}$

4.56 PVS error limitations

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TQ_MAX_PVS_LIH	O/V	0...FFFFH	0...1.999969	3.052E-5	-
Scaling factor for requested torque at clutch by pedal at PVS error					
FAC_TQ_MAX_PVS_BLS_BTS_LIM	O/V	0...FFFFH	0...1.999969	3.052E-5	-
Scaling factor for driver requested torque at clutch by pedal at PVS / Brake state detection					
LV_ACT_PVS_BLS_BTS_TQ_LIM	O/V	0...1H	0...1	1	-
Flag for activation limitation of driver requested torque at clutch (Brake / PVS)					

Input data:

TQ_MIN_CLU	TQ_MAX_CLU	LV_ACT_PVS_LIH	LV_IGK
VS	LV_BLS	LV_BTS	PV_AV_SEL
LV_AT	FAC_TQ_REQ_PV	LV_ERR_VS	

FUNCTION DESCRIPTION:

General information:

Due to Information of pedal value sensor additionally constrains can be performed to restrict vehicle dynamic:
- torque limitation due to PVS errors
- torque limitation due to PVS / Brake state (for AT vehicles only)

General Application conditions:

Activation: LV_IGK = 1

Deactivation: -

Initialization: FAC_TQ_MAX_PVS_LIH = 0

FAC_TQ_MAX_PVS_BLS_BTS_LIM = 0

LV_ACT_PVS_BLS_BTS_TQ_LIM = 0

Initialization conditions: same as in module ‘Diagnosis of Pedal value sensor (Application Incidences)’

Recurrence: 10 ms

Signal flow diagram:

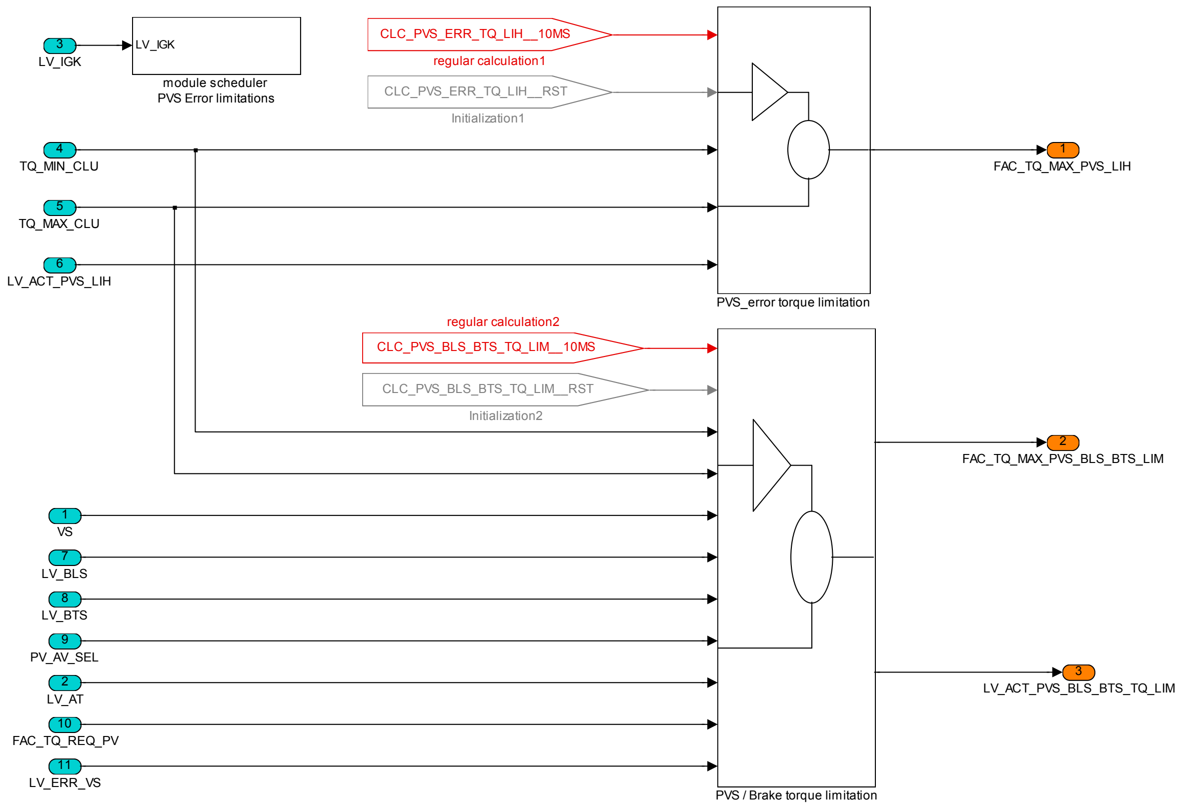

Figure 1: PVS error limitations

The module PVS error limitation is executed at function-call CLC_PVS_ERR_LIM__10MS.
Initialization is done at CLC_PVS_ERR_LIM__RST.

Calculation order (regular calculation):

1. PVS error torque limitation — on fcn-call CLC_PVS_ERR_TQ_LIH__10MS
2. PVS / Brake torque limitation — on fcn-call CLC_PVS_BLS_BTS_TQ_LIM__10MS

Initialization order:

1. PVS error torque limitation — on fcn-call CLC_PVS_ERR_TQ_LIH__RST
2. PVS / Brake torque limitation — on fcn-call CLC_PVS_BLS_BTS_TQ_LIM__RST

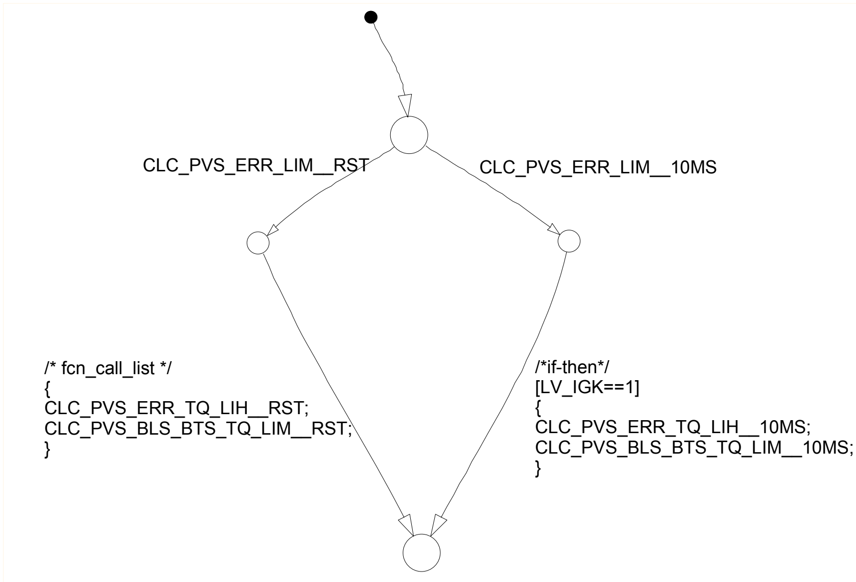

Figure 2: module scheduler “PVS error limitations”

4.56.1 PVS error torque limitation

General information:

As a consequence of a PVS error there may be a requirement to restrict the vehicle dynamic behavior. Therefore a limited scaling factor is calculated to restrict the driver requested torque. Additionally the positive gradient of scaling factor is limited to restrict vehicle acceleration.

Application conditions:

Activation: LV_IGK = 1

Deactivation: -

Signal flow diagram:

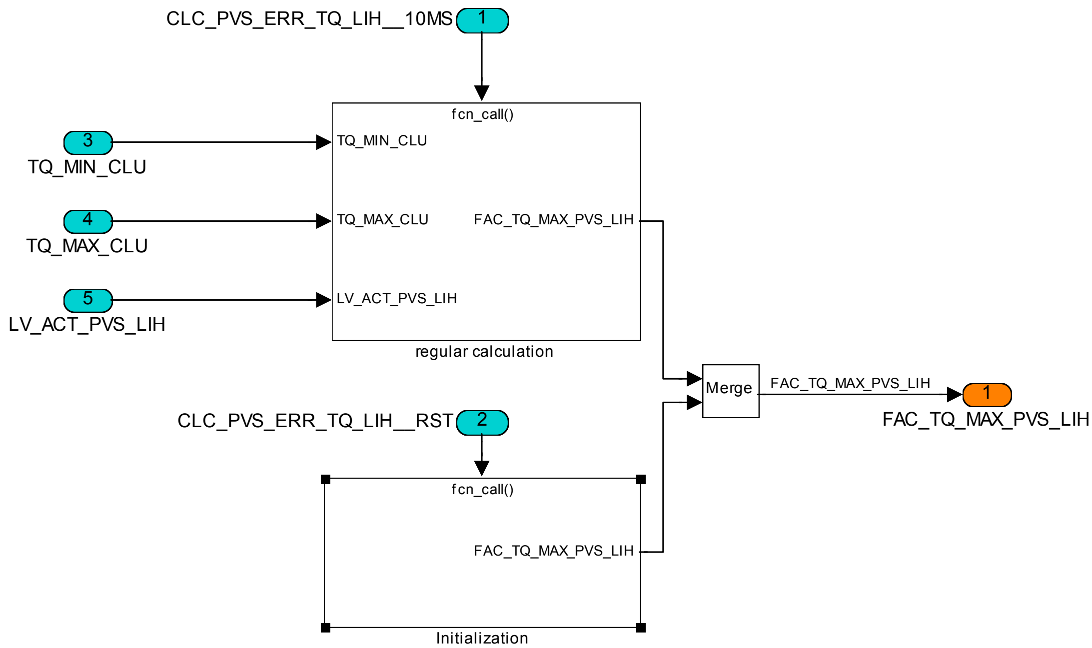

Figure 2: PVS error torque limitation

Description:

Regular calculation is done at function call CLC_PVS_ERR_TQ_LIH__10MS. Initialization is done at CLC_PVS_ERR_TQ_LIH__RST.

4.56.1.1 Initialization

At Initialization FAC_TQ_MAX_PVS_LIH is set to 0.

4.56.1.2 Regular calculation

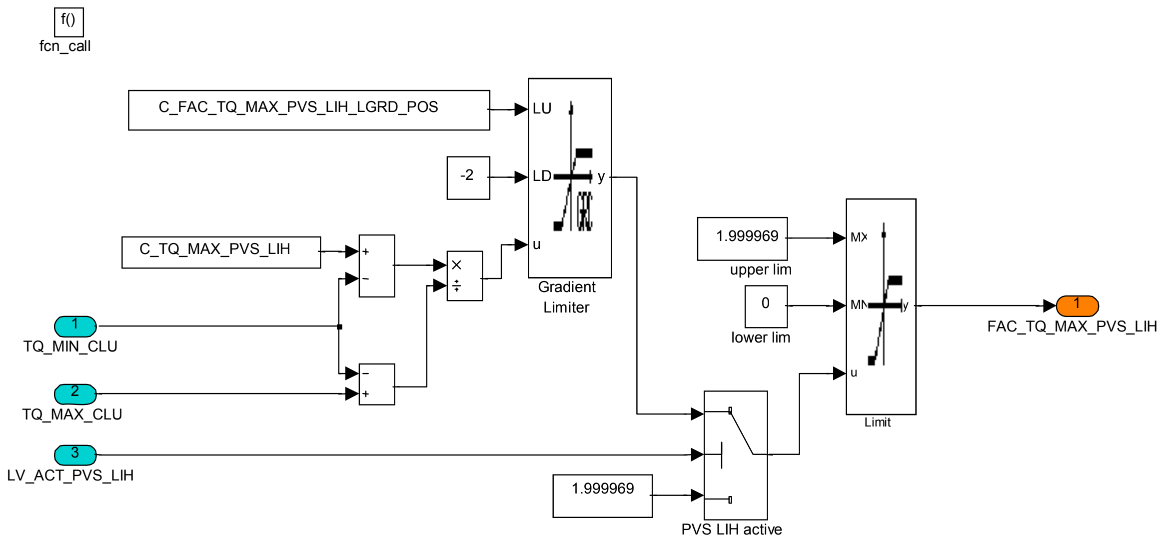

Figure 2: regular calculation

Description:

If a PVS error is debounced (LV_ACT_PVS_LIH = 1) the driver requested torque by pedal is limited to the maximum value C_TQ_MAX_PVS_LIH. As in torque management a scaling factor is required for calculation of engine torque, the limitation is done by the calculation of the scaling factor FAC_TQ_MAX_PVS_LIH. The positive gradient is limited to C_FAC_TQ_MAX_PVS_LIH_LGRD_POS.

If no PVS error is debounced (LV_ACT_PVS_LIH = 0), the factor is set to 1.999969.

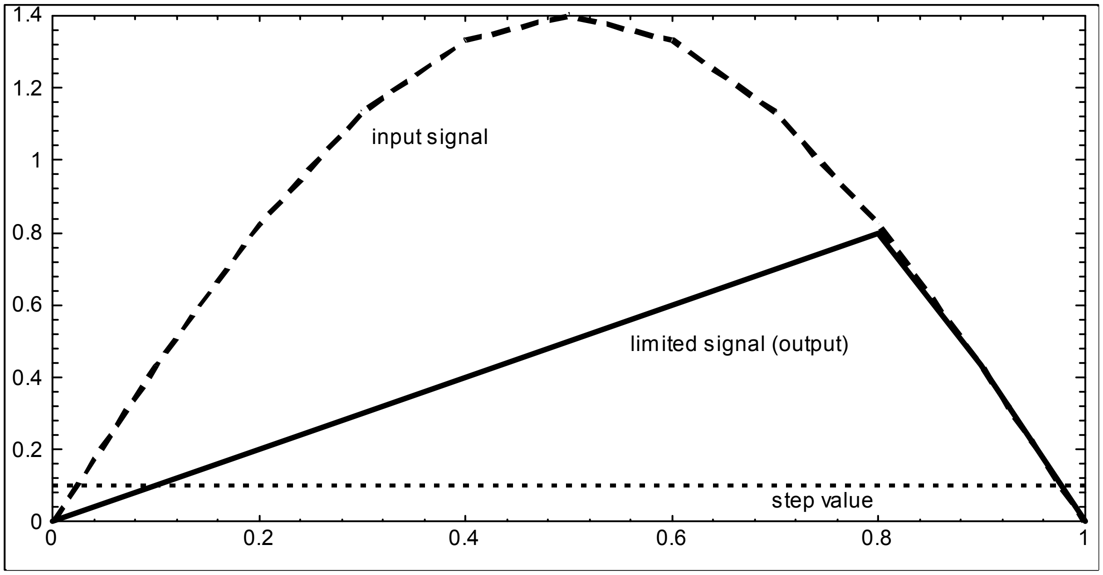
Formula section:

IF LV_ACT_PVS_LIH == 1
THEN FAC_TQ_MAX_PVS_LIH = (C_TQ_MAX_PVS_LIH – TQ_MIN_CLU) / (TQ_MAX_CLU -TQ_MIN_CLU)

{ The positive gradient is limited to C_FAC_TQ_MAX_PVS_LIH_LGRD_POS }

ELSE FAC_TQ_MAX_PVS_LIH = 1.999969
ENDIF

{ FAC_TQ_MAX_PVS_LIH is limited to max. 1.999969 and min. 0 } gradient limiter:



4.56.2 PVS / Brake torque limitation

General information:

To prevent a move away of the vehicle if both pedals (brake and gas pedal) are pressed, the driver requested torque can be limited to ensure that braking torque is higher than engine torque. Therefore a limited scaling factor is calculated depending on pedal activation.

General Application conditions:

Activation: LV_IGK = 1
LV_AT = 1

Deactivation: -

Signal flow diagram:

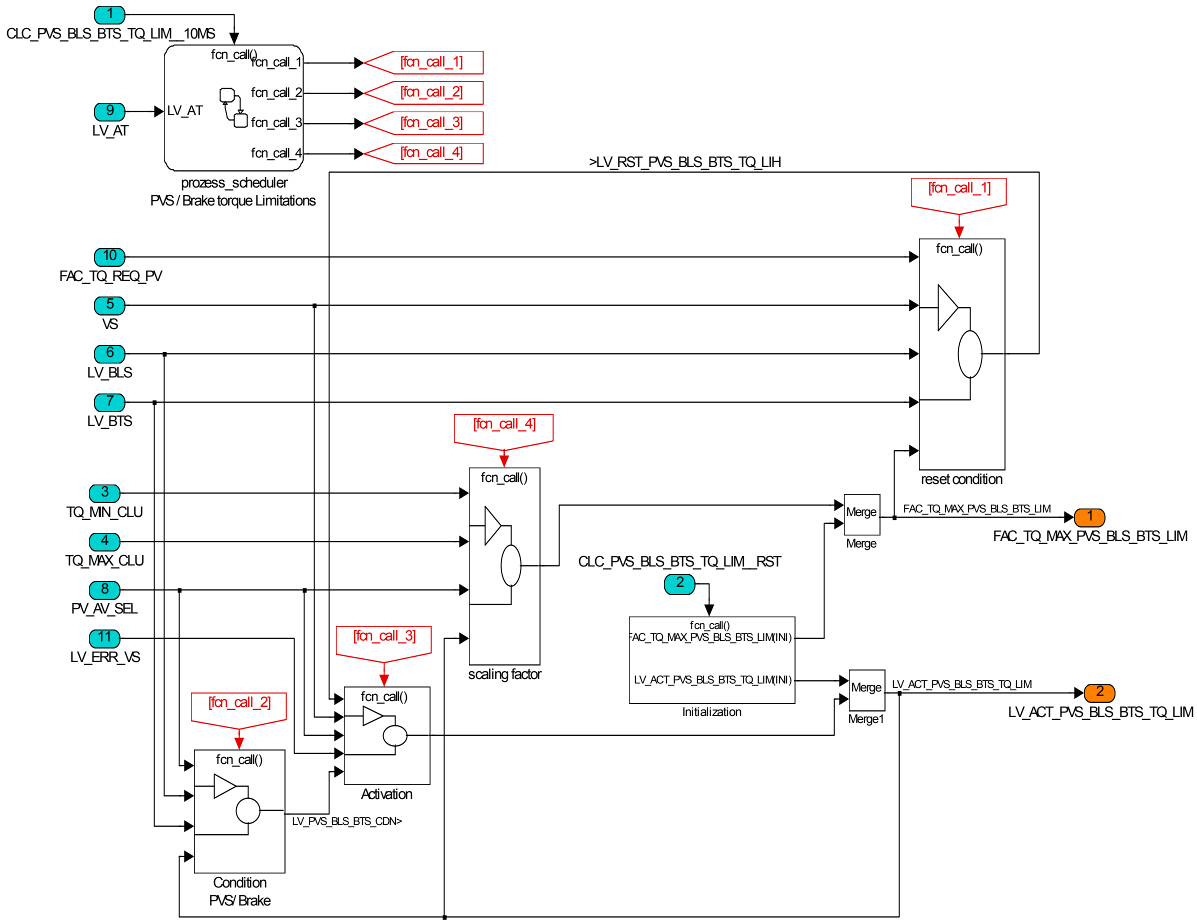


Figure 3: PVS / Brake torque limitation

Description:

Initialization:
Is done at function call CLC_PVS_BLS_BTS_TQ_LIM__RST

Calculation order:
(On function call CLC_PVS_BLS_BTS_TQ_LIM__10MS if LV_AT=1 only):

1. Reset condition on fcn_call_1
2. Condition PVS/ Brake on fcn_call_2
3. Activation on fcn_call_3
4. Scaling factor on fcn_call_4

4.56.2.1 Initialization

At Initialization FAC_TQ_MAX_PVS_BLS_BTS_LIM and LV_ACT_PVS_BLS_BTS_TQ_LIM are set = 0

4.56.2.2 Reset condition

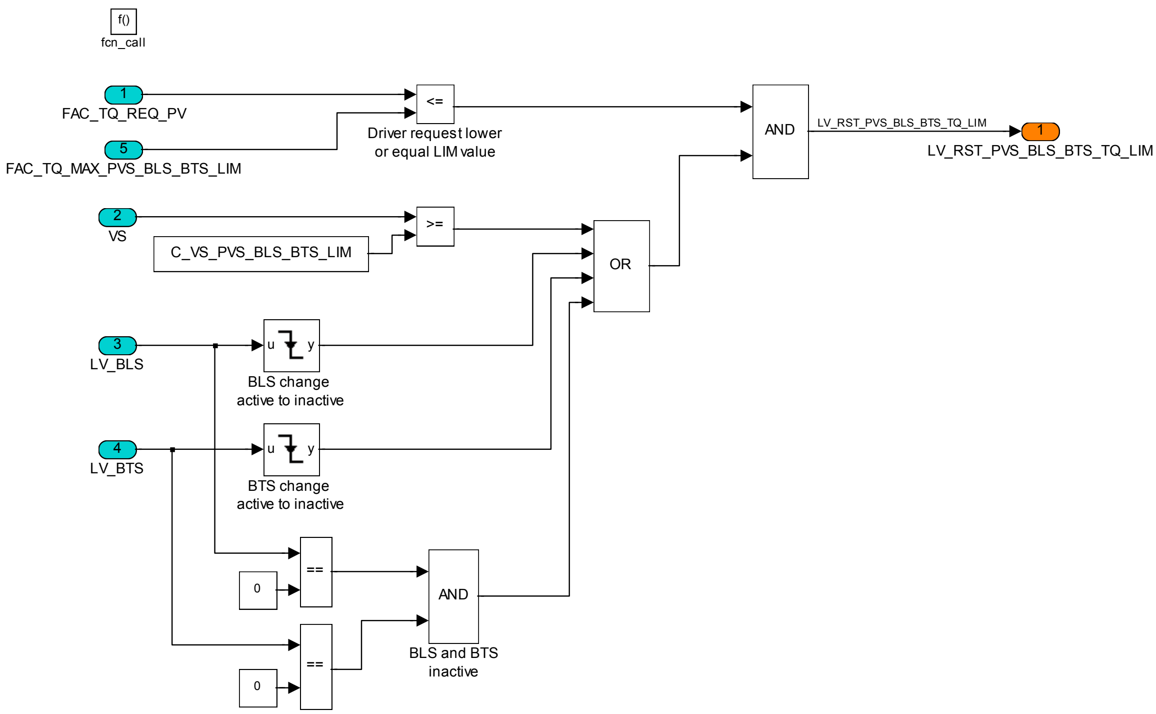

Figure 4: Reset condition

Description:

A limited scaling factor is calculated (after activation was done) till the reset conditions are fulfilled.

The reset flag LV_RST_PVS_BLS_BTS_TQ_LIM is set if the calculated scaling factor FAC_TQ_REQ_PV (real driver request) is lower or equal the limited scaling factor FAC_TQ_MAX_PVS_BLS_BTS_LIM **and**

-the vehicle speed is higher or equal C_VS_PVS_BLS_BTS_LIM or

-the brake changes to inactive (indicated by LV_BLS) or

-the brake changes to inactive (indicated by LV_BTS) or

-the brake is inactive (indicated if LV_BLS and LV_BTS are 0).

Formula section:

IF FAC_TQ_REQ_PV <= FAC_TQ_MAX_PVS_BLS_BTS_LIM **AND**

[VS >= C_VS_PVS_BLS_BTS_LIM **or**

($LV\_BLS_{(K-1)}$ == 1 and $LV\_BLS_{(K)}$ == 0 **)** **or**

($LV\_BTS_{(K-1)}$ == 1 and $LV\_BTS_{(K)}$ == 0 **)** **or**

(LV_BLS == 0 and LV_BTS == 0 **)** **]**

THEN LV_RST_PVS_BLS_BTS_TQ_LIM = 1

ELSE LV_RST_PVS_BLS_BTS_TQ_LIM = 0

ENDIF

4.56.2.3 Condition PVS / Brake

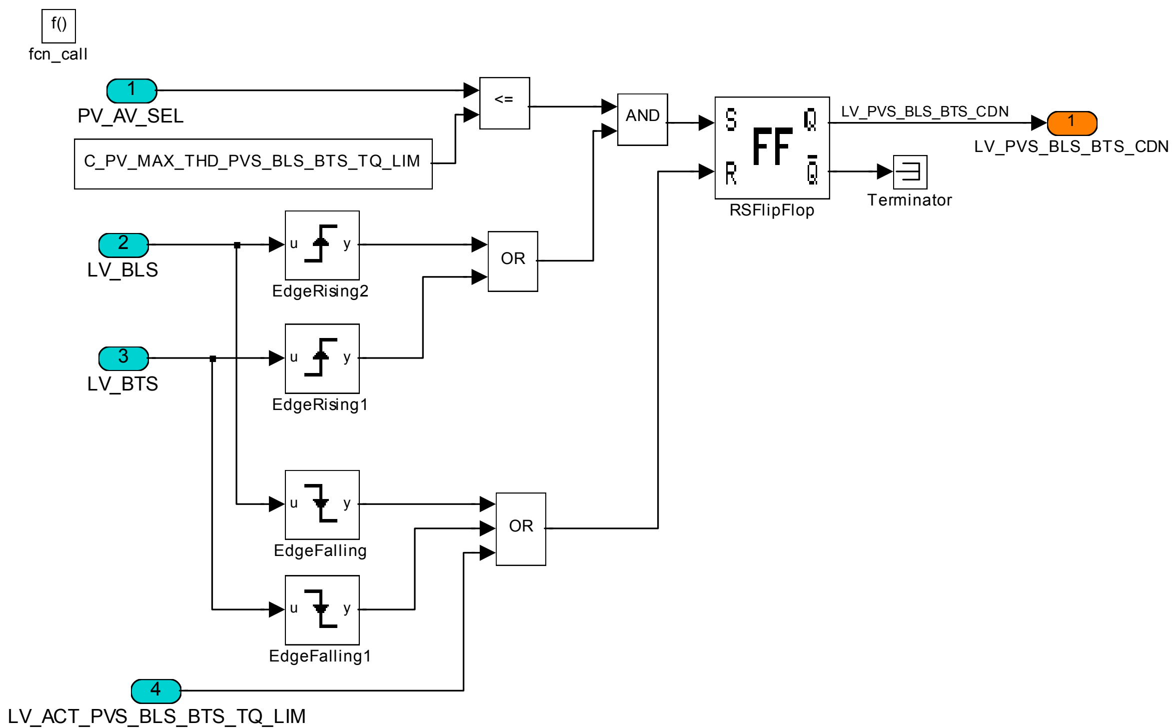

Figure 5: Condition PVS / Brake

Description:

The first condition which has to be fulfilled for a calculation of a limited scaling factor is the detection of brake activation (LV_BLS or LV_BTS) while the gas pedal is released (PV_AV_SEL <= C_PV_MAX_THD_PVS_BLS_BTS_TQ_LIM). The condition is reset if a transition of one brake bit from 1 to 0 is detected or the limitation has got active (LV_ACT_PVS_BLS_BTS_TQ_LIM = 1).

Formula section:

IF LV_ACT_PVS_BLS_BTS_TQ_LIM$_{(K-1)}$ == 1 **or**

(LV_BLS$_{(K-1)}$ == 1 and LV_BLS$_{(K)}$ == 0 **)** **or**

ENDIF

4.56.2.4 Activation

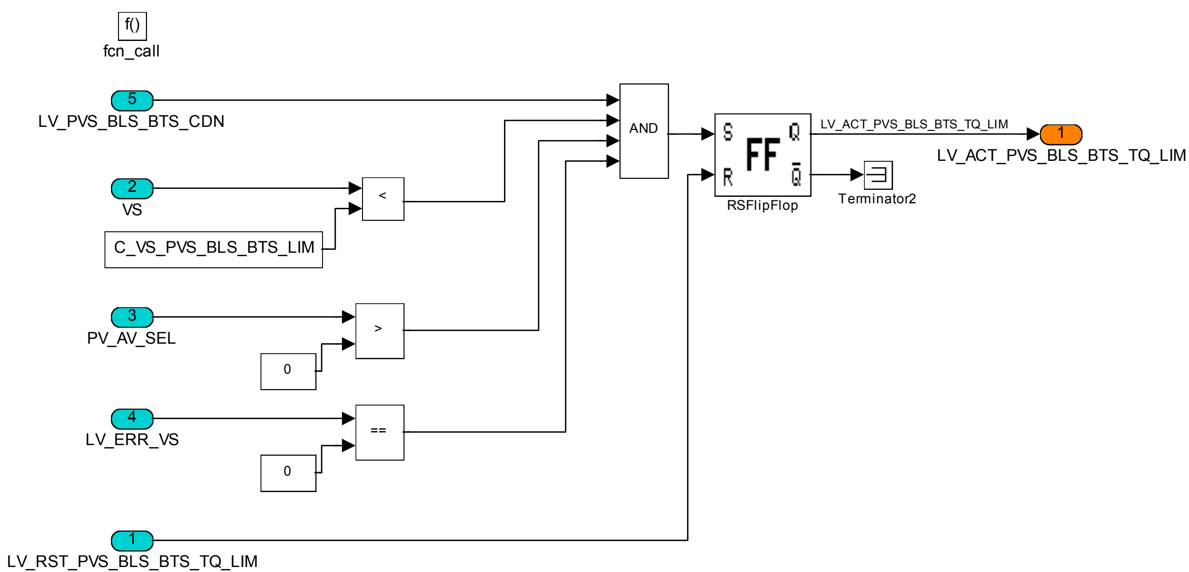

Figure 6: Activation

Description:

A limited scaling factor will be calculated if the flag LV_ACT_PVS_BLS_BTS_TQ_LIM is set.

The bit is set if the first condition has been fulfilled (LV_PVS_BLS_BTS_CDN = 1) and the vehicle speed is below C_VS_PVS_BLS_BTS_LIM threshold and no fault is detected on VS signal (LV_ERR_VS = 0) and the pedal value is higher 0% (PV_AV_SEL >0%).

The reset flag LV_RST_PVS_BLS_BTS_TQ_LIM resets the activation bit.

Formula section:

IF LV_RST_PVS_BLS_BTS_TQ_LIM == 1

THEN LV_ACT_PVS_BLS_BTS_TQ_LIM = 0

ELSE

IF LV_PVS_BLS_BTS_CDN == 1 **AND**

VS < C_VS_PVS_BLS_BTS_LIM **AND**

PV_AV_SEL > 0 **AND**

LV_ERR_VS == 0

THEN LV_ACT_PVS_BLS_BTS_TQ_LIM = 1

ENDIF

ENDIF

4.56.2.5 Scaling factor

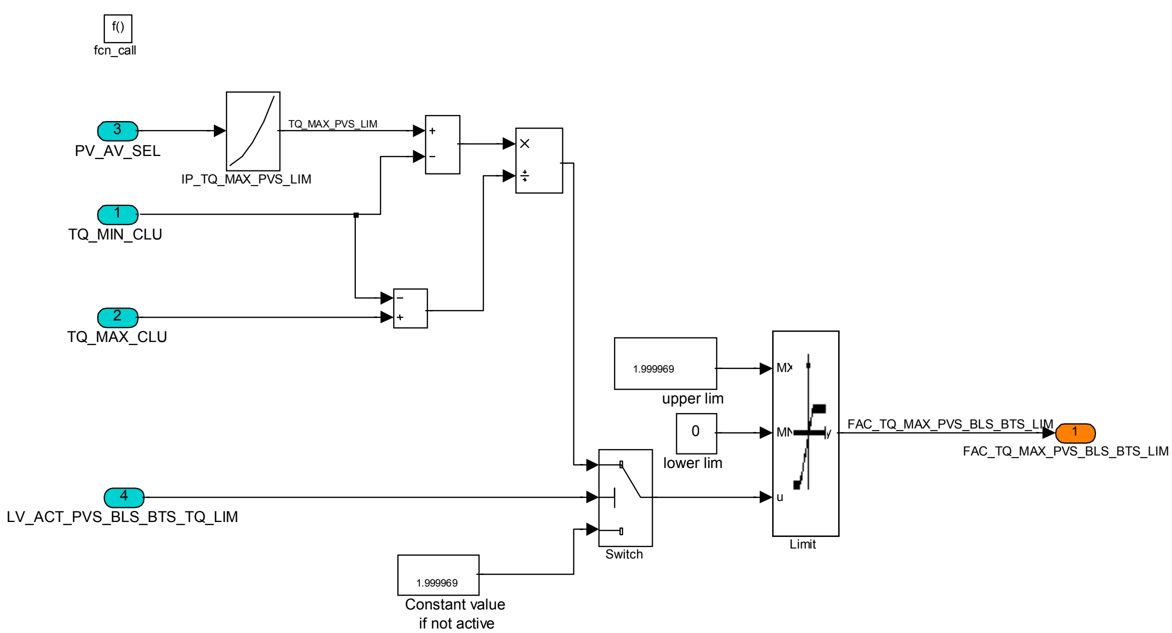

Figure 7: Scaling factor

Description:

If the activation conditions are fulfilled (LV_ACT_PVS_BLS_BTS_TQ_LIM ==1) the engine torque which can be requested by pedal is restricted to IP_TQ_MAX_PVS_LIM. As in torque management a scaling factor is required to calculate the engine torque, the scaling factor FAC_TQ_MAX_PVS_BLS_BTS_LIM is calculated for limitation.

If LV_ACT_PVS_BLS_BTS_TQ_LIM == 0 the factor is set to 1.999969.

Formula section:

TQ_MAX_PVS_LIM = IP_TQ_MAX_PVS_LIM (PV_AV_SEL)

IF LV_ACT_PVS_BLS_BTS_TQ_LIM ==1

THEN FAC_TQ_MAX_PVS_BLS_BTS_LIM = (TQ_MAX_PVS_LIM – TQ_MIN_CLU) / (TQ_MAX_CLU – TQ_MIN_CLU)

ELSE FAC_TQ_MAX_PVS_BLS_BTS_LIM = 1.999969

ENDIF

{ FAC_TQ_MAX_PVS_BLS_BTS_LIM is limited to max. 1.999969 and min. 0 }

Calibration data:

4.57 Kick down recognition / adaptation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_PVS_KD	O/V	0...1H	0...1	1	-
Flag for Kick-Down-Recognition (internally recognized from both PVS-Voltages)					
LV_KD	O/V	0...1H	0...1	1	-
Flag for Kick-Down-Recognition					
V_PVS_MAX_1	O/V	0...3FFH	0...4.995117	0.004883	V
Maximum voltage at upper mechanically stop PVS-channel 1					
V_PVS_MAX_2	O/V	0...3FFH	0...4.995117	0.004883	V
Maximum voltage at upper mechanically stop PVS-channel 2					

Input data:

V_PVS_FIL_1	V_PVS_FIL_2	LV_ERR_PVS_PRED	LV_ERR_PVS
LV_LIH_PVS_MOVE	LV_AT	LV_IGK	

FUNCTION DESCRIPTION:

General information:

The voltages of two PVS-channels depending on the PVS error system-status determine the Kick-Down operation.

General Application conditions:

Activation: LV_IGK == 1

LV_AT == 1

Deactivation: -

Initialization: LV_PVS_KD = 0

LV_KD = 0

V_PVS_MAX_1 = C_V_PVS_SP_MAX_1

V_PVS_MAX_2 = C_V_PVS_SP_MAX_2

Initialization conditions: same as in module ‘ Determination of accelerator pedal value (Application Incidences)

Recurrence: every 10 ms

Signal flow diagram:

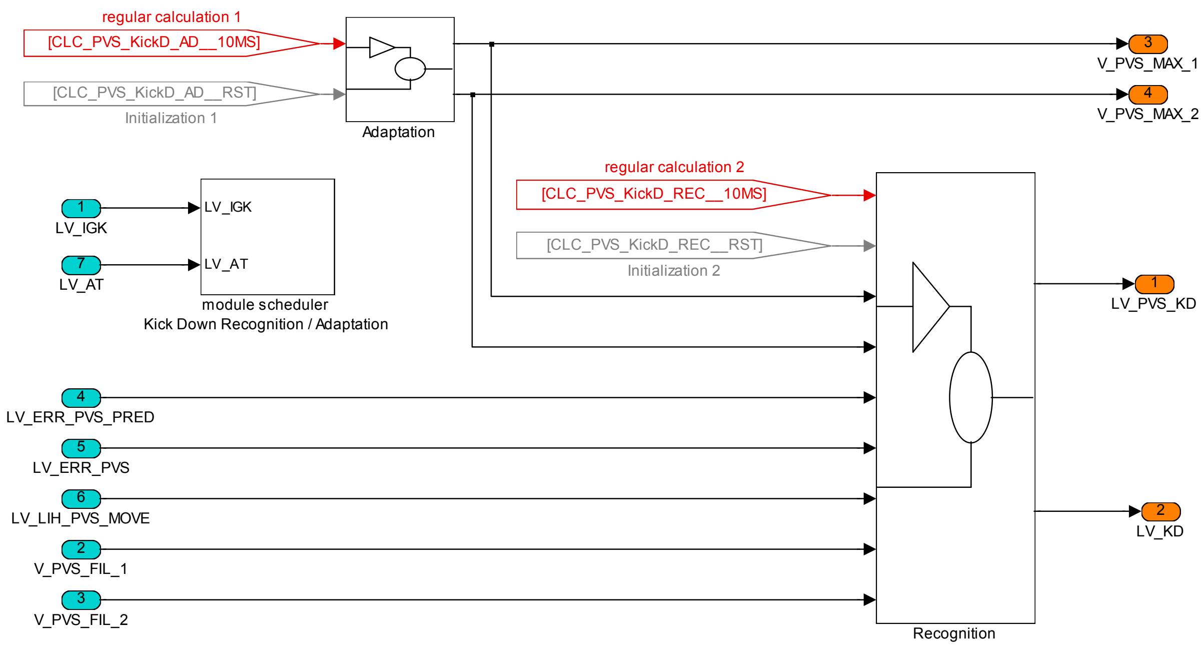

Figure 1: Kick Down Recognition / Adaptation

Description:

The module Kick Down Recognition / Adaptation is executed at function call CLC_PVS_KickD__10MS. Initialization is done at CLC_PVS_KickD__RST.

Calculation order (regular calculation):

1. Adaptation
2. Recognition

Initialization order:

1. Adaptation
2. Recognition

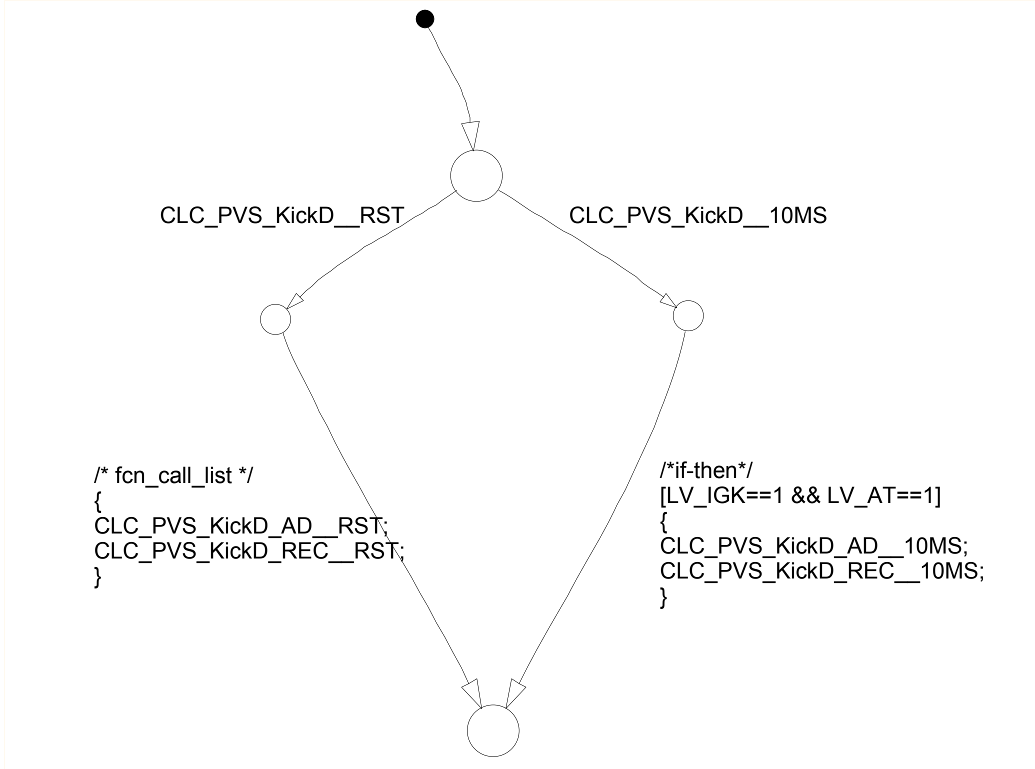

Figure 2: module scheduler “Kick Down Recognition / Adaptation”

4.57.1 Adaptation

General:

V_PVS_MAX_1 = C_V_PVS_SP_MAX_1 for channel 1 and
V_PVS_MAX_2 = C_V_PVS_SP_MAX_2 for channel 2.

In this case the calculation is only necessary at initialization and not every 10 ms.

4.57.2 Kick Down Recognition

Signal flow diagram:

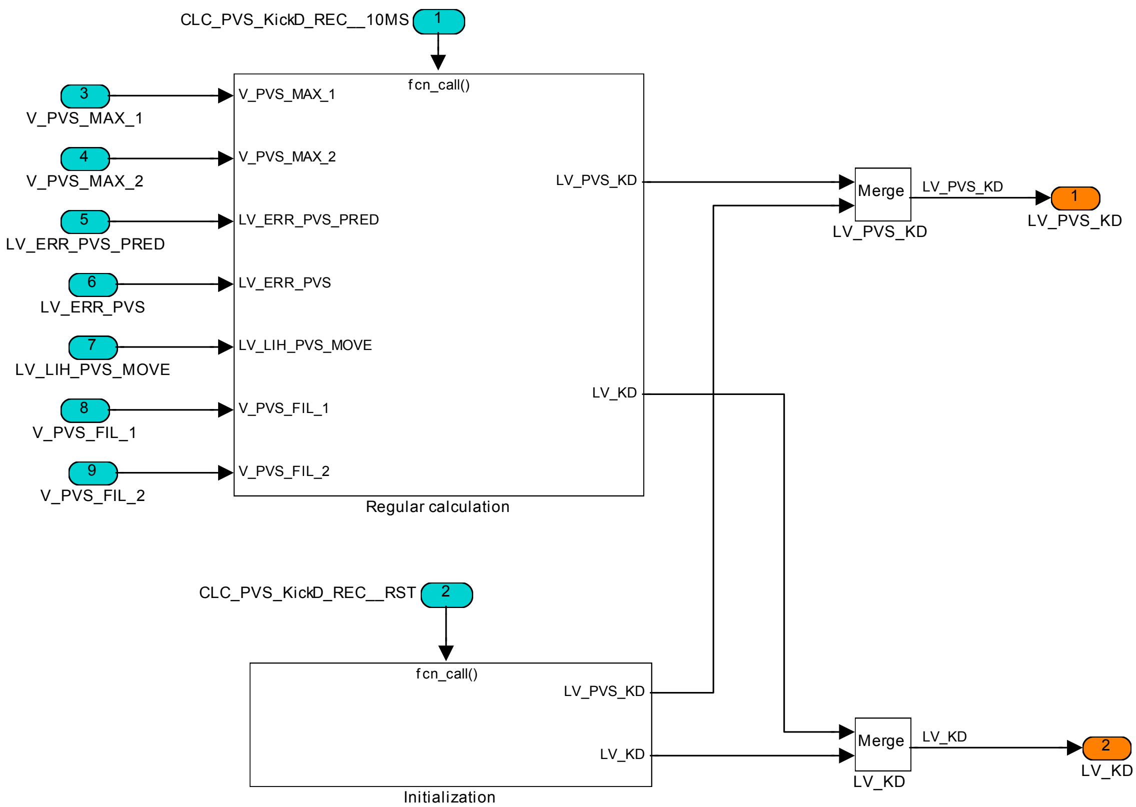

Figure 3: Kick Down Recognition

Description:

Regular calculation is done at function call CLC_PVS_KickD_REC__10MS. Initialization is done at CLC_PVS_KickD_REC__RST.

4.57.2.1 Initialization

At Initialization LV_PVS_KD and LV_KD are set to 0.

4.57.2.2 Regular calculation

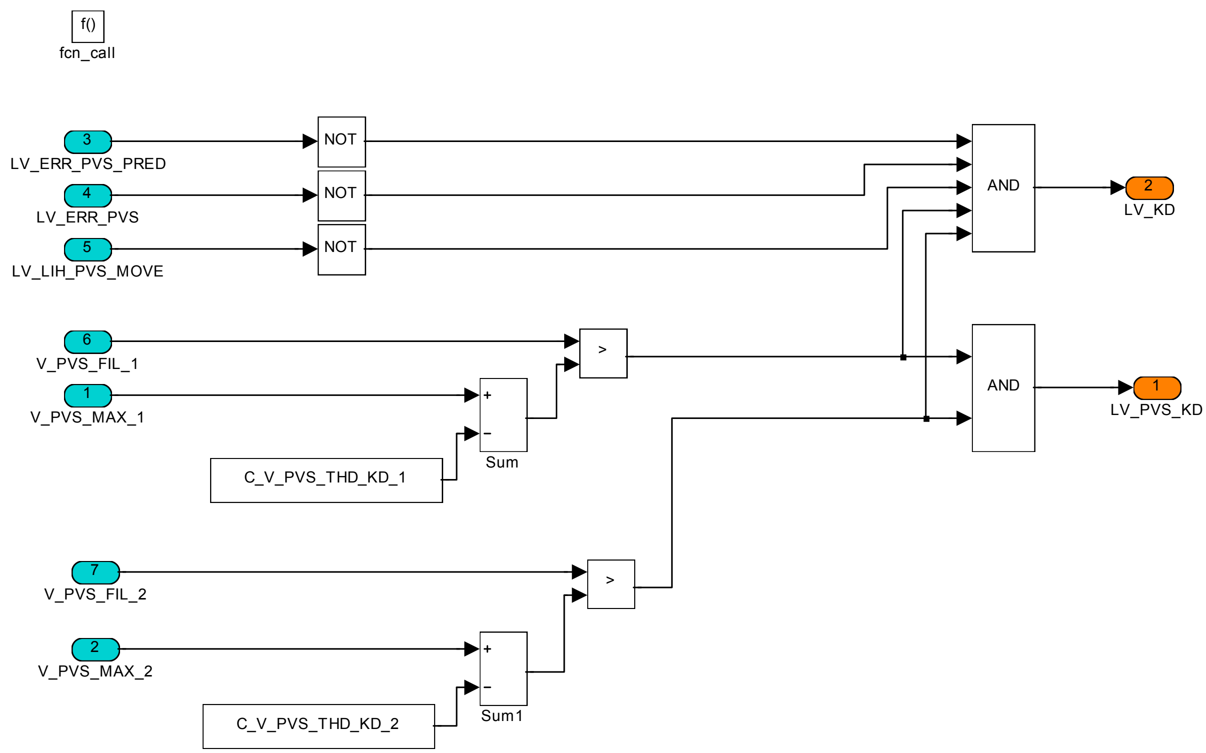

Figure 4: Regular calculation

Description:

Kick-Down recognition is done if there is no PVS-error predicted or present and the filtered signals of both channels exceed their thresholds.

Formula section:

Actual VIM position (rising feedback characteristic)					
VIM_AV_TMP_2	-	0...FFH	0...0.99609	3.9063e-3	[-]
Actual VIM position (falling feedback characteristic)					

Input data:

LV_IGK	V_VIM	V_VIM_AD_LONG	V_VIM_AD_SHO
CONF_VIM			

FUNCTION DESCRIPTION:

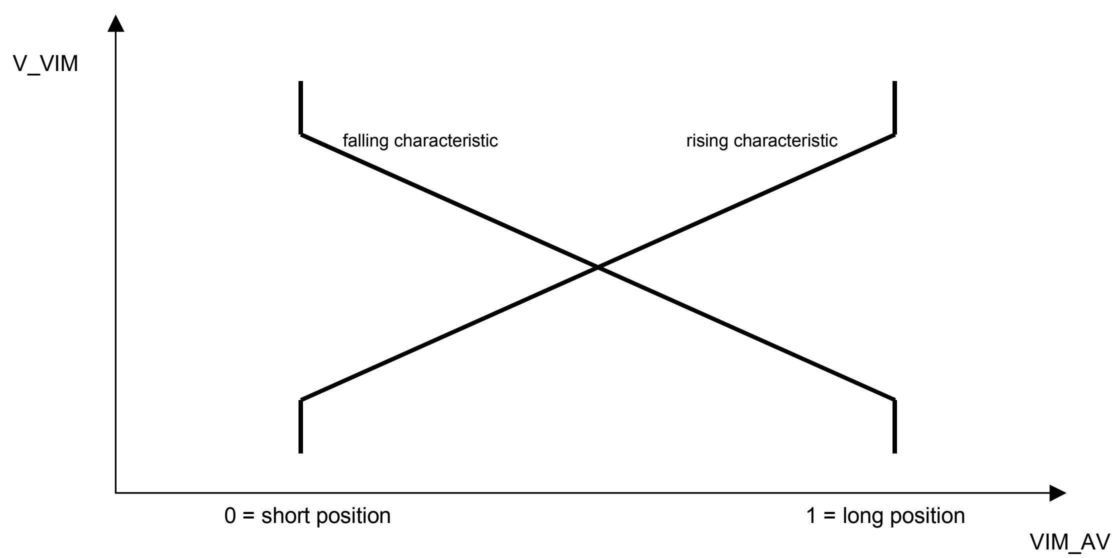
General information:

The calculation of the actual position of the variable intake manifold based on the feedback signal of the VIM actuator (V_VIM).

The values 0 and 1 point out the inactive (short intake length) or the switched (long intake length) position.

The measured voltage at the potentiometer is V_VIM. With the two adapted limitation stop values (V_VIM_AD_LONG/ SHO), V_VIM is transferred into VIM_AV.

The feedback characteristic (rising or falling characteristic) can be switched by a logical constant (LC_VIM_TYPE_SWI = 1 supports rising feedback characteristic).



Application conditions:

Initialisation: at LV_IGK = 0 → 1

VIM_AV = C_VIM_AV_SUB

Recurrence: 20 ms

Activation: LV_IGK = 1 and CONF_VIM = 2

Deactivation: LV_IGK = 0

Signal flow diagram:

4.59 Air Conditioning Pressure variables

4.59.1 Air Conditioning Pressure

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ACP	V/O	0...FFH	0...510	2	PSI
Air conditionning pressure					
ACP_RATIO	V	0...FFFFH	0...99.99847	0.001526	%
Air conditionning pressure ratio between V_ACP_MES and reference voltage					

Input data:

C_ACP_MIN_DIAG	V_ACP_MES	C_ACP_MAX_DIAG	VCC_SENS_SUB_MES

General information:

Acquisition reccurence : 100 ms

Formula section:

If V_ACP_MES >= C_ACP_MIN_DIAG

and V_ACP_MES <= C_ACP_MAX_DIAG

then ACP_RATIO = [V_ACP_MES / VCC_SENS_SUB_ MES] * 100

ACP = [ACP_RATIO – C_ACP_OFS] / C_ACP_SLOP

else ACP = 0

see Diagnosis and Limp home strategy in chapter A

endif

If the difference between the old and the new values of ACP exceeds the permissible gradient C_ACP_GRD_MAX, then the value remains unchanged. During the next measurement, if the maximum gradient is exceeded again, the new measured value will be stored in the RAM.

Errors are not stored with the monitoring of gradients. The only purpose is to extract invalid measured values (malfunctions).

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ACP_GRD_MAX	1	0...FFH	0...510	2	PSI
Maximum air conditioning pressure gradient					
C_ACP_OFS	1	0...FFFFH	0...99.99847	0,001526	%
Off value to calculate ACP					
C_ACP_SLOP	1	0...FFFFH	0...99.99847	0,001526	%/PSI
Gain value to calculate ACP					

4.59.2 AC pressure state STATE_ACP

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_ACP	V/O	0H 1H 2H 3H	ACP_L ACP_M_1 ACP_M_2 ACP_H	1	-
AC pressure state for cooling fans.					

Input data:

ACP	LV_ERR_ACP	LV_ERR_VCC_SENS_SUB	

FUNCTION DESCRIPTION:

General information:

The cooling fans are controlled according to the A/C pressure. For this purpose, the A/C pressure state is determined.

Formula section:

Initialization: At ECU initialization, STATE_ACP is set to ACP_L.

If (STATE_ACP = ACP_L **and** ACP **>** C_ACP_1_CFA)
then STATE_ACP **= ACP_M_1**

If (STATE_ACP = ACP_M_1 **and** ACP **<** C_ACP_1_CFA - C_ACP_HYS_1)
then STATE_ACP **= ACP_L**

If (STATE_ACP = ACP_M_2 **and** ACP **<** C_ACP_2_CFA - C_ACP_HYS_2)
then STATE_ACP **= ACP_M1**
If (STATE_ACP = ACP_M_1 **and** ACP **>** C_ACP_2_CFA)
then STATE_ACP **= ACP_M_2**

If (STATE_ACP = ACP_M_2 **and** ACP **>** C_ACP_3_CFA)
then STATE_ACP **= ACP_H**

If (STATE_ACP = ACP_H **and** ACP **<** C_ACP_3_CFA - C_ACP_HYS_3)
then STATE_ACP **= ACP_M_2**

Remark : C_ACP_1_CFA **<** C_ACP_2_CFA **<** C_ACP_3_CFA

Limp Home :

If LV_ERR_ACP = 1 *(Error currently present on AC pressure transducer)*

or LV_ERR_VCC_SENS_SUB = 1 *(Error currently present on voltage sypply for AC pressure transducer)*

then STATE_ACP = ACP_H

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ACP_1_CFA	1	0...FFH	0...510	2	PSI
AC pressure threshold for fans management.					
C_ACP_2_CFA	1	0...FFH	0...510	2	PSI
AC pressure threshold for fans management.

AC pressure hysteresis for STATE_ACP transition ACP_M_2 to ACP_M_1					
C_ACP_HYS_3	1	0...FFH	0...510	2	PSI
AC pressure hysteresis for STATE_ACP transition ACP_H to ACP_M_2					

4.60 Fuel pressure acquisition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FUP	V/O	0...FFFFH	0...173888	2.65	hPa
fuel pressure					

Input data:

AMP			

FUNCTION DESCRIPTION:

General information:

This file calculates the fuel pressure for port injection returnless fuel systems. The pressure is regulated by a mechanical pressure regulator. The reference pressure for that regulator is ambient pressure. Therefore the fuel pressure is an addition of the ambient pressure and the nominal feed pressure.

FUNCTION DESCRIPTION:

Initialization:

FUP = C_FUP_NOM + AMP

Recurrency: 100 ms

Formula section:

FUP = C_FUP_NOM + AMP

Calibration data:

Name	Dim	Hex.range	Phys.range	Res	Unit
C_FUP_NOM	1	0...FFFFH	0...5434.2598	0.08291	hPa
Nominal fuel pressure					

4.61 Gear ratio detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
GEAR	V/O	0...FFH	0...255	1	-
Common gear ratio independent from AT or MT					
GR_AT	V/O	0...FFH	0...255	1	-
Automatic transmission actual gear ratio					
GR_MT	V/O	0...FFH	0...255	1	-
Manual transmission gear ratio

Engine speed / vehicle speed ratio					
N_VS_RATIO_FIL	V/O	0...FFFFH	0...255.996	1/256	h/(km*min)
Filtered engine speed / vehicle speed ratio					
T_GR_CHG_LIM	V	0...FFH	0...2.55	0.01	s
Delay timer to confirm a limit change from wide to narrow					
T_NOT_PLAUS_GR	V	0...FFH	0...2.55	0.01	s
Delay timer for resetting the gear ratio of the manual transmission					
T_PLAUS_GR	V	0...FFH	0...2.55	0.01	s
Delay timer for setting the gear ratio of the manual transmission					

Input data:

VS_WORD	N	LV_ES	LV_ST
LV_AT	LV_CS	N_32	LV _ERR_VS
LV_PL	GR_AT_INTER	N_GRD	LV_DT
LC_DT_CS_USE	PV_AV		

General information:

Gear ratio calculation is depending of transmission type (manual or automatic) .

If either manual or semisequential transmission is detected, gear ratio is detected by using engine speed/vehicle speed ratio.

In case of automatic transmission, gear ratio is detected by using the CAN - Information of EGS.

In order to avoid transient torque or transient ignition interventions at gear shifts with manual transmission, the gear variable GR_MT is set to 0 at active clutch switch LV_CS.

The variable GEAR is a common gear ratio independent from AT or MT.

Application conditions:

Initialisation: following initalisations are required at reset or ignition key off to on :

GR_AT = 0
GEAR = 0
GR_MT = 0
GR_MT_PREV = 0
GR_SUB = 0
GR_SUB_PREV = 0

N_VS_RATIO=0

LV_N_GRD_POS = 0
LV_N_GRD_POS_PREV = 0
LV_WIDE_RNG_ACT_GR = 1

Reset delay time T_GR_CHG_LIM = 0
Reset delay time T_PLAUS_GR = 0
Reset delay time T_NOT_PLAUS_GR = 0

Recurrence: 10 ms

Activation: *In all engine operating states except LV_ES and LV_ST .*

Deactivation: *In engine operating states LV_ES and LV_ST.*
action: GR_MT = 0
GR_AT = 0

4.61.1 Configuration

The project has the possibility to use or not the clutch switch information in order to detect the gear ratio. This choice is proposed through the configuration bit : LC_GR_MT_CS_USE

If LC_GR_MT_CS_USE =1 (use of CS information to detect gear ratio)
then Strategy 1 is applied
else Strategy 2 is applied
endif

4.61.2 Manual transmission (LV_AT=0)

Formula section:

Determination of engine speed / vehicle speed ratio

If the gear ratio value is given by the CAN see directly "CAN messages EMS" specification.

The aim of this strategy is to put gr_mt to 0 when clutch is engaged. When vs_word is different from 0, calculation of N_VS_RATIO is made.
In case of failure, the ratio is set at its maximum value.

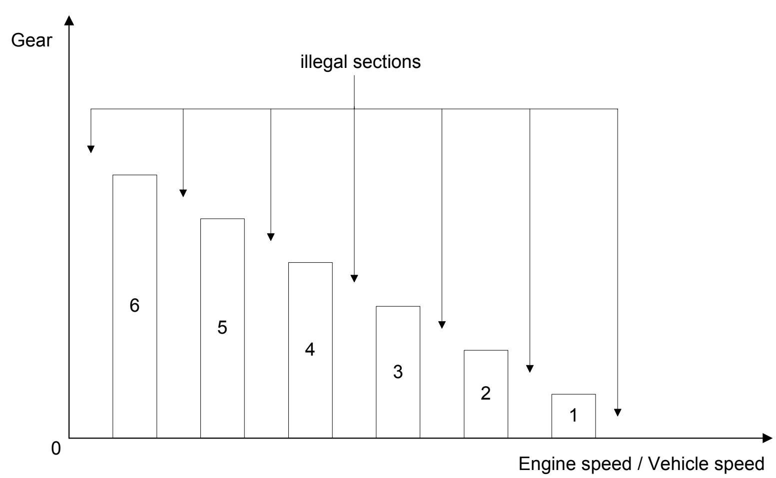
```
    If      (LV_AT = 0)
            If      (LV_ERR_VS = 0 and VS_WORD > 0)
then
                    N_VS_RATIO = N / VS_WORD
            else
                    N_VS_RATIO=FFFFH
                    GR_SUB_PREV = 0
            endif
    endif
```

4.61.2.1 Strategy 1: use of clutch switch information

Determination of gear position (variable GR_MT)

If a Manual Transmission is recognized the determination of the actual gear position is made by comparing the engine speed / vehicle speed ratio to the gear identification limits, during a stabilized duration C_GEAR_DLY_1.

The transition from a gear to gr_mt=0 must be confirmed during C_GEAR_DLY_2



Determination of gear box position (variable GR_MT)

The identification of a gear is made by engine speed to vehicle speed ratio.

```
If      LV_ES = 1 or LV_ST = 1 or LV_AT = 1 or
        N_VS_RATIO = FFFFH or LV_CS = 1
then    GR_MT = 0
else
        GR_SUB = ID_GR_MT (N_VS_RATIO)
        If      GR_SUB ≠ 0
        then    If      GR_SUB_PREV = 0
                then    T_NOT_PLAUS_GR = 0
                        Increment timer T_PLAUS_GR
                        GR_SUB_PREV = GR_SUB
                else    If      T_PLAUS_GR ≥ C_GEAR_DLY_1
                        then    GR_MT = GR_SUB
                                T_PLAUS_GR = 0
                        else    Increment timer T_PLAUS_GR
                        endif
                endif
        else    If      GR_SUB_PREV ≠ 0
                then    T_PLAUS_GR = 0
                        Increment timer T_NOT_PLAUS_GR
                        GR_SUB_PREV = GR_SUB
                else    If      T_NOT_PLAUS_GR ≥ C_GEAR_DLY_2
                        then    GR_MT = 0
                                T_NOT_PLAUS_GR = 0
                        else    Increment timer T_NOT_PLAUS_GR
                        endif
                endif
        endif
endif
```

4.61.3 Strategy 2: clutch switch information isn't used

Determination of gear box position (variable GR_MT)

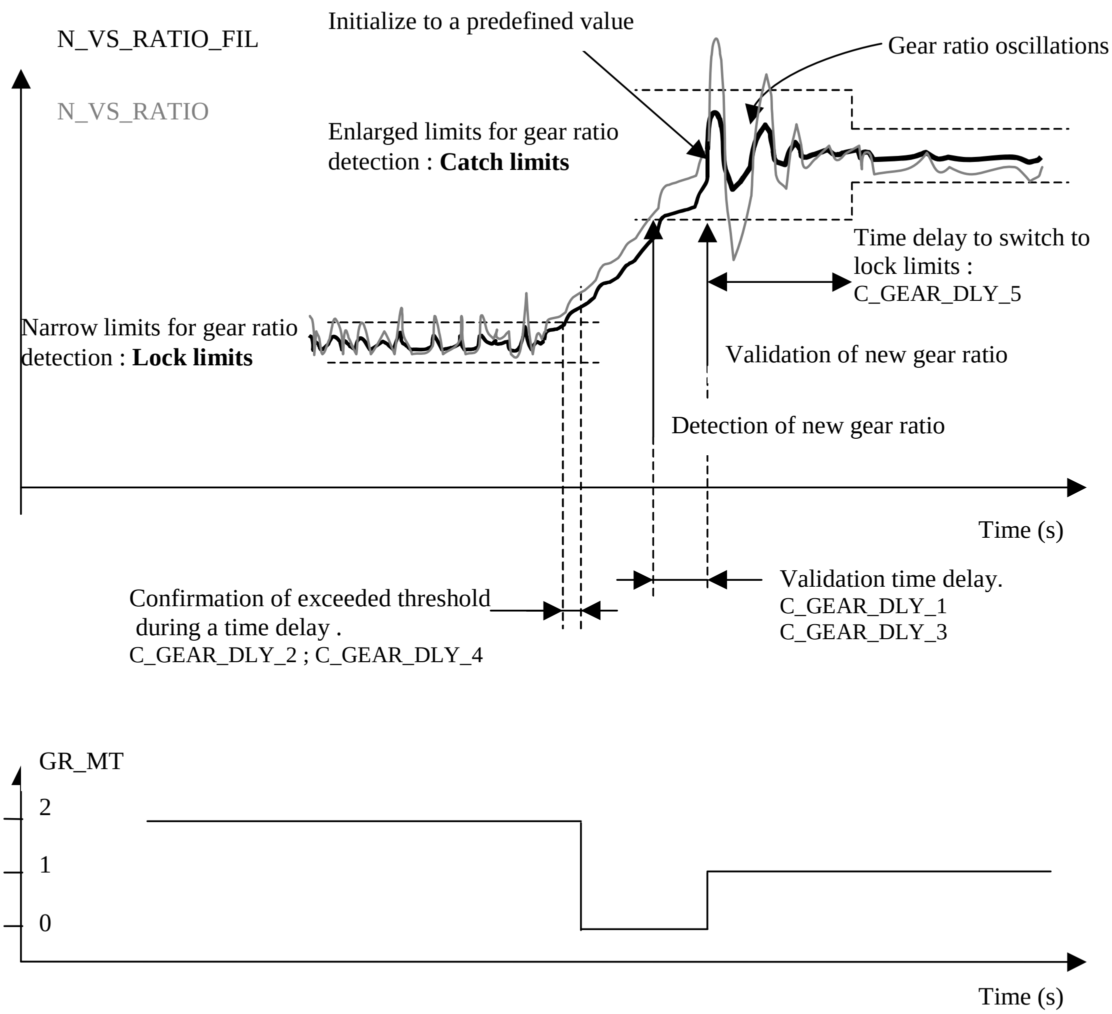
The aim of this strategy is to detect a gear change as fast as possible. It's based on a filtering which depend on present gear and engine speed in order to filter N_VS_RATIO oscillations (see gear ratio filtering). The gear identification is made by comparing the result of filtering (N_VS_RATIO_FIL) to predefined thresholds during a confirmation or validation time. We establish two kinds of limits:

Wide or catch limits: to detect a change from gear 0

Narrow or lock limits: to detect a change to gear 0.

The switch from the wide limits to the narrow limits is done after a time delay (C_GEAR_DLY_5).

Note: To avoid GR_MT oscillations, between gear 0 and the original gear as soon as the vehicle is declutched, we conserve the narrow limits only for the previous gear (see GR_MT_PREV). On the other hand, the change to the other gears is defined by the wide limits.



Determination of gear box position (variable GR_MT)

If a manual transmission is recognized, the identification of a gear is made by comparing the N_VS_RATIO_FIL to the gear identification limits, during a stabilized duration.

```
If          LV_ES = 1 or LV_ST = 1 or LV_AT = 1
then
            GR_MT = 0
            GR_MT_PREV = 5
            GR_SUB_PREV = 0
            N_VS_RATIO_FIL = 0
else        (Gear Ratio Filtering; Limits Determination)
    If      (LV_DT = 0 and LC_DT_CS_USE= 0 and PV_AV ≤ C_PV_AV_GEAR_MIN)
    then    GR_MT = 0
            GR_SUB = ID_GR_MT_RNG_1(N_VS_RATIO_FIL)
    else
            If      LV_WIDE_RNG_ACT_GR = 1 (Wide limit active)
            then    GR_SUB = ID_GR_MT_RNG_1 (N_VS_RATIO_FIL)
                     If     GR_SUB = GR_MT_PREV and GR_MT=0
                    then    (Narrow limit active)
                            GR_SUB = ID_GR_MT_RNG_2 (N_VS_RATIO_FIL)
                    endif
            else    (Narrow limit active)
                    GR_SUB = ID_GR_MT_RNG_2 (N_VS_RATIO_FIL)
            endif

            If      GR_SUB ≠ 0
            then    If      GR_SUB_PREV = 0
                    then    T_NOT_PLAUS_GR = 0
                            Increment timer T_PLAUS_GR
                            GR_SUB_PREV = GR_SUB
                    else    If      T_PLAUS_GR ≥ C_GEAR_DLY_3
                            then    GR_MT = GR_SUB

                            else    Increment timer T_NOT_PLAUS_GR
                            endif
                    endif
            endif
    endif
endif
```

Reset of GR_MT_PREV at stopped vehicle:
```
If      VS_WORD = 0
then    GR_MT_PREV = 0
endif
```

Gear Ratio Filtering :

The aim is to filter engine speed oscillations which can appear during a gear change.

```
if      N_VS_RATIO(n) = FFFFH
then    N_VS_RATIO_FIL(n) = FFFFH
else    N_VS_RATIO_FIL(n) = N_VS_RATIO_FIL(n-1) + ID_CRLC_N_VS_RATIO_FIL *
        (N_VS_RATIO(n) -N_VS_RATIO_FIL(n-1))
endif
```

Limits Determination :

As long as the engine state is part load, we use the wide limits. On the other hand, for the other engine states, as soon as the engine speed gradient is lower than a threshold, we use the narrow limits after a time delay (C_GEAR_DLY_5).

```

Timer for the detection of a closed drive train.					
T_DT_IS_SHIFT	V	0...FFFFH	0...655.35	0.01	s
Timer for the detection of a closed drive train in idle speed.					
LV_N_GEAR_SHIFT_BEG_AUTH	V	0...1H	0...1	1	-
Authirization for storing N_GEAR_SHIFT_BEG.					
T_PV_AV_GR_SUB	V	0...FFFFH	0...655.35	0.01	s
Timer for the detection of a closed drive train, if GR_SUB is <> 0					

Input data:

LV_CS	LV_AT	LV_DRI	VS
GR_MT	N_GRD	LV_ES	PV_AV
LV_PUC	N_DIF_REF_LPF_AJ	LV_IS	GR_SUB
LV_CLU_SWI	N	TQI_REQ_DRIV	N_VS_RATIO_FIL
MAF	PV_CRU	LV_PU	

General information:

Drive train engaged active (LV_DT=1) means drive train is closed, engine torque is transmitted to the wheels and the vehicle is running (VS >= C_VS_MIN_DT). For the anti - jerk function the DT detection is expanded. The drive train is engaged after Clutch switch is detected and a positive engine speed gradient is detected.

The dependabillity to the vehicle-speed has different reason for AT and MT vehicle.

AT:

With engaged gear it´s normally not necessary to have an agressive idle-speed control. The only exception is a sudden breaking at slowly moving vehicle with engaged gear. In this case it´s necessary to switch to the strong P_D - parameter map of the idle-speed control to avoid idle-speed break-down.

MT:

At start of the vehicle without pushing the accelerator pedal it´s necessary to switch as fast as possible to the smooth P_D idle-speed control map to avoid vehicle jerking. Depending on slip of the clutch it may last too long until a gear-position determination is possible. Therefore in this case the switching from agressive to the smooth P_D map can happen even at slow vehicle speed.

Nevertheless the actualisation of LV_DT is strongly depending on the update-rate of the input signal ‘VS’.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: at reset, LV_DT = 0; T_DT_TRANS = 0; T_DT_IS_SHIFT = 0

Update rate: 10 ms

4.62.1 Configuration

The project has the possibility to use or not the clutch switch information in order to detect the drive train. This choice is proposed through the configuration bit : LC_DT_CS_USE

If LC_DT_CS_USE =1 (use of CS information to detect drive train engaged)
then Strategy 1 is applied
else Strategy 2 is applied
endif

4.62.2 Manual transmission

Strategy 1 : use clutch switch information

Formula section:

```
If    LV_AT = 0
Then
      If      LV_ES = 0
      Then
              If      LV_CS change from 0 to 1 or
              (GR_MT = 0  and   VS <  C_VS_MIN_DT)
              Then  LV_DT = 0
              Else
                      If      LV_CS = 0 and N_GRD > C_N_GRD_MIN_DT
                      Then  LV_DT = 1
                      Endif
              Endif
      Else    LV_DT=0
      Endif
Endif
```

Strategy 2: the clutch switch information isn't reliable or available:

Formula section:

Detection of engine overshoot at gear shifts:

```
If    PV_AV                     = 0                          and
      VS                        > C_VS_N_RISE_GEAR_SHIFT     and
      N                         > C_N_RISE_GEAR_SHIFT        and
      LV_DT                     = 1
then
      if    LV_N_GEAR_SHIFT_BEG_AUTH = 1
      then
      N_GEAR_SHIFT_BEG = N
      T_N_RISE_GEAR_SHIFT  =  C_T_N_RISE_GEAR_SHIFT
      LV_N_GEAR_SHIFT_BEG_AUTH = 0
      endif
      if          N > N_GEAR_SHIFT_BEG + IP_N_GEAR_SHIFT_OFS        and
                  T_N_RISE_GEAR_SHIFT  > 0
      then        gear shifting is detected by the engine speed overshoot
                  LV_N_RISE_GEAR_SHIFT = 1
                  LV_N_GEAR_SHIFT_BEG_AUTH = 1
      else
                  LV_N_RISE_GEAR_SHIFT = 0
      endif
      decrement T_N_RISE_GEAR_SHIFT
else
      LV_ N_RISE_GEAR_SHIFT           = 0
      LV_N_GEAR_SHIFT_BEG_AUTH        = 1
endif
```

Upper voltage threshold for WRAF sensor signal					

4.63.1 EGCP_SIGCVLSL3

The raw output voltage representing lambda which is provided by BSW is processed within this module and mapped with the system variable VLS_UP[i].

The signal acquisition shall take place at BSW level and the value VLS_UP_RAW[i] will be updated every 10 ms. The output of this module VLS_UP[i] is same as the raw value delivered by BSW.

The signal is monitored for possible clipping due to saturation effects with signal levels close to the range limits of the output amplifier.

The bit LV_VLS_UP_INIT[i] is not applicable here and hence initialized to zero.

The calculation shall be done for all exhaust cylinder banks.

NC_CBK_EX_NR defines the number of exhaust banks. For vector elements, the variable extension „_i“ is used in the model instead of „[i]“ as found in the textual description.

Function Description

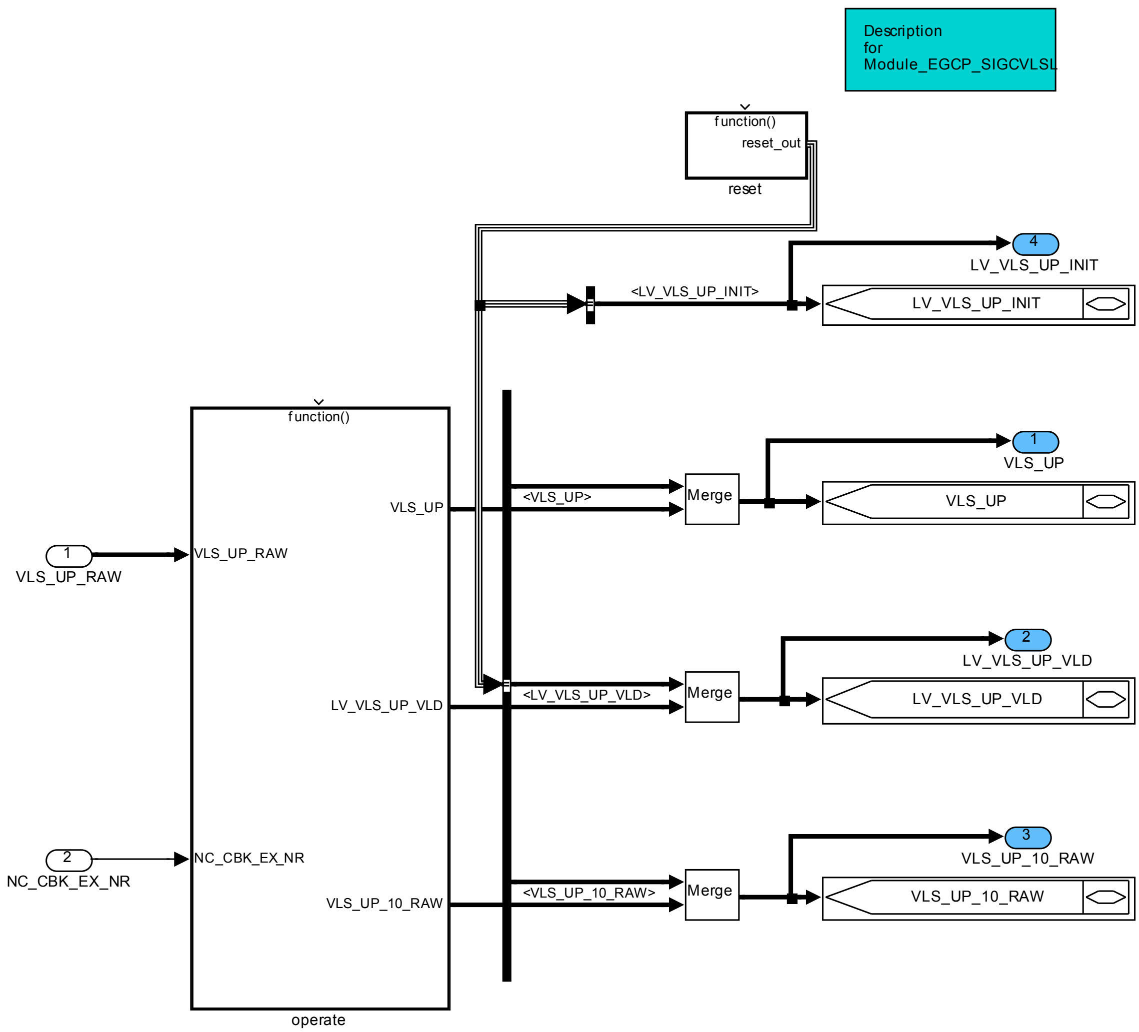

Figure 394 EGCP_SIGCVLSL3

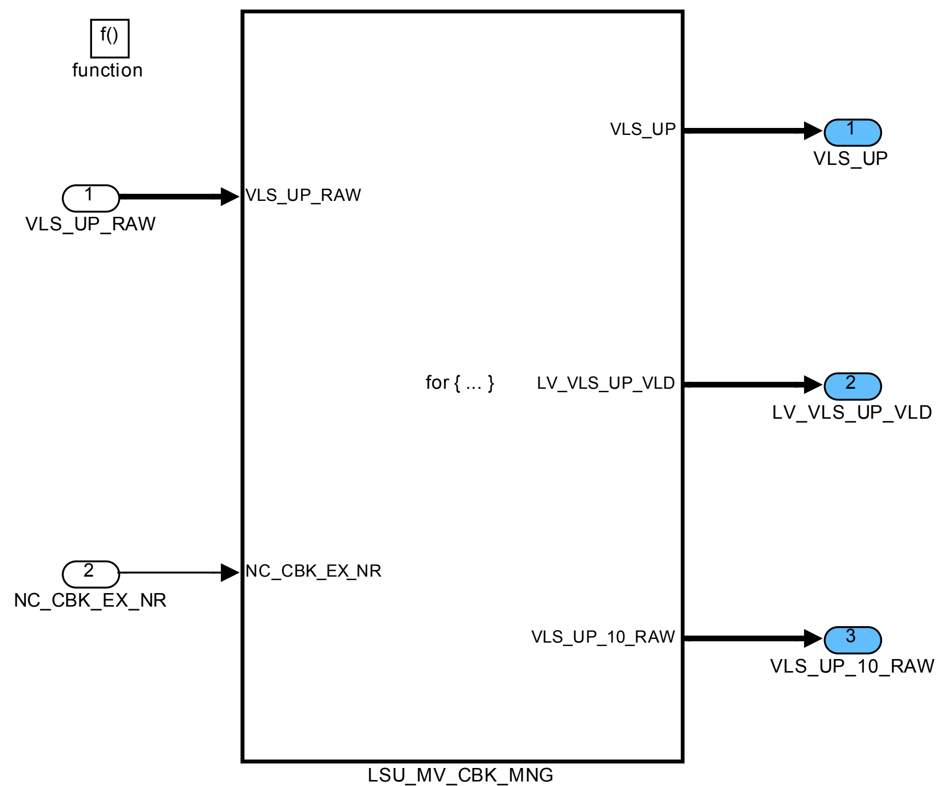

Figure 395 EGCP_SIGCVLSL3/ operate

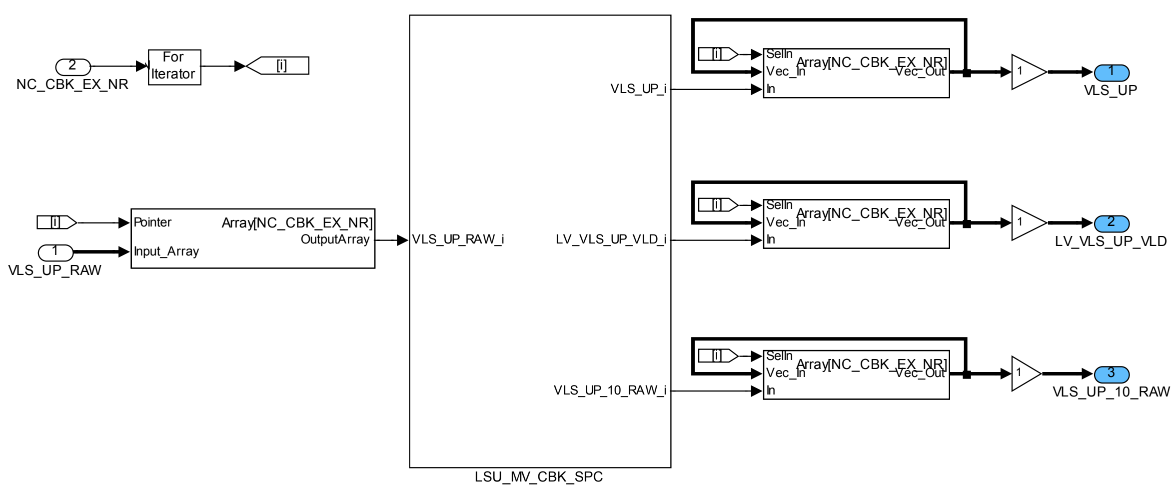

Figure 396 EGCP_SIGCVLSL3/ operate/ LSU_MV_CBK_MNG

Detection of voltage clipping

The raw signal voltage is always compared with limit values and checked for clipping of signal if any. Accordingly the flag LV_VLS_UP_VLD[i] will be set.

FUNCTION DESCRIPTION:

General information:

The function shall provide the output variable R_IT_LS_DOWN[i], the internal resistance of the oxygen sensor. The resistance is dependent on the operating temperature of the sensor and may be used for oxygen sensor diagnosis.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

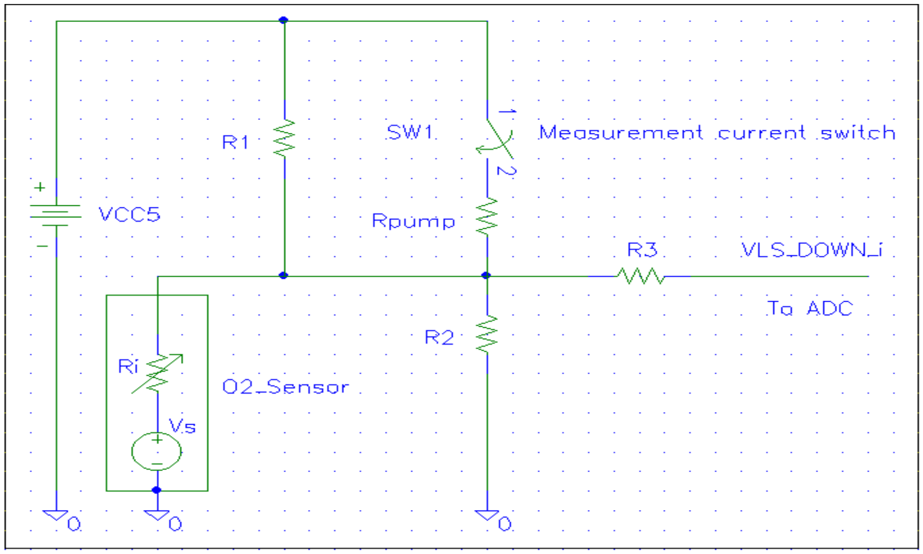

Figure 1 Simplified measurement circuit schematic, Internal resistance determination

Signal flow diagram:

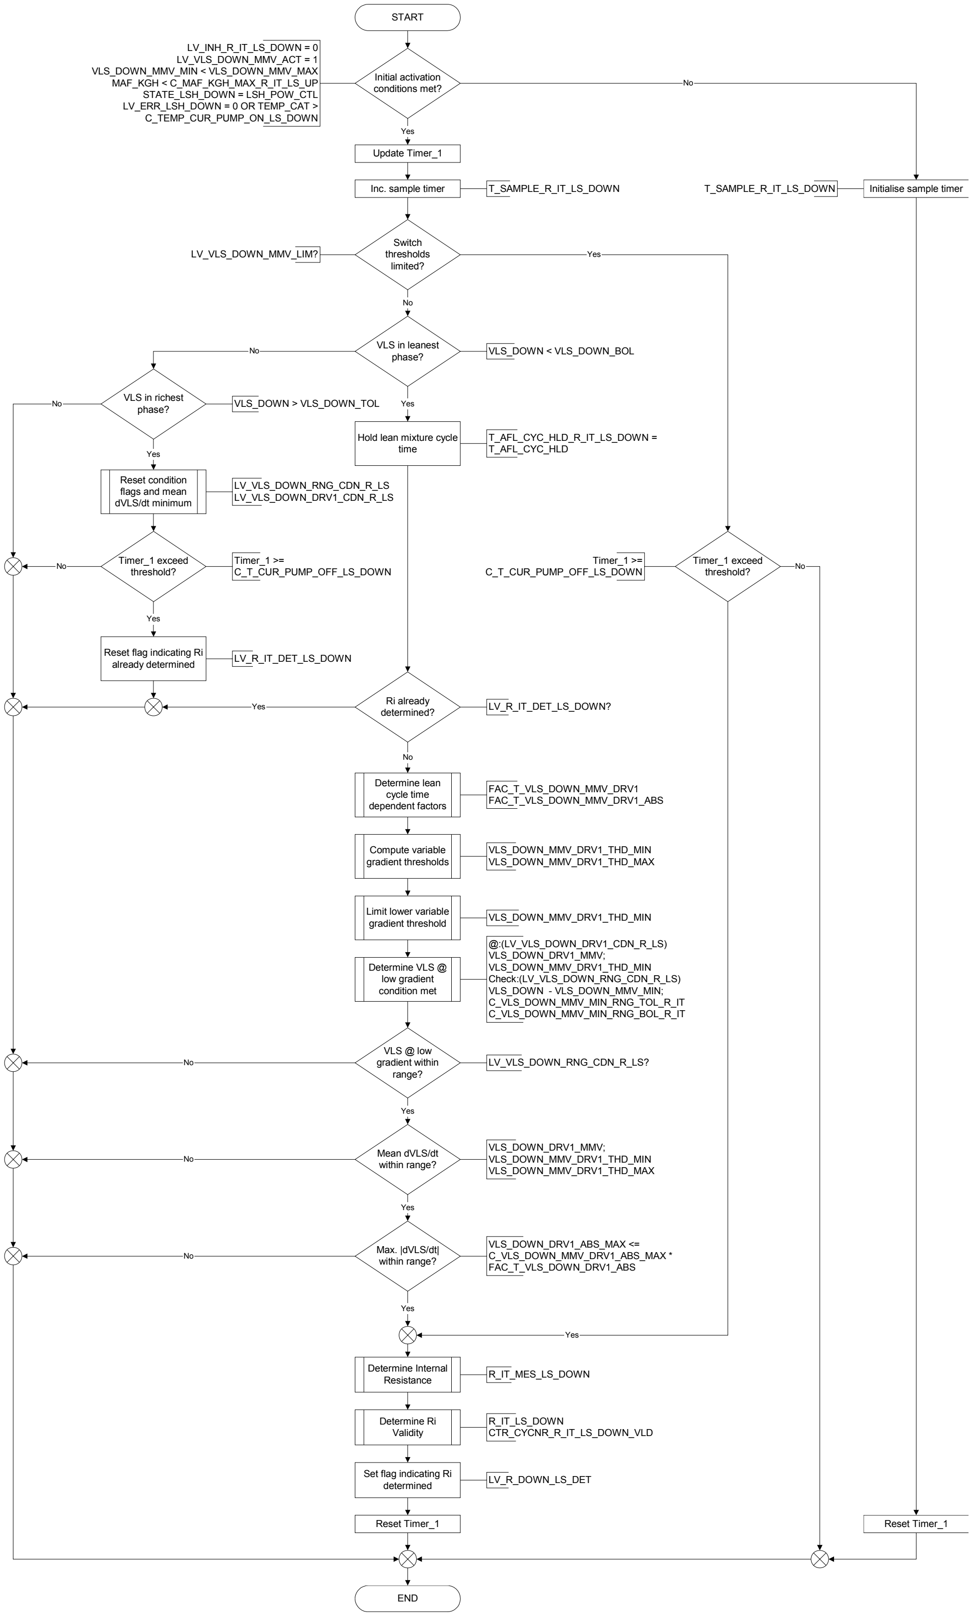

Figure 2 Function flow chart, Internal resistance determination

Description:

The internal resistance of the oxygen sensor shall be determined by use of the oxygen sensor interface circuit *Figure 1* (Capacitors not shown). The internal resistance provides information as to the tip temperature of the sensor and may be used for diagnosis purposes and operative readiness determination.

Under normal conditions, the switch SW1 shall be open and the oxygen sensor signal voltage (VLS_DOWN[i]) is measured by the microcontroller.

The potential divider (resistors R_1 & R_2) shall be permit the operation readiness of the oxygen sensor to be determined and enable electrical fault conditions to be detected.

Periodically, for a limited amount of time, the switch SW1 shall be closed and a voltage of approx. 4.8 V connected through resistor R_{pump} to the oxygen sensor signal connection. This shall cause current to flow into the sensor and through the internal resistance R_i, thereby “pumping” the sensor. The resultant voltage acquired at the microcontroller input shall permit the internal resistance of the sensor to be calculated by use of a formula shown in the formula section below.

Prior to permitting the determination of the internal resistance, a number of conditions shall be determined to be met:

The initial activation conditions shall require that: No function inhibit is requested (LV_INH_R_IT_LS_DOWN[i] = 0); Delay since deactivation since last overrun fuel cut-off passed (LV_VLS_DOWN_MMV_ACT); The initial post initialisation transients have passed for the VLS_DOWN_MMV_xxx[i] inputs (VLS_DOWN_MMV_MIN[i] < VLS_DOWN_MMV_MAX[i]); The engine load threshold has not been exceeded (MAF_KGH < C_MAF_KGH_MAX_R_IT_LS_DOWN); The oxygen sensor heater state LSH_POW_CTL has been reached; No heater OBDI error has been detected in the relevant heater driver (LV_ERR_LSH_DOWN[i]) or should a heater driver fault have been detected, the modelled catalyst temperature TEMP_CAT shall exceed the threshold C_TEMP_CUR_PUMP_ON_LS_DOWN

Once the above conditions have been met, an internal timer (*TIMER_1*) shall be started and timer T_SAMPLE_R_IT_LS_DOWN[i] shall be updated. The latter timer shall be initialised with its maximum value of 655.35 s. This ensures that the temperature limits for the validity function are correctly initialised. The further procedure shall depend on the status of the oxygen sensor signal, as determined by LV_VLS_DOWN_MMV_LIM. Should the VLS_DOWN_MMV_xxx[i] signals be limited, i.e. no or little oxygen sensor amplitude is present, the function shall determine the internal resistance every (C_T_CUR_PUMP_OFF_LS_DOWN + C_T_CUR_PUMP_ON_LS_DOWN + C_T_DLY_CUR_PUMP_LS_DOWN). Otherwise the oxygen sensor signal shall be determined to have significant amplitude and the internal resistance determination shall only be carried out in lean phases where the oxygen sensor signal is relatively flat and stable. This is achieved by the following conditions:

If the oxygen sensor signal is lean (VLS_DOWN[i] < VLS_DOWN_BOL[i]) and neither the resistance determination has been carried out yet in this lean phase nor the determination be locked out due to the minimum off time (LV_R_IT_DET_LS_DOWN[i] = 0) then the function shall determine the lean cycle time dependent factors FAC_T_VLS_DOWN_MMV_DRV1[i] & FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] from the appropriate maps IP_FAC_T_DRV1_VLS_DOWN_MMV & IP_FAC_T_VLS_DOWN_MMV_DRV1_ABS respectively. These factors shall be dependent on the held lean cycle time from the previous lean cycle (T_AFL_CYC_HLD_R_IT_LS_DOWN[i]). Should the cycle time decrease then it is intended that the factors shall increase and vice versa.

The thresholds for the gradient condition shall then be computed. These thresholds (VLS_DOWN_MMV_DRV1_THD_MAX[i] & VLS_DOWN_MMV_DRV1_THD_MIN[i]) are directly proportional to the amplitude of the difference between VLS_DOWN_MMV_xxx[i] signals. Furthermore, VLS_DOWN_MMV_DRV1_THD_MIN[i] shall be modified by factor FAC_T_VLS_DOWN_MMV_DRV1[i]. The factor FAC_T_VLS_DOWN_MMV_DRV1[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD_R_IT_LS_DOWN[i] is valid.

The variable threshold VLS_DOWN_MMV_DRV1_THD_MIN[i] shall be limited so that its value is not less than that of VLS_DOWN_DRV1_MMV_MIN[i] * C_FAC_VLS_DOWN_MMV_DRV1_THD_MIN.

The function shall then wait for the oxygen sensor signal gradient to exceed the minimum threshold (VLS_DOWN_DRV1_MMV[i] ≥ VLS_DOWN_MMV_DRV1_THD_MIN[i]) and then determine whether the absolute oxygen sensor signal voltage is within a particular range of the VLS_DOWN_MMV_MIN[i] signal (VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT ≤ VLS_DOWN[i] ≤ VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT). If this is the case, the VLS_DOWN[i] shall be considered to be consistent with previous lean phase amplitudes and resistance determination may be carried out. This condition shall only be carried out once per lean phase. i.e. at transition from rich to lean. The fulfilment of the gradient condition is indicated by LV_VLS_DOWN_DRV1_CDN_R_LS[i] and the fulfilment of the range condition by LV_VLS_DOWN_RNG_CDN_R_LS[i].

If the range condition has been met, the gradient is in a particular range (VLS_DOWN_MMV_DRV1_THD_MIN[i] ≤ VLS_DOWN_DRV1_MMV[i] ≤ VLS_DOWN_MMV_DRV1_THD_MAX[i]) and the oxygen sensor signal is determined to be stable in the short term (VLS_DOWN_DRV1_ABS_MAX[i] ≤ C_VLS_DOWN_MMV_DRV1_ABS_MAX * FAC_T_VLS_DOWN_MMV_DRV1_ABS[i]) then resistance determination is requested (LV_R_IT_REQ_LS_DOWN[i] = 1). The factor FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD_R_IT_LS_DOWN[i] is valid.

Once internal resistance determination has been requested, the Basic SW shall take a single VLS_DOWN[i] sample and store as VLS_DOWN_CUR_PUMP_OFF[i]. SW1 shall be switched ON, at time C_T_CUR_PUMP_ON_LS_DOWN[i] and the VLS_DOWN[i] shall be masked. A second oxygen sensor signal voltage sample shall be taken and stored as VLS_DOWN_CUR_PUMP_ON[i]. SW1 shall then be switched OFF and masking shall continue for a time C_T_DLY_CUR_PUMP_LS_DOWN, after which the VLS_DOWN[i] shall return to normal following of the oxygen sensor signal voltage. Masking shall be discontinued if the oxygen sensor signal voltage exceeds VLS_DOWN_CUR_PUMP_ON[i] + C_VLS_HYS_R_IT_LS_DOWN during the time C_T_DLY_CUR_PUMP_LS_DOWN after switching off SW1. Adding the voltage hysteresis shall prevent the function to discard lambda sensor voltage masking if the first VLS_DOWN[i] value after switching off the pump current is larger than the last VLS_DOWN[i] value while pumping due to signal noise.

The internal resistance R_IT_MES_LS_DOWN[i] shall be determined using the formula stated with the main variables being oxygen sensor voltage prior to pumping, VLS_DOWN_CUR_PUMP_OFF[i], and signal voltage during pumping, VLS_DOWN_CUR_PUMP_ON[i].

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, a counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available.

NOTE: During the time where SW1 is switched on, (LV_R_IT_REQ_LS_DOWN[i]=1) the output voltage of the oxygen sensor (VLS_DOWN[i]) does not represent the true A/F ratio and is therefore invalid and shall not be used as such. The basic software shall mask the response of the sensor to pumping by keeping the voltage constant during this time by using the last VLS_DOWN[i] sample prior to activating SW1.

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, the validity of the resistance shall be checked:

Should the validity function not be inhibited (LC_R_IT_VLD_INH_LS_DOWN = 0), then the tip temperature of the ceramic shall be determined from a map. TTIP_MES_LS_DOWN[i] represents the nominal temperature, TTIP_MES_TOL_LS_DOWN[i] represents the maximum temperature (R_IT_MES_LS_DOWN[i] * (1 – C_FAC_R_IT_ERR_NEG_LS_DOWN)), i.e. temperature for resistance with negative measurement error and TTIP_MES_BOL_LS_DOWN[i] represents the minimum temperature (R_IT_MES_LS_DOWN[i] * (1 + C_FAC_R_IT_ERR_NEG_LS_DOWN)), i.e. temperature for resistance with positive measurement error. A low pass filter shall then be applied to the upper and lower temperature limits to represent the maximum possible temperature gradient between resistance samples. Dependent on the direction of change of resistance between two measurements, either constant C_CRLC_TTIP_RISE_R_IT_LS_DOWN (rising temp.) or C_CRLC_TTIP_FALL_R_IT_LS_DOWN (falling temp.) shall be applicable. The final filter constant used, limited to a maximum of 1, shall be the aforementioned constant multiplied by the time between resistance samples (T_SAMPLE_R_IT_LS_DOWN[i]). This shall be to compensate for the irregular sample time.

Should then the ceramic tip temperature fall within the temperature limit bounds, the measured resistance shall be considered to be valid, shall be passed to the output variable R_IT_LS_DOWN[i], the counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available and the T_SAMPLE_R_IT_LS_DOWN[i] shall be reset. If the above temperature condition is not met, R_IT_LS_DOWN[i] shall be maintained at its last value and the filtered temperature limits shall be reset to their previous values, i.e. the resistance value shall be ignored.

Should the validity function be inhibited then for each new resistance the R_IT_MES_LS_DOWN[i] shall be passed to R_IT_LS_DOWN[i] and the counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented.

In the case of significant oxygen sensor amplitude (LV_VLS_DOWN_MMV_LIM = 0) and the sensor signal be in the rich phase (VLS_DOWN[i] > VLS_DOWN_TOL[i]), the flags LV_VLS_DOWN_RNG_CDN_R_LS[i] & LV_VLS_DOWN_DRV1_CDN_R_LS[i] shall be reset. Furthermore, if these conditions have been met and the timer *TIMER_1* exceeds C_T_CUR_PUMP_OFF_LS_DOWN then LV_R_IT_DET_LS_DOWN[i] shall be reset, thereby permitting the internal resistance to be determined in the next cycle should the appropriate conditions be met.

For reference reasons of OBD II diagnosis the value R_IT_MDL_LS_DOWN_NEW[i] is calculated out of heating power, exhaust gas temperature and MAF_KGH.

Application conditions:

Recurrence: T_SAMPLE_1 = 10 ms

The function shall be carried out once every 10 ms. The internal resistance value shall only be calculated after “pumping” the oxygen sensor. See recurrence there. Reference internal rsistance shall be calculated with recurrence 1 s.

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

R_IT_LS_DOWN[i] = 65535
R_IT_MES_LS_DOWN[i] = 65535
R_IT_MDL_LS_DOWN_NEW[i] = 65535

(1 - IP_CRLC_TTIP_REF_MDL_LS_DOWN) +

IP_CRLC_TTIP_REF_MDL_LS_DOWN * TEG_CAT_DOWN_MDL[i]

% IP (MAF_KGH)

R_IT_MDL_LS_DOWN_NEW[i] = IP_R_IT_MDL_LS_DOWN_NEW

% IP (POW_MMV_LSH_DOWN[i]; TTIP_REF_MDL_MMV_LS_DOWN[i])

Determine lean cycle time dependent factors:

If (CTR_AFL_CYC[i] ≥ C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN)

then FAC_T_VLS_DOWN_MMV_DRV1[i] =
IP_FAC_T_DRV1_VLS_DOWN_MMV (T_AFL_CYC_HLD_R_IT_LS_DOWN[i])

FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] =
IP_FAC_T_VLS_DOWN_MMV_DRV1_ABS (T_AFL_CYC_HLD_R_IT_LS_DOWN[i])

else FAC_T_VLS_DOWN_MMV_DRV1[i] = 1
FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] = 1

endif.

Compute variable gradient thresholds:

VLS_DOWN_MMV_DRV1_THD_MAX[i] = C_VLS_DOWN_MMV_DRV1_THD_MAX *
C_FAC_VLS_DOWN_MMV_DRV1_THD *
(VLS_DOWN_MMV_MAX[i] -
VLS_DOWN_MMV_MIN[i])

VLS_DOWN_MMV_DRV1_THD_MIN[i] = C_VLS_DOWN_MMV_DRV1_THD_MIN *
C_FAC_VLS_DOWN_MMV_DRV1_THD *
(VLS_DOWN_MMV_MAX[i] -
VLS_DOWN_MMV_MIN[i]) *
FAC_T_VLS_DOWN_MMV_DRV1[i]

Limit lower variable gradient threshold:

VLS_DOWN_MMV_DRV1_THD_MIN[i] = MAX(VLS_DOWN_MMV_DRV1_THD_MIN[i],
VLS_DOWN_DRV1_MMV_MIN[i] *
C_FAC_VLS_DOWN_MMV_DRV1_THD_MIN)

Determine VLS_DOWN at low gradient condition met:

If (LV_VLS_DOWN_DRV1_CDN_R_LS[i] = 0) **&**
(VLS_DOWN_DRV1_MMV[i] ≥ VLS_DOWN_MMV_DRV1_THD_MIN[i])

then LV_VLS_DOWN_DRV1_CDN_R_LS[i] = 1
If (VLS_DOWN[i] ≤
(VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT)) **&**
(VLS_DOWN[i] ≥
(VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT))

then LV_VLS_DOWN_RNG_CDN_R_LS[i] = 1

else LV_VLS_DOWN_RNG_CDN_R_LS[i] = 0

endif

endif.

NOTE: VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT shall not cause an overflow and VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT shall not cause an underflow.

Determine internal resistance:

Recurrence: T_SAMPLE_3 = 1 ms

If LV_R_IT_REQ_LS_DOWN[i] = 1

then

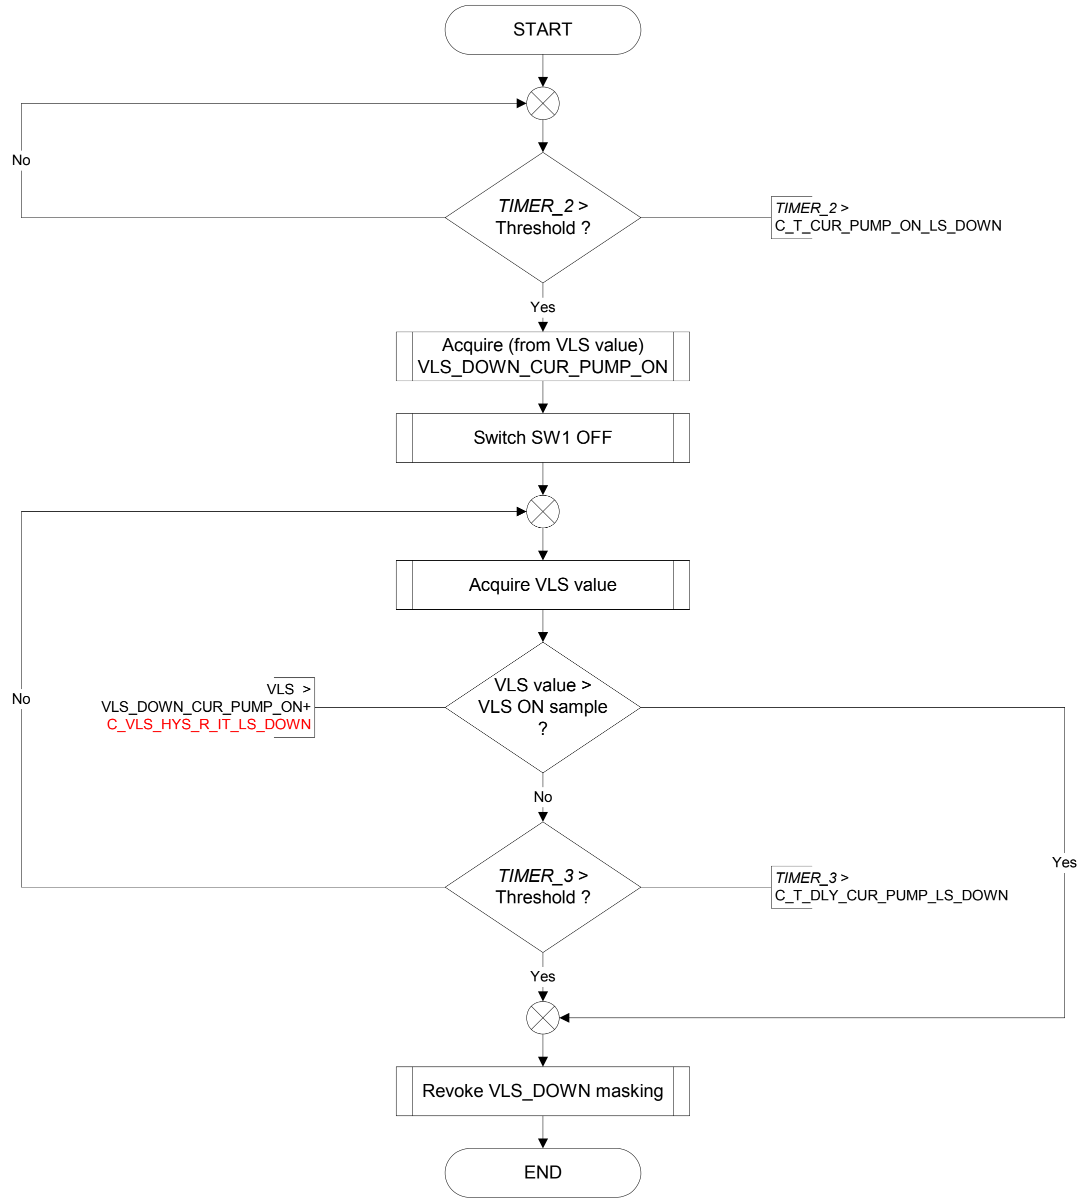

Figure 3 Function flow chart, Internal resistance determination

LV_R_IT_REQ_LS_DOWN[i] = 0

endif

Calculation of Internal resistance:

The internal resistance shall be determined as follows:

R_IT_MES_LS_DOWN[i] = NC_R_REF_LS_DOWN * (VLS_DOWN_CUR_PUMP_ON[i] - VLS_DOWN_CUR_PUMP_OFF[i]) / {NC_VLS_DOWN_CUR_PUMP_REF - (VLS_DOWN_CUR_PUMP_ON[i] - VLS_DOWN_CUR_PUMP_OFF[i])* NC_FAC_R_REF_LS_DOWN - VLS_DOWN_CUR_PUMP_ON[i]}

Determine internal resistance validity:

The following function shall be carried once out for every new resistance value determined.

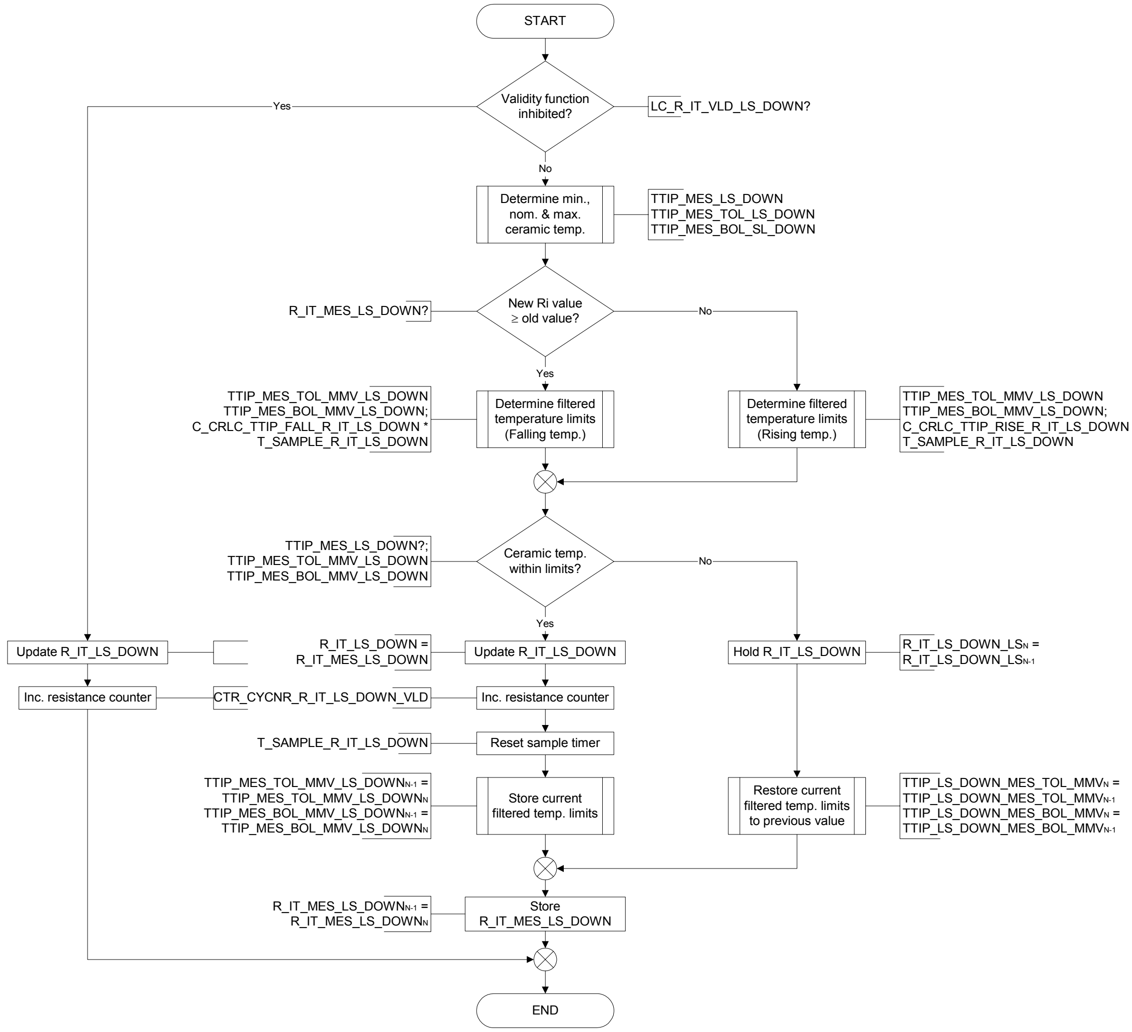

Figure 4 Function flow chart, Internal resistance validity determination

If (LC_R_IT_VLD_INH_LS_DOWN = 0)

4.64.1 Application specific conditions for oxygen sensor internal resistance

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating that downstream sensor internal resistance determination shall be inhibited when set					

Input data:

NC_CBK_EX_NR	LV_ES		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The Boolean flag LV_INH_R_IT_LS_DOWN[i] shall indicate whether the downstream oxygen sensor internal resistance determination shall be permitted to take place. When set, no resistance determination shall take place.

Description:

No application specific conditions have been defined to date. Internal resistance determination shall always take place (LV_INH_R_IT_LS_DOWN[i] shall be initialised to and remain 0).

Application conditions:

Initialisation:

The following initialisation shall be carried out upon leaving the engine state Engine Stop (LV_ES).

LV_INH_R_IT_LS_DOWN[i] = 0

Activation:

None defined at present.

Deactivation:

None defined at present.

Formula section:

None defined at present.

FUNCTION DESCRIPTION:

General information:

The function shall provide the output variable R_IT_LS_UP[i], the internal resistance of the oxygen sensor. The resistance is dependent on the operating temperature of the sensor and may be used for oxygen sensor diagnosis.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

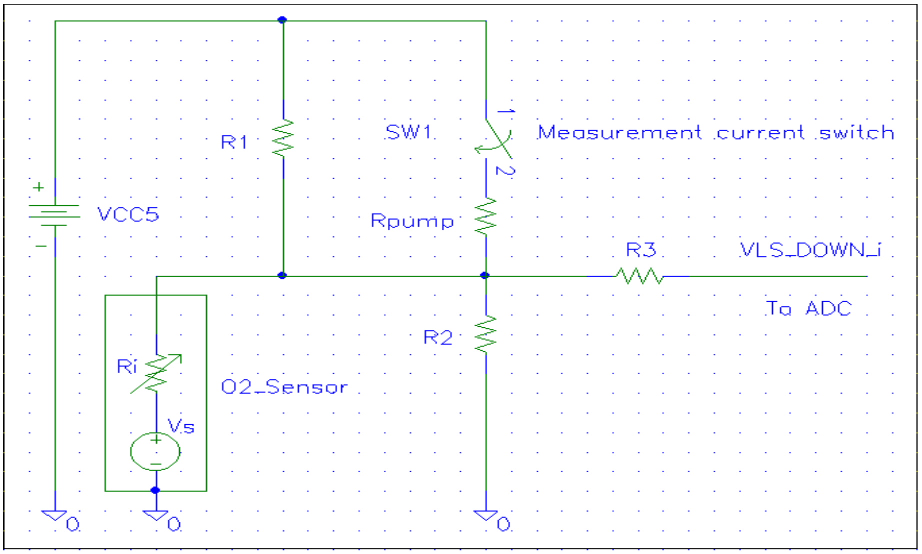

Figure 1 Simplified measurement circuit schematic, Internal resistance determination

Signal flow diagram:

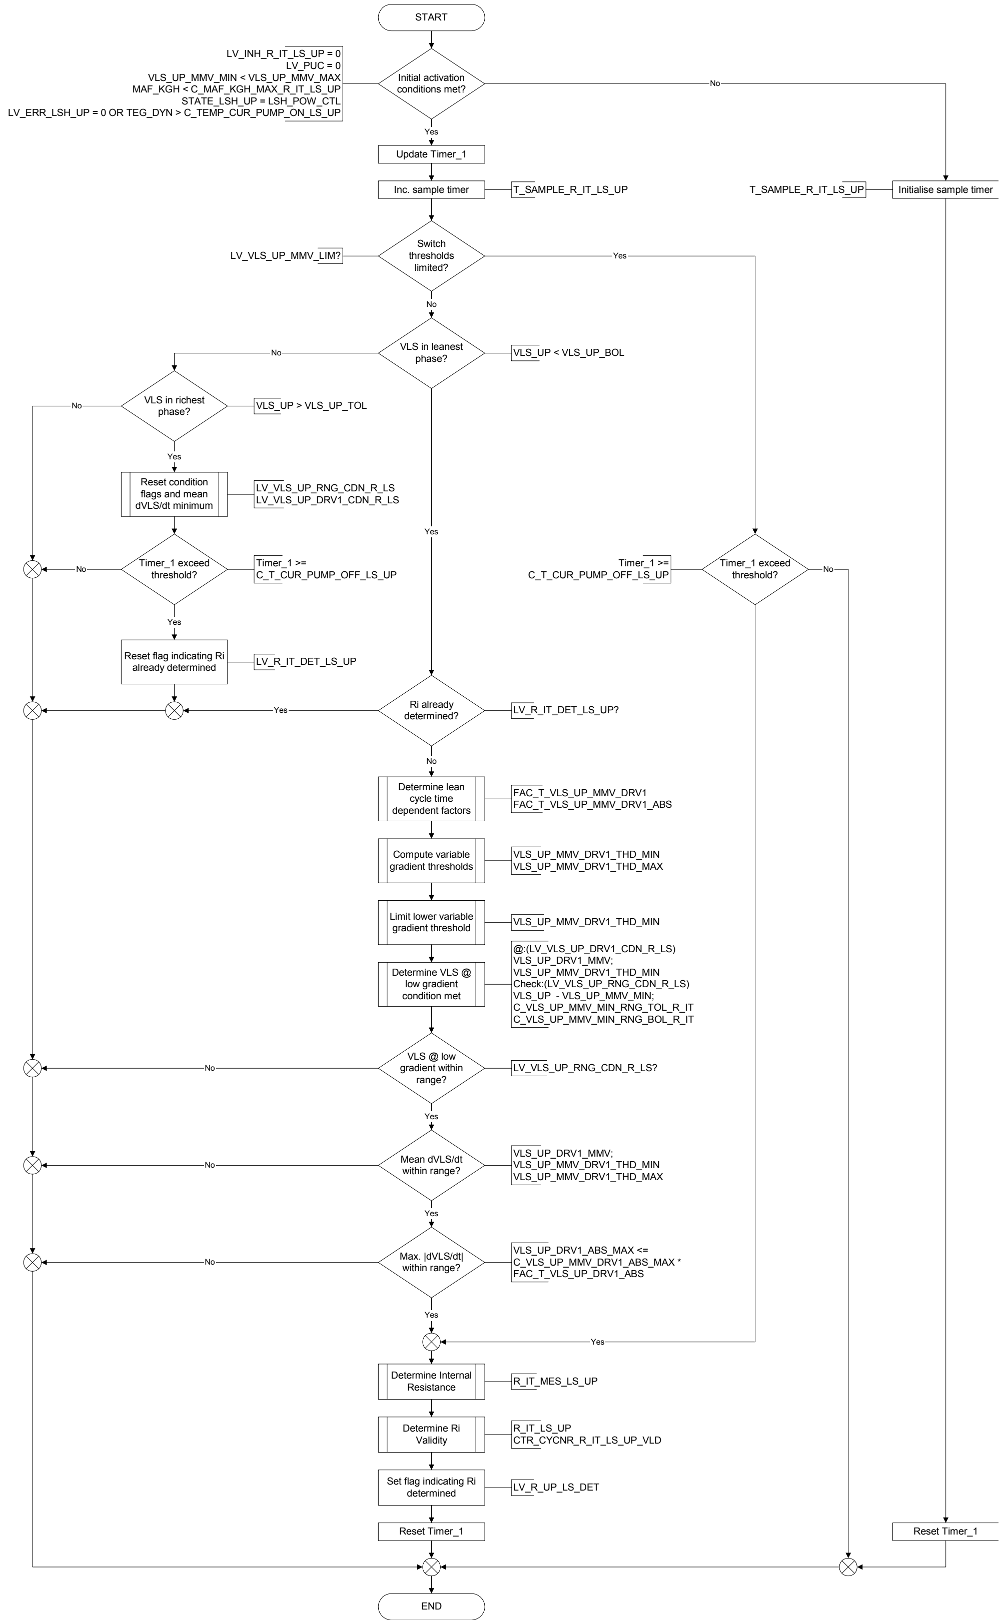

Figure 2 Function flow chart, Internal resistance determination

Description:

The internal resistance of the oxygen sensor shall be determined by use of the oxygen sensor interface circuit *Figure 1* (Capacitors not shown). The internal resistance provides information as to the tip temperature of the sensor and may be used for diagnosis purposes and operative readiness determination.

Under normal conditions, the switch SW1 shall be open and the oxygen sensor signal voltage (VLS_UP[i]) is measured by the microcontroller.

The potential divider (resistors R_1 & R_2) shall be permit the operation readiness of the oxygen sensor to be determined and enable electrical fault conditions to be detected.

Periodically, for a limited amount of time, the switch SW1 shall be closed and a voltage of approx. 4.8 V connected through resistor R_{pump} to the oxygen sensor signal connection. This shall cause current to flow into the sensor and through the internal resistance R_i, thereby "pumping" the sensor. The resultant voltage acquired at the microcontroller input shall permit the internal resistance of the sensor to be calculated by use of a formula shown in the formula section below.

Prior to permitting the determination of the internal resistance, a number of conditions shall be determined to be met:

The initial activation conditions shall require that: No function inhibit is requested (LV_INH_R_IT_LS_UP[i] = 0); Delay since deactivation since last overrun fuel cut-off passed (LV_PUC); The initial post initialisation transients have passed for the VLS_UP_MMV_xxx[i] inputs (VLS_UP_MMV_MIN[i] < VLS_UP_MMV_MAX[i]); The engine load threshold has not been exceeded (MAF_KGH < C_MAF_KGH_MAX_R_IT_LS_UP); The oxygen sensor heater state LSH_POW_CTL has been reached; No heater OBDI error has been detected in the relevant heater driver (LV_ERR_LSH_UP[i]) or should a heater driver fault have been detected, the modelled catalyst temperature TEG_DYN shall exceed the threshold C_TEMP_CUR_PUMP_ON_LS_UP

Once the above conditions have been met, an internal timer (*TIMER_1*) shall be started and timer T_SAMPLE_R_IT_LS_UP[i] shall be updated. The latter timer shall be initialised with its maximum value of 655.35 s. This ensures that the temperature limits for the validity function are correctly initialised. The further procedure shall depend on the status of the oxygen sensor signal, as determined by LV_VLS_UP_MMV_LIM. Should the VLS_UP_MMV_xxx[i] signals be limited, i.e. no or little oxygen sensor amplitude is present, the function shall determine the internal resistance every (C_T_CUR_PUMP_OFF_LS_UP + C_T_CUR_PUMP_ON_LS_UP + C_T_DLY_CUR_PUMP_LS_UP). Otherwise the oxygen sensor signal shall be determined to have significant amplitude and the internal resistance determination shall only be carried out in lean phases where the oxygen sensor signal is relatively flat and stable. This is achieved by the following conditions:

If the oxygen sensor signal is lean (VLS_UP[i] < VLS_UP_BOL[i]) and neither the resistance determination has been carried out yet in this lean phase nor the determination be locked out due to the minimum off time (LV_R_IT_DET_LS_UP[i] = 0) then the function shall determine the lean cycle time dependent factors FAC_T_VLS_UP_MMV_DRV1[i] & FAC_T_VLS_UP_MMV_DRV1_ABS[i] from the appropriate maps IP_FAC_T_DRV1_VLS_UP_MMV & IP_FAC_T_VLS_UP_MMV_DRV1_ABS respectively. These factors shall be dependent on the held lean cycle time from the previous lean cycle (T_AFL_CYC_HLD[i]). Should the cycle time decrease then it is intended that the factors shall increase and vice versa.

The thresholds for the gradient condition shall then be computed. These thresholds (VLS_UP_MMV_DRV1_THD_MAX[i] & VLS_UP_MMV_DRV1_THD_MIN[i]) are directly proportional to the amplitude of the difference between VLS_UP_MMV_xxx[i] signals. Furthermore, VLS_UP_MMV_DRV1_THD_MIN[i] shall be modified by factor

FAC_T_VLS_UP_MMV_DRV1[i]. The factor FAC_T_VLS_UP_MMV_DRV1[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_UP AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD[i] is valid.

The variable threshold VLS_UP_MMV_DRV1_THD_MIN[i] shall be limited so that its value is not less than that of VLS_UP_DRV1_MMV_MIN[i] * C_FAC_VLS_UP_MMV_DRV1_THD_MIN.

The function shall then wait for the oxygen sensor signal gradient to exceed the minimum threshold (VLS_UP_DRV1_MMV[i] ≥ VLS_UP_MMV_DRV1_THD_MIN[i]) and then determine whether the absolute oxygen sensor signal voltage is within a particular range of the VLS_UP_MMV_MIN[i] signal (VLS_UP_MMV_MIN[i] - C_VLS_UP_MMV_MIN_RNG_BOL_R_IT ≤ VLS_UP[i] ≤ VLS_UP_MMV_MIN[i] + C_VLS_UP_MMV_MIN_RNG_TOL_R_IT). If this is the case, the VLS_UP[i] shall be considered to be consistent with previous lean phase amplitudes and resistance determination may be carried out. This condition shall only be carried out once per lean phase. i.e. at transition from rich to lean. The fulfilment of the gradient condition is indicated by LV_VLS_UP_DRV1_CDN_R_LS[i] and the fulfilment of the range condition by LV_VLS_UP_RNG_CDN_R_LS[i].

If the range condition has been met, the gradient is in a particular range (VLS_UP_MMV_DRV1_THD_MIN[i] ≤ VLS_UP_DRV1_MMV[i] ≤ VLS_UP_MMV_DRV1_THD_MAX[i]) and the oxygen sensor signal is determined to be stable in the short term (VLS_UP_DRV1_ABS_MAX[i] ≤ C_VLS_UP_MMV_DRV1_ABS_MAX * FAC_T_VLS_UP_MMV_DRV1_ABS[i]) then resistance determination is requested (LV_R_IT_REQ_LS_UP[i] = 1). The factor FAC_T_VLS_UP_MMV_DRV1_ABS[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_UP AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD[i] is valid.

Once internal resistance determination has been requested, the Basic SW shall take a single VLS_UP[i] sample and store as VLS_UP_CUR_PUMP_OFF[i]. SW1 shall be switched ON, at time C_T_CUR_PUMP_ON_LS_UP[i] and the VLS_UP[i] shall be masked. A second oxygen sensor signal voltage sample shall be taken and stored as VLS_UP_CUR_PUMP_ON[i]. SW1 shall then be switched OFF and masking shall continue for a time C_T_DLY_CUR_PUMP_LS_UP, after which the VLS_UP[i] shall return to normal following of the oxygen sensor signal voltage. Masking shall be discontinued if the oxygen sensor signal voltage exceeds the VLS_UP_CUR_PUMP_ON[i] + C_VLS_HYS_R_IT_LS_UP value during the time C_T_DLY_CUR_PUMP_LS_UP after switching off SW1. Adding the voltage hysteresis shall prevent the function to discard lambda sensor voltage masking if the first VLS_UP[i] value after switching off the pump current is larger than the last VLS_UP[i] value while pumping due to signal noise.

The internal resistance R_IT_MES_LS_UP[i] shall be determined using the formula stated with the main variables being oxygen sensor voltage prior to pumping, VLS_UP_CUR_PUMP_OFF[i], and signal voltage during pumping, VLS_UP_CUR_PUMP_ON[i].

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, a counter CTR_CYCNR_R_IT_LS_UP_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available.

NOTE: During the time where SW1 is switched on, (LV_R_IT_REQ_LS_UP[i]=1) the output voltage of the oxygen sensor (VLS_UP[i]) does not represent the true A/F ratio and is therefore invalid and shall not be used as such. The basic software shall mask the response of the

sensor to pumping by keeping the voltage constant during this time by using the last VLS_UP[i] sample prior to activating SW1.

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, the validity of the resistance shall be checked:

Should the validity function not be inhibited (LC_R_IT_VLD_INH_LS_UP = 0), then the tip temperature of the ceramic shall be determined from a map. TTIP_MES_LS_UP[i] represents the nominal temperature, TTIP_MES_TOL_LS_UP[i] represents the maximum temperature (R_IT_MES_LS_UP[i] * (1 – C_FAC_R_IT_ERR_NEG_LS_UP)), i.e. temperature for resistance with negative measurement error and TTIP_MES_BOL_LS_UP[i] represents the minimum temperature (R_IT_MES_LS_UP[i] * (1 + C_FAC_R_IT_ERR_NEG_LS_UP)), i.e. temperature for resistance with positive measurement error. A low pass filter shall then be applied to the upper and lower temperature limits to represent the maximum possible temperature gradient between resistance samples. Dependent on the direction of change of resistance between two measurements, either constant C_CRLC_TTIP_RISE_R_IT_LS_UP (rising temp.) or C_CRLC_TTIP_FALL_R_IT_LS_UP (falling temp.) shall be applicable. The final filter constant used, limited to a maximum of 1, shall be the aforementioned constant multiplied by the time between resistance samples (T_SAMPLE_R_IT_LS_UP[i]). This shall be to compensate for the irregular sample time.

Should then the ceramic tip temperature fall within the temperature limit bounds, the measured resistance shall be considered to be valid, shall be passed to the output variable R_IT_LS_UP[i], the counter CTR_CYCNR_R_IT_LS_UP_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available and the T_SAMPLE_R_IT_LS_UP[i] shall be reset. If the above temperature condition is not met, R_IT_LS_UP[i] shall be maintained at its last value and the filtered temperature limits shall be reset to their previous values, i.e. the resistance value shall be ignored.

Should the validity function be inhibited then for each new resistance the R_IT_MES_LS_UP[i] shall be passed to R_IT_LS_UP[i] and the counter CTR_CYCNR_R_IT_LS_UP_VLD[i] shall be incremented.

In the case of significant oxygen sensor amplitude (LV_VLS_UP_MMV_LIM = 0) and the sensor signal be in the rich phase (VLS_UP[i] > VLS_UP_TOL[i]), the flags LV_VLS_UP_RNG_CDN_R_LS[i] & LV_VLS_UP_DRV1_CDN_R_LS[i] shall be reset. Furthermore, if these conditions have been met and the timer *TIMER_1* exceeds C_T_CUR_PUMP_OFF_LS_UP then LV_R_IT_DET_LS_UP[i] shall be reset, thereby permitting the internal resistance to be determined in the next cycle should the appropriate conditions be met.

For reference reasons of OBD II diagnosis the value R_IT_MDL_LS_UP_NEW[i] is calculated out of heating power, exhaust gas temperature and MAF_KGH.

Application conditions:

Recurrence: *T_SAMPLE_1 = 10 ms*

T_SAMPLE_2 = 1s

The function shall be carried out once every 10 ms. The internal resistance value shall only be calculated after “pumping” the oxygen sensor. See recurrence there. Reference internal rsistance shall be calculated with recurrence 1 s.

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

R_IT_LS_UP[i] = 65535

4.65.1 Application specific conditions for oxygen sensor internal resistance

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_R_IT_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating that upstream sensor internal resistance determination shall be inhibited when set					

Input data:

NC_CBK_EX_NR	LV_ES		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

The Boolean flag LV_INH_R_IT_LS_UP[i] shall indicate whether the upstream oxygen sensor internal resistance determination shall be permitted to take place. When set, no resistance determination shall take place.

Description:

No application specific conditions have been defined to date. Internal resistance determination shall always take place (LV_INH_R_IT_LS_UP[i] shall be initialised to and remain 0).

Application conditions:

Initialisation:

The following initialisation shall be carried out upon leaving the engine state Engine Stop (LV_ES).

LV_INH_R_LS_UP[i] = 0

Activation:

None defined at present.

Deactivation:

None defined at present.

Formula section:

None defined at present.

4.66 Clutch switch detection

4.66.1 Signal acquisition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CS	V/O	0...1H	0...1	1	-
Clutch switch					

Input data:

LV_AT	LV_IM_CS_PN		

Function description:

Initialisation:

at Reset:

IF LV_IM_CS_PN = 1 or
LV_AT = 1
THEN LV_CS = 0 (clutch pedal released)
ELSE LV_CS = 1 (clutch pedal actuated)

Recurrence: 10 ms

To detect if the clutch is depressed or not, LV_IM_CS_PN is evaluated.

Formula section:

IF LV_IM_CS_PN = 1 or
LV_AT = 1
THEN LV_CS = 0 (clutch pedal released)
ELSE LV_CS = 1 (clutch pedal actuated)

4.66.2 Clutch activation detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CS_ACT_DC	O/V	0...1	0...1	1	-
Logical Variable for detected clutch-pedal activation during present DC					

FUNCTION DESCRIPTION:

Function is used to detect if clutch pedal activation was recognized at least one time in present driving cycle.

Application conditions:

Initialisation: at reset: LV_CS_ACT_DC = 0

Recurrence: 100 ms

Activation: LV_IGK = 1

Formula section:

If LV_CS_ACT_DC = 0
Then **If** LV_CS 0->1
or
LV_CS 1->0
Then LV_CS_ACT_DC = 1
Endif
Endif

4.67 Oil Temperature TOIL

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TOIL	V/O	0...C8H	-40...160	1	°C
Oil temperature value after gradient limitation					
TOIL_STOP	V/O/S	0...C8H	-40...160	1	°C
Oil temperature at transition to engine stop (ES)					

Input data:

CONF_TOIL_MDL	LV_ERR_TOIL	TOIL_MDL_FSD	TOIL_MES
C_TOIL_MIN_DIAG	C_TOIL_MAX_DIAG	LV_ERR_TOIL_STUCK	LV_ERR_TOIL_PLAUS_L
LV_ERR_TOIL_PLAUS_H	C_TOIL_GRD_MAX	TOIL_MDL	

FUNCTION DESCRIPTION:

4.67.1 Oil temperature acquisition

General information:

The measured oil temperature TOIL_MES is monitored for implausible gradient by a gradient limitiation. The gradient limitation is not used as diagnostic function, it is only intended to fade-out implausible values (like noise).

CONF_TOIL_MDL shows if there is a manual request for using the TOIL model (from FSD) by switch C_CONF_TOIL_MDL = 1 or for using TOIL_MDL by switch C_CONF_TOIL_MDL = 2.

Application conditions:

Initialisation at Reset : TOIL = from calculation with TOIL_MES init value
(same calculation of TOIL like normal recurrence incl. range check,
as described in Formula Section)

Activation : At every engine operating state

The application recurrence is **1 sec.**

Formula section:

If (LV_ERR_TOIL = 0 *(No error at oil temperature signal)*
and LV_ERR_TOIL_STUCK = 0 *(No stuck Signal detected)*
and LV_ERR_TOIL_PLAUS_L = 0 *(No unplausible low value detected)*
and LV_ERR_TOIL_PLAUS_H = 0 *(No unplausible high value detected)*
and CONF_TOIL_MDL = 0) *(TOIL Sensor present)*
then
if TOIL_MES < C_TOIL_MIN_DIAG **or**
TOIL_MES > C_TOIL_MAX_DIAG
then $TOIL_n = TOIL_{n-1}$ *(keep previous value)*
else
if $TOIL\_MES_n < TOIL\_MES_{n-1} - C\_TOIL\_GRD\_MAX$
then $TOIL = TOIL\_MES_{n-1} - C\_TOIL\_GRD\_MAX$ *(limit TOIL by negative gradient)*
else
if $TOIL\_MES_n > TOIL\_MES_{n-1} + C\_TOIL\_GRD\_MAX$
then $TOIL = TOIL\_MES_{n-1} + C\_TOIL\_GRD\_MAX$
(limit TOIL by positive gradient)
else $TOIL = TOIL\_MES_n$ *(measured value from sensor)*
else
if CONF_TOIL_MDL = 2
then TOIL = TOIL_MDL *(calculated value)*
else TOIL = TOIL_MDL_FSD *(calculated value from Fuel System Diagnosis)*

4.67.2 Oil temperature at engine stop

General information:

The engine oil temperature at engine stop (TOIL_STOP) is determined at each transition to the engine operating state "Engine Stop". TOIL_STOP will be stored in the non-volatile memory durint the ECU'S self holding phase.

Application conditions:

Initialisation at Reset : TOIL_STOP = TOIL_STOP
(stored in the non-volatile memory)

Initialisation at Engine Run to Engine Stop (ERU_to_ES) :
TOIL_STOP = TOIL

Activation : At every engine operating state

4.68 Oil Temperature TOIL (Appl. Inc.)

Output data:

```

Recurrence: 1000 msec

Signal flow diagram:

30-NOV-99

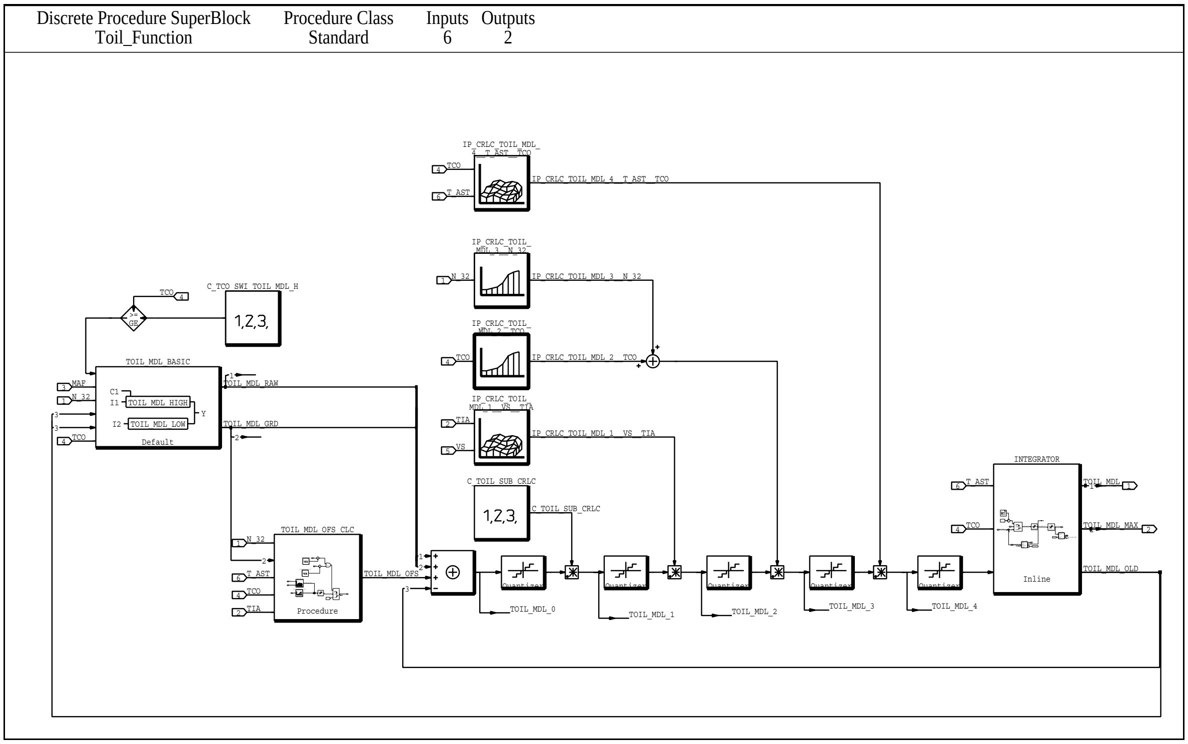

Figure 1: Toil_Function

Description:

TOIL_MDL Calculation:

The Oiltemperature calculation is splitted up in two „ways“. The "LOW-PART" based on the coolant temperature (TCO) and the TCO-gradients. In the high temperature range (TCO-temperature > IP_TCO_SWI_TOIL_MDL_H) the calculation of TOIL_MDL is done in the "HIGH-PART". This path based on the MAP (IP_TOIL_SUB__N32__MAF) dependend on the engine load and engine speed.

Both pathes of the TOIL calculation constitutes the BLOCK "TOIL_MDL_BASIC". The outputvalues are TOIL_MDL_RAW and TOIL_MDL_GRD. Both values are used for the multiplication with the weighting factors in order to get the calculated oil temperature (TOIL_MDL_CLC). The high resolution of TOIL_MDL_CLC (High-Byte) is transferred in the modeled oiltemperature TOIL_MDL (only the HIGH-Byte is used for TOIL_MDL with resolution 1°C).

The coolant temperature TCO is used for the initialization value for the "LOW-PART". The initialization for the toilmodel starting in the "HIGH-PART" is done at the first request of the function.

Formula section:

Calculation of TOIL_MDL_RAW, TOIL_MDL_GRD:

If (TCO >=IP_TCO_SWI_TOIL_MDL_H)

then TOIL_MDL_RAW =TOIL_MDL_H

TOIL_MDL_GRD = 0

else TOIL_MDL_RAW =TOIL_MDL_L

TOIL_MDL_GRD = TOIL_MDL_L_GRD

Endif

Calculation of TOIL_MDL:

TOIL_MDL_0 =		TOIL_MDL_RAW	(RAW-VALUE)
	+	TOIL_MDL_GRD	(Gradient)
	+	TOIL_MDL_OFS	(Offset)
	-	TOIL_MDL_OLD	(TOIL_MDLn-1)

TOIL_MDL_1 = TOIL_MDL_0 * C_TOIL_SUB_CRLC

TOIL_MDL_2 = TOIL_MDL_1 * IP_CRLC_TOIL_MDL_1__VS__TIA

TOIL_MDL_3 = TOIL_MDL_2 *(IP_CRLC_TOIL_MDL_2__TCO +
IP_CRLC_TOIL_MDL_3__N_32)

TOIL_MDL_4 = TOIL_MDL_3 *IP_CRLC_TOIL_MDL_4__T_AST__TCO

TOIL_MDL_CLC = TOIL_MDL_4 + TOIL_MDL_OLD

4.69.1 TOIL_MDL_HIGH

19-MAY-99

Discrete Procedure SuperBlock	Procedure Class	Inputs	Outputs
TOIL_MDL_HIGH	Standard	4	2

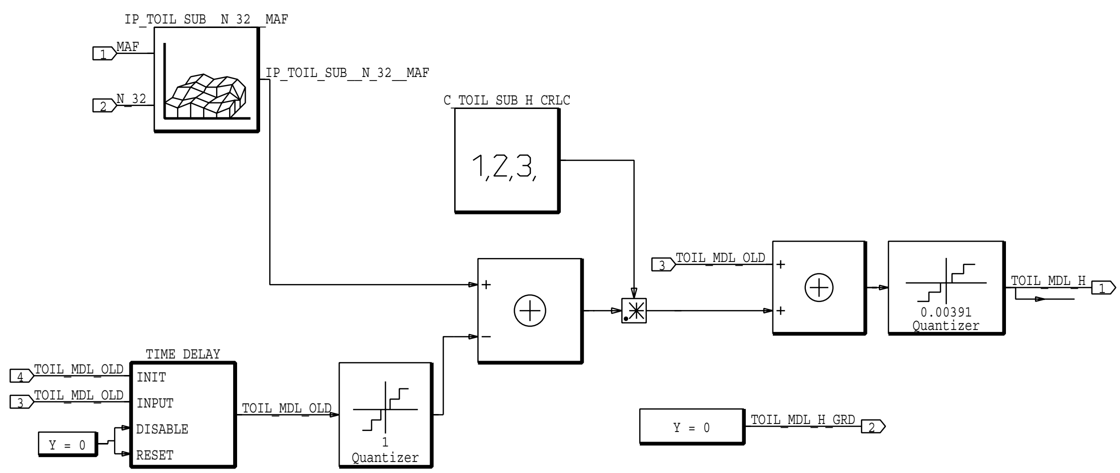

Figure 2: TOIL_MDL_HIGH

Description:

Calculation of TOIL_MDL_H

In the oiltemperature area the Modul TOIL_MDL_H is used for the calculation (TCO > IP_TCO_SWI_TOIL_MDL_H). In the high path of the calculation, no temperature gradients are used (TOIL_MDL_H_GRD =0). For the start during high temperatures, the model will be initialized by the first request of the function. The oiltemperature based on stationair temperature for steady states (engine speed and load N_32, MAF).

Initialization by first request of the function

TOIL_MDL_H = TOIL_MDL_CLC

Formula Section

** Initialisisation*

If TCO >= IP_TCO_SWI_TOIL_MDL_H

then TOIL_MDL_H = TOIL_MDL_CLC

Endif.

Calculation of TOIL_MDL_H, TOIL_MDL_MAX:

TOIL_MDL_Hn **=** TOIL_MDL_OLD **+** C_TOIL_SUB_H_CRLC
***** (IP_TOIL_SUB__N_32__MAF **–** TOIL_MDL_OLD)

TOIL_MDL_MAX **= max** (TOIL_MDL) for current driving cycle.

4.69.2 TOIL_MDL_LOW

19-MAY-99

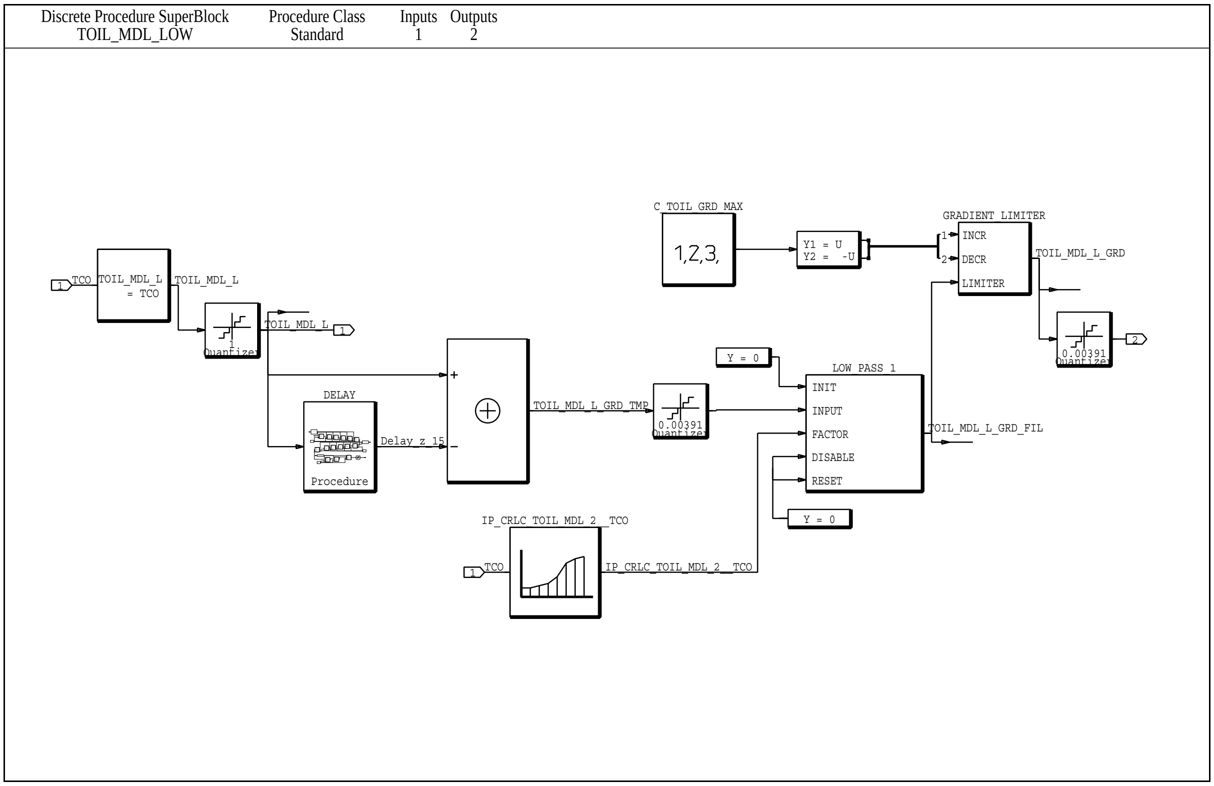

Figure 3: TOIL_MDL_LOW

Description:

Calculation of TOIL_MDL_L:

In the Oiltemperature range TCO < IP_TCO_SWI_TOIL_MDL_H the calculation will be done in the functionblock TOIL_MDL_L. The calculation based on the TCO behaviour in regard to the actuall engine state including weighting factors.

Initialization:

TOIL_MDL_L_GRD_FIL	= 0
TOIL_MDL_L_GRD	= 0
TOIL_MDL_L	= TCO
TOIL_MDL_(n-1)...TOIL_MDL_(n-15)	= TCO

Formula Section:

TOIL_MDL_L = TCO

TOIL_MDL_L_GRD_TMP = TOIL_MDL_L - TOIL_MDL_L(n-15)

TOIL_MDL_L_GRD_FIL = TOIL_MDL_L_GRD_FIL(n-1)
+ IP_CRLC_TOIL_MDL_2__TCO *
(TOIL_MDL_L_GRD_TMP - TOIL_MDL_L_GRD_FIL(n-1))

If TOIL_MDL_L_GRD_FIL >= C_TOIL_GRD_MAX

then TOIL_MDL_L_GRD = C_TOIL_GRD_MAX

else

4.70 Power Steering acquisition variable

(This functional will be activated only if CONF_PSTE = 1.)

4.70.1 Power steering Pressure Voltage Signal

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_PSP_MES	V/O	0...3FFH	0...4,995	4.88e-3	V
Power steering Pressure Voltage Signal (before electrical Diagnosis)					

Input data:

PSP_BAS			

FUNCTION DESCRIPTION:

General information:

The raw value for power steering pressure voltage signal (PSP_BAS) is measured by continuous conversion (10 bits) every 10 msec.

The value of the numeric conversion is adapted to take into account of the electronic component drift. The result of this adaptation must be linearized according to the pressure sensor response.

The corresponding value of the first measurement after hardware reset is used for initialization.

Formula section:

The voltage from the power steering pressure voltage signal is converted to the measured power steering pressure V_PSP_MES.

$$V\_PSP\_MES = (1/10) * \sum_{n=1}^{n=10} PSP\_BAS_n$$

4.70.2 Power steering pressure PSP

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PSP	V/O	0...FFH	0...25.5	0.1	Mpa
Power steering pressure					
PSP_RATIO	V	0...FFFFH	0...99.99847	0.001526	%
Power steering pressure ratio between V_PSP_MES and reference voltage					
LV_PSP	V/O	0...01H	0...1	1	-
Logic value for power steering activation					

Input data:

V_PSP_MES	VCC_SENS_SUB_MES		

General information:

Acquisition reccurence : 10 ms

Formula section:

If V_PSP_MES >= C_PSP_MIN_DIAG

and V_PSP_MES <= C_PSP_MAX_DIAG

then PSP_RATIO = [V_PSP_MES / VCC_SENS_SUB_MES] * 100

PSP = [PSP_RATIO – C_PSP_OFS] / C_PSP_SLOP

else see Diagnosis and Limp home strategy in chapter A

endif

If the difference between the old and the new values of PSP exceeds the permissible gradient C_PSP_GRD_MAX, then the value remains unchanged. During the next measurement, if the maximum gradient is exceeded again, the new measured value will be stored in the RAM.

Errors are not stored with the monitoring of gradients. The only purpose is to extract invalid measured values (malfunctions).

Definition of LV_PSP

If PSP > C_PSP_H_THD with LV_PSP = 0

then LV_PSP = 1

else **if** PSP < C_PSP_L_THD with LV_PSP = 1

then LV_PSP = 0

Calibration data:

4.70.3 Power steering pressure gradient PSP_GRD

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PSP_GRD	V	8000H...7FFFH	-1882...+1881,94	14.7/256	MPa/s
Power steering pressure position gradient					
PSP_GRD_MMV	V/O	8000H...7FFFH	-1882...+1881,94	14.7/256	MPa/s
Power steering pressure position gradient filtered value					

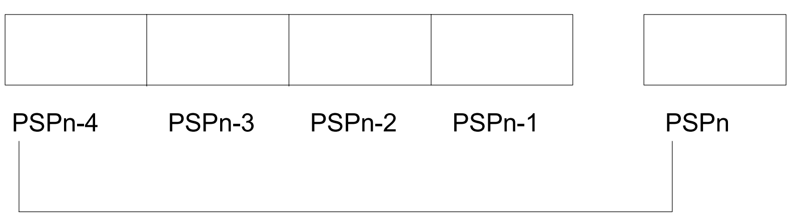
Input data:

PSP			

FUNCTION DESCRIPTION:

General information:

The power steering pressure gradient is calculated every 10 ms.
Therefore, the converted power steering pressure values are written into a ring buffer. This means that the last four power steering pressure values are available in addition to the current power steering pressure value.



The power steering pressure gradient is based on the change in power steering pressure angle over 40 ms.

Application conditions

Activation : at every engine state

Deactivation : -

Initialization : -

Formula section

$PSP\_GRD = PSP_{n} - PSP_{n-4}$

$PSP\_GRD\_MMV_{i} = PSP\_GRD\_MMV_{n-i} + C\_CRLC\_PSP * (PSP\_GRD - PSP\_GRD\_MMV_{i-1})$

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CRLC_PSP	1	0..FFFFH	0..1	1/65535	-
Filtering valur for Power steering gradiant with PSP_GRD					

4.71 Detection of Driver Request Passive

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CT	V/O	0...1H	0...1	1	-
Logical variable for detecting driver request passive					

Input data:

LV_MTC_CUR_OFF	FAC_TQ_REQ_CLU	N_32	

General information:

In this context 'driver request' stands for the driver wish itself, the cruise control or the vehicle speed limitation.
The detection of LV_CT = 0 (torque request from driver, cruise control or vehicle speed limiter) is done by evaluating the torque scaling factor FAC_TQ_REQ_CLU.
In case of LV_MTC_CUR_OFF = 1 (no more throttle control), the throttle will remain in the fixed limp home position, which is around 8° (depending on the used throttle); this is a part load position (LV_CT = 0). All torque requests can only be realized by spark advance interaction or single cylinder cut off coordination. For this purpose the driver passive detection is deactivated (LV_CT = 0).

Application conditions:

Recurrence: 10ms

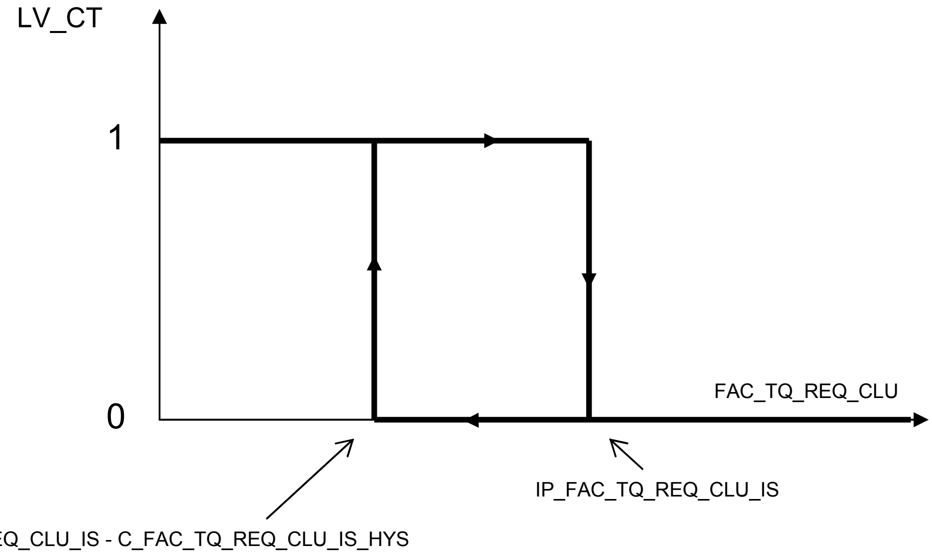
Activation: at every engine state

Deactivation: -

Initialization: at reset: LV_CT = 1

Formula section:

```
if      LV_MTC_CUR_OFF = 1
then    LV_CT = 0
else    if      LV_CT = 1
        then    if      FAC_TQ_REQ_CLU > IP_FAC_TQ_REQ_CLU_IS
                then    LV_CT = 0
                endif
        else    if      (FAC_TQ_REQ_CLU ≤ IP_FAC_TQ_REQ_CLU_IS
                                        - C_FAC_TQ_REQ_CLU_IS_HYS)
                then    LV_CT = 1
                endif
        endif
endif
```



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

4.72 Brake switch variables

4.72.1 Signal acquisition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_BLS	V / O	0..1H	0..1	1	-
Brake Light Switch					
LV_BTS	V / O	0..1H	0..1	1	-
Brake Test Switch					

Input data:

LV_PIN_BLS	LV_PIN_BTS	LV_ES	LV_AT

FUNCTION DESCRIPTION:

General information:

The Bits LV_BLS and LV_BTS are set depending on evaluating the discrete Signals LV_PIN_BLS and LV_PIN_BTS.

Application conditions:

Initialisation: at reset

LV_BLS = 0

LV_BTS = 0

Recurrence: 10 ms

Activation: LV_IGK = 1

Deactivation: otherwise

Formula section:

If LV_ES = 0

Then LV_BLS = LV_PIN_BLS

LV_BTS = CPL(LV_PIN_BTS)

Else **If** LC_ENA_BLS_BTS_ENG_STOP = 1 **and** LV_AT = 1

(to allow LV_BLS/LV_BTS calculation at stopped engine for TCU only if required)

Then LV_BLS = LV_PIN_BLS

LV_BTS = CPL(LV_PIN_BTS)

Endif

Endif

4.72.2 Brake Toggling Detection (LV_BRAKE_TOG_EVE)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_BRAKE_TOG_EVE	V / O	0..1H	0..1	1	-
Logical Variable for detected brake toggling					

Input data:

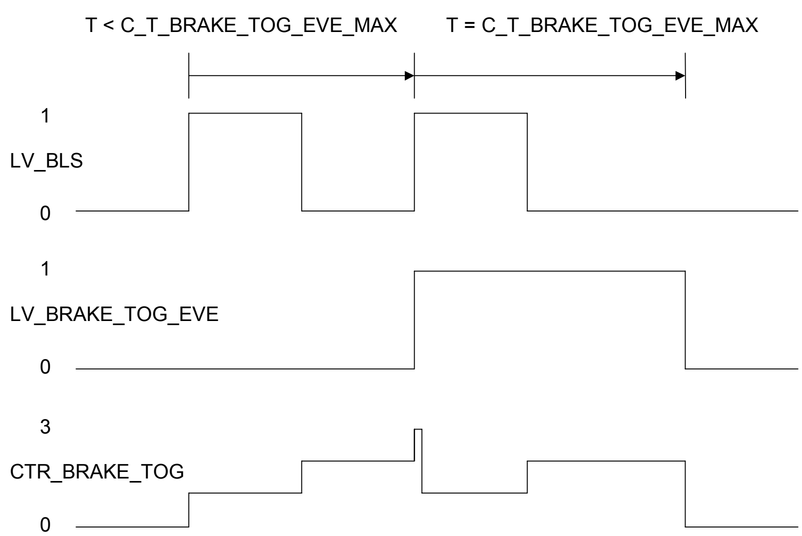
LV_BLS	LV_IGK	LV_ES	

FUNCTION DESCRIPTION:

General information:

If the driver pushes frequently the brake pedal, the brake booster can lead to pressure changes in the intake manifold, which then can affect other functions.
Therefore at detection of this brake toggle operation the bit LV_BRAKE_TOG_EVE = 1 is set.

If LV_BLS = 1, then the time C_T_BRAKE_TOG_EVE_MAX is started. If the transition from LV_BLS = 1 to LV_BLS = 0 and back to LV_BLS = 1 is detected before the time has elapsed, then the bit LV_BRAKE_TOG_EVE = 1 is set and the time C_T_BRAKE_TOG_EVE_MAX is restarted.
If the time elapses without detection of LV_BLS = 1 to LV_BLS= 0 to LV_BLS = 1, then LV_BRAKE_TOG_EVE is set back to 0.



Application conditions:

Activation:

LV_IGK = 1

and LV_ES = 0

Deactivation: otherwise

Initialisation: at reset

LV_BRAKE_TOG_EVE = 0

LV_BRAKE_TOG_EVE_CHK_ENA = 0

LV_BLS_TOG_OLD = 0

T_BRAKE_TOG = 0

CTR_BRAKE_TOG = 0

Update Rate: 100 ms

Formula section:

```
IF   LV_IGK = 1   AND
     LV_ES = 0
THEN
     IF   LV_BRAKE_TOG_EVE_CHK_ENA = 0
     THEN
          IF   LV_BLS_TOG_OLD = 0   AND
               LV_BLS = 1
          THEN
               CTR_BRAKE_TOG = 1
               T_BRAKE_TOG = C_T_BRAKE_TOG_EVE_MAX
               LV_BRAKE_TOG_EVE_CHK_ENA = 1
          END
     ELSE
          IF   T_BRAKE_TOG ≠ 0
          THEN
               T_BRAKE_TOG = T_BRAKE_TOG(k-1) - update rate
          ELSE
               CTR_BRAKE_TOG = 0
               LV_BRAKE_TOG_EVE = 0
               LV_BRAKE_TOG_EVE_CHK_ENA = 0
```

```
            END

            IF      T_BRAKE_TOG ≠ 0          AND
                    LV_BLS_TOG_OLD ≠ LV_BLS
            THEN
                    CTR_BRAKE_TOG = CTR_BRAKE_TOG(k-1) + 1

                    IF      CTR_BRAKE_TOG >= 3
                    THEN
                            CTR_BRAKE_TOG = 1
                            LV_BRAKE_TOG_EVE = 1
                            T_BRAKE_TOG = C_T_BRAKE_TOG_EVE_MAX
                    END
            END
    END

    LV_BLS_TOG_OLD = LV_BLS

ELSE
        LV_BLS_TOG_OLD = 0
        LV_BRAKE_TOG_EVE = 0
        LV_BRAKE_TOG_EVE_CHK_ENA = 0
        T_BRAKE_TOG = 0
        CTR_BRAKE_TOG = 0
END
```

4.72.3 Brake pedal activation detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_BLS_BTS_ACT_DC	O/V	0...1	0...1	1	-
Logical Variable for detected brake-pedal activation during present DC					

FUNCTION DESCRIPTION:

Function is used to detect if brake pedal activation was recognized at least one time in present driving cycle.

Application conditions:

Initialisation: at reset: LV_BLS_BTS_ACT_DC = 0

Recurrence: 100 ms

Activation: LV_IGK = 1

Formula section:

If LV_BLS_BTS_ACT_DC = 0
Then If LV_BLS = 1
and
LV_BTS = 1
Then LV_BLS_BTS_ACT_DC = 1
Endif
Endif

Calibration data:

2nd Filtered electrical load PWM signal from Alternator for N_SP_IS calculation					
GEN_LOAD_GRD_MMV	V/O	8000 ... 7FFFH	-100 ... 99.996	3.051e-3	%/10ms
Filtered alternator load gradient signal					
GEN_LOAD_TMP	V	0...FFH	0...99.6	0.4	%
Electrical Load Signal from Alternator (Input signal from Basis SW)					

Input data:

LV_IGK	CONF_BAT		

General information:

The electrial load information is coming from alternator as PWM signal type.

The goal is to compute the alternator load for torque loss compensation to keep idle stability and to make battery charging by increment of engine speed in case of low battery voltage.

Application conditions:

Activation : LV_IGK = 1 **and** all engine operating state

Deactivation : -

Initialization : GEN_LOAD = GEN_LOAD_MMV = GEN_LOAD_MMV_FIL = 0 at reset

GEN_LOAD_GRD_MMV = 0 at reset

Recurrence: : 10ms

Formula section:

GEN_LOAD_TMP = Duty of GEN_LOAD PWM signal (INPUT from BSW)

if CONF_BAT = 0

then GEN_LOAD = GEN_LOAD_TMP

else GEN_LOAD = 100% - GEN_LOAD_TMP

to change the PWM state of Valeo regulator for BEM from positive to negative

Duty cycle

$$GEN\_LOAD\_MMV_n = GEN\_LOAD\_MMV_{n-1} + (GEN\_LOAD_n - GEN\_LOAD\_MMV_{n-1}) * C\_CRLC\_GEN\_LOAD$$

$GEN\_LOAD\_MMV\_FIL_n = GEN\_LOAD\_MMV\_FIL_{n-1} + (GEN\_LOAD\_MMV_n$

$- GEN\_LOAD\_MMV\_FIL_{n-1}) * C\_CRLC\_GEN\_LOAD\_MMV$

If there is no signal switching during the 21ms(specified inside SW), the PWM value is set to 99.6% if the GEN_LOAD level is low and the PWM value is set to 0% if the GEN_LOAD level is high.

$GEN\_LOAD\_GRD = GEN\_LOAD\_MMV_n – GEN\_LOAD\_MMV_{n-1}$

$GEN\_LOAD\_GRD\_MMV = GEN\_LOAD\_GRD\_MMV_{n-1} +$

$(GEN\_LOAD\_GRD_n - GEN\_LOAD\_GRD\_MMV_{n-1})$

Filtered Fuel tank level value					
V_FTL_SUB_MMV	V/O	0...FFH	0...4.985	0.0195	Volt
Filtered V_FTL_SUB value (from sub FTL sensor)					

Input data:

V_FTL	VB	LV_IGK	CONF_DIAGCP_VOL
V_FTL_SUB	C_FTL_LIH	LV_ERR_FTL_STUCK	LV_ERR_FTL_STUCK_H
LV_ERR_FTL_SUB_STUCK	LV_ERR_FTL		

FUNCTION DESCRIPTION:

The FTL information is issued from Fuel tank sensor.

This acquisition is done by wires. not by CAN.

4.74.1 FTL Hardware acquisition

General information:

The FTL is monitored for invalid gradient and values.

Acquisition recurrence : 0.1 s.

Initialisation:

FTL = FTL_MES (after Key on)

Formula section:

The FTL_MES is monitored for unplausible gradient.

FTL = FTL_MES
FTL_MES = IP_FTL_MES__V_FTL

except if :

If the difference between the old and the new FTL value exceeds the permissible gradient C_FTL_GRD_MAX. then the FTL value remains unchanged.

During the next measurement. if the maximum gradient is exceeded again. the new measured value will be stored in the RAM.

Errors are not stored with the monitoring of gradients. The only purpose is to extract invalid measured values (malfunctions).

Remark :

If the key off (LV_IGK 1->0) is detected, the previous FTL value is kept because the V_FTL value goes to 0 V.

4.74.2 Voltage battery correction

General information:

The FTL is corrected depending on battery voltage.

Recurrence : 0.1 s.

Formula section:

FTL_VB_COR = FTL * IP_FAC_FTL__VB__FTL

4.74.3 Filtered Fuel Tank Pressure FTL_MMV

General information:

The FTL_VB_COR is filtered to avoid big fluctuations due to fuel sloshes.

Recurrence : 0.1 s.

Initialisation:

FTL_MMV = FTL_VB_COR (after key on)

V_FTL_SUB_MMV = V_FTL_SUB (after key on)

Formula section:

If LV_ERR_FTL = 0
and LV_ERR_FTL_STUCK = 0
and LV_ERR_FTL_STUCK_H = 0
and LV_ERR_FTL_SUB_STUCK = 0
then

4.76 Engine off duration

4.76.1 Engine Off Timer

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_ES	V/O	0...FFFFH	0...65535	1	[min]
Engine off duration time					
T_ES_DIAG	V/O	0...FFFFFFH	0...16777215	1	[sec]
Engine off duration time, high resolution (for diagnosis, value not stopped at LV_ST_END)					
T_ES_IGK	V/O	0...FFFFFFH	0...16777215	1	[sec]
Engine off time at IGK_OFF --> ON (for diagnosis interface)					
T_IGK_ON	V/O	0...FFFFH	0... 65535	1	[sec]
Reference Timer started at IGK ON (for diagnosis interface)					
LV_T_ES_NOT_PLAUS	V/O	0...1H	0...1	1	-
Flag indication T_ES value is not plausible					
LV_T_ES_RST	V/O	0...1H	0...1	1	-
Flag indication T_ES value is currently resetted					
LV_T_ES_ACT	V/O/S	0...1H	0...1	1	-
Flag indication engine off timer is not yet activated for the first time					
T_ES_RST_ACT	V	0....FFFFH	0....65535	1	-
0H = no warm reset/ AF50H 0 warm reset – Word is stored every sec to reset resistant (RAM CHECK resistant) memory as value and complement					

Input data:

LV_ES	LV_IGK	LV_ST_END	LV_ERR_T_ES_PLAUS
LV_VB_OFF			

Import actions :

ACTION_INFR_EONVStartTimer ( )
Start the timer of the PIC
ACTION_INFR_EONVResetTimer ( )
Reset the basic timer of the PIC
ACTION_INFR_EONVReadTimer (Lv_cmd, T_es **)**
Engine Off timer is read in from PIC

FUNCTION DESCRIPTION:

General information:

The engine off duration time T_ES will be used mainly in temperature critical functions like injection and dew point recognition.

The engine off timer is running in a separate micro controller and is controlled by commands over a dedicated SPI line.

As soon as the condition LV_ES = 1 and LV_IGK = 1 is recognised the value of T_es is read from basic software and T_ES, T_ES_DIAG, T_ES_IGK are updated. The timer values must be upated before functions using this data are called (example, injection functions).

The engine off timer T_ES value is stopped after Start end detection, while the T_ES_DIAG timer for diagnosis is only resetted at transition to stopped engine.

At first Power on (new ECU) or after loss of NVMY or disconnected battery, the engine off timer is not started, as there is not yet a transition to stopped engine detected. Therefore the plausibility flag LV_T_ES_NOT_PLAUS = 1 is set.

For calibration purpose an add on value C_T_ES_MAN can be set to the Engine off timer value.

Due to communication delay with PIC controller a reset of the engine off timer takes a few 100 msec. The flag LV_T_ES_RST shows, that the engine off timer value could be delayed. This is important for other functionalities with higher recurrence using it.

To avoid a wrong Initialisation of values which are using T_ES after a warm reset (software reset), it has to be ensured, that LV_T_ES_NOT_PLAUS is set to 1 in case of warm reset. This is handled via the word T_ES_RST_ACT, which is saved in reset independent memory with value and complement value. This special part of the memory is not deleted in case of warm reset (Software reset). In case of cold reset (hardware reset) this information is lost.

Application conditions:

Initialisation:

at first power on or NVMY error:

LV_T_ES_ACT = 0

at reset:

if T_ES_RST_ACT = AF50h (**and** complement value = 50AFh)

then *warm reset (SW-reset) is detected*

LV_T_ES_NOT_PLAUS = 1

endif

Hint: To perform the battery off detection with engine off timer is has to be ensured by SW, that the reset of engine off timer has to be done prior to reset of LV_VB_OFF.

T_ES, T_ES_DIAG must be updated during initialization before being used in temperature critical functions like injection and dew point recognition.

4.77 Engine roughness segment time correction

4.77.1 Phasing reference for the acquisition of engine roughness segment time

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_MES	V/O	0...BH	0...11	1	[-]
Phasing reference of ER segment acquisition					

Input data:

SEG_NR	NC_CYL_NR	LV_SYN_ENG	

FUNCTION DESCRIPTION:

The ER segments provided by the aggregate ENSD, are used to observe in-cylinder combustion effects on crankshaft. The cylinder x combustion is located between cylinder X tdc and cylinder X+1 tdc. Consequently, at X+1 tdc, the T_SEG_ER obtained is relative to cylinder X combustion, a delay of 1 tdc between SEG_NR value at cylinder observed *(NC_SEG_DLY_ER_MES=1)*.

Exceptionally, if the segment is located after ER segment, this delay must be cancelled *(NC_SEG_DLY_ER_MES=0)*, because in such case the phasing reference SEG_NR is updated after T_SEG_ER acquisition.

SEG_NR_MES, the ER segments phasing reference, will be used to identify which cylinder is observed with the current engine roughness segment, it's particularly useful for ER segment adaptive values identification.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

SEG_NR_MES = 0

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

SEG_NR_MES = (SEG_NR – NC_SEG_DLY_ER_MES) % NC_CYL_NR

Buffer of cylinder engine roughness raw segment times					
LV_ENA_SEG_T_MES	V/O	0...1H	0...1	1	[-]
Engine roughness segment time validity flag					

Input data:

T_SEG_ER	LV_SYN_ENG	LV_LIH_ERR_CRK	LV_INH_MIS_CRK
NC_CYL_NR	LV_ERR_CRK		

General information:

Here's described the segment time buffers management & control

ER current raw segment time:

T_SEG_ER *(input from ENSD)*

Coming directly from the ENSD aggregate and update at each ER segment task according ER segment counter *(SEG_NR_MES)*.

Actual ER segment time sample is considered **unvalid** if :

- Engine synchronisation is disable (LV_SYN_ENG = 0)
- When on one crankshaft revolution at least one tooth less or more has been detected (LV_INH_MIS_CRK = 1 before antibounce counter),
- When the crahshaft error or limp home is activated (LV_ERR_CRK = 1 or LV_LIH_ERR_CRK = 1)
- SEG_T_MES obtained exceeds a defined valid range (C_SEG_T_MES_MIN & C_SEG_T_MES_MAX)

Cylinder ER raw segment times:

SEG_T_MES & SEG_T_MES_CYL[NC_CYL_NR] *(outputs)*

This is a buffer where T_SEG_ER values *(after data casting)* are stored according SEG_NR_MES counter. It allows having a memory of raw ER segments on a complete engine cycle. These values will be used by the ER adaptive learning process.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

SEG_T_MES = 0x7FFFFF

For x = 0 ... NC_CYL_NR-1

SEG_T_MES_CYL[x] = 0x7FFFFF

EndFor

4.77.2.1 Correction of the engine roughness segment adaptive values

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_AD_COR_ER	V	0...FFFFH	-7.8125...7.81226	0.2384e-3	[°/oo]
ER segment adaptive values correction versus engine speed (for each segment)					

Input data:

LV_AT	N_32	NC_CYL_NR	

FUNCTION DESCRIPTION:

General information:

Due to crankshaft flexion appearance at high engine speed that decreases the misfire detection efficiency, an open-loop adaptive correction value depending on engine speed for each cylinder can be introduced per type of transmission.

A correction can be applied only for each singular segment of the flywheel.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

SEG_AD_COR_ER = 0

Recurrence: Segment

Activation: LV_ENA_SEG_T_MES = 1

Deactivation: LV_ENA_SEG_T_MES = 0

Formula section:

4.77.3 Engine roughness segment time correction

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	O	0...7FFFFFH	0...1999999.7	0.2384186	[µs]
ER corrected segment times buffer (after adaptation)					
SEG_T_COR	V/O	0...7FFFFFH	0...1999999.7	0.2384186	[µs]
Current ER corrected segment time					

Input data:

LV_SYN_ENG	SEG_AD_MMV_ER[NC_CYL_NR]		

FUNCTION DESCRIPTION:

General information:

The prerequisite for a reliable engine roughness evaluation is an accurate ER segment time measurement.

As the crankshaft flywheel teeth are subject to manufacturing tolerances, geometrical run-out and off-center installation which result in angles modulation, consequently the measured raw segment periods aren't similar and have systematic inaccuracies regarding other segments.

As these inaccuracies are systematic, they can be "learned" by an adaptive process during fuel cut-off periods and used for ER segment time correction. This adaptive process is described in the module : Engine roughness adaptive learning process.

ER segment adaptive values: SEG_AD_MMV_ER[NC_CYL_NR] *(inputs)*

ER adaptive values are stored according SEG_NR_MES counter. These adaptive values are obtained and updated by the ER segment adaptive values learning process. There's one ER segment adaptive value per engine cylinder.

Remark: The SEG_AD_MMV_ER_x are stored in ECU non-volatile memory.

ER current corrected segment time: SEG_T_COR *(output)*

This value is the current result of the ER segment correction process obtained with T_SEG_ER as input.

<u>ER corrected segment times buffer:</u> SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF] *(outputs)*

This is a buffer where are stored SEG_T_COR values (ER corrected segment time current value) who are needed for ER calculation.

SEG_T_COR is stored according a FIFO management (first in, first out).

SEG_T_COR_BUF buffer size depends on engine type:

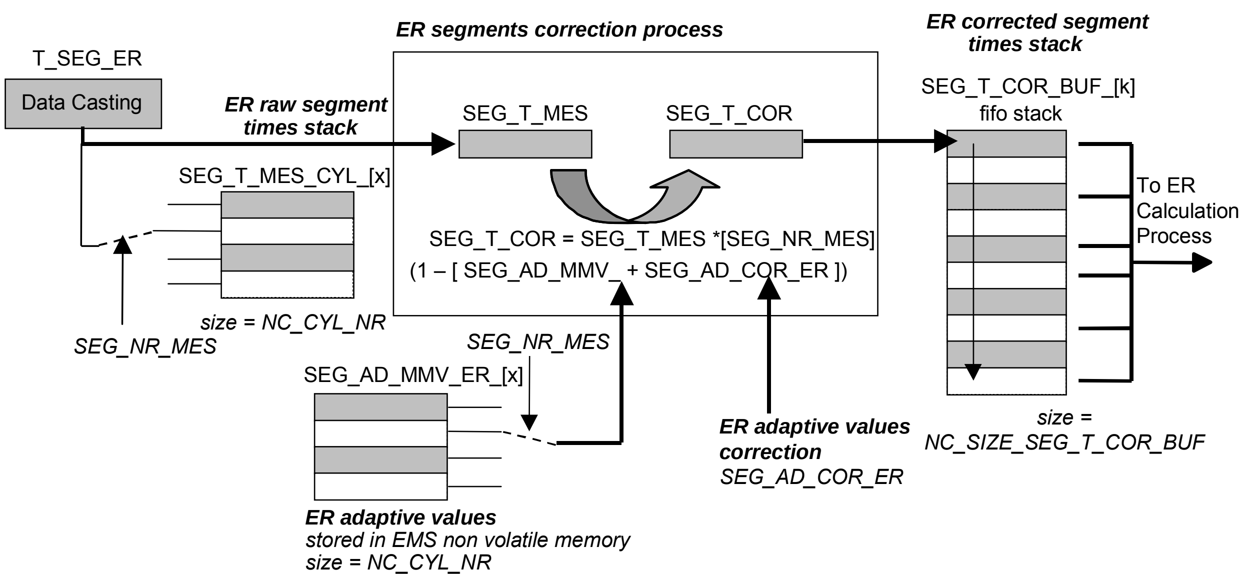
NC_SIZE_SEG_T_COR_BUF = *11 segment time samples for a 5 & 10 cylinder engine*

NC_SIZE_SEG_T_COR_BUF = *9 segment time samples for 4 & 8 cylinder engine*

NC_SIZE_SEG_T_COR_BUF = *7 segment time samples for 3 & 6 cylinder engine*

NC_SIZE_SEG_T_COR_BUF = *13 segment time samples for a 12 cylinder engine*

This size NC_SIZE_SEG_T_COR_BUF *is determined by the ER sample number required by ER calculation according engine type.*



<u>**Application conditions:**</u>

Initialisation: at ECU reset, Engine Stop ***Or*** *Deactivation event*

SEG_T_COR = 0x7FFFFF

For k = 0 to NC_SIZE_SEG_T_COR_BUF-1

SEG_T_COR_BUF[k] = 0x7FFFFF

EndFor

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

If(1) LV_ENA_SEG_T_MES = 0

Then(1) SEG_T_COR = 0x7FFFFF

For(2) k = 0 to NC_SIZE_SEG_T_COR_BUF-1

SEG_T_COR_BUF[k] = 0x7FFFFF

EndFor(2)

Else(1) SEG_T_COR =

SEG_T_MES * (1 – [SEG_AD_MMV_ER[SEG_NR_MES] + SEG_AD_COR_ER])

For(2) k : 1 to NC_SIZE_SEG_T_COR_BUF-1

SEG_T_COR_BUF[k] is managed as a FIFO stack *(SEG_T_COR_BUF last value is lost)*

EndFor(2)

SEG_T_COR_BUF[0] = SEG_T_COR

EndIf(1)

Where:

SEG_T_MES : *Current uncorrected ER segment time after data casting*

SEG_T_COR : *Current ER corrected segment time*

SEG_AD_MMV_ER[SEG_NR_MES] :

ER segment adaptive value corresponding to current T_SEG_ER phasing

SEG_AD_COR_ER :

Adaptive value correction versus engine speed corresponding to current T_SEG_ER phasing

Configuration data:

Size of the array of engine roughness corrected segment times					

4.77.4 Engine roughness calculation

4.77.5 General information

The engine roughness index (ER) is a system variable relative to crankshaft segments behaviour. This index is mainly used by the misfire monitoring & algorithms dedicated to combustion process control.

Integration version for 3,4,5,6,8,10 & 12 cylinder engines.

The engine roughness system variable is calculated each ER window end occurrence, every time the engine is running & synchronised.

4.77.6 Engine roughness segment reference

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_ER	V/O	0...BH	0...11	1	[-]
ER segment counter for segment identification (0 ... NC_CYL_NR - 1)					

Input data:

SEG_NR	NC_CYL_NR	LV_SYN_ENG	

Due to engine roughness definition, there is a delay of C_SEG_DLY_ER segments between ER actual value and the segment that was observed by this ER value.

SEG_NR_ER will be used to identify which cylinder is observed with the engine roughness system variable, it's particularly useful for misfire cylinder identification.

The segment counter SEG_NR_ER with the limit 0...(NC_CYL_NR - 1) is incremented in the same way as the common segment counter SEG_NR.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation condition event*

SEG_NR_ER = 0

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Engine roughness valid calculation control flag					

Input data:

SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	LV_ENA_SEG_T_MES	N	LV_AT

Description:

All ER components calculations are based on corrected segment time acquisitions buffer values SEG_T_COR_BUF.

As soon as an invalid segment has been detected during acquisition process (LV_ENA_SEG_T_MES = 0) or segment adaptive calculation, ER calculation & misfire detection have to be disabled (LV_ENA_ER = 0).

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation condition event*

LV_ENA_ER = 0

Recurrence: Segment

Activation:

Engine roughness calculation is executed only if:

NC_SIZE_SEG_T_COR_BUF consecutive valid ER segment times have been acquired & stored in SEG_T_COR_BUF buffer.

"**Valid**" stands for:

LV_ENA_SEG_T_MES = 1 on NC_SIZE_SEG_T_COR_BUF consecutive ER segments

And no ER components calculation overflow on current segment *(DRV0, DRV1, DRV2 and ER components)*

And N <= C_N_MAX_ER

And [(N >= C_N_MIN_ER_MT **and** LV_AT = 0) **or**

(N >= C_N_MIN_ER_AT **and** LV_AT = 1)]

In this case:

ER components are calculated as described below.

LV_ENA_ER = 1 *(if no overflow occurs during ER components calculation)*

Deactivation:

Engine roughness calculation is stopped & initialised when at least one of the NC_SIZE_SEG_T_COR_BUF consecutive segment times have been acquired & stored in SEG_T_COR_BUF buffer have been detected unvalid.

"**Unvalid**" stands for:

LV_ENA_SEG_T_MES = 0 at least one time on NC_SIZE_SEG_T_COR_BUF consecutive ER segments

Or at least one calculation overflow occurs one of ER components *(DRV0, DRV1, DRV2 or ER component)* on current segment.

Or N > C_N_MAX_ER

Or (N < C_N_MIN_ER_MT **and** LV_AT = 0)

Or (N < C_N_MIN_ER_AT **and** LV_AT = 1)

In that case :

LV_ENA_ER = 0

ER components are initialised to 0

ER additive correction components					

Input data:

LV_AT	LOAD_MIS	N_32	NC_CYL_NR

FUNCTION DESCRIPTION:

General information:

The misfire detection based on ER index can be complicated by the torsional/flexion vibrations especially with multiple cylinder engines with a long crankshaft. This affects on misfire detection efficiency, especially at high engine speed.

To balance this phenomenon, after segment timing correction with ER adaptive values *(see ER segment correction process)*, an irregular operation is determined from the measured cylinder segment times, cylinder specific additive and multiplicative corrections are applied on the raw engine roughness value *(ER_RAW)*.

FAC_ADD_ER[NC_CYL_NR] and FAC_GAIN_ER[NC_CYL_NR] correction coefficients are based on calibration tables specific to each cylinder and to transmission type (MT/AT).

Application conditions:

Initialisation: at ECU reset, at Engine Stop ***Or*** *on Deactivation condition event*

For x = 0 to NC_CYL_NR-1

FAC_GAIN_ER[x] = 1

FAC_ADD_ER[x] = 0

EndFor

Recurrence: *Segment*

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Engine roughness without curvature component					

Input data:

SEG_T_COR	SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	NC_CYL_NR	FAC_DRV2_ER
CRLC_DRV2_ER			

General information :

The engine roughness calculation needs three individual components: a static component (DRV0_ER), a dynamic component (DRV1_ER) and a curvature component (DRV2_ER). These component definitions are specific to the engine cylinder number (see following related subchapters).

DRV2_MMV_ER is the filtered curvature component correction (DRV2_ER) who allows adding an artificial positive offset on ER value in case of dynamic curvature effects. This feature had a safety effect against wrong detection in case of segment oscillations.

ER_RAW is the engine roughness value without curvature component (DRV2_MMV_ER), used by cylinder balancing and engine warm up monitoring modules.

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

DRV0_ER = DRV1_ER = DRV2_ER = DRV2_MMV_ER = ER_RAW = 0

Recurrence: Segment

Activation: LV_ENA_ER = 1

Cylinder normalised engine roughness values					

Input data:

THD_AD_ER	SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	N	C_SEG_DLY_ER

Description:

ER is the complete engine roughness value including all ER components (DRV0_ER, DRV1_ER & DRV2_MMV_ER), specified & used by misfire detection module.

ER_STND is the normalised engine roughness value versus engine speed that could be amplified by a gain C_FAC_SCA_ER_STND. This is the nominal engine roughness value divided by the corresponding cubic corrected ER segment time $(SEG\_T\_COR\_BUF[C\_SEG\_DLY\_ER])^3$. The cubic segment time is calculated by using a mantisse and an exponent.

ER & ER_STND calculation formula are generic to all engine type.

A positive offset (THD_AD_ER) is added to ER components as long as the ER adaptive learning process hasn't been executed. This, in a way to avoid wrong misfire detection in engine operation areas where crankshaft decelerations due to a misfire are very close to ER noise due to the flywheel mechanical tolerances.

This offset decreases as the ER adaptive learning progress. At the end of the learning process, this offset is null *(see next chapter ER adaptive values learning process for more informations)*.

Once the ER fast adaptive learning stage has been executed, these flywheel mechanical tolerances are sufficiently reduced to able to detect misfire in full legal range without adding a positive offset.

ER_CYL_x and ER_STND_CYL_x are the engine roughness values obtained for corresponding cylinder x, these values are switched according SEG_NR_ER segment reference.

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

ER = 0

ER_STND = 0

For x = 0 to NC_CYL_NR-1

ER_CYL[x] = 0

ER_STND_CYL[x] = 0

EndFor

Recurrence: Segment

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Formula section:

Engine roughness:

ER = ER_RAW + DRV2_MMV_ER + THD_AD_ER

ER_CYL[SEG_NR_ER] = ER

Normalised Engine roughness versus engine speed:

If N < C_N_MAX_ER_STND

Then

ER_STND = 2 $^{\text{(C\_FAC\_SCA\_ER\_STND)}}$ * ER / (SEG_T_COR_BUF[C_SEG_DLY_ER])^3

// for the calculation, be carefull with the order of the calculation (risk to loose information with the division)

ER_STND_CYL[SEG_NR_ER] = ER_STND

Else

4.79 Engine roughness adaptive learning process

General information:

To reduce systematic noises generated by target wheel mechanical tolerances, an adaptive learning process is required to improve the signal noise ratio on engine roughness variable and to avoid wrong misfire detection at high engine speed / low load.

ER segment adaptive values learning process is based on ER segments timing observation according a geometrical reference (ER segment time 0, SEG_NR_MES = 0).

During an engine deceleration in fuel cut-off mode on all cylinders (LV_INJ_CUT, no engine combustion influences), due to crankshaft inertia, engine speed can be considered in a short horizon as constant, thus on one engine cycle (720°Crk) timing dissimilarities between segment reference and others will be observed. For longer horizon observation, a deceleration is applied according current segment position in the engine cycle.

When all adaptation conditions fulfilled (smooth deceleration in fuel cut-off conditions), an adaptive values learning process is performed every **720° crank angle**, starting with **segment 0** *(adaptive process reference).*

If there is no cylinder specific mechanical damage or crankshaft torsion/flexion, the adaptation values for cylinders with the same mechanical segment will be approximately identical :

3 cylinder engine	4 cylinder engine	5 cylinder engine	6 cylinder engine	8 cylinder engine	10 cylinder engine	12 cylinder engine

TPS_GRD	TPS_AV	LV_STATE_RR	LOAD_GRD_MIS
MAF_DIF	LV_INH_APP_ER_AD	LV_INH_OBD_ER_AD	

FUNCTION DESCRIPTION:

Description:

LV_SEG_AD_FDOUT_ER combines all system conditions to generate a fade out condition as input for the generic segment adaptation process.

Update rate: segment occurrence for conditions & data process

10ms for free running decounters

Application conditions:

Activation: *LV_ENA_SEG_T_MES = 1*

Deactivation: *LV_ENA_SEG_T_MES = 0*

Action on deactivation event ***Or*** *ECU reset:*

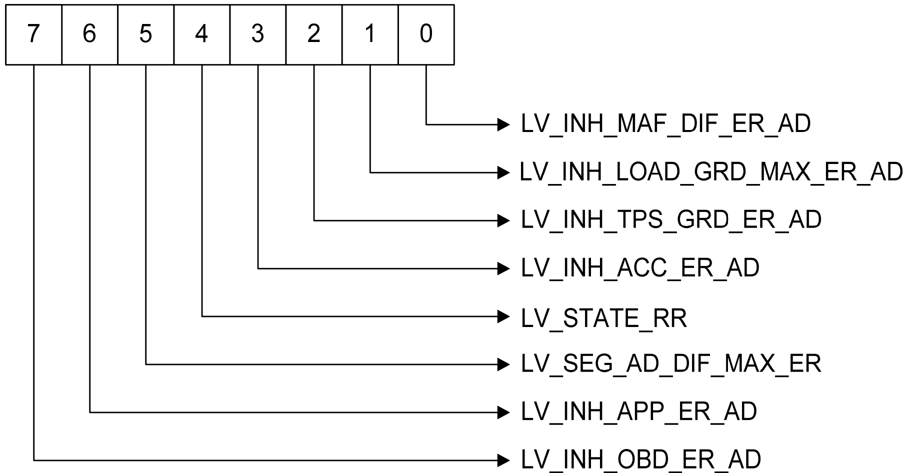
LV_SEG_AD_FDOUT_ER = 1

SEG_AD_FDOUT_ER_CDN = 0xFF

SEG_AD_FDOUT_ER_CDN_NR = 8

Definition of segment adaptation fade out conditions carrier:

SEG_AD_FDOUT_ER_CDN : *Carrier used for fade-out conditions merge*



4.79.1.1 Configurable Fade-out Management

Application conditions:

The Fade out management of the segment adaptive process can be configured with a bitfield mask calibration that allow to take in account or not some conditions set in the carrier.

If the corresponding bit in the SEG_AD_FDOUT_ER_CDN carrier structure is set to 0 in C_MASK_SEG_AD_FDOUT_ER calibration, then the corresponding condition will not fade-out the segment adaptive process via LV_SEG_AD_FDOUT_ER.

The number of fade-out conditions not masked by this calibration is set in SEG_AD_FDOUT_ER_CDN_NR.

Formula section:

SEG_AD_FDOUT_ER_CDN_NR =

sum (SEG_AD_FDOUT_ER_CDN **&** C_MASK_SEG_AD_FDOUT_ER)

! (bitfield operation) !

If SEG_AD_FDOUT_ER_CDN_NR ≠ 0

Then LV_SEG_AD_FDOUT_ER = 1

Else LV_SEG_AD_FDOUT_ER = 0

EndIf

4.79.1.2 Maximum air-mass gradient

Due to trailing throttle / acceleration transition problems it is necessary to disable ER segment learning process for a short period when the air-mass gradient per segment exceeds a calibration value.

Application conditions:

ER segment adaptation is disabled while the absolute of the air-mass gradient exceeds the value mentioned below:

After the last triggering of this segment adaptation is suppressed for a period of C_T_MAF_DIF_DLY_ER_AD.

Formula section:

If | MAF_DIF | > IP_MAF_DIF_MAX_ER_AD(MAF)

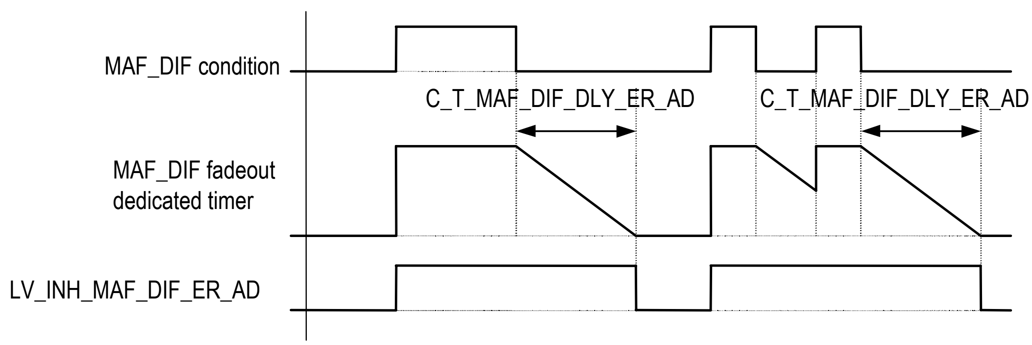
Then

After condition rising edge triggering, LV_INH_MAF_DIF_ER_AD flag is set to 1 as long as condition is true.

After condition falling edge triggering, LV_INH_MAF_DIF_ER_AD flag is hold to 1 for a period of C_T_MAF_DIF_DLY_ER_AD.

EndIf

Fade out behaviour summary:



4.79.1.3 Maximum actual load gradient

Due to general intervention of the torque model it's necessary to disable ER segment adaptation for a short period when the actual torque gradient exceeds a calibration value.

Application conditions:

ER segment adaptation is disabled while the absolute of the torque gradient – here LOAD_GRD_MIS the reference for Misfire detection process – exceeds the value mentioned below.

After the last triggering of this segment adaptation is suppressed for a period of C_T_LOAD_GRD_DLY_ER_AD.

Formula section:

If LOAD_GRD_MIS > IP_LOAD_GRD_ER_AD(LOAD_MIS)

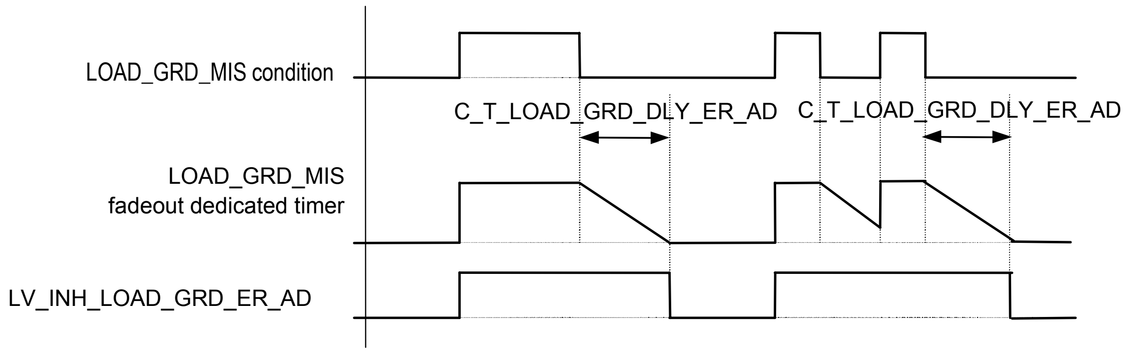
Then

After condition rising edge triggering, LV_INH_LOAD_GRD_MAX_ER_AD flag is set to 1 as long as condition is true.

After condition falling edge triggering, LV_INH_LOAD_GRD_MAX_ER_AD flag is hold to 1 for a period of C_T_LOAD_GRD_DLY_ER_AD.

EndIf

Fade out behaviour summary:



4.79.1.4 Maximum throttle gradient

Due to trailing throttle / acceleration transient problems at low load it is necessary to disable ER segment adaptation for a short period when the throttle gradient exceeds a calibration value.

Application conditions:

ER segment adaptation is disabled while the throttle position gradient exceeds the value mentioned below.

After the last triggering of this segment adaptation is suppressed for a period of C_T_TPS_GRD_DLY_ER_AD.

Formula section:

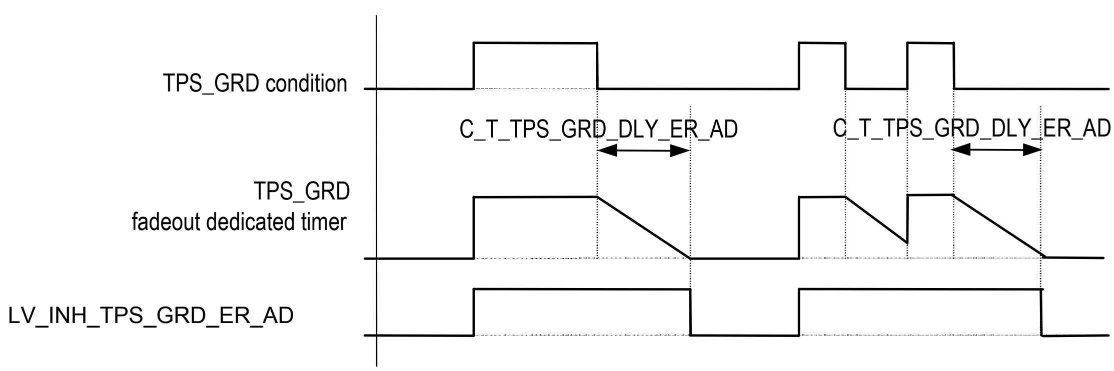
If TPS_GRD > IP_TPS_GRD_MAX_ER_AD(TP_AV)

Then

After condition rising edge triggering, LV_INH_TPS_GRD_ER_AD flag is set to 1 as long as condition is true.

After condition falling edge triggering, LV_INH_TPS_GRD_ER_AD flag is hold to 1 for a period of C_T_TPS_GRD_DLY_ER_AD.

EndIf



4.79.1.5 Air - conditioning compressor activation

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine.

This load jump can cause an ER segment period jump and crankshaft vibration.

Application conditions:

Engine roughness segment adaptation can be suppressed for the applicable constant period C_T_ACCOUT_DLY_ER_AD, starting if the air - conditioning compressor is switched on or off (LV_ACCOUT_RLY changes from 0 to 1 or from 1 to 0), during this period LV_INH_ACC_ER_AD is set to 1.

Formula section:

If LV_ACCOUT_RLY = 0 → 1
Or LV_ACCOUT_RLY = 1 → 0
Then LV_INH_ACC_ER_AD is set to 1 during C_T_ACCOUT_DLY_ER_AD
EndIf

4.79.1.6 Rough road condition active

Due to possible feedback from the driven wheels to the crankshaft it is necessary to fade out. ER segment adaptation when rough road condition is active (LV_STATE_RR = 1).

4.79.1.7 Engine roughness adaptive values on the same physical segment out of range

Due to possible feedback from Dual Mass Flywheel oscillations *(see transmission/crankshaft design)* in adaptive process engine speed range, fluctuations on ER adaptive values of identical physical segments can induce dissimilarity in ER segment correction. LV_SEG_AD_DIF_MAX_ER indicates that the engine roughness adaptive values difference on the same physical segment is out of range.

This flag is produced in the following chapter called: Engine roughness adaptive values difference on the same physical segment out of range.

4.79.1.8 Application specific inhibition request for engine roughness adaptive process

Due to possible accessories triggering specific to the application (CVT shifts...), an inhibition of the engine roughness adaptive process can be applied.

The inhibition is applied when LV_INH_APP_ER_AD = 1.

4.79.1.9 Inhibition request for engine roughness adaptive process linked to OBD errors

Due to possible troubles induced by OBD I sensors errors (CAM, CRK...), the engine roughness adaptive process can be inhibited by the flag LV_INH_OBD_ER_AD.

The inhibition is applied when LV_INH_OBD_ER_AD = 1.

Input data:

LV_INH_OBD_ER_AD	LV_AT	N_32	DRV1_ER
LV_INJ_CUT	LV_ENA_SEG_T_MES	LV_ENA_ER	LV_SEG_AD_RST_ER_EOL
SEG_NR_MES	NC_CYL_NR	SEG_T_COR	

Description:

The adaptive process is managed in two phases:

- A fast adaptive process for end of line procedures (EOL), who allow a fast convergence to ER flywheel adaptive values.
- At the end of the fast adaptive process, a slow adaptive process who will monitor ER adaptive values during the engine lifetime.

An end of line specific filtering mode, to be used on EOL or special service request.

At the beginning of the segment adaptation learning process, it is necessary to upper the engine roughness value with an additional offset (THD_AD_ER), depending on the target wheel tolerances to be excepted.

The segment time adaptation is defined here on 3 different engine speed ranges (Low = _L, Middle = _MID and High = _H speed) to allow a specific crankshaft behaviour learning on each relevant engine speed area.

For instance, a flywheel with a ± 0.3°Crk mechanical tolerance on the ER segment corresponds to following segment drift:

Engine Type	ER Segment length	Induced Drift with ± 0.3°Crk tolerance on ER segment
3 cyl engine	240°Crk	2.5‰
4 cyl engine	180°Crk	3.33‰
5 cyl engine	144°Crk	4.17‰
6 cyl engine	120°Crk	5‰
8 cyl engine	90°Crk	6.68‰
10 cyl engine	72°Crk	8.33‰
12 cyl engine	60°Crk	10.00‰

The value by which the ER is increased at the beginning is gradually reduced to zero in a linear way until the 95% correction is obtained.

This number of steps is controlled by an internal adaptation counter CTR_SEG_AD_ER.

4.79.3.1 Engine roughness adaptive learning process

First time initialisation :

The ER segment adaptive values learning process is initialised when :

- ECU is initialised for the first time *(flash memory formatting)*
- A loss of adaptation values has been detected *(flash memory corrupted)*.
- A specific external tool request occurs *(use of **LV_SEG_AD_RST_ER_EOL**)*

// ER segment adaptive process control variables reseted

CTR_SEG_AD_ER = 0

DELTA_CRK_DIF_MAX_ER = NC_CYL_NR * 4 * C_CRK_DIF_MAX_ER

LV_SEG_AD_AVL_ER = 0

Update rate: ER segment task, every engine cycle when SEG_NR_MES = 0 ; SEG_T_MES_0 segment acquired.

Application conditions:

Activation/Deactivation: (based on LV_SEG_AD_RAW_ER evaluation)

// Raw adaptive value monitoring activation

If LV_INH_OBD_ER_AD = 0 *// OBDI inhibition conditions - See App. Inc.*
And LV_INJ_CUT = 1 *// All cylinders shut-off*

FUNCTION DESCRIPTION:

Segment adaptation only makes sense in the engine operating state trailing throttle fuel cut-off (LV_PUC). It allows to determinate the coefficients for ER segment adaptive values filters used in the learning process.

Three different stages can be differentiate:

- Fast ER segment adaptive values filtering mode, used to quickly obtain valid adaptive values when the EMS is new.

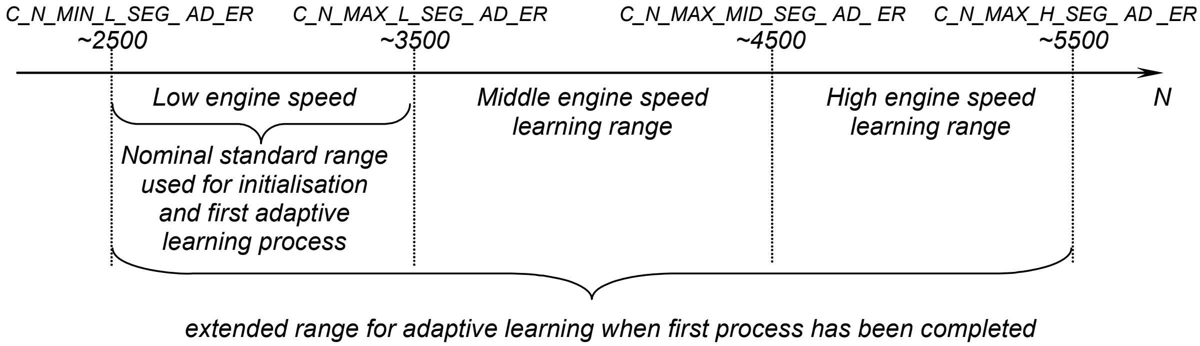
  Since Segment Time Adaptive Process is not completed *(ie. LV_SEG_AD_AVL_ER = 0*), the segment adaptation is only performed and learnt in the low engine speed range (*C_N_MIN_L _SEG_AD_ER* < *N_32* < *C_N_MAX_L_ SEG_AD_ER*).
  In this first case, only one global adaptation value is defined: the same value of segment adaptation will be calculated and applied for all engine speed range (*ie. SEG_AD_MMV_L_[SEG] with SEG_AD_MMV_H_[SEG] = SEG_AD_MMV_MID_[SEG] = SEG_AD_MMV_L_[SEG] in this case*).

- Nominal ER segment adaptive values filtering mode, used to monitor adaptive values during engine lifetime.

  When the first Adaptive Process has been completed *(ie. LV_SEG_AD_AVL_ER = 1*), then the Adaptive Process versus engine speed can take place
  In this case, the Engine Speed area for adaptation enabled will be enlarged (*C_N_MIN_L_SEG_AD_ER* < *N_32* < *C_N_MAX_H_SEG_AD_ER*) and the adaptation values will then be defined and performed according to the running engine speed range (*individual and separate calculation of SEG_AD_MMV_L_[SEG]*

for low N, SEG_AD_MMV_MID_[SEG] for mid N and SEG_AD_MMV_H_[SEG] for high N).

- EOL specific filtering mode, to be used on EOL or special service request.



LV_SEG_AD_LIM_ER is set if at least one SEG_AD_MMV_ER_L/MID/H[x] value exceeds C_SEG_AD_MAX_ER.

First time initialisation :

The ER segment adaptive values learning process is initialised when :

- ECU is initialised for the first time *(flash memory formatting)*
- A loss of adaptation values has been detected *(flash memory corrupted)*.
- A specific external tool request occurs *(use of LV_SEG_AD_RST_ER_EOL defined in Application Incidences file)*

// ER segment adaptive values reseted

For x = 0 ... [NC_CYL_NR-1]

SEG_AD_MMV_ER_L[x] = SEG_AD_MMV_ER_MID[x] = SEG_AD_MMV_ER_H[x] = 0

EndFor

LV_SEG_AD_LIM_ER = 0

Initialisation at ECU reset:

For x = 0...(NC_CYL_NR - 1)

SEG_AD_RAW_MMV_ER[x] = SEG_AD_MMV_ER_L[x]

EndFor

Update rate: ER segment occurrence

Application conditions:

This process is executed every engine cycle when SEG_T_MES_0 (reference segment) is acquired and when the monitoring of the adaptive learning process is active

Activation: LV_SEG_AD_RAW_ER = 1

Process on activation transient:

If LC_SEG_AD_LIM_REAC_ER = 1 *// reactivation of the adaptive values range check*

Then LV_SEG_AD_LIM_ER = 0

Else No Operation

EndIf

Deactivation: LV_SEG_AD_RAW_ER = 0

ER adaptive values difference on same physical segment (Segment 5 & Identical)					
#ENDIF					

Input data:

SEG_NR_MES	NC_CYL_NR		

General information:

Due to possible feedback from Dual Mass Flywheel oscillations *(see transmission/crankshaft design)* in adaptive process engine speed range, fluctuations on ER adaptive values of identical physical segments can induce dissimilarity in ER segment correction.

If difference between identical physical segments ER fast filtered adaptive values exceeds a calibratable gap, a fade out is applied.

ER identical physical segments adaptive value differences are evaluated each 720°Crk, for that this process is executed every engine cycle when SEG_T_MES_0 (*SEG_NR_MES = 0)* is acquired and when the adaptive monitoring process is active.

C_N_MAX_L_SEG_AD_ER_AT			

FUNCTION DESCRIPTION:

The adaptative values from the three engine speed areas have be read and written into SEG_AD_MMV_ER[x] depending on engine speed.

For the definition of SEG_AD_MMV_ER[x], the following cases are considered:

For [x] = 0...NC_CYL_NR - 1

The calculation is done for the **actual active segment**
Update of SEG_AD_MMV_[x] occurs **when** segment **[x]** is active (*SEG_AD_MMV_1 is updated for x = 1, SEG_AD_MMV_2 is updated for x = 2, etc...*)

Update rate: ER segment occurrence

4.80.1 General information:

Attention - This specification version (402U02) is only valid for software variants which are providing the input variables ER and DRV1_ER as 32 bit values.

The engine roughness signal ER as well as the dynamic part of the engine roughness signal DRV1_ER are used as basis for the calculation of the input signal for the cylinder balancing control functions. The calculations are kept cylinder individual corresponding on the actual segment number SEG_NR_ER.

The module "Engine roughness signal preparation for cylinder balancing" is divided in two separate chapters. Within the first part the calculation of the input signals for the cylinder balancing controller is done, while the second part is providing fade out conditions while cylinder balancing has to be interrupted.

Application Condition

4.80.1.2 Input signals for cylinder balancing adaptation functions

The ER values are used to calculate normalized cylinder selective engine roughness values ER_STND_BAL. After normalization (multiplication by N_32^3), the cylinder selective values are filtered by a Median Filter and a PT1-Filter.

In addition, moving mean values are built (ER_STND_MMV_STD_BAL[SEG_NR_ER]) for the calculation of cylinder specific standard deviations (ER_STD_BAL[SEG_NR_ER]).

The standard deviation ER_STD_DIF_BAL is calculated by subtracting the moving mean values ER_STND_MMV_STD_BAL[SEG_NR_ER] from the ER_STND_BAL values.

The resulting difference ER_STD_DIF_BAL is multiplied with a weighting factor for negative and positive values (C_FAC_ER_STD_NEG/POS_BAL). Afterwards a moving mean value is calculated based on this weighted signal.

To allow a cylinder specific adaptation via the engine roughness, a specific signal has to be created for each cylinder. Therefore, from the variable ER_STND_MMV_BAL[SEG_NR_ER] the value ER_STND_MMV_MV_BAL (average value of all cylinder specific moving mean values) is subtracted.

The values ER_STD_MMV_BAL[SEG_NR_ER], ER_STND_MMV_BAL[SEG_NR_ER] and ER_STND_MMV_STD_BAL[SEG_NR_ER] are stored in the non-volatile memory (NVMY) and used for initialization issues at next engine run.

4.80.1.3 Calculation of cylinder balancing acceleration fade out conditions

Multiplying the dynamic component (DRV1_ER) part of the engine roughness calculation with the engine speed by the power of three normalizes the signal. The defined signal is reproducing the engine acceleration in numbers. If the acceleration is quite high or low, in case of speeding up or down, the cylinder balancing adaptation is stopped for a certain number of segments. The number of segments are stored in a counter, which is counting back to zero in certain steps as mentioned in the signal flow diagram.

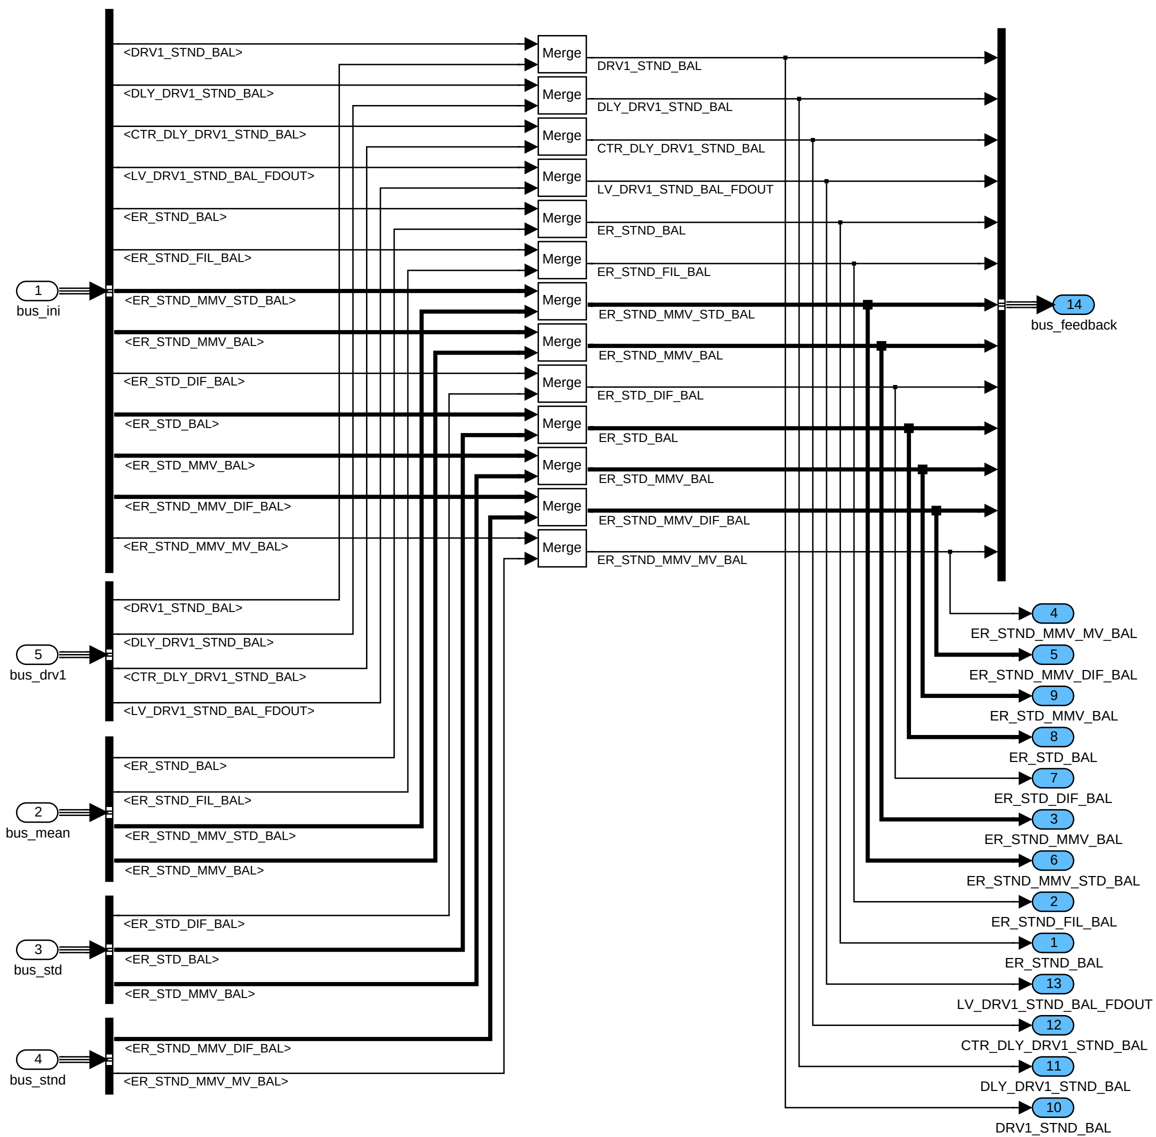

Figure 417 CYBL_SIGNAL/ SIG_MNG

4.81 Mass Air Flow variables

4.81.1 Altitude correction MAF_FAC_ALTI_MMV

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_FAC_ALTI_MMV	V/O	0...FFH	0...1.992	7.78 E-3	-
Mass air flow correction factor for altitude.					

Input data:

AMP_AD			

FUNCTION DESCRIPTION:

Formula section:

In order to take in account different atmospheric pressures at different altitudes, an altitude correction factor MAF_FAC_ALTI_MMV is calculated from division of AMP_AD by 1013 mbar.
The altitude correction factor is applied to TIPR_CST, TI_CST and ISAPWM_INI_I_ST during start and is taken into account as activation condition for evaporative emission control diagnosis and fuel system diagnosis.

Calculation of MAF_FAC_ALTI_MMV:

MAF_FAC_ALTI_MMV is calculated in all engine operation states:

MAF_FAC_ALTI_MMV = AMP_AD / 1013

Application recurrence : **1 sec.**

MAF_FAC_ALTI_MMV is stored in non-volatile memory. For a new car MAF_FAC_ALTI_MMV is initialised to 1.

4.82 Total running time

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
TRT	V/O/S	0...FFFFFFFFH	0...119304.6470 8	2.78E-05	[h]
Total running time					
TRT_FMY	-/S	0...FFFFFFFFH	0...119304.6470 8	2.78E-05	[h]
Total running time at failure memory cleared					

Input data:

LV_IGK	LV_ES		

Function description:

The total running time is incremented by 100ms each if the conditions "ignition key ON" and "engine running" has been detected.

The total running time is saved in the non-volatile memory at the end of the driving cycle.

Formula section:

IF LV_IGK = 1 AND LV_ES = 0

THEN TRT = TRT + 2,7778e-5h

ELSE TRT = TRT

Total running time at last time failure memory cleared

Purpose of this stragey is to memorize the total running time at the last time the failure memory was cleared.

Application conditions:

Initialisation: on failure memory clear service received

TRT_FMY = TRT

Recurrence: -

Activation: -

Deactivation: -

FUNCTION DESCRIPTION:

General information:

The Engine Position Manager provides a summary of camshaft and crankshaft synchronization status information to the system. It sets the operating modes of camshaft and crankshaft acquisition depending on synchronization status, availability, and detected failures. The signal source for engine position will be selected based on the activated operating mode.

Camshaft and crankshaft signal acquisition will be set passive for a calibrated delay after key-off has been detected at low engine speed, and for another calibrated delay after a loss of synchronization at low engine speed. This avoids wrong injection, ignition and diagnosis with backward rotation after rapid key-off/on or stalling.

i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

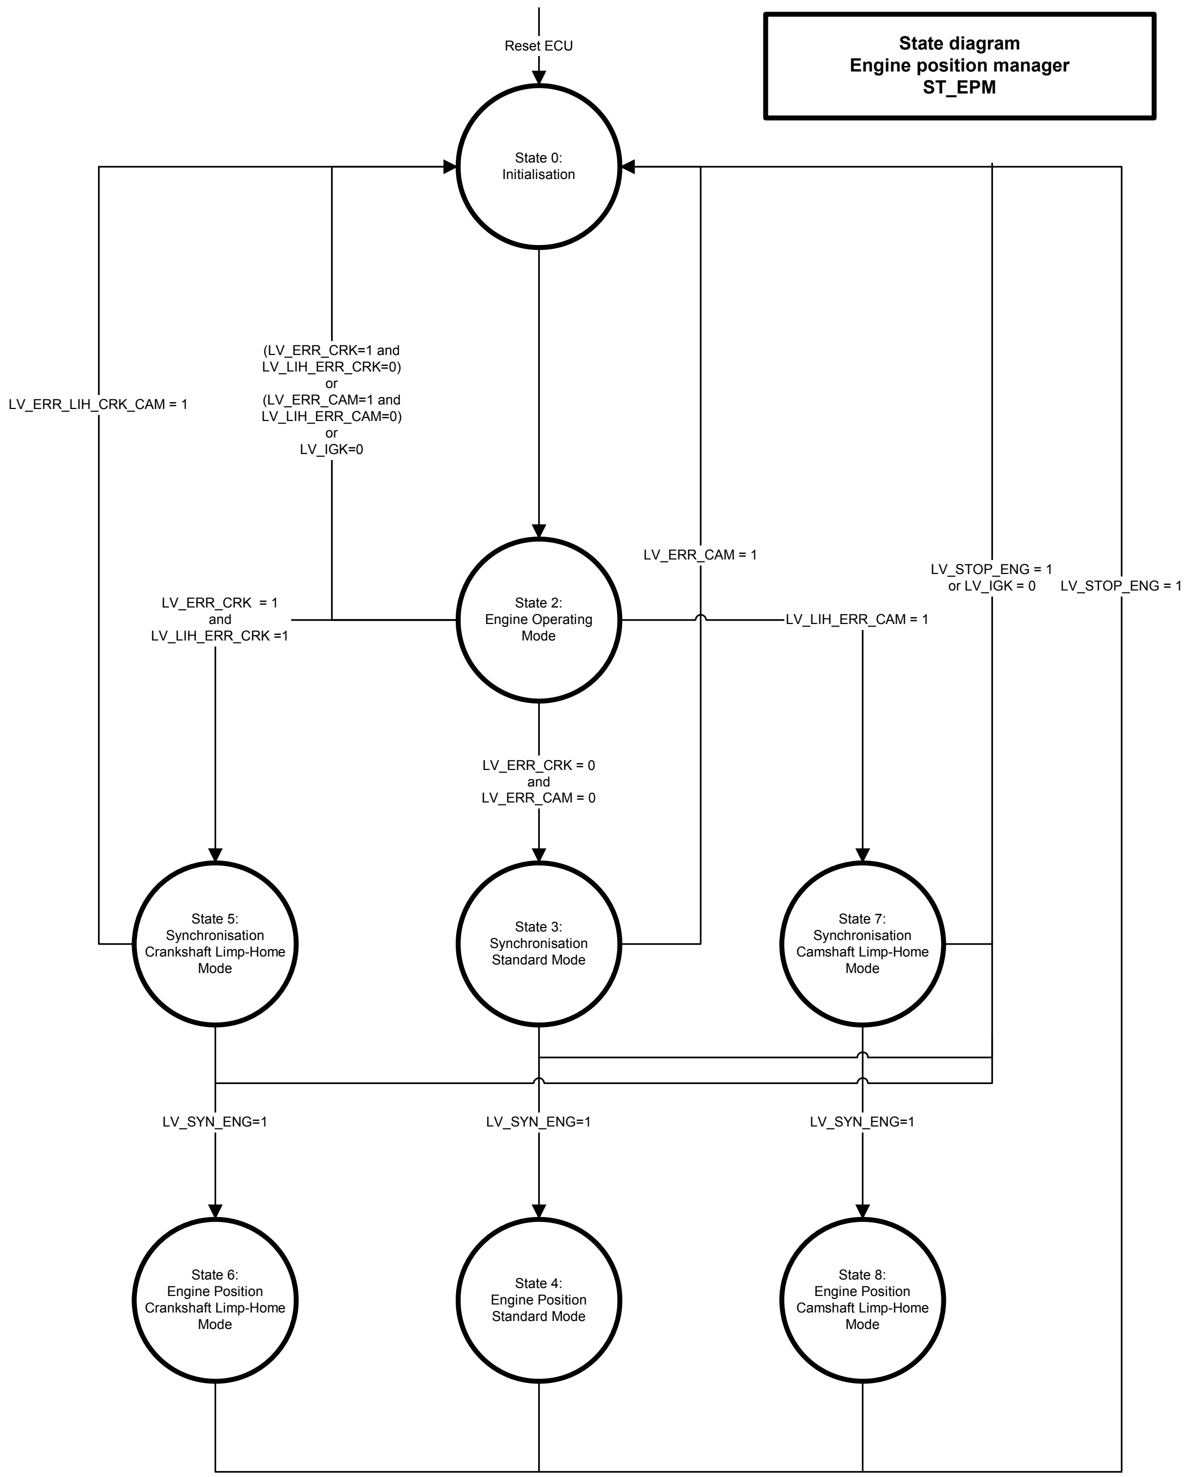
Engine synchronized (LV_SYN_ENG)	Yes (LV_SYN_ENG = 1)	No (LV_SYN_ENG = 0)
Crankshaft sensor available (LV_ERR_CRK = 0) At least one camshaft sensor available (LV_ERR_CAM = 0)	Standard Mode: Engine position and speed calculation with crankshaft sensor signal	Standard Mode Engine synchronisation with camshaft and crankshaft sensor information
Crankshaft sensor available (LV_ERR_CRK = 0) Failure on **all** Camshaft sensors (LV_ERR_CAM = 1)	Limp home Cam: Engine position and speed calculation with crankshaft sensor signal	Limp home Cam: Engine synchronisation without camshaft sensor information
Crankshaft sensor failure (LV_ERR_CRK = 1) At least one camshaft sensors available for crank limp-home (LV_ERR_LIH_CRK_CAM = 0)	Limp home Crank: Engine position and speed calculation without crankshaft sensor signal.	Limp home Crank: Engine synchronisation without crankshaft sensor information
Crankshaft sensor failure (LV_ERR_CRK = 1)		Engine synchronisation fiasco: Engine cannot be synchronized

Failure on **all** Camshaft sensors available for crank limp-home (LV_ERR_LIH_CRK_CAM = 1)		

Application conditions:

Recurrence: *10 ms*

4.83.1 State flow diagram



Initialisation:

LV_ERR_CAM is reset at 0 to 1 transition of LV_IGK

LV_CRK_MISS_RUN_ENG is reset and timer C_T_DLY_STOP_ENG stopped at 1 to 0 transition of LV_IGK

Formula section:

Activation of engine position calculation standard mode

Activation of segment period calculation

Activation of segment number correction in camshaft limp home()

Activation of speed gradient calculation

Activation of crankshaft sensor phase angle correction

Activation of engine stop detection ()

Activation of Engine backwards rotation detection ()

Transition action:

To state 0: **If** C_T_DLY_STOP_ENG > 0

And LV_IGK = 1

And LV_CRK_MISS_RUN_ENG = 0

Then LV_CRK_MISS_RUN_ENG = 1

Start timer C_T_DLY_STOP_ENG

Reset LV_CRK_MISS_RUN_ENG after timer has elapsed

Endif

4.83.2 Definition of the sub-function tasks

4.83.2.1 Fast Engine synchronization

General information:

Fast engine synchronization is in charge to synchronize as soon as the crankshaft signal acquisition is synchronized and a camshaft signal information is available on the selected camshaft.

Application conditions:

Recurrence: on 0 to 1 transition of LV_CAM_SYN_CRK

Formula section:

If LV_CAM_SYN_CRK = 1

Then LV_SYN_ENG = 1

Endif

4.83.2.2 Slow Engine synchronization

General information:

Slow engine synchronization is activated when a failure was detected on at least one camshaft sensor. The engine is synchronized as soon as a number of calibratable camshaft edges has occured (engine synchronized when synchronization is validated). This avoids multiple injection and ignition events with wrong synchronization.

Application conditions:

Recurrence: at every active camshaft edge and on 0 to 1 transition of LV_CAM_SYN_CRK

The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Formula section:

Increment CTR_VLD_CAM_SYN_CRK

If LV_CAM_SYN_CRK = 1

Then **If** CTR_VLD_CAM_SYN_CRK > C_NR_VLD_CAM_SYN_CRK

Then LV_SYN_ENG = 1

Endif

Endif

4.83.2.3 Crankshaft limp-home synchronization

General information:

Only the informations of the selected camshaft signal is used to perform the engine synchronization.
i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: at every camshaft edge

Formula section:

If   LV_SYN_CAM_IN(EX)[i] = 1 for the selected camshaft signal
Then   LV_FIRST_VLD_TOOTH = 1
    LV_RUN_ENG = 1
    LV_SYN_ENG = 1
Endif

4.83.2.4 Camshaft limp-home synchronization

General information:

No camshaft signals are available for the Crank/Cam synchronization so the engine synchronization is performed as soon as the crankshaft is synchronized (the engine revolution can not be identified so a default value is used).

Application conditions:

Recurrence: at every reference gap

Formula section:

If   LV_CRK_SYN = 1
Then   LV_SYN_ENG = 1
Endif

4.83.2.5 Synchronisation validation

General information:

Synchronisation is validated as soon as a number of calibratable camshaft edges has occured. During validation phase, the angular distance between cam/crk events is checked. Engine synchronisation is reset if one of the tests fails.
i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: *at every active camshaft edge and on 0 to 1 transition of LV_CAM_SYN_CRK as long as LV_SYN_VLD = 0*

The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Formula section:

Increment CTR_VLD_CAM_SYN_CRK

If LV_CAM_SYN_CRK = 1

Then **If** CTR_VLD_CAM_SYN_CRK > C_NR_VLD_CAM_SYN_CRK

Then LV_SYN_VLD = 1

Deactivation of Camshaft/Crankshaft synchronisation for the camshaft signal selected for this synchronization:

LV_ACT_SYN_CRK_CAM_IN(EX)[i] = 0

Endif

Endif

4.83.2.6 Synchronisation validation in camshaft limp home

General information:

Synchronization validation information is set as soon as it is requested by “Synchronization determination in camshaft limp home” module which is then deactivated.

Application conditions:

Initialisation: none

Recurrence: each segment event

Formula section:

If LV_SYN_VLD_CAM_LIH = 1
Then LV_SYN_VLD = 1
Deactivation of Synchronization determination in camshaft limp home()
End if

4.83.2.7 Camshaft Selection for synchronisation

General information:

Target wheels on intake and exhaust camshafts may be different, and all may be useable for synchronization. A camshaft signal can only be selected if no error is detected on the respective camshaft (LV_ERR_CAM_IN(EX)[i] = 0). For port-injection engines activation of synchronization mode on intake camshafts should be preferred. Pre-injection needs to be synchronized with intake timing, and the engine position for pre-injection is calculated from the synchronization signal.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Formula section:

The selection order is given by the following table:

	NC_PRI_SYN_CAM_CBK = 1	NC_PRI_SYN_CAM_CBK = 2
NC_PRI_SYN_CAM_IN = 0	CAM_EX_1 CAM_EX_2 CAM_IN_1 CAM_IN_2	CAM_EX_2 CAM_EX_1 CAM_IN_2 CAM_IN_1
NC_PRI_SYN_CAM_IN = 1	CAM_IN_1 CAM_IN_2 CAM_EX_1 CAM_EX_2	CAM_IN_2 CAM_IN_1 CAM_EX_2 CAM_EX_1

The first camshaft sensor in the above list which fulfills the following conditions is selected:

- physically present in the system (configuration data NLC_CAM_IN, NLC_CAM_EX and NC_NR_CAM_CBK)
- no failure reported on it (LV_ERR_CAM_IN(EX)[i] = 0)

The crankshaft synchronization mode is activated on one camshaft signal by setting LV_ACT_SYN_CRK_CAM_IN(EX)[i] for the selected camshaft.

LV_ERR_CAM is set if all available camshaft sensors report and error.

4.83.2.8 Camshaft Selection for limp-home

General information:

Target wheels on intake and exhaust camshafts may be different, and not all may be useable for limp-home. The availability of camshaft sensors for limp-home is given by NLC_LIH_CAM_IN(EX) and NC_NR_CAM_CBK. A camshaft signal can only be selected if no error is detected on the respective camshaft (LV_ERR_CAM_IN(EX)[i] = 0).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Formula section:

The selection order is given by the following table:

	NC_PRI_LIH_CAM_CBK = 1	NC_PRI_LIH_CAM_CBK = 2
NC_PRI_LIH_CAM_IN = 0	CAM_EX_1 CAM_EX_2	CAM_EX_2 CAM_EX_1

	CAM_IN_1 CAM_IN_2	CAM_IN_2 CAM_IN_1
NC_PRI_LIH_CAM_IN = 1	CAM_IN_1 CAM_IN_2 CAM_EX_1 CAM_EX_2	CAM_IN_2 CAM_IN_1 CAM_EX_2 CAM_EX_1

The first camshaft sensor in the above list which fulfills the following conditions is selected:

- physically present in the system (configuration data NLC_CAM_IN, NLC_CAM_EX_IN and NC_NR_CAM_CBK)
- no failure reported on it (LV_ERR_CAM_IN(EX)[i] = 0)
- available for crankshaft limp-home (NLC_LIH_CAM_IN = 1 or NLC_LIH_CAM_EX = 1)

The crankshaft limp-home mode is activated on one camshaft signal by setting LV_ACT_LIH_CRK_CAM_IN(EX)[i] for the selected camshaft.

LV_ERR_LIH_CRK_CAM is set if no more camshaft sensors is available.

4.83.2.9 Engine stop detection

Application conditions:

Recurrence: 10ms

Formula section:

LV_STOP_ENG is set if one of the conditions in the table below are met:

In Standard mode (States 3 and 4)	In Camshaft limp-home mode (States 7 and 8)	In Crankshaft limp-home mode (States 5 and 6)	In Engine position Standard and Camshaft limp-home mode (States 4 and 8)
LV_CRK_STOP = 1	LV_CRK_STOP = 1	LV_CAM_STOP_IN(EX)[i] = 1 for the selected camshaft signal	LV_ENG_BACK_CFM switches from 0 to 1
LV_ORNG_CAM_SYN_CRK = 1 (*)			
LV_ERR_CRK = 1 And LC_INH_LIH_CRK = 0			

(*) This information is available as long as LV_SYN_VLD = 0.

4.83.2.10 Camshaft self-synchronisation reactivation

General information:

When the self-synchronization of a camshaft signal goes to the fiasco state (LV_CAM_STOP_IN(EX)[i] = 1), the self-synchronization on this camshaft signal will be reactivated as soon as possible. If this camshaft is selected for the synchronization in crankshaft limp-home mode an engine stop is detected (by *engine stop detection()* sub-function task) and a new synchronization is restarted.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: 10ms

Formula section:

For all available camshaft signal sensors:

If LV_CAM_STOP_IN(EX)[i] = 1
And LV_ACT_LIH_CRK_CAM_IN(EX)[i] = 0
Then Activation of Camshaft self-synchronisation for this camshaft signal
Endif

4.83.2.11 *Calculation of PSN_ENG_CRK in standard mode()*

General information:

Formula section:

Before synchronization (LV_SYN_ENG = 0):

Truth table					
LV_CRK_SYN n	0	1			
LV_CRK_SYN n-1	0	0		1	
LV_CAM_SYN_CRK n	0	0	1	0	1
LV_CAM_SYN_CRK n-1	0	0	0	0	0
Engine position action	**1**	**2**	**3**	**4**	**5**

Action 1:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

Action 2:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

PSN_ENG_CRK_GAP = 360° - NC_OFS_TDC0_REF_CRK

Action 3:

PSN_ENG_CRK = 360° - NC_OFS_TDC0_REF_CRK + PSN_ENG_CRK_OFS

Action 4:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

PSN_ENG_CRK_GAP n = PSN_ENG_CRK_GAP n-1 + (360°/NC_NR_TOOTH)

Action 5:

PSN_ENG_CRK = PSN_ENG_CRK_GAP + PSN_ENG_CRK_OFS

After the synchronization (LV_SYN_ENG = 1):

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 720°.

4.83.2.12 *Calculation of PSN_ENG_CRK in camshaft limp-home mode()*

General information:

Formula section:

Before synchronization (LV_SYN_ENG = 0):

Truth table		
LV_CRK_SYN n	0	1
LV_CRK_SYN n-1	0	0
Engine position action	**1**	**2**

Action 1:

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 360°

Action 2:

PSN_ENG_CRK = 720° - NC_OFS_TDC0_REF_CRK

After the synchronization (LV_SYN_ENG = 1):

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 720°

4.83.2.13 *PSN_ENG_CRK correction in camshaft limp-home()*

General information:

This function updates PSN_ENG_CRK depending on synchronization determination test result in camshaft limp home.

Application conditions:

Initialisation: none

Recurrence: none

Activation: LV_SEG_NR_UPD_REQ = 1

Deactivation: LV_SEG_NR_UPD_REQ = 0

Formula section:

PSN_ENG_CRK = PSN_ENG_CRK + (360°CRK / NC_NR_GAP)

4.83.2.14 *Calculation of PSN_ENG_CAM_LIH_CRK()*

General information:

The purpose of this function is to provide engine position during crankshaft limp-home. In crankshaft limp-home, the engine position is calculated from the camshaft sensor selected by LV_ACT_LIH_CRK_CAM_IN(EX)[i].

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Initialization: PSN_ENG_CAM_LIH_CRK = 0

Recurrence: every camshaft signal edge

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

For z = IDX_EDGE_CAM_IN(EX)[i] and the camshaft sensor selected for crankshaft limp home by LV_ACT_LIH_CRK_CAM_IN(EX)[i]:

If z is a falling camshaft signal edge

Then **If** NC_ACT_CAM_EDGE_LIH = 1

Or

NC_ACT_CAM_EDGE_LIH = 3

Then PSN_ENG_CAM_LIH_CRK = NC_PSN_EDGE_CAM_IN(EX)[z][i] +

Average value of PSN_EDGE_AD_CAM_IN(EX)[z][i] for all falling camshaft signal edges

Else *no update of PSN_ENG_CAM_LIH_CRK*

Endif

Else **If** NC_ACT_CAM_EDGE_LIH = 2

Or

NC_ACT_CAM_EDGE_LIH = 3

Then PSN_ENG_CAM_LIH_CRK = NC_PSN_EDGE_CAM_IN(EX)[z][i] +

Average value of PSN_EDGE_AD_CAM_IN(EX)[z][i] for all rising camshaft signal edges

Else *no update of PSN_ENG_CAM_LIH_CRK*

Endif

End

4.83.2.15 Engine backwards rotation detection ()

General information:

The aim of this function is to detect a change in the direction of engine rotation which would lead to a false crankshaft teeth counter value and thus to a wrong timing for injection and/or ignition events. This could occur at low engine speed with hard compression phases.
This functionality gets a lower performance if camshaft target wheel is symmetrical as only the tests on crankshaft signal can be done (Action 1 and Test 2).
i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Initialisation: at reset or engine stalling (LV_STOP_ENG transition from 0 to 1)
LV_ENG_BACK_DET = 0
LV_ENG_BACK_CFM = 0

Recurrence: 10ms and every camshaft edge (for all camshaft sensors) and every reference gap and at engine stalling (LV_STOP_ENG transition from 0 to 1)

Activation: LC_ENG_BACK_INH = 0

Deactivation: when application conditions are not fulfilled

Formula section:

If **(** N_TOOTH < C_N_NOT_REST **And** LV_CRK_MISS_TOOTH = 1 **)**

or LV_ENG_BACK_DET = 1

Then LV_ENG_BACK_DET = 1

Activation of Engine backwards rotation confirmation ()

Else LV_ENG_BACK_DET = 0

LV_ENG_BACK_CFM = 0

End

LV_CRK_MISS_TOOTH is reset after reading.

At transition from 0 to 1 of LV_ENG_BACK_DET, CTR_TEST_ENG_BACK_RST = C_NR_TEST_ENG_BACK_RST.

Engine backwards rotation confirmation ():

The following table shows the test or action to perform in function of the current event.The event is a detection of a camshaft edge (CAM) or a detection of reference gap (GAP) or an engine stall (Engine stall).

Event	GAP	Engine stall	CAM
Test / Action	Action 1	Test 2	Test 3

Action 1:

This event means that the reference gap has been detected at the expected position (the number of teeth between 2 gaps is correct) and that the number of camshaft edges over last engine cycle is correct for all camshaft sensors and thus that engine backwards rotation is not confirmed.

If abs(CTR_EDGE_CAM_IN(EX)[i] - CTR_EDGE_CAM_IN(EX)[i] at GAP(n-2)) = NC_NR_EDGE_CAM_IN(EX)

for all available CAM sensors with LV_ERR_CAM_IN(EX)[i] = 0

/* number of camshaft edges over last engine cycle equal to theoritical one */

Then CTR_TEST_ENG_BACK_RST = CTR_TEST_ENG_BACK_RST - 1

Endif

If CTR_TEST_ENG_BACK_RST = 0

Then LV_ENG_BACK_DET = 0

Endif

Test 2:

This event means that the number of teeth between 2 gaps is not correct due to engine backwards rotation which is thus confirmed.

If LV_LOST_SYN_CRK = 1

Then LV_ENG_BACK_CFM = 1

Test 3:

This test is only done on the camshaft signal that generated the event. It checks wether camshaft signal position is correct versus crankshaft signal or versus previous camshaft signal. If not, engine backwards rotation is confirmed.

If LV_ERR_CAM_IN(EX)[i] = 0

Then **if** **{**

(LV_SYN_CAM_IN(EX)[i] = 1 'z value, which represents camshaft edge number, is know as camshaft is self-synchronized

And

(PSN_ENG_ENSD ≤ NC_PSN_EDGE_CAM_IN(EX)[z][i] - C_DYW_CAM_CRK_SYN_ADC_IN(EX)

Or PSN_ENG_ENSD ≥ NC_PSN_EDGE_CAM_IN(EX)[z][i] + C_DYW_CAM_CRK_SYN_RTD_IN(EX)) **)**

Or

LV_ORNG_RATIO_CAM_IN(EX)[i] = 1 **}**

Then LV_ENG_BACK_CFM = 1

Else **if** LV_SYN_CAM_IN(EX)[i] = 1

Then LV_ENG_BACK_DET = 0

End

End

End

FUNCTION DESCRIPTION:

At engine stalling (LV_STOP_ENG 0 to 1), all output data are set to initialization value.

4.84.1 Engine Position Calculation Standard Mode

General information:

The function provides output values for engine position in standard operating mode.

Application conditions:

Initialisation: PSN_ENG = PSN_ENG_ENSD = 0

Recurrence: every update of the corresponding input values

Formula section:

PSN_ENG = PSN_ENG_ENSD (resolution conversion)

PSN_ENG_ENSD = PSN_ENG_CRK + ID_CRK_PHA_COR

PSN_ENG_SYN_MIN = PSN_ENG_SYN_CAM_MIN

PSN_ENG_SYN_MAX = PSN_ENG_SYN_CAM_MAX

The resolution of variables that are exported outside the aggregate is different from the resolution used internally!

4.84.2 Engine Position Calculation Crankshaft Limp-Home Mode

General information:

The function provides output values for engine position in crankshaft limp-home mode.

Application conditions:

Initialisation: PSN_ENG = PSN_ENG_ENSD = 0

Recurrence: every update of the corresponding input values

Formula section:

PSN_ENG = PSN_ENG_ENSD (resolution conversion)

PSN_ENG_ENSD = PSN_ENG_CAM_LIH_CRK

PSN_ENG_SYN_MIN = PSN_ENG_SYN_CAM_MIN

PSN_ENG_SYN_MAX = PSN_ENG_SYN_CAM_MAX

The resolution of variables that are exported outside the aggregate is different from the resolution used internally!

4.84.3 Segment Period Calculation

General information:

The function provides output values for the segment period.

The engine cycle is divided into a number of TDC periods corresponding to the number of cylinders NC_CYL_NR. The corresponding time intervals T_SEG_AV are measured between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC.

The segment number SEG_NR indicates the number of the cylinder that will be next in the firing order. A control signal is generated to trigger execution of segment synchronous tasks.

Application conditions:

Initialisation: T_SEG_AV is set to the maximum value

SEG_CTR = 0

SEG_NR = 0

Activation: LV_RUN_ENG = 1

Recurrence : when LV_RUN_ENG is set
And when LV_CRK_SYN is set
And every segment trigger

Formula section:

T_SEG_AV = T_SEG_ENSD saturated to maximum value at low speed.

At engine synchronization, SEG_NR is initialized with current segment number.

SEG_CTR is incremented at every segment.

4.84.4 Segment number correction in camshaft limp home

General information:

This function updates SEG_NR value in camshaft limp home mode depending on synchronization determination test result.

Application conditions:

Initialisation: none

Recurrence: none

Activation: LV_SEG_NR_UPD_REQ = 1

Deactivation: LV_SEG_NR_UPD_REQ = 0

Formula section:

SEG_NR = SEG_NR + NC_CYL_NR / (2 * NC_NR_GAP)

4.84.5 Engine speed N, N_32, N_MMV

General information:

The engine speed is determined in each segment from the segment period T_SEG_ENSD.

Application conditions:

Activation: LV_RUN_ENG = 1

Recurrence: when LV_RUN_ENG is set
And when LV_CRK_SYN is set
And every segment trigger

Formula section:

N = $\frac{2*60}{NC\_CYL\_NR*T\_SEG\_ENSD}$ for T_SEG_ENSD in s

N_32 = N in resolution 32 rpm

Before synchronization and at synchronization, one engine speed is output at the moment when crankshaft rotation is validated. The output value will be calculated from the most recent tooth period (see “Segment Period Calculation”)

N_MMV is the moving mean value calculated on the last 720° CRK:

N_MMV = $\frac{N_n + N_{n-1} + \ldots + N_{n-NC\_CYL\_NR}}{NC\_CYL\_NR}$

Before engine synchronisation N_MMV = N. After engine synchronisation and before the first engine cycle is completed, N_MMV is calculated as the mean value of the most recent segments of this cycle.

Set N_FAST to N if no fast engine speed calculation is required.

If C_N_FAST_SWI = 0

Then N_FAST = N

Endif

4.84.6 Fast Engine speed based on last tooth period

General information:

Provide engine speed calculated every 10ms on the last crankshaft tooth period during cranking, synchronisation and start phase. Calculation is done until speed threshold is reached.
If, during running, Engine speed becomes lower than this threshold, this calculation is started again
In the formula after, T_TOOTH in s is the time for the last crankshaft tooth period, acquired in BSW just before the 10ms trigger event used for update rate of N_TOOTH here.

Application conditions:

Initialisation: N_TOOTH = 0

Recurrence : 10ms

Activation: LV_RUN_ENG = 1

Deactivation: LV_RUN_ENG = 0

Formula section:

If N_32 <= C_N_TOOTH_END

Then N_TOOTH = 60 / (NC_NR_TOOTH * T_TOOTH)

Endif

If C_N_FAST_SWI = 1

Then N_FAST = N_TOOTH

Endif

4.84.7 Fast Engine Speed based on Half-Segment Period Calculation

General information:

This function provides fast engine speed based on half-segment period.

Application conditions:

Initialisation: T_SEG_HALF_AV is set to the maximum value

Recurrence: before synchronization: once at transition from LV_RUN_ENG from 0 to 1
after synchronization: every ½ segment trigger **and** segment trigger

Activation: LV_RUN_ENG = 1

Formula section:

If C_N_FAST_SWI = 2

Then N_FAST = $\frac{60}{NC\_CYL\_NR * T\_SEG\_HALF\_ENSD}$

Endif

T_SEG_HALF_AV = T_SEG_HALF_ENSD saturated to maximum value at low speed.

4.84.8 Fast Engine Speed based on Crankshaft Tooth Window

General information:

This function provides fast engine speed output based on a crankshaft window at the end of each segment. Updated every segment

Application conditions:

Initialisation: N_FAST = 0

Recurrence : every segment trigger

Activation: LV_RUN_ENG = 1
And
(C_N_FAST_SWI = 3 **Or** C_N_FAST_SWI = 4)

Deactivation: C_N_FAST_SWI <> 3 **And** C_N_FAST_SWI <> 4

Formula section:

N_CRK_WIN = $\frac{60}{T\_CRK\_WIN\_ENSD} \quad \frac{NC\_CRK\_WIN\_SEG\_LEN}{360° CRK}$

If C_N_FAST_SWI = 3

Then N_FAST = N + C_FAC_N_FAST * (N_CRK_WIN n – N_CRK_WIN n-1)

Endif

If C_N_FAST_SWI = 4

Then N_FAST = N + C_FAC_N_FAST * (N n – N_CRK_WIN n-1)

Endif

4.84.9 Engine speed gradient N_GRD, N_GRD_H_RES

General information:

The engine speed gradient is the acceleration of the crankshaft in rpm/s. For engins with an even number of cylinders (2...8), the gradient is calculated from the duration of the most recent engine revolution, and the duration of the previous engine revolution. With this calculation, the gradient is free from errors due to mechanical tolerances of the crankshaft target wheel.

For three-cylinder engins, the gradient is calculated from the most recent segment time, and the segment time before. Errors from mechanical tolerances of the crankshaft target wheel are not corrected, but are supposed to have a minor effect due to the greater angle of the segments.

Application recurrence: every segment trigger

Formula section:

For even cylinder numbers, the duration of the most recent engine revolution is the sum of the most recent NC_CYL_NR/2 segment times. For e.g. a four-cylinder engine, this is:

$$T\_REV\_AV = T\_SEG\_ENSD_{n} + T\_SEG\_ENSD_{n-1}$$

The duration of the previous engine revolution is for the example of a four-cylinder engine:

$$T\_REV\_PREV = T\_SEG\_ENSD_{n-2} + T\_SEG\_ENSD_{n-3}$$

N_GRD calculation:

N_GRD_H_RES =

$$\frac{60*(T\_REV\_PREV - T\_REV\_AV)}{T\_REV\_PREV * T\_REV\_AV * 0.5*(T\_REV\_PREV + T\_REV\_AV)}$$

for T_REV_AV and T_REV_PREV in s

N_GRD = N_GRD_H_RES in resolution 32 rpm/s.

The resolution of the segment time introduces an error into the calculation of the engine speed gradient, depending on engine speed.

For a timer resolution of 0.25µs, a difference of 1 timer tick between T_REV_AV and T_REV_PREV corresponds to:

0.015 rpm/s at 600 rpm

and 15 rpm/s at 6000 rpm

For three-cylinder engins, the gradient is calculated as follows:

N_GRD_H_RES =

$$\frac{2*60*(T\_SEG\_ENSD_{n-1} - T\_SEG\_ENSD_{n})}{3*T\_SEG\_ENSD_{n-1}*T\_SEG\_ENSD_{n}*0.5*(T\_SEG\_ENSD_{n-1} + T\_SEG\_ENSD_{n})}$$

N_GRD = N_GRD_H_RES in resolution 32 rpm/s.

The resolution of the segment time introduces an error into the calculation of the engine speed gradient, depending on engine speed.

A difference of 1 timer tick between $T\_SEG\_ENSD_{n}$ and $T\_SEG\_ENSD_{n-1}$ corresponds to:

0.51 rpm/s at 600 rpm

and 51 rpm/s at 6000 rpm

4.84.10 Crankshaft Sensor Phase Angle Correction

General information:

The sensor phase angle is defined as the rotation angle of the target wheel between the mechanical reference and the electrical reference for a tooth of the target wheel.

The mechanical reference in the target wheel drawing usually is the trailing edge of a tooth in the defined rotation direction. The mechanical reference position is reached when the center of the sensor is aligned to that angular reference.

The electrical reference may be on the falling or on the rising edge of the sensor output signal, see active edge definition in the acquisition of crankshaft signal. The reference position is reached when the sensor output signal switches (for active sensors) respectively has its zero crossing (for VR sensors).

A retard of the electrical reference relative to the mechanical edge is defined as a positive phase angle. With most sensors, the signal edge is generated at the center of each tooth at low speed. At high speed the signal edge may be retarded.

The typical phase angle ID_CRK_PHA_COR (at typical air gap and operating temperature) of the used sensor/target wheel combination is calibrated in a table versus engine speed. The value corresponding to the actual engine speed is added to the actual engine position delivered from crankshaft acquisition, in order to obtain a corrected engine position (see position calculation in the first chapter of this specification).

Application conditions:

Recurrence: every segment trigger

Activation: LV_CRK_SYN = 1

Deactivation: LV_CRK_SYN = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_TOOTH_END	1	0...FFH	0...8160	32	[rpm]
Engine speed threshold for N_TOOTH calculation at engine start

Maximum engine speed during former / current driving cycle – Resolution 32 rpm					

Input data:

LV_RUN_ENG	N_32		

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

N_32_MAX_TOT_DC = 0H

- otherwise: N_32_MAX_TOT_DC restored form non-volantile memory
- at LV_IGK 0 ->1 and reset: N_32_MAX_DC = 0

Recurrence: segment synchronous

Activation: LV_RUN_ENG = 1

Deactivation: -

Formula section:

If N_32 > N_32_MAX_DC

Then N_32_MAX_DC = N_32

Endif

If N_32 > N_32_MAX_TOT_DC

Then N_32_MAX_TOT_DC = N_32

Endif

4.86 Synchronization determination in camshaft limp home

Output data:

INH_INJ	TCO_CMN	VB_CMN	SEG_NR
NC_CAM_LIH_SWI			

FUNCTION DESCRIPTION:

General information:

This functions aims at initializing the variables used by ENSD or others aggregates in case no camshaft limp home method has been selected.

Description:

Application conditions:

Initialisation: none

Recurrence: at reset

Activation: NC_CAM_LIH_SWI = “None”

Deactivation: NC_CAM_LIH_SWI ≠ “None”

Formula section:

LV_SYN_VLD_CAM_LIH = 0
LV_CAM_LIH_EXT_ENA = 0
LV_SEG_NR_UPD_REQ = 0

Remark: as this module is only a stub, N, N_GRD, SEG_CTR, LV_VS_RUN, INH_INJ, TCO_CMN, VB_CMN and SEG_NR are not used.

FUNCTION DESCRIPTION:

General information:

The function provides a feedback about the actual camshaft position relative to the engine position measured with the crankshaft sensor. The signals of one, two or four camshaft sensors are treated (intake and/or exhaust camshaft on one or two cylinder banks).

The actual engine position is captured with every camshaft signal edge. The camshaft position is calculated as the difference between the captured engine position, and the engine position measured on the respective camshaft. The difference may be due to tolerances, or due to an intentional displacement by a camshaft phasing system (VVTI).

Two different adaptive learning algorithms eliminate the tolerances, in order to measure exactly the VVTI displacement.

The reference position adaptation is done for all signal edges. It is performed on all intake camshafts as long as LV_DI_AD_REF_CAM_IVVT_IN = 0. It is performed on all exhaust camshafts as long as LV_DI_AD_REF_CAM__IVVT_EX = 0. The camshafts are then situated in their respective VVTI passive positions. After the completion of the adaptation LV_AD_END_CAM_IN(EX)[i] is set and PSN_AD_CAM_IN(EX)[i] is calculated as the mean value of all adaptated signal edges. The reference edge has the index 1. It is the first electrical falling edge of the camshaft signal after TDC0.

The position of other signal edges is adapted continuously relative to the reference signal edge, in order to always deliver a coherent position information.

Both adaptation algorithms are performed only at a limited dynamic variation of the camshaft position measured at the reference edge.

The logical calibration bit LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] is set if the VVTI system is inhibited on the corresponding camshafts. The respective camshafts will be treated like being constantly in the VVTI passive position. If an engine has more camshaft sensors then VVTI actuators, then NLC_IVVT_IN(EX) = 0 indicates that VVTI is not existing on intake or on exhaust camshafts.

4.87.1 Engine Position Determination from Camshaft signal

General information:

As soon as camshaft is self-synchronized, the actual engine position is calculated at every camshaft signal edge from theorical position plus adaptation value for the actual signal edge index.

i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Recurrence :   *every CAM active edge*

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]

PSN_ENG_CAM_IN(EX)[i] (n) = NC_PSN_EDGE_CAM_IN(EX)[z][i] +
PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) +
ID_CAM_PHA_COR

4.87.2 Camshaft Position Output

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN(EX)[i] = 1 **And** LV_SYN_VLD = 1

Recurrence: *every update of IDX_EDGE_CAM_IN(EX)[i]*

Initialization:

PSN_CAM_IN(EX)[i] = 0
PSN_EDGE_CAM_IN(EX)[z][i] = 0

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]

PSN_EDGE_CAM_IN(EX)[z][i] = PSN_ENG_ENSD - PSN_ENG_CAM_IN(EX)[i]

In the following calculations, the resolution has to be converted:

PSN_CAM_IN(EX)[i] = PSN_EDGE_CAM_IN(EX)[z][i]

PSN_DIF_EDGE_CAM_IN(EX)[i] = PSN_ENG_ENSD (n) - PSN_ENG_ENSD (n-1)

T_DIF_EDGE_CAM_IN(EX)[i] = T_SEG_CAM_IN(EX)[i]

4.87.3 Camshaft Position Adaptation

4.87.3.1 Reference Position Adaptation

General information:

The reference position adaptation is done whenever it is not disabled by the corresponding flag from VVTI, or if there is no VVTI on that camshaft, and if the condition for limited dynamic variation of the camshaft position is true. A flag is set to signal successful adaptation.

The flag is reset when the adaptation inhibit conditions become false.

If LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1

Then LV_AD_END_CAM_IN(EX)[i] = 0

The camshaft position output value should be zero in VVTI passive position. At each ocurrence of the reference camshaft signal edge, a portion of the position deviation is added to the previous adaptation value, as long as adaptation conditions are true, this is done for all the camshaft signal edges.

If the conditions stay true for a number of revolutions, then the flag for successful end of adaptation is set (LV_AD_END_CAM_IN(EX)[i] = 1).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN(EX)_I =1 **And** LV_SYN_VLD = 1

And

LV_DI_AD_REF_CAM_IVVT_IN(EX) = 0 **Or** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 1 **Or** NLC_IVVT_IN(EX) = 0

Recurrence: *every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)*

Initialization:

LV_AD_END_CAM_IN(EX)[i] = 0

CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] are initialized to 0)

PSN_AD_CAM_IN(EX)[i] = Sum **(** PSN_EDGE_AD_CAM_IN(EX)[z][i]

for z = 1…NC_NR_EDGE_CAM_IN(EX) **)** / NC_NR_EDGE_CAM_IN(EX)

(resolution conversion)

LV_CAM_AD_SAVE_IN(EX)[i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, LV_CAM_AD_SAVE_IN(EX)[i] is initialized to 0)

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

At reset: CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

(All these adaptive values has to be reset in case of cam/crk mechanical change (Chain change, camshaft sensor change…))

Formula section:

If |PSN_EDGE_CAM_IN(EX)[1][i] (n) – PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| < C_GRD_AD_REF_MAX_CAM_IN(EX)

Then increment CTR_REV_AD_REF_CAM_IN(EX)[i]

The adaptation values are calculated for all indexes (for z = 1…NC_NR_EDGE_CAM_IN(EX))

PSN_EDGE_AD_CAM_IN(EX)[z][i] (n) = PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_REF_CAM_IN(EX) * PSN_EDGE_CAM_IN(EX)[z][i]

Else CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

Endif

If CTR_REV_AD_REF_CAM_IN(EX)[i] >= C_NR_REV_AD_REF_CAM_IN(EX)

Then CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

PSN_AD_CAM_IN(EX)[i] = Sum **(** PSN_EDGE_AD_CAM_IN(EX)[z][i]

for z = 1…NC_NR_EDGE_CAM_IN(EX) **)** / NC_NR_EDGE_CAM_IN(EX)

(resolution conversion)

If LV_CAM_AD_SAVE_IN(EX)[i] = 1

Then **If** |CAM_PSN_LST_REF_AD_IN(EX)[i] - PSN_EDGE_AD_CAM_IN(EX)[1][i]| < C_TOL_TOOTH_OFF_CAM_IN(EX)

Then CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

Else nothing

Endif

LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 1 *(to allow the ONE_TOOTH_OFF diagnosis only if a reference adaptation has been done after the very first one)*

Else **If** C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0

Then CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

LV_CAM_AD_SAVE_IN(EX)[i] = 1 *(set at the end of the very first reference adaptation)*

Else nothing

Endif

Endif

LV_AD_END_CAM_IN(EX)[i] = 1

Else

LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 0

Endif

If LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1

Then CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

Endif

4.87.3.2 Continuous Edge Position Adaptation

The continuous position adaptation is enabled at a limited dynamic variation of the camshaft position measured at the reference signal edge.

The difference of the actual camshaft position measured at the reference edge, and the actual camshaft position measured at any other signal edge, is calculated once per camshaft revolution. That difference is multiplied with a cofficient (<<1) and added to the previous adaptation value to form the new adaptation value, which is applied in the following camshaft revolution. This way the camshaft position output value calculated at any signal edges will approach the camshaft position output value calculated at the reference signal edge.

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN[i] = 1 **And** LV_SYN_VLD = 1

And

LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1 **And** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 0 **And** NLC_IVVT_IN(EX) = 1

Recurrence: *every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)*

Initialization:

PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] is initialized to 0)

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

Formula section:

For the following equations, the index z of the camshaft signal edges equals IDX_EDGE_CAM_IN(EX)[i] (z=1 for reference edge). The adaptation values are calculated for all indexes from 2 to NC_NR_EDGE_CAM_IN(EX).

If |PSN_EDGE_CAM_IN(EX)[1][i] (n) - PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| < C_GRD_AD_MAX_CAM_IN(EX)

Then PSN_EDGE_AD_CAM_IN(EX)[z][i] (n) = PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_CAM_IN(EX) * (PSN_EDGE_CAM_IN(EX)[z][i] - PSN_EDGE_CAM_IN(EX)[1][i])

Endif

4.87.3.3 Reference adaptive values save authorization at Powerlatch

Before saving the adaptive values in NVMY during PWL, it is important to check if they are correct. Even if the REF_CRK_CAM error is not set, the calculated adaptive values can be wrong (for example, the error flag could have been reset on a quick key 0 to 1 transition).

Application conditions:

Activation:

ECU_STATE = PWL

Recurrence: *once during PWL, for all camshaft edges of all present camshaft sensors, before saving the NVMY adaptive values*

Initialization:

LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0

Formula section:

If PSN_EDGE_AD_CAM_IN(EX)[z][i] < C_TOL_REF_CRK_CAM_MIN_IN(EX)

or PSN_EDGE_AD_CAM_IN(EX)[z][i] > C_TOL_REF_CRK_CAM_MAX_IN(EX)

Then LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1

Else

If LV_CAM_AD_SAVE_IN(EX)[i] = 1

And

CAM_PSN_LST_REF_AD_IN(EX)[i] <> PSN_EDGE_AD_CAM_IN(EX)[1][i]

And

C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0

Then LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1

Else *nothing, (if LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] has been set to 1 due to anyone of the camshaft edges, it must stay to 1 and the adaptive will not be saved. Contrary, if all the camshaft edges are correct, adaptive values can be saved, LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] must stay at 0)*

Endif

Endif

PUT_WG_OPEN	N	LC_TCHA_CONF	LV_ENA_PUT

FUNCTION DESCRIPTION:

General information:

Basic charge air pressure PUT_WG_OPEN is defined as the stationary pressure upstream throttle if the throttle is completely open and the wastegate is controlled to be open. This basic charge air pressure varies between individual engines. These variations are learnt in the present module and stored in dependence of engine speed.

Application conditions:

Initialisation: at ECU reset

T_DLY_PUT_WG_OPEN_AD = C_T_DLY_PUT_WG_OPEN_AD_INI

LV_CDN_PUT_WG_OPEN_AD = 0

if (checksum error) **or** LC_AD_CLR_PUT_WG_OPEN **then**

PUT_WG_OPEN_AD [...] = 0

else

read PUT_WG_OPEN_AD from non volatile memory

endif

Recurrence: 10 ms

Activation: LC_TCHA_CONF = 1 **and** LV_ST_END = 1

Deactivation: LC_TCHA_CONF = 0 **or** LV_ST_END = 0

Formula section:

PUT_WG_OPEN_AD_ADD = PUT_WG_OPEN_AD (N)

Calculated turbo charger speed					

4.90.1 CHRG_MDLADCHA0

General information:

This module calculates the turbocharger rotational speed with a special interpolation algorithm for the charger map.

Actual charger speed for NC_NR_TCHA chargers and charger speed setpoint are calculated using the same algorithm.

The square root calculation is based on a shifting algorithm implemented in order to improve calculation accuracy.

Deactivation: never

Function description

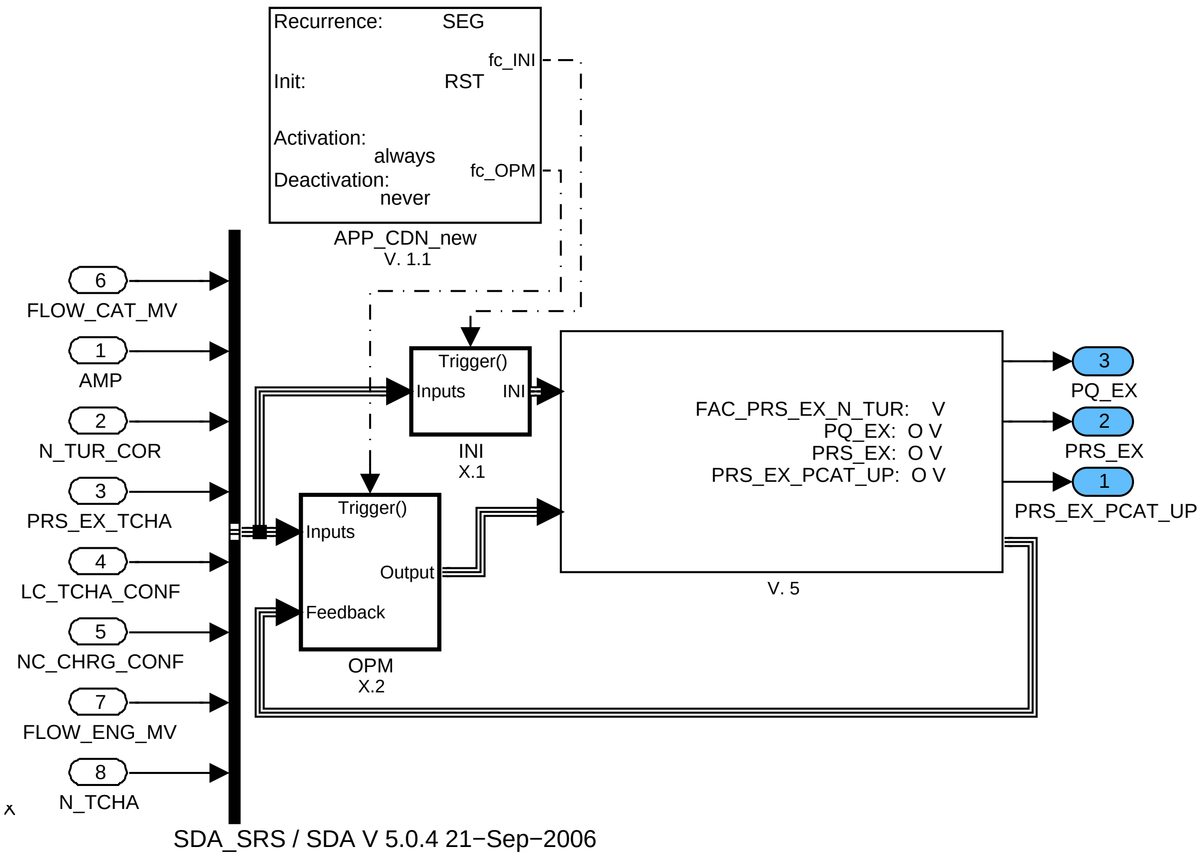

Figure 434:
Path: EGPR_DTSYSMODULE

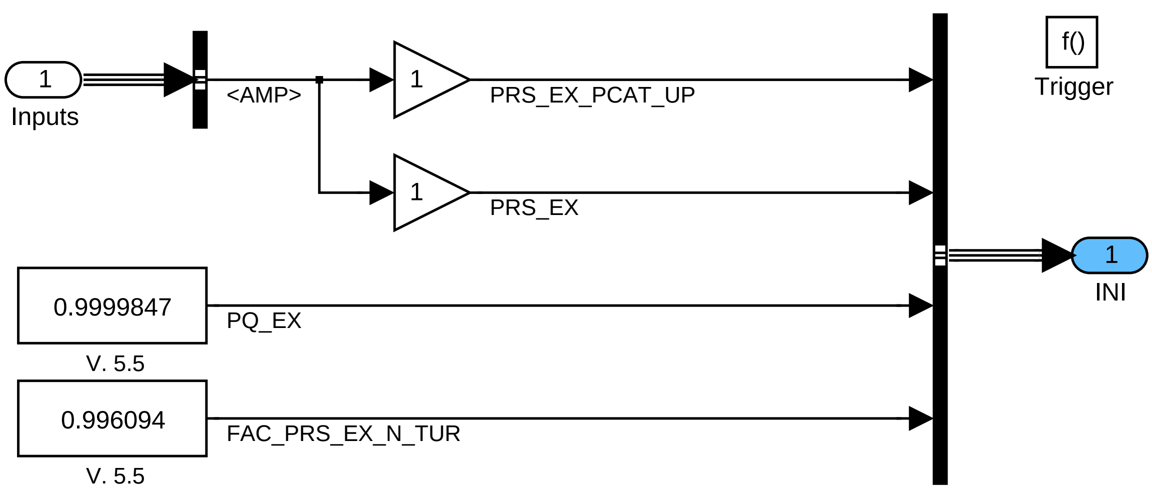

Figure 435:
Path: EGPR_DTSYSMODULE/INI

4.91.1 Calculation of the exhaust pressure

The calculation of the exhaust pressure is split into two parts. First is the pressure increase due to catalyst and second part is the pressure increase due to turbine (if available).

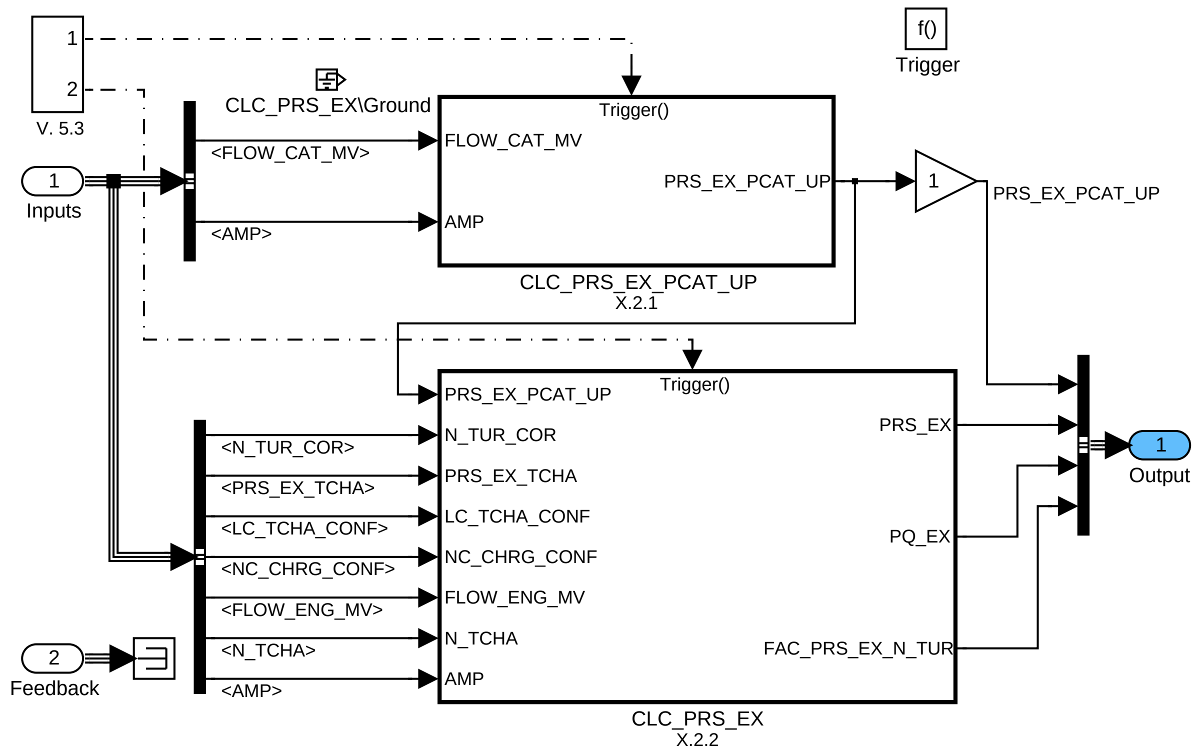

Figure 436:
Path: EGPR_DTSYSMODULE/OPM

4.91.1.1 Calculation of pressure increase due to catalyst

The pressure increase due to catalyst is mainly depending on the flow through the engine. The pressure increase itself is modelled by a simple map.

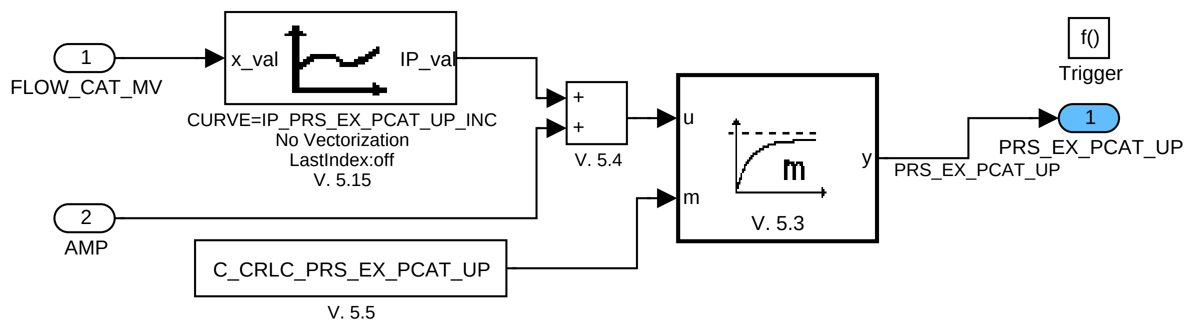

Figure 437:
Path: EGPR_DTSYSMODULE/OPM/CLC_PRS_EX_PCAT_UP

4.91.1.2 Calculation of pressure increase due to turbine

In case of turbo engine an additional pressure increase is present due to turbine. The main input for this calculation is coming from the CHRG aggregate.

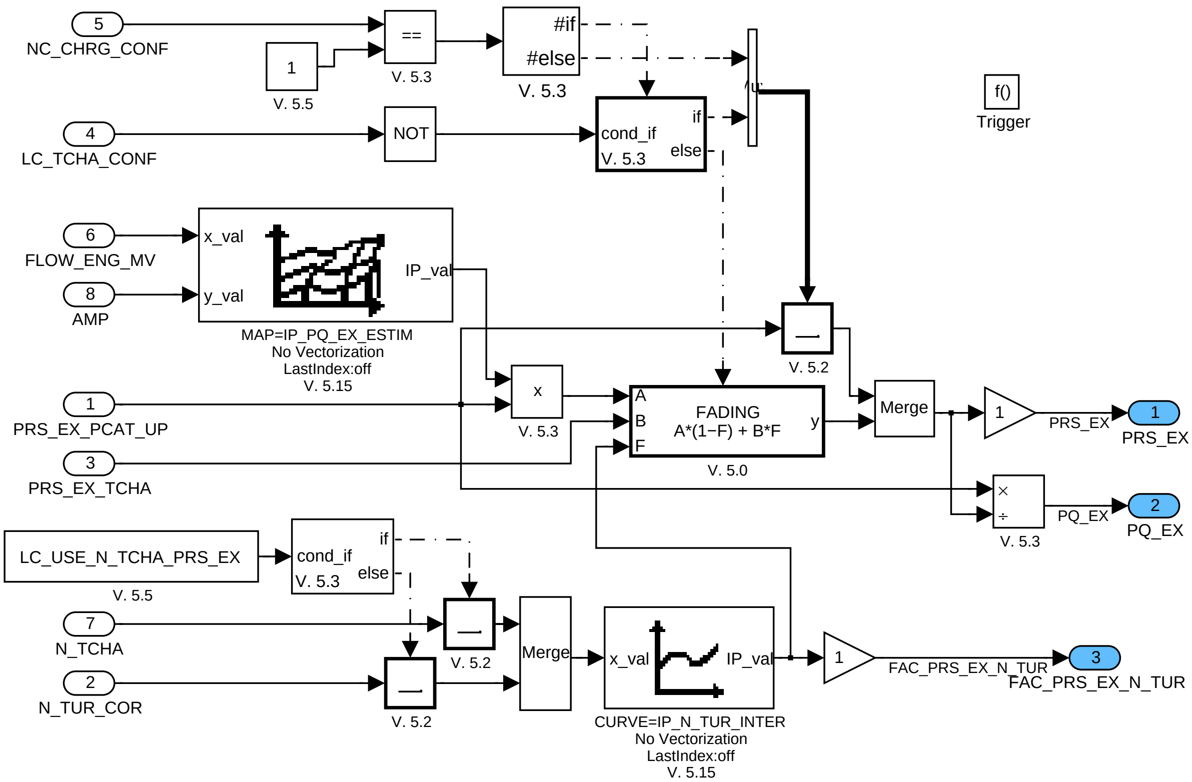

Figure 438:
Path: EGPR_DTSYSMODULE/OPM/CLC_PRS_EX

4.92.2 Main calculation for the flow through the catalyst

In this block the flow through the catalyst is calculated.

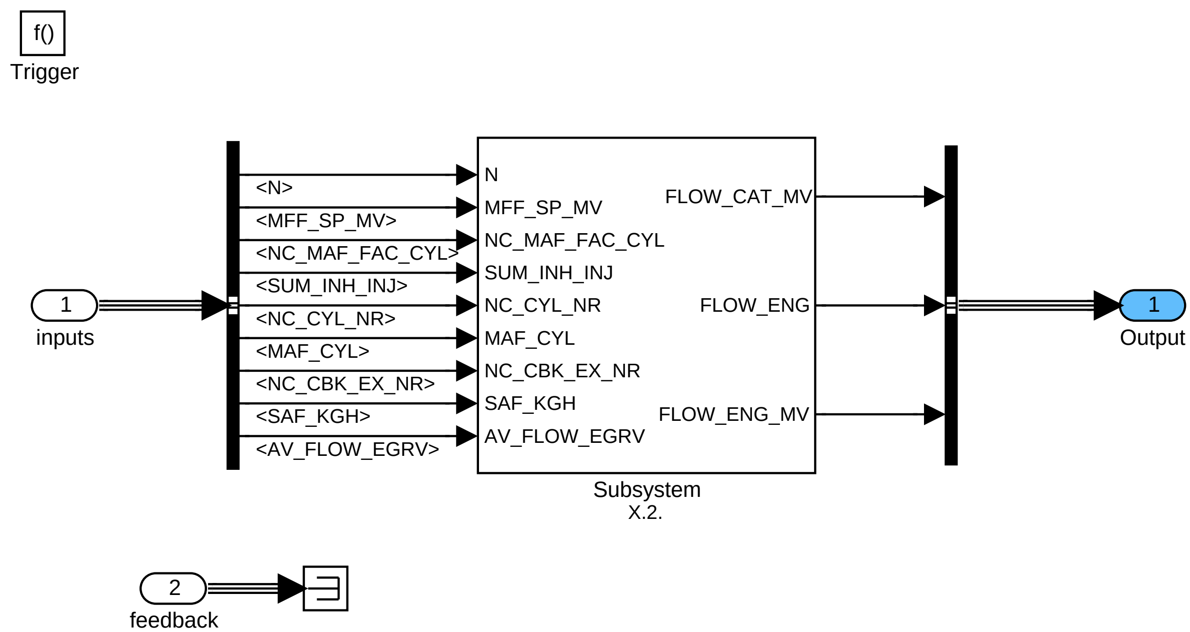

Figure 441:
Path: EGPR_MDLADNTCHAI0/OPM

4.92.2.1 Calculation of the flow through the catalyst

For the calculation of the exhaust pressure the flow through the catalyst has to be determined. This flow is consisting out of the mass air flow through into the engine and the injected fuel mass. Additionally the EGR and secondary air has to be considered. At least the mean value for the single bank has to be calculated.

Pressure ratio at the wastegate actuator EPC					

4.94.1 CHRG_MDLADPWGAC0

General information:

The wastgate actuator pressure PRS_WG_ACR can be measured or modelled. If a wastegate actuator pressure sensor is available (LV_ENA_PRS_WG_ACR = 1), the measured value PRS_WG_ACR_MES is used, otherwise a modelled value is used instead. The modelled or measured value can be overwritten by a manual value C_PRS_WG_ACR_MAN.

Two electropneumatic converter (EPC) types are covered. For C_TYP_EPC_WG_ACR = 0 both supply pressure and ambient pressure influence the wastegate actuator pressure. For C_TYP_EPC_WG_ACR = 1 only supply pressure influences the wastegate actuator pressure.

The behaviour of the EPC type 0 is modelled using two different algorithms switched by LC_PQ_EPC_OUT.

general specification

For LC_PQ_EPC_OUT = 0 IP_PQ_EPC_OUT describes the ratio between absolute pressures at the output and at the input of the EPC:

$$PQ\_EPC\_OUT = \frac{PRS\_WG\_ACR}{PRS\_WG\_ACR\_EPC\_L}$$

For LC_PQ_EPC_OUT = 1 IP_PQ_EPC_OUT describes the ratio between pressure differences at the output and at the input of the EPC:

$$PQ\_EPC\_OUT = \frac{PRS\_WG\_ACR - PRS\_WG\_ACR\_EPC\_L}{PRS\_WG\_ACR\_EPC\_H - PRS\_WG\_ACR\_EPC\_L}$$

To take into account the filling behaviour of the wastegate actuator the wastegate actuator pressure is low pass filtered.

Position of wastegate actuator depending on engine flow and wastegate actuator pressure					

4.95.1 CHRG_MDLADPSNWG0

The wastegate position PSN_WG is modelled by means of a map depending on the flow engine and on pressure difference at the wastegate actuator PRS_DIF_WG_ACR. The modelled value can be overwritten by a manual value C_PSN_WG_MAN

The present specification describes a wastegate position model based on wastegate actuator pressure for a wastegate with one controlled pressure.

The pneumatic force at the actuator FOC_WG_ACR_SP has to compensate the sum of the spring force and exhaust gas pressure force. The force at wastegate actuator caused by spring is negative calibrated. It means, negative force opens the wastegate.

Modeled reduced area of the recirculation actuator (used if LC_AR_RED_RCL_MDL = 1)					

4.96.1 CHRG_MDLADPSNRC0

The recirculation actuator position PSN_RCL can be measured or modelled. If a recirculation actuator position sensor is available and delivers a valid value (LV_ENA_PSN_RCL=1), the measured value PSN_RCL_MES is used, otherwise a modelled value is used instead. A manual value (_MAN) can overwrite both measured and model value.

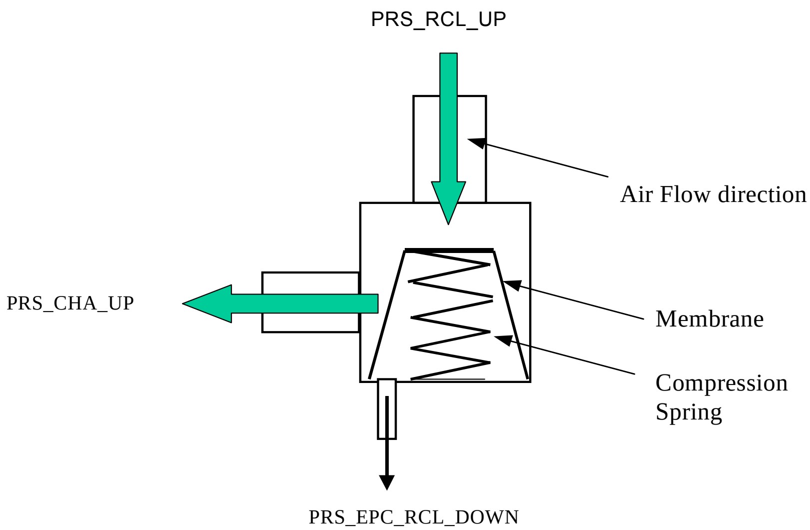
general specification

Two models are proposed:

_ simple model: the model value is a low pass filtered set point PSN_RCL_SP

_ more sophisticated models: the modeled reduced section of the RCL actuator AR_RED_RCL_MDL is determined based on the three pressures applied on the actuator: PRS_CHA_UP, PRS_RCL_UP and PRS_EPC_RCL_DOWN . The position of the actuator is defined based on AR_RED_RCL_MDL.

Example of RCL hardware



The position of the RCL valve depends on the balance forces of the compression spring and the three pressures applied on the membrane.

4.97 Recirculation actuator position control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CMD_RCL_OPEN	O/V	0...1H	0...1	1	-
Digital control signal for opening of switching recirculation actuator (recirculation valve)					
PWM_RCL	O	0...FFFFH	0...99.998	0.00152587	%
Control signal for opening of continous recirculation actuator (recirculation flap or proportional valve)					

Input data:

PSN_RCL_SP	LC_TCHA_CONF		

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_PSN_RCL_THD_DIG_CTL	1	0...FFFFH	0...99.998474	0.00152588	%
Threshold for digital recirculation actuator position control					
LC_CMD_RCL_OPEN_MAN	1	0...1H	0...1	1	-
Digital control signal for recirculation valve given by application system					
LC_CMD_RCL_OPEN_MAN_ACT	1	0...1H	0...1	1	-
Activation of digital control signal for recirculation valve given by application system					

4.97.1 CHRG_ACCTLRCAC0

The present specification describes the simplest possible switching control of the recirculation actuator position (NC_PSN_CTL = 1). If the position setpoint PSN_RCL_SP is greater than a threshold C_PSN_RCL_THD_DIG_CTL then LV_CMD_RCL_OPEN is set to 1 to completely open the actuator. Otherwise LV_CMD_RCL_OPEN is set to 0 to completely close the actuator.

More sophisticated controllers can be specified as versions of this specification. In the present version PWM_RCL is a dummy output to have a common output interface with these other specification versions which are designed to control a continuous recirculation actuator (flap or proportional valve).

LDPM_PQ_TUR_1_CHRG	10	0...FFFFH	0...15.9997559	2.44141E-4	-
Standard turbine flow : FLOW_TUR * TEG_TUR_UP_SQRT / PRS_EX					

4.98.1 CHRG_MDLADTUR0

The turbine model calculates the exhaust gas-mass flow through the turbine (internal calculations are done in kg/h for flow) and the turbine power delivered to the charger. All mechanical losses are calculated in the turbine model, even the mechanical losses of the charger.

The basic module for the turbine flow is a standard turbine map.

To make the map calculable it is necessary, to calculate PQ_TUR. The break points I is the turbine rotation speed and the pressure quotient at the turbine. The output FLOW_TUR_STND is multiplied by the last valid exhaust pressure PRS_EX and divided by the square root of exhaust gas temperature upstream turbine TEG_TUR_UP_ABS_SQRT.

LDPM_PQ_EX_PSI_WG	16	0...FFFFH	0...0.99998474	1.52588E-5	-
PSI coefficient for waste gate flow					

4.99.1 CHRG_MDLADFLOWG0

The flow at the waste gate can be modelled und calculated similar to that at a throttle. The throttling will be taken into account with the reduced area at the waste gate The inputs are the pressure quotient PQ_EX (ambient pressure AMP divided by exhaust pressure PRS_EX), the exhaust pressure (PRS_EX), the reduced area of the waste gate (AR_RED_WG) and the absolute exhaust temperature.

The term of the flow calculation at the waste gate depending on the exhaust gas temperature is stored in the map IP_FLOW_WG _CON_1.

This module calculates also the torque at the waste gate caused by the exhaust gas pressure difference at the waste gate.

This calculation is based on a product of the reduced opening area of the wastegate, a factor depending on the exhaust gas constant, the adiabatic coefficient and the absolute exhaust temperature, the “Psi waste gate function (PSI_WG)” and the exhaust pressure.

4.100 CAN interface

4.100.1 General information

The communication between the engine management system and the TCS control unit as well as the transmission control unit is done via the CAN bus.

This function description refers only to the torque management related CAN data. For a detailed description of the CAN functions please refer to the separate CAN specification.

To clearly distinguish between variables which are used for EMS internal calculation and variables that are available on the CAN all CAN-related variables are marked with the extension „*_CAN*“ at their name. However, in this chapter only the EMS internal variable names are used.

Recurrence : see CAN specification.

Reference : latest CAN specification version from HMC

4.100.2 CCP CAN Variables

CAN ID's:

Message Name	ID
CCP Receive	06A0H
CCP Transmit	06A1H
DAQ Segment	06A2H
DAQ Time	06A3H
DAQ Display	06A4H

Size multiplied by 7 is the number of bytes that can be displayed (e.g. 15*7 = 105 Bytes @ 10ms synchronous)

Variable Name	Value	Bytes
NC_ODT_SYNC_SIZE	10	70
NC_ODT_TIME_SIZE	10	70
NC_ODT_DISP_SIZE	20	140

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ODT_SYNC_SIZE	1	0 ... FFH	0 ... 255	1	-
size of synchronous ODT table					
NC_ODT_TIME_SIZE	1	0 ... FFH	0 ... 255	1	-
size of time (10ms) ODT table					
NC_ODT_DISP_SIZE	1	0 ... FFH	0 ... 255	1	-
size of display list table					

4.100.3 CAN variables

4.100.3.1 CAN variables from TCU1 Message

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

If LC_INH_MSR is set to 1, input signals from TCS for MSR are ignored and, following EMS internal function are initialized as following,

If LC_INH_MSR = 1
Then LV_MSR_REQ = 0
and TQI_MSR_REQ =0 [Nm]

If LC_TQI_MSR_REQ_MAN is set to 1,TQI_MSR_REQ is just set to C_TQI_MSR_REQ_MAN regardless LC_INH_MSR and even there is no TCS unit.

If LC_TQI_MSR_REQ_MAN = 1
then LV_MSR_REQ = 1
and TQI_MSR_REQ = C_TQI_MSR_REQ_MAN
else TQI_MSR_REQ = (TQI_MSR_CAN*TQ_STND) / 100%

If LC_TQI_ASR_REQ_MAN is set to 1,TQI_ASR_REQ & TQI_ASR_SLW_REQ are just set to C_TQI_ASR_REQ_MAN & C_TQI_ASR_SLW_REQ_MAN.

If LC_TQI_ASR_REQ_MAN = 1
then LV_ASR_REQ = 1
and TQI_ASR_REQ = C_TQI_ASR_REQ_MAN
and TQI_ASR_SLW_REQ = C_TQI_ASR_SLW_REQ_MAN
else TQI_ASR_REQ = (TQI_TCS_CAN*TQ_STND) / 100%
and TQI_ASR_SLW_REQ=(TQI_SLW_TCS_CAN*TQ_STND) / 100%

if bit 2 of TCU_OBD = 1

then LV_MIL_ACT_REQ = 1

else LV_MIL_ACT_REQ = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_INH_MSR	1	0...1H	0 ... 1	1	
Inhibition bit to make disable torque request signal from MSR					
LC_TQI_MSR_REQ_MAN	1	0...1H	0 ... 1	1	
Manual MSR torque request enabled					
C_TQI_MSR_REQ_MAN	1	0...7FFFH	0...1023.97	0.03125	Nm
Manual applied Indicated MSR torque request					
LC_TQI_ASR_REQ_MAN	1	0...1H	0 ... 1	1

C_TQI_ASR_REQ_MAN	1	0...7FFFH	0...1023.97	0.03125	Nm
Manual applied Indicated ASR torque request – Fast path					
C_TQI_ASR_SLW_REQ_MAN	1	0...7FFFH	0...1023.97	0.03125	Nm
Manual applied Indicated ASR slow torque request – Slow path					
LC_TCS1_OFF	1	0...1H	0 ... 1	1	-
Inhibition of TCS1 message receiving					

4.100.5 Timeout counter for CAN messages

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TOUT_CTR_TCU1	V/O	0…FFH	0…2,55	0.01	s
Timeout counter TCU1 message					
TOUT_CTR_TCU2	V/O	0…FFH	0…2,55	0.01	s
Timeout counter TCU2 message					
TOUT_CTR_TCU3	V/O	0…FFH	0…2,55	0.01	s
Timeout counter TCU3 message					
TOUT_CTR_TCS1	V/O	0…FFH	0…2,55	0.01	s
Timeout counter TCS1 message					
TOUT_CTR_TCS2	V/O	0…FFH	0…5,1	0.02	s
Timeout counter TCS2 message					
TOUT_CTR_FATC2	V/O	0…FFH	0…25,5	0.1	s
Timeout counter FATC2 message					

Input data:

CONF_TCS	CONF_TCU		

If (CONF_TCU = 00H (AT) or CONF_TCU = 0AH (CVT), then a timeout counter TOUT_CTR_TCU1 (for TCU1 message) and if CONF_TCU = 00H (AT) then TOUT_CTR_TCU2 (for TCU2 message) and TOUT_CTR_TCU3 (for TCU3 message) is incremented every 10 ms. If a new valid TCU1/TCU2/TCU3 message is detected, then the related timeout counter TOUT_CTR_TCU1/2/3 is resetted to 0. After reaching NC_TOUT_MAX the values of the related TCU message are set to INIT value.

If TCS configuration is detected (CONF_TCS = 1), then a timeout counter TOUT_CTR_TCS1 (for TCS1 message) is incremented every 10 ms. If a new valid TCS1 message is detected, then the timeout counter TOUT_CTR_TCS1 is resetted to 0. After reaching NC_TOUT_MAX the values of the TCS1 message are set to INIT value.

If TCS configuration is detected (CONF_TCS = 1), then a timeout counter TOUT_CTR_TCS2 (for TCS2 message) is incremented every 20 ms. If a new valid TCS2 message is detected, then the timeout counter TOUT_CTR_TCS2 is resetted to 0. After reaching NC_TOUT_MAX_TCU2 the values of the TCS2 message are set to INIT value.

A timeout counter TOUT_CTR_FATC2 (for FATC2 message) is incremented every 100 ms. If a new valid FATC2 message is detected, then the timeout counter TOUT_CTR_ FATC2 is resetted to 0. After reaching NC_TOUT_MAX the values of the FATC2 message are set to INIT value.

NC_TOUT_MAX = 50

NC_TOUT_MAX_TCU2 = 25

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_TOUT_MAX	-	0...FFH	0...255	1	-
Maximum value for Message time out					
NC_TOUT_MAX_TCU2	-	0...FFH	0...255	1	-
Maximum value for Message time out of TCS2					

4.100.6 EMS Output Signals to the CAN

General information:

This paragraph shows some variables produced by the EMS exported to the CAN. For more informations, please refer to the CAN specification.

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_CTR_STE_CAN	-	0...FFFFH	0...65535	10	ms
Counter for CAN power up delay					
LV_STE_CAN_OUT	-	0...1H	0...1	1	-
Flag indicating power up delay for output messages to CAN has passed					
LV_STE_TCU1_CAN_IN	O	0...1H	0...1	1	-
Flag indicating power up delay for input messages from CAN has passed					
EMS1_CAN[8]	-	0...255H	0...255	1	-
8 Byte CAN Frame for EMS1 message					
EMS2_CAN[8]	-	0...255H	0...255	1	-
8 Byte CAN Frame for EMS2 message					
EMS4_CAN[8]	-	0...255H	0...255	1	-
8 Byte CAN Frame for EMS4 message					

Application conditions:

Initialisation: at reset: all values = 0

Recurrence: 10 ms

Description:

After startup the ECU delayes sending EMS messages on CAN for 250ms:

Formula section:

```
If      T_CTR_STE_CAN < FFFFh
Then    Increment T_CTR_STE_CAN by 1
EndIf

If      LV_STE_CAN_OUT = 0
Then    If      T_CTR_STE_CAN >= 25
        Then    LV_STE_CAN_OUT = 1
        EndIf
EndIf

If      LV_STE_TCU1_CAN_IN = 0
        If      T_CTR_STE_CAN >= 25
        Then    LV_STE_TCU1_CAN_IN = 1
        EndIf
EndIf
```

Send CAN messages:

```
If      CCP CAN messages are NOT inhibited via KWP2000 Service
        "DisableEnableNormalMessageTransmission"
Then    If      LV_STE_CAN_OUT = 1
        Then    Fill Can Buffer EMSx_CAN with data
                Transmit EMSx Messages
        EndIf
EndIf
```

4.100.7 Torque variable definitions

4.100.7.1 Standard torque (TQ_STND)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_STND	V/O	0 ... 3FH	0 ... 630	10	Nm
standard engine torque					

The standard engine torque **TQ_STND** is taken from C_TQ_STND and transmitted by the engine management system to the CAN stations (TCS control unit and TCU).

It is the reference torque to which the torque reduction quantities are related. The result are relative torque quantities as percentage which are put on the CAN.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TQ_STND	1	0 ... 3FH	0 ... 630	10	Nm
standard engine torque					

4.100.7.2 Status of Torque Intervention (STATE_TQ_INTV)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_TQ_INTV	V/O	0...3H	0...3	1	
status torque intervention from EMS					
TQ_INTV_REL_ERR	V/O	0 ... FFH	0 ...0,996	0,0039	100%
relative error as difference between actual torque and requested torque related to the standard torque					

Input data:

TQI_AV	TQI_GS_REQ	TQI_ASR_REQ	TQ_STND
LV_AUTH_TQ_PAT	LV_TQ_IGA_ENA		

General information:

The engine management system uses the variable **STATE_TQ_INTV** to inform the transmission control unit and/or the traction system control unit about the state of the torque intervention. That means if and to which extent an ignition angle intervention and/or a cylinder shut-off intervention are admitted.

Status	Bit 5	Bit 4	Meaning
0	**0**	**0**	The desired intervention regarding ignition angle retardation and cylinder shut-off is executed. (Default value)
1	**0**	**1**	The desired intervention regarding ignition angle retardation and cylinder shut-off is executed; however, the requested target torque can not be adjusted precisely (torque steps)
2	**1**	**0**	The torque reduction regarding the ignition angle retardation cannot be completely executed. A cylinder shut-off is not possible at this time. Therefore a remaining torque (as difference between TQI_ASR/GS_REQ and TQI_AV) is present and cannot be reduced.
3	**1**	**1**	The desired torque intervention for TCS regarding the ignition angle and cylinder shut-off can no longer be executed. The torque intervention is terminated, the engine management system resets the requested engine torque to the TQI value using a ramp.

Activation of TQ_INTV_REL_ERR and STATE_TQ_INTV calculation:

TQI_TCS_CAN < FFh or TQI_TCU_CAN < FFh

Deactivation: TQI_TCS_CAN = FFh and TQI_TCU_CAN = FFh

Formula section:

Relative Error of torque reduction intervention

TQ_INTV_REL_ERR = (TQI_AV – TQI_xx_REQ) / TQ_STND

Status of torque intervention:

Status 0: **If** $|TQ\_INTV\_REL\_ERR| \le C\_TQ\_INTV\_REL\_ERR\_MAX$
then STATE_TQ_INTV = 0

Status 1: **If** $|TQ\_INTV\_REL\_ERR| > C\_TQ\_INTV\_REL\_ERR\_MAX$
and LV_AUTH_TQ_PAT = 1
then STATE_TQ_INTV = 1

Status 2: **If** $|TQ\_INTV\_REL\_ERR| > C\_TQ\_INTV\_REL\_ERR\_MAX$
and LV_AUTH_TQ_PAT = 0
then STATE_TQ_INTV = 2

Status 3: **If** no torque intervention is possible
LV_TQ_IGA_ENA = 0 **and** LV_AUTH_TQ_PAT = 0
then STATE_TQ_INTV = 3
and TQ_INTV_REL_ERR is set to 100%

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TQ_INTV_REL_ERR_MAX	1	0 ... FFH	0 ...0,996	0,0039	100%
threshold for relative error of torque intervention for status output					

4.100.8 Definition of Engine Identification value

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ENG_CHR	V/O	0...FH	0...15	1	-
Engine Characteristic – Kind of fuel, ETS					
ENG_VOL	V/O	0...FFH	0...25,5	0,1	L
Engine Displacement					

General information:

This variable is to give an information for an engine identification(ex. Engine volume and engine type) for automatic variant coding.

Formula section:

1) Engine Characteristic (ENG_CHR)

- Initial value: 00H

ENG_CHR = C_ENG_CHR

Conversion:

ENG_CHR				Function
Reserv.	ETC	FUEL		
0	0	0	0	Fuel – Gasoline, non-ETC

2) Engine displacement

ENG_VOL = C_ENG_VOL

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ENG_CHR	1	0 ... 06H	0 ...6	1	-
Engine Characteristic – Kind of fuel, ETC					
C_ENG_VOL	1	0 ... FFH	0 ...25,5	0,1	L
Engine Displacement					

4.101 CAN Messages EMS (Appl. Inc.)

4.101.1 Variables for fleet monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TOIL_GB_MAX_TOT_DC	V/O/S	0...FEH	-40...214	1	°C
Former / current driving cycle maximum A/T fluid temperature					

Input data:

TOIL_GB	LV_IGK		

Description:

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

TOIL_GB_MAX_TOT_DC = 0H

- otherwise: restored from non-volantile memory

Recurrence: 10ms

Activation: LV_IGK = 1

Deactivation: -

Formula section:

If TOIL_GB ≠ FFh

If TOIL_GB > TOIL_GB_MAX_TOT_DC

Then TOIL_GB_MAX_TOT_DC = TOIL_GB

Endif

Endif

4.102 Engine Efficiency state

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ENG_EFF_STATE	V/O	0H 1H 2H	LOW NORMAL HIGH	1	-
Engine Efficiency state					
T_DLY_ENG_EFF_STATE_SWI	V	0 ..FFH	0...25.5	1	s
Delay timer before a switch of engine efficency state is allowed after last switch					
LV_ENG_EFF_SWI_INH	V	0 ..1H	0...1	1	-
Flag indication a switch of engine efficiency state is inhibited					

Input data:

LV_BLS	LV_PU	LV_PUC	VS
N_32	LV_CS	CONF_BAT	LV_GS_ACT
LV_IS	TQ_REQ_CLU	PV_AV	GR_MT
CONF_CRU			

FUNCTION DESCRIPTION:

General information:

The engine efficiency is determined depending on the Torque request, the brake pedal value, the vehicle speed, engine speed and engine state. At high engine efficiency the battery is charged, at low the alternator load can be decreased.

Application conditions:

Initialisation: *at Reset:* ENG_EFF_STATE = NORMAL
T_DLY_ENG_EFF_STATE_SWI_=
C_T_DLY_ENG_EFF_STATE_SWI
LV_ENG_EFF_SWI_INH = 0

Recurrence: *100 ms*

Activation: CONF_BAT = 1

Formula section:

Calculation of Inhibit conditions for Engine efficiency state switch:

if LV_AT = 1
then **if** LV_GS_ACT = 1
gear change at Automatic Transmission vehicle
then LV_ENG_EFF_SWI_INH = 1
else LV_ENG_EFF_SWI_INH = 0

```
            endif
    else    if      CONF_CRU = 1

5 Engine operating states

Table of Contents

Index

T

5.1 General

A distinction is made on principle between the basic operating states and the auxiliary functions.

The basic operating states (e.g. **LV_ES**, **LV_ST**, **LV_IS**, **LV_PL**, **LV_PU** & **LV_PUC**) are independent basic functions which can only occur alternatively. Contrary to this, auxiliary functions can be simultaneously active and they always are superimposed on a basic operating state.

5.1.1 Engine operating state detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_ENG	V/O	0...0H 1...1H 2...2H 3...3H 4...4H 5...5H	"ES" "ST" "IS" "PL" "PU" "PUC"	-	-
Engine operating state					

Input data:

LV_ES	LV_ST	LV_IS	LV_PL
LV_PU	LV_PUC		

General information:

If the detection of an engine operating state influences several output signals, this engine operating state is described in the chapter ” Basic Operating States ”.

The engine operating state transitions are dependent on **throttle position** and **engine speed.**

The driver must be able to switch - off the engine by the ignition key in any operating state. To implement this, the battery voltage is measured.

For more explanations, refer to “ Acquisition of ignition key battery voltage “ in the major chapter “ Inputs “.

5.1.2 Function initialization

After initialization of the operating system and self - diagnosis of the control unit, the engine functions are assigned to their initial values.

The first measured values are diagnosed and backup values are made available as appropriate.

5.1.2.1 Reset with the system running

Input data:

N	NC_N_MIN	N_32	IP_N_MAX_TOL_ST__TCO
LV_ST			

FUNCTION DESCRIPTION:

General information:

If a reset occurs for N >= NC_N_MIN, initialization is performed as for an under-voltage reset.

In the case of an engine speed N_32 >= IP_N_MAX_TOL_ST__TCO the engine operating state start (LV_ST) is not executed.

Instead, the system immediately branches to the current engine operating state.

5.1.3 Engine operating state " Engine Stopped " (LV_ES)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ES	V/O	0...01H	0...1	1	-
Engine operating state " Engine Stopped " - Engine Operating State = ES.					

Input data:

LV_IGK	LV_ST	N	NC_N_MIN

FUNCTION DESCRIPTION:

General information:

The engine operating state engine stopped (LV_ES) is characterized by ignition key **on** (LV_IGK **= 1** (Active)) and N **<** NC_N_MIN.

In this engine operating state, the functions are assigned to initialization values.

The entire scope of diagnosis and actuator control is accessible.

Application conditions:

Deactivation:

Exit to **LV_ST :** Start

During the synchronisation phase, the tooth duration is taken into account to calculate the engine speed.

If N >= NC_N_MIN is detected in the operating state engine stopped (LV_ES)

then the fuel pump is switched on

(refer to chapter : " Relays control " in major chapter " Auxiliary Functions ")

and the first injection is performed

(refer to chapter : " Fuel injection output " in major chapter " Outputs ")

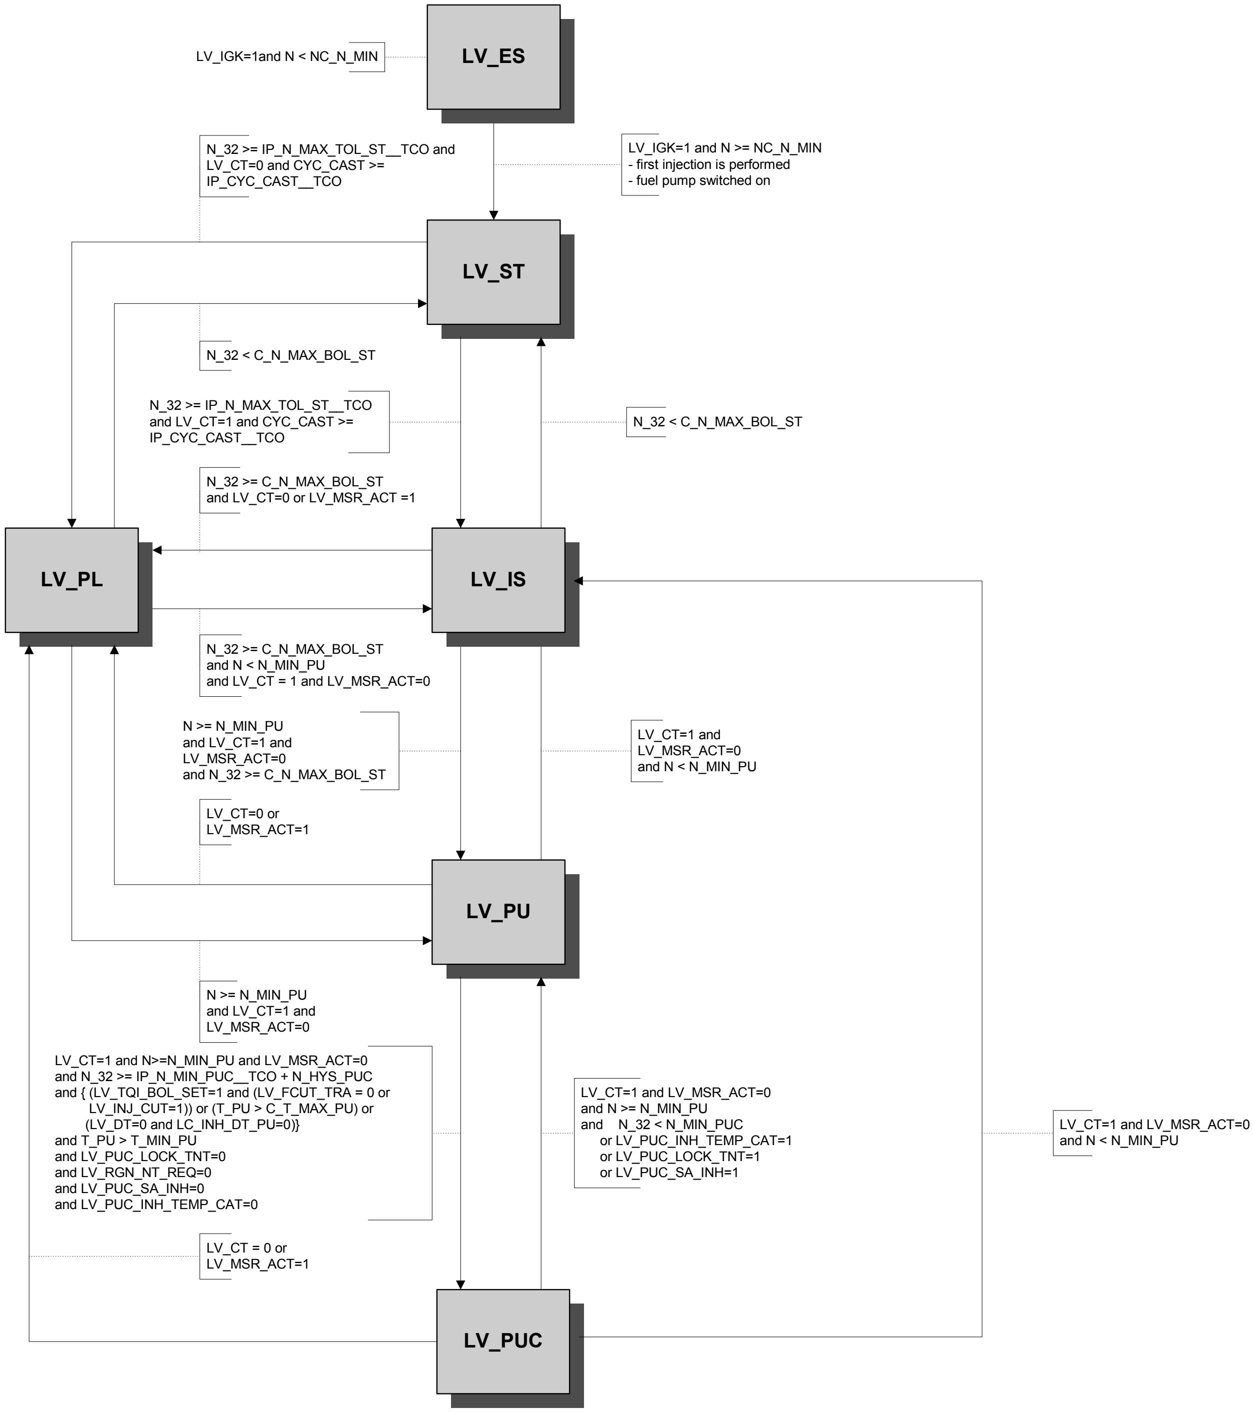
5.1.4 General Drawing

LV_ES : Engine Stopped

LV_PL : Part Load

LV_ST : Engine Start

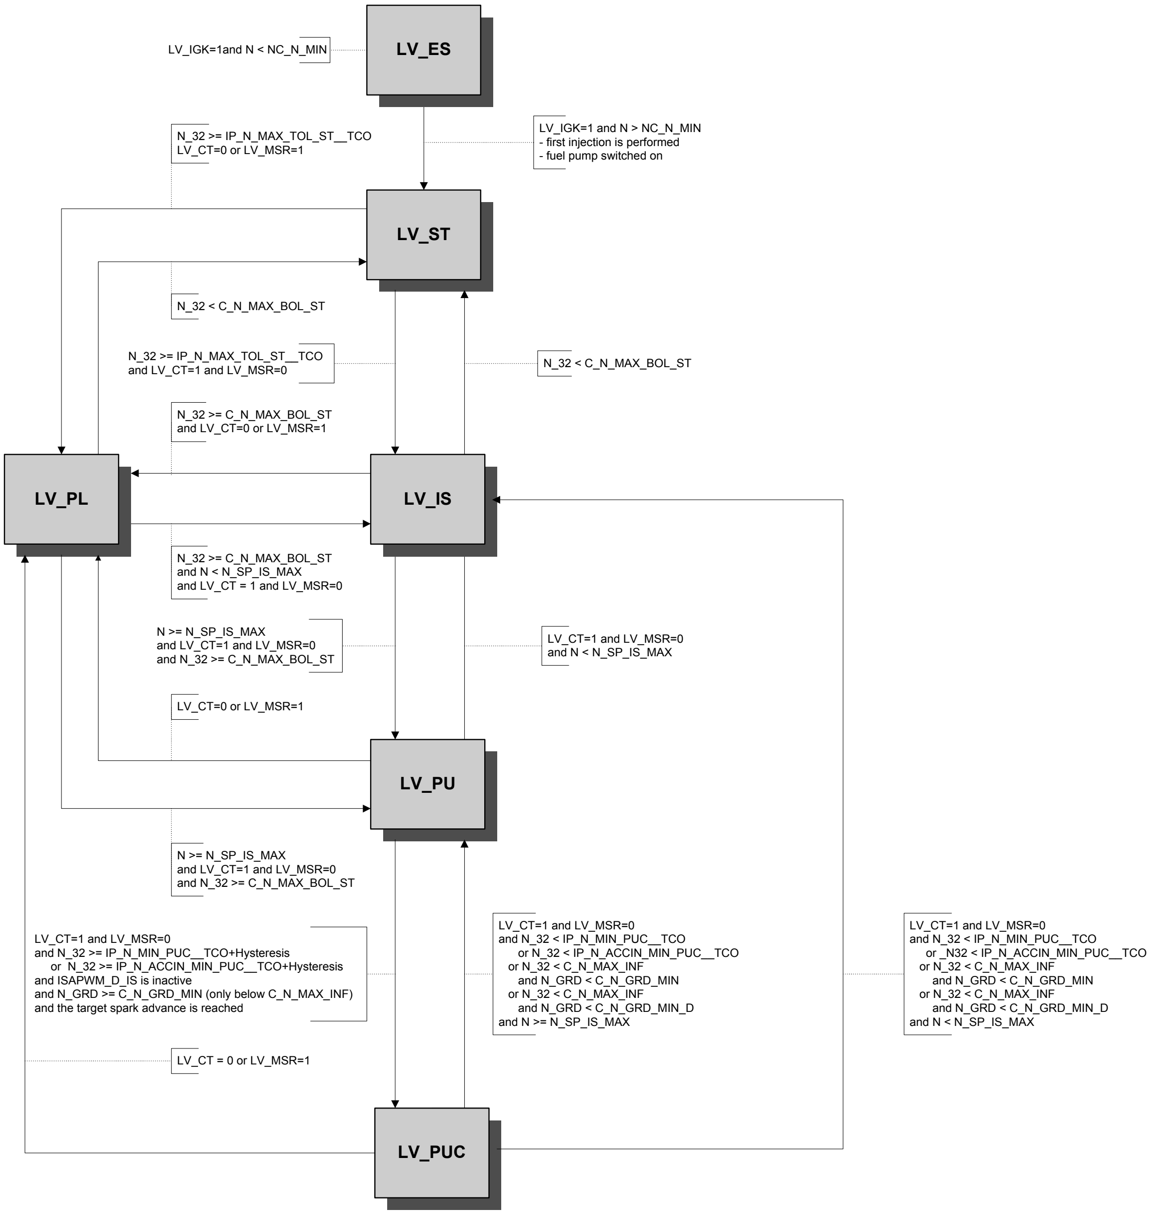
LV_PU : Trailing Throttle



LV_IS : Idle Speed

LV_PUC : Trailing Throttle Fuel Cut Off

5.1.5 General Drawing



LV_ES	:	Engine Stopped
LV_ST	:	Start
LV_IS	:	Idle Speed
LV_PL	:	Part Load
LV_PU	:	Trailing Throttle
LV_PUC	:	Trailing Throttle Fuel Cut Off
LV_FL	:	Full Load

5.2 Basic Operating States : LV_ST, LV_IS, LV_PL, LV_PU & LV_PUC

5.2.1 Engine operating state : " Start " (LV_ST)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ST	V / O	0...1H	0...1	-	-
Engine operating state "Start"					
LV_ST_END	V / O	0...1H	0...1	-	-
Engine operating state "Start" not active					

Input data:

LV_CT	N	TCO	LV_IS
LV_PL	N_MAX_TOL_ST	LV_ES	CYC_CAST

FUNCTION DESCRIPTION:

The engine operating state "Start" (**LV_ST**) is detected from part load and idle speed via means of engine speed.

Application conditions:

Recurrence: segment-synchronous; only once per 10 ms

Determination of LV_ST:

Deactivation:

1) **Exit to LV_IS :** Idle Speed
a) N >= N_MAX _TOL_ST
b) **and** LV_CT = 1
c) **and** CYC_CAST >= IP_CYC_CAST__TCO

2) **Exit to LV_PL :** Part Load
a) N >= N_MAX_TOL_ST
b) **and** LV_CT = 0
c) **and** CYC_CAST >= IP_CYC_CAST__TCO

Determination of LV_ST_END:

If LV_ST = 1 **or** LV_ES = 1
then LV_ST_END = 0
else LV_ST_END = 1

Note : N and N_MAX_TOL_ST have different resolution (1 rpm & 32 rpm)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_CYC_CAST__TCO	9	0...FFFF H	0...65535	1	Seg
LDPM_TCO_9	9	0...FE H	-48...142.5	0.75	°C
Cycle counter to define the duration of the start phase charcterised by LV_ST					

5.2.2 Engine operating state : " Idle Speed " (LV_IS)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_IS	V / O	0...1H	0...1	1	-
Engine operating state "Idle Speed"					
T_IS	V / O	0...FFFFH	0...655.35	0.01	s
Cumulated time in engine operating state Idle Speed and vehicle stopped					

Input data:

LV_CT	N_32	N	N_SP_IS
LV_MSR_ACT	LV_ST	LV_PL	LV_PU
N_MIN_PU	LV_N_INC_TCU_ACT		

Application conditions:

Recurrence: segment-synchronous; only once per 10 ms

Deactivation:

1) **Exit to LV_ST :** Start
a) N_32 < C_N_MAX _BOL_ST

2) **Exit to LV_PL :** Part Load
a) N_32 >= C_N_MAX_BOL_ST
b) **and** LV_CT = 0
or LV_MSR_ACT = 1

3) **Exit to LV_PU :** Trailing Throttle
a) N >= N_MIN_PU
b) **and** LV_CT = 1
c) **and** N_32 >= C_N_MAX_BOL_ST
d) **and** LV_MSR_ACT = 0
e) **and** LV_N_INC_TCU_ACT = 0

Calculation of the Timer T_IS (Cumulated time with LV_IS = 1 and VS = 0) **:**

If (LV_IS = 1 **and** Transition VS > 0 -> VS = 0)
or (VS = 0 **and** Transition LV_IS = 0 -> LV_IS = 1)
Then TI_IS = 0
Else **If** LV_IS = 1
and VS = 0
Then T_IS is incremented every 0.01s until it reaches max. value 655.35 s

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_MAX_BOL_ST	1	0...FFH	0...8160	32	rpm
Engine speed threshold to detect LV_ST or LV_PL from LV_IS					

5.2.3 Engine operating state : ” Part Load ” (LV_PL)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_PL	V / O	0...1H	0...1	1	-
Engine operating state „Part Load“					

Input data:

LV_CT	N_32	N	N_SP_IS
LV_ST	LV_IS	LV_PU	LV_MSR_ACT
C_N_MAX_BOL_ST	N_MIN_PU		

Application conditions:

Recurrence: segment-synchronous; only once per 10 ms

Deactivation:

1) **Exit to LV_ST :** Start
a) N_32 < C_N_MAX _BOL_ST

2) **Exit to LV_IS :** Idle Speed
a) N_32 >= C_N_MAX_BOL_ST
b) **and** N < N_MIN_PU
c) **and** LV_CT = 1
d) **and** LV_MSR_ACT = 0

3) **Exit to LV_PU :** Trailing Throttle
a) N >= N_MIN_PU
b) **and** LV_CT = 1
c) **and** LV_MSR_ACT = 0

5.2.4 Engine operating state : ” Trailing Throttle ” (LV_PU)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_PU	V / O	0...1H	0...1	-	-
Engine operating state „Trailing throttle“					
T_MIN_PU	V / O	0...FFFFH	0...655.35	0.01	s
Minimum duration of PU state					
T_PU	V / O	0...FFFFH	0...655.35	0.01	s
Time elapsed into LV_PU					
N_MIN_PU	V	0...1FE0H	0...8160	1	rpm
Minimum engine speed of PU state					
T_PU_TCU	V	0...FFFFH	0...655.35	0.01	s
Time elapsed into LV_PU after after entry of PU by TCU request					

Input data:

LV_CT	N_32	N_GRD	N_SP_IS
LV_AT	LV_PUC_INH_TEMP_CAT	LV_TQI_BOL_SET	LV_PL
LV_IS	LV_PUC	C_N_DIF_MAX_IS	N_MIN_PUC
N	N_HYS_PUC	LV_MSR_ACT	LV_DT
N_DIF_MMV	LV_PUC_LOCK_TNT	LV_RGN_NT_REQ	LV_PUC_SA_INH
C_N_DIF_FAC	LV_FCUT_TRA	LV_INJ_CUT	LC_INH_DT_PU
VS	GR_AT	LV_N_INC_TCU_ACT	SWI_CC

Application conditions:

Recurrence: segment-synchronous; only once per 10 ms

Deactivation:

1) **Exit to LV_PL :** Part Load
a) LV_CT = 0
or LV_MSR_ACT = 1

2) **Exit to LV_IS :** Idle Speed
a) LV_CT = 1
b) **and** **(** N < N_MIN_PU **or** LV_N_INC_TCU_ACT = 1 **)**
c) **and** LV_MSR_ACT = 0

3) **Exit to LV_PUC :** Trailing Throttle Fuel Cut Off

a) LV_CT = 1
b) **and** N >= N_MIN_PU
c) **and** LV_MSR_ACT = 0
d) **and** N_32 >= N_MIN_PUC + N_HYS_PUC
e) **and** **{**(LV_TQI_BOL_SET = 1)
and (LV_FCUT_TRA = 0 or LV_INJ_CUT=1)
or (T_PU > C_T_MAX_PU) ;maximum PU - time
or (LV_DT = 0 **and** LC_INH_DT_PU = 0)**}** ;open drivetrain
f) **and** **{** (T_PU_TCU = 0 **and** T_PU > T_MIN_PU) ;normal driving
or ($T\_PU\_TCU_{(n-1)}$ > 0 **and** $T\_PU\_TCU_{(n)}$ = 0) **}** ; N increased by TCU
g) **and** LV_PUC_LOCK_TNT = 0
h) **and** LV_RGN_NT_REQ = 0
i) **and** LV_PUC_SA_INH = 0

j) **and** LV_PUC_INH_TEMP_CAT = 0
k) **and** LV_N_INC_TCU_ACT = 0 ;to delay exit to PUC till N increment by TCU finished

Activation of the timer T_PU:

Recurrence: 10 ms

If LV_PU = 1

then T_PU incremented until FFFF H

else T_PU is initialized with 0

Activation of the timer T_PU_TCU:

Recurrence: 10 ms

If LV_N_INC_TCU_ACT = 1 -> 0

then T_PU_TCU is initialized with IP_T_MIN_PU_TCU

endif

if T_PU_TCU >0

and LV_N_INC_TCU_ACT = 0

then T_PU_TCU is decremented until 0

else T_PU_TCU = 0

endif

Note : T_PU_TCU is calculated to delay transition from PU to PUC when N increaed by TCU request

Definition of T_MIN_PU

If LV_AT = 0
Then **If** LV_DT = 0
Then T_MIN_PU = C_T_MIN_PU
Else T_MIN_PU = C_T_MIN_PU_DT
Else
If LV_DT = 0
Then T_MIN_PU = C_T_MIN_PU_AT
Else T_MIN_PU = IP_T_MIN_PU_AT_DT (N_32)

Note : T_MIN_PU is updated only at the entry in PU (transition XX --> PU).
If LV_DT state changes during PU, then T_MIN_PU is not updated.

Definition of N_MIN_PU

LV_AT = 0

In idle(LV_IS) :

N_MIN_PU = N_SP_IS + C_N_DIF_MAX_IS – N_DIF_MMV * C_N_DIF_FAC

Out of idle :

N_MIN_PU = N_SP_IS + C_N_DIF_MAX_IS

LV_AT = 1

In idle(LV_IS) :

If SWI_CC = 0

Then N_MIN_PU = N_SP_IS + IP_N_DIF_MAX_IS_0 – N_DIF_MMV * C_N_DIF_FAC

Else N_MIN_PU = N_SP_IS + IP_N_DIF_MAX_IS_1 – N_DIF_MMV * C_N_DIF_FAC_CC

Out of idle :

If SWI_CC = 0

Then N_MIN_PU = N_SP_IS + IP_N_DIF_MAX_IS_0

Else N_MIN_PU = N_SP_IS + IP_N_DIF_MAX_IS_1

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

5.2.5.1 Minimum engine speed for LV_PUC detection

Application conditions:

Recurrence: segment syncronous; only once per 10 ms

Description:

The engine speed threshold for the detection of LV_PUC is derived from a characteristic as a function of coolant temperature (TCO) and gear (GR_MT; GR_AT):
ID_N_MIN_PUC__TCO__GR_MT/AT (LV_RLY_ACCOUT = 0, SWI_CC = 0)

During converter clutch lock up activation, the engine speed threshold for the detection of LV_PUC is derived from

ID_N_MIN_PUC_CC__TCO__GR_AT (LV_RLY_ACCOUT =0, SWI_CC <> 0)

There is a special characteristic for air conditioning compressor active (LV_RLY_ACCOUT = 1) and also function of coolant temperature (TCO) and gear (GR_MT; GR_AT):
ID_N_ACCOUT_MIN_PUC__TCO__GR_MT/AT (LV_RLY_ACCOUT =1, SWI_CC = 0)

During converter clutch lock up activation with air conditioning compressor active, the engine speed threshold for the detection of LV_PUC is derived from

ID_N_ACCOUT_MIN_PUC_CC__TCO__GR_AT (LV_RLY_ACCOUT =1, SWI_CC <> 0)

5.2.5.2 LV_PUC Hysteresis

Application conditions:

Recurrence: Segment

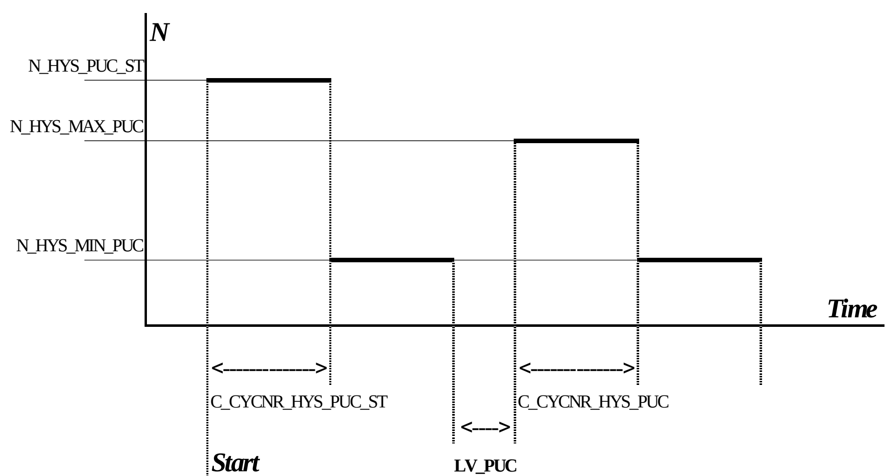
Description:

During Trailing Throttle Fuel Cut Off (LV_PUC = 1), the engine speed hysteresis is continuously calculated to a higher value **ID_N_HYS_MAX_PUC__GR_MT/AT (in case of SWI_CC = 0) or ID_N_HYS_MAX_PUC_LOCK_UP__GR_AT(in case of SWI_CC ≠ 0)** depending on status for converter lockup clutch(SWI_CC), and a cycle counter is loaded with an adjustable number, **C_CYCNR_HYS_PUC**.

The cycle counter is decremented at intervals of a crank angle segment (CRK) in any engine operating state except Trailing Throttle Fuel Cut Off (LV_PUC = 1). If LV_N_INC_TCU_ACT = 1 -> 0 or SWI_CC is converted to 0 from another state with cycle counter decremented, the cycle counter is set to 0 at once.

After the counter has reached its lower limit, the engine speed hysteresis is continuously calculated to the lower value **ID_N_HYS_MIN_PUC__GR_MT/AT(in case of SWI_CC = 0) or ID_N_HYS_MIN_PUC_LOCK_UP__GR_AT(in case of SWI_CC ≠ 0)** depending on status for converter lockup clutch(SWI_CC). This measure is to prevent the injection system from being switched on and off continuously, which is undesirable.

If the coolant temperature is below the threshold **C_TCO_MIN_PUC_ST** when the engine is started, then this engine speed hysteresis is increased to an adjustable value **ID_N_HYS_PUC_ST__GR_MT/AT**, for an adjustable number of cycles **C_CYCNR_HYS_PUC_ST** (This results in faster catalyst heat-up during trailing throttle operation). Otherwise the value ID_N_HYS_MAX_PUC__GR_MT/AT (in case of SWI_CC = 0) or ID_N_HYS_MAX_PUC_LOCK_UP__GR_AT (in case of SWI_CC ≠ 0) is used for C_CYCNR_HYS_PUC cycles



N_HYS_PUC calculation

(1) For engine state transition ES -> ST

```
If      TCO < C_TCO_MIN_PUC_ST
then
        CYCNR_HYS_PUC = C_CYCNR_HYS_PUC_ST
        if      LV_AT = 1
        then
                N_HYS_PUC = ID_N_HYS_PUC_ST__GR_AT
        else
                N_HYS_PUC = ID_N_HYS_PUC_ST__GR_MT
        endif
else
        CYCNR_HYS_PUC = C_CYCNR_HYS_PUC
        If      LV_AT = 1
        then
                If      SWI_CC = 0
                then
                        N_HYS_PUC = ID_N_HYS_MAX_PUC__GR_AT
                else
                        N_HYS_PUC = ID_N_HYS_MAX_PUC_LOCK_UP__GR_AT
                endif
        else
                N_HYS_PUC = ID_N_HYS_MAX_PUC__GR_MT
        endif
endif
```

(2) For every segment

```
If      LV_PUC = 1
then
        CYCNR_HYS_PUC = C_CYCNR_HYS_PUC
        If      LV_AT = 1
        then
                If      SWI_CC = 0
                then
                        N_HYS_PUC = ID_N_HYS_MAX_PUC__GR_AT
                else
                        N_HYS_PUC = ID_N_HYS_MAX_PUC_LOCK_UP__GR_AT
                endif
        else
                N_HYS_PUC = ID_N_HYS_MAX_PUC__GR_MT
        endif
else
        If      CYCNR_HYS_PUC = 0
        then
                if      LV_AT = 1
                then
                        If      SWI_CC = 0
                        then
```

N_HYS_PUC = ID_N_HYS_MIN_PUC__GR_AT
else
N_HYS_PUC = ID_N_HYS_MIN_PUC_LOCK_UP__GR_AT
endif
else
N_HYS_PUC = ID_N_HYS_MIN_PUC__GR_MT
endif
else
CYCNR_HYS_PUC is decremented.

5.2.6 Logical variable trailing trottle fuel cut-off request LV_PUC_REQ

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_PUC_REQ	V / O	0...1 H	0...1	1	-
Logical variable trailing throttle fuel cut off request					

Input data:

LV_PU	LV_PUC		

General information:

LV_PUC_REQ is set at trailing throttle conditions. It is evaluated in module “Minimum torque at clutch”.

Activation: at every engine state

Recurrence: segment-syncronous; only once per 10 ms

Formula section:

LV_PUC_REQ = LV_PU or LV_PUC

5.3 Administration of calculation optimization

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_SEG_HALF	V/O	0 ... FH	0 ... 15	1	-
Half segment counter					
STATE_CLC_RED	V/O	0 ... FFH	0 ... 255	1	-

Start number of intake bank for calculations					
CTR_CBK_IN_NR_STOP_CLC	V/O	0 ... 1H	1 ... 2	1	-
Stop number of intake bank for calculations					
CTR_CBK_EX_NR_ST_CLC	V/O	0 ... 1H	1 ... 2	1	-
Start number of exhaust bank for calculations					
CTR_CBK_EX_NR_STOP_CLC	V/O	0 ... 1H	1 ... 2	1	-
Stop number of exhaust bank for calculations					

Input data:

NC_CYL_NR	LV_ST_END	N_32	SEG_NR
NC_IN_REF	NC_LAMB_REF	NC_CYL_NR	

FUNCTION DESCRIPTION:

General information:

This module is used for administration of runtime reduction and calculation optimization steps.

Pay Attention! This module has to be placed in the operating system immediately after the calculation of N_32 and SEG_NR, which are calculated by the ENSD aggregate. All aggregates, which are affected by calculation optimization, have to be calculated afterwards.

5.3.1 Half segment counter

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset or at every transition of LV_ES from 0 -> 1 do:
#if (NC_USE_SEG_HALF_AVL = 1)
#then CTR_SEG_HALF = (2 * NC_CYL_NR) - 1
#else CTR_SEG_HALF = (2 * NC_CYL_NR) - 2
#endif

Recurrence : #if (NC_USE_SEG_HALF_AVL = 1)
#then half segment synchronous
#else segment synchronous
#endif

This chapter describes the behavior of the half segment loop counter. If a half segment trigger is available by the ECU system the counter is incremented by one each half segment event. If only a segment trigger is available, the counter is incremented by two each segment event. Every 720° CRK the counter is set back to zero.

Application hint:

If a half segment trigger is available by the ECU system, set NC_USE_SEG_HALF_AVL to 1, else set it to 0 and insert the task in the segment synchronous environment.

Formula Section :

#if (NC_USE_SEG_HALF_AVL = 1)

#then

$$CTR\_SEG\_HALF_{(n)} = (CTR\_SEG\_HALF_{(n-1)} + 1)\ \mathbf{MODULO}\ (2 * NC\_CYL\_NR)$$

#else

$$CTR\_SEG\_HALF_{(n)} = (CTR\_SEG\_HALF_{(n-1)} + 2)\ \mathbf{MODULO}\ (2 * NC\_CYL\_NR)$$

#endif

5.3.2 Runtime optimization

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset or at every transition of LV_ES from 0 -> 1 do:

STATE_CLC_RED = NC_STATE_CLC_RED_SEG_1

CTR_CYL_NR_ST_CLC = 0

CTR_CYL_NR_STOP_CLC = (NC_CYL_NR - 1)

CTR_CBK_IN_NR_ST_CLC = 1 (physical meaning)

CTR_CBK_IN_NR_STOP_CLC = NC_CBK_IN_NR

CTR_CBK_EX_NR_ST_CLC = 1 (physical meaning)

CTR_CBK_EX_NR_STOP_CLC = NC_CBK_EX_NR

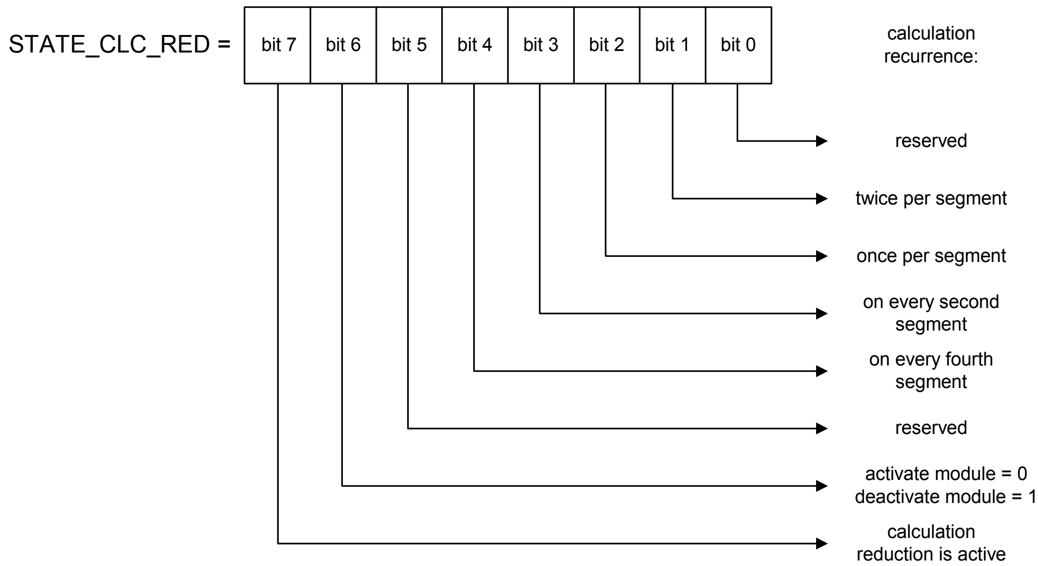
Recurrence : #if (NC_USE_SEG_HALF_AVL = 1)
#then half segment synchronous
#else segment synchronous
#endif

This chapter describes runtime optimization steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to the intake or exhaust bank, which is allocated to the related cylinder by NC_IN_REF and NC_LAMB_REF.

For engine charge optimization a half segment calculation recurrence is introduced, which depends on an engine speed threshold. Below this threshold MAF, MFF and TI calculation will be updated twice per segment (half segment calculation). Because of that a higher engine dynamic can be realized especially for low engine speeds.

Formula Section :

5.3.2.1 Definition of STATE_CLC_RED



5.3.2.1.1 Definitions of the non calibrateable constants to generate STATE_CLC_RED

CTR_CBK_EX_NR_ST_CLC = 1 (physical meaning)

CTR_CBK_EX_NR_STOP_CLC = NC_CBK_EX_NR (physical meaning)

(3) ENDIF

Application hint

ID_CTR_CYL_NR_CLC describe the cylinder number, which will be calculated exclusive on the segment with the number SEG_NR, even if the runtime reduction is active. Therefor you have to specify the segment cylinder relation here proper to your engine type. For example (8 cyl. engine):

SEG_NR Segment number	ID_CTR_CYL_NR_CLC Exclusive calculated cylinder
0	3
1	4
2	5
3	6
4	7
5	0
6	1
7	2

Note that the related intake and exhaust banks will be calculated automatically by NC_IN_REF and NC_LAMB_REF.

5.4 Full Load Detection

Output data:

Name	Mod.	Hex. Limit	Phys. Limit	Resol.	Unit
LV_FL	V/O	0...1H	0...1		-
Logical bit which indicates the full load request					
LV_FL_RAW	V/O	0...1H	0...1		-
Full load because of pedal value detected					

Input data:

PV_AV	N_32	TCO	VS
FAC_TQ_REQ_CLU	LV_FCUT_IND	LV_N_MAX	LV_LAM_LIM_MIN_i
LV_LAM_LIM_MAX_i			

Functions description:

General information:

The primary task of the module “Full load detection” is to detect the full load request of the driver. The indicator for the full load request is the logical variable LV_FL which sets the trigger for the mixture enrichment in module “Full load enrichment”.

The driver request for full load enrichment is represented by the logical variable LV_FL. If the actual pedal value PV_AV exceeds a certain calibrateable threshold, LV_FL_RAW is set to one. The threshold, which is derived by the map ID_PV_AV_FL, can vary with engine speed.

Certain conditions must be fullfilled to set the full load request LV_FL regardless of the drivers demand.

Application conditions:

Initialisierung: with reset LV_FL_RAW = 0
LV_FL = 0

Recurrence: 20 ms

Activation: all engine operating states

Formula:

If(1) PV_AV **>** ID_PV_AV_FL
or FAC_TQ_REQ_CLU > IP_FAC_TQ_REQ_CLU_FL
then(1) LV_FL_RAW = 1
else (1) **if(2)** PV_AV < ID_PV_AV_FL - C_PV_AV_HYS_FL
or FAC_TQ_REQ_CLU < IP_FAC_TQ_REQ_CLU_FL
-C_FAC_TQ_REQ_CLU_HYS_FL
then(2) LV_FL_RAW = 0
endif(2)
endif(1)

If(1) LV_FL_RAW = 1
and N_32 **>=** C_N_MIN_FL
and TCO **>=** C_TCO_MIN_FL
and VS **>=** C_VS_MIN_FL
and LV_FCUT_IND = 0
and LV_N_MAX = 0
and LV_LAM_LIM_MIN_i = 0
and LV_LAM_LIM_MAX_i = 0
then(1) LV_FL = 1
else(1) LV_FL = 0
endif(1)

Calibration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
C_PV_AV_HYS_FL	1	0...FFH	0...99.6%	0.3906	%
pedal value hysteresis for full load detection

Hysterisis for LV_FL detection for FAC_TQ_REQ_CLU parameter					

5.5 Auxilary functions for engine states

5.5.1 Statistical data for fleet monitoring

General information:

The variables defined in this module should give a general overview about the vehicle usage during a monitoring period.

5.5.1.1 Number of starts

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_CST_LOW_ALTI	O/V/S	0...FFH	0...255	1	[-]
Number cold starts at low altitude					
CTR_CST_HIGH_ALTI	O/V/S	0...FFH	0...255	1	[-]
Number of cold starts at high altitude					
CTR_WST	O/V/S	0...FFH	0...255	1	[-]
Number of warm starts					
CTR_HST_LOW_ALTI	O/V/S	0...FFH	0...255	1	[-]
Number of hot starts at low altitude					
CTR_HST_HIGH_ALTI	O/V/S	0...FFH	0...255	1	[-]
Number of hot starts at high altitude					

Input data:

LV_ST_END	TCO	AMP_AD	

Description:

Application conditions:

Initialisation: - at first ECU power up and non-volatile memory lost:

all Variables = 0

- otherwise: restored from non-volatile memory

Recurrence: *once at exit start (LV_ST_END = 0 -> 1)*

Activation: -

Deactivation: -

Formula section:

```
IF      TCO < C_TCO_MAX_CST
THEN IF     AMP_AD > C_AMP_AD_MAX_ST_HIGH_ALTI

FUNCTION DESCRIPTION:

In case of an unexpected engine/vehicle behaviour (stall or self acceleration) environment data should be stored for root cause analysis; For that reason the 8 values before and 2 values after the unexpected event should be avaiable.

Application conditions:

Initialisation: - at first ECU power up or non-volatile memory lost:

all saved variables = 0

- otherwise: all saved variables restored from NVMY

- at reset or LV_IGK 0 ->1:

T_INH_AST_ENG_STALL = C_T_AST_MIN_ENG_STALL

all others: 0

Recurrence: 200 ms

Activation: LV_IGK = 1 **and**

LV_ENG_STALL_SAVE_END = 0 **and**

LV_AC_SPO_SAVE_END = 0

Deactivation: *otherwise*

Formula section:

If T_INH_AST_ENG_STALL > 0

Then **If** LV_ST_END = 1

Then $T\_INH\_AST\_ENG\_STALL_{(n)} = T\_INH\_AST\_ENG\_STALL_{(n-1)} – 0.2s$

Endif

Endif

IF T_INH_AST_ENG_STALL = 0

and N < C_N_MAX_ENG_STALL

THEN LV_ENG_STALL = 1

ENDIF

$AC\_VEH = AC\_VEH + (((VS_n – VS_{n-1}) / 200ms) – AC\_VEH) * C\_FAC\_AC\_VEH\_MMV$

IF N > C_N_MIN_AC_SPO

and N_GRD > C_N_GRD_MIN_AC_SPO

and ((NC_ETC_CONF = 0 **and** PV_AV < C_PV_AV_MAX_AC_SPO) **or**

(NC_ETC_CONF = 1 **and** PV_CRU < C_PV_AV_MAX_AC_SPO))

and AC_VEH > C_AC_MIN_AC_SPO

THEN LV_AC_SPO = 1

ELSE LV_AC_SPO = 0

IF NC_STATE_LSL_UP_IF = 1 *(linear upstream sensor system)*

THEN FAC_LAM_COR_CMN = FAC_LAM_COR

ELSE FAC_LAM_COR_CMN = FAC_LAM_COR (different phys. resolution!!!!)

ENDIF

THEN SAVE_XXX[9] = XXX

DATA_SAVE_CASE = 2h *(AC_SPO)*

LV_AC_SPO_SAVE_END = 1

ENDIF

In computing, the **modulo** operation finds the remainder of division of one number by another.

Given two numbers, *a* (the dividend) and *m* (the divisor), *a* modulo *m* (abbreviaties as *a* mod *m*) is the remainder, on division of *a* by *m*. For instance the expression "7 mod 3" would evaluate to 1.

$$(a \bmod m) = a - \left\lfloor \frac{a}{m} \right\rfloor \cdot m$$

The floor function returns the integer result of the division a/m.

5.6 Auxiliary start function

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CYC_ST	V/O	0...FFH	0...255	1	-
Cycle counter during start if the first injection is applied					
CYC_CAST	V/O	0...FFFFH	0...65535	1	-
Cycle counter during start and after start (reset at exit start to after start)					
T_AST	V/O	0...FFFFH	0...6553.5	0.1	s
Time after exit start to after start					
T_AST_STOP	V/O/S	0...FFFFH	0...6553.5	0.1	s
Time after exit start to after start saved in the non-volatile memory at engine shut down					
LV_STALL	V/O/S	0...1H	0...1	1	-
Flag indicating that the engine stalled with ignition key on					
LV_ST_ES	V/O	0...1H	0...1	1	-
Flag indicating that the engine did not exit start before the engine stopped					
LV_ST_VLD	-	0...1H	0...1	1	-
indicating that the last engine start was ok					

Input data:

LV_ST	LV_ST_END	LV_ES	SUM_INH_INJ
LV_RUN_ENG	LV_ST_INJ_AUTH		

FUNCTION DESCRIPTION:

General information:

The “Auxiliary start function” puts flags, time- and cycle-counters at the other function’s disposal. The flags are necessary to deal with the different ways to shut down the engine. The time- and cycle-counters are used very often, mainly in the warm up and catalyst heating functions but also in the restart function.

5.6.1 “Start break off” detection: LV_ST_ES

Description:

The “Start break off” (LV_ST_ES = 1) is detected if the engine stops without leaving the “Start”. Additionally the cycle counter CYC_ST has to reach a minimum number of cycles C_CYC_ST_MIN_ST_ES. The check of the minimum number of cycles is necessary to avoid a “start break off” detection in case of a to short activation of the starter.
In case of a “Start break off” detection the cycle counter CYC_ST is not reset to zero (see definition of CYC_ST).
The “Start break off”-Bit LV_ST_ES is reset at the next exit from “Start” to “Idle speed” or “Part load” and at reset.

Application conditions:

Initialisation: at transition LV_ST_END = 0 -> 1

(Systemevent: Exit “Start” to “Part load” or “Idle”):

LV_ST_VLD = 1

LV_ST_ES = 0

at transition LV_RUN_ENG = 0 -> 1

(Systemevent: “Engine stopped” to “Engine running”)

LV_ST_VLD = 0

Recurrence: once

Activation: at transition LV_ES = 0 -> 1

(Systemevent: “Engine running” to “Engine stopped”)

Formula section:

If LV_ST_VLD = 0 **and**
CYC_ST ≥ C_CYC_ST_MIN_ST_ES **then**

LV_ST_ES = 1

endif

5.6.2 “Engine stall” detection: LV_STALL

Description:

“Engine stall” is detected very time the engine stops after leaving the start without the request by means of injection cut off (SUM_INH_INJ number of cut of cylinders).
In case of a “Engine stall” detection the fuel mass for the next restart is handled differently (see “Restart function”).
The “Engine stall”-Bit LV_STALL is reset at the next exit from “Start” to “Idle speed” or “Part load” and is stored in the non-volatile memory for the next start.

Application conditions:

Initialisation: at transition LV_ST_END = 0 -> 1

(Systemevent: Exit “Start” to “Part load” or “Idle”):

LV_STALL = 0

Recurrence: once

Activation: at transition LV_ES = 0 -> 1

(Systemevent: “Engine running” to “Engine stopped”)

Formula section:

If LV_ST_VLD = 1 **and**

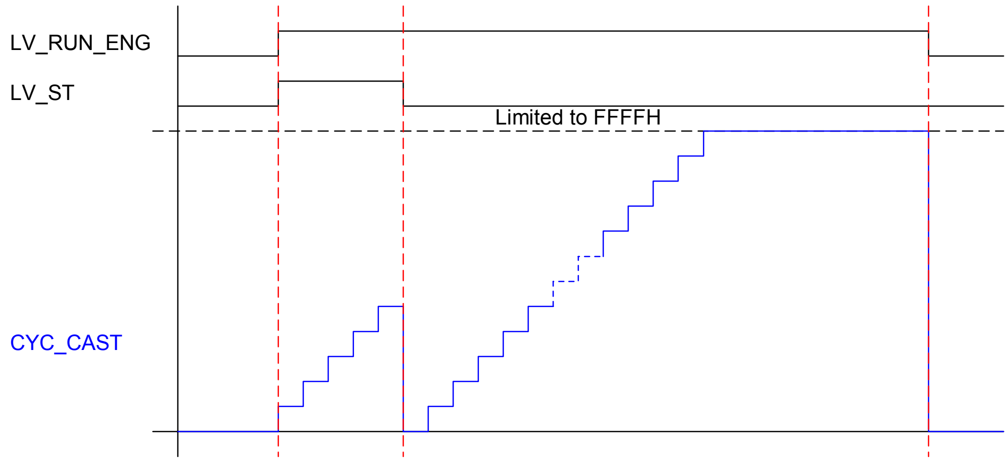
SUM_INH_INJ <= C_NR_MAX_INH_INJ_STALL **then**

LV_STALL = 1

endif

5.6.3 Cycle counter: CYC_CAST

Signal flow diagram:



Description:

The cycle counter CYC_CAST starts counting if the engine is running (LV_RUN_ENG = 1). At exit "Start" and if the engine stops the counter is rest to zero. It is limited to its maximum value.

Application conditions:

Initialisation:	at transition LV_ES = 0 -> 1	(engine stopped) **or**	
	at transition LV_ST = 1 -> 0	(exit start):	CYC_CAST = 0
Recurrence:	every segment		
Activation:	LV_RUN_ENG = 1		
Deactivation:	-		

Formula section:

If CYC_CAST < 65535 (FFFFH) **then**

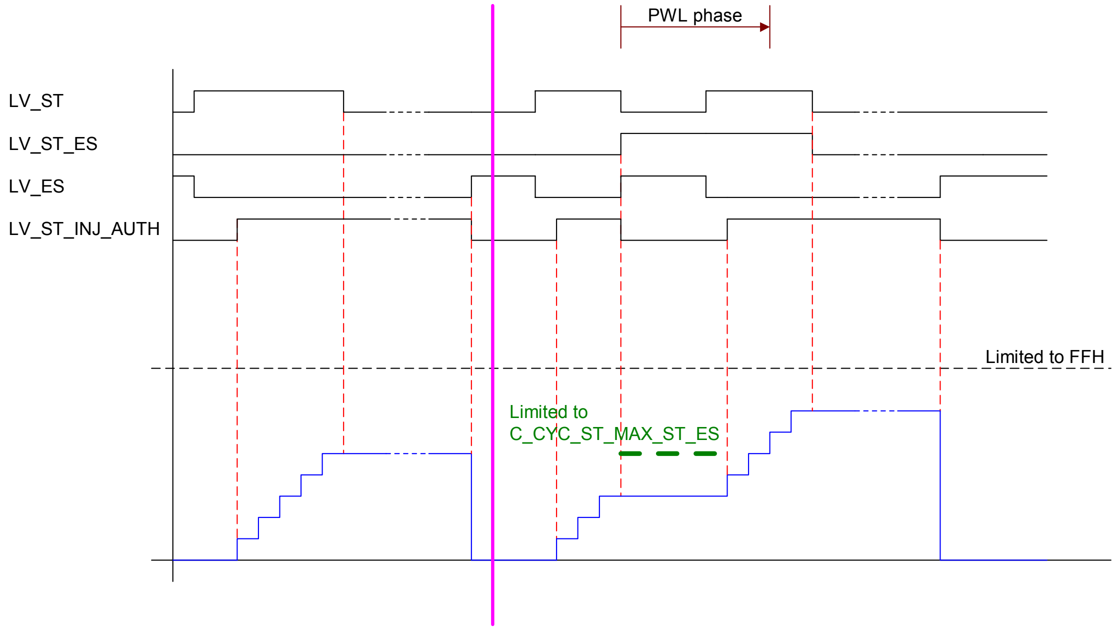
$CYC\_CAST_{n} = CYC\_CAST_{n-1} + 1$

else $CYC\_CAST_{n} = CYC\_CAST_{n-1}$

endif

5.6.4 Start cycle counter: CYC_ST

Signal flow diagram:



Description:

The cycle counter CYC_ST starts counting if the engine is in the start phase and the first injection is authorised (LV_ST_INJ_AUTH = 1). It stops counting at exit “Start”.
If the engines stops and no “Start break off” is detected (LV_ST_ES = 0) CYC_ST is reset to zero. Otherwise CYC_ST stays on its last value or is set to a maximum value C_CYC_ST_MAX_ST_ES if this maximum value is exceeded.

Application conditions:

Initialisation: at transition LV_ES = 0 -> 1

(Systemevent “Engine running” to “Engine stopped”):

If(1) LV_ST_ES = 1 **then**

If(2) CYC_ST > C_CYC_ST_MAX_ST_ES **then**

CYC_ST = C_CYC_ST_MAX_ST_ES

else(2) $CYC\_ST_{n} = CYC\_ST_{n-1}$

endif(2)

else(1) CYC_ST = 0

endif(1)

Recurrence: every segment

Activation: LV_ST = 1

Deactivation: -

Formula section:

If CYC_ST < 255 (FFH) **and**
LV_ST_INJ_AUTH = 1 **then**
$CYC\_ST_{n} = CYC\_ST_{n-1} + 1$
else $CYC\_ST_{n} = CYC\_ST_{n-1}$
endif

5.6.5 Time after start and the saved value after engine stopped: T_AST / T_AST_STOP

Description:

T_AST is a timer, which is started at exit “Start” to “Part load” or ”Idle speed”. It is limited to its maximum value.
If the engine stops the value of T_AST is stored in the non-volatile value T_AST_STOP. Afterwards T_AST is reset to zero.

Application conditions:

Initialisation: at transition LV_ST_END = 1 -> 0 (deactivation)
(“Engine running out of start” to “Engine stopped”):
T_AST_STOP = T_AST
T_AST = 0

Recurrence: 100 ms

Activation: LV_ST_END = 1

Deactivation: -

Formula section:

If T_AST < 6553.5s (FFFFH) **then**
$T\_AST_{n} = T\_AST_{n-1} + 0.1s$
else $T\_AST_{n} = T\_AST_{n-1}$

endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CYC_ST_MIN_ST_ES	1	0...FFH	0...255	1	-
Minimum number of cycles necessary to detect “Start break off”					
C_CYC_ST_MAX_ST_ES	1	0...FFH	0...255	1	-
Maximum number of cycles CYC_ST is set to in case of a “Start break off” detection

Time after start threshold for catalyst heating after start					

5.7.1 General information

This module activates the catalyst heating in general and makes a distinction between after start and low load catalyst heating.

Application Condition

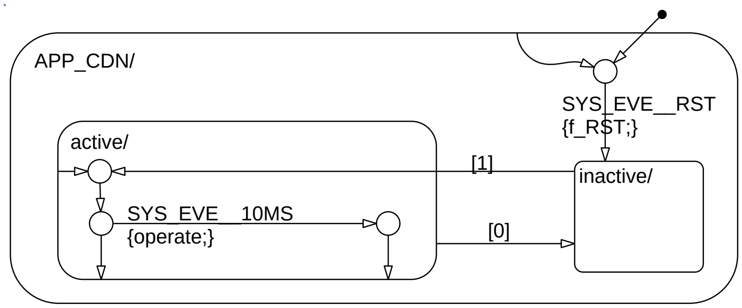

Figure 1 EXTC_ISPCLchc0/ APP_CDN/ Chart

Function Description

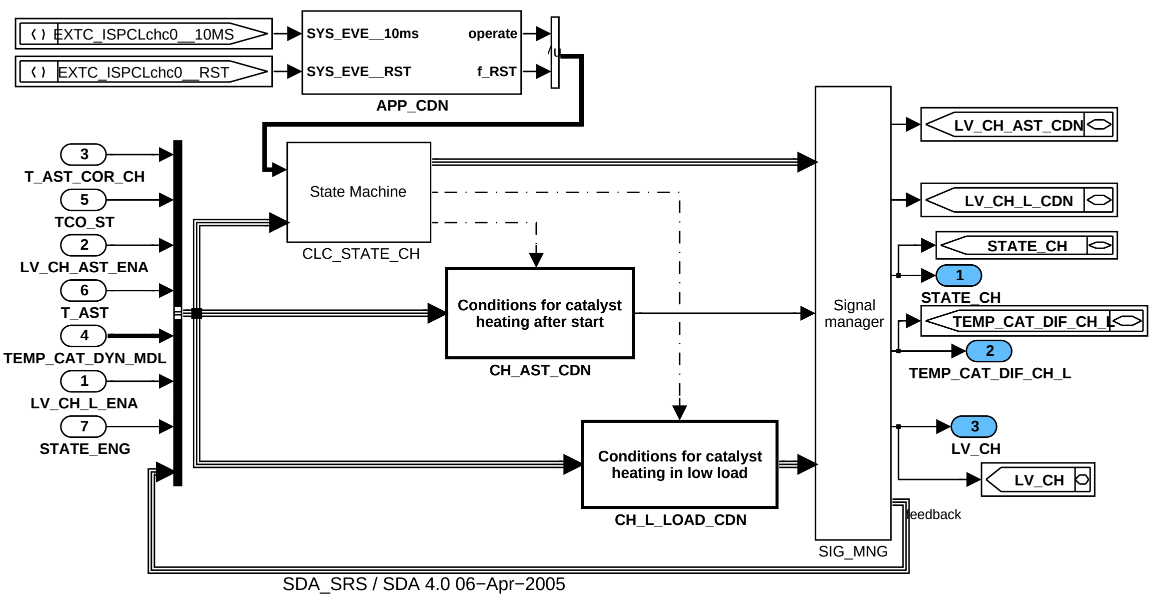

Figure 2 EXTC_ISPCLchc0

5.7.1.1 State Machine

In the passive state 'CH_OFF' first the conditions for after start cataylst heaitng ('CH_AST') are checked –via the function call f_CLC_CH_AST_CDN. If they are not true, conditions for low load heating ('CH_L_LOAD') are checked –via the function call f_CLC_CH_L_CDN. If 'CH_AST' of 'CH_L_LOAD' is active only the conditions for this state are checked.

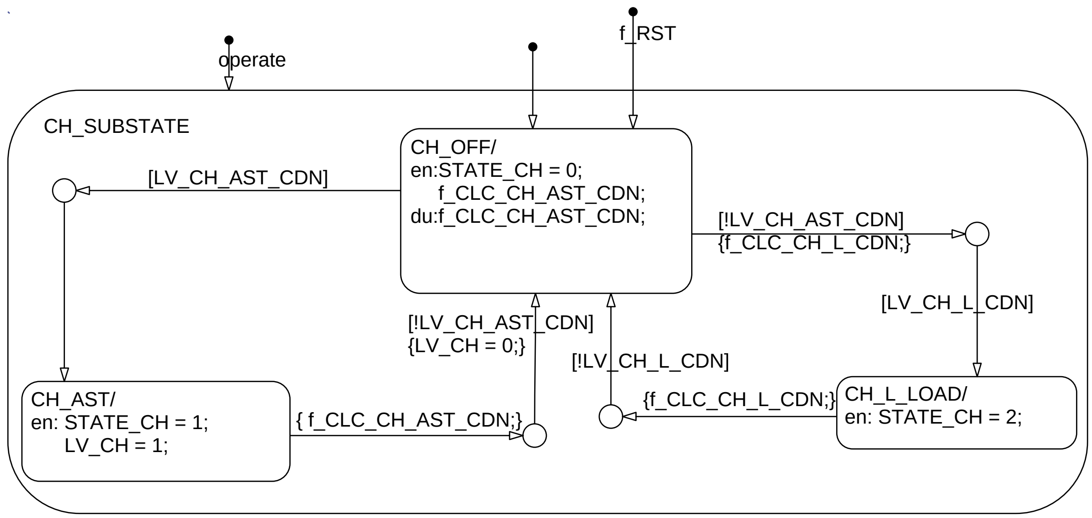

Figure 3 EXTC_ISPCLchc0/ CLC_STATE_CH/ SUB_2

5.7.1.2 Conditions for catalyst heating after start

The map-output is evaluated only as long as the engine is stopped. After that the output will not change anymore. TEMP_CAT_DYN_MDL can only be regarded after the engine runs because the temperature is initialised at system event "engine stopped to engine run".

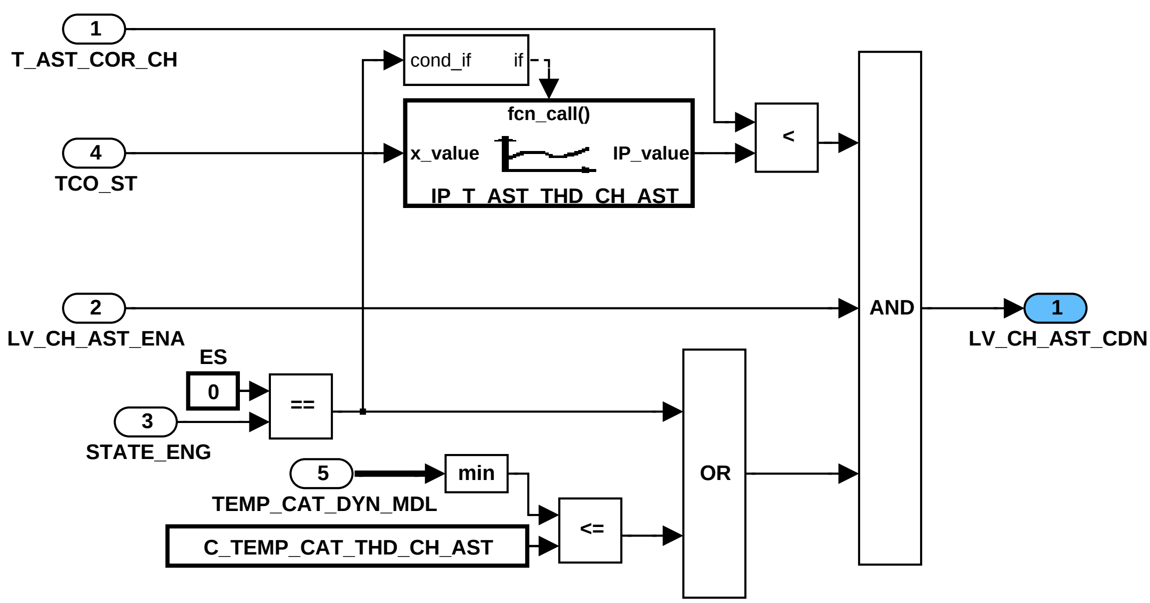

Figure 4 EXTC_ISPCLchc0/ CH_AST_CDN/ SUB

5.7.1.3 Conditions for catalyst heating in low load

The activation of low load catalyst heating depends on the catalyst temperature. TEMP_CAT_DIF_CH_L is the difference between the actual catalyst temperature and a calibratable temperature setpoint which is to be reached through heating measures. The value is negative if the catalyst has to be heated up. Via a T_AST –threshold it is possible to make after start catalyst heating higher prior.

general specification

The activation of low load catalyst heating depends on the catalyst temperature. TEMP_CAT_DIF_CH_L is the difference between the actual catalyst temperature and a calibratable temperature setpoint which is to be reached through heating measures. The value is negative if the catalyst has to be heated up. Via a T_AST –threshold it is possible to make after start catalyst heating higher prior.

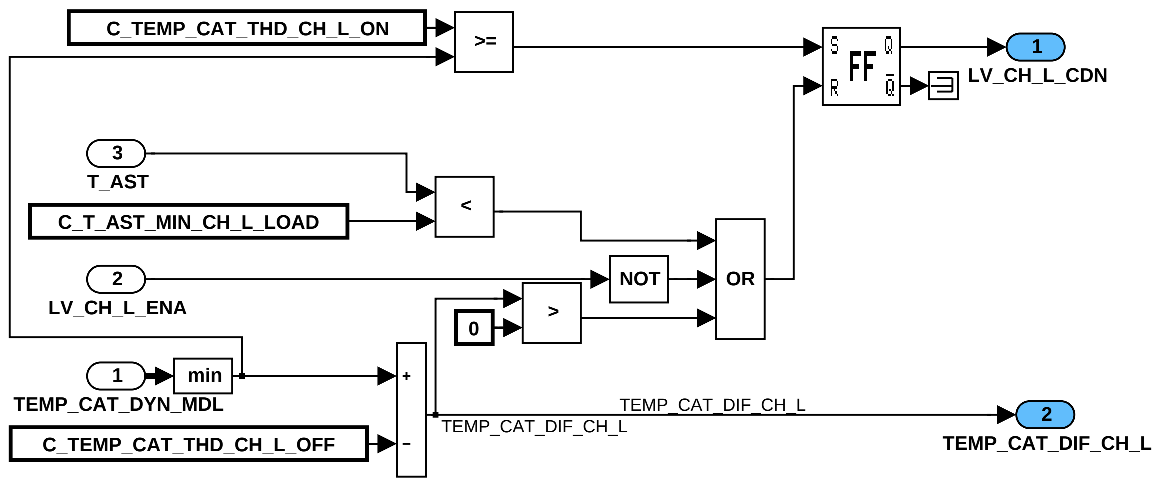

Figure 5 EXTC_ISPCLchc0/ CH_L_LOAD_CDN/ SDA48

5.8 Catalyst heating coordination (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Catalyst age depending correction of T_AST for after start catalyst heating					

Input data:

LV_ES	LV_DRI	LV_ACIN	VS
TCO	LV_ST	T_AST	T_ES

5.8.1 1s - Function

FUNCTION DESCRIPTION:

LV_CH_SET_OFF serves to cancel catalyst heating (LV_CH) by observing a catalyst temperature equivalent (MAF_INT_CH) and comparing it with a threshold. Additionally a TIA_ST and AMP_AD condition is to be fullfilled to serve drivability and break-booster requirements.

Recurrence: 1 s

Initialisation: MAF_INT_CH = 0 at LV_ES = 1 or LV_ST = 1

LV_CH_SET_OFF = 0 at reset

Application conditions:

Activation: In all engine states except LV_ST and LV_ES.

Deactivation: LV_CH_SET_OFF = 1

Formula section:

$MAF\_INT\_CH_{i} = MAF\_INT\_CH_{i-1} + MAF\_KGH$

Note: MAF_INT_CH and MAF_KGH have different resolutions!

5.8.2 100ms - Function

Recurrency: 100 ms

Initialisation: at transition from START(LV_ST) to PL or IS

LV_CH_AST_ENA = 1

LV_CH_L_ENA = 0

Application conditions:

Activation: all engine states

Formula section:

LV_TI_CH = LV_LAMB_CH

T_AST_COR_CH = T_AST *(function can be added to enlarge catalyst heating time due to catalyst aging)*

If MAF_INT_CH > C_MAF_INT_CH_MAX
or TIA_ST < C_TIA_ST_MIN_CH
or AMP_AD < C_AMP_AD_MIN_CH
then LV_CH_SET_OFF = 1

If LV_CH_AST_ENA = 1
Then **If** LV_CH_SET_OFF = 1
or VS > C_VS_MAX_CH
or (LV_DRI = 1 and TCO > C_TCO_DRI_MIN_CH)
or (LV_ACIN = 1 and TCO > C_TCO_ACIN_MIN_CH)
or T_ES < C_T_ES_THD_CH_AST
then LV_CH_AST_ENA = 0

**/ LV_CH_AST_ENA is irreversible until next RESET.*

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

NC_N_IGA_UPD_RATE	1	0...FFH	0...8.16E+3	32	rpm
Threshold on engine speed to change update rate of IGA calculation					

6.1.1 General information:

In this module, the spark advance that has to be applied to the ignition coil (IGA_AV[x]) is determined for each cylinder individually according to the actual engine capability and the actual torque request.

The ignition value IGA_AV[x] to apply on cylinder x is determined versus the fast torque intervention set point (IGA_SP), knock constraints (IGA_CYL_KNK[x]), IGA_MIN and IGA_BAS_COR[i].

Manual calibration of the actual ignition angle can be done if the flag LC_IGA_MAN_ACT = 1 For End of Line process, it is also possible to specify the ignition angle to be applied via the IGA_EOLP input by setting the flag LV_IGA_EOL_ACT to 1

IGA_DIF_TQ_REQ is the output from the torque management functions to realise the torque setpoint. This request from torque management is translated in IGA_SP within this module. IGA_SP is limited between IGA_MIN and IGA_BAS_COR[i] .

IGA_BAS_COR[i] is the corrected basic ignition angle which is realised if no other requests like knock control or torque requests (via IGA_SP) require a retarded ignition angle.

For engine having a multiple cylinder banks configuration (NC_CBK_IN_NR > 1) a cylinder bank specific Corrected Basic Ignition Angle IGA_BAS_COR[i] – with i designating the corresponding cylinder bank – is calculated.

The reference ignition angle IGA_REF_COR is a theoretical ignition angle at maximum engine torque. It is the reference value to all ignition angles for the calculation of all the ignition efficiencies.

According to application choice (*LC_IGA_ST_ENA = 1 or 0; read only after an ECU reset*), the ignition during start phase is not managed through the torque (via IGA_SP) but by using the input value IGA_ST.

At the end of start phase the transition from IGA_ST to the set point ignition IGA_AV_1[x] is done through a gradient limitation (*IP_IGA_LGRD_AST).*

Function Description

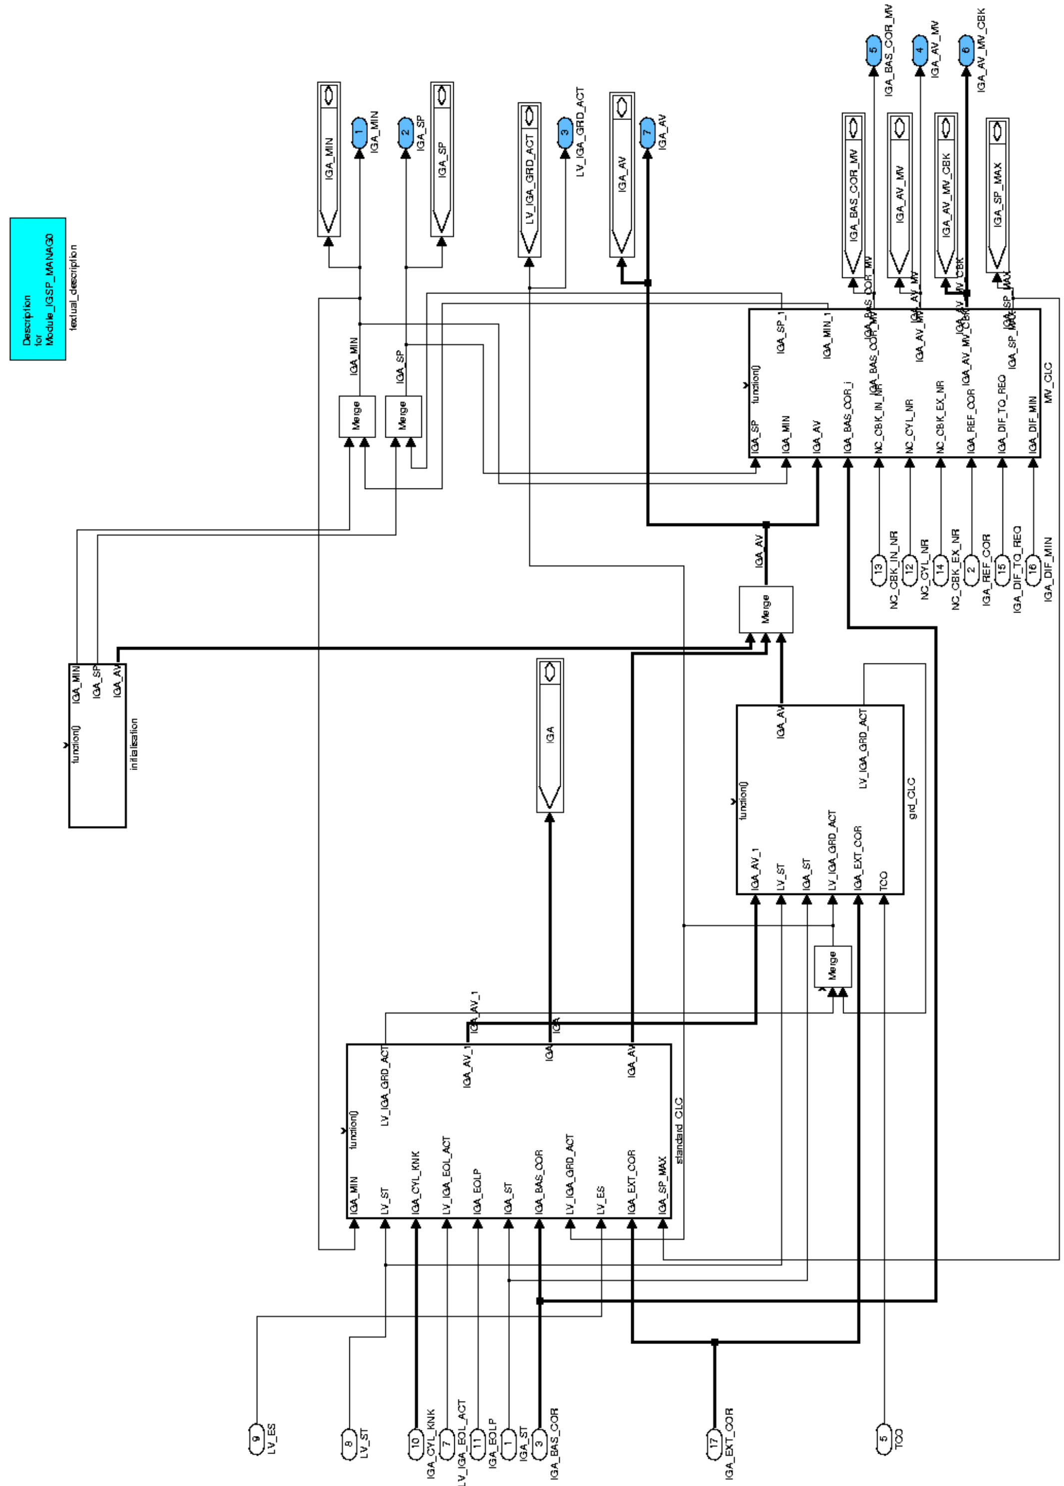

Figure 1 IGSP_MANAG0

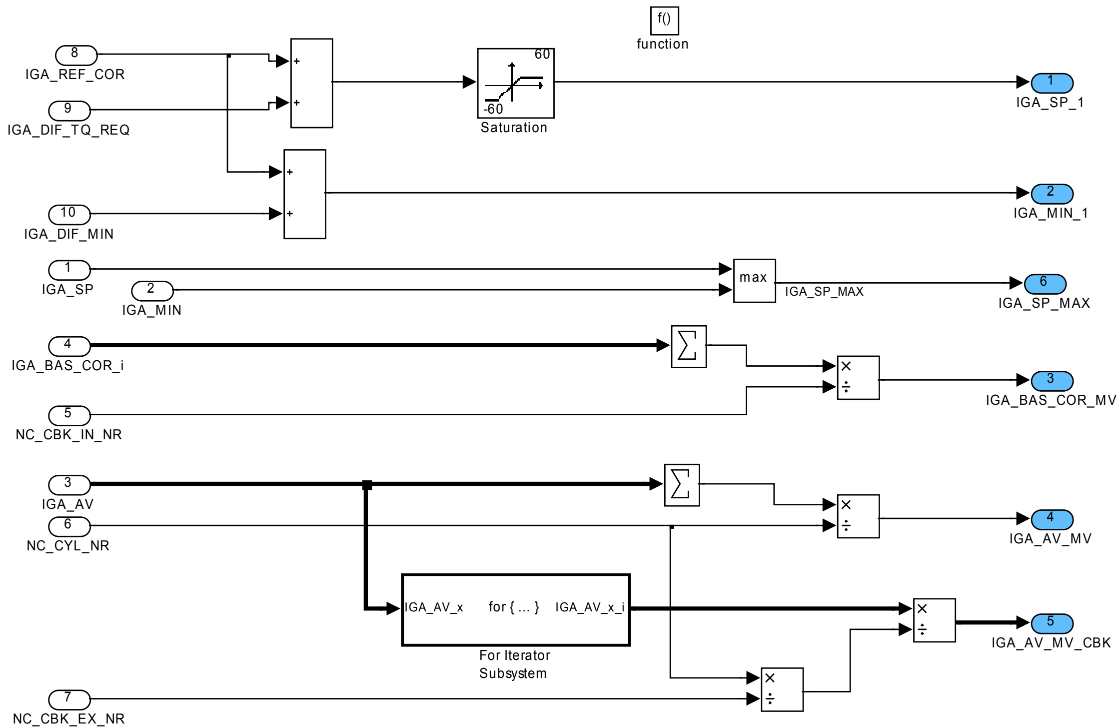

Figure 2 IGSP_MANAG0/ MV_CLC

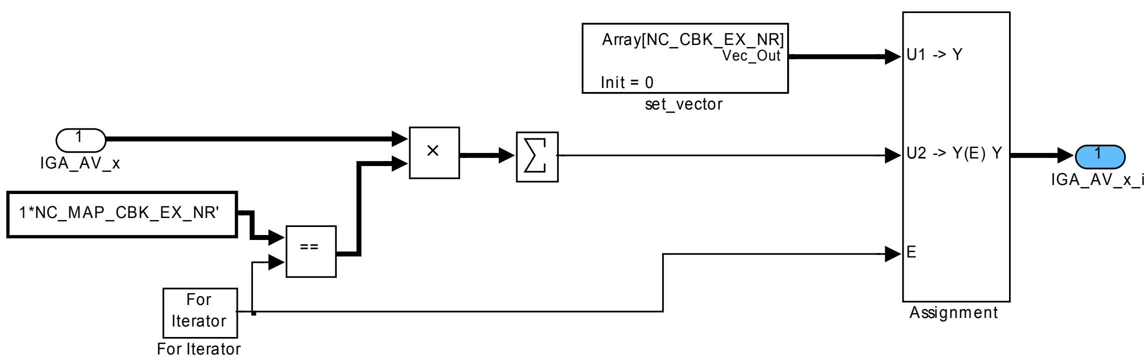

Figure 3IGSP_MANAG0/ MV_CLC/ For Iterator Subsystem

IGSP_MANAG0/GRD_CLC

IGA_ST is used during the starting phase.

At transition from LV_ST = 1 to 0, the ignition value at the end of start (IGA_ST) is returned to the ignition value out of start (IGA_AV_1[x]) using the change limitation IP_IGA_LGRD_AST. This gradient come-back on ignition angle out of start is applied every TDC.

The figure herafter gives an overview of the IGA calculated during and just after start phase if LC_IGA_ST_ENA is activated.

Basic ignition angle efficiency					

6.2.1 General Information

To be consistent with the specific ignition management during start phase, the efficiency must be initialised during this phase. Otherwise, the efficiencies are calculated versus ignition deviations from the reference value.

In case of engine with multiple cylinder bank configuration (NC_CBK_EX_NR>1), for a more efficient modelling and control of the exhaust gas temperature, a cylinder bank specific actual ignition efficiency is determined for each bank.

In order to manage the knock effects on the torque co-ordination (unlocking of the knock control with the throttle opening), two different efficiencies are calculated on the corrected basic ignition angle. The first one include the mean value of the knock correction, the second one only takes care of a filtered value of this knock correction. In this way, the effect of the knock control on the torque management can be smoothened according to the filter constant (and even inhibited if the filter constant is set to 0).

Additive External correction on IGA at Start					
IGA_EXT_COR[NC_CYL_NR]	O/V	80...7FH	-48...47.625	0.375	°CRK
Additive external ignition angle correction					

Input data:

LV_HOM_RUN	NC_CBK_NR	IGA_BAS_VVT_COR	IGA_REF_VVT_COR
IGA_BAS_AMP_COR	IGA_BAS_PORT_COR_i	IGA_REF_PORT_COR	IGA_ADD_ER_BAL[NC_CYL_NR]
LV_CH	LV_IS	TCO	

FUNCTION DESCRIPTION:

General information:

The basic and reference ignition angle have to be corrected due to influence of other external sub-systems(ex. VVTI) . These corrections are summed up to be added to the reference ignition angle within the module "General correction on Ignition angle".

Application conditions:

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Initialisation: -

Update Rate: IGA_REF_INTER_COR => 10ms
IGA_BAS_INTER_COR_i => 10ms

Formula section:

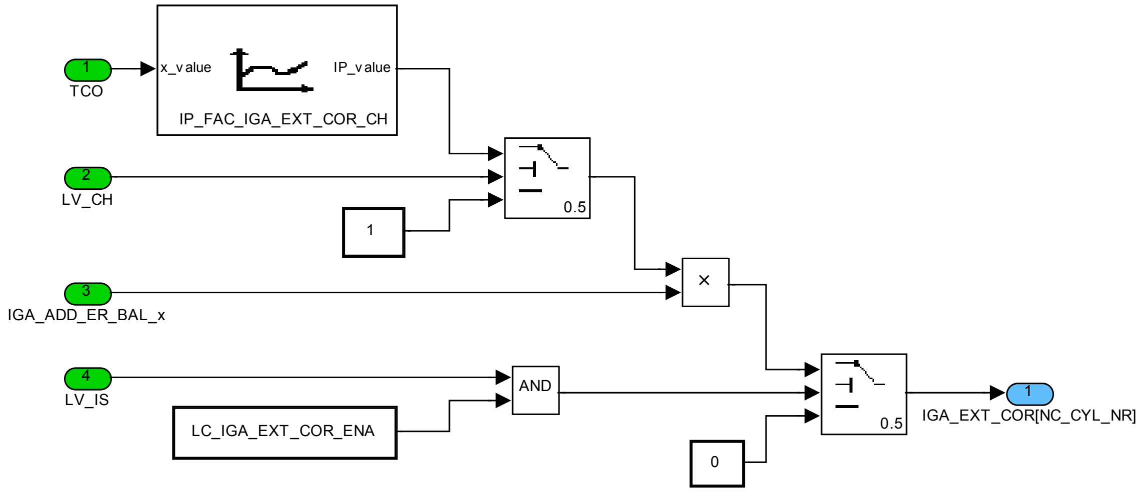
IGA_REF_INTER_COR = IGA_REF_VVT_COR
+ IGA_REF_PORT_COR

IGA_BAS_INTER_COR_i = IGA_BAS_VVT_COR+
+ IGA_BAS_PORT_COR_i

+ IGA_BAS_AMP_COR

IGA_ST_COR = 0

Correction of the basic ignition angle due to cylinder balancing though IGA intervention during idle speed



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_IGA_EXT_COR_ENA	1	0...1H	0...1	1	-
Logical switch to enable external ignition angle correction

LDP_TCO_IP_FAC_IGA_EXT_COR_CH	6	0...FEH	-48...142.5	0.75	°C
Ignition angle correction factor for additive cylinder balancing value at catalyst heating					

6.4 Dwell time control (open loop)

6.4.1 Dwell time calculation

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TD	O/V	0...FFFFH	0....262,14	0,004	ms
Dwell time					

Input data:

TD_FAC	VB	N_32	LV_HOM_RUN

FUNCTION DESCRIPTION:

The dwell time raw value calculation is based on the simulation done by the HW-group. At any time an adaptation or correction factor has to be multiplied or added in this chapter.

The dwell time open-loop control value is stored in terms of a battery voltage and engine speed related characteristics.

Application conditions:

Initialisation: TD = C_TD_INI *at reset*

Recurrence: 10 ms

Activation: *at every engine state* **if** LV_HOM_RUN = 1

Formula section

TD = IP_TD(VB,N_32) * TD_FAC + C_TD_AS

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
IP_TD	8*8	0...FFFFH	0...262,14	0,004	ms
LDPM_VB_1_IGRE	8	0…FFH	0….26	0,102	V
LDPM_N_32_1_IGRE	8	0…FFH	0….8160	32	rpm
Dwell time correction versus battery voltage and engine speed					
C_TD_AS	1	F800...7F0H	-8,192..8,128	0,004	ms
Dwell time offset usual value: 0 ms					
C_TD_INI	1	0...FFFFH	0...262,14	0,004	ms
initial value for dwell time control (typ. Value 3ms for standart coils and <2ms for pencil coils)					

6.5 Dwell time factor calculation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TD_FAC	O/V	1...FFH	1/128....255/128	1/128	-
General dwell time control factor					

Input data:

TCO	N_32		

FUNCTION DESCRIPTION:

General information:

The dwell time factor is to increase the basic dwell time depending on coolant temperature.

This function is requested by HMC.

Initialisation : at reset

TD_FAC = IP_FAC_TD

Recurrence: 10 ms

Activation: all engine operating states

Formula section:

TD_FAC = IP_FAC_TD

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
IP_FAC_TD	8*8	1...FFH	1/128....255/128	1/128	-
LDP_TCO_IP_FAC_TD	8	0…FEH	-48….142.5	0,75	˚C
LDP_N_32_IP_FAC_TD	8	0…FFH	0….8160	32	rpm
Dwell time correction factor versus coolant temperature and engine speed					

6.6 Ignition Inhibition

6.6.1 Ignition inhibition at ignition key off

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_INH_IGC_IGK	V/O	0..1H	0..1	1	-
Flag to Inhibit ignition at IGK off					
CTR_CYC_IGK_OFF	V	0..FFH	0..255	1	-
Cycle counter with ignition off					

Input data:

LV_IGK	N_32	TCO	PREV_STATE_IV

Description:

If the the engine is running and the ignition key is turned off only the injection is inhibited but there is still a ignition spark. An effect of this is that despite zero injection there is combustion because of HCs from wall film, canister purge etc. As a result of this present HCs a combustion happens and the engine stalls very slow. This situation is worse at low coolant temperatures (TCO) because of the high wall film masses.
To guarantee a fast engine stall in case of ignition key off the ignition has to be inhibited too. To ensure that the injected fuel mass of all cylinders is ignited every cylinder has to be ignited once more after ignition key is turned off.

Application conditions:

Initialisation: at reset and deactivation

LV_INH_IGC_IGK = 0

CTR_CYC_IGK_OFF = 0

Recurrence: Segment syncronous
Activation: LV_IGK **=** 0
Deactivation: LV_IGK **=** 1

Formula section:

Increment counter CTR_CYC_IGK_OFF

If LV_IGK **=** 0
and N_32 **<** C_N_ES_IGC
and CTR_CYC_IGK_OFF > ID_CTR_CYC_IGK_OFF
and PREV_STATE_IV **=** 0
Then LV_INH_IGC_IGK **=** 1
Else LV_INH_IGC_IGK **=** 0

The ignition inhibition is done immediately

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
C_N_ES_IGC	1	0...FFH	0...8160	32	rpm
enigne speed threshold condition for ignition deactivation					
ID_CTR_CYC_IGK_OFF	6	0...FF	0...255	1	-
LDP_TCO_CTR_CYC_IGK_OFF	6	0..FE	-48...142.5	0.5	°C
Maximum ignition cycles with ignition switched off					

6.7 TD and IGA switches

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TD_IGC_x	O/V	0..FFFFH	0...262.14	0,004	ms
Dwell time duration					
IGA_IGC_x	O/V	0..FFH	-35.625...60	0,375	°CRK
Ignition angle of cylinder x					

Input data:

IGA_AV_x	TD	TD_FAC_MIN	TD_FAC_MAX
NC_CYL_NR	LV_ES	LV_IGK	LV_FIRST_VLD_TOOTH
LV_IGC_x_EXT_ADJ	IGC_x_EXT_ADJ	LV_INH_IGC[NC_CYL_NR]	

Import actions:

ACTION_INFR_SetIgnDwell(IN <>, IN <>, IN <>, IN <>)
ACTION_INFR_SetIgnAngle(IN <>, IN <>)
ACTION_INFR_SetIgcDwellTest(IN <>, IN <>)

FUNCTION DESCRIPTION:

This module should cover all necessary switches between the different dwell times and ignition angles to ensure two outputs, TD_IGC and IGA_IGC_x. This version is only used if there is only one combustion mode to rename the dwell time and the ignition angle to be coherent with the generic system structure.

Initialisation : at reset

TD_IGC_x = TD
IGA_IGC_x = IGA_AV_x

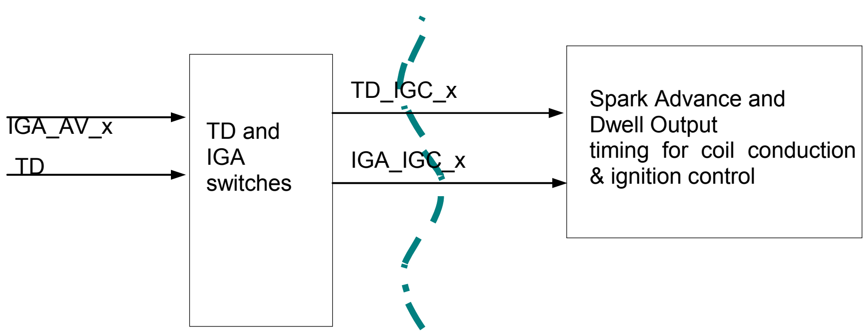
For x = 0 to NC_CYL_NR - 1

ACTION_INFR_SetIgnDwell(x,TD_FAC_MIN,TD_IGC[x],TD_FAC_MAX)

ACTION_INFR_SetIgnAngle(x,IGA_IGC[x])

Endfor

Signal flow diagram:



6.7.1 Dwell time switch

Application conditions:

Activation: Engine synchronized

Recurrence: 10ms

Formula section:

TD_IGC_x = TD

For x = 0 to NC_CYL_NR - 1

ACTION_INFR_SetIgnDwell(x,TD_FAC_MIN,TD_IGC[x],TD_FAC_MAX)

Endfor

6.7.2 Dwell time switch Ignition Actuator Tests Diagnosis

Application conditions:

Activation:	[	LV_ES = 1	*// Actuator tests activation*
	and	LV_IGK = 1	
	and	LV_FIRST_VLD_TOOTH = 0	
	and	LV_INH_IGC[x] = 0	
	and	at least one LV_IGC_x_EXT_ADJ = 1]	
Deactivation:	[	LV_ES = 0	*// Actuator tests deactivation*
	or	LV_IGK = 0	
	or	LV_FIRST_VLD_TOOTH = 1	
	or	LV_INH_IGC[x] = 1	
	or	at least one LV_IGC_x_EXT_ADJ = 0]	
Recurrence:	On transition of IGC_x_EXT_ADJ from 0 to 1		

System description:

For ignition coil actuator tests purpose, the Dwell Time has to be applied and transmitted to BSW via action. A specific service is used for those tests purposes.

Formula section:

TD_IGC_x = TD

```
For     x = 0 to NC_CYL_NR – 1
        If      LV_IGC_x_EXT_ADJ = 1
        Then    On transition of IGC_x_EXT_ADJ from 0 to 1        and
                LV_FIRST_VLD_TOOTH = 0
                ACTION_INFR_SetIgcDwellTest(x,TD_IGC[x])

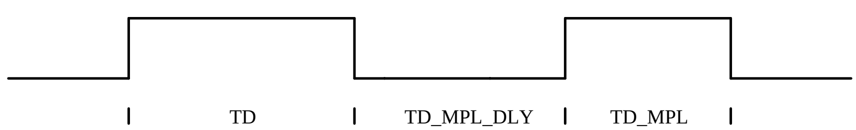
6.8.1 Calculation of parameters for multiple spark

FUNCTION DESCRIPTION:

With this function several subsequent sparks could be created. The delay time to create a spark and the time to reload the coil are defined in tables depending on battery voltage.

At start and for the following application conditions, the ignition is controlled by means of multiple sparks.

After an adjustable combustion period (C_TD_T_MPL), the ignition coil is loaded with a specific dwell time (IP_TD_MPL) to create successive sparks. The number of successive sparks is defined as IGN_MPL_NR.



The MPL Sparks are maintained during a time (C_T_CTR_TD_MPL_AST or C_T_CTR_TD_MPL) after the end of the activation condition, before exiting this MPL procedure (*Application Multiple Spark Maintenance for a time before Exit Case*)

Application conditions:

Initialisation:	IGN_MPL_NR	= 0	
	TD_MPL	= 0	
	TD_MPL_DLY	= 0	
	T_CTR_TD_MPL	= 0	*At reset*

Recurrence: 10 ms

6.9 Ignition Activation Control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
INH_IGC	V/O	0...FFH	0...255	1	-
Inhibition of selected cylinder					

Input data:

LV_IMOB_IGC_OFF	LV_ENG_OFF_DMF_IGN	LV_IGN_INJ_LOCK_REQ	LV_INH_IGC_IGK

FUNCTION DESCRIPTION:

Application conditions:

Initialisation : at reset

Activation: engine synchronised

Output driver deactivation

General information

The decision to inhibit an ignition stage is taken for each output before the turn on at TD_ON_x.

Ignition shut off requested by Immobilizer:

if LV_IMOB_IGC_OFF = 1

then all ignition must be shut off: INH_IGC = xxxx1111

Ignition shut off requested by DMF Oscillation Detection:

if LV_ENG_OFF_DMF_IGN = 1

then all ignition must be shut off: INH_IGC = xxxx1111

Ignition shut off requested by Backward Engine Rotation Detection:

if LV_IGN_INJ_LOCK_REQ = 1

then all ignition must be shut off: INH_IGC = xxxx1111

Ignition shut off requested after ignition switch off:

if LV_INH_IGC_IGK = 1

then all ignition must be shut off: INH_IGC = xxxx1111

If one bit within INH_IGC is set to 1, then the corresponding ignition output is immediately inhibited. The ignition output remains inhibited while the INH_IGC is unchanged.

6.10 Basic ignition angle at start (IGA_ST)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_ST	O/V	0..FFh	-35.625..60	0.375	°CRK
Basic ignition angle at start					

Input data:

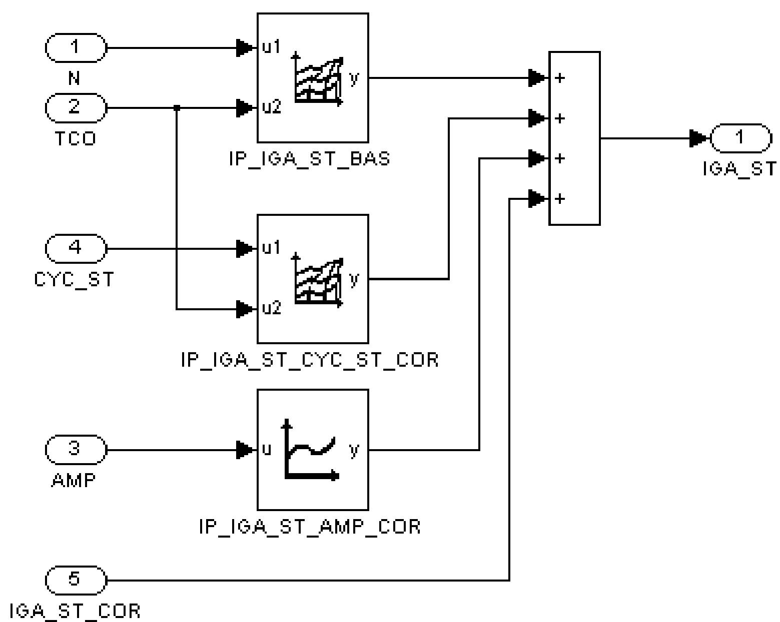
N	TCO	CYC_ST	AMP
LV_ST	IGA_ST_COR		

FUNCTION DESCRIPTION:

General information:

The ignition angle at start is basically dependent on the engine speed N and coolant temperature TCO determined by the map IP_IGA_ST_BAS. Additionally a map dependent on the ambient pressure AMP corrects this basic ignition angle. To avoid backfiring due to the fast increase of the combustion chamber temperature a second correction dependent on the cycle counter CYC_ST and the coolant temperature is added. IGA_ST_COR is added for project specific corrections.

Signal flow diagram:



Application conditions :

Activation : LV_ST = 1

Deactivation : LV_ST = 0

Initialisation : IGA_ST = 0°crk at reset

Update rate : every TDC and every 10 ms

Formula section :

IGA_ST = IP_IGA_ST_BAS
+ IP_IGA_ST_CYC_ST_COR
+ IP_IGA_ST_AMP_COR
+ IGA_ST_COR

Calibration data:

6.11 Ingition angle correction due to Port flap influence

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_BAS_PORT_COR_i	V/O	80...7FH	-48...47.6	0.375	°CRK
basic ignition angle correction with active port flap					
IGA_REF_PORT_COR	V/O	80...7FH	-48...47.6	0.375	°CRK
reference ignition angle correction with active port flap					

Input data:

FAC_PORT_DEAC	N_32	MAF_HB	LV_HOM_RUN
CONF_PORT	NC_CBK_NR		

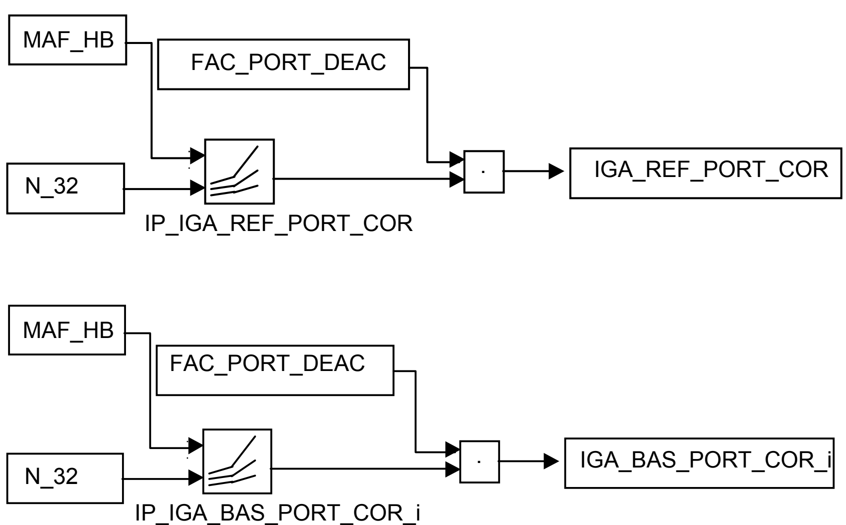
FUNCTION DESCRIPTION:

For engines equipped with a port flap it is necessary to have an ignition angle correction depending on the position of the port flap. This correction is an additive correction on the basic and the reference ignition angle (--> “corrected basic ignition angle” and “corrected reference ignition angle”).

Therefore the basic and reference ignition angle is to be calibrated with open (deactivated) port flap (FAC_PORT_DEAC = 0) and afterwards this correction has to be applied depending on load point (N, MAF) and port flap position (FAC_PORT_DEAC)

For systems with cylinder bank selective ignition angles (NC_CBK_NR = 2) this function is bank selective too. _i represents the cylinder bank. The ignition correction for the reference ignition angle (IGA_REF_PORT_COR) must not be cylinder bank selective, as the reference ignition angle is not bank selective. So IGA_REF_PORT_COR is calculated via FAC_PORT_COR_MV

Signal flow diagram:



Application conditions:

Initialisation: IGA_BAS_PORT_COR_i = IGA_REF_PORT_COR = 0
at reset and with LV_IGK = 0 --> 1

Recurrence: 10 ms

Activation: LV_HOM_RUN = 1
and CONF_PORT = 1

Deactivation: LV_HOM_RUN = 0
or CONF_PORT = 0

Formula section:

If N_32 ≤ C_N_THD_PORT_IGA_COR

then IGA_BAS_PORT_COR_1 = IP_IGA_BAS_PORT_COR_1 * FAC_PORT _DEAC

NC_CBK_NR = 2

IGA_BAS_PORT_COR_2 = IP_IGA_BAS_PORT_COR_2 * FAC_PORT _DEAC

end

IGA_REF_PORT_COR = IP_IGA_REF_PORT_COR * FAC_PORT_DEAC

else IGA_BAS_PORT_COR_1 = 0

NC_CBK_NR = 2

IGA_BAS_PORT_COR_2 = 0

end

IGA_REF_PORT_COR = 0

6.12.1 General information:

The calculation of the correction- or adaptation values is performed, depending on the settings of the corresponding logical activation variable. LV_IGA_ADD_ER_BAL_ENA is used to enable the correction path, while LV_IGA_ADD_AD_ER_BAL_ENA enables the adaptation path. As soon as the corresponding logical value is set to "1" in combination with additional activation conditions, the calculation is started.

The calculated additive adaptation value IGA_ADD_AD_ER_BAL[NC_CYL_NR] for each cylinder is stored in the non-volatile memory to be available for initialization issues at next engine run.

With use of the manual reset it is possible to initialize the additive correction- or adaptation values with zero at any time. In this case, the flags which indicate the exceeding of a controller output limitation are set to zero as well (refer: "Initialization at Manual Reset")

Calculation of segment tasks CLC_OPERATE_SEG CLC_IGA_ANG_COR_VALUE

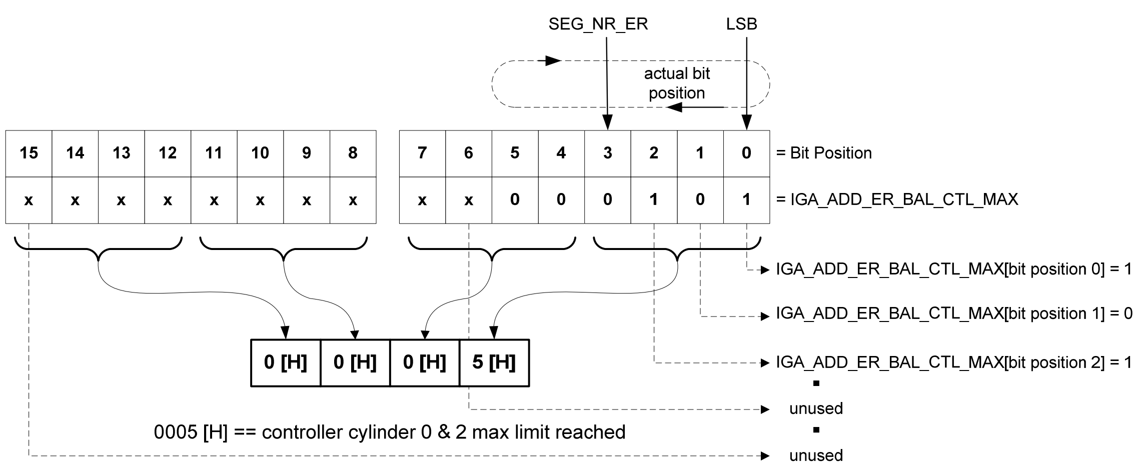
The calculation of the ignition angle correction values are only performed if the corresponding enable bit LV_IGA_ADD_ER_BAL_ENA is set to logical "1" in combination with additional activation conditions. In this case, a separate correction value for each cylinder is determined with use of a PI-controller.

As soon as a PI-controller of one cylinder is reaching its maximum, a corresponding value is set to "1" to indicate the related cylinder. To save memory resources, the information for all cylinders is located within one output data (WORD) is used to indicate one cylinder. It is possible to handle up to 16 cylinders with this method.

For a description more in detail please have a look to the signal flow diagram below. As example, a six-cylinder engine with two PI-controllers, which have reached the limits is shown.

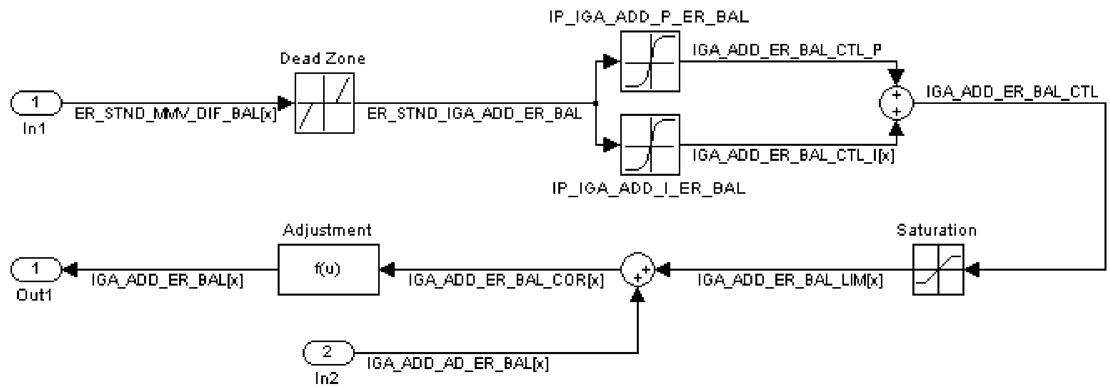
Signal flow diagram:

-Signalization of controller max.output value reached for ignition path



Note: always the complete WORD (16 BIT) is displayed as visible value

-Calculation of the ignition angle correction / adaptation values in general



Note: [_x] is representing [SEG_NR_ER] in the signal flow diagram above

Controller Equations

For the additive correction mode, a separate of NC_CYL_NR controllers exists operating in parallel (one controller for each cylinder).

The computation of the output values is carried out every C_CYCNR_IGA_ADD_ER_BAL engine cycles (= calibrateable number of engine cycles).

Only in case of C_CYCNR_IGA_ADD_ER_BAL = 1, the calculation of the additive path is done without interruption. At every segment the corresponding cylinder correction value is built.

If the computation is not done at every engine cycle (C_CYCNR_MFF_ADD_ER_BAL > 1), the trigger of the controller output calculation is always related to SEG_NR_ER = 0.

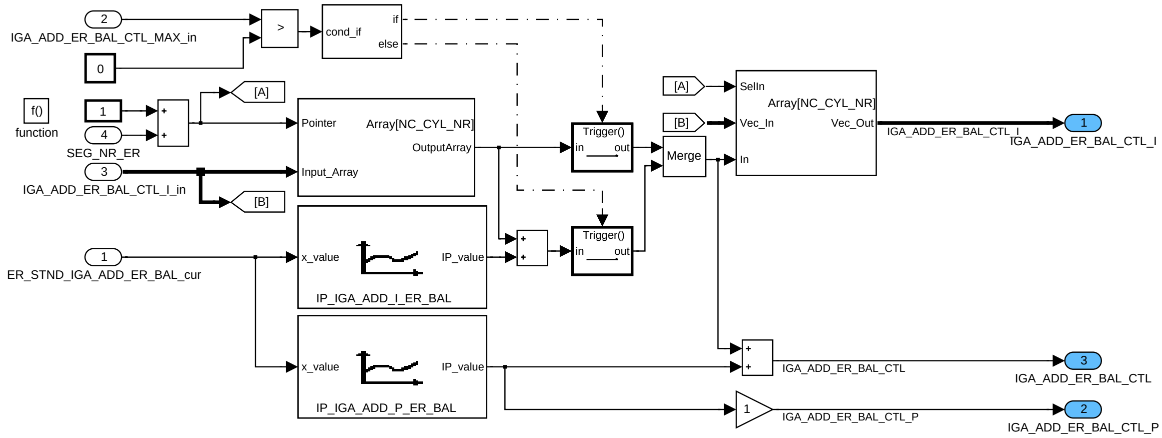

Figure 37 CYBL_M30602G02/ OPM/ operate_SEG/ CLC_OPERATE_SEG/ CLC_IGA_ANG_COR_VALUE/ CTL_EQUATIONS

Limitation of the Controller Output

The outputs of the controllers are limited to a calibratable threshold. If one controller output has reached the limit, a flag is set to once and the corresponding segment number is displayed.

Correction of limited controller output values with adaptation values

The limited controller output values are corrected with the currently available adaptive correction values, which are saved in the NVMY and updated at Activation or Deactivation of the additive adaptation path (LV_IGA_ADD_AD_ER_BAL_ENA).

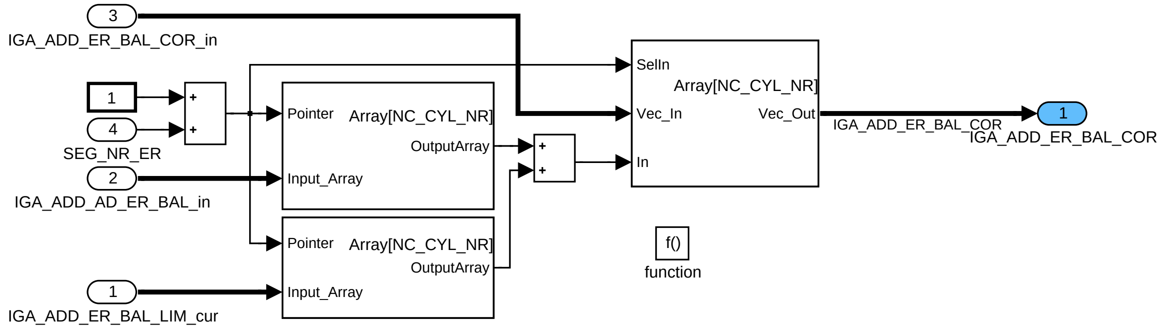

Figure 42 CYBL_M30602G02/ OPM/ operate_SEG/ CLC_OPERATE_SEG/ CLC_IGA_ANG_COR_VALUE/ COR_LIM_CTL_OUT_VALUE

Observation of corrected controller output values for OBD issues

The additive correction values out of the correction path are observed for OBD purposes. As soon as the minimum maximum diagnosis threshold is exceeded, a corresponding flag for the related cylinder is set. In this case the OBD system is indicated to handle the further failure treatment. The diagnosis thresholds have always to be less or equal to the absolute minimum maximum controller output limits.

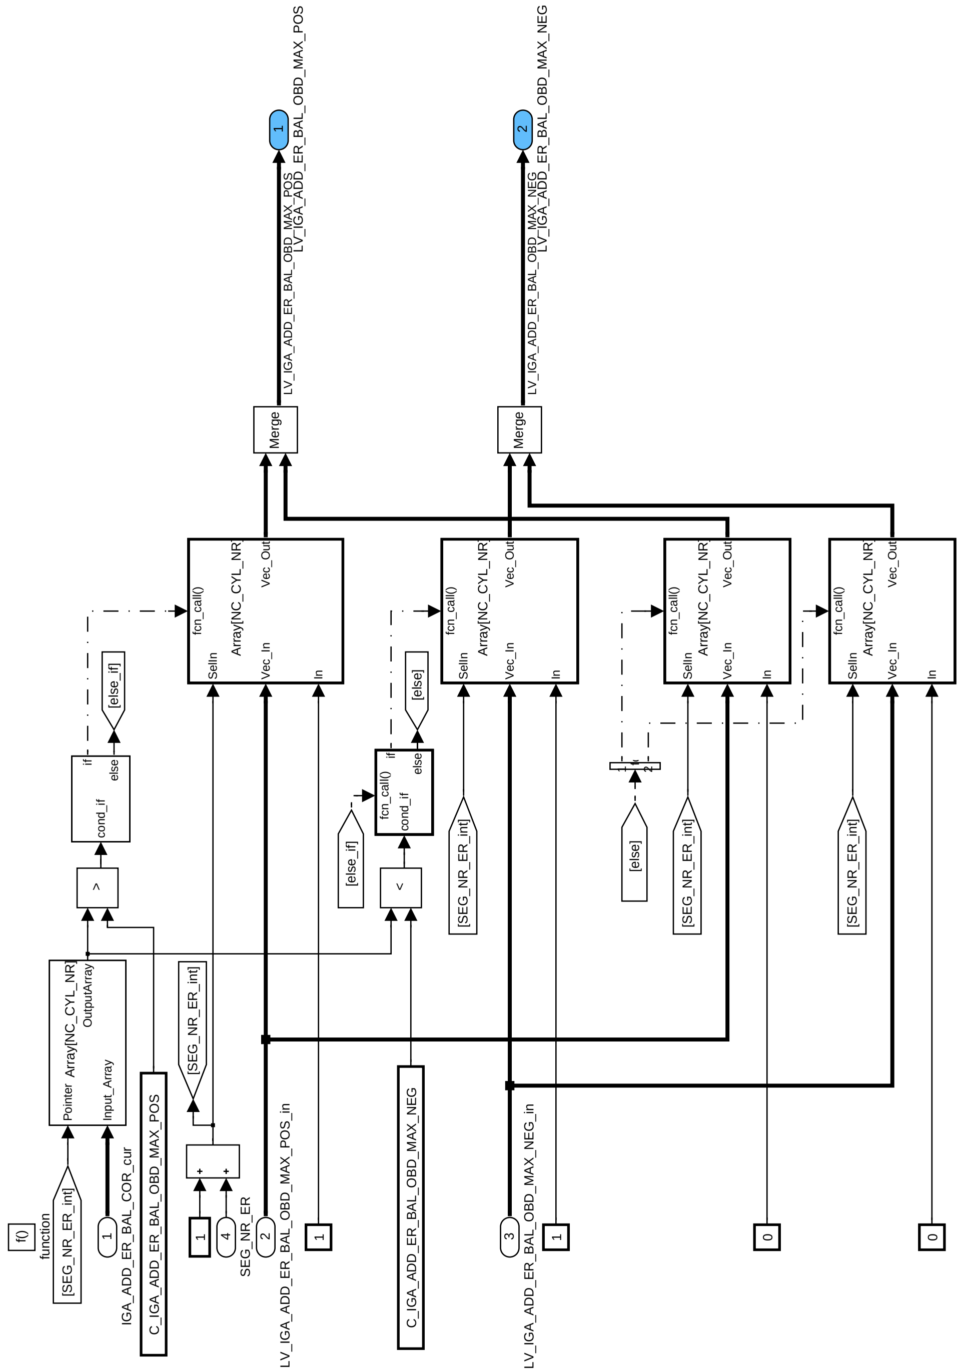

Figure 43 CYBL_M30602G02/ OPM/ operate_SEG/ CLC_OPERATE_SEG/ CLC_IGA_ANG_COR_VALUE/ COR_CTL_OUT_VALUE_OBD

Calculation of segment tasks CLC_OPERATE_SEG CLC_ADD_INJ_T_VALUE

The corrected NC_CYL_NR controller output values are adjusted dependent on the corresponding segment number SEG_NR_ER. During the function is activated, at every new segment the corresponding IGA_ADD_ER_BAL value is updated. Due to this correction the sum of all adaptation output values remains zero to guarantee that the overall injection spreading stays unchanged.

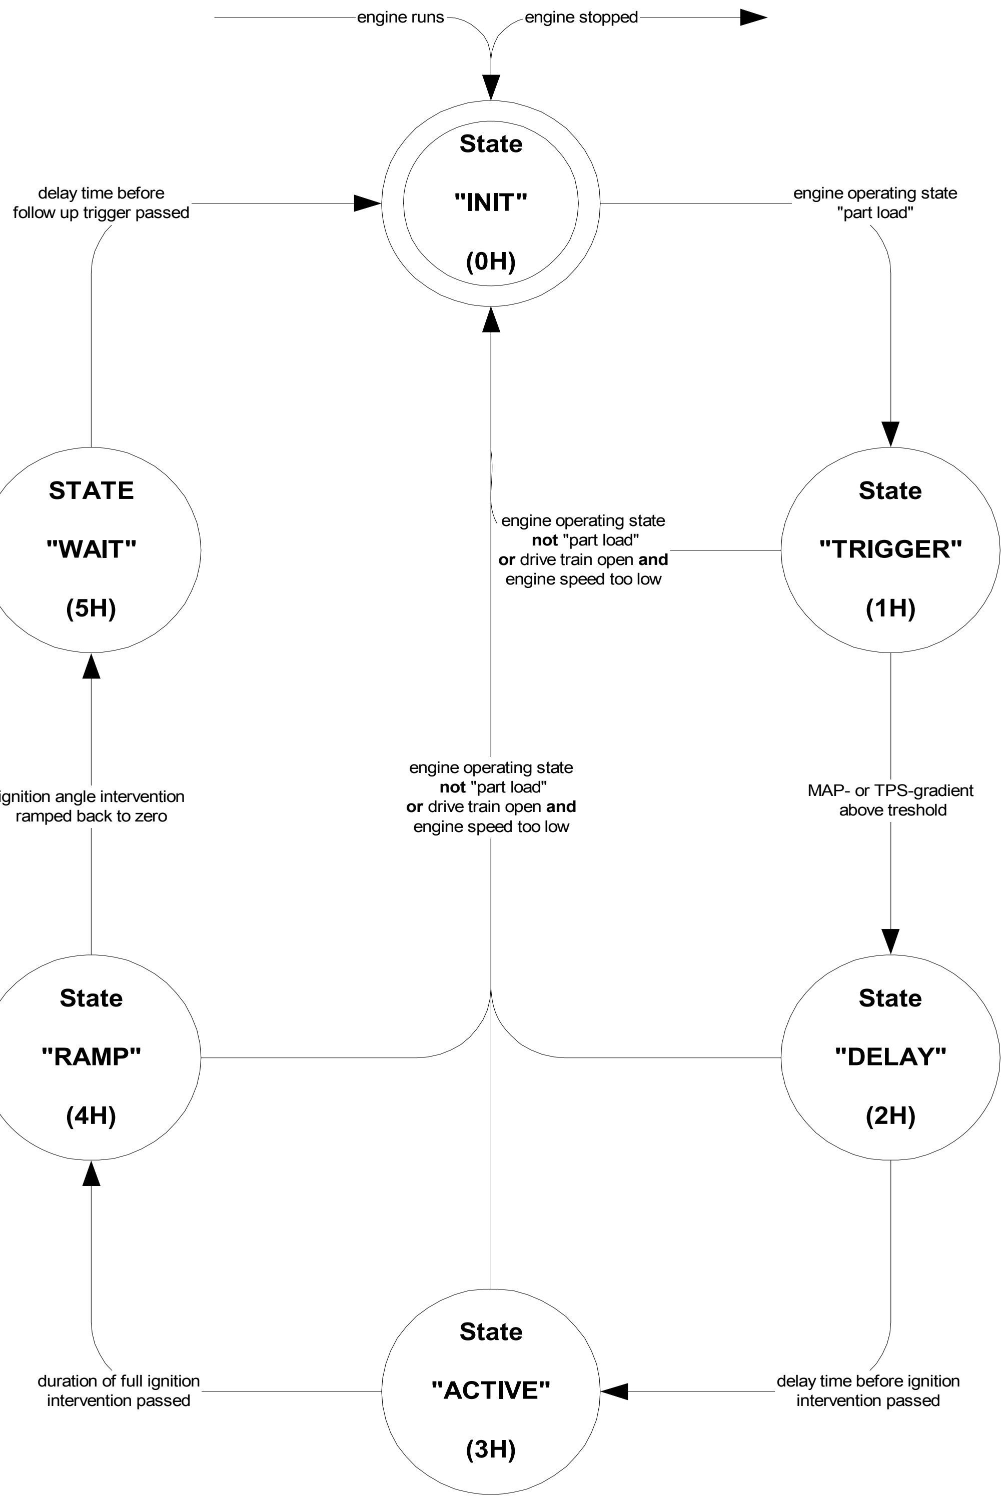
LV_PL	LV_AT	LV_TPS_GRD_UP	GEAR

Function description:

General Information:

In case the throttle position gradient or the intake manifold pressure gradient exceeds adjustable limits (“load dynamics”), an ignition angle intervention shall be performed in order to avoid knocking combustion.
After detection of load dynamics, the ignition intervention is not activated, before a calibratable number of segments has passed. During this delay the determined ignition adjustment (dependent on engine opereating point, vehicle speed and gear) is updated towards stronger interventions. At the end of the delay time - after the last update - the ignition intervention will be executed unchanged for a calibratable number of cycles.
After the end of this constant intervention phase, the ignition adjustment is reset to zero with calibratable incremet steps.
The ignition angle intervention of load dynamics is terminated whenever the drive train is detected open in combination with engine speed below a minimum threshold or in case engine operating state part load is left.
Since the trigger conditions (throttle- and pressure gradient) for ignition angle adjustment are linked by an "OR" operator, it might occur that both conditions are satisfied after a short time, thus causing a reiterated, undesired ignition angle intervention. To prevent this effect an adjustable waiting time before the next trigger of load dynamics can be applied.

Signal flow diagram:



In any state except RAMP and WAIT state, if ID_CYC_IGA_TRA_KNK_DLY = 0 and the triggering conditions are fulfilled, the spark timing retard(IGA_TRA_KNK) should be performed immediately without any delay.

6.15 Minimum Ignition Angle

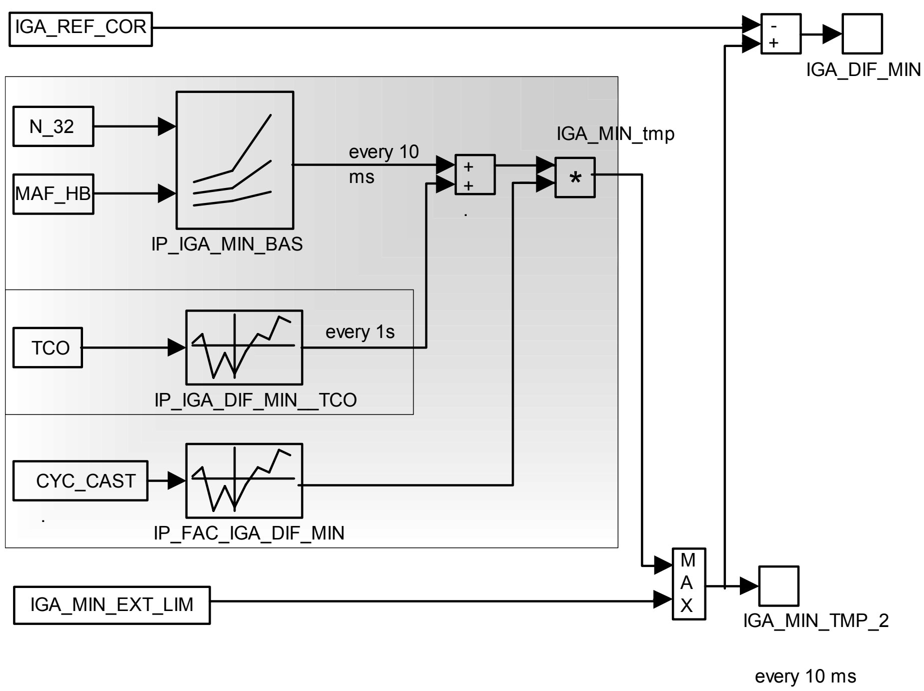
Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_DIF_MIN	O/V	0..FFH	0..-95.625	0.375	°CRK
Difference from minimum ignition angle to reference ignition angle					
IGA_MIN_TMP_2	V	0..FFH	-23.625..72	0.375	°CRK
minimum ignition angle internal value					

Input data:

LV_HOM_RUN	N_32	MAF_HB	TCO
IGA_REF_COR	CYC_CAST	IGA_MIN_EXT_LIM	

FUNCTION DESCRIPTION:



General information:

The minimum ignition angle IGA_MIN is the minimum allowable ignition angle which is possible to apply to the engine in hom. mode. The intension of this minimum ignition angle IGA_MIN is the absolut latest ignition angle, where the engine has complete combustion. Other aspects like exhaused gas temperature are taken into account somewhere else.
The IGA_MIN calculated from a basic value of the minimum ignition angle corrected with a temperature dependent additive term and a factor depending on engine cycles after start.

Application conditions:

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Initialisation: IGA_MIN_TMP_2 = -23.625 °CRK at reset
IGA_DIF_MIN = 0

Update Rate: IP_IGA_DIF_MIN_BAS => 10 ms
IP_IGA_DIF_MIN_TCO => 1000 ms

Formula section:

Maximum possible spark retard:

In all practical cases IGA_DIF_MIN is a negative value which is the maximum allowable spark retard. It includes the coolant temperature correction and a cycle factor (for engine protection. pollution condition. etc…).

IGA_MIN_tmp = **(**IP_IGA_MIN_BAS (__N_32__MAF_HB) + IP_IGA_DIF_MIN_TCO**)**
***** IP_FAC_IGA_DIF_MIN_CYC_CAST

Minimum ignition angle (absolute value):

IGA_MIN_TMP_2 **= MAX (** IGA_MIN_tmp **;** IGA_MIN_EXT_LIM **)**

IGA_DIF_MIN **=** IGA_MIN_TMP_2 **–** IGA_REF_COR

Calibration data:

6.15.1 External Limitation on Minimum Ignition (version for absolute IGA_MIN appl.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_DRI	V	0..FFFFH	655,35	0.01	Sec.
Time after Drive engaged to apply low Spark advance during Gear Shift					
IGA_MIN_EXT_LIM	V/O	0..FFH	-23.625..72	0.375	°CRK
minimum ignition angle during gear change of AMT					

Input data:

LV_HOM_RUN	LV_DRI	LV_GS_ENA	IGA[NC_CYL_NR]
SPK_RTD_TCU	TCO		

FUNCTION DESCRIPTION:

Depending on driving condition, Spark Advance is limited during Torque Reduction request for Gear Shift.

Application conditions:

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Initialisation: IGA_MIN_EXT_LIM = -23.625 °CRK (0 hex)

T_DRI = 0

Recurrence: 10 ms

Formula section:

- *T_DRI definition* **:**

If LV_DRI = 0
Then T_DRI = 0
Else
  If Transition LV_DRI = 0 -> 1
  Then T_DRI is set to C_T_DRI
  Else T_DRI is decremented by 0,01 sec. Until it reaches 0

- *IGA_MIN_EXT_LIM definition* **:**

If LV_GS_ENA = 1
Then
  If SPK_RTD_TCU < FFH
  Then IGA_MIN_EXT_LIM = Min(SPK_RTD_TCU, IGA)

  Else **If** T_DRI > 0
    Then IGA_MIN_EXT_LIM = IP_IGA_GS_1
    Else IGA_MIN_EXT_LIM = C_IGA_GS_2

Else IGA_MIN_EXT_LIM = -23,625°CRK (0 hex)

- Remark:

When IGA_MIN_EXT_LIM is returned to -23.625°CRK (0 hex), there are 10ms delay and when IGA_MIN_EXT_LIM is returned to IP_IGA_GS_1 or C_IGA_GS_2, there are 30ms delay to avoid a sudden drop of TQI_AV by released IGA_AV limitation.

IGA is averaged value of IGA[NC_CYL_NR].

Minimum ignition angle versus exhaust gas temperature					

6.16.1 General information

The minimum ignition angle IGA_DIF_MIN is the minimum allowable retard on ignition angle that is possible to apply to the engine. Hence, it only includes the combustion stability concern. It does not take into account any thermal effect. It should be used during the torque intervention phases in order to produce a fast reduction of the torque.

Applying this minimum ignition angle as actual ignition angle results in efficiency losses that leads to an exhaust gas overheating and/or engine damages.

In order to avoid overheating of the components in the exhaust-system branch, minimum spark retard has to be limited in accordance with the actual exhaust gas temperature TEG_DYN_UP_CAT[NC_CYL_CBK_NR].

Moreover to determine the maximum possible torque reserve for catalyst heating, the torque reserve co-ordination module needs the minimum ignition angle efficiency and the minimum ignition angle with exhaust branch protection efficiency in order to limit and choose the different torque reserve requests.

Hence another minimum spark retard difference have to be calculated IGA_DIF_MIN_TEG which takes into account the exhaust gas system protection. It is the maximum between the one calculated versus the maximal exhaust gases temperature of TEG_DYN_UP_CAT[NC_CYL_CBK_NR] and the basic one IGA_DIF_MIN.

Classically IGA_DIF_MIN is calculated from a basic value of the minimum ignition angle corrected with a temperature dependent additive term. The basic minimum spark advance is here extracted from a calibration map.

To calculate the minimum spark retard limitation according to the exhaust gas temperature the map IP_IGA_DIF_MIN_TEG is used. TEG_HYS_IGA_DIF_MIN is used as input for this map. This intermediate variable TEG_HYS_IGA_DIF_MINrepresents the exhaust gas temperature TEG_DYN_UP_CAT[NC_CYL_CBK_NR] increased by an hysterisis in order to anticipate the exhaust-system branch overheat.

So, in all practical cases IGA_DIF_MIN is a negative value that is the maximum allowable spark retard for engine stable running and pollutant conditions. It includes the coolant temperature correction. The exhaust gas temperature limitation is then taken into account in IGA_DIF_MIN_TEG.

The influence of the ignition angle on the exhaust gas temperature results from the ignition angle efficiency. Thus - in order to calibrate easily the map IP_IGA_DIF_MIN_TEG - one should use the efficiencies resulting from IGA_DIF_MIN values with the map IP_EFF_IGA and limit these efficiencies according to the actual exhaust gas temperature to avoid exhaust-system branch overheat. Then, thanks to the reverse map IP_IGA_DIF_EFF or thanks to the torque model for ignition angle efficiency, it is possible to calculate the value of the map IP_IGA_DIF_MIN_TEG.

The actual exhaust gas temperature TEG_DYN_UP_CAT[NC_CYL_CBK_NR] can be either measured by a sensor on the exhaust-system branch or calculated from an exhaust gas temperature model.

For engines with multiple cylinder banks, this temperature TEG_DYN_UP_CAT of exhaust gas before catalyst is defined and dedicated for each cylinder banks individually. Since here the limitation of ignition retard is just a protective function versus the catalyst overheating, only the maximal value from all those cylinder bank related TEG_DYN_UP_CAT temperature will be taken into account.

Note:

Two different update rates are used in the following calculations: for everything related to exhaust temperature only 1000ms rate is used to update calculation in synchronisation with the exhaust temperature updates (the one of TEG_DYN_UP_CAT[NC_CYL_CBK_NR]); for calculations related to ignition angle a 10 time faster update rate of 100ms.

These calculations are only performed when engine is running (not stalled) in homogenous mode after the end of start phase.

Setpoint spark retard for torque setpoint					

6.17.1 General Informationn

In homogeneous combustion mode (LV_HOM_RUN = 1), this module delivers the output IGA_DIF_TQ_REQ. The output IGA_DIF_TQ_REQ represents the ignition retard with reference to IGA_REF_COR that is necessary to generate the indicated engine torque TQI_SP. IGA_DIF_TQ_REQ is a function of the ignition angle efficiency setpoint EFF_IGA_SP, which, in turn, is calculated out of the Reference Indicated Torque TQI_REF and the actual efficiencies EFF_SCC_AV, EFF_EGR_HOM, and EFF_LAMB_AV.

During certain driving or operating modes (e.g. ‘Economy Mode’), the ignition intervention will be disabled by the Dynamic Torque Manager (i.e. LV_TQ_IGA_ACT = 0). In that case, IGA_DIF_TQ_REQ will be set to a passive value of 95.625 °Crk, resulting in a final ignition angle setpoint equal to IGA_BAS_COR.

In order to smooth the ignition angle setpoint behavior during transitions out of PUC, the efficiency EFF_SCC_AV might be replaced by a passive value of 1. This option can be chosen by the calibration switch LC_EFF_MOD_SCC (=0).

In order to ensure that the engine fires at IGA_MIN when the ignition is turned off (to avoid engine speed overshoots), the EFF_SCC_AV is set to 1 in this case.

6.18.1 General information:

For homogenous application, the basic ignition angle is calculated from a basis spark advance map depending on engine speed and load and includes the correction due to the actual value of richness.

To manage engine with an EMS defined for an ignition angle related to multiple cylinder banks (*NC_CBK_IN_NR*) this module can be used as many times as cylinder banks there are in the engine. Each time a different Basic Ignition Angle IGA_BAS[i] – *with i designating the corresponding cylinder banks considered* – is calculated to define and to allow a specific behaviour for each different cylinder bank.

In this aim different (*ie. specifically defined and related for each cylinder bank*) calibration maps IP_IGA_BAS[i] and IP_IGA_BAS_LAMB (*for correction versus lambda value*) can be used to produce different and cylinder bank specifically related Basic Ignition Angles.

In order to avoid determining a basic ignition angle IGA_BAS[i] greater than the reference one, care as to be taken during the calibration: One has to have a look on the calibration values written comparing each time the basic and reference ignition to ensure that basic ignition remains smaller than the reference one calibrated.

FUNCTION DESCRIPTION:

General information:

The valve overlap influences the gas exchange process, and therefore, the amount of the residual gases in the combustion chamber. The portion of the residual gases influences the ignition delay and combustion velocity. Effects of the valve overlap on the ignition angle are taken into account. It is realized by means of correction values that are to add to the normal ignition angle.

Description:

The correction IGA_BAS_VVT_COR influences the actual ingnition angle, IGA_REF_VVT_COR is used for the reference ignition angle used in torque management. The algorithm for the basic and for the reference ignition angle correction is the same.

The primary ignition angle correction is calculated from the map IP_IGA_BAS(_REF)_COR_IVVT_IN(_EX) dependent on MAF and N. A correction value is to calibrate for such valve overlap that is prevailing in the corresponding operating point. There can be different valve overlap due to the camshaft position setpoint strategy or a failure. The primary correction is then corrected by means of IP_IGA_BAS(_REF)_COR_IVVT_IN(_EX) dependent on the actual camshaft position CAM_AV_IVVT_IN(_EX)_i and VO_IND_i. The correction for an individual camshaft is then IGA_BAS(_REF)_COR_IVVT_IN(_EX)_i.

The resulting ignition angle correction IGA_BAS(_REF)_VVT_COR depends on the configuration of the IVVT system. If there is only one camshaft effectively phased the resulting correction equals the individual camshaft correction. If both inlet and exhaust are phased the resulting correction is the sum of the inlet and of the exhaust individual correction. In case of the system with two camshaft banks (both cylinder lines effectively phased) the minimum individual correction from bank 1 and bank 2 is taken.

Application conditions:

Initialization:

At reset, at deactivation:

IGA_BAS_VVT_COR = 0

IGA_REF_VVT_COR = 0

Recurrence:

20 ms

Activation:

LV_ES = 0

Deactivation:

Not activation

6.22 Application incidences for knock control, adaptation

6.22.1 Knock Control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNK_CTL_DIS	O/V	0...1H	0...1	1	-
knock control disabled due to malfunctions					
IGA_CYL_KNK_x	V	0...80H	-48...0	0.375	°CRK
knock advance correction					
IGA_MV_KNK_ADD	V	0...80H	-48...0	0.375	°CRK
mean value of knock advance correction					

Input data:

LV_ERR_CRK	LV_ERR_CAM	LV_ERR_KNKS_1	IGA_TRA_KNK
IGA_ADJ_KNK_x	IGA_MV_ADJ_KNK	LV_LIH_ERR_CRK	

General information:

To activate the knock control, a macro function (KNK_CTL_DIS) is executed which checks if knock control is disabled due to malfunctions.

If KNK_CTL_DIS = 0 the conditions are fulfilled and the knock control is enabled.

Update Rate: every segment

Formula section:

if LV_ERR_CRK = 1 **or**
LV_LIH_ERR_CRK = 1 **or**
LV_ERR_CAM = 1 **or**
LV_ERR_KNKS_1 = 1
then KNK_CTL_DIS = 1
else KNK_CTL_DIS = 0
endif

IGA_CYL_KNK_x = IGA_ADJ_KNK_x + IGA_TRA_KNK

IGA_MV_KNK_ADD = IGA_MV_ADJ_KNK + IGA_TRA_KNK

The Calculation of IGA_CYL_KNK_x is done at every TDC and for every cylinder.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_IGA_LGRD_3	1	100 ... 7FFFH	0,375 ... 48	0,00146	°crk
gradient limitation when underspending knock load threshold					

6.22.2 Knock control adaptation

6.22.2.1 Adaptation circuit 1

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNK_AD1_DIS	O/V	0...1H	0...1	1	-
adaptation circuit 1 disabled					
LV_KNK_AD_RD_ENA	O/V	0...1H	0...1	1	-
reading from adaptation table enabled					

Input data:

IGA_SP	IGA_AV_MV	TQ_ADD_CH	KNK_CTL_DIS
LV_ERR_TPS	LV_ERR_IGC	LV_ERR_TIA	LV_ERR_TCO

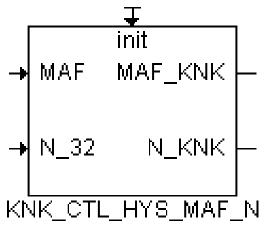
6.23 Knock Control

6.23.1 Overview

6.23.2 Pre-processing

6.23.2.1 Hysteresis Function for MAF and N_32



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_KNK	V/O	0...FFH	0...1389	5.447	mg/Stroke
Mass air flow with hysteresis					
N_KNK	V	0...FFH	0...8160	32	1/min
Engine speed with hysteresis					

Input data:

MAF	N_32		

General information:

Hysteresis functions for engine speed and air-mass changes are defined for the tables relevant for the knock control in order to avoid steps recognisable for the driver due to small changes of the operation point.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: MAF_KNK = N_KNK = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

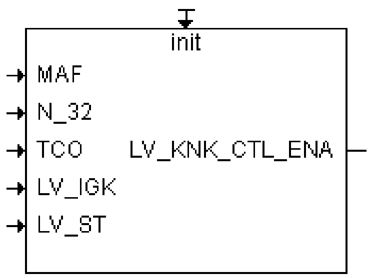
if **|(N_32 - N_KNK)| >= C_N_IGA_HYS_KNK**
N_KNK = N_32
else
N_KNK remains unchanged
end if

if **|(MAF - MAF_KNK)| >= C_MAF_IGA_HYS_KNK**
MAF_KNK = MAF
else
MAF_KNK remains unchanged
end if

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_IGA_HYS_KNK	1	0....FFH	0...8160	32	1/min
Speed Hysteresis for Knock Control					
C_MAF_IGA_HYS_KNK	1	0....FFH	0...1389	5.447	mg/Stroke
Air-Mass Hysteresis for Knock Control					

6.23.2.2 Knock Control Enable



KNK_CTL_ENA

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_KNK_CTL_ENA	V/O	0...1H	0...1	1	-
Boolean for knock control enabled					

Input data:

MAF_KNK	N_32	TCO	LV_IGK
LV_ST			

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: LV_KNK_CTL_ENA = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

```
if      (LV_ST = 1  or  LV_IGK = 0)
        LV_KNK_CTL_ENA = 0
else
        if      (MAF_KNK  >= IP_MAF_MIN_KNK__N_32__TCO)
                LV_KNK_CTL_ENA = 1
        else
             LV_KNK_CTL_ENA = 0
        end if
end if
```

If the relevant air-mass is below the air-mass threshold (LV_KNK_CTL_ENA = 0), only the noise value calculation is executed.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

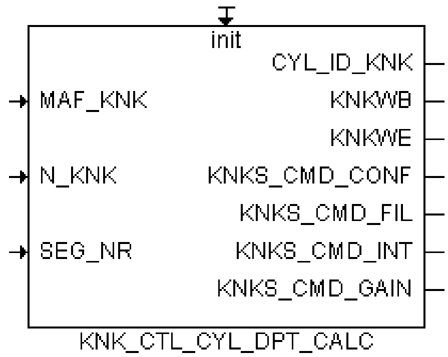
6.23.2.3 Cylinder Dependent Calculations



6.23.2.3.1 Cylinder Number for Knock Control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CYL_ID_KNK	V/O	0...FFH	0...255	1	-
cylinder number for knock control					

Input data:

SEG_NR			

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

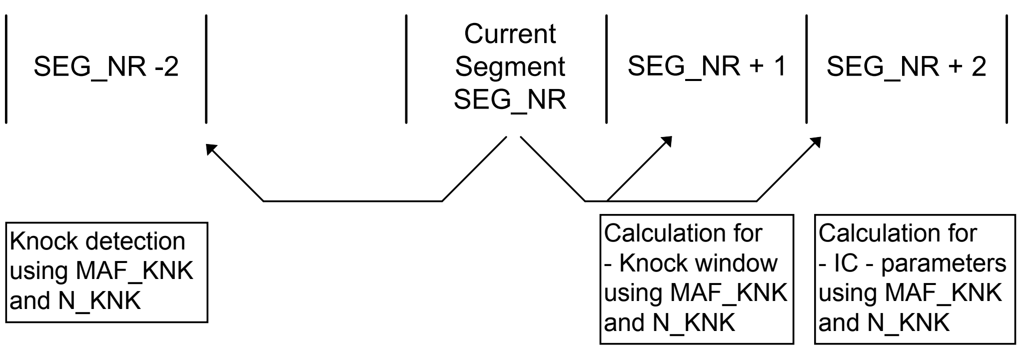
Initialization: CYL_ID_KNK = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

CYL_ID_KNK = SEG_NR - 2

Description:



6.23.2.3.2 Knock Measurement Window

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNKWB_x	V/O	0... RNG_WB_HEX	0… RNG_WB	0.375	° CRK
Beginning of Measurement Window Cyl.x					
KNKWE_x	V/O	1... RNG_WE_HEX	0.375... RNG_WE	0.375	° CRK
End of Measurement Window Cyl.x					

Input data:

MAF_KNK	N_KNK	SEG_NR	

General information:

The knock detection is performed for cylinder-individually defined measurement windows since knock-typical oscillations only occur for certain crankshaft angles. The measurement windows (crank angle of beginning and end) are specified as function of the engine speed and load.
If the estimated 'End of the Knock Measurement Window' is lower or equal compared to the 'Beginning of the Knock measurement Window', both values are initialized.

The crank angle for the beginning of the knock measurement window is taken for each cylinder from the respective table IP_KNKWB_x according to the firing order.

The crank angle for the end of the knock measurement window is taken for each cylinder from the respective table IP_KNKWE_x according to the firing order.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: at reset

KNKWB_x = NC_KNKWB_INI

KNKWE_x = NC_KNKWE_INI

Update Rate: every segment

Formula section:

Definition of cylinder dependent knock window ranges:

```
RNG_WB        = (720° / NC_CYL_NR) - 12°
RNG_WB_HEX    = HEX(RNG_WB / 0.375°)
RNG_WE        = (720° / NC_CYL_NR) - 6°
RNG_WE_HEX    = HEX(RNG_WE / 0.375°)

KNKWB_x = IP_KNKWB_x__N__MAF
KNKWE_x = IP_KNKWE_x__N__MAF

if    (KNKWE_x <= KNKWB_x)
      KNKWB_x = NC_KNKWB_INI
      KNKWE_x = NC_KNKWE_INI
end if
```

N.B.: x represents current SEG_NR + 1

Description:

Gain adaptation for Cyl. x (Signed offset)					
LV_KNK_AD	V	0...1H	0...1	1	-
Flag for adaptative learning of engine noise enabled					

Input data:

N_KNK	MAF_KNK	SEG_NR	NC_KNKS_CONF
LV_KNK_CTL_ENA	LV_KNK_TRA_MAF	LV_KNK_TRA_N	NL_x
N_32	LV_ERR_KNKS_1	C_NL_MIN_DIAG	

FUNCTION DESCRIPTION:

General information:

The knock control in the engine management works with the ATM40 device. The output value of the integrator after the end of the measurement window is fed as Knock Value KNKS through an analogue channel to the control algorithm.
(Further information may be obtained in "Applications Guide to ATM40".)

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization:
KNKS_CMD_INT_x = 0 at reset
KNKS_CMD_FIL_x = 0 at reset
KNKS_CMD_GAIN_x = 0 at reset
KNKS_CMD_CONF_x = value of conf. bit at position x in NC_KNKS_CONF at reset
KNK_CMD_GAIN_AD_x = 0 when ECU is brand new or at EEPROM error

Update Rate: every segment

Activation : **General condition for Cyl. x gain adaptation calculation :**

If LV_KNK_CTL_ENA = 1
And LV_KNK_TRA_MAF = 0
And LV_KNK_TRA_N = 0
And NL_x > C_NL_MIN_DIAG
And C_KNK_AD_N_MIN < N_32 < C_KNK_AD_N_MAX
And LV_ERR_KNKS_1 = 0
Then
LV_KNK_AD = 1
Else
LV_KNK_AD = 0

Formula section:

KNKS_CMD_INT_x = IP_ITC_KNK_x

KNKS_CMD_FIL_x = ID_FIL_FRQ_KNK_x

KNKS_CMD_GAIN_x = IP_GAIN_KNK_x + KNKS_CMD_GAIN_AD_x

KNKS_CMD_GAIN is limited to maximum 63.

Calculation of knock signal amplification controller for Cyl. x (Calculation takes place every C_KNK_AD_CTR TDCs for all cylinders) **:**

If LV_KNK_AD = 1 **during** C_KNK_AD_CTR TDCs

Then *Perform gain adaptation of all cylinders*

If | NL_x – IP_NL_KNK_AD | > C_NL_KNK_AD_THD

Then

If NL_x > IP_NL_KNK_AD

Then KNKS_CMD_GAIN_AD_x $_{i}$ = KNKS_CMD_GAIN_AD_x $_{i-1}$ + 1

Else KNKS_CMD_GAIN_AD_x $_{i}$ = KNKS_CMD_GAIN_AD_x $_{i-1}$ – 1

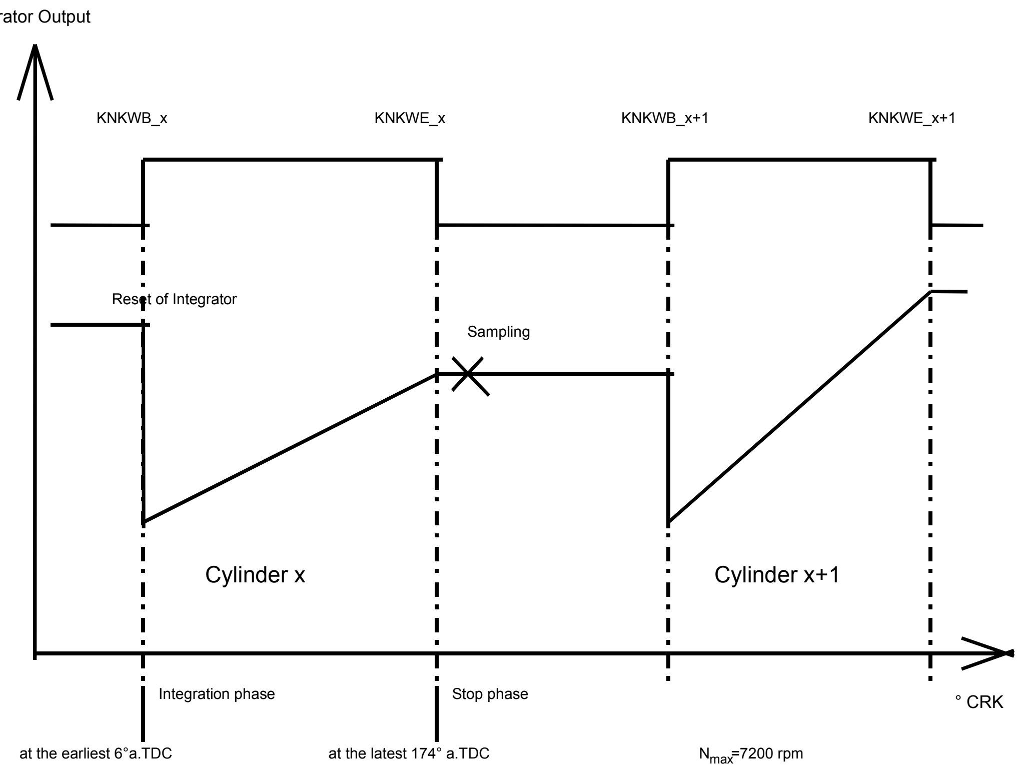
Else

KNKS_CMD_GAIN_AD_x remains unchanged

Limitation : KNKS_CMD_GAIN_AD_x is limited between C_KNK_CMD_GAIN_AD_MIN and C_KNK_CMD_GAIN_AD_MAX.

N.B.: x represents current SEG_NR + 2

Description (example for 4 cylinder engine):



Note: These calibration data have to be adjusted if the processor sampling rate is changed.

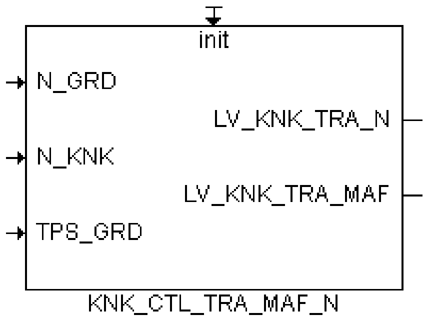
6.23.2.4 Load and Speed Dynamics



6.23.2.4.1 Speed Dynamics Function

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_KNK_TRA_N	V	0...1H	0...1	1	-
Logical variable for Engine Speed Dynamic Function active or passive					

Input data:

N_GRD	N_KNK		

FUNCTION DESCRIPTION:

General information:

In order to keep track with the noise values for large engine speed gradients (LV_KNK_TRA_N = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA.
Care needs to be given to the absolute function evaluation, so that there is no difference in the treatment of positive and negative speed gradients.
Furthermore the values of Knock -Adaptation-circuits 1 + 2 are only read at active speed dynamics.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: LV_KNK_TRA_N = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

if **(|N_GRD| >= ID_N_GRD_MAX_KNK__N)**

LV_KNK_TRA_N = 1

else

LV_KNK_TRA_N = 0

end if

Calibration data:

6.23.2.4.2 Load Dynamics Function

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_KNK_TRA_MAF	V	0...1H	0...1	1	-
Logical variable for Load Dynamic Function active or passive					

Input data:

MAF_DIF	N_KNK		

FUNCTION DESCRIPTION:

General information:

In order to keep track with the noise values for large (positive) load gradients (LV_KNK_TRA_MAF = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA. Load dynamics is recognised, as soon as the MAF difference exceeds the threshold ID_MAF_DIF_TRA_KNK__N. After the triggering of the load dynamics the special filtering constant C_NL_CRLC_TRA is applied for the number of ID_CYCNR_FAC_TRA_KNK__N cycles. The cycle counter CYCNR_FAC_TRA_KNK is newly re-loaded as long as the MAF difference exceeds the threshold ID_MAF_DIF_TRA_KNK__N. In addition, at active load dynamics function, the knock detection (KNK_THD_x) is made less sensitive with the help of the factor C_FAC_TRA_KNK.
The values from the knock adaptation-circuits 1 + 2 are only read.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: LV_KNK_TRA_MAF = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

if **(MAF_DIF > ID_MAF_DIF_TRA_KNK__N)**

LV_KNK_TRA_MAF = 1 for ID_CYCNR_FAC_TRA_KNK__N cycles

else

if **(ID_CYCNR_FAC_TRA_KNK__N has elapsed)**
LV_KNK_TRA_MAF = 0

end if

end if

```

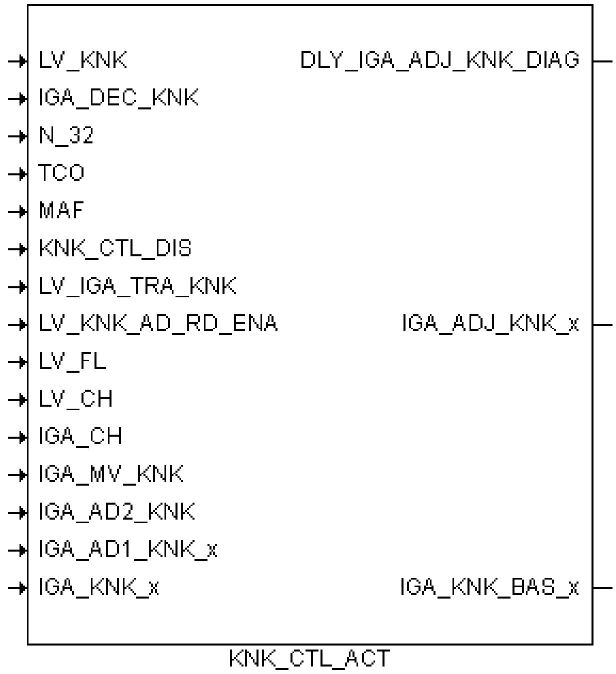
N.B.: x represents current CYL_ID_KNK

Different adjustment decrements are also produced due to the different knock intensities. Then it is possible to react to hard knock-strikes with a greater ignition - timing retardation.

6.23.3.2 Knock control active



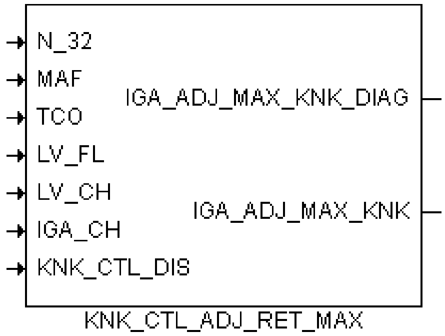
General information:

The spark retard is calculated cylinder-individual at every firing event. The spark retard due to the knock control system is determined by the spark retard due to knocking combustion (IGA_KNK_x) plus the spark retard due to the adaptation circuit 1 (IGA_AD1_KNK_x) and adaptation circuit 2 (IGA_AD2_KNK). The sum of these retard components is limited to a maximum spark retard.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	LV_ES = 1
Initialisation:	-
Update Rate:	every segment

6.23.3.2.1 Calculation of Maximum Retard Adjustment



FUNCTION DESCRIPTION:

General information:

Please note that this maximum spark retard is an absolute ignition angle referring to TDC.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	-
Initialisation:	-
Update Rate:	every segment

Formula section:

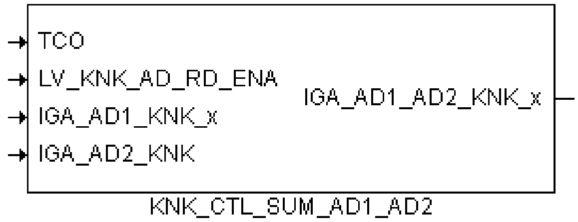
IGA_BAS_MAX_KNK = IP_IGA_BAS_MAX_KNK(N_32, MAF)

IGA_OFS_MAX_KNK = IP_IGA_OFS_MAX_KNK(N_32, MAF)

FAC_IGA_MAX_KNK = IP_FAC_IGA_MAX_KNK(TCO, TIA)

IGA_ADJ_MAX_KNK = IGA_BAS_MAX_KNK + (IGA_OFS_MAX_KNK * FAC_IGA_MAX_KNK)

6.23.3.2.2 Total sum of Adaptation Circuit 1 and 2



FUNCTION DESCRIPTION:

Application conditions:

Activation: at every engine state except engine stop

Deactivation: -

Initialisation: IGA_AD1_AD2_KNK_x = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

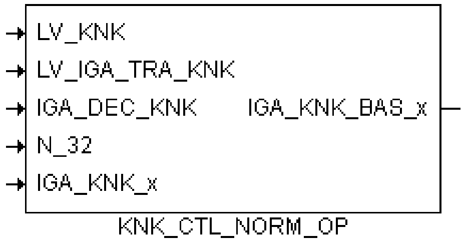
if LV_KNK_AD_RD_ENA = 1

then IGA_AD1_AD2_KNK_x = (IGA_AD1_KNK_x + IGA_AD2_KNK) * IP_FAC_AD_KNK_TCO__TCO

else IGA_AD1_AD2_KNK_x = 0

endif

6.23.3.2.3 Normal Operation



FUNCTION DESCRIPTION:

General information:

The spark retard is calculated cylinder-individual at every firing event. The spark retard due to the knock control system is determined by the spark retard due to knocking combustion (IGA_KNK_x) plus the spark retard due to the adaptation circuit 1 (IGA_AD1_KNK_x) and adaptation circuit 2 (IGA_AD2_KNK). The sum of these retard components is limited to a maximum spark retard.
In case of knock free operation (LV_KNK=0) and LV_KNK_CTL_ENA = 1 the Ignition retard due to knock control is re-set to zero (Controlled reset at Knock-free operation).
The controlled ignition-timing reset remains active until either the map ignition timing (IGA_KNK_BAS_x = 0) is reached or until knocking occurs.

Formula section:

if (LV_KNK = 1)

then IGA_KNK_BAS_x = IGA_KNK_x - IGA_DEC_KNK

else Controlled reset at Knock-free operation

  if (LV_IGA_TRA_KNK = 0)

  then IGA_KNK_BAS_x = IGA_KNK_x + IP_IGA_INC_KNK__N

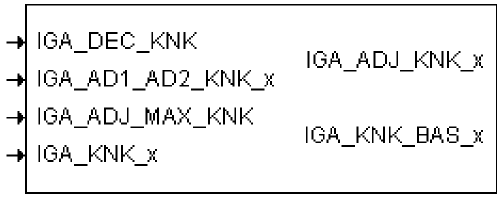
  else IGA_KNK_BAS_x = IGA_KNK_x

  end if

end if

N.B.: x represents current CYL_ID_KNK

6.23.3.2.4 Limp Home Operation



KNK_CTL_LIH

FUNCTION DESCRIPTION:

General information:

After an diagnosis error on the knock control system is detected (KNK_CTL_DIS = 1) the limp home spark retard level is achieved via spark retard Intensity 1 (IGA_DEC_KNK).
This ignition angle is also executed if a knock control related malfunction is detected (KNK_CTL_DIS = 1).

Formula section:

Knock control adaptation is inhibited for NC_DLY_IGA_ADJ_KNK_DIAG_LIH (*100ms)

IGA_ADJ_KNK_CTL_DIS = IP_IGA_KNK_CTL_DIS(N_32, MAF)

check if limphome spark retard level is already reached

if IGA_KNK_x - IGA_DEC_KNK + IGA_AD1_AD2_KNK_x **<**
IGA_ADJ_KNK_CTL_DIS - IGA_WOUT_KNK

limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard

then

IGA_KNK_BAS_x = IGA_ADJ_KNK_CTL_DIS - IGA_AD1_AD2_KNK_x – IGA_WOUT_KNK

IGA_ADJ_KNK_x = IGA_ADJ_KNK_CTL_DIS – IGA_WOUT_KNK

limphome spark retard level not yet reached

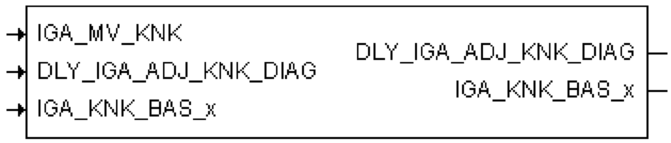
else

IGA_KNK_BAS_x = IGA_KNK_x - IGA_DEC_KNK

IGA_ADJ_KNK_x = IGA_KNK_BAS_x + IGA_AD1_AD2_KNK_x

end if

6.23.3.2.5 Control Exursion limit



KNK_CTL_CTL_EX_LIM

FUNCTION DESCRIPTION:

General information:

The control excursion limit is used to limit the difference of the ignition adjustment angle through knock- control of the single cylinders to a certain value. All 720 °CRK the arithmetic mean value of the cylinder ignition adjustment angles IGA_KNK_BAS_x is calculated:
All 720/Cyl. °CRK a test will be done, to see whether the ignition adjustment angle of the just calculated cylinder is more retarded or advanced than
|IGA_MV_KNK - C_IGA_ DIF_MIN_MAX_KNK|. In this case the knock control adjustment angle is limited to the control excursion limit.

Formula section:

Case Differentiation:

if IGA_KNK_BAS_x > IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK

advance limitation:

then IGA_KNK_BAS_x = IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK

else

if IGA_KNK_BAS_x < IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK

retard limitation:

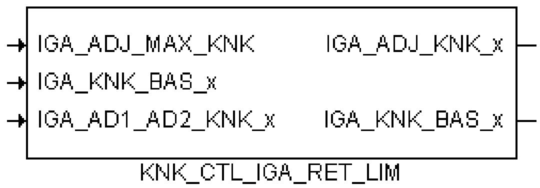
then IGA_KNK_BAS_x = IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK

endif

end if

N.B.: x represents current CYL_ID_KNK

6.23.3.2.6 Limitation of total ignition retard



Formula section:

check if limphome spark retard level is already reached

if IGA_KNK_BAS_x + IGA_AD1_AD2_KNK_x **<** IGA_ADJ_MAX_KNK - IGA_WOUT_KNK

limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard

then

IGA_KNK_BAS_x = IGA_ADJ_MAX_KNK – IGA_AD1_AD2_KNK_x – IGA_WOUT_KNK

IGA_ADJ_KNK_x = IGA_ADJ_MAX_KNK – IGA_WOUT_KNK

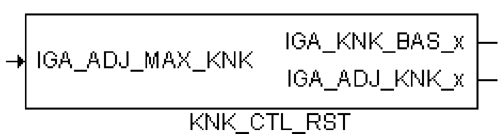
else

IGA_ADJ_KNK_x = IGA_KNK_BAS_x + IGA_AD1_AD2_KNK_x

end if

N.B.: x represents current CYL_ID_KNK

6.23.3.2.7 Reset of Knock control



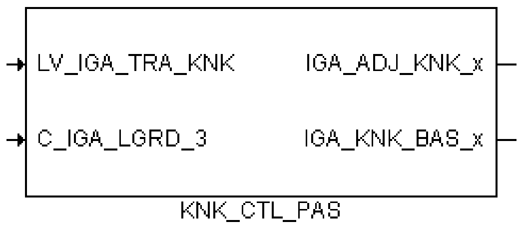
Formula section:

IGA_KNK_BAS_x = 0°CRK

IGA_ADJ_KNK_x = IGA_ADJ_MAX_KNK - IGA_WOUT_KNK

N.B.: x represents current CYL_ID_KNK

6.23.3.3 Knock control passiv (Reset after abandoning the Knock-Operating-Limit)



FUNCTION DESCRIPTION:

General information:

If the operating limit falls below (LV_KNK_CTL_ENA = 0), then the sum of the ignition adjustment angle IGA_KNK_BAS_x + IGA_AD1_KNK_x + IGA_AD2_KNK is re-set to 0, with the change limitation C_IGA_LGRD_3 - however referring to 720° CRK -, in order to reach the map ignition timing.
The adapted ignition adjustment angle itself IGA_AD1_KNK_x and IGA_AD2_KNK remains unchanged, so that this can be used again after crossing the operating limit.

Formula section:

if (LV_IGA_TRA_KNK = 0)

then

IGA_ADJ_KNK_x = IGA_ADJ_KNK_X$_{(N-1)}$ + C_IGA_LGRD_3

IGA_KNK_BAS_x = 0

else

IGA_ADJ_KNK_x = IGA_ADJ_KNK_X$_{(N-1)}$ (remains unchanged)

IGA_KNK_BAS_x = 0

end if

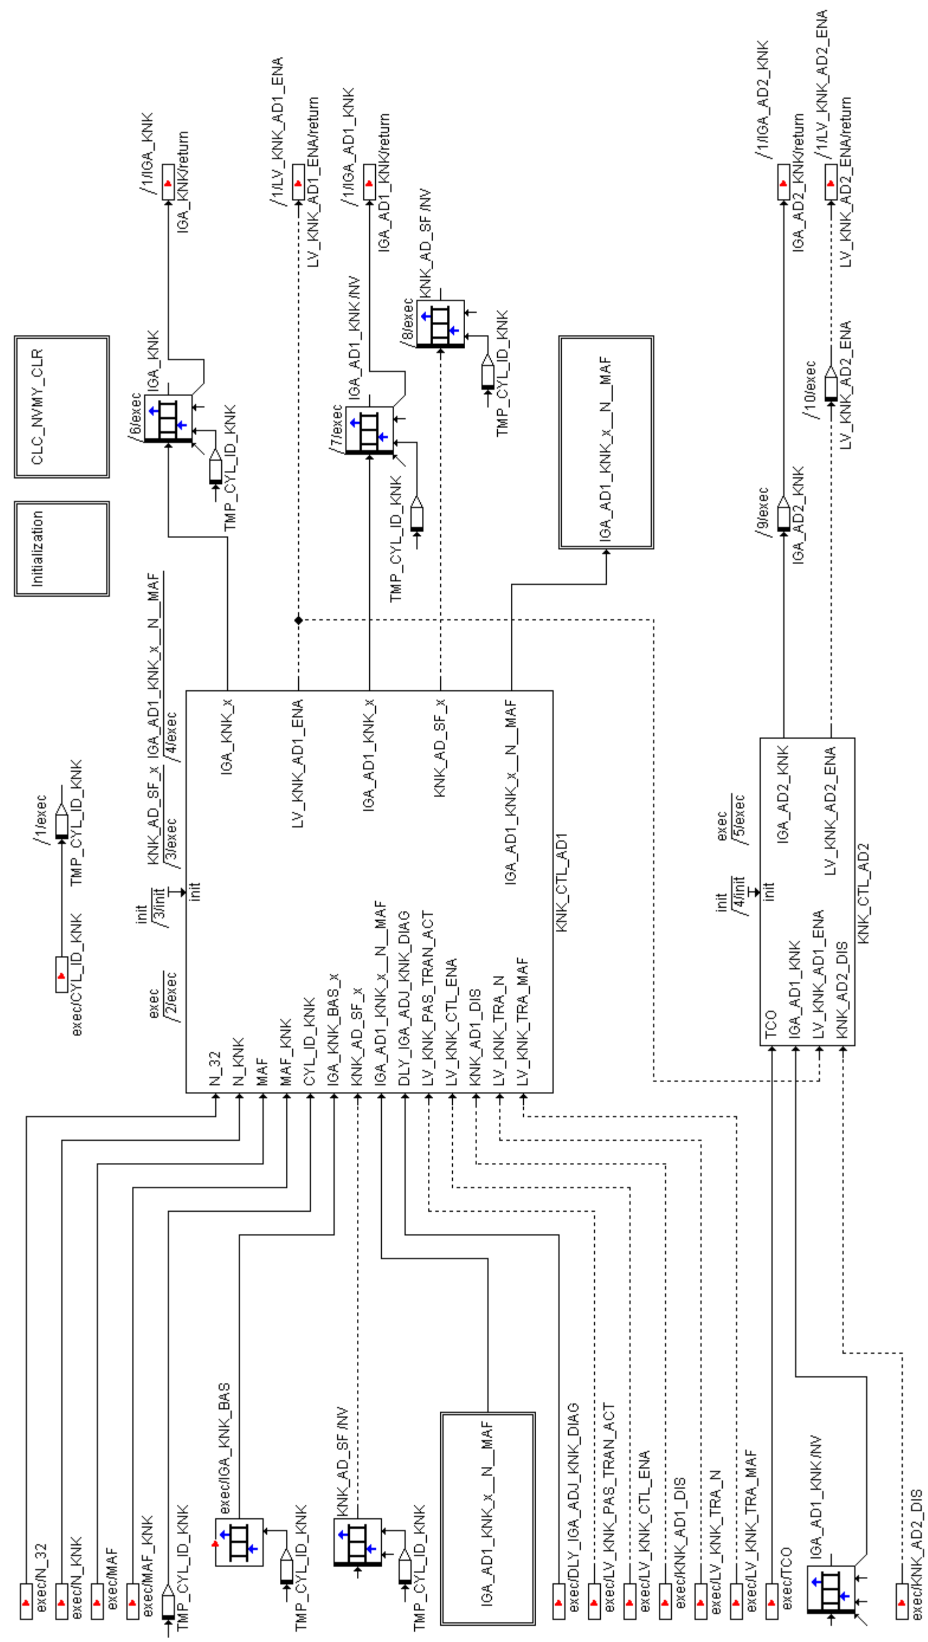
6.23.4 Knock Adaptation

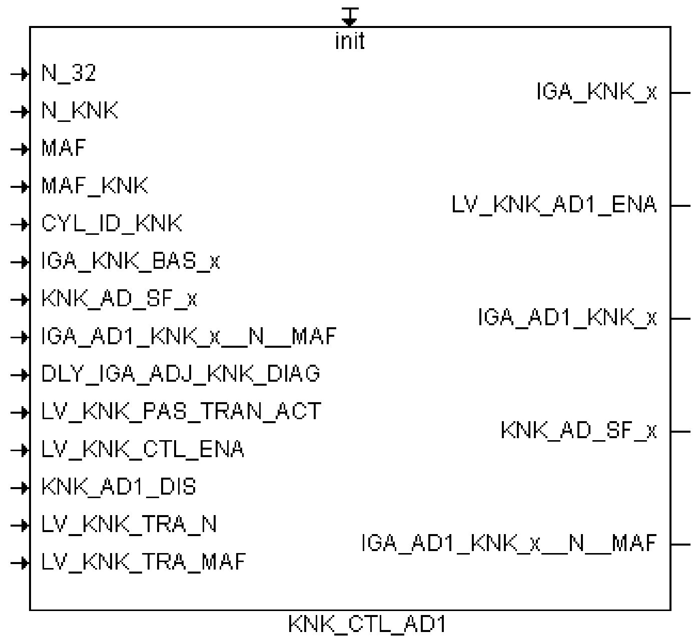


FUNCTION DESCRIPTION:

The knock adaptation consists of two so-called adaptation-circuits. A cylinder individual knock adaptation (adaptation circuit 1), which depends on load and speed, should compensate such as the compression ratio difference between each cylinder. The input for the adaptation circuit 1 is the spark retard due to knocking combustions.

The second part of the knock adaptation (adaptation circuit 2) offsets the ignition of the total speed and load range (in the area where the knock control is active) as well as each cylinder. This adaptation should compensate possible fuel grade differences. The input of the adaptation circuit 2 is the average mean value of all cylinders of the adaptation circuit 1.

6.23.4.1 Adaptation Circuit 1



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Input data:

N_KNK	MAF_KNK	IGA_KNK_BAS_x	LV_KNK_TRA_MAF
LV_KNK_TRA_N	LV_KNK_CTL_ENA	LV_KNK	ID_IGA_DEC_KNK_1__N
DLY_IGA_ADJ_KNK_DIAG	LV_KNK_PAS_TRAN_ACT	MAF	N_32
KNK_AD1_DIS	IGA_AD_x__N__MAF	CYL_ID_KNK	

FUNCTION DESCRIPTION:

General information:

A table IGA_AD_x__N__MAF exists for each cylinder. These tables contain the cylinderindividual ignition adjustment angles due to knocking combustion, which have been determined by the knock control at the respective operating points. The size of this table is defined by the calibration table ID_IGA_AD1_KNK_SIZE__N__MAF.

Storage of Adaptation-Circuit 1 in the NVMY after the power latch of the ECU

After the power latch mode of the ECU all adapted spark corrections in the cylinder individual adaptation maps IGA_AD_x are stored in the non-volatile memory and read back at the next KEY ON.
The ignition retardation IGA_AD1_KNK_x of the adaptation circuit 1 is increased by C_IGA_AD1_INC_KNK during the post operating phase before storing the values. With this function it is possible to reduce large adapted values without fulfilling the adaptation conditions.
The adaptation tables may be initiated in new condition or through maintenance service with 0 °CRK.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: -

Initialisation: IGA_AD1_KNK_x = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

Activation / Deactivation:

check conditions for adaption 1

if KNK_AD1_DIS = 0
    and C_SWI_AD_KNK = 0
    and LV_KNK_CTL_ENA = 1
    and LV_KNK_TRA_MAF= 0
    and LV_KNK_TRA_N = 0
    and DLY_IGA_ADJ_KNK_DIAG = 0
    and MAF >= ID_MAF_MIN_AD1_KNK
] **and** C_TCO_AD1_MIN_KNK < TCO < C_TCO_AD1_MAX_KNK

Adaptation 1 enabled

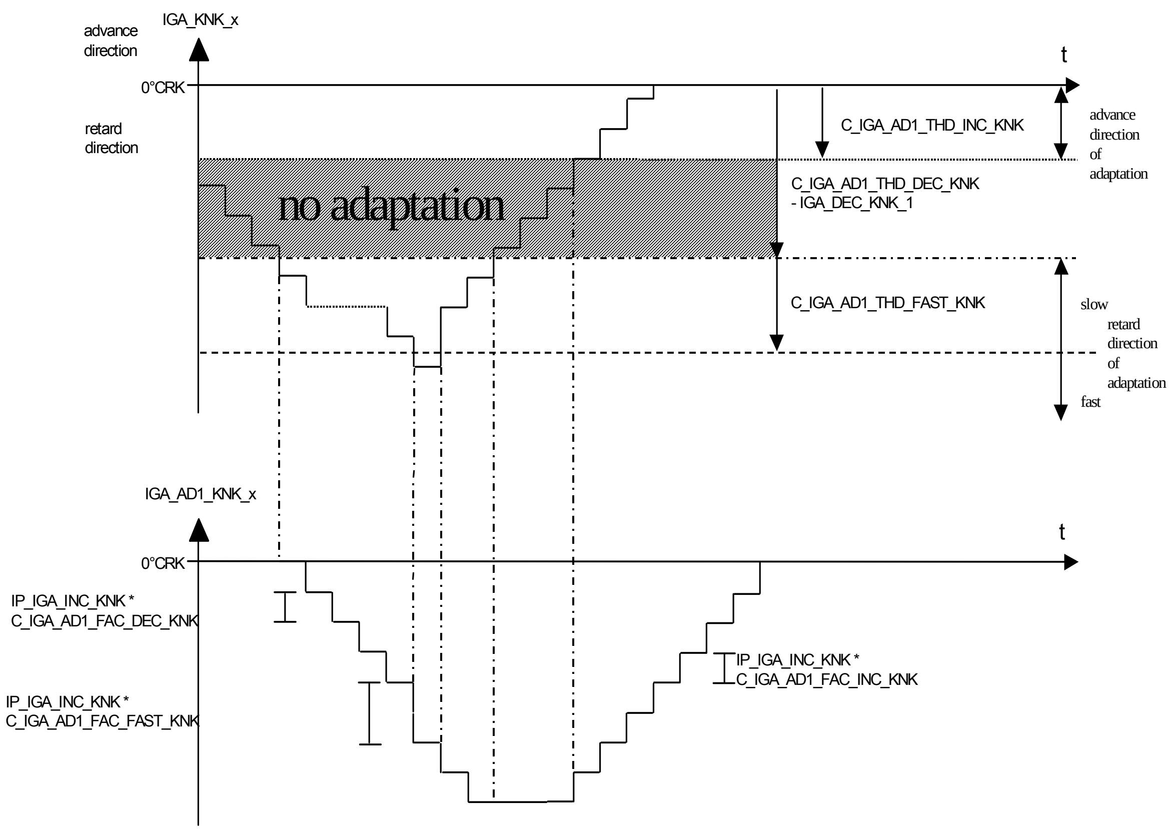
then LV_KNK_AD1_ENA = 1

Adaptation 1 disabled

else LV_KNK_AD1_ENA = 0
Adaptation value IGA_AD1_KNK_x restored from cylinder individual adaptation maps with change limitation:

IGA_AD1_KNK_x →C_IGA_AD1_LGRD_POS/NEG_KNK→ID_IGA_AD1_KNK_x__N__MAF

end if



Adaptation algorithm:

adaptation 1 active
if LV_KNK_AD1_ENA = 1
then
check adaptation direction range
if IGA_KNK_BAS_x > C_IGA_AD1_THD_INC_KNK

adaptation in advance direction
then $IGA\_AD1\_KNK\_x_i$ = $IGA\_AD1\_KNK\_x_{i-1}$ + IP_IGA_INC_KNK * C_IGA_AD1_FAC_INC_KNK

check if knock control adjustment outside dead zone
elseif IGA_KNK_BAS_x < C_IGA_AD1_THD_DEC_KNK - ID_IGA_DEC_KNK_1__N
and
C_IGA_AD1_THD_INC_KNK > C_IGA_AD1_THD_DEC_KNK - ID_IGA_DEC_KNK_1__N
adaptation in retard direction
then
check of adaptation speed range
if IGA_KNK_BAS_x < (C_IGA_AD1_THD_DEC_KNK – ID_IGA_DEC_KNK_1__N - C_IGA_AD1_THD_FAST_KNK)
fast adaptation
then $IGA\_AD1\_KNK\_x_i$ = $IGA\_AD1\_KNK\_x_{i-1}$ - IP_IGA_INC_KNK * C_IGA_AD1_FAC_FAST_KNK

IGA_KNK_x = IGA_KNK_BAS_x + IP_IGA_INC_KNK * C_IGA_AD1_FAC_FAST_KNK
slow adaptation
else $IGA\_AD1\_KNK\_x_i$ = $IGA\_AD1\_KNK\_x_{i-1}$ - IP_IGA_INC_KNK*C_IGA_AD1_FAC_DEC_KNK

IGA_KNK_x = IGA_KNK_BAS_x + IP_IGA_INC_KNK*C_IGA_AD1_FAC_DEC_KNK
end if

knock control adjustment in dead zone
else IGA_AD1_KNK_x remains unchanged

endif
adaptation 1 inactive
else IGA_KNK_x = IGA_KNK_BAS_x

endif

In case of adaptation in retard direction the knock control value IGA_KNK_x is calculated by adding IP_IGA_INC_KNK * (C_IGA_AD1_FAC_DEC_KNK or C_IGA_AD1_FAC_FAST_KNK) to IGA_KNK_BAS_x in advance direction. Due to this the total spark retard IGA_ADJ_KNK_x stays constant and will not be adjusted additional in retard direction by the adaptation circuit 1.

In case of no knock detection (LV_KNK = 0) this behaviour prevents also to adjust the adaptation value in retard direction, while the knock control value runs already in advance direction.

- **Treatment of IGA_AD1_KNK in case of changing operating point :**

if IGA_AD1_KNK_x_{n-1} < IGA_AD1_KNK_x_n

then IGA_AD1_KNK_x_{n-1} →C_IGA_AD1_LGRD_POS_KNK→IGA_AD1_KNK_x_n

else IGA_AD1_KNK_x_{n-1} →C_IGA_AD1_LGRD_NEG_KNK→IGA_AD1_KNK_x_n

endif

- **Treatment during transition from knock control passive to active (LV_KNK_PAS_TRAN_ACT = 1):**

The adaptation value IGA_AD1_KNK_x is restored from the cylinder individual adaptation maps ID_IGA_AD1_KNK_x without change limitation

meanvalue of actual retard adjustment by adaptation circuit 1					

Input data:

LV_KNK_AD1_ENA	IGA_AD1_KNK_x	TCO	KNK_AD2_DIS

FUNCTION DESCRIPTION:

General information:

At high knock intensities the ignition timing pre-control value IGA_AD2_KNK is moved slowly in retarded direction. A movement in advanced direction follows at longer knock-free operation, whereby the advanced movement is limited to the basic ignition map.

Storage of Adaptation-Circuit 2 in the NVMY after the power latch of the ECU
In new condition or by service maintenance IGA_AD2_KNK is initialised with 0.

For the adaptation Circuit 2 all 720 °CRK an arithmetic mean value is calculated using the cylinder-individual ignition adjustment angle of the adaptation circuit 1.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: -

Initialisation: IGA_MV_AD1_KNK = 0 at reset and engine running to engine stop

Update Rate: every 720°CRK

Formula section:

$$IGA\_MV\_AD1\_KNK = \frac{\sum_{i=1}^{NC\_CYL\_NR} (IGA\_AD1\_KNK\_x)}{NC\_CYL\_NR}$$

if C_TCO_AD2_MIN_KNK < TCO < C_TCO_AD2_MAX_KNK

then LV_TCO_AD2_KNK = 1

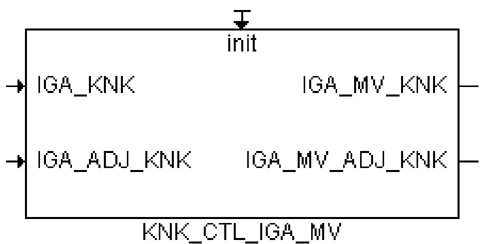
6.23.5 Post-processing

6.23.5.1 Meanvalues of knock-control ignition adjustment



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_MV_KNK	V	0...80H	-48...0	0.375	°CRK
meanvalue of actual retard adjustment without adaptation values					
IGA_MV_ADJ_KNK	V/O	0...80H	-48...0	0.375	°CRK
meanvalue of actual retard adjustment with adaptation values					

Input data:

IGA_KNK_x	IGA_ADJ_KNK_x		

Application conditions:

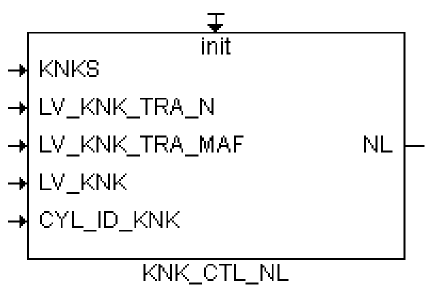
Activation:	at every engine state except engine stop
Deactivation:	-
Initialisation:	IGA_MV_KNK = IGA_MV_ADJ_KNK = 0
	at reset and engine running to engine stop
Update Rate:	every 720°CRK

Formula section:

$$\mathbf{IGA\_MV\_KNK} = \frac{\sum_{i=1}^{NC\_CYL\_NR} (\mathbf{IGA\_KNK\_x})}{\mathbf{NC\_CYL\_NR}}$$

$$\mathbf{IGA\_MV\_ADJ\_KNK} = \frac{\sum_{i=1}^{NC\_CYL\_NR} (\mathbf{IGA\_ADJ\_KNK\_x})}{\mathbf{NC\_CYL\_NR}}$$

6.23.5.2 Noise Value



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
NL_x	V/O	0...FFFFH	0...5	7.6*10-5	V
Floating mean value of the noise signal					

Input data:

KNKSx	LV_ KNK_ TRA_N	LV_KNK_TRA_MAF	LV_KNK
CYL_ID_KNK	C_KNK_THD_MAX		

FUNCTION DESCRIPTION:

The noise value is cylinder-individually calculated as sliding average from the knock values. The averaging constant is either C_NL_CRLC, if no knock control transient function is active (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0) or C_NL_CRLC_TRA, when a knock control transient function is active (LV_KNK_TRA_N = 1 or LV_KNK_TRA_MAF = 1).

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: NL_x = C_KNK_THD_MAX at reset or engine running to engine stop

Update Rate: every segment

Formula section:

if **(LV_KNK_TRA_N or LV_KNK_TRA_MAF)**
NL_x = NL_x + (KNKSx – NL_x) * C_NL_CRLC_TRA
else
NL_x = NL_x + (KNKSx – NL_x) * C_NL_CRLC
end if

NL_x shows always the measured noise value from the ATM40 device. The noise value is calculated always (independant from detection of knocking combustion).

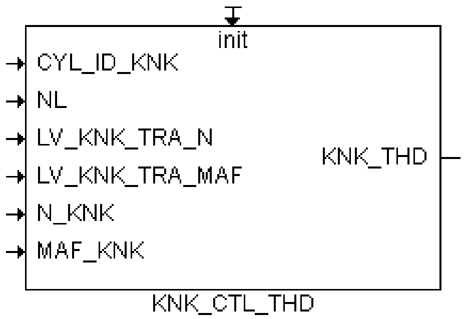
If knocking combustions are detected (LV_KNK = 1) after knock-free operation, the first and the second noise value isn`t used to calculate the noise level (NL_x remains unchanged), the third and the following are taken into consideration for calculation of noise level.

N.B.: x represents current CYL_ID_KNK

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_NL_CRLC	1	0...FFH	0...1	0.004	-
Averaging Constant for Noise Value Calculation					
C_NL_CRLC_TRA	1	0...FFH	0...1	0.004	-
Averaging Constant for Noise Value Calculation for Transient Case					

6.23.5.3 Relative and Absolute Knock Threshold



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNK_THD_x	V/O	0...FFH	0...5	0.02	V
Knock Threshold cylinder x					

Input data:

NL_x	CYL_ID_KNK	LV_KNK_TRA_MAF	LV_KNK_TRA_N
N_KNK	MAF_KNK		

FUNCTION DESCRIPTION:

General information:

The knock threshold (KNK_THD_x) is the limit for the knock values (KNKSx), which are used for knock decision. If the knock values are greater or equal to the knock threshold, then knocking is recognised (LV_KNK = 1) and an ignition timing retardation follows. If the knock values are smaller, knocking is not detected (LV_KNK = 0) and the relevant KNK-ignition-angle is reset (→ Knock-free Operation after Knocking).

The knock threshold is calculated for each cylinder separately and depends on the cylinder-individual noise value. Calculation of the knock threshold occurs with help from the cylinder-individual knock factors ID_FAC_THD_KNK_x and knock summand ID_ADD_KNK__N.

If the noise value is above the minimum threshold C_NL_MIN, the knock threshold is calculated on the basis of the cylinder-individually noise value NL_x. If the noise value is below C_NL_MIN this value is used as noise value for calculation of the knock threshold. If the knock threshold is above C_THD_MAX_KNK this value is used as knock threshold (Limitation).

N.B.: The actual knock value $KNKSx_n$ is not used in the calculation of the actual knock threshold $KNK\_THD\_x_n$ but in the calculation of the next threshold $KNK\_THD\_x_{n+1}$. So the decision knocking combustion yes/no is done with using the knock threshold $KNKSx_{n-1}$.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: KNK_THD_x = 5V at reset and engine running to engine stop

Update Rate: every segment

Formula section:

The lower absolute threshold is one value for all cylinders and is represented by the constant C_NL_MIN.

```
If    NL_x &lt; C_NL_MIN
      NL_LIM = C_NL_MIN
else
      NL_LIM = NL_x
end if
```

```
if    (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0)
      KNK_THD_x = ( NL_LIM + ID_KNK_THD_ADD ) * ID_FAC_THD_KNK_x
else
      KNK_THD_x = ( NL_LIM + ID_KNK_THD_ADD ) * ID_FAC_THD_KNK_x *
                        C_FAC_TRA_KNK
end if
```

The knock threshold is generally limited to C_KNK_THD_MAX:

```
If  (KNK_THD_x > C_KNK_THD_MAX)
    KNK_THD_x = C_KNK_THD_MAX
end if
```

N.B.: x represents current CYL_ID_KNK

(*) The correction factor **C_FAC_TRA_KNK** is part of the KNK-load dynamics function and is effective after recognised load dynamics **ID_CYCNR_FAC_TRA_KNK__N** cycles.

The knock factor is the multiplicative part used for calculation of the knock threshold from the noise value.
The knock summand is an additive correction of the knock noise value. Thereby the knock threshold can be moved, dependent on the speed, in a positive or negative direction.

Remark: The input value TI_FAC_x and TI_ADD_x are the output value of the module "Coordination of Injection Time Correction Factors for Cylinder Balancing ". If the Cylinder Balancing Function is not used than TI_FAC_x and TI_ADD_x have to be initalized in an "Initialization Module" as follows:

TI_FAC _x =1

TI_ADD _x = 0

FUNCTION DESCRIPTION:

General information:

This module calculates the cylinder individual injection times, which shall be applied at the injectors.

7.1.1 Calculation of TI_1_HOM_x

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: at reset: TI_1_HOM_CLC_MIN_TMP = 262.14 ms
TI_1_HOM_CLC_MAX_TMP = 0 ms

Recurrence: LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Formula section:

7.1.1.1 Calculation of the minimal applied injection time

In order to avoid linearity problems, the injection time needs minimum limitation.

TI_MIN = IP_TI_MIN (Input: VB)

7.1.1.2 Calculation of the cylinder individual injection times

TI_1_HOM_CLC_x = MFF_SP_1_HOM_x * C_FAC_MFF_TI_STND_k * FAC_TI_1_PRS_HOM * TI_FAC_x * TI_TUN_IV_x + TI_TUN_ADD_IV_x + TI_ADD_DLY_1_HOM + TI_ADD_x

Note:

The pattern NC_IN_REF (project specific) is used for allocation of physical cylinders to intake bank 1 and intake bank 2.

7.1.1.3 Calculation of minimum and maximum injection times

For each calculation run the minimum and maximum injection time will be calculated:

(1) FOR x **=** CTR_CYL_NR_ST_CLC_INJR **TO** CTR_CYL_NR_STOP_CLC_INJR

CTR_UPD_NR_CYL = CTR_UPD_NR_CYL + 1

TI_1_HOM_CLC_MIN_TMP = MIN (TI_1_HOM_CLC_MIN_TMP, TI_1_HOM_CLC[x])

TI_1_HOM_CLC_MAX_TMP = MAX (TI_1_HOM_CLC_MAX_TMP, TI_1_HOM_CLC[x])

(1) ENDFOR

If calculation reduction is not active minimum and maximum injection times will be updated immediately.

If calculation reduction is active, the minimum and maximum injection times will be updated only after all cylinders were calculated – then a new cycle starts. If new extreme values are occurring, minimum and maximum injection times will be updated immediately, independent on the calculation reduction state.

(2) IF STATE_CLC_RED & NC_STATE_CLC_RED_ACT = 0
OR
CTR_UPD_NR_CYL >= NC_CYL_NR

(2) THEN

CTR_UPD_NR_CYL = 0

TI_1_HOM_CLC_MIN = TI_1_HOM_CLC_MIN_TMP

TI_1_HOM_CLC_MAX = TI_1_HOM_CLC_MAX_TMP

Set the temporary minimum and maximum to the opposite limits, therefore it is possible to find new minimum and maximum values on next calculation run.

TI_1_HOM_CLC_MIN_TMP = 262.14 ms

TI_1_HOM_CLC_MAX_TMP = 0 ms

(2) ELSE

TI_1_HOM_CLC_MIN **= MIN(**TI_1_HOM_CLC_MIN, TI_1_HOM_CLC_MIN_TMP**)**

TI_1_HOM_CLC_MAX **= MAX(**TI_1_HOM_CLC_MAX, TI_1_HOM_CLC_MAX_TMP**)**

(2) ENDIF

7.1.1.4 Calculation of the final cylinder individual homogeneous injection times

(3) IF

LC_TI_1_HOM_MAN_ACT = 1

(3) THEN

TI_1_HOM_x = C_TI_1_HOM_MAN

LV_TI_1_HOM_MIN = 0

(3) ELSE

(4) IF

TI_1_HOM_CLC_MIN < TI_MIN

(4) THEN

TI_1_HOM_x = TI_1_HOM_CLC_x + (TI_MIN - TI_1_HOM_CLC_MIN)
Note! Adjust each cylinder to the minimum injection time, therefor the cylinder individual time offsets between the cylinders will be observed.

LV_TI_1_HOM_MIN = 1

(4) ELSE

TI_1_HOM_x = TI_1_HOM_CLC_x

LV_TI_1_HOM_MIN = 0

(4) ENDIF

(3) ENDIF

Note: For calibration purposes the injection time TI_1_HOM_x can be set manually to the value C_TI_1_HOM_MAN.

7.1.2 Calculation of LV_AUTH_TI_MIN_AFL

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: -

Recurrence: 10 ms

If homogeneous lean mode is active (STATE_CMB_CTL = 2) and the electrical injection time is smaller than (TI_MIN + C_TI_MIN_OFS), the combustion mode changes to homogeneous stochiometric mode. Switching back to homogeneous lean mode is allowed at the earliest if the delay time C_ T_AUTH_TI_MIN_AFL has elapsed.

(1) IF

LV_AFL_CLC = 0

(1) THEN

LV_AUTH_TI_MIN_AFL = 0

T_AUTH_TI_MIN_AFL = 0

(1) ELSE

(2) IF

LV_AUTH_TI_MIN_AFL = 0

AND

STATE_CMB_CTL = 2 (homogeneous lean mode)

AND

TI_1_HOM_CLC_MIN < (TI_MIN + C_TI_MIN_OFS)

(2) THEN

LV_AUTH_TI_MIN_AFL = 1

T_AUTH_TI_MIN_AFL = C_ T_AUTH_TI_MIN_AFL

(2) ELSE

(3) IF

T_AUTH_TI_MIN_AFL (n) > 0

(3) THEN

T_AUTH_TI_MIN_AFL (n+1) = T_AUTH_TI_MIN_AFL (n) – 0.01 [s]

(3) ELSE

LV_AUTH_TI_MIN_AFL = 0

(3) ENDIF

(2) ENDIF

(1) ENDIF

End of injection for preinjection					
TRL_EOI_MIN_PRE_INJ	-	0 ... 780H	0 ... 720	0.375	°CRK
Latest end of injection angle for pre injection					
TRL_TI_PRE_INJ [NC_CYL_NR]	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Pre injection time					

Transfer data from I/O SW:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TRL_INJ_StateOfPrevInj_x	-	-	0...1	1	-
Cylinder individuel flag which indicates whether last injection was activated or deactivated					
TRL_SOI_1_MES_x	-	0 ... 780H	0 ... 720	0.375	°CRK
Actual performed SOI of the first injection pulse, estimated					
TRL_EOI_1_ MES_x	-	0 ... 780H	0 ... 720	0.375	°CRK
Actual performed EOI of the first injection pulse, estimated					
TRL_TI_1_ MES_x	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Cylinder individual injection time, first pulse					
TRL_SOI_2_MES_x	-	0 ... 780H	0 ... 720	0.375	°CRK
Actual performed SOI of the second injection pulse, estimated					
TRL_EOI_2_ MES_x	-	0 ... 780H	0 ... 720	0.375	°CRK
Actual performed EOI of the second injection pulse, estimated					
TRL_TI_2_ MES_x	-	0 ... FFFFH	0 ... 262.14	0.004	ms
Cylinder individual injection time, second pulse					
TRL_TRIG_EOI_LIM(CYL_AV)	-	-	-	-	-
Trigger at every EOI_LIM_x					

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CYL_AV	-	0 ... 7 H	0 ... 7	1	-
Function parameter of TRL_TRIG_EOI_LIM, which indicate the actual logical cylinder number for that cylinder which EOI_LIM was reached.					
TRL_NC_REF_EOI_LIM	-	0 ... FC40 H	0 ... -360	0.375	°CRK
Offset of the EOI_LIM reference point after TDC					

Note: The prefix TRL to a data xxx (e.g. TI_1_x) indicates a I/O SW function interface for that data.

FUNCTION DESCRIPTION:

7.2.1 Reset tasks

Application conditions:

Activation: at reset

Deactivation: -

Initialization: -

Recurrence: once at reset

Note! This task has to be called first in calculation order of reset tasks.

This chapter describe the procedures required at reset for an accurate engine start.

7.2.1.1 Formula Section:

TRL_NC_EOI_LIM = NC_EOI_LIM → transfer to I/O-SW

REF_EOI_LIM = TRL_NC_REF_EOI_LIM → receive from I/O-SW

STATE_INJ_MOD_SWI_ACT = 0

7.2.2 First valid tooth tasks

Application conditions:

Activation: at first valid tooth

Deactivation: -

Initialization: -

Recurrence: once at first valid tooth

This chapter describe the procedures required at first valid tooth for an accurate engine start.

7.2.2.1 Formula Section:

INH_IV_DYN = 0

NR_CYL_OFS_INH_IV_DYN = C_NR_CYL_OFS_INH_IV_DYN

INJ_MOD_GLOBAL = NC_INJ_MOD_HOM
OR ...bitwise
NC_INJ_MOD_SINGLE

(1) IF STATE_ST_PRE **=** NC_ST_ENA_PRE_INJ ..bitwise

(1) THEN

(1) FOR x = 0 **TO** (NC_CYL_NR –1) **DO:**

INJ_MOD[x] = INJ_MOD_GLOBAL

TRL_TI_PRE_INJ[x] = TI_PRE_INJ[x] → transfer to I/O-SW

TRL_EOI_ PRE_INJ[x] = EOI_ PRE_INJ[x] → transfer to I/O-SW

TRL_EOI_MIN_PRE_INJ = EOI_MIN_PRE_INJ → transfer to I/O-SW

(1) ENDFOR

(1) ELSE

(2) FOR x = 0 **TO** (NC_CYL_NR –1) **DO:**

INJ_MOD[x] = INJ_MOD_GLOBAL

(2) ENDFOR

(1) ENDIF

LV_INJ_UPD_TRM = 0

Note! Synchronised injection will be enabled after first valid tooth only if at least one injection time calculation was completed (LV_INJ_UPD_TRM = 1) and engine is synchronised.

NR_TRIG_EOI_LIM_AV = 0

NR_TRIG_EOI_LIM_PREV = 0

7.2.2.2 State indication: configuration of preinjection was finished

Indicate in state variable STATE_ST_PRE that the preinjection data are transferred to I/O-SW and the configuration of preinjection was finished.

STATE_ST_PRE **=** STATE_ST_PRE **OR** NC_ST_CONF_PRE_END ...bitwise

7.2.3 Segment synchronous tasks

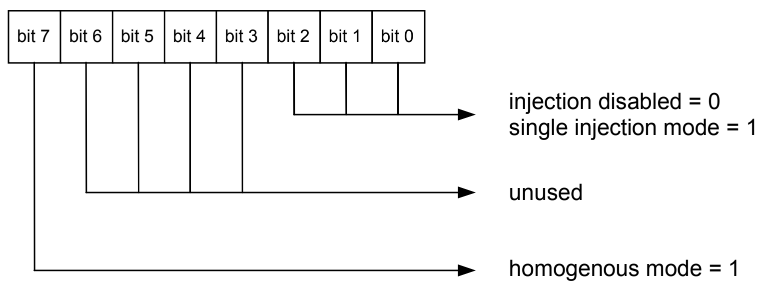
Application conditions:

Activation:	every engine state	
Deactivation:	-	
Initialization:	see item 1.1	
Recurrence:	LV_ST_END = 0:	10 ms
	LV_ST_END = 1:	segment synchronous

7.2.3.1 Generation of INJ_MOD_GLOBAL (global injection mode)

7.2.3.1.1 Definition of INJ_MOD_GLOBAL

INJ_MOD_GLOBAL =



e.g.: homogeneous mode + single injection mode

INJ_MOD_GLOBAL =

1	0	0	0	0	0	0	1

File: INJ_MOD_GLOBAL.vsd

7.2.3.1.2 Definitions of the non calibrateable constants to generate INJ_MOD_GLOBAL

NC_INJ_MOD_DI = 0x00H
NC_INJ_MOD_HOM = 0x80H
NC_INJ_MOD_SINGLE = 0x01H
NC_INJ_MOD_PRE_INJ = 0x04H
NC_INJ_MOD_MASK_1 = 0x80H
NC_INJ_MOD_MASK_2 = 0x07H

7.2.3.1.3 Calculation of INJ_MOD_GLOBAL

Have to be done at first valid tooth only.

7.2.3.2 Transfer data

Cylinder individual transfer data:

(1) FOR x = 0 **TO** (NC_CYL_NR-1) **DO:**
"Transfer Section" for cylinder x (see chapter 7.2.5 Common Transfer Operations).

LV_INH_INJ_x = Bit x of INH_INJ

TRL_LV_INH_INJ_x = LV_INH_INJ_x → transfer to I/O-SW

Note! Pay attention on data consistency of LV_INH_INJ_x.

TRL_LV_ADD_PULSE_x = LV_ADD_PULSE_x → transfer to I/O-SW

TRL_EOI_MIN_x = EOI_MIN_x → transfer to I/O-SW

TRL_TI_PLS_1_x = TI_1_x → transfer to I/O-SW

TRL_EOI_1_x = EOI_1_x → transfer to I/O-SW

(1) ENDFOR

TI_ADD_PULSE_MIN = IP_TI_ADD_PULSE_MIN (Input: VB)

FAC_ADD_PULSE = IP_FAC_ADD_PULSE (Input: N_32)

TI_ADD_DLY = TI_ADD_DLY_1_HOM

Global transfer data:
(mode independent and not cylinder individual data)

TRL_SOI_MAX = SOI_MAX → transfer to I/O-SW

TRL_FAC_ADD_PULSE = FAC_ADD_PULSE → transfer to I/O-SW

TRL_TI_ADD_PULSE_MIN = TI_ADD_PULSE_MIN → transfer to I/O-SW

TRL_TI_ADD_DLY = TI_ADD_DLY → transfer to I/O-SW

After transfer a TRL_TRIG_INJ_UPD call is required.
Identify the engine position after injection data update. It is referenced to EOI_LIM.
Note! If the engine position information is not available CRK_PSN_ENG_INJ_UPD should be assigned to zero.

CRK_PSN_ENG_INJ_UPD = ((720° - PSN_ENG - EOI_LIM_0)+720°) MODULA 720°

Indicate, that at least one data set was sent to I/O-SW.

LV_INJ_UPD_TRM = 1

7.2.4 EOI_LIM triggered tasks

Application conditions:

Activation: every TRIG_EOI_LIM event

Deactivation: -

Initialization: -

Recurrence: at TRL_TRIG_EOI_LIM[x]

Note! x represents the current assigned cylinder number cyl_av, which is used by subsequent data calculations.

7.2.4.1 Transfer data

CTR_PSN_INH_IV_DYN = (STATE_INH_IV_DYN / 2^{16}) **AND** 0xF ... bitwise

(1) FOR x = cyl_av **DO:**

NR_CYL_INH_IV_DYN = (NC_CYL_NR + x - NR_CYL_OFS_INH_IV_DYN)
MODULO NC_CYL_NR

(1) IF (STATE_INH_IV_DYN **AND** $2^{\text{CTR\_PSN\_INH\_IV\_DYN}}$) ≠ 0 ... bitwise

(1) THEN

Cylinder will be switched off:

INH_IV_DYN = INH_IV_DYN **OR** $2^{\text{NR\_CYL\_INH\_IV\_DYN}}$ ... bitwise

(1) ELSE

Cylinder will be switched on:

INH_IV_DYN = INH_IV_DYN **AND NOT**($2^{\text{NR\_CYL\_INH\_IV\_DYN}}$) ... bitwise

(1) ENDIF

(1) ENDFOR

CTR_PSN_INH_IV_DYN = CTR_PSN_INH_IV_DYN + 1

(2) IF CTR_PSN_INH_IV_DYN ≥ NC_INJ_INH_SWI_IV_SHIFT_NR

(2) THEN

CTR_PSN_INH_IV_DYN = 0

(2) ENDIF

STATE_INH_IV_DYN = (STATE_INH_IV_DYN **AND** 0x0000FFFF) ... bitwise
OR ... bitwise
(CTR_PSN_INH_IV_DYN * 2^{16}) ... bitwise

INH_INJ = INH_IV **OR** INH_IV_DYN ... bitwise

LV_INH_INJ_OLD = LV_INH_INJ[NR_CYL_INH_IV_DYN]

LV_INH_INJ[NR_CYL_INH_IV_DYN] = Bit NR_CYL_INH_IV_DYN of INH_INJ

Note! Pay attention on data consistency of INH_INJ, INH_IV_DYN and LV_INH_INJ[x].

SUM_INH_INJ = The sum of the digits of INH_INJ

(3) IF LV_INH_INJ[NR_CYL_INH_IV_DYN] ≠ LV_INH_INJ_OLD

(3) THEN

TRL_LV_INH_INJ[NR_CYL_INH_IV_DYN] = LV_INH_INJ[NR_CYL_INH_IV_DYN]
→ transfer to I/O-SW

(3) ENDIF

Please Note! STATE_INH_IV_DYN is an output data of cylinder shut off specification. The content of the data will be changed in this interrupt procedure. Pay attention on data consistency, even at cylinder shut off module.

7.2.4.2 Transfer of measured injection related data from I/O-SW

After an Injection was performed, the (cylinder individual) SOI, EOI and TI of that injection is indicated at the output interface as:

SOI_1_MES_x ... actual performed SOI of the first injection pulse (estimated)

EOI_1_MES_x ... actual performed EOI of the first injection pulse (estimated)

TI_1_MES_x ... actual performed injection time of the first injection pulse

SOI_2_MES_x ... actual performed SOI of the additional injection pulse (estimated)

EOI_2_MES_x ... actual performed EOI of the additional injection pulse (estimated)

TI_2_MES_x ... actual performed injection time of the additional injection pulse

(1) FOR x = cyl_av **DO:**

SOI_1_MES_x = TRL_SOI_1_MES_x → receive from I/O-SW

EOI_1_MES_x = TRL_EOI_1_MES_x → receive from I/O-SW

TI_1_MES_x = TRL_TI_1_MES_x → receive from I/O-SW

SOI_2_MES_x = TRL_SOI_2_MES_x → receive from I/O-SW

EOI_2_MES_x = TRL_EOI_2_MES_x → receive from I/O-SW

TI_2_MES_x = TRL_TI_2_MES_x → receive from I/O-SW

(1) ENDFOR

7.2.4.3 Calculation of LV_STATE_PREV_IV_x and PREV_STATE_IV

(1) FOR x = cyl_av **DO:**

LV_STATE_PREV_IV_x = TRL_INJ_StateOfPrevInj_x → receive from I/O-SW

(INJ_StateOfPrevInj_x = 1 .... logical cylinder x was injected)

(INJ_StateOfPrevInj_x = 0 .... logical cylinder x was not injected)

(1) IF

LV_STATE_PREV_IV_x = 1

(1) THEN

Set bit_x of PREV_STATE_IV (the corresponding cylinder was injected)

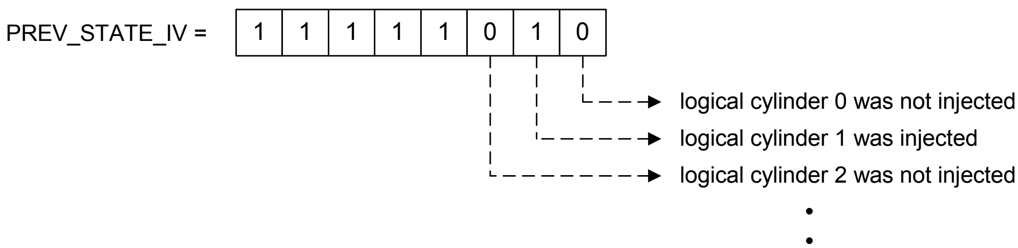
(1) ELSE

Clear bit_x of PREV_STATE_IV (the corresponding cylinder was not injected)

(1) ENDIF

Note! Pay attention on data consistency of PREV_STATE_IV and LV_STATE_PREV_IV_x.

(1) ENDFOR



7.2.4.4 Indication of actual and previous number of TRIG_EOI_LIM

The variable cyl_av is delivered from the I/O SW and indicates the actual TRIG_EOI_LIM

NR_TRIG_EOI_LIM_PREV = NR_TRIG_EOI_LIM_AV

NR_TRIG_EOI_LIM_AV = cyl_av

Note! cyl_av is a parameter of the TRL_TRIG_EOI_LIM function interface.

7.2.5 Common Transfer Operations

Note! x represents an assigned cylinder number, which is defined in the upper data calculation function.

(1) IF

LV_TI_EXT_ADJ_x = 0

(1) THEN

TI_1_x = TI_1_HOM_x

EOI_1_x = EOI_1_HOM_x

(1) ELSE

TI_1_x = TI_EXT_ADJ_x ... service tool intervention

EOI_1_x = C_EOI_EXT_ADJ

(1) ENDIF

EOI_MIN_x = EOI_MIN_HOM

LV_ADD_PULSE_x = LV_ADD_PULSE_ENA

Remark:

Minimum injection time for additional pulse:

In case of single injection and homogeneous mode a second injection pulse can be applied by the basic software at transient engine operation (as a result of an injection update). For this pulse a minimum injection time TI_ADD_PULSE_MIN is defined.

Each of the applied IP_TI_ADD_PULSE_MIN data should be smaller than the smallest calculated TI_MIN.

7.2.6 Start with pre injection

Application conditions:

Deactivation: **(**STATE_ST_PRE **AND** NC_ST_FIRST_INJ_END**)** = NC_ST_FIRST_INJ_END ...bitwise

Activation: **(**STATE_ST_PRE **AND (**NC_ST_ACT_PRE_INJ **OR** NC_ST_CONF_PRE_END**))** = NC_ST_ACT_PRE_INJ **OR** NC_ST_CONF_PRE_END ...bitwise

Initialization: -

Recurrence: NC_ECU_SAMPLE_FAST (the recurrence has to be same recurrence as the output of the ENSD aggregate)

Note! Deactivation condition has to be checked before the activation condition.

Formula Section:

TRL_EOI_ PRE_INJ[0] = EOI_ PRE_INJ[0] → transfer to I/O-SW

TRL_INJ_MOD_GLOBAL = NC_INJ_MOD_PRE_INJ → transfer to I/O-SW

STATE_ST_PRE **=** STATE_ST_PRE **OR** NC_ST_FIRST_INJ_END ...bitwise

Note! Indicate in state variable STATE_ST_PRE that the preinjection mode is transferred to I/O-SW and the preinjection is in progress. One preinjection pulse per cylinder is performed by the I/O SW. After a pulse is done the mode changes from preinjection mode to synchronised mode, managed by the I/O-SW cylinder individual.

7.2.7 Synchronised start

Application conditions:

Deactivation: (STATE_ST_PRE **AND** NC_ST_FIRST_INJ_END) = NC_ST_FIRST_INJ_END ...bitwise

Activation: **(**STATE_ST_PRE **AND (**NC_ST_ACT_SYN_INJ **OR** NC_ST_CONF_PRE_END**))** = NC_ST_ACT_SYN_INJ **OR** NC_ST_CONF_PRE_END ...bitwise

Initialization: -

Recurrence: NC_ECU_SAMPLE_FAST (the recurrence has to be same recurrence as the output of the ENSD aggregate)

Note! Deactivation condition has to be checked before the activation condition.

Formula Section:

(1) IF LV_INJ_UPD_TRM = 1

Check if at least one data set was sent to I/O-SW before starting the injection.

(1) THEN

TRL_INJ_MOD_GLOBAL = INJ_MOD_GLOBAL → transfer to I/O-SW

After transfer a TRL_TRIG_INJ_UPD call is required.

STATE_ST_PRE = STATE_ST_PRE **OR** NC_ST_FIRST_INJ_END ...bitwise
Note! Indicate in state variable STATE_ST_PRE that engine is synchronised and injection has been started.

(1) ENDIF

7.2.8 Engine stop

Application conditions:

Activation: at transition of LV_ES from 0 -> 1

Deactivation: -

Initialization: -

Recurrence: every transition of LV_ES from 0 -> 1

This chapter describe the engine stop procedure as required for this specification.

7.2.8.1 Formula Section:

Disable task interruption up to here:

INJ_MOD_GLOBAL = NC_INJ_MOD_HOM
OR ...bitwise
NC_INJ_MOD_DI

(1) FOR x = 0 **TO** (NC_CYL_NR –1) **DO:**

INJ_MOD[x] = INJ_MOD_GLOBAL

(1) ENDFOR

STATE_ST_PRE = STATE_ST_PRE **OR** NC_ST_FIRST_INJ_END ...bitwise

Now, task interruption can be enabled again.

TRL_INJ_MOD_GLOBAL = NC_INJ_MOD_DI → transfer to I/O-SW

PREV_STATE_IV = 0 (No Injection is performed by I/O-SW from this time)

(2) FOR x = 0 **TO** (NC_CYL_NR –1) **DO:**

LV_STATE_PREV_IV[x] = 0

(2) ENDFOR

7.3 Configuration of Preinjection

7.3.1 Pre injection configuration and phase

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
EOI_PRE_INJ[NC_CYL_NR]	O/V	0 ... 780H	0 ... 720	0.375	°CRK
End of injection for preinjection					
EOI_MIN_PRE_INJ	O/V	0 ... 780H	0 ... 720	0.375	°CRK
Latest end of injection angle for pre injection					
STATE_ST_PRE	O/V	0 ... FFH	0 ... 255	1	-
State for start pre injection					
PSN_DIF_ENG_SYN_THD	V	0 ... 780H	0 ... 720	0.375	°CRK
Difference of the min and max estimated engine position in the non syn. phase to trigger a preinjection					
PSN_DIF_ENG_SYN	V	0 ... 780H	0 ... 720	0.375	°CRK
Difference of the min and max estimated engine position in the non syn. phase					

Input data:

NC_CYL_NR	LV_ERR_CAM	TCO	TI_PRE_INJ[NC_CYL_NR]
PSN_ENG_SYN_MIN	PSN_ENG_SYN_MAX	INH_INJ	N
NC_ECU_SAMPLE_FAST	LV_RUN_ENG		

Description:

The definition of the variables represents the ASW part of the preinjection strategy as well as the interface to the BSW.

FUNCTION DESCRIPTION:

The aim is to **pre-synchronise** and start the engine as fast as possible. The experience has shown, that when the engines was switched off, it will stop in the most of the cases at the same specific positions. This information can be used together with the information of relative engine positions PSN_ENG_SYN_MIN and PSN_ENG_SYN_MAX to pre-synchronise the engine. In the case that the difference of PSN_ENG_SYN_MIN and PSN_ENG_SYN_MAX is lower than the threshold PSN_DIF_ENG_SYN_THD than the probability to put the pre injection on the valid cylinder with a good phasing is 100%. The preinjection shall carried out with the **latest possible** CRK angle for the preinjection, PSN_ENG_SYN_MAX. Due to the fact, that PSN_ENG_SYN_MAX is nearly fix and PSN_ENG_SYN_MIN change from tooth to tooth and in addition to that the EOI phasing calculation is done with PSN_ENG_SYN_MIN, the first pre injection angle has to be corrected by PSN_DIF_ENG_SYN.

The angle ANG_ENG_SYN_DLY describes beside the GAP (see case 1) and the CAM (see case 2) event a third event (see case 3). In the case that the running engine turns already ANG_ENG_SYN_DLY and no CAM or GAP event occur, then the variable PSN_ENG_SYN_MAX will set to the next possible CAM or GAP position. The angle ANG_ENG_SYN_DLY is defined in the aggregate ENSD.

Injection phasing for preinjection:

The cylinder individual start-of-preinjection-angle EOI_PRE_INJ [NC_CYL_NR] is calculated only once after the first valid tooth of the crankshaft signal is detected. It take into consideration the strong engine speed increase at start via the table ID_EOI_PRE_INJ_OFS. The preinjection is finished after all NC_CYL_NR – 1 injections are applied.

Application conditions:

Initialisation: at reset :

STATE_ST_PRE = NC_STATE_ST_PRE_INIT

Activation: At first valid tooth.

Recurrence: only once at activation

Formula section:

PSN_DIF_ENG_SYN_THD = IP_PSN_DIF_ENG_SYN_THD

IF TCO <= C_TCO_MAX_PRE_INJ_SEQ

{first injection will be carried out sequential after synchronisation}

THEN STATE_ST_PRE = NC_ST_ENA_SYN_INJ

{first injection will be carried out as preinjection}

ELSE STATE_ST_PRE = NC_ST_ENA_PRE_INJ

END

EOI_MIN_PRE_INJ = IP_EOI_MIN_PRE_INJ

{latest end of injection angle for pre injection and for identifying of the first injected cylinder}

FOR CYC_PRE = 0 **TO** NC_CYL_NR – 1 **DO**

EOI_PRE_INJ [CYC_PRE] = IP_EOI_PRE_INJ + ID_EOI_PRE_INJ_OFS

IF (TI_PRE_INJ [CYC_PRE] = 0)

{first injection will be carried out sequential after synchronisation}

THEN STATE_ST_PRE = NC_ST_ENA_SYN_INJ

END

END FOR

IF LV_ERR_CAM = 1

THEN STATE_ST_PRE = NC_ST_ENA_SYN_INJ

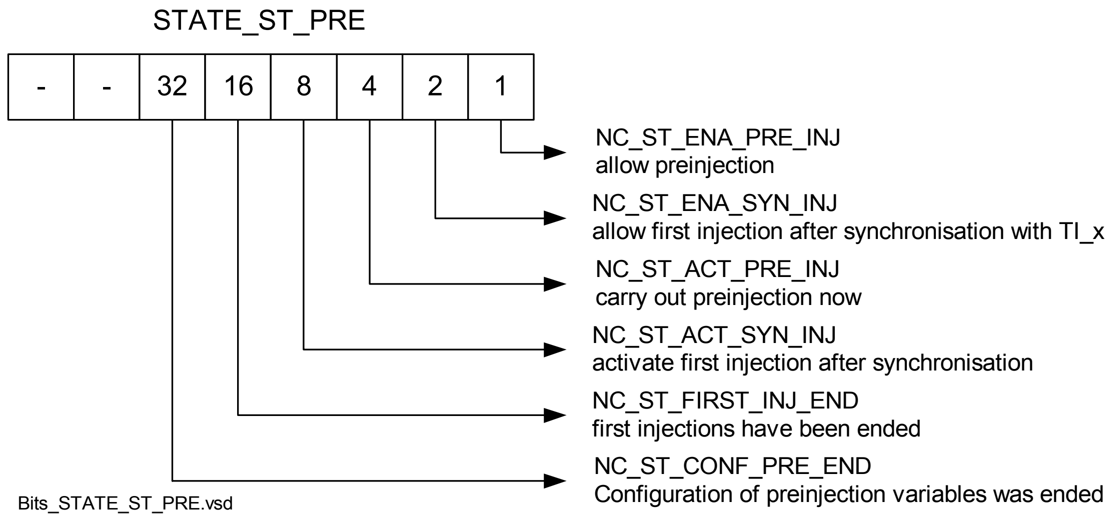
END

In the transfer function to I/O SW the state NC_ST_CONF_PRE_END is set in order to signalise, that the variables were successfully configured and have reached the BSW.

Note:

The counter CYC_PRE is a local variable.

Definition of STATE_ST_PRE:



Bits_STATE_ST_PRE.vsd

The NC variables to indicate the start state are defined as:

NC_STATE_ST_PRE_INIT = 00H

NC_ST_ENA_PRE_INJ = 01H

NC_ST_ENA_SYN_INJ = 02H

NC_ST_ACT_PRE_INJ = 04H

NC_ST_ACT_SYN_INJ = 08H

NC_ST_FIRST_INJ_END = 10H

NC_ST_CONF_PRE_END = 20H

7.3.2 Enable pre injection

FUNCTION DESCRIPTION:

General information:

Several conditions has to be fulfilled in order to permit a preinjection. In the case, that a preinjection shall carried out, the bit of STATE_ST_PRE = NC_ST_ENA_PRE_INJ, otherwise the standard injection with the fuel mass TI_CYL_x is applied synchronously and STATE_ST_PRE = NC_ST_ENA_SYN_INJ.

The preinjection will carried out at the moment when the difference, PSN_DIF_ENG_SYN, of PSN_ENG_SYN_MAX and PSN_ENG_SYN_MIN is lower than the threshold PSN_DIF_ENG_SYN_THD. This event is indicated by setting the bit NC_ST_ACT_PRE_INJ. The function is activated at the moment when the first valid tooth was passed and the pre injection variables were configured.

In the transfer function to I/O SW the state NC_ST_FIRST_INJ_END is set.

Application conditions:

Initialisation: -

Recurrence: NC_ECU_SAMPLE_FAST (the recurrence has to be the same recurrence as the output of the ENSD aggregate)

Deactivation: STATE_ST_PRE **AND** NC_ST_FIRST_INJ_END = NC_ST_FIRST_INJ_END

{Deactivation condition has to be checked before the activation condition}

Activation: STATE_ST_PRE **AND** NC_ST_CONF_PRE_END = NC_ST_CONF_PRE_END

Formula section:

```
PSN_DIF_ENG_SYN = ((PSN_ENG_SYN_MAX - PSN_ENG_SYN_MIN)+720°) MODULA 720°
IF   PSN_DIF_ENG_SYN  <  PSN_DIF_ENG_SYN_THD  AND INH_INJ = 0  THEN
     IF LV_RUN_ENG = 1   THEN                          {engine running detected}

        {Check start with pre injection}
        IF  STATE_ST_PRE AND NC_ST_ENA_PRE_INJ =  NC_ST_ENA_PRE_INJ  THEN
            IF  N < C_N_LOW_ENA_PRE_THD               {low engine speed range detected}
              THEN STATE_ST_PRE = NC_ST_CONF_PRE_END

7.3.3 Restart function

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_ST_REST	V/O	0...FFH	0...1,9922	0,0078	-
Restart-factor for the correction of the mass fuel flow at start					
LV_REST	V/O	0...1H	0...1	1	-
Flag indicating that a restart correction factor not equal to one is applied to the mass fuel flow calculation					

Input data:

TCO	TCO_STOP	T_AST_STOP	T_ES_REST
LV_T_ES_REST_VLD	LV_STALL	LV_ES	LV_ST_ES

FUNCTION DESCRIPTION:

General information:

In order to improve re-starts, a correction factor on the mass fuel flow during pre-injection and start injection is calculated. This factor can in- or decreases the mass fuel flow.

If a valid value for the engine-off-time is available (LV_T_ES_REST_VLD = 1) the factor is calculated dependent on the engine condition at shut down (IP_FAC_REST) and the engine-off-time (IP_REST).
The engine condition at shut down is determined by the coolant temperature at shut down TCO_STOP and the engine running time of the last driving cycle T_AST_STOP which are both stored in non volatile memory. The engine-off-time T_ES_REST and the decision of validity LV_T_ES_REST_VLD comes out of the application incidences for the restart function. In case of engine stalling detection (LV_STALL = 1) an additional correction factor is applied to the calculation of the restart factor.

If no valid value for the engine-off-time is available the standard restart function detects the necessity of a restart correction dependent on T_AST_STOP and the difference between the actual TCO and TCO_STOP (maximal difference: C_TCO_DIF_MAX_REST).
The restart factor is determined by the map IP_FAC_STND_REST dependent on the actual coolant temperature TCO. In case of engine stalling detection (LV_STALL = 1) an additional correction factor is applied to the calculation of the restart factor too.

The flag LV_REST indicates that a restart correction factor not equal to zero is applied to the mass fuel flow calculation.

Application conditions:

Activation: LV_ES = 1

Deativation: -

Initialisation: at reset: FAC_ST_REST = 1; LV_REST = 0

Recurrence: 10ms

7.3.4 Restart function (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_ES_REST	V/O	0...FFFFH	0...65535	1	[min]
Engine-off-time for the restart calculation					
LV_T_ES_REST_VLD	V/O	0...1H	0...1	1	[-]
Flag indicating that the engine-off-time for the restart calculation is valid					

Input data:

LV_T_ES_NOT_PLAUS	T_ES		

FUNCTION DESCRIPTION:

General information:

This function is used to decide whether the valid engine off time is available or not.

To avoid wrong calculation at unplausible T_ES the bit LV_T_ES_REST_VLD has to be set to zero to tell the restart function to use the standard functionality with the comparison of TCO_STOP (or TCO_REST) and TCO.

Application conditions:

Initialisation: *at reset:*
LV_T_ES_REST_VLD = 0
T_ES_REST = 65535 min

Activation: *LV_ES = 1*

Deactivation: *LV_ES = 0*

Recurrence: 10 ms

Formula section:

If LV_T_ES_NOT_PLAUS = 0

Then LV_T_ES_REST_VLD = 1

T_ES_REST = T_ES

Else LV_T_ES_REST_VLD = 0

T_ES_REST = 65535 min

Endif

7.3.4.1 Ambient pressure correction

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_ST_AMP	V/O	0...FFH	0...1.9922	0.0078	-
Injection correction at start upon AMP					

Input data:

AMP	LV_ST_END		

FUNCTION DESCRIPTION:

General information:

The purpose of this strategy is to correct the injection time depending on the ambient pressure before the MAF (manifold air pressure) variable is available.

Application conditions:

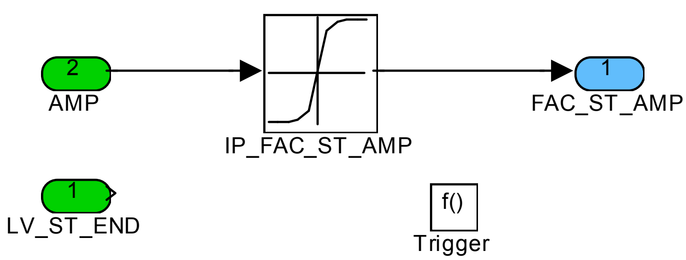
Activation: LV_ST_END =0

Deactivation: -

Initialization: -

Recurrence: 10 ms

Signal flow diagramm:



Formula section:

FAC_ST_AMP = IP_FAC_ST_AMP

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_FAC_ST_AMP	6	0...FFH	0...1.9922	0.0078	-
LDP_AMP_IP_FAC_ST_AMP	6	0...FFFFH	0...5434	0.083	hPa
Cranking injection time correction upon ambient pressure					

7.3.5 Basic injection mass for homogeneous mode

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MFF_BAS	V/O	0...FFFFH	0...1389	0.02119	mg/stk
Basic injection fuel mass flow (homogenious charge)					

Input data:

MAF	LV_ST_END		

FUNCTION DESCRIPTION:

General information:

The basic injected fuel mass MFF_BAS in homogeneous mode is calculated out of the stoichiometric factor C_MFF_FAC and the air mass per stroke MAF. It is the required fuel mass to run the engine at lambda 1.

As soon as the engine is running (LV_ES = 0) MFF_BAS is calculated. During start this is not required, but this inhibits a peak in the wallfilm compensation due to its activation.

Application condition:

Activation: every engine state

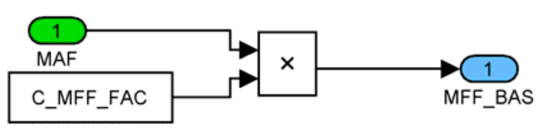
Deactivation: -

Initialization: -

Recurrance: LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment synchronous

Signal flow diagramm:



Formula section:

MFF_BAS = C_MFF_FAC * MAF

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_MFF_FAC	1	0...FFFFH	0..0.125	1.9074E-6	-
Constant for stoichiometric air/fuel ratio (=1/14.7)					

7.4 Injector dead time corrections

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TI_ADD_DLY_1_HOM	V/O	8000...7FFFH	-131.07...131.07	0.004	ms
Injector dead time correction, MPI engines					
TI_ADD_DLY_TEMP_COR	V	8000...7FFFH	-131.07...131.07	0.004	ms
Injector dead time correction, MPI engines					

Input data:

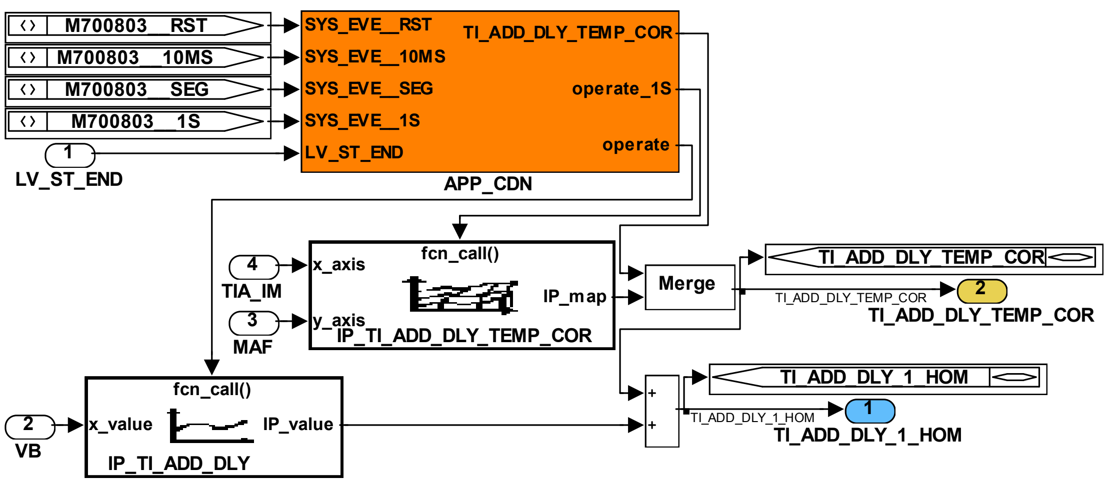
VB	LV_ST_END	MAF	TIA_IM

FUNCTION DESCRIPTION:

General information:

The module calculates the offset of the characteristic line of the injector. The calculation depends on battery voltage VB, intake air temperature TIA and mass air flow MAF.

Signal flow diagram:



7.4.1 Segment synchronous tasks

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: -

Recurrence: LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment synchronous

Formula section:

TI_ADD_DLY_1_HOM = IP_TI_ADD_DLY + TI_ADD_DLY_TEMP_COR

7.4.2 Time synchronous tasks

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: at reset: TI_ADD_DLY_TEMP_COR = 0

Recurrence: 1000 ms

Formula section:

TI_ADD_DLY_TEMP_COR = IP_TI_ADD_DLY_TEMP_COR

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Initialization value of post start enrichment factor					
LV_AST	V/O	0..1H	0...1	1	-
Flag to indicate that after-start function is active					
LV_AST_END	V/O	0..1H	0...1	1	-
Flag to indicate the end of after-start function					
CYC_PUC_WUP	V	0...FFFFH	0...65535	1	-
Cycle counter for PUC operation					
CYC_WUP	V	0...FFFFH	0...65535	1	-
Cycle counter for the deactivation of the cold post start correction					

Input data:

TCO	TIA_IM	CYC_CAST	LV_PUC
LV_AT	LV_ES	LV_ST_END	AMP
N_32	MAP	FAC_ST_REST	LV_ERR_PORT
CONF_PORT	PORT_AV	FAC_FQ_ST_AD	

FUNCTION DESCRIPTION:

General information:

This enrichment takes place just after start in order to ensure the first combustions in cold conditions. CYC_CAST and CYC_WUP counts the number of segments beginning with after-start (LV_ST_END = 1, LV_AST = 1). But CYC_WUP can be stopped or decreased in case of PUC operation dependend on the calibration of C_FAC_DEC_WUP_PUC.

The value ADD_MFF_CAST_INI is determined from IP_ADD_MFF_CAST_INI (or IP_ADD_MFF_CAST_INI_AT in case of an automatic transmission) only once if the function is activated. IP_ADD_MFF_DEAC_CAST is the deactivation factor updated every segment.

In case that the port flap is activated (closed) a different deactivation factor is applied.

Application conditions:

Activation: LV_ST_END = 1 **and** LV_AST_END = 0

Deactivation: -

Initialization: at reset **or** at transition LV_ES 0 ->1:
LV_AST = 0; LV_AST_END = 0; ADD_MFF_CAST = 0; CYC_PUC_WUP = 0

at activation:
LV_AST = 1
If LV_AT = 1
then ADD_MFF_CAST_INI = IP_ADD_MFF_CAST_INI_AT * IP_FAC_REST_CAST * IP_FAC_AMP_CAST
else ADD_MFF_CAST_INI = IP_ADD_MFF_CAST_INI * IP_FAC_REST_CAST * IP_FAC_AMP_CAST

Recurrence: segment synchronous

Formula section:

If LV_PUC = 1

then $CYC\_PUC\_WUP_n = CYC\_PUC\_WUP_{n-1} + 1$

CYC_WUP = CYC_CAST – C_FAC_DEC_WUP_PUC * CYC_PUC_WUP

endif

If CONF_PORT = 1 **and** LV_ERR_PORT = 0
and PORT_AV >= C_PORT_AV_THD_MFF_CAST

then ADD_MFF_CAST = ADD_MFF_CAST_INI * IP_ADD_MFF_DEAC_CAST_PORT * (1 + (FAC_FQ_ST_AD – 1) * C_FAC_FQ_ST_AD_AST)

else

ADD_MFF_CAST = ADD_MFF_CAST_INI * IP_ADD_MFF_DEAC_CAST * (1 + (FAC_FQ_ST_AD – 1) * C_FAC_FQ_ST_AD_AST)**endif**

The value ADD_MFF_CAST_INI is determined from IP_ADD_MFF_CAST_INI (or IP_ADD_MFF_CAST_INI_AT in case of an automatic transmission) only once if the function is activated.

IP_ADD_MFF_DEAC_CAST is the deactivation factor updated every segment.

If ADD_MFF_CAST = 0(0H)

then LV_AST = 0

LV_AST_END_= 1

endif

FUNCTION DESCRIPTION:

7.7.1 Definition of the injection range

Application conditions:

Activation: at reset

Deactivation: -

Initialization: -

Recurrence: once at reset

The fuel can be injected within a defined window over a range of 720 °CRK. The cylinder individual zero position of this range is defined via the constants NC_REF_EOI_LIM and NC_EOI_LIM with reference to the ignition TDC of cylinder 0, see figure below.

Formula section:

Related to tdc cylinder 0:

FOR x = 0 **TO** (NC_CYL_NR-1) **DO**:

EOI_LIM[x] = REF_EOI_LIM + NC_EOI_LIM - x * (720 / NC_CYL_NR)

SOI_LIM[x] = EOI_LIM[x] + 720 °CRK

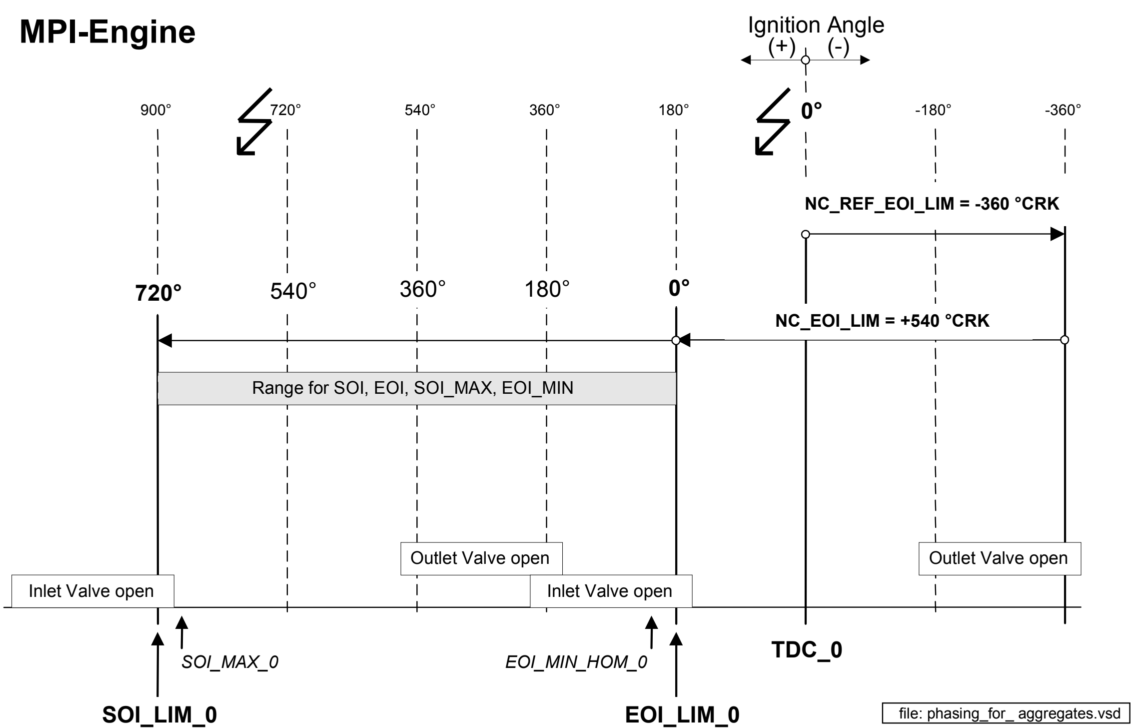
ENDFOR

Definition of the non calibrateable constants:

(NC_REF_EOI_LIM = -360°CRK, defined in I/O SW, assigned to REF_EOI_LIM)

NC_EOI_LIM = 540 °CRK

MPI-Engine



7.7.2 Injection phasing for preinjection

Preinjection is only applied on MPI engines, see Specification “Configuration of preinjection”.

The pre injection function has a separate interface to the basic software. As long as the pre injection function is active the basic software drives the injectors via this interface.

The function is activated after at first valid tooth and is deactivated after a defined number of preinjections are performed.

After the preinjection is finished the injection is performed as described in the following chapters:

FUNCTION DESCRIPTION:

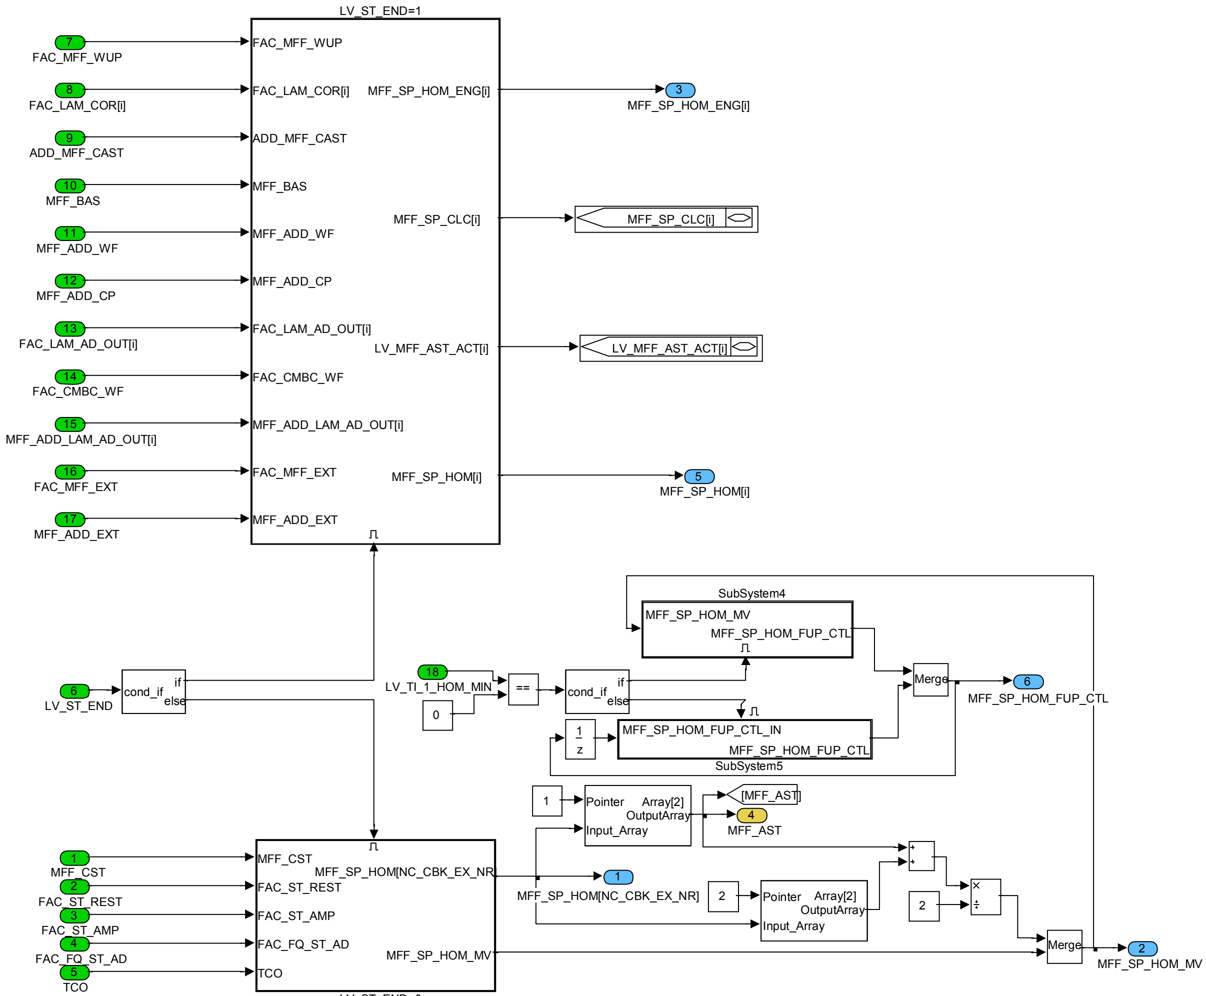
General information:

After key on for the calculation of the injected fuel mass there are different stages distinguished:

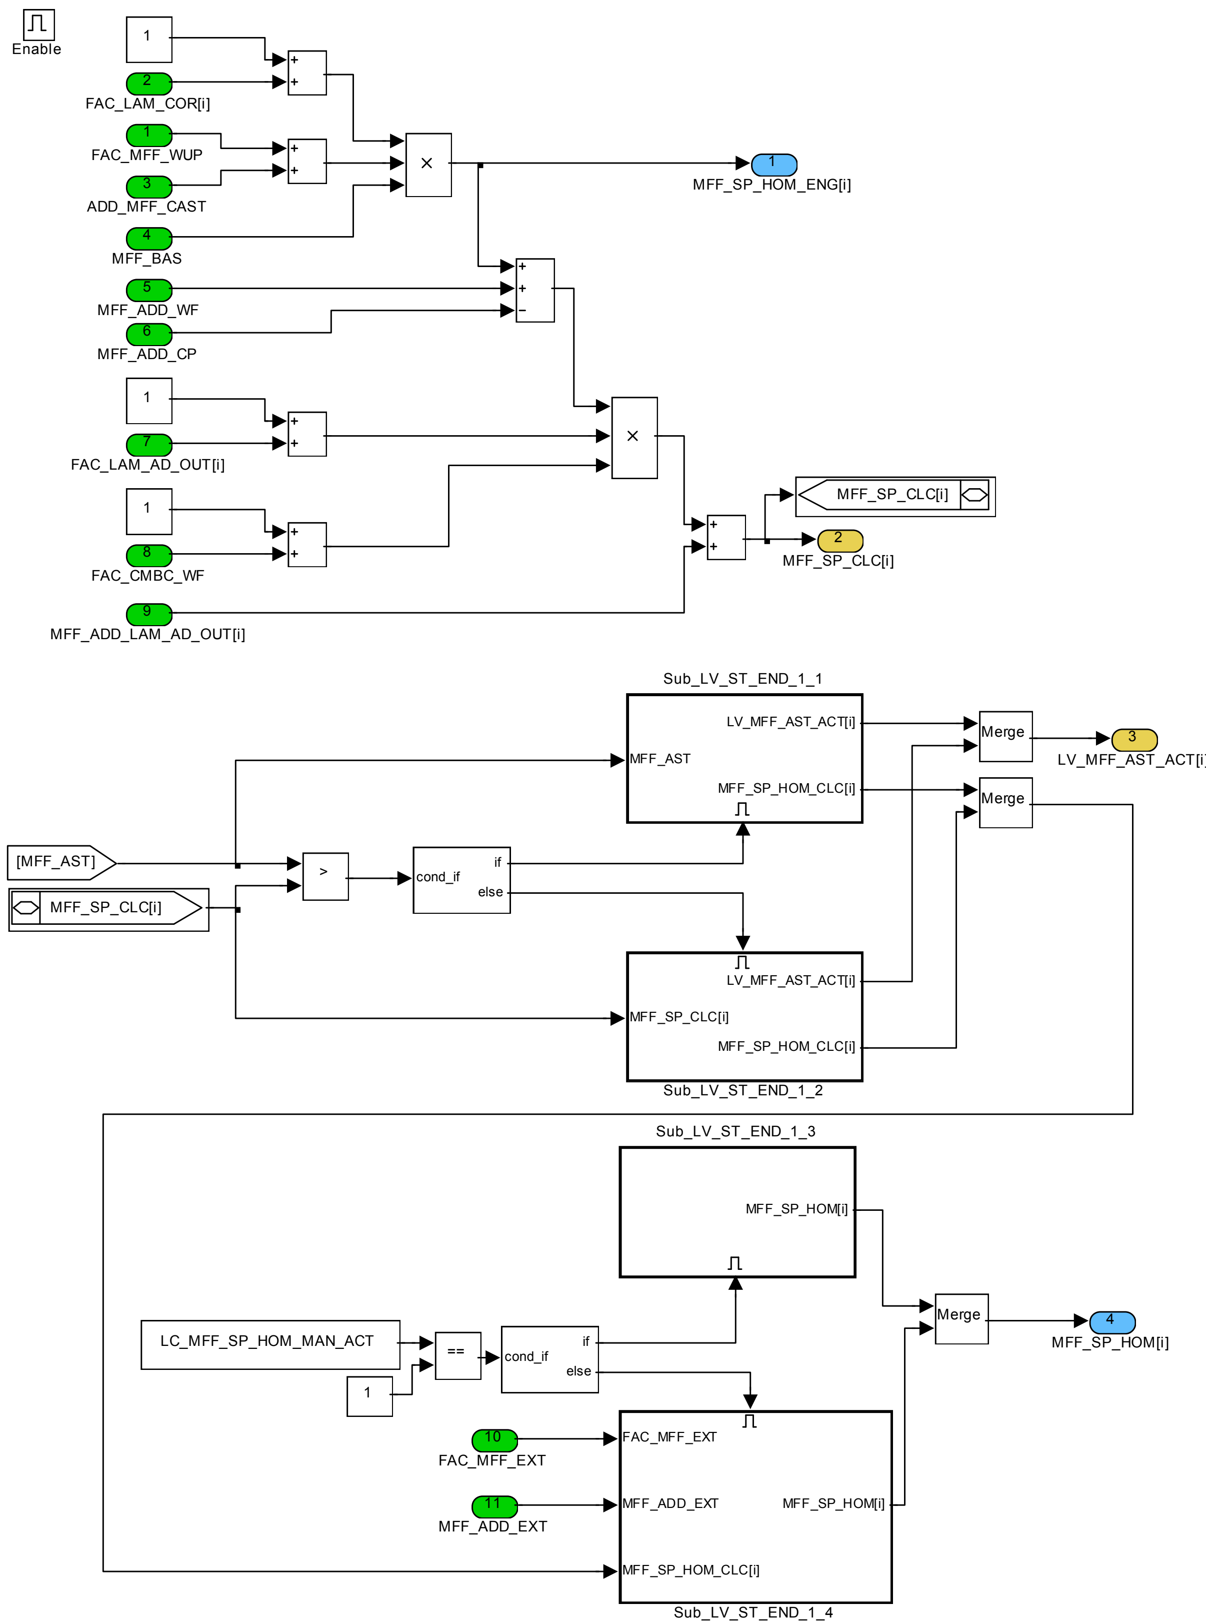
- Start pre injection
- Mass fuel flow at start
- Mass fuel flow out of start

Signal flow diagramm:

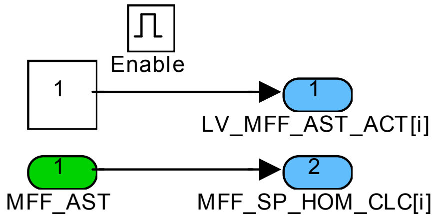
Mainsystem:



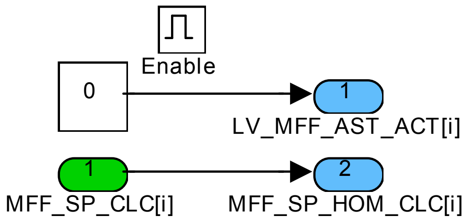
Subsystem LV_ST_END=1:



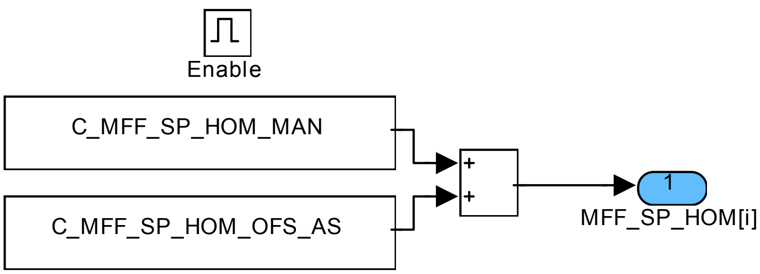
Sub_LV_ST_END_1_1:



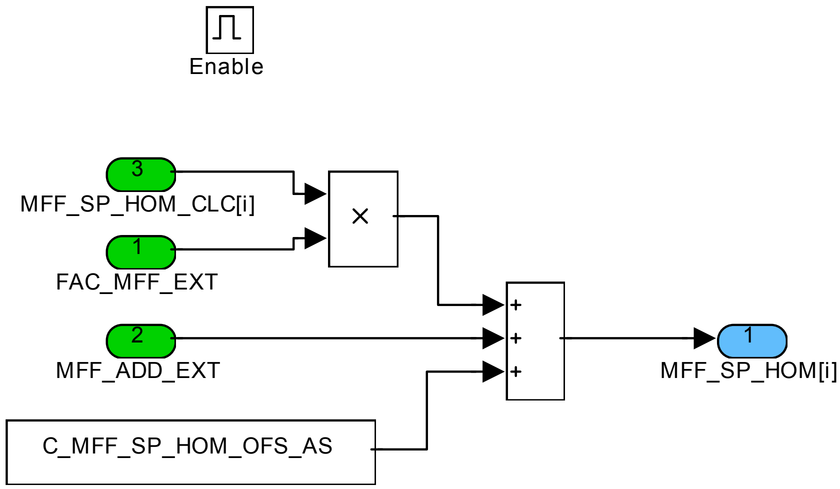
Sub_LV_ST_END_1_2:



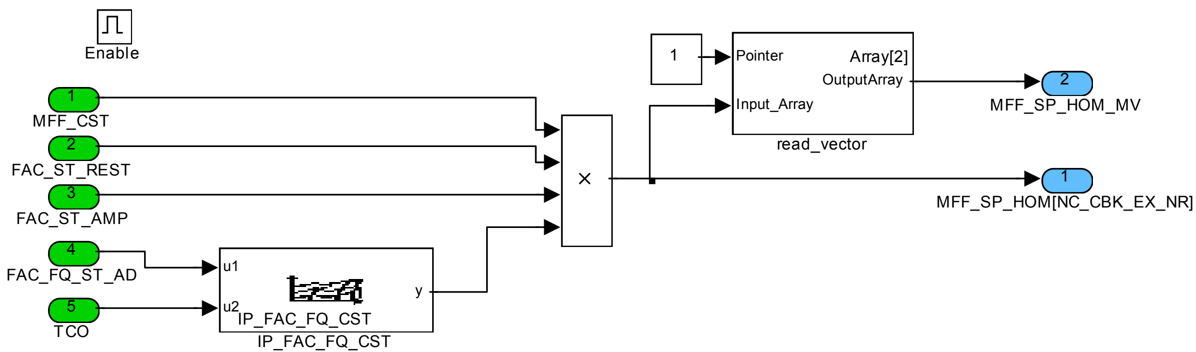
Sub_LV_ST_END_1_3:



Sub_LV_ST_END_1_4:



Subsystem LV_ST_END=0:



Start pre injection

Preinjection is only applied on MPI engines, see Specification “Start pre injection”.

The pre injection function has a separate interface to the basic software. As long as the pre injection function is active the basic software drives the injectors via this interface.

The function is activated at first valid tooth and is deactivated after a defined number of preinjections are performed.

After the preinjection is finished the injection is performed as described in the following chapters:

7.9.1.1 Mass fuel flow at start

Application condition:

Activation:	LV_ST_END = 0
Deactivation:	-
Initialization:	-
Recurrance:	10 ms

MFF_SP_HOM[NC_CBK_EX_NR] =	(MFF_CST	*Start injection fuel mass*
	* FAC_ST_REST	*Re-start correction factor*
	* FAC_ST_AMP	*Altitude correction*
	* IP_FAC_FQ_CST)	*Correction factor from fuel quality adaptation*
	* FAC_MFF_ST_EXT	*external correction factor for start*

MFF_SP_HOM_MV = MFF_SP_HOM[1]

7.9.1.2 Mass fuel flow out of start

Application condition:

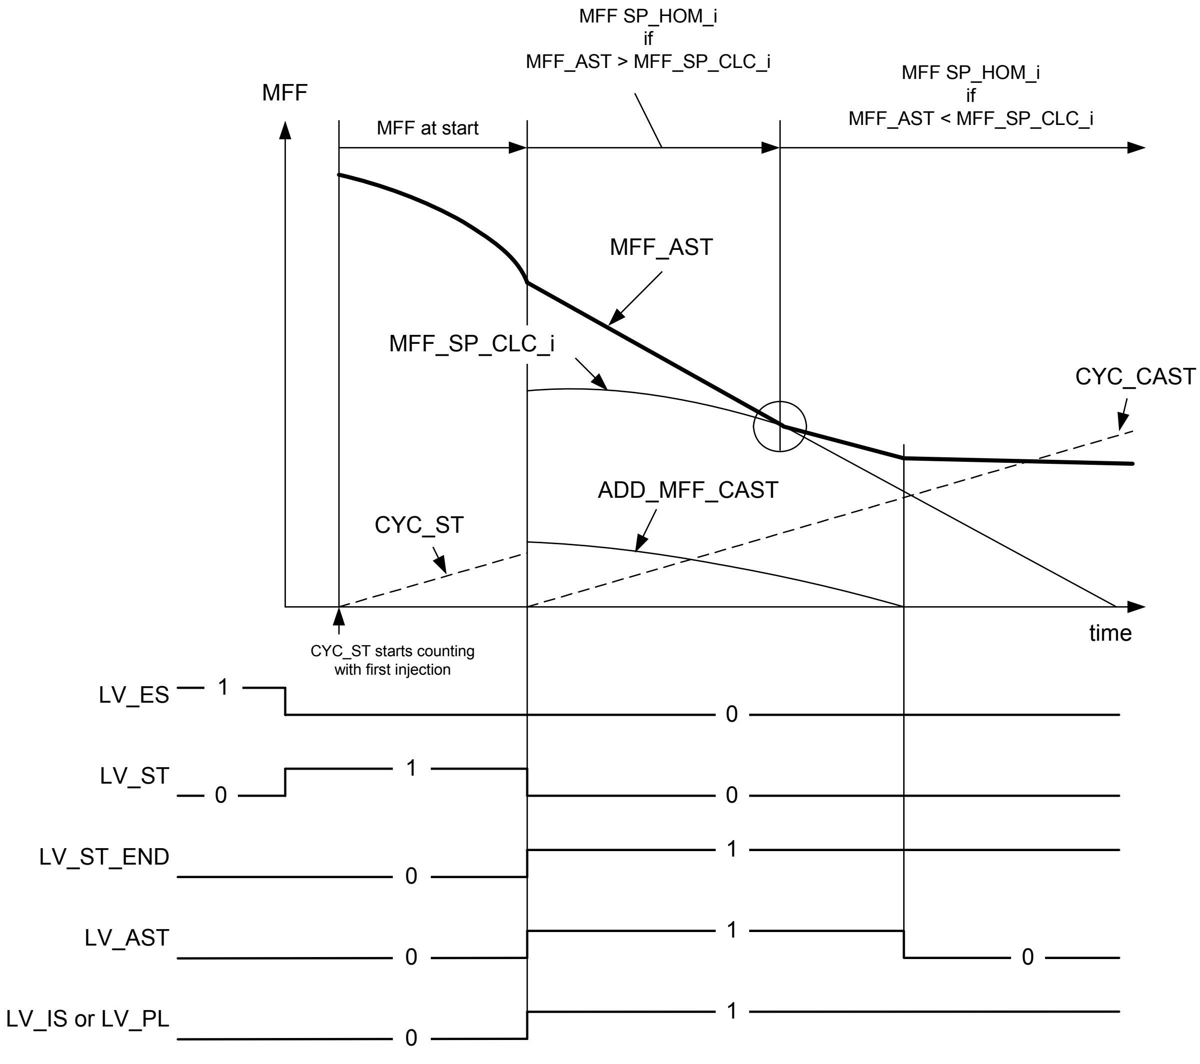
Activation:	LV_ST_END = 1
Deactivation:	-
Initialization:	at LV_ST_END = 0 ->1: MFF_LGRD_AST = IP_MFF_LGRD_AST MFF_AST = MFF_SP_HOM[1] (last value off MFF at start)
Recurrence:	segment synchronous

7.9.1.2.1 Mass fuel flow during after-start

If LV_ST_END is set to one (start is finished) the fuel mass flow for after-start MFF_AST is initialized with the last calculated MFF_SP_HOM[1] (calculated at start). MFF_AST is ramped down with the decrement MFF_LGRD_AST. The decrement is defined once at initialization from IP_ MFF_LGRD_AST.

In parallel MFF_SP_CLC[i] is calculated (see next chapter). Afterwards MFF_SP_CLC[i] and MFF_AST are compaired and the bigger value is selected for futher calculations.

MFF_AST(n) = MFF_AST(n-1) – MFF_LGRD_AST



File: FMSP_HOM.vsd

7.9.1.2.2 Calculation of MFF_SP_CLC[i]

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

Input data:

FAC_ST_REST	TCO	NC_CYL_NR	
C_FAC_MFF_TI_STND_1	FAC_FQ_ST_AD	LV_ST_ES	NC_NR_TOOTH
AMP	TIA		

FUNCTION DESCRIPTION:

General information:

The cylinder individual pre-injection-time TI_PRE_INJ[CYC_PRE] is calculated only once after the first valid tooth of the crankshaft signal is detected.

The calculation of the pre-injection is fuel mass based but the output value TI_PRE_INJ[CYC_PRE] is time based, therefore at the end a conversion from MFF to TI is performed.

The basic pre-injection fuel mass is determined by the map IP_MFF_PRE_INJ_BAS. The behaviour of the intake manifold and the volumetric efficiency are taken into consideration and therefore the pre injection mass will be weighted by a factor from the map ID_FAC_MFF_PRE_DEAC. In case of a previous transition from “start” to “engine stop” the correction factor C_MFF_PRE_FAC_ST_ES for a new pre-injection will be applied. The counter CYC_PRE is only a local variable in the range of 0 to NC_CYL_NR-1.

Engine cranking speed can be considered to determine final pre-injection fuel mass. Cause engine cranking speed (N_PRE_INJ) is updated on the first valid crank tooth using last crank tooth period from BSW, N_PRE_INJ has big deviation from actual working point. So, Decision of ID_FAC_N_MFF_PRE_INJ should be carefully made.

Application conditions:

Activation: after first valid tooth of crankshaft signal is detected

Recurrence: only once at activation.

Formula section:

N_PRE_INJ = 60 / (NC_NR_TOOTH * Tooth Period From BSW)

FOR CYC_PRE = 0 **TO** NC_CYL_NR - 1

FAC_FQ_ST_AD_FTL	N_32	TCO	

FUNCTION DESCRIPTION:

General information:

The purpose of fuel quality adaptation is to make sure that the engine runs without any dependency on fuel quality. This aim is realised by an increasing or a decreasing of the injection time by a factor. For that the fuel quality is recognised by the engine speed gradient at start.

The bit LV_FQ_ST_AD activates fuel quality adaptation. Some parts of the fuel quality adaptation; the temperature range selection and the adaptation factor output; must be activated earlier because they are necessary for the calculation of the first start injection. The counter CTR_FQ_ST_AD_END retards the end of the fuel quality adaptation function in order to wait for the plausibility of the FTL CAN signal. In the case, that the fuel tank level changed between two engine stops, the saved adaptation factors will be weighted by FAC_FQ_ST_AD_FTL.

The adaptation values are stored if the whole function ended without any error. The stored adaptation factors are initialised to 1 for after the ECU is brand new.

Application conditions:

7.13.1.1 End of adaptation

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_FQ_ST_AD_END	V	0...1H	0...1	1	-
End of adaptation (but not end the fuel quality function)					
LV_FQ_ST_AD_END_N	V	0...1H	0...1	1	-
End of adaptation (but not end the fuel quality function) due to engine speed overshoot					

Input data:

CYC_FQ_ST_AD	LV_FQ_ST_AD	N_32	N_SP_IS

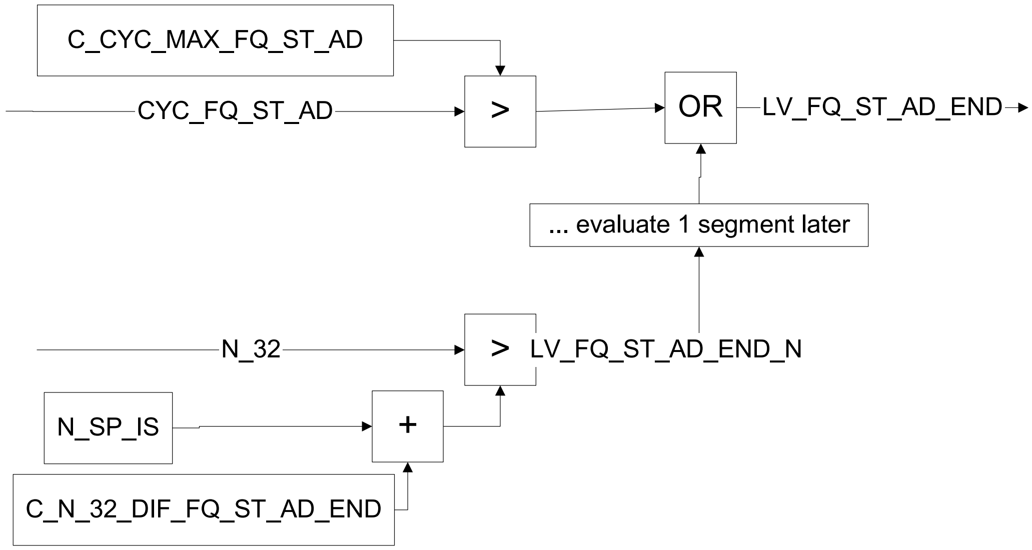
FUNCTION DESCRIPTION:

General information:

The adaptation is activated for a certain number of combustion cycles. If the cycle counter is bigger than the cycle counter threshold for adaptation end, the adaptation is stopped. The cycle counter starts with the value 1. The adaptation is stopped too, in the case when the engine speed overshoot a certain threshold beyond the idle speed setpoint N_SP_IS, due to a very good fuel.

The fuel quality adaptation function ends later (see. LV_FQ_ST_AD_END_1) because the adaptation values still have to be saved in the NVMY.

Signal flow diagram:



Application conditions:

Activation:	LV_FQ_ST_AD = 1
Deactivation:	after transition LV_FQ_ST_AD = 1 → 0
Initialisation:	LV_FQ_ST_AD_END = 0
	LV_FQ_ST_AD_END_N = 0
	at *reset* and at *transition from engine run to engine stop*
Recurrence:	every TDC

Formula section:

IF (CYC_FQ_ST_AD > C_CYC_MAX_FQ_ST_AD) **OR**
(LV_FQ_ST_AD_END_N = 1)
THEN LV_FQ_ST_AD_END = 1
ELSE LV_FQ_ST_AD_END = 0

{The detection of the engine speed overshoot is placed after the evaluation of CYC_FQ_ST_AD, because the FQA will end one segment later and the FQA can still evaluate the last combustion.}
IF (N_32 > N_SP_IS + C_N_32_DIF_FQ_ST_AD_END)
THEN LV_FQ_ST_AD_END_N = 1

Maximum threshold for counter of minimum engine speed difference					

Input data:

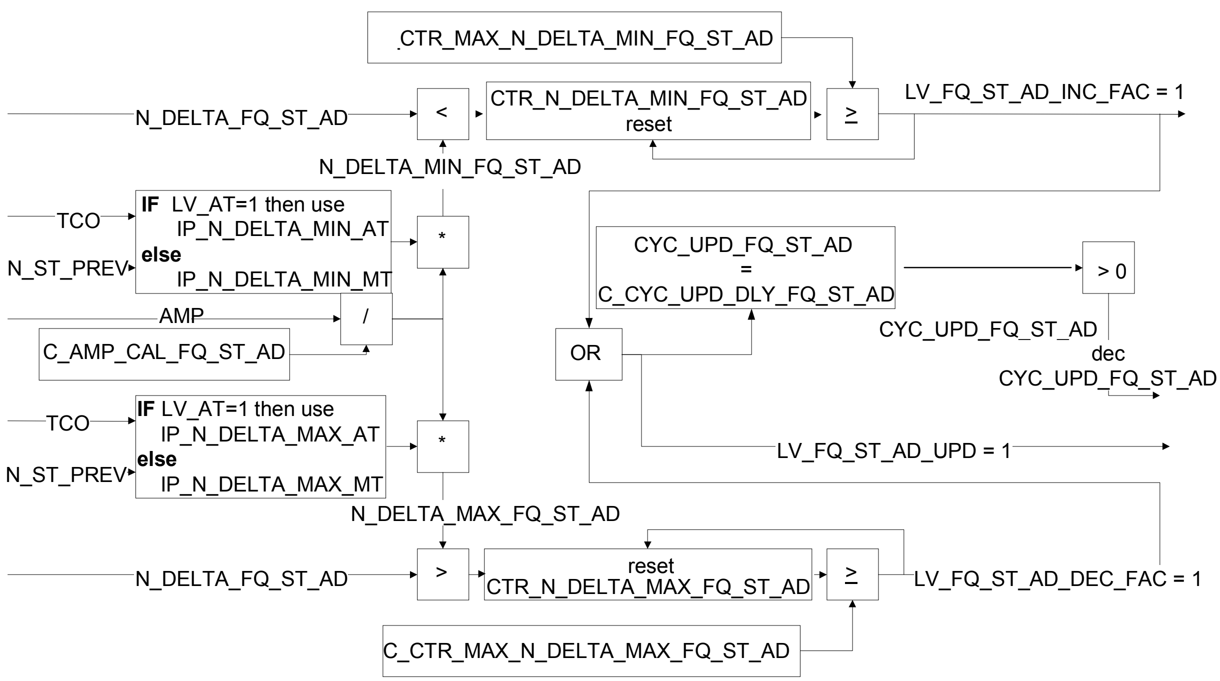
N_DELTA_FQ_ST_AD	TCO	N_ST_PREV	AMP
CYC_FQ_ST_AD	LV_FQ_ST_AD	LV_AT	DIST

FUNCTION DESCRIPTION:

General information:

The whole function is based on the analysis of the increase of the engine speed during the start. If a too low engine speed gradient at start is detected the adaptation factor for the start fuel injection time will be increased. Engine speed gradients being too low are leading to a decrease of the adaptation factor.

Signal flow diagram:



Description:

An upper and a lower limit give the intended engine speed increase. A map corrected by the ambient air pressure determines each limit. These maps are dependent on the previous engine speed and the coolant temperature. Each time the real engine speed increase is outside these limits this event is counted either by the upper limit counter CTR_N_DELTA_MAX_FQ_ST_AD or by the lower limit counter CTR_N_DELTA_MIN_FQ_ST_AD. If an adaptation took place, the function wait a certain number of TDC´s, determined by C_CYC_UPD_DLY_FQ_ST_AD, until a new evaluation can take place. This is due to the effect, that a new adapted fuel amount has to be aspirated, compressed and burned before it can be evaluated. The decision to in- or decrease the adaptation factor is made dependent on the counter maxima. After that the counter is reset.

Application conditions:

Activation: LV_FQ_ST_AD = 1

Deactivation: after transition LV_FQ_ST_AD = 1 → 0

Initialisation: all counters = 0; LV _FQ_ST_AD_INC_FAC = 0;

Factor to decrement FAC_FQ_ST_AD linear for temperatures above range 1					

Input data:

TCO			

FUNCTION DESCRIPTION:

General information:

The coolant temperature at start is classified into range 0 to 4 but a fuel adaptation will only carried out in the ranges 1 to 3. Temperature range 0 represent the higher temperature area and range 4 is assigned for the lower temperature area. In the range 4 only the adaptation value FAC_FQ_ST_AD from the range 1 and 3 will be applied. In the range 0 the value FAC_FQ_ST_AD will linear decremented with the factor FAC_FQ_ST_AD_DEC_TCO.

Depending on the temperature range the related bit LV_FQ_ST_AD_TCO_ST_RNG_x is set to 1. If one of the 3 bits within temperature range 1 to 3 is set to 1 and the coolant temperature at start is smaller than the max. coolant temperature for wall film correction, the bit LV_FQ_ST_AD_WF is set to 1. If the coolant temperature at start is classified into one of the three temperature ranges and if it is smaller than the max. coolant temperature for after start injection correction, the bit LV_FQ_ST_AD_AST is set to 1.

7.13.5 In-/decrementation step

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
DELTA_FAC_FQ_ST_AD	V	80...7FH	-1...0.992	0.0078	-
In-/decrementation step for the fuel quality adaptation factor					

Input data:

LV_FQ_ST_AD_TCO_ST_RNG_1	LV_FQ_ST_AD_TCO_ST_RNG_2	LV_FQ_ST_AD_TCO_ST_RNG_3
LV_FQ_ST_AD_INC_FAC	LV_FQ_ST_AD_DEC_FAC	LV_FQ_ST_AD

FUNCTION DESCRIPTION:

General information:

At the beginning of the function either the decrease or increase bit is active. If the incrementation bit is active, one of the incrementation constants, depending on TCO_ST, are taken over as the value of the Inc-/decrementation factor DELTA_FAC_TI ST_AD. If these conditions are fulfilled, the constant related to start temperature is taken over as the value of the Inc-/decrementation factor DELTA_FAC_FQ_ST_AD.

Signal flow diagram:

Application conditions:

Activation: LV_FQ_ST_AD = 1

Deactivation: after transition LV_FQ_ST_AD = 1 → 0

Initialisation: DELTA_FAC_FQ_ST_AD = 0;

at *reset* and at *transition from engine run to engine stop*

Recurrence: every TDC

Formula section:

7.13.6 Correction factor for changing fuel tank level

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_FQ_ST_AD_FTL	O/V	0...FFH	0 ... 0.996	0.0039	-
Correction for FTL influence of the fuel quality adaptation					
FAC_FTL_CHG	V	0...FFH	0 ... 0.996	0.0039	-
Factor of changed fuel tank level					

Input data:

FTL_AV_FQ_ST_AD	FTL_SAVE_FQ_ST_AD	LV_FQ_ST_AD	

FUNCTION DESCRIPTION:

General information:

In the case that the fuel tank level has changed after engine stop and start again, it can be supposed that the fuel tank has been filled up. For that reason, the fuel quality could have changed and the adaptive factor will be reduced.

Application conditions:

Initialisation: at reset and at transition from engine run to engine stop

FAC_FQ_ST_AD_FTL = 0

Recurrence: every TDC

Activation: LV_FQ_ST_AD = 1

Deactivation: after transition LV_FQ_ST_AD = 1 → 0

FUNCTION DESCRIPTION:

IF FTL_AV_FQ_ST_AD < (FTL_SAVE_FQ_ST_AD – C_FAC_FQ_ST_AD_FTL_HYS)
THEN *{Fuel tank was drained}*
FAC_FQ_ST_AD_FTL = 0.996
ELSE
IF FTL_AV_FQ_ST_AD > FTL_SAVE_FQ_ST_AD
THEN
FAC_ FTL_CHG = (FTL_AV_FQ_ST_AD – FTL_SAVE_FQ_ST_AD) / FTL_AV_FQ_ST_AD
FAC_FQ_ST_AD_FTL = IP_FQ_FTL_CHG
ELSE
FAC_FQ_ST_AD_FTL = 0

Adaptation factor for the temperature range 3					
FAC_FQ_ST_AD_RNG_2	V	0...FFH	0 ...1.992	0.0078	-
Adaptation factor for the temperature range 3					
FAC_FQ_ST_AD_RNG_3	V	0...FFH	0 ...1.992	0.0078	-
Adaptation factor for the temperature range 3					

Input data:

DELTA_FAC_FQ_ST_AD	LV_FQ_ST_AD_TCO_ST_RNG_1	LV_FQ_ST_AD_TCO_ST_RNG_2
LV_FQ_ST_AD_TCO_ST_RNG_3	LV_FQ_ST_AD_END	LV_FQ_ST_AD
LV_FQ_ST_AD_INI_FAC	LV_FQ_ST_AD_TCO_ST_RNG_0	LV_FQ_ST_AD_TCO_ST_RNG_4
FAC_FQ_ST_AD_SAVE_RNG_1	FAC_FQ_ST_AD_SAVE_RNG_2	FAC_FQ_ST_AD_SAVE_RNG_3
LV_FQ_ST_AD_DEC_FAC	FAC_FQ_ST_AD_DEC_TCO	LV_REST

FUNCTION DESCRIPTION:

General information:

If the function has once detected that an in- or decrease of the adaptation value for a specific temperature range is necessary then an in- or decrease of the adaptation values for the other temperature ranges will also be necessary but with a different in-/decrementation step. To handle this the actual in-/decrementation step is added to the adaptation value with different weighting factors.

Description:

As long as LV_FQ_ST_AD = 0 the adaptation factors for the different temperature ranges FAC_FQ_ST_AD_TCO_ST_RNG_x are equal to the saved adaptation factors FAC_FQ_ST_AD_SAVE_TCO_ST_RNG_x. If the adaptation is active (LV_FQ_ST_AD = 1) then the weighted in-/decrementation steps DELTA_FAC_FQ_ST_AD_RNG_x are added to the adaptation factors. These factors are limited by the parameters C_FAC_FQ_ST_AD_MIN_TCO_ST_RNG_x and C_FAC_FQ_ST_AD_MAX_TCO_ST_RNG_x. The variables DELTA_FAC_FQ_ST_AD_RNG_x are only local variables. An initialisation of the adaptation factors can be forced by setting the bit LC_FQ_ST_AD_INI_FAC to 1. In case a decrementation was detected, the factors of the other temperature ranges will be weighted again by the factor C_FAC_FQ_ST_AD_DEC_COR.

Signal flow diagram:

Application conditions:

Activation: first valid tooth before preinjection calculation

Deactivation: LV_FQ_ST_AD = 1 → 0

Initialisation: **IF(1)** LC_FQ_ST_AD_INI_FAC_MAN = 1 or LV_FQ_ST_AD_INI_FAC = 1 **THEN**

FAC_FQ_ST_AD = C_FAC_FQ_ST_AD_INI

C_FTL_SAVE_FQ_ST_AD	1	0 ... FFH	0 ... 0.996	0.0039	-
Default value fuel tank level for fuel quality adaptation stored in the non volatile memory					

FUNCTION DESCRIPTION:

General information:

The purpose of the fuel quality adaptation function (FQA) is to make sure that the engine runs without any dependency on fuel quality. This aim is realised by an increasing or a decreasing of a fuel quality factor. For that the fuel quality is recognised by the engine speed gradient at start.

Application conditions:

Initialisation: at reset

LV_FQ_ST_AD_NOT_VLD_EXT = 0
CYC_ST_FQ_ST_AD = 0
LV_REST_FQ_ST_AD = 0
LV_FQ_ST_AD_INI_FAC = 0
T_SEG_FQ_ST_AD = 0
FTL_AV_FQ_ST_AD = 0
/ read* FTL_SAVE_FQ_ST_AD *from non volatile memory */*
***If** non stored NVMY values* **or** *NVMY has a checksum error*

Then FTL_SAVE_FQ_ST_AD = C_ FTL_SAVE_FQ_ST_AD

at transition from engine run to engine stop
FTL_AV_FQ_ST_AD = FTL_MMV / 100 *(actual value)*
FTL_SAVE_FQ_ST_AD = FTL_AV_FQ_ST_AD

Recurrence: every TDC

Activation: LV_FQ_ST_AD_INH = 0

Deactivation: LV_FQ_ST_AD_INH = 1

Formula section:

The execution of fuel quality adaptation function is prohibited depending on one of the following error and state bits or the variable PV_AV is greater than 0. In the case of a port injection engine, the logical variable LV_ST_H_PRS_ACT for a HPDI engine has to be defined and set to 0 in the chapter general.

```
IF  LV_ERR_CAM = 1                      OR
    LV_ERR_CRK = 1                      OR
    LV_ERR_MAF = 1                      OR
    LV_ERR_MAP = 1                      OR
    LV_ERR_TCO = 1                      OR
    LV_ERR_VB = 1                       OR
    LV_ERR_IGC = 1                      OR
    LV_ERR_IV = 1                       OR
    PV_AV > 0                           OR

    THEN
            LV_FQ_ST_AD_NOT_VLD_EXT = 1
    ELSE
            LV_FQ_ST_AD_NOT_VLD_EXT = 0
ENDIF
```

The variable CYC_ST_FQ_ST_AD describes the number of segments from the moment when 8 valid teeth were detected.

CYC_ST_FQ_ST_AD = CYC_ST

If a restart was detected and carried out then this event has to be signalised to the fuel quality adaptation in order to disable the module.

```
        IF          (LV_REST = 1        OR      LV_REST_FQ_ST_AD = 1)
        THEN        LV_REST_FQ_ST_AD = 1
        ELSE        LV_REST_FQ_ST_AD = 0
ENDIF
```

The range of the ECU frequency dependent segment time T_SEG_AV is converted and assigned to the fuel quality adaptation segment time T_SEG_FQ_ST_AD

T_SEG_FQ_ST_AD = T_SEG_AV

The change of the fuel tank level FTL is taken into consideration if a FTL signal is available.

IF LV_ERR_FTL = 0 /* Fuel tank level signal is available */
then FTL_AV_FQ_ST_AD = FTL_MMV / 100
else FTL_AV_FQ_ST_AD = 0.996
endif

Under specific circumstances an initialisation of the stored adaptation factors from the NVMY can be forced.

LV_FQ_ST_AD_INI_FAC = 0

Setpoint of turbine temperature for overheating prevention					

7.18.1 General information

If the actual temperature before turbine TEG_DYN_UP_TUR exceeds TEG_TUR_OHP_SP (calibratable via IP_TEG_TUR_UP_SP) the logical value LV_LAMB_TUR_OHP is set to 1 and a P-I-controller is activated. LAMB_TUR_OHP is ramped down to decrease the turbine temperature and afterwards (at uncritical temperatures) ramped up until LAMB_BAS to avoid a step in LAMB_SP.

Application Condition

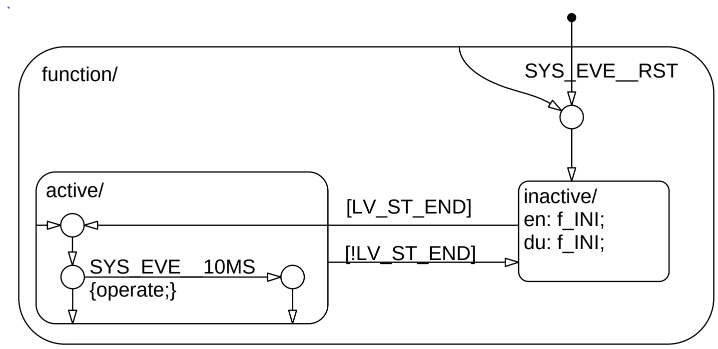

Figure 8 EXTC_ISPCLohc0/ APP_CDN/ Chart

Function Description

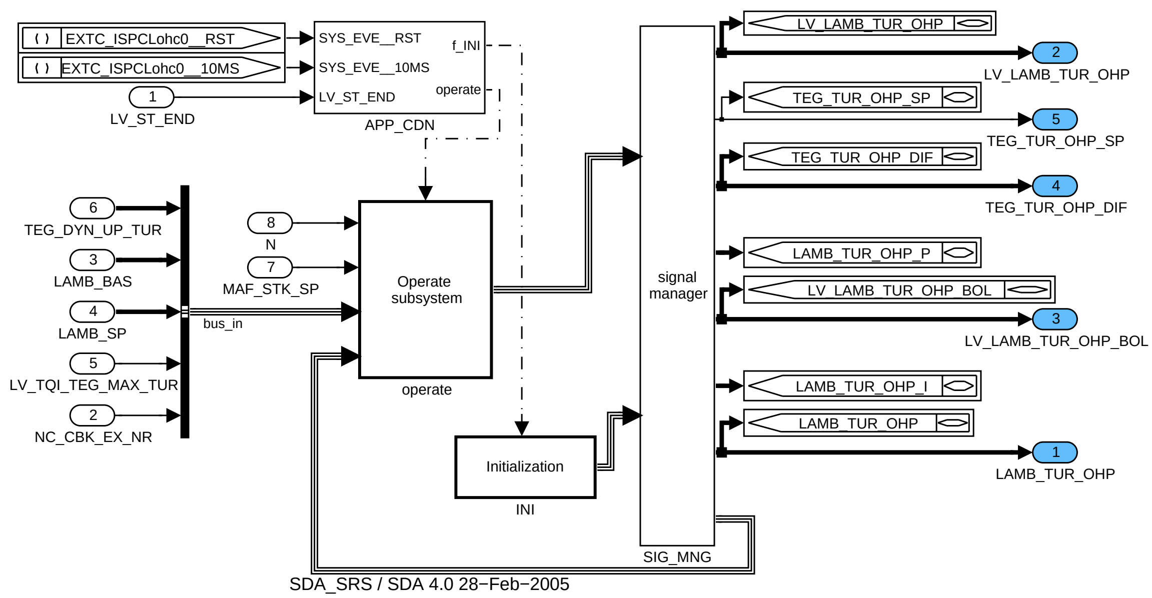

Figure 9 EXTC_ISPCLohc0

7.18.1.1 Initialization

The values are set to passive values at Reset and during engine stop.

7.18.1.2 Operate subsystem

Via IP_TEMP_TUR_OHP_SP the target temperature for the controller is generated. If this value is increasing it is filtered via C_CRLC_TEG_TUR_OHP_SP.

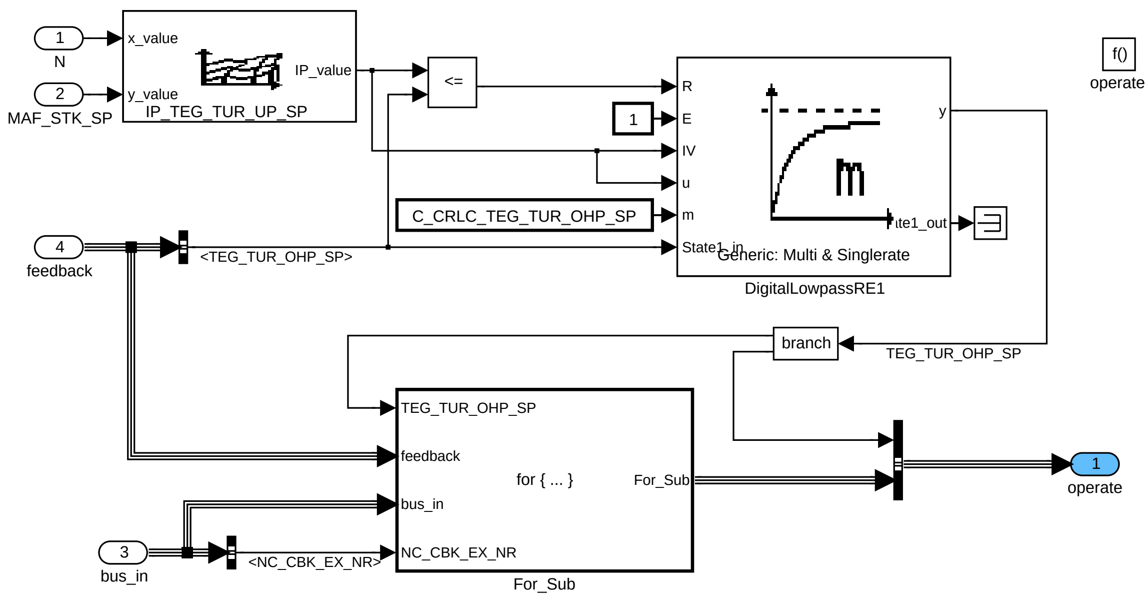

Figure 10 EXTC_ISPCLohc0/ operate

For – loop system

The calculations in this subsystem and lower are done for each exhaust bank separately –the variables have the index n. TEG_TUR_OHP_DIF is the control deviation and input for the controller. If it has negative values the temperature is too high and the controller is activated. There are two parts of the controller: 1. RAMP_DOWN for too high temperature and 2. RAMP_UP for deactivation ramp if TEG_TUR_OHP_DIF is again in positive range. LAMB_TUR_OHP_I <= LAMB_BAS is used for deactivation - to ramp LAMB_TUR_OHP until LAMB_BAS.

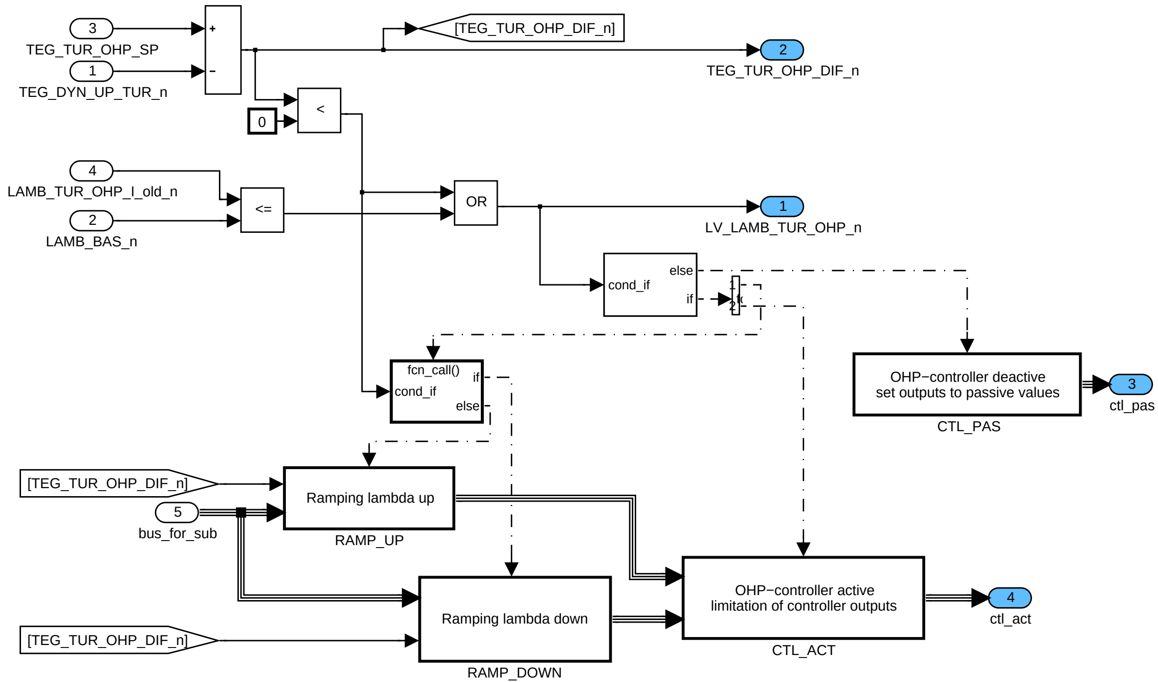

Figure 11 EXTC_ISPCLohc0/ operate/ For_Sub/ SUB

Ramping lambda up

If the temperature is lower than the setpoint the lambda-setpoint is ramped up again via P-Part and I-Part. With LC_LAMB_TUR_OHP_RAMP_UP it is ensured that the I-Part independent from the control deviation increases. The I-part is frozen as long as the torque reduction for overheating prevention is active (LV_TQI_TEG_MAX_TUR=1).

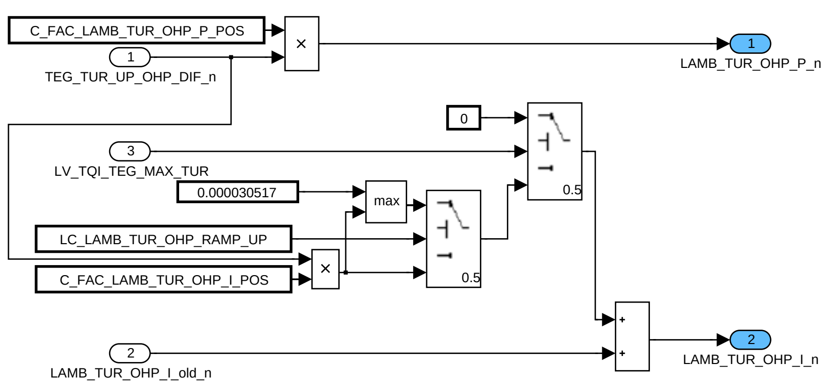

Figure 12 EXTC_ISPCLohc0/ operate/ For_Sub/ SUB/ RAMP_UP/ RAMP_UP_SUB

i

Ramping lambda down

If temperature is in critical range the lambda-setpoint is ramped down via a P-Part and an I-Part to reduce the temperature. Via LC_LAMB_TUR_OHP_RAMP_DOWN it can be ensured that the I-part is ramped down independent from the control deviation (with too small control deviation LAMB_TUR_OHP_I keeps its old value).

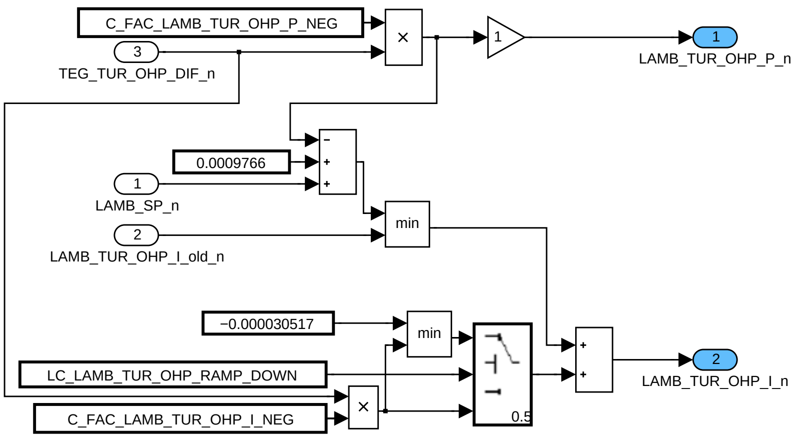

Figure 13 EXTC_ISPCLohc0/ operate/ For_Sub/ SUB/ RAMP_DOWN/ RAMP_DOWN_SUB

OHP-controller active -limitation of controller outputs

During active controller, the I- and P-Part either from RAMP_UP or from RAMP_DOWN subsystem are added. The I-Part and the addition-result are minimum-imitated. If one of this limitations is reached LV_LAMB_TUR_OHP_BOL is set to 1.

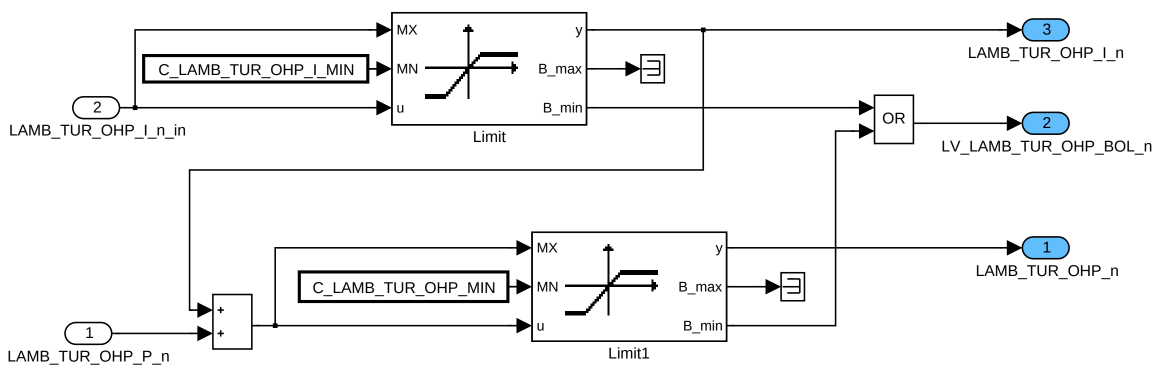

Figure 14 EXTC_ISPCLohc0/ operate/ For_Sub/ SUB/ CTL_ACT/ CTL_ACT_SUB

OHP-controller deactive -set outputs to passive values

This subsystem is calculated, if the controller is deactivated. The outputs are set to passive values.

7.19.1 General information

If the temperature in the exhaust gas line exceeds a certain limit, the catalyst converter or even the exhaust gas line can be destroyed. To reduce the temperature the lambda is ramped down.

Application Condition

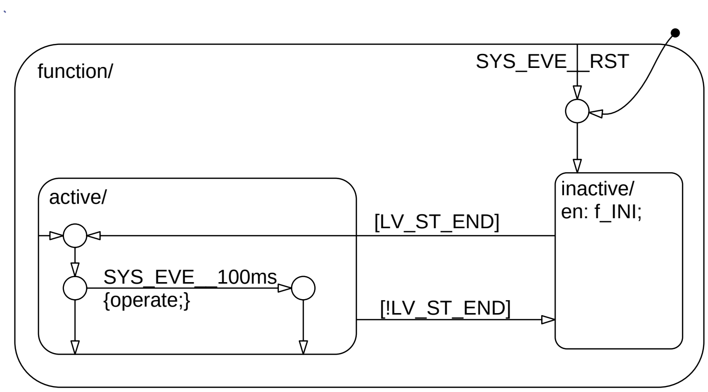

Figure 16 EXTC_REQGNOHL0/ APP_CDN/ Chart

Function Description

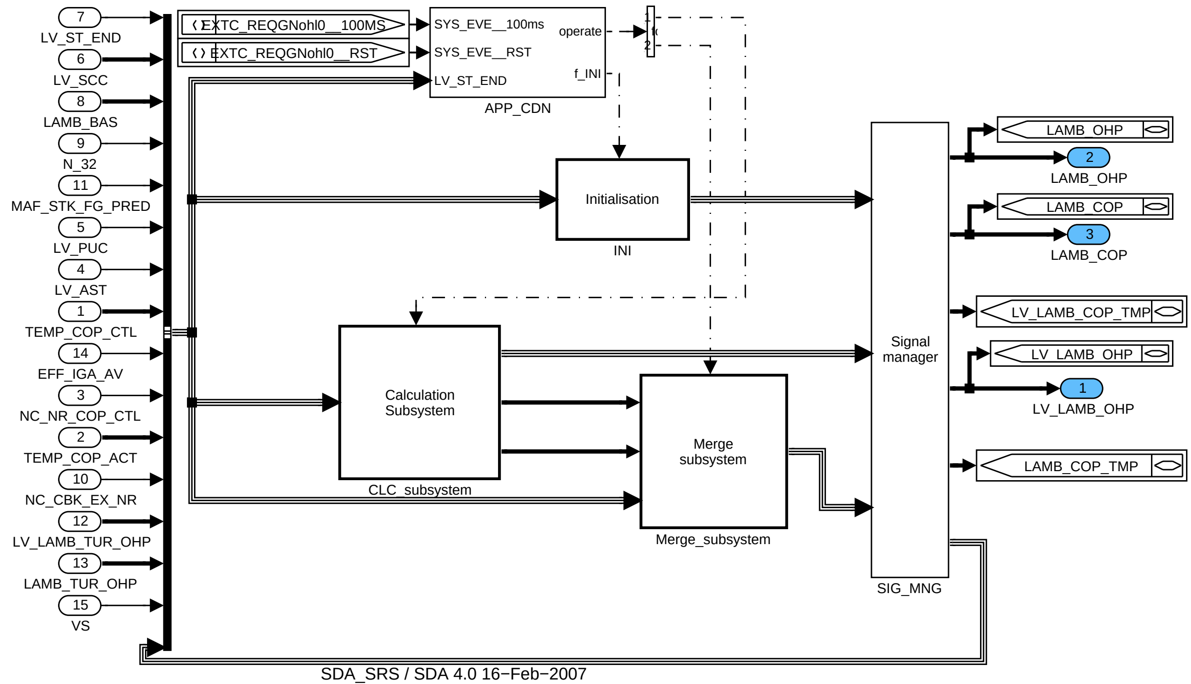

Figure 17 EXTC_REQGNOHL0

7.19.1.1 Initialisation

The values are initialised at reset. Each value of LAMB_COP_TMP is initialised with 32 and each of LV_LAMB_COP with 0.

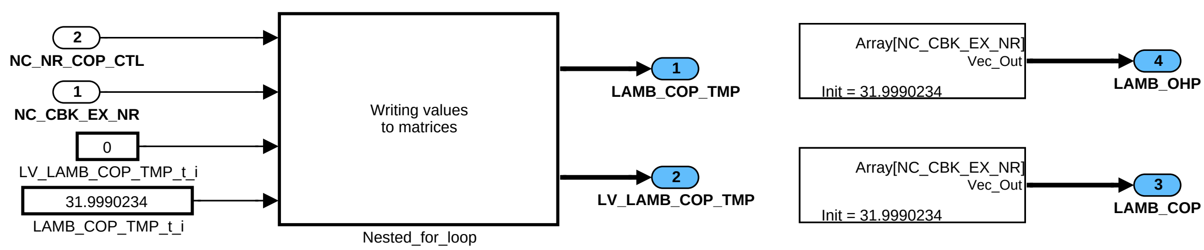

Figure 18 EXTC_REQGNOHL0/ INI/ SUB

7.19.1.2 Calculation subsystem

LAMB_COP_MIN is the minimum lambda-value for overheating prevention. LAMB_COP_PCTL is a pre-controlled value and is used for 1st value at controller activation or as additive part during active controller. This is selectable via LC_LAMB_PCTL_INI_COP.

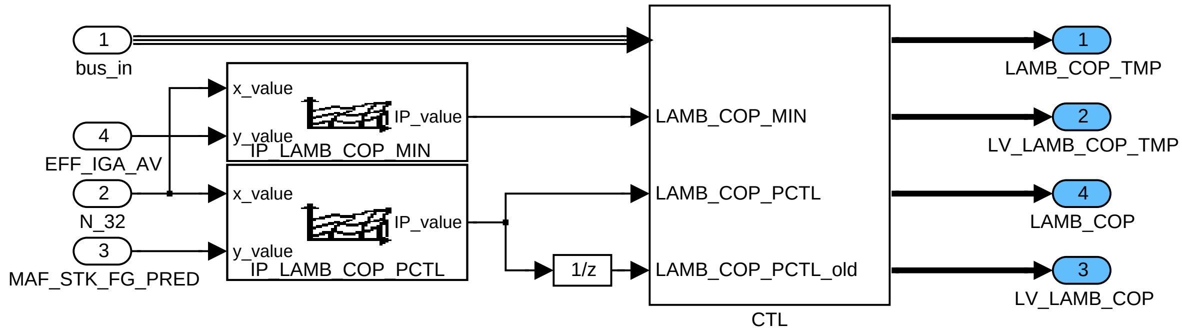

Figure 19 EXTC_REQGNOHL0/ CLC_subsystem/ SUB

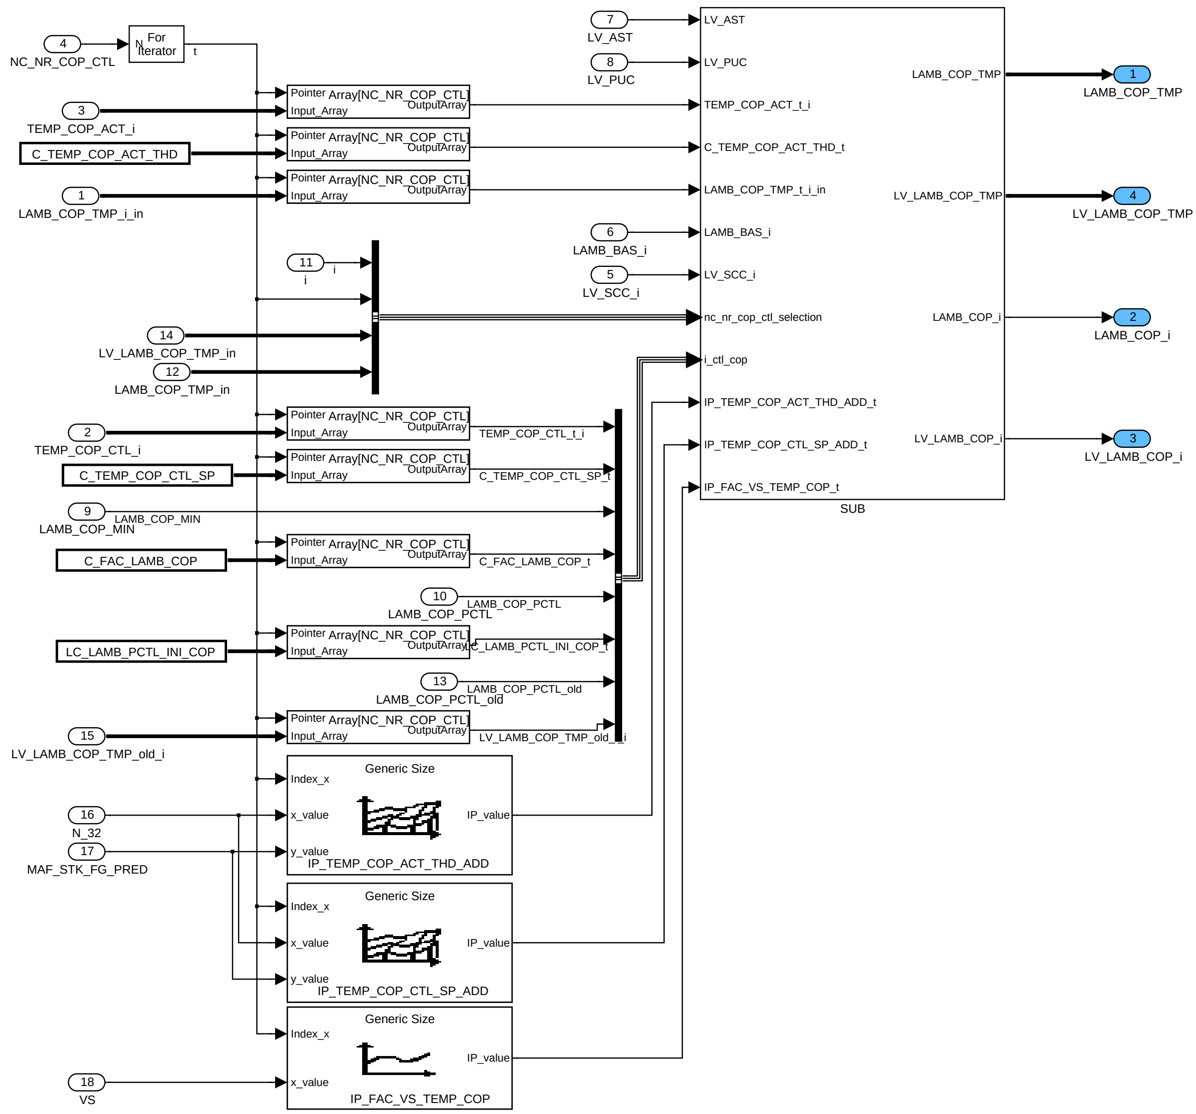

Figure 20 EXTC_REQGNOHL0/ CLC_subsystem/ SUB/ CTL/ bank_selection/ NC_NR_COP_CTL_selection

Activation/Deactivation

This function is inside a nested for-loop-system - one loop from 1 to NC_CBK_EX_NR (index = i) and the other one from 1 to NC_NR_COP_CTL (index = t).

NC_NR_COP_CTL is the number of catalyst overheating prevention controllers. TEMP_COP_CTL and TEMP_COP_ACT can contain 1 or 2 bankselective (NC_CBK_EX_NR) temperatures for e.g. exhaust gas temperature before catalysator and temperature in the catalyst.

The activation of the lambda controllers (for each bank 1 or 2 controllers) is done via TEMP_COP_ACT and C_TEMP_COP_ACT_THD.

If LAMB_COP_TMP_t_i > LAMB_BAS_i the lambda value is ramped up again and the controller can be deactivated.

In the subsystem vector_matrix the scalar LAMB_COP_TMP_t_i is written to a NC_NR_COP_CTL-vector LAMB_COP_INTER (LAMB_COP_i than is the richest lambda value for one exhaust bank) and to a NC_NR_COP_CTL/NC_CBK_EX_NR – dimensional matrix LAMB_COP_TMP. The same way for LV_LAMB_COP_TMP_t_i: LV_LAMB_COP_TMP is the matrix and LV_LAMB_COP is the bank-specific value.

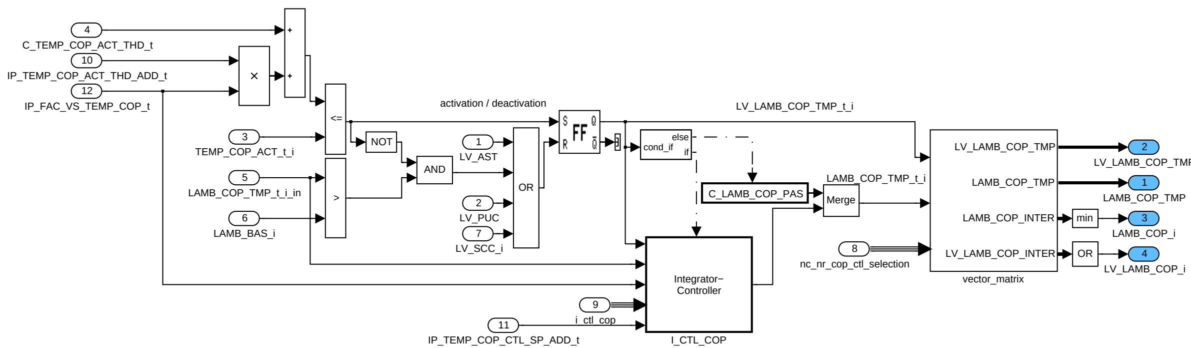

Figure 21 EXTC_REQGNOHL0/ CLC_subsystem/ SUB/ CTL/ bank_selection/ NC_NR_COP_CTL_selection/ SUB

Integrator-Controller

This I – controller is developed to be used with static temperatures, because in this way the control path is eliminated to avoid undesirable oscillation.

C_TEMP_COP_CTL_SP_t minus TEMP_COP_CTL_t_i is the control deviation.

The block "IntegratorKREL" integrates the Product of C_FAC_LAMB_COP_TMP_t and the control deviation. The output is limited to LAMB_COP_MIN and LAMB_COP_PAS.

If LC_ LAMB_PCTL_INI_COP is 1 the controller works as I-controller. If the LC is 0, the precontrolled part via IP_LAMB_COP_PCTL is also used.

7.20.1 General information

TEMP_COP_ACT and TEMP_COP_CTL are used in the module "Catalyst overheating prevention". The exhaust gas temperature before catalysator and the catalysator temperature are controlled for each bank – therefore the outputs are matrices (x-dimension: NC_CBK_EX_NR; y-dimension NC_NR_COP_CTL).

Application Condition

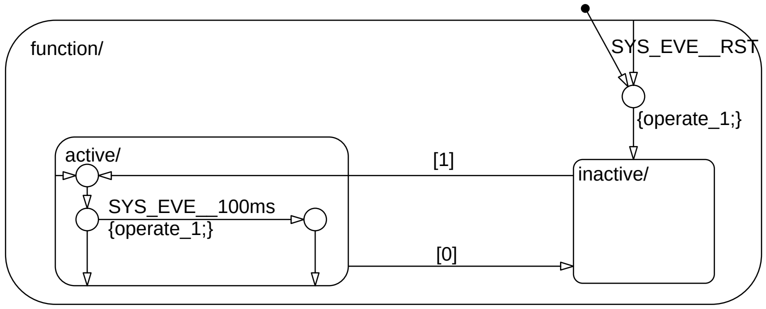

Figure 25 EXTC_ISPCLohpai0/ APP_CDN/ Chart

Function Description

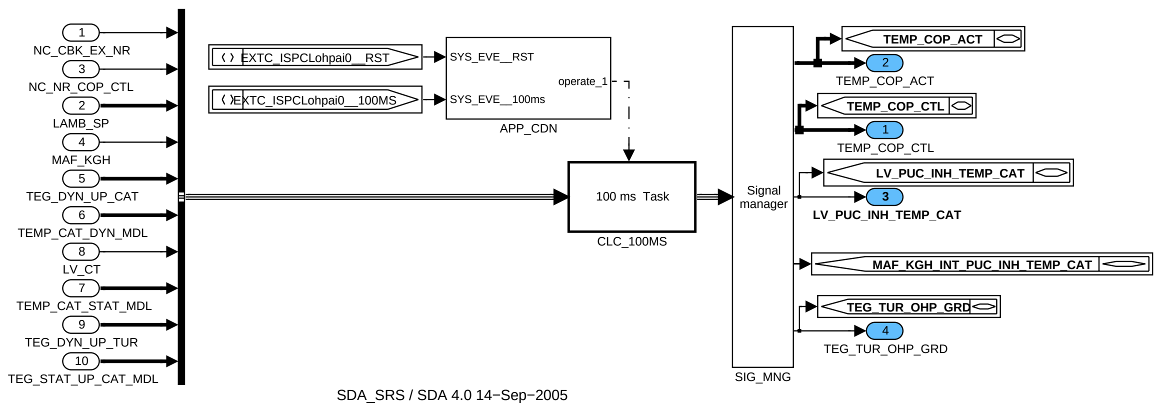

Figure 26 EXTC_ISPCLohpai0

7.20.1.1 100 ms Task

LV_PUC_INH_TEMP_CAT is set depending on catalyst temperature thresholds and reset after passing a hysteresis or if the clutch is opened or the driver request is 0. The activation threshold depends on a special MAF-integral that increases during mixture enrichment (HC-storage) and decreases in stoichiometric or even lean mixture.

TEG_TUR_OHP_GRD is used for turbine protection function activation.

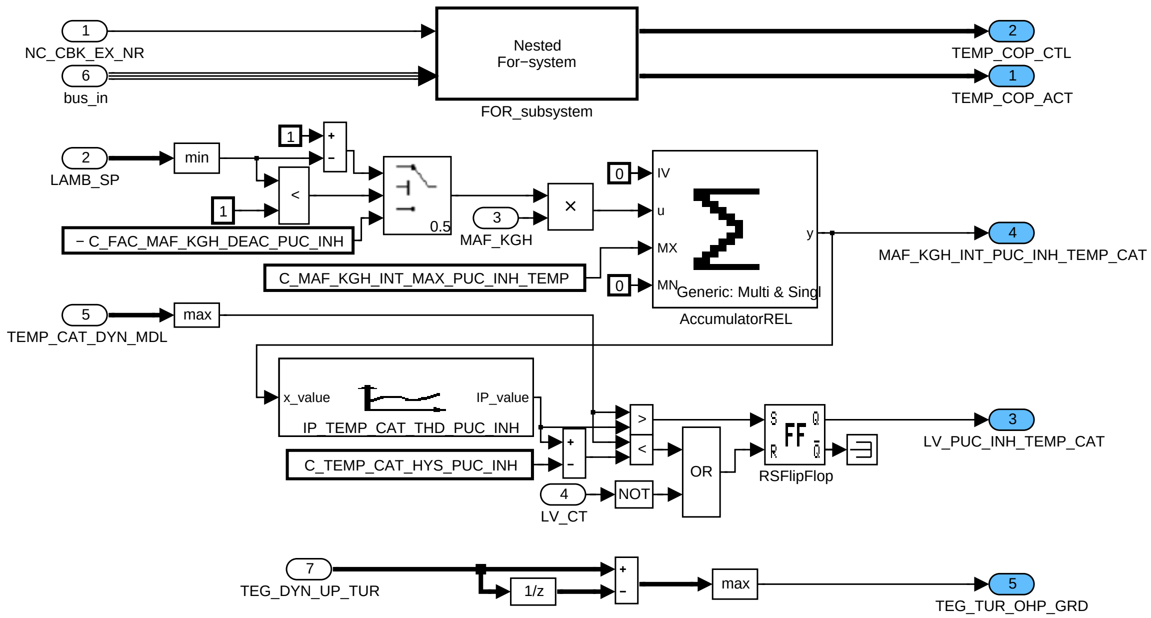

Figure 27 EXTC_ISPCLohpai0/ CLC_100MS/ SUB

Nested For-system

There are 2 temperature-controller for catalyst overheating prevention. The 1st one controls the temperatures before the catalyst and the 2nd one the catalyst temperature itself. For activation dynamic temperatures are used (TEG_DYN_UP_CAT and TEMP_CAT_DYN_MDL) and for controlling static temperatures are used (TEG_STAT_UP_CAT and TEMP_CAT_STAT_MDL).

7.21.1 General Information

In order to maximize the torque output of the engine at higher loads, it is possible to operate the engine with a richer fuel/air mixture. If full load conditions are detected (i.e. LV_FL=1), LAMB_FL will directly impact the lambda setpoint in the module ‘Lambda coordination’.

LAMB_FL is calculated from the map IP_LAMB_FL. In order to reduce torque jumps at the transition to Full load, the algorithm offers the possibility to define a ramp function for LAMB_FL by means of the map IP_LAMB_DEC_FL.

VS	LV_N_LIM_ETC_LIH	LV_ERR_MAP	LV_FQ_ST_AD
LV_PSTE	PSP	TCO	LV_ERR_TCO

FUNCTION DESCRIPTION:

General information:

In order to achieve an engine speed stabilization at idle (LV_IS), a mixture correction can be performed as soon as the idle speed control is active.

Injection time correction is calculated versus :

- Deviation to Nominal Idle Speed N_DIF_COR
- Catalyst Heating Torque Reserve TQ_ADD_CH (Slightly Lean Lambda can lead to engine speed undershoot in case of strong CH)

Two TCO_ST zones are defined in order to calibrate different corrections for emission area and for cold start area.

In order to avoid Engine Speed small oscillations when TI_IS is active, final TI-correction is filtered: in decreasing direction if TI_IS > 0, in increasing direction if TI_IS < 0.

Injection time correction is disabled in case of relevant failure.

Application conditions:

Activation : all engine operating states

FUNCTION DESCRIPTION:

General information:

The load detection provides an air-mass flow signal MAF (i.e. the airflow into the cylinder), that is valid for all engine operating states (and also during transient load changes). This value, which is updated segment synchronous, is used to calculate the basic injection time TIB.

To compensate the build-up / removal of the fuel film in the intake ducts, the instationary wall film compensation function provides a (additive) positive / negative injection time TI_ADD_WF.

The transient function is activated for the first time during the transition from the engine operating state ST to PL / IS and applies in all operating states (except ES and ST).

A 2nd order model, with a fast and a (nearly identical) slow part is used to compensate the quantity of the wall-applied fuel film (in the following referred to as "wall-film") stored in the intake ducts.

To obtain the load-dependend wall-film compensation, the wall-film differential quantity between two sampling steps is determined both, for the slow and the fast path on the basis of the injection period difference (i.e. load difference). The fast and slow part of the wall-film differential quantity is determined by two first-order time-delay elements. The total compensation quantity *TI_ADD_WF* is the sum of the fast and the slow quantity.

Calculation recurrence: segment synchronous

7.22.1 Initialization of the counter

Initialization: *if* LV_ST_END = 0 → 1 : SEG_CTR_WF = C_SEG_CTR_WF_INI

A segment counter SEG_CTR_WF is initialized with C_SEG_CTR_WF_INI at the transition from start to any other engine operating state and then decremented (every TDC) to zero.

7.22.2 Calculation of the wallfilm compensation (must be done every TDC)

Activation: *if* LV_ST_END = 1

7.22.2.1 Estimation of the direction of the load transient (LV_TIB_DIF_POS)

Based on the basic injection time TIB an estimation of the direction of load transient is done. If the injection time is increasing, the load is increasing (positive load transient, LV_TIB_DIF_POS = 1), otherwise a negative load is added (LV_TIB_DIF_POS = 0). To prevent jittering, a hysteresis IP_TIB_DIF_POS_HYS must be exceeded.

<u>Conversion TI to MFF:</u>

TIB = MFF_BAS * C_FAC_MFF_TI_STND_1

Only for the first calculation run do: TIB_{n-1} to $TIB_{n-NC\_CYL\_NR}$ = TIB_n (array)

if (LV_TIB_DIF_POS = 0) **and**
($TIB_n - TIB_{n-1}$) ≥ IP_TIB_DIF_POS_HYS

then

LV_TIB_DIF_POS = 1

endif

if (LV_TIB_DIF_POS = 1) and

($TIB_n - TIB_{n-1}$) ≤ - IP_TIB_DIF_POS_HYS

then

LV_TIB_DIF_POS = 0

endif

Note: For the first calculation cycle the variable LV_TIB_DIF_POS = 0.

(*n* denotes the actual and *n-1* the previous segment)

7.22.2.2 Determination of the wall-film differential quantity TI_DIF_FAST/SLOW_WF_POST_THD

The amount of the wall film stored in the intake duct *MASS_FAST/SLOW_WF* (which is proportional to the injection timing) depends on the engine speed, the load and the direction of the transient (LV_TIB_DIF_POS).

With the logical variables *LC_CYL_SEL_FAST/SLOW* it is possible to determine the change in wall-film amount cylinderselective (triggered by the segment number SEG_NR). <u>The maximum allowed number of NC_CYL_NR is in the current software limited to NC_CYL_NR = 8. This has to be changed if more required.</u>

The change of the wall-film due to the load transient is

if (LC_CYL_SEL_FAST = 1)
then
if (LV_TIB_DIF_POS = 1)
then
TI_DIF_FAST_WF =

$$\frac{IP\_MASS\_FAST\_POS\_WF(N\_32, TIB_n) - IP\_MASS\_FAST\_POS\_WF(N\_32, TIB_{n - NC\_CYL\_NR})}{NC\_CYL\_NR}$$

else

TI_DIF_FAST_WF =

$$\frac{IP\_MASS\_FAST\_NEG\_WF(N\_32, TIB_n) - IP\_MASS\_FAST\_NEG\_WF(N\_32, TIB_{n - NC\_CYL\_NR})}{NC\_CYL\_NR}$$

endif

else

if (LV_TIB_DIF_POS = 1)
then
TI_DIF_FAST_WF =

IP_MASS_FAST_POS_WF(N_32, TIB_n) – IP_MASS_FAST_POS_WF(N_32, TIB_{n-1})

else

TI_DIF_FAST_WF =

IP_MASS_FAST_NEG_WF(N_32, TIB_n) – IP_MASS_FAST_NEG_WF(N_32, TIB_{n-1})

endif

endif

for the fast path and

if (LC_CYL_SEL_SLOW = 1)
then
if (LV_TIB_DIF_POS = 1)
then
TI_DIF_SLOW_WF =

$$\frac{IP\_MASS\_SLOW\_POS\_WF(N\_32, TIB_n) - IP\_MASS\_SLOW\_POS\_WF(N\_32, TIB_{n - NC\_CYL\_NR})}{NC\_CYL\_NR}$$

else
TI_DIF_SLOW_WF =

$$\frac{IP\_MASS\_SLOW\_NEG\_WF(N\_32, TIB_n) - IP\_MASS\_SLOW\_NEG\_WF(N\_32, TIB_{n - NC\_CYL\_NR})}{NC\_CYL\_NR}$$

endif

else
if (LV_TIB_DIF_POS = 1)
then

TI_DIF_SLOW_WF =
IP_MASS_SLOW_POS_WF(N_32, TIB_n) - IP_MASS_SLOW_POS_WF(N_32, $TIB_{n - 1}$)

else

TI_DIF_SLOW_WF =
IP_MASS_SLOW_NEG_WF(N_32, TIB_n) - IP_MASS_SLOW_NEG_WF(N_32, TIB_{n-1})

endif

endif

for the slow path. This change in the amount of fuel stored in the wall film has to be compensated by the wall-film function.

If the difference in the wall-applied fuel mass is below a temperature dependent threshold, or it is negative and the number of segments after start is still below C_SEG_CTR_INH_NEG_WF, the injection time correction due to the wallfilm is prohibited.

TI_DIF_FAST_WF_THD = IP_TI_DIF_FAST_WF_THD , updated every second

```
if    abs( TI_DIF_FAST_WF ) < TI_DIF_FAST_WF_THD        or
      [        TI_DIF_FAST_WF < 0                   and
               C_SEG_CTR_INH_NEG_WF segments after start are not elapsed
]
then
               TI_DIF_FAST_WF_POST_THD = 0
else
               TI_DIF_FAST_WF_POST_THD = TI_DIF_FAST_WF
Endif
```

TI_DIF_SLOW_WF_THD = IP_TI_DIF_SLOW_WF_THD , updated every second

```
if  abs( TI_DIF_SLOW_WF ) < TI_DIF_SLOW_WF_THD          or
      [        TI_DIF_SLOW_WF < 0                   and
               C_SEG_CTR_INH_NEG_WF segments after start are not elapsed
]
then
               TI_DIF_SLOW_WF_POST_THD = 0
else
               TI_DIF_SLOW_WF_POST_THD = TI_DIF_SLOW_WF
endif
```

7.22.2.3 Temperature and engine speed correction of the wall-film compensation quantity

Depending on engine speed and coolant temperature the fuel quantity for wall-film compensation has to be corrected by a multiplicative factor. This factor is depending on the direction of the load transient:

POS applies if: $TIB_n - TIB_{n-1} \geq 0$
NEG applies if: $TIB_n - TIB_{n-1} < 0$

```
if    LV_TIB_DIF_POS = 1
then
      if    LV_IS = 1     and
            VS = 0        and
            abs (TIB[n] – TIB[n-1]) < IP_TI_DIF_WF_IS_POS
      then
            TI_COR_FAST_WF = TI_DIF_FAST_WF_POST_THD *
                             IP_TI_TCO_POS_FAST_WF_IS
            TI_COR_SLOW_WF = TI_DIF_SLOW_WF_POST_THD *
                             IP_TI_TCO_POS_SLOW_WF_IS
      else
            TI_COR_FAST_WF = TI_DIF_FAST_WF_POST_THD *
                             IP_TI_TCO_POS_FAST_WF
            TI_COR_SLOW_WF = TI_DIF_SLOW_WF_POST_THD *
                             IP_TI_TCO_POS_SLOW_WF
else
      if    LV_IS = 1     and
            VS = 0        and
            abs (TIB[n] – TIB[n-1]) < IP_TI_DIF_WF_IS_NEG
      then
                  TI_COR_FAST_WF = TI_DIF_FAST_WF_POST_THD *
                                   IP_TI_TCO_NEG_FAST_WF_IS
                  TI_COR_SLOW_WF = TI_DIF_SLOW_WF_POST_THD *
                                   IP_TI_TCO_NEG_SLOW_WF_IS
            else
                  TI_COR_FAST_WF = TI_DIF_FAST_WF_POST_THD  *
                                   IP_TI_TCO_NEG_FAST_WF
                  TI_COR_SLOW_WF = TI_DIF_SLOW_WF_POST_THD *
                                   IP_TI_TCO_NEG_SLOW_WF
endif
```

The compensation of effects due to intake air temperature at the inlet valves is done seperately for the fast and slow path

```
FAC_COR_TCYL_FAST_WF    =    IP_FAC_COR_TCYL_FAST_WF
FAC_COR_TCYL_SLOW_WF    =    IP_FAC_COR_TCYL_SLOW_WF
TI_COR_FAST_WF = TI_COR_FAST_WF * FAC_COR_TCYL_FAST_WF
TI_COR_SLOW_WF = TI_COR_SLOW_WF * FAC_COR_TCYL_SLOW_WF
```

After the calculation of TI_COR_FAST/SLOW_WF the software divides the result by 8. If the result is rounded, not the original, but the absolute value of TI_COR_FAST/SLOW_WF shall be rounded. That means, negative values between -1 and -7 would be (divided by 8 and) rounded to 0.

Correction of wall-applied fuel film during PU or PUC
During PU or PUC, a transfer from a slow wall-film quantity into a fast wall-film quantity can be obtained as a function of *C_FAC_WF_PU* or *C_FAC_WF_PUC*.

```
if    LV_PU
```

then

TI_DIF_FAST_PU_WF = TI_COR_FAST_WF +
(1- C_FAC_WF_PU) * TI_COR_SLOW_WF

*TI_DIF_SLOW_PU_WF = TI_COR_SLOW_WF * C_FAC_WF_PU*

elseif LV_PUC
then

TI_DIF_FAST_PU_WF = TI_COR_FAST_WF +
(1- C_FAC_WF_PUC) * TI_COR_SLOW_WF

TI_DIF_SLOW_PU_WF = TI_COR_SLOW_WF * C_FAC_WF_PUC

else

TI_DIF_FAST_PU_WF = TI_COR_FAST_WF

TI_DIF_SLOW_PU_WF = TI_COR_SLOW_WF

endif

7.22.2.4 Calculation of the fast and slow compensation quantity

The fuel quantity *TI_ADD_WF* needed to compensate the wall-applied fuel film consists of the following components: TI_FAST_WF for a quick compensation, *TI_SLOW_WF* for a slow compensation. At idle, the quick reduction constant IP_TI_CRLC_POS/NEG_FAST_WF is reduced by the adjustable value C_TI_CRLC_FAST_WF_IS. The wallfilm compensation quantity is now calculated as follows:

if LV_TIB_DIF_POS = 1 (positive load change)
then

TI_SLOW_WFn = TI_DIF_SLOW_PU_WFn * IP_TI_CRLC_POS_SLOW_WF +

(1 - IP_TI_CRLC_POS_SLOW_WF) * TI_SLOW_WFn-1

if (LV_IS = 0) (not in idle)
then

TI_FAST_WFn = TI_DIF_FAST_PU_WFn * IP_TI_CRLC_POS_FAST_WF +

(1 - IP_TI_CRLC_POS_FAST_WF) * TI_FAST_WFn-1

else (in idle: LV_IS = 1)

TI_FAST_WFn = TI_DIF_FAST_PU_WFn *

(IP_TI_CRLC_POS_FAST_WF - C_TI_CRLC_FAST_WF_IS) +

(1 - (IP_TI_CRLC_POS_FAST_WF - C_TI_CRLC_FAST_WF_IS)) *
TI_FAST_WFn-1

endif

else (negative load *LV_TIB_DIF_POS = 0*)

TI_SLOW_WFn = TI_DIF_SLOW_PU_WFn * IP_TI_CRLC_NEG_SLOW_WF +

(1 - IP_TI_CRLC_NEG_SLOW_WF) * TI_SLOW_WFn-1

if *(LV_IS = 0)* (not in idle)
then

TI_FAST_WFn = TI_DIF_FAST_PU_WFn *
IP_TI_CRLC_NEG_FAST_WF +

(1 - IP_TI_CRLC_NEG_FAST_WF) * TI_FAST_WFn-1

else (in idle: *LV_IS = 1)*

TI_FAST_WFn = TI_DIF_FAST_PU_WFn *

(IP_TI_CRLC_NEG_FAST_WF - C_TI_CRLC_FAST_WF_IS) +

(1 - (IP_TI_CRLC_NEG_FAST_WF - C_TI_CRLC_FAST_WF_IS)) *

TI_FAST_WFn-1

endif

endif

7.22.2.5 Thresholds for TI_FAST_WF and TI_SLOW_WF

To prevent the wall-film function from jittering, under steady state engine operating wall-film corrections are forbidden. If the absolute value of *TI_FAST/SLOW_WF* is less than the calibratable threshold *IP_TI_FAST/SLOW_WF_THD*, no correction of the injection timing will be performed. The thresholds are functions of the basic injection time TIB.

Setting the calibratable constant LC_DEAC_FAST_WF and / or LC_DEAC_SLOW_WF to one will deactivate the fast and / or slow path of the wallfilm compensation.

if abs(TI_FAST_WF) < IP_TI_FAST_WF_THD or

LC_DEAC_FAST_WF = 1

then

TI_FAST_WF_POST_THD = 0

else

TI_FAST_WF_POST_THD = TI_FAST_WF

endif

if abs(TI_SLOW_WF) < IP_TI_SLOW_WF_THD **or**

LC_DEAC_SLOW_WF = 1

then

TI_SLOW_WF_POST_THD = 0

else

TI_SLOW_WF_POST_THD = TI_SLOW_WF

Endif

7.22.2.6 Calculation of the total compensation quantity

The total transition compensation quantity *TI_ADD_WF* is calculated as follows:

TI_ADD_WF = TI_FAST_WF_POST_THD + TI_SLOW_WF_POST_THD

_+ TI_ADD_WF_VO

7.22.2.7 Calculation of wall film correction facor from fuel quality adaptation

FAC_TI_WF_COR_FQ = 1 + ((FAC_FQ_ST_AD * C_FAC_WF_FQ_ST_AD +

TI_IS_MMV_MAX – 1) * IP_FAC_FQ_WF)

7.22.2.8 Correction of TI_ADD_WF for the first tip in

A segment counter SEG_CTR_WF is initialized with C_SEG_CTR_WF_INI at the transition from start to any other engine operating state and then decremented to zero (see chapter 7.22.1).
Dependent on the actual value of SEG_CTR_WF and the coolant temperature at engine start (TCO_ST) the positive wall film compensations of TI_ADD_WF can be increased by a factor.

if TI_ADD_WF > 0 **and**
SEG_CTR_WF > 0

then

TI_ADD_WF = TI_ADD_WF *
(1 + IP_TI_TCO_ST_FAC_WF * IP_SEG_CTR_FAC_WF)

Endif

<u>Conversion of TI to MFF with fuel quality adaptation factor applied:</u>

* FAC_TI_WF_COR_FQ **else**

if LC_WF_COR_NEG_FQ_ENA = 1

then MFF_ADD_WF = TI_ADD_WF / C_FAC_MFF_TI_STND_1
/ FAC_TI_WF_COR_FQ

else MFF_ADD_WF = TI_ADD_WF / C_FAC_MFF_TI_STND_1

endif

endif

elseMFF_ADD_WF = TI_ADD_WF / C_FAC_MFF_TI_STND_1

7.22.2.9 endif**Correction of the wall-film compensation during post-start**

During engine start, the intake manifold pressure is initialized with the adapted ambient pressure. Subsequently the engine evacuates the manifold. Therefore a continously decreasing load signal is obtained, so that negative wall-film compensation quantities are calculated although a wall-applied fuel film is built-up. Therefore negative wall-film quantities are prohibited for C_SEG_CTR_INH_NEG_WF cycles: during the first C_SEG_CTR_INH_NEG_WF cycles (segments) after transition from engine operating state ST to PL or IS, *TI_ADD_WF* is limited to 0.

Input data:

LV_ST_END	VO	LV_PUC	TIB
TCO_ST	TCO	LV_IS	N_32
NC_CYL_NR	LV_TI_IS_MMV_MAX_DEAC		

FUNCTION DESCRIPTION:

General information:

The backflow of residual gas from the cylinder to the intake manifold depends on the actual valve overlap VO. With increasing VO the backflow increases and evaporates wall film from the intake valve disc and from the wall of the intake manifold until a new wall film equilibrium condition results. Especially at cold engine condition this additional fuel amount leads to a rich mixture within the cylinder. With decrasing VO the backflow decreases and the wall film is build up. This leads to a lean mixture within the cylinder.
In both cases the exhaust emissions downstream catalyst are negatively influenced.

This functionality compensates increase or lack of fuel amount within the cylinder.

Application conditions:

Initialisation:

at reset: FAC_WF_VO_FDOUT = 1

at LV_ST_END = 0 → 1:

FAC_TCO_ST_COR_WF_POS_VO = IP_FAC_TCO_ST_COR_WF_POS_VO

FAC_TCO_ST_COR_WF_NEG_VO = IP_FAC_TCO_ST_COR_WF_NEG_VO

(Temperature correction factors of the calculated wall film amount at start)

at LV_TI_IS_MMV_MAX_DEAC = 0 → 1: launch T_TPS_WF_VO_DEAC timer

Recurrence: segment synchronous

Deactivation: TCO > C_TCO_VO_COR_THD

Activation: LV_ST_END = 1 and (LC_WF_VO_COR_ENA_GLOBAL = 1 or LV_IS = 1)

Controlled reset factor of the injection time correction as a function of the energy flow through the engine					
MFF_SUM	V	0...FFFFH	0...44448	0.67823	mg
Total injected mass fuel flow since engine start					

Input data:

TCO	TIA_IM	MAF	LV_ST_END
TCO_ST	LV_PUC	MFF_SP_MV	

FUNCTION DESCRIPTION:

General Information:

To compensate the effects off wall film in the combustion chamber, the combustion chamber wallfilm compensation can be active parallel with post-start, warm-up, and catalyst heating. Thus an increase in the lean mixture at cold start can be avoided. The compensation factor FAC_CMBC_WF depends on integral of the mass fuel flow (MFF_SUM). The difference (TCO – TIA_IM) is used as an indicator for cold cylinder walls.

Application conditions:

Activation: LV_ST_END = 1

Deactivation: -

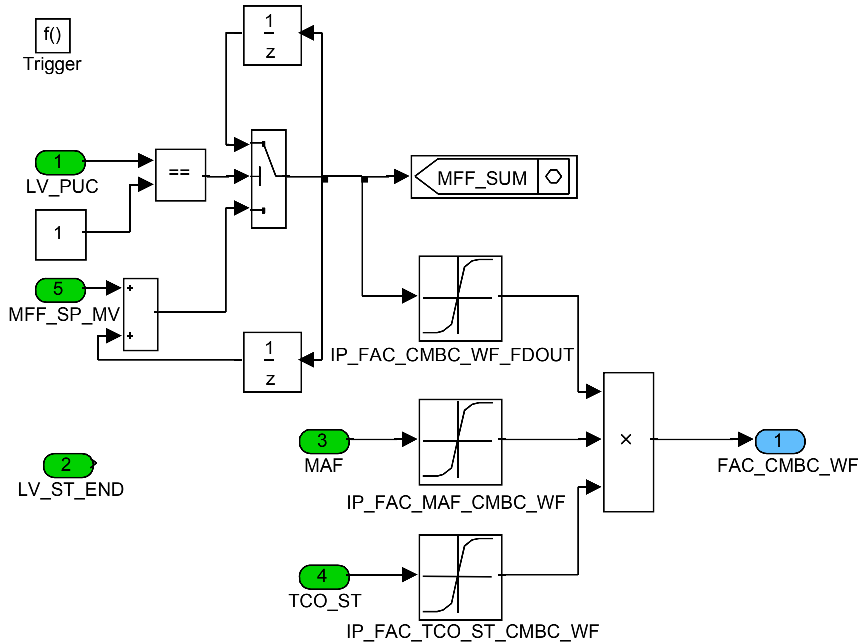
Initialisation: at reset: MFF_SUM = 0
FAC_CMBC_WF_FDOUT = 1

Recurrency: segment synchronous

Duration for the combustion chamber wallfilm compensation.

The value MFF_SP_MV is integrated and the function runs until a certain mass of fuel is reached.

Signal flow diagram:



Formula section:

(1) IF

(TCO – TIA_IM) < ID_TEMP_DIF_TCO_TIA

AND

FAC_CMBC_WF_FDOUT ≠ 0

(1) THEN

(2) IF

LV_PUC = 1

(2) THEN

7.24 Injection Pressure Correction – Homogeneous Mode, 1. Pulse

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TI_1_PRS_HOM	V/O	0 ... FFFFH	0...15.9997	2.4414e-4	-
correction factor to compensate the influence of the varying pressure difference at the injector, 1. pulse					
PRS_DEC_INJ_1_HOM	V/O	0 ... FFFFH	0...173888	2.65	hPa
pressure difference at the injector, 1. pulse					

Input data:

MAP	FUP	FAC_TI_TFU	LV_ST_END

FUNCTION DESCRIPTION:

General information:

The module calculates a correction factor to compensate the influence of the varying pressure difference at the injector (FUP – MAP) and the influence of the fuel temperature on the injected fuel mass.

Application conditions:

Activation: every engine state

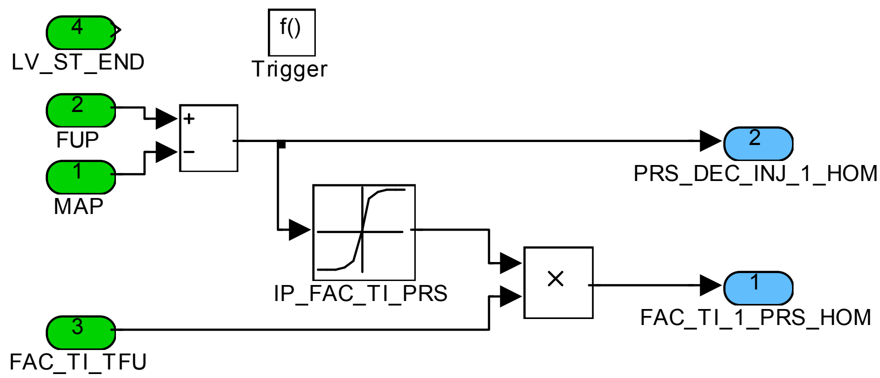
Deactivation: -

Initialisation: at reset: FAC_TI_1_PRS_HOM = 1

Update rate: LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment synchronous

Signal flow diagram:



Formula section:

The pressure difference at the injector, which is input for the map IP_FAC_TI_PRS, is calculated from fuel rail pressure and the manifold pressure.

PRS_DEC_INJ_1_HOM = FUP – MAP

(PRS_DEC_INJ_1_HOM is input data for IP_FAC_TI_PRS)

The total correction factor results from a multiplication of the output of IP_FAC_TI_PRS the fuel temperature dependent input variable FAC_TI_TFU.

FAC_TI_1_PRS_HOM = IP_FAC_TI_PRS * FAC_TI_TFU

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

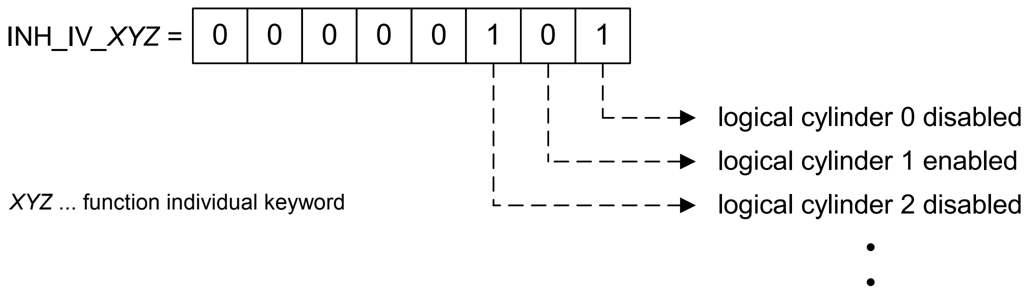
7.28 Cylinder Shut Off

__Overview__

Static fuel shut off:
In several engine operating- and system states and in case of malfunctions of the injection or ignition system the fuel injection must be disabled at individual cylinders. All the shut off requirements are coordinated, hence these requirements have to have the same structure as described below:



Dynamic fuel shut off:
The information which cylinder has to be shut off static, is coded within a byte (with the length of 8 bit) at the cylinder corresponding position.
In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.

Please note! Injections, which are already started, are not stopped.

INH_IV_MON =

0	0	0	0	0	0	0	0

ENDIF

7.28.1.4 Misfire Detection

INH_IV_MIS (Input pattern)

7.28.1.5 Pull Fuel Cut Off

To guarantee a moderate transition from trailing throttle PU to trailing throttle fuel cut off, the transition is handled by the module “Sequential fuel cut off and restart fuel feed”, see chapter Cylinder Individual Fuel Shut Off with Pattern. After the transition is finished (indicated by the flag LV_SEL_CYL) all cylinders are shut off by INH_IV_PUC.

IF LV_PUC = 1
AND
LV_SEL_CYL = 0

THEN all cylinders are shut off

INH_IV_PUC =	1	1	1	1	1	1	1	1

ELSE no cylinder is shut off

INH_IV_PUC =	0	0	0	0	0	0	0	0

ENDIF

7.28.1.6 Engine speed limitation

IF LV_N_MAX_REQ_FCUT = 1

THEN all cylinders are shut off

INH_IV_N_MAX_REQ_FCUT =	1	1	1	1	1	1	1	1

ELSE no cylinder is shut off

INH_IV_N_MAX_REQ_FCUT =	0	0	0	0	0	0	0	0

ENDIF

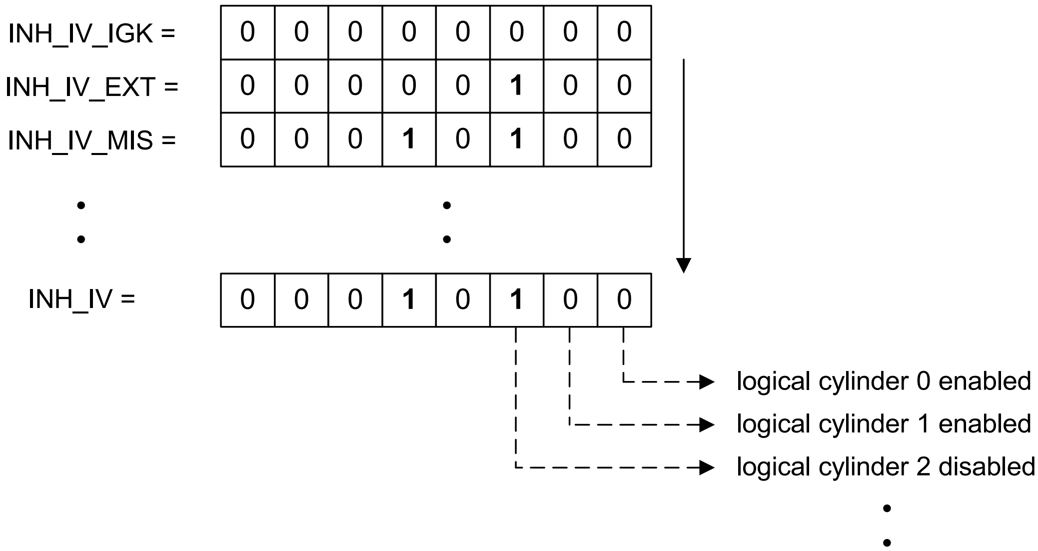
7.28.1.7 Shut Off Pattern from Application Incidences

INH_IV_EXT (Input pattern)

Additional shut off requirements are coordinated within the module “Cylinder Shut Off (Application Incidences)”.

7.28.1.8 Coordination of the Static Fuel Shut Off Requirements

The output pattern INH_IV is the bitwise OR of all pattern, linked with a mask $((2^{NC\_CYL\_NR})-1)$.
As an example see below:



Please note! Injections which are already started are not stopped.

7.28.2 Dynamic fuel shut off

In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.

Injections, which are already started, are not stopped.

The map ID_INH_SWI_IV contains (NC_CYL_NR * 2 +1) different pattern with calibrate able shut off sequences. Every pattern is allocated to an index NR_PAT (mapping points).

There are two requirements for “Dynamic fuel shut off” to this module:

NR_PAT_SEL_CYL is an index defined by the module “Sequential fuel cut off and restart fuel feed”.

NR_PAT_SCC is an index defined by the module “Torque based pattern calculation”.

NR_PAT is the index corresponding to the highest shut off level (number of cylinders disabled) of these both requirements. A certain pattern is repeated until this index changes.

NR_PAT_OLD = NR_PAT

NR_PAT = MAX (NR_PAT_SEL_CYL, NR_PAT_SCC)

INH_SWI_IV = ID_INH_SWI_IV

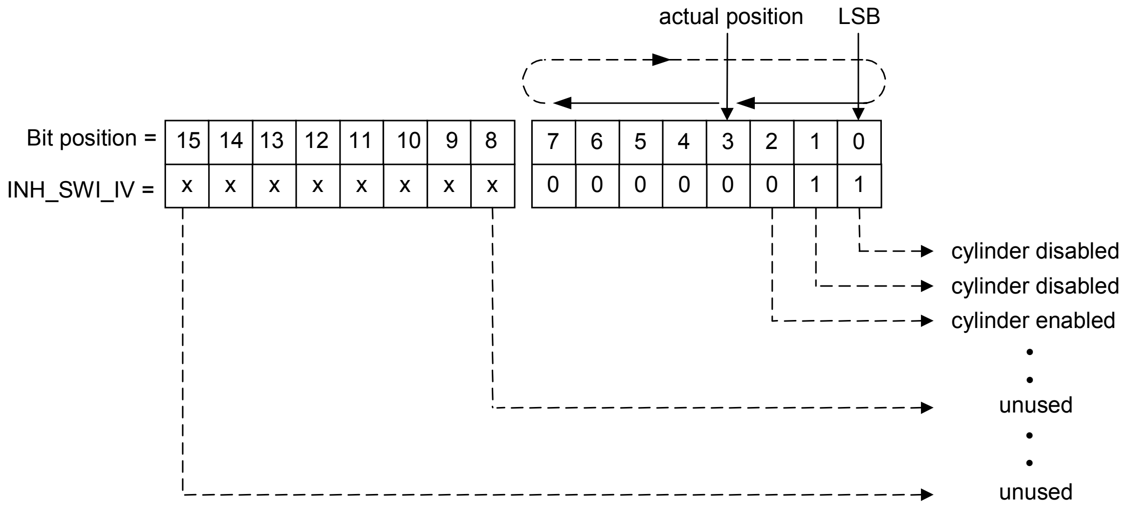
For example a map ID_INH_SWI_IV for an 4-cylinder engine with different shut off sequences :

Shut-off pattern (Index)	Pattern Binary according to firing number for 4cyl engine							
NR_PAT	1	3	4	2	1	3	4	2
0	0	0	0	0	0	0	0	0
1	1	0	0	0	0	0	0	0
2	1	0	0	0	1	0	0	0
3	1	0	0	1	0	0	1	0
4	1	0	1	0	1	0	1	0
5	1	1	0	1	1	1	0	0
6	1	1	1	0	1	1	1	0
7	1	1	1	1	1	1	1	0
8	1	1	1	1	1	1	1	1

Note:

To guarantee that the algorithm works correct, the table ID_INH_SWI_IV has to be applied as follows: The higher the index NR_PAT, the higher the number of cylinders deactivated.

<u>INH_SWI_IV is defined as follows:</u>



(e.g. NC_INJ_INH_SWI_IV_SHIFT_NR = 8, actual bit position = 4):

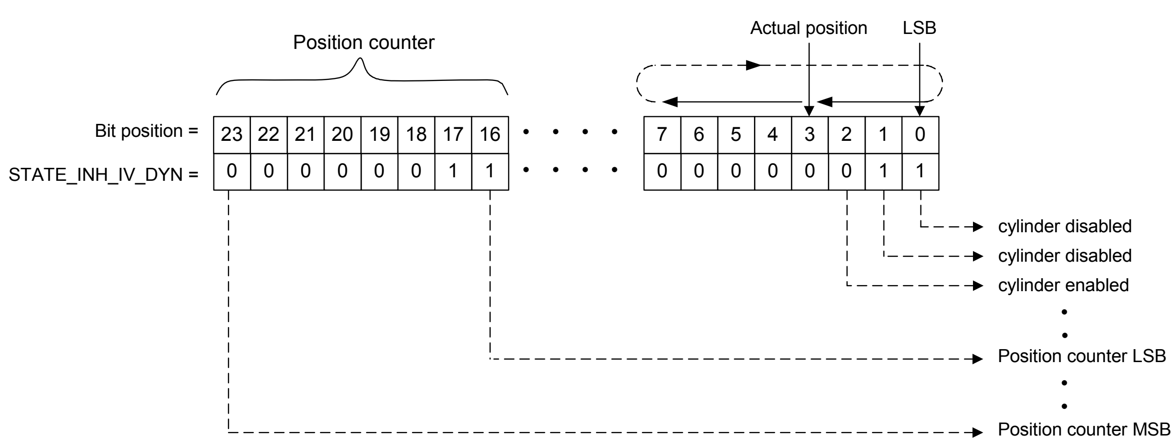
If the bit at a bit position = 1 → cylinder disabled
If the bit at a bit position = 0 → cylinder enabled

The length of the pattern is 16 bit. NC_INJ_INH_SWI_IV_SHIFT_NR defines how many bits are used for the shut off sequence.

NC_CYL_NR < = NC_INJ_INH_SWI_IV_SHIFT_NR < = 16

<u>Calculation of STATE_INH_IV_DYN:</u>

Definition of STATE_INH_IV_DYN:



Note! The position counter data field inside STATE_INH_IV_DYN will be updated at TRIG_EOI_LIM[x].
It contains the 'Actual position' inside the shut off pattern sequence.

Injection reactivation when leaving trailing throttle fuel cutoff:

For a fast injection reactivation when leaving trailing throttle fuel cutoff, the information of the shut off pattern for the dynamic shut off contained in INH_IV_DYN is reset, so INH_INJ is inmediatly reset (see subchapter "Coordination of shut off information for basic software"). The request to activate all cylinders is inmediatly done (INH_INJ = 0), so this allows a faster injection reactivation.It has to be taken into account, that depending on the injection phasing (SOI), the injection will be performed or not.

(1) IF LV_PUC: 1 -> 0 AND LC_ENA_FAST_INJ_REAC = 1

(1) THEN INH_IV_DYN = 0

(1) ENDIF

Select between two different algorithm for STATE_INH_IV_DYN calculation:

(1) IF LC_SWI_MOD_INH_IV_DYN = 0

(1) THEN Classic mode: If NR_PAT increases, then STATE_INH_IV_DYN starts always with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the 'Actual position' stays unchanged and a new shut off pattern – or the old one – is used based on INH_SWI_IV – see picture above.

(2) IF NR_PAT > NR_PAT_OLD

(2) THEN
Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(2) ELSE
Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:
STATE_INH_IV_DYN = STATE_INH_IV_DYN **AND** 0xFFFF0000 ...bitwise
OR ...bitwise
INH_SWI_IV **AND** 0x0000FFFF ...bitwise

Note! Pay attention of data consistency of STATE_INH_IV_DYN.

(2) ENDIF

(1) ELSE Modern mode: Only if NR_PAT was zero and increases, then STATE_INH_IV_DYN starts with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the 'Actual position' stays unchanged and a new shut off pattern – or the old one – is used based on INH_SWI_IV – see picture above.

(3) IF (NR_PAT_OLD = 0) **AND** (NR_PAT > NR_PAT_OLD)

(3) THEN
Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(3) ELSE
Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:

STATE_INH_IV_DYN = STATE_INH_IV_DYN **AND** 0xFFFF0000 ...bitwise
OR ...bitwise
INH_SWI_IV **AND** 0x0000FFFF ...bitwise

Note! Pay attention of data consistency of STATE_INH_IV_DYN.

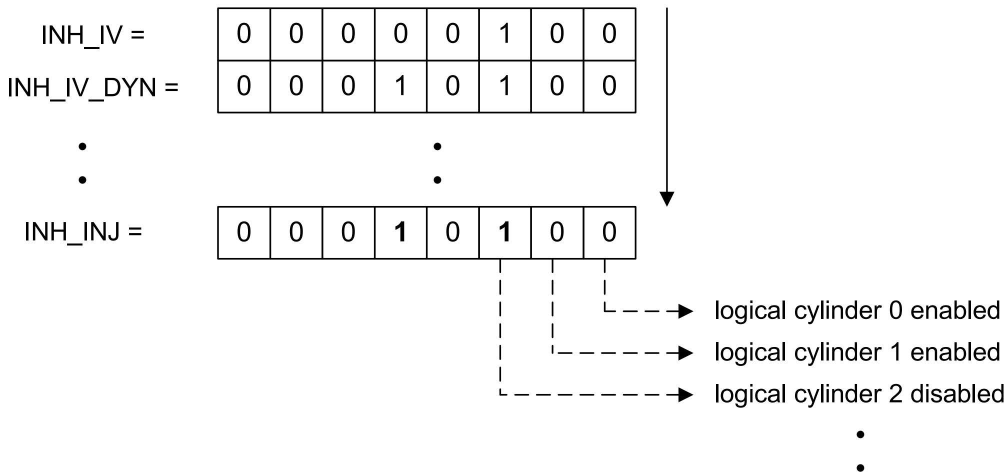
(3) ENDIF

(1) ENDIF

7.28.3 Coordination of shut off information for basic software (INH_INJ)

The output pattern INH_INJ is the bitwise OR of the pattern INH_IV and INH_IV_DYN, linked with a mask $((2^{NC\_CYL\_NR}) - 1)$.

As an example see below:



Note! Pay attention of data consistency of INH_IV.

7.28.4 Shut Off Status Information

SUM_INH_IV .... sum of INH_IV

SUM_INH_IV_CBK_i .... sum of those bits within INH_IV which are allocated to exhaust cylinderbank i, with i = 1 for exhaust cylinderbank 1 and i = 2 for exhaust cylinderbank 2.

SUM_INH_IV_DYN ..... sum of INH_IV_DYN

SUM_INH_INJ ..... sum of INH_INJ

SUM_INH_IV_TOT_CBK_i

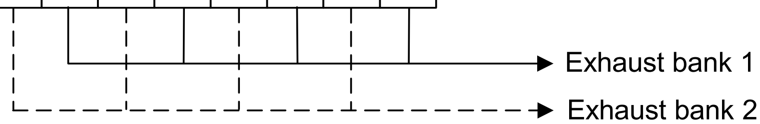
.... sum of those bits within INH_INJ which are allocated to exhaust cylinderbank i, with i = 1 for exhaust cylinder bank 1 and i = 2 for exhaust cylinderbank 2.

Note! Pay attention on data consistency of SUM_INH_INJ and SUM_INH_IV_DYN

Note:

The allocation between physical cylinders and exhaust cylinderbank 1 and 2 is defined by the pattern NC_LAMB_REF. For example an 8 cylinder engine:

7	6	5	4	3	2	1	0	... Logical Cylinder
1	0	1	0	1	0	1	0	... NC_LAMB_REF



```
(1) IF   SUM_INH_INJ <>  0
(1) THEN
        LV_FCUT_IND = 1            (at least one cylinder is shut off)
    (2) IF      SUM_INH_INJ >= NC_CYL_NR
    (2) THEN                       (all cylinders are shut off)
                LV_INJ_CUT = 1
                (3) FOR i = 1 TO NC_CBK_EX_NR DO:
                    LV_SCC[i] = 1        (i = 1 and 2, for exhaust cylinder bank 1 and 2)
                (3) ENDFOR
    (2) ELSE
                LV_INJ_CUT = 0
                (4) FOR i = 1 TO NC_CBK_EX_NR DO:
                    (5) IF      SUM_INH_IV_CBK[i] ≠ 0
                        Or      ( SUM_INH_IV_TOT_CBK[i] ≠ 0
                                And     LC_SWI_MOD_SCC = 1 )
                    (5) THEN
                            LV_SCC[i] = 1
                    (5) ELSE
                            LV_SCC[i] = 0
                    (5) ENDIF
                (4) ENDFOR
    (2) ENDIF
(1) ELSE
        LV_FCUT_IND = 0
        LV_INJ_CUT = 0
        (6) FOR i = 1 TO NC_CBK_EX_NR DO:
            LV_SCC[i] = 0
        (6) ENDFOR
(1)  ENDIF
```

Reccurence: if LV_ST_END = 0: 10 ms

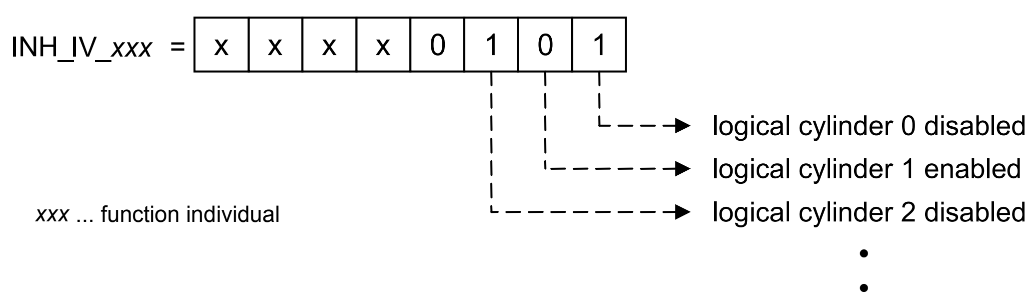
if LV_ST_END = 1: segment synchronous

Formula section:

7.29.1 General

In several engine operating- and system states and in case of malfunctions the fuel injection must be disabled at individual cylinders.

All the shut off requirements are coordinated, hence these requirements have to have the same structure as discribed below:



The information which cylinder has to be shut off static, is coded within a byte (with the length of 4 bit) at the cylinder corresponding position.

7.29.2 Static Fuel Shut Off Requirements

INH_IV_TPS_AD

Shut off request by TPS adaptation, for IGBT protection (all cylinders)

INH_IV_MIS_GEN

Shut off sequence from misfire generator, for tuning purposes (individual cylinders)

INH_IV_IMOB

Shut off request by Immobilizer (all cylinders)

if LV_IMOB_INJ_OFF = 1
then INH_IV_IMOB = xxxx1111
else INH_IV_IMOB = xxxx0000

INH_IV_DMF

Shut off request by Dual Mass Flywheel Oscillation Detection (all cylinders)

if LV_ENG_OFF_DMF_INJ = 1
then INH_IV_DMF = xxxx1111
else INH_IV_DMF = xxxx0000

INH_IV_ENSD

Shut off request by Backward Engine Rotation Detection (all cylinders)

if LV_IGN_INJ_LOCK_REQ = 1
then INH_IV_ENSD = xxxx1111
else INH_IV_ENSD = xxxx0000

INH_IV_EXT_ADJ

Shut off request from external service tester, only in IS available (individual cylinders)

7.29.3 Coordination of the Static Fuel Shut Off Requirements

The output pattern INH_IV_EXT is the bitwise OR of all pattern INH_IV_xxx.
As an example see below:

INH_IV_xxx =	x	x	x	x	0	0	0	0
INH_IV_yyy =	x	x	x	x	0	**1**	0	0
INH_IV_zzz =	x	x	x	x	**1**	**1**	0	0
•				•				
•				•				
INH_IV_EXT =	x	x	x	x	**1**	**1**	0	0

Basic function „Reactivation fuel feed at acceleration enrichment“					

Input data:

TCO	N_32	MFF_BAS	LV_STATE_PREV_IV_x
MAP	LV_ST_END	N_GRD	TPS_AV
TPS_GRD	NR_TRIG_EOI_LIM_PREV	NR_TRIG_EOI_LIM_AV	LV_FL
LV_CT	LV_PUC	LV_PU	LV_IS
LV_ES	LV_PL		

General information:

During PUC, the manifold wall-film becomes cut down until it has completely disappeared. In order to guarantee, after a cylinder shut-off, safe firing with fast torque build-up without misfiring of the reactivation cylinder, this must be supplied with an extra amount of fuel for the following reasons:

- increased charge due to lack of residual exhaust gas
- wall-film degradation during cylinder shut-off

Because of the different numbers of cutoff cycles for the cylinders, the extra fuel amount is calculated individually for each cylinder.

The following function delivers, for every cylinder, an additive extra fuel amount MFF_ADD_REAC_CYL_x which considers wall film degradation (partly or completely) as well as an overall factor FAC_TI_REAC for the first 15 engine working cycles after reactivation.

Application conditions:

Activation:	LV_ST_END = 1	
Deactivation:	-	
Initialisation:	at reset and if LV_ES = 0 → 1:	LV_INF = 0 LV_TI_RIS = 0 LV_TI_RPU = 0 LV_TI_RPL = 0 LV_TI_RAE = 0 FAC_TI_REAC = 1
	LV_ES = 0 → 1:	MFF_DIF_WF_x = 0 MFF_ADD_REAC_CYL_x = 0 FAC_TI_REAC_x = 1 CYCNR_REAC = 0
Recurrence:	different	

7.30.1 Control flags for simulation of wall film degradation

7.30.1.1 Intercept function : (LV_INF)

FUNCTION DESCRIPTION:

General information:

In the engine operating states trailing throttle (LV_PU) or trailing throttle fuel cut off (LV_PUC), the **intercept function (LV_INF)** can be enabled below an engine speed threshold C_N_MAX_INF.

For this purpose, the engine speed gradient N_GRD is monitored.

If the negative engine speed gradient exceeds the adjustable constant C_N_GRD_MIN during trailing throttle fuel cut off the injection will be reactivated to counteract the high negative engine speed gradient.

Formula section:

Recurrence: segment synchronous

If	LV_CT	=	1	**and**
	N_32	<	C_N_MAX_INF	**and**
	N_GRD	<	C_N_GRD_MIN	
then	LV_INF	=	1	
else	LV_INF	=	0	

7.30.1.2 Reactivation Fuel Feed functions : (LV_TI_REAC)

In order to rebuild the previously removed wall-applied fuel film during reactivation fuel feed from trailing throttle fuel cut-off (LV_PUC), the injection time is increased by a specific value.

Any transition LV_PUC → LV_IS / LV_PU / LV_PL triggers also the reactivation fuel feed function.

Formula section:

If one of the reactivation fuel feed functions is active **then** LV_TI_REAC is set to 1.

If the Reactivation function is terminated (see Ch. 7: Injection at restart fuel feed, all MFF_ADD_REAC_CYL_x = 0 and all FAC_TI_REAC_x = 1) **or** the engine operating state is neither LV_IS nore LV_PU nore LV_PL **then** LV_TI_REAC is set to 0.

7.30.1.2.1 At Transition from:

(the following calculations are done only at state transition)

PUC to IS

LV_TI_RIS = 1
LV_TI_REAC = 1

LV_TI_RPL = 0

LV_TI_RAE = 0

LV_TI_RPU = 0

PUC to PL

IF

7.30.2 Simulation of the wall film degradation

Recurrence: segment synchronous

Function description:

Determination of the logical cylinder to be calculated:

Effected logical cylinder x = NR_TRIG_EOI_LIM_AV

In addition:
IF
NR_TRIG_EOI_LIM_PREV not NR_TRIG_EOI_LIM_FMSP_OLD
THEN
an additional logical cylinder x = NR_TRIG_EOI_LIM_PREV is calculated
ENDIF

NR_TRIG_EOI_LIM_FMSP_OLD = NR_TRIG_EOI_LIM_AV

(NR_TRIG_EOI_LIM_FMSP_OLD ..... internal variable)

General information:

The wall-film degradation is represented with the cylinder-individual variables MFF_DIF_WF_x. With beginning cutoff of cylinder x, MFF_DIF_WF_x is allocated the negative current basic fuel mass MFF_BAS, multiplied by ID_FAC_MFF_TCO_NEG_WF. The multiplier takes into account the dependence of the wall film quantity on the coolant temperature. During cutoff of cylinder x, MFF_DIF_WF_x is incremented by an engine speed-dependent value ID_MFF_INC_WF every 720°CRK, until the cylinder cutoff is ended or until MFF_DIF_WF_x = 0 has occurred (MFF_DIF_WF_x > 0).
The start and stop of cylinder cutoff is distinguished by the cylinder selective variable LV_STATE_PREV_IV_x. This LV is updated once per 720°CRK at every cylinders EOI_LIM and shows whether an injection has occurred or not during the previous working cycle.

Formula section:

When LV_STATE_PREV_IV_x changed from 1 to 0:

MFF_DIF_WF_x = -MFF_BAS * ID_FAC_MFF_TCO_NEG_WF

When LV_STATE_PREV_IV_x is 0 and was 0 before:

$$MFF\_DIF\_WF\_x_n = MFF\_DIF\_WF\_x_{n-1} + ID\_MFF\_INC\_WF$$

If
$MFF\_DIF\_WF\_x_n > 0$
then
$MFF\_DIF\_WF\_x_n = 0$

7.30.3 Extra fuel quantity at reactivation

Recurrence: segment synchronous

Function description:

General information:

Additive extra fuel quantity: at reactivation of a cylinder the extra fuel quantity is composed from the current basic fuel mass MFF_BAS multiplied by ID_FAC_MFF_TCO_POS_WF, shortened by the cylinder individual remaining wall-film and multiplied by another factor dependant from manifold pressure MAP. In the subsequent course this extra fuel quantity is reduced by decrementing it till 0.

Multiplicative extra fuel quantity: at reactivation of a cylinder the counter CYCNR_REAC starts with 1 and will be incremented after every (main-) injection once per working cycle. The extra fuel amount is realised by the table value FAC_TI_REAC. Moreover, this factor depends on the type of reactivation.

Formula section:

If LV_STATE_PREV_IV_x changed from 0 to 1:
First enrichment after reactivation (last working cycle with LV_STATE_PREV_IV_x = 0):
MFF_ADD_REAC_CYL_x = (MFF_BAS * ID_FAC_MFF_TCO_POS_WF + MFF_DIF_WF_x) * IP_FAC_MFF_MAP_WF

If LV_STATE_PREV_IV_x is 0 and was 0 before:
MFF_ADD_REAC_CYL_x = (MFF_BAS * ID_FAC_MFF_TCO_POS_WF + MFF_DIF_WF_x) * IP_FAC_MFF_MAP_WF

Following enrichment (when LV_STATE_PREV_IV_x = 1):
$MFF\_ADD\_REAC\_CYL\_x_n = MFF\_ADD\_REAC\_CYL\_x_{n-1} - ID\_MFF\_DEC\_WF$
$MFF\_ADD\_REAC\_CYL\_x_n$ is limited to 0 and the calculation is finished when 0 is reached and 15 cycles are calculated.

When LV_STATE_PREV_IV_x changed from 0 to 1:
CYCNR_REAC_x = 1

Later: $CYCNR\_REAC\_x_n = CYCNR\_REAC\_x_{n-1} + 1$ (till = 16)

When CYCNR_REAC_x < 16,
then FAC_TI_REAC_x = ID_FAC_TI_RIS or ID_FAC_TI_RPL

ID_FAC_TI_RIS is used for “soft REAC” when (LV_TI_RIS = 1 or LV_TI_RPU = 1 LV_TI_RPL = 1) and LV_INF = 0 and LV_FL = 0 and LV_TI_RAE = 0
ID_FAC_TI_RPL is used for “hard REAC” in all other cases.

If
LV_TI_RPL or LV_TI_RAE
then
if
TPS_GRD ≥ ID_TPS_GRD_BOL_AE

then
LV_TI_RAE = 1
LV_TI_RPL = 0
else
LV_TI_RAE = 0
LV_TI_RPL = 1
endif
endif

If
(LV_TI_RIS = 1 or LV_TI_RPU = 1 or LV_TI_RPL = 1)
and LV_INF = 0
and LV_FL = 0
and LV_TI_RAE = 0
then
FAC_TI_REAC_x = ID_FAC_TI_RIS
else
FAC_TI_REAC_x = ID_FAC_TI_RPL
endif

If a change of the status “soft REAC” to the status “hard REAC” once occurs (change from ID_FAC_TI_RIS to ID_FAC_TI_RPL), the status “hard REAC” is kept until the reactivation is finished (all variables FAC_TI_REAC_x are similar to 1).

If CYCNR_REAC_x = 16,
then FAC_TI_REAC_x = 1.0

LV_PU	LV_PUC	LV_PL	LV_IS
LV_DT	LV_AT	GEAR	LV_ES
LV_ST	T_SEG_AV		

FUNCTION DESCRIPTION:

General information:

At transition from trailing throttle to trailing throttle fuel cut off, torque jumps generally occur at trailing throttle fuel cut off which are noticeable as jerks in the vehicle. To reduce the torque at this transition, the ignition timing is retarded and the combustion air is adjusted to small values.

These procedures however do not always achieve the required torque reduction, because ignition timing and combustion air can only be reduced that far, that jerk free engine operation is still possible.

To support the above mentioned torque reduction measurement, it is possible that the injection is switched on and/or switched off for individual cylinders within a defined number of engine cycles (on and/or deactivation) incase of PUC and reentry into Idle.

The engine speed gradient is monitored in order to cancel the selective reentry idle at rapid engine speed drops. If the engine speed gradient is below the threshold C_N_GRD_MIN_SEL_RIS or N_DIF_COR is greater than or equal to C_N_DIF_MAX_SEL_RIS then all cylinders are immediately activated (Pattern index 0)

7.31.1 Calculation of TQI_SP_SLOW dynamic

Description:

This value is needed for fast restart of fuel feed.

Application conditions:

Initialisation: TQI_SP_SLOW_DIF = 0

Recurrence: 20ms

Activation: at every engine state

Deactivation: -

Formula section:

TQI_SP_SLOW_DIF = TQI_SP_SLOW(n) - TQI_SP_SLOW(n-1)

7.31.2 NR_PAT_SEL_CYL calculation

Recurrence: Segment-synchronous

7.31.2.1 Calculation of T_OSC_DT:

```
if LV_AT = 0
then      T_OSC_DT = ID_T_OSC_DT(GEAR)
else      T_OSC_DT = 0
endif
```

Description (Example for 4-cylinder engines)

At a transition LV_PU → LV_PUC,. LV_PUC → LV_IS and LV_PUC → LV_PL , 32 cycles (8 x 720°CRK) in case of a 4-cylinder can be influenced. To realize this, a table ID_PAT_SEL_CYL contains the sequences of injection patterns (0...7), predefined in the table ID_PAT_IND. “ NR_SEL_CYL ” means the logical number in the shut off sequence (1...8).

Application conditions:

Activation:

At active cylinder specific transitions LV_SEL_CYL =1

7.31.2.2 Transition from PU → PUC (CASE 1)

The entrance in the transition pattern for PUC follows, when all conditions for PUC are fulfilled.

if LC_ENA_FCUT_AJ = 0 or LV_AT = 1
then
NR_SEL_CYL starts from 1 and is incremented every 720 °KW until its maximum value. In case of deactivation NR_SEL_CYL is reset to 1.

```
else
if (LV_DT = 0 and LC_INH_DT_PU = 0)
then    NR_SEL_CYL = 8
        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
        T_FCUT_AJ is initialized with T_OSC_DT / 2
else    NR_SEL_CYL = C_NR_SEL_CYL_1
        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
        LV_SEL_CYL = 1
        if T_FCUT_AJ - T_SEG_AV = 0
```

then NR_SEL_CYL = 8

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)

T_FCUT_AJ is initialized with T_OSC_DT / 2

LV_SEL_CYL = 0

else $NR\_SEL\_CYL_n = NR\_SEL\_CYL_{n-1}$

T_FCUT_AJ is decremented

end

end

end

The transition is completed, when the last of the 32 transition cycles has run out. The pattern index applied as last one has to be the highest used for the cut-off strategy , that means all cylinders are cut off. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern or while the time sequence an engine operating state change to PU, PL or IS happens, all cylinders are switched on immediatedly (pattern index : “0“), NR_SEL_CYL is reset to 1.

7.31.2.3 Transition from PUC → IS or PUC → PU (CASE 2)

The entrance in the transition pattern for RIS (reactivation idle speed) follows, when all conditions for IS resp. PU are fulfilled.

if LC_ENA_FCUT_AJ = 0 or LV_AT = 1

then

NR_SEL_CYL starts from 1 and is incremented every 720 °KW until its maximum value.

else

if (LV_DT = 0 and LC_INH_DT_PU = 0)

then NR_SEL_CYL = 8

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)

T_FCUT_AJ is initialized with T_OSC_DT / 2

else NR_SEL_CYL = C_NR_SEL_CYL_2

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)

LV_SEL_CYL = 1

if T_FCUT_AJ - T_SEG_AV = 0

then NR_SEL_CYL = 8

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)

T_FCUT_AJ is initialized with T_OSC_DT / 2

LV_SEL_CYL = 0

else $NR\_SEL\_CYL_n = NR\_SEL\_CYL_{n-1}$

T_FCUT_AJ is decremented

end

end

end

The transition pattern is completed, when the last cycle of the 32 transition cycles has run out. The pattern number applied as last one has to be „0“ , that means all cylinders are switched on. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern or while time sequence a engine operating state change to PUC happens, the transition pattern or time sequence for RIS runs out to its end and after that the transition pattern for PUC starts, if required.

If the function is deactivated (see deactivation conditions), all cylinders are switched on immediatedly. In case of deactivation NR_SEL_CYL is reset to 1.

7.31.2.4 Transition from PUC → PL (CASE 3)

The entrance in the transition pattern for RPL (reactivation part load) follows, when all conditions for PL are fulfilled.

```
if LC_ENA_FCUT_AJ = 0 or LV_AT = 1
then
        NR_SEL_CYL starts from 1 and is incremented every 720 °KW until its
        maximum value. In case of deactivation NR_SEL_CYL is reset to 1.
else
        if (LV_DT = 0 and LC_INH_DT_PU = 0)
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                T_FCUT_AJ is initialized with T_OSC_DT / 2
        else    NR_SEL_CYL = C_NR_SEL_CYL_3
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                LV_SEL_CYL = 1
                if T_FCUT_AJ - T_SEG_AV = 0
                then    NR_SEL_CYL = 8
                        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                        T_FCUT_AJ is initialized with T_OSC_DT / 2
                        LV_SEL_CYL = 0
                else    NR_SEL_CYL_n = NR_SEL_CYL_n-1
                        T_FCUT_AJ is decremented
                end
        end
end
```

The transition pattern is completed, when the last cycle of the 32 transition cycles has run out. The pattern number applied as last one has to be „0“ , that means all cylinders are switched on. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern a engine operating state change to PUC happens, the transition pattern for reentry PL runs out to its end and after that the transition pattern for PUC starts, if required. If the function is deactivated, all cylinders are switched on immediatedly.

Deactivation:

- LV_ES = 1 **or**
- LV_ST = 1 **or**
- LV_IGK = 0 **or**
- Pattern completed **or**
- N_GRD ≤ C_N_GRD_MIN_SEL_RIS **or**
- N_DIF_COR ≥ C_N_DIF_MAX_SEL_RIS **or** (only valid for transition PUC → IS resp PUC → PU ; checked each segment)
- TQI_SP_SLOW_DIF ≥ C_TQI_SP_SLOW_DIF_MAX (only valid for transition PUC →PL; checked each segment)

At passive cylinder specific transitions:

LV_SEL_CYL = 0 and NR_SEL_CYL = 1

T_FCUT_AJ is initialized with T_OSC_DT / 2

Transition tables

The transition pattern indexes are adjustable in the table ID_PAT_SEL_CYL. There are 8 fade out patterns which are applicable per transition table (definition of patterns see chapter 7, "Cylinder shut off with pattern").

The following cases are distinguished in ID_PAT_SEL_CYL:

CASE 1: Trailing throttle fuel cut off (PUC)
CASE 2: Restart IS (RIS)
CASE 3: Restart PL (RPL)

Example for shut-off sequences with 8 levels and a shut off pattern for the 4 next injections (4-cylinder)

CASE_SEL_CYL↓ NR_SEL_CYL →

	1	***2***	***3***	***4***	***5***	***6***	***7***	***8***
1	1	1	2	2	3	3	4	4
2	5	5	5	6	6	7	7	0
3	5	6	6	7	0	0	0	0

According shut off sequences: (0 : Injection, 1: no injection)

Case 1 1 0 0 0 1 0 0 0 1 0 1 0 1 0 1 0 1 0 1 1 1 0 1 1 1 1 1 1 1 1 1 1

Case 2 0 1 1 1 0 1 1 1 0 1 1 1 0 1 0 1 0 1 0 1 0 0 0 1 0 0 0 1 0 0 0 0

Case 3 0 1 1 1 0 1 0 1 0 1 0 1 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Formula section:

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL

Application assistances

Handling of reactivation functions (out of PUC):

Injection (Reactivation fuel feed) : To ensure, that all cylinders get at least once the same amount of TI_ADD_REAC, TI_ADD_REAC is not decremented as long as sequential transition PUC → IS resp. PUC → PL is ongoing.

Ignition: The according reactivation functions are not concerned by sequential transition functions.

Handling of engine states:

The detection of PU, PUC, PL and IS is not concerned by sequential transition functions.

LV_ST_END			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The Lambda probe is initialized as not operable (LV_LS_UP_READY[i] = 0, LV_LS_UP_READY_CDN[i] = 0) after leaving engine start. Also, a delay of length ID_T_DLY_CHK_LS_UP_READY is started, which has to pass before the main part of the readiness check is enabled.

Independently, a warmup delay timer starts with the value of ID_T_TOUT_LS_UP_READY whenever a prolonged fuel cut off phase has ended or if the dewpoint was exceeded for the first time in a driving cycle. This is to diagnose the time until readiness recognition after start and after excessive cooling due to driving conditions. The flag LV_T_TOUT_LS_UP_READY[i] is set if this time has elapsed and readiness check is enabled via LV_T_DLY_CHK_LS_UP_READY[i].

The Lambda probe is recognized as ready when VLS_UP[i] falls below the lean voltage threshold C_VLS_UP_AFL_THD_READY or when VLS_UP[i] rises above the rich voltage threshold C_VLS_UP_AFR_THD_READY or when the internal resistance R_IT_LS_UP[i] falls below the threshold C_R_IT_THD_LS_UP_READY.

The initial delay occurs only once after engine start, while the warmup delay is applied every time the dewpoint is revoked or a long fuel cutoff phase is detected. If extended fuel cutoff is expected to cool down the sensor too much, a limit for the mass air flow integral during PUC may also be applied.

Limited operability

If a heater error (LV_ERR_LSH_UP[i] = 1) or a sensor signal stroke error (LV_ERR_STK_LS_UP[i] = 1) is present, readiness detection will take into account heating by the exhaust gas. The flag LV_LS_UP_READY_CDN[i] is set to indicate this limited operability condition. In this mode, readiness is assumed if the exhaust gas temperature exceeds the threshold C_TEG_DYN_MIN_LS_UP_READY, the dewpoint was passed and the signal has exceeded the limits of C_VLS_UP_AFL_MAX_DIAG_READY or C_VLS_UP_AFR_MIN_DIAG_READY at least once.

Readiness is revoked if the temperature falls below the threshold. The flag LV_T_TOUT_LS_UP_READY[i] is reset to zero and the warmup timer is restarted as soon as the temperature is high enough again.

REMARKs:

1) Delayed readiness detection is monitored by testing for (LV_T_TOUT_LS_UP_READY[i] = 1 and LV_LS_UP_READY[i] = 0). If necessary for other reasons, closed loop lambda control after ID_T_TOUT_LS_UP_READY timeout may be forced by using (LV_T_TOUT_LS_UP_READY[i] = 1) as an alternative condition for closed loop enable.
2) This revision of readiness detection relies on a good dewpoint detection to run soon after engine start.
3) If excessive cooling in PUC is not a concern, C_MAF_INT_PUC_MAX_LS_UP_READY must be set to its upper limit (hex value FFFFh). If readiness must be revoked during long PUC phases, this constant should be set to the maximum length of a PUC phase which is tolerated by the sensor.

FUNCTION DESCRIPTION:

General information:

If two separate cylinder banks are concerned, then
 i = 1, for cylinder bank 1
 i = 2, for cylinder bank 2

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account.

The function shall permit oxygen sensor heating under open and closed loop control.

Signal flow:

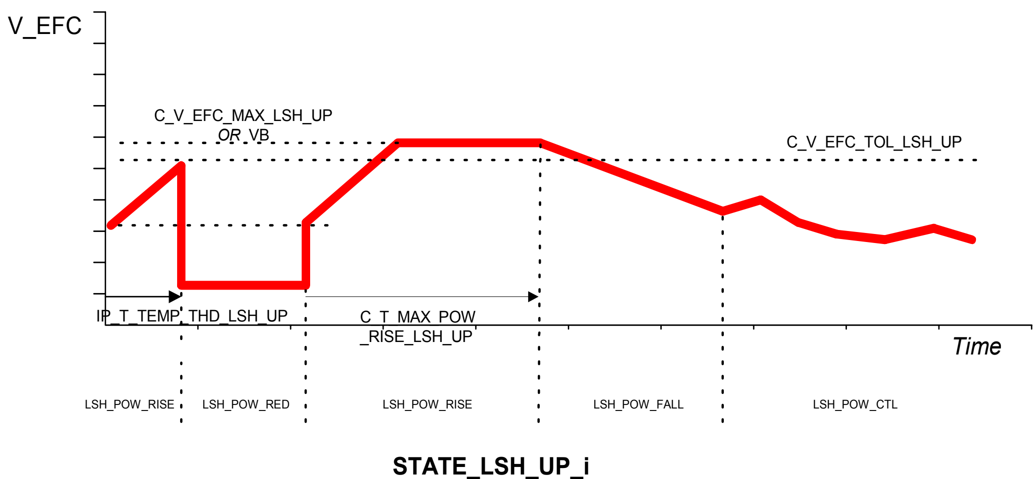

Figure 1: Course of effective heater voltage over time / state

Description:

The heater control shall be realised by use of a state machine. Each upstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated.

Heating shall commence should the activation conditions listed below be met. i.e. when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the corresponding bank is not set (LV_INH_LSH_UP[i] = 0). The appropriate heater state shall change to LSH_POW_RISE and the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_UP[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_LSH_UP.

Should the state LSH_POW_RISE is switched from LSH_VB_PROT or LSH_TEMP_PROT, the effective heater voltage shall be incremented with the gradient of

C_V_EFC_INC_PORT_LSH_DOWN. In the other cases, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_DOWN. In order to prevent sensor from over heating when the sensor is already warm, C_V_EFC_INC_PORT_LSH_DOWN has to be set samller than C_V_EFC_INC_LSH_DOWN.

The continuation of the heating gradient shall depend on whether the dew point at the sensor location has been determined to have been exceeded, i.e. the temperature of the inner manifold wall at the sensor location has exceeded the temperature threshold where water in the exhaust gas may condense, as determined by LV_TEG_MIN_THD[i].

Should the dew point not have been exceeded (LV_TEG_MIN_THD[i] = 0) but timer T_POW_RISE_LSH_UP[i] has equalled or exceeded IP_T_TEMP_THD_LSH_UP, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_UP. In this case, the heater state shall be set to LSH_POW_RED.

The reduced heating state shall persist until the dew point in the exhaust gas system has been determined to have been exceeded, i.e. until LV_TEG_MIN_THD[i] = 1, at which point the heater state shall return to LSH_POW_RISE. The effective heater voltage shall be set to the same effective heater voltage as determined at start (IP_V_EFC_INI_LSH_UP), which may be modified by the calibration data C_V_EFC_STEP_LSH_UP, may be further incremented with a gradient of C_V_EFC_INC_LSH_UP without danger of damaging the oxygen sensor and the timer T_POW_RISE_LSH_UP[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_UP determined at function start.

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEG_MIN_THD[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Dependent on whether closed loop control is permitted, the heater management shall enter either LSH_POW_CTL or LSH_POW_FALL. Should closed loop be permitted (LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0) and the ceramic temperature reference be valid (LV_V_REF_VLD_R_IT_LS_UP[i] = 1) and ceramic temperature exceed the set temperature (TTIP_MES_LS_UP[i] ≥ C_TTIP_SP_LS_UP[i]) then the state machine shall change to LSH_POW_CTL and the timer shall be frozen. This state change shall permit the controller to take over heating when the the operative readiness has been detected in order to prevent under- & overshoot of the ceramic temperature. Should the conditional operative readiness be set (LV_LS_UP_READY_CDN[i] = 1) then the state machine shall also enter state LSH_POW_CTL and stop the timer. This shall permit the heater stability diagnosis to be carried out even when the heater is sufficiently defective to prevent the set temperature from being reached. Should the closed loop controller be inhibited or the ceramic temperature calibration be faulty, and T_POW_RISE_LSH_UP[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_UP (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

If there has been a hot sensor restart i.e. TCO_ST >= (TCO_STOP - C_TCO_DIF_MAX_LSH_UP_REST) and VLS_UP moves outside the thresholds for readiness detection i.e. (VLS_UP > C_VLS_UP_AFR_THD_READY or VLS_UP < C_VLS_UP_AFL_THD_READY) the heater management shall leave "LSH_POW_RISE" and enter "LSH_POW_CTL" and the bit LV_LSH_UP_REST shall be set. This condition prevents sensors with powerful heaters (e.g. NTK UFLO 3.7 Ohm) and no closed loop heater capability from overheating during a hot start or repeated engine stop and start following a cold start. The constant C_TCO_ST_MIN_LSH_UP_REST allows this condition to be activated above a certain TCO_ST or to be deactivated completely for WRAF sensors / sensors with greater thermal inertia / weaker heater.

If LV_LSH_UP_REST = 1 the first C_CTR_R_IT_LS_UP_VLD_REST valid internal resistance values are checked and the effective heater voltage is offset by C_V_EFC_ADD_LSH_UP_REST whenever R_IT_LS_UP is less than C_R_IT_LS_UP_MIN_REST.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_UP until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_UP alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_UP * IP_FAC_V_EFC_TEG_LSH_UP. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

Should, however, the Boolean flag LV_TEG_MIN_THD[i] be reset whilst in the state LSH_POW_FALL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage may be carried out in open loop or closed loop mode. Unless either the closed loop control inhibit bit (LV_INH_LSH_CTL_CLL_LSH_UP[i]) is set or the reference voltage validity bit (LV_V_REF_VLD_R_IT_LS_UP[i]) is reset, the effective heater voltage shall be controlled in closed loop mode. Closed loop control conditions met shall be indicated by setting LV_LSH_CTL_CLL_LSH_UP[i]. Should at any time one of the above conditions no longer be met, the heater controller shall revert to open loop control, reset the closed loop variables and reset LV_LSH_CTL_CLL_LSH_UP[i].

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_UP and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_UP) may be required for the reasons outlined above.

In the closed loop heater control mode, a PI controller, that affects the open loop effective heater voltage in an additive manner, shall regulate the effective heater voltage such that the temperature specified by C_TTIP_SP_LS_UP[i] is maintained. The closed loop control may be further described as follows:

The current temperature of the oxygen sensor (TTIP_MES_LS_UP[i]) shall be obtained and the difference between this temperature and the set temperature computed to obtain the input variable to the controller (TTIP_MES_DIF_LS_UP[i]). Note that this variable shall be computed in both open and closed loop control modes but shall only be used in the closed loop control mode.

The controller shall then determine the appropriate additive voltage (V_EFC_CTL_ADD_LSH_UP[i]) by computing the P and I terms separately and then adding the two terms.

The P term (V_EFC_CTL_P_LSH_UP[i]) shall calculate a voltage proportional to the temperature difference and thus converting a temperature delta into voltage. The P term shall only be calculated when the absolute temperature difference (TTIP_MES_DIF_LS_UP[i]) equals or exceeds a constant (C_TTIP_DIF_MIN_CTL_P_LS_UP). This shall be achieved via the map IP_FAC_xxx_P_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_P_LSH_UP shall permit global parameter changes to be made.

The I term (V_EFC_CTL_I_LSH_UP[i]) shall calculate an integral of a voltage that shall be proportional to the temperature difference and thus converting a temperature delta into voltage. This shall be achieved via the map IP_FAC_xxx_I_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_I_LSH_UP shall permit global parameter changes to be made.

Once the additive voltage has been determined, this shall then be added to the open loop control voltage along with a calibration system constant (C_V_EFC_AS_LSH_UP) to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_UP[i]) shall be computed from the open loop value, the closed loop additive term and the global correction value.

The closed loop control computations shall be suspended should either the Boolean flag LC_LSH_CTL_CLL_INH_LSH_UP[i] be set or the ceramic temperature no longer be valid, for example due to an active reference voltage measurement, as indicated by LV_TTIP_MES_VLD_LS_UP[i] being reset. This shall freeze the P and I terms at their last calculated value. Upon revoking the suspension, the controller shall continue to compute from where the point immediately prior to the suspension, i.e. shall not start anew. Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_UP[i] & LV_V_EFC_LIM_MAX_LSH_UP[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEG_MIN_THD[i] be reset whilst in the state LSH_POW_CTL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_UP, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_UP[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_UP. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0, T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the

LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_CAT_UP_MDL[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_CAT_UP_MDL_MAX_LSH_UP, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending closed loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL, the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open / closed loop control. The closed loop controller shall not be started anew. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_UP[i] equal or exceed the threshold C_V_EFC_TOL_LSH_UP.

In this instance, the timer T_V_EFC_TOL_LSH_UP[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_UP, timer T_V_EFC_LIM_LSH_UP[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_UP[i] should fall below the threshold C_V_EFC_TOL_LSH_UP at any time, LV_V_EFC_LIM_TOL_LSH_UP[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_UP[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_UP[i]. Once the timer T_V_EFC_LIM_LSH_UP[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_UP, both timers shall be reset and timer T_V_EFC_TOL_LSH_UP[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_UP again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_UP[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_UP, C_V_EFC_MAX_ST_LSH_UP or VB dependent on the value of T_POW_RISE_LSH_UP[i].

If T_POW_RISE_LSH_UP[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_UP STEP or conditions regarding T_AST and STATE_LSH_UP[i] then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

If T_POW_RISE_LSH_UP[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_UP then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_UP[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_UP[i] shall be the lower of the values V_EFC_CLC_LSH_UP[i] & C_V_EFC_LIM_LSH_UP otherwise V_EFC_LSH_UP[i] shall be set to V_EFC_CLC_LSH_UP[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_UP[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_UP & NC_LSHPWM_BOL_LSH_UP. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_UP.

Should at any time an inhibit flag be set (LV_INH_LSH_UP[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_UP[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_UP[i]. On a transition of the inhibit bit LV_INH_LSH_UP[i] from 1 $\rightarrow$ 0, the heater function shall start from anew.

Application conditions:

Activation:

At any engine operating state.

Deactivation:

-

Time recurrence:

The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms.

The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms.

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle:

STATE_LSH_UP[i] = LSH_OFF
T_POW_RISE_LSH_UP[i] = 0
T_V_EFC_TOL_LSH_UP[i] = 0
T_V_EFC_LIM_LSH_UP[i] = 0
LSHPWM_UP[i] = 0
V_EFC_CTL_P_LSH_UP[i] = 0
V_EFC_CTL_I_LSH_UP[i] = 0
V_EFC_CTL_ADD_LSH_UP[i] = 0
V_EFC_LSH_UP[i] = 0
V_EFC_CLC_LSH_UP[i] = 0
V_EFC_ADD_LSH_UP_REST = 0
LV_LSH_CTL_CLL_LSH_UP[i] = 0
LV_V_EFC_LIM_BOL_LSH_UP[i] = 0
LV_V_EFC_LIM_TOL_LSH_UP[i] = 0

LV_V_EFC_LIM_MAX_LSH_UP[i] = 0
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0
LV_LSH_UP_REST = 0
TTIP_MES_DIF_LS_UP[i] = 0

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_UP[i] & LV_INH_LSH_CTL_CLL_LSH_UP[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater closed loop control function respectively

Formula section:

7.33.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

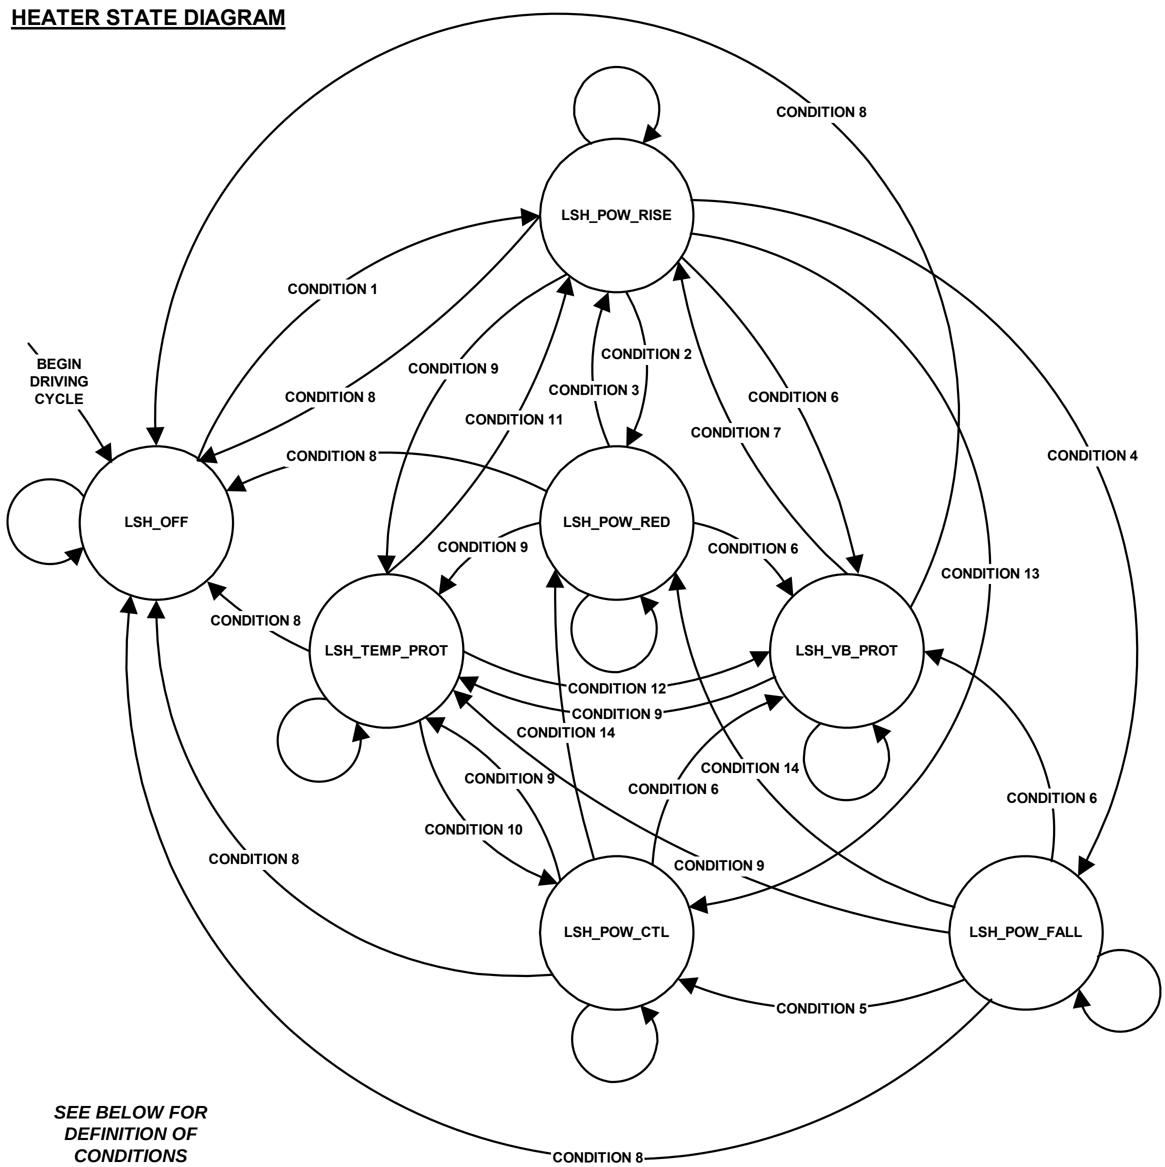

Figure 2: Heater management state diagram

C_FAC_CTL_P_LSH_UP

else

V_EFC_CTL_P_LSH_UP[i] = 0

endif

endif

endif.

Note: In cases where the effective heater voltage has been limited as shown by the state of the Boolean flag LV_V_EFC_LIM_BOL_LSH_UP[i], the controller shall only be permitted to increase the effective voltage. In the case of limiting via Boolean flags LV_V_EFC_LIM_TOL_LSH_UP[i] & LV_V_EFC_LIM_MAX_LSH_UP[i] the closed loop control shall only be permitted to decrease the effective heater voltage. In all other cases, the controller shall effectively be suspended, i.e. P & I terms shall remain unchanged but applied, until the applicable limitation is revoked. Upon revoking the limitation, the function shall resume to compute the P & I terms according to the conditions specified above.

Combine P and I terms:
V_EFC_CTL_ADD_LSH_UP[i] =
V_EFC_CTL_P_LSH_UP[i] + V_EFC_CTL_I_LSH_UP[i]

Note: Although variables V_EFC_CTL_P_LSH_UP[i] and V_EFC_CTL_I_LSH_UP[i] are defined as words, the summation shall be carried out as a 16 bit addition and the resultant 16 bit value converted to an 8 bit value, by taking the high byte, and placed in V_EFC_CTL_ADD_LSH_UP[i]. This shall prevent controller from stopping short of the target temperature.

End Case B: *Closed loop control; Not suspended:*

Compute effective heater voltage from open loop control and closed loop delta voltages:

For Bank 1; i = 1

V_EFC_LSH_UP_CLC[i] = IP_V_EFC_CTL_LSH_UP (N_32, TEG_CAT_UP_MDL[i]) +
V_EFC_LSH_UP_CTL_ADD[i] + C_V_EFC_AS_LSH_UP + V_EFC_ADD_LSH_UP_REST

Note: If (IP_V_EFC_CTL_LSH_UP + V_EFC_LSH_UP_CTL_ADD[i] + C_V_EFC_AS_LSH_UP) < 0 , i.e. would cause the effective heater voltage to be negative, V_EFC_LSH_UP_CLC[i] shall be limited to 0 and further reduction of the effective heater voltage via by the closed loop controller P & I terms shall be prevented by setting LV_V_EFC_LSH_UP_LIM_BOL[i], until the

sum less than zero condition is no longer met at which point LV_V_EFC_LSH_UP_LIM_BOL[i] shall be reset.

For Bank 2; i = 2

V_EFC_LSH_UP_CLC[i] = IP_V_EFC_CTL_LSH_UP (N_32, TEG_CAT_UP_MDL[i])* IP_FAC_V_EFC_TEG_LSH_UP + V_EFC_LSH_UP_CTL_ADD[i] + C_V_EFC_AS_LSH_UP + V_EFC_ADD_LSH_UP_REST

Note: If (IP_V_EFC_CTL_LSH_UP* IP_FAC_V_EFC_TEG_LSH_UP + V_EFC_LSH_UP_CTL_ADD[i] + C_V_EFC_AS_LSH_UP) < 0 , i.e. would cause the effective heater voltage to be negative, V_EFC_LSH_UP_CLC[i] shall be limited to 0 and further reduction of the effective heater voltage via by the closed loop controller P & I terms shall be prevented by setting LV_V_EFC_LSH_UP_LIM_BOL[i], until the sum less than zero condition is no longer met at which point LV_V_EFC_LSH_UP_LIM_BOL[i] shall be reset.

```

7.33.3 Oxygen sensor heater driver duty cycle computation

The PWM duty cycle for the appropriate heater driver shall continually be calculated in all heater states at the specified recurrence.

If (STATE_LSH_UP[i] = LSH_OFF)

then LSHPWM_UP[i] = LSHPWM_EXT_LS_UP[i]

else **If** (VB ≥ C_VB_MAX_PROT_LSH_UP)

then LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 1

LSHPWM_UP[i] = $C\_V\_EFC\_PROT\_VB\_LSH\_UP^2 * 100 / VB_N^2$

else LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0

LSHPWM_UP[i] = $V\_EFC\_LSH\_UP[i]_N^2 *$

$C\_FAC\_V\_EFC\_AS\_LSH\_UP * 100 / VB_N^2$

If LSHPWM_UP[i] ≥ NC_LSHPWM_TOL_LSH_UP

then LSHPWM_UP[i] = NC_LSHPWM_TOL_LSH_UP

else **If** LSHPWM_UP[i] ≤ NC_LSHPWM_BOL_LSH_UP

then LSHPWM_UP[i] = NC_LSHPWM_BOL_LSH_UP

else LSHPWM_UP[i] = LSHPWM_UP[i]

endif

endif

endif

endif.

The value C_FAC_V_EFC_AS_LSH_UP is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. ≥ 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

TEMP_INI_LS_UP[NC_CBK_EX_NR]	V/O	8000 ... 7FFFH	-2048...2047.94	62.5e-3	°C
Oxygen sensor temperature at engine start					

Input data:

NC_CBK_EX_NR	LV_ST_END	LV_ERR_OBD_VLD_LSH_UP[i]	LV_ERR_TTIP_OBD_LS_UP[i]
		LV_LSH_SCG_ACT_LSH_UP[i]	LV_ERR_LSH_UP[NC_CBK_EX_NR]
TEG_DYN_LS_UP[NC_CBK_EX_NR]		LV_LSHPWM_UP_EXT_ADJ	

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

Description:

The Boolean constant LC_LSH_UP[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_UP[i] shall be reset. When reset, LV_INH_LSH_UP[i] shall be set.

The Boolean flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall indicate whether closed loop heating shall be inhibited or not. Should either the Boolean constant LC_LSH_CTL_CLL_LSH_UP[i] be reset or the Boolean input data LV_ERR_OBD_VLD_LSH_UP[i], LV_ERR_TTIP_OBD_LS_UP[i], LV_LSH_SCG_ACT_LSH_UP[i] or LV_ERR_LSH_UP[i] be set then the Boolean inhibit flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be set (open loop heater control), otherwise LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be reset (closed loop heater control permitted).

The oxygen sensor temperature at start TEMP_INI_LS_UP[i] shall be obtained from the value TEG_DYN_LS_UP out of the model in EXTD.

Application conditions:

Activation:

Transition from engine start: LV_ST_END = 1

Deactivation:

Transition to engine stop: LV_ST_END = 0

Time recurrence:

Once every 1 s.

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle.

LV_INH_LSH_UP[i] = 0
LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0

TEMP_INI_LS_UP[i] = TEG_DYN_LS_UP[i]

Formula section:

If LV_LSHPWM_UP_EXT_ADJ = 1

Then LV_INH_LSH_UP[i] = 1

Else LV_INH_LSH_UP[i] = **!** LC_LSH_UP[i]

Endif

If LC_LSH_CTL_CLL_LSH_UP[i] = 0

or LV_ERR_OBD_VLD_LSH_UP[i] = 1

or LV_ERR_TTIP_OBD_LS_UP[i] = 1

or LV_LSH_SCG_ACT_LSH_UP[i] = 1

or LV_ERR_LSH_UP[i] = 1

then LV_INH_LSH_CTL_CLL_LSH_UP[i] = 1

else LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0

endif.

Calculation of Oxygen sensor temperature at engine start

One time determination after finishing engine state start

IF LV_ST_END = 1 for first time after LV_ST_END = 0

Then TEMP_INI_LS_UP[i] = TEG_DYN_LS_UP[i]

Endif

VLS_DOWN[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

The function shall evaluate the oxygen sensor signal voltage and compute a number of resultant values that may be used by other functions. These values shall include:

1. Moving mean of sensor voltage first derivative, i.e. average signal gradient
2. Minimum value of moving mean of sensor voltage first derivative in lean phase
3. Absolute maximum of sensor voltage first derivative over defined number of previous samples, i.e. measure of sensor voltage stability
4. Moving mean value of lean sensor voltage
5. Moving mean value of rich sensor voltage.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)

i = 1, for single exhaust cylinder bank

Signal flow diagram:

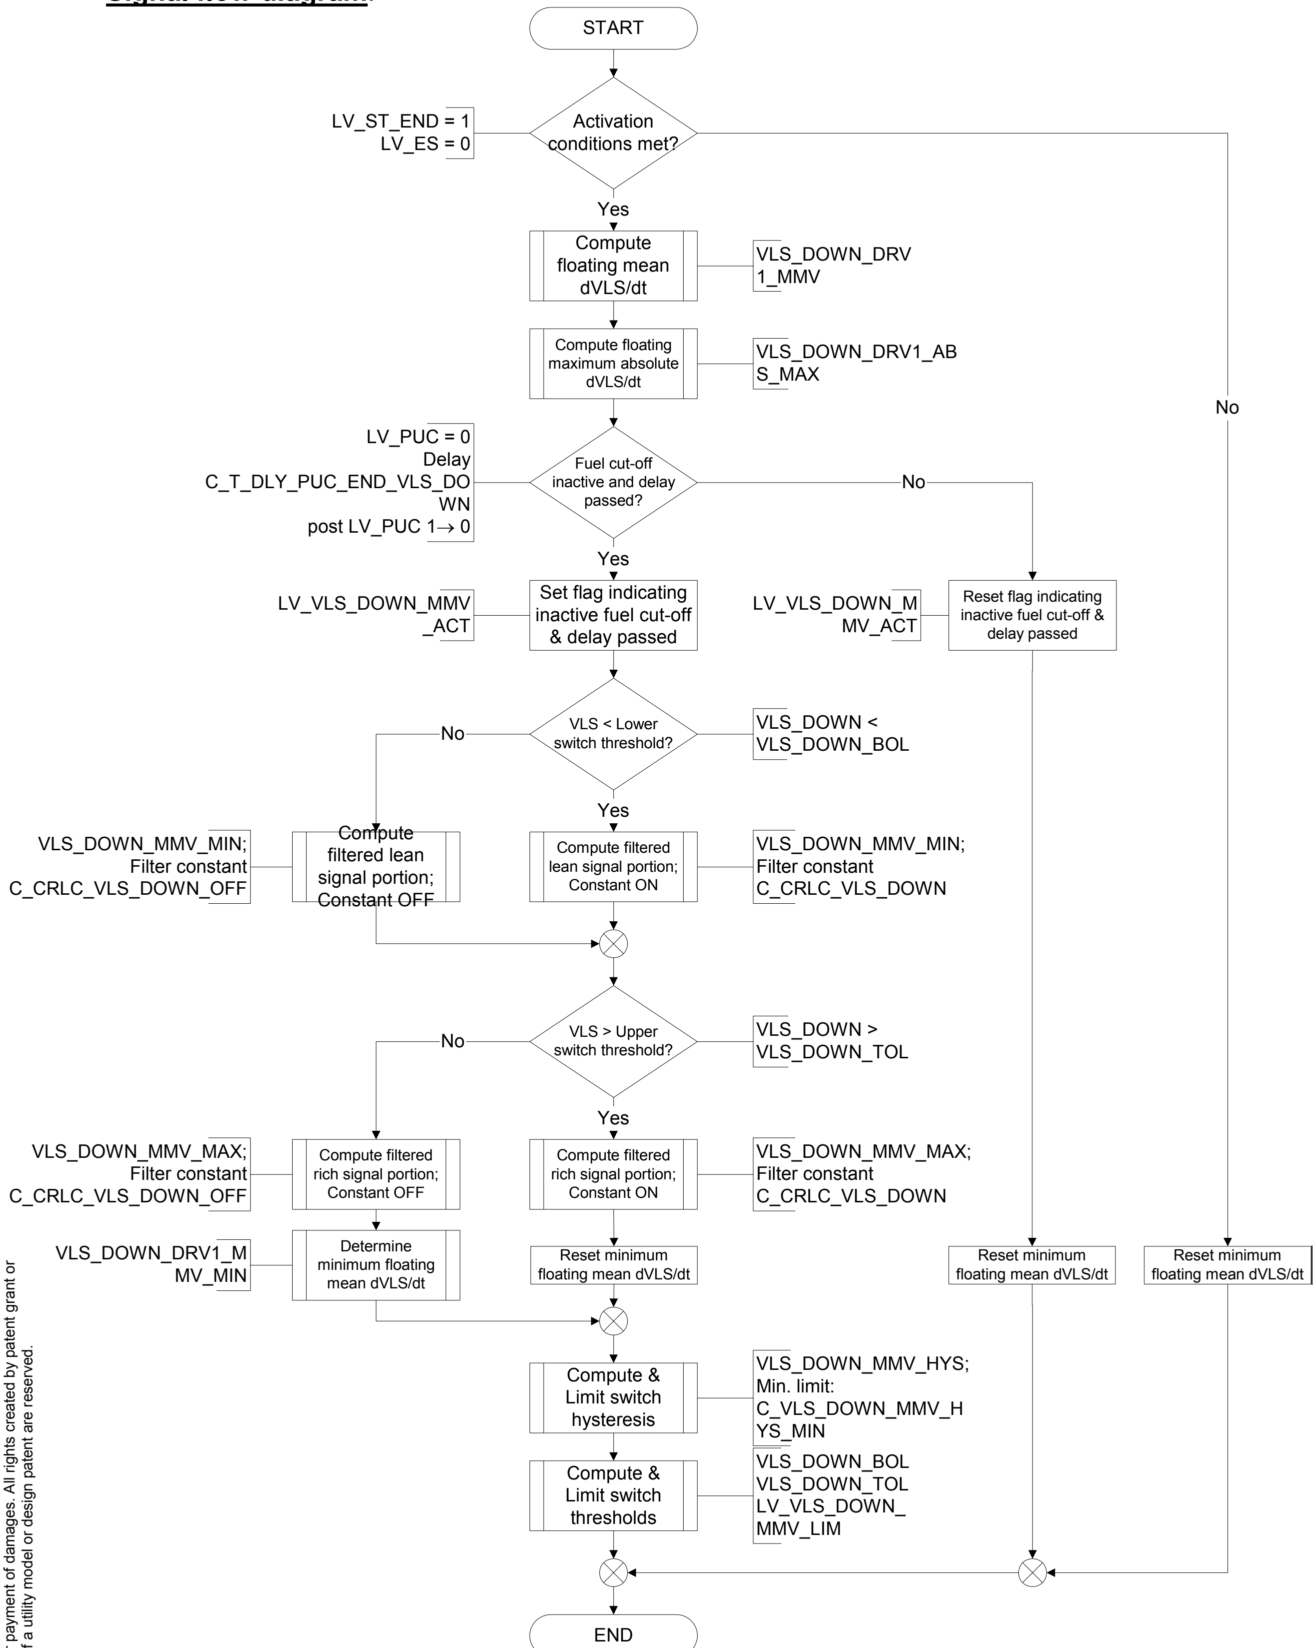

Figure 1 Function flow chart, Signal evaluation

Description:

The function shall evaluate the downstream oxygen sensor signal VLS_DOWN[i] and provide variables quantifying the signal characteristics: Floating mean gradient, Floating maximum signal deviation between samples, Filtered mean rich signal voltage & Filtered mean lean signal voltage (voltage will deviate from stable level signal with ageing of the catalyst). This shall be carried out as follows:

The function shall be activated should the engine state transition out of start (LV_ST_END = 1) and shall be deactivated should the engine stop state (LV_ES = 1) be entered.

Once the activation conditions have been met the function may be described in the following blocks:

1. Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]: The moving mean value of oxygen sensor signal voltage first derivative VLS_DOWN_DRV1_MMV[i] shall be computed by averaging the last differences between consecutive VLS_DOWN[i] samples, i.e. the most current difference ($VLS\_DOWN[i]_N$ - $VLS\_DOWN[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal gradient.

2. Computation of absolute maximum of first derivative VLS_DOWN_DRV1_ABS_MAX[i]: The absolute maximum of the oxygen sensor voltage first derivative VLS_DOWN_DRV1_ABS_MAX[i] shall be computed by taking the maximum of the absolute values of the last differences between consecutive VLS_DOWN[i] samples, i.e. the most current difference ($VLS\_DOWN[i]_N$ - $VLS\_DOWN[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal stability.

3. Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]: The computation of the moving mean value of lean and rich sensor voltages, associated switch thresholds and switch hysteresis shall only be carried out when the overrun fuel cut-off flag is reset (LV_PUC = 0) and the time C_T_DLY_PUC_END_VLS_DOWN has passed since the deactivation of the last occurring engine state PUC (i.e. LV_PUC $1 \rightarrow 0$). The lean and rich mean signal voltages shall be implemented by use of first order low pass filtering and floating switching thresholds. For example:

Should the VLS_DOWN[i] signal exceeds the threshold VLS_DOWN_TOL[i], the rich mean signal voltage VLS_DOWN_MMV_MAX[i] shall be computed by filtering the VLS_DOWN[i] signal with filter constant C_CRLC_VLS_DOWN. This shall continue until threshold VLS_DOWN_TOL[i] is no longer exceeded, after which VLS_DOWN_MMV_MAX[i] shall be computed by filtering with filter constant C_CRLC_VLS_DOWN_OFF. This constant is much smaller than C_CRLC_VLS_DOWN and the effect is to cause the VLS_DOWN_MMV_MAX[i] to follow the rich peaks. The OFF constant shall permit the VLS_DOWN_MMV_MAX[i] signal to follow the VLS_DOWN[i] signal for sudden decreases in signal amplitude, i.e. maximum VLS_DOWN[i] lower than VLS_DOWN_TOL[i].

The same procedure shall be carried out for the computation of VLS_DOWN_MMV_MIN[i], i.e. where VLS_DOWN[i] falls below VLS_DOWN_BOL[i], VLS_DOWN_MMV_MIN[i] shall be computed with filter constant C_CRLC_VLS_DOWN and where VLS_DOWN[i] no longer falls below VLS_DOWN_BOL[i], the filter constant C_CRLC_VLS_DOWN_OFF shall be used.

4. Determination of the minimum value of the moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]: The same conditions as for the computation of VLS_DOWN_MMV_xxx[i] shall apply. Should VLS_DOWN[i] fall below or equal VLS_DOWN_TOL[i], $VLS\_DOWN\_DRV1\_MMV\_MIN[i]_N$ shall be equal to the lower of $VLS\_DOWN\_DRV1\_MMV\_MIN[i]_{N-1}$ & VLS_DOWN_DRV1_MMV[i]. When VLS_DOWN[i] exceeds VLS_DOWN_TOL[i], the LV_PUC condition in conjunction with delay

C_T_DLY_PUC_END_VLS_DOWN is not met or the function is deactivated, VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.

5. Compute & limit switch hysteresis: The value of the hysteresis, VLS_DOWN_MMV_HYS[i], used to determine the switching thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be made proportional using factor C_FAC_VLS_DOWN_MMV_HYS to the oxygen sensor signal amplitude, as determined by taking the absolute difference of the moving mean lean / rich variables. The hysteresis shall also be limited so that it may not fall below the calibrateable threshold C_VLS_DOWN_MMV_HYS_MIN.

6. Compute & limit switch thresholds: The function shall limit the minimum amplitude of the difference between the moving mean lean / rich variables (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) to twice that of the switch hysteresis, VLS_DOWN_MMV_HYS[i].

Should the amplitude of the aforementioned difference fall below the said threshold, both the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be set to the average of the moving mean lean / rich variables, the moving mean lean / rich variables are recalculated based on the limited switching thresholds and hysteresis and the flag LV_VLS_DOWN_MMV_LIM[i] shall be set to indicate that switch threshold limiting is active.

Should no limiting be required, the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be calculated based on the switch hysteresis, moving mean lean variable and moving mean rich variable respectively. The flag LV_VLS_DOWN_MMV_LIM[i] shall be reset to indicate that no switch threshold limiting is being carried out.

The above blocks shall be cycled through once every function recurrence.

Application conditions:

Recurrence:

The function shall be carried out once every oxygen sensor acquisition, i.e. every 10 ms.

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

VLS_DOWN_MMV_MIN[i] = C_VLS_DOWN_INI_MIN
VLS_DOWN_MMV_MAX[i] = C_VLS_DOWN_INI_MAX
VLS_DOWN_BOL[i] = C_VLS_DOWN_INI_MAX
VLS_DOWN_TOL[i] = C_VLS_DOWN_INI_MIN
VLS_DOWN_MMV_HYS[i] = C_VLS_DOWN_MMV_HYS_MIN
LV_VLS_DOWN_MMV_LIM[i] = 0
LV_VLS_DOWN_MMV_ACT = 0
VLS_DOWN_DRV1_MMV[i] = 0
VLS_DOWN_DRV1_MMV_MIN[i] = 0
VLS_DOWN_DRV1_ABS_MAX[i] = 0

Buffer contents from which VLS_DOWN_DRV1_MMV[i] & VLS_DOWN_DRV1_ABS_MAX[i] computed = 0.

Activation:

If LV_ST_END = 1

then ***Function activated***

endif.

Deactivation:

If LV_ST_END = 0

then ***Function deactivated***
VLS_DOWN_DRV1_MMV_MIN[i] = 0

endif.

Formula section:

The following function shall be carried out in the order listed and as indicated by the function flow chart:

Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]

$$\text{VLS\_DOWN\_DRV1\_MMV[i]} = \frac{\sum_{x=0}^{5}\left(\text{VLS\_DOWN}[i]_{N-x} - \text{VLS\_DOWN}[i]_{N-(x+1)}\right)}{6 * 10\text{ms}}$$

The above may be facilitated for example by use of a 6 value ring buffer. The most current difference, (VLS_DOWN$[i]_N$ - VLS_DOWN$[i]_{N-1}$), would overwrite the oldest difference in the buffer, (VLS_DOWN$[i]_{N-5}$ - VLS_DOWN$[i]_{N-6}$), and the average of the buffer contents recalculated.

Computation of absolute maximum of first derivative number of previous samples VLS_DOWN_DRV1_ABS_MAX[i]

$$\text{VLS\_DOWN\_DRV1\_ABS\_MAX[i]} = \text{MAXIMUM}\left|{}_{x=0}^{5}\left(\text{VLS\_DOWN}[i]_{N-x} - \text{VLS\_DOWN}[i]_{N-(x+1)}\right)\right|$$

The above may be facilitated for example by use of the same 6 value ring buffer, as proposed above for the computation of VLS_DOWN_DRV1_MMV[i]. The function would calculate the absolute values of the buffer contents and take the maximum of these values.

Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]

If (LV_PUC = 0) **&**
(delay since last LV_PUC 1 → 0 transition ≥ C_T_DLY_PUC_END_VLS_DOWN)

then LV_VLS_DOWN_MMV_ACT = 1
If (VLS_DOWN[i] < VLS_DOWN_BOL[i])

then *Compute moving mean lean signal, filter constant ON*

else *Compute moving mean lean signal, filter constant OFF*

endif

If (VLS_DOWN[i] > VLS_DOWN_TOL[i])

then *Compute moving mean rich signal, filter constant ON*
VLS_DOWN_DRV1_MMV_MIN[i] = 0

else *Compute moving mean rich signal, filter constant OFF*
Determine minimum of moving mean of first derivative

endif

Compute & limit switch hysteresis

Compute & limit switch thresholds

else LV_VLS_DOWN_MMV_ACT = 0
Reset timer used for delay C_T_DLY_PUC_END_VLS_DOWN
VLS_DOWN_DRV1_MMV_MIN[i] = 0

endif.

Compute moving mean lean signal, filter constant ON

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

$$VLS\_DOWN\_MMV\_MIN[i]_N = VLS\_DOWN\_MMV\_MIN[i]_{N-1} * (1-C\_CRLC\_VLS\_DOWN) + VLS\_DOWN[i]_N * C\_CRLC\_VLS\_DOWN$$

Compute moving mean lean signal, filter constant OFF

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

$$VLS\_DOWN\_MMV\_MIN[i]_N = VLS\_DOWN\_MMV\_MIN[i]_{N-1} * (1-C\_CRLC\_VLS\_DOWN\_OFF) + VLS\_DOWN[i]_N * C\_CRLC\_VLS\_DOWN\_OFF$$

Compute moving mean rich signal, filter constant ON

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

$$VLS\_DOWN\_MMV\_MAX[i]_N = VLS\_DOWN\_MMV\_MAX[i]_{N-1} * (1-C\_CRLC\_VLS\_DOWN) + VLS\_DOWN[i]_N * C\_CRLC\_VLS\_DOWN$$

Compute moving mean rich signal, filter constant OFF

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

$$VLS\_DOWN\_MMV\_MAX[i]_N = VLS\_DOWN\_MMV\_MAX[i]_{N-1} * (1-C\_CRLC\_VLS\_DOWN\_OFF) + VLS\_DOWN[i]_N * C\_CRLC\_VLS\_DOWN\_OFF$$

Determine minimum of moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]

The determination of the minimum of VLS_DOWN_DRV1_MMV[i] shall take place when the condition VLS_DOWN[i] ≤ VLS_DOWN_TOL[i] has been met. In this case:

VLS_DOWN_DRV1_MMV_MIN[i] = MIN(VLS_DOWN_DRV1_MMV_MIN[i],
VLS_DOWN_DRV1_MMV[i])

Should the above condition no longer met, the LV_PUC with delay condition not be met or the initial activation conditions not be met then VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.

Compute & limit switch hysteresis

VLS_DOWN_MMV_HYS[i] = | (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) | * C_FAC_VLS_DOWN_MMV_HYS

If (VLS_DOWN_MMV_HYS[i] < C_VLS_DOWN_MMV_HYS_MIN)

then VLS_DOWN_MMV_HYS[i] = C_VLS_DOWN_MMV_HYS_MIN

endif.

Compute & limit switch thresholds

If ((VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i])
≤ 2 * VLS_DOWN_MMV_HYS[i])

then VLS_DOWN_BOL[i] = (VLS_DOWN_MMV_MAX[i] + VLS_DOWN_MMV_MIN[i]) / 2
VLS_DOWN_TOL[i] = (VLS_DOWN_MMV_MAX[i] + VLS_DOWN_MMV_MIN[i]) / 2

VLS_DOWN_MMV_MIN[i] = VLS_DOWN_BOL[i] - VLS_DOWN_MMV_HYS[i]
VLS_DOWN_MMV_MAX[i] = VLS_DOWN_TOL[i] + VLS_DOWN_MMV_HYS[i]

LV_VLS_DOWN_MMV_LIM[i] = 1

else VLS_DOWN_BOL[i] = VLS_DOWN_MMV_MIN[i] + VLS_DOWN_MMV_HYS[i]
VLS_DOWN_TOL[i] = VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_HYS[i]

LV_VLS_DOWN_MMV_LIM[i] = 0

endif.

7.36 Downstream oxygen sensor operative readiness detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_LS_DOWN_READY[NC_CBK_EX_NR]	O/V	0...1H	0...1	1	-
Logical variable for operative readiness of downstream oxygen sensor(s)					

Input data:

LV_PUC	MAF_INT_PUC	LV_ES	NC_CBK_EX_NR
VLS_DOWN[NC_CBK_EX_NR]		TEG_CAT_DOWN_MDL[NC_CBK_EX_NR]	
LV_TEG_CAT_DOWN_MIN_THD[NC_CBK_EX_NR]		STATE_LSH_DOWN[NC_CBK_EX_NR]	

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The operative readiness of the downstream oxygen sensor(s) shall be determined by this function to allow other functions to act accordingly dependent upon the readiness.

Description:

The operative readiness shall only be determined for a downstream oxygen sensor that has not yet been determined as being operatively ready (i.e. LV_LS_DOWN_READY[i] = 0).

The operative readiness shall be determined by analysing the downstream oxygen sensor voltage (VLS_DOWN[i]) and determining whether the voltage has left a pre-determined voltage band (voltage level at ADC input driven by potential divider in input interface for cold oxygen sensor, voltage level will leave band dependent upon A/F ratio present at the oxygen sensor location).

A second condition shall permit the forced operative readiness state, should the voltage level condition not be met, by assuming that when the catalyst temperature model has reached a pre-determined threshold, that the downstream oxygen sensor is also at operating temperature and functioning.

The operative readiness of the downstream oxygen sensor(s) shall be recorded in the variable LV_LS_DOWN_READY[i].

Application conditions:

Initialisation:

The oxygen sensor shall be initialised as inoperable (LV_LS_DOWN_READY[i]= 0) after a reset, in the state *Engine Stop*, when during PUC the MAF integral exceeds a calibrated threshold or when the dew point was exceeded once and LV_TEG_CAT_DOWN_MIN_THD[i] switches again to 0

if [*reset occurs* **or** LV_ES = 1 **or** (LV_PUC = 1 **and**

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then

i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account. The function shall permit oxygen sensor heating under open loop control.

Signal flow:

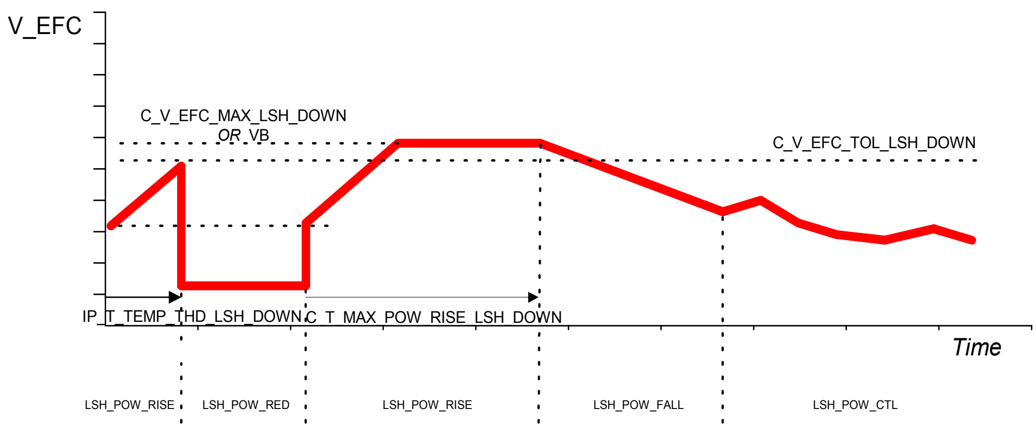

Figure 1: Course of effective heater voltage over time / state

Description:

The heater control shall be realised by use of a state machine. Each downstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated.

Heating shall commence should the activation conditions listed below be met. i.e. when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the corresponding bank is not set (LV_INH_LSH_DOWN[i] = 0). The appropriate heater state shall change to LSH_POW_RISE and the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_DOWN[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_LSH_DOWN.

Should the state LSH_POW_RISE is switched from LSH_VB_PROT or LSH_TEMP_PROT, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_PORT_LSH_DOWN. In the other cases, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_DOWN. In order to prevent sensor from over heating when the sensor is already warm, C_V_EFC_INC_PORT_LSH_DOWN has to be set samller than C_V_EFC_INC_LSH_DOWN.

The continuation of the heating gradient shall depend on whether the dew point at the sensor location has been determined to have been exceeded, i.e. the temperature of the inner manifold wall at the sensor location has exceeded the temperature threshold where water in the exhaust gas may condense, as determined by LV_TEG_CAT_DOWN_MIN_THD[i].

Should the dew point not have been exceeded (LV_TEG_CAT_DOWN_MIN_THD[i] = 0) but timer T_POW_RISE_LSH_DOWN[i] has equalled or exceeded IP_T_TEMP_THD_LSH_DOWN, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_DOWN. In this case, the heater state shall be set to LSH_POW_RED.

The reduced heating state shall persist until the dew point in the exhaust gas system has been determined to have been exceeded, i.e. until LV_TEG_CAT_DOWN_MIN_THD[i] = 1, at which point the heater state shall return to LSH_POW_RISE. The effective heater voltage shall be set to the same effective heater voltage as determined at start (IP_V_EFC_INI_LSH_DOWN), which may be modified by the calibration data C_V_EFC_STEP_LSH_DOWN, may be further incremented with a gradient of C_V_EFC_INC_LSH_DOWN without danger of damaging the oxygen sensor and the timer T_POW_RISE_LSH_DOWN[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_DOWN determined at function start.

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEG_CAT_DOWN_MIN_THD[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Should T_POW_RISE_LSH_DOWN[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_DOWN (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_DOWN until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_DOWN alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_DOWN * IP_FAC_V_EFC_TEG_LSH_DOWN. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

If there has been a hot sensor restart i.e. TCO_ST >= (TCO_STOP - C_TCO_DIF_MAX_LSH_DOWN_REST) and VLS_DOWN moves outside the thresholds for readiness detection i.e. (VLS_DOWN > C_VLS_DOWN_AFR_THD_READY or VLS_DOWN < C_VLS_DOWN_AFL_THD_READY) the heater management shall leave "LSH_POW_RISE" and enter "LSH_POW_CTL" and the bit LV_LSH_DOWN_REST shall be set. This condition prevents sensors with powerful heaters (e.g. NTK UFLO 3.7 Ohm) and no closed loop heater capability from overheating during a hot start or repeated engine stop and start following a cold start. The constant C_TCO_ST_MIN_LSH_DOWN_REST allows this condition to be activated above a certain TCO_ST or to be deactivated completely for WRAF sensors / sensors with greater thermal inertia / weaker heater.

If LV_LSH_DOWN_REST = 1 the first C_CTR_R_IT_LS_DOWN_VLD_REST valid internal resistance values are checked and the effective heater voltage is offset by C_V_EFC_ADD_LSH_DOWN_REST whenever R_IT_LS_DOWN is less than C_R_IT_LS_DOWN_MIN_REST.

Should, however, the Boolean flag LV_TEG_CAT_DOWN_MIN_THD[i] be reset whilst in the state LSH_POW_FALL, the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage is carried out in open loop mode.

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_DOWN and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_DOWN) may be required for the reasons outlined above.

To the open loop control voltage a calibration system constant (C_V_EFC_AS_LSH_DOWN) can be added to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_DOWN[i]) shall be computed from the open loop value and the global correction value.

Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_DOWN[i] & LV_V_EFC_LIM_MAX_LSH_DOWN[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEG_CAT_DOWN_MIN_THD[i] be reset whilst in the state LSH_POW_CTL, then the open loop controller terms shall be reset, the Boolean flags to indicate open loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_DOWN, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_DOWN. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0, T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i] shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_CAT_DOWN_MDL[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_CAT_DOWN_MDL_MAX_LSH_DOWN, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending open loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL, the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open loop control. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i] shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_DOWN[i] equal or exceed the threshold C_V_EFC_TOL_LSH_DOWN.

In this instance, the timer T_V_EFC_TOL_LSH_DOWN[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN, timer T_V_EFC_LIM_LSH_DOWN[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_DOWN[i] should fall below the threshold C_V_EFC_TOL_LSH_DOWN at any time, LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_DOWN[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_DOWN[i]. Once the timer T_V_EFC_LIM_LSH_DOWN[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_DOWN, both timers shall be reset and timer T_V_EFC_TOL_LSH_DOWN[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_DOWN[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_DOWN, C_V_EFC_MAX_ST_LSH_DOWN or VB dependent on the value of T_POW_RISE_LSH_DOWN[i].

If T_POW_RISE_LSH_DOWN[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN or conditions regarding T_AST and STATE_LSH_DOWN[i] then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

If T_POW_RISE_LSH_DOWN[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_DOWN[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_DOWN[i] shall be the lower of the values V_EFC_CLC_LSH_DOWN[i] & C_V_EFC_LIM_LSH_DOWN otherwise V_EFC_LSH_DOWN[i] shall be set to V_EFC_CLC_LSH_DOWN[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_DOWN[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_DOWN & NC_LSHPWM_BOL_LSH_DOWN. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_DOWN.

Should at any time an inhibit flag be set (LV_INH_LSH_DOWN[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_DOWN[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_DOWN[i]. On a transition of the inhibit bit LV_INH_LSH_DOWN[i] from 1 $\rightarrow$ 0, the heater function shall start from anew.

<u>Application conditions:</u>

Activation:

At any engine operating state.

Deactivation:

-

Time recurrence:

The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms. T_SAMPLE_1 = 100ms

The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms. T_SAMPLE_2 = 10ms

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle:

STATE_LSH_DOWN[i] = LSH_OFF

T_POW_RISE_LSH_DOWN[i] = 0

T_V_EFC_TOL_LSH_DOWN[i] = 0

T_V_EFC_LIM_LSH_DOWN[i] = 0

LSHPWM_DOWN[i] = 0

V_EFC_LSH_DOWN[i] = 0

V_EFC_CLC_LSH_DOWN[i] = 0

V_EFC_ADD_LSH_DOWN_REST = 0

LV_V_EFC_LIM_BOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_TOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_MAX_LSH_DOWN[i] = 0

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

LV_LSH_DOWN_REST = 0

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_DOWN[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater open loop control function respectively

<u>Formula section:</u>

7.37.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

HEATER STATE DIAGRAM

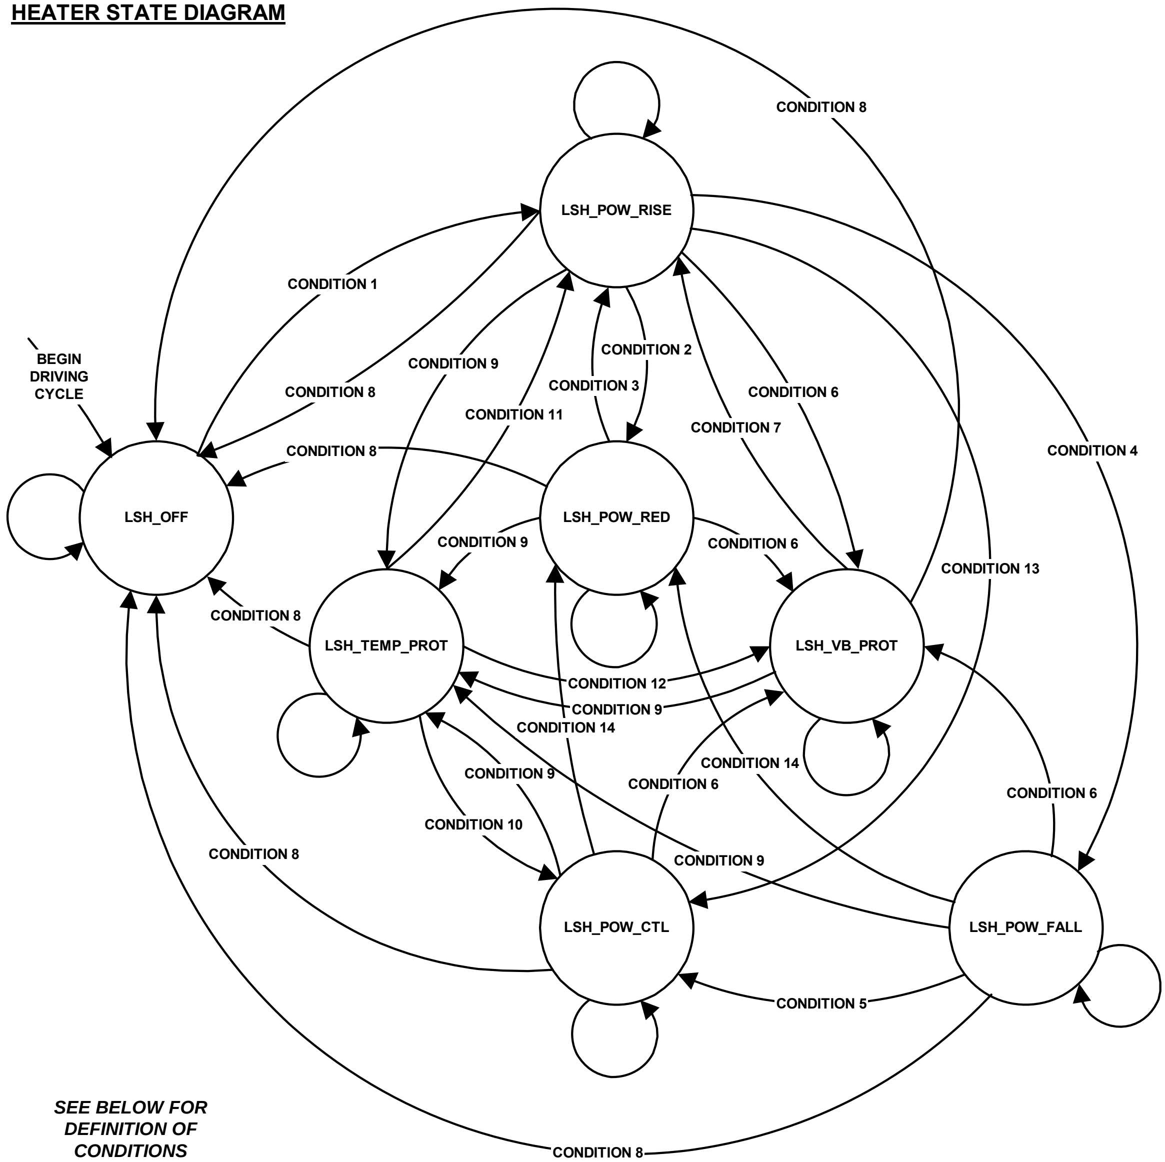

Figure 2: Heater management state diagram

STATE_LSH_DOWN[i] "LSH_OFF"

Actions:

T_POW_RISE_LSH_DOWN[i] = 0

T_V_EFC_TOL_LSH_DOWN[i] = 0

T_V_EFC_LIM_LSH_DOWN[i] = 0

V_EFC_LSH_DOWN[i] = 0

V_EFC_CLC_LSH_DOWN[i] = 0

LV_V_EFC_LIM_BOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_TOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_MAX_LSH_DOWN[i] = 0

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

Note: The above listed actions must be carried out at least once when the state has been entered for the first time or from any other state! The action below must be executed on every recurrence while in this state.

Condition 1:"LSH_OFF to LSH_POW_RISE"

LV_ST_END = 1 **&**

LV_INH_LSH_DOWN[i] = 0

Transition actions:

V_EFC_CLC_LSH_DOWN[i] = IP_V_EFC_INI_LSH_DOWN (TEMP_INI_LS_DOWN[i])

Timer T_POW_RISE_LSH_DOWN[i] shall be started

STATE_LSH_DOWN[i] = LSH_POW_RISE

STATE_LSH_DOWN[i] "LSH_POW_RISE"

Actions:

If Previous state of STATE_LSH_DOWN[i] = LSH_TEMP_PROT or LSH_VB_PROT

Then $V\_EFC\_CLC\_LSH\_DOWN[i]_{N} = V\_EFC\_CLC\_LSH\_DOWN[i]_{N-1} +$ C_V_EFC_INC_PROT_LSH_DOWN*T_SAMPLE_1

Else $V\_EFC\_CLC\_LSH\_DOWN[i]_{N} = V\_EFC\_CLC\_LSH\_DOWN[i]_{N-1} +$ C_V_EFC_INC_LSH_DOWN* T_SAMPLE_1

Endif

Increment timer T_POW_RISE_LSH_DOWN[i]

Note: See section "Oxygen sensor heater voltage protection" for notes on limiting the applied heater voltage.

Condition 8:"LSH_POW_RISE to LSH_OFF"

LV_ST_END = 0 **or** LV_INH_LSH_DOWN[i] = 1

Transition actions:

STATE_LSH_DOWN[i] = LSH_OFF

Condition 9:"LSH_POW_RISE to LSH_TEMP_PROT"

TEG_CAT_DOWN_MDL[i] > C_TEG_CAT_DOWN_MDL_MAX_LSH_DOWN **&**

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

Transition actions:

STATE_LSH_DOWN[i] = LSH_TEMP_PROT

Condition 6:"LSH_POW_RISE to LSH_VB_PROT"

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 1

Transition actions:

STATE_LSH_DOWN[i] = LSH_VB_PROT

Condition 2:"LSH_POW_RISE to LSH_POW_RED"

T_POW_RISE_LSH_DOWN[i] ≥ IP_T_TEMP_THD_LSH_DOWN (TEMP_INI_LS_DOWN[i]) **&**

LV_TEG_CAT_DOWN_MIN_THD[i] = 0

Transition actions:

STATE_LSH_DOWN[i] = LSH_POW_RED

Condition 13:"LSH_POW_RISE to LSH_POW_CTL"

(TCO_ST > C_TCO_ST_MIN_LSH_DOWN_REST **&**
TCO_ST >= TCO_STOP - C_TCO_DIF_MAX_LSH_DOWN_REST **&**
(VLS_DOWN > C_VLS_DOWN_AFR_THD_READY **or** VLS_DOWN < C_VLS_DOWN_AFL_THD_READY))
Transition actions:

LV_LSH_DOWN_REST = 1 *%bit set if transition to "LSH_POW_CTL" caused by the LSH_DOWN_REST conditions.*

Stop timer T_POW_RISE_LSH_DOWN[i] and freeze value

STATE_LSH_DOWN[i] = LSH_POW_CTL

Condition 4:"LSH_POW_RISE to LSH_POW_FALL"

T_POW_RISE_LSH_DOWN[i] ≥ C_T_MAX_POW_RISE_LSH_DOWN + IP_T_TEMP_THD_LSH_DOWN

% IP_ ... (TEMP_INI_LS_DOWN[i])

Transition actions:

Stop timer T_POW_RISE_LSH_DOWN[i] and freeze value

STATE_LSH_DOWN[i] = LSH_POW_FALL

STATE_LSH_DOWN[i] "LSH_POW_RED"

Actions:

V_EFC_CLC_LSH_DOWN[i] = C_V_EFC_RED_LSH_DOWN

Condition 8:"LSH_POW_RED to LSH_OFF"

LV_ST_END = 0 **or** LV_INH_LSH_DOWN[i] = 1

Transition actions:

STATE_LSH_DOWN[i] = LSH_OFF

<u>Condition 9</u>:*"LSH_POW_RED to LSH_TEMP_PROT"*

TEG_CAT_DOWN_MDL[i] > C_TEG_CAT_DOWN_MDL_MAX_LSH_DOWN **&**

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

Transition actions:

7.37.3 Oxygen sensor heater driver duty cycle computation

The PWM duty cycle for the appropriate heater driver shall continually be calculated in all heater states at the specified recurrence.

If STATE_LSH_DOWN[i] = LSH_OFF

then LSHPWM_DOWN[i] = LSHPWM_EXT_LS_DOWN[i]

else **If** VB ≥ C_VB_MAX_PROT_LSH_DOWN

then LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 1

LSHPWM_DOWN[i] = $C\_V\_EFC\_PROT\_VB\_LSH\_DOWN^2 * 100 / VB_N^2$

else LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

LSHPWM_DOWN[i] = $V\_EFC\_LSH\_DOWN[i]_N^2$ *

C_FAC_V_EFC_AS_LSH_DOWN *100 / VB_N^2

If LSHPWM_DOWN[i] ≥ NC_LSHPWM_TOL_LSH_DOWN

then LSHPWM_DOWN[i] = NC_LSHPWM_TOL_LSH_DOWN

else **If** LSHPWM_DOWN[i] ≤ NC_LSHPWM_BOL_LSH_DOWN

then LSHPWM_DOWN[i] = NC_LSHPWM_BOL_LSH_DOWN

else LSHPWM_DOWN[i] = LSHPWM_DOWN[i]

endif

endif

endif

endif.

The value C_FAC_V_EFC_AS_LSH_DOWN is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. ≥ 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

Input data:

		LV_ST_END	LV_LSHPWM_DOWN_EXT_ADJ
NC_CBK_EX_NR	TEG_DYN_LS_DOWN[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The Boolean constant LC_LSH_DOWN[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_DOWN[i] shall be reset. When reset, LV_INH_LSH_DOWN[i] shall be set.

The oxygen sensor temperature at start TEMP_INI_LS_DOWN[i] shall be obtained from the value TEG_DYN_LS_DOWN out of the model in EXTD.

Application conditions:

Activation:

LV_ST_END = 1

Deactivation:

LV_ST_END = 0

Time recurrence:

Once every 1 s.

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle.

LV_INH_LSH_DOWN[i] = 0
TEMP_INI_LS_DOWN[i] = TEG_DYN_LS_DOWN[i]

Formula section:

If LV_LSHPWM_DOWN_EXT_ADJ = 1

Then LV_INH_LSH_DOWN[i] = 1

Else LV_INH_LSH_DOWN[i] = **!** LC_LSH_DOWN[i]

Endif

Once at every LV_ST_END 0-> 1

TEMP_INI_LS_DOWN[i] = TEG_DYN_LS_DOWN[i]

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Timer indicating duration of LV_AFL[i] lock					
CTR_AFL_CYC[NC_CBK_EX_NR]	V/O	0...FFFFH	0...65535	1	-
Counter indicating number of air fuel cycles					

Input data:

LV_ST_END	LV_ES	MAF	N_32
LV_LAM_LSCL[NC_CBK_EX_NR]		LV_LS_UP_READY[NC_CBK_EX_NR]	
VLS_UP[NC_CBK_EX_NR]		NC_CBK_EX_NR	

FUNCTION DESCRIPTION:

General information:

The function shall evaluate the oxygen sensor signal voltage and compute a number of resultant values that may be used by other functions. These values shall include:

1. Flag indicating whether Air-Fuel Ratio is currently lean or rich
2. Cycle times for lean and rich periods
3. Timer indicating duration of LV_AFL[i] lock-out
4. Counter indicating number of complete AF cycles since last lambda controller activation

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank

Signal flow diagram:

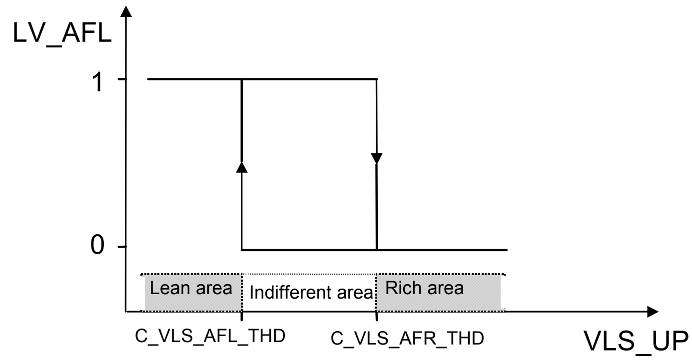

Figure 1 Diagram showing state and hysteresis of LV_AFL[i] as function of VLS_UP[i]

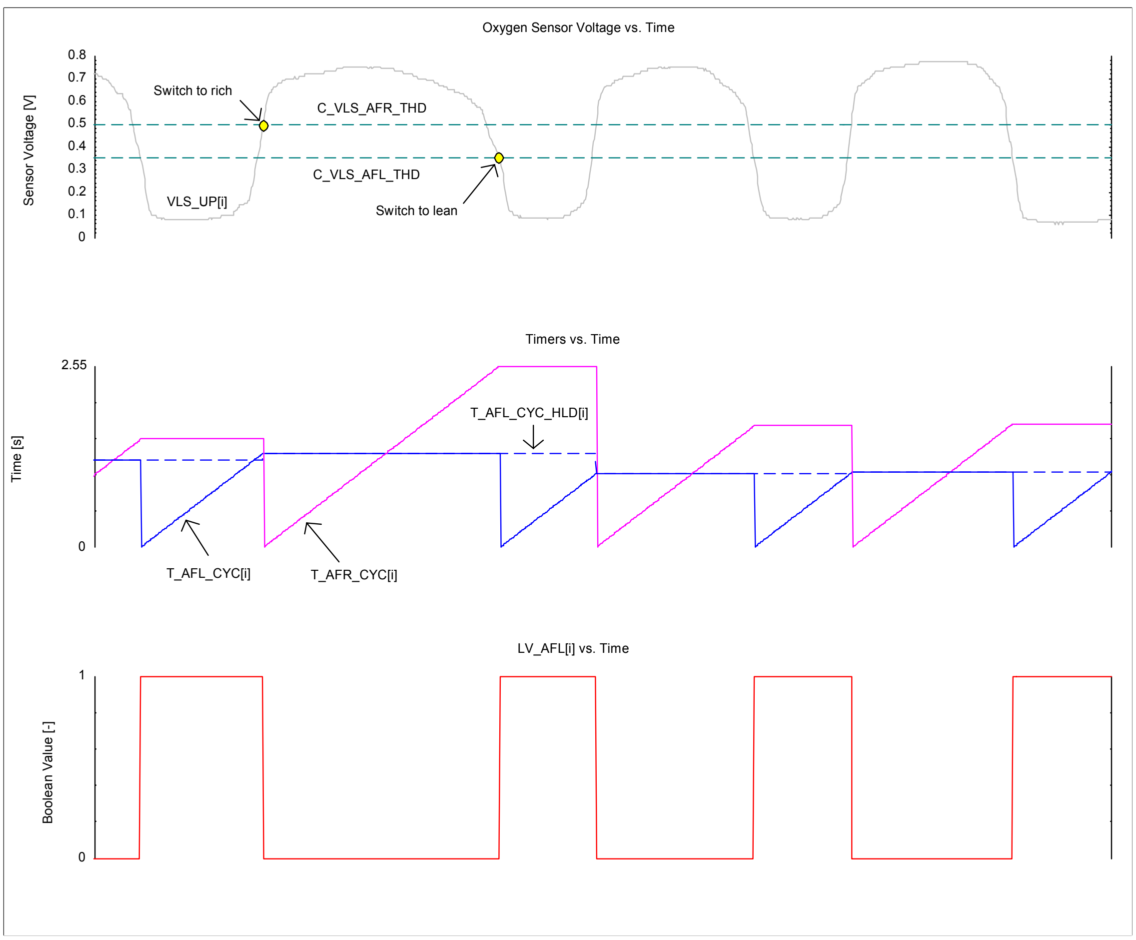

Figure 2 Physical relationship between values, Air-Fuel cycle evaluation

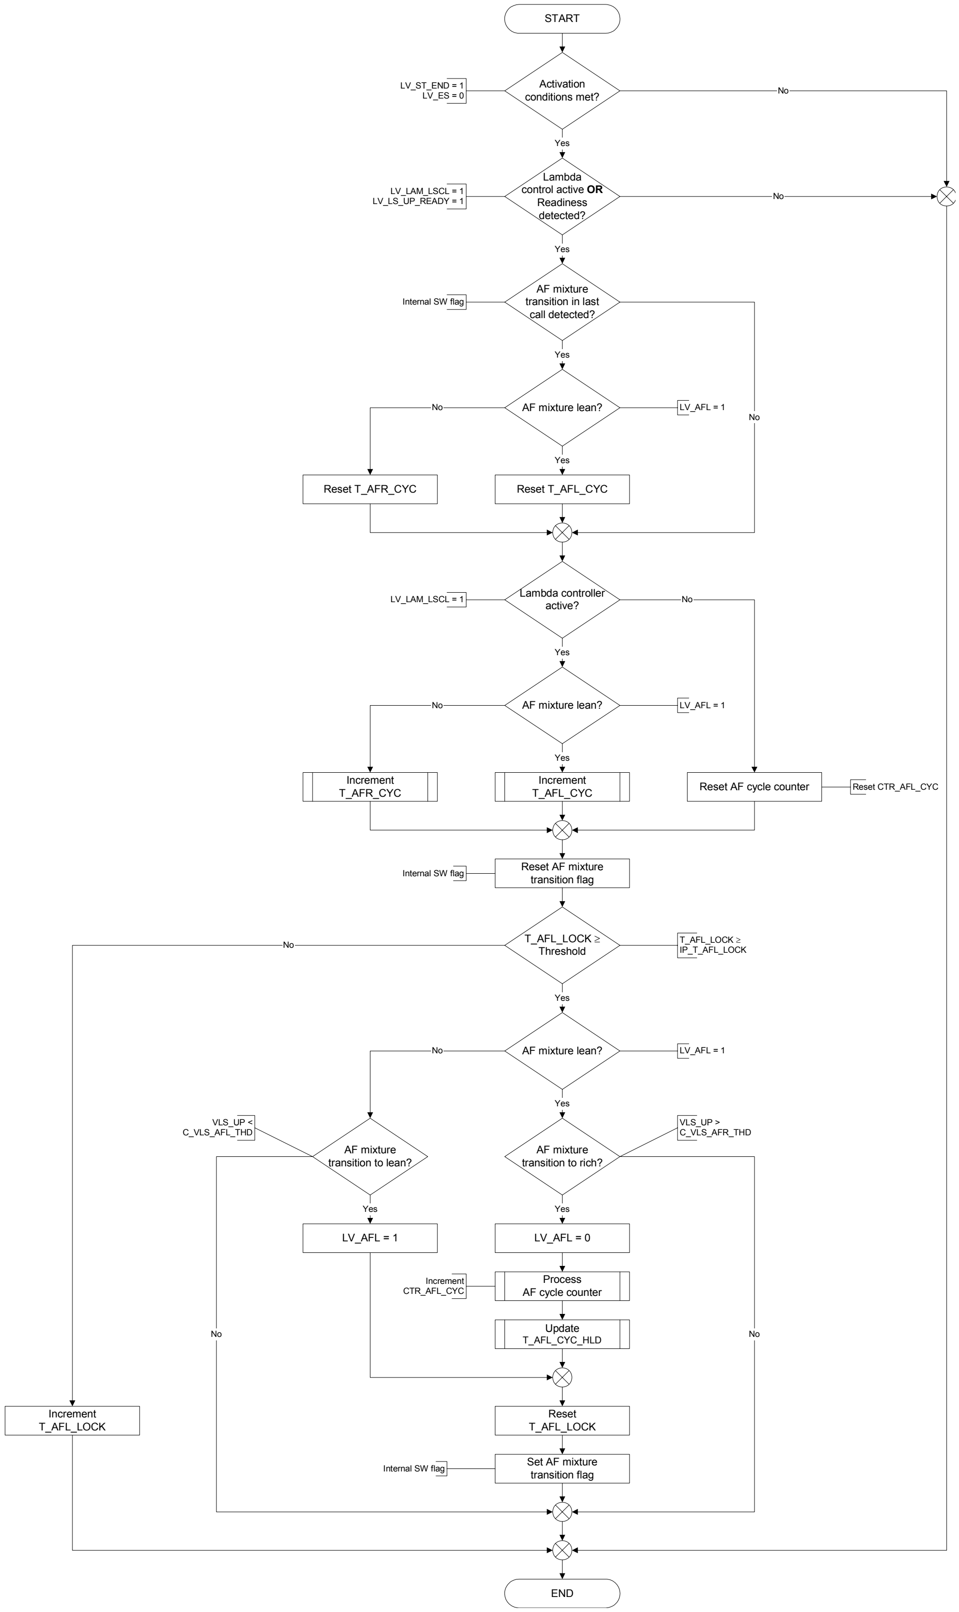

Figure 3 Function flow chart, Air-Fuel cycle evaluation

Description:

The function shall provide an indication of the current Air-Fuel mixture ratio, i.e. mixture lean or rich, and determine the lean and rich cycle time separately for further evaluation by other functions. This shall be carried out as follows:

The function shall be activated should the engine state transition out of start (LV_ST_END = 1) and shall be deactivated should the engine stop state (LV_ES = 1) be entered.

Two further activation conditions apply to the function: The lambda controller shall be active (LV_LAM_LSCL[i] = 1) or the oxygen sensor shall be determined to be in a state of operative readiness (LV_LS_UP_READY[i]).

Once the activation conditions have been met the function may be described in three blocks:

1. Resetting of lean / rich cycle timers: Once a AF mixture transition has been detected elsewhere in the function, the respective timer shall be reset dependent on the current state of the AF mixture, as determined by LV_AFL[i] (rich to lean transition; reset T_AFL_CYC[i], lean to rich transition; reset T_AFR_CYC[i]).

2. Timer / counter incrementation: Should the lambda controller be active, as determined by LV_LAM_LSCL[i] = 1, the function shall increment the respective timer dependent on the current state of the AF mixture, as determined by LV_AFL[i] (lean mixture; increment T_AFL_CYC[i], rich mixture; increment T_AFR_CYC[i]). Should at any time the lambda controller be deactivated, the function shall reset the counter CTR_AFL_CYC[i].

3. AF transition detection: The function shall detect a change in AF mixture from lean to rich or vice versa ignoring possible jitter in the oxygen sensor signal. This shall be facilitated by the following method: If the timer T_AFL_LOCK[i] falls below the threshold IP_T_AFL_LOCK, the timer shall be incremented and no further action shall take place in the current recurrence. Should, during following recurrence cycles, the timer equal or exceed the threshold and if the AF mixture flag is currently indicating lean, the function shall observe the VLS_UP[i] signal for a change to rich as indicated by VLS_UP[i] exceeding the threshold C_VLS_AFR_THD. Once this has occurred, the LV_AFL[i] flag shall be changed to indicate a rich mixture (LV_AFL[i] = 0), a counter CTR_AFL_CYC[i] shall be incremented to indicate the number of complete AF cycles since the last activation of the lambda controller, the output data T_AFL_CYC_HLD[i] shall be updated with T_AFL_CYC[i], the timer T_AFL_LOCK[i] shall be reset and a SW internal flag set to indicate the AF mixture transition. The same procedure, except incrementation of counter CTR_AFL_CYC[i], applies for a currently rich mixture. A transition to a lean mixture shall be detected by VLS_UP[i] falling below threshold C_VLS_AFL_THD.

Remark: The timer T_AFL_LOCK[i] and associated engine operating point dependent threshold IP_T_AFL_LOCK reduce the effect of rapid oxygen sensor signal changes, noise generated by cylinder to cylinder AF mixture deviations, that would cause the lambda controller to execute a P-jump. The mapped lock-out time represents the delay between injection of the AF mixture and the burnt AF mixture reaching and being detected by the oxygen sensor. The lock-out time shall not exceed the exhaust gas delay for any particular engine operating point otherwise the lambda controller frequency will be affected. Oxygen sensor signal changes occurring within this delay time may not be considered to be due to the change in controlled lambda but from noise and shall be ignored.

The above three blocks shall be cycled through once every function recurrence.

Application conditions:

Recurrence:

The function shall be carried out once every oxygen sensor acquisition, i.e. every 10 ms.

T_SAMPLE = 10 ms

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

LV_AFL[i] = 0
T_AFL_CYC[i] = 0
T_AFL_CYC_HLD[i] = 0
T_AFR_CYC[i] = 0
T_AFL_LOCK[i] = 2.55 (i.e. FFH)
CTR_AFL_CYC[i] = 0

Activation:

If (LV_ST_END = 1) **&**
(LV_ES = 0)

then ***Function activated***

endif.

Deactivation:

If (LV_ST_END = 0) **or**
(LV_ES = 1)

then ***Function deactivated***

endif.

Formula section:

If (LV_LAM_LSCL[i] = 1) **or**
(LV_LS_UP_READY[i] = 1)

then **If** (*AF mixture transition flag* = ***Set***)

then **If** (LV_AFL[i] = 1)

then T_AFL_CYC[i] = 0

else T_AFR_CYC[i] = 0

endif

endif

If (LV_LAM_LSCL[i] = 1)

then **If** (LV_AFL[i] = 1)

then *Increment T_AFL_CYC[i]*

else *Increment T_AFR_CYC[i]*

endif

else CTR_AFL_CYC[i] = 0

endif
Reset *AF mixture transition flag*

If (T_AFL_LOCK[i] ≥ IP_T_AFL_LOCK)

then If (LV_AFL[i] = 1)

then If (VLS_UP[i] > C_VLS_AFR_THD)

then LV_AFL[i] = 0
Increment CTR_AFL_CYC[i]
T_AFL_CYC_HLD[i] = T_AFL_CYC[i]
T_AFL_LOCK[i] = 0
Set *AF mixture transition flag*

endif

else If (VLS_UP[i] < C_VLS_AFL_THD)

then LV_AFL[i] = 1
T_AFL_LOCK[i] = 0
Set *AF mixture transition flag*

endif

endif

else *Increment T_AFL_LOCK[i]*

endif

endif.

Increment T_AFL_CYC[i] / Increment T_AFR_CYC[i]

The timers T_AFL_CYC[i] & T_AFR_CYC[i] shall be incremented according to their specified conditions until they reach a maximum value of FFFFH at which point they shall no longer be incremented.

Increment CTR_AFL_CYC[i]

The Air-Fuel cycle counter CTR_AFL_CYC[i] shall be incremented for every lean to rich AF mixture transition, to indicate that a complete AF cycle has passed. The counter shall be incremented in such manner until it reaches a maximum value of FFFFH at which point it shall no longer be incremented.

Note: The internal flag indicating a AF mixture transition shall be reset after the AF counter CTR_AFL_CYC[i] has been processed.

Increment T_AFL_LOCK[i]

The timer T_AFL_LOCK[i] shall be incremented according to the specified conditions until it reaches a maximum value of FFH at which point it shall no longer be incremented.

LV_AFL[i] transition lock-out time after transition of AF mixture					

7.39 Upstream oxygen sensor signal voltage

7.39.1 Signal evaluation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VLS_UP_DRV1_MMV[NC_CBK_EX_NR]	V/O	8000...7FFFH	-2.5...2.499924	7.6294E-5	V/10ms
Mean of buffer containing 1st derivative of VLS_UP[i] signal					
VLS_UP_DRV1_MMV_MIN[NC_CBK_EX_NR]	V/O	8000...7FFFH	-2.5...2.499924	7.6294E-5	V/10ms
Minimum value of mean of buffer containing 1st derivative of VLS_UP[i] signal in lean phase					
VLS_UP_DRV1_ABS_MAX[NC_CBK_EX_NR]	V/O	0...FFFFH	0...4.999924	7.6294E-5	V/10ms
Absolute maximum value within buffer containing 1st derivative of VLS_UP[i] signal					
VLS_UP_MMV_MIN[NC_CBK_EX_NR]	V/O	0...FFFFH	0...4.999924	7.6294E-5	V
Mean oxygen sensor lean voltage					
VLS_UP_MMV_MAX[NC_CBK_EX_NR]	V/O	0...FFFFH	0...4.999924	7.6294E-5	V
Mean oxygen sensor rich voltage					
VLS_UP_BOL[NC_CBK_EX_NR]	V/O	0...3FFH	0…4.995117	4.8828E-3	V
Variable switching threshold for calculation of VLS_UP_MMV_MIN[i]					
VLS_UP_TOL[NC_CBK_EX_NR]	V/O	0...3FFH	0…4.995117	4.8828E-3	V
Variable switching threshold for calculation of VLS_UP_MMV_MAX[i]					
VLS_UP_MMV_HYS[NC_CBK_EX_NR]	V	0...3333H	0…0.999985	7.6294E-5	V
Variable hysteresis used to determine switching thresholds					
LV_VLS_UP_MMV_LIM[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating VLS_UP_MMV_xxx[i] signals being limited when set					
LV_VLS_UP_MMV_STK_VLD[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating VLS_UP_MMV_xxx[i] signals valid when set					

Input data:

LV_ST_END	LV_ES	LV_PUC	NC_CBK_EX_NR

VLS_UP[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

The function shall evaluate the oxygen sensor signal voltage and compute a number of resultant values that may be used by other functions. These values shall include:

1. Moving mean of sensor voltage first derivative, i.e. average signal gradient
2. Minimum value of moving mean of sensor voltage first derivative in lean phase
3. Absolute maximum of sensor voltage first derivative over defined number of previous samples, i.e. measure of sensor voltage stability
4. Moving mean value of lean sensor voltage
5. Moving mean value of rich sensor voltage.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank

Signal flow diagram:

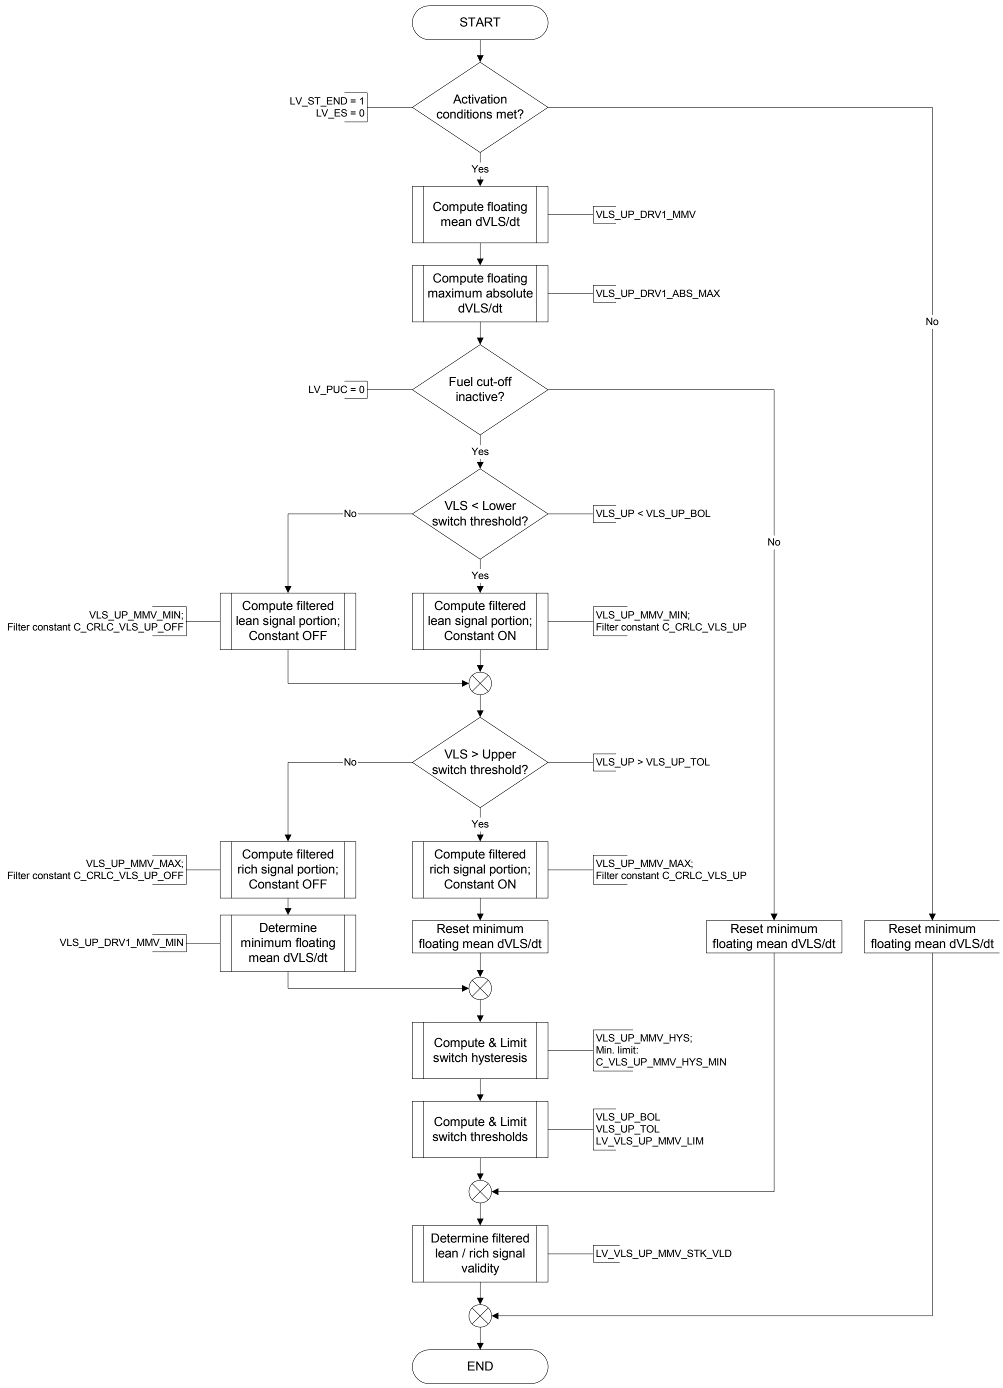

Figure 1 Function flow chart, Signal evaluation

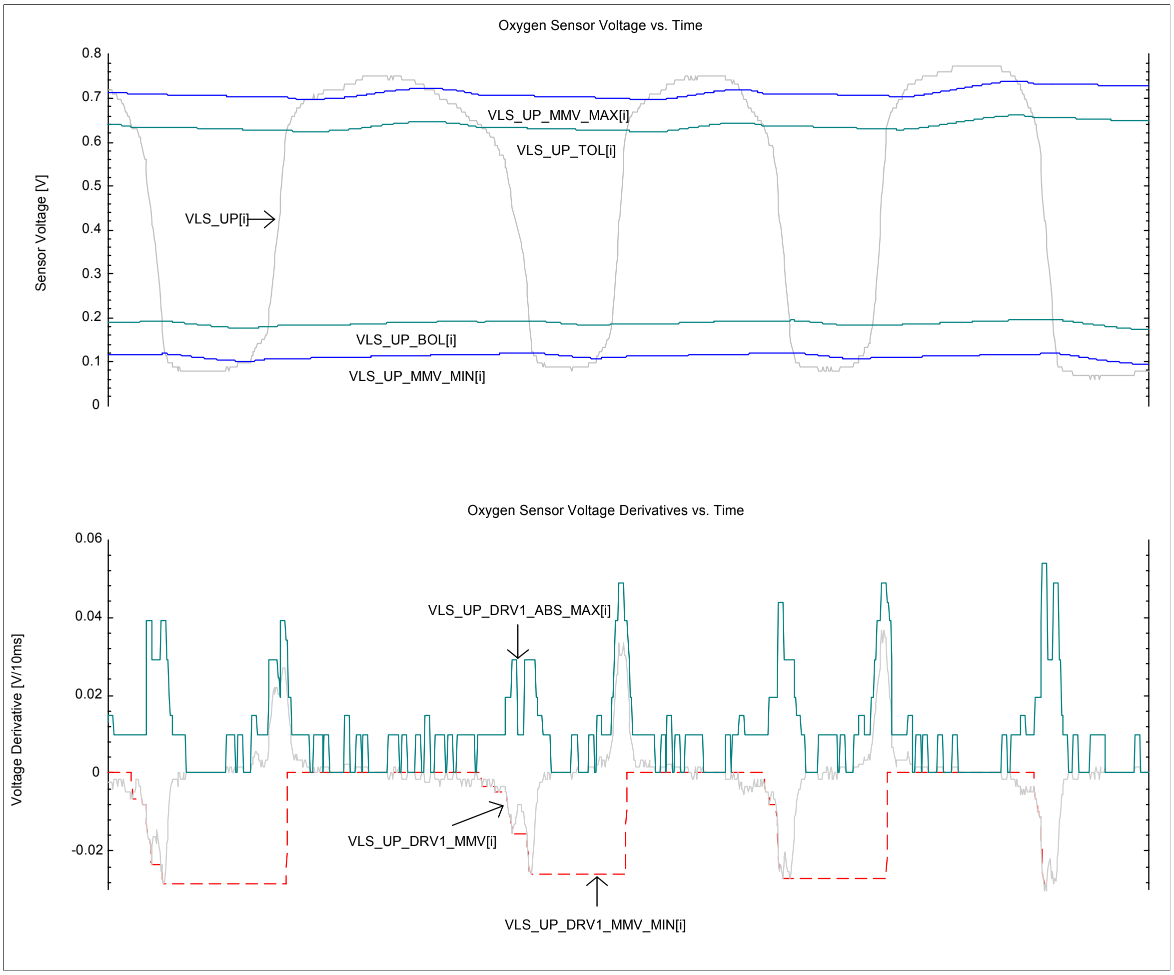

Figure 2 Physical relationship between values, Signal evaluation

Description:

The function shall evaluate the upstream oxygen sensor signal VLS_UP[i] and provide variables quantifying the signal characteristics: Floating mean gradient, Floating maximum signal deviation between samples, Filtered mean rich signal voltage & Filtered mean lean signal voltage. Furthermore, the validity of the latter two characteristics shall be provided. This shall be carried out as follows:

The function shall be activated should the engine state transition out of start (LV_ST_END = 1) and shall be deactivated should the engine stop state (LV_ES = 1) be entered.

Once the activation conditions have been met the function may be described in the following blocks:

1. Computation of moving mean of first derivative VLS_UP_DRV1_MMV[i]: The moving mean value of oxygen sensor signal voltage first derivative VLS_UP_DRV1_MMV[i] shall be computed by averaging the last differences between consecutive VLS_UP[i] samples, i.e. the most current difference ($VLS\_UP[i]_N$ - $VLS\_UP[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal gradient.

2. Computation of absolute maximum of first derivative VLS_UP_DRV1_ABS_MAX[i]: The absolute maximum of the oxygen sensor voltage first derivative VLS_UP_DRV1_ABS_MAX[i] shall be computed by taking the maximum of the absolute values of the last differences between consecutive VLS_UP[i] samples, i.e. the most current difference ($VLS\_UP[i]_N$ - $VLS\_UP[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal stability.

3. Computation of moving mean value of lean and rich sensor voltages, VLS_UP_MMV_xxx[i]: The computation of the moving mean value of lean and rich sensor voltages, associated switch thresholds and switch hysteresis shall only be carried out should the logical flag for overrun fuel cut-off be reset (LV_PUC = 0). The lean and rich mean signal voltages shall be implemented by use of first order low pass filtering and floating switching thresholds. For example:

Should the VLS_UP[i] signal exceeds the threshold VLS_UP_TOL[i], the rich mean signal voltage VLS_UP_MMV_MAX[i] shall be computed by filtering the VLS_UP[i] signal with filter constant C_CRLC_VLS_UP. This shall continue until threshold VLS_UP_TOL[i] is no longer exceeded, after which VLS_UP_MMV_MAX[i] shall be computed by filtering with filter constant C_CRLC_VLS_UP_OFF. This constant is much smaller than C_CRLC_VLS_UP and the effect is to cause the VLS_UP_MMV_MAX[i] to follow the rich peaks. The OFF constant shall permit the VLS_UP_MMV_MAX[i] signal to follow the VLS_UP[i] signal for sudden decreases in signal amplitude, i.e. maximum VLS_UP[i] lower than VLS_UP_TOL[i].

The same procedure shall be carried out for the computation of VLS_UP_MMV_MIN[i], i.e. where VLS_UP[i] falls below VLS_UP_BOL[i], VLS_UP_MMV_MIN[i] shall be computed with filter constant C_CRLC_VLS_UP and where VLS_UP[i] no longer falls below VLS_UP_BOL[i], the filter constant C_CRLC_VLS_UP_OFF shall be used.

4. Determination of the minimum value of the moving mean of first derivative VLS_UP_DRV1_MMV_MIN[i]: The same conditions as for the computation of VLS_UP_MMV_xxx[i] shall apply. Should VLS_UP[i] fall below or equal VLS_UP_TOL[i], $VLS\_UP\_DRV1\_MMV\_MIN[i]_N$ shall be equal to the lower of $VLS\_UP\_DRV1\_MMV\_MIN[i]_{N-1}$ & VLS_UP_DRV1_MMV[i]. When VLS_UP[i] exceeds VLS_UP_TOL[i], LV_PUC = 1 or the function is deactivated, VLS_UP_DRV1_MMV_MIN[i] shall be reset to 0.

5. Compute & limit switch hysteresis: The value of the hysteresis, VLS_UP_MMV_HYS[i], used to determine the switching thresholds VLS_UP_BOL[i] & VLS_UP_TOL[i] shall be made proportional using factor C_FAC_VLS_UP_MMV_HYS to the oxygen sensor signal amplitude, as determined by taking the absolute difference of the moving mean lean / rich

variables. The hysteresis shall also be limited so that it may not fall below the calibrateable threshold C_VLS_UP_MMV_HYS_MIN.

6. Compute & limit switch thresholds: The function shall limit the minimum amplitude of the difference between the moving mean lean / rich variables (VLS_UP_MMV_MAX[i] - VLS_UP_MMV_MIN[i]) to twice that of the switch hysteresis, VLS_UP_MMV_HYS[i].

Should the amplitude of the aforementioned difference fall below the said threshold, both the switch thresholds VLS_UP_BOL[i] & VLS_UP_TOL[i] shall be set to the average of the moving mean lean / rich variables, the moving mean lean / rich variables are recalculated based on the limited switching thresholds and hysteresis and the flag LV_VLS_UP_MMV_LIM[i] shall be set to indicate that switch threshold limiting is active.

Should no limiting be required, the switch thresholds VLS_UP_BOL[i] & VLS_UP_TOL[i] shall be calculated based on the switch hysteresis, moving mean lean variable and moving mean rich variable respectively. The flag LV_VLS_UP_MMV_LIM[i] shall be reset to indicate that no switch threshold limiting is being carried out.

7. Determine validity of moving mean lean / rich sensor voltages: The function shall determine whether the moving mean lean / rich signals are valid to permit certain use in other functions. The validity of the signals VLS_UP_MMV_MIN[i] & VLS_UP_MMV_MAX[i], as indicated by the logical variable LV_VLS_UP_MMV_STK_VLD[I], is determined to be given once the moving mean lean / rich signals have begun to stabilise after function activation, i.e. when VLS_UP_MMV_MIN[i] is less than VLS_UP_MMV_MAX[i] and once sufficient Air-Fuel cycles, as denoted by CTR_AFL_CYC[i], have passed since lambda controller activation (C_CTR_VLS_UP_AFL_CYC_MIN cycles) and where the lambda controller is still active (LV_LAM_LSCL[i] = 1).

The above blocks shall be cycled through once every function recurrence.

Application conditions:

Recurrence:

The function shall be carried out once every oxygen sensor acquisition, i.e. every 10 ms.

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

VLS_UP_MMV_MIN[i] = C_VLS_UP_INI_MIN
VLS_UP_MMV_MAX[i] = C_VLS_UP_INI_MAX
VLS_UP_BOL[i] = C_VLS_UP_INI_MAX
VLS_UP_TOL[i] = C_VLS_UP_INI_MIN
VLS_UP_MMV_HYS[i] = C_VLS_UP_MMV_HYS_MIN
LV_VLS_UP_MMV_LIM[i] = 0
VLS_UP_DRV1_MMV[i] = 0
VLS_UP_DRV1_MMV_MIN[i] = 0
VLS_UP_DRV1_ABS_MAX[i] = 0
LV_VLS_UP_MMV_STK_VLD[i] = 0

Buffer contents from which VLS_UP_DRV1_MMV[i] & VLS_UP_DRV1_ABS_MAX[i] computed = 0.

Activation:

If (LV_ST_END = 1) **&**
(LV_ES = 0)

then ***Function activated***

endif.

Deactivation:

If (LV_ST_END = 0) **or**
(LV_ES = 1)

then ***Function deactivated***
VLS_UP_DRV1_MMV_MIN[i] = 0

endif.

Formula section:

The following function shall be carried out in the order listed and as indicated by the function flow chart:

Computation of moving mean of first derivative VLS_UP_DRV1_MMV[i]

$$VLS\_UP\_DRV1\_MMV[i] = \frac{\sum_{x=0}^{5}\left(VLS\_UP[i]_{N-x} - VLS\_UP[i]_{N-(x+1)}\right)}{6 * 10ms}$$
