A.89.4 RBM interface for RCL Plausibilty - stucked open - diagnosis:

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the RCL plausibility - stuck open - monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_PLAUS_OPEN_RCL data.

Within STATE_RBM_PLAUS_OPEN_RCL, three different informations are defined:

_ Conditions for monitoring are met long enough to detect malfunction (bit 0)
(no intrusive operation, no short trip)
_ Monitor disabled because of system malfunction (bit 1)
(depending on failure status: pending)
_ Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_OPEN_RCL = 0
at LV_DC 0 → 1 transition :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_OPEN_RCL = 0
on failure memory reset :
bit 1 of STATE_RBM_PLAUS_OPEN_RCL = 0

Recurrence: **1 s**

Activation: LC_TCHA_CONF =1 **And** (LV_DC 0 → 1 transition **Or** LV_DC = 1)

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

{ Specific, the project shall list hereafter all failures that can inhibit the RCL plausibility - stuck open - monitor }
{ Global failures which aren't managed by Error Management shall not appear here, because their pending status doesn't exist }

Minimum threshold for OC diagnosis window					
C_WG_EL_PWM_DIAG_MIN_SCP	1	0...FFH	0...99.609375	0.390625	%
Minimum threshold for SCP diagnosis window					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_PSD_DLY_WG	1	1...FH	1...15	1	-
Number of recurrences with diagnosis deactivation after diagnosis activation conditions are met (= 2)					

Import actions:

ACTION_ERRM_FilterMulticondition(IN <XX>, IN <cdn_diag_XX>, IN <err_diag_XX>, IN <c_abc_inc_XX>, IN <c_abc_max_XX>, OUT <lv_err_XX>)
This action computes the elementary anti-bounce filter for one failure treatment and returns filter result
ACTION_INFR_GetElDiagWg(OUT <CDN_DIAG_WG>, OUT <ERR_DIAG_WG>)
This action reads the failure and the conditions information for each symptom from the infrastructure

A.90.1 General information

The Waste Gate (WG) is driven by the ECU via an output driver. The failure detection is done by ECU hardware. The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_WG executions, to avoid the usage of wrong infrastructure information.

Error-symptoms and conditions are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> SYM_0: Short circuit to battery (SCP)
 │ │ └───> SYM_1: Short circuit to ground (SCG)
 │ └─────> SYM_2: Open circuit (OC)
 └───────> SYM_3
```

Configuration for diagnostic symptoms:

Diagnostic WG	Symptoms	Nb	Filter type
WG	SCP	*0*	*MPL_STD_INI*
	SCG	*1*	
	OC	2	
		3	

The data LV_END_DIAG_WG and LV_CDN_DIAG_WG are not present in output data, since they are not used by other functions. Nevertheless; they are provided in error management and always visible.

The error management variables are initialized according to filter type.

Application Condition

ACTION_ERRM_NoFilterReset(**IN** <IDX_DIAG>, **OUT** <LV_ERR>)

General Information

This module performs three diagnosis operations from three different error sources. The first diagnosis, which tests if the turbo charger speed is too high, is called every 100 ms.

The second diagnosis tests if the adapted values of the basic charge air pressure (PUT_WG_OPEN_AD) are above or below defined thresholds.

Similar to the second diagnosis, the third diagnosis tests if the adapted values of the pressure control upstream of throttle (PUT_CTL) are below or above defined thresholds.

The second and third diagnoses are called every second.

A.91.1 General information

Turbo charger speed diagnosis

For turbo charged engines charged engine operation is disabled for the rest of the current driving cycle if charger speed exceeds a critical threshold. If this happens the error bit LV_ERR_TCHA_PROT is set. The symptom of the error code is not handled by anti-bouncing.

Error symptoms for the diagnosis function are defined as following:

> SYM_0
> SYM_1: Too high charger speed
> SYM_2
> SYM_3

Configuration for diagnostic symptoms:

Diagnostic TCHA_PROT	Symptoms	Nb	Filter type
Turbo charger diagnosis			*NO_FIL*
	Too high charger speed	*SYM_I*	

The error management variables are initialized according to filter type.

A.91.2 CHRG_TCHADIAG0/OP_1S

Basic charge air pressure adaptation diagnosis and PUT_CTL diagnosis

The module performs the diagnoses for basic charge air pressure (PUT_WG_OPEN) adaptation and for PUT_CTL adaptation every second.

Basic charge air pressure adaptation diagnosis (PUT_WG_OPEN_AD)

Tests if the adapted values of the basic charge air pressure (PUT_WG_OPEN_AD) are above or below defined thresholds (C_PUT_WG_OPEN_AD_BOL and C_PUT_WG_OPEN_AD_TOL, respectively). If at least one value in PUT_WG_OPEN_AD is outside of the thresholds, the error flag LV_ERR_PUT_WG_OPEN_AD is set. No anti-bounce filters are used.

Error-symptoms for the diagnosis function are defined as following:

> SYM_0: PUT_WG_OPEN adaptation values below lower threshold
> SYM_1: PUT_WG_OPEN adaptation values above upper threshold
> SYM_2
> SYM_3

Configuration for diagnostic symptoms:

Diagnostic PUT_WG_OPEN _AD	Symptoms	Nb	Filter type
Turbo charger diagnosis			*NO_FIL*
	PUT_WG_OPEN adaptation values below lower threshold	*SYM_0*	
	PUT_WG_OPEN adaptation values above upper threshold	SYM_1	

The error management variables are initialized according to filter type.

PUT_CTL diagnosis

Tests if the adapted values of the pressure control upstream of throttle (PUT_CTL) are below or above defined thresholds (C_PRS_DIF_WG_ACR_SP_AD_BOL and C_PRS_DIF_WG_ACR_SP_AD_TOL, respectively). If at least one value in PRS_DIF_WG_ACR_SP_AD is outside of the thresholds, the error flag LV_ERR_PRS_DIF_WG_SP_AD is set. No anti-bounce filters are used.

Error-symptoms for the diagnosis function are defined as following:

> SYM_0: PUT_CTL adaptation values below lower threshold
> SYM_1: PUT_CTL adaptation values above upper threshold
> SYM_2
> SYM_3

Configuration for diagnostic symptoms:

Diagnostic PUT_CTL	Symptoms	Nb	Filter type
Turbo charger diagnosis			*NO_FIL*
	PUT_CTL adaptation values below lower threshold	*SYM_0*	
	PUT_CTL adaptation values above upper threshold	SYM_1	

The error management variables are initialized according to filter type.

Input data:

LV_BLS	LV_BTS	LV_IGK	LV_ES
LV_INH_DIAG_BLS_BTS	LC_ENA_BLS_BTS_ENG_STOP	LV_AT	

General information:

The brake light switch (BLS) and the brake test switch (BTS) are checked for plausibility versus each other. The anti-bounce counter is incremented, if BLS and BTS are not plausible longer than C_T_1_BLS_BTS_NOT_PLAUS_MIN or C_T_2_BLS_BTS_NOT_PLAUS_MIN sec. depending on case, or if BTS is reased and BLS was not detected as pushed.

The anti-bounce counter is decremented if "braking" and "not braking" are clearly detected.

BLS - BTS error symptoms :

```
[ | | | ]

LV_ERR_VCC_SENS_SUB			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the analog input signal (V_PSP_MES) from power steering pressure sensor to the micro-controller via the multiplexed.
The application recurrence is **100 ms**.

Description:

Error symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> Short circuit to Vbatt (SCB)                 (= SYM_0)
 │  │  └────> Short circuit to GND (SCG) or Open load (OL)  (= SYM_1)
 │  └───────>                                             (= SYM_2)
 └──────────> -                                           (= SYM_3)
```

Application conditions:

The error detection is performed only if the power steering pressure sensor option has been recognized (CONF_PSTE has been set to 1).

Initialisation: at LV_IGK 0->1 or Reset LV_INH_DIAG_PSP = 0

Activation: **If** LV_IGK = 1

And LV_INH_DIAG_PSP = 0

Then LV_CDN_DIAG_PSP = 1

Else LV_CDN_DIAG_PSP = 0 (*Deactivation)*

Input data:

GEN_LOAD	LV_IGK	LV_ST_END	LV_ES
GEN_LOAD_MMV	VB_MMV	N	TCO
CONF_GEN_LOAD	LV_ERR_RLY_MAIN	LV_CDN_VB_OBD1	CONF_BAT

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the input signal (PWM) from the alternator about the current load condition.

This diagnosis is performed in two conditions.

1) During Pre-driving

At key On and engine stop condition, the PWM value from alternator is kept to pre-defined specific value(Valeo : 29%, Denso : 19%) and if the PWM value show 0% or 100%, it is defined as error.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │  │  │  └─> Short circuit to GND (SCG)                      (= SYM_0)
 │  │  └────> Short circuit to Vbatt or Open load (SCB/OL)    (= SYM_1)
 │  └───────> -                                               (= SYM_2)
 └──────────> -                                               (= SYM_3)
```

2) During driving

Because short circuit to ground could not be distinguished to normal 100% GEN_LOAD, the diagnosis is performed only to detect open circuit & short circuit battery error.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │  │  │  └─> -                                               (= SYM_0)
 │  │  └────> Short circuit to Vbatt or Open load (SCB/OL)    (= SYM_1)
 │  └───────> -                                               (= SYM_2)
 └──────────> -                                               (= SYM_3)
```

Application conditions:

Initialisation: *at reset*

If CONF_BAT = 0

then GEN_LOAD_MAX_DIAG_ES = C_GEN_LOAD_MAX_DIAG_ES

GEN_LOAD_MIN_DIAG_ES = C_GEN_LOAD_MIN_DIAG_ES

A.98 Fuel Tank Level (FTL) input Signal Diagnosis

General information:

The purpose is to diagnose invalid values of the fuel tank level signal coming from the sender.
No fuel level sensor diagnosis in case of engine operating states start (LV_ST) and engine stopped (LV_ES) and CONF_DIAGCP = 0 and CONF_DIAGCP_VOL = 0.

A.98.1 FTL electrical diagnosis

Output data:

Input data:

LV_IGK	V_FTL	LV_ST	LV_ES
LV_CDN_VB_OBD1	VB	CONF_DIAGCP_VOL	CONF_DIAGCP
V_FTL_SUB	LV_ST_END		

DESCRIPTION:

Error-symtoms are defined to this diagnosis function as following :

Short circuit to Vbatt (=SYM_0)

Short circuit to GND or Open line (=SYM_1)

Remark: Calculation of LV_END_DIAG_FTL_EL and LV_END_DIAG_FTL_SUB_EL see generic calculation "End of diagnosis" in anti bounce algorithm.

Application conditions:

Initialisation: *at new DC*

- LV_ERR_FTL_EL = 0
- LV_CDN_DIAG_FTL_EL= 0
- LV_END_DIAG_FTL_EL = 0
- LV_ERR_FTL_SUB_EL = 0
- LV_CDN_DIAG_FTL_SUB_EL = 0
- LV_END_DIAG_FTL_SUB_EL = 0

```
If    LV_ST_END = 0 -> 1
Then  CTR_DLY_FTL_DIAG = C_CTR_DLY_FTL_DIAG
 and  CTR_DLY_FTL_SUB_DIAG = C_CTR_DLY_FTL_DIAG
endif
```

Recurrence: *0.1 s*

Activation:

The diagnosis is enabled only if LV_IGK = 1 and LV_CDN_VB_OBD1 = 1 and CONF_DIAGCP > 0 and CONF_DIAGCP_VOL > 0 and LV_ST = 0 and LV_ES = 0.

LV_CDN_DIAG_FTL_EL condition:

```
If      LV_IGK = 1
and     LV_ST = 0
and     LV_ES = 0
and     LV_CDN_VB_OBD1 = 1
and     CONF_DIAGCP > 0
then    if    CONF_DIAGCP_VOL = 1    (single FTL sensor)
        and   CTR_DLY_FTL_DIAG = 0
        then  LV_CDN_DIAG_FTL_EL = 1
              LV_CDN_DIAG_FTL_SUB_EL = 0
        else  if    CONF_DIAGCP_VOL = 2        (dual FTL sensors)
              and   CTR_DLY_FTL_SUB_DIAG = 0
              then  LV_CDN_DIAG_FTL_EL = 1
                    LV_CDN_DIAG_FTL_SUB_EL = 1
              endif
        endif
endif
```

Detection:

Due to no clamping voltage with fuel level sensor, electrical diagnosis is performed after the delay counter CTR_DLY_FTL_DIAG has run out with C_CTR_DLY_FTL_DIAG since V_FTL (or V_FTL_SUB) is above(or below) the threshold.

1) main FTL electrical diagnosis

'Short to battery Voltage' :

If $V\_FTL_{(n)}$ > C_V_FTL_MAX_DIAG
and $V\_FTL_{(n-1)}$ <= C_V_FTL_MAX_DIAG
then CTR_DLY_FTL_DIAG has set to C_CTR_DLY_FTL_DIAG
endif

If CTR_DLY_FTL_DIAG has run out
and VB < C_VB_MAX_FTL_DIAG
and $V\_FTL_{(n)}$ > C_V_FTL_MAX_DIAG

LV_ERR_FTL_SUB_INTM	LV_INH_DIAG_FTL_STUCK		

Description:

The purpose is to diagnose the fuel tank level signal from fuel level sender.

The fuel level signal stuck is detected when the filtered FTL signal (FTL_MMV) is not changed during accumulated mileage with engine running. The mileage is accumulated regardless driving cycle and an error is detected when the mileage counter reaches to calibrated constant.

The diagnosis takes place only if LV_IGK = 1 and LV_CDN_VB_OBD2 = 1 and CONF_DIAGCP > 0 and CONF_DIAGCP_VOL > 0.

Error-symptoms are defined to this diagnosis function as following :

FTL signal stuck (=SYM_0)

FTL_SUB signal stuck (=SYM_0)

Remark : Calculation of LV_END_DIAG_FTL_STUCK, LV_END_DIAG_FTL_SUB_STUCK, LV_CDN_DIAG_FTL_STUCK and LV_CDN_DIAG_FTL_SUB_STUCK

see generic calculation "End of diagnosis" in anti bounce algorithm.

and CTR_FCO_FTL_STUCK = 0
and CTR_FCO_FTL_SUB_STUCK = 0
then FTL_MMV_REF_INI calculation

* FTL_MMV_REF_INI calculation :

1. SUM (FTL_MMV i) = Sum of all FTL_MMV values during C_T_DIF_FTL_MMV
2. FTL_MMV_MV_PER value is mean value during C_T_DIF_FTL_MMV and SUM(FTL_MMVi) is calculated every **0.1 sec**.
   FTL_MMV_MV_PER = [SUM (FTL_MMV i)] / (C_T_DIF_FTL_MMV / 0.1 [s])
3. The reference FTL initial value is average value during C_NR_FTL_REF_INI.

$$\mathrm{FTL\_MMV\_REF\_INI} = \frac{\sum_{0}^{\mathrm{C\_NR\_FTL\_REF\_INI}} \mathrm{FTL\_MMV\_MV\_PER}}{\mathrm{C\_NR\_FTL\_REF\_INI} + 1}$$

If there is an interruption during FTL_MMV_REF_INI calculation, this calculation routine is repeated again.

If	FTL_MMV_REF_INI calculation is finished (C_NR_FTL_REF_INI is passed)		
or	Delay time (= C_T_DIF_FTL_MMV * C_NR_FTL_REF_INI) has passed since LV_CDN_DIAG_FTL_STUCK = 1		
then	LV_FTL_STUCK_DIAG_ACT = 1		
	FTL_MMV_POS_DIAG = FTL_MMV_REF_INI		
	FTL_MMV_NEG_DIAG = FTL_MMV_REF_INI		
	CTR_FCO_FTL_STUCK = 0		
endif			

If	FTL_MMV_REF_INI calculation is finished (C_NR_FTL_REF_INI is passed)
or	Delay time (= C_T_DIF_FTL_MMV * C_NR_FTL_REF_INI) has passed since LV_CDN_DIAG_FTL_SUB_STUCK = 1
then	LV_FTL_SUB_STUCK_DIAG_ACT = 1
	V_FTL_SUB_REF_INI = V_FTL_SUB_MMV
	V_FTL_SUB_POS_DIAG = V_FTL_SUB_MMV
	V_FTL_SUB_NEG_DIAG = V_FTL_SUB_MMV
	CTR_FCO_FTL_SUB_STUCK = 0
endif	

At the end of DC, the FTL_MMV_REF_INI & V_FTL_SUB_REF_INI are saved in NVMY.

FTL_MMV_DIF_POS(NEG)_DIAG calculation:

An error (fuel sender stuck) is detected if the average fuel level FTL_MMV does not change (up ⇒ tank fill-up, down ⇒ fuel is consumed) for a certain mileage with the engine running.

1) main FTL

If	LV_FTL_STUCK_DIAG_ACT = 1		
or	LV_FTL_STUCK_H_DIAG_ACT = 1		
then	**if**	LV_ERR_FTL = 0	
	then	**if**	FTL_MMV < FTL_MMV_NEG_DIAG
		then	FTL_MMV_NEG_DIAG = FTL_MMV
		endif	
		if	FTL_MMV > FTL_MMV_POS_DIAG
		then	FTL_MMV_POS_DIAG = FTL_MMV
		endif	
	else	$FTL\_MMV\_NEG\_DIAG_{(n)} = FTL\_MMV\_NEG\_DIAG_{(n-1)}$	
		$FTL\_MMV\_POS\_DIAG_{(n)} = FTL\_MMV\_POS\_DIAG_{(n-1)}$	

```
            endif
            FTL_MMV_DIF_POS_DIAG = FTL_MMV_POS_DIAG – FTL_MMV_REF_INI
            FTL_MMV_DIF_NEG_DIAG = FTL_MMV_NEG_DIAG – FTL_MMV_REF_INI
endif
```

2) sub FTL

```
If      LV_FTL_SUB_STUCK_DIAG_ACT = 1
then    if      LV_ERR_FTL = 0
        then    if      V_FTL_SUB_MMV < V_FTL_SUB_NEG_DIAG
                then    V_FTL_SUB_NEG_DIAG = V_FTL_SUB_MMV
                endif
                if      V_FTL_SUB_MMV > V_FTL_SUB_POS_DIAG
                then    V_FTL_SUB_POS_DIAG = V_FTL_SUB_MMV
                endif
        else    V_FTL_SUB_NEG_DIAG(n) = V_FTL_SUB_NEG_DIAG(n-1)
                V_FTL_SUB_POS_DIAG(n) = V_FTL_SUB_POS_DIAG(n-1)
        endif
        V_FTL_SUB_DIF_POS_DIAG = V_FTL_SUB_POS_DIAG – V_FTL_SUB_REF_INI
        V_FTL_SUB_DIF_NEG_DIAG = V_FTL_SUB_NEG_DIAG – V_FTL_SUB_REF_INI
endif
```

If the end of driving cycle, FTL_MMV_POS(NEG)_DIAG & V_FTL_SUB_POS(NEG) are stored in the NVMY.

CTR_FCO_FTL_STUCK calculation

1) main FTL fuel consumption

```
If      (       LV_FTL_STUCK_DIAG_ACT = 1
        or      LV_FTL_STUCK_H_DIAG_ACT = 1   )
and     LV_END_DIAG_FTL_STUCK = 0
and     LV_END_DIAG_FTL_STUCK_H = 0
then    CTR_FCO_FTL_STUCK(n) = CTR_FCO_FTL_STUCK(n-1)
                        + (FCO_SUM(n) -  FCO_SUM(n-1) )
else    CTR_FCO_FTL_STUCK = 0
endif
```

2) sub FTL fuel consumption

```
If      CONF_DIAGCP_VOL = 2     (dual FTL)
and     LV_FTL_SUB_STUCK_DIAG_ACT = 1
and     LV_END_DIAG_FTL_SUB_STUCK = 0
```

then $CTR\_FCO\_FTL\_SUB\_STUCK_n = CTR\_FCO\_FTL\_SUB\_STUCK_{n-1} + (FCO\_SUM_n - FCO\_SUM_{n-1})$

else CTR_FCO_FTL_SUB_STUCK = 0

endif

The CTR_FCO_FTL_STUCK & CTR_FCO_FTL_SUB_STUCK are saved in NVMY at the end of driving cycle.

CONF_DIAGCP_VOL			

Description:

The purpose is to diagnose the fuel tank level signal from fuel level sender.

The fuel level signal stuck is detected when the filtered FTL signal (FTL_MMV) is not changed during accumulated mileage with engine running. The mileage is accumulated regardless driving cycle and an error is detected when the mileage counter reaches to calibrated constant.

The diagnosis takes place only if LV_IGK = 1 and LV_CDN_VB_OBD2 = 1 and CONF_DIAGCP > 0 and CONF_DIAGCP_VOL > 0.

Error-symptoms are defined to this diagnosis function as following :

FTL signal stuck high (=SYM_1)

Remark : Calculation of LV_END_DIAG_FTL_STUCK_H see generic calculation "End of diagnosis" in anti bounce algorithm.

Application conditions:

Initialisation: *at new DC*

- LV_END_DIAG_FTL_STUCK_H = 0
- LV_FTL_STUCK_H_DIAG_ACT = 0
- LV_ERR_FTL_STUCK_H = 0

If Loss of NVMY or NVMY reset
or failure memory reset (LC_ERR_FMY_CLR)
then LV_FTL_STUCK_H_DIAG_ACT = 0
LV_END_DIAG_FTL_STUCK_H = 0
endif

Recurrence : 0.1 sec.

Activation:

LV_CDN_DIAG_FTL_STUCK condition : same with "FTL plausibility diagnosis – stuck"

Formula section:

FUNCTION DESCRIPTION:

General information:

The purpose of this diagnosis is to detect an implausible gradient on the FTL_MES or V_FTL_SUB signal.

The diagnostic function checks wether the difference between one measured fuel tank level value FTL_MES and the succeeding value is too big. To avoid mis-detection of FTL signal-jump by fuel sloshing, limited dynamic conditions must be fulfilled and sudden vehicle movement should be avoided.

The diagnosis is continuously active if LV_IGK = 1 and LV_CDN_VB_OBD2 = 1 and CONF_DIAGCP > 0 and CONF_DIAGCP_VOL > 0.

Remark : Calculation of LV_END_DIAG_FTL_INTM or LV_END_DIAG_FTL_SUB_INTM see generic calculation "End of diagnosis" in anti bounce algorithm.

NC_PSD_DLY_ALTER	1	1...FH	1...15	1	[-]
Number of recurrences with diagnosis deactivation after diagnosis activation conditions are met (typical 2)					

Import actions:

ACTION_ERRM_FilterMulticondition(IN<XX>, IN< CDN_DIAG_ALTER >, IN< ERR_DIAG_ALTER >, IN<C_ABC_INC_ALTER>, IN<C_ABC_MAX_ALTER>, OUT<LV_ERR_ALTER>)

FUNCTION DESCRIPTION:

General information:

The Alternator is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.
The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description

Error-symptoms are defined to this diagnosis function as following :

ERR_SYM_ALTER:

```
□□□□
 │ │ │ └─> Short circuit to Vbatt    SCP     (= SYM_0)
 │ │ └───> Short circuit to GND      SCG     (= SYM_1)
 │ └─────> Open load                 OL      (= SYM_2)
 └───────> -                                 (= SYM_3)
```

Application conditions:

Initialisation: LV_ERR_ALTER, ERR_SYM_ALTER, LV_END_DIAG_ALTER are initialized according Filter-type.
at reset LV_CDN_DIAG_ALTER = 0

Recurrence: 100 ms

Activation: CONF_BAT = 1 **and** (LV_ERR_ALTER=0 **or** LV_END_DIAG_ALTER=0) **and** LV_CDN_VB_OBD1=1

Deactivation: When the activation condition is not fulfilled

Formula section:

If LV_INH_DIAG_ALTER = 0
Then
Basic diagnosis conditions CDN_DIAG_ALTER is set according driver information
Failure symptoms ERR_DIAG_ALTER is set according driver information

If LV_INH_DIAG_ALTER change from 1 to 0 (Activation conditions is set) it's necessary to set CDN_DIAG_ALTER=0 during NC_PSD_DLY_ALTER recurrences
Then
CDN_DIAG_ALTER = 0
Else
{ Diagnosis info valid: no inhibition during NC_PSD_DLY_ALTER recurrences }

{ Inhibition of open load symptom (SYM_2) : }

If LC_ALTER_DIAG_OC_INH = 1
Then
bit 2 of ERR_DIAG_ALTER = 0 { The open load (SYM_2) is removed }
Endif

Endif
Else
CDN_DIAG_ALTER = 0
Endif

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_ALTER and ERR_DIAG_ALTER.

ACTION_ERRM_FilterMulticondition (IN<NC_IDX_DIAG_ALTER>, IN< CDN_DIAG_ALTER >, IN< ERR_DIAG_ALTER >, IN<C_ABC_INC_ALTER>, IN<C_ABC_MAX_ALTER>, OUT<LV_ERR_ALTER>)
This algorithm determines:

ERR_SYM_ALTER	(Detected error symptom for alternator diagnosis)
LV_ERR_ALTER	(Error flag for debounced error of alternator)
LV_CDN_DIAG_ALTER	(Diagnostics condition information)
LV_END_DIAG_ALTER	(End of diagnosis information)

A.100.2 Alternator plausibility diagnostic

Output data:

Failure index for plausibility alternator diagnostic					

Import actions:

ACTION_ERRM_FilterSymptom(IN<IDX_DIAG>, IN< LV_CDN_DIAG_XX >, IN< ERR_SYM_XX >, IN< C_ABC_INC_XX >, IN< C_ABC_MAX_XX >, IN< C_ABC_DEC_XX >, OUT< LV_ERR_XX >)

Error treatment

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	Name (XX)	Description	Nr		
Alternator plausibility diagnosis	ALTER_PLAUS	-	0	MEM	NO
		-	1		
		-	2		
		Plausibility failure	3		

FUNCTION DESCRIPTION:

General information:

Error detection in case of alternator voltage is low during a delay, but the battery voltage stays at the same voltage. The MEM filter type is used to avoid vehicle effect in case of intermittent error.

Description:

Error-symptoms are defined to this diagnosis function as following :

ERR_SYM_ALTER_PLAUS

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                          (= SYM_0)
 │  │  └────> -                          (= SYM_1)
 │  └───────> -                          (= SYM_2)
 └──────────> -Plausibility failure      (= SYM_3)
```

Application conditions:

Initialization at reset, at key transition and at CLRFMY event :

CTR_DIAG_ALTER_PLAUS = C_DLY_ALTER_DIAG_PLAUS
CTR_DIAG_ALTER_OK =0
The other diagnostic data are initialized according filtering configuration.

Recurrence: 100 ms

Activation: CONF_BAT = 1 **and** LV_ES=0 **and** VS>0 **and** LV_ERR_ALTER=0

Deactivation: When activation function is not filling in
In case of activation condition is false then init treatment is applied :
CTR_DIAG_ALTER_PLAUS = C_DLY_ALTER_DIAG_PLAUS
CTR_DIAG_ALTER_OK = 0
LV_CDN_DIAG_ALTER_PLAUS = 0

Formula section:

Diagnostic condition calculation :

```
If  C_ALTPWM_DIAG_ENA_MIN < ALTPWM < C_ALTPWM_DIAG_ENA_MAX
Then
   { When the battery voltage is low the number of good result is increased }
   If      VB < C_VB_ALTER_DIAG_MAX
   Then
           CTR_DIAG_ALTER_OK = CTR_DIAG_ALTER_OK + 1
   Endif

   { When the delay is elapsed the condition is set }
   CTR_DIAG_ALTER_PLAUS = CTR_DIAG_ALTER_PLAUS - 0.1s

   If      CTR_DIAG_ALTER_PLAUS=0
   Then
           LV_CDN_DIAG_ALTER_PLAUS=1
   Else
           LV_CDN_DIAG_ALTER_PLAUS=0
   Endif
Else
    { When the condition on ALTPWM is not fill in the diagnostic is re-initialized }
    LV_CDN_DIAG_ALTER_PLAUS = 0
    CTR_DIAG_ALTER_PLAUS = C_DLY_ALTER_DIAG_PLAUS
    CTR_DIAG_ALTER_OK = 0
Endif
```

Symptoms calculation :

```
If   LV_CDN_DIAG_ALTER_PLAUS=1
Then
    { When the counter of good diagnostic is too low the failure is set }
    If  CTR_DIAG_ALTER_OK < C_CTR_DIAG_ALTER_OK
    Then
           ERR_SYM_ALTER_PLAUS = SYM_3
    Else
           ERR_SYM_ALTER_PLAUS = NO_SYM
    Endif

    { The diagnostic is re-initialized }
    CTR_DIAG_ALTER_PLAUS = C_DLY_ALTER_DIAG_PLAUS
    CTR_DIAG_ALTER_OK =0

Endif
```

For failure and error management treatment the anti-bounce mechanism is called :

```
ACTION_ERRM_FilterSymptom( IN<NC_IDX_DIAG_ALTER_PLAUS>,
IN<LV_CDN_DIAG_ALTER_PLAUS>, IN<ERR_SYM_ALTER_PLAUS>,
IN<C_ABC_INC_ALTER_PLAUS>, IN<C_ABC_MAX_ALTER_PLAUS>, IN<1>,
OUT<LV_ERR_ALTER_PLAUS>)
```

Timer for TCU2 timeout diagnosis					

Input data:

VB	LV_IGK	N_32	LV_STE_TCU1_CAN_IN
TOUT_CTR_TCU1	CONF_TCU		

FUNCTION DESCRIPTION:

General information:

The diagnosis function checks the receiving of messages from the TCU via the CAN plus the correct transmission of messages via the CAN.

Error symptoms are defined to the diagnosis functions as following:

TIMEOUT_TCU1:

```
□□□□
│ │ │ └─> -                                   (= SYM_0)
│ │ └───> -                                   (= SYM_1)
│ └─────> -                                   (= SYM_2)
└───────> No Message received from TCU        (= SYM_3)
```

CAN_BUS_OFF:

```
□□□□
│ │ │ └─> -                                   (= SYM_0)
│ │ └───> -                                   (= SYM_1)
│ └─────> Communication Problem on the CAN    (= SYM_2)
└───────>-                                    (= SYM_3)
```

CAN_FRF:

```
□□□□
│ │ │ └─> Freeze frame request via CAN        (= SYM_0)
│ │ └───> -                                   (= SYM_1)
│ └─────> -                                   (= SYM_2)
└───────> -                                   (= SYM_3)
```

Application conditions:

Initialisation:

Recurrence: 10ms

Activation:

If LV_IGK = 1
and VB > C_VB_MIN_CAN_DIAG
and N_32 > C_N_MIN_CAN_DIAG
then **if** T_DLY_CAN_DIAG >= C_T_DLY_MIN_CAN_DIAG
then LV_CAN_DIAG_ACT = 1
else LV_CAN_DIAG_ACT = 0
$T\_DLY\_CAN\_DIAG_{(n)} = T\_DLY\_CAN\_DIAG_{(n-1)} + 1$
else T_DLY_CAN_DIAG = 0
LV_CAN_DIAG_ACT = 0

Before the diagnosis starts after ignition on, a time of 140 ms is waited for initialization TCU.

After activation of the CAN-diagnosis the timer T_DLY_TIMEOUT_TCU1 and T_DLY_TIMEOUT_TCU2 are started. If the TCU1 timer reaches the maximum value

C_MAX_TIMEOUT_TCU1 without having received a message, the anti-bounce counter is incremented with C_ABC_INC_TIMEOUT_TCU1 and the timer starts again.
If the TCU2 timer reaches the maximum value C_MAX_TIMEOUT_TCU1 without having received a message all TCU2 values are set to init values and the timer starts again

If again no message arrives, this process repeats until the anti-bounce counter reaches C_ABC_MAX_TIMEOUT_TCU1 and the failure bit LV_ERR_TIMEOUT_TCU1 is set.

If a message is transfered incorrect on the bus to one of the CAN-connected components (e.g. due to electrical interference on the CAN), the anti-bounce counter is incremented with C_ABC_INC_CAN_BUS_OFF.

The receiving of a message (in case of a Timeout-Error) or the correct transfer of a message (in case of a transfer error) decrements the corresponding anti-bounce counter with 1.
As soon as one of the CAN-Diagnosis related error bits is set to one then LV_ERR_CAN = 1. It is reset to 0 if all the corresponding anti-bounce counters are 0.

If CAN message transimission is suppressed by key-word service request (disableNormalMessageTransmission (28h)) or CAN_BUS_OFF error is detected (LV_ERR_CAN_BUS_OFF =1) TIMEOUT_TCU1 diagnosis is inhibited (LV_INH_DIAG_TIMEOUT_TCU1 = 1).

If CAN_FRF Diagnosis is enabled (LC_ENA_CAN_FRF_DIAG = 1) and the TCU requests a freeze frame & MIL ON via CAN(TCU_OBD) via TCU_OBD, the LV_ERR_CAN_FRF is set to 1, else LV_ERR_CAN_FRF is set to 0. If LC_ENA_CAN_FRF_DIAG = 0 then diagnosis is deactivated.

The Freeze Frame which is requested by TCU has to be cleared if there is no more freeze frame request from TCU regardless of current warm-up cycle counter in EMS ECU.

<u>* Emergency operation:</u>

If the error CAN_BUS_OFF occurs
then initialization values for each message will be set

If the error TIMEOUT_TCU1 occurs
then initialization values for the TCU-message will be set

For more detailed information please refer to the CAN-specification.

<u>Application conditions:</u>
* Debounce :

Anti-bounce counter increment:	C_ABC_INC_CAN_BUS_OFF C_ABC_INC_TIMEOUT_TCU1
Maximum value of anti-bounce counter:	C_ABC_MAX_CAN_BUS_OFF C_ABC_MAX_TIMEOUT_TCU1

Present failure (0: Passive, 1: Active)					
LV_END_DIAG_TQ_LIM_INTV	O/V	0...1H	0...1	1	-
Result of diagnosis (0: Passive, 1: Active)					

Input data:

LV_TQ_LIM_INTV	LV_MTC_CUR_OFF	LV_IGK	LV_ST
LV_ES			

FUNCTION DESCRIPTION:

General information:

The objective of this function is to determine the number of intervention actions concerning the torque request for safety and to set the failure table entry if the counter exceeds a calibratable threshold.

The monitoring level generates a desired indicated torque TQI_SP_MON. If the actual torque TQI_AV exceeds this value for more than a calibratable threshold a torque demand for the slow and the fast path is generated. The flag LV_TQ_LIM_INTV shows whether this torque intervention is active or not (see chapter D – "Torque request for safety").

Application conditions:

Initialisation: ECU reset **OR** transition LV_IGK = 0 → 1
LV_CDN_DIAG_TQ_LIM_INTV = 0
ERR_SYM_TQ_LIM_INTV = NO_SYM
LV_ERR_TQ_LIM_INTV = 0

Recurrence: 100 ms

Activation: LV_MTC_CUR_OFF == 0 **AND** LV_ST == 0 **AND** LV_ES == 0
Set LV_CDN_DIAG_TQ_LIM_INTV = 1

Deactivation: LV_MTC_CUR_OFF == 1 **OR** LV_ST == 1 **OR** LV_ES == 1
Set LV_CDN_DIAG_TQ_LIM_INTV = 0

Formula section:

IF LV_TQ_LIM_INTV == 1
THEN ERR_SYM_TQ_LIM_INTV = 01h (Maximum allowed value exceeded)
ELSE ERR_SYM_TQ_LIM_INTV = 0h
ENDIF

After debounce LV_ERR_TQ_LIM_INTV = 1

Configuration data :

Diagnosis	Symptom	Nr	ABC type
Torque intervention for safety active TQ_LIM_INTV	Actual or requested torque higher than allowed limit	0	See remarks below

Remarks:

- decrement must be calibrated with maximum value
- if failure is present, no healing possible
- anitbounce counter is initialized with zero at reset
- LV_END_DIAG_TQ_LIM_INTV is calculated in antibounce algorithm

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_TQ_LIM_INTV	1	0...FFH	0...255	1	-
Debounce counter increment value for torque request for safety diagnosis					
C_ABC_DEC_TQ_LIM_INTV	1	0...FFH	0...255	1	-
Debounce counter decrement value for torque request for safety diagnosis					
C_ABC_MAX_TQ_LIM_INTV	1	01...FFH	1...255	1	-
Debounce counter maximum value for the for torque request for safety diagnosis					

A.104 Reset resistant ETC- Limp Home

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_N_LIM_REQ_RST_CHK	V / O	0H...1H	0...1	1	-
Flag to be set if LIH_ACT is set after reset					
LIH_ACT	V/S	0H...FFFFH	0...65536	1	-
0H = no ETC-Limp Home / AF50H = ETC-Limp Home active – Word is stored every 100 ms to reset resistant memory and stored twice as complement					

Input data:

LV_ERR_PVS	LV_ERR_TPS	LV_N_LIM_REQ_RST_CHK	LV_IGK
LV_N_LIM_REQ_MON	LV_ERR_TQI_N_MAX_MON		

FUNCTION DESCRIPTION:

General information:

If ETC-Limp home is active, performance is limited for the driver. After a reset of the ECU this limitation of performance is lost from one second to another. To prevent this dangerous situation the word LIH_ACT is saved to reset independant memory every 100 ms. This special part of memory is not deleted in case of warm reset (software reset). In case of cold reset (hardware reset) even information in this reset resistant memory is lost.

While initializing the ECU the word LIH_ACT is been read out of the reset resistant memory. If it is set, LV_N_LIM_REQ_RST_CHK is set to 1 for the current driving cycle. At transition LV_IGK = 1 → 0 or if the failure memory is been deleted, LV_N_LIM_REQ_RST_CHK and LIH_ACT are reset to 0.

Application Conditions:

Recurrence: 100ms

Initialisation:

at reset (but not in case of warm-reset) **OR**
at transition LV_IGK = 1 → 0 **OR**
after clearing failure memory

LV_N_LIM_REQ_RST_CHK = 0
LIH_ACT = 0

The following initialization is only used after warm-reset :

IF after warm-reset LIH_ACT = AF50 hex (44880 dec)
(read after warm-reset from reset resistant memory)

THEN LV_N_LIM_REQ_RST_CHK = 1
(to be written only once while initializing ECU)

ELSE LV_N_LIM_REQ_RST_CHK = 0
(to be written only once while initializing ECU)

ENDIF.

Activation:

LV_IGK = 1

Deactivation:

LV_IGK = 0

<u>Formula section:</u>

IF LV_ERR_PVS = 1 **OR**
LV_ERR_TPS = 1 **OR**
LV_N_LIM_REQ_MON = 1 **OR**
LV_ERR_TQI_N_MAX_MON = 1 **OR**
LV_N_LIM_REQ_RST_CHK = 1

THEN LIH_ACT = AF50 hex (44880 dec)
(to be written to reset resistant memory every 100ms)

ELSE LIH_ACT = 0 (to be written to reset resistant memory every 100ms)

ENDIF.

A.105 Exhaust gas temperature sensor diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TEG_MES[NC_NR_TEG_SENS]	O	0...1H	0...1	1	-
Global error flag for each sensor					

Input data:

NC_NR_TEG_SENS

A.105.1 General info:

This module is just to define LV_ERR_TEG_MES even if no sensor is available because this value is used as input in other functions.

Function Description

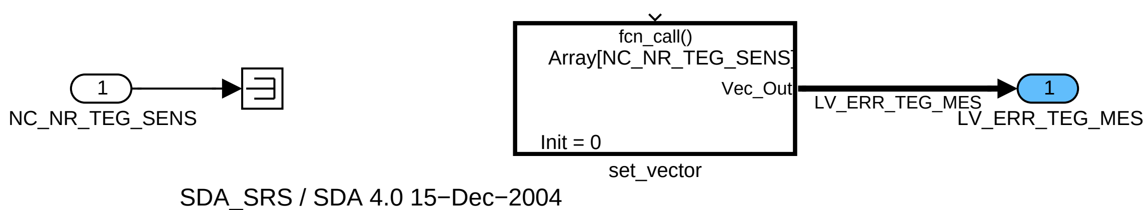

Figure 92 EXTD_SIGDG0

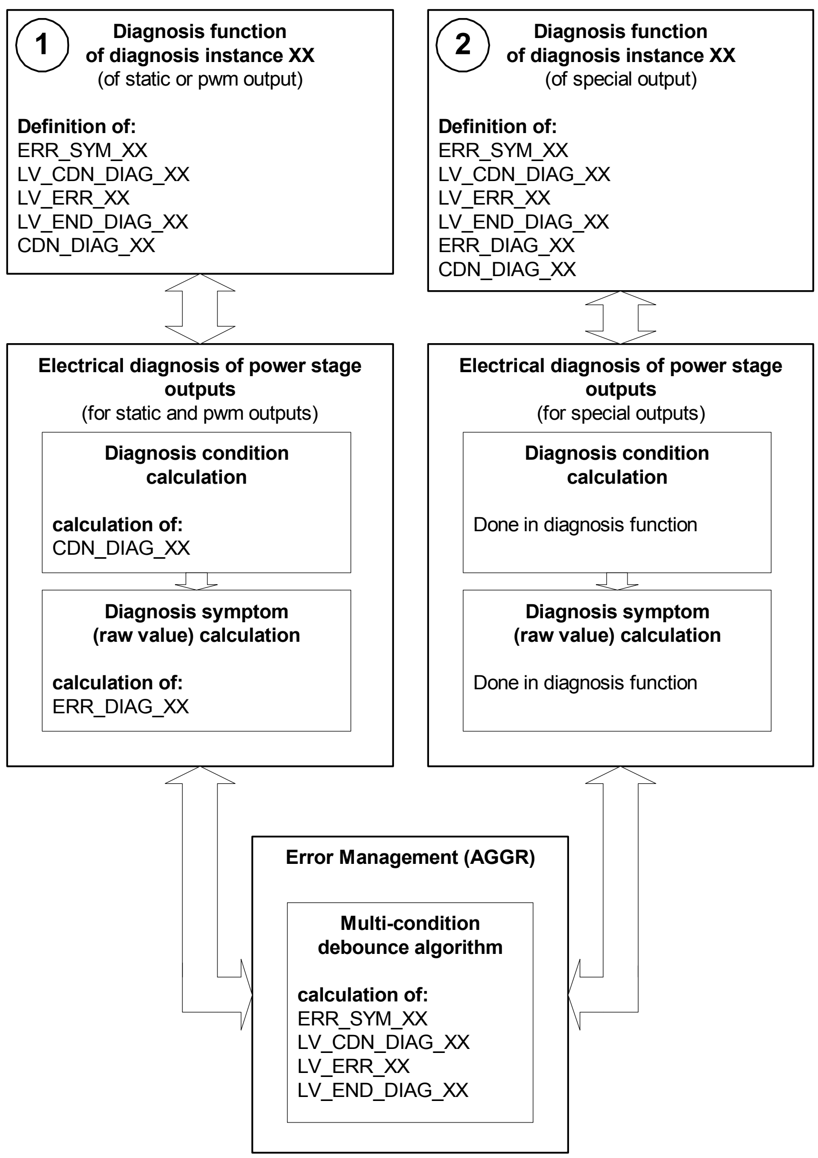
A.106 Electrical diagnosis of power stage outputs

FUNCTION DESCRIPTION:

General information:

In this function description the electrical diagnosis of power stage outputs is specified. Because of the possibility of different hardware configurations, the specification is splited into three parts plus one common part for the symptom debounce and error management treatment.

- Diagnosis of static outputs (e.g. relays)
- Diagnosis of pwm outputs (e.g. VVT actuator)
- Diagnosis of special outputs (other hardware configurations)



According these three different kind of driver outputs the management of the electrical diagnosis is different between static/pwm outputs and special outputs (see previous picture case 1 and 2).

For all types of these diagnoses three main calculations must be done:

- Diagnosis condition calculation
- Diagnosis symptom (raw value) calculation
- anti-bounce mechanism with error management treatments

In the following chapter these treatments are described.

A.106.1 Diagnosis of static outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	LV_INH_DIAG_XX		

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >, OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

General information:

The purpose is to diagnose electrical errors detected by the hardware for static outputs. The signal is controlled by the ATIC 39.

The driver can distinguish between three symptoms: ‘Short to battery’ SCB, ‘Short to ground’ SCG and ‘Open circuit’ OC.

Description:

By the diagnosis condition calculation the information given by the BSW (‘Diagnosis of symptom ... is valid’) that shows, that a diagnosis of a symptom was possible, since the last recurrence of the diagnosis function, is displayed for each symptom within the value CDN_DIAG_XX.

The information of the failure symptom is also delivered by the BSW (‘Failure symptom ... detected by HW’). According this information the diagnosis symptom (raw value) calculation is performed to set ERR_DIAG_XX.

The calculation of LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX and LV_END_DIAG_XX is done in the Multi-condition debounce algorithm (part of Error Management AGGR).

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation: CDN_DIAG_XX = 0

Formula section:

Diagnosis condition calculation:

CDN_DIAG_XX = 0

Diagnosis condition calculation for symptom 'Short to battery' SCB:

If 'Diagnosis of symptom SCB is valid' (BSW information)

Then bit 0 of CDN_DIAG_XX = 1

Endif

Diagnosis condition calculation for symptom 'Short to ground' SCG:

If 'Diagnosis of symptom SCG is valid' (BSW information)

Then bit 1 of CDN_DIAG_XX = 1

Endif

Diagnosis condition calculation for symptom 'Open circuit' OC:

If 'Diagnosis of symptom OC is valid' (BSW information)

Then bit 2 of CDN_DIAG_XX = 1

Endif

Diagnosis symptom (raw value) calculation:

Symptom calculation for 'Short to battery' SCB:

If	'Failure symptom SCB detected by HW'	(BSW information)
Then	bit 0 of ERR_DIAG_XX = 1	
Else	bit 0 of ERR_DIAG_XX = 0	
Endif		

Symptom calculation for 'Short to ground' SCG:

If	'Failure symptom SCG detected by HW'	(BSW information)
Then	bit 1 of ERR_DIAG_XX = 1	
Else	bit 1 of ERR_DIAG_XX = 0	
Endif		

Symptom calculation for 'Open circuit' OC:

If	'Failure symptom OC detected by HW'	(BSW information)
Then	bit 2 of ERR_DIAG_XX = 1	
Else	bit 2 of ERR_DIAG_XX = 0	
Endif		

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

A.106.2 Diagnosis of PWM outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	LV_INH_DIAG_XX	XXPWM	

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >,
OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose electrical errors detected by the hardware for PWM outputs. The signal is controlled by ATIC39.
The driver can distinguish between three symptoms: 'Short to battery' SCB, 'Short to ground' SCG and 'Open circuit' OC.

Because of the different filter times for SCB, SCG and OC detection, the diagnosis window, where a symptom can be detected, is defined for each symptom. A diagnosis window is defined by a minimum and a maximum duty cycle of the PWM signal controlled by the output of the driver.

SCB diagnosis window:

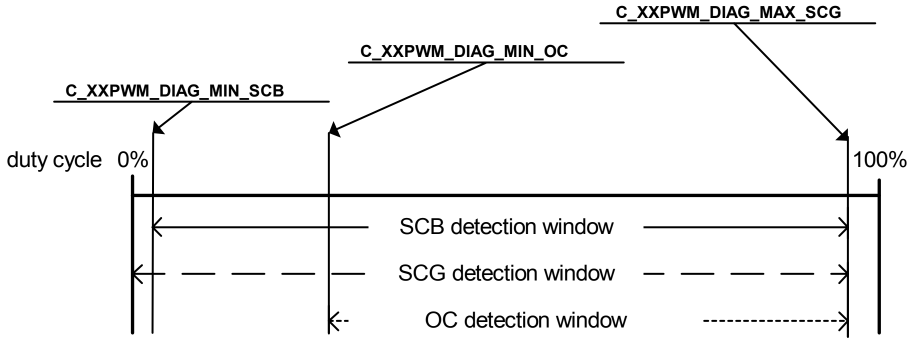
C_XXPWM_DIAG_MIN_SCB <-------> C_XXPWM_DIAG_MAX_SCG

SCG diagnosis window:

0 <-------> C_XXPWM_DIAG_MAX_SCG

OC diagnosis window:

C_XXPWM_DIAG_MIN_OC <-------> C_XXPWM_DIAG_MAX_SCG



For some diagnosis it's not necessary to define different diagnosis windows for each symptom. This is possible for all diagnosis, where a limitation of the duty cycle range is made within the function which controls the corresponding output. The limitation must be made in this way, that a diagnosis of all three symptoms can always (if LV_INH_DIAG_XX= 0) be made (CDN_DIAG_XX = 7H, LV_CDN_DIAG_XX = 1).

These two possibilities of a diagnosis condition calculation are described in the following chapter. It's distinguished between a "open range" (different diagnosis windows for each symptom necessary) and a "limited" duty cycle calculation.

A.106.2.1 Diagnosis condition calculation

A.106.2.1.1 "Open range" duty cycle

Description:

For an output with an "open range" duty cycle range, a diagnosis result of a symptom can be considered as valid, if the duty cycle of the PWM output was in the right window at least one time between two calculations of the diagnosis function and not only if diagnosis function is called. To have a better reflection of this behavior, the diagnosis condition is calculated independently of the diagnosis function.

If the recurrence of the 'diagnosis condition' calculation is the same like the 'symptom' calculation, the 'diagnosis condition' calculation must be treated after the 'symptom' calculation to have a new diagnosis condition CDN_DIAG_XX information of the following diagnosis window for the next symptom calculation.

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation CDN_DIAG_XX = 0

Formula section:

Diagnosis window calculation:

If 0 <= XXPWM < C_XXPWM_DIAG_MIN_SCB
Then bit 1 of CDN_DIAG_XX = 1
Diagnosis of SCG is valid

Else **If** XXPWM < C_XXPWM_DIAG_MIN_OC
Then bit 0 and bit 1 of CDN_DIAG_XX = 1
Diagnosis of SCB, SCG is valid

Else **If** XXPWM <= C_XXPWM_DIAG_MAX_SCG
Then bit 0, bit 1 and bit 2 of CDN_DIAG_XX = 1
Diagnosis of SCB, SCG and OC is valid
Endif
Endif
Endif

A.106.2.1.2 "Limited" duty cycle

Description:

For an output with a "limited" duty cycle range, the diagnosis result of a symptom can always be considered as valid, because of the current duty cycle. It only can be invalid because special conditions managed by the BSW.

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation: CDN_DIAG_XX = 0

Formula section:

bit 0, bit 1 and bit 2 of CDN_DIAG_XX = 1

Diagnosis of SCB, SCG and OC is valid

A.106.2.2 Diagnosis symptom (raw value) calculation

FUNCTION DESCRIPTION:

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

Formula section:

Symptom calculation for 'Short to battery' SCB:

If 'Failure symptom SCB detected by HW' (BSW information)

Then bit 0 of ERR_DIAG_XX = 1

Else bit 0 of ERR_DIAG_XX = 0

Endif

Symptom calculation for 'Short to ground' SCG:

If 'Failure symptom SCG detected by HW' (BSW information)

Then bit 1 of ERR_DIAG_XX = 1

Else bit 1 of ERR_DIAG_XX = 0

Endif

Symptom calculation for 'Open circuit' OC:

If 'Failure symptom OC detected by HW' (BSW information)

Then bit 2 of ERR_DIAG_XX = 1

Else bit 2 of ERR_DIAG_XX = 0

Endif

Diagnosis condition from BSW verification:

Diagnosis condition calculation for symptom 'Short to battery' SCB:

If 'Diagnosis of symptom SCB is not valid' (BSW information)

Then bit 0 of CDN_DIAG_XX = 0

Endif

Diagnosis condition calculation for symptom 'Short to ground' SCG:

If 'Diagnosis of symptom SCG is not valid' (BSW information)

Then bit 0 of CDN_DIAG_XX = 0

Endif

Diagnosis condition calculation for symptom 'Open circuit' OC:

If 'Diagnosis of symptom OC is not valid' (BSW information)

Then bit 0 of CDN_DIAG_XX = 0

Endif

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

CDN_DIAG_XX = 0 (after failure debouncing and error management treatment)

A.106.3 Diagnosis of special outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	ERR_DIAG_XX	CDN_DIAG_XX	

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >, OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

General information:

The purpose is to diagnose electrical errors detected by the hardware for special outputs. Special outputs are outputs, which cannot be treated like "normal" static or pwm outputs, like described in the previous chapters.

Description:

The diagnosis condition calculation for the driver output is done in the diagnosis function of the diagnosis instance XX. It's displayed for each symptom within the value CDN_DIAG_XX. Also the diagnosis symptom (raw value) calculation (ERR_DIAG_XX) is performed in the diagnosis function for special outputs.

The calculation of LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX and LV_END_DIAG_XX is done in the Multi-condition debounce algorithm (part of Error Management AGGR).

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after CDN_DIAG_XX > 0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: -

Formula section:

Diagnosis condition / Diagnosis symptom (raw value) calculation:

CDN_DIAG_XX and ERR_DIAG_XX are calculated in the diagnosis function.

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_PSD_DLY	1	0 ... FFH	0 ... 255	1	-
The diagnosis is reactivated after (LV_INH_DIAG_XX 1->0 or CDN_DIAG_XX >0 (depending on case)) and LV_IGK 0->1 and reset and FMY reset after NC_PSD_DLY recurrences.					

A.107 Battery Sensor diagnostic

A.107.1 Sensor diagnostic

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_BAT_SENS	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)

NC_IDX_DIAG_BAT_SENS	1	1...FFFFH	1...65535	1	[-]
Failure index for battery sensor diagnostic					

Import actions:

ACTION_ERRM_FilterSymptom(IN<IDX_DIAG>, IN< LV_CDN_DIAG_XX >, IN< ERR_SYM_XX >, IN< C_ABC_INC_XX >, IN< C_ABC_MAX_XX >, IN< C_ABC_DEC_XX >, OUT< LV_ERR_XX >)

Error treatment

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	Name (XX)	Description	Nr		
Battery sensor diagnosis	BAT_SENS	Time out after reset	0	MEM	NO
		Invalid message	1		
		Error response	2		
		-	3		

FUNCTION DESCRIPTION:

General information:

Error detection on the battery sensor depends of the smart battery sensor message received and the time to get a message valid after power on. The MEM type filter is used to avoid vehicle effect in case of intermittent error.

Description:

Error-symptoms are defined to this diagnosis function as following

ERR_SYM_BAT_SENS

```
□□□□
│ │ │ └─> Time out after reset          (= SYM_0)
│ │ └───> Invalid message               (= SYM_1)
│ └─────> Error response                (= SYM_2)
└───────> -                             (= SYM_3)
```

Application conditions:

Initialization at reset :

CTR_DLY_BAT_SENS_ENA = C_DLY_BAT_SENS_ENA

The other standard diagnostic data are initialized according filtering configuration.

Recurrence: 100 ms

Activation: CONF_BAT = 1 **and** CONF_BAT_LIN = 2 (Hella sensor)

Deactivation: When activation function is not filling in

Formula section:

Diagnostic condition calculation :

```
If  CTR_DLY_BAT_SENS_ENA  > 0
Then
     CTR_DLY_BAT_SENS_ENA  = CTR_DLY_BAT_SENS_ENA  - 1
     LV_CDN_DIAG_BAT_SENS=0
Else
     LV_CDN_DIAG_BAT_SENS=1
Endif
```

Symptoms calculation :

```
If(1)  LV_CDN_DIAG_BAT_SENS=1
Then(1)

     { SYM_2 : Error response  }
     If (2)    LV_DFT_SENS_BAT_LIN=1
     Then(2)
               ERR_SYM_BAT_SENS = SYM_2
      Else(2)

          { SYM_1 : Invalid message }
          If(3)         LV_SENS_BAT_LIN_VLD=0
          Then(3)
                        ERR_SYM_BAT_SENS = SYM_1
          Else(3)

             { SYM_0 : Time out after reset }
             If(4)      LV_SENS_BAT_LIN_FIRST_VLD=0
             Then(4)
                        ERR_SYM_BAT_SENS = SYM_0
             Else(4)
                        ERR_SYM_BAT_SENS = NO_SYM { No failure detected  }
             Endif(4)
          Endif(3)
     Endif(2)
Else(1)
     ERR_SYM_BAT_SENS unchanged
Endif(1)
```

For failure and error management treatment the anti-bounce mechanism is called :

ACTION_ERRM_FilterSymptom(IN<NC_IDX_DIAG_BAT_SENS>, IN<LV_CDN_DIAG_BAT_SENS>, IN<ERR_SYM_BAT_SENS>, IN<C_ABC_INC_BAT_SENS>, IN<C_ABC_MAX_BAT_SENS>, IN<1>, OUT<LV_ERR_BAT_SENS>)

A.107.2 System voltage plausibility diagnostic

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_VB_PLAUS	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					
LV_CDN_DIAG_VB_PLAUS	V	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
LV_END_DIAG_VB_PLAUS	V	0...1H	0...1	1	[-]
Diagnostic performed at least one time					
LV_ERR_VB_PLAUS	O/V	0...1H	0...1	1	[-]
Present failure after filtering of system voltage plausibility diagnostic					
CTR_DIAG_VB_PLAUS	V	0..FFH	0…25.5	0.1	[s]
Counter to manage the plausibility diagnostic duration					
CTR_DIAG_VB_PLAUS_OK	V	0...FFH	0…255	1	[-]
Counter of number time battery voltage conform					

Input data:

CONF_BAT	CONF_BAT_LIN	VB	VB_H_MMV
LV_ERR_BAT_SENS	LV_END_DIAG_BAT_SENS	LV_CDN_VB_OBD1	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_VB_PLAUS	1	0...FFH	0...255	1	[-]
Antibounce counter increment					
C_ABC_MAX_VB_PLAUS	1	1...FFH	1...255	1	[-]
Maximum value for antibounce counter

Delta voltage to detect battery system voltage plausibility failure					
C_DLY_VB_PLAUS	1	0..FFH	0…25.5	0.1	[s]
Delay to determinate plausibility diagnostic failure (typical value 10)					
C_CTR_DIAG_VB_PLAUS_OK	1	1..FFH	1…255	1	[-]
Number minimum of time the battery voltage test has to be good (typical value 3)					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_IDX_DIAG_VB_PLAUS	1	1...FFFFH	1...65535	1	[-]
Failure index for system voltage plausibility diagnostic					

Import actions:

ACTION_ERRM_FilterSymptom(IN<IDX_DIAG>, IN< LV_CDN_DIAG_XX >, IN< ERR_SYM_XX >, IN< C_ABC_INC_XX >, IN< C_ABC_MAX_XX >, IN< C_ABC_DEC_XX >, OUT< LV_ERR_XX >)

Error treatment

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	Name (XX)	Description	Nr		
System voltage plausibility diagnostic	VB_PLAUS	-	0	MEM	NO
		-	1		
		-	2		
		System voltage plausibility	3		

FUNCTION DESCRIPTION:

General information:

Error detection in case of there is a different voltage between battery voltage measured on the ECM and received from the LIN battery sensor.

Description:

Error-symptoms are defined to this diagnosis function as following :

ERR_SYM_VB_PLAUS

```
□□□□
│ │ │ └─> -                              (= SYM_0)
│ │ └───> -                              (= SYM_1)
│ └─────> -                              (= SYM_2)
└───────> System voltage plausibility    (= SYM_3)
```

Application conditions:

Initialization at reset, at key transition and at CLRFMY event :

CTR_DIAG_VB_PLAUS = C_DLY_VB_PLAUS
CTR_DIAG_VB_PLAUS_OK =0
The other diagnostic data are initialized according filtering configuration.

Recurrence: 100 ms

Activation: CONF_BAT = 1 **and** CONF_BAT_LIN = 2

Deactivation: *never*

Formula section:

Diagnostic condition calculation :

{ The diagnostic condition is set when the sensor is a smart sensor, the battery sensor LIN diagnostic is passed and battery voltage OBD1 condition fullfil }

```
if        LV_ERR_BAT_SENS = 0
    and   LV_END_DIAG_BAT_SENS = 1
    and   LV_CDN_DIAG_OBD1 = 1
Then

   { When the two battery voltage values are very different }
   If     |VB - VB_H_MMV| <= C_VB_H_MMV_DELTA_MAX
   Then
          CTR_DIAG_VB_PLAUS_OK = CTR_DIAG_VB_PLAUS_OK + 1
   Endif

   { When the delay is elapsed the condition is set }
   CTR_DIAG_VB_PLAUS = CTR_DIAG_VB_PLAUS - 0.1s

   If     CTR_DIAG_VB_PLAUS=0
   Then
          LV_CDN_DIAG_VB_PLAUS=1
   Else
          LV_CDN_DIAG_VB_PLAUS=0
   Endif
Else
    { When the condition is not fill in the diagnostic is re-initialized }
    LV_CDN_DIAG_VB_PLAUS = 0
    CTR_DIAG_VB_PLAUS = C_DLY_VB_PLAUS
    CTR_DIAG_VB_PLAUS_OK = 0
Endif
```

Symptom calculation :

If(1) LV_CDN_DIAG_VB_PLAUS=1
Then(1)

{ When the counter of good diagnostic is too low the failure is set }
If CTR_DIAG_VB_PLAUS_OK < C_CTR_DIAG_VB_PLAUS_OK
Then
ERR_SYM_VB_PLAUS = SYM_3
Else
ERR_SYM_VB_PLAUS = NO_SYM
Endif

{ The diagnostic is re-initialized }
CTR_DIAG_VB_PLAUS = C_DLY_VB_PLAUS
CTR_DIAG_VB_PLAUS_OK =0
Else(1)
ERR_SYM_VB_PLAUS unchanged
Endif(1)

For failure and error management treatment the anti-bounce mechanism is called :

ACTION_ERRM_FilterSymptom(IN<NC_IDX_DIAG_VB_PLAUS>, IN<LV_CDN_DIAG_VB_PLAUS>, IN<ERR_SYM_VB_PLAUS>, IN<C_ABC_INC_VB_PLAUS>, IN<C_ABC_MAX_VB_PLAUS>, IN<1>, OUT<LV_ERR_VB_PLAUS>)

A.108 Port Flap Diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_PORT	V/O	0...1H	0...1	1	-
Error currently present on port flap					
PORTPWM_DIAG	V/O	8000...7FFFH	-100...99.99	0.003	%
Port flap pulse width modulation in case of port flap error					
T_PORT_DLY3	V	0...FFH	2.55	0.01	s
Delay time before Port Flap Pulse width modulation is switched off in case of port flap error					

Input data:

LV_ERR_PORT_POTI	LV_ERR_PORT_AD	LV_ERR_PORT_STUCK_CLOSE	LV_IGK
PORTPWM	LV_ERR_PORT_RNG	LV_ERR_VCC_SENS_SUB	CONF_PORT
LV_ERR_PORT_EL		LV_ERR_PORT_STUCK_OPEN	

FUNCTION DESCRIPTION:

Application conditions:

Initialization: At reset or at transition LV_IGK 0 -> 1:

LV_ERR_PORT = 0

PORTPWM_DIAG = 0%

Recurrence: 10 ms

Activation: at CONF_PORT = 1 **and** LV_IGK = 1

Deactivation: at LV_IGK = 0 **or** CONF_PORT = 0

General information:

The Port flap diagnosis is performed by electrical diagnosis for Power Stage and Potentiometer and Plausibility diagnosis.

The electrical diagnosis of the Potentiometer is divided in two symptoms:

- Signal line „shorted to Plus“or „line broken“
- Signal line „short to Ground“

There are four plausibility diagnosis :

- Adaptation failed
- Flap stuck opened
- Flap stuck closed
- Flap moves to slow or to unplausible range (Range/Performance)

Formula section:

Global error flag for PORT diagnosis:

if(1) LV_ERR_PORT_POTI = 1
or LV_ERR_PORT_STUCK_OPEN = 1
or LV_ERR_PORT_STUCK_CLOSE = 1
or LV_ERR_PORT_RNG = 1
or LV_ERR_PORT_EL = 1
or LV_ERR_PORT_AD = 1
or LV_ERR_VCC_SENS_SUB = 1
then(1) LV_ERR_PORT(n) = 1
else(1) LV_ERR_PORT(n) = 0
endif(1)

Moment of general port flap error setting:

if(1) LV_ERR_PORT(n-1) = 0
and LV_ERR_PORT(n) = 1
then(1) T_PORT_DLY3 = C_T_PORT_DLY3
endif(1)

Port flap pulse width modulation for limp home position:

if(1) LV_ERR_PORT(n) = 1
then(1) if(2) T_PORT_DLY3 = 0
then(2) PORTPWM_DIAG = 0 %
else(2) PORTPWM_DIAG = C_PORTPWM_DIAG
decrement T_PORT_DLY3 by 1H every 10ms
endif(2)
else(1) PORTPWM_DIAG = 0%
endif(1)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_PORTPWM_DIAG	1	8000...7FFFH	-100...99.99	0.003	%
port flap pulse width modulation to reach Limp home position					
C_T_PORT_DLY3	1	0...FFH	0...2.55	0.01	s
Delay time before Port Flap Pulse width modulation is switched off in case of port flap error					

A.108.1 Potentiometer Diagnosis (LV_ERR_PORT_POTI)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_PORT_POTI	V/O	0...1H	0...1	1	-
Error currently present on potentiometer of Port flap					
LV_CDN_DIAG_PORT_POTI	V/O	0..1H	0..1	1	-
Diagnosis condition PORT POTI diagnosis					
LV_END_DIAG_PORT_POTI	V/O	0...1 H	0...1	1	-
End of diagnosis PORT_POTI diagnosis					
ERR_SYM_PORT_POTI	V/O	0H 1H 2H 4H 8H	NO_SYM SYM 0 SYM 1 SYM 2 SYM 3	1	-
Error Symptom PORT POTI diagnosis					

Input data:

V_PORT	LV_CDN_VB_OBD1	LV_IGK	CONF_PORT
LV_ERR_VCC_SENS_SUB			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the analog input signal from the PORT-potentiometer to the microcontroller.

Error-symptoms: are defined to this diagnosis function as following

```
□□□□
 │ │ │ └─> Short circuit to Plus or Line break      (= SYM_0)
 │ │ └───> Short circuit to GND                     (= SYM_1)
 │ └─────> -                                        (= SYM_2)
 └───────> -                                        (= SYM_3)
```

Application conditions:

Initialisation: at Reset, at LV_IGK= 0--> 1, set all variables = 0

Recurrence: *10 ms*

Activation:
if LV_IGK = 1
and LV_CDN_VB_OBD1 = 1
and CONF_PORT = 1
and LV_ERR_VCC_SENS_SUB = 0
then LV_CDN_DIAG_PORT_POTI = 1
else LV_CDN_DIAG_PORT_POTI = 0
endif

Deactivation: -

Formula section:

if(1) V_PORT > C_V_MAX_PORT_DIAG

then(1) ERR_SYM_PORT_POTI = "SYM_0"

symptom "line shorted to Plus" or "line broken" is active

LV_ERR_PORT_POTI = 1 (after debounce)

else(1)

if(2) V_PORT < C_V_MIN_PORT_DIAG

then(2) ERR_SYM_PORT_POTI = "SYM_1"

symptom "line shorted to Ground" is active

LV_ERR_PORT_POTI = 1 (after debounce)

else(2) ERR_SYM_PORT_POTI = "NO_SYM"

endif(2)

endif(1)

The bit LV_ERR_PORT_POTI is set irreversible, reset at transition LV_IGK 0 -> 1

Calculation of LV_END_DIAG_PORT_POTI and antibounce counter:
- see chapter " Anti bounce Algorithm"

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_V_MIN_PORT_DIAG	1	0...3FFH	0...5	0.0048	V
Voltage threshold for detection of PORT-poti signal line shorted to ground					
C_V_MAX_PORT_DIAG	1	0...3FFH	0...5	0.0048	V
Voltage threshold for detection of PORT-poti signal line shorted to battery voltage or broken					
C_ABC_INC_PORT_POTI	1	0...FFH	0...255	1	-
Antibounce Counter Increment for Port Potentiometer Diagnosis					
C_ABC_MAX_PORT_POTI	1	0...FFH	0...255	1	-
Maximum value of Antibounce Counter Increment for Port Potentiometer Diagnosis					

A.108.2 Mechanical Diagnosis: Port Flap stuck closed

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_ERR_PORT_STUCK_CLOSE	V/O	0...1H	0...1	1	-
PORT_Flap stuck in Closed Position (after debounce)					
LV_CDN_DIAG_PORT_STUCK_CLOSE	V/O	0..1H	0..1	1	-
Diagnosis condition PORT_STUCK_CLOSE diagnosis					
LV_END_DIAG_PORT_STUCK_CLOSE	V/O	0...1 H	0...1	1	-
End of diagnosis PORT_STUCK_CLOSE diagnosis					
ERR_SYM_PORT_STUCK_CLOSE	V/O	0H 1H 2H 4H 8H	NO_SYM SYM 0 SYM 1 SYM 2 SYM 3	1	-
Error Symptom PORT_STUCK_CLOSE diagnosis					
T_PORT_DLY4	V/O	0...FFH	0..2.55	0.01	s
timer for Port Stuck Closed diagnosis					

Input data:

LV_IGK	LV_CDN_VB_OBD2	PORT_SP	CONF_PORT
LV_ERR_PORT_POTI	V_PORT	LV_PORT_AD_VLD	LV_ERR_PORT_EL
LV_ERR_VCC_SENS_SUB			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose whether the port flap stucks in closed position. This is performed with the Potentiometer value.

If the Port flap is required to open a timer T_PORT_DLY4 is decremented. If the counter reaches 0 and the Potentiometer value is still near the adapted Closed Position, then the Port Flap is determined to stuck closed.

Error-symptoms: are defined to this diagnosis function as following

```
□□□□
| | | └─> Port Flap stuck close          (= SYM_0)
| | └───> -                              (= SYM_1)
| └─────> -                              (= SYM_2)
└───────> -                              (= SYM_3)
```

Application conditions:

Initialization: At reset, at transition LV_IGK 0 -> 1:

LV_ERR_PORT_POTI	V_PORT	LV_PORT_AD_VLD	LV_ERR_PORT_EL
LV_ERR_VCC_SENS_SUB	LV_ERR_PORT_RNG	LV_ERR_PORT_STUCK_CLOSE	

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose wheter the Port flap stucks in opened position. This is performed with the Potentiometer value.

If the Port flap is required to close a timer T_PORT_DLY5 is decremented. If the timer reaches 0 and the Potentiometer value is still near the adapted Open position, then the Port flap is determined to stuck open. As the H-bridge output diagnosis cannot detect open circuit this can be also a symtom for an open circuit at supply line.

Error-symptoms: are defined to this diagnosis function as following

```
[ ][ ][ ][ ]
 |  |  |  └─> Port Flap stuck open or open circuit of DC-motor supply   (= SYM_0)
 |  |  └────> -                                                        (= SYM_1)
 |  └───────> -                                                        (= SYM_2)

LV_ERR_VCC_SENS_SUB	C_V_PORT_STUCK_CLOSE	T_PORT_DLY4	T_PORT_DLY5
PORTPWM_DIAG			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose wheter the Port flap is moving to slow or if the shaft is not connected properly to the Port Flap motor. This is performed with the Potentiometer value.

If a Port flap setpoint change is required and the related timer is decremented to 0 then the Potentiometer value is checked. If the value is between the learned open and closed value, then this indicates in a slow moving Port Flap or stucked Flap (Setpoint could not be reached in the required time), if the value is below the learned open or above the learned close value, this is an indication that the Flap shaft is not connected properly to the DC motor unit.

Error-symptoms: are defined to this diagnosis function as following

```
□□□□
│ │ │ └─> Port Flap moves too slow or stucked between open and close   (= SYM_0)
│ │ └───> Port Flap shaft not connected properly to DC-Motor unit       (= SYM_1)
│ └─────> -                                                             (= SYM_2)
└───────> -                                                             (= SYM_3)
```

B.1 Misfire detection

B.1.1 Global fade out switch for misfire detection and monitoring

Description:

There is one global switch which can be used for inhibiting all the MISF aggregate modules:

- Generic misfire parameters & fade-out conditions : Aggr MISF, chapter OBDII
- Legal misfire detection fade-out conditions : Aggr MISF, chapter OBDII
- Rough road detection : Aggr MISF, chapter OBDII
- Crankshaft oscillation detection : Aggr MISF, chapter OBDII
- Misfire detection : Aggr MISF, chapter OBDII
- Appl. Inc. for misfire detection : Aggr MISF, chapter OBDII
- Misfire rate and criterions determination : Aggr MISF, chapter OBDII
- Appl. Inc. for Misfire rate and criterions determination : Aggr MISF, chapter OBDII

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
LC_MIS_INH	1	0...1H	0...1	1	[-]
Global switch to disable all misfire monitoring related modules (Inhibition with = 1)					

B.1.2 Misfire detection thresholds determination for engine roughness index

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
FAC_THD_ER	V	0...400H	0...4	3.9063e-3	[–]
Global gain multiplicative correction applied to basic misfire detection thresholds					
THD_ER	V/O	8000...7FFFH	-32768...32767	1	[µs]
Misfire detection threshold for current ER value					
THD_ER_BUF[NC_SIZE_THD_ER_BUF]	V	8000...7FFFH	-32768...32767	1	[µs]
Misfire detection threshold stack for ER evaluation					
THD_ER_CYL[NC_CYL_NR]	V	8000...7FFFH	-32768...32767	1	[µs]
Cylinder Misfire detection threshold for current ER value					

Input data:

N_32	TCO	LV_AT	FAC_THD_APP_ER
N	LV_IS	LOAD_MIS	INH_INJ
SEG_NR_ER	LV_ENA_SEG_T_MES	NC_CMB_CONF	LV_S_ACT
LV_HOM_AFL_ACT	THD_ER_CLC	LV_DRI	

Function description:

ER strategy misfire detection is based on a comparison between a cylinder specific ER value (nominal or normalised) and a threshold who is relative to the engine parameters when this same cylinder was in intake phase (threshold relative to combustion conditions image).

The engine roughness value ER depends strongly on the current operating point, both in its spread during undisturbed engine operation, and in the signal amplitude in case of an actual misfire.

ER misfire detection thresholds are defined according basic threshold maps and threshold corrections :

- *A basic threshold map:*

This map is function of engine load and speed which are calibrated for engine at operating temperature as well as for adapted transmitter gear. One map is assigned through the vehicle transmission type, idle speed condition & the combustion mode.

- *A threshold temperature correction:*

A temperature correction is applied to compensate larger signal amplitudes arise of ER values at lower engine temperatures. This correction is relative to TCO value.

- *A threshold correction during active injection valve cut-off:*

If one or several injection valves are cut off selectively by the engine management system (IV diagnoses ...), then the cylinder or cylinders are excluded from the misfire check. Due to the system, the signal amplitude of the ER value is reduced with a misfire at another cylinder. To improve the detection for this period, the absolute amount of the threshold can be reduced multiplicatively with the factor IP_FAC_THD_IV_ER(N_32) or IP_FAC_THD_IV_S_ER(N_32) *(in stratifed mode)*. *FAC_THD_IV_ER is a temporary data.*

- *A threshold correction defined in application incidences:*

FAC_THD_APP_ER is a threshold multiplicative correction who is defined in the misfire detection application incidences file.

B.1.2.1 Multiplicative correction for misfire thresholds

Application conditions:

Initialisation: *FAC_THD_IV_ER = 1*

Recurrence: every ENRD segment task

Activation: *LV_ENA_SEG_T_MES = 1*

And *LC_MIS_INH = 0*

Deactivation: *LV_ENA_SEG_T_MES = 0*

Or *LC_MIS_INH = 1*

Formula section:

#IF NC_CMB_CONF = AFS_S Or AFS_AFL_S

If INH_INJ = 0

Then FAC_THD_IV_ER = 1

ElseIf LV_S_ACT = 1

Then FAC_THD_IV_ER = IP_FAC_THD_IV_S_ER(N_32)

Else FAC_THD_IV_ER = IP_FAC_THD_IV_ER(N_32)

EndIf

#ELSE

If INH_INJ = 0

Then FAC_THD_IV_ER = 1

Else FAC_THD_IV_ER = IP_FAC_THD_IV_ER(N_32)

EndIf

#ENDIF

FAC_THD_ER = IP_FAC_THD_TCO_ER(TCO) * FAC_THD_IV_ER * FAC_THD_APP_ER

Remark : Given the update rate of TCO is 100ms, the value of ip_fac_thd_tco_er(tco) can be updated at this rate (CPU Load).

B.1.2.2 Misfire detection threshold buffers management

To manage the delay between cylinder intake phase and cylinder ER values, buffers are used to store threshold values before using for detection.

THD_ER_BUF[NC_SIZE_THD_ER_BUF] buffer is managed as a FIFO stack.

THD_ER_BUF[0] threshold value is the one obtained at current segment.

THD_ER is threshold value delayed and who will be used for detection with current segment ER value. This delay between ER value and cylinder corresponding threshold depends on engine cylinder number (NC_CYL_NR).

B.1.2.3 Misfire detection threshold based on engine roughness value (THD_ER)

By using the ER value for misfire detection, the engine speed has the greatest influence on basic thresholds definition. On the other hand, by using the ER_STND values for misfire detection, the engine load has the greatest influence on basic thresholds definition.

The influence of the engine load on the detection thresholds can change rapidly during instationary operation, it is urgently necessary to determine and to temporarily store the threshold values already at the time of the actual combustion before the calculatory check.

note: at each ER segment occurence, THD_ER_BUF is shifted with one memory unit (FIFO management) before determination process.

Application conditions:

Initialisation: at ECU reset **Or** engine stop

THD_ER = 0x8000

// ER Threshold buffer init on ER buffer reinitialisation

For k = 0 : NC_SIZE_THD_ER_BUF-1

THD_ER_BUF[k] = 0x8000 *// For all buffer cells*

EndFor

For x = 0 : NC_CYL_NR-1

THD_ER_CYL[x] = 0x8000 *// For all cylinders*

EndFor

Recurrence: every ENRD segment task

Activation: *LV_ENA_SEG_T_MES = 1*

***And** LC_MIS_INH = 0*

Deactivation: *LV_ENA_SEG_T_MES = 0*

***Or** LC_MIS_INH = 1*

Actions on Deactivation event:

THD_ER = 0x8000

// ER Threshold buffer init on ER buffer reinitialisation

For k = 0 : NC_SIZE_THD_ER_BUF-1

THD_ER_BUF[k] = 0x8000 *// For all buffer cells*

EndFor

For x = 0 : NC_CYL_NR-1

THD_ER_CYL[x] = 0x8000 *// For all cylinders*

EndFor

Formula section:

Input data:

LV_DET_THD_DELTA	LV_ENA_ER	LV_DIAG_MIS	NC_CYL_NR
LV_ZDLY_DIAG_MIS	SEG_NR_ER	LV_DET_THD_DELTA_FIL_MEM	LV_REQ_INH_MIS
ER_FIL	NLC_CONF_ER_MV		

General information:

The system identifies misfiring by monitoring engine roughness index. Misfiring causes the angular velocity of the crankshaft to drop in an angular range specific to the cylinder in question.

Misfire detection is based on nominal engine roughness (ER) by using THD_ER detection threshold.

The identification of the cylinder(s) detected in misfire is realised according SEG_NR_ER segment reference (see definition and scheme in ENRD aggregate) *(Chapter system variables)*.

THD_ER is already phased according ER delay *(see detection thresholds management)*.

Application conditions:

Initialisation: at ECU reset, at Engine Stop ***Or*** *at Deactivation Event*

LV_DET_MIS = LV_DET_THD_MIS = LV_DET_THD_FIL = ~~LV_DET_THD_DELTA =~~ 0

LV_INH_IV_OFF_DET_MIS_APP	V	0...1H	0...1	1	-
Misfire detection fade out request flag due to cylinder shut-off condition (App.)					

Input data:

LV_SEG_AD_DIF_MAX_ER	LV_ENA_ER	LC_MIS_INH	C_SUM_INH_IV_MAX_MIS
LV_PUC_DET_MIS	SEG_NR	PREV_STATE_IV	SUM_INH_INJ
LV_INH_N_MAX_DET_MIS	INH_IV_MIS	INH_IV_MIS_GEN	LC_REQ_MIS_GEN

FUNCTION DESCRIPTION:

Misfire detection process can be inhibited when one of the following function requires an inhibition.

Application conditions:

Activation: LV_ENA_ER = 1

And LC_MIS_INH = 0

Deactivation: LV_ENA_ER = 0

Or LC_MIS_ INH = 1

Initialisation: at ECU reset, at Engine Stop ***Or*** *at LC_MIS_INH 0 to 1 transition LV_INH_APP_DET_MIS = 1*

Update rate: *updated every segment before misfire detection function*

Formula section:

If LV_SEG_AD_DIF_MAX_ER = 1

Or LV_FIRST_EOL_FDOUT = 1

Or LV_INH_IV_OFF_DET_MIS_APP =1

Then LV_INH_APP_DET_MIS = 1

Else LV_INH_APP_DET_MIS = 0

EndIf

B.2.4.1 Misfire detection inhibition at End of line test

B.2.5 FUNCTION DESCRIPTION:

When the engine start is occurred for the first time at the production line, the misfire error may be detected because the fuel is not fully delivered to fuel line from the fuel tajnk. To avoid the misfire detection at EOL, the misfire monitoring shall be inhibited(LV_FIRST_EOL_FDOUT = 1) during the first engine running time(NC_MAX_T_AST_FIRST_EOL_FDOUT) after the first ECU powered-up.

This misfire monitoring ON / OFF state information (LV_STATE_MIS_ON) is sent to a scan tool via KWP.

Application conditions:

Initialization : At ECU- first time powered-up

LV_FIRST_EOL_FDOUT = 1

LV_STATE_MIS_ON = 0

Activation : LV_IGK = 1

Recurrence : 1 sec

Formula section:

If LV_FIRST_EOL_FDOUT = 0 (EOL check already done)

Then LV_STATE_MIS_ON = 1 (Misfire mon. is ON, bit for KWP support)

Else

IF LV_ST_END = 1

And T_AST >= NC_MAX_T_AST_FIRST_EOL_FDOUT

THEN

LV_FIRST_EOL_FDOUT = 0 (Saved into ROM at the end of DC, not any more set to 1 during the whole the ECU life time)

ENDIF

EndIf

B.2.5.1 Inhibition of MISF diagnosis for specific cylinder shut-off.(App.)

Inhibition of MISF diagnosis for specific cylinder shut-off.(App.) can be activated by LC_INH_IV_OFF_DET_MIS_APP=0. When this module is activated, bit for generic inhibition for specific cylinder shut-off should be deactivated. This can be done by zero setting for generic inhibition bit of C_MASK_INH_DET_MIS which enables to inhibit the flag in the carrier MIS_DET_CDN_INH ("Legal misfire detection fade-out").

<u>Application conditions:</u>

Initialisation: *at Reset, Engine Stop,* ***Or*** *on Deactivation event*

LV_IV_OFF_DET_MIS_APP = 0

LV_INH_IV_OFF_DET_MIS_APP = 0

Recurrence: *every segment task*

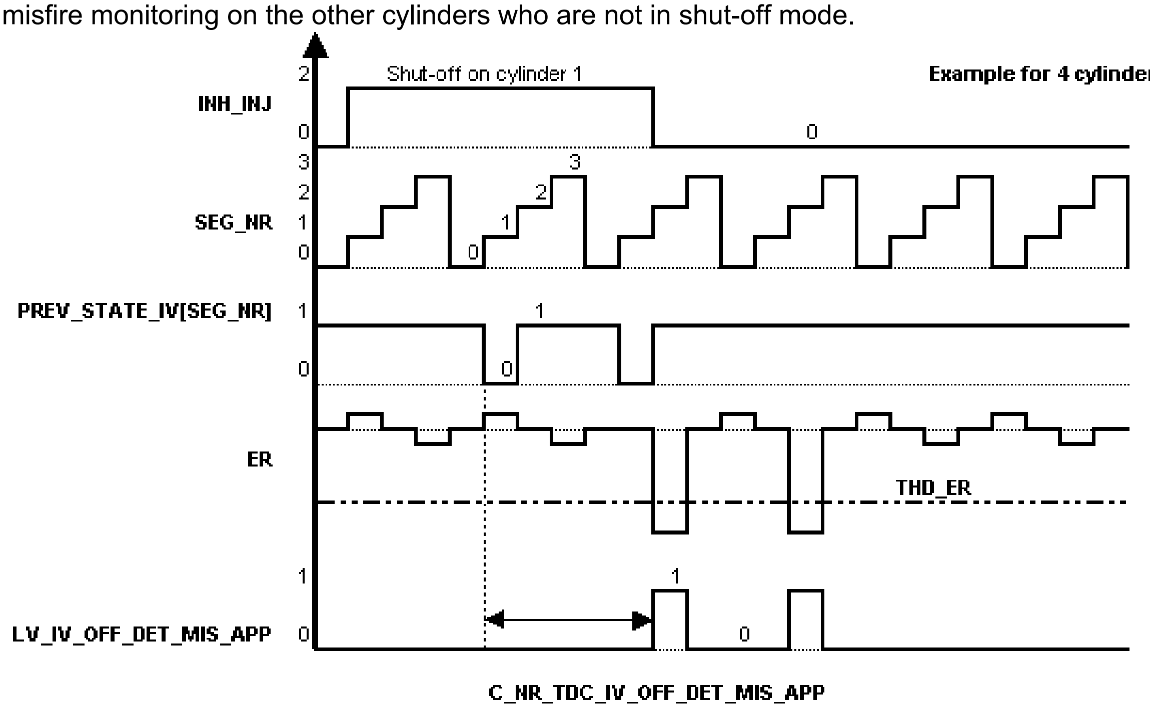
Activation: *LC_MIS_INH = 0* ***AND*** *LC_INH_IV_OFF_DET_MIS_APP=0*

Deactivation: *LC_MIS_INH = 1* ***OR*** *LC_INH_IV_OFF_DET_MIS_APP=1*

Misfire detection can be suppressed for the cylinder(s), for which injection has been shut-off.

<u>Cylinder specific shut-off:</u>

If the current cylinder checked by misfire detection is shut-off by any EMS function a fade-out can be applied for the misfire detection of this cylinder.
Due to the delay between the misfire index and the injection current informations, a calibration delay (C_NR_TDC_IV_OFF_DET_MIS_APP) has been introduced on LV_IV_OFF_DET_MIS_APP.
This delay synchronises MISF & INJR informations in a way to apply correctly the fade-out on the proper cylinder during individual cylinder shut-off operations, and to be able the perform the misfire monitoring on the other cylinders who are not in shut-off mode.



Formula section:

Cylinder fuel shut-off:

If PREV_STATE_IV[SEG_NR] = 0 (*indexed by cylinder bit position)*

And INH_IV_MIS = 0 *(no cylinder shut-off due to misfire detection)*

And LC_REQ_MIS_GEN = 0 *(no cylinder shut-off due to internal misfire generator)*

Then LV_IV_OFF_DET_MIS_APP = 1 after a C_NR_TDC_IV_OFF_DET_MIS_APP delay

Else LV_IV_OFF_DET_MIS_APP = 0 after a C_NR_TDC_IV_OFF_DET_MIS_APP delay

EndIf

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_IV_OFF_DET_MIS_APP = 1

Formula section:

Information for General Fuel Shut-Off and Limit number of Cylinder Shut-Off can be refer to Section " Legal Misfire Detection Fade-Out Conditions".

General definition:

If LV_PUC_DET_MIS = 1 (General Fuel Shut-Off)

Or LV_IV_OFF_DET_MIS_APP = 1 (Specific Cylinder Shut-Off)

Or **{**SUM_INH_INJ >= C_SUM_INH_IV_MAX_MIS (Limit Number of Cylinder Shut-Off)

And **[(**INH_IV_MIS = 0 *(no cylinder shut-off due to misfire detection)*

And INH_IV_MIS_GEN = 0 *(no cylinder shut-off due to internal misfire generator)*

And LC_DISA_INH_IV_OFF_DET_MIS_APP = 1**)**

Or LC_DISA_INH_IV_OFF_DET_MIS_APP = 0 **]}**

Then LV_INH_IV_OFF_DET_MIS_APP = 1

(and reset C_NR_TDC_IV_OFF_DET_MIS_DLY delay counter)

Else LV_INH_IV_OFF_DET_MIS_APP = 0 after C_NR_TDC_IV_OFF_DET_MIS_DLY delay

EndIf

Calibration data:

B.2.9 Definition of dummy values for ER-calculation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ER_FIL	O/V	FF800000 ...7FFFFFH	-2000000... 1999999.76158	0.2384186	[µs]
Filtered Engine roughness					
ER_DELTA	O	FF800000 ...7FFFFFH	-2000000... 1999999.76158	0.2384186	[µs]
Delta Engine roughness on same physical segment					
LV_DET_THD_DELTA_FIL_MEM	O	0...1H	0...1	1	[-]
Single misfire detected based only on threshold criterion on delta mean values (continuous and stored)					
LV_DET_THD_DELTA	O	0...1H	0...1	1	[-]
Single misfire detected based only on ER_DELTA criterion (before fade out test)					

Input data:

ER	LV_ENA_ER		

FUNCTION DESCRIPTION:

This function calculates all the ER signals used for detection

Application conditions:

Initialisation: at ECU reset, at Engine Stop To Runing

ER_FIL = ER_DELTA = 0

Recurrence: updated every segment **before** misfire detection function

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Formula section:

ER_FIL = ER

ER_DELTA = 0

LV_DET_THD_DELTA_FIL_MEM = 0

LV_DET_THD_DELTA = 0

Configuration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
NLC_CONF_ER_MV	1	0...1H	0...1	1	[-]
Mean ER correction enable					

B.2.10 Misfire detection calibration ease

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ER_THD_RATIO	V	0...FFFFH	0...399.99389	6.1035e-3	[%]
clipped ratio between engine roughness index and detection threshold					

Input data:

LV_ENA_ER	ER	THD_ER	LC_MIS_INH

General information:

For calibration ease, a ratio between ER value and the ER detection threshold can be integrated. ER values are proportionnal to engine speed, thus the detection and fade-out calibration in transients engine operating points are choosey. Data visualisation and scalling have always to be updated according current engine operating point.

After precalibration, with the introduction of such ratio, the misfire detection check and validation will be much more easier for tuning team.

Ratio close to zero : no risk of misfire detected.
Ratio close to 100% or above : misfire detected by threshold *(before fade-out check)*.

Description:

Application conditions:

Activation: *LV_ENA_ER = 1*
And *LC_MIS_INH = 0*

Deactivation: *LV_ENA_ER = 0*
Or *LC_MIS_INH = 1*

Initialisation: ECU reset ***Or*** *on Deactivation event*

ER_THD_RATIO = 0

Update rate: updated every segment after misfire detection function

Formula section:

If ER < 0

ER_THD_RATIO = **min** (ER / THD_ER , C_ER_THD_RATIO_MAX)

Else ER_THD_RATIO = 0

Endif

Calibration data:

B.2.11 Current Misfire Detection Threshold

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
THD_ER_CLC	V/O	8000...7FFFH	-32768...32767	1	[µs]
Value of the table used for Misfire detection threshold at current segment					

Input data:

N_32	LV_DRI	LV_AT	LC_MIS_INH
N	LV_IS	LOAD_MIS	LV_ENA_SEG_T_MES

General information:

THD_ER_CLC represents the current value used for determination of the misfire detection threshold. This data must be calculated before THD_ER calculation and after LOAD_MIS calculation.

Application conditions:

Initialisation: at ECU reset **Or** engine stop
THD_ER_CLC = 0x8000

Recurrence: every ENRD segment task

Activation: *LV_ENA_SEG_T_MES = 1*
And *LC_MIS_INH = 0*

Deactivation: *LV_ENA_SEG_T_MES = 0*
Or *LC_MIS_INH = 1*

Actions on Deactivation event : THD_ER_CLC = 0x8000

Formula section:

LOAD_GRD_MIS	V/O	0...7FFFH	0...99.99694	3.0518e-3	[%]
Normalised engine load gradient for misfire detection					

Input data:

AMP	TCO	MAF	LV_ENA_SEG_T_MES
FAC_GAIN_LOAD_MIS	TQI_AV	LC_MIS_INH	MAP

FUNCTION DESCRIPTION:

In order to cover all the combustion states of an engine (Hom. AFS, AFL & Strat.) in torque based engine control, a general variable LOAD_MIS that represents the ratio of engine load – whatever should be the load definition depending on engine combustion state (*eg. MAF in Hom. and TQI_AV in Strat.*) – is defined for the purpose of the Misfire function and the calculation of the ER-misfire detection thresholds.

Depending on the project choice configuration (*with C_CONF_LOAD_MIS*), in Homogenous combustion mode this Misfire load variable should be either MAF, MAP or TQI_AV. In the other hand this Misfire load variable is always TQI_AV in Stratified combustion mode.

Legally, the presence of engine misfire in the engine operating region is bounded by the positive torque line (i.e. engine load with the transmission in neutral) and an engine speed value.

The zero load line is a function of the engine speed and depends on the engine combustion mode (for GDI application), coolant temperature and atmospheric pressure.

Application conditions:

Initialisation: All variables are initialised to 0 at reset, at engine stop **Or** at LC_MIS_INH 0 to 1 transition

LOAD_GRD_MIS is first time calculated when LOAD_MIS stack have been fill in (4 segments).

Recurrence: every segment task

Activation: LV_ENA_SEG_T_MES = 1

And LC_MIS_INH = 0

Deactivation: LV_ENA_SEG_T_MES = 0

Or LC_MIS_INH = 1

Formula section:

Normalised engine load dedicated to misfire detection

For each misfire segment, the following stack is serviced:

LOAD_MIS_3 =LOAD_MIS_2

LOAD_MIS_2 =LOAD_MIS_1

LOAD_MIS_1 = LOAD_MIS

If C_CONF_LOAD_MIS = 0

Or LV_S_ACT = 1

Then *LOAD_MIS_Temp* = TQI_AV / IP_TQI_AV_MAX_MIS(N_32) *// TQI_AV based*

ElseIf C_CONF_LOAD_MIS = 1

Then *LOAD_MIS_Temp* = MAF / IP_MAF_MAX_MIS(N32) *// MAF based*

Else *LOAD_MIS_Temp* = MAP / C_MAP_MAX_MIS *// MAP based*

EndIf

LOAD_MIS = FAC_GAIN_LOAD_MIS * *LOAD_Temp* *// Application incidence correction*

LOAD_GRD_MIS = | LOAD_MIS - LOAD_MIS_3 |

Note : LOAD_MIS calculation steps are checked against division by zero
LOAD_MIS_Temp is a non visible, temporary value

LC_MIS_INH	LV_IS	OPM_AV	TCO
LV_IGA_GRD_ACT	IGA_BAS_COR_MV		

General information:

Generic fade out (LV_REQ_APP_INH_MIS) is based on all conditions who could create unreliable conditions for misfire detection :

- Engine gradients (engine load, throttle, combustion mode & ignition angle transients).
- Crankshaft jolt effects who can distrub detection process (rough road, drivetrain oscillations, air conditionner & accessoiries activation/deactivation).
- OBDI errors on one of the sensors used by the misfire monitoring process.

All these different conditions are merge into a carrier (MIS_DET_CDN_APP_INH).

Application conditions:

Initialisation: at ECU reset, at Engine Stop **Or** at LC_MIS_INH 0 to 1 transition

LV_REQ_APP_INH_MIS = 1

MIS_DET_CDN_APP_INH = 2047

MIS_DET_CDN_APP_INH_NR = 11

MAP_DIF_MIS = 0

IGA_DIF_MIS = 0

IGA_BAS_DIF_MIS = 0

IGA_MIS_2 = 0

IGA_MIS_1 = 0

IGA_MIS = 0

Recurrence: segment task for data process

10 ms for free running timers

Activation: LV_ENA_ER = 1

And LC_MIS_INH = 0

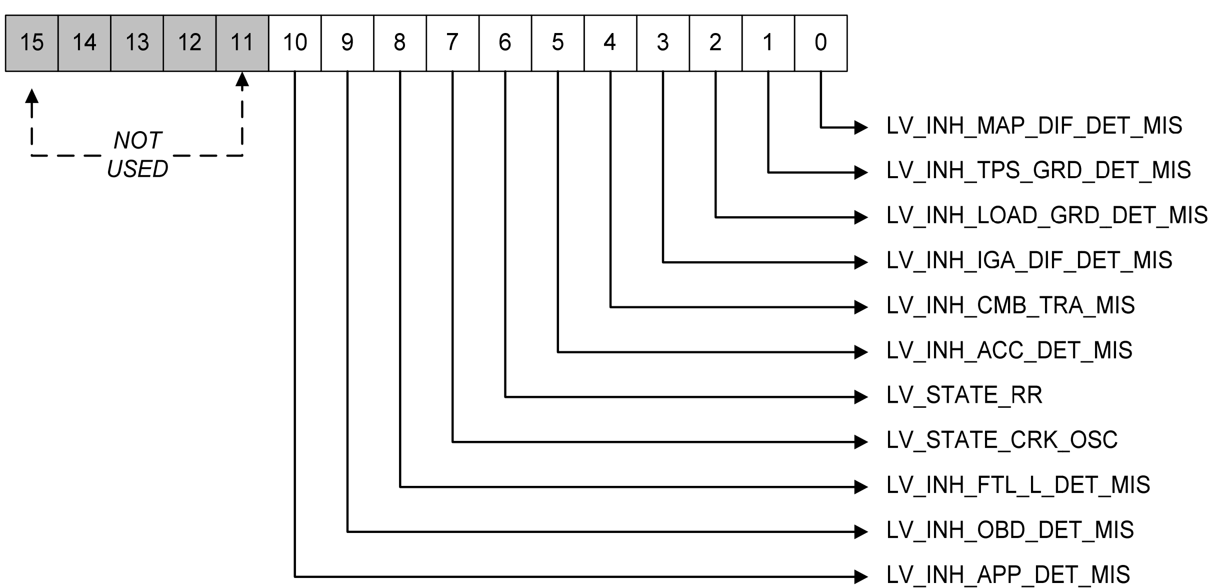
Deactivation: LV_ENA_ER = 0

Or LC_MIS_INH = 1

Remark : Timers used for delay are 10 ms free running decounters, they are not linked to activation/deactivation conditions described above.

B.3.2.1 Generic fade out condition carrier definition

MIS_DET_CDN_APP_INH



remark : MIS_DET_CDN_APP_INH is updated at current misfire task

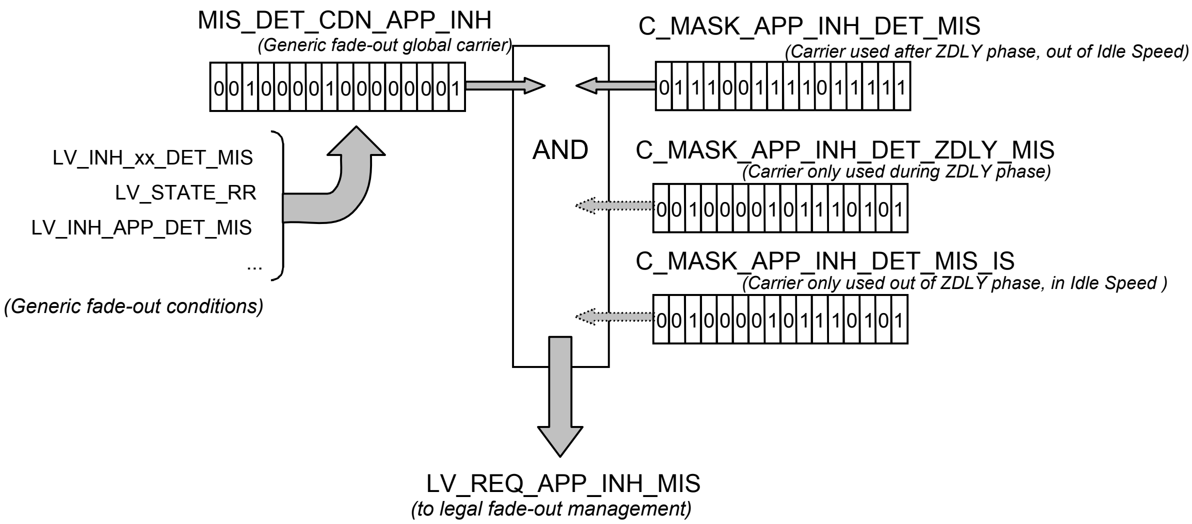
B.3.2.2 Configurable generic fade-out management

Generic fade out management during zero delay phase, nominal phase & idle speed engine state can be configurated via 3 bitfield masks that allow to take in account or not some conditions in a phase and not in the other.

If the corresponding bit in the MIS_DET_CDN_APP_INH carrier structure is set to 0 in C_MASK_APP_INH_DET_ZDLY_MIS, C_MASK_APP_INH_DET_MIS or C_MASK_APP_INH_DET_MIS_IS calibration, then the corresponding condition will not fade-out misfire detection.

For the definition of C_MASK_APP_INH_DET_ZDLY_MIS, C_MASK_APP_INH_DET_MIS & C_MASK_APP_INH_DET_MIS_IS masks please refer to the legal requirements & customer recommendations.

Overview:



Formula section:

If(1) CTR_T_ZDLY_MIS != 0

Then(1) *// ZDLY phase*

MIS_DET_CDN_APP_INH_NR =

sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_ZDLY_MIS)

(bitfield operations)

Else(1)

If(2) LV_IS = 1

Then(2) *// Idle Speed engine state*

MIS_DET_CDN_APP_INH_NR =

sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_MIS_IS)

(bitfield operations)

Else(2) *// Out of idle speed engine state*

MIS_DET_CDN_APP_INH_NR =

sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_MIS)

(bitfield operations)

EndIf(2)

EndIf(1)

If MIS_DET_CDN_APP_INH_NR != 0

Then LV_REQ_APP_INH_MIS = 1

Else LV_REQ_APP_INH_MIS = 0

EndIf

B.3.2.3 Maximum manifold air-pressure gradient

Due to trailing throttle / acceleration transition problems, it could be necessary to disable misfire detection for a short period when the manifold air-pressure gradient exceeds an applicable value.

Application conditions:

In all homogeneous combustion mode, Misfire detection is disabled when the amount of the MAP gradient exceeds IP_MAP_DIF_MAX_MIS(MAP)

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_MAP_DIF_DET_MIS = 1

Formula section:

MAP_DIF_MIS = | $MAP_{(n)}$ - $MAP_{(n-2)}$ |

If LV_S_ACT = 0

And MAP_DIF_MIS > IP_MAP_DIF_MAX_MIS(MAP)

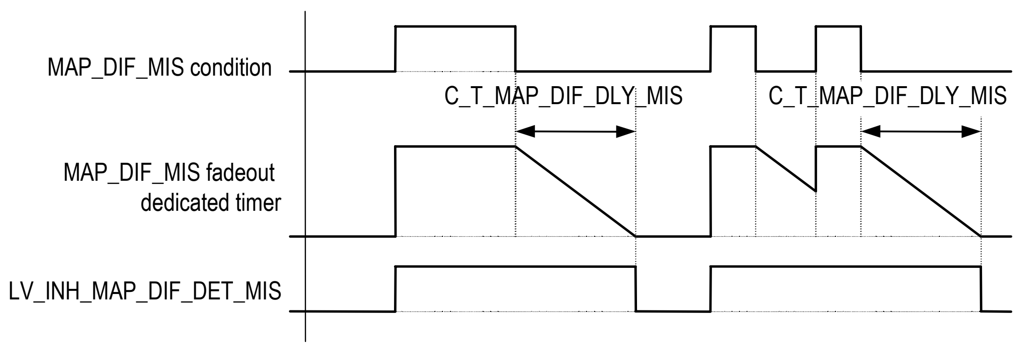
Then

After condition rising edge triggering, LV_INH_MAP_DIF_DET_MIS flag is set to 1 as long as condition is true.

After condition falling edge triggering, LV_INH_MAP_DIF_DET_MIS flag is hold to 1 for a period of C_T_MAP_DIF_DLY_MIS.

EndIf

Fade out behaviour summary:



B.3.2.4 Maximum throttle gradient

Due to trailing throttle / acceleration transient problems at low load, it is necessary to disable misfire detection for a short period when the throttle gradient exceeds an applicable value.

Application conditions:

Misfire detection can be disabled when the amount of the throttle gradient exceeds the applicable value hereunder mentioned. But during the 0-delay activation of the misfire monitoring, driver-induced fade-out is allowed:

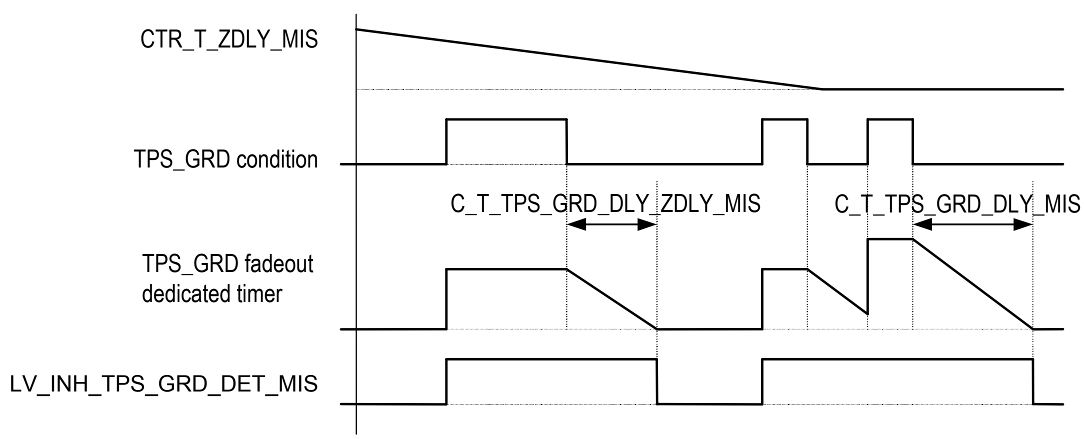
Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_TPS_GRD_DET_MIS = 1

Formula section:

If(1) CTR_T_ZDLY_MIS = 0
Then(1)
  If(2) TPS_GRD > IP_TPS_GRD_MAX_MIS(TPS_AV)
  Then(2)
    After condition rising edge triggering, LV_INH_TPS_GRD_DET_MIS flag is set to 1 as long as condition is true.
    After condition falling edge triggering, LV_INH_TPS_GRD_DET_MIS flag is hold to 1 for a period of C_T_TPS_GRD_DLY_MIS.
  EndIf(2)
Else(1)
  If(2) TPS_GRD > IP_TPS_GRD_ZDLY_MIS(TPS_AV)
  Then(2)
    After condition rising edge triggering, LV_INH_TPS_GRD_DET_MIS flag is set to 1 as long as condition is true.
    After condition falling edge triggering, LV_INH_TPS_GRD_DET_MIS flag is hold to 1 for a period of C_T_TPS_GRD_DLY_ZDLY_MIS.
  EndIf(2)
EndIf(1)

Fade out behaviour summary:



B.3.2.5 Maximum engine load gradient

Due to trailing throttle / acceleration transient problems at low load, it could be necessary to disable misfire detection for a short period when the engine load exceeds an applicable value.

Application conditions:

Misfire detection can be disabled when the amount of engine load gradient exceeds a calibration value, this value is switched according combustion mode. Fade out delay is also specific to combustion mode.

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

EndIf(2)

If(2) LV_IGA_GRD_ACT = 0 *// out of IGA engine start calculation phase*

And IGA_BAS_DIF_MIS > IP_DELTA_IGA_BAS_MIS(N_MIS,LOAD_MIS)

Then(2) After condition rising edge triggering, LV_INH_IGA_DIF_DET_MIS flag is set to 1 as long as condition is true.

Else(2) After condition falling edge triggering, LV_INH_IGA_DIF_DET_MIS flag is hold to 1 for a period of C_NR_TDC_IGA_BAS_DIF_MIS.

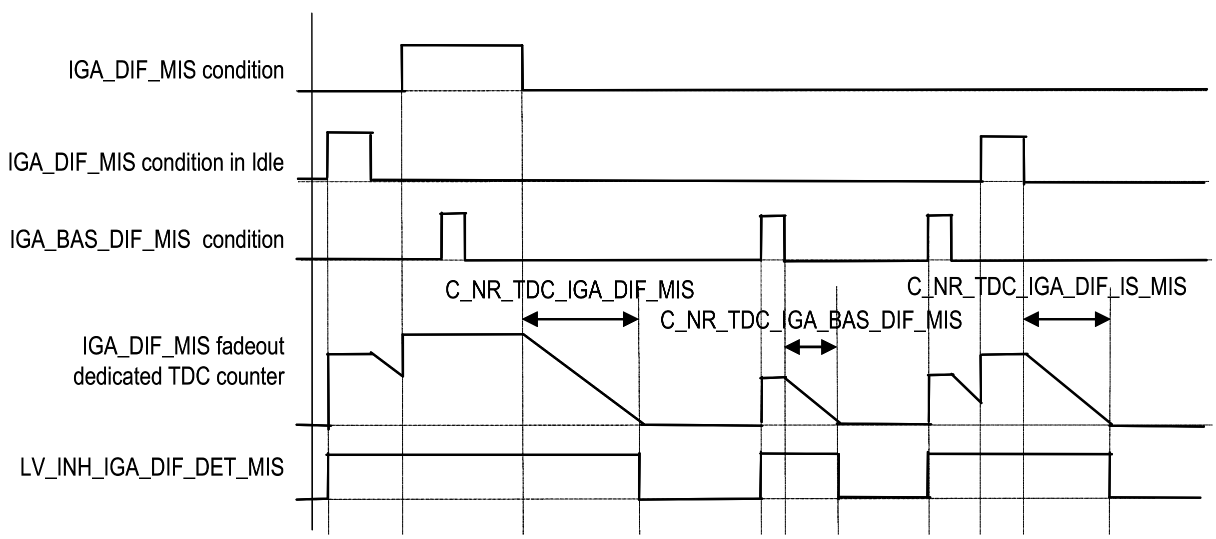
When this period is exceeded without retriggering, LV_INH_IGA_DIF_DET_MIS releases to 0.

EndIf (2)

EndIf(1)

// note: the TDC decounter is retriggered only if the considered preload calibration is greater than the decounter actual value.

Fade out behaviour summary:



B.3.2.7 Combustion mode transients

Application conditions:

While the combustion manager is in transient state, the misfire detection can be disabled to have a proper base for evaluation of the ER-misfire detection thresholds, which are defined for the stationary modes (AFS, AFL & S).

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_CMB_TRA_MIS = 1

Formula section:

#If NC_CMB_CONF = AFS_S Or AFS_AFL_S

If OPM_AV = x -> 1 (x is different of 1)

Then LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_S_MIS tdc's

EndIf

#EndIf

#If NC_CMB_CONF = AFS_AFL Or AFS_AFL_S

If OPM_AV = x -> 3 (x is different of 3)

Then LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_AFL_MIS tdc's

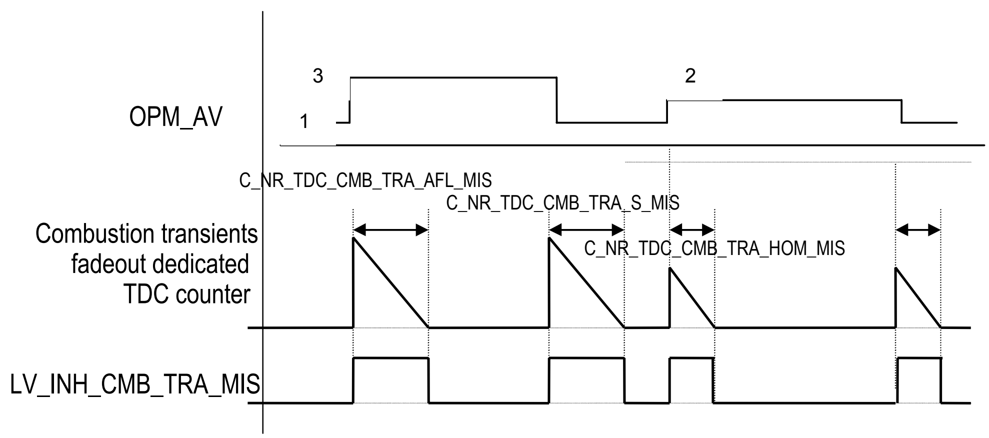
EndIf

#EndIf

If OPM_AV = x -> 2 (x is different of 2)

Then LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_HOM_MIS tdc's

EndIf



B.3.2.8 Air - conditioning compressor activation

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine.
This load jump can cause a segment period jump and crankshaft vibration, depending on the engine operating state and load request.

Application conditions:

Misfire detection can be suppressed for the applicable constant period C_T_ACCOUT_DLY_MIS, starting if the air - conditioning compressor is switched on or off (LV_ACCOUT_RLY changes from 0 to 1 or from 1 to 0), during this period LV_INH_ACC_DET_MIS is set to 1.

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_ACC_DET_MIS = 1

Formula section:

If LV_ACCOUT_RLY = 0 –> 1
Or LV_ACCOUT_RLY = 1 –> 0
Then LV_INH_ACC_DET_MIS is set to 1 during C_T_ACCOUT_DLY_MIS
EndIf

B.3.2.9 Rough road detection

Application conditions:

Misfire detection can be suppressed when the status of the *rough road detection* is active (LV_STATE_RR = 1).

B.3.2.10 Crankshaft oscillation detection

Application conditions:

Misfire detection can be suppressed when the status of the *crankshaft oscillation detection* is active (LV_STATE_CRK_OSC = 1).

B.3.2.11 Low fuel level

Application conditions:

Misfire detection can be suppressed when the low fuel level is detected (LV_INH_FTL_L_DET_MIS=1).

B.3.2.12 OBDI diagnosis fade-out

Application conditions:

LV_INH_OBD_DET_MIS combines all OBD project specific error bits to generate an input for the generic misfire detection fade-out conditions. *See definition in Misfire detection - Application Incidences file.* Misfiring detection can be suppressed if LV_INH_OBD_DET_MIS = 1

B.3.2.13 Application incidences fade-out

Application conditions:

LV_INH_APP_DET_MIS combines all project specific special conditions to generate an input for the generic misfire detection fade-out conditions. *See definition in Misfire detection - Application Incidences file*. Misfiring detection can be suppressed if LV_INH_APP_DET_MIS = 1

B.4 Legal Misfire Detection Fade-Out Conditions

B.4.1 General information

This chapter is relative to misfire detection fade out management as defined by legal texts linked to functionnal OBD diagnosis (OBDII, EOBD...).

Continuous misfire monitoring from engine starting instant:

- ***Engine start instant*** *: the point when the engine reaches a speed 150 rpm below the normal, warmed-up idle speed (as determined in the drive position for vehicles equipped with an automatic transmission) (CARB definition).*
  - *One engine cycle (2 crankshaft revolutions) is allowed to initialise misfire detection process (see CTR_TDC_ZDLY_MIS using).*

Fade out conditions may disable misfire monitoring with the following conditions:

- **Minimum engine speed** : N_IS_SP - 150 rpm *(US)*
- **Maximum engine speed** : Redline engine speed *(US)* or 4500 rpm *(EC)*
- **Minimum engine load** :

  Zero load line (engine positive torque line)

  A line joining the point (3000 rpm, zero load) and a point (6000 rpm, 135 hPa *(or 4 inches Hg)* above the zero load line)
- **Minimum coolant or ambiant temperature**

  Below 20°F (US) or -7°C (EC) *(equivalent),*

  Or If Engine start coolant temperature is below 20°F, until current temperature reaches warm up engine temperature 70°F.
- **Minimum atmospheric pressure**

  Elevations above 8000 feet above sea level (US) or 2 500 meters (EC)
- **Time after start**

  A 5s time after start fade-out can be allowed for EC market

  Such kind of fade out is prohibited for US market (see CARB requirement for zero delay misfire monitoring activation)
- **Cylinder shut-off**

  During fuel cut-off phase, on a specific cylinder shut-off or the number of cylinder in shut-off is too important, misfire diagnosis may be fade out *(no injection/combustion occurs)*

B.4.2 Misfire detection fade out management

Output data:

Misfire Detection Phase State Machine					

Input data:

N	LV_RUN_ENG	LV_ES	

FUNCTION DESCRIPTION:

CARB requests an activation of the misfire monitoring and diagnosis as off engine start. Particular fade-out conditions are required during the first 5 seconds since engine running. In this section the flag representing the request is defined, and is used in several other modules that are concerned with this requirement *(LC_REQ_ZDLY_MIS = 1).*

For non-CARB applications, this special monitoring is not required and has to be de-activated *(LC_REQ_ZDLY_MIS = 0).*

A state-based approach is taken for the activation of the misfire detection algorithms, distinguishing the separate monitoring during the first 5 seconds and the 'nominal' monitoring afterwards, and preparatory phases. During the monitoring phases, the normal fade-out mechanisms are used, corrected for some fade-outs that are not allowed during the first 5 seconds.

Application conditions:

Activation:

Engine Start LV_RUN_ENG = 1

Deactivation:

Engine Stop LV_RUN_ENG = 0 **Or** ECU reset

Remark: At deactivation, ALL internal and external variables related to the legal fade out misfire detection conditions must be reset to 0.
In nominal mode (after engine start and zero delay period), the state machine executes no operations.

Formula section:

At engine start-up (LV_RUN_ENG switches from 0 to 1) the system starts in STATE_DIAG_MIS = 0 (initialisation phase).

In the case of a CARB-application, special monitoring takes placed during C_T_ZDLY_MIS seconds. The timer is started at detection of engine running:

If LC_REQ_ZDLY_MIS = 1
And STATE_DIAG_MIS = 0
Then CTR_T_ZDLY_MIS = C_T_ZDLY_MIS
EndIf

Transition initialisation state to preparation states for 0-delay OR to nominal monitoring

If LC_REQ_ZDLY_MIS = 1
And STATE_DIAG_MIS = 0
And N > C_N_MIN_ZDLY_MIS
Then ***Zero-Delay Activation of Misfire Detection***
STATE_DIAG_MIS = 1
CTR_TDC_ZDLY_MIS = C_NR_TDC_ZDLY_MIS
ElseIf LC_REQ_ZDLY_MIS = 0
And STATE_DIAG_MIS = 0
And N > C_N_MIN_ZDLY_MIS
Then ***Standard Activation of Misfire Detection***
STATE_DIAG_MIS = 3
CTR_TDC_ZDLY_MIS = C_NR_TDC_ZDLY_MIS
Else ***Initialisation Phase***
LV_DIAG_MIS = 0
LV_ZDLY_DIAG_MIS = 0
EndIf

Transition back to the initialisation phase

If LV_ES = 1
And STATE_DIAG_MIS <> 0
Then ***In case of engine stop, return to initialisation phase***
STATE_DIAG_MIS = 0
EndIf

Transition preparation state 0-delay monitoring to 0-delay monitoring state

If	LC_REQ_ZDLY_MIS = 1	CARB application
And	STATE_DIAG_MIS = 1	0-delay preparation state
And	N > C_N_MIN_ZDLY_MIS	engine speed over threshold
And	CTR_TDC_ZDLY_MIS = 0	1 engine cycle passed
Then	STATE_DIAG_MIS = 2	
	LV_ZDLY_DIAG_MIS = 1	
EndIf		

Transition preparation nominal state to nominal monitoring state

If	LC_REQ_ZDLY_MIS = 0	standard application
And	STATE_DIAG_MIS = 3	preparation monitoring state
And	N > C_N_MIN_ZDLY_MIS	engine speed over threshold
And	CTR_TDC_ZDLY_MIS = 0	1 engine cycle passed
Then	STATE_DIAG_MIS = 4	
	LV_DIAG_MIS = 1	
EndIf		

Transition 0-delay monitoring state to nominal monitoring state

If	LC_REQ_ZDLY_MIS = 1	*CARB application*
And	STATE_DIAG_MIS = 2	*0-delay monitoring state*
And	N > C_N_MIN_ZDLY_MIS	*engine speed over threshold*
And	CTR_TDC_ZDLY_MIS = 0	*1 engine cycle passed*
And	CTR_T_ZDLY_MIS = 0	*timer finished (typically 5 seconds)*
Then	STATE_DIAG_MIS = 4	
	LV_DIAG_MIS = 1	
	LV_ZDLY_DIAG_MIS = 0	
EndIf		

The counter CTR_T_ZDLY_MIS is decremented at every time instance of 10 ms when STATE_DIAG_MIS != 0.

The counter CTR_TDC_ZDLY_MIS is decremented with 1 at every TDC.

(both counters are saturated to 0)

Rermark: During the 0-delay misfire detection, no fade-outs are allowed for crankshaft oscillation, rough road detection and zero-load line conditions (see appropriate sections). However, it is allowed to have so-called driver-induced fade-outs (e.g. gradient on pedal value). This latter section has been added.

At hot resets, the system starts again in the initialisation phase.

Calibration data:

N	LOAD_MIS	LOAD_MIN_MIS	TCO
AMP	LV_ST	SEG_NR	LC_MIS_INH
LV_AT	LV_DC	INH_INJ	TCO_ST
LV_REQ_APP_INH_MIS	LV_INJ_CUT	SUM_INH_INJ	C_N_MIN_ZDLY_MIS

FUNCTION DESCRIPTION:

General information:

Legal fade out (LV_REQ_INH_MIS) is based on all fade out conditions allowed by the legal texts for continuous misfire monitoring.

All these different fade-out conditions are merge into a global carrier (MIS_DET_CDN_INH).

Timers used for fade-out conditions delays are free running timers who are not deactivated according following conditions.

Application conditions: *(global to Misfire detection legal fade out conditions chapter)*

Initialisation: at Reset, Engine Stop, **Or** on Deactivation event

LV_PUC_DET_MIS = 0

LV_IV_OFF_DET_MIS = 1

LV_REQ_INH_MIS = 1

MIS_DET_CDN_INH = 127

MIS_DET_CDN_INH_NR = 7

Recurrence: every segment task

Activation: *LC_MIS_INH = 0*

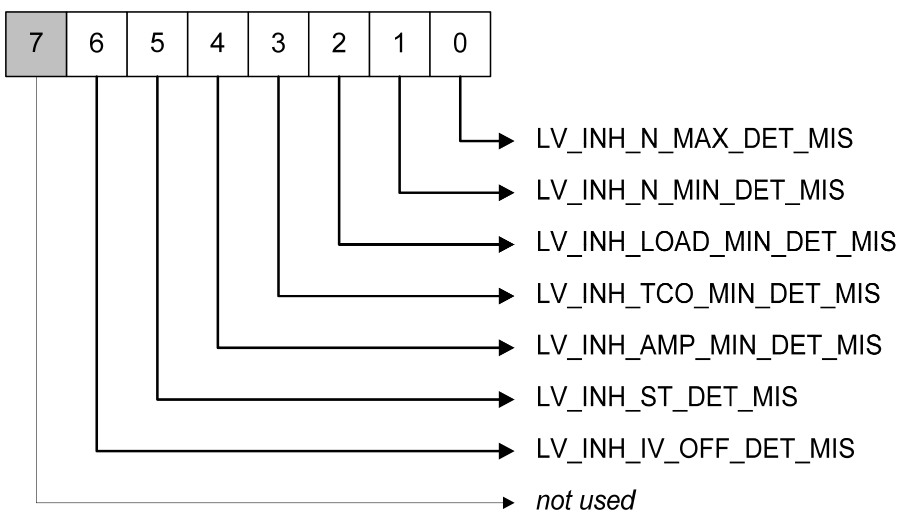
Deactivation: *LC_MIS_INH = 1*

B.4.3.1 Fade out carrier definition

Misfire fade out conditions carrier:

MIS_DET_CDN_INH

Carrier used for fade-out conditions merge
(legal fade-out overview)



B.4.3.2 Configurable Fade-out Management

Application conditions:

Fade out management during zero delay phase & nominal phase can be configurated via 2 bitfield masks that allow to take in account or not some conditions in a phase and not in the other.

If the corresponding bit in the MIS_DET_CDN_INH carrier structure is set to 0 in C_MASK_INH_DET_ZDLY_MIS or C_MASK_INH_DET_MIS calibration, then the corresponding condition will not fade-out misfire detection.

For the definition of C_MASK_INH_DET_ZDLY_MIS & C_MASK_INH_DET_MIS masks please refer to the legal requirements & customer recommendations.

Formula section:

If CTR_T_ZDLY_MIS ≠ 0

Then

MIS_DET_CDN_INH_NR = sum(MIS_DET_CDN_INH & C_MASK_INH_DET_ZDLY_MIS)

(bitfield operations)

Else

MIS_DET_CDN_INH_NR = sum(MIS_DET_CDN_INH & C_MASK_INH_DET_MIS)

(bitfield operations)

EndIf

If MIS_DET_CDN_INH_NR ≠ 0

Or LV_REQ_APP_INH_MIS = 1 *// Fade out request linked to misfire detection method*

Then LV_REQ_INH_MIS = 1 *// General fade out request*

Else LV_REQ_INH_MIS = 0

EndIf

B.4.3.3 Maximum engine speed fade-out

Application conditions:

The misfire monitoring can be inhibated when the engine speed reachs the maximum engine speed imposed by the market target : Redline engine speed for US applications or 4500 rpm for EC applications.

Moreover this information is use to stop misfire monitoring process for high speed if not required (limitation of cpu load especially for european application).

Formula section:

If (N > C_N_MAX_MIS)

Then LV_INH_N_MAX_DET_MIS = 1

Else LV_INH_N_MAX_DET_MIS = 0

EndIf

B.4.3.4 Minimum engine speed fade-out

The irregular engine operation test is performed as soon as the above-mentioned condition is disabled.

Important:

- C_N_MIN_MIS is defined by the current configuration of the index used for misfire detection in the current application. C_N_MIN_MIS should be lower than C_N_MIN_ZDLY_MIS.
- C_N_MIN_ZDLY_MIS is defined as the engine speed set-point for a warm engine minus 150 rpm. After passing below the C_N_MIN_ZDLY_MIS threshold, one is allowed one engine cycle (meaning for example for a 4-cylinder engine 4 tdc's) before reactivating the output of the misfire detection algorithm. Misfire detection is suppressed for a period of C_NR_TDC_INH_MIS tdc's.
- It should be checked in each application that within the allowed number of TDC's proper misfire detection index values have been re-obtained. Typically, it should be possible to restart misfire detection earlier.

Application conditions:

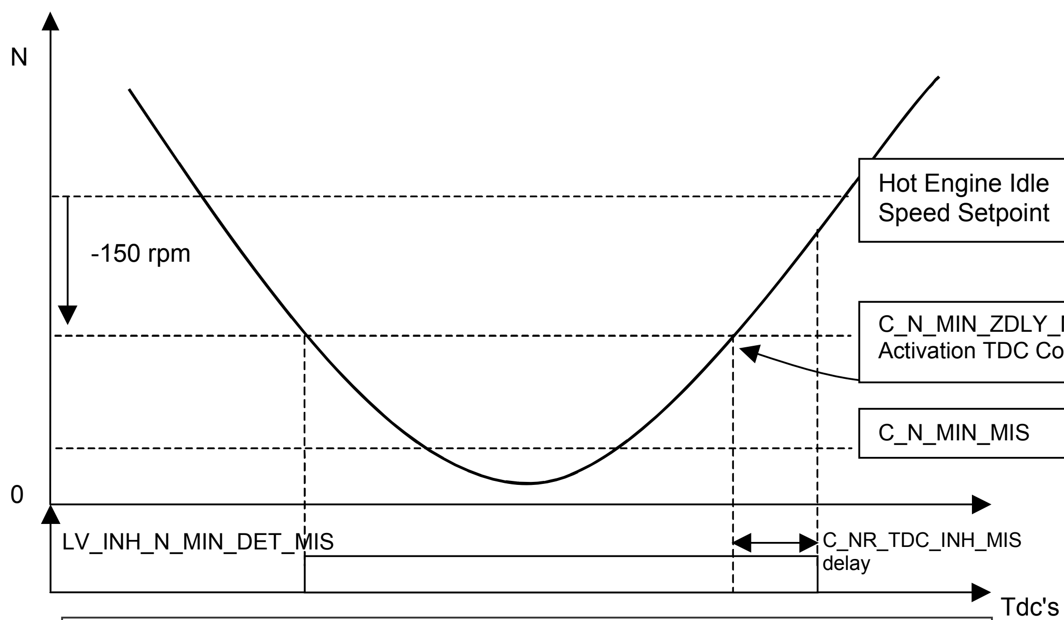
N < C_N_MIN_ZDLY_MIS

Engine speed below CARB requirements *(used for US applications)*.

Typically, once N < C_N_MIN_ZDLY_MIS, the output of the misfire detection is inhibited, allthough the calculation is still valid. C_NR_TDC_ZDLY_MIS tdc's decounter is started at passing engine speed C_N_MIN_ZDLY_MIS again. Once the decounter is at 0, misfire detection index output is allowed.

N < C_N_MIN_MIS

Engine speed below misfire detection index resolution *(used for CE applications)*. If the engine speed falls below C_N_MIN_MIS.



Explanation on the mechanism to re-activate the misfire detection after an engine speed drop

As the misfiring test is not mandatory and risky over a certain engine speed threshold, a fade out condition is tested on engine rpm (not allowed for US market).

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_N_MIN_DET_MIS = 1

Formula section:

If N < C_N_MIN_ZDLY_MIS
 Or N < C_N_MIN_MIS
Then LV_INH_N_MIN_DET_MIS = 1
Else LV_INH_N_MIN_DET_MIS = 0
 caution : see specific reactivation conditions above when N > C_N_MIN_ZDLY_MIS, C_NR_TDC_INH_MIS delay used
EndIf

B.4.3.5 Minimum engine load

Application conditions:

Below a specific load (zero load), fluctuations in engine speed cannot be detected, even in the event of misfire. In this case, the misfire detection is disabled.

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_LOAD_MIN_DET_MIS = 1

Formula section:

If LOAD_MIS < LOAD_MIN_MIS
Then LV_INH_LOAD_MIN_DET_MIS = 1
Else LV_INH_LOAD_MIN_DET_MIS = 0
EndIf

B.4.3.6 Minimum coolant temperature

Application conditions:

Misfire detection can be disabled when the coolant temperature is below a threshold (20°F / -7°C). Additionally when the coolant temperature at engine start is below this threshold, the misfire monitoring can be disable on that driving cycle until the current engine temperature reaches a warm up temperature threshold (70°F / 21°C):

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_TCO_MIN_DET_MIS = 1

Formula section:

LV_TEMP : temporary bit used to check only one occurence per engine start

Initialisation : LV_TEMP = 0 at ECU reset ***Or*** *LV_DC 0 -> 1*

If TCO < C_TCO_MIN_MIS

Or (TCO_ST < C_TCO_MIN_MIS

And TCO < C_TCO_WUP_MIN_MIS

And *LV_TEMP = 0*)

Then LV_INH_TCO_MIN_DET_MIS = 1

Else LV_INH_TCO_MIN_DET_MIS = 0

LV_TEMP = 1

EndIf

B.4.3.7 Minimum atmospheric pressure

Application conditions:

Misfire detection can be disabled when the atmospheric pressure is below a threshold:

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_AMP_MIN_DET_MIS = 1

Formula section:

If AMP < C_AMP_MIN_MIS

Then LV_INH_AMP_MIN_DET_MIS = 1

Else LV_INH_AMP_MIN_DET_MIS = 0

EndIf

B.4.3.8 After start

Application conditions:

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_ST_DET_MIS = 1

Misfire detection can be suppressed (see legal requirements - forbidden for CARB zero delay requirements) for a C_T_DLY_ST_MIS duration after the engine exits the operating state start (LV_ST), during this period LV_INH_ST_DET_MIS is set to 1, even if C_T_DLY_ST_MIS = 0.

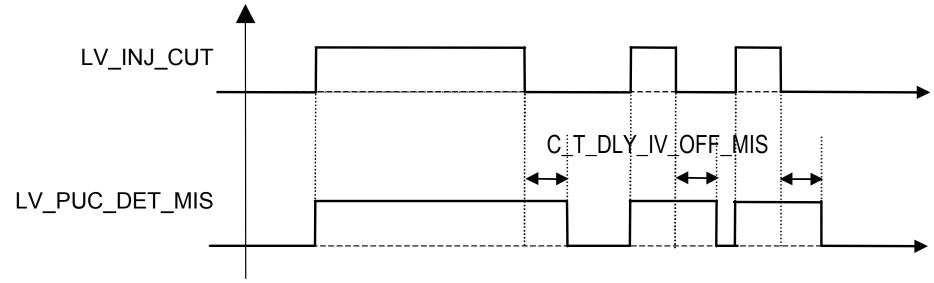
B.4.3.9 Injection shut-off

Application conditions:

Misfire detection can be suppressed for the cylinder(s), for which injection has been shut-off.

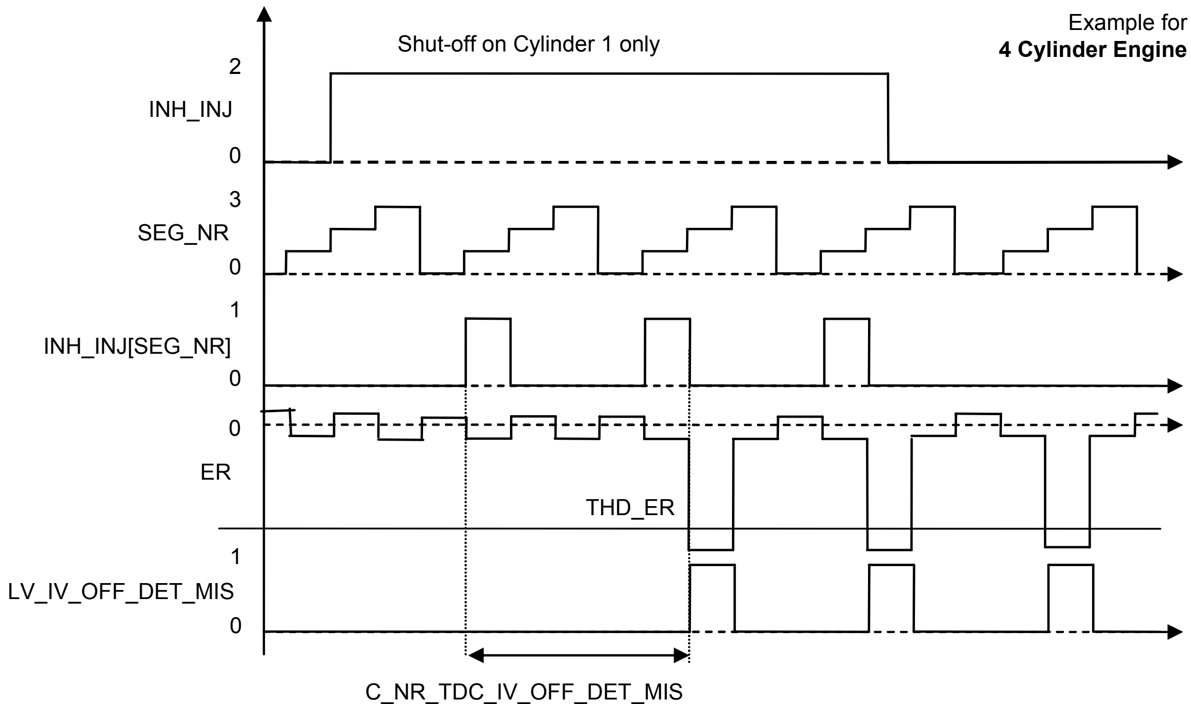
General fuel shut-off:

LV_INJ_CUT indicates a general fuel shut-off. LV_PUC_DET_MIS bit includes a calibration delay time (C_T_DLY_IV_OFF_MIS) triggered at fuel cut-off condition falling edge, in a way to start the misfire detection only after crankshaft oscillations due to fuel reactivation.



Cylinder specific shut-off:

If the current cylinder checked by misfire detection is shut-off by any EMS function even MISF limp home functionnality), a fade-out can be apply for the misfire detection of this cylinder. Due to the delay between the misfire index and the injection current informations, a calibration delay (C_NR_TDC_IV_OFF_DET_MIS) has been introduced on LV_IV_OFF_DET_MIS. This delay synchronises MISF & INJR informations in a way to apply correctly the fade-out on the proper cylinder during individual cylinder shut-off operations, and to be able the perform the misfire monitoring on the other cylinders who are not in shut-off mode.



Limit number of cylinders shut-off:

If the number of shut-off cylinders reaches a calibration data (C_SUM_INH_IV_MAX_DET_MIS), reliable misfire detection is impossible. In such case is preferable to inhibate misfire detection.

Formula section:

General fuel shut-off:

If LV_INJ_CUT = 1 *// All cylinders are shut off*

Then LV_PUC_DET_MIS = 1

Else LV_PUC_DET_MIS = 0 after C_T_DLY_IV_OFF_MIS delay time

EndIf

Cylinder fuel shut-off:

If INH_INJ[SEG_NR] = 1 *// indexed by cylinder bit position*

Then LV_IV_OFF_DET_MIS = 1 after a C_NR_TDC_IV_OFF_DET_MIS delay

Else LV_IV_OFF_DET_MIS = 0 after a C_NR_TDC_IV_OFF_DET_MIS delay

EndIf

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_IV_OFF_DET_MIS = 1

Formula section:

General definition:

If LV_PUC_DET_MIS = 1

Or LV_IV_OFF_DET_MIS = 1

Or SUM_INH_INJ >= C_SUM_INH_IV_MAX_MIS

Then LV_INH_IV_OFF_DET_MIS = 1

Else LV_INH_IV_OFF_DET_MIS = 0

EndIf

Calibration data:

B.5 Misfire rate determination and error management

General information:

The misfire rate determination and misfire specific error management are applied to the following CARB misfire legal definitions:

- **CARB A misfire failure criterion** *(LV_MIS_STATE_A)*:

Risk of catalyst damage, monitoring interval over 200 crankshaft revolutions (= 200 * NC_CYL_NR / 2 TDCs) during the driving cycle.

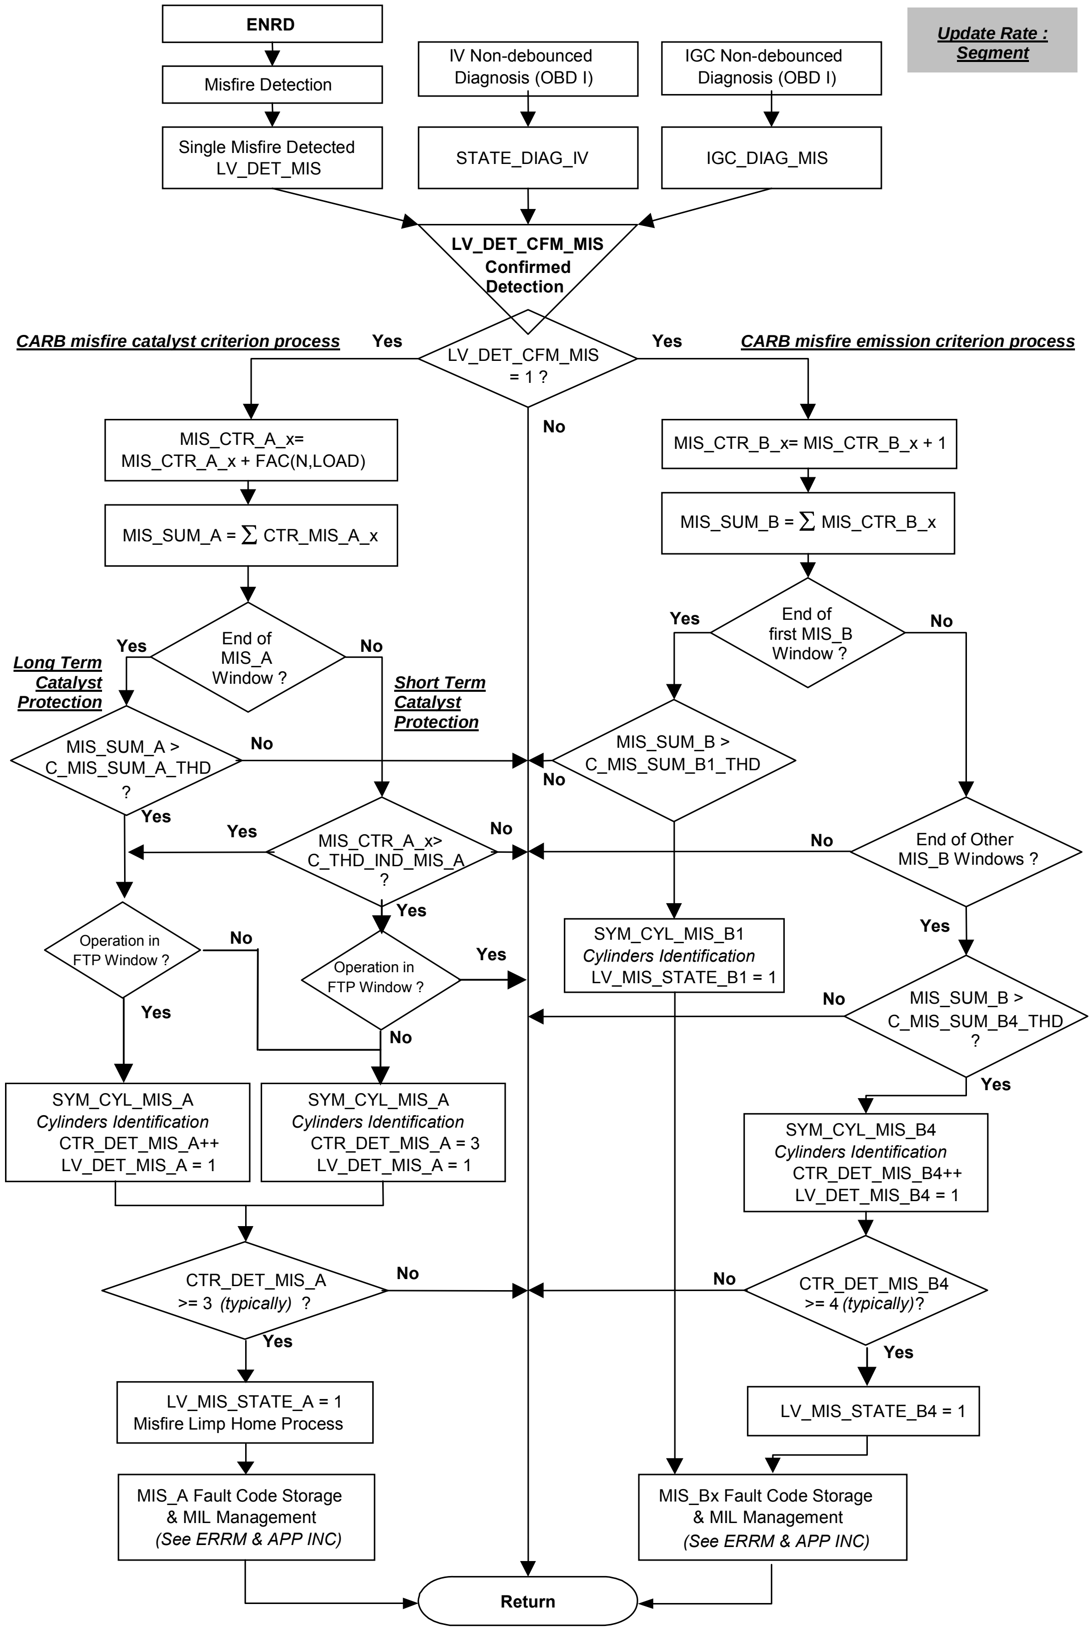
- **CARB B1 misfire failure criterion** *(LV_MIS_STATE_B1):*

Emission increase, monitoring interval over the first 1000 crankshaft revolutions (= 1000 * NC_CYL_NR / 2 TDCs) of the driving cycle.

- **CARB B4 misfire failure criterion** *(LV_MIS_STATE_B4):*

Emission increase, monitoring interval over 1000 crankshaft revolutions (= 1000 * NC_CYL_NR / 2 TDCs). For criterion confirmation, misfire must be take place for 4 monitoring intervals (consecutive or not).

MIS_A, MIS_B1 & MIS_B4 Handling Flowchart diagram:



B.5.1 Combination of different diagnosis reliability levels (misfire detection, ignition, injection)

Input data:

LV_DET_MIS	STATE_DIAG_IV	IGC_DIAG_MIS	LOAD_MIS
N_32	INH_IV_MIS	SEG_NR_ER	LV_HOM_AFL_ACT
LV_S_ACT	LV_INH_IGC_DIAG_MIS	LV_INH_IV_DIAG_MIS	NC_CMB_CONF
LC_MIS_INH			

FUNCTION DESCRIPTION:

General information:

Due to their physical principle, the individual diagnostic functions have a different diagnostic relevance depending on the operating point.

To achieve the best possible detection of misfires, the individual diagnostic methods are combined. Here with an assumed misfire of a part function, an operating point dependent weighting factor, which reflects the reliability of this part function in the current operating point, is taken from a map. If the sum of these three values now exceeds a threshold for one combustion, then misfire is detected.

The value which is not debounced is used as input value of the IV and IGCFB diagnoses. The injection for a cylinder is cut off exclusively by the CARB error mechanism and not by the IV and IGCFB diagnostic functions.

Application conditions:

Misfire segment after detection, before CARB diagnosis

Application conditions:

Update rate: every segment

Activation:

LC_MIS_INH = 0

Deactivation:

LC_MIS_INH = 1

Initialisation on ECU reset, on LV_DC 0 to 1 transition and on LC_MIS_INH 0 to 1 transition:

SUM_FAC_DIAG_MIS = 0

FAC_ER_DIAG_MIS = 0

FAC_IGC_DIAG_MIS= 0

FAC_IV_DIAG_MIS = 0

LV_DET_CFM_MIS = 0

Formula section:

The output from the misfire detection, injection and ignition diagnosis functions is influenced by weighting interpolated table, giving the reliability of the individual functions.

- A weighting value of **0** means that detection is not possible for this engine operating point.

- A value equal to or greater than **1** indicates reliable detection.

- The values in between represent the corresponding levels of reliability.

- Irregular engine operation weighting (LV_DET_MIS = 1):

If misfiring is suspected by the irregular engine operation test, a weighting factor for the corresponding engine operating point is applied. This factor is derived from tables according combustion mode.

Convention for combustion mode determination:

#If NC_CMB_CONF = AFS_AFL Or AFS_AFL_S

If OPM_AV = 3 (homogeneous-stratified)

Then xx = "HOM_S"

EndIf

#EndIf

#If NC_CMB_CONF = AFS_S Or AFS_AFL_S

If OPM_AV = 1 (stratified)

Then xx = "S"

EndIf

#EndIf

If OPM_AV <> 1 and OPM_AV <> 3 (homogeneous)

Then xx = "AFS"

EndIf

If LV_DET_MIS = 1

Then FAC_ER_DIAG_MIS = IP_FAC_ER_xx_DIAG_MIS(N_32, LOAD_MIS)

Else FAC_ER_DIAG_MIS = 0

EndIf

- Ignition diagnosis weighting (IGC_DIAG_MIS):

IGC_DIAG_MIS is the not debounced carrier from Ignition diagnosis, which has to be delayed due to misfire detection *(according segment reference SEG_NR_ER-1, cylinder x compression phase)*. If misfiring is suspected by the ignition diagnosis function, a weighting factor for the corresponding engine operating point is applied.

This factor is derived from IP_FAC_IGC_DIAG_MIS table.

For the time the number of cylinders shut off due to misfire detection limp home reaches or exceeds the applicable number of C_MIS_NR_OFF_IV_IGCFB, FAC_IGC_DIAG factor is forced to ‘’1’’ *(test based on INH_IV_MIS carrier)*.

If(1) IGC_DIAG_MIS[SEG_NR_ER] = 1

And LV_INH_IGC_DIAG_MIS = 0

Then(1)

If(2) number of bits set to "1" in INH_IV_MIS carrier structure >= C_MIS_NR_OFF_IV_IGCFB

Then(2) FAC_IGC_DIAG_MIS = 1

Else(2) FAC_IGC_DIAG_MIS = IP_FAC_IGC_DIAG_MIS(N_32, LOAD_MIS)

EndIf(2)

Else(1) FAC_IGC_DIAG_MIS = 0

EndIf(1)

- Injection diagnosis weighting (STATE_DIAG_IV) :

STATE_DIAG_IV is a not debounced carrier from Injection valves diagnosis.

Injection valve in default is identifed according segment reference SEG_NR_ER within the bitfield structure STATE_DIAG_IV.

If misfiring is suspected by the injection valve diagnosis function, a weighting factor for the corresponding engine combustion mode is applied.

If STATE_DIAG_IV[SEG_NR_ER] = 1

And LV_INH_IV_DIAG_MIS = 0

Then FAC_IV_DIAG_MIS = IP_FAC_IV_DIAG_MIS(N_32, LOAD_MIS)

Else FAC_IV_DIAG_MIS = 0

EndIf

- Formation of a cylinder - specific diagnosis weighting sum :

The sum of the three weighting values SUM_FAC_DIAG_MIS is performed for the individual cylinder. as soon as one of the three diagnosis function suspects misfiring.

SUM_FAC_DIAG_MIS = FAC_ER_DIAG_MIS

+ FAC_IGC_DIAG_MIS

+ FAC_IV_DIAG_FAC

If SUM_FAC_DIAG_MIS >= 1

Then LV_DET_CFM_MIS = 1 *misfire status is confirmed*

Else LV_DET_CFM_MIS = 0 *no misfire*

EndIf

Former / current driving cycle misfire detection cylinder counters (ISO15031 Data $0C)					
CTR_MIS_DC_MMV_CYL[NC_CYL_NR]	V/O/S	0...FFFFH	0...65535	1	[-]
Exponential weighted moving average (EWMA) misfire counters (ISO15031 Data $0B)					

Input data:

LV_DET_CFM_MIS	LV_ENA_ER	LC_MIS_INH	SEG_NR_ER
LV_DC			

FUNCTION DESCRIPTION:

General information:

These counters are incremented at each misfire detection based on misfire index evaluation *(after crossed diagnosis with IGC & IV OBDI diags evaluation)*. Thus, it's possible to determine the total number of misfire detected during engine lifetime and during current driving cycle.

Moreover, cylinder misfire counters have been introduced for Mode 6 communication service, as described in last ISO specification available (ISO/DIS 15031-5.8).

Note: CTR_MIS_TOT_DC & CTR_MIS_DC_CYL[NC_CYL_NR] are initialised only at engine running to keep the information after engine stop.

B.5.2.1 NVMY Data Formating

On non volatile memory formatting **or** on NV memory corruption detection:

CTR_MIS_TOT_NVMY = 0

On non volatile memory formatting **or** on NV memory corruption detection **or** failure memory clearing :

CTR_MIS_TOT_DC = 0

For(1) x = 0 : NC_CYL_NR-1

  CTR_MIS_DC_CYL[x] = 0

  CTR_MIS_DC_MMV_CYL[x] = 0

EndFor(1)

B.5.2.2 Initialisation of former / current driving cycle counters

Initialisations:

- at ECU reset
  NVMY data loading
- at LV_DC 0 -> 1 transition event
  CTR_MIS_TOT_DC = 0
  For(1) x = 0 : NC_CYL_NR-1
  CTR_MIS_DC_CYL[x] = 0
  EndFor(1)

B.5.2.3 Increment of misfire counters during current driving cycle

Application conditions:

Activation:	*LV_ENA_ER = 1*	
	And	*LC_MIS_INH = 0*
Deactivation:	*LV_ENA_ER = 0*	
	Or	*LC_MIS_INH = 1*
Update rate:	Segment task	

Formula section:

If LV_DET_CFM_MIS = 1

Then CTR_MIS_TOT_DC = CTR_MIS_TOT_DC + 1 *// with saturation*

CTR_MIS_TOT_NVMY = CTR_MIS_TOT_NVMY + 1 *// with saturation*

CTR_MIS_DC_CYL[SEG_NR_ER] = CTR_MIS_DC_CYL[SEG_NR_ER] + 1 *// with saturation*

EndIf

B.5.2.4 Update of the EWMA misfire counters

Exponential weighted moving average (EWMA) misfire counters are updated at the beginning of the driving cycle based on former driving cycle values.

Update rate: at LV_DC 0 -> 1 transition event *before CTR_MIS_DC_CYL[x] reset*

For x = 0 : NC_CYL_NR-1

CTR_MIS_DC_MMV_CYL[x] =

0.9 * CTR_MIS_DC_MMV_CYL[x] + 0.1 * CTR_MIS_DC_CYL[x]

EndFor

B.5.3 Exhaust cylinder bank reference for misfire detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_CBK_ER	V	0...FFH	0...255	1	[-]
Exhaust cylinder bank reference for misfire monitoring					

Input data:

SEG_NR_ER	LV_SYN_ENG	NC_CBK_EX_NR	NC_CYL_NR

FUNCTION DESCRIPTION:

For catalyst damage and/or emission criterion, misfire diagnosis functions can be set via calibration data in a way to be able to detect criterions according exhaust cylinder bank phasing instead of a global criterion detection.

Exhaust cylinder bank reference for misfire detection allows to increase these criterions on the dedicated cylinder bank weighting factor if the misfire detected has effect on the impacted cylinder bank and not on the other (if multiple exhaust cylinder bank design).

Description:

The exhaust cylinder bank reference SEG_NR_CBK_ER is determinate according the segment reference SEG_NR_ER. It already includes the delay introduced by the misfire index chosen.

Application conditions:

Update rate: Segment task

Activation: *LV_SYN_ENG = 1*

Deactivation: *LV_SYN_ENG = 0*

Initialisation on Deactivation condition:

SEG_NR_CBK_ER = 0

Initialisation: at ECU reset

SEG_NR_CBK_ER = 0

Formula section:

SEG_NR_CBK_ER = NC_CBK_EX_NR_MISF[SEG_NR_ER]

Configuration data:

NC_CBK_EX_NR	FAC_MIS_A_THD_IND_APP	FAC_MIS_SUM_A_THD_APP	

Description:

With a CARB A misfire rate criterion, the emissions are increased and there is a risk of catalyst damage if the cylinder causing the failure criterion can not be shut off.

Detection:

The check for misfire rate violation **CARB A** comprises 200 crankshaft revolutions *(100 * NC_CYL_NR tdc's)* for statistic misfiring and cyclewise monitoring for best possible catalyst protection.

If a confirmed misfiring is detected on ER current TDC (LV_DET_CFM_MIS=1), a weighting factor (MIS_A_FAC) is added to the cylinder-specific counter MIS_CTR_A[SEG_NR_ER], extracted from an interpolated table *(see APP. INC.)* who depends on engine combustion mode and current operating point. The increment represents the severity of catalyst damage.

Statistic:

The monitoring for Misfire **CARB A** is performed continuously in intervals of 200 crankshaft revolutions.

Monitoring during CARB A window:

To guarantee best possible catalyst protection, the cylinder-specific counters are monitored each cycle. For that purpose, MIS_CTR_A[SEG_NR_ER] is compared to the applicable value C_MIS_A_IND_THD representing the critical threshold for single cylinder misfiring.

If the threshold is reached outside of the FTP cycle, the concerning cylinder is shut off immediately. CARB A misfire criterion is confirmed, else the criterion will be evaluated at the end of the 200 crankshaft revolution window.

Monitoring at the end of 200 crankshaft revolutions:

At the end of each monitoring interval the cylinder-specific sums MIS_CTR_A[NC_CYL_NR] and the global sum (MIS_SUM_A) are available.

If the sum MIS_SUM_A is greater than the threshold C_MIS_SUM_A_THD, the cylinder with the highest misfire rate is determined (by comparing the different MIS_CTR_A[NC_CYL_NR] values).

Then operation inside/outside of the FTP-area is checked by comparison of the counter CTR_FTP_CDN_MIS_A / MIS_NR_TDC_A with the threshold C_RATIO_FTP_CDN_MIS_A. If the FTP tdc's ratio is lower than the threshold, not enough operating points have been inside the FTP-window and therefore operation outside FTP-area is detected (LV_FTP_MIS_A=0). This is done in order to fulfil the CARB-regulations, which require MIL-illumination at first threshold exceeding outside the FTP-area and at third exceeding inside the FTP-area.

Therefore the counter CTR_DET_MIS_A is incremented inside the FTP-area at each threshold exceeding. That means it reaches the maximum of C_NR_DET_MAX_MIS_A = 3 only if the threshold is exceeded in 3 succeeding monitoring intervals.

Outside the FTP-area the failure CARB A is validated immediately. The counter is reset only after an ECU-reset.

Even if we are inside the FTP-area, a specific application request (according catalyst temperature or else) LV_REQ_APP_CTR_MIS_A can force to validate immediately the failure CARB A *(see legal requirements & customer wishes).* This request is defined in associated Application Incidences file.

Note: cylinder and Exhaut cylinder bank specific counters are respectively indexed with SEG_NR_ER and SEG_NR_CBK_ER phase reference counters to take in account ERND delay in misfire monitoring process

Application conditions:

Initialisation: *at ECU reset, at LV_DC 0 - > 1 transition, at LC_MIS_INH 0 to 1 transition & at MIS_A or MIS_[NC_CYL_NR] errors clearing*

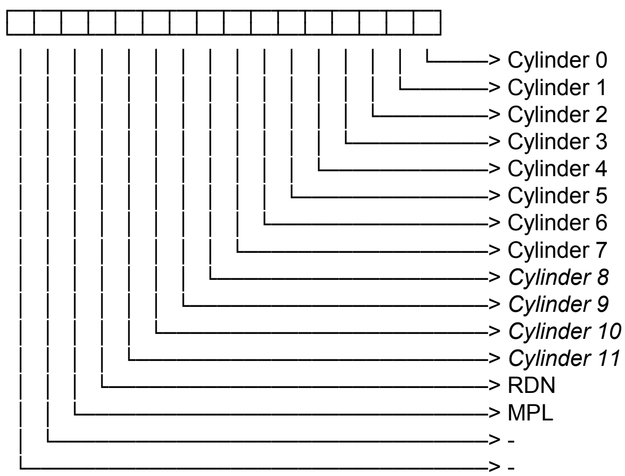
<u>Reset of Misfire Status</u>*:*

The Misfire Status CARB A is resetted at the end of the driving cycle → see formula section

B.5.4.8 Misfire Cylinder Identification SYM_CYL_MIS_A

The location of detected cylinders with misfire status CARB A is coded in a carrier word:

SYM_CYL_MIS_A



B.5.4.9 Misfire Cylinder Limp Home process:

Cylinder shut off is limited by a C_MIS_MAX_NR_OFF_IV maximum number of cylinders that can be shut-off simultaneously

Each time, the misfire cylinder limp home process on one (or more) cylinder(s) is triggered, the corresponding cylinder counter(s) CTR_MIS_A_LIH_CYL[NC_CYL_NR] is(are) unitary incremented.

The location of switched off Cylinder(s) x is set to 1 in INH_IV_MIS, other cylinder bits are set to 0.

<u>On the same driving cycle</u>, if after a cylinder shut-off cancellation, a new cylinder MIS_A criterion occurs during CARB A window, the sytem must shut-off this cylinder once more.

<u>Carrier structure :</u>

INH_IV_MIS

B.5.4.10 Conditions for Cylinder switch back on

Update rate: *every 100ms, independently of MIS_A window process & conditions*

Cylinder(s) x can be switched on according two different methods:

1. Cylinder(s) x can be switched back on at the end of the driving cycle

   LC_CONF_INH_IV_MIS = 0

2. Cylinder(s) x can be switched back on after a defined number of fuel cut-off phases **and** at the end of the driving cycle

   LC_CONF_INH_IV_MIS = 1

   For this purpose, the system performs a test for the applicable number C_MIS_MIN_NR_PUC of trailing throttle fuel cut-off LV_PUC cycles, since the last cylinder(s) shutoff.

   Therefore, the trailing throttle fuel cut-off LV_PUC flag must have been active for the applicable minimum period C_T_MIS_MIN_PUC.

   If the condition concerning the minimum number of trailing throttle fuel cut-off events is met. Cylinder shut-off is cancelled at the end of the last trailing throttle fuel cut-off phase only for cylinders who answer to the conditions CTR_MIS_A_LIH_CYL[x] < C_NR_MAX_MIS_A_LIH_CYL *(check for all cylinders),* all other cylinders stay in fuel cut-off up to end of the driving cycle.

Cylinder shut-off is also cancelled after engine stopped LV_ES.

B.5.4.11 Process on cylinder shut-off cancellation

Update rate: *every TDC, independently of MIS_A window process & conditions*

FAC_MIS_SUM_B4_THD_APP	NLC_ENA_SCDN_NEW	LV_ERR_IN_WIN_MIS_A	

Description:

The purpose is to detect a misfire rate causing an emission increase. The failure criterion entry is performed by direct statistical evaluation.

Detection:

The check for misfire rate violation CARB comprises 1.000 crankshaft revolutions (500*NC_CYL_NR tdc's).

Each combustion during these 1.000 crankshaft revolutions is monitored for misfiring.

If a confirmed misfiring is detected on ER current TDC (LV_DET_CFM_MIS=1), the cylinder-specific misfire counter MIS_CTR_B[SEG_NR_ER] is incremented by one.

In every driving cycle a distinction is made between misfires detected during the first 1000 crankshaft revs after engine start (**CARB B1**) and misfires detected in later observing intervals. In the second case, a misfire rate violation must take place during four monitoring intervals to recognise misfire (**CARB B4**).

Statistic:

At the end of the first 1.000 crankshaft revolutions, the added cylinder-specific sums are evaluated. If the sum exceeds the applicable value C_THD_MIS_B1_AT/MT, **CARB B1** misfire criterion is detected.

At the end of each following 1.000 crankshaft revolutions interval, the added cylinder-specific sums are evaluated. If the sum exceeds the applicable value C_THD_MIS_B1_AT/MT the anti-bounce counter CTR_DET_MIS_B4 will be incremented till its maximum C_NR_DET_MAX_MIS_B4 (typical = 3) is reached. If the sum does not exceed C_THD_MIS_B1_AT/MT, CTR_DET_MIS_B4 remains unchanged.

To filter out those cylinders with low misfire rates, the cylinder-specific counters MIS_CTR_B[NC_CYL_NR] shall be compared to the applicable value C_THD_MIS_B_MIN before storage takes place.

If none of the cylinder-specific counters is higher than C_THD_MIS_B_MIN, a maximum choice is done and the cylinder with the highest misfire rate is entered into failure memory.

Application conditions:

Description:

If Misfire criterion is detected on one cylinder with at least one of the CARB_A, CARB_B1 or CARB4 default criterions, the corresponding cylinder error is set.

Each cylinder supply at least one P-code (error is set directly without debounce).

The symptom is always corresponding to the last error occurence, and the error is reseted only when all misfire criterions on this cylinder have disappeared.

Error-symptoms are defined to this diagnosis function as following :

```
[ | | | ]
 |  |  |  └─> - Cylinder in misfire, Criterion default : MIS_A     (= SYM_0)
 |  |  └────> - Cylinder in misfire, Criterion default : MIS_B1    (= SYM_1)

B.7.1 General information

The misfire detection based on engine roughness index (ER) may be disturbed by crankshaft oscillations when single misfire (random) occurs, especially for front drive vehicles crankshaft in the low engine speed / high engine load area (in combination with a 3rd, 4th or 5th gear ratio). A single misfire acts as a drivetrain / crankshaft oscillations trigger, in this case the ER index is distrubed by these oscillations, in some conditions it is practically not possible to distinguish on ER index, real misfire towards speed drop caused through crankshaft speed oscillations.

The trigger for such oscillations can be a single misfire, an obstacle, a big torque change or others instantaneous conditions.

The principle of this crankshaft / drivetrain oscillation detection is to detect such an oscillation and then to fade-out the misfire detection for a short period to avoid over-detection.

Initialisation: *on ECU reset, on LC_MIS_INH 0 to 1 transition*

SEG_SUM_FRQ_CRK_OSC = 0

DRV0_ER_SUM_OSC = 0

EndIf

Update rate: Segment

B.7.2 Detection description

The final decision about crankshaft oscillation consists of two parts:

- The detection of a critical engine roughness oscillation frequency.
- The detection of a critical engine roughness oscillation amplitude.

If both parts fulfilled at the same time their own detection criterion, a crankshaft oscillation is detected. The reason therefore is, that even at constant speed due to normal little speed variations a high frequency or at a normal acceleration phase a big amplitude is possible.

B.7.2.1 Determination of a critical engine roughness frequency

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

If Bit sign between $DRV0\_ER_{(n-1)}$ and $DRV0\_ER_{(n)}$ changes

Then SEG_SUM_FRQ_CRK_OSC = IP_SEG_MIN_FRQ_CRK_OSC(N_32)

ElseIf SEG_SUM_FRQ_CRK_OSC ≠ 0

Then SEG_SUM_FRQ_CRK_OSC = SEG_SUM_FRQ_CRK_OSC - 1

EndIf

If SEG_SUM_FRQ_CRK_OSC ≠ 0

Then LV_FRQ_CRIT_CRK_OSC = 1 *// Critical crankshaft frequency status is active*

Else LV_FRQ_CRIT_CRK_OSC = 0

EndIf

B.7.2.2 Determination of a critical engine roughness oscillation amplitude

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

If Bit sign between $DRV0\_ER_{(n-1)}$ and $DRV0\_ER_{(n)}$ changes

Then $DRV0\_ER\_SUM\_OSC_{(n)} = |DRV0\_ER_{(n)}|$

Else $DRV0\_ER\_SUM\_OSC_{(n)} = DRV0\_ER\_SUM\_OSC_{(n-1)} + |DRV0\_ER_{(n)}|$

// with saturation

EndIf

DRV0_ER_SUM_THD_OSC = IP_DRV0_ER_THD_OSC(N_32, LOAD_MIS)

If DRV0_ER_SUM_OSC > DRV0_ER_SUM_THD_OSC

Then LV_AMPL_CRIT_CRK_OSC = 1 *// Critical crankshaft amplitude status is active*

Else LV_AMPL_CRIT_CRK_OSC = 0

EndIf

B.7.2.3 Determination of crankshaft oscillation final status

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

If in the same time, both conditions are active, a crankshaft oscillation status is triggered :

If LV_FRQ_CRIT_CRK_OSC = 1

And LV_AMPL_CRIT_CRK_OSC = 1

Then After condition rising edge triggering, LV_STATE_CRK_OSC flag is set to 1 as long as condition is true.

After condition falling edge triggering, LV_STATE_CRK_OSC flag is hold to 1 for a period of C_DLY_TDC_CRK_OSC tdc's, even if LV_CRK_OSC_DET_ACT is then set to 0.

EndIf

LV_ENA_T_SEG_RR	V	0...1H	0...1	1	[-]
Two consecutive WSS segment periods are valid					

Input data:

LV_AT	LV_INH_APP_RR	T_SEG_RR_0	T_SEG_RR_1
VS	LC_MIS_INH		

FUNCTION DESCRIPTION:

General information:

Rough road conditions must be detected to prevent erroneous misfire detection that could be caused by jollity tracks influence on crankshaft via the drive train.

The speed disturbance of vehicle wheels is used to evaluate the rough road conditions. Therefore, the EMS control unit uses an acquired signal coming from wheel speed sensors *(WHEEL_GRD)*.

The basically integration possibility consists by using magnetic sensor mounted on driven wheel on the right side (*preferred for cars with left driver*) where the presence probability of a jollity track is greater.

However, transmission from the left to the right side has also been observed depending on the chassis and other circumstances, so that a limited detection of unilateral rough-road conditions on the left side is also possible.

The number of integrated teeth for one segment depends on the number of teeth per revolution of the wheel speed. An angle of about 30 ° is preferable (e.g. an integration of 4 teeth is used for a wheel with 48 teeth).

Rough road event task:

The rough road detection task is triggered at the end of each wheel target segment.

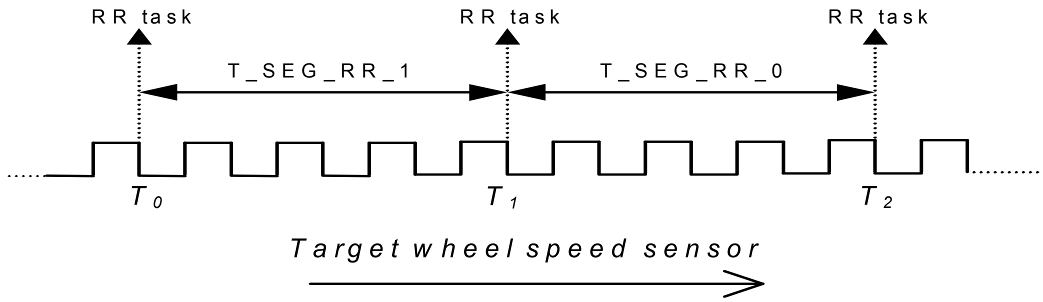
Process sequence:

- *Wheel target segment time acquisition*
- *Filtered & raw wheel gradient determination*
- *Rough road detection*

B.8.1.1 Wheel segment time acquisition control

General information:

T_SEG_RR_1 is the segment period preceding T_SEG_RR_0.



To be calculated in reliable conditions, rough road detection index needs a least two successive wheel segments.

Accordingly, the wheel segment acquisition process provide a control flag (LV_ENA_T_SEG_RR) who indicates that:

- no timer overflow and/or acquisition trouble occurs during last two consecutive wheel segments acquisitions
- two last wheel segments acquisitions are included within safe timing range *(speed sensor maximum timing acquirement & disablement for very high speed who reduce dedicated CPU load)*

Formula section:

If T_SEG_RR_0 is acquired & valid *(no dedicated timer overflow)*

And T_SEG_RR_0 <= C_T_SEG_RR_MAX

And T_SEG_RR_0 >= C_T_SEG_RR_MIN

And T_SEG_RR_1 is acquired & valid *(no dedicated timer overflow)*

And T_SEG_RR_1 <= C_T_SEG_RR_MAX

And T_SEG_RR_1 >= C_T_SEG_RR_MIN *(divide by zero protection)*

Then LV_ENA_T_SEG_RR = 1

Else LV_ENA_T_SEG_RR = 0

EndIf

Segment limitation reasons:

- C_T_SEG_RR_MAX

In lower vehicle speed range, the ABS sensor may no longer supply a valid output signal. In this case, the rough road value is computed only if two valid & consecutive segment periods have been measured in sequence.

- C_T_SEG_RR_MIN

For rough road index calculation, segment time have to be non-null to prevent division by zero in WHEEL_GRD calculation. It also allows limiting dedicated rough road detection CPU load at very high vehicle speed.

B.8.1.2 Rough road indexes determination

General information:

Rough road detection is based on a wheel gradient WHEEL_GRD evaluation. The raw values WHEEL_GRD are used in a floating averaging, to restrict suppression to actual rough road conditions. The current rough road value WHEEL_GRD_MMV from floating averaging is retained.
Note: To allow a fast filter initialisation, in case of LV_ENA_T_SEG_RR = 0 → 1 transition, $WHEEL\_GRD\_MMV_n$ and $WHEEL\_GRD\_MMV_{n-1}$, have to be initialised to WHEEL_GRD current value. Then for following valid samples, filtering is processed as described.

Update rate: rough road event task

Formula section:

If(1) LV_ENA_T_SEG_RR = 1

And LC_MIS_INH = 0

Then(1)

$$WHEEL\_GRD = \left| \frac{T\_SEG\_RR\_1 - T\_SEG\_RR\_0}{T\_SEG\_RR\_1} \right| * 1000 [‰]$$

If(2) LV_AT = 1

$WHEEL\_GRD\_MMV_n = WHEEL\_GRD\_MMV_{n-1}$

$+ C\_WHEEL\_GRD\_CRLC\_RR\_AT * (WHEEL\_GRD_n - WHEEL\_GRD\_MMV_{n-1})$

Else(2)

$WHEEL\_GRD\_MMV_n = WHEEL\_GRD\_MMV_{n-1}$

$+ C\_WHEEL\_GRD\_CRLC\_RR\_MT * (WHEEL\_GRD_n - WHEEL\_GRD\_MMV_{n-1})$

EndIf(2)

Else(1)

WHEEL_GRD = 0

WHEEL_GRD_MMV = 0

EndIf(1)

B.8.2 Detection of rough road status

Description:

The rough road detection is active within a valid engine speed range and when no error on rough road information is detected. If such error occurs, a calibration limp home rough road status can be applied according SI/customer requirements:

- LC_STATE_RR_LIH = 0, the misfire monitoring will not be inhibated if such error occurs. A specific Pcode can be saved if a misfire error is detected and if at the same time an error on CAN rough road information is set.
- LC_STATE_RR_LIH = 1, the misfire monitoring will be inhibated if such error occurs.

Update rate: rough road event task

Initialisation: At ECU reset event

LV_STATE_RR = 0

SUM_RR = 0

Activation condition:

	VS > C_VS_MIN_RR
And	VS < C_VS_MAX_RR
And	LV_INH_APP_RR = 0
And	LV_ENA_T_SEG_RR = 1
And	LC_MIS_INH = 0

Limp home:

If LV_INH_APP_RR = 1 *// OBD I wheel speed sensors diagnosis or any other*
// fade out conditions (ABS acting, ASR ...)

Then LV_STATE_RR = LC_STATE_RR_LIH *(see customer requirements)*

SUM_RR counter is frozen

CTR_T_DLY_RR = 0

EndIf

Formula section:

Rough road detection threshold determination:

If LV_AT = 1

Then WHEEL_GRD_MMV_THD = IP_WHEEL_THD_AT(VS)

Else WHEEL_GRD_MMV_THD = IP_WHEEL_THD_MT(VS)

EndIf

If WHEEL_GRD_MMV >= WHEEL_GRD_MMV_THD

Then LV_STATE_RR = 1

CTR_T_DLY_RR = C_T_DLY_RR

SUM_RR = SUM_RR + 1 *(with saturation)*

ElseIf CTR_T_DLY_RR != 0

Then LV_STATE_RR = 1

Else LV_STATE_RR = 0

EndIf

Remarks:
When the detection of rough road is effective, the logical value LV_STATE_RR is activated for a period of C_T_DLY_RR. This duration is triggered each time that WHEEL_GRD_MMV exceeds the threshold. The rough road events number is saved in the counter SUM_RR that is initialised at the ECU reset.

B.8.3 Rough Road Fade Out Timer Management

The timer dedicated to apply a delay on rough road status at each rough road detection occurence is management with a time task.

Update rate: 10 ms

Initialisation: At ECU reset event

CTR_T_DLY_RR = 0

Formula Section:

If CTR_T_DLY_RR != 0

Then CTR_T_DLY_RR = CTR_T_DLY_RR - 1 *(hexadecimal operation)*

Else LV_STATE_RR = 0

EndIf

FTL_MMV_OLD	V/S	0...FFFFH	0...100	0.0015	%
Fuel level in previous driving cycle (used for refuelling-detect at stopped engine)					
FTL_MMV_ST	V	0...FFFFH	0...100	0.0015	%
Starting Fuel level at new DC					

Input data:

TAM	FTL_MMV	LV_DT	T_VS_MIN_INI_DIAGCP
LV_FTL_NEW_END	LV_ST_END	LV_DC	T_AST

General information:

The purpose of the refulling detection is to correct the fuel temperature in case of refuelling.

Initialisation:

If there are no stored values or a checksum error in adaptation values has occured
then set default value (FTL_MMV_OLD = FTL_MMV)
else use previously stored values
endif

If LV_DC = 0 →1
then LV_FTL_NEW = 0
T_MAX_FTL_NEW = 0
endif

If T_AST ≥ C_T_MAX_FTL_NEW
and LV_DC = 1
then FTL_MMV_ST = FTL_MMV (once)
endif

If LV_DC = 1 → 0
then LV_FTL_NEW = 0
T_MAX_FTL_NEW = 0
if LV_FTL_NEW_END = 1 *(FTL_MMV_OLD is saved*
then FTL_MMV_OLD = FTL_MMV *in a non volatile memory after*
endif *refueling detection calculation)*
endif

FTL_MMV_OLD value is allowed if the calculation of a detected refuelling (LV_FTL_NEW_END = 1) is finished in the last driving cycle. And it is updated with FTL_MMV after refuelling (stopped or running) is detected (see formular section).

Activation: **If** LV_DC =1

and TAM ≥ C_TAM_MIN_FTL_NEW

and T_AST ≥ C_T_MAX_FTL_NEW + 1 [sec]

Formula section:

- Refuelling at stopped engine happened (between current and last driving-cycle)

```
If      FTL_MMV_ST – FTL_MMV_OLD > C_FTL_MMV_DIF
then    LV_FTL_NEW = 1
        FTL_MMV_OLD = FTL_MMV_ST
endif
```

- Refuelling at running engine

```
If      LV_DT = 0
then    if     FTL_MMV – FTL_MMV_ST > C_FTL_MMV_DIF
        then   LV_FTL_NEW = 1
               FTL_MMV_ST = FTL_MMV
               FTL_MMV_OLD = FTL_MMV
        endif
endif
```

- Timer for refuelling detection:

```
If      LV_FTL_NEW  = 1
then    T_MAX_FTL_NEW is incremented
endif

If      T_MAX_FTL_NEW  > C_T_MAX_FTL_NEW
then    LV_FTL_NEW = 0
        T_MAX_FTL_NEW  = 0
        "perform once  T_AST_COR correction;  see next chapter 1.5.3 Calculation
        of fuel temperature"
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TAM_MIN_FTL_NEW	1	0...FEH	-48...142.5	0.75	°C
Minimum TAM threshold for refuelling detection

Timer for inhibition of leak detection diagnosis					

B.9.5 Fuel temperature model

B.9.5.1 Ambient temperature for fuel temperature model

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TAM_FUEL_TEMP	V/S	0...FEH	-48...142.5	0.75	°C
Temperature ambient for fuel temperature model					
T_VS_MIN_TAM_FUEL_TEMP	V	0...FFFFH	0...65535	1	s
Timer for VS-condition fulfilled (after initialisation of fuel temperature model)					
T_FTL_MMV_NEW_END	V	0...FFFFH	0...65535	1	[s]
Timer for calculation of refuelling detection					

Input data:

TAM	LV_DC	T_VS_MIN_INI_DIAGCP	VS
C_VS_MIN_INI_DIAGCP			

General information:

The most important input data for the fuel temperature model is the ambient temperature TAM. The ambient temperature sensor is exposed to rediation heat from the engine and the asphalt road. Therefore, an approximately reliable ambient temperature from the sensor is only useful over a determined engine speed (C_VS_MIN_INI_DIAGCP). Under this engine speed threshold the last TAM value is frozen.

Application conditions:

Initialisation: **If** LV_DC = 1
and T_VS_MIN_INI_DIAGCP 1 → 0
then TAM_FUEL_TEMP = TAM
T_VS_MIN_TAM_FUEL_TEMP = C_T_VS_MIN_TAM_FUEL_TEMP
T_FTL_MMV_NEW_END = 1 [sec]
endif

Formula section:

If T_VS_MIN_INI_DIAGCP = 0
and VS ≥ C_VS_MIN_INI_DIAGCP
then T_VS_MIN_TAM_FUEL_TEMP is decremented
else T_VS_MIN_TAM_FUEL_TEMP
= C_T_VS_MIN_TAM_FUEL_TEMP
endif

If T_VS_MIN_TAM_FUEL_TEMP = 0
then TAM_FUEL_TEMP = TAM
else TAM_FUEL_TEMP keeps old value (frozen last TAM_FUEL_TEMP - value)
endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_VS_MIN_TAM_FUEL_TEMP	1	0...FFFFH	0...65535	1	s
Minimum time for VS-condition (after initialisation of fuel temperature model)					

B.9.5.2 Engine running time until initialisation of fuel temperature model

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_AST_INIT_COR	V	0...FFFFH	0...65535	1	sec
Engine running time until initialisation of fuel temperature model					
T_AST_INIT_COR_OLD	V/S	0...FFFFH	0...65535	1	sec
Saved engine running time until initialisation of fuel temperature model					

Input data:

LV_DC	T_VS_MIN_INI_DIAGCP	LV_T_ES_NOT_PLAUS	T_ES_DIAGCP

General information:

The engine running time from engine start until the initialisation of the fuel temperature model must be taken into account.

Application conditions:

Initialisation:

If there are no stored values or a checksum error in adaptation values has occured
then set default values
(T_AST_INIT_COR_OLD = 0 [sec])
else use previously stored values
endif

If LV_DC = 0 → 1
and LV_T_ES_NOT_PLAUS = 0
then T_AST_INIT_COR = T_AST_INIT_COR_OLD
* IP_FAC_T_AST_INIT_COR_OLD (T_ES_DIAGCP)
endif

If LV_DC = 1 → 0
then **if** T_VS_MIN_INI_DIAGCP > 0 [sec]
then T_AST_INIT_COR_OLD = T_AST_INIT_COR
else T_AST_INIT_COR_OLD = 0 [sec]

B.9.8 Correction factor due to fuel quality

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TI_ST_AD_DIAGCP	O/V	0...FFH	0...1.992	0.0078	-
Fuel quality correction factor					
FAC_TI_ST_AD_DIAGCP_OLD	O/V/S	0...FFH	0...1.992	0.0078	-
Saved fuel quality correction factor					

Input data:

FAC_FQ_ST_AD	LV_FQ_ST_AD_END_1	TCO_ST	

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to correct the actual leakage area (see chapter Evaporative System Monitoring) in case of fuels with high fuel evaporation or fuels with high vapor pressure. Fuels with high vapor pressure (low values of FAC_TI_ST_AD_DIAGCP) leads to overdetection in the leak detection diagnosis. Therefore the actual leakage area must be reduced accordingly.

Application conditions:

Initialisation: **If** there are no stored values or a checksum error in adaptation values has occured
then set default value (FAC_TI_ST_AD_DIAGCP_OLD = 1)
else use previously stored values

Formula section:

If LV_FQ_ST_AD_END_1 = 0 → 1

then **if** C_TCO_ST_MIN_ST_AD_DIAGCP ≤ TCO_ST ≤ C_TCO_ST_MAX_ST_AD_DIAGCP

then FAC_TI_ST_AD_DIAGCP = IP_FAC_FQ_ST_AD_DIAGCP

else FAC_TI_ST_AD_DIAGCP = FAC_TI_ST_AD_DIAGCP_OLD

If LV_DC 1 → 0

then FAC_TI_ST_AD_DIAGCP_OLD = FAC_TI_ST_AD_DIAGCP

FAC_TI_ST_AD_DIAGCP_OLD is saved in a non volatile memory!

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Weighted fuel quality factor for evaporative system monitoring					

B.10 Evaporative System Monitoring – Vacuum Leak Detection based on Model Parameter Estimation

B.10.1 Summary

The leak detetction function (DIAGCP) permits the detection of leaks in the evaporative emission control system with a diameter of 0.5 mm and more.

The evaporative emission control system is hermetically sealed off from the atmosphere by means of a shutoff valve (SOV) on the charcoal canister. When the evaporative emission control valve opens, the engine generates a vacuum in the fuel tank, and the pressure differential curve in the evaporative emission control system is measured by means of a tank pressure sensor in the evaporative emission control system.

If the vacuum generated within a monitoring period increases above a defined threshold, a leak is detected.

The monitoring algorithm is based on a model of leakage in a tank, which is suitable for parameter estimation. The method is very robust against harmonic and white noise pressure-signal-disturbances and gives insight into the functional dependences of fuel volume, temperature and ambient pressure.

It is sensitive to a pressure-signal offset. Hence, an offset determination is included.

A correction parameter is calculated during an evaporation test phase to consider the increase of pressure due to unsaturated HC vapour.

An information about fuel volume is necessary.

Recurrence : *40 ms for all States with exception of :*
“*Monitoring Conditions (see application incidences)“. 1000 ms*
“*Actuator test for SOV”. 20 ms*

B.10.2 Applied tank pressure sensor characteristic

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
Differential pressure tank - ambient					
DTP_MOD_6	V/O/S	8000...7FFFH	-40.96...40.96	0.00125	hPa
Differential pressure tank – ambient, stored for mode 06 communication					
DTP_RAW	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
Differential pressure tank – raw value; without offset correction					
DTP_MES	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
Differential pressure tank – filtered value; without offset correction					

Input data:

V_DTP	DTP_OFS	LV_END_DIAG_MEC_SOV	

The DTP and DTP_RAW sample rate is **40ms.**

Exception: During normal engine run (STATE_DIAGCP = START, PAS, T_DLY_3, CLD and LV_FUC_MISS_DIAG_CDN = 0) DTP is determined **every 1000 ms**.

Formula section:

The pressure value is derived from a map:

DTP_RAW = IP_DTP_V_DTP

DTP_MES $_{(n)}$ = DTP_MES $_{(n-1)}$ + C_DTP_MES_CRLC * (DTP_RAW $_{(n)}$ - DTP_MES $_{(n-1)}$)

DTP = DTP_MES - DTP_OFS

⇒ At initialisation DTP_OFS is resetted.

⇒ Determination of DTP_OFS (*see chapter "Determination of Sensor Offset*")

Special treatment for diagnostic Test Mode:

The following calculation of output values for Scan Tool SAE 1979 Mode $06 takes place only at the end of a complete diagnostic-cycle (LV_END_DIAG_MEC_SOV = 1)

DTP_MOD_6 = DTP

The value DTP_MOD_6 should be initialized with 0 in case of failure memory is cleared.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_DTP_V_DTP	6	0...FFFFH	-40.96...40.96	0.00125	hPa

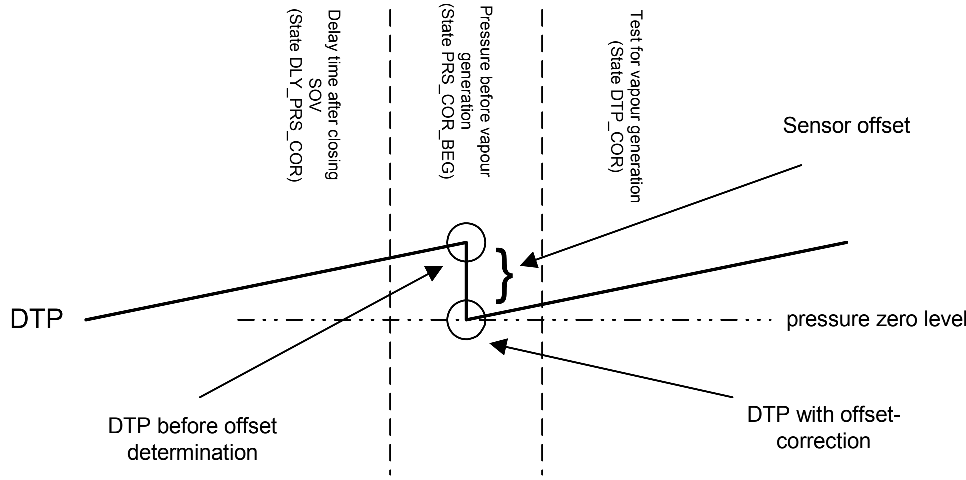
Characteristic tank-pressure-sensor					
C_DTP_MES_CRLC	1	0...FFH	0...0.996	3.9e-3	-
Dynamic filter factor for the DTP_MES calculation					

B.10.2.1 Overview about ´DTP Sensor Offset Correction´:



B.10.2.2 Determination of DTP_MV

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_MV	V	8000...7FFFH	-40.96...40.96	0.00125	hpa
Pressure mean value					

Input data:

DTP	STATE_DIAGCP	LV_DIAGCPS_ACT	LV_FUC_MISS_DIAG_CDN

Description:

A mean value (DTP_MV) out of 4 pressure values is calculated (every 40ms) during LV_DIAGCPS_ACT = 1 or LV_FUC_MISS_DIAG_CDN = 1

Formula section:

If LV_DIAGCPS_ACT = 1

or LV_FUC_MISS_DIAG_CDN = 1

then $DTP\_MV_i = (DTP_i + DTP_{i-1} + DTP_{i-2} + DTP_{i-3}) / 4$

else *no calculation of DTP_MV*

endif

B.10.3 Determination of “Limited Dynamics DTP” condition

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
DTP_MV_DYW	V	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Mean value of DTP					
DTP_DIF_DYW	V	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Mean value of the differential pressure between tank and ambient for limited dynamic condition					
LV_PRS_LIM_DYN_DIAGCP	V	0...1H	0...1	1	-
Boolean for limited pressure curve dynamics condition existing					

Input data:

DTP	STATE_DIAGCP		

General information:

The “limited dynamics DTP” condition is introduced in order to filter out pressure values resulting from pressure fluctuations in the tank (caused by a door being slammed or by abrupt braking of a slowly rolling vehicle, etc.) that might cause false error signalling.

First, the mean value of the current pressure DTP_i is formed with the value DTP_{i-1} last measured: $DTP\_MV\_DYW_i = (DTP_i + DTP_{I-1}) / 2$

The dynamics window value DTP_DYW depends on the current state:

- C_DTP_DYW_1 — during test for vapour generation (DLY_PRS_COR state and DTP_COR state, except PRS_COR_BEG state)
- C_DTP_DYW_2 — during evacuation phase (DTP_EVAC state) and model parameter estimation (DLY_DIAG state);
- C_DTP_DYW_3 — during diagnosis (DTP_DIAG state)
- C_DTP_DYW_4 — during VAP_CHK state

The limited dynamics condition (LV_PRS_LIM_DYN_DIAGCP = 1) is monitored from “DLY_PRS_COR” state to “DTP_DIAG” state and it continuous to exist, while the pressure DTP stays within the dynamic window DTP_DYW, except during determination of sensor offset (PRS_COR_BEG – state).

If T_DTP_GRD_VAP_CHK
$| DTP\_MV\_DYW_i - DTP_i = DTP\_DIF\_DYW | <$ "DTP DYW value"

then LV_PRS_LIM_DYN_DIAGCP = 1

else LV_PRS_LIM_DYN_DIAGCP = 0; switch to *´Wait Period´*

endif

Depending on the current state the DTP DYW value is C_DTP_DYW_1, C_DTP_DYW_2 or C_DTP_DYW_3

The function switches immediately to the *'Wait Period'* mode if the limited dynamics condition is violated.

Only during *´Test for vapour generation´* the function waits until the time C_T_1_DIAGCP has passed, before the *´Wait Period ´*is activated.

Only during ´Evacuation´ the function switches to the "ERR_CLOSE_CPS" before the *´wait period´* is activated

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_DTP_DYW_1	-	0...7FFFH	0...40.96	0.00125	hPa
Dynamic window during test for vapour generation					
C_DTP_DYW_2	-	0...7FFFH	0...40.96	0.00125	hPa
Dynamic window during evacuation phase and model parameter estimation					
C_DTP_DYW_3	-	0...7FFFH	0...40.96	0.00125	hPa
Dynamic window during diagnosis period					
C_DTP_DYW_4	-	0...7FFFH	0...40.96	0.00125	hPa
Dynamic window during VAP_CHK					

B.10.4 Monitoring Algorithm

B.10.4.1 Purging in engine operating state part load (PL)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_PL_DIAGCP	V	0...FFFFH	0...6553.5	0.100	s
Minimum purge time during MAX_PURGE in part-load condition					

Input data:

CL_MMV	REL_FLOW_CPS	STATE_DIAGCP	LV_PL
LV_IS			

Description:

High canister saturation during the vacuum generation period may cause problems with the idle-speed.

Therefore, depending on the result of the determination of the degree of charcoal-canister saturation, purging must take place for a period T_PL_DIAGCP in the engine operating state *´part load´* before the diagnosis function is started. This avoids high canister saturation during evacuation.

In the engine operating states *trailing throttle* (PU), *trailing throttle fuel cut-off* (PUC), *idle* (IS) and *wide-open throttle* (FL), the counter for T_PL_DIAGCP is stopped:

T_PL_DIAGCP is set after each determination of the degree of charcoal-canister saturation (transition of STATE_CP from RAMP_OPEN to MAX_PURGE) or after each interruption of EVAP-Diagnosis.

In the engine operating states *´Part Load´* (PL) **and** (STATE_CP = MAX_PURGE **or** RAMP_CLOSE), the counter for T_PL_DIAGCP is decremented, otherwise it is stopped.

Recurrence: *100ms*

Formula section:

Initialisation:

If Transition of STATE_CP = RAMP_OPEN to STATE_CP = MAX_PURGE

or (interruption of DIAGCP and transition to wait period, i.e. STATE_DIAGCP=T_DLY_3)

then **If** CL_MMV < C_CL_MMV_PL_DIAGCP

and REL_FLOW_CPS > C_REL_FLOW_MIN_CP_DIAGCP

then T_PL_DIAGCP = C_T_1_PL_DIAGCP (*short time*)

else T_PL_DIAGCP = C_T_2_PL_DIAGCP (*long time*)

endif

Decrementation of T_PL_DIAGCP:

If LV_PL = 1

and STATE_CP = MAX_PURGE

or STATE_CP = RAMP_CLOSE

then T_PL_DIAGCP = decremented

else no decrementation of T_PL_DIAGCP

endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_REL_FLOW_MIN_CP_DIAGCP	-	0...FFFFH	0...1	0.000015	-

C_T_1_PL_DIAGCP	-	0...FFFFH	0...6553.5	0.100	s
Minimum purging time with no high canister saturation					
C_T_2_PL_DIAGCP	-	0...FFFFH	0...6553.5	0.100	s
Minimum purging time with high canister saturation					

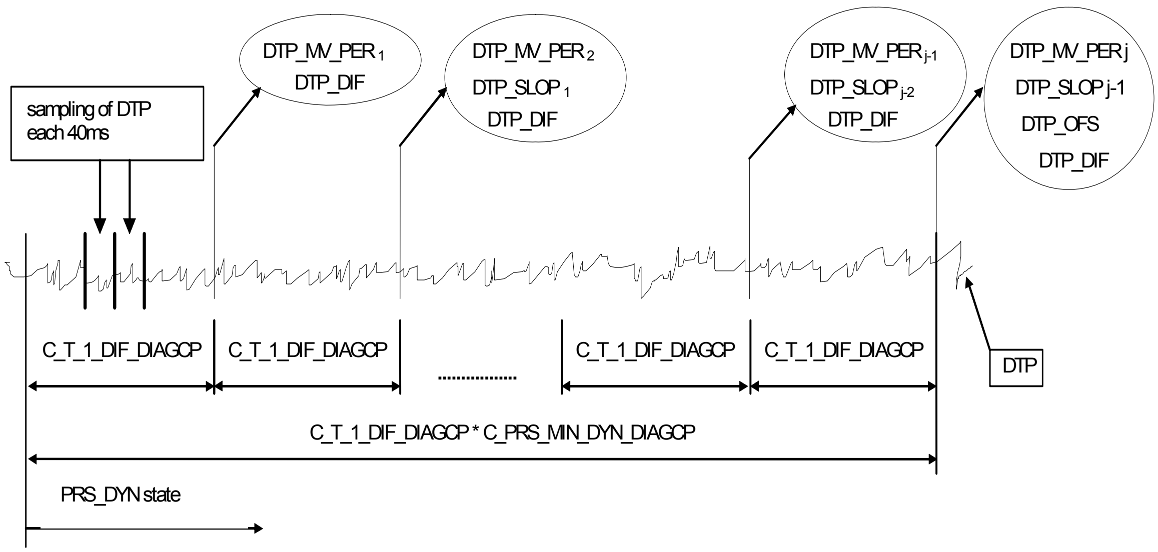
B.10.4.2 Determination of Signal fluctuation and Pressure Slope (PRS_DYN state)

Description:

At the beginning of the diagnostic algorithm the pressure signal fluctuation shall be as small as possible.

The function tests for *´signal fluctuation´* as soon as the monitoring algorithm is released, in the same time the *‘pressure-slope’* determination and the *´plausibility check´* for DTP signal noisy error (refer to chapter A: *DTP Sensor Diagnosis*) are performed.

Overview of the ´Signal Fluctuation Cycle´:



Where j = 0,1,2,3,...C_PRS_MIN_DYN_DIAGCP

Explanation:

⇒ After each C_T_1_DIF_DIAGCP – cycle, the counter for C_PRS_MAX_DYN_DIAGCP is incremented, independently of a violation of the limited dynamics.

⇒ The counter for C_PRS_MIN_DYN_DIAGCP is only incremented if no limited dynamics violation was present during the C_T_1_DIF_DIAGCP- cycle. The counter is reset to zero if the limited dynamics condition was not fulfilled. That means, this counter represents the number of cycles without limited dynamics vialation (´good cycles´).

This C_T_1_DIF_DIAGCP – cycle is repeated until either:

C_PRS_MIN_DYN_DIAGCP periods are reached - in case of no limited dynamic violation

or

C_PRS_MAX_DYN_DIAGCP periods are reached - in case of limited dynamic violation and C_PRS_MIN_DYN_DIAGCP could not be reached

⇒ In fact, the minimum physical value of C_PRS_MAX_DYN_DIAGCP must be the calibrated value of C_PRS_MIN_DYN_DIAGCP. If it is not the case, the watchdog made by C_PRS_MAX_DYN_DIAGCP * 0.04 [s] will be always reached before the determination of DTP_OFS.

B.10.4.2.1 Determination of signal fluctuation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_DIF	V/O	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Maximum DTP range during C_T_1_DIF_DIAGCP					
DTP_DIF_MOD_6	V/O/S	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Maximum DTP range during C_T_1_DIF_DIAGCP stored for mode 06-communication					
DTP_MAX	V	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Max DTP - value during C_T_1_DIF_DIAGCP					
DTP_MIN	V	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Min DTP - value during C_T_1_DIF_DIAGCP					
LV_DTP_NOISE	V/O	0...1H	0...1	1	-
Boolean for Noisy DTP signal					

Input data:

DTP			

Description:

The minimum and maximum pressure (DTP_MIN and DTP_MAX) are determined during the period C_T_1_DIF_DIAGCP * C_PRS_MIN_DYN_DIAGCP. If the pressure difference DTP_DIF = DTP_MAX - DTP_MIN is smaller than C_DTP_DIF_MAX the pressure signal fluctuation is low and the system switches to *´CLOSE_CPS´* state.

DTP_DIF is determined again, if the pressure difference between DTP_MAX and DTP_MIN is greater than C_DTP_DIF_MAX. This cycle is repeated until the condition is met.

The algorithm is stepped to the "*Wait Period*" if C_PRS_MAX_DYN_DIAGCP periods of C_T_1_DIF_DIAGCP is reached. In this case the signal noisy of the "Differential Tank Pressure Sensor" is too high (LV_DTP_NOISE = 1).

Formula section:

If DTP_DIF = DTP_MAX - DTP_MIN ≤ C_DTP_DIF_MAX
for each C_T_1_DIF_DIAGCP
during C_PRS_MIN_DYN_DIAGCP *subsequent time periods*

then *step to ´CLOSE_CPS´ state*

else repeat until the conditions are met

If C_PRS_MAX_DYN_DIAGCP periods of C_T_1_DIF_DIAGCP are reached

then LV_DTP_NOISE = 1 ;step to *´Wait Period´*

endif

⇒ LV_DTP_NOISE is resetted at the end of *´Wait Period´* and at the beginning of a new driving cycle

⇒ The measurement of signal fluctuation is repeated by C_PRS_MIN_DYN_DIAGCP

⇒ The *´Conditions for DIAGCP´* must be met continuously

⇒ During the PRS_DYN state the canister purge function is in normal operation and the CPPWM is calculated according to this

Special treatment for Diagnostic Test Mode:

DTP_DIF is stored as DTP_DIF_MOD_6, if C_PRS_MAX_DYN_DIAGCP periods are reached or STATE_DIAGCP changes 1 → 2 or LV_DTP_NOISE transition 0->1.

The value DTP_DIF_MOD_6 should be initialized with 0 in case of failure memory is cleared.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_DTP_DIF_MAX	-	8000H...7FFFH	-40.96...40.96	0.00125	hPa
Maximum allowed pressure-signal fluctuation to start DIAGCP					
C_T_1_DIF_DIAGCP	-	0...FFH	0...25.5	0.1	s
Time-period to determine signal fluctuation and pressure slope just before vapour generation					
C_PRS_MIN_DYN_DIAGCP	-	2…FFH	2…255	1	-
Minimum number of C_T_1_DIF_DIAGCP periods					
C_PRS_MAX_DYN_DIAGCP	-	2…FFH	2…255	1	-
Maximum number of C_T_1_DIF_DIAGCP periods					

B.10.4.2.2 Determination of pressure slope

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_MV_PER	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
Pressure mean-value during C_T_1_DIF_DIAGCP					
DTP_SLOP_END	V/O	8000...7FFFH	-409,6...409,587	12,5E-3	hPa/s
Pressure slope					
LV_DTP_SLOP_END	V/O	0...1H	0...1	-	-
Flag for stable pressure slope					

Input data:

DTP			

Description:

The pressure slope is determined in [hPa/sec]. For this purpose the pressure mean-value during the period C_T_1_DIF_DIAGCP is calculated.

The sampling rate is **40 ms**.

If DTP_MV_PER $_j$ and DTP_MV_PER $_{j-1}$ are valid (after 2 measurements cycles) then the pressure slope determination is possible:

Formula section:

Pressure mean-value:

DTP_MV_PER $_j$ = [sum (DTP $_i$)] / (C_T_1_DIF_DIAGCP / 0.04[s])

sum (DTP $_i$) := Sum of all pressure values during C_T_1_DIF_DIAGCP

Pressure slope:

DTP_SLOP_END j-1 = (DTP_MV_PER j - DTP_MV_PER j-1)
/ (C_T_1_DIF_DIAGCP - 0.1[s])

Where i and j are two different counters :

i : every **40** ms, DTP sampling rate.

j : number of C_T_1_DIF_DIAGCP times during ´*PRS_DYN*´ state.

Formula section:

Detection:

If | DTP_SLOP_END j | < C_DTP_SLOP_MAX

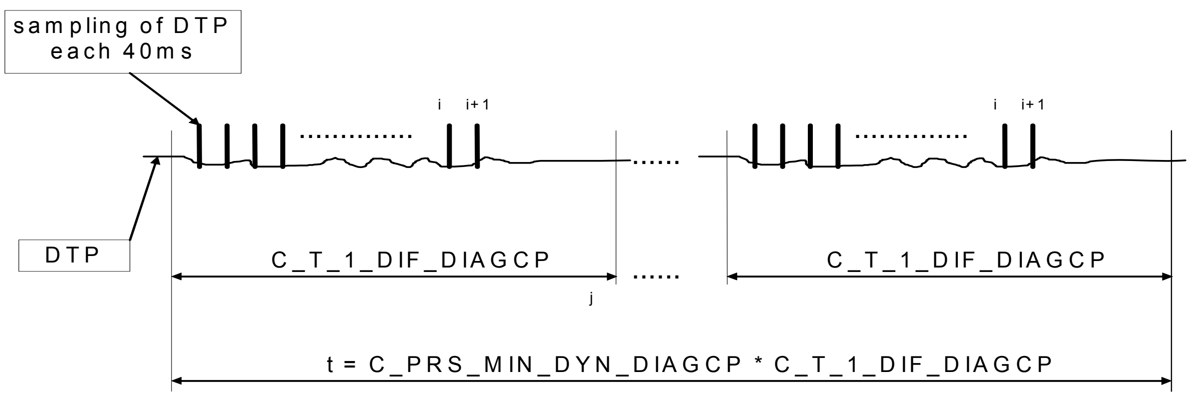
for each C_T_1_DIF_DIAGCP
during C_PRS_MIN_DYN_DIAGCP *subsequent time-periods*

then LV_DTP_SLOP_END = 1 (pressure-slope is stable); switch to *´CLOSE_CPS´* state

else LV_DTP_SLOP_END = 0; step to *´Wait Period´*

endif

⇒ LV_DTP_SLOP_END = 1 at the beginning of each C_T_1_DIF_DIAGCP



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_DTP_SLOP_MAX	-	0000...7FFFH	0...409.5875	0.0125	hPa/s
Maximum pressure slope threshold used to determine sensor offset					

B.10.4.3 CPS closing with a ramp (CLOSE_CPS state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DIAGCPS_ACT	V/O	0...1H	0...1	1	-
Flag indicating CP not active and DIAGCP active (1), or the opposite (0)					

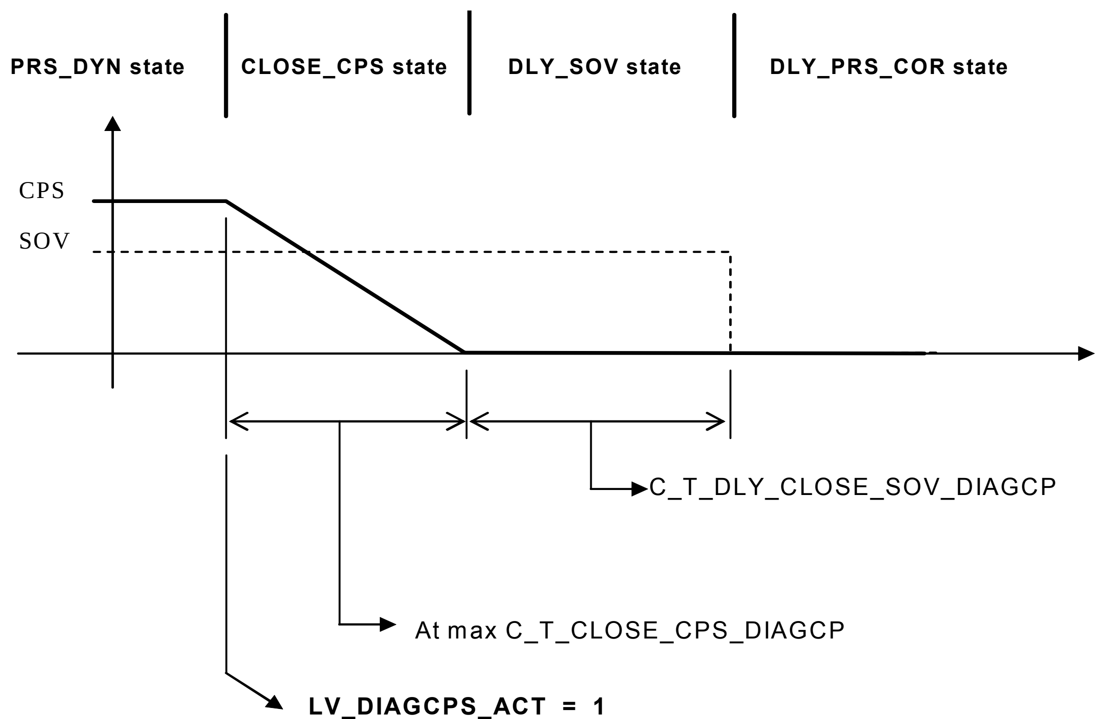
Input data:

FLOW_SP_CPS	FLOW_SP_CPS_EXT	STATE_DIAGCP	

Description:

The transition from ´*PRS_DYN*´ state to ´*CLOSE_CPS*´ state is only possible if no noisy DTP signal is present (LV_DTP_NOISE=0) and the pressure slope is stable (LV_DTP_SLOP=1).

The evaporative emission control is switched to the ´evaporative emission control valve closed mode´ (NO_PURGE) and disabled during diagnosis. Therefore FLOW_SP_CPS_EXT is set to FLOW_SP_CPS and then the CPS is closing with a ramp given by C_FLOW_CPS_SP_CLOSE_DIAGCP. If the CPS is not totally closed after C_T_CLOSE_CPS_DIAGCP then the CPS must be closed suddenly. The lambda adaptation is also disabled.



Formula section:

If STATE_DIAGCP = CPS_CLOSE
then LV_DIAGCPS_ACT = 1 **and**
FLOW_SP_CPS_EXT = FLOW_SP_CPS

The CPS-closing is performed by:
$FLOW\_SP\_CPS\_EXT_{n}$ = $FLOW\_SP\_CPS\_EXT_{n-1}$ - C_FLOW_CPS_SP_CLOSE_DIAGCP

If C_T_CLOSE_CPS_DIAGCP is reached
then $FLOW\_SP\_CPS\_EXT_{n} = 0$

If the CPS is not totally closed after C_T_CLOSE_CPS_DIAGCP then the CPS must be closed suddenly.

If $FLOW\_SP\_CPS\_EXT_{n} = 0$
then STATE_DIAGCP = DLY_SOV

In VAP_CHK the CPS is also controlled by the Monitoring Function

If STATE_DIAGCP = VAP_CHK
then LV_DIAGCPS_ACT = 1

Note:

⇒ FAC_LAM_MV_MMV[1] correction during LV_DIAGCPS_ACT = 1 through calculation of the additive fuel flow correction MFF_ADD_DIAGCP *(see chapter "Injection Time Correction")*

⇒ Disabling of the lambda adaptation: see ´*Auxiliary Functions*´, chapter "Lambda Adaption" and "Evaporative Emission Control"

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_CLOSE_CPS_DIAGCP	-	0...FFH	0...25.5	0.100	s
Time for CPS closing ramp after transition from purge function to evap. monitoring					
C_FLOW_CPS_SP_CLOSE_DIAGCP	-	0...FFFFH	0...7.999	0.000122	kg/h
Closing ramp of the CPS at the beginning of the evap. monitoring					

B.10.4.4 SOV closing delay State (DLY_SOV state)

Description:

The charcoal canister shutoff valve is closed after waiting C_T_DLY_CLOSE_SOV_DIAGCP. The status of the shut-off-valve is represented by LV_SOV_REQ.

Formula section:

If	C_T_DLY_CLOSE_SOV_DIAGCP has passed	
then	LV_SOV_REQ = 1	(Request to close SOV)
else	LV_SOV_REQ = 0	(Request to open SOV)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DLY_CLOSE_SOV_DIAGCP	-	0...FFH	0...25.5	0.100	s
Delay time between closing the CPS and closing the SOV					

B.10.4.5 Delay time after closing SOV (DLY_PRS_COR state)

Input data:

DTP			

Description:

If the shutoff valve is closed, a delay time C_T_DLY_COR_BEG_DIAGCP is started. After this delay time, the algorithm switches to PRS_COR_BEG (determination of the sensor offset).

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DLY_COR_BEG_DIAGCP	-	0...FFH	0...25.5	0.100	s
Delay time before determination of start pressure					

B.10.4.6 Determination of sensor offset (PRS_COR_BEG state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_OFS	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
Pressure sensor offset					

Input data:

DTP_MV			

Description:

To get a reliable monitoring result, it's necessary to determine the actual sensor-offset. During the whole monitoring algorithm the pressure-signal will be corrected by the sensor-offset for all necessary calculations.
Because of the DTP-correction

The limited pressure curve dynamics is not checked in this state.

Formula Section:

⇒ Determination of Sensor Offset

$$DTP\_OFS_{n} = DTP\_OFS_{n-1} + DTP\_MV$$

DTP_OFS is valid for the whole engine run or until the next determination of this offset is performed. DTP_OFS is resetted at next engine run.

B.10.4.7 Test for vapour generation (DTP_COR state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_COR	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
DTP corrected by C_DTP_BAS_COR in the vapour generation phase					
DTP_DIF_COR	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
DTP difference during the vapour generation phase					
DTP_DIF_COR_MOD_6	V/O/S	8000...7FFFH	-40.96...40.96	0.00125	hPa
DTP difference during the vapour generation phase stored for mode 06-communication					
FAC_DIAGCP_MDL_ESTIM	V	0000...FFFFH	0...0.467	7.126e-6	-
Estimated DIAGCP leakage-parameter due to vapour generation in DTP_DIAG					
TAM_DIAGCP	V/O	0...FEH	-48...142.5	0.75	°C
Ambient temperature at the moment of EVAP monitoring performance					

Input data:

DTP	FAC_DIAGCP_MDL_BAS	C_DTP_DIF_CPS_DIAGCP	TAM

Description:

In order not to take in account DTP jittering, DTP is kept to 0 if it is increasing by less than C_DTP_HYS_POS or decreasing by less than C_DTP_HYS_NEG.

If DTP i >= C_DTP_HYS_NEG

and DTP i <= C_DTP_HYS_POS

then DTP i = 0

endif

During *'Test for vapour generation'* the actual pressure value has to be corrected by C_DTP_BAS_COR (virtual pressure shift to negative direction). This mathematical offset is used to have the same reference as the calculation of the FAC_DIAGCP_MDL_END.

DTP_COR i = DTP i - C_DTP_BAS_COR

During the time-period C_T_1_DIAGCP (DTP_COR state) the '*Model Parameter Estimation'* for *'Vapour generation'* is active (see chapter "*Model Parameter Estimation*").

The result FAC_DIAGCP_MDL_BAS is the correction value for the 'Diagnosis' period due to vapour generation.

If FAC_DIAGCP_MDL_BAS > C_FAC_DIAGCP_MDL_BAS_MAX

then the diagnosis is aborted and the system switches to "wait period".
At the same time a new NORMAL_PURGE State of the CP-Function is initiated (LV_NORM_PURGE_END_1 = 0, see chapter Cooperation with the caniter purge function

If LV_NORM_PURGE_END_1 is set to 1 by Canister purge function (MAX_PURGE function finished), the diagnosis algortihm starts from the beginning.

DTP difference during the vapour generation phase:

During DTP_COR state, the increase or decrease of DTP is calculated as follows:

DTP_DIF_COR = DTP_MV

- If during *test of vapour generation* the pressure drops more than C_DTP_DIF_CPS_DIAGCP, the debouncing of the error 'evaporative emission control valve jammed in open position' is started (see chapter "*Mechanical evaporative emission control valve error*").
- If no errors are detected, the function switches to the 'evacuation' state.

Special treatment for Diagnostic Test Mode:

If readyness of symptom "MEC_CPS" is detected or MEC_CPS error is detected, DTP_DIF_COR is stored as DTP_DIF_COR_MOD_6. (STATE_DIAGCP changes 6 $\rightarrow$ 7 or LV_ERR_MEC_CPS transition 0 -> 1, the last value of DTP_DIF_COR is stored as DTP_DIF_COR_MOD_6)

The value DTP_DIF_COR_MOD_6 should be initialized with 0 in case of failure memory is cleared.

Correction factor ´ FAC_DIAGCP_MDL_ESTIM´:

When FAC_DIAGCP_MDL_BAS is obtained (that represents the slope of the DTP square root), a correction factor is applied by using the map IP_FAC_DIAGCP_MDL_ESTIM, to estimate the slope of the DTP square root due to the vapour generation we have in the DTP_DIAG state:

FAC_DIAGCP_MDL_ESTIM = IP_FAC_DIAGCP_MDL_ESTIM

TAM used for EVAP monitoring:

At the moment of FAC_DIAGCP_MDL_ESTIM determination during DTP_COR, need to store TAM as TAM_DIAGCP which is used for diagnosis:

TAM_DIAGCP = TAM

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_1_DIAGCP	1	0...FFH	0...25.5	0.1	S
Duration of test for vapour generation					
C_DTP_BAS_COR	1	8000...7FFFH	-40.96...40.96	0.00125	Hpa
DTP correction value during vapour generation period					
C_FAC_DIAGCP_MDL_BAS_MAX	1	0000...FFFFh	0...0.467	7.126e-6	-
Maximum allowed leakage parameter during vapour generation period					
C_DTP_HYS_POS	1	0000...7FFFH	0...40.96	0.00125	Hpa
Hysteresis not to take in account small DTP variation during vapor generation in case of positive values					
C_DTP_HYS_NEG	1	8000...7FFFH	-40.96...40.96	0.00125	Hpa
Hysteresis not to take in account small DTP variation during vapor generation in case of negative values					
IP_FAC_DIAGCP_MDL_ESTIM	4*6	0000...FFFFH	0...0.467	7.126e-6	-
LDP_FAC_DIAGCP_MDL_BAS	4	0000...FFFFH	0...0.467	7.126e-6	
LDPM_TAM	6	00..FEH	-48...142.5	0.75	°C
Vapour generation correction factor					

B.10.4.8 Pressure before evacuation (PRS_EVAC_BEG state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_BEG_DIAGCP	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
Mean DTP value before the evacuation phase					
FTL_MMV_DIAGCP	V/O	0...FFFFH	0...100	0.0015	%
Fuel mean volume from FTL sensor at moment of EVAP monitoring performance					

Input data:

DTP_MV	STATE_DIAGCP	ERR_SYM_MEC_CPS	FLOW_SP_CPS_EXT
C_FLOW_CPS_SP_INC_DIAGCP			

Description:

The system switches to the ´*PRS_EVAC_BEG*´ state if the period C_T_1_DIAGCP is reached. The pressure mean value (DTP_MV) out of the first 4 pressure values – is stored as ´*DTP_BEG_DIAGCP*´, the pressure before evacuation.

Before the pressure mean value DTP_BEG_DIAGCP is calculated, the evacuation is started, i.e. the CPS valve is opened at least one increment.

In case of DTP decrease during Vapour Generation phase due to environmental condition, the diagnosis switches to the ´Wait Period´. The diagnosis will be performed when monitoring condition will be fulfilled again.

Formula Section:

If C_T_1_DIAGCP is reached

then STATE_DIAGCP = PRS_EVAC_BEG

and DTP_BEG_DIAGCP = DTP_MV

and FTL_MMV_DIAGCP = FTL_MMV (at the moment of EVAP monitoring)

end

If DTP_BEG_DIAGCP ≤ C_DTP_HYS_NEG

or ERR_SYM_MEC_CPS = SYM_0

then the diagnosis is aborted and the system switches to the "*Wait Period*"

end

B.10.4.9 Evacuation phase (DTP_EVAC state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FLOW_SP_CPS_EXT	V/O	0...FFFFH	0...8	0.000122	kg/h
Setpoint for MAF_CPS at evacuation					
DTP_DIF_ACT	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
Pressure difference during evacuation					
DTP_DIF_ACT_MOD_6	V/O/S	8000...7FFFH	-40.96...40.96	0.00125	hPa
Pressure difference during evacuation stored for mode 06-communication					
LV_DTP_EVAC_INC	V/O	0...1H	0...1	1	-
Boolean for fast large leak error is detected					
LV_T_DLY_DTP_EVAC_INC	V/O	0...1H	0...1	1	-
Boolean for time delay setting					
DTP_MV_REF	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
Reference tank pressure for tank cap open detection					
T_DLY_DTP_EVAC_INC	V/O	0...FFH	0...25.5	0.1	S
Time delay for large leak detection					
LV_DTP_EVAC_CPS_END	V/O	0...1H	0...1	1	-
Boolean to show the end of CPS fully opening					
DTP_DIF_EVAC	V/O	8000...7FFFH	-40.96...40.96	0.00125	hPa
Pressure difference before reaching DTP evacuation target					

Input data:

LAM_MV_i	STATE_DIAGCP	FAC_LAM_MV_MMV[NC_CBK_EX_NR]	DTP_BEG_DIAGCP
LV_LAM_LIM_MIN_i	DTP	FAC_LAM_DIAGCP	DTP_MV
FLOW_SP_CPS_VAP_CHK	LV_DTP_SLOP_CLC_END	FTL_MMV	N_DIF

B.10.4.9.1 Opening and closing of the CPS:

To open and close the canister purge valve for controlling the evacuation period, a value FLOW_SP_CPS_EXT is calculated. It is a setpoint for the desired mass air flow through the CPS performed by the Evaporative emission control function.

At the beginning of evacuation FLOW_SP_CPS_EXT is incremented to C_FLOW_CPS_SP_DIAGCP using an increment C_FLOW_CPS_SP_INC_DIAGCP.

At the end of DTP slop calculation, FLOW_SP_CPS_EXT is updated accordring to DTP differences between DTP_DIF_ACT & C_DTP_DIF_DIAGCP.If STATE_DIAGCP = VAP_CHK then FLOW_SP_CPS_EXT = FLOW_SP_CPS_VAP_CHK

Initialization :

Initialization at the beginning of DTP_EVAC

LV_DTP_EVAC_CPS_END = 0

FLOW_SP_CPS_EXT = 0

Formula section:

If STATE_DIAGCP = 8h (DTP_EVAC)

then **if** FLOW_SP_CPS_EXT < C_FLOW_CPS_SP_DIAGCP

and LV_DTP_EVAC_CPS_END = 0

then FLOW_SP_CPS_EXT is incremented with C_FLOW_CPS_SP_INC_DIAGCP until C_FLOW_CPS_SP_DIAGCP

endif

if FLOW_SP_CPS_EXT = C_FLOW_CPS_SP_DIAGCP

then LV_DTP_EVAC_CPS_END = 1 (kept until next initialization)

endif

if LV_DTP_EVAC_CPS_END = 1 (after CPS once fully opening)

and DTP_MV < C_DTP_DIF_MIN_SLOP

and LV_DTP_SLOP_CLC_END = 1 (after double slop calculation)

then DTP_DIF_EVAC = DTP_DIF_ACT - C_DTP_DIF_DIAGCP

FLOW_SP_CPS_EXT = IP_FLOW_CPS_SP_DIAGCP (FTL_MMV, DTP_DIF_EVAC)

endif

else if STATE_DIAGCP = Fh (VAP_CHK)

then FLOW_SP_CPS_EXT = FLOW_SP_CPS_VAP_CHK

else FLOW_SP_CPS_EXT = 0

endif

B.10.4.9.2 “Regular” - Closing of the CPS (CLOSE_CPS state):

In the following cases FLOW_SP_CPS_EXT is set to 0 without change limitation (further actions see “Injection time correction”)

End of evacuation period

If no impermissible deviations from FAC_LAM_MV_MMV[1] are registered, the system waits until the pressure has dropped by C_DTP_DIF_DIAGCP. Then FLOW_SP_CPS_EXT is set to 0 (suddenly), before advancing to “Release of Parameter Estimation (DLY_DIAG-state)”.

Function interruption:

If the bits LV_STATE_CDN_DIAGCP (activation conditions violated) or LV_PRS_LIM_DYN_DIAGCP (limited dynamics violated) changing from 1 to 0 during evacuation, FLOW_SP_CPS_EXT is set to 0 (suddenly) and the *´Wait Period´* is activated.

B.10.4.9.3 "Irregular" - Closing of the CPS (ERR_CLOSE_CPS state)

In the following cases, FLOW_SP_CPS_EXT is reduced to 0 via ramp with the slope C_FLOW_CPS_SP_DEC_DIAGCP (STATE_DIAGCP = ERR_CLOSE_CPS)

Lambda deviation at evacuation

The lambda controller value (FAC_LAM_MV_MMV[1]) is shifted for more than C_FAC_LAM_MAX_DIAGCP (for leaning the mixture), respectively for more than C_FAC_LAM_MIN_DIAGCP (enrich the mixture) from the lambda control mean value at the beginning of evacuation (FAC_LAM_DIAGCP),

```
If  {   FAC_LAM_DIAGCP – FAC_LAM_MV_MMV[1] >= C_FAC_LAM_MAX_DIAGCP
    or  FAC_LAM_DIAGCP – FAC_LAM_MV_MMV[1] <= C_FAC_LAM_MIN_DIAGCP
        // Conditions for breaking off
    or  LV_LAM_LIM_MIN_i = 1              }
        // the lambda controller is limited in lean direction
and {   DTP_DIF_ACT <= C_DTP_DIF_MIN_DIAGCP
        // missing tank cap not suspected, see next paragraph
    or  N_DIF > C_N_DIF_MAX_DIAGCP   }
        // RPM oscillations are limited for engine stability
```

the diagnosis is aborted (´ERR_CLOSE_CPS´ state). That means FLOW_SP_CPS_EXT is reduced to 0 via a ramp with the slope C_FLOW_CPS_SP_DEC_DIAGCP. When FLOW_SP_CPS_EXT reaches 0 then LV_DIAGCPS_ACT is set to 0 and the system switches to "Wait period".

As soon as the diagnosis is aborted the SOV is opened (for SOV-diagnosis reasons):

If STATE_DIAGCP = ERR_CLOSE_CPS

then LV_SOV_REQ = 0 (Request to open SOV)

The system waits for the next determination of the degree of charcaol-canister saturation. (see chapter 1.5.12 "Cooperation with the canister purge function")

Tank cap missing

If the pressure does not drop by at least C_DTP_DIF_MIN_DIAGCP (STATE_DIAGCP=ERR_CLOSE_CPS) during the maximum possible time period C_T_MAX_CPS, *'tank cap missing'* is detected. In that case FLOW_SP_CPS_EXT is reduced to 0 via a ramp with the slope C_FLOW_CPS_SP_DEC_DIAGCP. *(see chapter "Tank cap missing during leak detection algorithm")*

Large leak

If the pressure drops by more then C_DTP_DIF_DIAGCP during the above period, a 'large leak´ is detected and registered, and the diagnosis is disabled for this driving cycle. In that case FLOW_SP_CPS_EXT is reduced to 0 via a ramp with the slope C_FLOW_CPS_SP_DEC_DIAGCP. (see chapter "*Large leak*")

If the pressure increases more than the previous pressure, timer (=C_T_DTP_MV_EVAC_INC) will be set and the previous pressure is memorised to detect large leak early. If not, evaporative system monitoring can be stopped due to too much lambda deviation at hot condition.

Formula section:

DTP_DIF_ACT = DTP_MV - DTP_BEG_DIAGCP

If DTP_DIF_ACT ≤ C_DTP_DIF_DIAGCP

then switch to 'DLY_DIAG' state (see above: "*End of evacuation period*")

elseif LV_DTP_EVAC_INC = 1

then error detection ´large leak´ (see above: "*Large leak*")

else

if C_T_MAX_CPS has passed

then

if DTP_DIF_ACT >= C_DTP_DIF_MIN_DIAGCP

then error detection 'tank cap missing' (see above: "*Tank cap missing during leak detection algorithm*")

else error detection ´large leak´ (see above: "*Large leak*")

endif

else continue the state ´DTP_EVAC´

endif

endif

Formular section – Fast large leak error detection :

Activation :

If STATE_DIAGCP = 8 (DTP_EVAC)

and FLOW_SP_CPS_EXT = C_FLOW_CPS_SP_DIAGCP

and LV_DTP_EVAC_INC = 0

then

if LV_T_DLY_DTP_EVAC_INC = 0

then

if DTP_DIF_ACT <= C_DTP_MV_EVAC_DIF

then

T_DLY_DTP_EVAC_INC = C_T_DTP_MV_EVAC_INC

LV_T_DLY_DTP_EVAC_INC = 1

DTP_MV_REF = DTP_MV_{N-1}

endif

endif

if T_DLY_DTP_EVAC_INC is elapsed

then **if** │DTP_MV – DTP_MV_REF│ <= C_DTP_MV_EVAC_INC

then

endif

endif

else

LV_T_DLY_DTP_EVAC_INC = 0

T_DLY_DTP_EVAC_INC = 0

DTP_MV_REF = 0

endif

Special treatment for Diagnostic Test Mode:

If readyness of symptom ´LARGE_LEAK´ or ´FUC_MISS´ is detected, DTP_DIF_ACT is stored as DTP_DIF_ACT_MOD_6

The value DTP_DIF_ACT_MOD_6 should be initialized with 0 in case of failure memory is cleared.

Boolean for slope calculation ending during evac					
DTP_SLOP_MMV_DIF_MMV	V	0…FFFFH	0…819.2	0.0125	hPa/s
Mean value variation of DTP slope to determine DTP slope calculation ending during evac					

Input data:

DTP	STATE_DIAGCP	TCO_ST	T_AST
C_T_DTP_GRD_DIAGCP			

General information:

High ambient temperatures have a big influence on the DTP behavior as well as on the components.

Above a certain temperature DTP behavior becomes unlinear and there is a risk of leak detection even with a tight system. Therefore we analyze the DTP behavior during evacuation to have a good picture of the temperature. The diagnosis is aborted if a 0.5 mm leak is detected when DTP slope variation during evacuation is greater than a threshold (see also chapter “Evaporative emission control diagnosis error - 0.5 mm leak”).

Formula section:

a.) During the complete 'Evacuation period' the following check is performed every 40 msec:

If STATE_DIAGCP = DTP_EVAC

then

$DTP\_MMV_{(n+1)} = DTP\_MMV_{(n)} + C\_DTP\_MMV\_CRLC * (DTP_{(n+1)} - DTP\_MMV_{(n)})$

$DTP\_SLOP_{(n+1)} = (DTP\_MMV_{(n+1)} - DTP\_MMV_{(n)}) / 0.04 [s]$

$DTP\_SLOP\_MMV_{(n+1)} = DTP\_SLOP\_MMV_{(n)} + C\_DTP\_SLOP\_MMV\_CRLC * (DTP\_SLOP_{(n+1)} - DTP\_SLOP\_MMV_{(n)})$

Initialisation:

$DTP\_MMV_{(n)} = DTP_{(n)}$

$DTP\_SLOP\_MMV_{(n)} = 0$

$DTP\_SLOP\_MMV\_DIF\_MMV_{(n)} = 0$

LV_DTP_SLOP = 0

LV_DTP_SLOP_CLC = 0

LV_DTP_SLOP_CLC_END = 0

b.) C_T_MAX_FAC_SLOP_MMV seconds after beginning of evacuation the following calculations are done:

If $DTP\_SLOP\_MMV_{(n)} > DTP\_SLOP\_MMV\_MAX$
then $DTP\_SLOP\_MMV\_MAX = DTP\_SLOP\_MMV_{(n)}$

If $DTP\_SLOP\_MMV_{(n)} < DTP\_SLOP\_MMV\_MIN$
then $DTP\_SLOP\_MMV\_MIN = DTP\_SLOP\_MMV_{(n)}$

$DTP\_SLOP\_MMV\_DIF = |DTP\_SLOP\_MMV\_MAX - DTP\_SLOP\_MMV\_MIN|$

$DTP\_SLOP\_MMV\_DIF\_MMV_{(n)} = DTP\_SLOP\_MMV\_DIF\_MMV_{(n-1)}$

$+ C\_DTP\_SLOP\_DIF\_MMV\_CRLC * (DTP\_SLOP\_MMV\_DIF_{(n)} - DTP\_SLOP\_MMV\_DIF\_MMV_{(n-1)})$

If $| DTP\_SLOP\_MMV\_DIF\_MMV_{(n-1)} - DTP\_SLOP\_MMV\_DIF\_MMV_{(n)} | < C\_DTP\_SLOP\_DIF\_MMV\_DIF$

then LV_DTP_SLOP_CLC_END = 1

else LV_DTP_SLOP_CLC_END = 0

endif

If *DTP_SLOP_MMV_DIF after C_T_DTP_GRD_DIAGCP is elapsed*

then LV_DTP_SLOP_CLC = 1

else LV_DTP_SLOP_CLC = 0 *(0.5mm evacuation error is valid)*

endif

c.) Stable slop is determined at DLY_DIAG state :

If STATE_DIAGCP = 09H (DLY_DIAG state)

and { (DTP_SLOP_MMV_DIF >= IP_DTP_MAX_DIF_SLOP

and EOL_STATE_DIAGCP = EOL_PAS)

or

(DTP_SLOP_MMV_DIF >= IP_DTP_MAX_DIF_SLOP_EOL

and EOL_STATE_DIAGCP <> EOL_PAS) }

// EOL_STATE_DIAGCP <> EOL_PAS means EVAP monitoring was done at EOL test,

and LV_DTP_SLOP_CLC = 1

or {T_AST < C_T_AST_MIN_DIAGCP_1

and C_TCO_ST_MIN_DIAGCP_1 < TCO_ST < C_TCO_ST_MAX_DIAGCP_1}

then LV_DTP_SLOP = 1

else LV_DTP_SLOP = 0 *(0.5mm evacuation error is valid)*

endif

Remark: If IP_DTP_MAX_DIF_SLOP = 0, the symptom LEAK_SMALL_05MM is not available in the whole driving cycle.

In addition the availability of the symptom LEAK_SMALL_05MM can be shifted an arbitrarily time after start (dependently of TCO_ST).

LV_DTP_SLOP = 1 is kept after first transition 0→1

LV_DTP_SLOP_CLC = 1 is kept after first transition 0→1

Initialisation:

a) C_T_MAX_FAC_SLOP_MMV seconds after beginning of evacuation:

$DTP\_SLOP\_MMV\_MAX_{(n)} = DTP\_SLOP\_MMV_{(n)}$

$DTP\_SLOP\_MMV\_MIN_{(n)} = DTP\_SLOP\_MMV_{(n)}$

Calibration data:

B.10.4.10 Fuel flow correction during opened CPS

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_FAC_LAM_DIAGCP	V/O	0...1H	0...1	-	-
Boolean information for Lambda control to set FAC_LAM_MV_MMV to FAC_LAM_DIAGCP					
FAC_LAM_DIAGCP	V/O	8000...7FFFH	-50...50	0.0015	%
LAM_MV value at the beginning of CPS opening					
CL_INTER	V/O	0H...FFFFH	0...8	0.000122	-
Last CL for injection time correction					
MFF_ADD_DIAGCP	V/O	0...FFFFH	0...1389	0.02119	mg/stk
Mass fuel flow correction during evacuation period (interface reasons)					

Input data:

CL_MMV	CL_MMV_CLC_END	MAF_CPS	LV_NORM_PURGE_END_1
N	LV_DIAGCPS_ACT	STATE_DIAGCP	LV_FAC_LAM_DIAGCP_END[NC_CBK_EX_NR]

Calculation of the additive fuel flow correction MFF_ADD_DIAGCP

General information:

During several phases the CPS will be opened more than the normal purge-function allows for idle-speed condition. The additive fuel flow correction MFF_ADD_DIAGCP is calculated by help of the actual canister load CL_MMV and supports the lambda controller to keep the A/F Ratio at 1.

Formula section:

If LV_NORM_PURGE_END_1 = 1
then CL_INTER = C_FAC_TI_DIAGCP *CL_MMV_CLC_END
else CL_INTER = C_FAC_TI_DIAGCP *CL_MMV
endif

Calculation of MFF_ADD_DIAGCP; Necessary for interface reasons; kg/h – mg/stk):

If LV_DIAGCPS_ACT = 1
then **if** STATE_DIAGCP = DLY_DIAG (09h)
then **if** MFF_ADD_DIAGCP > 0
then MFF_ADD_DIAGCP (n) = MFF_ADD_DIAGCP (n-1) – C_MFF_DEC_DIAGCP
endif
else MFF_ADD_DIAGCP = CL_INTER * MAF_CPS
endif
else MFF_ADD_DIAGCP = 0
endif

Remark:

- Factor required for conversion *kg/h - mg/stk:* 10^5 / (N * NC_CYL_NR * 3)

FAC_LAM_MV_MMV[1] correction during Evacuation:

Although applying an additive MFF-Correction during Evacuation, the Lambda controller has to correct the rest of the lambda deviation.

To avoid Lambda-Jumps at the “Closing Step” of the CPS (LV_FAC_LAM_DIAGCP = 1) the system shifts the lambda controller *to the Lambda controller mean value before CPS opening (FAC_LAM_DIAGCP)*, but only if FAC_LAM_DIAGCP – FAC_LAM_COR[1] > 0 (Lambda controller difference in lean direction)

See also chapter 7, injection-Lambda controller.

As soon as the lambda shift has been performed by LACO, LV_FAC_LAM_DIAGCP_END[i] is set by LACO.

See also LACO aggregate.

If LV_FAC_LAM_DIAGCP_END[i] = 1
then LV_FAC_LAM_DIAGCP = 0
FAC_LAM_DIAGCP[i] = 0
endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_FAC_TI_DIAGCP	-	0...FFH	0...1	0,0039	-
Scaling factor for MFF_ADD_DIAGCP					
C_MFF_DEC_DIAGCP	-	0...FFFFH	0...1389	0.02119	mg/stk
Mass fuel flow correction decrement after evacuation period (interface reasons)					

B.10.4.11 Dynamic window on MAF fluctuation during ´Evacuation´ period:

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_MMV_DIAGCP	V	0...FFFFH	0...1389	0.0212	mg/stk
MAF dynamic window value during the evacuation					

Input data:

MAF			

Description:

During the *´Evacuation´* period the diagnosis is aborted (ERR_CLOSE_CPS) and switched to “wait period” state., if the MAF fluctuation is bigger than C_MAF_MMV_DIAGCP (e.g. “air conditionning” activation).

Formula section :

During the complete 'Evacuation period' the following check is performed:

$MAF\_MMV\_DIAGCP_{(n)} =$

$MAF\_MMV\_DIAGCP_{(n-1)} + C\_MAF\_MMV\_CRLC\_DIAGCP * (MAF_{(n)} - MAF\_MMV\_DIAGCP_{(n-1)})$

If $\left| MAF\_MMV\_DIAGCP - MAF \right| < C\_MAF\_MMV\_DIAGCP$

then continue 'Evacuation'

else perform 'ERR_CLOSE_CPS'

switch to 'Wait period' (automatically after 'ERR_CLOSE_CPS')

MAF_MMV_DIAGCP is initialised with MAF at beginning of 'Evacuation period'.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_MAF_MMV_DIAGCP	1	0...FFFFH	0...1389	0.0212	mg/stk
Maximum threshold for MAF dynamic window value during the evacuation					
C_MAF_MMV_CRLC_DIAGCP	1	0...FFH	0...0.996	3.9e-3	-
Dynamic filter coefficient for the MAF_MMV_DIAGCP calculation					

B.10.4.12 Cooperation with the canister purge function

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_STATE_RST_CLC_END	V/O	0…1H	0…1	1	
Bit signalling high vapour generation or high lambda deviation at evacuation phase					
T_CLC_END	V/O	0...FFH	0…255	1	s
time since LV_NORM_PURGE_END_1 was set to 1					

Input data:

STATE_INTR_DIAGCP	LV_NORM_PURGE_END_1		

Description:

Because of exorbitant vapour generation or too high lambda deviation at the evacuation phase, a new MAX_PURGE phase of the canister purge function must be awaited. This is realized by setting the bit LV_STATE_RST_CLC_END.

Recurrence : 1000 ms

Formula section:

If Bit # 1 **or** Bit # 2 of STATE_INTR_DIAGCP = **changes** to 1
then LV_STATE_RST_CLC_END = 1 ;new MAX_PURGE mode is needed
If LV_NORM_PURGE_END_1 = 1
then increment timer T_CLC_END

If LV_NORM_PURGE_END_1 **changes** 0 → 1
or new Driving cycle detetcted
then LV_STATE_RST_CLC_END = 0 ;MAX_PURGE mode finished
reset timer T_CLC_END

B.10.4.13 Gradient method

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DTP_GRD	V	8000...7FFFH	-40.96...40.96	0.00156	hPa/s
Tank pressure gradient for determination of tank level					
FAC_DIAGCP_VOL	V	0..FFH	0...99.61	0.39	%
Fuel tank level evaluation obtained by gradient method					
DTP_DIF_ACT_GRD_DIAGCP	V	8000...7FFFH	-40.96...40.96	0.00125	hPa
Differential DTP during C_T_DTP_GRD_DIAGCP					
T_DTP_GRD_DIAGCP	V	0..FFFFH	0...2621.4	0.04	s
Duration time for fuel tank level evaluation					

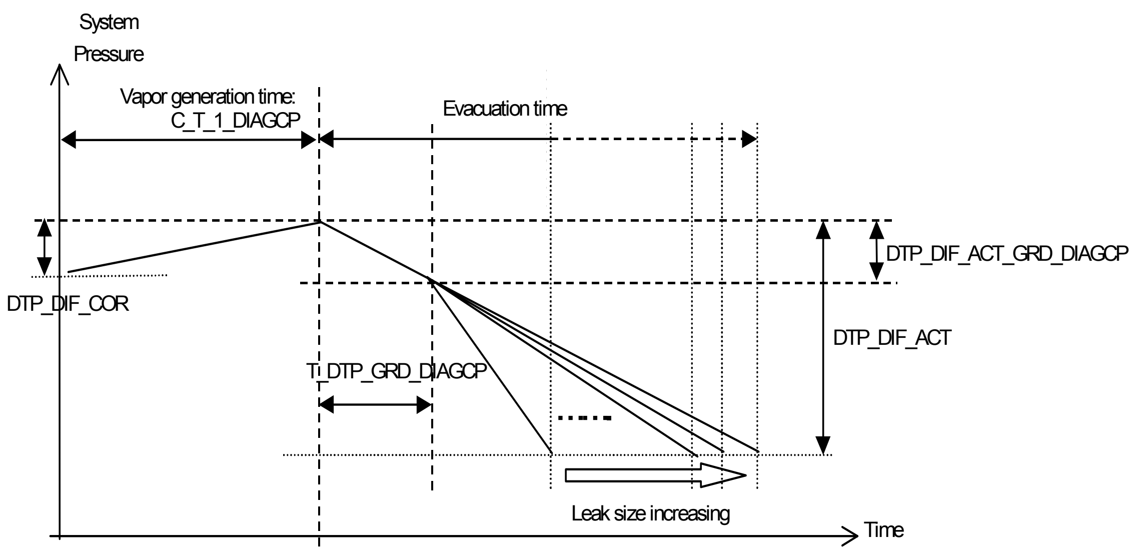
Input data:

DTP_DIF_COR	DTP_DIF_ACT	FAC_DIAGCP_MDL_BAS	C_T_1_DIAGCP
CONF_DIAGCP_VOL	LV_ERR_FTL	FTL_MMV	

Description:

For determination of the tank level the pressure gradient during ‘test for vapour generation’ and during ‘evacuation’ is analyzed. With increasing fuel level the gradient will be higher due to less air volume which has to be evacuated. The gradient during ‘test for vapour generation’ is taken into acount because high evaporation influences the evacuation time.

The duration of the evacuation phase for pressure gradient calculation is defined by C_T_DTP_GRD_DIAGCP. The corresponding pressure decrease is stored as DTP_DIF_ACT_GRD_DIAGCPi.



Formula section:

During C_T_DTP_GRD_DIAGCP seconds the following is calculated for every sampling step:

For i = 0 to n

DTP_DIF_ACT_GRD_DIAGCPi = DTP_DIF_ACTi

DTP_GRDi = (DTP_DIF_ACT_GRD_DIAGCPi / T_DTP_GRD_DIAGCP) -
(DTP_DIF_COR / C_T_1_DIAGCP)

where T_DTP_GRD_DIAGCP is the current evacuation time for gradient calculation since beginning of evacuation.

Calculation of FAC_DIAGCP_VOL (if no FTL available) :

If CONF_DIAGCP_VOL = 0 (no FTL information)

or LV_ERR_FTL = 1 (FTL sensor error)

then FAC_DIAGCP_VOL = IP_FAC_DIAGCP_VOL (DTP_GRD) *
IP_FAC_DIAGCP_VOL_COR (FAC_DIAGCP_MDL_BAS)

else FAC_DIAGCP_VOL = FTL_MMV

endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_FAC_DIAGCP_VOL	1*8	0..FFH	0...99.61	0.39	%
LDP_DTP_GRD__IP_FAC_DIAGCP_VOL	8	0...FFFFH	-40.96...40.96	0.00125	hPa/s

DIAGCP_VOL correction depending on the vapor generation during DTP_COR					
C_T_DTP_GRD_DIAGCP	1	1...FFFFH	0.04...2621.4	0.04	s
Duration of the gradient calculation during ´evacuation phase´					

B.10.4.14 Release of 'Model Parameter Estimation' (DLY_DIAG state)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_FAC_DIAGCP_MDL	V	0...1H	0...1	-	-
Signal for start parameter estimation : (0) for final stop, (1) for start					

Input data:

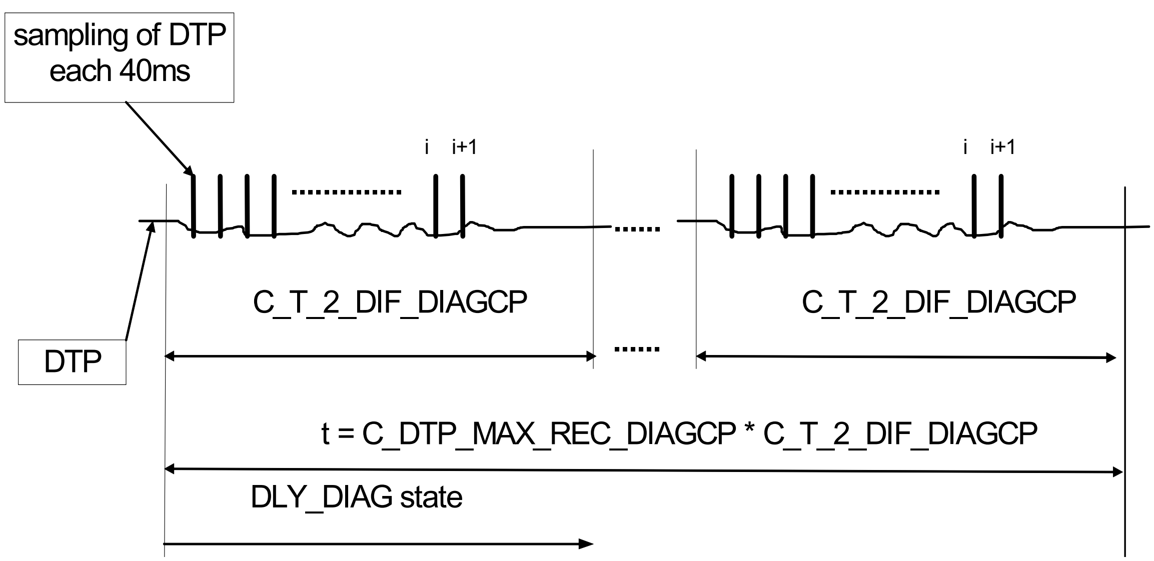
DTP_MV	STATE_DIAGCP	DTP_MV_PER	DTP_SLOP
FAC_DIAGCP_VOL	EOL_STATE_DIAGCP		

General Information:

After closing the CPS at the end of the *´Evacuation Period´* the pressure will continue to drop due to storing effects in the tube system. The pressure slope determination is introduced in order to recognize the reversal of the pressure (DTP_SLOP > C_DTP_SLOP_MIN_DIAGCP). The system will be checked for tightness and the fuel volume must be within a certain range (see chapter 1.2 *´Monitoring Conditions´*).

The pressure slope is determined in [hPa/sec]. For this purpose the pressure mean-value (DTP_MV_PER) during the period C_T_2_DIF_DIAGCP is calculated, starting at the end of 'Evacuation' period.

Overview of ´DLY_DIAG´ state:



The fuel-volume check is be by-passed in case of end-of-line test, i.e. EOL_STATE_DIAGCP must be passive:

If EOL_STATE_DIAGCP <> EOL_ACT

then

if C_FAC_DIAGCP_VOL_MIN ≤ FAC_DIAGCP_VOL ≤ C_FAC_DIAGCP_VOL_MAX

then continue ‘DLY_DIAG’ state until start of ‘Model Parameter Estimation’

else switch to ’Wait period'

Formula section:

If DTP_MV_PER $_{j}$ and DTP_MV_PER $_{j-1}$ are valid (after 2 measurements cycles) then the pressure slope determination is possible:

DTP_MV_PER $_{j}$ = [SUM (DTP $_{i}$)] / (C_T_2_DIF_DIAGCP / 0.040 [s])

SUM (DTP $_{i}$) = Sum of all pressure values during C_T_2_DIF_DIAGCP

Pressure slope:

DTP_SLOP j-1 = (DTP_MV_PER j - DTP_MV_PER j-1)
/ (C_T_2_DIF_DIAGCP - 0.1 [s])

Start of Model Parameter Estimation:

The Model Parameter Estimation starts if the pressure increases again above the start pressure C_DTP_DIAGCP with a positive slope.

IF DTP_SLOP >= C_DTP_SLOP_MIN_DIAGCP

then **if** DTP_MV > C_DTP_DIAGCP

then LV_FAC_DIAGCP_MDL = 1 (start parameter estimation; ´DTP_DIAG´ state)

else **if** C_DTP_MAX_REC_DIAGCP is reached

then EVAP-system detection 'leak-free'

else next calculation of ´DTP_SLOP´

endif

endif

else switch to *´Wait Period´*

endif

Additionally it is permanentely checked, if during ´Model Parameter Estimation´ DTP_MV falls below C_DTP_MV_MIN_DIAGCP. This case of DTP-undershoot the diagnosis is immediately aborted:

If STATE_DIAGCP = DLY_DIAG
and DTP_MV < C_DTP_MV_MIN_DIAGCP
then switch to *´Wait Period´*
endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Minimum pressure threshold to stop parameter estimation					

B.10.4.15 Diagnosis (DTP_DIAG state)

B.10.4.15.1 Diagnosis ‘Model Parameter Estimation’

For parameter estimation the actual pressure value $DTP_{(i)}$ is used.

The parameter estimation is performed if LV_FAC_DIAGCP_MDL = 1 and lasts C_T_2_DIAGCP seconds.

The estimation-result **FAC_DIAGCP_MDL_DIAG** is used for the actual leakage determination. (see chapter “Model Parameter Estimation”).

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_2_DIAGCP	-	0...FFH	0...25.5	0.1	s
Duration time to diagnosis model parameter estimation					

B.10.4.15.2 Fuel tank level (FTL) information

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FTV_COR_DIAGCP	V	0...FFH	0...99.61	0.39	liters
Air-fuel volume correction (included tank elasticity correction)					

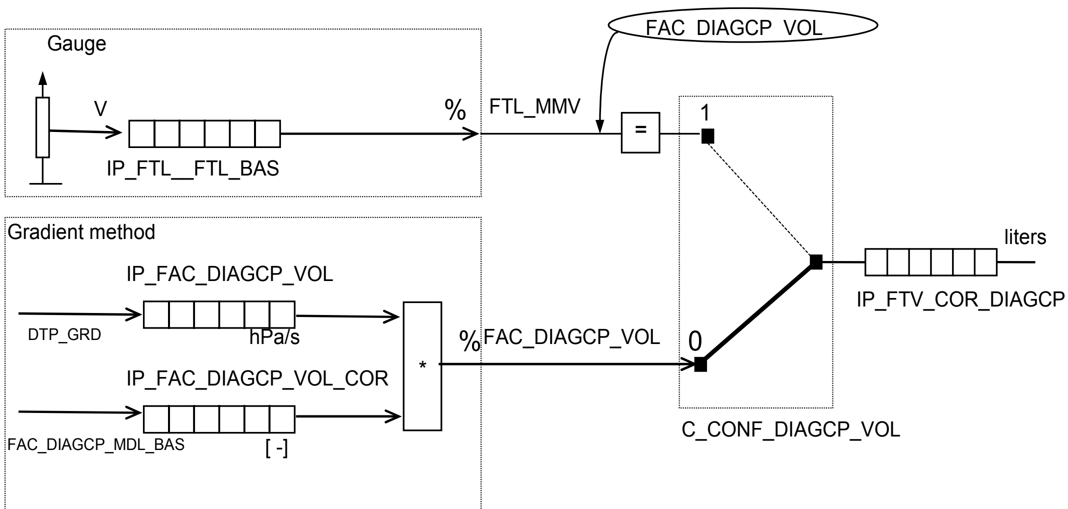
Input data:

FAC_DIAGCP_VOL	FTL_MMV	CONF_DIAGCP_VOL	LV_ERR_FTL

General information:

It is helpful to get approximately the fuel tank level because the diagnosis depends on the volume of the *fuel-air mixture* in the tank. As many possibilities to determine the FTL exist, we use a calibrated switch to select the source of the FTL information. To select the input to use for FTL information see C_CONF_DIAGCP_VOL in general chapter.

Description:



In case of using the gauge input for FTL information (CONF_DIAGCP_VOL = 1), the FAC_DIAGCP_VOL value is freezed at the transition of DTP_EVAC to DLY_DIAG.

When FTL is malfunction, the FAC_DIAGCP_VOL is determined by gradient method (see next chapter) and not switched to FTL_MMV at the transition of DTP_EVAC to DLY_DIAG with C_CONF_DIAGCP_VOL = 1.

FTV_COR_DIAGCP represents the fuel-air mixture in the tank.

Formula Section:

FTV_COR_DIAGCP = IP_FTV_COR_DIAGCP

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_FTV_COR_DIAGCP	12	0...FFH	0...99.61	0.39	liters
LDPM_FAC_DIAGCP_VOL	12	0...FFH	0...99.61	0.39	%
Aif-fuel volume correction function of FAC_DIAGCP_VOL (%)					

B.10.4.15.3 Determination of actual leakage area

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_DIAGCP_MDL_END	V	0000...FFFFH	0...0.467	7.126e-6	-
Final leakage parameter (including correction due to vapour generation)					
AR_DIAGCP	V	0000...FFFFH	0...0.1348	2.05e-6	cm²
Reduced leakage area estimated					

Input data:

FAC_DIAGCP_MDL_DIAG	FAC_DIAGCP_MDL_ESTIM	AMP	FTV_COR_DIAGCP
TEMP_COR_DIAGCP	FAC_TI_ST_AD_DIAGCP		

Description:

The estimated parameter from 'Diagnosis Period' has to be corrected due to vapour generation:

=> FAC_DIAGCP_MDL_END = FAC_DIAGCP_MDL_DIAG - FAC_DIAGCP_MDL_ESTIM

FAC_DIAGCP_MDL_END = f(fuel-tank-air-volume, ambient-pressure, ambient-temperature, leaksize)

If DIAG_MDL_END < 0

then DIAG_MDL_END = 0

Now the actual leakage can be determined:

AR_DIAGCP = ((FTV_COR_DIAGCP * FAC_DIAGCP_MDL_END) / IP_AMP_SQRT) * IP_FAC_DIAGCP

Where AR_DIAGCP is the reduced leakage area : alpha*A.

In this formula, the volume correction is applied in m^3 whereas as output it is defined in liters (see chapter "Fuel tank level information").

Theoritically : $\text{IP\_FAC\_DIAGCP} = \sqrt{\frac{2*\rho*T_0}{P_0*ambient-temperature}}$

Where the ambient temperature is equal to 293 K (20°C).

In the map IP_AMP_SQRT the square-root of the ambient-pressure is calibrated.

IP_AMP_SQRT = sqrt (AMP)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_AMP_SQRT	6	0...FFFFH	0...34.641	5.286E-4	√hPa
LDP_AMP_IP_AMP_SQRT	6	0...FFFFH	0...5434	0.083	hPa
Square root of AMP					
IP_FAC_DIAGCP	6*8	0...FFH	0...0.996	3.9E-3	-
LDP_TEMP_COR_DIAGCP_IP_FAC	8	0...FEH	-48...142.5	0.75	°C
LDP_FAC_TI_ST_AD_DIAGCP_IP_FAC	6	0...FFH	0...1.992	0.0078	-
Fuel temperature and fuel quality factor					

B.10.4.15.4 Determination of actual leakage-diameter

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_DIAM_DIAGCP	V/O	0...FFH	0...4.127	16.184e-3	Mm
Reduced leakage diameter					
FAC_DIAM_DIAGCP_MOD_6	V/O/S	0...FFH	0...4.127	16.184e-3	Mm
Reduced leakage diameter stored for mode 06-communication					

Input data:

AR_DIAGCP	FAC_DIAGCP_MDL_BAS		

The existing leakage (reduced-) diameter can be determined:

FAC_DIAM_DIAGCP = IP_FAC_SQRT_AR_DIAGCP

Where :

IP_FAC_SQRT_AR_DIAGCP = 200 * sqrt (AR_DIAGCP / pi)

IF C_DIAM_MIN_DIAGCP_VAP_CHK < FAC_DIAM_DIAGCP
< C_DIAM_MAX_DIAGCP_VAP_CHK
and FAC_DIAGCP_MDL_BAS < C_FAC_DIAGCP_MAX_VAP_CHK
and C_T_2_DIAGCP is elapsed
and LC_VAP_CHK_INH = 0
then the system switches to DLY_VAP_CHK state
else the system switches to “control diagnostic error – 0.5 mm”
endif

Special treatment for Diagnostic Test Mode:

If readyness of symptom LEAK_SMALL_05MM or LEAK_SMALL_1MM is detected, FAC_DIAM_DIAGCP is stored as FAC_DIAM_DIAGCP_MOD_6

The value FAC_DIAM_DIAGCP_MOD_6 should be initialized with 0 in case of failure memory is cleared.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_FAC_DIAGCP_MAX_VAP_CHK	1	0000...FFFFh	0...0.467	7.126e-6	-
Maximum FAC_DIAGCP_MDL_BAS value to start VAP_CHK					
C_DIAM_MIN_DIAGCP_VAP_CHK	1	00...FFH	0...4.127	16.184e-3	Mm
Minimum FAC_DIAM_DIAGCP value to start VAP_CHK					
C_DIAM_MAX_DIAGCP_VAP_CHK	1	00...FFH	0...4.127	16.184e-3	Mm
Maximum FAC_DIAM_DIAGCP value to start VAP_CHK					
LC_VAP_CHK_INH	-	0...1h	0...1	1	-
Deactivate VAP_CHK					
IP_FAC_SQRT_AR_DIAGCP	20	0...FFH	0...4.127	16.184e-3	mm
LDP_AR_DIAGCP_IP_FAC_SQRT	20	0...FFFFH	0...0.1348	2.05e-6	cm²
Square root of DIAGP_AR					

B.10.4.16 Delay time before changing to VAP_CHK state

Input data:

STATE_DIAGCP			

Description:

At transition into this state, a delay time C_T_DLY_VAP_CHK is started. After this delay time, the algorithm switches to VAP_CHK.

Formula section:

If STATE_DIAGCP = DLY_VAP_CHK
then LV_SOV_REQ = 0
endif

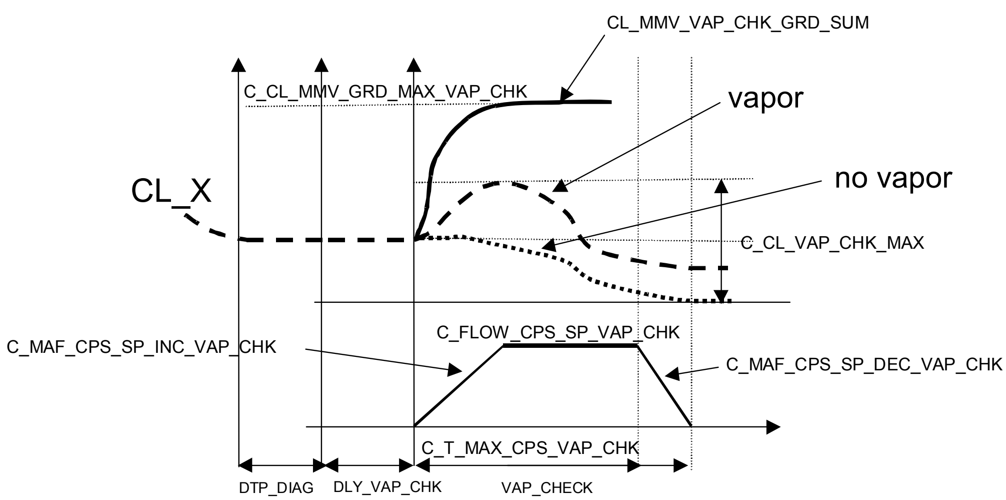
Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DLY_VAP_CHK	1	0...FFH	0…10.20	0.04	s
Delay time before vapor check					

B.10.4.17 Vapor Monitoring (STATE_DIAGCP = VAP_CHK)

Summary:

At certain ambient conditions (t_{amb}, p_{amb}, Δp_{amb}, fuel vapor pressure) the fuel tends to evaporate only at reduced system pressure although with the result of FAC_DIAGCP_MDL_BAS below a threshold. This can lead to an over detection in the diagnosis phase, due to no or incorrect correction of the DTP slope. The evaporated fuel that is in the fuel tank system can be visualised by purging the system immediately after the diagnosis. A calculated Canister Load CL_VAP_CHK (depending on the lambda control behaviour and analogue the CP – function) will show the amount of fuel vaporised in the tank system in terms of gradient (CL_MMV_VAP_CHK_GRD) and absolute value (CL_MMV_VAP_CHK).



Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FLOW_SP_CPS_VAP_CHK	V/O	0...FFFFH	0...8	0.000122	kg/h
flow setpoint for MAF_CPS at evacuation for CL gradient check					
LV_VAP_CHK_END	V	0...1H	0...1	-	-
Flag indicating that VAP_CHK is finished					
T_VAP_CHK	V	0...FFH	0…10.20	0.04	s
Timer during purge on for CL gradient check					
CL_VAP_CHK	V	0H...FFFFH	0...8	0.000122	-
Canister load CL calculated for vapor check					
CL_MMV_VAP_CHK	V	0H...FFFFH	0...8	0.000122	-
Canister load (mean value) calculated for gradient check					
CL_MMV_VAP_CHK_GRD	V	0H...FFFFH	0...8	0.000122	-
Canister load (mean value) gradient					
CL_VAP_CHK_TMP	V	0H...FFFFH	0...8	0.000122	-
Canister load temporary value					
T_DTP_GRD_VAP_CHK	V	0…FFH	0…10.20	0.04	s
Timer for GRD calculation					
MFF_VAP_CHK_DIAGCP	V	8000H...7FFFH	-8...8	0.000244	kg/h
Fuel flow from the ACF to check CL behaviour					
FAC_LAM_DIF_CP_VAP_CHK	V	8000H...7FFFH	-50...50	0.0015	%
Lambda deviation calculated during vapor check					
CL_MMV_VAP_CHK_GRD_SUM	V	0H...FFFFH	0...8	0.000122	-
Sum of Canister load (mean value) gradient					
FAC_LAM_0_CP_VAP_CHK	V	8000H...7FFFH	-50...50	0.0015	%
Initial lambda value at the beginning of VAP_CHK state					

Input data:

C_RAF_CLC_CP	FAC_LAM_MV_MMV[NC_CBK_EX_NR]	LV_LAM_LIM_MIN_i	LV_PRS_LIM_DYN_DIAGCP
MAF	FAC_LAM_DIAGCP	MFF_ADD_CP_KGH	N_32
LAM_MV_i	MAF_TOT_CP_DLY_MMV	CL_INTER	C_FAC_DIAGCP_MAX_VAP_CHK
FLOW_DLY_MMV_CP			

General information:

To check the VAP_CHK gradient after evacuation, a value FLOW_SP_CPS_VAP_CHK is calculated to purge the system. It is a setpoint for the requested mass flow through the CPS performed by the Evaporative Emission Control function.

Application conditions:

Initialisation by transition into state

T_VAP_CHK = 0

FLOW_SP_CPS_VAP_CHK = 0

LV_VAP_CHK_END = 0

FAC_LAM_DIF_CP_VAP_CHK = 0

FAC_LAM_0_CP_VAP_CHK = LAM_MV_I

MFF_VAP_CHK_DIAGCP = 0

CL_VAP_CHK = 0

CL_VAP_CHK_TMP = CL_VAP_CHK (=0)

T_DTP_GRD_VAP_CHK = C_T_DTP_GRD_VAP_CHK

CL_MMV_VAP_CHK = 0

CL_MMV_VAP_CHK_GRD = 0

CL_MMV_VAP_CHK_GRD_SUM = 0

Opening of the valve:

At the beginning of the VAP_CHK state, FLOW_SP_CPS_VAP_CHK is increased to C_FLOW_CPS_SP_VAP_CHK by C_FLOW_CPS_SP_INC_VAP_CHK

FLOW_SP_CPS_VAP_CHK is increased or set to C_FLOW_CPS_SP_VAP_CHK for max. C_T_MAX_CPS_VAP_CHK.

Closing of the valve:

In the following cases, FLOW_SP_CPS_VAP_CHK is reduced to 0 via the slope C_FLOW_CPS_SP_DEC_VAP_CHK (STATE_DIAGCP = VAP_CHK):

Normal end of purge phase or if the lambda controller value (FAC_LAM_MV_MMV[1]) is shifted for more than C_FAC_LAM_MAX_VAP_CHK (for lean mixture), respectively for more than C_FAC_LAM_MIN_VAP_CHK (rich mixture) from the lambda control mean value at the beginning of evacuation (FAC_LAM_DIAGCP),

Formula section:

If FAC_LAM_DIAGCP - FAC_LAM_MV_MMV[1] >=C_FAC_LAM_MAX_VAP_CHK
or FAC_LAM_DIAGCP - FAC_LAM_MV_MMV[1] <= C_FAC_LAM_MIN_VAP_CHK
or the lambda controller is limited in lean direction (LV_LAM_LIM_MIN_i = 1)
or { (CL_MMV_VAP_CHK_GRD_SUM$_{(n)}$ > C_CL_MMV_GRD_MAX_VAP_CHK
    or CL_MMV_VAP_CHK > C_CL_VAP_CHK_MAX)
    and FAC_DIAGCP_MDL_BAS < C_FAC_DIAGCP_MAX_VAP_CHK }
then FLOW_SP_CPS_VAP_CHK is reduced by C_FLOW_CPS_SP_DEC_VAP_CHK to 0 (and also if trigger conditions not furthermore fulfilled).
    if FLOW_SP_CPS_VAP_CHK = 0
    then system switches to "wait period"
    endif
else **if** T_VAP_CHK(n) < C_T_MAX_CPS_VAP_CHK
    then T_VAP_CHK(n) = T_VAP_CHK(n-1) + 1
        if (CL_MMV_VAP_CHK_GRD_SUM$_{(n)}$ > C_CL_MMV_GRD_MAX_VAP_CHK
        or CL_MMV_VAP_CHK > C_CL_VAP_CHK_MAX)
        and FAC_DIAGCP_MDL_BAS < C_FAC_DIAGCP_MAX_VAP_CHK

then FLOW_SP_CPS_VAP_CHK is reduced by C_FLOW_CPS_SP_DEC_VAP_CHK to 0 and switch to STATE_DIAGCP = T_DLY_3 and set STATE_INTR_DIAGCP = 14

else

if FLOW_SP_CPS_VAP_CHK < C_FLOW_CPS_SP_VAP_CHK

then FLOW_SP_CPS_VAP_CHK is increased by C_FLOW_CPS_SP_INC_VAP_CHK to C_FLOW_CPS_SP_VAP_CHK

else FLOW_SP_CPS_VAP_CHK= C_FLOW_CPS_SP_VAP_CHK

endif

endif

else FLOW_SP_CPS_VAP_CHK is reduced by C_FLOW_CPS_SP_DEC_VAP_CHK to 0 (and also if trigger conditions not furthermore fulfilled).

if (FLOW_SP_CPS_VAP_CHK = 0

and T_VAP_CHK >= C_T_MAX_CPS_VAP_CHK)

then LV_VAP_CHK_END = 1

endif

endif

Setting of STATE_INTR_DIAGCP

If wait period is due to FAC_LAM_DIAGCP or LV_LAM_LIM conditions, then STATE_INTR_DIAGCP = 3 (Limited dynamics not fulfilled)

If wait period is due to CL_MMV_VAP_CHK_GRD_SUM or CL_MMV_VAP_CHK conditions, then STATE_INTR_DIAGCP = 14 (VAP_CHK too high)

The injection time is corrected as in chapter “Injection time correction during opened CPS” described.

The SOV is open during this complete state LV_SOV_REQ = 0

Function interruption:

LV_PRS_LIM_DYN_DIAGCP (limited dynamics violated) changes from 1 to 0 during cps opened, FLOW_SP_CPS_VAP_CHK is set to 0 (suddenly) and the ´Wait Period´ is activated.

When the valve is opened to purge the system, the degree of HC saturation VAP_CHK is calculated. The gradient of this value and the delta to the last valid loading degree can be an indicator for high vapour generation in the evacuation phase. A detected leak can be suppressed and the diagnosis start again (transition into STATE_DIAGCP = T_DLY_3).

Calculation of FAC_LAM_DIF_CP_VAP_CHK:

if FAC_LAM_0_CP_VAP_CHK - FAC_LAM_MV_MMV[1] <= C_FAC_LAM_COR_MIN_VAP_CHK

then FAC_LAM_DIF_CP_VAP_CHK = FAC_LAM_0_CP_VAP_CHK - FAC_LAM_MV_MMV[1] - C_FAC_LAM_COR_MIN_VAP_CHK

elseif FAC_LAM_0_CP_VAP_CHK - FAC_LAM_MV_MMV[1] >= C_FAC_LAM_COR_MAX_VAP_CHK

then FAC_LAM_DIF_CP_VAP_CHK = FAC_LAM_0_CP_VAP_CHK - FAC_LAM_MV_MMV[1] - C_FAC_LAM_COR_MAX_VAP_CHK

endif

Calculation of MFF_VAP_CHK_DIAGCP:

MFF_VAP_CHK_DIAGCP = MAF_TOT_CP_DLY_MMV * FAC_LAM_DIF_CP_VAP_CHK / C_RAF_CLC_CP+ MFF_ADD_CP_KGH

Calculation of CL_VAP_CHK, CL_MMV_VAP_CHK:

if FLOW_DLY_MMV_CP = 0

then CL_VAP_CHK = 0

else CL_VAP_CHK = MFF_VAP_CHK_DIAGCP / FLOW_DLY_MMV_CP

endif

if CL_VAP_CHK < 0 THEN CL_VAP_CHK = 0

elseif CL_VAP_CHK > C_CL_MAX_VAP_CHK

then CL_VAP_CHK = C_CL_MAX_VAP_CHK

else CL_VAP_CHK = CL_VAP_CHK

endif

Calculation of CL_MMV_GRD , CL_MMV_VAP_CHK

CL_MMV_VAP_CHK(n) = (1- IP_CL_CRLC_RAMP_OPEN_VAP_CHK) * CL_MMV_VAP_CHK(n-1) + IP_CL_CRLC_RAMP_OPEN_VAP_CHK *CL_VAP_CHK (n)

DEC(T_DTP_GRD_VAP_CHK)

if T_DTP_GRD_VAP_CHK = 0

then CL_MMV_VAP_CHK_GRD = CL_VAP_CHK - CL_VAP_CHK_TMP

$CL\_MMV\_VAP\_CHK\_GRD\_SUM_{(n)} = CL\_MMV\_VAP\_CHK\_GRD\_SUM_{(n-1)} + CL\_MMV\_VAP\_CHK\_GRD$

CL_VAP_CHK_TMP = CL_VAP_CHK

T_DTP_GRD_VAP_CHK = C_T_DTP_GRD_VAP_CHK (re-init timer)

endif

Total number of DTP samples during C_T_y_DIAGCP					
CTR_SUM_DTP	V	0...FFFFH	0...65535	1	-
actual number of calculation operations beginning with 0					

Input data:

DTP	DTP_COR		

General information:

In order to fulfilled the need for DIAGCP_MDL_x range and resolution, TOT_DIF_SIG_x is limited for the final result to -52237.54...+52237.54.

The parameter estimation delivers two parameters which describe the characteristic of the pressure curve, FAC_DIAGCP_MDL_BAS and FAC_DIAGCP_MDL_DIAG.

These parameters are a function of leakage-size, fuel-level, ambient-pressure and ambient-temperature

The parameters determined during test for 'Vapor Generation' are marked with **_BAS**.

In this case the input is DTP_COR.

The parameters determined during test for 'Diagnosis Period' are marked with **_DIAG**.

In this case the input is DTP.

Formula section:

$$FAC\_DIAGCP\_MDL\_x = \frac{6}{N^3 \bullet SAMPLE} \bullet \left| DTP\_TOT\_DIF\_x \right|$$

with :

TOT_DIF_SIG_x (n) = $\sum_{n=0}^{N-1} \left[(N-1) - 2 \bullet n \right] \bullet IP\_DTP\_MDL\_DIAGCP(n)$

IP_DTP_MDL_DIAGCP = sqrt [DTP(n)]

N := Total number of DTP samples during C_T_y_DIAGCP

(DTP_TOT_SUM in the software)

SAMPLE := sample-rate of pressure signal DTP(n) [s]

n := actual number of calculation operations beginning with 0.

(CTR_SUM_DTP in the software)

y := 1; 2

x := BAS; DIAG

Remark : the increment in the sum TOT_DIF_SIG_x, is the value ONE :

=> For each recurrence n = n+1

DIAGCP_MDL_x is calculated only once with the last value of TOT_DIF_SIG_x.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_DTP_MDL_DIAGCP	20	0...FFFFH	-6.377...6.376	1.946e-4	√hPa
LDP_DTP_IP_DTP_MDL_DIAGCP	20	0...FFFFH	-40.96...40.96	1.25E-3	hPa
Signed square root of DTP					

B.10.6 Wait period

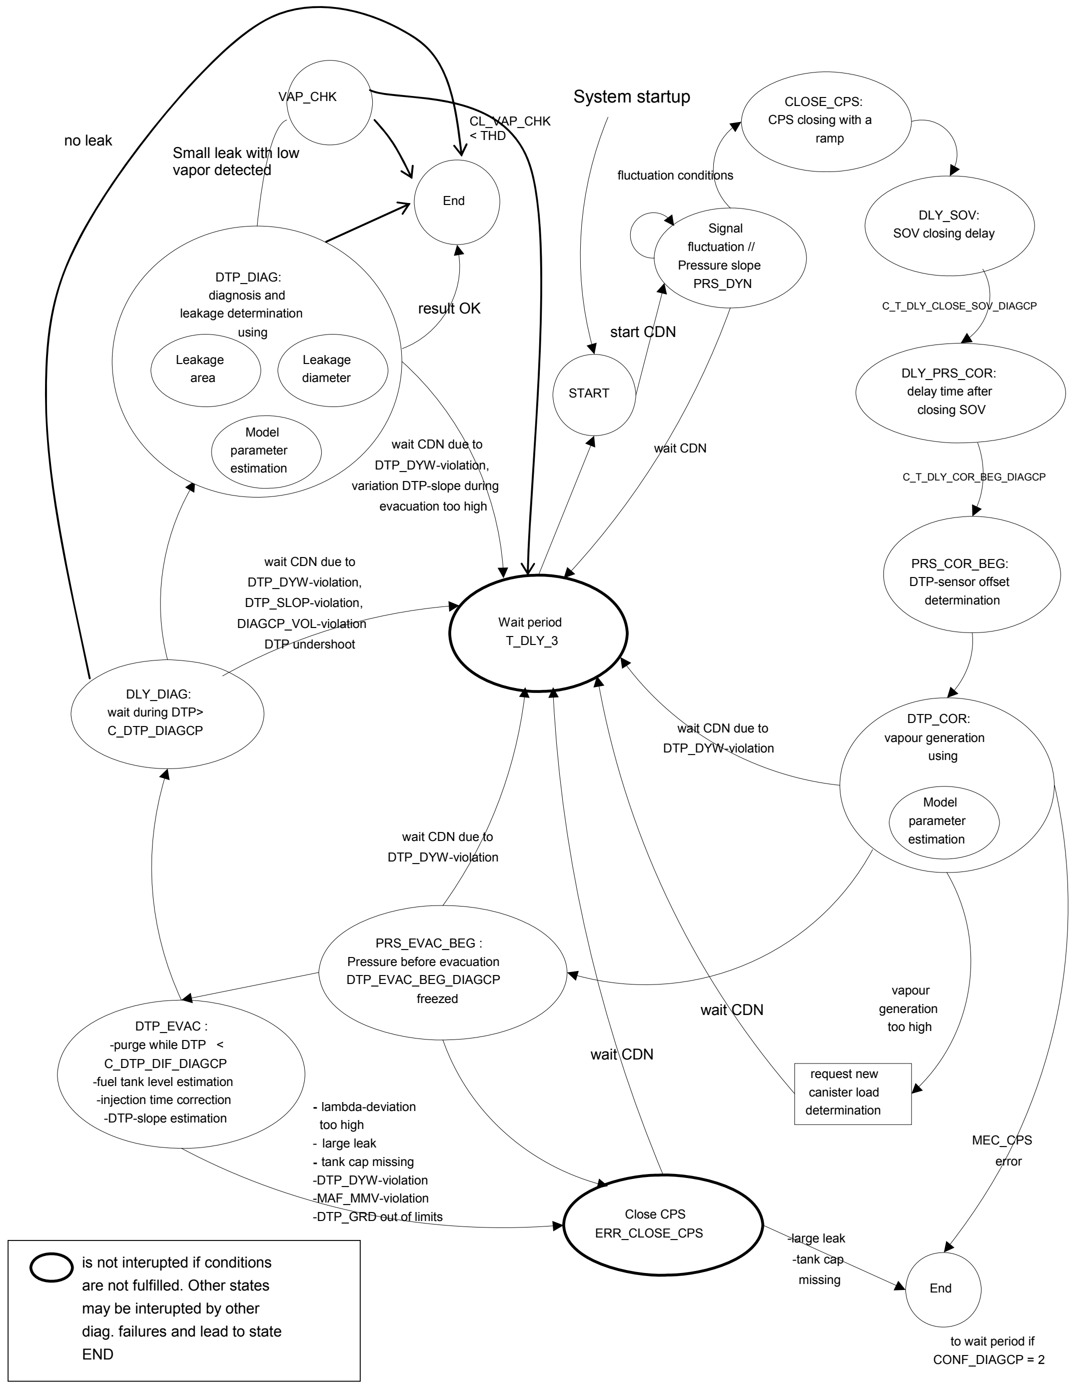
At interruption of DIAGCP without result the delay time C_T_DLY_3_DIAGCP is started. If C_T_DLY_3_DIAGCP has expired, and all diagnosis conditions exist, the diagnosis function is restarted with '*determination of sensor offset*'.

The wait period can be used to assure stabilisation of the pressure in the tank before the diagnosis is restarted. During the wait period the timer T_DIAGCP is stopped.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DLY_3_DIAGCP	1	0...FFFFH	0...6553.5	0.100	s
Delay time for restart of DIAGCP					

Description of the status transitions:



B.10.7 Actuator test for SOV

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SOV	V/O	0...1H	0...1	-	-
Boolean for SOV closed					
LV_SOV_REQ	V	0...1H	0...1	-	-
Request for switching the SOV valve					

Input data:

LV_SOV_ACT_EXT_ADJ	LV_SOV_EXT_ADJ	CTR_ABC_SOV	

General information:

The diagnosis tool intervention for SOV actuator test has first priority and interrupts the DIAGCP algortithm. If the actuator test for SOV is not active the SOV is switched according to the demands of the evaporative system monitoring function (LV_SOV_REQ).

Application conditions:

Initialization: at start of driving cycle

LV_SOV_REQ = 0

Recurrence: 20 ms

Formula section:

```
If      LV_SOV_ACT_EXT_ADJ = 1
then    external adjustment active
        If    LV_SOV_EXT_ADJ = 1
        then  LV_SOV = 1
        else  LV_SOV = 0
        endif
else    external adjustment not active at the moment
        LV_SOV = LV_SOV_REQ
endif
```

with LV_SOV also the HW-pin "SOV" must be switched:

```
If    CTR_ABC_SOV = 0
Then  no error symptom detected yet -> normal operation
      LV_SOV = 0  => diagnosis pulse time 0.45ms (=0.34% duty @ 7.6 Hz)
      LV_SOV = 1  => diagnosis pulse time 0ms (=100% duty)
Else  error symptom detected -> send additional test pulses for improved diagnosis
      LV_SOV = 0  => diagnosis pulse time 0.45ms (=0.34% duty @ 7.6 Hz)
      LV_SOV = 1  => diagnosis pulse time 0.45ms (=99.66% duty @ 7.6 Hz)
Endif
```

B.10.8 Fuel cap missing

B.10.8.1 Fuel cap missing detection out of leak detection algorithm

Output data:

Input data:

LV_INH_DIAGCP	STATE_CP	MAF_CPS	LV_IS
DTP	LV_DC	LV_CPPWM_EXT_ADJ	LV_SOV_ACT_EXT_ADJ
LV_STATE_CDN_DIAGCP	DTP_MV	VS	CONF_DIAGCP
STATE_DIAGCP	LV_DTP_PLAUS_READY	CL_MMV	AMP_AD
FAC_DIAGCP_VOL	LV_STATE_RR	LV_ERR_FUC_MISS_1	LV_ST_END
FTL_MMV	C_FTL_MAX_DIAGCP	PQ	

General information:

The purpose of the function is to detect a missing fuel cap independently from the vakuum leak detection function. Therefore the *charcoal-canister shutoff valve (SOV)* is closed during a MAX_PURGE state. This operation generates a vacuum in the fuel system. If it is not possible to evacuate the fuel system, a missing tank cap is detected.

Application conditions:

Initialisation:

⇒ *T_DLY_1_FUC_MISS_DIAG:*

The timer T_DLY_1_FUC_MISS_DIAG is resetted, if at least one of the activation condition is not met (LV_FUC_MISS_DIAG_CDN = 0) or at start of a new driving cycle (LV_DC 0→1).

⇒ *T_DLY_2_FUC_MISS_DIAG:*

The timer T_DLY_2_FUC_MISS_DIAG is resetted, if at least one of the activation condition is not met (LV_FUC_MISS_DIAG_CDN = 0) or at start of a new driving cycle (LV_DC 0→1).

⇒ *T_DLY_3_FUC_MISS_DIAG:*

If LV_IS = 1→ 0 (transition) or VS > 0 or LV_FUC_MISS_DIAG_END = 0 then T_DLY_3_FUC_MISS_DIAG = 0

⇒ *T_DLY_4_FUC_MISS_DIAG:*

If LV_FUC_MISS_DIAG_READY = 0→1 then T_DLY_4_FUC_MISS_DIAG = C_T_DLY_4_FUC_MISS_DIAG

At start of a new driving cycle (LV_DC = 0→1) T_DLY_4_FUC_MISS_DIAG = 0

⇒ NR_CYC_FUC_MISS_DIAG, NR_CYC_INTR_FUC_MISS_DIAG, LV_FUC_MISS_DIAG_END, LV_FUC_MISS_DIAG_READY and LV_DIAG_CHK_MPL_FUC_MISS are resetted to 0 at start of a new driving cycle (LV_DC 0→1).

Recurrence: *1000ms, if LV_FUC_MISS_DIAG_CDN = 0*
40ms, if LV_FUC_MISS_DIAG_CDN = 1

Activation:

If STATE_DIAGCP = START, CLD or PAS
and LV_ST_END = 1
and CONF_DIAGCP > 0
then Activation of FUC_MISS diagnosis
endif

Formula section:

- *Conditions for FUC_MISS Diagnosis (LV_FUC_MISS_DIAG_CDN = 1)*

Configuration byte C_CONF_DIAGCP:

The fuel cap missing diagnosis is only running if C_CONF_DIAGCP ≠ 0

(CONF_DIAGCP > 0, not passive).

B.10.8.1.1 Fuel Cap Diagnosis sequence

- *Determination of the pressure mean value (DTP_MV_FUC_MISS_DIAG) before starting the diagnosis*

After C_T_DLY_1_FUC_MISS_DIAG has elapsed, DTP_MV_FUC_MISS_DIAG = DTP_MV This is the pressure before starting the FUC_MISS diagnosis:

If LV_FUC_MISS_DIAG_CDN = 1
and C_T_DLY_1_FUC_MISS_DIAG has elapsed
then DTP_MV_FUC_MISS_DIAG = DTP_MV
else no determination of DTP_MV_FUC_MISS_DIAG
endif

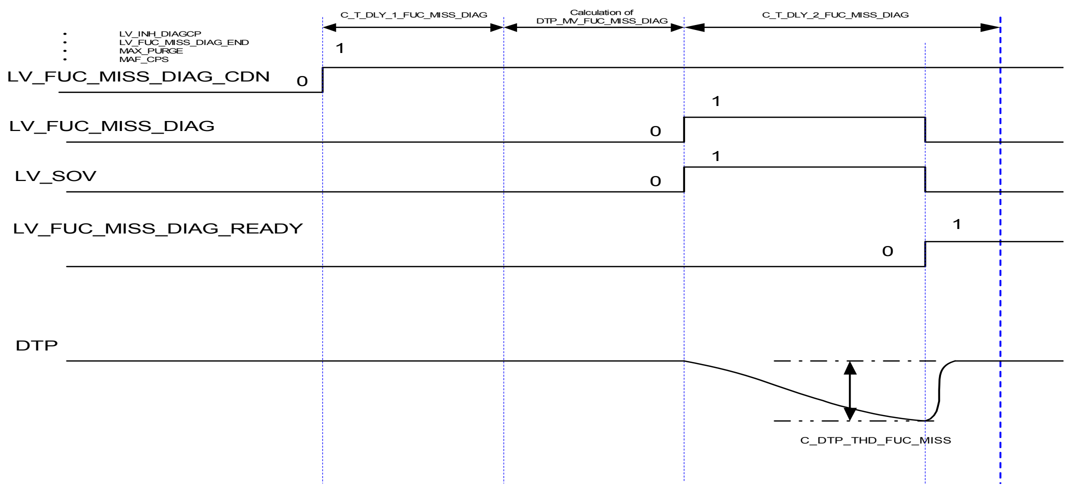
- *Start of “Missing Fuel Cap Diagnosis”*

If LV_FUC_MISS_DIAG_CDN = 1
and C_T_DLY_1_FUC_MISS_DIAG is reached
then LV_FUC_MISS_DIAG = 1
and T_DLY_2_FUC_MISS_DIAG timer is incremented
and LV_SOV_REQ = 1
else LV_FUC_MISS_DIAG = 0
and T_DLY_2_FUC_MISS_DIAG = 0
and LV_SOV_REQ = 0
endif

- *End of “Missing Fuel Cap Diagnosis” (one FUC_MISS diagnosis cycle)*

If LV_FUC_MISS_DIAG = 1
and C_T_DLY_2_FUC_MISS_DIAG has elapsed
or DTP - DTP_MV_FUC_MISS_DIAG = DTP_DIF_FUC_MISS_DIAG ≤ C_DTP_THD_FUC_MISS
then LV_FUC_MISS_DIAG = 0
LV_SOV_REQ = 0
LV_FUC_MISS_DIAG_READY = 1
endif

B.10.8.1.2 Function Diagram:



B.10.8.1.3 Triggering a renewed “FUC_MISS Diagnosis” after a longer Ídle State Duration´

After a longer idle duration (e.g. refuelling with running engine), the FUC_MISS diagnosis algorithm is activated again (only, if multiple check is not running)

If LV_IS = 1
and VS = 0
} for longer than C_T_DLY_3_FUC_MISS_DIAG seconds
and LV_FUC_MISS_DIAG_END = 1 (Multiple check is not running)
then LV_FUC_MISS_DIAG_END = 0 (diagnosis algorithm is started again)
NR_CYC_FUC_MISS_DIAG = 0
LV_DIAG_CHK_MPL_FUC_MISS = 0
LV_FUC_MISS_DIAG_READY = 0
T_DLY_4_FUC_MISS_DIAG = 0
endif

B.10.8.1.4 Multiple Check:

Because of statistical reasons, the fuel cap diagnosis algorithm should be performed more times per driving cycle, if the first diagnosis cycle in driving cycle has been finished with a diagnostic error.

- **Activation of multiple check:**

If FUC_MISS_DIAG algorithm is completed
(LV_FUC_MISS_DIAG_READY = 0→1)
then NR_CYC_FUC_MISS_DIAG = NR_CYC_FUC_MISS_DIAG + 1
endif

If LV_FUC_MISS_DIAG_READY = 1
and LV_ERR_FUC_MISS_1 = 1
then LV_DIAG_CHK_MPL_FUC_MISS = 1
endif

If LV_DIAG_CHK_MPL_FUC_MISS = 1
and LV_FUC_MISS_DIAG_READY = 1
and NR_CYC_FUC_MISS_DIAG < C_NR_CYC_FUC_MISS_DIAG_MAX
then LV_FUC_MISS_DIAG_READY = 0
else LV_FUC_MISS_DIAG_END = 1
endif

- **Delay time between FUC_MISS_DIAG cycles during running multiple check**

If T_DLY_4_FUC_MISS_DIAG > 0
then T_DLY_4_FUC_MISS_DIAG is decremented
else no decrementation
endif

B.10.8.1.5 Cancelling because of too many interruptions (LV_SOV = 1 at missing fuel cap diagnosis)

If LV_FUC_MISS_DIAG = 1→ 0 (transition)
and LV_FUC_MISS_DIAG_CDN = 1→ 0 (transition)
then NR_CYC_INTR_FUC_MISS_DIAG = NR_CYC_INTR_FUC_MISS_DIAG + 1
if NR_CYC_INTR_FUC_MISS_DIAG >= C_NR_CYC_INTR_FUC_MISS_DIAG
then LV_FUC_MISS_DIAG_END = 1
(FUC_MISS diagnosis algorithm is finished)
endif

<u>Special treatment for Diagnostic Test Mode:</u>

If LV_FUC_MISS_DIAG_READY = 1 the value of DTP_DIF_FUC_MISS_DIAG is stored as DTP_DIF_FUC_MISS_DIAG_MOD_6 for mode 06-communication

Calibration data:

B.10.9 Total diagnosis time

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_DIAGCP	V	0...FFH	0...255	1	s
Total duration of evap. monitoring					

Input data:

STATE_DIAGCP			

The time from the beginning of the *´determination of the signal fluctuation´* to the end of the ´diagnosis´ is displayed by the ramcell T_DIAGCP.

The timer doesn' t run **IF** STATE_DIAGCP = T_DLY_3
= START
= PAS
= CLD

The timer is resetted at the beginning of the evap. monitoring (STATE_DIAGCP changes to PRS_DYN).

B.10.10 Function control, Configuration and State Display

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
STATE_DIAGCP	V/O	0...FFH	0...255	1	-
States during evaporative system monitoring					
STATE_INTR_DIAGCP	V	0...FFFFH	0...65535	1	-
Information byte at interruption of DIAGCP					
LV_DIAGCP_CHK_MPL	V	0...1H	0...1	1	-
Multiple check active					
NR_CYC_DIAGCP	V	0...FFH	0...255	1	-
Total number of completed DIAGCP Cycles					
NR_CYC_INTR_DIAGCP	V/O	0...FFH	0...255	1	-
Total number of DIAGCP Interruptions befor completing one cycle					
LV_DIAGCP_END	V	0...1H	0...1	1	-
Diagnosis completed for this driving cycle					

Input data:

LV_ERR_VAP_LEAK_1	LV_ERR_VAP_LEAK_2	LV_ERR_MEC_CPS	C_CONF_DIAGCP
LV_ERR_VAP_LEAK_10	LV_ERR_FUC_MISS		

Function control:
Because of statistical reasons, the leak detection algorithm should be performed more times per driving cycle, if the first diagnosis cycle per driving cycle was finished with a diagnostic error.
Should the algorithm be interrupted too much before completing one diagnostic cycle, it should be aborted until end of driving cycle.

Formula section:

Activation of Multiple Check

If DIAGCP algorithm completed
then NR_CYC_DIAGCP = NR_CYC_DIAGCP + 1
NR_CYC_INTR_DIAGCP = 0

If LV_ERR_VAP_LEAK_1 = 1 (Only very small leak detetcted)
and LV_ERR_VAP_LEAK_2 = 0
and LV_ERR_VAP_LEAK_10 = 0
and LV_ERR_FUC_MISS = 0
then LV_DIAGCP_CHK_MPL = 1 *(Multiple check activated)*
else **if** LV_ERR_VAP_LEAK_2 = 1
or LV_ERR_VAP_LEAK_10 = 1
or LV_ERR_FUC_MISS = 1
then LV_DIAGCP_CHK_MPL = 0 *(Multiple check deactivated)*
endif

If NR_CYC_DIAGCP < C_NR_CYC_DIAGCP_MAX
and LV_DIAGCP_CHK_MPL = 1
then enable new DIAGCP algorithm
else Function completed for this DC, STATE_DIAGCP = PAS, LV_DIAGCP_END = 1

Cancelling because of too many interruptions

If DIAGCP algorithm interrupted (at every jump to State T_DLY_3)
then NR_CYC_INTR_DIAGCP = NR_CYC_INTR_DIAGCP + 1

If NR_CYC_INTR_DIAGCP = C_NR_CYC_INTR_DIAGCP_MAX
then abort DIAGCP algorithm for this DC, STATE_DIAGCP = CLD

If DIAGCP algorithm completed
then reset NR_CYC_INTR_DIAGCP

Initialisation:

NR_CYC_DIAGCP , NR_CYC_INTR_DIAGCP, LV_DIAGCP_CHK_MPL and LV_DIAGCP_END are set to 0 at Start of a new Driving cycle

Configuration byte C_CONF_DIAGCP:

C_CONF_DIAGCP is used to configure the DIAGCP-Algorithm (for application purposes).

0: passive
1: until NR_CYC_DIAGCP_MAX >= C_NR_CYC_DIAGCP_MAX
(LV_DIAGCP_CHK_MPL = 1)
2: Continuous run (algorithm is performed continuously only interrupted by the wait period)

DIAGCP States display:

STATE_DIAGCP =	0 - ST	(START)
	1 - PDYN	(PRS_DYN)
	2 - CLSCPS	(CLOSE_CPS)
	3 - DLYSOV	(DLY_SOV)
	4 - DLYPCOR	(DLY_PRS_COR)
	5 - PCORBEG	(PRS_COR_BEG)
	6 - PCOR	(DTP_COR)
	7 - PEVBEG	(PRS_EVAC_BEG)
	8 - PEV	(DTP_EVAC)
	9 - DLYDIA	(DLY_DIAG)
	A - PDIA	(DTP_DIAG)
	B - T_DLY_3

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose mechanical damage of the SOV. symptom **MEC_SOV.** The diagnosis is performed by anti-bouncing.

Description:

Error-symtoms are defined to this diagnosis function as following :

```
□□□□
|  |  |  └─> -    SOV stucks in closed position        (= SYM_0)
|  |  └────> -                                         (= SYM_1)
```

Remark: Calculation of LV_END_DIAG_MEC_SOV see generic calculation “End of diagnosis” in anti bounce algorithm.

Application conditions:

Activation:

```
If      LV_ST_END = 1
and     VB > C_VB_MIN_DIAGCP
and     CONF_DIAGCP > 0
and     LV_DTP_PLAUS_READY = 1      (DTP Plausibility check performed)
and     LV_ERR_DTP = 0              (no DTP error present)
and     LV_ERR_SOV = 0              (no electr. SOV error present)
and     LV_CDN_VB_OBD2 = 1
and     LV_SOV = 0
then    diagnosis for the symptom MEC_SOV is available
        LV_CDN_DIAG_MEC_SOV = 1
else    diagnosis for the symptom MEC_SOV is not available
        LV_CDN_DIAG_MEC_SOV = 0
endif
```

Formula section:

Delay time counter calculation before MEC_SOV detection :

```
If      DTP < C_DTP_MIN_SOV
then    if      T_DTP_MES < C_T_DTP_MES
        then    if      V_DTP > C_V_DTP_MAX_DIAG
                or      V_DTP < C_V_DTP_MIN_DIAG
                then    Stop  T_DTP_MES
                else    T_DTP_MES increase
                endif
        else    Stop  T_DTP_MES
        endif
else    Reset  T_DTP_MES
endif
```

MEC_SOV failure detection :

```
if       DTP < C_DTP_MIN_SOV
and      T_DTP_MES >= C_T_DTP_MES
and      LV_ST_END = 1
and      LV_DIAGCPS_ACT = 0
and      LV_ERR_DTP = 0 (no tank pressure sensor error)
and      C_V_DTP_MIN_DIAG <= V_DTP <= C_V_DTP_MAX_DIAG
         (no DTP electrical sensor error)
then     'Canister shut off valve (SOV) stuck' is detected
         and     symptom MEC_SOV is active, anti bounce counter is incremented
                 (with C_ABC_INC_MEC_SOV)
         and     ERR_SYM_MEC_SOV = SYM_0
         and     LV_ERR_MEC_SOV = 1 (after debounce)
else if  DTP > C_DTP_NOM_SOV
then     the anti bounce counter of MEC_SOV is decremented
         and     ERR_SYM_MEC_SOV = NO_SYM
         and     LV_ERR_MEC_SOV = 0 (after rebounce)
endif
```

Remark : For the SOV stuck diagnosis formular, refer to 'DTP electrical diagnosis and SOV stuck diagnosis' chapter.

Increment of debounce counter: C_ABC_INC_MEC_SOV
Maximum value of debounce counter: C_ABC_MAX_MEC_SOV

Additional measures:

Disable evaporative emission control for the time the error is present and
disable evaporative emission control diagnosis for this driving cycle

Application assistances:

In the case of error , the following functions are concerned:

- Evaporative Emission Control: disabled
- Leak detetction : disabled indirectly by disabled EVAP function
- Diagnosis MEC_CPS : disabled indirectly by disabled leak detetction

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

B.11.2.1.1 Evaporative emission control diagnostic error – 0.5 mm (not MIL relevant)

General information:

The symptom name is **LEAK_1 (0.5mm)**. The diagnosis is performed by statistics. The error detection is “hard”. The error is detected based on the statistic result when the leakage diameter (FAC_DIAM_DIAGCP) is within certain limits.

For VAP_LEAK_2 (1.0mm) MIL management during VAP_LEAK_1 diagnosis, software refers to DTC (P0442 : small leak).

Description:

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
│ │ │ └─> -   VAP_LEAK_1      (= SYM_0)
│ │ └───> -                   (= SYM_1)
│ └─────> -                   (= SYM_2)
```

Application conditions:

Initialisation: at new driving cycle and at reset

- LV_ERR_VAP_LEAK_1 = 0
- all 0 for VAP_LEAK_1 diagnosis
- SUM_DIAG_VAP_LEAK_1 = 0
- SUM_ERR_VAP_LEAK_1 = 0

Activation:

If STATE_DIAGCP = 1 – 10H (leak diagnosis); 15-16H (VAP_CHK)
then diagnosis for the symptom **VAP_LEAK_1** is available
LV_CDN_DIAG_VAP_LEAK_1 = 1
else diagnosis for the symptom **VAP_LEAK_1** is not available
LV_CDN_DIAG_VAP_LEAK_1 = 0
endif

Formula section:

If C_T_2_DIAGCP is elapsed **or** LV_VAP_CHK_END = 1
or (STATE_DIAGCP = DLY_DIAG (9H)
and DTP_MV <= C_DTP_DIAGCP
and C_DTP_MAX_REC_DIAGCP is reached)
(state DTP_DIAG is finished or state VAP_CHK is finished or 'leak-free')

then

If { (C_DIAM_MAX_DIAGCP > FAC_DIAM_DIAGCP > C_DIAM_MIN_DIAGCP and
EOL_STATE_DIAGCP = EOL_PAS) // at normal test
or
(C_DIAM_MAX_DIAGCP_EOL > FAC_DIAM_DIAGCP > C_DIAM_MIN_DIAGCP_EOL and
EOL_STATE_DIAGCP <> EOL_PAS) } // at EOL test

then **if** LV_DTP_SLOP = 0
then symptom **VAP_LEAK_1** is active

B.11.2.1.3 Evaporative emission control diagnostic error – 1.0 mm

General information:

The symptom name is **VAP_LEAK_2 (1mm)**. The error is detected as soon as the leakage diameter (FAC_DIAM_DIAGCP) exceeds a limit. And no more leak check will be performed at the same driving cycle after 1.0 mm leak is detected.

For VAP_LEAK_1 (0.5mm) MIL management during VAP_LEAK_2 diagnosis, software refers to DTC (P0456 : very small leak).

Description:

Error-symtoms are defined to this diagnosis function as following :

```
□□□□
 │ │ │ └─> -    VAP_LEAK_2          (= SYM_0)
 │ │ └───> -                        (= SYM_1)
```

T_DLY_2_FUC_MISS_DIAG	LV_END_DIAG_VAP_LEAK_1	LV_END_DIAG_VAP_LEAK_2	LV_END_DIAG_VAP_LEAK_1_MIL
V_DTP_MAX_DIAG	V_DTP_MIN_DIAG	C_V_DTP_THD_DIAG	

B.11.3.1 Fuel cap missing detection during leak detection algorithm

General information:

The symptom name is **FUC_MISS.**

Error detection:

The pressure in the tank system DTP does not drop by at least C_DTP_DIF_MIN_DIAG during evacuation. Alternatives to a missing tank cap is a very large leakage, the evaporative emission control valve may stuck in the closed position or the DTP signal “clamps” (DTP plausibility error)

Description:

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -   FUC_MISS (detection during EVAP)          (= SYM_0)
 │ │ └───> -                                             (= SYM_1)
```

Application conditions:

Initialisation: at new driving cycle

– LV_ERR_FUC_MISS = 0

Activation:

If STATE_DIAGCP = 8H (DTP_EVAC state)
then diagnosis for the symptom **FUC_MISS** is available
LV_CDN_DIAG_FUC_MISS = 1
else diagnosis for the symptom **FUC_MISS** is not available
LV_CDN_DIAG_FUC_MISS = 0
endif

Formula section:

If DTP_DIF_ACT >= C_DTP_DIF_MIN_DIAGCP
and V_DTP_MAX_DIAG – V_DTP_MIN_DIAG >= C_V_DTP_THD_DIAG
then symptom **FUC_MISS** is active
ERR_SYM_FUC_MISS = SYM_0
LV_ERR_FUC_MISS = 1
LV_ERR_DIAGCP_2 = 1 (global error bit is active)
LV_END_DIAG_FUC_MISS = 1
LV_END_DIAG_VAP_LEAK_1 = 1
LV_END_DIAG_VAP_LEAK_2 = 1
LV_END_DIAG_VAP_LEAK_1_MIL = 1

else symptom **FUC_MISS** is not active
ERR_SYM_FUC_MISS = NO_SYM
ERR_SYM_FUC_MISS_1 = NO_SYM
LV_ERR_FUC_MISS = 0 (reset error bit; if already set)
LV_ERR_FUC_MISS_1 = 0 (reset error bit; if already set)
LV_ERR_DIAGCP_2 = 0 (reset error bit; if already set)
LV_END_DIAG_FUC_MISS = 1
endif

Special treatment for readyness generation:

If STATE_DIAGCP changes 8 $\rightarrow$ 9 (State DTP_EVAC passed)
then symptom **FUC_MISS** and **FUC_MISS_1** is **available** and **inactive**
and readyness detection for these symptoms has been performed in this driving cycle

Application assistances:

No other functions concerned.

B.11.3.2 Fuel Cap Missing detection out of leak detection algorithm – Error Management

General information:

The symptom name is **FUC_MISS_1.**

Description:

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
│ │ │ └─> -                (= SYM_0)
│ │ └───> FUC_MISS_1       (= SYM_1)
```

Application conditions:

Initialisation: at new driving cycle

– LV_ERR_FUC_MISS_1 = 0

Activation:

If T_DLY_2_FUC_MISS_DIAG is running
then diagnosis for symptom **FUC_MISS_1** is available
LV_CDN_DIAG_FUC_MISS_1 = 1
else diagnosis for symptom **FUC_MISS_1** is not available
LV_CDN_DIAG_FUC_MISS_1 = 0
endif

Formula section:

```
If       DTP_DIF_FUC_MISS_DIAG > C_DTP_THD_FUC_MISS
         (during T_DLY_2_FUC_MISS_DIAG is running)
then     LV_ERR_DIAGCP_2 = 1     (global error bit is active)

    if   LC_FMY_ACT_FUC_MISS_DIAG = 1
    then symptom FUC_MISS_1 is active
         ERR_SYM_FUC_MISS_1 = SYM_1
         LV_ERR_FUC_MISS_1 = 1
         LV_END_DIAG_FUC_MISS_1 = 1
    else symptom FUC_MISS_1 is not active
         ERR_SYM_FUC_MISS_1 = NO_SYM
              if    T_DLY_2_FUC_MISS_DIAG is elapsed
              then  LV_END_DIAG_FUC_MISS_1 = 1
              endif
    endif

else     symptom FUC_MISS_1 is inactive
         ERR_SYM_FUC_MISS_1 = NO_SYM
         LV_ERR_FUC_MISS_1 = 0
         if    T_DLY_2_FUC_MISS_DIAG is elapsed
         then  LV_END_DIAG_FUC_MISS_1 = 1
               if    LC_FMY_ACT_FUC_MISS_DIAG = 1
               then  symptom FUC_MISS is inactive
                     ERR_SYM_FUC_MISS = NO_SYM
                     LV_ERR_FUC_MISS = 0
                     LV_ERR_DIAGCP_2 = 0     (global error bit is inactive)
               endif
         endif
endif
```

Application hint for LC_FMY_ACT_FUC_MISS_DIAG:

⇒ LC_FMY_ACT_FUC_MISS_DIAG = 1: Failure memory and MIL evaluation are active
⇒ LC_FMY_ACT_FUC_MISS_DIAG = 0: Failure memory and MIL evaluation are not active

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit

B.12.4 Interface to Rate Base Monitoring Module

B.12.4.1 Definition of common Bit 2 setting for all diagnosis performed during Evaporative System Monitoring

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_STATE_RBM_EVAP_BIT_2	O/V	0 ... 7H	0 ... 7H	1	-
Boolean to indicate that individual RBM conditions for EVAP Monitoring are fullfilled					
T_AST_EVAP_RBM	V	0...FFFFH	0...65535	1	s
Comulative time (depending on ambient temperature) since engine start					

Input data:

TAM	TCO_ST	TAM_ST	

FUNCTION DESCRIPTION

Description:

For the interface to RBM module, Bit 2 of STATE_RBM_xxx is used to show if individual conditions to detect an “RBM driving cycle” are set. In this chapter are defined conditions to set Bit2 for STATE_RBM of EVAP monitoring.

Application conditions:

Initialisation: LV_STATE_RBM_EVAP_BIT_2 = 0

T_AST_EVAP_RBM = 0

Recurrence: 1 sec.

Formula section:

Cumulative time (depending on ambient temperature) since engine start:

If C_TAM_MIN_EVAP_RBM <= TAM <= C_TAM_MAX_EVAP_RBM
(ambient temperature greater than or equal to 40 degrees Fahrenheit but less than or equal to 95 degrees Fahrenheit)

then **if** T_AST_EVAP_RBM >= C_T_AST_EVAP_RBM

then T_AST_EVAP_RBM keeps old value

else T_AST_EVAP_RBM = T_AST_EVAP_RBM + 1s

endif

else no incrementation of T_AST_EVAP_RBM

endif

Bit 2 - Coordination of STATE_RBM_xx for diagnosis running during EVAP monitoring:

If LV_STATE_RBM_EVAP_BIT_2 = 0

then **if** T_AST_EVAP_RBM >= C_T_AST_EVAP_RBM
(time since start is greater than or equal to 600 seconds)

and C_TCO_ST_MIN_EVAP_RBM <= TCO_ST <= C_TCO_ST_MAX_EVAP_RBM
(engine coolant temperature at engine start is greater than or equal to 40

degrees Fahrenheit but less than or equal to 95 degrees Fahrenheit)

and TCO_ST <= (TAM_ST + C_TAM_ST_HYS_EVAP_RBM)
(less than or equal to 12 degrees Fahrenheit higher than ambient temperature at engine start

then LV_STATE_RBM_EVAP_BIT_2 = 1

endif

endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TAM_MIN_EVAP_RBM	-	0...FEH	-48...142.5	0.75	°C
Minimum ambient temperature threshold for EVAP_RBM					
C_TAM_MAX_EVAP_RBM	-	0...FEH	-48...142.5	0.75	°C
Maximum ambient temperature threshold for EVAP_RBM					
C_T_AST_EVAP_RBM	-	0...FFFFH	0...65535	1	s
Minimum comulative time since engine start for incrementation of the evaporative system monitor denominator					
C_TCO_ST_MIN_EVAP_RBM	-	0...FEH	-48...142.5	0.75	°C
Minimum engine start temperature threshold for EVAP_RBM					
C_TCO_ST_MAX_EVAP_RBM	-	0...FEH	-48...142.5	0.75	°C
Maximum engine start temperature threshold for EVAP_RBM					
C_TAM_ST_HYS_EVAP_RBM	-	0...FEH	0...190. 5	0.75	°C
Ambient temperature hysteresis for EVAP_RBM					

B.12.4.2 RBM interface for the detection of a 'noisy' DTP sensor signal (ERR_DTP_NOISE)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_DTP_NOISE	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor 'noisy' DTP sensor signal for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_DTP_NOISE	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of noisy DTP sensor failure, for application purposes					

Input data:

STATE_DIAGCP	CTR_COMP_RBM_DTP_NOISE	CTR_CDN_RBM_DTP_NOISE	
LV_INH_DIAGCP	LV_END_DIAG_DTP_NOISE		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CPS Mechanical failure and the Rate-Based Monitoring statistics is defined with STATE_RBM_DTP_NOISE data.

Within STATE_RBM_DTP_NOISE three different information are defined:

Information about bit 0 of STATE_RBM_DTP_NOISE:

Conditions for monitoring are met long enough to detect malfunction (no intrusive operation, no short trip)

Information about bit 1 of STATE_RBM_DTP_NOISE:

Monitor disabled because of system malfunction

Information about bit 2 of STATE_RBM_DTP_NOISE:

Monitor individual RBM conditions encountered within this DC

Application conditions:

Initialisation: *at ECU reset and LV_DC 0 → 1 transition :*
STATE_RBM_DTP_NOISE = 0
on failure memory reset :
bit 1 of STATE_RBM_DTP_NOISE = 0

Recurrence: 1 sec.

Activation: LV_DC = 1

De-activation: LV_DC = 0

Formula section:

```

```

B.12.4.3 RBM interface for CPS failure (ERR_MEC_CPS)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_MEC_CPS	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor CPS Mechanical failure for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_MEC_CPS	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of CPS Mechanical failure, for application purposes					

Input data:

STATE_DIAGCP	CTR_COMP_RBM_MEC_CPS	CTR_CDN_RBM_MEC_CPS	
LV_INH_DIAGCP	LV_END_DIAG_MEC_CPS		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CPS Mechanical failure and the Rate-Based Monitoring statistics is defined with STATE_RBM_MEC_CPS data.

Within STATE_RBM_MEC_CPS three different information are defined:

Information about bit 0 of STATE_RBM_MEC_CPS:

Conditions for monitoring are met long enough to detect malfunction (no intrusive operation, no short trip)

Information about bit 1 of STATE_RBM_MEC_CPS:

Monitor disabled because of system malfunction

Information about bit 2 of STATE_RBM_MEC_CPS:

Monitor individual RBM conditions encountered within this DC

Application conditions:

Initialisation: *at ECU reset and LV_DC 0 → 1 transition :*

STATE_RBM_MEC_CPS = 0

on failure memory reset :

bit 1 of STATE_RBM_MEC_CPS = 0

Recurrence: 1 sec.

Activation: LV_DC = 1

De-activation: LV_DC = 0

Formula section:

```
If      bit 0 of STATE_RBM_MEC_CPS = 0    (Numerator increment condition)
then    if    {     STATE_DIAGCP >= 7h    (Vapor generation check (6h) finished)
              and   STATE_DIAGCP <> Bh      (No wait period)       }
              or    LV_END_DIAG_MEC_CPS = 1
        then  bit 0 of STATE_RBM_MEC_CPS = 1
        endif
endif

If      bit 1 of STATE_RBM_MEC_CPS = 0
then    if    LV_INH_DIAGCP = 1  (Diagnosis inhibited)
        then  bit 1 of STATE_RBM_MEC_CPS = 1
        endif
endif
```

- No special condition defined in CARB Mail-out for MEC_CPS diagnosis

Bit 2 of STATE_RBM_MEC_CPS = 1 (always)

Calculation of actual RBM rate (for application purposes)

```
If      CTR_CDN_RBM_MEC_CPS_DIAG = 0
then    RATE_RBM_MEC_CPS = FFFFH
else    RATE_RBM_MEC_CPS
                 = ( CTR_COMP_RBM_MEC_CPS / CTR_CDN_RBM_MEC_CPS )
endif
```

B.12.4.4 RBM interface for “Small Leak” (0,5 and 1mm Leak)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_VAP_LEAK_1	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor EVAP Small Leakage for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_VAP_LEAK_1	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of EVAP Small Leakage, for application purposes					

Input data:

	CTR_COMP_RBM_VAP_LEAK_1	CTR_CDN_RBM_VAP_LEAK_1	
LV_STATE_RBM_EVAP_BIT_2	LV_INH_DIAGCP	SUM_DIAG_VAP_LEAK_1	

FUNCTION DESCRIPTION:

General information:

With this module the interface between the EVAP Small Leakage failure and the Rate-Based Monitoring statistics is defined with STATE_RBM_VAP_LEAK_1 data.

Within STATE_RBM_VAP_LEAK_1 three different information are defined:

Information about bit 0 of STATE_RBM_VAP_LEAK_1:

Conditions for monitoring are met long enough to detect malfunction (no intrusive operation, no short trip)

Information about bit 1 of STATE_RBM_VAP_LEAK_1:

Monitor disabled because of system malfunction

Information about bit 2 of STATE_RBM_VAP_LEAK_1:

Monitor individual RBM conditions encountered within this DC

Application conditions:

Initialisation: *at ECU reset and LV_DC 0 → 1 transition :*

STATE_RBM_VAP_LEAK_1 = 0

on failure memory reset :

bit 1 of STATE_RBM_VAP_LEAK_1 = 0

Recurrence: 1 sec.

Activation: LV_DC = 1

De-activation: LV_DC = 0

Formula section:

If bit 0 of STATE_RBM_VAP_LEAK_1 = 0 (Numerator increment condition)
then **if** SUM_DIAG_VAP_LEAK_1 = 1 (1st diagnosis at multiple check)
then bit 0 of STATE_RBM_VAP_LEAK_1 = 1
endif
endif

If bit 1 of STATE_RBM_VAP_LEAK_1 = 0
then **if** LV_INH_DIAGCP = 1 (Diagnosis inhibited)
then bit 1 of STATE_RBM_VAP_LEAK_1 = 1
endif
endif

- As special conditions for EVAP monitoring are defined in CARB Mail-out, common flag LV_STATE_RBM_EVAP_BIT_2 is used to set Bit 2 :

Bit 2 of STATE_RBM_VAP_LEAK_1 = LV_STATE_RBM_EVAP_BIT_2

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_VAP_LEAK_1_DIAG = 0
then RATE_RBM_VAP_LEAK_1 = FFFFH
else RATE_RBM_VAP_LEAK_1
= (CTR_COMP_RBM_VAP_LEAK_1 / CTR_CDN_RBM_VAP_LEAK_1)
endif

B.12.4.5 RBM interface for “Large Leak” (Large Leak or Tank Cap missing out of EVAP monitoring)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_FUC_MISS_1	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor EVAP Large Leakage for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_FUC_MISS_1	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of EVAP Large Leakage, for application purposes					

Input data:

LV_END_DIAG_FUC_MISS_1	CTR_COMP_RBM_FUC_MISS_1	CTR_CDN_RBM_FUC_MISS_1	
LV_STATE_RBM_EVAP_BIT_2			

FUNCTION DESCRIPTION:

General information:

With this module the interface between the Tank Cap missing failure and the Rate-Based Monitoring statistics is defined with STATE_RBM_FUC_MISS_1 data.

Within STATE_RBM_FUC_MISS_1 three different information are defined:

Information about bit 0 of STATE_RBM_FUC_MISS_1:

Conditions for monitoring are met long enough to detect malfunction (no intrusive operation, no short trip)

Information about bit 1 of STATE_RBM_FUC_MISS_1:

Monitor disabled because of system malfunction

Information about bit 2 of STATE_RBM_FUC_MISS_1:

Monitor individual RBM conditions encountered within this DC

Application conditions:

Initialisation: *at ECU reset and LV_DC 0 → 1 transition :*
STATE_RBM_FUC_MISS_1 = 0
on failure memory reset :
bit 1 of STATE_RBM_FUC_MISS_1 = 0

Recurrence: 1 sec.

Activation: LV_DC = 1

De-activation: LV_DC = 0

Formula section:

```
If      bit 0 of STATE_RBM_FUC_MISS_1 = 0    (Numerator increment condition)
then    if      LV_END_DIAG_FUC_MISS_1 = 1

                    CTR_CDN_RBM_FUC_MISS_1 )
endif
```

B.12.4.6 Counters to determine why EVAP monitoring not running in case of Idle phase longer than 30 sec.

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_EVAP_T_IS	V/S	0...FFH	0...255	1	-
Total number of 30 sec. Idle phases with vehicle stopped to perform EVAP monitoring					
CTR_EVAP_T_DLY_3	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP monitoring disabled because system still in “Wait” period					
CTR_EVAP_DTP_DIAG	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. still running (DTP_DIAG) after 30 sec.					
CTR_EVAP_DIAGCP_START	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. disabled due to system not ready					
CTR_EVAP_INTR_DIAGCP	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is started but aborted before it is finished					
CTR_EVAP_TCO	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is not started because TCO is too low					
CTR_EVAP_T_AST	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is not started because time after Start is too low					
CTR_EVAP_T_PL_DIAGCP	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is not started because T_PL_DIAGCP > 0					
CTR_EVAP_INTR_1	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to too high vapor generation					
CTR_EVAP_INTR_2	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to too big Lambda cotnroller deviation					
CTR_EVAP_INTR_4	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to too high MAF fluctuation					
CTR_EVAP_INTR_5	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to too high DTP slope variation					
CTR_EVAP_INTR_12	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to fuel level out of range					
CTR_EVAP_INTR_10	V/S	0...FFH	0...255	1	-
Number of Idle phases where EVAP mon. is aborted due to other condition					
LV_T_DLY_3	V	0...1H	0...1	1	-
Boolean flag to indicate if STATE_DIAGCP = “T_DLY_3” at the beginning of an Idle phase with VS = 0					
LV_INC_CTR_EVAP	V	0...1H	0...1	1	-
Boolean flag to indicate that CTR_EVAP_xx counters can be incremented					

Input data:

T_IS	STATE_DIAGCP	C_TAM_MIN_EVAP_RBM	TAM
C_T_IS_RBM	T_AST	C_TAM_MAX_EVAP_RBM	VS
T_PL_DIAGCP	ID_T_AST_MIN_DIAGCP	C_TCO_MIN_DIAGCP	TCO
STATE_INTR_DIAGCP	ID_T_AST_MIN_DIAGCP_2	TCO_ST	

FUNCTION DESCRIPTION:

General information:

Target of this module is to monitor inside ECU why is EVAP monitoring not peformed if there is an Idle phase with vehicle stopped longer than 30 sec. To improve as much as possible in-use performance ratio, reason why EVAP monitoring is not performed is determined via some counters (14) :

- Global counter CTR_EVAP_T_IS is counting number of Idle phases with vehicle stopped longer than 30 sec.

- Main counters (CTR_EVAP_T_DLY_3, CTR_EVAP_DTP_DIAG, CTR_EVAP_DIAGCP_START, CTR_EVAP_INTR_DIAGCP) are checking if EVAP monitoring is :
    - Not started because system in "Wait" state (CTR_EVAP_T_DLY_3)
    - Not started because system is not ready (CTR_EVAP_DIAGCP_START)
    - Started but not finished (CTR_EVAP_DTP_DIAG -> Diagnosis still on-going after 30 sec., CTR_EVAP_INTR_DIAGCP -> Diagnosis aborted)

- Sub-counters give more informations why was EVAP monitoring not started or aborted (TCO too low, Time after Start too low, Purge time in Part Load too low, Vapor generation too high, Lambda deviation too high, MAF variation too high, DTP slope variation during evacuation too high, Fuel level out of range....)

Application conditions:

Initialisation: If ECU is brand new or LC_CTR_EVAP_RST = 1, then all CTR_EVAP_xxx are initialised to 0

Recurrence: 500 msec.

Activation: LV_DC = 1

De-activation: LV_DC = 0

Formula section:

- Definition of LV_T_DLY_3 (*check if STATE_DIAGCP = "T_DLY_3" at the beginning of Idle phase with VS = 0*) :

If $TI\_IS_{(n)} < T\_IS_{(n-1)}$ (*TI_IS reseted -> New Idle phase with VS = 0*)
Then
  If STATE_DIAGCP = "T_DLY_3"
  Then LV_T_DLY_3 = 1
  Else LV_T_DLY_3 = 0
  Endif
Endif

- Check there is a new Idle phase with vehicle stopped longer than 30 sec. -> CTR_EVAP_xx to be incremented (LV_INC_CTR_EVAP) :

If STATE_DIAGCP <> "PAS" (*EVAP monitoring not yet performed*)
  and T_IS > C_T_IS_RBM (*Idle phase with vehicle stopped of more than 30sec.)*
  and C_TAM_MIN_EVAP_RBM < TAM < C_TAM_MAX_EVAP_RBM
  (*Ambient temperature limits to set Bit 2 of STATE_RBM for EVAP monitoring*)
Then
  LV_INC_CTR_EVAP = 1
Else
  LV_INC_CTR_EVAP = 0

- Check why EVAP monitoring was not completed in case of long Idle phase with vehicle stopped:

If (1) Transition LV_INC_CTR_EVAP = 0 -> 1
Then (1) CTR_EVAP_T_IS = CTR_EVAP_T_IS + 1
(*Total number of Idle phases where possible to perform EVAP monitoring)*
If (2) LV_T_DLY_3 = 1 (*STATE_DIAGCP = "T_DLY_3 since begin of Idle*)
Then (2) CTR_EVAP_T_DLY_3 = CTR_EVAP_T_DLY_3 + 1
Else (2)
If (3) STATE_DIAGCP = "DLY_DIAG" **or** "DTP_DIAG" (*diagnosis on-going at take-off*)
Then (3) CTR_EVAP_DTP_DIAG = CTR_EVAP_DTP_DIAG + 1
Else (3)
If (4) STATE_DIAGCP = "START" (*diagnosis not ready to Start*)
Then (4) CTR_EVAP_DIAGCP_START = CTR_EVAP_DIAGCP_START+1
(*Total number of EVAP monitoring disabled due to system not ready*)
If TCO < C_TCO_MIN_DIAGCP
Then CTR_EVAP_TCO = CTR_EVAP_TCO + 1
If T_AST < max (ID_T_AST_MIN_DIAGCP, ID_T_AST_MIN_DIAGCP_2)
Then CTR_EVAP_T_AST = CTR_EVAP_T_AST + 1
If T_PL_DIAGCP > 0
Then CTR_EVAP_T_PL_DIAGCP=CTR_EVAP_T_PL_DIAGCP+1
Else (4)
If (5) STATE_DIAGCP = "T_DLY_3" **or** "ERR_CLOSE_CPS"
(*Diagnosis was started but aborted before finished*)
Then (5) CTR_EVAP_INTR_DIAGCP = CTR_EVAP_INTR_DIAGCP+1
If Bit 1 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_1 = CTR_EVAP_INTR_1 + 1
(*vapor generation too high*)
If Bit 2 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_2 = CTR_EVAP_INTR_2 + 1
(*Lambda deviation too high during evacuation*)
If Bit 4 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_4 = CTR_EVAP_INTR_4 + 1
(*MAF variation too high during evacuation*)
If Bit 5 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_5 = CTR_EVAP_INTR_5 + 1
(*DTP slope variation during evacuation too high*)
If Bit 12 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_12 = CTR_EVAP_INTR_12 + 1
(*Fuel level out of range*)
If Bit 10 of STATE_INTR_DIAGCP = 1
Then CTR_EVAP_INTR_10 = CTR_EVAP_INTR_10 + 1
(*Interruption due to other condition*)
Endif (5)
Endif (4)
Endif (3)
Endif (2)
Endif (1)

Calibration data:

General information:

The objective function of the fuel system diagnosis is to monitor the lambda control output and the lambda adaptation values in various areas. It should also cover the PCV monitoring where the lambda control output is considered in the idle range. Breaking the adaptation and lambda controller limits for a long time, which may have been caused by failures in the fuel or intake system will involve emission rise and therefore shall be diagnosed by fuel system diagnosis. Fuel system diagnosis is active as soon as the general activation conditions are fulfilled and the lambda controller is activated. That means the function monitors the lambda controller output independent on whether the lambda adaptation is activated. As soon as the lambda controller limits are exceeded (after an applicable time), the request for lambda adaptation will be set (LV_LAM_LIM_MFF_AD_i = 1). Figure 1 shows the monitoring area of fuel system diagnosis where the activation area of lambda adaptation is subset of lambda controller activation area. The diagnosis action is exemplary shown in Figure 2 for lambda controller output limited.

FSD errors are located in three failure memories with two and four symptoms each:

ERR_SYM_FSD_i:

NO_SYM:	no symptom
SYM_0:	maximum limit of additive adaptation value reached
SYM_1:	minimum limit of additive adaptation value reached
SYM_2:	maximum limit of multiplicative adaptation value (lower area) reached
SYM_3:	minimum limit of multiplicative adaptation value (lower area) reached

ERR_SYM_FSD_FAC_H_i:

NO_SYM:	no symptom
SYM_0:	maximum limit of multiplicative adaptation value (upper area) reached
SYM_1:	minimum limit of multiplicative adaptation value (upper area) reached

ERR_SYM_FSD_LAM_LIM_i:

NO_SYM:	no symptom
SYM_0:	lambda control in dead stop (upper limit)
SYM_1:	lambda control in dead stop (lower limit)

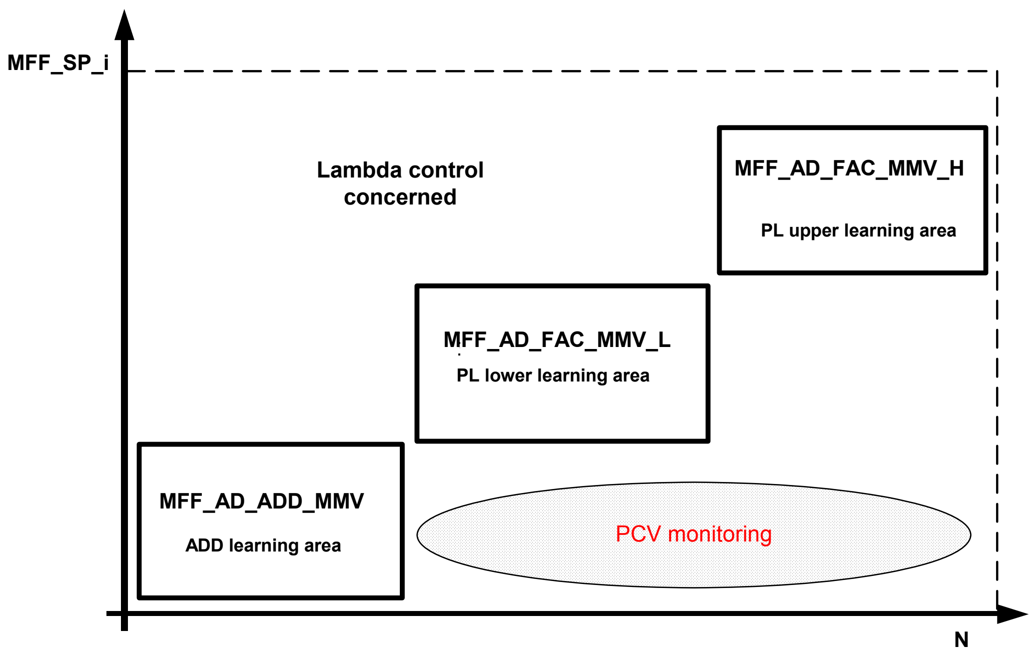

Figure 1: Monitoring area of fuel system diagnosis

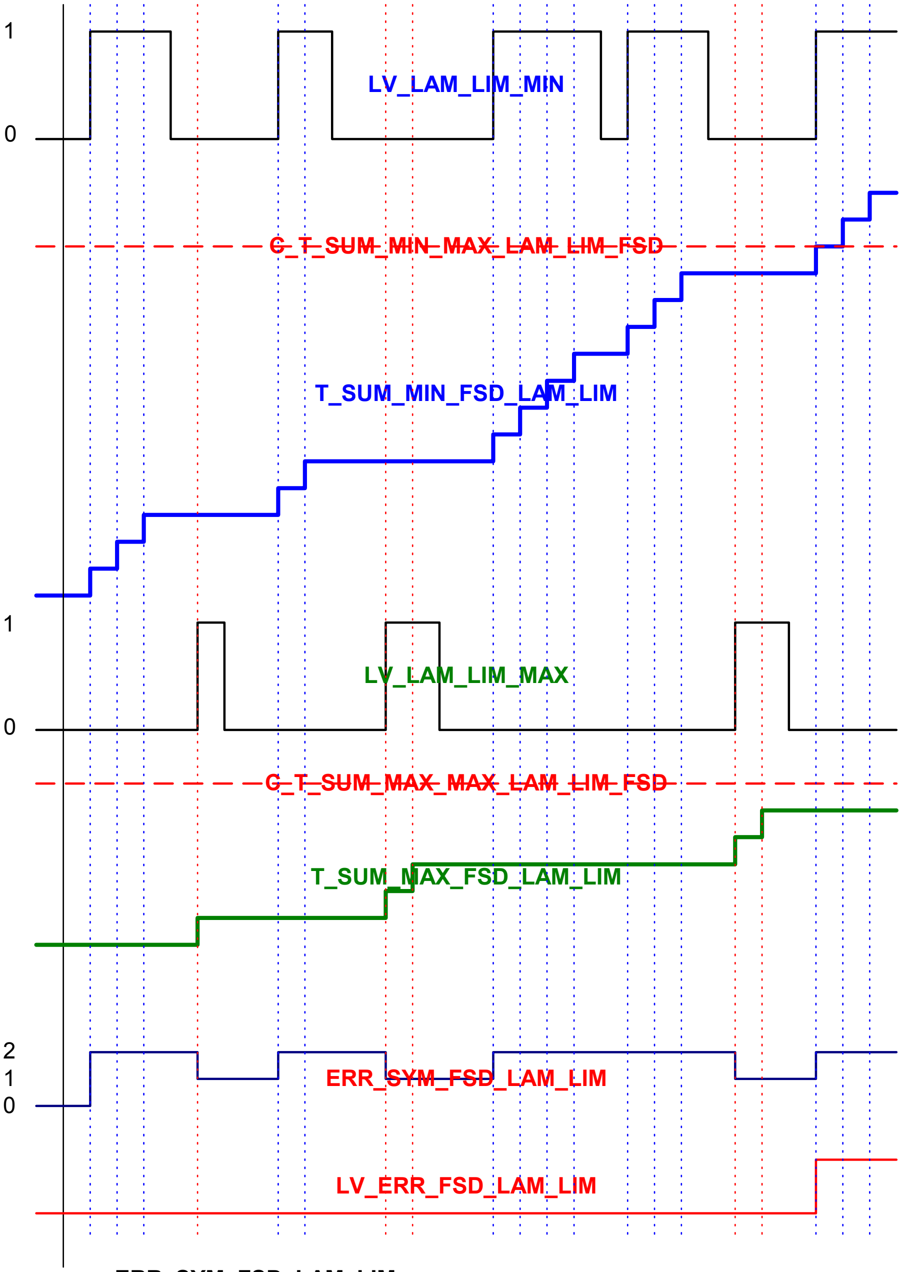

ERR_SYM_FSD_LAM_LIM=:
0: no symptom
1: lambda control in dead stop (upper limit)
2: lambda control in dead stop (lower limit)

Figure 2: Example of diagnosis action in case of lambda control in dead stop

ERR_SYM_FSD_i	=	0
ERR_SYM_FSD_FAC_H_i	=	0
ERR_SYM_FSD_LAM_LIM_i	=	0

CTR_STOP_FSD is restored out of the non-volatile memory.

At reset, LV_DC = 0 → 1 and clear error memory:

LV_END_DIAG_FSD_i	=	0
LV_END_DIAG_FSD_FAC_H_i	=	0
LV_END_DIAG_FSD_LAM_LIM_i	=	0

Only at reset:

TOIL_MAX = TOIL_MDL_FSD **and** calculate $ID\_STOP\_DEC\_FSD_{n-1}$ based on TOIL_MAX

B.13.2 Fuel system diagnosis inhibition due to fuel dilution in engine oil

For high rate of evaporated fuel (diluted in the engine oil) during the rich warm-up phase under cold start conditions, the lambda controller may reach the rich side limitation C_LAM_MIN. In this case, in order to prevent an error display, the fuel system diagnosis shall be deactivated.
According to TCO_ST the corresponding counter CTR_STOP_FSD is incremented once at every transition from engine stop to engine start. According to the maximum oil temperature during the last engine run the counter is decremented at every engine stop. The maximum oil temperature during last engine run is always calculated out of TOIL_MDL_FSD.

Incremental feed:

if LV_ES = 1 → LV_ST = 1 (*engine operating state: "engine stopped → start"*)

then

$CTR\_STOP\_FSD_n = CTR\_STOP\_FSD_{n-1} + ID\_STOP\_INC\_FSD\_\_TCO\_ST$

endif

Decrementing:

The decremental action of CTR_STOP_FSD shall be updated every 1 second on following condition:

if $ID\_STOP\_DEC\_FSD_n > ID\_STOP\_DEC\_FSD_{n-1}$

then

$CTR\_STOP\_FSD_n = CTR\_STOP\_FSD_{n-1} - (ID\_STOP\_DEC\_FSD_n - ID\_STOP\_DEC\_FSD_{n-1})$

endif

Recurrence: 20 ms

Activation:

- all engine operating states

Deactivation:

-

Formula section:

B.13.3 Oil temperature calculation (TOIL_MAX)

TOIL_MAX **=** max (TOIL_MDL_FSD) during the last engine running (LV_ES = 0)

FUNCTION DESCRIPTION:

General information:

LV_INH_DIAG_FSD represents the influence by errors deactivating the Fuel system diagnosis.
LV_INH_DIAG_FSD_CP respects a maximum threshold for the charcoal canister load in specific states of STATE_CP.
If LC_INH_FSD_MAN_DEAC is 1 the FSD diagnosis is not inhibited by a present error.

Description:

Application conditions:

Initialisation: *at LV_IGK = 0 -> 1, reset and clear error memory*

all variables are initialised with 0

Recurrency: *20ms*

Activation: *at all engine states*

Formula section:

Input data:

N	MAF	TPS_GRD	LAM_MV_i
LV_IGK	LV_ST_END	MAF_KGH	LV_AFL[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

For a twin branch exhaust line the calculation of the limited dynamic condition LV_LDC_CAT_i has the same structure for both exhaust lines and is calculated for each line separately. To differentiate variables and calibration data the index i is used.

i = 1, for cylinder bank 1
i = 2, for cylinder bank 2

The limited dynamic conditions LV_LDC_CAT_i for catalyst efficiency and OBDII oxygen sensor diagnosis exists and is set high if the limited dynamic conditions for engine speed (1.1), mass air flow (1.2) and LAM_MV_i (1.3) exist and the threshold C_MAF_INT_MIN_CAT for the integral of the air flow is exceeded. Moreover the summation of the trottel position gradient TPS_GRD_SUM_i must not exceed C_TPS_GRD_SUM_MAX.

Application conditions:

Recurrence: Ta = 0.02 s

Activation: LV_ES = 0 **AND** LV_ST = 0 % after leaving the engine state ST

Deactivation: LV_ES = 1

B.15.1 Limited engine speed (N) dynamics

The floating mean value N_MMV_CAT is computed using the averaging constant C_N_CRLC_CAT. The limited dynamics condition only exist while the engine speed N lies within the dynamics window around N_MMV_CAT:
If the above limited dynamics condition is violated, the floating mean value N_MMV_CAT is set to the current engine speed in order to reach the limited dynamics condition faster:

Formula section:
N_MMV_CAT = N_MMV_CAT * (1 -C_N_CRLC_CAT) + C_N_CRLC_CAT * N

```
IF | N - N_MMV_CAT | < C_N_DYW_CAT
THEN
    LV_N_LDC = 1
ELSE
    LV_N_LDC = 0
    N_MMV_CAT = N
END
```

B.15.2 Limited mass air flow (MAF) dynamics

The floating mean value MAF_MMV_CAT is computed using the averaging constant C_MAF_CRLC_CAT. The limited dynamics condition only exist while the air mass MAF stays within the dynamics window around MAF_MMV_CAT:
If the above limited dynamics condition is violated, the floating mean value MAF_MMV_CAT is set to the current air-mass value in order to reach the limited dynamics condition faster:

Formula section:
MAF_MMV_CAT = MAF_MMV_CAT * (1 - C_MAF_CRLC_CAT) +
C_MAF_CRLC_CAT * MAF

```
IF | MAF - MAF_MMV_CAT | < C_MAF_DYW_CAT
THEN
    LV_MAF_LDC = 1
ELSE
    LV_MAF_LDC = 0
    MAF_MMV_CAT = MAF
END
```

B.15.3 Limited mean oxygen value (LAM_MV_i) dynamics

The floating mean value LAM_MV_MMV_CAT_i is computed using the averaging constant C_LAM_MV_CRLC_CAT:

The limited dynamics condition continues to exist while the mean oxygen value LAM_MV_i stays within the dynamics window around LAM_MV_MMV_CATi:
If the above limited dynamics condition is violated, the floating mean value LAM_MV_MMV_CAT_i is set to the current mean oxygen value in order to reach the limited dynamics condition faster:

Formula section:

```
LAM_MV_MMV_CAT_i  =  LAM_MV_MMV_CAT_i * (1 - C_LAM_MV_CRLC_CAT) +
                     C_LAM_MV_CRLC_CAT * LAM_MV_i

IF | LAM_MV_i - LAM_MV_MMV_CAT_i | < C_LAM_MV_DYW_CAT
THEN
    LV_LAM_MV_LDC_i = 1
ELSE
    LV_LAM_MV_LDC_i = 0
    LAM_MV_MMV_CAT_i  = LAM_MV_i
END
```

B.15.4 Limited dynamic bit: LV_LDC_CAT_i

If C_TPS_GRD_SUM_MIN is larger than C_TPS_GRD_SUM_MAX the TPS gradient summation TPS_GRD_SUM will be no conditon to determine the limited dynamic bit LV_LDC_CAT_i

```
IF   LV_N_LDC = 1 AND LV_MAF_LDC = 1 AND LV_LAM_MV_LDC_i = 1
THEN
     IF       MAF_INT_LDC_CAT_i =<  C_MAF_INT_MIN_CAT
     THEN LAM_P_CTR_LDC_CAT       = 0
              MAF_INT_LDC_CAT_i[n+1]  = MAF_INT_LDC_CAT_i[n] +
                                        MAF_KGH * NC_FAC_MAF_INT
                  % NC_FAC_MAF_INT = 20ms/3,6
     ELSE

              T_TPS_GRD_DEC_SUM_i = T_TPS_GRD_DEC_SUM_i + 1

              IF  T_TPS_GRD_DEC_SUM_i > C_TPS_GRD_DEC_SUM
              THEN
                  TPS_GRD_SUM_i[n+1] = TPS_GRD_SUM_i[n] –
                                             C_TPS_GRD_DEC
                          % The decrementation by C_TPS_GRD_DEC is done all
                          % C_TPS_GRD_DEC_SUM calculation intervalls
                  T_TPS_GRD_DEC_SUM_i = 0
              END

              IF      C_TPS_GRD_SUM_MIN < C_TPS_GRD_SUM_MAX
              THEN  % TPS_GRD_SUM is condition for limited dynamic bit
                      IF      LV_LDC_CAT_i = 0
                      THEN  %  limited dynamic bit deactive, activation possible
                              IF      TPS_GRD_SUM_i <= C_TPS_GRD_SUM_MIN
                              THEN  if       LV_AFL = 0 → 1 or LV_AFL = 1 → 0
                                    then     LAM_P_CTR_LDC_CAT(n) =
                                             LAM_P_CTR_LDC_CAT(n-1)  + 1
                                             until C_LAM_P_CTR_LDC_CAT
                                    if       LAM_P_CTR_LDC_CAT ≥ C_LAM_P_CTR_LDC_CAT
                                             % activation of limited dynamic bit
                                    then     LV_LDC_CAT_i = 1
                              END
                      ELSE  % limited dynamic bit active, deactivation possible
                              IF      TPS_GRD_SUM_i > C_TPS_GRD_SUM_MAX
                              THEN  % deactivation of limited dynamic bit
                                    LV_LDC_CAT_i = 0
                                    LAM_P_CTR_LDC_CAT       = 0
                              END
                      END
              ELSE
                      LV_LDC_CAT_i = 1
              ENDIF
     ENDIF
ELSE
     LV_LDC_CAT_i              = 0
     TPS_GRD_SUM               = 0
     MAF_INT_LDC_CAT_i         = 0
     T_TPS_GRD_DEC_SUM_i   = 0
```

LAM_P_CTR_LDC_CAT = 0
ENDIF

*** Remark**
The update rate of LV_AFL is 10 ms and LAM_P_CTR_LDC_CAT is 20 ms.
But, it will not make a problem because normally lean/rich half duration will be surely longer than 20ms and it will be even better to do not count for LV_AFL jittering.

The P-jump counter to set LV_LDC_CAT is used only if C_TPS_GRD_SUM_MIN < C_TPS_GRD_SUM_MAX as otherwise LV_LDC_CAT is set immediately

B.16 Oxygen Sensor Diagnosis Management

B.16.1 Upstream oxygen sensor final diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean error flag, fault currently present on upstream oxygen sensor signal					

Input data:

LV_ERR_EL_LS_UP[NC_CBK_EX_NR]	LV_IGK	LV_ERR_PUC_LS_UP[NC_CBK_EX_NR]	LV_ERR_STK_LS_UP[NC_CBK_EX_NR]
LV_ERR_LSH_UP[NC_CBK_EX_NR]	LV_ERR_OBD_LSH_UP[NC_CBK_EX_NR]	LV_ERR_SWT_LS_UP[NC_CBK_EX_NR]	LV_ERR_FRQ_LS_UP[NC_CBK_EX_NR]
NC_CBK_EX_NR	LV_ST_END	LV_ERR_CHG_LS_UP[NC_CBK_EX_NR]	

FUNCTION DESCRIPTION:

This function summarizes the result of all diagnosis related to the upstream oxygen sensor, which are:

- The upstream sensor heater diagnosis:
  - Electrical failure LV_ERR_LSH_UP[i];
  - OBD2 Failure LV_ERR_OBD_LSH_UP[i];

- The oxygen sensor signal electrical diagnosis (bit LV_ERR_EL_LS_UP[i]), which shall detect the following faults:
  - Short circuit of the oxygen sensor signal line to GND
  - Short circuit of the oxygen sensor signal line to Vbatt
  - Open circuit (line break) in the connection to oxygen sensor element

- The following signal plausibility checks shall be carried out:
  - Overrun fuel cut-off (PUC) oxygen sensor signal plausibility
  - Oxygen sensor signal voltage excursion plausibility

- The OBD2 signal diagnosis:
  - Oxygens sensor switching time monitoring
  - Oxygens sensor control frequency check

- The oxygen sensor swapped signal diagnosis. This diagnosis is intended to detect swapped upstream sensors for systems with two exhaust banks. For one bank system this diagnosis is not active, i.e. LV_ERR_CHG_LS_UP[i] = 0.

LV_DIAG_PLAUS_SYM_LSL_UP[i] is generated to serve a common interface to Appl. Inc. of heater management.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** <u>at clearing error memory</u>:

LV_ERR_LS_UP[i] = 0

Recurrence:

This function shall be carried out every 100ms.

Activation / Deactivation:

The diagnosis will be carried out only if LV_ST_END = 1

Formula section:

If LC_LS_UP_DIAG_ACT[i] = 1
and (LV_ERR_EL_LS_UP[i] = 1

B.16.2 Downstream oxygen sensor final diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_LS_DOWN[NC_CBK_EX_NR]	V/O	0H...1H	0...1	1	-
Final diagnostic of the downstream oxygen sensor					

Input data:

LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]	LV_ST_END	LV_ERR_SWT_LS_DOWN[NC_CBK_EX_NR]	LV_ERR_PUE_LS_DOWN[NC_CBK_EX_NR]
NC_CBK_EX_NR	LV_IGK	LV_ERR_LSH_DOWN[NC_CBK_EX_NR]	LV_ERR_OBD_LSH_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

This function summarizes the result of all diagnosis related to the downstream oxygen sensor, which are:

- The downstream sensor heater diagnosis:
  - Electrical failure LV_ERR_LSH_DOWN[i];
  - OBD2 Failure LV_ERR_OBD_LSH_DOWN[i];

- The oxygen sensor signal electrical diagnosis (bit LV_ERR_EL_LS_DOWN[i]), which shall detect the following faults:
  - Short circuit of the oxygen sensor signal line to GND
  - Short circuit of the oxygen sensor signal line to Vbatt
  - Open circuit (line break) in the connection to oxygen sensor element

- The following signal dynamic and plausibility checks shall be carried out:
  - Monitoring the rich-lean switching times in the trailing throttle fuel cut-off (LV_ERR_SWT_LS_DOWN[i])
  - Monitoring the sensor voltage after leaving trailing throttle fuel cut-off (LV_ERR_PUE_LS_DOWN[i])

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

LV_ERR_LS_DOWN[i] = 0

Recurrence:

The function should be carried out once every 100 ms.

Activation / Deactivation:

The diagnosis will be carried out only if LV_ST_END = 1

Formula section:

If	LC_LS_DOWN_DIAG_ACT[i] = 1
and	(LV_ERR_EL_LS_DOWN[i]= 1
or	LV_ERR_SWT_LS_DOWN[i] = 1
or	LV_ERR_PUE_LS_DOWN[i] = 1
or	LV_ERR_LSH_DOWN[i] = 1
or	LV_ERR_OBD_LSH_DOWN[i] = 1
or	LC_LS_DOWN_ERR[i] = 1)
then	LV_ERR_LS_DOWN[i] = 1
else	LV_ERR_LS_DOWN[i] = 0
endif	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_LS_DOWN_DIAG_ACT[i]	1	0...1H	0...1	1	-
Manual activation bit for downstream oxygen sensor final diagnosis					
LC_LS_DOWN_ERR [i]	1	0...1H	0...1	1	-
Opportunity for manual setting of LV_ERR_LS_DOWN[i] = 1					

B.16.3 Definition of interface flags

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_OBD_VLD_LSH_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating the validation of correspondent symptom (transmitted to the error management)					
LV_ERR_TTIP_OBD_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating that fault is present and has been debounced					

Input data:

NC_CBK_EX_NR	LV_ST_END		

FUNCTION DESCRIPTION:

General information:

Heater OBD2 TTIP error can occur not only due to heater malfunctioning ageing but also due to an *open circuit* in certain sensor lines, therefore this function shall be consulted to validate a symptom given by the WRAF sensor dynamic diagnosis. For BIN/BIN systems the flag is therefore set to 0 as dummy flag.

Application conditions:

Initialisation: at reset or LV_ST_END = 1 all variables are set = 0

Recurrence: This function shall run every 1s (if formula text is added).

Activation / Deactivation:

The diagnosis will be carried out only if LV_ST_END = 1

Formula section:

No formula text defined up to now

DETECTION ALGORITHM

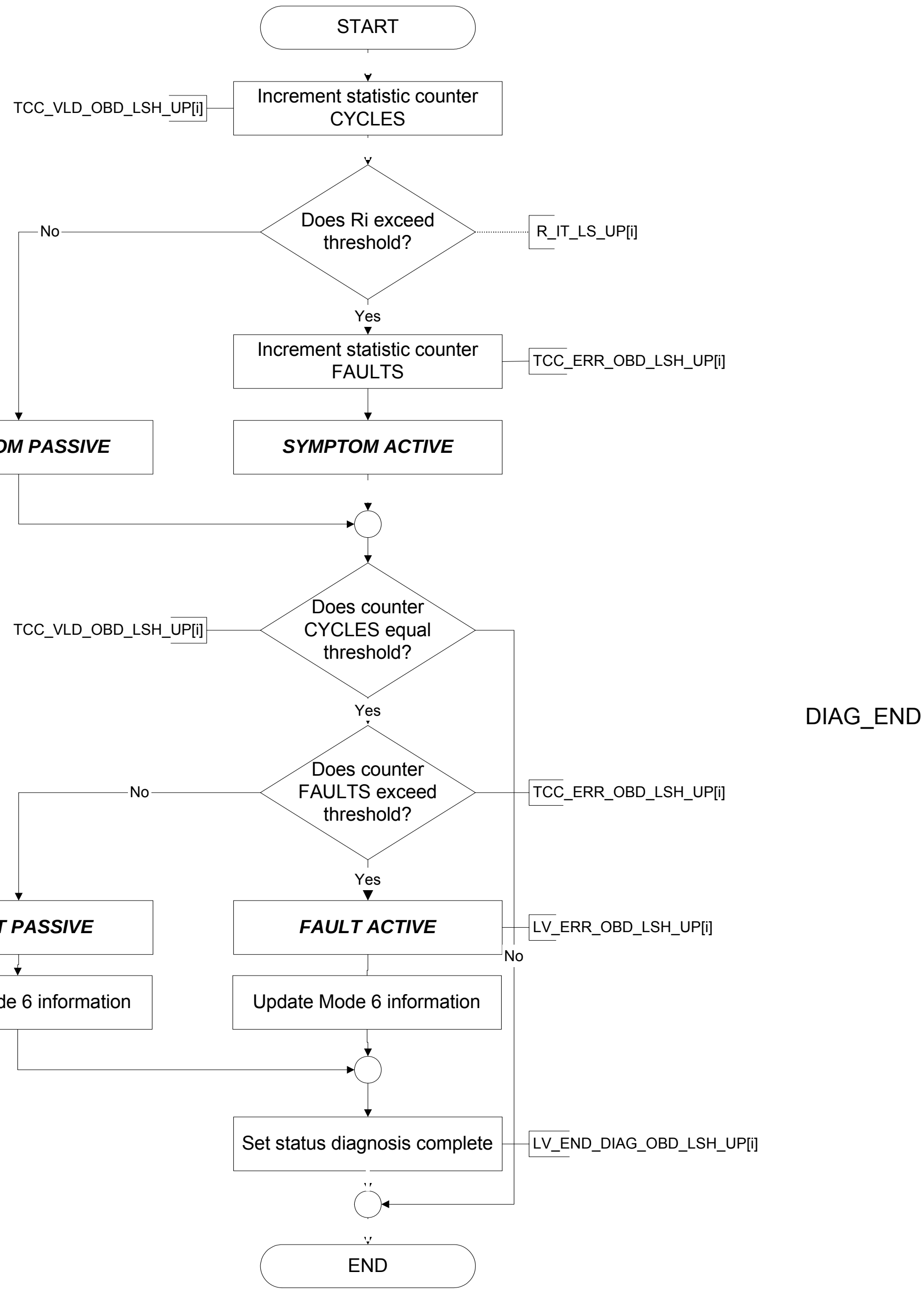
Detection Algorithm:



Description:

The upstream oxygen sensor heater circuit shall detect any loss in heater power that would cause a drop in the sensor operating temperature, thereby possibly causing exhaust gas emissions to rise above the applicable standards or prevent the sensor signal from being used as a diagnostic system monitoring device.

Losses in heater power may occur due to, for example, ageing of the heater element, defective wiring, increased heater cct. connector contact resistance, defective heater driver etc.

The hereafter mentioned diagnosis strategy is based on the comparison of the oxygen sensor internal resistance to an absolute threshold during operating conditions where the exhaust gas temperature has been determined to be sufficiently low as to cause the sensor ceramic temperature to fall outside normal operating levels, in cases where a power is insufficient.

The functionality of the diagnosis may be described in further detail below:

The initial diagnosis application condition; LV_ST_END shall ensure that the engine is running and has left the start phase but not yet entered the engine stop phase, LV_INH_DIAG_OBD_LSH_UP[i] shall ensure that the project specific application conditions (Application Incidences) have been met and LV_END_DIAG_OBD_LSH_UP[i] shall ensure that the diagnosis only be carried out once per driving cycle.

In order to ensure that the sensor has reached its normal operating temperature, the heater management state STATE_LSH_UP[i] shall be determined to be in the open loop control state LSH_POW_CTL, the sensor shall be determined to be in a state of operative readiness via LV_LS_UP_READY[i], the battery voltage VB shall be in a range determined to be fit for carrying out OBD2 diagnosis shown by LV_VB_CDN_OBD_2 and the heater duty-cycle LSHPWM_UP[i] shall be determined to be within calibrateable range C_LSHPWM_MIN_LSH_UP & C_LSHPWM_MAX_LSH_UP.

Should the above initial and operative conditions have been determined to be met, a timer, denoted herein as *TIMER_1*, shall be started. The timer shall run until a calibrateable threshold C_T_DLY_POW_CTL_OBD_LSH_UP is equalled or exceeded. Once this delay has passed, the status of the OBDI error bits LV_ERR_EL_VLS_UP[i] & LV_ERR_LSH_UP[i] shall be read to ensure that no signal electrical or plausibility faults and no heater electrical faults are present in the sensor cct. under test. The delay shall ensure that sufficient time passes to permit completion of the OBDI monitoring prior to the start of OBDII monitoring.

Should no OBDI faults be present, the modelled exhaust gas temperature TEG_DYN_LS_UP[i] shall be compared to a calibrateable threshold C_TEG_DYN_MAX_OBD_LSH_UP. Due tolerances in the determination of the sensor internal resistance and in the case of a functional heater, the maximum resistance value may be given by a minimum tolerance sensor at a much lower temperature than for a maximum tolerance sensor at a higher temperature. Therefore, in the case of diagnosis based on an absolute internal resistance threshold, a certain temperature tolerance exists. The above mentioned temperature threshold shall lie below the minimum temperature determined from analysis of the internal resistance tolerances and be sufficient to cool the sensor ceramic element to below normal operating conditions, in the case of a heater fault.

Should the exhaust gas temperature be determined to equal or fall below the threshold, the monitoring strategy shall ensure that the sensor be cooled sufficiently long by the exhaust gas to enable differentiation between a functional and non-functional heater cct. (The time required is dependent on the thermal capacity of the system at the sensor location and the forced convection cooling of the sensor location). This shall be achieved by integrating the heat flux of the forced convection thermal transfer between sensor and exhaust gas, this being a measure for the cooling energy of the exhaust gas. The heat flux shall be calculated by determining the difference between the typical set sensor operating temperature C_TEMP_SP_OBD_LSH_UP and the modelled exhaust gas temperature TEG_DYN_LS_UP[i] and multiplying the result by the factor IP_FAC_MAF_OBD_LSH_UP representing the heat transfer coefficient and surface area concerned in the thermal transfer. As the heat transfer coefficient is a function of the velocity of the exhaust gas, the factor shall be mapped and dependent on the current mass airflow MAF_KGH.

The resultant integral POW_INT_OBD_LSH_UP[i] shall be compared to a calibrateable threshold C_POW_INT_MIN_OBD_LSH_UP. Each time that the threshold be exceeded for the first time, e.g. first time after engine start or after the power integral has been reset, the CTR_CYCNR_R_IT_OBD_LS_UP[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_UP_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_CYCNR_R_IT_OBD_LS_UP[i] with that of CTR_CYCNR_R_IT_LS_UP_VLD[i]. Should the counters be unequal, then a new value is available and CTR_CYCNR_R_IT_OBD_LS_UP[i] shall be updated with CTR_CYCNR_R_IT_LS_UP_VLD[i]. If this conditions and all the above conditions be met, LV_END_DIAG_OBD_LSH_UP[i] shall be set and the diagnosis shall be considered to be active and the current monitoring cycle valid.

Once the current monitoring cycle has been determined to be valid, a counter TCC_VLD_OBD_LSH_UP[i] shall be incremented, denoting the number of valid monitoring cycles carried out to date. The internal resistance R_IT_LS_UP[i] shall be compared to a threshold IP_R_IT_THD_OBD_LSH_UP which is dependent on the modelled tip temperature of a new sensor (including safety margin) and the number of valid diagnosis cycles TCC_VLD_OBD_LSH_UP. Should the resistance equal or exceed the threshold, a heater fault shall be determined to be present in the current cycle and a counter TCC_ERR_OBD_LSH_UP[i] shall be incremented, denoting the number of heater faults within the valid monitoring cycles carried out to date.

In order to comply with OBDII requirements, the current R_IT_LS_UP[i] value used shall be made available to an external tester. This information is Mode 6 information. Hence once the comparison to the threshold has been carried out, the latest measured internal resistance and threshold values (R_IT_L_MES_OBD_LSH_UP[i] and R_IT_L_REF_OBD_LSH_UP[i]) shall be copied to the respective Mode 6 interface variables R_IT_OBD_LS_UP[i] and R_IT_THD_OBD_LSH_UP[i] for the no error case. In the error case the variables R_IT_H_MES_OBD_LSH_UP[i] and R_IT_H_REF_OBD_LSH_UP[i] shall be handed out.

Once a calibrateable number of valid monitoring cycles C_TCC_THD_OBD_LSH_UP has been determined to have been carried out, the diagnosis shall carry out a n-out-of-m statistical evaluation of the results. Should the number of determined heater faults exceed a calibrateable threshold C_TCC_THD_ERR_OBD_LSH_UP, the oxygen sensor heater under test shall be considered to be faulty for the current driving cycle and flag LV_ERR_OBD_LSH_UP[i] shall be set.

If the number of faults does not exceed the threshold, LV_ERR_OBD_LSH_UP[i] shall be reset.

Once the statistical evaluation has been carried out, no further monitoring cycles shall be executed in the remaining driving cycle. This is achieved by setting LV_END_DIAG_OBD_LSH_UP[i].

NOTES:

A. The integral POW_INT_OBD_LSH_UP[i] shall be reset to 0 should the exhaust gas temperature exceed the applicable threshold. This would cause the sensor to be re-heated from the exhaust gas once again and a certain delay would be required prior to the sensor being cooled long enough to permit valid diagnosis to occur.

B. The timer *TIMER_1* and integral POW_INT_OBD_LSH_UP[i] shall be reset should any of the initial entry or operative readiness conditions no longer be met or an OBDI fault be detected in the sensor under test. This may cause the sensor to leave its normal operating conditions and the OBDII diagnosis shall be required to start from the beginning as the sensor operating conditions would require time to stabilise should the conditions be met again.

C. The statistic counters TCC_VLD_OBD_LSH_UP[i] and TCC_ERR_OBD_LSH_UP[i] shall not be reset by changing conditions and therefore shall only increment or remain frozen during any given monitoring cycle. The counters shall only be reset at the beginning of a new driving cycle.

D. Projects that provide for an internal statistical error management shall use their internal error management and apply this wherever reference to TCC_VLD_OBD_LSH_UP[i], TCC_ERR_OBD_LSH_UP[i], C_TCC_THD_OBD_LSH_UP & C_TCC_THD_ERR_OBD_LSH_UP is made.

E. The variable STATE_OBD_LSH_UP[i] shall indicate, at the end of the each monitoring cycle, the status of the diagnosis within that cycle. The following correlation of variable content to description shall apply:

0:	DIAG_OFF	Initialisation state; no conditions met
1:	DIAG_INIT	Initial conditions & application incidences met only
2:	LS_READY	Sensor operatively ready conditions met + 1,
3:	OBD_1_DLY	OBDI monitoring completion delay exceeded + 1 & 2
4:	OBD_1_CHK	No OBDI faults present +1, 2 & 3
5:	TEG_THD	Exhaust gas below threshold + 1, 2, 3 & 4
6:	POW_INT	Power integral exceeded + 1,2,3,4 & 5
7:	DIAG_ACT	***Diagnosis detection active***
8:	DIAG_END	***Diagnosis detection complete***

Application conditions:

Initialisation:

The following variables (Mode "S") shall be initialised at checksum error:

LV_ERR_OBD_LSH_UP[i] = 0

R_IT_THD_OBD_LSH_UP[i] = 65535

R_IT_OBD_LSH_UP[i] = 65535

The following variables shall be initialised at reset, at the transition ignition key on (i.e. LV_IGK = 0 -> 1) and upon clearing error memory:

LV_CDN_DIAG_OBD_LSH_UP[i] = 0
ERR_SYM_OBD_LSH_UP[i] = 0
LV_ERR_OBD_LSH_UP[i] = 0
STATE_OBD_LSH_UP[i] = 0
TEMP_DIF_OBD_LSH_UP[i] = 0
POW_INT_OBD_LSH_UP[i] = 0
TCC_VLD_OBD_LSH_UP[i] = 0
TCC_ERR_OBD_LSH_UP[i] = 0
CTR_CYCNR_R_IT_OBD_LS_UP[i] = 0
R_IT_L_MES_OBD_LSH_UP[i] = 0
R_IT_L_REF_OBD_LSH_UP[i] = 0
R_IT_H_MES_OBD_LSH_UP[i] = 0
R_IT_H_REF_OBD_LSH_UP[i] = 0

The following variable shall be initialised at reset, at every new driving cycle (i.e. LV_DC = 0 -> 1) and upon clearing error memory:

LV_END_DIAG_OBD_LSH_UP[i] = 0

Reset *TIMER_1*

R_IT_OBD_LSH_UP[i], R_IT_THD_OBD_LSH_UP[i] shall be initialised with the last value from the previous driving cycle stored in non-volatile memory after RESET.

NOTE: TIMER_1 refers to a program specific timer and is not intended to represent a variable name!

Recurrence:

The OBDII oxygen sensor heater diagnosis shall be carried out once per driving cycle. The diagnosis shall require a number of monitoring cycles to be carried out to permit statistical evaluation of the results. These monitoring cycles shall occur every 1 s, until a calibrateable number of valid diagnosis cycles has been exceeded.

Once this threshold has been completed, the OBDII oxygen sensor heater diagnosis shall no longer be carried out until a new driving cycle is initiated.

Should an OBDII heater fault be detected, the application assistances (Functions that are defined to be affected by the state of the oxygen sensor signal) shall remain active for the remainder of the driving cycle. The restarting of the affected functions during the next driving cycle shall be carried out according to the project philosophy.

then „Diagnosis detection complete“

endif.

NOTES: The state variable STATE_OBD_LSH_UP[i] *shall only be validated at the completion of the current monitoring cycle, i.e. the state should not vary within the current 1 s monitoring cycle, but indicate at the end of the current cycle , the last state reached, dependant upon the branches.*

The variable CTR_CYCNR_R_IT_OBD_LS_UP[i] shall be updated with the current value of the input variable CTR_CYCNR_R_IT_LS_UP_VLD[i] on each occasion that the integral POW_INT_OBD_LSH_UP[i] exceeds the threshold for the first time. For further function calls where the integral condition is met, the one-off update shall not be carried out. This shall continue until the integral condition is no longer met.

Formula section:

Calculation of cooling energy integral:

Determine difference between typical sensor operating temperature and exhaust gas temperature:

TEMP_DIF_OBD_LSH_UP[i] = (C_TEMP_SP_OBD_LSH_UP - TEG_DYN_LS_UP[i])

(NOTE: Resolution of temperature difference is reduced from 0.0625 °C, resolution of the individual temperature variables, to 1 °C; The difference shall be limited to provide only positive values, i.e. ≥ 0)

The integral of heat flux (in Watts) provides a measure for the total cooling energy of the exhaust gas (in Joules):

$POW\_INT\_OBD\_LSH\_UP[i]_{(n)}$ =($POW\_INT\_OBD\_LSH\_UP[i]_{(n-1)}$ +
TEMP_DIF_OBD_LSH_UP[i] *
IP_FAC_MAF_OBD_LSH_UP)

B.19.1 Upstream oxygen sensor heater OBDII monitoring (Appl. inc.)

B.19.1.1 Inhibition of oxygen sensor upstream heater diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_OBD_LSH_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean inhibit flag for O2 sensor heater OBDII monitoring					
LV_INH_DIAG_RBM_OBD_LSH_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean inhibit flag for Rate Based Monitoring of O2 sensor heater OBDII diagnosis					

Input data:

LV_IGK	LV_ERR_MAF	LV_ERR_RATIO_CHK	NC_CBK_EX_NR
LV_ST_END	LV_ERR_SCG_LS_UP[NC_CBK_EX_NR]	LV_ERR_OC_LS_UP[NC_CBK_EX_NR]	LV_ERR_SCP_LS_UP[NC_CBK_EX_NR]
LV_ERR_LSH_UP[NC_CBK_EX_NR]	LV_CDN_VB_OBD2	TCO_ST	TCO_STOP
CONF_LAM	LV_ERR_MAP		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function shall evaluate the application conditions applicable to the oxygen sensor heater OBDII monitoring and provide the result in a single boolean flag. This flag shall represent the interface to the main diagnosis function. Additionally the inhibition bit for Rate Based Monitoring is evaluated.

Description:

The oxygen sensor heater OBD II monitoring shall be ihibited if one of the following listed errors was recognized:

- LV_ERR_MAF/MAP shall indicate a fault in the mass air flow measurement which may have an effect on the modelled exhaust gas temperature (TEG_DYN). Such a faulty value may cause the heating to be incorrectly performed leading to a secondary fault entry.
- LV_ERR_RATIO_CHK shall indicate a fault due to the load – throttle position sensor diagnosis. Such a fault may cause incorrect heating to be performed.
  - LV_ERR_SCG_LS_UP, LV_ERR_OC_LS_UP and LV_ERR_SCP_LS_UP shall indicate a fault of the oxygen upstream sensor probe. Such a fault may lead to wrong internal resistance values.

- LV_ERR_LSH_UP shall indicate a fault of the oxygen upstream sensor heater. Such a fault may cause insufficient heating and may lead to false error entries.
- If TCO_ST has not decreased sufficiently compared with TCO_STOP the exhaust system is still warm and a heater error cannot be detected, therefore the OBD2 diagnosis is inhibited.

Application conditions:

Initialisation:

The following variables shall be initialised at reset and at the ignition key transition on (i.e. LV_IGK = 0 -> 1):

LV_INH_DIAG_OBD_LSH_UP[i] = 0

LV_INH_DIAG_RBM_OBD_LSH_UP[i] = 0

Recurrence:

The function shall be carried out once every 1s.

Activation:

LV_ST_END = 1

Deactivation:

LV_ST_END = 0

Formula section:

If (LV_ERR_MAF = 0) **&**
(LV_ERR_MAP = 0) **&**
(LV_ERR_RATIO_CHK = 0) **&**

R_IT_LS_UP_1_ENVD_L

Application assistances:

Recommendation: The Application Assistances shall be maintained for the remaining duration of the driving cycle.

- Evaporative emission system:
  Control - activation of Minimum Operation
  System diagnosis - Inhibit
- Lambda control (Only for exhaust gas temperatures lower than O2 sensor lowest operating temperature):
  Control - Return to open-loop mode (Bank selectively)
  NOTE: Closed loop control may be permitted if the signal voltage excursion is large enough
  Adaptation - Inhibit (Bank selectively)
  Downstream trim regulation - Inhibit (Bank selectively)
- Oxygen sensor / Lambda controller diagnosis:
  O2 sensor upstream voltage excursion diagnosis - Inhibit (Bank selectively)
  O2 sensor upstream response time diagnosis - Inhibit (Bank selectively)
  O2 sensor lambda control limit diagnosis - Inhibit (Bank selectively)
  O2 sensor upstream frequency diagnosis - Inhibit (Bank selectively)
  O2 sensor upstream signal voltage diagnosis (Bank selectively)
  O2 sensor upstream signal plausibility diagnosis (Bank selectively)
  O2 sensor downstream response time diagnosis (Bank selectively)
  O2 sensor downstream signal voltage diagnosis (Bank selectively)
  O2 sensor downstream PUC end diagnosis (Bank selectively)
- Idle speed adaptation - Inhibit
- Knock adaptation - Inhibit
- MAF / TPS-Plausibility diagnosis - Inhibit
- Fuel system diagnosis - Inhibit (indirectly via LV_LSCL)

- Catalyst efficiency diagnosis - Inhibit (Bank selectively) (indirectly via LV_LSCL)

LV_ERR_VCC_PVS_2	LV_ERR_MAP_PLAUS		

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the OBD_LSH_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_OBD_LSH_UP[i] data.

Within STATE_RBM_OBD_LSH_UP[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_OBD_LSH_UP[i] = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_OBD_LSH_UP[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_OBD_LSH_UP[i]= 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_OBD_LSH_UP[i] = 1

The pending status of the following failures has to be checked only once:

Dependence	Error			
NC_CBK_EX_NR	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_SCG_LS_UP[i]	LV_ERR_SCP_LS_UP[i]	LV_ERR_OC_LS_UP[i]
	LV_ERR_MAF_SCG_OC	LV_ERR_MAF_SCP	LV_ERR_LSH_UP[i]	LV_ERR_VCC_PVS_2
	LV_ERR_MAP_PLAUS	LV_ERR_EL_MAP		

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_OBD_LSH_UP[i] = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_OBD_LSH_UP[i] = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_OBD_LSH_UP_1 = 0
then RATE_RBM_OBD_LSH_UP_1 = FFFFH
else RATE_RBM_OBD_LSH_UP_1
= (CTR_COMP_RBM_OBD_LSH_UP_1 / CTR_CDN_RBM_OBD_LSH_UP_1)
endif

Every 1 s :

If bit 0 of STATE_RBM_OBD_LSH_UP[i] = 0

Then

If LV_END_DIAG_OBD_LSH_UP[i] = 1

Then

bit 0 of STATE_RBM_OBD_LSH_UP[i] = 1

Endif

Endif

If bit 1 of STATE_RBM_OBD_LSH_UP[i] = 0

Then

If LV_INH_DIAG_RBM_OBD_LSH_UP[i] = 1

Then

bit 1 of STATE_RBM_OBD_LSH_UP[i] = 1

Endif

Endif

B.20 OBD II diagnosis of the lambda trim control

T_DLY_I_LAM_ADJ[NC_CBK_EX_NR]	LV_LAM_ADJ_PER_VLD[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_DC

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

To fulfill the legal requirements of the OBDII lambda sensor diagnosis, the trim of the lambda control by the lambda sensor signal downstream of the catalytic converter must be monitored in addition to the diagnosis of the lambda sensor upstream of the catalytic converter (by determining the switching times and the control frequency). In the case of a diagnostic error, a plausibility check of the trim control diagnosis can be performed to assign the faulty behavior to the control sensor or the monitoring sensor.
Faulty behavior of the lambda sensors upstream or downstream the catalytic converter exists if sensor limits are reached and in this way one of the emission values in the FTP test is exceeded by 1.5 fold.

Description:

If the I-share of the adaptation value T_DLY_I_LAM_ADJ[i] exceeds the diagnostic threshold C_T_DLY_LAM_MAX_DIAG for the first time the time counters T_DLY_LAM_SUM_RST_DIAG[i] and T_DLY_LAM_SUM_MAX_DIAG[i] are started. T_DLY_LAM_SUM_RST_DIAG[i] is incremented as long as the diagnosis conditions are fulfilled. T_DLY_LAM_SUM_MAX_DIAG[i] is incremented also as long as the diagnostic threshold is exceeded. If T_DLY_I_LAM_ADJ[i] falls again below the diagnostic threshold, then the T_DLY_LAM_SUM_MAX_DIAG[i] is stopped. A failure is detected as soon as T_DLY_LAM_SUM_MAX_DIAG[i] is above the threshold C_T_DLY_LAM_SUM_MAX_DIAG. Exceeds T_DLY_LAM_SUM_RST_DIAG[i] the calibrateable limit and no failure was detected (ERR_SYM_LAM_ADJ[i] = "NO_SYM) all time counters are reseted. Incrementation starts again, if the threshold for T_DLY_I_LAM_ADJ[i] is exceeded again. If the engine is stopped the time counters are reseted also.
For the minimum threshold T_DLY_LAM_SUM_MIN_DIAG[i] the procedure is analogous.

Is there a failure present ERR_SYM_LAM_ADJ[i] ≠ "NO_SYM as described above the validity of the controller period is checked. If no complete controller period of the I component has occurred after the trim control was active (LV_LAM_ADJ_PER_VLD[i]), the malfunction is assigned to the lambda sensor downstream of the catalytic converter otherwise to the upstream sensor.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) are initialised with 0 at every LV_IGK = 0 ->1 and reset
LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 , at reset and at FMY clear.

Recurrence: 1s

Activation:

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC _CBK_EX_NR = 2) then
   i = 1, for exhaust cylinder bank 1
   i = 2, for exhaust cylinder bank 2
otherwise (NC _CBK_EX_NR = 1)
   i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: LV_INH_DIAG_DLY_LAM[I] is initialised with 1 at ervery LV_IGK = 0 -> 1 and at reset

Recurrence: 1s

Activation:: at every engine state

Formula section:

else		
	LV_INH_DIAG_DLY_LAM[I] = 1	(Dynamic fuel trim diagnosis disabled)
endif		

Application assistances:

For binary systems only:

Due to the increasing P jump delay times of the trim control, the control frequency of the lambda controller will decrease simultaneously. In the case of a faulty behaviour of the trim control, it must be ensured that the control frequency diagnosis of the lambda sensor upstream of the catalytic converter does not detect any successive error. The control frequency is determined by the mixture change detection of the lambda sensor upstream of the catalytic converter, i.e. the delay times of the trim controls are not considered separately.

FUNCTION DESCRIPTION:

General information:

The monitor sensor diagnosis consists of three separate tests. These tests are carried out at the beginning or at the end of the pull fuel cut-off (PUC). In detail there are the tests monitoring of the rich-lean switching time, monitoring of the signal voltage during PUC and monitoring of the signal voltage motion after PUC. The purpose of these tests is the recognition of emission relevant sensor errors caused by changes in the sensor behaviour or by electrical errors like open circuits.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

FUNCTION DESCRIPTION:

General information:

Changes in the dynamic behaviour of the monitor sensor can be detected by the recognition of the rich-lean switching time after fuel cut-off.

Description:

After detection of the PUC engine operating state, the rich-lean switching time of the lambda sensor is determined and weighted depending upon the mass air flow in the intake system. The functioning of the sensor is diagnosed by comparison of the mean value of the weighted switching time with a limit. The functioning is guaranteed in this test if the switching time is below the limit.
The switching time diagnosis shall be finished for the current driving cycle, if C_CTR_SWT_DIAG_LS_DOWN valid switching times are calculated.
The rich-lean switching time of the sensor is determined in defined ranges of the mass air flow. A prerequisite for performing the diagnosis is that the voltage of the monitor sensor at the time of activating the trailing throttle fuel cut-off VLS_DOWN_TRAN_PUC[i] is above the threshold C_VLS_PUC_MIN_DIAG_SWT_LS_DOWN. The voltage value of the sensor at the time of trailing throttle fuel cut-off VLS_DOWN_TRAN_PUC[i] is required for the calculation of the dynamic limits for switching point determination and must be stored for the diagnostic period.
If the sensor voltage drops below the value C_FAC_VLS_MAX_DIAG_SWT_LS_DOWN * VLS_DOWN_TRAN_PUC[i], the switching time determination starts and the cycle counter CTR_SWT_ACT_LS_DOWN[i] has to be started. The counting process is ended if the limit C_FAC_VLS_MIN_DIAG_SWT_LS_DOWN * VLS_DOWN_TRAN_PUC[i] is exceeded downwards. The value of the cycle counter CTR_SWT_ACT_LS_DOWN[i] is a measure of the rich-lean switching time of the monitor sensor.
If a rich peak which exceeds C_VLS_HYS_DIAG_SWT_LS_DOWN occurs during determination of the switching time, its determination is interrupted and the relevant switching time is no longer further processed. The determination of the sensor switching times must also be interrupted if PUC is left.
Simultaneously to incrementation of CTR_SWT_ACT_LS_DOWN[i] the counter CTR_SWT_ACT_RBM_LS_DOWN[i] shall be incremented until the corresponding ratio CTR_QUO_SWT_RBM_LS_DOWN[i] exceeds the threshold for a defective lambda probe C_CTR_SWT_LS_DOWN. After this condition has been fulfilled the valid cycle counter CTR_SWT_LS_DOWN[i] shall be incremented. This procedure ensures that within each diagnostic cycle and after completion of the required total number of diagnostic cycles a probe malfunction can be detected as is demanded by ARB.
A valid value of the switching times for the monitor sensor must be weighted depending upon the minimum value for the mass flow during the determination of the switching time of the lambda sensor MAF_KGH_MIN_PUC. The weighting factor is determined via the map IP_FAC_CYCNR_MAX_LS_DOWN_ACT.
If for the determined switching time of the monitor sensor doesn't exceed the limit the sensor is diagnosed as functioning in this part of the diagnosis. The corresponding value must be saved for the scantool SAE 1979 independly if there is an error or not.
After the valid determination of switching time, the end of switching time diagnosis is indicated.

FUNCTION DESCRIPTION:

General information:

With level monitoring of the monitor sensor after leaving PUC unplausible voltage values due to short circuit to ground can be detected and a plausibility check upstream / downstream sensor can be made.

Description:

If the general conditions for activating the diagnostic function are fulfilled and If MAF_INT_PUC_NOT_ACT exceeds the value C_MAF_INT_DIAG_PUE_LS_DOWN, then the diagnosis must be made.

If no unplausible lambda sensor voltage of the downstream sensor after PUC is detected ERR_SYM_PUE_LS_DOWN[i] = "NO_SYM" shall be set and the counter is decremented. After calibratable number of checks C_CTR_END_DIAG_PUE_LS_DOWN the end of diagnosis flag LV_END_DIAG_PUE_LS_DOWN[i] shall be set to 1 and VLS_DIF_SAVE_ DIAG_LS_DOWN[i] equal to VLS_DIF_MIN_DIAG_PUE_LS_DOWN[i].

Application conditions:

Initialisation:

If At LV_IGK 0->1 **or** reset **or** <u>at clearing error memory</u>

then reset of all variables and bits to 0 except LV_END_DIAG_xx and:

- VLS_SAVE_DIAG_LS_DOWN which shall be initialized with its saved value. Reset only at clearing error memory.
- LV_DIAG_PUE_VLD_LS_DOWN[i] = 1

endif

If At LV_DC = 0->1 **or** reset **or** <u>at clearing error memory</u>

then reset LV_END_DIAG_xx:

endif

Recurrence: 20 ms

Activation / Deactivation:

If LV_DIAG_MPL_CDN_LS_DOWN[i] =1

and LV_END_DIAG_PUE_LS_DOWN[i] = 0

then LV_CDN_DIAG_PUE_LS_DOWN[i] =1

(leaving PUC check enabled)

else LV_CDN_DIAG_PUE_LS_DOWN[i] =0

(leaving PUC check disabled)

LV_DIAG_PUE_VLD_LS_DOWN[i] = 1

endif

Formula section:

Check if MAF_INT_PUC_NOT_ACT has been reset:

if MAF_INT_PUC_NOT_ACT$_n$ < MAF_INT_PUC_NOT_ACT$_{n-1}$
then LV_MAF_INT_PUC_NOT_ACT_RST = 1

Check if VLS_DOWN[i] was active in the past (once it is set it is not reset during the DC)

if VLS_DOWN[i] < C_VLS_AFL_THD_DIAG_LS_DOWN
then LV_VLS_DOWN_AFL[i] = 1 *// Lean voltage reached*

B.23 Activation conditions for diagnosis of the monitor sensors

1.1. Calculation of inhibition for diagnosis and for Rate Based Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DIAG_MPL_INH_LS_DOWN[NC_CBK_EX_NR]	O/V	0...1H	0...1	1	-
OBD II function dowmstream sensor: application incidences for inhibition					
LV_INH_DIAG_RBM_MPL_LS_DOWN[NC_CBK_EX_NR]	O/V	0...1H	0...1	1	-
OBD II function dowmstream sensor: application incidences for inhibition of Rate Based Monitoring					

Input data:

LV_ERR_CAM	LV_ERR_CRK	LV_ERR_TCO	LV_ERR_TPS
LV_ERR_VS	LV_ERR_RATIO_CHK	LV_ERR_FSD[NC_CBK_EX_NR]	LV_IGK
LV_ERR_MEC_OPEN_CPS	LV_ERR_EL_CPS	LV_ERR_PUE_LS_DOWN[NC_CBK_EX_NR]	LV_ERR_SWT_LS_DOWN[NC_CBK_EX_NR]
LV_ERR_LS_UP[NC_CBK_EX_NR]	LV_ERR_LSH_DOWN[NC_CBK_EX_NR	LV_ERR_OBD_LSH_DOWN[NC_CBK_EX_NR]	LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]
LV_MIS_STATE_B	LV_ST_END	STATE_ERR_IV	LV_SAV
LV_ERR_MAF	LV_LS_DOWN_OBD_2_MAN_DEAC[NC_CBK_EX_NR]	LV_SAP	NC_CBK_EX_NR
LV_ERR_IV[NC_CYL_NR]	LV_ERR_MWSS	LV_CDN_VB_OBD2	LV_ERR_MAP
LV_MIS_STATE_A	CONF_LAM	CONF_CAT_EFF	LV_ERR_CAM_IN[NC_NR_CAM_CBK]
LV_ERR_CAM_EX[NC_NR_CAM_CBK]	LV_ERR_MEC_IVVT_IN_i	LV_ERR_MEC_IVVT_EX_i	

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

If one of the below mentioned conditions is not fulfilled, the inhibit bit interrupts the downstream oxygen sensor diagnosis. The inhibition bit for Rate Based Monitoring is set if one of the listed errors below is recognized.

The logical variable LV_LS_DOWN_OBD_2_MAN_DEAC[i] is set via LC_LS_DOWN_OBD_2_MAN_DEAC[i] which provides the opportunity of manual deactivation of the OBDII diagnostic package for downstream sensors.

Application conditions:

Initialization: *at every LV_IGK = 0-> 1 and reset all variables are initialized with 0*

Recurrence: *100 ms*

Activation: *after leaving engine start LV_ST_END = 1*

Formula section:

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the SWT_LS_DOWN[i] and PUE_LS_DOWN[i] monitors and the Rate-Based Monitoring statistics is defined with STATE_RBM_SWT_LS_DOWN[i] and STATE_RBM_PUE_LS_DOWN[i] data, respectively.

Within STATE_RBM_SWT_LS_DOWN[i] and STATE_RBM_PUE_LS_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_SWT_LS_DOWN[i] = 0

bit 0, bit 1 and bit 2 of STATE_RBM_PUE_LS_DOWN[i] = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_SWT_LS_DOWN[i] = 0

bit 0 and bit 1 of STATE_RBM_PUE_LS_DOWN[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_SWT_LS_DOWN[i] = 0

bit 1 of STATE_RBM_PUE_LS_DOWN[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_SWT_LS_DOWN[i] = 1

bit 2 of STATE_RBM_PUE_LS_DOWN[i] = 1

The pending status of the following failures has to be checked only once:

For ETC and non_ETC variants:

Dependence	Error			
	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_VCC_PVS_2		
	LV_ERR_MAF_SCG_OC	LV_ERR_MAF_SCP	LV_ERR_EL_MAP	LV_ERR_MAP_PLAUS

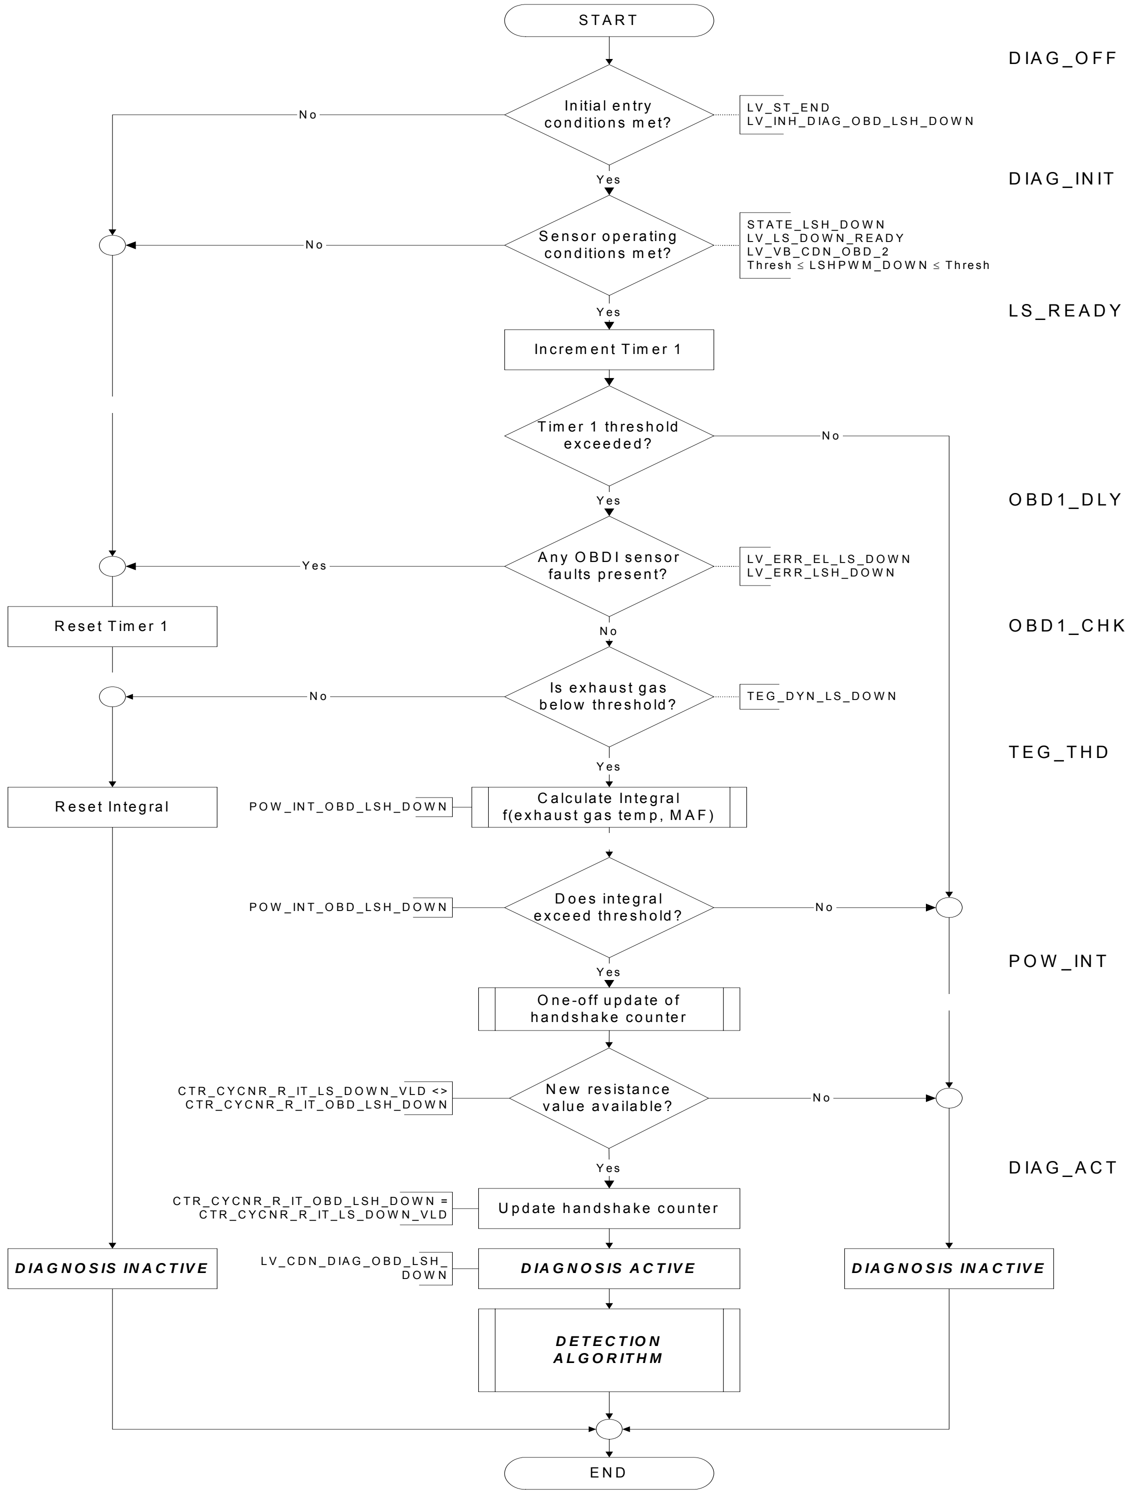
FUNCTION DESCRIPTION:

General information:

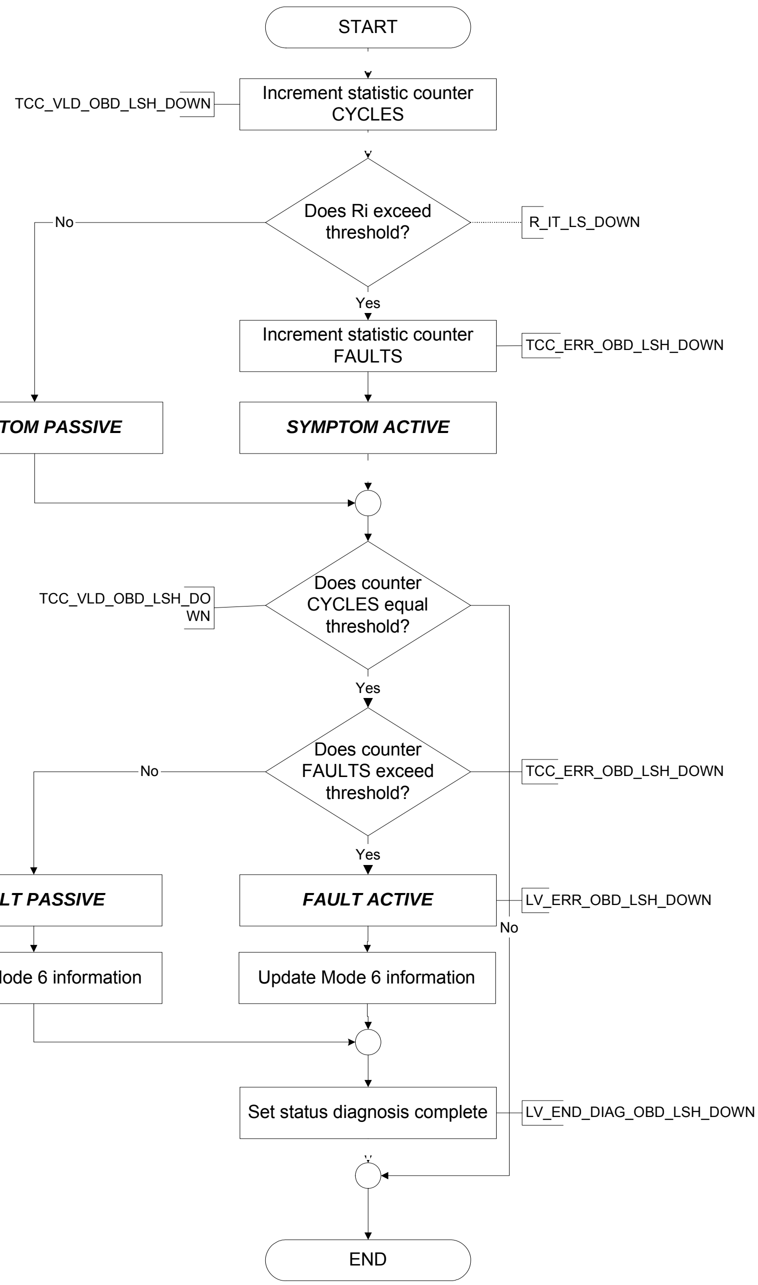
The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Signal flow diagram:

Activation conditions:



Detection Algorithm:



Description:

The downstream oxygen sensor heater circuit shall detect any loss in heater power that would cause a drop in the sensor operating temperature, thereby possibly causing exhaust gas emissions to rise above the applicable standards or prevent the sensor signal from being used as a diagnostic system monitoring device.

Losses in heater power may occur due to, for example, ageing of the heater element, defective wiring, increased heater cct. connector contact resistance, defective heater driver etc.

The hereafter mentioned diagnosis strategy is based on the comparison of the oxygen sensor internal resistance to an absolute threshold during operating conditions where the exhaust gas temperature has been determined to be sufficiently low as to cause the sensor ceramic temperature to fall outside normal operating levels, in cases where a power is insufficient.

The functionality of the diagnosis may be described in further detail below:

The initial diagnosis application condition; LV_ST_END shall ensure that the engine is running and has left the start phase but not yet entered the engine stop phase, LV_INH_DIAG_OBD_LSH_DOWN[i] shall ensure that the project specific application conditions (Application Incidences) have been met and LV_END_DIAG_OBD_LSH_DOWN[i] shall ensure that the diagnosis only be carried out once per driving cycle.

In order to ensure that the sensor has reached its normal operating temperature, the heater management state STATE_LSH_DOWN[i] shall be determined to be in the open loop control state LSH_POW_CTL, the sensor shall be determined to be in a state of operative readiness via LV_LS_DOWN_READY[i], the battery voltage VB shall be in a range determined to be fit for carrying out OBD2 diagnosis shown by LV_VB_CDN_OBD_2 and the heater duty-cycle LSHPWM_DOWN[i] shall be determined to be within calibrateable range C_LSHPWM_MIN_LSH_DOWN & C_LSHPWM_MAX_LSH_DOWN.

Should the above initial and operative conditions have been determined to be met, a timer, denoted herein as *TIMER_1*, shall be started. The timer shall run until the threshold T_DLY_OBD_LSH_DOWN_TMP is equalled or exceeded. Once this delay has passed, the status of the OBDI error bits LV_ERR_EL_LS_DOWN[i] & LV_ERR_LSH_DOWN[i] shall be read to ensure that no signal electrical or plausibility faults and no heater electrical faults are present in the sensor cct. under test. The delay shall ensure that sufficient time passes to permit completion of the OBDI monitoring prior to the start of OBDII monitoring.

Should no OBDI faults be present, the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] shall be compared to a calibrateable threshold C_TEG_DYN_MAX_OBD_LSH_DOWN. Due tolerances in the determination of the sensor internal resistance and in the case of a functional heater, the maximum resistance value may be given by a minimum tolerance sensor at a much lower temperature than for a maximum tolerance sensor at a higher temperature. Therefore, in the case of diagnosis based on an absolute internal resistance threshold, a certain temperature tolerance exists. The above mentioned temperature threshold shall lie below the minimum temperature determined from analysis of the internal resistance tolerances and be sufficient to cool the sensor ceramic element to below normal operating conditions, in the case of a heater fault.

Should the exhaust gas temperature be determined to equal or fall below the threshold, the monitoring strategy shall ensure that the sensor be cooled sufficiently long by the exhaust gas to enable differentiation between a functional and non-functional heater cct. (The time required is dependent on the thermal capacity of the system at the sensor location and the forced convection cooling of the sensor location). This shall be achieved by integrating the heat flux of the forced convection thermal transfer between sensor and exhaust gas, this being a measure for the cooling energy of the exhaust gas. The heat flux shall be calculated by determining the difference between the typical set sensor operating temperature C_TEMP_SP_OBD_LSH_DOWN and the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] and multiplying the result by the factor IP_FAC_MAF_OBD_LSH_DOWN representing the heat transfer coefficient and surface area concerned in the thermal transfer. As the heat transfer coefficient is a function of the velocity of the exhaust gas, the factor shall be mapped and dependent on the current mass airflow MAF_KGH.

The resultant integral POW_INT_OBD_LSH_DOWN[i] shall be compared to the threshold POW_INT_MIN_OBD_LSH_DOWN_TMP. Each time that the threshold be exceeded for the first time, e.g. first time after engine start or after the power integral has been reset, the CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_CYCNR_R_IT_OBD_LS_DOWN[i] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. If this conditions and all the above conditions be met, LV_CDN_DIAG_OBD_LSH_DOWN[i] shall be set and the diagnosis shall be considered to be active and the current monitoring cycle valid.

Once the current monitoring cycle has been determined to be valid, a counter TCC_VLD_OBD_LSH_DOWN[i] shall be incremented, denoting the number of valid monitoring cycles carried out to date. The internal resistance R_IT_LS_DOWN[i] shall be compared to a calibrateable threshold IP_R_IT_THD_OBD_LSH_DOWN which is dependent on the modelled tip temperature of a new sensor (including safety margin) and the number of valid diagnosis cycles completed TCC_VLD_OBD_LSH_DOWN. Should the resistance equal or exceed the threshold, a heater fault shall be determined to be present in the current cycle and a counter TCC_ERR_OBD_LSH_DOWN[i] shall be incremented, denoting the number of heater faults within the valid monitoring cycles carried out to date.

In order to comply with OBDII requirements, the current R_IT_LS_DOWN[i] value used shall be made available to an external tester. This information is Mode 6 information. Hence once the comparison to the threshold has been carried out, the latest measured internal resistance and threshold values (R_IT_L_MES_OBD_LSH_DOWN[i] and R_IT_L_REF_OBD_LSH_DOWN[i]) shall be copied to the respective Mode 6 interface variables R_IT_OBD_LS_DOWN[i] and R_IT_THD_OBD_LSH_DOWN[i] for the no error case. In the error case the variables R_IT_H_MES_OBD_LSH_DOWN[i] and R_IT_H_REF_OBD_LSH_DOWN[i] shall be handed out.

Once the number of valid monitoring cycles TCC_THD_OBD_LSH_DOWN_TMP has been determined to have been carried out, the diagnosis shall carry out a n-out-of-m statistical evaluation of the results. Should the number of determined heater faults exceed the threshold TCC_THD_ERR_OBD_LSH_DOWN_TMP, the oxygen sensor heater under test shall be considered to be faulty for the current driving cycle and flag LV_ERR_OBD_LSH_DOWN[i] shall be set.

If the number of faults does not exceed the threshold, LV_ERR_OBD_LSH_DOWN[i] shall be reset.

Once the statistical evaluation has been carried out, no further monitoring cycles shall be executed in the remaining driving cycle. This is achieved by setting LV_END_DIAG_OBD_LSH_DOWN[i].

Should, according to project philosophy, the diagnosis be activated for an end of line (EOL) test, specific threshold conditions for the diagnosis delay timer, the power integral, the required number of test and error indicating cycles may be chosen to shorten the time until recognition of diagnosis end.

NOTES:

F. The integral POW_INT_OBD_LSH_DOWN[i] shall be reset to 0 should the exhaust gas temperature exceed the applicable threshold. This would cause the sensor to be re-heated from the exhaust gas once again and a certain delay would be required prior to the sensor being cooled long enough to permit valid diagnosis to occur.

G. The timer *TIMER_1* and integral POW_INT_OBD_LSH_DOWN[i] shall be reset should any of the initial entry or operative readiness conditions no longer be met or an OBDI fault be detected in the sensor under test. This may cause the sensor to leave its normal operating conditions and the OBDII diagnosis shall be required to start from the beginning as the sensor operating conditions would require time to stabilise should the conditions be met again.

H. The statistic counters TCC_VLD_OBD_LSH_DOWN[i] and TCC_ERR_OBD_LSH_DOWN[i] shall not be reset by changing conditions and therefore shall only increment or remain frozen during any given monitoring cycle. The counters shall only be reset at the beginning of a new driving cycle.

I. Projects that provide for an internal statistical error management shall use their internal error management and apply this wherever reference to TCC_VLD_OBD_LSH_DOWN[i], TCC_ERR_OBD_LSH_DOWN[i], TCC_THD_OBD_LSH_DOWN_TMP & TCC_THD_ERR_OBD_LSH_DOWN_TMP is made.

J. The variable STATE_OBD_LSH_DOWN[i] shall indicate, at the end of the each monitoring cycle, the status of the diagnosis within that cycle. The following correlation of variable content to description shall apply:

0:	DIAG_OFF	Initialisation state; no conditions met
1:	DIAG_INIT	Initial conditions & application incidences met only
2:	LS_READY	Sensor operatively ready conditions met + 1,
3:	OBD1_DLY	OBDI monitoring completion delay exceeded + 1 & 2
4:	OBD1_CHK	No OBDI faults present +1, 2 & 3
5:	TEG_THD	Exhaust gas below threshold + 1, 2, 3 & 4
6:	POW_INT	Power integral exceeded + 1,2,3,4 & 5
7:	DIAG_ACT	***Diagnosis detection active***
8:	DIAG_END	***Diagnosis detection complete***

Application conditions:

Initialisation:

The following variables shall be initialised at reset, at the transition ignition key on (i.e. LV_IGK = 0 -> 1) and at clearing the error memory:

LV_CDN_DIAG_OBD_LSH_DOWN[i] = 0
ERR_SYM_OBD_LSH_DOWN[i] = 0
LV_ERR_OBD_LSH_DOWN[i] = 0
STATE_OBD_LSH_DOWN[i] = 0
TEMP_DIF_OBD_LSH_DOWN[i] = 0
POW_INT_OBD_LSH_DOWN[i] = 0
TCC_VLD_OBD_LSH_DOWN[i] = 0
TCC_ERR_OBD_LSH_DOWN[i] = 0
CTR_CYCNR_R_IT_OBD_LS_DOWN[i] = 0
R_IT_L_MES_OBD_LSH_DOWN[i] = 0
R_IT_L_REF_OBD_LSH_DOWN[i] = 0
R_IT_H_MES_OBD_LSH_DOWN[i] = 0
R_IT_H_REF_OBD_LSH_DOWN[i] = 0

The following variable shall be initialised at reset, at every new driving cycle (i.e. LV_DC = 0 -> 1) and upon clearing error memory:

LV_END_DIAG_OBD_LSH_DOWN[i] = 0

Reset *TIMER_1*

R_IT_OBD_LSH_DOWN[i] and R_IT_THD_OBD_LSH_DOWN[i] shall be initialised with the last value from the previous driving cycle stored in non-volatile memory after RESET.

NOTE: TIMER_1 refers to a program specific timer and is not intended to represent a variable name!

Recurrence:

The OBDII oxygen sensor heater diagnosis shall be carried out once per driving cycle. The diagnosis shall require a number of monitoring cycles to be carried out to permit statistical evaluation of the results. These monitoring cycles shall occur every 1 s, until a calibrateable number of valid diagnosis cycles has been exceeded.

Once this threshold has been completed, the OBDII oxygen sensor heater diagnosis shall no longer be carried out until a new driving cycle is initiated.

Should an OBDII heater fault be detected, the application assistances (Functions that are defined to be affected by the state of the oxygen sensor signal) shall remain active for the remainder of the driving cycle. The restarting of the affected functions during the next driving cycle shall be carried out according to the project philosophy.

then „Diagnosis detection complete“

endif.

NOTES: The state variable STATE_OBD_LSH_DOWN[i] *shall only be validated at the completion of the current monitoring cycle, i.e. the state should not vary within the current 1 s monitoring cycle, but indicate at the end of the current cycle , the last state reached, dependant upon the branches.*

The variable CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated with the current value of the input variable CTR_CYCNR_R_IT_LS_DOWN_VLD[i] on each occasion that the integral POW_INT_OBD_LSH_DOWN[i] exceeds the threshold for the first time. For further function calls where the integral condition is met, the one-off update shall not be carried out. This shall continue until the integral condition is no longer met.

Formula section:

Calculation of cooling energy integral:

Determine difference between typical sensor operating temperature and exhaust gas temperature:

TEMP_DIF_OBD_LSH_DOWN[i] = (C_TEMP_SP_OBD_LSH_DOWN - TEG_DYN_LS_DOWN[i])

(NOTE: Resolution of temperature difference is reduced from 0.0625 °C, resolution of the individual temperature variables, to 1 °C; The difference shall be limited to provide only positive values, i.e. ≥ 0)

The integral of heat flux (in Watts) provides a measure for the total cooling energy of the exhaust gas (in Joules):

$POW\_INT\_OBD\_LSH\_DOWN[i]_{(n)}$ = ($POW\_INT\_OBD\_LSH\_DOWN[i]_{(n-1)}$ + TEMP_DIF_OBD_LSH_DOWN[i] * IP_FAC_MAF_OBD_LSH_DOWN)

(NOTE: Integral shall be limited to its maximum hex limit, i.e. FFFFH or 65535 digits, to prevent overflow.)

Detection: (Assumes "Diagnosis detection active") **See also NOTE D above!**

LV_INH_DIAG_RBM_OBD_LSH_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Flag to inhibit rate based monitoring for oxygen sensor heater OBDII diagnosis					

Input data:

LV_ERR_MAP	LV_ERR_MAF	LV_ERR_RATIO_CHK	LV_ST_END
LV_IGK	NC_CBK_EX_NR	NLC_LSH_RLY_EFP	LV_EFP
LV_ERR_RLY_EFP	TCO_ST	TCO_STOP	CONF_LAM
CONF_CAT_EFF			

FUNCTION DESCRIPTION:

General information:

This function shall evaluate the application conditions applicable to the oxygen sensor heater OBDII monitoring and provide the result in a single boolean flag. Additionally the interfaces for Rate Based Monitoring RBM are provided.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Description:

The oxygen sensor heater OBD II monitoring shall be ihibited if one of the following listed errors was recognized:

- LV_ERR_MAF shall indicate a fault in the mass air flow measurement which may have an effect on the modelled exhaust gas temperature. Such a faulty value may cause the heating to be incorrectly performed leading to a secondary fault entry.
- LV_ERR_MAP shall indicate a fault in the manifold air pressure measurement which may have an effect on the modelled exhaust gas temperature (TEG_DYN). Such a fault value may cause the heating to be incorrectly performed leading to a secondary fault entry.
- In some systems the positive feed of the oxygen sensor heater may be connected to the electrical fuel pump relay as indicated by NLC_LSH_RLY_EFP = 1. In this case, if the electrical fuel pump is switched off or if the fuel pump relay is defective, no heating will occur and the heater driver will recognize an incorrect heater fault. Hence the OBD II heater diagnosis shall be inhibited if LV_EFP = 0 or if LV_ERR_RLY_EFP = 1.
- LV_ERR_RATIO_CHK shall indicate a fault due to the load – throttle position sensor diagnosis. Such a fault may cause incorrect heating to be performed.

- If TCO_ST has not decreased sufficiently compared with TCO_STOP the exhaust system is still warm and a heater error cannot be detected, therefore the OBD2 diagnosis is inhibited

The same OBD I errors are evaluated for inhibition of Rate Based Monitoring.

Application conditions:

Initialisation:

The following variables shall be initialised at reset and at the ignition key transition on (i.e. LV_IGK = 0 -> 1):

LV_INH_DIAG_OBD_LSH_DOWN[i] = 0

Recurrence:

The function shall be carried out once every 1s.

Activation:

LV_ST_END = 1

Deactivation:

LV_ST_END = 0

Formula section:

Inhibition of Rate Based Monitoring

If LV_ERR_MAF = 1 **or**
LV_ERR_MAP = 1 **or**
LV_ERR_RATIO_CHK = 1
then
LV_INH_DIAG_RBM_OBD_LSH_DOWN[i] = 1
else
LV_INH_DIAG_RBM_OBD_LSH_DOWN[i] = 0
endif.

Inhibition of oxygen sensor heater OBD II diagnosis

If TCO_STOP – TCO_ST < C_TCO_DIF_MIN_OBD_LSH_DOWN **or**
LV_ERR_MAF = 1 **or**
LV_ERR_MAP = 1 **or**
LV_ERR_RATIO_CHK = 1 **or**

LV_ERR_EL_MAP	LV_ERR_MAP_PLAUS	LV_ERR_VCC_PVS_2	

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the OBD_LSH_DOWN[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_OBD_LSH_DOWN[i] data.

Within STATE_RBM_OBD_LSH_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_OBD_LSH_DOWN[i] = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_OBD_LSH_DOWN[i] = 1

The pending status of the following failures has to be checked only once:

LV_ERR_EL_MAP	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_MAF_SCP	LV_ERR_MAF_SCG_OC
LV_ERR_RLY_EFP	LV_ERR_MAP_PLAUS	LV_ERR_VCC_PVS_2	

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0 **do**

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

with all XX failures of the above list.

The necessity of monitoring LV_ERR_RLY_EFP depends on system configuration, i.e. whether NLC_LSH_RLY_EFP is set or not (see section 1.1).

#If (NLC_LSH_RLY_EFP = 1)

#Then LV_ERR_RLY_EFP

#Endif

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If (bit 0 of STATE_RBM_OBD_LSH_DOWN[i] = 0 **and**
LV_END_DIAG_OBD_LSH_DOWN[i] = 1)
Then bit 0 of STATE_RBM_OBD_LSH_DOWN[i] = 1
Endif

If (bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0 **and**
LV_INH_DIAG_RBM_OBD_LSH_DOWN[i] = 1)
Then bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 1
Endif

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_OBD_LSH_DOWN_1 = 0
then RATE_RBM_OBD_LSH_DOWN_1 = FFFFH
else RATE_RBM_OBD_LSH_DOWN_1
= (CTR_COMP_RBM_OBD_LSH_DOWN_1 / CTR_CDN_RBM_OBD_LSH_DOWN_1)
endif

B.25 Upstream oxygen sensor diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DIAG_PLAUS_SYM_LSL_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Debounced diagnosis result of the signal plausibility for the wide range A/F sensor					
LV_DIAG_MPL_END_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Bit to indicate end of complete upstream sensor diagnosis					
LV_CDN_DIAG_MPL_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Status of permission for multiple diagnosis upostream					

Input data:

LV_END_DIAG_SWT_LS_UP[NC_CBK_EX_NR]	LV_ST_END	LV_END_DIAG_FRQ_LS_UP[NC_CBK_EX_NR]	LV_IGK
NC_CBK_EX_NR	LV_INH_DIAG_LS_UP[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function indicates the completion of the upstream oxygen sensor diagnosis by setting the boolean variable LV_DIAG_MPL_END_LS_UP[i]. LV_DIAG_PLAUS_SYM_LSL_UP[i] is generated to serve a common interface to Appl. Inc. of heater management.

Application conditions:

Initialisation:

Recurrence:

This function shall be carried out every 100ms.

Activation:

LV_ST_END = 1

Deactivation:

LV_ST_END = 0

Formula section:

If LV_END_DIAG_SWT_LS_UP[i] = 1
and LV_END_DIAG_FRQ_LS_UP[i] = 1
then LV_DIAG_MPL_END_LS_UP[i] = 1
endif

If LV_INH_DIAG_LS_UP [i] = 0
then LV_CDN_DIAG_MPL_LS_UP[i] = 1
else LV_CDN_DIAG_MPL_LS_UP[i] = 0
endif

B.26 OBDII Oxygen Sensor diagnosis with multiple check

LV_CDN_DIAG_MPL_LS_UP[NC_CBK_EX_NR]	LV_DC		

FUNCTION DESCRIPTION:

General information:

If an error has been registered within the corresponding engine operating cycle, which disables the oxygen sensor switching time monitoring, the checking algorithm for this engine operating cycle is aborted without rendering a result. If an error has been debounced for the oxygen sensor switching time monitoring, catalyst efficiency monitoring must be aborted for the corresponding cylinder group in the corresponding engine operating cycle.

Description:

In order to detect oxygen sensor switching problems, the sensor signals are monitored for reversal points while the switching times are being measured. If a reversal point is detected, this oxygen sensor signal change is not used to determine the sensor switching time. Since the sensor switching times fluctuate considerably during normal engine operation, the switching times are averaged.

The oxygen sensor signals are sampled every 10 ms. (This precludes an accurate determination of the individual sensor switching times. Only greater deviations of the oxygen sensor switching times from the normal value can be detected.)

When the oxygen sensor switching time monitoring has been completed rendering a result, the function indicates to the error storage mechanism that it is ready for the corresponding engine operating cycle.

Simultaneously to measuring the switching times from rich to lean the switching time for a limit sensor is determined out of SWT_THD_MAX_MIN[i] and an additional timer SWT_THD_RBM_MAX_MIN[i] which is increased until RATIO_CYCNR_RBM_AFL[i] fulfills the error criterion. The same holds for the switching time from lean to rich. Each time the error criterion is reached the counters CYCNR_RBM_AFL_SUM[i] and CYCNR_RBM_AFR_SUM[i] are increased. The end bit for Rate Based Monitoring purpose is set if the diagnosis end threshold C_CYCNR_SUM_MIN is exceeded. This procedure ensures that within each voltage transition a switching time limit probe could have been detected as is demanded by ARB.

Application conditions:

Initialisation: At LV_IGK = 0 -> 1, reset or by clearing the error memory shall all variables be initialised to 0 except LV_END_DIAG_xx and the variables saved in the non-volatile memory.

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

Recurrence:

This function shall be carried out every 10ms, except the “Determination of relative thresholds” which shall be carried out every 1s.

Activation / Deactivation:

If LV_CDN_DIAG_MPL_LS_UP[i] = 1

and LV_END_DIAG_RBM_SWT_LS_UP[i] = 0

then If C_CYCNR_SUM_MIN = 0

then *Switching time diagnosis switched off*

endif

B.26.1.1 Determination of relative thresholds

Description:

The relative thresholds VLS_THD_MAX[i] and VLS_THD_MIN[i] (10-90% signal excursion of VLS_UP_MMV_MAX[i] and VLS_UP_MMV_MIN[i]) are used to determine the oxygen sensor switching times from lean to rich mixture operation and back.

Formula section:

// updated every 1s

VLS_THD_MAX[i] = VLS_UP_MMV_MIN[i] + (VLS_UP_MMV_MAX[i] - VLS_UP_MMV_MIN[i]) * 0.9

VLS_THD_MIN[i] = VLS_UP_MMV_MIN[i] + (VLS_UP_MMV_MAX[i] - VLS_UP_MMV_MIN[i]) * 0.1

B.26.1.2 Switching time from rich to lean

While the oxygen sensor signal VLS_UP[i] is greater than VLS_THD_MAX[i], the counter SWT_THD_MAX_MIN[i] is set to 0. When the signal drops below the threshold VLS_THD_MAX[i], the counter SWT_THD_MAX_MIN[i] is started. The logical variable LV_DIAG_SWT_LS_UP_AFR_CDN[i] ensures that VLS_UP[i] has exceeded VLS_THD_MAX[i] before switching time determination when set. While VLS_UP[i] > VLS_THD_MIN[i], the counter is incremented with each sensor sampling cycle. The counter SWT_THD_RBM_MAX_MIN[i] is incremented until the ratio RATIO_CYCNR_RBM_AFL[i] exceeds the limit for error detection.

If the oxygen sensor signal drops below the threshold VLS_THD_MIN[i], the counter is stopped.

If a „rich peak“ which exceeds $VLS\_UP[i]_{n-1}$ + C_VLS_HYS occurs while the switching time is being determined, the switching time determination is aborted.

Formula section:

```
If      LV_DIAG_SWT_LS_UP_AFR_ENA[i] = 1
Then  If     VLS_UP[i] > VLS_THD_MAX[i]
      then LV_DIAG_SWT_LS_UP_AFR_CDN[i] = 1
      endif
      if    LV_DIAG_SWT_LS_UP_AFR_CDN[i] = 1

B.26.1.3 Switching time from lean to rich

Description:

While the oxygen sensor signal VLS_UP[i] is smaller than VLS_THD_MIN[i], the counter SWT_THD_MAX_MIN[i] is set to 0. The logical variable LV_DIAG_SWT_LS_UP_AFL_CDN[i] ensures that VLS_UP[i] has been smaller than VLS_THD_MIN[i] before switching time determination when set. When the signal exceeds the threshold VLS_THD_MIN[i], the counter SWT_THD_MAX_MIN[i] is started. While VLS_UP[i] < VLS_THD_MAX[i], the counter is incremented with each sensor sampling cycle. The counter SWT_THD_RBM_MAX_MIN[i] is incremented until the ratio RATIO_CYCNR_RBM_AFR[i] exceeds the limit for error detection.

If the oxygen sensor signal exceeds the threshold VLS_THD_MAX[i], the counter is stopped.

If a „lean peak“ which falls below $VLS\_UP[i]_{n-1}$ - C_VLS_HYS occurs while the switching time is being determined, the switching time determination is aborted.

Formula section:

If LV_DIAG_SWT_LS_UP_AFR_ENA[i] = 0

then **if** VLS_UP[i] < VLS_THD_MIN[i]

then LV_DIAG_SWT_LS_UP_AFL_CDN[i] = 1

endifif LV_DIAG_SWT_LS_UP_AFL_CDN[i] = 1

then **If** VLS_THD_MIN[i] < VLS_UP[i]

then **if** $VLS\_UP[i]_n > VLS\_UP[i]_{n-1}$ - C_VLS_HYS

then **if** VLS_UP[i] < VLS_THD_MAX[i]

then SWT_THD_MAX_MIN[i] = SWT_THD_MAX_MIN[i] + 1

```

```

endif

B.26.1.4 Averaging of sensor switching times

Description:

Since the sensor switching times fluctuate considerably, the valid sensor switching times are averaged during the check cycle.

In addition to this, the limit for the switching time is read from a map for each valid oxygen sensor switching operation.

Formula section:

```
If      LV_END_DIAG_SWT_LS_UP[i] = 0
then    if      determination of switching time rich/lean was OK
        then    RATIO_CYCNR_AFL[i] =
                SWT_THD_MAX_MIN[i] / ID_T_MAX_CYCNR_AFL

                RATIO_SUM_CYCNR_AFL[i] =
                RATIO_SUM_CYCNR_AFL[i] + RATIO_CYCNR_AFL[i]
                T_SUM_SWI_AFR_AFL[i] =
                T_SUM_SWI_AFR_AFL[i] + SWT_THD_MAX_MIN[i]
                T_SUM_MAX_SWI_AFR_AFL[i] = T_SUM_MAX_SWI_AFR_AFL[i] +
                ID_T_MAX_CYCNR_AFL
        endif
        If      determination of switching time lean/rich was OK
        then    RATIO_CYCNR_AFR[i] =
                SWT_THD_MAX_MIN[i] / ID_T_MAX_CYCNR_AFR
                CYCNR_AFR_SUM[i]  = CYCNR_AFR_SUM[i]  + 1
                RATIO_SUM_CYCNR_AFR[i] =
                RATIO_SUM_CYCNR_AFR[i] + RATIO_CYCNR_AFR[i]
                T_SUM_SWI_AFL_AFR[i] =
                T_SUM_SWI_AFL_AFR[i] + SWT_THD_MAX_MIN[i]
                T_SUM_MAX_SWI_AFL_AFR[i] = T_SUM_MAX_SWI_AFL_AFR[i] +
                ID_T_MAX_CYCNR_AFR
        endif
endif
```

B.26.1.5 Error detection for switching time diagnosis

Description:

The oxygen sensor switching times are ok when the switching time ratio from rich to lean as well as the switching time ratio from lean to rich are smaller than the corresponding limits. At the end of a complete diagnostic cycle the ratio values are evaluated and LV_END_DIAG_SWT_LS_UP[i] is set to 1. That means, that the diagnosis is stopped for this driving cycle.

Formula section:

```
If      LV_END_DIAG_SWT_LS_UP[i] = 0
then    If      CYCNR_AFL_SUM[i]   > C_CYCNR_SUM_MIN
        and     CYCNR_AFR_SUM[i]   > C_CYCNR_SUM_MIN
        then    RATIO_MV_CYCNR_AFL[i] =
                RATIO_SUM_CYCNR_AFL[i] / CYCNR_AFL_SUM[i]
                RATIO_MV_CYCNR_AFR[i] =
                RATIO_SUM_CYCNR_AFR[i] / CYCNR_AFR_SUM[i]
                LV_END_DIAG_SWT_LS_UP[i] = 1
                evaluation for scantool communication
        endif
        if      RATIO_MV_CYCNR_AFR[i] < C_RATIO_MV_CYCNR_AFR
        and     RATIO_MV_CYCNR_AFL[i] < C_RATIO_MV_CYCNR_AFL
        and     C_RATIO_MIN_DIF < (RATIO_MV_CYCNR_AFL[i] -
                RATIO_MV_CYCNR_AFR[i] ) < C_RATIO_MAX_DIF

FUNCTION DESCRIPTION:

General Information:

The check cycle can be started following an oxygen controller lambda transition.

The diagnosis threshold C_CTR_CYC_SUM_MIN must be applied such that the checking algorithm for the oxygen sensors upstream from the catalyst is terminated before the catalyst efficiency algorithm. This is done in order to permit the backup trip recognition for catalyst efficiency monitoring to be set in time in the event of an oxygen sensor error.

When the oxygen sensor control frequency check has been completed rendering a result, the function indicates to the error storage mechanism that it is ready for the corresponding engine operating cycle. If an error has been registered within the corresponding engine operating cycle which disables the oxygen sensor control frequency check, the checking algorithm for this engine operating cycle is aborted without rendering a result. If an error has been debounced for the oxygen sensor control frequency check, catalyst efficiency monitoring must be aborted for the corresponding cylinder group in the corresponding engine operating cycle.
In order to ensure that a lambda probe malfunction could have been detected for Rate Based Monitoring additional timer conditions have been implemented. Each time the lambda voltage

switches from rich to lean the timer T_AFR_CYC_RBM[i] is incremented until the ratio RATIO_CYC_RBM_AFR_SUM[i] exceeds the failure criterion. The same holds of course for the transition from lean to rich. If the required number of diagnostic cycles has been exceeded in this way the "RBM end bit" is set. This procedure does not lead to a prolonged diagnosis time.

Description:

The rich T_AFR_CYC[i] and lean T_AFL_CYC[i] dwell times and the check cycle counter CTR_CYC_SUM[i] are evaluated to check the oxygen sensor control frequency. These are also used to determine the catalyst efficiency.
In addition to this, the limits for the maximum rich and lean dwell times are derived from a map for each valid oxygen controller cycle.

Application conditions:

Initialisation: At LV_IGK = 0 -> 1, reset or by clearing the error memory shall all variables be initialised to 0 except LV_END_DIAG_xx and the variables saved in the non-volatile memory

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

Recurrence:

This function shall be carried out every 10ms.

Activation / Deactivation:

If LV_CDN_DIAG_MPL_LS_UP[i] = 1
and LV_AFL[i] *changed at least one time*
and **(** LV_END_DIAG_RBM_FRQ_LS_UP[i] = 0
or LV_FRQ_DIAG_REQ_LS_UP[i] = 1 **)**
and **(**LC_O2L_LAM_REQ_CAT_DIAG = 0
or LV_O2L_LAM_REQ_CAT_DIAG = 0**)**
then */Frequency check diagnosis active*
LV_CDN_DIAG_FRQ_LS_UP[i] = 1
else */Frequency check diagnosis passive*
LV_CDN_DIAG_FRQ_LS_UP[i] = 0
LV_DIAG_FRQ_LS_UP_RBM_AFR[i] = 0
LV_DIAG_FRQ_LS_UP_RBM_AFL[i] = 0
endif

Initialisation: *additional to initialisation conditions of chapter 1*

If LV_FRQ_DIAG_REQ_LS_UP[i] = 1

and CTR_CYC_SUM[i] > C_CTR_CYC_SUM_MIN

then reset of all variables and bits, **but not :**

LV_FRQ_DIAG_REQ_LS_UP[i]

CTR_FRQ_VLD_DIAG_MPL_LS_UP[i]

LV_FRQ_DIAG_SYM_LS_UP[i]

SAVE variables saved in non-volatile memory

endif

B.26.2.1 Dwell time calculation

Description:

The ***T_DLY_LAM_ADJ[i]*** value must be the value witch was active at the last p-jump, because this value was used for the p-jump delay T_DLY_POS_LAM[i] or T_DLY_NEG_LAM[i]. See Calculation of T_DLY_LAM_P_OLD[i] below.

Formula section:

LV_ERR_MEC_IVVT_EX_i	LV_ERR_CAM_IN[NC_NR_CAM_CBK]	LV_ERR_CAM_EX[NC_NR_CAM_CBK]	

FUNCTION DESCRIPTION:

Within this function the inhibition bit for the binary oxygen sensor multiple diagnosis is defined.

Description:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: **at LV_IGK = 0-> 1 and at reset all variables are initialized with 0**

Recurrence: **10 ms**

Activation / Deactivation:

If **N_32 > engine speed for leaving start -> LV_ST_END =1**

and **LV_IGK = 1**

then **enable corresponding diagnosis**

else **disable corresponding diagnosis**

endif

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the SWT_LS_UP[i] and FRQ_LS_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_SWT_LS_UP[i] and STATE_RBM_FRQ_LS_UP[i] data, respectively.

Within STATE_RBM_SWT_LS_UP[i] and STATE_RBM_FRQ_LS_UP[i], three different information are defined:

- **Conditions for monitoring are met long enough to detect malfunction (bit 0) (no intrusive operation, no short trip)**
- **Monitor disabled because of system malfunction (bit 1) (depending on failure status: pending)**
- **Monitor individual RBM conditions encountered within this DC (bit 2)**

Application conditions:

Initialisation:

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_SWT_LS_UP[i] = 0
bit 0, bit 1 and bit 2 of STATE_RBM_FRQ_LS_UP[i] = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_SWT_LS_UP[i] = 0
bit 0 and bit 1 of STATE_RBM_FRQ_LS_UP[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_SWT_LS_UP[i]= 0
bit 1 of STATE_RBM_FRQ_LS_UP[i]= 0

Recurrence: **1s**

Activation: ***LV_DC = 1***

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_SWT_LS_UP[i] = 1

bit 2 of STATE_RBM_FRQ_LS_UP[i] = 1

The pending status of the following failures has to be checked only once:

For ETC and non-ETC variants :

Dependence	Error			
NC_CBK_EX_NR	LV_ERR_MAP_PLAUS	LV_ERR_VCC_PVS_2	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_TCO_EL
	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_ERR_TCO_PLAUS	LV_ERR_MAF_SCG_OC
	LV_ERR_MAF_SCP	LV_ERR_CRK_SYN	LV_ERR_CRK_PLAUS	LV_ERR_CRK_TOOTH_PER
	LV_ERR_EL_MAP	LV_ERR_CRK_TOOTH	LV_ERR_PER_CAM_IN_i	LV_ERR_PER_CAM_EX_i
	LV_ERR_PLAUS_CAM_IN_i	LV_ERR_PLAUS_CAM_EX_i	LV_ERR_SYN_CAM_IN_i	LV_ERR_SYN_CAM_EX_i
	LV_ERR_REF_CRK_CAM_IN_i	LV_ERR_REF_CRK_CAM_EX_i	LV_ERR_SYN_CRK_CAM_IN_i	LV_ERR_SYN_CRK_CAM_EX_i
	LV_ERR_CPS	LV_ERR_MEC_CPS	LV_ERR_FSD[NC_CBK_EX_NR]	LV_ERR_OBD_LSH_UP[NC_CBK_EX_NR]
	LV_ERR_LSH_UP[NC_CBK_EX_NR]			

Additionnal diagnosis to be checked only for ETC variant :

LV_ERR_TPS_VCC	LV_ERR_TPS_MAF_1	LV_ERR_TPS_MAF_2	LV_ERR_TPS_1
LV_ERR_TPS_2			

Additionnal diagnosis to be checked only for ISA variant :

LV_ERR_TPS_EL	LV_ERR_ISA_1	LV_ERR_ISA_2	LV_ERR_VCC_TPS

CTR_SAVE_SWT_LS_DOWN[NC_CBK_EX_NR]	MAF_HB	TEMP_CAT_STAT_MDL[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank
The signals from the control sensor upstream and the associated monitoring sensor downstream from the catalyst are used for catalyst diagnosis.

If a catalyst has good conversion properties, the oscillating lambda signal upstream from the catalyst - generated by the lambda controller (which shall ensure defined O2-load of catalyst) – is smoothed by the ***O****xygen* ***S****torage* ***C****apacity* of the catalyst.

If the conversion provided by the catalyst is low due to aging, poisoning from leaded fuel or misfiring, then the oscillating lambda signal upstream of the catalyst also exist downstream of the catalyst. The lambda oscillation downstream of the catalyst is detected by an oxygen sensor (monitoring sensor).

Every monitored catalyst or combination of catalysts shall be displayed when the HC emission exceeds the applicable emission test threshold.

Application conditions:

Recurrence: T_SAMPLE = 0.02 sec

Activation: LV_IGK transition 0 -> 1 (ignition key on) **OR** LC_AD_CLR_CAT_DIAG transition 0 -> 1 (reset of CAT-diagnosis values)

Deactivation: *LV_IGK = 1 -> 0 (ignition off)*

Initialization:
At activation and clearing CAT-Diagnosis values: reset of all variables and bits except those described below:
CTR_O2L_TRA_CAT_DIAG[i] = **1** %set transition counter at first to 1

IF EEPROM does not work)

THEN % default values are set

EFF_CAT_DIAG[i] = 0

CTR_CAT_DIAG_TOT[i] = 0

ELSE

IF EFF_CAT_DIAG[i] ≠ 0 **OR** CTR_CAT_DIAG_TOT ≠ 0

THEN no initialisation % New DC has been started from PWL and values from previous DC are still available / not yet stored in EEPROM.

ELSE % previously stored value is assigned

EFF_CAT_DIAG[i] = EFF_CAT_DIAG[i] stored in EEPROM

CTR_CAT_DIAG_TOT[i] = CTR_CAT_DIAG_TOT[i] stored in EEPROM

ENDIF

ENDIF

% Catalyst diagnosis should be reactivated not only at new driving cycle, but at clearing CAT-diagnosis values too.

Description:

The diagnosis algorithm is realized with a state machine in order to improve specification understanding and coherence between specification and SW.

Monitoring cycle:(STATE_CAT_DIAG[i]: CYC_LEAN and CYC_RICH)
The first monitoring cycle is started following the rich-lean change (LV_FAC_P_POS_LAM[i] 1->0). A monitoring cycle lasts one complete lambda controller period (2 subsequent lambda richness changes). Several monitoring cycles are needed to finish the diagnosis.

VLS_DOWN signal from monitoring lambda sensor is converted with inverse sensor characteristic to LAMB_CAT_DOWN[i].

In the Wait State before the first cycle after every reactivation (rich-lean change LV_FAC_P_POS_LAM) only LAMB_CAT_DOWN_MV[i] is calculated. LAMB_CAT_DOWN_SUM[i] is obtained by the integration (therefore factor T_SAMPLE used) of the LAMB_CAT_DOWN[i] over a complete monitoring cycle.

LAMB_CAT_DOWN_MV[i] is the mean value of the LAMB_CAT_DOWN[i] - lambda downstream the catalyst.

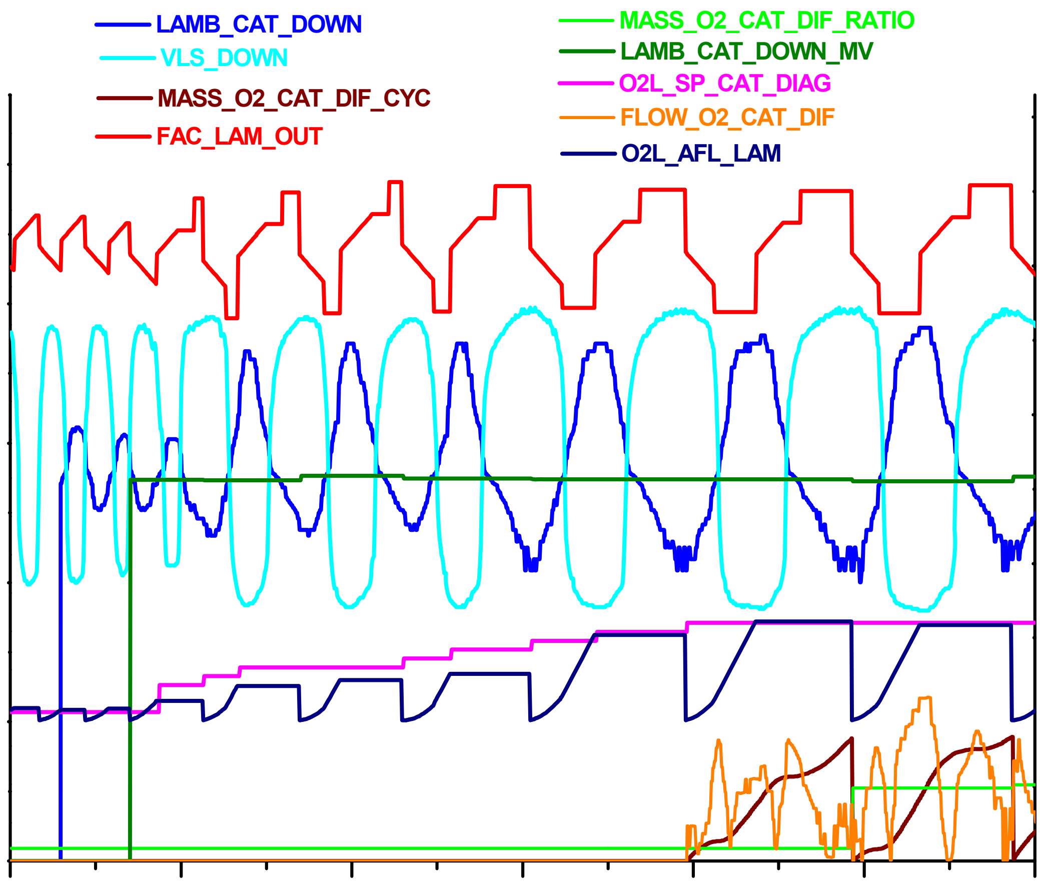
It will be observed, if LAMB_CAT_DOWN_MV[i] is in the right range, than the lambda and trim controller will be switch over to Cat Diag active. Trim control is switched to Cat Diag parameters (P-share to 0, I-share with own calibration and VLS setpoint depends from EFF_CAT_DIAG value)

At activation of catalyst diagnosis the O2-load of catalyst is switched to higher O2L_SP_CAT_DIAG (transition soft switch with ramp up from beginning O2-load (lambda controller switched in not active catalyst diagnosis) to aim O2-load with active cat diag in C_CTR_O2L_TRA_CAT_DIAG cycles so, that the mean value O2-load remains constant).

The calculation of MASS_O2_CAT_DIF_CYC[i] is based on LAMB_CAT_DOWN_MV[i] of the previous monitoring cycle. MASS_O2_CAT_DIF_CYC[i] is the integrated difference between current LAMB_CAT_DOWN[i] signal and LAMB_CAT_DOWN_MV[i] of the previous monitoring cycle multiplied with MAF_CYL so it means the O2 mass comming out of catalyst during 1 diagnosis period.

MASS_O2_CAT_DIF_CYC[i] is related to product of lambda controller (to O2-load of catalyst – comming into catalyst) and weighted with factor IP_FAC_MASS_O2_CAT_DIAG_xx .. to normalize the influence of working point. Result is MASS_O2_CAT_DIF_RATIO[i] - the diagnosis value of one monitoring cycle.

Illustration monitoring cycle



Validity check: (STATE_CAT_DIAG_i: Transition CYC_RICH -> CYC_LEAN)
The obtained MASS_O2_CAT_DIF_CYC[i] of a monitoring cycle is only used for the calculation of the diagnosis value if the validity check was passed (*STATE_VLD_CAT_DIAG_i reach the minimum value for validity*)

To pass the validity check it is necessary that:

- LAMB_CAT_DOWN[i] must cross at least once LAMB_CAT_DOWN_MV[i] of the previous monitoring: 0.bit of STATE_VLD_CAT_DIAG_i is set.

OR

- The deviation between LAMB_CAT_DOWN[i] and LAMB_CAT_DOWN_MV[i] of the last monitoring cycle is smaller than C_LAMB_CAT_MV_DELTA_MAX: 1.bit of STATE_VLD_CAT_DIAG_i is set.

OR

- LAMB_CAT_DOWN[i] cross two times LAMB_CAT_DOWN_MV[i] of the previous monitoring (periodically braking down of VLS_DOWN occurs): 2.bit of STATE_VLD_CAT_DIAG_i is set.

AND

- Difference between actual and the LAMB_CAT_DOWN_MV[i] of the last monitoring cycle is not too high (if LAMB_CAT_DOWN[i] cross two times LAMB_CAT_DOWN_MV[i], higher difference allowed): 3.bit of STATE_VLD_CAT_DIAG_i is set.

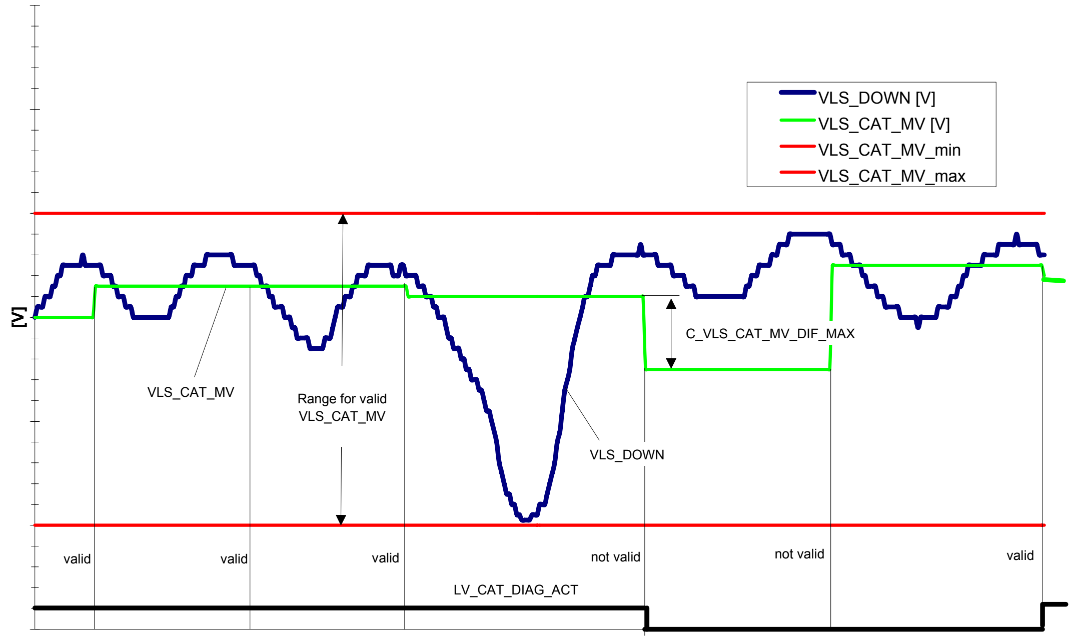
AND

- LAMB_CAT_DOWN_MV[i] is in the right range 4.bit of STATE_VLD_CAT_DIAG_i is set.

AND

- Catalyst temperature dynamic is limited: 5.bit of STATE_VLD_CAT_DIAG_i is set.

Illustration validity check



Calculation of diagnosis value: (STATE_CAT_DIAG[i]: Transition CYC_RICH -> CYC_LEAN)

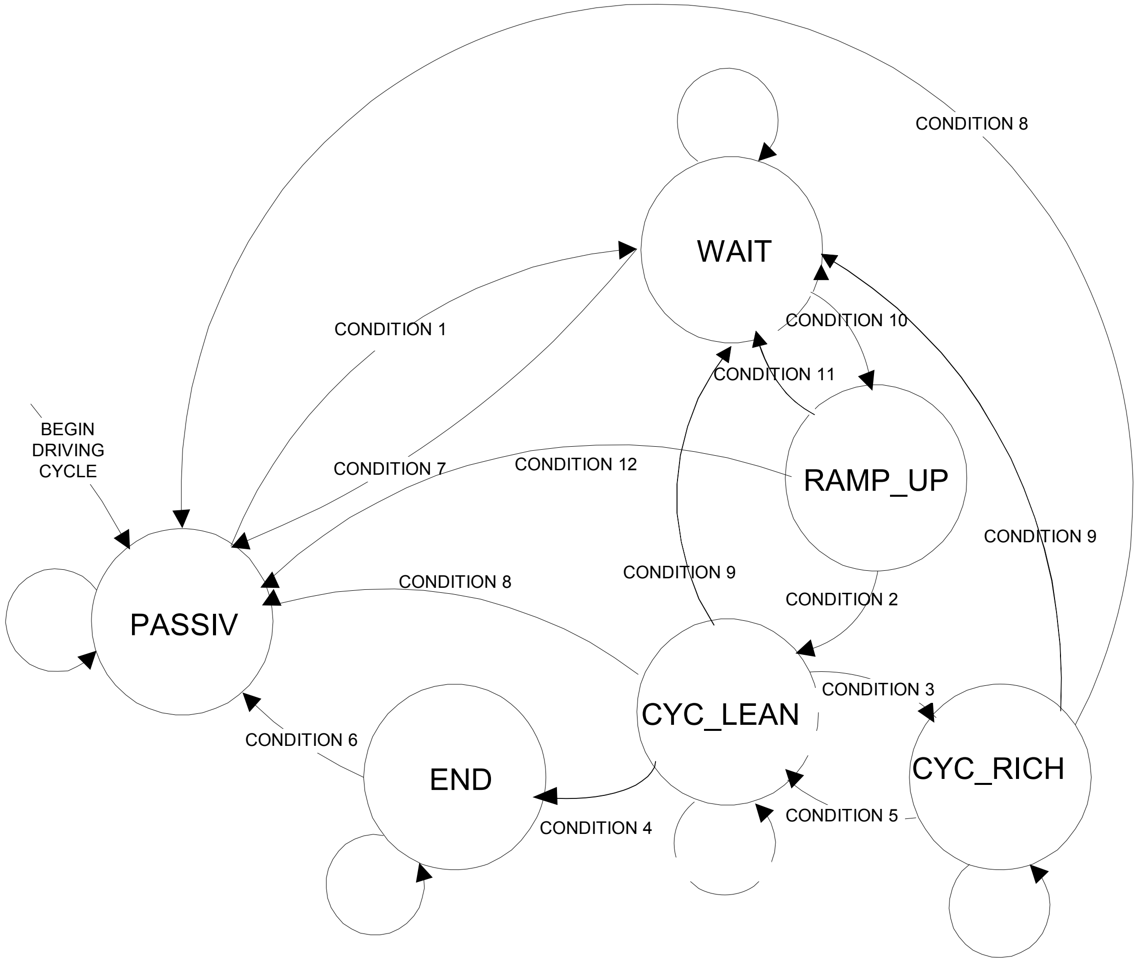
Monitoring cycle counter CTR_CAT_DIAG[i] is incremented for each valid monitoring cycle.

MASS_O2_CAT_DIF_CYC[i] is weighted by engine speed and load (IP_FAC_MASS_O2_CAT_DIAG_XX). From that calculation MASS_O2_CAT_DIF_RATIO[i] results. MASS_O2_CAT_DIF_RATIO[i] is summed up for all monitoring cycles. That summation give MASS_O2_CAT_DIF_RATIO_SUM[i]. Finally, the average of MASS_O2_CAT_DIF_RATIO_SUM[i] over all valid monitoring cycles give the diagnosis value EFF_CAT_DIAG[i]

End of diagnosis: (STATE_CAT_DIAG[i]: Transition CYC_LEAN -> END)

If the necessary number of valid monitoring cycles CTR_CAT_DIAG[i] reaches C_CTR_MIN_CAT_DIAG the diagnosis is ended for that driving cycle and the catalyst diagnosis value EFF_CAT_DIAG[i] is calculated and stored in the EEPROM.
The monitoring counter CTR_CAT_DIAG[i] is used to set the readiness code. For this reason C_CTR_MIN_CAT_DIAG must be reached in the emission test cycle.

State diagram: STATE_CAT_DIAG[i]



Note: The priorities of the conditions to change between states is defined by order described below.

B.28.1 Diagnosis algorithm

B.28.2 Application Assistance

For OBD II O2 sensor diagnosis: C_CTR_MIN_CAT_DIAG has to be applied higher then the thresholds C_SUM_CYC_MIN_DIAG and C_SUM_CYCNR_MIN_DIAG (LV_LS_FRQ_DIAG_READY -> 1 and LV_LS_SWT_DIAG_READY -> 1).

They have to be reached before STATE_CAT_DIAG[i] is set to END.

Hint:
An active catalyst diagnosis can disable the module “Downstream Fuel Trim Regulation” also a additional lambda offset can be imposed on the basic lambda setpoint in the module “Basic Lambda setpoint”. When the catalyst diagnosis is completed the above functions return to their normal operation.

B.28.3 Overview: Chronological order of diagnosis algorithm:

Triggering of catalyst diagnosis calculation by p-jump of lambda controller LV_FAC_P_POS_LAM[i] 0->1 and 1->0...

O2L_SP_CAT_DIAG[i] = IP_O2L_SP_CAT_DIAG (N_32, MAF_HB)

%setpoint of the O2-load 'with CAT DIAG' for the lambda controller (output, not used here)

1) LAMB_CAT_DOWN[i] = IP_LAMB_CAT(VLS_DOWN[i]) %every recurrence

2) $LAMB\_CAT\_DOWN\_SUM[i]_{n+1}$ = $LAMB\_CAT\_DOWN\_SUM[i]_{n}$ + LAMB_CAT_DOWN[i]

%every recurrence

3) LAMB_CAT_DOWN_MV[i] = LAMB_CAT_DOWN_SUM[i] / CTR_LAMB_CAT_DOWN_SUM[i]

(after end of current diagnosis period)

4) FLOW_O2_CAT_DIF[i] = 0.23 * (1000/3600)[g/s] * I1/LAMB_CAT_DOWN_MV[i] - 1/LAMB_CAT_DOWN[i] I * (MAF_CYL[kg/h] / NC_CBK_EX_NR)

5) $MASS\_O2\_CAT\_DIF\_CYC[i]_{n+1}$ = $MASS\_O2\_CAT\_DIF\_CYC[i]_{n}$ + FLOW_O2_CAT_DIF[i]*T_SAMPLE[ms] %every recurrence

6) MASS_O2_CAT_DIF_RATIO[i] = MASS_O2_CAT_DIF_CYC[i] * IP_FAC_TEMP_CAT_DIF_STAT / (O2L_AFL_LAM_HLD[i] * IP_FAC_MASS_O2_CAT_DIAG_XX) $\Rightarrow$ with XX for AT or MT (after end of current diagnosis period)

7) $MASS\_O2\_CAT\_DIF\_RATIO\_SUM[i]_{n+1}$ = $MASS\_O2\_CAT\_DIF\_RATIO\_SUM[i]_{n}$ + MASS_O2_CAT_DIF_RATIO[i]

(after end of current diagnosis period and passed validity check)

8) EFF_CAT_DIAG[i] = MASS_O2_CAT_DIF_RATIO_SUM[i] / CTR_CAT_DIAG[i]

(Catalyst diagnosis value after diagnosis finished)

B.28.4 Application Incidence for Catalyst Efficiency Diagnosis (OSC Method)

B.28.4.1 Diagnosis inhibition flag

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_INH_DIAG_CAT_DIAG_i	V	0...1H	0...1	1	
Flag to inhibit catalyst diagnosis function if there is a component failure					
LV_CL_CALC_AVL	V/O	0...1H	0...1	1	-
Flag to inhibit Cat. Dianosis in case of Min-Purge (pre-defined to 0)					

Input data:

LV_DC	LV_ERR_CRK	LV_ERR_CAM_IN_i	LV_ERR_MAP
LV_ERR_MAF	LV_ERR_TCO	LV_ERR_TPS	LV_CDN_DIAG_CAT_DIAG_i
LV_ERR_VS	LV_MIS_STATE_B1	LV_MIS_STATE_A	LV_MIS_STATE_B4
LV_ERR_LS_DOWN_[NC_CBK_EX_NR]	LV_ERR_FSD[NC_CBK_EX_NR]	LV_ERR_LS_UP_[NC_CBK_EX_NR]	LV_FAC_P_POS_LAM[NC_CBK_EX_NR]
LV_ERR_AMP		LV_ERR_MEC_IVVT_EX_i	LV_ERR_CPS
LV_ERR_IGC	LV_ERR_IV[NC_CYL_NR]	LV_ERR_MEC_IVVT_IN_i	
LV_CDN_VB_OBD2	LV_ERR_MEC_CPS	LV_ERR_FSD_LAM_LIM_i	LV_ERR_LOAD_TPS_PLAUS
STATE_CP	CL_MMV	LV_ERR_PUC_LS_DOWN	LV_ERR_CAM_EX[NC_NR_CAM_CBK]

FUNCTION DESCRIPTION:

If one of the following components fail the catalyst efficiency diagnosis function is stopped by LV_INH_DIAG_CAT_DIAG_i= 1.

The inhibition of the catalyst diagnosis can be deactivated by LC_INH_DIAG_CAT_DIAG_MAN_DEAC = 1.

For LC_INH_DIAG_CAT_DIAG_MAN_DEAC = 1 the catalyst diagnosis function is not inhibited by a component failure. In that way the diagnosis conditions can be ensured for application reasons.

T_VLS_CYC_EFC_i is defined to have an interface to the OSC cat. diagnosis that fits for different definitions (different physical limit) of the lean / rich dwell time of the AFR.

Application conditions:

Recurrence: 0.02 sec

Activation: LV_DC transition 0 -> 1 (start driving cycle)

Deactivation: LV_DC transition 1 -> 0 (driving cycle terminated)

Formula section:

```
IF
        STATE_CP = MIN_PURGE AND CL_MMV < C_CL_ MAX_CAT_DIAG
        THEN LV_CL_CALC_AVL = 1
        ELSE LV_CL_CALC_AVL = 0
ENDIF

IF      (Inhibition due to OBD-I error)
        LV_ERR_CAM_IN_i = 1
   OR   LV_ERR_CAM_EX_i = 1
   OR   LV_ERR_CRK = 1
   OR   LV_ERR_TCO = 1
   OR   LV_ERR_MAF = 1
   OR   LV_ERR_MAP = 1
   OR   LV_ERR_VS = 1
   OR   LV_ERR_TPS = 1
   OR   LV_ERR_AMP =1
   OR   LV_ERR_CPS = 1
   OR   LV_ERR_IGC = 1
   OR   LV_ERR_IV[NC_CYL_NR] = 1
   OR   LV_ERR_MEC_IVVT_IN_i = 1
   OR   LV_ERR_MEC_IVVT_EX_i = 1
   OR   LV_CDN_VB_OBD2 = 0
   OR   LV_ERR_PUC_LS_DOWN_i = 1

        (Inhibition due to OBD-II error)
   OR   LV_ERR_MEC_CPS = 1

   OR   LV_ERR_FSD_LAM_LIM_i =1

   OR   LV_ERR_LOAD_TPS_PLAUS = 1
   OR   LV_ERR_LS_UP[NC_CBK_EX_NR] = 1
        (summary error bit of upstr. Lambda sensor due to OBD I and OBD II error)

   OR   LV_ERR_LS_DOWN[NC_CBK_EX_NR] = 1
        (summary error bit of downstr. Lambda sensor due to OBD I and OBD II error)

   OR   LV_ERR_FSD[NC_CBK_EX_NR] = 1
   OR   LV_MIS_STATE_A = 1
   OR   LV_MIS_STATE_B1 = 1
   OR   LV_MIS_STATE_B4 = 1

 AND    LC_INH_DIAG_CAT_DIAG_MAN_DEAC = 0
THEN    LV_INH_DIAG_CAT_DIAG_i= 1
ELSE    LV_INH_DIAG_CAT_DIAG_i = 0
```

Remark:
The calculation of lean/rich dwell time is done in the Lambda Control and imported into the Catalyst diagnosis function directly from there.

Calibration data:

B.28.4.2 O2 sensors diagnosis end flag grouping

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_LS_UP_DIAG_END[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	
Flag for Upstream O2 sensor diagnosis (relevant for Catalyst Diagnosis) end status					
LV_LS_DOWN_DIAG_END[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Flag for Downstream O2 sensor diagnosis (relevant for Catalyst Diagnosis) end status					

Input data:

LV_END_DIAG_SWT_LS_UP[NC_CBK_EX_NR]	LV_END_DIAG_FRQ_LS_UP[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

As an Upstream O2 sensor failure can cause high Catalyst Diagnosis result (i.e. slow control frequency of upstream O2 sensor), it is checked if all relevant Upstream O2 sensor diagnosis are finished before to decide for Catalyst Diagnosis failure.

As a Downstream O2 sensor failure can lead only to a non-detection of a faulty Catalyst, LV_LS_DOWN_DIAG_ END[NC_CBK_EX_NR] = 1.

Application conditions:

Recurrence: 1 sec

Activation: LV_DC transition 0 -> 1 (start driving cycle)

Deactivation: LV_DC transition 1 -> 0 (driving cycle terminated)

Formula section:

If LV_END_DIAG_SWT_LS_UP[NC_CBK_EX_NR] = 1 **and**
LV_END_DIAG_FRQ_LS_UP[NC_CBK_EX_NR] = 1
Then
LV_LS_UP_DIAG_END[NC_CBK_EX_NR] = 1
Else
LV_LS_UP_DIAG_END[NC_CBK_EX_NR] = 0

LV_LS_DOWN_DIAG_ END[NC_CBK_EX_NR] = 1 always.

B.28.4.3 Interface to Rate-Based Monitoring

LV_ERR_VCC_PVS_2	LV_ERR_MAP_PLAUS		

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the Catalyst Diagnosis and the Rate-Based Monitoring statistics is defined with STATE_RBM_CAT_DIAG[NC_CBK_EX_NR].

Within STATE_RBM_CAT_DIAG[NC_CBK_EX_NR], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation:

at ECU reset :
bit 0, bit 1 and bit 2 of STATE_RBM_ CAT_DIAG[NC_CBK_EX_NR] = 0
at LV_DC 0 → 1 transition :
bit 0 and bit 1 of STATE_RBM_ CAT_DIAG[NC_CBK_EX_NR] = 0
on failure memory reset :
bit 1 of STATE_RBM_ CAT_DIAG[NC_CBK_EX_NR] = 0

Recurrence: 1s

Activation: *LV_DC = 1*

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_ CAT_DIAG[NC_CBK_EX_NR] = 1

The pending status of the following failures has to be checked only once:

For ETC and non-ETC variants :

B.30 Activation conditions for catalyst efficiency and O2 sensor diagnosis(bin/bin)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CAT_DIAG_CDN_ACT[NC_CBK_EX_NR]	V/O	0 ... 1H	0 ... 1	1	
Activation conditions for O2 sensor and catalyst efficiency diagnosis (OSC-method)					
MAF_INT_DLY_CAT_DIAG[NC_CBK_EX_NR]	V	0...FFFFH	0...1820.42	0.028	g
Air mass flow integral after conditions fullfilled for cat diag activation					

Input data:

AMP_AD	N_32	LV_CL_CALC_AVL	T_DLY_P_LAM_ADJ[NC_CBK_EX_NR]
LV_SAWUP	LV_IGK	LV_LAM_LSCL[NC_CBK_EX_NR]	LV_LAM_STOP[NC_CBK_EX_NR]
STATE_CP	CL_MMV		STATE_LSH_DOWN[NC_CBK_EX_NR]
	TCO		LV_LS_DOWN_READY[NC_CBK_EX_NR]
MAF_CYL	MAF		LV_CAT_PURGE_ACT[NC_CBK_EX_NR]
TEMP_CAT	VS	NC_CBK_EX_NR	LV_LDC_CAT[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank

That function determines the common activation flag LV_CAT_DIAG_CDN_ACT[i] for catalyst efficiency (OSC method) and O2 sensor diagnosis. The common activation flag LV_CAT_DIAG_CDN_ACT[i] can be set manually by LC_CAT_DIAG_CDN_ACT_MAN.

Application conditions:

Recurrence: T_SAMPLE = 0.02 sec

Activation: LV_IGK transition 0 -> 1 (ignition key on) **OR** new activation after Fault memory cleared (CLR_FMY)

Deactivation: LV_IGK = 1 -> 0 (ignition off)

MAF_INT_DLY_CAT_DIAG[i] is initialized by 0 at each activation and at Failure memory reset.

Formula section:

C_PQ_PUT_CTL	LV_ST_END	LV_MAF_SWI	LV_INH_MAP_CTL
AR_RED_BAS	AR_RED_AD_FAC_COR		

FUNCTION DESCRIPTION:

General information:

The load/TPS plausibility check proofs the consistency between load and throttle position. The plausibility is checked by comparing the excitation of the controller (reduced area if PQ <= C_PQ_PUT_CTL (which is defined in IMM, 30404T01.00A), pressure if PQ > C_PQ_PUT_CTL) with the corresponding "basic" value (AR_RED_BAS if area controlled, PUT if pressure controlled). In addition, the area adaptation values (AR_RED_AD_ADD and AR_RED_AD_FAC) are checked seperatly. This is necessary, because at closed throttle small absolute values (e.g. due to leakage air adaptation) may result in large relative values that pretend a bad system.

If the current load and throttle position signals are not consistent (inplausible) a flag is set, that indicates problems in the plausibility check (LV_ERR_LOAD_TPS_PLAUS=1).

If the controller excitation (or area adaptation value) is above a calibratable threshold, i.e. it is large compared to the corresponding basic reduced area, it is assumed, that an error in the system occured. The unplausibility detected only states, that the actual load and throttle position do not fit together and therefore a large controller excitation is required to bring them into line.

If the fuel system diagnosis is available it is possible to identify the reason of the unplausibility (i.e. error in the load signal or throttle position). To get reasonable results from the FSD, a certain delay time is required before accessing the FSD results.

Application conditions:

Initialization:
LV_CDN_DIAG_LOAD_TPS_PLAUS = 0
LV_END_DIAG_ LOAD_TPS_PLAUS = *Refer to filtering configuration for the initialisation value*
LV_ERR_ LOAD_TPS_PLAUS = *Refer to filtering configuration for the initialisation value*
ERR_SYM_ LOAD_TPS_PLAUS = *Refer to filtering configuration for the initialisation value*
If *LV_IGK = 1 and LV_ST_END= 0--->1*

Then

LV_PUT_CTL_RST=LV_AR_RED_CTL_RST=LV_ERR_RATIO_CHK=PUT_MDL_DIF_MMV=PUT_MDL_DIF_MMV_REL=AR_RED_DIF_REL_MMV=0

endif

Recurrence: ***20 ms*** all tasks except the following

Activation:

if **(**LV_IGK = 1 and LV_ST_END = 1) **and**
LV_ERR_LOAD_TPS_PLAUS=0 **and**
LV_INH_LOAD_TPS_PLAUS = 0 **and**
C_N_MIN_LOAD_TPS_PLAUS < N_32 < C_N_MAX_LOAD_TPS_PLAUS **and**
C_PQ_MIN_LOAD_TPS_PLAUS < PQ < C_PQ_MAX_LOAD_TPS_PLAUS **and**
(C_MAP_DRV1_MIN_LOAD_TPS_PLAUS < MAP_DRV1 < C_MAP_DRV1_MAX_LOAD_TPS_PLAUS)

then

LV_CDN_DIAG_LOAD_TPS_PLAUS=1

else

LV_CDN_DIAG_LOAD_TPS_PLAUS=0

endif

All the calculations for the plausibility checks are only done, if the function is activated, i.e. LV_CDN_DIAG_LOAD_TPS_PLAUS = 1, otherwise the plausibility check is stopped and all values are stored until reactivation.

B.31.1 Plausibility check of area adaptation values

Description:

The additive and multiplicative adaptation values of the reduced area are checked seperatly. If one of them exceeds the corresponding threshold, a related error flag is set, if the value is inside the thresholds the respective flag is reset. Because adaptation is done with a slow recurrence, no filtering of the adaptation values is required and they are directly used.

Formula section:

Check the additive adaptation mean moving value of the reduced area.

If (AR_RED_AD_ADD-AR_RED_AD_ADD_MMV) < C_AR_RED_AD_ADD_PLAUS_MIN **or**

(AR_RED_AD_ADD -AR_RED_AD_ADD_MMV > C_AR_RED_AD_ADD_PLAUS_MAX

then

Symptom "additive adaption out of range" is active, anti-bounce counter increment

ERR_SYM_LOAD_TPS_PLAUS = 1H

else

Symptom "additive adaption out of range" is passive, anti-bounce counter decrement

ERR_SYM_LOAD_TPS_PLAUS = 0H

Endif

Check the multiplicative adaptation value of the reduced area.

If AR_RED_AD_FAC < C_AR_RED_AD_FAC_PLAUS_MIN **or**
AR_RED_AD_FAC > C_AR_RED_AD_FAC_PLAUS_MAX

then

Symptom "multiplicative adaption out of range" is active, anti-bounce counter increment

ERR_SYM_LOAD_TPS_PLAUS = 2H

else

Symptom "multiplicative adaption out of range" is passive, anti-bounce counter decrement

ERR_SYM_LOAD_TPS_PLAUS = 0H

endif

Filtering :

Apply filter on current symptoms
If filtering result available (after debounce)
LV_ERR_LOAD_TPS_PLAUS = filtering result
LV_END_DIAG_LOAD_TPS_PLAUS = 1
Delivery the result to Error Management
Endif

B.31.2 Plausibility check of reduced area controller excitation

Description:

In the plausibility check only the steady state conditions are of interest. Therefore the controller excitations fo the reduced area controller is smoothed with a low pass filter. This controller output is only calculated as long as the corresponding controller is active. If the plausibility check is deactivated (LV_CDN_DIAG_LOAD_TPS_PLAUS = 0) the calculation of the moving mean value from the reduced area controller output is stopped (but not reset).

In case of no AMP sensor is available, diagnosis threshold must be set versus AMP in order too take in account possible variation of Ambient Pressure (ECU reset at high altitude, vehicle transportation on a truck from high to low altitude or vice-versa).

If the filtered reduced area controller AR_RED_DIF_REL_MMV reaches the thresholds AR_RED_DIF_REL_PLAUS_MIN or AR_RED_DIF_REL_PLAUS_MAX the plausibility check error is set to active.

Formula section:

if PQ <= C_PQ_PUT_CTL

then

$$AR\_RED\_DIF\_REL\_MMV_N = AR\_RED\_DIF\_REL\_MMV_{N-1} * (1 - C\_CRLC\_AR\_RED\_DIF\_REL) + AR\_RED\_DIF\_REL_N * C\_CRLC\_AR\_RED\_DIF\_REL$$

endif

AR_RED_SUM_COR_ACT_REL = AR_RED_DIF_REL_MMV + AR_RED_AD_FAC_COR +
((AR_RED_AD_ADD – AR_RED_AD_ADD_MMV) * 100 / AR_RED_BAS)

(converted to phys. resolution of AR_RED_SUM_COR_ACT_REL)

Calculation of diagnosis thresholds

AR_RED_DIF_REL_PLAUS_MIN = IP_AR_RED_DIF_REL_PLAUS_MIN

AR_RED_DIF_REL_PLAUS_MAX = IP_AR_RED_DIF_REL_PLAUS_MAX

Check the reduced area controller excitation

if PQ <= C_PQ_PUT_CTL **and**
(AR_RED_SUM_COR_ACT_REL < AR_RED_DIF_REL_PLAUS_MIN **or**
AR_RED_SUM_COR_ACT_REL > AR_RED_DIF_REL_PLAUS_MAX **)**
then

Symptom “filtered reduced area controller out of range” is active, anti-bounce counter increment

ERR_SYM_LOAD_TPS_PLAUS = 4H

else

Symptom “filtered reduced area controller out of range” is passive, anti-bounce counter decrement

ERR_SYM_LOAD_TPS_PLAUS = 0H

Endif

Filtering :

Apply filter on current symptoms
If filtering result available (after debounce)
LV_ERR_LOAD_TPS_PLAUS = filtering result
LV_END_DIAG_LOAD_TPS_PLAUS = 1
Delivery the result to Error Management
Endif

B.31.3 Plausibility check of pressure controller excitation

Description:

In the plausibility check only the steady state conditions are of interest. Therefore the controller excitation of the pressure controller is smoothed with a low pass filter. This filtered controller output is only calculated as long as the controller itself is active. If the plausibility check is deactivated (LV_CDN_DIAG_LOAD_TPS_PLAUS = 0) the calculation of the moving mean value from the pressure controller output is stopped (but not reset).

Like in the algorithm for reduced area plausibility check, in case of no AMP sensor is available, diagnosis threshold must be set versus AMP in order too take in account possible variation of Ambient Pressure (ECU reset at high altitude, vehicle transportation on a truck from high to low altitude or vice-versa).

If the ratio of the filtered pressure controller and the (adapted) ambient pressure PUT_MDL_DIF_MMV_REL reaches the threshold PUT_MDL_DIF_REL_PLAUS_MIN or PUT_MDL_DIF_REL_PLAUS_MAX the plausibility check error is set to active.

Formula section:

if PQ > C_PQ_PUT_CTL
then

$$PUT\_MDL\_DIF\_MMV_{N} = PUT\_MDL\_DIF\_MMV_{N-1} * (1 - C\_CRLC\_PUT\_MDL\_DIF) + PUT\_MDL\_DIF_{N} * C\_CRLC\_PUT\_MDL\_DIF$$

$$PUT\_MDL\_DIF\_MMV\_REL = \frac{PUT\_MDL\_DIF\_MMV}{PUT}$$

endif

Calculation of diagnosis thresholds

PUT_MDL_DIF_REL_PLAUS_MIN = IP_PUT_MDL_DIF_REL_PLAUS_MIN

PUT_MDL_DIF_REL_PLAUS_MAX = IP_PUT_MDL_DIF_REL_PLAUS_MAX

Check the ambient controller excitation

if PQ > C_PQ_PUT_CTL **and**
(PUT_MDL_DIF_MMV_REL < PUT_MDL_DIF_REL_PLAUS_MIN **or**
PUT_MDL_DIF_MMV_REL > PUT_MDL_DIF_REL_PLAUS_MAX **)**
then

Symptom “filtered ambient controller out of range” is active, anti-bounce counter increment

ERR_SYM_LOAD_TPS_PLAUS = 8H

else

Symptom “filtered ambient controller out of range” is passive, anti-bounce counter decrement

ERR_SYM_LOAD_TPS_PLAUS = 0H

Endif

Filtering :

Apply filter on current symptoms
If filtering result available (after debounce)
LV_ERR_LOAD_TPS_PLAUS = filtering result
LV_END_DIAG_LOAD_TPS_PLAUS = 1
Delivery the result to Error Management
Endif

B.31.4 Reset and additional measures to be taken

Description:

If a debounced unplausibility is detected the reduced area controller and the pressure controller must be reset (also for the rest of the driving cycle). Precontrolled state of the intake manifold model (without controller excitation) is precondition to be able to decide which of the sensors caused the error.

Temporary the old flag indicating an unplausibility´, LV_ERR_RATIO_CHK, will be provided too.

Yet only a few generic actions taken on plausibility error are defined:

- The Intake Manifold Model goes from closed to open loop and in addition the controllers are reset.
- The adaptation of the ambient pressure is forbidden.

Additional project-specific actions can be defined in the "Application incidence for load/TPS plausibility check".

Formula section:

if LV_ERR_LOAD_TPS_PLAUS = 1
then

if LV_MAF_SWI = 1 **or** LV_INH_MAP_CTL = 1
then LV_AR_RED_CTL_RST = 1 all set for this DC
LV_PUT_CTL_RST = 1

endif

LV_ERR_RATIO_CHK = 1

endif

B.32 Identification of reason for unplausibility (only possible if LC_USE_FSD = 1)

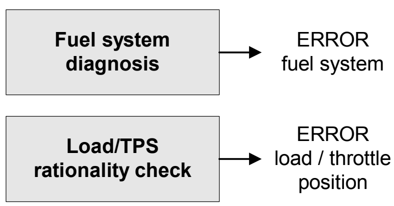
Description:

The load/TPS rationality check can detect unplausibilities in the system, but only in combination with the output of the FSD (fuel system diagnosis) it is possible to identify the faulty sensor (load or throttle position). Usually the reduced area and the pressure controller will be deactivated (and reset) if a plausibility error occurs. This means, the IMM goes to precontrolled (the system will be α-N-controlled) and the only signal used is the throttle position, it means MAF is calculated based on TPS signal but no sensor signal. Therefore if the FSD detects an error in the fuel path, this means that the TPS signal is bad. If the FSD detects no error this means, the unplausibility was caused from a faulty load sensor.



ERROR fuel system	0	1	0	1
ERROR load / throttle position	0	0	1	1
	-	-	load	TPS

The diagnosis can be started if the FSD-diagnosis has been finished a diagnosis window (LV_END_DIAG_WIN_FSD[i] = 1).

If there are two banks (i=0,1), it is necessary to take into account both of them.

FUNCTION DESCRIPTION:

General information:

Depending on projects specific requirements, the load/TPS plausibility check can be inhibited by setting LV_INH_LOAD_TPS_PLAUS = 1.

Application conditions:

Initialization: LV_INH_LOAD_TPS_PLAUS is set 0 at reset
or at transition LV_DC: 0 →1

Recurrence: **20 ms**

Activation: **if** LV_DC=1

B.33.1 Inhibition of the load/TPS plausibility check

If an error is marked in the throttle channel plausibility flag and yet no channel is detected as faulty, the load/TPS plausibility check will be inhibited until the plausibility check for throttle position sensor is finished.

```

Import actions:

ACTION_ERRM_GetLvEndDiag(IN <IDX_DIAG>, OUT <LV_END_DIAG>)
Action that returns the status of the failure availability
ACTION_ERRM_NoFilterReset(IN <IDX_DIAG>, OUT <LV_ERR>)
This action resets data filter in case of no filter usage
ACTION_ERRM_NoFilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <LV_ERR_SET>, IN <LV_ERR_RST>, IN <LV_END_DIAG>, OUT <LV_ERR>)
This action returns the result on symptoms detected at each diagnostic recurrence, when no filter is used

B.34.1 General Information:

For systems equipped with more air pressure sensors the plausibility diagnosis is done by comparing the measured pressures at stopped engine, when there is ambient pressure everywhere, also at the throttle and in the intake manifold. If two sensors show the same pressure and a third differs significantly, the third sensor is implausible.

If there are only two pressure sensors or if the implausibility occurs in an engine state when only two pressures are equal or close to each other, then only an implausible pair on sensors can be pointed to. In another engine state is tried to find out, which of the two sensors is faulty.

Implausibilities are detected based on the following relations

AMP = PUT in ES and PWL

AMP = MAP in ES and PWL

PUT = MAP in ES and PWL

AMP = PUT in FL for non charged engines

PUT = MAP in FL for charged engines

MAP is higher in ES than in IS

MAP is higher in FL than in IS

PUT is higher in FL than in ES for charged engines

PUT > AMP in FL for charged engines

PUT = AMP in PU/PUC for charged engines

For naturally aspirated engines, when the engine is standing or in full load, if the difference between the measured AMP and MAP values is above a certain threshold, a counter is started and incremented up to a certain maximum value. If this maximum is reached, a preliminary error flag, LV_SYM_AMP_MAP_PLAUS_ES and the corresponding error symptoms are set. However, the setting of the preliminary bit is not registered in the error memory. This is done in order to detect the exact origin of the deviation i.e. is the MAP sensor or AMP sensor faulty.

Once the preliminary error bit is set, the value of MAP_MES is checked when engine is in state idle or part load. If there is no change in the value of the measured manifold pressure compared to the pressure measured during engine stop or full load, it can be concluded that the MAP sensor is faulty. If however the value of MAP_MES does change, it is most probably a defective AMP sensor but it could also be due to a faulty(e.g. clogging up) air cleaner. In such a case, before the AMP sensor is replaced in the car, it should be made sure there is no clogging in the air cleaner.

For MAF-systems equipped with a MAP sensor the plausibility diagnosis for the manifold air pressure sensor is done as following:

At stopped engine or PWL, when there is ambient pressure everywhere, also at the throttle and in the intake manifold, it is monitored whether the measured manifold air pressure is within the maximum possible and the minimum possible ambient pressure (calibratable thresholds coming from the module ambient pressure adaptation).

When the engine is running the plausibility is checked between the MAP value measured from the MAP sensor and the MAP value calculated by the air path model (from the engine speed, the TPS value and the MAF sensor value). If the difference between these two values is over a calibratable threshold then it is supposed that the MAP sensor is faulty (assumed that the MAF sensor is all right).

If a system is not equipped with one of the pressure sensors, the function parts concerning this sensor are omitted in the software by means of compiler switches

SWITCH_CASE

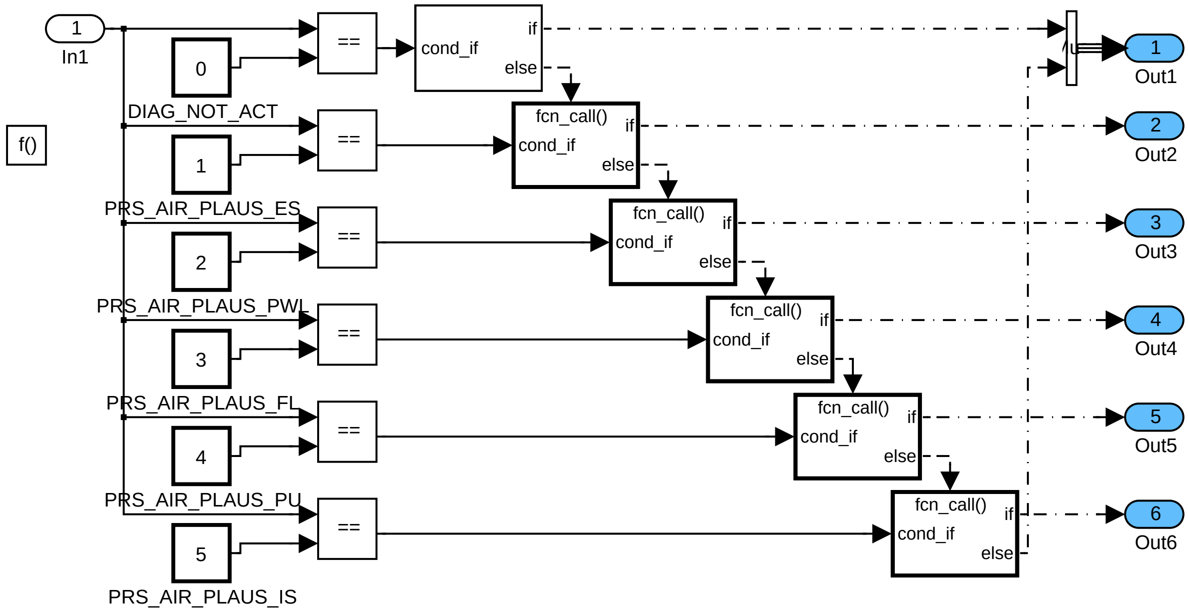

Figure 11 INSY_PLADGAMP0/ operate_100MS/ Switch_Case

SUB_3: Overview over all possible pressure sensor plausibilities in ES or PWL:

For systems equipped with more air pressure sensors the plausibility diagnosis is done by comparing the measured pressures at stopped engine, when there is ambient pressure everywhere, also at the throttle and in the intake manifold. If two sensors show the same pressure and a third differs significantly, the third sensor is implausible.

If there are only two pressure sensors or if the implausibility occurs in an engine state when only two pressures are equal or close to each other, then only an implausible pair on sensors can be pointed to. In another engine state it is tried to find out, which of the two sensors is faulty.

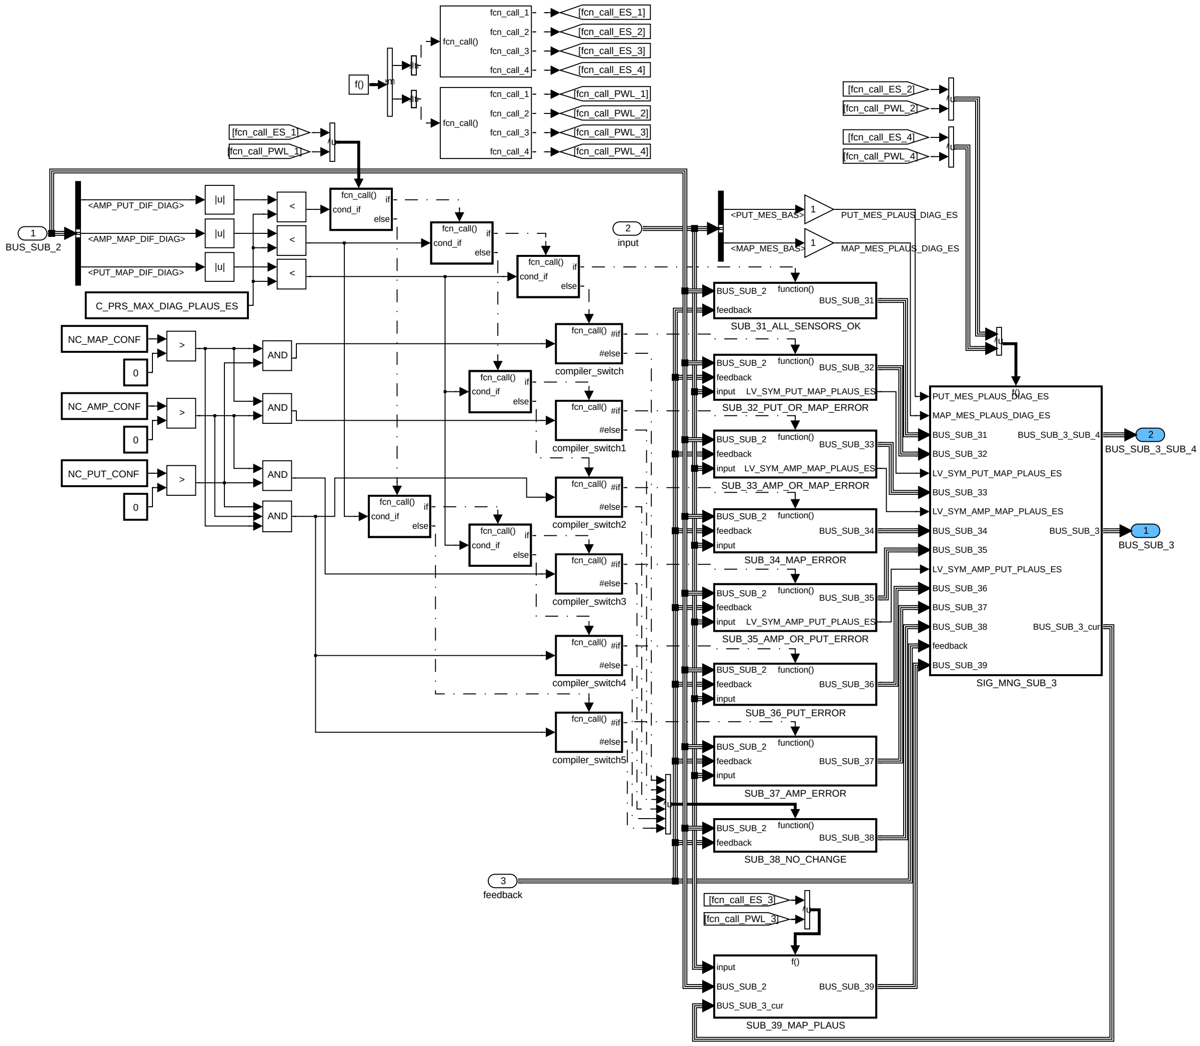

Figure 12 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL

SUB_31: All available pressure sensors are O.K.:

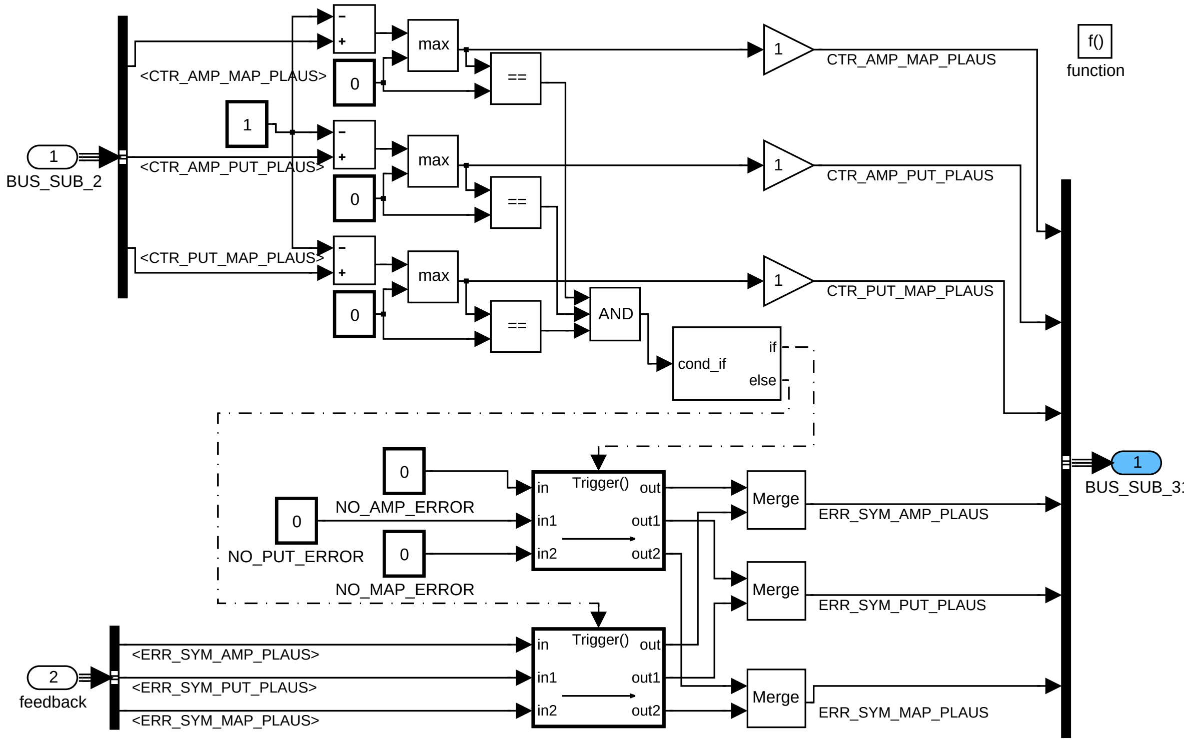

Figure 13 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_31_ALL_SENSORS_OK

SUB_32: Detection that PUT-sensor or MAP-sensor is defective:

Only these two pressure sensors are available. A difference between the two pressures is detected in the current state ES or PWL. If you have been in state idle speed before entering the current state ES or PWL then the defective sensor can be pointed out and the corresponding error symptom is set. But if you haven´t been in state idle speed before, only an implausible pair of sensors can be pointed out and a preliminary flag is set: LV_SYM_PUT_MAP_PLAUS_ES. Another engine state is necessary to point out which sensor is defective.

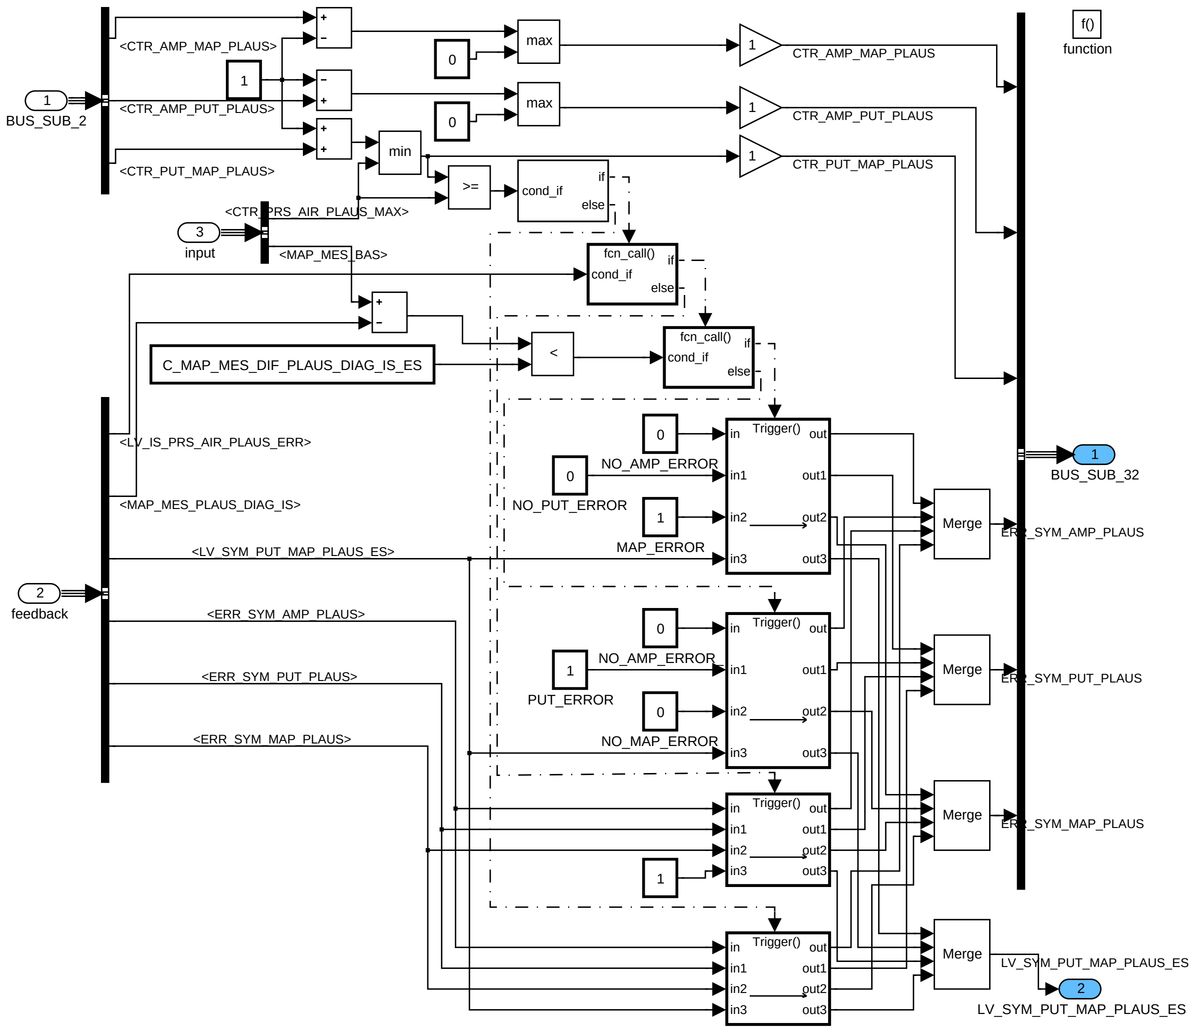

Figure 14 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_32_PUT_OR_MAP_ERROR

SUB_33: Detection that AMP-sensor or MAP-sensor is defective:

Only these two pressure sensors are available. A difference between the two pressures is detected in the current state ES or PWL. If you have been in state idle speed before entering the current state ES or PWL then the defective sensor can be pointed out and the corresponding error symptom is set. But if you haven´t been in state idle speed before, only an implausible pair of sensors can be pointed out and a preliminary flag is set: LV_SYM_AMP_MAP_PLAUS_ES. Another engine state is necessary to point out which sensor is defective.

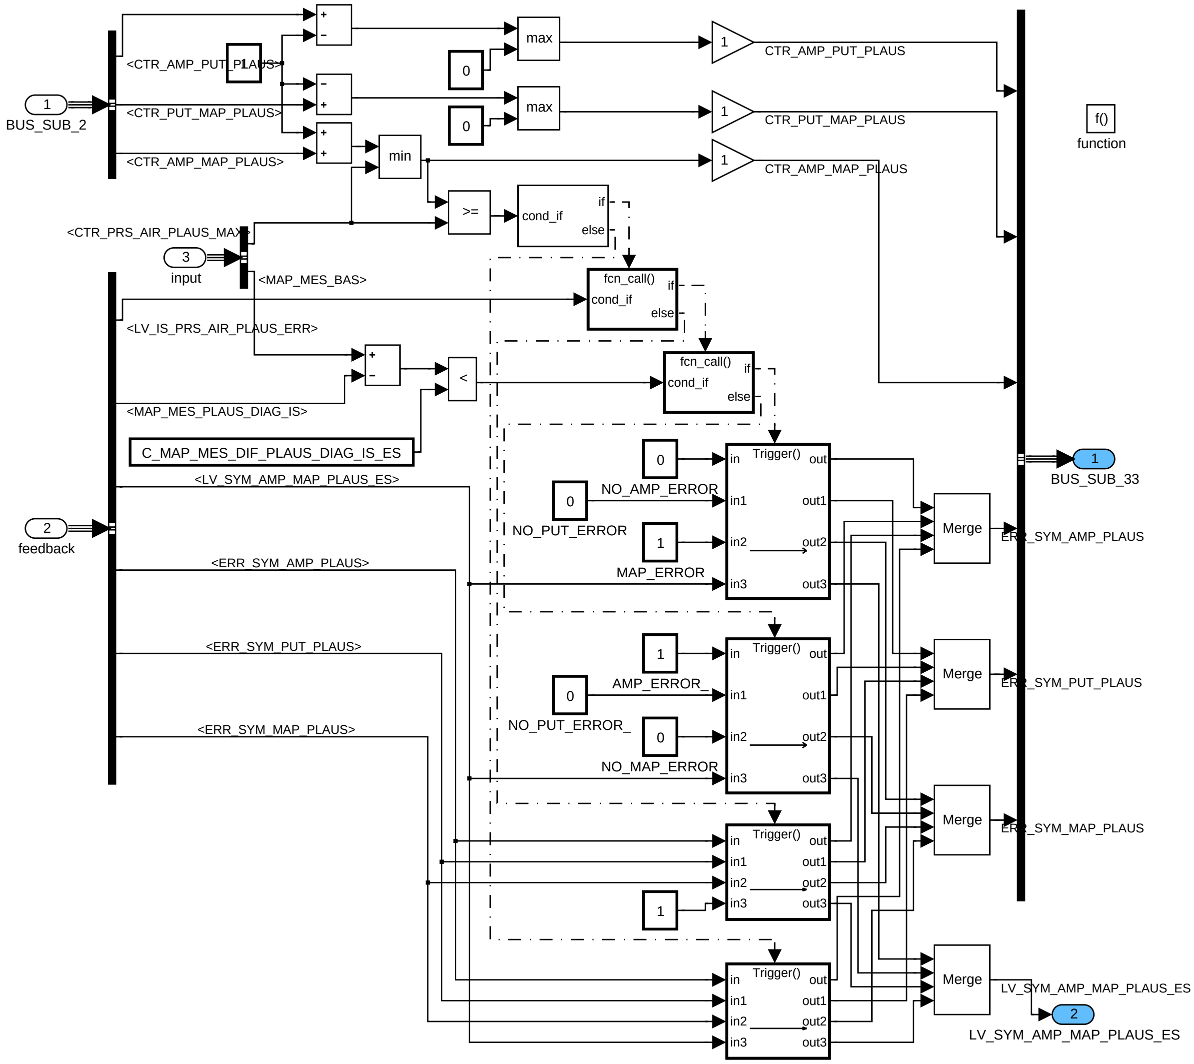

Figure 15 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_33_AMP_OR_MAP_ERROR

SUB_34: Detection that MAP-sensor is defective:

Three pressure sensors are available. The AMP-sensor and the PUT-sensor show the same pressure in the current state ES or PWL and the third sensor (MAP) differs significantly. So the MAP-sensor is supposed to be defective and the corresponding error symptom is set.

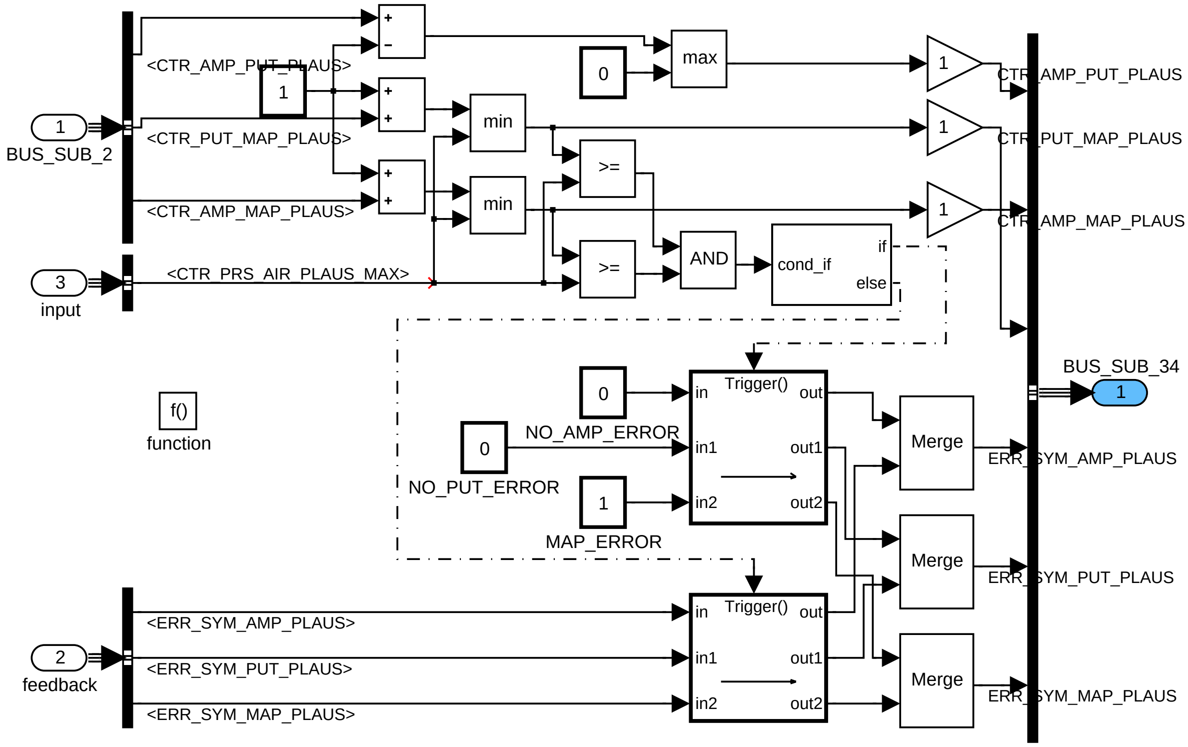

Figure 16 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_34_MAP_ERROR

SUB_35: Detection that AMP-sensor or PUT-sensor is defective:

Only these two pressure sensors are available. A difference between the two pressures is detected in the current state ES or PWL. If you have been in state full load before entering the current state ES or PWL then the defective sensor can be pointed out and the corresponding error symptom is set. But if you haven´t been in state full load before, only an implausible pair of sensors can be pointed out and a preliminary flag is set: LV_SYM_AMP_PUT_PLAUS_ES. Another engine state is necessary to point out which sensor is defective

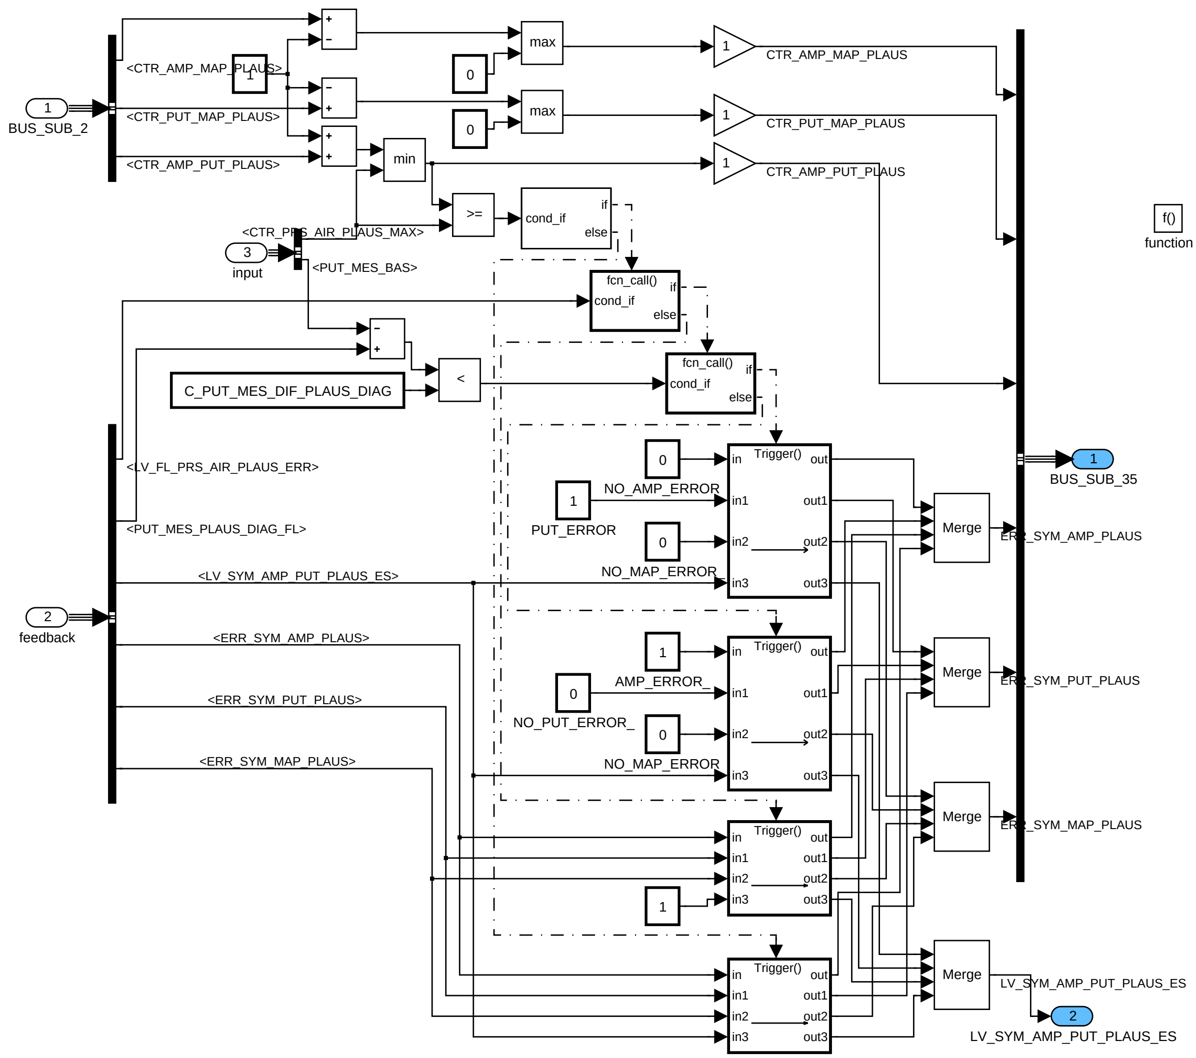

Figure 17 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_35_AMP_OR_PUT_ERROR

<u>SUB_36: Detection that PUT-sensor is defective:</u>

Three pressure sensors are available. The AMP-sensor and the MAP-sensor show the same pressure in the current state ES or PWL and the third sensor (PUT) differs significantly. So the PUT-sensor is supposed to be defective and the corresponding error symptom is set.

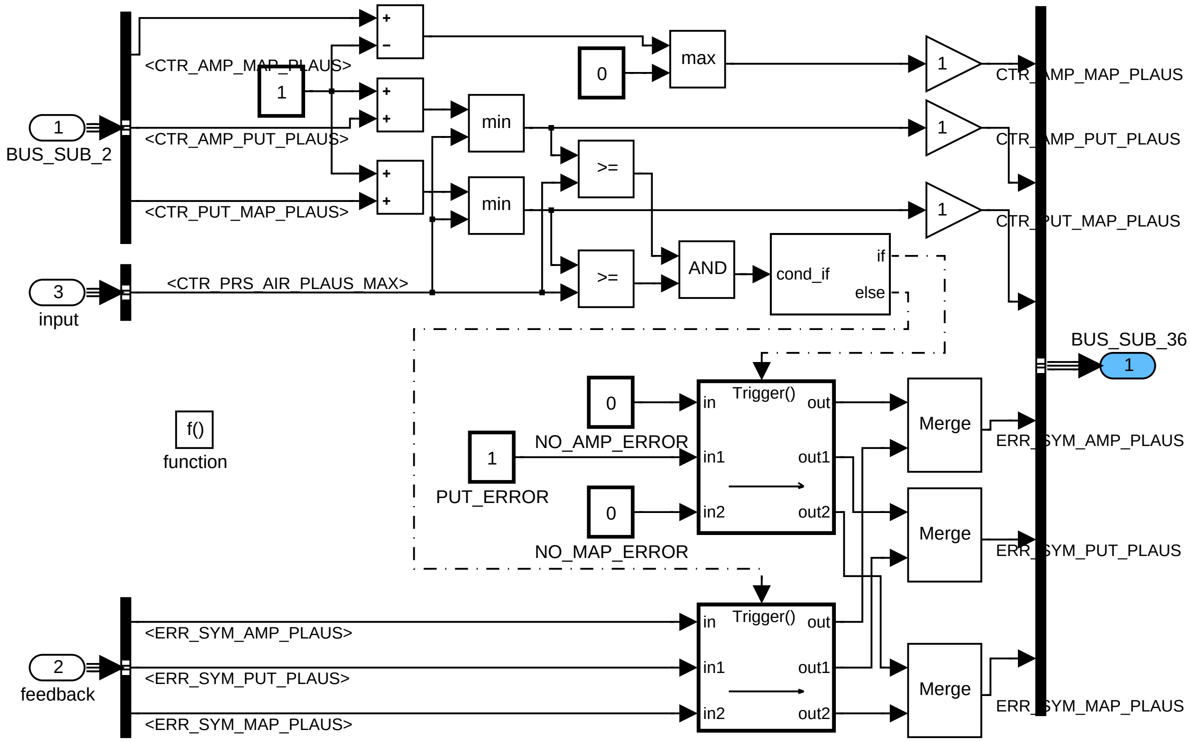

Figure 18 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_36_PUT_ERROR

SUB_37: Detection that AMP-sensor is defective:

Three pressure sensors are available. The PUT-sensor and the MAP-sensor show the same pressure in the current state ES or PWL and the third sensor (AMP) differs significantly. So the AMP-sensor is supposed to be defective and the corresponding error symptom is set.

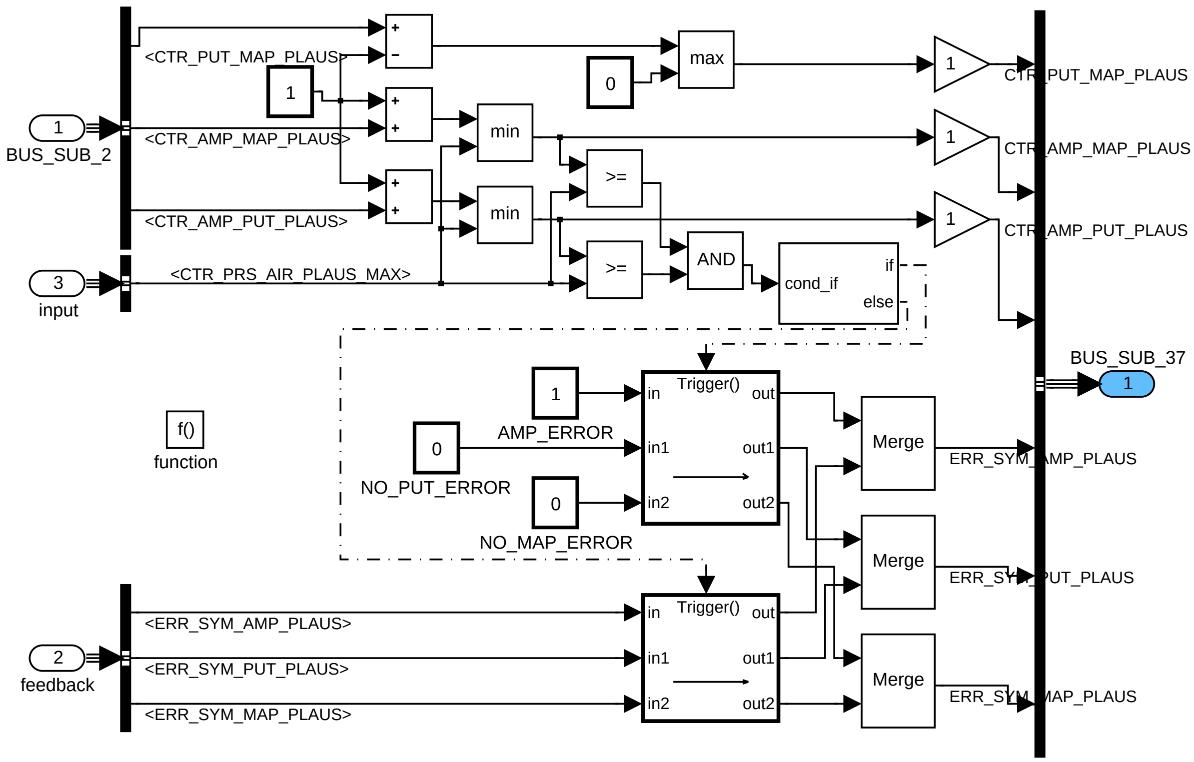

Figure 19 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_37_AMP_ERROR

<u>SUB_38: No change of error symptoms requested in state ES or PWL:</u>

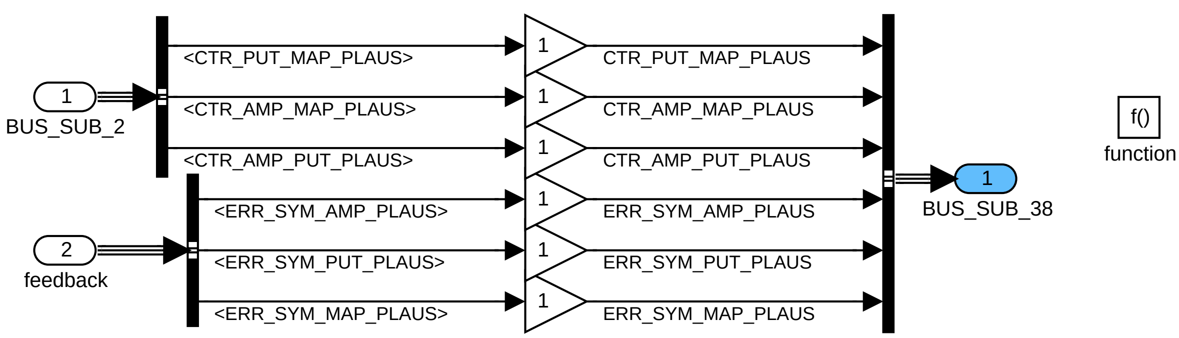

Figure 20 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_38_NO_CHANGE

<u>SUB_39: MAP plausibility for MAF-systems equipped with a MAP-sensor:</u>

<u>SUB_39: MAP plausibility for MAF-systems equipped with a MAP-sensor (at state ES or PWL):</u>

At engine standing or at PWL it is monitored whether the measured manifold air pressure is within the maximum possible and the minimum possible ambient pressure. If not then the corresponding error symptom is set.

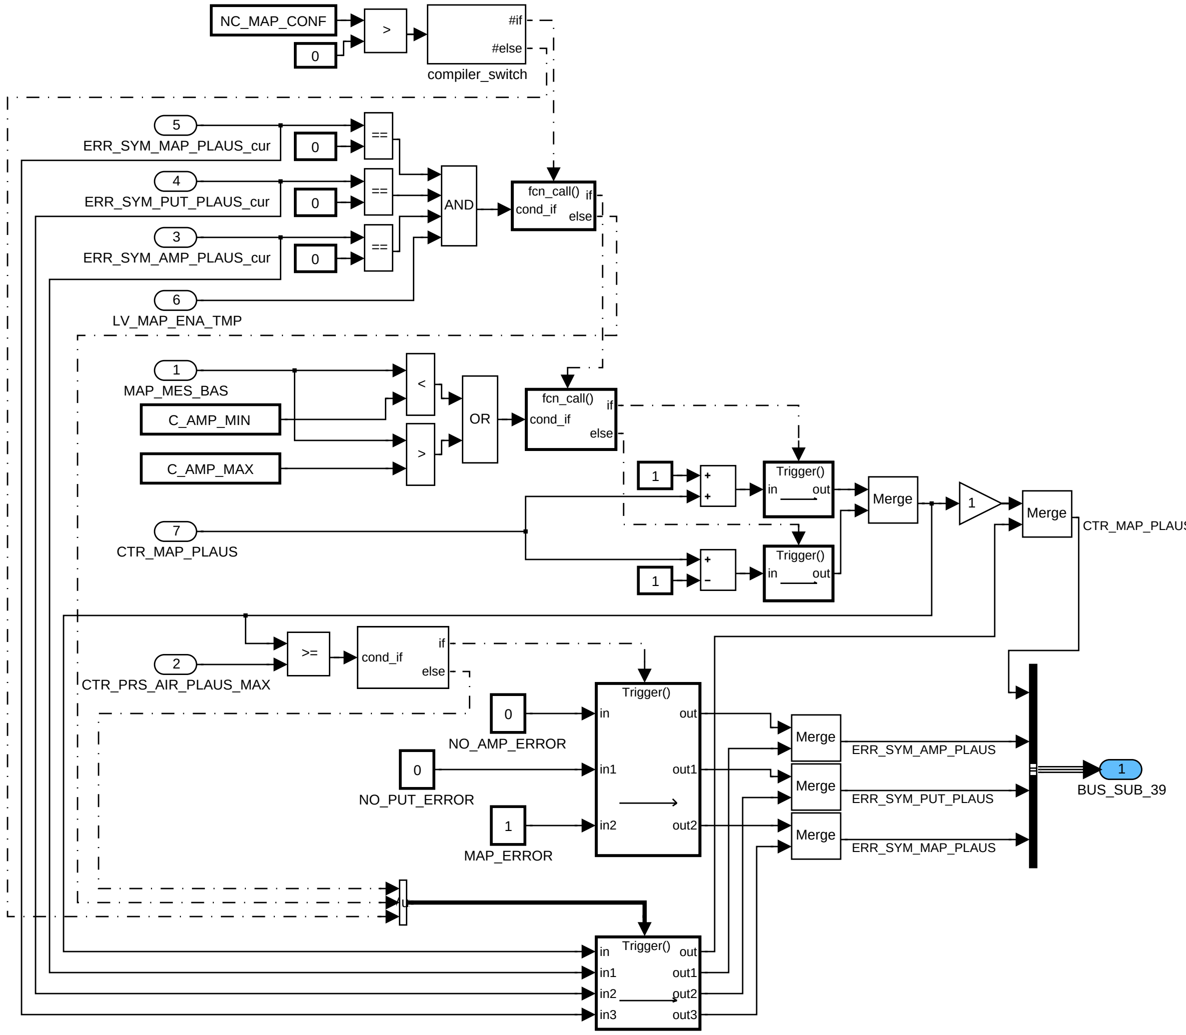

Figure 21 INSY_PLADGAMP0/ operate_100MS/ SUB_3_PRS_AIR_PLAUS_ES_PWL/ SUB_39_MAP_PLAUS/ SUB_39_MAP_PLAUS

<u>SUB_4: Implausible pair of pressure sensors (detected in PWL) registered in error management:</u>

Depending on LC_PRS_AIR_SENS_2_ERR_SAVE it can be decided whether an implausible pair of pressure sensors, that was detected in state PWL, should be registered in the error management and an LV_ERR should be set or not.

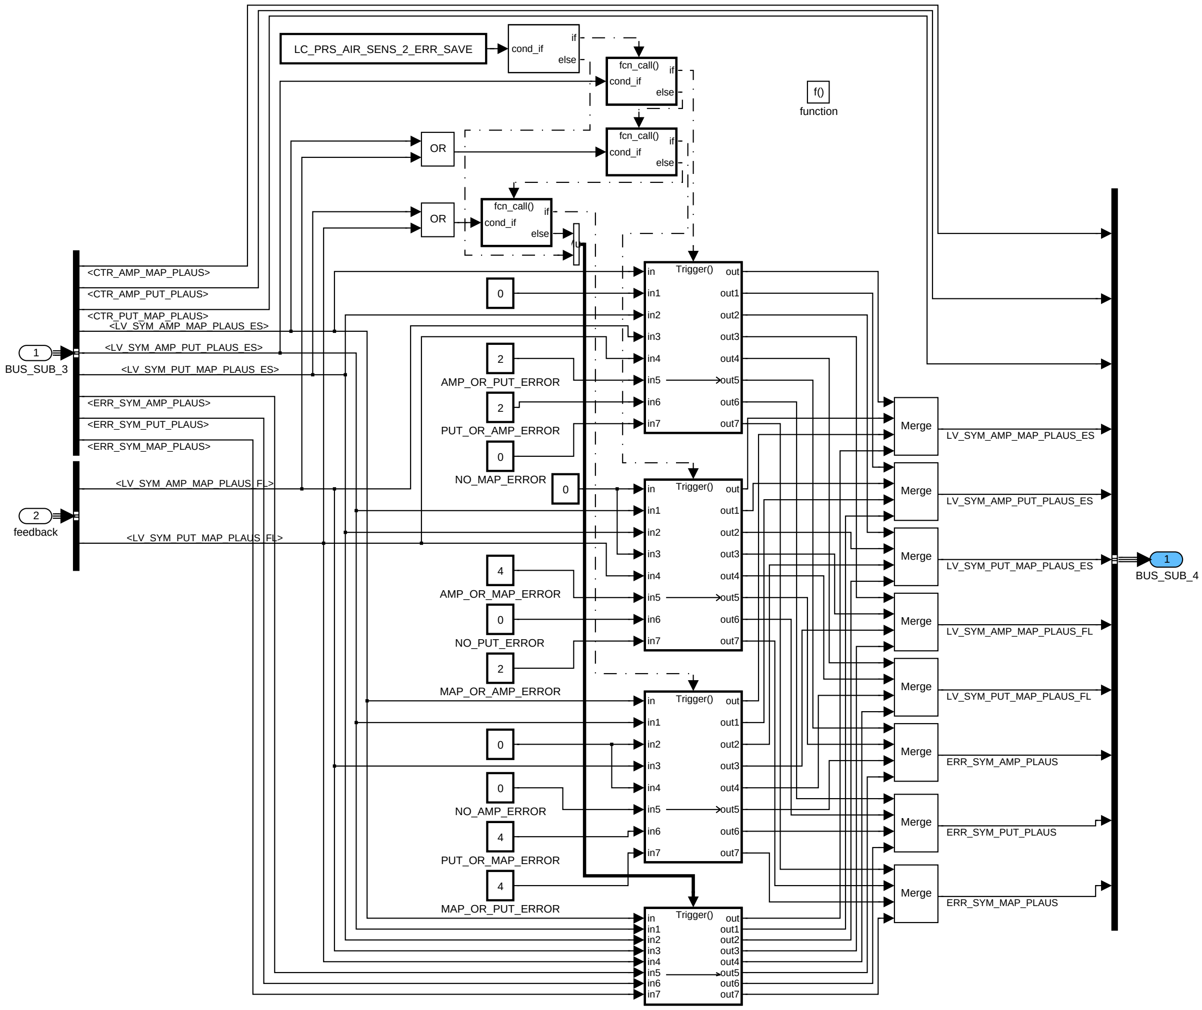

Figure 22 INSY_PLADGAMP0/ operate_100MS/ SUB_4_PRS_AIR_PLAUS_PWL

SUB_5: Overview over all possible pressure sensor plausibilities in FL:

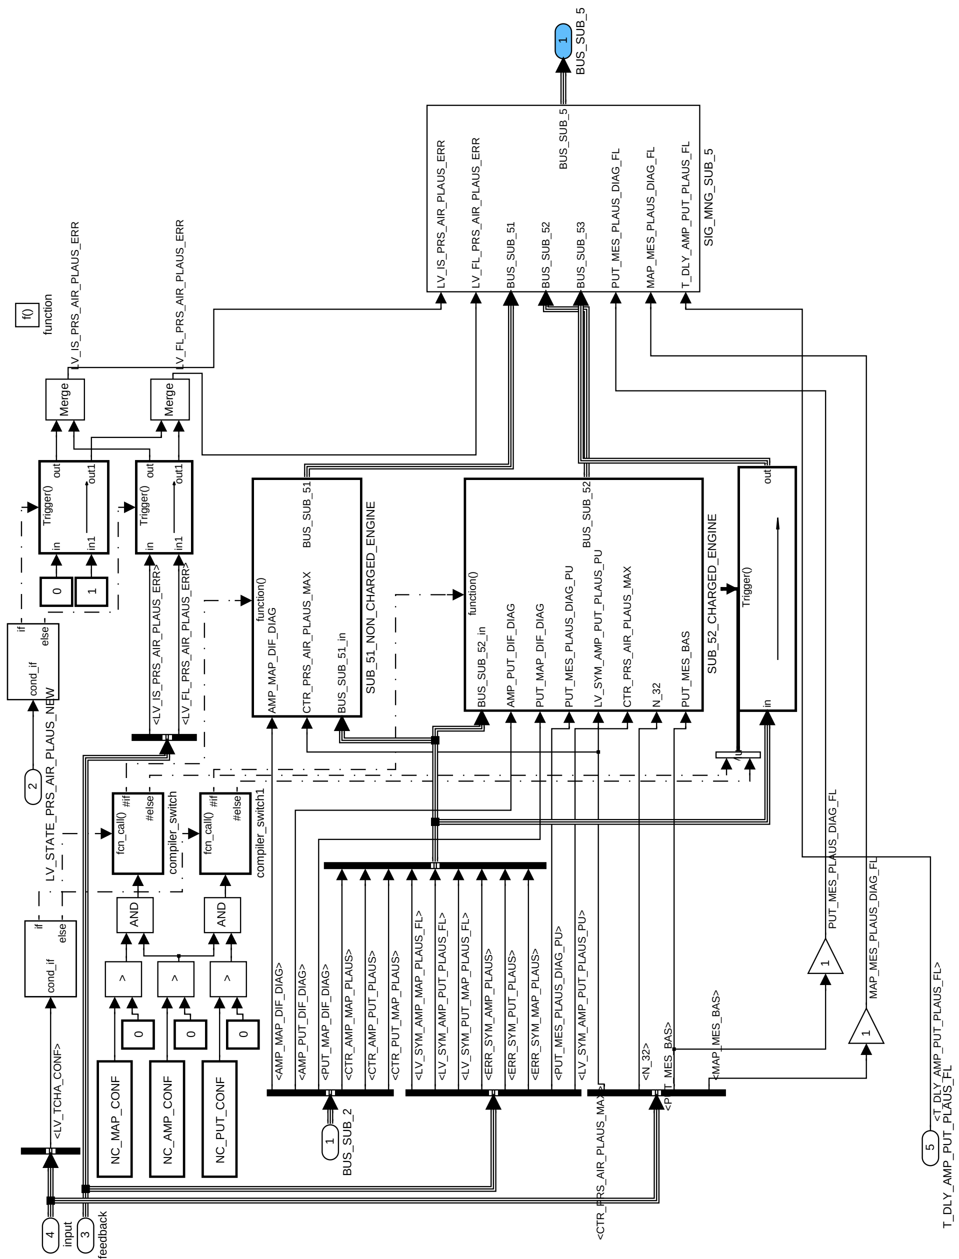

Figure 23 INSY_PLADGAMP0/ operate_100MS/ SUB_5_PRS_AIR_PLAUS_FL

SUB_51: Detection of implausible pressure sensors at FL for non charged engines:

At full load there is ambient pressure at the throttle and also nearly in the intake manifold for non charged engines, so the AMP-sensor and the MAP-sensor should show nearly the same pressure. If not, a preliminary flag is set LV_SYM_AMP_MAP_PLAUS_FL.

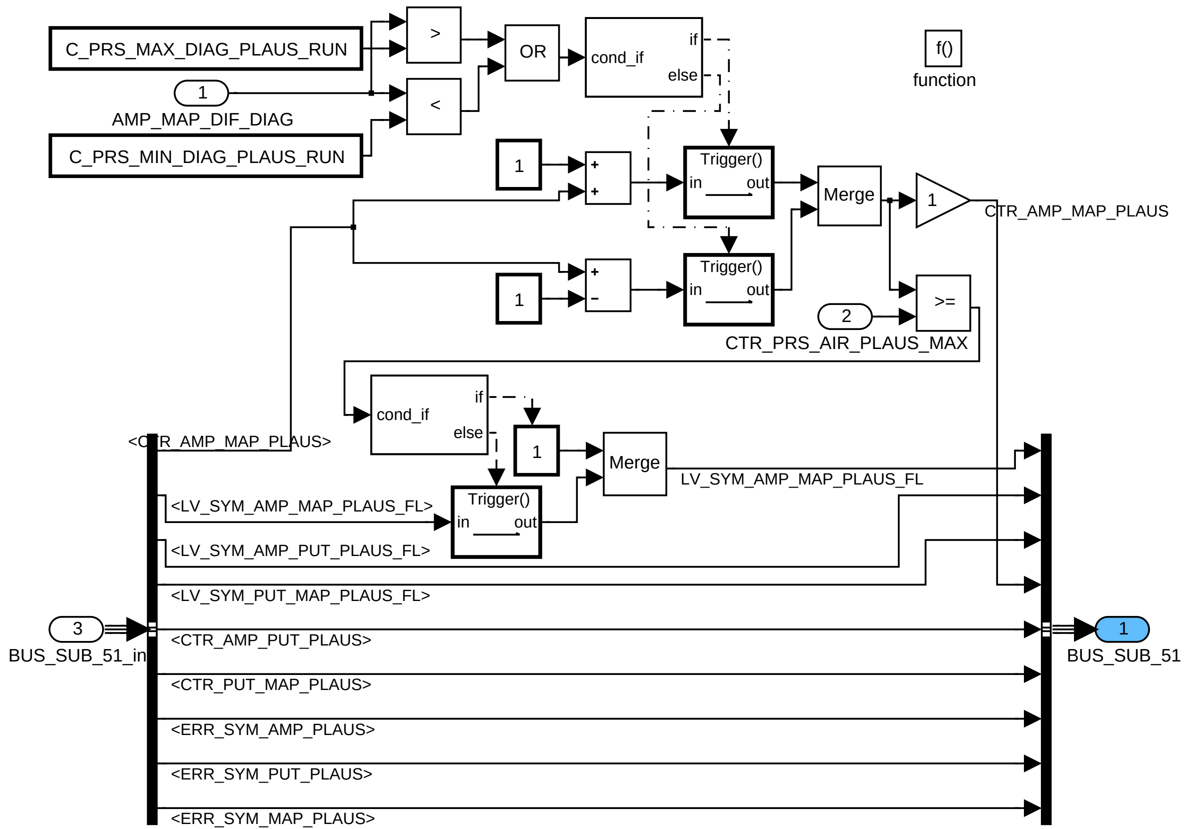

Figure 24 INSY_PLADGAMP0/ operate_100MS/ SUB_5_PRS_AIR_PLAUS_FL/ SUB_51_NON_CHARGED_ENGINE

SUB_52: Detection of implausible pressure sensors at FL for charged engines:

At full load for charged engines, the pressure upstream throttle is equal to the intake manifold pressure, so the PUT-sensor and the MAP-sensor should show nearly the same pressure. If not, a preliminary flag is set LV_SYM_PUT_MAP_PLAUS_FL.

The pressure upstream throttle is bigger than the ambient pressure for charged engines at full load, so the PUT-sensor and the AMP-sensor should show a certain pressure difference. If the difference is small and you have been in state pull before then the defective sensor can be pointed out and the corresponding error symptom is set. But if you haven´t been in state pull before, only an implausible pair of sensors can be pointed out and a preliminary flag is set: LV_SYM_AMP_PUT_PLAUS_FL. Another engine state is necessary to point out which sensor is defective.

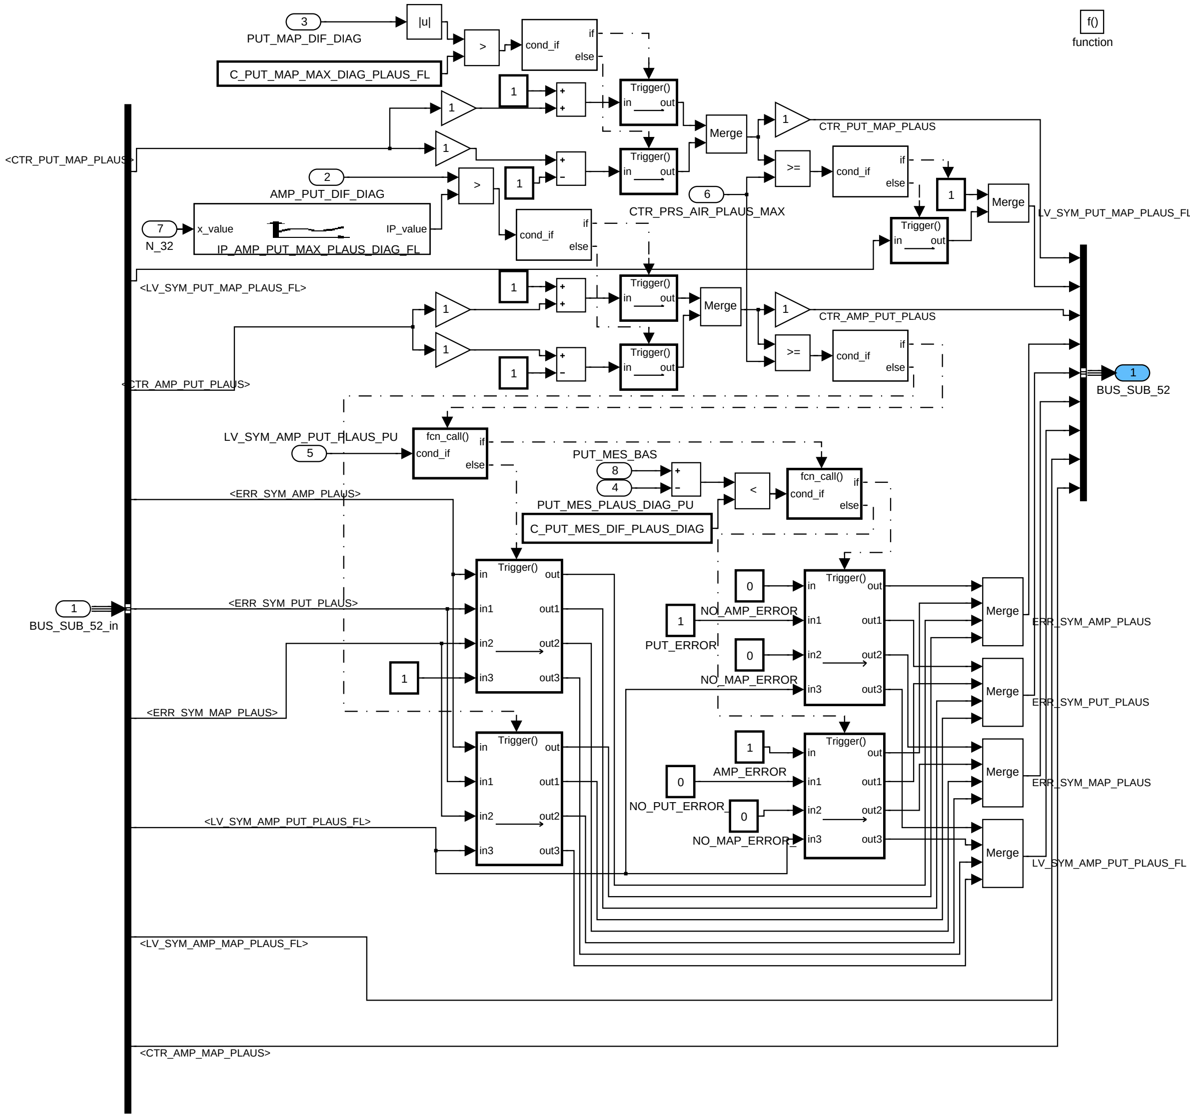

Figure 25 INSY_PLADGAMP0/ operate_100MS/ SUB_5_PRS_AIR_PLAUS_FL/ SUB_52_CHARGED_ENGINE

SUB_6: Overview over all possible pressure sensor plausibilities in engine state pull:

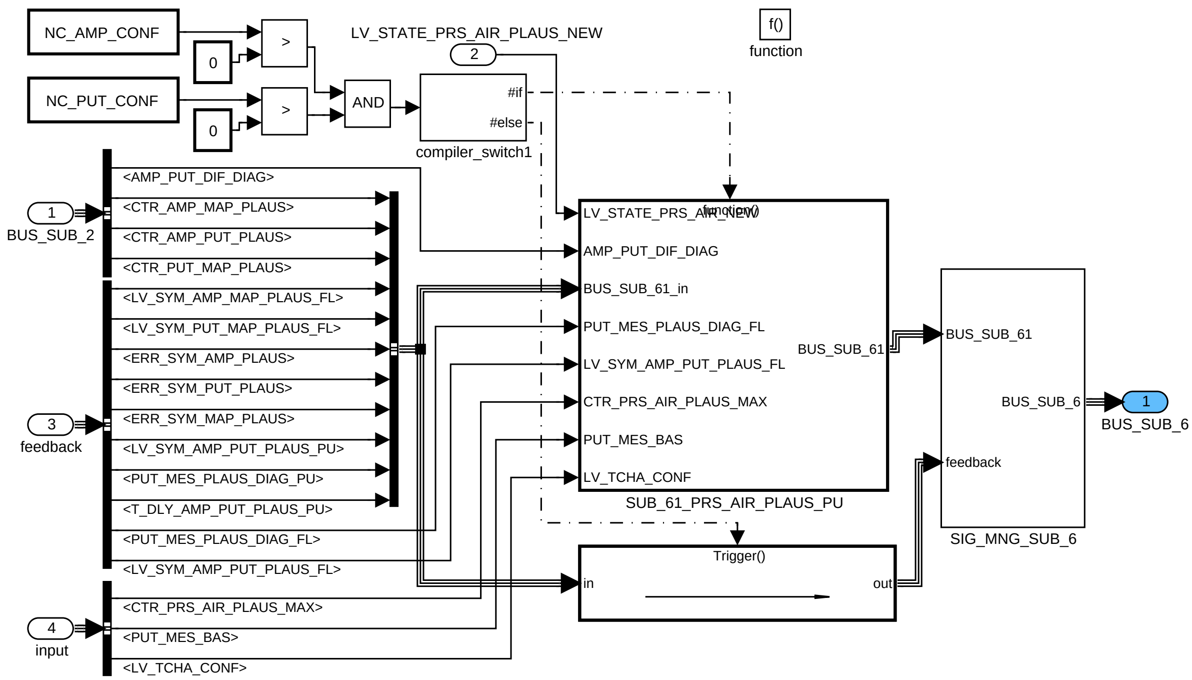

Figure 26 INSY_PLADGAMP0/ operate_100MS/ SUB_6_PRS_AIR_PLAUS_PU

SUB_61: Detection of implausible pressure sensors in engine state pull:

The pressure upstream throttle is equal to the ambient pressure in engine state pull, so the PUT-sensor and the AMP-sensor should show nearly the same pressure. If there is a difference and you have been in state full load before then the defective sensor can be pointed out and the corresponding error symptom is set. But if you haven´t been in state full load before, only an implausible pair of sensors can be pointed out and a preliminary flag is set: LV_SYM_AMP_PUT_PLAUS_PU. Another engine state is necessary to point out which sensor is defective.

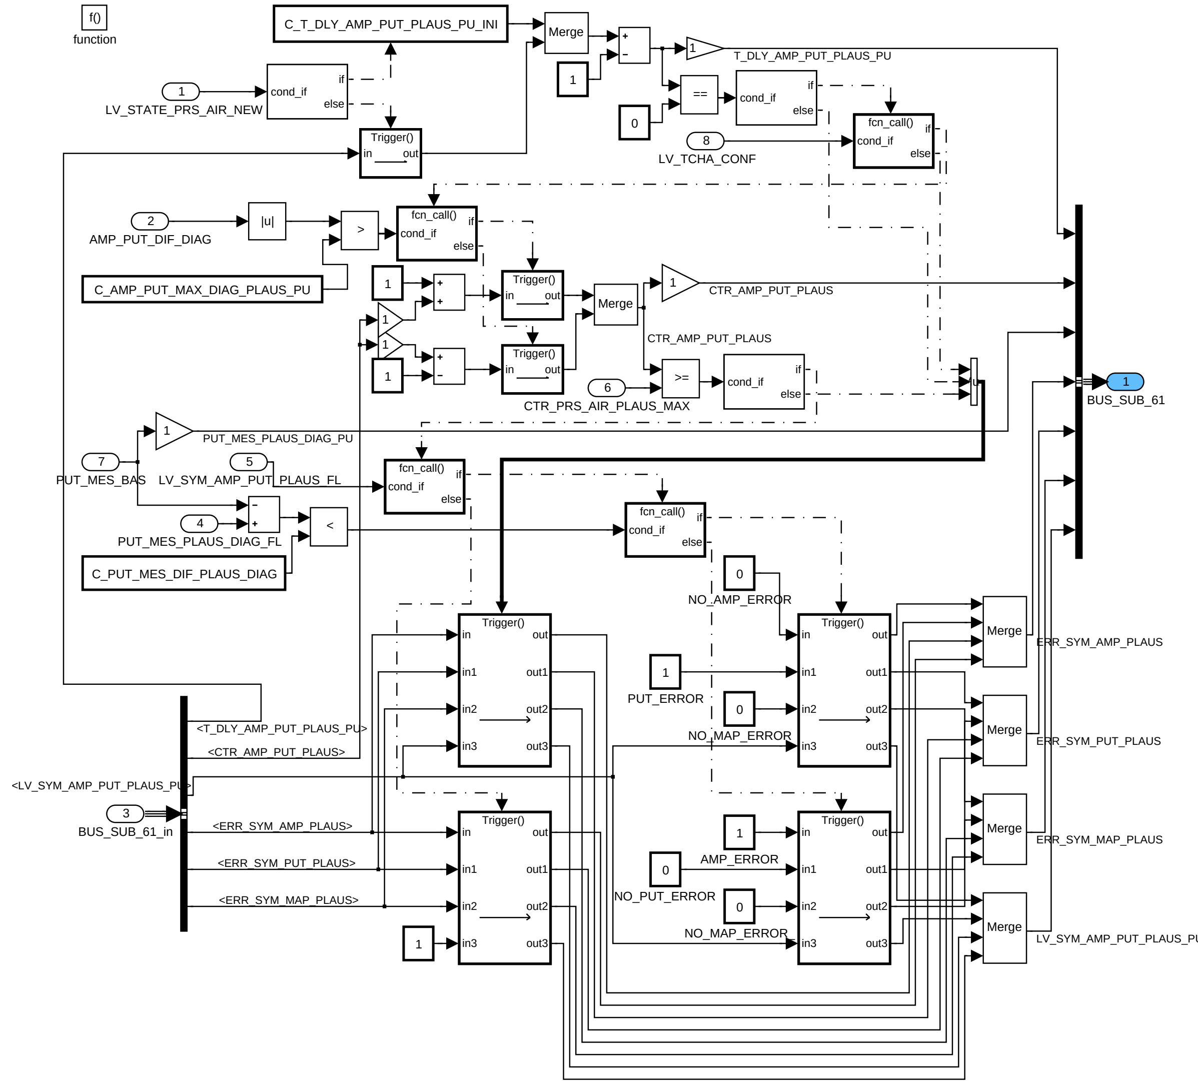

Figure 27 INSY_PLADGAMP0/ operate_100MS/ SUB_6_PRS_AIR_PLAUS_PU/ SUB_61_PRS_AIR_PLAUS_PU

SUB_7: Overview over all possible pressure sensor plausibilities in engine state idle speed:

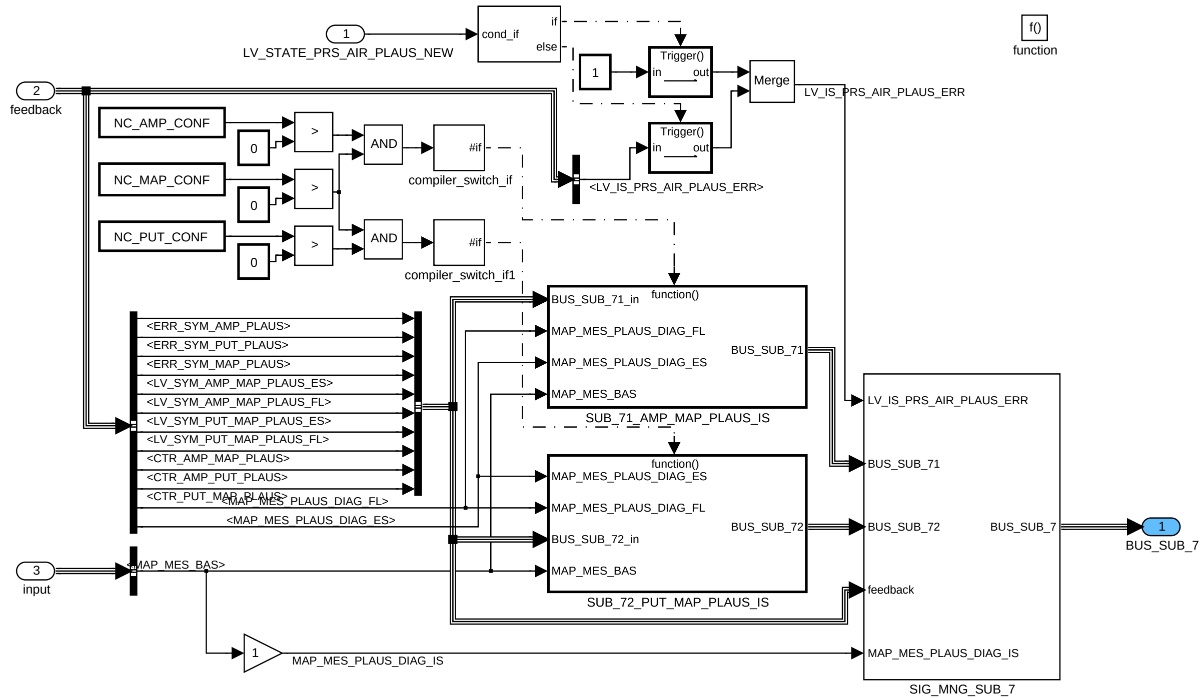

Figure 28 INSY_PLADGAMP0/ operate_100MS/ SUB_7_PRS_AIR_PLAUS_IS

SUB_71: Detection of defective AMP-sensor or MAP-sensor in engine state idle speed:

If the preliminary error bit LV_SYM_AMP_MAP_PLAUS_ES or LV_SYM_AMP_MAP_PLAUS_FL is set, the value of MAP_MES is checked when engine is in state idle or part load. If there is no change in the value of the measured manifold pressure compared to the pressure measured during engine stop or full load, it can be concluded that the MAP sensor is faulty. If however the value of MAP_MES does change, it is most probably a defective AMP sensor.

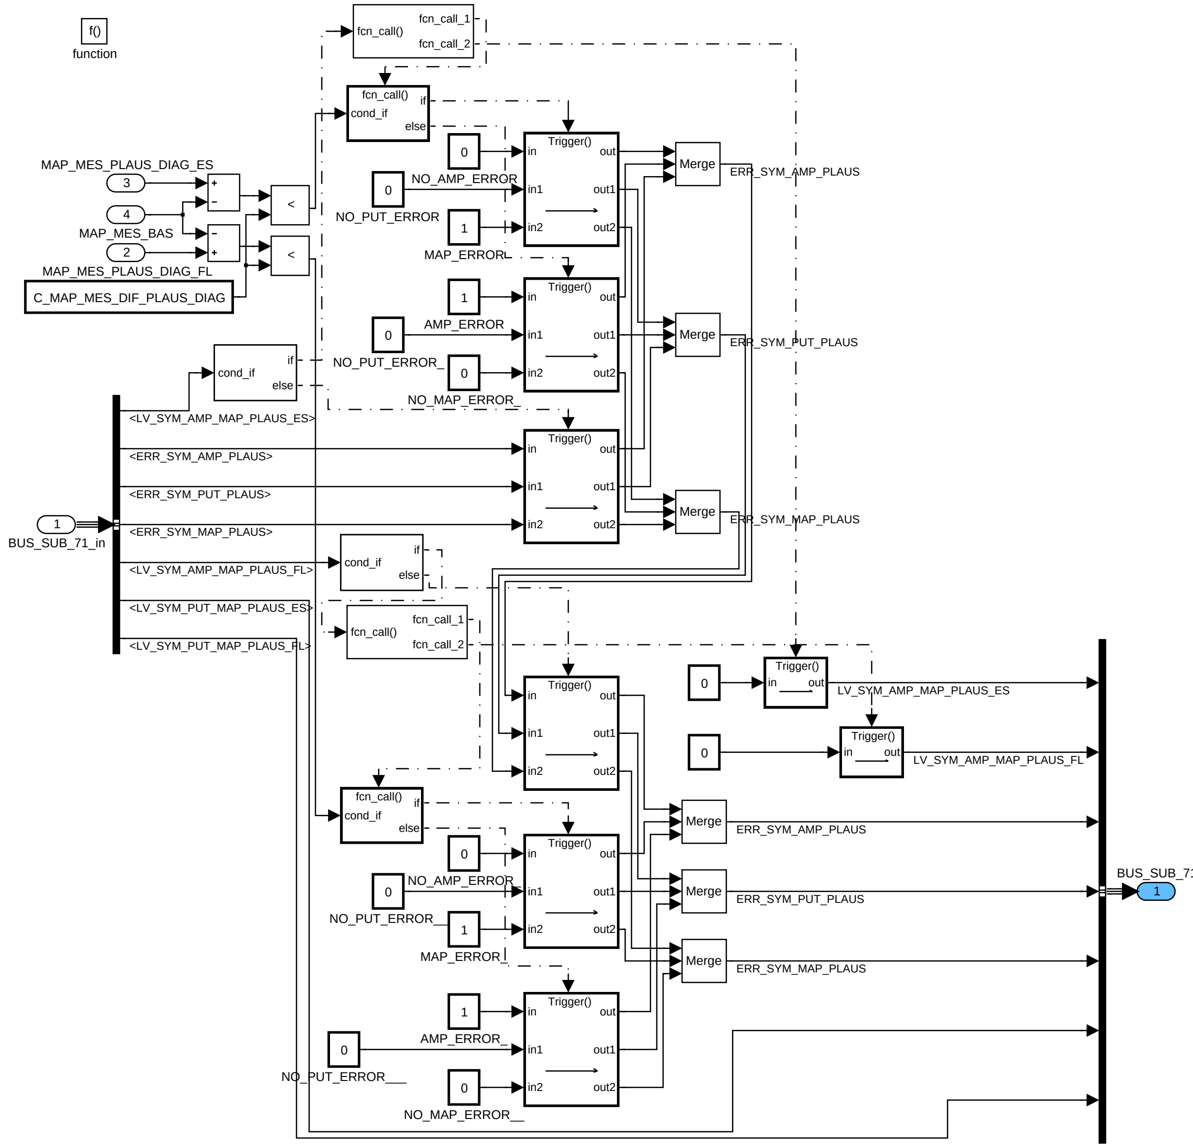

Figure 29 INSY_PLADGAMP0/ operate_100MS/ SUB_7_PRS_AIR_PLAUS_IS/ SUB_71_AMP_MAP_PLAUS_IS

SUB_72: Detection of defective PUT-sensor or MAP-sensor in engine state idle speed:

If the preliminary error bit LV_SYM_PUT_MAP_PLAUS_ES or LV_SYM_PUT_MAP_PLAUS_FL is set, the value of MAP_MES is checked when engine is in state idle or part load. If there is no change in the value of the measured manifold pressure compared to the pressure measured during engine stop or full load, it can be concluded that the MAP sensor is faulty. If however the value of MAP_MES does change, it is most probably a defective PUT sensor.

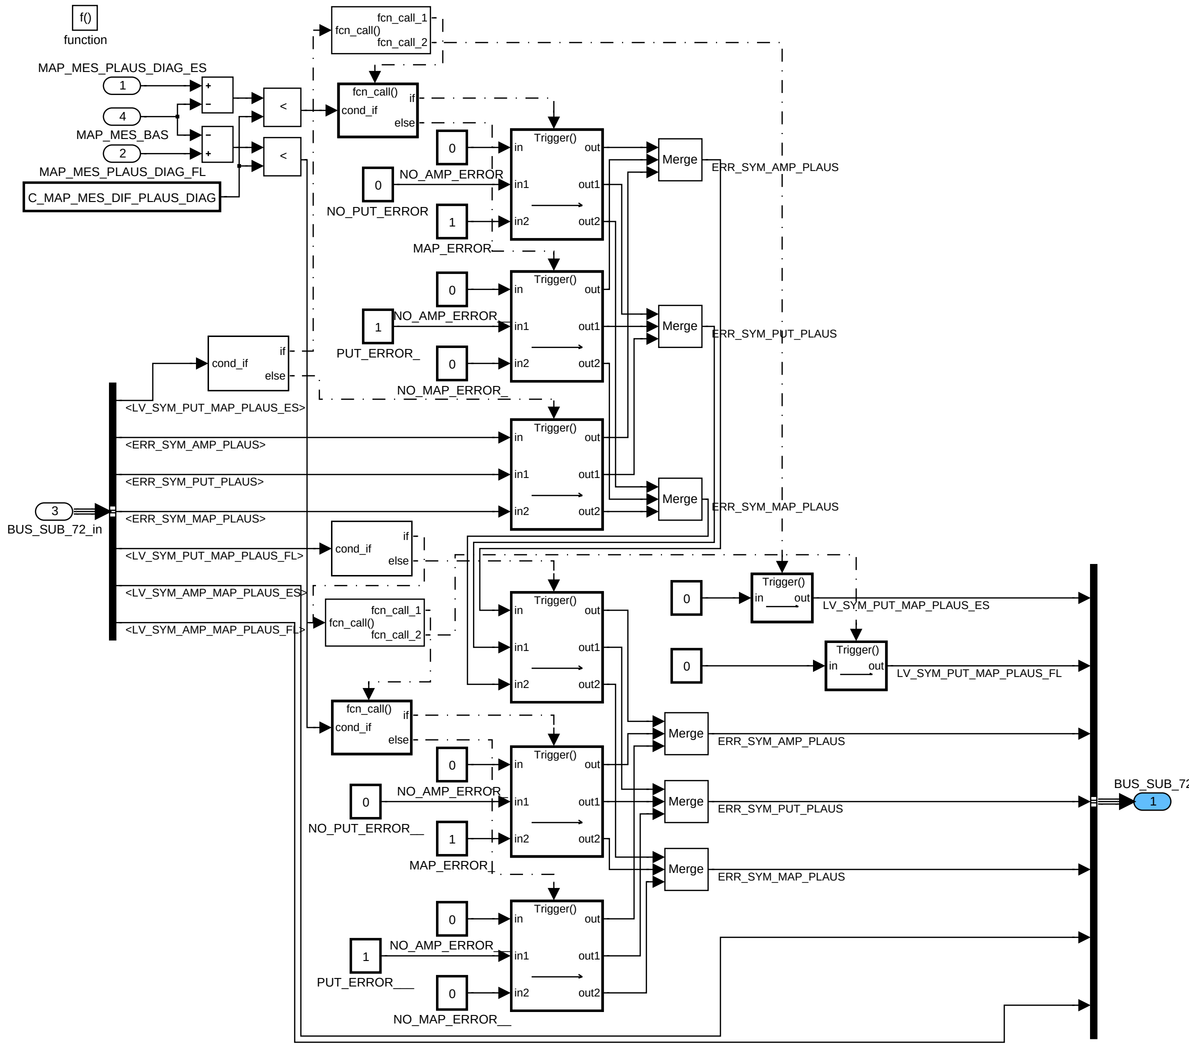

Figure 30 INSY_PLADGAMP0/ operate_100MS/ SUB_7_PRS_AIR_PLAUS_IS/ SUB_72_PUT_MAP_PLAUS_IS

<u>SUB_8: MAP plausibility for MAF-systems equipped with a MAP-sensor (when engine is running):</u>

This test is for MAF-systems with only one pressure sensor, the MAP sensor. The purpose of this test is to check the plausibility between the MAP value measured from the MAP sensor and the MAP value calculated by the air path model (from the engine speed, the TPS value and the MAF sensor value).

Import actions:

ACTION_ERRM_FilterSymptom(IN <XX>, IN <lv_cdn_diag_XX>, IN <err_sym_XX>, IN <c_abc_inc_XX>, IN <c_abc_dec_XX>, IN <c_abc_max_XX>, OUT <lv_err_XX>)
This action computes the elementary anti-bounce filter for one failure treatment and returns filter result
ACTION_ERRM_GetLvEndDiag(IN <XX>, OUT <lv_end_diag_XX>)
This action returns the end-of-diagnosis flag

B.36.1 General information

The purpose of this diagnosis is to detect several failures related with the charge air pressure and the wastegate behaviour.

In case the charge air pressure is **too high** any of the following reasons could cause this bad behaviour:

wastegate stuck closed

defect engine

closed exhaust system

defect EPC pressure supply or stuck closed

If this failure is present, the turbo charge protection will react to avoid to damage the engine and to ensure a good driveability of the car.(see Turbo Protection Specification)

In case the charge air pressure is **too low** any of the following reasons could cause this bad behaviour:

defect charger

leaky air tube or intercooler

recirculation valve stuck open

defect EPC stuck open

Error-symptoms for the Charge air pressure (CAP) diagnoses are defined as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> SYM_0
 │ │ └───> SYM_1
 │ └─────> SYM_2
 └───────> SYM_3: CAP too high (CAP_H)/ CAP too low (CAP_L)/ Basic CAP too low (CAP_L_BAS)
```

The error-management variables are initialized according to filter-type.

Diagnosis for "Charge Air Pressure too high" (CAP_H)

In case of LV_IN_PROT = 1 the calibration C_ABC_MAX_CAP_H is taken instead of C_ABC_INC_CAP_H as anti bounce counter. This ensures an immediate error entry without debouncing.

HINT: If the error flag is set, a torque reduction must be executed.

B.37.1 Interface for RBM – Charge air pressure LOW diagnosis (CAP_L)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CAP_L monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_CAP_L data.

Within STATE_RBM_CAP_L, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for this diagnosis)

Application conditions:

Initialisation:

at ECU reset:

bit 0, bit 1 and bit 2 of STATE_RBM_CAP_L = 0 at LV_DC 0 → 1 transition:

bit 0 and bit 1of STATE_RBM_CAP_L = 0
bit 2 of STATE_RBM_CAP_L = 1

on failure memory reset:

bit 1 of STATE_RBM_CAP_L = 0

Recurrence: 1 s

Activation: LV_DC = 1 **and** LC_TCHA_CONF = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_PUT_PLAUS	LV_ERR_EL_PUT	LV_ERR_VCC_SENS_SUB	

If(1) { CPU optimization at LV_DC 0 → 1 transition }
CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }
Then(1) **While** bit 1 of STATE_RBM_CAP_L = 0 **do**
with each XX failure of the above list :
ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)
If(2) XX has a pending status
Then(2) bit 1 of STATE_RBM_CAP_L = 1
Endif(2)
Endwhile
Else(1) { the dynamic failure memory is empty }
No action
Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_CAP_L = 0
Then **If** LV_END_DIAG_CAP_L = 1
Then bit 0 of STATE_RBM_CAP_L = 1
Endif
Endif
If bit 1 of STATE_RBM_CAP_L = 0
Then **If** LV_INH_DIAG_RBM_CAP = 1
Then bit 1 of STATE_RBM_CAP_L = 1
Endif
Endif

- Calculation of actual RBM rate (for application purposes)

recurrence: 1 s

If CTR_CDN_RBM_CAP_L = 0
then RATE_RBM_CAP_L = FFFFH
else RATE_RBM_CAP_L
= (CTR_COMP_RBM_CAP_L / CTR_CDN_RBM_CAP_L)
endif

B.37.2 Interface for RBM – Charge air pressure LOW diagnosis (CAP_L_BAS)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CAP_L_BAS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_CAP_L_BAS data.

Within STATE_RBM_CAP_L_BAS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0) (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1) (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2) (not valid for this diagnosis)

Application conditions:

Initialisation:

at ECU reset:
bit 0, bit 1 and bit 2 of STATE_RBM_CAP_L_BAS = 0

Input data:

LV_PUC	TCO	TCO_ST	TCO_SUB
LV_ST_END	TIA_THR_ST	T_DIAG_AST	RATIO_T_IS_AST
LV_CDN_VB_OBD_2	LV_INH_DIAG_TCO_PLAUS		

FUNCTION DESCRIPTION:

General information:

To monitor the activation of the lambda control after start above a coolant temperature threshold (OBD II requirement), a plausibilization between the coolant temperature increase (TCO) and the calculated coolant temperature increase (TCO_SUB) is made.

The coolant temperature plausibility diagnosis is performed once per engine run.

If the engine stalls and the coolant temperature plausibility diagnosis has not run out, then at the next engine start the timer will be initialized new and the diagnosis starts again. When the diagnosis is finished, the Boolean for end of coolant temperature plausibility diagnosis is set.

Remark: *At the time when the "TCO-plausibility diagnosis" is performed, it is not possible to distinguish between a "TCO-plausibility error" and a "Thermostat error" (which can only be detected later). Therefore a "TCO-plausibility error" is entered, even if the problem may be related to the Thermostat (in order to activate the limp home in case there is really a problem with the coolant temperature sensor).*
That means, if additionally to the "TCO- plausibility error" a "Thermostat diagnosis error" is detected, the "TCO-plausibility error" can be ignored.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
□□□□

Input data:

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_IGK
LV_ST_END	LV_ERR_TIA_THR	LV_ERR_TCO_STUCK_H	

FUNCTION DESCRIPTION:

General information:

The coolant temperature sensor plausibility diagnosis is performed at transition from the logical value for “Start” from “1” to “0”. If the engine stalls or one of the conditions for inhibiting the diagnosis is present, it will be stopped and starts again at the next engine start.

The diagnosis is finished as soon as the boolean for end of coolant temperature sensor plausibility diagnosis is set to “1”. In this case the boolean for coolant temperature plausibility error indicates either a not plausible (= 1) or a normal (= 0) coolant temperature sensor signal.

Depending on project specific requirements, the coolant temperature sensor plausibility diagnosis can be inhibited by setting of LV_INH_DIAG_TCO_PLAUS.

Application conditions:

*Initialisation at RESET **or** EXIT_ST **or** LV_IGK = 0 -> 1 **or** FMY clear:*

LV_INH_DIAG_TCO_PLAUS= 0

LV_INH_DIAG_RBM_TCO_PLAUS = 0

		CTR_CDN_RBM_TCO_PLAUS	CTR_COMP_RBM_TCO_PLAUS

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TCO_PLAUS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TCO_PLAUS data.

Within STATE_RBM_TCO_PLAUS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_PLAUS = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1of STATE_RBM_TCO_PLAUS = 0

bit 2 of STATE_RBM_TCO_PLAUS = 1

on failure memory reset :

bit 1 of STATE_RBM_TCO_PLAUS = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_ERR_TCO_STUCK_H

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_TCO_PLAUS = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_TCO_PLAUS = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_TCO_PLAUS = 0

Then

If LV_END_DIAG_RBM_TCO_PLAUS = 1

Then bit 0 of STATE_RBM_TCO_PLAUS = 1

Endif

Endif

If bit 1 of STATE_RBM_TCO_PLAUS = 0

Then

LV_PL	N	VS	MAF_KGH
LV_IS	LV_PUC	LV_FL	

FUNCTION DESCRIPTION:

General information:

The diagnosis is based on monitoring the alteration of the coolant temperature signal (TCO) (positive and negative change) to determine a malfunctioning sensor stuck signal at high coolant temperature values.

Even at high coolant temperature values at engine start, a smooth change of the coolant temperature signal can be observed. Either at special engine operating conditions after a specific time interval or due to temperature changes caused by the coolant thermostat.

The diagnosis is performed only once per engine run. The symptom of the error code is not handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
│ │ │ │ │

Input data:

TCO_MES	TCO_ST	TCO_SUB	LV_ST_END
LV_CDN_VB_MIN_DIAG	LV_INH_DIAG_TCO_STUCK		

FUNCTION DESCRIPTION:

General information:

The purpose of the signal stuck diagnosis is to detect a stuck measured coolant temperature sensor signal. The diagnosis function checks if after a variation of the calculated coolant temperature substitute value (TCO_SUB) also a variation of the measured coolant temperature value (TCO_MES) is detected.

The diagnosis is performed only once per engine run. The symptom of the error code is not handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
□□□□
│ │ │ └─> -                                        (= SYM_0)

FUNCTION DESCRIPTION:

General information:

For OBDII systems, it is required by CARB to check if Coolant Temperature " Stuck in Range Above the Lowest Maximum Enable Temperature". That means, ECU shall detect a malfunction if the ECT sensor inappropriately indicates a temperature above the lowest maximum enable temperature required by the OBD II system to enable other diagnostics (e.g., an OBD II system that requires ECT to be less than 90 degrees Fahrenheit at engine start to enable a diagnostic must detect malfunctions that cause the ECT sensor to inappropriately indicate a temperature above 90 degrees Fahrenheit).

In case the system is equipped with an Oil Temperature sensor this diagnostic compares coolant temperature and oil / intake air temperature at Start : if both oil and intake air temperature indicate a low value (e.g. 35°C), but coolant temperature indicates a higher value (e.g. 55°C), then a failure is detected.
This diagnostic must be used only for systems where it is ensured that TOIL is cooling down quicker than TCO.
In case the system is not equipped with TOIL sensor the cooling down behavior of the engine is checked depending on the engine off time. At cooled down engine the Coolant Temperature may not exceed a threshold dependent on TIA_ST.

Application conditions:

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TCO_STUCK_RNG monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TCO_STUCK_RNG data.

Within STATE_RBM_TCO_STUCK_RNG, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation:

at ECU reset:

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_STUCK_RNG = 0

at LV_DC 0 → 1 transition:

bit 0 and bit 1of STATE_RBM_TCO_STUCK_RNG = 0

bit 2 of STATE_RBM_TCO_STUCK_RNG = 1

on failure memory reset:

bit 1 of STATE_RBM_TCO_STUCK_RNG = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once:

TCO_SUB	N	LV_INH_DIAG_TH	LV_CDN_VB_OBD_2
LV_ST_END			

FUNCTION DESCRIPTION:

General information:

Task of the coolant thermostat is to effect a quick engine warm up after start. The thermostat is closed after engine start to limit the cooling-liquid circulation until the thermostat regulating temperature is reached. The thermostat opens at this temperature and the limitation of the cooling-liquid circulation is finished. If an opened stuck thermostat occurs, the cooling-liquid circulation will not be limited after start. That means an increase of the engine warm up time and can cause emission increase as well.

To take this behaviour into consideration, an opened stuck thermostat must be detected if either other diagnosis functions are inhibited or the coolant temperature does not reach its operating temperature within 20°F. The conditions for inhibiting the diagnosis are described in the chapter “Application incidences for coolant thermostat monitoring”. The coolant temperature model (TCO_SUB) must simulate the worst engine warm up temperature behaviour for a normal working thermostat (heating on. A/C on. etc.) after start until the thermostat opening temperature is reached.

Description:

The error detection is done by a comparison between the raw value of the coolant temperature sensor and the value of the coolant temperature substitute model.

Error-symptoms are defined to this diagnosis function as following:

```
□□□□
│ │ │ └─> -                 (= SYM_0)
│ │ └───> -                 (= SYM_1)
│ └─────> -                 (= SYM_2)
└───────> TH open stuck     (= SYM_3)
```

B.48.1 Activation condition for thermostat monitoring

FUNCTION DESCRIPTION:

General information:

The initialization of the function is performed as soon as EXIT_ST is detected. In this case it is regardless if the actual thermostat diagnosis status is set to enabled or canceled.

Thermostat diagnosis is performed as soon as all conditions below are fulfilled at the same time. The function is enabled at once if LV_ST_END is set to “1”. A minimum and a maximum threshold for the coolant temperature at start are limiting the diagnosis activation range as well as a minimum threshold for the intake air temperature at start.

Thermostat monitoring is finished if either the logical value for “thermostat diagnosis finished” or the logical value for “thermostat diagnosis cancelled” equals to “1”. In this case the diagnosis activation bit is set to “0” (LV_ACT_DIAG_TH = 0).

Application conditions:

Initialisation at EXIT_ST:

LV_ERR_TH = 0

LV_CDN_DIAG_TH = 0

ERR_SYM_TH = “NO_SYM”

LV_END_DIAG_RBM_TH = 0

LV_END_DIAG_RBM_TH_TMP = 0

B.48.2 Coolant thermostat functionality check

FUNCTION DESCRIPTION:

General information:

Task of the functionality check is to detect a stuck open thermostat. Correct functionality is not guaranteed if the coolant temperature does not reach a specified warmed up temperature.

The thermostat functionality check is enabled as long as the boolean for "coolant thermostat diagnosis activated" is set to "1". As soon as EXIT_ST is detected, all timers and initialization values are set to neutral values.

Application conditions:

Initialisation at EXIT_ST:

TIA_DE_DIAG_TH = 0°C

T_TCO_DE_DIAG_TH = 0s

TCO_DE_INI_DIAG_TH = 0°C

TCO_DE_DIAG_TH = 0°C

LV_TCO_DE_MAX_DIAG_TH = 0

TIA_MIN_DIAG_TH = TIA_THR_ST

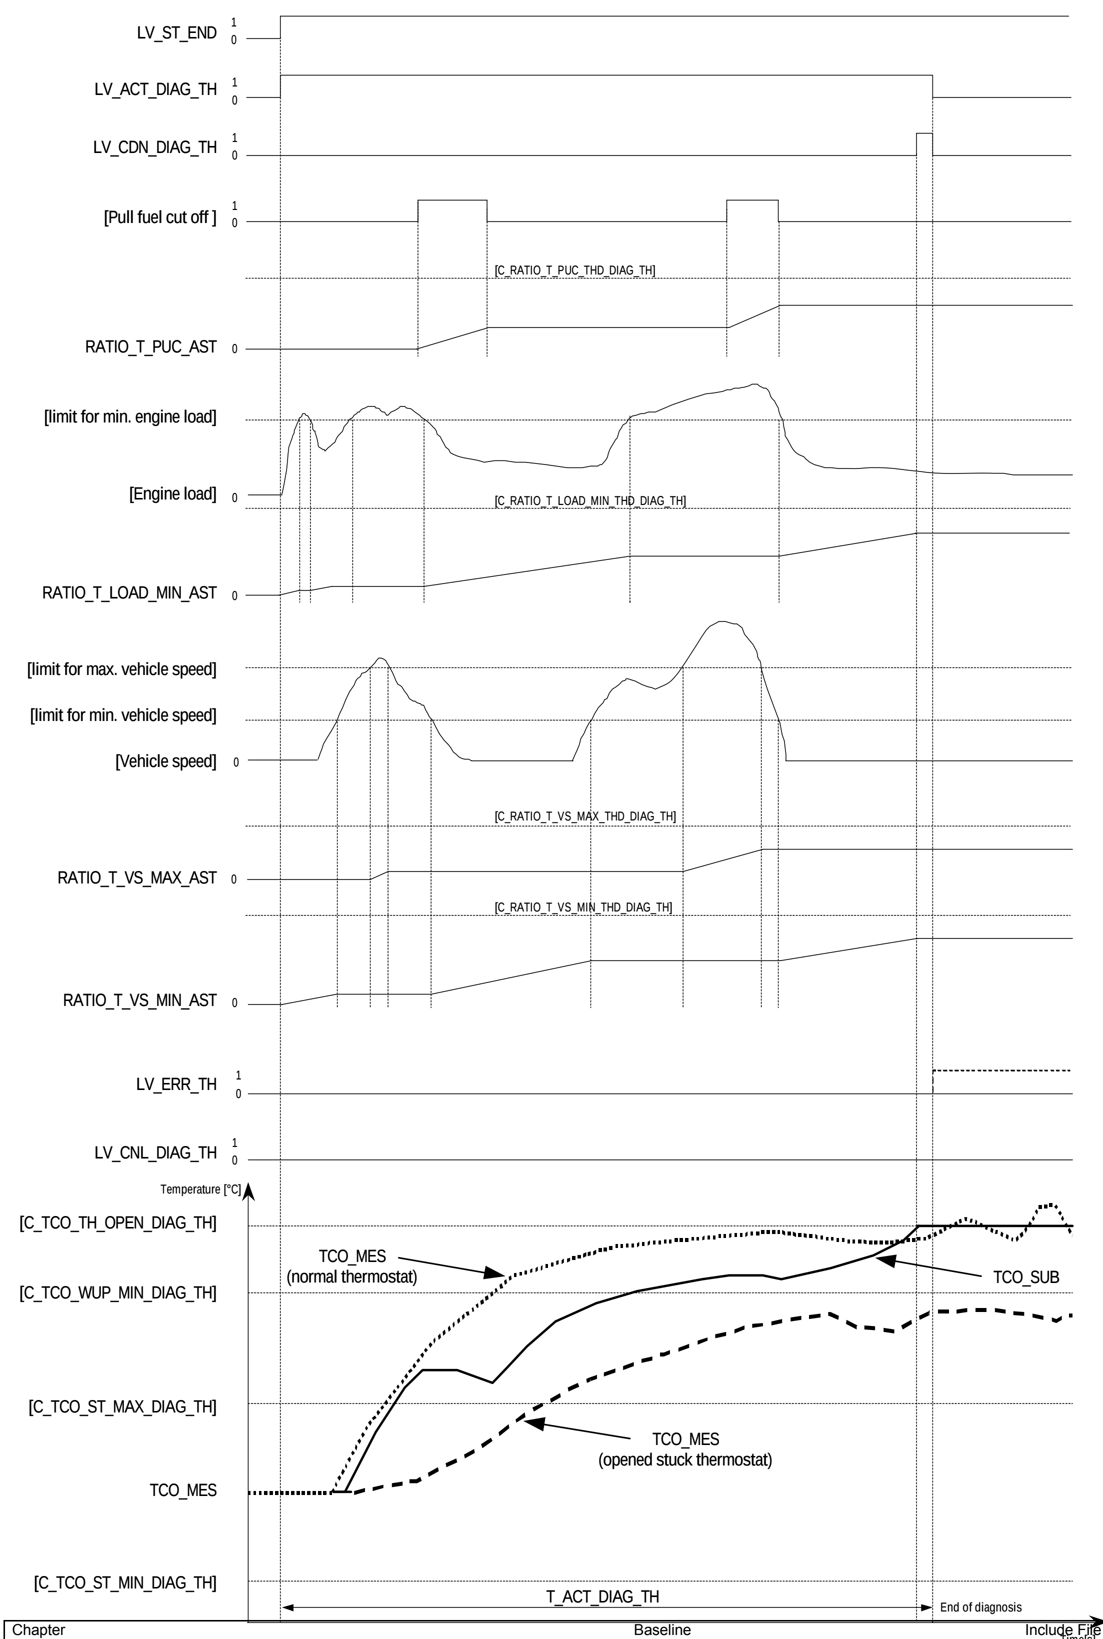
Recurrence: 1000 ms

Activation: LV_ACT_DIAG_TH = 1

(Coolant thermostat functionality check enabled)

Deactivation: LV_ACT_DIAG_TH = 0

(Coolant thermostat functionality check disabled)



Signal flow diagram:

Formula section:

LV_INH_DIAG_TH	LV_CNL_DIAG_TH	LV_ERR_TCO_STUCK_H	LV_ERR_TCO_STUCK_RNG
LV_ERR_MAP			

FUNCTION DESCRIPTION:

General information:

The coolant thermostat diagnosis is performed at transition from the logical value for “engine stop” from “1” to “0”. If the engine stalls or one of the conditions for inhibiting the diagnosis is present, it will be stopped and starts again at the next engine start.

The diagnosis is finished as soon as the boolean for end of coolant thermostat diagnosis is set to “1”. In this case the boolean for coolant thermostat error indicates either an open stuck thermostat (= 1) or a normal working thermostat (= 0).

Depending on project specific requirements, the coolant thermostat diagnosis can be inhibited by setting of LV_INH_DIAG_TH.

Application conditions:

Initialisation at RESET or EXIT_ST or LV_IGK = 0 -> 1 ***or*** *FMY clear:*

LV_INH_DIAG_TH = 0

LV_INH_DIAG_RBM_TH = 0

STATE_DIAG_TH="ST"

B.50 Rate Base Monitoring interface for thermostat monitoring.

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
STATE_RBM_TH	O/V	0 ... 7H	0...7	1	-
Interface of thermostat monitoring with the Rate-Based Monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_TH	V	0 ... FFFFH	0 ... 7,99572	0,000122	-
Actual RBM rate for Thermostat Monitoring , for application purpose					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_RBM_TH	LV_INH_DIAG_RBM_TH
CTR_CDN_RBM_TH	CTR_COMP_RBM_TH		

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the thermostat monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TH data.

Within STATE_RBM_TH, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TH = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1of STATE_RBM_TH = 0

bit 2 of STATE_RBM_TH = 1

on failure memory reset :

bit 1 of STATE_RBM_TH = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_ERR_TCO_STUCK_H
LV_ERR_TCO_STUCK_RNG			

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_TH = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_TH = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_TH = 0

Then

If LV_END_DIAG_RBM_TH = 1

Then bit 0 of STATE_RBM_TH = 1

Endif

Endif

If bit 1 of STATE_RBM_TH = 0

Then

If LV_INH_DIAG_RBM_TH = 1

Then bit 1 of STATE_RBM_TH = 1

Endif

Endif

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_TH = 0
then RATE_RBM_TH = FFFFH
else RATE_RBM_TH
= (CTR_COMP_RBM_TH / CTR_CDN_RBM_TH)
endif

B.51 Dynamic Error Management

FUNCTION DESCRIPTION:

General information:

This module is the heart of the dynamic error management function. It defines statement of principles and mechanism of dynamic error management function.

Dynamic error management receives results from diagnosis function (may be filtered by antibounce algorithm). These results are, in this module, managed as diagnosis failure following **CARB** and **EOBD** standards.

In addition, this module uses generic services defined by others modules (priority rules for example).

B.51.1 Diagnosis failure description

B.51.1.1 Failures definition

Description:

Dynamic error management manages failures, which have different states.

Detected failure

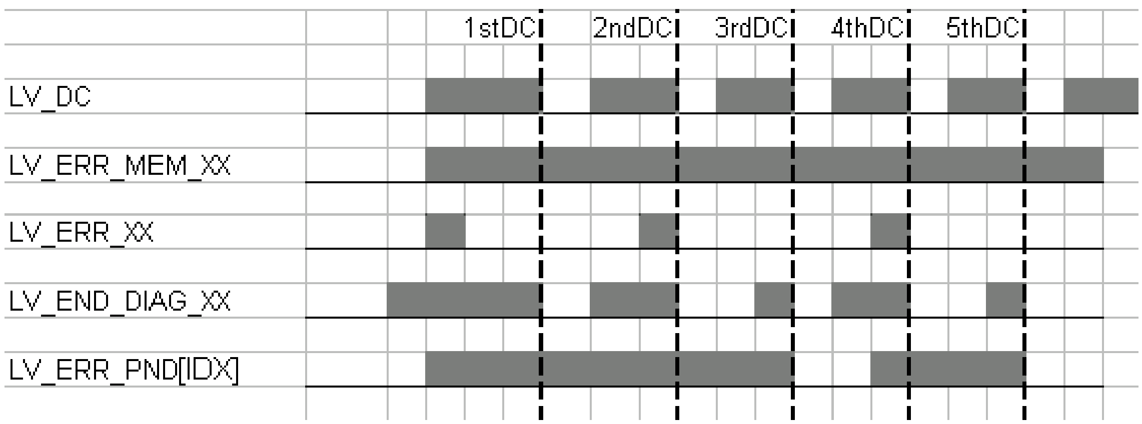
The detected failure is provided by a defective system (the error provided by this system is basic). It occurs when the diagnosis test and diagnosis condition of at least one symptom or more are true and disappears in other cases.

Present failure

The present failure is the detected failure after filtering. The real entry point of the error management is the present failure.

Pending failure

The pending failure is the detected failure after filtering. The failure shall stay pending until detection of a whole driving cycle without the failure present and the diagnosis done.



Temporary failure

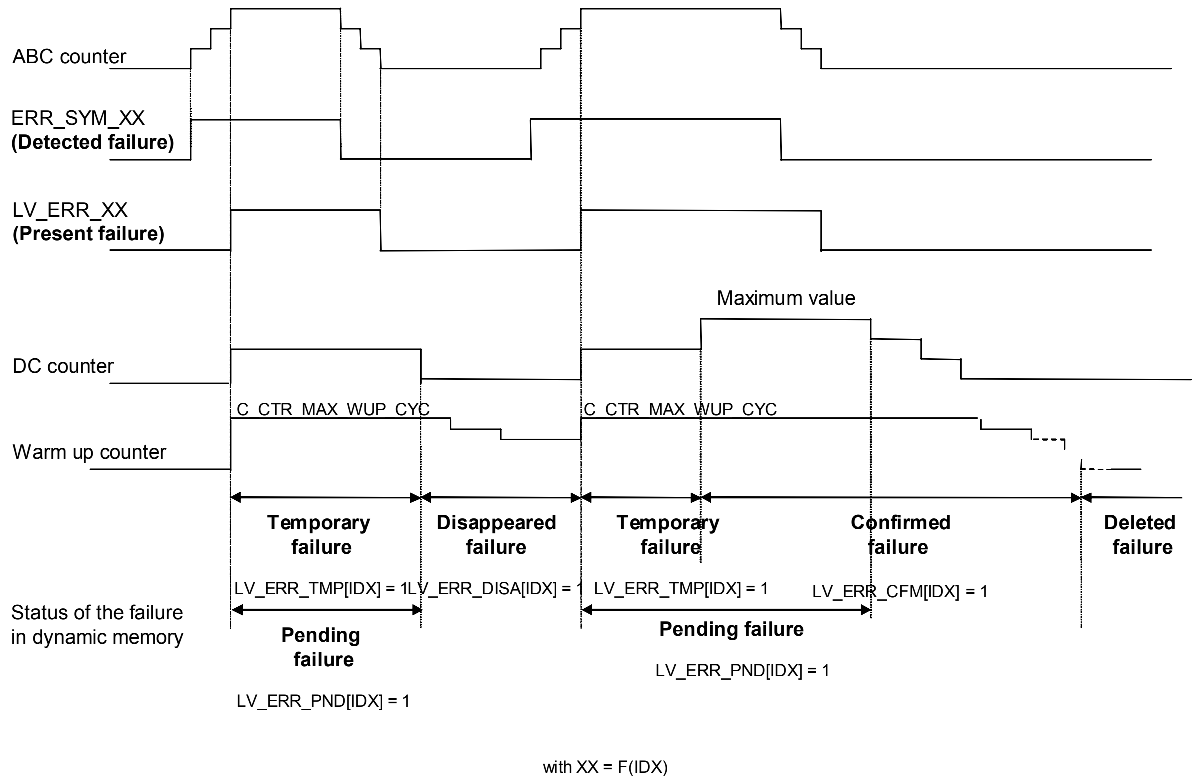
A failure is considered as temporary when this failure is present and leaves this state either when this failure is confirmed or disappeared (in this case, this failure isn't confirmed).

Disappeared failure

A failure is considered as disappeared, when no failure was detected during a complete driving cycle and the failure wasn't confirmed. It leaves this state either when the failure reoccurs or when the warm-up counter reaches 0.

Confirmed failure

A failure is considered as confirmed when the driving cycle counter reaches the maximum value and leaves this state when the warm-up counter reaches 0.



B.51.1.2 Failures information

Description:

Each failure is constituted of informations, which are stored in the memory.

Some informations are allocated in the static memory. It means that these informations are available for each failure.

Static memory: XX represents any failure defined in the application (index of XX∈[1...65535])

- ABC counter	CTR_ABC_XX
- End of diagnosis counter	CTR_ABC_END_DIAG_XX
- End of diagnosis flag	LV_END_DIAG_XX
- Readiness flag	LV_READY_XX
- Diagnosis condition	LV_CDN_DIAG_XX
- Detected symptom	ERR_SYM_XX
- Present failure	LV_ERR_XX
- Failure is stored in dynamic memory	LV_ERR_MEM_XX

- Failure present at least one time since failure memory cleared LV_ERR_LST_CLR_XX

Some informations are allocated in the dynamic memory. It means that these informations are created in memory in case of a new dynamic failure entry (limited number of dynamic entries managed with priority rules).

Dynamic memory : IDX∈ [0...NC_NR_ERR_DYN-1]

- Frequency counter	CTR_FRC[IDX]
- Driving cycle counter	CTR_DC[IDX]
- Warm up counter	CTR_WUP_CYC[IDX]
- Memorized the first symptom (DTC)	ERR_SYM_MEM[IDX]
- Memorized the last symptom (DTC)	ERR_SYM_LST[IDX]
- Environmental data (Freeze frame)	ENVD_OBD[u][m]
	ENVD_CUS_CMN[v][m]
	ENVD_CUS_SET_CMN[W][x][m]
	ENVD_CUS_SET_SPC[y][z][m]
- Confirmed failure	LV_ERR_CFM[IDX]
- Disappeared failure	LV_ERR_DISA[IDX]
- Memorized MIL activation flag	LV_DC_MAX[IDX]
- Failure during DC	LV_ERR_DC[IDX]
- Temporary failure	LV_ERR_TMP[IDX]
- Pending failure	LV_ERR_PND[IDX]
- Marked failure	LV_ERR_MKD[IDX]

Remark :

To keep the link between the index of the failure in dynamic memory and the index of the failure in static memory, a transfer function is defined by : XX = F (IDX)

with m=IDX_FRF[IDX]

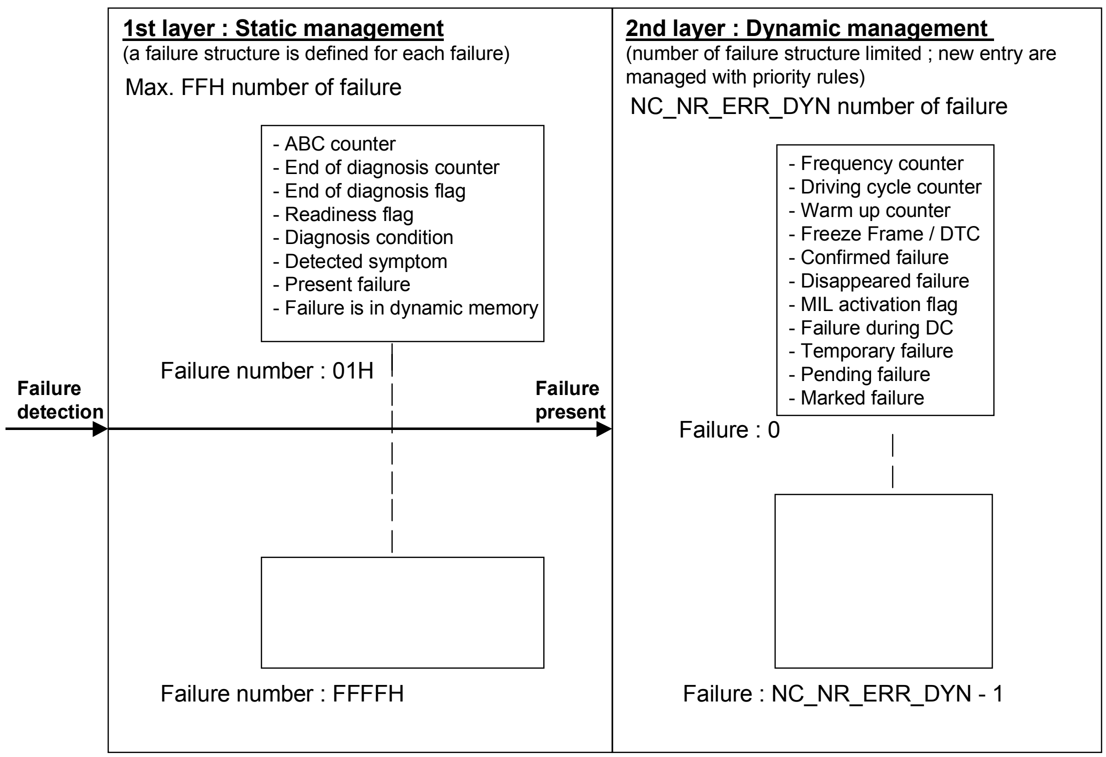
B.51.2 Memory management

Description:

As explained above, the memory is managed as two layers.

The first layer is managed as static memory. According to failure detection, ABC counter and end of diagnosis counter are incremented or decremented. Present failure information is the output of this layer. All failures are managed in the first layer.

When a present failure appears, it may provoke a dynamic entry in the second layer (dynamic) of the memory. In this second layer, only present failures are managed. The number of failure structure is limited to a maximum value defined by NC_NR_ERR_DYN.



B.51.2.1 Failures configuration

Description:

For every diagnosis two bytes exist to configure the failure. The following items can be influenced :

- control of dashboard lamp (MIL and/or Warning lamp 1 and/or Warning lamp 2)
- the emission relevance of a failure
- failure priority, used for failure storage

The definition of these bytes is done in Failure Class module.

B.51.2.2 Store / Erase a failure in 2nd layer memory

Description:

This module manages the "Entry" (storage) and "Exit" (deleting) of failures in the 2nd layer memory.

Storage :

Syntax : ACTION_ERRM_StoreErr (IN <XX>)

Parameter (in) : XX number of the failure to store in dynamic memory

Parameter (out) : -

Short description :

If other modules call the action to store the failure XX with ACTION_ERRM_StoreErr (IN<XX>) then the failure XX (with XX = F(IDX)) is taken into the 2nd layer memory and :

- frequency counter (number of occurrences of present failure) is updated ;
- the DTC is stored with ACTION_ERRM_StoreDtc (IN<IDX>) (if needed) ;
- the Freeze Frame is stored with ACTION_ERRM_StoreFrf (IN<IDX>) ;
- the index of diagnosis instance XX is stored in DIAG_INST[IDX] for visualisation

Deleting :

Syntax : ACTION_ERRM_EraseErr (IN <IDX>)

Parameter (in) : IDX index of failure in 2nd layer memory to erase

Parameter (out) : -

Short description :

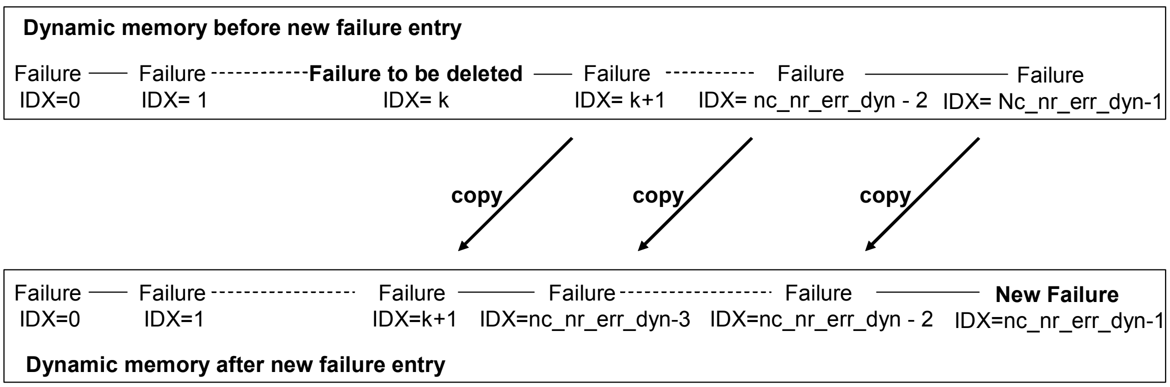
If other modules call the action to erase the failure XX with ACTION_ERRM_EraseErr (IN<IDX>) then the failure IDX is taken out of the 2nd layer memory and :

- the failure is stored in history memory with ACTION_ERRM_StoreHistory (IN<IDX>) ;
- the DTC of the failure is erased with ACTION_ERRM_EraseDtc (IN<IDX>) ;
- the Freeze Frame of the failure is erased with ACTION_ERRM_EraseFrf (IN<IDX>) ;
- similar conditions of the failure are erased with ACTION_ERRM_EraseScdn (IN<XX>) if existing

2nd layer memory description :

It is useful to sort the failures in the sequence in which they occurred ; first failure has index (IDX) number zero, second failure has index (IDX) number one, ... For example, when a new failure entry is accepted (memory is full), one failure is deleted, sorting algorithm is respected and the new failure entry is stored in last position.

In any case, sorting algorithm must be always respected.



Application conditions:

Initialization : On saved RAM lost

CTR_ERR_DYN_NR = 0 ; LV_ERR_MEM_XX = 0

CTR_FRC[IDX] = 0; LV_ERR_TMP[IDX] = 0; LV_ERR_MKD[IDX] = 0

ACTION_ERRM_StoreHistory (IN<IDX>)

ACTION_ERRM_EraseDtc (IN<IDX>)

ACTION_ERRM_EraseFrf (IN<IDX>)

If failure is using similar conditions functionality (see Similar conditions Appli.Inc.) (LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)

Then ACTION_ERRM_EraseScdn (IN<XX>)

(with XX=F(IDX))

Endif

Failure XX (with XX=F(IDX)) is cleared (all data in 2nd layer memory related to failure IDX are filled with 0 ; all data in static memory related to failure XX are unchanged)

LV_ERR_MEM_XX = 0 (with XX = F(IDX))

CTR_ERR_DYN_NR = CTR_ERR_DYN_NR –1

Temporary flag management :

For each failure in 2nd layer memory

If LV_ERR_CFM[IDX] = 1
or LV_ERR_DISA[IDX] = 1
Then LV_ERR_TMP[IDX] = 0
Endif

B.51.2.3 Clear failure memory

Description:

For development conveniences, it is often useful to reinit all failure in the memory. This is possible by setting the calibration bit LC_ERR_FMY_CLR to 1.

Application conditions:

Initialisation: -

Recurrence: -

Activation: LC_ERR_FMY_CLR 0 → 1 transition

Formula section:

Treatment performed at global clearing request (e.g. Mode$04) :

If LC_ERR_FMY_CLR = 1

Then Reset failure memory (all data in 2nd layer memory and all data in static memory, e.g. LV_ERR_LST_CLR)

CTR_ERR_DYN_NR = 0

ACTION_ERRM_*ClcPermanentIniErrm*()

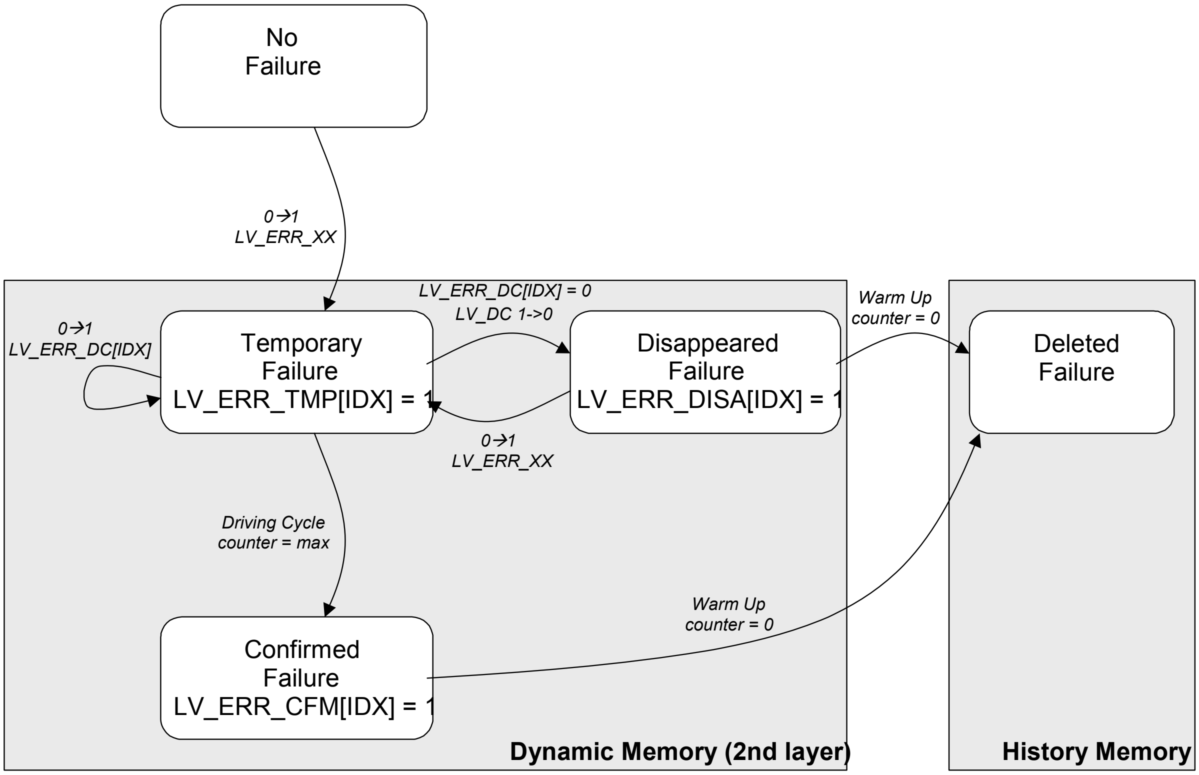
Endif

B.51.3 Failure management

B.51.3.1 State diagram

Description:

In the following diagram, the failure state progress is described.



There are also additional transitions possible due to :

- Overwriting/Erasement by priority rule or Tool Request :

  Temporary Failure → Deleted Failure

  Disappeared Failure → Deleted Failure

  Confirmed Failure → Deleted Failure

	Driving Cycle counter value	Warm Up counter value
No Failure	0	0
Temporary Failure	[0, Max [without having reached Max	Max
Confirmed Failure	[0, Max] with having reached Max	] 0, Max]
Disappeared Failure	0	] 0, Max]
Deleted Failure	0	0

B.51.3.2 Present failure occurred

Description:

When a failure occurs (becomes present), this failure shall be stored in the 2nd layer memory (if possible). If the 2nd layer memory is full and marked mode is not set, a choice is made in the module “Priority rules” :

- RESP is set to OK by priority rules, if the failure can be stored in the 2nd layer memory ; in this case IDX gives the index of the failure to be replaced into dynamic memory;
- RESP is set to NOK by priority rules if the failure can’t be stored in the 2nd layer memory.

To monitor the failure, ACTION_ERRM_TrigErrDyn shall be called when the failure occurs (the failure is evaluated or re-evaluated) or the failure is removed.

Application conditions:

Initialisation: -

Recurrence: -

Activation: at LV_END_DIAG_XX 0 → 1 transition

with (LV_ERR_XX = 1 **and** LV_ERR_MEM_XX = 1)

or

at LV_ERR_XX 1 → 0 transition

(due to the physical default disappears only: it means that a clear failure memory or diagnosis initialization aren’t activation condition)

Formula section:

ACTION_ERRM_TrigErrDyn (IN<XX>)
This action is called to indicate that a new failure has occurred, although failure is not stored.

Application conditions:

Initialisation: -

Recurrence: -

Activation: LV_ERR_XX 0 → 1 transition **with** LV_END_DIAG_XX = 1

or

LV_END_DIAG_XX 0 → 1 transition

with (LV_ERR_XX = 1 **and** LV_ERR_MEM_XX = 0)

Formula section:

If (1) CTR_ERR_DYN_NR < NC_NR_ERR_DYN

or LV_ERR_MEM_XX = 1

Then (1) ACTION_ERRM_StoreErr (IN<XX>)

Else (1) **If (2)** LV_MKD_MOD = 0

Then (2) ACTION_ERRM_PrioRule (OUT<RESP>, OUT<IDX>)

If (3) RESP = OK

Then (3) ACTION_ERRM_EraseErr (IN<IDX>)

ACTION_ERRM_StoreErr (IN<XX>)

Endif (3)

Endif (2)

Endif (1)

ACTION_ERRM_TrigErrDyn (IN<XX>)
This action is called to indicate that a new failure has occurred.

B.51.3.3 Present failure occurred

Application conditions:

Initialisation: -

Recurrence: -

Activation: at LV_END_DIAG_XX 0 → 1 transition (independant of LV_ERR value)

Formula section:

call ACTION_ERRM_TrigFarm(XX)

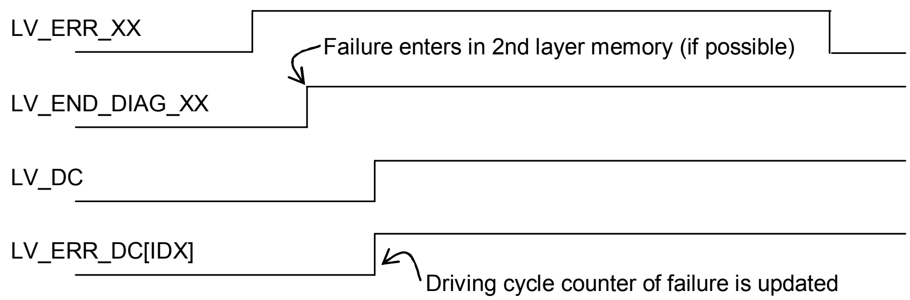
B.51.3.4 Error occurred during present driving cycle

Description:

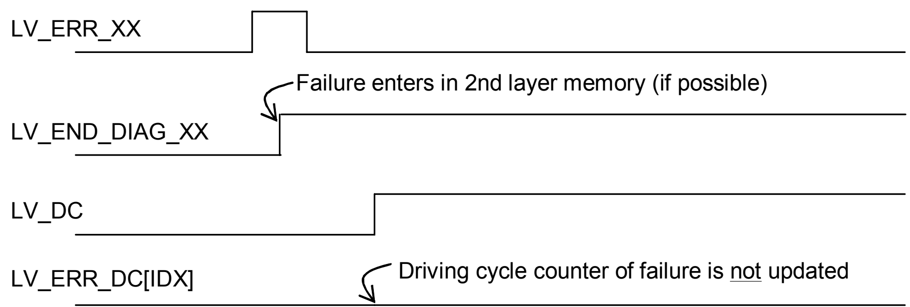
An active flag called LV_ERR_DC[IDX] indicates that an error XX (with XX = F(IDX)) has occurred during a driving cycle.

Even if the error disappears during the driving cycle, the flag remains active during the whole driving cycle.

Failure present, then driving cycle is recognized, then failure not present



Failure present, then failure not present, then driving cycle is recognized



Application conditions:

Initialisation: at ECU reset **or** transition LV_DC 1->0 after treatment done at this event

LV_ERR_DC[IDX] = 0

Recurrence: same as the diagnosis routine

all failures are updated at transition 0->1 of LV_DC

Activation: at every engine operating state

Formula section:

If LV_ERR_XX = 1 (failure is present)

and LV_END_DIAG_XX =1 (current diagnosis is available)

	and LV_DC = 1	(within driving cycle)
	and LV_ERR_MEM_XX =1	(failure is stored in dynamic memory)
Then	LV_ERR_DC[IDX] = 1	(it remains 1 until the next initialization)
Endif		

B.51.3.5 Driving Cycle Counter management

Description:

The driving cycle counter CTR_DC[IDX] is associated to each failure which has a structure defined in second layer of memory.

This counter is incremented at each driving cycle in the following way:

- for all failures not using SCDN functionality (withLC_ENA_SCDN=0 or NLC_ENA_SCDN=0), when the associated failure gets present (LV_ERR_DC[IDX]).
- for failures using SCDN functionality (with LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)
    - when the failure gets present the first time (and stored)
    - when the failure gets present again in a following driving cycle
    - when the failure gets present again in another driving cycle (not previous) (driving cycle counter of this failure is != 0/max before new occurrence), if the similar conditions functionality decides, that the incrementation is possible

The driving cycle counter is decremented at the end of a driving cycle in the following cases:

- for all failures not using SCDN functionality (or LC_ENA_SCDN=0 or NLC_ENA_SCDN=0), when the associated failure was not present the complete DC (LV_ERR_DC[IDX] = 0).
- for failures using SCDN functionality (with LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)
    - when similar conditions are encountered without failure (for failure with present MIL illumination)
    - when the similar conditions functionality decides that the decrementation is possible (for temporary failure or confirmed failure with no present MIL illumination)

The driving cycle counter is useful for MIL management and warm-up counter management (see specific chapter).

With the calibration LC_ENA_SCDN it’s possible to enable/disable the similar conditions functionality. If LC_ENA_SCDN = 0 the failures using SCDN functionality (see similar conditions Appl.Inc) are treated like normal failures in the driving cycle counter management.

Application conditions:

Initialization: On saved RAM lost

LV_DC_MAX[IDX] = 0

CTR_DC[IDX] = 0

LV_ERR_DISA[IDX] = 0

LV_ERR_CFM[IDX] = 0

Recurrence: -

Activation: -

Formula section:

Treatment for all failures not using SCDN functionality (with LC_ENA_SCDN=0 or NLC_ENA_SCDN=0) stored in 2nd layer memory :

Conditions to increment the driving cycle counter :

At LV_ERR_DC[IDX] 0 → 1 transition

XX=f(IDX)

LV_ERR_DISA[IDX] = 0

If LV_DC_MAX[IDX] =1 (for confirmed failure with MIL ON)

Then

CTR_DC[IDX] = DC_MAX_XX (counter is forced to max.)

ACTION_ERRM_*GetMILRelevant*(XX,PRM_LV_MIL_RLV)

If PRM_LV_MIL_RLV= 1 (MIL illuminated and Failure OBD relevant)

Then

Permanent fault code has to be stored, if not yet done due to memory full

ACTION_ERRM_*StorePermanentCode* (XX)

Endif

Else

CTR_DC[IDX] = CTR_DC[IDX] + DC_INC_XX

If CTR_DC[IDX] ≥ DC_MAX_XX

Then

CTR_DC[IDX] = DC_MAX_XX

LV_DC_MAX[IDX] = 1 (failure becomes confirmed)

LV_ERR_CFM[IDX] = 1

ACTION_ERRM_*GetMILRelevant*(XX,PRM_LV_MIL_RLV)

If PRM_LV_MIL_RLV= 1 (MIL illuminated and Failure OBD relevant)

Then

Permanent fault code has to be stored

ACTION_ERRM_*StorePermanentCode* (XX)

Endif

Endif

Endif

Conditions to decrement the driving cycle counter :

At transition LV_DC 1 -> 0:

If LV_ERR_DC[IDX] = 0
and LV_END_DIAG_XX = 1
Then LV_ERR_PND[IDX] = 0 (Pending fault is erased)
If LV_ERR_CFM[IDX] = 1 (for confirmed failure)
Then **If** LV_DC_MAX[IDX] =1
Then CTR_DC[IDX] = CTR_DC[IDX] - DC_DEC_XX
If CTR_DC[IDX] $\leq$ 0
Then LV_DC_MAX[IDX] = 0
CTR_DC[IDX] = 0
ACTION_ERRM_*ErasePermanentCode* (XX)
Endif
Else CTR_DC[IDX] = 0
Endif
Else (for temporary failure)
CTR_DC[IDX] = 0
LV_ERR_DISA[IDX] = 1 (failure disappeared)
Endif
Endif

Treatment for failures using SCDN functionality (LC_ENA_SCDN=1 and NLC_ENA_SCDN=1) (running within DC) stored in 2nd layer memory.

Conditions to increment the driving cycle counter :

Done upon ACTION_ERRM_IncrementDCctrSCDN call:

(see also similar conditions specification)

Description:

Syntax : ACTION_ERRM_IncrementDCctrScdn (IN <XX>)

Parameter (in) : XX failure in static memory with XX=F(IDX)

Parameter (out) :

Short description:

With the ACTION_ERRM_IncrementDCctrScdn (IN <XX>) the driving cycle counter for the failure XX stored in 2nd layer memory at position IDX, which is using similar conditions functionality, is incremented. This action is called at the end of a diagnosis window in the following cases :

- failure occurred and similar conditions are recorded
- failure already stored in a previous driving cycle. Now failure gets present again and was also present in last driving cycle.
- failure already stored in a previous driving cycle. Now failure gets present again with SCDN recognition for detected failure.
- failure already stored in a previous driving cycle and LV_DC_MAX[IDX] = 1 (MIL is illuminated, if LC_MIL_ON =1).

For details see similar conditions specification.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

ACTION_ERRM_IncrementDCctrScdn (IN<XX>) :

XX=f(IDX)

If LV_ERR_MEM_XX = 1 (failure XX is stored in 2nd layer memory)

Then LV_ERR_DISA[IDX] = 0

If LV_DC_MAX[IDX] =1 (for confirmed failure with MIL on)

Then

CTR_DC[IDX] = DC_MAX_XX (counter is forced to max.)

ACTION_ERRM_*GetMILRelevant*(XX,PRM_LV_MIL_RLV)

If PRM_LV_MIL_RLV= 1

(MIL illuminated and Failure OBD relevant)

Then

Permanent fault code has to be stored, if not yet done due to memory full

ACTION_ERRM_*StorePermanentCode* (XX)

Endif

Else ACTION_ERRM_ConfirmErrScdn (OUT<DCconf>, IN<XX>)

(allows direct failure confirmation; see similar conditions Appl.Inc.)

If DCconf = YES

Then

CTR_DC[IDX] = DC_MAX_XX (counter is forced to max.)

Else

CTR_DC[IDX] = CTR_DC[IDX] + DC_INC_XX

Endif

If CTR_DC[IDX] ≥ DC_MAX_XX

Then

CTR_DC[IDX] = DC_MAX_XX

LV_DC_MAX[IDX] = 1 (failure confirmed)

LV_ERR_CFM[IDX] = 1

LV_ERR_TMP[IDX] = 0

ACTION_ERRM_*GetMILRelevant*(XX,PRM_LV_MIL_RLV)

If PRM_LV_MIL_RLV= 1

(MIL illuminated and Failure OBD relevant)

Then

Permanent fault code has to be stored

ACTION_ERRM_*StorePermanentCode* (XX)

Endif

Endif

Endif

Endif

<u>Conditions to decrement the driving cycle counter :</u>

At transition LV_DC 1 -> 0:

If LV_ERR_DC[IDX] = 0

and LV_END_DIAG_XX = 1

Then ACTION_ERRM_DecrementDCctrSCDN (OUT<DCdec>, IN<XX>)

(with XX=F(IDX))

The similar conditions functionality decides, if it's possible to decrement the driving cycle counter.

```
If      DCdec = YES                            (decrementing is possible)
Then    LV_ERR_PND[IDX] = 0                    (Pending fault is erased)
        If      LV_ERR_CFM[IDX] = 1            (for confirmed failure)
        Then    If      LV_DC_MAX[IDX] = 1
                Then    CTR_DC[IDX] = CTR_DC[IDX] - DC_DEC_XX
                        If      CTR_DC[IDX] ≤ 0
                        Then    LV_DC_MAX[IDX] = 0
                                CTR_DC[IDX] = 0
                                ACTION_ERRM_ErasePermanentCode (XX)
                        Endif
                Else
                        CTR_DC[IDX] = 0
                Endif
        Else                                   (for temporary failure)
           CTR_DC[IDX] = 0
           LV_ERR_DISA[IDX] = 1                (failure disappeared)
        Endif
Endif
Endif
```

B.51.3.6 Warm-Up counter management

Description:

As soon as the failure gets present and stored in the memory, the warm-up cycle counter is initialized.

With every valid warm-up cycle with no error occurrence, the warm-up cycle counter is decremented by 1. If the warm-up cycle counter reaches zero the error is deleted from the 2nd layer memory.

Application conditions:

Initialization:	on saved ram lost CTR_WUP_CYC[IDX]= 0
Recurrence:	-
Activation:	only at transition LV_DC 1 -> 0

Formula section:

Treatment for all failures not using SCDN functionality (or LC_ENA_SCDN = 0) stored in 2nd layer memory :

Condition to decrement the warm up counter :

The following treatment is done for all failure stored in 2nd layer memory **and only at transition LV_DC 1 -> 0** (**before** treatment of driving cycle counter decrementing at end of driving cycle):

If (LV_WUP_CYC = 1 **and** C_CTR_MAX_WUP_CYC != 255)
the warm-up cycle is recognised and failure healing is possible
Then **If** (CTR_DC[IDX] = 0 **and** LV_ERR_DC[IDX] = 0)
the MIL is extinguished and no failure in this driving cycle
or
(CTR_DC[IDX] != 0 **and** LV_DC_MAX[IDX] = 0
case before the MIL may be illuminated
and LV_ERR_DC[IDX] = 0 **and** LV_END_DIAG_XX = 1)
the failure is no more pending
Then CTR_WUP_CYC[IDX] = CTR_WUP_CYC[IDX] - 1
If CTR_WUP_CYC[IDX] = 0
Then ACTION_ERRM_EraseErr (IN<IDX>)
Endif
Endif
Endif

Treatment for failures using SCDN functionality (and LC_ENA_SCDN = 1) (running within DC) stored in 2nd layer memory.

Condition to decrement the warm up counter :

The following treatment is done for all failure stored in 2nd layer memory **and only at transition LV_DC 1 -> 0** (**before** treatment of driving cycle counter decrementing at end of driving cycle):

If LV_WUP_CYC = 1
Then **If** CTR_DC_IDX = 0
and LV_ERR_DC_IDX = 0
Then CTR_WUP_CYC_IDX = CTR_WUP_CYC_IDX - 1
If CTR_WUP_CYC_IDX = 0
Then ACTION_ERRM_EraseErr (IDX)
Endif
Endif
Endif

Condition to reload the warm up counter :

The following treatment is done for failure XX when it is stored in 2nd layer memory **when ACTION_ERRM_StoreErr (IN<XX>) is called :**

CTR_WUP_CYC[IDX] = C_CTR_MAX_WUP_CYC

B.51.4 Miscellaneous services to get information

B.51.4.1 API for determination of pending status of failures

General information:

This API shall be called to determine if any XX failure is pending or not.

Description:

Syntax: ACTION_ERRM_CheckPendingStatus (IN <PRM_IDX_DIAG>, OUT <PRM_LV_ERR_PND>)

Parameter(in): PRM_IDX_DIAG Diagnostic instance of the XX failure

Parameter(out): PRM_LV_ERR_PND State of the failure :

= 1 failure is pending (or it's impossible to determine its status)

= 0 failure is not pending

Short Description: This API shall be used to verify if a failure stored in the dynamic memory has the pending status or not. When it impossible to determine if the fault is pending or not (failure not store because the dynamic memory is full), this failure should be considered as pending anyway.

Application conditions:

Initialisation: -

Recurrence: -

Activation: at action call

Deactivation: -

Formula section:

If (1) *{ the XX failure analysed is present in the dynamic memory }*

LV_ERR_MEM_XX = 1 (with XX = F(IDX))

Then (1)

If (2) *{ IDX is the failure index, in the dynamic memory }*

LV_ERR_PND[IDX] = 1

Then (2)

PRM_LV_ERR_PND = 1

Else (2)

PRM_LV_ERR_PND = 0

Endif (2)

Else (1)

{ failure not stored in the dynamic memory }

If (2) LV_ERR_XX = 1

Then (2)

{ the failure is stored in the static memory but it's not present in the dynamic memory : impossible to determine its status }

{ then the failure shall be considered as pending }

PRM_LV_ERR_PND = 1

Else (2)

{ the failure is neither stored in the static memory nor in the dynamic memory }

PRM_LV_ERR_PND = 0

Endif (2)

Endif (1)

B.51.4.2 Get the "Failure set since last clear" state

Description for ACTION_ERRM_*GetErrLastClr*

ACTION_ERRM_*GetErrLastClr* (<PRM_IDX_ERR>, <PRM_LV_ERR_LST_CLR>)					
This action indicates if a failure has been set already once since the last failure memory clear.					
Parameter	**Type**	**Hex. Limits**	**Phys. limits**	**Resol.**	**Unit**
PRM_IDX_ERR	IN	0...FFFFH	0...65535	1	[-]
Diagnostic failure instance					
PRM_LV_ERR_LST_CLR	OUT	0...1H	0...1	1	[-]
Failure set at least once since last failure memory clear					

General information:

This API shall be called to determine if any XX failure has been set at least one time since memory clear

Formula section:

If PRM_IDX_ERR != 0

Then

with XX = PRM_IDX_ERR

PRM_LV_ERR_LST_CLR = LV_ERR_LST_CLR_XX

Else

PRM_LV_ERR_LST_CLR = 0

Endif

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_ERR_DYN	1	1...FFH	1...255	1	[-]
Maximum number of failure defined in dynamic structure (typical value : 10)					

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CTR_MAX_WUP_CYC	1	0...FFH	0...255	1	[-]
Initialization value for the warm-up cycle of diagnostics					
LC_ERR_FMY_CLR	1	0...1H	0...1	1	[-]
Boolean to clear failure memory when set to 1					

B.52 Dynamic Error Management (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_WUP_CYC	V/O	0...1H	0...1	1	[-]
Warm-up cycles calculation inhibition					
TCO_DSL_CMN	V/O	0...FEH	-48...142.5	0.75	[°C]
Coolant temperature (used only in ERRM for GS-DS diversity)					
TCO_ST_DSL_CMN	V/O	0...FEH	-48...142.5	0.75	[°C]
Coolant temperature at start (used only in ERRM for GS-DS diversity)					

Input data:

TCO	TCO_ST		

Export actions:

ACTION_ERRM_TrigErrDyn (IN <XX>)
This action is called by the error management function when a new failure occurs

B.52.1 Warm-up cycle inhibition

FUNCTION DESCRIPTION:

Description:

Application conditions:

Initialisation: at ECU reset

LV_INH_WUP_CYC = 0

TCO_DSL_CMN = TCO

TCO_ST_DSL_CMN = TCO_ST

Recurrence: 100 ms

Activation: LV_IGK = 1

Deactivation: -

Formula section:

Project shall describe hereafter all conditions to inhibit warm-up cycle counter computation (e.g. with TCO failure, the warm-up cycle evaluation isn't possible).

By default configuration, the warm-cycle computation is not inhibited.

LV_INH_WUP_CYC = 0

The following data are used for different data type between DS and GS:

TCO_DSL_CMN = TCO

TCO_ST_DSL_CMN = TCO_ST

B.52.2 API for Trigger Event

General information:

This file defines the Action "ACTION_ERRM_TrigErrDyn" called by the error management function when a failure occurs or disappears.

The contain of this action should be provided by the project team

Description:

Syntax: ACTION_ERRM_TrigErrDyn (IN <XX>)

Parameter (in): XX diagnostic instance of failure ≡ index of failure in static memory

Parameter (out): -

Short description: This action allows to inform the communication tools in line as soon as a failure occurs

Application conditions:

Initialisation: -

Recurrence: -

Activation: at action request

Formula section:

ACTION_ERRM_TrigErrDyn (XX):

B.53 Cycle manager

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DC	V/O	0...1H	0...1	1	[-]
driving cycle status flag					
LV_WUP_CYC	V/O	0...1H	0...1	1	[-]
Warm-up cycle status flag					
LV_STATE_WUP	V/O	0...1H	0...1	1	[-]
tco state for exceeding the warm-up cycle tco threshold					

Input data:

LV_IGK	LV_ST_END	LV_ES	TCO_DSL_CMN
TCO_ST_DSL_CMN	LV_INH_WUP_CYC		

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TCO_WUP_THD	1	0...FEH	-48...142.5	0.75	[°C]
Minimum value for warm-up cycle detection					
C_TCO_WUP_INC	1	0...FEH	-48...142.5	0.75	[°C]
Minimum increase of the coolant temperature for warm-up cycle detection					
C_TCO_ST_MAX_INH_WUP_CYC	1	0...FEH	-48...142.5	0.75	[°C]
maximum engine temperature at start to detect warm up cycle (customer requirement 71,1°C)					

Import actions:

ACTION_ERRM_*ClcPermanentResetDC* ( )

B.53.1 Driving cycle

FUNCTION DESCRIPTION:

General information:

Description:

A driving cycle consists of a vehicle operation phase from engine startup to engine shutoff and includes the power-lach phase after the engine running phase (In order manage all OBD failures set only in PWL phase).

After key is on, the flag LV_DC is set when the engine exits from “engine start” state.

The flag LV_DC is reset at the end of the power-latch phase before the NVMY management. In case of a LV_IGK 0→1 transition during the powerlatch phase or at ECU reset LV_DC is also reseted.

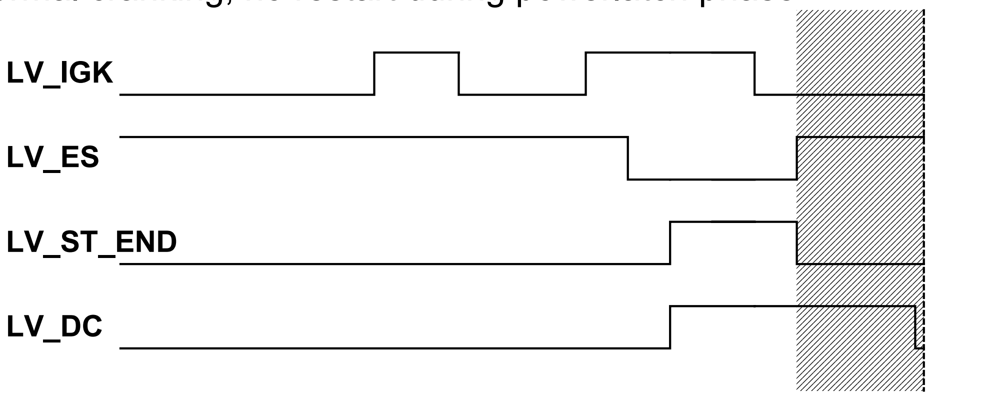
Remark :

For simplification and global coherence, the following rule is applied:

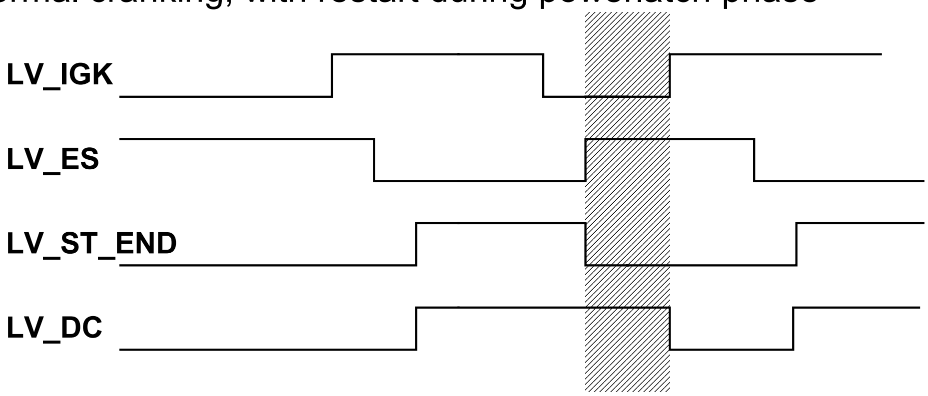
Engine stalling is ignored (if engine restarts after stalling, without key-off/key-on transition, the cycle is considered as the same driving cycle).

Signal flow diagram:

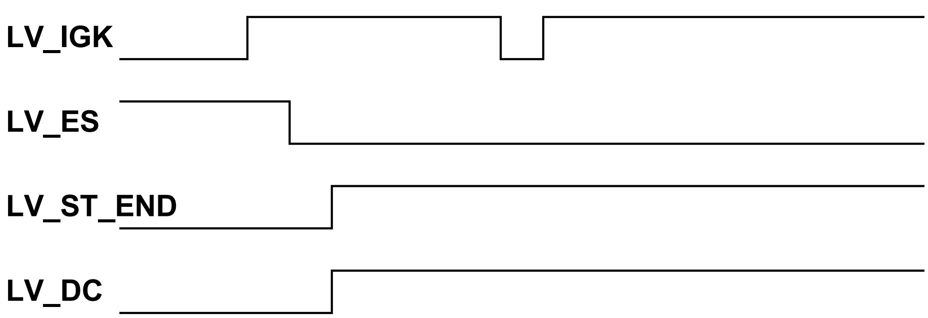
Normal cranking, no restart during powerlatch phase



Normal cranking, with restart during powerlatch phase



Short key off/on while engine is running



Application conditions:

Initialisation: At ECU reset

LV_DC = 0

Before storage of data of the error management within the NVMY the driving cycle is finished.

Recurrence: -

Activation: see Formula section

Formula section:

Activation:

If LV_ST_END 0→1 transition

Then

LV_DC = 1

Endif

Deactivation:

If LV_IGK 0→1 transition

and

LV_ES =1

Then

LV_DC = 0

Before clearing static and dynamic memory (e.g. LV_END_DIAG_XX) call :

ACTION_ERRM_*ClcPermanentResetDC*()

Endif

If End of power-latch phase is reached (before NVMY storing)

Then

LV_DC = 0

Before clearing static and dynamic memory (e.g. LV_END_DIAG_XX) call :

ACTION_ERRM_*ClcPermanentResetDC*()

Endif

B.53.2 Warm-Up Cycle and Warm-Up Status

FUNCTION DESCRIPTION:

General information:

The detection of the warm-up cycle is based on the coolant temperature. The warm-up cycle is detected as soon as the coolant temperature reaches C_TCO_WUP_THD and the change with regard to the starting temperature exceeds C_TCO_WUP_INC. These values are defined by law, so a change of these values is only for development validation commodity.

The application must guarantee warm-up cycle detection when a coolant temperature sensor error exists.

Therefore if a coolant temperature sensor error has been debounced, the threshold for warm-up cycle detection are referred to the backup coolant temperature value computed by the engine control (see chapter “Diagnosis and emergency operation“).

The warm-up status is needed for similar driving conditions test.

Application conditions:

Initialisation: At ECU reset or LV_DC 1→0 transition (after warm-up cycle counter management)

LV_WUP_CYC =0
LV_STATE_WUP = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

```
If    LV_INH_WUP_CYC = 0
Then
        If    TCO_DSL_CMN > C_TCO_WUP_THD
        Then
              LV_STATE_WUP = 1
              If    TCO_DSL_CMN > (TCO_ST_DSL_CMN + C_TCO_WUP_INC)
                    and
                    TCO_ST_DSL_CMN < C_TCO_ST_MAX_INH_WUP_CYC
              Then
                          LV_WUP_CYC = 1
              Endif
        Endif
Endif
```

Calibration hint:

C_TCO_WUP_THD =	at least 72 °C for gasoline engines	(OBD II requirement)
	at least 70 °C for gasoline engines	(EOBD requirement)
C_TCO_WUP_INC =	at least 23 °C for gasoline engines	(OBD II requirement)
	at least 22 °C for gasoline engines	(EOBD requirement)

In case of Diesel systems, recommended values are the same, except :

C_TCO_WUP_THD = at least 60 °C for diesel engines (OBD II requirement)

C_TCO_ST_MAX_INH_WUP_CYC = 71,1 °C (customer specific requirement)

Pointer to make the link between the failure and the freeze frame					

Note:

The link between the failure stored in the dynamic error mangement at position *IDX* is made with IDX_FRF[*IDX*]. E. g. a failure stored at the position *IDX* = 2 belongs to freeze frame ENVD_..._[m] with m = IDX_FRF[2]

Input data:

ENVD_CONF_OBD[NC_NR_ENVD_OBD]	ENVD_CONF_CUS_CMN[NC_NR_ENVD_CUS_CMN]	ENVD_CONF_CUS_SET_CMN[NC_NR_ENVD_CUS_SET_CMN]
CTR_FRC[NC_NR_ERR_DYN]	NC_NR_ERR_DYN	LV_ERR_DISA[NC_NR_ERR_DYN]

Export actions:

ACTION_ERRM_StoreFrf (IN <IDX>)
This action stores the freeze frame of the failure IDX
ACTION_ERRM_EraseFrf (IN <IDX>)
This action erases the freeze frame of the failure IDX
ACTION_ERRM_StorePrevFrf (IN <XX>)
This action stores the prestored freeze frame for the diagnosis instance XX

FUNCTION DESCRIPTION:

General information:

This module describes the structure of the freeze frame and manages the storage and deleting of the freeze frame.

A freeze frame is a group of vehicle environment data catched when a failure occurs.

Freeze frame is filled up with variables, which are not limp home values : the variables are set up before going to the limp home.

A freeze frame is made of many parts :

- FRF_OBD: Environmental data, which are common to all failures and stored on time. It's only updated, if the failure has disappeared before and occurs again.

  The content is defined by law. It's called usually CARB Freeze Frame and the content is according to SAE J1979.

  Size of this part is defined by configuration data NC_NR_ENVD_OBD affected value is in the Environmental data (Appl. Inc.) module.

  Contents of this part is fixed and defined in Environmental data (Appl. Inc.) module.

- FRF_CUS_CMN : Environmental data, which are common to all failure.

  It's stored one time, if NC_ ENVD_CUS_CMN_UPD = 0.

  With NC_ ENVD_CUS_CMN_UPD = 1, FRF_CUS_CMN is updated, if the failure was disappeared before and occurs again.

  The content is not required by law.

  Size of this part is defined by configuration data NC_NR_ENVD_CUS_CMN; affected value is in the Environmental data (Appl. Inc.) file.

  Contents of this part is fixed and defined in the Environmental data (Appl. Inc.) module.

- FRF_CUS_SET_CMN : Environmental data, which are common to all failure and stored many times. The content is not required by law. For each failure occurrence several catches (called sets) can be done.

  Size of this part is defined by configuration data, affected value is in the Environmental data (Appl. Inc.) module :

  NC_NR_FRF_SET for number of sets per freeze frame

  NC_NR_ENVD_CUS_SET_CMN for number of common data (in bytes) in each set

  Contents of this part is fixed and defined in the Environmental data (Appl. Inc.) module.

- FRF_CUS_SET_SPC : Environmental data, which are specific to each failure and stored many times. The content is not required by law. For each failure occurrence several catches (called sets) can be done.

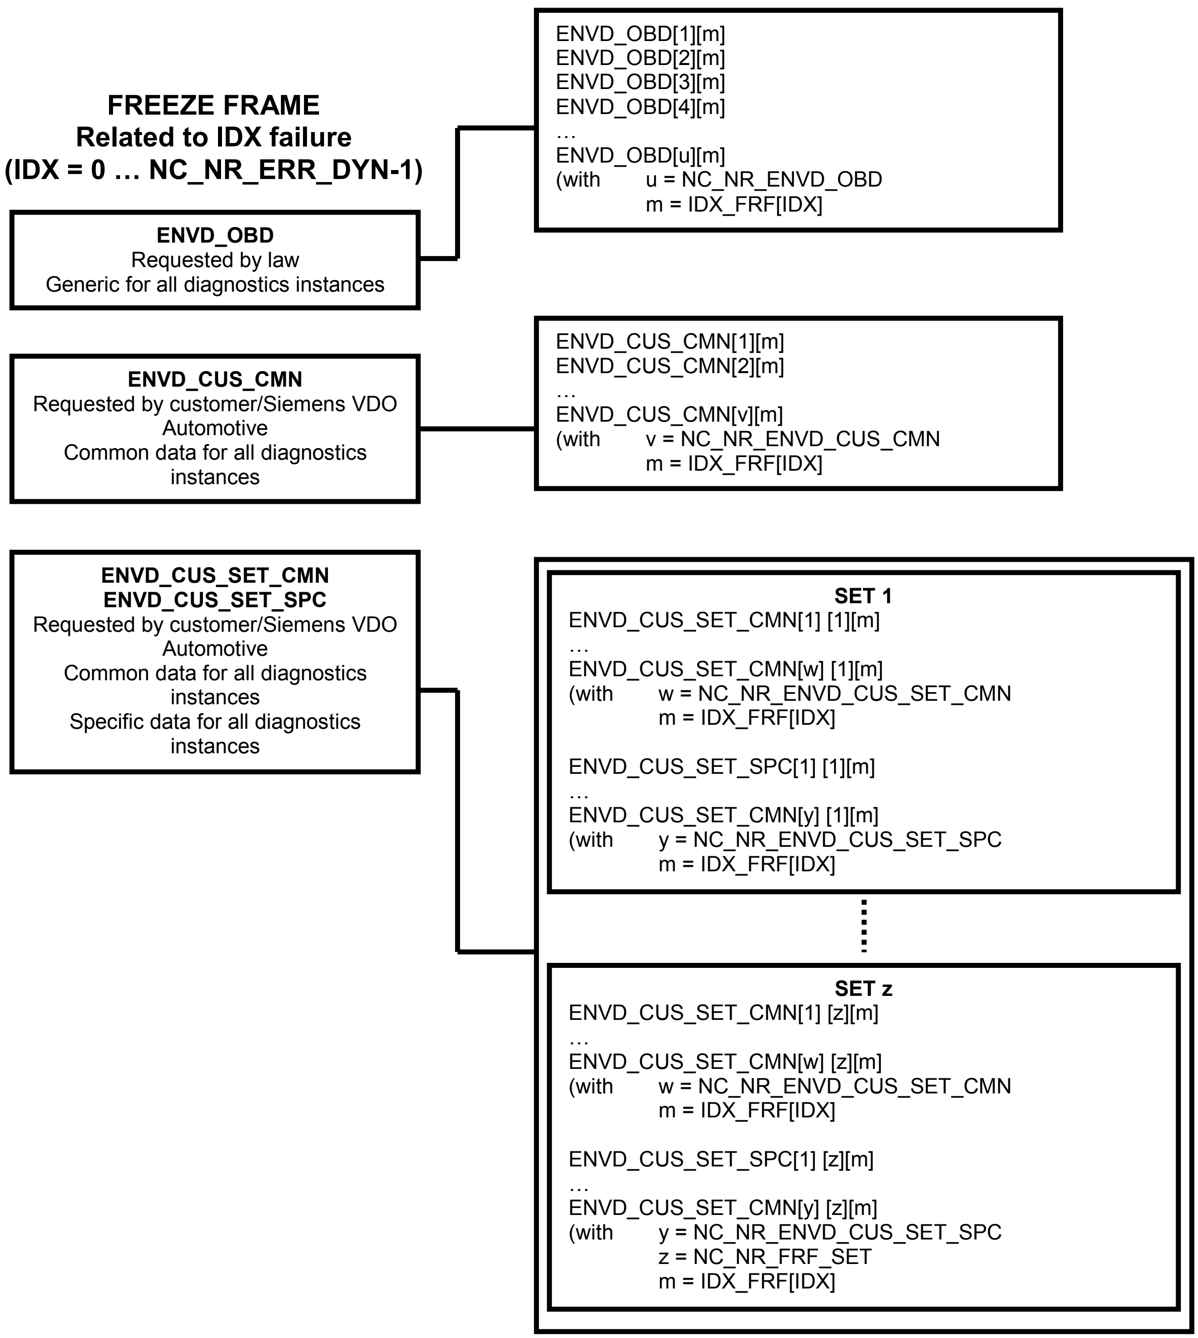
  Size of this part is defined by configuration data, affected value is in Environmental data (Appl. Inc.) module :

  NC_NR_FRF_SET for number of sets per freeze frame

  NC_NR_ENVD_CUS_SET_SPC for number of specific data (in bytes) in each set

  Contents of this part is defined by calibration, process is described in the last chapter of this module.

Signal flow diagram:



Remark: This signal flow diagram doesn't include the prestored freeze frame functionality described in chapter 1.4.

B.54.1 Freeze frame storage

Description:

Syntax : ACTION_ERRM_StoreFrf (IN <IDX>).

Parameter (in) : IDX Index of failure in 2nd layer memory to store the freeze frame

Parameter (out) : -

Short description :

When the failure IDX gets present, the storage of a freeze frame is done in the 2nd layer memory by calling the action ACTION_ERRM_StoreFrf (IDX).

If several failures occur (TCO sensor, injector 1, injector 4), a freeze frame is stored for each failure. For ram memory limitation, the number of freeze frame is limited to NC_NR_ERR_DYN.

If same failure occurs several times (occurrence of the failure is defined by the frequency counter CTR_FRC[IDX]), the following rules are applied :

- 1st occurrence :

  ⇨ Store FRF_OBD +FRF_CUS_CMN +FRF_CUS_SET_CMN + FRF_CUS_SET_SPC

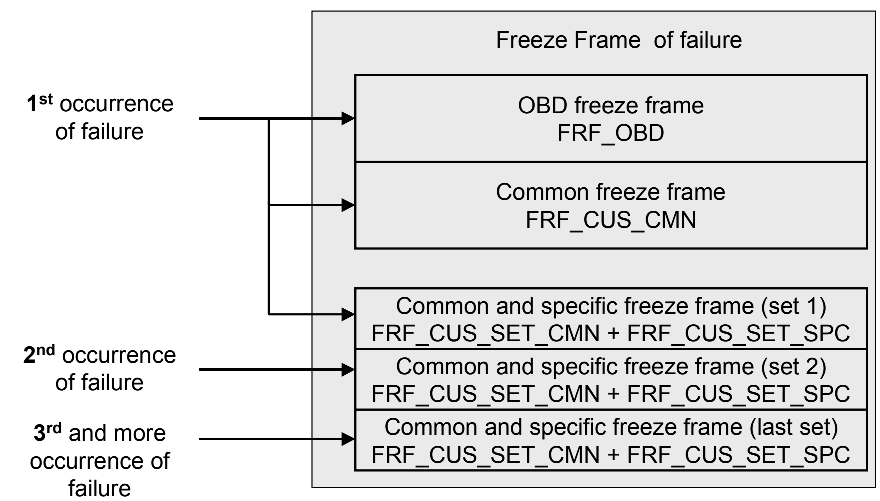
- occurrence ∈ [2 to NC_NR_FRF_SET]

  ⇨ Store FRF_CUS_SET_CMN + FRF_CUS_SET_SPC

- occurrence > NC_NR_FRF_SET

  ⇨ Replace last FRF_CUS_SET_CMN + FRF_CUS_SET_SPC

Example with NC_NR_FRF_SET set to 3



Freeze frame informations are available as long as the failure is not erased in 2nd layer memory.

Remark: Special behavior for FRF_OBD and FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed.

Application conditions:

Initialization: after system initialization the freeze frame is restored from non volatile memory or in case of a damaged non volatile memory the freeze frame is initialized with zero

Recurrence: -

Activation: at Action request

Formula section:

ACTION_ERRM_StoreFrf (IDX) :

If CTR_FRC[IDX] = 1

Then (1st occurrence : storage

With u = 1 ... NC_NR_ENVD_OBD

v = 1 ... NC_NR_ENVD_CUS_CMN

w = 1 ... NC_NR_ENVD_CUS_SET_CMN

y = 1 ... NC_NR_ENVD_CUS_SET_SPC)

If (NC_NR_ENVD_PREV != 0 and

(with t related to failure XX, see Environmental data Appli.Inc.)

Else **If** (LV_ERR_DISA[IDX] = 1)

Failure was in disappeared state before this occurrence

Then ENVD_OBD[u][m] = ENVD_CONF_OBD[u]

Freeze frame ENVD_OBD is updated

If (NC_ ENVD_CUS_CMN_UPD = 1)

Then ENVD_CUS_CMN[v][m]= ENVD_CONF_CUS_CMN[v]

FRF_CUS_CMN is updated

Endif

Endif

ENVD_CUS_SET_CMN[w][z][m] = ENVD_CONF_CUS_SET_CMN[w]

ENVD_CUS_SET_SPC[y][z][m] = ID_ERR_ENVD_XX [y]

(with XX = F(IDX))

Endif

Endif

B.54.2 Freeze frame deleting

Description:

Syntax : ACTION_ERRM_EraseFrf (IN <IDX>).

Parameter (in) : IDX Index of failure in 2nd layer memory to store the freeze frame

Parameter (out) : -

Short description :

When the failure IDX is erased from 2nd layer memory, the freeze frame of this failure is also erased by calling the action ACTION_ERRM_EraseFrf (IDX).

Application conditions:

Initialization: -

Recurrence: -

Activation: at Action request

Formula section:

ACTION_ERRM_EraseFrf (IDX) :

(Erase OBD freeze frame, common freeze frame and all specific freeze frame

With u = 1 ... NC_NR_ENVD_OBD

v = 1 ... NC_NR_ENVD_CUS_CMN

w = 1 ... NC_NR_ENVD_CUS_SET_CMN

y = 1 ... NC_NR_ENVD_CUS_SET_SPC

z = 1 ... NC_NR_FRF_SET)

ENVD_OBD[u][m] = 0

ENVD_CUS_CMN[v][m] = 0

ENVD_CUS_SET_CMN[w][z][m] = 0

ENVD_CUS_SET_SPC[y][z][m] = 0

B.54.3 Calibratable set of environmental data

Description:

The freeze frame part called FRF_CUS_SET_SPC contains environmental data, which are :

- specific to each failure, not required by law ;
- and calibratable.

This chapter describes "how to define by calibration the contents of FRF_CUS_SET_SPC".

The calibratable system of environmental data is managed via tables defined as following:

ID_ENVD_FAC : Configuration table, which describes all possible environmental data, which can be stored in a freeze frame (specific part) ;

Affected value defined in Environmental data (Appl. Inc.) module.

ID_ERR_ENVD_XX : Calibration table, which defines for each failure XX a maximum of NC_NR_ENVD_CUS_SET_SPC environmental data, which should be stored.

Example :

To store the environmental data TIA and TCO_ST in case of TCO failure ;

MAP and AMP in case of EGR failure ;

First, you should defined the possible environmental data in ID_ENVD_FAC table :

ID_ENVD_FAC[1] = &TIA

ID_ENVD_FAC[2] = &TCO_ST

ID_ENVD_FAC[3] = &MAP

ID_ENVD_FAC[4] = &AMP

Then, you should declare for each failure, the environmental data to stored :

ID_ERR_ENVD_TCO[1] = 1 ; ID_ERR_ENVD_TCO [2] = 2

ID_ERR_ENVD_EGR[1] = 3 ; ID_ERR_ENVD_EGR [2] = 4

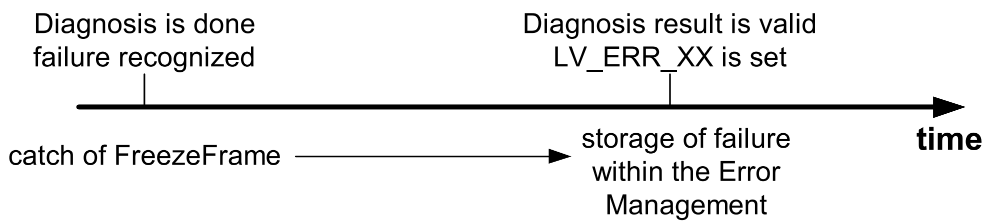
B.54.4 Prestored freeze frame

FUNCTION DESCRIPTION:

General information:

Usually the content for the freeze frame is catched, when the failure is stored within the failure memory. In special cases, when the entry of a failure within the failure memory is delayed, it's necessary to catch the content for the freeze frame at the same time as the failure information is available.

Example:



Description:

Syntax : ACTION_ERRM_StorePrevFrf (IN <XX>).

Parameter (in) : XX diagnosis instance

Parameter (out) : -

Short description :

If ACTION_ERRM_StorePrevFrf (XX) is called by the diagnosis instance XX, a "prestored" freeze frame for diagnosis instance XX is stored. It's used as content for the freeze frame, if the failure is entered in the failure memory later.

Application conditions:

Initialization: -

Recurrence: -

Activation: at Action request

Formula section:

ACTION_ERRM_StorePrevFrf (XX) :

with t related to failure XX, see Environmental data Appli.Inc.

ENVD_PREV_OBD[u][t] = ENVD_CONF_OBD[u]

ENVD_PREV_CUS_CMN[v][t] = ENVD_CONF_CUS_CMN[v]

ENVD_PREV_CUS_SET_CMN[w][t] = ENVD_CONF_CUS_SET_CMN[w]

ENVD_PREV_CUS_SET_SPC[y][t] = ID_ERR_ENVD_XX[y] (with XX = F(IDX))

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
ID_ERR_ENVD_XX	NC_NR_ENVD_CUS_SET_SPC	1...FFH	1...255	1	[-]
LDP_1_ID_ERR_ENVD_XX	NC_NR_ENVD_CUS_SET_SPC	0...FFH	0...255	1	[-]
Freeze frame FRF_CUS_SET_SPC : environmental data contents for failure XX					

Configuration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
NC_NR_ENVD_OBD	-	1...FFH	1...255	1	[-]
Number of different environment data (in bytes) which are fixed by the law (stored one time)					
NC_NR_ENVD_CUS_CMN	-	1...FFH	1...255	1	[-]
Number of different environment data (in bytes) which are common for all diagnosis instance (stored one time)					
NC_NR_ENVD_CUS_SET_CMN	-	0...FFH	0...255	1	[-]
Number of different environment data (in bytes) which are common for all diagnosis instance (stored many time)					
NC_NR_ENVD_CUS_SET_SPC	-	1...FFH	1...255	1	[-]
number of different environment data (in bytes) which are specific to each diagnosis instance (stored many time)typical value is 4					
NC_NR_FRF_SET	-	1...FFH	1...255	1	[-]
Number of different environment data groups (set) which can be store for one freeze frametypical value is 3 ; the value 0 is forbidden					
NC_ENVD_CUS_CMN_UPD	-	0...1H	0...1	1	[-]
Selection of FRF_CUS_CMN update method					
NC_NR_ENVD_PREV	-	1...FFH	1...255	1	[-]
Number of different failure instances XX using prestored freeze frameIf NC_NR_ENVD_PREV = 0 , then no prestored freeze frame functionality required					
NC_ID_ENVD_FAC	-	1...FFH	1...255	1	[-]
Size of ID_ENVD_FAC table					
ID_ENVD_FAC[255]	-	1...FFH	1...255	1	[-]
Possible stored environmental data in FRF_CUS_SET_SPC					

Configuration data detailed description:

NC_NR_ENVD_CUS_SET_SPC : Typical value is 4.

NC_NR_FRF_SET : Typical value is 3.
The value 0 is forbidden.

NC_ ENVD_CUS_CMN_UPD 0: FRF_CUS_CMN is not updated when failure status changes from "disappeared" to "temporary/confirmed".
1: FRF_CUS_CMN is updated when failure status changes from "disappeared" to "temporary/confirmed".

NC_NR_ENVD_PREV 0: No pre-stored freeze frame functionality required

Size of ID_ENVD_FAC is defined according number of data in the table ; maximum size is 255.

B.55.1 Configuration of size and content of Environmental data (freeze frame)

FUNCTION DESCRIPTION:

General information:

Description:

This file defines sizes and contents of Environmental data (freeze frame) catched when a failure occurs.

All data in italic are comments.

Freeze frame part	Characteristics	Value
FRF_OBD	Number of data (in bytes)	NC_NR_ENVD_OBD = 33
	Contents	ENVD_CONF_OBD[1] = LOAD_CLC **(PID 04h)** *Calculated load value (%)*

B.55.2 Configuration of update of FRF_CUS_CMN

Description:

This file defines the update of the FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed. To follow specific customer requirements, this file is a template to be fulfilled by project team.

Update of FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed.	NC_ENVD_CUS_CMN_UPD = 1 0: no update 1: update

B.55.3 Configuration for prestored freeze frame

Description:

This file defines the usage of the prestored freeze frame functionality. To follow specific customer requirements, this file is a template to be fulfilled by project team.

Number of diagnosis instances XX using prestored freeze frame	NC_NR_ENVD_PREV = 2

Diagnosis instance XX	**prestored freeze frame number (t)**
CAT_DIAG_1	1
VAP_LEAK_1_MIL	2

Remark: The usage of the prestored freeze frame functionality must be limited for special diagnosis functions, because of memory consumption.

B.56 Statistical data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
T_DTC_CLR	V/O/S	0...FFFFH	0...65535	1	[min]
Time since diagnostic trouble codes cleared					
DIST_ACT_MIL	V/O/S	0...FFFFH	0...65535	1	[km]
Global distance traveled while the MIL is illuminated					
DIST_REL_ACT_MIL	- /S	0...FFFFFFFFH	0...4294967295	1	[km]
Relative distance to calculate distance traveled while the MIL is illuminated					
CTR_ACT_MIL	- /S	0...FFH	0...255	1	[-]
Counter for warm up cycle with MIL Off					
T_ACT_MIL	V/O/S	0...FFFFH	0...65535	1	[min]
Minutes run by the engine while MIL activated					
T_ACT_MIL_60	V/S	0...3CH	0...60	1	[s]
Seconds run by the engine while MIL activated for T_ACT_MIL calculation (0 ... 59)					
DIST_DTC_CLR	V/O/S	0...FFFFH	0...65535	1	[km]
Distance since diagnostic trouble codes cleared					
DIST_REL_DTC_CLR	V/S	0...FFFFFFFFH	0...4294967295	1	[km]
Distance at following event : diagnostic trouble codes cleared

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NLC_MIL_ACT_REQ	1	0...1H	0...1	1	[-]
External MIL request is taken or not into account for DIST_ACT_MIL and T_ACT_MIL calculation (0 : not taken and 1 : taken)					

Import actions:

ACTION_ERRM_MonitorEnableStatus (INOUT < MonitorEnableStatus>)
This action allows to read the MonitorEnableStatus information

FUNCTION DESCRIPTION:

General information:

EOBD/CARB official requirements include a list of statistical data related to Error Management. These statistical data are counters and timers related to Error Management events. You can find below, in the following chapters, a description of all these requirements.

B.56.1 Time since diagnostic trouble codes cleared

Description:

Purpose of this strategy is to compute the time accumulated by the vehicle since diagnostic trouble codes cleared (referenced in ISO15031 as Modes 01h & 02h PID4Eh). It is simply an indication for I/M (Inspection/Maintenance), of the last time an external test equipment was used to clear DTCs.

Application conditions:

Initialization: on non-volatil memory reset or lost
or on failure erase service received
T_DTC_CLR = 0

Recurrence : 1 minute ±1 second, after event : on “failure erase” service received

Activation : -

Deactivation: -

Formula section :

{ T_DTC_CLR is updated at required recurrence }
{ T_DTC_CLR shall saturate to its maximal value 65535 }

If T_DTC_CLR < 65535
Then
T_DTC_CLR = T_DTC_CLR + 1
Endif

B.56.2 Distance counters since MIL activation and Minutes run by the engine with MIL activated

Description:

According to ISO/DIS 15031-5.8 (Road vehicles — Communication between vehicle and external equipment for emissions-related diagnostics — Part 5: Emissions-related diagnostic services), ECU must be able to indicate :

- the distance travelled while the MIL is activated
- the number of minutes run by the engine while MIL is activated

Distance Travelled While MIL is Activated

The purpose is to compute the covered distance while the MIL is illuminated (MIL blinking is considered as a MIL illumination). This mileage (DIST_ACT_MIL) is a global distance :

- which is not linked with any failure and is independent from the Pre-drive check
- which is dependent from the global inhibition MIL boolean
- which is dependent of the MIL request
- which is readable with Scan-Tool with kilometer as unit

Conditions for “Distance travelled” counter :

- reset to 0 when MIL state changes from deactivated to activated by this ECU
- accumulate counts in km if MIL is activated (ON)
- do not change value while MIL is not activated (OFF)
- reset to 0 if diagnostic information is cleared either by service 04h or 40 warm-up cycles without MIL activated
- do not wrap to 0 if value is FFFFh

Minutes run by the engine while MIL activated

The purpose is to compute the time accumulated while MIL is activated (Modes 01h & 02h PID4Dh). This duration shall be cleared when failure memory is erased and after 40 warm-up cycles.

Conditions for “Minutes run by the engine while MIL activated” counter :

- reset to 0 when MIL state changes from deactivated to activated by this ECU
- accumulate counts in minutes if MIL is activated (ON)
- do not change value while MIL is not activated (OFF)
- reset to 0 if diagnostic information is cleared either by service 04h or 40 warm-up cycles without MIL activated
- do not wrap to 0000h if value is FFFFh

Application conditions:

Initialization: On saved ram lost

or [(STATE_MIL transition OFF -> MIL_FLL or OFF -> ON)

and LV_MIL_ACT_REQ = 0]
or (NLC_MIL_ACT_REQ = 1
and LV_MIL_ACT_REQ transition 0 -> 1
and bit 1 of C_CONF_MIL = 1
and STATE_MIL = OFF)
or failure erase service received
DIST_REL_ACT_MIL = DIST
DIST_ACT_MIL = 0
CTR_ACT_MIL = C_CTR_MAX_WUP_CYC
T_ACT_MIL = 0
T_ACT_MIL_60 = 0

Recurrence: upon LV_DC 1→0 transition and 1 s

Activation: LV_ES = 0

Formula section:

Each 1s:

```
If(1)   STATE_MIL = MIL_FLL
        or
        STATE_MIL = ON
        or
        (NLC_MIL_ACT_REQ = 1 and LV_MIL_ACT_REQ = 1
        and bit 1 of C_CONF_MIL = 1)
Then(1)
        If(2)   ( DIST – DIST_REL_ACT_MIL ) < 65535
        Then(2)
                DIST_ACT_MIL = DIST – DIST_REL_ACT_MIL
        Else(2)
                DIST_ACT_MIL = 65535
        Endif(2)
        T_ACT_MIL_60 = T_ACT_MIL_60 + 1 s
        If(2)   (T_ACT_MIL_60 = 60)
        Then(2)
                T_ACT_MIL_60 = 0
                If(3)   T_ACT_MIL < 65535
                Then(3)
                        T_ACT_MIL = T_ACT_MIL + 1 min
                Else(3)
```

T_ACT_MIL = 65535

Endif(3)

Endif(2)

Endif(1)

At LV_DC 1→0 transition :

If(1) LV_WUP_CYC = 1

and

(LV_MIL_ACT_REQ = 0 during all the warm-up cycle

or bit 1 of C_CONF_MIL = 0 **or** NLC_MIL_ACT_REQ = 0**)**

and

STATE_MIL was OFF during all the warm-up cycle

and

CTR_ACT_MIL > 0

Then(1)

CTR_ACT_MIL = CTR_ACT_MIL –1

If(2) CTR_ACT_MIL = 0

Then(2)

DIST_REL_ACT_MIL = DIST

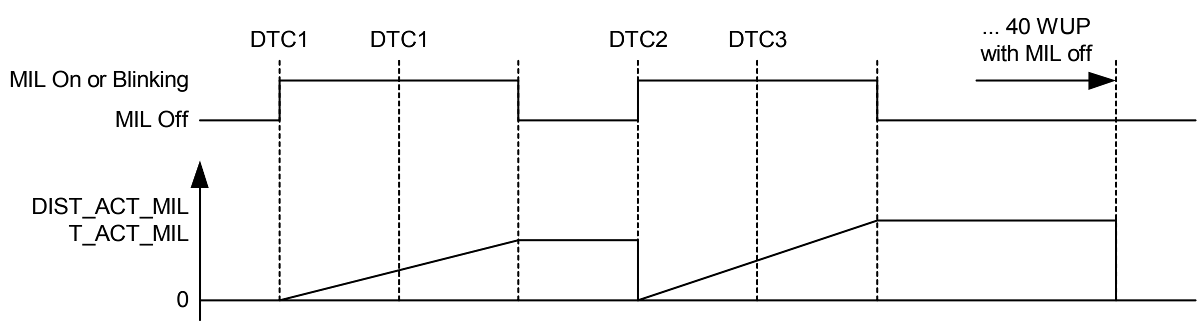
DIST_ACT_MIL = 0

T_ACT_MIL = 0

T_ACT_MIL_60 = 0

Endif(2)

Endif(1)



B.56.3 Distance since diagnostic trouble codes cleared

Description :

general specification

Purpose of this strategy is to compute the distance accumulated by the vehicle since diagnostic trouble codes cleared (referenced in ISO15031 as mode01h&02hPID31h). It is simply an indication for Inspection/Maintenance, of the last time an external test equipment was used to clear DTCs.

Application conditions:

Initialization:	on non-volatil memory reset or lost
	or
	on failure erase service received DIST_DTC_CLR = 0 DIST_REL_DTC_CLR = DIST
Recurrence :	1 second
Activation :	-
Deactivation:	-

Formula section :

{ DIST_DTC_CLR is updated regularly regarding DIST }
{ DIST_DTC_CLR shall saturate to its maximal value 65535 km}

```
If      DIST - DIST_REL_DTC_CLR < 65535
Then
        DIST_DTC_CLR = DIST - DIST_REL_DTC_CLR
Else
        DIST_DTC_CLR = 65535
Endif
```

B.56.4 Number of warm-ups since diagnostic trouble codes cleared

Description:

Purpose of this strategy is to compute number of warm-ups since diagnostic trouble codes cleared (referenced in ISO15031 as Modes 01h & 02h PID30h). It's just an indication for Inspection/Maintenance, to determine the last time an external test equipment was used to clear DTCs.

Application conditions:

Activation : On LV_WUP_CYC 0 $\rightarrow$ 1 transition

Initialization: On non-volatil memory reset or lost
or on failure erase service received
CTR_WUP_DTC_CLR=0

Recurrence : none, executed single time on activation.

Formula section:

{ on detection of a warm-up cycle CTR_WUP_DTC_CLR is incremented }
{ CTR_WUP_DTC_CLR shall saturate to its maximal value 255 }

If CTR_WUP_DTC_CLR < 255
Then
CTR_WUP_DTC_CLR = CTR_WUP_DTC_CLR + 1
Endif

B.56.5 Monitor enable/completion status for the current driving cycle

General information:

Purpose of this strategy is to get the follwoing informations :
- if a diagnosis (a monitor) is disabled for rest of this monitoring cycle or not (referenced in ISO15031 as Modes 01h & 02h PID41h).
- if a diagnosis (a monitor) is completed for the current monitoring cycle or not (referenced in ISO15031 as Modes 01h & 02h PID41h).

Each concerned diagnosis is part of a generic list : Misfire, Fuel system, Comprehensive component, Catalyst, Heated catalyst, Evaporative system, Secondary air system, A/C system refrigerant, Oxygen sensor, Oxygen sensor heater, EGR system monitoring.

MonitorEnableStatus :
Each bit of STATE_ENA_OBD variable contains status for each predefined diagnosis as defined below :
Enable status of a diagnosis this monitoring cycle:
- NO (STATE_ENA_OBD[n]=0) means disabled for rest of this monitoring cycle
  or not supported in C_STATE_READY_OBD_1 & C_STATE_READY_OBD_2
- YES (STATE_ENA_OBD[n]=1) means enabled for this monitoring cycle.

MonitorCompletionStatus :
Each bit of STATE_CMPL_OBD variable contains status for each predefined diagnosis as defined below :
Completion status of a diagnosis this monitoring cycle:
- YES (STATE_CMPL_OBD[n]=0) means monitor complete this monitoring cycle, or not supported in C_STATE_READY_OBD_1 & C_STATE_READY_OBD_2
- NO (STATE_CMPL_OBD[n]=1) means monitor not complete this monitoring cycle.

Bit 0 to 7 of STATE_ENA_OBD[0..7] :

- bit0: Misfire monitoring
- bit1: Fuel system monitoring
- bit2: Comprehensive component monitoring
- bit3: GS/DS vehicle (NLC_OBD_DSL = 1 for DS, 0 for GS)
- bit4: reserved
- bit5: reserved
- bit6: reserved
- bit7: reserved

Bit 8 to 15 of STATE_ENA_OBD[8..15] :

- bit8: Catalyst monitoring
- bit9: Heated catalyst monitoring
- bit10: Evaporative system monitoring
- bit11: Secondary air system monitoring
- bit12: A/C system refrigerant monitoring
- bit13: Oxygen sensor monitoring
- bit14: Oxygen sensor heater monitoring
- bit15: EGR system monitoring monitoring

Bit 0 to 7 of STATE_CMPL_OBD[0..7] :

- bit0: Misfire monitoring
- bit1: Fuel system monitoring
- bit2: Comprehensive component monitoring
- bit3: GS/DS vehicle (NLC_OBD_DSL = 1 for DS, 0 for GS)
- bit4: reserved
- bit5: reserved
- bit6: reserved
- bit7: reserved

Bit 8 to 15 of STATE_CMPL_OBD[8..15] :

- bit8: Catalyst monitoring
- bit9: Heated catalyst monitoring
- bit10: Evaporative system monitoring
- bit11: Secondary air system monitoring
- bit12: A/C system refrigerant monitoring
- bit13: Oxygen sensor monitoring
- bit14: Oxygen sensor heater monitoring
- bit15: EGR system monitoring monitoring

Application conditions:

Initialization: on LV_DC 1 $\rightarrow$ 0 transition

STATE_ENA_OBD = 0

STATE_CMPL_OBD = 0

Recurrence : 10 seconds

Activation : -

Deactivation: -

<u>Formula section :</u>

                    endif
            EndIf
```

EndIf

Comprehensive component monitoring status bit :

If CONF_KOBD = 0
Then
  If Bit 2 of C_STATE_MONI_CMPL_OBD_1 = 0
  (this option is used to have similar behaviour of readiness and completion status of comprehensive components monitoring)
  Then
    If LV_END_DIAG_XX = 1 for all diagnosis XX defined below
    Take into account all LV_END_DIAG_XX which fulfill the following condition:
    this XX failure has the status CARB_CC (see tables of failures)
    and the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
    Then Bit 2 of STATE_CMPL_OBD = 0
    Endif
  Else Readiness for Comprehensive component status is always set
  Bit 2 of STATE_CMPL_OBD = 0
  EndIf
Else (CONF_KOBD = 1)
Readiness for Comprehensive component status is always set
Bit 2 of STATE_CMPL_OBD = 0
EndIf

Catalyst monitoring bit :

If LV_END_DIAG_XX = 1 for all diagnosis XX defined below
Take into account all LV_END_DIAG_XX which fulfill the following condition:
this XX failure has the status CARB_CAT (see tables of failures) **and** the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then Bit 8 of STATE_CMPL_OBD = 0
Endif

Heated catalyst bit :

If LV_END_DIAG_XX = 1 for all diagnosis XX defined below
Take into account all LV_END_DIAG_XX which fulfill the following condition:
this XX failure has the status CARB_HC (see tables of failures) **and** the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then Bit 9 of STATE_CMPL_OBD = 0
Endif

Evaporative system monitoring bit :

If (LV_END_DIAG_XX = 1 for all diagnosis XX defined below **or** LV_ERR_XX = 1 for one of diagnosis XX defined below)
Take into account all LV_END_DIAG_XX or LV_ERR_XX = 1 which fulfill the following condition:
this XX failure has the status CARB_EVAP(see tables of failures) **and**

the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then Bit 10 of STATE_CMPL_OBD = 0
Else
If LV_END_DIAG_VAP_LEAK_1 = 1
then Bit 10 of STATE_CMPL_OBD = 0
Endif

Endif
Remark: If once Bit 10 of STATE_CMPL_OBD is set to 0, it is kept to 0 in the driving cycle.

Secondary air system monitoring bit :

If LV_END_DIAG_XX = 1 for all diagnosis XX defined below
Take into account all LV_END_DIAG_XX which fulfill the following condition:
this XX failure has the status CARB_SA (see tables of failures) **and**
the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then Bit 11 of STATE_CMPL_OBD = 0
Endif

A/C system refrigerant monitoring bit :

If LV_END_DIAG_XX = 1 for all diagnosis XX defined below
Take into account all LV_END_DIAG_XX which fulfill the following condition:
this XX failure has the status CARB_AC (see tables of failures) **and**
the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then Bit 12 of STATE_CMPL_OBD = 0
Endif

Oxygen sensor monitoring bit :

If (LV_END_DIAG_XX = 1 for all diagnosis XX defined below **or**
LV_ERR_XX = 1 for one of diagnosis XX defined below)

Take into account all LV_END_DIAG_XX or LV_ERR_XX = 1 which fulfill the following condition:
this XX failure has the status CARB_LS (see tables of failures) **and**
the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then Bit 13 of STATE_CMPL_OBD = 0
Endif
Remark: If once Bit 13 of STATE_CMPL_OBD is set to 0, it is kept to 0 in the driving cycle.

Oxygen sensor heater monitoring bit :

If (LV_END_DIAG_XX = 1 for all diagnosis XX defined below **or**
LV_ERR_XX = 1 for one of diagnosis XX defined below)

Take into account all LV_END_DIAG_XX or LV_ERR_XX = 1 which fulfill the following condition:

B.57 Statistical data (Appl. Inc.)

FUNCTION DESCRIPTION:

General information:

EOBD/CARB regulation and ISO standards requirements include a list of statistical data related to Error Management. These statistical data are counters and timers related to Error Management events. You can find below in following chapters a description of all these requirements (depends on customer needs).

B.57.1 Monitor enable status for the current driving cycle

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_ENA_OBD_STAT	V	0...FFFFH	0...65535	1	[-]
Monitor enable status for the current driving cycle. Stays 0 for current DC, if disable status is reached					

Input data:

C_STATE_READY_OBD_1	C_STATE_READY_OBD_2	AMP	C_AMP_MIN_MIS
C_AMP_MIN_FSD	CTR_STOP_FSD	C_STOP_MAX_FSD	AMP_AD
C_AMP_MIN_CAT_LS_DIAG	C_AMP_AD_MIN_DIAGCP	NLC_OBD_DSL	

Export actions:

ACTION_ERRM_MonitorEnableStatus (IN,OUT < MonitorEnableStatus>)
This action allows to read the MonitorEnableStatus information

Description :

Purpose of this strategy is to get the follwoing informations :
- if a diagnosis (a monitor) is disabled for rest of this monitoring cycle or not (referenced as Mode01h&02hPID41h ISO15031).

Each concerned diagnosis is part of a generic list : Misfire, Fuel system, Comprehensive component, Catalyst, Heated catalyst, Evaporative system, Secondary air system, A/C system refrigerant, Oxygen sensor, Oxygen sensor heater, EGR system monitoring.

MonitorEnableStatus :
Each bit of MonitorEnableStatus variable contains status for each predefined diagnosis as defined below :
Enable status of a diagnosis this monitoring cycle: NO (MonitorEnableStatus[n]=0) means disabled for rest of this monitoring cycle, YES (MonitorEnableStatus[n]=1) means enabled for this monitoring cycle.

Bit 0 to 7 of MonitorEnableStatus[0..7] :

```
┌┬┬┬┬┬┬┬┐
└┴┴┴┴┴┴┴┘
 | | | | | | | └─> bit0: Misfire monitoring
 | | | | | | └───> bit1: Fuel system monitoring
 | | | | | └─────> bit2: Comprehensive component monitoring
 | | | | └───────> bit3: GS/DS vehicle (NLC_OBD_DSL = 1 for DS, 0 for GS)
 | | | └─────────> bit4: reserved
 | | └───────────> bit5: reserved
 | └─────────────> bit6: reserved
 └───────────────> bit7: reserved
```

Bit 8 to 15 of MonitorEnableStatus[8..15] :

```
┌┬┬┬┬┬┬┬┐
└┴┴┴┴┴┴┴┘
 | | | | | | | └─> bit8: Catalyst monitoring
 | | | | | | └───> bit9: Heated catalyst monitoring
 | | | | | └─────> bit10: Evaporative system monitoring
 | | | | └───────> bit11: Secondary air system monitoring
 | | | └─────────> bit12: A/C system refrigerant monitoring
 | | └───────────> bit13: Oxygen sensor monitoring
 | └─────────────> bit14: Oxygen sensor heater monitoring
 └───────────────> bit15: EGR system monitoring monitoring
```

Description :

Syntax :	ACTION_ERRM_MonitorEnableStatus (IN,OUT < MonitorEnableStatus >)
Parameter(in) :	No parameter
Parameter(out) :	MonitorEnableStatus with the same format as here described before
Short Description :	This API calculate and returns the monitor enable status result information in the software structure.

Application conditions:

Activation : -

Initialization: at LV_DC 1 -> 0 and reset
STATE_ENA_OBD_STAT = FFFFh
STATE_ENA_OBD = C_STATE_READY_OBD_2 (bit 8...15) +
C_STATE_READY_OBD_1 (bit 0...7)

Recurrence : -

Formula section:

{ action call definition shall define the strategy related to each supported diagnosis }
{ each bit of MonitorEnableStatus shall be computed according diagnosis strategy }

Project specific MonitorEnableStatus computation

Databyte B:

Misfire monitoring status bit:

If Bit 0 of STATE_ENA_OBD_STAT = 0
then Bit 0 of STATE_ENA_OBD = 0 (Once Monitor Status is disabled it remains so.)
elseif AMP > C_AMP_MIN_MIS

Bit 15 of MonitorEnableStatus = 1

MonitorEnableStatus [0..7] = MonitorEnableStatus [0..7] and C_STATE_READY_OBD_1
MonitorEnableStatus [8..15] = MonitorEnableStatus [8..15] and C_STATE_READY_OBD_2

B.57.7 Driving cycles counters since DTC present

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_DC_ERR_DET[NC_NR_ERR_DYN]	O/V/S	0 ... FFH	0 ... 255	1	-
Number of driving cycles since DTC detection, for the failure XX=F(IDX)					
CTR_DC_ERR_DET_DIAG_CDN[NC_NR_ERR_DYN]	O/V/S	0 ... FFH	0 ... 255	1	-
Number of driving cycle since DTC detection, with diag started within these driving, cycles for the failure XX=F(IDX)					
LV_CDN_DIAG_DC[NC_NR_ERR_DYN]	V	0 .... 1H	0 ... 1	1	-
This flag permits to detect that diag. conditions have been met during driving cycle, for the failure XX=F(IDX)					
CTR_DC_ERR_DET_DIAG_CMPL[NC_NR_ERR_DYN]	O/V/S	0 ... FFH	0 ... 255	1	-
Number of driving cycle since DTC detection, with diag completed during these driving cycles, for the failure XX=F(IDX)					

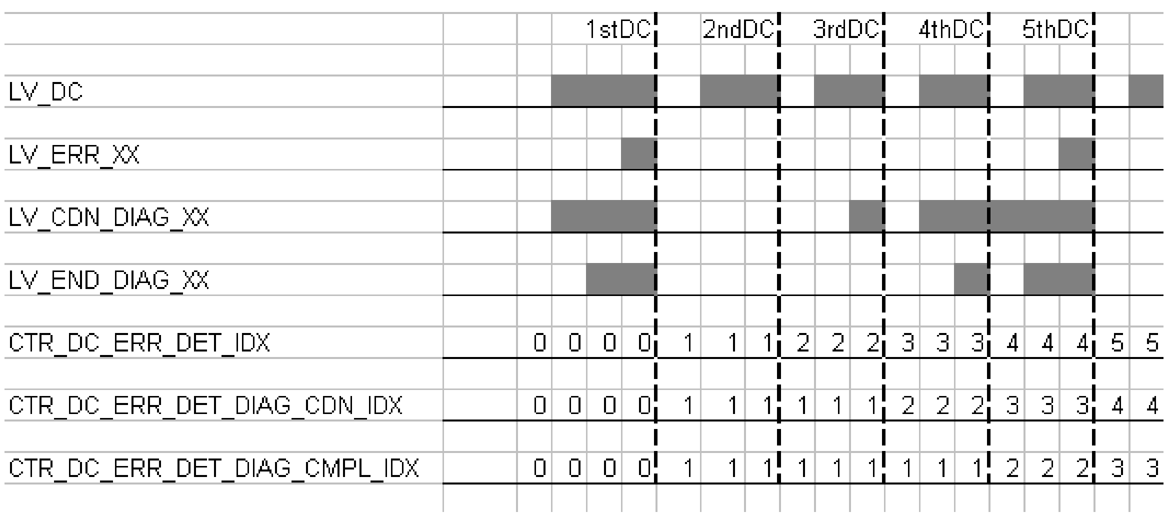
Input data:

LV_DC	LV_ERR_DC[NC_NR_ERR_DYN]	LV_END_DIAG_XX	LV_CDN_DIAG_XX
	LV_ERR_MEM_XX		

FUNCTION DESCRIPTION:

General information:

Purpose of this strategy is to compute number of driving cycles since detection of diagnostic trouble codes.



Signal flow diagram:

None

Description:

Purpose of this formula section is to detect that diag. conditions have been met during driving cycle.

Application conditions:

Initialisation: at LV_DC 1 → 0 transition
LV_CDN_DIAG_DC[IDX]=0

Recurrence: none, executed only once on activation

Activation: at LV_CDN_DIAG_XX 0 → 1 transition
and
LV_ERR_MEM_XX=1

Deactivation: -

Formula section:

{ on detection of diagnosis conditions LV_CDN_DIAG_DC[IDX] is updated}

LV_CDN_DIAG_DC[IDX]=1

Description :

Purpose of this section is to compute the number of driving cycles regarding the following events :
- detection of diagnostic trouble codes (action call)
- detection of an error in last driving cycle (LV_ERR_DC[IDX])
- detection of diag. conditions have been met during last driving cycle (LV_CDN_DIAG_DC[IDX])
- detection of diag. completion have been met during last driving cycle (LV_END_DIAG_XX)

Application conditions:

Activation : at LV_DC 1 → 0 transition

Initialization: on non-volatil memory reset or lost
or on failure erase service received
or on dynamic failure memory erase
CTR_DC_ERR_DET[IDX] = 0
CTR_DC_ERR_DET_DIAG_CDN[IDX] = 0
CTR_DC_ERR_DET_DIAG_CMPL[IDX] = 0

Recurrence : none, executed only once on activation

Formula section:

{ detection of an error in last driving cycle shall start counters }

{ on detection of an error in driving cycle counters are updated }
{ counters shall saturate to there maximal value 255 }

```
If        LV_ERR_DC[IDX]= 1

Minimum vehicle speed threshold to start timer T_VS_RBM					

FUNCTION DESCRIPTION:

General information:

To gain more information about the monitoring performance under real world conditions, CARB required to implement software algorithms to track and report in-use performance for the following monitors in a standardized format: Catalyst, Oxygen sensor, Evaporating system, EGR system, VVT system and Secondary air system.

For this kind of statistic different counters are necessary:

- Ignition cycle counter

  Counter that indicates the number of ignition cycles a vehicle has experienced

- General denominator

  Measures the number of times a vehicle is operated under standardized conditions

- Monitor individual numerator

  Measures the number of driving cycles in which the monitor was done

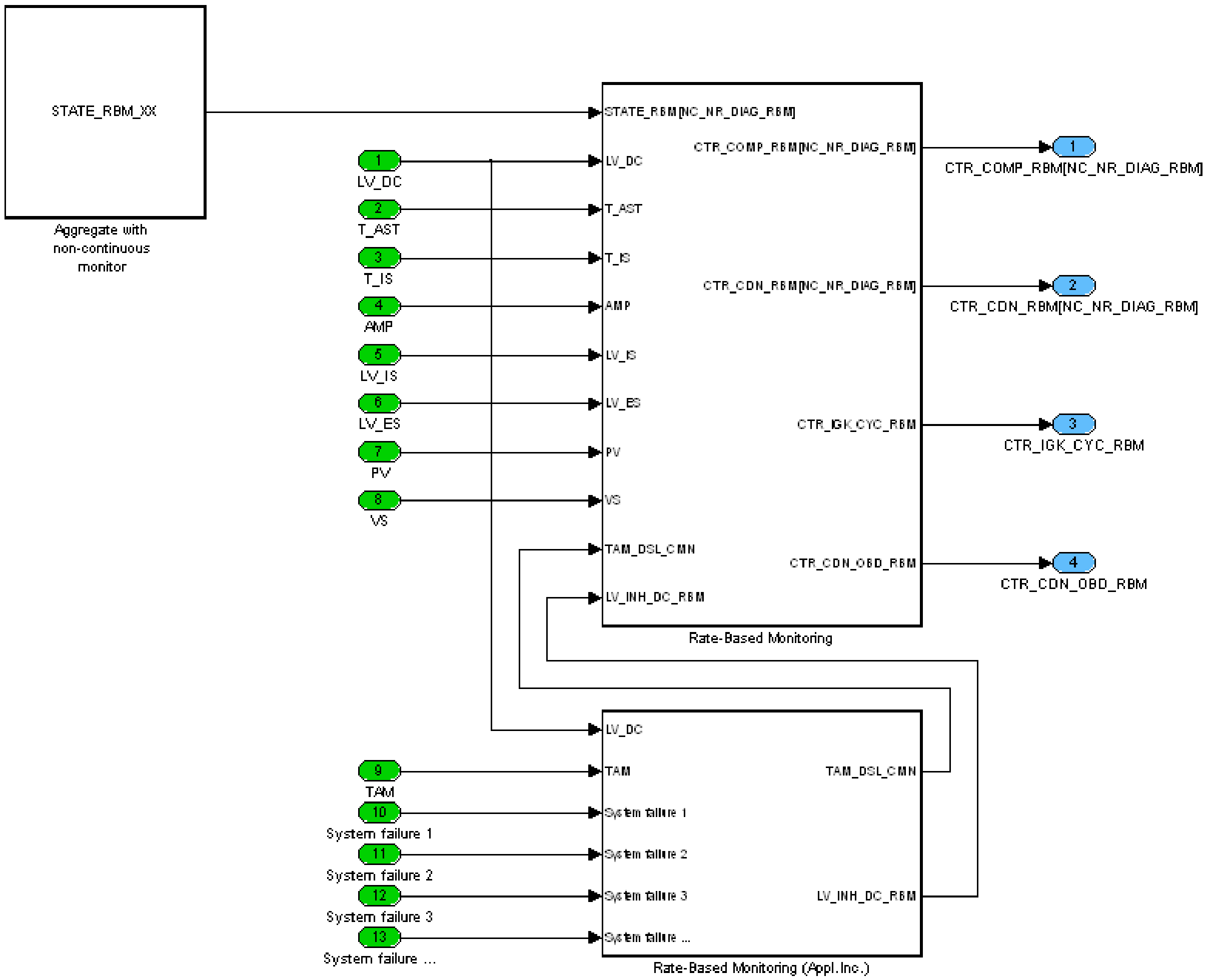
- Monitor individual denominator

  Counter that indicates the number of times a vehicle is operated under monitor individual conditions.

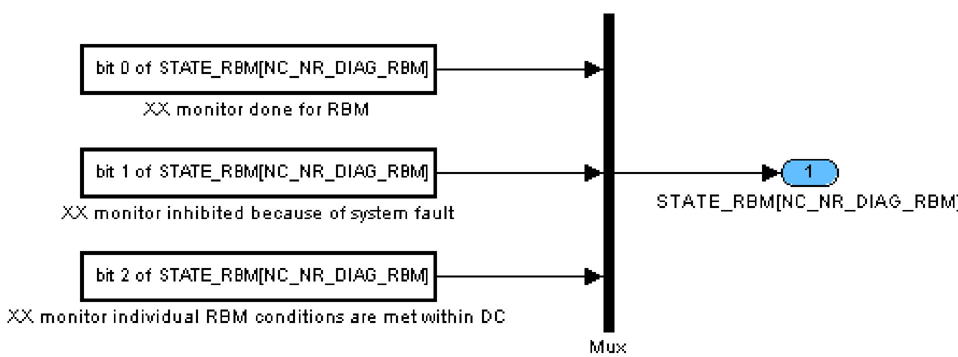
All these counters are set to zero only when a non-volatile memory reset occurs (e.g. reprogramming). They will not be initialized with zero on any other circumstances including when a scan-tool command to clear fault codes is received.

Signal flow diagram:

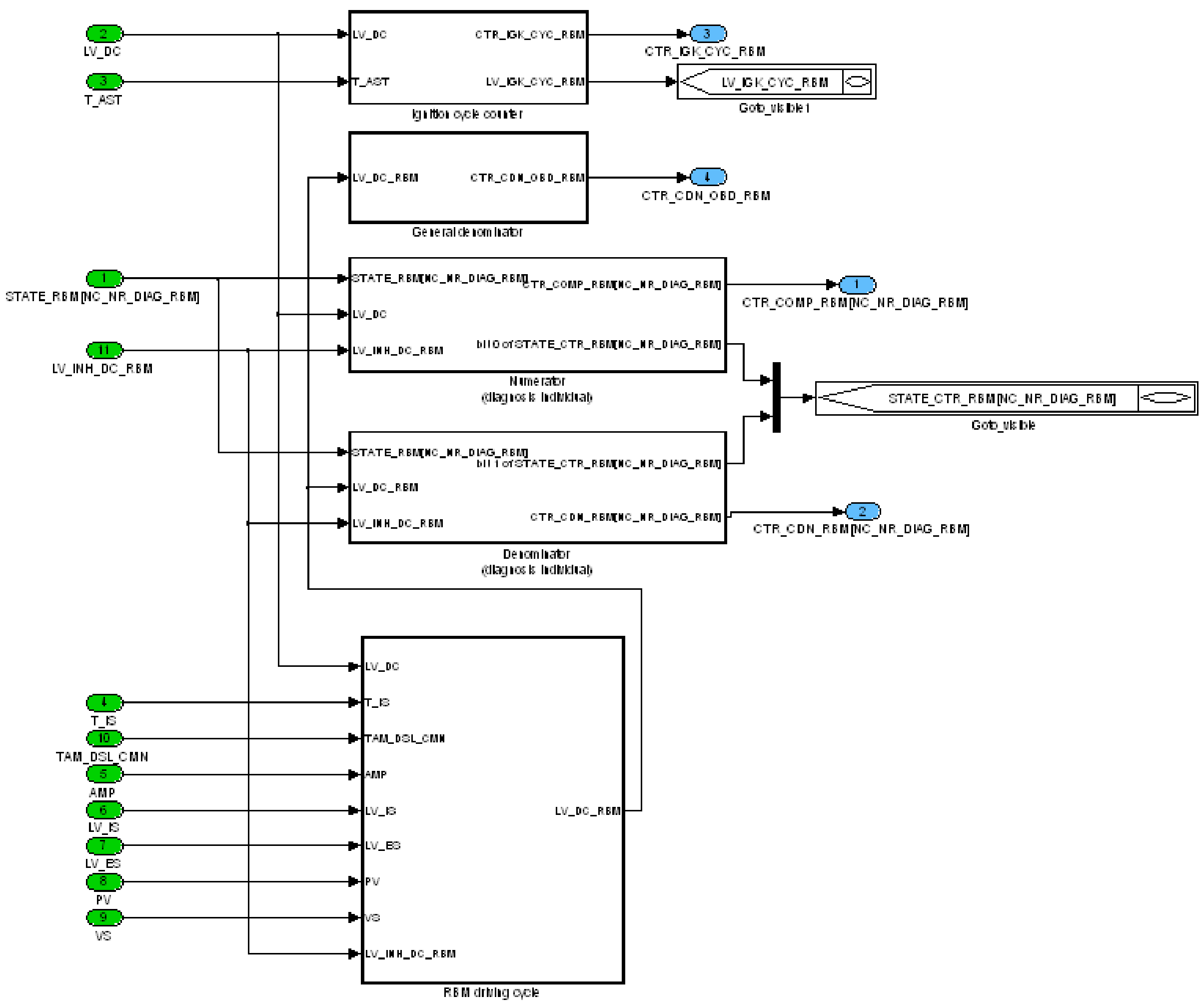
Overview :



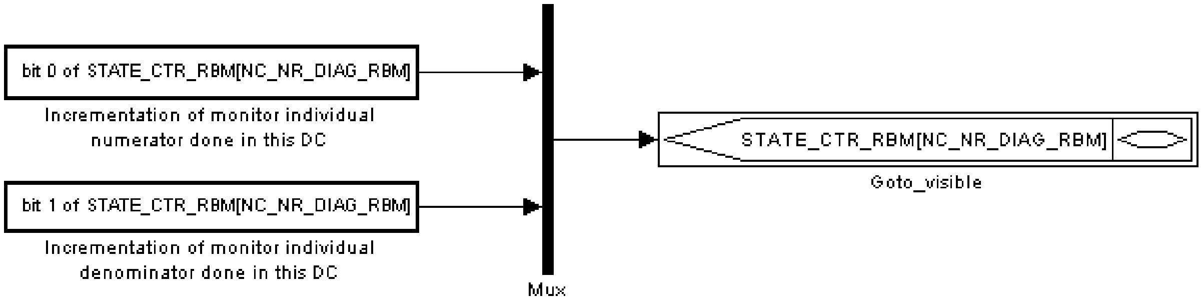
STATE_RBM[NC_NR_DIAG_RBM] definition :



Modules of Rate-Based Monitoring :



STATE_CTR_RBM[NC_NR_DIAG_RBM] definition:



B.58.1 Ignition cycle counter

Description:

The number of ignition cycles since the first ECU power up are counted within CTR_IGK_CYC_RBM. The counter is incremented each time a driving cycle with engine running for at least 2 seconds (±1s) (C_DLY_AST_RBM) is detected. This value is only initialized with 0 on saved RAM lost (or reprogramming). If CTR_IGK_CYC_RBM is incremented LV_IGK_CYC_RBM is set to 1 to indicate that counter is already incremented within this driving cycle.

If the counter reaches its maximum value, the value is set to 0 on the next calculation.

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_IGK_CYC_RBM = 0

at reset

CTR_IGK_CYC_RBM = restored from NVMY

at LV_DC 0 → 1 transition and ECU reset

LV_IGK_CYC_RBM = 0

Recurrence: 1 s

Activation: LV_DC = 1 **and** LV_IGK_CYC_RBM = 0

Formula section:

Quantity of driving cycles calculation:

If T_AST >= C_DLY_AST_RBM (time after start at least C_DLY_AST_RBM)

Then

If CTR_IGK_CYC_RBM = 65535 (maximum value of CTR_IGK_CYC_RBM)

Then

CTR_IGK_CYC_RBM = 0

Else

CTR_IGK_CYC_RBM = CTR_IGK_CYC_RBM + 1

Endif

LV_IGK_CYC_RBM = 1 (CTR_IGK_CYC_RBM incremented this DC)

Endif

B.58.2 General denominator calculation

Description:

The counter for the general denominator CTR_CDN_OBD_RBM is incremented each time a valid DC with standardized vehicle operation (LV_DC_RBM = 1) is recognized. The numbers of driving cycles are counted since the first ECU power up. This value is only initialized with 0 on saved RAM lost (or reprogramming).

If the counter reaches its maximum value, the value is set to 0 on the next calculation.

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_CDN_OBD_RBM = 0

at reset

CTR_CDN_OBD_RBM = restored from NVMY

Recurrence: -

Activation: LV_DC_RBM 0→1 transition

Formula section:

If CTR_CDN_OBD_RBM = 65535 (maximum value of CTR_CDN_OBD_RBM)

Then

CTR_CDN_OBD_RBM = 0

Else

General denominator calculation:

CTR_CDN_OBD_RBM = CTR_CDN_OBD_RBM + 1

Endif

B.58.3 Monitor individual numerator calculation

Description:

For all monitors requiring Rate-Based Monitoring (m = 0 to (NC_NR_DIAG_RBM – 1)) a numerator must be calculated. This numerator CTR_COMP_RBM[m] is incremented, if the conditions for the monitor were present for a sufficient time (bit 0 of STATE_RBM[m] = 1), but only one time within the driving cycle. This value is only initialized with 0 on saved RAM lost (or reprogramming)

If the counter CTR_CDN_RBM[m] is halved, because of maximum value limitation, the value CTR_COMP_RBM[m] is also divided by 2 (positive rounded).

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_COMP_RBM[m] = 0

at reset

CTR_COMP_RBM[m] = restored from NVMY

at LV_DC 0 →1 transition or ECU reset

STATE_CTR_RBM[m] = 0

with m = 0 to (NC_NR_DIAG_RBM – 1)

Recurrence: 10 s **or** LV_DC 1 → 0 transition

Activation: LV_INH_DC_RBM = 0 **and** LV_DC = 1

Formula section:

For m = 0 to (NC_NR_DIAG_RBM – 1)
all monitor requiring Rate-Based Monitoring
{ see specification "Rate-Based Monitoring (Appl. Inc.)" }
If bit 0 of STATE_CTR_RBM[m] = 0
(Incrementation of CTR_COMP_RBM[m] not yet done in this DC)

Then **If** bit 0 of STATE_RBM[m] = 1
(monitor is done for RBM)

and bit 1 of STATE_RBM[m] = 0
(monitor isn't inhibited because of a system fault)

Then CTR_COMP_RBM[m] = CTR_COMP_RBM[m] + 1

bit 0 of STATE_CTR_RBM[m] = 1
(Incrementation of CTR_COMP_RBM[m] done in DC)

Endif

Endif

Endfor

B.58.4 Monitor individual denominator calculation

Description:

In comparison to the counter CTR_IGK_CYC_RBM, counting the numbers of driving cycles (longer C_DLY_AST_RBM) since the first ECU power-up, the monitor individual denominator is counting the number of DC in which special vehicle/driving and ambient conditions are met individually for each monitor.

The counter CTR_CDN_RBM[m] is managed individually for each monitor (m = 0 to (NC_NR_DIAG_RBM – 1)), for which the monitoring of the real in-use performance is made. To increment the monitor denominator, some common conditions must be fulfilled (LV_DC_RBM = 1) but also monitor individual conditions. These monitor individual conditions are managed within the monitor function (bit 2 of STATE_RBM[m]). The value is only initialized with 0 on saved RAM lost (or reprogramming).

If the counter CTR_COMP_RBM[m] is halved, because of maximum value limitation, the value CTR_CDN_RBM[m] is also divided by 2 (positive rounded).

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_CDN_RBM[m] = 0

at reset

CTR_CDN_RBM[m] = restored from NVMY

with m = 0 to (NC_NR_DIAG_RBM – 1)

Recurrence: 10 s **or** LV_DC 1 → 0 transition (before LV_DC_RBM initialisation performed at LV_DC 1 → 0)

Activation: LV_INH_DC_RBM = 0 **and** LV_DC_RBM = 1

Formula section:

For m = 0 to (NC_NR_DIAG_RBM – 1)
all monitor requiring Rate-Based Monitoring
{ see specification "Rate-Based Monitoring (Appl. Inc.)" }
If bit 1 of STATE_CTR_RBM[m] = 0
(incrementation is not done yet)

Then **If** bit 1 of STATE_RBM[m] = 0
(monitor is not inhibit, because of a system fault)

and bit 2 of STATE_RBM[m] = 1
(monitor individual RBM conditions are met within this DC)

Then CTR_CDN_RBM[m] = CTR_CDN_RBM[m] +1

bit 1 of STATE_CTR_RBM[m] = 1
(incrementation is done within DC)

Endif
Endif
Endfor

B.58.5 Counter overflow treatment for monitor individual numerator and denominator

Description:

If either the numerator or denominator for a specific component reaches the maximum value (65535), both numbers shall be divided by two before either is incremented again to avoid overflow problems.

Application conditions:

Initialisation: -

Recurrence: -

Activation: LV_DC 0 → 1 transition

Formula section:

For m = 0 to (NC_NR_DIAG_RBM – 1)
all monitor requiring Rate-Based Monitoring
{ see specification "Rate-Based Monitoring (Appl. Inc.)" }
If CTR_CDN_RBM[m] = 65535 (maximum value of CTR_CDN_RBM[m])

or

CTR_COMP_RBM[m] = 65535 (maximum value of CTR_COMP_RBM[m])

Then CTR_CDN_RBM[m] = CTR_CDN_RBM[m] / 2

CTR_COMP_RBM[m] = CTR_COMP_RBM[m] / 2

Endif

Endfor

B.58.6 Standardized vehicle operation for Rate-Based Monitoring

<u>FUNCTION DESCRIPTION:</u>

<u>General information:</u>

For the calculation of the denominators for Rate-Based Monitoring, CARB standardized vehicle operations, which must be met to increment the denominator counter.

<u>Description:</u>

A special driving cycle (LV_DC_RBM) for Rate-Based Monitoring is defined, which is set, if the following standardized vehicle operations are fulfilled:

- Cumulated trip length (time since engine start) T_AST_RBM >= C_T_AST_RBM

  (CARB : 600 s)
- Cumulative vehicle operation >= C_VS_THD_RBM for minimum of C_T_VS_RBM

  (CARB : >= 40 km/h (25mph) for at least 300 s)
- Continuous vehicle operation in idle equal or longer than C_T_IS_RBM (accelerator pedal released and vehicle speed less or equal than 1 mph)

  (CARB : 30 s)

with

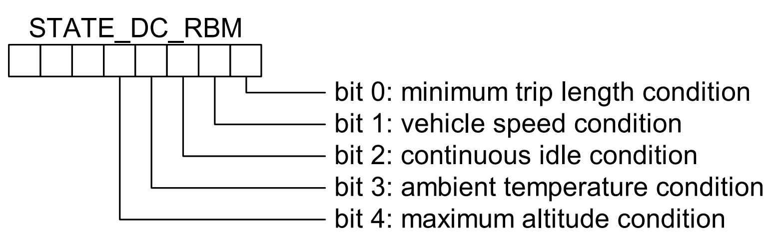
- altitude such as ambient pressure AMP > C_AMP_MIN_RBM

  (CARB : 8000 feet)
- ambient temperature (TAM_DSL_CMN) >= C_TAM_MIN_RBM

  (CARB : 20 °F)

Remark: to manage data type diversity between GS and DS divisions, TAM_DSL_CMN variable is updated with ambient temperature information every 100 ms.

Within STATE_DC_RBM the different conditions necessary to set LV_DC_RBM are visualized.



bit value = 0: condition not met yet; bit value = 1: condition met

Application conditions:

Initialisation: at LV_DC 0 → 1 transition **or** reset

LV_DC_RBM = 0

STATE_DC_RBM = 0H

T_AST_RBM = 0 s

T_VS_RBM = 0 s

T_IS_RBM = 0 s

at LV_DC 1 → 0 transition

after individual numerator/denominator computations:

LV_DC_RBM = 0

STATE_DC_RBM = 0H

Recurrence: 100 ms

Activation: LV_DC = 1

and

LV_DC_RBM = 0

and
LV_INH_DC_RBM = 0

Formula section:

Ambient temperature

Endif (1)

<u>Global information about DC including standardized vehicle operations</u>

If (1) STATE_DC_RBM = 1FH (all conditions are met)

Then (1) LV_DC_RBM = 1

Endif (1)

B.58.7 Cold start conditions detection

<u>FUNCTION DESCRIPTION:</u>

<u>General information:</u>

The individual monitor condition established for evaporative system denominator calculation (see §1968.2 - 4.3.2, section D) can be applied for other diagnoses (bit 2 calculation of STATE_RBM_xx) that require extended monitoring evaluation (e.g. coolant or intake air rationality).

<u>Description:</u>

Cold start conditions are set within the driving cycle when: (see §1968.2 - 4.3.2, section D)

- Cumulative time since engine start is greater than or equal to 600 seconds while at an ambient temperature of greater than or equal to 40 degrees Fahrenheit but less than or equal to 95 degrees Fahrenheit
- Engine cold start occurs with engine coolant temperature at engine start greater than or equal to 40 degrees Fahrenheit but less than or equal to 95 degrees Fahrenheit and less than or equal to 12 degrees Fahrenheit higher than ambient temperature at engine start.

Application conditions:

Initialisation: at RST system event **or** at LV_DC 0 → 1 transition

LV_DC_CDN_CST_RBM = 0

T_AST_CST_RBM = 0 s

TAM_ST_DSL_CMN = TAM_DSL_CMN

Recurrence: 100ms

Activation: LV_DC = 1

and

LV_DC_CDN_CST_RBM = 0

and

LV_INH_DC_RBM = 0

Dectivation: LV_DC = 0

or

LV_DC_CDN_CST_RBM = 1

or

LV_INH_DC_RBM = 1

Formula section:

If(1) C_TAM_MIN_CST_RBM <= TAM_DSL_CMN <= C_TAM_MAX_CST_RBM
(ambient temperature greater than or equal to 40 degrees Fahrenheit but less than or equal to 95 degrees Fahrenheit)

Then(1)

If(2) T_AST_CST_RBM >= C_T_AST_CST_RBM
(time since start is greater than or equal to 600 seconds)

Then(2)

T_AST_CST_RBM is frozen

If(3) C_TCO_ST_MIN_CST_RBM <= TCO_ST_DSL_CMN <= C_TCO_ST_MAX_CST_RBM
(engine coolant temperature at engine start is greater than or equal to 40 degrees but less than or equal to 95 degrees Fahrenheit)

and
TCO_ST_DSL_CMN <= (TAM_ST_DSL_CMN + C_TAM_ST_HYS_CST_RBM)
(less than or equal to 12 degrees Fahrenheit higher than ambient temperature at engine start)

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT <PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With the value LV_INH_DC_RBM the inhibition of the standardized vehicle operation calculation and the disablement of all numerators and denominators are controlled.

Description:

The OBD II system shall disable all numerators and denominators calculations if a malfunction of any component used to determine if the following criteria (i.e., vehicle speed, ambient temperature, elevation, idle operation, engine cold start, time of operation, ...) are satisfied has been detected. Calculations shall resume as soon as the malfunction is no longer present.

- Criteria required to set LV_DC_RBM (standardized vehicle operation)

  - Cumulated trip length (time since engine start) T_AST_RBM ≥ C_T_AST_RBM (CARB : 600 s)
  - Cumulative vehicle operation ≥ C_VS_THD_RBM for minimum of C_T_VS_RBM (CARB : 40 km/h (25 mph) for at least 300 s)
  - Continuous vehicle operation in idle of C_T_IS_RBM or longer (accelerator pedal pedal released and vehicle speed less or equal than 1 mph) (CARB : 30 s)

with
  - Altitude such as ambient pressure AMP > C_AMP_MIN_RBM (CARB : 8000 feet)
  - Ambient temperature (TAM) ≥ C_TAM_MIN_RBM (CARB : 20 °F)

- Criteria required for Secondary Air system

  The Secondary Air system has been operated for a time greater than or equal to 10 s. Short trips and intrusive operations (end of line tests, repair tests, ...) shall not be included.

- Criteria required for Evaporative System Monitor

  - Cumulative time since engine start is greater or equal to 600 s while at an ambient temperature of greater than or equal to 40 °F but less than or equal to 95 °F.
  - Engine cold start occurs with engine coolant temperature at engine start greater than or equal to 40°F but less than or equal to 95°F and less than or equal to 12 °F higher than ambient temperature at engine start.

Application conditions:

Initialisation: *at ECU reset and LV_DC 0 → 1 transition :*

Endif

B.59.3 Clear rate base monitoring statistics

Import actions:

ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)

Description:

For development conveniences, it is often useful to reinit the rate base monitoring statistics. This is possible by setting the calibration bit LC_RBM_CLR to 1.

Otherwise, like requested by CARB, RBM statistics must be reseted in case of ECU reprogramming (Application SW or Calibration data). During development phase RBM statistics shall not be reset at calibration reprogramming (using LC_RBM_NOT_CLR_DATA_FLASH = 1), but this must be disbaled for serial production (LC_RBM_NOT_CLR_DATA_FLASH = 0).

Application conditions:

Initialisation: -

Recurrence: 1s

Activation: 0 → 1 transition of LC_RBM_CLR

Formula section:

If LC_RBM_CLR = 1
Or ECU reprogramming of Application SW
Or (ECU reprogramming of Calibration data
And LC_RBM_NOT_CLR_DATA_FLASH = 0)
Then ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>, SYNCHRONIZATION<CALL>)
Endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_RBM_CLR	1	0...1h	0...1	1	-
reinit the rate base monitoring statistics at LC_RBM_CLR 0->1					
LC_RBM_NOT_CLR_DATA_FLASH	1	0...1h	0...1	1	-
No deletion of the rate base monitoring statistics at calibration reprogramming					

B.59.4 Ambient air temperature adaptation to handle GS/DS data types differences

Output data:

Name	Mode	Hex. limits	Phys. Limitslimits	Resol.	Unit
TAM_DSL_CMN	O	0...FEH	-48...142.5	0.75	[°C]
Ambient temperature (used within ERRM only to support GS/DS data types diversity)					

Input data:

TAM			

FUNCTION DESCRIPTION:

Description:

Some temperatures values can be delivered from Diesel or Gasoline system:

Ambient temperature TAM

As data types may be different, the following fomula section shall be used to allow adaptation to each environment.

Application conditions:

Initialisation: *at ECU reset*

TAM_DSL_CMN = TAM

Recurrence: 1 s

Activation: always

Formula section:

TAM_DSL_CMN = TAM

B.60 Failure Classes

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
WAL_CONF_XX	O	0...FFH	0...255	1	[-]
Lamp configuration for failure XX					
PRI_CONF_XX	O	0...7H	0...7	1	[-]
Priority configuration for failure XX					
CTR_DC_INC_XX	O	0...FFH	0...255	1	[-]
Increment of the driving cycle counter for failure XX					
CTR_DC_DEC_XX	O	0...FFH	0...255	1	[-]
Decrement of the driving cycle counter for failure XX					
CTR_DC_MAX_XX	O	0...FFH	0...255	1	[-]
Maximum value of the driving cycle counter for failure XX					

FUNCTION DESCRIPTION:

General information:

Because the diagnosis system becomes more and more complex, to avoid multiplication of calibrations and to help the tuning team for simplifying the calibration process, each failure is defined via classes of failure.

Each class defines the type of this failure as emission relevant or not, as MIL handling or not, as using driving cycle for MIL illumination, and so on.

The configuration of a failure is defined by WAL_CONF_XX, PRI_CONF_XX, CTR_DC_INC_XX, CTR_DC_DEC_XX and CTR_DC_MAX_XX.

Format of WAL_CONF_XX		
Bit	Logical value	Description
0	LC_WAL_1_ON	Enable WAL_1 (0 : Off / 1 : On) See details in “Lamp management” module.
1	LC_WAL_2_ON	Enable WAL_2 (0 : Off / 1 : On) See details in “Lamp management” module.
2	LC_MIL_ON	Enable MIL (0 : Off / 1 : On) See details in “Lamp management” module.
3	LC_MIL_FLL	Enable flash mode for MIL (0 : Off / 1 : On) See details in “Lamp management” module.
4	LC_OBD_ERR	Defines failure as a “CARB/EOBD failure” (emission relevant). (failure visible via scantool) 0 : failure is not considered as a “CARB/EOBD failure” 1 : failure is considered as a “CARB/EOBD failure”

Format of PRI_CONF_XX		
Bit	**Logical value**	**Description**
0	LC_ERR_PRI_1	This option defines the priority of the XX diagnosis.
1	LC_ERR_PRI_2	It is used for storage of failure and freeze frame.
2	LC_ERR_PRI_3	000: lowest priority for errors which are not significant for emission 011: highest priority for errors, which are not significant for emission 100: lowest priority for errors, which are significant for emission 111: highest priority which are significant for emission See details in “Priority rules” module. For emission relevant (EOBD, CARB) failure : LC_ERR_PRI_3 = 1 For non emission relevant failure : LC_ERR_PRI_3 = 0

B.60.1 Failure assignation

For each failure XX, a failure class is allocated. The failure class number makes this affectation, which is a calibration named C_ERR_CLAS_XX.

This table is defined in the “General Diagnosis Information”.

Diagnosis instance	Failure Class number Class A / Class B
Failure XX	C_ERR_CLAS_XX
Failure YY	C_ERR_CLAS_YY
...	...

The failure class number is a byte divided in two subclasses named class B (defined by the most significant quartet) and class A (defined by the less significant quartet).

Failure class number for failure XX

C_ERR_CLAS_XX =

(	Class B		)	(	Class A		)

B.60.2 Failure class definition

A failure class defines for a failure, which belongs to this failure class :

Part sub-class A :

- if the failure have impact on MIL illumination or not ;
- if the failure have impact on MIL blinking or not ;
- if the failure have impact on Warning Lamp 1 or not ;
- if the failure have impact on Warning lamp 2 or not ;
- if the failure is considered as a CARB/EOBD failure (emission relevant)
  (failure visible with scantool, failure can set OBD freeze frame for mode 2h)

Part sub-class B :

- the increment value for driving cycle counter management ;
- the maximum value of driving cycle counter ;
- the decrement value for driving cycle counter management ;
- the priority of the failure.

Each subclass of a failure class is composed of 4 bits, so 16 different values are possible for each subclass. For each subclass, some values are predefined and some values are reserved for improvement/validation and are managed by calibration.

Sub Class A definition : ID_ERR_CLAS_A_FMT (1 byte x 16)

Subclass A Value (i) in hex / Name	**Description**	**ID_ERR_CLAS_A_FMT [i]**
0 / NO_LAMP	*- Predefined value –* Failure without impact on any lamp	%0000 0000 (in binary)

E / DC_CUS_6	*Free for customer definition*	-	-	-	-
F / DC_CUS_7	*Free for customer definition*	-	-	-	-

Formula section:

For each failure XX allocated to the failure class number C_ERR_CLAS_XX :

CTR_DC_INC_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][0]

CTR_DC_MAX_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][1]

CTR_DC_DEC_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][2]

Bit 0,1,2 of PRI_CONF_XX = ID_ERR_CLAS_B_FMT [4 Most Significant Bit of C_ERR_CLAS_XX][3]

Remark: The increment of the DC counter (*) for the failures defined by the failure classes LAW_L, LAW_M and LAW_H depends on the required regulation (Carb/EOBD).

B.60.3 Example

To define the failure MIS_A (Misfiring A) as :

- a failure with high priority
- with only impact on MIL (On and Blinking)

Set the failure MIS_A in class number 64 (in hex) with C_ERR_CLAS_MIS_A = 64H.

That means :

- The value of sub class B is 6H => failure with high priority ;
- The value of sub class A is 4H => Failure with impact on MIL (On and blinking) ;

= > Failure is a "CARB/EOBD failure"

DC_INC_MIS_A = 3

DC_MAX_MIS_A = 6

DC_DEC_MIS_A = 2

WAL_CONF_MIS_A = %0001 1100 (in binary)

PRI_CONF_MIS_A = %0000 0110 (in binary)

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_ERR_CLAS_XX	1	0...FFH	0...255	1	[-]
Failure class number for failure XX					
ID_ERR_CLAS_A_FMT	16	0...FFH	0...255	1	[-]
LDPM_CLAS_A_ID_CLAS_FMY	16	0...FFFFH	0...65535	1	[-]
Sub Class A definition					
ID_ERR_CLAS_B_FMT	4*16	0...FFH	0...255	1	[-]
LDP_CLAS_B_ID_CLAS_FMY	4	0...FFFFH	0...65535	1	[-]
LDPM_CLAS_A_ID_CLAS_FMY	16	0...FFFFH	0...65535	1	[-]
Sub Class B definition					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ERR_PRI_H	1	0...7H	0...7	1	[-]
Failure with priority ≥ NC_ERR_PRI_H are considered as high priority failures					

B.60.4 Action for MIL relevance

Export actions:

ACTION_ERRM_*GetMILRelevant* (IN <PRM_IDX_ERR >, OUT <PRM_LV_MIL_RLV>)
This action is used to know if the failure is MIL relevant or not

Description for actions:

ACTION_ERRM_*GetMILRelevant* (<PRM_IDX_ERR >, <PRM_LV_MIL_RLV>)					
This actions returns: - 0 if the failure is not MIL relevant - 1 if the failure is MIL relevant					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_IDX_ERR	IN	0...FFFFH	0...65535	1	[-]
Diagnostic failure instance					
PRM_LV_MIL_RLV	OUT	0...1H	0...1	1	[-]
Mil relevant failure					

Formula section:

PRM_LV_MIL_RLV = 0

If PRM_IDX_ERR ! = 0

Then

MIL relevant means enable MIL or enable flash mode for MIL and CARB/EOBD failure (visible via scantool)

If (bit 2 **or** bit 3 of WAL_CONF_XX = 1) **and** bit 4 of WAL_CONF_XX = 1

Then PRM_LV_MIL_RLV = 1

Endif

Endif

B.60.5 Failure Class Definition (Customer Specific)

In addition to the standard pre defined failure classes also customer specific failure classes can be defined (Sub class B: Value from 9h to Fh).

Sub Class B definition : ID_CLAS_B_FMT (4 bytes x 16) continued

		ID_CLAS_B_FMT			
Subclass B **Value (i) in hex/ Name**	**Description**	**[i] [0]** **DC inc**	**[i] [1]** **DC max**	**[i] [2]** **DC dec**	**[i] [3]** **Priority**
9 / DC_CUS_1	*Free for customer definition* Carb/EOBD failure with high priority (for debounce in 1 DC)	3	3	1	6
A / DC_CUS_2	*Free for customer definition*	-	-	-	-
B / DC_CUS_3	*Free for customer definition*	-	-	-	-
C / DC_CUS_4	*Free for customer definition*	-	-	-	-
D / DC_CUS_5	*Free for customer definition*	-	-	-	-
E / DC_CUS_6	*Free for customer definition*	-	-	-	-
F / DC_CUS_7	*Free for customer definition*	-	-	-	-

B.61 Lamp management

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_MIL	V/O/S	0...2H	0...2	1	[-]
State of MIL illumination commanded by error management (ON (1), OFF (0), MIL_FLL (2))

Timer for pre-drive check duration					

Input data:

LV_ES	SYM_CYL_MIS_A	LV_WAL_1_ACT_REQ	LV_WAL_2_ACT_REQ
LV_MIS_STATE_A	LV_DC_MAX[NC_NR_ERR_DYN]	INH_IV_MIS	WAL_CONF_XX
LV_IGK	LV_MIL_ACT_REQ	LV_ERR_XX	STATE_READY_OBD_1
STATE_READY_OBD_2	LV_ST		

FUNCTION DESCRIPTION:

General information:

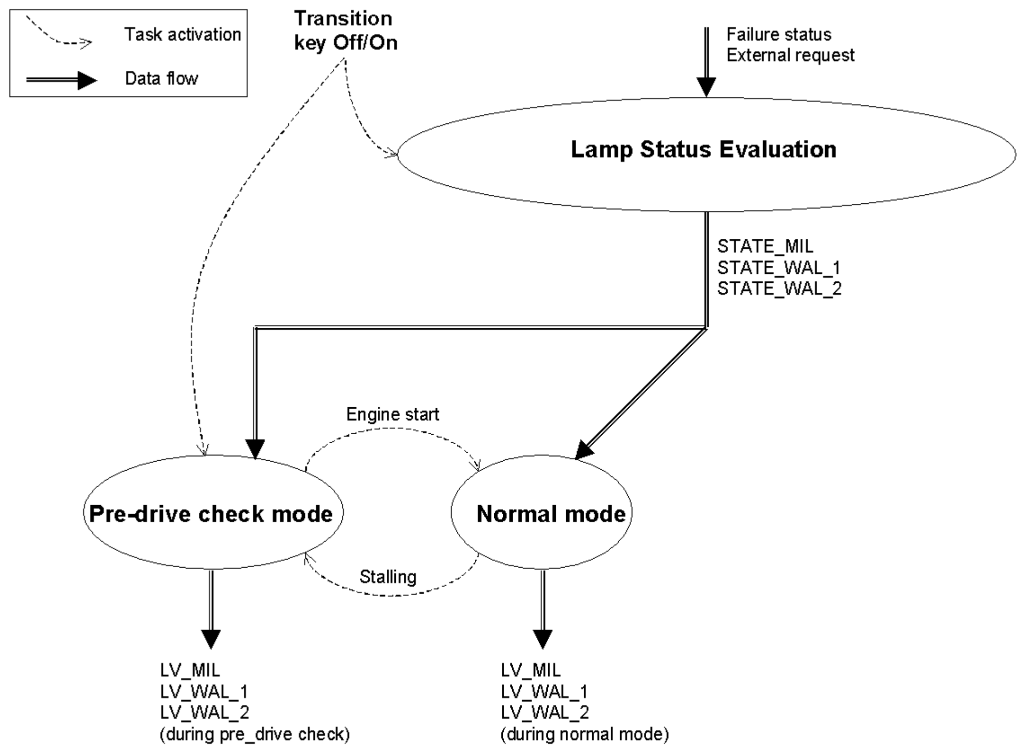
It is possible to manage up to three different lamps. They are called:

- MIL: Malfunction Indicator Lamp; this lamp is used to inform the vehicle driver in case of failures which can affect emissions.
- WAL_1: Warning Lamp 1 and WAL_2: Warning Lamp 2; these lamps are used to inform the vehicle driver in case of others failures.

For each lamp, a task evaluated the state of MIL, WAL_1 and WAL_2. These states STATE_MIL, STATE_WAL_1 and STATE_WAL_2 are respectively what error management commanded to the lamps regard to failure status.

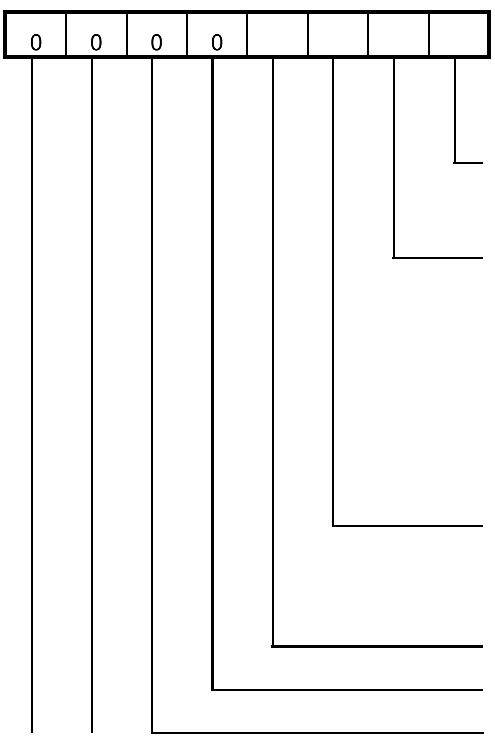
Then, the real physical state of each lamp (LV_MIL for MIL, LV_WAL_1 for WAL_1 and LV_WAL_2 for WAL_2) is build related to the mode in which they are. Lamps behavior is based on two modes:

- A predrive check mode between transition LV_IGK 0->1 and engine start; this mode is used to check the correct lamps working.
- A normal mode for the rest of the time.



A configuration byte is defined for each lamp: C_CONF_XXX (with XXX = MIL C_CONF_MIL, WAL_1 or WAL_2, C_CONF_WAL_1 C_CONF_WAL_2).

It is then possible to inhibit a lamp illumination, to allow or not external request for lamp illumination and to link lamp illumination each other's.



bit 0 of C_CONF_XXX : Global lamp XXX inhibition bit
0 : lamp XXX illumination is authorized
1 : lamp XXX is never illuminated except by an external request for lamp XXX

bit 1 of C_CONF_XXX : Lamp XXX request enable bit
0 : lamp XXX request input is never taken into account
1 : lamp XXX request input is taken into account

For MIL :
bit 2 of C_CONF_XXX: Special behavior for the Misfiring A failure in case of cylinder cut off.
0 : Without management of cylinder cut off
1 : With management of cylinder cut off
For WAL_1 and WAL_2 :
bit 2 of C_CONF_XXX : Illumination of MIL instead of lamp XXX
0 : no links between lamp XXX and MIL
1 : MIL is illuminated if illumination of lamp XXX is requested

bit 3 of C_CONF_XXX :
Inhibition of Predrive check for lamp XXX
0: Predrive check for lamp XXX enabled
1: Predrive check for lamp XXX disabled

Not used

Not used

Not used

Not used

Impact of each failure on lamp is defined in WAL_CONF_XX byte:

- bit 0 : if set, the present failure may caused a WAL_1 illumination ;
- bit 1 : if set, the present failure may caused a WAL_2 illumination ;
- bit 2 : if set, the failure may caused a MIL illumination when driving cycle counter reaches maximum ;
- bit 3: if set, the present failure may cause a MIL blinking.

B.61.1 Lamp Status Evaluation

Description:

Management of WAL_1 and WAL_2

Behavior of WAL_1 and WAL_2 are identical. WAL_1 and WAL_2 may be illuminated (state is ON) or not (state is OFF). When the global lamp inhibition bit is not set, the lamp is requested to illuminate:

- if at least one failure is present (LV_ERR_XX) with the corresponding bit of WAL_CONF_XX (bit 0 for WAL_1, bit 1 for WAL_2) in enable position and this failure is stored in 2nd layer memory ;
- or in case of allowed lamp request.

Management of MIL

MIL internal management is based on 3 states:

- STATE_MIL = OFF (MIL is requested continuously off)
- STATE_MIL = ON (MIL is requested continuously on)
- STATE_MIL = MIL_FLL (MIL is requested blinking at 1 Hz)

When the global MIL inhibition bit is not set, the MIL is requested to illuminate (ON):

- if at least one failure has reached its driving cycle maximum value and is unequal to zero (LV_DC_MAX[IDX]) with the corresponding bit of WAL_CONF_XX (bit 2) in enable position and this failure is stored in 2nd layer memory ;
- or in case of allowed lamp request ;
- or WAL_1 is requested to be illuminated and WAL_1 is link with MIL ;
- or WAL_2 is requested to be illuminated and WAL_2 is link with MIL ;

When the global MIL inhibition bit is not set, the MIL is requested to be blinking at 1hz (MIL_FLL):

- if at least one failure is present (LV_ERR_XX) with the corresponding bit of WAL_CONF_XX (bit 3) in enable position and this failure is stored in 2nd layer memory ;

A special calculation can be enabled for Misfire A failure with the management of cylinder shut off (bit 2 of C_CONF_MIL):

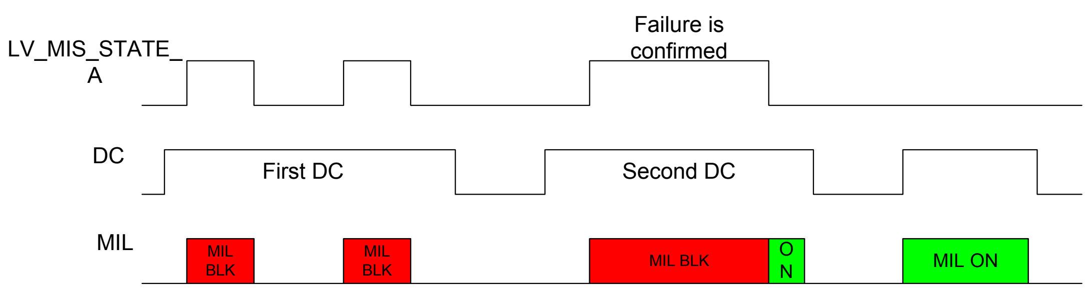
- bit 2 of C_CONF_MIL = 0: When a misfire A failure (LV_MIS_STATE_A) is present, the MIL is blinking.
- bit 2 of C_CONF_MIL = 1: If Misfire A failure (LV_MIS_STATE_A) is present with cylinder cut off, the MIL is blinking only for a calibratable time (C_DLY_INH_IV_MIS). After this time, the MIL is ON again.

Beware: The “blinking mode” is priority mode compared to “continuous on mode”.

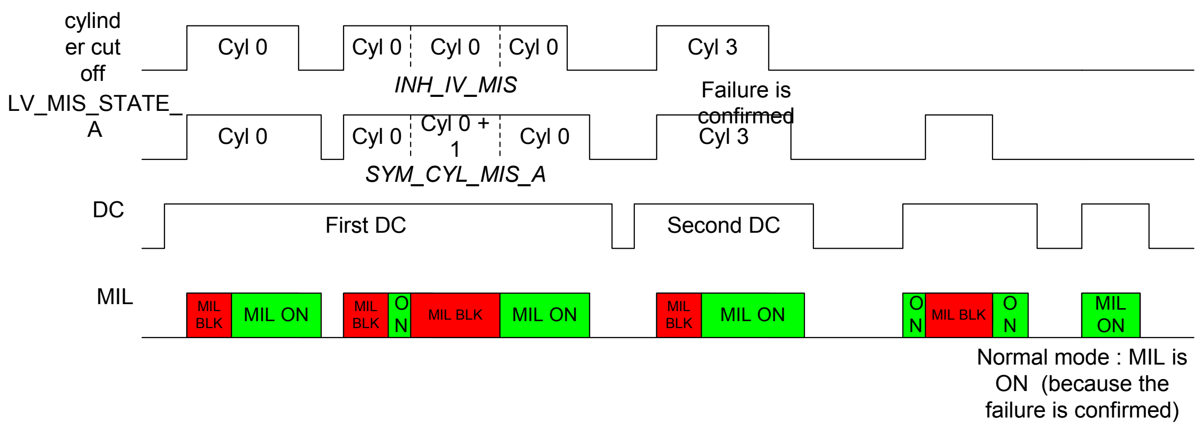
Signal flow diagram:

Special behavior for Misfire A failure with bit LC_MIL_INH_IV_MIS of C_CONF_MIL:

Behavior of Misfiring failure MIS_A without management of cylinder cut off (LC_MIL_INH_IV_MIS = 0)



Behavior of Misfiring A failure with management of cylinder cut off (LC_MIL_INH_IV_MIS = 1) :



Application conditions:

Initialization: -

Recurrence: 500 ms

Activation: -

Formula section:

If bit 0 of C_CONF_WAL_1 = 1 (lamp WAL_1 illumination not authorized)
Then STATE_WAL_1 = OFF (lamp WAL_1 is off)
Else **If** at least one failure in 2nd layer memory has:
(LV_ERR_XX and bit 0 of WAL_CONF_XX) = 1
(lamp WAL_1 illumination by a failure)
Then STATE_WAL_1 = ON (lamp WAL_1 is on)
Else STATE_WAL_1 = OFF (lamp WAL_1 is off)
Endif
Endif

If bit 0 of C_CONF_WAL_2 = 1 (lamp WAL_2 illumination not authorized)
Then STATE_WAL_2 = OFF (lamp WAL_2 is off)
Else **If** at least one failure in 2nd layer memory has:
(LV_ERR_XX and bit 1 of WAL_CONF_XX) = 1
(lamp WAL_2 illumination by a failure)
Then STATE_WAL_2 = ON (lamp WAL_2 is on)
Else STATE_WAL_2 = OFF (lamp WAL_2 is off)
Endif
Endif

If bit 0 of C_CONF_MIL = 1 (MIL illumination not authorized)

Then STATE_MIL = OFF (MIL is requested continuously off)

Else **If** at least one failure in 2nd layer memory has:

(LV_DC_MAX[IDX] and bit 2 of WAL_CONF_XX) = 1

(at least one failure request to illuminate the MIL)

or (STATE_WAL_1 = ON and bit 2 of C_CONF_WAL_1 = 1)

(a failure illuminates WAL_1 and WAL1 is linked with MIL)

or (STATE_WAL_2 = ON and bit 2 of C_CONF_WAL_2 = 1)

(a failure illuminates WAL_2 and WAL_2 is linked with MIL)

Then STATE_MIL = ON (MIL is requested continuously on)

Else STATE_MIL = OFF (MIL is requested continuously off)

Endif

If LV_MIS_STATE_A = 1

(CARB A misfire failure criterion)

then **if** bit 2 of C_CONF_MIL = 0

(Without management of cylinder shut off for the misfiring A)

then STATE_MIL = MIL_FLL

(MIL is requested blinking at 1Hz)

else (Management of cylinder shut off for the misfiring A)

If (any cylinder bit within SYM_CYL_MIS_A 0 -> 1

and corresponding bit within INH_IV_MIS is set to 1)

Then STATE_MIL = MIL_FLL only during C_DLY_INH_IV_MIS

After C_DLY_INH_IV_MIS, STATE_MIL = ON

mode = ‘blink mode during a delay + continuous ON’

Endif

if any cylinder bit within SYM_CYL_MIS_A 0 -> 1

and corresponding bit within INH_IV_MIS is set to 0

then mode = ‘blink mode’

Endif

If mode = ‘blink mode’

Then **if** any cylinder bit SYM_CYL_MIS_A is set

And

corresponding bit within INH_IV_MIS remains to 0

(no transition 1-> 0 of the corresponding bit during the failure)

Then mode = ‘blink mode’

Else mode =‘blink mode during a delay + continuous ON’

```
                        Endif
                Endif
                If      mode = 'blink mode'
                Then    STATE_MIL = MIL_FLL
                        (MIL is requested blinking at 1Hz)
                else    if      C_DLY_INH_IV_MIS isn't achieved
                        Then    STATE_MIL = MIL_FLL
                                (MIL is requested blinking at 1Hz)
                        Else    STATE_MIL = ON
                                (MIL is requested continuously on)
                        Endif
                Endif
        Endif
Endif
If      at least one failure in 2nd layer memory has :
        (LV_ERR_XX and bit 3 of WAL_CONF_XX) = 1
        (at least one failure request to blink the MIL)
Then    STATE_MIL = MIL_FLL
        (MIL is requested blinking at 1Hz)
Endif
```

Endif

Remark:

For the misfiring A failure (treated as a particular case), the Bit 3 of WAL_CONF_XX mustn't be set to 1 by calibration (only bit 2 for continuous MIL illumination).

B.61.2 Lamp mode

B.61.2.1 Predrive Check mode

Description:

Predrive check mode is used to enable a visual check of the correct lamp working. Additionally it can be used to display readiness status as an option (MIL blinking).

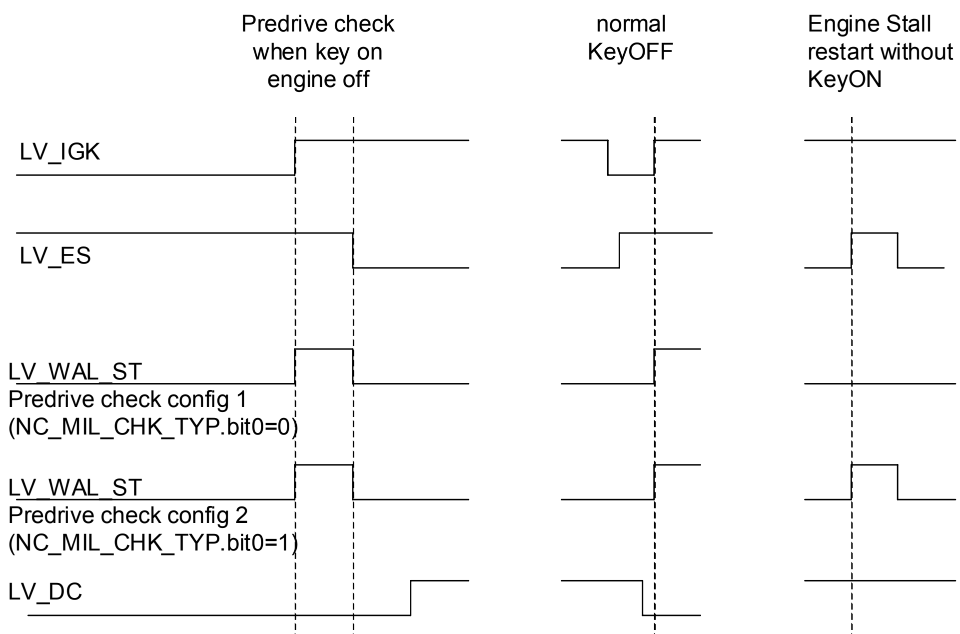
Nevertheless a failure may also illuminate a lamp. Illumination of lamp during pre-drive check mode is performed only when :

- the global lamp inhibition bit is not set (bit 0 of C_CONF_XXX = 1) and the lamp individual predrive check inhibition is not set (bit 3 of C_CONF_XXX = 1)
- or error management commands a lamp

A) Configuration of predrive check behaviour in case of stalling event:

with NC_MIL_CHK_TYP (bit 0)

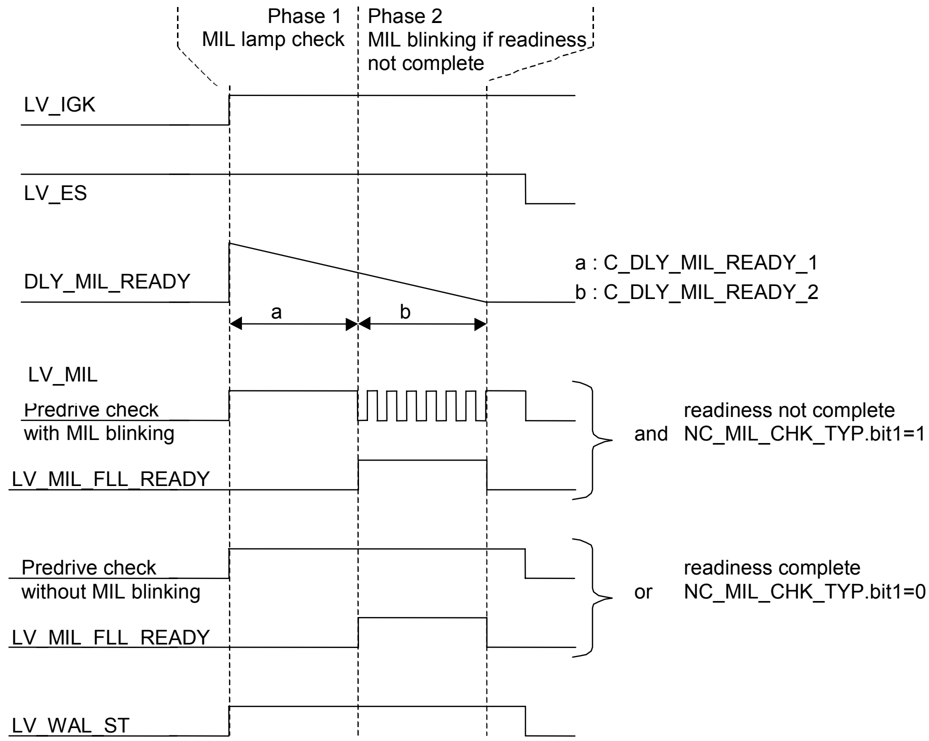
Predrive check mode phase can be defined in 2 ways:
- between key on transition LV_IGK 0->1 and engine start (bit 0 of NC_MIL_CHK_TYP=0)
- or between key on transition LV_IGK 0->1 and engine start, plus between an engine stall event and engine start (bit 0 of NC_MIL_CHK_TYP=1)



B) Configuration of MIL blinking readiness status functionality:

with NC_MIL_CHK_TYP (bit 1)

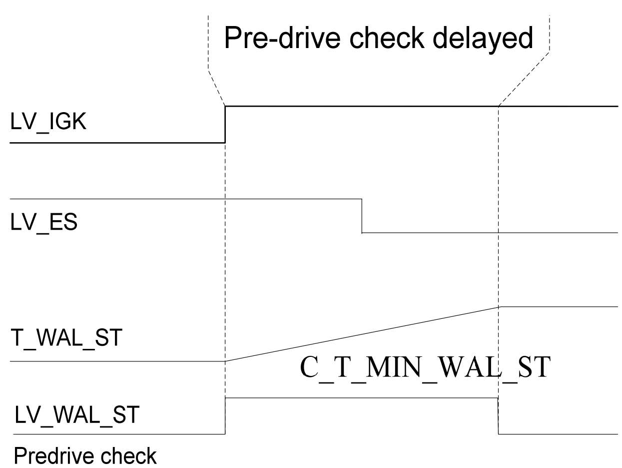
During predrive check mode, you can display the status of readiness codes through the MIL warning lamp : the MIL is blinking if readiness not complete.
This strategy is part of predrive check and does not affect the MIL status (STATE_MIL).



C) Management of minimum time of predrive check duration

-> only relevant after engine cranking (LV_ES 1->0)

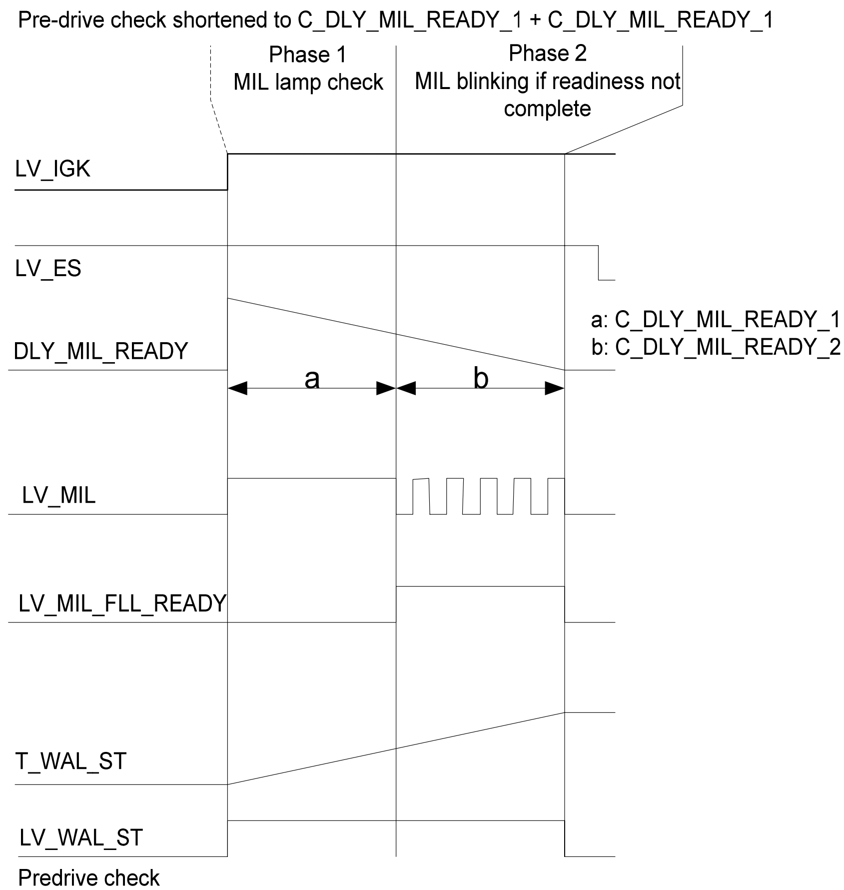
Wih the calibration C_T_MIN_WAL_ST it's possible to set a minimum time for the predrive check duration independant of engine cranking (LV_ES 1->0). This gives the possibility to illuminate the Mil for predrive check (e.g. in case of a quick start).



D) Management of maximum time of predrive check duration

-> only relevant before engine cranking (LV_ES = 0)

With the calibration LC_T_MAX_WAL_ST_ENA, it's possible to activated the maximum time of predrive check functionality. If this functionality is activated (LC_T_MAX_WAL_ST_ENA = 1) the maximum predrive check duration before engine cranking is C_DLY_MIL_READY_1 + C_DLY_MIL_READY_2. This gives the possibility to finish the predrive check before engine cranking e.g. in case of a long key on engine stop phase.



Application conditions:

Initialization: At LV_IGK transition 0 to 1
T_WAL_ST = 0 **and** LV_MIL_FLL_READY=0

At LV_ES transition 0 to 1
T_WAL_ST = 0

At LV_IGK transition 1 to 0 or if reset
LV_WAL_ST = 0 (Pre-drive check mode deactivated)

Recurrence: 500 ms and at LV_IGK 0 -> 1 transition

Activation: (pre-drive check enable between “stalling event/engine start”)

bit 0 of NC_MIL_CHK_TYP=1

and **[(**LV_IGK = 1 **and** LV_ES = 1**)**

or **(**LV_IGK = 1 **and** LV_ST = 1

and C_T_ MIN_WAL_ST >0 **and**

T_WAL_ST < C_T_ MIN_WAL_ST**)]**

and (T_WAL_ST < C_DLY_READY_1 + C_DLY_READY_2

or LC_T_MAX_WAL_ST_ENA = 0)

and (bit 0 of C_CONF_WAL_1 = 0

or bit 0 of C_CONF_WAL_2 = 0

or bit 0 of C_CONF_MIL = 0)

or

(pre-drive check disable between “stalling event/engine start”)

bit 0 of NC_MIL_CHK_TYP=0
and transition LV_IGK 0 ->1 **and** LV_ES = 1

and (T_WAL_ST < C_DLY_READY_1 + C_DLY_READY_2

or LC_T_MAX_WAL_ST_ENA = 0)

and (bit 0 of C_CONF_WAL_1 = 0

or bit 0 of C_CONF_WAL_2 = 0

or bit 0 of C_CONF_MIL = 0)

Deactivation: **(**LV_ES = 0 (engine not stopped)

and T_WAL_ST >= C_T_ MIN_WAL_ST**)**

(minimum time of predrive check reached)

or

((LV_ES = 1 (engine stopped)

and T_WAL_ST >= C_DLY_READY_1 + C_DLY_READY_2

and LC_T_MAX_WAL_ST_ENA = 1**)**

(maximum time of predrive check reached)

or LV_IGK=0 (or key off)

Formula section:

LV_WAL_ST=1 during activation of this formula section.
LV_WAL_ST=0 and LV_MIL_FLL_READY=0 during deactivation of this formula section (end of predrive check).

T_WAL_ST = T_WAL_ST + 0.5 s

```
If    bit 1 of NC_MIL_CHK_TYP = 1                                  (if readiness display enable)
Then

      If        transition of LV_WAL_ST from 0 to 1            (on beginning of predrive check)
      Then                                                              (initialize time delay)
                Initialize Delay time DLY_MIL_READY with
                C_DLY_MIL_READY_1+C_DLY_MIL_READY_2
      Endif
      DLY_MIL_READY = DLY_MIL_READY - 0.5 s

                                                   (check if delay is within the timing window)

B.61.2.2 Normal mode

The normal mode is defined as "not to be in pre-drive check mode".

B.61.2.3 All modes

Description:

The following treatment is done in pre-drive check mode and in normal mode.

Application conditions:

Initialization: at transition LV_IGK 1->0 or if reset
LV_MIL = 0 (MIL is off)
LV_WAL_1 = 0 (WAL_1 is off)
LV_WAL_2 = 0 (WAL_2 is off)

Recurrence: 500 ms and at LV_IGK 0 -> 1 transition

Activation: LV_IGK=1

Formula section:

If STATE_MIL = MIL_FLL
Then LV_MIL blink at 1Hz
Else If (STATE_MIL = ON **or** (LV_MIL_ACT_REQ = 1 **and** bit 1 of C_CONF_MIL = 1))
(allowed MIL request)
AND (LV_MIL_FLL_READY=0 **or** bit 3 of C_CONF_MIL = 1)
(case MIL blinking during the pre-drive check: readiness not completed)
Then LV_MIL = 1

Else If we are in normal mode **or** bit 3 of C_CONF_MIL = 1
(predrive check not authorized for MIL)
Then LV_MIL = 0
Endif
Endif
Endif

If STATE_WAL_1 = ON **or** (LV_WAL_1_ACT_REQ = 1 **and** bit 1 of C_CONF_WAL_1 = 1)
(allowed lamp WAL_1 request)

Then LV_WAL_1 = 1
Else If we are in normal mode **or** bit 3 of C_CONF_WAL_1 = 1
(pre drivecheck not authorized for WAL_1)
Then LV_WAL_1 = 0
Endif
Endif

Request of WAL 2 activation by others					

B.62.1 External request management

FUNCTION DESCRIPTION:

General information:

With below formula :

- No direct MIL or warning lamp (WAL_1, WAL_2) request is used.
- All lamps requests (connected to the final output variables LV_MIL and LV_WAL_1 and LV_WAL_2) result from diagnostic or safety routines are treated by the driving cycle management of the dynamic error memory.

Application conditions:

Activation: -

Deactivation: -

Initialization: At ECU reset:

LV_WAL_1_ACT_REQ = 0

LV_WAL_2_ACT_REQ = 0

Recurrence: -

Formula section:

B.62.2 Connection between lamps and infrastructure

FUNCTION DESCRIPTION:

General information:

Purpose of this module is to make the connection between lamps management dataflow and CAN inter-system. This strategy controls warning lamps through CAN inter-system. Warning lamps comprise MIL(Malfunction Lamp Indicator) and customer specific warning lamps 1 and 2.

Signal flow diagram:

-

Description:

Purpose of this strategy is to switch on and off lamps according LV_MIL, LV_WAL_1, LV_WAL_2 state of warning lamps.

Application conditions:

Initialisation:

Recurrence: 500ms

Activation: at ECU reset

Deactivation: -

Formula section:

-

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_LAMP	1	0...3H	0...3	1	[-]
Quantity of warning lamps					

B.63 Priority rules

Input data:

PRI_CONF_XX	WAL_CONF_XX	LV_ERR_DISA[NC_NR_ERR_DYN]	LV_DC_MAX[NC_NR_ERR_DYN]
LV_ERR_CFM[NC_NR_ERR_DYN]	NC_ERR_PRI_H		

Export actions:

ACTION_ERRM_PrioRule (OUT <RESP>, OUT <IDX>)
This action performs priority rules, when failure memory is full, to say if the new failure is accepted or not.

FUNCTION DESCRIPTION:

General information:

The dynamic error management module calls this module in case of present failure occurrence when the 2nd layer memory is full.

It defines criteria to store or not this failure in the 2nd layer memory (dynamic memory). Only one failure occurrence is stored.

Results of this module is either:

- "storage of new failure not possible"
- or ("storage of new failure possible" ; index of failure to delete in 2nd layer memory)

In case of new failure entry whereas the dynamic memory is full (number of stored failure = NC_NR_ERR_DYN), different criteria are applied to prioritize the failure:

- A new failure is more important than a disappeared failure
- Failure priority as defined in PRI_CONF_XX ;
  - Chronological failure order

    If NLC_OLD_ERR_PRI = 1: old failure has priority regards of new failure;

    (Failure i older than failure j means failure i has entered 2nd layer memory before failure j)

    If NLC_OLD_ERR_PRI = 0: new failure has priority regards of old failure;

    (Failure i newer than failure j means failure i has entered 2nd layer memory after failure j)

Additional features of this functionality:

- MIL can never be switched off
- Failure setting the OBD freeze frame (e.g. used for diagnostic communication with scantool / mode 2h) cannot be erased.
- The "increased priority" can be enabled with the configuration NLC_INC_ERR_PRI. This priority is a final rule, which is used, if it's not possible to enter a failure with any of the other possibilities. Then it's possible (only for failure with priority >= 4) to store the failure, if a confirmed failure not of the highest priority (priority < NC_ERR_PRI_H), which is not illumination the MIL anymore, can erased instead.

If the new failure entry is not accepted because of the priority, this failure will not be stored in the 2nd layer memory but limp home is activated, thus the freeze frame is not memorized and also no lamp management for this failure is possible.

Description:

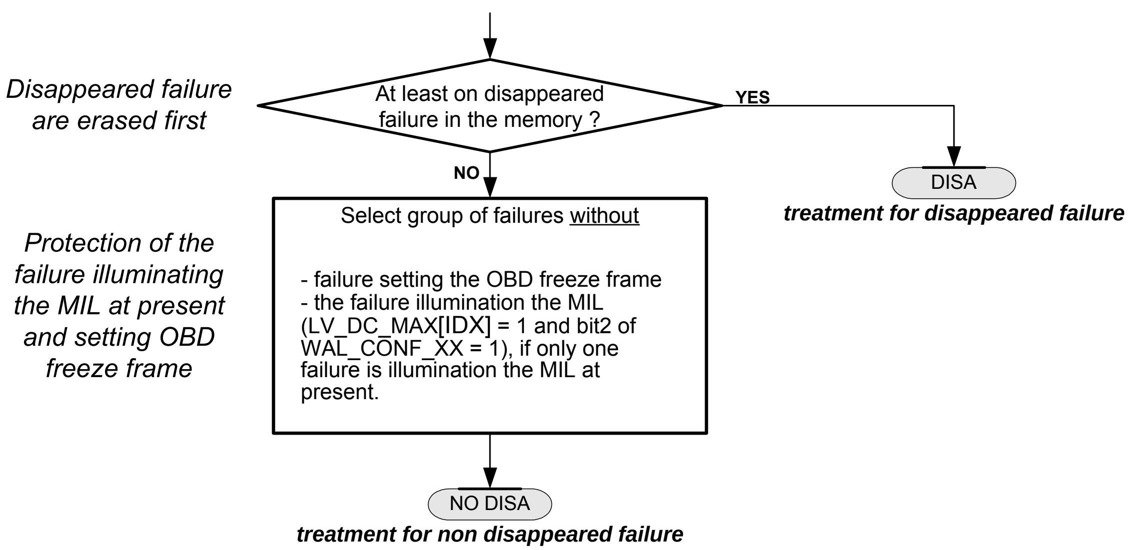
Syntax :	ACTION_ERRM_PrioRule (OUT <RESP>, OUT <IDX>)	
Parameter (in) :	-	
Parameter (out) :	RESP	OK if storage is possible; NOK if storage is not possible
	IDX	Index of failure in 2nd layer memory to delete
Short description :	This action performs priority rules, when failure memory is full, to say if the new failure is accepted or not.	

Application conditions:

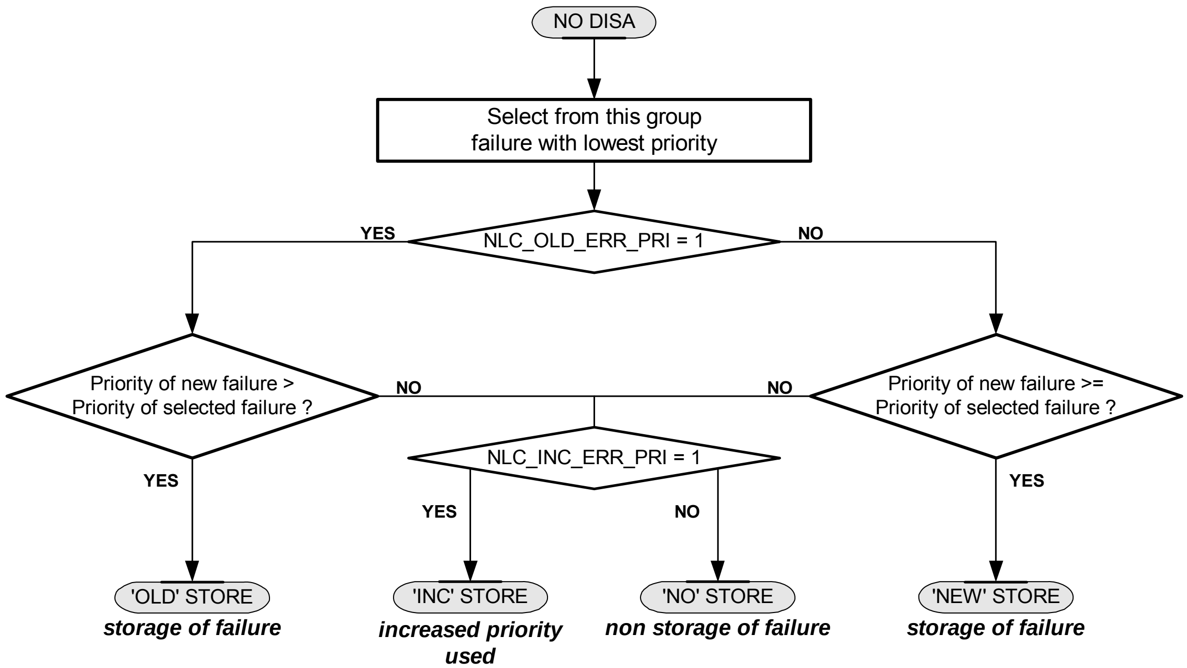
Activation:	-
Recurrence:	-
Deactivation:	at action request

Formula section:

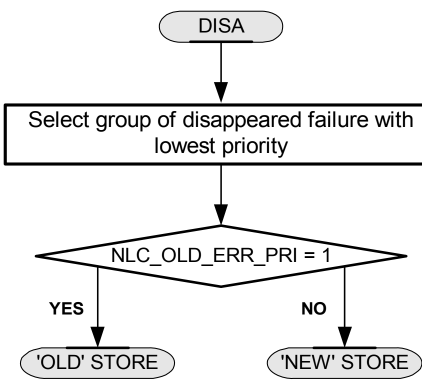
ACTION_ERRM_PrioRule (RESP, IDX) :



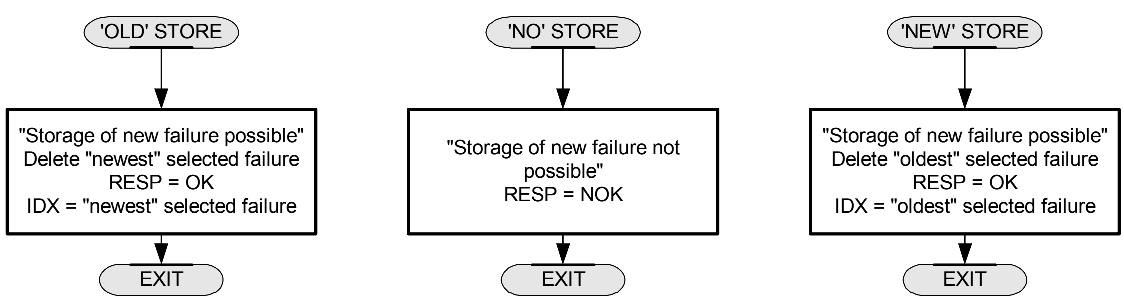
Treatment for non disappeared failure:



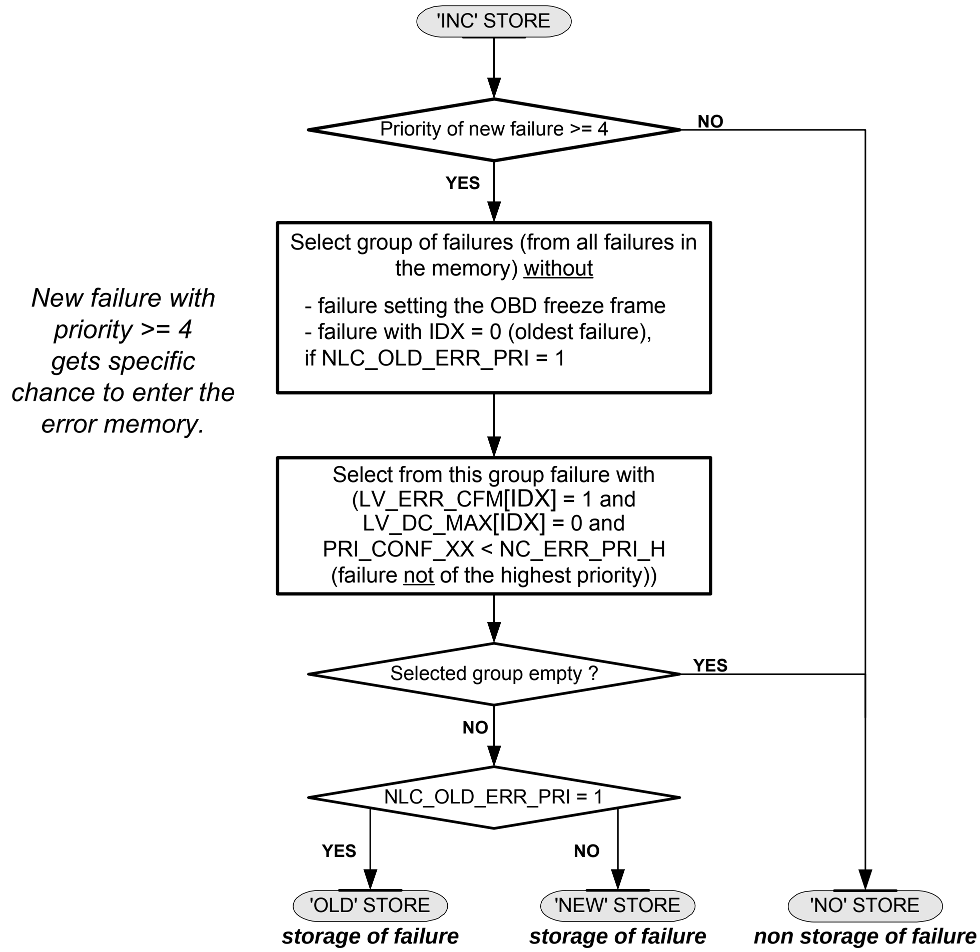
Treatment for disappeared failure:



Storage / non storage of failure:



Increased priority (with NLC_INC_ERR_PRI = 1):



Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Selection of old failure priority face to new failure					
NLC_INC_ERR_PRI	1	0...1H	0...1	1	[-]
Enable/disable increased failure priority					

Configuration data detailed description:

NLC_OLD_ERR_PRI : Set this bit to 1 to give priority to old failure regarding new failure.
Set this bit to 0 to give priority to new failure regarding old failure.

NLC_INC_ERR_PRI : Set this bit to 1 to enable increased failure priority.
Set this bit to 0 to disable increased failure priority.

B.64 Readiness codes

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_READY_XX	V/O/S	0...1H	0...1	1	[-]
Readiness flag related to diagnosis XX					

Input data:

LV_END_DIAG_XX	LV_ERR_DC[NC_NR_ERR_DYN]	LV_DC_MAX[NC_NR_ERR_DYN]	LV_DC
LV_ERR_MEM_XX	LV_EOL_OBD_DC	LV_ERR_XX	

Export actions:

ACTION_ERRM_InitReadiness ( )
This action initialise all the readiness flag

FUNCTION DESCRIPTION:

General information:

Readiness flag allows to know if a full diagnostic check (not in EOL phase) has been done or not (minimum number of checks necessary for MIL illumination if failure is present).

A readiness flag is defined for each diagnosis (LV_READY_XX). Based on these flags, readiness code status (2 bytes STATE_READY_OBD_1 and STATE_READY_OBD_2) are generated in the Communication Interface (API) file for Carb mode.

Readiness flags are mainly used by after market service and inspections maintenance. When after market achieves a repair, the system should be controlled before to give back the car to its owner.

Because some failure need a long time (and may be 2 DC) to be diagnosed, the repair operator need an as quick as possible information meaning the repairs is OK.

The readiness flag indicates when it is set to 0 that :

- the diagnosis related to failure XX is done since the last “clear DTC” service received.
- and if a failure XX is present, MIL would be illuminated.

For after market time optimisation, in case of no failure at all, the readiness flag is set to 0.

The readiness flag indicates when it is set to 1 that :

- the diagnosis related to failure XX is not done since the last “clear DTC” service received.
- or if a failure XX is present, MIL is not still illuminated (may takes many driving cycle).

After failure erase, all bits associated to supported functions are set to 1.

When the system has executed enough driving cycles for determining if MIL should be switch On or not, all the readiness flags are in 0 state. At this occurrence, failures which may have switch on the MIL could be considered as repaired if MIL is Off.

B.64.1 Readiness flag set to 0

Description:

The readiness flag LV_READY_XX is set to 0 when enough driving cycle has been done without failure XX.

Application conditions:

Initialization: On saved ram lost

LV_READY_XX = 1

Recurrence: at the recurrence of activation condition

Activation: at transition LV_DC 0->1
or at transition LV_END_DIAG_XX 0->1

Formula section:

```
If    LV_READY_XX = 1                              (diag XX not still ready)
      and LV_DC = 1                                (driving cycle valid)
            and LV_END_DIAG_XX = 1                       (diag done)
            and LV_EOL_OBD_DC = 0                        (not in EOL tests)
Then        If    LV_ERR_MEM_XX = 1                (failure in 2nd layer memory)
            Then  If    LV_ERR_DC[IDX] = 0         (no failure present this DC)
                  Then  LV_READY_XX = 0            (diag XX is ready)
                  Else  If    LV_DC_MAX[IDX] = 1
                        Then  LV_READY_XX = 0      (diag XX is ready)
                        Endif
                  Endif
            Else  If    LV_ERR_XX = 0
                  Then  LV_READY_XX = 0            (diag XX is ready)
                  Endif
            Endif
Endif
```

B.64.2 Readiness flag reinitialisation (set to 1)

Description:

Syntax : ACTION_ERRM_InitReadiness ( )

Parameter(in) : No parameter

Parameter(out) : No parameter

Short description :

The readiness flag LV_READY_XX is reinitialized (set to 1) upon communication tool request via the action ACTION_ERRM_InitReadiness ( ).

This reinitilisation is always done when all failure are erased from failure memory.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

For every failure : LV_READY_XX = 1

B.64.3 Readiness code information update

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_READY_OBD_1	V/O/S	0...FFH	0...255	1	[-]
Readiness code completion status 1					
STATE_READY_OBD_2	V/O/S	0...FFH	0...255	1	[-]
Readiness code completion status 2					
STATE_READY_OBD_3	V/O/S	0...FFH	0...255	1	[-]
Readiness code completion status 3					

Input data:

LV_DC			

Import actions:

ACTION_ERRM_ReadReadinessCode(INOUT<ReadinessCode>, OUT<ResultReadinessCode>)
ACTION_ERRM_ReadReadinessCodCus(INOUT<ReadinessCode>, OUT<ResultReadinessCode>)

Description:

Purpose of this paragraph is to update readiness code completion status. This update shall be done :

- at end of driving cycle, for readiness status display,
- on action call, for customer tool and Scan Tool coherency with STATE_READY_OBD_X.

Important remark: each time ACTION_ERRM_ReadReadinessCode is called Readiness codes completion status (STATE_READY_OBD_1 and STATE_READY_OBD_2) are calculated.

Application conditions:

Activation: at LV_DC 1→ 0 transition

Initialization: on non-volatil memory reset/lost **or** on failure erase service received

STATE_READY_OBD_1 = FFh,

STATE_READY_OBD_2 = FFh
{FFh value indicates that readiness code is not yet computed}

Recurrence: none, executed single time on activation.

Formula section:

{ Action call to update STATE_READY_OBD_1 and STATE_READY_OBD_2 }

Call ACTION_ERRM_ReadReadinessCode(INOUT<STATE_READY_OBD_1, STATE_READY_OBD_2>, OUT<ResultReadinessCode>)

Application conditions:

Activation : at LV_DC 1→ 0 transition

Initialization: on non-volatil memory reset/lost

or

on failure erase service received
STATE_READY_OBD_3 = FFh
{ *FFh value permits to indicate that readiness is not yet computed* }

Recurrence : none, executed single time on activation.

Formula section:

{ Action call to update STATE_READY_OBD_3 }

Call ACTION_ERRM_ReadReadinessCodCus(INOUT<STATE_READY_OBD_3>, OUT<ResultReadinessCode>)

B.65 Similar conditions

Export actions:

ACTION_ERRM_DecrementDCctrScdn (OUT <DCdec>, IN <XX>)
This action calculates the possibility to decrement the driving cycle counter related to failure XX
ACTION_ERRM_EraseScdn(IN <XX>)
This action erase the similar conditions related to failure XX (if existing)
ACTION_ERRM_CdnDiagScdn (IN <XX>)
This action is used to calculate a ratio to recognize the similar condition without failure
ACTION_ERRM_EndWinScdn (IN <XX>, IN <EXC>)
This is used to store similar conditions and recognize similar condition with or without failure

Import actions:

ACTION_ERRM_IncrementDCctrScdn (IN <XX>)

FUNCTION DESCRIPTION:

General information:

The different states of a failure are managed regards their driving cycle and warm up cycle counters values (see Dynamic error management core for details).

For Misfire and Fuel system failures, some additional conditions should be fulfilled to increment and decrement their driving cycle counter. These additional conditions are related to engine conditions and are called similar conditions.

When similar conditions without failure are fulfilled for the failure XX already stored in the dynamic memory in a previous driving cycle, bit 2 of STATE_SCDN[k] is set to 1. That means, that the driving cycle counter of failure XX could be decremented at the end of the driving cycle if the failure XX will not get present till this treatment. If an exceedance is reported by the diagnostic function (bit 5 of STATE_SCDN[k] is set to 1), the driving cycle counter is not decremented at the end of the DC. Exception: Driving cycle counter decrementation linked with C_CTR_SCDN_EQU_DC_MAX DCs, see description below.

Also the incrementation of the driving cycle counter of a failure stored in dynamic memory is controlled by the similar conditions functionality. The incrementation done in the error management core is triggered by the ACTION_ERRM_IncrementDCctrScdn (XX) in the following cases:

- Similar conditions are recorded

  (bit 0 of STATE_SCDN[k] 0->1).
- A failure already stored in memory occurs again in the following driving cycle (bit 2 of STATE_SCDN[k] = 1).
- A temporary failure or a confirmed failure with MIL off (LV_DC_MAX[IDX] = 0) occurs again not in the following driving cycle but with similar conditions with failure (bit 1 of STATE_SCDN[k] = 1).
- A confirmed failure with MIL on (LV_DC_MAX[IDX] = 1) occurs again.

In all of these cases, the driving cycle counter is incremented (bit 4 of STATE_SCDN[k] 0→1).

For a temporary failure or confirmed failure with MIL off (LV_DC_MAX[IDX] = 0), even if similar conditions are not recognized during a C_CTR_CDN_EQU_DC_MAX number of driving cycles, the driving cycle counter of the failure can be decremented after C_CTR_CDN_EQU_DC_MAX driving cycles.

Similar conditions functionality is inhibited when LC_ENA_SCDN=0 or NLC_ENA_SCDN=0.

Remark:

To keep the link between the index of the failure using the similar condition and the index of the failure in static memory, a transfer function is defined: k = Scdn (XX). The link between the diagnosis instance and the similar conditions instance k is described in the application incidence of similar condition.

B.65.1 Ratio calculation to recognize the similar condition without failure

Description:

For the recognition of similar conditions the current engine speed / load conditions are compared with the recorded similar conditions window.

Based on two counters calculated with this algorithm the SCDN recognition at end of the diagnostic window is done. (see next chapter)

- CTR_SCDN_EQU[k]

  counting the number of times engine speed / load conditions are within the recorded similar conditions window (with LV_CDN_DIAG_XX = 1)

- CTR_SCDN_SUM[k]

  counting the number of times the diagnosis conditions are set (LV_CDN_DIAG_XX = 1)

The calculation of the counters is stopped, if an exceedance is reported from diagnostic function.

Syntax : ACTION_ERRM_CdnDiagScdn (IN <XX>)

Parameter (in) : XX failure XX using similar condition instance XX

Parameter (out) : -

Short description:

This action is called at each diagnosis condition. It is used to calculate a ratio to recognize the similar condition with or without failure.

Application conditions:

Initialization: at transition LV_DC 0 -> 1 or reset

bit 0, bit 3 of STATE_SCDN[k] = restored from NVMY
bit 1, bit 2, bit 4, bit 5 of STATE_SCDN[k] = 0

CTR_SCDN_EQU[k] = 0
CTR_SCDN_SUM[k] = 0

Recurrence:

Activation: At action request **and** LV_DC = 1
and LC_ENA_SCDN = 1 and NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

k = Scdn (XX)

If bit 0 of STATE_SCDN[k] = 1 (similar conditions are recorded for failure XX)

and bit 5 of STATE_SCDN[k] = 0 (no exceedance reported from diagnostic function)

Then **If** LV_CDN_DIAG_XX = 1

Then CTR_SCDN_SUM[k] ++

(check if current N, LOAD_SCDN point is within SCDN window)

If N <= N_SCDN_MAX_EQU[k]

and N >= N_SCDN_MIN_EQU[k]

and LOAD_SCDN <= LOAD_SCDN_MAX_EQU[k]

and LOAD_SCDN >= LOAD_SCDN_MIN_EQU[k]

Then CTR_SCDN_EQU[k] ++

Endif

Endif

B.65.2 Record and recognition of similar conditions at end of diagnosis window

Description:

The similar conditions are stored for a failure XX (or updated) in the following cases:

- The similar conditions are frozen within the window N/LOAD_MAX/MIN_SCDN_EQU[k], if the corresponding failure is stored in the memory (failure gets present the first time)
- The similar conditions are stored again (updated) within the window N/LOAD_MAX/MIN_SCDN_EQU[k], if the corresponding failure occurs again and the driving cycle counter of this failure was 0 before.

In both cases bit 0 of STATE_SCDN[k] is 0 before the storage.

The recognition of similar conditions for detected failure is done by comparing, if the actual N/LOAD point is within the stored SCDN window. If also the same warmup status is reached at this time, similar conditions with failure are recognized. This calculation is done at the action call depending of the monitoring function, only in the following case:

- Similar conditions are stored in a previous driving cycle (bit 0 of STATE_SCDN[k] = 1)
- and the same failure XX was not present the last driving cycle. In case of same failure present last driving cycle, the driving cycle counter is incremented without asking for similar conditions.
- and failure is not illuminating the MIL. In case failure is illuminating the MIL at present the driving cycle counter is set to the maximum without asking for similar conditions.

- and driving cycle counter not already incremented in this driving cycle

If no error is present at the end of the diagnosis window, the ratio (CTR_SCDN_EQU[k] / CTR_SCDN_SUM[k]) is compared with the threshold C_CTR_SCDN_NOT_ERR_THD[k]. If the threshold and the same warmup status are reached at this time, similar conditions without failure are recognized.

This calculation is done at the end of a diagnosis window, only if no failure XX is present in the following cases:

- Similar conditions are already recorded for failure XX (bit 0 of STATE_SCDN[k] = 1) in a previous driving cycle
- Similar conditions were not already encountered within this driving cycle with no failure
- no exceedance reported from diagnostic function (bit 5 of STATE_SCDN[k] = 0)
- Driving cycle counter was not incremented this driving cycle yet.

Syntax :	ACTION_ERRM_EndWinScdn (IN <XX>, <EXC>)	
Parameter (in) :	XX	failure XX using similar condition instance XX
	EXC	Exceedance reported from Diagnostic function
Parameter (out) :	-	

Short description:

This action is called at each end of diagnosis windows if there's no failure or when the failure gets present or when an exceedance is recognized by the diagnostic function. This usage of this function depends on the diagnostic function. It is used for recognition of similar condition with or without failure

Application conditions:

Initialization: -

Recurrence: -

Activation: At action request **and** LV_DC = 1
and LC_ENA_SCDN = 1 **and** NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

k = Scdn(XX)

If EXC = 1 (Exceedance reported from Diagnostic function)

Then bit 5 of STATE_SCDN[k] = 1

Endif

B.65.3 SCDN storage and recognition for detected failure performed last DC

Description:

According regulation the information, if a failure XX (using SCDN functionality) was present the last driving cycle, must be respected to increment the DC counter. In case of a new failure occurrence, if the same failure was present the last driving cycle, the driving cycle counter must be incremented (if not already incremented this driving cycle) independently of similar conditions.

Application conditions:

Initialization: -

Recurrence:

Activation: At LV_DC transition 1 -> 0 **and**

LC_ENA_SCDN = 1 **and** NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

For k = 0 to NC_NR_WIN_SCDN - 1

k = Scdn(XX); XX = F(IDX)

If LV_ERR_DC[IDX] = 1 (failure present in this DC)

Then bit 3 of STATE_SCDN[k] = 1
(failure present the last driving cycle)

CTR_SCDN_EQU_DC[k] = C_CTR_SCDN_EQU_DC_MAX
(re-initialization of similar conditions counters)

Else bit 3 of STATE_SCDN[k] = 0
(failure not present the last driving cycle)

Endif

EndFor

B.65.4 SCDN usage to decrement driving cycle counter

Description:

Syntax : ACTION_ERRM_DecrementDCctrScdn (OUT <DCdec>, IN <XX>)

Parameter (in) : XX number of failure to store in dynamic memory

Parameter (out) : DCdec YES if decrementation of DC counter is possible

NO if decrementation of DC counter is not possible

Short description:

At the end of a driving cycle (LV_DC 1->0) the driving cycle counter for the failure XX can be decremented if similar conditions without failure are recognized and no exceedance reported from diagnostic function (bit 5 of STATE_SCDN[k] = 0) (used for misfire monitoring). For temporary failure or confirmed failure with MIL off, even if similar conditions are not recognized during a C_CTR_CDN_EQU_DC_MAX number of driving cycle, the driving cycle counter of the failure can be decremented after C_CTR_CDN_EQU_DC_MAX driving cycles.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

k = Scdn(XX)

DCdec = NO (decrementation of DC counter is not possible)

If bit 2 of STATE_SCDN[k] = 1 (similar conditions encountered with no failure)

and bit 5 of STATE_SCDN[k] = 0 (no exceedance reported)

Then DCdec = YES (decrementation of DC counter is possible)

Else **If** LV_DC_MAX[IDX] = 0 (failure is temporary or confirmed with MIL off)

Then CTR_SCDN_EQU_DC[k] = CTR_SCDN_EQU_DC[k] – 1

If CTR_SCDN_EQU_DC[k] = 0

bit 2 of STATE_SCDN[k] = 1

DCdec = YES (decrementation of DC counter is possible)

Endif

Endif

Endif

If DCdec = YES

and **(**LV_DC_MAX[IDX] = 0 (failure is temporary or confirmed with MIL off and DC counter of failure will be 0 after decrementation)

or **(**LV_DC_MAX[IDX] = 1 **and** CTR_DC[IDX] <= DC_DEC_XX**))**

(failure is confirmed with MIL on and MIL will be switched off after decrementation)

Then bit 0 of STATE_SCDN[k] = 0 (The SCDN window of failure XX will be updated With new engine conditions (N / LOAD (min/max)) at next failure occurrence)

Endif

B.65.5 Similar conditions erase

Description:

Syntax : ACTION_ERRM_EraseScdn (IN <XX>)

Parameter (in) : XX number of failure to store in dynamic memory

Parameter (out) : -

Short description:

The similar conditions are erased by calling the action ACTION_ERRM_EraseScdn :
- when saved ram lost (at initialization)
- when corresponding failure is erased (see dynamic error management core module)

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

k = Scdn (XX)

STATE_SCDN[k] = 0

N_MAX_SCDN_ EQU [k] = 0 [rpm]

N_MIN_SCDN_EQU[k] = 8160 [rpm]

LOAD_MAX_SCDN_EQU[k] = 0 [%]

LOAD_MIN_SCDN_EQU[k] = 99.60937 [%]

CTR_SCDN_EQU_DC[k] = 0

LV_WUP_SCDN_EQU[k] = 0

CTR_SCDN_EQU[k] = 0

CTR_SCDN_SUM[k] = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

B.66 Similar conditions (Appl. Inc.)

B.66.1 Similar conditions window definition

Input data:

NC_NR_WIN_SCDN	LV_CDN_DIAG_FSD[NC_CBK_EX_NR]	LV_CDN_DIAG_FSD_LAM_LIM[NC_CBK_EX_NR]	LV_END_DIAG_WIN_FSD[NC_CBK_EX_NR]
LV_END_DIAG_WIN_FSD_LAM_LIM[NC_CBK_EX_NR]	LV_CDN_DIAG_DELTA_I_LAM [NC_CBK_EX_NR]	LV_END_DIAG_WIN_DELTA_I_LAM[NC_CBK_EX_NR]	NC_STATE_LSL_UP_IF
LV_END_DIAG_WIN_LAM_ADJ[NC_CBK_EX_NR]	LV_CDN_DIAG_LAM_ADJ [NC_CBK_EX_NR]		

Import actions:

ACTION_ERRM_CdnDiagScdn (IN <XX>)
ACTION_ERRM_EndWinScdn (IN <XX>, IN <EXC>)

FUNCTION DESCRIPTION:

General information:

This file defines the usage of the similar conditions functionality. To follow specific customer requirements, this file is a template to be fulfilled by project team.

B.66.1.1 Similar conditions data definition

There is only some failure using the similar condition so this table allows to do the link between the index of the failure in static memory and the index of the failure using the similar condition:

- for NC_STATE_LSL_UP_IF = 0

Diagnosis instances XX using similar conditions functionality	NC_NR_WIN_SCDN = 7 *(Note: see ERRM configuration data)*
Diagnosis instance XX	**similar conditions instance (k)**
FSD_1	0
MIS_0	1
MIS_1	2
MIS_2	3
MIS_3	4
FSD_LAM_LIM_1	5
LAM_ADJ[1]	6
	(NC_NR_WIN_SCDN - 1)

- for NC_STATE_LSL_UP_IF = 1

Diagnosis instances XX using similar conditions functionality	NC_NR_WIN_SCDN = 7 *(Note: see ERRM configuration data)*

Diagnosis instance XX	similar conditions instance (k)
FSD_1	0
MIS_0	1
MIS_1	2
MIS_2	3
MIS_3	4
FSD_LAM_LIM_1	5
DELTA_I_LAM_1	6
	(NC_NR_WIN_SCDN - 1)

One function is defined to do the link between the index of the failure in static memory and the index of the failure using the similar condition: k = Scdn(XX)

B.66.1.2 Treatment activated by the fuel system diagnosis for the similar condition (for both NC_STATE_LSL_UP_IF = 0 and NC_STATE_LSL_UP_IF = 1)

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Application conditions:

Initialisation: -

Recurrence: fuel system diagnosis recurrency

Activation: -

Formula section:

Adaptation to calculate a ratio used to recognize the similar condition with or without failure:

If LV_CDN_DIAG_FSD_1 = 1

Then ACTION_ERRM_CdnDiagScdn (FSD_1)
Endif

Adaptation for the record and recognition of similar conditions:

If LV_END_DIAG_WIN_FSD_1 = 0 ->1

Then

Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

ACTION_ERRM_EndWinScdn (FSD_1, 0)

Endif

If LV_CDN_DIAG_FSD_LAM_LIM_1 = 1

Then ACTION_ERRM_CdnDiagScdn (FSD_LAM_LIM_1)
Endif

Adaptation for the record and recognition of similar conditions:

If LV_END_DIAG_WIN_FSD_LAM_LIM_1 = 0 ->1

Then

Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

ACTION_ERRM_EndWinScdn (FSD_LAM_LIM_1, 0)

Endif

B.66.1.3 Treatment activated by the dyanmic fuel trim diagnosis for the similar condition (only for NC_STATE_LSL_UP_IF = 1)

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Application conditions:

Only valid for NC_STATE_LSL_UP_IF = 1

Initialisation: -

Recurrence: dynamic fuel trim diagnosis recurrency (100 ms)

Activation: -

Formula section:

Adaptation to calculate a ratio used to recognize the similar condition with or without failure:

If LV_CDN_DIAG_DELTA_I_LAM_1 = 1

Then ACTION_ERRM_CdnDiagScdn (DELTA_I_LAM_1)

Endif

Adaptation for the record and recognition of similar conditions:

If LV_END_DIAG_WIN_DELTA_I_LAM_1 = 0 ->1

Then

Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

ACTION_ERRM_EndWinScdn (DELTA_I_LAM_1, 0)

Endif

B.66.1.4 Treatment activated by the dyanmic fuel trim diagnosis for the similar condition (only for NC_STATE_LSL_UP_IF = 0)

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>>, IN <EXC>) actions using for the similar condition.

Application conditions:

Only valid for NC_STATE_LSL_UP_IF = 0

Initialisation: -

Recurrence: dynamic fuel trim diagnosis recurrency (1s)

Activation: -

Formula section:

Adaptation to calculate a ratio used to recognize the similar condition with or without failure:

If LV_CDN_DIAG_LAM_ADJ[1] = 1

Then ACTION_ERRM_CdnDiagScdn (LAM_ADJ[1])
Endif

Adaptation for the record and recognition of similar conditions:

If LV_END_DIAG_WIN_LAM_ADJ[1] = 0 ->1

Then

Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

ACTION_ERRM_EndWinScdn (LAM_ADJ[1], 0)

Endif

B.66.2 SCDN usage for direct failure confirmation

Export actions:

ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>)
This action calculates the possibility to confirm a failure XX directly

Description:

Syntax : ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>)

Parameter (in) : XX number of failure to store in dynamic memory

Parameter (out) : DCconf 1 if failure must be confirmed directly

0 if failure should not be confirmed directly

Short description:

With the ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>) the value DCconf is transmitted to the driving cycle counter management to give the possibility to confirm a failure directly by incrementing the driving cycle counter for the failure XX to the maximum. This treatment must be done in the following situation:

A temporary failure XX caused by misfire B is in the memory and a failure XX caused by misfire A occures (not stored before). Then the misfire B depending failure can be erased and the misfire A failure can be confirmed directly.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

ACTION_ERRM_ConfirmErrScdn (DCconf, XX):

DCconf = 0 (direct confirmation of failure XX is not possible)

B.66.3 Definition of similar conditions load

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LOAD_SCDN	O/V	0...FFH	0...99.60937	0.390625	%
Engine load for SCDN calculation					

Input data:

LOAD_CLC			

Description:

The calculated load SAE1979 LOAD_CLC is used for similar condition.

Application conditions:

Initialisation: At reset:

LOAD_SCDN = LOAD_CLC

Recurrence: 100 ms

Activation: -

Formula section:

LOAD_SCDN = LOAD_CLC

B.66.4 Definition of switch for use of similar conditions load

Short description:

As this switch was not defined in ERRM core module, it is defined in application incidences. It always has to be calibrated to **LC_ENA_SCDN = 1** for OBD-projects**.**

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ENA_SCDN	1	00H...FFH	0...255	1	-
Switch to enable similar conditions					

B.67 Error management communication interface

Output data:

Export actions:

ACTION_ERRM_ReadDtcByTypeOfDtc (IN <TypeOfDtc>, IN <LevelOfDtc>, INOUT <ListOfDtc>, OUT <ResultDtc>)
This action returns a list of DTC. All the DTC returns have the same type defined by the parameter TypeOfDtc
ACTION_ERRM_ReadDtcByDtc (IN <DtcIdentifier>, IN <LevelOfDtc>, OUT <ResultDtc>)
This action returns a result to learn if a DTC number of a certain level is stored in memory. ACTION_ERRM_ReadInfoByTypeOfDtc (IN <TypeOfDtc>, IN <InfoIdentifier>, INOUT <ListOfDtcInfo>, OUT <ResultDtc>)
This action returns a structure of data of DTCs. All the data returned are related to DTC, which have the same type defined by the parameter TypeOfDtc and which are stored in dynamic memory.
ACTION_ERRM_ReadInfoByDtc (IN <DtcIdentifier>, IN <LevelOfDtc>, IN <InfoIdentifier>, INOUT <ListOfDtcInfo>, OUT <ResultDtc>)
This action returns a structure of data of a DTC, which is stored in dynamic memory.
ACTION_ERRM_ReadDtcLevelByDtcLevel (IN <DtcIdentifier>, IN <LevelOfDtc>, INOUT <ListofDtc>, OUT <ResultDtc>)
This action returns a Customer DTCLevel of Law DTCLevel which is stored in dynamic memory or returns a Law DTCLevel of Customer DTCLevel which is stored in dynamic memory.
ACTION_ERRM_ReadQuantityOfDtc (IN <TypeOfDtc>, IN <LevelOfDtc>, INOUT <Quantity>, OUT <ResultQuantity>)
This action returns the quantity of DTCs with a certain type, which are stored in memory.
ACTION_ERRM_ReadFrfByDtc (IN <TypeOfFF>, IN <FFIdentifier>, IN <DtcIdentifier>, IN <LevelOfDtc>, INOUT <Frf>, OUT <ResultFrf>)
This action returns a Freeze_Frame (with a particular type) related to the DTC given in parameter.
ACTION_ERRM_ClrInfoByTypeOfDtc (IN <TypeOfDtc>, OUT <ResultClrInfo>)
This action clear all the failure in dynamic memory associated to DTC with a certain type.
ACTION_ERRM_ClrInfoByDtc (IN <DtcIdentifier>, IN <LevelOfDtc>, OUT <ResultClrInfo>)
This action clear the failure in dynamic memory associated to a DTC number.
ACTION_ERRM_ControlDtcSettings (IN <MarkedMode>)
This action allows to activate or deactivate the marked mode. In this mode all new failure which appears are marked and then erased when we leave this mode.
ACTION_ERRM_ActivateMarkedMode (IN <MarkedMode>)

This API shall be used to activate/deactivate the marked mode.
ACTION_ERRM_ReadReadinessCode (INOUT <ReadinessCode>, OUT <ResultReadinessCode>)
This action allows to read the readiness code information
ACTION_ERRM_ReadReadinessCodCus (INOUT <ReadinessCode>, OUT <ResultReadinessCode>)
This action allows to read the customer specific readiness code information CARB_OTHER/NO_CARB
ACTION_ERRM_SelectRbmData (INOUT <ListRbmData>, OUT < ResultRbmData >)
This action is used to request the selection of data to be transmitted by the Communication Mode $09
ACTION_ERRM_SelectRbmByGroup (IN < GroupName >, INOUT < ListOfRbmDataByGroup >, OUT < ResultRbmDataSelection >)
This action determines within one single group, the data with lowest ratios.
ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)
This action clears all the Rate-Based Monitoring statistics

Import actions:

ACTION_ERRM_EraseErr (IN <IDX>)
ACTION_ERRM_InitReadiness ( )
ACTION_ERRM_ClcPermanentByErr (IN <PRM_IDX_ERR>)

FUNCTION DESCRIPTION:

General information:

This chapter provides an open interface for other module which have link with error management functionality (communication module for instance). This interface is described with API (Application Programming Interface) to provide access to dynamic data flow in contrast to static data flow accessed directly through variable names.

By calling API, you can access in failure memory data related to Error Management such freeze frame and DTC stored, readiness code state and so on.

An API can have some input parameters.

Results returns by the API are defined as output parameters.

To returns functional results, a software structure (buffer) is used that allows to returns some data with not fixed size (a list of data for instance).

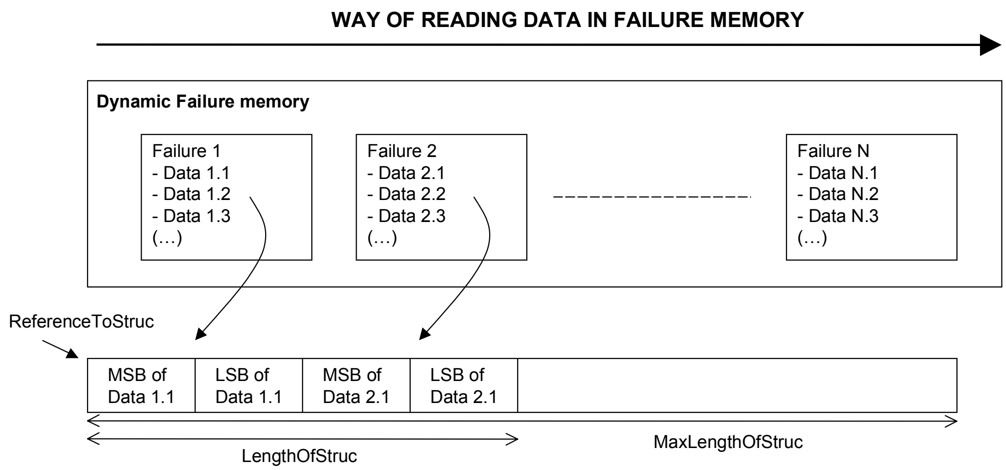
This structure is defined by the parameter in INOUT.

In the output parameter, a flag indicate if the software buffer is full or not.

Way of reading the failure memory :

API has to read through the failure memory to access some data related to Error Management.

In this case the failure memory is read in the order following the first failure entry, that means the oldest one. Thus the software structure is fill in first with data related to first failure entry (if need), then with data related to second failure entry (if need) and so on.



GENERAL IMPORTANT REMARK:

Please take care that the parameter PERMANENT is only linked to permanent memory (e.g. no impact on dynamic memory). For all services err_sym_dtc is still calculated with err_sym_mem and err_sym_lst (no link to err_sym_perm)

Fot the APIs :

- ACTION_ERRM_ReadDtcByDtc,
- ACTION_ERRM_ReadInfoByTypeOfDtc,
- ACTION_ERRM_ReadInfoByDtc,
- ACTION_ERRM_ReadDtcLevelByDtcLevel,
- ACTION_ERRM_ClrInfoByTypeOfDtc

It's forbidden to use the parameter PERMANENT for TypeOfDTC

For Mode 0Ah, the two APIs which must be used are

- ACTION_ERRM_ReadQuantityOfDtc with PERMANENT parameter for TypeOfDtc
- ACTION_ERRM_ReadDtcByTypeOfDtc with PERMANENT parameter for TypeOfDtc

Description of parameters IN, OUT, INOUT used by API:

The INPUT parameters used by API and their authorised value are defined below :

TypeOfDtc : Type of Dtc

Authorised values for TypeOfDtc are :

- ALL : all the DTC stored in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- ALL FIRST: all the DTC stored at the first time in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- ALL LAST: all the DTC stored at the last time in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- PRESENT : all the DTC of present failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_XX = 1
- PENDING : all the DTC of pending failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_PND[IDX] = 1
- TEMPORARY : all the DTC of temporary failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_TMP[IDX] = 1
- CONFIRMED : all the DTC of confirmed failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_CFM[IDX] = 1
- DISAPPEARED : all the DTC of disappeared failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_DISA[IDX] = 1
- MARKED : all DTC of failure marked and stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_MKD[IDX] = 1
- NOT MARKED : all DTC of failure not marked and stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_MKD[IDX] = 0
- OBD : all DTC related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)

- OBD FIRST: all the DTC stored at the first time in Dynamic memory related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)
- OBD LAST: all the DTC stored at the last time in Dynamic memory.related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)
- PERMANENT : all the DTC of permanent fault memory
  Failures concerned in error management : LV_ERR_PERM[IDX_PERM] = 1
- Logical AND combination between these values.
  For instance : PRESENT and CONFIRMED are failure in error management with flags : LV_ERR_MEM_XX = 1 and LV_ERR_XX = 1 and LV_ERR_CFM[IDX] = 1.

Calculation of ERR_SYM_DTC[IDX] and SYM_CYL_DTC_XX following the TypeOfDtc parameter:

For all failure except the misfiring failure treated by type :

case TypeOfDtc

ALL : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] **or** ERR_SYM_MEM[IDX]

ALL FIRST: ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]

ALL LAST : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]

PRESENT : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]

PENDING : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]

TEMPORARY : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]

CONFIRMED : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]

DISAPPEARED : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]

MARKED : ERR_SYM_DTC[IDX] =
ERR_SYM_LST[IDX] **or** ERR_SYM_MEM[IDX]

NOT MARKED : ERR_SYM_DTC[IDX] =
ERR_SYM_LST[IDX] **or** ERR_SYM_MEM[IDX]

OBD : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] **or** ERR_SYM_MEM[IDX]

OBD FIRST : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]

OBD LAST : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]

(!! independant of dynamic memory !!)

PERMANENT : ERR_SYM_PERM[IDX_PERM]

End case

For the misfiring failure treated by type (XX = MIS_A, MIS_B1 or MIS_B4)

IF NLC_TREAT_DIAG_MIS = 0

case TypeOfDtc

ALL : SYM_CYL_DTC_XX = SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

ALL FIRST : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

ALL LAST: SYM_CYL_DTC_XX = SYM_CYL_LST_XX

PRESENT: SYM_CYL_DTC_XX = SYM_CYL_LST_XX

PENDING : SYM_CYL_DTC_XX = SYM_CYL_LST_XX

TEMPORARY : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

CONFIRMED : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

DISAPPEARED : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

MARKED : SYM_CYL_DTC_XX = SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

NOT MARKED : SYM_CYL_DTC_XX =
SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

OBD : SYM_CYL_DTC_XX = SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

OBD FIRST: SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

OBD LAST: SYM_CYL_DTC_XX = SYM_CYL_LST_XX

PERMANENT : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX

End case

ENDIF { NLC_TREAT_DIAG_MIS = 0 }

For the logical AND combination between the different TypeOfDtc values, the ERR_SYM_DTC[IDX] or SYM_CYL_DTC_XX will be calculated with a binary logical AND from the associated carrier symptom.

For instance : PRESENT and CONFIRMED are failure in error management with flags : LV_ERR_MEM_XX = 1 and LV_ERR_XX = 1 and LV_ERR_CFM[IDX] = 1.
It means : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] **&** ERR_SYM_MEM[IDX],
SYM_CYL_DTC_XX = SYM_CYL_LST_XX **&** SYM_CYL_MEM_XX.

Calculation of ERR_SYM_DTC[IDX] and SYM_CYL_DTC_XX in case the API doesn't use the TypeOfDtc parameter :

ERR_SYM_DTC[IDX] = ERR_SYM_LST **or** ERR_SYM_MEM[IDX]

SYM_CYL_DTC_XX = SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

DtcIdentifier : Number of the DTC (identifier)

Authorised value for DtcIdentifier are : NO_DTC, ...<integer>

TypeOfFF : Type of Freeze Frame

Authorised values for TypeOfFF are :

- LAW : part of the freeze frame defined by the law (Carb)
- CUS_CMN : part of the freeze frame defined for the customer and not in the set
- CUS_SET : part of the freeze frame defined for the customer and in the set
- All combination of these values.

LevelOfDtc : Allowing to access to OBD error codes or customer error codes.

Authorised values for LevelOfDtc are :

- LAW : the DTC corresponds to a OBD DTC (Carb)
- CUS : the DTC corresponds to a specific customer DTC

FFIdentifier : Number of FF (identifier)

Authorised values for FFIdentifier are :

- FIRST : first freeze frame is requested
- SECOND : second freeze frame is request
- ...

MarkedMode : State of the marked mode

Authorised values for MarkedMode are :

- ON : marked mode activation : all failure stored are marked.
- OFF : marked mode deactivation (normal mode)

InfoIdentifier : Identifier for the diagnosis related information which is returned by the API (only words are returned)

Authorised information for InfoIdentifier are (only one information is returned by the API):

- CTR_ABC_XX
- CTR_ABC_END_DIAG_XX
- LV_END_DIAG_XX
- LV_READY_XX
- LV_CDN_DIAG_XX
- ERR_SYM_XX
- LV_ERR_XX
- LV_ERR_MEM_XX
- CTR_FRC[IDX]
- CTR_DC[IDX]
- CTR_WUP_CYC[IDX]
- ERR_SYM_MEM[IDX]
- ERR_SYM_LST[IDX]
- ERR_SYM_DTC[IDX]
- LV_ERR_CFM[IDX]
- LV_ERR_DISA[IDX]
- LV_ERR_TMP[IDX]

- LV_ERR_PND[IDX]
- LV_ERR_PERM[IDX]
- LV_DC_MAX[IDX]
- LV_ERR_DC[IDX]
- LV_ERR_MKD[IDX]
- C_ERR_CLAS_XX
- WAL_CONF_XX
- PRI_CONF_XX
- DC_INC_XX
- DC_DEC_XX
- DC_MAX_XX
- ID_ERR_DTC_XX[0][0]
- ID_ERR_DTC_XX[0][1]
- ID_ERR_DTC_XX[0][2]
- ID_ERR_DTC_XX[0][3]
- ID_ERR_DTC_XX[0][4]

if NC_NR_DTC_FMT = 0

(Manage 6 DTC per failure)

- ID_ERR_DTC_XX[0][5]

else

(Manage 10 DTC per failure)

- ID_ERR_DTC_XX[1][0]
- ID_ERR_DTC_XX[1][1]
- ID_ERR_DTC_XX[1][2]
- ID_ERR_DTC_XX[1][3]
- ID_ERR_DTC_XX[1][4]

endif

Please note that some application incidences can provide additional project specific informations.

The OUTPUT parameters used by API and their authorised value are defined below :

ResultDtc : Result to say if there is some DTC in memory corresponding to the API request

Authorised values for ResultDtc are :

1st bit of ResultDtc :

- (0) NO_DTC_PRESENT : there is no DTC in memory corresponding to the API request
- (1) DTC_PRESENT : there is some DTC in memory corresponding to the API request

2nd bit of ResultDtc :

- (0) NO_BUFFER_FULL : The software buffer used to return data is not full
- (1) BUFFER_FULL : The software buffer used to return data is full

ResultFrf : Result to say if there is some Freeze Frame in memory corresponding to the API request

Authorised values for ResultFrf are :

1st bit of ResultFrf :

- (0) NO_FRF_PRESENT : there is no freeze frame in memory corresponding to the API request
- (1) FRF_PRESENT : there is some freeze frame in memory corresponding to the API request

2nd bit of ResultFrf :

- (0) NO_BUFFER_FULL : The software buffer used to return data is not full
- (1) BUFFER_FULL : The software buffer used to return data is full

ResultQuantity : Result to say if the result of the API is valid.

Authorised values for ResultQuantity are :

1st bit of ResultQuantity :

- (0) NO_DTC_PRESENT : there is no DTC in memory corresponding to the API request
- (1) DTC_PRESENT : there is some DTC in memory corresponding to the API request

ResultClrInfo : Result to say if the clear DTC made by the API is done or not.

Authorised values for ResultClrInfo are :

1st bit of ResultClrInfo :

- (0) INFO_CLEARED : DTC are cleared by the call of the API
- (1) INFO_NOT_CLEARED : no DTC is cleared by the call of the API

ResultReadinessCode : Result to say if the API is done or not.

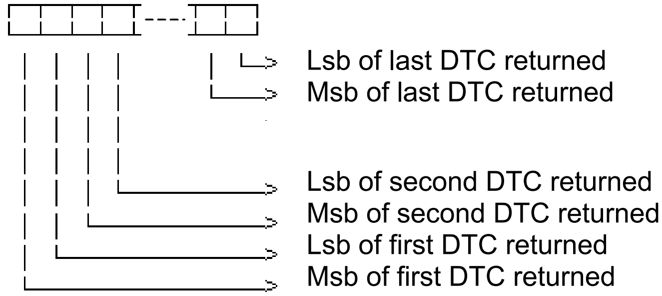
Authorised values for ResultReadinessCode are :

1st bit of ResultReadinessCode :

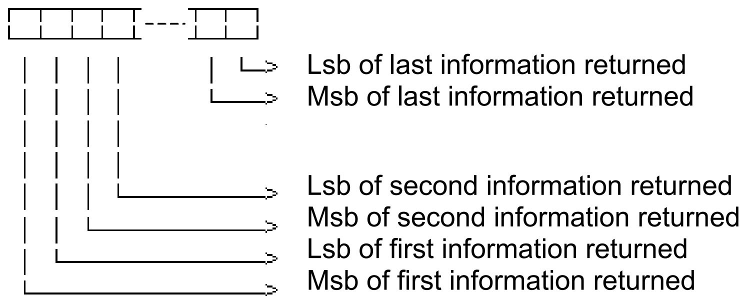
- (0) POSITIVE_RESPONSE : the call of the API is successful
- (1) NEGATIVE_RESPONSE : the call of the API is not successful

The INPUT/OUTPUT parameters used by API and their authorised value are defined below :

- ListOfDtc : Software structure filled up with a list of DTC

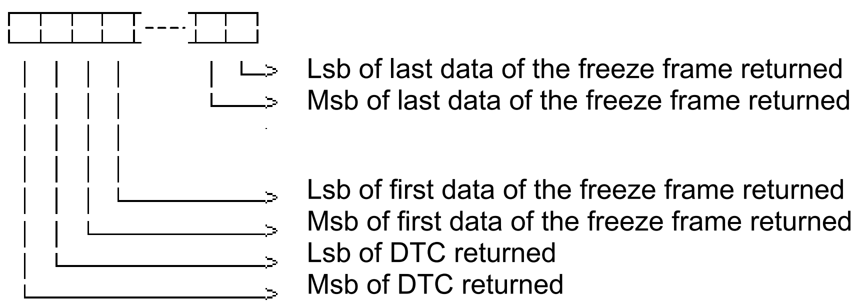


- ListOfDtcInfo : Software structure filled up with a list of DTCInfo



- Quantity : Software structure filled up with a quantity of DTC

- Frf : Software structure filled up with a freeze frame



- ReadinessCode : Software structure filled up with readiness code

B.67.1 API for reading Diagnostic Trouble Code (DTC)

B.67.1.1 Request a list of DTCs by type of DTC.

Description :

Syntax : ACTION_ERRM_ReadDtcByTypeOfDtc (
IN <TypeOfDtc>,
IN <LevelOfDtc>,
INOUT <ListOfDtc>,
OUT <ResultDtc>)

Parameter(in) :	TypeOfDtc	Type of DTC which is requested by the API.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if some DTC is in memory
Parameter(inout) :	ListOfDtc	Software structure fills up with a ListOfDtc

Short Description : This API returns a list of DTCs. All the DTC returns have the same type defined by the parameter TypeOfDtc and the same level defined in LevelOfDtc.

For each failure, if NC_NR_DTC_FMT = 0 then 6 DTC are defined : one DTC for each symptom (OBD or Customer), one OBD global DTC, one customer global DTC else 10 DTC are defined : one OBD DTC for each symptom, one OBD global DTC, one customer specific DTC number for each symptom and one customer global DTC.

When LevelOfDtc = LAW : OBD Dtc is request

If NC_ERR_DTC_REQ_OBD = SYMPTOM, the DTC is build up following the detected symptom. If more than one symptom is detected, a DTC per symptom detected is returned. There is a particular case for Misfiring failure. For this failure, the DTC number is built up following the cylinder where the misfiring is detected.

If NC_ERR_DTC_REQ_OBD = FAILURE, the OBD global DTC is returned.

When LevelOfDtc = CUS : Customer Dtc is request

If NC_ERR_DTC_REQ_CUS = SYMPTOM, the DTC is build up following the detected symptom. If more than one symptom is detected, a DTC per symptom detected is returned. There is a particular case for Misfiring failure. For this failure, the DTC number is built up following the cylinder where the misfiring is detected.

If NC_ERR_DTC_REQ_CUS = FAILURE, the customer global DTC is returned.

Application conditions:

Deactivation : -

                  Then  software structure fill up with
                        ID_ERR_DTC_MIS [ 1 ] [ NC_CYL_NR ]
                  Endif
```

```
                For each cylinder bit i which is set in SYM_CYL_DTC_XX
                        software structure fill up with
                        ID_ERR_DTC_MIS[ 1 ] [ i ]
                Endfor
            Endif
        Endif
      Endif
   Endfor
 Endif
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

If there is duplicated DTC then only the oldest is returned

B.67.1.2 Request a DTC by DTC number

Description :

Syntax : ACTION_ERRM_ReadDtcByDtc (
IN <DtcIdentifier>,
IN <LevelOfDtc>,
OUT <ResultDtc>)

Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory

Short Description : This API returns a result to learn if a DTC number of a certain level is stored in memory.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

B.67.2 API for reading the status of Diagnostic Trouble Code

B.67.2.1 Request a list of status of DTCs by type of DTC

Description :

Syntax : ACTION_ERRM_ReadInfoByTypeOfDtc (
IN <TypeOfDtc>,
IN <InfoIdentifier>,
INOUT <ListOfDtcInfo>,
OUT < ResultDtc>)

Parameter(in) :	TypeOfDtc	Type of DTC which is requested by the API.
	InfoIdentifier	Information which is returned by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns a diagnosis information. All the information returned are related to DTC which have the same type defined by the parameter TypeOfDtc and which are stored in memory.

Diagnosis information returned is defined by InfoIdentifier parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1^{st} bit of ResultDtc = NO_DTC_PRESENT

2^{nd} bit of ResultDtc = NO_BUFFER_FULL

For each failure stored in dynamic memory,

If the failure belongs to group defined by the parameters TypeOfDtc

Then 1^{st} bit of ResultDtc = DTC_PRESENT

ListOfDtcInfo is fill up with data of this failure corresponding to InfoIdentifier.

Endif

EndFor

During all the software structure filling-in, if the software buffer is full then 2^{nd} bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

B.67.2.2 Request a status of a DTC by DTC number

Description :

Syntax : ACTION_ERRM_ReadInfoByDtc (
IN <DtcIdentifier>,
IN <LevelOfDtc>,
IN <InfoIdentifier>,
INOUT <ListOfDtcInfo>,
OUT <ResultDtc>)

Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
	InfoIdentifier	Information which is returned by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns a structure of diagnosis information related to a DTC which is stored in dynamic memory.

Diagnosis information returned is defined by InfoIdentifier parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultDtc = NO_DTC_PRESENT

2nd bit of ResultDtc = NO_BUFFER_FULL

```
For each failure IDX stored in dynamic memory,

                        If DtcIdentifier = ID_ERR_DTC_MIS[1][i]
                        Then    1st bit of ResultDtc = DTC_PRESENT
                                ListOfDtcInfo is fill up with data of this failure
                                corresponding to InfoIdentifier.
                        Endif
                Endfor
        Endif
    Endif
Endfor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the status of the first DTC found (oldest DTC) is returned.

B.67.2.3 Request a DTCLevel by an another DTCLevel

Description :

Syntax : ACTION_ERRM_ReadDtcLevelByDtcLevel (
IN <DtcIdentifier>,
IN <LevelOfDtc>,
INOUT <ListOfDtc>,
OUT <ResultDtc>)

Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns the customer DTC from the Law DTC or the DTC Law from the DTC customer following the 'levelofDTC' parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultDtc = NO_DTC_PRESENT

2nd bit of ResultDtc = NO_BUFFER_FULL

                Then    1st bit of ResultDtc = DTC_PRESENT
                        ListOfDtc is fill up with ID_ERR_DTC_MIS[0][i]
                        Exit
                Endif
         Endfor
      Endif
   Endif
Endfor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the status of the first DTC found (oldest DTC) is returned.

B.67.3 API for reading the number of Diagnostic Trouble Code

B.67.3.1 Request the quantity of DTC with a certain type stored in memory

Description :

Syntax :	ACTION_ERRM_ReadQuantityOfDtc (IN <TypeOfDtc>, IN <LevelOfDtc>, INOUT <Quantity>, OUT <ResultQuantity>)	
Parameter(in) :	TypeOfDtc LevelOfDtc	Type of DTC which is requested by the API. OBD or customer DTC is requested by the API
Parameter(out) :	ResultQuantity	Boolean to say if there is at least 1 DTC in memory
Parameter(inout) :	Quantity	Software structure fill up with quantity of Dtc
Short Description :	This API returns the quantity of DTCs with a certain type, which are stored in memory. Quantity of DTCs is the number of failures in memory. If failures have same DTC values then they are counted once.	

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

Endif
```

For each duplicated DTC, the corresponding quantity will be subtracted. Duplicated DTC will be counted once.

B.67.4 API for reading the Freeze Frame

B.67.4.1 Request a freeze frame with a certain type by DTC

Description :

Syntax : ACTION_ERRM_ReadFrfByDtc(
IN <TypeOfFF>,
IN <FFIdentifier>,
IN <DtcIdentifier>,
IN < LevelOfDtc>
INOUT <Frf>
OUT <ResultFrf>)

Parameter(in) :	TypeOfFF	Type of freeze frame which are request by the API
	FFIdentifier	Identifier of freeze frame requested
	DtcIdentifier	Identifier of DTC of the freeze frame requested
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultFrf	Boolean to say if requested freeze frame is present
Parameter(inout) :	Frf	Software structure fill with Freeze frame

Short Description : This API returns a freeze frame or a part of freeze frame.

With the parameter TypeOfFF, some different part of a freeze frame (defined by the law or by the customer - including set or not) can be returned.

The parameter FFIdentifier is not used (reserved for future improvement).

The freeze frame can be requested :

- by DTC ; in this case the parameters DtcIdentifier and LevelOfDtc should be fulfilled.
- for the CARB/EOBD request (mode 02h) ; in this case, the parameter DtcIdentifier has to be set to NO_DTC, the parameter TypeOfFF has to be set to LAW, and the parameter FFIdentifier has to be set to FIRST.

  The freeze frame associated to the oldest Carb failure among highest priority Carb failure is returned.

See definitions of freeze frame in module “Environmental data” module in “Error management” aggregate.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultFrf = NO_FRF_PRESENT

                                            TypeOfFF
                                            Exit
                                    Endif
                            Endif
                            For each cylinder bit i which is set in SYM_CYL_DTC_XX
                                    If DtcIdentifier = ID_ERR_DTC_MIS[1][i]
                                    Then    1st bit of ResultFrf = FRF_PRESENT
                                            Software structure is filled-up with DtcIdentifier plus
                                            freeze frame of failure according parameter
                                            TypeOfFF
                                            Exit
                                    Endif
                            Endfor
                    Endif
            Endif
    Endfor
Endif
```

"Software structure is filled-up with freeze frame of failure according parameter TypeOfFF" means :

(for failure IDX)

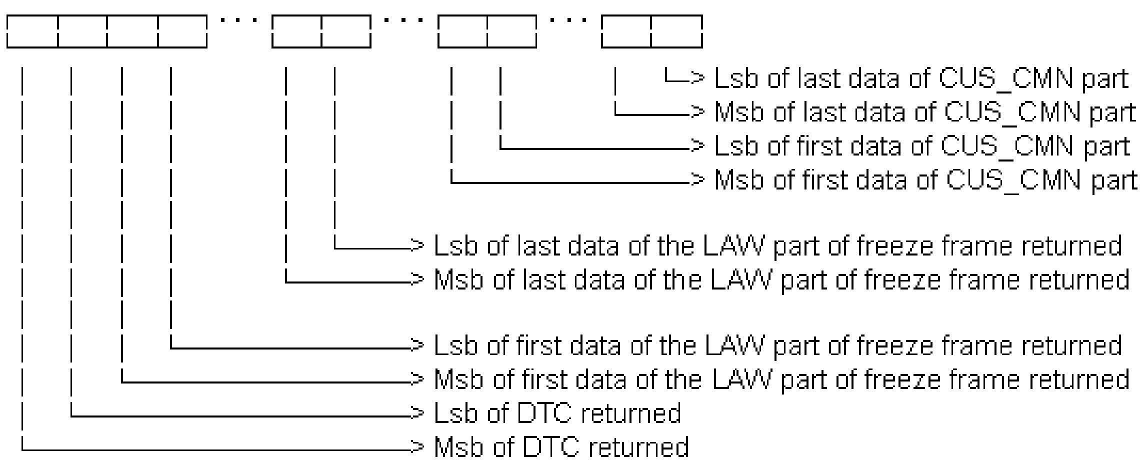
Software structure is filled-up with DTCIdentifier plus the softwate structure defined below :

If TypeOfFF = LAW
Then Software structure is fill up with ENVD_OBD[u][IDX]
Endif
If TypeOfFF = CUS_CMN
Then Software structure is fill up with ENVD_CUS_CMN[v][IDX]
Endif
If TypeOfFF = CUS_SET
Then Software structure is fill up with
ENVD_CUS_SET_CMN[w][z][IDX] + ENVD_CUS_SET_SPC[y][z][IDX]
Endif

Combination of parameter Type OfFF is possible. For instance if TypeOfFF is equal to LAW and CUS_CMN, both part are returned. In case of multiple part of freeze frame to returned, , the following order is respected :

- Part LAW of the freeze frame is returned first ;
- Part CUS_CMN of the freeze frame is then returned ;
- Part CUS_SET of the freeze frame is then returned .

Example : In the case of a request with TypeOfFF = LAW and CUS_CMN then the following structure is returned :



When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the freeze frame of the first DTC is found (oldest DTC) and returned by the API.

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultFrf is set to BUFFER_FULL, software process is aborted.

B.67.5 API for erasing Diagnostic information

B.67.5.1 Clear the failure associated to DTC with a certain type.

Description :

Syntax : ACTION_ERRM_ClrInfoByTypeOfDtc (
IN <TypeOfDtc>,
OUT < ResultClrInfo>)

Parameter(in) : TypeOfDtc Type of DTC which is requested by the API

Parameter(out) : ResultClrInfo Indicate if some DTC are cleared or not

Short Description : This API clear all the failure in dynamic memory associated to DTC with a certain type. It permits also to reinitialised all readiness code.

Remark :

For reason of design, and time resource, it's recommended to activate this API when engine stop. (Ref. SAE Mode $04).

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

ResultClrInfo = INFO_NOT_CLEARED

For each failure stored in dynamic memory,

If the failure belongs to failures group defined by the parameter TypeOfDtc

Then ACTION_ERRM_EraseErr (IN<IDX>, SYNCHRONIZATION<CALL>)

All data in static memory related to failure XX (with XX = F(IDX)) is also cleared

ACTION_ERRM_ClcPermanentByErr(XX)

ResultClrInfo = INFO_CLEARED

Endif

Endfor

In the case TypeOfDTC = All, then, the whole static memory shall be cleared (same behavior as clear failure memory using LC_ERR_FMY_CLR calibration bit)

{ Permanent calculation at ERRM clearing }

In case of TypeOfDTC = All, then call also ACTION_ERRM_ClcPermanentIniErrm( )

{ All readiness bit are reinitialised }

ACTION_ERRM_InitReadiness (SYNCHRONIZATION<CALL>)

Retransmit "failure erase service received"

B.67.5.2 Clear the failure associated to a DTC

Description :

Syntax :

```
ACTION_ERRM_ClrInfoByDtc (
        IN <DtcIdentifier>,
        IN <LevelOfDtc>,
        OUT < ResultClrInfo>)
```

Parameter(in) :	DtcIdentifier	Number of DTC which is requested (identifier)
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultClrInfo	to say if some DTC are cleared or not

Short Description : This API clear all the failure in dynamic memory associated to a DTC. The erasing is also applicable when there are identical DTC identifiers in the memory.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
ResultClrInfo = INFO_NOT_CLEARED
{ All readiness bit are reinitialised }
ACTION_ERRM_InitReadiness ( SYNCHRONIZATION<CALL> )
For each failure stored in dynamic memory do
    If   failure is not with status = CARB_MIS

    Endif
Endfor
```

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is not stopped. That means that all failure with the right DTC are erased.

B.67.6 API to manage the entry or exit of “Marked Mode”

B.67.6.1 Activate/deactivate the marked mode with clear failure

Description :

Syntax : ACTION_ERRM_ControlDtcSettings (IN <MarkedMode>)

Parameter(in) : MarkedMode State of marked mode

Short Description : This API permits to activate or deactivate the marked mode. In this mode all new failure which appears are marked and then erased when we leave this mode (useful in End Of Line phase). For errm inhibition, please refer to ACTION_ERRM_ActivateMarkedMode ().

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

If MarkedMode = ON

Then LV_MKD_MOD = 1

Else LV_MKD_MOD = 0

For each failure (IDX) stored in dynamic memory,

If LV_ERR_MKD[IDX] = 1

Then ACTION_ERRM_EraseErr (IN<IDX>)

All data in static memory related to failure XX (with XX = F(IDX)) is also cleared
ACTION_ERRM_ClcPermanentByErr(XX)

Endif

EndFor

Endif

B.67.6.2 Activate/deactivate the marked mode without clearing failures

Description :

Syntax : ACTION_ERRM_ActivateMarkedMode (IN <MarkedMode>)

Parameter(in) : MarkedMode State of marked mode ON or OFF

Short Description : This API shall be used to activate/deactivate the marked mode. In this mode, each new occuring failure is marked.
This is useful for ERRM inhibition. This inhibition may be used during a reprogramming phase.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

If MarkedMode = ON

Then LV_MKD_MOD = 1

Else LV_MKD_MOD = 0

Endif

B.67.6.3 Deactivation of marked mode (security mechanism)

Description:Purpose of this module is to add a security mechanism regarding marked mode. Because marked mode permits to inhibit error management, a strategy shall be introduced to avoid wrong inhibition.

This strategy is to deactivate marked mode when a at the end of driving cycle is detected. After driving cycle ends, reactivation of marked mode is the not supportedor at the next reset.

Application conditions:

Initialisation: none

Recurrence: none

Activation: at DCOFF event **or** at RST event

Deactivation: none

Formula section:

If LV_MKD_MOD = ON

Then

MarkedMode = OFF

ACTION_ERRM_ ControlDtcSettings (IN <MarkedMode >)

B.67.7 API for reading readiness code

B.67.7.1 Read the readiness code information

Description :

Syntax : ACTION_ERRM_ReadReadinessCode (
INOUT <ReadinessCode>,
OUT <ResultReadinessCode>)

Parameter(inout) : ReadinessCode   Software structure fill with readiness code

Short Description : This API calculate and returns the readiness code information in the software structure.

Readiness code information are build from readiness flags.

Please see “Readiness Code” module of the “Error management” aggregate for more details.

Application conditions:

Deactivation : -

Initialization: -

At failure erasure and saved ram lost
LV_READY_MISF_KOBD = 1, LV_READY_FSD_KOBD = 1

Recurrence : -

Formula section :

ResultReadinessCode = NEGATIVE_RESPONSE

(Calculation of STATE_READY_OBD_1)

STATE_READY_OBD_1 :

```
 ┌─┬─┬─┬─┬─┬─┬─┬─┐
 └─┴─┴─┴─┴─┴─┴─┴─┘
  | | | | | | | └─> bit0 : Misfire monitoring supported
  | | | | | | └───> bit1 : Fuel system monitoring supported
  | | | | | └─────> bit2 : Comprehensive component monitoring supported

```

STATE_READY_OBD_2 = C_STATE_READY_OBD_2

<u>The readiness code calculation is performed in two steps:</u>

1. setting of readiness of a specific group CARB_YY (e.g. CARB_SA, CARB_EVAP), depending on the dynamic Error Management. If at least one failure XX is confirmed with bit 4 of WAL_CONF_XX = 1 of the group CARB_YY, then the readiness of this group can be set to ready.
2. setting of readiness of a specific group CARB_YY, depending on the failure XX individual readiness information LV_READY_XX. E.g. in case of a failure free system only step 2 is used for the readiness code calculation.

<u>Step 1:</u>

If CTR_ERR_DYN_NR != 0 (at least one failure stored in Error Management)

Then **For** IDX = 0 to CTR_ERR_DYN_NR – 1

If bit 4 of WAL_CONF_XX = 1 (failure is emission relevant)
with XX = DIAG_INST[IDX]

and LV_ERR_CFM[IDX] = 1 (failure is confirmed)

Then case CARB_YY for failure XX

CARB_MIS: Bit 4 of STATE_READY_OBD_1 = 0
CARB_FSD: Bit 5 of STATE_READY_OBD_1 = 0
CARB_CC: Bit 6 of STATE_READY_OBD_1 = 0
CARB_CAT: Bit 0 of STATE_READY_OBD_2 = 0
CARB_HC: Bit 1 of STATE_READY_OBD_2 = 0
CARB_EVAP: Bit 2 of STATE_READY_OBD_2 = 0
CARB_SA: Bit 3 of STATE_READY_OBD_2 = 0
CARB_AC: Bit 4 of STATE_READY_OBD_2 = 0
CARB_LS: Bit 5 of STATE_READY_OBD_2 = 0

CARB_LSH: Bit 6 of STATE_READY_OBD_2 = 0

CARB_EGR: Bit 7 of STATE_READY_OBD_2 = 0

Endif

Endfor

Endif

<u>Step 2:</u>

<u>Distinction between GS vehicle and DS vehicle</u>

Bit 3 of STATE_READY_OBD_1 = NLC_OBD_DSL

Misfire monitoring status bit4 :

```
If          CONF_KOBD = 0
Then
            If      Bit 4 of C_STATE_READY_CMPL_OBD_1 = 0
            Then

Endif

ReadinessCode structure is filled up with : C_STATE_READY_OBD_2, STATE_READY_OBD_1 and STATE_READY_OBD_2.

ResultReadinessCode = POSITIVE_RESPONSE

Definition of Readiness Code:

In C_STATE_READY_OBD_1, a bit set to 1 means that corresponding test is supported according to the J1979 standard.

C_STATE_READY_OBD_1 :

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 │ │ │ │ │ │ │ └─>  bit0 : Misfire monitoring supported
 │ │ │ │ │ │ └───>  bit1 : Fuel system monitoring supported
 │ │ │ │ │ └─────>  bit2 : Comprehensive component monitoring supported
 │ │ │ │ └───────>  bit3 : GS/DS vehicle (NLC_OBD_DSL = 1 for DS, 0 for GS)
 │ │ │ └─────────>  bit4 = 0 (reserved)
 │ │ └───────────>  bit5 = 0 (reserved)
 │ └─────────────>  bit6 = 0 (reserved)
 └───────────────>  bit7 = 0 (reserved)
```

With C_STATE_READY_OBD_CMPL_OBD_1, it's possible to set directly Misfire, Fuel system, and comprehensive component readiness codes to "ready" status.

In C_STATE_READY_OBD_2, a bit set to 1 means that corresponding test is supported according to the J1979 standard.

C_STATE_READY_OBD_2:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐   GS name / DS name
└─┴─┴─┴─┴─┴─┴─┴─┘
 │ │ │ │ │ │ │ └─>  bit 0 : Catalyst / NMHC Catalyst monitoring
 │ │ │ │ │ │ └───>  bit 1 : Heated catalyst / NOx Cat-Adsorber monitoring
 │ │ │ │ │ └─────>  bit 2 : Evaporative system monitoring / reserved
 │ │ │ │ └───────>  bit 3 : Secondary air system / Boost pressure monitoring
 │ │ │ └─────────>  bit 4 : A/C system refrigerant monitoring
 │ │ └───────────>  bit 5 : Oxygen sensor / Exhaust Gas sensor monitoring
 │ └─────────────>  bit 6 : Oxygen sensor heater / PM Filter monitoring
 └───────────────>  bit 7 : EGR system monitoring
```

Readiness MIS, FSD, CC directly set to ready					

Calibration data detailled description for C_STATE_READY_CMPL_OBD_1 :

Readiness code calculation for CARB_MIS, CARB_FSD, CARB_CC diagnosis :

0: readiness of conserned group is calculated based on the readiness of each comprehensive component diagnostic

1: readiness of conserned group always indicates "ready"

C_STATE_READY_CMPL_OBD_1:

- bit0 : 0
- bit1 : 0
- bit2 : 0
- bit3 : 0
- bit4 : set directly readiness for Misfire monitoring
- bit5 : set directly readiness Fuel system monitoring
- bit6 : set directly readiness Comprehensive component monitoring
- bit7 : 0

B.67.7.2 Read the readiness code information for customer specific purpose

Description :

Syntax : ACTION_ERRM_ReadReadinessCodCus(
INOUT <ReadinessCode>,
OUT <ResultReadinessCode>)

Parameter(inout): ReadinessCode — Software structure filled-up with customer specific readiness code

Short Description : This API calculates and returns the readiness code information in the software structure.

Readiness code information are built thanks to readiness flags.

Please see “Readiness Code” module of the ERRM aggregate for more details.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

ResultReadinessCode = NEGATIVE_RESPONSE

(Calculation of STATE_READY_OBD_3)

STATE_READY_OBD_3 :

```
|_|_|_|_|_|_|_|_|
 | | | | | | | └─> bit0 : for diagnosis classified as CARB_OTHER
 | | | | | | └───> bit1 : for diagnosis classified as NO_CARB
 | | | | | └─────> bit2 : 0
 | | | | └───────> bit3 : 0
 | | | └─────────> bit4 : 0
 | | └───────────> bit5 : 0
 | └─────────────> bit6 : 0
 └───────────────> bit7 : 0
```

STATE_READY_OBD_3 = C_STATE_READY_OBD_3

Diagnosis classified as CARB_OTHER bit0:

If ∑ (LV_READY_XX) = 0
Take into account all LV_READY_XX which fulfill the following condition:
this XX failure has the status CARB_OTHER (see tables of failures) **and**
the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then Bit 0 of STATE_READY_OBD_3 = 0
Endif

Diagnosis classified as NO_CARB bit1

If ∑ (LV_READY_XX) = 0
Take into account all LV_READY_XX which fulfill the following condition:
this XX failure has the status NO_CARB (see tables of failures) **and**
the bit 4 of WAL_CONF_XX = 0 (CARB/EOBD failure)

Then Bit 1 of STATE_READY_OBD_3 = 0
Endif

ReadinessCode structure is filled-up with : C_STATE_READY_OBD_3, STATE_READY_OBD_3.

ResultReadinessCode = POSITIVE_RESPONSE

<u>Definition of Readiness Code:</u>

This readiness code does not follow existing J1979 standard.

C_STATE_READY_OBD_3 :

```
|_|_|_|_|_|_|_|_|
 | | | | | | | └─> bit0 : for diagnosis classified as CARB_OTHER
 | | | | | | └───> bit1 : for diagnosis classified as NO_CARB

Status configuration for customer specific readiness code					

B.67.8 Rate-Based Monitoring - Communication interface

FUNCTION DESCRIPTION:

Description:

The Rate-Based Monitoring statistics shall be reported to the Scan-Tool via the Mode $09.

The data to be transmitted are :

- Ignition cycle counter
- General denominator
- For each group of monitors, individual numerator and denominator of the monitor which has the lowest In-Use Performance ratios.

These statistics are required and transmitted within Mode $09 for the monitors of the following groups :

- Catalyst bank 1
- Catalyst bank 2
- Oxygen sensor upstream bank 1
- Oxygen sensor upstream bank 2
- EGR system and/or VVT system
- Secondary air system
- Evaporating system
- Oxygen sensor downstream bank 1
- Oxygen sensor downstream bank 2

The selection of data to be displayed on Scan-Tool shall respect some rules :

- For each group of monitors, the individual numerator and denominator of monitor which has the lowest numerical In-Use Performance ratio shall be reported.
- If two or more specific monitors of the same group have identical ratios, the corresponding numerator and denominator for the specific monitor that has the highest denominator shall be reported.
- Depending on system configurations, some components might not exist (e.g. O2 Sensor for bank 2 on vehicles with 1 bank engine). In this case the numerator and denominator shall be set to 0.

B.67.8.1 API to select Rate-Based Monitoring data to be transmitted via Mode $09

The following paragraph descibes the data selection algorithm to be executed only once (for CPU load saving reason), upon external tool request via Mode $09, by calling an API.

Syntax : ACTION_ERRM_SelectRbmData (INOUT < ListRbmData >, OUT < ResultRbmData >)

Parameter (in) : No parameter

Parameter (out) : ResultRbmData

Parameter(inout) : ListRbmData

Short description : This API calculates and returns the Rate-Based Monitoring data to be transmitted to the Scan-Tool, when requested by the Mode 09$ (InfoType $08).

ResultRbmData : Indicates if the API has been executed or not.

Authorised values for ResultRbmDataSelection are :

- POSITIVE_RESPONSE : the call of the API is successful
- NEGATIVE_RESPONSE : the call of the API is unsuccessful

ListRbmData : Software structure filled-up with 16 counters of 2 bytes coming from Rate-Based Monitoring

B.67.8.2 API to select RBM statistic with lowest in-use performance ratio within one single group

General information:

This API shall be used to determine, within one single group (see specification “Rate-Based Monitoring (Appl. Inc.)”), the counters of the monitor which has the lowest in-use performance ratio.

Description:

Syntax : ACTION_ERRM_SelectRbmByGroup (

IN < GroupName >

INOUT < ListRbmDataByGroup >,

OUT < ResultRbmDataByGroup >)

Parameter (in) : GroupName

Parameter (out) : ResultRbmDataByGroup

Parameter(inout) : ListRbmDataByGroup

Short description : This API calculates and returns the Rate-Based Monitoring data with lowest ratios, within one single group.

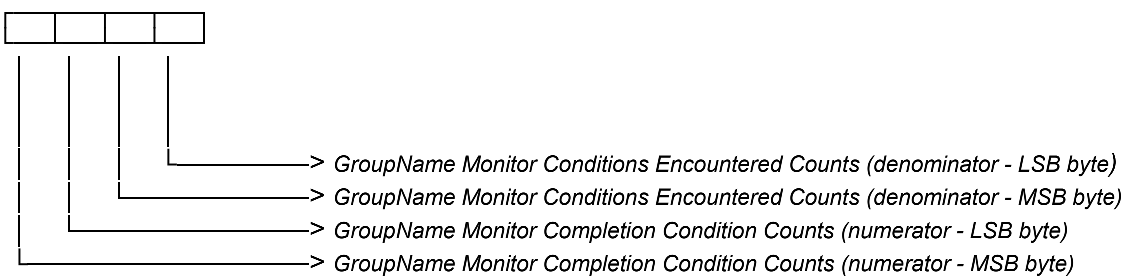
GroupName : Group name requested. See specification “Rate-Based Monitoring (Appl. Inc.)”

ResultRbmDataByGroup : Indicates if the API has been executed or not.

Authorised values for ResultRbmDataByGroup are :

- POSITIVE_RESPONSE : the call of the API is successful
- NEGATIVE_RESPONSE : the call of the API is unsuccessful

ListRbmDataByGroup : Software structure filled-up with the Rate-Based Monitoring counters of 2 bytes related to the requested group name.



Application conditions:

Initialization : -

Recurrence : -

Activation : at Action call

Deactivation : -

Formula section:

{ For CPU optimization reasons, this implementation assumes that Groups Names are ordered as indicated in the Rate-Based Monitoring (Appl. Inc.) file : Groups Names order must be respected and monitors belonging to a same group shall be joined }

{ If this requirement isn't respected, data sent to the Scan-Tool might be erroneous }

ResultRbmDataByGroup = NEGATIVE_RESPONSE

B.67.8.3 API to clear all Rate-Based Monitoring statistics

General information:

Regulation text :
"Each number shall be reset to zero only when a non-volatile memory reset occurs (e.g., reprogramming event, etc.) or, if the numbers are stored in keep-alive memory (KAM), when KAM is lost due to an interruption in electrical power to the control module (e.g., battery disconnect, etc.). Numbers may not be reset to zero under any other circumstances including when a scan tool command to clear fault codes or reset KAM is received."

The service provided in this paragraph shall be used to clear all the Rate-Based Monitoring statistics after a reprogramming session of ECU software and/or calibration data.

This service shall not be called when a Scan Tool command to clear faults (Mode 04$) is received.

Description:

Syntax : ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)

Parameter(in) : No parameter.

Parameter(out) : ResultClrInfo to inform if RBM statistics are cleared or not

Short Description : This API clear all the Rate-Based Monitoring statistics

Remark : For design and CPU resource reasons, this API shall be called while engine is stopped.

Application conditions:

Initialization : -

Recurrence : -

Activation : at Action call

Deactivation : -

Formula section:

ResultClrInfo = STATISTICS_NOT_CLEARED

CTR_IGK_CYC_RBM = 0

CTR_CDN_OBD_RBM = 0

For m = 0 to (NC_NR_DIAG_RBM –1) **do**

CTR_CDN_RBM[m] = 0

CTR_COMP_RBM[m] = 0

Endfor

ResultClrInfo = STATISTICS_CLEARED

Configuration data:

Input data:

NC_ERR_DTC_REQ_OBD	NC_ERR_DTC_REQ_CUS		

FUNCTION DESCRIPTION:

General information:

Description:

This file defines which DTC number to sent to the communication tool in case of DTC request. To follow specific customer, this file is a template to be fullfilled by project team.

All data in italic are comments.

Caracteristics	Value
DTC number to sent to CARB communication tool	NC_ERR_DTC_REQ_OBD = 0 Example : set this bit to 0 to sent symptom OBD DTC set this bit to 1 to sent global OBD DTC
DTC number to sent to customer communication tool	NC_ERR_DTC_REQ_CUS = 0 Example : set this bit to 0 to sent symptom customer DTC set this bit to 1 to sent global customer DTC

B.69 Diagnosis Trouble Code Management (DTC)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_MEM[NC_NR_ERR_DYN]	V/O/S	0...FH	0...15	1	[-]
Memorized detected symptom of the failure IDX (for the DTC building)					
ERR_SYM_LST[NC_NR_ERR_DYN]	V/O/S	0...FH	0...15	1	[-]
Memorized the last detected symptom of the failure IDX (for the DTC building)					
#IF NLC_TREAT_DIAG_MIS = 0					
SYM_CYL_MEM_MIS_A	V/O/S	0...FFFFH	0...65535	1	[-]
memorized cylinder with misfire A (for the DTC building)					
SYM_CYL_MEM_MIS_B1	V/O/S	0...FFFFH	0...65535	1	[-]
memorized cylinder with misfire B1 (for the DTC building)					
SYM_CYL_MEM_MIS_B4	V/O/S	0...FFFFH	0...65535	1	[-]
memorized cylinder with misfire B4 (for the DTC building)					
SYM_CYL_LST_MIS_A	V/O/S	0...FFFFH	0...65535	1	[-]
Memorized the last cylinder of the misfire A failure (for the DTC building)					
SYM_CYL_LST_MIS_B1	V/O/S	0...FFFFH	0...65535	1	[-]
Memorized the last cylinder of the misfire B1 failure (for the DTC building)					
SYM_CYL_LST_MIS_B4	V/O/S	0...FFFFH	0...65535	1	[-]
Memorized the last cylinder of the misfire B4 failure (for the DTC building)					
#ENDIF					
ERR_DTC[NC_NR_ERR_DYN]	V/O/S	0...FFFFH	0...65535	1	[-]
DTC code stored in memory for failure IDX					

Input data:

ERR_SYM_XX	SYM_CYL_MIS_A	SYM_CYL_MIS_B1	SYM_CYL_MIS_B4
NC_CYL_NR	NLC_TREAT_DIAG_MIS		

Export actions :

ACTION_ERRM_StoreDtc (IN <IDX>)
This action stores the memorized symptom of the first occurrence of the failure IDX to build the DTC
ACTION_ERRM_StoreDtcLst (IN <IDX>)
This action stores the memorized symptom of the last occurrence of the failure IDX to build the DTC
ACTION_ERRM_EraseDtc (IN <IDX>)
This action erases the memorized symptom of the failure IDX

FUNCTION DESCRIPTION:

General information:

Purpose of this module is to catch some data (ERR_SYM_XX) when a failure occurs. Then, these data (ERR_SYM_MEM[IDX] and ERR_SYM_LST_[IDX]) are used to generate a code called DTC upon communication tool request (see Communication interface module). Additionally, for visualization (for communication tool, developpment purposes), a DTC code is stored in memory (ERR_DTC_[IDX]).

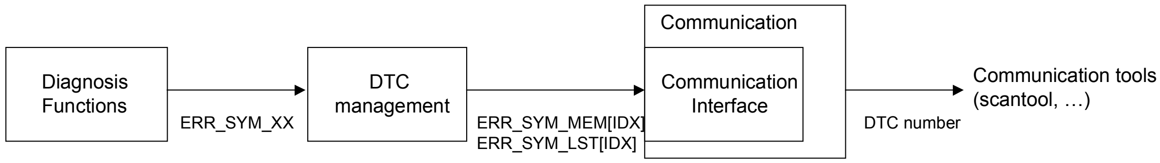
The DTC is a code used to identify the symptom of the failure or the failure (global failure). It is an interface between the diagnosis and the communication.

The customer and/or EOBD/CARB according to the standard J2012 define this DTC.

DTC encoding for regulation EOBD/CARB shall be done using J2012 definition (2 bytes interpreted [0000h to FFFFh] in hex, [P0000 to U3FFF] in J2012).

DTC encoding for customer is free. It can be in decimal, or applying J2012 definition, or any other encoding definition.

Signal flow diagram:



B.69.1 DTC Storage

B.69.1.1 DTC Storage / First occurence

Description:

When the failure IDX gets present (1^{st} occurrence), the detected of the first symptom is stored in the 2^{nd} layer memory by calling the action ACTION_ERRM_StoreDtc (IN<IDX>). Additionally, a DTC code is stored in dynamic memory for visualization :

- related to the symptom DTC if NC_ERR_DTC_CONF = 0
- related to the failure OBD DTC if NC_ERR_DTC_CONF = 1
- related to the customer specific symptom DTC if NC_ERR_DTC_CONF = 2
- related to the customer specific failure DTC if NC_ERR_DTC_CONF = 3

Syntax :	ACTION_ERRM_StoreDtc (IN <IDX>)	
Parameter (in) :	IDX	Index of failure in 2^{nd} layer memory to store the DTC
Parameter (out) :	-	
Short description :	This action stores the memorised symptom of the first occurrence of the failure IDX to build the DTC	

Application conditions:

Initialization: ERR_SYM_MEM[IDX] is restored from the NVMY

SYM_CYL_MEM_MIS_A, SYM_CYL_MEM_MIS_B1 and

SYM_CYL_MEM_MIS_B4 are restored from NVMY

In case of damaged NVMY, ERR_SYM_MEM[IDX] = 0

SYM_CYL_MEM_MIS_A = 0,

SYM_CYL_MEM_MIS_B1 = 0,

SYM_CYL_MEM_MIS_B4 = 0,

ERR_DTC[IDX] = 0

Recurrence: -

Activation: at Action request

Formula section:

```
If    NLC_TREAT_DIAG_MIS = 0

ID_ERR_DTC_XX [NC_NR_DTC_FMT] [i] with XX = F(IDX)

Else (many bit is set in ERR_SYM_LST[IDX])

ERR_DTC[IDX] =

ID_ERR_DTC_XX [NC_NR_DTC_FMT] [5 - NC_NR_DTC_FMT]

with XX = F(IDX)

Endif

Endif

B.69.2 DTC storage for the Misfiring (with NLC_TREAT_DIAG_MIS = 0, Misfire by type)

Description:

As describe above, the cylinder in default is memorised at the first occurrence. In this part each new cylinder in default will be memorised.

Application conditions:

Initialization:	treated above
Recurrence:	For Misfire A, B1 and B4:
	Misfire segment synchronous
Activation:	-

Formula section:

For a misfiring A diagnosis :

SYM_CYL_MEM_MIS_A is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_A

For a misfiring B1 diagnosis :

SYM_CYL_MEM_MIS_B1 is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_B1

For a misfiring B4 diagnosis :

SYM_CYL_MEM_MIS_B4 is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_B4.

B.69.3 DTC deleting

Description:

When the failure IDX is erased from 2nd layer memory, the memorised detected symptom is also erased by calling the action ACTION_ERRM_EraseDtc (IN <IDX>).

Syntax :	ACTION_ERRM_EraseDtc (IN <IDX>)	
Parameter (in) :	IDX	Index of failure in 2nd layer memory to store the DTC
Parameter (out) :	-	
Short description :	This action erases the memorised symptom of the failure IDX	

Application conditions:

Initialization: -

Recurrence: -

Activation: at Action request

Formula section:

If NLC_TREAT_DIAG_MIS = 0

(Misfire are treated by type (LV_ERR_MIS_A, MIS_B1 and MIS_B4 is defined))

Then For a misfiring A diagnosis :

SYM_CYL_MEM_MIS_A = 0

SYM_CYL_LST_MIS_A = 0

ERR_DTC[IDX] = 0

For a misfiring B1 diagnosis :

SYM_CYL_MEM_MIS_B1 = 0

SYM_CYL_LST_MIS_B1 = 0

ERR_DTC[IDX] = 0

For a misfiring B4 diagnosis :

SYM_CYL_MEM_MIS_B4 = 0

SYM_CYL_LST_MIS_B4 = 0

ERR_DTC[IDX] = 0

Endif

For other diagnoses, including misfire diagnoses if treated by cylinder (LV_ERR_MIS_x is defined) :

ERR_SYM_MEM[IDX] = 0

ERR_SYM_LST[IDX] = 0

ERR_DTC[IDX] = 0

B.69.4 Calibratable DTC number

Description:

The DTC numbers are defined by a calibration table called ID_ERR_DTC_XX.

This table defined for each failure XX :

a) with NC_NR_DTC_FMT = 0

- a DTC number for each symptom of the failure XX
- a global OBD DTC number for the failure XX
- a global customer specific DTC number

b) with NC_NR_DTC_FMT = 1

- a OBD DTC number for each symptom of the failure XX
- a global OBD DTC number for the failure XX
- a customer specific DTC number for each symptom of the failure XX
- a global customer specific DTC number

When a DTC is request by a diagnostic tool, the Communication Interface module build up the DTC number with information :

- ERR_SYM_MEM[IDX] and / or ERR_SYM_LST[IDX] stored in 2^{nd} layer memory ;
- Contents of table ID_ERR_DTC_XX .

There is a particular case for misfiring (MIS_A, MIS_B1, MIS_B4) diagnosis. The DTC numbers are defined by cylinder in a calibration table called ID_ERR_DTC_MIS.

(used if NLC_TREAT_DIAG_MIS = 0; Misfire by type)

- ID_ERR_DTC_MIS[0] [i] is the DTC for misfiring detection on the cylinder number i +1
- ID_ERR_DTC_MIS[0] [NC_CYL_NR] is the DTC for multiple misfiring
- ID_ERR_DTC_MIS[0] [NC_CYL_NR +1] is the DTC for random misfiring

- ID_ERR_DTC_MIS[1] [i] is the customer DTC for misfiring detection on the cylinder number i+1
- ID_ERR_DTC_MIS[1] [NC_CYL_NR] is the customer DTC for multiple misfiring
- ID_ERR_DTC_MIS[1] [NC_CYL_NR +1] is the customer DTC for random misfiring

Example 1:

The failure TCO (coolant temperature) is stored in the 2nd layer memory. The calibratable table of DTC has the following value :

a) with NC_NR_DTC_FMT = 0

DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure	Specific customer code
ID_ERR_DTC_ TCO [0] [0] = 0118h (P0118)	ID_ERR_DTC_ TCO [0] [1] = 0117h (P0117)	ID_ERR_DTC_ TCO [0] [2] = 0119h (P0119)	ID_ERR_DTC_ TCO [0] [3] = 0116h (P0116)	ID_ERR_DTC_ TCO [0] [4] = 0115h (P0115)	ID_ERR_DTC_ TCO [0] [5] = 30

b) with NC_NR_DTC_FMT = 1

	DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure
OBD DTC	ID_ERR_DTC_ TCO [0] [0] = 0118h (P0118)	ID_ERR_DTC_ TCO [0] [1] = 0117h (P0117)	ID_ERR_DTC_ TCO [0] [2] = 0119h (P0119)	ID_ERR_DTC_ TCO [0] [3] = 0116h (P0116)	ID_ERR_DTC_ TCO [0] [4] = 0115h (P0115)
Customer DTC	ID_ERR_DTC_ TCO [1] [0] = 31	ID_ERR_DTC_ TCO [1] [1] = 32	ID_ERR_DTC_ TCO [1] [2] = 33	ID_ERR_DTC_ TCO [1] [3] = 34	ID_ERR_DTC_ TCO [1] [4] = 30

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_TCO regards the symptom detected.

Example 2 :

One failure misfiring (LV_ERR_MIS_A, LV_ERR_MIS_B1 or LV_ERR_MIS_B4) is stored in the 2nd layer memory. The application is a NC_CYL_NR -cylinder engine. The calibratable table of DTC has the following value :

	Misfiring on 1st cylinder	Misfiring on 2nd cylinder	Misfiring on 3rd cylinder	Misfiring on 4th cylinder	...	Misfiring on NC_CYL_NR th cylinder	Multiple Misfiring	Random Misfiring
OBD DTC	ID_ERR_ DTC_MIS [0] [0] = 0301h (P0301)	ID_ERR_ DTC_MIS [0] [1] = 0302h (P0302)	ID_ERR_ DTC_MIS [0] [2] = 0303h (P0303)	ID_ERR_ DTC_MIS [0] [3] = 0304h (P0304)	...	ID_ERR_ DTC_MIS [0] [NC_CYL_NR - 1] = 03xxh (P03xx)	ID_ERR_ DTC_MIS [0] [NC_CYL_NR] = 0300h (P0300)	ID_ERR_ DTC_MIS [0] [NC_CYL_NR + 1] = 0300h (P0300)
Customer DTC	ID_ERR_ DTC_MIS [1] [0] = 11	ID_ERR_ DTC_MIS [1] [1] = 12	ID_ERR_ DTC_MIS [1] [2] = 13	ID_ERR_ DTC_MIS [1] [3] = 14	...	ID_ERR_ DTC_MIS [1] [NC_CYL_NR - 1] = 16	ID_ERR_ DTC_MIS [1] [NC_CYL_NR] = 10	ID_ERR_ DTC_MIS [1] [NC_CYL_NR + 1] = 10

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_MIS regards the symptom detected.

Calibration data:

Name	Dim	Hex. Limits	Phys. Limits	Resol.	Unit
ID_ERR_DTC_XX	NC_LDP_1_DTC_TABLE_SIZE * NC_LDP_2_DTC_TABLE_SIZE	0...FFFFH	0...65535	1	[-]

B.70 Diagnosis Trouble Code Management (DTC) (Appl. Inc.)

Input data:

NC_CONF_DTC_COD	NC_CHG_DTC_FMT	NC_TREAT_MIS_DIAG	

FUNCTION DESCRIPTION:

General information:

Description:

This file defines which DTC number to store for visualisation. To follow specific customer requirement and this file is to be fullfilled by project team.

All data initalic are comments.

Caracteristics	Value
DTC number to store for visualisation	NC_CONF_DTC_COD = **0** *Example : set to 0 for storage of symptom DTC* *set to 1 for storage of global DTC* *set to 2 for storage of symptom customer DTC* *set to 3 for storage global customer DTC*
Number of calibratable DTCs	NC_CHG_DTC_FMT = **0** *Example : set to 0 for 6 DTCs* *set to 1 for 10 DTCs* *(6DTCs + symptom customer DTCs)*

Two ways of the treatment of misfire failures are possible within the error management:

- Misfire by type (LV_ERR_MIS_A, MIS_B1 and MIS_B4 is defined)
- Misfire by cylinder (LV_ERR_MIS_x is defined)

Characteristics	Value
Way of treatment of misfire failure	NC_TREAT_MIS_DIAG = **1** *Example : set to 0 to treat Misfire by type* (LV_ERR_MIS_A, LV_ERR_MIS_B1 and MIS_B4 is defined) *set to 1 to treat Misfire by cylinder* *(LV_ERR_MIS_X is defined)*

B.71 History memory

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_ERR_HIS_NR	V/O/S	0...FFH	0...255	1	[-]
Number of failures stored in the history memory					
ERR_HIS_DTC[NC_NR_ERR_HIS]	V/O/S	0...FFFFH	0...65535	1	[-]
DTC of failure in history memory					
ERR_HIS[NC_NR_ERR_HIS][NC_NR_HIS]	O/V/S	0...FFH	0...255	1	[-]
Array for data to be stored in history memory					

Output data detailed description:

ERR_HIS_DTC[NC_NR_ERR_HIS] array counts NC_NR_ERR_HIS elements (1… NC_NR_ERR_HIS).

ERR_HIS[NC_NR_ERR_HIS][NC_NR_HIS] array counts NC_NR_ERR_HIS x NC_NR_HIS elements (1…NC_NR_ERR_HIS, 1… NC_NR_HIS).

Input data:

ERR_HIS_CONF[NC_NR_HIS]	ERR_DTC[NC_NR_ERR_DYN]		

Export actions:

ACTION_ERRM_StoreHistory (IN <IDX>)
This action stores the failure IDX in the history memory

FUNCTION DESCRIPTION:

General information:

This module is called by the dynamic error management module just before erasing a failure in the 2nd layer memory (dynamic memory).

The principle is to copy some data related to this failure in a separate memory, called history memory. So the failure become historic failure.

The number of historic failure is limited to a maximum of NC_NR_ERR_HIS. When this maximum number is reach, new historic failure entry deletes the oldest historic failure in memory (“first in first out” principle).

History memory is defined by :

- ERR_HIS_DTC[x] with : x = index of failure in history memory

  A DTC number related to the failure.

- ERR_HIS[x][y] with : x = index of failure in history memory

  y = index of data stored for failure x in history memory

  Some others data.

Contents of history memory is the same for each failure and defined in History memory (Appl. Inc.) module.

The history memory can be read and erased separately by dedicated diagnosis tool service.

The history memory can be deleted by setting the calibration LC_ERR_FMY_HIS_CLR to 1.

B.71.1 Store a failure in history memory

Description:

Syntax :	ACTION_ERRM_StoreHistory (IN <IDX>)
Parameter (in) :	IDX Index of failure to store in history memory
Parameter(out) :	-
Short description :	This action stores a failure in history memory

Application conditions:

Initialization:	after system initialization the history memory is restored from non-volatile memory or in case of a damaged non volatile memory the history memory is initialized with zero
Recurrence:	-
Activation:	at action request

Formula section:

If CTR_ERR_HIS_NR < NC_NR_ERR_HIS

Then CTR_ERR_HIS_NR = CTR_ERR_HIS_NR + 1

Else ERR_HIS_DTC[x] = ERR_HIS_DTC[x+1] (“first in first out” principle)

ERR_HIS[x][y] = ERR_HIS[x+1][y] (with x = 1...CTR_ERR_HIS_NR–1, y = 1..NC_NR_HIS)

Endif

ERR_HIS_DTC[x] = ERR_DTC[IDX]

ERR_HIS[x][y] = ERR_HIS_CONF[y]

(with x = 1.. NC_NR_HIS, y = CTR_ERR_HIS_NR)

B.71.2 Clear the History Memory

Description:

The history memory can be erased by setting the calibration bit LC_ERR_FMY_HIS_CLR at 1.

Application conditions:

Initialization: after system initialization the history memory is restored from non-volatile memory or in case of a damaged non volatile memory the history memory is initialized with zero

Recurrence: -

Activation: at LC_ERR_FMY_HIS_CLR 0→1 transition

Formula section:

ERR_HIS_DTC[x] = 0

ERR_HIS[x][y] = 0

(with x = 1 ... NC_NR_ERR_HIS

y = 1 ... NC_NR_HIS)

CTR_ERR_HIS_NR = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ERR_FMY_HIS_CLR	1	0...1H	0...1	1	[-]
Calibration to clear the history memory (when set to 1)					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_ERR_HIS	1	0...FFH	0...255	1	[-]
Max number of failure in the historic memory					
NC_NR_HIS	1	0...FFH	0...255	1	[-]
Max number of data (in bytes) to stored for a failure in the historic memory					

B.72 History memory (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_HIS_CONF[NC_NR_HIS]	O	0 ... FFH	0 ... 255	-	-
Contents of history memory					

Input data:

Reference timer value for TIA plausibility diagnosis					
TIA_REF_PLAUS_TIA[NC_SENS_NR_TIA]	-	0...FEH	-48...142.5	0.75	[°C]

Reference TIA value for TIA_DIF_PLAUS_TIA determination

Input data:

TIA_MES[NC_SENS_NR_TIA]	STATE_ENG	LV_IGK
LV_INH_DIAG_PLAUS_TIA[NC_SENS_NR_TIA]	NC_SENS_NR_TIA	VS
ERR_SYM_INTM_TIA[NC_SENS_NR_TIA]	LV_CDN_VB_MIN_DIAG	MAF_KGH
ERR_SYM_DYN_TIA[NC_SENS_NR_TIA]	ERR_SYM_EL_TIA[NC_SENS_NR_TIA]	PQ_CHA[NC_NR_TCHA]

FUNCTION DESCRIPTION:

General information:

Version valid for:

NC_CHRG_CONF <> 0 And NC_EGR_CONF = 0 And NC_TIA_CONF = 10,13

Important:

. Project with TIA sensor only (NC_TAM_CAN_USE = 0):
The aim of this functionnality is to verify the right dynamic [not low/not too high] of a TIA sensor under dedicated driving conditions. This check is the only feasable when an additionnal TAM sensor is not available.

. Project with TIA sensor + TAM sensor via CAN (NC_TAM_CAN_USE = 1):
An additionnal functionnality must be implemented in the SW to detect an offset (temperature shift) on TIA value. This check is verified within "TAM plausibility diagnosis" (Refer to module xxB05xxx).

NC_SENS_NR_TIA has been defined depending on the TIA hardware definition (NC_TIA_CONF value).

The diagnosis detects failures on air intake temperature signal from a dedicated sensor. This diagnosis is necessary as a number of OBD II functionnalities and/or diagnosises are based on air intake temperature value (e.g.: generic TCO plausibility diagnosis)

The intake air temperature is expected to decrease significantly when the vehicule is run at high vehicule speed and intermediate load and limited charge pressure ratio during a sufficient period of time. If this decrease of temperature is too small/big (or if the temperature increases instead) then the symptom “PLAUS_DEC” (“DEC” for “decrease”) is set.
Respectively, the intake air temperature is expected to increase significantly when:
. the vehicule is run at low vehicule speed and low load or
. the vehicule is run in charge mode at high load

and this during a sufficient period of time. If this increase of temperature is too small/big (or if the temperature decreases instead) then the symptom “PLAUS_INC” (“INC” for “increase”) is set.

In engine warm conditions, the two tests are performed successively (test "INC_CHK" --> test "DEC_CHK" --> test "INC_CHK" --> ...etc ...) and the failure counter is incremented each time the symptom “PLAUS_DEC” or “PLAUS_INC” is set.

During the first part of the engine warm up phase, the “temperature increase ” and “temperature decrease” checks are delayed until the dynamic (increase and decrease) of TIA sensor is sufficient (detectable).

Remark: TIA is the main parameter for TCO and TAM plausibility diagnosis. Consequently:
_ TIA plausibility diagnosis has been designed independantely of TCO and TAM.
_ The engine warm up is evaluated by computing an integral of mass air flow (instead of TCO)

B.74 TIA Plausibility Diagnostic (application incidence)

B.74.1 General:

The functionnality described in this module is necessary only if TIA plausibilty diagnosis functionnality is used by the Project.

This specification is a template. It has to be adapted to the specifics needs of each Project.

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_PLAUS_TIA[NC_SENS_NR_TIA]	LV_ERR_DYN_TIA[NC_SENS_NR_TIA]
NC_SENS_NR_TIA	LV_ERR_MAF	LV_ERR_VS	LV_ERR_EL_TIA[NC_SENS_NR_TIA]
LV_ERR_INTM_TIA[NC_SENS_NR_TIA]	LV_ERR_LOAD_PLAUS	LV_ERR_MAF_SCG_OC	LV_ERR_MAF_SCP
CTR_CDN_RBM_PLAUS_TIA_IM_CYL	CTR_COMP_RBM_PLAUS_TIA_IM_CYL	LV_ERR_MAP	LV_ERR_EL_MAP
LV_ERR_VCC_PVS_2	LV_ERR_MAP_PLAUS		

B.74.2 Project specific inhibition conditions:

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_PLAUS_TIA[NC_SENS_NR_TIA]	V/O	0..1H	0..1	1	-
Inhibition condition for TIA plausibility diagnosis					
LV_INH_DIAG_RBM_PLAUS_TIA[NC_SENS_NR_TIA]	V	0...1H	0...1	1	-
TIA plausibility diagnosis inhibition condition for RBM interface definition					

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_PLAUS_TIA allows to deactivate the corresponding diagnostic.

The Formula section must be updated by the Project. The Calibration data list must be completed.

The project can add additionnal conditions if desired.

FUNCTION DESCRIPTION:

Application conditions:

Initialization: **At** Reset: LV_INH_DIAG_PLAUS_TIA = 0

Reccurence: **100 ms**

Activation: always active

Deactivation: -

Formula section:

For m = 1 to NC_SENS_NR_TIA

If LV_ERR_MAF = 0 (el.)
And LV_ERR_MAP = 0 (el.)
And LV_ERR_LOAD_PLAUS = 0 (MAF or MAP plaus.)
And LV_ERR_VS = 0
And LV_ERR_EL_TIA[m] = 0
And LV_ERR_INTM_TIA[m]= 0
And LV_ERR_DYN_TIA[m]= 0
Then LV_INH_DIAG_RBM_PLAUS_TIA[m] = 0
Else LV_INH_DIAG_RBM_PLAUS_TIA[m] = 1
Endif

If LC_INH_DIAG_PLAUS_TIA = 0
And LV_INH_DIAG_RBM_PLAUS_TIA[m] = 0
Then LV_INH_DIAG_PLAUS_TIA[m] = 0
Else LV_INH_DIAG_PLAUS_TIA[m] = 1
Endif

End for m

Configuration for diagnostic symptoms :

Diagnostic	Symptom Description	Symptom	Filter type
PLAUS_TIA_IM_CYL	TIA increase error	SYM_0	*STD_INI*
	TIA decrease error	SYM_1	
		SYM_2	
		SYM_3	

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_ABC_INC_PLAUS_TIA	1	0..FFH	0..255	-	
Antibounce counter increment for TIA plausibility diagnosis					
C_ABC_MAX_PLAUS_TIA	1	1..FFH	1..255	-	
Maximum value for antibounce counter for TIA plausibility diagnosis					
LC_INH_DIAG_PLAUS_TIA	1	0..1H	0..1	-	
Inhibition switch of TIA plausibility diagnosis					

B.74.3 RBM interface:

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
STATE_RBM_PLAUS_TIA[NC_SENS_NR_TIA]	O/V	0 ... FFH	0 ... 255	1	-
Interface of TIA plausibility diagnosis monitor with the Rate-Based Monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_PLAUS_TIA_IM_CYL	V	0 ... FFFFH	0 ... 7,99572	0,000122	-
Actual RBM rate for TIA Plausibility Diagnosis , for application purpose					

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

NC_SENS_NR_TIA has been defined depending on the TIA hardware definition (NC_TIA_CONF value).

The RBM interface has to be defined for the NC_SENS_NR_TIA sensor(s).
(See “Loop For m = 1 to NC_SENS_NR_TIA” below).

With this module the interface between the TIA plausibility monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_PLAUS_TIA[NC_SENS_NR_TIA] data.

Within STATE_RBM_PLAUS_TIA[NC_SENS_NR_TIA], three different informations are defined:

_ Conditions for monitoring are met long enough to detect malfunction (bit 0)

(no intrusive operation, no short trip)

_ Monitor disabled because of system malfunction (bit 1)

(depending on failure status: pending)

_ Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

For m = 1 to NC_SENS_NR_TIA

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_TIA[m] = 0

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_TIA[m] = 0

on failure memory reset :

bit 1 of STATE_RBM_PLAUS_TIA[m] = 0

End for m

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition and LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_VS (Vehicle Speed Sensor “B” Range/Performance - OBD-market)
LV_ERR_LOAD_PLAUS (Mass or Volume Air Flow Circuit Range / Performance)
LV_ERR_MAF_SCG_OC (Mass or Volume Air Flow Circuit Low Input)
LV_ERR_MAF_SCP (Mass or Volume Air Flow Circuit high Input)
LV_ERR_EL_MAP (Manifold air pressure electrical failure)
LV_ERR_MAP_PLAUS
LV_ERR_VCC_PVS_2
LV_ERR_EL_TIA[NC_SENS_NR_TIA]
LV_ERR_INTM_TIA[NC_SENS_NR_TIA]
LV_ERR_DYN_TIA[NC_SENS_NR_TIA]

For m = 1 to NC_SENS_NR_TIA
  If(1) { CPU optimization at LV_DC 0 → 1 transition }
      CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn’t empty }
  Then(1) **While** bit 1 of STATE_RBM_PLAUS_TIA[m] = 0 **do**
      with each TIA plausibility failure of the above list :
      ACTION_ERRM_CheckPendingStatus(IN<XX>,
      OUT<PendingStatus>, SYNCHRONIZATION<CALL>)
      If(2) **XX** has a pending status
      Then(2) bit 1 of STATE_RBM_PLAUS_TIA[m] = 1
      Endif(2)
    Endwhile
  Else(1) { the dynamic failure memory is empty }
    No action
  Endif(1)
End for m

Every 1 s :

For m = 1 to NC_SENS_NR_TIA

  If bit 0 of STATE_RBM_PLAUS_TIA[m] = 0
  Then **If** LV_END_DIAG_PLAUS_TIA[m] = 1
      Then bit 0 of STATE_RBM_PLAUS_TIA[m] = 1
      Endif
  Endif

  If bit 1 of STATE_RBM_PLAUS_TIA[m] = 0
  Then **If** LV_INH_DIAG_RBM_PLAUS_TIA[m] = 1
    { Cross dependency of the monitor defined by the project }
    { List here failures that can inhibit TIA plausibility monitor }

Then bit 1 of STATE_RBM_PLAUS_TIA[m] = 1
Endif
Endif

bit 2 of STATE_RBM_PLAUS_TIA[m] = 1

End for m

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_PLAUS_TIA_IM_CYL = 0
then RATE_RBM_PLAUS_TIA_IM_CYL = FFFFH
else RATE_RBM_PLAUS_TIA_IM_CYL
= (CTR_COMP_RBM_PLAUS_TIA_IM_CYL / CTR_CDN_RBM_PLAUS_TIA_IM_CYL)
endif

FUNCTION DESCRIPTION:

General information:

Version valid for: NC_TAM_CAN_USE = 1 And NC_EGR_CONF = 0

Important:

. Project with TIA sensor only (NC_TAM_CAN_USE = 0):
This diagnosis is not needed

. Project with TIA sensor + TAM sensor via CAN (NC_TAM_CAN_USE = 1):
This diagnosis can detect:

- an offset (temperature shift) on TAM value
- an offset (temperature shift) on TIA value

The result of the diagnosis must be "TAM or TIA unplausible" (1 unique Pcode)

The aim is to check whether the measured ambient temperature signal is plausible or not. This OBDII diagnosis is necessary as the ambient temperature information is used by other OBDII strategies (ex: Evap Syst. Monitoring).

Two checks are considered:

_ "engine cold check":

this test is performed only:

. if cold start conditions are verified and
. if the first TAM_MES_MMV valid value is available
. if the intake air temperature and ambient air temperatures are stable during a predefined period of time [in order to avoid false detection in case of following scenarios: use of an engine block heater / vehicle driven from a warm location to a cold location – and vice versa ...]. Additionally a temperature difference calculation above a vehicle speed threshold (for a calibrateable period of time) avoids error entries caused by warming-up in the sun.

The ambient air temperature is defined as not plausible if the difference between the ambient temperature and the air intake temperature is too high. Intermediate "cold check" symptom "PLAUS_H" is set.
The ambient temperature value is defined as plausible if it is similar to the intake air temperature value (intermediate "cold check" symptom "NO_SYM").

_ "engine hot check":

this test is performed:

. if "engine cold check" was not possible (conditions not met) and
. if the heat quantity stored in the Manifold (high storage occurs during long idle/engine shut off periods, or in high charge mode) has been sufficiently decreased
. if engine warm conditions are verified (nominal values for engine coolant temperature) and
. if the vehicle is run under defined conditions (load, engine speed, vehicle speed, ...) for a sufficient time and
. if intake air temperatures and ambiant temperatures values stability is sufficient

Then the ambient air temperature can be approached by:
TAM_MDL = TIA - offset(mass air flow, engine speed, air and engine temperature)
The ambient air temperature is defined as not plausible if the difference between the ambient temperature TAM_MES_MMV and the modeled ambient air temperature TAM_MDL is too low [respectively too high]. Intermediate "hot check" symptom "PLAUS_L" [respectively "PLAUS_H"] is set.

The ambient temperature value is defined as plausible if TAM_MDL and TAM_MES_MMV values are similar (intermediate “hot check” symptom “NO_SYM”).

Remark: the "hot check" result is available when a same symptom has been detected C_CTR_SYM_PLAUS_TAM_HOT_MAX consecutives times.
(e.g: with C_CTR_SYM_PLAUS_TAM_HOT_MAX = 3: "PLAUS_H" can be set only when this symptom has been detected 3 consecutive times).

_ TAM plausibility error definition:

. if “engine cold check” was possible:

End of diagnosis condition is set
Final error value = result from "cold test"

. if “engine cold check” was not possible and “engine hot check” was possible:

End of diagnosis condition is set
Final error value = result from "hot test"

. if “engine cold check” and “engine hot check” were both not possible:

End of diagnosis condition is not set (diagnosis could not be done within this driving cycle)
Final error value = "NO_SYM"

Signal flow diagram:

Description:

Application conditions:

Initialisation:

At Clear of FMY

LV_CDN_DIAG_PLAUS_TAM = 0
LV_END_DIAG_PLAUS_TAM = 0
ERR_SYM_PLAUS_TAM = NO_SYM
LV_ERR_PLAUS_TAM = 0

T_HEAT_PLAUS_HOT = T_HEAT_PLAUS_HOT_REF = C_T_HEAT_PLAUS_HOT_INI

TIA_PLAUS_TAM_COLD_MIN = TIA_PLAUS_TAM_COLD_MAX
= TIA_PLAUS_TAM_HOT_MIN = TIA_PLAUS_TAM_HOT_MAX
= TAM_MDL_PLAUS_TAM_HOT
= TIA_TMP

TAM_PLAUS_TAM_COLD_MIN = TAM_PLAUS_TAM_COLD_MAX
= TAM_PLAUS_TAM_HOT_MIN = TAM_PLAUS_TAM_HOT_MAX
= TAM_MES_MMV

TEMP_DIF_PLAUS_TAM_REF_CAL_MIN = +95.25°C
TEMP_DIF_PLAUS_TAM_REF_CAL_MAX = -96.00°C

All other variables from Output data list - excepted "specific variable list" (see below) must be initialized to 0H

At *LV_ES = 0 -> 1*

T_VS_DIAG_PLAUS_TAM_COLD = C_T_VS_DIAG_PLAUS_TAM_COLD

At *Reset*

Same initialization variable list/procedure as at "Clear of FMY" (see above) + specific variable list (see below):

Specific variable list:

TAM_MDL_PLAUS_TAM_HOT = TAM_MDL_PLAUS_TAM_HOT_BAS are initialized with:

If there is no previously TAM_MDL_PLAUS_TAM_HOT value saved in the NVMY
Or the EEPROM does not work
Then 20.25°C
Else Min(TAM_MDL_PLAUS_TAM_HOT saved in NVMY; TIA_TMP)
Endif

TAM_MDL_PLAUS_TAM_HOT_DIF = 0

(comment: these 3 variables must not be reseted at "Clear of FMY" otherwise it leads to false detection – due to the filtering on TAM_MDL_PLAUS_TAM_HOT)

T_VS_DIAG_PLAUS_TAM_COLD = C_T_VS_DIAG_PLAUS_TAM_COLD

Recurrence: 100ms *(necessary as OBD2 diag. / even if TAM calc. Rec. = 1s only)*

Activation: CONF_TAM ≠ 0

Deactivation: activation condition not met

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TAM plausibility after start monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_PLAUS_TAM data.

Within STATE_RBM_PLAUS_TAM, three different informations are defined:

_ Conditions for monitoring are met long enough to detect malfunction (bit 0)
(no intrusive operation, no short trip)

_ Monitor disabled because of system malfunction (bit 1)
(depending on failure status: pending)

_ Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_TAM = 0

at LV_DC 0 → 1 transition :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_TAM = 0

on failure memory reset :
bit 1 of STATE_RBM_PLAUS_TAM = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

Input data:

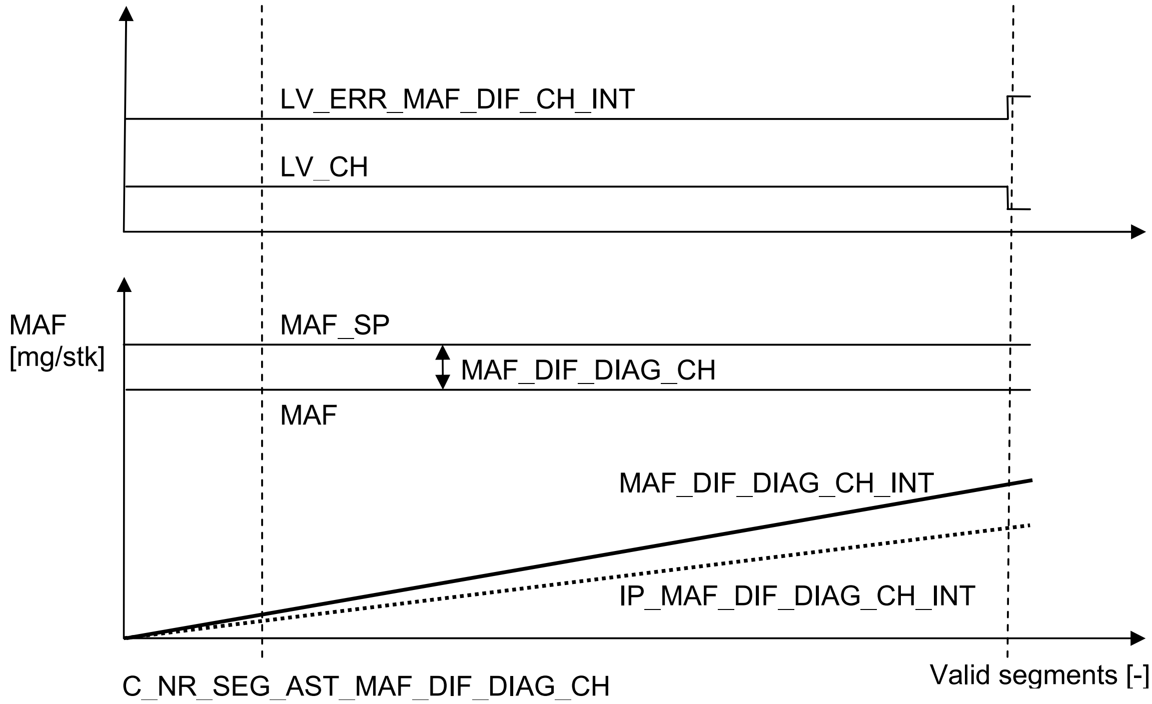
LV_ST_END	LV_CH	LV_INH_DIAG_MAF_DIF_CH_INT	MAF
MAF_SP			

FUNCTION DESCRIPTION:

General information:

This diagnostic function has been developed due to cold start strategy monitoring (CSSM) requirements.

The purpose of this monitoring is to detect MAF_SP – MAF deviations during the catalyst heating phase, as these deviations could lead to a retarded catalyst light off. Positive differences between MAF_SP and MAF are integrated, if the MAF_SP_GRD_DIAG_CH is below the threshold C_MAF_SP_GRD_DIAG_CH for a certain amount of segments C_NR_SEG_CTR_MAF_DIF_DIAG_CH. If NR_SEG_CTR_MAF_DIF_DIAG_CH_2 > C_NR_SEG_AST_MAF_DIF_DIAG_CH, then the integrated value MAF_DIF_DIAG_CH_INT is compared with IP_MAF_DIF_DIAG_CH_INT, but only at the transition LV_CH = 1 → 0. If the value MAF_DIF_DIAG_CH_INT is greater than IP_MAF_DIF_DIAG_CH_INT at the end of the catalyst heating phase, the error LV_ERR_MAF_DIF_CH_INT is detected.



General information:

Within this chapter the monitoring values for the actual diagnostic function are calculated.

Application conditions:

LV_ST_END	LV_ERR_MAF	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_MAP
LV_ERR_TPS	LV_ERR_EL_CPS	FAC_FQ_ST_AD	TI_IS_MMV_MAX

FUNCTION DESCRIPTION:

General information:

The mass air flow deviation monitoring is performed, if the logical value LV_ST_END = 1 and LV_CH = 1. If the engine stalls or one of the conditions for inhibiting the diagnosis is present, it will be stopped and will start again, when conditions above are met.

The diagnosis is finished as soon as the boolean for end of mass air flow monitoring is set to “1”. In this case the boolean for mass air flow monitoring indicates either a faulty (= 1) or a normal (= 0) working air path.

Depending on projects specific requirements, the MAF deviation monitoring can be inhibited by setting LV_INH_DIAG_MAF_DIF_CH_INT = 1.

Application conditions:

Initialisation at reset or LV_ST_END = 0 ->1:

LV_INH_DIAG_MAF_DIF_CH_INT = 0

Recurrence: every segment TDC

Activation: LV_ST_END = 1

FUNCTION DESCRIPTION:

General information:

With this module the interface between the MAF deviation monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_MAF_DIF_CH_INT data.

Within STATE_RBM_MAF_DIF_CH_INT, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (only if catalyst heating is active more than 10s)

Application conditions:

Initialisation:

at ECU reset:

bit 0, bit 1 and bit 2 of STATE_RBM_MAF_DIF_CH_INT = 0

at LV_DC 0 → 1 transition:

bit 0, bit 1 and bit 2 of STATE_RBM_MAF_DIF_CH_INT = 0

on failure memory reset:

bit 1 of STATE_RBM_MAF_DIF_CH_INT = 0

at reset or LV_ST_END = 0 → 1:

T_MAF_DIF_DIAG_CH = 0s

Recurrence: 1s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

For ETC system (NC_ETC_CONF = 1) :

LV_ERR_MAF_SCG_OC	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_MAF_SCP	LV_ERR_TPS_1
LV_ERR_TPS_2	LV_ERR_TPS_MAF_1	LV_ERR_TPS_MAF_2	LV_ERR_TPS_VCC
LV_ERR_TPS_AD	LV_ERR_TPS_AD_SPR	LV_ERR_TPS_ST_CHK	LV_ERR_MTC_DR
LV_ERR_MTC_CTL	LV_ERR_EL_MAP	LV_ERR_MAP_PLAUS	LV_ERR_VCC_PVS_2

For non-ETC-system (NC_ETC_CONF = 0) :

LV_ERR_MAF_SCG_OC	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_MAF_SCP	LV_ERR_TPS_EL
LV_ERR_VCC_TPS	LV_ERR_EL_MAP	LV_ERR_MAP_PLAUS	LV_ERR_VCC_PVS_2

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_MAF_DIF_CH_INT = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_MAF_DIF_CH_INT = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s:

If LV_CH = 1

Then T_MAF_DIF_DIAG_CH$_{(n)}$ = T_MAF_DIF_DIAG_CH$_{(n-1)}$ +1s

Else T_MAF_DIF_DIAG_CH$_{(n)}$ = 0s

Endif

If bit 0 of STATE_RBM_MAF_DIF_CH_INT = 0

Then

If LV_END_DIAG_ MAF_DIF_CH_INT = 1

Then bit 0 of STATE_RBM_MAF_DIF_CH_INT = 1

Endif

Endif

If bit 1 of STATE_RBM_MAF_DIF_CH_INT = 0

Then

If LV_INH_DIAG_MAF_DIF_CH_INT = 1

Then bit 1 of STATE_RBM_MAF_DIF_CH_INT = 1

Endif

Endif

If bit 2 of STATE_RBM_MAF_DIF_CH_INT = 0

Then

If T_MAF_DIF_DIAG_CH >= C_T_MAF_DIF_DIAG_CH

Then bit 2 of STATE_RBM_MAF_DIF_CH_INT = 1

Endif

Endif

B.80.1 Engine Off Timer Runtime Error

Description:

The Diagnosis of the Engine Off Time is realised by comparing the external Engine Off timer value calculated in separate micro controller with an ECU internal timer that counts the time after Ignition key on.
Aditionally it is checked, that T_ES counter is resetted and activated again correct after Engine stop is detected. Therefore the Engine off timer value have to be inside a window after transition from running to stopped engine

Error-symtoms and conditions are defined to this diagnosis function as following:

```
□□□□
│ │ │ └─> -   Engine off timer not resetted or activated   (= SYM_0)
│ │ └───> -   (not used)                                   (= SYM_1)
│ └─────> -   (not used)                                   (= SYM_2)
└───────> -   Engine off timer inaccurate                  (= SYM_3)
```

Application conditions:

Initialisation:

at reset: LV_DET_ERU_ES = 0

at transition LV_ES = 0 --> 1:

T_ES_DEC_CTR = C_T_ES_DEC_CTR

LV_DET_ERU_ES = 1

according filter type: "STD"

Recurrence: 1000ms

Activation:

if	LC_ENA_T_ES_PLAUS_DIAG = 1	*diagnosis is enabled*
and	T_ES_DIAG < FFFFFFH	*engine off time below maximum*
and	C_VB_MIN_T_ES < VB <= C_VB_MAX_T_ES	*VB inside uC Operation range*
and	LV_T_ES_ACT = 1	*Engine off timer already activated*
then	LV_CDN_DIAG_T_ES_PLAUS = 1	*condition for DIAG fulfilled*
else	LV_CDN_DIAG_T_ES_PLAUS = 0	
endif		

Formula Section:

Accuracy check

T_ES_DIF = abs [T_ES_DIAG – T_ES_IGK - T_IGK_ON]

if LV_IGK = 1

and C_T_IGK_ON_MIN < T_IGK_ON < FFFFH

then **if** T_ES_DIF < C_T_DIF_MAX_T_ES_PLAUS + C_FAC_MAX_T_ES_PLAUS * T_IGK_ON

Comparsion between value of external uC ES timer and Main Controller value:
After IGK on, the difference has to be smaller than threshold

then ERR_SYM_T_ES_PLAUS = 0h *(NO_SYM)*

LV_ERR_T_ES_PLAUS = 0

else ERR_SYM_T_ES_PLAUS = 8h *(SYM_3)*

LV_ERR_T_ES_PLAUS = 1 *(without debounce)*

LV_END_DIAG_T_ES_PLAUS = 1

endif

Reset and Activation check:

If LV_DET_ERU_ES = 1
and T_ES_DEC_CTR = 0
then if C_T_ES_DIAG_MAX>= T_ES_DIAG >= C_T_ES_DIAG_MIN
then ERR_SYM_T_ES_PLAUS = 0h *(NO_SYM)*
LV_ERR_T_ES_PLAUS = 0
LV_DET_ERU_ES = 0
LV_END_DIAG_T_ES_PLAUS = 1
else ERR_SYM_T_ES_PLAUS = 1h *(SYM_0)*
LV_ERR_T_ES_PLAUS = 1
LV_DET_ERU_ES = 0
LV_END_DIAG_T_ES_PLAUS = 1
endif
endif

$T\_ES\_DEC\_CTR_n = T\_ES\_DEC\_CTR_{n-1} - 1$

ACTION_ERRM_GetLvEndDiag(IN <XX>, OUT <lv_end_diag_XX>)
This action returns the end-of-diagnosis flag

B.82.1 General information

Stuck close diagnosis:

As long as the RCL EPC is deactivated, the RCL valve is closed (the spring force pushes the membrane). The activation of the RCL valve actuator must lead to a smooth decrease of the pressure upstream throttle (PUT_MES). If it is not verified (strong PUT oscillations noticed), we conclude that the valve remains stuck in closed position).

Stuck open diagnosis:

In part load, the RCL valve is not activated (except in case of necessity of manifold protection from overpressure) and the pressure upstream throttle reaches high values in charger mode.

If the pressure upstream throttle is not sufficient then we conclude that the RCL valve is stuck in fully open position.

This diagnosis can detect an RCL valve stuck in fully open position or any **equivalent** [if C_PUT_MDL_RCL_OPEN_DIF_NEG calibrated with a small value, e.g.: 30hPa] **– or higher** [if C_PUT_MDL_RCL_OPEN_DIF_NEG calibrated with a high value, e.g.: 200hPa] – air leakage between the output of the compressor and upstream the throttle. This leakage could be the consequence of a hose disconnected on the Intake system, a porous intercooler or a wastegate stuck in intermediate or in fully open position.

The result of the diagnosis must be "RCL open **or** Porous Intercooler **or** Hose disconnected **or** Air leakage between the output of the compressor and upstream the throttle" (1 unique Pcode).

Error-symptoms are defined to the "stuck-close" or "stuck open" diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> SYM_0: stuck close /stuck open
 │ │ └───> SYM_1
 │ └─────> SYM_2
 └───────> SYM_3
```

The error-management variables are initialized according to filter-type.

STUCK_CLOSE_DIAG: Diagnosis and setting of error symptom

If ERR_SYM_PLAUS_CLOSE_RCL = 0, the RCL valve opens correctly; PUT_RCL_INT is always < PUT_RCL_INT_THD_OPEN in this case because of LV_CDN_DIAG_PLAUS_CLOSE_RCL definition. In case of PUT_RCL_INT_THD_OPEN < PUT_RCL_INT < PUT_RCL_INT_THD_CLOSE the position of the valve cannot be distinguished between closed and open and LV_CDN_DIAG_PLAUS_CLOSE_RCL = 0.

Calibration to clear permanent failure memory (at 0->1 transition)					

FUNCTION DESCRIPTION:

General information:

Any DTC that is commanding MIL on must be logged as a permanent fault code in non-volatile memory. A Permanent DTC can only be erased by the vehicle's OBD II system.

Vehicle owners and technicians would not be able to clear or erase permanent fault codes by any generic or manufacturer specific scan tool command (or by disconnecting the battery). Instead, these fault codes would only be allowed to be self-cleared by the OBD II system itself (ERRM), once the monitor responsible for setting that fault code has run enough times to confirm that the fault was no longer present.

The permanent fault code is set as soon as the failure gets the confirmed status (MIL is switched on).
The permanent fault code is erased after self-healing of the failure, when the MIL goes off. Subsequent to a clearing of the failure memory (e.g. Mode $04), the permanent fault code is erased if the diagnostic that caused the permanent fault code to be stored has been fully executed and determined the malfunction is no longer present.

A minimum of four permanent fault codes shall be retained by by the OBD II system (ERRM). But the permanent failure memory may be adjusted over the four elements size thanks to NC_NR_ERR_PERM configuration data.
Permanent fault codes may not be erased when ECU is reprogrammed unless the readiness status for all monitored components is set to "not complete" in conjunction with the reprogramming event.

The permanent failure memory structure is defined as follow:

Index: IDX_PERM $\in$ [1...NC_NR_ERR_PERM]

- Permanent fault index ERR_PERM[IDX_PERM]
- Permanent fault code LV_ERR_PERM[IDX_PERM]
- Failure is only permanent due ERRM data clearing LV_ERR_CLR[IDX_PERM]
- Permanent Fault symptom ERR_SYM_PERM[IDX_PERM]
- Permanent memorized cylinder with misfire A, B1, B4 SYM_CYL_PERM_XX

B.83.1 Permanent failure memory

FUNCTION DESCRIPTION:

General information:

The permanent failure memory is a data structure containing NC_NR_ERR_PERM elements. Permanent faults codes are stored there, with a chronological order, but the clearing is done randomly, because it is based on the natural failure healing. When the data structure is full, no additional permanent fault code can be entered, until an empty space is freed within the structure.
The permanent failure memory must retain at least four permanent faults codes.

Application conditions:

Initialisation: *at NVMINI system event*

CTR_ERR_PERM_NR = 0

For IDX_PERM = 1 to NC_NR_ERR_PERM

ERR_PERM[IDX_PERM] = 0

LV_ERR_CLR[IDX_PERM] = 0

B.83.4 Impact of error management data clearing inside permanent memory

Description for actions:

ACTION_ERRM_*ClcPermanentIniErrm* ( )					
This action is called when all error management data is cleared (e.g. Mode $04 executed by scan tool). After an overall data clearing of error management data, permanent errors are marked in order to allow a self clearing at the end of next driving cycle, if the following conditiong are gathered: - diagnosis has run long enough to detect a possible malfunction - malfunction not present					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
No parameter					

Formula section:

For IDX_PERM = 1 to NC_NR_ERR_PERM

If(1) LV_ERR_PERM[IDX_PERM] = 1

Then(1)

(A permanent fault code is stored at IDX_PERM position)

LV_ERR_CLR[IDX_PERM] = 1

Else(1)

(No permanent fault code stored as from position IDX_PERM until end)

Exit

Endif(1)

Endfor

B.83.5 Impact of failure clearing (with diagnostic tool) inside permanent memory

Description for actions:

ACTION_ERRM_*ClcPermanentByErr* (< PRM_IDX_ERR >)					
This action is called when one unique failure is cleared by a diagnostic tool. After clearing of any individual failure, the related permanent code is marked to allow a self clearing at the end of next driving cycle, if the following conditiong are gathered: - diagnosis has run long enough to detect a possible malfunction - malfunction not present					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_IDX_ERR	IN	0...FFFFH	0...65535	1	[-]
Failure index					

Formula section:

For IDX_PERM = 1 to NC_NR_ERR_PERM

B.83.7 Get failure permanent status

Description for actions:

ACTION_ERRM_*GetErrPerm* (<PRM_IDX_ERR>, <PRM_LV_ERR_PERM>)					
This action is called to know if a given failure has a permanent code stored or not.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_IDX_ERR	IN	0...FFFFH	0...65535	1	[-]
Failure index					
PRM_LV_ERR_PERM	OUT	0...1H	0...1	1	[-]
Permanent status					

Formula section:

For IDX_PERM = 1 to NC_NR_ERR_PERM

If(1) ERR_PERM[IDX_PERM] = PRM_IDX_ERR

Then(1)

PRM_LV_ERR_PERM = 1

Exit

Else(2)

PRM_LV_ERR_PERM = 0

Endif(1)

Endfor

B.83.8 Clearing of permanent failure memory, in development

FUNCTION DESCRIPTION:

Description:

For development conveniences, it is often useful to reinitialise the permanent failure memory. This is possible by setting the calibration bit LC_ERR_PERM_CLR to 1.

Application conditions:

Initialisation: *at RST system event*

LV_ERR_PERM_CLR_OLD = LC_ERR_PERM_CLR

at IGKON system event

LV_ERR_PERM_CLR_OLD = LC_ERR_PERM_CLR

Recurrence: 1 s

Activation: Always

Formula section:

(Detection of LC_ERR_PERM_CLR 0 → 1 transition)

```
If    (LV_ERR_PERM_CLR_OLD = 0
      and
      LC_ERR_PERM_CLR = 1)
Then
      For IDX_PERM = 1 to NC_NR_ERR_PERM
            ERR_PERM[IDX_PERM] = 0
            LV_ERR_CLR[IDX_PERM] = 0
            LV_ERR_PERM[IDX_PERM] = 0
            ERR_SYM_PERM[IDX_PERM] = 0 (NO_SYM)
      Endfor
      If NLC_TREAT_DIAG_MIS = 0
      Then
            (XX stands for MIS_A, MIS_B1, and MIS_B4)
            SYM_CYL_PERM_XX = 0
      Endif
      CTR_ERR_PERM_NR = 0
Endif
LV_ERR_PERM_CLR_OLD = LC_ERR_PERM_CLR
```

Minimal engine speed to limit MAF_SP with MAF_MAX_COR					
LC_MAF_SP_MAN	1	0...1H	0...1	1	-
Logical variable for MAF setpoint manual					

C.1.1 INSY_ISPCLLOAD0

For a MPI configuration the value of the MAF setpoint is equal to MAF_SP_TOI.

There is a switch that allows to set a manual value of MAF_SP and no calculation of MAF_SP will be done.

The output values are MAF_SP, MAF_KGH_SP and MAP_SP. The last two are input values into inverse air path for throttle setpoint calculation.

Depending on MAF_SP by multiplication with engine speed N and the scaling factor NC_MAF_FAC_CYL (= 8333.3 stroke*kg*min/mg/h for a four cylinder engine) the setpoint MAF_KGH_SP is calculated.

For the desired cylinder charge in kg/h it is possible to calculate for the actual engine speed the manifold air pressure MAP_SP necessary to relize this air mass flow.

Function Description

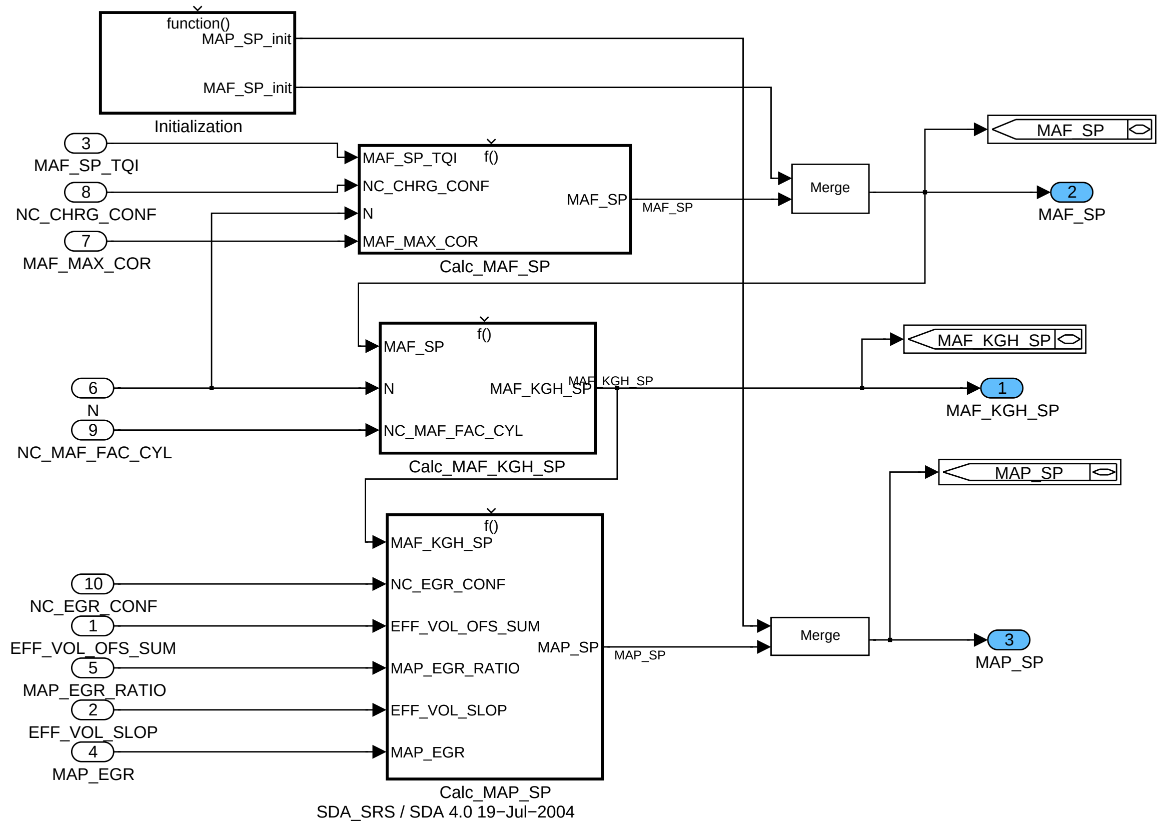

Figure 1 INSY_ISPCLLOAD0

C.1.1.1 Calculation of MAF_KGH_SP

MAF_KGH_SP is the desired air mass flow in kg/h which satisfy the adjusted torque.

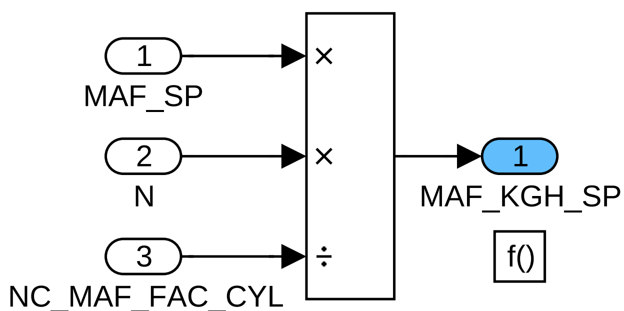

Figure 2 INSY_ISPCLLOAD0/ Calc_MAF_KGH_SP

C.1.1.2 Calculation of MAF_SP

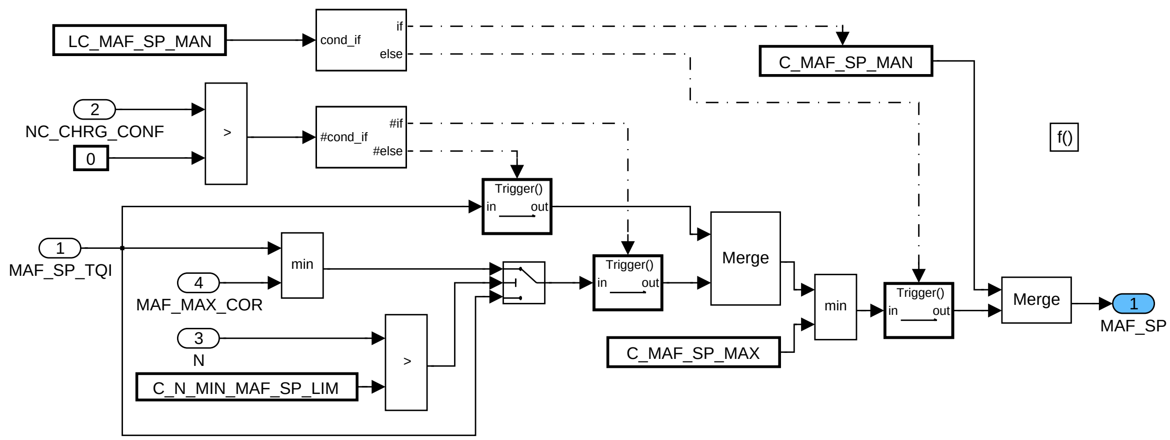

Figure 3 INSY_ISPCLLOAD0/ Calc_MAF_SP

C.1.1.3 Calculation of air flow function rate MAP_SP

For a certain engine speed the mass flow into the intake manifold is corresponding with a certain manifold pressure under steady state engine operating.

There is linear correlation between the setpoint of manifold pressure MAP_SP and the mass flow. The two interpolation tables are the same as in the intake manifold model (function: volumetric efficiency)

In case the intake pressure is not equal to zero the calculation of the setpoint of the pressure considers this intake pressure.

FUNCTION DESCRIPTION:

General information:

With the setpoint of the manifold pressure and the ambient pressure it is possible to calculate the opening of the throttle TPS_SP.

This modul will generate 2 calibratable data LC_AR_RED_FIL_ENA and LC_TPS_FIL_ENA to switch ON/OFF the filters.

Application conditions:

Initialisation: At Reset and LV_IGK = 0 -> 1

LV_MAP_SP_THR =0
TPS_SP_MDL = 0 °TPS
OPG_SP_MDL_ISA =0 (never changed)

(Calculation of throttle values PSI setpoint for C_PQ_MAX)
PSI_SP_TPS_PQ_SP_MAX = ID_MAF_FAC_OFS (C_PQ_SP_MAX)
- ID_MAF_FAC_SLOP (C_PQ_SP_MAX)* C_PQ_SP_MAX

Recurrence: 10 ms

Activation: at every engine operation state

Deactivation: -

Remark: **if** LC_TPS_SP_MAN_ENA = 1 **then**
"Only capitel1.1 will be realize"
else "go directly to1.2 till 1.4"
endif

C.2.1 Final throttle position setpoint value

If the flag LC_TPS_SP_MAN_ENA is set, the throttle position setpoint will always be the calibratable value IP_TPS_SP_MAN. If the flag is unset, the calculated TPS_SP_MDL will be realized.

If LC_TPS_SP_MAN_ENA = 1
And LV_PL = 1
Then TPS_SP_MDL = IP_TPS_SP_MAN(N_32,PV_AV)
Endif

C.2.2 Calculation of the air flow function rate PSI_SP

With the setpoint of the manifold pressure MAP_SP and the pressure upstream throttle PUT it is possible to calculate an approximation value of the air flow function rate PSI_SP. Before the pressure ratio PQ_SP (= MAP_SP / PUT_IVS) is need. For the calculation of the pressure upstream the throttle PUT_IVS the I-value of the ambient controller, delayed with a first order time delay, is included in the inverse model. PQ_SP is limited to a calibratable threshold C_PQ_SP_MAX.

If LC_TCHA_CONF =0
Then *(non turbo charger)*
PUT_IVS = PUT_MDL_DIF_I_MMV + AMP - IP_PRS_LOSS_AIC
(MAF_KGH_SP, VS)
PQ_SP_1= MAP_SP / PUT_IVS
(The input of the table IP_PRS_LOSS_AIC is the airflow MAF_KGH_SP and the vehicle speed VS. The table is identical with the table of the pressure decrease in the air cleaner.)
Else *(turbo charger)*
If LC_PUT_IVS_PUT_PRED = 1
Then PUT_IVS = PUT_MDL_DIF_I_MMV + PUT_PRED

Else PUT_IVS = PUT_MDL_DIF_I_MMV + PUT

Endif

The pressure quotient setpoint PQ_SP is kept equal to 1 as MAP_SP is bigger than the basic charge air pressure PUT_WG_OPEN minus a calibratable offset IP_PPUT_ DIF_PQ_SP_1 or when MAP_SP is decreasing till the threshold minus the hysteresis in the MAP_SP (this hysteresis drop shouldn´t allow that the throttle closes, it muss keep fully open). This threshold means the pressure up the throttle at steady engine operation with fully open wastegate (turbo charge idle speed).It depends on the engine speed and on the ambient pressure (altitude influence).

PRS_THD_PQ_SP = PUT_WG_OPEN + IP_PUT_ DIF_PQ_SP_1 (N_32, AMP)

If ((MAP_SP >PRS_THD_PQ_SP) or (MAP_SP >PRS_THD_PQ_SP – C_MAP_SP_HYS_CHRG **And** LV_MAP_SP_THR = 1))

Then PQ_SP_1 = 0.999985

LV_MAP_SP_THR =1

Else PQ_SP_1 = MAP_SP / PUT_IVS

LV_MAP_SP_THR =0

Endif

Endif

The flag LV_MAP_SP_THR defines if the MAP_SP has once exceed the corresponding threshold and keeps at least over the threshold minus the hysteresis value.

If LC_TPS_FIL_ENA = 1

Then PQ_SP = MIN (C_PQ_SP_MAX, PQ_SP_1)

Else PQ_SP = PQ_SP_1

Endif

In the INSY-controller a factor is introduced which reduce the I-part of the controller at fast load changes. To detect fast load changes the difference between the last and the current filtered PQ_SP is built.

$$PQ\_SP\_LPF\_AR\_RED\_PUT = PQ\_SP\_LPF\_AR\_RED\_PUT_{(n-1)} + IP\_CRLC\_PQ\_SP\_AR\_RED\_PUT * (PQ\_SP - PQ\_SP\_LPF\_AR\_RED\_PUT_{(n-1)})$$

$$PQ\_SP\_GRD\_AR\_RED\_PUT = PQ\_SP\_LPF\_AR\_RED\_PUT – PQ\_SP\_LPF\_AR\_RED\_PUT_{(n-1)}$$

The input of the two tables ID_MAF_FAC_SLOP and ID_MAF_FAC_OFS is the pressure ratio PQ_SP. The tables are idential with the tables of the intake manifold model (function: estimation of the pressure quotients).

PSI_SP = ID_MAF_FAC_OFS (PQ_SP) - ID_MAF_FAC_SLOP (PQ_SP)* PQ_SP

C.2.3 Calculation of the basic throttle position setpoint TPS_SP_1_BAS

With the corrected air mass flow demand MAF_KGH_SP it is possible to calculate the necessary reduced area at the throttle.

To reduce a trembling throttle a smoothing function for wide open throttle conditions is found. If the setpoint of the pressure quotient PQ_SP is close to 1, the setpoint of the reduced throttle area AR_RED_SP_1 is delayed with a first order time delay. Otherwise in fact of the negative infinite slope of the psi function the jitter of the throttle can not avoid. In this way a moving mean setpoint AR_RED_SP_MMV_1 are calculated.

The setpoint for MAF_THR has to decrease with FLOW_CPS, the air coming from canister purge valve.

AR_RED_SP_1=(MAF_KGH_SP – FLOW_CPS) / (PSI_SP * MAF_MDL_CON_1* PUT_IVS)

(Caclulation AR_RED_SP_PQ_MAX at C_PQ_MAX for charger TPSTransition Control)

AR_RED_SP_PQ_MAX_1 = (MAF_KGH_SP – FLOW_CPS)
/ (PSI_SP_TPS_PQ_SP_MAX * MAF_MDL_CON_1* PUT_IVS)

If LC_AR_RED_FIL_ENA = 1 **then**

PQ_SP_MIN = MIN(PQ, PQ_SP)

CRLC_AR_RED_SP = IP_CRLC_AR_RED_SP(PQ_SP_MIN)

$AR\_RED\_SP\_MMV\_1_{N} = AR\_RED\_SP\_MMV\_1_{N-1} * (1 - CRLC\_AR\_RED\_SP) + AR\_RED\_SP\_1_{N} * CRLC\_AR\_RED\_SP$

(Caclulation AR_RED_SP_PQ_MAX at C_PQ_MAX for charger TPSTransition Control)

$AR\_RED\_SP\_PQ\_MAX\_MMV\_1_{N} = AR\_RED\_SP\_PQ\_MAX\_MMV\_1_{N-1} * (1 - CRLC\_AR\_RED\_SP) + AR\_RED\_SP\_PQ\_MAX\_1_{N} * CRLC\_AR\_RED\_SP$

Else

$AR\_RED\_SP\_MMV\_1_{N} = AR\_RED\_SP\_1_{N}$

(Caclulation AR_RED_SP_PQ_MAX at C_PQ_MAX for charger TPS Transition Control)

$AR\_RED\_SP\_PQ\_MAX\ MMV\_1_{N} = AR\_RED\_SP\_PQ\_MAX\ \_1_{N}$

Endif

For the correction of steady state model errors the additive and multiplicative adaptation corrections AR_RED_AD_ADD and AR_RED_AD_FAC_COR and the relative I-value AR_RED_DIF_I_REL of the area reduced controller are included in the inverse model. AR_RED_DIF_I_REL is delayed with a first order time delay.

AR_RED_SP_MMV = [(AR_RED_SP_MMV_1 – AR_RED_AD_ADD) /
(1 + AR_RED_AD_FAC_COR + AR_RED_DIF_I_REL_MMV)]
* (1 / FAC_AR_RED_MAF)

(Caclulation AR_RED_SP_PQ_MAX at C_PQ_MAX for charger TPS Transition Control)

AR_RED_SP_PQ_MAX_MMV =
[(AR_RED_SP_PQ_MAX_MMV_1 – AR_RED_AD_ADD) /
(1 + AR_RED_AD_FAC_COR + AR_RED_DIF_I_REL_MMV)]
* (1 / FAC_AR_RED_MAF)

With the setpoint of the reduced area at the throttle the basic throttle position setpoint is determined. The interpolation table exists already in the intake manifold model. (Caclulation AR_RED_SP_PQ_MAX at C_PQ_MAX for charger TPS Transition Control)

If LV_AT= 1 **then**

TPS_SP_MDL_BAS = IP_TPS_SP_MDL_BAS_AT (AR_RED_SP_MMV)

(Throttle Setpoint required to give PQ = C_PQ_SP_MAX)

TPS_SP_PQ_MAX = IP_TPS_SP_MDL_BAS_AT(AR_RED_SP_PQ_MAX_MMV)

Else

TPS_SP_MDL_BAS = IP_TPS_SP_MDL_BAS_MT (AR_RED_SP_MMV)

TPS_SP_PQ_MAX = IP_TPS_SP_MDL_BAS_MT(AR_RED_SP_PQ_MAX_MMV)

Endif

MAF_SP_RATIO = Min(MAF_SP / MAF_MAX_COR , IP_MAF_SP_RATIO_MAX (N_32, PV_AV))

Remark :
If LV_CRU_ACT = 1, PV_CRU is used for MAF_SP_RATIO instead of PV_AV

The maximum value for the throttle position setpoint is depending on the engine speed N_32 and the setpoint of the mass air flow MAF_SP. This value can not be exceeded.

<u>In case of charger configuration</u> at ignition key off (LV_IGK = 0) and the Engine speed is below the calibratable threshold C_TPS_CLOSE_N_THD, the throttle position is limited to the calibratable value C_TPS_SP_IGK_OFF.

If LC_TCHA_CONF = 0

Then *(non turbo charger)*

If LV_AT = 0

Then TPS_SP_MDL_MAX
= Max(IP_TPS_SP_MDL_MAX_PV_MT(N_32,PV_AV),TPS_SP_MDL_BAS))

Else TPS_SP_MDL_MAX
= Max(IP_TPS_SP_MDL_MAX_PV_AT(N_32,PV_AV),TPS_SP_MDL_BAS))

Endif

Remark :
If LV_CRU_ACT = 1, PV_CRU is used for TPS_SP_MDL_MAX_PV_AT/MT calculation instead of PV_AV.

Else *(turbo charger)*

If LV_IGK = 1 **Or** N_32 > C_TPS_CLOSE_N_THD

Then TPS_SP_MDL_MAX = IP_TPS_SP_MDL_MAX(N_32, MAF_SP)

Else TPS_SP_MDL_MAX = C_TPS_SP_IGK_OFF

Endif

Endif

As long as MAF_SP_RATIO exceeds the threshold C_PQ_SP_MAX, the basic throttle position setpoint TPS_SP_MDL_BAS_COR is calculated as a linear function of the ratio of MAF_SP and MAF_MAX_COR. In this way it is possible to get a full open throttle position depending on the mass air flow setpoint.
During this time the threshold C_PQ_SP_MAX is needed as the correlation point of MAF_SP_RATIO. The basic throttle position setpoint TPS_SP_MDL_BAS is calculated with PQ_SP, which also is limited by C_PQ_SP_MAX.
As soon as MAF_SP_RATIO < C_PQ_SP_MAX the value TPS_SP_MDL_BAS is updated with the actual values.

For charged engines with LC_TPS_SP_MDL_PI_CTL = 1 a TPS-transition function can be activated to improve the throttle control at transition from PQ_SP = C_PQ_SP_MAX to natural boost using a PI controller to match MAP to MAP_SP.

If (LC_TPS_SP_MDL_PI_CTL = 0) *(Old Transition Function Active)*

If (LC_TPS_FIL_ENA = 1) **and** (MAF_SP_RATIO >= C_PQ_SP_MAX)

Then

TPS_SP_MDL_BAS_COR = TPS_SP_MDL_BAS +

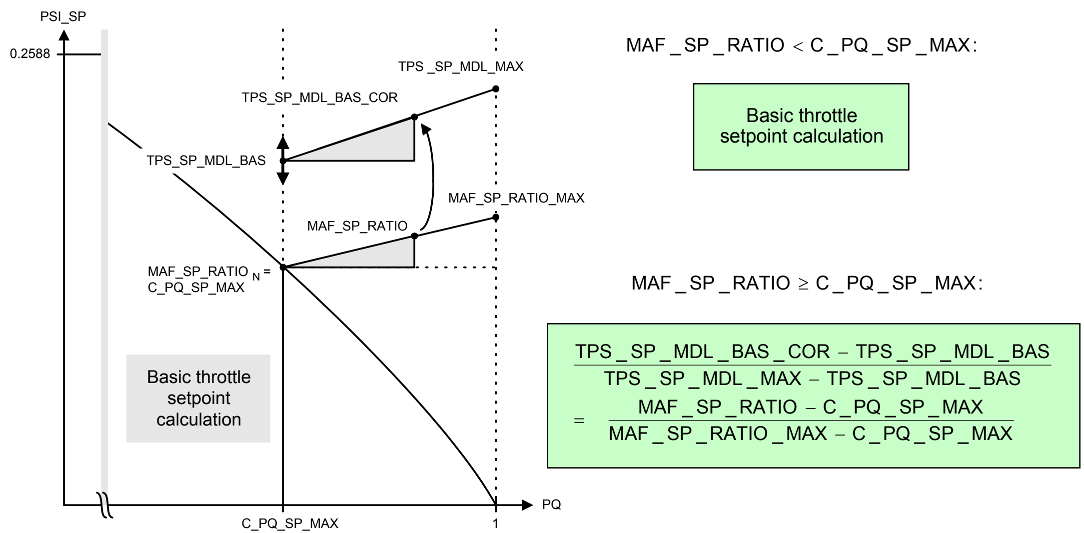
((MAF_SP_RATIO - C_PQ_SP_MAX)/
(1 - C_PQ_SP_MAX))*
(TPS_SP_MDL_MAX - TPS_SP_MDL_BAS)

If $TPS\_SP\_MDL\_BAS\_COR_n > TPS\_SP\_MDL\_BAS\_COR\_FIL_{n-1}$

Then $TPS\_SP\_MDL\_BAS\_COR\_FIL_n = TPS\_SP\_MDL\_BAS\_COR_n$

Else $TPS\_SP\_MDL\_BAS\_COR\_FIL_n$
$= TPS\_SP\_MDL\_BAS\_COR\_FIL_{n-1} + (TPS\_SP\_MDL\_BAS\_COR_n -$
$TPS\_SP\_MDL\_BAS\_COR\_FIL_{n-1}) * C\_CRLC\_TPS\_SP\_MDL\_BAS\_COR$

Else TPS_SP_MDL_BAS_COR_FIL = TPS_SP_MDL_BAS



$$\frac{TPS\_SP\_MDL\_BAS\_COR - TPS\_SP\_MDL\_BAS}{TPS\_SP\_MDL\_MAX - TPS\_SP\_MDL\_BAS} = \frac{MAF\_SP\_RATIO - C\_PQ\_SP\_MAX}{MAF\_SP\_RATIO\_MAX - C\_PQ\_SP\_MAX}$$

C.2.4 **Else** *(New Transition controller function activated)*

If PQ_SP > C_PQ_SP_MAX *(Transition controller becomes active)*

Then

TPS_SP_MDL_MIN_TMP = MIN (TPS_SP_PQ_MAX , TPS_SP_MDL_BAS)

IF LV_MAP_SP_THR = 1 *(Flag for fully boosted operation, so force throttle open using an artificial control difference)*

Then

MAP_DIF_TPS_SP_CTL = C_MAP_DIF_TPS_SP_MAX_OPEN

Else

(control difference for transition controller)

MAP_DIF_TPS_SP_CTL = MAP_SP – MAP

End

(Calculate transition controller terms)

TPS_SP_MDL_P_CTL = IP_P_CTL_TPS_SP_MDL (N , MAP_DIF_TPS_SP_CTL) * MAP_DIF_TPS_SP_CTL

TPS_SP_MDL_I_CTL_TMP =

IP_I_CTL_TPS_SP_MDL(N, MAP_DIF_SP_TPS_CTL) * MAP_DIF_TPS_SP_CTL) + TPS_SP_MDL_I_CTL(n-1)

(Anti windup logic for I Controller Term)

If (TPS_SP_MDL_MIN_TMP + TPS_SP_MDL_P_CTL + TPS_SP_MDL_I_CTL_TMP) > TPS_SP_MDL_MAX

Then

TPS_SP_MDL_I_CTL = TPS_SP_MDL_I_CTL (n-1)

Else

TPS_SP_MDL_I_CTL = TPS_SP_MDL_I_CTL_TMP

End if

(final throttle postion, before MAX limitation, TPS_SP_MDL_BAS_COR_FIL used as temporary variable)

TPS_SP_MDL_BAS_COR_FIL= TPS_SP_MDL_MIN_TMP + TPS_SP_MDL_P_CTL +TPS_SP_MDL_I_CTL

Index tables ID_MAF_FAC_OFS and ID_MAF_FAC_SLOP are defined in module “ intake manifold model”.

Interpolation table IP_PRS_LOSS_AIC is defined in module “Pressure decrease through the air cleaner”.

C.3 Throttle setpoint calculation at start

Output data:

Name	Mode	Hex. limits	Phys. Limit	Resol.	Unit
TPS_SP_ST	O/V	0...3FFFH	0...119.5	0.0073	°TPS
TPS setpoint at start					
TPS_REL_ST	V	0...FFFFH	0...100	0.0015	%
relative TPS setpoint at start					

Input data:

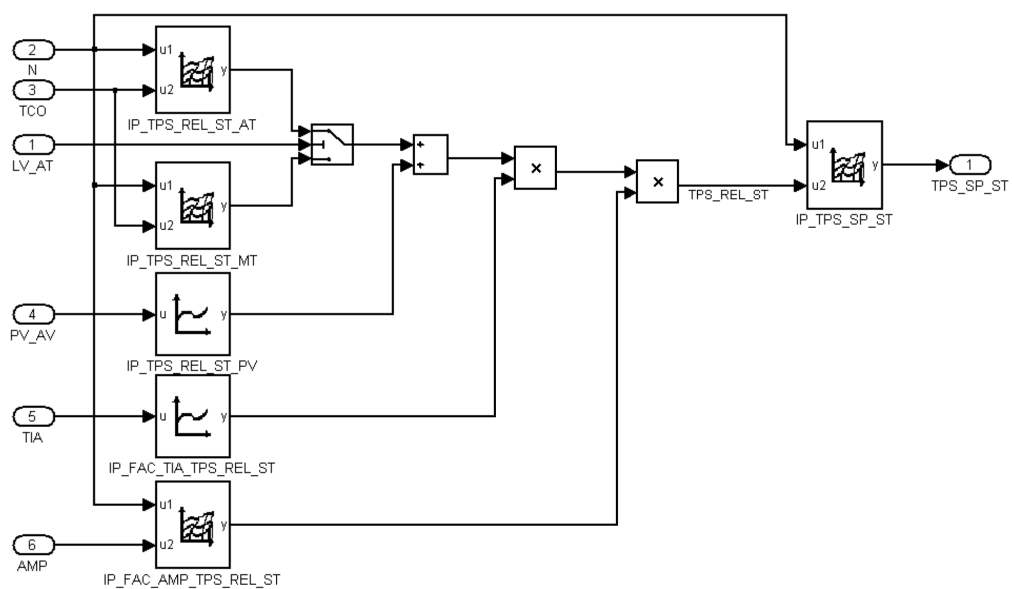
LV_AT	N	TCO	PV_AV
TIA	AMP	LV_ST	

FUNCTION DESCRIPTION:

General information:

During start a separate TPS setpoint at start is calculated. There are two basic maps (dependent on N and TCO) for manual and automatic transmission, which deliver the percentage of the opening of the throttle. This basic value is corrected by an offset dependent on the pedal value and factors dependent on intake air temperature TIA and ambient pressure AMP. The applied TPS setpoint is determined by a map dependent on the percentage and the engine speed N. This map can be used to correct the non linear behavior of the throttle (reduced area) or the behavior of the complete intake manifold.

Signal flow diagram:



Application conditions:

Initialisation: TPS_SP_ST = 0

Recurrence: 10 ms

Activation: LV_ST = 1

Formula section:

If LV_AT = 1 **then**

LV_TPS_SP_LIH	LV_TPS_PWL	LV_TPS_AD_ACT	LV_TPS_SP_EXT_ADJ
LV_ST	LV_ES	LV_PL	TCO
N			

FUNCTION DESCRIPTION:

This module describes the calculation of the throttle position setpoint TPS_SP which is used as an input variable in the module "ETC Position Controller".

The module consists of two blocks (see figure 1): In a first step the setpoint is selected depending on the engine state, in a second step the selected value is limited. This limitation acts as protection so that the throttle blade does not hit the mechanical limits with too high energy. Otherwise the throttle body could be damaged.

The setpoint before limitation TPS_SP_SEL is selected from the following variables:

- Throttle position setpoint when the position controller is switched off: TPS_LIH
- Throttle position setpoint during the post operating phase: TPS_SP_PWL
- Throttle position setpoint during adaptation: TPS_SP_AD
- Throttle position setpoint in case of external activation: TPS_SP_EXT_ADJ
- Throttle position setpoint at start: TPS_SP_ST
- Throttle position setpoint for engine stopped: TPS_SP_ES
- Basic throttle position setpoint TPS_SP_MDL, output of the inverse intake manifold model

From TPS_SP_SEL the final setpoint TPS_SP is generated by means of a limitation function which is including a limitation by absolute values.

The setpoint is determined every 10 ms, except during adaptation (5 ms).

Sign al flow diagram:

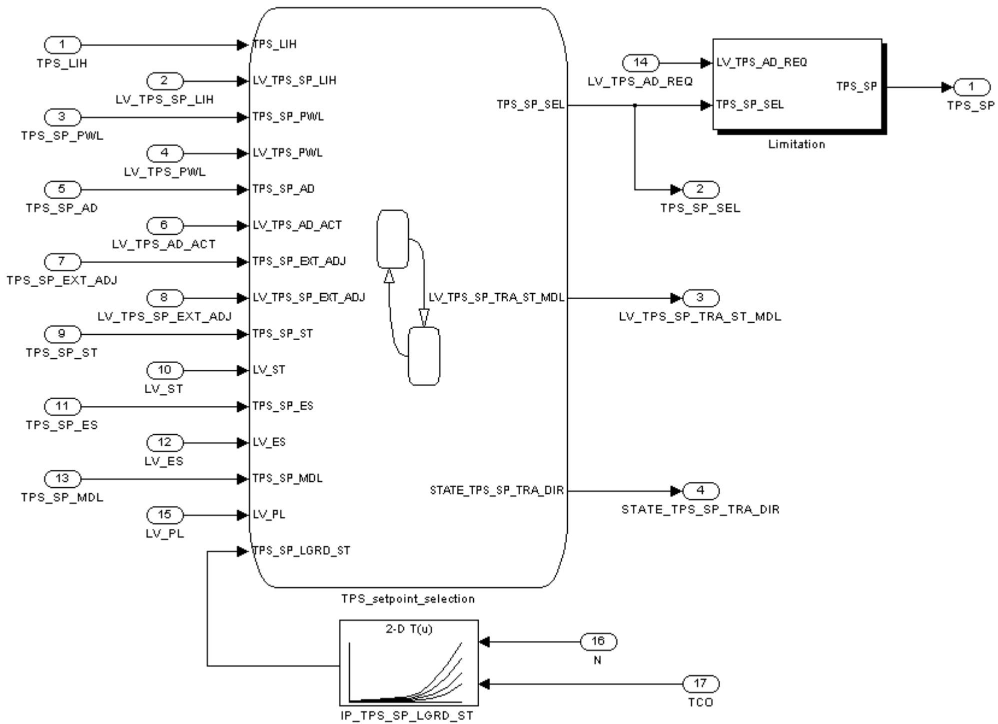

Figure 6: Throttle position setpoint selection and limitation.

Application conditions:

Activation:	at every engine state	
Deactivation:	-	
Initialisation:	*at reset:*	LV_TPS_SP_TRA_ST_MDL = 0
		STATE_TPS_SP_TRA_DIR = INIT
		TPS_SP = TPS_CTL = TPS_SP_SEL = 0;
	at exit start:	LV_TPS_SP_TRA_ST_MDL = 1
Update rate:	10 ms and 5 ms during adaptation, if TPS_SP_AD is active ! (see chapter “Throttle position setpoint during adaptation”)	

C.4.1 Throttle position setpoint selection

Description:

For the selection logic see figure 2.

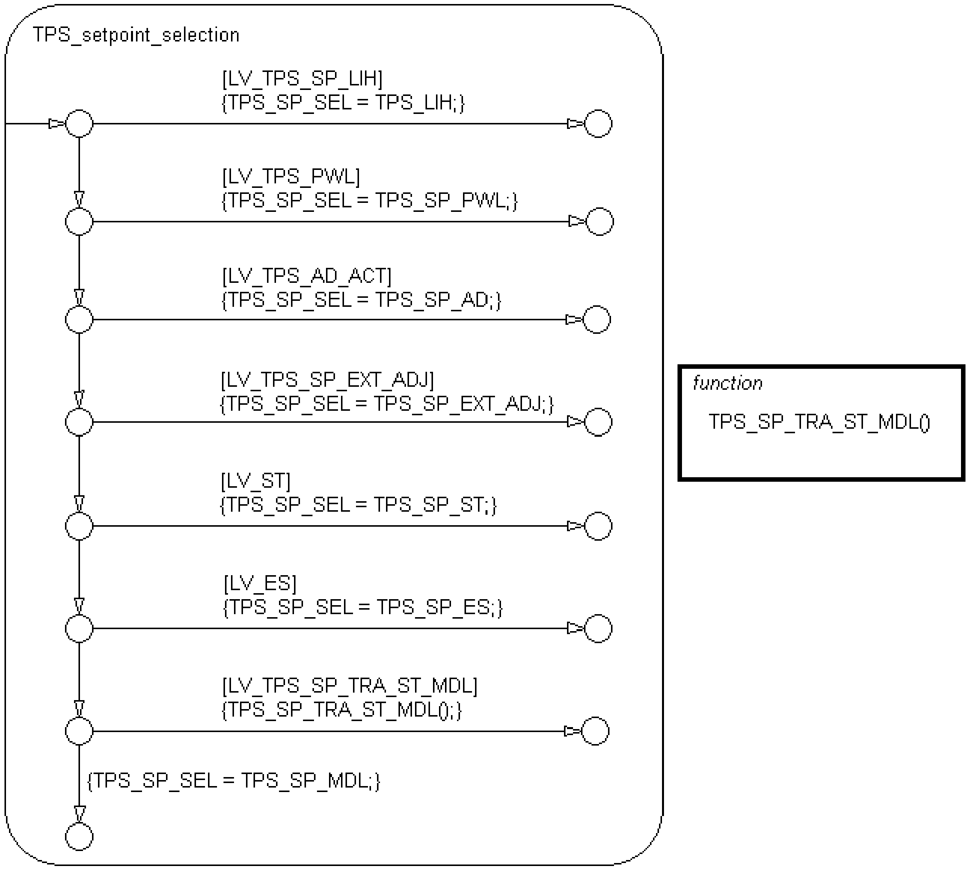

Figure 7: Throttle position setpoint selection block.

Throttle position setpoint for ETC controller switched off

In case of the ETC controller switched off the TPS setpoint is set to the limp home position TPS_LIH.

Throttle position setpoint during post operating phase

To avoid that for Key-Off condition the throttle actuator is without control current and set to limp home position, a throttle position setpoint during the post operating phase is available.

Throttle position setpoint during adaptation

During TPS adaptation the throttle position setpoint is set from the adaptation module.

Throttle position setpoint by external device

In case of request by an external device the throttle position setpoint is set by the value TPS_SP_EXT_ADJ.

Throttle position setpoint during start

During the engine state "Start" (LV_ST = 1) the throttle position setpoint is determined by the special variable TPS_SP_ST.

Throttle position setpoint for engine stopped

During the engine state "Engine stopped" (LV_ES = 1) the throttle position setpoint is determined by the special variable TPS_SP_ES.

Throttle position setpoint for transient phase after start

When the start phase is finished (LV_ST = 1 -> 0), then after a segment delay counter (to allow stabilization of the MAF_SP_RATIO during the after-start transition) a transient phase is following (LV_TPS_SP_TRA_ST_MDL = 1) where the pre-controlled setpoint from the start phase is approaching the TPS_SP_MDL from Intake Manifold Model.

Formula section:

if(1) LV_TPS_SP_LIH = 1

then(1) *(Throttle position setpoint for limp-home is requested)*

TPS_SP_SEL = TPS_LIH

else(1) **if** LV_TPS_PWL = 1

then *(Throttle position setpoint for power-latch is requested)*

TPS_SP_SEL = TPS_SP_PWL

else **if** LV_TPS_AD_ACT = 1

then *(Throttle position setpoint for TPS Adaptation is requested)*

TPS_SP_SEL = TPS_SP_AD

```
else if   LV_TPS_SP_EXT_ADJ = 1

C.4.2 Throttle position setpoint limitation

Description:

The task of this function is a protection mechanism for the throttle blade. Therefore, it must be evaluated after the TPS setpoint selection.

For adjusting the setpoint to the physics of the throttle the variable TPS_SP_SEL is limited by absolute values, for the non adapted throttle (LV_TPS_AD_REQ = 1 remains set after adaptation) the values indicated by "(_TPS_AD_REQ)" are used.

The throttle position setpoint may not fall below the value C_TPS_SP_MIN(_TPS_AD_REQ) or exceed C_TPS_SP_MAX(_TPS_AD_REQ), see figure 3.

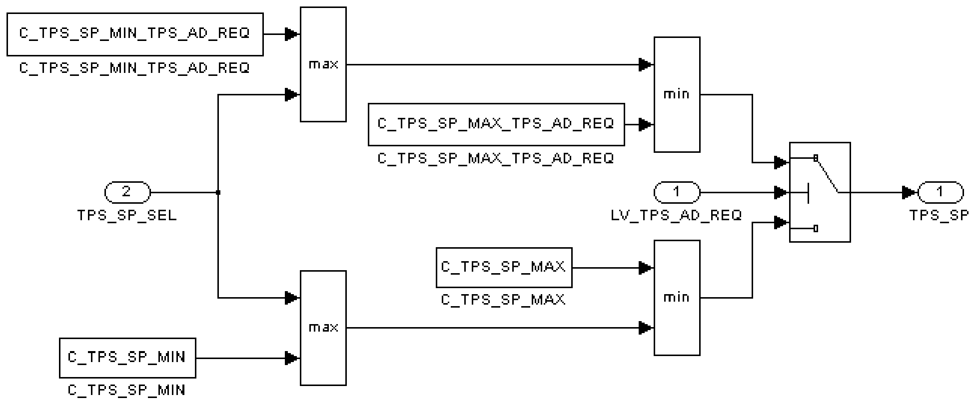

Figure 3: Throttle position setpoint limitation.

Formula section:

if (TPS_SP_SEL > C_TPS_SP_MAX(_TPS_AD_REQ))
then TPS_SP = C_TPS_SP_MAX(_TPS_AD_REQ)
else **if** TPS_SP_SEL < C_TPS_SP_MIN(_TPS_AD_REQ)
then TPS_SP = C_TPS_SP_MIN(_TPS_AD_REQ)
else TPS_SP = TPS_SP_SEL
endif
endif

Bit active for external input of throttle position setpoint					
TPS_SP_EXT_ADJ_1	V	0...3FFFH	0...119.5	0.0073	°TPS
Throttle position setpoint of external device about PV_AV					
LV_TPS_SP_EXT_ADJ_1	V	0...1H	0...1	1	-
Bit active for external input of throttle position setpoint for PV_AV setpoint					

Input data:

LV_ES	LV_IGK	PV_AV	TPS_EXT_ADJ
LV_TPS_EXT_ADJ	LV_ENG_OFF_DMF_TPS_ISA	N_32	

Description:

For different tasks during calibration phase and for service procedures at the workshops, it is necessary to implement an external adjustment at throttle position.
When an engine is shut-off due to DMF oscillation, external adjustment can be applied as long as engine running (LV_ES = 0).

Application conditions:

Initialisation: 0

Recurrence: 10 ms

Activation: LV_IGK == 1

Formula section:

{C_TPS_SP_EXT_ADJ_ENA = 0 : no external adjustment}

{C_TPS_SP_EXT_ADJ_ENA = 1 : Only manual setpoint}

{C_TPS_SP_EXT_ADJ_ENA = 2 : only PV_AV depended setpoint}

{C_TPS_SP_EXT_ADJ_ENA = 3 : adjustment about PV_AV and manual setpoint}

if **(** PV_AV > C_PV_AV_EXT_ADJ_MIN **)** **and**
LV_ES **and**
(C_TPS_SP_EXT_ADJ_ENA == 2 **or**
C_TPS_SP_EXT_ADJ_ENA == 3 **)**
then LV_TPS_SP_EXT_ADJ_1 = 1
TPS_SP_EXT_ADJ_1 = IP_TPS_SP_EXT_ADJ
else LV_TPS_SP_EXT_ADJ_1 = 0
TPS_SP_EXT_ADJ_1 = 0
endif

```
if      LV_TPS_SP_EXT_ADJ_1            or
        C_TPS_SP_EXT_ADJ_ENA == 1      or
        C_TPS_SP_EXT_ADJ_ENA == 3      or
        LV_TPS_EXT_ADJ = 1     (for actuator test with service tester)     or

C.5.3 Throttle position setpoint for ETC limp-home

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_TPS_SP_LIH	V/O	0...1H	0...1	1	-
ETC setpoint for the limp-home position is active					

Input data:

LV_MTC_CUR_OFF	LV_TPS_SP_LIH_REQ		

Application conditions:

Initialisation: LV_TPS_SP_LIH = 1

Recurrence: 10 ms

Activation: in every engine state

Formula section:

LV_TPS_SP_LIH = LV_MTC_CUR_OFF **or** LV_TPS_SP_LIH_REQ

C.5.4 Throttle position setpoint during post operating phase

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
TPS_SP_PWL	V/O	0...3FFFH	0...119.5	0.0073	°TPS
Throttle position setpoint during post operating phase					
LV_TPS_PWL	V/O	0...1H	0...1	1	-
Bit for throttle position setpoint in post operating phase active					
T_TPS_PWL	-	0...FFFFH	0...655.35	0.01	s
Time after engine stop					

Input data:

LV_ES	LV_IGK	N_32	

General information:

To avoid that for ‚Power Down‘ the currentless throttle is set to the limp home position, for a tuneable time period a throttle position setpoint during the post operating phase is available.
A time counter is started on detection of ignition key OFF and N < 32 rpm (engine stopped). If the counter reaches its maximum C_T_MTC_ISA_OFF, the throttle is actuated to the setpoint C_TPS_SP_PWL_UP by the current TPS_SP and then de-energized. Thus, it is ensured that the throttle are closed until a defined time after ignition key OFF and engine stopped.

If the throttle is already deenergized when ignition key OFF is detected, it is not re-energized.

Application conditions:

Initialisation: *at reset and at transition igk off to on,*

LV_TPS_PWL = 0

Recurrence: 10ms, This module is calculated before the chapter “ETC position controller (application incidences)” !

Activation: in every engine state

Formula section:

C.6.1 Digital position controller

Description:

The position controller is carried out as a robust digital position controller. Calibration data are determined according to Siemens internal controller design algorithms. The position controller consists of a PD – controller in backwards direction (static amplification = 1) and a amplitude correction function PDT_1 as well as amplification factor Kp in forward direction.

To avoid additional delay between AD conversion and calculation it is necessary that the routines for calculation of TPS_ETC and MTCPWM are called directly after the AD conversion is finished. Output of MTCPWM starts immediately after its calculation.

Signal flow diagram:

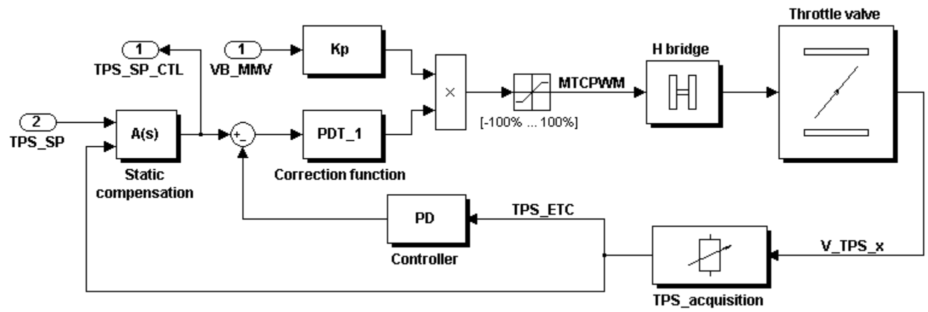

Figure 1: Electronic throttle control

Application conditions:

Initialisation:	tps_etc(k-1)	= TPS_LIH_INI
	mtc_ctl_1(k-1)	= mtc_ctl_3(k-1) = 0
	MTCPWM	= 0
Recurrence:	2 ms	
Activation:	see below	

Formula section:

{mtc_ctl_1/2/3 are 32 bit variables. They are introduced to do the calculations with higher resolution (6 bit, 0.00729 / 64 °TPS). }

if LV_MTC_CUR_OFF == 0

then *{Controller active}*

{Controller backward direction}

MTCPWM = 0

endif

Update HW-Pin with new MTCPWM value

<u>Signal flow diagram:</u>

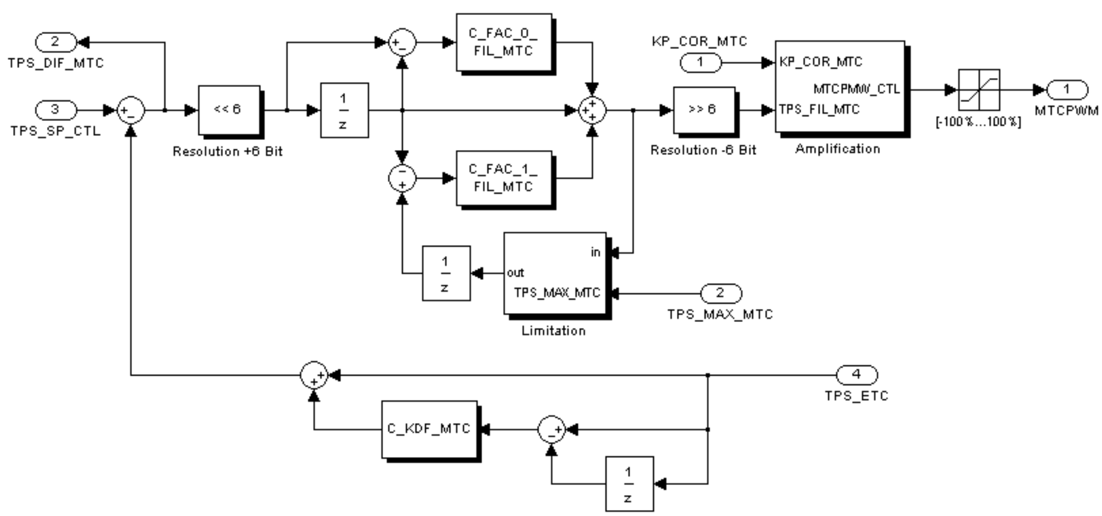

Figure 2: Technical realization, digital position controller

C.6.2 Controller amplification

<u>Description:</u>

The circuit amplification is held constantly under consideration of the battery voltage. The maximum input value of the PT_1 part of the transfer function in forward direction is calculated depend on controller amplification and battery voltage.

<u>Application conditions:</u>

Initialisation: KP_COR_MTC = C_KP_MTC

TPS_MAX_MTC = 100% / C_KP_MTC

Recurrence: 10 ms

Activation: at every engine state

Formula section:

FAC_VB_MTC = IP_FAC_VB_MTC(VB_MMV)

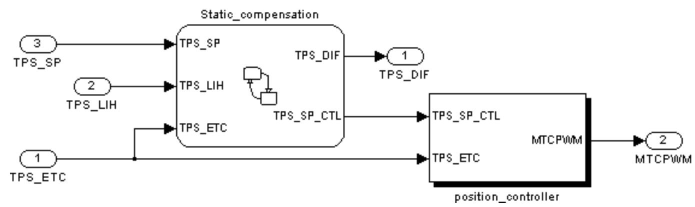
KP_COR_MTC = C_KP_MTC * FAC_VB_MTC

TPS_MAX_MTC = MTCPWM_LIM / KP_COR_MTC

C.6.3 Compensation of the system deviation

Description:

This function compensates the static control deviation of the throttle position controller. Therefore, it must be evaluated after the TPS setpoint selection and limitation. The digital position controller operates without integrator but with a high circuit amplification, consequently the position control has a small system deviation.



Signal flow diagram:

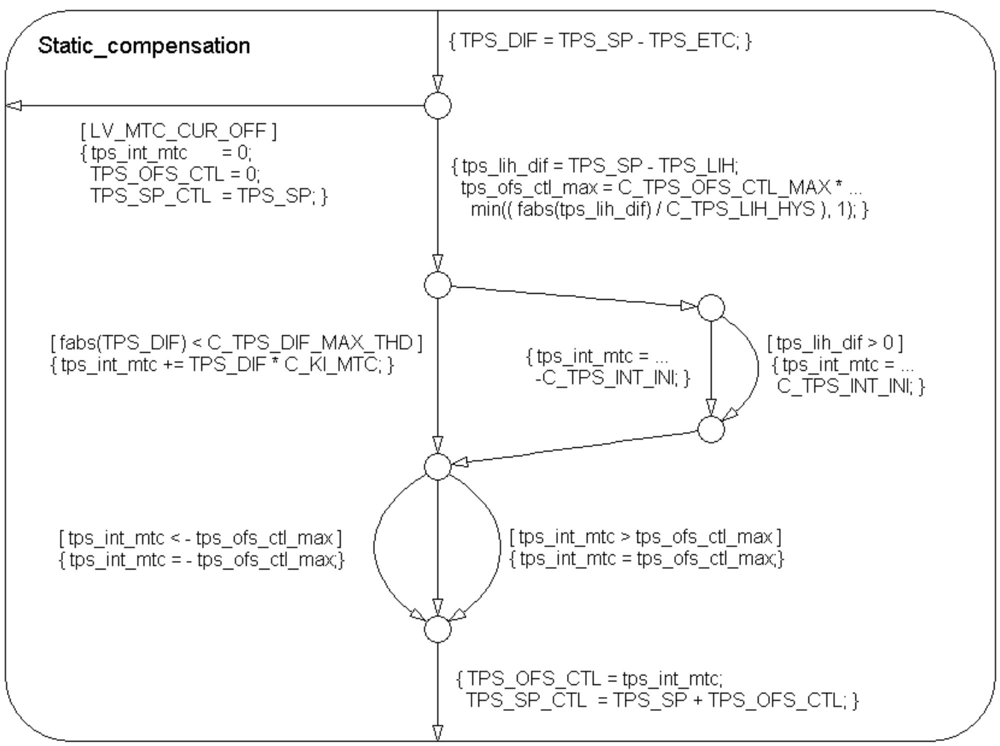


Figure2: Technical realization, static integrator

Application conditions:

Initialisation: TPS_DIF = TPS_OFS_CTL = TPS_SP_CTL = 0

Recurrence: 10 ms

Activation: at every engine state

Formula section:

```
{ Calculation of the system deviation }
TPS_DIF = TPS_SP – TPS_ETC(k)
if      LV_MTC_CUR_OFF
then    { power stage is switched off }
        tps_int_mtc      = 0
        TPS_OFS_CTL      = 0
        TPS_SP_CTL       = TPS_SP
else    { power stage is switched on }
        tps_lih_dif      = TPS_SP – TPS_LIH
        { calculation of the integrator limitation depend on the limp-home position }
        tps_ofs_ctl_max  = ...
            C_TPS_OFS_CTL_MAX * MIN[ ( | tps_lih_dif | / C_TPS_LIH_HYS ), 1 ]
        if      | TPS_DIF | < C_TPS_DIF_MAX
        then    { tps_int_mtc is calculated with a higher resolution than TPS_DIF  }
                tps_int_mtc + = TPS_DIF * C_KI_MTC
        else    { Integrator initalization }
                if      tps_lih_dif > 0
                then    tps_int_mtc = C_TPS_INT_INI
                else    tps_int_mtc = - C_TPS_INT_INI
                endif
        endif
        { limitation of the integrator output }
        if      tps_int_mtc < - tps_ofs_ctl_max
        then    tps_ int_mtc = - tps_ofs_ctl_max
        else    if      tps_int_mtc > tps_ofs_ctl_max
                then    tps_int_mtc = tps_ofs_ctl_max
                endif
        endif
        TPS_OFS_CTL      = tps_int_mtc
        { calculate the setpoint for the position controller }
        TPS_SP_CTL       = TPS_SP + TPS_OFS_CTL
endif
```

C.6.4 Reduced output limitation of the position controller

Description:

This function provides a higher availability of ETC control in case of long and high MTCPWM's (e.g. hard moving throttle blade, due to contamination or anything else).

In the diagnostic module "ETC actuator diagnosis" the moving mean value of the position controller output MTC_PWM is calculated. If the moving mean value MTCPWM_MMV exceeds a defined threshold then output limitation will be requested (LV_MTCPWM_RED_REQ = 1) by below function. The output limitation will be deactivated if the controller output falls below a second threshold (hysteresis).

Application conditions:

Initialisation: LV_MTCPWM_RED_REQ = 0, MTCPWM_LIM = 100 %

Recurrence: 10 ms

Activation: at every engine state

Formula section:

```
if      LV_MTCPWM_RED_REQ == 1
then    { Deactivate reduced output limitation of the position controller }
        if      MTCPWM _MMV < C_ MTCPWM _LIM_DI * FAC_VB_MTC
        then    LV_MTCPWM_RED_REQ = 0
        endif
else    { Activate reduced output limitation of the position controller }
        if      MTCPWM _MMV > C_ MTCPWM _LIM_ENA * FAC_VB_MTC
        then    LV_MTCPWM_RED_REQ = 1
        endif
endif

if      LV_ MTCPWM _RED_REQ == 1
then    { Reduced output of the position controller }
        MTCPWM _LIM = C_ MTCPWM _LIM * FAC_VB_MTC
else    { Limitation between -100 % and 100 % PWM output }
        MTCPWM _LIM = 100 %
endif
```

D Torque Management

Table of Contents

Index

A

C

D.1 Torque Coordination General

General information:

The aggregate *Torque Setpoint* defines the central indicated torque request to be produced at the engine. Therefore, several torque setpoints (internal and external) are considered and prioritised. The decisive outputs of the aggregate are TQI_SP_SLOW (torque setpoint for air path), TQI_SP (torque setpoint for ignition path) and TQI_SP_FAST_S (torque setpoint for stratified combustion mode). These torques are inputs to the aggregate *Torque determination and realization*.

The modules of this aggregate define the main track of the torque structure. The following figure shows the chain of the main important modules of the aggregate.

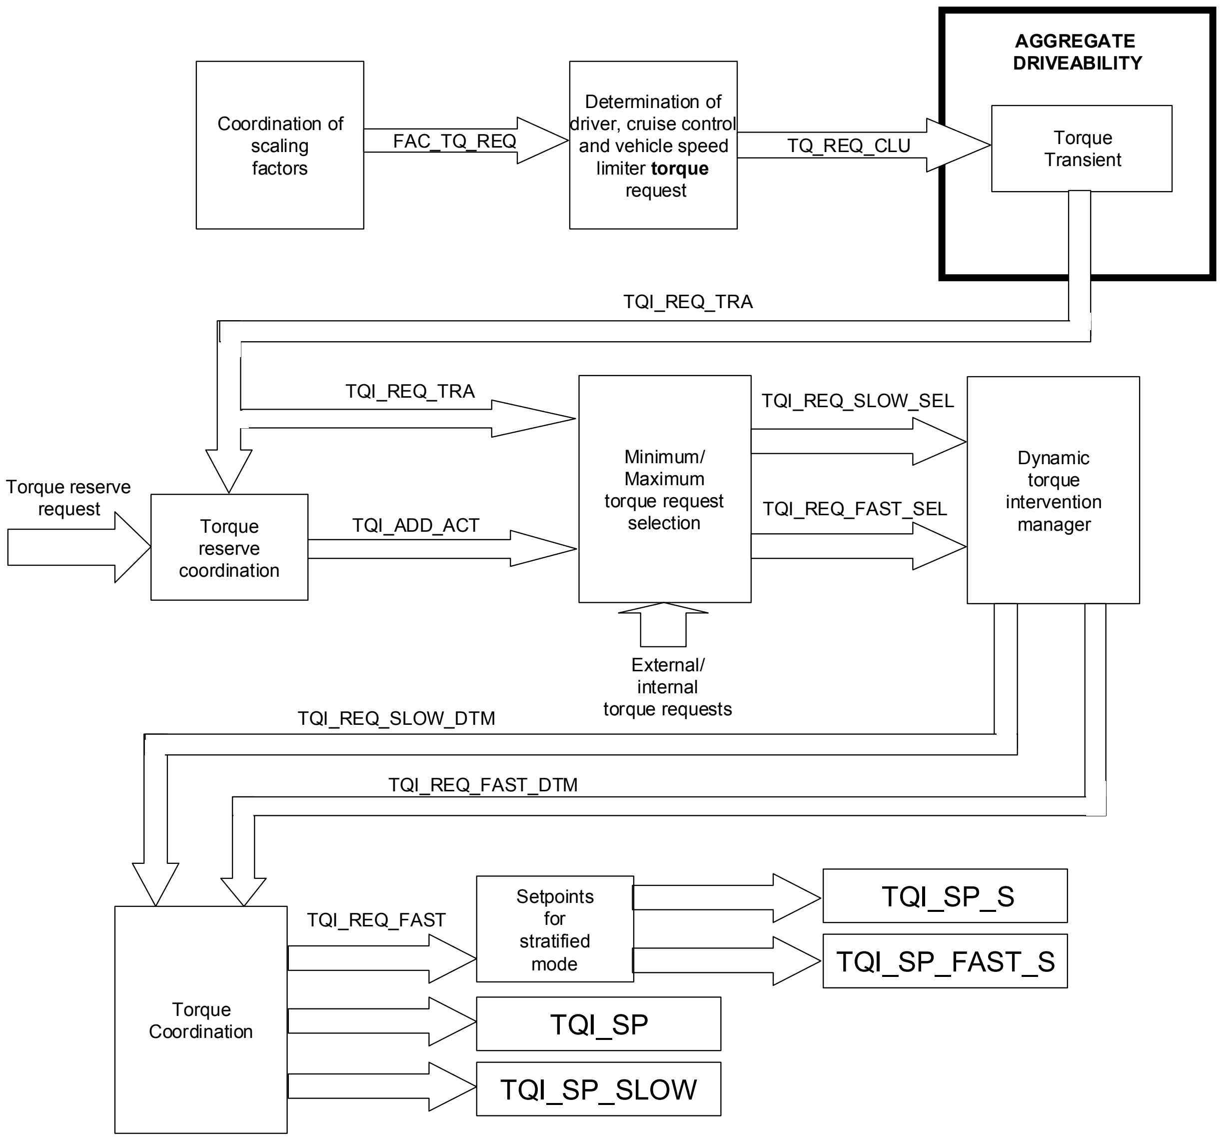

Figure 1: *Aggregate Torque Setpoint: major modul chain (not all modules of the aggregates are shown)*

The module’s attribution to the internal aggregate segmentation can be done as follows:

Coordination of scaling factors for requested torque

This module coordinates the torque scaling factors for driver, cruise control and vehicle speed limiter requests. The result is a coordinated scaling factor FAC_TQ_REQ.

Detection of driver passive

The detection of driver, cruise control or vehicle speed limiter passive is done with LV_CT (LV_CT = 1 means driver, cruise control or vehicle speed limiter passive). The bit is used (for example) in the engine operating states to detect LV_IS, LV_PL, ... = 0 or 1. The determination of LV_CT is done with the torque scaling factor FAC_TQ_REQ_CLU, which contents driver, cruise control or vehicle speed limiter requests.

Full load detection (template)

The primary task of the module “Full load detection” is to detect the full load request of the driver or - if requested – of cruise control. The indicator for the full load request is the logical variable LV_FL which constitutes the trigger for the full load enrichment in module “Full load enrichment”.
Under certain conditions it is necessary to suppress the full load request regardless of the driver demand. Such conditions can also be defined in this template.

Torque request at clutch general

With the scaling factor FAC_TQ_REQ (from *Coordination of scaling factors for requested torque*) the requested torque at clutch TQ_REQ_CLU is calculated.

Torque control at start

The engine start torque TQ_ST influences the torque at clutch during start phase; as a result it determines the engine speed transient response. TQ_ST is imported into module “Minimum Torque at Clutch” in the aggregate *Torque determination and realization* in order to increase engine speed during start phase.

Torque request for safety (Appl. Inc.) (template)

The module "Torque request for safety" needs a flag for having external torque demands, which can increase torque, as an input. Also, an activation flag for the module *Torque request for safety* is defined.

Torque request for safety

This module generates a torque request for safety for the slow (air) path and the fast (ignition) path, if the actual indicated engine torque exceeds the desired indicated engine torque, which is generated in the monitoring level, by more than a calculated threshold. Since the monitoring concept normally uses wide torque ranges to prevent permanent reactions of monitoring level 2, a limitation in level 1 can prevent failure torque developments inside the range of TQI_SP_MON and TQI_SP_MON plus offset from monitoring level 2.

Torque request for safety diagnosis

The objective of this function is to determine the number of intervention actions concerning the torque request for safety and to set the failure table entry if the counter exceeds a calibratable threshold. Under normal conditions, this module has no influence. It is meant to support the calibration. If the diagnosis leads to an entry in the failure table, this is a hint for the calibration guy that something in the calibration of the module *Torque request for safety* is still not well calibrated.

Torque based engine power limitation (template)

With the help of this function, the maximum allowed indicated engine torque can be limited (power limitation). For example, this limitation could consider a torque limitation to protect the gear box or a torque limitation in case of low fuel pressure (f.e. because the high pressure fuel pump is defective).

Torque reserve coordination

A torque reserve is a torque neutral increase of load with simultaneous retardation of ignition angle. Such torque reserves can be requested by different functions to increase the engine dynamics (i.e. idle speed controller) or to put thermodynamic energy into the exhaust system (to heat the catalyst or to desulfate the NO_X-trap). In the *Torque reserve coordination* all these torque reserve requests are coordinated and limited to a maximum allowed torque reserve, which is derived from the efficiency of the minimum allowed ignition angle. The output is a torque request TQI_ADD_ACT, which is torque request TQI_REQ_TRA plus torque reserve (TQ_ADD_REQ(_CH)).

Dynamic torque request coordination

This module coordinates project-specific dynamic requests for the realization of torque, expressed in dynamic logical bits (LV_TQ_DYN_xxx). They are used in the Dynamic torque intervention manager.

Dynamic torque intervention manager

The intention of the Dynamic Torque intervention Manager (DTM) is to have a central coordination of dynamic torque requests. It controls the realization of a torque request via the slow air path and the fast path with ignition intervention, fuel cut-off or lambda variation. It produces two kinds of outputs:

- Torque requests for slow and fast path for correct representation based on the Torque Structure.
- Logical values for switching different fast path realization variants to either their passive values or setpoint calculation via Torque Structure.

The state machine is controlled via dynamic control bits, that allow different states of intervention variants. Also the transitions from one state to the other can be influenced.

So the DTM finally adjusts the dynamic requirements from the control bits and gives the possibility to use several transitions between the different requirements.

Minimum / Maximum torque request selection (template)

This module coordinates all internal and external torque requests. It generates TQI_REQ_SLOW_SEL for the slow torque path (load) and TQI_REQ_FAST_SEL which represents the fast torque path (ignition, cylinder cut-off and lambda).

Torque coordination

The Torque Coordination module contains two functionalities.

First, there is the consideration of the limitation torques calculated in *Torque request for safety.*

Second, the module *Torque Coordination* calculates in homogeneous mode slow and fast torque setpoints (TQI_SP_SLOW for the air path and TQI_SP for ignition or also for fuel cut-off and lambda.

Torque setpoint for stratified mode

The module delivers the torque setpoint TQI_SP_FAST_S which is the decisive setpoint for the torque realization (fuel mass calculation) in the stratified combustion mode.
The second output, TQI_SP_S, is a torque setpoint that is not influenced by the fast torque interventions of the Idle Speed Controller and the Anti Jerk Controller. In the module 'Torque based fuel mass setpoint for stratified mode', this parameter will be converted into a fuel mass equivalent (MFF_SP_S) which will be utilized as load breakpoint for engine actuators with slow dynamics (e.g. FUP, EGR, PORT).
The input value TQI_REQ_FAST is delivered from the fast torque minimum/maximum selection where all internal and external torque are coordinated.

Following input values are considered:

TQ_DIF_P_D_FAST_IS; output from idle speed controller
TQ_DIF_AJ; output from anti jerk controller

D.2 Torque Control at Engine Start

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ST	V / O	8000 .. 7FFF H	-1024 .. 1023.97	0.03215	Nm
Engine Start Torque					
TQ_ST_1	V	8000 .. 7FFF H	-1024 .. 1023.97	0.03215	Nm
Engine Start Torque raw value					

Input data:

N_DIF	LV_TQ_MIN_CLU	TCO	

FUNCTION DESCRIPTION:

General information:

The engine start torque TQ_ST influences the torque at clutch during start phase as a result it determines the engine speed transient response. It is calculated from a one dimensional map versus engine speed difference N_DIF.

TQ_ST is imported into module “Minimum Torque at Clutch” in order to increase engine speed during start phase. Depending on the tuning data in IP_TQ_ST the engine speed overshoot canbe limitted to bring it to its setpoint at idle.

Activation: LV_TQ_MIN_CLU = 0

Deactivation: LV_TQ_MIN_CLU = 1

Initialization: TQ_ST = 0 Nm at reset

Update rate: 10 ms

Formula section:

TQ_ST_1 = IP_TQ_ST

if TQ_ST_1 >= TQ_ST then
TQ_ST = TQ_ST_1
else
$TQ\_ST_k = TQ\_ST_{k-1} + C\_CRLC\_TQ\_ST * (TQ\_ST\_1 - TQ\_ST_{k-1})$ (MMV calculation)
end

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_TQ_ST	8x8	0 .. FFFF H	-1024 .. 1023.97	0.03125	Nm

Start correction of engine friction losses					

Input data:

N	TCO	MAF_CYL_STK	TOIL
TCO_ST	TQ_DIF_IS_AD	TQ_LOSS_ADD	LV_ST_END
TQFR_DELTA_ADD	TQ_LOSS_ACC		

FUNCTION DESCRIPTION:

General information:

Target of the module “Torque Losses” is the determination of the overall torque losses of the engine. The torque losses mainly consist of the frictional and pumping losses and the additional torque losses caused by auxiliaries (e.g. air conditioning compressor). The model also considers the temperature dependency of the frictional losses, the break-in losses at start, project specific corrections and the adaptation of series spread.

Signal flow diagram

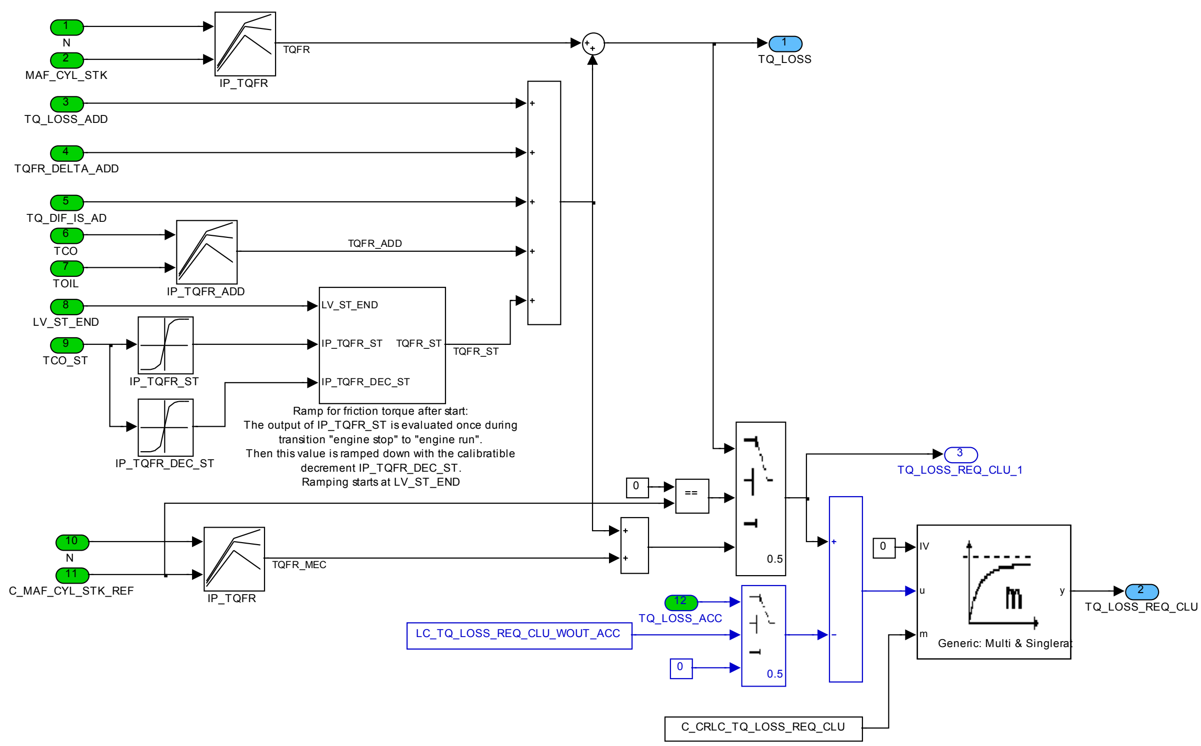

Figure 1: *Calculation of TQ_LOSS and TQ_LOSS_REQ_CLU*

Description :

The module has two main output parameters. These are TQ_LOSS and TQ_LOSS_REQ_CLU.

TQ_LOSS represents the unfiltered overall engine torque losses. It contains the frictional and pumping losses including project-specific corrections, the correction for temperature and after-start phase, the adaptation torque from the idle speed adaptation and the torque losses of auxiliaries.

TQ_LOSS_REQ_CLU represents the filtered value of the overall engine torque losses but unlike TQ_LOSS it does not depend on the mass of air flow into the cylinder. TQ_LOSS_REQ_CLU is used for the determination of the minimum and the maximum torque at clutch. The aim of this second parameter is an enhanced driveability of HPDI-vehicles during transitions between homogeneous and stratified combustion mode (please refer to tuning guide). The functionality is not HPDI-specific and can also be used for MPI-systems. Dependent on the calibration of the constant C_MAF_CYL_STK_REF TQ_LOSS_REQ_CLU derives either from TQFR_MEC or TQFR.

The single components of TQ_LOSS and TQ_LOSS_REQ_CLU can be described as follows:

1. Friction and pumping losses TQFR

TQFR represents the engine immanent friction and pumping losses. TQFR depends on engine speed N and the air mass into the cylinder MAF_CYL_STK.

2. Temperature correction TQFR_ADD

TQFR_ADD considers the coolant and oil temperature dependency of the friction losses.

3. Start correction TQFR_ST

TQFR_ST takes into consideration the increased friction losses right after start.

4. Idle speed adaptation of the engine immanent torque losses TQ_DIF_IS_AD

The idle speed adaptation torque TQ_DIF_IS_AD corrects deviations of engine immanent torque losses due to tolerances in series production. It is determined in the module “Idle speed adaptation”.

5. Torque losses of additional consumers TQ_LOSS_ADD

TQ_LOSS_ADD represents the interface to module “Coordination of additional torque losses” and expresses the torque requests of relevant auxiliaries (e.g. ACC).

6. Correction of the frictional and pumping losses TQFR_DELTA_ADD

TQFR_DELTA_ADD is a corrective parameter for the friction and pumping losses. It is calculated in the template “Correction of friction and pumping losses”. So the model for the friction and pumping losses can be corrected or extended for projectspecific purposes (e.g. Turbo, VVL,...).

7. The mechanical friction losses TQFR_MEC

TQFR_MEC represents the mechanical friction losses at wide open throttle. Although it is calculated from the same map as TQFR, it does not depend on mass of air flow and so it does not change during transitions between homogeneous and stratified combustion mode.

Application conditions:

Activation:	at every engine state
Deactivation:	-
Initialization:	TQ_LOSS = 0 Nm at reset
	TQ_LOSS_REQ_CLU = 0 at reset
	TQFR_ADD = IP_TQFR_ADD (TCO,TOIL)
Update rate:	optimised recurrency for each parameter

Formula section:

Calculation of the friction and pumping losses TQFR

TQFR = IP_TQFR (N, MAF_CYL_STK) **every 20 ms**

Calculation of TQFR_MEC :

TQFR_MEC = IP_TQFR (N, C_MAF_CYL_STK_REF) **every 20 ms**

Calculation of the torque losses of auxiliaries TQ_LOSS_ADD

TQ_LOSS_ADD is determined in the template “Coordination of additional torque losses”

Calculation of the project-specific corrections TQFR_DELTA_ADD

TQFR_DELTA_ADD is determined in the template “Correction of friction and pumping losses”

Calculation of the start correction TQFR_ST

$TQFR\_ST_0$ = IP_TQFR_ST (TCO_ST) calculated once at the beginning of engine-operating-state ST

TQFR_DEC_ST = IP_TQFR_DEC_ST (TCO_ST)

TQFR_ST is calculated once during transition from "engine stop" to "engine run". Afterwards, it is ramped down by the decrement IP_TQFR_DEC_ST, as soon as LV_ST_END = 1:

IF LV_ST_END == 1

IF $TQFR\_ST_{k-1}$ > TQFR_DEC_ST

THEN

TQFR_ST = 0

ELSE

$TQFR\_ST_k = TQFR\_ST_{k-1} - TQFR\_DEC\_ST$ **every 100 ms**

END

Calculation of the idle speed adaptation torque TQ_DIF_IS_AD

TQ_DIF_IS_AD is determined in module “Idle Speed Adaptation”

Calculation of the temperature correction TQFR_ADD

TQFR_ADD = IP_TQFR_ADD (TCO,TOIL) **every 20 ms**

Calculation of the unfiltered overall torque losses TQ_LOSS

TQ_LOSS = TQFR
+ TQFR_ADD
+ TQFR_ST
+ TQ_DIF_IS_AD
+ TQ_LOSS_ADD
+ TQFR_DELTA_ADD

every 10 ms

Calculation of TQ_LOSS_REQ_CLU and low pass filtering:

IF C_MAF_CYL_STK_REF == 0
THEN
TQ_LOSS_REQ_CLU_1 = TQ_LOSS
ELSE
TQ_LOSS_REQ_CLU_1 = TQFR_MEC
+ TQFR_ADD
+ TQFR_ST
+ TQ_DIF_IS_AD
+ TQ_LOSS_ADD
+ TQFR_DELTA_ADD
END

IF LC_TQ_LOSS_REQ_CLU_WOUT_ACC
THEN
TQ_LOSS_REQ_CLU = TQ_LOSS_REQ_CLU_1– TQ_LOSS_ACC
ELSE
TQ_LOSS_REQ_CLU = TQ_LOSS_REQ_CLU_1
END

$$TQ\_LOSS\_REQ\_CLU_{k} = TQ\_LOSS\_REQ\_CLU_{k-1} + C\_CRLC\_TQ\_LOSS\_REQ\_CLU * (TQ\_LOSS\_REQ\_CLU - TQ\_LOSS\_REQ\_CLU_{k-1})$$

every 10 ms

Remark : Convergent calculation of filter !

D.6 Coordination of additional torque losses

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_LOSS_ADD	V/O	8000 .. 7FFFH	-1024 .. 1023.97	0.03125	Nm
additional torque losses					

Input data:

TQ_LOSS_ECF	TQ_LOSS_ACC	TQ_LOSS_PSTE	TQ_LOSS_PSTE_PSPT
TQ_LOSS_ALTER	TQ_LOSS_AMP	CONF_PSTE	

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_ADD expresses the overall additional engine torque losses. In this module the additional losses have to be coordinated.

TQ_LOSS_xxx from external consumers are considered by special torque loss input values:

TQ_LOSS_ACC	air conditioning compressor
TQ_LOSS_ECF	electric cooling fan
TQ_LOSS_ALTER	electric load from alternator
TQ_LOSS_PSTE	power steering pressure from switch
TQ_LOSS_PSTE_PSPT	power steering pressure from analog transducer

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: TQ_LOSS_ADD = 0 Nm at reset

Update Rate: 10 ms

Formula section:

TQ_LOSS_ADD = TQ_LOSS_ACC
+ TQ_LOSS_ECF
+ TQ_LOSS_ALTER
+ TQ_LOSS_AMP
+ TQ_LOSS_PSTE (if CONF_PSTE = 0)
+ TQ_LOSS_PSTE_PSPT (if CONF_PSTE = 1)

D.7 Altitude correction for torque loss

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_LOSS_AMP	V/O	8000 .. 7FFFH	-1024 .. 1023.97	0.03125	Nm
Altitude correction for torque losses					
AMP_DIF	V/O	8000...7FFF H	-2717...2716.96	0.083	hPa
AMP difference compared to the reference AMP					

Input data:

AMP	PQ		

FUNCTION DESCRIPTION:

General information:

At high elevations, lower ambient pressure causes lower exhaust backpressure, so pumping losses to be lower.
To compensate this, the altitude correction for torque losses is introduced.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: TQ_LOSS_AMP = 0 Nm at reset

Update Rate: 10 ms

Formula section:

AMP_DIF = C_AMP_REF - AMP

TQ_LOSS_AMP = IP_TQ_LOSS_AMP__AMP_DIF__PQ

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_TQ_LOSS_AMP	8*8	0...FFFF H	-1024 .. 1023.97	0.03125	Nm
LDP_AMP_DIF__TQ_LOSS_AMP	8	0...FFFFH	-2717...2716.96	0.083	hPa
LDP_PQ__TQ_LOSS_AMP	8	0...FFFFH	0...0.999985	1.52e-5	-
Altitude correction for torque losses					
C_AMP_REF	1	0...FFFF H	0...5434	0.083	hPa
The reference altitude pressure					

D.8 Correction of friction and pumping losses

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQFR_DELTA_ADD	O/V	8000...7FFFH	-1024...1023.97	0.03125	Nm

Input data:

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: TQFR_DELTA_ADD = 0 at reset

Recurrence: project-specific recurrency, dependent on the fastest input

Activation: At every engine state

Deactivation:

Formula section:

TQFR_DELTA_ADD = 0

D.9 Torque Loss and Reserve for ACC

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_ACC	V/O	8000...7FFF H	-1024...1023.97	0.03125	Nm
Torque reserve for switching on air conditioning compressor					
TQ_LOSS_ACC	V/O	8000 ... 0 H	-1024 ... 0	0.03125	Nm
Engine torque losses air conditioning compressor					
T_ACC_SLOW	V	0 ... FF H	0 ... 255	1	s
Timer for duration of transient TQ_LOSS_ACC correction					
T_ACC_FAST	V	0 ... FF H	0 ... 2.55	0.01	s
Timer for duration of transient TQ_LOSS_ACC correction					
FAC_TQ_LOSS_ACC_ON	V	0 ... FF H	0 ... 16	0.0627	-
TQ_LOSS_ACC weighting factor					
TQ_LOSS_ACC_AD	V	8000 ... 7FFF H	-1024 ... 1023.97	0.03125	Nm
Engine torque losses air conditioning compressor from adaption					
TQ_MAX_ACC_FATC	V/O	8000 ... 0 H	-1024 ... 0	0.03125	Nm
Maximum engine torque losses air conditioning via CAN					

Input data:

TQ_DIF_IS_AD_ACC	TIA	N_32	LV_RLY_ACCOUT_CTRL
LV_PRS_ACC	ACP	CONF_ACP	VS
T_IS_AST	TCO	TAM	LV_IS
VS	CONF_ACC_FATC	TQ_LOSS_ACC_CAN	LV_RLY_ACCOUT

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_ACC must display the air-conditioner compressor power requirements.

In this case the needed torque to drive the ACC is depending on the actual pressure of the ACC-fluid (LV_PRS_ACC, ACP), the air intake temperature and the actual pumping-speed (proportional to engine-speed).

The calculation of the torque loss starts prior to ACC activation (LV_RLY_ACCOUT_CTRL = 1).

The ACC adaptation value TQ_DIF_IS_AD_ACC, determined in the module "idle speed adaptation", is added to the calculated ACC torque.

Special correction at activation :

To take into account the gradually closing of the electro-magnetic clutch and the increased starting-torque of the ACC at activation and deactivation (fast phenomenon), a special weighting factor is multiplied to the basic torque losses.

A timer T_ACC_FAST is started at transition LV_RLY_ACCOUT_CTRL 0 -> 1 and runs until it´s maximum value. It is input for the table IP_FAC_TQ_LOSS_ACC_ON_FAST which is a weighting factor for ACC activation.

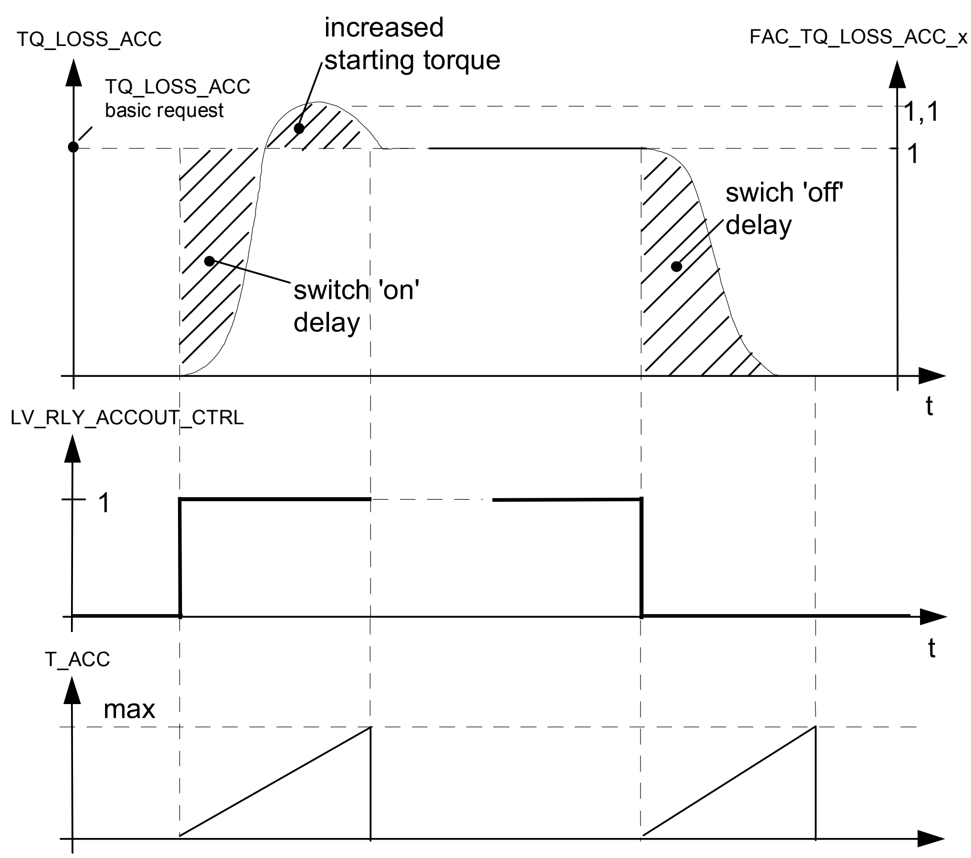
To take into account the variation of the fluid pressure inside the ACC during the first seconds of activation (slow phenomenon), a second special weighting factor is multiplied to the basic torque losses.

A timer T_ACC_SLOW is started at transition LV_RLY_ACCOUT_CTRL 0 -> 1 and runs until it´s maximum value. It is input for the table IP_FAC_TQ_LOSS_ACC_ON_SLOW which is a weighting factor for ACC activation.

Special correction at deactivation :

The timer T_ACC_FAST is also started at transition LV_RLY_ACCOUT_CTRL 1 -> 0 and runs until it´s maximum value. It is input for the table IP_FAC_TQ_LOSS_ACC_OFF which is the weighting factor for ACC deactivation.

These transient corrections are only active during a limited time after activation and deactivation of the climatic compressor.



D.9.1 Determination of Torque Loss ACC

The determination of TQ_LOSS_ACC starts parallel to the ACC relay activation.

Activation: Every engine state

Deactivation: -

Initialisation: at reset: TQ_LOSS_ACC = 0

Update Rate: 10 ms

Formula section:

activation of TQ_LOSS_ACC calculation including transient correction;

IP_FAC_TQ_LOSS_ACC_ON_FAST is regarded until T_ACC_FAST has reached it´s max. value,

IP_FAC_TQ_LOSS_ACC_ON_SLOW is regarded until T_ACC_SLOW has reached it´s max. value,

otherwise the multiplikation factor is ‘1’;

D.9.2 Determination of Torque Lead for ACC

To avoid drivability impact at ACC switching it´s necessary to define a torque reserve.

Activation: Every engine state

Deactivation: -

Initialisation: at reset: TQ_ADD_ACC = 0

Update Rate: 10 ms

Formula section:

if LV_RLY_ACCOUT_CTRL = 1 **and** LV_IS = 1 **and** VS < C_VS_MAX_TQ_ADD_ACC

TQ_ADD_ACC = IP_TQ_ADD_ACC (TAM) * IP_FAC_TQ_ADD_ACC(T_ACC_FAST)

else

TQ_ADD_ACC = 0 Nm

end

Basic engine torque losses by electric cooling fan in case of C_CONF_CFA = 0					
TQ_LOSS_ECF_TRA	V	8000 .. 0 H	-1024 .. 0	0.03125	Nm
Transient engine torque losses by electric cooling fan in case of C_CONF_CFA = 0					

Input data:

STATE_CFA	N_32	CFAPWM_CFA	CONF_CFA
N	STATE_CFA_IS		

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_ECF represents the engine torque loss due to power consumption by the electric cooling fan (ECF).

ECF power consumption value[W] in ID_POW_LOSS_ECF is converted to Nm by specified formula as below.

Application conditions:

Activation: at every engine operating state

Deactivation: -

Initialisation: at reset

Recurrence: 100 ms

(see: “ENTE scheduler”)

Formula section:

Definition of TQ_LOSS_ECF_BAS

TQ_LOSS_ECF_BAS = (ID_POW_LOSS_ECF_0 * 60) / (2 * 3.141828 * N)

Definition of TQ_LOSS_ECF_TRA

If Transition STATE_CFA_IS(n) > STATE_CFA_IS(n-1)

Then TQ_LOSS_ECF_TRA is set to ID_TQ_LOSS_ECF_TRA
and reset to 0 using change limitation TQ_LOSS_ECF_TRA
C_LGRD_TQ_LOSS_ECF_TRA.

If Transition STATE_CFA_IS(n) < STATE_CFA_IS(n-1)

Then TQ_LOSS_ECF_TRA = 0

```
If      N_32 > C_N_MIN_TQ_LOSS_ECF
then    if        CONF_CFA = 0
        then      TQ_LOSS_ECF = TQ_LOSS_ECF_BAS + TQ_LOSS_ECF_TRA
        else
           if     CONF_CFA = 1
           then   TQ_LOSS_ECF = ( IP_POW_LOSS_ECF_1 * 60 ) / ( 2 * 3.141828 * N )
           endif
        endif
else    TQ_LOSS_ECF = 0
endif
```

The change of TQ_LOSS_ECF is limited by limitation gradient C_LGRD_TQ_LOSS_ECF.

Engine torque losses power steering					
TQ_LOSS_PSTE_TRA	V/O	8000 .. 0 H	-1024 .. 0	0.03125	Nm
Engine torque losses power steering					
TQ_ADD_PSTE	V/O	8000...7FFFH	-1024...1023.97	0.03125	Nm
Engine torque reserve for power steering					

Input data:

LV_PSTE	N	TCO	LV_IS
CONF_PSTE	T_AST	VS	

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_PSTE describes the needed torque during activation of power steering.

When the load of the power steering changes, an additional TQ_LOSS is applied in order to ensure a rapid compensation. This is performed by the TQ_LOSS_PSTE_TRA term.

High pressure in the power steering circuit: **LV_PSTE = 1**

Low pressure in the power steering circuit: **LV_PSTE = 0**

Additionally a torque reserve term, TQ_ADD_PSTE may be used to provide futher capacity to compensate rapidly changing torque requirements.

Application conditions

Activation : all engine operating state if TCO >= C_TCO_MIN_PSTE

CONF_PSTE = 0

Update Rate: 10 ms

Initialization : TQ_LOSS_PSTE = 0

TQ_LOSS_PSTE_BAS = 0

TQ_LOSS_PSTE_TRA = 0

TQ_ADD_PSTE = 0

Formula section:

Input data:

GEN_LOAD_MMV	LV_ES	LV_IGK	GEN_LOAD
LV_ERR_GEN_LOAD	N	N_SP_IS	LV_IS
VB	VB_MMV	GEN_LOAD_GRD_MMV	VS

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_ALTER represents the engine torque loss due to power consumption of the alternator. TQ_LOSS_ALTER is generated by the Load Signal of the generator. To avoid engine speed undershoot in Idle, a transient correction is applied in case of sudden jump of Alternator Load.

Application conditions:

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0 **and** LV_ES = 1

Initialisation: at reset -> TQ_LOSS_ALTER = TQ_LOSS_ALTER_BAS = TQ_LOSS_ALTER_TRA = 0, VB_REF = 14 Volt, VB_DIF = 0

TQ_ADD_ALTER = 0

Update Rate: 10 ms

Formula section:

** TQ_LOSS_ALTER_BAS calculation :*

TQ_LOSS_ALTER_BAS = IP_TQ_LOSS_ALTER__GEN_LOAD_MMV__N
* IP_FAC_TQ_LOSS_ALTER__VB_MMV__N

The change of TQ_LOSS_ALTER_BAS is limited by limitation gradient C_LGRD_TQ_LOSS_ALTER.

** TQ_LOSS_ALTER_TRA calculation :*

TQ_LOSS_ALTER_TRA is used only in Idle and set in case of sudden jump of GEN_LOAD signal causing an engine speed undershoot.

- Activation condition of TQ_LOSS transient correction (LV_TQ_LOSS_ALTER_TRA = 1) :

If LV_TQ_LOSS_ALTER_TRA = 0
and LV_IS = 1
and GEN_LOAD_MMV < C_GEN_LOAD_MMV_ALTER_TRA_MAX
and GEN_LOAD > C_GEN_LOAD_TRA_MIN % sudden jump of GEN_LOAD
and N <= N_SP_IS – C_N_SP_IS_ALTER_TRA *% engine speed undershoot*
Then LV_TQ_LOSS_ALTER_TRA = 1

- Deactivation condition of TQ_LOSS transient correction (LV_TQ_LOSS_ALTER_TRA = 0) :

If LV_TQ_LOSS_ALTER_TRA = 1
and **(** LV_IS = 0 **or** N > N_SP_IS – C_N_SP_IS_ALTER_TRA **)**
Then LV_TQ_LOSS_ALTER_TRA = 0

D.13 Torque based catalyst heating

Overview

The torque model calculates the spark retardation for catalyst heating depending on air mass flow increase.

The air mass flow increase depends on the torque reserve which is generated in this module. The actually indicated torque TQI_AV will not be influenced.

D.13.1 Catalyst heating after start

Application Condition

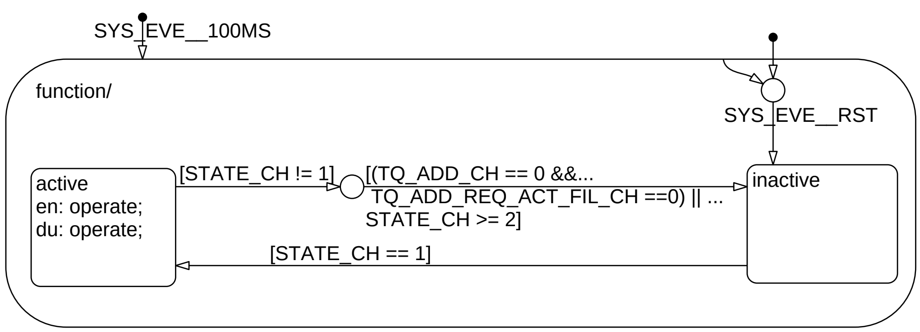

Figure 11 EXTC_REQGNcht0/ TQ_ADD_CH_AST/ APP_CDN/ Chart

Function Description

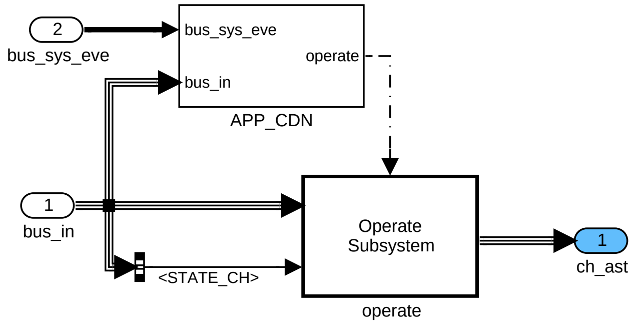

Figure 12 EXTC_REQGNcht0/ TQ_ADD_CH_AST

D.13.1.1 Operate Subsystem

The function is divided into active catalyst heating and deactive – for ramping torque reserve to 0.

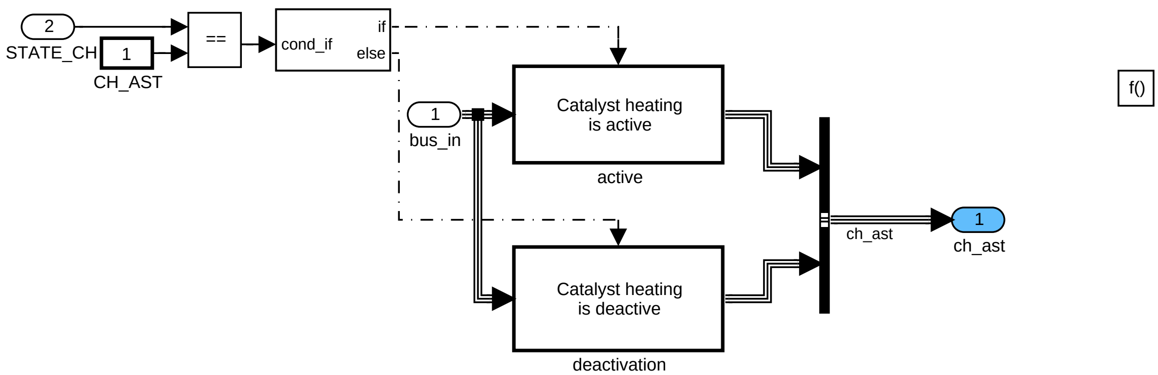

Figure 13 EXTC_REQGNcht0/ TQ_ADD_CH_AST/ operate

Catalyst heating is active

TQ_ADD_REQ_ACT_FIL_CH cannot be used for an ignition increase at dynamic torque request. It can be set to 0 with C_TQ_ADD_CH_FIL_LGRD = 0.

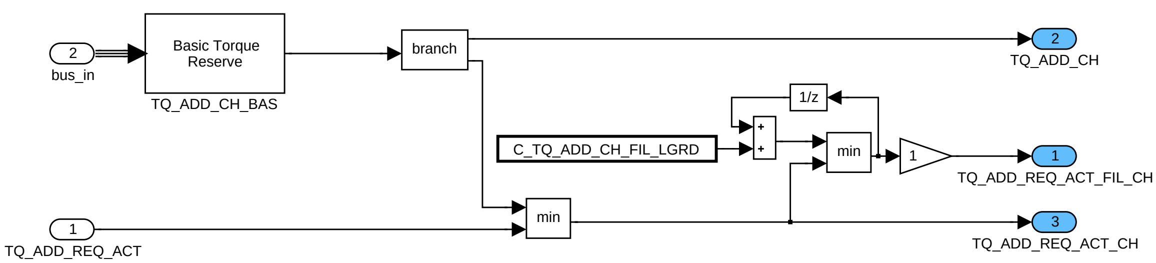

Figure 14 EXTC_REQGNcht0/ TQ_ADD_CH_AST/ operate/ active/ SUB

Basic Torque Reserve

FAC_CH_RED can be adapted by the project.

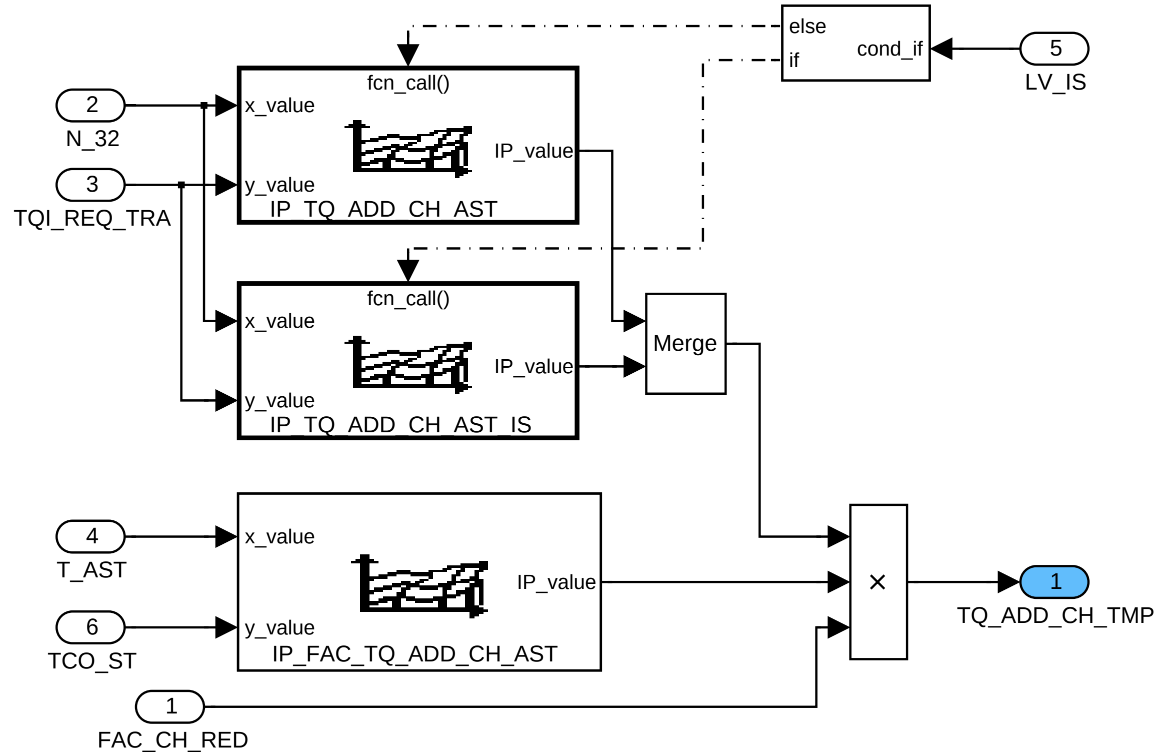

Figure 15 EXTC_REQGNcht0/ TQ_ADD_CH_AST/ operate/ active/ SUB/ TQ_ADD_CH_BAS/ SUB

Catalyst heating is deactive

TQ_ADD_CH and TQ_ADD_REQ_ACT_FIL_CH are ramped down. TQ_ADD_REQ_ACT is the actual torque reserve request.

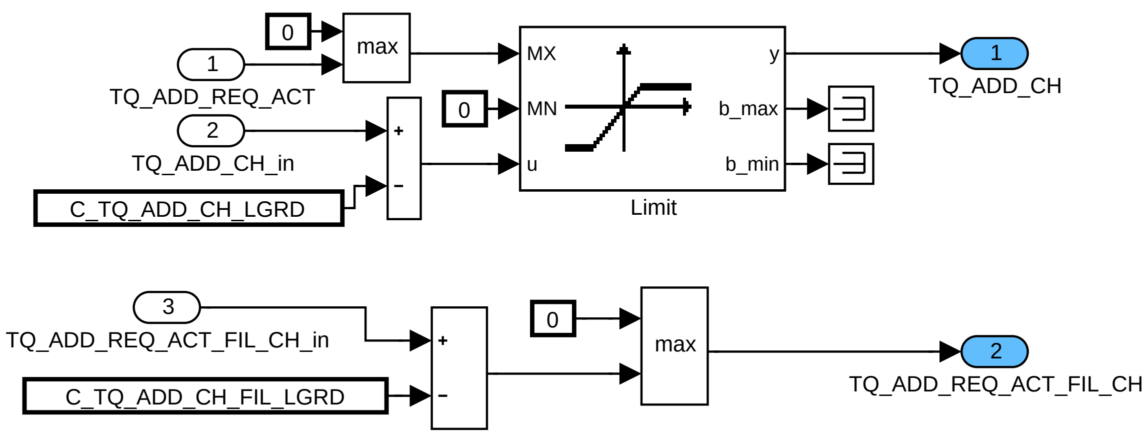

Figure 16 EXTC_REQGNcht0/ TQ_ADD_CH_AST/ operate/ deactivation/ SUB

D.13.2 Catalyst heating in low load

This function can be activated to avoid a catalyst temperature lower than its working temperature.

Application Condition

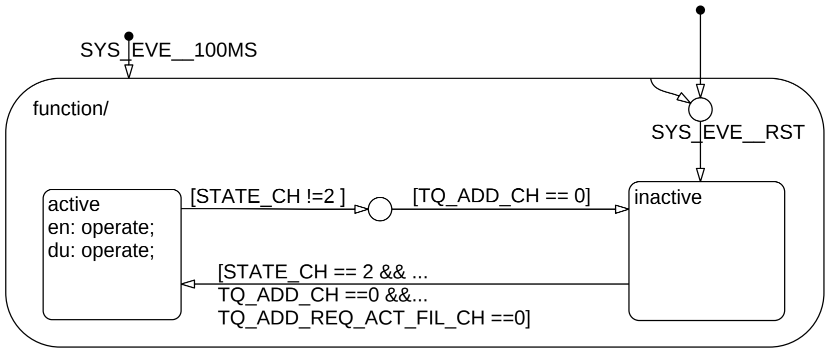

Figure 17 EXTC_REQGNcht0/ TQ_ADD_CH_L/ APP_CDN/ Chart

Function Description

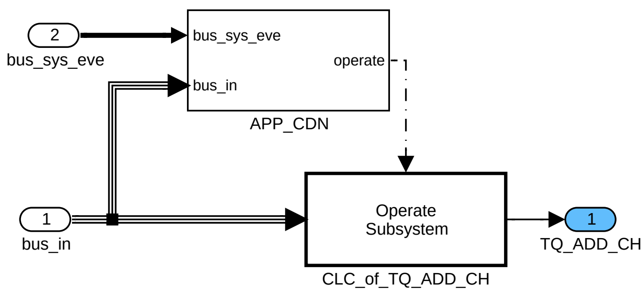

Figure 18 EXTC_REQGNcht0/ TQ_ADD_CH_L

D.13.2.1 SUBFUNCTION: CLC_of_TQ_ADD_CH

Operate Subsytem

The function is in principle a P - controller. The output is filtered, the difference from one calculation to another is limited by C_TQ_ADD_CH_L_LGRD.

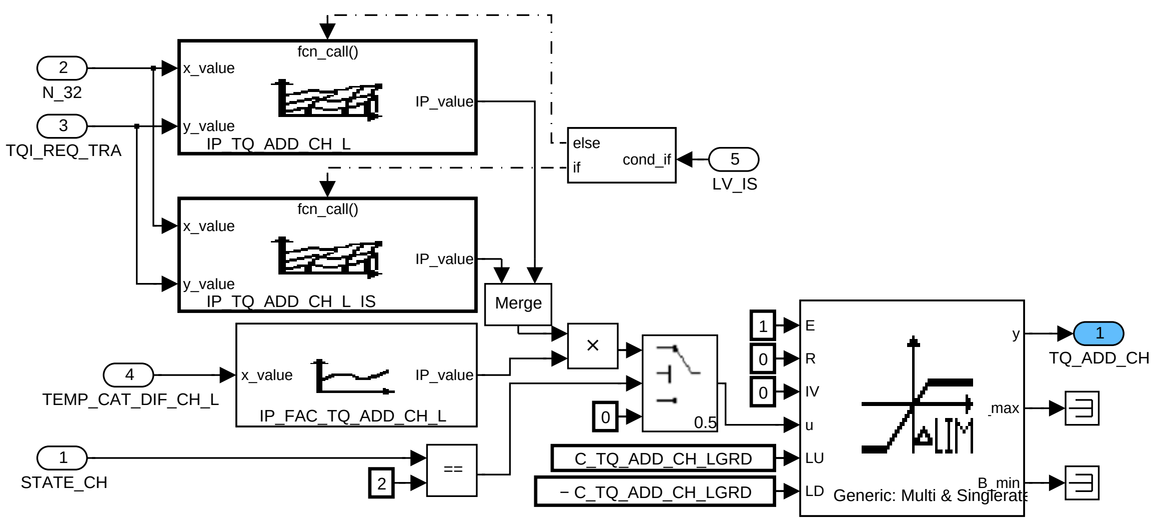

Figure 19 EXTC_REQGNcht0/ TQ_ADD_CH_L/ CLC_of_TQ_ADD_CH/ SUB

Request for minimum torque reserve for catalyst heating is active					

Input data:

AMP	LV_DRI	LV_CH	LV_AT
TIA	LV_RLY_ACCOUT	LV_IS	TQ_ADD_CH

FUNCTION DESCRIPTION:

General information:

For active catalytic converter heating a spark retardation is necessary to increase the exhaust gas temperature. The reduced engine torque due to spark retardation must be compensated by increased intake mass air flow to have no influence on torque at clutch.

This function describes the output data FAC_CH_RED. This factor can reduce the torque reserve for catalyst heating for different ambient conditions and for automatic transmission depending on whether LV_DRI is selected or not, and whether the A/C is selected or not.
In order to avoid any jumps of the torque reserve as LV_DRI or LV_RLY_ACCOUT are selected, a gradient is applied on FAC_CH_RED_DRI and FAC_CH_RED_ACIN. However, FAC_CH_RED_DRI remains active even if neutral is selected anew (braking performances).

The calculation of the reduction factor starts with LV_CH=1, but does not end when LV_CH is deactivated (1->0), since the torque reserve for catalyst heating TQ_ADD_CH is still applied for a while through a deactivation ramp. Therefore in this case, the factor FAC_CH_RED must be kept frozen.

TQI_GS_SLOW_REQ	ETL_TCU_CAN	CONF_ETL_TCU	TQI_REQ_TRA
TQI_BAS_MAX	PV_AV		

FUNCTION DESCRIPTION:

General information:

During a gear shift operation of the automatic transmission a low engine torque helps the transmission to perform a smooth gear shift and avoids sudden changes of wheel slip that could cause problems on certain road surfaces, i.e. wet or icy roads. The transmission control unit (TCU) demands a torque reduction via CAN, which can be realized by spark retard (fast path) or throttle closing/opening (slow path).

A torque intervention for gear shift is enabled depending on the engine state, current engine torque and the value of the requersted torque.

If the GS torque reduction intervention function is enabled (LV_GS_ENA = 1), then TQI_GS_REQ, which is received from CAN, is at first limited to IP_TQI_GS_MIN_FAST_DEC (or IP_TQI_GS_MIN_FAST_DEC_ESP if there is ESP torque request) then copied into TQI_GS_FAST_DEC. Then the requested torque is adjusted only by ignition retardation.

In case of available engine torque reduction request for slow path from the TCU (CONF_ETL_TCU = 1), TQI_GS_SLOW_DEC is used to reduce the engine torque in some specific cases (ex. stall RPM check or Accel. just after N/D shift) to protect the automatic transmission. Alternatively (CONF_ETL_TCU = 2) a proportion of the fast path torque reduction can also be implemented in the slow path. The proportion used is a function of engine speed, duration of gearshift and gas pedal position.

If the GS torque increment intervention function is enabled (LV_GS_TQI_INC_ENA = 1), then TQI_GS_INC_REQ, which is received from CAN, is at first limited to IP_TQI_GS_MAX_INC then copied into TQI_GS_FAST/SLOW_INC. Then the requested torque is adjusted by ignition advance and Throttle opening.

LC_TQI_ASR_REQ_MAN	N_SP_IS_RATIO_ASR	TQ_LOSS	TQ_CONV
TQI_AV	TQI_AV_EMS	CONF_ASR_SLOW	N_32
LV_ERR_MAP			

FUNCTION DESCRIPTION:

General information:

The ASR torque reduction is performed only when LV_ASR_ACT = 1 (see chapter "Minimum/ Maximum Torque Request Selection").

TQI_ASR_BOL is used to limit the minimum ASR Torque reduction request to avoid engine stall (engine speed stabilized to N_SP_IS + C_N_ADD_ASR_SP).

In case a TCS control unit can send only a fast TQ reduction request (CONF_ASR_SLOW = 0), the EMS can calculate a slow TQ reduction request out of the fast request.

Application conditions:

Initialisation: at reset LV_ASR_ACT = 0

TQI_ASR_FAST = 1023.97 Nm

TQI_ASR_SLOW = 1023.97 Nm

TQI_ASR_BOL = 1023.97 Nm

TQI_ASR_SLOW_CLC = 1023.97 Nm

TQI_DIF_EMS_ASR_FAST = 1023.97 Nm

T_DLY_TQI_ASR_SLOW_FAST = 0 s

Recurrence: 10 ms

Activation: at LV_IGK = 1

Deactivation: -

Formula section:

D.17 Torque Request for Cruise Control

D.17.1 Torque request of EMS internal Cruise control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TQ_REQ_CRU	V/O	0 .. FFFF H	0 .. 1.999969	3.0517E-5	-
scaling factor for requested torque at clutch from cruise control					

Input data:

FAC_TQ_CRU	LV_CRU_ACT	VS_CRU_FIL	VS_SP_DRIV_CRU
FAC_TQ_REQ_DRIV	FAC_TQ_CRU_INI	CONF_CRU	

General information:

Depending on the cruise controller manipulated variable FAC_TQ_CRU the interpretation of torque request is calculated. Regarding the different resolutions the output of cruise control is converted to resolutions at the torque structure interface.

If the Cruise Control is deactivated by resetting CONF_CRU, then the FAC_TQ_REQ_CRU is set to 0.

Application conditions:

Activation: every engine state

CONF_CRU = 1

Recurrence: 10 ms

Initialization: FAC_TQ_REQ_CRU = 0 at reset

Deactivation: **If** CONF_CRU = 0

then FAC_TQ_REQ_CRU = 0

Formula section:

General calculation after initialisation:

$$FAC\_TQ\_REQ\_CRU = \frac{FAC\_TQ\_CRU}{99{,}6\%}$$

At initialisation of Cruise control:

To get a smooth transition into cruise controlled drive the initialisation ramp is, depending on vehicle speed, in relation to the vehicle speed demand by the driver:

This query once :

IF (1) LV_CRU_ACT = 0 to 1

and FAC_TQ_CRU / 99,6% > FAC_TQ_REQ_DRIV

Then (1.1) at the first time FAC_TQ_REQ_CRU = FAC_TQ_REQ_DRIV

This query until the end condition (until (1)) is fulfilled:

IF (2) VS_CRU_FIL ≤ VS_SP_DRIV_CRU

Then (2)

FAC_TQ_REQ_CRU = FAC_TQ_REQ_CRU + C_LGRD_TQ_CRU_INC_1

Else (2)

FAC_TQ_REQ_CRU = FAC_TQ_REQ_CRU + C_LGRD_TQ_CRU_INC_2

Until (1.1) FAC_TQ_REQ_CRU >= FAC_TQ_CRU / 99,6%

Else (1)

$$FAC\_TQ\_REQ\_CRU = \frac{FAC\_TQ\_CRU}{99{,}6\%}$$

Endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_LGRD_TQ_CRU_INC_1	V/O	0 .. FFFF H	0 .. 1.999969	3.0517E-5	-

C_LGRD_TQ_CRU_INC_2	V/O	0 .. FFFF H	0 .. 1.999969	3.0517E-5	-
Change limitation for cruise control requesrt out of higher vehicle speed					

D.18 Torque request for MSR

FUNCTION DESCRIPTION:

To avoid the vehicle from skidding (on road surfaces with low friction coefficient, e.g. ice) during PU or PUC due to high engine friction torque, the drag torque has to be reduced.

By increasing the indicated engine torque, wheel slip is reduced, leading to a higher lateral stability of the wheels

D.18.1 Enable conditions for MSR intervention

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MSR_ENA	V/O	0...1H	0...1	1	-
Logical variable for MSR intervention enabling					

Input data:

LV_MSR_INH_INT_MSR	LV_MSR_INH_T_MSR	LC_INH_MSR	LV_ST
LV_ASR_REQ	LV_ERR_TPS	TQI_MSR_CAN	VS
LV_MSR_INH_MON	LV_IGK	LV_ERR_CAN	LC_TQI_MSR_REQ_MAN
LV_ES	LV_N_LIM_ETC_LIH	LV_OFF_MTC_MON	

FUNCTION DESCRIPTION:

General information:

The MSR intervention function is enabled if the vehicle speed is higher than C_VS_MIN_MSR and no errors at relevant components are recognized and MSR must not be inhibited by safety relevant functions (time counter, plausibiltity check, Monitoring of MSR)

Furthermore no ASR-request and no TPS-failure is active

Application conditions:

Initialisation: at reset

LV_MSR_ENA = 0

Recurrence: 10 ms

Activation: LV_IGK = 1

Formula section:

If LC_TQI_MSR_REQ_MAN = 1

or

(LV_ES = LV_ST = 0

and LV_MSR_REQ = 1

and LV_ASR_REQ = 0

and LV_MSR_INH_T_MSR = 0

D.18.2 MSR intervention

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQI_MSR	V/O	0...7FFFH	0...1023.97	0.03125	Nm
Value for fast torque intervention due to MSR					
LV_MSR_ACT	V/O	0.1H	0.1	1	-
Logical variable for torque intervention due to MSR					

Input data:

LV_MSR_REQ	LV_MSR_ENA	LV_IGK	TQI_TCS_CAN
TQI_MSR_CAN	TQI_MSR_REQ	LC_TQI_MSR_REQ_MAN	

FUNCTION DESCRIPTION:

General information:

If following conditions are fulfilled, the torque intervention for MSR is performed(LV_MSR_ACT = 1),

1) a torque intervention request from the MSR is recognized through LV_MSR_REQ = 1
2) the MSR intervention function is enabled (LV_MSR_ENA = 1)
3) The sum of the complemental value of TQI_MSR_CAN through TQI_TCS_CAN and TQI_MSR_CAN is FFh.

These variables are handed over to the relevant torque coordination functions.

Application conditions:

Initialisation: at reset
LV_MSR_ACT = 0
TQI_MSR = 0 Nm

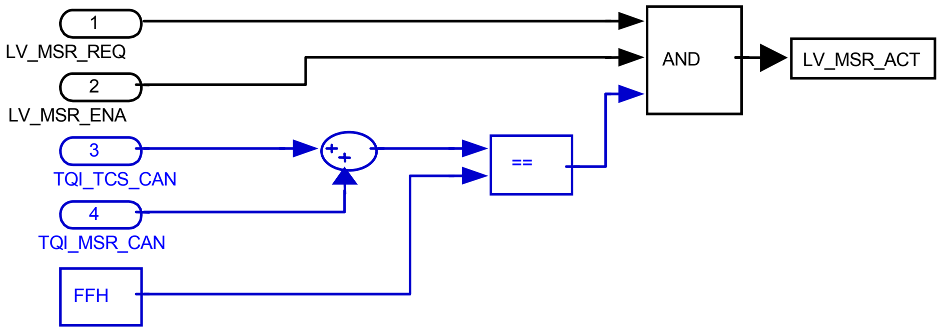
Recurrence: 10 ms

Activation: LV_IGK = 1

Formula section:

If LC_TQI_MSR_REQ_MAN = 1
or
(LV_MSR_REQ = 1
and LV_MSR_ENA = 1
and (TQI_TCS_CAN + TQI_MSR_CAN) = FFh)
Then LV_MSR_ACT = 1
and TQI_MSR = TQI_MSR_REQ
Else LV_MSR_ACT = 0
and TQI_MSR = 0 Nm

Signal flow diagram:



D.18.2.1 MSR Plausibility check

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Turbine temperature difference threshold for activation of overheating prevention					

D.19.1 General information

The torque based turbine overheating prevention is an additional way after the lambda enrichment to reduce the turbine temperature. Therefore the information of the lambda turbo overheating prevention will be used for the activation and calculation of the TQ- intervention. If the lambda enrichment is not sufficient to reduce the exhaust gas temperature on the turbine the calculation of the torque intervention will be activated. Additional to this torque intervention the overspeed- and wastegate influence is considered on the charger side.

Application Condition

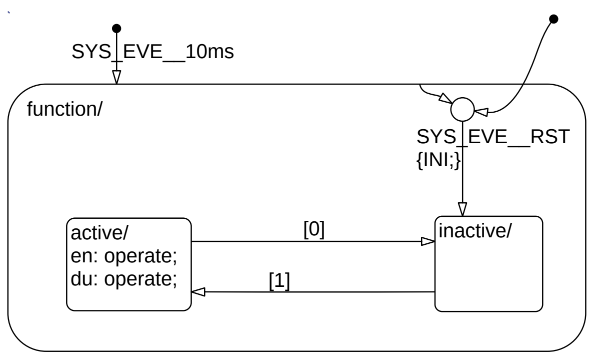

Figure 20 EXTC_ISPCLohp0/ APP_CDN/ Chart

Function Description

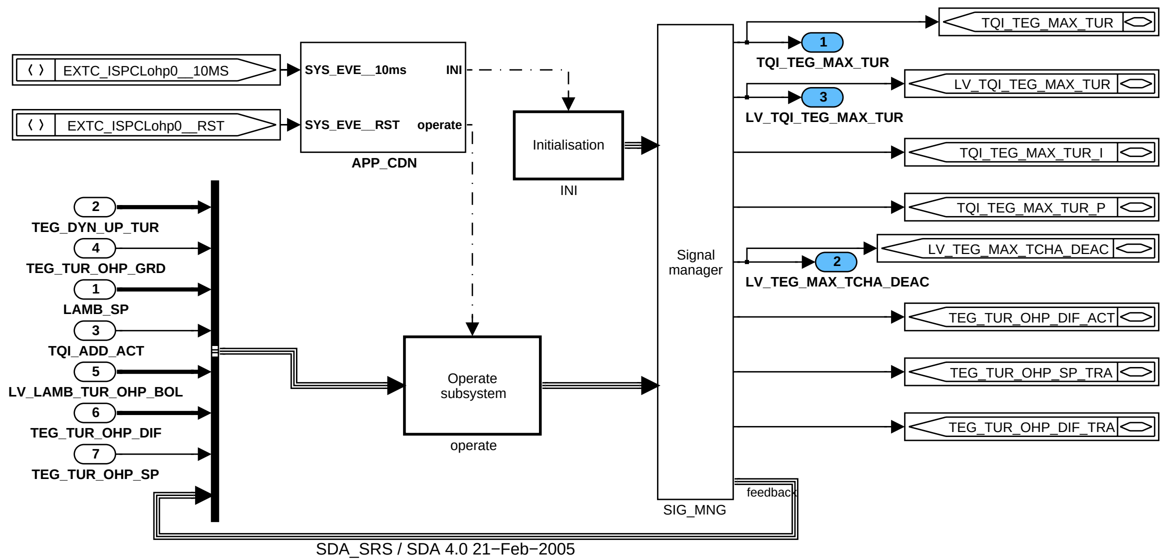

Figure 21 EXTC_ISPCLohp0

D.19.1.1 Initialisation

The outputs are initialised at reset.

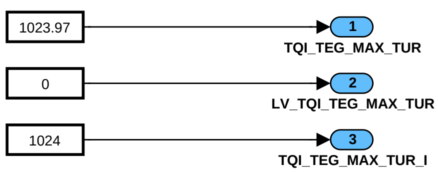

Figure 22 EXTC_ISPCLohp0/ INI/ SUB

D.19.1.2 Operate subsystem

If C_TEG_DYN_TUR_MAX_TCHA_DEAC is reached the turbo will be deactivated (function s. CHRG) and there will be a failure entry. The normal case is that the controller-function is calculated.

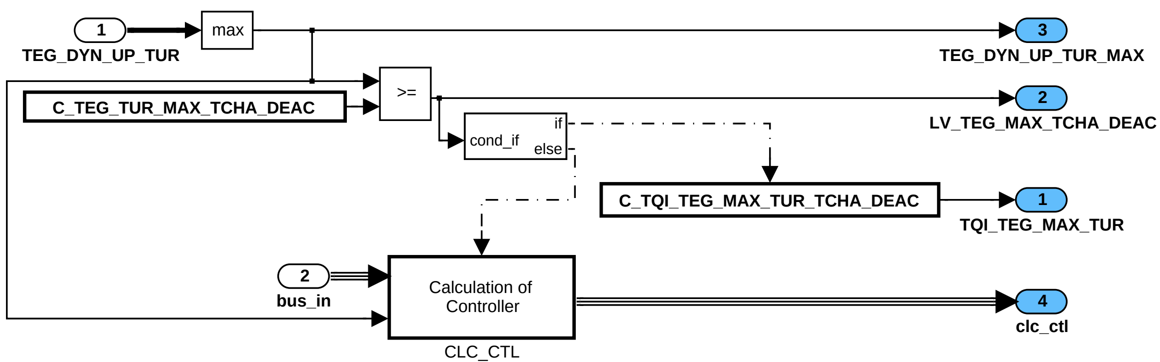

Figure 23 EXTC_ISPCLohp0/ operate/ SUB

Calculation of controller

The activation of the controller is depending on the temperature gradient. Via C_LAMB_SP_MAX_TQI_TEG_MAX_TUR you can calibrate a Lambda-setpoint that has to occur to activate the torque-limitation (1st the temperature-controller via lambda shell be active and reduce the lambda-setpoint). The I-part of the controller is ramped up after deactivation. As long as it not has reached TQI_ADD_ACT the controller stays active.

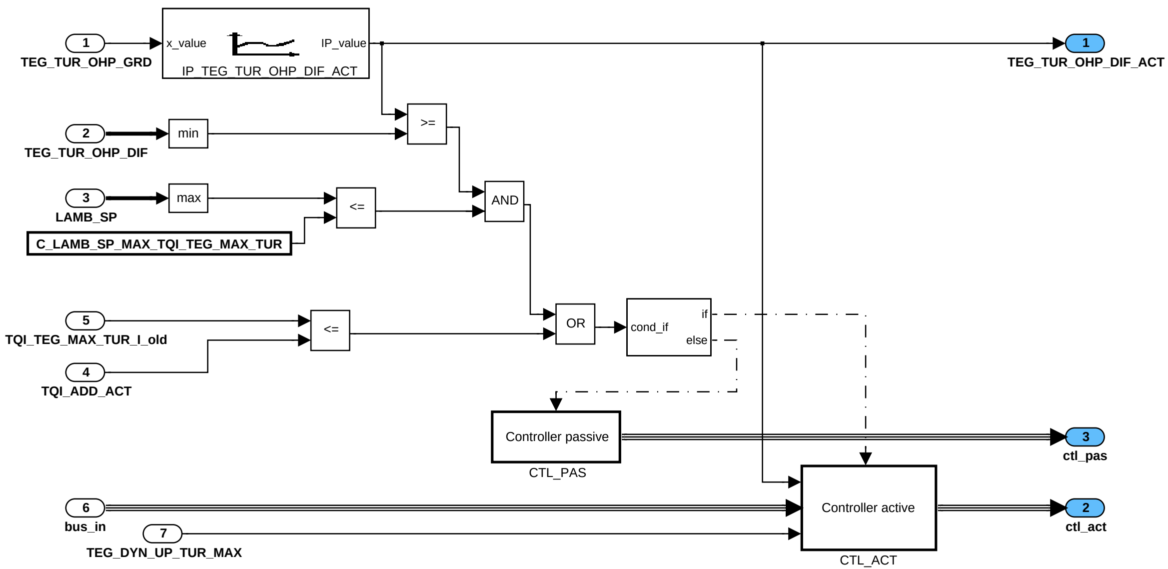

Figure 24 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB

Controller active

This function part is only calculated if the controller is active. LV_TQI_TEG_MAX_TUR is set to 1. Via [TEG_TUR_OHP_SP_TRA – turbine temperature] –the control deviation- it is decided if torque has to be reduced (TEG is too hot) or if the limitation can be increased (TEG is not too hot).

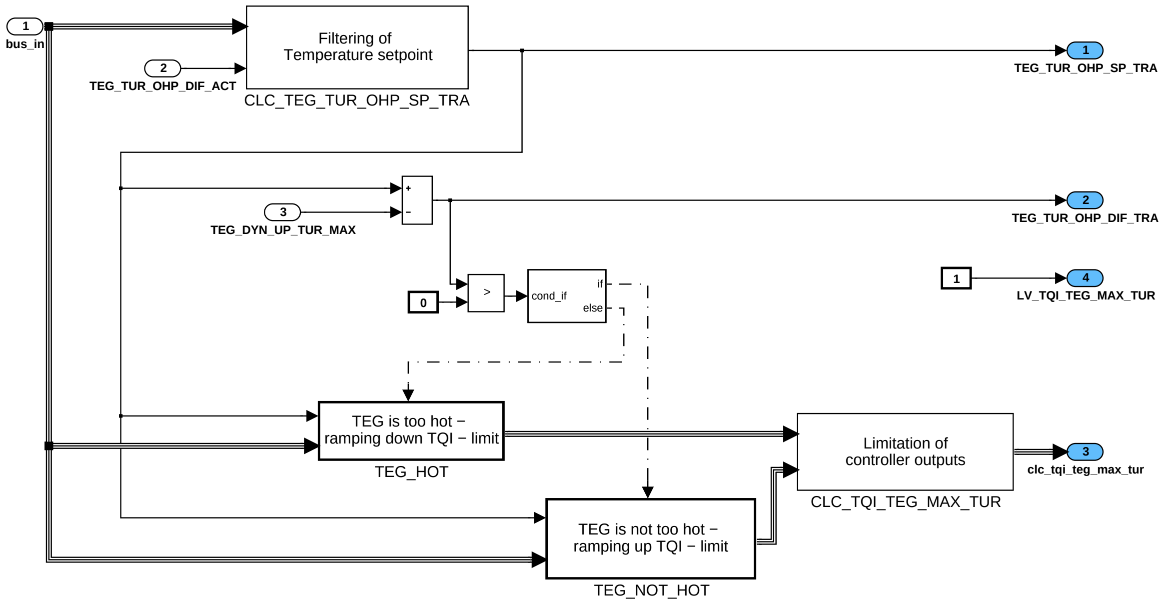

Figure 25 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_ACT/ SUB

Filtering of temperature setpoint

The temperature setpoint can be filtered. The first value after controller activation is the temperature setpoint (input from “Turbo charger overheating prevention” – via lambda enrichment) minus the gradient-depending activation-temperature-difference.

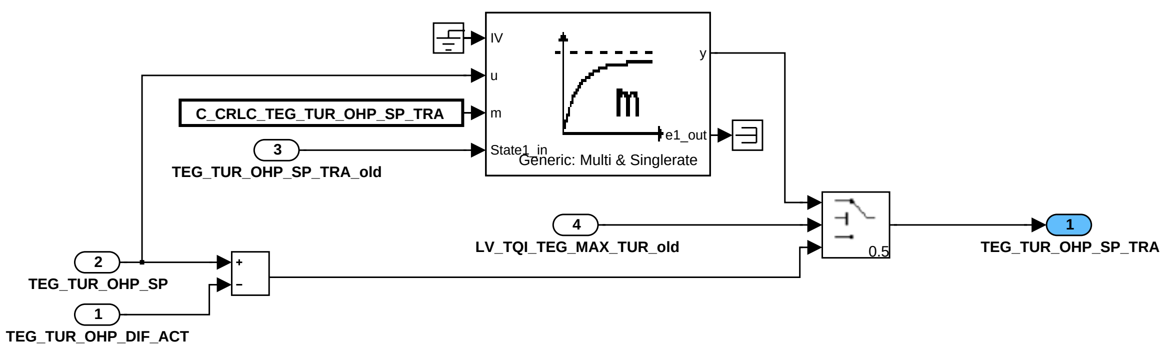

Figure 26 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_ACT/ SUB/ CLC_TEG_TUR_OHP_SP_TRA/ SUB

TEG is too hot - ramping down TQI - limit

The P-part is the product of a factor and the control deviation. The I-part is based on a minimum selection of the old value or the actual torque (inclusive torque reserve). The new term is also the product of a factor and the control deviation. With LC_TQI_TEG_WOUT_LAMB_ENA it is possible to choose to freeze the I-part or not in the case that the temperature-controller via lambda is not at its bottom limit.

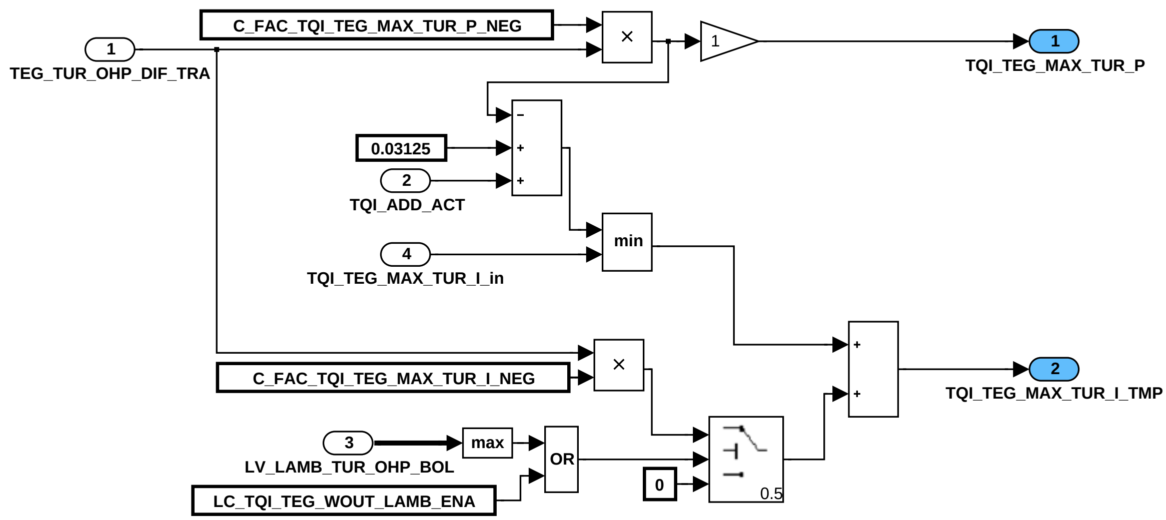

Figure 27 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_ACT/ SUB/ TEG_HOT/ SUB

TEG is not too hot - ramping up TQI - limit

There are several calibration data for down and up – ramping.

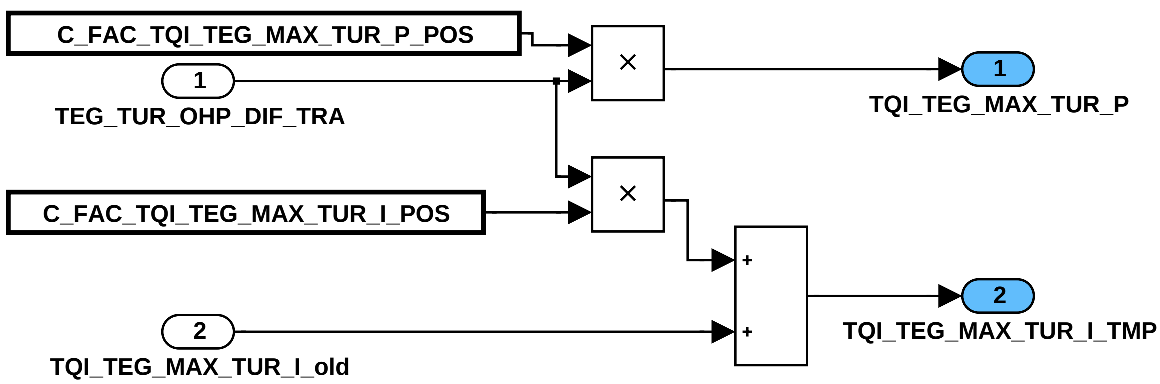

Figure 28 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_ACT/ SUB/ TEG_NOT_HOT/ SUB

Limitation of controller outputs

The I-part is limited. The addition with the P-part gives the controller output TQI_TEG_MAX_TUR. This value also is limited.

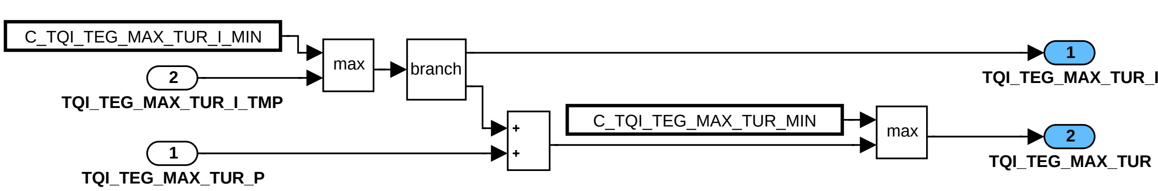

Figure 29 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_ACT/ SUB/ CLC_TQI_TEG_MAX_TUR/ SUB

Controller passive

If the temperature is in no critical range, the output variables are set to passive values.

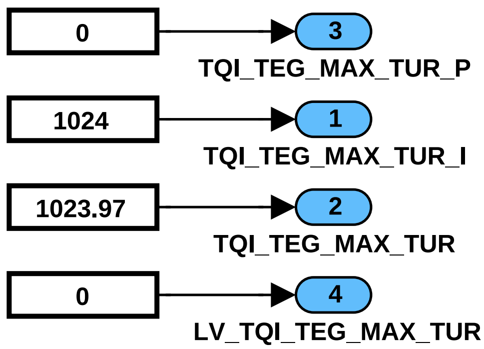

Figure 30 EXTC_ISPCLohp0/ operate/ SUB/ CLC_CTL/ SUB/ CTL_PAS/ SUB

D.20 Torque based overheating prevention

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQI_MAX_OHP	O/V	0...7FFFH	0...1.02397E+3	0.03125	Nm
Maximum indicated torque due to overheating prevention (of cat. or turbine)					
LV_TQI_OHP	O/V	0...1H	0...1	1	-
indicates if overheating prevention (of catalyst or turbo charger) is active					
LV_TQI_COP	V	0...1H	0...1	1	-
torque limitation due to COP requested					
POW_MAX_COP	V	0...FFFFH	0...439.22	0.0067020643	KW
maximum indicated power due to catalyst temperature					
TQI_TEG_MAX_COP	V	0...7FFFH	0...1.02397E+3	0.031250038	Nm
maximum indicated torque due to catalyst overheating prevention					

Input data:

TQI_TEG_MAX_TUR	LV_TQI_TEG_MAX_TUR	LAMB_COP[NC_CBK_EX_NR]	N_32
TEMP_CAT_DYN_MDL[NC_CBK_EX_NR]	TQI_AV		

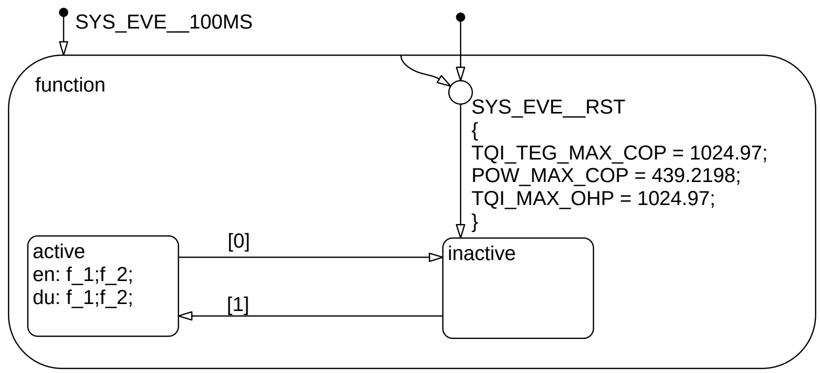
Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_LAMB_MIN_POW_COP	1	0...7FFFH	0...31.999	9.76563E-4	-
Lambda threshold for activation of COP power limitation					
C_POW_COP_DELTA	1	0...FFH	0...17.0903	0.0670206	kW/s
De- or increase of power limitation ramp					
C_POW_COP_MIN	1	0...FFFFH	0...439.22	0.0067020643	KW
minimum indicated power during torque reduction for COP					
C_TEG_MIN_POW_COP	1	0...7FFFH	-273.15 ... 1.77479E+3	0.0625	°C
Threshold of exhaust gas temperature for activation of COP power limitation					

D.20.1 General information

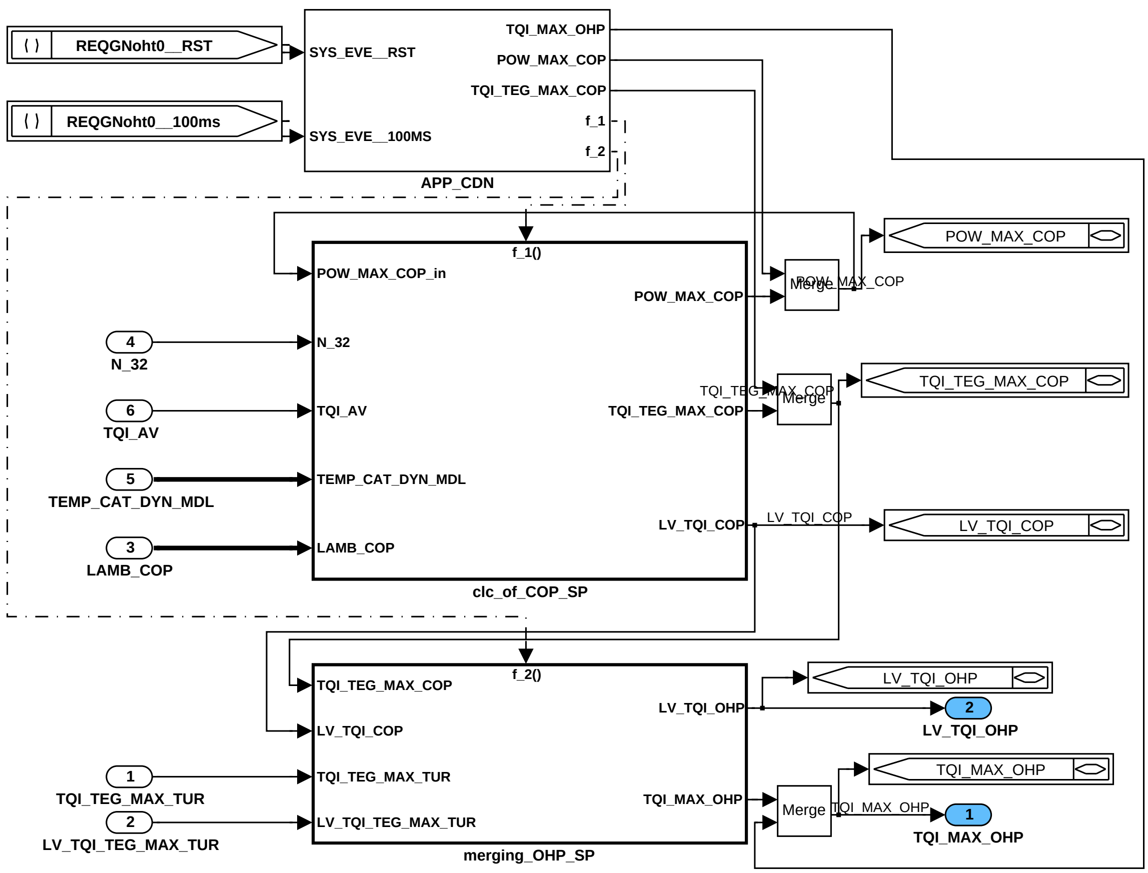
In case of critical catalyst temperatures the exhaust gas is cooled down by enrichment. If the lambda runs below the threshold C_LAMB_COP_POW_MIN the engine power has to be reduced as a second path to limit the maximum exhaust gas temperature. Once the exhaust gas temperature falls below C_TEG_POW_LIM the maximum engine power is ramped up again to the maximum value. These ramps have to calibrated slow to prevent a bad influence of driveability.

Application Condition



EXTC_REQGNoht0/APP_CDN/Chart

Function Description



SDA_SRS / SDA 3.1 22−Sep−2003

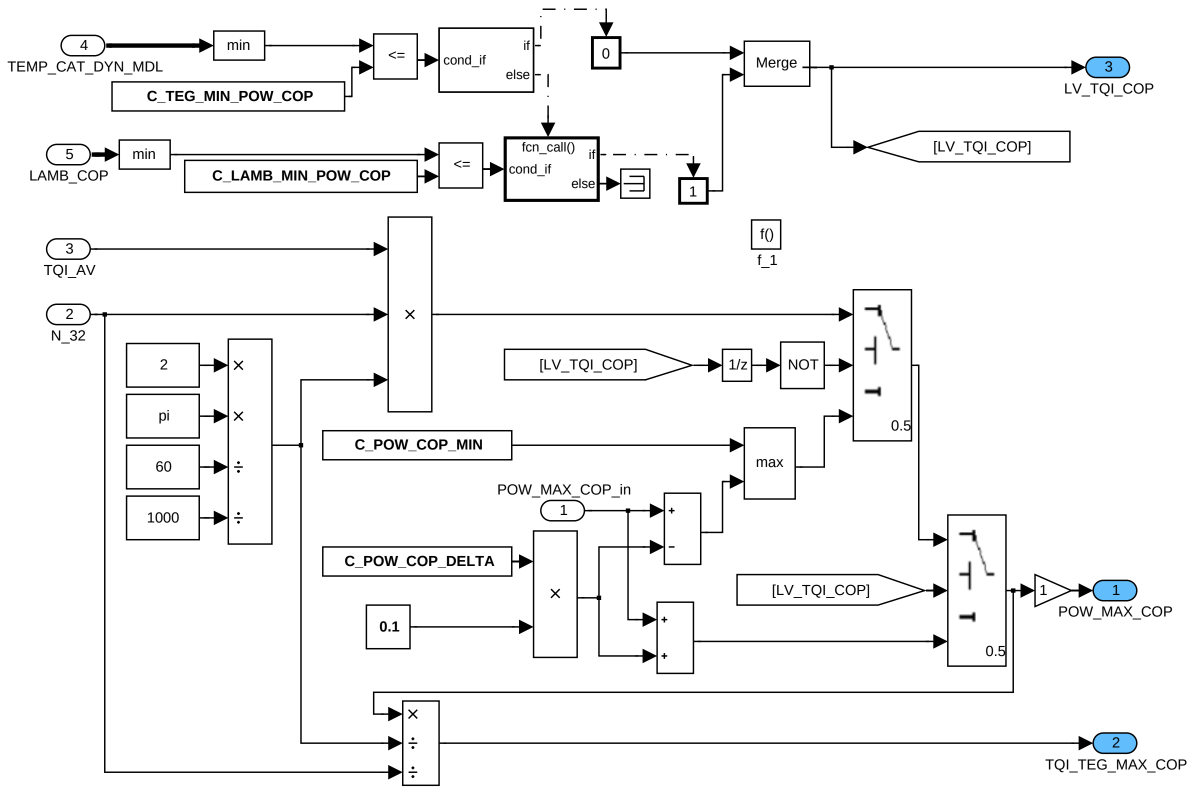
EXTC_REQGNoht0

D.20.1.1 Calculation of COP setpoints

In the case that LV_TQI_COP becomes 1, POW_MAX_COP has to be initialised with TQI_AV to get a smooth air reduction.

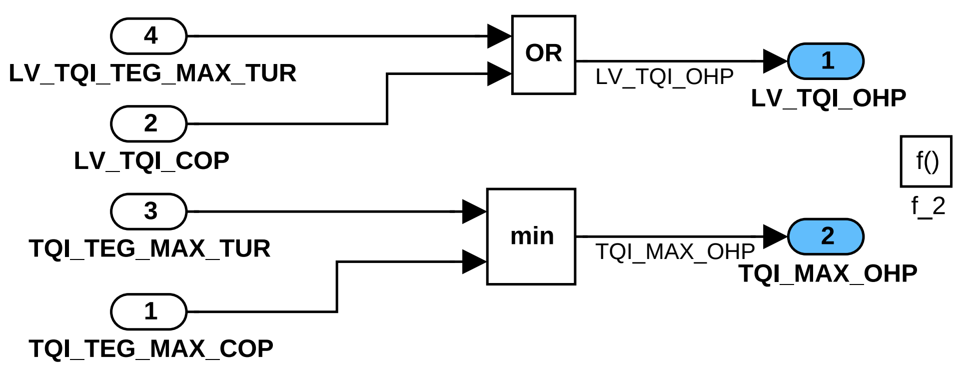
If LV_TQI_COP becomes 0 again, POW_MAX_COP is increased to its maximum value.

In order to realize the requested power limitation, it has to be converted in equivalent torque.



EXTC_REQGNoht0/clc_of_COP_SP

The maximum torque values due overheating prevention of turbine and catalyst are merged to LV_TQI_OHP and TQI_MAX_OHP.



EXTC_REQGNoht0/merging_OHP_SP

D.21 Engine Torque Limitation

D.21.1 Torque limitation coordination

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQI_P_MAX_SLOW	V/O	8000 ... 7FFFH	-1024 ... 1023.97	0.03125	Nm
Maximum allowed indicated torque due to torque limitation (slow path)					
TQI_P_MAX_FAST	V/O	8000 ... 7FFFH	-1024 ... 1023.97	0.03125	Nm
Maximum allowed indicated torque due to torque limitation (fast path)					

Input data:

TQI_TCHA_PROT	TQI_MAX_OHP		

General information:

With the help of this function, the maximum allowed indicated torque can be limited (power limitation). Limitations for the turbocharger, exhaust system and overboost are coordinated here. The limitations are only introduced to the slow (air) path of the torque model.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: at reset TQI_P_MAX_SLOW = 1023.97 Nm
TQI_P_MAX_FAST = 1023.97 Nm

Update rate: 10 ms

Calculation order

1) chapter 1.2 with recurrence: 40 ms

2) chapter 1.3 with recurrance 40 ms

3) this chapter (1.1) with recurrence: 10 ms

Formula section:

TQI_P_MAX_FAST = 1023.97 Nm

TQI_P_MAX_SLOW = min (TQI_MAX_OHP, TQI_TCHA_PROT, TQI_POW_LIM, TQI_POW_IGA)

D.21.2 Permanent Power Limitation including Overboost

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

TQI_POW_MAX_REQ_CLU_2	-	8000...7FFFH	-1024... 1023.96875	0.03125	[Nm]
Maximum indicated torque for power limitation used for the driver request calculation (overboost strategy 2)					
TQ_MAX_BAS_FTL	V	8000...7FFFH	-1024... 1023.96875	0.03125	[Nm]
Maximum torque based on fuel tank level					

Input data:

TQ_AV	N_32	TQ_LOSS	TCO
VS	TOIL	LC_TCHA_CONF	TQ_LOSS_REQ_CLU
TQI_SP_SLOW	FAC_TQ_REQ	FTL	

General information:

This function provides the possibility to limit the maximum engine torque to TQ_MAX_BAS, depending on TCO and TOIL. An additional overboost torque IP_TQ_OVB_BAS (N_32) could be provided for a limited time. The transition between overboost torque und nominal torque TQ_MAX_BAS is done by ramp functions.

Application conditions:

Initialisation: TQI_POW_MAX_REQ_CLU = 1024 Nm
TQ_MAX_BAS = 1024Nm
CTR_OVB = 65535
CTR_TQ_OVB = 0
LV_TQ_OVB_FDOUT = 0
TQI_POW_LIM = 1024 Nm
FAC_TQ_OVB_AVL = 1 at reset

Recurrence: 40ms

Activation: at every engine operation state, if LC_TCHA_CONF = 1

Formula section:

TQ_MAX_BAS_TCO = IP_TQ_MAX_BAS_TCO (N_32, TCO)

TQ_MAX_BAS_TOIL = IP_TQ_MAX_BAS_TOIL (N_32, TOIL)

TQ_MAX_BAS_FTL = IP_TQ_MAX_BAS_FTL (FTL)

TQ_MAX_BAS = MIN (TQ_MAX_BAS_TCO, TQ_MAX_BAS_TOIL, TQ_MAX_BAS_FTL)
TQI_MAX_BAS = TQ_MAX_BAS - TQ_LOSS
TQ_OVB_BAS = IP_TQ_OVB_BAS (N_32) ;additional overboost ;torque range

For engine protection the overboost torque could be weighted by vehicle speed and oil temperature:

FAC_OVB_TOIL = IP_FAC_OVB_TOIL (TOIL)
FAC_OVB_VS = IP_FAC_OVB_VS (VS)
TQ_OFS_MAX_OVB = TQ_OVB_BAS * FAC_OVB_TOIL * FAC_OVB_VS

D.21.2.1 Overboost strategy 1

This strategy works with a counter to activate and deactivate the overboost. It only limits the torque setpoint without influencing the driver request calculation.

This section is *only calculated for C_OVB_MOD = 0 or C_OVB_MOD = 2*.

Calculation of de/increasing torque ramp:

If TQ_AV > TQ_MAX_BAS ;max. permanent torque exceeded?
then LV_TQ_OVB_MAX = 1 ;activate decreasing ramp
else LV_TQ_OVB_MAX = 0 ;activate increasing ramp
endif;

If LV_TQ_OVB_MAX = 1
then CTR_OVB(N) = MIN [C_CTR_OVB_INI; CTR_OVB(N-1) – C_CTR_OVB_DEC]
else CTR_OVB(N) = MIN [C_CTR_OVB_INI; CTR_OVB(N-1) + C_CTR_OVB_INC]
endif;

Calculation of the overboost torque range and maximum torque threshold:

The following formula could be explained by seperation of 3 different cases:
Counter value CTR_OVB > C_CTR_OVB_THD: full overboost torque available
Counter value 0 < CTR_OVB < C_CTR_OVB_THD: available overboost torque is ramped up/down
Counter value CTR_OVB = 0: no overboost torque available

TQ_OVB = TQ_OFS_MAX_OVB * MIN [CTR_OVB / C_CTR_OVB_THD; 1]

TQ_POW_LIM = TQ_MAX_BAS + TQ_OVB
TQI_POW_LIM_1 = TQ_POW_LIM - TQ_LOSS
(= indicated engine torque with current overboost)

TQI_POW_MAX_REQ_CLU_1 =

TQ_MAX_BAS + TQ_OFS_MAX_OVB – TQ_LOSS_REQ_CLU
(= indicated engine torque with maximum overboost)

Calibration hint: The time with maximum overboost torque TQ_OVB_BAS is determined by C_CTR_OVB_INI > C_CTR_OVB_THD.

D.21.2.2 Overboost strategy 2

To avoid a dead zone of the pedal when the overboost is over, this algorithm increases or decreases the reference torque for the driver request calculation depending on the state of the overboost function. This is done via TQI_POW_MAX_REQ_CLU_2, which limits the Maximum torque at clutch. The same value is also fed into the Minimum/Maximum torque request selection to ensure a limitation of the torque setpoint.

This section is *only calculated for C_OVB_MOD = 1 or C_OVB_MOD = 3*.

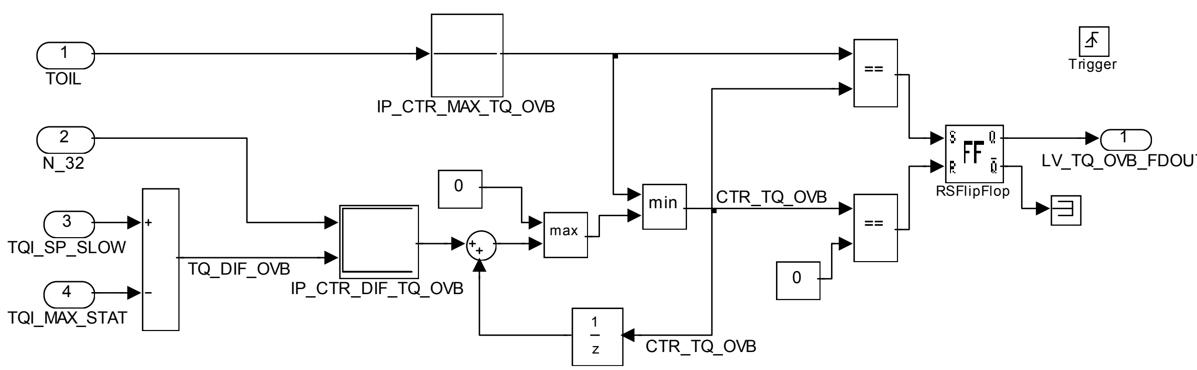
The maximum indicated torque for stationary engine operation is calculated as:

TQI_MAX_STAT = TQ_MAX_BAS - TQ_LOSS_REQ_CLU

Depending on the difference TQ_DIF_OVB between slow setpoint for the indicated engine torque and maximum torque for stationary operation, a counter is incremented and decremented. Increment and decrement are defined in IP_CTR_DIF_TQ_OVB, which must be calibrated to positive values for TQ_DIF_OVB > 0 and negative values for TQ_DIF_OVB < 0. The maximum value of the counter IP_CTR_MAX_TQ_OVB is a function of the oil temperature. When the counter reaches this maximum value, a fade out of the overboost is requested with LV_TQ_OVB_FDOUT. The flag is reset to zero when the counter reaches zero.

(Hint for SW implementation: Note data type conversions for the interpolation map IP_CTR_DIF_TQ_OVB because input and output of the map must be unsigned.)

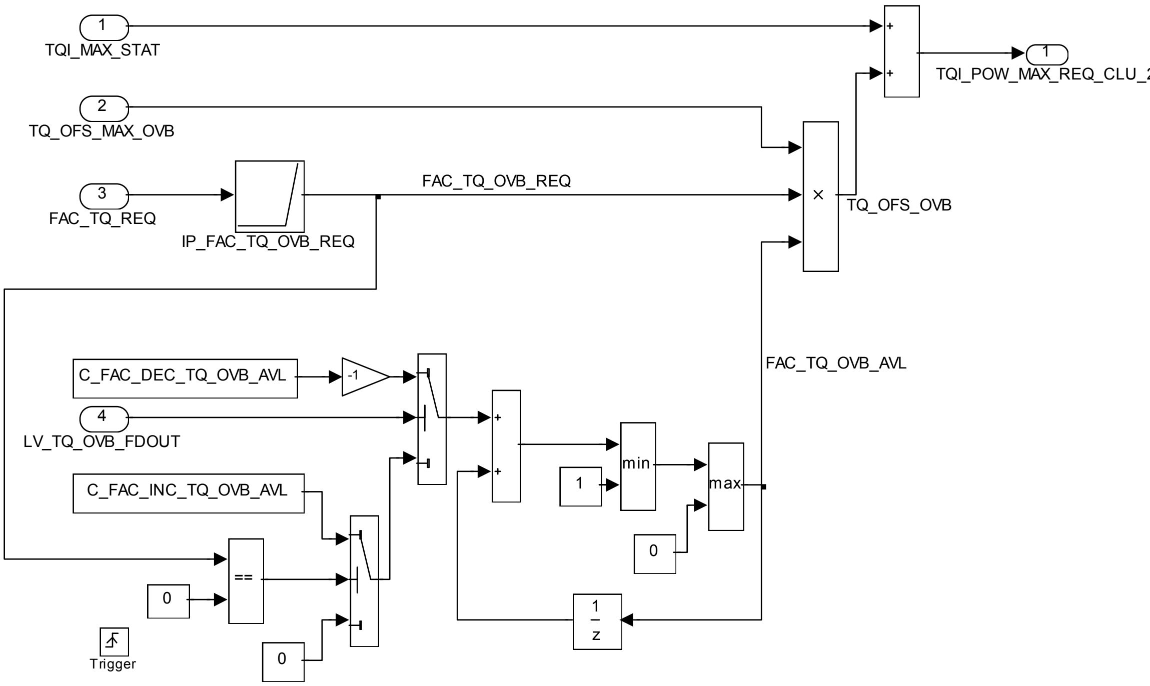
To calculate the overboost torque offset TQ_OFS_OVB, the maximum overboost offset TQ_OFS_MAX_OVB is multiplied by two factors.



The first factor FAC_TQ_OVB_REQ serves to activate the overboost depending on the driver request. This is realized with a map IP_FAC_TQ_OVB_REQ with the input FAC_TQ_REQ. The map shall be calibrated zero at small scaling factors to deactivate the overboost offset and shall increase to 1 at higher scaling factors to request the full overboost.

The second factor FAC_TQ_OVB_AVL defines which percentage of the overboost is currently available. If a regeneration is requested, this factor is ramped down to zero in order to fade out the overboost. If no regeneration is requested and if FAC_TQ_OVB_REQ is zero, FAC_TQ_OVB_AVL is ramped up to make the overboost available again. The check of FAC_TQ_OVB_REQ ensures that the overboost function does not increase the torque request without action of the driver.

The maximum allowed torque TQI_POW_MAX_REQ_CLU_2 is the maximum stationary torque TQI_MAX_STAT plus the overboost offset TQ_OFS_OVB.



D.21.2.3 Coordination of overboost output variables

The output TQI_POW_MAX_REQ_CLU is taken into account for the Maximum torque at clutch. It will therefore influence the reference of the driver request. In contrast to this, TQI_POW_LIM is taken into account in the Minimum/Maximum torque request selection and will just limit the torque request.

If C_OVB_MOD = 0

then *Use overboost strategy 1:*

TQI_POW_MAX_REQ_CLU = TQI_POW_MAX_REQ_CLU_1
TQI_POW_LIM = TQI_POW_LIM_1

elseif C_OVB_MOD = 1

Use overboost strategy 2:

TQI_POW_MAX_REQ_CLU = TQI_POW_MAX_REQ_CLU_2
TQI_POW_LIM = TQI_POW_MAX_REQ_CLU_2

elseif C_OVB_MOD = 2

Use overboost strategy 1, with no limitation of driver request:

TQI_POW_MAX_REQ_CLU = 1023.96875Nm
TQI_POW_LIM = TQI_POW_LIM_1

else *Use overboost strategy 2 with no limitation of driver request:*

(calibration of C_OVB_MOD = 3)

TQI_POW_MAX_REQ_CLU = 1023.96875 Nm
TQI_POW_LIM = TQI_POW_MAX_REQ_CLU_2

endif;

torque reduction due to IGA retard					
IGA_DIF_POW_THD	V	0...80H	-48...0	0.375	[°CRK]
Activation threshold for torque reduction due to IGA retard					

Input data:

IGA_MV_ADJ_KNK	MAF_HB	N_32	TQI_AV
TQI_MAX_BAS	EFF_TOT_BAS_SLOW	TQI_REF	

Application conditions:

Initialisation: TQI_POW_IGA = 1024 Nm
TQ_DELTA_POW_IGA = 0 Nm at reset

Recurrence: 40ms

Activation: at every engine operation state, if LC_TCHA_CONF = 1

General information:

The IGA retards of due to knock events are compared to a calibrated minimum ignition angle (IP_IGA_DIF_COP_MIN). In case the minimum ignition angle is exceeded, the actual torque is reduced.

Formula section:

The following IGA condition triggers the power limitation, whereas the TQI condition usually controls the deactivation.

IGA_DIF_POW_THD = IP_IGA_DIF_COP_MIN (MAF_HB, N_32)
+ IP_IGA_ADD_COP_MIN_TIA_N_32 (TIA;N_32)
***Hint for SW**: IGA_DIF_POW_THD must be limited to -48 and 0 °CRK*

If IGA_MV_ADJ_KNK < IGA_DIF_POW_THD
then LV_POW_IGA = 1
else LV_POW_IGA = 0

The initialisation of TQI_POW_IGA_INI is made in a way that the MAF_SP course is continous and smooth:

If LV_POW_IGA = 0 -> 1
then TQI_POW_IGA_INI = TQI_REF * EFF_TOT_BAS_SLOW
TQ_DELTA_POW_IGA = 0
endif

Calculation of TQI_POW_IGA: The decrease and increase of the torque request is done by an I-Controller.

If LV_POW_IGA = 1

then $TQ\_DELTA\_POW\_IGA_{n}$ =
$TQ\_DELTA\_POW\_IGA_{n-1}$ +
[C_TQ_DELTA_POW_IGA_I * (IP_IGA_DIF_COP_MIN(MAF_HB,N_32) - IGA_MV_ADJ_KNK)];

Limitation:
0 <= TQ_DELTA_POW_IGA <= C_TQ_DELTA_POW_IGA_MAX

Maximum indicated torque:
TQI_POW_IGA = TQI_POW_IGA_INI – TQ_DELTA_POW_IGA

else Increase torque to maximum value (deactivation):
$TQI\_POW\_IGA_{n} = TQI\_POW\_IGA_{n-1} + C\_TQ\_DELTA\_POW\_IGA\_DEAC$

endif

Final limitation of TQI_POW_IGA to an absolute level below TQ_MAX_BAS

If TQI_POW_IGA < TQI_MAX_BAS – IP_TQ_DELTA_POW_IGA_MAX_ABS (TAM)
then TQI_POW_IGA = TQI_MAX_BAS – IP_TQ_DELTA_POW_IGA_MAX_ABS (TAM)
endif

Calibration data:

LDP_TQI_SP_MAF_IP_MAF_SP	12	0...7FFFH	0...1023.97	0.03125	Nm
Setpoint mass air flow depending on slow torque setpoint					

D.22.1 General Information

The output parameter MAF_SP_TQI represents the mass air flow setpoint for the homoge-neous combustion mode. It is utilized as an input parameter for the reverse Intake Manifold Model, where it is translated into a setpoint for the opening angle of the throttle blade. MAF_SP_TQI is obtained from the map IP_MAF_SP (inverse map of IP_TQI_REF) as a function of engine speed N_32 and the corrected torque setpoint TQI_SP_MAF.

The torque setpoint TQI_SP_MAF is principially a function of TQI_SP_SLOW and EFF_TOT_BAS_SLOW. Since the engine requires a minimum amount of air/fuel-mixture for stable combustion, TQI_SP_MAF is limited to TQI_MIN_PU at light load conditions. In the case of fuel cut-off (LV_PUC = 1), TQI_MIN_PU is utilized to control the absolute pressure in the intake manifold.

Input data:

LV_ES			

D.24.1 General Information

For certain modes of fuel injection deactivation it might be necessary to have a correspond-ing basic efficiency for fuel cut-off (e.g. cylinder bank deactivation). There can also be more than one mode with a certain efficiency, so this needs to be coordinated.

This module can be adapted to project specific needs for calculation of EFF_SCC_BAS. With the logical variable LV_EFF_BAS_REQ the value EFF_SCC_BAS is obtained from EFF_SCC_BAS_REQ.

D.25.1 General Information

The objective of this module is to generate a torque intervention by fuel cut-off pattern.

This torque intervention could be caused by several conditions which are summarized in the label LV_AUTH_TQ_PAT (see chapter 1.1.1 "Authorization for single cylinder cut-off"). The label LV_FCUT_FAST can be used for project specific fast fuel cut-off conditions.

Based on the TQI_REQ_FAST and the TQI_REF corrected with the basic a/f ratio efficiency and the ignition angle efficiency an efficiency setpoint for the single cylinder cut-off EFF_SCC_SP is calculated, which leads to the pattern index NR_PAT_SCC (see chapter "Setpoint efficiency fuel cut-off").

In general, a torque reduction could be realized by spark retarding or single cylinder cut-off. With the scaling factor FAC_IGA_MIN_TEG_IGA_BAS a scaling between earliest cylinder cut-off (no spark retarding) and latest cylinder cut-off (full spark retarding up to IGA_MIN) can be realized (see chapter"Determination of scaling factor").

Function Description

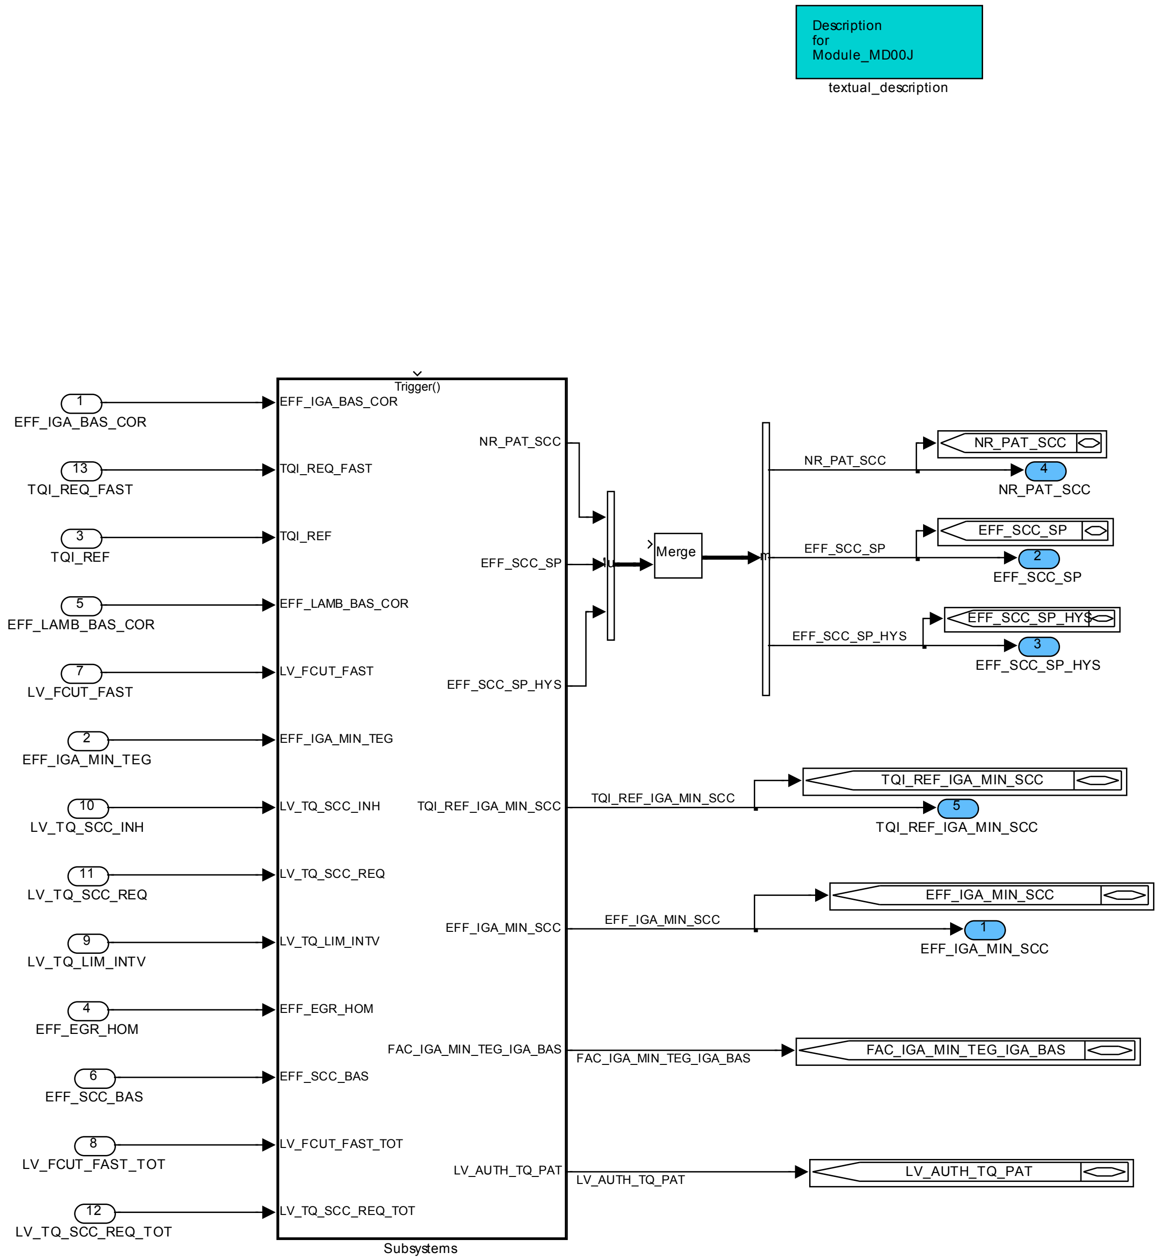

Figure 35 MD00J

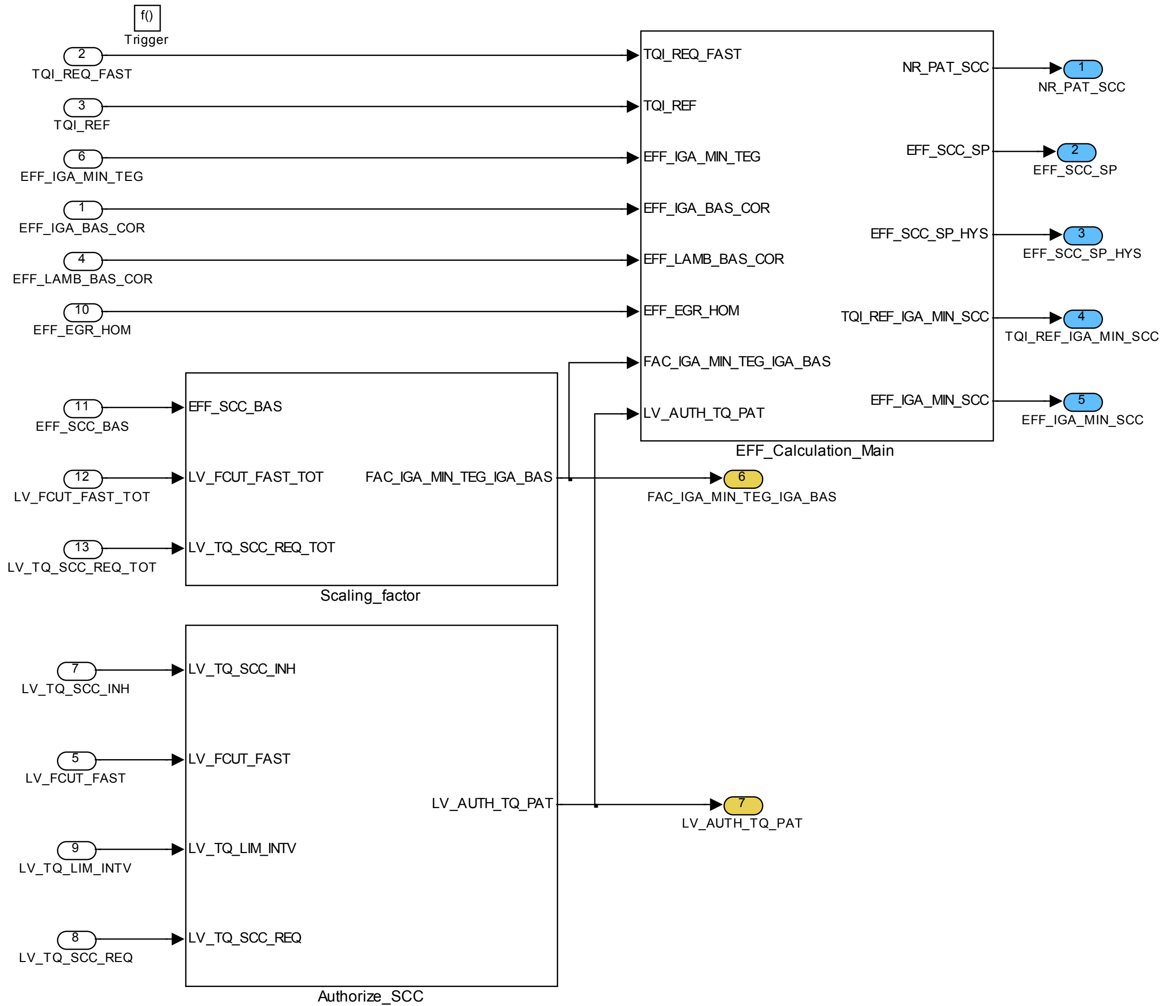

Figure 36 MD00J/ Subsystems

The authorization flag is set depending on:

- a manual enabling => LV_TQ_SCC_ENA_MAN
- a request from torque management => LV_TQ_SCC_REQ and LV_TQ_SCC_INH
- a request from safety concept => LV_TQ_LIM_INTV (see module "Torque request for safety")
- other project specific requests for fast fuel cut-off => LV_FCUT_FAST without control of dynamic torque management

Due to logical calibration constants nearly all of these request can be inhibited, except of the request from safety concept LV_TQ_LIM_INTV.

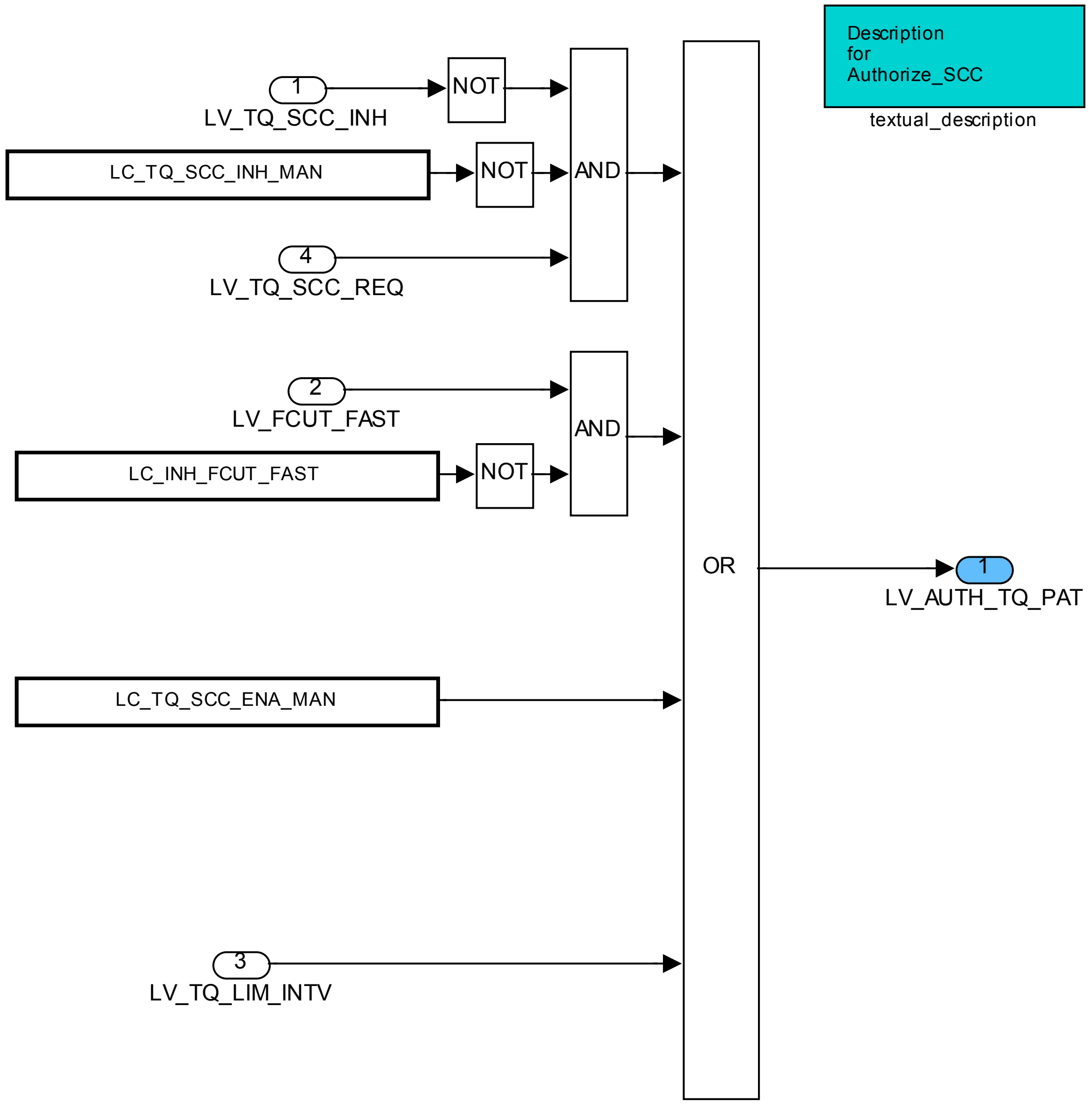

Figure 37 MD00J/ Subsystems/ Authorize_SCC

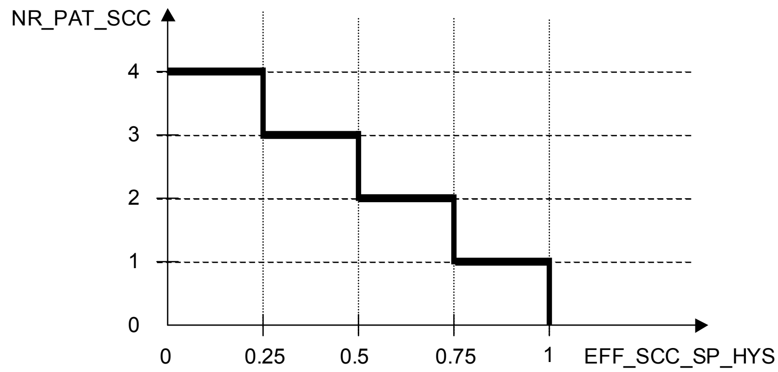
general specification

Depending on the authorization flag LV_AUTH_TQ_PAT the efficiency EFF_SCC_SP is set to the calculated value EFF_SCC_SP_1 or is set equal to "1". Additionally, two application labels allow to manipulate the efficiency setpoint (LC_EFF_SCC_SP_MAN and C_EFF_SCC_SP_MAN). Depending on the efficiency setpoint a pattern is calculated. To avoid uncomfortable jumps of pattern, if the setpoint EFF_SCC_SP jitters, the calculation of the pattern index NR_PAT_SCC is done by applying a hysteresis C_EFF_SCC_SP_HYS on EFF_SCC_SP.



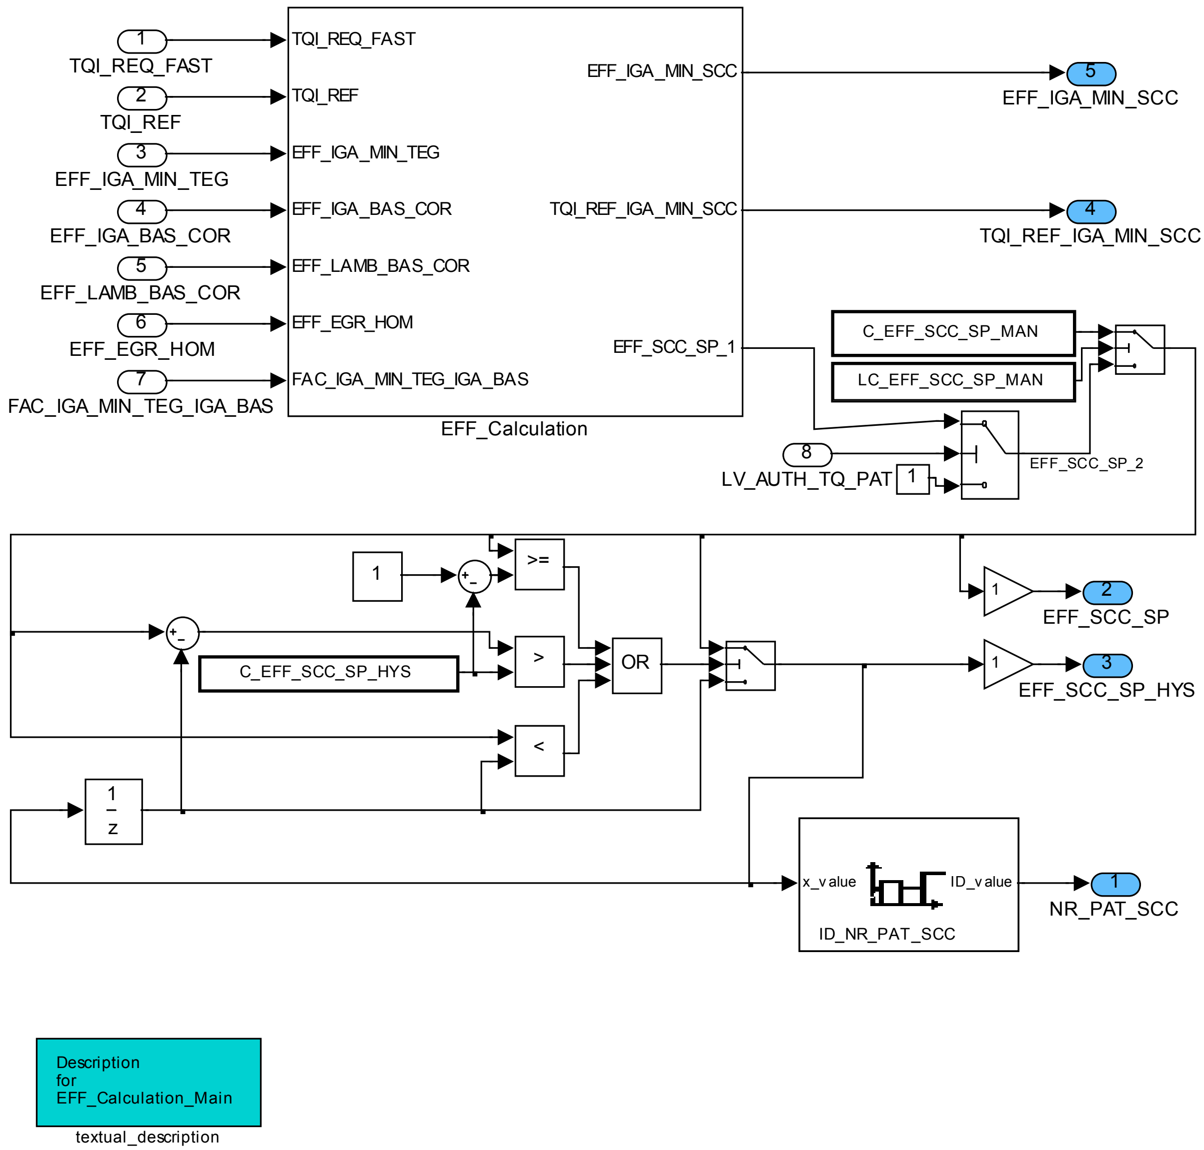


Figure 38 MD00J/ Subsystems/ EFF_Calculation_Main

general specification

The efficiency for single cylinder cut-off depends on the ratio between TQI_REQ_FAST and TQI_REF corrected with the basic efficiencies for a/f ratio and ignition angle. Generally, a scaling between EFF_IGA_MIN_TEG and EFF_IGA_BAS_COR is possible. The philosophy of this function is to give the customer the possibility to work with minimum ignition angle before fuel cut-off or to work with the basic ignition angle.

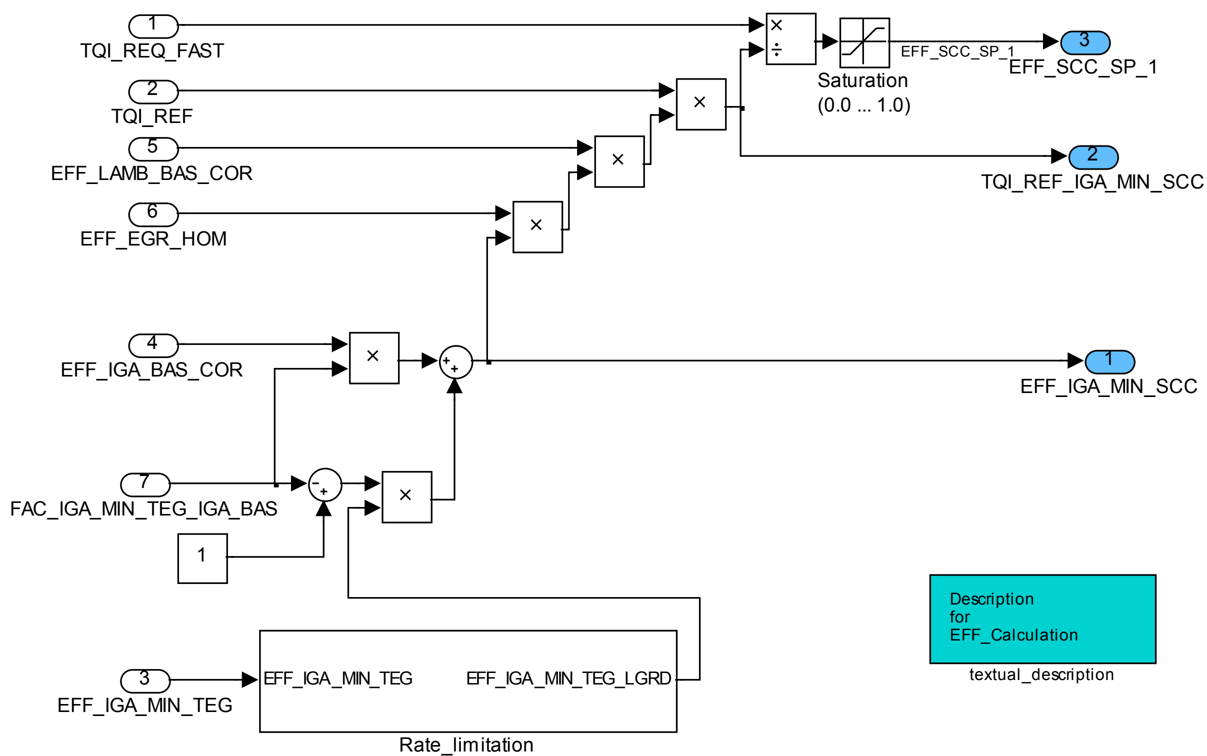

Figure 39 MD00J/ Subsystems/ EFF_Calculation_Main/ EFF_Calculation

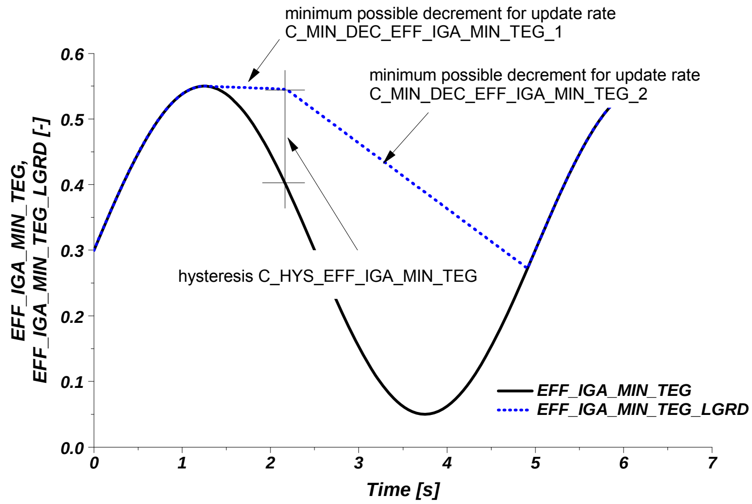
Changes of the efficiency EFF_IGA_MIN_TEG has to be limited in falling direction to avoid high frequent jumps between pattern and spark retarding. Therefore a calibratable rate limit function is added. The principle application parameters for these rate limitations are C_MIN_DEC_EFF_IG_MIN_TEG_1, C_MIN_DEC_EFF_IG_MIN_TEG_2 and C_LGRD_EFF_IGA_MIN_TEG. The background is illustrated in figure 2.



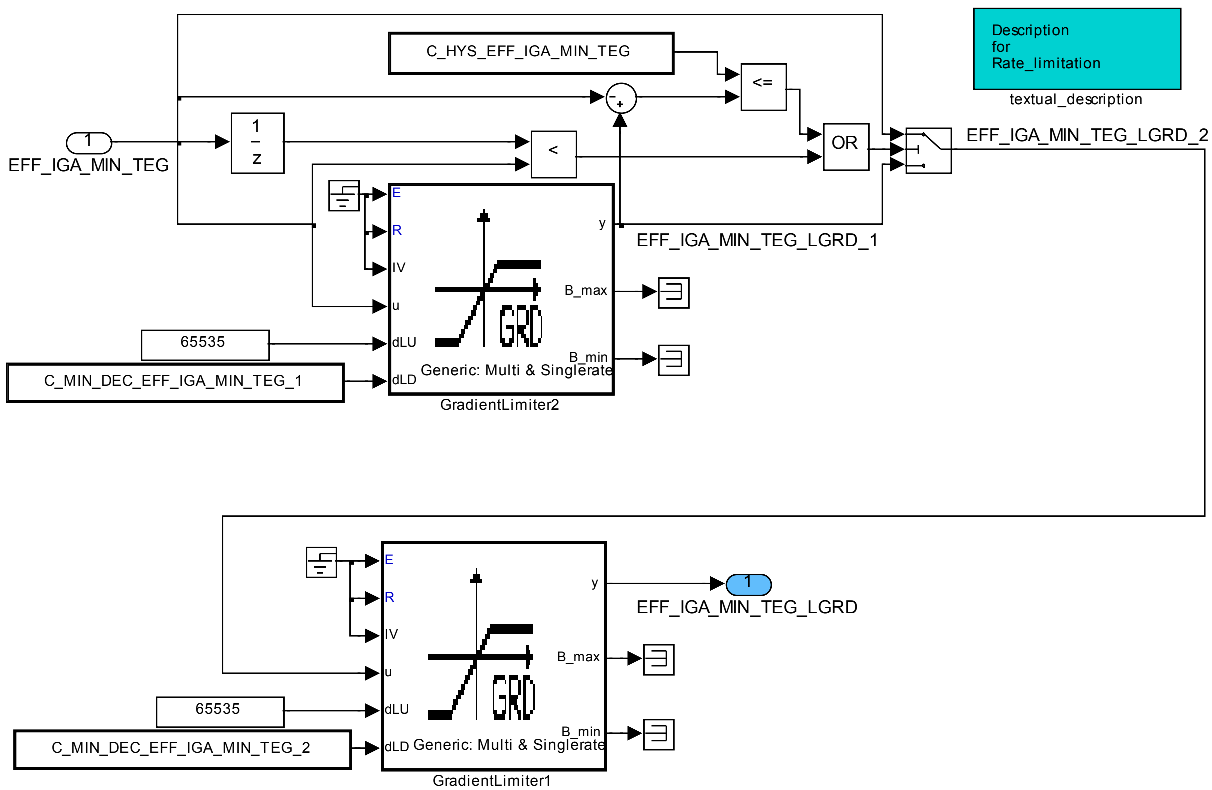


Figure 40 MD00J/ Subsystems/ EFF_Calculation_Main/ EFF_Calculation/ Rate_limitation

The factor FAC_IGA_MIN_TEG_IGA_BAS is used to scale between the efficiencies EFF_IGA_MIN_TEG (corrected basic minimum ignition angle including spark retard limitation due to exhaust gas temperature) and EFF_IGA_BAS_COR (corrected basic minimum ignition angle without spark retard limitation due to exhaust gas temperature). For a torque intervention due to gear shift, traction control, engine speed limitation and fast fuel cut-off the possibility of deactivating this scaling factor must be realized. So the scaling factor can be set equal to "1", if one of that interventions is active and if this method will be allowed (LC_ENA_FCUT_TOT_... = 1). It is also set equal to "1", if the basic efficiency for fuel cut-off is smaller than "1".

D.27 Coordination of Scaling Factors for Requested Torque

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TQ_CRU_SUB	V	0..FFFFH	0..1.999969	3.052E-5	-
Result of the maximum selection between driver demand and cruise control demand					
FAC_TQ_REQ	O/V	0..FFFFH	0..1.999969	3.052E-5	-
Torque factor from pedal value interpretation, cruise control or vehicle speed limiter					
LV_INTV_CRU	O/V	0..1H	0..1	1	-
Boolean signals intervention of cruise control (CRU demand is equal or greater than driver demand)					
LV_INTV_VSL	O/V	0..1H	0..1	1	-
Boolean signals intervention of vehicle speed limiter (VSL demand is less than driver demand)					
LV_TQ_CRU_ACT	O/V	0..1H	0..1	1	-
Boolean signals intervention of cruise control (CRU demand greater than driver demand)					

Input data:

FAC_TQ_REQ_CRU	FAC_TQ_REQ_DRIV	FAC_TQ_REQ_VSL	LV_ACT_VSL
LV_ACT_CRU			

FUNCTION DESCRIPTION:

General information:

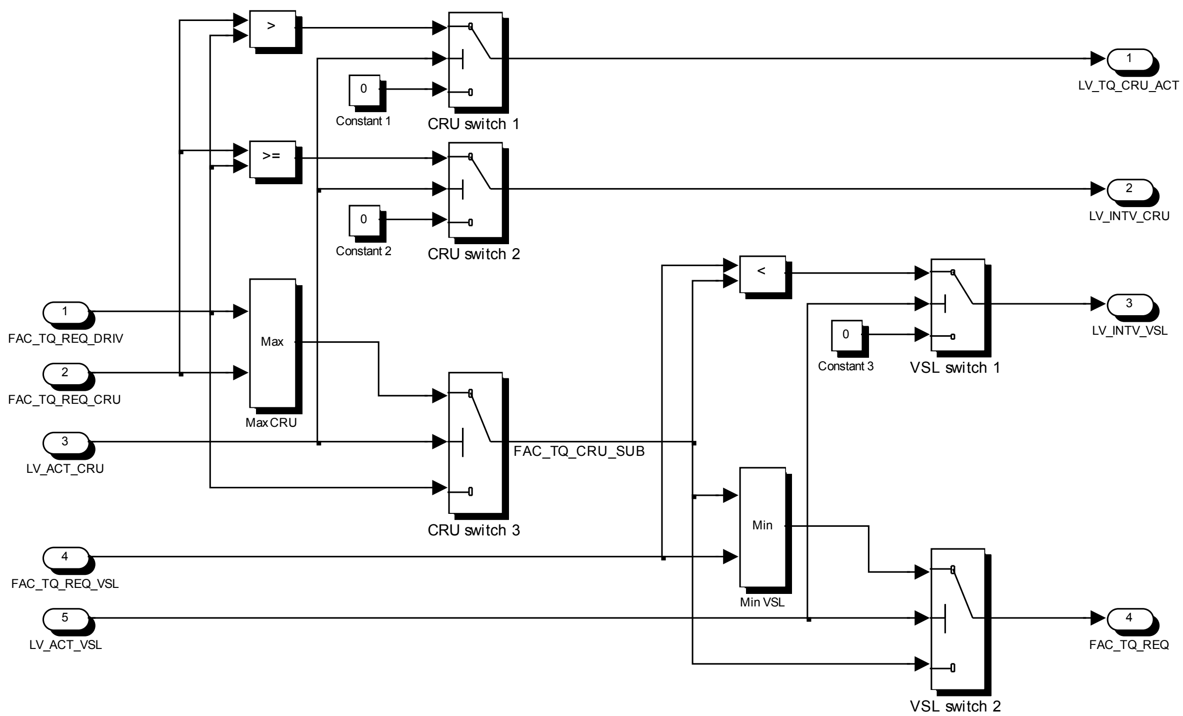
Not only the driver can provide a scaling factor but also the cruise control or the vehicle speed limiter. A coordination is necessary as all three scaling factors can request a torque demand simultaneously.

As the driver has a higher priority than the cruise control, the scaling factors FAC_TQ_REQ_DRIV (driver) and FAC_TQ_REQ_CRU (cruise control) are coordinated by a maximum selection with the output FAC_TQ_CRU_SUB. The intervention of the cruise control is indicated by the two booleans LV_TQ_CRU_ACT and LV_INTV_CRU. The coordination between the cruise control and the driver is only done if the cruise control is active (LV_ACT_CRU = 1).

As the vehicle speed limiter has a higher priority than the driver or the cruise control, the scaling factors FAC_TQ_CRU_SUB (driver or cruise control) and FAC_TQ_REQ_VSL (vehicle speed limiter) are coordinated by a minimum selection. The intervention of the speed limiter is indicated by the boolean LV_INTV_VSL. The coordination between the driver (cruise control) and the vehicle speed limiter is only done if the limiter is active (LV_ACT_VSL = 1).

FAC_TQ_REQ is exported and can also be used from the transmission control unit for calculation of gear shifting points.

Signal flow diagramm:



Application conditions:

Recurrence:	20 ms Attention: this module has to be synchronized with the 10 ms calculations.
Activation:	at every engine state
Deactivation:	-
Initialization:	at reset LV_TQ_CRU_ACT = 0 LV_INTV_CRU = 0 LV_INTV_VSL = 0 FAC_TQ_CRU_SUB = 0 FAC_TQ_REQ = 0
Hint:	If the cruise control is not available the scaling factor FAC_TQ_REQ_CRU and the boolean LV_ACT_CRU have to be set to zero. If the vehicle speed limiter is not available the scaling factor FAC_TQ_REQ_VSL has to be set to its maximum value and the boolean LV_ACT_VSL has to be set to zero.

Formula section:

Maximum selection between driver and cruise control:

```
if        LV_ACT_CRU = 1
then      FAC_TQ_CRU_SUB = Max(FAC_TQ_REQ_CRU, FAC_TQ_REQ_DRIV)
          if      FAC_TQ_REQ_CRU > FAC_TQ_REQ_DRIV
          then    LV_TQ_CRU_ACT = 1
          else    LV_TQ_CRU_ACT = 0
          endif
          if      FAC_TQ_REQ_CRU ≥ FAC_TQ_REQ_DRIV
          then    LV_INTV_CRU = 1
          else    LV_INTV_CRU = 0
          endif
else      FAC_TQ_CRU_SUB = FAC_TQ_REQ_DRIV
          LV_TQ_CRU_ACT = 0
          LV_INTV_CRU = 0
endif
```

Minimum selection between driver or cruise control and vehicle speed limiter:

```
if        LV_ACT_VSL = 1
then      FAC_TQ_REQ = Min(FAC_TQ_CRU_SUB, FAC_TQ_REQ_VSL)
          if      FAC_TQ_REQ_VSL < FAC_TQ_CRU_SUB
          then    LV_INTV_VSL = 1
          else    LV_INTV_VSL = 0
          endif
else      FAC_TQ_REQ = FAC_TQ_CRU_SUB
          LV_INTV_VSL = 0
endif
```

D.28 Torque Request at Clutch General

Output data:

Indicated requested torque determined from TQ_REQ_CLU					

Input data:

FAC_TQ_REQ	TQ_MAX_CLU	TQ_MIN_CLU	TQ_LOSS
LV_DT	LV_IS	LV_TQ_MIN_CLU	LV_PU
LV_PUC			

General information:

The module "Torque Request at Clutch General" supplies the torque structure with the torque request at clutch TQ_REQ_CLU_1 from the driver, the cruise control or the vehicle speed limiter.

The torque interpretation factor FAC_TQ_REQ_CLU scales between the minimum torque at clutch TQ_MIN_CLU and the maximum torque at clutch TQ_MAX_CLU.

TQI_MIN_REQ is the minimum indicated engine torque which can be requested from the driver, the cruise control or the vehicle speed limiter and is used inside the torque structure for minimum torque limitations.

FUNCTION DESCRIPTION:

Deactivation: -

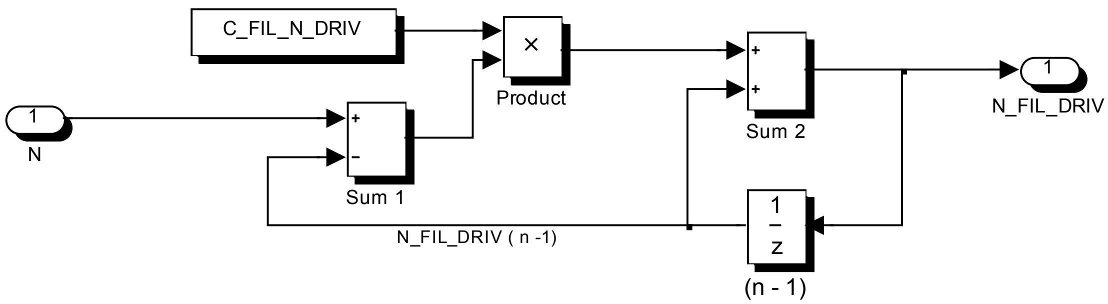
D.29.1 Engine speed filtered value

General information:

The engine speed N is filtered by an IIR filter of first order. The result N_FIL_DRIV is used in the subsequent pedal value interpredation.

Formula section:



D.29.2 Management of scaling factor for requested torque at clutch from driver

General information:

The scaling factor FAC_TQ_REQ_PV is the interpretation of the torque wish of the driver depending on engine speed and pedal value.

For variants with automatic transmission vehicle the driver interpretation map IP_FAC_TQ_REQ_DRIV_AT and IP_FAC_TQ_REQ_DRIV_R_AT are used to determine the scaling factor FAC_TQ_REQ_PV.

Determination of FAC_TQ_REQ_DRIV_AT

If	GEAR = 7
Then	FAC_TQ_REQ_DRIV_AT = IP_FAC_TQ_REQ_DRIV_R_AT
Else	FAC_TQ_REQ_DRIV_AT = IP_FAC_TQ_REQ_DRIV_AT

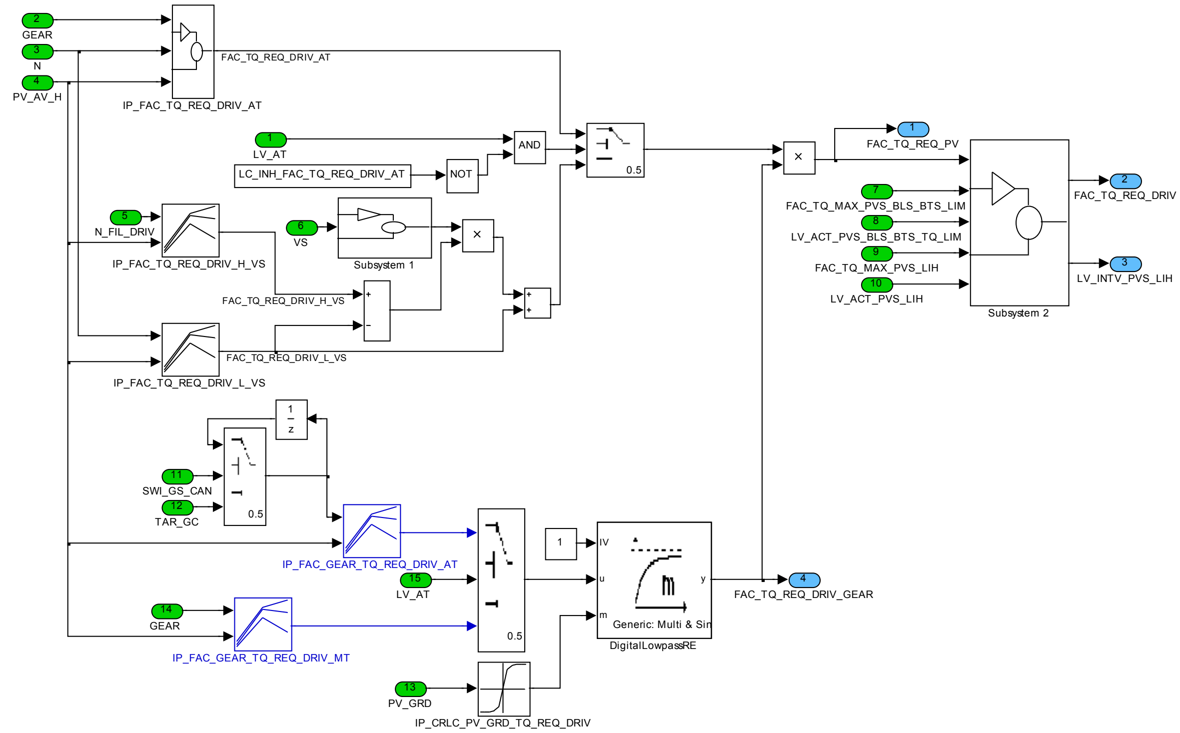
If a manual transmission is detected then the management of scaling factor is divided up in

- scaling factor for low vehicle speeds and
- scaling factor for high vehicle speeds.

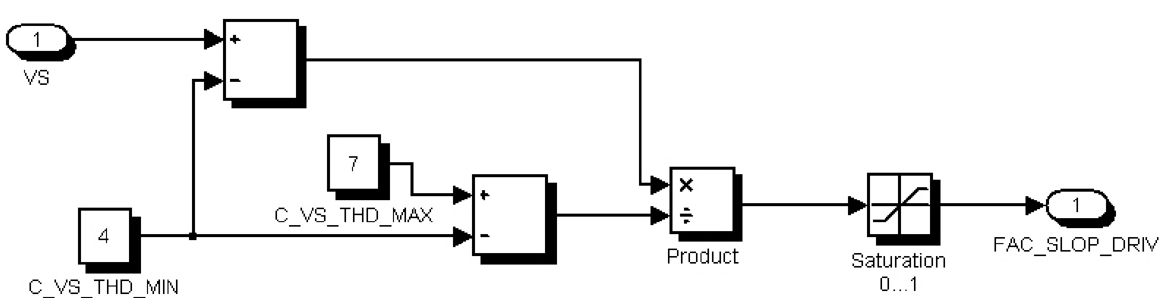
At low vehicle speeds the driver interpretation map IP_FAC_TQ_REQ_DRIV_L_VS is used and at high vehicle speeds the map IP_FAC_TQ_REQ_DRIV_H_VS is used.

An additional scaling factor that is a function of currently engaged gear and pedal position may be calibrated. This factor is filtered with the filter constant based on pedal gradient.

Signal flow diagram:



The weighing factor FAC_SLOP_DRIV between the two driver interpretation maps is set to zero at and below a vehicle speed of C_VS_THD_MIN and is set to one at and above a vehicle speed of C_VS_THD_MAX. Between the two thresholds the factor is linearly interpolated depending on the vehicle speed.
The calculation of FAC_SLOP_DRIV is done in subsystem 1 shown in the following signal flow diagram.



general specification

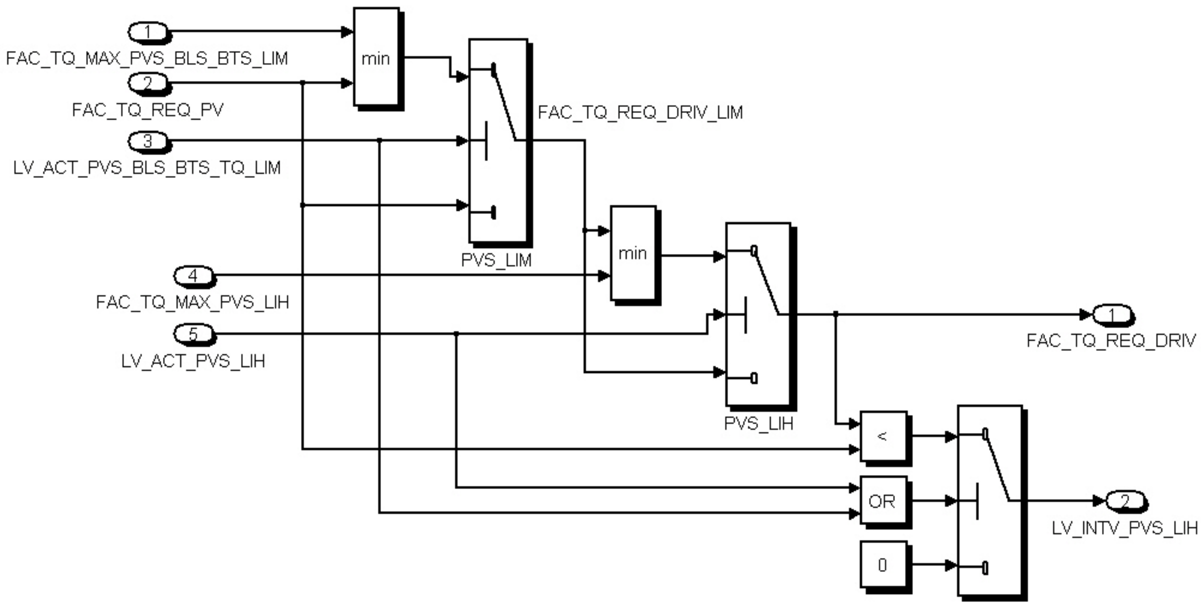
The scaling factor from driver FAC_TQ_REQ_PV can be restricted in two cases:

a) PVS-brake torque limitation, if both the accelerator pedal and the brake pedal are applied simultaneously

b) PVS error, if an error of the pedal value sensor is detected

An active constraint is indicated by the boolean LV_INTV_PVS_LIH.

The restrictions are realized by two minimum selections. The result is the scaling factor FAC_TQ_REQ_DRIV and is calculated in the subsystem 2 shown in following diagram.



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

D.30.1 General Information

TQ_MAX_CLU is the maximum effective torque which can be requested from driver or cruise control. If the torque is not limited by other functions (see below), the value is determined from the map IP_TQI_REF and TQ_LOSS_REQ_CLU. The map IP_TQI_REF is defined in the module 'Reference and Basic Torque'. Note that the original breakpoint MAF is replaced by the breakpoint MAF_MAX_COR!

The parameter C_TQI_FAC_FL allows to increase the maximum torque which can be requested to avoid that the maximum real engine torque is not scooped out totally. But by increasing C_TQI_FAC_FL the backlash at the upper pedal position also increases.

TQI_POW_MAX_REQ_CLU is defined in the module 'Torque based engine power limitation' and describes the upper limit for the maximum indicated engine torque. This parameter can be utilized to perform temporary or permanent torque limitations (e.g. overboost, customer torque limitation) that shall not lead to a backlash at high pedal values.

TQI_BAS_MAX represents the maximum available Basic indicated torque and is utilized in the Torque Reserve Coordination.

D.31.1 General Information

TQ_MIN_CLU is the minimum torque at clutch which can be requested from driver and cruise control.

The integral part of the idle speed controller is an input in TQ_MIN_CLU to avoid a deadzone for the driver torque demand.

The factor FAC_N_DIF_IS models the self stabilizing capability of an SI engine. The factor FAC_N_DIF_IS is a hyperbolic function versus N.

The start torque TQ_ST influences the engine speed curve during start phase. At transition to engine stopped the logical variable LV_TQ_MIN_CLU is initialized with zero.

If LV_TQ_MIN_CLU is 0 then TQ_ST and if LV_TQ_MIN_CLU = 1 then TQ_MIN_CLU_2 is considered for TQ_MIN_CLU. The evaluation of LV_TQ_MIN_CLU is done independently from the engine states PU or PUC.

If LV_TQ_MIN_CLU is set to 1 then LV_TQ_MIN_CLU remains to this value until transition engine run to engine stop.

If trailing throttle fuel cut-off is requested (LV_PUC = 1) then TQ_MIN_CLU is set to the minimum possible engine torque TQ_LOSS. It is possible by calibration to achieve the same during trailing throttle (LV_PU = 1) by means of the switch LC_INH_PU_REQ (=0).

TQI_MIN_REQ_PU, which is calculated from the 2-d map IP_TQI_MIN_REQ_PU(N_32, TCO) and the 1-d map IP_TQI_MIN_REQ_PU_OFS_AMP(AMP), is the minimum requested indicated torque if the driver is off the pedal. The maximum between TQ_MIN_REQ_PU and TQ_MIN_CLU_1 is added to TQ_DIF_I_IS and results in TQ_MIN_CLU_2.

The map IP_TQI_MIN_REQ_PU works in combination with map IP_TQI_MIN_PU and has to be tuned in parallel with it. In PU phase both maps determines the steady state ignition angle.

IP_TQI_MIN_PU determines the load whereas IP_TQI_MIN_REQ_PU affects the ignition angle. If both are equal the ignition angle in PU is identical with IGA_BAS_COR. If IP_TQI_MIN_REQ_PU is zero and TQ_MIN_CLU_1 identical with TQ_LOSS then the ignition angle is at IGA_MIN. So the ignition angle in PU can be shifted from IGA_MIN to IGA_BAS_COR by adjusting IP_TQI_MIN_REQ_PU.

D.32.1 Determination of the torque compensation for converter torque (TQ_CONV)

FUNCTION DESCRIPTION:

General information:

TQ_CONV describes the *hydraulic torque losses* inside the converter of an automatic gearbox. They are due to the speed difference between the converter turbine and pump.

In order to assist the idle speed controller, TQ_CONV is calculated for a reference condition with an engine speed at N_SP_IS. As a result, TQ_CONV is bigger than the real converter torque for N < N_SP_IS and smaller for N > N_SP_IS.

The converter torque adaptation value TQ_DIF_IS_AD_CONV is calculated in the idle speed adaptation module. It represents changes in the density of the transmission medium (oil) over the lifetime.

The change of the idle speed setpoint N_SP_IS during gearshift is synchronised with the converter torque request by application of a time delay T_DLY_N_SP_IS after engaging the gear.

It can be chosen if the information of the ETCU (electronic transmission control unit) is used (concerning turbine speed, transmission oil temperature or converter torque itself). There is the possiblility to calibrate transient effects, converter torque requests for drivetrain not engaged (park or neutral) and torque reserves, which are active when the feedforward torque requests are built up. Furthermore, the status of the converter lockup clutch is evaluated.

TQ_CONV is **not** considered in the torque losses, for these are defined as torque requests on the engine side (the converter is transmission side). This implies, that **TQ_CONV is a positive value**.

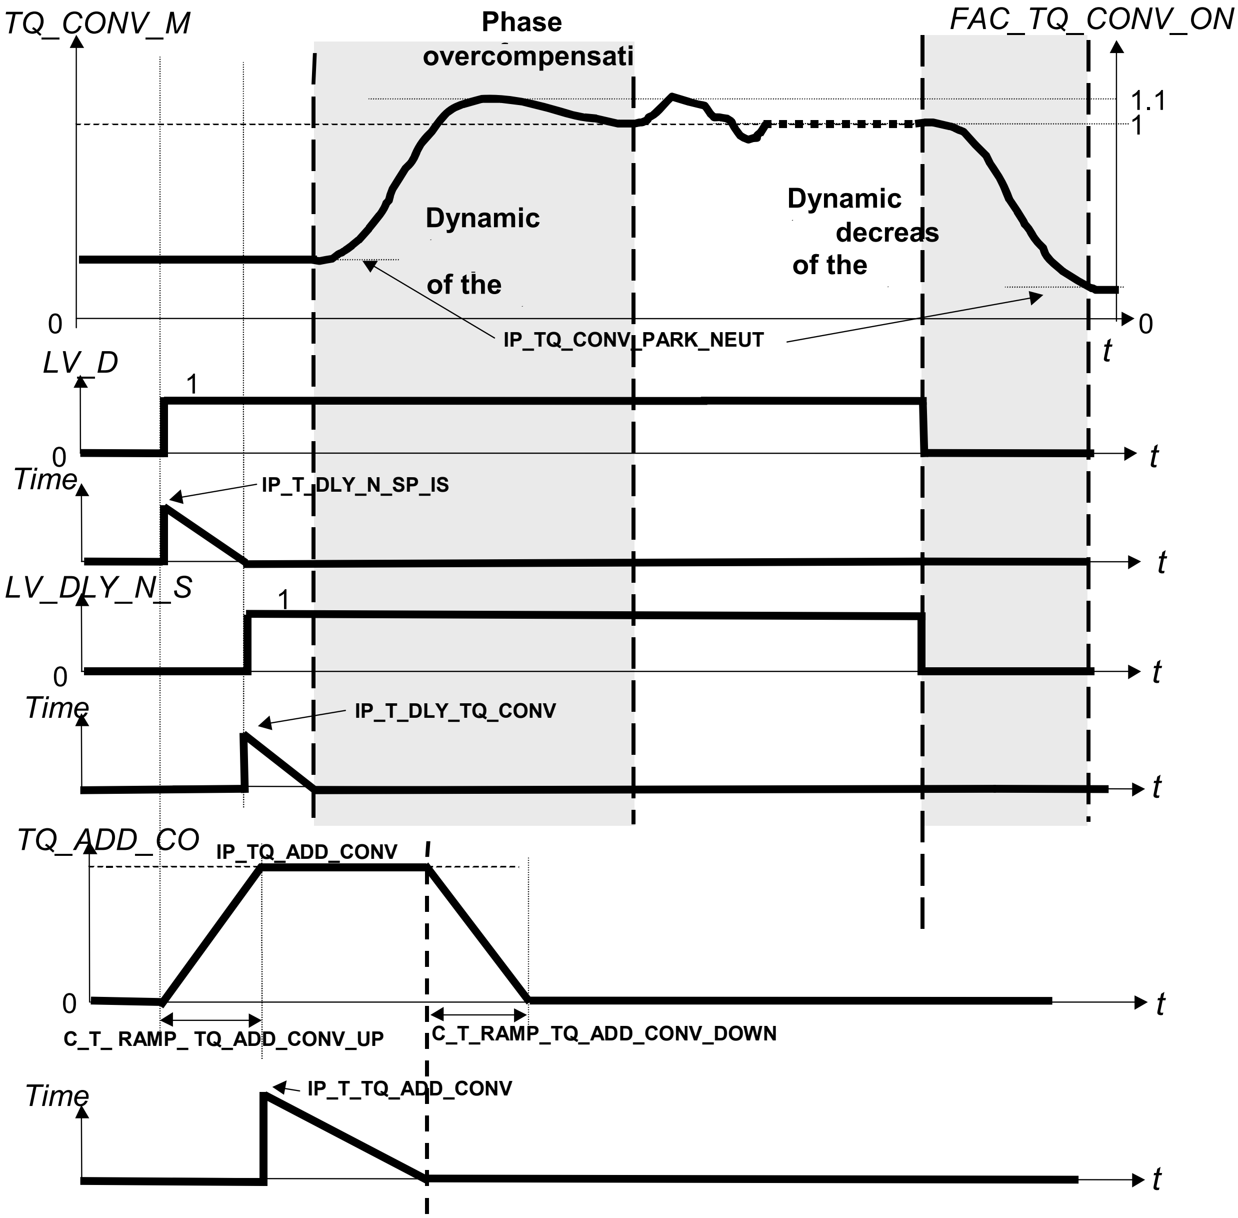

Figure 1: *Modelled converter torque and converter torque reserve*

Figure 1 shows: if LV_DRI is set (i.e. drivetrain is engaged), a calibratible delay time IP_T_DLY_N_SP_IS later the idle speed setpoint is changed (when LV_DLY_N_SP_IS = 1). Afterwards, another delay time IP_T_DLY_TQ_CONV_XX later the converter torque is built up. XX means DRI or RE, depending is Drive or Reverse gear is engaged. The converter torque reserve TQ_ADD_CONV starts ramping as soon as LV_DRI changes from 0 → 1. The final value is held until IP_T_TQ_ADD_CONV is run out **or** – a case, which is not shown in figure 1 – when LV_DRI changes from 1→ 0.

Application conditions:

Initialisation:	TQ_CONV_MDL	= 0 Nm	
	TQ_ADD_CONV	= 0 Nm	
	TQ_CONV	= 0 Nm	
	LV_DLY_N_SP_IS	= 0	
	N_TUR_CONV_INTER	= 0 rpm	
	TOIL_GB_INTER	= 0 °C	
	N_RATIO_CONV	= 0	
	TQ_CONV_MDL_MEM	= 0 Nm	
	TQ_CONV_MDL_DYN	= 0 Nm	
	T_FAC_TQ_CONV_OFF	= 655.35 s	(maximum value)
	T_FAC_TQ_CONV_ON	= 0	
	T_DLY_N_SP_IS	= 0 s	
	T_DLY_TQ_CONV	= 0 s	
	XX	= DRI	
	LV_TQ_ADD_CONV_RAMP_UP	= 0	at reset

Recurrence:
IF LV_IS = 1
THEN 20 ms
ELSE 40 ms
ENDIF

Activation: **IF** LV_AT == 1 **AND** LC_TQ_CONV_INH == 0

Deactivation:
IF LV_AT == 0 **OR** LC_TQ_CONV_INH == 1
THEN TQ_CONV = 0
ENDIF

Scheduling: This function has to be calculated **immediate before the module "Minimum torque at clutch"**

Formula section:

First, a step width for the timer has to be defined:

IF LV_IS == 1
THEN STEP_T = 2 `% STEP_T = (update rate)/10ms`
ELSE STEP_T = 4

ENDIF

If a turbine speed from the ETCU is availible and valid, then this value can be used for the calculation of the converter torque. Otherwise, a modelled value is determined:

IF LC_N_TUR_CONV_ETCU_ACT == 1
AND LV_ERR_N_TUR_CONV_ETCU == 0
AND VS >= C_VS_MIN_N_TUR_CONV_ETCU
THEN N_TUR_CONV_INTER = N_TUR_CONV
ELSE N_TUR_CONV_INTER = IP_N_TUR_CONV
ENDIF

If the oil temperature of the gear box from ETCU is availible, then this value can also be used. Otherwise, the oil temperature of the engine (TOIL) is used as the model value:

IF LC_TOIL_GB_ETCU_ACT == 1
AND LV_ERR_TOIL_GB_ETCU == 0
THEN TOIL_GB_INTER = TOIL_GB
ELSE TOIL_GB_INTER = TOIL
ENDIF

A speed relation is needed for the following calculations:

N_RATIO_CONV = N_TUR_CONV_INTER / N_SP_IS

Converter torque:

As explained before, a modelled value is used in case there is no value from ETCU availible or this value is not valid. For this model, a term IP_FAC_CONV is used which includes the of transmission oil's density and the converter's circuit diameter. The value IP_FAC_TQ_CONV(N_RATIO_CONV) is the power number of the converter. A distinction in the gear position between park/neutral and gear engaged is made:

IF(1) LC_TQ_CONV_ETCU_ACT == 1
AND LV_ERR_TQ_CONV_ETCU == 0
THEN(1) TQ_CONV = TQ_CONV_ETCU + TQ_DIF_IS_AD_CONV
ELSEIF(1) LC_TQ_CONV_ETCU_ACT == 0
OR LV_ERR_TQ_CONV_ETCU == 1
THEN(1) {

}

ELSEIF(4) LC_TQ_CONV_NEW_INH == 1

TQ_CONV = IP_FAC_CONV * IP_FAC_TQ_CONV * N_SP_IS ^{2}
+ TQ_DIF_IS_AD_CONV

ENDIF(4) } **`% end condition part for modelled value`**

ENDIF(1)

Drive/Reverse dependent table :

Some tables (IP_T_DLY_TQ_CONV_XX, IP_FAC_TQ_CONV_ON_XX, IP_FAC_TQ_CONV_OFF_XX) are depending on which gear is selected : DRIVE or REVERSE. In case of transition to NEUTRAL, it is necessary to memorize the gear (: DRIVE or REVERSE) which was used before NEUTRAL.

If GEAR = 7 `% Reverse engaged or disengaged`

Then XX = RE

Elsif GEAR = 1 or 2 or 3 or 4 or 5 `% Drive engaged or disengaged`

Then XX = DRI

Else XX remains unchanged `% previous setting (RE or DRI)`
`% is kept in Neutral (gear = 0)`

Endif

D.32.2 Determination of the torque reserve for converter torque (TQ_ADD_CONV)

If the real torque request of the converter is higher than the feed forward controlled one (TQ_CONV), then the idle speed controller should compensate this difference. Especially in case of converter torque increase (at transition), this possible difference between reality and feed-forward control must be compensated very fast. To make this possible, a torque reserve can be built up. This torque reserve TQ_ADD_CONV can be built up and reduced with ramps. It can be defined in dependance of the transmission oil temperature and takes effect for a calibratible time IP_T_TQ_ADD_CONV.

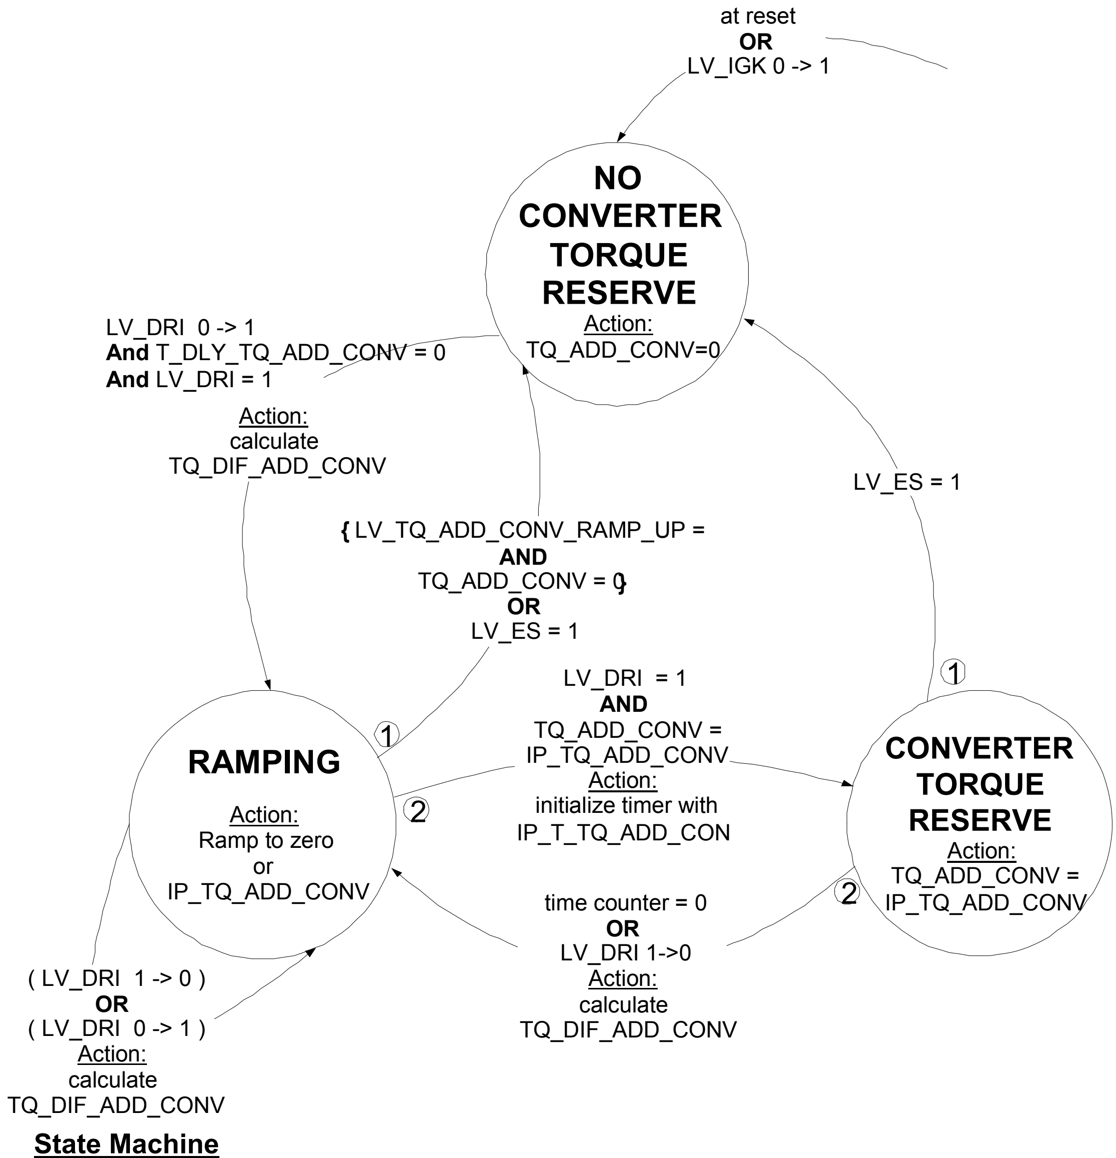

Figure 2: *State machine of the converter torque reserve*

To see each transition condition, please refer the *Figure 2:* ***State machine of the converter torque reserve***.

A. NO CONVERTER TORQUE RESERVE Mode:

D.33 Torque reserve for transmission

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_TRANS	O	8000H...7FFFH	-1024...1023.97	0.03125	Nm
Central torque reserve for transmission					

Input data:

TQ_ADD_CONV			

FUNCTION DESCRIPTION:

General information:

All torque reserve requests which are needed for transmission (f.e. torque reserve requests for converter, CVT or automized manual transmission) are resumed here. The central output is TQ_ADD_TRANS, which is an input to the torque reserve coordination.

Application conditions:

Initialisation: TQ_ADD_TRANS = 0 Nm

Recurrence: 10 ms

Activation: at every engine state

Deactivation: -

Scheduling: *This module should be calculated **after** the modules to determine the*

Transmission torque reserve requests and **before the torque reserve coordination.**

Formula section:

TQ_ADD_TRANS = TQ_ADD_CONV

D.34 Torque Transient Parameters

STATE_TQ_RANGE	STATE_TQ_PHA	N_32	LV_IS
LV_AT	GEAR	TQ_REQ_CLU	PV_AV
N	N_TUR_CONV_RAW	SWI_CC	LV_CT
LV_DT	VS	LV_GS_ENA	LV_DROF_AT_ACT

FUNCTION DESCRIPTION:

General information:

The T_TRA parameter is the target value for the filtered signal when to reach the setpoint (unfiltered torque request).
This revision support manual and automated transmission. It allows variant coding.
TQ Transient Filtering for AT considering converter clutch lock-up state : Normally, the level of tip-out shock when the converter clutch is fully lock up is greater than that of no lock up control. TQ filtering time(T_INC/DEC TRA) can be adjusted separetely in order to improve the tip-out shock in case of fully lock-up (SWI_CC = 2)
TQ Transient Filtering for MT considering gear-shift and tip-in : When gear is shifted while vehicle running, Separated TQ filtering time can be applied in order to prevent vibration/shock at tip-in condition.
When TCU request TQ reduction control (spark time retard control), TQ filtering can be inhibited. (T_TRA = 0, by setting of LC_TQ_FIL_OFF_SPK_RTD_TCU = 1).

Depending on engine speed and selected gear, different thresholds can be set for the transition between the 3 torque transient ranges. It is important that before the torque transient range is determined, this threhold determination is performed. The most efficient solution is to call this spec via 2 function calls, the first one to determine only the torque transient thresholds, the second one to determine the transient time T_TRA.

For drive-off in an AT vehicle, it is possible to limit the engine torque via a different function (Driver Request Limitation) in this case it is possible to disable the torque transient function. It is possible to disable the function only for increasing torques, only for decreasing torques, or in all cases.

Application conditions:

Initialisation: *T_TRA = 0*

TQ_RANGE_SEL_OFS = 0

DELTA_N_TUR_ENG = 0

LV_INH_TQ_FIL = 0

All T_INC/DEC_TRA_AT/MT_1/2/3 = 0

LV_TQ_TRA_FIL_MT_GS = 0

TQ_TRA_THD_UP/DOWN_1/2 = 0

Recurrence: 10ms function call from "Torque Transient"

Activation: every engine state

TQ filtering inhibition in case of TQ reduction request from TCU:

If LV_AT = 1

And LC_TQ_FIL_OFF_SPK_RTD_TCU = 1

And LV_GS_ENA = 1

Then

LV_INH_TQ_FIL = 1 // Deactivate TQ filtering

T_TRA = 0

Else

LV_INH_TQ_FIL = 0 // Activate TQ filtering(Cal. T_TRA)

EndIf

Deactivation: LV_INH_TQ_FIL = 1

Formula section:

Calculation of speed difference between torque converter turbine speed and engine speed : DELTA_N_TUR_ENG

IF LV_AT = 1

THEN DELTA_N_TUR_ENG = N_TUR_CONV_RAW - N

ELSE DELTA_N_TUR_ENG = 0

TQ filtering for AT considering converter clutch lock-up condition :

```
If      LV_AT = 1               // AT vehicle
Then
    If          SWI_CC = 2 or 3        // fully locked up
        and     abs(N – N_TUR_CONV_RAW) ≤ C_N_DIF_LOCK_CONV_CS

TQ ranges for filtering:

This section of the specification should be called by a seperate function call from the torque transient function. It is necessary to determine the correct thresholds before the range determination can take place.

The thresholds for each ramp are determined from maps against engine speed and gear for each transmission variant.

TQ_RANGE_SEL_OFS = IP_TQ_RANGE_SEL_OFS(TQ_REQ_CLU)

```
If          LV_AT = 1              // AT vehicle

D.35 Torque Transient

General Information

Due to it's physical properties the car can be considered as a two-mass-spring-system, producing oscillations on rapid torque increas. To prevent the powertrain from jerks the requested torque from driver or cruise control TQ_REQ_CLU is filtered. The torque increase or decrease is realized by torque ramps. The output value is TQ_REQ_TRA_CLU (torque at clutch) and the corresponding TQI_REQ_TRA (indicated torque).

For a more spontaneous reaction of the vehicle and to ensure that the actual torque (TQI_AV) follows best the torque setpoint (TQI_REQ_TRA) a torque reserve TQ_ADD_TRA can be tuned. This torque reserve value is added on the air path whereas a fast spark retard (if it is necessary) ensure that the actual torque and the setpoint are converging.

A second functionality is to damp uncomfortable behavior of the car because of the load cycle at zero crossing torque. In that torque range a ramp function is applied that reduces engine movement between its bearings.

See also the module Torque reserve for Torque Transient for additional functionality.

D.35.1 Generic Activation Conditions

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_REQ_TRA_CLU	V / O	8000 .. 7FFF H	-1024 .. 1023.97	0.03125	Nm
Torque request at clutch after transient torque function					
TQ_REQ_DIF_TRA	V / O	8000 .. 7FFF H	-1024 .. 1023.97	0.03125	Nm
Deviation of TQ_REQ_CLU and TQ_REQ_TRA_CLU limited to “0” Nm					
TQ_REQ_TRA_OLD_CLU	V	8000 .. 7FFF H	-1024 .. 1023.97	0.03125	Nm
Old torque value at steady state conditions					
TQI_REQ_TRA	V / O	8000 .. 7FFF H	-1024 .. 1023.97	0.03125	Nm
Indicated torque request after transient torque function					
LV_TQ_TRA	V	0...1 H	0 ... 1	1	-
Logical variable transient torque function acitve					
LV_TQ_TRA_DYN	V / O	0...1 H	0 ... 1	1	-
Logical variable spark retard requested due to driver dynamics					
STATE_TQ_PHA	V / O	0 H 1 H 2 H	TQ_PHA_CONST TQ_PHA_INC TQ_PHA_DEC	1	-
State of torque transient phase					
STATE_TQ_RANGE	V / O	1 H 2 H 3 H	TQ_RANGE_1 TQ_RANGE_2 TQ_RANGE_3	1	-
Range of TQ_REQ_TRA_CLU					

Input data:

TQ_REQ_CLU	TQ_LOSS	N_GRD	T_TRA
TQ_RANGE_SEL_OFS	TQ_TRA_THD_UP_1	TQ_TRA_THD_UP_2	TQ_TRA_THD_DOWN_1
TQ_TRA_THD_DOWN_2			

Application conditions:

Initialisation:	at reset
	TQ_REQ_TRA_CLU = 0
	TQ_REQ_TRA_OLD_CLU = 0
Recurrence:	10 ms
Activation:	at every engine state
Deactivation:	-

Description:

The torque transient filter is activated only, if the torque request represented by TQ_REQ_CLU is not constant, in the states "INC" or "DEC". In the other case the output TQ_REQ_TRA_CLU is equal to the input TQ_REQ_CLU (state "CONST").

Formula section:

```
If      (TQ_REQ_CLU >= TQ_REQ_TRA_CLU + C_TQ_TRA_HYS) OR
        (TQ_REQ_CLU <= TQ_REQ_TRA_CLU – C_TQ_TRA_HYS) AND NOT
        (LC_TQ_TRA_INH)
then    LV_TQ_TRA = 1
        If    TQ_REQ_CLU > TQ_REQ_TRA_CLU
        then  STATE_TQ_PHA = 1           %"INC"
        else  STATE_TQ_PHA = 2           %"DEC"
        endif
else    STATE_TQ_PHA = 0                 % "CONST"
endif
```

From torque increase to steady state conditions:

```
if      TQ_REQ_TRA_CLU >= TQ_REQ_CLU
then    STATE_TQ_PHA = 0                 % "CONST"
endif
```

From torque decrease to steady state conditions:

```
if      TQ_REQ_TRA_CLU <= TQ_REQ_CLU
then    STATE_TQ_PHA = 0                 % "CONST"
endif
if      STATE_TQ_PHA == 0                % "CONST"
then    LV_TQ_TRA = 0
        TQ_REQ_TRA_CLU = TQ_REQ_CLU
        TQ_REQ_TRA_OLD_CLU = TQ_REQ_CLU
endif
```

D.35.2 TQ_TRA_THD aquisition

According to the calculation sequence here the algorithm from the module "Torque transient parameters", where the torque thresholds are calculated is called here as a function call. This MUST take place in one cycle.

TQ_TRA_THD_UP/DOWN_1 / 2 = FUNCTION CALL ("Torque Transient Parameters")

After the threshold are calculated the function returns to the next chapter.

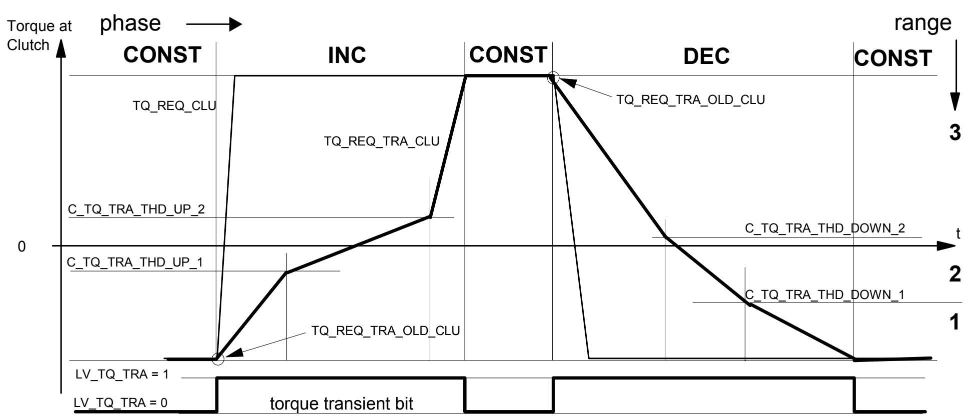
D.35.3 Phase-range detection

Description:

Since there are different requirements for the torque transient ramps depending on the range of the torque request and also on its direction it is necessary to detect these states.

The torque ranges are choosen depending on calibrateable thresholds (determined in torque transient parameter function).

The selected values are necessary to obtain a time constant information from the function module "Torque Transient parameter" and obtained via a second function call to the torque transient parameter function.



Formula section:

Criterion for range selection:

a) Torque increase

If STATE_TQ_PHA == 1 %"INC"

Then

If the N_GRD- condition was true for the last cycle, the range detection is not applied until TQ_REQ_TRA_CLU exceeds TQ_TRA_THD_UP_2 + TQ_RANGE_SEL_OFS.

STATE_TQ_RANGE =	Condition
1	TQ_REQ_TRA_CLU < TQ_TRA_THD_UP_1 + TQ_RANGE_SEL_OFS
2	TQ_TRA_THD_UP_1 + TQ_RANGE_SEL_OFS <= TQ_REQ_TRA_CLU < TQ_TRA_THD_UP_2 + TQ_RANGE_SEL_OFS
3	TQ_REQ_TRA_CLU >= TQ_TRA_THD_UP_2 + TQ_RANGE_SEL_OFS

b) Torque decrease

Elseif STATE_TQ_PHA == 2 %"DEC"

Then

If the N_GRD- condition was true for the last cycle, the range detection is not applied until TQ_REQ_TRA_CLU is below TQ_TRA_THD_DOWN_1 + TQ_RANGE_SEL_OFS.

STATE_TQ_RANGE =	Condition
1	TQ_REQ_TRA_CLU < TQ_TRA_THD_DOWN_1 + TQ_RANGE_SEL_OFS
2	TQ_TRA_THD_DOWN_1 + TQ_RANGE_SEL_OFS <= TQ_REQ_TRA_CLU < TQ_TRA_THD_DOWN_2 + TQ_RANGE_SEL_OFS
3	TQ_REQ_TRA_CLU >= TQ_TRA_THD_DOWN_2 + TQ_RANGE_SEL_OFS

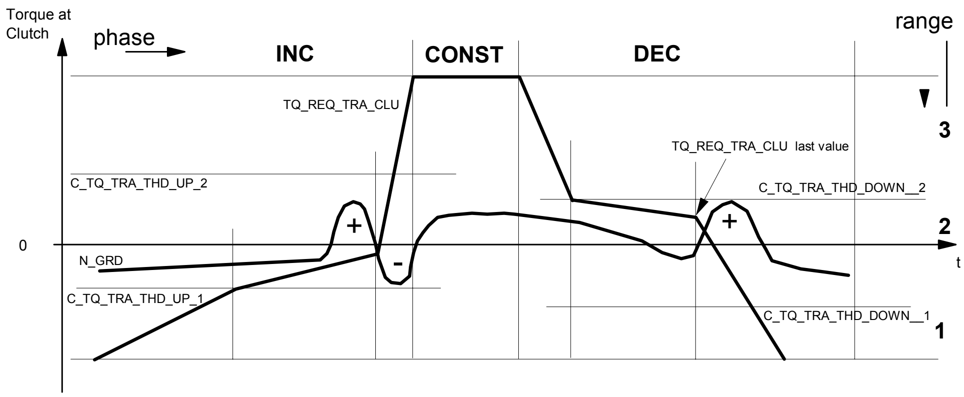
End

Under normal conditions no direct jump happens from range 1 to range 3 and vice versa, every range is passed through completely.

Special conditions are N_GRD-condition and T_TRA - condition.

Exceptional N_GRD-condition:

In range 2 only a slow ramp is performed. This range can be left immediatly, when the engine has done its movement from one stopper to the other due to load cycle, detected by the engine speed gradient.



If the N_GRD condition comes true , range 2 is left and the stored TQ_REQ_TRA_OLD_CLU is updated.

If STATE_TQ_RANGE == 2 **AND** STATE_TQ_PHA == 1
AND (N_GRD < C_N_GRD_THD_NEG)
then TQ_REQ_TRA_OLD_CLU = TQ_REQ_TRA_CLU (only once)
If TQ_REQ_CLU > TQ_TRA_THD_UP_2 + TQ_RANGE_SEL_OFS
then STATE_TQ_RANGE =3
else STATE_TQ_RANGE=2
endif
endif

If STATE_TQ_RANGE == 2 **AND** STATE_TQ_PHA == 2
AND (N_GRD > C_N_GRD_THD_POS)
then TQ_REQ_TRA_OLD_CLU = TQ_REQ_TRA_CLU (only once)
If TQ_REQ_CLU < TQ_TRA_THD_DOWN_1 + TQ_RANGE_SEL_OFS
then STATE_TQ_RANGE =1
else STATE_TQ_RANGE =2
endif
endif

If the N_GRD condition was not true in range 2, the stored value TQ_REQ_TRA_OLD_CLU is initialized at leaving range 2 and entry into a new range. TQ_REQ_TRA_OLD_CLU is set to the last filtered torque request, which contains the upper range limit incl. offset for increasing torque and the lower range limit incl. offset for decreasing torque request.

```
If      N_GRD condition was not true AND
        ((STATE_TQ_RANGE == 3 AND STATE_TQ_PHA == 1) or
        (STATE_TQ_RANGE == 1 AND STATE_TQ_PHA ==2))
Then    TQ_REQ_TRA_OLD_CLU = TQ_REQ_TRA_CLU ( only once )
End
```

If transient conditions are true and direct change from torque increase to decrease and vice versa happens then TQ_REQ_TRA_OLD_CLU = TQ_REQ_TRA_CLU and a new selection of range is done.

```
If      STATE_TQ_RANGE == 1 or STATE_TQ_RANGE == 3
Then    TQ_REQ_2 = TQ_REQ_CLU
        TQ_REQ_1 = TQ_REQ_TRA_OLD_CLU
Else    if      STATE_TQ_RANGE == 2 and STATE_TQ_PHA == 1  %"INC"
        Then    TQ_REQ_2 = TQ_TRA_THD_UP_2 + TQ_RANGE_SEL_OFS
                TQ_REQ_1 = TQ_TRA_THD_UP_1 + TQ_RANGE_SEL_OFS
        Elseif  STATE_TQ_RANGE == 2 and STATE_TQ_PHA == 2  %"DEC"
        Then    TQ_REQ_2 = TQ_TRA_THD_DOWN_1 + TQ_RANGE_SEL_OFS
                TQ_REQ_1 = TQ_TRA_THD_DOWN_2 + TQ_RANGE_SEL_OFS
        End
End
```

D.35.4 T_TRA aquisition

According to the calculation sequence here the algorithm from the module "Torque transient parameters" where the T_TRA time is calculated as a function call. It is important, that the shift of the states STATE_TQ_RANGE and STATE_TQ_PHA from phase-range-detection takes place at the same cycle as obtaining the result and handover to the next chapter. This MUST take place in one cycle.

T_TRA = FUNCTION CALL ("Torque Transient Parameters")

Where "Torque Transient parameters" consumes from here

(STATE_TQ_RANGE, STATE_TQ_PHA).

After T_TRA is calculated the function returns to the next chapter.

D.35.5 Generic torque transient filter

Description:

The torque transient filter calculates a filtered torque request. If the requested torque is faster than a certain ramp time it is filtered that the setpoint is reached within a certain time depending on phase, range and gear (and exceptional conditions).

Application conditions:

Initialisation:	at reset
	TQ_REQ_TRA_CLU = 0
	TQ_DIF_TRA = 0
	TQI_REQ_TRA = 0
Recurrence:	*10ms*
Activation:	STATE_TQ_PHA <> 0
Deactivation:	STATE_TQ_PHA == 0

Formula section:

If T_TRA == 0

then exit to STATE_TQ_PHA = 0

else TQ_DIF_TRA = ((TQ_REQ_2 - TQ_REQ_1) / T_TRA) * recurrence (10ms)

endif

Following integrator is calculated time synchonous each update rate:

TQ_REQ_TRA_CLU(n) = TQ_REQ_TRA_CLU(n-1) + TQ_DIF_TRA

Calculated after State machine:

Formula section:

Indicated requested transient torque:

TQI_REQ_TRA = **MAX**(0,(TQ_REQ_TRA_CLU - TQ_LOSS))

Deviation of unfiltered and filtered torque request at clutch:

TQ_REQ_DIF_TRA is used for indicating a torque reserve request.

TQ_REQ_DIF_TRA = TQ_REQ_CLU – TQ_REQ_TRA_CLU

Calculation of LV_TQ_TRA_DYN:

LV_TQ_TRA_DYN is used for information when high dynamic torque is requested.

If STATE_TQ_RANGE = 1

Then LV_TQ_TRA_DYN = 1

Else LV_TQ_TRA_DYN = 0

Endif

Calibration data:

Torque reserve output from map IP_TQ_ADD_TRA_MAX for transient torque					
FAC_TQ_TRA	V	0...FFFFH	0 ... 32	0.0004883	-
Weighting factor for TQ_REQ_DIF_TRA					

Input data:

N_32	TQ_REQ_DIF_TRA		

FUNCTION DESCRIPTION:

At transient conditions the torque reserve TQ_ADD_TRA builds up a certain load potential that can be used to accelerate the slow airpath without violating the torque transient ramp. If a fast torque increase is needed for following the positive torque ramp setpoint, spark advance can be done very fast. TQ_ADD_TRA is obtained from a by FAC_TQ_REQ_DIF_TRA weighted difference. This value must be limited in both directions from the maps IP_TQ_ADD_TRA_xxx.

If ignition intervention is allowed this function can be used to accelerate the slow path with reduced ignition intervention for torque decrease.

Application conditions:

Initialisation: at reset

TQ_ADD_TRA = 0 Nm

TQ_ADD_TRA_1 = 0 Nm

TQ_ADD_TRA_2 = 0 Nm

FAC_TQ_TRA = 0

Recurrence: *10 ms*

Activation: *at every engine state*

Deactivation: -

IP_MAF_SP	N_32	TQ_DIF_ADD_IS_TOL	NC_MAF_FAC_CYL
LV_IS	TQ_ADD_HEAT_ACC		

FUNCTION DESCRIPTION:

General information:

The torque reserve is a torque neutral increase of the cylinder charge by adding TQ_ADD_REQ or TQ_ADD_REQ_CH to the driver torque request TQI_REQ_TRA.

general specification

The torque reserve coordination delivers the torque value TQI_ADD_ACT.

TQI_ADD_ACT is the input for “Minimum/Maximum Torque Request Selection”. Without external torque intervention TQI_ADD_ACT will be transformed to TQI_REQ_SLOW. This torque request will than be used at “Torque Coordination” to determine the necessary cylinder charge torque setpoint TQI_SP_SLOW, which leads to the needed air mass flow setpoint MAF_SP_TQI.

The logical output-variable LV_TQ_ADD_REQ indicates if the requested torque reserve is applied or not.

The indicated engine torque request inclusive torque reserve TQI_ADD_ACT is always limited to the maximum possible value TQI_ADD_MAX. The limitation is necessary due to the fact that the increase of cylinder-charge must be compensated by spark retardation. The spark-retardation itself is only possible until the minimum ignition angle is reached.

For catalyst heating or for NO_X-trap desulfation the determination of TQI_ADD_MAX is done with IGA_MIN (EFF_IGA_MIN) which is independent from the actual exhaust gas temperature.

All other torque reserve-requests are limited, if high exhaust gas temperature can damage the catalytic converter or the outlet-valve. For this purpose the limitation TQI_ADD_MAX_TEG is determined as a function of IGA_MIN_TEG (EFF_IGA_MIN_TEG). The torque reserve for torque transient is treated separately, since it could become negative for reasons of air path acceleration.

In case of LV_HOM_RUN = 0 the input value TQI_REQ_TRA will directly copied to the output variable TQI_ADD_ACT.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: at reset

TQI_ADD_ACT = 0 Nm

TQ_ADD_ACT = 0 Nm

LV_TQ_ADD_REQ = 0

Update rate: 10 ms

Remark:

All TQI values are limited during calculation and output to minimum “0” Nm !

Overview:

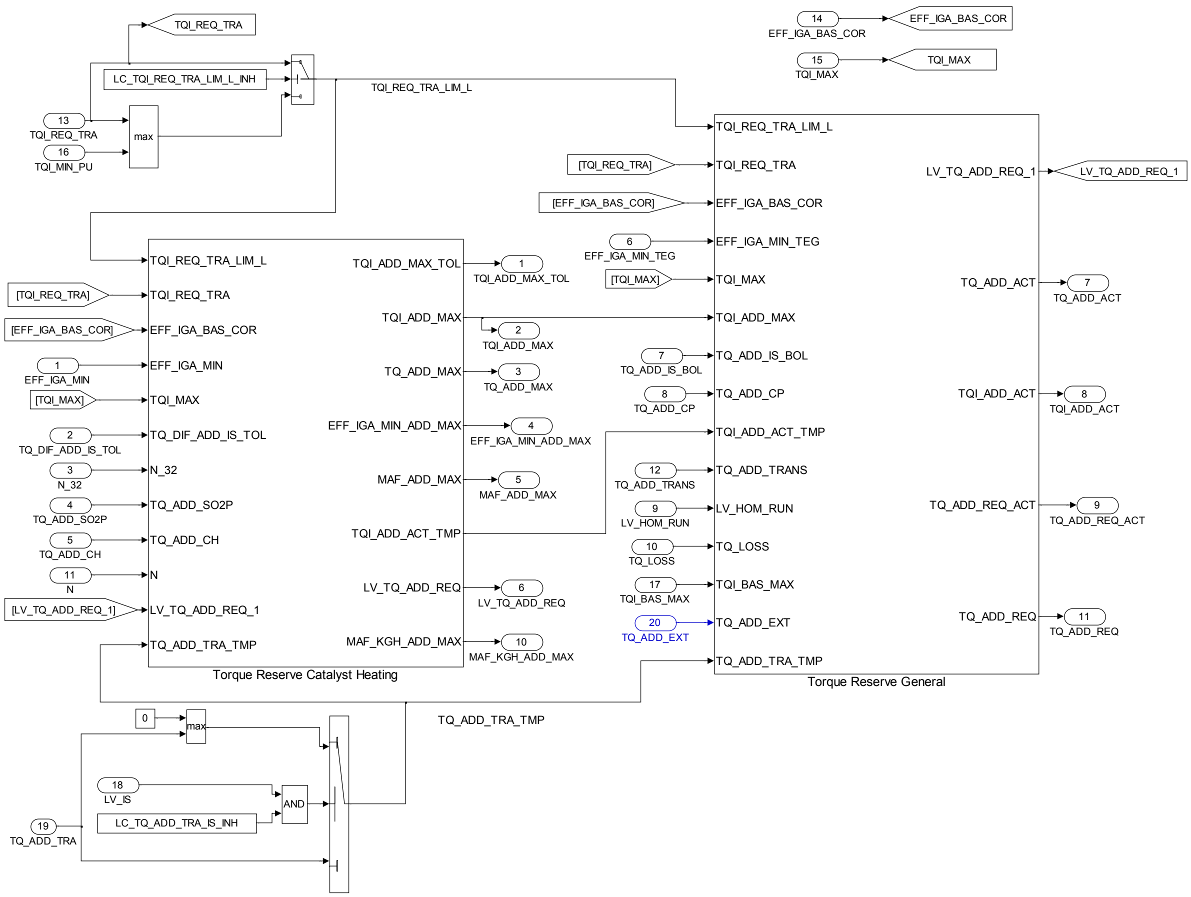

Figure 1: *Torque reserve coordination*

The torque reserve coordination is separated into the two functional blocks “Torque Reserve Catalyst Heating” and “Torque Reserve General”.

Both blocks are calculated during the 10 ms update rate.

D.37.1 Torque reserve catalyst heating

Overview:

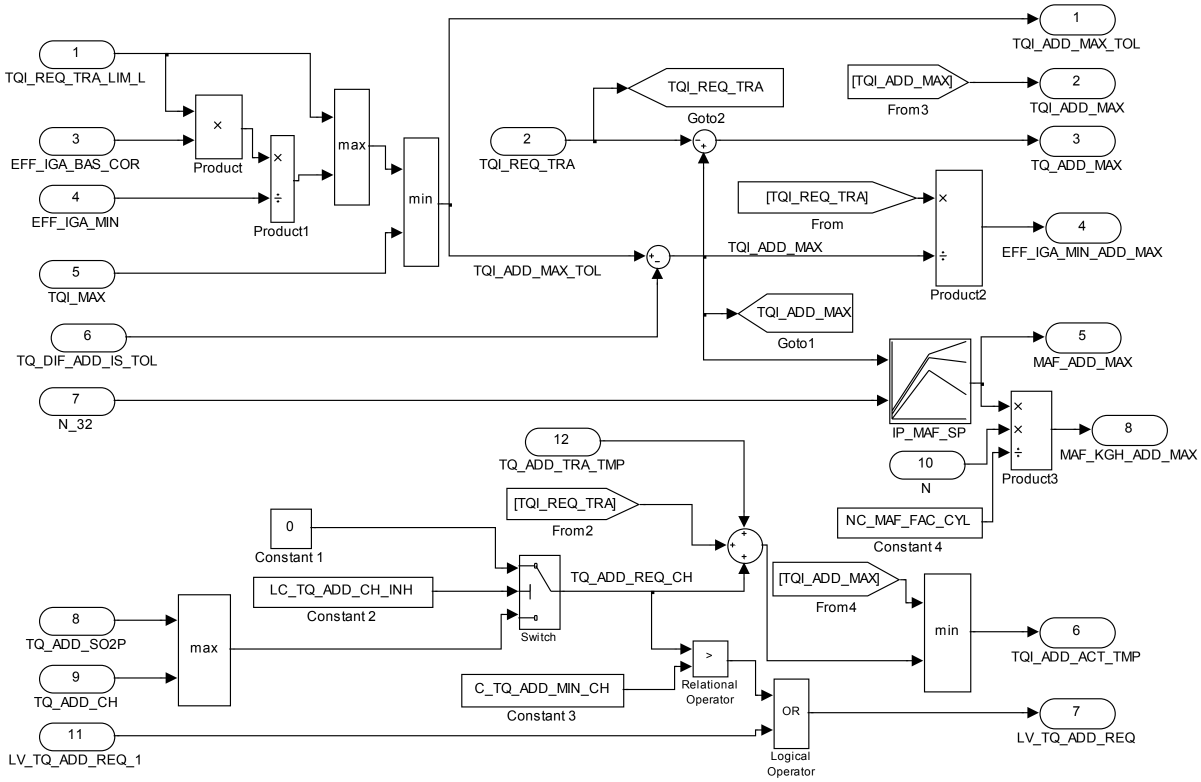

Figure 2: *Torque reserve catalyst heating*

During catalyst heating or NO_X-trap desulfation the limitation TQI_ADD_MAX is determined on basis of EFF_IGA_MIN, which is independant of the exhaust gas temperature. For the calculation of the maximum allowed torque reserve, a value TQI_REQ_TRA_LIM_L is used (see figure 1), which is TQI_MIN_PU at its minimum. Therewith, TQI_ADD_MAX can never reach zero.

For ISC request the torque-reserve TQ_DIF_ADD_IS_TOL must be taken into consideration.

The value TQ_ADD_MAX is determined as

TQ_ADD_MAX = TQI_ADD_MAX – TQI_REQ_TRA,

which is the maximum possible torque reserve.

With help of EFF_IGA_MIN_ADD_MAX and MAF_KGH_ADD_MAX (MAF_ADD_MAX) the NO_X-trap temperature model can estimate the potential of cat-heating energy which is actually available.

TQI_ADD_MAX and TQI_ADD_ACT_TMP will be used at “Torque Reserve General” to determine TQI_ADD_ACT.

Formula section:

MAF_KGH_ADD_MAX = MAF_ADD_MAX * N / NC_MAF_FAC_CYL

D.37.2 Torque Reserve General

Overview:

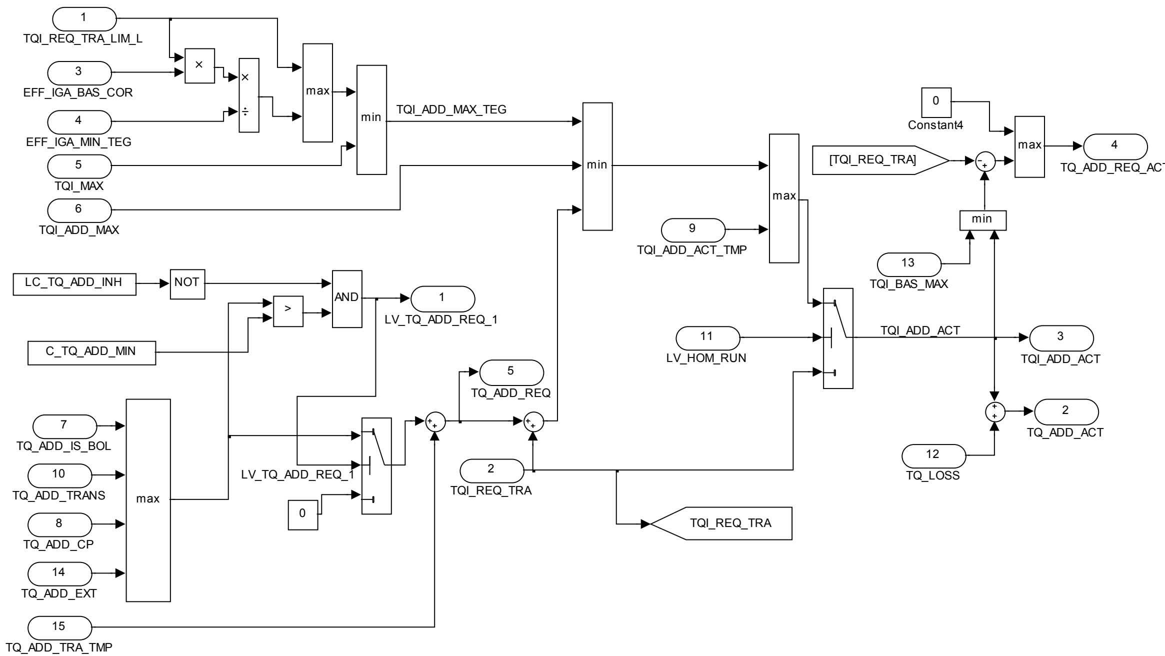

Figure 3: *Torque Reserve General*

For "General Torque Reserve Coordination" the limitation TQI_ADD_MAX_TEG is determined on basis of the EFF_IGA_MIN_TEG value which takes into consideration the actual exhaust gas temperature. For the calculation of the maximum allowed torque reserve, a value TQI_REQ_TRA_LIM_L is used (see figure 1). TQI_REQ_TRA_LIM_L is at its minimum TQI_MIN_PU, and so the maximum allowed torque reserve always unequal zero.

There must be a second limitation upto TQI_ADD_MAX because this value also includes the ISC request TQ_DIF_ADD_IS_TOL.

To prevent limitations of the catalyst heating torque reserve request, TQI_ADD_ACT_TMP is considered at the end of the torque reserve determination chain, dirctly before the definition of TQI_ADD_ACT.

At stratified combustion (LV_HOM_RUN=0), TQI_REQ_TRA will directly be copied to TQI_ADD_ACT.

Calibration data:

D.38.1 FUNCTIONAL DESCRIPTION:

D.38.2 General information:

This module is used to adapt project specific torque reserve requests to the interfaces of the module 'Torque reserve coordination'.

The specific torque reserve requests are max-selected for further coordination in 'Torque reserve coordination'. They are expected to be positive and just to contain the torque reserve request only without driver request or similar. For this realization only the torque reserve requests considering a maximum torque reserve limited by exhaust gas temperature.

Since no other request exists for high exhaust gas energy, the related output value is initialized to zero.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: at reset

TQ_ADD_EXT = 0 Nm

Update rate: 10 ms

Formula section:

TQ_ADD_EXT = max (0,
TQ_ADD_ALTER,
TQ_ADD_TRANS,
TQ_ADD_ACC,
TQ_ADD_PSTE,
TQ_ADD_PSTE_PSPT,
TQ_ADD_PL)

D.39 Minimum Indicated Engine Torque Offset during PUC (Binary Lambda Sensor)

Output data:

LDPM_N_32_2_TQDR	12	0...FFH	0...8160	32	1/min
Minimum load limitation on indicated torque level in PUC phase					

D.39.1 General Information

The output TQI_ADD_PUC is utilized as offset to the basic minimum indicated torque limitation in the module ‘Minimum indicated engine torque at trailing throttle’. The offset is active during fuel cut-off only and ensures a feasible manifold absolute pressure.

In a system configuration with binary lambda sensor, the LSL gain adapation request LV_MAP_PUC_LIM_ACT_LSL_GAIN_AD is delivered from a stub module (interface consistency). It is permanently set to zero and thus, has no functional influence.

The timer is functionally relevant only for the configuration with a linear lambda sensor. With a binary lambda sensor, the timer is not being used but has to be defined for interface consistency.

Minimum load limitation on indicated torque level in PU phase					

D.41.1 General Information

In case of homogeneous combustion, TQI_MIN_PU is the minimum limitation for TQI_SP_MAF at trailing throttle condition to ensure either a safe combustion process at low load conditions or a feasible manifold absolute pressure during fuel cut-off. It is formed by a basic limitation TQI_MIN_PU_1, an AMP correction offset TQI_MIN_PU_OFS_AMP, and, during trailing throttle fuel cut-off, by an additional offset TQI_ADD_PUC.

The parameter LV_TQI_BOL_SET indicates that a minimum indicated engine torque has been reached. The test for this condition can be performed in three different modes. LV_TQI_BOL_SET is utilized to trigger state transitions in the Aggegate Engine Operating States (ENOS).

The parameter LV_TQI_BOL_MAF_SET is set to 1 if the minimum engine load (air path) has been reached. It is utilized in ‘Dynamic Torque Request Coordination’.

FUNCTION DESCRIPTION:

General information:

This module coordinates project-specific requests for the Dynamic Torque intervention Manager.

Dynamic requests from torque structure intern as well as external requests (e.g. from driving stability systems) are collected and priorised. This module description is seperated into a calculation of ignition angle intervention and a calculation for single cylinder cut-off request (SCC).

A special dynamic request is LV_N_MAX: it has an influence on both types of intervention depending on calibration.

This module contains also the calculation of for request of SCC patterns independent from Dynamic Torque intervention Manager in case of gear shift for preventing engine speed overshoot.

Application conditions:

Initialisation: *LV_TQ_DYN_0_REQ = 1*

LV_TQ_DYN_1_REQ = 0

LV_TQ_DYN_0_DRIV = 1

LV_TQ_DYN_1_DRIV = 0

LV_TQ_DYN_DRIV = 1

LV_FCUT_FAST = 0

LV_x_TOT = 0; x is any string

Recurrence: 10ms

Activation: all engine states

Deactivation: -

D.42.1 Dynamic torque requests for ignition angle intervention

Description:

To adjust the Dynamic Torque intervention Manager mode dynamic request bits are calculated. Two bits allow to adjust the mode to realize torque requests with a combustion engine at the following modes (see also the DTM function):

	LV_TQ_DYN_1_x	LV_TQ_DYN_0_x
Economy mode: realization of torque request without ignition intervention (fast path setpoint includes airpath dynamic)	0	0
High dynamic mode: identical setpoint for slow and fast path leads to ignition intervention for fastest possible torque request realization	0	1
Torque reduction only by ignition angle adjustment	1	0
Torque reserve mode: requests, that an additional torque request in slow path accelerate the slow path or for ignition angle retardation	1	1

An additional output LV_TQ_DYN_DRIV marks, if an "converging torque mode" at transition from "eco" to "high dynamic" is allowed.

Note: The priorisation of dynamic requests must be considered with priorisation of torque requests in "Minimum/Maximum torque request selection". For this realization of the module, any "high dynamic" request wins and the torque requests resulting from the "Minimum/Maximum selection module" will be realized like this, no matter if the *corresponding torque won the selection or not. This is done to ensure that the driving stabilty function have the dynamic highest priorisation.*

D.42.1.1 Dynamic requests that require convergence to high dynamic mode

FUNCTION DESCRIPTION:

Driver demand:

The driver demand can be realized in "eco" and "high dynamic" torque mode. For the transition from "eco" to "high dynamic" a "convergence function" for the torque request in fast path is allowed (see the specification "Dynamic Torque intervention Manager"). So this logic contains all the requests for transition to "high dynamic" via "convergence" function.

Formula section:

If **not** LC_TQ_DYN_DRIV_INH ; manual high dynamic request inhibited

else FAC_DYN_DRIV_DEC = C_FAC_DYN_DRIV_DEC_2 ; 'conv' at running car
endif
else FAC_DYN_DRIV_DEC = C_FAC_DYN_DRIV_DEC ; 'conv' in all other cases
endif

D.42.1.2 Dynamic requests for direct transition to high dynamic mode EMS internal

FUNCTION DESCRIPTION:

Other intervention requests from Torque structure:

This logic collects all EMS internal requests for transition to high dynamic mode without convergence function. The bit LV_TQ_DYN_DRIV is also required as it requests "high dynamic" as well.

For engine speed limitation several intervention modes are possible:

- intervention by ETC only (depending on MAF),
- an additional ignition intervention,
- intervention by ignition and fuel cut-off patterns or
- MAF and patterns

This can be adjusted by C_STATE_N_MAX. In any case for ignition or fuel cut-off pattern LV_N_MAX requires high dynamic mode. If only MAF and pattern is allowed, the ignition retardation is prevented via an algorithm in 'Torque based pattern calculation' that controls the activation of fuel cut-off in comparison of ignition retardation.

Formula section:

```
If    LV_TQ_ADD_REQ = 1                        ; active torque reserve
      or (LV_ACT_AJ = 1 and not LC_TQ_DYN_AJ_ACT_INH) ; active anti jerk function
      or LV_REQ_ISC = 1                        ; request idle speed controller
      or (STATE_CMB_CTL &lt;> HOM_AFS and STATE_CMB_CTL &lt;> HOM_AFL)
                                               ; any other operation than HOM_AFS
                                               ; or HOM_AFL needs fast intervention mode
      or LV_ST = 1                             ; in start
      or ((LV_DT = 0 or VS < C_VS_MIN_DT_FAST )
             and LC_TQ_DYN_DT_VS_TRA_INH)      ; while gear shift or at standing car
      or (LV_N_MAX = 1 and C_STATE_N_MAX <> 0)       ; LV_N_MAX must request
                                               ;'high dyn' mode also for pattern w/o IGA
      or LV_PAS_RAMP_ACT_P_D_IS = 1            ; PD-part passive ramp active (idle speed
                                               controller)
      or (LV_PAS_RAMP_ACT_I_IS = 1
         and  LC_TQ_DYN_PAS_RAMP_ACT_I_IS_INH)
                                               ; I-part passive ramp active (idle speed
                                               controller)
      or LV_TQ_LIM_INTV = 1                    ; torque intervention for safety active
then        LV_TQ_DYN_EMS = 1
else        LV_TQ_DYN_EMS = 0
endif
```

D.42.1.3 Dynamic requests for transition to high dynamic mode EMS external

Description:

For automatic transmission a torque increase as well as a decrease can be demanded as dynamic request.

For example ASR wants the fastest possible desired torque setting when active. Dynamic requests can also require torque increase as driving stability algorithms (MSR) or automatic gear shift and external cruise controller.

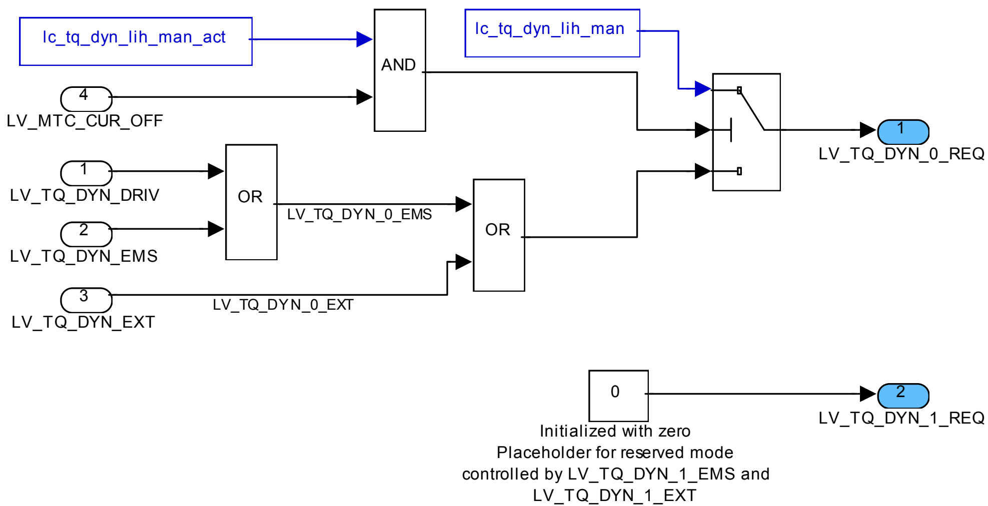
So all external requests from driving stability functions lead to immediate intervention.

Formula section:

LV_TQ_DYN_EXT =	LV_GS_ENA = 1	**or**
	LV_ASR_ACT =1	**or**
	LV_MSR_ACT =1	**or**

D.42.2 Final priorisation of dynamic requests

Signal flow diagram:



Formula section:

EMS-internal requests (reserved; LV_TQ_DYN_0_EMS used internally only)

LV_TQ_DYN_0_EMS = LV_TQ_DYN_DRIV

or LV_TQ_DYN_EMS

EMS-external requests (for info only, no calculation)

LV_TQ_DYN_0_EXT = LV_TQ_DYN_EXT

LV_TQ_DYN_1_EXT = 0

As long as all requests require the "High dynamic mode" and the reserved mode is not used no calculations are done for LV_TQ_DYN_1_EMS and LV_TQ_DYN_1_EXT to save memory.

Highest priority for Limp Home mode:

If (LV_MTC_CUR_OFF = 1 **and** LC_TQ_DYN_LIH_MAN_ACT)

Then	LV_TQ_DYN_0_REQ =	LC_TQ_DYN_LIH_MAN	
	LV_TQ_DYN_1_REQ =	0	; this bit is reserved
Else	LV_TQ_DYN_0_REQ =	LV_TQ_DYN_0_EMS **or** LV_TQ_DYN_0_EXT	
	LV_TQ_DYN_1_REQ =	0	; this bit is reserved
endif			

D.42.3 Dynamic torque requests for single cylinder cut-off

D.42.3.1 Fuel cut-off authorized by DTM

Description:

Here all dynamic requests for SCC patterns are collected that can be authorized by the DTM depending on IGA intervention state.
The LC_TQ_DYN_SCC_x_ENA defines if a fuel shut-off pattern is applied. The LC_TQ_SCC_REQ_TOT_x_ENA defines if fuel shut-off pattern is applied immediatly (1) or a calibrateable ignition retardation is allowed (0). For LV_N_MAX a state C_STATE_N_MAX is used to define the intervention mode (see calibration data section). For engine speed limitation at stopped vehicle, no ignition intevention is allowed.

Formula section:

LV_TQ_DYN_SCC = (LV_ASR_ACT **and** LC_TQ_DYN_SCC_ASR_ENA) **or**
(LV_GS_ENA **and** LC_TQ_DYN_SCC_GS_ENA) **or**
[LV_N_MAX **and**
(C_STATE_N_MAX == 2 **or** C_STATE_N_MAX == 3)]

LV_TQ_SCC_REQ_TOT =
(LV_ASR_ACT **and** LC_TQ_SCC_REQ_TOT_ASR_ENA) **or**
(LV_GS_ENA **and** LC_TQ_SCC_REQ_TOT_GS_ENA) **or**
[LV_N_MAX **and** (C_STATE_N_MAX == 3)] **or**
[LV_N_MAX_VS_0]

D.42.3.2 Fast fuel cut-off

Description:

The objective of this chapter is to define the condition for single cylinder cut-off. If fast fuel cut-off is enabled, cylinder deactivation will be managed by the torque management, but without DTM.

The fast fuel cut-off will be enabled for the following situation:

- the coolant temperature must exceed a calibrateable threshold
- the accelerator pedal must be released and the clutch has to be opened; Torque Request after Torque Transient Function has to be zero (This allows a calibrateable time delay at gear zero via Torque Transient function)

For preventing unwanted injection intervention at transition to IS a threshold can be applied, keeping distance for shut-off to reinjection in IS.

The request can be deactivated in "Torque based pattern calculation".

Formula section:

IF (LV_PL == 1 **or** LV_PU ==1) **AND** % activation condition
TCO >= C_TCO_MIN_FCUT_FAST **AND**
LV_CS == 1 **AND**
LV_ERR_CS = 0 **AND**
LV_CT == 1 **AND**
TQI_REQ_TRA <= C_TQI_REQ_TRA_THD_FCUT_FAST **AND**
N_32 >= C_N_MIN_FCUT_FAST
THEN LV_FCUT_FAST = 1
ELSE LV_FCUT_FAST = 0
END

LV_FCUT_FAST_TOT = LC_FCUT_FAST_TOT

Calibration data:

D.43 Authorization of ignition intervention

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_TQ_IGA_ENA	O / V	0 .. 1H	0 .. 1	1	-
Logical variable for enabling ignition intervention					

Input data:

LV_ACT_AJ	LV_REQ_ISC	LV_TQ_DYN_IGA	

FUNCTION DESCRIPTION:

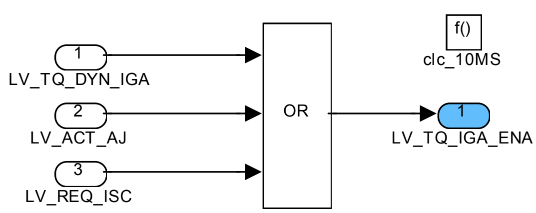
This chapter is triggered separate from the previous chapter !

This is the final instance in torque setpoint calculation for authorization of ignition intervention. If the output is active, ignition intervention is authorized. It *must* be calculated after:

- Dynamic Torque Management
- Anti jerk controller
- Idle speed controller

or any algorithm that requires immediate ignition intervention. It should be calculated directly before Torque coordination. Otherwise Anti Jerk and Idle speed controller output are cut for one sample at activation.

Signal flow diagram:



Formula section:

LV_TQ_IGA_ENA = LV_TQ_DYN_IGA
or LV_ACT_AJ
or LV_REQ_ISC

Application conditions:

Initialisation: LV_TQ_IGA_ENA = 1

Recurrence: 10ms

Activation: at every engine state

Deactivation: -

D.44 Minimum/Maximum Torque Request Selection

NR_TQ_SEQ_FAST	V	0..FF H	0..255	1	-
Number of torque request that has won the selection for fast path					

Input data:

TQI_ADD_ACT	TQI_GS_SLOW_DEC	TQI_N_MAX	TQI_MIN_REQ
TQI_REQ_TRA	TQI_GS_SLOW_INC	TQI_GS_FAST_DEC	TQI_GS_FAST_INC
TQI_ASR_SLOW	TQI_ASR_FAST	TQI_MSR	TQI_MAX_ETC
TQI_P_MAX_SLOW	TQI_P_MAX_FAST		

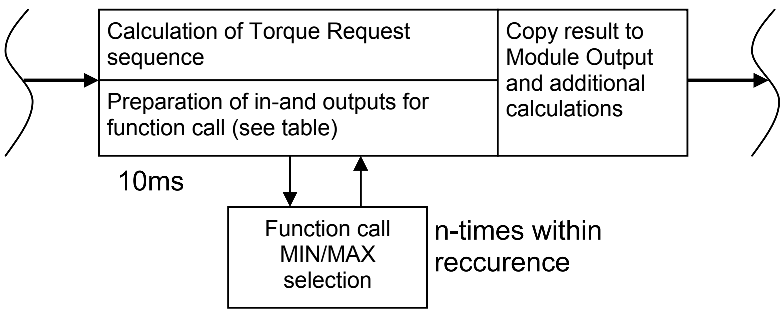
FUNCTION DESCRIPTION:

General information:

This module coordinates all internal and external torque requests. It generates TQI_REQ_SLOW_SEL for the slow torque path (load) and TQI_REQ_FAST_SEL which represents the fast torque path (ignition, cylinder cut-off and lambda).

This is done by a sequence of function calls (SW uses macro), where the last priorised torque request is compared to a torque request according to the priorisation in the sequence. The information which torque request has won the comparison is stored. Each sequence is called once in a recurrence with n function calls, where n is the number of torque requests per path to be priorised. If the torque requests have identical values, the request with higher number in the sequence wins the comparison.

The higher the number of a request in the sequence the higher it's priorisation



Application conditions:

Initialisation:	at reset:	TQI_REQ_SLOW_SEL = 0 Nm
		TQI_REQ_FAST_SEL= 0 Nm
		TQI_EMS = 0 Nm
		LV_TQ_INC = 0
Recurrence:	10 ms	
Activation:	at every engine state	
Deactivation:	-	

D.44.1.1 Slow path minimum/maximum selection

Description:

The following tables describe the priorisation of the torque inputs and the selection type Minimum or Maximum compared to the previously calculated value. It also describes when an intermediate value has to be calculated for further comparison.

There are two sequences, one for the slow path, the other one for the fast path.

The LV_MIN_MAX_SEL describes the selection type: LV_MIN_MAX_SEL = 0 means a minimum selection, if it is one it requests a maximum selection (see also the Minimum / Maximum selection function). The name of the function is "min_max_sel".

The following table shows the sequence for the slow path and the type of selection.

Priorisation Table - Slow Path (Prio_Table_Slow):

Sequence Order **nr_seq**	Torque Input **tq_inp**	Min/Max selection **lv_min_max_sel**	Reserved	Value stored in:
1	TQI_ADD_ACT	1*)		
2	TQI_P_MAX_SLOW	0		
3	TQI_GS_SLOW_DEC	0		
4	TQI_N_MAX	0		
5	TQI_MAX_ETC	0		
6	TQI_ASR_SLOW	0		
7	TQI_MIN_REQ	1		TQI_INTER_SLOW
8	TQI_GS_SLOW_INC	1		
9	TQI_MSR	1		TQI_REQ_SLOW_SEL

The sequence organizes the function calls of the selection macro and provides the input data to the function.

*) This first value is a maximum selection with the initialization value 0.

Formula section:

The variables in small letters are used internally only. See the chapter "Minimum Maximum selection function" for the parameters of the function call.

Initialisation: tq_out = 0;

nr_seq_out = 0;

Sequence:

```
For nr_seq = 1 to 9
        tq_inp1 = tq_out;
        tq_inp2 = value "tq_inp" from "Prio_Table_slow(nr_seq)";
        nr_seq_inp1 = nr_seq_out;
        nr_seq_inp2 = nr_seq;
        lv_min_max_sel = id_min_max_sel(nr_seq);
        [tq_out, nr_seq_out]  = FCN_CALL(min_max_sel)
        if nr_seq = 6
        then TQI_INTER_SLOW=tq_out
        endif
endfor
TQI_REQ_SLOW_SEL = tq_out;
NR_TQ_SEQ_SLOW = nr_seq_out;
```

D.44.1.2 Fast path minimum/maximum selection

Description:

Priorisation Table - Fast Path (Prio_Table_Fast):

Sequence Order **nr_seq**	Torque Input **tq_inp**	Min/Max selection **lv_min_max_sel**	Reserved	Value stored in:
1	TQI_REQ_TRA	1*)		
2	TQI_P_MAX_FAST	0		
3	TQI_N_MAX	0		
4	TQI_GS_FAST_DEC	0		
5	TQI_ASR_FAST	0		
6	TQI_GS_FAST_INC	1		TQI_INTER_FAST
7	TQI_MIN_REQ	1		
8	TQI_MSR	1		TQI_REQ_FAST_SEL

The calculation for the fast path is equal to the slow path. Additionally one more intermediate value is calculated.

*) This first value is a maximum selection with the initialization value 0.

Formula section:

All variables used internally are written in small letters.

Initialisation: tq_out = 0;

nr_seq_out = 0;

Sequence:

For nr_seq = 1 **to** 8

tq_inp1 = tq_out;

tq_inp2 = value "tq_inp" from "Prio_Table_Fast(nr_seq)";

nr_seq_inp1 = nr_seq_out;

nr_seq_inp2 = nr_seq;

lv_min_max_sel = id_min_max_sel(nr_seq);

[tq_out, nr_seq_out] = FCN_CALL(min_max_sel)

if nr_seq == 5

then TQI_INTER_FAST = tq_out;

endif

endfor

TQI_REQ_FAST_SEL = tq_out;

NR_TQ_SEQ_FAST = nr_seq_out;

D.44.1.3 Additional Calculations

For analyzing the minimum/maximum torque request selection additional values are needed, but they do have no affect to slow or fast path or do not come from the sequential calculation.

Formula section:

TQI_EMS = min (TQI_REQ_TRA, TQI_N_MAX, TQI_P_MAX_FAST)

If TQI_EMS < TQI_INTER_FAST

Then LV_TQ_INC = 1

Else LV_TQ_INC = 0

Endif

TQI_REQ_FAST_INC = TQI_GS_FAST_INC

TQI_REQ_FAST_DEC = min (TQI_REQ_TRA, TQI_GS_FAST_DEC)

D.44.1.4 Minimum Maximum selection function

Application conditions:

Initialisation: *tq_out = 0; nr_seq_out = 0;*

Recurrence: function call, nr_seq-times in one recurrence from the sequence

Activation: function call

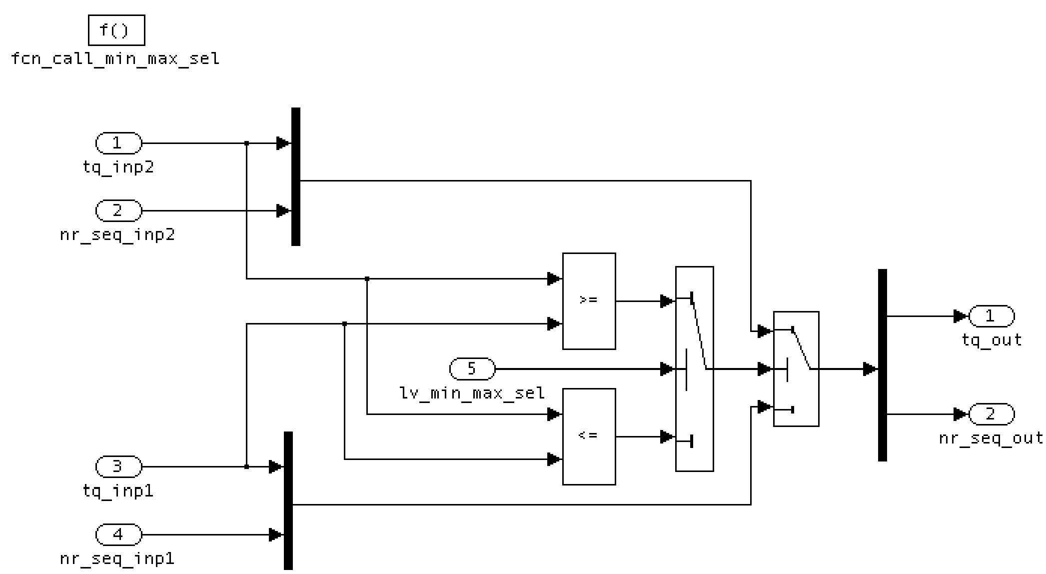
Deactivation: -

Description:

This function produces as output a torque and its corresponding position in the priorisation sequence. The result can be a minimum or a maximum of two torque request inputs, depending on a selection bit. If both torque requests have the same value, the request with higher number in the sequence wins the selection.

This function is called *n*-times within one reccurence, where *n* is the number of torque requests per sequence.

Signal flow diagram:



D.45 Dynamic Torque intervention Manager

General information:

The intention of the Dynamic Torque intervention Manager (DTM) is to have a central coordination of dynamic torque requests. It controls the realization of a torque request via the slow air path and the fast path with ignition intervention, fuel cut-off or lambda variation. It produces two kinds of outputs:

- Torque requests for slow and fast path for correct representation based on the Torque Structure.
- Logical values for switching different fast path realization variants to either their passive values or setpoint calculation via Torque Structure.

The state machine is controlled via dynamic control bits, that allow different states of intervention variants. Also the transitions from one state to the other can be influenced.
The description of the DTM is parted into three chapters: one for manipulation of the slow air path and the ignition path, another one for authorizing fuel cut-off and a last one for lambda variation. According to this is the priorisation of the different possibilities of torque intervention.
So the DTM finally adjusts the dynamic requirements from the control bits and gives the possibility to use several transitions between the different requirements.

D.45.1 Coordination ignition

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_TQ_DYN_IGA	V / O	0 .. 1 H	0 .. 1	1	-

TQI_BAS	LV_TQ_DYN_DRIV	LV_HOM_RUN	LV_MTC_CUR_OFF
FAC_DYN_DRIV_DEC			

FUNCTION DESCRIPTION:

General information:

This chapter contains the coordination of slow air path and ignition path. There are three states, where a certain torque input is fed through:

- "economy mode", where ignition intervention is not allowed
- "high dynamic mode", where ignition intervention is allowed
- "torque reserve mode", where the torque request for the airpath can be influenced (this mode is currently without function).

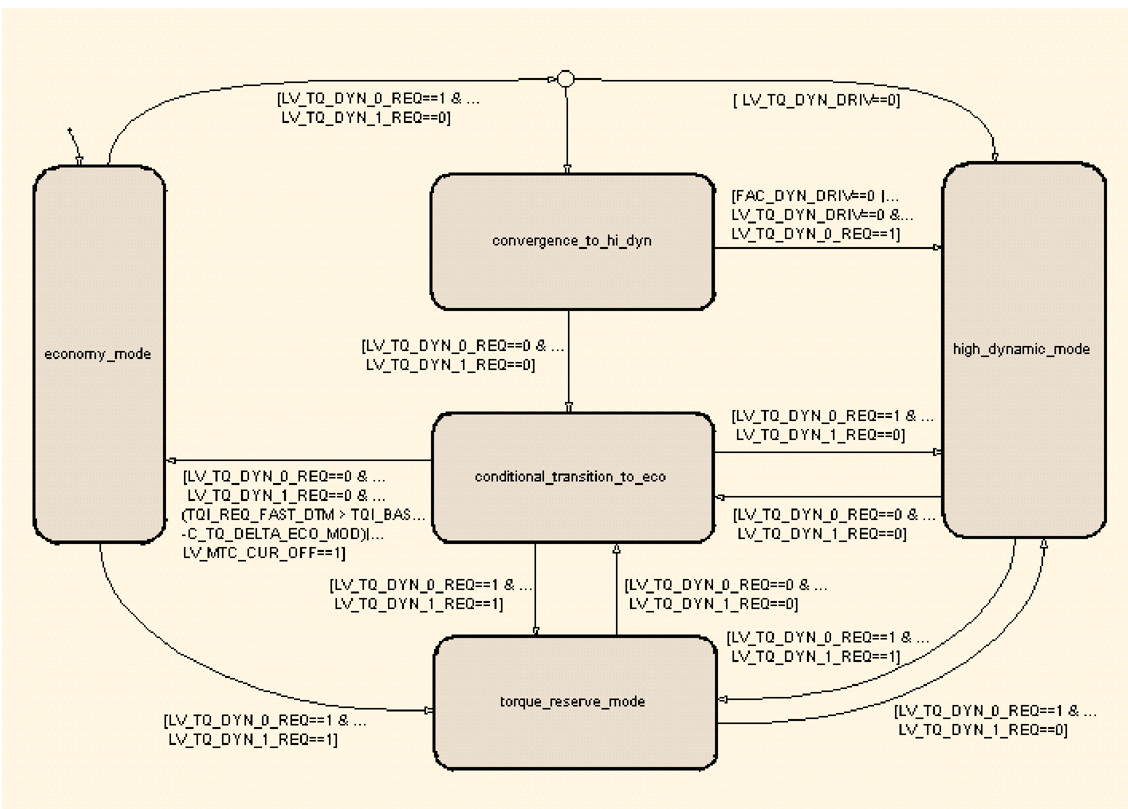
Furthermore there are transition states:

- "convergence to high dynamic mode" for smooth transition from the input to TQI_REQ_FAST_DTM in "eco" to the input in "high dynamic"
- "conditional transition to economy mode" for preventing torque jumps on exit from any mode to "economy mode" .

All these states are controlled by the dynamic control bits LV_TQ_DYN_x_REQ. For the transitions additionally a bit for low dynamic request is taken into consideration: LV_TQ_DYN_DRIV.

For correct behavior it is absolutely necessary that the logical variables for dynamic requests are coordinated correctly. See the specification of "Dynamic torque request coordination"

Signal flow diagram:



Description:

The several states define the assignment of the input TQI_REQ_SLOW_SEL and TQI_REQ_FAST_SEL to the outputs TQI_REQ_SLOW/FAST_DTM.

The state machine produces also the logical output

LV_TQ_DYN_IGA

to authorize or prohibit ignition intervention. The logical state 1 means fast intervention is allowed, the logical state=0 means the fast intervention is prohibited.

In "economy" input to the fast path is TQI_BAS, therefore no fast intervention is applied. In "high dynamic" the torque request inputs are just fed through, spark retard is allowed.

For transition from "eco" to "high dynamic" there are two possibilities:

1. A high dynamic request leads to direct entry of high dynamic.
2. A low dynamic request enters the "convergence to high dynamic". Here an convergence function performs a smooth transition for the fast path from TQI_BAS to the new target value for the fast path.

To avoid large changes in spark advance no direct entry to "economy mode" is allowed. The increment to reach the target torque request is limited to C_TQ_DELTA_MAX_COMP. A calibrateable C_TQ_DELTA_ECO_MOD defines the maximum allowed torque jump on reentry of "economy mode".

If there is a problem with the state machine when a undefined state is produced then the default state is set.

Note: The convergence factor FAC_DYN_DRIV_DEC must not be zero. It is recommended to have a bigger value then 0.001 (equals 10 sec converging time). Otherwise it is possible only to leave the convergence state with high dynamic request but not from LV_TQ_DYN_DRIV.

Application conditions:

Activation: at every engine state

D.45.2 Coordination single cylinder fuel cut-off (Torque based pattern calculation)

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_TQ_SCC_REQ	V/O	0..1H	0, 1	1	-
Logical variable for enabling pattern fuel cut-off					
LV_TQ_SCC_INH	V/O	0..1H	0, 1	1	-
Logical variable for inhibit pattern fuel cut-off					

Input data:

LV_TQ_DYN_SCC	STATE_TQ_DYN_IGA	LV_ES	LV_ST

FUNCTION DESCRIPTION:

General information:

This part coordinates, if fast fuel cut-off via torque based pattern calculation is allowed or not.

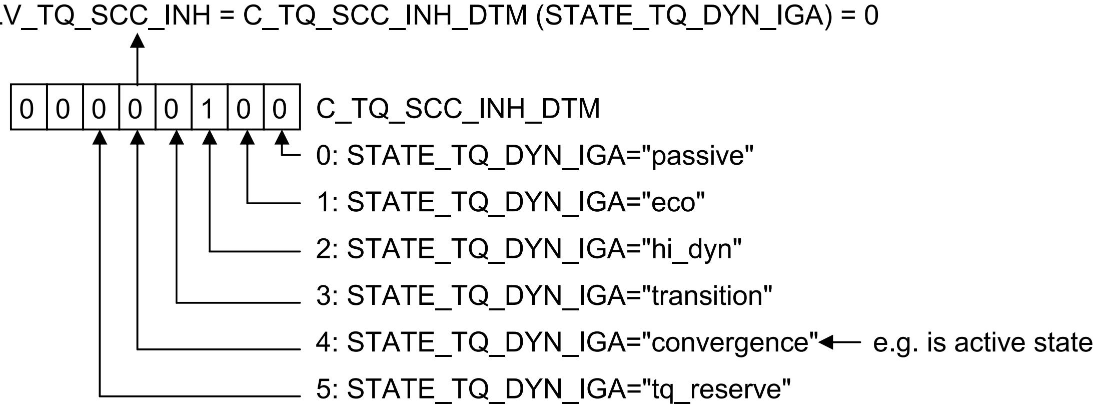
Description:

The current revision contains the following functionality (test state):

Assignment of SCC to certain states of the ignition intervention manager; SCC can only be active in the choosen states.

This is realized by a byte, where LV_TQ_SCC_INH is result of the bit of this byte (C_TQ_SCC_INH_DTM) with index STATE_TQ_DYN_IGA.

LV_TQ_SCC_INH = C_TQ_SCC_INH_DTM (STATE_TQ_DYN_IGA) = 0



Single cylinder cut-off depending on STATE_TQ_DYN_IGA is switched off at FFH for C_STATE_TQ_DYN_IGA. In this case it is authorized only by LV_TQ_DYN_SCC.

Application conditions:

Initialisation: at deactivation

LV_TQ_SCC_INH = 1

Recurrence: 10ms

Activation: at every engine state except LV_ST or LV_ES

Deactivation: -

Formula section:

LV_TQ_SCC_REQ = LV_TQ_DYN_SCC

If C_TQ_SCC_INH_DTM = FFh

then

LV_TQ_SCC_INH = NOT(LV_TQ_DYN_SCC)

else

LV_TQ_SCC_INH = BIT(STATE_TQ_DYN_IGA) from C_TQ_SCC_INH_DTM

end

Application conditions:

Initialisation: all zero

Recurrence: 10msec

Activation: at every engine state

D.46.2 Torque Coordination

FUNCTION DESCRIPTION:

General information:

In case of homogeneous combustion, the module “Torque coordination” coordinates slow and fast torque requests which are realized by the air path and ignition (also fuel cut-off and lambda possible).
The output value TQI_SP_SLOW of the slow path contains the request from the idle speed controller.
TQI_SP is the target torque in homogeneous combustion which has to be realized by the fast torque path. It contains additional torque request from idle speed controller and anti jerk controller. Both have the highest priority and connat be overrun by any torque request.

In case of full load a lambda efficiency quotient is applied to the fast path as a correction factor to prevent ignition angle retardation at full load conditions.

The torque setpoint C_TQI_SP_MAN can be set manually by application tool if the logical constant LC_TQI_SP_MAN_ACT = 1.

It is possible to limit the output TQI_SP to ensure that a minimum torque reserve is applied, this ensures correct catalyst heating.

When the ignition is turned off, the injection is stopped, this can result in a earlier spark angle (via EFF_SCC < 1), and due to the wall film continued combustion with a resulting engine speed increase. In order to eliminate this effect, the torque setpoint is set to 0 when the ignition is off.

Application conditions:

Initialisation: at reset:

TQI_SP = TQI_FAST = TQI_REQ_FAST = 0 Nm

TQI_SP_SLOW = TQI_REQ_SLOW = 0 Nm

FAC_TQI_REQ_FL = 1

Recurrence: 10 ms

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Engine speed deviation threshold for activation anti jerk function at deceleration					

Input data:

N	LV_AT	GEAR	LV_ES

FUNCTION DESCRIPTION:

This module includes the anti jerk controller and activation parameters that need to be adapted to the drivetrain configuration. Within this module it is possible to define several configurations as for example AT and MT choosen via variant coding or it could also only contain one variant to reduce calculation time and "dead" maps.

Application conditions:

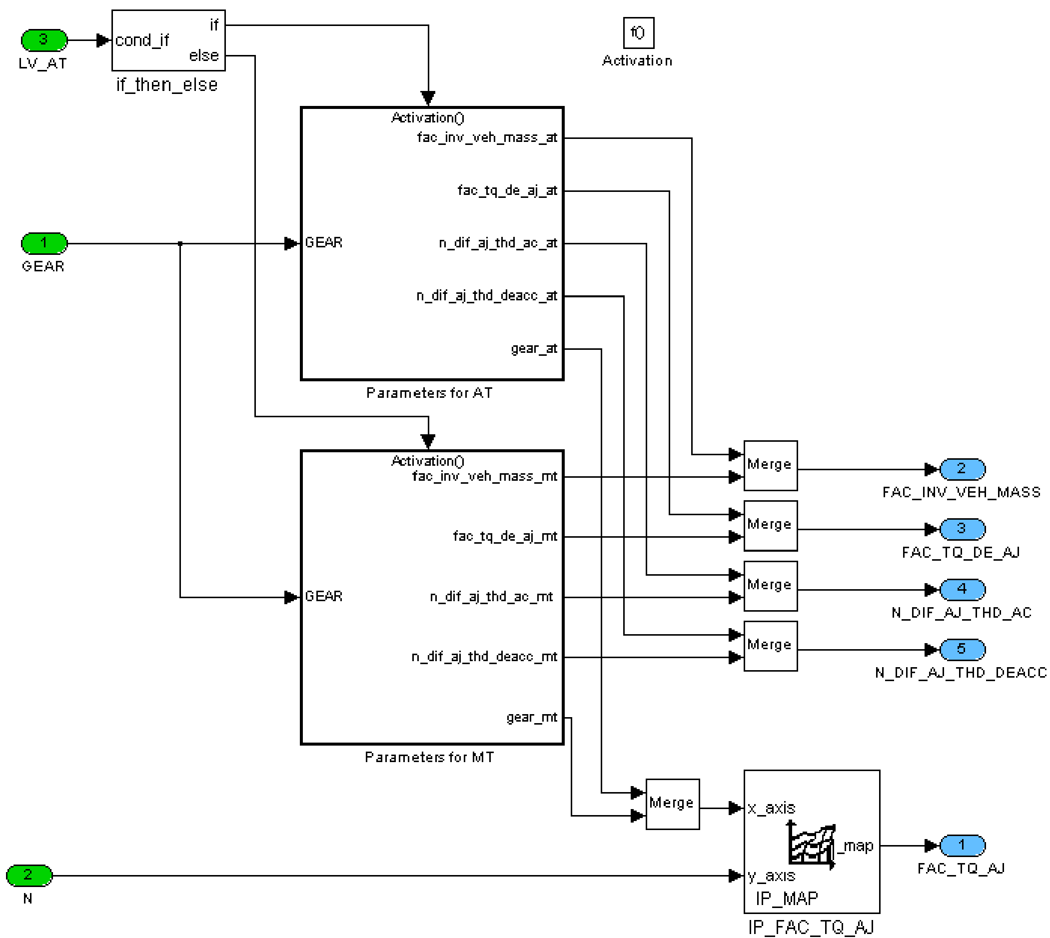
Initialisation: at reset all outputs = 0

Recurrence: 10 ms

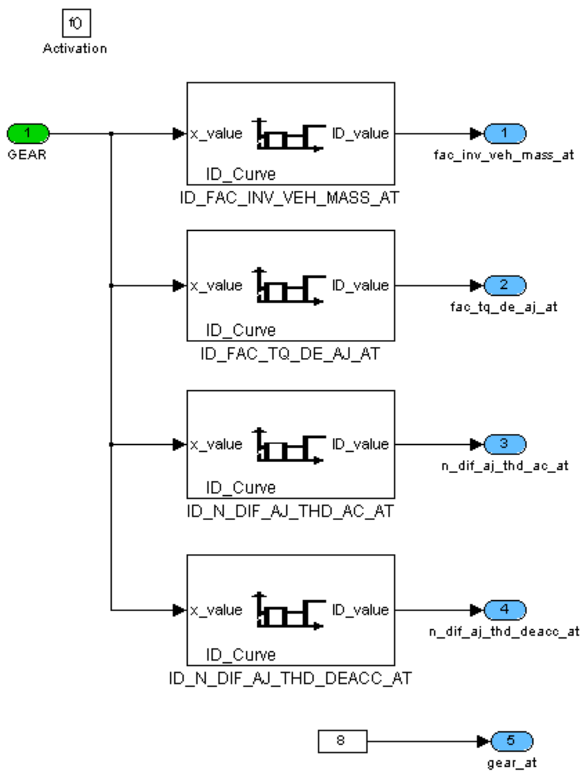
Activation: LV_ES == 0

Deactivation: LV_ES == 1

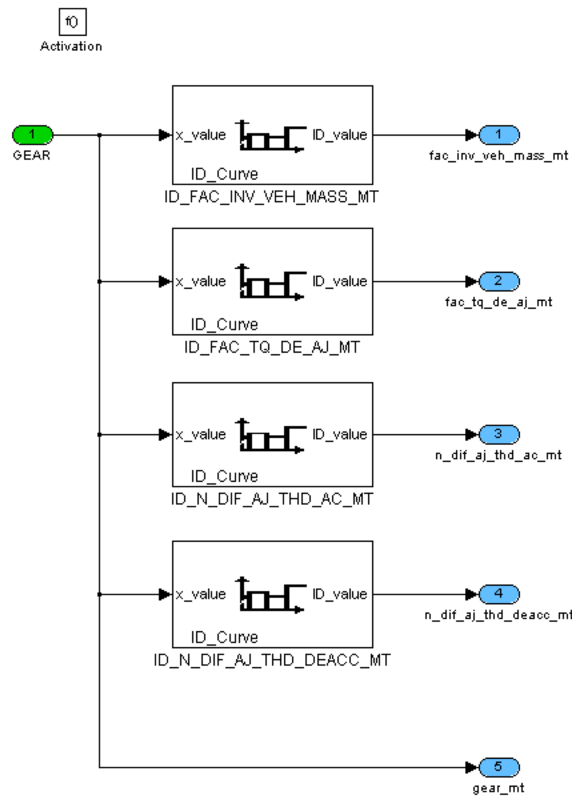
Signal flow diagram:



Block Parameters for AT



Block Parameters for MT



Description:

This project specific solution allows variant coding for manual and automatic transmission with a maximum of seven gears (R,N,1-5). Since R is treated as the 1st gear from gear ratio detection it is possible to put in *eight* gears using seven breakpoints.

For an AT the last breakpoint (8, see Signalflow diagram) from IP_FAC_TQ_AJ is reserved for calibration. Therefore for this variant FAC_TQ_AJ depends only on engine speed and not on gear. Note, that it is only necessary to have anti jerk intervention for locked converter.

LV_ASR_ACT	LV_MSR_ACT	LV_ERR_CRK	LV_ERR_IV[NC_CYL_NR]
LV_ERR_MWSS	LV_ERR_CAM_IN_i	LV_ERR_VS	LV_MIS_STATE_A
LV_MIS_STATE_B			

FUNCTION DESCRIPTION:

General information:

The anti jerk controller must be activ only at certain activation conditions. Within this chapter the activation conditions are fitted to project specific needs, depending on engine and drivetrain configuration.

The inputs requesting anti jerk can be separated into static signal that do not require a reinitialization and signals where a reinitialization of the reference engine speed model and the anti jerk controller is necessary.

There is also the possibility the inhibit anti jerk via static signals.

Application conditions:

Initialisation: at reset all outputs = 0

Recurrence: 10 ms

Activation: LV_ES = 0

Deactivation: LV_ES = 1

Formula section:

LV_PAS_AJ_INP = LV_FCUT_IND or LV_GS_ACT or LV_ASR_ACT or LV_MSR_ACT

If LV_ERR_CRK = 1 **or**
LV_ERR_IV[NC_CYL_NR] = 1 **or**
LV_ERR_MWSS = 1 **or**
LV_ERR_CAM_IN_i =1 **or**
LV_ERR_VS =1 **or**

TQI_FAST	TQ_LOSS	FAC_TQ_AJ	FAC_TQ_DE_AJ
FAC_INV_VEH_MASS	LV_ES		

FUNCTION DESCRIPTION:

General information:

The anti-jerk function damps jerk effects of the vehicle at sudden acceleration or deacceleration. Vehicle jerking results in an engine-speed oscillation. The deviation of the actual engine-speed to a 'not jerking' modelized engine-speed is the indicator for a jerking vehicle.

The anti jerk function damps oscillation of the powertrain at vehicle acceleration or deacceleration by an torque intervention in phase with the calculated engine-speed deviation N_DIF_AJ.

According to torque structure calculation a spark intervention is applied.

The anti-jerk function consists of three main parts:

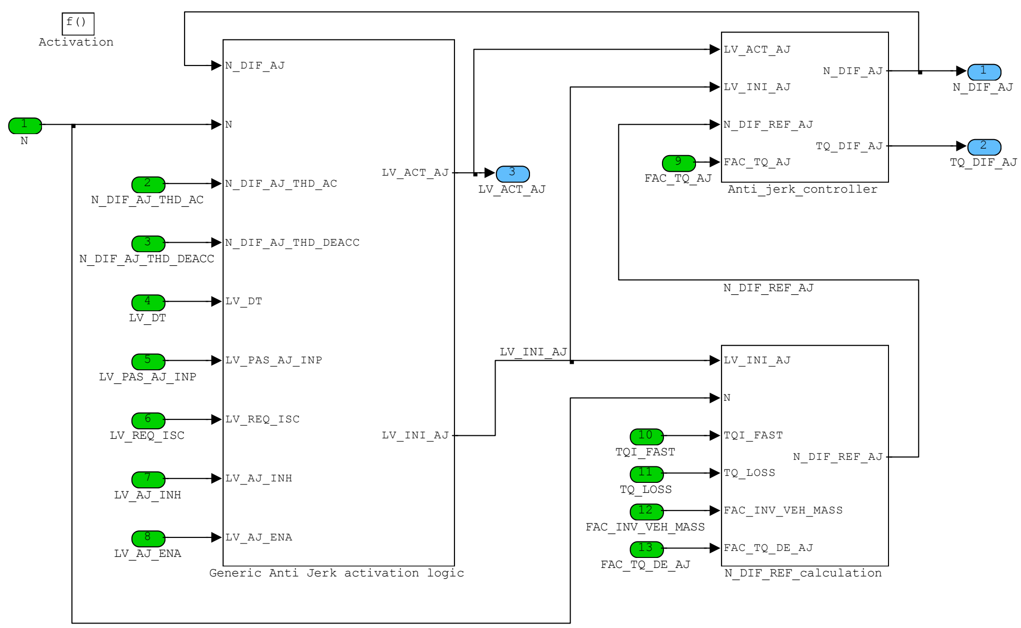
- Generic activation and trigger condition
- Determination of engine-speed oscillation N_DIF_REF_AJ
- Anti-jerk controller (with determination of N_DIF_AJ and TQ_DIF_AJ)

The engine speed oscillation is calculated from a reference engine speed signal and the real engine speed. From this deviation the output TQ_DIF_AJ for spark influence is produced.

Application conditions:

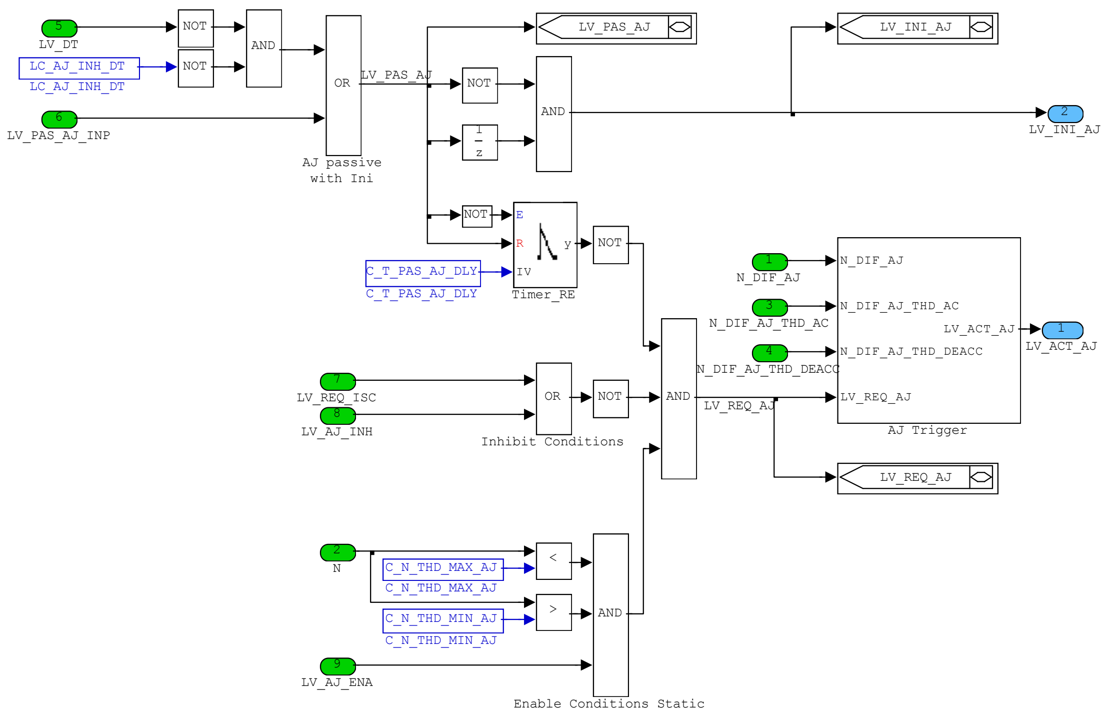
Initialisation:	at reset all outputs and intermediate values = 0
	at reset LV_INI_AJ = 1 for one recurrence
Recurrence:	10ms
Activation:	LV_ES == 0
Deactivation:	LV_ES == 1

Signal flow diagram:



D.49.1 Anti Jerk Activation and Trigger

Signal flow diagram:



Description:

The generic activation provides two inputs to mark an anti jerk request. Active LV_DT or LV_PAS_AJ_INP (input for project specific activation) lead to an initialisation of the controller. This input should be used when the modelled engine speed does not represent the real engine speed, e.g. at open drive train.

Another input , LV_AJ_ENA enables the trigger algorithm without initialisation and should be used for static signals.

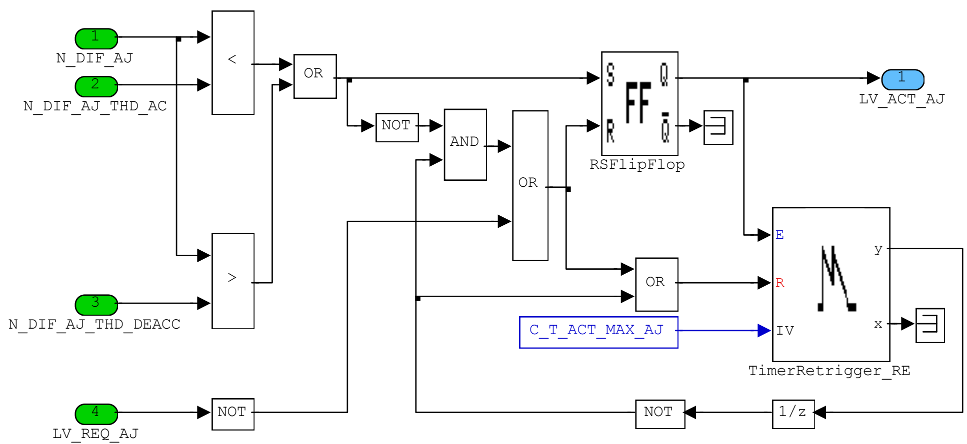
Inhibit conditions (LV_REQ_ISC, LV_AJ_INH) can prevent an anti jerk intervention. Also the anti jerk intervention can only be active within a calibrateable engine speed range.

AJ Trigger Algorithm

If an anti jerk request LV_REQ_AJ is active, the controller is activated by a trigger event depending on the deviation N_DIF_AJ of reference engine speed and real engine speed. Once the trigger occured the anti jerk activation lasts until the timer C_T_ACT_MAX_AJ is out or the LV_REQ_AJ gets inactive. If LV_REQ_AJ stays active while the timer has run out, the trigger can get active immediatly again. There should be no delay, if LV_REQ_AJ and the trigger condition are true.

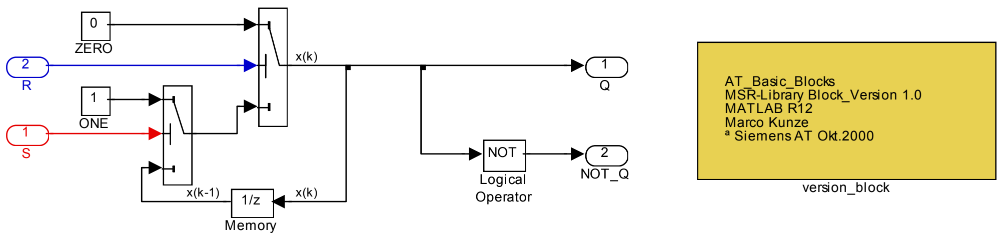
Anti Jerk is triggered immediatly at the first wave exceeding the thresholds.

Signal flow diagram:

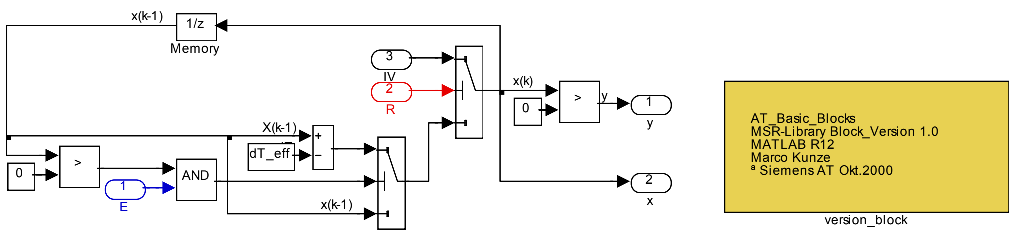


Important for RSFlipFlop and Timer: reset (R) priority is higher then set (S/E) priority.
See next page for details.

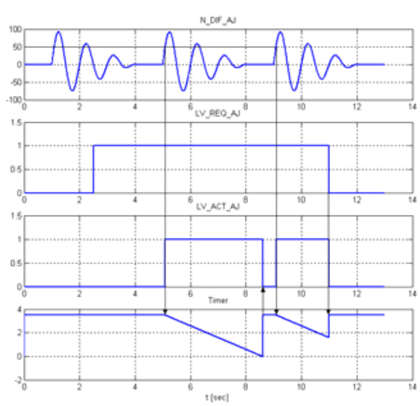
RSFlipFlop:

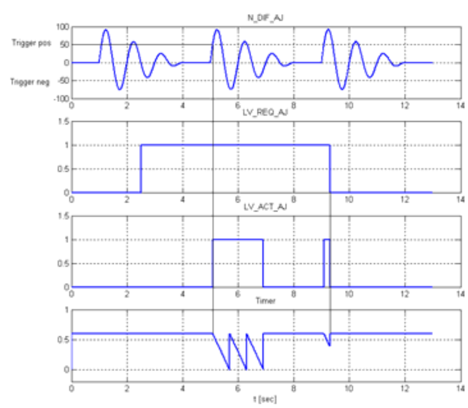


TimerRetrigger:



Signals:



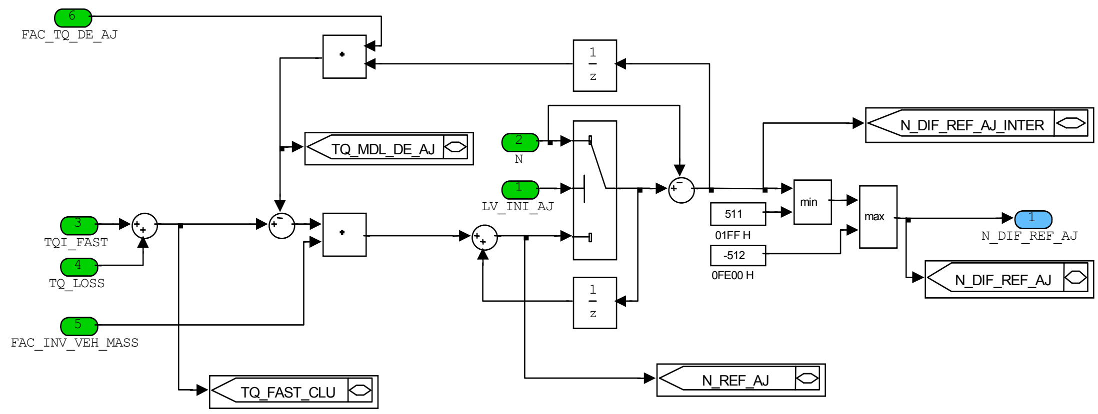


Case1: The Timer lasts longer then a jerk signal.
The LV_ACT_AJ is reset by the timer or missing LV_REQ_AJ.

Case2: The Timer lasts shorter than a jerk signal.
If the trigger condition ist fulfilled immediate restart of the timer is done. So there is no interuption of the LV_ACT_AJ.

Determination of Engine-Speed Oscillation N_DIF_REF_AJ

Signal flow diagram:



Application conditions:

Initialisation: at reset or LV_INI_AJ == 1

⇒ N_DIF_REF_AJ = 0; N_REF_AJ = N

The engine speed oscillation at jerking vehicle is determined with help of the real measured and a modelized (not jerking) engine speed (N_REF_AJ).

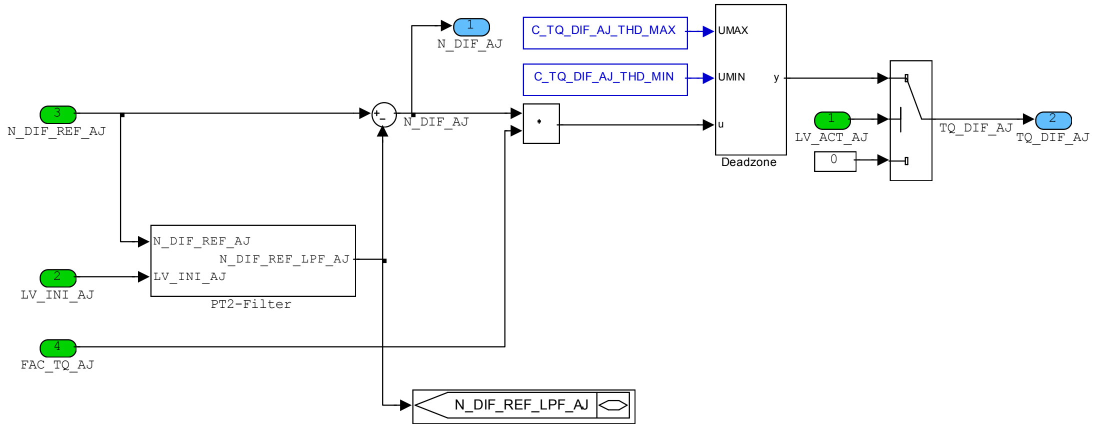
For this purpose a modelized engine speed N_REF_AJ is calculated from the actual torque request at clutch TQ_FAST_CLU = TQI_FAST + TQ_LOSS by integration. The actual vehicle-mass and moment of inertia is taken into consideration by the factor FAC_INV_VEH_MASS. This factor includes also the update rate of 10 ms.

The remaining deviation N_DIF_REF_AJ is used to determine the high frequent part of engine-speed oszillation N_DIF_AJ.

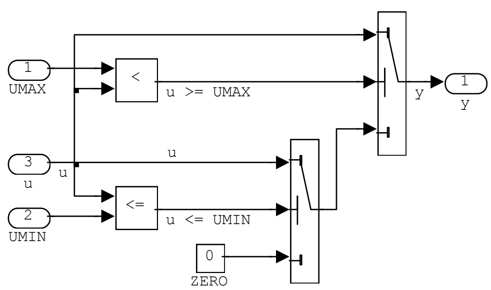
A proportional feedback loop with N_DIF_REF_AJ as input, corrects the 'input torque' TQ_FAST_CLU to adjust the reference non-jerking engine-speed to the measured engine speed N, performing an 'adaptation' of changed real-world conditions.

D.49.2 Anti-Jerk Controller

Signal flow diagram:



Dead zone:



For anti-jerk torque intervention only the high-frequent part of the engine speed oscillation is used, to damp the unpleasant oszillations (e.g. in range: 2 up to 10 Hz) but not to limit the acceleration capability of the vehicle.

The high-pass filter of N_DIF_REF_AJ is realized in two steps:

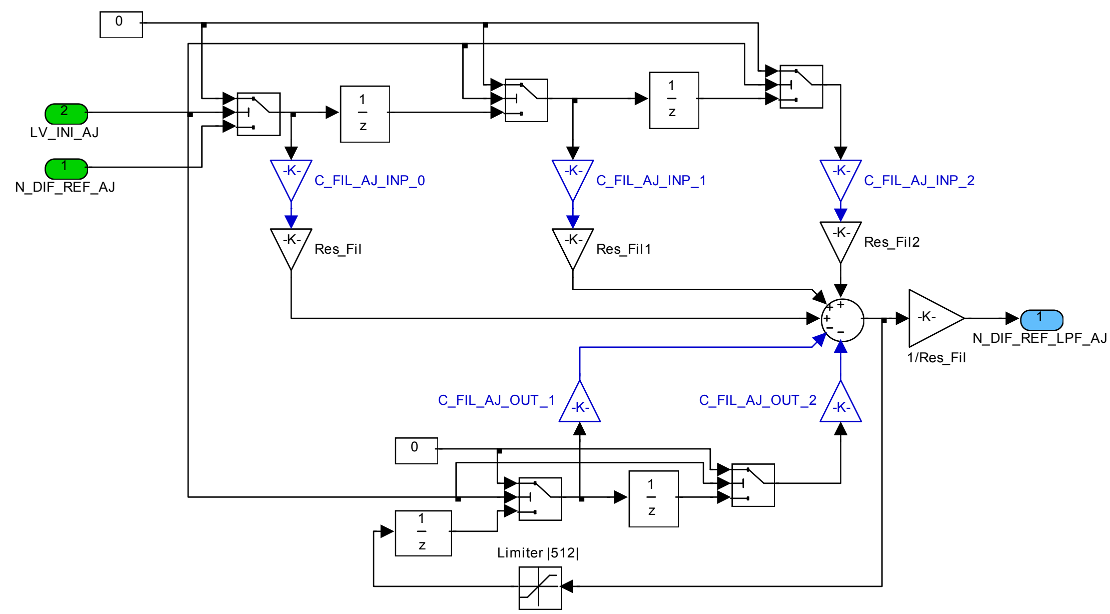
First step - low pass filtering of N_DIF_REF_AJ ⇒ N_DIF_REF_LPF_AJ represents the deviation of modelized and real engine-speed

Second step - The difference of INPUT and OUTPUT of the low-pass filter represents the high-pass filtered engine-speed oscillation which is the basis for anti-jerk torque intervention.

Proportional to this difference N_DIF_AJ the damping torque output TQ_DIF_AJ is determined.

D.49.2.1 Recursive low pass filter of second order

Signal flow diagram:



Application conditions:

Initialisation: at reset or LV_INI_AJ == 1 ⇒ N_DIF_REF_LPF_AJ = 0

Description:

The main problem for digital PT2 filter is the influence of the signal quantization to the behavior of the filter output. Bad signal quantisation can risk the stabillity of the filter or create a signal offset between filter in- and output.

For the N_DIF_REF_AJ filter the input and output is fixed to the same resolution of 1 rpm.

To minimize the error due to quantization at internal calculation, the resolution is increased by the factor 64. This increased resolution is included in the filter constants (INP_0; INP_1, INP_2).

To receive an output with resolution of 1 rpm the filtered value N_DIF_REF_LPF_AJ is divided by 64 before the determination of N_DIF_AJ is done.

The feedback signal N_DIF_REF_AJ, with increased internal resolution, is limited to +/- 512 rpm.

Formula section

N_DIF_REF_LPF_AJ(n)	=	C_FIL_AJ_INP_0 *	N_DIF_REF_AJ(n)
	+	C_FIL_AJ_INP_1 *	N_DIF_REF_AJ(n-1)
	+	C_FIL_AJ_INP_2 *	N_DIF_REF_AJ(n-2)
	-	C_FIL_AJ_OUT_1 *	N_DIF_REF_LPF_AJ(n-1)
	-	C_FIL_AJ_OUT_2 *	N_DIF_REF_LPF_AJ(n-2)

To minimize the disturbance due to gear shift intervention, the PT2 filter in- and output is initialized with ´0´, if the gear-shift intervention is finished (LV_PAS_AJ transition 1 ⇒ 0; detected in LV_INI_AJ).

The time-delay C_T_PAS_AJ_DLY must have passed before the AJ algorithm can be released (LV_REQ_AJ = 1) again. See the module 'Anti Jerk activation conditions' for more information.

Activation of calculation of EFF_SCC_AV for two cycles (current and previous)					

D.50.1 General Information

Calculation of EFF_SCC_BAS

EFF_SCC_BAS is the basic efficiency for single cylinder fuel cut-off and is utilized during permanent fuel cut-off interventions (e.g. cylinder bank specific fuel cut-off). With an external request from "Basic fuel cut-off coordination", a requested basic efficiency is applied. A calibrateable constant can be set for the basic efficiency, if enabled.

Calculation of EFF_SCC_AV

EFF_SCC_AV is the efficiency that represents the actual impact of fuel cut-off interventions on the indicated engine torque.

Every fuel cut-off intervention deriving from

- pattern (engine speed limitation, ASR, GS, etc.)
- trailing throttle fuel cut-off

- misfire
- engine stop

is considered.

The calculation of this parameter can be performed in two alternative ways (by means of LC_EFF_SCC_AV_MOD_SEL).

Mode_1 (LC_EFF_SCC_AV_MOD_SEL=0):

The value is calculated as the number of opened injectors at the ***last two or four revolutions*** divided by the number of cylinders NC_CYL_NR or twice NC_CYL_NR. The input value PREV_STATE_IV (byte) defines the status of each injector during the last finished injection cycle. If a cylinder-allocated bit of PREV_STATE_IV is active, the injection was performed for the respective cylinder.

The injection information in PREV_STATE_IV is used to calculate a vertical sum. This sum is stored in SUM_PREV_STATE_IV. The value SUM_PREV_STATE_IV_OLD is the stored vertical sum from the segment n-1. With NC_CYC_ADD_ACT set to 1, the efficiency is calculated as average value over two combustion cycles.

Mode_2 (LC_EFF_SCC_AV_MOD_SEL=1):

The value is calculated as ratio between the number of injected cylinders for the ***next injection cycle*** (NC_CYL_NR - SUM_INH_INJ) and the total number of cylinders NC_CYL_NR. The value SUM_INH_INJ is calculated in the module ‘Cylinder Shut-off’ and represents the number of deactivated injectors for the following injection cycle.

With NC_CYC_ADD_ACT set to 1, the efficiency is calculated as average value over two combustion cycles.

D.51.1 General Information

This module delivers torque efficiencies EFF_LAMB_xxx depending on the difference of the input lambda value (LAMB_BAS_COR_MV, LAMB_SP_MV, LAMB_BAS_COR_MAX and LAMB_SP_BAS_MV) to corrected reference lambda LAMB_REF_COR.

The map IP_EFF_LAMB is used for different inputs for LAMB_DIF, LAMB_DIF_BAS, LAMB_DIF_AV, LAMB_DIF_MAX and LAMB_DIF_SP_BAS.

Product of mass moment of inertia of rotating engine parts and PI/30					

D.52.1 General Information

TQI_AV is the actual indicated engine torque produces either in homogeneous or stratified combustion mode. The combustion mode is indicated by the logical variable LV_S_ACT (1 ... stratified combustion; 0 ... homogeneous combustion). TQ_AV is the actual static effective torque at clutch. TQE is the actual effective torque at clutch inclusive inertia.

These values are used for external units (e.g. traction control and gear box) as a feedback signal.

The dynamic torque is derived as follows:

TQE_DIF = J (kg*m^2) * $d\omega/dt$ (1/s^2)

TQE_DIF = J (kg*m^2) * $\pi/30 *$ N_GRD (1/min/s)

TQE_DIF = C_FAC_TQE (kg*m^2*min) * N_GRD (1/min/s)

C_FAC_TQE = J (kg*m^2) * $\pi/30$

LV_TQ_LIM_ACT	LV_ST	TQI_REF_MAX	FAC_TQ_REQ_MON
TQI_EMS			

FUNCTION DESCRIPTION:

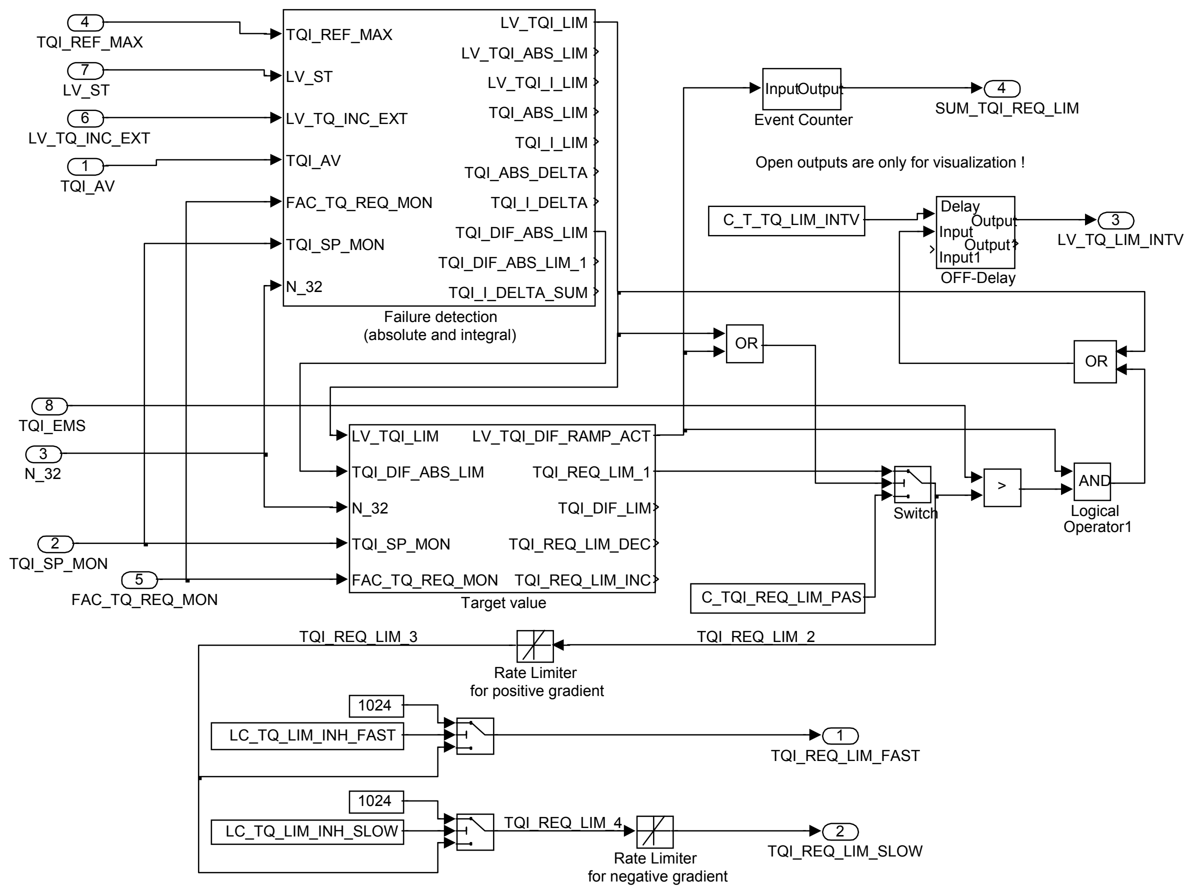
General information:

The overall ETC monitoring concept monitors the torque development of the engine by comparing the actual indicated engine torque TQI_AV_MON with the desired indicated engine torque TQI_SP_MON.

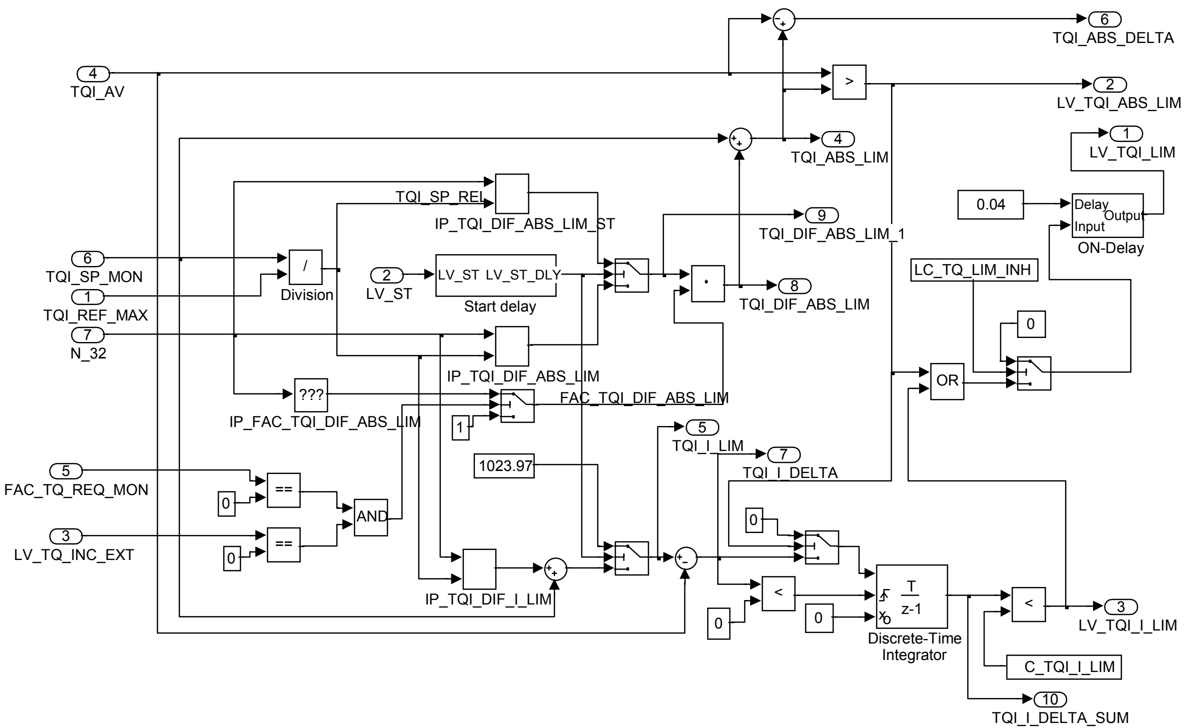
This module *Torque request for safety* generates a limitation torque request for the slow (air) path and the fast (ignition) path, if the actual indicated engine torque TQI_AV exceeds the desired indicated engine torque, which is generated in the monitoring level (TQI_SP_MON), by more than a calculated threshold TQI_DIF_LIM.

Signal flow diagram:

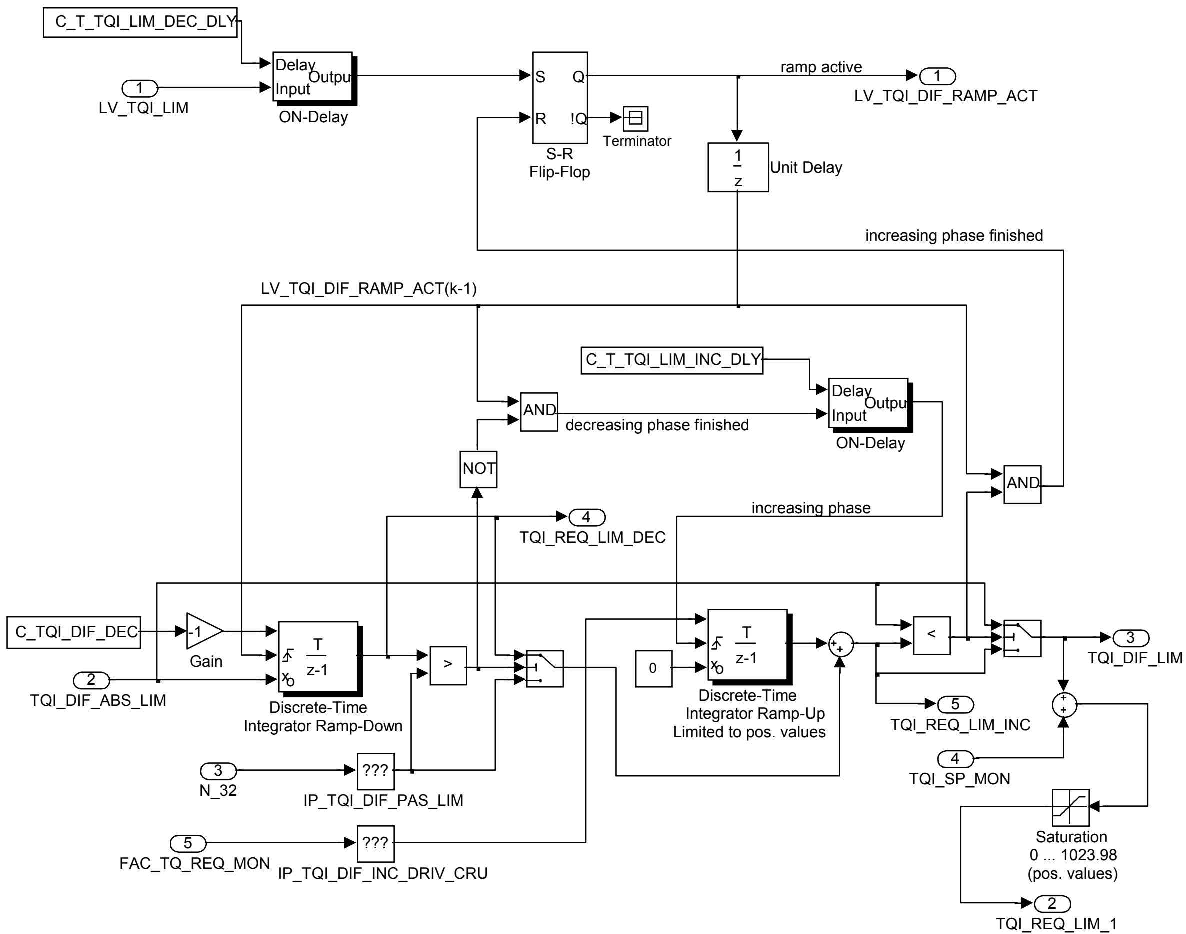
Overview:



Failure detection:



Target value:



Description:

Failure detection:

If TQI_AV exceeds a absolute threshold (TQI_SP_MON + TQI_DIF_ABS_LIM) or a integrated value of TQI_AV > TQI_I_LIM reached the threshold C_TQI_I_LIM, a torque intervention due to this module is active after a ON-Delay.

A ON-delay is necessary because of this module is not synchronized to the module ‘Desired indicated engine torque’ of level 2. No ON-delay could cause inaccurate torque limitation in case of a high positive torque gradient in level 1 while TQI_SP_MON is not updated yet.

Target value:

After the torque intervention is active, TQI_REQ_LIM_1 is ramped down.

After the target value has been reached, the target value TQI_REQ_LIM_1 is ramped up again.

Overview:

To avoid uncomfortable jumps when leaving the intervention function by choosing the passive value a rate limiter for positive gradients is used. The output of this function is TQI_REQ_LIM_3.

For the slow air path the torque request change can be limited in falling direction, to adjust a more comfortable intervention and to force the systems to react on this intervention necessacity either more with the fast or the slow path.

The bits LC_TQ_LIM_INH_SLOW/FAST allow to avoid generating torque inteventions in the slow or the fast path.

Application conditions:

Activation: LV_TQ_LIM_ACT = 1

Deactivation: otherwise

Initialization: (at reset or LV_TQ_LIM_ACT = 0)

LV_TQ_LIM_INTV	= 0
LV_TQI_LIM	= 0
TQI_REQ_LIM_FAST	= C_TQI_REQ_LIM_PAS
TQI_REQ_LIM_SLOW	= C_TQI_REQ_LIM_PAS
TQI_REQ_LIM_3	= C_TQI_REQ_LIM_PAS
TQI_I_DELTA_SUM	= 0
all other integrators	= {maximum positive value}
all timers	= {timer init value}
T_TQ_LIM_INTV	= 0

Update rate 40 ms

Scheduling: this function has to be calculated immediate after the module ‘Torque request for safety (Appl. Inc.)’

Formula section:

Overview:

```
IF      LC_TQ_LIM_INH_FAST == 1
THEN    TQI_REQ_LIM_FAST = 1023.97 Nm
ELSE    TQI_REQ_LIM_FAST = TQI_REQ_LIM_3
ENDIF
IF      LC_TQ_LIM_INH_SLOW == 1
THEN    TQI_REQ_LIM_4 = 1023.97 Nm
ELSE    TQI_REQ_LIM_4 = TQI_REQ_LIM_3
ENDIF
```

ON-Delay:

```
IF  {input}        == 0
THEN
    {output}       = 0
    {timer}        = {delay}
ELSE
    IF    {timer(k)}     == 0
    THEN
          {output}       = 1
    ELSE  {timer(k)}     = {timer(k-1)} - {update rate}
    ENDIF
ENDIF
```

Off-Delay:

```
IF      [ ( (TQI_EMS  >  TQI_REQ_LIM_2) AND (LV_TQI_DIF_RAMP_ACT == 1) )
        OR  ( LV_TQI_LIM == 1 ) ]
THEN    (LV_TQ_LIM_INTV = 1
        T_TQ_LIM_INTV = C_T_TQ_LIM_INTV)
ELSE    IF    T_TQ_LIM_INTV == 0
        THEN  LV_TQ_LIM_INTV = 0
        ELSE  T_TQ_LIM_INTV = T_TQ_LIM_INTV - [update rate]
        ENDIF
ENDIF
```

Event Counter:

IF (LV_TQI_DIF_RAMP_ACT$_{k-1}$ == 0 **AND** LV_TQI_DIF_RAMP_ACT$_k$ == 1)

THEN SUM_TQI_REQ_LIM = SUM_TQI_REQ_LIM + 1

ENDIF

{SUM_TQI_REQ_LIM must be stored in non-volatile memory until failure memory is cleaned.}

Rate limiter for positive gradient:

IF (TQI_REQ_LIM_2 > (TQI_REQ_LIM_3$_{k-1}$ + C_TQI_LIM_INC))

THEN TQI_REQ_LIM_3$_k$ = TQI_REQ_LIM_3$_{k-1}$ + C_TQI_LIM_INC

ELSE TQI_REQ_LIM_3$_k$ = TQI_REQ_LIM_2

ENDIF

Rate limiter for negative gradient:

IF (TQI_REQ_LIM_4 < (TQI_REQ_LIM_ SLOW$_{k-1}$ – C_TQI_LIM_DEC))

THEN TQI_REQ_LIM_SLOW$_k$ = TQI_REQ_LIM_SLOW$_{k-1}$ - C_TQI_LIM_DEC

ELSE TQI_REQ_LIM_SLOW$_k$ = TQI_REQ_LIM_4

ENDIF

Target value and Failure detection:

Discrete time integrator:

IF {integrator} = {active}
THEN
{integrator output(k)} = {integrator output(k-1)} + {integrator input}
ELSE
{integrator output(k)} = {integrator init}
ENDIF

The discrete time integrator for the ramp-down is limited to the entire phys. range (–1024 ... +1023.97 Nm).

The discrete time integrator for the ramp-up is limited to pos. values (0 ... +1023.97 Nm).

SR flip-flop:

It works like a normal SR-flip-flop. The following special case has to be considered:

IF S == 1 **AND** R == 1
THEN Q=0
ENDIF

Failure detection

Start delay:

IF LV_ST == 1
THEN { LV_ST_DLY = 1
$T\_MAX\_ST\_DUR_k$ = C_T_MAX_ST_DUR }
ELSE { **IF** T_MAX_ST_DUR == 0
THEN LV_ST_DLY = 0
ELSE $T\_MAX\_ST\_DUR_k$ = $T\_MAX\_ST\_DUR_{k-1}$ - [update rate]
ENDIF }
ENDIF

FAC_TQI_DIF_ABS_LIM:

IF FAC_TQ_REQ_MON == 0 **AND** LV_TQ_INC_EXT == 0
THEN FAC_TQI_DIF_ABS_LIM = IP_FAC_TQI_DIF_ABS_LIM (N_32)
ELSE FAC_TQI_DIF_ABS_LIM = 0.9962 {upper limit => no factor needed}
ENDIF

TQI_DIF_ABS_LIM = IP_TQI_DIF_LIM(_ST) * FAC_TQI_DIF_ABS_LIM

TQI_I_LIM:

IF LV_ST_DLY == 1
THEN TQI_I_LIM = 1023.97 Nm (passive value to inhibit function in the start phase)
ELSE TQI_I_LIM = TQI_SP_MON + IP_TQI_DIF_I_LIM
ENDIF

only necessary for calibration:

TQI_ABS_DELTA_REL = TQI_ABS_DELTA / TQI_ABS_LIM
TQI_I_DELTA_REL = TQI_I_DELTA / TQI_I_LIM

Initialisation: at Ignition off → on:

TQI_ABS_DELTA_REL_MEM=0.996

TQI_ABS_DELTA_MEM = 1023.97Nm

TQI_I_DELTA_REL_MEM = 0.996

TQI_I_DELTA_MEM = 1023.97Nm

IF TQI_ABS_DELTA_REL < TQI_ABS_DELTA_REL_MEM

THEN TQI_ABS_DELTA_REL_MEM = TQI_ABS_DELTA_REL

ENDIF

IF TQI_ABS_DELTA < TQI_ABS_DELTA _MEM

THEN TQI_ABS_DELTA _MEM = TQI_ABS_DELTA

ENDIF

D.54 Application Incidences for Torque Request for Safety

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_TQ_INC_EXT	V/O	0...1	0...1	1	-
Flag for having external torque demands which can increase torque					
LV_TQ_LIM_ACT	V/O	0...1	0...1	1	-
Activation flag for module 'Torque request for safety'					

Input data:

FUNCTION DESCRIPTION:

General information:

The objective of this module is to define the application incidences for the module "Torque request for safety".

Description:

The module "Torque request for safety" needs a flag for having external torque demands, which can increase torque, as an input. Up to now, only MSR can leed to increasing torque.

Application conditions:

Initialisation: none

Recurrence: 40 ms

Activation: at every engine state

Deactivation: none

Scheduling: this function has to be calculated immediate before the module 'Torque request for safety'

Formula section:

LV_TQ_LIM_ACT = 0 {Torque request for safety inactive}

LV_TQ_INC_EXT = 0

D.55 Engine torque status

D.55.1 Ratio between current and standard engine torque capabilities

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
RATIO_TQI_BAS_MAX_STND	V/O	0...FFH	0...2	0,0078	-
Standard Torque Ratio : final value sent to TCU					
RATIO_TQI_BAS_MAX_STND_1	V	0...FFH	0...2	0,0078	-
Standard Torque Ratio : AMP effect					
RATIO_TQI_BAS_MAX_STND_2	V/S	0...FFFFH	0...2	3.0517e-5	-
Standard Torque Ratio : IGA effect					
RATIO_TQI_BAS_MAX_STND_2_INTER	V	0...FFH	0...2	0,0078	-
IGA term – intermediate value					
RATIO_TQI_BAS_MAX_STND_3	V	0...FFH	0...2	0,0078	-
Standard Torque Ratio : TIA effect					
EFF_IGA_BAS_TMP	V/O	0..FFFFH	0..1.999969	3.0517e-5	-
Auxiliary ignition efficiency related to basic ignition angle					
IGA_BAS_TMP	V	0..FFH	-35.625..60	0.375	°CRK
Basic ignition angle, intermediary internal variable, only for calculation purposes					

Input data:

TIA	AMP	LAMB_SP_MV	EFF_IGA_BAS_COR
MAF_HB	IGA_REF	LV_KNK_CTL_ENA	N_32
TCO	IP_IGA_BAS[NC_CBK_IN_NR]	IP_EFF_IGA	IP_IGA_BAS_LAMB

FUNCTION DESCRIPTION:

General information:

To adapt the gear shift strategy, the Transmission Control Unit (TCU) needs the information about long-term changes of the engine torque capabilities due to special operating conditions (e.g. environmental conditions, fuel quality).

Description:

The present function calculates the output RATIO_TQI_STD, which gives the ratio of the currently available torque from the engine, compared to a standard torque. This information is based on 3 main parameters: TIA, AMP and ignition (which includes knock intervention and eventually low fuel qualities).
- Actual TIA and AMP are compared to calibratable standard values. (note : TIA < TIA_standard would lead to an efficiency bigger than 1. This is not wanted, therefore the TIA effect is set to 1 in this case)
- Actual ignition is compared to the basic ignition. As this factor is very depending of the working point, the calculation is done only in some specific N-MAF windows in which the knock effects are supposed to be the biggest, in order to get a worst case value. Additionaly, the factor is filtered to send a more steady value to the TCU.

The factor relative to ignition is stored at ECU off, because at restart it may take a certain time before the N-MAF window is met again. Is is possible to reset the store values via calibration (see specification reset of adaptative values).

Application conditions:

Initialisation at ECU reset :

RATIO_TQI_BAS_MAX_STND	= 1
RATIO_TQI_BAS_MAX_STND_1	= 1
RATIO_TQI_BAS_MAX_STND_2_INTER	= 1
RATIO_TQI_BAS_MAX_STND_2	= last stored value if available, or 1 if no saved data available

Recurrence: 100 ms

Activation: all engine states except LV_ES and LV_ST

Deactivation: LV_ES = 1 or LV_ST = 1

Formula section:

Ambient Pressure Effect

RATIO_TQI_BAS_MAX_STND_1 = (AMP / C_AMP_RATIO_TQI_BAS_MAX_STND)

Ignition Effect

IGA_BAS_TMP = IP_IGA_BAS_0 (N_32,MAF_HB) *Basic map for spark advance*
+ IP_IGA_BAS_LAMB (LAMB_SP_MV) *Correction for variable lambda*

EFF_IGA_BAS_TMP= IP_EFF_IGA (IGA_BAS_TMP – IGA_REF)

RATIO_TQI_BAS_MAX_STND_2_INTER = EFF_IGA_BAS_COR / EFF_IGA_BAS_TMP

If TCO > C_TCO_MIN_RATIO_TQI_BAS_MAX_STND
and N_32 < C_N_MAX_RATIO_TQI_BAS_MAX_STND
and N_32 > C_N_MIN_RATIO_TQI_BAS_MAX_STND
and MAF_HB > C_MAF_MIN_RATIO_TQI_BAS_MAX_STND
and MAF_HB < C_MAF_MAX_RATIO_TQI_BAS_MAX_STND

then **RATIO_TQI_BAS_MAX_STND_2** =
$RATIO\_TQI\_BAS\_MAX\_STND\_2_{n-1} + C\_CRLC\_RATIO\_TQI\_BAS\_MAX\_STND\_2 * (RATIO\_TQI\_BAS\_MAX\_STND\_2\_INTER_{n} - RATIO\_TQI\_BAS\_MAX\_STND\_2_{n-1})$

else RATIO_TQI_BAS_MAX_STND_2 is not updated

Intake Air Temperature Effect

If TIA > C_TIA_RATIO_TQI_BAS_MAX_STND

then **RATIO_TQI_BAS_MAX_STND_3** =
(C_TIA_RATIO_TQI_BAS_MAX_STND + 273,15) / (TIA + 273,15)

else RATIO_TQI_BAS_MAX_STND_3 = 1

General Result

RATIO_TQI_BAS_MAX_STND = RATIO_TQI_BAS_MAX_STND_1 *
RATIO_TQI_BAS_MAX_STND_2 *
RATIO_TQI_BAS_MAX_STND_3

General Limitation

D.55.2 Actual Torque from EMS

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQI_AV_EMS	V / O	8000 ... 7FFF H	-1024 ... 1023.97	0.03125	Nm
Actual indicated engine torque without external interventions					

Input data:

LV_GS_ENA	SPK_RTD_TCU	TQI_GS_REQ	LV_PUC
LV_ASR_ACT	LV_ASR_REQ	TQI_ASR_REQ	TQI_AV
TQI_REF	TQI_REF_IGA	TQI_EMS	TQ_DIF_P_D_FAST_IS
EFF_IGA_MIN	EFF_LAMB_AV	NC_ETC_CONF	TQI_REQ_TRA
TQI_BAS_MAX	LV_MSR_ENA	LV_MSR_ACT	TQI_MSR_REQ
ETL_TCU_CAN			

FUNCTION DESCRIPTION:

General information:

TQI_AV_EMS is the actual indicated torque without considering the external interventions due to GS or ASR.

Description:

Non-ETC system

As long as no external inetrvention is enabled nor requested, or while the engine state LV_PUC is active, TQI_AV_EMS is forced to TQI_AV.

In the other cases, the recalculation of the actual engine torque is performed based on TQI_EMS (torque request before GS and ASR intervention) added to the torque intervention from idle speed control (TQ_DIF_P_D_FAST_IS), but limited on the one hand to the maximum available torque based on N, MAF, lambda and max spark advance considering ambient and engine temperatures as well as knock control (TQI_REF_IGA*EFF_LAMB_AV), and on the other hand to the minimum possible torque defined by TQI_REF * EFF_IGA_MIN.

ETC system

Becasue TPS is used to fulfil the torque intervention request and MAF value is directly impacted by it, we could not use the same formula like non-ETC system.

So, the TQI_AV_EMS is concluded by Minimum selection between the driver request torque (TQI_REQ_TRA) and Maximum available torque at basic condition (TQI_BAS_MAX).

Application conditions:

Initialisation at ECU reset :	TQI_AV_EMS = 0 Nm
Recurrence:	10 ms
Activation:	LV_HOM_RUN = 1
Deactivation:	LV_HOM_RUN = 0

Formula section:

```
if      [LV_GS_ENA = 0
     or TQI_GS_REQ >= TQI_AV_EMS(n-1)]
and     [LV_ASR_ACT = 0
     or LV_ASR_REQ = 0
     or TQI_ASR_REQ >= TQI_AV_EMS(n-1)]
and     [LV_MSR_ACT = 0
     or LV_MSR_ENA = 0
     or TQI_MSR_REQ =< TQI_AV_EMS(n-1)]
and     [ETL_TCU_CAN >= TQI_AV_EMS(n-1)]
or      LV_PUC = 1
then No external intervention or PUC
        TQI_AV_EMS = TQI_AV
else Recalculation of TQI_AV without considering the external requests
     if   NC_ETC_CONF = 0 (Non-ETC system)
     then TQI_AV_EMS = max [TQI_REF * EFF_IGA_MIN ;
          min (TQI_REF_IGA * EFF_LAMB_AV; TQI_EMS + TQ_DIF_P_D_FAST_IS)]
     else NC_ETC_CONF = 1 (ETC system)
          if    TQI_TCS_CAN < 100% or TQI_MSR_CAN > 0%
                 or  ETL_TCU_CAN < 100% (FFh)      % slow path request present
          then  TQI_AV_EMS = Min [TQI_REQ_TRA ; Max (TQI_BAS_MAX; TQI_AV)]
          else  TQI_AV_EMS = max [TQI_REF * EFF_IGA_MIN ;
          min (TQI_REF_IGA * EFF_LAMB_AV; TQI_EMS + TQ_DIF_P_D_FAST_IS)]
```

Remark : After the transition to no torque intervention (TQI_AV_EMS = TQI_AV) from torque intervention (TQI_AV_EMS = Formula), the TQI_AV_EMS has to be calculated by formula during 50ms (5 recurrences) to avoid a sudden drop of TQI_AV_EMS by difference of control recurrence between IGA_AV (segment recurrence) and TQI_AV (10 ms recurrence).

D.56 Indicate significant inaccuracy in torque calculation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TQI	O/V	0...1H	0...1	1	-
Flag to indicate significant inaccuracy in torque calculation					

Input data:

LV_ERR_MAF	LV_ERR_CRK	LV_ERR_TPS	LV_ES
LV_ERR_MAP			

D.56.1 General Information

LV_ERR_TQI provides information about the accuracy/trustworthiness of the calculated torque value that is transmitted via CAN. In case that a failure of a relevant sensor or actuator is detected, this flag is set to 1.

Application conditions:

Initialisation :

Recurrence: 40 ms

Activation: LV_ES = 0

Deactivation: LV_ES = 1

Function Description

If LV_ERR_MAF = 1
or LV_ERR_MAP = 1
or LV_ERR_CRK = 1
or LV_ERR_TPS = 1
then LV_ERR_TQI = 1

D.57 Variables for fleet monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_AV_MAX_DC	O/V	8000...7FFFH	-1024...1023.97	0.03125	Nm
maximum engine torque in current driving cycle					
TQ_AV_MAX_TOT_DC	O/V/S	8000...7FFFH	-1024...1023.97	0.03125	Nm
maximum engine torque in former / current driving cycle					

Input data:

TQ_AV	LV_ES		

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost

TQ_AV_MAX_TOT_DC = 8000H (-1024 Nm)

- otherwiste: resored from non-volantile memory
- at LV_IGK 0->1 and reset:

TQ_AV_MAX_DC = 0

Recurrence: 10 ms

Activation: LV_ES = 0

Deactivation: -

Formula section:

If TQ_AV > TQ_AV_MAX_DC

Then TQ_AV_MAX_DC = TQ_AV

Endif

If TQ_AV > TQ_AV_MAX_TOT_DC

Then TQ_AV_MAX_TOT_DC = TQ_AV

Endif

D.58 Driver Request Limitation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_REQ_CLU	V/O	8000 ... 7FFFH	-1024 ... 1023.97	0.03125	Nm
Requested torque at clutch					
TQ_MAX_DROF_AT	V	8000 ... 7FFFH	-1024 ... 1023.97	0.03125	Nm
Maximum allowed clutch torque for drive off					
T_DROF_AT	V	0..FFFFH	0...655.35	0.01	s
Drive off timer - AT					
LV_DROF_AT_ACT	V/O	0..1H	0...1	1	-
Flag to show torque limitation active					

Input data:

VS	PV_AV_H	LV_AT	GEAR
LV_CT	TQ_REQ_CLU_1	PV_AV	N
LV_ES			

General information:

In order to gain the desired torque profile (as shown in the figure 1) during drive-off in an AT vehicle, the driver requested torque can be limited. This limitation is scheduled after the module "Torque Request at Clutch General", which now produces the output TQ_REQ_CLU_1, and before Torque Transient, which consumes the output from this spec TQ_REQ_CLU.

Whilst this function is active, the standard driveability torque transient function may be disabled, or may continue to be active.

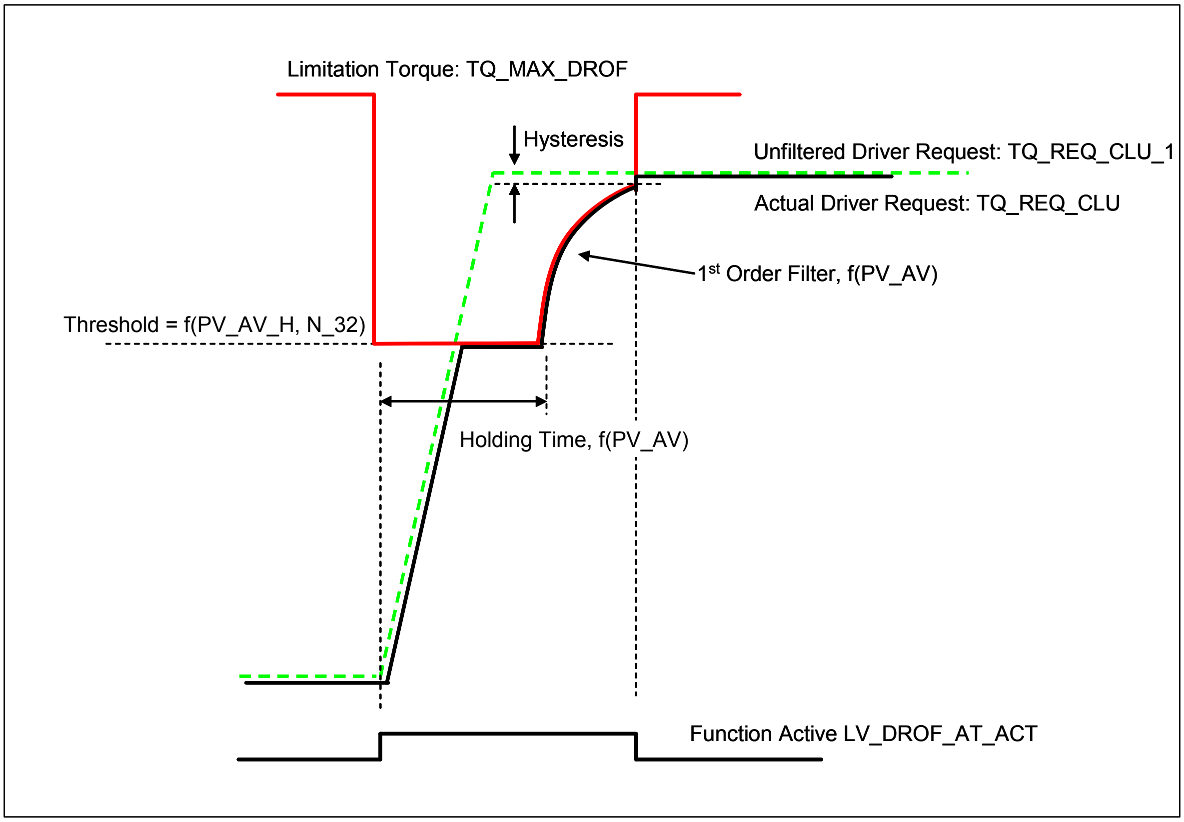

Figure 1: Desired torque profile at drive off

Application conditions:

Activation:	*at every engine state*	
Deactivation:	-	
Initialization:	at reset	TQ_REQ_CLU = 0 Nm
		TQ_MAX_DROF_AT = 1023.97 Nm
		T_DROF_AT = 0 s
		LV_DROF_AT_ACT = 0
Update rate:	10 ms	

Formula section:

```
IF    LV_ES = 1 or LV_AT = 0 or LC_DROF_AT_ENA = 0
THEN
      # Function disabled
      TQ_REQ_CLU = TQ_REQ_CLU_1
      TQ_MAX_DROF_AT = 1023.97 Nm
      LV_DROF_AT_ACT = 0

ELSE
      # Function Enabled
      IF      VS < C_VS_MAX_DROF_AT and GEAR = 1 and LV_CT = 1->0 (falling flank)
      THEN  LV_ DROF_AT_ACT = 1       # Function turned on
      ENDIF

      IF      LV_CT = 1
      THEN LV_DROF_AT_ACT = 0         # Function turned off
      ENDIF

      IF      LV_DROF_AT_ACT = 1
      THEN
              Increment T_DROF_AT
              IF      T_DROF_AT < IP_T_HLD_DROF_AT(PV_AV)

X

E.1 General

E.1.1 Basic Idea

The Monitoring Concept has to prevent an ETC system from dangerous behaviour like sudden acceleration against the driver's intent. At first faults, this must be without intervention of the driver. To avoid immobile cars at first faults, a limited limp home function is activated. This means the dynamic behaviour of the car is limited, and so in case of another (second) fault, the driver must possibly react (activation of brake pedal). The accepted fault reaction time is 500 ms. Minor deviations in the order of about 5% are possible due to run time fluctuations, aging effects and temperature influences. No or low engine power is seen as a safe state.

The Siemens ETC-Monitoring-Concept is based on the ETC-Safety-Concept of VDA Arbeitskreis E-Gas using the following main modification:

Additional, diverse AD-converter in monitoring unit (MU) for monitoring af A/D conversion. The used analog voltage must be non-constant, the frequency of the voltage changes must match to the synchronisation constraints given in the Processor Monitoring.

The monitoring concept consists of three levels, as shown in the following figure:

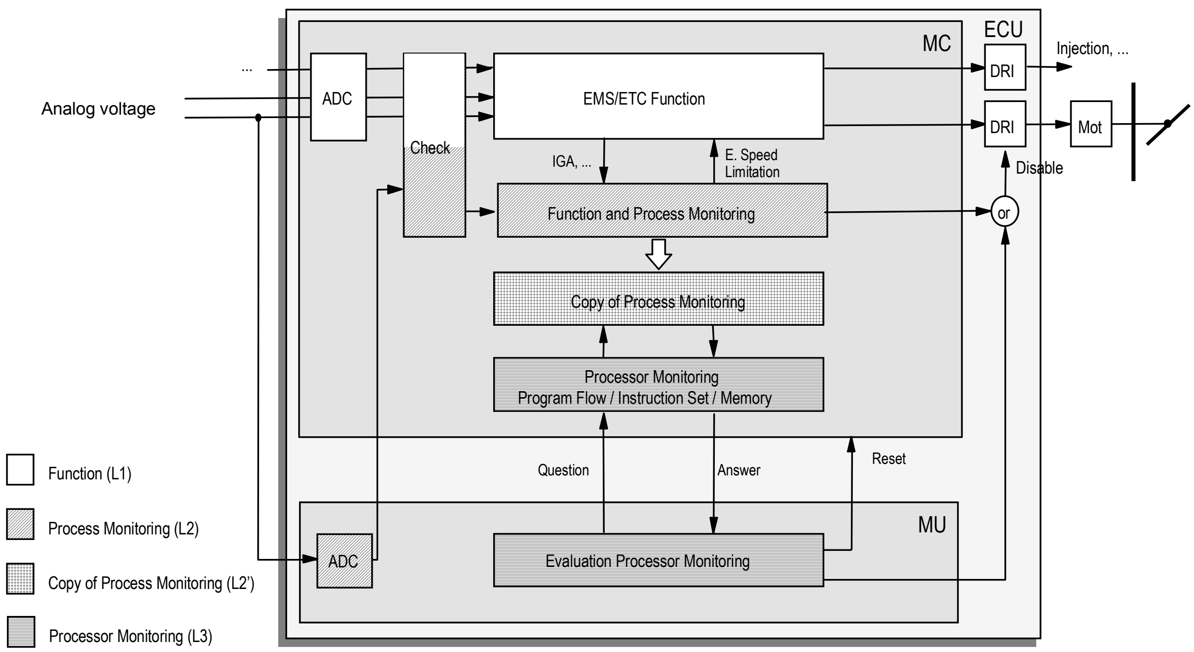

Figure 1: The three levels of the monitoring concept.

- The function level is located on the main processor (MC).
- The function/process monitoring level is also located on the main processor.
- The processor monitoring level is located on the main processor and on the monitoring processor (MU).

E.1.1.1 Function Level (VDA-name: Level 1)

The function level performs standard EMS functions including ETC functionality (description *not* to be found in this chapter):

- Determination of the drivers demand (via PVS) including standard diagnosis (signal range check, ...)
- Determination of throttle position (via TPS) including standard diagnosis (signal range check, ...)
- Receiving external torque requests (e.g. ASR, MSR, ...) including standard diagnosis (e.g. monitoring CAN by parity bit, ...). External modules must generate correct torque requests (safety requirement!) the ECU can only check, whether the transmission of this request was without faults.
- Internal calculation of torque requests (ISC, Cruise Control)
- Co-ordination and realisation of requested torque

- output: throttle position, ignition angle, injection time and cylinder cut off

E.1.1.2 Process Monitoring Level (VDA-name: Level 2)

The process monitoring performs monitoring of sensors, actuators, torque effective functions, torque co-ordination, and torque realization as a check of the function level.

The description can be found in the modules:

- Process Monitoring
- Monitoring Sensor Signals (e.g. PVS, TCO, ...)
- Monitoring Internal Signals (e.g. MAF, N_32, ...)
- Monitoring CAN Signals
- Torque Monitoring
- Fault Reaction

E.1.1.3 Processor Monitoring Level (VDA-name: Level 3)

The processor monitoring monitors proper processor function: memory, operations of the processor, program flow, analog digital conversion

The description can be found in the modules:

- Processor Monitoring
- Communication between MC and MU
- Fault Reaction

There are additional port extensions located on the monitoring unit. Note that this functionality is not a core functionality of level 3:

- Input / Output (Description of port extension facility of the monitoring unit)

E.1.2 Hardware Safety Module

The main-processor (MC) and the monitoring processor (MU, incl. port extensions) are connected via an internal communication. MU has its own oscillator (ceramic resonator).

When resetting, MC gives a reset signal to MU so it will also reset. This enables synchronisation between them.

Via the internal communication informations are excanged. This informations belongs to: test calculations (level 2'), program flow of MC, monitoring of ADC, port extensions.

For the purpose of test calculations answers are compared to known results on MU. In case of faults, the power stages of the throttle and the injectors are disabled.

One analog voltage is connected with the first AD-channel of MU and the dedicated channel on MC. The MU value is transmitted to MC only to check the ADCs. Remaining AD-channels and digital outputs can be used as port extension (no monitoring function, but it has to be assured, that no damaging voltage is fed to the ports in case of any fault).

E.2 Analog and pseudo digital inputs

E.2.1 Analog inputs on MU

Output data: (on MU)

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
AN_BUF_0	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN0 on MU (used for monitoring)					
AN_BUF_1	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN1 on MU					
AN_BUF_2	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN2 on MU					
AN_BUF_3	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN3 on MU					
AN_BUF_8	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN8 on MU					
AN_BUF_10	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN10 on MU					
AN_BUF_12	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN12 on MU					
AN_BUF_13	O	000h ... 3FFh	0 ... 4.995	5/1024	V
AD-value of AIN13 on MU					
LV_ERR_CONV_AN_MU	O	0 ... 1h	0 ... 1	1	1
Status flag of analog-digital conversion (indicates a fault if set)					

Note: The inputs AIN2 and AIN3 are only conducted for the 44pin package. The scope of these variables are the MU only. They are available on MC only, if the contents is transferred via SPI communication.

FUNCTION DESCRIPTION:

General information:

The MU offers up to seven 10bit AD-channels for the analog port extension. One AD-channel (AIN0) is used for Monitoring of the A/D-conversion. This signal is converted by MU directly after monitoring communication. The right behaviour of the AIN0 is checked every time the signal is converted. When the AD-conversions start, it is checked that the EOC-bit (End Of Conversion) of the control register is set and reset properly. If the bit LV_ERR_CONV_AN_MU is set, it indicates an error of the AD-conversion when converting the channel used for the monitoring of A/D conversion (AIN0).
The AD-channels are converted every communication cycle, therefore the values of the AD conversions are newer than one communication cycle.

E.2.2 Special Threshold Inputs

Output data: (on MU)

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
EMUL_DIG_INP	O	00h ... FFFFh	0 ... 65535	1	1
Level of special threshold analog inputs					

Note: The scope of this variable is the MU only. It is available on MC only, if the contents is transferred via SPI communication.

FUNCTION DESCRIPTION:

General information:

The analog input pins AIN4 and AIN5 are converted for the emulation of some digital inputs only. This special threshold bits are set, if the voltage is above the upper threshold they are reset if the voltage is below the lower limit. The intermediate values form a Schmitt-triggered hyseresis.

EMUL_DIG_INP

15 (MSB)	14 ... 9	8	7	6	5	4	3	2	1	0 (LSB)
0	0	AD13-level	AD12-level	AD10-level	AD8-level	AD5-Level	AD4-Level	AD3-Level	AD2-Level	AD1-level

Application conditions:

Initialisation: Reset all bits

Recurrence: each A/D conversion

Activation: always

E.3 Digital output port extension

Input data:

OUT_PORT_MU			

FUNCTION DESCRIPTION:

General information:

Due to free resources, the MU is used for digital output port extension. The bitword OUT_PORT_MU is transmited from MC to MU, see "Communcation between MC and MU". The bits of OUT_PORT_MU represent the value of the port pins.

OUT_PORT_MU:

7 (MSB)	6	5	4	3	2	1	0 (LSB)
PF7	PF6	*PF2*	*PB2*	*PB1*	(PA7)	PA6	*PA5*

Note: The pins PB1, PB2, PF2 and PA5 only conducted for the 44pin package. Pin PA7 is reserved for the power off timer (POT), it is only available as output if the POT is permanently disabled.

After a reset or power up the MU initializes the digital ports as input first, see "Communication between MC and MU". In the initialization the pins are configurated as output ports. If the ports are not configurated as outputs, they are switched to a high impedance state.
The pins of the digital output Port Extension are updated within 1ms after communication.

E.3.1 Generation of Diagnosis Pulses on the Digital Output Port Extension

Input data:

NR_DGO_PLS_MU	T_DGO_PLS_MU		

FUNCTION DESCRIPTION:

General information:

The MU offers the possibility to generate diagnosis pulses on the digital output port extension. The MC sends two bytes to the MU. The value NR_DGO_PLS_MU shows the port pin:

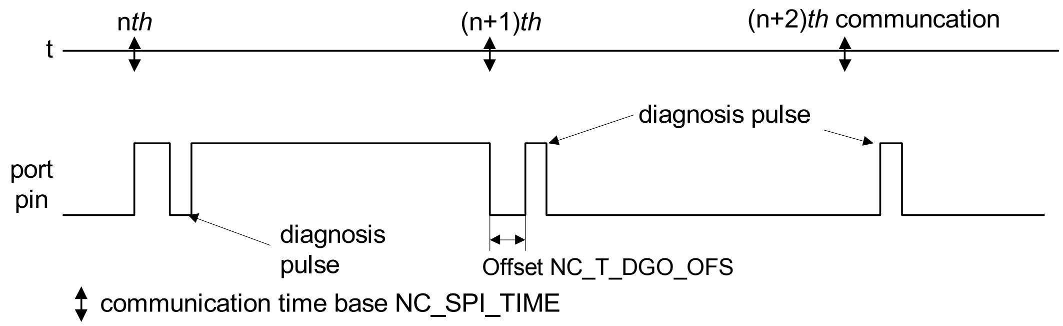
NR_DGO_PLS_MU

NR_DGO_PLS_MU	Pin
1	*PA5*
2	PA6
3	(PA7)
4	*PB1*
5	*PB2*
6	*PF2*
7	PF6
8	PF7

Note: The pins PB1, PB2, PF2 and PA5 only conducted for the 44pin package. Pin PA7 is reserved for the power off timer (POT). It is only available if the POT is permanently disabled.

All other values of NR_DGO_PLS_MU belongs to no diagnosis pulse. The value T_DGO_PLS_MU shows the length of one pulse. The allowed values for T_DGO_PLS_MU is 0 to FFh, the physical limits are 37 to 2069 µs. A fluctiation of about 50µs is possible.

The diagnosis pulse is generated NC_DGO_T_OFS after communication. The level of the pulse is the inverted output lebvel; it high if the output level is low, it is low if the output level is high.



Note:

Due to interrupt response time, T_DGO_PLS_MU has an additional offset of 5.5µs.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_T_DGO_OFS	1	0 ... FFh	0 ... 255	1	Ms
Time to wait after communcation to send diagnosis pulse					

E.4 Communication between MC and MU

Input data: (on MC, transmitted from MU to MC)

SW_VERS_MU	ERR_COD_MU	RST_CTR_MU	ABC_MON2_MU
TEST_REC_IDX_MON2	SYN_PFM_MU	SPI_CKS_MC_MU	SPI_HD_MC_MU
LV_ERR_TMP_MU	NC_ENA_PORT_MU	LV_ERR_CONV_AN_MU	

Note: These data are sent from the MU and received by the MC. They are available on MC after the dedicated communication

Input data: (on MU, from function "Analog and pseudo digital inputs")

AN_BUF_0	AN_BUF_1	AN_BUF_2	AN_BUF_3
AN_BUF_8	AN_BUF_10	AN_BUF_12	AN_BUF_13

Output data: (on MC):

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
ACQ_MU[NC_ACQ_MU_NR]	V/O	000h ... 3FFh FFFFh	0 ... 4.9951 "undefined"	5/1024 -	V -
10 bit A/D value on MC, FFFFh simply denotes "undefined" as the result of the AD conversion					
EMUL_DIG_INP	V/O	00h ... FFFFh	0 ... 65535	1	1
Level of special threshold analog inputs					

Note: On the MU, the input data for the ADC channels are AN_BUF_x which are described in "Analog and pseudo digital inputs." ACQ_MU is an array with the index ranging from 0 to NC_ACQ_MU_NR-1. During the monitoring communications (except the INIT state communication) from MU to MC, AN_BUF_0 is mapped to ACQ_MU[0], see the subsections "Predrive State of Communication", "Normal State of Communication", and "Disable State of Communication"; during the AD communications from MU to MC, the AN_BUF_x, for x > 0, are mapped to entries of ACQ_MU[y] as explictily described in the subsections "AD Communication 1" and "AD Communication 2."

Transferred data to MU, input on MC, output on MU:

SW_COMP_NR_MC	OUT_PORT_MU	NR_DGO_PLS_MU	T_DGO_PLS_MU
RESP_MON2_MC	RESP_PFM_MC	SPI_CKS_MC_MU	SPI_HD_MC_MU
RST_CTR_MC	LV_DR_OFF_MU_MON		

Note: These data are sent to MU, the values have to be assigned on MC before the dedicated communication.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_T_SPI_COM	1	00h ... FFh	0...255	1	ms
Nominal time grid for monitoring communication					
NC_T_SPI_MAX	1	00h ... FFh	0...255	1	ms
Maximum time periode between two consecutive monitoring communications					
NC_T_SPI_MIN	1	00h ... FFh	0...255	1	ms
Minimum time periode between two consecutive monitoring communications					
NC_ACQ_MU_NR	1	00h ... 07h	0 ... 7	1	1
Maximum index value of the array ACQ_MU					

E.4.1 Tranmission protocol and Monitoring communication

E.4.1.1 SPI transmission protocol

FUNCTION DESCRIPTION:

The communication is effected in full duplex mode (fdx) according to the SPI transmission protocol. MC and MU are connected to the SPI bus of the ECU. Regarding the SPI protocol, there is physically one master and one or several slaves.

As the spi communication to any other slaves must not affect the monitoring communication at all, the monitoring communication has the highest priority. The MC is only allowed to start other communications (see also “AD communications”) if this non monitoring communication does not affect timeout of the monitoring communication.

The master controls the character exchange by generation of the clock according to the baud rate. In the case of a communication between MC and MU, there is a master (MC) and a slave (MU). The MC initiates the character exchange with the chip select line.

General information:

During operation of the ECU, MC and MU permanently exchange data in terms of messages which assist the MU in monitoring the correct execution of the monitoring software in the MC.

The communication runs through an INIT-State, PREDRIVE-State, NORMAL-State. The DISABLE state is related to detected faults, see chapter “Disable State of Communication”.

An exception is the EOLT-SW (end of line test). An overview of the EOLT mode is given in chapter “Communication between MC and MU”.

Figure 1 gives an overview of all possible states of the communication.

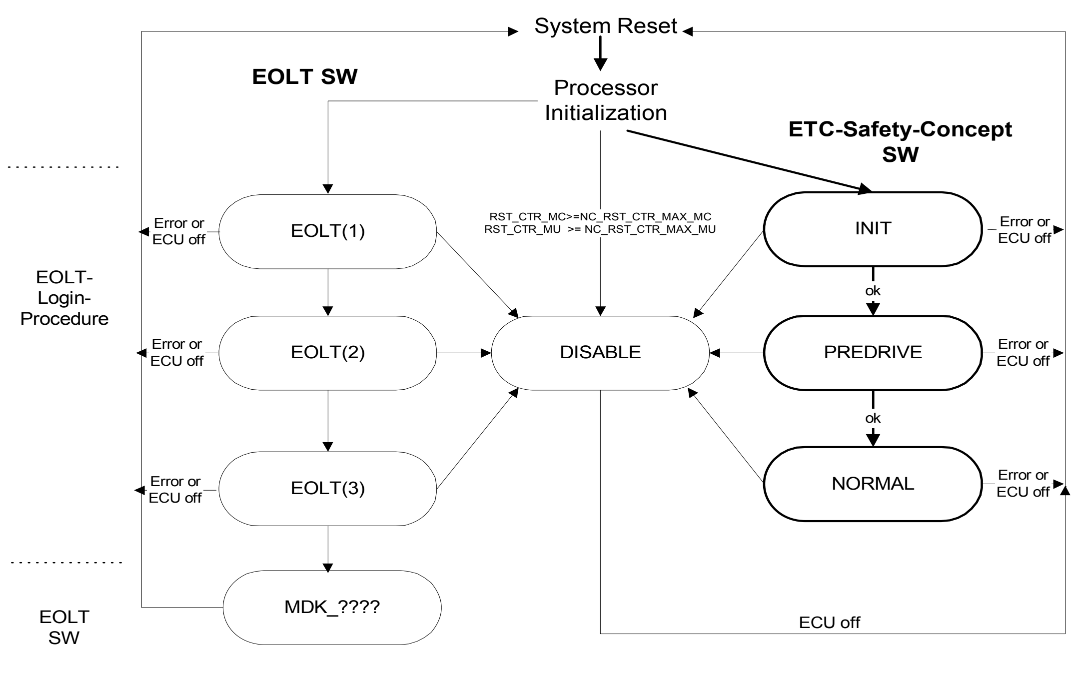


Figure 1: States of the communication

The transitions of the states are controlled by the communication between MC and MU. In the different states different actions are carried out.

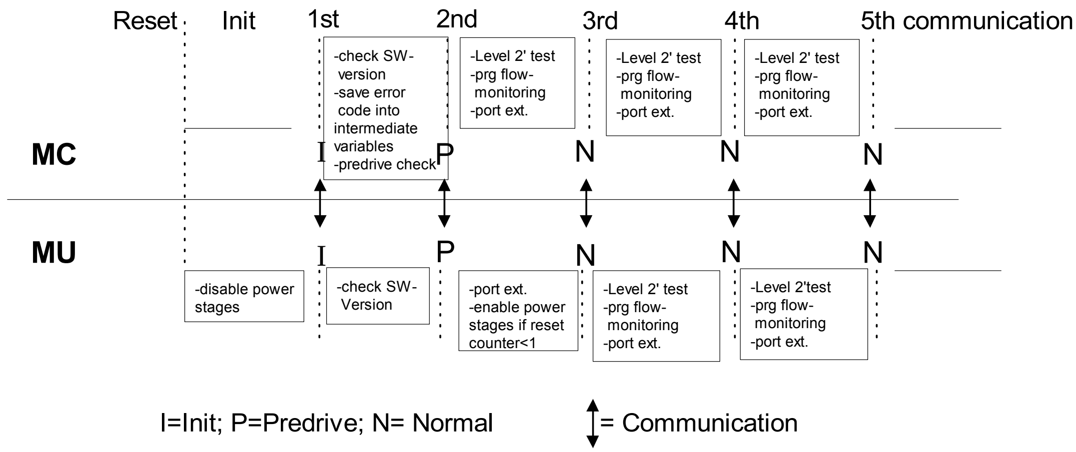

Figure 2: Time Chart of communications in fault free case

E.4.1.1.1 Structure of transferred blocks

FUNCTION DESCRIPTION:

There exist buffers for receiving data and sending data: SPI_BUF_RECV and SPI_BUF_SEND on MU, SPI_TRM_BUF_MU and SPI_RCV_BUF_MU on MC. At runtime all four of these buffers have the same size. The data to be sent have to be copied into the buffers before the communication, the reveiced data has to be copied into the variables after the fault free communication. Each communication the contents of the buffers are transferred:

- MC sends to MU / MU receives from MC (SPI_TRM_BUF_MU->SPI_BUF_RECV)
- MU sends to MC / MC receives from MU (SPI_BUF_SEND->SPI_RCV_BUF_MU)

A monitoring communication block consists of 8 bytes.

In a block sent from MC to MU byte 0 and 1 are the header, whereas bytes 2 to 6 form the data. In a block sent from MU to MC byte 0 is a dummy byte, byte 1 is the heaer byte.

According to the header the interpretation of the data block is done. Because the MC triggers the communication it is neccesary that MU interprets the first header byte during the communication. So after reception of the first byte this byte is interpreted as header by MU before the next byte is transferred. Due to full duplex communication mode the MU has to sent a dummy byte in the first byte of communication block.

The byte 7 is the checksum of the bytes 0 till 6 and is used for monitoring the communication.

Sent monitoring communication block from MC to MU:

Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6	Byte 7
Header	Header	Data	Data	Data	Data	Data	Chksum

Sent monitoring communication block from MU to MC:

Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6	Byte 7
Dummy	Header	Data	Data	Data	Data	Data	Chksum

Definition of header and dummy bytes

	Hex	Bit
INIT	12h	0001 0010
PREDRIVE	CFh	1100 1111
NORMAL	ADh	1010 1101
AD_1	7Eh	0111 1110
AD_2	7Fh	0111 1111
EOLT	85h	1000 0101
DISABLE	3Bh	0011 1011
DUMMY	00h	0000 0000

In the following sections the data bytes, byte 2 till byte 6, are not described explicitly, instead only the variable names forming the data block are listed. If not all bytes of the data block are used, the remaining have to be filled with DUMMY.

E.4.1.1.2 Init State of Communication

FUNCTION DESCRIPTION:

At the beginning of the communication (see **Figure 2**), MC and MU transmit the following data in the INIT communication:

Init State transfer data

Byte No.	MC->MU	MU->MC
0	SPI_HD_MC_MU	DUMMY
1	SPI_HD_MC_MU	SPI_HD_MU_MU
2	RST_CTR_MC, SW_COMP_NR_MC, ENA_PORT_MU	ERR_COD_MU, RST_CTR_MU, NC_SW_VERS_MU->SW_VERS_MU
3		
4		
5		
6		
7	SPI_CHKS_MC_MU	SPI_CHKS_MU_MU

The values of the header bytes are INIT

The contents of data are described in the chapters “Processor Monitoring”, “Fault Reaction of Processor Monitoring” and "Digital Output Port Extension".

E.4.1.1.3 Predrive State of Communication

FUNCTION DESCRIPTION:

In fault free case the second communication (see **Figure 2**) is the PREDRIVE communication. The following data are transmitted :

Predrive State transfer data

Byte No.	MC->MU	MU->MC
0	SPI_HD_MC_MU	DUMMY
1	SPI_HD_MC_MU	SPI_HD_MU_MU
2	ENA_PORT_MU, OUT_PORT_MU, NR_DGO_PLS_MU, T_DGO_PLS_MU	TEST_REC_IDX_MON2, ABC_MON2_MU, LV_ERR_CONF_AN_MU, AN_BUF_0->ACQ_MU[0], LV_ERR_TMP_MU, SYN_PFM_MU
3		
4		
5		
6		
7	SPI_CHKS_MC_MU	SPI_CHKS_MU_MU

The values of header bytes are PREDRIVE

E.4.1.1.4 Normal State of Communication

FUNCTION DESCRIPTION:

In fault free case the third and all following communication (see **Figure 2**) are NORMAL communications. The following data are transmitted:

Normal State transfer data

Byte No.	MC->MU	MU->MC
0	SPI_HD_MC_MU	DUMMY
1	SPI_HD_MC_MU	SPI_HD_MU_MU
2	RESP_PFM_MC, RESP_MON2_MC, LV_DR_OFF_MU_MON, OUT_PORT_MU, NR_DGO_PLS_MU, T_DGO_PLS_MU	TEST_REC_IDX_MON2, ABC_MON2_MU, LV_ERR_CONV_AN_MU, AN_BUF_0->ACQ_MU[0], LV_ERR_TMP_MU, SYN_PFM_MU
3		
4		
5		
6		
7	SPI_CHKS_MC_MU	SPI_CHKS_MU_MU

The values of the header bytes are NORMAL

E.4.1.1.5 Disable State of Communication

Input data:

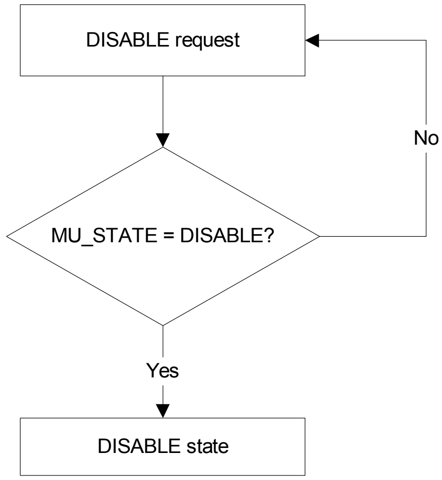
SPI_HD_MC_MU	SPI_HD_MU_MU	LV_ERR_MC	

FUNCTION DESCRIPTION:

There are several ways to change into DISABLE-State.

1. If the MC detects failures and the value of the reset counter RST_CTR_MC already reached its maximum. In this case LV_ERR_MC is set.
2. If the MU detects failures and the value of the reset counter RST_CTR_MU already reached its maximum. In this case LV_ERR_MU is set.

3. When shutting down the ECU, it is necessary to stop the processor monitoring. This is initialized by the MC, MU receives a DISABLE command next communication:



4. The MU receives a DISABLE-Command (header SPI_HD_MC_MU) from the MC.
5. The MC receives a DISABLE-Command (header SPI_HD_MU_MU) from the MU.

Disable State transfer data

<table>
<tr><th>Byte No.</th><th>MC->MU</th><th>MU->MC</th></tr>
<tr><td>0</td><td>SPI_HD_MC_MU</td><td>DUMMY</td></tr>
<tr><td>1</td><td>SPI_HD_MC_MU</td><td>SPI_HD_MU_MU</td></tr>
<tr><td>2</td><td rowspan="5">RST_CTR_MC, OUT_PORT_MU,
NR_DGO_PLS_MU, T_DGO_PLS_MU</td><td rowspan="5">ERR_COD_MU, RST_CTR_MU,
AN_BUF_0->ACQ_MU[0]</td></tr>
<tr><td>3</td></tr>
<tr><td>4</td></tr>
<tr><td>5</td></tr>
<tr><td>6</td></tr>
<tr><td>7</td><td>SPI_CKS_MC_MU</td><td>SPI_CKS_MU_MU</td></tr>
</table>

The values of the header bytes are DISABLE

So, if either LV_ERR_MC or LV_ERR_MU is set the reason for the transition into DISABLE state is a fault detected by the Processor Monitoring. Otherwise (neither LV_ERR_MC is set nor LV_ERR_MU is set) the transition is based on shutting down the ECU.

If one of the conditions mentioned above is fulfilled, the MU disables the power stages and the following monitoring functions are deactivated:

- Program Flow Monitoring
- Communication Monitoring
- Copy of process monitoring

Still avaliable in DISABLE state are:

- Analog input port extensions, including AD-communication
- Digital output port extensions, including generation of diagnosis pulses

E.4.2 Request for Transition to Disable State

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MU_DI_STATE	O/V	0h 1h 2h 3h	MU_DI_NOT_REQ MU_DI_BUSY MU_DI_ERR MU_DI_OK	1	1
State of MU Disable request					

Export action:

ACTION_ECM3_DisableRequest(OUT <flag>)
Action to perfom a transition to DISABLE

FUNCTION DESCRIPTION:

General information:

Like given above ("Disable State of Communication") a transition to Disable can be performed without any Processor Monitoring fault. This transition has to be performed for switching off the monitoring functionality of the MU in case of entering the power latch phase or for shutting down the ECU. This transition can be triggered by any other parts of the software calling cyclical ACTION_ECM3_DisableRequest().

To initialize this transition to Disable the MC sends a DISABLE command (header) to the MU. The MU has to respond by sending a Disable header next communication.

The variable MU_DI_STATE indicates the state of the MU (seen form MC) according to the Disable request. There are several states:

MU_DI_STATE		Meaning
0h	MU_DI_NOT_REQ	No disable request
1h	MU_DI_BUSY	Disable requested. MU did not respond up till now and no timeout
2h	MU_DI_ERR	Disable requested. MU did not respond within the defined time periode
3h	MU_DI_OK	Disable requested. MU responded with Disable header

Application conditions:

Initialisation: MU_DI_STATE = 0h /* No disable request */
After each power up or reset

Description of ACTION_ECM3_DisableRequest( ):

Description:

Syntax: **ACTION_ECM3_DisableRequest(OUT <*flag*>)**

Parameter (OUT): ***flag***

Formula section:

ACTION_ECM3_DisableRequest(SYNCHRONISATION ASYNCHRONOUS)

- Requests transition to Disable
- Sets the parameter ***flag*** according to
  - set, if (MU_DI_STATE=MU_DI_OK) or (MU_DI_STATE=MU_DI_ERR)
  - reset in all other cases.

E.4.3 Communication dedicated to Port Extension

The port extensions are described in “Digital output port extension” and “Analog and pseudo digital inputs”. Within the following sections the initialisation and data transfer are described.

E.4.3.1 Initialisation of the Port Extensions

Input data: (on MU)

ENA_PORT_MU			

FUNCTION DESCRIPTION:

During initialisation the digial port extensions has to be configurated.

After power up or reset the system runs through different states, see “Processor Monitoring”.

The digital output port extensions are configurated with the transferred bit pattern ENA_PORT_MU sent to MU in the INIT and PREDRIVE communication. If these two received values are identical and plausible, the value is stored in a reset safe RAM area on MU. If the two values are not identically or any of them is not plausible, a communication error is assumed, see “Fault Reactions on Processor Monitoring”.

After all other resets running not through the INIT and PREDRIVE states this reset safe stored value is used for initialisation.

ENA_PORT_MU has the same structure as OUT_PORT_MU and indicates which pins are avaliable for digital output port extension, if the dedicated bit in ENA_PORT_MU is set. The structure of OUT_PORT_MU is described in “Digital output port extension”.

On MC the value sent in the INIT and PREDRIVE communication is a constant, NC_ENA_PORT_MU.

If it is not possible to set the digital output pins according to the received byte ENA_PORT_MU (caused i.ie. by a communication error) the MU enables all digital output pins.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ENA_PORT_MU	1	00h ... FFh	0 ... 255	1	-
Bit pattern on MC, set to MU for initializing the digital output port extension					

E.4.3.2 AD communications

After the INIT communcation the AD-communications can be performed between two monitoring communcations, if the timing of the monitoring communication is not affected, see “SPI transmission protocol”. An AD communication is triggered like every communication by the MC. Therefore the MC sends the according header bytes. With interpreting the first received header byte the MU knows the structure and contents of the block to be sent to MC. As the communication is full duplex, the MC has to sent the value DUMMY in the data bytes.

The structure and contents of the transferred data are described in "Analog and pseudo digital inputs".

Note how duing the two AD communications, the data in AN_BUF_x are mapped to the entries of ACQ_MU[y].

E.4.3.2.1 AD Communication 1

In this communication the following ADC values are transferred:

Byte No.	MC->MU	MU->MC
0	SPI_HD_MC_MU	DUMMY
1	SPI_HD_MC_MU	SPI_HD_MU_MU
2	DUMMY	AN_BUF_1 -> ACQ_MU[1], AN_BUF_8 -> ACQ_MU[2], AN_BUF_12 -> ACQ_MU[3], AN_BUF_13 -> ACQ_MU[4]
3		
4		
5		
6		
7	SPI_CKS_MC_MU	SPI_CKS_MU_MU

The values of the header bytes are AD_1

E.4.3.2.2 AD Communication 2

In this communication the following ADC values are transferred:

Byte No.	MC->MU	MU->MC
0	SPI_HD_MC_MU	DUMMY
1	SPI_HD_MC_MU	SPI_HD_MU_MU
2	DUMMY	EMUL_DIG_INP, AN_BUF_2 -> ACQ_MU[5], AN_BUF_3 -> ACQ_MU[6], AN_BUF_10 -> ACQ_MU[7]
3		
4		
5		
6		
7	SPI_CKS_MC_MU	SPI_CKS_MU_MU

The values of the header bytes are AD_2

E.4.4 Monitoring of communication

FUNCTION DESCRIPTION:

During operation, MC and MU exchange exclusively messages with a length of 8 characters. Monitoring of the communication is done on both processors, MC and MU. The contents of the received data buffer is only evaluated in case of faultless communication. The nominal value of the cycle time is NC_T_SPI_COM. The cycle time is affected by runtime fluctuations of the operating system of MC. Shorter or longer messages are recognized as inadmissible and result in error treatments. The characters within the message are transferred in direct succession. Thus, the message transfer time is essentially fixed (minor fluctuations are possible due to other activated interrupts in MU).

E.4.4.1 Communication monitoring on MC

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ABC_HD_MC	-	00h ... FFh	0...255	1	-
anti-bounce counter for command/header monitoring					
ABC_CKS_MC	-	00h ... FFh	0...255	1	-
anti-bounce counter for checksum monitoring					
SPI_CKS_MC_MU	-	00h ... FFh	0...255	1	-
Checksum of the MC ->MU communication					
SPI_CKS_CLC_MU_MU	-	00h ... FFh	0...255	1	-
Calculated checksum of the MU ->MC communication					
SPI_HD_MC_MU	-	00h ... FFh	0...255	1	-
Header of the MC ->MU communication					
MC_STATE	-	12h CFh ADh 3Bh	"INIT" "PREDRIVE" "NORMAL" "DISABLE"	1	-
State of the communication on MC					

Input data:

SPI_CKS_MU_MU	SPI_HD_MU_MU		

FUNCTION DESCRIPTION:

The MC checks the checksum of the transferred block. The MU calculates a checksum (SPI_CKS_MU_MU) and sends this checksum in the last byte, see “Structure of transferred blocks”. After block reception the MC calculates the checksum with the same algorithm (SPI_CKS_CLC_MU_MU) and compares it with the sent one.

Formula section:

IF (SPI_CKS_CLC_MU_MU <> SPI_CHKS_MU_MU) **THEN**

IF (MC_STATE==INIT) || (MC_STATE==PREDRIVE) **THEN**

ABC_CKS_MC = NC_ABC_MAX_CKS_MC

central failure reaction carried out (refer to chapter: “Fault reaction”).

ELSE

ABC_CKS_MC += NC_ABC_INC_CKS_MC

IF (ABC_CKS_MC >= NC_ABC_MAX_CKS_MC) **THEN**

central failure reaction carried out

(refer to chapter: “Fault reaction”).

ENDIF

ENDIF

ELSE

IF (ABC_CKS_MC>0) **THEN**

ABC_CKS_MC –

ENDIF

ENDIF

Furthermore the MC checks, if the MU sends the right command/header (INIT, PREDRIVE, NORMAL) at the right moment. Therefore the received header must be plausible to the state of the MC.

In case of fault free communication the MC state stored in MC_STATE is updated. Allowed values of MC_STATE are INIT, PREDRIVE, NORMAL and DISABLE. The headers AD_1 and AD_2 do not change the state.

The following transitions are allowed:

MC_STATE (before communication)	**SPI_HD_MU_MU** (received header)	**MC_STATE** (after communcation)
INIT	PREDRIVE	PREDRIVE
	DISABLE	DISABLE
	AD_1	INIT
	AD_2	INIT
PREDRIVE	NORMAL	NORMAL
	DISABLE	DISABLE
	AD_1	PREDRIVE
	AD_2	PREDRIVE
NORMAL	NORMAL	NORMAL
	DISABLE	DISABLE
	AD_1	NORMAL
	AD_2	NORMAL
DISABLE	INIT	DISABLE
	PREDRIVE	DISABLE
	NORMAL	DISABLE
	DISABLE	DISABLE
	AD_1	DISABLE
	AD_2	DISABLE

All other combinations are defined as wrong header.

Formula section:

```
IF (wrong header) THEN
    IF ( MC_STATE == INIT ) or ( MC_STATE == PREDRIVE ) THEN
        ABC_HD_MC = NC_ABC_MAX_HD_MC
        central failure reaction is carried out
        (refer to chapter: “Fault reaction”).
    ENDIF
    IF  ( MC_STATE == NORMAL)
        ABC_HD_MC+=NC_ABC_INC_HD_MC
        IF (ABC_HD_MC >= NC_ABC_MAX_HD_MC)THEN
            central failure reaction is carried out.
        ENDIF
    ENDIF
ELSE
    IF (ABC_HD_MC>0) THEN ABC_HD_MC—; ENDIF
ENDIF
```

Configuration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
NC_ABC_INC_HD_MC	1	00h ... FFh	0...255	1	-
Increment value of anti-bounce counter for monitoring of the command/header					
NC_ABC_MAX_HD_MC	1	00h ... FFh	0...255	1	-
Maximum value of anti-bounce counter for monitoring of the command/header					
NC_ABC_INC_CKS_MC	1	00h ... FFh	0...255	1	-
Increment value of anti-bounce counter for monitoring of the checksum					
NC_ABC_MAX_CKS_MC	1	00h ... FFh	0...255	1	-
Maximum value of anti-bounce counter for monitoring of the checksum					

E.4.4.2 Communication monitoring on MU

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ABC_TOUT_MAX_MU	-	00h ... FFh	0...255	1	-
Anti-bounce counter for maximum timeout monitoring					
ABC_TOUT_MIN_MU	-	00h ... FFh	0...255	1	-
Anti-bounce counter for minimum timeout monitoring					
T_SPI_COM	-	00h ... FFh	0...255	1	ms
Counter to measure the time since the last communication

Actual checksum of the MC ->MU communication					
SPI_HD_MU_MU	-	00h ... FFh	0...255	1	-
Header of the MU ->MC communication					
MU_STATE	-	12h CFh ADh 3Bh	"INIT" "PREDRIVE" "NORMAL" "DISABLE"	1	-
State of the communication on MU					

Input data:

SPI_CKS_MC_MU	SPI_HD_MC_MU		

FUNCTION DESCRIPTION:

The communication cycle time is affected by runtime fluctuations of the operating system of MC. MU monitors the cycle time. This cycle time has to fulfill: NC_T_SPI_MIN ≤ T_SPI_COM ≤ NC_T_SPI_MAX. T_SPI_COM is the measured, elapsed time since the last monitoring communication. The timeout monitoring starts with the INIT communication, it is not carried out in DISABLE.

Application conditions:

Initialisation: ABC_TOUT_MIN_MU=ABC_TOUT_MAX_MU=
ABC_HD_MU=ABC_CKS_MU=0 after reset or power up

Formula section:

IF (MU_STATE==PREDRIVE) or (MU_STATE==NORMAL) **THEN**

    IF (T_SPI_COM > NC_T_SPI_MAX) **THEN**

        ABC_TOUT_MAX_MU += NC_ABC_INC_TOUT_MAX_MU

        IF (ABC_TOUT_MAX_MU >= NC_ABC_MAX_TOUT_MAX_MU) **THEN**

            central failure reaction is carried out

            (refer to chapter: “Fault reaction”)

```
            ENDIF
        ELSE
            IF (ABC_TOUT_MAX_MU>0) THEN ABC_TOUT_MAX_MU --; ENDIF

            IF (T_SPI_COM < NC_T_SPI_MIN) THEN
                ABC_TOUT_MIN_MU += NC_ABC_INC_TOUT_MIN_MU
                IF (ABC_TOUT_MIN_MU >= NC_ABC_MAX_TOUT_MIN_MU) THEN
                    central failure reaction is carried out.
                ENDIF
            ELSE
                IF (ABC_TOUT_MIN_MU>0) THEN ABC_TOUT_MIN_MU --; ENDIF
            ENDIF
        ENDIF
    ENDIF
    T_SPI_COM = 0
```

The MC calculates a checksum of its send message. This byte is sent as last (SPI_CHKS_MC_MU). After the reception of the message, the MU calculates the checksum (SPI_CKS_CLC_MC_MU) and compares this one with the received checksum.

Formula section:

```
IF (SPI_CHKS_MC_MU<>SPI_CKS_CLC_MC_MU) THEN
    IF ( MU_STATE == INIT ) or ( MU_STATE == PREDRIVE ) THEN
        ABC_CKS_MU = NC_ABC_MAX_CKS_MU
        central failure reaction is carried out
        (refer to chapter: “Fault reaction”).
    ENDIF
    IF  ( MU_STATE == NORMAL)
        ABC_CKS_MU+=NC_ABC_INC_CKS_MU
        IF (ABC_CKS_MU >= NC_ABC_MAX_CKS_MU)THEN
            central failure reaction is carried out.
        ENDIF
    ENDIF
ELSE
    IF (ABC_CKS_MU>0) THEN ABC_CKS_MU—; ENDIF
ENDIF
```

Furthermore the MU checks, if the MC sends the right command/header (INIT, PREDRIVE, NORMAL, AD_1, AD_2) at the right moment. Therefore the received header must be plausible to the state of the MU.

In case of fault free communication the MU state stored in MU_STATE is updated. Allowed values of MU_STATE are INIT, PREDRIVE, NORMAL and DISABLE. The headers AD_1 and AD_2 do not change the state.

The following transitions are allowed:

MU_STATE (before communication)	**SPI_HD_MC_MU** (received header)	**MU_STATE** (after communcation)
INIT	PREDRIVE	PREDRIVE
	DISABLE	DISABLE
	AD_1	INIT
	AD_2	INIT
PREDRIVE	NORMAL	NORMAL
	DISABLE	DISABLE
	AD_1	PREDRIVE
	AD_2	PREDRIVE
NORMAL	NORMAL	NORMAL
	DISABLE	DISABLE
	AD_1	NORMAL
	AD_2	NORMAL
DISABLE	INIT	DISABLE
	PREDRIVE	DISABLE
	NORMAL	DISABLE
	DISABLE	DISABLE
	AD_1	DISABLE
	AD_2	DISABLE

All other combinations are defined as wrong header.

Formula section:

IF (wrong header) **THEN**

IF (MU_STATE == INIT) or (MU_STATE == PREDRIVE) **THEN**

ABC_HD_MU = NC_ABC_MAX_HD_MU

central failure reaction is carried out

(refer to chapter: “Fault reaction”).

ENDIF

IF (MU_STATE == NORMAL)

ABC_HD_MU+=NC_ABC_INC_HD_MU

IF (ABC_HD_MU >= NC_ABC_MAX_HD_MU)**THEN**

central failure reaction is carried out.

ENDIF

ENDIF

ELSE

IF (ABC_HD_MU>0) **THEN** ABC_HD_MU—; **ENDIF**

ENDIF

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ABC_INC_TOUT_MAX_MU	1	00h ... FFh	0...255	1	-
Increment value of anti-bounce counter for maximum timeout monitoring

Maximum value of anti-bounce counter for monitoring of the checksum					

E.4.5 End of Line Test

The software of the MU comprises a test mode. It can be activated with special commands by the SPI-Communication. If the test mode is activated, the software of the Safety-Concept is not carried out. The only way to leave the test mode is a reset.

E.4.5.1 Entry into EOLT-SW

The EOLT-Mode can be reached if the first command after reset or after DISABLE-Mode is „EOLT“. The MU tests the conditions for entry into the EOLT. The MC must send the three special messages EOLT(1), EOLT(2) and EOLT(3) in a precise time window, before the MU jumps into EOLT-SW.

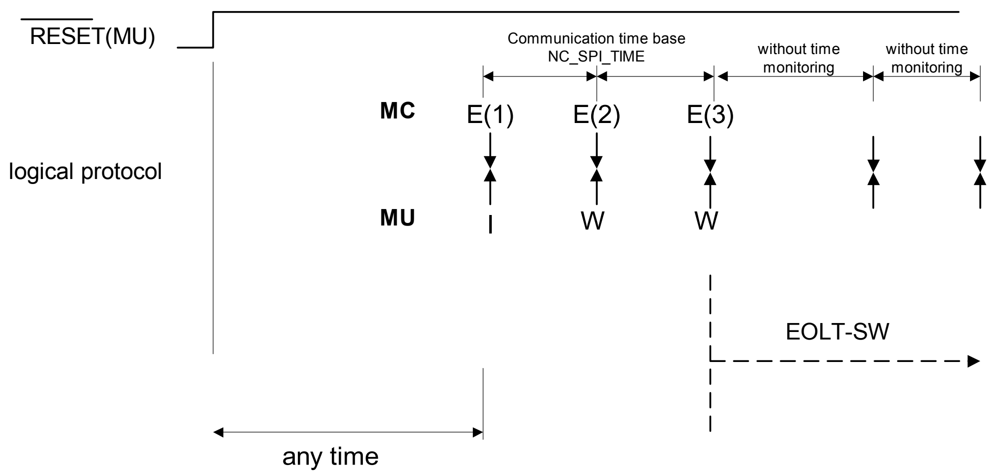

Figure 3: Time chart of entry EOLT-SW

Explanation of

Figure 3

E(1) = EOLT(1)

E(2) = EOLT(2)

E(3) = EOLT(3)

I = INIT
W = WRONG

E.4.5.2 EOLT Commands

After a successful entry procedure, different commands can be called. The communication between MC and MU is full duplex communication. Therefore it is necessary to call two communications for every command. The first to send the command to MU and the second to receive the answer from the MU.

These commands can be sent to MU during the EOLT

Command	Value	description
MDK_READ_ANA	01h	Read the four analog inputs
MDK_READ_PORT	02h	Read all digital inputs
MDK_WRITE_PORT	03h	Write all digital outputs
MDK_BIST	04h	Read the selftest-result
MDK_READ_MEMORY	05h	Read the memory of the MU

E.4.6 Availability of AD values in MU

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
ACQ_MU[NC_ACQ_MU_NR]	V/O	000h ... 3FFh FFFFh	0 ... 4.9951 “undefined”	5/1024 -	V -
10 bit A/D value on MC, FFFFh simply denotes “undefined” as the result of the AD conversion					

Input data (transferred from MU to MC):

AN_BUF_0	AN_BUF_1	AN_BUF_2	AN_BUF_3
AN_BUF_8	AN_BUF_10	AN_BUF_12	AN_BUF_13

Additionally, indicators when monitoring, AD_1 or AD_2 communications are faulty are needed; refer to section “Communication monitoring on MC.”

FUNCTION DESCRIPTION:

General information:

This function describes a mechanism to determine whether new AD values are available on the MU, and whether the AD-related communiations were faulty.
In order to achieve this, the data ACQ_MU[x] on the MC shall be initialised to FFFFh (which denotes an undefined singal by the AD converter, see above range definition of ACQ_MU[y]).
In this way, the MC can detect whether valid new data have been transmitted by the MU or not; as long as no values are available, the old values are not overwritten and so the stay undefined for as long as necessary.
Similarly, should one of the AD-related communications fail, the corresponding entries in ACQ_MU[y] (see “Predrive State of Communication”, “Normal State of Communication”, “Disable State of Communication”, “AD Communication 1”, and “AD Communication 2”) shall be set to FFFFh, again to signal to the MC that there are no currently valid AD values available on the MU.

Application conditions:

Initialisation: Preset all elements of the array ACQ_MU with FFFFh

Recurrence: each communication (Predrive, Normal, Disable, AD1 or AD2)

Activation: always

Formula section:

IF ("last communication faultless") **THEN**

"Assign the value of AN_BUF_x to the corresponding entry ACQ_MU[y] as described in "Predrive State of Communication", "Normal State of Communication", "Disable State of Communication", "AD Communication 1", and "AD Communication 2."

ELSE

IF ("monitoring communication faulty") **THEN**

ACQ_MU[0] = FFFFh

ELIF ("AD_1 communication faulty") **THEN**

ACQ_MU[1] = FFFFh

ACQ_MU[2] = FFFFh

ACQ_MU[3] = FFFFh

ACQ_MU[4] = FFFFh

ELIF ("AD_2 communication faulty") **THEN**

ACQ_MU[5] = FFFFh

ACQ_MU[6] = FFFFh

ACQ_MU[7] = FFFFh

ENDIF

ENDIF

E.5 PROCESS MONITORING

Import actions:

ACTION_ECM3_ServicePfm(IN <n>)

Note: This action is defined in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". This action has to be executed as last instruction after all tasks has been executed. After the first block of tasks the action has to be called with argument 1, after the second with 2, after the third with 3 and after the fourth with 4. At the very end of the scheduler finally the action has to be called with argument 6, 7, and 0.

ACTION_ECM2_LockPws()
ACTION_ECM2_UnlockPws()

Note: These two actions are defined in module "Fault Reaction of process monitoring".

Input data:

LV_RLY_MAIN_DLY_ERR	LV_DIAG_END_RLY_MAIN_DLY		

General information:

The task of process monitoring is to check whether ETC / torque functions (located in function level) work properly and to take a fault reaction, if not. The task scheduler defines the correct sequencing of all called monitoring functions within the four task slots (see figure 1) and the related action calls for program flow monitoring (see “import actions”)

Formula Section:

IF LV_DIAG_END_RLY_MAIN_DLY == 1 **AND** LV_RLY_MAIN_DLY_ERR == 0
THEN
ACTION_ECM2_UnlockPws();
/* Has to be executed exactly once! */
Tasks/ECM2-functions activated according to table 1 starting with task "1";
ELSE ACTION_ECM2_LockPws();
ENDIF

Table 1: Distribution of the process monitoring functionality over four tasks. The task scheduler is executed every 10 ms. Within one task, the different functions are executed in the order according to the rows of the table.

Task 1 (k)	Task 2 (k+10 ms)	Task 3 (k+20 ms)	Task 4 (k+30 ms)
Application incidences of process monitoring(k)	Application incidences of process monitoring(k+10ms)	Application incidences of process monitoring(k+20ms)	Application incidences of process monitoring(k+30ms)
Monitoring of A/D-conversion	Monitoring of pedal value signals	Monitoring of engine speed limitation	Actual indicated engine torque
Monitoring of TCO	Monitoring of mass air flow	Monitoring of CAN signals	Desired indicated engine torque
Monitoring of engine speed	Monitoring of torque losses	Monitoring of cruise control conditions	Monitoring of actual indicated engine torque
Monitoring of idle speed controller	Monitoring of maximum torque at clutch	Monitoring of minimum torque at clutch	Fault reaction of process monitoring
ACTION_ECM3_ ServicePfm(1)	ACTION_ECM3_ ServicePfm(2)	ACTION_ECM3_ ServicePfm(3)	ACTION_ECM3_ ServicePfm(4)
ACTION_ECM3_ ServicePfm(0)	ACTION_ECM3_ ServicePfm(0)	ACTION_ECM3_ ServicePfm(0)	Error memory management of process monitoring
			ACTION_ECM3_ ServicePfm(6)
			ACTION_ECM3_ ServicePfm(7)
			ACTION_ECM3_ ServicePfm(0)

E.6 Debounce Mechanism

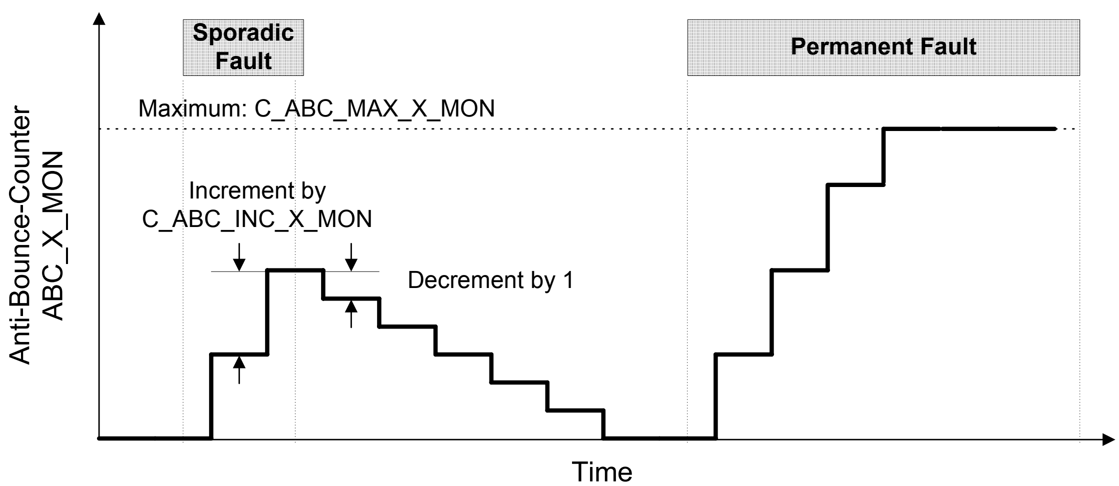
FUNCTION DESCRIPTION:

General information:

Many diagnosis algorithms need a debounce mechanism in order to avoid a faulty diagnosis caused by normal disturbances. Since the process monitoring is intended to represent redundancy to the functions of level 1, there is also a redundant debounce mechanism required. That means an algorithm with separate code, ROM- and RAM data. The debounce algorithm is used for the functions of level 2 and 2' (copy of process monitoring).

Description:

The anti-bounce-counter ABC_X_MON is increased by C_ABC_INC_X_MON, if the conditions for fault detection are fulfilled. Otherwise, the anti-bounce counter is decremented by 1. If the anti-bounce-counter ABC_X_MON exceeds its threshold C_ABC_MAX_X_MON the first time during this engine running, the relating error-flag is set and a fault can be stored in the customer error memory.



Application conditions:

The activation, deactivation and recurrency of this module depends on the data of the related diagnosis function.

Formula section:

```
IF   (Fault detection condition fulfilled)
THEN
     Increment ABC_X_MON by C_ABC_INC_X_MON
     (limited to C_ABC_MAX_X_MON)
ELSE
     Decrement ABC_X_MON by 1          (limited to 0)
```

E.7 Application Incidences and Configuration of Process Monitoring

Import actions:

ACTION_ECM3_Service0TaskPfm(0)
ACTION_ECM3_Service1TaskPfm(0)
ACTION_ECM3_Service0TaskPfm(1)
ACTION_ECM3_Service1TaskPfm(1)
ACTION_ECM3_Service0TaskPfm(2)
ACTION_ECM3_Service1TaskPfm(2)
ACTION_ECM3_Service0TaskPfm(3)
ACTION_ECM3_Service1TaskPfm(3)
ACTION_ECM3_Service0TaskPfm(4)
ACTION_ECM3_Service1TaskPfm(4)

Note: This actions are defined in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument has the value 1,2,3 respective 4.

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>, IN <reg>)
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Note: This actions are defined in chapter "Processor Monitoring", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

E.7.1 Initialization conditions

FUNCTION DESCRIPTION:

General information:

The application condition for the initialization of e.g. the error bits, the anti-bounce-counters and other variables of the process monitoring is commonly defined here for all modules of the process monitoring. There is only a reference to the following definition of the application conditions in the different modules.

The error bits, anti-bounce-counters and other variables are initialized
- at reset
- at transition from LV_IGK = 0 to 1
- at clearing of the failure memory

There is one exception from the rule above. If the reset counter at the monitoring unit increased up to 7 resets, the fault reaction of the monitoring unit will be continued until the power supply of the monitoring unit is switched off.

E.8 Chapter 1

E.8.1 Application incidences for the activation conditions of process monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_N_LIM_ETC_MON	V/O	0 ... 1 H	0 ... 1	1	-
Logical variable for activation of engine speed limitation monitoring					
LV_TQI_MON_ACT_MON	V/O	0 ... 1 H	0 ... 1	1	-
Logical variable for torque monitoring active					
LV_IGK_MON	O/V	0...1H	0...1	1	[-]
Logical variable for ignition key on					

Input data:

LV_N_LIM_REQ_MON	LV_IGK	LV_ERR_PVS_1	LV_ERR_PVS_2
LV_ERR_PVS_RATIO	LV_ERR_TPS	PV_AV_MON	LV_MTC_CUR_OFF
V_TPS_1_BAS	V_TPS_2_BAS		

FUNCTION DESCRIPTION:

General information:

The logical variable LV_N_LIM_ETC_MON indicates, that any etc-safety-function of level 1, 2 or 3 has requested engine speed limitation at 1500 rpm or ignition key is switched off. The monitoring of the engine speed limitation is also active, when

- any fault of the ETC-system (pedal value sensor, throttle position sensor, throttle actuator, power stage) is present and the driver demand is zero or
- throttle is disabled and at least one throttle position signal is outside the specified limp home position

The torque monitoring can only be active, when the ignition key is on and the throttle is not disabled. Otherwise the control of the torque is not possible and torque monitoring is forbidden. This is not a risk, because engine is switched off or in limp home mode then and the monitoring of the engine speed limitation is active in most cases (at least when the driver releases the pedal).

The logical variable LV_IGK is copied to level 2 in the variable LV_IGK_MON, because it is used as a deactivation condition for the monitoring of PVS in level 2. In order to ensure the safety, the variable LV_IGK_MON is also used for the calculation of the global activation conditions LV_N_LIM_ETC_MON and LV_TQI_MON_ACT_MON.

Application conditions:

Activation: at every engine state

Deactivation: otherwise

Initialisation: for condition see 'Application Incidences of Process Monitoring'

LV_N_LIM_ETC_MON = 0

LV_TQI_MON_ACT_MON = 0

LV_IGK_MON = 0

Update Rate: 40 ms

Formula section:

ACTION_ECM3_Service0TaskPfm(1)

LV_IGK_MON = LV_IGK

Activation of monitoring of engine speed limitation:

```
IF   LV_IGK_MON              =    0     OR    {during ignition-key OFF}
     LV_N_LIM_REQ_MON        =    1     OR    {request from level 2}

     [(LV_ERR_PVS_1          =    1     OR    {engine limp home mode}
     LV_ERR_PVS_2            =    1     OR
     LV_ERR_PVS_RATIO        =    1     OR
     LV_ERR_TPS              =    1     OR
     LV_MTC_CUR_OFF          =    1)    AND

     PV_AV_MON               =    0]    OR    {request for reversible SAS}

     (LV_MTC_CUR_OFF         =    1     AND
     (V_TPS_1_BAS >  C_V_TPS_1_LIH_MON  OR    {throttle not in limp home position}
     V_TPS_2_BAS <  C_V_TPS_2_LIH_MON))

THEN
     LV_N_LIM_ETC_MON        =    1
ELSE
     LV_N_LIM_ETC_MON        =    0
ENDIF
```

Activation of torque monitoring:

```
IF   LV_IGK_MON              =    1     AND   {ignition-key ON}
     LV_MTC_CUR_OFF          =    0           {MTC NOT switched off}
THEN
     LV_TQI_MON_ACT_MON      =    1
ELSE
     LV_TQI_MON_ACT_MON      =    0
ENDIF
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_V_TPS_1_LIH_MON	1	0 ... 3FF H	0 ... 4.995117	0.0049	V
Threshold for detection of throttle position 1 outside limp home position					
C_V_TPS_2_LIH_MON	1	0 ... 3FF H	0 ... 4.995117	0.0049	V
Threshold for detection of throttle position 2 outside limp home position					

E.8.2 Aplication incidences for monitoring of torque demand from idle speed controller

E.8.2.1 Application incidences for monitoring driver request passive

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_CT_MON	V	0 ... 1H	0 ... 1	1	-
Logical bit for detecion of driver request passive					

Input data:

LV_TQI_MON_ACT_MON	LV_CT		

FUNCTION DESCRIPTION:

The aim of this chapter is the monitoring of the variable LV_CT which indicates whether a ‘driver request’ is present or not where the request can be not only from the driver but also from other sources like cruise control or vehicle speed limitation functionality.

As long as the impact between LV_CT = 0 and LV_CT = 1 can be tolerated in terms of torque thresholds, the value can be copied to L2 without plausibility check.

Application conditions:

Activation: LV_TQI_MON_ACT_MON = 1

Deactivation: otherwise

Initialisation: for condition see ‘Application Incidences of Process Monitoring’
LV_CT_MON = 1

Update Rate: 40 ms

Formula section:

LV_CT_MON = LV_CT

E.8.2.2 Application incidences for monitoring of idle speed setpoint

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
N_DIF_SP_IS_MON	V/O	80 ... 7FH	-4096 ... 4064	32	rpm
Deviation of actual engine speed from idle speed setpoint

LV_N_INC_TCU_ACT	LV_CT_MON	LV_ERR_CAN_BUS_OFF	LV_ERR_TIMEOUT_TCU1

FUNCTION DESCRIPTION:

General information:

The objective of this function is the monitoring of the idle speed setpoint(N_SP_IS) and the corrected idle speed setpoint. Both of these values have to be monitored because they are important inputs for the the torque monitoring functionalities. This function consists of two sections.This section includes the monitoring of the basis idle-speed setpoint , the Level 2 model value for the idle-speed setpoint and other relevant variables that are important inputs for the torque monitoring.

Application conditions:

Activation: LV_TQI_MON_ACT_MON = 1

Deactivation: otherwise

Initialisation: for condition see 'Application Incidences of Process Monitoring'

N_DIF_SP_IS_MON = 0 rpm
N_SP_IS_RATIO_MON = 0 rpm
N_SP_IS_MON = 0 rpm

Update Rate: 40 ms

E.8.2.2.1 Plausiblisation of external influences on idle-speed setpoint

Formula section:

FAC_RAMP_NEG_P_D_IS_MON = C_FAC_RAMP_P_D_MON

E.8.2.2.2 Calculation of idle-speed setpoint model value

General information:

The basis idle speed setpoint is limited by a coolant temperature dependent maximum value, IP_N_SP_IS_BAS_MAX_MON. The actual idle speed setpoint,N_SP_IS_MON, is under normal conditions equal to the basis setpoint, N_SP_IS_LIM. Depending on a LC bit, the deviation between engine speed and the idle speed setpoint is calculated in two paths:

- **LC_N_SP_IS_CLC_CALC_MON = 0** – N_SP_IS_MON and the N_DIF-moving mean value (N_DIF_MMV_MON) are relevant
- **LC_N_SP_IS_CLC_CALC_MON = 1** – Only the corrected idle speed setpoint (N_SP_IS_CLC_MON) is relevant

The corrected idle speed setpoint (N_SP_IS_COR - which is directly calculated from N_SP_IS) is limited to a maximum and minimum value i.e. engine speed (N_32_MON) and idle speed setpoint (N_SP_IS_MON) respectively. The outputs of the function are:

- ratio between idle speed setpoint and actual engine speed - **N_SP_IS_RATIO_MON**
- deviation of actual engine speed from idle speed setpoint - **N_DIF_SP_IS_MON**
- deviation of actual engine speed from N_SP_IS - **N_DIF_MON**

General information:

The ISC can be active either when the engine is in idle state(LV_REQ_ISC=1) or when the DROF functionality is active or under certain conditions in trailing-throttle state (LV_PU=1) and part-load state (LV_PL=1) and. So all of these possible "ISC-active" phases have to be monitored. The activation conditions are based on the L1 ISC activation conditions as described in the module 'Application incidences for the idle speed controller'. In addition to the normal activation states, a 'NOT_ACTIVE' state is generated in order to be able to monitor the ISC if the activation information from the function level is faulty.

Formula section:

Fault of any PVS power supply detected by level 2 diagnosis					

Input data:

LV_BLS	LV_BTS	LV_ERR_BLS_BTS	

FUNCTION DESCRIPTION:

General information:

In order to be able to use the generic module for the monitoring of the pedal value signals in level 2, different informations about the state of the brake are combined to one resulting information LV_BRAKE_MON. LV_BRAKE_MON is set, when at least one sensor (brake light switch or brake test switch) indicates an activated brake or a fault of a brake switch has been detected.

The state of the brake light switch (BLS) is checked via a direct read command on the port register. The information about the brake test switch (BTS) is evaluated, using a variable from the basic software, which is also used by the functions of level 1. A separate read command on the port register is not possible here, because the signal is measured via a multiplexer.

The usage of the error flags for the power supply voltages (LV_ERR_VCC_PVS_x_MON) of the pedal value sensor depends on the configuration of the power supply and the availability of diagnosis information in level 1. It is assumed, that faults detected in the power supply are handled in the same way as signal range faults of the corresponding pedal value sensor channels.

A separate power supply voltage diagnosis is necessary in level 2 in case of no redundant power supply is used for PVS supply and no PVS supply diagnosis is integrated in the PVS sensor.

Application conditions:

Activation: at every engine state

Deactivation: otherwise

Initialisation: for condition see ‘Application Incidences of Process Monitoring’

LV_BRAKE_MON = 0

Idle speed setpoint from external influences					

Input data:

N_DIF_MON	LV_CT_MON	LV_PUC	C_N_DIF_HYS_IS_PU_MON
EFF_SCC_MON	C_N_DIF_MAX_IS_MON	STATE_REQ_ISC_MON	TQ_CONV

FUNCTION DESCRIPTION:

General information:

The objective of this function is the determination of the error-detection paths of the minimum torque at clutch. The error-detection is divided into PU state and non-PU state. This separation is done because the biggest influence on the value of the minimum torque that is available at the clutch is the self-stabilising factor FAC_N_SP_IS_RATIO_MON and this has a parabolic trajectory where the transition point from the positive values to TQ_LOSS_MON is around the idle-speed setpoint(N_SP_IS_MON). STATE_ERR_DET_TQ_MIN_MON is an input into the module 'Monitoring of minimum torque at clutch'.

Application conditions:

Activation: LV_TQI_MON_ACT_MON = 1

Scalling factor for monitoring driver request, without gear factor					
FAC_TQ_REQ_DRIV_GEAR_MON	V	0...FFH	0...1.992	0.0078125	-
Gear dependent driver request weigting factor					

Input data:

PV_AV_MON	TQI_MIN_PU	TQI_INC_CAN_MON	N_32_MON

FUNCTION DESCRIPTION:

General information:

The objective of this function is to plausibilise the adaptive drive dynamics factor coming from the function level. This factor is used to calculate an adapted driver request PV_AV_AD_MON which is an important input for the module 'Desired indicated engine torque'. The idea behind this changed PV_AV_MON value is to adapt the engine response to the driver request depending on his or her driving-behaviour i.e. either a very sporty driver(quite active on the gas pedal) or a relatively passive driver(not so active on the gas pedal).

The torque demands from cruise control, electronic gear shift control and the electronic stability program are set to zero, if these functions are not available. Otherwise, the torque demands have to be copied to the corresponding variable of level 2 and these variables have to be checked for plausibility (e.g. CAN monitoring, CRU monitoring, control units [ESP, EGS] with internal plausibility check).

Application conditions:

Activation: LV_TQI_MON_ACT_MON = 1

Deactivation: otherwise

Initialisation: for condition see 'Application Incidences of Process Monitoring'
PV_AV_AD_MON = 0%
TQI_MIN_PU_MON = 0 Nm

TQI_MIN_PU_MAX_MON = 0 Nm
TQI_INC_EXT_MON = 0 Nm
FAC_TQ_REQ_DRIV_1_MON = 0 Nm
FAC_TQ_REQ_DRIV_GEAR_MON = 0 Nm
FAC_TQ_REQ_DRIV_TMP_MON = 0 Nm

Update Rate: 40 ms

Formula section:

ACTION_ECM3_Service0TaskPfm(4)

The scalling factor for monitoring driver request is calculated from a maximum choice between AT and MT scalling factor of level 1 and multiplied with a weighting factor for driver request as a function of gear and pedal value.

Caution:
For this the unplausibilized level 1 information gear has been used. This can only be done, if the worst case between the different gear is not leading to a too important variation of the desired indicated engine torque.

In order to keep the old core module "Desired indicated engine torque", the calculated scalling factor for monitoring driver request, is calculated back to a modified pedal value signal, witch is used in the module "Desired indicated engine torque",to calculate the desired indicated engine torque.

E.11.2 Forced injection shut off for Level 2 - engine speed limitation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_OFF_IV_N_LIM_ETC_MON	O/V	0 ... 1 H	0 ... 1	1	-
Reversible fuel Cut Off Switch for all cylinders					

Input data:

N_32_MON	LV_N_LIM_ETC_MON		

FUNCTION DESCRIPTION:

General information:

In order to ensure a safe injection cut off while engine speed limitation is active (LV_N_LIM_ETC_MON ==1) and the engine speed is above the threshold C_N_THD_FCUT_N_LIM_ETC_MON the resulting logical variable LV_OFF_IV_N_LIM_ETC_MON is used at individual cylinder shut off functionality.
(same use and priority as LV_OFF_IV_MON).

Application conditions:

Activation: at every engine state

Deactivation: otherwise

Initialisation: for condition see ‘Application Incidences of Process Monitoring’

LV_OFF_IV_N_LIM_ETC_MON = 0

Update Rate: 40 ms

Formula section:

IF (LV_N_LIM_ETC_MON == 1)
AND (N_32_MON > C_N_THD_FCUT_N_LIM_ETC_MON)
THEN LV_OFF_IV_N_LIM_ETC_MON = 1 ;
ELSE LV_OFF_IV_N_LIM_ETC_MON = 0 ;

ACTION_ECM3_Service1TaskPfm(4)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Engine speed threshold for forced injection cut off in SAS mode					

E.12 Monitoring of analog-digital-conversion

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_CONV_MON	O/V	0...1H	0...1	1	-
Logical variable for ADC error					
ABC_CONV_MON	V	0...FFH	0...255	1	-
Anti bounce counter ADC error					

Input data:

ACQ_MC_0_MON	ACQ_MU_0_MON		

Import actions:

ACTION_ECM3_Service2TaskPfm(IN <n>)
ACTION_ECM3_Service3TaskPfm(IN <n>)

Note: This actions are define in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument has the value 1.

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>, IN <reg>)
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Note: This actions are define in chapter "Processor Monitoring", subsection "RAM test on MC for processor monitoring". All variables with Mode O and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ACQ_CONV_HYS_MON	1	0...FFH	0...4.98	0.01953	V
Maximum allowed difference between the voltages on main controller and on monitoring unit					
C_ABC_INC_CONV_MON	1	0...FFH	0...255	1	-
Anti bounce counter increment (additive value in case of ADC error)					
C_ABC_MAX_CONV_MON	1	1...FFH	1...255	1	-
Value at which ADC error is recognized, when reached					

E.12.1 General Information:

The analog-digital-converter (ADC) diagnosis is performed by comparing two digital signals. The according analog signal is the same, it is digitalized once on the main controller (ACQ_MC_0_MON) and also on the monitoring unit (ACQ_MU_0_MON).

On an error free system both values are not allowed to differ more than the hysteresis C_ACQ_CONV_HYS_MON.

This hysteresis also covers differences caused by the different sampling times.

Threshold for the min. TCO temperature while TCO_SUB is higher than C_TCO_SUB_THD_MAX_MON					
C_TCO_SUB_THD_MAX_MON	1	0...FE00H	-48...142.5	0.00293	°C
Threshold for the max. TCO_SUB temperature while TCO is lower than C_TCO_THD_MIN_MON					

E.13.1 FUNCTION PART: ECM2_DTSYSTCO

General information:

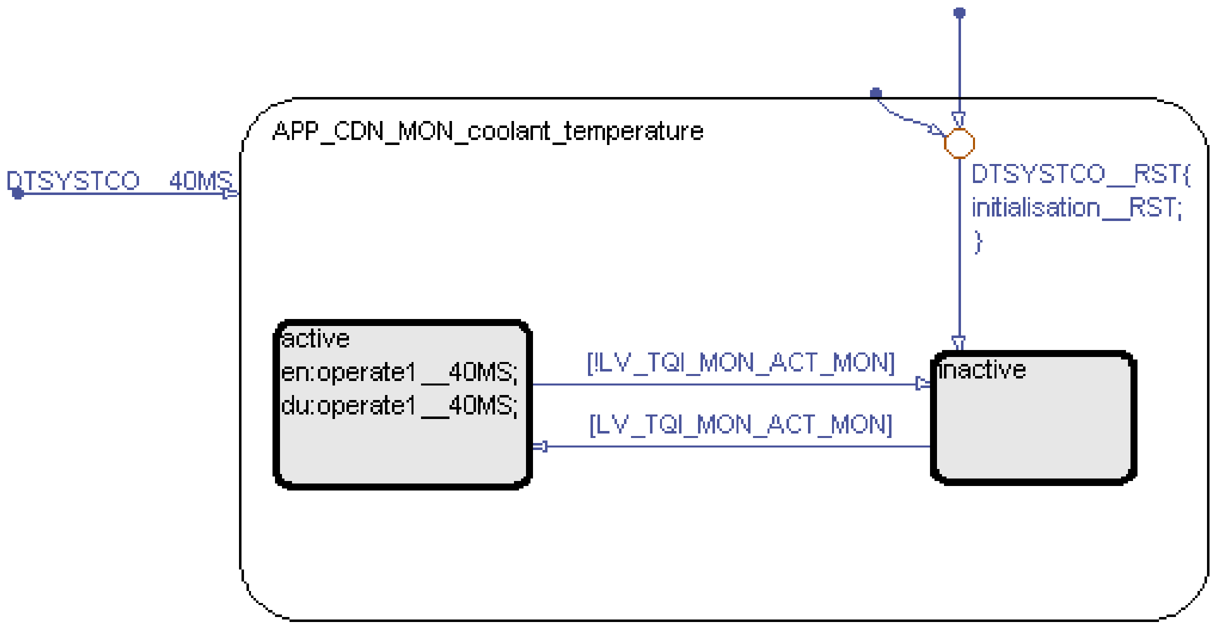
A sudden decrease in the coolant temperature TCO caused by a fault can lead to an undesired increase of the torque demand and thus to an undesired acceleration of the car because of the temperature dependent friction compensation. Therefore the negative temperature gradient of TCO shall be limited in the function level. In order to detect process faults, the gradient of the coolant temperature which is copied to the process monitoring level is also limited, i.e. to C_TCO_GRD_MAX_MON. Also the diagnosis for a too low TCO-sensor temperature is monitored. The resulting value TCO_MON is then used within the monitoring level. If a fault in TCO leads to an increased engine torque in the idle speed controller the module ‘Monitoring of idle speed controller’ detects this fault as an increased torque demand from the idle speed controller.

In case of an error free system the temperature TCO_MON used in the monitoring level should be the same as the temperature TCO used in the function level.

An additional timer is needed to compensate the different recurrencies of level 1 and level 2. The maximum counter threshold C_T_TCO_GRD_MAX_MON and the maximum negative temperature gradient C_TCO_GRD_MAX_MON need to be adapted in regard to the function recurrency and to C_TCO_GRD_MAX of level 1.

The resolution of T_TCO_GRD_MON and C_T_TCO_GRD_MAX_MON depend on the update rate of the module.

Application Condition



Note: DTSYSTCO__RST includes the function calls as defined in application incidences.

E.14.1 Monitoring of PD controller

General information:

The objective of this function is the monitoring of the torque demand from the PD-part of the idle speed controller function. Depending on the speed deviation to the idle speed setpoint and the coolant temperature a maximum PD-part is generated (the worst case values for the PD-part in the function level, i.e. great PD-part values are allowed for the most negative speed gradients => for N < N_SP_IS_MON and for N > N_SP_IS_MON small PD-part values are allowed). To additionally monitor the activation of the idle-speed controller in L1, a model value(STATE_REQ_ISC_MON) of the activation status is calculated in the module 'Application incidences of process monitoring'. To effectively plausiblise the values of TQ_DIF_P_D_IS and TQ_DIF_I_IS from the function level, both the monitoring thresholds as well as the activation condition model value are used.

The functionality that is depicted in the following pages consists of two fault scenarios:

Error Path – ISC not active:

Case 1: If the ISC is in the ramp limit operation due to deactivation of ISC, this ramp function is monitored. If LV_PAS_RAMP_ACT_P_D_CHG_MON is 1(i.e. indicates a change of STATE_PAS_RAMP_ACT_P_D_IS(0) from 0 to 1 or a flank change between two L2 sample times), the ramp calculation is triggered. It is first checked if the L1 ramp start-value is below the maximum PD-part. If this is the case, a ramp decrement TQ_ADD_P_D_ IS_MON is calculated and the L1 start-value,TQ_DIF_P_D_IS_MON, plus a calibratable additive constant is copied to TQ_DIF_P_D_IS_RAMP_MON. During the ramp operation, the ramp model value is calculated by adding the ramp decrement to the model value ($TQ\_DIF\_P\_D\_IS\_RAMP\ \_MON_{k-1}$) from the previous recurrency. If however the ramp start-value is greater than the threshold, TQ_DIF_P_D_IS_MAX_MON, then LV_RAMP_P_D_BEG_VALUE_WRG_MON is set to one. The difference between monitored and modelled PD-part is set as a visible variable for application work.

In the error detection part of this functionality, either $TQ\_DIF\_P\_D\_IS\_MON_k$ > TQ_DIF_P_D_IS_RAMP_MON or LV_RAMP_P_D_BEG_VALUE_WRG_MON==1 will lead to the error flag STATE_ERR_TQ_DIF_P_D_IS_MON being set.

Case 2: If the ISC is not active and the engine in the overspeed range i.e. STATE_ REQ_ISC_MON = NOT_ACTIVE, a torque demand from the PD-part of the controller greater than the passive value of zero indicates an error in the function level.

Error Path – ISC active:

Case 1: The ISC is when the engine is in idle state(LV_IS=1) or under certain conditions also in trailing-throttle(LV_PU=1) or part-load(LV_PL=1). So all of these possible "ISC-active" phases have to be monitored. A fault is set, if L1 declares the ISC be active and if L2 also detects the same based on plausiblised activation conditions (STATE_ REQ_ISC_MON = IDLE or TRAILING_THR or PART_LOAD) and if the monitored PD-part TQ_DIF_P_D_IS_MON exceeds the maximum PD-part TQ_DIF_P_D_IS_MAX_ MON.

Case 2: If in L1 the ISC is active(LV_REQ_ISC=1) but the activation conditions in L2 are not fulfilled i.e. STATE_ REQ_ISC_MON ≠ IDLE or TRAILING_THR or PART_LOAD, then if TQ_DIF_P_D_IS_MON is greater than a threshold value (C_TQ_P_D_ISC_NOT_ ACT_MAX_MON), the error-flag STATE_ERR_TQ_DIF_P_D_IS_MON is set .

If one of the errors above is detected, a fault is declared after debouncing by the idle speed controller montoring.

E.14.2 Monitoring of I controller

General information:

The objective of this function is the monitoring of the torque demand from the I-part of the idle speed controller function. Two different faults scenarios are considered:

Error Path – ISC not active:

Case 1: If the ISC is actually in the ramp limit operation due to deactivation of ISC, this ramp function is monitored. If LV_PAS_RAMP_ACT_I_CHG_MON is 1(i.e. indicates a change of STATE_PAS_RAMP_ACT_I_IS(0) from 0 to 1 or a flank change between two L2 sample times), a ramp decrement (TQ_ADD_I_IS_MON) is calculated and the actual I-part (TQ_DIF_I_IS_MON) plus a calibratable additive constant is copied to TQ_DIF_I_IS_RAMP_MON. Further on, TQ_DIF_I_IS_RAMP_MON is calculated by adding the calculated ramp decrement to the last delayed value. A fault is set, if TQ_DIF_I_IS_MON > TQ_DIF_I_IS_RAMP_MON or greater than the monitoring threshold C_TQ_DIF_I_IS_MAX_MON. If one of the errors is detected, a fault is declared after debouncing. The difference between monitored and modelled value is declared as a visible variable for application purposes.

Case 2: If in L2 idle speed controller is not active i.e. STATE_ REQ_ISC_MON = NOT_ ACTIVE but the I-part in the function level has not reached the passive value C_TQ_PAS_ I_IS_MON at the end the deactivation ramp, then an error is declared.

Error Path – ISC active:

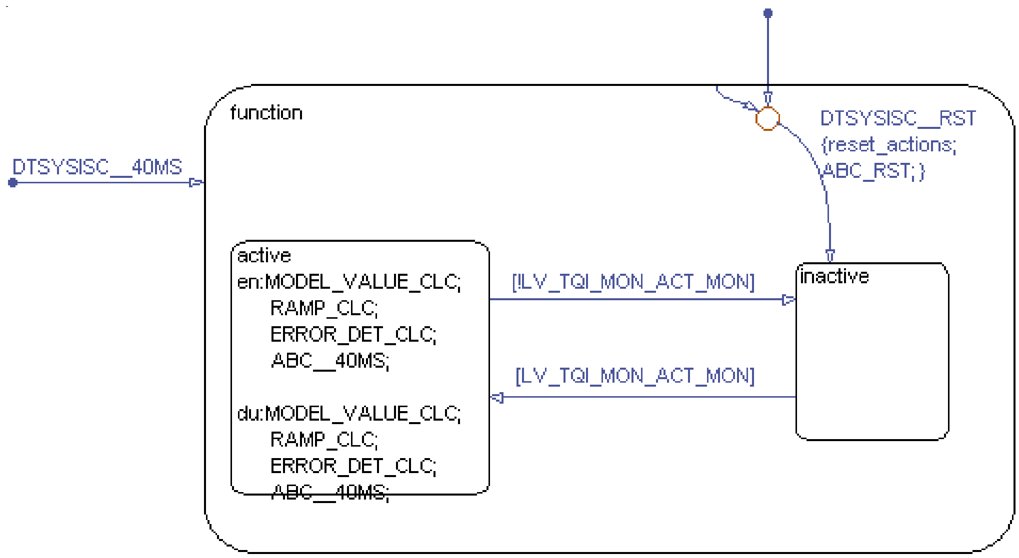
Case 1: The ISC can be active either when the engine is in idle state(LV_IS=1) or under certain conditions in trailing-throttle state (LV_PU=1) and part-load state (LV_PL=1).So all of these possible “ISC-active” phases have to be monitored. A fault is set, if L1 declares the ISC be active and if L2 also detects the same based on plausiblised activation conditions (STATE_ REQ_ISC_MON = IDLE or TRAILING_THR or PART_LOAD) and if torque demand fromL1, TQ_DIF_I_IS_MON, exceeds a threshold value C_TQ_DIF_I_IS_MAX _MON.

Case 2: If in L1 the ISC is active(LV_REQ_ISC=1) but the monitoring functionality detects this activation to be ‘faulty’ i.e. (STATE_ REQ_ISC_MON ≠ IDLE or TRAILING_THR or PART_LOAD), then an I-part torque demand from L1 greater than a threshold value (C_TQ_I_ISC_NOT _ACT_MAX_MON) will lead to an error detection.

If one of the errors above is detected, a fault is declared after debouncing by the idle speed controller montoring.

Note: The value of STATE_PAS_RAMP_ACT_I_IS(bit coded byte) and STATE_PAS_RAMP_ ACT_P_D_IS(bit coded byte) for the current recurrency (represented by STATE_PAS_RAMP_ACT_I_IS_0 and STATE_PAS_ RAMP_ACT_P_D_IS_0 respectively in the signal flow diagrams) are stored in the bit position 1.

Application Conditions



***Initialisation(DTSYSISC__RST)*:** for condition see 'Application Incidences of Process Monitoring'.

Function Description

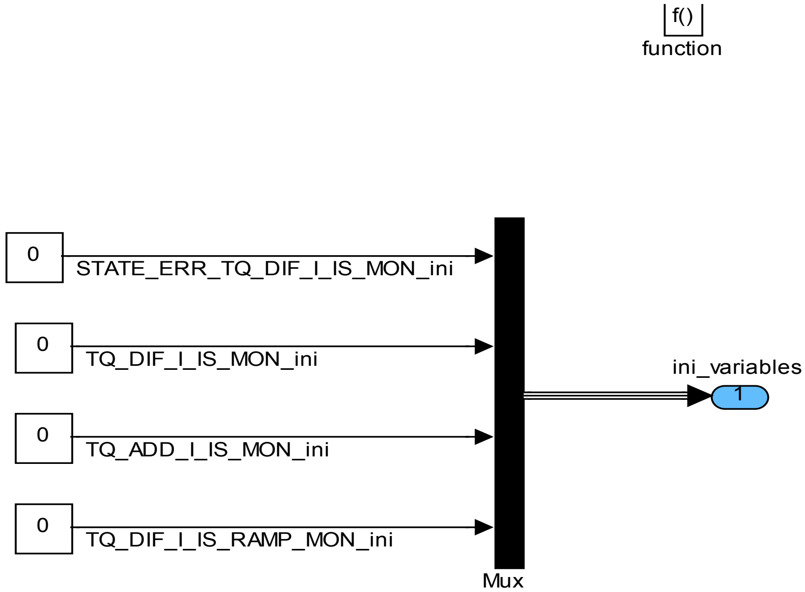

Figure 20 ECM2_DTSYSISC/ Monitoring_of_I_part/ Initialisation

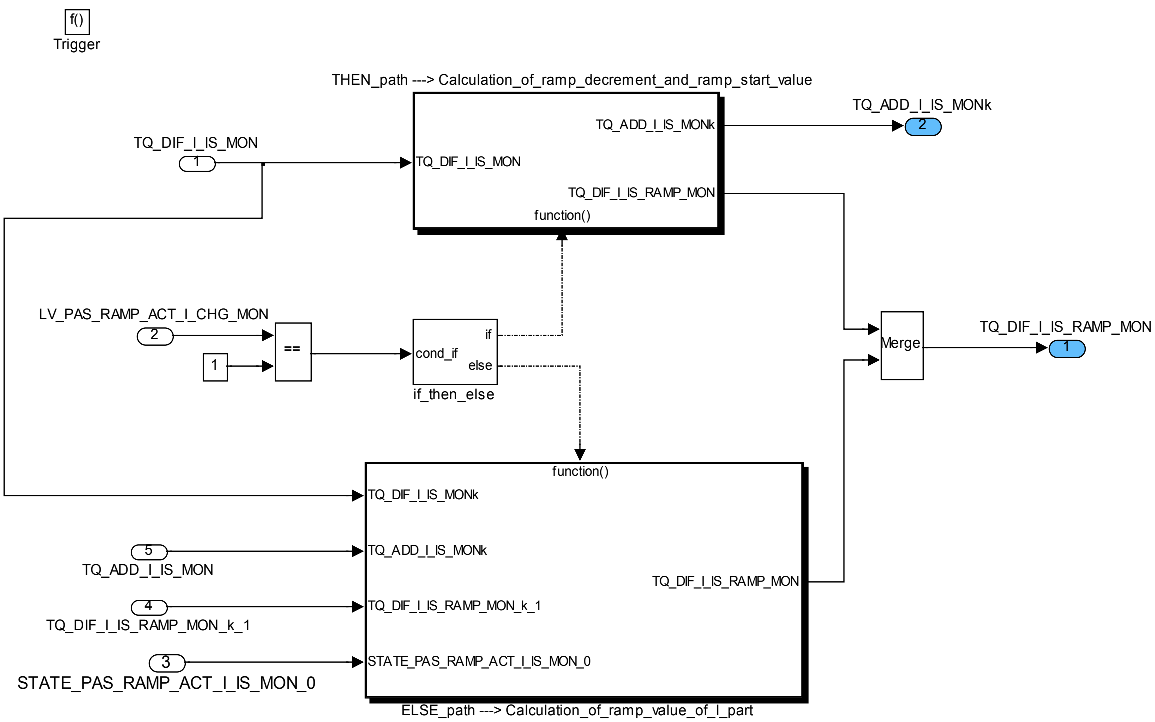

Figure 21 ECM2_DTSYSISC/ Monitoring_of_I_part/ Ramp_calculation

Note: The minimum I-ramp increment/decrement is equal to the resolution of TQ_ADD_I_IS_MON (0.03125Nm). If the theoretically calculated **absolute value** of TQ_ADD_I_IS_MON is ***smaller* than the resolution and not equal to zero**, then is to be limited to the resolution.This would lead to a faster ascent/descent of the deactivation ramp i.e. shorter ramp time. If the theoretical value of TQ_ADD_I_IS_MON is equal to zero, this value is then maintained.

For e.g: theoretical value = -0.04 Nm ---> Limited value = -0.03125 Nm
theoretical value = -0.01 Nm ---> Limited value = -0.03125 Nm
theoretical value = 0.04 Nm ---> Limited value = 0.0625 Nm
theoretical value = 0.01 Nm ---> Limited value = 0.03125 Nm

E.15.1 ECM2_DTSYSTQLO

Import actions:

ACTION_ECM3_Service6TaskPfm(IN<n>)
ACTION_ECM3_Service7TaskPfm(IN<n>)

Note: This actions are defined in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument n has the value 2.

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>, IN <reg>)
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Note: This actions are defined in chapter "Processor Monitoring", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

General information:

The objective of this function is the monitoring of the torque losses. It observes both level 1 values, TQ_LOSS and TQ_LOSS_REQ_CLU (filtered TQ_LOSS without pumping losses), that is exclusively used for the determination of TQ_MIN_CLU and TQ_MAX_CLU.

It has to be distinguished between engine immanent torque losses (e.g. TQFR) and not engine immanent torque losses (e.g. TQ_LOSS_ACC), that are determined in the module "Appl. Inc. and configuration of process monitoring".

A fault is detected after debouncing, if the monitored torque losses are smaller than the modelled ones or the difference between TQ_LOSS and TQ_LOSS_REQ_CLU is greater than a calibratable threshold (maximum pumping losses).

ACTION_ECM3_Service8TaskPfm(3)
ACTION_ECM3_Service9TaskPfm(3)

Note: These actions are defined in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument has the value 3.

ACTION_ECM3_WriteChkCpl(IN<type>,INOUT<xyz_MON>, OUT<xyz_MON_CPL>, IN reg>)
ACTION_ECM3_ChkCpl(IN<type>, IN<xyz_MON>, IN<xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN<type>, OUT <reg>, IN<xyz_MON>, IN<xyz_MON_CPL>)

Note: These actions are defined in chapter "Processor Monitoring", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

General information:

The objective of this function is the monitoring of the minimum torque at clutch. The model takes into account that a great part of the minimum torque at clutch could be the integral part of the ISC. Therefore the difference of monitored minimum torque at clutch and I-part of ISC is compared to a torque *threshold* which is dependent on:**1)** the engine self stabilising factor (function of ratio between engine speed and idle speed setpoint) **2)** TQ_LOSS_REQ_CLU_MON and **3)** TQ_CONV_MAX_MON. For engine speeds above idle speed setpoint this difference must be negative. For speeds below idle speed setpoint great values for minimum torque at clutch are allowed.

One exception of the above mentioned rule is at engine start. If the engine is in start phase, an constant additive term is taken into account for the threshold (see also "Chapter D – Minimum Torque at Clutch"). To monitor this start torque term, the actual engine speed is compared to an upper threshold for the engine start end-speed. In addition to the I-part of ISC, the two other factors influencing the minimum torque at clutch are hydraulic torque losses inside the converter of an automatic gearbox - TQ_CONV_MAX_MON (which depends on coolant temperature and idle speed setpoint) and the minimum requested indicated torque in the PU phase - TQI_MIN_REQ_PU_MON. However, if the engine is in PU or PUC mode TQ_MIN_ CLU_MDL is set to minimum possible torque that the driver can request i.e. TQ_LOSS_MON.

The plausiblisation of the L1 value, TQ_MIN_CLU, against a L2 model value is done based on current engine state. The variable STATE_ERR_DET_TQ_MIN_MON (calculated in the module 'Application incidences of process monitoring') is used to switch between the different error-detection paths. If the engine is in PU or PUC and the L1 minimum torque at clutch value is greater than TQ_LOSS_MON, then an error state is set. If however the engine is neither in PU or PUC, then the L1 value is compared to the L2 model value TQ_MIN_CLU_MDL_4_MON. If any of the error states are set, a fault is detected after debouncing.

Note: These actions are defined in chapter "Processor Monitroing", subsection "RAM test on MC for processor monitoring". All variables with Mode "O" and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

General information:

The objective of this function is the monitoring of the maximum torque at clutch. The maximum torque at clutch is compared to a model threshold value (TQ_MAX_CLU_MAX_MON). The factors influencing this threshold are: IP_TQI_REF_MAX_MON (the worst case condition i.e. maximum possible fresh air entering in the cylinder is taken into account inside this map) and TQ_LOSS_REQ_CLU_MON. A fault is detected after debouncing, if the maximum torque at clutch exceeds this threshold.

Non calibratable data for N_32_SUB_MON calculation					

E.19.1 FUNCTION PART: ECM2_DTSYSN

General information:

The comparison of the engine speed N_32 to an engine speed substitute N_32_SUB_MON, calculated in the monitoring level, performs the monitoring of the engine speed used in the monitoring level.

N_32_SUB_MON is calculated from a segment timing information that is generated by a software timer solution in the BSW (T_SEG_SW). The software timer is triggered by crankshaft segments and produces time stamps for the trigger events. From these timing informations the signal T_SEG_SW is determined (resolution: 1µs).

The engine speed signals N_32 and N_32_SUB_MON are compared to each other by means of a relative deviation. The ratio of the difference of N_32 and N_32_SUB_MON related to the minimum of the two values is not allowed to deviate more than the maximum difference IP_N_32_DIF_REL_MAX_MON, depending on MAX_N_32 value. Otherwise a process fault is assumed.

On an error free system N_32 is copied to N_32_MON. If an engine speed error is detected, the maximum value of N_32 and N_32_SUB_MON is copied to N_32_MON to prevent from a sleeping fault in the module ‚Monitoring of engine speed limitation'.

Note: This version of engine speed monitoring is for systems where a second hardware timer, which in other versions was delivering the signal SEG_T_MES, is not available on the ECU and where the missing timer is substituted by a software timer solution in the BSW.

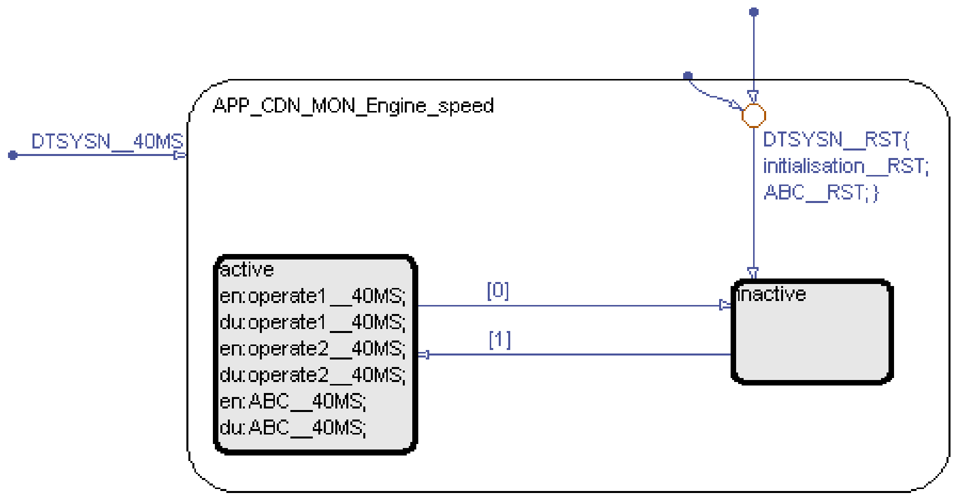
For configuration data:

NC_T_SEG_N_32_CLC is a constant for the calculation of N_32_SUB_MON from T_SEG_SW:

$$NC\_T\_SEG\_N\_32\_CLC = \frac{2*60*1000000}{NC\_CYL\_NR*\{resol.\ of\ \ N\_32\_SUB\_MON\}}$$

with *NC_CYL_NR* : number of cylinders

Application Condition



Note: DTSYSN__RST includes the function calls as defined in application incidences.

E.20.1 ECM2_DTSYSPVS

Import actions:

ACTION_ECM3_Service2TaskPfm(2)
ACTION_ECM3_Service3TaskPfm(2)

Note: These actions are defined in chapter "Processor Monitoring", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument has the value 2.

ACTION_ECM3_WriteChkCpl(IN<type>, INOUT<xyz_MON>, OUT<xyz_MON_CPL>, IN<reg>)
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN<type>, OUT<reg>, IN<xyz_MON>, IN<xyz_MON_CPL>)

Note: These actions are defined in chapter "Processor Monitoring", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

General information:

The pedal value diagnosis is made in the monitoring level in order to check the V_PVS input value of the torque monitoring function (level 2).

After the diagnosis, a resulting pedal value PV_AV_MON is used as input for the torque monitoring function.

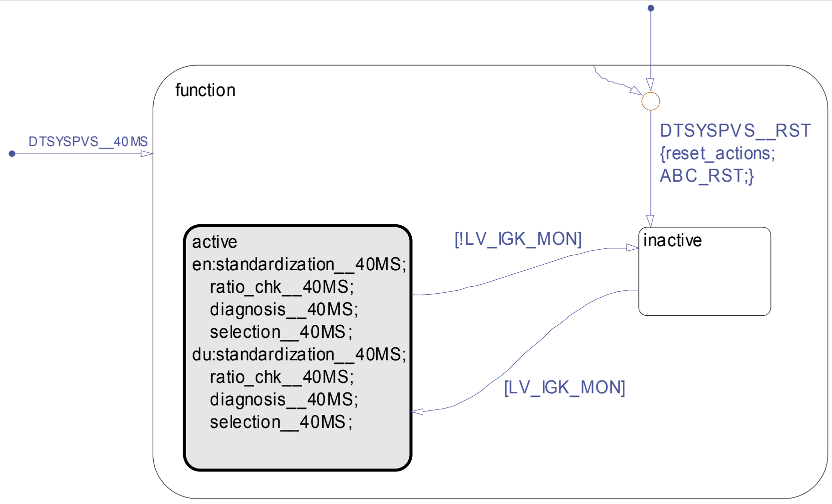
A malfunction of level 1 will be assumed, if a ratio error of the two redundant pedal values is diagnosed after debouncing, yet no PVS failure was detected previously by the PVS diagnosis function of level 1. The following errors were detected:

- The difference between the standardized values PV_AV_1_MON and PV_AV_2_MON is too large.
- The diagnosis system of level 2 detects a PVS ratio fault and no fault is detected by the diagnosis of level 1.
- Any PVS error-BIT of the PVS diagnosis in level 1 has been reset without permission.

To ensure that the PVS diagnosis of level 1 detects a fault earlier than the PVS ratio diagnosis of level 2, the fault detection time of the diagnosis function in level 2 has to be adjusted that it exceeds the fault detection time of level 1. Therefore, all level 1 PVS diagnosis thresholds, all constants of the debounce counters and the cycle time have to be taken into account.

The input values V_PVS_1_BAS and V_PVS_2_BAS are directly read from the A/D-converter buffer.

Application Condition



***Initialisation(DTSYSPVS__RST)*:** for condition see 'Application Incidences of Process Monitoring'.

Function Description

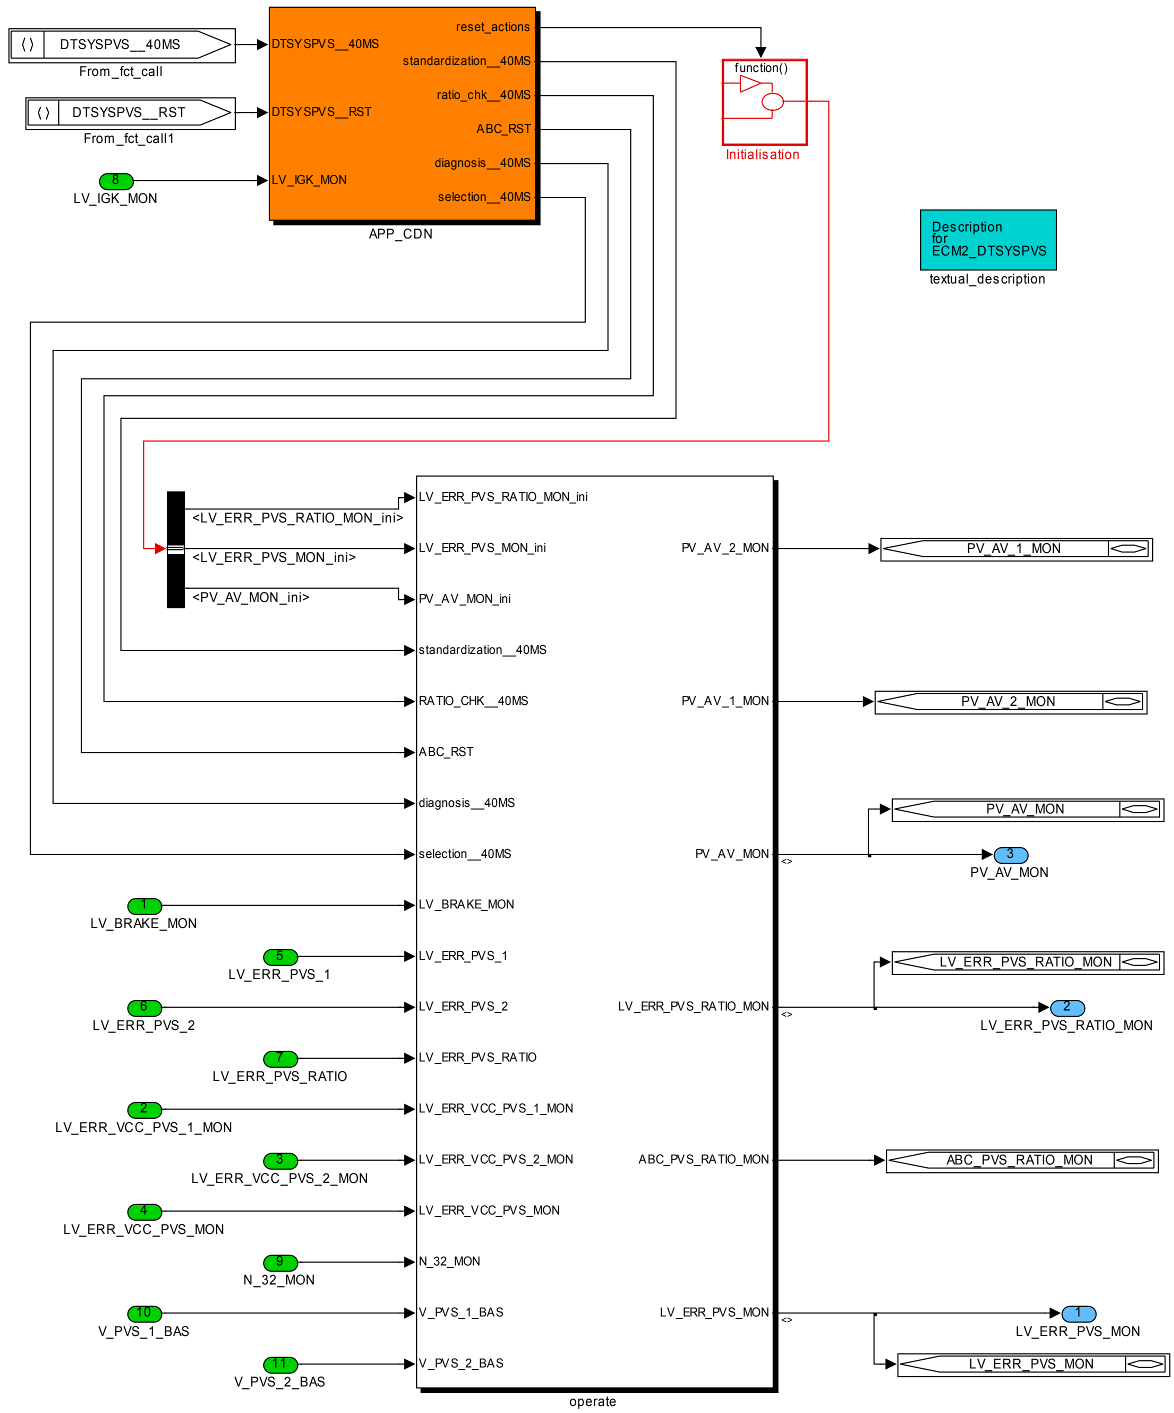


Figure 52 Monitoring functionality overview

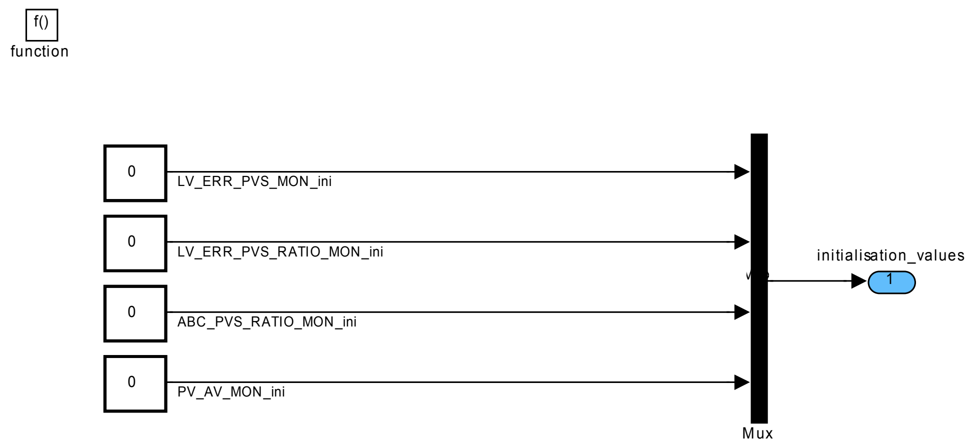

Figure 53 ECM2_DTSYSPVS/ Initialisation

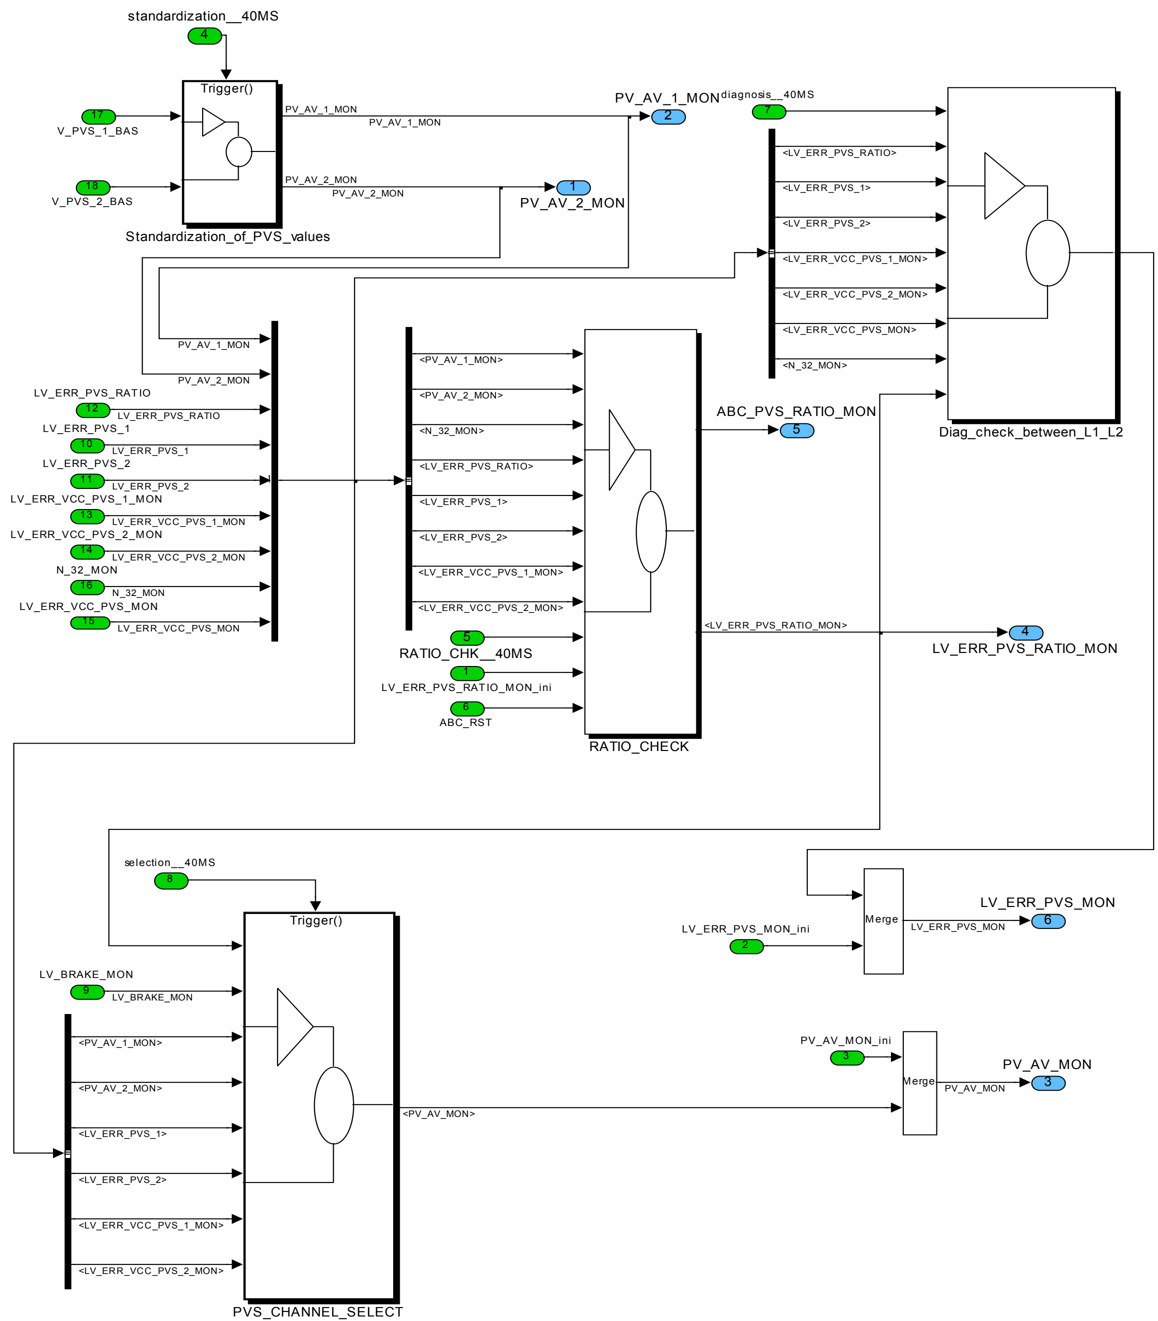

Figure 54 ECM2_DTSYSPVS/ operate

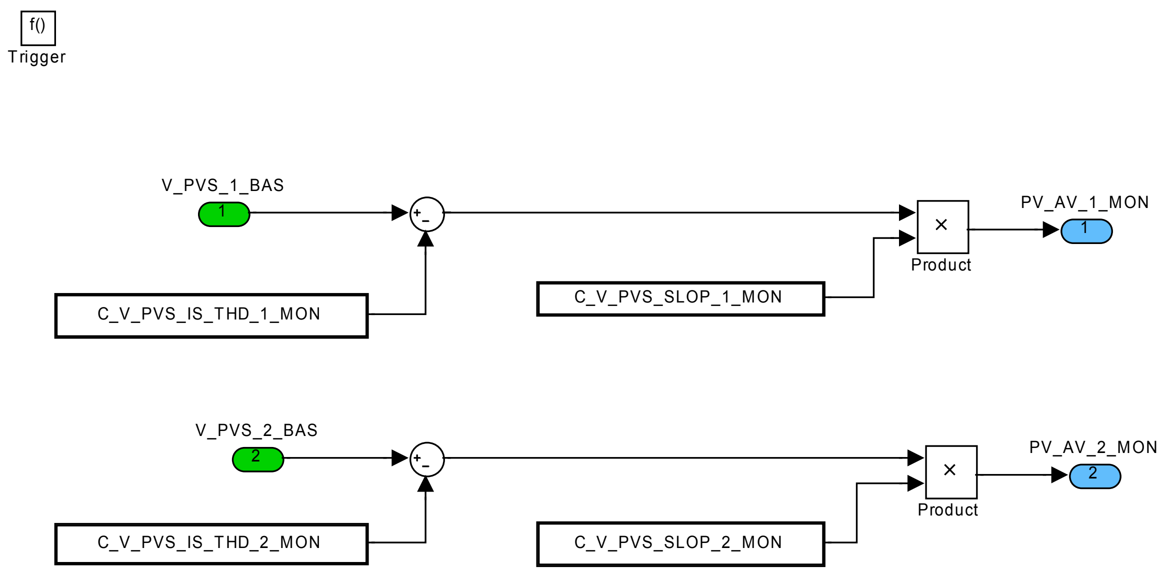

Figure 55 ECM2_DTSYSPVS/ operate/ Standardization_of_PVS_values

ECM2_DTSYSPVS/OPERATE/RATIO_CHECK

Both sensors of the PVS-system supply output signals, which are standardized between 0 and 99.6 %. In case of an error-free system (no signal range error detected), the difference between the standardized values PV_AV_1_MON and PV_AV_2_MON is not allowed to be greater than IP_PV_RATIO_HYS_MON.

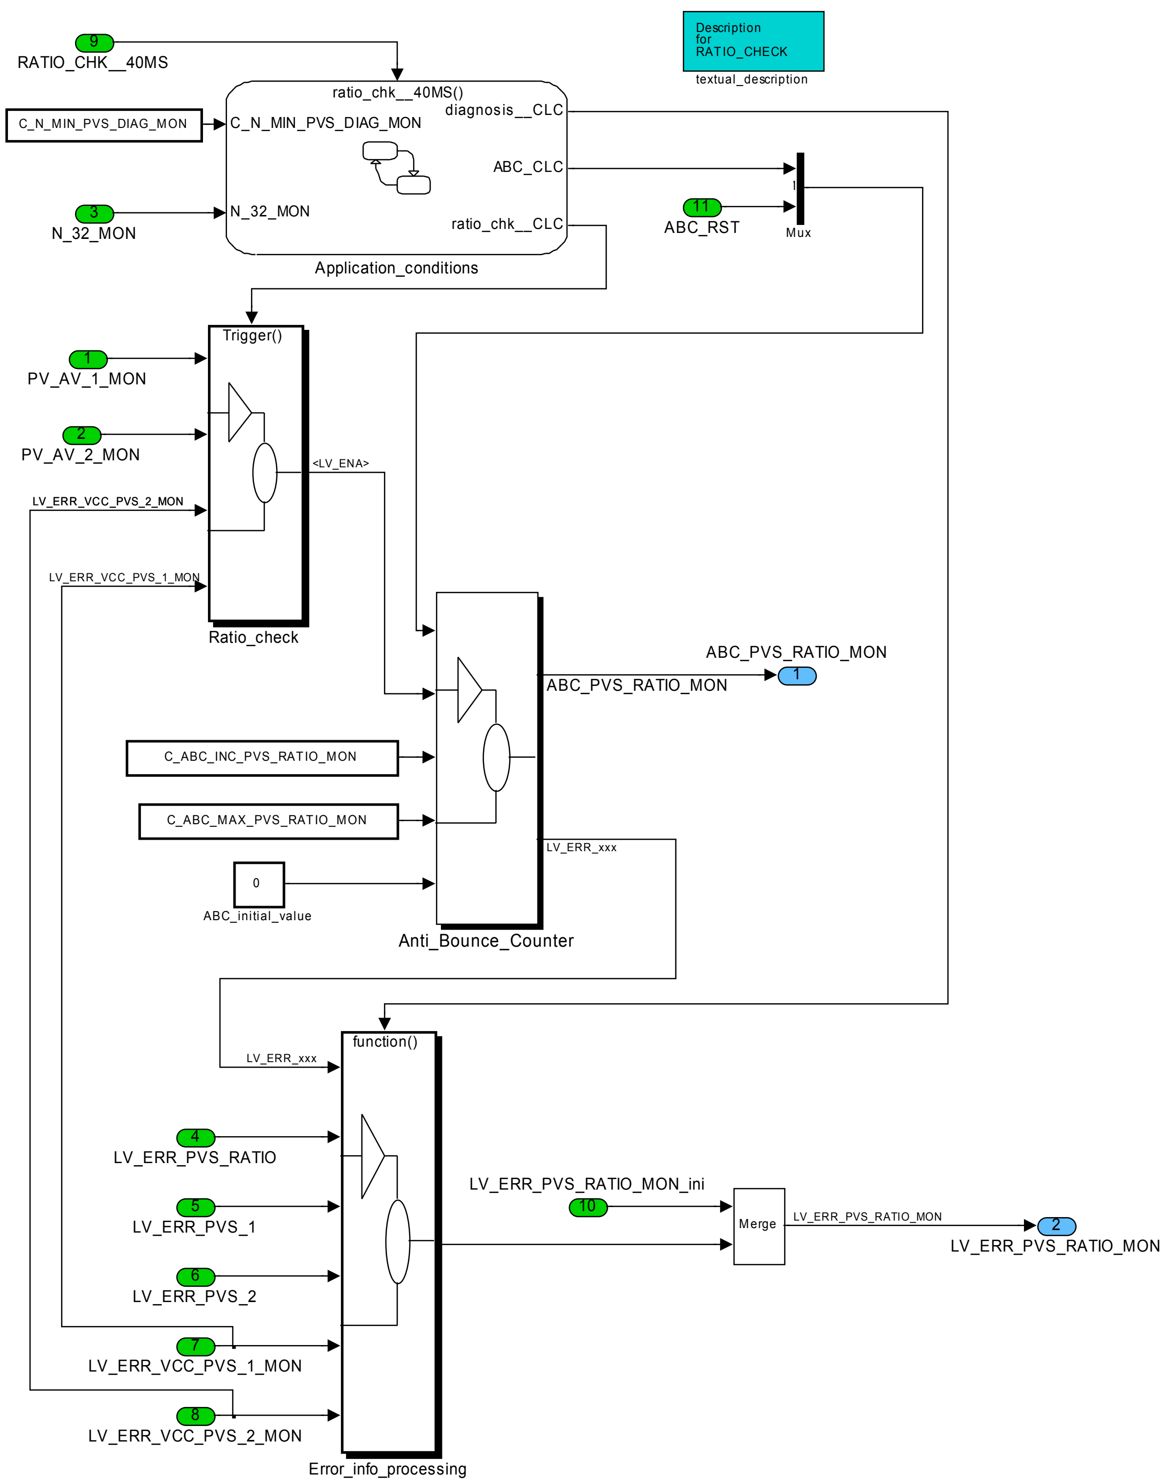

Figure 56 ECM2_DTSYSPVS/ operate/ RATIO_CHECK

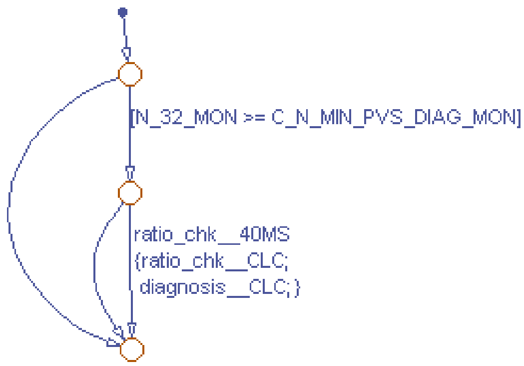

Figure: ECM2_DTSYSPVS/ operate/ RATIO_CHECK/Application_conditions

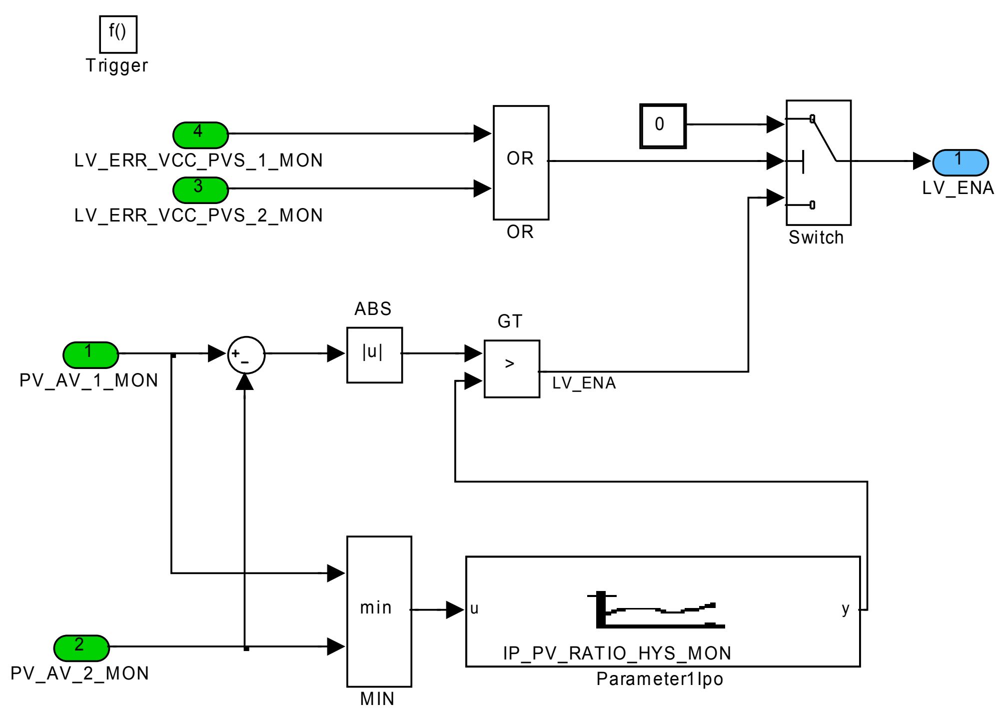

Figure 57 ECM2_DTSYSPVS/ operate/ RATIO_CHECK/ Ratio_check

ECM2_DTSYSPVS/OPERATE/RATIO_CHECK/ERROR_INFO_PROCESSING

The bits LV_ERR_VCC_PVS_1_MON and LV_ERR_VCC_PVS_2_MON are reversible. That means, the output LV_ERR_PVS_RATIO_MON has to be reversible also.
All PVS error information of the function level is considered. This allows the different process levels to be based on the same error information:

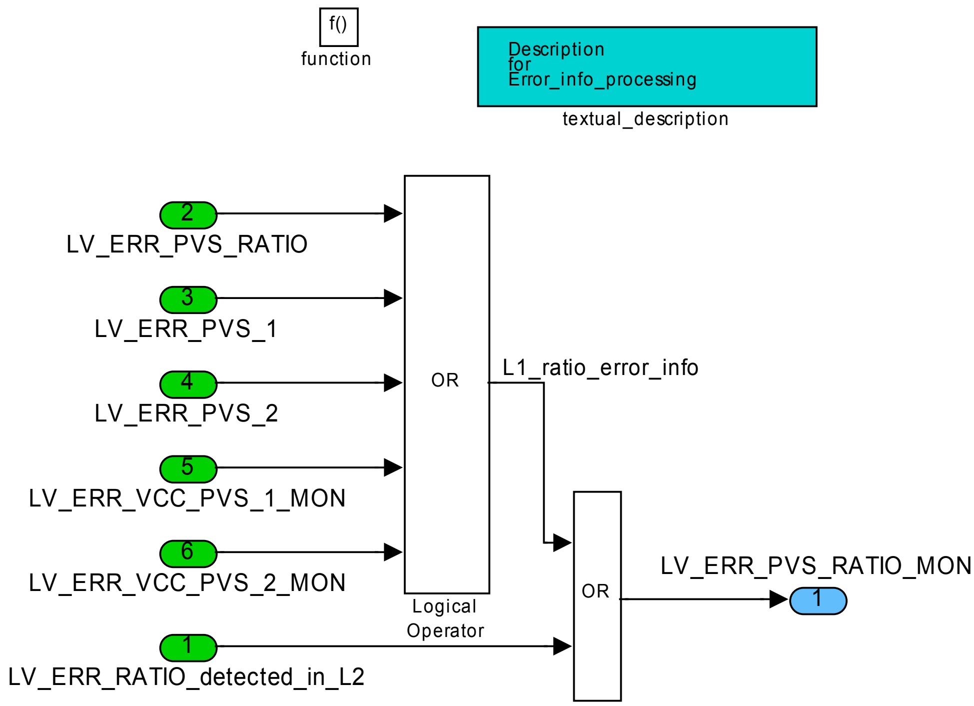

Figure 58 ECM2_DTSYSPVS/ operate/ RATIO_CHECK/ Error_info_processing

ECM2_DTSYSPVS/OPERATE/DIAG_CHECK_BETWEEN_L1_L2

If any PVS ratio error is detected in level 2 and no PVS error is detected in level 1, a fault of the PVS diagnosis in level 1 will be assumed.

There is also a check, whether an error-BIT of the PVS diagnosis in level 1 was reset without permission. This is done by using the result of LV_ERR_PVS_RATIO_MON of the last recurrence.

LV_ERR_VCC_PVS_MON is assumed to be a PVS supply voltage error flag of a level 2 diagnosis in case of any PVS supply voltage error.

LV_ERR_VCC_PVS_1_MON and LV_ERR_VCC_PVS_2_MON are error flags that result from Level 1 diagnosis of PVS-1 and PVS-2 supply voltage and are assigned to the

LV_ERR_VCC_PVS_1_MON and LV_ERR_VCC_PVS_1_MON respectively in the application incidences of process monitoring.

If an PVS monitoring error is detected and the error bit LV_ERR_PVS_MON is set, then this bit must not be reversible.

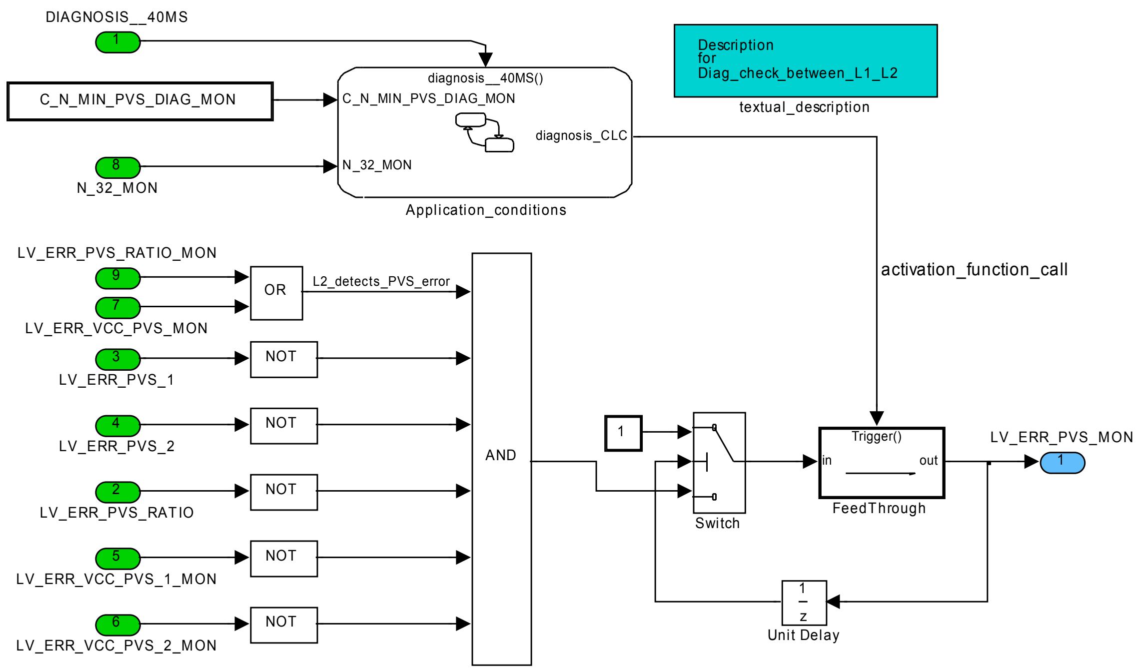

Figure 59 ECM2_DTSYSPVS/ operate/ Diag_check_between_L1_L2

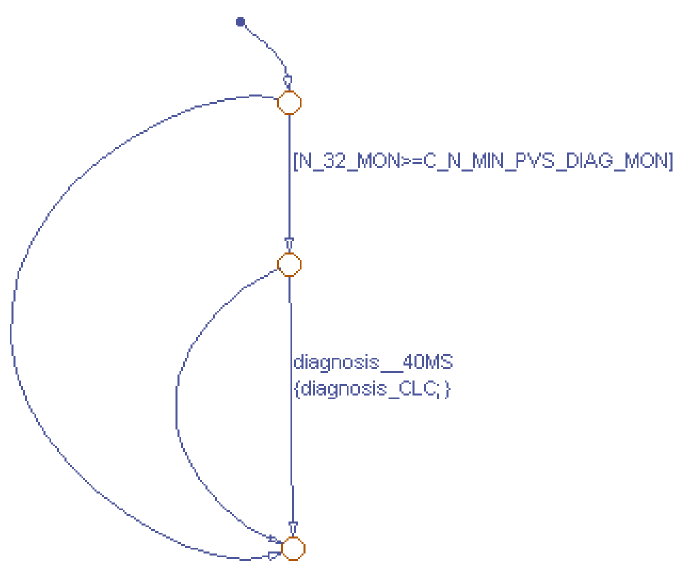

Figure: ECM2_DTSYSPVS/ operate/ Application_conditions

ECM2_DTSYSPVS/OPERATE/PVS_CHANNEL_SELECT

Depending on the plausibility, the degree of pedal activation PV_AV_MON is defined by the signals PV_AV_1_MON and PV_AV_2_MON, as follows:

Error Level	Error bits set	Analysis, error handling
0	-	PV_AV_MON = PV_AV_1_MON
1	LV_ERR_PVS_RATIO_MON	PV_AV_MON = MIN(PV_AV_1_MON, PV_AV_2_MON) (minimum)
2	LV_ERR_PVS_1 **OR** LV_ERR_VCC_PVS_1_MON	PV_AV_MON = PV_AV_2_MON (selection)
3	LV_ERR_PVS_2 **OR** LV_ERR_VCC_PVS_2_MON	PV_AV_MON = PV_AV_1_MON (selection)
4	(LV_ERR_PVS_1 OR LV_ERR_VCC_PVS_1_MON) **AND** (LV_ERR_PVS_2 OR LV_ERR_VCC_PVS_2_MON)	PV_AV_MON = 0 → driver demand not recoganizable

If any PVS error-BIT is set:

- PV_AV_MON will be limited to C_PV_LIH_MAX_MON.
- Use of the brake as a redundant driver demand:

  IF (LV_BRAKE_MON = 1)

  THEN

  PV_AV_MON = 0 (same as Error level 4)

ACTION_ECM3_Service5TaskPfm(2)

Note: This actions are defined in chapter "Processor Monitroing", subsection "Program Flow Monitoring services for Process Monitoring". The first action has to be executed as first instruction in this module, the second action has to be executed as last instruction of this module. The argument has the value 2.

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>, IN <reg>)
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Note: This actions are defined in chapter "Processor Monitroing", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

Note: the output variables V_TPS_x_MON are not checked by the RAM test of process monitoring (level 2') but are only used for error memory storage.

FUNCTION DESCRIPTION:

General information:

The ETC safety concept checks whether the level 1 mass air flow signal MAF is determined properly by the intake manifold model. In case that the value is correct it always exceeds a the level 2 value MAF_SUB_MON.

MAF_MON is equal to the high byte of the level 1 value MAF.

The variable MAF_MON is used for calculating the actual indicated engine torque TQI_AV_MON. Therefore it has to be checked that MAF_MON does not fall under the value of the physically present mass air flow. In case that the MAF_MON is smaller than the faultless one the torque monitoring function of the ETC safety concept (refer to the module "Monitoring of actual indicated engine torque" becomes less sensitive.

An additional TPS ratio check is performed. This function checks if any TPS failure has been detected in level 1 when a TPS ratio error is recognized in level 2.

Signal flow diagram:

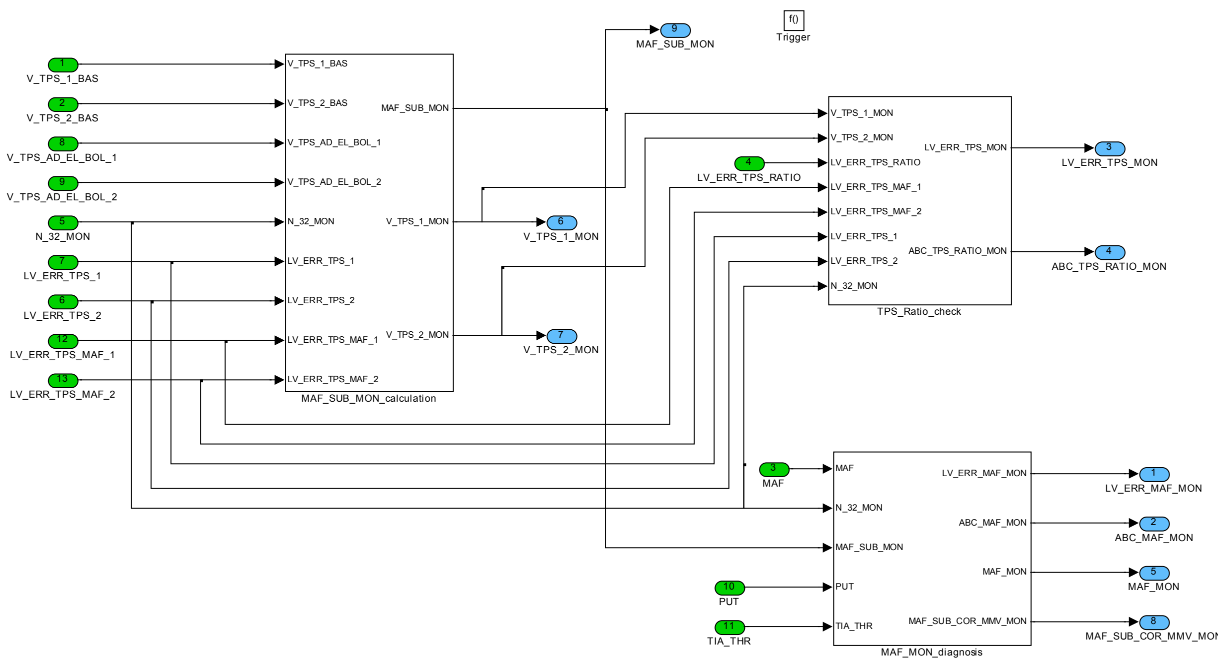

Figure 1: Monitoring of mass air flow signal (MAF_MON)Description:

Application conditions:

Activation:	*LV_TQI_MON_ACT_MON = 1*
Deactivation:	*otherwise*
Initialization:	*for condition see 'Application Incidences of Process Monitoring'*
	LV_ERR_TPS_MON = 0
	ABC_TPS_RATIO_MON = 0
	LV_ERR_MAF_MON = 0
	ABC_MAF_MON = 0
	MAF_MON = 0
	MAF_SUB_COR_MMV_MON = 0
	At deactivation:
	MAF_SUB_COR_MMV_MON(k) = 0
Update Rate:	*40 ms*

E.21.1 Mass air flow substitute (MAF_SUB_MON) calculation

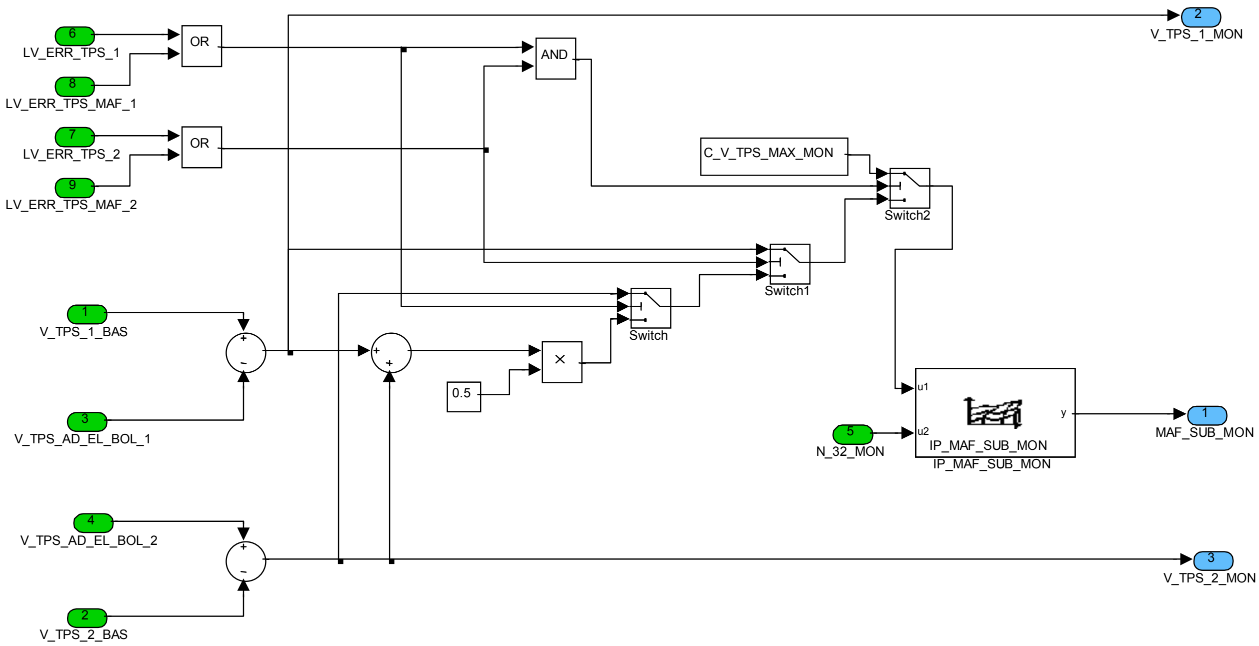

Figure 2: MAF_SUB_MON calculation

To reduce the tolerance of the MAF substitute signal MAF_SUB_MON the adapted voltage (V_TPS_AD_EL_BOL_x) of the lower limit of the TPS actuator is taken into consideration.

The TPS channel used for the mass air flow substitute calculation MAF_SUB_MON is selected according to the following table.

Error level	Error bits set	TPS channel used
0	-	AVERAGE(V_TPS_1_MON. V_TPS_2_MON)
1	LV_ERR_TPS_1 **or** LV_ERR_TPS_MAF_1	V_TPS_2_MON (selection)
2	LV_ERR_TPS_2 **or** LV_ERR_TPS_MAF_2	V_TPS_1_MON (selection)
3	(LV_ERR_TPS_1 **or** LV_ERR_TPS_MAF_1) and (LV_ERR_TPS_2 **or** LV_ERR_TPS_MAF_2)	TPS voltage set to: C_V_TPS_MAX_MON (max. voltage)

A higher error level always has higher priority to any lower error level: in case that LV_ERR_TPS_1 and LV_ERR_TPS_2 occur at the same time, the current TPS value is set to a substitute value C_V_TPS_MAX_MON. In case that level 1 has not detected any TPS failures, TPS is set to the mean average value calculated on basis of the measured TPS values V_TPS_1_MON and V_TPS_2_MON (refer to the module TPS_SEG).

E.21.2 MAF_MON diagnosis

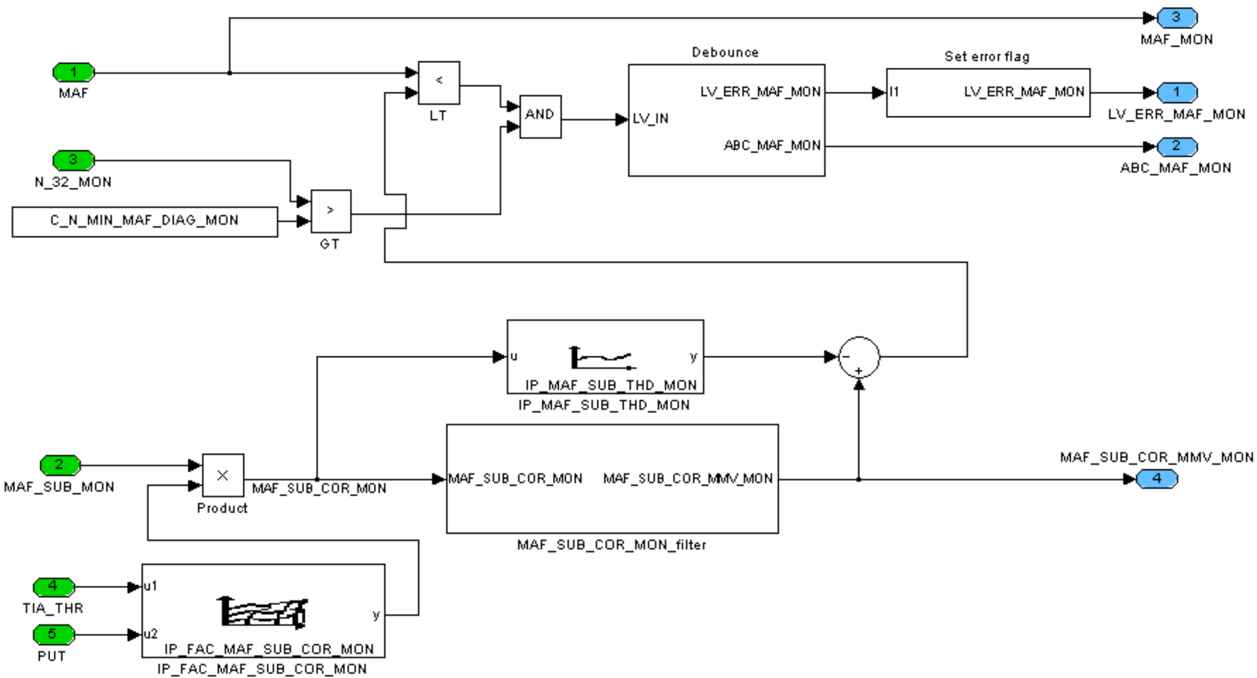

Figure 3: MAF_MON diagnosis

The high byte of the MAF signal being calculated by the intake-manifold-model is copied to MAF_MON for the use in further modules of the process monitoring (MAF_HB which is provided by the intake-manifold model as well is not used for the MAF monitoring to ensure that the level 1 functions and the related level 2 functions are working with consistent values).

For the diagnosis the MAF_MON signal is compared to a mass air flow substitute value MAF_SUB_COR_MMV_MON which is affected by the current engine speed N_32_MON, the current throttle position signal and ambient conditions (intake air temperature TIA_THR, pressure at throttle PUT). MAF_MON is not allowed to be smaller than a value MAF_SUB_COR_MMV_MON reduced by a correction value determined by IP_MAF_SUB_THD_MON.

The failure diagnosis becomes active in case that a certain engine speed has been reached to eliminate the inaccuracy both of the measured mass air flow meter in case of low engine speed and the inaccuracy of the reduced map (IP_MAF_SUB_MON).

To adapt the calculated signal to the dynamics of the intake manifold system (the air mass flow) a low pass filter for rising signals has been installed.

Formula section

The MAF signal is copied to the process monitoring (Level 2) RAM:

MAF_MON = MAF

MAF_SUB_COR_MON = MAF_SUB_MON • IP_FAC_MAF_SUB_COR_MON(TIA_THR.PUT)

BLOCK 1: MAF_SUB_COR_MON filter:

IF

(MAF_SUB_COR_MON > MAF_SUB_COR_MMV_MON(k-1))

THEN

MAF_SUB_COR_MMV_MON(k) =
MAF_SUB_COR_MMV_MON(k-1) * (1-C_MAF_SUB_CRLC_MON)
+ MAF_SUB_COR_MON(k) * C_MAF_SUB_CRLC_MON

ELSE

MAF_SUB_COR_MMV_MON(k) = MAF_SUB_COR_MON

Error recognition:

IF

(N_32_MON > C_N_MIN_MAF_DIAG_MON)
AND
(MAF_MON < (MAF_SUB_COR_MMV_MON – IP_MAF_SUB_THD_MON))

THEN

After debounce. a MAF_MON error is recognized and

LV_ERR_MAF_MON is set.

Increment: C_ABC_INC_MAF_MON

Maximum value: C_ABC_MAX_MAF_MON

E.21.3 TPS ratio check

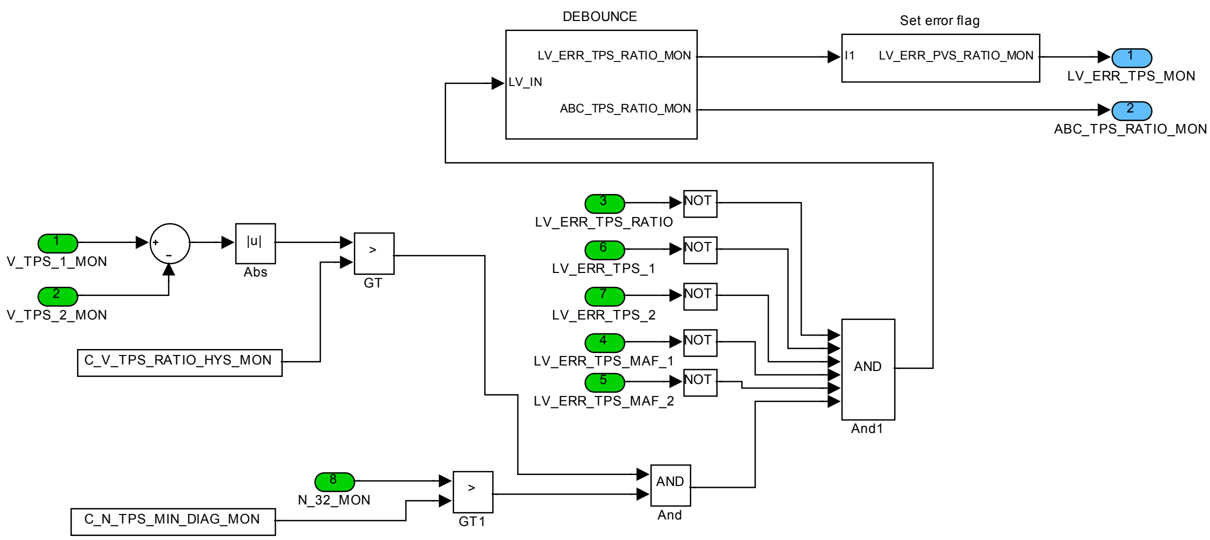

Figure 4: TPS ratio check

In a properly working system the difference between TPS channel 1 and TPS channel 2 is not allowed to exceed the threshold C_V_TPS_RATIO_HYS_MON.

Formula section:

Error recognition:

IF

(ABS(V_TPS_1_MON - V_TPS_2_MON) > C_V_TPS_RATIO_HYS_MON) AND
(N_32_MON > C_N_MIN_TPS_DIAG_MON) AND
(LV_ERR_TPS_RATIO = 0) AND
(LV_ERR_TPS_1 = 0) AND
(LV_ERR_TPS_2 = 0) AND
(LV_ERR_TPS_MAF_1 = 0) AND
(LV_ERR_TPS_MAF_2 = 0)

THEN

After debounce. LV_ERR_TPS_MON is set.

Increment: C_ABC_INC_TPS_RATIO_MON

Maximum value: C_ABC_MAX_TPS_RATIO_MON

Level 1 is assumed to detect a TPS ratio error earlier than Level 2. In case that error detection of level 1 fails a process monitoring fault is assumed and the error bit LV_ERR_TPS_MON is set.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Delay time for disable of cruise control charge demand in monitoring level					
C_VS_MIN_CRU_MON	1	0 ... FF H	0 ... 255	2	km/h
Minimum threshold for vehicle speed control active					

FUNCTION DESCRIPTION:

General information:

The cruise control function is able to request a lot of torque and to accelerate the car up to high speed. In order to avoid dangerous situations caused by a fault of the cruise control function, the main activation/deactivation conditions are monitored within the etc safety concept. Therefore the basic signals from the main switch and the brake are evaluated.

Application conditions:

Activation: LV_TQI_MON_ACT_MON = 1 and CONF_CRU = 1

Deactivation: otherwise

At deactivation, FAC_TQ_REQ_CRU_MON = 0

Initialisation (Must be done before activation of the function):

LV_CRU_INH_MON = 0

ABC_CRU_INH_MON = 0

T_CRU_INH_MON = 0

FAC_TQ_REQ_CRU_MON = 0

Update Rate: 40 ms

Formula section:

FAC_TQ_REQ_CRU_MON = FAC_TQ_REQ_CRU

IF LV_CRU_ACT = 1

THEN

  IF LV_CRU_INH_MON = 0

  THEN

    Initialize Timer: T_CRU_INH_MON = C_T_CRU_INH_MON

    IF LV_CRU_MAIN_SWI = 0 **OR**

      LV_BRAKE_MON = 1 **OR**

      VS < C_VS_MIN_CRU_MON

    THEN after debouncing with ABC_CRU_MON

      Inhibit cruise control non reversible until the initialization conditions for error bits are fulfilled (see application incidences for process monitoring)

      LV_CRU_INH_MON = 1

      FAC_TQ_REQ_CRU_MON = 0

    ENDIF

ELSE

  IF T_CRU_INH_MON = 0

  THEN

    FAC_TQ_REQ_CRU_MON = 0

  ELSE

    Decrement Timer T_CRU_INH_MON

  ENDIF

ENDIF

Anti-bounce counter: ABC_CRU_INH_MON

Anti-bounce counter increment: C_ABC_INC_CRU_INH_MON

Anti-bounce counter maximum: C_ABC_MAX_CRU_INH_MON

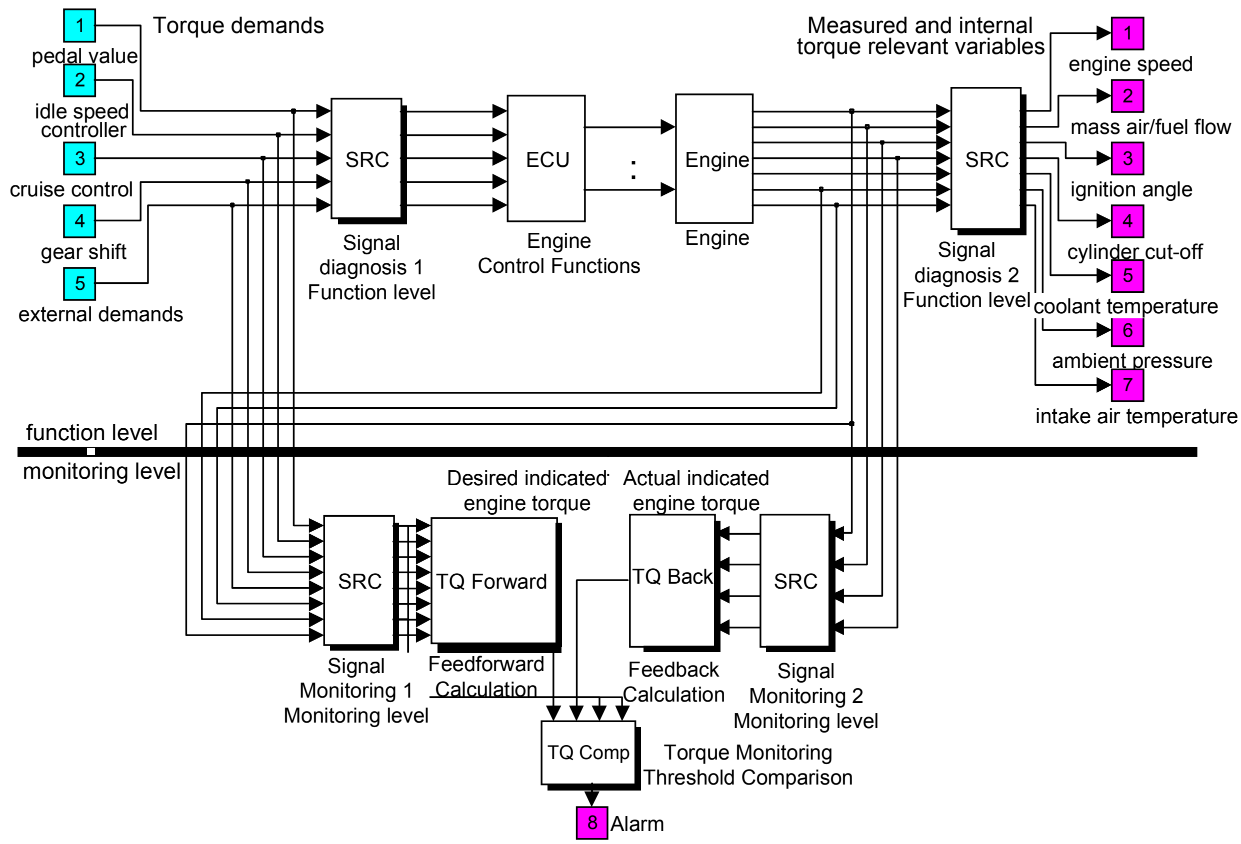
E.23 Torque Monitoring Overview

In the function level the various torque demands coming from the driver, the idle speed controller etc. are co-ordinated to a resulting quantfied charge setpoint. At the same time the actual indicated engine torque is calculated based on several measured and internal torque relevant variables.

The aim of the torque monitoring is to detect an increased actual indicated engine torque compared to the desired indicated engine torque. Therefore the co-ordination of the various torque demands and the calculation of the actual indicated engine torque done in the function level (level 1) is performed once again in the monitoring level (level 2), however with a simplified structure. Then the deviation between the actual (TQI_AV_MON) and the desired indicated engine torque (TQI_SP_MON) is checked for exceeding a threshold.

Signal flow diagram:

Overview



E.24 Desired indicated engine torque

Note: This actions are defined in chapter "Processor Monitroing", subsection "RAM test on MC for processor monitoring". All variables with Mode “O” and history variables in modules of the *Process Monitoring* have to be checked by the cyclical RAM test.

General information:

The objective of this module is to calculate the desired indicated engine torque which derives from the function level (level 1). All torque increasing demands are taken into account. The differents parts are:

- calculation of scaling factor for requested torque at clutch from driver(FAC_TQ_REQ_MON)
- depending on engine speed(N_32_MON) and adapted accelerator pedal activation degree (PV_AV_AD_MON)
- calculation of requested torque at clutch from driver
- adding internal increasing torque demands (TQ_DIF_P_D_IS_MON)
- switch from brake torque to indicated torque demands
- filtering the raw torque demand in falling direction to take into account the system response time (see also figure 1)
- maximum choice between internal and external torque demands
- If the engine is in the trailing throttle state i.e. no driver demand but limitation on indicated engine torque to ensure a safe combustion at low load conditions, then the torque setpoint in L2 is limited by TQI_MIN_PU_MON.

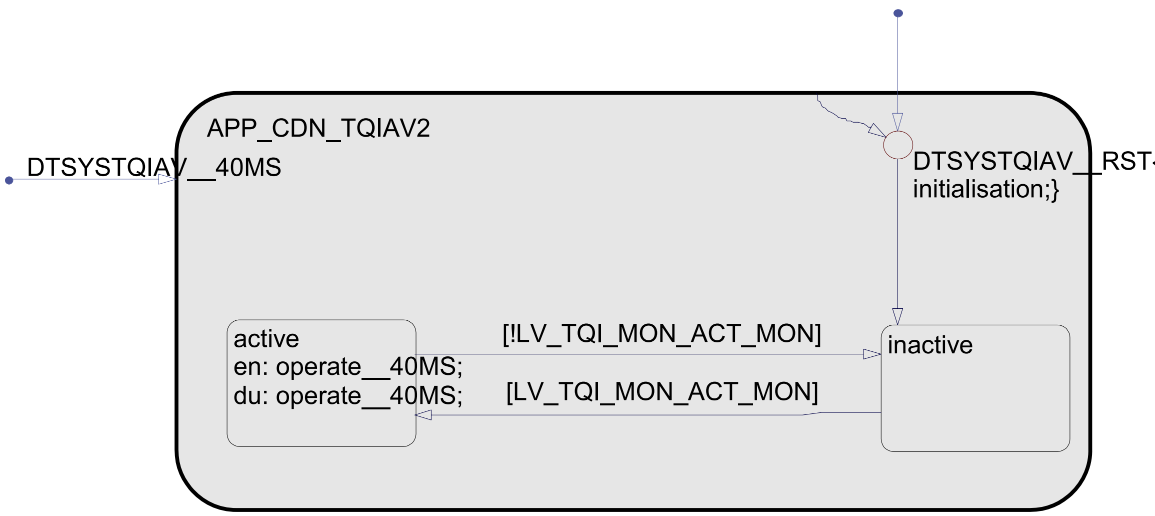
Basic ignition efficiency (process monitoring)

General information:

This module calculates the actual indicated engine torque TQI_AV_MON. Therefore the indicated engine torque TQI_REF_MON at reference conditions is corrected by the mean value IGA_AV_MV_MON of the actual ignition angles IGA_IGC_x. The maps and characteristic curves for reference torque and IGA efficiency represent simplified versions of the original calibration data of the corresponding functions in the control level. Additionally, the efficiency for cylinder cut-off is calculated from severe injection state information and is taken into account.

The calculation of the intermediate value EFF_SCC_1_MON is based on the function level. To monitor the input PREV_STATE_IV, the SUM_INH_INJ as the number for inhibited cylinders is used in EFF_SCC_2_MON. The maximum selection results into SCC – efficiency. To fade out invalid states during engine stop, efficiency calculation only works at engine speed above 32 rpm.

Application conditions



Note: DTSYSTQIAV__RST includes the function calls as defined in application incidences.

Anti bounce counter increment					
C_ABC_MAX_TQI_AV_MON	1	1 ... FF H	1 ... 255	1	-
Maximum value of anti-bounce counter					

General information:

The objective of this module is the comparison of the desired indicated engine torque TQI_SP_MON (feed-forward path) and the actual indicated engine torque TQI_AV_MON (feedback path). In the fault free case, the actual indicated engine torque should not exceed the desired indicated engine torque. A fault is detected after debouncing, when the actual indicated engine torque exceeds the setpoint value by more than a threshold value TQI_DIF_MAX_MON depending on engine speed and the desired torque.

TQI_AV_MON depends on the dynamics of the intake manifold and on the dynamics of the lambda sensor which means that a possible fault cannot be detected before a certain time. Hence for a fast diagnosis TQI_AV_MON is not suitable but can be replaced by TQI_SP which is compared to TQI_SP_MON. In case that TQI_SP_MON differs from TQI_SP by more than a certain value the error bit LV_ERR_TQI_AV_MON is set.

FUNCTION DESCRIPTION:

General information:

The objective of this module is to verify that the related level 1 function 'Engine speed limitation' works correctly. In case that the engine speed exceeds a certain speed level, the level 1 function activates ETC limp home mode (safety fuel cut-off) to protect the engine.

The level 2 function 'Monitoring of engine speed limitation' considers the status of the injection of all cylinders and the engine speed value and the ETC request flag (LV_N_LIM_ETC_MON). This flag is set to 1 if any function requests limp home activation.

In case that the engine speed exceeds the defined level 2 value C_N_MAX_MTC_LIH_THD_MON and limphome mode is requested (LV_N_LIM_ETC_MON = 1) and injection is active in at least one cylinder (PREV_STATE_IV ≠ 0; fuel cut-off is not active!), the related error bit LV_ERR_TQI_N_MAX_MON is set after having waited a certain debounce time defined by C_ABC_MAX_TQI_N_MAX_MON and C_ABC_INC_TQI_N_MAX_MON.
The injection status has to be checked to avoid that level 2 detects a failure in case that the engine speed exceeds the threshold although fuel cut-off has been put into action. This could happen if the vehicle is running down a hill and the engine speed increases because of the engine directly linked to the transmission.

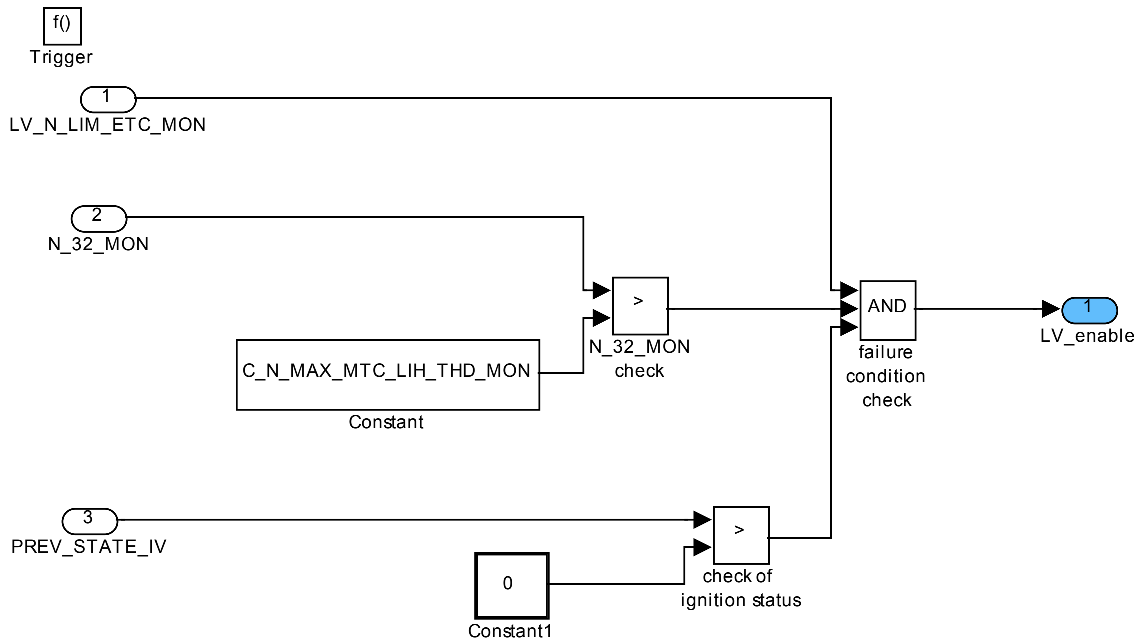

Figure 3 NLIM/ N_LIM_MON

E.28 Processor monitoring by copy of process monitoring (level 2')

General information:

A copy of the main part of the process monitoring (level 2) is built (called level 2') and used as a set of test calculations. The target is to verify the correct behaviour of the process monitoring at any time using predefined test data and comparing the resulting answer to the expected answer stored in a predefined table.

This processor monitoring function includes the monitoring functions described in the table below. However there is no real fault reaction like disable of throttle etc. released.

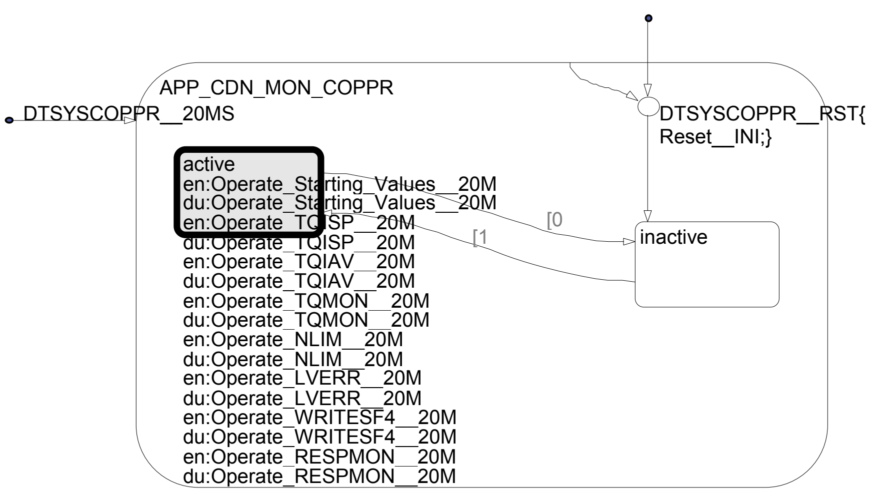
Since the answers of this test caclucations will be undecoded and compared to the predefined table ID_RESP_MON2 (see processor monitoring), it is important to generate a different answer for every index of starting values (NC_TEST_REC_IDX_MAX_MON2 different answers overall). The list of data points for the starting values must contain the indices 0...NC_TEST_REC_IDX_MAX_MON2-1 in ascending order. For detaills see also "Processor Monitoring" and "Processor Monitoring (Appl.Inc.)".

Table of software-code of level 2 modules that is included in level 2':

Module:	Specification:
Desired indicated engine torque	30E00K01.00E
Actual indicated engine torque	30E00L02.00D
Monitoring of actual indicated engine torque	30E00M02.00D
Monitoring of engine speed limitation	30E00I01.00D
Fault reaction of process monitoring	30E00G01.00E

The software-code of the level 2' sub-modules is an exact copy of software-code of the level 2 modules listed in the table above, with exceptions described in the following sub chapters.

Application conditions:



Function Description Overview:

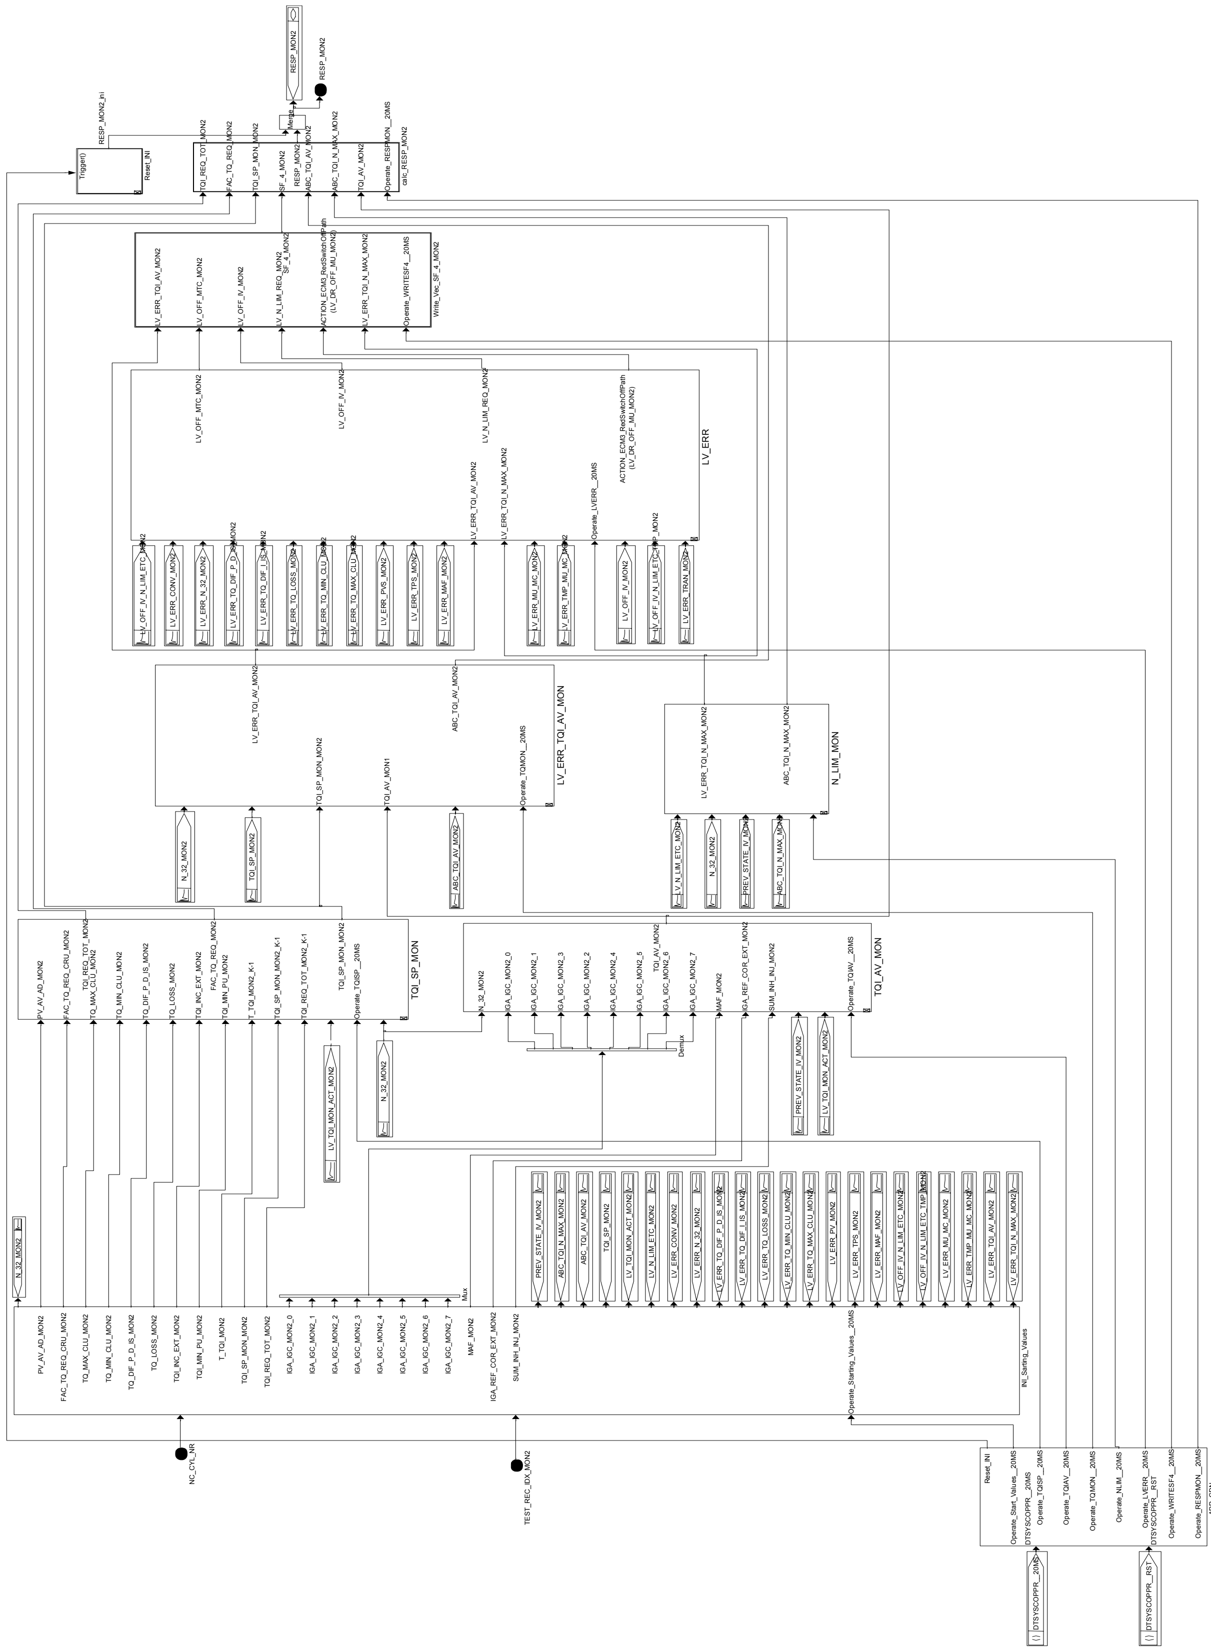


Figure 1 ECM2_DTSYSCOPPR

Desired non-delayed indicated engine torque, old value					
ID_T_TQI_MON2	**NC_TEST_REC_IDX_MAX_MON2**	0 ... FF H	0 ... 10.2	0.04	s
LDPM_TEST_REC_IDX_MON2	**NC_TEST_REC_IDX_MAX_MON2**	0 ... NC_TEST_REC_IDX_MAX_MON2-1	0 ... NC_TEST_REC_IDX_MAX_MON2-1	1	1
Dead time for delay of desired indicated engine torque, old value					

General information:

Based on the number of the question asked by the monitoring unit a corresponding set of starting values for the test caclucation is selected from the lists of starting values.

The values of LDPM_TEST_REC_IDX_MON2 are fixed. They depend on the maximum NC_TEST_REC_IDX_MAX_MON2 of the generated index TEST_REC_IDX_MON2. This leads to the phys. limits of 0 ... NC_TEST_REC_IDX_MAX_MON2-1 which corresponds to the hex. limits 0 ... NC_TEST_REC_IDX_MAX_MON2-1. The single values of LDPM_TEST_REC_IDX_MON2 are given by:

Cell	0	1	2	....	NC_TEST_REC_IDX_MAX_MON2-1
value	0	1	2	....	NC_TEST_REC_IDX_MAX_MON2-1

FUNCTION DESCRIPTION:

C_FIL_TQI_SP_OUT_1_MON2	1	8000 ... 7FFF H	-1.0 ... 0.999939	3.05e-5	-
Filter constant for realization of first order filer					
C_T_TQI_MON2	1	0 ... FF H	0 ... 10.2	0.04	S
Dead time for torque decrease					

General information:

The module has exactly the same functionality than the corresponding module 'Desired indicated engine torque' of level 2 (`30E00K01.00E`) except:

- No RAM test of output data performed
- No initialisation section included
- TQI_SP_MON (output) renamed to TQI_SP_MON_MON2
- All input data, output data and calibration data renamed to level 2' naming
  Example: xyz_MON renamed to xyz_MON2

E.28.3 Actual indicated engine torque

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TQI_AV_MON2	V	0 ... FF H	0 ... 510	2	Nm
actual indicated engine torque (process monitoring)					
EFF_SCC_MON2	V	0 ... FF H	0 ... 1.992156	7.843e-3	-
actual efficiency of cylinder cut-off for torque monitoring					
TQI_REF_MON2	V	0 ... FF H	0 ... 510	2	Nm
reference indicated engine torque (process monitoring)					
EFF_IGA_MON2	V	0 ... FF H	0 ... 1.992156	7.843e-3	-
actual ignition efficiency for torque monitoring					
IGA_DIF_AV_MON2	V	0 ... FF H	0 ... –95.625	0.375	°CRK
difference of IGA_AV_MV_MON and IGA_REF_COR_MON					

Input data:

N_32_MON2	MAF_MON2	IGA_IGC_MON2_x	IGA_REF_ COR_EXT_MON2
PREV_STATE_IV_MON2	SUM_INH_INJ_MON2	LV_TQI_MON_ACT_MON2	

Calibration data:

Name	Dim	Hex. Limits	Phys. Limits	Resol.	Unit
IP_TQI_REF_MON2	6x8	0 ... FF H	0 ... 510	2	Nm
LDP_N_32_MON2_IP_TQI_REF_MON2	6	0 ... FF H	0 ... 8160	32	rpm
LDP_MAF_MON2_IP_TQI_REF_MON2	8	0 ... FF H	0 ... 1389	5.43	mg/stk
Indicated engine torque at reference conditions (process monitoring)					
IP_IGA_REF_MON2	8x8	0 ... FF H	-35.625 ...60	0.375	°CRK
LDP_N_32_MON2_IP_IGA_REF_MON2	8	0 ... FF H	0 ... 8160	32	rpm
LDP_MAF_MON2_IP_IGA_REF_MON2	8	0 ... FF H	0 ... 1389	5.43	mg/stk
Reference ignition angle (process monitoring)					
IP_EFF_IGA_MON2	8	0 ... FF H	0 ... 1.992156	7.843e-3	-
LDP_IGA_DIF_AV_MON2_IP_EFF_MON2	8	0 ... FF H	0 ... –95.625	0.375	°CRK
Basic ignition efficiency (process monitoring)					

General information:

The module has exactly the same functionality than the corresponding module 'Actual indicated engine torque' of level 2 (`30E00L02.00D`) except:

- No RAM test of output data performed
- No initialisation section included
- All input data, output data and calibration data renamed to level 2' naming
  Example: xyz_MON renamed to xyz_MON2

E.28.4 Monitoring of actual indicated engine torque

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_ERR_TQI_AV_MON2	V	0 ... 1 H	0 ... 1	1	-
fault currently present in torque generation					
TQI_DIF_AV_MON2	V	0 ... FF H	0 ... 510	2	Nm
deviation between actual and desired indicated engine torque					
TQI_DIF_SP_MON2	V	0 ... FF H	0 ... 510	2	Nm
deviation between torque setpoint and desired indicated engine torque					
TQI_DIF_MAX_MON2	V	0 ... FF H	0 ... 510	2	Nm
Permitted deviation between actual and desired indicated engine torque					
ABC_TQI_AV_ MON2	V	0 ... FF H	0 ... 255	1	-
Anti bounce counter for fault in torque generation					

Input data:

TQI_SP_MON_MON2	TQI_AV_MON2	TQI_SP_MON2	N_32_MON2
	LV_TQI_MON_ACT_MON2		

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Factor for threshold diagnosis with TQI_SP					
C_ABC_INC_TQI_AV_MON2	1	0 ... FF H	0 ... 255	1	-
Anti bounce counter increment for torque monitoring					
C_ABC_MAX_TQI_AV_MON2	1	1 ... FF H	1 ... 255	1	-
Maximum value of anti-bounce counter for torque monitoring					

General information:

The module has exactly the same functionality than the corresponding module 'Monitoring of actual indicated engine torque' of level 2 (`30E00M02.00D`) except:

- No RAM test of output data performed
- No initialisation section included
- TQI_SP_MON (input) renamed to TQI_SP_MON_MON2
- All input data, output data and calibration data renamed to level 2' naming
  Example: xyz_MON renamed to xyz_MON2

E.28.5 Monitoring of engine speed limitation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TQI_N_MAX_MON2	V	0 ... 1 H	0 ... 1	1	-
Fault currently present in engine speed limitation					
ABC_TQI_N_MAX_MON2	V	0 ... FF H	0 ... 255	1	-
Anti-bounce-counter for fault in engine speed limitation					

Input data:

N_32_MON2	LV_N_LIM_ETC_MON2	PREV_STATE_IV_MON2	

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_N_MAX_MTC_LIH_THD_MON2	1	0 ... FF H	0 ... 8160	32	Rpm
Speed threshold for the detection of a fault in the engine speed limitation					
C_ABC_INC_TQI_N_MAX_MON2	1	0 ... FF H	0 ... 255	1	-
Anti bounce counter increment					
C_ABC_MAX_TQI_N_MAX_MON2	1	1 ... FF H	1 ... 255	1	-
Maximum value of anti-bounce counter					

General information:

The module has exactly the same functionality than the corresponding module 'Monitoring of engine speed limitation' of level 2 (`30E00I01.00D`) except:

- No RAM test of output data performed
- No initialisation section included
- All input data, output data and calibration data renamed to level 2' naming
  Example: xyz_MON renamed to xyz_MON2

E.28.6 Fault reaction of process monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_N_LIM_REQ_MON2	V	0 ... 1 H	0 ... 1	1	-
Request for engine speed limitation					
LV_OFF_MTC_MON2	V	0 ... 1 H	0 ... 1	1	-
Request for disable of MTC power stage by main controller					
LV_OFF_IV_MON2	V	0 ... 1 H	0 ... 1	1	-
Request for disable of IV power stage by main controller					
LV_ERR_TRAN_MON2	V	0 ... 1 H	0 ... 1	1	-
Flag for temporary fault during last recurrency					
LV_OFF_IV_N_LIM_ETC_TMP_MON2	V	0 ... 1 H	0 ... 1	1	-
Flag for temporary injection cut off during last recurrency					

Input data:

LV_ERR_CONV_MON2	LV_ERR_N_32_MON2	LV_ERR_TQ_DIF_P_D_IS_MON2	LV_ERR_TQ_DIF_I_IS_MON2
LV_ERR_TQ_LOSS_MON2	LV_ERR_TQ_MIN_CLU_MON2	LV_ERR_TQ_MAX_CLU_MON2	LV_ERR_PVS_MON2
LV_ERR_TPS_MON2	LV_ERR_MAF_MON2	LV_ERR_TQI_AV_MON2	LV_ERR_TQI_N_MAX_MON2
LV_ERR_MU_MC_MON2	LV_ERR_TMP_MU_MC_MON2	LV_OFF_IV_N_LIM_ETC_MON2	

General information:

The module has exactly the same functionality than the corresponding module ‘Fault reaction of process monitoring’ of level 2 (`30E00G01.00E`) except:

- No RAM test of output data performed
- No initialisation section included
- All input data, output data and calibration data renamed to level 2’ naming
  Example: xyz_MON renamed to xyz_MON2

The ACTION_ECM3_RedSwitchOffPath() is replaced, instead of the original action call LV_DR_OFF_MU_MON2 is set to 1.

The byte SF_4_MON2 is updated with the output flags after execution.

E.28.7 Calculation of final result for level 2' test calcucation

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
RESP_MON2	V/O	0 ... FFFF H	0 ... 65535	1	-
Answer of copy of process monitoring (Level 2’)					

Input data:

TQI_SP_MON_MON2	TQI_AV_MON2	FAC_TQ_REQ_MON2	ABC_TQI_AV_MON2
ABC_TQI_N_MAX_MON2	SF_4_MON2	TQI_REQ_TOT_MON2	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Res.	Unit
ID_RESP_MON2	**NC_TEST_REC_IDX_MAX_MON2**	0000h ... FFFFh	0 ... 65535	1	1
LDPM_TEST_REC_IDX_MON2	**NC_TEST_REC_IDX_MAX_MON2**	0 ... NC_TEST_REC_IDX_MAX_MON2-1	0 ... NC_TEST_REC_IDX_MAX_MON2-1	1	1
Assignment table for answer decoder of copy of process monitoring					

General information:

There is a possibility for faults, which lead to wrong interim results but to a correct final result of the test calculation. In order to ensure that such a kind of fault is detectable, the final result is composed of several interim results of the whole test calculation.

FUNCTION DESCRIPTION:

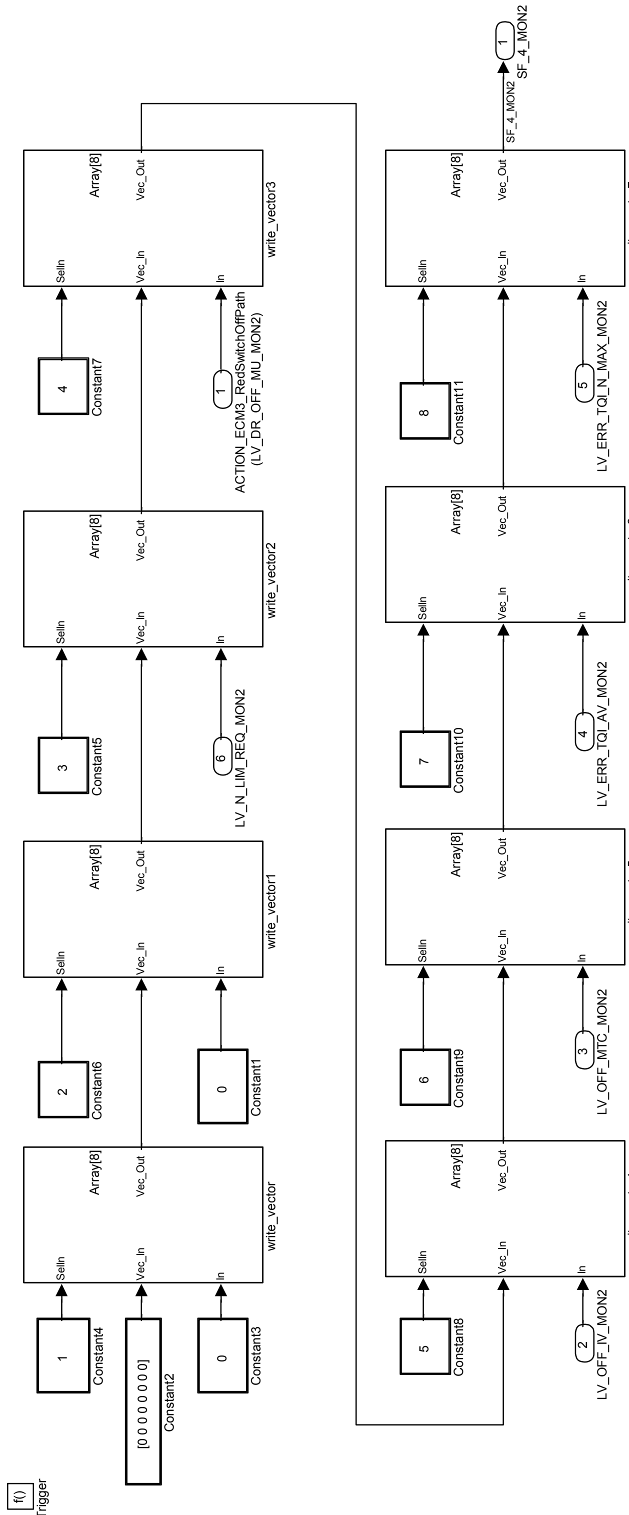

Figure 8 ECM2_DTSYSCOPPR/Rewrite_SF_4_MON2

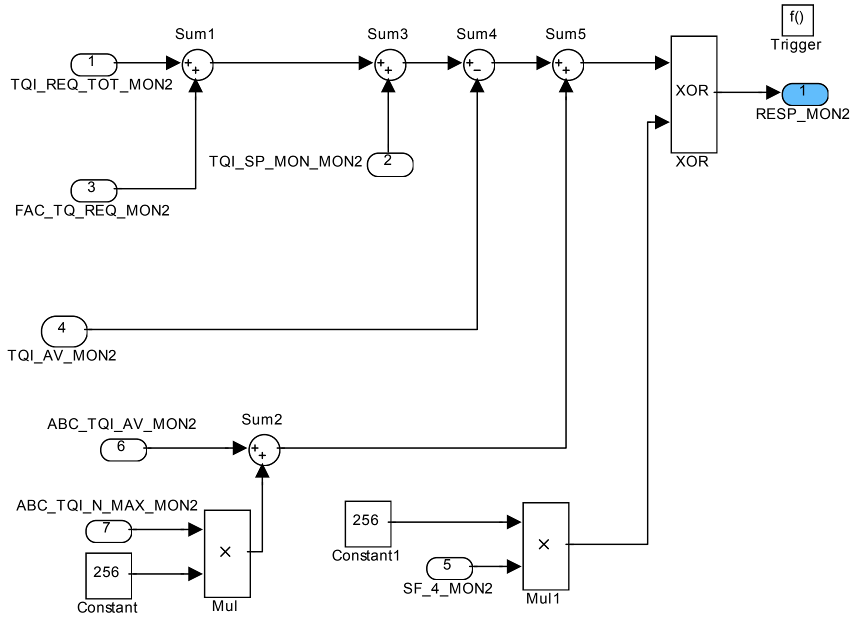

Figure 9 ECM2_DTSYSCOPPR/Calc_RESP_MON2

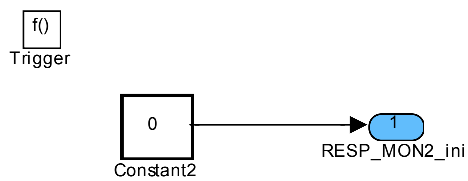

Figure 10 ECM2_DTSYSCOPPR/Reset_INI

All operations are performed with hexadecimal values only. The different units are not taken into account. The result of the operations and all intermediate results are 32 Bit word size, overflow and underflow is permitted.

Because all intermediate results have the size 32bit, only the low word (the least significant 16 bits) are taken as result RESP_MON2. In case of an underflow or overflow while computing the result there is still a significant change in the 16bit result RESP_MON2.

ID_RESP_MON2(TEST_REC_IDX_MON2) must fit to RESP_MON2 in case of a correct processing of test calulation with index TEST_REC_IDX_MON2.

E.29 Processor Monitoring

During operation of the electronic control unit (ECU), the Main Controller MC and the Monitoring Unit MU permanently exchange data to enable the MU the monitoring of the MC, especially to ensure the correct work of the Level 2 (process monitoring). This monitoring is the *Processor Monitoring* of the Monitoring Concept (Level 3). It is based on a set of test calculations (based on a Copy of Process Monitoring) as well as several other tests concerning communication and detection of memory faults. "Communication" used in the context of *Processor Monitoring* is a synonym for "Monitoring Communication". There are two independent interfaces to different power stages, MC as well as MU is able to disable the power stages separately.

According the figure “Sketch of the *Processor Monitoring* with two power stages” there exists two separate microcontrollers, MC and MU. Each microcontroller has its own memory and is running its own software. Therefore variables implemented on MU are not accessible by MC and vice versa, exept the values of the variables are transferred via the internal communication to the other mircocontroller. However, a consequence of this item is that one must carefully distinguish the scope of a variable according to the context.

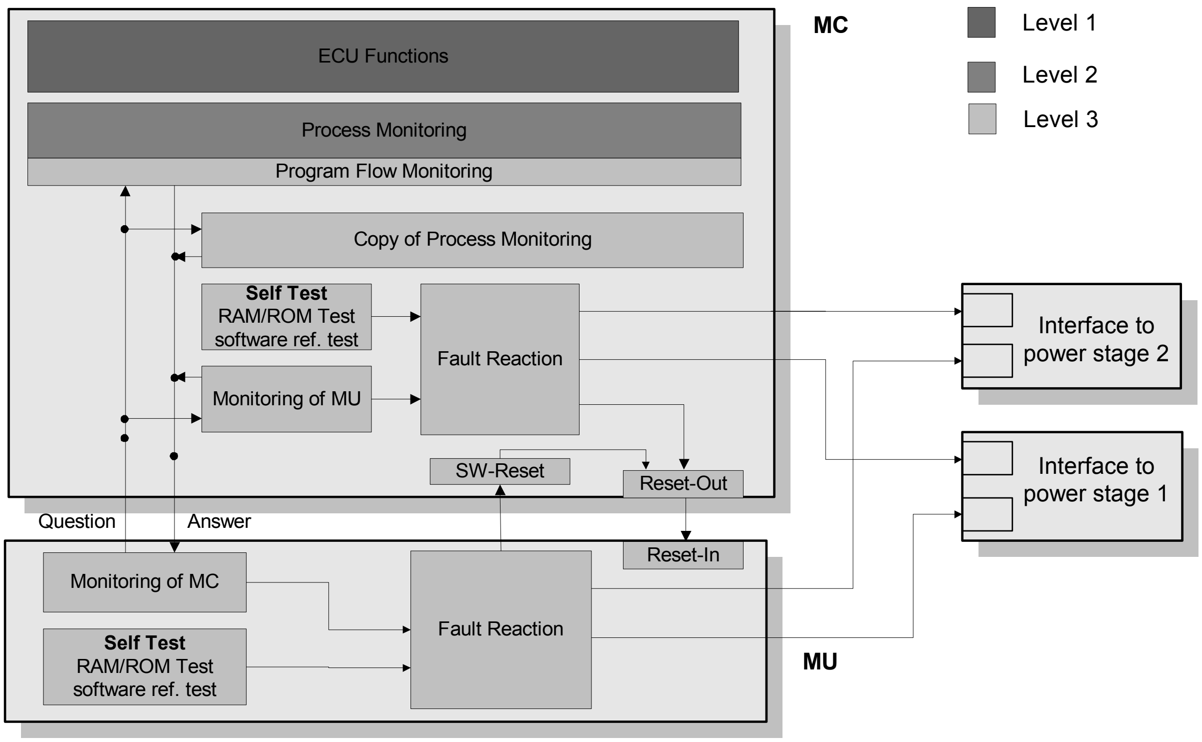

Figure 73: Sketch of the *Processor Monitoring* with two power stages

E.29.1 Delay of activation of Processor Monitoring

Input data:

LV_DIAG_END_RLY_MAIN_DLY	LV_RLY_MAIN_DLY_ERR		

FUNCTION DESCRIPTION:

Shortly after start-up, the Predrive Check (see section "Initialisation of the ECU") is performed in order to determine whether the MU can disable the safety-relevant power stages.

At the point when the Predrive Check is performed, it has to be ensured that the "environment" inside the ECU is in a suitable state: the check should only fail due to a real problem with the switch-off paths but not due to "extraneous" effects, like certain supply voltages not (yet) being available – such topics are not in the focus of the Predrive Check and consequently should not interfere with it.

Consequently, the Predrive Check has to be delayed until the environment is ready. While Processor Monitoring is not active, it has to be ensured that the power stages remain disabled (this has to be done in other SW).

As a matter of fact, in order to avoid harmful side effects, the **complete Processor Monitoring** function shall be delayed; in particular, no communications with the MU shall be triggered as long as the environment is not yet ready.

The readyness of the environment is provided via a dedicated diagnosis which is executed until a positive result is obtained or the power latch phase is entered; the delay shall be active as long as this diagnosis has not yet been completed (i.e., LV_DIAG_END_RLY_MAIN_DLY = 0) or has detected an error (i.e., LV_RLY_MAIN_DLY_ERR = 1). Consequently, Processor Monitoring shall only be activated when the diagnosis is completed (i.e., LV_DIAG_END_RLY_MAIN_DLY = 1) AND has not detected an error (i.e., LV_RLY_MAIN_DLY_ERR = 0).

Formula section:

IF ((LV_DIAG_END_RLY_MAIN_DLY = 1) **AND** (LV_RLY_MAIN_DLY_ERR = 0))

THEN

/ diagnosis has been completed with positive result */*

calculate Processor Monitoring function

ELSE

/ diagnosis not yet completed or negative result */*

skip the complete Processor Monitoring function package

ENDIF

E.29.2 Initialisation of the ECU

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_PRDR_ACT	O	0...1H	0...1	1	[-]
Active flag of PREDRIVE Check (0=inactive, 1=active)					

Input data:

RST_CTR_MC	RST_CTR_MU	LV_ERR_TMP_MU	LV_ERR_TMP_MC

FUNCTION DESCRIPTION:

After a reset or power up the ECU is initialized and the communication between MC and MU for the Monitoring Concept runs through an INIT-State, a PREDRIVE-State, into a NORMAL-State (Figure 74). The transitions of the states are controlled by the communication itself. In case of some faults a transition into DISABLE-State is performed. For details see chapter “Communication between MC and MU” and “Fault reaction of processor monitoring”. During the inizialisation also the digital output ports have to be configurated. For details see “Communication between MC and MU”.

In the different states different actions are carried out. In this chapter the main focus is the activation of the power stages.

Application conditions:

Initialisation: LV_PRDR_ACT = 1;

Recurrence: before calling the PREDRIVE check

Activation: always after each reset or power up

E.29.2.1 Reset or Power up

Both, MC and MU, run a self test, including a RAM and a ROM test. The MU disables the safety relevant power stages; the bit LV_PRDR_ACT is set before calling the PREDRIVE check. The MC enables all safety relevant power stages. The Predive check is done to make sure that the MU is able to disable the saftey relevant power stages, even if MC enables the power stages.

The Predrive Check itself is performed in the following sequence for all safety relevant power stages:

1. the partial result of the dedicated power stage is set to not ok.
2. kicks off the diagnosis of the dedicated power stage
3. the partial result is ok only, if
   - the diagnois is non-ambiguous
   - the diagnosis could be performed within a specific time periode
   - the power stage is disabled

After having collected all partial result the final result is set to ok only, if all partial results are ok. The final result of the Predrive Check is not stored in an intermediate variable to avoid unallowed changes in the time periode between storage and evaluation. If a storage of the result is needed, it has to be done with value and complement (like in "RAM test on MC for process monitoring") to provide a consitency check when evaluating the result.

In case of an error detected (i.e. RAM error) during active Predrive Check, the Predrive Check must be cancelled. In this case LV_PRDR_ACT has to be reset in order to be able to disable the safety relevant power stages. The result of the Predrive Check is not evaluated in this case.

In error free case after having received the result of the Predrive Check the INIT communication is performed.

E.29.2.2 INIT state communication

After the INIT communication the reset counters RST_CTR_MU and RST_CTR_MC are checked. If RST_CTR_MC or RST_CTR_MU (number of resets requested on MC or MU) is bigger than one, both controllers (MC and MU) disable the power stages. Therefore the reset counters have to be transferred in the INIT-communication.

After the INIT communication the error code and reset counter of the main controller as well as the error code and reset counter of the monitoring unit are avaliable. This values have to be copied (see "Fault reaction of processor monitoring") to maintain an optional error memory management.

A software reference check and a pin configuration check is done on both, MC and MU.

The result of the PREDRIVE-check is tested now. If the result of the Predive check indicates a fault then a fault reaction is carried out (see chapter “Fault reaction of processor monitoring”).

E.29.2.3 PREDRIVE state communication

The second communication is the PREDRIVE communication. MU sends LV_ERR_TMP_MU to MC (see “Fault reaction of processor monitoring”). If LV_ERR_TMP_MC is set, the MC has to disable the power stages, while a set LV_ERR_TMP_MU indicates the MC that the MU disables. So, if LV_ERR_TMP_MC or LV_ERR_TMP_MU is set the power stages are disabled temporary.

After the PREDRIVE communication the bit LV_PRDR_ACT is reset.

E.29.2.4 First NORMAL state communication

The third communication is a NORMAL state communication. If LV_ERR_TMP_MU and LV_ERR_TMP_MC are reset, the power stages are enabled after this communication. Otherwise the MC keeps the power stages disabled (LV_ERR_TMP_MC is set) or MU keeps the the power stages disabled (LV_ERR_TMP_MU is set). All other following monitoring communications will be NORMAL state or DISABLE state.

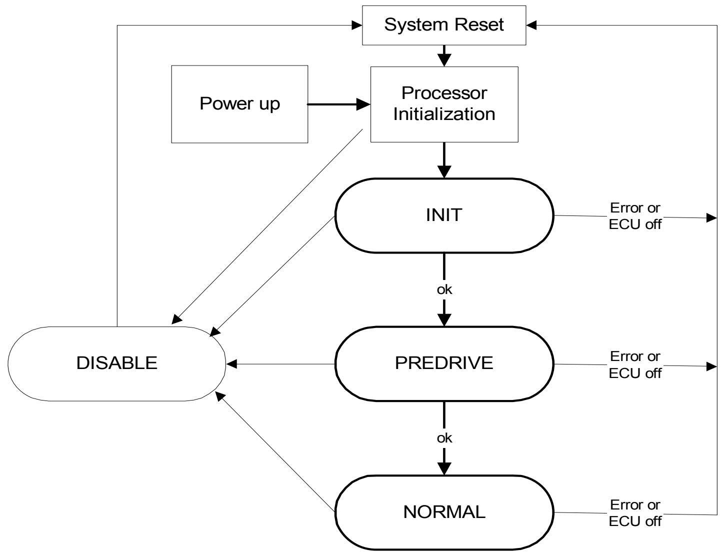

Figure 74: State of the monitoring communication of the ECU

E.29.3 ROM tests

E.29.3.1 Standard ROM Test on MC

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ROM_CRC_READY	V/O	0...1H	0...1	1	[-]
Indicates that the ROM test has been finished since last power up if set					

Note: LV_ROM_CRC_READY and its complement are located in the reset safe RAM area, as indicated by the mode “S”.

Input data:

ERR_COD_MC			

FUNCTION DESCRIPTION:

The standard ROM test checks the whole ROM (code, constant and calibration data) only after reset or power up. The CRC-32-Checksum is calculated in the background of the operating system. The Processor Monitoring checks cyclical whether the ROM test is finished or not. If the ROM test is finished and the Processor Monitoring detects an error, a fault reaction is performed directly (refer to chapter: “Fault reaction of processor monitoring”).
The standard ROM test has to be finished 3 minutes after power up or reset.

The variable LV_ROM_CRC_READY is mandatory to do a correct decrementation of the reset counter, see "Fault reaction of processor monitoring". If a reset is done because of a standard ROM test error or a cyclical ROM test error and after power up LV_ROM_CRC_READY has to be initialized with zero. Otherwise (in case of a reset not caused by any ROM error) LV_ROM_CRC_READY stays unchanged.

Application conditions:

Initialisation: LV_ROM_CRC_READY = 0; /* after power up */

LV_ROM_CRC_READY = 0; /* after reset caused by any ROM error */

No Initialization: after reset caused by other errors (no ROM error)

E.29.3.2 Cyclical ROM Test of Process Monitoring on MC

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ROM_CKS_ECU_CLC	-	0... FFFFFFFFFFFFFFFFH	0...1.84467E+19	1	[-]
Actual value of ECU code ROM test of process monitoring					
ROM_CKS_CAL_CLC_L	V	0...FFFFFFFFH	0...4294967295	1	[-]
Actual value of CAL data ROM test of process monitoring (low dword)					
ROM_CKS_CAL_CLC_H	V	0...FFFFFFFFH	0...4294967295	1	[-]
Actual value of CAL data ROM test of process monitoring (high dword)					

FUNCTION DESCRIPTION:

General information:

The ROM of the process monitoring has to be tested cyclically. After one procedure is finished it starts again. The tested areas consist of the algorithm code, the mathematics library functions and the calibration data. The several parts are located in different ranges of the whole ROM of the MC. The test procedure jumps from one part to the next.

The checksum is calculated as an 64bit addition checksum by adding up double words (32bit) of the ROM areas. To be able to process the 64bit values, the values are splitted into low double word and high double word. In this subsection symbolic 64bit identifiers are used in the formula section.

Before every start of the procedure the actual values have to be initialized with the init values NC_ROM_CKS_ECU_INI and NC_ROM_CKS_CAL_INI.

In case of a cyclical ROM error the redundant switch off path and a fault reaction is carried out. The redundant switch off path is activated using the action defined in "The redundant switch off path". The redundant switch off path performs a reset via MU, if the fault reaction on MC fails due to existing faults. If the fault reaction on MC is performed correct, the redundant switch off path has no effect.

Application conditions:

Initialisation:

ROM_CKS_CAL_CLC = NC_ROM_CKS_CAL_INI

ROM_CKS_ECU_CLC = NC_ROM_CKS_ECU_INI

Recurrence: 40 ms (10ms in case of a ROM error and after power up)

Activation: always

After every cycle the actual values of ROM_CKS_ECU_CLC and ROM_CKS_CAL_CLC are compared with the setpoint values NC_ROM_CKS_ECU and C_ROM_CKS_CAL.

for production software:

IF ((ROM_CKS_ECU_CLC != NC_ROM_CKS_ECU) **OR**
(ROM_CKS_CAL_CLC!= C_ROM_CKS_CAL))

THEN

ACTION_ECM3_RedSwitchOffPath()

central failure reaction carried out

(refer to chapter: “Fault reaction of processor monitoring”)

ENDIF

Note: *Application software may only be used during the development process of a specific product. Under all circumstances it is strictly forbidden to use in any procuction ECU.*

for application software only:

IF ((ROM_CKS_ECU_CLC != NC_ROM_CKS_ECU) **OR**
(ROM_CKS_CAL_CLC!= C_ROM_CKS_CAL))
AND
(LC_SWI_ROM_CKS_CAL!= NC_SWI_ROM_CKS_CAL_DEAC)

THEN

ACTION_ECM3_RedSwitchOffPath()

central failure reaction carried out

(refer to chapter: “Fault reaction of processor monitoring”)

ENDIF

The calculation of the checksum at runtime must last shorter than the recover time NC_T_RST_CTR_MC of the reset counter RST_CTR_MC on MC. This is mandatory to enter the DISABLE state in case of resets caused by ROM failures.

Normally the time grid of the ROM test is 40 ms (NC_T_ROM_CKS_MON). If a reset is done, because the cyclic ROM test of process monitoring (level 2) or the standard ROM test of level

1 detected a failure, the time grid is switched to 10 ms. After power up the standard ROM test runs also in the fast mode. After the second reset in order the power stages are disabled for the time periode NC_T_DR_DI_RST_MC or NC_T_DR_DI_RST_MU (see "Fault reaction of processor monitoring"). Therefore it must be ensured, that the cyclical ROM test of Process Monitoring on MC has to be finished within this time periode.

The checksum for the calibration data has to be applied to C_ROM_CKS_CAL by checking the result of ROM_CKS_CAL_CLC. The memory area of C_ROM_CKS_CAL and LC_SWI_ROM_CKS_CAL is not a part of the test area.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ROM_CKS_CAL_L	1	0...FFFFFFFFH	0...4294967295	1	[-]
Setpoint of ROM test process monitoring (low dword)					
C_ROM_CKS_CAL_H	1	0...FFFFFFFFH	0...4294967295	1	[-]
Setpoint of ROM test process monitoring (high dword)					
LC_SWI_ROM_CKS_CAL	1	0...FFH	0...255	1	[-]
Switch to set the fault of the CAL data ROM test inactive					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ROM_CKS_CAL_INI_L	1	0...FFFFFFFFH	0...4294967295	1	[-]
Init value of ROM_CKS_CAL_CLC (low dword)					
NC_ROM_CKS_CAL_INI_H	1	0...FFFFFFFFH	0...4294967295	1	[-]

E.29.3.3 Cyclical ROM Test on the MU

Output data: (on MU)

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
CRC_CKS_CLC_MU	-	0...FFFFH	0...65535	1	[-]
Actual calculated CRC16-Checksum					

FUNCTION DESCRIPTION:

The ROM of the MU is used to store data tables and program. The CRC-16 Checksum is calculated in the background function of the operating system (no other functions need processor power). If the calculation is finished the actual calculated value

CRC_CKS_CLC_MU is compared with the setpoint value NC_CRC_CKS_MU. If no faults are indicated the checksum is initialized again and the calculation starts again.

IF (CRC_CKS_CLC_MU != NC_CRC_CKS_MU)

THEN

central fault reaction is carried out

(refer to chapter: “Fault reaction of processor monitoring”)

ELSE

CRC_CKS_CLC_MU = NC_CRC_CKS_INI_MU;

/* start new calculation */

ENDIF

Configuration data: (on MU)

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
NC_ROM_START_ADR	1	0...FFFFH	0...65535	1	[-]
Start address of ROM-Test					
NC_ROM_STOP_ADR	1	0...FFFFH	0...65535	1	[-]
Stop address of ROM-Test					
NC_CRC_CKS_INI_MU	1	0...FFFFH	0...65535	1	[-]
Init value of CRC-Checksum					
NC_CRC_CKS_MU	1	0...FFFFH	0...65535	1	[-]
Setpoint CRC-Checksum					

An additional 8-bit-additions-checksum is calculated about the ROM area of the above-mentioned ROM-Test. This additional test is run cyclical too and in case of fault the central fault reaction is carried out, refer to chapter “Fault reaction of processor monitoring”.

Note: The calculation of the checksum at runtime must last shorter than the recover time NC_T_RST_CTR_MU of the reset counter RST_CTR_MU on MU. This is mandatory to enter the DISABLE state in case of resets caused by ROM failures.

E.29.4 RAM tests

E.29.4.1 Standard RAM Test on MC

FUNCTION DESCRIPTION:

The standard RAM test checks the whole RAM only during the initialisation after power up or reset. If an error is detected the central failure reaction is carried out (refer to chapter “Fault reaction of processor monitoring”). The fault reaction is either carried out directly, or the result of RAM test is saved as value and complement into different physical RAM areas and evaluated later.

The standard RAM test includes also the area of reset safe stored variables.

However, as the reset safe area of the RAM may not be changed after the test the original values have to be recovered.

Note: The standard RAM test at runtime must last shorter than the recover time NC_T_RST_CTR_MC of the reset counter RST_CTR_MC on MC. This is mandatory to enter the DISABLE state in case of resets caused by RAM failures. After the second reset in order the power stages are disable for the time periode NC_T_DR_DI_RST_MC or NC_T_DR_DI_RST_MU (see "Fault reaction of processor monitoring"). Therefore it must be ensured, that the standard RAM test on MC has to be finished within this time periode.

E.29.4.2 RAM test on MC for process monitoring

Export actions:

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>, IN <reg>)
Writes the register value into RAM and cross checks the written value. The complement is generated and stored.
ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)
Compares the value of xyz_MON with its complement xyz_MON_CPL
ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)
Read variable an its complement, checks value agains complement, register reg contains xyz_MON after action.

Note: All actions have to be implemented as macros to avoid function calls in the code of the *Process Monitoring*.

Descripiton for ACTION_ECM3_WriteChkCpl(...):

Description:

Syntax: ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>,
OUT <xyz_MON_CPL>, IN <reg>)

Parameter (IN):	type	data type of xyz_MON, xyz_MON_CPL and reg
	reg	register containing the value to be stored
Parameter (OUT):	xyz_MON_CPL	complement value of register/xyz_MON
Parameter (INOUT):	xyz_MON	variable to be written to RAM and checked

Formula section:

ACTION_ECM3_WriteChkCpl(IN <type>, INOUT <xyz_MON>, OUT <xyz_MON_CPL>,
IN <reg>, SYNCHRONISATION CALL)

- Store register value *reg* into RAM, location *xyz_MON*
- Generate complement *xyz_MON_CPL* using the value of *reg* and store complement in RAM, location *xyz_MON_CPL*.
- Read variable *xyz_MON* from RAM and compare read value with register value *reg*:

IF (xyz_MON != reg)

THEN

central fault reaction is carried out

ENDIF

Descripiton for ACTION_ECM3_ChkCpl(...):

Description:

Syntax: ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Parameter (IN):	type	data type of *xyz_MON* and *xyz_MON_CPL*
	xyz_MON	variable to be checked, stored in RAM
	xyz_MON_CPL	complement value of *xyz_MON*, stored in RAM

Formula section:

ACTION_ECM3_ChkCpl(IN <type>, IN <xyz_MON>, IN <xyz_MON_CPL>, SYNCHRONISATION CALL)

- Read variables *xyz_MON* and *xyz_MON_CPL* from RAM and compare read values:

  IF (*xyz_MON !*= complement(*xyz_MON_CPL*)) **THEN**

  central fault reaction is carried out

  ENDIF

Descripiton for ACTION_ECM3_ReadChkCpl(...):

Description:

Syntax: ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg>, IN <xyz_MON>, IN <xyz_MON_CPL>)

Parameter (IN) :	type	data type of *xyz_MON*, *xyz_MON_CPL* and *reg*
	xyz_MON	variable to be checked, stored in RAM
	xyz_MON_CPL	complement value of *xyz_MON*, stored in RAM
Parameter (OUT) :	reg	register containing value of *xyz_MON*

Formula section:

ACTION_ECM3_ReadChkCpl(IN <type>, OUT <reg> IN <xyz_MON>,
IN <xyz_MON_CPL>, SYNCHRONISATION CALL)

- Loads register *reg* with value stored in RAM, location *xyz_MON*
- Read variables *xyz_MON* and *xyz_MON_CPL* from RAM and compare read values:

  IF (*xyz_MON !*= complement(*xyz_MON_CPL*)) **THEN**

  central fault reaction is carried out

  ENDIF

FUNCTION DESCRIPTION:

General information:

The functionality of the process monitoring (level 2) is calculated cyclically. The calculation and the storage of intermediate results of the process monitoring functions is performed using the registers of the processor as far as possible. The registers are tested by the copy of process monitoring (level 3 and level 2' respectively, see "The test calculation Copy of process monitoring").

All variables located in the RAM of the process monitoring used in the next recurrence of the task (e.g. anti-bounce-counter) or in a successive task are stored in original and complementary form in the normal RAM area. After execution of a *Process Monitoring* module the results have to be copied from registers into variables located in the RAM. After the storage of a variable from an internal register to the RAM, the variable is loaded from RAM again and compared with the original value of the register. This procedure is done with the action ACTION_ECM3_WriteChkCpl(...) given above.
At the beginning of the following recurrence of the task, the two complementary variables are checked for plausibility. Also intermediate results, which can not be completely handled by the internal registers, are stored complementary and checked for plausibility. This is done at the begining of a *Process Monitoring* module using the action ACTION_ChkCpl(...) or ACTION_ECM3_ReadChkCpl(...). Hereby faults of the RAM cells and an undesired overwriting of the data by a faulty function will be detected and a fault reaction will be carried out without debouncing, see chapter “Fault reaction of processor monitoring”.

Application conditions:

Activation and Deactivation: According to the respective function modules.

Initialization: Before the first test of the complementary variables, the variables must be properly initialized using the action ACTION_ECM3_WriteChkCpl( ).

E.29.4.3 Standard RAM Test on MU

Output data: (on MU)

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
RAM_TEST_MU	-	0...FFH	0...255	1	[-]
Result of RAM test					
RAM_TEST_MU_CPL	-	0...FFH	0...255	1	[-]
Complement result of RAM test					

FUNCTION DESCRIPTION:

The RAM of the MU is used as a data storage area and a stack area for subroutine call and interrupt occurrences. The RAM is tested after a power-up-reset. After a software reset specific data are stored in a reset safe RAM area. These data are not allowed to overwrite through the RAM-Test. Therefore only the other area is tested after a software reset. After a power up also the reset safe RAM area is tested. The result of the RAM test is stored in RAM_TEST_MU and its complement RAM_TEST_MU_CPL. If RAM_TEST_MU or RAM_TEST_MU_CPL indicates a fault a fault reaction is carried out, refer to chapter “Fault reaction of processor monitoring”.

Note: The standard RAM test at runtime must last shorter than the recover time NC_T_RST_CTR_MU of the reset counter RST_CTR_MU on MU. This is mandatory to enter the DISABLE state in case of resets caused by RAM failures. After the second reset in order the power stages are disable for the time periode NC_T_DR_DI_RST_MC or NC_T_DR_DI_RST_MU (see "Fault reaction of processor monitoring"). Therefore it must be ensured, that the standard RAM test on MU has to be finished within this time periode.

Start value for the test record of Copy of Process Monitoring					

Input data: (on MU)

LV_DR_OFF_MU_MON	RESP_MON2_MC		

FUNCTION DESCRIPTION:

Note: The interface variables between level3 and level2' are described below in "Interface to Copy of Process Monitoring" detailed.

Application conditions:

Initialisation: ABC_MON2_MU=0 after reset or power up

General information:

In order to ensure the correct computation and processing on MC, a **test of the process monitoring** is performed in the NORMAL state, see Figure 74 or section "Communication between MC and MU". To validate the results it is neccesarry to compare the calculated result with a known, fixed result. Therefore the given start values are fixed at runtime. The calculations themselves are done with a copy of process monitoring (level 2'). The interface to this level is a start value (index number TEST_REC_IDX_MON2) and the 16-bit answer. This result RESP_MON2 of level 2' affects the final answer RESP_MON2_MC which is sent to MU. On MU this answer is compared with the expected result.

The mapping of the test index to the expected values must be one to one. Note, that the range of the index value generated on MU does not overlap the range of the expected result transferred to MU at all.

The start value TEST_REC_IDX_MON2 is transferred from MU to MC, see “Communication between MC and MU”.

The task level 2’ is executed every second communication cycle, so the result is evaluated on MU also every second communication cycle.

If the monitoring level of the process monitoring (see “Fault Reaction of Process Monitoring”) or the ROM test (see “Cyclical ROM Test of Process Monitoring on MC”) detects a critical error the copy of process monitoring is forced to give wrong answers. This mechanism, called the redundant switch off path, leads to a disable of the safety relevant power stages by the monitoring unit and is activated with set LV_DR_OFF_MU_MON. (refer to subsection "The redundant switch off path"). The variable LV_DR_OFF_MU_MON is monitored here with a recurrence of 2*NC_T_SPI_COM using the cyclical RAM test functions ("RAM test on MC for process monitoring").

For correct error memory management, it is mandatory to distinguish between the use of the redundant switch off path and wrong answers caused by wrong results of level 2’, see “Fault reaction of processor monitoring”.

Specifications of the test calculation evaluation on MU:

MU determines the test index TEST_REC_IDX_MON2. This index runs in default case (no faults, no exeptions) from the initial value 0 to NC_TEST_REC_IDX_MAX_MON2-1 with an increment of one. If the maximum value is reached, the index starts again with zero.

Exception: If the system recognizes that a test calculation provides an incorrect result, the same test calculation is repeated with the same input value, either until the error has been recognized reliably, or until it is ensured that there is no error (ABC_MON2_MU= 0).

As the result is evaluated on the MU, the repetition of the incorrect test calculation can only be initiated one step later. Thus, the MU requests only one time another calculation between the incorrect calculation and its repetition.

Example: Result of test calculation 2 is permanetly incorrect:

Sequence: 0,1,2,3,2,2,2,2.....

Evaluation of the answer:

The MU compares the result RESP_MON2_MC obtained with the corresponding value from the ROM. If the answer is correct, TEST_REC_IDX_MON2 is incremented and the anti bounce counter ABC_MON2_MU is decremented until zero. If not, the anti-bounce counter ABC_MON2_MU is incremented by NC_ABC_INC_MON2_MU. The maximum value of ABC_MON2_MU is limited to NC_ABC_MAX_MON2_MU.

Exeption: If there are two wrong answers in series, the second wrong answer is not evaluated, therefore the value of the anti bounce counter stays unchanged. This is mandatory to do a correct debouncing.

If ABC_MON2_MU>= NC_ABC_MAX_MON2_MU, the central fault reaction is carried out (refer to chapter: “Fault reaction of processor monitoring”) and ABC_MON2_MU is no longer incremented.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ABC_MAX_MON2_MU	1	0...FFH	0...255	1	[-]
Maximum value of anti-bounce counter of level 2' test calculations on MU					
NC_ABC_INC_MON2_MU	1	0...FFH	0...255	1	[-]
Increment value of anti-bounce counter of level 2' test calculations on MU					
NC_TEST_REC_IDX_MAX_MON2	1	0...FH	0...15	1	[-]
(NC_TEST_REC_IDX_MAX_MON2-1) is the maximum value for the index of test calculation Therfore NC_TEST_REC_IDX_MAX_MON2 answers are calculated cyclically					

E.29.5.1 Inspection of MU by the MC according to test calculation

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
ABC_MON2_TEST_MC	-	0...FFH	0...255	1	[-]
Anti-bounce counter to test anti-bounce counter of level2' test calculation on MU					
ABC_MON2_TEST_2_MC	-	0...FFH	0...255	1	[-]
Anti-bounce counter to test the incrementation of index for level2' test calculation on MU					

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: ABC_MON2_TEST_MU =ABC_MON2_TEST_2_MC=0 after reset or power up

The anti bounce counter ABC_MON2_MU of the copy of process monitoring is transferred from MU to MC. The MC tests cyclically in time periodes of NC_T_MON2_TEST_MC whether the anti-bounce counter of the MU is incremented by returning an incorrect result RESP_MON2_MC.

The system checks at time periodes of NC_T_MON2_TEST_MC whether the MU's anti-bounce counter ABC_MON2_MU is zero. If so, an incorrect result RESP_MON2_MC is sent from the MC to the MU as the result of the next test calculation. Then the MC checks whether the anti-bounce counter evaluated on MU and sent from MU to MC has changed. If the anti-bounce counter remains zero, incorrect results of the corresponding test calculations are sent from the MC to the MU cyclically, until the anti-bounce counter of the MU responds.

If the anti-bounce counter ABC_MON2_MU of the MU responds, the anti-bounce counter ABC_MON2_TEST_MC on MC is decremented until zero, otherwise the anti-bounce counter ABC_MON2_TEST_MC is incremented by the increment value NC_ABC_INC_MON2_TEST_MC. If the anti-bounce counter reaches its maximum value NC_ABC_MAX_MON2_TEST_MC, a central failure reaction carried out (refer to chapter: “Fault reaction of processor monitoring”). The value of ABC_MON2_TEST_MC is limited to NC_ABC_MAX_MON2_TEST_MC.

Furthermore the MC tests if the question index TEST_REC_IDX_MON2 determined by MU is changed as long as the anti bouncer ABC_MON2_MU is zero. In case of a detected error according to the question index the anti bounce counter ABC_MON2_TEST_2_MC is incremented by NC_ABC_INC_MON2_TEST2_MU, otherwise the anti bounce counter is decremented until zero. If the anti bounce counter in the MC reaches the maximum value NC_ABC_MAX_MON2_TEST_2_MU, a central failure reaction carried out (refer to chapter:

"Fault reaction of processor monitoring"). The value of ABC_MON2_TEST_2_MC is limited to NC_ABC_MAX_MON2_TEST_2_MC.

Configuration data:

Time base for inspection the evaluation of level2' test calculations, measured as multiple of NC_T_SPI_COM					

E.29.5.2 Interface to Copy of Process Monitoring

Output data: (from level 3 to level2')

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TEST_REC_IDX_MON2	V/O	0...3FH	0...63	1	[-]
Start value for the test record of Copy of Process Monitoring					
CONV_RESP_MON2	-	0...FH	0...15	1	[-]
Intermediate result of answer decoder					
RESP_MON2_MC	-	0...FFH	0...255	1	[-]
Decoded answer of the test calculation, transferred to MU					

Input data: (from level2' to level3)

RESP_MON2	ID_RESP_MON2	LDPM_TEST_REC_IDX_MON2

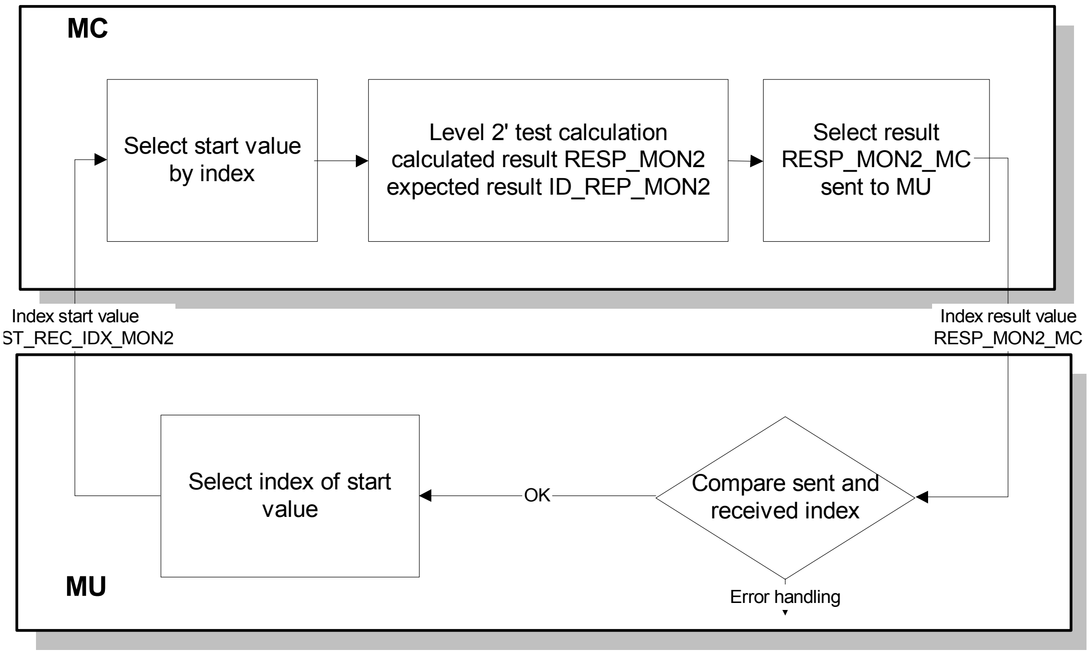

Figure 75: Interface to copy of process monitoring

FUNCTION DESCRIPTION:

As specified above the task copy of process monitoring (level 2') is called cyclically. The interface between level 3 and level 2' is performed in the following steps:

1. The input for level 2' is the start value TEST_REC_IDX_MON2.
2. The result of level 2' is the 16-bit answer RESP_MON2.
3. The value of RESP_MON2 has to be found in the array ID_RESP_MON2. This is done in the answer decoder.

TEST_REC_IDX_MON2 —level 2'→ RESP_MON2 —answer decoder→ CONV_RESP_MON2

4. The intermediate result CONV_RESP_MON2 and the scattering of wrong answers (see "Inspection of MU by the MC according to test calculation") forms the final result RESP_MON2_MC which is transferred to MU.

If the answer RESP_MON2 calculated by level 2' is incorrect, the value of RESP_MON2_MC indicates an error independent of the inspection of MU by the MC. Note also that the initial value of RESP_MON2_MC when entering the answer decoder indicates an error.

Note, that the calibration data ID_RESP_MON2 and LDPM_TEST_REC_IDX_MON2 are imported from "Copy of Process Monitoring". This data have to be calibrated in "Copy of Process Monitoring", they are needed here to evaluate the intermediate result CONV_RESP_MON2.

E.29.5.3 The redundant switch off path

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DR_OFF_MU_MON	V/O	0...1H	0...1	1	[-]
Bit for redundant switch off path (1=active)					
LV_DR_OFF_MU_MON_CPL	O	0...1H	0...1	1	[-]
Complement bit of redundant switch off path					

Export actions:

ACTION_ECM3_RedSwitchOffPath()
Activates the redundant switch off path

Note: This action has to be implemented as macros to avoid function calls in the code of the *Process Monitoring*.

FUNCTION DESCRIPTION:

This function activates the redundant switch off path. Therefore LV_DR_OFF_MU_MON is set and the copy of process monitoring (see “The test calculation Copy of process monitoring”) is forced to give wrong answers and transferred to MU next and the following communication. In “The test calculation Copy of process monitoring” also the cyclical RAM test of LV_DR_OFF_MU_MON is performed using the functions defined in "RAM test on MC for process monitoring"; the value LV_DR_OFF_MU_MON and LV_DR_OFF_MU_MON_CPL are checked for consitency. The recurrence is NC_T_SPI_COM.

LV_DR_OFF_MU_MON is transferred to MU only to ensure a correct error memory management (see “Fault reaction of processor monitoring”).

Descripiton for ACTION_ECM3_RedSwitchOffPath():

Description:

Syntax: ACTION_ECM3_RedSwitchOffPath()

Parameter: none

Formula section:

ACTION_ECM3_RedSwitchOffPath(SYNCHRONISATION CALL)

- Sets the variable LV_DR_OFF_MU_MON using ACTION_ECM3_WriteChkCpl()

Application conditions:

Initialisation: LV_DR_OFF_MU_MON = 0 /* using ACTION_ECM3_WriteChkCpl() */

Recurrence: only after power up or SW reset

E.29.6 Watchdog on the monitoring unit

FUNCTION DESCRIPTION:

General information:

A timer is used to generate a watchdog functionality on the monitoring unit. A software watchdog is used to ensure that endless program loops on the MU are detected. The operating system of the MU resets the watchdog timer cyclically. If the watchdog timer hasn't been reset for 100ms, the safety critical power stages are disabled and a software reset on MC is triggered via the NMI line. This causes a restart of the ECU.

E.29.7 Program Flow Monitoring (PFM)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
RESP_PFM_MC	-	0...FFH	0...255	1	[-]
Answer of the program flow monitoring					

Input data:

SYN_PFM_MU			

FUNCTION DESCRIPTION:

It is intended to achieve a program flow monitoring and to implement this in terms of an „intelligent" watchdog. This is to ensure that safety-related-program sections have been executed demonstrably in the expected time grid and also in the given sequence. Therefore modules of level2 (process monitoring) are monitored in the NORMAL state, see Figure 74 or section "Communication between MC and MU". The identifier byte RESP_PFM_MC is transferred to MU:

RESP_PFM_MC and SYN_PFM_MU:

7 (MSB)	6	5	4	3	2	1	0 (LSB)
Task 8	Task 7	Task 6	Task 5	Task 4	Task 3	Task 2	Task 1

Task *n* (*n* = 1 ... 8) is running in the nominal time gird NC_T_PFM_*n*_MU. The identifier RESP_PFM_MC is only generated in the MC, but not checked. After transfer to the MU each communication it is tested on MU. Here the word task is used for a given, fixed sequence of modules running in the same nominal time grid.

The following algorithm is used:

The MU generates a synchronization byte (SYN_PFM_MU) which is transferred to the MC. SYN_PFM_MU has the same binary structure as RESP_PFM_MC. SYN_PFM_MU is evaluated by MC to ensure, that the MU is still alive. Each bit in SYN_PFM_MU is inverted and used to initialize the dedicated bit in RESP_PFM_MC. Calling the modules to be program flow monitored influences finally the bits in RESP_PFM_MC. The final RESP_PFM_MC is transferred unchanged to MU in the following communication cycle and is evaluated there.

The n^{th} bit in RESP_PFM_MC is initialized within ACTION_ECM3_ServicePfm(*n*). Furthermore this action is used to initialize a specific bit pattern assigned to the task *n* (see stucture of RESP_PFM_MC and SYN_PFM_MU). This internal bit pattern is manipulated by ACTION_ECM3_Service*k*TaskPfm(*n*) at the entrance and the exit of each module to be program flow monitored within a given sequence of several mudules. After the execution of all modules this internal bit pattern is evaluated in ACTION_ECM3_ServicePfm() to form the n^{th} bit in RESP_PFM_MU. The available actions are desctibed later.

E.29.7.1 Inspection of MU by the MC on PFM

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ABC_PFM_TEST_MC	-	0...FFH	0...255	1	[-]
Anti-bounce counter of the program flow monitoring					

Input data:

SYN_PFM_MU			

FUNCTION DESCRIPTION:

General information:

Because this inspection is a test of the algorithm itself, it is needful to check the bits belonging to the task running in the shortest time gird only.

Application conditions:

Initialisation: ABC_PFM_TEST_MC=0 after power up or reset

The MC checks if the correct bits of SYN_PFM_MU are toggled by MU. If they are not toggled, the anti-bounce counter ABC_PFM_TEST_MC is incremented with NC_ABC_INC_PFM_TEST_MC. If ABC_PFM_TEST_MC gets bigger than or equal to ABC_MAX_PFM_TEST_MC, the central failure reaction carried out (refer to chapter: "Fault reaction of processor monitoring"). If no error is detected, ABC_PFM_TEST_MC is decremented until zero. ABC_PFM_TEST_MC is limited to ABC_MAX_PFM_TEST_MC.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ABC_INC_PFM_TEST_MC	1	0...FFH	0...255	1	[-]
Increment value of anti-bounce counter of program flow monitoring on MU					
NC_ABC_MAX_PFM_TEST_MC	1	0...FFH	0...255	1	[-]
Maximum value of anti-bounce counter of program flow monitoring on MU					

E.29.7.2 Inspection of MC by the MU on PFM

Output data: (on MU)

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Anti-bounce counter of the program flow monitoring for task 8					

Note: The value of the variable SYN_PFM_MU is set on MU and has to be transferred to MC via the internal communication.

Input data: (on MU)

RESP_PFM_MC			

Note: The value of this variable is set on MC and has to be transferred to MU via the internal communication.

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: ABC_PFM_n_MU=NC_ABC_INI_PFM_n_MU (n=1 ... 8) after power up or reset

RESP_PFM_MC is sent to the MU each communication. The bits of the according time levels are toggled at dedicated time intervals. SYN_PFM_MU sent to the MC must be saved for the next run. The currently determined RESP_PFM_MC and SYN_PFM_MU can be used to verify the program flow monitoring received from the MC.

In case of error, the appropriate anti-bounce counters ABC_PFM_n_MU (n=1 ... 8) are incremented with NC_ABC_INC_PFM_n_MU. If the anti-bounce counter in the MU gets bigger than or equal to the maximum value NC_ABC_MAX_PFM_n_MU, the central failure reaction is carried out (refer to chapter: “Fault reaction of processor monitoring”). If no error is detected, ABC_PFM_n_MU is decremented until zero. ABC_PFM_n_MU is limited to NC_ABC_MAX_PFM_n_MU.

ACTION_ECM3_Service1TaskPfm(IN <n>)
Action call to be done right after execution of 1st module to be program flow monitored
ACTION_ECM3_Service2TaskPfm(IN <n>)
Action call to be done right before execution of 2nd module to be program flow monitored
ACTION_ECM3_Service3TaskPfm(IN <n>)
Action call to be done right after execution of 2nd module to be program flow monitored
ACTION_ECM3_Service4TaskPfm(IN <n>)
Action call to be done right before execution of 3rd module to be program flow monitored
ACTION_ECM3_Service5TaskPfm(IN <n>)
Action call to be done right after execution of 3rd module to be program flow monitored
ACTION_ECM3_Service6TaskPfm(IN <n>)
Action call to be done right before execution of 4th module to be program flow monitored
ACTION_ECM3_Service7TaskPfm(IN <n>)
Action call to be done right after execution of 4th module to be program flow monitored
ACTION_ECM3_Service8TaskPfm(IN <n>)
Action call to be done right before execution of 5th module to be program flow monitored
ACTION_ECM3_Service9TaskPfm(IN <n>)
Action call to be done right after execution of 5th module to be program flow monitored
ACTION_ECM3_Service10TaskPfm(IN <n>)
Action call to be done right before execution of 6th module to be program flow monitored
ACTION_ECM3_Service11TaskPfm(IN <n>)
Action call to be done right after execution of 6th module to be program flow monitored
ACTION_ECM3_Service12TaskPfm(IN <n>)
Action call to be done right before execution of 7th module to be program flow monitored
ACTION_ECM3_Service13TaskPfm(IN <n>)
Action call to be done right after execution of 7th module to be program flow monitored
ACTION_ECM3_Service14TaskPfm(IN <n>)
Action call to be done right before execution of 8th module to be program flow monitored
ACTION_ECM3_Service15TaskPfm(IN <n>)
Action call to be done right after execution of 8th module to be program flow monitored
ACTION_ECM3_Service16TaskPfm(IN <n>)
Action call to be done right before execution of 9th module to be program flow monitored
ACTION_ECM3_Service17TaskPfm(IN <n>)
Action call to be done right after execution of 9th module to be program flow monitored
ACTION_ECM3_Service18TaskPfm(IN <n>)
Action call to be done right before execution of 10th module to be program flow monitored
ACTION_ECM3_Service19TaskPfm(IN <n>)
Action call to be done right after execution of 10th module to be program flow monitored
ACTION_ECM3_ServicePfm(IN <n>)
Action call to determine result of PFM which will be sent to the MU

Description of ACTION_ECM3_Service*k*TaskPfm(...), *k=0 ... 19*:

Description:

Syntax: ACTION_ECM3_ServicekTaskPfm(IN <*n*>)

Parameter (IN): *n* variable name of the bitpattern to be toggled

Parameter (OUT): -

Formula section:

ACTION_ECM3_Service*k*TaskPfm(IN <*n*>, SYNCHRONISATION CALL)

Changes bits in the bit pattern given by name *n* belonging to task *n*.

Description of ACTION_ECM3_ServicePfm(...):

Description:

Syntax:	ACTION_ECM3_ServicePfm(IN <*n*>)	
Parameter (IN):	*n*	variable name of the bitpattern to be toggled
Parameter (OUT):	-	

Formula section:

ACTION_ECM3_ServicePfm(IN <*n*>, SYNCHRONISATION CALL)

Calculates the final result of PFM which will be sent to the monitoring unit

General information:

Up to ten level 2 modules can be program flow monitored by the *Processor Monitoring* in one time grid. Therefore it is mandatory to sandwich the modules between services defined here. One service action call has to be done *before* the execution and another one right *after* the execution of a level 2 module instruction. Therefore the service actions ACTION_ECM3_Service*k*TaskPfm(*n*) are implemented. For the level 2 module *j* (with j=0 ... 9) the service action call ACTION_ECM3_Service*2j*TaskPfm(*n*) has to be done before the execution of the first instruction of the module. After the executing of the last instruction of the module the service action call ACTION_ECM3_Service*(2j+1)*TaskPfm(*n*) has to be done.

Finally at the end of all level 2 modules the answer bits in RESP_PFM_MC has to be determined using the service ACTION_ECM3_ServicePfm(*n*).

The agrument *n* belongs to the bits in RESP_PFM_MC and SYN_PFM_MU.

E.29.8 Interface to monitoring of A/D conversion

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ACQ_MC_0_MON	V/O	0...3FFH	0...4.99511	4.8828e-3	[V]
AD-value of the MC, monitored with RAM test function					
ACQ_MC_0_MON_CPL	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Complement of AD-value of MC					
ACQ_MU_0_MON	V/O	0...3FFH	0...4.99511	4.8828e-3	[V]
AD-value of MU, monitored with RAM test function					
ACQ_MU_0_MON_CPL	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Complement AD-value of MU					

Input data:

AN_BUF_0			

Note: This value is a direct input from the intenal communication receive buffer.

FUNCTION DESCRIPTION:

The ECU itself provides the possibility to monitor *all safety critical* A/D conversions. The A/D converters on both controllers, MC and MU, as well as the communication between MC and MU are involved. The digitalisation of *all safety critical* analog inputs on one controller is done with the *same* converter. This is realized with an internal mulitplexed input on both controllers, MC and MU. To do the monitoring of A/D conversion, it is mandatory that *one* analog input on MC is the same as the dedicated analog input on MU. This digitalized value has to be transmitted via the internal communication (for details refer to chapter “Communication between MC and MU”). By comparing one value (digitalized on MC) with the dedicated value (digitalized on MU) a monitoring of the A/D conversion of all saftey critical A/D values is possible. Conversion time as well as communication time has to be taken into account when comparing non constant values. Therefore one AD-channel of the MU (see “Analog and pseudo digital inputs”) is converted directly after the communication and transferred to MC.

On MC the received value is loaded in case of fault free communication from the receive buffer directly into a register. With the action ACTION_ECM3_WriteChkCpl( ) defined in "RAM test on MC for process monitoring" the variables ACQ_MU_0_MON and ACQ_MU_0_MON_CPL are stored and checked.

The ADC value of the dedicated channel on the MC is directly copied from the ADC readout into some intermediate variables. The storage of the variables has to be done with value and complement (like in "RAM test on MC for process monitoring") to provide a consitency check when evaluating the result. Like MU the MC converts the dedicated analog signal after the communication. The elapsed time between the measurements on MC and MU has to be less than 1ms.

After a fault free communication a register is loaded with the intermediate stored value. This register is used to store the value into ACQ_MC_0_MON and ACQ_MC_0_MON_CPL using the action ACTION_ECM3_WriteChkCpl( ).

For details on signal processing (based on ACQ_MU_0_MON and ACQ_MC_0_MON) see chapter “Monitoring of A/D conversion”. When passing the output signal ACQ_MC_0_MON and ACQ_MU_0_MON to the signal processing subroutine ("Monitoring of A/D conversion") they have to be checks with ACTION_ECM3_ReadChkCpl() against their complements. This is mandatory to do a correct RAM test.

Faults of the internal multiplexers are not monitored directly. As the redundancy of ACQ_MC_0_MON and ACQ_MU_0_MON is very important, the basic software for reading out the ADCs has to be coded by two different persons working independent of each other to provide diversy signal paths.

If there are more than one ADC available on MC or MU, the saftey relevant analog signals have to be converted on monitoried the ADCs.

Application conditions:

Initialisation: ACQ_MU_0_MON = ACQ_MC_0_MON = 0 using the ACTION_ECM3_WriteChkCpl()

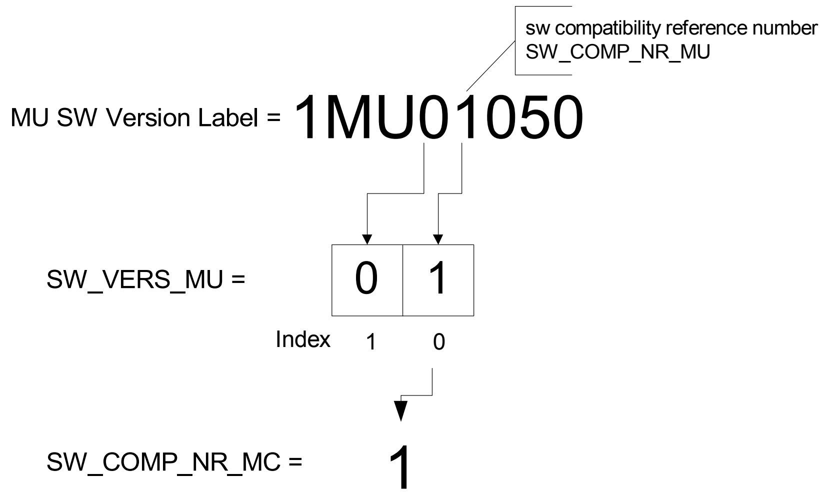
Recurrence: after each power up or reset

Activation: always

E.29.9 Software Reference Check

FUNCTION DESCRIPTION:

Each controller, MU and MC, has its own software version label which consists of characters. The software version reference SW_VERS_MU of the MU and the software compatibility number SW_COMP_NR_MC of MC are transmitted in the first communication, see chapter “Communication between MC and MU”. A software reference check is done on MC and MU.



Note: The given value of the Version Label is an example only.

The four characters of a software version referencene of MU has the following meaning:

Index	
1	Mask number
0	Software compatibility reference number

E.29.9.1 Software Reference Check on MC

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
SW_COMP_NR_MC	V	0...3FH	0...63	1	[-]
Software compatibility reference number of MC, sent to MU in the first communication					

Note: The value of the variable SW_COMP_NR_MC is set on MC and has to be transferred to MU via the intenal communication.

Input data:

SW_VERS_MU[NC_SW_VERS_MU_NR]			

Note: The value of this variable is set on MU and has to be transferred to MC via the internal communication.

The software compatibility reference number SW_COMP_NR_MC (one character) is initialized on MC with NC_SW_COMP_NR_MC. The MC compares SW_COMP_NR_MC with the software compatibility number of the MU after the first communication.

Formula section:

IF (SW_COMP_NR_MC <> SW_VERS_MU[0])

THEN

central failure reaction carried out

(refer to chapter: "Fault reaction of processor monitoring")

ENDIF

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_SW_COMP_NR_MC	1	0...3FH	0...63	1	[-]
Software version label of MC					

E.29.9.2 Software Reference Check on MU

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SW_VERS_MU[NC_SW_VERS_MU_NR]	V	0...3FH	0...63	1	[-]
software version label of MU					

Note: The value of this variable is set on MU and has to be transferred to MC via the internal communication. After the communication it is available on MC.

Input data: (on MU)

SW_COMP_NR_MC			

Note: The value of this variable is set on MC and has to be transferred to MU via the internal communication.

FUNCTION DESCRIPTION:

The characters of the data SW_VERS_MU on MU are initialised with the MU internal software version label NC_SW_VERS_MU. The two characters are transferred from MU to to MC in the INIT communication and stored in SW_VERS_MU on MC.

The internal software version reference number NC_SW_VERS_MU[0] of the MU is compared with the software compatibility number SW_COMP_NR_MC of MC after the INIT communication on MU:

IF (SW_COMP_NR_MC <> NC_SW_VERS_MU[0])

THEN

central fault reaction is carried out

(refer to chapter: "Fault reaction of processor monitoring")

ENDIF

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_SW_VERS_MU[NC_SW_VERS_MU_NR]	1	0...3FH	0...63	1	[-]
Software version reference of the MU, two bits are configurated via pins					
NC_SW_VERS_MU_NR	1	0...3FH	0...63	1	[-]
Dimension of the array SW_VERS_MU					

E.29.9.3 Pin configuration test

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MU_PIN_CONF	V	0...3H	0...3	1	[-]
Pin configuration of the variant coding of the MU					

General information:

During the initialization the MU reads two of its input pins, which are used for variant coding. Depending on this pin configuration, the MU runs different software. The read pins are transferred together with SW_VERS_MU[0] to the main controller. A pin configuration test is done on both controllers, like a Software Reference Check.

Each controller carries out its fault reaction, if the pin configuration indicates a fault, see also "Fault reaction of processor monitoring".

E.29.10 Switch off path activation due to endless resets on MC

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
ERR_COD_MC	V/O/S	0...FFH	0...255	1	[-]
Error code , which represents a failure detected by MC					

Note: ERR_COD_MC has to be located in the software reset safe RAM area; the exact meaning of the error codes can be found in “Fault reaction of processor monitoring.”

Input data:

RST_CTR_MC	ERR_COD_MU		

Additionally, information from the reset status register of MC is used.

FUNCTION DESCRIPTION:

General information:

In the presence of endless resets at ‘low frequency,’ the process monitoring may not be able to perform a fault reaction but the engine may produce high torque; in this context, ‘low frequency’ means that the resets occur during the fault reaction time of process monitoring.

In order to reduce the torque, the powerstages shall be disabled for as long as process monitoring is unable to react to any application software fault. This shall be achieved by triggering the redundant switch off path when endless resets are detected, refer to section “The redundant switch off path”.

Additionally, in order to distinguish this behaviour from a fault reaction by the process monitoring, a dedicated error code on the MC is set, see "Fault reaction of processor monitoring.”

Application conditions:

Initialisation: none

Recurrence: once

Activation: after each INIT communication (i.e., when ERR_COD_MU has become available)

Formula section:

IF (RST_CTR_MC = 0) **AND** (ERR_COD_MU = 0) **AND**

(reset status register on MC indicates a reset that has been triggered by the MC)

THEN

trigger redundant switch off path (refer to “The redundant switch off path”);

assign corresponding error code to ERR_COD_MC (see “Fault reaction of processor monitoring”)

ENDIF

E.30 Processor Monitoring (Appl. Inc.)

E.30.1 Communication between MC and MU

These data affects the communication itself as well as the monotoring of the communication on MC and MU.

Configuration data: (value assignment)

Name	Hex. value	Phys. value	Resol.	Unit
NC_T_SPI_COM	0Ah	10	1	ms
time for monitoring communication				
NC_T_SPI_MAX	0Dh	13	1	ms
Maximum time for timeout monitoring on MU				
NC_T_SPI_MIN	07h	7	1	ms
Minimum time for timeout monitoring on MU				
NC_ABC_INC_HD_MC	03h	3	1	1
increment value of anti bounce counter for maximum of header/command on MC				
NC_ABC_MAX_HD_MC	0Ch	12	1	1
maximum value of anti bounce counter for maximum of header/command on MC				
NC_ABC_INC_CKS_MC	03h	3	1	1
Increment value of anti bounce counter for monitoring of checksum on MC				
NC_ABC_MAX_CKS_MC	0Ch	12	1	1
Maximum value of anti bounce counter for monitoring of checksum on MC				
NC_ABC_INC_TOUT_MAX_MU	03h	3	1	1
Increment value of anti bounce counter for maximum timeout monitoring on MU				
NC_ABC_MAX_TOUT_MAX_MU	0Fh	15	1	1
Maximum value of anti bounce counter for maximum timeout monitoring on MU				
NC_ABC_INC_TOUT_MIN_MU	03h	3	1	1
Increment value of anti bounce counter for minimum timeout monitoring on MU				
NC_ABC_MAX_TOUT_MIN_MU	0Fh	15	1	1
Maximum value of anti bounce counter for minimum timeout monitoring on MU				
NC_ABC_INC_HD_MU	03h	3	1	1
Increment value of anti bounce counter for monitoring of header/command on MU				
NC_ABC_MAX_HD_MU	0Ch	12	1	1
Maximum value of anti bounce counter for monitoring of header/command on MU				
NC_ABC_INC_CKS_MU	03h	3	1	1
Increment value of anti bounce counter for monitoring of checksum on MU				
NC_ABC_MAX_CKS_MU	0Ch	12	1	1
Maximum value of anti bounce counter for monitoring of checksum on MU				

E.30.1.1 Initialisation of the Port Extensions

During initialisation (see “Processor Monitoring”) the digital output port extensions (see “Digital output port extensions”) are initialized (see “Communication between MC and MU”). NC_ENA_PORT_MU has the same structure like OUT_PORT_MU, which is described in chapter “Digital output port extensions”.

Configuration data: (value assignment)

Name	Hex. value	Binary value	Resol.	Unit
NC_ENA_PORT_MU	F9h	1111 1001	1	1
Bit pattern on MC, set to MU for initializing the digital output port extension				

E.30.2 Analog and pseudo digital inputs

E.30.2.1 Analog inputs on MU

Configuration data: (value assignment)

Name	Hex. limits	Phys. limits	Resol.	Unit
NC_ACQ_MU_NR	08h	8	1	1
Dimension of the array ACQ_MU				

E.30.3 Digital output port extension

E.30.3.1 Generation of Diagnosis Pulses on the Digital Output Port Extension

Configuration data: (value assignment)

Name	Hex. limits	Phys. limits	Resol.	Unit
NC_T_DGO_OFS	02h	2	1	ms
Time to wait after communication to send diagnosis pulse				

E.30.4 Processor monitoring

E.30.4.1 The test calcualtion Copy of process monitoring

Configuration data: (value assignment)

Name	Hex. value	Phys. value	Resol.	Unit
NC_ABC_INC_MON2_MU	03h	3	1	1
Increment value of anti bounce counter of level 2’ test calculations on MU				
NC_ABC_MAX_MON2_MU	0Ch	12	1	1
Maximum value of anti bounce counter of level 2’ test calculations on MU				
NC_TEST_REC_IDX_MAX_MON2	0Ch	12	1	1
(NC_TEST_REC_IDX_MAX_MON2-1) is the maximum value for the index of test calculation Therfore NC_TEST_REC_IDX_MAX_MON2 answers are calculated cyclically				

E.30.4.1.1 Inspection of MU by the MC according to test calculation level 2’

Configuration data: (value assignment)

Name	Hex. value	Phys. value	Resol.	Unit
NC_ABC_INC_MON2_TEST_MC	03h	3	1	1
Increment value of anti-bounce counter to test the anti-bounce counter of level 2’ test calculations on MU				
NC_ABC_MAX_MON2_TEST_MC	0Ch	12	1	1
Maximum value of anti-bounce counter to test the anti-bounce counter of level 2' test calculations on MU				
NC_ABC_INC_MON2_TEST_2_MC	03h	3	1	1
Increment value of anti-bounce counter to test the incrementation of level 2’ test calculation index on MU				
NC_ABC_MAX_MON2_TEST_2_MC	0Ch	12	1	1
Maximum value of anti-bounce counter to test the incrementation of level 2' test calculation index on MU				
NC_T_MON2_TEST_MC	0Fh	320	2*NC_T_SPI_COM	1
Time base for inspection the evaluation of level 2' test calculation on MU				

E.30.4.2 Program flow monitoring

The bits of RESP_PFM_MC and SYN_PFM_MU as well as the anti bounce counters of the program flow monitoring has to be assigned to specific tasks running on different time levels:

Configuration data: (value assignment)

Name	Hex. value	Phys. Value	Resol.	Unit
NC_ABC_INC_PFM_TEST_MC	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MC				
NC_ABC_MAX_PFM_TEST_MC	0Ch	12	1	1
Increment value of anti-bounce counter of program flow monitoring on MC				
NC_ABC_INC_PFM_1_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 1				
NC_ABC_MAX_PFM_1_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 1				
NC_ABC_INI_PFM_1_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 1				
NC_T_PFM_1_MU	01h	10	NC_T_SPI_COM	1
Time grid of task 1				
NC_T_CHK_PFM_1_MU	02h	20	NC_T_SPI_COM	1
Time to check PFM bits of task 1				
NC_ABC_INC_PFM_2_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 2				
NC_ABC_MAX_PFM_2_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 2				
NC_ABC_INI_PFM_2_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 2				
NC_T_PFM_2_MU	04h	40	NC_T_SPI_COM	1
Time grid of task 2				
NC_T_CHK_PFM_2_MU	08h	80	NC_T_SPI_COM	1
Time to check PFM bits of task 2				
NC_ABC_INC_PFM_3_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 3				
NC_ABC_MAX_PFM_3_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 3				
NC_ABC_INI_PFM_3_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 3				
NC_T_PFM_3_MU	04h	40	NC_T_SPI_COM	1
Time grid of task 3				
NC_T_CHK_PFM_3_MU	08h	80	NC_T_SPI_COM	1
Time to check PFM bits of task 3				
NC_ABC_INC_PFM_4_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 4				
NC_ABC_MAX_PFM_4_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 4				
NC_ABC_INI_PFM_4_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 4				
NC_T_PFM_4_MU	28h	40	1	ms
Time grid of task 4				
NC_T_CHK_PFM_4_MU	08h	80	NC_T_SPI_COM	1
Time to check PFM bits of task 4				
NC_ABC_INC_PFM_5_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 5				
NC_ABC_MAX_PFM_5_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 5				
NC_ABC_INI_PFM_5_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 5				

Name	Hex. value	Phys. Value	Resol.	Unit
NC_T_PFM_5_MU	04h	40	NC_T_SPI_COM	1
Time grid of task 5				
NC_T_CHK_PFM_5_MU	08h	80	NC_T_SPI_COM	1
Time to check PFM bits of task 5				
NC_ABC_INC_PFM_6_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 6				
NC_ABC_MAX_PFM_6_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 6				
NC_ABC_INI_PFM_6_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 6				
NC_T_PFM_6_MU	04h	40	NC_T_SPI_COM	1
Time grid of task 6				
NC_T_CHK_PFM_6_MU	08h	80	NC_T_SPI_COM	1
Time to check PFM bits of task 6				
NC_ABC_INC_PFM_7_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 7				
NC_ABC_MAX_PFM_7_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 7				
NC_ABC_INI_PFM_7_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 7				
NC_T_PFM_7_MU	0Ah	100	NC_T_SPI_COM	1
Time grid of task 7				
NC_T_CHK_PFM_7_MU	14h	200	NC_T_SPI_COM	1
Time to check PFM bits of task 7				
NC_ABC_INC_PFM_8_MU	03h	3	1	1
Increment value of anti-bounce counter of program flow monitoring on MU for task 8				
NC_ABC_MAX_PFM_8_MU	0Ch	12	1	1
Maximum value of anti-bounce counter of program flow monitoring on MU for task 8				
NC_ABC_INI_PFM_8_MU	0Ch	12	1	1
Init value of anti-bounce counter of program flow monitoring on MU for task 8				
NC_T_PFM_8_MU	64h	1000	NC_T_SPI_COM	1
Time grid of task 8				
NC_T_CHK_PFM_8_MU	C8h	2000	NC_T_SPI_COM	1
Time to check PFM bits of task 8				

Note: If the task *n* is not program flow monitored, the configuration data NC_ABC_INC_PFM_*n*_MU and NC_ABC_INI_PFM_*n*_MU must be set to zero.

E.30.5 Fault Reaction of Processor Monitoring

Configuration data: (value assignment)

Name	Hex. value	Phys. value	Resol.	Unit
NC_RST_CTR_MAX_MC	07h	7	1	1
Maximum value of software resets on MC				
NC_RST_CTR_MAX_MU	07h	7	1	1
Maximum value of software resets on MU				
NC_T_RST_CTR_MC	FFh	255	NC_T_SPI_COM	1
Time to decrement the reset counter on MC				
NC_T_RST_CTR_MU	18h	6144	256	ms
Time to decrement the reset counter on MU				
NC_T_DR_DI_RST_MC	34h	520	NC_T_SPI_COM	1
Time delay for enabling power stages after error reset on MC				
NC_T_DR_DI_RST_MU	34h	520	NC_T_SPI_COM	1
time delay for enabling power stages after error reset on MU				

E.30.6 Classification of Processor Faults

The fault reaction time of all safety critical faults must be shorter than the required fault reaction time of Process Monitoring, which is 500ms (see "General"; chapter E).

Safety critical Processor Monitoring faults are:

- Standard RAM test on MC
- Cyclical ROM test of Process Monitoring
- Program flow monitoring of Process Monitoring
- The test calculation Copy of process monitoring
  All test calculations and the debouncing of a fault must be performed within the fault reaction time

Additional the following tests are performed within 500ms:

- RAM test on MC for process monitoring.
  This test is also safety critical. Note, that the fault reaction time of this test is implicitly given by the scheduler of level2. The complete RAM test of Process Monitoring is performed within the recurrence time of the Process Monitoring modules.
- Watchdog on MU
  This test is a redundant test to the PFM.
- Inspection of MU by the MC according to test calculation (level 2')
  The aim of this test is the detection of dormant faults. One has to avoid, that a level 2 module get defect *and* the dedicated level 2' module is no longer tested because of a defect in the generation of the level 2' test index.
- Inspection of MU by the MC on PFM
  The aim of this test is the detection of a dormant fault. With this test it is ensured, that the evaluation of PFM data in level 3 are able to detect a PFM error.
- Communication monitoring (communication between MC and MU)
  This tests ensures a correct communication and data transfer between MC and MU. This tests are performed permanently, if the communication is active.

The following additional test are performed during the initialization only:

- Predrive Check
  The aim of this test is the detection of dormant fault
- Software reference check
- Pin configuration test

The following tests are not seen as safety critical:

- Standard ROM test on MC
  The aim of this test is the detection of a dormant fault. Note, that the ROM area of the Process Monitoring is teseted within the required fault reaction time. Therefore it is ensured, that the performance of the Process Monitoring is not affected by any ROM error.

E.31 Interface to power stages

See the following figure for the HW-schematic:

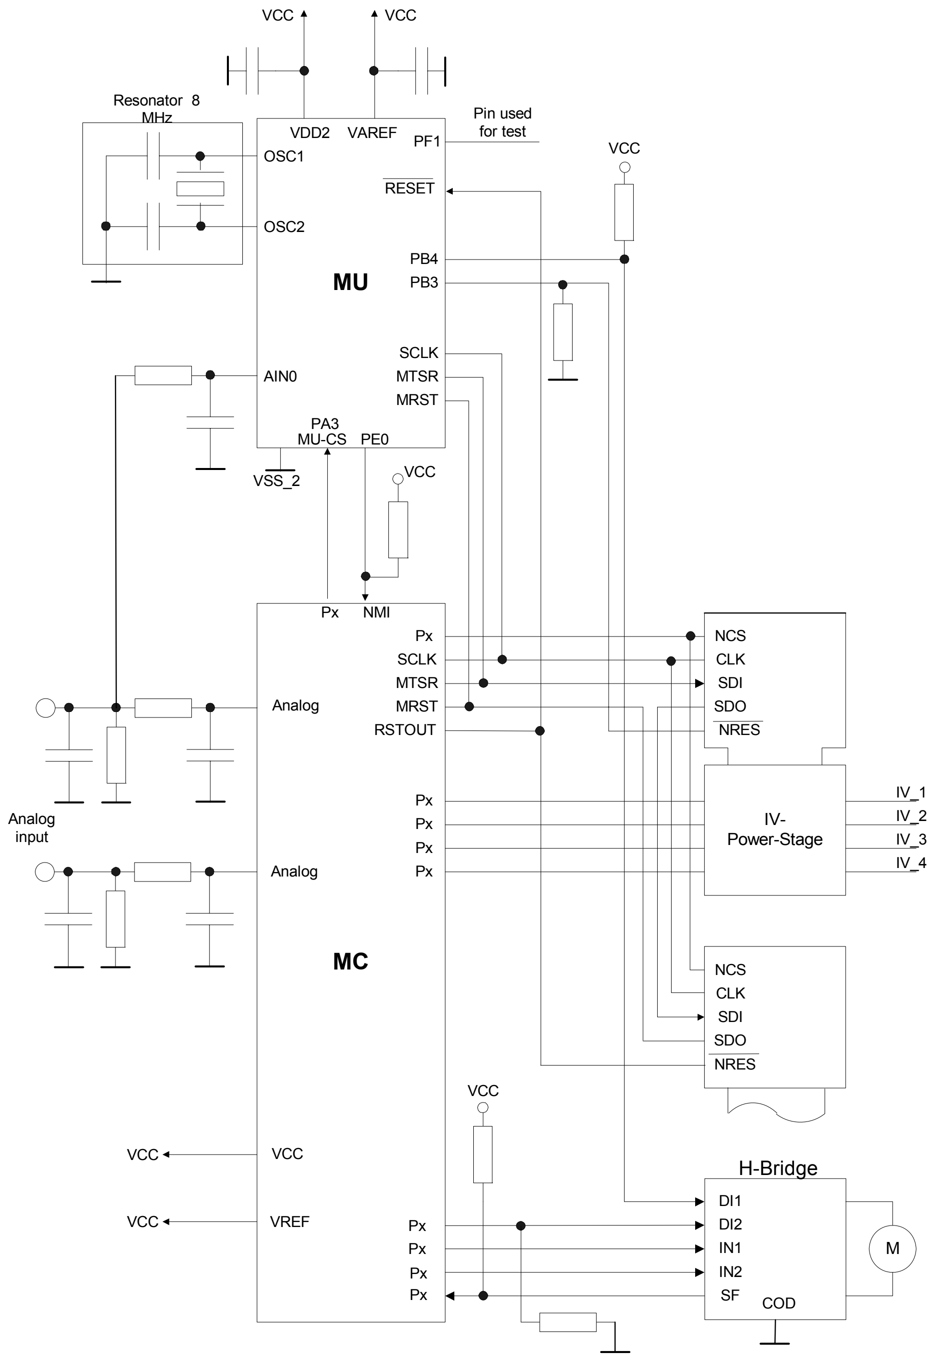


Figure 76: Hardware Safety Module

The main-processor (MC) and the monitoring processor (MU, incl. port extensions) are connected via SPI-communication. MU has its own oscillator (ceramic resonator).

When resetting, MC gives a reset signal to MU so it will also reset. This enables synchronisation between them.

In case of processor monitoring faults detected on MU, the throttle is disabled via PB4 and injectors are disabled via PB3. Via PB0, MU resets MC to increase availability.

The status when the powerstages are disabled via MU are:

PE0 = HIGH

PE1 = LOW (only for 32bit main controller applications)

PB3 = LOW

PB4 = HIGH

LV_ERR_TMP_MU = 1;

The analog input of first AD-channel on MU is connected to the dedicated analog input on the MC; the value is transmitted to MC only to check the ADCs. Remaining AD-channels and digital outputs can be used as port extension (no safety function, but it has to be assured, that no damaging voltage is fed to the ports in case of any fault).

E.32 Fault reaction of process monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_N_LIM_REQ_MON	O/V	0...1H	0...1	1	-
Request for engine speed limitation					
LV_OFF_IV_MON	O/V	0...1H	0...1	1	-
Request for disable of IV power stage by main controller					
LV_OFF_MTC_MON	O/V	0...1H	0...1	1	-
Request for disable of MTC power stage by main controller					
LV_ERR_TRAN_MON	V	0...1H	0...1	1	-
Flag for temporary fault during last recurrency					
LV_OFF_IV_N_LIM_ETC_TMP_MON	V	0...1H	0...1	1	-
Flag for temporary injection cut off during last recurrency

/* Disable injection and H-bridge */

Description for ACTION_ECM2_UnlockPws():

Description:

Syntax: ACTION_ECM2_UnlockPws()

Formula section:

LV_OFF_IV_MON = 0;

LV_OFF_MTC_MON = 0;

/* Enable injection and H-bridge for exactly one time */

General description

The objective of this module is to react on faults detected by the process and processor monitoring of the etc-monitoring-concept. The following actions are introduced depending on the error level and the degree of degradation.

disable of throttle power stage (LV_OFF_MTC_MON)

disable of injection power stage (LV_OFF_IV_MON)

transmission of wrong answers from level 2' to the monitoring processor in order to force the monitoring unit to reset the main controller and switch of the throttle and the injection power

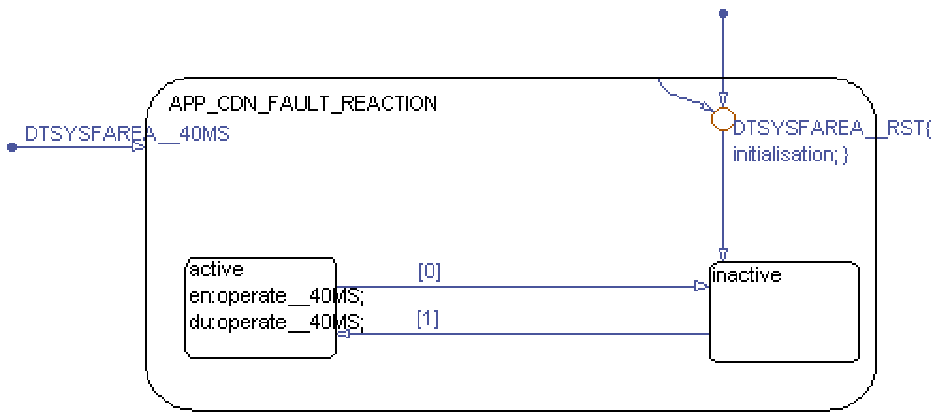
The following table shows the fault reactions corresponding to the underlying faults. No fault reaction is reset until next ignition key on (transition from LV_IGK = 0 to 1). There are only two exceptions, 1.) for a temporary fault detected by the processor monitoring on the main controller (LV_ERR_TMP_MU_MC) and 2.) for injection cut off (LV_OFF_IV_MON) during engine speed limitation.

Faults \ Fault reaction	Disable of MTC via main controller (LV_OFF_MTC_MON = 1)	Request engine speed limitation (LV_N_LIM_REQ_MON = 1)	Disable of IV via main controller (LV_OFF_IV_MON = 1)	Disable of MTC and IV via monitoring unit (ACTION_ECM3_RedSwitchOffPath())
LV_ERR_CONV_MON	X	X	Z	Z
LV_ERR_N_32_MON	X	X	Z	Z
LV_ERR_TQ_DIF_P_D_IS_MON	X	X	Z	Z
LV_ERR_TQ_DIF_I_IS_MON	X	X	Z	Z
LV_ERR_TQ_LOSS_MON	X	X	Z	Z
LV_ERR_TQ_MIN_CLU_MON	X	X	Z	Z
LV_ERR_TQ_MAX_CLU_MON	X	X	Z	Z
LV_ERR_PVS_MON	X	X	Z	Z
LV_ERR_TPS_MON	X	X	Z	Z
LV_ERR_MAF_MON	X	X	Z	Z
LV_ERR_TQI_AV_MON	X	X	Z	Z
LV_OFF_IV_N_LIM_ETC_MON*	Z	Z	X / 0	Z
LV_ERR_TQI_N_MAX_MON	X	Z	X	X
LV_ERR_MU_MC	X	Z	X	Z
LV_ERR_TMP_MU_MC*	X	Z	X	Z

* reversible during a driving cycle,

The map shows resulting states of output bits. The proceeding is top-down, e.g. the undermost set fault bit of a column defines the resulting state. Symbol “x” means the related bit is set, “z” the former result of present recurrency will not be changed and “0 “ resets the related bit, if the fault is not set.

LV_OFF_IV_MON must be calculated first by LV_OFF_IV_N_LIM_ETC_MON and than by non reversible fault reactions to be sure that a wrong write operation with LV_OFF_IV_MON = 0 is less prior than fault reactions with permanent fuel cut-off.



Application Condition

Note: DTSYSFAREA__RST includes the function calls as defined in application incidences.

E.33 Fault Reaction of Processor Monitoring

If the MC or the MU detect a processor fault, the safety critical power stages are disabled and a SW-reset is done. The disabling of the power stages is handled in different ways: The MU sets the level of the disable pins (see "Interface to power stages") and therefore directly disables the power stages, while the MC only sets some boolean variables, which are evaluated elsewhere, i.e. *Fault Reaction of Process Monitoring*.

The release of a SW-reset has to be implementend in the level 3 (*Processor Monitoring*) itself in a very robust way; it may not occure at all that the SW-reset is not carried out because of any dormant fault.

The subroutine ‘central fault reaction’ is called with parmeters which enables to know exactly where what kind of fault has been detected. The number of resets is limited on the MC and the MU separately. After this limited number of resets MC and MU are permanently disabled with disabled power stages for this drive cycle.

During the initialisation (see “Processor Monitoring”) both, MU and MC, keeps the power stages disabled if one of the reset counters (RST_CTR_MC, RST_CTR_MU) is bigger than one. Therefore the reset counters are transferred during the INIT communication, see “Communication between MC and MU”.

Both, MU and MC are able to request a reset. If the MU requests a reset, this is transferred to MC via NMI. Reseting the MC will automatically entail a reset on the MU.

It must be differentiated therefore whether a fault reaction is initiated on the MC or on the MU.

To enforce the ECU to enter a safe state, the safety critical power stage are disabled. There are two separate and independed paths to do this via MC and/or via MU.

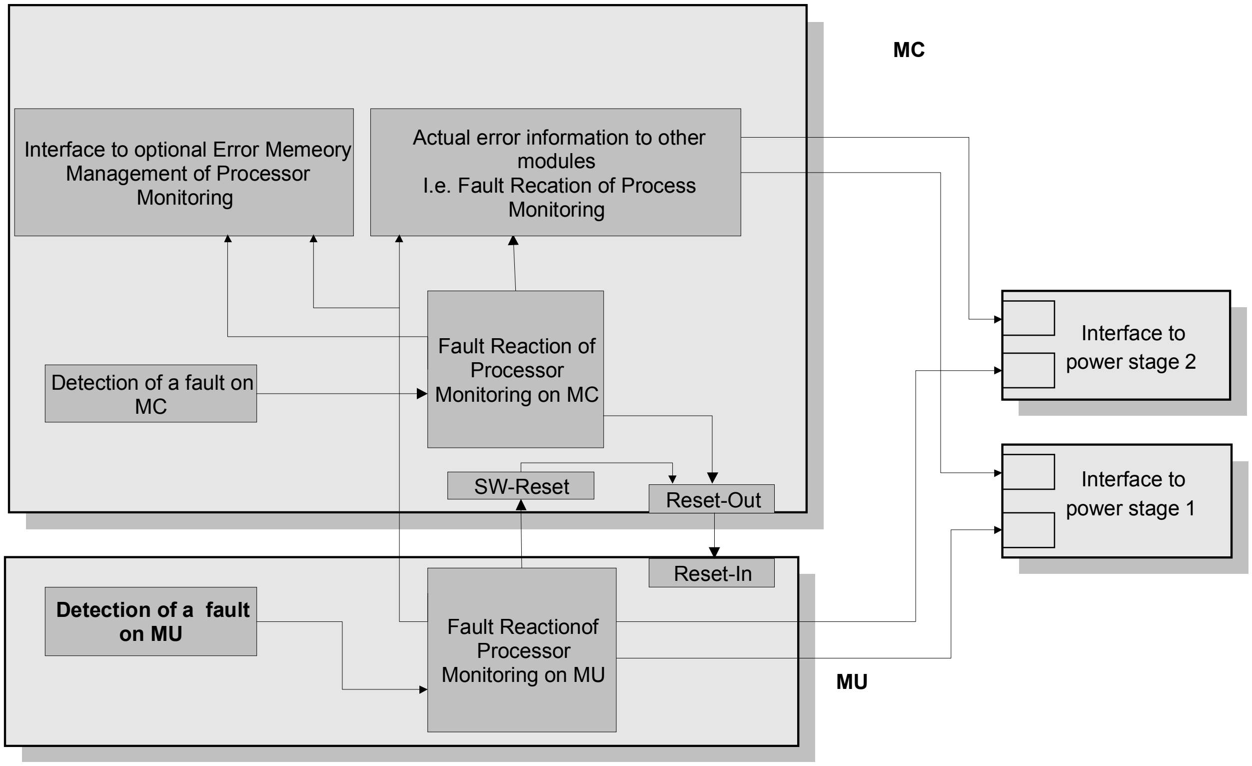

Figure 80: Fault Reaction paths of the *Processor Monitoring* with two power stages

E.33.1 Link between fault variables and initialization of MU fault variables on MC

FUNCTION DESCRIPTION:

General information:

In the first communication the values of the MU fault variables RST_CTR_MU and ERR_COD_MU are transferred from MU to MC, see "Communication between MC and MU". LV_ERR_TMP_MU on MC can also be updated only *after* a dedicated communication. Therefore it is mandatory to initialize this variables on MC *before* this communications, because the values set by MU are only avaliable *after* a fault free communication. The first communication could be delayed i.e. by the Predrive Check. Because other software moduls could evaluate the variables inbetween, a useful initialization is needed.

Application conditions:

Initialisation: LV_ERR_TMP_MU = 1; /* MU disables the power stages temporay */

RST_CTR_MU = 0;

ERR_COD_MU = 0h;

E.33.2 Fault Reaction of MC

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_ERR_MC	V/O	0h ... 1h	0...1	1	1
Final request for disabled power stages by processor monitoring on MC					
LV_ERR_TMP_MC	V/O	0h ... 1h	0...1	1	1
Temporary request for disabled power stages by processor monitoring on MC					
ERR_COD_MC	V/O/S	00h ... FFh	0...255	1	1
Error code , which represents a failure detected by MC					
RST_CTR_MC	V/O/S	00h ... FFh	0...255	1	1
Reset counter on MC					

Note: ERR_COD_MC and RST_CTR_MC have to be located in the software reset safe RAM area, as indicated by the mode “S”.

Input data:

SW_COMP_NR_MC	SW_VERS_MU	ABC_MON2_MU
ABC_PFM_TEST_MC	ABC_MON2_TEST_2_MC	ABC_CKS_MC
ABC_HD_MC	LV_ROM_CRC_READY	RST_CTR_MU

FUNCTION DESCRIPTION:

General information:

The MC has different fault locations:

ERR_COD_MC

Value	Meaning	Reason
0h	No error	
1h	Communication, checksum error	ABC_CKS_MC
2h	Communication, MU sends wrong command/header	ABC_HD_MC
3h	Predrive check error	MU is unable to disable the safety relevant power stages
4h	Software version, MU sends wrong SW version	SW_COMP_NR_MC, SW_VERS_MU
5h	Software version, MU sends wrong variant coding	Pin-Configuration
6h	Level 2’, MU does not increment ABC_MON2_MU	ABC_MON2_TEST_MU
7h	Level 2’, MU does not increment TEST_REC_IDX_MON2	ABC_MON2_TEST_2_MC
8h	Program flow monitoring, MU does not toggle the control bit(s)	ABC_PFM_TEST_MC
9h	ROM test of process monitoring (Level 2)	
Ah	RAM test of process monitoring (Level 2)	
Bh	Standard total ROM test	
Ch	Standard total RAM test	
Dh	Switch off path activation due to endless resets on MC	

After a power up ERR_COD_MC is initialized with zero.

Application conditions:

Initialisation: ERR_COD_MC = 0
after power up only

RST_CTR_MC = 0
after power up only

LV_ERR_TMP_MC = 1
after reset or power up

LV_ERR_MC = 0 after power up
LV_ERR_MC = 0 after reset if RST_CTR_MC <= NC_RST_CTR_MAX_MC
LV_ERR_MC = 1 after reset if RST_CTR_MC > NC_RST_CTR_MAX_MC

E.33.2.1 Setting of error flag on MC

If a fault is debounced, a central fault reaction carried out and the number of reset requests is counted. Before the first communication the reset safe stored reset counter RST_CTR_MC is evalauted to set the variable LV_ERR_TMP_MC:

Formula section:

```
/* In case of an error detected on MC: */
IF (RST_CTR_MC < NC_RST_CTR_MAX_MC) THEN
    RST_CTR_MC++;
    RESET on MC;
ELSE
    LV_ERR_MC = 1;
    RST_CTR_MC = NC_RST_CTR_MAX_MC + 1;
    /* The Predrive check has to be cancelled */
    enter DISABLE State

END

/* during initialization (after reset caused by MC or triggered by MU via NMI)   */
/* this block is executed every recurrence of a level 3 call in the             */
/* time periode of NC_T_DR_DI_RST_MC after reset or power up                    */
/* After this time periode LV_ERR_TMP_MC is reset                               */
IF (RST_CTR_MC > 1) OR (RST_CTR_MU > 1) THEN
    LV_ERR_TMP_MC = 1;
ELSE
    LV_ERR_TMP_MC = 0;
END

IF (RST_CTR_MC > NC_RST_CTR_MAX_MC) THEN
    LV_ERR_MC = 1;
    /* The Predrive check has to be cancelled */
    enter DISABLE State

END
```

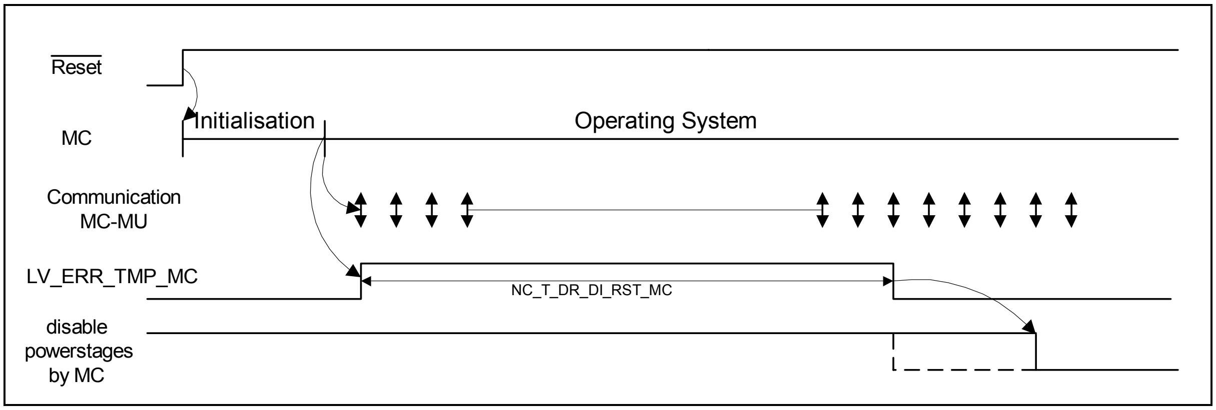
RST_CTR_MC is decremented if the time NC_T_RST_CTR_MC has passed *and* LV_ROM_CRC_READY is set (Standard ROM test finished, see "Processor Monitoring", subsection "Standard ROM Test on MC").

Note: All tests on MC at runtime must not last longer than NC_T_RST_CTR_MC. An exeption is the standard ROM test on MC.

E.33.2.2 Fault Reaction after second to (NC_RST_CTR_MAX_MC)th fault reset

(fault does not longer exist)

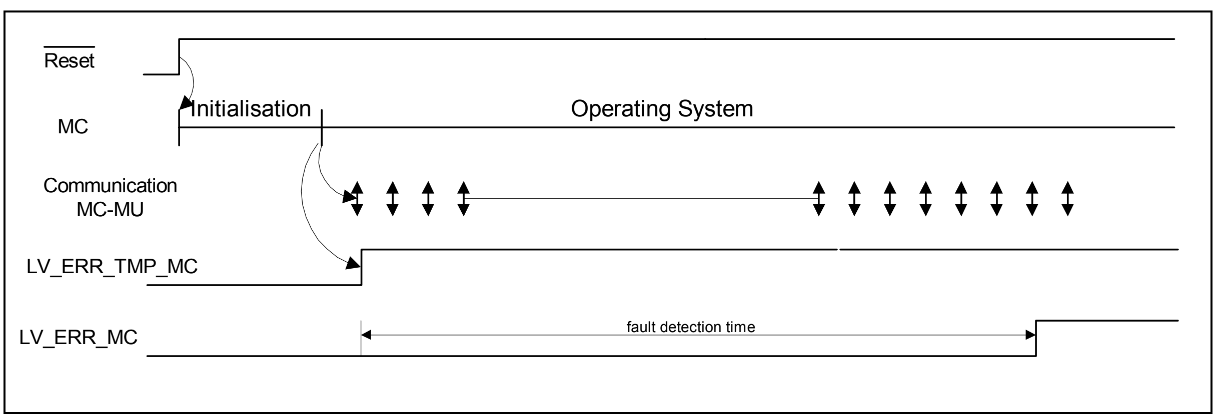
After the second error reset (RST_CTR_MC>1 or RST_CTR_MU>1) LV_ERR_TMP_MC is set and the MC waits NC_T_DR_DI_RST_MC before it enables the power stages (LV_ERR_TMP_MC = 0). Within the required fault reaction time all Processor Monitoring related tests have to be performed. During this time periode the safety relevant power stages must be disabled. The safety critical faults are listed in the subsection "Classification of Processor Faults". Processor Monitoring Faults during this time periode would lead to another reset with disabled power stages.



E.33.2.3 Fault Reaction after (NC_RST_CTR_MAX_MC)th fault reset

(fault still exists)

After the (NC_RST_CTR_MAX_MC)th fault reset on MC a complete test of MU and MC is performed. Faults during that test would lead to permanently disabled power stages for this driving cycle. The Predrive check must be cancelled, if active (see "Processor Monitoring", subsection "Reset or power up").



Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_T_RST_CTR_MC	1	00h ... FFFFh	0...65535*NC_T_SPI_COM	NC_T_SPI_COM	1
time to decrement the reset counter					
NC_T_DR_DI_RST_MC	1	00h ... FFh	0...255*NC_T_SPI_COM	NC_T_SPI_COM	1
Time delay for enabling power stages after error					
NC_RST_CTR_MAX_MC	1	00h ... FFh	0...255	1	1
max value of software resets on MC					

E.33.3 Fault Reaction of MU

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_COD_MU	V/O	00h ... FFh	0...255	1	1
Error code which represents an error on MC detected by MU					
RST_CTR_MU	V/O	00h ... FFh	0...255	1	1
reset counter on MU, transmitted to MC after reset					
LV_ERR_TMP_MU	V/O	0 ... 1h	0 ... 1	1	1
Request of MU to disable the power stages temporary, sent to MC					

Note: The values of these variables are available on MC after the dedicated internal communication. The MU internal variables ERR_COD_MU and RST_CTR_MU have to be located in the software reset safe RAM area.

Input data:

RAM_TEST_MU	RAM_TEST_MU_CPL	CRC_CKS_CLC_MU	NC_CRC_CKS_MU
ABC_MON2_MU	SW_COMP_NR_MC	NC_SW_VERS_MU	RST_CTR_MC
ABC_TOUT_MAX_MU	ABC_TOUT_MIN_MU	ABC_HD_MU	ABC_CKS_MU
ABC_PFM_1_MU	ABC_PFM_2_MU	ABC_PFM_3_MU	ABC_PFM_4_MU
ABC_PFM_5_MU	ABC_PFM_6_MU	ABC_PFM_7_MU	ABC_PFM_8_MU

FUNCTION DESCRIPTION:

Note:

The MU internal variables are not visible at all. Their values are available on MC after the dedicated internal communication only if the values are transferred.

General information:

The MU has different failure locations:

ERR_COD_MU

Value	Meaning	Reason
00h	no error	
01h	Wrong header/command in communication	ABC_HD_MU
02h	Checksum error in communication	ABC_CKS_MU
03h	Wrong pin configuration	
04h	MU-SW does not match MC-SW	SW_COMP_NR
05h	Maximum timeout communication error	ABC_TOUT_MAX_MU
06h	Minimum timeout communication error	ABC_TOUT_MIN_MU
07h	RAM error	RAM_TEST_MU, RAM_TEST_MU_CPL
08h	ROM error	(CRC_CKS_CLC<>NC_CRC_CKS)
09h	Wrong result of testcalculation level2' (redundant switch off path not activated)	ABC_MON2_MU
0Ah	Redundant switch off path was triggered by MC	LV_OFF_DR_MU_MON
0Bh	Program flow monitoring task 1	ABC_PFM_1_MU
0Ch	Program flow monitoring task 2	ABC_PFM_2_MU
0Dh	Program flow monitoring task 3	ABC_PFM_3_MU
0Eh	Program flow monitoring task 4	ABC_PFM_4_MU
0Fh	Program flow monitoring task 5	ABC_PFM_5_MU
10h	Program flow monitoring task 6	ABC_PFM_6_MU
11h	Program flow monitoring task 7	ABC_PFM_7_MU
12h	Program flow monitoring task 8	ABC_PFM_8_MU
13h	Watchdog error	
14h	Communication error, wrong enable byte	ENA_PORT_MU

After a power up ERR_COD_MU is initialized with zero.

Application conditions on MU:

Initialisation: ERR_COD_MU = 0
only after power up

LV_ERR_TMP_MU = 1
value copied into sent buffer accoring to reset counter on MU

E.33.3.1 Actual error response

If the failure is debounced, a central fault reaction is carried out and the number of reset requests is counted:

Formula section:

- disabling of power stages (see “Interface to power stages”)

IF (RST_CTR_MU < NC_RST_CTR_MAX_MU)

THEN

RST_CTR_MU++;

RESET on MC via NMI;

ELSE

RST_CTR_MU = NC_RST_CTR_MAX_MU + 1;

enter DISABLE state

ENDIF

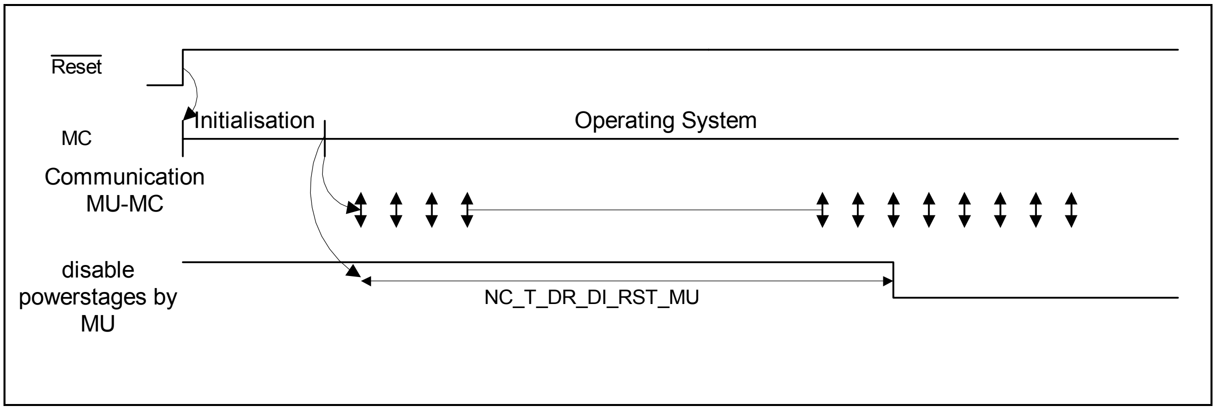
RST_CTR_MU is decremented every NC_T_RST_CTR_MU.

Note: All tests on MU at runtime must not last longer than NC_T_RST_CTR_MU.

E.33.3.2 Fault Reaction after second to (NC_RST_CTR_MAX_MU)th fault reset

(fault does not longer exist)

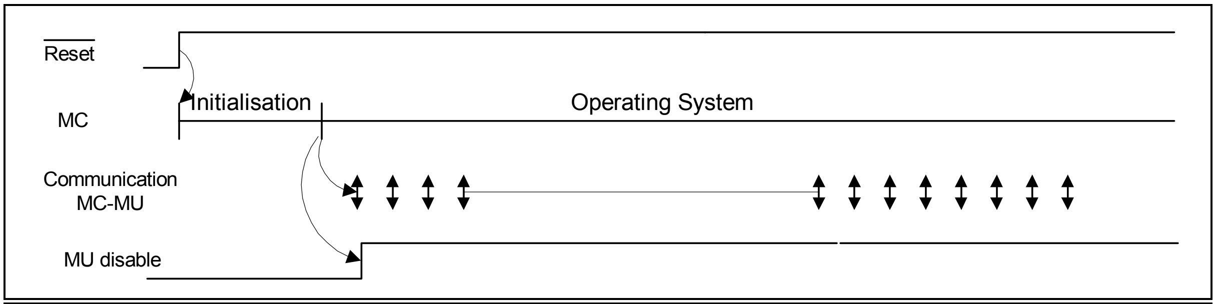
After the second error reset (RST_CTR_MU>1 or RST_CTR_MC>1) MU waits NC_T_DR_DI_RST_MU before it enables the power stages by resetting LV_ERR_TMP_MU. Within the required fault reaction time all Processor Monitoring related tests have to be performed. During this time periode the safety relevant power stages must be disabled. The safety critical fault are listed in the subsection "Classification of Processor Faults". Processor Monitoring Faults during this time periode would lead to another reset with disabled power stages.



E.33.3.3 Fault Reaction after the (NC_RST_CTR_MAX_MU)th fault reset

(fault still exists)

After the (NC_RST_CTR_MAX_MU)th fault reset on the MU a complete test of MU and MC is performed. Faults during that test would lead to permanently disabled power stages for this driving cycle.



Configuration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
NC_RST_CTR_MAX_MU	1	00h ... FFh	0...255	1	1
Max value of SW-reset on MU					
NC_T_RST_CTR_MU	1	00h ... FFh	0...255	256	ms
time to decrement the reset counter					
NC_T_DR_DI_RST_MU	1	00h ... FFh	0...255*NC_T_SPI_COM	NC_T_SPI_COM	1
Time delay for enabling power stages after error reset					

E.33.4 Evaluation of MU error information on MC

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_ERR_MU	V/O	0 ... 1h	0 ... 1	1	1
Request of MU to diasble the power stages permanently, sent to MC in DISABLE communication					

Input data:

RST_CTR_MU			

FUNCTION DESCRIPTION:

General information:

The variable LV_ERR_MU indicates on MC that the MU disables the power stages permanently for this driving cycle. LV_ERR_MU is set on MC, if the reset counter of MU reached its maximum. Therefore the reset counter of MU has to be transferred in the INIT and DISABLE communication, see "Communication between MC and MU".

Application conditions:

Initialisation: LV_ERR_MU = 0;

After reset or power up

Formula section:

IF (RST_CTR_MU > NC_RST_CTR_MAX_MU)

THEN

LV_ERR_MU = 1;

ENDIF

E.33.5 Interface to Error memory management of processor monitoring

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_COD_MC_SAVE	V/O	0 ... FFh	0 ... 255	1	1
Saved error code of main controller, value of ERR_COD_MC after first communication					
RST_CTR_MC_SAVE	V/O	0 ... FFh	0 ... 255	1	1
Saved reset counter of main controller, value of RST_CTR_MC after first communication					
ERR_COD_MU_SAVE	V/O	0 ... FFh	0 ... 255	1	1
Saved error code of monitoring unit, value of ERR_COD_MU after first communication on main controller					
RST_CTR_MU_SAVE	V/O	0 ... FFh	0 ... 255	1	1
Saved reset counter of monitoring unit, value of RST_CTR_MU after first communication on main controller					

Input data:

ERR_COD_MC	ERR_COD_MU	RST_CTR_MC	RST_CTR_MU

FUNCTION DESCRIPTION:

General information:

If the MC does a software reset due to an error, the MC saves the reason of that error in ERR_COD_MC prior to the reset. ERR_COD_MC is not deleted after a software reset.

The MU has no possibility to keep error information after power down. For this reason the error information is transmitted to MC. If MU releases a software reset due to an error, MU saves the cause of the error in ERR_COD_MU before. ERR_COD_MU is not deleted after a software reset. After the reset the error code is transmitted to MC.

The error code zero, indicates no detected faults. After a normal power up the error codes ERR_COD_MC and ERR_COD_MU are initialized with zero.

After the first communication past a fault reaction (INIT or DISABLE) the complete error information, the values of the main controller as well as the values of the monitoring unit, are available on the main contoller. To provide a storage of this error information the values of ERR_COD_MC, ERR_COD_MU, RST_CTR_MC and RST_CTR_MU has to be saved in other variables. After having updated ERR_COD_MC_SAVE, ERR_COD_MU_SAVE, RST_CTR_MC_SAVE and RST_CTR_MU_SAVE, the module given in "Error memory management of processor monitoring" is called.

To aviod uninitalizes variables ERR_COD_MC_SAVE, ERR_COD_MU_SAVE, RST_CTR_MC_SAVE and RST_CTR_MU_SAVE on MC before the first communcation, a initialization with zero in done.

Application conditions:

Initialisation: *ERR_COD_MC_SAVE = ERR_COD_MU_SAVE = RST_CTR_MC_SAVE = RST_CTR_MU_SAVE = 0*

Recurrence: after each power up or reset

Activation: always

Formula section:

After the first communication (INIT or DISABLE past a fault reaction):

ERR_COD_MC_SAVE = ERR_COD_MC;

ERR_COD_MU_SAVE = ERR_COD_MU;

RST_CTR_MC_SAVE = RST_CTR_MC;

RST_CTR_MU_SAVE = RST_CTR_MU;

CALL "Error memory management of processor monitoring"

E.33.6 Status of power stages by Processor Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_DR_MU_MC	V/O	1h 2h 4h 8h 10h E0h	"PREDRIVE" "TMP_DIS" "DISABLE_REQ" "DISABLE_MC" "DISABLE_MU" "ENABLE"	1	1
State of Processor Monitoring (MU and MC) according to the safety relevant power stages					
LV_ERR_TMP_MU_MC	V/O	0 ... 1h	0 ... 1	1	1
Reversible disabled power stages by processor monitoring (MC and/or MU)					
LV_ERR_MU_MC	V/O	0 ... 1h	0 ... 1	1	1
Irreversible disabled power stages by processor monitoring (MC and/or MU)					

Input data:

LV_ERR_MC	LV_ERR_MU	LV_ERR_TMP_MU	LV_ERR_TMP_MC
LV_PRDR_ACT	MU_DI_STATE		

FUNCTION DESCRIPTION:

General information:

- LV_ERR_TMP_MU_MC and LV_ERR_MU_MC provide the interface to *Process Monitoring* for disable request of the safety relevant power stages by MC to provide a redundant disabling
- STATE_DR_MU_MC provides an interface to the ASW

The overall state of the *Processor Monitoring* according to the disabling of the safety relevant power stages is stored in the variable STATE_DR_MU_MC, which depends on several logical variables and the state of disable request (refer to "Communication between MC and MU"). This state includes the disabling of the saftey relevant power stages by the MU regarding the predrive check.

- STATE_DR_MU_MC="ENABLE" belongs to a normal operation (no request for disabling the safety relevant power stages, no disable request, no predrive check in progress) of the *Processor Monitoring*. In this state the power stages are enabled with respect to the *Processor Monitoring*. The other way round STATE_DR_MU_MC<>"ENABLE" means disables power stages.
- STATE_DR_MU_MC="PREDRIVE" belongs to a state where the MU disables the power stages, while the MC performs the predrive check.
- ((STATE_DR_MU_MC!="PREDRIVE") AND (STATE_DR_MU_MC!="ENABLE")) belongs to states where the *Processor Monitoring* requests a disabling of the saftey relevant power stages by MC or by MU. Note, that on MC the disabling of the safety relevant power stages is **not** performed by the *Processor Monitoring* itself. It has to be performed elsewhere to perform a redundant disabling.

The logical output variables LV_ERR_TMP_MU_MC and LV_ERR_MU_MC indicate a disable request in case of a set variable:

- LV_ERR_TMP_MU_MC indicates a temporary, reversible disable request of the safety relevant power stages. It is set in case of a set LV_ERR_TMP_MU, a set LV_ERR_TMP_MC. In addition it is set in caser of a set LV_ERR_MU or a set LV_ERR_MC.
- LV_ERR_MU_MC indicates a final, irreversible disable request for this duty cycle of the safety relevant power stages. It is set in case of a set LV_ERR_MU or a set LV_ERR_MC.

Application conditions:

Initialisation: *STATE_DR_MU_MC = "PREDRIVE"*
LV_ERR_TMP_MU_MC = 1
LV_ERR_MU_MC = 0

Recurrence: *STATE_DR_MU_MC, LV_ERR_TMP_MU_MC and LV_ERR_MU_MC are updated each call of the Processor Monitoring as last task.*

Activation: *at each ECU state*

Deactivation: *never*

Formula section:

IF (LV_ERR_TMP_MU==1) **OR** (LV_ERR_TMP_MC==1) **OR**
(LV_ERR_MU==1) **OR** (LV_ERR_MC==1) **THEN** LV_ERR_TMP_MU_MC=1;
ELSE LV_ERR_TMP_MU_MC = 0;

IF (LV_ERR_MU==1) **OR** (LV_ERR_MC==1) **THEN** LV_ERR_MU_MC=1;

IF (LV_PRDR_ACT == 1) **THEN** STATE_DR_MU_MC = "PREDRIVE";
ELSE STATE_DR_MU_MC = "ENABLE";

IF (LV_ERR_TMP_MU_MC == 1) **THEN** STATE_DR_MU_MC = "TMP_DIS";
IF (MU_DI_STATE!=MU_DI_NOT_REQ) **THEN** STATE_DR_MU_MC = "DISABLE_REQ";
IF (LV_ERR_MU == 1) **THEN** STATE_DR_MU_MC = "DISABLE_MU";

IF (LV_ERR_MC == 1) **THEN** STATE_DR_MU_MC = "DISABLE_MC";

Input data:

LV_TQI_MON_ACT_MON	LV_ERR_TQI_N_MAX_MON	LV_ERR_N_32_MON
LV_ERR_PVS_MON	LV_ERR_TPS_MON	LV_ERR_MAF_MON
LV_ERR_TQI_AV_MON	LV_ERR_TQ_DIF_P_D_IS_MON	LV_ERR_TQ_DIF_I_IS_MON
LV_ERR_TQ_LOSS_MON	LV_ERR_TQ_MIN_CLU_MON	LV_ERR_TQ_MAX_CLU_MON
LV_ERR_CONV_MON	ERR_SYM_ECU	

FUNCTION DESCRIPTION:

General information:

When a fault is detected by the level 2 of the ETC-Monitoring concept and the reaction is released in the module ‘fault reaction of process monitoring’, the fault is transferred to the error memory management.

The memory area of all output data variables of this module is not permanently RAM tested, the memory area of this module is not cyclic ROM tested.

Description:

Since the different faults can occur in a successive way, they are stored in different locations of the error memory.

The first location contains the logical variables for a fault detected by the diagnosis of the input variables and are stored in LV_ERR_MON.

The faults LV_ERR_TQI_AV_MON and LV_ERR_TQI_N_MAX_MON are stored in separate locations (LV_ERR_TQI_MON and LV_ERR_N_MAX_MON) in order to be able to analyze a scenario of successive faults.

The information whether a warning lamp (ETC MIL) is switched on in case of an error can be found in the general OBD error code table.

Application conditions:

Activation: at every engine state
Deactivation: -
Initialization: for condition see 'Application Incidences of Process Monitoring'
All diagnosis flags (LV_END_DIAG*, LV_CDN_DIAG*, LV_ERR*) and ERR_SYM* has to be reset.
For LV_ERR_N_MAX_MON_SAVE the variables has to be initialized with zero, if a power up is recognized. A power up is detected, if the variables in the reset safe RAM are not consitend.
Update Rate: 40 ms

E.34.1 Error memory management of LV_ERR_MON

Formula section:

LV_CDN_DIAG_MON = 1

If (LV_ERR_CONV_MON = 1
Or LV_ERR_N_32_MON = 1
Or LV_ERR_TQ_DIF_P_D_IS_MON = 1
Or LV_ERR_TQ_DIF_I_IS_MON = 1
Or LV_ERR_TQ_LOSS_MON = 1

Or LV_ERR_TPS_MON = 1
Or LV_ERR_MAF_MON = 1)
Then
ERR_SYM_MON = SYM_3;
If (LV_ERR_MON = 0) **then**
Set environmental data for LV_ERR_MON according to
"Error Memory Management of Process Monitoring (Appl.Inc.)"
endif

```
        LV_ERR_MON = 1;
        LV_END_DIAG_MON = 1;
    Else
        ERR_SYM_MON = NO_SYM;
        LV_ERR_MON = 0;
        If { delay 520ms } then
        /* After the level2 fault reaction time of 500ms the errors are updated */
            LV_END_DIAG_MON = 1;
        Endif
    Endif
```

E.34.2 Error memory management of LV_ERR_TQI_MON

Formula section:

```
If (LV_TQI_MON_ACT_MON = 1)
Then
    LV_CDN_DIAG_TQI_MON = 1
    If      LV_ERR_TQI_AV_MON = 1
    Then
        ERR_SYM_TQI_MON = SYM_2;
        If (LV_ERR_TQI_MON = 0) then
            Set environmental data for LV_ERR_TQI_MON according to
                "Error Memory Management of Process Monitoring (Appl.Inc.)"
        endif
        LV_ERR_TQI_MON = 1;
        LV_END_DIAG_TQI_MON = 1;
    Else
        ERR_SYM_TQI_MON = NO_SYM;
        LV_ERR_TQI_MON = 0;
        If { delay 520ms } then
        /* After the level2 fault reaction time of 500ms the errors are updated */
            LV_END_DIAG_TQI_MON = 1;
        Endif
    Endif
Else
    LV_CDN_DIAG_TQI_MON = 0
Endif
```

E.34.3 Error memory management of LV_ERR_N_MAX_MON

The error LV_ERR_N_MAX_MON triggers the redundant switch off path (see "Fault Reaction of Process Monitoring") during the actual duty cycle. This finally leads to a reset after debouncing (see "Processor Monitoring"). The entry into the error memory has to be performed past reset. Therefore it is needful to store the error information reset safe; LV_ERR_N_MAX_MON_SAVE is located in the reset safe RAM area. The entry into the error memory is done past reset by evaluation of the information stored before reset.

Application conditions:

Initialisation: LV_ERR_N_MAX_MON_SAVE = 0
only after power up, no initialization after reset

Formula section:

```
LV_CDN_DIAG_N_MAX_MON = 1;
If    (LV_ERR_N_MAX_MON_SAVE = 1)          /* error detected last duty cycle */
Then
   /* error not jet passed to ERRM =>  transfer error information to ERRM*/
   ERR_SYM_N_MAX_MON = SYM_1;
   /* environment data are already reset safe stored before reset */
   LV_ERR_N_MAX_MON = 1;
   LV_END_DIAG_N_MAX_MON = 1;
   /* avoid more than one entry into error memory */
   if {delay 120ms} then
     /* this delay time periode depends on Processor Monitoring */
     /* After this time periode the reset has to be carried out */
     LV_ERR_N_MAX_MON_SAVE = 0;
   end
Else         /* error not detected last duty cycle */
     If (LV_ERR_N_MAX_MON = 1) then          /* error was stored last recurrence */
          ERR_SYM_N_MAX_MON = SYM_1;
          LV_END_DIAG_N_MAX_MON = 1;
     Else
        If { delay 520ms } then
          /* After the level2 fault reaction time of 500ms the errors are updated */
          LV_END_DIAG_N_MAX_MON = 1;
        End
     Endif
Endif
```

```

First Byte: The following rule is used:
The lower 5 BITs (BIT 0...4) are used for encoding the type of the fault (0dec ... 31dec can be used).
The higher 3 BITs (BIT 5...7) can be used to store additional logical information according the table above.

Bit definition of first byte:

BIT7 [| | | | | | |] BIT0

The information whether a warning lamp (ETC MIL) is switched on in case of an error can be found in the general OBD error code table.

In case of more than one error cause occurs, always the first error (according to the table above; see BIT 0...4 of first Byte for the order) is taken into account.

E.35.2 Diagnosis instance for ETC monitoring

DIAG_INST_MON was defined to be able to see different monitoring errors in an easy way.

Application conditions:

Initialization: *AT FMY reset DIAG_INST_MON = 0H*

Activation: *LV_ERR_MON = 1*

Update Rate: *according to "Error Memory management of Process Monitoring"*

Formula section:

IF	LV_ERR_N_32_MON = 1	**THEN**	DIAG_INST_MON = 1H
ELSE IF	LV_ERR_TQ_DIF_P_D_IS_MON = 1	**THEN**	DIAG_INST_MON = 2H
ELSE IF	LV_ERR_TQ_DIF_I_IS_MON = 1	**THEN**	DIAG_INST_MON = 3H
ELSE IF	LV_ERR_TQ_LOSS_MON = 1	**THEN**	DIAG_INST_MON = 4H
ELSE IF	LV_ERR_TQ_MIN_CLU_MON = 1	**THEN**	DIAG_INST_MON = 5H
ELSE IF	LV_ERR_TQ_MAX_CLU_MON = 1	**THEN**	DIAG_INST_MON = 6H
ELSE IF	LV_ERR_PVS_MON = 1	**THEN**	DIAG_INST_MON = 7H
ELSE IF	LV_ERR_TPS_MON = 1	**THEN**	DIAG_INST_MON = 8H
ELSE IF	LV_ERR_MAF_MON = 1	**THEN**	DIAG_INST_MON = 9H
ELSE IF	LV_ERR_CONV_MON = 1	**THEN**	DIAG_INST_MON = 10H

If more than one of above mentioned error occurs, just write the first one in the DIAG_INST_MON and do not overwrite this one by a second or third ... error.

E.35.3 Storage of last intermittent monitoring error

FUNCTION DESCRIPTION:

General information:

The purpose of this function is the visualization of the diagnosis instances that show intermittent monitoring error (antibounce counter >= 2) but do not enter into the dynamic error management structure, because the antibounce counter does not reach its maximum value.
If the antibounce counter of a monitoring error using the anti-bounce algorithm is incremented for the 2^{nd} time, it is stored in the array ERR_INTM_DIAG_INST_MON.

Application conditions:

Initialization:	At FMY reset or LC_ERR_INTM_MON_CLR 0 ->1
	ERR_INTM_DIAG_INST_MON = 0
	STATE_ERR_INTM_MON = 0
Recurrence:	*according to "Error Memory management of Process Monitoring"*
Activation:	LC_ERR_DET_UPD_MON = 1

Formula section:

```
If      ABC_N_32_MON >= 2

Indicates that diagnosis is completely finished					
ERR_SYM_MON_3	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Error symptom extracted from ERR_COD_MC and ERR_COD_MU					

Input data:

RST_CTR_MC_SAVE	RST_CTR_MU_SAVE	ERR_COD_MC_SAVE	ERR_COD_MU_SAVE

FUNCTION DESCRIPTION:

General information:

This module here provides a link to the customer error memory managment.

Detection of a point in time to store the error information non volatile

When a fault is detected by the Processor Monitoring (see "fault reaction of processor monitoring"), a reset is done or a transition to DISABLE is preformed. The complete error information is available on the main controller after the first communication past the reset or after the first DISABLE communication (cf. activation conditions of the module).

Performing the storage of the error information

If an error information is avaliable, LV_ERR_MON_3 performs a transition from 0 to 1. A set logical variable LV_CDN_DIAG_MON_3 indicates that the conditions for storing an error information is true; this is the case, if either ERR_COD_MC_SAVE or ERR_COD_MU_SAVE is nonzero.

A rising edge of LV_ERR_MON_3 triggers the storage of the error information ERR_SYM_MON_3 into the customer error memory. ERR_SYM_MON_3 consists of four bits:

Bit3	Bit2	Bit1	Bit0 (LSB)
8	4	2	1
Level 2' error	Error in selftest/ Predrive check error	not used	ROM/RAM error on MC

Regardless of whether an error is present, LV_END_DIAG_MON_3 must be set because this indicates the end of the "diagnosis", whether an error was found or not; a similar remark applies to LV_CDN_DIAG_MON_3.

Application conditions:

Initialisation: */* Performed by the standard RAM check */*

LV_ERR_MON_3 = 0;
LV_CDN_DIAG_MON_3 = 0;
LV_END_DIAG_MON_3 = 0;
ERR_SYM_MON_3 = NO_SYM;

Activation: This module is called by Processor Monitoring as a subroutine on demand in two places:

- after the INIT communication;
- after the first DISABLE communication when either RST_CTR_MC or RST_CTR_MU are greater than NC_RST_CTR_MC_MAX or NC_RST_CTR_MU_MAX, respectively.

In both cases the complete error information (MC and MU) is available on the MC.

Note: In case of a Processor Monitoring error one cannot ensure a correct error memory management due to a possible damaged ECU.

Formula section:

/ Initialisation: it is* **extremely important** *to reset LV_ERR_MON_3; otherwise, the first MON_3 error can never be updated */*

LV_ERR_MON_3 = 0;
LV_CDN_DIAG_MON_3 = 0;
ERR_SYM_MON_3 = NO_SYM;

IF ((ERR_COD_MC_SAVE>0) AND (RST_CTR_MC_SAVE>1)) **OR** */* MC error */*

((ERR_COD_MU_SAVE>0) AND (RST_CTR_MU_SAVE>1)) **THEN** */* MU error */*

/ When entering this block, an error code is set and diagnosis is finished */*

Set environmental data for LV_ERR_MON_3 according to "Error Memory Management of Process Monitoring (Appl.Inc.)"

/ Now set the filtered error information ERR_SYM_MON_3 */*

/ according to customer specification by evaluation of */*

/ ERR_COD_MC_SAVE, RST_CTR_MC_SAVE and */*

/ ERR_COD_MU_SAVE, RST_CTR_MU_SAVE */*

IF (RST_CTR_MC_SAVE>0) **THEN**

INH_IGC_MIS_GEN_16	V/O	0...FFFH	0...4095	1	[-]
Identification of cylinders shut off by ignition misfire generator					

Input data:

SEG_NR	N	TD_IGC[NC_CYL_NR]	IGA_AV[NC_CYL_NR]
EOI_LIM[NC_CYL_NR]	SOI_MAX		

FUNCTION DESCRIPTION:

According the project SI integration plan and/or customer requirements/wishes, a software misfire generator can be included on EMS softwares and used during integration validation and calibration stages. It is strongly recommended to remove this functionally on serial product software: integration choice via NLC_USE_MIS_GEN compilation switch.

Application conditions:

Initialisation: at reset & engine stalling

LV_MIS_GEN = 0

LV_MIS_GEN_DET = 0

INH_IV_MIS_GEN_16 = 0

INH_IGC_MIS_GEN_16 = 0

INH_IV_MIS_GEN = 0

INH_IGC_MIS_GEN = 0

No function calls to INJR & IGRE

Recurrence: Segment

Activation:

The regular or random misfiring generation is applied on ignition and/or injection sequences.

If LC_IGN_OFF_MIS_GEN = 1

Then Ignition cut-off mode

(using INH_IGC_MIS_GEN_16 carrier, see § Ignition misfire realisation)

LV_MIS_GEN is set to 1 according misfiring generation mode selected

(pseudo random or regular mode, see dedicated chapters below)

EndIf

If LC_INJ_OFF_MIS_GEN = 1

Then Injection cut-off mode

(using INH_IV_MIS_GEN_16 carrier, see § Injection misfire realisation)

LV_MIS_GEN is set to 1 according misfiring generation mode selected

(pseudo random or regular mode, see dedicated chapters below)

EndIf

If LC_IGN_OFF_MIS_GEN = 1

And LC_INJ_OFF_MIS_GEN = 1

Then Ignition and injection off modes (for the same TDC)

(using INH_IGC_MIS_GEN_16 & INH_IV_MIS_GEN_16 carrier)

LV_MIS_GEN is set to 1 according misfiring generation mode selected

(pseudo random or regular mode, see dedicated chapters below)

EndIf

If LC_IGN_OFF_MIS_GEN = 0

And LC_INJ_OFF_MIS_GEN = 0

Then No misfire generation allowed

LV_MIS_GEN = 0

INH_IV_MIS_GEN = 0

INH_IGC_MIS_GEN = 0

INH_IV_MIS_GEN_16 = 0

INH_IGC_MIS_GEN_16 = 0

No function calls to INJR & IGRE

EndIf

LV_MIS_GEN_DET = LV_MIS_GEN delayed with C_NR_TDC_DLY_MIS_GEN tdc's

INH_IV_MIS_GEN = u8(INH_IV_MIS_GEN_16) // management only for the 8 cylinders

INH_IGC_MIS_GEN = u8(INH_IGC_MIS_GEN_16)

F.1.1.1 Pseudo random misfiring generation mode

<u>Application conditions:</u>

The misfiring generation mode is authorised when the misfiring tuning function and the pseudo random misfiring tuning function are active.

This misfiring generation mode is global to all cylinders.

Recurrence: Segment

Activation:

If LC_REQ_MIS_GEN = 1

And C_MOD_MIS_GEN = 0

And SEG_NR = C_SEG_ST_MIS_GEN

Then Pseudo random misfiring generation is triggered

EndIf

Deactivation:

If LC_REQ_MIS_GEN = 0

Or C_MOD_MIS_GEN ≠ 0

Then Pseudo random misfiring generation mode is disabled

EndIf

Formula section:

A random ignition and/or injection is missing following the bitfield sequence ID_RND_PAT_MIS_GEN, where each bit corresponds to a TDC.

If the current bit value is 0 then the ignition and/or injection are missing; else ignition and injection are realised.

During the TDC where the ignition and/or injection are missing **And** if at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 **Or** LC_INJ_OFF_MIS_GEN = 1), the flag LV_MIS_GEN is set to 1 else the flag LV_MIS_GEN is set to 0.

F.1.1.2 Regular misfiring generation mode

Application conditions:

This generation mode is authorised when the misfiring tuning function and the regular misfiring tuning function are active.

This misfiring generation mode is global to all cylinders.

Recurrence: Segment

Activation:

If LC_REQ_MIS_GEN = 1

And C_MOD_MIS_GEN = 1

And SEG_NR = C_SEG_ST_MIS_GEN

Then Regular misfiring generation mode is triggered

EndIf

Deactivation:

If LC_REQ_MIS_GEN = 0

Or C_MOD_MIS_GEN ≠ 1

Then Regular misfiring generation mode is disabled

EndIf

Formula section:

Regular ignition and/or injection are missing every C_MIS_RATE tdc.

During the TDC where the ignition and/or injection are missing **And** if at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 **Or** LC_INJ_OFF_MIS_GEN = 1), the flag LV_MIS_GEN is set to 1 else the flag LV_MIS_GEN is set to 0.

F.1.1.3 Cylinder regular misfiring generation mode

Application conditions:

This generation mode is authorised when the misfiring tuning function and the regular misfiring tuning function are active.

This misfiring mode is dedicated to specific cylinder generation.

Recurrence: Segment

Activation:

If LC_REQ_MIS_GEN = 1

And C_MOD_MIS_GEN = 2

And SEG_NR = C_SEG_ST_MIS_GEN

Then Cylilnder regular misfiring generation mode is triggered

EndIf

Deactivation:

If LC_REQ_MIS_GEN = 0

Or C_MOD_MIS_GEN ≠ 2

Then Cylinder regular misfiring generation mode is disabled

EndIf

Formula section:

If(1) LC_MIS_RATE_ENA_CYL[SEG_NR] = 1

Then(1) Ignition and/or injection are missing on cylinder SEG_NR every C_RATE_MIS_CYL[SEG_NR] tdc's.

If(2) During the TDC where the ignition **And/Or** injection are missing

And at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 **Or** LC_INJ_OFF_MIS_GEN = 1),

Then(2) LV_MIS_GEN = 1

Else(2) LV_MIS_GEN = 0

EndIf(2)

Else(1) No Ignition and/or injection are missing on cylinder SEG_NR

LV_MIS_GEN is set to 0

EndIf(1)

F.1.1.4 Injection misfire realisation

Recurrence: Every engine cycle, phased with required cylinder injection

Formula section:

The injection misfire realisation is realised via the INH_IV_MIS_GEN_16 carrier. This is an input for the Injection Cylinder Shut-Off Application Incidences file.

Cylinder switched off by injection software misfire generator is set to 1 within INH_IV_MIS_GEN_16 carrier.

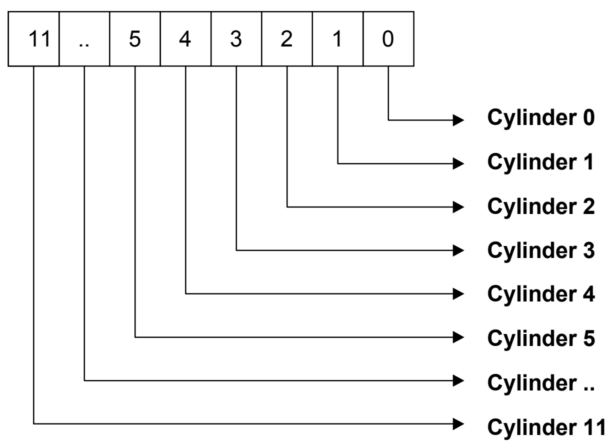
All others cylinder bits are reset to 0 only if not set by the misfire pattern defined for the current engine cycle

Important note on injection shut-off triggering:

To be effective, the injection shut-off on Cylinder x must be triggered before the injection time starts on this cylinder. To evaluate the correct phasing for the injection shut-off, the maximum SOI *(start of injection angle)* is evaluated.

INH_IV_MIS_GEN_16 carrier must be updated at the segment just before the maximum start of injection (SOI_MAX + EOI_LIM[0]) to be strictly taken in account on this injection phase.

INH_IV_MIS_GEN_16



F.1.1.5 Ignition misfire realisation

Recurrence: Every engine cycle, phased with required cylinder /coil ignition

Formula section:

The ignition misfire realisation is realised via the INH_IGC_MIS_GEN_16 carrier. This is an input for the Ignition Cylinder Shut-Off Application Incidences file.

Cylinder switched off by ignition software misfire generator is set to 1 within INH_IGC_MIS_GEN_16 carrier.

All others cylinder bits are reset to 0 only if not set by the misfire pattern defined for the current engine cycle

Important note on ignition shut-off triggering:

To be effective, the ignition shut-off on cylinder x must be triggered on the segment before the dwell time on the coil y starts for this cylinder x.

To evaluate the correct phasing for the ignition shut-off, the period TD_IGC[x] must be converted in angle and added to the IGA_AV[x] angle to defined the correct segment for triggering.

CAM_SP_IND_DIAG_IVVT_IN_i	CAM_SP_IND_DIAG_IVVT_EX_i	C_CAM_INI_IN	C_CAM_INI_EX

FUNCTION DESCRIPTION:

General information:

It is possible to emulate a faulty actuator.

Description:

The following possibilities of a faulty actuator emulation are possible:

C_IDX_DFCT_IVVT_IN(_EX)_i	Description
0	No failure
1	Actuator jams at active direction adjustment (IN - ADC, EX - RTD)
2	Actuator jams at passive direction adjustment (IN - RTD, EX - ADC)
3	Actuator jams at current position
4	Actuator responses slowly

Setting C_IDX_DFCT_IVVT_IN(_EX)_i = 0 starts healing the "failure". Transitions among 1, 2 and 3 have actually less meaning. The healing or slow response is to insert between these failure emulations.

Application conditions:

Initialization:

At reset, at transition "Engine run" → "Engine stop", at deactivation:

CAM_SP_IND_DFCT_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

CAM_SP_MMV_DFCT_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

At transition "Engine run" → "Engine stop", at deactivation:

LV_CAM_SP_DFCT_IVVT_IN(_EX)_i = 0

LV_CAM_JAM_ACT_IVVT_IN(_EX)_i = 0

LV_CAM_JAM_PAS_IVVT_IN(_EX)_i = 0

LV_CAM_JAM_IVVT_IN(_EX)_i = 0

Recurrence:

 # NC_NR_CBK_IVVT = 1:

360 °CRK linked task, see "IVVT Scheduler"

 # NC_NR_CBK_IVVT = 2:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

LV_ACT_IND_IVVT_IN(_EX)_i = 1

Deactivation:

Not activation

Formula section:

if C_IDX_DFCT_IVVT_IN(_EX)_i = 0

then *No failure*

FUNCTION DESCRIPTION

General information:

G.1.1 Summary

The cruise control (CRU) controls the vehicle speed by a P/I controller to the required target speed. The CRU button in the multifunction steering wheel activates the control functions, if no cut-off conditions or switch-on prohibitions are present.

The driver then can set the desired speed using the following functions:

- Set/Coast
- Resume/Acceleration
- Cancel
- OFF

G.1.1.1 Constant drive

After reaching the desired speed, the vehicle speed is kept constant independent of driving resistance changes which act on the vehicle, e.g. rising and falling gradient or headwind, if there are no abnormal termination conditions and the engine power or the braking effect is sufficient.

G.1.1.2 Setting/deceleration

By activating the SET/COAST function, the driver can store the current vehicle speed as desired speed and thus switch on the CRU system. Also the speed can be changed with a defined deceleration from the controlled constant drive. After reaching the desired speed, the constant drive function of the control is active.

G.1.1.3 Resume/acceleration

When the driver activates the RES function, the vehicle is accelerated from the current vehicle speed with a defined acceleration to the stored desired speed. The stored desired speed is the vehicle speed of the last control situation.
If the controlled constant drive function is active, the driver activates the acceleration mode by pressing the RES/ACCEL button. If the driver ends the function by releasing the button, the current vehicle speed is stored as new desired speed and the controlled constant drive function is activated.

G.1.1.4 Tip-up

Starting at controlled constant drive, the driver can increase his desired speed in steps of 1 k.p.h. by activating the TIP_UP function (press RES/ACCEL not longer than C_T_MIN_MSW). This function can be selected several times consecutively, thus the vehicle can be accelerated to a higher desired speed.

G.1.1.5 Tip-down

Starting at controlled constant drive, the driver can reduce his desired speed in steps of 1 k.p.h. by activating the TIP_DOWN function (press SET/COAST not longer than C_T_MIN_MSW). This function can be selected several times consecutively, thus the vehicle can be decelerated to a lower desired speed.

G.1.1.6 CANCEL

To switch the system off, the driver can select the CANCEL button of the multifunction steering wheel. In this way the cruise control system is switched off soft, and the desired speed remains stored for later activation by the RES function.

G.1.1.7 CRUISE ON/OFF

To switch the system on and off, the driver can select the CRUISE ON/OFF button of the multifunction steering wheel. In this way the cruise control system is switched on and off hard, and the desired speed doesn't remain stored for later activation by the RES function.
If the CRUISE ON/OFF button is detected during CONF_CRU = 0 then Cruise Control is learnt (CONF_CRU = 1), see Chapter "Variant Coding".

G.1.2 Ready state and display

A precondition for activating the CRU functions is the CRU ready state. After ECU initialization, the CRU state is initially passive. C_T_READY_CRU after ignition key on (LV_IGK = 1) the CRU state can be switched to the ready state by pressing the ON/OFF button once. To indicate CRU readiness to the driver, the signal LV_CRU_MAIN_SWI is set from 0 to 1. In this way the CRU ready lamp is activated at the instrument panel.

The transition to the passive state occurs by pressing the ON/OFF button once from the CRU ready state. The CRU ready lamp is then switched off.

G.1.3 Cruise control demand

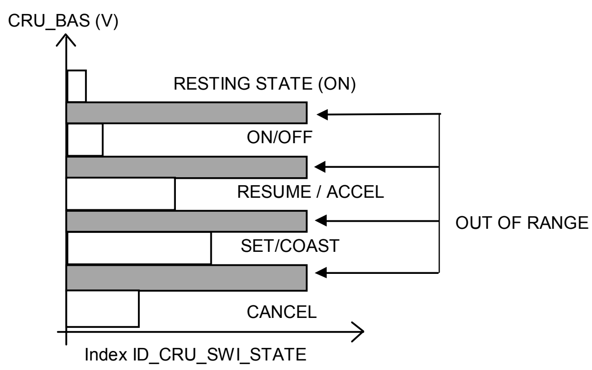
The cruise control button is measured via resistors from ignition power. The raw acquisition voltage CRU_BAS is perfomed every 10 ms.

This file is able to detect different voltage levels corresponding to the different positions of the cruise button.

If 2 buttons are depressed at the same time or if a ground problem occurs so that the ECU is not able to assign the right request versus the voltage input, then the CRU_SWI_STATE_TEMP = "OUT OF RANGE", and the cruise control is turned off.

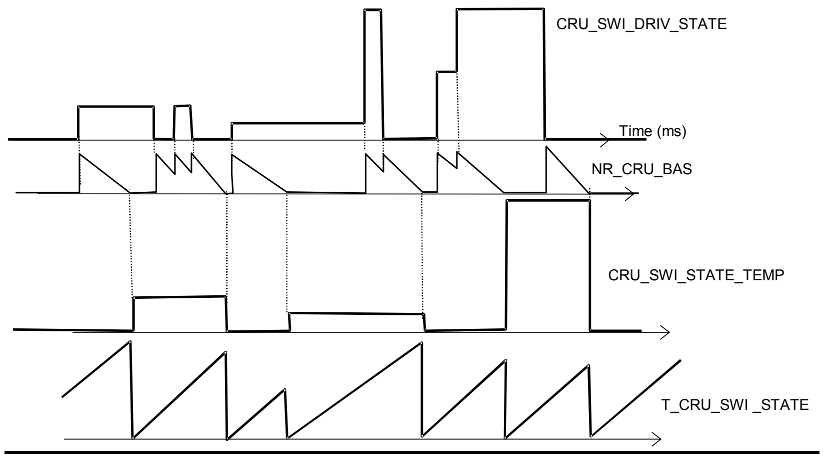
The voltage level must stay C_NR_CRU_BAS time in the same range to be valid. CRU_SWI_DRIV_STATE must be constant for the last C_NR_CRU_BAS consecutive calculations to be valid and provided as an output through CRU_SWI_STATE_TEMP.

Voltage and index relation (EXAMPLE):

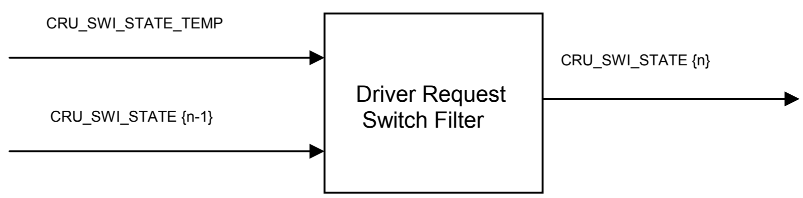


Validation of the switch level:

NR_CRU_BAS is set to C_NR_CRU_BAS at every transition of CRU_SWI_DRIV_STATE.
CRU_SWI_STATE_TEMP = CRU_SWI_DRIV_STATE once NR_CRU_BAS reach 0.
T_CRU_SWI_STATE is initialised to 0 at every transition of CRU_SWI_STATE_TEMP, and incremented while the state is stable.



G.1.4 Cruise request from driver



Simultaneously pressing two buttons (i.e. RES/ACC and SET/COAST) may not be detectable as an “Out Of Range” condition since the voltage tolerance of one button overlaps the tolerance of both pressed together.

The purpose of this module is to provide a means to overcome this issue by forcing a specific switch state (CANCEL) until an “all buttons released” condition may be verified.

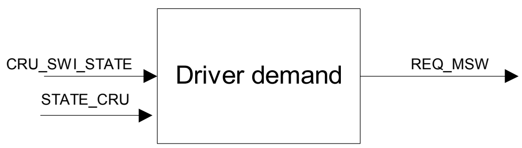
The applied switch output, CRU_SWI_STATE {n}, from table ID_FIL_CRU_SWI, depends on the previous switch output, CRU_SWI_STATE {n-1}, and the switch request from the driver, CRU_SWI_STATE_TEMP.

Example Operation:
If the Cancel button is detected, then this MUST be followed by a Rest State input (no buttons pressed) before any other input may be acknowledged (stuck button feature). If both the Cancel and RES/ACC are pressed simultaneously with the Cancel button released first; then the Cruise *Switch* State will remain in the Cancel State until a Switch Rest State is detected.

Example: The output of this table ID_FIL_CRU_SWI is **CRU_SWI_STATE {n}**

CRU_SWI_STATE {n} (Output)		**CRU_SWI_STATE_TEMP {n}**					
		REST STATE	*ON/OFF*	*CANCEL*	*RES/ACC*	*SET/ COAST*	*OUT OF RANGE*
Previous **CRU_SWI _STATE {n-1}**	*REST STATE*	Rest State	ON/OFF	Cancel	RES / ACC	SET/ COAST	OUT OF RANGE
	ON/OFF	Rest State	ON/OFF	Cancel	RES / ACC	SET/ COAST	OUT OF RANGE
	CANCEL	Rest State	ON/OFF	Cancel	Cancel	Cancel	Cancel
	ACC/ RES	Rest State	ON/OFF	Cancel	RES / ACC	SET/ COAST	OUT OF RANGE
	SET/ COAST	Rest State	ON/OFF	Cancel	RES / ACC	SET/ COAST	OUT OF RANGE
	OUT OF RANGE	Rest State	ON/OFF	Cancel	Cancel	Cancel	Cancel

G.1.5 Cruise request state



Some cruise buttons have multiple functions per position, such as RES/ACC or ON/OFF. The goal of this file is to "normalise" the different cruise button designs in order to keep a single cruise algorithm and state diagram afterward.

Example: When the driver activates the cruise switch with "RES/ACC" and the cruise control state is "PASSIVE", this means that the driver requests the "RESUME" function. If the cruise control state is "Constant driving" and the driver presses "RES/ACC", then the acceleration mode is activated.

The driver knows in which state the cruise control is currently in (ON, OFF, PASSIVE, …), therefore his demand must be calculated versus the button AND versus the actual state of the cruise control function.

Application conditions:

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Initialisation:

At reset: CRU_SWI_STATE = `RESTING STATE'

CRU_SWI_DRIV_STATE = `RESTING STATE'

NR_CRU_BAS = 0

T_CRU_SWI_STATE = 0

REQ_MSW = 'HARD_OFF'

LV_STATE_CRU_ON_OFF_SET_ENA =1

At transition LV_IGK = 0 → 1:

LV_CRU_MAIN_SWI = 0

T_CRU_SWI_STATE = 0

T_READY_CRU = 0

In case of Error or Initialisation of NVMY:

LV_CRU_MAIN_SWI = 0

T_READY_CRU = 0

REQ_MSW = 'HARD_OFF'

Recurrence: 10ms

Formula section:

```
if          LV_IGK = 1
then        T_READY_CRU (n) = T_READY_CRU (n-1) + 10ms
    if              CRU_SWI_DRIV_STATE <> ID_CRU_SWI_STATE
    then            NR_CRU_BAS = C_NR_CRU_BAS
                    CRU_SWI_DRIV_STATE = ID_CRU_SWI_STATE
    else    if              NR_CRU_BAS > 0
            then            NR_CRU_BAS (n) = NR_CRU_BAS (n-1) -1
            endif
    endif
    if              NR_CRU_BAS = 0
    then            CRU_SWI_STATE_TEMP = CRU_SWI_DRIV_STATE
                    CRU_SWI_STATE = ID_FIL_CRU_SWI
                    At transition of CRU_SWI_STATE_TEMP
                    T_CRU_SWI_STATE = 0
    endif

FUNCTION DESCRIPTION:

The State of cruise control is the evaluation of the request and the cruise conditions.
If one of the following conditions is detected, no controller can be activated or an activated controller function is switched off. In this case a distinction is made between hard (FAC_TQ_CRU = 0) and soft cut-off (FAC_TQ_CRU through ramp function to zero).

Application conditions:

Recurrence: 10 ms

Initialisation: At Reset, NVMY_CLR and LV_IGK from 0 to 1:
set LV_CRU_OFF_IRR = 0 and STATE_CRU_OFF_REV_SAVE = 0.

Formula section:

If req_msw = NONE
Then LV_MSW_IDLE = 1
If hard_off or soft_off is requested
Then LV_MSW_IDLE = 0
Endif

if LV_AT = 1
and GR_AT = 0 " *(gear in position N,P)"*
or GR_AT = 7 *"(gear in position R)"*
or [G_SEL_DISP = 08h *"(Sports mode)"*
and GR_AT <= C_TAR_GC_AC_RELE]
then LV_AC_RELE_TO_ECU = 1
else LV_AC_RELE_TO_ECU = 0
endif

G.1.6.2.1 Conditions for hard cut-off

The control functions of the cruise control can be activated only if:

- CRU ready state present LV_CRU_MAIN_SWI = 1

Irreversible cut-off due to diagnosis failures

With the following diagnosis errors the CRU is irreversible hard cut off for this engine run. The CRU-readiness and the CRU readiness light are reseted. The CRU function can be activated by LV_IGK=0/1 change, as long as no running diagnosis errors are present.

Formula section:

IF

1.	Error in MTC:	LV_ERR_MTC_CTL or LV_ERR_MTC_DR = 1	**or** *(1H)*
2.	Error TPS Limp Home:	LV_ERR_TPS = 1	**or** *(2H)*
3.	Error in brake light/test or clutch switch system	LV_ERR_BLS_BTS = 1 LV_ERR_CS = 1	**or** *(4H)* **or**
4.	Error in vehicle speed signal	LV_ERR_VS = 1, (sensor error)	**or** *(8H)*
5.	Error Level 2 Monitoring	LV_ERR_TQI_N_MAX_MON =1 LV_CRU_INH_MON =1 LV_N_LIM_REQ_MON =1	**or** *(10H)* **or** **or**

6. CAN Bus off: LV_ERR_CAN_BUS_OFF = 1 **or** *(20H)*
7. PVS-Error: LV_ERR_PVS = 1 **or** *(40H)*
8. Cruise switch error LV_ERR_CRU_SWI_1 = 1 **or** *(80H)*
   LV_ERR_CRU_SWI_2 = 1 **or**
   LV_ERR_CRU_SWI_3 = 1

Then LV_CRU_OFF_IRR = 1
REQ_CRU = Hard off (The cru readiness lamp is switched off.)

Else LV_CRU_OFF_IRR = 0
STATE_CRU_OFF_IRR = 00H
STATE_CRU_OFF_REV = 00H

Byte							
7	6	5	4	3	2	1	0

Error CRU SW	Error PVS	CAN Buss off	Monitoring level 2	Error VS	Brake SW **or** Clutch SW error	Error TPS	Error MTC

(Table: STATE_CRU_OFF_IRR)

Reversible cut-off:

If one of the following conditions is current in active CRU function, CRU is transferred by hard cut-off (FAC_TQ_CRU = 0) into the ready state without controlled drive:

IF

1. Main Switch off: LV_CRU_MAIN_SWI = 0 **or** (1H)
2. VS_CRU low: VS_CRU < C_VS_MIN_PLAUS_CRU for longer than C_T_DLY_CRU_OFF_REV_VS_FAULT **or** (2H)
3. Engine stopped: LV_ES = 1 **or** (4H)
4. Brake switch: LV_BLS = 1 **or** (8H)
   or LV_BTS = 1
   or if LV_AT = 1
   and LV_BLS_BTS_ACT_DC = 0
   or if LV_AT = 0
   and LC_INH_BLS_BTS_ACT_MT = 0
   and LV_BLS_BTS_ACT_DC = 0

   For MT-vehicles it is not mandatory to push brake pedal during vehicle start or gear select , so BLS/BTS switch acting might still not be detected at Cruise request Therefore this condition can be disabled via Application switch

5. Engine speed limitation be active: LV_N_MAX = 1 **or** (10H)

6. Run up lock: (| (N_VS_CRU$_n$ - N_VS_CRU$_{n-1}$) / N_VS_CRU$_{n-1}$ | * 100 > C_N_VS_MAX_CRU and LV_AT = 0) **or** (20H)

7. Exceeding a maximum acceleration: | AC_CRU | > C_AC_MAX_CRU for longer than C_T_DLY_CRU_OFF_REV_VS_FAULT **or** (40H) (not during active overtaking function)

8. Detection of clutch actuation with manual transmissions:
   if LV_AT = 0
   and (LV_IM_CS_PN =0 **or** (80H)
   or LV_CS_ACT_DC = 0)

9. Neutral Gear (A/T and M/T): (LV_AT = 0 and (GR_MT = 1 or GR_MT = 0))
   or (LV_AT = 1 and GR_AT = 0)
   for longer than C_T_DLY_CRU_OFF_REV_VS_FAULT
   or (100H)

10. REQ_MSW = HARD_OFF **or** (200H)

11. Overtaking function is active and vehicle speed limitation is activated **or** (400H)
    LV_VS_MAX = 1

12. Cruise release/disable request by TCU:
    LV_AC_RELE_TO_ECU = 1 **or** (800H)

Then REQ_CRU = Hard off

G.1.6.2.2 Conditions for soft cut-off

General information:

If one of the following conditions is detected, the controller function is switched off. In this FAC_TQ_CRU is set through ramp function to zero.

Formula section:

If

13. Detection of the REQ_MSW = SOFT_OFF function of the cruise control (10000H)

or

14. [if LV_CRU_OVER_ACT = 0 (20000H)

and {(Exceeding a permissible VS_DIF_CRU > speed deviation C_VS_SP_DIF_MAX_CRU

or Dropping below a permissible VS_DIF_CRU < speed deviation C_VS_SP_DIF_MIN_CRU)]

for longer than C_T_DLY_CRU_OFF_REV_VS_FAULT}

or

15. [if LV_CRU_OVER_ACT = 1 (40000H)

and (the overtaking time T_DLY_CRU >= C_T_DLY_MAX_CRU

or the target speed is exceeded:
(VS_SP_DRIV_CRU - VS_CRU >= C_VS_DIF_DLY_CRU_POS)

or (VS_SP_DRIV_CRU - VS_CRU < C_VS_DIF_DLY_CRU_NEG)]

or

16. VS_CRU >= C_VS_SP_CRU_MAX for longer than C_T_DLY_VS_SP_CRU_MAX (80000H)
If this condition is interupted then the time-counter is reset to 0

or

17. ASR- or MSR-control for minimum time active (100000H)
(LV_CRU_OFF_BY_ASR_MSR_CTL = 1)

Then REQ_CRU = Soft off

G.1.6.2.3 Overtaking function

Description:

If the driver torque request FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU and ≥ IP_FAC_TQ_REQ_CLU_IS__N_32 , then the controller detects overtaking and the value VS_DIF_I_CRU remains stored as threshold value. The time for the overtaking function T_DLY_CRU is started. The adjustable time C_T_DLY_MAX_CRU states whether start controlled constant drive is possible after ending the overtaking function.
During the overtaking function, 'Overdriving' FAC_TQ_REQ_DRIV by acceleration (ACCEL) and Tip-up functions is possible.
If the time C_T_DLY_MAX_CRU or the max. deviation from the stored target speed is exceeded, no automatic start of controlled constant drive is possible any more. The CRU mode is ended. The functions of the cruise control can be activated again exclusively by the multifunction steering wheel. At resume, after overtaking function is finished, the resume function is activated with the initialisation calculation of VS_DIF_I_CRU.
During the overtaking function the calculation of FAC_TQ_CRU is calculated normal with freezed I - share and calculated P-Share.

Application conditions:

Initialisation: LV_CRU_OVER_ACT = 0

Formula section:

If transition FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU
and FAC_TQ_REQ_DRIV > IP_FAC_TQ_REQ_CLU_IS__N_32
and STATE_CRU = "constant drive" (vehicle in cruise control)
Then $T\_DLY\_CRU_{n} = T\_DLY\_CRU_{n-1} + 10$ ms
LV_CRU_OVER_ACT = 1

"VS_DIF_I_CRU stored see calculation of I-Share"

if LV_CRU_OVER_ACT = 1
and T_DLY_CRU < C_T_DLY_MAX_CRU
and VS_SP_DRIV_CRU - VS_CRU < C_VS_DIF_DLY_CRU_NEG
and VS_SP_DRIV_CRU - VS_CRU > C_VS_DIF_DLY_CRU_POS
then **if** (transition FAC_TQ_REQ_DRIV <
FAC_TQ_REQ_CRU -C_FAC_TQ_REQ_HYS_CRU
or FAC_TQ_REQ_DRIV <
IP_FAC_TQ_REQ_CLU_IS - C_FAC_TQ_REQ_CLU_IS_HYS)

and VS_DIF_CRU > C_VS_DIF_MIN_CRU_OVER

then "RESUME" with initialisation of VS_DIF_I_CRU

LV_CRU_OVER_ACT = 0

else LV_CRU_OVER_ACT = 1

else Cruise control passive soft cut off, LV_CRU_OVER_ACT = 0

IF LV_CRU_OVER_ACT =1

and (REQ_MSW = =TIP_UP or ACC/SET)

Then **IF** LV_CRU_OVER_ACT_ACK = 0

Then REQ_CRU = "TIP_UP"

else LV_CRU_OVER_ACT = 0

REQ_CRU = REQ_MSW

Application conditions:

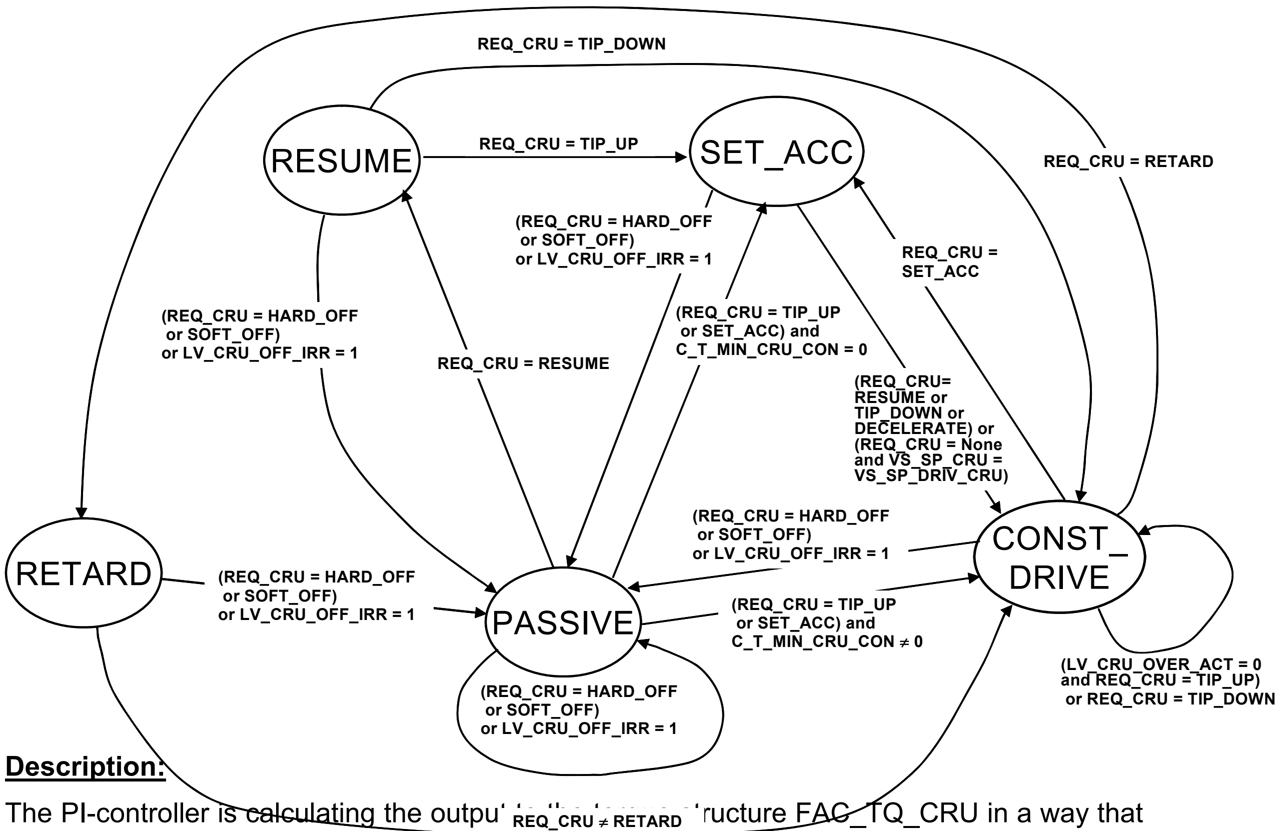
Recurrence: 100 ms

Initialisation: FAC_TQ_CRU = FAC_TQ_CRU_INI based on setting conditions
STATE_CRU = PASSIVE

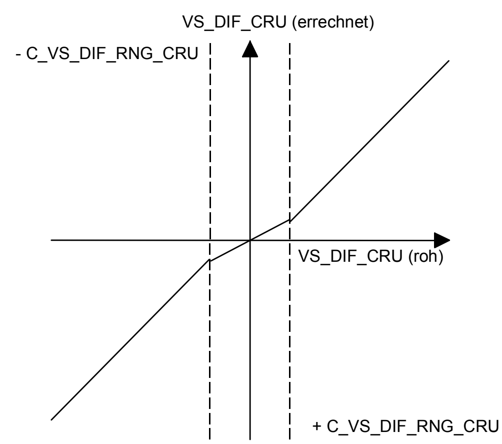
FUNCTION DESCRIPTION:Definition of the STATE_CRU:

The diagram below shows the state machine of the STATE_CRU.



Description:

The PI-controller is calculating the output to the torque structure FAC_TQ_CRU in a way that the current vehicle speed VS_CRU is controlled to reached and keep the vehicle speed setpoint VS_SP_CRU.



Formula section:

Basically calculation for all cruise states:

Total formula PI-controller:

FAC_TQ_CRU = (VS_DIF_CRU + VS_DIF_I_CRU) * IP_FAC_PROP_CRU

Conditions for change limitations of FAC_TQ_CRU:

$|FAC\_TQ\_CRU_{n-1} - FAC\_TQ\_CRU_n| \leq C\_ FAC\_TQ\_CRU\_LGRD$

At driving with an active cruise control the torque request FAC_TQ_CRU is limited to the maximum value C_FAC_TQ_CRU_MAX.

FAC_TQ_CRU <= C_ FAC_TQ_CRU_MAX

The raw value of the control deviation from the reference input variable VS_SP_CRU and the control variable VS_CRU is calculated as

VS_DIF_CRU (raw)= VS_SP_CRU - VS_CRU

To achieve a smooth control in the area of the target vehicle speed, the internal controller deviation VS_DIF_CRU can be reduced in the adjustable bandwidth | C_VS_DIF_RNG_CRU | by an applicable factor C_FAC_VS_DIF_RNG_CRU.

IF(1) |VS_SP_CRU - VS_CRU | ≤ C_VS_DIF_RNG_CRU

Then(1) VS_DIF_CRU = (VS_SP_CRU - VS_CRU) * C_FAC_VS_DIF_RNG_CRU

Else(1) If(2) (VS_SP_CRU - VS_CRU) > C_VS_DIF_RNG_CRU

Then(2) VS_DIF_CRU = (VS_SP_CRU - VS_CRU)
- C_VS_DIF_RNG_CRU
+ C_VS_DIF_RNG_CRU * C_FAC_VS_DIF_RNG_CRU.

Else(2) VS_DIF_CRU = (VS_SP_CRU - VS_CRU)
+ C_VS_DIF_RNG_CRU
- C_VS_DIF_RNG_CRU * C_FAC_VS_DIF_RNG_CRU.

Endif

I share calculation:

General calculation ***STATE_I_CRU = NORM***:

$$VS\_DIF\_I\_CRU_n = VS\_DIF\_I\_CRU_{n-1} + VS\_DIF\_CRU * IP\_FAC\_VS\_DIF\_I\_CRU$$

If the FAC_TQ_CRU on limitation (max, min value or freeze at PUC) then the **I** share is freezed **STATE_I_CRU = LIM** until a normal calculation of FAC_TQ_CRU is possible again. At or LV_CRU_OVER_ACT = 1 the **I** share is freezed **STATE_I_CRU = LIM,** but at the calculation of FAC_TQ_CRU is no interupt.

Setting at the transition “passive” to "setting" or "resume":

VS_DIF_I_CRU = FAC_TQ_CRU_INI / IP_FAC_PROP_CRU

*Calculation during freeze of I- share at SET/ACC, RES (**STATE_I_CRU= FREEZE**):*

$VS\_SP\_CRU\_STAT = VS\_SP\_CRU_n - VS\_SP\_CRU_{START}$

$VS\_DIF\_I\_CRU_{END} = VS\_DIF\_I\_CRU_{START} + IP\_FAC\_VS\_SP\_DIF\_I\_CRU * VS\_SP\_CRU\_STAT$

$VS\_DIF\_I\_CRU_{End}$ is calulated during the freeze of **I** share

FAC_TQ_CRU calculation during freeze of I- share at SET/ACC, RES, min/max limitation:

$FAC\_TQ\_CRU = (VS\_DIF\_CRU + VS\_DIF\_I\_CRU_{END}) * IP\_FAC\_PROP\_CRU$

On setting in PU/PUC or with very small FAC_TQ_REQ_DRIV (driver gets off the pedal before setting Cruise Control), a very small **I**-part initialisation would be the results which leads to an undershooting below the required target speed. To prevent this, the **I**-part initialisation value is calculated depending on AC_CRU, to get a better initialisation value.

FAC_TQ_CRU initialisation value:

IF LV_AT = 0

Then FAC_TQ_CRU_INI = FAC_TQ_REQ_DRIV_MMV * 99,998 % +
IP_FAC_TQ_CRU_INI_ADD_MT * AC_CRU

Else FAC_TQ_CRU_INI = FAC_TQ_REQ_DRIV_MMV * 99,998 % +
IP_FAC_TQ_CRU_INI_ADD_AT * AC_CRU

endif

G.1.7.1.1 Controlled constant drive (CONST_DRIVE)

For controlled constant drive, the reference input variable VS_SP_CRU corresponds to the last target speed reached, i.e. VS_SP_DRIV_CRU. No control of the reference input variable VS_SP_CRU is performed in this range.

The PI-controller is calculating the output to the torque structure FAC_TQ_CRU in a way that the current vehicle speed VS_CRU is controlled to keep the vehicle speed setpoint VS_SP_CRU. This is done until a cut-off condition arises or a condition for cruise control is infringed.

To be able to trigger trailing throttle fuel cut-off appropriately or not to trigger trailing throttle fuel cut-off, the value FAC_TQ_CRU is initially limited downwards to the value ((IP_FAC_TQ_REQ_CLU_IS__N_32 - C_FAC_TQ_REQ_CLU_CRU_IS_HYS)*99,998%). Thus the STATE_ENG “IS” is prevented. Only if the control deviation VS_DIF_CRU drops below C_VS_DIF_MIN_IS_CRU, the FAC_TQ_CRU set to zero. However, this zero setting will not take place in the first C_T_MIN_PUC_CRU seconds after entry into controlled constant drive. The trailing throttle fuel cut-off is deactivated when the control deviation exceeds the value C_VS_DIF_MAX_IS_CRU.

The calculation of the I-part is interrupted, if the torque request FAC_TQ_CRU is limited upwards or FAC_TQ_CRU ≤ ((IP_FAC_TQ_REQ_CLU_IS__N_32-C_FAC_TQ_REQ_CLU_IS_HYS)*99,998%).

Formula section:

FAC_TQ_CRU conditions:

IF T_CONST_DRIVE < C_T_MIN_PUC_CRU

Then FAC_TQ_CRU > ((IP_FAC_TQ_REQ_CLU_IS__N_32-
C_FAC_TQ_REQ_CLU_IS_CRU_HYS) * 99,998%).

ElseIF VS_DIF_CRU < C_VS_DIF_MIN_IS_CRU

Then FAC_TQ_CRU = 0

Else **IF** VS_DIF_CRU > C_VS_DIF_MAX_IS_CRU

Then FAC_TQ_CRU > ((IP_FAC_TQ_REQ_CLU_IS__N_32-
C_FAC_TQ_REQ_CLU_IS_CRU_HYS) * 99,998%).

Else calculation FAC_TQ_CRU $_{n}$= calculation FAC_TQ_CRU $_{n-1}$

Endif

Calibration data:

G.1.7.1.2 Cut-off of the CRU function

General information:

Soft cut-off

In the soft cut-off of the cruise control, the torque request from cruise control FAC_TQ_REQ_CRU is reduced to the driver request FAC_TQ_REQ_DRIV with the adjustable decrement IP_FAC_TQ_CRU_DEC__N_32 until the driver request is reached. FAC_TQ_CRU is then set to zero.

Hard cut-off

In the hard cut-off mode of the cruise control, the torque request FAC_TQ_CRU is set equal to zero. There is no limitation gradient. The CRU State is 'PASSIVE'.

Application conditions:

Activation: see Capter:Cut -off Conditions and switch- on prohibitions

Formula section:

Soft cut-off

For FAC_TQ_REQ_DRIV < FAC_TQ_REQ_CRU there results:

FAC_TQ_CRU = FAC_TQ_CRU $_{n-1}$ - IP_FAC_TQ_CRU_DEC __N_32 until

FAC_TQ_REQ_DRIV = FAC_TQ_REQ_CRU

Hard cut-off

FAC_TQ_CRU = 0

Then, the CRU ready status is reached. Only now can the CRU mode be activated again.

Input data:

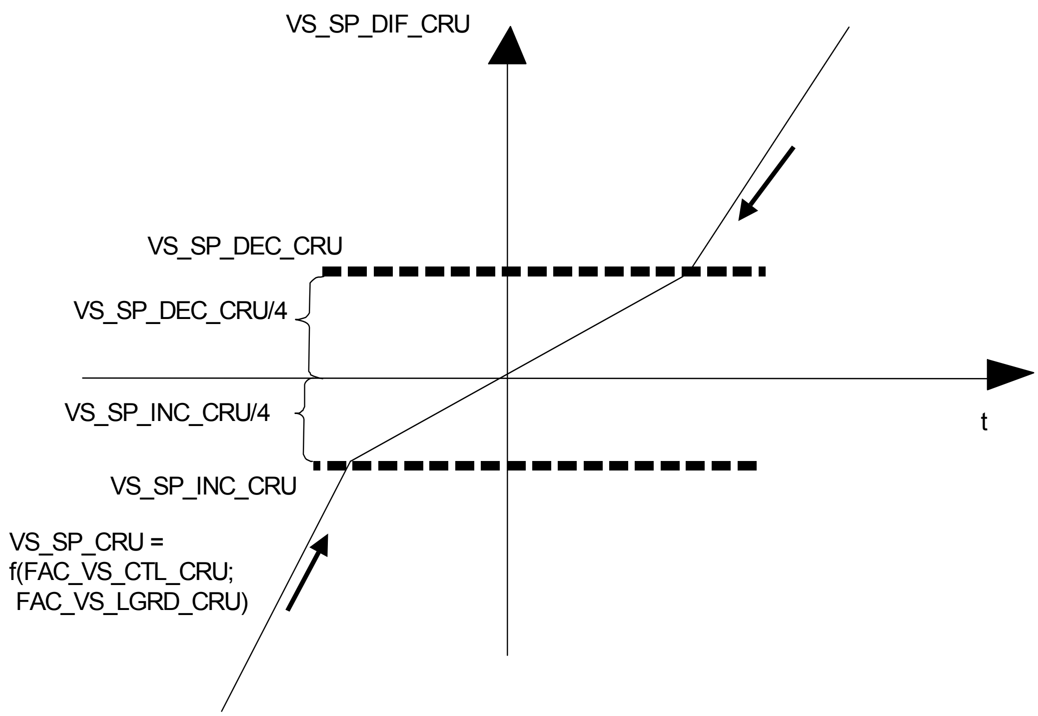
VS_SP_DRIV_CRU	VS_SP_DEC_CRU	VS_SP_INC_CRU	FAC_VS_CTL_CRU
FAC_VS_LGRD_CRU	VS_CRU		

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: VS_SP_CRU = VS_CRU

Description:



The vehicle speed setpoint VS_SP_CRU is set to the current speed of the vehicle VS_CRU at the start of the function.

general specification

The controlled acceleration of the vehicle is performed by controlled in/decrementation of the vehicle speed setpoint. At the start of the function, the time T_CTL_CRU is started and incremented in each computing cycle.
When VS_SP_DIF_CRU is less than VS_SP_DEC/INC_CRU the step size of the decrement/increment is reduced (to VS_SP_DEC_CRU/4 or VS_SP_INC_CRU/4).
A distinction is made between positive and negative acceleration.
For the definition of FAC_VS_CTL_CRU and FAC_VS_LGRD_CRU see next subchapters.

Formula section:

T_CTL_CRUn = T_CTL_CRUn-1 + 100 ms

VS_SP_DIF_CRU = VS_SP_CRU - VS_SP_DRIV_CRU

IF 0 < VS_SP_DIF_CRU ≤ VS_SP_DEC_CRU

Then $VS\_SP\_CRU_n$ = $VS\_SP\_CRU_{n-1}$ - VS_SP_DEC_CRU /4

Else **IF** VS_SP_DIF_CRU > VS_SP_DEC_CRU > 0

Then $VS\_SP\_CRU_n$ = $VS\_SP\_CRU_{n-1}$

- VS_SP_DEC_CRU Decrement
* FAC_VS_CTL_CRU Factor for controlling
* FAC_VS_LGRD_CRU Factor for intercepting

Else If (-1 * VS_SP_INC_CRU) ≤ VS_SP_DIF_CRU < 0

Then $VS\_SP\_CRU_n$ = $VS\_SP\_CRU_{n-1}$ + VS_SP_INC_CRU/4

Else **If** VS_SP_DIF_CRU < (-1 * VS_SP_INC_CRU)

Then $VS\_SP\_CRU_n$ = $VS\_SP\_CRU_{n-1}$

+ VS_SP_INC_CRU Increment
* FAC_VS_CTL_CRU Factor for controlling
* FAC_VS_LGRD_CRU Factor for intercepting

Dec / Incrementation is interrupted if
VS_DIF_CRU > C_VS_DIF_MAX_AC_CRU **or**
VS_DIF_CRU < C_VS_DIF_MIN_AC_CRU

Dec / Incrementation is continued if
VS_DIF_CRU <= C_VS_DIF_MAX_AC_CRU **or**
VS_DIF_CRU >= C_VS_DIF_MIN_AC_CRU

Calibration data:

G.1.7.3 Actuating the reference input variable

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_VS_CTL_CRU	V	0...FFH	0...1.9922	0.0078	-
Correction factor for actuating the reference input variable					

Input data:

T_CTL_CRU		LV_AT	

General information:

The multiplicative correction factor FAC_VS_CTL_CRU for in/decrementation of the vehicle speed setpoint in the controlled acceleration is calculated calculated separately for each case of the cruise control. The correction factor depends upon the time T_CTL_CRU. While the actuation of this function is active, the calculation of the I-controller part is interrupted and kept constant.

Formula section:

FAC_VS_CTL_CRU = IP_FAC_CRU_yy__T_CTL_CRU

A distinction is made between the following CRU functions:

Resume: IP_FAC_CRU_REST__T_CTL_CRU

Acceleration: IP_FAC_ CRU_AC__T_CTL_CRU

Deceleration: IP_FAC_ CRU_DECE__T_CTL_CRU

Calibration data:

G.1.7.4 Intercepting the reference input variable target acceleration

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_VS_LGRD_CRU	V	0...FFH	0...0.9984	0.0039	-
Factor for intercepting the reference input variable					

Input data:

VS_SP_CRU	VS_SP_DRIV_CRU	REQ_MSW	LV_RNG_L_REQ

General information:

To take the vehicle dynamics into account, the positive accelerations at high vehicle speeds must be reduced in the acceleration and resume functions. For this purpose, the accelerations must be valued with a factor FAC_VS_LGRD_CRU for in/decrementing the reference input variable. The acceleration is valued with 1 below the threshold C_VS_AC_MIN_CRU. If VS_SP_CRU exceeds this threshold, then the factor FAC_VS_LGRD_CRU is reduced linearly by a ramp function up to the upper threshold C_VS_AC_MAX_CRU. The maximum reduction can be set through the value C_FAC_AC_POS_CRU.
To achieve a comfortable interception of the vehicle speed setpoint, the multiplicative correction factor, which is limited dependent on speed, must be calculated when in/decrementing the vehicle speed setpoint in each case of the cruise control. While the interception of the reference input variable function is active, the calculation of the I-part is interrupted and kept constant. The correction factor depends upon the difference between vehicle speed setpointand the requested vehicle speed of the driver.

Formula section:

IF VS_SP_CRU < C_VS_AC_MIN_CRU
Then FAC_VS_LGRD_CRU = 1
Else If VS_SP_CRU > C_VS_AC_MAX_CRU
Then **IF LV_RNG_L_REQ = 1**

REQ_CRU	LV_CRU_OVER_ACT		

Application conditions:

Initialisation: VS_SP_DRIV_CRU = C_VS_MIN_CRU at LV_CRU_MAIN_SWI 0 to1

G.1.7.5.1 Resume (RES)

Description:

When the resume function is activated, the vehicle is brought to the last target speed with the adjustable positive or negative acceleration. In this case the control acceleration function is activated and the vehicle speed setpoint is controlled. When controlling the vehicle speed setpoint VS_SP_CRU, a distinction is made between an acceleration and a deceleration.
When the resume function is finished by pressing the SET/COAST button, the VS_SP_DRIV_CRU = VS_SP_CRU = VS_CRU. The SET/COAST button will be interpreted as SET. If a deceleration is required the SET/COAST button has to be pressed a second time.
In resume mode the vehicle speed setpoint is in/decremented every 100 ms.

To achieve a comfortable transition from the STATE_CRU = “PASSIVE” to “RESUME” at the start of the resume function, the I-part of the P/I controller is initialised depending on the acceleration of the vehicle.
At activation the resume mode after overtaking function is finished, the resume function is activated with the initialisation of FAC_TQ_CRU.

Formula section:

IF VS_CRU < VS_SP_DRIV_CRU

Then IF LV_RNG_L_REQ = 1

Then VS_SP_INC_CRU = 3.6 * C_AC_POS_CRU_RESU_RNG_L * 100 ms

G.1.7.5.2 Setting/acceleration (SET/ACC)

Description:

At the activation of the setting/acceleration function from the STATE_CRU = “PASSIVE” , the vehicle speed setpoint VS_SP_CRU and requested vehicle speed of the driver VS_SP_DRIV_CRU are set to the current vehicle speed VS_CRU.

On activating the setting/acceleration function from the STATE_CRU = “PASSIVE”, a timer T_CTL_CRU is started. After this timer reaches the value C_T_MIN_CRU_CON, the STATE_CRU changes from ‘controlled constant drive’ to ‘controlled acceleration’. The vehicle is brought to the required target speed with the adjustable positive ID_AC_POS_CRU_AC_MT/AT or negative acceleration IP_AC_NEG_CRU_AC__N__FAC_TQ_CRU. In this case the controlled acceleration function is activated and the vehicle speed setpoint VS_SP_CRU is controlled.
As long as the setting/acceleration function is active, the incrementation of the vehicle speed setpoint takes place per computing cycle (100 ms) with the controlled acceleration function.
On ending the setting/acceleration function by releasing the SET button, the target speed VS_SP_DRIV_CRU is set equal to the achieved vehicle speed VS_CRU. If the target speed VS_SP_DRIV_CRU stored in this way is greater than the current vehicle speed setpoint VS_SP_CRU, then the value VS_SP_CRU is incremented further by the value VS_SP_INC_CRU through the controlled acceleration function. If the current vehicle speed setpoint VS_SP_CRU is larger than the stored target speed VS_SP_DRIV_CRU, then the vehicle speed setpoint is decremented with the controlled acceleration function.

Formula section:

- REQ_MSW = ACC active:

G.1.7.5.3 Tip-up

Description:

On activating the TIP_UP function, the vehicle is accelerated to the last target speed reached VS_SP_DRIV_CRU plus C_VS_CRU_TIP_STEP. with the adjustable positive acceleration C_AC_POS_CRU_TIP. In this case the controlled acceleration function is activated and the vehicle speed setpoint VS_SP_CRU is controlled. At each activation of the TIP_UP function, the target speed VS_SP_DRIV_CRU is increased by C_VS_CRU_TIP_STEP.
If the absolute amount of the difference VS_DIF_CRU is greater than or equal to C_VS_DIF_MAX_CRU, the vehicle speed setpoint VS_SP_CRU is incremented per computing cycle (100 ms) with the controlled acceleration function as defined below:

Formula section:

```
IF      LV_CRU_OVER_ACT = 1   and   REQ_CRU = "TIP_UP"
Then    VS_SP_CRU =VS_SP_DRIV_CRU = VS_CRU
        LV_CRU_OVER_ACT_ACK = 1
else    LV_CRU_OVER_ACT_ACK = 0
endif
```

VS_SP_DIF_DRIV_CRU = VS_SP_DRIV_CRU – VS_CRU

G.1.7.5.4 Tip-down

Description:

On activating the TIP_DOWN function, the vehicle is decelerated to the last target speed reached VS_SP_DRIV_CRU minus C_VS_CRU_TIP_STEP by the adjustable negative acceleration C_AC_NEG_CRU_TIP. In this case the controlled acceleration function is activated and the vehicle speed setpoint VS_SP_CRU is controlled. At each activation of the TIP_DOWN function, the target speed VS_SP_DRIV_CRU is reduced by C_VS_CRU_TIP_STEP VS_SP_CRU and VS_SP_DRIV_CRU may not be less than C_VS_MIN_CRU.
If the absolute amount of the difference VS_DIF_CRU is greater than or equal to C_VS_DIF_MAX_CRU, the vehicle speed setpoint VS_SP_CRU is decrements per computing cycle (100 ms) with the controlled acceleration function. The torque request of the cruise control FAC_TQ_CRU is limited to the value (IP_FAC_TQ_REQ_CLU_IS__N_32*99,998%), so that no trailing throttle cut-off is triggered (except for: PUC was already active before TIP_DOWN).

Formula section:

IF VS_SP_DRIV_CRU < C_VS_MIN_CRU

Then VS_SP_DRIV_CRU = C_VS_SP_CRU_MIN

Else VS_SP_DRIV_CRU = VS_SP_DRIV_CRU - C_VS_CRU_TIP_STEP

IF |VS_DIF_CRU | >= C_VS_DIF_MAX_CRU

Then VS_SP_DEC_CRU = 3.6 * C_AC_NEG_CRU_TIP * 100 ms

$VS\_SP\_CRU_n = VS\_SP\_CRU_{n-1}$

- VS_SP_DEC_CRU :Decrement

* FAC_VS_CTL_CRU :Factor for controlling

* FAC_VS_LGRD_CRU :Factor for intercepting

Else VS_SP_CRU = VS_SP_CRU - C_VS_CRU_TIP_STEP

Endif

FAC_TQ_CRU >= ((IP_FAC_TQ_REQ_CLU_IS__N_32 - C_FAC_TQ_REQ_CLU_IS_HYS) * 99,998%)

VS_SP_CRU >= C_VS_MIN_CRU

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_AC_NEG_CRU_TIP	1	0...5C28H	0...511.9789	0.0217	m/s^2

C_VS_DIF_MAX_CRU	1	0...FFH	0...31.875	0.125	km.p.h.
Control difference threshold for incrementing VS_SP_CRU					

G.1.7.5.5 Deceleration

Description:

On activating the deceleration function, the vehicle is decelerated to the required target speed with the adjustable negative ID_AC_NEG_CRU_DEACC_MT/AT or positive acceleration C_AC_POS_CRU_DEACC (for the steady state). In this case the controlled acceleration function is activated and the vehicle speed setpoint VS_SP_CRU is controlled.
As long as the deceleration function is activated, the decrementation of the vehicle speed setpoint takes place per computing cycle (100 ms) with the controlled acceleration function.

On ending the deceleration function, the target speed VS_SP_DRIV_CRU is set equal with the reached vehicle speed VS_CRU. If the target speed VS_SP_DRIV_CRU thus stored is smaller than the current vehicle speed setpoint VS_SP_CRU, then the value VS_SP_CRU is decremented by the value VS_SP_DEC_CRU further via the controlled acceleration function. VS_SP_CRU and VS_SP_DRIV_CRU may not be smaller than C_VS_MIN_CRU. If the current vehicle speed setpoint VS_SP_CRU is smaller than the stored target speed VS_SP_DRIV_CRU, then the vehicle speed setpoint is incremented with the controlled acceleration function.

Formula section:

- REQ_MSW = DEC active:

  VS_SP_DEC_CRU = 3.6 * ID_AC_NEG_CRU_DEACC_MT/AT * 100 ms

  $VS\_SP\_CRU_{n}$ = $VS\_SP\_CRU_{n-1}$

  - VS_SP_DEC_CRU :Decrement

  * FAC_VS_CTL_CRU :Factor for controlling

  * FAC_VS_LGRD_CRU :Factor for intercepting

- REQ_MSW = DEC passive:

  VS_SP_DRIV_CRU = VS_CRU

  IF VS_SP_DRIV_CRU < VS_SP_CRU

  Then VS_SP_DEC_CRU = 3.6 * ID_AC_NEG_CRU_DEACC_MT/AT * 100 ms

  VS_SP_CRU = capter "calculation of controlled acceleration"

  Else VS_SP_INC_CRU = 3.6 * C_AC_POS_CRU_DEACC * 100 ms

  VS_SP_CRU = capter "calculation of controlled acceleration"

  Endif

As long as the decrementation of the vehicle speed setpoint VS_SP_CRU is active, the calculation of the I-part is released.

Calculation of VS_DIF_I_CRU until

VS_DIF_I_CRU + C_VS_DIF_DELTA_I < |VS_DIF_CRU|

G.1.7.5.6 OFF

In the OFF function, the last setpoint VS_SP_DRIV_CRU remains stored and soft cut-off is activated. If the engine running is stopped (LV_IGK, LV_ES) the CRU - readiness and the last speed-setpoint are to reset to their initial values.

G.1.8 Additional functions

G.1.8.1 Runup lock

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_VS_CRU	O/V	0...1FE0H	0...16320	2	min^{-1} / km.p.h.
Ratio between engine speed and vehicle speed					

Input data:

N	VS_WORD	LV_AT	

Application conditions:

Initialisation: 0 at reset

Activation: LV_AT = 0

Deactivation: LV_AT = 1

Recurrence: 100 ms

Description:

In vehicles with manual transmission, the ratio between engine speed and vehicle speed is monitored on activating a function of the cruise control. At the start of a function, the ratio

N_VS_CRU = N / VS_WORD is stored.

The instantaneous ratio between engine speed and vehicle speed is formed in each cycle

$N\_VS\_CRU_n = N_n / VS\_WORD_n$

Remark:

If the percentage ratio exceeds the threshold value C_N_VS_MAX_CRU, hard cut-off has to ocurrs.

G.1.8.2 Filter of Vehicle Speed for Cruise control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VS_CRU	O/V	0...FFFFH	0...511.9922	0.0078	km.p.h.
Vehicle speed for cruise control					
VS_CRU_FIL	O/V	0...FFFFH	0...511.9922	0.0078	km.p.h.
Filtered vehicle speed for cruise control					

Input data:

VS_WORD			

Application conditions:

Initialisation: 0 at reset

Activation: at every engine state

Recurrence: 10ms

General information:

Formula section:

$VS\_CRU\_FIL = VS\_CRU\_FIL_{n-1} + C\_GAIN\_VS\_CRU\_FIL * (VS\_WORD_n – VS\_CRU\_FIL_{n-1})$

$VS\_CRU = VS\_CRU\_FIL$

Calibration data:

C_GAIN_VS_CRU_FIL	1	0...FFFFH	0...1	1.526 E-5	-
Filter gain of the vehicle speed for cruise control					

G.1.9 Checking the conditions of the CRU mode

G.1.9.1 Acceleration monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
AC_CRU	O/V	8000...7FFFH	-15,72...15,72	0.00048	m/s^2
Vehicle acceleration in CRU					

Input data:

VS_CRU_FIL			

Application conditions:

Initialisation: 0 m/s² at reset

Recurrence: 10 ms

Description:

To monitor the vehicle dynamics in cruise control mode, the instantaneous acceleration of the vehicle is calculated in each computing cycle. The acceleration calculation is performed independently of the CRU mode with a 10 ms time pattern.

Formula section:

$$AC\_CRU = AC\_CRU + (((VS\_CRU\_FIL_n - VS\_CRU\_FIL_{n-1}) / 10ms) - AC\_CRU) * C\_FAC\_AC\_CRU\_MMV$$

Remark:
If the instantaneous acceleration exceeds the adjustable value C_AC_MAX_CRU, hard cut-off is performed, see chapter hard off conditions.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_FAC_AC_CRU_MMV	1	0...FFFFH	0...1	1.5E-05	-
Filtering AC_CRU					

G.1.9.2 Recognition ASR/ESP-control and valid minimum time

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CRU_OFF_BY_ASR_MSR_CTL	V/O	0...1H	0....1	1	-
Soft off condition depending on ASR, MSR interventions					

Input data:

LV_MSR_REQ	LV_ASR_REQ		

Application conditions:

Initialisation: 0 at reset

Recurrence: 100 ms

Description:

Recognition ASR/MSR-control and valid minimum time :

LV_CRU_OFF_BY_ASR_MSR_CTL = active:

Recognition due to the combination of the signals LV_MSR_REQ, LV_ASR_REQ .

LV_MSR_REQ	LV_TQ_ASR_REQ		function	minimum time before cut-off CRU

J.1.1 General information

The end of line test is used in the manufacturing plant or at the service for a functional check of the evaporative system and leakage check.

The diagnosis is started via the serial interface and works as in case of the “normal” evaporative diagnosis activation.

J.1.2 Conditions to start the diagnosis

Application conditions:

Activation:

To start the algorithm, the following conditions must exist:

- No electrical diagnostic error related to:
  - vehicle speed (LV_ERR_VS = 0)
  - magnetic wheel speed-sensor (LV_ERR_MWSS = 0)
  - intake air temperature (LV_ERR_TIA = 0)
  - coolant temperature (LV_ERR_TCO = 0 , LV_ERR_TCO_PLAUS = 0, LV_ERR_TCO_STUCK = 0, LV_ERR_TCO_GRD = 0)
  - evaporative emission control valve (LV_ERR_CPS = 0)
  - lambda controller (LV_ERR_FSD_LAM_LIM_i = 0)
  - O2 sensors (LV_ERR_LS_UP_i = 0)
  - ETC (LV_ERR_TPS = 0, LV_ERR_TPS_PLAUS = 0, LV_N_LIM_ETC_LIH = 0, LV_MTC_CUR_OFF = 0)
  - ISA (LV_ERR_ISC=0, LV_ERR_ISA_1=0, LV_ERR_ISA_2=0)
  - tank pressure sensor (LV_ERR_DTP =0)
  - shutoff valve (LV_ERR_SOV = 0)
  - shutoff valve stuck (LV_ERR_MEC_SOV = 0)
  - Load-sensor (LV_ERR_MAF = 0, LV_ERR_MAP = 0)
  - injector valves (LV_ERR_IV_x = 0)
  - ignition coils (LV_ERR_IGC = 0)
  - fuel system diagnosis (LV_ERR_FSD_i = 0)
  - catalyst damage misfire (LV_MIS_STATE_A = 0)
- VS < C_VS_MAX_DIAGCP
- Canister purge not forced to NO_PURGE mode by “lambda control limit diagnosis” (LV_CP_SET_CLOSE = 0)
- To avoid problems with low battery voltage, LV_CDN_VB_OBD2 = 1. If this condition is not fulfilled the system switches to ‘wait period’.
- Tank pressure has to be within a certain range :

  C_DTP_MIN_DIAG < DTP < C_DTP_MAX_DIAG
- Canister purge must be active: CP_STATE <> CP_NOT_ACTIVE
- No request of IVVT EOL to increase N_SP_IS. Need to avoid duplicate rpm increment

  LV_TRIP_ACT_IVVT_IN = 0 and LV_TRIP_ACT_IVVT_EX = 0

Deactivation:

The evaporative system monitoring is stopped for this engine run if an electrical or mechanical error is present or the leakage detection algoritm is finished:

- Diagnostic error related to:
  - vehicle speed sensor (LV_ERR_VS = 1)
  - magnetic wheel speed-sensor (LV_ERR_MWSS = 1)
  - coolant temperature sensor (LV_ERR_TCO = 1, LV_ERR_TCO_PLAUS = 1, LV_ERR_TCO_STUCK = 1, LV_ERR_TCO_GRD = 1)
  - intake air temperature sensor (LV_ERR_TIA = 1)
  - evaporative emission control valve (LV_ERR_CPS = 1)
  - lambda controller (LV_ERR_FSD_LAM_LIM_i = 1)
  - O2 sensor (LV_ERR_LS_UP_i = 1)
  - ETC (LV_ERR_TPS = 1, LV_ERR_TPS_PLAUS = 1, LV_N_LIM_ETC_LIH = 1, LV_MTC_CUR_OFF = 1)
  - ISA (LV_ERR_ISC=1, LV_ERR_ISA_1=1, LV_ERR_ISA_2=1)
  - tank pressure sensor (LV_ERR_DTP =1)
  - shutoff valve (LV_ERR_SOV = 1)
  - shutoff valve stuck (LV_ERR_MEC_SOV = 1)
  - Load-sensor (LV_ERR_MAF = 1, LV_ERR_MAP = 1)
  - injector valves (LV_ERR_IV_x = 1)
  - ignition coils (LV_ERR_IGC = 1)
  - fuel system diagnosis (LV_ERR_FSD_i = 1)
  - catalyst damage misfire (LV_MIS_STATE_A = 1)

or

- VS >= C_VS_MAX_DIAGCP
- Conditions of limited dynamics for pressure curve no longer fulfilled
- LV_CP_SET_CLOSE = 1
- LV_CDN_VB_OBD2 = 0
- Lambda Control loop opened (LV_LSCL_i = 0)

or

- Too high pressure increase during ´test for vapour generation´:
  FAC_DIAGCP_MDL_BAS > C_FAC_DIAGCP_MDL_BAS_MAX_EOL

or

- deviation of lambda-integrator above the threshold during ´evacuation´:

```
{  (    FAC_LAM_DIAGCP -  FAC_LAM_MV_MMV <= C_FAC_LAM_MIN_DIAGCP_EOL
   or   FAC_LAM_DIAGCP -  FAC_LAM_MV_MMV >= C_FAC_LAM_MAX_DIAGCP_EOL )
and
   (    DTP_DIF_ACT <= C_DTP_DIF_MIN_DIAGCP        //  missing tank cap not suspected
   or   N_DIF > C_N_DIF_MAX_DIAGCP_EOL        )    //  engine stability check
}
```

or

- error detection by the algorithm (CPS stuck, tank cap missing, large leak or small leak)

or

- algorithm finished without error detection

or

- Degree of canister saturation is too high: CL_MMV > C_CL_MMV_MAX_EOL

Remark: The EOL-test can be restarted by diagnosis tool without waiting period.

Delay time T_DLY_EOL_DIAGCP is set to C_T_DLY_EOL_DIAGCP after EOL-test(EOL_STATE from _ACT to _RDY) and decremented.

J.1.3 Outputs to the diagnostic tester

To evaluate the diagnosis result or to understand the cause of diagnosis end, it is neccessary to send some information via KW 2000 to the diagnosis tester:

- DTP
- FAC_DIAGCP_VOL
- FAC_DIAM_DIAGCP
- STATE_INTR_DIAGCP
- EOL_STATE_DIAGCP

In case of an error this will be entered in the normal failure memory (i.e. the DTCs are normally managed).

With :

EOL_STATE_DIAGCP =	0 - EOL_PAS	(EOL-test passive)
	1 - EOL_ACT	(EOL-test active, no result yet)
	2 - EOL_RDY	(EOL-test passive, result is present)

Calibration data:

FUNCTION DESCRIPTION:

General information:

The IVVT actuator test is realized by a short trip. The short trip is a forced diagnosis. It means that certain setpoints are prescribed. They must be reached in specified time.

Description:

The short trip is enabled only under certain conditions, see "IVVT Short Trip (Forced Diagnosis) - Application Incidences". The short trip is a direct error detection.

The prescribed camshaft positions of the short trip are: reference position, C_CAM_SP_TRIP_IVVT_IN(_EX), reference position. Each transition must be reached within the time C_T_ADJ_TRIP_IVVT_IN(_EX). If not the error flag LV_ERR_TRIP_IVVT_IN(_EX)_i is set 1. In this case the short trip must be inactivated by cancelling of the short trip request, see "IVVT Short Trip (Forced Diagnosis) - Application Incidences". A successful short trip is indicated by LV_TRIP_END_IVVT_IN(_EX) = 1.

Error-symptoms are defined to this diagnostic function as follows:

```
[ | | | ]
 │  │  │  └─> TRIP_IVVT_IN(_EX)_i          (= SYM_0)
 │  │  └────> (not used)                  (= SYM_1)
 │  └───────> (not used)                  (= SYM_2)
 └──────────> (not used)                  (= SYM_3)
```

FUNCTION DESCRIPTION:

Description:

The short trip is a special kind of IVVT forced diagnosis. There is no error management for it.

Application conditions:

Initialization: *At reset:* LV_INH_DIAG_TRIP_IVVT = 1
LV_DIAG_TRIP_AVL_IVVT_IN(_EX) = 0

Recurrence: *100 ms*

Activation: *At every engine state*

Formula section:

Conditions for short trip:

if LC_DIAG_TRIP_EXT_TEST_ACT_IVVT = 1
and LV_ACT_IVVT = 1
and C_N_32_MIN_TRIP_IVVT <= N_32 <= C_N_32_MAX_TRIP_IVVT
and C_TOIL_MIN_TRIP_IVVT <= TOIL <= C_TOIL_MAX_TRIP_IVVT
and VB >= C_VB_DIAG_TRIP_IVVT
and LV_ERR_TOIL = 0
and LV_ERR_TOIL_PLAUS_H = 0
and LV_ERR_TOIL_PLAUS_L = 0
and LV_ERR_TOIL_STUCK = 0
and LV_ERR_IV = 0
and LV_MTC_CUR_OFF = 0
and LV_OFF_MTC_MON = 0

and LV_ERR_LIH_IVVT = 0
and LC_CAM_SP_MAN_IVVT_IN = 0 *(NLC_IVVT_IN = 1)*
and LC_CAM_SP_MAN_IVVT_EX = 0 *(NLC_IVVT_EX = 1)*
then LV_INH_DIAG_TRIP_IVVT = 0
else LV_INH_DIAG_TRIP_IVVT = 1

Short trip activation:

if LV_INH_DIAG_TRIP_IVVT = 0
and LC_DIAG_TRIP_EXT_REQ_ST_IVVT = 1 **or** request by external tester
then LV_DIAG_TRIP_AVL_IVVT_IN(_EX) = 1
else LV_DIAG_TRIP_AVL_IVVT_IN(_EX) = 0

IVVT end-of-line test error detection:

Two symptoms can be distinguished: Target position not reached in specified time intake/exhaust. Both symptoms are handled by direct error entry.

Configuration for diagnositic symptoms:

Diagnostic	Symptom Description	Symptom	Filter type
TRIP_IVVT_IN_1	Trip IVVT	SYM_0	*STD*
		SYM_1	
		SYM_2	
		SYM_3	

List of Environmental Data to store in failure memory: DIAG_INST_ENVD
