The above may be facilitated for example by use of an 6 value ring buffer. The most current difference, ($VLS\_UP[i]_N$ - $VLS\_UP[i]_{N-1}$), would overwrite the oldest difference in the buffer, ($VLS\_UP[i]_{N-5}$ - $VLS\_UP[i]_{N-6}$), and the average of the buffer contents recalculated.

Computation of absolute maximum of first derivative number of previous samples VLS_UP_DRV1_ABS_MAX[i]

$$VLS\_UP\_DRV1\_ABS\_MAX[i] = MAXIMUM\left|{}_{x=0}^{5}\left(VLS\_UP[i]_{N-x} - VLS\_UP[i]_{N-(x+1)}\right)\right|$$

The above may be facilitated for example by use of the same 6 value ring buffer, as proposed above for the computation of VLS_UP_DRV1_MMV[i]. The function would calculate the absolute values of the buffer contents and take the maximum of these values.

Computation of moving mean value of lean and rich sensor voltages, VLS_UP_MMV_xxx[i]

If (LV_PUC = 0)

then **If** (VLS_UP[i] < VLS_UP_BOL[i])

then *Compute moving mean lean signal, filter constant ON*

else *Compute moving mean lean signal, filter constant OFF*

endif

If (VLS_UP[i] > VLS_UP_TOL[i])

then *Compute moving mean rich signal, filter constant ON*
VLS_UP_DRV1_MMV_MIN[i] = 0

else *Compute moving mean rich signal, filter constant OFF*
Determine minimum of moving mean of first derivative

endif

Compute & limit switch hysteresis

Compute & limit switch thresholds

else VLS_UP_DRV1_MMV_MIN[i] = 0

endif

Determine validity of moving mean lean / rich sensor voltages.

Compute moving mean lean signal, filter constant ON

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_UP.

$VLS\_UP\_MMV\_MIN[i]_N = VLS\_UP\_MMV\_MIN[i]_{N-1} * (1 - C\_CRLC\_VLS\_UP) + VLS\_UP[i]_N * C\_CRLC\_VLS\_UP$

Compute moving mean lean signal, filter constant OFF

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_UP_OFF.

$VLS\_UP\_MMV\_MIN[i]_N = VLS\_UP\_MMV\_MIN[i]_{N-1} * (1 - C\_CRLC\_VLS\_UP\_OFF) + VLS\_UP[i]_N * C\_CRLC\_VLS\_UP\_OFF$

Compute moving mean rich signal, filter constant ON

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_UP.

$VLS\_UP\_MMV\_MAX[i]_N = VLS\_UP\_MMV\_MAX[i]_{N-1} * (1 - C\_CRLC\_VLS\_UP) + VLS\_UP[i]_N * C\_CRLC\_VLS\_UP$

Compute moving mean rich signal, filter constant OFF

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_UP_OFF.

$VLS\_UP\_MMV\_MAX[i]_N = VLS\_UP\_MMV\_MAX[i]_{N-1} * (1 - C\_CRLC\_VLS\_UP\_OFF) + VLS\_UP[i]_N * C\_CRLC\_VLS\_UP\_OFF$

Determine minimum of moving mean of first derivative VLS_UP_DRV1_MMV_MIN[i]

The determination of the minimum of VLS_UP_DRV1_MMV[i] shall take place when the condition VLS_UP[i] ≤ VLS_UP_TOL[i] has been met. In this case:

VLS_UP_DRV1_MMV_MIN[i] = MIN(VLS_UP_DRV1_MMV_MIN[i], VLS_UP_DRV1_MMV[i])

Should the above condition no longer met, LV_PUC be active or the initial activation conditions not be met then VLS_UP_DRV1_MMV_MIN[i] shall be reset to 0.

Compute & limit switch hysteresis

VLS_UP_MMV_HYS[i] = **|** (VLS_UP_MMV_MAX[i] - VLS_UP_MMV_MIN[i]) **|** * C_FAC_VLS_UP_MMV_HYS

If (VLS_UP_MMV_HYS[i] < C_VLS_UP_MMV_HYS_MIN)

then VLS_UP_MMV_HYS[i] = C_VLS_UP_MMV_HYS_MIN

endif.

Compute & limit switch thresholds

If ((VLS_UP_MMV_MAX[i] - VLS_UP_MMV_MIN[i]) ≤ 2 * VLS_UP_MMV_HYS[i])

then VLS_UP_BOL[i] = (VLS_UP_MMV_MAX[i] + VLS_UP_MMV_MIN[i]) / 2
VLS_UP_TOL[i] = (VLS_UP_MMV_MAX[i] + VLS_UP_MMV_MIN[i]) / 2

VLS_UP_MMV_MIN[i] = VLS_UP_BOL[i] - VLS_UP_MMV_HYS[i]
VLS_UP_MMV_MAX[i] = VLS_UP_TOL[i] + VLS_UP_MMV_HYS[i]

LV_VLS_UP_MMV_LIM[i] = 1

else VLS_UP_BOL[i] = VLS_UP_MMV_MIN[i] + VLS_UP_MMV_HYS[i]
VLS_UP_TOL[i] = VLS_UP_MMV_MAX[i] - VLS_UP_MMV_HYS[i]

LV_VLS_UP_MMV_LIM[i] = 0

endif.

Determine validity of moving mean lean / rich sensor voltages

If (VLS_UP_MMV_MIN[i] < VLS_UP_MMV_MAX[i]) **&**
(LV_LAM_LSCL[i] = 1) **&**
(CTR_AFL_CYC[i] ≥ C_CTR_VLS_UP_AFL_CYC_MIN)

then LV_VLS_UP_MMV_STK_VLD[i] = 1

else LV_VLS_UP_MMV_STK_VLD[i] = 0

endif.

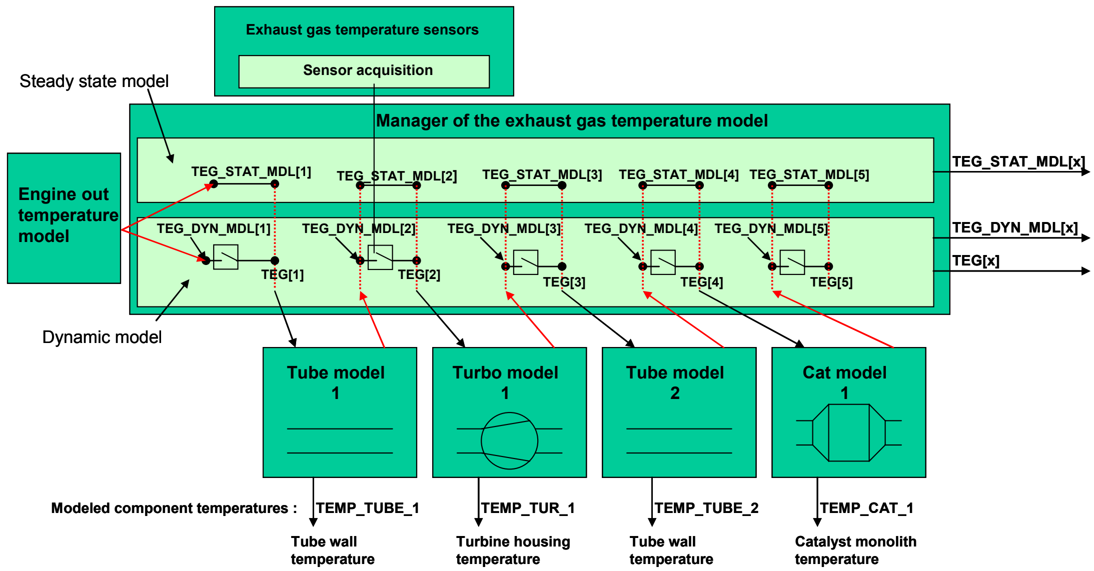
writes back the calculated data back to the arrays of the manager (TEG_DYN_MDL, ...)

7.40.1 General information:

The manager of the exhaust gas temperature model is the module which coordinates the different component models. Dependent on the configuration the manager calls the different

component models (Engine out, Tube, Catalyst, Turbine model) in the configured order and update rate. The results of the different component models are written back by the action "ACTION_EXTD_Data2Manag" into the values:
TEG_DYN_MDL
TEG_STAT_MDL
HUM_EX_GAS_MDL
LV_DEW_TEMP_DEW_MDL
Example:



If a sensor value is available and no sensor error is detected the output TEG, which is input for the next model, is equal to the measured value (TEG_MES) if the corresponding LC_TEG_MDL_SENS_ENA[NC_NR_TEG_SENS] is set to one. On the other hand if an error is detected or no sensor is available or the LC_TEG_MDL_SENS_ENA is equal zero TEG[i] is equal to TEG_DYN_MDL[i].

All dynamic exhaust gas temperatures are initializied with the component temperature upstream its position. The component temperature itselfe is initializied in the component model by using the stored temperature at engine shut down weighted by a cooling down factor dependent on the engine off duration time T_ES. Due to the fact that the engine out model has no component temperature TCO is used as component temperature.

In the given example the exhaust gas temperatures initialized as following:
TEG[1] = TEG_DYN_MDL[1] = TCO
TEG[2] = TEG_DYN_MDL[2] = TEMP_TUBE[1]
TEG[3] = TEG_DYN_MDL[2] = TEMP_TUR[1]
TEG[4] = TEG_DYN_MDL[2] = TEMP_TUBE[2]
TEG[5] = TEG_DYN_MDL[1] = TEMP_CAT[1]
The steady state temperatures TEG_STAT_MDL, the humidities HUM_EX_GAS_MDL and the dewpoint flags of the model LV_TEMP_DEW_MDL are all initialized with zero.

MAF_KGH_INT_DEW treshold for dew point detection for the lambda sensor up catalyst					

7.41.1 Dew point detection

This module is used to detect when the dew phase in the exhaust line is finished. This is necessary because the lambda sensors can only be heated with full power if there is no risk of thermal shock due to water drops. Therefore for each sensor (up- /down stream of the catalyst; bankselektive) a flag is set when the dew phase is over:

LV_TEMP_DEW_LS_UP[NC_CBK_EX_NR] for the upstream sensor

LV_TEMP_DEW_LS_DOWN[NC_CBK_EX_NR] for the downstream sensor

Three conditions are checked to set these bits:

1. The condition is that the physical model of the water condesation in the exhaust gas temperature model determines that there is no condensate in the exhaust line upstream the sensor. Therefore the exhaust gas temperature model delivers the flags LV_TEMP_DEW_MDL[NC_NR_TEG_MDL] for the different positions in the exhaust line.

2. Additionaly the model based wall temperatures are checked. The second condition is fulfilled if the coreponding temperatures (TEMP_TUBE; TEMP_TUR) are above the calibratable threshholds:
- IP_TEMP_THD_DEW_LS_UP for the upstream sensor
- IP_TEMP_THD_DEW_LS_DOWN for the downstream sensor

3. In the case that the exhaust gas temperature model is not jet well calibrated a third condition can be helpful to avoid sensor problems because it can be calibrated very fastly. Therefore a weithed integral of the mass air flow MAF_KGH_INT_DEW is calculated. The third condition is fulfilled if this integral is above the following threshholds:
- IP_MAF_KGH_INT_DEW_THD_LS_UP for the upstream sensor
- IP_MAF_KGH_INT_DEW_THD _LS_DOWN for the downstream sensor

To set the flags LV_TEMP_DEW_LS_xx either condition 1. and 2. are fullfilled or condition 3. is fullfilled.

The module consists out of three major function parts because of different update rates:

1. Calculation of the mass air flow integral: CLC__MAF_KGH_INT_DEW (update rate 1s)
2. Determination of the dew point (setting of the flags): CLC__LV_TEMP_DEW (update rate 100ms)
3. Incrementation of the cold start counter: CLC__COLD_ST_CTR (once at engine off)

7.42.1 General information:

The "engine out exhaust gas temperature model" is part of the complete exhaust gas temperature model. This part contains the calculation of the effective engine out exhaust gas temperature dependent on the engine operating parameters and the engine out exhaust gas humidity.

This module handles the following dependencies of the engine out exhaust gas temperature:
- Engine operating point (Engine speed N_TEG and load MAF_TEG)
- Ignition angle dependency
- Lambda dependency
- Correction for secondary air
- Engine out temperature during PUC operation
- Warm up correction versus coolant temperature TCO
- Correction versus intake air temperature TIA_CYL

For all other dependencies (VVT, EGR or MPL_XX) it is possible to add project specific corrections:
- TEG_ENG_OUT_ADD_CUS: additive correction on the engine out temperature
- FAC_TEG_ENG_OUT_CUS: multiplicative correction on the engine out temperature
- IGA_REF_TEG_ADD_CUS: additive correction on the reference ignition angle for the ignition angle dependency of the engine out temperature
- IGA_BAS_TEG_ADD_CUS: additive correction on the basic ignition angle for the ignition angle dependency of the engine out temperature
- FAC_TEG_ADD_IGA_CUS: additive correction of the map IP_FAC_TEG_ADD_IGA

Function Description

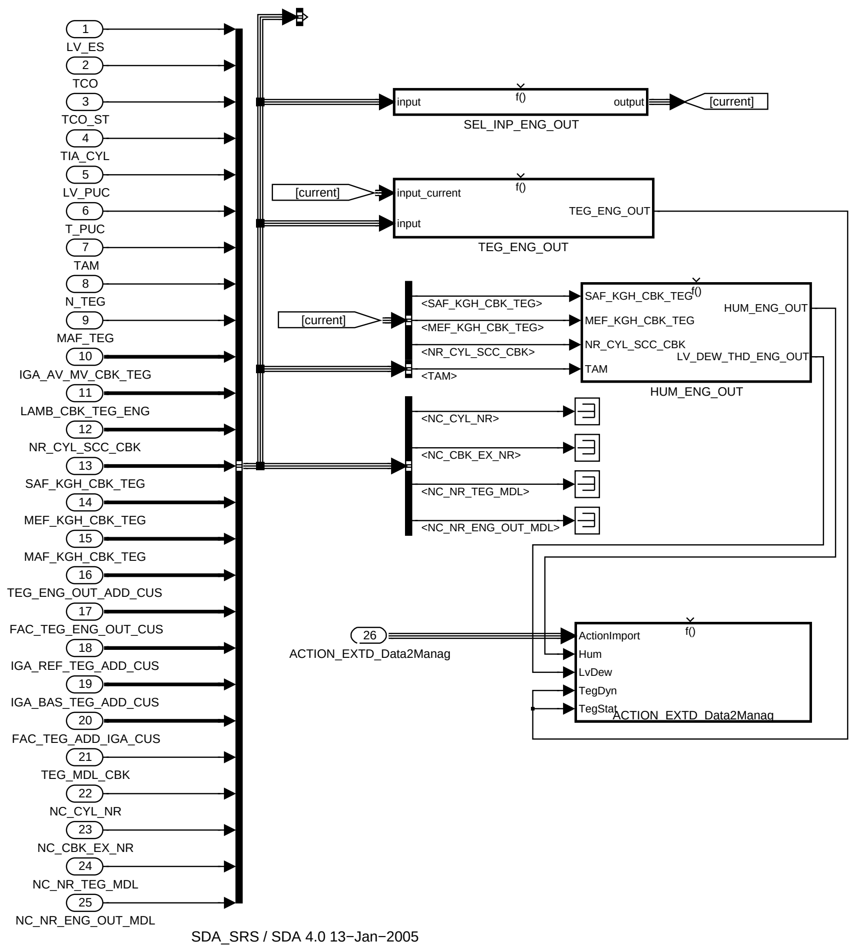

Figure 42 EXTD_MDLADengou0

7.42.1.1 HUM_ENG_OUT

In this function part the engine out exhaust gas humidity is determined. Therefore it is important to know that at lambda = 1 the engine produces a nearly constant amount of water (per kg exhaust gas) due to the combustion. This value can be calibrated in the calibration constant C_HUM_ENG_OUT. In the case of cylinder shut off no combustion takes place and so this amount of water has to be reduced dependent on the number of shut off cylinder on this cylinder bank. The so calculated exhaust gas humidity has to be increased by the intake air humidity. Thereby it is supposed that the relative humidity of the intake air is 100% because this is the worst case for the dew point calculation. So the intake air humidity is determined the map IP_HUM_EX_GAS_MAX with the ambient temperature TAM as input. Therefore TAM has to be converted to TEG_AM to have the same resolution as the exhaust gas temperature.

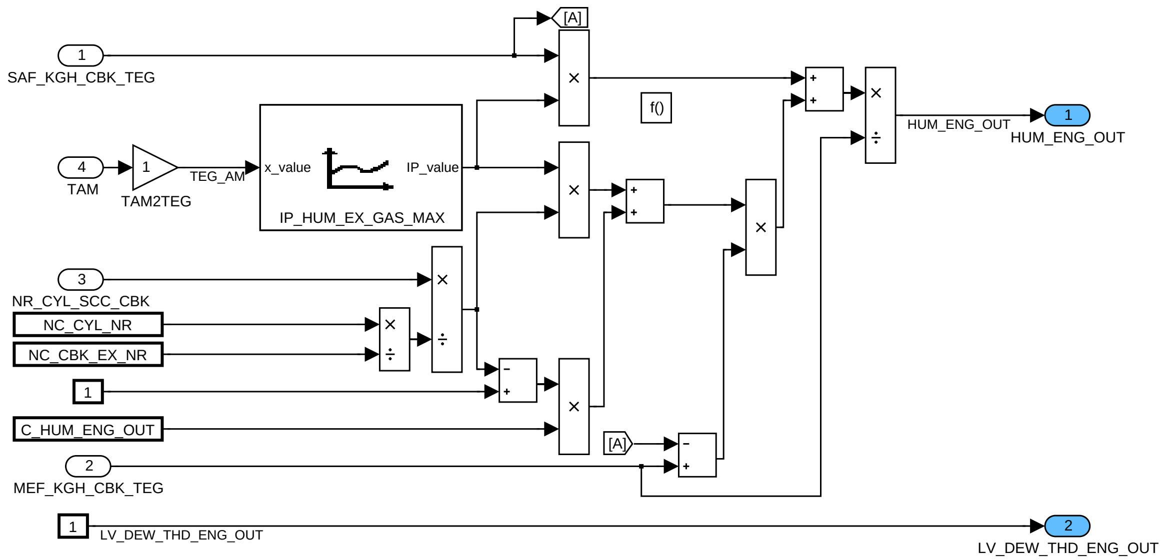

Figure 43 EXTD_MDLADengou0/ HUM_ENG_OUT

7.42.1.2 TEG_ENG_OUT

The calculation of the engine out exhaust gas temperature is split up in two parts. One part for the basic map and all additive correction CLC__TEG_ENG_OUT_BAS and one for all multiplicative corrections and the PUC calculations COR__TEG_ENG_OUT.

<u>CLC__TEG_ENG_OUT_BAS</u>

In this function part the basic effective engine out exhaust gas temperature is calculated. This basic engine out temperature is stored in the map IP_TEG_ENG_OUT_BAS. All corrections on this map will be zero if secondary air is inactive and the other parameters are equal to there calibrated basic values:

IGA_AV_MV_CBK_i = IP_IGA_BAS_TEG + project specific correction

LAMB_CBK_TEG_ENG_i = IP_LAMB_BAS_TEG

The ignition angle dependency is comparable with the ignition angle dependency of the torque model.

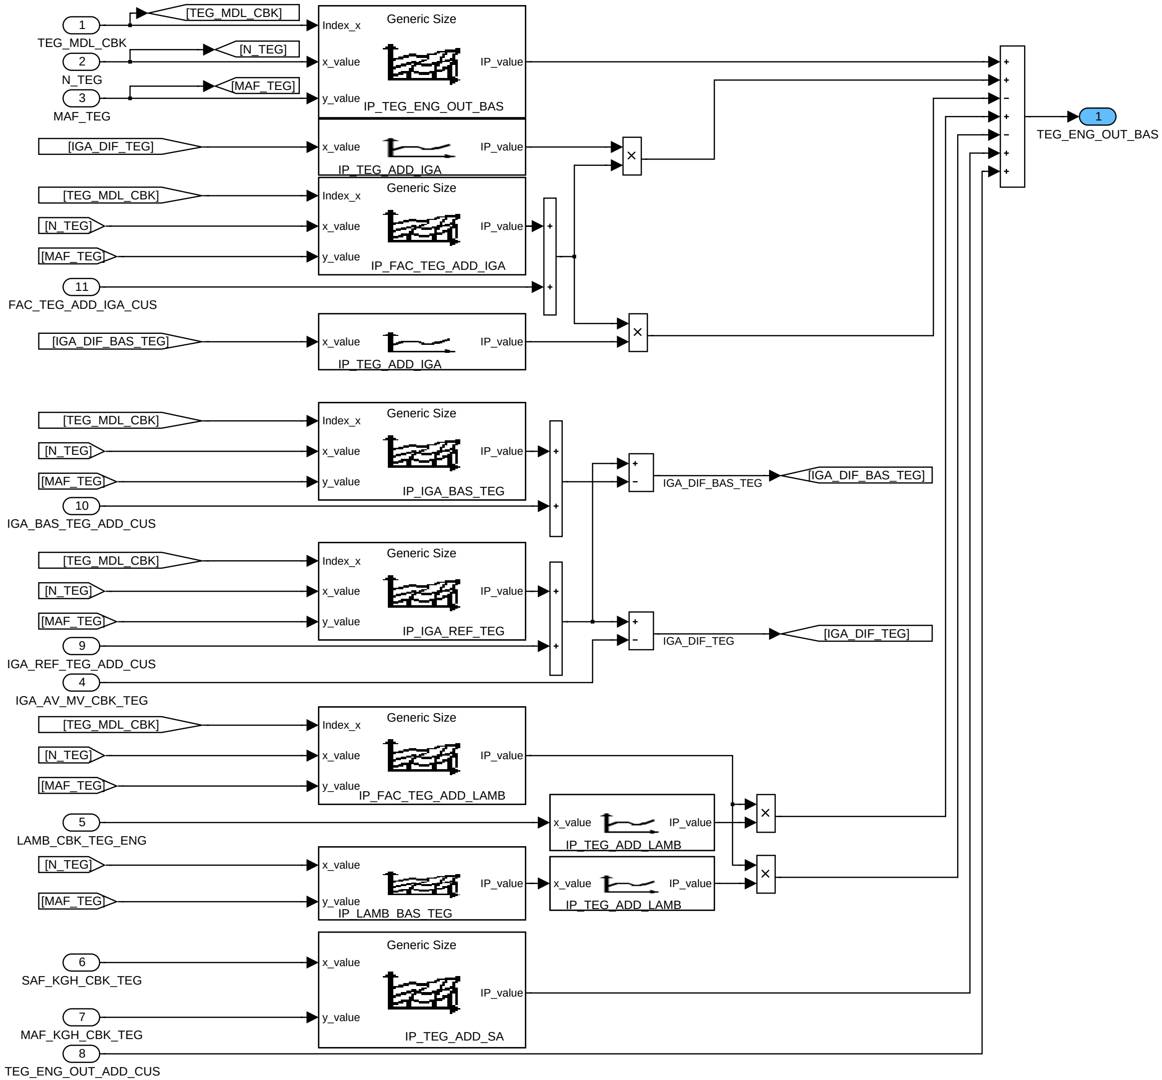

Figure 44 EXTD_MDLADengou0/ TEG_ENG_OUT/ CLC__TEG_ENG_OUT_BAS

COR__TEG_ENG_OUT

This part includes the multiplicative corrections on the previously calculated basic engine out exhaust gas temperature and the calculation of the engine out temperature at cylinder shut off TEG_SCC. It is important to know that all multiplicative corrections are calculated with the absolute value of the engine out exhaust gas temperature.

For the warm up phase it is possible to influence the engine out exhaust gas temperature dependent on TCO and TCO_ST with the map IP_FAC_TEG_TCO.

In the same way the exhaust gas temperature can be weighted dependent on TIA_CYL with the map IP_TEG_TIA.

The map IP_RATIO_TEG_SCC is used to switch over to PUC operation and to have a mixture temperature in case of single cylinder shut off. TEG_SCC is calculated in an own sub-function.

Acording Action Definition not found

7.43.1 General information:

The "tube exhaust gas temperature model" is part of the complete exhaust gas temperature model. This part models the behaviour of a simple exhaust tube like the exhaust manifold or other tubes where the exhaust gas is just cooled down. Therefore the outlet temperature TEG_DYN_DOWN_TUBE and the tube wall temperature TEMP_TUBE is calculated dependent on the ambient temperature TAM , on the inlet exhaust gas temperature TEG_DYN_UP_TUBE, on the mass exhaust gas flow MEF_KGH_CBK_TEG and on other input values. TEG_DYN_UP_TUBE and TEG_DYN_DOWN_TUBE are no visible values because they are just interim values for the calculation. The manager of the exhaust gas temperature model stores the result of the calculation in the array TEG with the correct index.

Initialisation of SRAM values at checksum error:

TEMP_TUBE[NC_NR_TUBE_MDL] = 0°C (1112H)

TEG_DYN_DOWN_TUBE_FIL[NC_NR_TUBE_MDL] = 0°C (1112H)

EGY_DEW_INT_TUBE[NC_NR_TUBE_MDL] = 0kJ (0H)

TEG_DYN_DOWN_TUBE_TMP[NC_NR_TUBE_MDL] = 0°C (1112H)

Application Condition

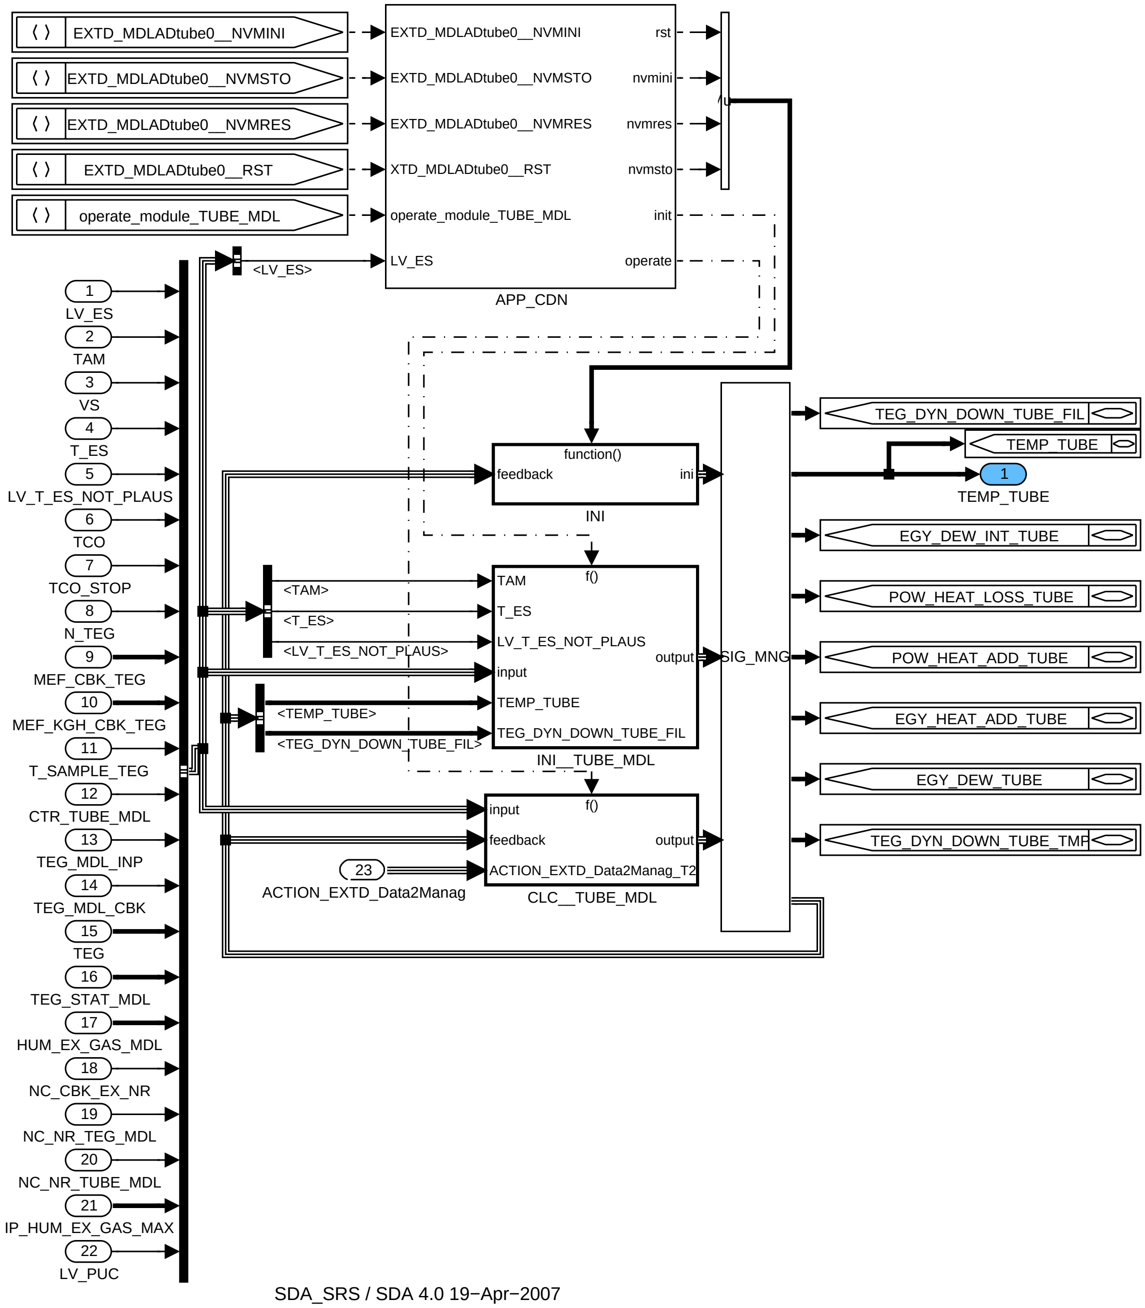

Figure 51 EXTD_MDLADtube0

7.43.1.1 Initialisation

Reset

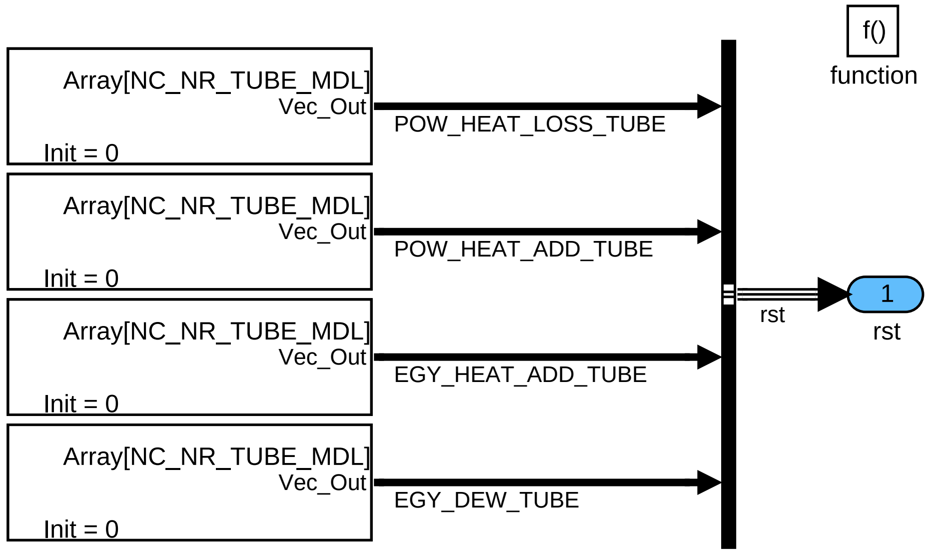

Figure 52 EXTD_MDLADtube0/ INI/ RST

Initialisation in case of brand new ECU or checksum error

TEMP_TUBE[NC_NR_TUBE_MDL] = 0°C (1112H)

TEG_DYN_DOWN_TUBE_FIL[NC_NR_TUBE_MDL] = 0°C (1112H)

EGY_DEW_INT_TUBE[NC_NR_TUBE_MDL] = 0kJ (0H)

TEG_DYN_DOWN_TUBE_TMP[NC_NR_TUBE_MDL] = 0°C (1112H)

Read NVMY

Read TEMP_TUBE[NC_NR_TUBE_MDL] and EGY_DEW_INT_TUBE[NC_NR_TUBE_MDL] from NVMY. Initialisation of TEG_DYN_DOWN_TUBE_FIL[NC_NR_TUBE_MDL] with TEMP_TUBE[NC_NR_TUBE_MDL].

Store NVMY

With LC_NO_TEMP_TUBE_CAL_ACT = 1 it can be chosen to store the value of TEG_DYN_DOWN_TUBE_FIL instead of TEMP_TUBE in EEPROM. This allows initialisation at next driving cycle even if TEMP_TUBE calculation is not calibrated.

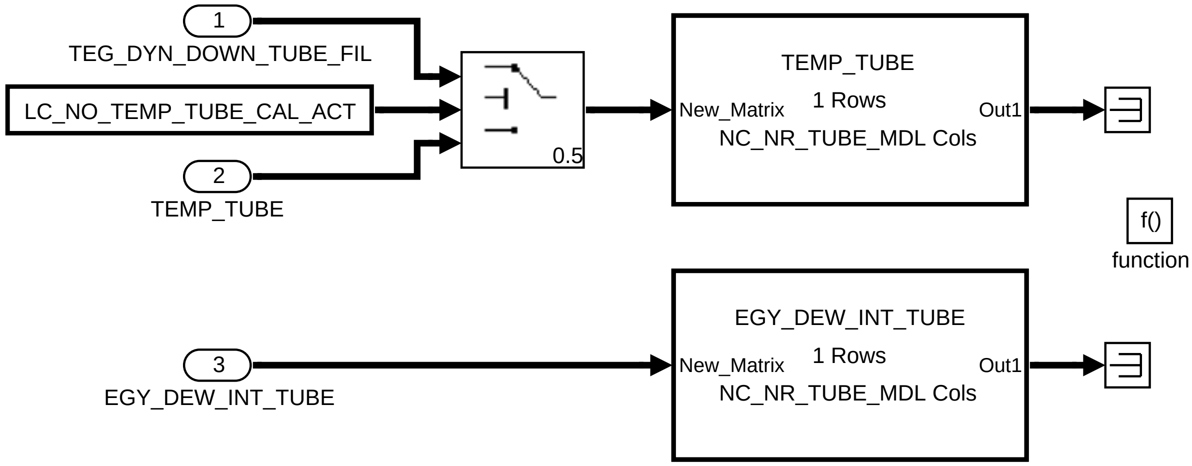

Figure 53 EXTD_MDLADtube0/ INI/ NVMSTO

7.43.1.2 INI__TUBE_MDL

For the "tube exhaust gas temperature model" the only value which has to be initialized is the tube wall temperature TEMP_TUBE because the tube is cooling down if the engine and also the ECU is off. There are two different calculations for the initialisation. One for a valid engine off duration time T_ES and one for the case that there is no engine off duration time is not available or not valid (LV_T_ES_NOT_VLD=1).

In both cases a factor is determined which represents the cooling down progress. If the factor is one the tube has not cooled down and is equal to the last tube wall temperature stored in the non volatile memory. If the factor is zero TEMP_TUBE is initialized with the ambient temperature TAM.

In the case that there is a valid engine off duration time available the factor is determined by a map versus T_ES.

In the other case the factor is determined by a map versus the coolant temperature cooling down progress RATIO_COOL_DOWN which is calculated out off TCO, TCO_STOP and TAM.

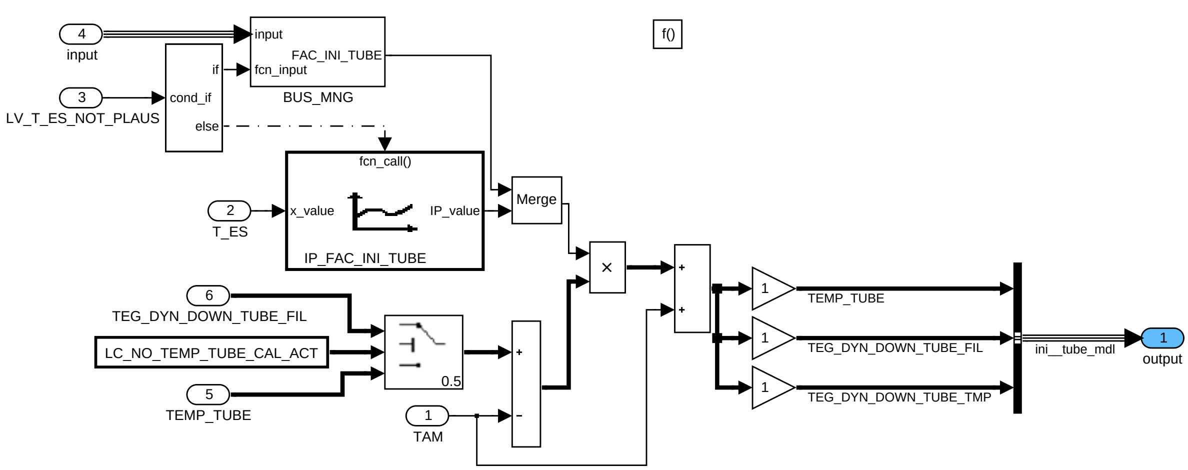

Figure 54 EXTD_MDLADtube0/ INI__TUBE_MDL

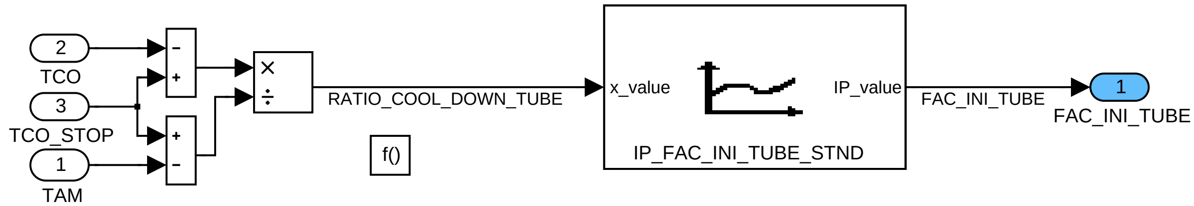

Figure 55 EXTD_MDLADtube0/ INI__TUBE_MDL/ BUS_MNG/ CLC_FAC_INI_TUBE_STND

7.43.1.3 CLC__TUBE_MDL

The calculation of the tube model is split up in four part:

- selection of the input values out of the arrays: SEL_INP_TUBE
- calculation of the steady state model: STAT_MDL_TUBE
- calculation of the dynamic model with dew point simulation: DYN_MDL_TUBE
- the writing back of the result to the manager by the action

SEL_INP_TUBE

The manager of the exhaust gas temperature model tells the tube model which values out of the arrays has to be used for the calculation. Thereby TEG_MDL_CBK is the index for the exhaust bank and TEG_MDL_INP determines the input index.

STAT_MDL_TUBE

For the steady state model the same calibration data are used as in the dynamic model. Out of the calibrated heat losses and heat gains and due to the condition for steady state that losses and gains are equal the exhaust gas temperature down tube for steady state is calculated with this equation.

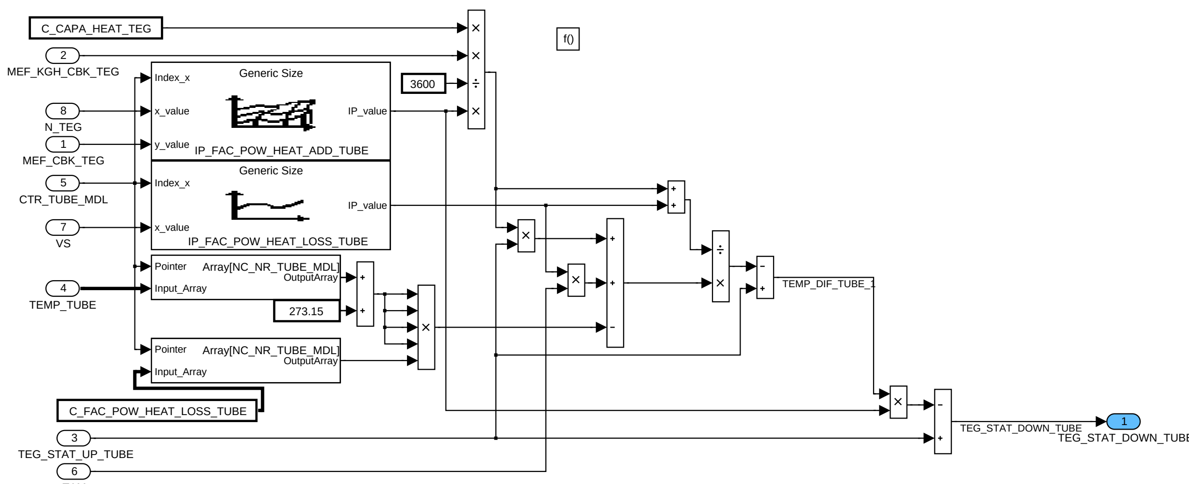

Figure 56 EXTD_MDLADtube0/ CLC__TUBE_MDL/ STAT_MDL_TUBE

DYN_MDL_TUBE

The dynamic part of the tube model is again split up in six sub-functions:

- calculation of the heat flows out of the calibration data: CLC__POW_HEAT_FLOW_TUBE

- calculation of the heat energy added to the tube during sample time of the model: CLC__EGY_HEAT_ADD_TUBE
- calculation of the exhaust gas temperature downstream the tube: CLC__TEG_DYN_DOWN_TUBE
- filtering of the calculated exhaust gas temperature downstream tube: CLC__TEG_DYN_DOWN_TUBE_FIL
- dew point calculations for the tube: CLC__DEW_TUBE
- determination of the temperature in/decrease of the tube wall temperature: CLC__TEMP_TUBE

CLC__POW_HEAT_FLOW_TUBE

In this sub-function the heat flows from the exhaust gas to the tube (heat gain) and the heat flow form the tube to the ambient (heat losses) are calculated based on the formulas:

Heat transfer of the exhaust gas to the tube:

$P_{\rightarrow tube} = \dot{Q} = \dot{m} \times c_p \times \left(t_{in} - t_{out}\right)$ with:

$\dot{m}$ = mass exhaust gas flow = MEF_KGH_CBK_TEG[kg/h]/3600[s/h]

c_p = heat capacity of the exhaust gas = C_CAPA_HEAT_TEG[kJ/(kg*K)]

t_{in} = inlet temperature = TEG_DYN_UP_TUBE

t_{out} = outlet temperature = TEG_DYN_DOWN_TUBE

$(t_{in} - t_{out}) = FAC\_POW\_HEAT\_ADD\_TUBE \times (t_{in} - t_{wall})$

Heat transfer from the tube to the ambient:

$P_{tube\rightarrow} = \dot{Q} = \alpha \times A \times \left(t_{wall} - t_{ambient}\right)$ with:

α = heat transfer coefficient

A = heat transfer surface

$\alpha \times A$ = IP_FAC_POW_HEAT_LOSS_TUBE

t_{wall} = wall temperature TEMP_TUBE

$t_{ambient}$ = ambient temperature TAM

Heat radiation to ambient (Stefan-Boltzmann):

$P_{tube\rightarrow} = \Phi_S = \varepsilon \times A \times T_{wall}^4$ with:

ε = heat radiation constant

A = heat radiation surface

$\varepsilon \times A$ = C_FAC_POW_HEAT_LOSS_TUBE

T_{wall} = wall temperature in Kelvin = TEMP_TUBE + 273.15

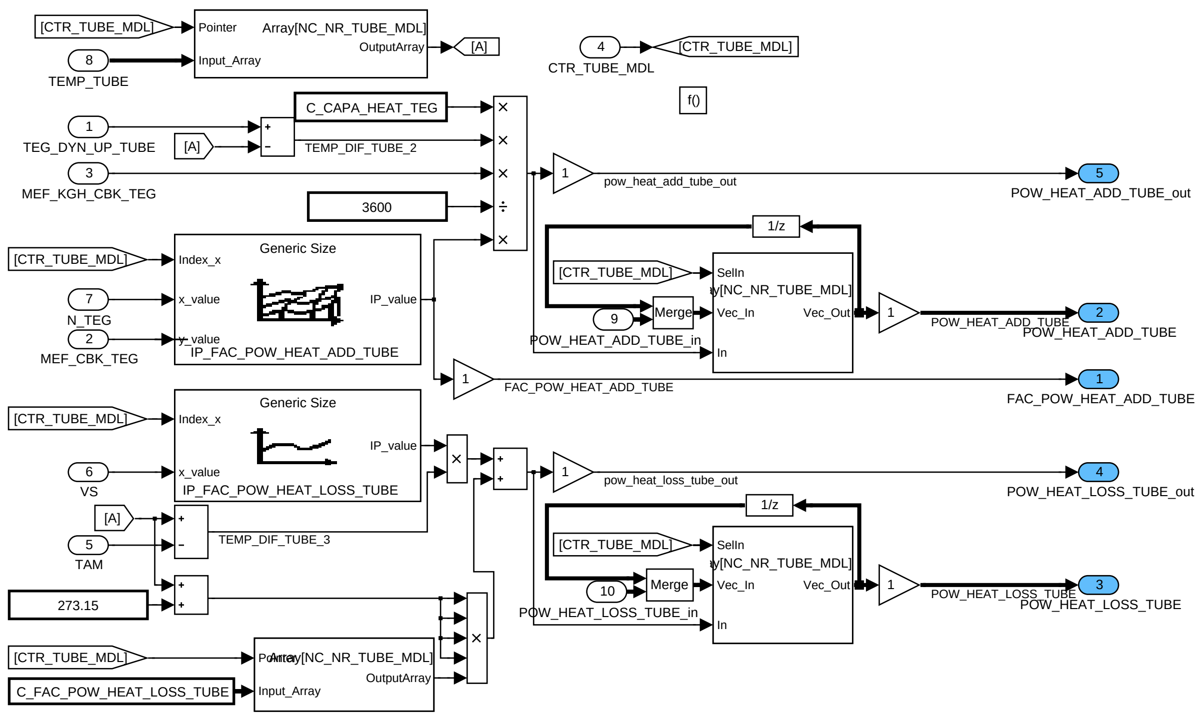

Figure 57 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__POW_HEAT_FLOW_TUBE

CLC__EGY_HEAT_ADD_TUBE

EGY_HEAT_ADD_TUBE is the overall heat energy which is transferred to the tube during sample time:

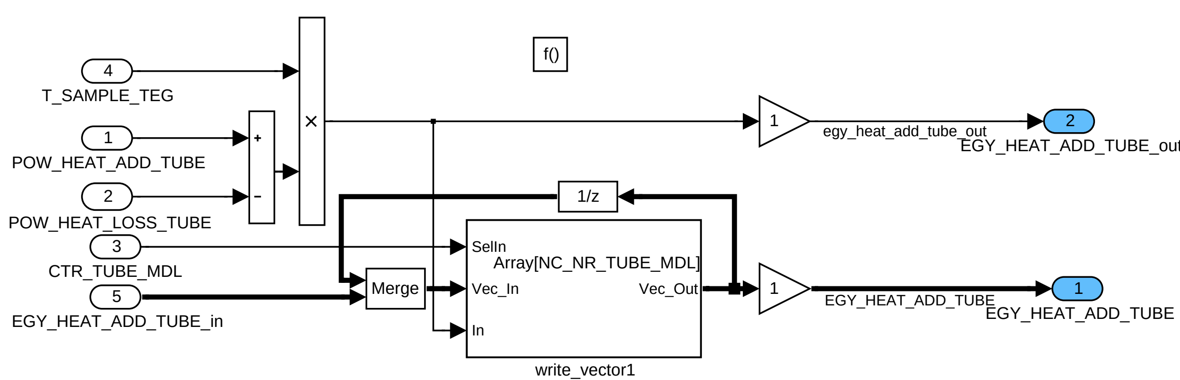

Figure 58 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__EGY_HEAT_ADD_TUBE

CLC__TEG_DYN_DOWN_TUBE

Out of the definition of FAC_POW_HEAT_ADD:

$$FAC\_POW\_HEAT\_ADD = \frac{(t_{in} - t_{out})}{(t_{in} - t_{wall})} =$$

$$\frac{(TEG\_DYN\_UP\_TUBE - TEG\_DYN\_DOWN\_TUBE)}{(TEG\_DYN\_UP\_TUBE - TEMP\_TUBE)} \Rightarrow$$

$$TEG\_DYN\_DOWN\_TUBE = TEG\_DYN\_UP\_TUBE -$$
$$FAC\_POW\_HEAT\_ADD\_TUBE \times (TEG\_DYN\_UP\_TUBE - TEMP\_TUBE)$$

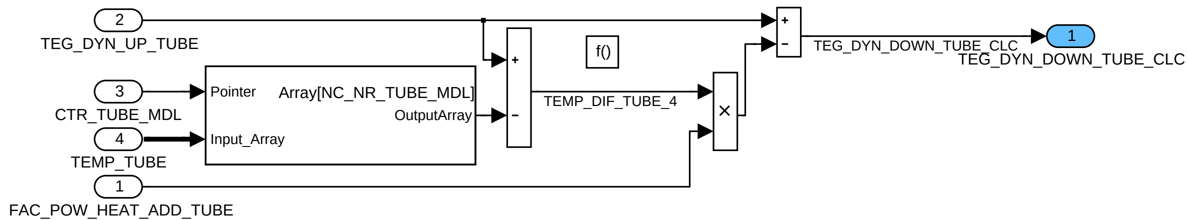

Figure 59 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__TEG_DYN_DOWN_TUBE

CLC__DEW_TUBE

The dew point calculation starts with the determination of the maximum of the humidity of the exhaust gas downstream tube HUM_DOWN_TUBE_MAX. The map for the calculation is dependent on the calculated exhaust gas temperature downstream tube. In the next step the bit LV_DEW_THD_TUBE is calculated in the sub-function CLC__LV_DEW_THD_TUBE. If this flag is set no dew point calculations are carried out (see NO_EGY_DEW_TUBE). Therefore EGY_DEW_TUBE and EGY_DEW_INT_TUBE are set to zero and the downstream exhaust gas humidity is equal to the upstream humidity.

If LV_DEW_THD_TUBE is not set CLC__EGY_DEW_INT_TUBE is calculated.

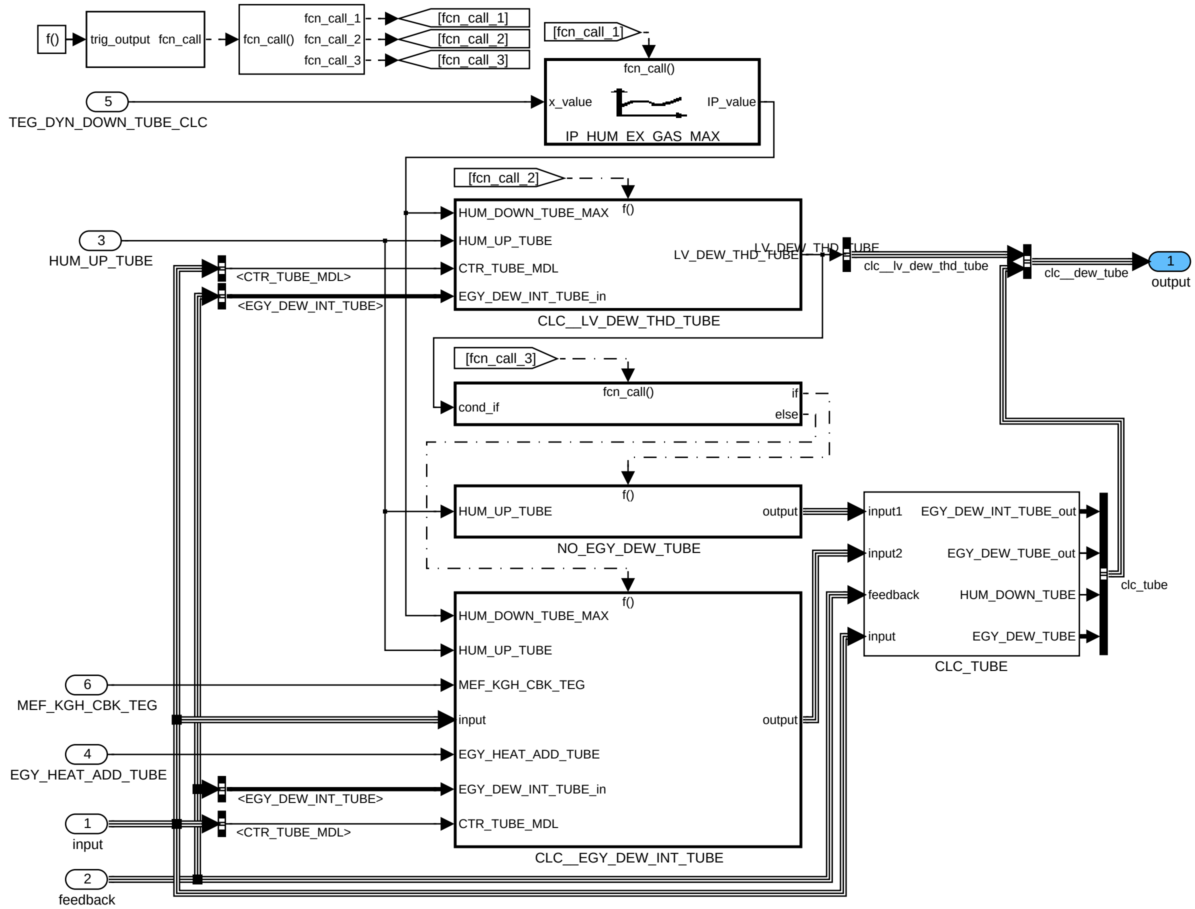

Figure 60 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__DEW_TUBE

CLC__LV_DEW_THD_TUBE

For the decision whether a dew point calculation is not necessary the following conditions have to be fulfilled:

- There is no condensation water in the tube: EGY_DEW_INT_TUBE = 0 and
- The exhaust gas temperature is high enough to take away the incoming water gaseous: HUM_DOWN_TUBE_MAX > HUM_UP_TUBE

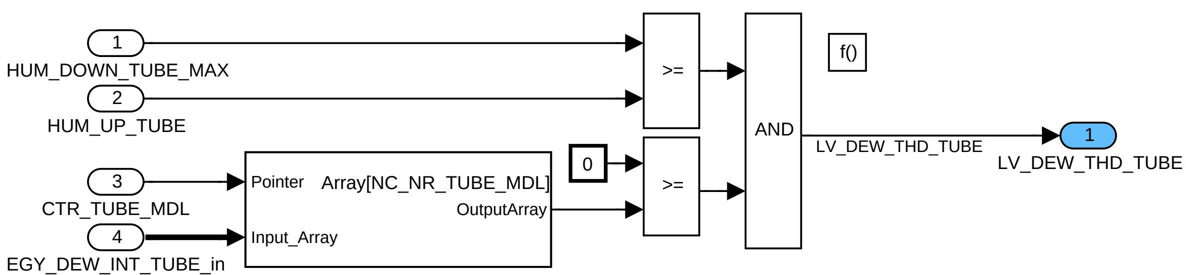

Figure 61 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__DEW_TUBE/ CLC__LV_DEW_THD_TUBE

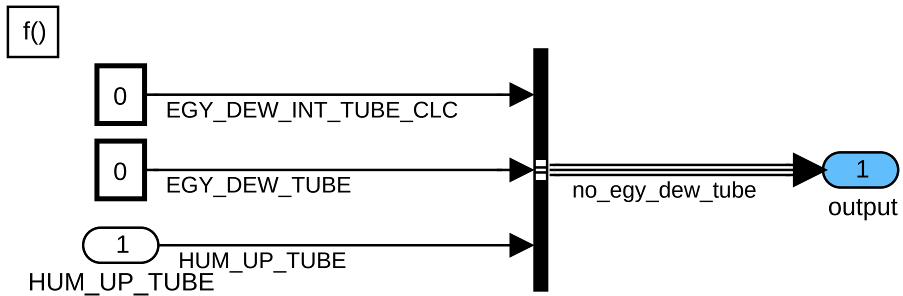

Figure 62 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__DEW_TUBE/ NO_EGY_DEW_TUBE

CLC__EGY_DEW_INT_TUBE

If LV_DEW_THD_TUBE is not set the following calculation is done:

At the first step it is necessary to decide whether condensation water film is build up or reduced. If the exhaust gas is to cold to take all water with it (HUM_DOWN_TUBE_MAX < HUM_UP_TUBE) the water film is build up and the dew energy EGY_DEW_TUBE is positive (EGY_DEW_POS is calculated). The other way round (HUM_DOWN_TUBE > HUM_UP_TUBE) the water film is reduced (EGY_DEW_NEG is calculated). The integrated dew energy EGY_DEW_INT_TUBE is in- or decreasing dependent on EGY_DEW_TUBE.

CLC__TEMP_TUBE

If the dew point calculation is finished and EGY_DEW_TUBE is calculated the new tube wall temperature is calculated. Therefore the tube wall temperature change is calculated:

$$\Delta t_{wall} = \frac{Q}{m \times c_p} = \frac{EGY\_HEAT\_ADD\_TUBE + EGY\_DEW\_TUBE}{IP\_CAPA\_HEAT\_TUBE}$$

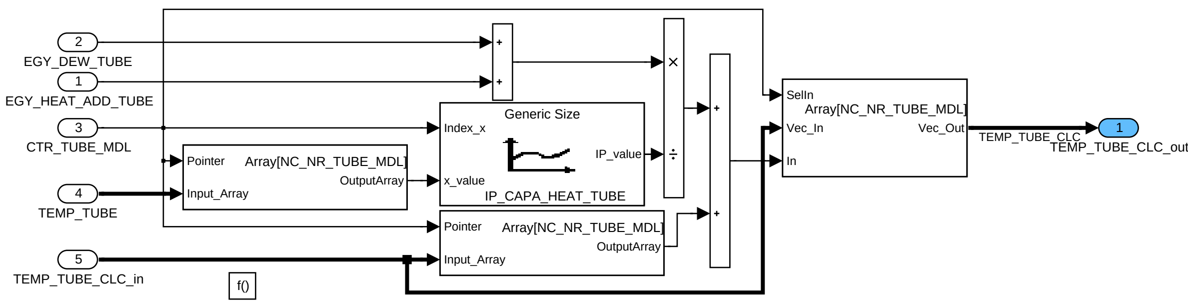

Figure 67 EXTD_MDLADtube0/ CLC__TUBE_MDL/ DYN_MDL_TUBE/ CLC__TEMP_TUBE

CLC__TEG_DYN_DOWN_TUBE_FIL

To simulate the measured behaviour of the exhaust gas temperature downstream tube it is possible to filter the previously calculated TEG_DYN_DOWN_TUBE. Due to the fact that this would only simulate the sensor filtering it is possible to decide whether the filtered value is used in the next component model. Therefore the switch LC_TEG_DYN_DOWN_TUBE_FIL_SEL has to be set to one. The filtered visible value TEG_DYN_DOWN_TUBE_FIL is always calculated to compare the model with the measured value.

Once no proper TEMP_TUBE calibration is done, LC_NO_TEMP_TUBE_CAL_ACT=1 allows switching between different filtering maps IP_CRLC_TEG_DYN_DOWN_TUBE[NC_NR_TUBE_MDL] and IP_CRLC_TEG_DYN_DOWN_TUBE_DEC[NC_NR_TUBE_MDL] depending on increasing or decreasing exhaust gas temperatures inside the tube. LC_NO_TEMP_TUBE_CAL_ACT=1 allows also activating an additional map for vehicle speed dependancy IP_FAC_VS_TEG[NC_NR_TUBE_MDL].

Import actions:

ACTION_EXTD_Data2Manag(IN <Hum>, IN <LvDew>, IN <TegDyn>, IN <TegStat>)
writes back the calculated data back to the arrays of the manager (TEG_DYN_MDL, ...)

7.44.1 General information:

The "catalyst exhaust gas temperature model" is part of the complete exhaust gas temperature model. This part models the behaviour of a catalyst where the exhaust gas is heated up in the first part of the catalyst by the exothermic reaction and cooled down in the second part. Therefore the model is also split up into two parts.

The catalyst monolith temperature TEMP_CAT is calculated in the fist part and the outlet exhaust gas temperature TEG_DYN_DOWN_CAT is calculated in the second part. TEG_DYN_UP_CAT and TEG_DYN_DOWN_CAT are no visible values because they are just interim values for the calculation. The manager of the exhaust gas temperature model stores the result of the calculation in the array TEG with the correct index.

Initialisation of SRAM value at checksum error:
TEMP_CAT[NC_NR_CAT_MDL] = 0°C (1112H)
EGY_DEW_INT_CAT_1[NC_NR_CAT_MDL] = 0 (0H)
EGY_DEW_INT_CAT_2[NC_NR_CAT_MDL] = 0 (0H)

Application Condition

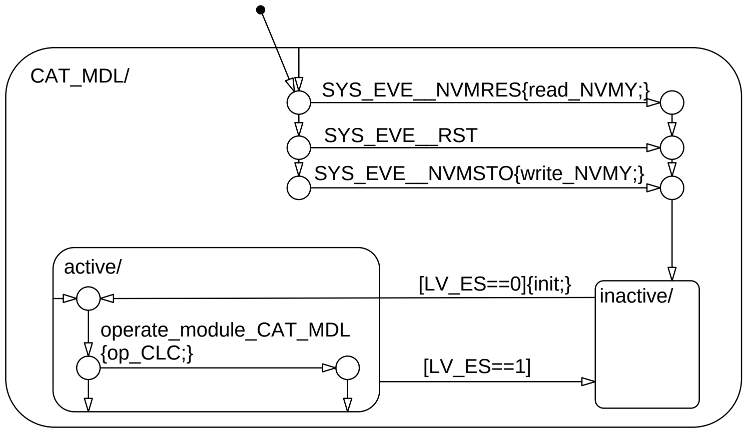

Figure 69 EXTD_MDLADcat0/ APP_CDN/ Chart

Function Description

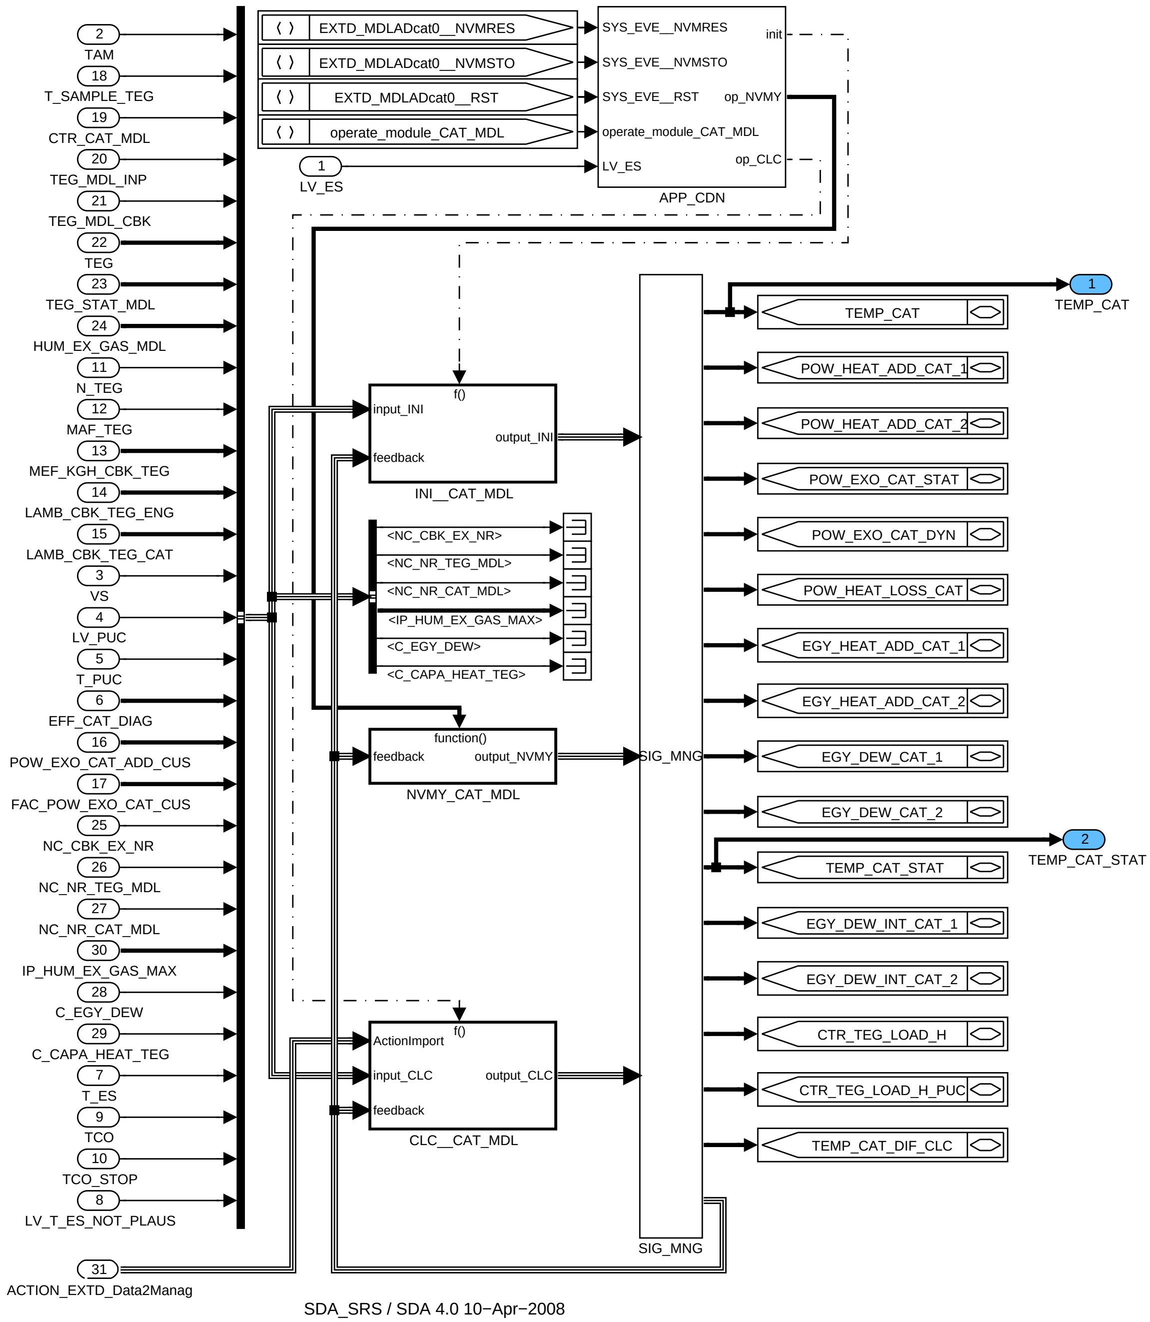

Figure 70 EXTD_MDLADcat0

7.44.1.1 NVMY

TEMP_CAT[NC_NR_CAT_MDL], EGY_DEW_INT_CAT_1[NC_NR_CAT_MDL] and EGY_DEW_INT_CAT_2[NC_NR_CAT_MDL] are read and write from NVMY.

7.44.1.2 INI__CAT_MDL

For the "catalyst exhaust gas temperature model" the only value which has to be initialized is the catalyst monolith temperature TEMP_CAT because the catalyst is cooling down if the engine and also the ECU is off. There are two different calculations for the initialisation. One for a valid engine off duration time T_ES and one for the case that there is no engine off duration time is not available or not valid (LV_T_ES_NOT_VLD=1).

In both cases a factor is determined which represents the cooling down progress. If the factor is one the catalyst has not cooled down and is equal to the last catalyst monolith temperature stored in the non volatile memory. If the factor is zero TEMP_CAT is initialized with the ambient temperature TAM.

In the case that there is a valid engine off duration time available the factor is determined by a map versus T_ES.

In the other case the factor is determined by a map versus the coolant temperature cooling down progress RATIO_COOL_DOWN which is calculated out off TCO, TCO_STOP and TAM.

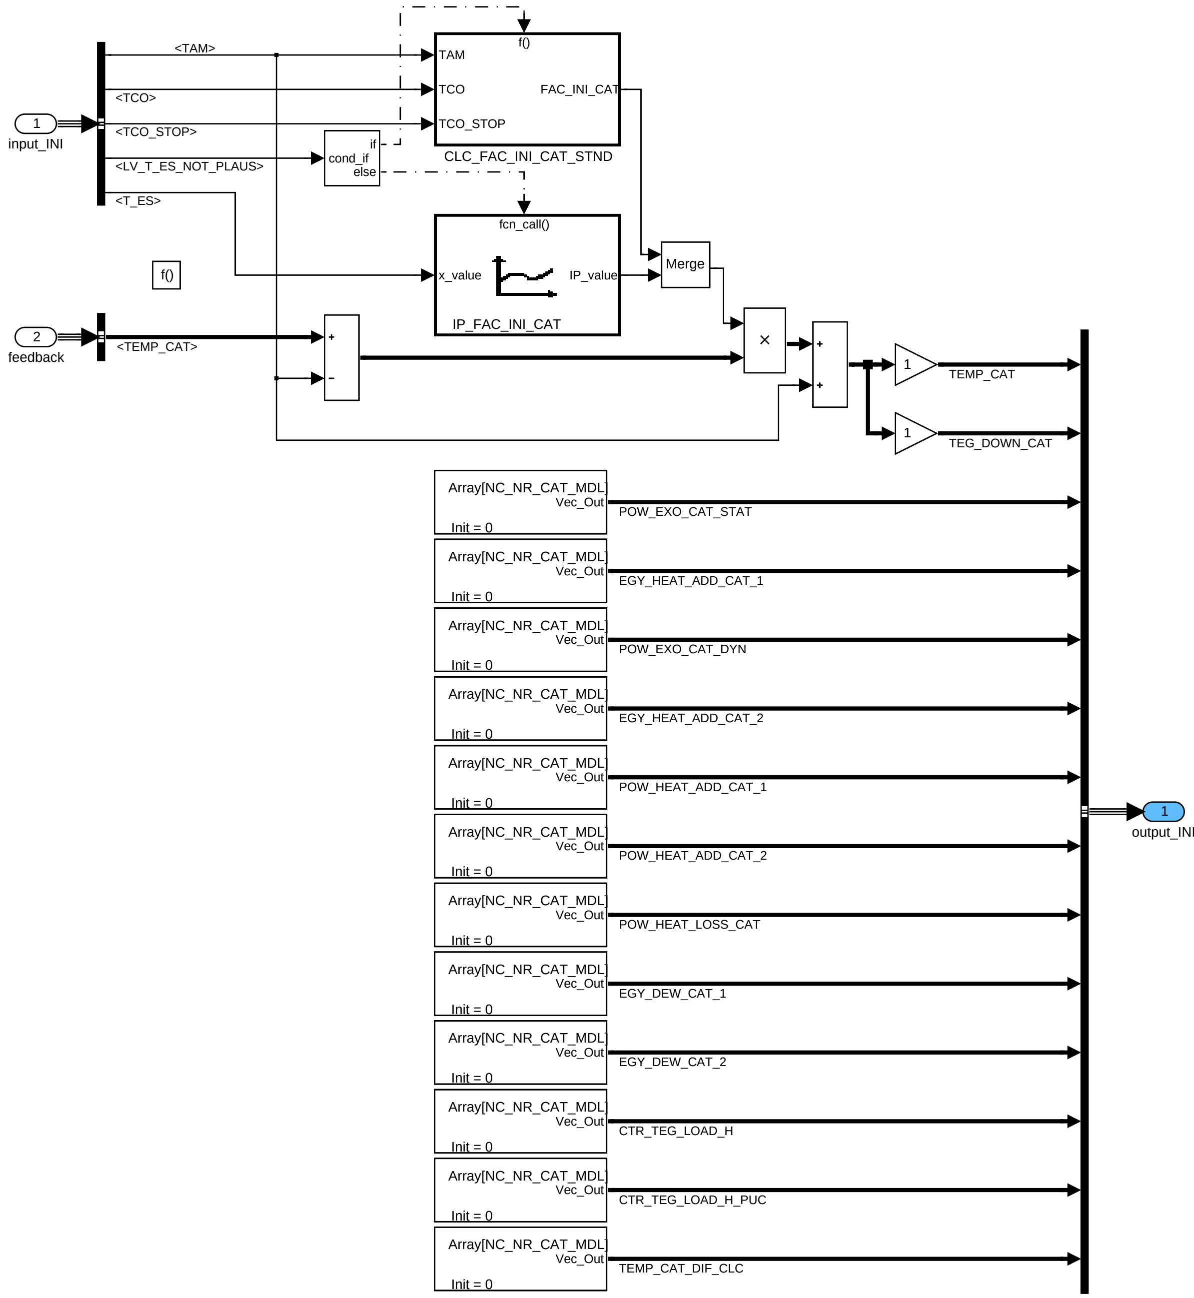

Figure 71 EXTD_MDLADcat0/ INI__CAT_MDL

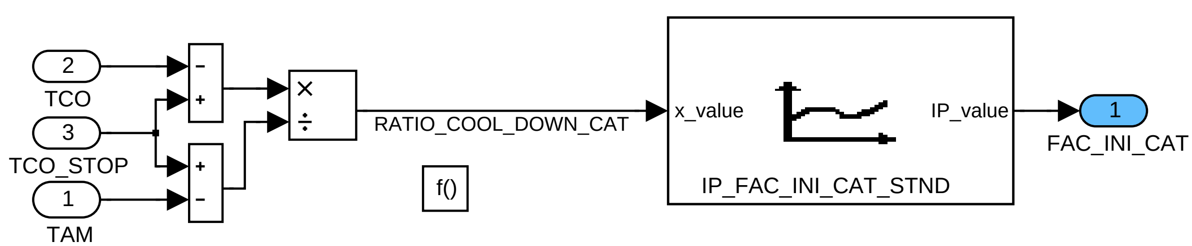

Figure 72 EXTD_MDLADcat0/ INI__CAT_MDL/ CLC_FAC_INI_CAT_STND

7.44.1.3 CLC__CAT_MDL

The calculation of the tube model is split up into five parts:

- selection of the input values out of the arrays: SEL_INP_CAT
- calculation of the exothermic: POW_EXO_CAT
- calculation of the steady state model: STAT_MDL_CAT
- calculation of the dynamic model with dew point simulation: DYN_MDL_CAT
- the writing back of the result to the manager by the action

POW_EXO_CAT

The basic exothermic power for lambda =1 without secondary is stored in the IP_POW_EXO_CAT. This value has to be corrected for different lambda by the map IP_FAC_LAMB_POW_EXO_CAT and this correction can be weighted versus engine operating point.

For PUC operation the exothermic power is normally zero because the exhaust gas is fresh air but at the transition to PUC the exothermic can become very high because of stored HC and CO. Therefore the map IP_POW_EXO_CAT_PUC can be calibrated with a factor greater than one for the first time after PUC operation. For long PUC operation time T_PUC the factor has to be zero.

High load counter CTR_TEG_LOAD_H_PUC used to consider high load operation duration for succeeding PUC condition temperature shape. Maps ID_CTR_INC_DEC_TEG_LOAD_H, ID_CTR_DEC_TEG_PUC and the calibration constant C_CTR_TEG_LOAD_H_MAX added for calculation of CTR_TEG_LOAD_H_PUC. This counter used for correction of the catalyst model via IP_POW_EXO_CAT_PUC during PUC.

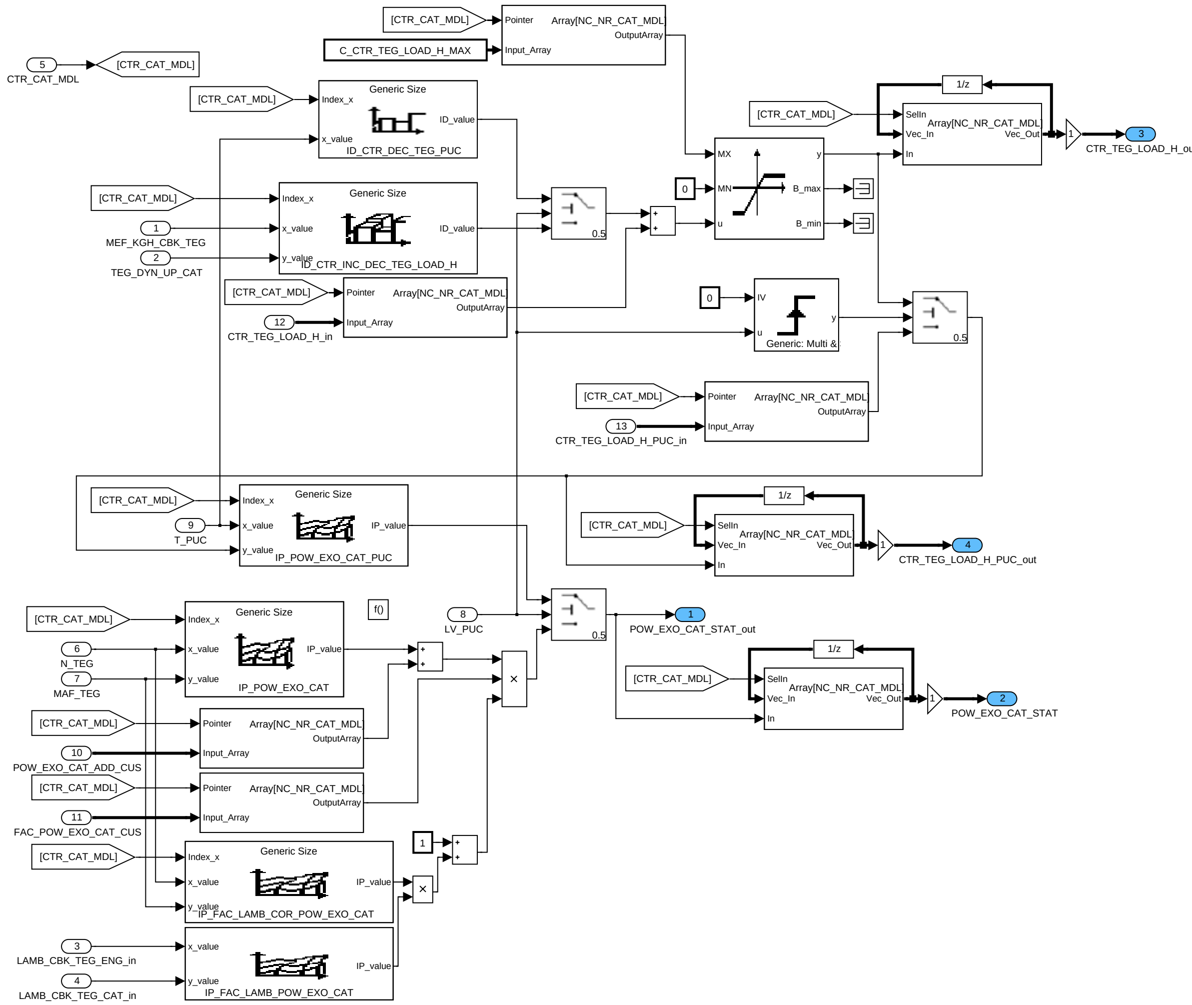

Figure 73 EXTD_MDLADcat0/ CLC__CAT_MDL/ POW_EXO_CAT

STAT_MDL_CAT

For the steady state model the same calibration data are used as in the dynamic model. During steady state conditions the catalyst monolith temperature TEMP_CAT_STAT for the first part is equal to the inlet steady state temperature TEG_STAT_UP_CAT plus the exothermic POW_EXO_CAT_STAT converted into a temperature dependent on the mass exhaust gas flow MEF_KGH_CBK_TEG and there heat capacity. For the second part TEG_STAT_DOWN_CAT is calculated in the same way but with now the heat losses are subtracted from the steady state monolith temperature TEMP_CAT_STAT.

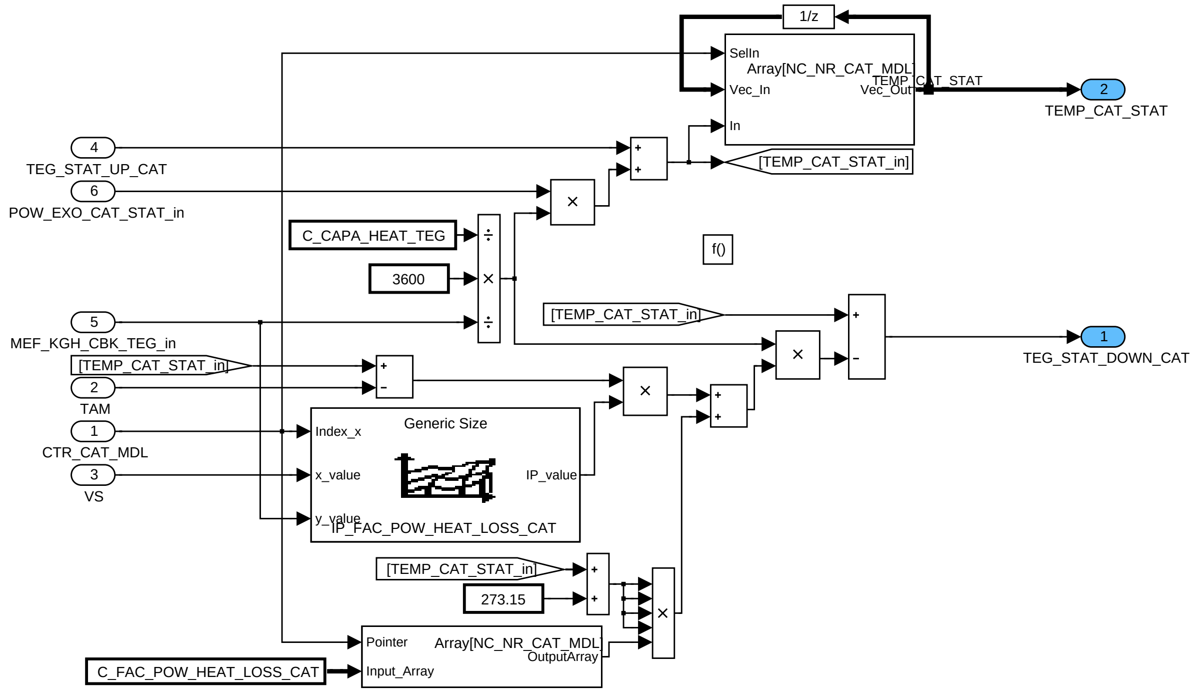

Figure 74 EXTD_MDLADcat0/ CLC__CAT_MDL/ STAT_MDL_CAT

DYN_MDL_CAT

The dynamic part of the catalyst model is again split up into six sub-functions:

- calculation of the heat flows: CLC__POW_HEAT_FLOW_CAT
- calculation of the heat energy: CLC__EGY_HEAT_ADD_CAT
- dew point calculations for the first part of the catalyst: CLC__DEW_CAT_1
- dew point calculations for the second part of the catalyst: CLC__DEW_CAT_2
- determination of the catalyst monolith temperature (first part): CLC__TEMP_CAT
- determination of the outlet exhaust gas temperature: CLC__TEG_DYN_DOWN_CAT

CLC__POW_HEAT_FLOW_CAT

The same formulas like in the "tube exhaust gas temperature model" are used for the following calculations. The only difference is that there is no factor FAC_POW_HEAT_ADD_CAT because it is assumed that the heat transfer coefficient for the heat transfer between exhaust gas and catalyst monolith is so big that the factor is one for all mass exhaust gas flows. A factor of one leads to the equality of exhaust gas temperature and monolith temperature. Additionally it is assumed that in the first part of the catalyst there are only heat gains due to exothermic reaction no heat losses and in the second part it is the other way round.

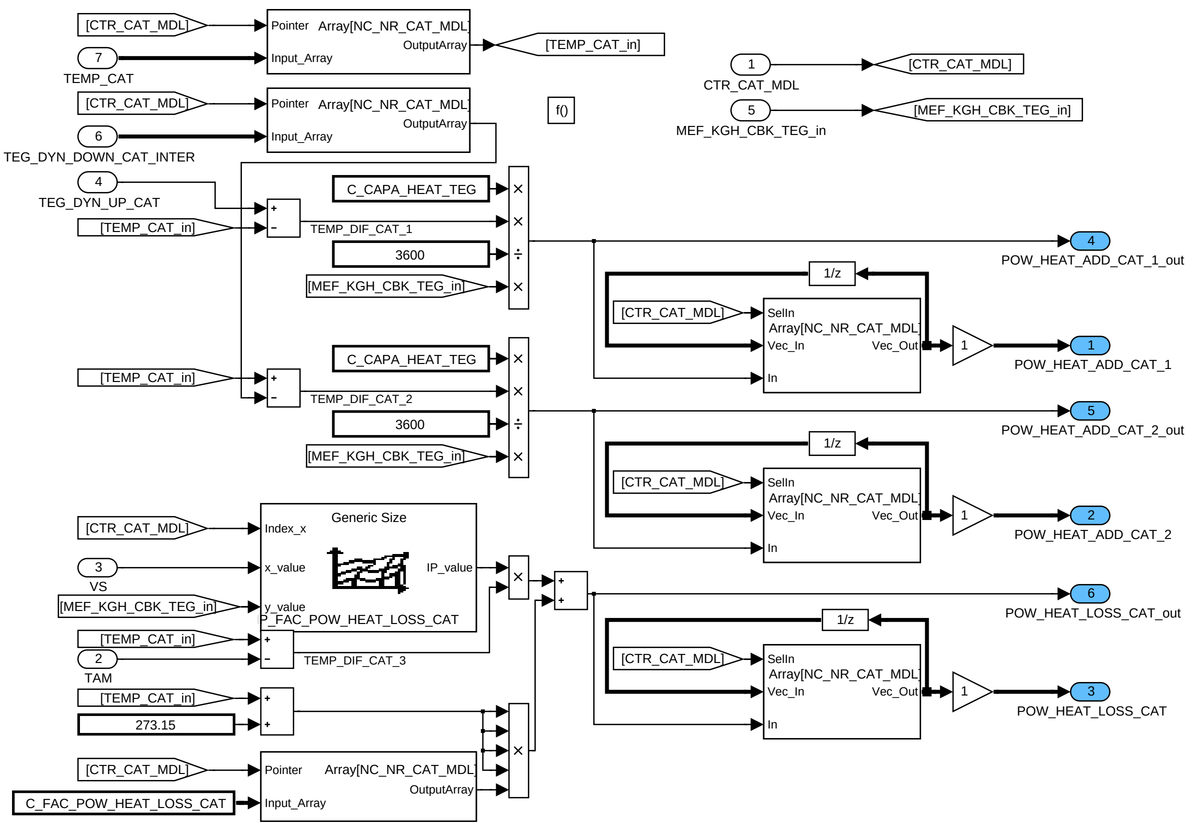

Figure 75 EXTD_MDLADcat0/ CLC__CAT_MDL/ DYN_MDL_CAT/ CLC__POW_HEAT_FLOW_CAT

CLC__EGY_HEAT_ADD_CAT

EGY_HEAT_ADD_CAT is the overall (except dew energy) heat energy added to the different parts of the catalyst. For the first part EGY_HEAT_ADD_CAT_1 is calculated out of the sum of POW_HEAT_ADD_CAT_1 and the POW_EXO_CAT_DYN multiplied with the sample time. In the second part the calculation is similar to a tube model: EGY_HEAT_ADD_CAT_2 is calculated out of the sum of heat gains and heat losses multiplied with the sample time.

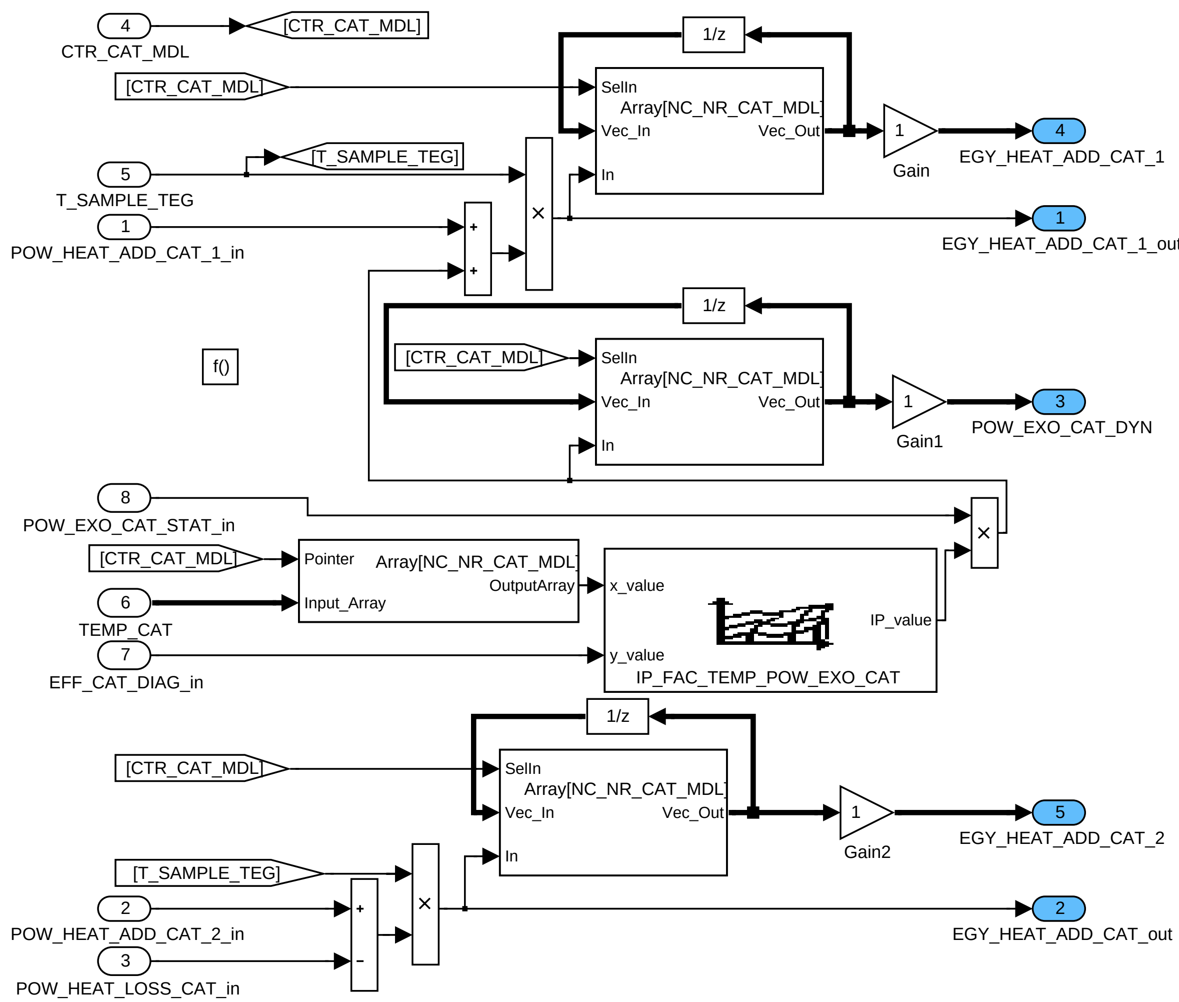

Figure 76 EXTD_MDLADcat0/ CLC__CAT_MDL/ DYN_MDL_CAT/ CLC__EGY_HEAT_ADD_CAT

CLC__DEW_CAT_1

All dew point calculations are similar to the dew point calculation in the "Tube exhaust gas temperature model": see CLC__DEW_TUBE

Replace:

CTR_TUBE_MDL → CTR_CAT_MDL
HUM_UP_TUBE → HUM_UP_CAT
HUM_DOWN_TUBE_MAX → HUM_CAT_MAX
HUM_DOWN_TUBE → HUM_CAT
TEG_DYN_DOWN_TUBE_CLC → TEMP_CAT
EGY_HEAT_ADD_TUBE → EGY_HEAT_ADD_CAT_1
EGY_DEW_TUBE → EGY_DEW_CAT_1
EGY_DEW_INT_TUBE → EGY_DEW_INT_CAT_1

CLC__DEW_CAT_2

All dew point calculations are similar to the dew point calculation in the "Tube exhaust gas temperature model": see CLC__DEW_TUBE

Replace:

CTR_TUBE_MDL → CTR_CAT_MDL
HUM_UP_TUBE → HUM_CAT
HUM_DOWN_TUBE_MAX → HUM_DOWN_CAT_MAX
HUM_DOWN_TUBE → HUM_DOWN_CAT
TEG_DYN_DOWN_TUBE_CLC → TEG_DYN_DOWN_CAT_INTER
EGY_HEAT_ADD_TUBE → EGY_HEAT_ADD_CAT_2
EGY_DEW_TUBE → EGY_DEW_CAT_2
EGY_DEW_INT_TUBE → EGY_DEW_INT_CAT_2

CLC__TEMP_CAT

If the dew point calculation is finished and EGY_DEW_CAT_1 was calculated the new catalyst monolith temperature is calculated. Therefore the catalyst monolith temperature change is calculated similar to the tube wall temperature in the tube model:

$$\Delta t_{monolith} = \frac{Q}{m \times c_p} = \frac{EGY\_HEAT\_ADD\_CAT + EGY\_DEW\_CAT\_1}{IP\_CAPA\_HEAT\_CAT\_1}$$

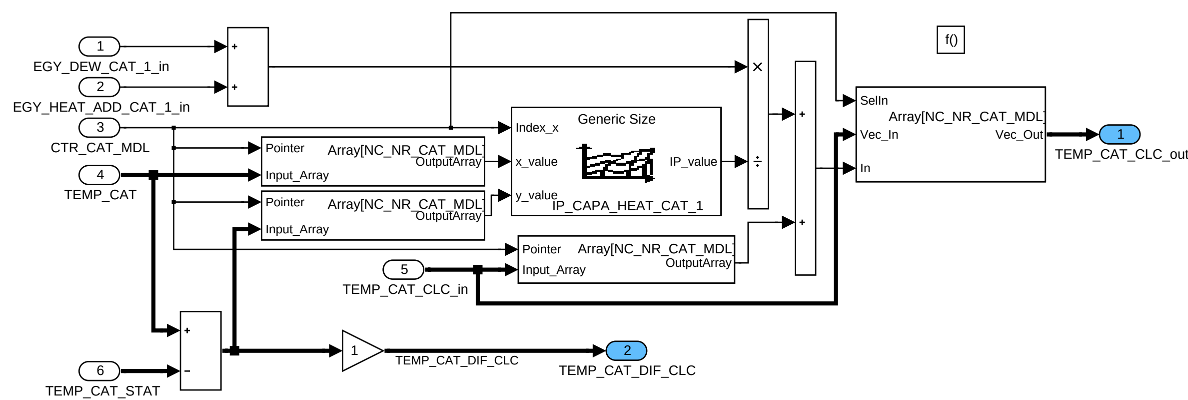

Figure 77 EXTD_MDLADcat0/ CLC__CAT_MDL/ DYN_MDL_CAT/ CLC__TEMP_CAT

CLC__TEG_DYN_DOWN_CAT

Due to the fact that the catalyst outlet exhaust gas temperature is equal to the monolith temperature of the second part the calculation of TEG_DYN_DOWN_CAT is equal to the calculation for TEMP_CAT but with all parameters of the second part.

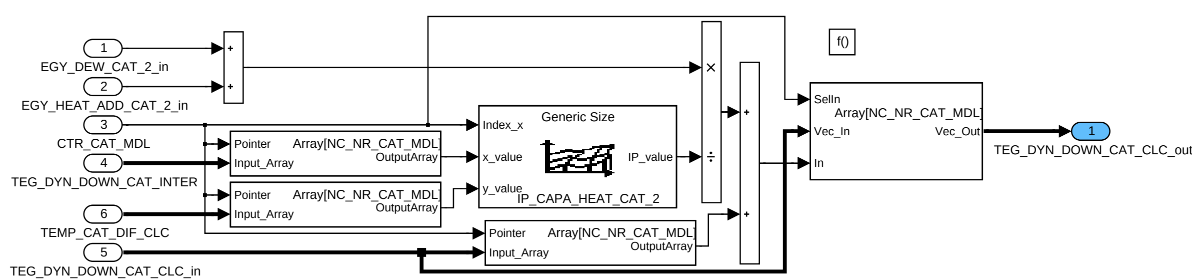

Figure 78 EXTD_MDLADcat0/ CLC__CAT_MDL/ DYN_MDL_CAT/ CLC__TEG_DYN_DOWN_CAT

calculation factor for the calculation of the heat flow from the exhaust gas to the turbine					

Import actions:

ACTION_EXTD_Data2Manag(IN <Hum>, IN <LvDew>, IN <TegDyn>, IN <TegStat>)
writes back the calculated data back to the arrays of the manager (TEG_DYN_MDL, ...)

7.45.1 General information:

The "turbine exhaust gas temperature model" is part of the complete exhaust gas temperature model. This part models the behaviour of a turbine in the exhaust line. In principle it is combination of a very easy turbine model and a tube model. The turbine model reduces the inlet exhaust gas temperature dependent on the turbine power POW_CBK_TEG_TUR.

Additionally there is the possibility to skip the turbine model to deal with non turbine engine variants in one software.

Initialisation of SRAM values at checksum error:

TEMP_TUR[NC_NR_TUR_MDL] = 0°C (1112H)

EGY_DEW_INT_TUR[NC_NR_TUR_MDL] = 0kJ (0H)

Function Description

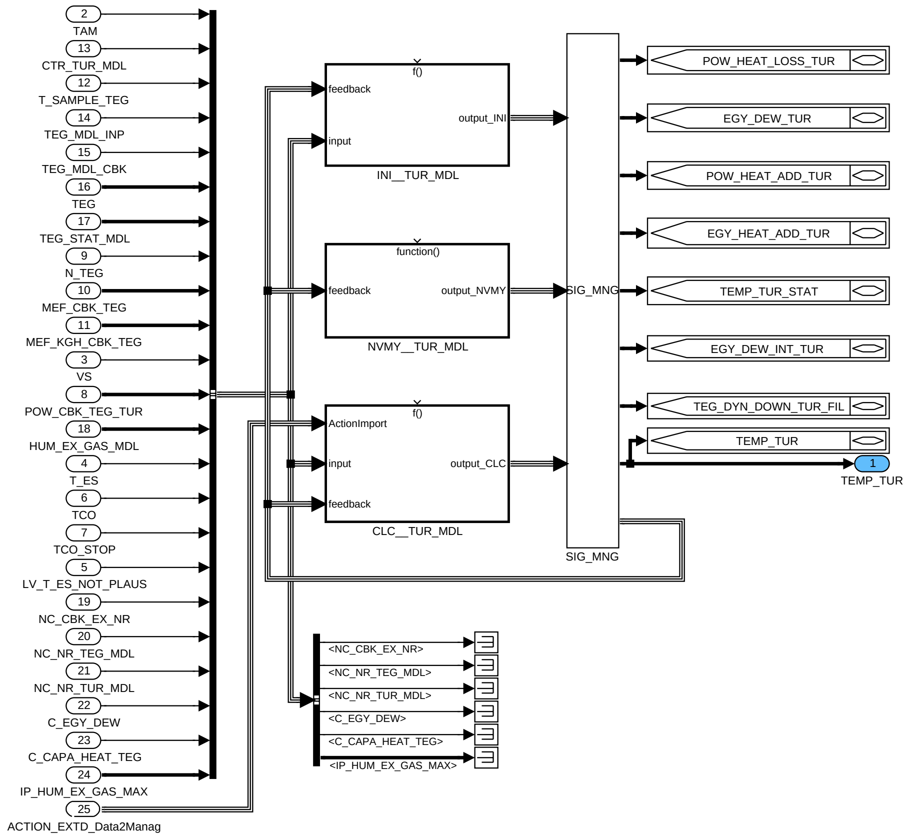

Figure 79 EXTD_MDLADturb0

7.45.1.1 INI__TUR_MDL

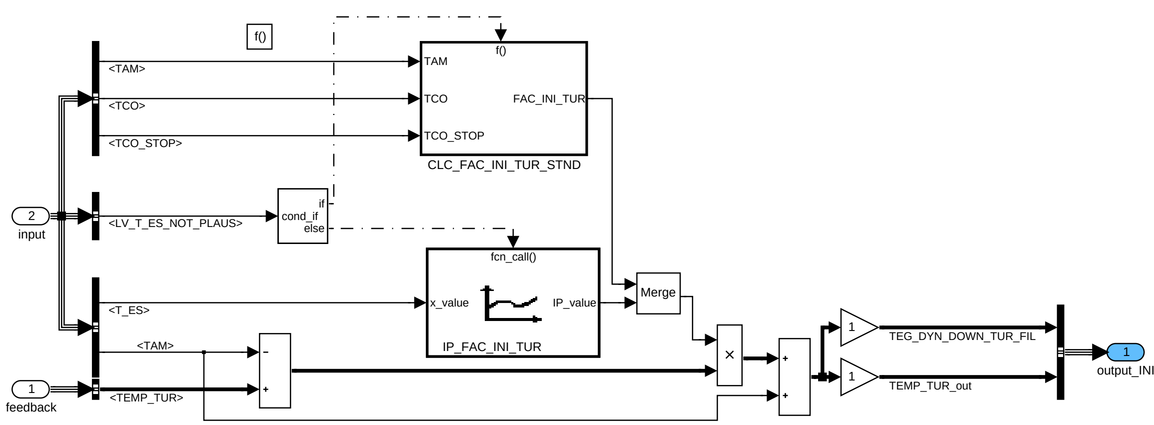

Figure 80 EXTD_MDLADturb0/ INI__TUR_MDL

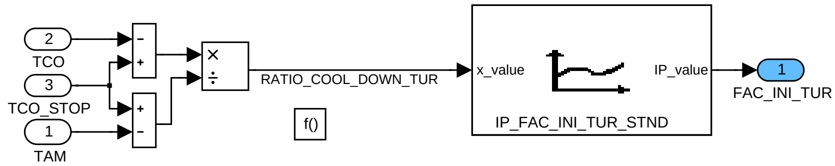

Figure 81 EXTD_MDLADturb0/ INI__TUR_MDL/ CLC_FAC_INI_TUR_STND

7.45.1.2 CLC__TUR_MDL

The calculation of the turbine model is split up in five part:
- selection of the input values out of the arrays: SEL_INP_TUR
- feed through in case of skipped turbine model: NOT_CLC
- calculation of the steady state model: STAT_MDL_TUR
- calculation of the dynamic model with dew point simulation: DYN_MDL_TUR
- the writing back of the result to the manager by the action

The switch LC_TUR_MDL_ENA has to be set to one to calculate the turbine model otherwise the calculation is skipped and the outlet temperature is equal to the inlet temperature. Due to the fact the most of the calculations are similar to the tube model most of the textual descriptions are skipped.

<u>SEL_INP_TUR</u>

The manager of the exhaust gas temperature model tells the turbine model which values out of the arrays has to be used for the calculation. Thereby TEG_MDL_CBK is the index for the exhaust bank and TEG_MDL_INP determines the input index.

<u>NOT_CLC</u>

Like described above the outlet temperature and the outlet humidity is set to there inlet values if the turbine model is skipped. Additionally LV_DEW_THD_TUR is set to one.

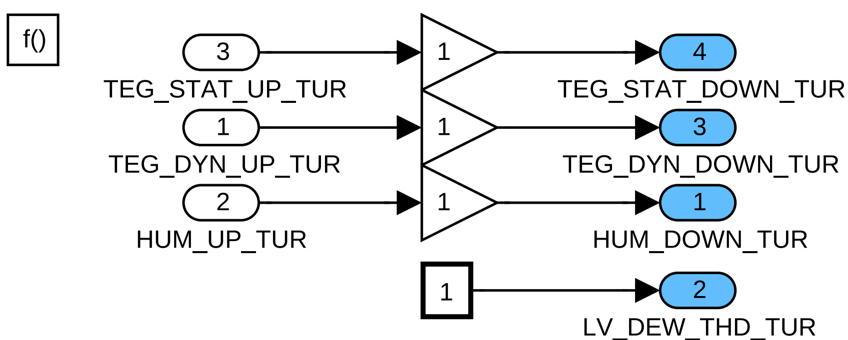

Figure 82 EXTD_MDLADturb0/ CLC__TUR_MDL/ NOT_CLC

STAT_MDL_TUR

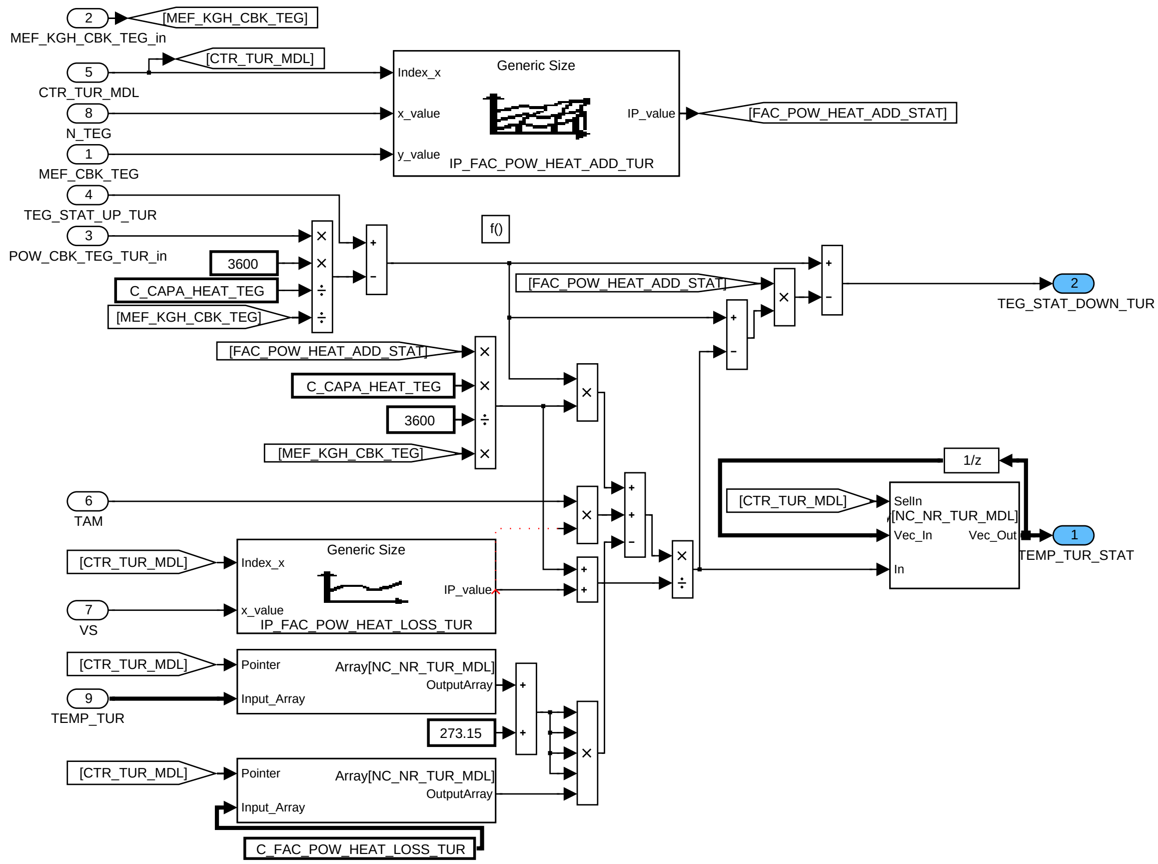

Figure 83 EXTD_MDLADturb0/ CLC__TUR_MDL/ STAT_MDL_TUR

DYN_MDL_TUR

The dynamic part of the turbine model is again split up in seven sub-functions:
- calculation of the temperature decrease due to the turbine: CLC__TEG_DYN_POW_TUR
- calculation of the heat flows out of the calibration data: CLC__POW_HEAT_FLOW_TUBE
- calculation of the heat energy added to the tube during sample time of the model: CLC__EGY_HEAT_ADD_TUBE
- calculation of the exhaust gas temperature downstream the tube: CLC__TEG_DYN_DOWN_TUBE
- filtering of the calculated exhaust gas temperature downstream tube: CLC__TEG_DYN_DOWN_TUBE_FIL
- dew point calculations for the tube: CLC__DEW_TUBE
- determination of the temperature in/decrease of the tube wall temperature: CLC__TEMP_TUBE

CLC__TEG_DYN_POW_TUR

The turbine power POW_CBK_TEG_TUR is the calculated turbine power and has to be determined by the turbo charger functionality. The turbine inlet temperature is decreased dependent on this power and dependent on the mass exhaust gas flow. This decreased temperature TEG_DYN_POW_TUR is used as input for all other calculations which are similar to the calculations in the tube exhaust gas temperature model.

Filtering constant for the filter of LAMB_CBK_TEG_CAT					

7.46.1 General information:

This module is just a template which deals with the most project needs. It is used as interface to the exhaust gas temperature model. It creates the necessary values for the calculation of the exhaust gas temperature model and gives the project the possibility for customer specific corrections of the main input values like:
Filtering of the ignition angle, engine speed, mass air flow, ...
Using measured lambda instead of lambda set point
Different calculation of the mass exhaust gas flow for projects with an unsymmetrical exhaust manifold

Additionally additive and multiplicative corrections on the engine out temperature and the catalyst exothermic can be applied by the values:
TEG_ENG_OUT_ADD_CUS
FAC_TEG_ENG_OUT_CUS
IGA_REF_TEG_ADD_CUS
IGA_BAS_TEG_ADD_CUS
FAC_TEG_ADD_IGA_CUS
POW_EXO_CAT_ADD_CUS
FAC_POW_EXO_CAT_CUS

These values can be used to add corrections for example for variable valve timing, external exhaust gas recirculation, bi-fuel engines or any other corrections which are necessary for the project.

Application Condition

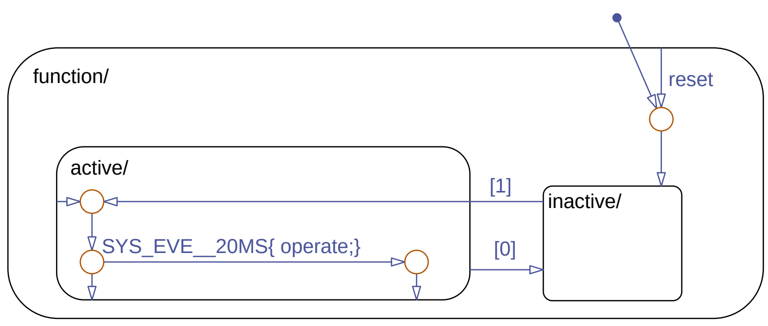

Figure 91 EXTD_MDLADai0/ APP_CDN/ Chart

Function Description

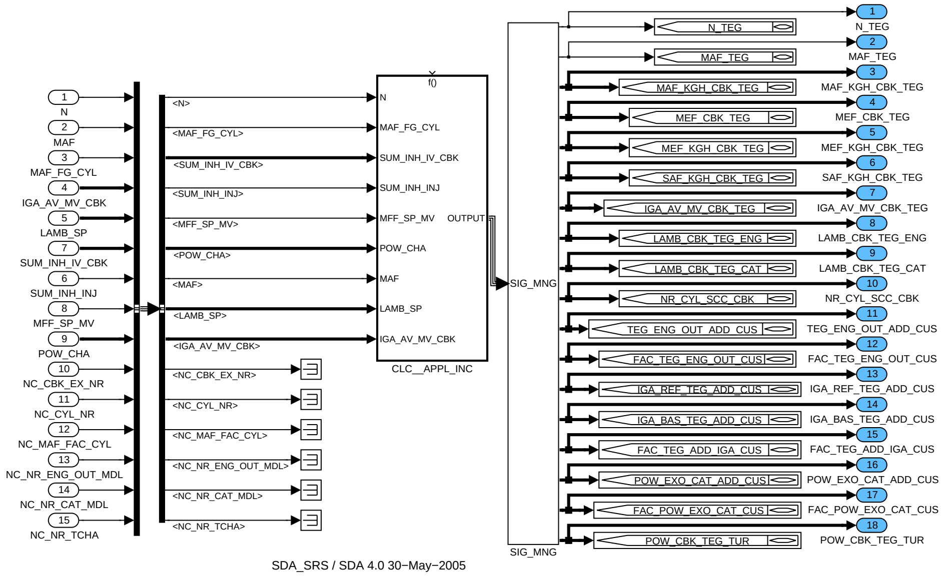

Figure 92 EXTD_MDLADai0

7.46.1.1 Calculation of the application incidences: CLC__APPL_INC

In this function part the initialisation of the non calculated corrections is done. Factors are initialized with one and additive corrections are initialized with zero.

Additionally the mapping of engine speed, mass air flow, ignition angle ... to the corresponding values for calculation of the exhaust gas temperature model is defined.

For the calculation of the mass exhaust gas flow the injected fuel mass, the mass air flow, the secondary air flow and the number of exhaust banks is used.

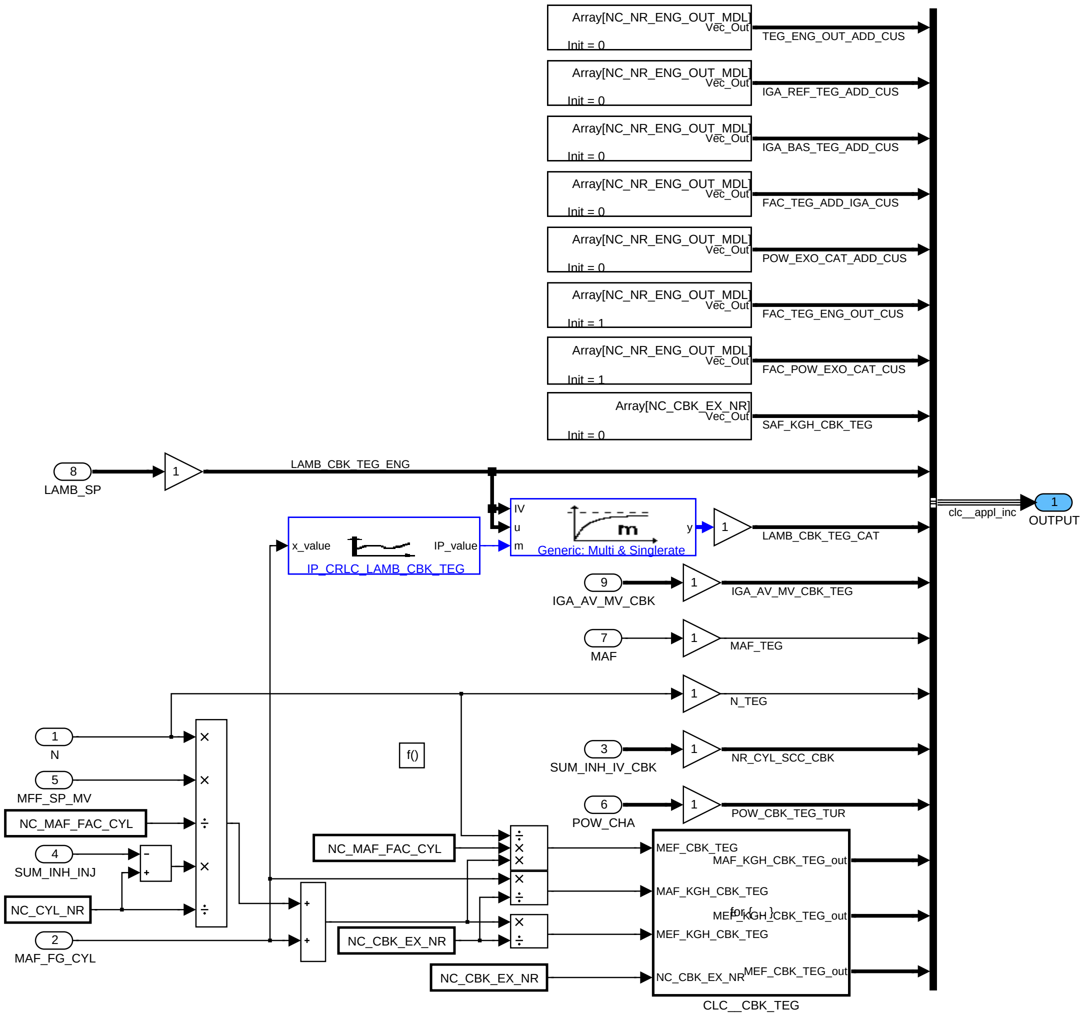

Figure 93 EXTD_MDLADai0/ CLC__APPL_INC

Setting of vectors for exhaust bank selective values: CLC__CBK_TEG

This function part describes that the single scalar values are stored in a vector with the same name.

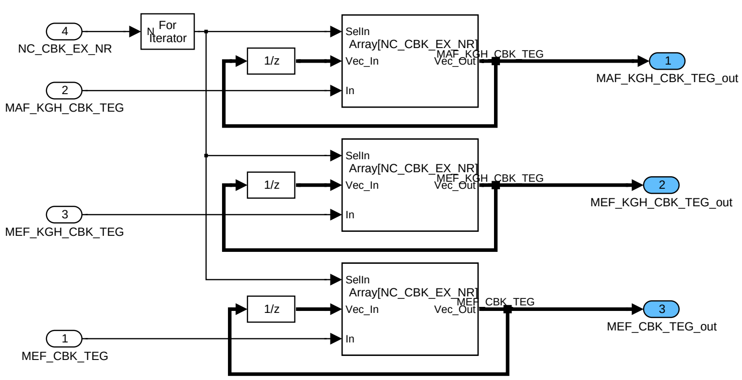

Figure 94 EXTD_MDLADai0/ CLC__APPL_INC/ CLC__CBK_TEG

7.46.2 Variables for fleet monitoring

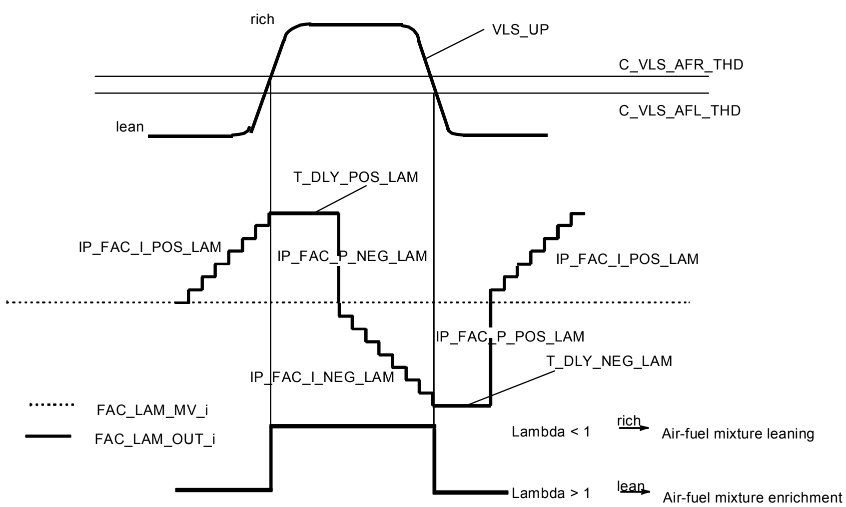
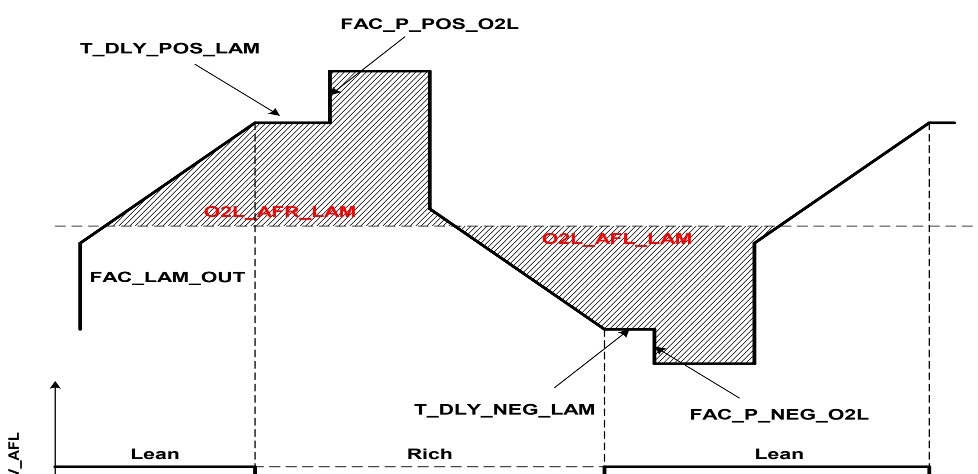
FUNCTION DESCRIPTION:

LV_O2L_LAM_RLS[i] = 0



LV_O2L_LAM_RLS[i] = 1



General Information:

The lambda control correction adjusts the fuel-air mixture to richness 1. The lambda controller uses a P/I strategy. It is adjusted to produce a leaner or a richer mixture according to the oxygen sensor information.

The P/I values are different in Idle (LV_IS) and in Part Load (LV_PL) or Trailing Throttle (LV_PU).

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank

7.47.5.1 Lambda controller limits

The limits for the lambda controller are C_FAC_LAM_MAX and C_FAC_LAM_MIN.
In case of closed A/F-loop before operability is detected (LV_LAM_LSCL = 1 and LV_LS_UP_READY = 0) the limits C_FAC_LAM_INI_MIN and C_FAC_LAM_INI_MAX are valid instead of C_FAC_LAM_MIN and C_FAC_LAM_MAX. These limits are valid until a transition from lean to rich is detected.
If the lambda adaptation value FAC_LAM_AD ≠ 0, these limits shall be changed.

```

7.47.5.3 Controller setting in part load or in trailing throttle:

7.47.5.3.1 Calculation of the transition flag PL-PU to IS

7.47.5.3.2 (LV_PL_PU_TRAN_IS_LAM)

After entry in idle (LV_IS) operation from part load (LV_PL) or trailing throttle (LV_PU), the P / I component of the lambda controller is switched to the P / I value for Idle (LV_IS) after an adjustable C_NR_RAF_CHG_IS_LAM number of P jumps.

```
if    (LV_PL_PU_TRAN_IS_LAM[i] = 1 and LV_IS = 1)
then
      if (CTR_RAF_CHG[i] – CTR_RAF_CHG_SAVE[i]) > C_NR_RAF_CHG_IS_LAM

7.47.5.3.5 Calculation of controller output

The counter CTR_T_DLY_LAM is used as a trigger to determine the instant of the control action. For CTR_T_DLY_LAM > 1 the delay time is waited, for CTR_T_DLY_LAM = 1 the P-jump action will be taken and for CTR_T_DLY_LAM = 0 the integral action will be released.
In case of a request from catalyst diagnosis the O_2 - load shall be adjusted to the requested setpoint. In that case the deviation of lambda controller output from the mean value of controller output shall be monitored. Should the absolute value of deviation exceed the maximum threshold, so the request shall be rejected. The maximum threshold is defined as the product of a constant, C_FAC_MV_O2L_MAX, and the absolute steady state maximum value of lambda controller output FAC_LAM_ABSV_STAT_MAX[i], which covers the ageing influence of the lambda sensor.

<u>**Detection of O2-load request and calculation of missing O2-load**</u>

7.47.5.3.5.2 Calculation of the controller output - case ' LV_O2L_LAM_RLS[i] = 1':

Depending on the state of the logical calibration data LC_FAC_P_O2L_LAM the control algorithm changes. Should the logical calibration data be set to 1, an additional P - jump has to be carried out to reach the missing O2 - load faster. Should the calibration data be set to zero, the missing O2 - load would be reached by solely delayed P - jump in opposite direction.

```

7.47.5.7 Controller limitation - calculation of FAC_LAM_LIM:

The value of the controller output shall be limited to FAC_LAM_MIN[i] and FAC_LAM_MAX[i] respectively.

```
if     FAC_LAM_OUT[i] > FAC_LAM_MAX[i]
then
    LV_FAC_LAM_LIM_MAX[i] = 1
    LV_FAC_LAM_LIM_MIN[i] = 0
    FAC_LAM_LIM[i] = FAC_LAM_MAX[i]
elseif     FAC_LAM_OUT[i] < FAC_LAM_MIN[i]
then
    LV_FAC_LAM_LIM_MIN[i] = 1
    LV_FAC_LAM_LIM_MAX[i] = 0
    FAC_LAM_LIM[i] = FAC_LAM_MIN[i]
else
    LV_FAC_LAM_LIM_MIN[i] = 0
    LV_FAC_LAM_LIM_MAX[i] = 0
    FAC_LAM_LIM[i] = FAC_LAM_OUT[i]
endif

FAC_LAM_OUT[i] = FAC_LAM_LIM[i]
```

7.47.5.8 Calculation of P-jump counter, FAC_LAM and FAC_LAM_MV

A P-jump takes place if a new P-part correction is done on FAC_LAM_OUT. FAC_LAM is the value of the controller output after each P-jump and FAC_LAM_MV is the mean value of two successive output signals after each P-jump.

if (LV_FAC_P_POS_LAM[i] = 0 $\rightarrow$ 1 **or** LV_FAC_P_POS_LAM[i] = 1 $\rightarrow$ 0)

then

FAC_LAM[i] = FAC_LAM_OUT[i]
FAC_LAM_MV[i]$_k$ = (FAC_LAM[i]$_{k-1}$ + FAC_LAM[i]$_k$) / 2

increment CTR_RAF_CHG[i]

The P-jump counter shows the number of executed P-jumps. The counter is increased without regard of overflow, i.e. if “255” is reached, with the next P-jump CTR_RAF_CHG[i] contains “0”.

endif

7.47.5.9 Calculation of FAC_LAM_MV_MMV_CP, FAC_LAM_MV_MMV, FAC_LAM_MV_MMV_LDC and FAC_LAM_MV_MMV_LDC_DIAG

FAC_LAM_MV_MMV_CP[i]$_k$ = FAC_LAM_MV_MMV_CP[i]$_{k-1}$ + (FAC_LAM_OUT[i]$_k$ - FAC_LAM_MV_MMV_CP[i]$_{k-1}$) * CRLC_FAC_LAM_MV_MMV_CP

used by canister purge function

FAC_LAM_MV_MMV[i]$_k$ = FAC_LAM_MV_MMV[i]$_{k-1}$+ (FAC_LAM_MV[i]$_k$ - FAC_LAM_MV_MMV[i]$_{k-1}$) * C_CRLC_FAC_LAM_MV_MMV

FAC_LAM_MV_MMV_LDC[i]$_k$ = FAC_LAM_MV_MMV_LDC[i]$_{k-1}$+ (FAC_LAM_MV[i]$_k$- FAC_LAM_MV_MMV_LDC[i]$_{k-1}$)*C_CRLC_FAC_LAM_MV_MMV_LDC

used by the function "Mean value calculation for limited dynamics"

FAC_LAM_MV_MMV_LDC_DIAG[i]$_k$ = FAC_LAM_MV_MMV_LDC_DIAG[i]$_{k-1}$+ (FAC_LAM_MV[i]$_k$- FAC_LAM_MV_MMV_LDC_DIAG[i]$_{k-1}$) *C_CRLC_FAC_LAM_MV_MMV_LDC_DIAG

used by limited dynamics for cat efficiency diagnosis

7.47.5.10 Calculation of the absolute maximum value of lambda controller output

if LV_FAC_P_POS_LAM[i] = 0 $\rightarrow$ 1
then
FAC_LAM_ABSV_STAT_MAX[i] = **abs(**FAC_LAM_ABSV_AFR[i] - FAC_LAM_ABSV_AFL[i]**)**

FUNCTION DESCRIPTION:

The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank

Application conditions:

Initialisation:

Recurrence: every 10 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

if LV_PUC = 1
then T_DLY_LSCL_REAC_PUC = C_T_DLY_LSCL_REAC_PUC

if LV_PUC = 0

endif
```

STATE_LS_1 calculation:

STATE_LS_i	
BIT	**Function**
0	lambda control open loop – has not yet satisfied conditions to go closed loop
1	lambda control closed loop – using oxygen sensor(s) as feedback for fuel control
2	lambda control open loop – due to driving conditions (e.g. power enrichment, decelaration enleanment)
3	lambda control open loop – due to detected system fault
4	lambda control closed loop – but fault with at least one oxygen sensor (may be using single oxygen sensor for fuel control)
5...7	reserved – always 0

Only one of the bits can be set at the same time. One of the bits must be set at every time. So the following values are possible for STATE_LS_1:

STATE_LS_1	Function
1	Lambda control open loop - has not yet satisfied conditions to go closed loop
2	Lambda control closed loop - using oxygen sensor(s) as feedback for fuel control
4	Lambda control open loop – due to driving conditions
8	Lambda control open loop – due to detected system fault
16	Lambda control closed loop – but fault with at least one oxygen sensor

For i = 1 to NC_CBK_NR:

if LV_LAM_LSCL_i = 1

then *(state of the fuel system at closed loop control)*

if LV_ERR_READY_LS_UP = 0

then STATE_LS_i = 2
(Lambda control closed loop - using oxygen sensor(s) as feedback for fuel control)

else STATE_LS_i = 16
(Lambda control closed loop – but fault with at least one oxygen sensor)

endif

else *(state of the fuel system at open loop control)*

FUNCTION DESCRIPTION:

General information:

The trim-controller causes a compensation of ageing effects of the upstream O_2-sensor as well as a better observance of the catalyst window during all the life of the vehicle.
According to downstream O_2-sensor voltage, a P-jump time delay is applied on the lambda regulation. The control value is composed of P and I-shares, both are determined depending on the downstream probe signal. The variance of the probe voltage from desired value is the basic characteristic. The desired value can be applied depending on the operating point, so that the dynamic lambda can be adjusted according to the operating range.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank

Application conditions:

Initialisation:

T_DLY_I_AD_LAM_ADJ[i] shall be read out the non-volatile memory.

In case of an E²Prom error, T_DLY_I_AD_LAM_ADJ[i] and T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i] shall be initialised by 0.

at reset:

T_DLY_I_LAM_ADJ[i] = T_DLY_I_AD_LAM_ADJ[i]

T_DLY_I_LAM_ADJ_CAT_DIAG[i] = T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i]

T_DLY_I_MV_LAM_ADJ[i] = T_DLY_I_AD_LAM_ADJ[i]

T_DLY_I_MV_LAM_ADJ_CAT_DIAG[i] = T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i]

at start of new driving cycle - LV_DC 0 → 1:

T_DLY_I_LAM_ADJ[i] = T_DLY_I_AD_LAM_ADJ[i]

T_DLY_I_LAM_ADJ_CAT_DIAG[i] = T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i]

T_DLY_I_MV_LAM_ADJ[i] = T_DLY_I_AD_LAM_ADJ[i]

T_DLY_I_MV_LAM_ADJ_CAT_DIAG[i] = T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i]

VLS_DIF_LAM_ADJ[i] = 0

VLS_DIF_SAVE_LAM_ADJ[i] = 0

T_DLY_P_LAM_ADJ[i] = 0

MAF_INT_LAM_ADJ_ACT[i] = 0

LV_LAM_ADJ_ACT[i] = 0

LV_MAF_INT_LAM_ADJ_CAT_PURGE[i] = 0

LV_LAM_ADJ_P_ACT[i] = 0

LV_LAM_ADJ_I_ACT[i] = 0

LV_LAM_ADJ_I_CAT_DIAG_ACT[i] = 0

CTR_PER_VLD_LAM_ADJ[i] = 0

LV_LAM_ADJ_PER_VLD[i] = 0

Recurrence: T_SAMPLE = 100 ms

Activation:

- LV_ST_END = 1

Deactivation:

- LV_ES = 1

Formula section:

7.49.1 Calculation of the deviation

The deviation is the difference between the setpoint value and the measured downstream sensor voltage.

7.49.2 Calculation of the internal state variable LV_LAM_ADJ_PER_VLD[i]

A statement regarding the behaviour of the downstream lambda sensor voltage is required e.g. to distinguish inside of the OBD trim-controller diagnosis whether an error on the upstream or downstream sensor occurs. LV_LAM_ADJ_PER_VLD[i] = 1 announces that the controller difference VLS_DIF_LAM_ADJ[i] was at least 10 times positive and 10 times negative. Otherwise and after every function activation must LV_LAM_ADJ_PER_VLD[i] set to 0.

7.49.3 Calculation of controller components

The dynamic fuel controller is made of a proportional- and an I-action controller. At the beginning of a new driving cycle the initial value of the integrator shall be initialised by the stored adaptation value.

7.49.3.1 Calculation of the air-mass-flow-integral

Regarding the first controller update after activation, the integral of air-mass-flow is calculated. Should the value of the integral be below the threshold, the calculation of the controller must be prevented.

7.49.3.1.1 Conditional release after PUC

After the catalyst enrichment function was completed, the threshold C_MAF_INT_LAM_ADJ_ACT_CAT_PURGE is the trigger for the release.

7.49.3.1.2 Conditional release after new activation

Should the value of the integral be over the threshold C_MAF_INT_LAM_ADJ_ACT, the calculation of the controller is released.

7.49.3.2 Calculation of the proportional-action controller (P component)

The P-share of the controller may only be carried out in applied N/MAF-areas. When these conditions are not fulfilled the corresponding P-share shall be set to 0.

7.49.3.3 Calculation of the integral-action controller (I component)

The I-share of the controller may only be carried out in applied MAF-areas provided that the limited dynamic is fulfilled. When these conditions are not fulfilled the corresponding I-share shall be stopped. At the beginning of a new driving cycle T_DLY_I_LAM_ADJ[i] is initialised by the stored value T_DLY_I_AD_LAM_ADJ[i] (adaptation value).
In case of activated catalyst diagnosis, the I component of dynamic fuel trim is released independent of MAF - area, being calculated with IP_T_DLY_I_LAM_ADJ_CAT_DIAG (LV_LAM_ADJ_I_CAT_DIAG_ACT[i] = 1).
In case of Cylinder shut-off, I component is stopped via LV_INH_LAM_ADJ_I[i] until VLS_DOWN indicates again a Rich mixture.

7.49.3.4 Limitation of the integrator

The output of the integrator shall be limited to C_T_DLY_I_MIN_LAM_ADJ and C_T_DLY_I_MAX_LAM_ADJ.

7.49.3.5 Calculation of the I-share mean value

Regarding the adaptation, the calculation of the I-share mean value is required using a low-pass filter. At the beginning of a new driving cycle T_DLY_I_MV_LAM_ADJ[i] is initialised by the stored value T_DLY_I_AD_LAM_ADJ[i] (adaptation value).

7.49.4 Calculation of the controller output

The total delay time of the downstream trim regulation is normalised by IP_FAC_T_DLY_LAM_ADJ on the corresponding Lambda shift.

7.49.5 Calculation of the adaptation value T_DLY_I_AD_LAM_ADJ[i] and T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i]

The value T_DLY_I_AD_LAM_ADJ[i] and T_DLY_I_AD_LAM_ADJ_CAT_DIAG[i] shall be calculated at the end of the driving cycle and stored in the flash memory.

FUNCTION DESCRIPTION:

General information:

There are many errors, which make it necessary to stop the trim control when they occur.

In case of cylinder shut-off (for example Traction Control torque reduction request), Trim controller I-term is inhibited via LV_INH_LAM_ADJ_I until VLS_DOWN indicates again a Rich mixture (VLS_DOWN > thd.).

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank

Application conditions:

Initialisation: at ECU reset:

LV_INH_LAM_ADJ[i]	=	1
LV_INH_LAM_ADJ_I[i]	=	0
LV_LDC_LAM_ADJ[i]	=	0
N_OFS_LDC_LAM_ADJ[i]	=	0
MAF_OFS_LDC_LAM_ADJ[i]	=	0
PV_AV_OFS_LDC_LAM_ADJ[i]	=	0
FAC_LAM_MV_OFS_LDC_LAM_ADJ[i]	=	0
MAF_INT_LDC_LAM_ADJ[i]	=	0
VLS_AV_LAM_ADJ[i]	=	0
VLS_AV_TMP_LAM_ADJ	=	0

Activation:

- at every engine operating state

Deactivation:

-

Recurrence: T_SAMPLE = 100 ms

Formula section:

Calculation of the inhibition flag for trim control:

if LV_ERR_CPS = 1
(canister purge system error active)
or LV_ERR_MEC_OPEN_CPS = 1
(canister purge system mechanical error active)
or LV_MIS_STATE_A = 1
(misfire state A active)
or LV_ERR_FSD[i] = 1 and LC_ENA_LAM_ADJ_ERR_FSD = 0)
(fuel system diagnosis error active)
or LV_ERR_MAF = 1

(inconsistencies between actual load and throttle position detected)
or LV_MIS_STATE_B = 1
(CARB B misfire detected)

then
LV_INH_LAM_ADJ[i] = 1
else
LV_INH_LAM_ADJ[i] = 0
endif

Calculation of the inhibition flag for trim control I-term:

```
if    LV_SCC[i] = 1
then          LV_INH_LAM_ADJ_I[i] = 1
else
      if      VLS_DOWN[i] > C_VLS_DOWN_INH_LAM_ADJ_I_SCC
      then    LV_INH_LAM_ADJ_I[i] = 0
      endif
  endif
```

Calculation of the actual value of downstream oxygen sensor voltage:

VLS_DELTA_LAM_ADJ_CAT_DIAG = IP_VLS_DELTA_LAM_ADJ_CAT_DIAG

```
if
(LV_LAM_ADJ_CAT_DIAG[i] = 0 and LC_VLS_DOWN_FIL_ACT = 0)
then
      VLS_AV_TMP_LAM_ADJ[i] = VLS_DOWN[i]
      VLS_AV_LAM_ADJ[i] = VLS_AV_TMP_LAM_ADJ[i]
else
      VLS_AV_TMP_LAM_ADJ[i] = VLS_AV_TMP_LAM_ADJ[i] +
                              (VLS_DOWN[i] - VLS_AV_TMP_LAM_ADJ[i] +
                                     VLS_DELTA_LAM_ADJ_CAT_DIAG)
                                  * IP_CRLC_VLS_LAM_ADJ_CAT_DIAG

      VLS_AV_LAM_ADJ[i] = VLS_AV_TMP_LAM_ADJ[i]

endif
```

SW hint: Definitions of "VLS" variables are not the same!

FUNCTION DESCRIPTION:

General information:

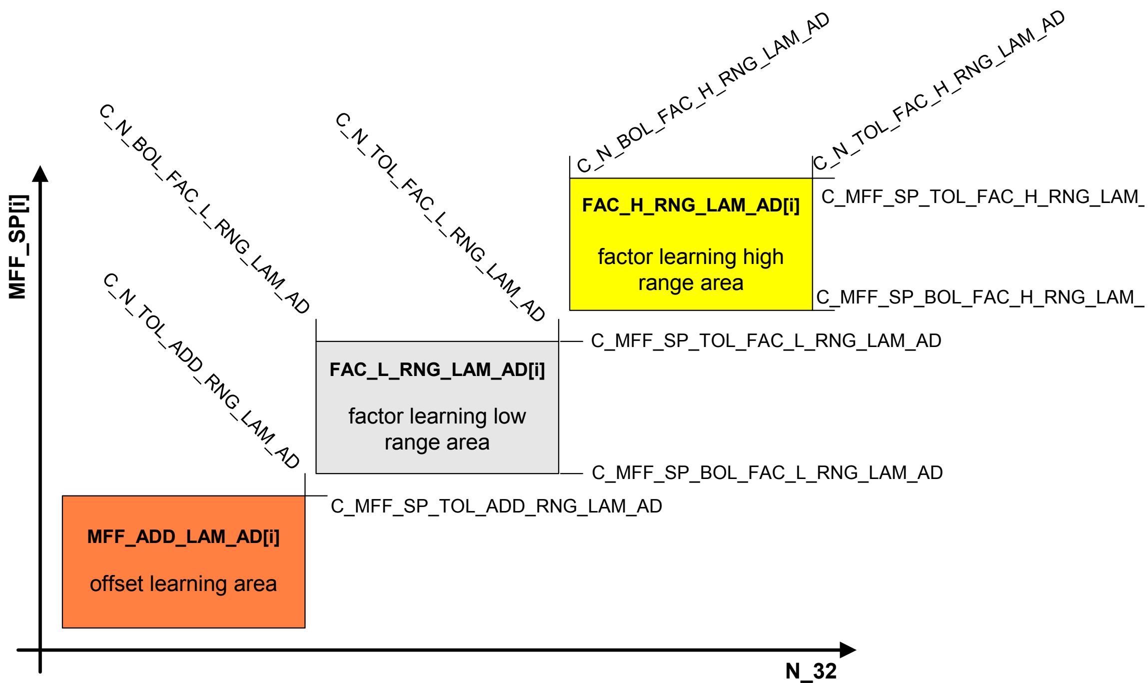
In order to compensate serial production tolerances of components, an adaptive (additive and two multiplicative) correction is calculated versus the averaged output of the lambda controller.
The additive and multiplicative adaptation corrections are used for calculating the injection time for all engine operating states, except at 'engine stop' and 'engine start'

The calculation shall be done for all exhaust cylinder banks.

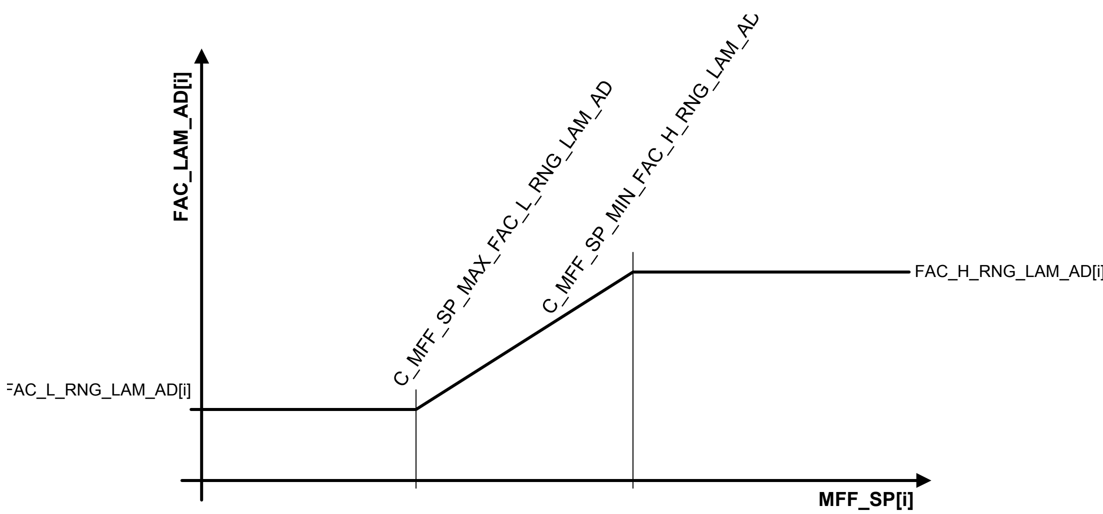
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Adaptation field diagram:



Interpolation diagram:



Description:

Lambda adaptation, for precision reason, needs to be performed at lambda equal 1 conditions. The function itself is activated by the corresponding LV_LAM_AD_ACT[i]. Depending on MFF_SEL_LAM_AD and N_32 three different adaptation fields (one offset and two factor areas) are observed. MFF_SEL_LAM_AD is determined as below,

If LC_SEL_MFF_SP_LAM_AD =1

Then MFF_SEL_LAM_AD = MFF_SP[i]

Else MFF_SEL_LAM_AD = MFF_BAS

EndIf

According to project philosophy homogeneous mode and suitable conditions can be forced by setting:

- LC_MFF_ADD_RNG_AFS_REQ_LAM_AD,
- LC_FAC_L_RNG_AFS_REQ_LAM_AD and / or
- LC_FAC_H_RNG_AFS_REQ_LAM_AD.

to 1. Then LV_LAM_AD_AFS_REQ is set to 1 in order to request lambda eq. 1 condition from the combustion manager.

Application conditions:

Initialisation: if ECU is brand new or at EEPROM error:
FAC_L_RNG_LAM_AD[i] = 0
FAC_H_RNG_LAM_AD[i] = 0
MFF_ADD_LAM_AD[i] = 0
FAC_MFF_ADD_FAC_LAM_AD[i] = 0

at ECU reset:
LV_LAM_AD_END = 0
LV_FAC_LAM_ADJ_LAM_AD[i] = 0
FAC_LAM_ADJ_LAM_AD[i] = 0 %
LV_LAM_AD_STOP[i] = 0
LV_LAM_AD_STOP_CBK_EX = 0
STATE_LAM_AD[i] = "INIT"
MFF_DELTA_ADD_LAM_AD[i] = 694.489403 mg/stk

LV_FAC_H_RNG_LIM_MIN_LAM_AD[i] = 0
LV_FAC_H_RNG_LIM_MAX_LAM_AD[i] = 0

Recurrence: T_SAMPLE = 20 ms

Activation: in all engine operating states

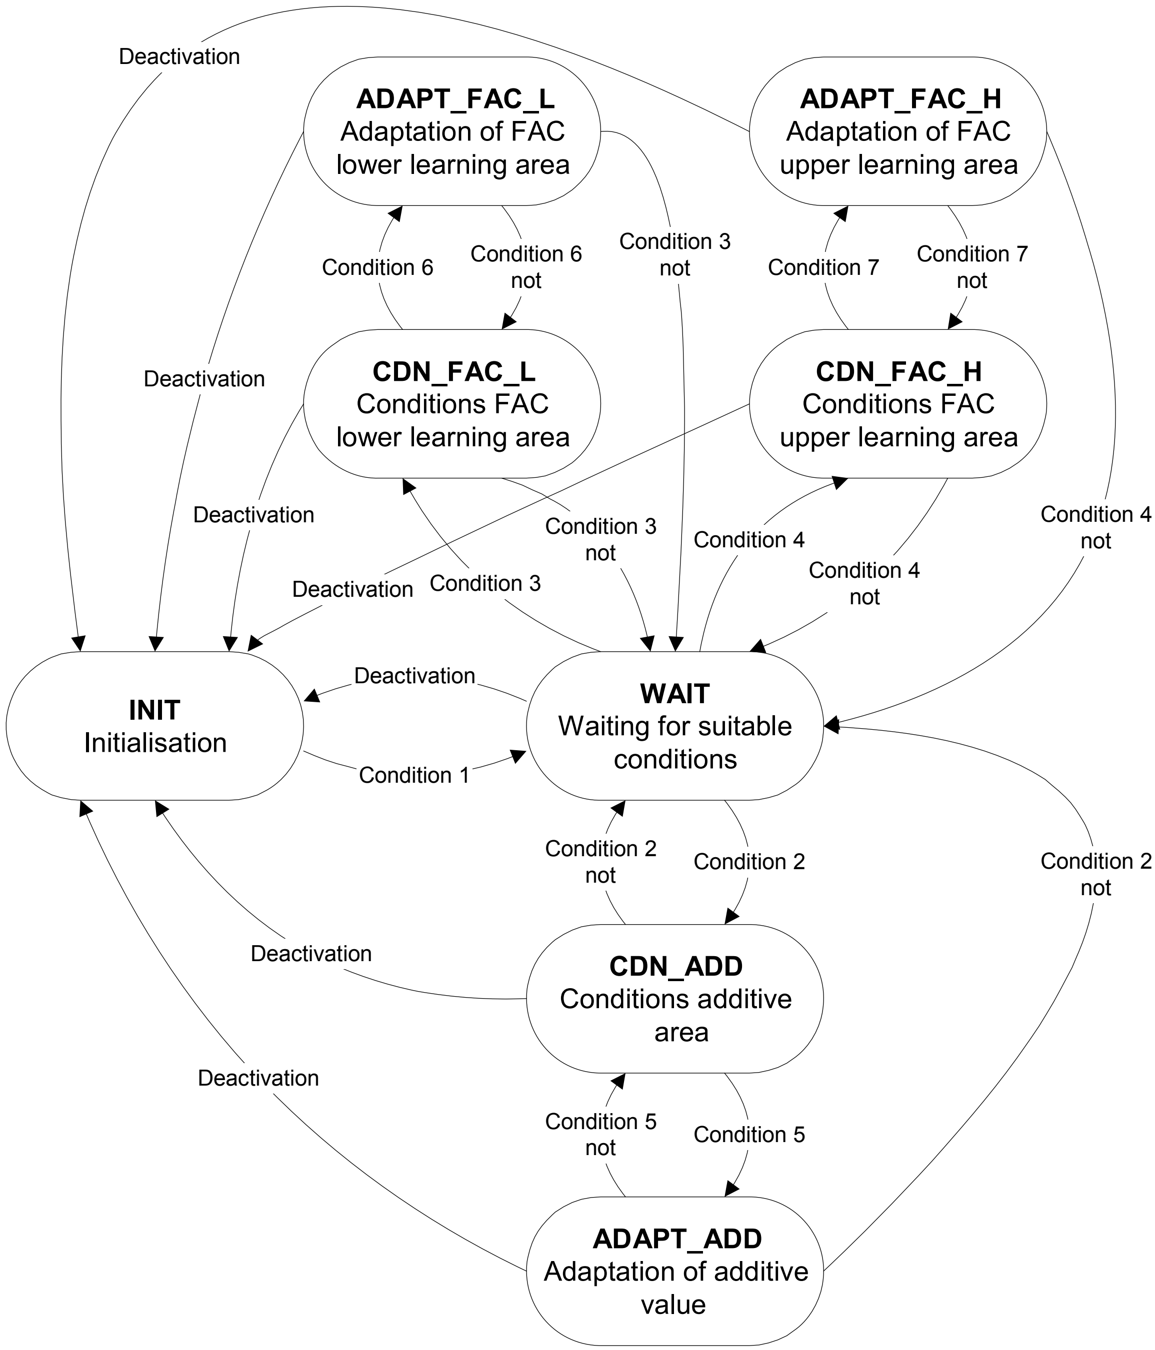
Deactivation: -

7.51.1 Sequence for lambda adaptation determination (state machine)

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

The priority of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

State machine diagram:



7.51.1.1 State "INIT"

Description:

After every engine start at every new activation the sequence starts with the INIT and switches to the state "WAIT" when activation conditions are fulfilled.

Formula section:

Actions:

LV_LAM_AD_END = 0

LV_LAM_AD_CDN = 0

LV_MFF_ADD_RNG_LAM_AD[i] = 0

LV_FAC_L_RNG_LAM_AD[i] = 0

LV_FAC_H_RNG_LAM_AD[i] = 0

LV_LAM_AD_AFS_REQ = 0

Condition 1: Transition to state "WAIT"

ENDIF

Actions during transition: CTR_RAF_CHG_LAM_AD[i] = 0

7.51.1.6 State "ADAPT_ADD"

Description:

Once the adaptation conditions are active, an adaptation takes place after NR_RAF_CHG_LAM_AD[i] lean ↔ rich air fuel ratio changes (by consideration of the value of CTR_RAF_CHG[i] signal). Another adaptation occurs after another NR_RAF_CHG_LAM_AD[i] lean ↔ rich air fuel ratio changes. In order to observe the priority of further lambda adaptations, the MMV value of the adapted factors and their respective differences to the further calculation are determined. In order to avoid big injection time deviation and to detect system failure the lambda adaptation values are limited.

Formula section:

7.51.2 Rewriting of adaptation correction with non volatile stored values

Description:

In case of an error of the WRAF sensor the adaptation correction values MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i] and FAC_H_RNG_LAM_AD[i] must be rewritten with the values stored at the end of the last driving cycle.

Formula section:

IF (LV_LAM_AD_DEAC_ERR[i] = 0 -> 1)
THEN
  rewrite MFF_ADD_LAM_AD[i] *with non volatile stored value*
  rewrite FAC_L_RNG_LAM_AD[i] *with non volatile stored value*
  rewrite FAC_H_RNG_LAM_AD[i] *with non volatile stored value*
ENDIF

7.51.3 Determination of the interpolated lambda adaptation factor

Description:

In order to meet the physical behaviour of engine components (especially the air mass flow sensor), the actual multiplicative factor is calculated out of the two determined factors by interpolation at every state.

Formula section:

```
IF (MFF_SP[i] <= IP_MFF_SP_MAX_FAC_L_RNG_LAM_AD)
THEN
   FAC_LAM_AD[i] = FAC_L_RNG_LAM_AD[i]
ELSE
   IF (MFF_SP[i] >= IP_MFF_SP_MIN_FAC_H_RNG_LAM_AD)
   THEN
      FAC_LAM_AD[i] = FAC_H_RNG_LAM_AD[i]
   ELSE    /* interpolation */
      FAC_LAM_AD[i] = FAC_L_RNG_LAM_AD[i] +
                      (MFF_SP[i] - IP_MFF_SP_MAX_FAC_L_RNG_LAM_AD) *
                      ( (FAC_H_RNG_LAM_AD[i] - FAC_L_RNG_LAM_AD[i]) /
                        (IP_MFF_SP_MIN_FAC_H_RNG_LAM_AD -
                         IP_MFF_SP_MAX_FAC_L_RNG_LAM_AD) )
   ENDIF
ENDIF
```

7.51.4 Calculation of the output signals for fuel mass flow set point correction

Description:

In order to avoid mixture problems when the engine has not reached its service temperature (warm up), lambda adaptation factors and their corresponding relative intermediate results can be decreased versus TCO and their own value (which is applied when the engine has its service temperature).
This is performed by weighting the adaptive factors as long as the lambda adaptation is disabled due to TCO ≤ C_TCO_MIN_LAM_AD (see: "application incidences").
The quotient of the additive relative factor is determined. The values MFF_LAM_ADD_LAM_AD_OUT[i] and MFF_SP[i] should be conditioned so, that FAC_MFF_ADD_LAM_AD_OUT[i] does not exceed the physical range of +/-100 %!
The relative lambda adaptation FAC_MFF_ADD_FAC_LAM_AD[i] as long term adaptation is calculated out of both adaptation factors.

Formula section:

```
IF (TCO <= C_TCO_MIN_LAM_AD)
THEN
   MFF_LAM_ADD_LAM_AD_OUT[i]  = (MFF_ADD_LAM_AD[i] * IP_FAC_N_MFF_ADD_LAM_AD) *
                                IP_FAC_WUP_MFF_ADD_LAM_AD
   FAC_LAM_AD_LAM_OUT[i] = (FAC_LAM_AD[i]  * IP_FAC_N_FAC_LAM_AD) *
                           IP_FAC_WUP_FAC_LAM_AD
ELSE
   MFF_LAM_ADD_LAM_AD_OUT[i] = MFF_ADD_LAM_AD[i] * IP_FAC_N_MFF_ADD_LAM_AD
   FAC_LAM_AD_LAM_OUT[i] = FAC_LAM_AD[i] * IP_FAC_N_FAC_LAM_AD
ENDIF

FAC_MFF_ADD_LAM_AD_OUT[i] = MFF_LAM_ADD_LAM_AD_OUT[i] / MFF_SP[i]

IF (LV_IGK = 1) AND (LV_ST_END =1)
THEN
   FAC_MFF_ADD_FAC_LAM_AD[i] = FAC_LAM_AD_LAM_OUT[i] +
FAC_MFF_ADD_LAM_AD_OUT[i]
ENDIF
```

7.51.5 Interface to lambda controller

Description:

A shift of the lambda controller output after the calculation of a valid adaptation value by FAC_LAM_ADJ_LAM_AD[i] is required in order to avoid rapid changes in the air fuel ratio caused by the lambda adaptation. FAC_LAM_ADJ_LAM_AD[i] is calculated in the states "ADAPT_ADD", "ADAPT_FAC_L" and "ADAPT_FAC_H".
The shift of the lambda controller output is not carried out, if the lambda controller is stopped. To avoid a loss of adaptation values in that case, the lambda controller shall confirm the successful lambda controller shift.
If the lambda controller does not confirm the controller shift by FAC_LAM_ADJ_LAM_AD[i] by setting LV_FAC_LAM_ADJ_LAM_AD_END[i] to 1, the lambda adaptation stops further calculations (LV_LAM_AD_STOP[i] is set to 1) until the controller shift is confirmed. FAC_LAM_ADJ_LAM_AD[i] shall be set to 0 and LV_FAC_LAM_ADJ_LAM_AD[i] and LV_LAM_AD_STOP[i] are reset, if at a stopped lambda adaptation the deactivating conditions are fulfilled.

Formula section:

IF (LV_LAM_AD_STOP[i] = 1) **AND**
   (LV_LAM_STOP[i] = 0)
THEN
   LV_FAC_LAM_ADJ_LAM_AD[i] = 1
ENDIF

If (LV_FAC_LAM_ADJ_LAM_AD_END[i] = 1)
THEN
   LV_FAC_LAM_ADJ_LAM_AD[i] = 0
   LV_LAM_AD_STOP[i] = 0
   CTR_RAF_CHG_LAM_AD[i] = 0
ENDIF

7.51.6 Check of requirements for time scheduler

Description:

In order to observe the priority of further lambda adaptations, the differences between the old and the new adapted factors are observed. According to the observed deviations the new maximum time for next adaptation is calculated regarding the present conditions. The output value for the time scheduler T_PRI_TOT_LAM_AD is not bank selective and represents the minimum time of all cylinder banks. In case of single exhaust cylinder bank T_PRI_TOT_LAM_AD is equal to T_PRI_LAM_AD[i] of this single bank.

Formula section:

set T_PRI_TOT_LAM_AD to 6553.5 s before executing FOR loop

set LV_LAM_AD_STOP_CBK_EX to 0 before executing FOR loop

T_PRI_TOT_LAM_AD = **MIN**(T_PRI_TOT_LAM_AD; T_PRI_LAM_AD[i])

LV_LAM_AD_STOP_CBK_EX = LV_LAM_AD_STOP_CBK_EX **OR** LV_LAM_AD_STOP[i]

the following IF statement must be executed after the FOR loop

```
IF (LV_LAM_AD_STOP_CBK_EX = 1)
THEN
   IF (T_PRI_TOT_LAM_AD ≥ C_T_PRI_MAX_LAM_AD)
   THEN
      LV_LAM_AD_END = 1
   ELSE
      LV_LAM_AD_END = 0
   ENDIF
ENDIF
```

7.52.1 LACO_ISPCLMVLDC0

This function calculates only differences between base values and their moving means values. These differences or deltas are to be used within the function that needs limited dynamic conditions. The evaluation of the limited dynamic bit is part of the function that need this flag. So the mean value calculation is concentrated in this function.

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Function Description

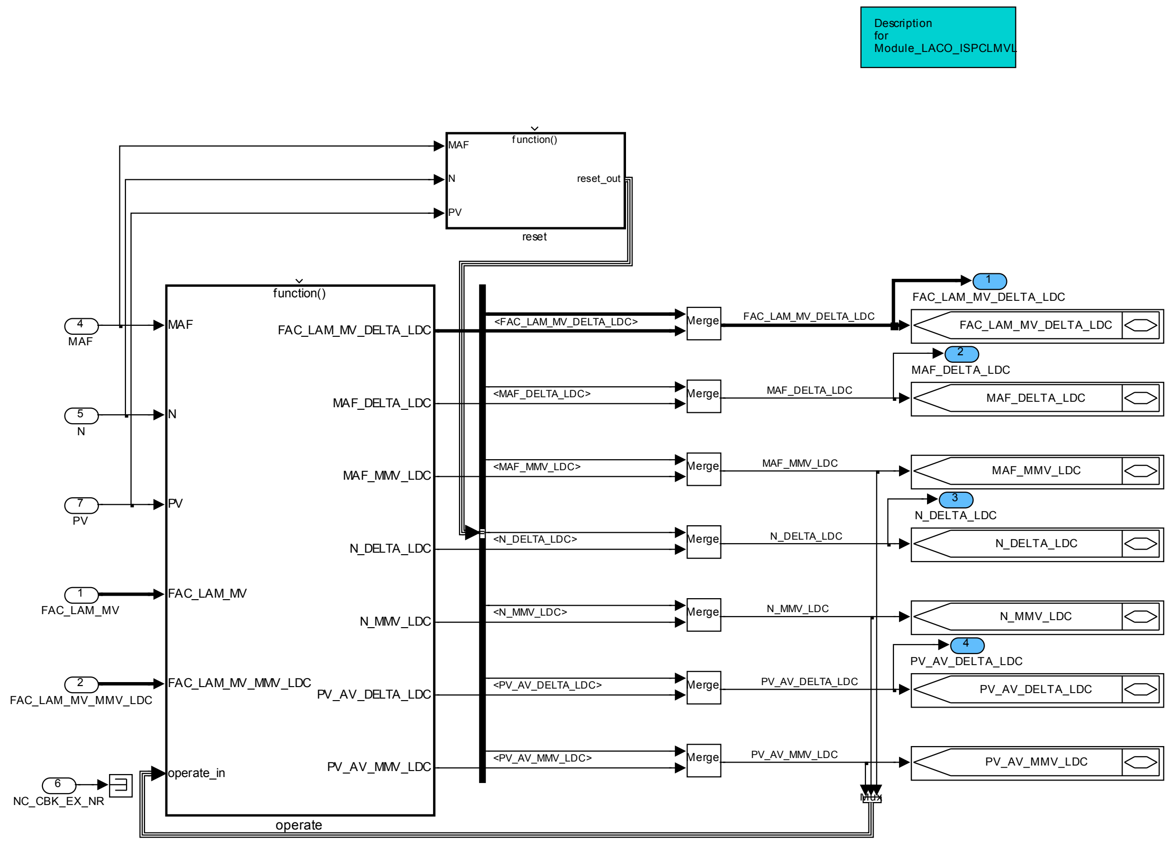

Figure 95 LACO_ISPCLMVLDC0

operate

This function calculates for the detection of the limited dynamics the moving mean values of engine speed (N and N_MMV_LDC), air mass flow (MAF and MAF_MMV_LDC) and degree of activation of the accelerator pedal (PV and PV_AV_MMV_LDC). Furthermore the difference between these input values and the moving mean values is calculated.

For the lambda control output only the difference is evaluated because the moving mean value calculation is located in the lambda control module itself because of easier realisation of shift operations of the moving mean value (FAC_LAM_MV_MMV_LDC[i]).

Remark: The difference calculation of lambda control output is a vector operation.

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The activation conditions of the lambda adaptation depend of:

- coolant temperature thresholds,
- temperature of intake air into manifold threshold,
- air mass flow threshold,
- no air mass flow pulsation detected,
- and several error flags that must be zero

If all activation conditions are fulfilled LV_LAM_AD_ACT[i] is set to 1. That means that the lambda adaptation can get active if no other inhibition defined in the lambda adaptation module is set. In case of upstream sensor failure LV_LAM_AD_DEAC_ERR[i] is set to 1.

The detection of the limited dynamics are calculated based the current engine speed, air mass flow, pedal value and filtered lambda control output. The input to this function is the difference between each of the mentioned base values and its moving mean values. If one of this differences exceeds a calibrated threshold a air mass flow integral is started to be calculated until a calibrated MAF threshold is reached. During the calculation the limited dynamics are not fulfilled (LV_LDC_LAM_AD[i] = 0). In order to reset difference between base value and moving mean value after each threshold exceeding a offset variable is introduced (see formula section).

Furthermore the correlation constant for calculation of adaptive values and the number of lean ↔ rich air fuel ratio changes between two adaptations are determined depending on idle speed conditions or request for forced lambda adaptation. The flag LV_INH_CTR_RAF_CHG_CTR[i] indicating that the counting of lean / rich mixture changes is inhibited is set to 1 when forced lambda adaptation is requested.

Application conditions:

Initialisation: at ECU reset:
LV_LAM_AD_ACT[i] = 0
CRLC_LAM_AD[i] = 0

7.54 Lambda Setpoint for Single Cylinder Fuel Shut Off

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LAMB_SCC[NC_CBK_EX_NR]	V/O	0 ... 7FFFH	0 ... 31.999	9.7656E-4	-
Lambda setpoint for single cylinder shut off					

Input data:

LV_SCC[NC_CBK_EX_NR]	LV_ST_END	LV_ES	TCO
NC_CBK_EX_NR			

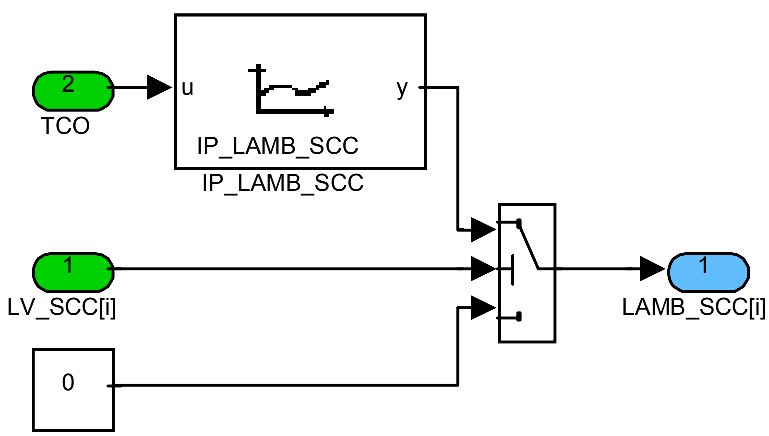
FUNCTION DESCRIPTION:

General information:

In case of single cylinder shut off one of the bank selective flags LV_SCC[i] is set to 1. Then the corresponding lambda value LAMB_SCC[i] is set to a value according to the mapping point of IP_LAMB_SCC (which should be equal or bigger than one). This is neccesary to protect the catalyst from unburnt hydrocarbons.

LAMB_SCC[i] is an input for the module “Lambda Coordination” and it is handled there with the highest priority against all other lambda requests.

Signal flow diagram:



Application conditions:

Activation: LV_ST_END = 1

Deactivation: -

Initialization at Reset or LV_ES = 0 -> 1: LAMB_SCC[i] = 0

Recurrence: every 10 ms

Formula section:

LV_ST_END	MAF	LV_HOM_AFL_ACT	LV_LAM_ADJ_CAT_DIAG[NC_CBK_EX_NR]
NC_CBK_EX_NR			

FUNCTION DESCRIPTION:

General information:

The basic lambda setpoint LAMB_BAS[i] is calculated as a function of load and engine speed. It is possible to correct the load - speed depending lambda setpoint for different coolant temperatures and the coolant temperature at engine start. This guarantees good driveability for lower coolant temperatures.

Two homogeneous engine operating modes are possible, the stoichiometric ($\lambda = 1$) mode and the lean air-fuel-mixture mode ($\lambda > 1$).

Signal flow diagram:

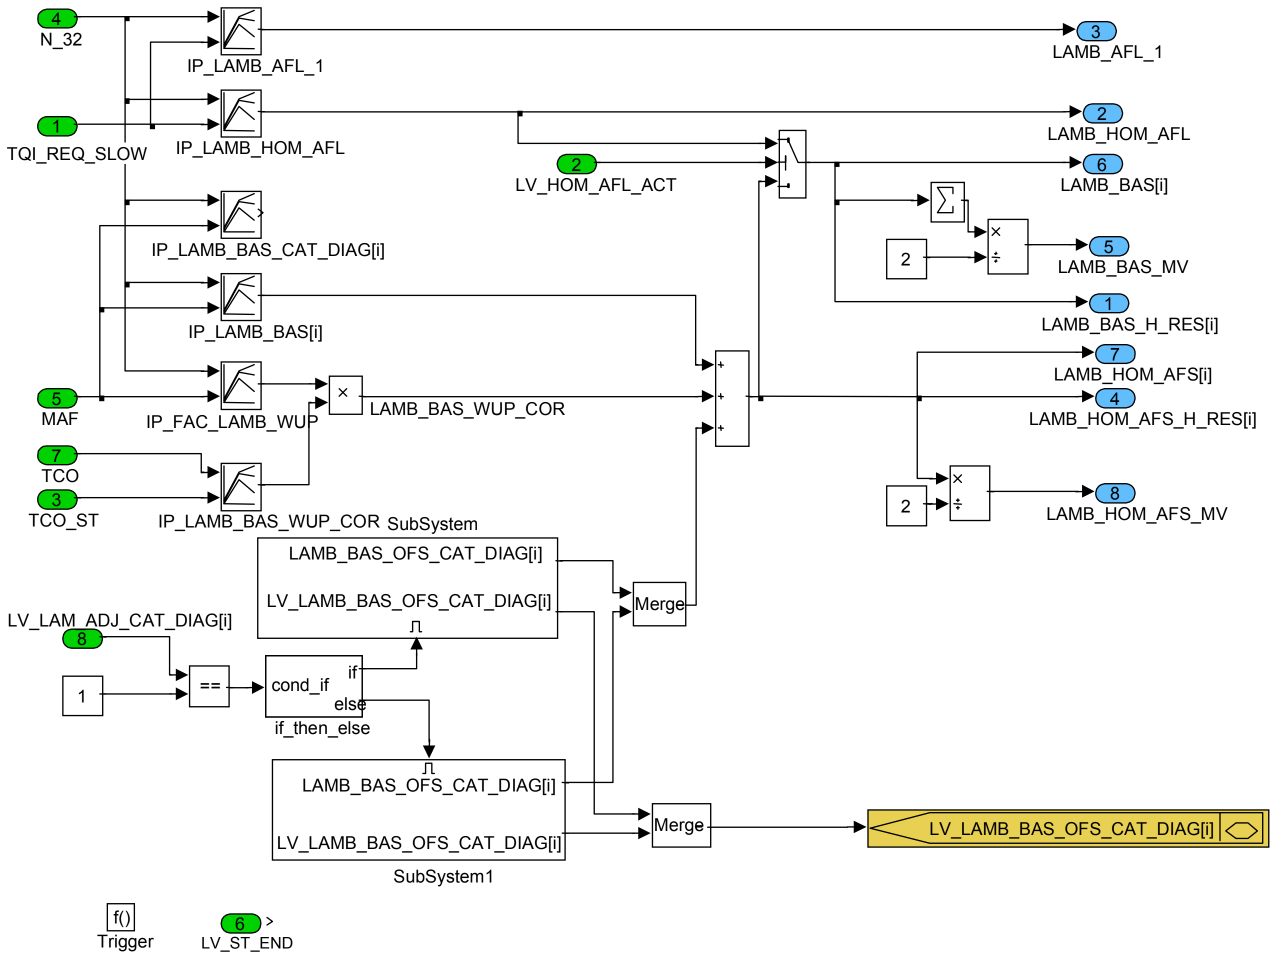

Diagram 1: Main flow

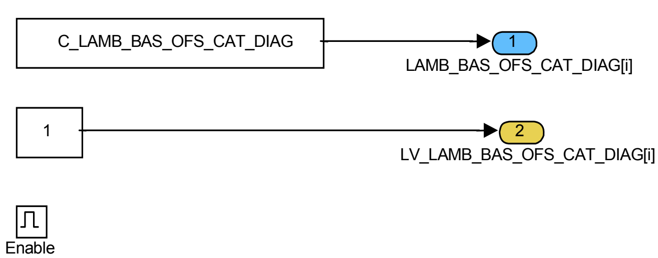

Diagram 2: Sub System

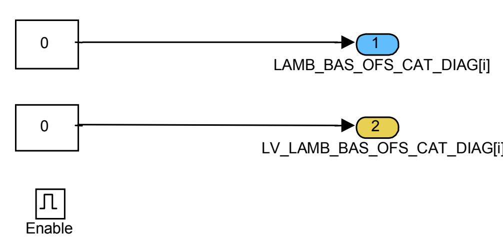

Diagram 3: Sub System1

Application conditions:

Activation: LV_ST_END = 1

Deactivation: -

Initialisation: at Reset or LV_ES = 0 -> 1: LAMB_BAS_H_RES[i] = 1
LAMB_BAS[i] = 1
LAMB_AFL_1 = 1
LAMB_HOM_AFL = 1
LAMB_HOM_AFS[i] = 1
LAMB_HOM_AFS_H_RES[i] = 1

Recurrence: 10 ms

Formula section:

The calculation of the basic lambda setpoint is executed in every engine operating state except engine start and engine stop. The load - speed depending value is corrected versus coolant temperature and coolant temperature at engine start and switches to AFL mode when requested. The step value for the switch is an extra output value.

The basic lambda setpoint is calculated with 2 different resolutions (LAMB_BAS[i] with a resolution of 0.98E-3 and LAMB_BAS_H_RES[i] with a resolution of 6.10E-5). The higher resolution is indicated in the variable by the suffix "_H_RES". If a transformation from high resolution variables to low resolution variables is necessary this calculation is indicated by a bit shift of 4 to the right (>> 4). The low resolution is 16-times lower ($2^4 = 16$). Vice versa from low to high resolution the bit shift is 4 times to the left (<<4).

LAMB_AFL_1 = IP_LAMB_AFL_1

LAMB_BAS_WUP_COR = IP_LAMB_BAS_WUP_COR * IP_FAC_LAMB_WUP

LAMB_HOM_AFL = IP_LAMB_HOM_AFL

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

(1) IF

LV_LAM_ADJ_CAT_DIAG[i] = 1

(In case of active catalyst diagnosis an offset is added to the basic lambda setpoint)

(1) THEN

LAMB_BAS_OFS_CAT_DIAG[i] = C_LAMB_BAS_OFS_CAT_DIAG

LV_LAMB_BAS_OFS_CAT_DIAG[i] = 1

(1) ELSE

DELTA_LAMB_SP_PUC[NC_CBK_EX_NR]	LV_LAMB_SP_EXT_ADJ[NC_CBK_EX_NR]	NC_CBK_EX_NR	

FUNCTION DESCRIPTION:

General information:

This module is calculated in homogenous mode only.

For the calculation of the lambda setpoint a coordination between the different lambda requirements with different priorities must be made. If there are lambda requirements of the same priority, the minimum or maximum lambda value is selected, see figure. The calculation is executed every 10 ms in every engine operating state except engine start.
The module manages, for example, to increase the engine torque (LAMB_FL) or to protect the catalyst from overheating (LAMB_COP[i]) or to regenerate the NOx-trap catalyst (LAMB_RGN[i]) or to heat up the catalyst more quickly after start (LAMB_CH) or not or handles the desulfation (LAMB_SO2P). The lambda request for single cylinder shut off is inserted twice to ensure the highest priority (higher than full load) and a feedback to torque calculation.

The input LAMB_BAS_H_RES[i] has a resolution of 6.1E-5. The high resolution is indicated by the suffix "_H_RES". All calculations in this module have to be done with this high resolution. For this all other inputs to the module must be transformed to this high resolution. The output variables are needed by the SW-modules which calculate with the high resolution and/or with a low resolution of 9.8E-4. Therefore a transformation back to lower resolution is necessary. This is indicated by a bit shift of 4 to the right (>> 4).

The low resolution is 16-times lower ($2^4 = 16$). Output variables without the suffix "_H_RES" have low resolution.

Signal flow diagram:

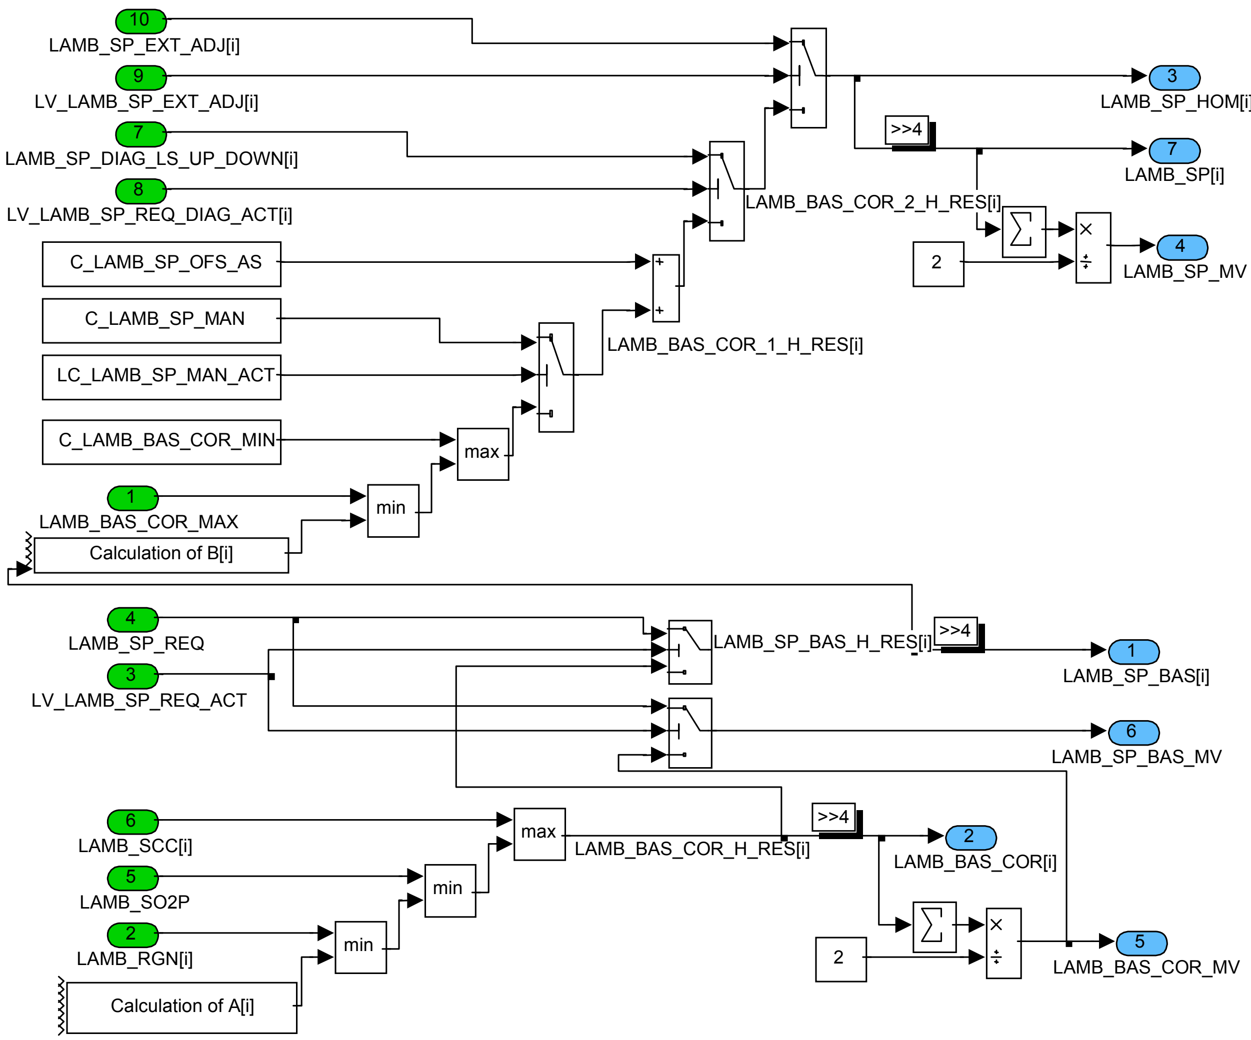

Diagram 4: Main flow

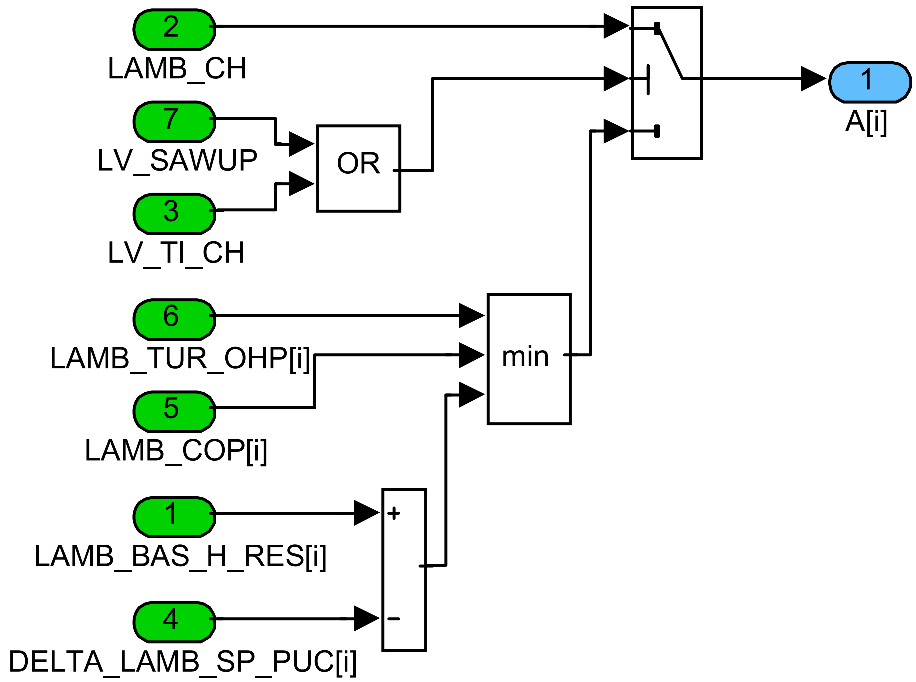

Diagram 5: Calculation of A[i]

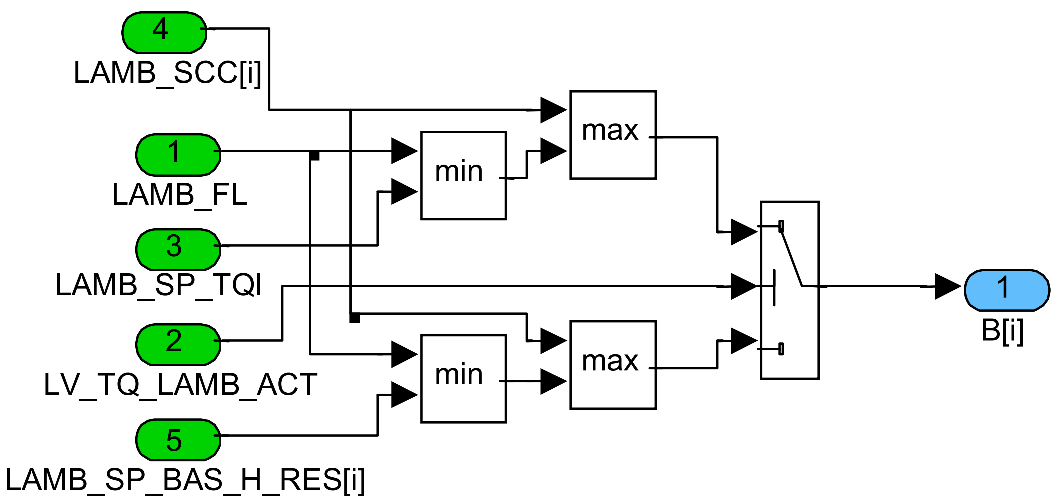

Diagram 6: Calculation of B[i]

Application conditions:

Activation: LV_ST_END = 1

Deactivation: -

Initialisation: at Reset or LV_ES = 0 -> 1: LAMB_SP[i] = 1
LAMB_SP_HOM[i] = 1
LAMB_BAS_COR[i] = 1

Recurrence: 10 ms

Formula section:

To simplify the survey, two intermediate values A[i] and B[i] are calculated. They have the high resolution (6.10E-5), but they are neither output nor visible.

7.56.1 Coordination of intermediate value A[i]:

The lambda request catalyst heating (LAMB_CH) is inserted if one of the two values LV_TI_CH=1 or LV_SAWUP=1.

In the other case, the minimal choice between basic lambda LAMB_BAS_H_RES[i] (including pull fuel cut-off (PUC) correction), LAMB_TUR_OHP[i] and LAMB_COP[i] for turbo charger respectively catalyst overheating prevention is chosen.

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

IF LV_TI_CH = 1
OR
LV_SAWUP = 1

THEN INTERMEDIATE_VALUE_A [i] = LAMB_CH

ELSE INTERMEDIATE_VALUE_A[i]
= MIN (LAMB_TUR_OHP[i], LAMB_COP[i], (LAMB_BAS_H_RES[i] –
DELTA_LAMB_SP_PUC[i]))

ENDIF
ENDFOR

7.56.2 Coordination of LAMB_BAS_COR[i] and it's mean value LAMB_BAS_COR_MV

The coordination handles the different lambda requirements with priority claim via minimum and maximum selections. At first, the smaller value between catalyst regeneration request (LAMB_RGN[i]) and the intermediate value A[i] is selected and entered in a second minimum selection with LAMB_SO2P for catalyst desulfation. Next is a maximum selection between the value selected before and the lambda request for single cylinder cut off LAMB_SCC[i]. The finally chosen value (shifted to low resolution) is a lambda output for TQI_SP_MAF calculation called LAMB_BAS_COR[i] .

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

LAMB_BAS_COR_H_RES[i] = MAX(LAMB_SCC[i], MIN(LAMB_SO2P, MIN(LAMB_RGN[i], INTERMEDIATE_VALUE_A[i])))

LAMB_BAS_COR [i] = LAMB_BAS_COR_H_RES[i] (>>4)

ENDFOR

For two cylinder banks (NC_CBK_EX_NR = 2) the mean value LAMB_BAS_COR is calculated:

LAMB_BAS_COR_MV = (LAMB_BAS_COR[1] + LAMB_BAS_COR[2]) / 2

For one bank solutions (NC_CBK_EX_NR = 1):

LAMB_BAS_COR_MV = LAMB_BAS_COR[1]

7.56.3 Calculation of LAMB_SP_BAS[i]

The input variable LV_LAMB_SP_REQ_ACT indicates whether there is a lambda setpoint request active or not. If the flag is active (LV_LAMB_SP_REQ_ACT = 1), LAMB_SP_BAS_H_RES[i] is set to the input value LAMB_SP_REQ, else LAMB_SP_BAS_H_RES[i] is equal to LAMB_BAS_COR_H_RES[i].

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

IF LV_ LAMB_SP_REQ_ACT = 1

THEN LAMB_SP_BAS_H_RES[i] = LAMB_SP_REQ (<<4)

ELSE LAMB_SP_BAS_H_RES[i] = LAMB_BAS_COR_H_RES[i]

ENDIF

LAMB_SP_BAS[i] = LAMB_SP_BAS_H_RES[i] (>>4)

ENDFOR

IF LV_ LAMB_SP_REQ_ACT = 1

THEN LAMB_SP_BAS_MV = LAMB_SP_REQ

ELSE LAMB_SP_BAS_MV = LAMB_BAS_COR_MV

ENDIF

7.56.4 Calculation of the intermediate value B[i]

In case of transition from hom. mode to hom. lean mode or back, the bit LV_TQ_LAMB_ACT is set to 1, and LAMB_SP_TQI is applied (if Single Cylinder Shut Off or Full Load Enrichment is not active).

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

IF LV_TQ_LAMB_ACT = 1

THEN INTERMEDIATE_VALUE_B[i] = MAX(LAMB_SCC[i], MIN(LAMB_FL, LAMB_SP_TQI))

ELSE INTERMEDIATE_VALUE_B[i] = MAX(LAMB_SCC[i], MIN(LAMB_FL, LAMB_SP_BAS_H_RES[i])

ENDIF

ENDFOR

7.56.5 Calculation of LAMB_BAS_COR_1_H_RES[i]

The intermediate value B[i] is checked, if a minimum or maximum threshold is exceeded. The minimum threshold is a calibratable constant and the maximum threshold is the input from an external module. After that, a manual application value C_LAMB_SP_MAN can be activated by a switch.

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

IF LC_LAMB_SP_MAN_ACT = 1

THEN LAMB_BAS_COR_1_H_RES[i] = C_LAMB_SP_MAN

ELSE LAMB_BAS_COR_1_H_RES[i] = MAX (C_LAMB_BAS_COR_MIN, MIN(LAMB_BAS_COR_MAX, INTERMEDIATE_VALUE_B[i]))

ENDIF

ENDFOR

7.56.6 Lambda coordination outputs LAMB_SP[i], LAMB_SP_H_RES[i] and the mean value LAMB_SP_MV

If the Lambda Sensor Test Function ist active (LV_LAMB_SP_REQ_DIAG_ACT[i] = 1), the output of the Lambda Coordination ist set to LAMB_SP_DIAG_LS_UP_DOWN[i].

FOR [i] = 1 **TO** NC_CBK_EX_NR **DO**:

(1) IF LV_LAMB_SP_REQ_DIAG_ACT[i] = 1

(1) THEN LAMB_BAS_COR_2_H_RES[i] = LAMB_SP_DIAG_LS_UP_DOWN[i]

(1) ELSE LAMB_BAS_COR_2_H_RES[i] = LAMB_BAS_COR_1_H_RES[i] + C_LAMB_SP_OFS_AS

(1) ENDIF

(2) IF LV_LAMB_SP_EXT_ADJ[i] = 1

(2) THEN LAMB_SP_HOM[i] = LAMB_SP_EXT_ADJ[i]

(2) ELSE LAMB_SP_HOM[i] = LAMB_BAS_COR_2_H_RES[i]

(2) ENDIF

LAMB_SP[i] = LAMB_SP_HOM[i] (>>4)

ENDFOR

For two cylinder banks (NC_CBK_EX_NR = 2) the mean value LAMB_SP_MV is calculated:

LAMB_SP_MV = (LAMB_SP[1] + LAMB_SP[2]) / 2

For one bank solutions (NC_CBK_EX_NR = 1):

LAMB_SP_MV = LAMB_SP[1]

Calibration data:

7.57 Catalyst enrichment function

7.57.1 Calculation of MAF integral during and after PUC phase

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_INT_PUC	V/O	0...FFFFH	0...1820.4167	0.0278	g
integral of mass air flow while active PUC					
MAF_INT_PUE	V/O	0...FFFFH	0...1820.4167	0.0278	g
integral of mass air flow while PUC is not active					

Input data:

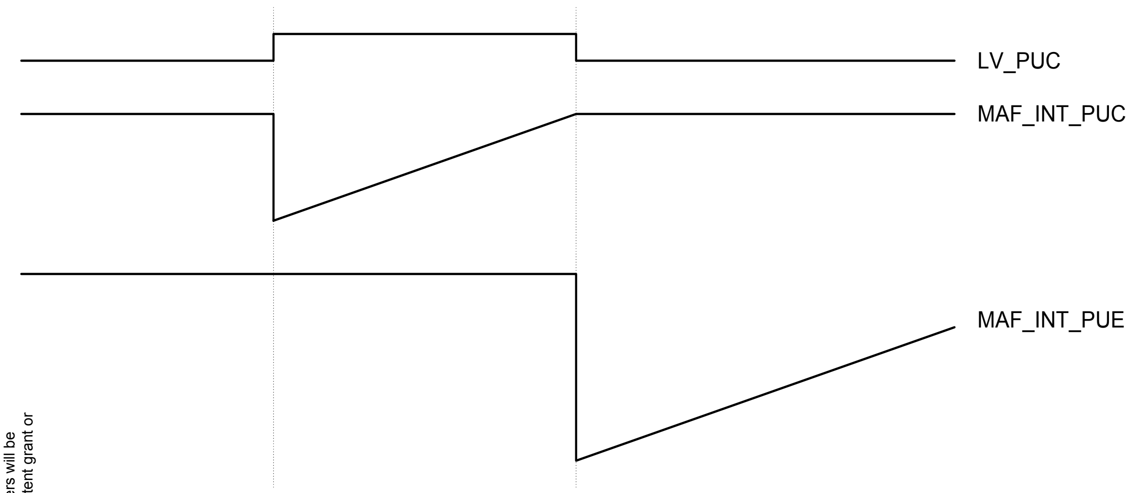
LV_PUC	MAF_CYL	LV_ST_END	LV_IGK

FUNCTION DESCRIPTION:

General information:

During pull fuel cutoff phase the mass air flow integral MAF_INT_PUC is calculated. This integral is used by the catalyst purge function for pre and main catalyst and by diagnosis functions for plausibility checks. After PUC the integral MAF_INT_PUE is calculated.

Signal flow diagram:



Description:

The calculation of MAF_INT_PUC is executed every TA as long as the operation status PUC is fulfilled (LV_PUC = 1). MAF_INT_PUC is initialized by 0 at each rising edge of LV_PUC.

MAF_INT_PUE is calculated when LV_PUC is not set and is initialized by 0 at each falling edge of LV_PUC.

Application conditions:

Initialisation: at LV_IGK = 0 -> 1 and at ECU reset
MAF_INT_PUC = 0
MAF_INT_PUE = 0

Recurrence: TA = 20 ms

Activation: LV_ST_END = 1

Deactivation: -

Formula section:

IF LV_PUC = 0 → 1 **THEN**
  MAF_INT_PUC = 0
ENDIF

IF LV_PUC = 1 → 0 **THEN**
  MAF_INT_PUE = 0
ENDIF

IF LV_PUC = 1 THEN
  MAF_INT_PUC = MAF_INT_PUC + MAF_CYL * NC_FAC_MAF_INT_20
ELSE
  MAF_INT_PUE = MAF_INT_PUE + MAF_CYL * NC_FAC_MAF_INT_20
ENDIF

NC_FAC_MAF_INT_20 = TA / 3.6 = 0.02 s / 3.6

Configuration data:

FUNCTION DESCRIPTION:

General information:

The catalyst purge function realizes a fast adjustment of optimized conditions for a high catalyst efficiency after a transition from pull fuel cutoff (PUC) or other lean air fuel mixture conditions to stoichiometric conditions. That requires a fuel enrichment in order to reduce the oxygen content inside the catalyst. The degree of the fuel enrichment depends on the oxygen and the NO_2 content in the catalyst.

The different purge cases after lean air fuel mixture condition, that are described within this function, are catalyst purge:

- after pull fuel cutoff (PUC),
- after secondary air injection (SA),
- after hot start (HST),
- catalyst heating (CH) with lean air fuel mixture condition,
- that is requested from other functions.

The function takes into account a cat configuration with pre and main catalyst. During pre cat purge a measure for the amount of the main cat purge is calculated. By means of calibration data the main cat purge can also be switched off (all values within IP_FAC_PCAT_MAIN_CAT_PUC must be set to zero).

For the pre cat purge a calculated amount of MAF (in case of PUC) or a calibrated amount of MAF (in case of SA, HST, CH) must pass through the catalyst. During this phase a measure for the amount of the main cat purge is determined. The requested cat purge is an exception because the here described function only reacts on the request and sets the lambda set point shift. The activation and deactivation of the cat purge is localized in the function that sends the request.

All cat purge functions – except the requested one – use a ramp to increase the lambda set point shift and to decrease it in case the main cat purge was activated. This is due to driveability. Both ramps can be switched off by setting the calibration data to its maximum value.

If two separate catalyst systems are concerned then

i = 1, for cylinder bank 1,

i = 2, for cylinder bank 2,

otherwise

i = 1.

Figure 99: Pre and main cat purge exemplarily shown for "after PUC purge"

Description:

Activation:

The general activation conditions of the cat purge function (pre and main cat purge) are summarized by the logical LV_INH_INT_PUC_i. It must be set to 0 as a pre condition to start the enrichment function for all lean air fuel mixture conditions - except for requested cat purge.

LV_PCAT_PURGE_PUC_i activates the function for cat purge after PUC phase (PUC). The logical is set to 1 if no inhibition is detected (LV_INH_INT_PUC_i = 0) and additionally the MAF integral calculated during PUC (MAF_INT_PUC) has exceeded the calibration limit C_MAF_INT_PUC_MIN or MAF_INT_ACT_PUC_i is above 0. This latter condition is an indication that the previous cat purge function after PUC was interrupted before the truncation condition MAF_INT_ACT_PUC_i = 0 was reached. Furthermore a transition from PUC phase (LV_PUC = 1 → 0) must have been recognized and therefore LV_PUC_TRIG must be set to 1 and no cylinder must be shut off (LV_IND_FCUT = 0).

LV_PCAT_PURGE_SA_i activates the function for cat purge after secondary air (SA) injection. The logical is set to 1 if no inhibition is detected (LV_INH_INT_PUC_i = 0) and the transition from "SA active" to "SA not active" (LV_SAWUP = 1 → 0) occurs. As cat purge after PUC has the highest priority LV_PCAT_PURGE_PUC_i and LV_MAIN_CAT_PURGE_i must both not be set. No cylinder must be shut off (LV_IND_FCUT = 0).

LV_PCAT_PURGE_HST_i activates the function for cat purge after hot start (HST). The logical is set to 1 if no inhibition is detected (LV_INH_INT_PUC_i = 0) and the end of a hot start is recognized (LV_ST_END = 0 → 1 and TCO_ST >= C_TCO_THD_HST). As cat purge after hot start has the lowest priority the logical variables LV_PCAT_PURGE_PUC_i, LV_PCAT_PURGE_SA_i, LV_PCAT_PURGE_CH_i and LV_MAIN_CAT_PURGE_i must not be set. No cylinder must be shut off (LV_IND_FCUT = 0).

LV_PCAT_PURGE_CH_i activates the function for cat purge after catalyst heating (CH) under lean conditions. The logical is set to 1 if no inhibition is detected (LV_INH_INT_PUC_i = 0) and the end of the heating phase (LV_TI_CH = 1 → 0) is recognized. As cat purge after PUC has the highest priority LV_PCAT_PURGE_PUC_i and LV_MAIN_CAT_PURGE_i must both not be set. Cat purge after SA and cat purge after CH have the same priority. No cylinder must be shut off (LV_IND_FCUT = 0).

LV_ACT_INT_PUC_AFL_i indicates that cat purge is requested by another function. The responsibility for activating cat purge is at the calling function.

Initialization:

If the flag for ignition key LV_IGK switches from 0 to 1 or at ECU reset the variables MAF_INT_ACT_PUC_i, DELTA_LAMB_SP_PUC_i, LV_ACT_INT_PUC_i, LV_PCAT_PURGE_PUC_i, LV_PCAT_PURGE_SA_i, LV_PCAT_PURGE_HST_i, LV_PCAT_PURGE_CH_i, LV_MAIN_CAT_PURGE_i and some internal variables (see formula section) must be set to 0.

For all different cases of catalyst purge – except for requested purge - the following variables are initialized at function activation as follows:

LV_DOWN_RAMP_ACT_i = 0

LV_VLS_DOWN_PUC_ACT_MAX_i = 0

MAF_INT_CAT_LOAD_i = 0

MAF_INT_SAMPLE_STEP_i = 0

MAF_INT_PURGE_REST_i = NC_MAF_INT_PURGE_MAX

QUO_MAF_INT_PURGE_i = 1 (FF hex)

In case of cat purge after PUC phase MAF_INT_ACT_PUC_i is initialized by IP_MAF_INT_ACT_PUC * IP_FAC_CAT_EFF_PUC + MAF_INT_ACT_PUC_i. This latter value is the remaining MAF integral of a previous purge function activation. MAF_INT_ACT_PUC_i is furthermore limited to the maximum value of C_MAF_INT_ACT_PUC_MAX. The factor FAC_ADD_PCAT_MAIN_CAT_PUC_i, that is an additional weighting factor for IP_FAC_PCAT_MAIN_CAT_PUC, is initialized by 1, because the map is calibrated for cat purge after PUC phase and therefore no weighting is necessary. IP_FAC_PCAT_MAIN_CAT_PUC is the temperature dependent volume ratio between pre and main cat. This factor map is used for main cat purge and must be calibrated with 0 in case that no main cat is implemented or no main cat purge is desired.

In case of cat purge after secondary air injection MAF_INT_ACT_PUC_i is initialized by C_MAF_INT_PCAT_PURGE_SA * IP_FAC_CAT_EFF_PUC. The factor FAC_ADD_PCAT_MAIN_CAT_PUC_i is initialized by C_FAC_ADD_PCAT_MAIN_CAT_PUC_SA. This latter calibration data is a weighting factor in order to realize deviations from the map that is given for cat purge after PUC phase. By means of this data main cat purge can also be switched off only for cat purge after secondary air injection.

In case of cat purge after hot start MAF_INT_ACT_PUC_i is initialized by C_MAF_INT_PCAT_PURGE_HST * IP_FAC_CAT_EFF_PUC. The factor FAC_ADD_PCAT_MAIN_CAT_PUC_i is initialized by C_FAC_ADD_PCAT_MAIN_CAT_PUC_HST. By means of this latter calibration data main cat purge can also switched off only for cat purge after hot start.

In case of cat purge after lean catalyst heating MAF_INT_ACT_PUC_i is initialized by C_MAF_INT_PCAT_PURGE_CH * IP_FAC_CAT_EFF_PUC. The factor FAC_ADD_PCAT_MAIN_CAT_PUC_i is initialized by C_FAC_ADD_PCAT_MAIN_CAT_PUC_CH. By means of this latter calibration data main cat purge can also switched off only for cat purge after catalyst heating.

After MAF_INT_ACT_PUC_i was calculated MAF_INT_CAT_LOAD_MAIN_i will be initialized for all different purge cases by MAF_INT_ACT_PUC_i * IP_FAC_PCAT_MAIN_CAT_PUC_i * FAC_ADD_PCAT_MAIN_CAT_PUC_i. The calculation is executed by using the 16 high-order bits of MAF_INT_ACT_PUC_i (right shift of 7) and rounding the lowest of these bits (((MAF_INT_ACT_PUC_i>>6)+1)>>1). So the multiplication can be executed with a 16 bit operation.

With this calculation a pre estimation of the main cat purge amount is done. At the end of pre cat purge the main cat purge amount is updated with the real MAF integral during pre cat purge (this can be different from MAF_INT_ACT_PUC_i in case of termination via downstream sensor). Finally the total purge integral is calculated (MAF_INT_TOT_PURGE_i).

Function description of pre cat purge:

Figure 97 describes the functionality for pre cat purge after PUC, SA, HST, CH and for the requested cat purge. Figure 98 shows the main cat purge. In Figure 99 the function sequence is given for cat purge after PUC with and without interruption of a new PUC phase. The function sequence for the other cases is similar; only the determination of the starting value for MAF_INT_ACT_PUC_i is different (see initialization).

Firstly the function detects whether a cat purge is requested by another function and PUC is not active. In this case the lambda set point shift is applied as long as LV_ACT_INT_PUC_AFL_i is set to 1.

If the function was activated because of cat purge after PUC (LV_PCAT_PURGE_PUC_i = 1) and a new PUC phase is recognized (LV_PUC = 1), the lambda set point shift is set to 0 and the activation conditions are all set to 0. The remaining MAF integral MAF_INT_ACT_PUC_i is not set to 0 in order to use it for next cat purge after PUC.

If one of the inhibition conditions is fulfilled (that means LV_INH_INT_PUC_i = 1) or a new PUC phase is recognized (in this case LV_PCAT_PURGE_PUC_i = 0), the lambda set point shift is set to 0, the remaining MAF integral MAF_INT_ACT_PUC_i is set to 0 and the activation conditions are all set to 0.

If the MAF integral MAF_INT_ACT_PUC_i has reached 0 or if the downstream sensor detects a rich mixture (VLS_DOWN_i > C_VLS_DOWN_PUC_ACT_MAX), the activation conditions for pre cat purge are set to 0 and the activation condition for main cat purge is set to 1. The purge amount for main cat purge (MAF_INT_CAT_LOAD_MAIN_i) is calculated based on the real pre cat purge MAF integral (MAF_INT_CAT_LOAD_i). Also this multiplication can be executed with a 16 bit operation by using only the 16 high-order bits and rounding of MAF_INT_CAT_LOAD_i as described above. The total purge integral (MAF_INT_TOT_PURGE_i) is updated and the ratio between of current rest integral and total MAF integral is calculated (QUO_MAF_INT_PURGE_i). The MAF integral MAF_INT_ACT_PUC_i is set to 0 (in case of sensor has detected rich mixture it could be still above 0).

The downstream sensor signal is only evaluated if the sensor is in heating mode and no error is detected (STATE_LSH_DOWN_i = HEATING and LV_ERR_LS_DOWN_i = 0). The detection of a rich mixture via downstream sensor is furthermore only activated if the sensor voltage was at least once below C_VLS_DOWN_PUC_ACT_MAX since the function was activated. This is indicated by LV_VLS_DOWN_PUC_ACT_MAX. It is set to 1 if the voltage was below the threshold. Otherwise it is 0.

Based of the current MAF_CYL and of the remaining MAF integral the remaining time can be calculated and compared to the time needed to ramp down the lambda set point shift. If the remaining time gets below half of the down ramp time the down ramping of DELTA_LAMB_SP_PUC_i is initiated. The down ramping is realized by subtracting the decrement C_DELTA_LAMB_SP_PUC_DEC from the current set point shift and taking the minimum of the result and the map value.

The remaining time is calculated by:

$t_{remaining}$ = MAF_INT_PURGE_REST_i / (MAF_CYL * IP_DELTA_LAMB_SP_PUC)

The ramp down time is calculated by:

t_{ramp_down} = DELTA_LAMB_SP_PUC_i * TA / C_DELTA_LAMB_SP_PUC_DEC

The condition $t_{remaining} < 0.5 * t_{ramp\_down}$ is realized by:

((MAF_CYL * IP_DELTA_LAMB_SP_PUC * NC_FAC_MAF_INT_20) * IP_DELTA_LAMB_SP_PUC) > (2 * MAF_INT_PURGE_REST_i * C_DELTA_LAMB_SP_PUC_DEC)

Depending on the condition above the determination of the lambda set point shift (DELTA_LAMB_SP_PUC_i) is executed. The down ramping is realized by a maximum allowed decrease per TA of the lambda shift. The up ramping is realized similar (maximum allowed increase of the shift per TA) if the condition is not fulfilled. If the down ramping was started once the bit LV_DOWN_RAMP_ACT_i is set. So, - by evaluating this flag -, if the down ramping condition is not fulfilled any mode (e.g. change of MAF_CYL) the lambda set point shift is kept constant.

Then the following calculations are carried out:

- calculation of MAF during one sample step (MAF_INT_SAMPLE_STEP_i); if the calculation result is 0 then MAF_INT_SAMPLE_STEP_i is set to NC_MAF_INT_SAMPLE_STEP_MIN;
- decreasing of MAF_INT_ACT_PUC_i by MAF_INT_SAMPLE_STEP_i;
- increasing of MAF_INT_CAT_LOAD_i by MAF_INT_SAMPLE_STEP_i;
- calculation of the remaining MAF integral MAF_INT_PURGE_REST_i;
- calculation of the ratio between current rest integral and total MAF integral QUO_MAF_INT_PURGE_i.

Function description of main cat purge:

If the condition LV_MAIN_CAT_PURGE_i is set to 1 the purge function for the main catalyst is activated. LV_MAIN_CAT_PURGE_i is set to one if the pre cat purge was not interrupted.

For the case that cat purge was requested by another function (via LV_ACT_INT_PUC_AFL_i) the purge of the main cat is included in the functionality for the pre cat. This became necessary because the control of cat purge in this case is outside the here described function.

The main cat purge is executed as long as the MAF integral MAF_INT_CAT_LOAD_MAIN_i has not reached 0. The start value was calculated during pre cat purge. When MAF_INT_CAT_LOAD_MAIN_i has reached 0 the lambda set point shift (DELTA_LAMB_SP_PUC_i) and LV_MAIN_CAT_PURGE_i are both set to 0. DELTA_LAMB_SP_PUC_i should be already 0 but as the determination of the down ramping condition is only a predication the resetting of DELTA_LAMB_SP_PUC_i is done anyway. If the main cat purge is interrupted by a new PUC phase or by the case that the inhibition conditions are getting valid DELTA_LAMB_SP_PUC_i and LV_MAIN_CAT_PURGE_i are also immediately set to 0.

As long as main cat purge is active the following calculations are carried out:

- determination of lambda set point shift as described for pre cat purge; the rest integral is determined directly by using MAF_INT_CAT_LOAD_MAIN_i;
- calculation of MAF during one sample step (MAF_INT_SAMPLE_STEP_i);
  if the calculation result is 0 then MAF_INT_SAMPLE_STEP_i is set to NC_MAF_INT_SAMPLE_STEP_MIN;
- decreasing of MAF_INT_CAT_LOAD_MAIN_i by MAF_INT_SAMPLE_STEP_i;
- calculation of the ratio between current rest integral and total MAF integral QUO_MAF_INT_PURGE_i.

Calculation of LV_ACT_INT_PUC_i:

If one of the activation conditions for pre cat purge or for main cat purge is active the flag LV_ACT_INT_PUC_i must be set to one. The conditions are given with the flags LV_PCAT_PURGE_PUC_i, LV_PCAT_PURGE_SA_i, LV_PCAT_PURGE_HST_i, LV_PCAT_PURGE_CH_i, LV_ACT_INT_PUC_AFL_i and LV_MAIN_CAT_PURGE_i.

Application conditions:

Initialisation:

At LV_IGK = 0 -> 1 and at ECU reset:
MAF_INT_ACT_PUC_i = 0
DELTA_LAMB_SP_PUC_i = 0
LV_ACT_INT_PUC_i = 0
LV_PCAT_PURGE_PUC_i = 0
LV_PCAT_PURGE_SA_i = 0
LV_PCAT_PURGE_HST_i = 0
LV_PCAT_PURGE_CH_i = 0
LV_MAIN_CAT_PURGE_i = 0
LV_PUC_TRIG_i = 0
LV_PUC_OLD_i = LV_PUC
LV_SAWUP_OLD_i = LV_SAWUP
LV_ST_END_OLD_i = LV_ST_END
LV_TI_CH_OLD_i = LV_TI_CH

For CAT purge after PUC phase (LV_PCAT_PURGE_PUC_i = 1):

```
IF LV_PCAT_PURGE_PUC_i = 0 → 1 THEN
   LV_DOWN_RAMP_ACT_i = 0
   LV_VLS_DOWN_PUC_ACT_MAX_i = 0
   MAF_INT_CAT_LOAD_i = 0
   MAF_INT_CAT_LOAD_MAIN_i = 0
   MAF_INT_SAMPLE_STEP_i = 0
   MAF_INT_PURGE_REST_i = NC_MAF_INT_PURGE_MAX
   MAF_INT_ACT_PUC_i = MIN(C_MAF_INT_ACT_PUC_MAX;
                      (IP_MAF_INT_ACT_PUC * IP_FAC_CAT_EFF_PUC + MAF_INT_ACT_PUC_i) )
   FAC_ADD_PCAT_MAIN_CAT_PUC_i = 1
   MAF_INT_CAT_LOAD_MAIN_i =
                    (16 high-order bits with lowest bit rounded of MAF_INT_ACT_PUC_i) *
                    IP_FAC_PCAT_MAIN_CAT_PUC_i * FAC_ADD_PCAT_MAIN_CAT_PUC_i
   MAF_INT_TOT_PURGE_i = MAF_INT_ACT_PUC_i + MAF_INT_CAT_LOAD_MAIN_i
   QUO_MAF_INT_PURGE_i = 1
   LV_PCAT_PURGE_SA_i = 0  /* reset all other purges */
   LV_PCAT_PURGE_HST_i = 0
   LV_PCAT_PURGE_CH_i = 0
   LV_MAIN_CAT_PURGE_i = 0
ENDIF
```

For CAT purge after SA phase (LV_PCAT_PURGE_SA_i = 1):

```
IF LV_PCAT_PURGE_SA_i = 0 → 1 THEN
   LV_DOWN_RAMP_ACT_i = 0
   LV_VLS_DOWN_PUC_ACT_MAX_i = 0
   MAF_INT_CAT_LOAD_i = 0
   MAF_INT_CAT_LOAD_MAIN_i = 0

FUNCTION DESCRIPTION:

General information:

If two separate catalyst systems are concerned then

i = 1, for cylinder bank 1,

i = 2, for cylinder bank 2.

If only one is considered then

i = 1

Description:

The activation conditions for the cat purge function (pre and main cat purge) are summarized by the logical LV_INH_INT_PUC_i. It must be set to 0 (cat purge not inhibited) as a pre condition to start the enrichment function for all lean air fuel mixture conditions - except for requested cat purge.

One of the following conditions must be met in order to set LV_INH_INT_PUC_i = 1:

- engine speed exceed a calibration limit: N_32 > C_N_MAX_CAT_PURGE
- engine cooling temperature is below or equal calibration limit:
  TCO ≤ C_TCO_ACT_PUC_MIN
- ASR intervention : LV_ASR_ACT = 1
- mass air flow exceed a calibration limit:
  MAF_CYL > C_MAF_CYL_ACT_INT_PUC_MAX
- the upstream oxygen sensor voltage crossed the voltage threshold C_THD_VLS_UP_CAT_PURGE from higher to lower
- the cat purge lambda difference will become lower or equal than C_THD_DELTA_LAMB_SP_PUC during the release of a Lambda Adaption phase
- If VLS_UP is below the threshold C_VLS_UP_THD_LEAN_PURGE after combustion MAF integral MAF_INT_PUE exceeds C_MAF_INT_PUE_MIN_LEAN_PURGE the purge mixture is determined to be lean (e.g. intake system leak).
- If VLS_DOWN is over threshold C_VLS_DOWN_MAX_CAT_PURGE (PUC is not long enough to make pre-catalyst lean) when MAF_INT_PUC_NOT_ACT exceeds C_MAF_INT_PUC_NOT_ACT_MAX_PURGE.

If these conditions are not met, then LV_INH_INT_PUC_i = 0.

As LV_INH_INT_PUC_i remains to 1 only 20msec. if one of above condition is met, a second flag LV_INH_INT_PUC_PUE_i is defined to indicate to Downstream O2 sensor diagnosis (PUE-diagnosis) that Catalyst Purge was early stopped : this flag is set to 1 if LV_INH_INT_PUC_i = 1 and reseted only at next PUC phase.

The temperature of the main cat is estimated by assuming a constant temperature difference (C_TEMP_DIF_PCAT_MAIN_CAT) between pre and main cat temperature. TEMP_CAT is the modeled pre cat temperature.

Application conditions:

Initialisation:	LV_INH_INT_PUC_i = LV_INH_INT_PUC_PUE_i = 1 all other outputs = 0
Recurrence:	TA = 20 ms
Activation:	always
Deactivation:	never

Formula section:

Set activation condition for inhibit CAT purge (LV_INH_INT_PUC_i = 1):

IF N_32 > C_N_MAX_CAT_PURGE **OR**

MFF_SP_HOM_CLC[NC_CBK_EX_NR]	PORT_AV_GRD	CONF_PORT	LV_ERR_PORT

FUNCTION DESCRIPTION:

General information:

The external intervention factor FAC_MFF_EXT is used as port flap correction factor.

During port flap closing (=activation) a wall film enleanment compensation can be considered; during port flap opening (= deactivation to passive position) a wall film enrichment compensation can be considered to compensate lambda deviations.

The wall film compensation is only applied in case of port flap variant set (CONF_PORT = 1) or no error on port flap control (LV_ERR_PORT = 0).

Application conditions:

Initialisation: at reset: FAC_MFF_EXT = 1
FAC_MFF_CST_EXT = 1
FAC_MFF_BAS_EXT = 1
FAC_MFF_ST_EXT = 1
MFF_SP_MAX_DC = 0

FAC_MFF_CST_EXT = 1

FAC_MFF_ST_EXT = 1

MFF_ADD_LAM_AD_OUT_EXT = C_N_TOL_ADD_RNG_LAM_AD * MFF_CO_IS/N_32

If MFF_SP_1_HOM[0] > MFF_SP_MAX_DC

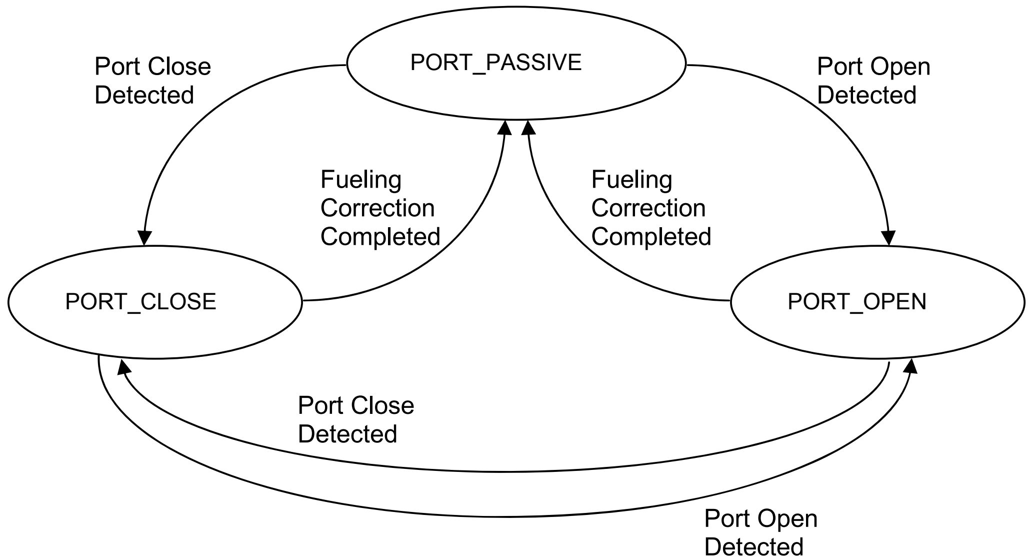
Then MFF_SP_MAX_DC = MFF_SP_1_HOM[0]

Endif

If CONF_PORT = 1 and LV_ERR_PORT = 0, then the following Port flap correction is calculated.

Port flap correction:

Diagram of port flap fuel correction state machine is shown below.



7.60.1 State PORT_PASSIVE

Formula Section :

FAC_MFF_EXT = 1

CYC_PORT_OPEN = 0

CYC_PORT_CLOSE = 0

Port flap open detection and Transition condition to PORT_OPEN

if PORT_AV_GRD <= C_PORT_GRD_OPEN_DET //port flap close-to-open transition

When the port flap opens, the gradient becomes negative, with C_PORT_GRD_OPEN_DET can be determined if the function gets active or not

then LV_PORT_OPEN_DET = 1

endif

Port flap close detection and Transition condition to PORT_CLOSE

if PORT_AV_GRD >= C_PORT_GRD_CLOSE_DET //port flap open-to-close transition

When the port flap closes, the gradient becomes positive, with C_PORT_GRD_CLOSE_DET can be determined if the function gets active or not

then LV_PORT_CLOSE_DET = 1

endif

7.60.1.1 Transition condition to PORT_OPEN

Formula Section :

if LV_PORT_OPEN_DET = 1
and FAC_PORT_DEAC >= C_FAC_PORT_OPEN_THD
then STATE_PORT_MFF_COR = PORT_OPEN
endif

7.60.1.2 Transition condition to PORT_CLOSE

Formula Section :

if LV_PORT_CLOSE_DET = 1
and FAC_PORT_DEAC <= C_FAC_PORT_CLOSE_THD
then STATE_PORT_MFF_COR = PORT_CLOSE
endif

7.60.2 State PORT_OPEN

Formula Section :

As long as the state machine stays in PORT_OPEN, the cycle counter is incremented continuously every recurrence.

Increment CYC_PORT_OPEN //limits to maximum

Fuel correction determination during PORT_OPEN transition

if LC_PORT_MFF_ADD_SEL = 1
then // Chosen to use additive to correct port open fueling
IF MFF_SP_HOM_CLC = 0
Then FAC_MFF_EXT = 1
Else
FAC_MFF_EXT = (1 + IP_MFF_ADD_PORT_OPEN / MFF_SP_HOM_CLC)
* IP_COR_TCO_MFF_PORT_OPEN
else // Chosen to use factor to correct port open fueling
FAC_MFF_EXT = IP_FAC_MFF_PORT_OPEN * IP_COR_TCO_MFF_PORT_OPEN
endif

7.60.2.1 Transition condition to PORT_PASSIVE

After completion of the port transition fuelling correction, state transits to PORT_PASSIVE

if CYC_PORT_OPEN >= C_CYC_PORT_OPEN_MAX //correction complete

then STATE_PORT_MFF_COR = PORT_PASSIVE

LV_PORT_OPEN_DET = 0 //reset port open/close detection

LV_PORT_CLOSE_DET = 0

endif

7.60.2.2 Transition condition to PORT_CLOSE

During the brief port-open fueling period, when port-close is detected, state transits to PORT_CLOSE through PORT_PASSIVE.

if PORT_AV_GRD >= C_PORT_GRD_CLOSE_DET //port flap open-to-close transition

then STATE_PORT_MFF_COR = PORT_PASSIVE

LV_PORT_OPEN_DET = 0

LV_PORT_CLOSE_DET = 1

endif

7.60.3 State PORT_CLOSE

Formula Section :

As long as the state machine stays in PORT_CLOSE, the cycle counter is incremented continuously every recurrence.

Increment CYC_PORT_CLOSE // limits to maximum

Fuel correction determination during PORT_CLOSE transition

if LC_PORT_MFF_ADD_SEL = 1

then // Chosen to use additive to correct port open fueling

IF MFF_SP_HOM_CLC = 0

Then FAC_MFF_EXT = 1

Else

FAC_MFF_EXT =(1+ IP_MFF_ADD_PORT_CLOSE / MFF_SP_HOM_CLC)

* IP_COR_TCO_MFF_PORT_CLOSE

else // Chosen to use factor to correct port open fueling

FAC_MFF_EXT = IP_FAC_MFF_PORT_CLOSE

* IP_COR_TCO_MFF_PORT_CLOSE

endif

7.60.3.1 Transition condition to PORT_PASSIVE

After completion of the port transition fueling correction, state transits to PORT_PASSIVE

if CYC_PORT_CLOSE >= C_CYC_PORT_CLOSE_MAX //correction complete

then STATE_PORT_MFF_COR = PORT_PASSIVE

LV_PORT_CLOSE_DET = 0 //reset port open/close detection

LV_PORT_OPEN_DET = 0

endif

7.60.3.1.1 Transition condition to PORT_OPEN

During the port close fueling period, when port-open is detected, state transits to PORT_OPEN through PORT_PASSIVE.

if PORT_AV_GRD <= C_PORT_GRD_OPEN_DET //port flap open-to-close transition

then STATE_PORT_MFF_COR = PORT_PASSIVE

LV_PORT_OPEN_DET = 1

LV_PORT_CLOSE_DET = 0

endif

7.61.2 Runtime reduction

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: -

Recurrence : LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment sychronous

This chapter describes runtime reduction steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to that intake or exhaust bank, which is allocated to the related cylinder by NC_IN_REF and NC_LAMB_REF. The control variables for cylinder and bank dependent calculations will be imported via CTR_CYL_NR_xxx and CTR_CBK_xxx data.

Formula Section :

7.61.2.1 Determine cylinder and bank numbers for follow up calculations

8.2.1 General

The controller consits of three parts:

- PD-part
- PD-part separation into slow and fast path
- I-part

The controller can be enabled/disabled with several calibration bits:

- If LC_ISC_INH == 1, then the idle speed controller is completly disabled:

TQ_DIF_P_D_IS = 0
TQ_DIF_P_D_SLOW_IS = 0
TQ_DIF_P_D_FAST_IS = 0
TQ_DIF_I_IS = 0

- If LC_TQ_DIF_P_D_INH_AS == 1, then only the PD-part is disabled:

TQ_DIF_P_D_IS = 0
TQ_DIF_P_D_SLOW_IS = 0
TQ_DIF_P_D_FAST_IS = 0

- If LC_TQ_DIF_I_INH_AS == 1, then only the I-part is disabled:

TQ_DIF_I_IS = 0

- If LC_TQ_ADD_I_INH_AS == 1, then only the I-part's increment (input of the integrator) is set to zero:

TQ_ADD_I_IS = 0 $\Rightarrow$ TQ_DIF_I_IS = const.

- Additionally, the controller can be disabled completely by an external diagnosis tool. Therefore, the variable LV_ISC_INH_EXT_ADJ is used. If LV_ISC_INH_EXT_ADJ == 1, then

TQ_DIF_P_D_IS = 0
TQ_DIF_P_D_SLOW_IS = 0
TQ_DIF_P_D_FAST_IS = 0
TQ_DIF_I_IS = 0.

8.2.2 Filtering of N_GRD

Application conditons:

Initialization: N_GRD_FIL_IS = N_SP_IS_COR_GRD_FIL_IS = 0 rpm/s at reset
Recurrence 10 ms
Activation: at every engine state
Scheduling: This function has to be calculated immediate **before the controller** and **after the application incidences**.

In order to be able to smooth the gradient for the idle speed control, a 1st order low-pass filter can be used to define N_GRD_FIL_IS.

Formula section:

$$N\_GRD\_FIL\_IS_k = N\_GRD\_FIL\_IS_{k-1} + (N\_GRD_k - N\_GRD\_FIL\_IS_{k-1}) \cdot C\_CRLC\_N\_GRD.$$

$$N\_SP\_IS\_COR\_GRD\_FIL\_IS_k = N\_SP\_IS\_COR\_GRD\_FIL\_IS_{k-1} + (N\_SP\_IS\_COR\_GRD_k - N\_SP\_IS\_COR\_GRD\_FIL\_IS_{k-1}) * C\_CRLC\_N\_GRD$$

8.2.3 PD- Controller

General information:

The PD-part is devided into three states:

STATE_P_D_ISC = P_D_PASSIVE:
Initialization (at reset or from LV_IGK = 0 → 1; from all other states in case of LV_ES = 1)

STATE_P_D_ISC = P_D_NORMAL:
In this state the evaluation of the controller maps takes place.

STATE_P_D_ISC = RAMP_TO_ZERO:
Ramp to passive value, which is always zero for the PD-part; in this state the PD-part is ramped down to zero in case of deactivation of the PD-part

Application conditons:

Initialization: TQ_DIF_P_D_IS = 0 Nm at reset
Recurrence 10 ms
Activation: at every engine state
Scheduling: This function has to be calculated immediate **before the module "Torque Coordination"** and **after the application incidences and the filtered gradient determination**.

Formula section:

For special function test, it´s possible to set TQ_DIF_P_D_IS = 0 Nm by application system or diagnostic tool (LV_ISC_INH_EXT_ADJ). The PD-controller can be activated/deactivated with the following calibration bits:

```
IF      { LC_TQ_DIF_P_D_INH_AS == 1 }          OR
        { LC_ISC_INH == 1 }                    OR
        { LV_ISC_INH_EXT_ADJ == 1 }
THEN
        TQ_DIF_P_D_IS = 0 Nm;
        TQ_DIF_P_D_SLOW_IS = 0 Nm;
        TQ_DIF_P_D_FAST_IS = 0 Nm;
ELSE
        Normal calculation
```

```
IF      LV_DT == 1
THEN    T_RAMP_LIM_P_D_IS = C_T_RAMP_LIM_P_D_DT_IS
ELSE    T_RAMP_LIM_P_D_IS = C_T_RAMP_LIM_P_D_IS
```

8.2.3.1 State Machine

FUNCTION DESCRIPTION:

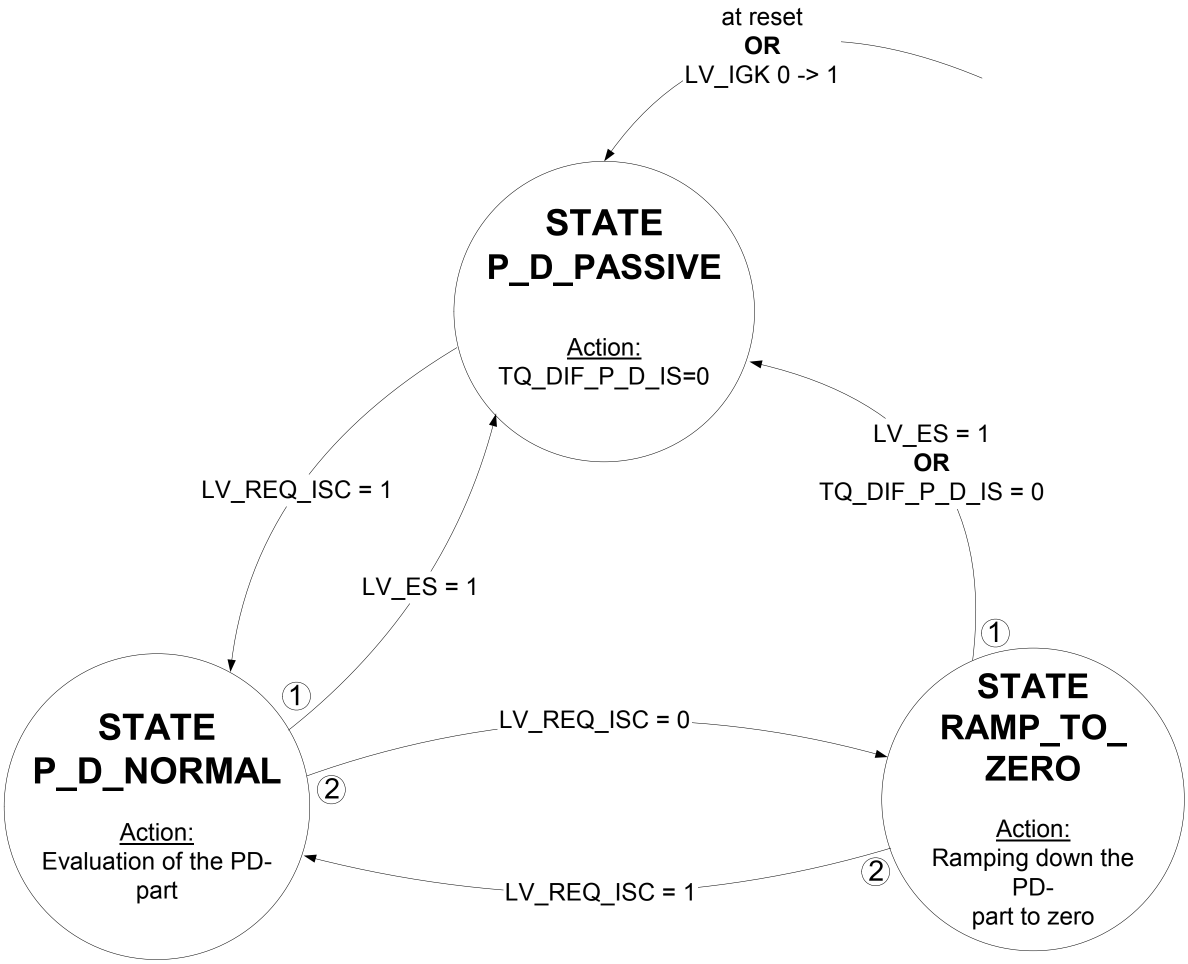

Figure 1: *State of the PD-part*

STATE_P_D_PASSIVE:

Actions:

TQ_DIF_P_D_IS = 0;

Transition conditions:

Transition to P_D_NORMAL: LV_REQ_ISC = 1

STATE_P_D_NORMAL:

Actions:

Signal flow diagram:

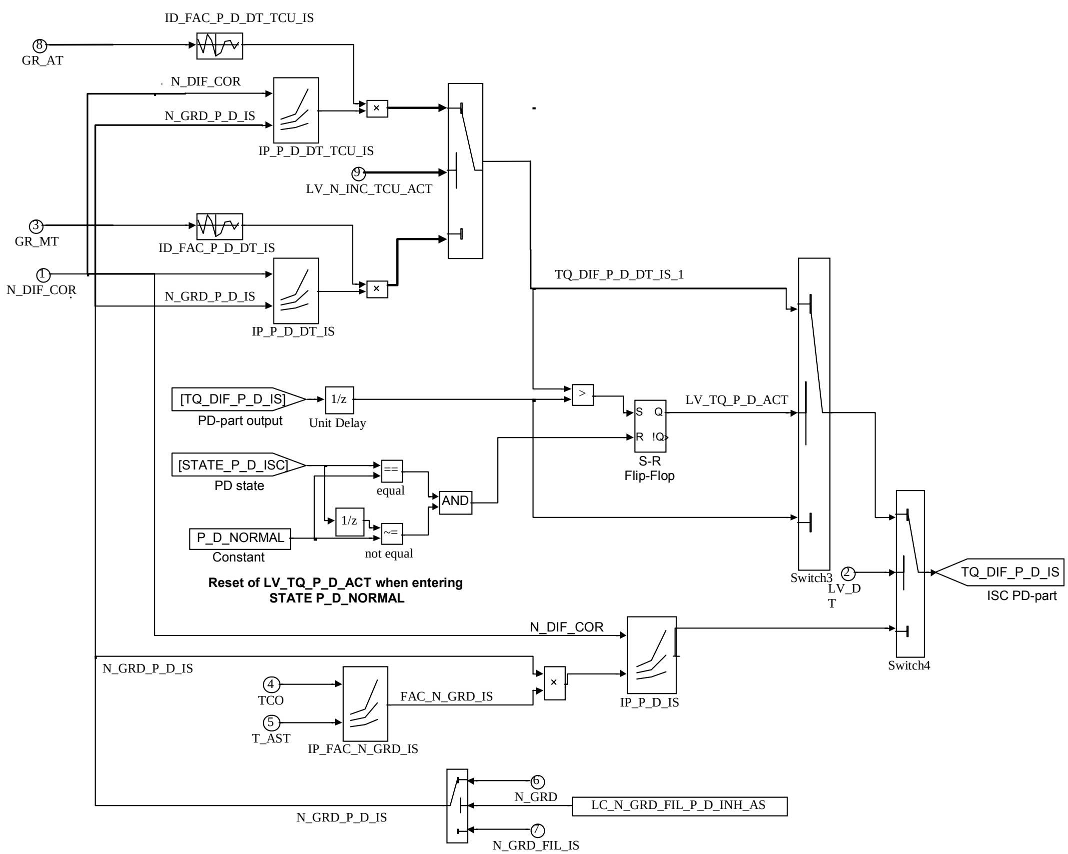

Figure 2: *Actions in state P_D_NORMAL*

Formular section:

Gradient switch:

IF LC_N_GRD_FIL_P_D_INH_AS = 1

THEN N_GRD_P_D_IS = N_GRD – (C_FAC_N_SP_IS_COR_P_D * N_SP_IS_COR_GRD)

ELSE N_GRD_P_D_IS = N_GRD_FIL_IS – (C_FAC_N_SP_IS_COR_P_D * N_SP_IS_COR_GRD_FIL_IS)

Two cases have to be distinguished in this state:

1. If **drivetrain** is **not engaged**, then TQ_DIF_P_D_IS is always the output of the map IP_P_D_IS.
2. If **drivetrain** is **engaged**, then TQ_DIF_P_D_IS is TQ_DIF_P_D_DT_IS_1, **with one exception at controller activation:** If the controller is activated when speed is falling at overspeed, then the controller may produce negative torque requests. These lead to torque jumps, which could be felt as inconvenient by the driver. To avoid these negative torque jumps at PD-ISC request, the output value TQ_DIF_P_D_IS is limited to zero, until the DT-map output value TQ_DIF_P_D_DT_IS_1 has a zero crossing and starts producing positive values, figure 3. This is reached with the logic shown in figure 2. LV_TQ_P_D_ACT is reseted when entering into P_D_NORMAL.

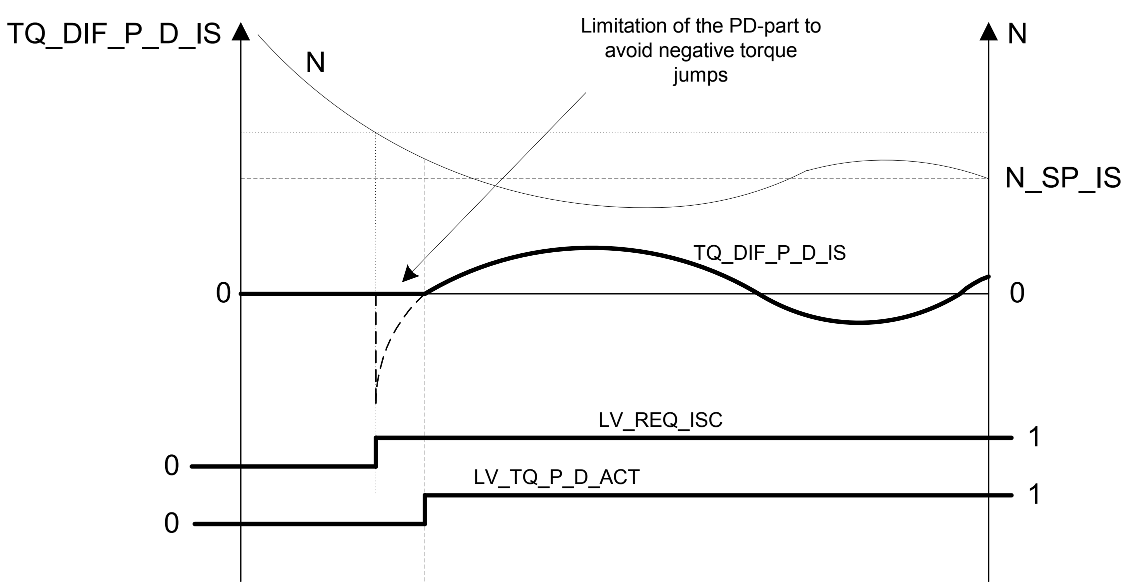

Figure 3: *Activation of the PD-part in case of LV_REQ_ISC = 1* ***AND*** *TQ_DIF_P_D_DT_IS_1 > TQ_DIF_P_D_IS*

IF $TQ\_DIF\_P\_D\_DT\_IS\_1_k$ > $TQ\_DIF\_P\_D\_IS_{k-1}$

OR $TQ\_DIF\_P\_D\_DT\_IS\_1_k$ > C_TQ_MIN_P_D_ACT

THEN LV_TQ_P_D_ACT = 1;

ELSE IF $STATE_k$ == P_D_NORMAL AND $STATE_{k-1}$ ~= P_D_NORMAL

THEN LV_TQ_P_D_ACT = 0;

Either TQ_DIF_P_D_IS is zero or equal to a ramp value (STATE RAMP_TO_ZERO) at activation of the PD-part, TQ_DIF_P_D_IS is always activated if TQ_DIF_P_D_DT_IS_1 is positive or higher than the ramp value.

The calculation of the PD-part is done as described in the following.

Evaluation of the maps:

If LV_N_INC_TCU_ACT = 0
then TQ_DIF_P_D_DT_IS_1 = IP_P_D_DT_IS · ID_FAC_P_D_DT_IS;
else TQ_DIF_P_D_DT_IS_1 = IP_P_D_DT_TCU_IS · ID_FAC_P_D_DT_TCU_IS
end

if LV_DT = 1

then if LV_TQ_P_D_ACT = 1

then TQ_DIF_P_D_IS = TQ_DIF_P_D_DT_IS_1

else TQ_DIF_P_D_IS = $TQ\_DIF\_P\_D\_IS_{k-1}$

else TQ_DIF_P_D_IS = IP_P_D_IS;

Transition conditions:

Transition to P_D_PASSIVE: LV_ES = 1
Transition to RAMP_TO_ZERO: LV_REQ_ISC = 0

Actions during transition to RAMP_TO_ZERO:

TQ_ADD_P_D_RAMP = [0 -$TQ\_DIF\_P\_D\_IS_{k-1}$] / T_RAMP_LIM_P_D_IS * update rate
LV_PAS_RAMP_ACT_P_D_IS = 1

The information about ramp limit operation due to deactivation of ISC is needed in the monitoring level. Therefore the flag LV_PAS_PAMP_ACT_P_D_IS is set.

STATE_RAMP_TO_ZERO:

Actions:

To prevent a torque jump if the PD part is on a certain value and the driver hits the pedal (transition to part load), it´s necessary to reduce the PD-part’s value by a deactivation ramp. The **target value** of the ramp operation is always TQ_DIF_P_D_IS = 0 [Nm].

if |TQ_DIF_P_D_IS| >= | TQ_ADD_P_D_RAMP |

then TQ_DIF_P_D_ISk = TQ_DIF_P_D_ISk-1 + TQ_ADD_P_D_RAMP

else TQ_DIF_P_D_IS = 0

The **minimum value** to be added per update rate while the ramp is active, is the resolution of TQ_ADD_P_D_RAMP. If the theoretically calculated value TQ_ADD_P_D_RAMP is smaller than the resolution, then the software will always limit TQ_ADD_P_D_RAMP to the resolution. This influences the real ramping time, which is in this case smaller than the calibrated one. The ramping slopes become steeper.

If the ramp is active while reentering into idle, STATE_P_D_ISC changes to P_D_NORMAL.

Transition conditions:

Transition to P_D_PASSIVE:	LV_ES = 1 **OR** TQ_DIF_P_D_IS = 0 Nm
Transition to P_D_NORMAL:	LV_REQ_ISC = 1

Actions during transition to P_D_PASSIVE:

LV_PAS_RAMP_ACT_P_D_IS = 0

Actions during transition to P_D_NORMAL:

LV_PAS_RAMP_ACT_P_D_IS = 0

LV_TQ_P_D_ACT = 0

8.2.3.2 Separation of PD-Controller Output (Slow / Fast)

This function is meant to have a possibility to reduce the controller's PD-gain in dependance of TCO to prevent a strong excitement of the engine and so to reduce the danger of an oscillating speed.

Signal flow diagram:

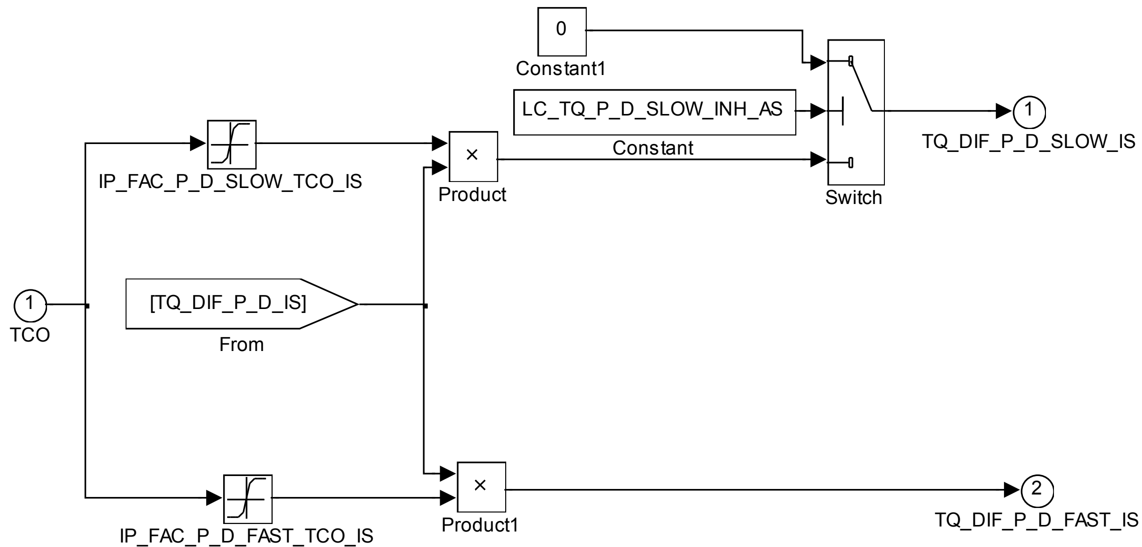

Figure 4: *Seperation into a slow and a fast path for the PD-controller*

For special function test, it´s possible to set TQ_DIF_P_D_SLOW_IS = 0 [Nm] by application system.

Determination of TQ_DIF_P_D_SLOW_IS:

if LC_TQ_P_D_SLOW_INH_AS == 1

then TQ_DIF_P_D_SLOW_IS = 0 [Nm]

else TQ_DIF_P_D_SLOW_IS = TQ_DIF_P_D_IS * IP_FAC_P_D_SLOW_TCO_IS

Determination of TQ_DIF_P_D_FAST_IS:

TQ_DIF_P_D_FAST_IS = TQ_DIF_P_D_IS * IP_FAC_P_D_FAST_TCO_IS

8.2.4 I-Controller

General information:

The integral part is devided into four states:

STATE_I_ISC = I_PASSIVE:
Initialization (at reset or when LV_IGK = 0 → 1; from all other states in case of LV_ES = 1)

STATE_I_ISC = I_NORMAL:
In this state the evaluation of the controller maps and the "normal" integration takes place.

STATE_I_ISC = RAMP_TO_LIM:
Ramp to limits; in this state the integral part is ramped down to the calibratible top/bottom limit values.

STATE_I_ISC = RAMP_TO_PAS:
Ramp to passive value 0 (); in this state the integral part is ramped down to zero in case LV_REQ_ISC = 0.

Application conditions:

Activation:	at every engine state
Point in time of calculation:	This function has to be calculated immediate **before the module "Minimum torque at clutch"** and **after speed and speed gradient determination**.
Initialization:	TQ_DIF_I_IS = 0 (STATE_I_ISC = 0, see the following figure 4).
Update Rate:	20 ms

Formula section:

For special function test, it´s possible to set TQ_ADD_I_IS = 0 Nm or TQ_DIF_I_IS = 0 Nm by application system or diagnostic tool (LV_ISC_INH_EXT_ADJ). The I-controller can be activated/deactivated with the following calibration bits:

IF LC_TQ_DIF_I_INH_AS = 1
or LC_ISC_INH = 1
or LV_ISC_INH_EXT_ADJ = 1
then TQ_DIF_I_IS = 0 Nm;
else **if** C_TQ_ADD_I_INH_AS = 1
then DD_I_IS = 0 Nm

Determination of the top/bottom limit values:

IF LV_DT = 1
THEN TQ_TOL_I_IS = C_TQ_TOL_I_DT_IS
TQ_BOL_I_IS = C_TQ_BOL_I_DT_IS
T_RAMP_LIM_I_IS = C_T_RAMP_LIM_I_DT_IS
ELSE TQ_TOL_I_IS = C_TQ_TOL_I_IS
TQ_BOL_I_IS = C_TQ_BOL_I_IS
T_RAMP_LIM_I_IS = C_T_RAMP_LIM_I_IS

The passive value (**target value**) of the ramp operation is depending on the activation status of the climatic compressor:

IF LV_ACCOUT_RLY = 1
THEN TQ_PAS_I_IS = C_TQ_PAS_I_ACC_IS
ELSE TQ_PAS_I_IS = C_TQ_PAS_I_IS

FUNCTION DESCRIPTION:

Signal flow diagram:

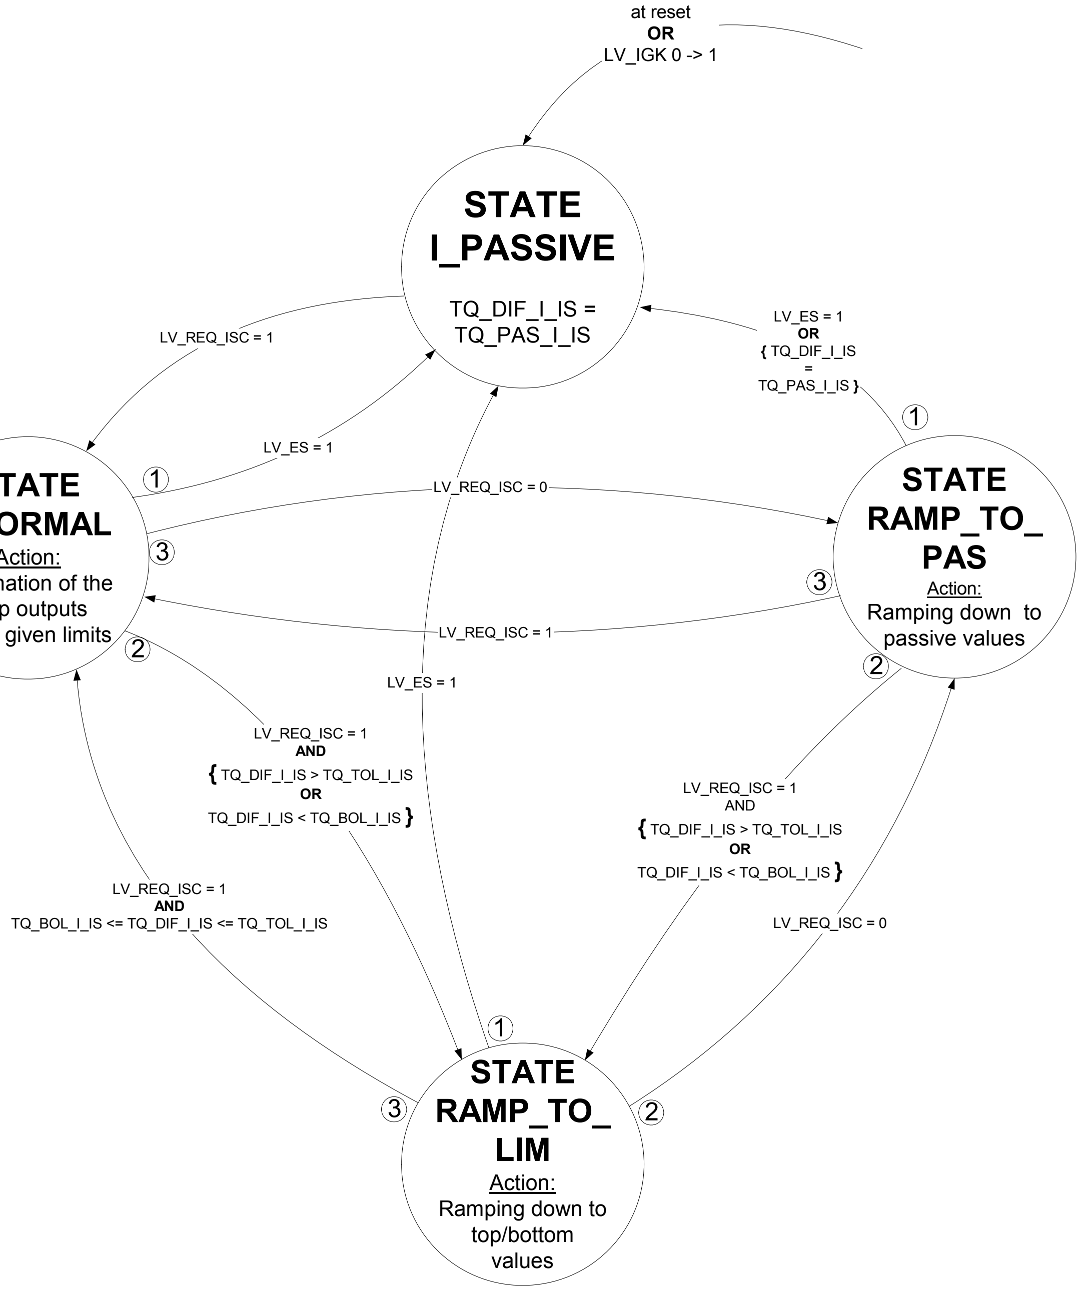

Figure 5: *State diagram of the integral part*

STATE I_PASSIVE

Actions:

TQ_DIF_I_IS = TQ_PAS_I_IS;

Transition conditions:

Transition to I_NORMAL: LV_REQ_ISC = 1

STATE I_NORMAL

Actions:

It can be chosen with LC_N_GRD_FIL_I_INH_AS, if a filtered gradient is used or not:

if LC_N_GRD_FIL_I_INH_AS = 1
then N_GRD_I_IS = N_GRD – (C_FAC_N_SP_IS_COR_I * N_SP_IS_COR_GRD)
else N_GRD_I_IS = N_GRD_FIL – (C_FAC_N_SP_IS_COR_I * N_SP_IS_COR_GRD_FIL_IS)

Calculation:

$TQ\_DIF\_I\_IS_{k} = TQ\_DIF\_I\_IS_{k-1} + TQ\_ADD\_I\_IS_{k}$

Determination of TQ_ADD_I_IS:

In STATE I_NORMAL, see figure 4, the "normal" integration takes place. A torque difference TQ_ADD_I_IS is determined in dependence of the speed deviation N_DIF_COR and the speed gradient N_GRD_I_IS (for LV_DT = 0) and only in dependance of the speed deviation N_DIF_COR for LV_DT = 1, figure 6.

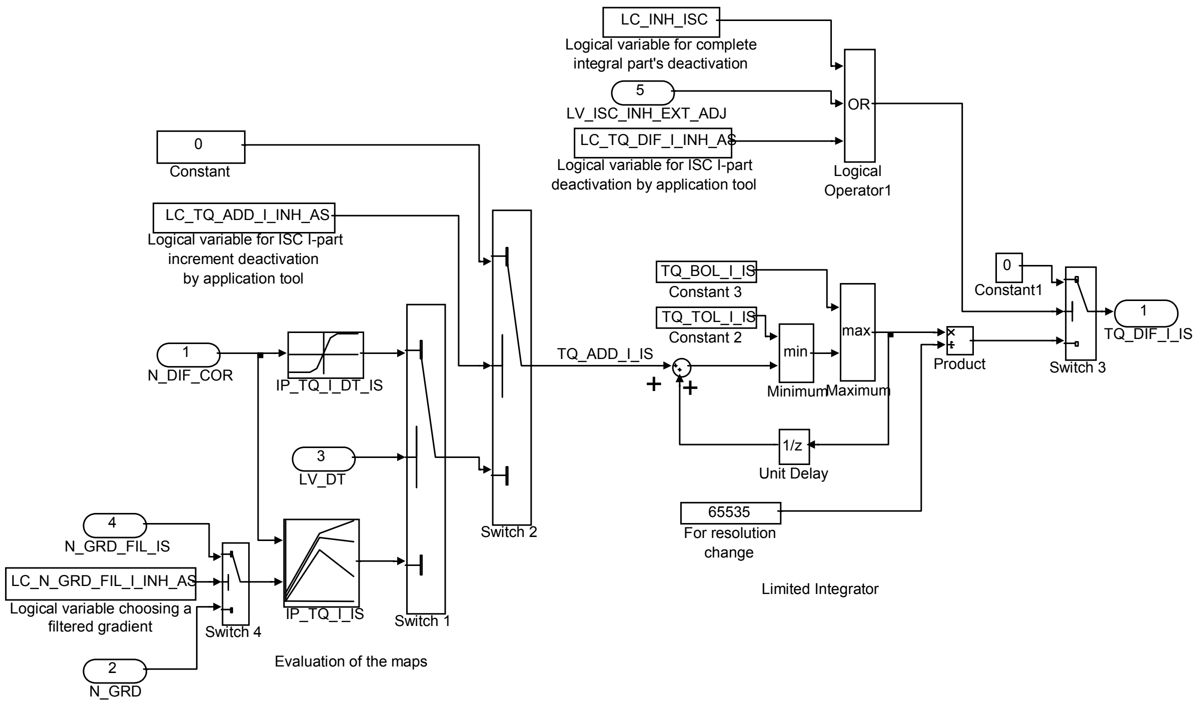

Figure 6: *Determination of TQ_ADD_I_IS and TQ_DIF_I_IS.*

The devision by 65535 is done to change the higher integration resolution to the usual torque resolution.

To reach two important targets, TQ_ADD_I_IS should be calibrated as follows:

- compensation of a speed offset
- automatic precalibration of the integral part: if there is a load active after the driver released the gas pedal (ACC, power steering, etc), then speed falls with a higher gradient into idle range than in comparision to the situation without load. This means, that the integral part should carry higher (positive) values to intercept speed. That means, that with the help of the gradient dependancy in the integral part an automatic precalibration of the TQ_ADD_I_IS (so TQ_DIF_I_IS) can be reached, which is load dependant. It must be said, that this interception function must be synchronized with the PD-part calibration. With the correct calibration, the passive values are not needed any more.

The integration takes place within calibratible boundaries, figure 7.

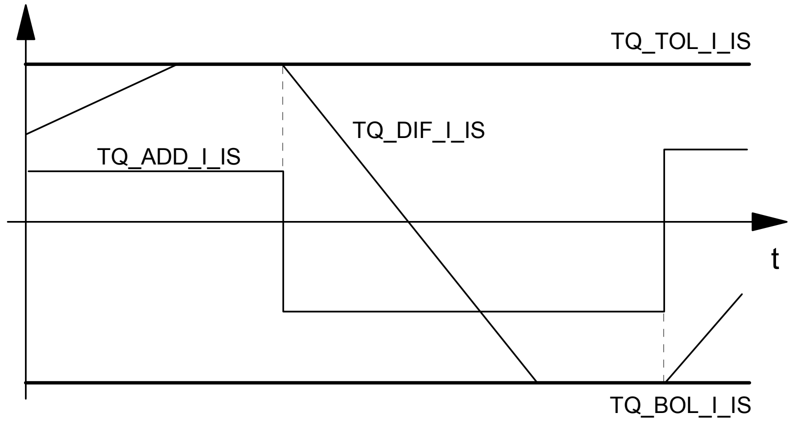

Figure 7: *Limited integration*

Transition conditions:

Transition to I_PASSIVE:	LV_ES = 0	
Transition to RAMP_TO_LIM:	LV_REQ_ISC = 1	**AND**
	[	
	TQ_DIF_I_IS > TQ_TOL_I_IS	**OR**
	TQ_DIF_I_IS < TQ_BOL_I_IS	
	]	
Transition to RAMP_TO_PAS:	LV_REQ_ISC = 0	

Actions during transition to RAMP_TO_LIM:

IF TQ_DIF_I_IS < TQ_BOL_I_IS

THEN TQ_LIM_I_IS = TQ_BOL_I_IS

ELSE TQ_LIM_I_IS = TQ_TOL_I_IS

ENDIF

TQ_ADD_I_RAMP = **[** TQ_LIM_I_IS – TQ_DIF_I_IS **]** / T_RAMP_LIM_I_IS * update rate

Actions during transition to RAMP_TO_PAS:

TQ_ADD_I_RAMP = **[** TQ_PAS_I_IS – TQ_DIF_I_IS **]** / T_RAMP_LIM_I_IS * update rate

LV_PAS_RAMP_ACT_I_IS = 1

STATE_RAMP_TO_LIM

If this state is active and so the integrator output is outside the allowed boundaries, its value is controlled back to the valid boundaries on a ramp.

Actions:

IF TQ_DIF_I_IS < TQ_BOL_I_IS
THEN TQ_LIM_I_IS = TQ_BOL_I_IS
ELSE TQ_LIM_I_IS = TQ_TOL_I_IS
ENDIF

IF ($|$TQ_LIM_I_IS - TQ_DIF_I_IS$_{k-1}|$ > $|$TQ_ADD_I_RAMP$|$)
THEN TQ_DIF_I_IS$_k$ = TQ_DIF_I_IS$_{k-1}$ + TQ_ADD_I_RAMP
ELSE TQ_DIF_I_IS = TQ_LIM_I_IS
ENDIF

The **minimum value** to be added per update rate while the ramp is active, is the resolution of TQ_ADD_I_RAMP. If the theoretically calculated value TQ_ADD_I_RAMP is smaller than the resolution, then the software will always limit TQ_ADD_I_RAMP to the resolution. This influences the real ramping time, which is in this case smaller than the calibrated one. The ramping slopes become steeper.

Transition conditions:

Transition to I_PASSIVE:	LV_ES = 1
Transition to RAMP_TO_PAS:	LV_REQ_ISC = 0
Transition to I_NORMAL:	LV_REQ_ISC = 1 **AND** TQ_BOL_I_IS $\leq$ TQ_DIF_I_IS $\leq$ TQ_TOL_I_IS

Actions during transition to RAMP_TO_PAS:

TQ_ADD_I_RAMP = **[** TQ_PAS_I_IS – TQ_DIF_I_IS **]** / T_RAMP_LIM_I_IS * update rate

LV_PAS_RAMP_ACT_I_IS = 1

STATE RAMP TO PAS

At deactivation of ISC the integrator output is controlled to a passive-value by ramp limit activation. The determination of the ramp takes place in the same way as described before for the top/bottom limit ramps.

Actions:

The ramp limit operation starts at deactivation of the ISC. The necessary increment (**TQ_ADD_I_RAMP**) to reach the required ramp-slope **is only calculated once while transitioning into this state**. This value is valid until deactivation of the ramp limit operation.

While transition into this state, so while the ramp is active, there could be a change in TQ_PAS_I_IS. If in this case TQ_ADD_I_RAMP is negative for example and the passive value is higher than the actual value, then the new requested passive value can never be reached, because TQ_ADD_I_RAMP is only calculated once. Therefore TQ_PAS_I_IS is fixed while transition into this state to prevent a wrong comparison in the following condition:

IF ($|$TQ_PAS_I_IS - TQ_DIF_I_IS$_k|$ > $|$TQ_ADD_I_RAMP$|$)

THEN TQ_DIF_I_IS$_k$ = TQ_DIF_I_IS$_{k-1}$ + TQ_ADD_I_RAMP

ELSE TQ_DIF_I_IS = TQ_PAS_I_IS

ENDIF

The **minimum value** to be added per update rate while the ramp is active, is the resolution of TQ_ADD_I_RAMP. If the theoretically calculated value TQ_ADD_I_RAMP is smaller than the resolution, then the software will always limit TQ_ADD_I_RAMP to the resolution. This influences the real ramping time, which is in this case smaller than the calibrated one. The ramping slopes become steeper.

Transition conditions:

Transition to I_PASSIVE:	LV_ES = 1	**OR**
	TQ_DIF_I_IS = TQ_PAS_I_IS	
Transition to RAMP_TO_LIM:	LV_REQ_ISC = 1	**AND**
	[	
	TQ_DIF_I_IS > TQ_TOL_I_IS	**OR**
	TQ_DIF_I_IS < TQ_BOL_I_IS	
	]	
Transition to I_NORMAL:	LV_REQ_ISC = 1	

Actions during transition to RAMP_TO_LIM:

IF TQ_DIF_I_IS < TQ_BOL_I_IS

THEN TQ_LIM_I_IS = TQ_BOL_I_IS

ELSE TQ_LIM_I_IS = TQ_TOL_I_IS

ENDIF

TQ_ADD_I_RAMP = **[** TQ_LIM_I_IS – TQ_DIF_I_IS **]** / T_RAMP_LIM_I_IS * update rate

LV_PAS_RAMP_ACT_I_IS = 0

Actions during transition to I_PASSIVE:

LV_PAS_RAMP_ACT_I_IS = 0

Actions during transition to I_NORMAL:

LV_PAS_RAMP_ACT_I_IS = 0

If idle speed control is reacitvated during the ramp limit operation then the integrator starts at the current TQ_DIF_I_IS value (Transition to I_NORMAL).

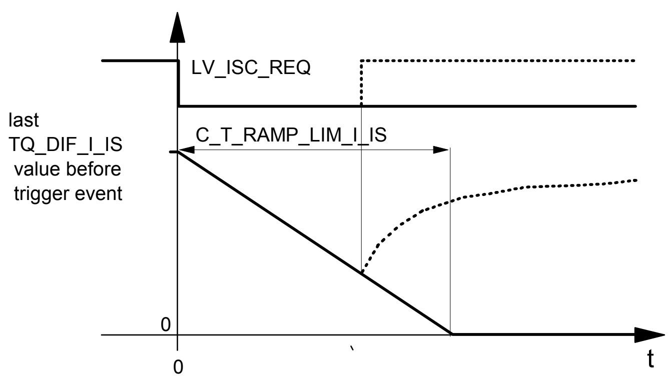

Figure 6: *Reactivation of the controller in case on an active ramp: the integral part starts again at the last ramp value (Transition to I_NORMAL)*

Time counter for ISC activation in PU					

Input data:

LV_ST	LV_IS	N	N_GRD
LV_PU	N_SP_IS	VS	LV_DT
LV_PL			

Application conditions:

Activation: **IF** LC_ISC_ACT_CDN_SWI == 1
THEN
Use these application incidences
ELSE
LV_REQ_ISC = LV_IS;
ENDIF;

At reset: STATE_REQ_ISC = ISC_PASSIVE

Update rate: 10 ms

8.3.1 General

The activation of the idle speed controller depends on different driving situations. Four states are distinguished. The actual status of the idle speed activation is stored in STATE_REQ_ISC.

State 0: Idle speed controller is passive **(STATE_REQ_ISC = ISC_PASSIVE)**.

State 1: Activation of the ISC after start **(STATE_REQ_ISC = AFTER_START)**.

State 2: "Normal activation": Activiation of the ISC in case of LV_IS = 1 **(STATE_REQ_ISC = NORMAL)**

State 3: Activation of the ISC if speed remains stationary at a certain value in trailing throttle state **(STATE_REQ_ISC = TRAILING_THR)**

State 4: Activation of the ISC in part load in case of underspeed, **(STATE_REQ_ISC = PART_LOAD)**.

The following state diagram illustrates the connection between these three cases, figure 1.

State machine:

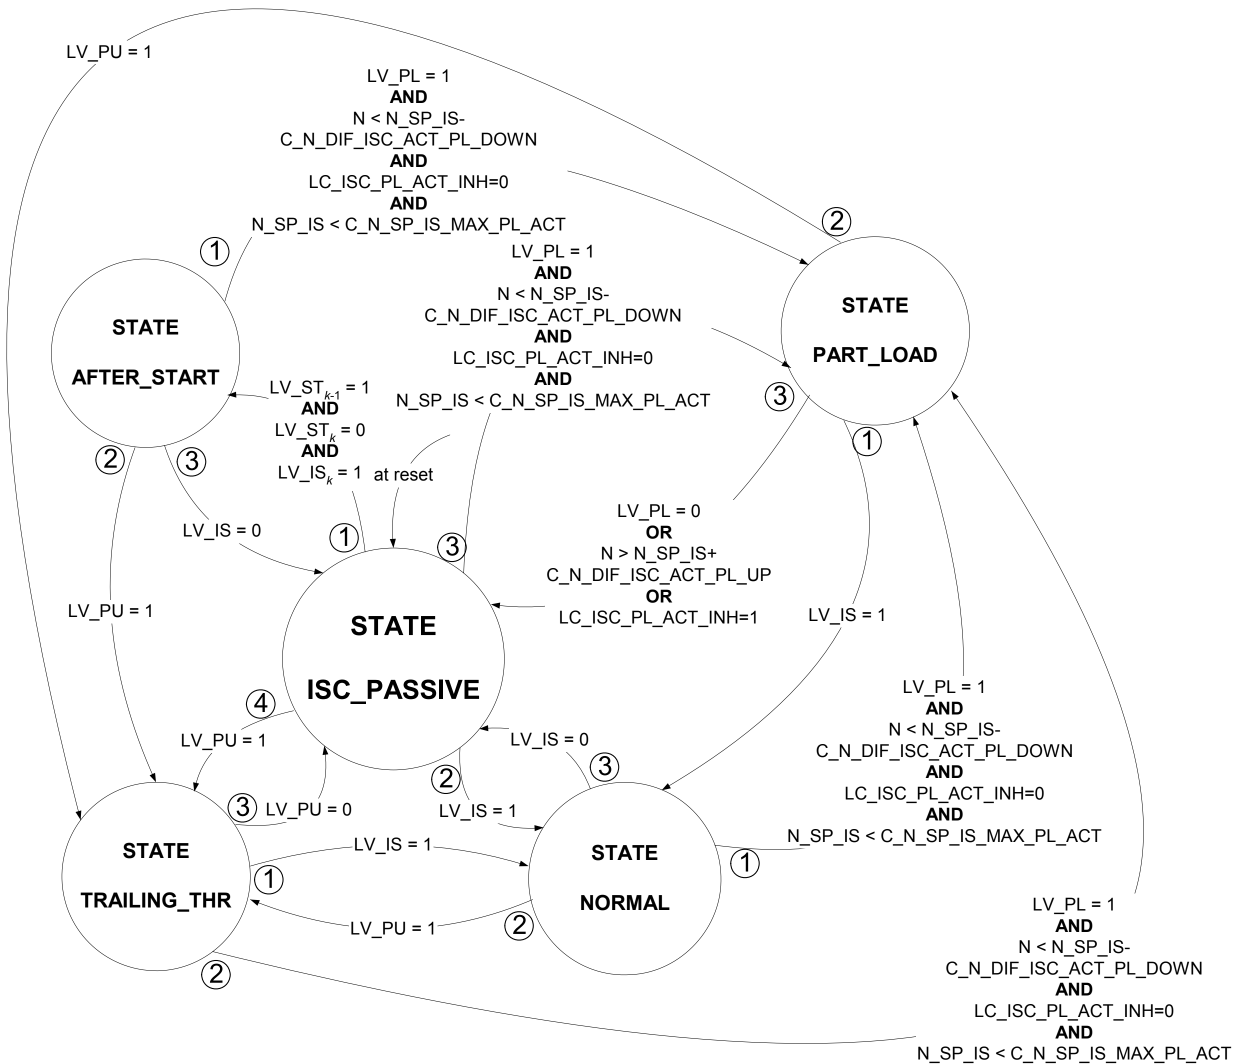

Figure 1: *State diagram of the ISC activation.*
The numbers at different transitions of one state to another represent the priority in which the transitions have to be checked.

8.3.2 ISC Passive (STATE ISC_PASSIVE)

FUNCTION DESCRIPTION:

This state is the idle speed controller passive state. The controller is deactivated if there is a transition to this state.

Formula section:

Action: LV_REQ_ISC = 0

Transition: see figure 1

Action during transition to AFTER_START: LV_NEG_N_GRD_FIL_MEM = 0
N_GRD_FIL_ISC_ACT_AST = 0

8.3.3 Checking ISC activation conditions after start (Entry into IS after ST, STATE AFTER_START)

FUNCTION DESCRIPTION:

After transition from engine state ST to IS, the activation of the ISC is requested if speed reaches a calibratible offset from N_SP_IS with a negative gradient N_GRD, figure 2. If speed does not reach this offset after decreasing and increasing again, the controller is also activated.

Transition: see figure 1

Action:

IF LC_ISC_ACT_AST_CDN_SWI == 1
THEN
LV_REQ_ISC = 1
ELSE
{

% Calculation of a filtered gradient for after start activation

$N\_GRD\_FIL\_ISC\_ACT\_AST_{k} = N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1} +$
$+ C\_CRLC\_N\_GRD\_FIL\_ISC\_ACT\_AST \cdot \{ N\_GRD_{k} - N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1} \}$

% If N reaches the calibratible offset N_SP_IS + C_N_DIF_ISC_ACT_AST
% with a negative gradient, then the controller is activated. If
% speed increases again *before* reaching N_SP_IS + C_N_DIF_ISC_ACT_AST,
% then the controller is activated, too. The falling gradient
% is layed up in LV_NEG_N_GRD_FIL_MEM.

IF N_GRD_FIL_ISC_ACT_AST < 0
THEN
LV_NEG_N_GRD_FIL_MEM = 1

IF **{** N < N_SP_IS + C_N_DIF_ISC_ACT_AST **}**
THEN
LV_REQ_ISC =1
ENDIF

ELSEIF **{** N_GRD_FIL_ISC_ACT_AST >= 0 **}** **AND**
{ LV_NEG_N_GRD_FIL_MEM == 1**}**

THEN
LV_REQ_ISC =1

ENDIF
}

After setting LV_NEG_N_GRD_FIL_MEM, its value will not be changed until the after start is left to STATE 0.

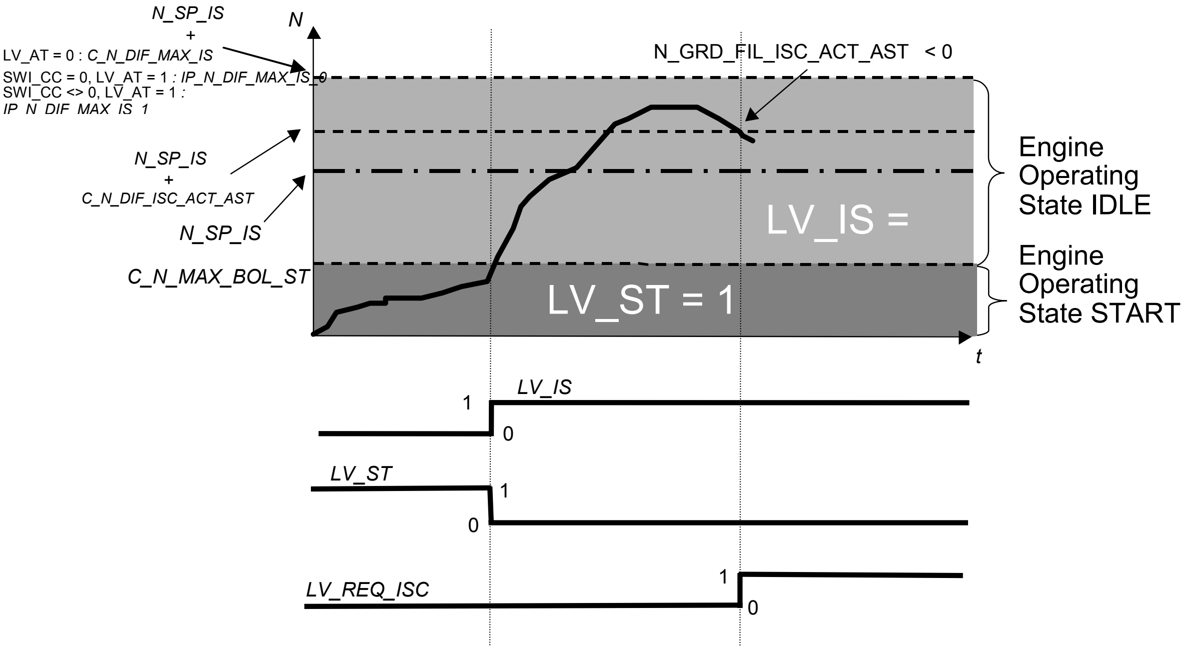

Figure 2: *ISC activation after start*

8.3.4 Checking ISC activation conditions for "normal activation", STATE NORMAL)

The idle speed controller is activated on principle in case of LV_IS = 1 (except STATE 1 is active).

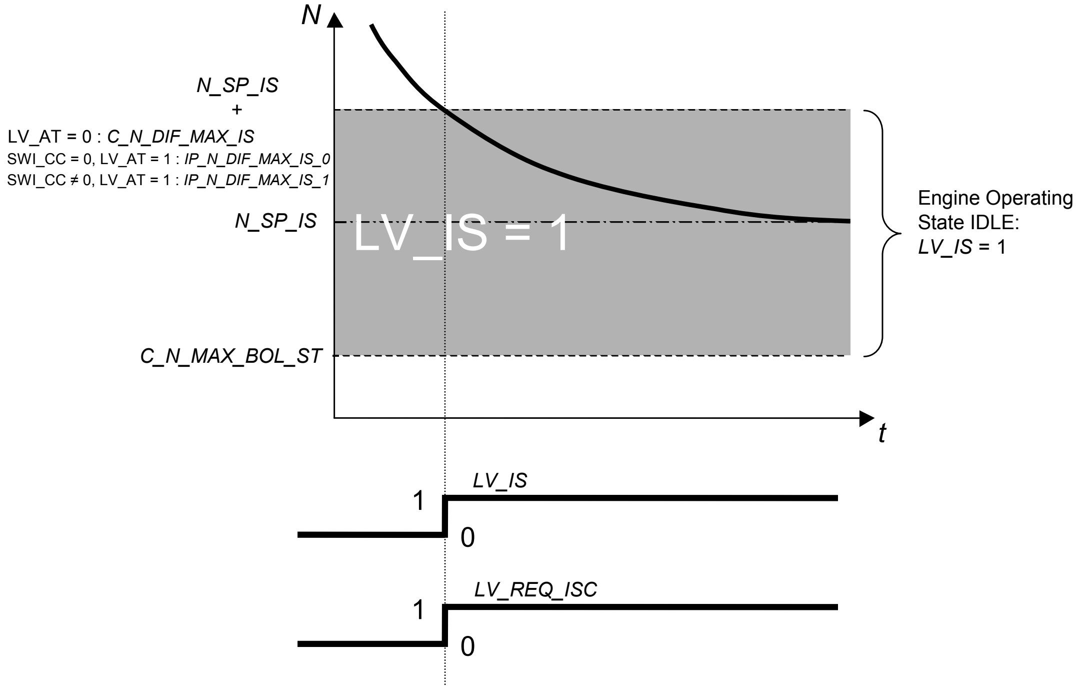

Figure 3: *Activation of the ISC in case of LV_IS = 1*

Formula section:

Transition: see figure 1

Action: LV_REQ_ISC = 1;

8.3.5 ISC activation in case of low engine speed decrease in trailing throttle state (LV_PU = 1, STATE TRAILING_THR)

If speed decrease in trailing throttle state is very low or speed does not decrease, the idle speed controller is activated after a calibratible time *C_T_DLY_ISC_ACT_PU*. The condition for that is a standing vehicle (VS=0). The counter is reseted and started when entering PU ($LV\_PU_{k-1} = 0 \rightarrow LV\_PU_k = 1$), figure 5.

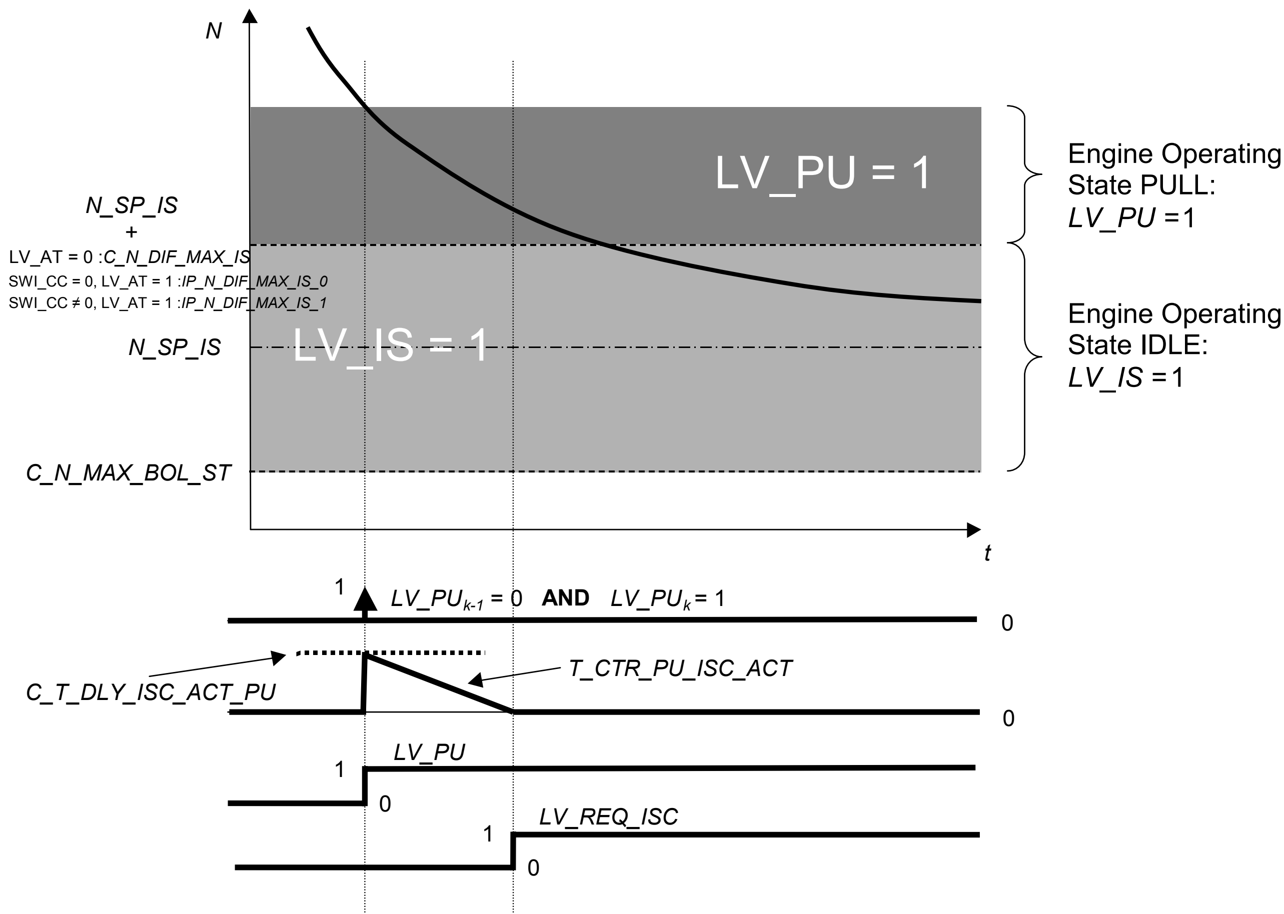

Figure 4: *Activation of the ISC in PU in case the speed decrease is too low and* ***the vehicle does not move (VS = 0)****. The counter starts from a tunable value C_T_DLY_ISC_ACT_PU and stops at zero.*

Formular section:

Transition: see figure 1

Action: *Initialize T_CTR_PU_ISC_ACT with C_T_DLY_ISC_ACT_PU and ramp it down*

IF **{** VS == 0 **OR** LV_DT == 0 **}** **AND** **{** T_CTR_PU_ISC_ACT == 0 **}**
THEN
LV_REQ_ISC = 1
ELSE
LV_REQ_ISC = 0
ENDIF

Calibration data:

8.3.6 Conditions for ISC part load activation (STATE PART_LOAD)

In part load, the driver or cruise control torque request can be so small, that the idle speed setpoint N_SP_IS cannot be held and speed is decreasing. In this case, the idle speed controller is used to guaranty N >= N_SP_IS. The conditions for activating the ISC in this case depend on the speed and a calibratible hysteresis, figure 6.

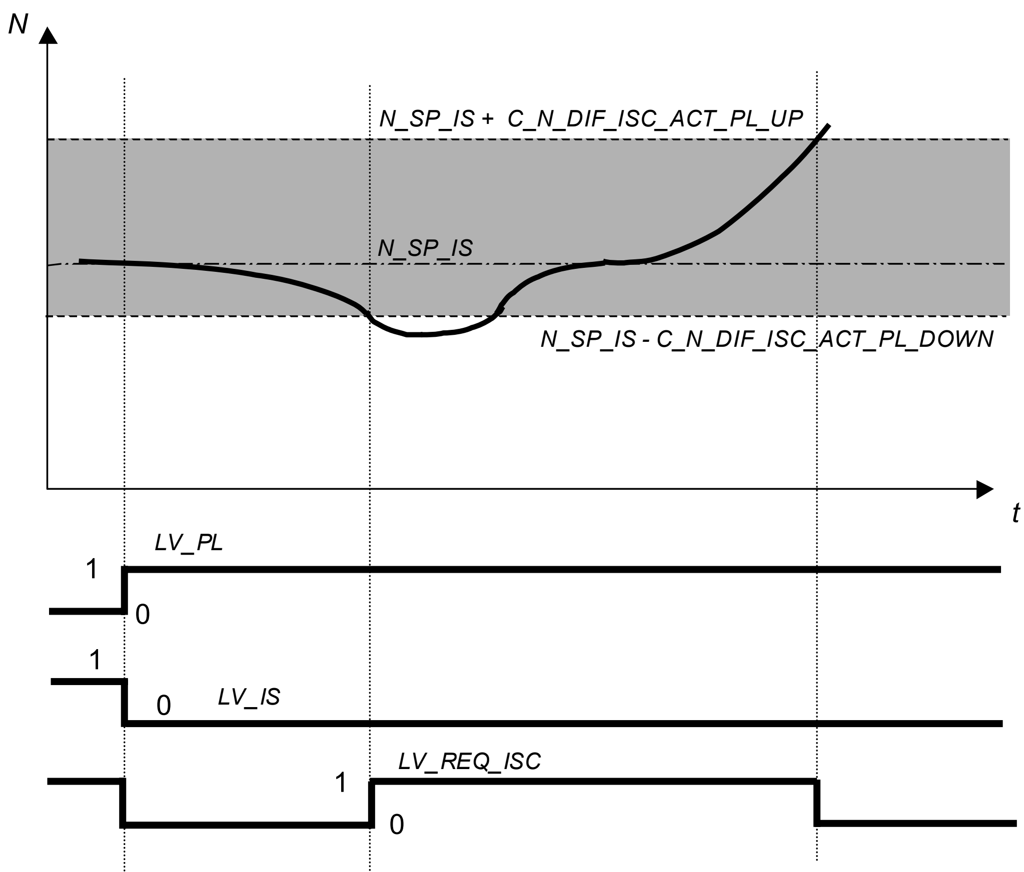

Figure 5: *Activating the ISC in part load*

Formula section:

Transition: see figure 1

Action: LV_REQ_ISC = 1

8.4 Idle Speed Adaptation

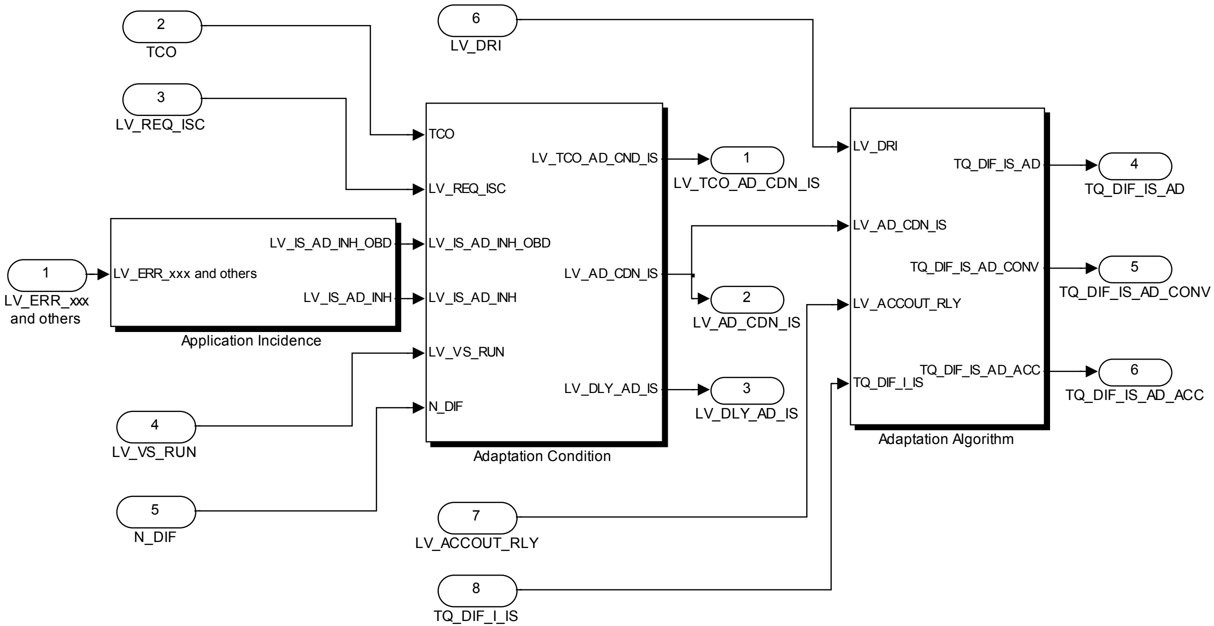

Figure 1: Idle Speed Adaptation, Overview

Functional Description:

The present adaptation is introduced to compensate spread and series variation of engine, air conditioning compressor and hydraulic converter torque losses. It is calculated during idle speed, using the integral part of the idle speed controller for the adaptation of three different parameters:

- TQ_DIF_IS_AD is the adaptation of the basic engine torque losses, without taking the drivetrain into account (disengaged gear),
- TQ_DIF_IS_AD_CONV is an adaptation of the hydraulic converter torque request at idle speed (for automatic transmission only),
- TQ_DIF_IS_AD_ACC is an adaptation value which consideres two adaptation cases depending on the actual situation:

  • air conditioning compressor and converter active at the same time
  • only air conditioning compressor active

The function consists of the following blocks:

- Application Incidence: Checks whether a relevant error has occurred.
- Adaptation Condition: Checks whether the adaptation conditions are fulfilled.
- Adaptation Algorithm: Calculation of the specific adaptation parameters.

These parameters are integrated directly in the specific functions, i.e. the adaptation of the converter torque TQ_DIF_IS_AD_CONV is used in the function "Converter torque" ...

Adaptation parameters for new torque consuming components should be integrated in the same way into the adaptation algorithm module.

8.5 Application Incidence

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_IS_AD_INH_OBD	V/O	0...1H	0...1	1	-
Application incidence value					
LV_IS_AD_INH	V/O	0...1H	0...1	1	-
Application incidence value (additional adaptation inhibitation conditions, project specific)					

Input data:

LV_ERR_IV[NC_CYL_NR]	LV_ERR_IGC	LV_ERR_TCO	LV_ERR_EL_CPS
LV_ERR_TIA_IM	LV_ERR_TIA_CYL	LV_ERR_MAF	LV_ERR_VS
LV_ERR_TIA_THR	LV_MIS_STATE_A	LV_ERR_MEC_CPS	LV_ERR_LAM_LIM_i
LV_ERR_TAM	LV_TQ_ADD_ENG_STALL_ACT	LV_ERR_MAP	NC_ETC_CONF

FUNCTION DESCRIPTION:

Application conditions:

Initialization: at reset

LV_IS_AD_INH_OBD = 0

LV_IS_AD_INH = 0

Recurrence: 100 ms

Activation: at every engine state

Formula section:

IF NC_ETC_CONF = 1
THEN LV_IS_AD_INH = LV_TQ_ADD_ENG_STALL_ACT
ELSE LV_IS_AD_INH = 0
ENDIF

LV_IS_AD_INH is introduced to allow project specific adaptation inhibitation conditions. It is sampled in the adaptation conditions.

Signal flow diagram:

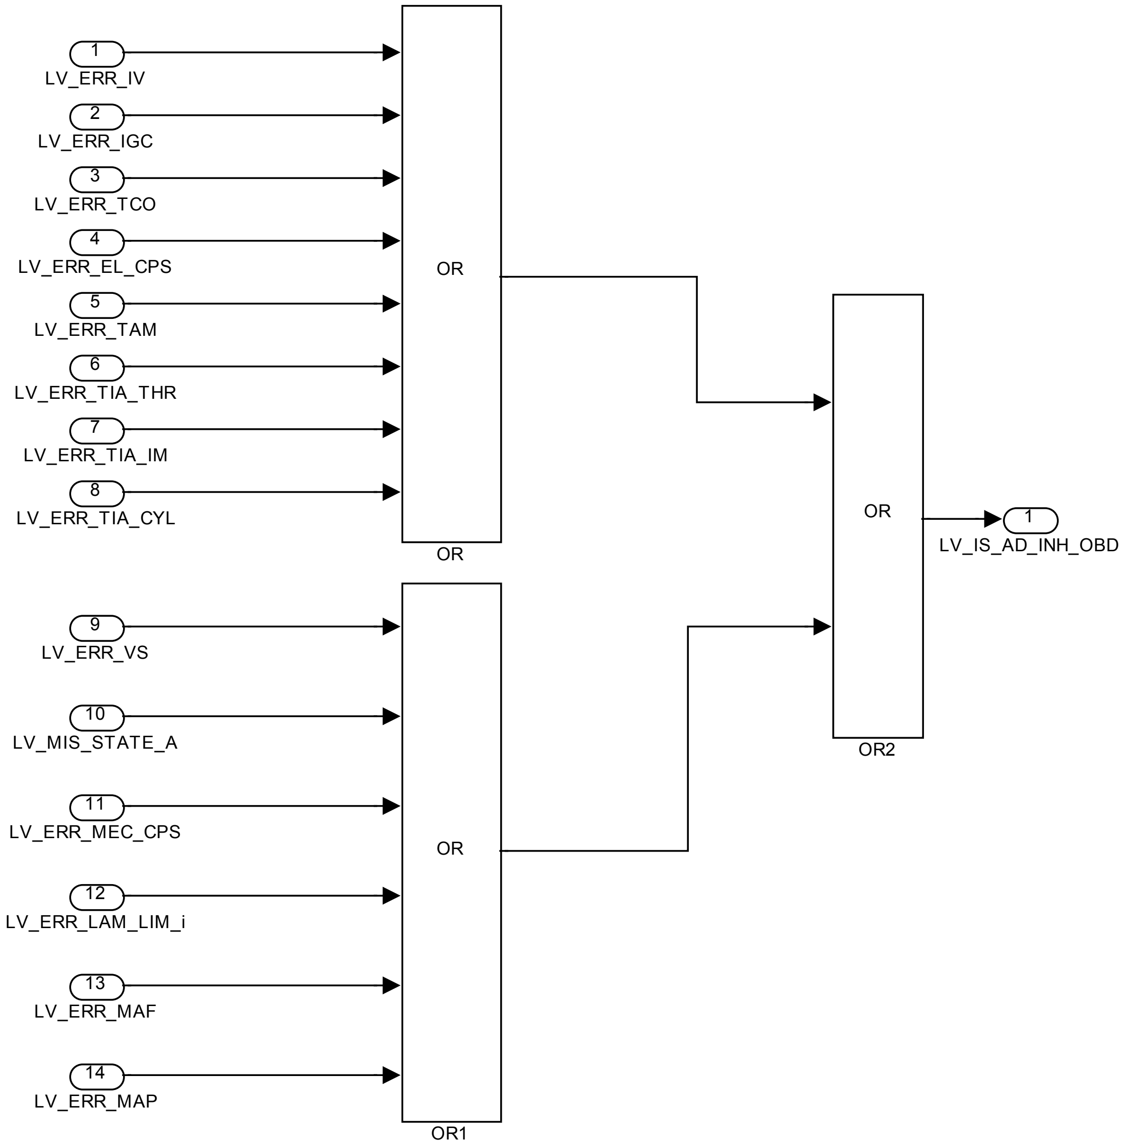

***Figure 1**: Application Incidence; calculation of LV_IS_AD_INH_OBD*

Description:

The block *Application Incidence* considers the following error bits:

LV_ERR_IV, LV_ERR_IGC, LV_ERR_TCO, LV_ERR_EL_CPS, LV_ERR_TAM, LV_ERR_TIA_THR, LV_ERR_TIA_IM, LV_ERR_TIA_CYL, LV_ERR_MAF, LV_ERR_MAP, LV_ERR_VS,, LV_MIS_STATE_A, LV_ERR_MEC_CPS, LV_ERR_LAM_LIM_i

with $i \in N$.

If one of these error bits is set, LV_IS_AD_INH_OBD = 1.
Adaptation is not allowed, if LV_IS_AD_INH_OBD = 1 (see application conditions).

8.6 Adaptation Condition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_AD_CDN_IS	V/O	0...1H	0...1	1	-

Input data:

LV_DRI	LV_ACCOUT_RLY	TQ_DIF_I_IS	LV_AD_CDN_IS

Signal flow diagram:

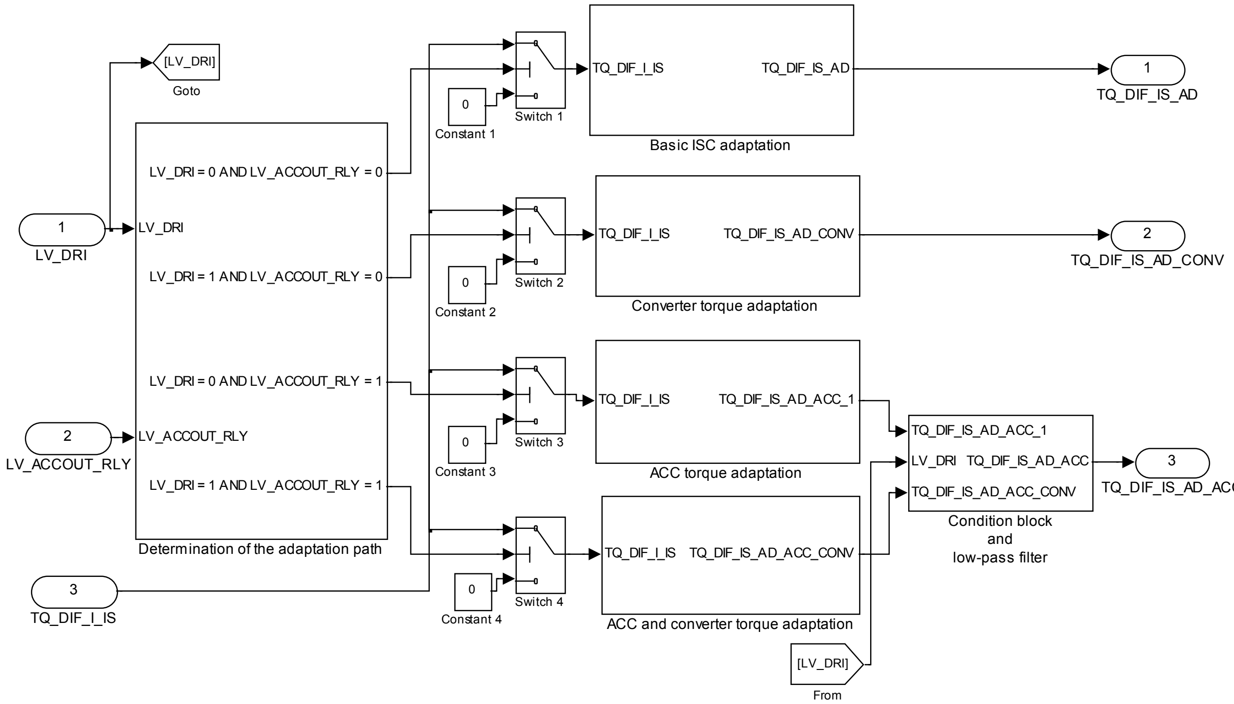

Figure 1: *Adaptation Algorithm*

The four adaptation blocks and the condition block will be described in the following function description.

Initialization:

At first initialization and after a checksum failure, all parameters are set to zero:

TQ_DIF_IS_AD	= 0,
TQ_DIF_IS_AD_INTER	= 0,
TQ _DIF_IS_AD_CONV	= 0,
TQ _DIF_IS_AD_CONV_INTER	= 0
TQ_DIF_IS_AD_ACC	= 0,
TQ_DIF_IS_AD_ACC_1_INTER	= 0,
TQ_DIF_IS_AD_ACC_CONV_INTER	= 0.

Application conditions:

Activation:

LV_AD_CDN_IS = 1

Deactivation:

LV_AD_CDN_IS = 0

Update rate:

100 ms

FUNCTION DESCRIPTION:

As soon as the adaptation conditions are fulfilled (LV_AD_CDN_IS = 1), one of the four adaptation parameters is calculated dependent on the actual situation:

- The adaptation of ACC and CONV (TQ_DIF_IS_AD_ACC_CONV) is calculated if the gear is engaged (LV_DRI = 1) and the air conditioning compressor is switched on (LV_ACCOUT_RLY = 1).
- If LV_ACCOUT_RLY = 1 and LV_DRI = 0, the adaptation of the air conditioning compressor is calculated.
- The Hydraulic converter torque adaptation TQ_DIF_IS_AD_CONV is calculated if LV_DRI = 1 and LV_ACCOUT_RLY =0.
- The basic adaptation of the idle speed controller (TQ_DIF_IS_AD) is calculated if the gear is disengaged (LV_DRI = 0) and the air conditioning compressor is switched off (LV_ACCOUT_RLY = 0).

Therefore, a fraction of the integral part of the idle speed controller (C_FAC_TQ_DIF_IS_AD_xx * TQ_DIF_I_IS) is added at each cycle to the concerned adaptation parameter, whose value is limited through a min/max limiter. The adaptation parameters are stored, even after deactivation of the function. These values are used as start values after re-entering into the same adaptation path.

The outputs of the different adaptation paths are always covered with values of the last adaptation, even if the adaptation conditions are not fulfilled or the engine is not in idle. But these values will only be adapted (changed) if the certain adaptation path is activated and they are certainly only considered in the single modules (“Torque Loss and Lead for ACC”, “Converter Torque”) in conformance with the actual situation (ACC on, drivetrain engaged). Only the basic torque losses (TQ_DIF_IS_AD) are always considered in the module “Torque Losses”.

TQ_DIF_IS_AD_CONV is considered in the converter torque calculation module, TQ_DIF_IS_AD_ACC and TQ_DIF_IS_AD_ACC_CONV in the calculation of the air conditioning compressor losses. TQ_DIF_IS_AD is added in the torque losses.

The three torque adaptation blocks "Basic ISC adaptation", "ACC torque adaptation" and "ACC and converter torque adaptation" have the following structure, figure 2.

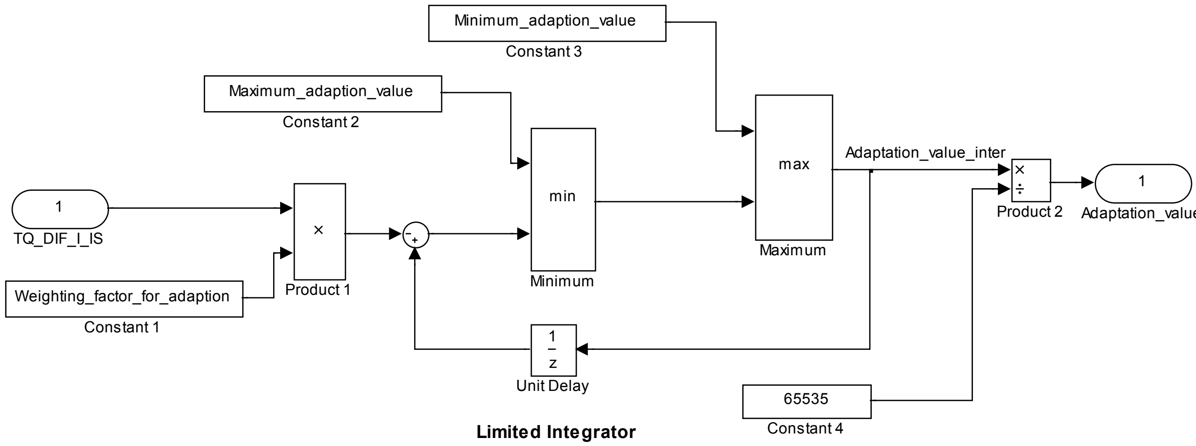

Figure 2: *Adaptation algorithm for the torque adaptation values*

The following constants are valid depending on the situation:

IF { LV_DRI = 0 } **AND** { LV_ACCOUT_RLY = 0 }

```
% calculate TQ_DIF_IS_AD
```

Weighting_factor_for_adaptation = C_FAC_TQ_DIF_IS_AD;
Maximum_adaptation_value = C_TQ_DIF_IS_AD_MAX;
Minimum_adaptation_value = C_TQ_DIF_IS_AD_MIN;
Adaptation_value_inter = TQ_DIF_IS_AD_INTER;
Adaptation_value = TQ_DIF_IS_AD;

ENDIF;

IF { LV_DRI = 0 } **AND** { LV_ACCOUT_RLY = 1 }

```
% calculate TQ_DIF_IS_AD_ACC_1
```

Weighting_factor_for_adaptation = C_FAC_TQ_DIF_IS_AD_ACC;
Maximum_adaptation_value = C_TQ_DIF_IS_AD_ACC_MAX;
Minimum_adaptation_value = C_TQ_DIF_IS_AD_ACC_MIN;
Adaptation_value_inter = TQ_DIF_IS_AD_ACC_1_INTER;
Adaptation_value = TQ_DIF_IS_AD_ACC_1;

ENDIF;

```
IF  { LV_DRI = 1 } AND { LV_ACCOUT_RLY = 1 }
  % calculate TQ_DIF_IS_AD_ACC_CONV
  Weighting_factor_for_adaptation = C_FAC_TQ_DIF_IS_AD_ACC_CONV;
  Maximum_adaptation_value        = C_TQ_DIF_IS_AD_ACC_CONV_MAX;
  Minimum_adaptation_value        = C_TQ_DIF_IS_AD_ACC_CONV_MIN;
  Adaptation_value_inter          = TQ_DIF_IS_AD_ACC_CONV_INTER;
  Adaptation_value                = TQ_DIF_IS_AD_ACC_CONV;
ENDIF;
```

The integration is done with high resolution values (long signed word, xxx_INTER). These long signed word values are stored. The following equations are valid:

TQ_DIF_IS_AD = TQ_DIF_IS_AD_INTER / 65535

TQ_DIF_IS_AD_CONV = TQ_DIF_IS_AD_CONV_INTER / 65535

TQ_DIF_IS_AD_ACC_1 = TQ_DIF_IS_AD_ACC_1_INTER / 65535

TQ_DIF_IS_AD_ACC_CONV = TQ_DIF_IS_AD_ACC_CONV_INTER / 65535

This describes the conversion from high resolution (signed long word) to “normal” resolution (signed word). Only the high word is taken from the signed long word value.

The following figure 3 shows the determination of the adaptation value for the converter torque calculation, which describes the hydraulic converter torque losses.

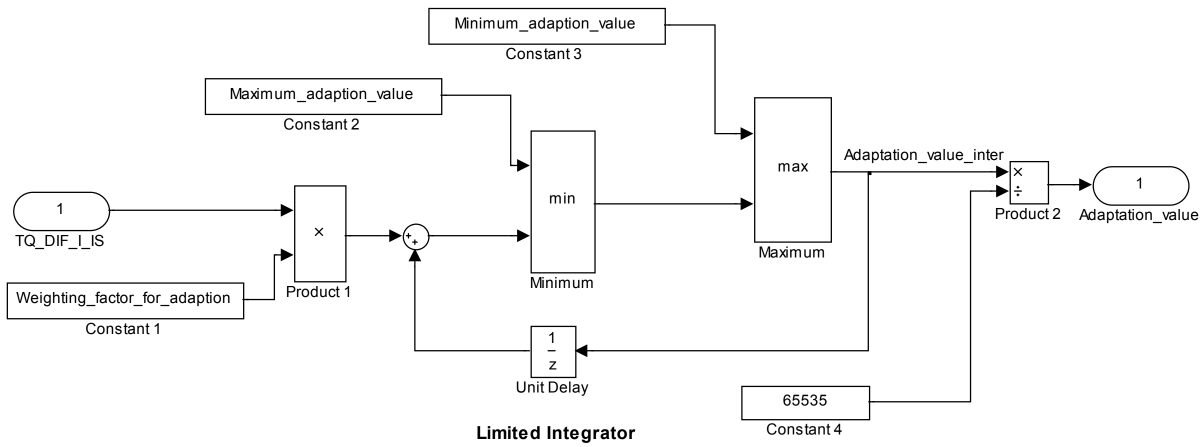

Figure 3: *Adaptation of the converter losses*

Mind that the summing point of the integrator for the converter torque determination consists of two plus signs, while those of the others consist of a minus and a plus (compare figure 2 with figure 3).

The following constants are valid for the converter torque adaptation value:

IF { LV_DRI = 1 } **AND** { LV_ACCOUT_RLY = 0 }

```
% calculate TQ_DIF_IS_AD_CONV
```

Weighting_factor_for_adaptation = C_FAC_TQ_DIF_IS_AD_CONV;
Maximum_adaptation_value = C_TQ_DIF_IS_AD_CONV_MAX;
Minimum_adaptation_value = C_TQ_DIF_IS_AD_CONV_MIN;
Adaptation_value_inter = TQ_DIF_IS_AD_CONV_INTER;
Adaptation_value = TQ_DIF_IS_AD_CONV;

ENDIF;

In order to be able to use one input for the ACC torque losses module, a switch is introduced to change between TQ_DIF_IS_AD_ACC_1 and TQ_DIF_IS_AD_ACC_CONV in dependance of the actual situation. To prevent abrupt changes in TQ_DIF_IS_AD_ACC (in case the switch changes from TQ_DIF_AD_IS_ACC_CONV to TQ_DIF_AD_IS_ACC_1), the output value of the switch is smoothed by a low pass filter, figure 4.

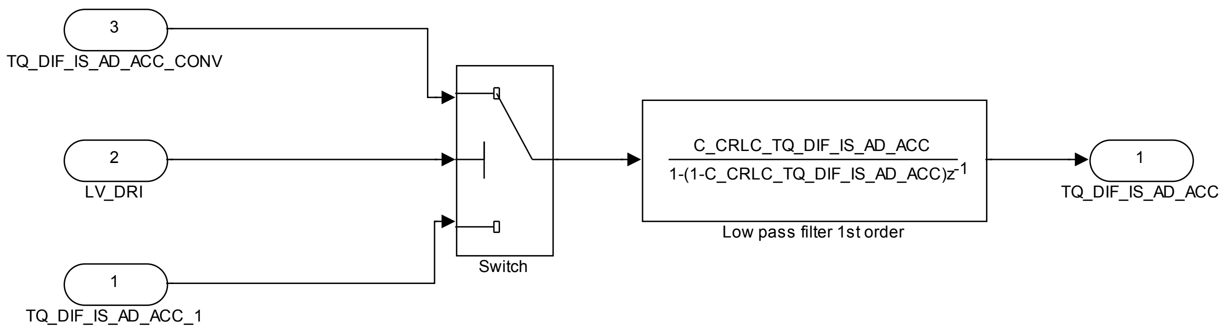

Figure 4: *Switch and low pass filter for smoothed transitions from "ACC torque adaptation" to "ACC and converter torque adaptation" and opposite*

The condition “LV_DRI=1” in the last IF-THEN command consideres the transient effects of the low-pass filter. If drivetrain is engaged, the engine is in idle and ACC is off, it’s advantageous to keep the switch at the upper position (TQ_DIF_IS_AD_ACC = TQ_DIF_IS_AD_ACC_CONV): if in this case the driver switches on ACC, TQ_DIF_IS_AD_ACC is already at the correct adaptation value in conformance with the actual situation. The additional switching condition “LV_ACCOUT_RLY=1” is not necessary, since TQ_DIF_IS_AD_ACC is added to TQ_LOSS_ACC in “Torque Loss and Lead for ACC” only in case of “ACC on”.

```
% Switch no. 37 in figure 1 and output low-pass filter
```

IF LV_DRI = 1

TQ_DIF_IS_AD_ACC = TQ_DIF_IS_AD_ACC_CONV (*low-pass filtered*);

ELSE

TQ_DIF_IS_AD_ACC = TQ_DIF_IS_AD_ACC_1 (*low-pass filtered*);

END;

During the first ACC adaptations, TQ_DIF_IS_AD_ACC may be erroneous and should therefore be limited to small values.

The speed of the adaptation process is defined through the calibration parameter C_FAC_TQ_DIF_IS_AD_xx and the function’s update rate, and should be very slow compared to variations of the integral part of the idle speed controller (C_FAC_TQ_DIF_IS_AD_xx << 1). In this case, the compensation of the added torque request is done automatically by the idle speed controller.

Further on, C_FAC_TQ _DIF_IS_AD_xx should be adjusted when the update rate changes.

Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves					

Input data:

N_DIF	N_GRD	N	LV_IS
TQI_ADD_MAX_TOL	TQI_REQ_TRA	TQI_REQ_TRA	N_SP_IS
TQ_ADD_ENG_STALL	TCO	TQ_ADD_N_DIF_INT_IS	

General Information:

The module „Idle Speed Torque Reserve“ consists of two parts:

1. Idle speed torque reserve due to low engine speed
2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves

1. Idle speed torque reserve due to low engine speed

Depending on the predicted engine speed difference N_DIF_PRED a torque reserve by increasing the load is calculated. If actual engine speed falls it is possible to increase load before the actual engine speed is below the engine speed setpoint for idle speed. At the same time a spark retard compensates the supposed torque increase. So a quick torque increase by spark advance can be realized to stabilize engine speed at its setpoint.

For negative gradients of TQ_ADD_IS_BOL_1 a PT1-filter for TQ_ADD_IS_BOL calculation is applied to avoid torque jumps caused by fast changes of ignition angle. For positive gradients of the input TQ_ADD_IS_BOL_1 the output value TQ_ADD_IS_BOL is identical to the input.

2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves

At high torque reserve requests (ex.: catalyst heating) the ignition angle can be retarded down to the minimum ignition angle IGA_MIN. This may cause problems with idle speed stability. In order to prevent speed from oscillating in case the actual ignition angle is in the near of IGA_MIN caused by high torque reserves, the maximum availible torque reserve must be limited. In order to reach this, a tunable calibration constant C_TQ_DIF_ADD_IS_TOL is introduced. C_TQ_DIF_ADD_IS_TOL has the same influence than TQ_ADD_IS_BOL: while the last defines a minimum torque reserve, C_TQ_DIF_ADD_IS_TOL takes influence on the maximum torque reserve in idle.

The availible torque reserve range is shown in figure 1.

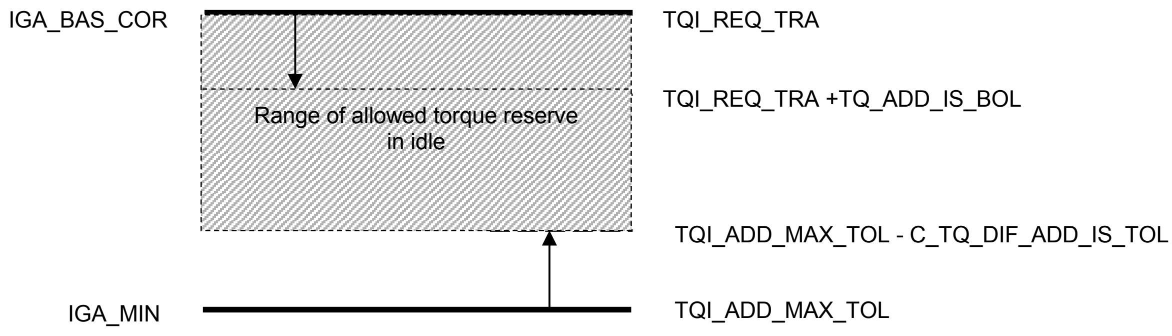

Figure 1: *Availible torque reserve range after limiting:*
TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL defines the maximum torque reserve in idle

Since C_TQ_DIF_ADD_IS_TOL is a calibratable constant, this may cause a conflict situation as shown in figure 2.

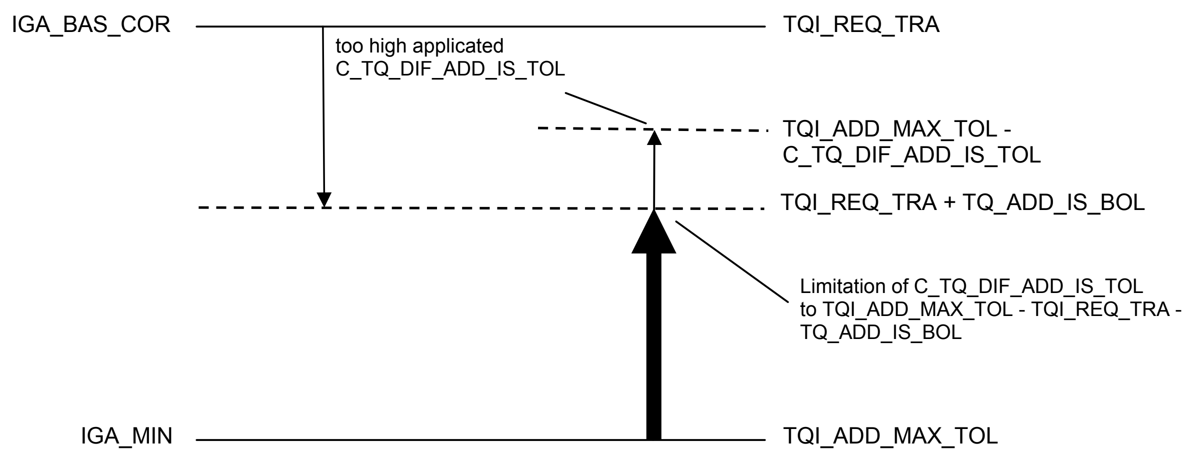

Figure 2: *Limiting C_TQ_DIF_ADD_IS_TOL in case of a conflict*

In this case TQ_ADD_IS_BOL has a higher priority than C_TQ_DIF_ADD_IS_TOL, since the possibility of moving the ignition angle in direction spark advance by building up a torque reserve is more essential than keeping it at a certain point from IGA_MIN, which „only“ causes irregular running. The condition for a non-critical situation, figure 1, is

TQI_REQ_TRA + TQ_ADD_IS_BOL <= TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL (1)

Solving this relation leads to

C_TQ_DIF_ADD_IS_TOL <= TQI_ADD_MAX_TOL - TQI_REQ_TRA - TQ_ADD_IS_BOL (2)

If relation (2) is not fulfilled, C_TQ_DIF_ADD_IS_TOL is limited, figure 3.

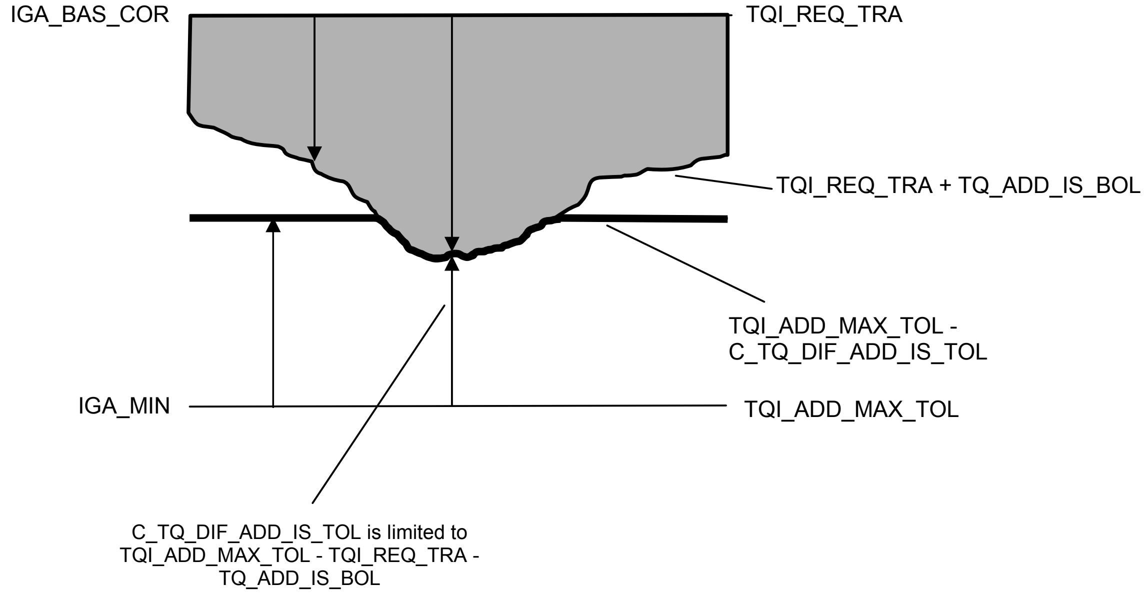

***Figure 3:** Limiting C_TQ_DIF_ADD_IS_TOL in case TQI_REQ_TRA + TQ_ADD_IS_BOL is greater than TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL*

Signal flow diagram:

8.8.2 Idle Speed Torque Reserve to prevent engine stall

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_ENG_STALL	V/O	0 ... 7FFFH	0 ... 1023.97	0.03125	Nm
Additional Idle torque reserve to avoid engine stall in case of deviation between TPS_AV1 and TPS_AV_2					
LV_TQ_ADD_ENG_STALL_ACT	V/O	0…1H	0…1	1	-
Activation condition for additional Idle torque reserve to avoid engine stall					
TPS_AV_DIF	V	0…3FFFH	0… 119.5	0.0073	°TPS
Absolute difference between TPS_AV_1 and TPS_AV_2					

Input data:

LV_CT	MAF_MES	TPS_AV_1	TPS_AV_2
N	ERR_SYM_MAF_SCG_OC	LV_ST	LV_ERR_TPS
STATE_TPS_DIAG	LV_ES	MAP_MES	ERR_SYM_EL_MAP
ERR_SYM_LOAD_TPS_PLAUS			

General Information:

With ETC system, a deviation between TPS inputs (TPS_AV_1 & TPS_AV_2) can lead to an engine stall. For example, if TPS_AV_1 is abnormally higher than TPS_AV_2, calculated TPS position (average of TPS_AV_1 and TPS_AV_2) will increase. To keep throttle position set-point, system will close the throttle, and this is leading to an engine stall.

To avoid this, an additional torque reserve (to increase throttle position set point) is triggered in case of :

- deviation between TPS_AV_1 and TPS_AV_2 and
- low position of TPS_AV_1 or TPS_AV_2 and
- low measured MAF *(indicates that throttle is abnormally closed)* and
- Engine speed undershot

8.8.3 Idle Speed Torque Reserve increase to eliminate engine speed oscillations

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_N_DIF_INT_IS	V/O	0 ... 7FFFH	0 ... 1023.97	0.03125	Nm
Additional Idle torque reserve to eliminate engine speed oscillations					
LV_N_DIF_INT_IS	V	0...1H	0...1	1	-
Flag to indicate if check for idle speed oscillations is active					
N_DIF_INT_IS	V	0...FFFFH	0...65535	1	rpm
Integrated delta engine speed setpoint to actual engine speed					

Input data:

LV_IS	N_DIF_COR		

General Information:

In certain conditions, it may be possible that during idle an engine speed oscillation occurs that cannot be damped by the normal idle controller. In this module an oscillation is detected and an increased torque reserve is applied. This give the idle controller more authority (on the fast / spark path) which allows better damping of oscillations.

FUNCTION DESCRIPTION:

Application conditions :

Initialization: at reset and deactivation

TQ_ADD_N_DIF_INT_IS = 0 Nm

LV_N_DIF_INT_IS = 0

N_DIF_INT_IS = 0

Update Rate: 10 ms

Activation: LV_IS = 1

Deactivation: (LV_IS = 0 **and** N_DIF_INT_IS = 0) **or** LV_ES = 1

Formula section :

Start / stop integrator

if LV_IS = 0

then LV_N_DIF_INT_IS = 0

endif

if LV_IS = 1 **and** N_DIF_COR > 0 **and** T_AST > C_T_AST_N_DIF_INT

then LV_ N_DIF_INT_IS = 1

endif

Fill / empty integrator

if LV_ N_DIF_INT_IS = 1

then

$N\_DIF\_INT\_IS_n$ = max (0,

$N\_DIF\_INT\_IS_{n-1}$ + | N_DIF_COR | - C_N_DIF_INT_DEC)

NB Absolute value of N_DIF_COR is used

else

$N\_DIF\_INT\_IS_n$ = max (0, $N\_DIF\_INT\_IS_{n-1}$ - C_N_DIF_INT_DEC)

endif

Calculate desired torque reserve

TQ_ADD_N_DIF_INT_IS = IP_TQ_ADD_N_DIF_INT_IS (N_DIF_INT_IS)

Calibration data:

Time after start to enable engine speed oscillation detection					

8.9 Torque Reserve for canister purge at idle

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_CP	V/O	8000 .. 7FFFF H	-1024 ... 1023.97	0.03125	Nm
Torque reserve for canister purge at idle					

Input data:

CL_MMV	LV_IS	CP_STATE	

General Information:

In the canister purge function, a relative flow is used for controlling the canister purge solenoid (CPS):

REL_FLOW_CPS = MAF_CPS / MAF_CYL. (1)

This relative flow is a function of the canister load and so is constant:

REL_FLOW_CPS = f(CL) = const. (2)

These two equations mean that raising *MAF_CYL* by opening the throttle leads to a raising of *MAF_CPS* in order to keep the condition in eq.(2) fulfilled. This means that the purging rates of the canister purge solenoid raise, too and this leads to a better scouring of the ACF. In other words, if a torque reserve is produced in idle when the canister purge function is active, the purging rates raise.

The function has another very important effect. Canister purge solenoids have lower relative opening errors at high mass flows. As explained, opening the throttle by a torque reserve means opening the CPS and this means reducing relative errors. This leads to a better controlling of the CPS.

The torque reserve for canister purge in idle should be active, when the canister purge function is in a controlled mode. In this case the state of evaporative emission control is MAX_PURGE:

CP_STATE = MAX PURGE (3)

Signal flow diagram:

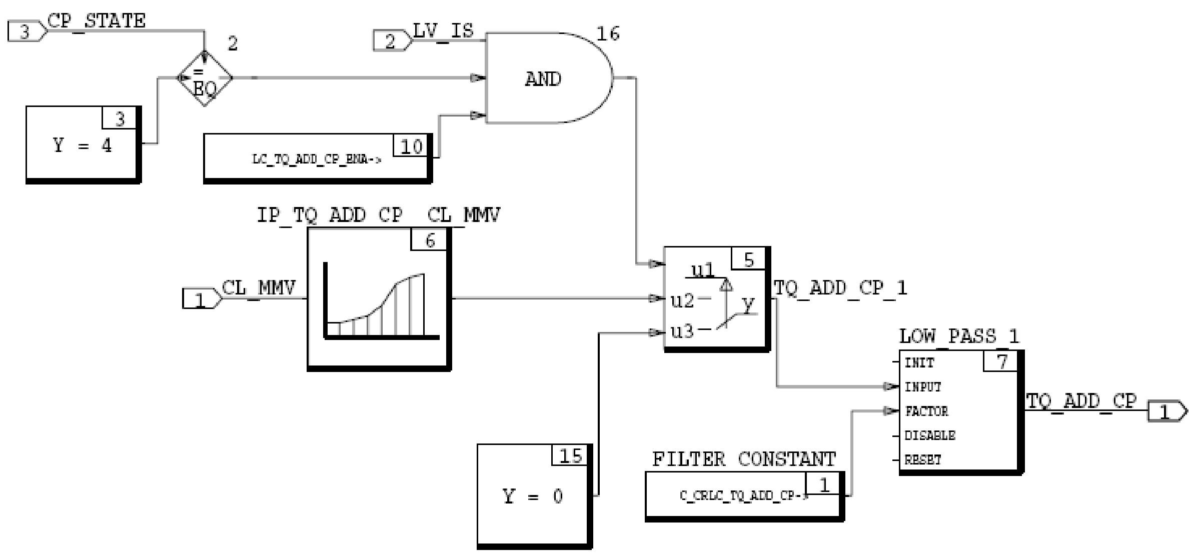

Figure 1: *Torque reserve for canister purge at idle*

FUNCTION DESCRIPTION:

General information:

Activation:		LV_IS = 1
	and	CP_STATE = MAX_PURGE
	and	LC_TQ_ADD_CP_ENA = 1
Deactivation:	**if**	LV_IS = 0
	or	CP_STATE ≠ MAX_PURGE
	or	LC_TQ_ADD_CP_ENA = 0
	When the function is deactivated, the value TQ_ADD_CP_1 should be equal zero: TQ_ADD_CP_1 = 0.

FUNCTION DESCRIPTION:

General information:

The air condition compressor relay LV_RLY_ACCOUT is controlled by the ECU. It is enabled and disabled versus LV_ACIN and LV_ACCIN information. In order to keep a stable engine speed when A/C compressor is activated or dis-activated, idle speed valve correction are triggered in advance with LV_RLY_ACCOUT_CTRL.

In case of Start in high altitude, A/C compressor is disabled during a specific time delay in order to improve braking performance (lower pressure in intake manifold).

In order to eliminate slogging noise when A/C compressor is clutched after long soaking time, the A/C compressor can be activated during cranking.

In case of A/T vehicle, to avoid a shock with the A/C activation transition during A/T gear shift, A/C control needs to be delayed after the A/T gear shift done.

Remind : LV_ACIN : Air condition selected
LV_ACCIN : Air condition requested

Application conditions:

Initialisation: at transition engine run to engine stop all variables are reset

Recurrence: 40ms; except deactivation condition 7 , 8 (100ms)

Activation: (***LV_RLY_ACCOUT = ON***)

If CONF_ACC = 1 (Corresponding “Variant Coding” is set)
and engine operating states engine stopped (LV_ES) not active
and engine operating state start (LV_ST) not active
and air condition selected (LV_ACIN = ACIN)
and air condition requested (LV_ACCIN = ACCIN)
and LV_RLY_ACCOUT= OFF since more than C_ACCIN_DLY_5 seconds (time counted with T_ACCIN_DLY, STATE_ACC_DLY = ACCIN_DLY_5)
and TCO ≤ C_TCO_5_CFA
and LV_AC_OFF_REQ_BRK = 0
and LV_GS_ACT = 0 and time delay of C_T_GS_ACT_DLY is elapsed after LV_GS_ACT = 1 -> 0 (time counted with T_GS_ACT_DLY)

then LV_RLY_ACCOUT_CTRL is enabled immediately
and LV_RLY_ACCOUT is enabled after IP_ACCIN_DLY_2__N_32 seconds.
and Timer T_GS_ACT_DLY is reset

* *Deactivation* (**LV_RLY_ACCOUT = OFF**) :

If one of the deactivation conditions are true, LV_RLY_ACCOUT and LV_RLY_ACCOUT_CTRL are disabled whatever the activation conditions are.

1 - **If** Transition from LV_ST -> LV_IS
or LV_ST -> LV_PL
then STATE_ACC_DLY = ACCIN_DLY_4
If AMP_AD < C_AMP_AD_ACCIN_DLY_4 **or**
LV_ERR_MAF = 1 **or**
LV_ERR_MAP = 1
then T_ACCIN_DLY = IP_ACCIN_DLY_4__TCO_ST__TIA_ST
else T_ACCIN_DLY = ID_ACCIN_DLY_4__TCO_ST

else
If Transition LV_ACIN = 0 -> 1 **and**
T_AST > C_ACIN_DLY_4
then T_ACCIN_DLY reseted to 0
else Timer normally down to 0

2 - **If** T_ACCIN_DLY = 0

then LV_RLY_ACCOUT_CTRL is enabled immediately
LV_RLY_ACCOUT is enabled **after** IP_ACCIN_DLY_2__N_32

else LV_RLY_ACCOUT and LV_RLY_ACCOUT_CTRL are disabled immediately

3 - **If** acceleration enrichment due to full load (LV_FL) active
and VS **<** C_ACCIN_VS_MAX

then if LV_GS_ACT = 0 and time delay of C_T_GS_ACT_DLY is elapsed after
LV_GS_ACT = 1 -> 0 (time counted with T_GS_ACT_DLY)

then STATE_ACC_DLY = ACCIN_DLY_1
LV_RLY_ACCOUT_CTRL and LV_RLY_ACCOUT are disabled immediately
during C_ACCIN_DLY_1 seconds (time counted with T_ACCIN_DLY).

Remark:
If LC_ENA_ACCIN_CT = 1
Then If LV_CT = 1 (no acceleration)
Then A/C deactivation timer is initialized

4 - **If** LV_ACCIN **=** 0 (-)
then if LV_GS_ACT = 0 and time delay of C_T_GS_ACT_DLY is elapsed after
LV_GS_ACT = 1 -> 0 (time counted with T_GS_ACT_DLY)
then LV_RLY_ACCOUT_CTRL is disabled immediately
LV_RLY_ACCOUT is disabled **after** IP_ACCIN_DLY_3__N_32 seconds.

5 - **If** TCO **>** C_TCO_5_CFA

then if LV_GS_ACT = 0 and time delay of C_T_GS_ACT_DLY is elapsed after
LV_GS_ACT = 1 -> 0 (time counted with T_GS_ACT_DLY)

then LV_RLY_ACCOUT_CTRL is disabled immediately

LV_RLY_ACCOUT is disabled **after** IP_ACCIN_DLY_3__N_32 seconds

until TCO ≤ C_TCO_5_CFA - C_ACCOUT_TCO_HYS

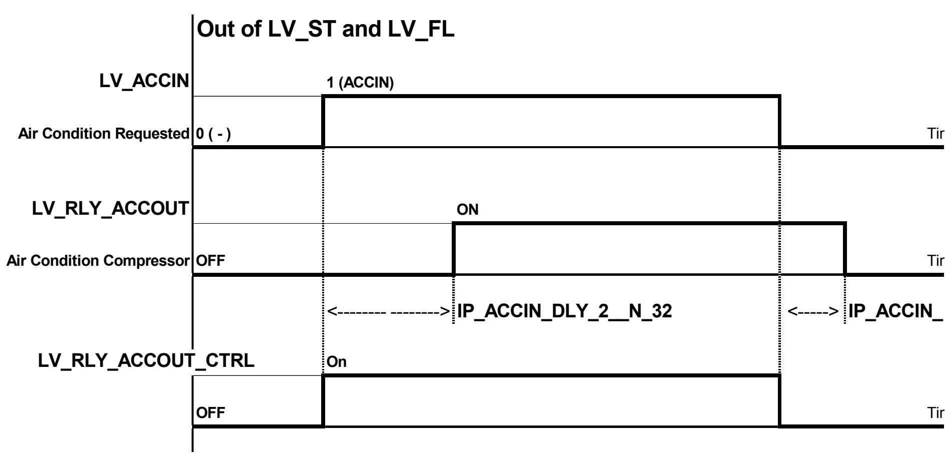
Description:



Activation of air condition compressor relay at engine start

** Initialization :*

LV_RLY_ACCOUT_ST is set to 0 at engine stop (LV_ES)

** Activation* (**LV_RLY_ACCOUT_ST = ON)**

If Transition from ES to ST

and TIA > C_TAM_MIN_ACC_ST

and TCO – TIA < C_HYS_TAM_ACC_ST

and VB > C_VB_MIN_ACC_ST

Then LV_RLY_ACCOUT_ST = 1 during C_T_ACCOUT_ST_ACT

Else LV_RLY_ACCOUT_ST = 0

Activation of air condition compressor relay by external tester

If CONF_ACC = 1 and LV_RLY_ACCOUT_EXT_ADJ = 1, then RLY_ACCOUT is controlled by LV_ACT_ACCOUT_EXT_ADJ

Priority Rules:

LV_ACT_ACCOUT_EXT_ADJ has highest priority on LV_RLY_ACCOUT : If CONF_ACC = 1 and LV_ACCOUT_EXT_ADJ = 1 then LV_RLY_ACCOUT **=** LV_ACT_ACCOUT_EXT_ADJ

LV_RLY_ACCOUT_ST has priority on LV_RLY_ACCOUT : If LV_RLY_ACCOUT_ST = 1, then LV_RLY_ACCOUT **=** LV_RLY_ACCOUT_ST

Selection of air condition input for cooling fan control:

** Initialization :* LV_ACC_CFA = 0

** Activation* : at every engine state

If LC_ACC_CFA_SEL = 1

then **if** LV_RLY_ACCOUT = 1 *(A/C compressor active)*

then LV_ACC_CFA = 1

else LV_ACC_CFA = 0

else **if** LV_ACIN = 1 *(A/C selected in dashboard)*

then LV_ACC_CFA = 1

else LV_ACC_CFA = 0

Calibration data:

EGR flow setpoint at the valve					
V_EGR	O	0...3FFH	0...4.995117	5/1023	V
EGR valve opening raw acquisition					

Input data:

General information:

For systems without external Exhaust Gas Recirculation (NC_EGR_CONF = 0) the aggregate outputs of EGRC have to be initialized to neutral values. If no EGR is available, the present module and the EGRC configuration module will be the only modules of the EGRC aggregate present in the ECU software. If EGR is available, the present module will not be present in the ECU software.

Recurrence : once after ECU reset.

General information:

During development optional modules can be not implemented yet. Other modules can need the outputs of these not implemented functions as inputs. To satisfy their interfaces the output variables of of these not implemented functions are initialized here.
Specific for VW EMS2 Entwicklungsplattform: suitable only for systems with mono-turbo, one exhaust bank, low MAF range !

PRS_CHRG_DOWN_MAX is a dummy to satisfy INSY inputs.

Application conditions:

Initialisation: PRS_CHRG_DOWN_MAX = 5434 hPa
PRS_AIC_DOWN_TCHA [1] = AMP
LV_TCHA_CONF = LC_TCHA_CONF

standard initialisation of all other outputs with 0

Recurrence: see below

Activation: LC_TCHA_CONF = 1

Dectivation: LC_TCHA_CONF = 0

Formula section:

All output variables not calculated in the formula section keep their initialization values.

Calculations to be performed before the CHRG package

Recurrence: segment synchronous

VB_MMV	TCO	N_32	LV_ERR_VIM
LV_ERR_VCC_SENS_SUB	LV_ERR_VIM_FB_EL	CONF_VIM	

FUNCTION DESCRIPTION:

General information:

The delivered voltage from the VIM- potentiometer indicates the position of the variable intake manifold. Physically the potentiometer delivers a linear rising voltage-characteristic with 0...5V. The stops in short and long position are adapted once for the whole engine life.

This occurs while engine operating state PUC, to avoid drivability effects and to guarantee sufficient low pressure in the intake manifold for the vacuum box.

The learned values are stored at the end of the driving cycle as „non-volatile“.

If no VIM- adaptation was fulfilled for the whole engine life or the adaptation values were lost (LV_VIM_AD_VLD = 0) the values V_VIM_AD_SHO/ LONG are set to default values. Otherwise these values are stored in the non volatile memory of the ECU and are valid till the next adaptation was successful.

While adaptation is active and STATE_VIM_AD = VIM_AD_SHORT_STOP the setpoint LV_VIM_SP_AD is set to 1 (request to control the control valve). After a calibratable delay time (C_T_HLD_VIM_AD) V_VIM_SHO is calculated as an average value (starting with V_VIM_AD_SHO) for C_T_VIM_AD seconds.

Then the VIM is set to the long position (STATE_VIM_AD = VIM_AD_LONG_STOP) (LV_VIM_SP_AD is set to 0) and after the same hold time V_VIM_LONG is calculated as an average value (starting with V_VIM_AD_LONG) for C_T_VIM_AD seconds.

If these values V_VIM_SHO and V_VIM_LONG are within a valid range, these values are copied into V_VIM_AD_SHO/ LONG and saved (together with LV_VIM_AD_VLD) in the non volatile memory of the ECU.

The adaptation has to be calculated immediately before adaptation diagnosis.

Application conditions:

Initialisation: at reset and LV_IGK = 0 $\rightarrow$ 1

	VIM_AD_ERR_CTR = 0	
If	at least one VIM adaptation took place for whole engine life	
and	no checksum error was detected	
Then	LV_VIM_AD_VLD = 1	*;adaptation values available*
Else	LV_VIM_AD_VLD = 0	*;no adaptation values are available*
Endif		

If	LV_VIM_AD_VLD = 1	
Then	V_VIM_SHO = V_VIM_AD_SHO	
	V_VIM_LONG = V_VIM_AD_LONG	
	STATE_VIM_AD = VIM_AD_OK	
	LV_VIM_AD_REQ = 0	
Else	V_VIM_AD_SHO = C_V_VIM_SHO_INI	*;never a successful adaptation*
	V_VIM_SHO = C_V_VIM_SHO_INI	*fulfilled, no adaptation values*
	V_VIM_AD_LONG = C_V_VIM_LONG_INI	*available,*
	V_VIM_LONG = C_V_VIM_LONG_INI	
	STATE_VIM_AD = VIM_AD_PUC_TIMER	
	LV_VIM_AD_REQ = 1	
	LV_VIM_SP_AD = 0	
	T_MIN_PUC_VIM_AD = C_T_MIN_PUC_VIM_AD	

Endif

Recurrence: 20 ms

Activation: CONF_VIM = 2

Formula section:

Activation of adaptation:

```
If      (LV_VIM_AD_REQ = 1                           and    ;adaptation requested
        [(LC_VIM_AD_PUC_ENA = 1 and   LV_PUC=1)
        or      LC_VIM_AD_PUC_ENA = 0 ]

        T_HLD_VIM_AD = C_T_HLD_VIM_AD
        T_VIM_AD = C_T_VIM_AD
Endif
```

Adaptation algorithm (this is a sequence of actions to do in this order):

Adaptation of short position:

If STATE_VIM_AD = VIM_AD_SHORT_STOP

Then LV_VIM_AD_ACT = 1 *;VIM adaptation active*

LV_VIM_SP_AD = 0 *;switching to short position*

timer T_HLD_VIM_AD is decremented

If timer T_HLD_VIM_AD = 0 *;enough time in short position*

Then timer T_VIM_AD is decremented

Endif

If T_VIM_AD > 0 *;adaptation value calculation active*

Then $V\_VIM\_SHO_N = V\_VIM\_SHO_{N-1} * (1 – C\_CRLC\_V\_VIM) + V\_VIM_N * C\_CRLC\_V\_VIM$

Else STATE_VIM_AD = VIM_AD_LONG_STOP

T_HLD_VIM_AD = C_T_HLD_VIM_AD

T_VIM_AD = C_T_VIM_AD

;adaptation of short position finished, switch to next adaptation step

Endif

Endif

Adaptation of long position:

If STATE_VIM_AD = VIM_AD_LONG_STOP

Then LV_VIM_SP_AD = 1 *;switching to long position*

T_HLD_VIM_AD is decremented

If timer T_HLD_VIM_AD = 0 *;enough time in long position*

Then timer T_VIM_AD is decremented

Endif

If T_VIM_AD > 0 *;adaptation value calculation active*

General Information

The variable intake manifold serves to increase the engine torque by adjusting the length of the intake manifold. Lengthen the intake manifold increases the engine torque with low engine speed, shorten the lenght helps to increase engine power with high engine speed.
The setpoint of the variable intake manifold (LV_VIM_SP) is set by the (not interpolated) table ID_VIM_SP depending on N_32 and MAF_SP_TQI.

Application Conditions

Initialization: RST, ES2ERU
Recurrence: 20MS
Activation: CONF_VIM > 0
Deactivation: CONF_VIM == 0

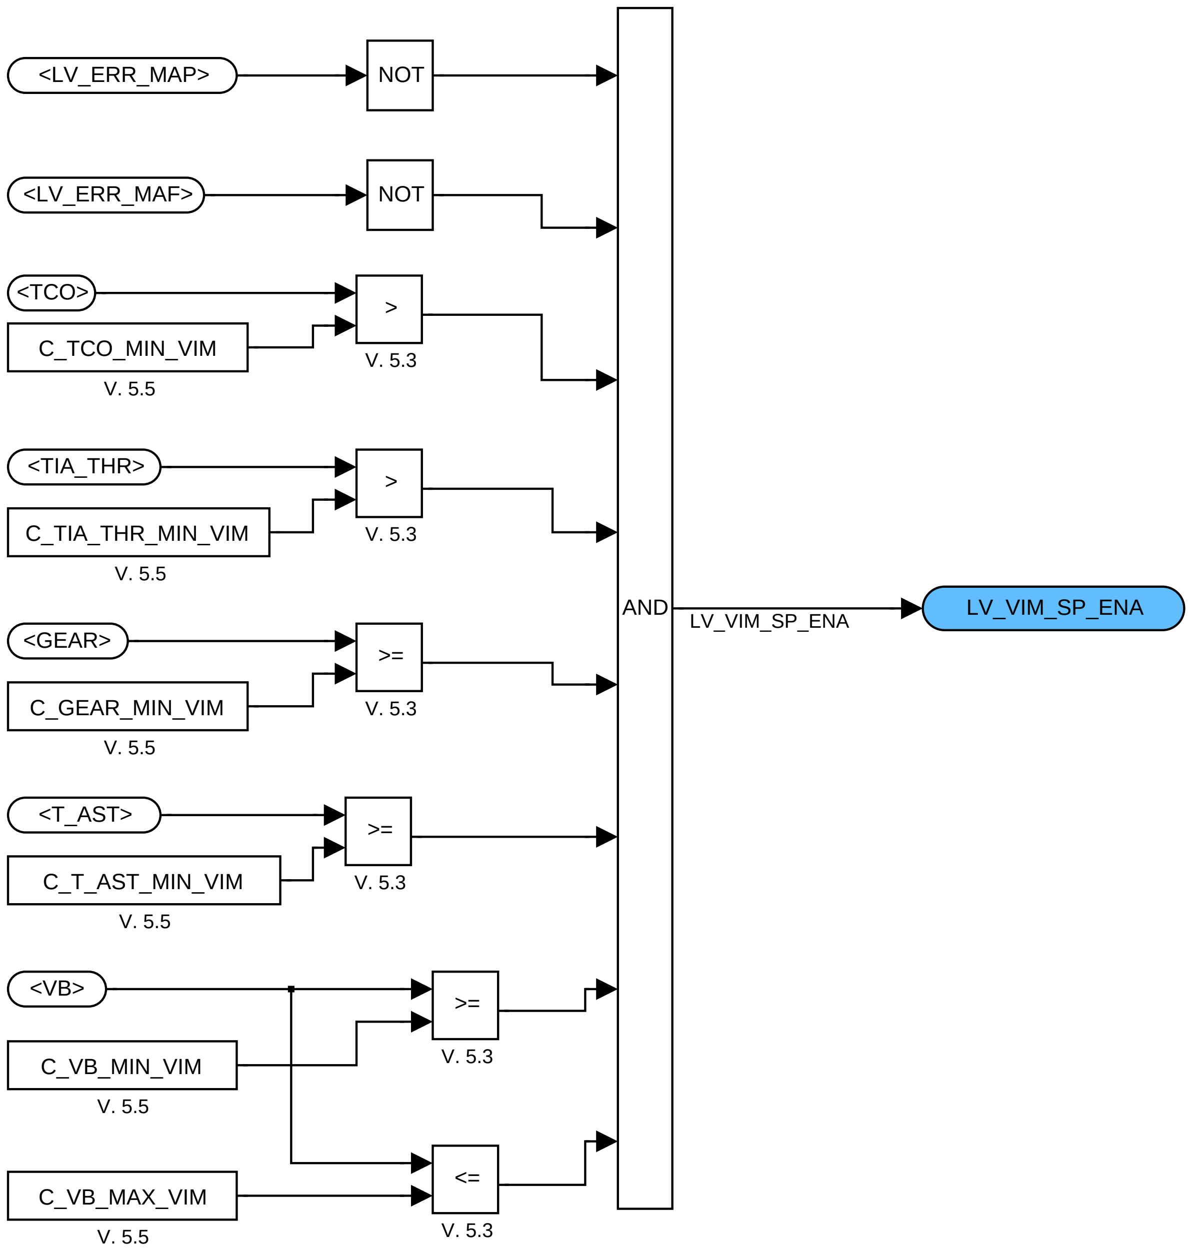

Figure 8:
Path: VIMA_M9006/OPM_20MS/VIM_SP_ENA

9.9.2.3 Calculation of the basic VIM - setpoint LV_VIM_SP_RAW

To avoid drivability problems by switching too often, hysteresises on the switching engine speed and load setpoint are set. If the value of N_32_VIM_COR or MAF_SP_TQI leaves the hysteresis, then the new setpoint is fixed via ID_VIM_SP and N_32_VIM_COR and MAF_SP_TQI are saved as N_32_VIM_SWI and MAF_SP_TQI_VIM_SWI.

MAF moving mean value					
MAF_STK_CYL	V/O	0...FFFFH	0...2778	0.0423896	[mg/stk]
Air mass flow out of the intake manifold per stroke					

Input data:

MAF	MAF_CYL	MAF_DIF	MAF_FG_CYL
MAF_HB	MAF_KGH	MAF_KGH_FG_PRED	MAF_KGH_MES
MAF_MDL_MV	MAF_MMV	MAF_THR	MAF_MDL_DIF
MAF_CYL_STK			

FUNCTION DESCRIPTION:

General information:

As there are projects that work with a higher mass air flow than other projects before, an extension of the MAF ranges has to be done. This module provides all the MAF variables that are exported out of the aggregate INSY with the new ranges and the new resolution. So the interfaces between INSY and other aggregates are satisfied.

Application conditions:

Activation: all engine operating states

Initialisation:

Recurrence: segment synchronously

Formula section:

MAF_KGH_ACQ = MAF_KGH_MES
MAF_KGH_CYL = MAF_CYL
MAF_KGH_ENG = MAF_KGH
MAF_KGH_FG_CYL = MAF_FG_CYL
MAF_KGH_FG_PRED_CYL = MAF_KGH_FG_PRED
MAF_KGH_MDL_DIF = MAF_MDL_DIF
MAF_KGH_MDL_MV = MAF_MDL_MV
MAF_KGH_THR = MAF_THR
MAF_STK_DIF = MAF_DIF
MAF_STK_FG_PRED = MAF
MAF_STK_FG_PRED_HB = MAF_HB
MAF_STK_MMV = MAF_MMV
MAF_STK_CYL = MAF_CYL_STK

9.10.2 Exported MAF variables from INSY with extended range that are calculated every 10ms

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
MAF_KGH_SP_ENG	V/O	0...FFFFH	0...4095.9375	0.0625	[kg/h]
Setpoint mass air flow into the manifold					
MAF_STK_SP	V/O	0...FFFFH	0...2778	0.0423896	[mg/stk]
MAF setpoint output for inverse air path					
MAF_STK_SP_S	V/O	0...FFFFH	0...2778	0.0423896	[mg/stk]
MAF setpoint for stratified mode					

Input data:

MAF_KGH_SP	MAF_SP	MAF_SP_S	NC_INJ_CONF

FUNCTION DESCRIPTION:

General information:

As there are projects that work with a higher mass air flow than other projects before, an extension of the MAF ranges has to be done. This module provides all the MAF variables that are exported out of the aggregate INSY with the new ranges and the new resolution. So the interfaces between INSY and other aggregates are satisfied.

Application conditions:

Activation: all engine operating states

Initialisation:

Recurrence: 10ms

Formula section:

MAF_KGH_SP_ENG = MAF_KGH_SP
MAF_STK_SP = MAF_SP
#If NC_INJ_CONF = 1
#Then
MAF_STK_SP_S = MAF_SP_S
#Else
MAF_STK_SP_S = 0
#Endif

9.10.3 Exported MAF variables from INSY with extended range that are calculated every 20ms

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
MAF_KGH_INT_PUC_ACT	V/O	0...FFFFH	0...5825.33333	0.0888889	[g]
air mass flow integral during pull cut off phase					
MAF_KGH_INT_PUC_NOT_ACT	V/O	0...FFFFH	0...5825.33333	0.0888889	[g]
air mass flow integral out of pull cut off phase					

Input data:

MAF_INT_PUC_ACT	MAF_INT_PUC_NOT_ACT		

FUNCTION DESCRIPTION:

General information:

As there are projects that work with a higher mass air flow than other projects before, an extension of the MAF ranges has to be done. This module provides all the MAF variables that are exported out of the aggregate INSY with the new ranges and the new resolution. So the interfaces between INSY and other aggregates are satisfied.

Application conditions:

Activation: all engine operating states

Initialisation:

Recurrence: 20ms

Formula section:

MAF_KGH_INT_PUC_ACT = MAF_INT_PUC_ACT
MAF_KGH_INT_PUC_NOT_ACT = MAF_INT_PUC_NOT_ACT

9.10.4 Exported MAF variables from INSY with extended range that are calculated every 40ms

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
MAF_STK_MAX_COR	V/O	0...FFFFH	0...2778	0.0423896	[mg/stk]
Maximum possible fresh air entering in the cylinder (open throttle)					
MAF_STK_MIN_COR	V/O	0...FFFFH	0...2778	0.0423896	[mg/stk]
Minimum available fresh air going into the cylinder					

Input data:

MAF_MAX_COR	MAF_MIN_COR		

FUNCTION DESCRIPTION:

General information:

As there are projects that work with a higher mass air flow than other projects before, an extension of the MAF ranges has to be done. This module provides all the MAF variables that are exported out of the aggregate INSY with the new ranges and the new resolution. So the interfaces between INSY and other aggregates are satisfied.

Application conditions:

Activation: all engine operating states

Initialisation:

Recurrence: 40ms

Formula section:

MAF_STK_MAX_COR = MAF_MAX_COR
MAF_STK_MIN_COR = MAF_MIN_COR

9.11 General Port Flap

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PORTPWM_TMP	V/O	8000H...7FFFH	-100...99.99	0.003	%
PORTPWM before overload protection					
V_PORT	V/O	0...3FFH	0...5	0.00488	V
Port flap potentiometer signal					
FRQ_PORTPWM	V/O	0...FFH	1000...8650	30	Hz
Frequency of PWM for Port Flap					

Input data:

PORTPWM_CTL	PORT_FB_BAS	PORTPWM_DIAG	CONF_PORT
LV_ERR_PORT	LV_PORT_AD_VLD	V_PORT_AD_TOL	V_PORT_AD_BOL
PORT_SP			

FUNCTION DESCRIPTION:

General information:

The port flap inside the intake port influences the gas flow into the combustion chamber, and thus, the gas motion within the chamber. The activation of the port flap increases the gas velocity into the combustion chamber. This improves the gas mixture formation process, ignition properties of the mixture and the combustion process. The port flap is only closed one time after start and opened again dependent on different after Start conditions

The intake port is fully open if the flap is in 0° position and fully closed at 73°. The port flap is driven by an electric DC motor with worm gear. The motor is driven by an H-bridge and energized with a duty cycle. Positive duty cycles activate the worm gear motor to close the Port Flap negative values of the duty cycle are used to open the Port flap. 0% duty cycle keep the port flap in the actual position due to the selflocking of the worm gear. The actual port flap position is measured by means of a potentiometer, PORT_FB_BAS.

To avoid hard strikes against the mechanical stop positions the PORTPWM_TMP is limited to C_PORTPWM_TMP_MAX during acting of PORT Flap close to the mechanical stop positions, which are learned during Adaptation.

Application conditions:

Recurrence: 10 ms

Activation: CONF_PORT = 1

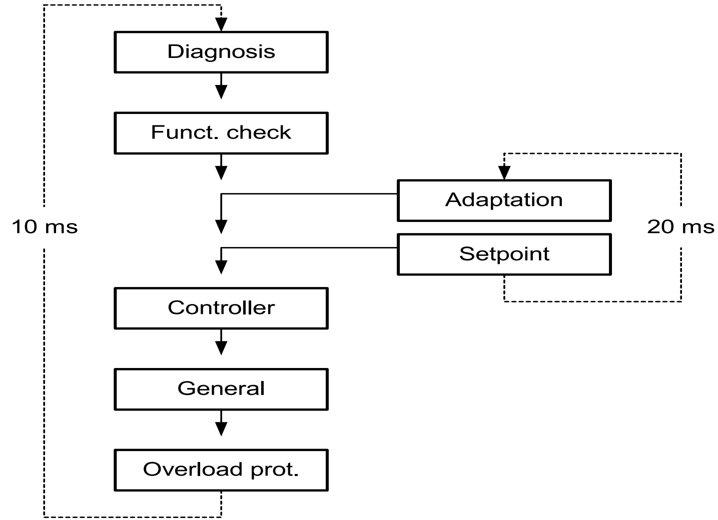

Figure: Sequence of port flap tasks.

Formula section:

Frequency of PWM for Port Flap:

FRQ_PORTPWM = C_FRQ_PORTPWM

Potentiometer signal:

V_PORT = PORT_FB_BAS

Determination of port flap energization PWM:

If$_1$ LV_ERR_PORT = 0

Then$_1$

If$_2$ LV_PORT_AD_VLD= 1

Then$_2$ *mechanical Stop Position learned*

If$_3$ PORT_SP = 1

And V_PORT > V_PORT_AD_TOL – C_V_PORT_DIF_THD

Then$_3$ PORTPWM_TMP = min (PORTPWM_CTL; C_PORTPWM_TMP_MAX)

Limit Port PWM near TOL to avoid hard strikes against mechanical stop

Else$_3$

If$_4$ PORT_SP = 0

And V_PORT < V_PORT_AD_BOL + C_V_PORT_DIF_THD

Then$_4$ PORTPWM_TMP = max (PORTPWM_CTL;

-C_PORTPWM_TMP_MAX)

Limit Port PWM near BOL to avoid hard strikes against *mechanical stop*

Hint: As the PWM values to open PORT have to be negative here the <u>absolute</u> smallest value has to be result of the MIN election (i.e.-10% versus -30% --> PORTPWM_TMP is limited to -10%)

Else$_4$ PORTPWM_TMP = PORTPWM_CTL

Endif$_4$

Endif$_3$

Else$_2$ PORTPWM_TMP = PORTPWM_CTL

Endif$_2$

Else$_1$ PORTPWM_TMP = PORTPWM_DIAG

Endif$_1$

<u>Calibration data:</u>

Bit indication, whether PORT SP remains open					

Input data:

LV_PORT_SP_EXT_ADJ	PORT_SP_EXT_ADJ	TCO_ST	VB
TIA_ST	T_AST	AMP	N_32
LV_PORT_AD_VLD	LV_PL	LV_IGK	

FUNCTION DESCRIPTION:

General information:

The port flap influences the gas flow into the combustion chamber, and thus, the gas motion within the chamber.

The Port Flap will be closed, if all activation conditions for closing are fullfilled (i.e TCO_ST, TIA_ST, AMP, VB). The closing is additionally allowed at warm engine if the adaptation has not been performed yet to be able to do adaptation at end of line test or at service. (Hint: This also has to be considered in the calibration of the IP_PORT_SP)

The Port Flap will be opened depending on T_AST and TCO_ST and will remain opened till the next restart.

The Port Flap is only closed during Idle speed condition and will be opened (and remains open) as soon as Part Load is detected

Additionally the Port Flap can be activated by external request or by Application system.

Application conditions:

Recurrence: 20 ms

Initialization: *At reset:* PORT_SP = 0 (open)

LV_PORT_SP_PAS = 0

At LV_IGK = 0--> 1: LV_PORT_SP_PAS = 0

Activation: In every engine state

V_PORT	V_PORT_SLOPE	V_PORT_AD_BOL	PORT_SP
LV_ERR_PORT_POTI	C_PORT_BOL	C_PORT_TOL	T_PORT_DLY4
T_PORT_DLY5			

FUNCTION DESCRIPTION:

General information:

A linear potentiometer is used for the port flap position feed-back. The potentiometer is supplied by 5 V from the ECU. The physical range of the flap position corresponds to the electrical range of the Potentiometer, see the figure "Port flap position feed-back".

The real port flap stop position, C_PORT_BOL and C_PORT_TOL, and the real potentiometer signal are adapted after movement see "Adaptation of Lower and Higher Port Flap Stop Positions".

The actual port flap position PORT_AV is calculated from the measured signal V_PORT. As mentioned above, a linear potentiometer is used. The quantities V_PORT_BOL and V_PORT_SLOPE are determined in "Adaptation of Lower and Higher Port Flap Stop Positions". If there is an error of the potentiometer the replacement value C_PORT_AV_DFT is taken.

The port flap position is needed in other functionalities, e.g., volumetric efficiency. In order to express the opening relatively the relative port flap position FAC_PORT_DEAC is calculated. The reference angle is C_PORT_TOL, so FAC_PORT_DEAC has its values from 0 to 1.

For Fleet Monitoring the MIN/MAX values of Potentiometer and Gradient are stored.

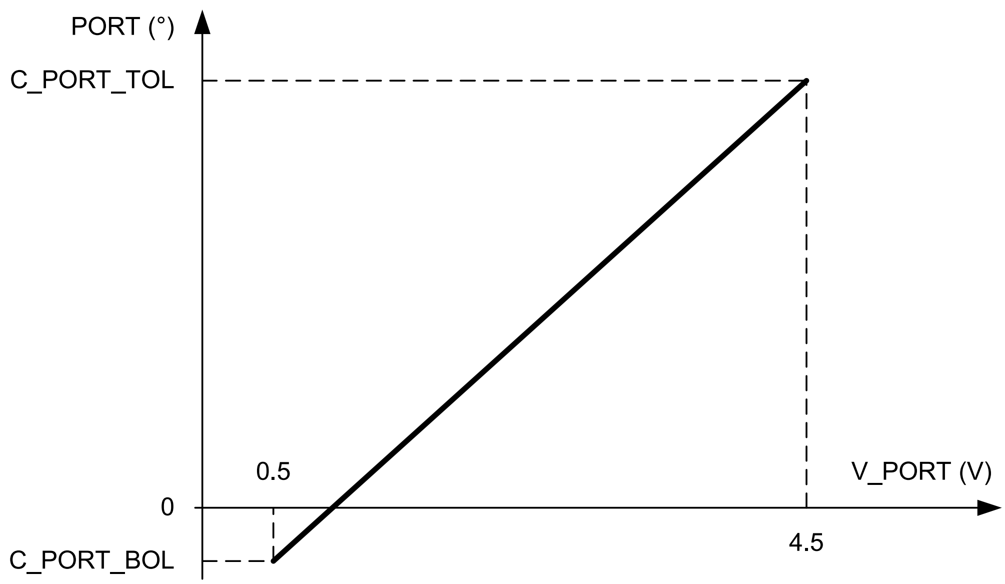

Figure: Port flap position feed-back.

Application conditions:

Initialisation: *at first Power up or loss of NVMY*

V_PORT_OPEN_MAX_TOT_DC = 0H (0V)

V_PORT_OPEN_MIN_TOT_DC = 3FFH (5V)

V_PORT_CLOSE_MAX_TOT_DC = 0H (0V)

V_PORT_CLOSE_MIN_TOT_DC = 3FFH (5V)

PORT_AV_GRD_OPEN_MAX_TOT_DC = F000H (-1000°/sec)

PORT_AV_GRD_OPEN_MIN_TOT_DC = 0H (0°/sec)

PORT_AV_GRD_CLOSE_MAX_TOT_DC = 0H (0°/sec)

PORT_AV_GRD_CLOSE_MIN_TOT_DC = 1000H (1000°/sec)

Otherwise restored from NVMY

at reset:

PORT_AV_GRD_MAX_DC = 0H (0°/sec)

PORT_AV_GRD_MIN_DC = 0H (0°/sec)

Recurrence: 10 ms

Activation: At every engine state

Formula section:

Port flap position feed-back:

if$_1$ LV_ERR_PORT_POTI = 1

then$_1$ PORT_AV = C_PORT_AV_DFT

else$_1$ PORT_AV = (V_PORT - V_PORT_AD_BOL) * V_PORT_SLOPE + C_PORT_BOL

endif$_1$ PORT_AV_GRD = (PORT_AV(n) – PORT_AV(n-4))*25 /sec

Calculation of FAC_PORT_DEAC:

FAC_PORT_DEAC = abs(PORT_AV) / C_PORT_TOL

Calculation of MIN/MAX values for Fleet Monitoring:

```
if          PORT_SP = 0
      and   PORT_AV_GRD <  - C_PORT_GRD_MOVE_DET
            movement of Port Flap is detected (opening)
then  if    PORT_AV_GRD < PORT_AV_GRD_MIN_DC
      then  PORT_AV_GRD_MIN_DC = PORT_AV_GRD
      endif

if          PORT_SP = 1
      and   PORT_AV_GRD > C_PORT_GRD_MOVE_DET
            movement of Port Flap is detected (closing)
then  if    PORT_AV_GRD > PORT_AV_GRD_MAX_DC
      then  PORT_AV_GRD_MAX_DC = PORT_AV_GRD
      endif
endif

Input data:

PORT_SP	V_PORT	PORT_AV_GRD	LV_ES

FUNCTION DESCRIPTION:

General information:

The Port Flap controller is driven by IP_PORTPWM_CTL_CLOSE or IP_PORTPWM_CTL_OPEN map dependent on the desired Setpoint and Potentiometer Position to open or to close the Flap. As soon as the Port Flap is not moving anymore and the difference between actual position and position after last energizing is smaller than a threshold a counter is decreased. If the counter is at 0 the PORTPWM_CTL is switched to Holding PWM for closed position to counteract Airflow at closed position and switched off for open position and the flags LV_PORT_TOL_CDN (for Closed position) respectively LV_PORT_BOL_CDN (for open Position) are set.

This flags are used to activate the check of mechanical stop positions. (see Adapatation of Port Flap Stop positions)

V_PORT	LV_PORT_TOL_CDN	LV_PORT_BOL_CDN	LV_IGK
LV_ERR_VCC_SENS_SUB	LV_ERR_PORT_POTI	LV_ERR_PORT_EL	

FUNCTION DESCRIPTION:

General information:

The port flap position is measured by means of a linear potentiometer. The physical range of the flap position corresponds to the electrical range from In order to have individual value for each port flap an adaptation of lower and higher port flap stop position is done. The adaptation delivers the potentiometer signals of the flap in the stop positions V_PORT_AD_TOL and V_PORT_AD_BOL. They are saved in non-volatile memory, i.e., they are available at the beginning of a new driving cycle, if there has not been a checksum error. The potentiometer slope can be calculated from adapted values.

The adaptation is only performed in case of unvalid adaptation results, i.e adaptation was not sucessfully finished or due to external Adaptation request.

Application conditions:

9.15.1 Initialization:

At first power on or NVMY error :

LV_PORT_AD_VLD = 0

Timer for applying PORTPWM for Powerstage Diag					

Input data:

PORTPWM_TMP	VB	TCO	LV_ERR_PORT_EL
LV_ERR_PORT	LV_ES		

General information:

In order to avoid the port flap electric motor overload the timer T_PORT_DLY1 starts if the critical pulse width modulation C_PORTPWM_OVL_LIM is exceed. If the timer T_PORT_DLY1 reaches its limit C_T_PORT_DLY1 the pulse width modulation is reduced to the value C_PORTPWM_DFT and the timer is reset.

The calibratable delay time C_T_PORT_DLY2 defines the duration of the PWM on C_PORTPWM_DFT. If PORTPWM_TMP undershoots C_PORTPWM_OVL_LIM before the delay C_T_PORT_DLY2 expires, then PORTPWM_TMP is the output signal. The count down of the delay C_T_PORT_DLY2 continues.

To perform the Powerstage diagnosis at least a Minimum PWM is necessary. Therefore if there is no request to move the Port Flap (PORTPWM_TMP = 0), then a PWM switch pattern is applied.

Application conditions:

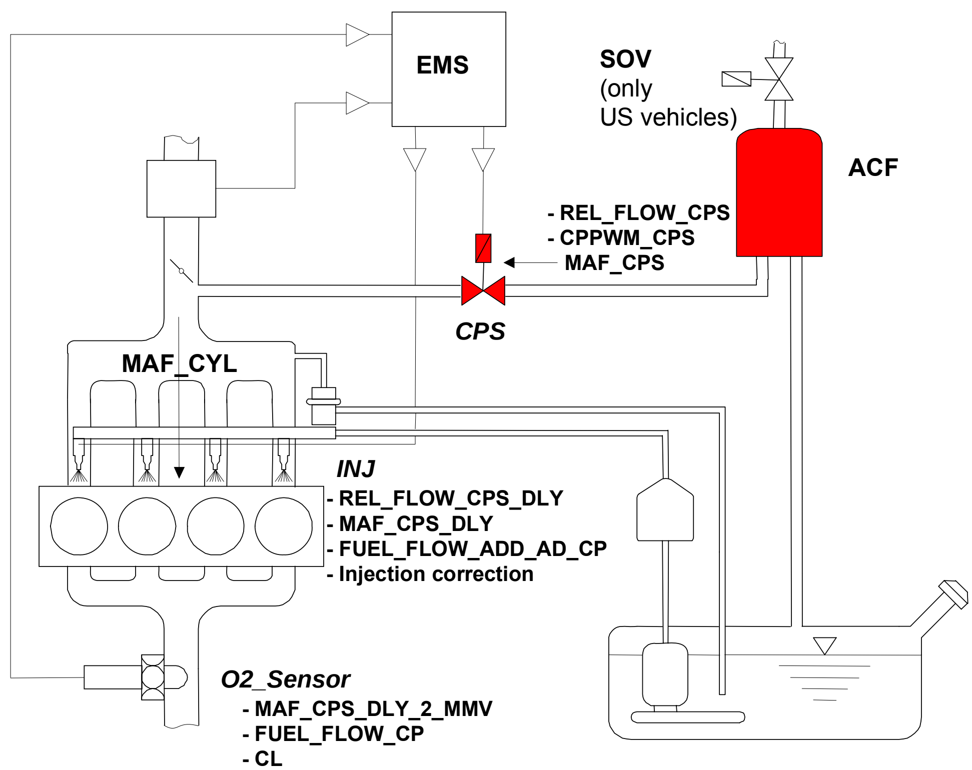
9.17 Evaporative Emission Control

General information:

The evaporative emissions of the fuel tank system are stored in a activated charcoal filter ACF to prevent an escape of the gas to the environment. The loading capacity of the filter is limited. So the filter must be purged temporarily. Therefore the canister purge solenoid CPS, that is positioned between the charcoal filter and the intake manifold is opened by the engine management system. To prevent driveability and emission problems, the opening of the CPS and so the purge flow FUEL_FLOW_CP must be controlled.

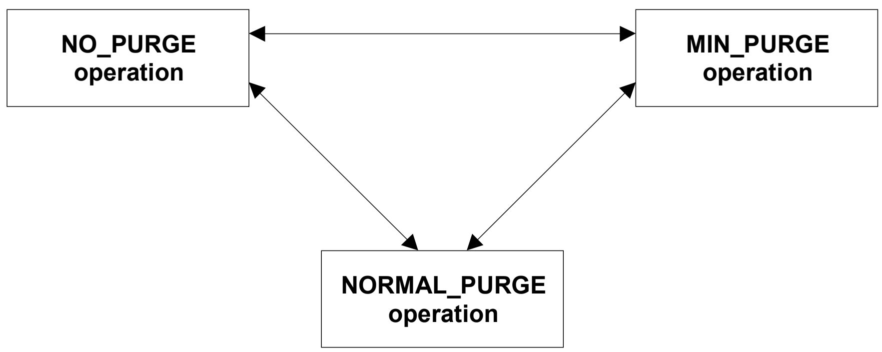
With the Evaporative Emission Control function the opening of the CPS is controlled in dependence on the fuel mass stored in the canister. Therefore the canister load CL is calculated using the measured mass air flow MAF, the deviation of the lambda-control when the CPS is open, the mass flow FLOW_CPS through the CPS and the stoichiometric constant of the fuel C_FUEL_FAC_CP. The opening period CPPWM of the CPS is controlled in dependence on the canister load CL.



general specification

<u>The Evaporative Emission Control consists of the following partial functions:</u>

NO_PURGE	no purging of the activated charcoal filter (ACF)
MIN_PURGE	purging of the activated charcoal filter (ACF) with unknown loading of the ACF, purging with low mass flow through the canister purge solenoid
NORMAL_PURGE	purging in dependence on the canister load CL of the activated charcoal filter (ACF), the MAX_PURGE consists of the phases RAMP_OPEN, MAX_PURGE and RAMP_CLOSE



During enabled Evaporative Emission Control (LV_CP_ENA = 1) one of the three partial function is activated in dependence of the engine operating conditions.

<u>Application conditions:</u>

Activation: LV_CP_ENA = 1

Recurrence: 100ms

9.17.1 Activation of the Evaporative Emission Control Function

Output data:

Logical value for enabled EVAP-Control					

Input data:

LV_ES	LV_ST	LV_AST	TCO
T_AST_DC	TCO_ST	CONF_CP	EOL_STATE_DIAGCP

FUNCTION DESCRIPTION:

General information:

The Evaporative Emission Control function is enabled (LV_CP_ENA=1), if the coolant temperature is higher than a threshold value C_TCO_MIN_CP and the time after start is greater than a threshold ID_T_AST_CP__TCO_ST. The function is active during all engine operating states except the following states:

engine stop, engine start, post-start function function active.

Formula section:

```
if          TCO ≥ C_TCO_MIN_CP
     and    LV_ES = 0
     and    LV_ST = 0
     and    LV_AST = 0
     and    CONF_CP > 0
then        if      EOL_STATE_DIAGCP <> EOL_PAS
            then    LV_CP_ENA = 1

Accumulated time of total TI-adaptation duration					

Input data:

CL_MMV	C_CL_MIN_CP	LV_CP_ENA	T_MIN_CP
T_CP_TI_AD_SP			

FUNCTION DESCRIPTION:

General information:

The engine operation is divided into 3 time ranges. After transition from the engine operating state start (LV_ST 1->0) the time period CP_T_1 is active (CP_T_STATE=1 (Hex.)) if the Evaporative Emission Control is enabled (LV_CP_ENA=1). During this period the Evaporative Emission Control is possible if the conditions for the function are fulfilled. This period ends if the time T_CP exceeds the maximum time C_T_1_CP or the canister load CL_MMV is lower than a threshold value C_CL_MIN_CP and the time T_CP was greater than T_MIN_CP (see chapter “Partial Functions of the Evaporative Emission Control”). After that period there is a continuous alternation of the time periods TI_T_AD and CP_T_2. First the lambda adaptation is activated if the conditions are fulfilled. This phase is active for a time T_CP_AD_1 (CP_T_STATE=3 (Hex.)). When the time T_CP is greater than T_CP_AD_1 the period CP_T_2 (CP_T_STATE=2 (Hex.)) is active and the Evaporative Emission Control is possible if the conditions are fulfilled. This period ends if the time T_CP exceeds the maximum time C_T_2_CP or the canister load CL_MMV is lower than a threshold value C_CL_MIN_CP and the time T_CP was greater than T_MIN_CP (see chapter “Partial Functions of the Evaporative Emission Control”).

The time period for lambda adaptation is variable due to the stop conditions for the purge period. If the purge period is stopped because the time T_CP has reached the limit C_T_1/2_CP the time period T_CP_AD_1= T_CP_TI_AD_SP. If the purge period is stopped because the canister load CL_MMV is lower than a threshold value C_CL_MIN_CP the time period T_CP_AD_1= T_CP_TI_AD_SP +C_T_1/2_CP-T_CP (actual time at the end of the purge period).

The time T_CP is the actual time state of the Evaporative Emission Control.

If the Evaporative Emission Control is activated after engine start ST, the lambda adaptation is activated first (CP_T_STATE=3 (Hex.)).

When the Evaporative Emission Control is not enabled (LV_CP_ENA=0), the time control is not active (CP_T_STATE=0) and the lambda adaptation is possible, if the conditions are fulfilled (see chapters “Lambda Adaptation and Evaporative Emission Control” and “Injection”).

Setting of Initilization values for RAMP_OPEN (see chapter RAMP_OPEN)

LV_CP_ACT =0

<u>For the different functions the following conditions must be fulfilled:</u>

- ***Conditions for NO_PURGE:***

1. Cylinder Shut-Off or Pull Fuel-Cut-Off active (LV_FCUT_CP=1) or
2. Authorization by projectspecific conditions fulfilled (LV_OBD_AUTH_CP_CLOSE=1) or
3. Lambda adaptation time period active (CP_T_STATE=3 (Hex.))
   and **{** MIN_PURGE active (CP_STATE=2 (Hex.) or
   NO_PURGE active (CP_STATE=1 (Hex.) or
   LV_RAMP_CLOSE_END=1 **}**
4. EVAP-system monitoring active (LV_ACT_DIAGCP=1 or LV_ACT_DIAGCPS=1) or
5. Lambda sensor diagnosis active (LV_CP_SET_CLOSE=1) or
6. Difference pressure environment-intake manifold PRS_CPS = AMP-MAP is lower than a threshold value C_PRS_MAX_1_CPS (supercharger engine) or
7. If NO_PURGE is active PRS_CPS = AMP-MAP is lower than a threshold value C_PRS_MAX_2_CPS (supercharger engine) (tuning: C_PRS_MAX_2_CPS>C_PRS_MAX_1_CPS) or
8. Idle speed active (LV_IS=1) and ambient air temperature TIA is lower than a threshold value C_TIA_MIN_CP (acoustic problems with the CPS at low ambient temperatures) or
9. **{**Injection time correction of lambda controller TI_LAM exceeds threshold values
   (TI_LAM > IP_TI_LAM_MAX_CP__TIA or TI_LAM < C_TI_LAM_MIN_CP)
   ->this check must ***only be done*** in case of secondary air system diagnosis
   STATE_SAV_DIAG=not active (= 0hex) and leak detection not active LV_ACT_DIAGCPS = 0**}** or
10. Lambda controller limited (LV_LAM_LIM_MAX_CYCNR=1) or

11. Maximum value of REL_FLOW_CPS is limited to 0
(IP_FUEL_FLOW_MAX_CP=0 or IP_REL_FLOW_MAX_CPS=0)
12. Lambda controller active with limitation
(LV_LAM_LIM_MAX=1 or LV_LAM_LIM_MIN=1)

- ***Conditions for MIN_PURGE:***

1. Conditions for NO_PURGE are not fulfilled and
2. Authorization by projectspecific conditions fulfilled or
(LV_OBD_AUTH_CP_MIN=1)
3. Lambda control in open-loop state (LV_LSCL_i = 0) or
Activation signal for the lambda controller stop mode is fulfilled
(LV_LAM_STOP = 1) or
Flag stop mode activation of lambda controller by wall film is setted
(LV_LAM_NOT_STAT_CDN = 1) or
4. Long time hot idle soaking and unstable engine conditions with
Engine idle state (LV_IS = 1) and
High intake air temperature (TIA > C_TIA_MAX_MIN_PURGE) and
High coolant temperature (TCO > C_TCO_MAX_MIN_PURGE) and
No temperature sensor failure (LV_ERR_TCO = 0 and LV_ERR_TIA = 0) and
Time limit for idle time after starting reached
(T_IS_AST > C_T_IS_AST_MIN_PURGE) and
High purge flow during unstable (REL_FLOW_CPS > C_REL_FLOW_CPS_MIN_PURGE) or
High torque difference during unstable (TQ_DIF_I_IS > C_TQ_DIF_I_IS_MIN_PURGE)
Then MIN_PURGE is activated and kept during C_T_MIN_CP_MIN_PURGE

- ***Conditions for NORMAL_PURGE:***

*Conditions for **RAMP_OPEN**:*

1. Conditions for NO_PURGE are not fulfilled and
2. Conditions for MIN_PURGE are not fulfilled and
3. Limited dynamics for speed and load (LV_LDC_CP=1) and
4. Engine speed within defined limits (C_N_CP_BOL<N_32<C_N_CP_TOL) and
5. Mass air flow within defined limits (IP_MAF_CP_BOL<MAF<IP_MAF_CP_TOL) and
6. Difference pressure environment-intake manifold PRS_CPS=AMP-MAP is and
greater than a threshold value C_PRS_MAX_3_CPS
7. Mean value of lambda control within threshold values and
(This check is only done once at start of RAMP_OPEN)
(C_LAM_0_CP_MIN < LAM_MV_i < IP_LAM_0_CP_MAX__TIA)
8. MAX_PURGE or RAMP_CLOSE not active or
9. RAMP_OPEN operation not finished (LV_RAMP_OPEN_END=0)

*Conditions for **MAX_PURGE**:*

1. Conditions for NO_PURGE are not fulfilled and
2. Conditions for MIN_PURGE are not fulfilled and
3. RAMP_OPEN operation normally finished (LV_RAMP_OPEN_END=1) or
   MAX_PURGE was disabled and disabling time was lower than
   a threshold value C_T_DI_MAX_CP (CP_NORM_DEAC_STATE=2 (Hex.))

*Conditions for **RAMP_CLOSE**:*

1. Time limit for RAMP_OPEN or MAX_PURGE operation reached or
   (T_CP>C_T_1_CP for first purge after start or T_CP>C_T_2_CP)
2. Canister load CL_MMV is lower than a threshold value and time limit
   for MAX_PURGE operation (T_CP> T_MIN_CP) is reached

If the one of the functions MIN_PURGE or RAMP_OPEN or MAX_PURGE or RAMP_CLOSE is active, the logical value LV_CP_ACT is set.

The transitions between the partial functions are defined in a separate chapter.

9.17.3.1 NO_PURGE Operation

General information:

In the NO_PURGE state of the Evaporative Emission Control no calculation of the relative CPS flow REL_FLOW_CPS, the fuel flow from the activated charcoal filter (ACF), the Canister Load CL and the additive adaptation value for the injection time correction will be done.

The transitions from and to the other partial functions are described in a separate chapter.

Formula section:

REL_FLOW_CPS=0

T_DLY_4_DIAGCP = 0

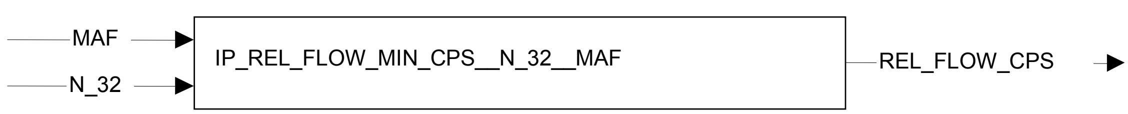
9.17.3.2 MIN_PURGE Operation

General information:

In the MIN_PURGE state the relative CPS flow is calculated from the map IP_REL_FLOW_CPS_MIN.

Signal flow diagram:

Calculation of REL_FLOW_CPS for MIN_PURGE:



(diagram above is valid for LV_REL_FLOW_MIN_CPS_S_ACT = 0)

The transitions from and to the other partial functions are described in a separate chapter.

Formula section:

if	LV_REL_FLOW_MIN_CPS_S_ACT = 0
then	REL_FLOW_CPS = IP_REL_FLOW_MIN_CPS__N_32__MAF

else REL_FLOW_CPS = REL_FLOW_MIN_CPS_S

endif

T_DLY_4_DIAGCP = 0

9.17.3.3 NORMAL_PURGE Operation

FUNCTION DESCRIPTION:

General information:

If the conditions for NORMAL_PURGE are fulfilled the NORMAL_PURGE operation is proceeded in the following sequence:

RAMP_OPEN -> MAX_PURGE -> RAMP_CLOSE

This sequence can change, if one of the phases is disabled for a short time and the interrupt is not longer than an applicable time constant C_T_DI_RAMP_OPEN_CP (CP_NORM_DEAC_STATE=1 (Hex.)) or C_T_DI_MAX_CP (CP_NORM_DEAC_STATE=2 (Hex.)).

Formula section:

REL_FLOW_MAX_CPS = IP_REL_FLOW_MAX_CPS__N_32__MAF

9.17.3.3.1 RAMP_OPEN Operation

FUNCTION DESCRIPTION:

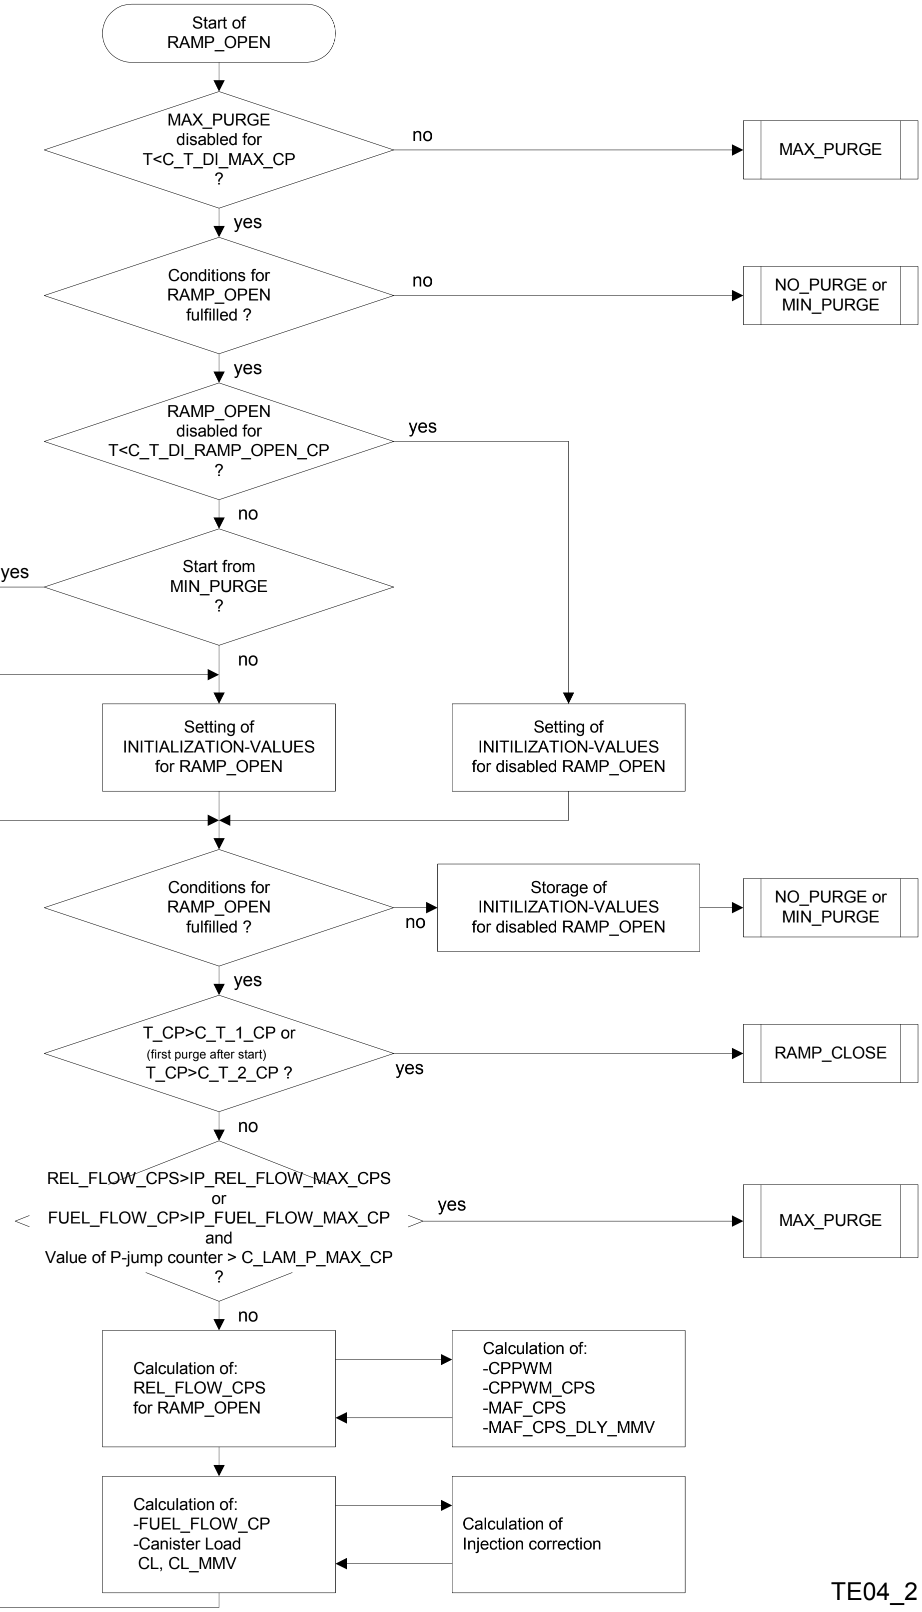
General information:

At the start of the NORMAL_PURGE the load CL of the ACF is not known. Therefore the CPS is opened slowly using a ramp function. So a high deviation of the lambda control shall be prevented. Normally RAMP_OPEN starts from NO_PURGE. If NO_PURGE time (T_CP_AD_1) is long enough, software can start to calculate CL_MMV with initialization data (C_CL_ST_CP). But if NO_PURGE time is shorter than threshold (C_T_CL_ST_CP), software may use the latest CL_MMV (CL_MMV_CLC_END) as its initialization because the stored fuel gas of canister does not change much.

The RAMP_OPEN operation is finished, when the relative flow through the CPS REL_FLOW_CPS is greater than a threshold value IP_REL_FLOW_MAX_CPS or the fuel flow FUEL_FLOW_CP is greater than a maximum map-value IP_FUEL_FLOW_MAX_CP. Then the relative opening of the CPS REL_FLOW_CPS is hold constant at the last value and a counter of P-jumps of the lambda controller starts. When the number of P-jumps is higher than a threshold C_LAM_P_CTR_MAX_CP than the RAMP_OPEN operation ends. Then the logical variable LV_RAMP_OPEN_END is set to 1 and the MAX_PURGE operation starts. If the time T_CP since the start of the RAMP_OPEN operation is greater than the constant C_T_1_CP (for the first purge after start) or C_T_2_CP, the RAMP_OPEN operation ends. Then the logical variables LV_RAMP_OPEN_END and LV_MAX_PURGE_END are set to 1 and the RAMP_CLOSE operation starts immediately.

Signal flow diagram:

RAMP_OPEN



TE04_2

- ***INITIALIZATION-VALUES for RAMP_OPEN***

Before the CPS is opened the following INITIALIZATION-VALUES for RAMP_OPEN are set:

CL_MMV_OLD=0
CL_MMV_DI=0
FUEL_FLOW_CP=0
LAM_0_CP=LAM_MV_i
LV_MAX_PURGE_END=0
LV_RAMP_CLOSE_END=0
LV_RAMP_OPEN_END=0
LV_TI_LAM_COR_CP=0
LV_WAIT_RAMP_OPEN=0
TI_LAM_CP=0
LAM_P_SUM_CP =0
LV_P_JUMP_ACT_CP=0
if T_CP_AD_1_OLD >= C_T_CL_ST_CP
or T_CP_AD_1_OLD = 0 (first RAMP_OPEN)
then CL = C_CL_ST_CP
CL_MMV = C_CL_ST_CP
else CL = CL_MMV_CLC_END
CL_MMV = CL_MMV_CLC_END
Endif

MAF_FG_CYL(n-1)=MAF_FG_CYL
MAF_FG_CYL(n-2)=MAF_FG_CYL
MAF_CYL_DLY=0
MAF_CYL_DLY(n-2)=MAF_FG_CYL
MAF_DLY_MMV=0
REL_FLOW_CPS=0
REL_FLOW_CPS_OLD=0
REL_FLOW_CPS_OLD_MIN=0
T_DI_MAX_CP=0
T_DI_RAMP_OPEN_CP=0
T_WAIT_RAMP_OPEN=0
LV_NORM_PURGE_END_1 = 0
T_DLY_4_DIAGCP = 0

MAF_FG_CYL(n-1) and MAF_FG_CYL(n-2) are internal values for PADÉ-Filter not MAF_FG_CYL from IMM.

- ***INITIALIZATION-VALUES for disabled RAMP_OPEN***

If the RAMP_OPEN operation was disabled (Conditions for RAMP_OPEN are not fulfilled) for a time t<C_T_DI_RAMP_OPEN_CP (CP_NORM_DEAC_STATE=1 (Hex.)), the following INITIALIZATION-VALUES for disabled RAMP_OPEN are set:

CL=CL_DI
CL_MMV=CL_MMV_DI
CL_MMV_OLD=CL_MMV_OLD_DI
REL_FLOW_CPS=REL_FLOW_CPS_DI
REL_FLOW_CPS_OLD=REL_FLOW_CPS_OLD_DI
REL_FLOW_CPS_OLD_MIN=REL_FLOW_CPS_OLD
LAM_0_CP=LAM_0_CP_DI
MAF_CYL_DLY_OLD=MAF_FG_CYL
MAF_DLY_MMV=0
T_DLY_4_DIAGCP = 0

If the RAMP_OPEN operation is disabled, the following actual values for CL_DI, CL_MMV_DI, CL_MMV_OLD_DI, REL_FLOW_CPS_DI, REL_FLOW_CPS_OLD_DI and LAM_0_CP_DI before the operation is disabled are stored:

CL_DI=CL
CL_MMV_DI=CL_MMV
CL_MMV_OLD_DI=CL_MMV_OLD
REL_FLOW_CPS_DI=REL_FLOW_CPS
REL_FLOW_CPS_OLD_DI=REL_FLOW_CPS_OLD

LAM_0_CP_DI=LAM_0_CP

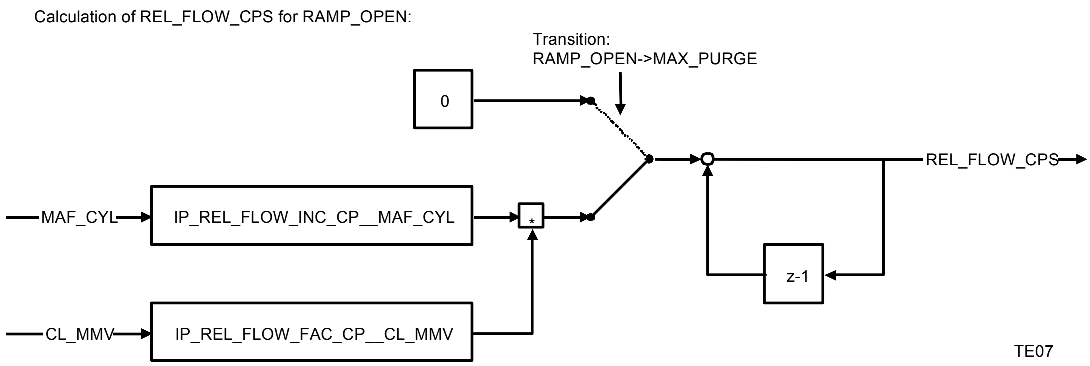
If the disabling time is longer than C_T_DI_RAMP_OPEN_CP or RAMP_OPEN was disabled because of too high deviations of the lambda controller (TI_LAM<C_TI_LAM_MIN_CP or TI_LAM>IP_TI_LAM_MAX_CP) then RAMP_OPEN starts completely new.

- ***Calculation of REL_FLOW_CPS for RAMP_OPEN***

The opening of the CPS is controlled by the value of REL_FLOW_CPS. This value describes the ratio of the flow through the CPS to the mass air flow MAF_FG_CYL. So a too high deviation of the lambda control at transient engine operation can be avoided. When the RAMP_OPEN operation is activated this value is incremented from the INITIALIZATION-VALUES. The increment value depends on the product of the map values of IP_REL_FLOW_INC_CP and IP_REL_FLOW_FAC_CP__CL_MMV. The opening speed of the CPS is so controlled by the mass air flow MAF_CYL and the load CL of the activated charcoal canister ACF.

When the relative flow through the CPS REL_FLOW_CPS is greater than a threshold value IP_REL_FLOW_MAX_CPS or the fuel flow FUEL_FLOW_CP is greater than a maximum map-value IP_FUEL_FLOW_MAX_CP, the relative opening of the CPS REL_FLOW_CPS is hold constant at the last value and a counter of P-jumps of the lambda controller starts. When the number of P-jumps is higher than a threshold C_LAM_P_CTR_MAX_CP than the RAMP_OPEN operation ends.

Signal flow diagram:



- ***Calculation of FUEL_FLOW_CP and Canister Load CL, CL_MMV***

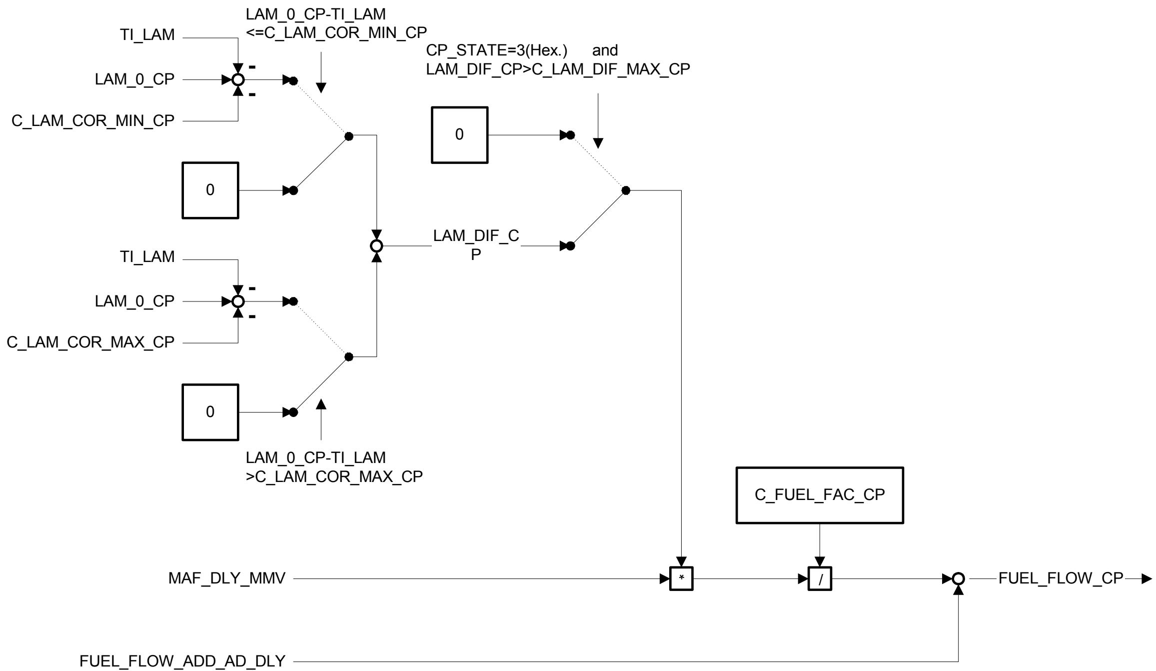
The fuel flow from the ACF when the CPS is open causes a deviation of the lambda control. This fuel flow can be calculated as a function of the difference of the lambda control values with closed/opened CPS LAM_DIF_CP, the mass air flow MAF_DLY_MMV and a constant value C_FUEL_FAC_CP. The constant C_FUEL_FAC_CP considers the influence of the fuel. The mass air flow MAF_DLY_MMV is the filtered value of MAF_FG_CYL using a Padé-filter and a moving mean value calculation to consider the delay time between the mass air flow MAF_FG_CYL and the TI_LAM calculation. The LAM_DIF_CP value can be shifted by a constant value C_LAM_COR_CP_MIN/MAX if they have the same value, to admit deviations of the lambda control. If C_LAM_COR_CP_MIN/MAX is applied as a window, LAM_DIF_CP is 0 in this window to avoid unstable CL behaviour.

The additive adaptive correction of the injected fuel mass flow FUEL_FLOW_ADD_AD_DLY caused by the canister purge is also regarded in the calculation. The calculation of the FUEL_FLOW_ADD_AD_DLY value is described in a separate chapter.

When the deviation of the lambda control LAM_DIF_CP is higher than a threshold value C_LAM_DIF_MAX or lower than -C_LAM_DIF_MAX, the fuel injection time is corrected by an additive correction value. LAM_DIF_CP is then set to 0 because the lambda deviation is corrected.

Signal flow diagram:

Calculation of FUEL_FLOW_CP for RAMP_OPEN:



TE10

The load CL of the ACF is calculated as the ratio of the fuel flow FUEL_FLOW_CP and the mass flow MAF_CPS_DLY_2_MMV through the CPS. The mass flow MAF_CPS_DLY_2_MMV is the filtered value of MAF_CPS_DLY using a Padé-filter and a moving mean value calculation to consider the delay time between the MAF_CPS_DLY and the FUEL_FLOW_CP calculation. The minimum and maximum values of this ratio are limited by 0 and C_CL_MAX_CP. The value of CL is filtered using a moving mean value calculation. The filter constant CL_CRLC depends on the mass air flow MAF and the engine speed N_32. During RAMP_OPEN operation the filter constant CL_CRLC for the CL_MMV calculation is different to the values during MAX_PURGE/RAMP_CLOSE to realize faster constants. The value of CL_MMV is only calculated when the engine is operated at limited dynamics (LV_LDC_CP=1), the difference pressure environment-intake manifold PRS_CPS is greater than a threshold value C_PRS_MAX_3_CPS and the value of IP_FUEL_FLOW_MAX_CP is greater than 0. Additionally is CL an CL_MMV not calculated after transition from NO_PURGE or MIN_PURGE to RAMP_OPEN until the time delay from the map IP_T_DLY_CP__MAF_CYL plus the time C_T_DLY_CP_CL has elapsed.

            ENDIF
ELSE        LV_RAMP_OPEN_END=0
ENDIF
```

- ***Calculation of CL_MMV_OLD and REL_FLOW_CPS_OLD***

When the RAMP_OPEN operation is disabled the injection time is corrected during the transition to the MIN_PURGE or NO_PURGE operation (CP_TRA_STATE=1 or 2 (Hex.)). For this the last stored value of CL_MMV_OLD and the actual value of REL_FLOW_CPS (if REL_FLOW_CPS_AV is lower than REL_FLOW_CPS_OLD) are used to calculate the value of FUEL_FLOW_ADD_AD_CP. When the transition phase is over, the injection time isn't corrected any longer.

ENDIF
```

9.17.3.3.2 MAX_PURGE Operation

General information:

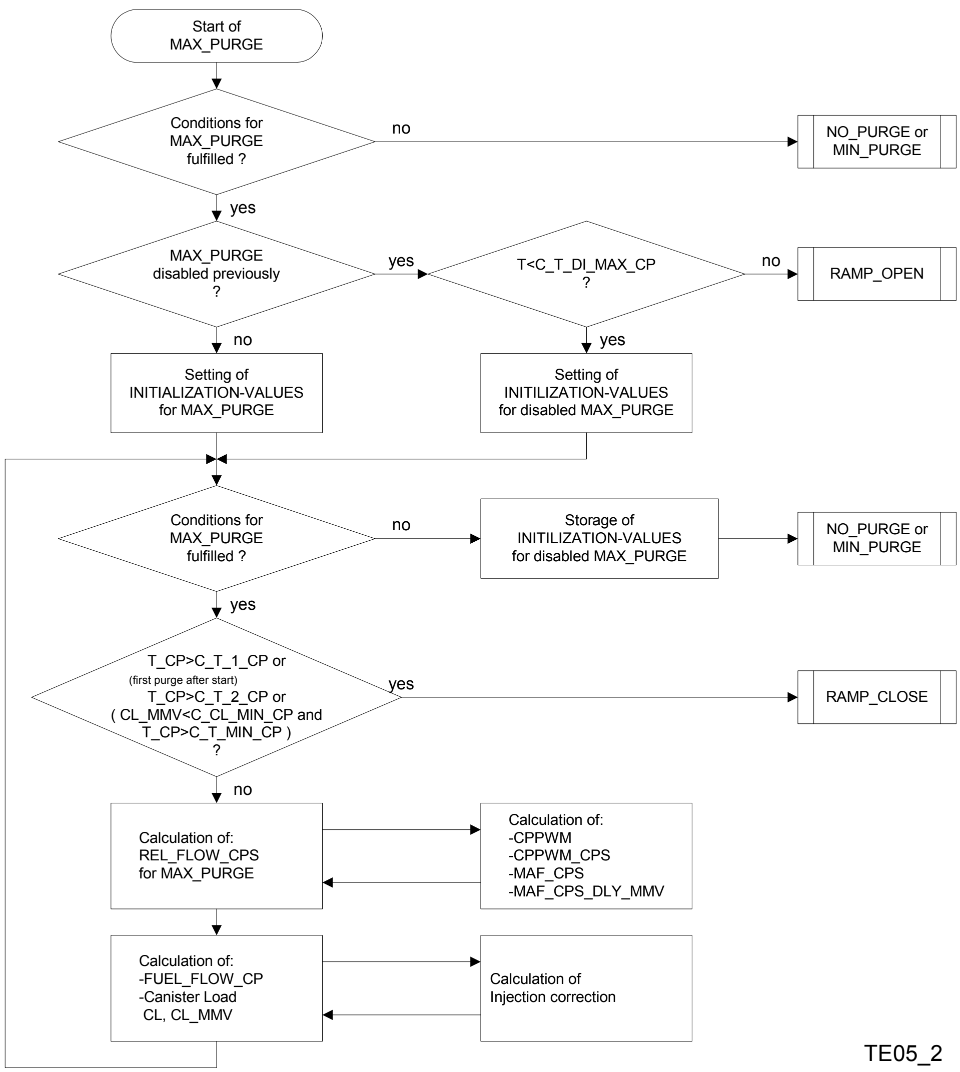
The MAX_PURGE operation is started when the RAMP_OPEN operation is finished (LV_RAMP_OPEN_END=1).

During MAX_PURGE operation the value of REL_FLOW_CPS and so the opening of the CPS is controlled by the load CL_MMV of the ACF.

The MAX_PURGE operation ends, when the purge time T_CP since the start of the NORMAL_PURGE operation is greater than the constant C_T_1_CP (for the first purge after start) or C_T_2_CP or if the canister load CL_MMV is lower than a threshold value C_CL_MIN_CP and the time T_CP is greater than T_MIN_CP. Then the value of LV_MAX_PURGE_END is set to 1 and the RAMP_CLOSE operation starts.

Signal flow diagram:

MAX_PURGE



- ***INITIALIZATION-VALUES for MAX_PURGE***

Before MAX_PURGE operation is started the last calculated values of the RAMP_OPEN operation are set as INITIALIZATION-VALUES for MAX_PURGE. For the initialization of the moving mean value calculation of the TI_LAM value the following value is set:

TI_LAM_CP_MMV(n-1)=TI_LAM

- ***INITIALIZATION-VALUES for disabled MAX_PURGE***

If the MAX_PURGE operation was disabled (Conditions for MAX_PURGE are not fulfilled) for a time t<C_T_DI_MAX_CP, the following INITIALIZATION-VALUES for disabled MAX_PURGE are set:

LAM_0_CP =LAM_0_CP_DI

CL_MMV =CL_MMV_DI

REL_FLOW_CPS =REL_FLOW_CPS_DI

MAF_CYL_DLY_OLD=MAF_FG_CYL

MAF_DLY_MMV =0

If the MAX_PURGE operation is disabled, the following actual values for CL_DI, REL_FLOW_CPS_DI and LAM_0_DI before the operation is disabled are stored:

LAM_0_CP_DI =LAM_0_CP

CL_MMV_DI =CL_MMV

REL_FLOW_CPS_DI=REL_FLOW_CPS

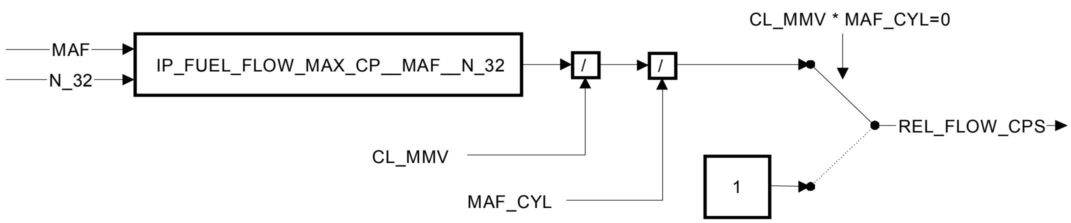
IF the disabling time is longer than C_T_DI_MAX_CP, the value of CL_MMV_DI is set to 0.

- ***Calculation of REL_FLOW_CPS for MAX_PURGE***

The value of REL_FLOW_CPS during MAX_PURGE operation is calculated as a function of the moving mean value of the canister load CL_MMV, the mass air flow into the cylinders of the engine and an applicable value IP_FUEL_FLOW_MAX_CP, that is dependent on the mass air flow MAF and the speed N_32 of the engine. REL_FLOW_CPS is calculated so, that the fuel flow FUEL_FLOW_CP is kept constant to the mapped value IP_FUEL_FLOW_MAX_CP.

<u>Signal flow diagram:</u>

Calculation of REL_FLOW_CPS for MAX_PURGE:

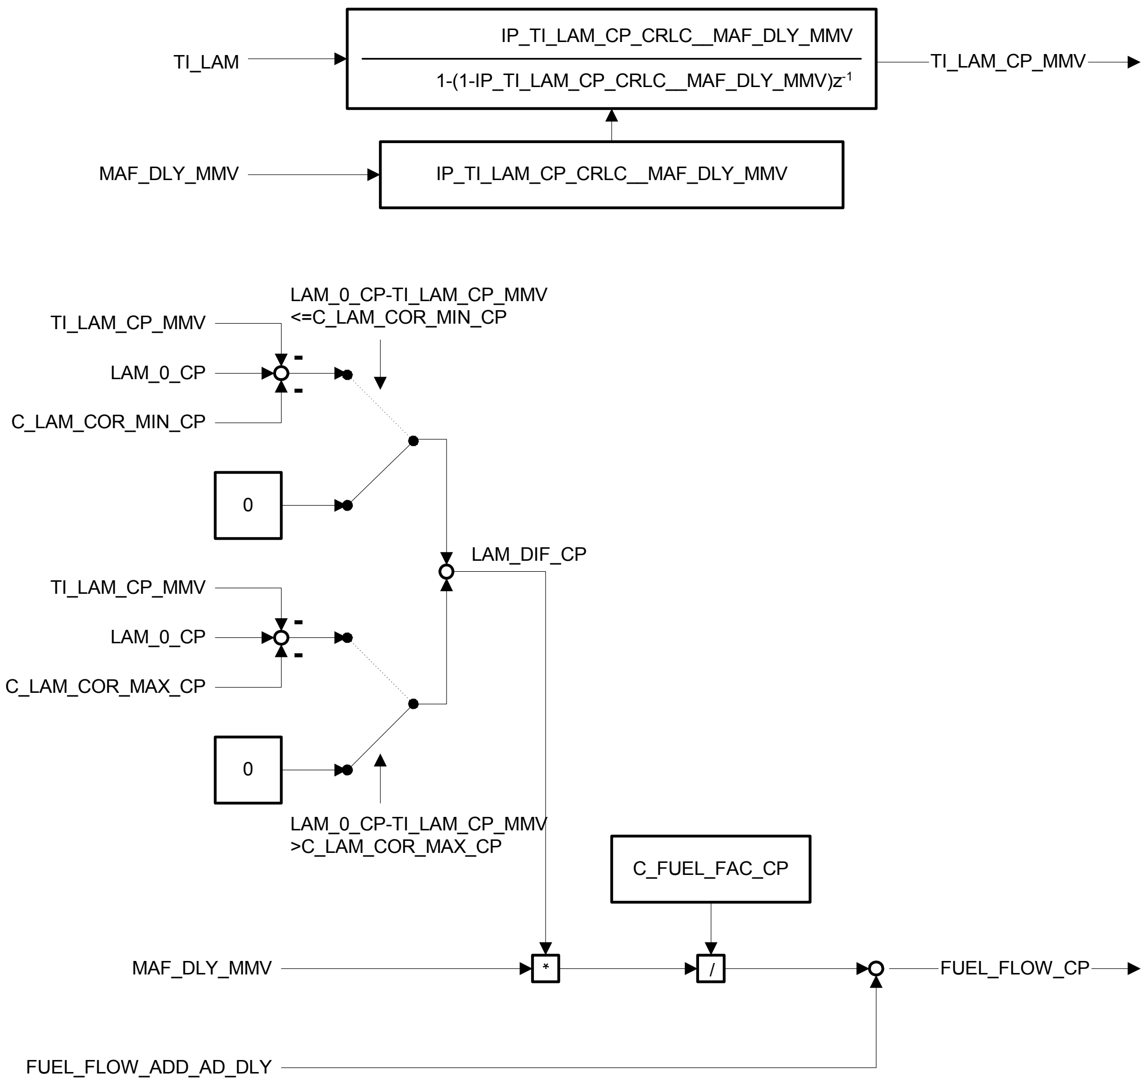


- ***Calculation of FUEL_FLOW_CP and Canister Load CL, CL_MMV***

Unlike the calculation of FUEL_FLOW_CP in RAMP_OPEN operation for this calculation in MAX_PURGE the moving mean value TI_LAM_CP_MMV of TI_LAM is used as input to filter the influence of the closed loop lambda control. The other calculations are the same as in RAMP_OPEN operation.

Signal flow diagram:

Calculation of FUEL_FLOW_CP for MAX_PURGE:



TE11

The calculation of the canister load CL is the same as used in the RAMP_OPEN operation. For the calculation of the moving mean value CL_MMV only the value IP_CL_CRLC is used.

Signal flow diagram:

Calculation of Canister Load CL, CL_MMV for MAX_PURGE:

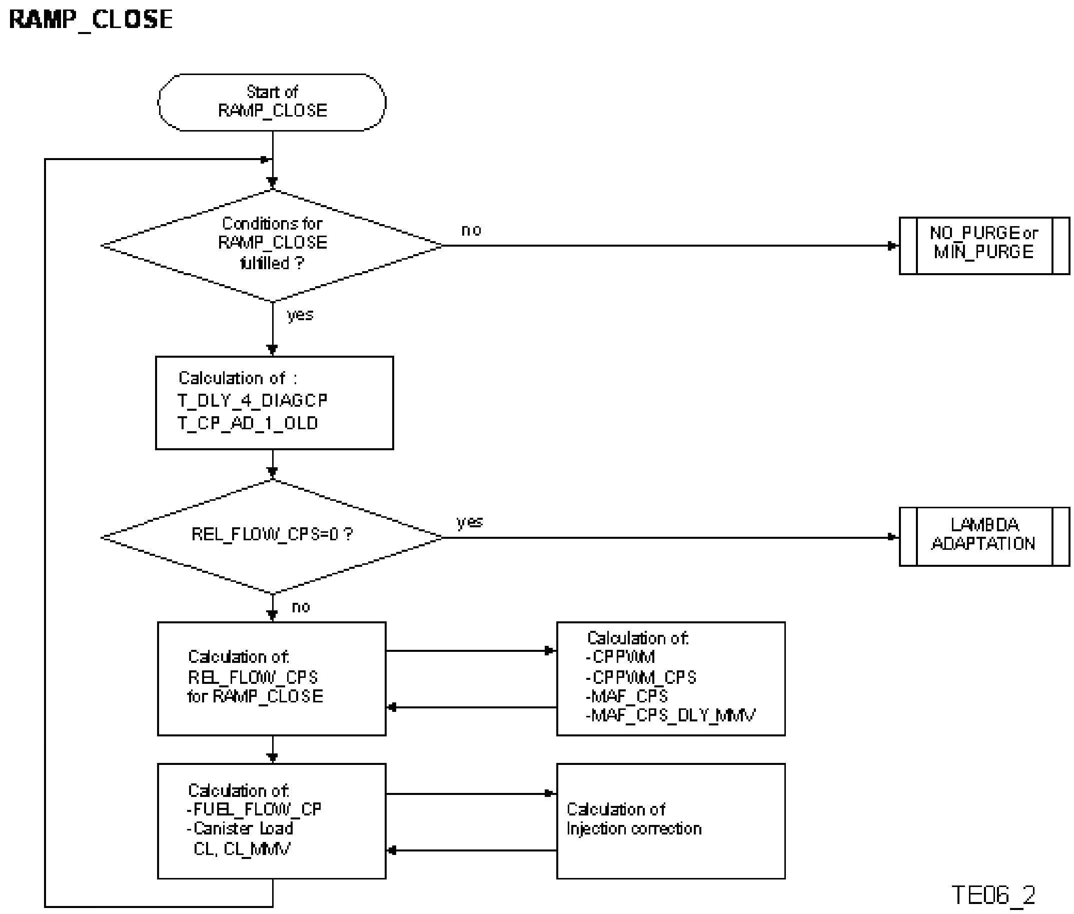
9.17.3.3.3 RAMP_CLOSE Operation

FUNCTION DESCRIPTION:

General information:

The RAMP_CLOSE operation starts, if the RAMP_OPEN or the MAX_PURGE operation is finished.

Signal flow diagram:



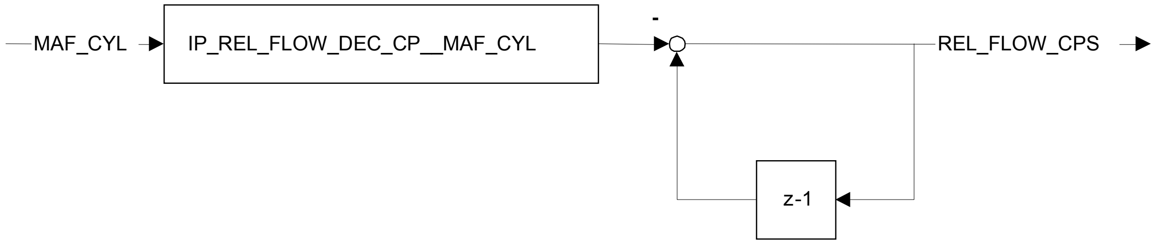
The RAMP_CLOSE operation ends when the value of REL_FLOW_CPS is 0 and T_PL_DIAGCP is 0. Then the variable LV_RAMP_CLOSE_END is set to 1 and the lambda adaptation is started.

- ***Calculation of REL_FLOW_CPS for RAMP_CLOSE***

When the RAMP_CLOSE operation is activated REL_FLOW_CPS is decremented. The decrement value depends on the map values of IP_REL_FLOW_DEC_CP__MAF_CYL. The closing speed of the CPS is so controlled by the mass air flow MAF_CYL. The Initialization value of REL_FLOW_CPS for RAMP_CLOSE is the last calculated value of MIN(REL_FLOW_CPS, IP_REL_FLOW_MAX_CPS) if the preceding operation was MAX_PURGE. If the RAMP_OPEN operation was preceding the Initialization value is the last calculated value of REL_FLOW_CPS of the RAMP_OPEN operation.

Signal flow diagram:

Calculation of REL_FLOW_CPS for RAMP_CLOSE:



- **Calculation of FUEL_FLOW_CP, TI_LAM_CP_MMV and LAM_DIF_CP**

The calculations of this values are the same as in MAX_PURGE operation.

- ***Calculation of CPPWM, CPPWM_CPS and MAF_CPS***

The calculation of the CPS control signals CPPWM, CPPWM_CPS and the mass flow through the CPS MAF_CPS is described in a separate chapter.

Formula section:

- ***Calculation of T_DLY_4_DIAGCP & T_CP_AD_1_OLD***

At the beginning of RAMP_CLOSE, delay timer T_DLY_4_DIAGCP should be set to 0 and NO_PURGE duration time should be kept with T_CP_AD_1_OLD.

T_DLY_4_DIAGCP = 0

T_CP_AD_1_OLD = T_CP_AD_1

- ***Calculation of REL_FLOW_CPS for RAMP_CLOSE***

REL_FLOW_CPS(n)=REL_FLOW_CPS(n-1)-IP_REL_FLOW_DEC_CP

- ***Calculation of CL, CL_MMV***

```
If      MAF_CPS_DLY_2_MMV < C_MAF_CPS_DLY_2_MMV_MIN
then    CL=0
else    CL = FUEL_FLOW_CP / MAF_CPS_DLY_2_MMV
endif

if      CL<0

ENDIF
```

9.17.3.3.4 Calculation of MAF_CYL_DLY and MAF_DLY_MMV:

FAC_1 = IP_T_DLY_CP__MAF_CYL /0.1 ***#(0.1=time recurrence)***

FAC_2 = FAC_1*FAC_1/3

MAF_CYL_DLY$_{(n)}$ = 1 / (1+FAC_1+FAC_2)

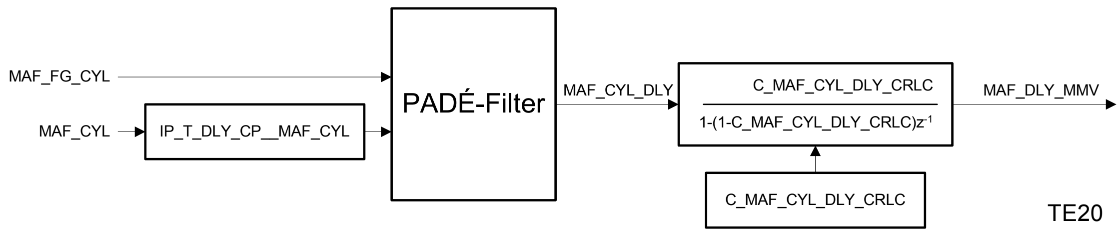
$$* [(1\text{-}FAC\_1+FAC\_2)*(MAF\_FG\_CYL_{(n)} - MAF\_CYL\_DLY_{(n-2)}) + 2*(1\text{-}FAC\_2) * (MAF\_FG\_CYL_{(n-1)} - MAF\_CYL\_DLY_{(n-1)})] + MAF\_FG\_CYL_{(n-2)}$$

$$\mathbf{MAF\_DLY\_MMV_{(n)}} = (1 - C\_MAF\_CYL\_DLY\_CRLC) * MAF\_DLY\_MMV_{(n-1)} + C\_MAF\_CYL\_DLY\_CRLC * MAF\_CYL\_DLY_{(n)}$$

MAF_CYL_OLD2 = MAF_CYL_OLD for next step = $MAF\_FG\_CYL_{(n-2)}$

MAF_CYL_OLD = MAF_FG_CYL for next step = $MAF\_FG\_CYL_{(n-1)}$

Calculation of MAF_CYL_DLY and MAF_CYL_DLY_MMV:



9.17.3.3.5 Storage of values for EVAP System Monitoring

FUNCTION DESCRIPTION:

When the MAX_PURGE operation ends, because the time T_CP is greater than C_T_1_CP (first purge after start) or C_T_2_CP or the canister load CL_MMV is lower than a threshold value C_CL_MIN_CP and the time T_CP is greater than T_MIN_CP, the last calculated value of the canister load CL_MMV is stored as CL_MMV_NORM_PURGE_END before RAMP_CLOSE operation starts. This value is used as Input for the OBDII EVAP-System Monitoring. If MAX_PURGE is disabled because of fuel cut off (LV_FCUT_CP=1) or a too low pressure difference (PRS_CPS<C_PRS_MAX_1_CPS) and during the disabling time the time for the lambda adaptation phase starts, then also the last value of CL_MMV is used as CL_MMV_NORM_PURGE_END.

For the EVAP system monitoring also the constant LV_NORM_PURGE_END_1 is required. This logical value is set to 1 if the RAMP_CLOSE operation ends. If MAX_PURGE is disabled because of fuel cut off (LV_FCUT_CP=1) or a too low pressure difference (PRS_CPS<C_PRS_MAX_1_CPS) and during the disabling time the time for the lambda adaptation phase starts then also LV_NORM_PURGE_END_1 is set to 1.

Formula section:

- ***Calculation of CL_MMV_NORM_PURGE_END***

IF **{** T_CP>C_T_1_CP (first purge after start)
or T_CP>C_T_2_CP
or (CL_MMV<C_CL_MIN_CP and T_CP > T_MIN_CP) **}**
THEN CL_MMV_NORM_PURGE_END=CL_MMV
ELSEIF CP_STATE=MAX_PURGE and

```
               (LV_FCUT_CP=1 or PRS_CPS<C_PRS_MAX_1_CPS)
THEN           CL_MMV_NORM_PURGE_END=CL_MMV
ELSE           CL_MMV_NORM_PURGE_END=0
ENDIF
```

- ***Calculation of LV_NORM_PURGE_END_1***

```
IF                   LV_RST_NORM_PURGE_END=1
THEN                 LV_NORM_PURGE_END_1=0
ELSEIF               LV_RAMP_CLOSE_END=1
THEN       IF              LV_NORM_PURGE_END_1=0
           THEN            LV_NORM_PURGE_END_1
                           = LV_RAMP_OPEN_END  and  LV_MAX_PURGE_END
           ELSE            LV_NORM_PURGE_END_1 = LV_NORM_PURGE_END_1
           ENDIF
ELSEIF     CP_STATE=MAX_PURGE                    and
           CP_T_STATE=T_TI_AD_ACTIVE             and
           (LV_FCUT_CP=1 or PRS_CPS<C_PRS_MAX_1_CPS)
THEN       LV_NORM_PURGE_END_1 = 1
ELSE       LV_NORM_PURGE_END_1 = LV_NORM_PURGE_END_1
ENDIF
```

9.17.3.4 Transitions between the Partial Functions

General information:

During enabled Evaporative Emission Control (LV_CP_ENA=1), there is a continuous check, which partial function is activated. Depending on the conditions an alternation of the partial functions is possible. So in addition to the normal transitions to the partial functions some extra transitions are possible.

The following transitions are possible:

1. NO_PURGE ----> MIN_PURGE (CP_TRA_STATE=1 (Hex.))
2. NO_PURGE <---- MIN_PURGE (CP_TRA_STATE=2 (Hex.))
3. RAMP_OPEN <---- NO_PURGE (CP_TRA_STATE=0 (Hex.))
4. RAMP_OPEN ----> NO_PURGE (CP_TRA_STATE=3 (Hex.))
5. RAMP_OPEN <---- MIN_PURGE (CP_TRA_STATE=0 (Hex.))
6. RAMP_OPEN ----> MIN_PURGE (CP_TRA_STATE=4 (Hex.))
7. MAX_PURGE <---- NO_PURGE (CP_TRA_STATE=0 (Hex.))
8. MAX_PURGE ----> NO_PURGE (CP_TRA_STATE=5 (Hex.))
9. MAX_PURGE <---- MIN_PURGE (CP_TRA_STATE=0 (Hex.))
10. MAX_PURGE ----> MIN_PURGE (CP_TRA_STATE=6 (Hex.))
11. RAMP_CLOSE ----> NO_PURGE (CP_TRA_STATE=7 (Hex.))
12. RAMP_CLOSE ----> MIN_PURGE (CP_TRA_STATE=8 (Hex.))
13. RAMP_OPEN ----> RAMP_CLOSE (CP_TRA_STATE=9 (Hex.))
14. MAX_PURGE ----> RAMP_CLOSE (CP_TRA_STATE=A (Hex.))
15. WAIT_RAMP_OPEN_PURGE <---- MIN_PURGE (CP_TRA_STATE=B (Hex.))
16. WAIT_RAMP_OPEN_PURGE ----> MIN_PURGE (CP_TRA_STATE=C (Hex.))

Normally the transitions are performed with a decrease/increase of the relative flow through the CPS REL_FLOW_CPS as it is performed in the RAMP_OPEN / RAMP_CLOSE operation with the following exceptions:

- REL_FLOW_CPS is set to 0 without transition in ramp mode:

If injection fuel cut off is active (LV_FCUT_CP=1) or
If PRS_CPS is lower than C_PRS_MAX_1_CPS or
If EVAP / CPS diagnosis is active or
(LV_CP_SET_CLOSE=1, LV_ACT_DIAGCP=1, LV_ACT_DIAGCPS=1)

If injection time correction of lambda controller or
TI_LAM is higher or lower than threshold values
(TI_LAM> IP_TI_LAM_MAX_CP__TIA or TI_LAM<C_TI_LAM_MIN_CP)
If lambda controller is limited (LV_LAM_LIM_MAX_CYCNR=1) or
If maximum value of REL_FLOW_CPS is limited to 0 or
(IP_FUEL_FLOW_MAX_CP=0 or IP_REL_FLOW_MAX_CPS=0)
If Lambda controller active with limitation
(LV_LAM_LIM_MAX=1 or LV_LAM_LIM_MIN=1)

- If the RAMP_OPEN or the MAX_PURGE operation was interrupted (NO_PURGE or MIN_PURGE active) and the interrupt-time is lower than the adjustable times C_T_DI_RAMP_OPEN_CP (RAMP_OPEN operation) or C_T_DI_MAX_CP (MAX_PURGE operation), the INITIALIZATION-VALUES of REL_FLOW_CPS for disabled RAMP_OPEN or disabled MAX_PURGE are set. So the RAMP_OPEN or MAX_PURGE operation starts immediately with the values, which were stored when the operation was interrupted. When the interrupt time is longer than the times C_T_DI_RAMP_OPEN_CP or C_T_DI_MAX_CP the NORMAL_PURGE always starts with the RAMP_OPEN operation. Therefore the variable LV_RAMP_OPEN_END is set to 0 when the MAX_PURGE operation was disabled for a time period longer than C_T_DI_MAX_CP.
- For the transition to the RAMP_OPEN from MIN_PURGE operation the CPS is closed for an adjustable time C_T_WAIT_RAMP_OPEN and then the CPS is opened in order to get useful start values of the lambda controller for the determination of the canister load CL.

Transitions from the partial functions MIN_PURGE or NO_PURGE to RAMP_CLOSE operation are not possible.

The transition ends (CP_TRA_STATE=0 (Hex.)), when the value of REL_FLOW_CPS is equal to the setpoint value of the active partial function.

9.17.4 Diagrams of Outputs (Examples)

The Figures 1-3 show the signals of

-the relative flow REL_FLOW_CPS through the CPS

-the corrected PWM signal CPPWM_CPS for the CPS opening

-the Lambda-Controller output TI_LAM

-lambda deviation with active canister purge LAM_DIF_CP

-calculated fuel flow through the CPS FUEL_FLOW_CP

-additive adaptive fuel flow FUEL_FLOW_ADD_AD_CP for injection time correction

-additive adaptive injection correction

-calculated canister load CL_MMV

-relative fuel flow REL_FUEL_FLOW_CP through the CPS

as a function of time for different operating conditions.

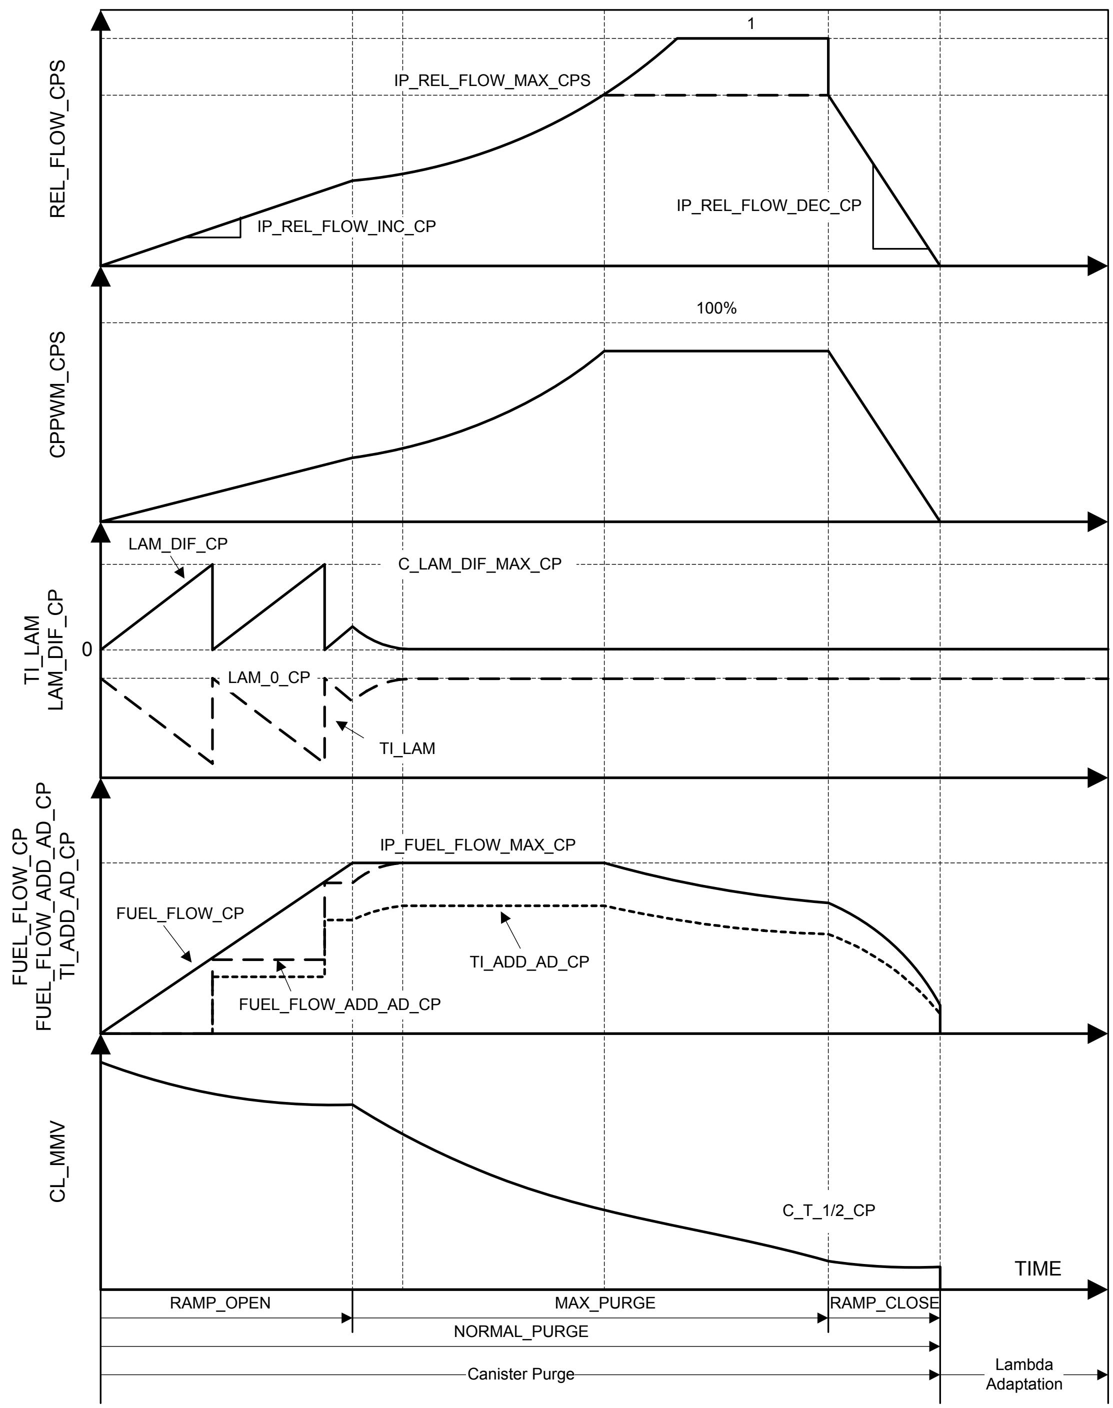

Fig.1 shows an example of operation without interruption.

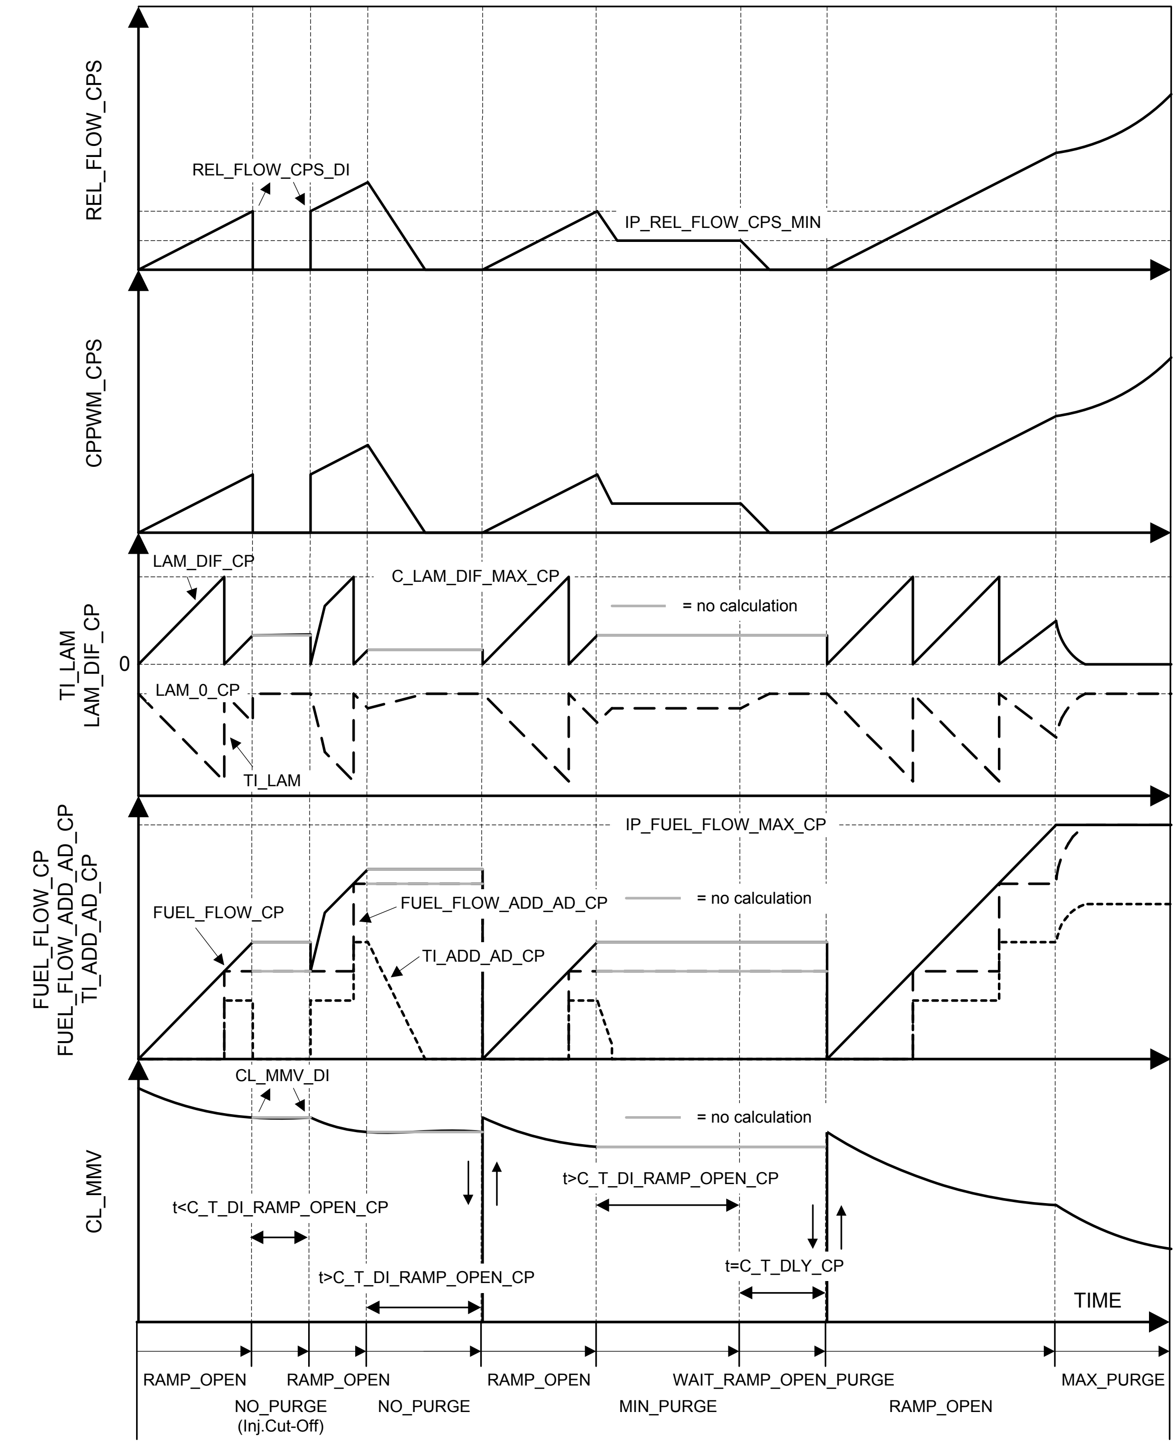

Fig.2 shows an example of RAMP_OPEN operation with some interruptions and transitions to NO_PURGE and MIN_PURGE operation.

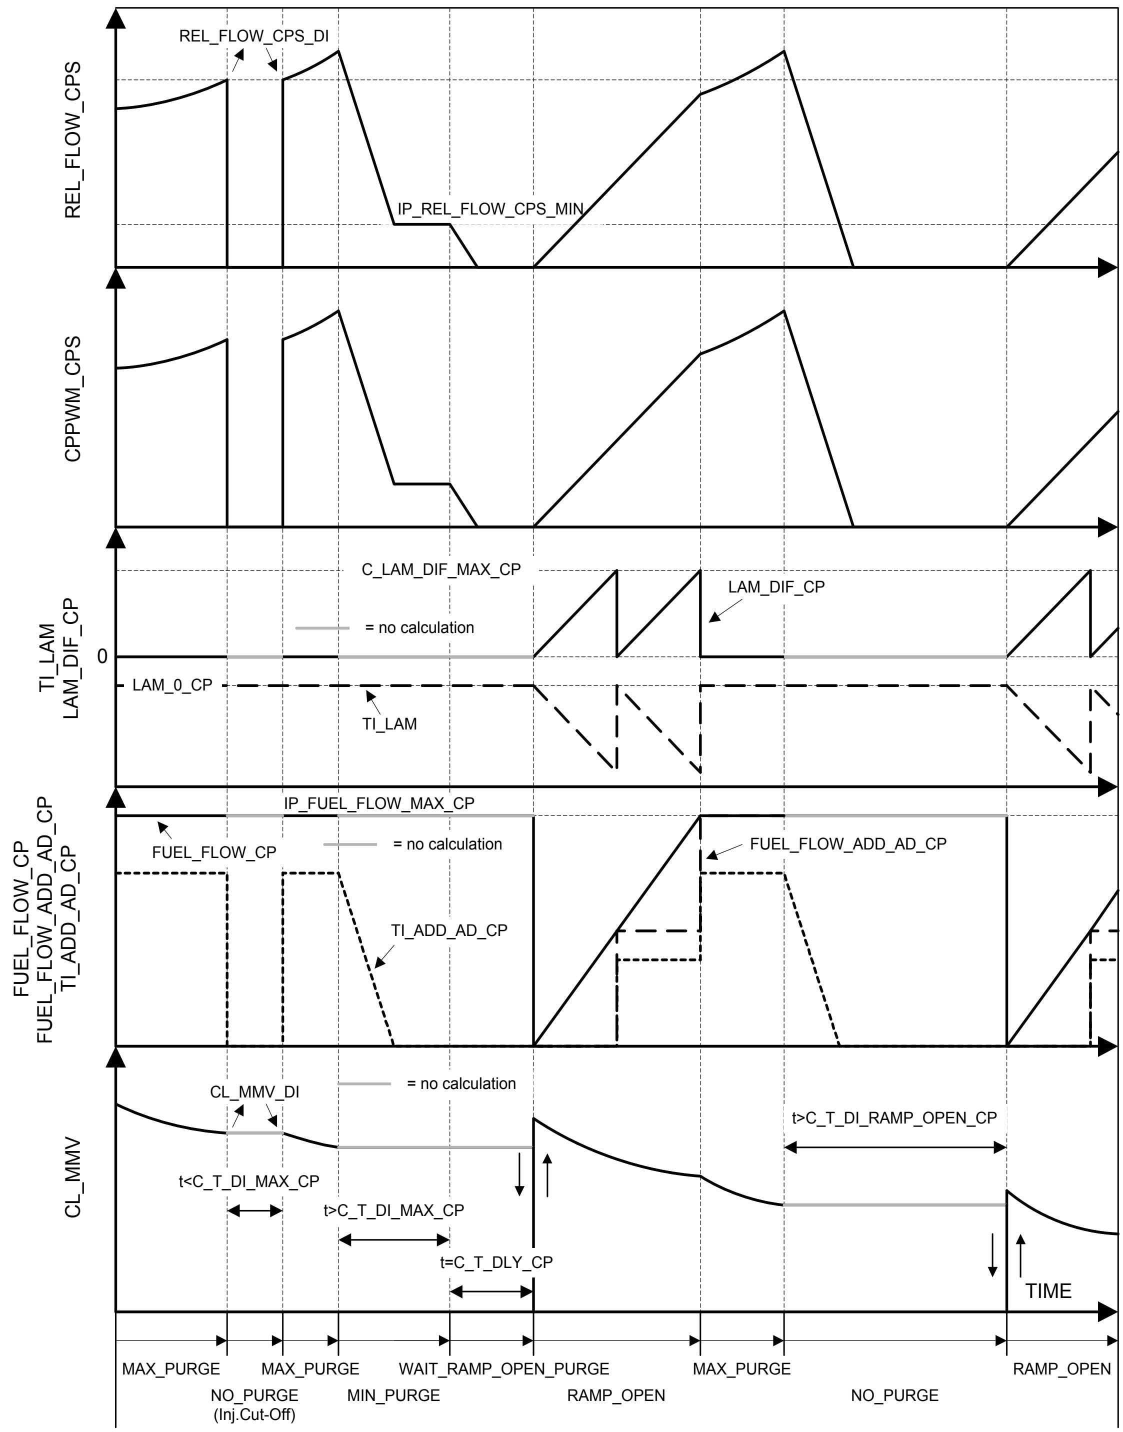

Fig.3 shows an example of MAX_PURGE operation with some interruptions and transitions to NO_PURGE and MIN_PURGE operation.

9.18 Application incidences for the Evaporative Emission Control

Application conditions:

Initialisation: -

Recurrence: 20ms

Activation: at every engine state

Formula section:

The following conditions must be fulfilled for activation of **NO_PURGE** and setting of the flag LV_OBD_AUTH_CP_CLOSE:

If LV_ERR_CPS = 1 (diagnosis error CPS)
or LV_ERR_MEC_CPS = 1 (diagnosis error CPS)
or LV_ERR_SOV = 1 (diagnosis error SOV)
or LV_ERR_MEC_SOV = 1 (diagnosis error SOV)
or LV_ERR_LAM_LIM_i = 1 (diagnosis error lambda control)
or LV_CPS_INH_REQ_CAM_OFS_AD = 1 (Camshaft offset adaptation active)
then LV_OBD_AUTH_CP_CLOSE = 1
else LV_OBD_AUTH_CP_CLOSE = 0

For activation of **MIN_PURGE** and setting of the flag LV_OBD_AUTH_CP_MIN the following conditions must be fulfilled:

If LV_ERR_TIA = 1 (air temperature sensor)
or LV_ERR_TCO = 1 (coolant temperature sensor)
or LV_ERR_MAF = 1 (mass air flow sensor)
or LV_ERR_MAP = 1 (intake manifold pressure sensor)
or LV_ERR_TPS = 1 (throttle position sensor)
or LV_ERR_MTC_DR = 1 (throttle position controller/actuator)
or LV_ERR_LS_UP = 1 (lambda sensor output voltage)
or LV_ERR_IV[NC_CYL_NR] = 1 (injector output)
or LV_ERR_IGC = 1 (ignition output)
then LV_OBD_AUTH_CP_MIN = 1
else LV_OBD_AUTH_CP_MIN = 0

9.18.1 Definition of REL_FLOW_CPS during stratified mode in MIN_PURGE

LV_REL_FLOW_MIN_CPS_S_ACT = 0
REL_FLOW_MIN_CPS_S = 0

9.18.2 Project specific bit conversion for CP function

- Limited dynamic condition for canister purge:

  if **|** MAF_{n-2} **-** MAF_n **| <** C_MAF_DYW_CP
  then LV_LDC_CP = 1
  else LV_LDC_CP = 0

- Special lambda control limits during canister purge:

  if CP_STATE **=** RAMP_OPEN **or** MAX_PURGE **or** WAIT_RAMP_OPEN
  then LV_LAM_THD_CP **=** 1
  else LV_LAM_THD_CP **=** 0

If there is no purging (LV_LAM_THD_CP = 0) the lambda controller output values (P,I,D-parts) are limited by the constants: C_LAM_P_MIN/MAX, C_LAM_I_I_MIN/MAX, C_LAM_D_MIN/MAX and C_LAM_OUT_MIN/MAX.
In case of purging (LV_LAM_THD_CP = 1) the lambda controller output values are limited by: C_LAM_P_MIN/MAX_CP, C_LAM_I_I_MIN/MAX_CP and C_LAM_OUT_MIN/MAX_CP

- Detection of fuel cut off for canister purge:

  LV_FCUT_CP **=** LV_IND_FCUT

- Lambda controler limitation activ for some cyles

  LV_LAM_LIM_MAX_CYCNR **=** 0

- Boolean for Lambda shift value of Lambda controller:

  Before the lambda control calculation is done the following bit has to be set:

  if LV_TI_LAM_COR_CP 0 → 1

  then LV_LAM_ADJ_CP **=** 1

- Lambda shift value for Lambda controller:

  if LV_FAC_LAM_DIAGCP **=** 0

  then LAM_ADJ_CP **=** TI_LAM_CP

  else LAM_ADJ_CP **=** (FAC_LAM_DIAGCP **-** TI_LAM)

- After the lambda control shift is done, the following values have to be reset:

  LV_LAM_ADJ_CP = 0

  LAM_ADJ_CP = 0

- Logical values for enabled lambda adaptation

  LV_MFF_AD_ENA **=** 1

- Bit signalizing high vapour generation or high lambda deviation at evacuation phase:

  LV_RST_NORM_PURGE_END = LV_STATE_RST_CLC_END

- Moving mean value of MAF_CYL_DLY:

  MAF_TOT_CP_DLY_MMV = MAF_DLY_MMV

- State of evaporative emission control function:

  STATE_CP = CP_STATE (assigned to each other without converting the hexvalues)

  STATE_CP is normally input for aggregates and described with other hexvalues of the symbolic statenames (eg. MAX_PURGE = 0Ah; here we have MAX_PURGE = 04h). Due to software-reasons it is necessary to have only ONE definition of a symbolic name. This is no problem, because every access to STATE_CP is done by the symbolic name, and not by the corresponding hex-number.

- Time after first start of driving cycle:

  T_AST_DC = T_AST

- Lambda controller output:

  If LC_TI_LAM_SWI_MAN_ACT = 0

  then TI_LAM = FAC_LAM_LIM

  else TI_LAM = FAC_LAM_MV_MMV_CP[NC_CBK_EX_NR]

- Upper threshold of controller output exceeded:

  LV_LAM_LIM_MAX = LV_LAM_LIM_MAX_1

- Bottom threshold of controller output exceeded:

LV_LAM_LIM_MIN = LV_LAM_LIM_MIN_1

- Only for interface reasons: LAM-P-jump delay time of the catalyst purge function:

  LV_ACT_DIAGCP = LV_DIAGCP_ACT

- Flag indicating CP not active and DIAGCP active (1), or the opposite (0):

  LV_ACT_DIAGCPS = LV_DIAGCPS_ACT

Hint: The bits or data LV_FCUT_CP, LV_RST_NORM_PURGE_END, MAF_TOT_CP_ DLY_MMV, FLOW_CPS, STATE_CP, T_AST_DC, LV_LAM_LIM_MAX , LV_LAM_LIM_MIN, LV_ACT_DIAGCP and LV_ACT_DIAGCPS are not visible.
They have at all times the value of LV_IND_FCUT, LV_STATE_RST_CLC_END, MAF_DLY_MMV, CP_STATE, T_AST, LV_LAM_LIM_MAX_1, LV_LAM_LIM_MIN_1, LV_DIAGCP_ACT, and LV_DIAGCPS_ACT !

9.18.3 Limits of Canister Purge Valve Opening

The value of CPPWM_CPS is limited to meet the requirements of the CPS-diagnosis to

NC_CPPWM_CPS_BOL **=** C_CPPWM_CPS_BOL

NC_CPPWM_CPS_TOL **=** C_CPPWM_CPS_TOL

9.18.4 Stop of opening ramp of CPS valve due to detection of lean mixture

Conditions for stopping opening ramp of the CPS valve are fullfilled if the controller is stopped by injection time limitation (LV_TI_1_HOM_MIN = 1) or if LAM_COR correction during RAMP_OPEN operation is started (LV_LAM_ADJ_CP 0 → 1):

If (1) LV_TI_1_HOM_MIN = 1

or LV_LAM_ADJ_CP 0 → 1

then (1) LV_CP_RAMP_OPEN_STOP = 1

else (1) **If (2)** LV_AFL[NC_CBK_EX_NR] = 1

or CL_MMV >= C_CL_MMV_MAX_CP

then (2) LV_CP_RAMP_OPEN_STOP = 0

9.18.5 Calculation of LV_CLOSE_ACT_CP

If LV_TI_AD_CP_INH = 0

then LV_CLOSE_ACT_CP = 1

else LV_CLOSE_ACT_CP = 0

9.18.6 Variable minimum time duration for canister purge time phase

To optimize the evaporative fuel emissions during hot conditions the minimum canister purge time can be switched from C_T_MIN_CP to C_T_MIN_CP_MAX.

Application conditions:

Initialisation: *T_CP_TI_AD_SP* **=** *C_TI_T_AD_1 in every case*

at reset: **if** LV_DC = 0 **then** LV_T_MIN_CP = 0

Recurrence: *100ms*

Activation: LV_DC=1 **and** LV_T_MIN_CP=0

Dea*ctivation:* LV_DC=0 **or** LV_T_MIN_CP=1

Formula section:

if TCO_ST **<** C_TCO_ST_T_MIN_CP

or TIA **<** C_TIA_T_MIN_CP

or T_AST **>** C_T_AST_T_MIN_CP

then LV_T_MIN_CP **=** 1 (until end of DC)

selection of different time constants

if LV_T_MIN_CP **=** 1

then T_MIN_CP **=** C_T_MIN_CP (cold conditions)

else T_MIN_CP **=** C_T_MIN_CP_MAX (hot conditions)

CPPWM_FRQ	V/O	4...FFH	4...255	1	Hz
Frequency of the canister purge solenoid pwm-signal					

Input data:

MAF_HB	N_32	LV_ACT_DIAGCPS	

General information:

Especially in the non linear flow range area of the canister purge solenoid the minimum flow depends strongly at the PWM-frequency. In general low flow rates can be achieved better with a low PWM-frequency. But at a low PWM-frequency the cylinder to cylinder deviation can become worse.
To find the optimal compromis it is necessary to apply the frequency of the canister purge solenoid PWM-signal.
Two CPPWM-frequencies are applied depending on the actual MAF and engine speed.

Application conditions:

Recurrence: 100ms

Activation: *at every engine state*

Signal flow diagram:

Input data:

LV_CP_ENA	CP_STATE	CP_TRA_STATE	CL_MMV_OLD
REL_FLOW_CPS_OLD_MIN	MAF_FG_CYL	MAF_DLY_MMV	MAF_CPS_DLY
CL_MMV_DI	CL_MMV	MAF_CPS_DLY_2_MMV	N
MAF_CYL	LV_TI_LAM_COR_CP	NC_CYL_NR	

FUNCTION DESCRIPTION:

Application conditions:

Recurrence: 20ms

Activation:

EVAP-Control is enabled, LV_CP_ENA = 1

Deactivation:

EVAP-Control is disabled, LV_CP_ENA = 0

FUEL_FLOW_ADD_AD_DLY = 0
FUEL_FLOW_ADD_AD_CP = 0
MFF_ADD_LAM_CP = 0

General information:

9.19.1.1 Calculation of the Additive Adaptive Correction of the Injection Time MFF_ADD_LAM_CP

When the Evaporative Emission Control is active, the fuel injection time TI is corrected by an additive value MFF_ADD_LAM_CP to avoid emission and driveability problems caused by the fuel flow through the CPS. This correction is only done during NORMAL_PURGE operation.

9.19.1.1.1 Injection Time Correction during RAMP_OPEN

During RAMP_OPEN operation the injection time is corrected as soon as the deviation of the lambda control value LAM_DIF_CP is greater than an adjustable value C_LAM_DIF_MAX_CP. Then the actual calculated relative CPS flow REL_FLOW_CPS_AV and the actual moving mean value of the canister load CL_MMV are used as REL_FLOW_CPS_OLD and CL_MMV_OLD to calculate the value of the FUEL_FLOW_ADD_AD_CP and the lambda controller value TI_LAM is corrected by the value of C_LAM_DIF_MAX_CP. This procedure is repeated everytime, when the value of LAM_DIF_CP is greater than the threshold value C_LAM_DIF_MAX_CP. If the injection time was corrected and after the correction the value of LAM_DIF_CP is lower than the threshold value -C_LAM_DIF_MAX_CP the actual moving mean value of the canister load CL_MMV is used as CL_MMV_OLD to calculate the value of the FUEL_FLOW_ADD_AD_CP and the lambda controller value TI_LAM is not corrected (see also chapter Evaporative Emission Controll).

With the value of FUEL_FLOW_ADD_AD_CP and the actual speed N the additive adaptive correction of the injection mass MFF_ADD_LAM_CP is calculated. This value is added with a minus sign to the formula of the injection time (see chapter INJECTION).

When the RAMP_OPEN operation is disabled the injection time is corrected during the transition to the MIN_PURGE or NO_PURGE operation (CP_TRA_STATE=1 or 2 (Hex.)). For this the last stored value of CL_MMV_OLD and the actual value of REL_FLOW_CPS (if REL_FLOW_CPS_AV is lower than REL_FLOW_CPS_OLD) are used to calculate the value of FUEL_FLOW_ADD_AD_CP. When the transition phase is over, the injection time isn't corrected any longer.

The additive adaptive correction of the injected fuel mass FUEL_FLOW_ADD_AD_CP is also regarded in the calculation of FUEL_FLOW_CP. To consider the time delay between the mass air flow MAF_CYL and TI_LAM calculation a filtered value FUEL_FLOW_ADD_AD_DLY is calculated.

9.19.1.1.2 Injection Time Correction during MAX_PURGE and RAMP_CLOSE

During MAX_PURGE and RAMP_CLOSE operation there is a continuous additive adaptive correction of the injection time. The additive fuel flow FUEL_FLOW_ADD_AD_CP is calculated from the calculated and time delayed mass flow through the CPS MAF_CPS_DLY and the filtered canister load CL_MMV. The delay of MAF_CPS is necessary to take the gas flow time from the CPS to the injection valve into consideration.

The calculation of the value of the additive adaptive injection time correction is the same as it is used during RAMP_OPEN operation.

When the MAX_PURGE or the RAMP_CLOSE operation is disabled the injection time is corrected during the transition to the MIN_PURGE or NO_PURGE operation (CP_TRA_STATE=5,6,7 or 8(Hex.)). Therefore the last calulated value of CL_MMV_DI and the actual value of MAF_CPS_DLY are used to calculate the value of FUEL_FLOW_ADD_AD_CP. After the transition phase there is no correction of the injection time.

The additive adaptive correction of the injected fuel mass FUEL_FLOW_ADD_AD_CP is also regarded in the calculation of FUEL_FLOW_CP. To consider the time delay between the mass air flow MAF_CYL and the lamda controller calculation a filtered value FUEL_FLOW_ADD_AD_DLY is calculated (see also chapter Evaporative Emission Controll).

LV_CP_ENA	LV_ACT_DIAGCP		REL_FLOW_MAX_CPS
MAP	LV_CPS_FRQ_SWI		

General information:

The setpoint of the mass flow through the CPS FLOW_COR_CPS is calculated using the actual calculated values of REL_FLOW_CPS, MAF_CYL and the two correction factors IP_FAC_AMP_CP and IP_FAC_TIA_CP. These factors are used to correct the influence of the ambient pressure and the ambient temperature.

The PWM-signal to control the opening of the CPS CPPWM is calculated from the map IP_CPPWM as a function of the flow setpoint FLOW_COR_CPS and the pressure difference PRS_CPS. The influence of the battery voltage VB on the opening of the CPS is corrected by the additive value CPPWM_VB_ADD.

The opening of the CPS can also be controlled from the application system with the additive constant C_CPPWM_AS.

If the OBD II evaporative system monitoring function is active (LV_ACT_DIAGCP=1 or LV_ACT_DIAGCPS=1), the opening of the CPS is controlled by the value of CPPWM_CP_DIAGCP (see chapter OBDII functions).

If the OBD I CPS monitoring function is active (LV_CPPWM_EXT_ADJ=1), the opening of the CPS is controlled by the value of CPPWM_EXT_ADJ. In addition the flow through the CPS can be controlled with the input FLOW_SP_CPS_EXT if LV_ACT_DIAGCPS=1 (see chapter OBDI functions).

When the value of the PWM signal CPPWM is lower than 100%, the mass flow through the CPS MAF_CPS is equal to the setpoint value FLOW_SP_CPS. When the CPS is full opened, MAF_CPS is calculated from the map IP_MAF_CPS as a function of the pressure difference PRS_CPS.

The value of CPPWM_CPS is limited to fulfill the requirements of the CPS-diagnosis : NC_CPPWM_CPS_BOL < CPPWM_CPS < NC_CPPWM_CPS_TOL.

The actual value of REL_FLOW_CPS can be lower than the calculated value. Therefore REL_FLOW_CPS_AV is calculated using MAF_CPS and MAF_FG_CYL. This value is filtered using a Padé-filter and a moving mean value calculation. The filter is needed for the calculation of the MAF_CPS_DLY value. MAF_CPS_DLY is needed for the injection time correction calculation. Here the delay of MAF_CPS is needed to take the time delay between the CPS and the injection valve and mixing effects in the intake manifold into consideration.

9.20.1 Calculation of the Mass Flows MAF_CPS, MAF_CPS_DLY, MAF_CPS_DLY_2_MMV and CPPWM

Application conditions:

Recurrence: 20 ms

FUNCTION DESCRIPTION:

General information:

tbd

Signal flow diagram:

tbd

Description:

tbd

Application conditions:

Activation:

LC_CPS_AD_ENA=1

Deactivation:

otherwise

Update Rate:

100 ms

Formula section:

The following adaptation conditions are checked the whole time during CPS adaptation.

If LV_IS = 1 and
PRS_CPS > C_PRS_AD_MAX_CPS and
FLOW_COR_CPS < C_FLOW_AD_MAX_CPS and
CP_STATE = 4 (MAX_PURGE active)

Then all adaptation conditions are fulfilled (2)
Else adaptation conditions are not fulfilled (1)

1) Adaptation conditions are not fulfilled

CPS_AD_STEP_CTR = T_CPS_AD = 0

2) All adaptation conditions are fulfilled

Step 0: Start of Adaptation

```
If      CL_MMV >= C_CL_AD_MAX_CPS
Then    FLOW_COR_CPS_OLD = FLOW_COR_CPS
        CPS_AD_STEP_CTR = 1
Else    CPS_AD_STEP_CTR = 0
Endif
```

Step 1: Calculation of the additive adaptive CPPWM correction

```
If      CL_MMV >= C_CL_AD_MAX_HYS_CPS
Then    If      CPPWM_ADD_AD(n) < C_CPPWM_AD_MAX
        Then    CPPWM_ADD_AD(n) = CPPWM_ADD_AD(n-1) + C_CPPWM_AD
        Else    CPPWM_ADD_AD(n) = C_CPPWM_AD_MAX
Else    CPS_AD_STEP_CTR = 2
        CPPWM_ADD_AD(n) = CPPWM_ADD_AD(n-1)
```

Step 2: Calculation of memory value of the additive adaptive CPPWM_AD_MEM

```
If      T_CPS_AD(n) < C_T_AD_MAX_CPS          and
        CL_MMV >= C_CL_AD_MIN_CPS
Then    T_CPS_AD(n) = T_CPS_AD(n-1) + 1
        CPPWM_ADD_AD(n) = CPPWM_ADD_AD(n-1)
Else    T_CPS_AD = 0
        CPS_AD_STEP_CTR = 0
        If      CL_MMV < C_CL_AD_MIN_CPS
        Then    CPPWM_AD_MEM(n) = CPPWM_AD_MEM(n-1)
        Else    CPPWM_AD_MEM(n) = CPPWM_ADD_AD(n)
        Endif
Endif
```

If the following conditions are fulfilled, the calculation of CPPWM_ADD_AD takes place at the whole time during CPS adaptation.

Calculation of CPPWM_ADD_AD

```
If      CPPWM_AD_MEM ≠ 0                and
        CPS_AD_STEP_CTR = 0
Then    If      FLOW_COR_CPS <= FLOW_COR_CPS_OLD
        Then    CPPWM_ADD_AD = CPPWM_AD_MEM
        Else    If      FLOW_COR_CPS < C_FLOW_AD_MAX_CPS
                Then    CPPWM_ADD_AD =
                        (C_FLOW_AD_MAX_CPS - FLOW_COR_CPS) /
                        (C_FLOW_AD_MAX_CPS - FLOW_COR_CPS_OLD)
                        * CPPWM_AD_MEM
                Else    CPPWM_ADD_AD = 0
                Endif
        Endif
Else    CPPWM_ADD_AD = CPPWM_ADD_AD
Endif
```

9.22 Cooling and condenser fan control

FUNCTION DESCRIPTION:

General information:

The configuration constant NC_ECF_CONF allows to determine the wanted fan control strategy. In principal it is possible to choose between a RLY- or a PWM-control architecture. A RLY/PWM fan control strategy in parallel is also existing. In this case the aggregate architecture allows to switch either the control of RLY-fan(s) or the control of PWM–fan(s) during ECU runtime depending on the setting of the configuration bit CONF_CFA. The control of both variants (RLY- and PWM-fan(s)) in parallel at the same time is not allowed.

The following fan control architecture is adjusted:

NC_ECF_CONF = 2 ➔ control of cooling fan(s) by Relay(s) **or** PWM(s)
(CONF_CFA = 0 for RLY- control)

(CONF_CFA = 1 for PWM- control)

The configuration bit CONF_CFA is representing the activated control algorithm. Either the functions for RLY-fan(s) or the functions for PWM-fan(s) are activated. Both control functions are never activated in at the same time.

For each RLY- and PWM-controlled fan, control signals have to be generated by the “Cooling and condenser fan control” module to provide valid interfaces to other functions located inside or outside the aggregate ENTE.

As soon as the RLY-fan control function is activated, the PWM-fan control function is disabled and vice versa. It is not possible to vary the number of available cooling fans [NC_ECF_NR] at the vehicle (hardware components) for the RLY- and PWM-control strategy. The setting of the total number of cooling fans at the vehicle [NC_ECF_NR] is equal for both control strategies. For the configuration of NC_ECF_NR the higher amount of the available RLY-fan(s) or PWM-fan(s) should be taken into consideration.

NC_ECF_NR = ***[1]***

Because the number of RLY output stages [NC_ECF_RLY_NR] per cooling fan at the vehicle [NC_ECF_NR] is regardless for the PWM-fan control function, the value have to be adjusted dependent on the hardware configuration of the RLY-fan(s).

NC_ECF_RLY_NR = ***[2]***

9.22.1 Condition for high Coolant Temperature control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CDN_CFA_TCO_H	V/O	0...1H	0...1	1	-
Condition for high TCO cooling fan control					

Input data:

TAM	TIA	VS	N_32
MAF	TPS	AMP_AD	LV_ERR_TPS
LV_ERR_TIA	LV_ERR_ACP		

FUNCTION DESCRIPTION:

General information:

In order to allow a higher TCO value under certain conditions by reduced cooling fan activity (fuel economy improvement), the logical variable LV_CDN_CFA_TCO_H is implemented.

LV_CDN_CFA_TCO_H is calculated independant of CONF_CFA as valid for both cooling fan control methods (Relay or PWM).Application conditions:

Initialisation at RESET: LV_CDN_CFA_TCO_H = 0

Recurrence: **40 msec**

Activation: at every engine operating state

FUNCTION DESCRIPTION:

General information:

This function is only called if CONF_CFA is set to 0 (RLY type cooling fan).

The cooling and condenser fan relays are controlled by the EMS via the logic switches LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_ NR].

Because two relays per cooling fan are available (LOW / HIGH) at the vehicle, the number of RLY output stages per cooling fan is set to NC_ECF_RLY_NR = [2].

The logical variables for the control of the fan stages LV_RLY_FAN_L and LV_RLY_FAN_H are combined within the logical output LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_NR] as following:

- LV_ACT_ECF[1][1] = LV_RLY_FAN_L (LOW)
- LV_ACT_ECF[1][2] = LV_RLY_FAN_H (HIGH)

LV_RLY_FAN_L and LV_RLY_FAN_H are set **ON** or **OFF** depending on:

- coolant temperature TCO
- air condition status: A/C request LV_ACIN or A/C Compr. Relay LV_RLY_ACCOUT (depending on selection by LC_ACC_CFA_SEL)

- vehicle speed state VS_STATE_CFA
- Pressure in the A/C circuit LV_PRS_ACC
- External adjustment by service tester LV_CFA_EXT_ADJ
- high TCO cooling fan control function LV_CDN_CFA_TCO_H

The computation of the variable STATE_CFA determines the level of the two logic outputs LV_RLY_FAN_L and LV_RLY_FAN_H.

If the pressure in the A/C circuit is high (LV_PRS_ACC = 1) and A/C on (LV_ACC_CFA = 1) then cooling and condenser fans speed is set to high in order to fastly decrease the pressure.

In order to allow a higher TCO value under certain conditions by reduced cooling fan activity (fuel economy improvement), the logical variable LV_CDN_CFA_TCO_H is implemented.

Application conditions:

Initialisation at RESET:	POW_OUT_ECF_RLY = 0% LV_ACT_ECF[NC_ECF_NR][NC_ECF_RLY_NR] = 0
Recurrence:	**40 msec**
Activation:	CONF_CFA = 0 *(RLY type cooling fan)* at every engine operating state
Deactivation:	-

(see: “ENTE scheduler”)

Description:

LV_RLY_FAN_L		LV_RLY_FAN_H = 0: Cooling Fan	LV_RLY_FAN_H = 0: STATE_CFA	LV_RLY_FAN_H = 0: Condenser Fan	LV_RLY_FAN_H = 1: Cooling Fan	LV_RLY_FAN_H = 1: STATE_CFA	LV_RLY_FAN_H = 1: Condenser Fan	LV_ACC_CFA
0		OFF		OFF				0
0			**0**			**2** 1)		
0		OFF		OFF				1
1		LOW		LOW	HIGH		HIGH	0
1			**1**			**3**		
1		LOW		LOW	HIGH		HIGH	1

1) only for actuator test

The states of LV_RLY_FAN_L, LV_RLY_FAN_H, LV_ACC_CFA correspond to:

Logical state **0** ⇔ **OFF:** **+12 Volt** present on the corresponding pin - out of the ECU

Logical state **1** ⇔ **ON:** **Ground** present on the corresponding pin - out of the ECU

Application conditions:

Following intermediate variables are used to manage cooling fan relays and ISA corrections :

STATE_CFA : Final value to command ECU outputs for cooling fan relays

STATE_CFA_IS : used to activate idle speed valve correction. It is set to new STATE_CFA value a little in advance

STATE_CFA_1 : Cooling fan state only determined from TCO, VS_STATE_CFA, LV_ACC_CFA. It does not take in account special cases like Start, High pressure in A/C circuit, cooling fans activation during power latch phase, TCO sensor error

STATE_CFA_NEW : Cooling fan state only determined from indexed table without taking in account TCO hysteresis

STATE_CFA_IS calculation:

STATE_CFA_IS is used to activate the idle speed valve corrections (ISAPWM_CFA).

If Engine operating state LV_ES **= 1**
and TCO **>=** C_TCO_ON_CFA_ES
then A timer is started and STATE_CFA_IS = STATE_CFA_1
when timer has reached ID_ON_CFA_ES__TIA_THR__TCO then STATE_CFA_IS = 0
else **If** T_AST **<=** C_T_OFF_CFA_ST
then STATE_CFA_IS **= 0**
else **If** LV_ERR_TCO **= 1**
(error currently present on coolant temperature sensor)
or LV_ERR_TCO_STUCK = 1
or LV_ERR_TCO_GRD = 1
or LV_ERR_TCO_PLAUS = 1
or LV_ERR_ACP = 1
or (LV_PRS_ACC **= 1** **and** LV_ACC_CFA **= 1**)
then STATE_CFA_IS **= 3** *(high pressure in A/C circuit)*
else STATE_CFA_IS **=** STATE_CFA_1 *(low pressure in A/C circuit)*
endif
endif
endif

STATE_CFA calculation:

STATE_CFA is equal to STATE_CFA_IS except if STATE_CFA_IS value is updated. Then a time delay is applied to increase or decrease STATE_CFA.

If LV_CFA_EXT_ADJ = 1
then STATE_CFA = STATE_CFA_EXT_ADJ
else **If** STATE_CFA_IS (n) **=** STATE_CFA_IS (n-1) *(STATE_CFA_IS stays constant)*
then STATE_CFA **=** STATE_CFA_IS
else
If STATE_CFA_IS(n) **>** STATE_CFA_IS (n-1) *(STATE_CFA_IS increases)*
then STATE_CFA **=** STATE_CFA_IS after the time delay C_T_RTD_INC_2_x_CFA

If [(LV_PRS_ACC **=** 1 or STATE_ACP = ACP_H)
and LV_ACC_CFA **= 1**]
then C_T_RTD_INC_x_CFA **=** C_T_RTD_INC_2_1_CFA
else C_T_RTD_INC_x_CFA **=** C_T_RTD_INC_2_0_CFA
endif
else (*STATE_CFA_IS decreases)*
STATE_CFA **=** STATE_CFA_IS after the time delay C_T_RTD_DEC_2_CFA
endif
endif
endif

STATE_CFA_NEW calculation:

The STATE_CFA_NEW is calculated depending on the configuration of LV_ACC_CFA, CONF_ACP and STATE_ACP.

1a) If LV_ACC_CFA = 0 and CONF_ACP = 0 and LV_CDN_CFA_TCO_H = 0

STATE_CFA_NEW = ID_STATE_CFA__TCO__VS_STATE_CFA

1b) If LV_ACC_CFA = 0 and CONF_ACP = 0 and LV_CDN_CFA_TCO_H = 1

STATE_CFA_NEW = ID_STATE_CFA_TCO_H__TCO__VS_STATE_CFA

2a) If LV_ACC_CFA = 0 and CONF_ACP = 1 and LV_CDN_CFA_TCO_H = 0

STATE_CFA_NEW = ID_STATE_CFA__TCO__VS_STATE_CFA

2b) If LV_ACC_CFA = 0 and CONF_ACP = 1 and LV_CDN_CFA_TCO_H = 1

STATE_CFA_NEW = ID_STATE_CFA_TCO_H__TCO__VS_STATE_CFA

3) If LV_ACC_CFA = 1 and CONF_ACP = 0

STATE_CFA_NEW = ID_ACIN_STATE_CFA__TCO__VS_STATE_CFA

4) If LV_ACC_CFA = 1 and CONF_ACP = 1 and STATE_ACP = ACP_H

STATE_CFA_NEW = ID_STATE_CFA_ACP_H__TCO__VS_STATE_CFA

5) If LV_ACC_CFA = 1 and CONF_ACP = 1 and STATE_ACP = ACP_M_2

STATE_CFA_NEW = ID_STATE_CFA_ACP_M_2__TCO__VS_STATE_CFA

6) If LV_ACC_CFA = 1 and CONF_ACP = 1 and STATE_ACP = ACP_M_1

STATE_CFA_NEW = ID_STATE_CFA_ACP_M_1__TCO__VS_STATE_CFA

7) If LV_ACC_CFA = 1 and CONF_ACP = 1 and STATE_ACP = ACP_L

STATE_CFA_NEW = ID_STATE_CFA_ACP_L__TCO__VS_STATE_CFA

STATE_CFA_1 calculation:

If (LV_ACC_CFA **or** VS_STATE_CFA **or** STATE_ACP changes)
or STATE_CFA_NEW **>** STATE_CFA_1
Then STATE_CFA_1 **=** STATE_CFA_NEW
and TCO_HYS_CFA is set to -48°C

If STATE_CFA_NEW **<** STATE_CFA_1
and TCO_HYS_CFA = -48°C
Then TCO_HYS_CFA = TCO - C_TCO_HYS_CFA

If TCO **<** TCO_HYS_CFA
Then STATE_CFA_1 **=** STATE_CFA_NEW
and TCO_HYS_CFA is set to -48°C

Remark : C_TCO_HYS_CFA must be smaller than TCO intervalls in indexed map ID_(ACIN_)STATE_CFA.

POW_OUT_ECF_RLY = ID_POW_OUT_ECF

FUNCTION DESCRIPTION:

General information:

This function is only called if CONF_CFA is set to 1.

The activation of the PWM cooling fan is controlled by the ECU via ECFPWM[NC_ECF_NR].

Because one RLY or PWM cooling fan is available (CFAPWM_CFA) at the vehicle, the number of fans is set to NC_ECF_NR = 1.

The signal for the control of the pulse width modulated fan CFAPWM_CFA is located within the output variable ECFPWM[NC_ECF_NR] as following:
- ECFPWM[1] = CFAPWM_CFA

The electric fan is controlled with a 300 Hz PWM signal to regulate its rotational speed. The calculated pulse width modulation depends on:

- Coolant temperature	TCO_CFA
- The vehicle speed state for cooling fan	VS_STATE_CFA
- The moving average value of battery voltage	VB_MMV
- Air condition selected / compressor actvie	LV_ACC_CFA
- Status of pressure switch	LV_PRS_ACC
- Air conditioning pressure state	STATE_ACP
- Flag to enable high coolant temperature control	LV_CDN_CFA_TCO_H

Application conditions:

Recurrence: *200ms*

Initialisation :

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop(LV_ES)
CFAPWM_CFA = C_CFAPWM_MIN

CFAPWM_BAS = 0

CFAPWM = 0

CFAPWM_MIN_HYS = 0

CFAPWM_COR_FIL = 0

CFAPWM_LGRD = 0

Initialisation at RESET:

ECFPWM[NC_ECF_NR] = C_CFAPWM_MIN

POW_OUT_ECF_PWM = 0%

Activation: CONF_CFA = 1 *(PWM type cooling fan)*

at every engine operating state

To start the new calculation of pulse width modulation, the time C_T_CFAPWM_AST has to be elapsed after transition from engine Start ST. The time condition is reset each time the ignition key is switched off.

Deactivation: -

(see: "ENTE scheduler")

9.22.4 Calculation of CAFPWM_CFA at engine stop

If LV_CFA_EXT_ADJ = 1

then CFAPWM_CFA = CFAPWM_EXT_ADJ

else **if** Engine operating state LV_ES **= 1**

then **if** TCO **>=** C_TCO_ON_CFA_ES

then A timer is started and CFAPWM_CFA is calculated.

when the timer has reached ID_ON_CFA_ES__TIA_THR__TCO,

CFAPWM_CFA is set to C_CFAPWM_MIN.

(Due to this function, power latch time could be extended by ID_ON_CFA_ES)

else CFAPWM_CFA = C_CFAPWM_MIN

endif

else **if** T_AST **<=** C_T_CFAPWM_AST

then CFAPWM_CFA = C_CFAPWM_MIN

endif

endif

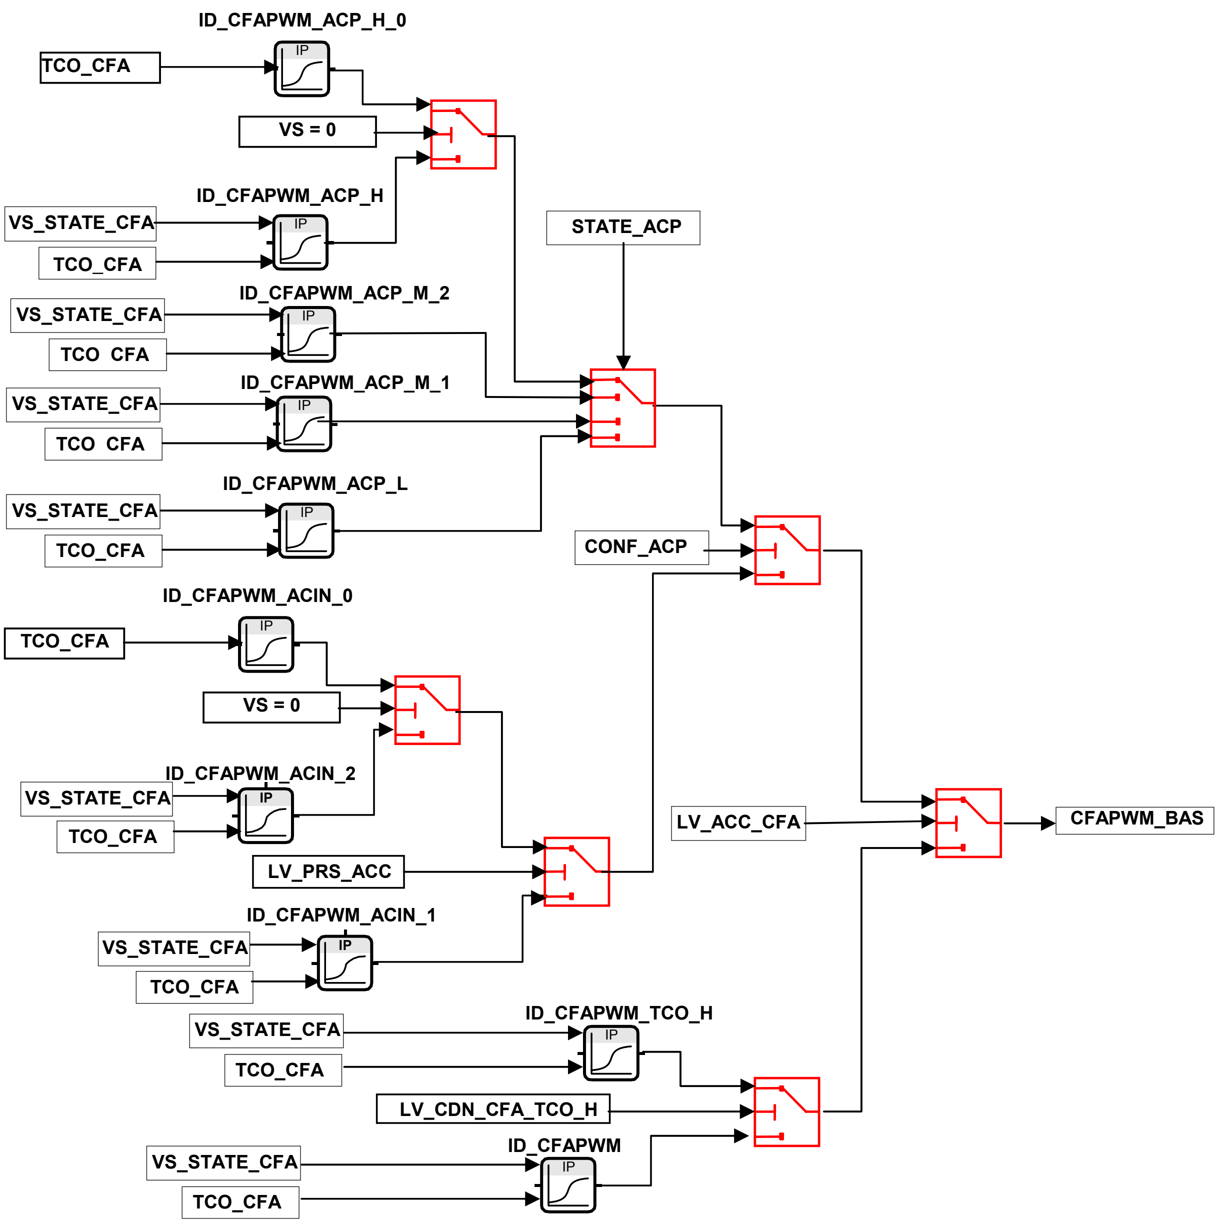
endif

9.22.5 Calculation of CFAPWM_BAS:

Description:

The basic fan control PWM table is selected by condition of LV_ACC_CFA, CONF_ACP and STATE_ACP.

Signal flow diagram:



Formula section:

1) Basic CFAPWM with LV_ACC_CFA = 0

```
if      LV_ACC_CFA = 0
        if      LV_CDN_CFA_TCO_H = 0
        then    CFAPWM_BAS = ID_CFAPWM__VS_STATE_CFA__TCO_CFA
        else    CFAPWM_BAS = ID_CFAPWM_TCO_H__VS_STATE_CFA__TCO_CFA
        endif
endif
```

2) Basic CFAPWM with LV_ACC_CFA = 1

In case of CONF_ACP = 0

```
if      LV_PRS_ACC = 0
then    CFAPWM_BAS = ID_CFAPWM_ACIN_1__VS_STATE_CFA__TCO_CFA
else    if      LV_PRS_ACC = 1
        then    if      VS = 0
                then    CFAPWM_BAS = ID_CFAPWM_ACIN_0__TCO_CFA
                else    CFAPWM_BAS = ID_CFAPWM_ACIN_2__VS_STATE_CFA__TCO_CFA
                endif
        endif
endif
```

In case of CONF_ACP = 1

```
if      STATE_ACP = ACP_L
then    CFAPWM_BAS = ID_CFAPWM_ACP_L__VS_STATE_CFA__TCO_CFA
else    if      STATE_ACP = ACP_M_1
        then    CFAPWM_BAS = ID_CFAPWM_ACP_M_1__VS_STATE_CFA__TCO_CFA
        else    if      STATE_ACP = ACP_M_2
                thenCFAPWM_BAS=ID_CFAPWM_ACP_M_2__VS_STATE_CFA__TCO_CFA
                else    if      STATE_ACP = ACP_H
                        then    if      VS = 0
                                then    CFAPWM_BAS =
                                          ID_CFAPWM_ACP_H_0__VS_STATE_CFA__TCO_CFA
                                else    CFAPWM_BAS =
                                          ID_CFAPWM_ACP_H__VS_STATE_CFA__TCO_CFA
```

endif

endif

endif

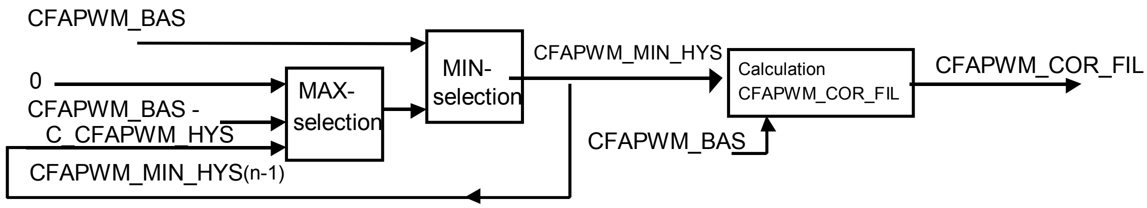
endif

endif

Filtering of CFAPWM_BAS

To avoid frequently changing electric fan speeds (noise problem), CFAPWM_BAS is filtered as follows.

Signal flow diagram:

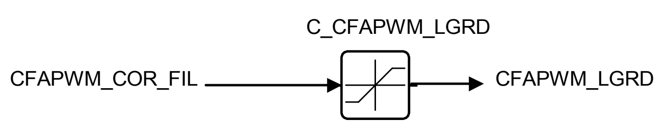


Formula section:
Calculation of CFAPWM_COR_FIL:

if CFAPWM_BAS = 0
then CFAPWM_COR_FIL = 0
else
  If CFAPWM_BAS > 0 and CFAPWM_MIN_HYS = 0
  then CFAPWM_COR_FIL = CFAPWM_BAS
  else CFAPWM_COR_FIL = CFAPWM_MIN_HYS + C_CFAPWM_HYS
  endif
endif

The value C_CFAPWM_HYS determines the filter effect.

Abrupt changes of this speed are slowed down by the gradient limitation:



To have an option for a manual application correction, the application constant is add.

CFAPWM = CFAPWM_LGRD + C_CFAPWM_AS

To take into account the battery voltage variation, the CFAPWM is corrected as following.

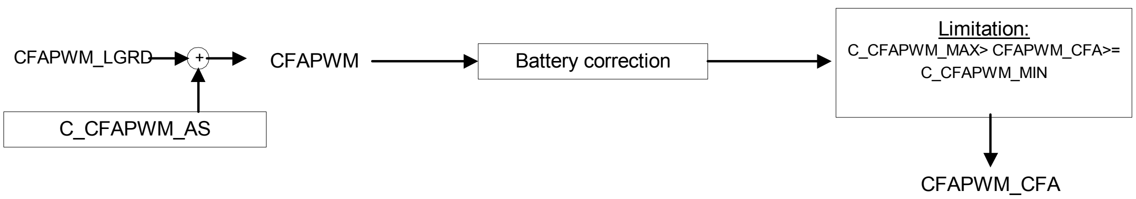
CFAPWM_CFA = IP_CFAPWM_CFA__CFAPWM__VB_MMV

Limitation of CFAPWM_CFA to values between C_CFAPWM_MIN and C_CFAPWM_MAX occurs as the last action before the output.

Limitation:

CFAPWM_CFA >= C_CFAPWM_MIN **and**
CFAPWM_CFA < C_CFAPWM_MAX

Signal flow diagram:



Definition of TCO_CFA

Initialsation : TCO_CFA = TCO at reset or tansition LV_IGK = 0 → 1

If TCO < TCO_CFA - C_TCO_CFA_HYS

Then TCO_CFA = TCO

Else **if** TCO > TCO_CFA

then TCO_CFA = TCO

if TCO < TCO_CFA and the difference between TCO & TCO_CFA is smaller than C_TCO_CFA_HYS, TCO_CFA will not be changed.

Emergency operation by TCO error detection

In case of TCO error detection, CFAPWM_CFA is set to C_CFAPWM_MAX immediately.

If LV_ERR_TCO **= 1**

or LV_ERR_TCO_STUCK = 1

or LV_ERR_TCO_GRD = 1

or LV_ERR_TCO_PLAUS = 1

then CFAPWM_CFA = C_CFAPWM_MAX

POW_OUT_ECF_PWM = ECFPWM[NC_ECF_NR]

Minimum power latch time					
LV_MU_INH_PWL_TRAN_ES_EL	O	0...1H	0...1	1	-
Flag active in shudown-phase : IGK on is not accepted without reset (Point of no return for ECU)					
CTR_PWL_ACTION	V	0...FFH	0...255	1	-
Counter for proceeding PWL shut down if there is no response from MU					
LV_ECM3_DISABLE_REQ	-	0...1H	0...1	-	-
Flag indicating disable state of MU					
T_PWL	V/O	0...FFFFH	0...6553.5	0.1	[s]
Time elapsed since power-latch phase has started					

Input data:

PWL_LOCK_CDN[bit 0]	LV_IGK		

Import action:

ACTION_ECM3_DisableRequest (OUT<>)
Action to perform a transition to DISABLE

FUNCTION DESCRIPTION:

General information:

The ECU keeps active for a specific time after ignition key off (LV_IGK = 0). This is for example to save adaptation values in EEPROM or for some engine cooling reasons. The minimum ECU power latch time (T_MIN_PWL) can be extended by other functions using the byte PWL_LOCK_CDN.

Application conditions:

Initialisation:

- With every transition to power latch the counter CTR_PWL_ACTION is initialized to NC_CTR_PWL_ACTION and the minimum power latch time T_MIN_PWL is initialized with C_T_MIN_PWL and the related bit of PWL_LOCK_CDN is set
- When leaving the power latch phase the counter CTR_PWL_ACTION is set to NC_CTR:PWL_ACTION and the minimum power latch time is cancelled and the realted bit of PWL_LOCK_CDN is reset
- LV_PWL = 0 with power up and with LV_IGK = 0 --> 1
- T_PWL = 0 at reset and at leaving the power latch phase

- At reset: LV_MU_INH_PWL_TRAN_ES_EL = 0, CTR_PWL_ACTION = 0, LV_ECM3_DISABLE_REQ = 0

Recurrence: 100 ms

Description:

As long as PWL_LOCK_CDN ≠ 0 the power latch time is extended for 100 ms more.

Description of the byte PWL_LOCK_CDN:

PWL_LOCK_CDN = 1	(ICU 1)
PWL_LOCK_CDN = 2	(ICU 2)
PWL_LOCK_CDN = 4	(engine cooling Managment)
PWL_LOCK_CDN = 8	(Minimum power latch time not exceeded)
PWL_LOCK_CDN = 16	(VVTI)
PWL_LOCK_CDN = 32	(Main relay diagnosis)
PWL_LOCK_CDN = 64	(ISA cleaning function)

While ECU power latch time is active (PWL_LOCK_CDN ≠ 0 and T_MIN_PWL ≠ 0):

LV_PWL = 1
T_MIN_PWL = T_MIN_PWL – 100ms
T_PWL = T_PWL +100ms

If (T_MIN_PWL = 0 **and** PWL_LOCK_CDN = 0) **or**
LV_MU_INH_PWL_TRAN_ES_EL = 1 (already in shut down)
Then LV_ECM3_DISABLE_REQ = ACTION_ECM3_DisableRequest()
Remark: for ISA ACTION_ECM3_DisableRequest() is 1 (never changed)
If PWL_LOCK_CDN = 0 **or**
LV_ECM3_DISABLE_REQ =1 (already in shut down)
Then activate shut-down mechanism (Action for shut-down mechanism):
(ECU re-Power-up by ignition switch(IGK) on is forbidden)

LV_MU_INH_PWL_TRAN_ES_EL=0
LV_PWL = 0

- The safety controller (MU) is deactivated, reactivation by IGK is forbidden.
- After deactivation of the MU, the function specific initializations with “end of power latch phase” are done.
- The power-supply-pin of the ECU is switched off.
- ECU is waiting in endless-loop serving the watchdog until power is off or a new ignition key on is detected : LV_KEY_OFF=0
- With new LV_IGK = 1 a complete ECU power up is carried out (ECU reset by SW), not by Watchdog.

Else CTR_PWL_ACTION = CTR_PWL_ACTION -1
LV_MU_INH_PWL_TRAN_ES_EL = 1
Endif
Else CTR_PWL_ACTION = NC CTR_PWL_ACTION
Endif

Remark for ETC version:

The power latch phase prefaces the switch off of the ECU. If the ignition was switched off and as a result the engine stopped, the power latch phase starts. This is shown in ECU_STATE which takes the value ECU_STATE=PWL & LV_PWL=1. The minimum duration of PWL is the calibratable time C_T_MIN_PWL. Till the end of this power latch actions, it is possible to prevent the ECU switch-off by switching ignition on again. If this(switching ignition on again) happens not, next is the switch off of the ECU's monitoring unit (MU) and setting of LV_MU_INH_PWL_TRAN_ES_EL=1.

When this value(LV_MU_INH_PWL_TRAN_ES_EL) is 1, a possible LV_IGK=1 is suppressed in order to allow the ECU-switch-off(the ECU will be switched on immidiately after complete shut down). The switch off of the MU is checked by the main processor. This action extends the power latch phase more. Hereafter the last action before complete shut off takes place : the storage of all nonvolatile data to the memory.

Calibration data:

Reference indicated engine torque on which controller output is applied					

Input data:

N_MAX_THD	N	N_GRD	TQI_AV
TQI_REQ_TRA	GEAR	LV_AT	N_32

FUNCTION DESCRIPTION:

General information:

The objective of this function is to protect the engine against overspeed and therefore to control the engine speed. A PI controller is used to hold the engine speed at the engine speed limit setpoint, which derives from the module 'Engine speed limit coordination' from chapter 4. Engine overspeed mainly is controlled by reduction of engine torque. The output value of this module is TQI_N_MAX, which is an input in the torque coordination module. Different tasks are designed in this module:

- prediction of engine speed to avoid great engine speed overshoots, especially in the first phase of controlling
- activation of speed limit controller due to speed deviation between predicted engine speed and engine speed limit
- PI controller
- activation of fuel cut off for exceeding the engine speed limit for more than a calibratable difference
- rate limiter for the output in increasing direction to avoid uncomfortable jumps in the torque demand

Application conditions:

Activation:	*at every engine state*		
Deactivation:	-		
Initialization:	TQI_N_MAX	= C_TQI_MAX_PAS	at reset
	N_GRD_FIL	= 0	at reset
	N_GRD_FIL_FIL	= 0	at reset
	LV_N_MAX	= 0	at reset
Update Rate:	10 ms		

9.24.1 Overview

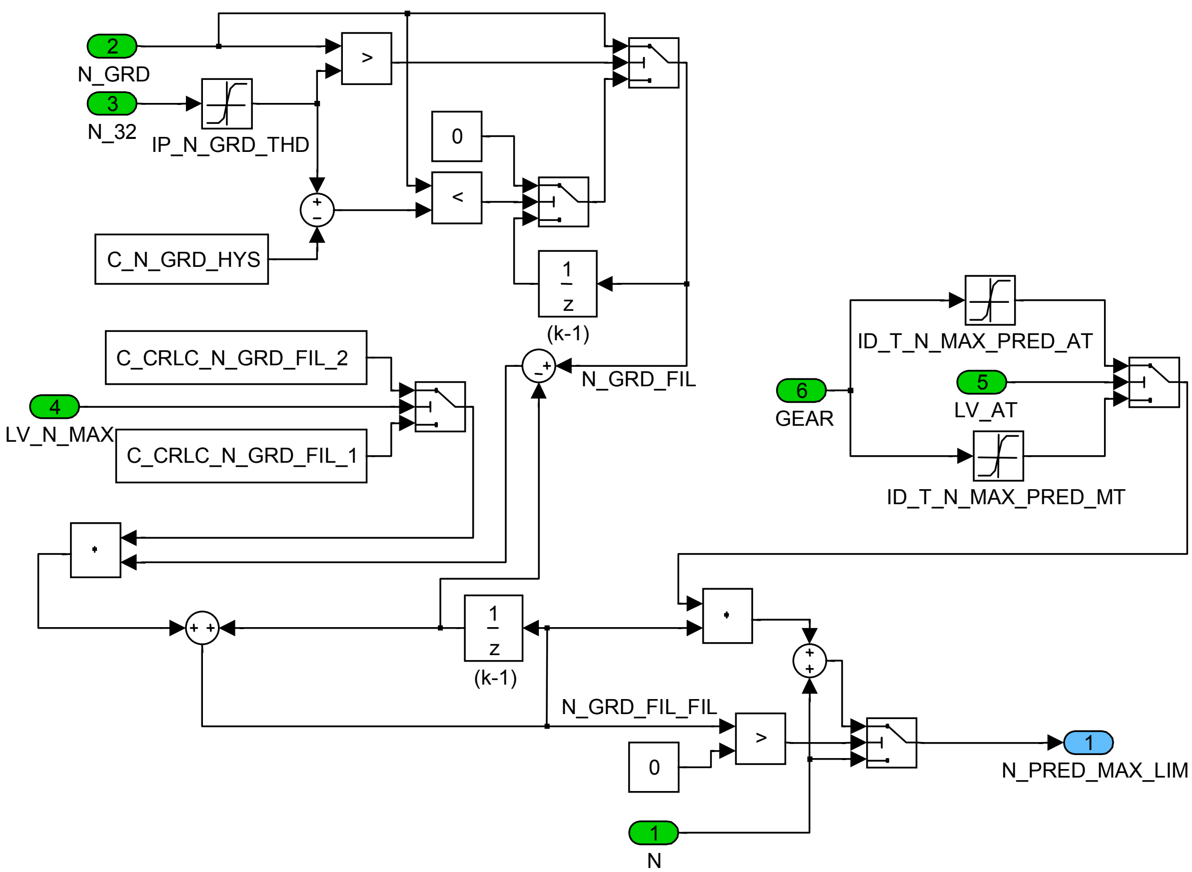
9.24.2 Prediction of engine speed

Signal flow diagram:



Formula section:

The engine speed prediction shall activate the engine speed limitation controller before the real engine speed reaches the threshold N_MAX_THD. Therefore the complete controller has a PID behaviour at activation, to prevent high engine speed overshoot.

The prediction is deactivated, if the controller has stopped the engine speed increase. During the following period the PI controller can guarantee the engine speed limitation up to N_MAX_THD without predicting the engine speed.

Due to a bad resolution of N_GRD, the prediction is only calculated, if a clear high engine speed gradient is detected. This is possible by comparing the gradient N_GRD with an engine speed depending threshold IP_N_GRD_THD__N_32.

The prediction is stopped latest, if the real engine speed is no longer increasing (N_GRD =< 0).

To prevent sudden changes for the engine speed limit controller input at activation or deactivation, it is necessary to have a PT1 filter for the engine speed controller input. So a negative feed back of the controller output to the real engine speed is prevented.

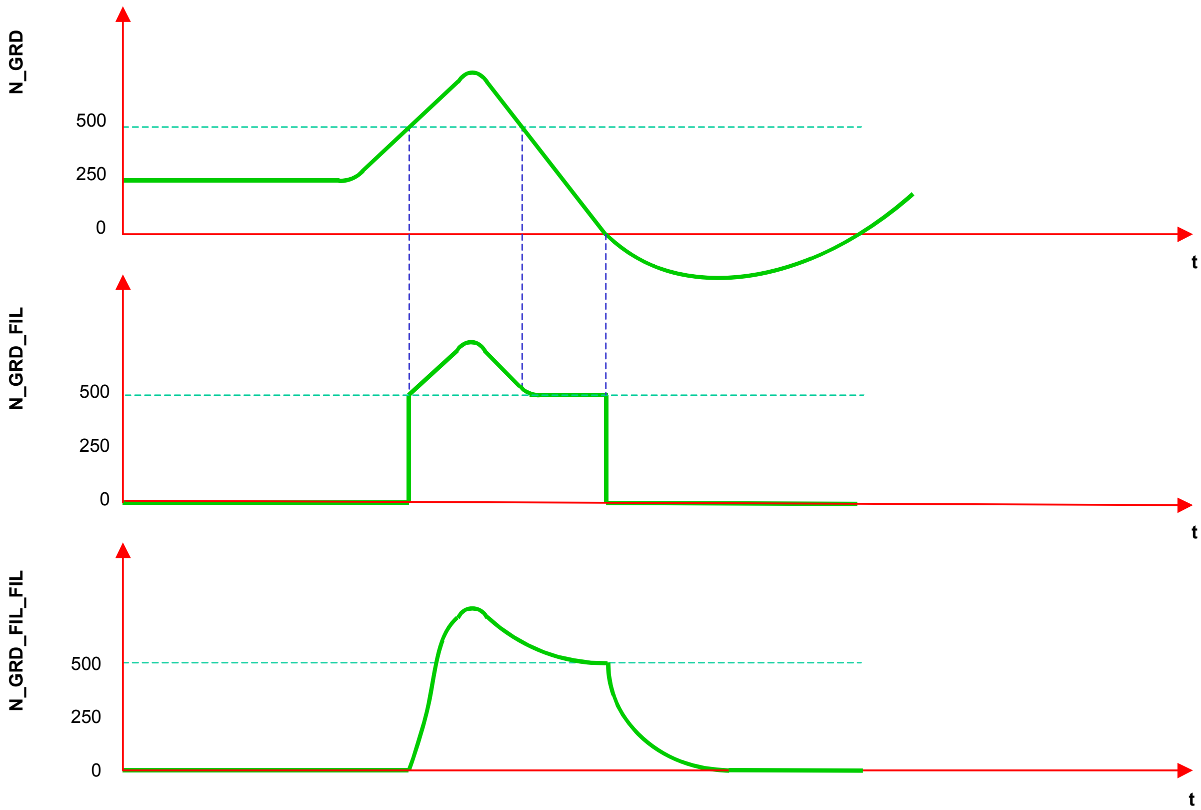


Figure 1: Filtering of engine speed gradient

IF (N_GRD > IP_N_GRD_THD__N_32)

Fuel pump relay control					

Input data:

LV_ES	LV_IGK	LV_VS_MAX	LV_INJ_CUT
LV_EFP_EXT_ADJ	LV_ACT_EFP_EXT_ADJ		

FUNCTION DESCRIPTION:

General information:

Recurrence : 40ms

Activation:

The fuel pump is switched **ON** for **C_T_EFP_IGK** during the transition from the control unit initialization to engine operating state engine stopped (LV_ES = 1) with ignition key **ON** (LV_IGK = active).
The fuel pump relay can be also switched by external adjustment (LV_EFP_EXT_ADJ = 1); If external adjustment is active, the relay is controlled by LV_ACT_EFP_EXT_ADJ.

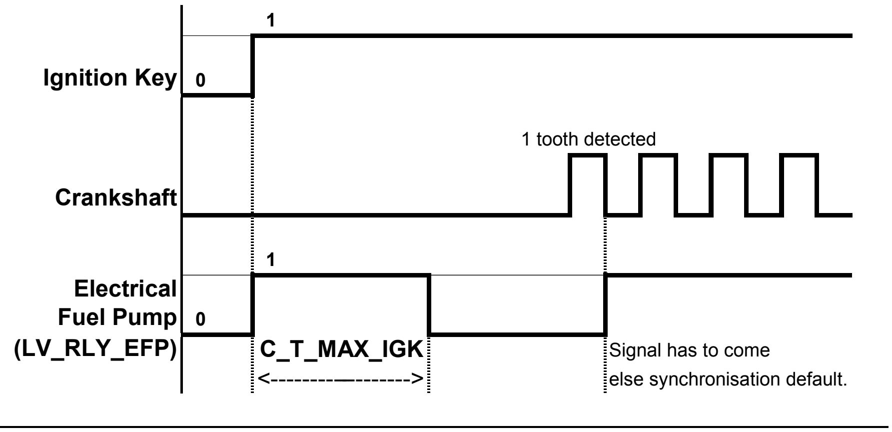
Dectivation:

Following ignition key **OFF** (LV_IGK = passive), the fuel pump is switched **OFF** after a waiting period **C_T_EFP**.

The fuel pump can also be deactivated, after a waiting period **C_T_EFP**, in the following case :

- vehicule speed limitation (LV_VS_MAX = 1) **AND** all cylinder switched off (LV_INJ_CUT = 1)

Description:



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

accumulated fuel consumption(10ms task based on FCO_SUM)					

Input data:

LV_IGK	LV_ES	MFF_SP_MV	EFF_SCC_AV
T_SEG_AV	VS	DIST_FCO	

FUNCTION DESCRIPTION:

General information:

The accumulated fuel consumption is calculated based on the setpoint of the injection. This value (MFF_SP in mg/stk.) is converted to the injected fuel quantity in µl while using the conversion factor C_FCO_STND and simultaneous correction with the actual efficiency of fuel cut-off.

FCO_KPL_TOT, overall fuel consumption rate in Km/L , is calculated based on the vehicle moving distance after engine start and accumulated fuel consumption.

FCO_KPL_VRU , overall fuel consumption rate in Km/L while vehicle running, is calculated based on the vehicle moving distance after engine start and accumulated fuel consumption only while vehicle running.

FCO_KPL, instant fuel consumption rate in Km/L, is calculated when vehicle is running (VS > 0) , which can be assumed using instant fuel consumption quantity (FCO_SUM_TEMP) and converted vehicle running distance from vehicle speed information (VS).

Moving mean value of FCO_KPL, FCO_KPL_MMV, is obtained by filtering FCO_KPL.

Application conditions:

Initialisation: At ECU reset :

FCO_SUM = FCO_KPL = 0

FCO_SUM_10 = FCO_SUM_DIF = 0

FCO_KPL_VRU = FCO_KPL_TOT = 0

Update rate:	segment synchronous	: Calcuation of fuel consumption
	10msec	*: Calcuation of FCO_SUM_10/DIF*

9.27.1 CHRG_REQGNPROTP0

To prevent the air intake system downstream turbo charger compressor from being annihilated by too high pressure difference inside (manifold air pressure) to outside (ambient air pressure) the following function was developed.

The two different conversion tables for IP_MAP_AMP_DIF_IN_PROT and IP_PUT_AMP_DIF_IN_PROT will contain the pressure values **above ambient pressure at nominal ambient pressure (1013hPa)** which the intake manifold respectively the air intake system between turbo charger compressor and throttle can bear to contain. It is dependent on the air mass flow because at different air mass flows different safety ranges between the adjusted value and a possible damage of components may be desired if different instationary effects occur. This also takes into account that the air intake system upstream and downstream throttle possibly have different maximum pressure values which they can resist.

The pressure prediction depends on the air mass flow because a higher mass air flow will lead to a faster increase of the pressure inside the air intake system at the same failure cause. The prediction time is a measure for the time the functionality looks towards the future with the current pressure gradient. So if a long prediction time is adjusted, the air intake protection function will be very sensible. (Refer to signal overview!)

Each the pressure in the intake manifold and upstream throttle will be predicted in the shown manner. If the predicted pressure, after time T_xxx_AMP_DIF_PRED has expired, exceeds the adjustable threshold xxx_AMP_DIF_IN_PROT the logical variable LV_IN_PROT_xxx is set valid.

Dependent on the time span you want to predict the pressure conditions, the measured pressure value differences (xxx_AMP_DIF_GRD) are weightened differently. In addition to the current measured value a predicted pressure value (xxx_AMP_DIF_PRED) is calculated.

Ignition Shut off request for all cylinders because of dual mass flywheel oscillation					
LV_ENG_OFF_DMF_TPS_ISA	V/O	0...1H	0...1	1	-
TPS/ISA shut off request because of dual mass flywheel oscillation					

Input data:

N_TOOTH	LV_ES	LV_ST	LV_AT
TCO			

Function description:

General information:

To avoid a strong oscillation of the dual mass flywheel while operating the engine close to the resonance frequency for a longer time it could be necessary to shut-down the engine.

For this the injection (and additionally the ignition) can be deactivated until next ES. The function is only applied to MT vehicles.

Description:

The oscillation detection is done by checking the engine speed (high resolution engine speed N_TOOTH) against exceedance of rpm window. If the engine speed exceeds a minimum threshold C_N_MIN_DMF then a timer is initialized with C_T_DMF and decremented. If now the engine speed exceeds a maximum threshold C_N_MAX_DMF before the timer reached 0 then the DMF oscillation counter CTR_DMF is incremented.

C_N_MIN_DMF and C_N_MAX_DMF should be calibrated around the DMF resonance rpm.

If the counter reaches a maximum threshold the engine is shut down by injection switch-off until the next engine stop detection. Additionally the ignition can be switched-off. TPS/ISA can be closed In order to improve engine shut-off pattern (LC_ENG_OFF_DMF_TPS_ISA = 1).

Once the engine speed leaves the oscillation range above C_N_MAX_RST_DMF the counter is reset to 0.

At low temperatures the dual mass flywheel typically does not have a resonance problem, so the function can be deactivated.

Recurrence: 10 ms

Application conditions:

Activation:

If LV_ES = 0 **and** LV_ST = 0 *(All engine operating state except ES or ST)*

and LV_AT = 0 *(only for M/T vehicle)*

and *TCO > C_TCO_MIN_DMF* (only above certain TCO threshold)

Initialisation (with LV_ES --> LV_ST):

LV_ENG_OFF_DMF_INJ = 0

LV_ENG_OFF_DMF_IGN = 0

LV_ENG_OFF_DMF_TPS_ISA = 0

T_DMF = 0

CTR_DMF = 0

Formula section:

If N_TOOTH > C_N_MAX_RST_DMF *(engine speed above oscillation range)*

or LV_ES = 1 *(engine stopped)*

then CTR_DMF = 0 *(reset oscillation counter)*

and T_DMF = 0 *(reset oscillation timer)*

else *(engine speed within oscillation range, no ES)*

if N_TOOTH < C_N_MIN_DMF *(engine speed below min. threshold)*

then (re-)initialize timer T_DMF with C_T_DMF *(start time ctr. for max. thd oscillation)*
(as long as N_TOOTH is below the threshold the timer has to be restarted again and again in order to count the time between passing the MIN threshold and reaching the MAX threshold)

else decrement T_DMF *(decrement timer until reaching 0)*

if N_TOOTH > C_N_MAX_DMF *(engine speed above max. threshold)*

and T_DMF > 0 *(max threshold exceeded before timer reach 0)*

then increment CTR_DMF *(oscillation event detected)*

and T_DMF = 0 *(reset T_DMF for next oscillation)*

if CTR_DMF > C_CTR_MAX_DMF *(number of oscillations above threshold)*

then LV_ENG_OFF_DMF_INJ = 1 *(deactivate injection irreversible up to next ES)*

if LC_ENG_OFF_DMF_IGN = 1 *(additional ignition shut-off configured)*

then LV_ ENG_OFF_DMF_IGN = 1 *(additionally deactivate ignition)*

if LC_ENG_OFF_DMF_TPS_ISA = 1

then

LV_ENG_OFF_DMF_TPS_ISA = 1

End if

Difference between the last and the actual temporary coolant temperature moving mean value					
TCO_GRD_MMV_TMP	-	8000...7FFFH	-96...95.99707	2.93E-03	[°C/s]
Temporary coolant temperature gradient moving mean value					

Input data:

TCO			

FUNCTION DESCRIPTION:

General information:

The control of the coolant temperature is using the coolant temperature gradient as input to avoid temperature overshooting and oscillations of the coolant temperature.

Because of the rough resolution of the coolant temperature value a filter (PT1 filter_1) is used to smooth the signal. The difference between the actual moving mean value and the last valid moving mean value is calculated at every second. In this case, the gradient values are always related to the physical unit Celsius per second [°C/s]. An additional filter (PT1 filter_2) in combination with an amplifier is generating the coolant temperature gradient for calibration issues.

Application conditions:

Initialisation:

If Reset

then TCO_MMV_TMP = TCO

$TCO\_MMV\_TMP_{(n-1)}$ = TCO

TCO_GRD_MMV = 0

TCO_GRD_MMV_TMP = 0

$TCO\_GRD\_MMV\_TMP_{(n-1)}$ = 0

TCO_GRD = 0

endif

Recurrence: 1000 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

Calculation of the coolant temperature moving mean value:

TCO_MMV_TMP = TCO * C_CRLC_TCO_MMV +

$TCO\_MMV\_TMP_{(n-1)}$ * (1 – C_CRLC_TCO_MMV)

Calculation of the difference between the moving mean values:

TCO_GRD_MMV = ($TCO\_MMV\_TMP_{(n)}$ - $TCO\_MMV\_TMP_{(n-1)}$) / 1 sec.

Calculation of the temperature gradient moving mean value:

TCO_GRD_MMV_TMP = TCO_GRD_MMV * C_CRLC_TCO_GRD_MMV +

$TCO\_GRD\_MMV\_TMP_{(n-1)}$ * (1 – C_CRLC_TCO_GRD_MMV)

Calculation of the coolant temperature gradient:

TCO_GRD = TCO_GRD_MMV_TMP * C_FAC_TCO_GRD

Signal flow diagram:

LV_ERR_ECF_EL_PWM	POW_OUT_ECF_PWM	NC_ECF_NR	NC_ECF_CONF
LV_ERR_ECF_EL_RLY	POW_OUT_ECF_RLY	CONF_CFA	

FUNCTION DESCRIPTION:

General information:

This manager specifies the sequencing of project specific ENTE tasks.

Description:

Within the aggregate ENTE, the cooling fan functions (acquisition, control, diagnosis, torque loss) are handled project specific with use of HOOK modules. Because different projects use different update rates for the functions, it is necessary to handle the function calls specific within this module.

Application conditions:

General Information

general specification

The Battery state of charge is the ratio between the actual battery charge and the maximum charge.
The determination of the actual battery charged is based on the Integration of the current delivered by the battery Sensor over time, Positive current (= battery is charged) and negative current (= battery is discharged). The accumulated Charge value is added to the Initial value of the battery at Reset.

The Initial value is determined two ways:

The battery voltage decreases depending on engine off time and Battery Temperature to a constant value at parked vehicle. If this phase is long enough the battery voltage can be used for first determination of the Initial Load. If the engine off time is to short then the value of the last Driving cycle is used for Initialization.

Additionally a new reference calculation is done if the Ignition is on and the alternator is not charging the battery. After the Polarization voltage disappeared a timer is decremented checking voltage and current are constant. After this timer is zero the reference value is calculated by a MAP depending on actual Battery voltage and Battery temperature. The value is corrected depending on the actual current.

The data CONF_BAT_LIN is used for battery sensor choice : 0=analog, 1=semi-smart, 2=smart .

<u>Application Conditions</u>

Initialization: RST, NVMRES, NVMINI, NVMSTO
Recurrence: 10MS, 1S
Activation: CONF_BAT==1 && LV_ERR_BAT_SENS==0 && ((LV_VB_SENS_LIN_INI_END==1 && LV_SENS_LIN_READY==1) || CONF_BAT_LIN==0)
Deactivation: if activation not true

General Information

Target of Battery Management is to control the Battery State of Charge in a window, where charging and discharging is possible. This is done by control of the Alternator voltage. Increasing the Alternator voltage increases the SOC (dependent on consumers) and vice versa.
This allows to charge the battery where the engine efficiency is high and to decrease the Alternator Voltage Setpoint in state with low efficiency to decrease torque consumed by Alternator.
The highest priority after cranking is to bring the battery as soon as possible to the desired state of charge to enable restart without problem. Therefore if the SOC is below a threshold the charging has to be done independent of engine efficiency.
Afterwards the SOC is controlled in a window between SOC_WIN_MIN and SOC_WIN_MAX. Target is to keep the Alternator voltage constant till the thresholds are passed. Afterwards the Alternator voltage is de/increased stepwise, till the direction of SOC is changed again. Then the new Alternator voltage is kept constant again.
Additionally it is possible to increase SOC after start depending on different values (T_AST, SOC_INI to high target C_SOC_HIGH and to decrease to a low Target C_SOC_LOW afterwards, before SOC is controlled inside window. This logic can be switched on via LC_SOC_HIGH_LOW.

Timer to confirm preliminary blower switch					

Input data:

LV_HDLP	V_PC_FAN	LV_FATC_BLWR_MAX_CAN	CONF_PC_FAN
VB			

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_STATE_CHA_OPT_INI	1	0...FFFFH	0...65535	1	[-]
Charge option state at initialization					
C_PC_FAN_HIGH	1	0...FFH	0...99.6	0.3905	[%]
Percentage of voltage level to detect blower "HIGH" state					
C_T_PC_FAN_SWI	1	0...FFH	0...25.5	0.1	[sec]
Time before switch of bit 1 of _STATE_CHA_OPT is allowed					

FUNCTION DESCRIPTION:

General information:

The charge option arbitration is calculate according system state :
- Bit 0=1: Head Lamp active
- Bit 1=1: Passenger Compartment Fan High
- Bit 2....10 not defined yet

For the Passenger compartment Fan "HIGH" detection the signal can be transmitted via CAN Information or Analog Input. To avoid switches at Analog input due to quick voltage drops caused by Inductance of blower motor a timer is introduced, which allows a switch only after the voltage level is confirmed during time C_T_PC_FAN_SWI.

Application conditions:

Initialisation: *at Reset:* STATE _CHA_OPT = C_STATE_CHA_OPT_INI
T_PC_FAN_SWI = C_T_PC_FAN_SWI

Recurrence: *100 ms*

Activation: always

Formula section:

if LV_HDLP = 1

```
then     STATE_CHA_OPT = x x x x x x x x x x 1 BIN
else     STATE_CHA_OPT = x x x x x x x x x x 0 BIN
endif

LV_ERR_ALTER	LV_ERR_VB_PLAUS	TCO_ST	LV_ERR_ALTER_PLAUS
LV_SENS_LIN_READY	LV_ERR_ALTER_CHA_PLAUS		

FUNCTION DESCRIPTION:

General information:

The required System voltage is transmitted to the Alternator via PWM duty cycle.

The required Voltage setpoint is applied first by a Precontroller ALTPWM_PCTL. To adapt differences between the required Setpoint and the Actual value a closed loop control with PI-controller is realized. The system Voltage deviation is the input signal for the PI-controller.

With the C_CONF_ALT_MAN the controller value can be assigned to manual values C_ALTPWM_MAN. Additionally it is possible to apply an additive part C_ALTPWM_AS to the calculated value

Application conditions:

Inizialization: *at Reset:* ALTPWM_PCTL = 0%

ALTPWM_I = 0%

ALTPWM_P = 0%

ALTPWM = 0%

LV_INH_BEM = 0

Recurrence: 100 ms

Activation: CONF_BAT = 1

Deactivation: CONF_BAT = 0

Formula section:

Controller precalculations:

```
If         QBAT_TOT > C_QBAT_TOT_INH_BEM

9.35.1 General information:

Cylinder Balancing via Engine Roughness means a correction of the cylinder individual ignition angles to achieve a balancing of the indicated torque (TQI) between the single cylinders based on Engine Roughness calculation. Target is to achieve a smooth engine running.

In order to compensate these torque differences, e.g. caused by manufacturing tolerances of the intake manifold, an additive adaptation correction of the ignition angles is carried out depending on different operation conditions.

The functionality of Balancing Management is realized in form of a state machine. That means that there are states with corresponding settings of outputs, and there are conditions to go from one to another state. The calculation of the adaptation values is controlled by the different states of the state machine.

By means of the logical constant LC_IGA_ADD_ER_BAL_ENA it is possible to enable (LC_IGA_ADD_ER_BAL_ENA = 1) or disable (LC_IGA_ADD_ER_BAL_ENA = 0) the additive adaptation in part load. At idle speed the additive adaptation is always enabled.

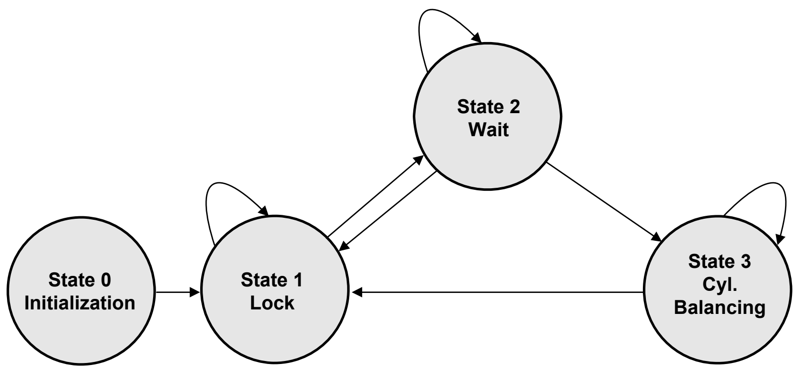
Description of the Cylinder Balancing Manager:

State diagram:



Cylinder Balancing Manager: State 0[H] – "Initialization"

After initializing the state changes at once to state "Lock". The state "Initialization" is active for at least one recurrence.

Cylinder Balancing Manager: State 1[H] – "Lock"

The algorithm stays in this state until the flags LV_IGA_ER_BAL_ENA is set to "1". This flag is set when certain conditions for controlling and adaptation are fulfilled.

Cylinder Balancing Manager: State 2[H] – "Wait"

After transition to this state the function – Engine Roughness Signal Preparation for Cylinder Balancing – starts to calculate.

The counter CTR_IGA_ER_BAL_ENA starts to run. It counts down from the calibrate able initial value C_CTR_IGA_ER_BAL_ENA_INI to zero (decrease of "1" every engine cycle).

Furthermore the input values ER_STND_MMV_BAL[SEG_NR_ER] and ER_STD_MMV_BAL[SEG_NR_ER] has to below a certain limit:

Cylinder Balancing Manager: State 3[H] - Cylinder Balancing

After transition to this state the calculation described in the Cylinder Balancing functions (Engine roughness signal preparation for Cylinder balancing, Cylinder balancing via IGA intervention) start to run.

The input values ER_STND_MMV_BAL[SEG_NR_ER] and ER_STD_MMV_BAL[SEG_NR_ER] have to be below a certain limit (analogue to state 2).

In order to compensate torque differences, e.g. caused by manufacturing tolerances of the intake manifold system, an additive adaptation correction of the applied ignition angle is carried out in the state "Cylinder Balancing" depending on several activation conditions.

The additive adaptation correction is applied only in this state (Cylinder Balancing).

9.36.1 General information:

The Appl. Inc. module is used to keep the cylinder balancing functions modular. Therefore the activation conditions for the signal preparation functions, the balancing manager and the cylinder balancing adaptation functions are set within this module. The cylinder balancing functions are activated as soon as the corresponding activation condition is enabled (=1).

With the logical variable LV_IGA_ER_BAL_ENA_EXT it is possible to adapt the main enable condition (to start cylinder balancing via IGA intervention) with additional external requirements. The flag is used as input signal for the cylinder balancing manager.

With the logical variable LV_IGA_AD_ER_BAL_ENA_EXT it is possible to adapt the main adaptation condition (to start cylinder balancing adaptation via IGA intervention) with additional external requirements. The flag is used as input signal for the cylinder balancing manager.

A logical calibration constant is available to stop all cylinder balancing interventions at once. In case of LC_ER_BAL_STOP_MAN = 1, several activation conditions for the cylinder balancing functions are disabled (=0). If the logical constant is enabled (=1), a re-initialisation ("0"[hex]) of all output values occurs.

FUNCTION DESCRIPTION:

General information:

This manager specifies the sequencing of all CYBL tasks.

Description:

Within the cylinder balancing package (CYBL), all functions for Cylinder balancing via engine roughness" (CYBL_ER) are included. This scheduler has to manage the coordination of all involved parts.

Application conditions:

Recurrence: see formula section below

Activation: at every engine operating state

Deactivation: -

Formula section:

9.37.1 Non volatile memory tasks (CYBL_ER):

NVMY_STB

9.38 IVVT Configuration

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
LV_NOT_ADJ_CAM_IVVT_IN_i	O/V	0...1H	0...1	1	-
Camshaft_IN_i: 0 = with adjustment, 1 = without adjustment					
LV_NOT_ADJ_CAM_IVVT_EX_i	O/V	0...1H	0...1	1	-
Camshaft_EX_i: 0 = with adjustment, 1 = without adjustment					

Input data:

CONF_CAM_VVT_EX			

FUNCTION DESCRIPTION:

General information:

An **i**nfinitely **v**ariable **v**alve **t**iming system (IVVT) is an optional part of the engine. It allows to phase the opening period of the valves. It works with the engine oil system. The complete functionality is included in the aggregate VVTI (**V**ariable **V**alve **Ti**ming). The determination of the phasing is provided by evaluations of the crankshaft and camshaft sensor signals in the aggregate ENSD (**En**gine **S**peed **D**etermination).

Description:

The first step of the IVVT functionality specification is the definition of the engine camshaft phasing configuration, i.e., how many actuators are used. A cylinder bank is a group of cylinders with their own inlet and exhaust camshaft. The number of cylinder banks is given by NC_NR_CBK_IVVT. The inlet and exhaust side can be adjusted on each other independently. The camshaft phasing strategy is given by NLC_IVVT_IN and NLC_IVVT_EX.

There can be 1 or 2 cylinder banks given by NC_NR_CBK_IVVT. The index _i indicates the cylinder bank in data. It is a placeholder for _1 or _1 and _2. The current configuration limits allow four independent actuators, two on the inlet and two on the exhaust side. There are variables describing the inlet and exhaust side and each camshaft individually. They are named …_IVVT_IN, …_IVVT_IN_i, …_IVVT_EX and …_IVVT_EX_i. The abbreviated notation is …_IVVT_IN(_EX) and …_IVVT_IN(_EX)_i. Also, the maximum configuration has variables …_IVVT_IN, …_IVVT_IN_1, …_IVVT_IN_2, …_IVVT_EX, …_IVVT_EX_1 and …_IVVT_EX_2, e.g., a V-engine. On the other side, a minimum configuration, e.g., an engine with one bank and one actuator on the inlet side, has only …_IVVT_IN and …_IVVT_IN_1. The other variables do not exist in this case. It is realized by compilation with NC_NR_CBK_IVVT, NLC_IVVT_IN and NLC_IVVT_EX as compiler switches. This rule is valid for data containing IVVTPWM or IVVTHPWM and ending with …_IN, …_IN_i, …_EX or …_EX_i, too.

There are some reasons for having redundant software, i.e., for more actuators as mounted, and tuneable data for the configuration of the actuators. A compilation creates variables of the type …_IVVT_IN, …_IVVT_IN_i, …_IVVT_EX and …_IVVT_EX_i as mentioned above. Variables for nonexisting actuators (redundant variables) are switched off by LC_NOT_ADJ_CAM_IVVT_IN_i for Inlet and LC_NOT_ADJ_CAM_IVVT_EX_i or CONF_CAM_VVT_EX for Exhaust side.

Application conditions:

Initialization:

At reset:

If LC_NOT_ADJ_CAM_IVVT_IN_i = 0
then LV_NOT_ADJ_CAM_IVVT_IN_i = 0
else LV_NOT_ADJ_CAM_IVVT_IN_i = 1

If LC_NOT_ADJ_CAM_IVVT_EX_i = 0
and CONF_CAM_VVT_EX = 1
then LV_NOT_ADJ_CAM_IVVT_EX_i = 0
else LV_NOT_ADJ_CAM_IVVT_EX_i = 1

This construction ensures that an unintentional change of LC_NOT_ADJ_CAM_IVVT_IN(_EX)_i by the application during IVVT performance will have no effects.

Configuration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
NC_NR_CBK_IVVT	1	1...2H	1...2	1	-
Number of camshaft cylinder banks					
NLC_IVVT_IN	1	0...1H	0...1	1	-
Inlet side configuration: 0 = without actuator, 1 = with actuator					
NLC_IVVT_EX	1	0...1H	0...1	1	-
Exhaust side configuration: 0 = without actuator, 1 = with actuator					

Calibration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit

Camshaft_IN_i: 0 = with adjustment, 1 = without adjustment					
LC_NOT_ADJ_CAM_IVVT_EX_i	1	0...1H	0...1	1	-
Camshaft_EX_i: 0 = with adjustment, 1 = without adjustment					

9.39 IVVT Scheduler

FUNCTION DESCRIPTION:

General information:

The sequencing of individual IVVT tasks is specified in this scheduler. The names of chapters correspond to the individual tasks.

The tasks are divided into core ones and hook ones. The hook tasks are specified in hook modules. Each project can have different algorithms there.

9.39.1 IVVT Sequence of Tasks at Used Camshaft Edges

0 = first camshaft revolution for IVVT task scheduling, 1 = second one; inlet					
LV_CAM_REV_IVVT_EX_i	-	0...1H	0...1	1	-
0 = first camshaft revolution for IVVT task scheduling, 1 = second one; exhaust					

Input data:

IDX_EDGE_CAM_IN_i	IDX_EDGE_CAM_EX_i	NC_NR_EDGE_CAM_IN
T_DIF_EDGE_CAM_IN_i	T_DIF_EDGE_CAM_EX_i	NC_NR_EDGE_CAM_EX
PSN_DIF_EDGE_CAM_IN_i	PSN_DIF_EDGE_CAM_EX_i	NC_NR_CBK_IVVT
STATE_MASK_EDGE_CAM		

FUNCTION DESCRIPTION:

Description:

A camshaft impulse wheel has two edges at least, generally NC_NR_EDGE_CAM_IN(_EX). It is possible to specify which edges will be used by IVVT over two camshaft revolutions. The specification is done by means of the array of bit fields C_IDX_MASK_EDGE_PSN(_CTL)_IVVT_IN(_EX)_i[3]. It is possible to distinguish the camshaft position tasks and the controlling tasks. There are three engine speed ranges that can have different camshaft edge masking. In order to avoid too frequent changes between the ranges at the engine speed threshold the hysteresis C_N_32_MASK_HYS_EDGE_CAM is used. STATE_MASK_EDGE_CAM expresses which engine speed range is currently in use. It is sufficient to update STATE_MASK_EDGE_CAM every 360 °CRK, see Chap. 9.39.3 "IVVT Sequence of 360 °CRK Linked Tasks".

Examples of some masks:

Hexadecimal to binary conversion:

Hexadecimal	Binary			
0	0	0	0	0
1	0	0	0	1
2	0	0	1	0
3	0	0	1	1
4	0	1	0	0
5	0	1	0	1
6	0	1	1	0
7	0	1	1	1
8	1	0	0	0
9	1	0	0	1
A	1	0	1	0
B	1	0	1	1
C	1	1	0	0
D	1	1	0	1
E	1	1	1	0
F	1	1	1	1

The "half-moon-type" camshaft wheel using both edges would have:

C_IDX_MASK_EDGE_... = 0 0 0 0 0 0 0 F H
0000 0000 0000 0000 0000 0000 0000 1111 B

An eight-segment target wheel using every other edge would have:

C_IDX_MASK_EDGE_... = 0 0 0 0 5 5 5 5 H
0000 0000 0000 0000 0101 0101 0101 0101 B

Any camshaft wheel using one edge in two camshaft revolutions would have:

C_IDX_MASK_EDGE_... = 0 0 0 0 0 0 0 1 H
0000 0000 0000 0000 0000 0000 0000 0001 B

This is reasonable for the camshaft position control at very high engine speeds. The time between two used camshaft edges can be still satisfactory for good control quality and it saves runtime.

Further, this part of the scheduler specifies the sequence of calling the tasks at used camshaft edges.

Note to "IVVT Holding PWM": If the engine is not running the recurrence of this task is 10 ms.

The application has a possibility to check the calibration data for IVVT delay. The measurement of the actual delay is enabled if LC_ENA_DLY_MES_IVVT = 1.

Input data not used at the moment:
PSN_DIF_EDGE_CAM_IN(_EX)_i

Application conditions:

Initialization:

At transition "engine run" → "engine stop":

LV_MASK_EDGE_CTL_IVVT_IN(_EX)_i = 0

LV_MASK_EDGE_PSN_IVVT_IN(_EX)_i = 0

Recurrence: *At each camshaft edge*

Activation: *At every engine state*

Formula section:

Masking of camshaft edges and time between masked edges:

```
if      IDX_EDGE_CAM_IN(_EX)_i(n) <= IDX_EDGE_CAM_IN(_EX)_i(n-1)
then    LV_CAM_REV_IVVT_IN(_EX)_i =

9.39.2 IVVT Sequence of Camshaft Edge Tasks at Camshaft Sensor Error

Input data:

LV_ERR_CAM_TOT	LV_ERR_LIH_IVVT		

FUNCTION DESCRIPTION:

Description:

In case of a camshaft sensor error no proper performance of the IVVT system is possible. The tasks in Chap. 9.39.1 "IVVT Sequence of Tasks at Used Camshaft Edges" have then no triggering event. Therefore, when an error is recognized some tasks are called up every 360 °CRK in order to ensure proper limp home operation.

Application conditions:

Recurrence: 360 °CRK

Activation: LV_ERR_LIH_IVVT = 1

and LV_ERR_CAM_TOT = 1

Formula section:

Sequence of camshaft edge tasks at camshaft sensor error:

FUNCTION DESCRIPTION:

Description:

STATE_MASK_EDGE_CAM for the camshaft edge masking, see Chap. 9.39.1 "IVVT Sequence of Tasks at Used Camshaft Edges", is updated every 360 °CRK.

A 360 °CRK linked task has its reccurence based on 360 °CRK. It means that it can be one engine revolution or two or three, etc. The reccurence of some tasks can be tuned in four engine speed ranges by means of ID_NR_REV_SDL_IVVT. This feature is dedicated for the run time optimization.

Further, this part of the scheduler specifies the sequence of calling the 360 °CRK linked tasks.

If there is a failure in the crankshaft signal acquisition a substitute signal manages the 360 °CRK reccurence.

Application conditions:

Initialization:	At reset:
	STATE_MASK_EDGE_CAM = 0
	At transition "engine run" → "engine stop":
	STATE_MASK_EDGE_CAM = 0
	CTR_REV_SDL_IVVT = 0
	LV_TRIG_REV_SDL_IVVT = 0
Recurrence:	360 °CRK
Activation:	At every engine state

Formula section:

Current mask of edges:

Transition from STATE_MASK_EDGE_CAM = 0:

```
if      N_32 > C_N_32_MASK_1_EDGE_CAM + C_N_32_MASK_HYS_EDGE_CAM
then    STATE_MASK_EDGE_CAM = 1
endif
```

Transition from STATE_MASK_EDGE_CAM = 1:

```
if      N_32 <= C_N_32_MASK_1_EDGE_CAM
then    STATE_MASK_EDGE_CAM = 0
elseif  N_32 > C_N_32_MASK_2_EDGE_CAM + C_N_32_MASK_HYS_EDGE_CAM
then    STATE_MASK_EDGE_CAM = 2
endif
```

Transition from STATE_MASK_EDGE_CAM = 2:

```
if      N_32 <= C_N_32_MASK_2_EDGE_CAM
then    STATE_MASK_EDGE_CAM = 1
```

```
endif
```

1 = request for activation adaptation of reference position, 0 = no request					

Input data:

N_32	TOIL	VB	LV_ST_END
LV_ERR_LIH_IVVT	LV_AD_END_IVVT		

FUNCTION DESCRIPTION:

General information:

The IVVT system can be in active or inactive state. The active state means that the camshaft position is controlled to a desired position (setpoint). It is the normal prevailing state. The state is inactive in certain circumstances which do not allow controlling, or it is better not to control. Then, the passive stop position is the target one.

Description:

There are different reasons for getting the IVVT system into the inactive state. The states are depicted by means of STATE_IVVT.

IVVT states:

STATE_IVVT	Abbr.	Description
PASSIVE	PA	inactive: after engine start or out of battery voltage range or oil temperature below minimum limit
READY	RE	inactive: oil temperature above maximum threshold (depending on engine speed)
ACT_ADAPT	AD	inactive: activation adaptation of reference position after "PASSIVE" state, i.e., successful adaptation is required for IVVT activation
ENABLE	EN	active: controlling
LIMP_HOME	LH	inactive or partially active: a failure does not allow proper IVVT performance

The engine oil system needs some time after the engine start to build up oil pressure necessary for IVVT performance. To ensure this, the IVVT system remains in the inactive state, "PASSIVE", for the time ID_DLY_ST_IVVT which depends on the oil temperature.

Further, the reference position adaptation is required, "ACT_ADAPT". The adaptation is enabled if the conditions for IVVT performance are fulfilled, i.e., the battery voltage and the oil temperature (C_VB_MIN_IVVT, C_VB_MAX_IVVT, C_TOIL_MIN_IVVT). The state remains inactive till the adaptation is finished successfully. Then, the IVVT states becomes active, "ENABLE".

The conditions for IVVT performance are checked continiously. If only one of the thresholds C_VB_MIN_IVVT, C_VB_MAX_IVVT or C_TOIL_MIN_IVVT is crossed IVVT is switched into the inactive state, "PASSIVE". If later these conditions are fulfilled again a new activation adaptation of the reference position is required, "ACT_ADAPT".

If the oil temperature rises over IP_TOIL_MAX_IVVT the IVVT system is inactivated, "READY". If the oil temperature returns into the allowed range IVVT becomes active, "ENABLE", if the activation adaptation has been already finished successfully, or remains inactive, "ACT_ADAPT", if the adaptation has been interrupted due to the high temperature.

The inactivation due to C_VB_MIN_IVVT, C_VB_MAX_IVVT or C_TOIL_MIN_IVVT has a higher priority than the one due to IP_TOIL_MAX_IVVT.

There are the hystereses C_VB_HYS_IVVT and C_TOIL_HYS_IVVT for avoiding too frequent transitions between the active and inactive state at the battery voltage and oil temperature thresholds.

The inactivation due to a failure, "LIMP_HOME", is held on till the transition "Engine run" → "Engine stop". Then, the activation starts from "PASSIVE" as usual. The transition from "LIMP_HOME" to "PASSIVE" during the engine operation is possible if LV_ERR_LIH_IVVT becomes 0 and C_DLY_LIH_IVVT > 0. C_DLY_LIH_IVVT delays this transition.

The figure "IVVT state diagram" illustrates transitions between the individuall IVVT states.

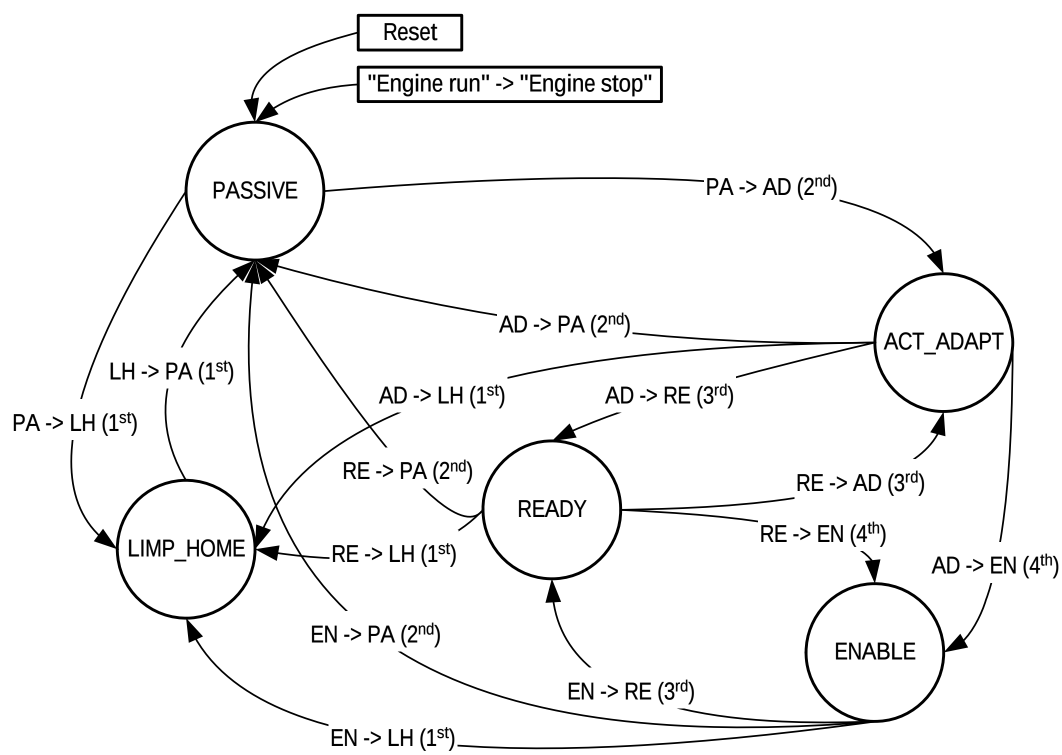

Figure: "IVVT state diagram."

Application conditions:

Initialization:

At reset:

STATE_IVVT = "PASSIVE"

At transition "Engine run" → "Engine stop":

LV_ACT_IVVT = 0

STATE_IVVT = "PASSIVE"

LV_AD_REQ_IVVT = 0

At transition LV_ST_END = 0 → 1:

Start Timer ID_DLY_ST_END_IVVT

Recurrence:

360 °CRK

Activation:

At every engine state

Formula section:

For transition identifiers see figure "IVVT state diagram". The number in brackets at the transition identifier means the order in which the corresponding transition condition is queried in a state.

9.41 IVVT Camshaft Position

FUNCTION DESCRIPTION:

General information:

There are several possibilities for defining a position of the camshaft. The chosen one is described bellow.

Description:

Camshaft phasing design data are illustrated in Figure "Camshaft position". The maximum adjustment range is given by C_CAM_ADJ_RNG_MAX_IVVT_IN(_EX). The next point is the adjustment direction. Actuators working with the engine oil system and controlled by a magnetic valve have a passive stop position, or reference position. It means that the IVVT system without energization moves towards, or remains in the passive stop position. The IVVT system configuration is: the passive stop position of the exhaust camshaft is advanced, of the inlet camshaft retard.

The camshaft position is the crank angle coordinate of the top point of the cam. The crank angle axis has its zero point in the top-center crank position of the gas exchange phase.

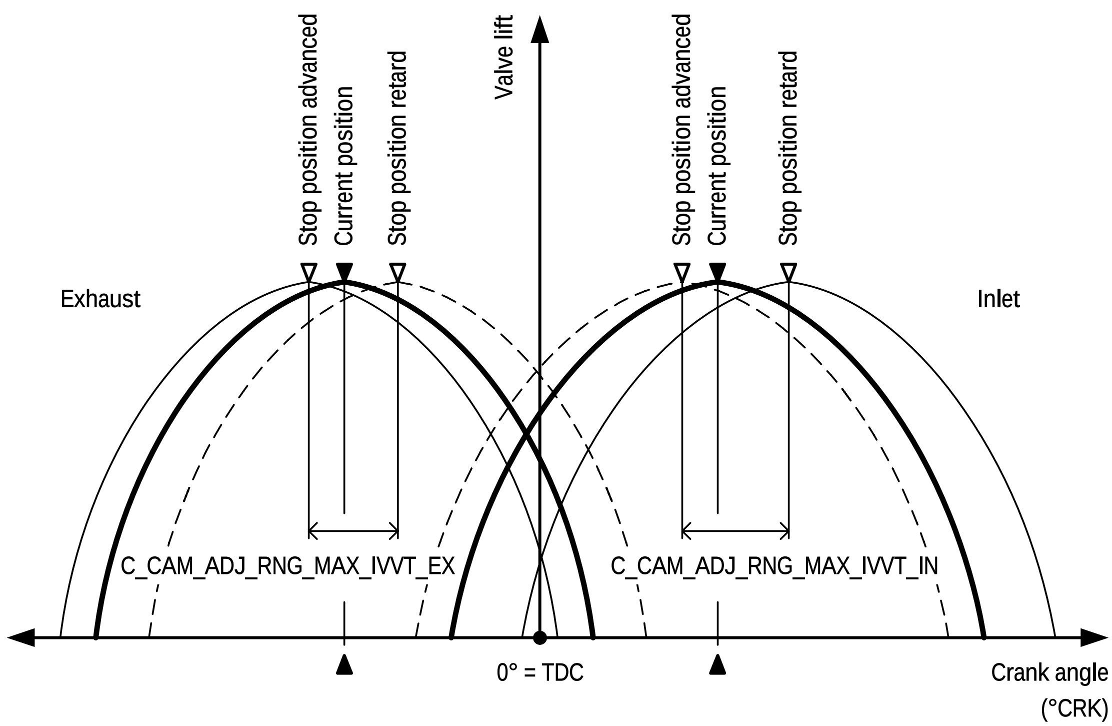

Figure: "Camshaft position."

The position mentioned above represents the design situation. Each component has certain tolerances. Further, the camshaft position is determined from the camshaft and crankshaft sensor signals. There are inaccuracies at the measurement. Therefore, the obtained reference reference position of the camshaft differs from the designed one, i.e., C_CAM_INI_IN(_EX).

This diference is detected by an adaptation of the reference positions. It is obvious that the camshaft must be in its passive stop position. The difference between the design reference position and the current one is PSN_AD_CAM_IN(_EX)[i]. The sign of this quantity is clear from the formula used: difference equals obtained position minus design position.

Information delivered by ENSD during engine operation is the difference between the adapted reference position and current position of a camshaft (difference equals current position minus adapted reference position), see PSN_CAM_IN(_EX)[i] in Figure "Camshaf position in IVVT".

The adapted reference positions define IVVT coordinate systems. It means the adapted reference position of the inlet camshaft is the point C_CAM_INI_IN of the inlet coordinate system. The same applies for the exhaust side with C_CAM_INI_EX. The camshaft positions used in IVVT are CAM_AV_IVVT_IN[i] and CAM_AV_IVVT_EX[i].

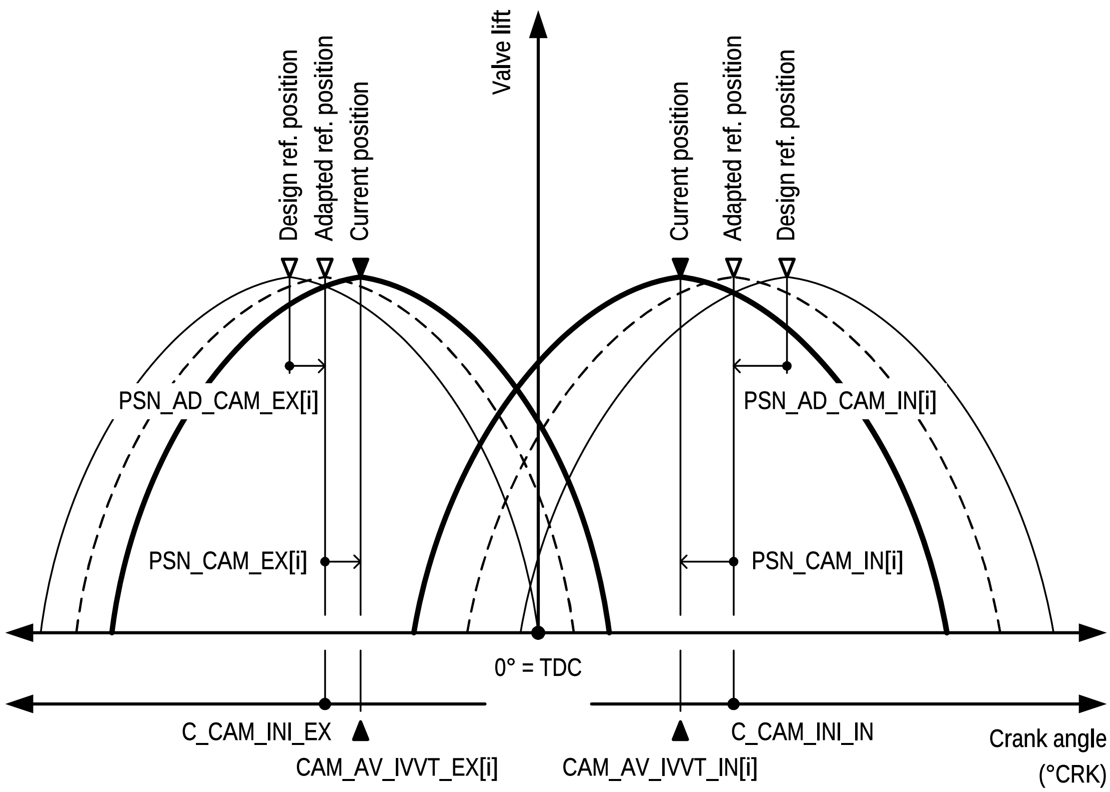

Figure: "Camshaft position in IVVT."

9.41.1 Stop Positions

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
CAM_ADJ_MAX_IVVT_IN	V/O	0...FFH	60...155.625	0.375	[°CRK]
Maximum adjustement stop position of inlet camshaft

NC_NR_CBK_IVVT	N_32		

FUNCTION DESCRIPTION:

Description:

The camshaft position determination is disturbed if there are failures at the crankschaft and/or camshaft signal acquisition. If the position cannot be determined C_CAM_INI_IN(_EX) is taken as a substitute value. If there are only sporadic disturbances the previous value is taken.

The camshaft position can oscillate due to changing torques on the camshaft. A mean value is needed for the IVVT position control. The oscillation can disturb the control especially at reaching a steady setpoint.

The mean camshaft position change CAM_CHG_IVVT_IN(_EX)[i] and the amplitude of the changes CAM_OSC_AMPL_IVVT_IN(_EX)[i] is evaluated.

The camshaft position is filtered dependent on CAM_OSC_AMPL_IVVT_IN(_EX)[i] and CAM_CHG_IVVT_IN(_EX)[i], ID_CRLC_CAM_IVVT. Following limit cases can occur:

1. The mean change is zero and the amplitude is non-zero. It means that the camshaft keeps its mean position and oscillates. A strong filtering is to apply.
2. The mean change equals the amplitude. It means that the camshaft changes its mean position without oscillation. A weak filtering is to apply.

An example:

- The mean change equals half of the amplitude. It means that the camshaft changes its mean position as well as oscillate. A moderate filtering is to apply.

If the mean camshaft movement changes its direction the case 1 occurs for short time. It means a strong filering that is not required in such case. Therefore, the descent of the correlation constant is limited by ID_CRLC_CHG_NEG_LIM_CAM_IVVT. Also, the aim to follow the mean change is prioritised to the filtering of the oscillations.

NC_NR_CBK_IVVT			

FUNCTION DESCRIPTION:

Description:

The bank mean camshaft position CAM_MV_IN(_EX) is used for common consideration of both inlet and of both exhaust camshaft position in an V-engine. If there is only one camshaft bank, the mean value is equal the single available value.

The valve overlap is the distance between the inlet valve openig point and the exhaust valve closing point expressed in °CRK, see Figure "Valve overlap". There are two valve overlaps in an V-engine, VO_IND[i]. A mean value can be created, VO. Engines with one camshaft bank have VO equals to VO_IND[1].

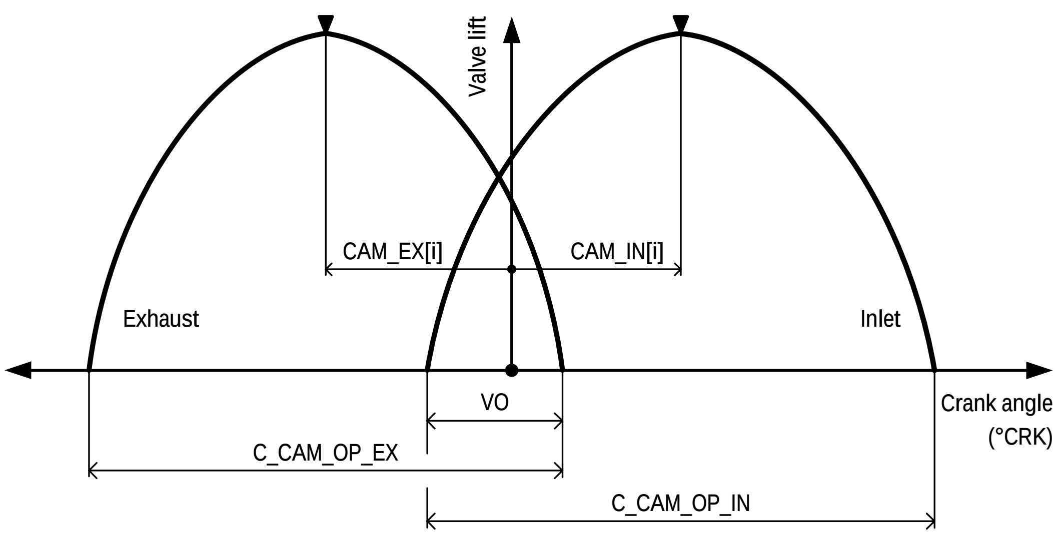

Figure: "Valve overlap."

Application conditions:

Initialization:

At reset:

CAM_MV_IN(_EX) = C_CAM_INI_IN(_EX)

VO = VO_IND[i] =

(C_CAM_OP_IN + C_CAM_OP_EX) / 2 - C_CAM_INI_IN + C_CAM_INI_EX

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

At every engine state

Formula section:

1 = IVVT system is close to maximum adjustement stop position, 0 = not close; exhaust					

Input data:

CAM_SP_IVVT_IN	CAM_SP_IVVT_EX		
LV_ACT_IND_IVVT_IN[NC_NR_CBK_IVVT]	LV_ACT_IND_IVVT_EX[NC_NR_CBK_IVVT]		

FUNCTION DESCRIPTION:

Description:

The information whether the IVVT system is close to the maximum adjustment stop position is needed in other IVVT functionalities. There can be some effects which do not allow to reach the mean maximum adjustment stop position, e.g., component tolerances, chain/belt oscilations. Also, there would always remain a camshaft position deviation with regard to the setpoint. Diagnoses and adaptations could give wrong results.

If the mean maximum adjustment stop position is exceeded in case of "a long actuator" during a short overshoot, the control algorithm will manage this situation as normal control deviation. Therefore, LV_ADJ_MAX_IVVT_IN(_EX)[i] is 0 in this case.

Application conditions:

Initialization:

At deactivation, at transition "Engine run" → "Engine stop":

LV_ADJ_MAX_IVVT_IN(_EX)[i] = 0

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

LV_ACT_IND_IVVT_IN(_EX)[i] = 1

Formula section:

```
if      Inlet:
                CAM_SP_IVVT_IN <=

FUNCTION DESCRIPTION:

General information:

Two cases are distinguished for the reference position adaptation. The first one is the activation adaptation, see "IVVT State". It is necessary for activating the IVVT system, e.g., after the engine start. The second case is an adaptation if IVVT is active. This adaptation is dedicated for the revaluation of the camshaft position determination by ENSD for changed conditions, e.g., the engine temperature (engine lengthening). There is no direct impact on the IVVT functionality.

Description:

The activation adaptation is managed by the IVVT state algorithm, see "IVVT State". It means that if LV_AD_REQ_IVVT = 1 an adaptation is required and the conditions for it are fulfilled. This request resets LV_AD_END_IVVT to 0. If ENSD reports the end of all adaptations LV_AD_END_IVVT is set to 1. LV_DI_AD_REF_CAM_IVVT_IN(_EX) is to 1, too. This is an information for ENSD that the adaptation end has been recognized.

The reference position adaptation is done in the IVVT active state, too. It is assumed that the camshaft position setpoint reaches the reference position in some engine operating points. The adaptation is enabled everytime if the setpoint reaches the area near the reference position, LV_CAM_SP_REF_AD_DI_IVVT equals 0 and the delay C_DLY_AD_REF_IVVT for the camshaft adjusting expires. If ENSD reports the end of all inlet/exhaust adaptations, i.e., the inlet and the exhaust adaptation are independent, LV_DI_AD_REF_CAM_IVVT_IN(_EX) is set to 1, i.e., the adaptation end has been recognized. If the conditions for the adaptation still persist the adaptation is started over and over again.

Application conditions:

9.45.1 INSY_MANAGCAMAD

General Information

In any IC-engine, the positions of the inlet and exhaust camshaft(which have a big influence on the air-mass-flow and emission behaviour) have certain tolerances resulting for e.g. from shift in relative position between camshaft-actuator and actual camshaft position, sensor inaccuracies, manufacturing errors etc. Such tolerances can also vary from one engine to other. Consequently, the camshaft position measured in the reference engine(which was used to calibrate the volumetric efficiency data) could be quite different from a serial production engine making the calculated air mass inaccurate i.e. it would lead to a wrong calculation of the air flowing into the cylinder - the modelled value of MAF_CYL would not be equal to the real air flow into the cylinder, eventually leading to emission problems. In addition to the tolerances in the camshaft position, an error in the throttle area(for e.g. production tolerances or pollution) which can also lead to a wrong air-mass flow, has to be learnt.

The aim of the adaptation is to learn the shift in absolute position of the inlet and exhaust camshafts with respect to the reference engine. The results of the adaptation are offsets to the camshaft position. The adaptation algorithm is based on air flow balance under steady state conditions. It involves the following steps which are coordinated by this module:

waiting for stationary conditions of N, MAP_MES and other variables

adjustment of camshaft to certain inlet and exhaust positions

At each camshaft position, variables like N, MAP_MES, CAM_IN/EX etc. are measured and mean value over certain number of recurrences calculated.

Optimisation algorithm(based on gradient check method) which minimizes the least squared error over all camshaft positions i.e. $\sum(MAF\_THR_i - MAF\_CYL_i)^2$. The parameters that can be varied to find the optimum are CAM_OFS_IVVT_IN, CAM_OFS_IVVT_EX and AR_RED_AD_ADD_REQ_CAM_OFS_AD (reduced area adaptation value to learn non-camshaft related errors)

The variable STATE_CAM_OFS_AD represents the current status of the adaptation. In the state 'Detection_of_AD_OPP', the current engine operating point is compared with the

N/MAP operating points that are needed for camshaft-adaptation. If the current N and MAP_MES match with one of the desired operating points in ID_N_OPP_CAM_OFS_AD and ID_MAP_MES_OPP_CAM_OFS_AD, the bit LV_CAM_OFS_AD _OPP_CDN is set to 1. The index variables IDX_OPP_CAM_ OFS_AD_TMP and IDX_MAP_OPP_CAM_OFS_AD_TMP indicate at which one of the required engine speed/load operating conditions the engine is currently at.

When LV_CAM_OFS_AD_OPP_CDN has been set, the camshaft-adaptation can be started. It is first checked if the AR_RED_AD_ADD value for the detected operating point has already been learnt. If it is has not yet been learnt, then its calculation is triggered in state ‘Request_for_AR_RED_AD’. The reduced-area adaptation values are learnt at a certain inlet/exhaust position where a position error has little influence on the air-mass flow. This is done in conjunction with the Reduced-area adaptation functionality. Once the AR_RED_AD_ADD calculation has been completed, the state machine transits to state ‘Adaptation_Active’. The actual learning of the position error involves the following steps:

- Adjustment of the desired camshaft position (ID_CAM_SP_IVVT_IN/EX_CAM_OFS_AD) – STATE

- Limited dynamic check for relevant variables(LV_LDC_CAM_OFS_ AD_ACT).

- Once the variables have reached a stable value, several signals needed for adaptation are measured over C_CYCNR_SIG_REC_MAX recurrences and their mean value calculated.

- Above mentioned steps done for all the required camshaft positions.

- After signal acquisition mentioned above is carried out successfully(LV_CAM_SP_ADJ_TOT_END=1), the optimisa- tion algorithm is triggered in states ‘OPTIMIZATION' and 'POST_OPTIMIZATION’ .

During the camshaft adjustment process, if the activation conditions are not fulfilled anymore, the adaptation is aborted and all relevant variables initialised in the state 'PASSIVE”. If the adaptation starts again, the adjustment of the camshaft will start again from the first camshaft position combination.

Figure 101 INSY_MANAGCAMAD/ INITIALISATION

9.45.1.2 NVMY data Handling

The initialisation of the NVMY data should be done during ECU-FIRST-POWER-ON(Brand new ECU) or when an EEPROMN-ERROR occurs or when the adaptation is activated externally (LV_CAM_OFS_AD_EXT_REQ=1). For the external activation, NVMY data are reset only if the adaptation has not been carried out already in the current DC.

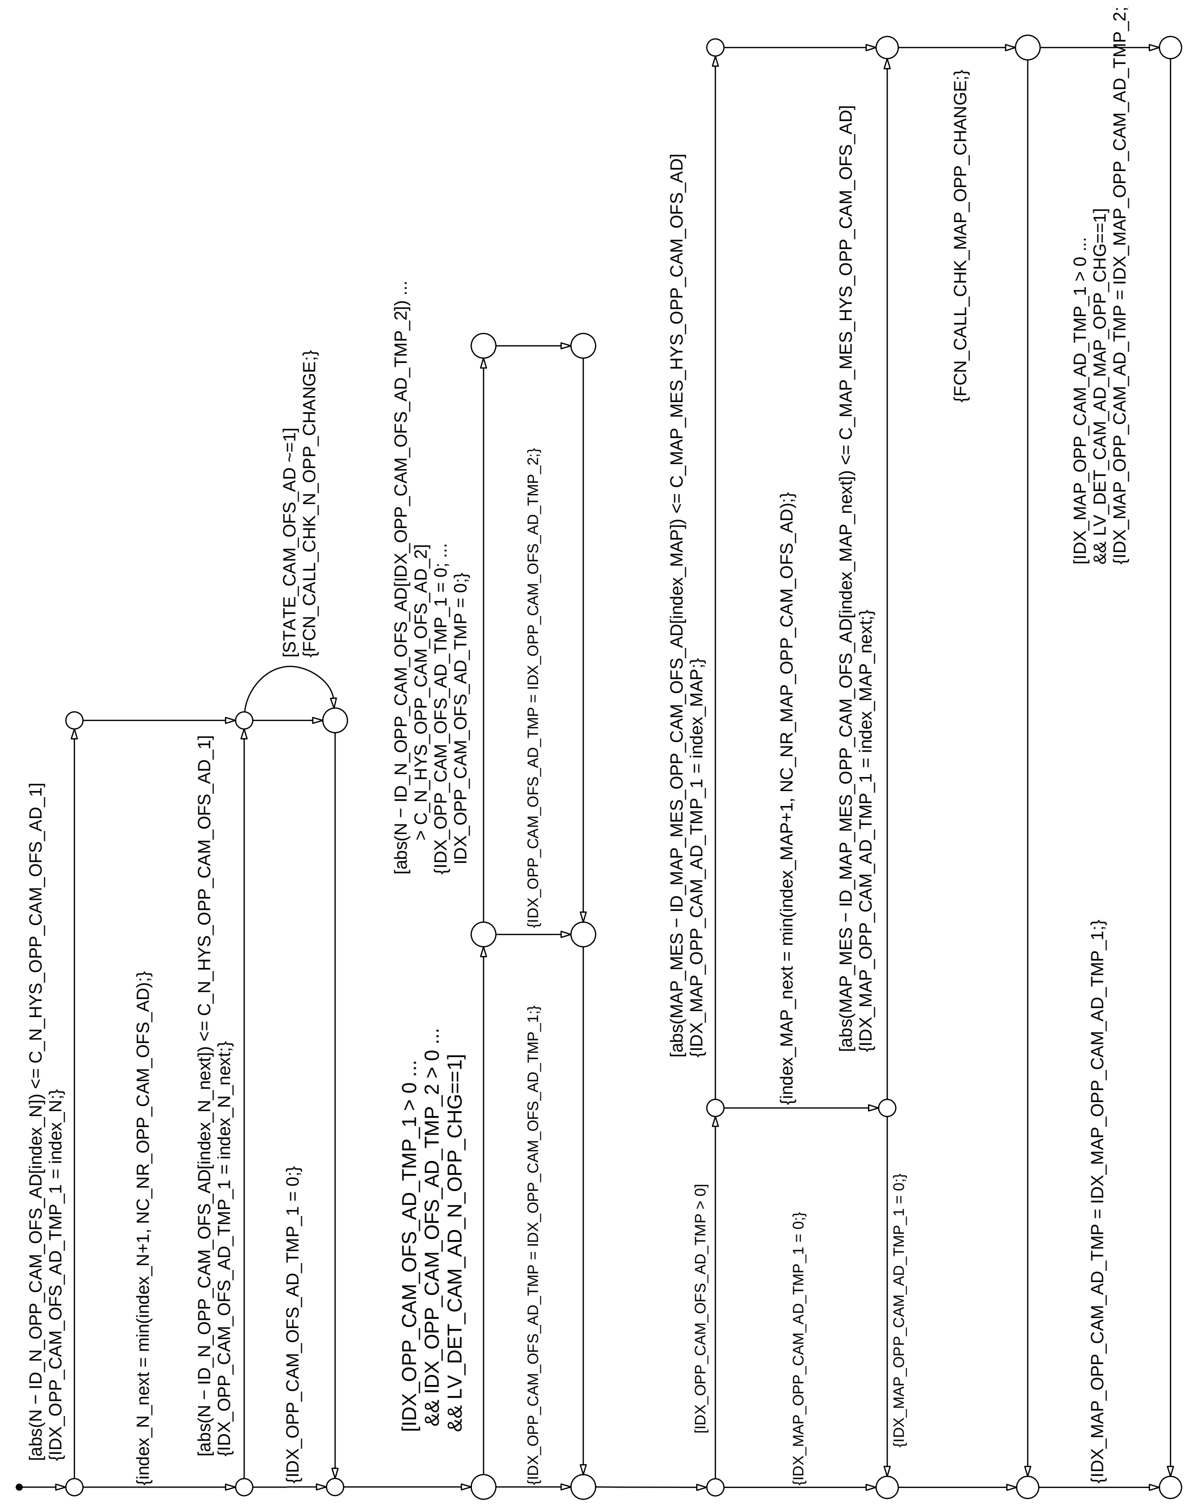

Figure 106 INSY_MANAGCAMAD/ OPERATE/ Adap_Operating_point_eval/ Finding_engine_operating_point

Detection of speed/load operating point change during adaptation

If during the signal acquisition phase of the adaptation or AR_RED_ AD_ADD calculation, the engine speed or manifold pressure were to change leading to a shift in value of IDX_OPP_CAM_OFS_AD or IDX_MAP_OPP_CAM_ OFS_AD, the value of these indices are frozen at their previous value to avoid the adaptation from being interrupted or adjusted the camshaft to a new position For software purposes the following variables were introduced:

IDX_OPP_CAM_OFS_AD = max(1,IDX_OPP_CAM_OFS_AD_TMP)

IDX_MAP_OPP_CAM_OFS_AD = max(1,IDX_MAP_OPP_CAM_AD_TMP)

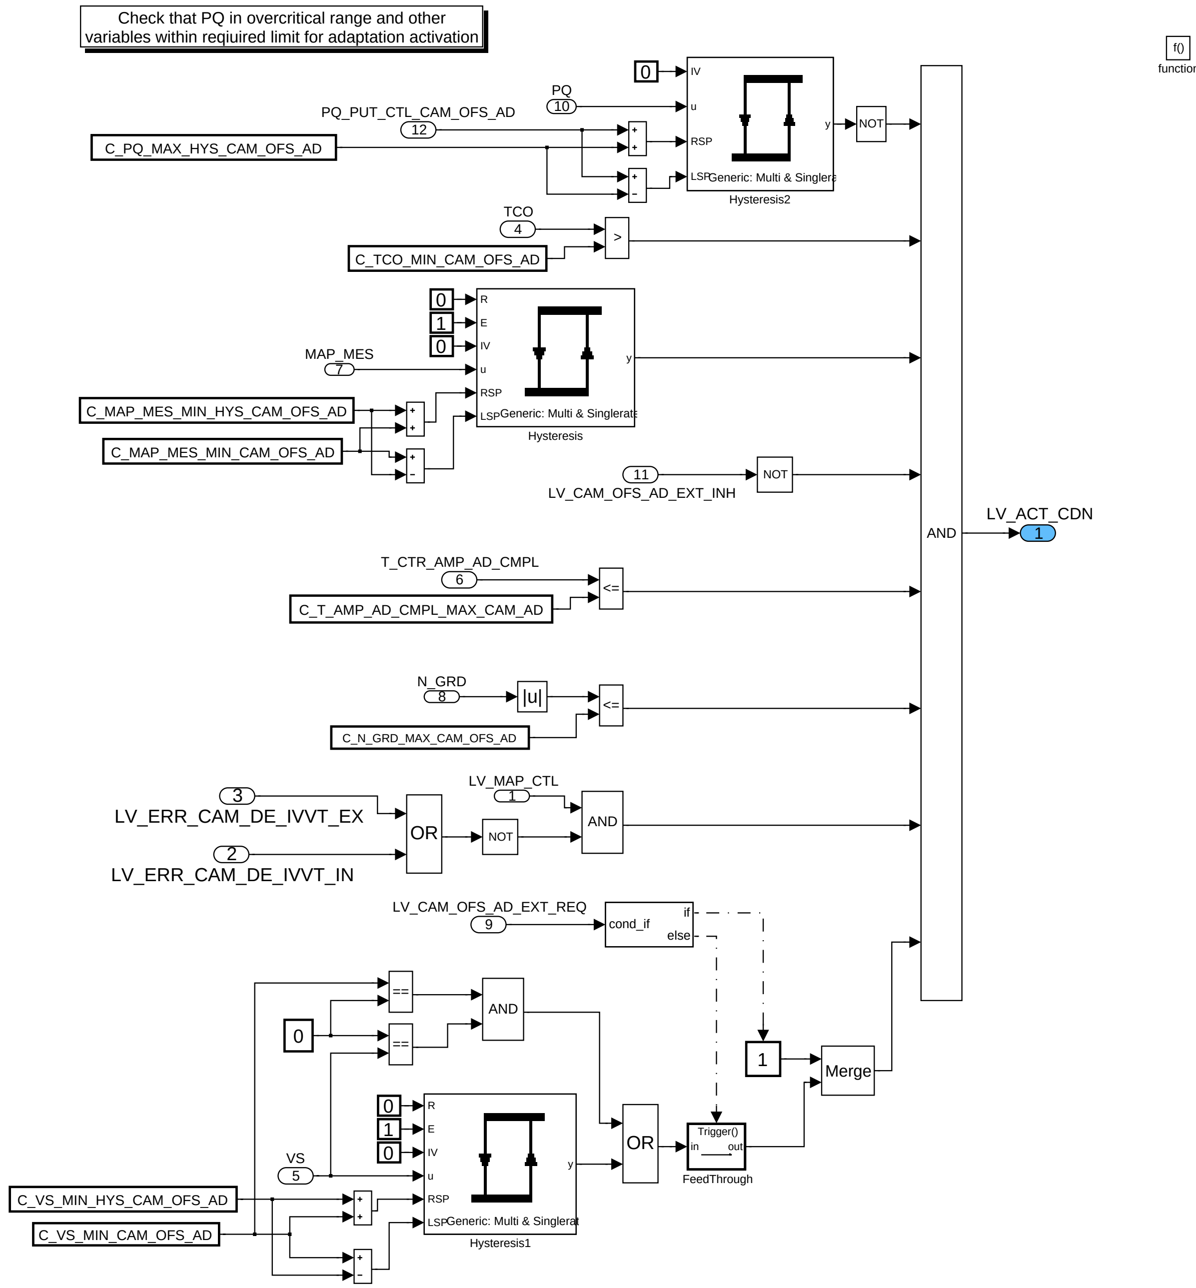

Figure 109 INSY_MANAGCAMAD/ OPERATE/ Adap_Operating_point_eval/ ADDITIONAL_ACT_CDNs_CHK

Evaluation of Adaptation results

After a successful adaptation run, the 'quality' of the results i.e. CAM_OFS_IVVT_IN/EX_OPTM_OUT is checked to make sure that the optimisation algorithm has detected a position error which is within a plausible range. This is done to ensure that other functionalities which might eventually use the adaptation results for a correction of the inlet/exhaust position work with the correct values. This is done by first checking whether CAM_OFS_IVVT_IN/EX are within a certain range – C_CAM_OFS_IVVT_L_THD and

C_CAM_OFS_IVVT_MAX and the squared error at the end of the optimisation is below a certain value. If these conditions are not fulfilled, the results are not utilised.

Under normal driving conditions on the road, the algorithm for the same engine operating point will always vary by several degrees due to reasons like averaging during the signal acquisition and changing environmental conditions. Another reason for the range check is, inlet/exhaust position error below a certain value(depending on the engine, normally around 2-3°CRK) do not have much effective influence on the air-mass flow into the cylinder. The least-squared error on the other hand gives a good indication of how well the optimisation algorithm was able to learn the position error. A high squared error indicates that the algorithm was not able to completely learn the error.

If the adaptation constantly learns a camshaft position error which is bigger than the threshold C_CAM_OFS_IVVT_MAX, then this is used as an indication that there are other errors in the air-path which have not been detected or have changed without being detected by a diagnosis i.e. small hole in intake-manifold, change in Blowby characteristics, a jump in the camshaft-driving-chain etc.

9.46.1 Function description

Function Description

This specification is used to implement customer specific requirements on the adaptation. It is divided into two parts with the first part used to coordinate the external activation for e.g. during End-of-Line test or workshop tests etc. The request for such activations can be done either through an externally connected tester/scan-tool or by other ECU functionalities. The second part involved the project specific calculation of the data required for the determination of the adaptation specific MAF_THR and MAF_CYL i.e. influence of the VIM and PORT flaps on the volumetric efficiency.

9.47.1.2 AR_RED_AD_ADD calculation for Camshaft offset adaptation

In this subsystem, the request for the calculation of the reduced-area adaptation by the Camshaft-offset adaptation functionality is coordinated. The aim of the CAM_OFS_AD functionality is to learn an error in the inlet/exhaust camshaft position that may lead to an error in the calculation of the air-mass flow into the cylinder(MAF_ CYL). Since the adaptation is based on air-mass-flow balance equations, tolerances in any of the engine components(in addition to the camshaft) that influence air flow into the cylinder will also be interpreted by this functionality as a camshaft position error. In order to avoid this, a camshaft position combination having little influence on the air-mass flow into the cylinder(from ID_CAM_SP_IN/EX_AR_RED_AD_CAM_AD) will be utilised to learn any error/tolerances of the throttle-plate area(reduced-area).

In the intake manifold model, the error in the reduced-area is learnt by the reduced area-adaptation functionality. When the CAM_OFS_AD function has detected that engine is in one of the desired adaptation operating points(LV_CAM_OFS_AD_OPP_ CDN=1), the calculation of AR_RED_AD_ADD is triggered. For this, the existing AR_RED_AD_ADD value learnt by the IMM functionalities is saved temporarily and AR_RED_AD_ADD is reset to zero. Once this is done, the camshaft is adjusted to the desired inlet/exhaust position and the learning of the adaptation value is started. The value learned is written into AR_RED_AD_ADD_ REQ_CAM_OFS_AD.

If the reduced-area adaptation were to be interrupted due to some external influences(for e.g. LV_ERR_MAP/MAF), the adaptation result at that point of time will be saved in AR_RED_AD_ADD_REQ_CAM_OFS_AD. At the start of the next reduced-area adaptation calculation instance for the CAM_OFS_AD , the value saved in AR_RED_AD_ADD_REQ_CAM_OFS_AD will be used as the initial value for

AR_RED_AD_ADD

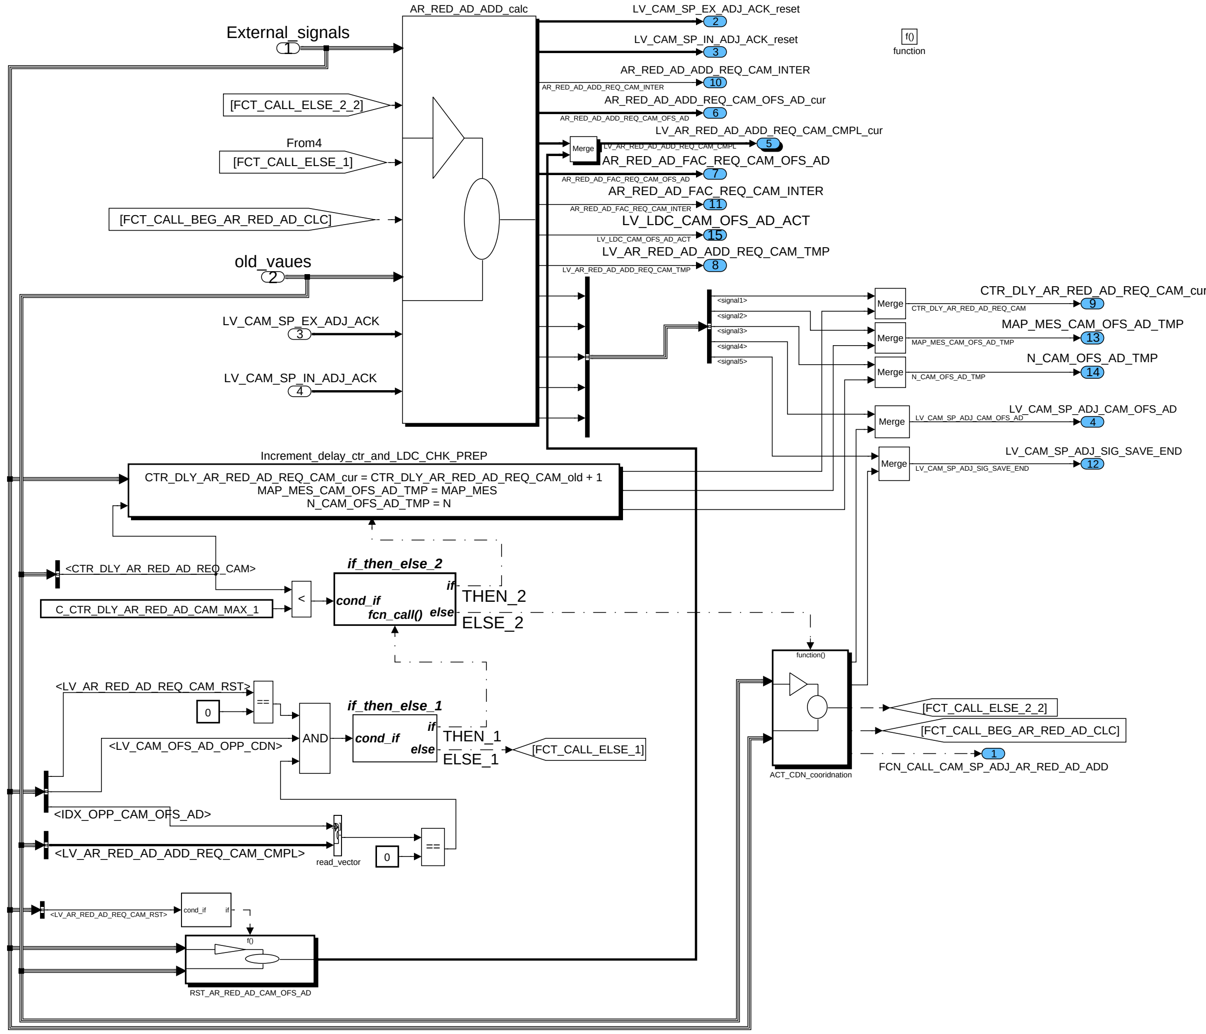

Figure 131 INSY_M908F/ AR_RED_AD_REQ_coordination

Coordination of activation conditions for AR_RED_AD_ADD calculation

When the conditions for the AR_RED_AD_ADD learning are fulfilled, it is checked if FLOW_CPS = 0 before starting the camshaft adjustment in order to avoid learning any errors of the canister-purge-flow model into the AR_RED_AD_ADD value learnt for camshaft-offset adaptation. If however the AR_RED_AD_ADD learning is already running and canister purge flow were to be come active, LV_LDC_CAM_OFS_AD_ACT is set to zero in the subsystem AR_RED_AD_ADD_calc and consequently the entire camshaft-offset adaptation run aborted.

9.47.1.3 Detection of limited dynamics condition

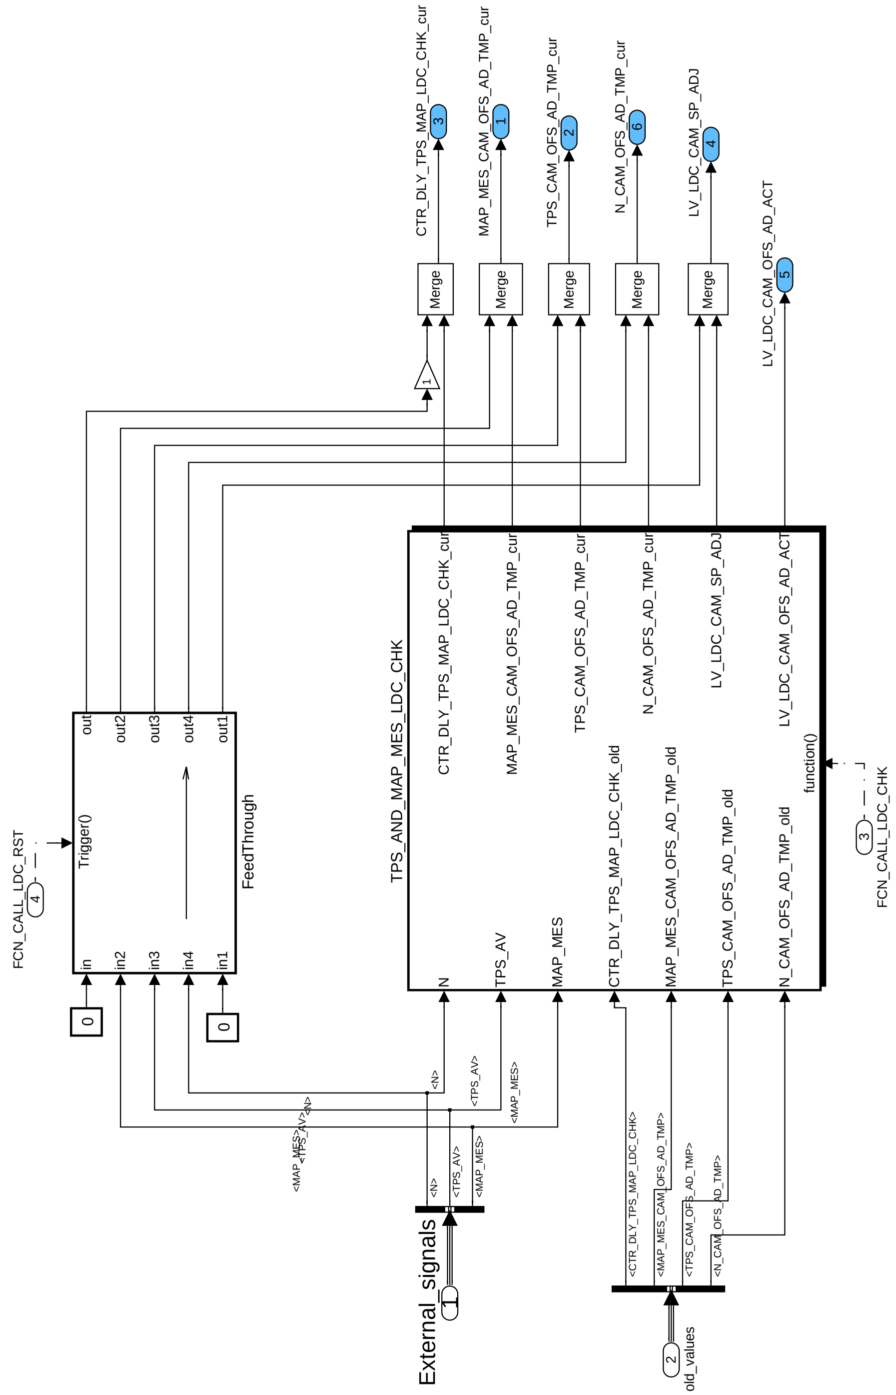

Figure 139 INSY_M908F/ LDC_CHECK

Limited Dynamics check for MAP_MES and other relevant variables

In order to determine if TPS_AV is stationary or not, the difference between TPS_AV and its low-pass filtered value is compare to a threshold. If this difference is greater than the threshold, C_TPS_DELTA_MAX_CAM_AD, then LV_LDC_CAM_ OFS_AD_ACT is set to zero. If however the TPS_AV signal is within the LDC threshold, then the limited dynamics condition check is declared as fulfilled. Consequently the adjustment of the camshaft for adaptation purposes can be started.

The LDC check for MAP_MES is started when the camshaft has reached the desired inlet/exhaust position needed for adaptation. First a delay time is started to take into consideration a change in intake manifold pressure that results from shift in camshaft position. At the end of the delay, it is assumed that MAP_MES has reached a relatively stable value and therefore the pressure value is saved in a temporary variable, MAP_MES_CAM_OFS_AD_TMP. During the signal acquisition phase, the measured manifold pressure is constantly compared with MAP_MES_CAM_OFS_AD_TMP. If there is a significant increase or decrease in the pressure during the signal acquisition phase, the signal acquisition is aborted and the adaptation stopped to avoid learning a wrong position error due to inaccuracies resulting from the averaged MAP_MES value which is used for the MAF_CYL_CAM_OFS_AD calculation.

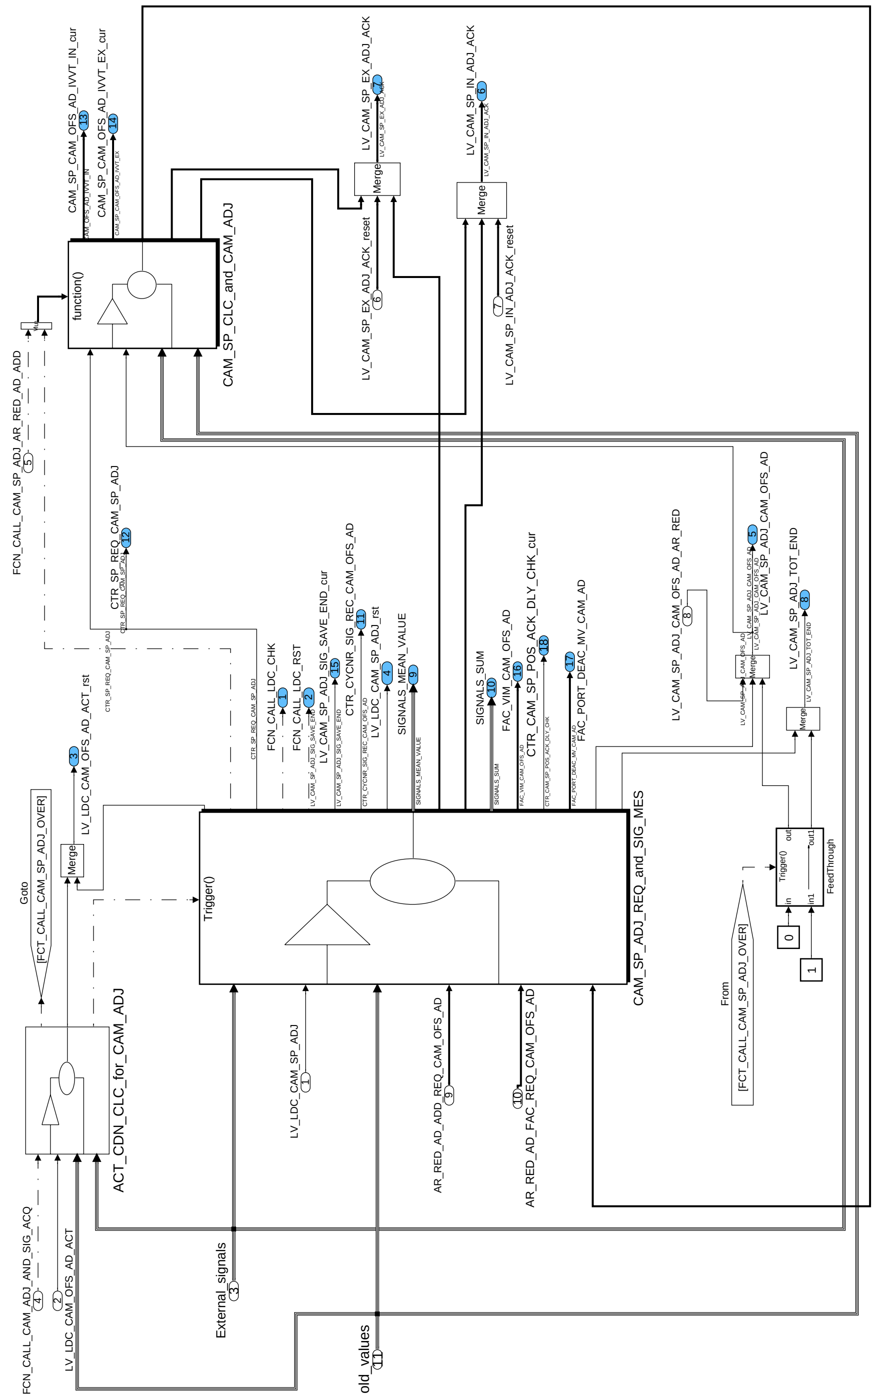

Figure 141 INSY_M908F/ CAM_OFS_AD_ACTIVE

Coordination of activation conditions for camshaft adjustment and signal acquisition

When the conditions for the camshaft adjustment are fulfilled (LV_CAM_OFS_AD_OPP _CDN =1), it is checked if FLOW_CPS = 0 before the inlet and exhaust adjustment is allowed in order to avoid learning any errors in the canister-purge-flow model into the camshaft-position-error. If the canister purge flow were to be come active during the signal acquisition phase, LV_LDC_CAM_OFS_AD_ACT is set to zero in the subsystem

CAM_SP_ADJ_REQ_and_SIG_MES and consequently the entire camshaft-offset adaptation run is aborted.

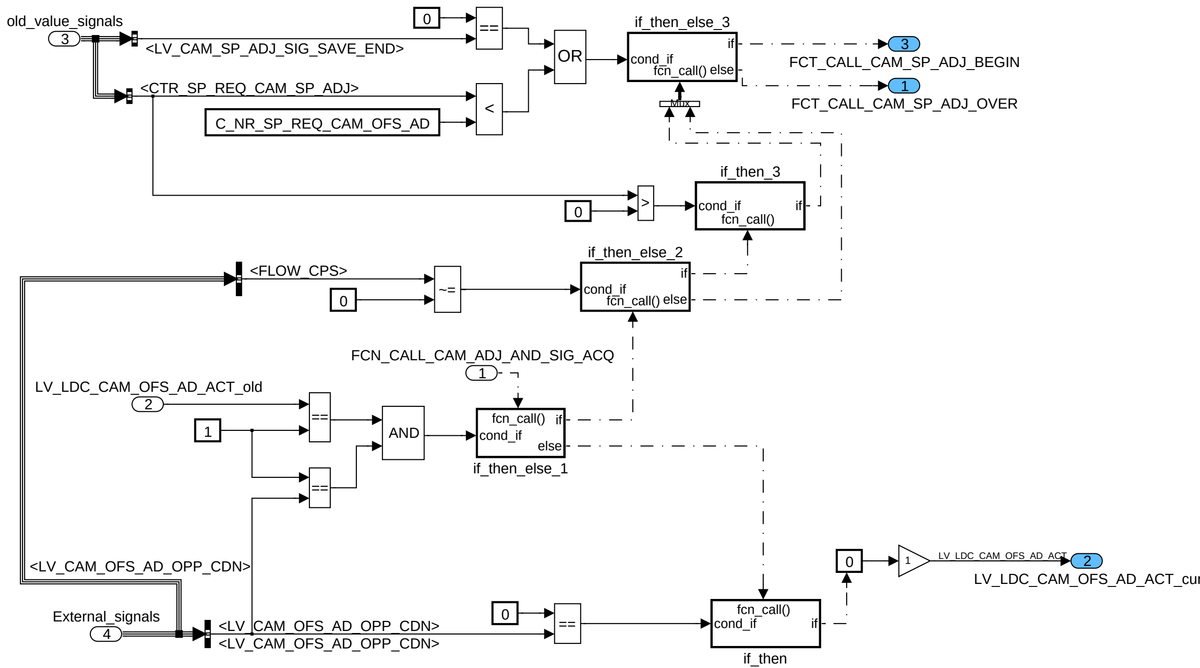

Figure 142 INSY_M908F/ CAM_OFS_AD_ACTIVE/ ACT_CDN_CLC_for_CAM_ADJ

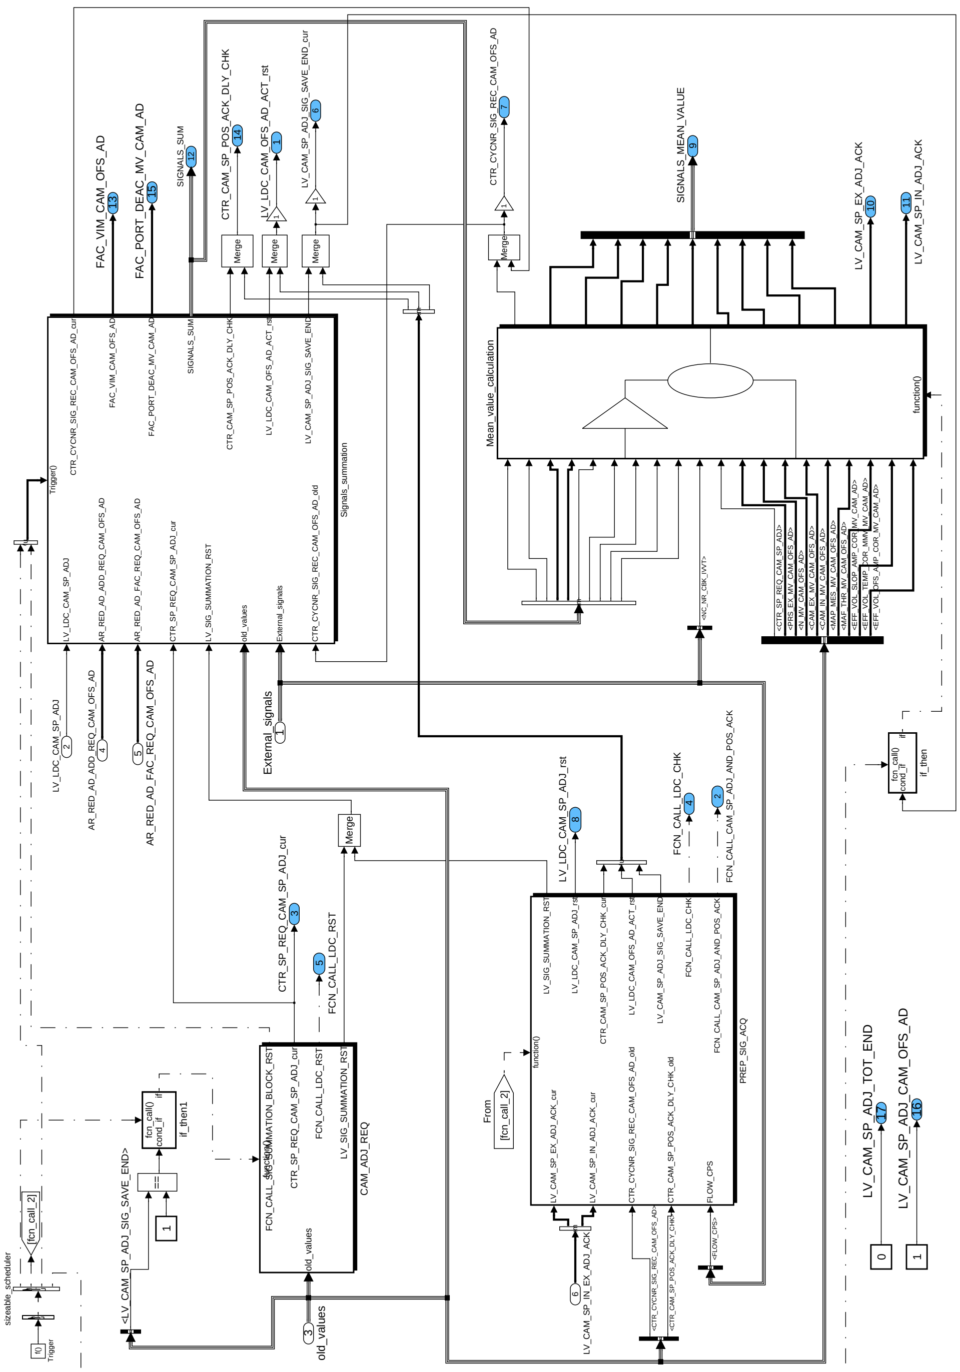

Figure 143 INSY_M908F/ CAM_OFS_AD_ACTIVE/ CAM_SP_ADJ_REQ_and_SIG_MES

INSY_M908F/CAM_OFS_AD_ACTIVE/CAM_SP_ADJ_REQ_AND_SIG_MES/PREP_SIG_ACQ

The logical bits LV_CAM_SP_IN/EX_ACK_ADJ are checked to see if the inlet and exhaust camshafts on both the cylinder banks have reached the desired position(CAM_SP_CAM_OFS_AD_IVVT_IN/EX). If the desired camshaft position has been set, the limited dynamics check for MAP_MES is started. During the signal acquisition phase, if the camshaft moves away from the desired setpoint(for e.g. due to oscillation), the bit LV_LDC_CAM_SP_ADJ is set to zero and the adaptation-run is aborted by the camshaft-offset adaptation manager functionality.

Calculation of desired camshaft setpoint and coordination of camshaft adjustment

Based on which N/MAP operating point the engine currently is running on, the inlet and exhaust camshaft positions are chosen from the maps ID_CAM_SP_IVVT_IN/EX_CAM_OFS_AD and then actively adjusted by the VVTI functionality. Once the desired position of the inlet and exhaust camshaft on each cylinder bank has actually been, a logical bit is set(LV_CAM_SP_IN/EX_ADJ_ACK_i) to indicate this status so that the signal acquisition process can be started.

9.48.1 Function Description

In the first part(subsystem Optimisation_1), the data required for calculating MAF_CYL, MAF_THR and the derivates of the squared error(MAF_DIF_CAM_OFS_AD_SQ_TOT) at each camshaft position are prepared. If an iteration is over (LV_CAM_OFS_AD_OPTM_CYC_END =1) , the counter CTR_CYC_OPTM_CAM_OFS_AD is incremented and the optimisation results (CAM_OFS_IVVT_IN(_EX)_OPTM_OUT) are used in the calculation of the CAM variables for the next iteration cycle.

Between the first and second optimisation parts, the modules 'Volumetric efficiency' and 'Camshaft-offset adaptation manager (Appl. Inc.)' are called where the data prepared in the first optimisation part is used to calculate EFF_VOL_OFS/SLOP_BAS_REQ_CAM_OFS_AD. This result is then used in part 2 of this module. In the subsystem Optimisation_2, the algorithm to calculate the air mass related variables and camshaft position error involves several steps:

- Calculation of volumetric efficiencies using basic EFF_VOL data and measured data.
- Calculation of MAF_CYL_CAM_OFS_AD, MAF_THR_CAM_OFS_AD and air-mass flow difference.
- Calculation of squared error derivative over CAM_IN and CAM_EX.

In each iteration, the three steps mentioned above are done for each one of the camshaft positions adjusted during the adaptation. At the end of an iteration, the camshaft position error is learnt.

The optimisation calculates a delta to the inlet and exhaust camshaft position respectively. The third optimisation parameter involves learning all non-camshaft related errors which is done in the specification 'Activation conditions and Data Acquisition for Camshaft-offset adaptation'

Calculation of inlet&exhaust camshaft position error at the end of each optimisation iteration

At the end of each optimisation routine, the camshaft-position error is calculated based on the least-sqaured error calculated in the subsystems in the block OPTIMISATION_2. It is based on the following mathematical relationship:

$$Param_i = Param_{i-1} - (2 * optimisation\_step\_size * \sum(e * \frac{de}{dparam}))$$

where i is the iteration number, e=MAF_DIF_CAM_OFS_AD_SQ, optimsation_stepsize = CTR_STEP_DIST_OPTM_IN/EX and the term

$$\sum(e * \frac{de}{dparam}) = MAF\_DIF\_SQ\_DRV1\_TOT\_IN/EX$$

STATE_CAM_SP_IVVT_EX	O/V	0H 1H 2H 3H 4H	SP_NOT SP_HOM_AFS SP_HOM_AFL SP_S SP_MAN	1	-
Exhaust camshaft position setpoint state					

Input data:

STATE_CMB_CTL	LV_ACT_TOT_IVVT_IN	LV_ACT_TOT_IVVT_EX	

FUNCTION DESCRIPTION:

General information:

The setpoint premanger chooses which type of the setpoint is to take for the current engine state, especially combustion mode or special circumstances. Depending on this choise a setpoint is calculated in a corresponding module if necessary. The calculated or a special setpoint is processed in the setpoint postmanager. Then, it is used in the camshaft position controlling.

Description:

Three combustion modes are considered in an engine. They are: homogeneous stoichiometric "HOM_AFS", homogeneous lean "HOM_AFL" and stratified "S". Each mode has its individual camshaft position setpoints "SP_CMB_HOM_AFS", "SP_CMB_HOM_AFL" and "SP_CMB_S". Each transition among the three combustion modes must adopt one of the three available setpoint sets.

The state STATE_CAM_SP_IVVT_IN(_EX) expresses which type of the setpoint is to take for the current engine state. The setpoint state is "SP_NOT" if the setpoint calculation is not activated. The states "SP_HOM_AFS", "SP_HOM_AFL" and "SP_S" correspond to the three combustion modes.

No calculation of the setpoint for one of the combustion modes is needed if the setpoint is determined by other procedure with a higher priority, i.e. setpoint given by the application manually, "SP_MAN".

Application conditions:

Initialization:

At reset, at deactivation, at transition "Engine run" → "Engine stop":

STATE_CAM_SP_IVVT_IN(_EX) = "SP_NOT"

Recurrence:

360 °CRK linked task, see "IVVT Scheduler"

Activation:

LV_ACT_TOT_IVVT_IN(_EX) = 1

Deactivation:

Not activation

Formula section:

if LC_CAM_SP_MAN_IVVT_IN(_EX) = 1

then *Manual setpoint*

STATE_CAM_SP_IVVT_IN(_EX) = "SP_MAN"

elseif ID_CMB_IVVT = "SP_CMB_HOM_AFS"

then *Setpoint for homogeneous stoichiometric*

FUNCTION DESCRIPTION:

General information:

The matching setpoint is assigned into a common variable for the preparation of the setpoint for controlling. The basic setpoint value is worked up, if necessary, due to IVVT controlling reasons.

Description:

One of the possible setpoints (as described in "IVVT Setpoint Premanager") is chosen in dependence on the STATE_CAM_SP_IVVT_IN(_EX).

The application has the possibility to add the offset CAM_SP_CLC_IVVT_IN(_EX) to the setpoint. This offset is linked with the active adjustment direction, i.e. a positive value moves the setpoint more away from the reference position.

The calculated camshaft position setpoint after the transition from the inactive into the active IVVT state need not to be the reference position. The IVVT system would start the adjustment with its maximal velocity. This could lead to the engine speed disturbances. In order to avoid this the setpoint changes with C_CAM_SP_LGRD_STEP_IVVT steps only. This setpoint with limited gradient is used only during the time C_T_CAM_SP_LGRD_IVVT after the transition into the active state. After that, step changes of the setpoint are not limited any more.

The current calculated setpoint CAM_SP_CLC_IVVT_IN(_EX) is handed over for the camshaft position control only if it differs from the previous setpoint CAM_SP_IVVT_IN(_EX). The difference must be bigger than C_CAM_SP_DIF_MIN_IVVT.

Unsuitable calibration data may cause that the camshaft position setpoint is out of the physically possible range from C_CAM_INI_IN(_EX) to CAM_ADJ_MAX_IVVT_IN(_EX). Therefore, the setpoint is limited to this interval.

If the calculated setpoint is close to the reference position, the reference position is taken for the setpoint.

The information about the point in time of the camshaft position setpoint calculation is needed in other IVVT functionalities. Tasks with a faster recurrency need to know whether the setpoint is old or new from the point of view of the faster task.

Application conditions:

Initialization:

At reset, at deactivation, at transition "Engine run" → "Engine stop":

CAM_SP_PREL_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

At reset, at activation:

CAM_SP_LGRD_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

At activation:

T_CAM_SP_LGRD_IVVT_IN(_EX) = T_DLY_MES_IVVT

Recurrence:

360 °CRK linked task, see "IVVT Scheduler"

Activation:

STATE_CAM_SP_IVVT_IN(_EX) <> "SP_NOT"

Deactivation:

Not activation

Formula section:

Choosing setpoint:

if STATE_CAM_SP_IVVT_IN(_EX) = "SP_MAN"

then *Manual setpoint*

CAM_SP_CLC_IVVT_IN(_EX) = C_CAM_SP_MAN_IVVT_IN(_EX)

elseif STATE_CAM_SP_IVVT_IN(_EX) = "SP_HOM_AFS"

then *Setpoint for homogeneous stoichiometric*

CAM_ADJ_MAX_IVVT_EX			

General information:

If the engine speed is low and the oil temperature high there can be insufficient oil supply. If both inlet and exhaust camshaft should move simultaneously there can be slow adjustments of both camshafts. Therefore, the exhaust adjustment is stopped in such case, i.e. the inlet is prioritized to the exhaust.

Description:

If the deviation between the exhaust camshaft position (CAM_MV_EX due to 2-bank systems) and setpoint is bigger than ID_CAM_DIF_MIN_PRI_IVVT an exhaust adjustment is to realize. The inlet side is to check. If no inlet adjustment or only a small one is to realize, i.e. the deviation between the position and setpoint is smaller than ID_CAM_DIF_MIN_PRI_IVVT or the inlet side moves only slowly or does not move, the exhaust is phased in the regular way, otherwise it is held until the above inlet condition is not satisfied.

NC_NR_CBK_IVVT			

FUNCTION DESCRIPTION:

Description:

The measured MAF into the engine is not suitable as load parameter for the determination of the setpoint. The camshaft position has influence on the MAF, also, there can be feedback effects. Therefore, a feedback-free air mass flow is needed instead of the measured one. This is fulfilled by MAF_IVVT, i.e. the current air mass flow setpoint for torque interventions.

The camshaft position setpoints for the homogeneous stoichiometric combustion mode are calculated from maps based on the N and MAF_IVVT. There are maps for two coolant temperature levels. The coolant temperature effects are considered by weighting factors.

In order to speed up the catalyst heating, special camshaft positons can be used. This module provides the setpoint manipulation solely by additive contibutions.

During PU and PUC, both intake and exhaust setpoints are forced to full retard position to ensure minimum values overlap.

Application conditions:

Initialization: At reset: CAM_SP_HOM_AFS_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

CAM_SP_HOM_AFS_ADD_IVVT_IN(_EX) = 0 °CRK

CAM_SP_ADD_TMP_IVVT_IN(_EX) = 0°CRK

Recurrence: 360 °CRK linked task, see "IVVT Scheduler"

Activation: STATE_CAM_SP_IVVT_IN(_EX) = "SP_HOM_AFS"

Deactivation: Not activation

Formula section:

MAF_IVVT calculation

MAF_DIF_IVVT = max (0; MAF_SP_TQI - MAF)

FAC_MAF_DYN_IVVT = IP_FAC_MAF_DYN_IVVT

MAF_SP_TQI_DYN =

FAC_MAF_DYN_IVVT * MAF_SP_TQI + (1 - FAC_MAF_DYN_IVVT) * MAF

FAC_CAM_SP_PL_AMP_IVVT_IN/EX = IP_FAC_CAM_SP_PL_AMP_IVVT_IN/EX

The calculation above is done to avoid bigger MAF_IVVT deviations during turbo lag. While there is a big difference between MAF and MAF_SP due to the turbo lag, MAF_IVVT can be set to MAF and back to MAF_SP after the turbo lag is over.

If LC_MAF_SP_SENS = 1

then MAF_IVVT = MAF (from sensor)

```
else    if      LC_MAF_SP_MAN = 1
        then    MAF_IVVT = C_MAF_SP_MAN
        else    if      LC_TCHA_CONF = 1
                then    MAF_IVVT = Min ( MAF_MAX_COR, MAF_SP_TQI_DYN )
                else    MAF_IVVT = Min ( MAF_MAX_COR, MAF_SP_TQI )
                endif
        endif
endif
```

Coolant temperature weighting factor for inlet camshaft position setpoint, part load					
FAC_CAM_SP_PL_IVVT_EX	V	80...7FH	-4...3.97	0.031	-
Coolant temperature weighting factor for exhaust camshaft position setpoint, part load					

Input data:

TCO	TCO_ST		

FUNCTION DESCRIPTION:

Description:

The coolant temperature influence on the camshaft position setpoints is taken into account by the weighting factors FAC_CAM_SP_IS_IVVT_IN/EX and FAC_CAM_SP_PL_IVVT_ IN/EX. The characteristics for the part load are used for the full load.

Application conditions:

Initialization:

Recurrence: 1 s

Activation: *At every engine state*

Formula section:

FAC_CAM_SP_IS_IVVT_IN/EX = IP_FAC_CAM_SP_IS_IVVT_IN/EX

Exhaust camshaft position setpoint for homogeneos lean combustion mode					

Input data:

STATE_CAM_SP_IVVT_IN	STATE_CAM_SP_IVVT_EX	C_CAM_INI_IN	C_CAM_INI_EX

FUNCTION DESCRIPTION:

Description:

At the moment the camshaft position setpoint for homogeneos lean combustion mode is always the reference position.

Application conditions:

Initialization:

At reset:

CAM_SP_HOM_AFL_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

Recurrence:

360 °CRK linked task, see "IVVT Scheduler"

Activation:

STATE_CAM_SP_IVVT_IN(_EX) = "SP_HOM_AFL"

Formula section:

CAM_SP_HOM_AFL_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

9.55 IVVT Setpoint for Stratified

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
CAM_SP_S_IVVT_IN	O/V	0...FFH	60...155.625	0.375	°CRK
Inlet camshaft position setpoint for stratified combustion mode

Exhaust camshaft position setpoint for stratified combustion mode					

Input data:

C_CAM_INI_IN	C_CAM_INI_EX		
STATE_CAM_SP_IVVT_IN	STATE_CAM_SP_IVVT_EX		

FUNCTION DESCRIPTION:

General information:

This is the stub module for the camshaft position setpoint for stratified combustion mode.

Description:

The default camshaft position setpoint is the reference position C_CAM_INI_IN(_EX).

Application conditions:

Initialization:

At reset:

CAM_SP_S_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

Recurrence:

360 °CRK linked task, see "IVVT Scheduler"

Activation:

STATE_CAM_SP_IVVT_IN(_EX) = "SP_S"

Formula section:

CAM_SP_S_IVVT_IN(_EX) = C_CAM_INI_IN(_EX)

LV_TRIP_ACT_IVVT_IN	LV_TRIP_ACT_IVVT_EX		

FUNCTION DESCRIPTION:

General information:

The individual camshaft setpoint is selected dependent on the IVVT system configuration and on the status of the short trip.

Description:

The setpoint CAM_SP_IND_DIAG_IVVT_IN(_EX)_i is a result of the setpoint strategy and IVVT control algorithm. It is used in the diagnosis and for the camshaft position control. It is possible to emulate a faulty actuator. Then a different setpoint is used for the camshaft position control.

Application conditions:

Initialization:

At reset, at transition "Engine run" → "Engine stop", at deactivation:

CAM_SP_IND_DIAG_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

Recurrence:

 # NC_NR_CBK_IVVT = 1:

360 °CRK linked task, see "IVVT Scheduler"

 # NC_NR_CBK_IVVT = 2:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

LV_ACT_IND_IVVT_IN(_EX)_i = 1

Deactivation:

Not activation

Formula section:

LV_CAM_SP_DFCT_IVVT_IN_i	LV_CAM_SP_DFCT_IVVT_EX_i		

FUNCTION DESCRIPTION:

General information:

The individual setpoint value is worked up, if necessary, due to IVVT tuning or controlling reasons.

Description:

It is possible to emulate a faulty actuator. If LV_CAM_SP_DFCT_IVVT_IN(_EX)_i = 1 then CAM_SP_IND_DFCT_IVVT_IN(_EX)_i is the setpoint used in the camshaft position control algorithm (CAM_SP_IND_IVVT_IN(_EX)_i). It can be for example a blocked actuator. The diagnosis works with the setpoint from the setpoint strategy and IVVT control algorithm CAM_SP_IND_DIAG_IVVT_IN(_EX)_i. If LV_CAM_SP_DFCT_IVVT_IN(_EX)_i = 0 then CAM_SP_IND_IVVT_IN(_EX)_i equals CAM_SP_IND_DIAG_IVVT_IN(_EX)_i and the IVVT system works in the normal mode.

The bank balancing algorithm or improper short trip calibration may cause that the setpoint is out of the physically possible range from C_CAM_INI_IN(_EX) to CAM_ADJ_MAX_IVVT_IN(_EX). Therefore, the setpoint is limited to this interval. If the setpoint is close to the reference position, the reference position is taken for the setpoint.

The information about the camshaft position setpoint dynamics is needed in other IVVT functionalities. If there are only small changes it is called limited dynamics.

Application conditions:

Initialization:

At reset, at transition "Engine run" → "Engine stop", at deactivation:

CAM_SP_IND_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

At transition "Engine run" → "Engine stop", at deactivation:

LV_CAM_SP_DYW_IVVT_IN(_EX)_i = 0

At reset, at deactivation:

CAM_SP_DYW_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

Recurrence:

 # NC_NR_CBK_IVVT = 1:

360 °CRK linked task, see "IVVT Scheduler"

 # NC_NR_CBK_IVVT = 2:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

LV_ACT_IND_IVVT_IN(_EX)_i = 1

Deactivation:

Not activation

Formula section:

FUNCTION DESCRIPTION:

General information:

The position control of each camshaft is realized with the individual setpoint. This enables different setpoints for bank 1 and bank 2, which is used for the bank position balancing.

9.58.1 IVVT Camshaft Position for Balancing

Description:

This subfunction is active only for NC_NR_CBK_IVVT = 2. It is realized in the scheduler.

The evaluation of the differences between the camshafts in individual banks must not be disturbed by the jitter of the position signal or stochastic camshaft movements. Therefore the camshaft position is filtered. The filtering method is the moving mean value creation.

Application conditions:

Initialization:

 # NC_NR_CBK_IVVT = 2:

At reset, at transition "Engine run" → "Engine stop":

CAM_MMV_BAL_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

In every engine state

Formula section:

 # NC_NR_CBK_IVVT = 2:

CAM_MMV_BAL_IVVT_IN(_EX)_i(n) =

CAM_MMV_BAL_IVVT_IN(_EX)_i(n-1) + C_CRLC_CAM_BAL_IVVT *

(CAM_AV_IVVT_IN(_EX)_i - CAM_MMV_BAL_IVVT_IN(_EX)_i(n-1))

9.58.2 IVVT Bank Balancing

Deactivation:

Not activation

Formula section:

Calculate preliminary adjustment velocity:

VEL_CAM_BAL_IVVT_IN(_EX)_i[0] {°CRK/s} =
(CAM_MMV_BAL_IVVT_IN(_EX)_i(n) {°CRK} –
CAM_MMV_BAL_IVVT_IN(_EX)_i(n-1) {°CRK}) /
(60 {sec/min} / N {1/min})

Filter adjustment velocity (2-step filtering):

```
for     m = 0 to 1
        VEL_DIR_CAM_BAL_IVVT_IN(_EX)_i[m][0] =
        sign(   VEL_CAM_BAL_IVVT_IN(_EX)_i[m](n) -
                VEL_CAM_BAL_IVVT_IN(_EX)_i[m](n-1)    )
        if              VEL_DIR_CAM_BAL_IVVT_IN(_EX)_i[m][0] =
                        VEL_DIR_CAM_BAL_IVVT_IN(_EX)_i[m][1]
                and     VEL_DIR_CAM_BAL_IVVT_IN(_EX)_i[m][0] =
                        VEL_DIR_CAM_BAL_IVVT_IN(_EX)_i[m][2]
        then
                VEL_CAM_BAL_IVVT_IN(_EX)_i[m+1] =
                VEL_CAM_BAL_IVVT_IN(_EX)_i[m]
        else
                VEL_CAM_BAL_IVVT_IN(_EX)_i[m+1] =
                VEL_CAM_BAL_IVVT_IN(_EX)_i[m+1](n-1) + 0.5 *

Import actions:

ACTION_INFR_StartPulseIvvt(IN < Ivvt >, IN < Ivvtpwm >, IN < Frq_Ivvtpwm >, IN < T_Ivvtpwm >)
This action starts a time limited pulse width modulation energisation for the camshaft Ivvt.
ACTION_INFR_StopPulseIvvt(IN < Ivvt >)
This action stops the time limited pulse width modulation energisation for the camshaft Ivvt.

FUNCTION DESCRIPTION:

General information:

The IVVT controller is the main tool to adjust the target camshaft position. Small deviations or a drift of the camshaft position from the setpoint are managed by the holding pulse width modulation adaptations.

Description:

There are several kinds of the solenoid valve energization. The low level energization is an energization with PWM close to 0 %. The camshaft moves and remains in the reference position (passive stop position). If the solenoid valve is energized with the high level PWM, i.e., close to 100 %, the camshaft moves and remains in the active stop position. If a camshaft position somewhere in the adjustment range is to hold the holding pulse width modulation energization is used. It is about 40 to 60 % PWM.

Generally, the holding energization is applied. It is interrupted by time limited low or high level energizations (adjustment energizations) if there is a change of the camshaft position setpoint or the actual position does not correspond with the setpoint. If the energization time is very short (less than ~3-7 ms, tuneable) the low level is substituted by 0 % and the high level by 100 %. It does not disturb the output signal diagnosis, see "IVVT Output Signal Diagnosis". The reason for using 0 % level for short energization times is obvious from the figure "Short energization time". There is a similar situation for 100 % when "OFF" start is used.

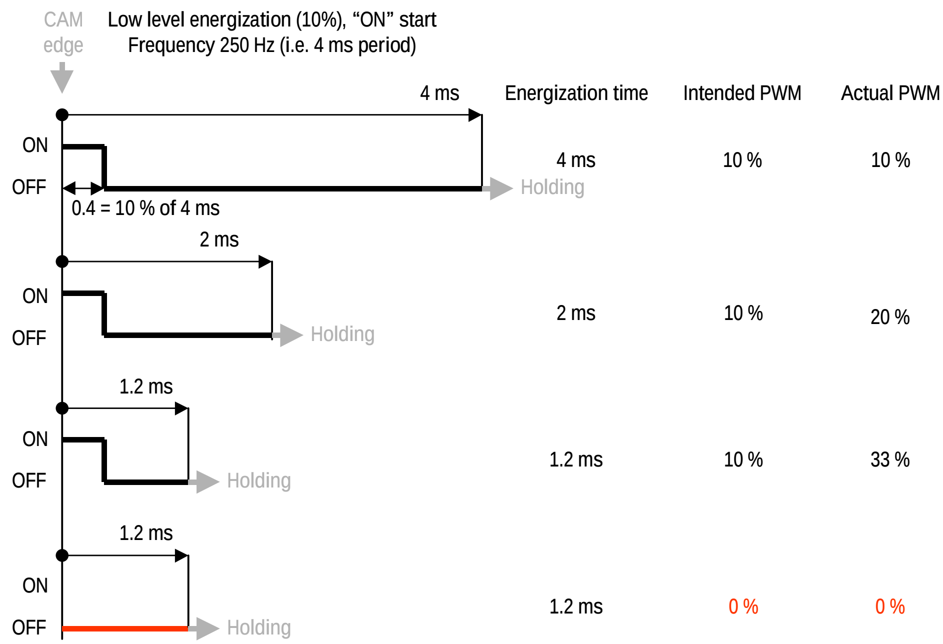

Figure: Short energization time.

The main goals of the IVVT controlling are to exploit the maximum design adjustment speed of the actuator without control overshoots, to keep the deviation of the camshaft position from the setpoint small, to keep the actuator in the holding energization without control interventions as long as possible.

There are three characteristics of the system influencing the design of the IVVT controller. They are the actuator delay, the assumption of linear position independent adjustment speed and the solenoid valve delay.

Due to the actuator delay it would not be suitable to use a control comparing the actual camshaft position and the setpoint. The delay would cause that there would be a big system deviation for a long time. In order to avoid overshoots a slow control would be necessary. The control behaviour would have long undershoots.

Therefore, Pre-control is used in the IVVT controller together with P-control. A special camshaft position is calculated. It is a modelling with an fictitious actuator without the delay, i.e., non-delayed camshaft position. The difference between the camshaft position setpoint and the non-delayed position is used for the Pre-control. The non-delayed position follows immediately a change of the setpoint with the actuator adjustment speed. If the non-delayed position reaches the new setpoint after the end of its change the Pre-control becomes inactive. Also, the Pre-control responds quickly on the setpoint changes and is not too long due to the actuator delay. The Pre-control output is an adjustment energization time.

The Pre-control roughly reaches the setpoint. It is a modelling, also, it must be applied with certain safety in order not to have overshoots. Therefore, the residual system deviation is controlled with P-control. The non-delayed camshaft position is delayed by means of a buffer. This leads to a modelled camshaft position. The difference between the actual camshaft position and the modelled one is used for the P-control. The P-control output is an adjustment energization time, too.

The adjustment energization times from the Pre-control and P-control are summed. The resultant energization time plus the solenoid valve delay is then the controller output. The desired adjustment direction determines whether low or high level energization is taken.

If there are only small system deviations very short energization times are calculated. If they are smaller than a threshold they are integrated. If the threshold is reached the integrated energization time is carried out and the integral is set to 0. The integral is set to 0, too, if an energization into the opposite direction is needed.

The controller is called at each used camshaft edge, see "IVVT Scheduler". The current camshaft position is determined at the camshaft edge. The energization time calculated by the controller can be longer as the time between two used camshaft edges. This effect is considered in the controller. For example, the solenoid valve is opened and its delay need not be added any more.

Hint to the moment of usage and moment of calculation of some variables: Some quantities specified in "Output data" are used in the controller before they are assigned to. It means that the values from the previous controller step are used. Therefore, the initializations are very important, too.

The signal flow within the controller is shown in Figure "Controller signal flow" schematically. The names of quantities are abbreviated, i.e. _IVVT_IN(_EX)_i is avoided for the sake of simplicity and clarity.

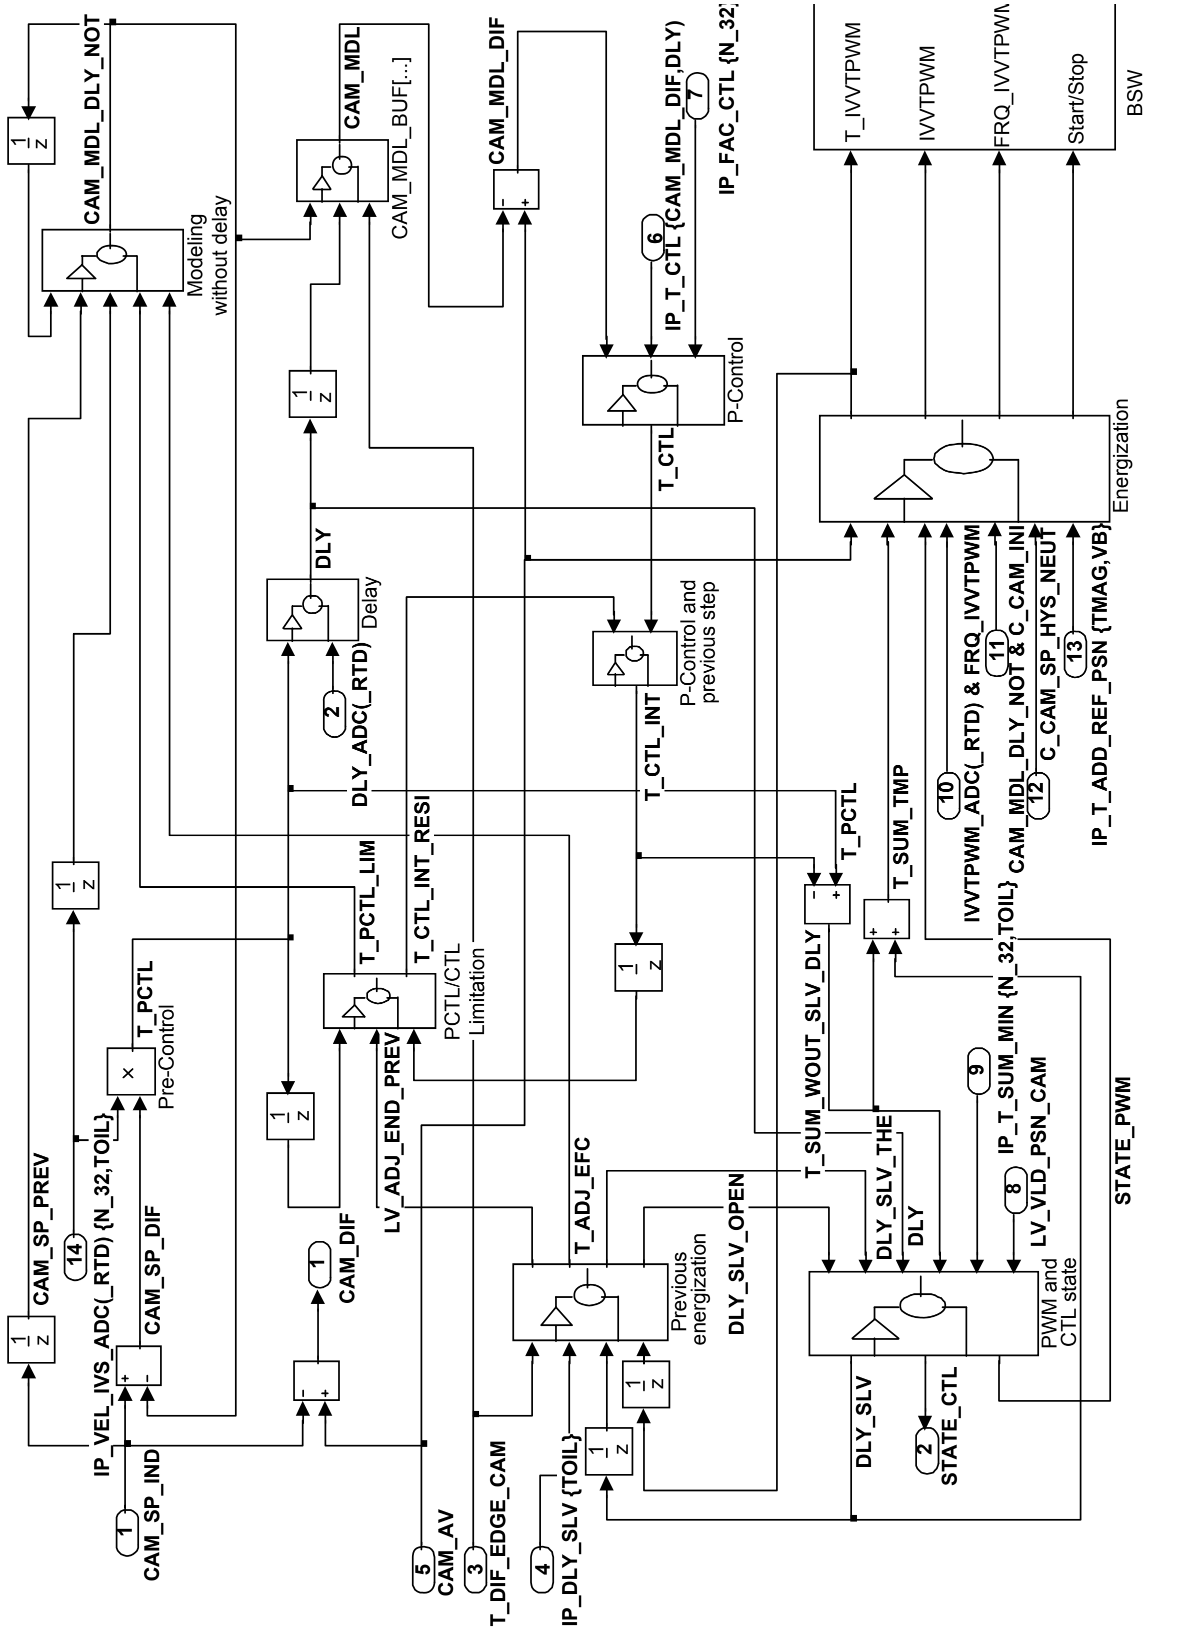

Figure: Controller signal flow.

Application conditions:

Recurrence: At each used camshaft edge, see "IVVT Scheduler"

Activation: LV_ACT_IND_IVVT_IN(_EX)_i = 1
and N_32 <= C_N_32_DI_CTL_IVVT

Calculated adjustment delay; retard; exhaust					

Input data:

LV_ACT_TOT_IVVT_IN	LV_ACT_TOT_IVVT_EX	N_32	TOIL

FUNCTION DESCRIPTION:

General information:

It takes some time till the camshaft phase changes noticeable after the start of the energization. This time is named the adjustment delay. The delay is used in the control algorithm.

Description:

The delay depends especially upon the camshaft (inlet/exhaust), adjustment direction (advanced/retard), engine speed and oil temperature. The delays are in the maps IP_DLY_ADC(_RTD)_IVVT_IN(_EX) depending on the engine speed and oil temperature.

Application conditions:

Initialization:

Recurrence:

360 °CRK linked task, see "IVVT Scheduler"

Activation:

LV_ACT_TOT_IVVT_IN(_EX) = 1

Formula section:

DLY_ADC(_RTD)_IVVT_IN(_EX) = IP_DLY_ADC(_RTD)_IVVT_IN(_EX)

Calibration data:

CAM_ADJ_MAX_IVVT_IN	CAM_ADJ_MAX_IVVT_EX		
LV_ACT_IND_IVVT_IN_i	LV_ACT_IND_IVVT_EX_i		

FUNCTION DESCRIPTION:

General information:

In order to check the calibration data for the calculation of the IVVT delay there is a possibility to measure the current delay (see LC_ENA_DLY_MES_IVVT in "IVVT Scheduler").

Description:

The camshaft must not be close to one of the stop positions. The system must be in the holding position long enough before the measurement can start. Long enough means that STATE_CTL_IVVT_IN(_EX)_i reaches "HLD_ADAP". If the camshaft adjustement is bigger than C_CAM_DIF_MIN_DLY_IVVT after the energization start the delay has passed.

In dependence on the actual reccurence there can be some inaccuracies in the measurement of the delay especially at low engine speed.

Application conditions:

Initialization:

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

At every engine state

Formula section:

if LV_ACT_IND_IVVT_IN(_EX)_i = 0

or

Inlet:

(CAM_AV_IVVT_IN_i >= C_CAM_INI_IN - C_CAM_HYS_DLY_IVVT

and LV_ADJ_RTD_IVVT_IN_i = 1)

or

(CAM_AV_IVVT_IN_i <=

CAM_ADJ_MAX_IVVT_IN + C_CAM_HYS_DLY_IVVT

1 = break point change in TMAG_IVVT list of data points for IP_IVVTHPWM, 0 = no change (exhaust)					

Input data:

TOIL	TCO	IP_IVVTHPWM	IP_IVVTHPWM_EX
TEG_DYN_UP_CAT	VS	CONF_CAM_VVT_EX	

FUNCTION DESCRIPTION:

General information:

The solenoid valve characteristics depends on the coil temperature. Especially, this temperature affects the holding pulse width modulation. The substitute coil temperature is calculated from maps based on the oil and coolant temperature.

In order to take into account the different mounting positions between the intake OCV and exhaust OCV, for the exhaust coil temperature an offset is added depending on modeled exhaust gas temperature and vehicle speed to describe the heat transfer from the exhaust line to the exhaust coil. For calibration purpose the Coil Temperature Offset of the Exhaust side can be adapted manually.

Description:

The modeled OCV coil temperature TMAG_IVVT(_EX) is used as input for the holding PWM IP_IVVTHPWM(_EX).

The information about a change of the TMAG_IVVT(_EX) breakpoint is indicated by LV_CHG_TMAG_IVVT_IN/EX, and used for the holding PWM adaptation algorithm.

Application conditions:

Initialization: *At reset:* *TMAG_IVVT = IP_TMAG_IVVT*

TMAG_IVVT_OFS_EX = 0

LV_CHG_TMAG_IVVT_IN/EX = 0

If CONF_CAM_VVT_EX = 1

then TMAG_IVVT_EX = IP_TMAG_IVVT

else TMAG_IVVT_EX = 0 H

endif

Recurrence: 1 s

Activation: At every engine state

Formula section:

Coil Temperature Calculation:

OCV Coil Temperature (Intake):

TMAG_IVVT = IP_TMAG_IVVT *(depending on TOIL and TCO)*

OCV Coil Temperature (Exhaust):

If CONF_CAM_VVT_EX = 1

then exhaust camshaft with adjustment

If LC_TMAG_IVVT_OFS_EX_MAN = 1

Import actions:

ACTION_INFR_SetHoldIvvt(IN < Ivvt >, IN < Ivvthpwm >, IN < Frq_Ivvthpwm >)
This action sets a holding pulse width modulation energisation for the camshaft Ivvt.

FUNCTION DESCRIPTION:

General information:

The holding pulse width modulation signal must be distinguished for the inactive and active IVVT state.

Description:

If the state is inactive small pulse width is needed in order to reach and hold the reference position. If the IVVT state is active the controller determines when the current camshaft position is to be held. The corresponding holding PWM IP_IVVTHPWM(_EX) is a characteristic of the solenoid valve. It depends on the coil temperature and battery voltage.

Due to several reasons, e.g., component tolerances, inaccuracy in the coil temperature determination, the holding pulse width modulation is adapted. The adaptation contribution IVVTHPWM_AD_IN(_EX)_i[…] is always added to the basic value IP_IVVTHPWM(_EX).

If the adaptation is in progress IVVTHPWM_DE_AD_IN/EX_i is non-zero, otherwise it is zero.

It is possible to offset the holding pulse width modulation for each camshaft by means of C_IVVTHPWM_OFS_IN(_EX)_i.

It is possible to apply substitute solenoid valve energization for each individual camshaft, e.g., manually or externally.

If the IVVT system is inactive the PWM signal for the passive stop position can be replaced by the oil control solenoid valve cleaning signal IVVTPWM_CLE_SLV_IN(_EX). Active cleaning is indicated by LV_ACT_CLE_SLV_IVVT = 1.

Application conditions:

Initialization: At reset:

IVVTHPWM_IN_i = IVVTPWM_RTD_IN

IVVTHPWM_EX_i = IVVTPWM_ADC_EX

xx = IN(_EX)_i

yy = IVVT_IN(_EX)_i

The frequencies of IVVT energization signals are calculated here.

Description:

The frequency of the pulse width modulations is a function of the battery voltage.

Application conditions:

Initialization: At reset:

FRQ_IVVTHPWM = IP_FRQ_IVVTHPWM

FRQ_IVVTPWM = IP_FRQ_IVVTPWM

Recurrence: 100 ms

Activation: In every engine state

Formula section:

FRQ_IVVTHPWM = IP_FRQ_IVVTHPWM

FRQ_IVVTPWM = IP_FRQ_IVVTPWM

Calibration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
IP_FRQ_IVVTHPWM	4	32H...1F4H	50...500	1	Hz
LDPM_VB_1_VVTI	4	0...FFH	0...26	0.1	V
Frequency of holding pulse width modulation; both inlet and exhaust					
IP_FRQ_IVVTPWM	4	32H...1F4H	50...500	1	Hz
LDPM_VB_1_VVTI	4	0...FFH	0..26	0.1	V
Frequency of pulse width modulation for adjustment energization; both inlet and exhaust					

9.65 IVVT PWM Adjustment Levels

Output data:

Input data:

VB	TMAG_IVVT	TMAG_IVVT_EX	CONF_CAM_VVT_EX

FUNCTION DESCRIPTION:

General information:

The levels of adjustment energizations are calculated here.

Description:

The functional level of the adjustment pulse width modulation is defined by C_IVVTPWM_ADC/RTD_IN/EX. There is the factor IP_FAC_VB_IVVTPWM for the battery voltage influence and IP_FAC_TMAG_IVVTPWM_IN(_EX) for solenoid temperature influence. The resulting correction factor is the product of the individual factors.

Application conditions:

Initialization: At reset:

FAC_COR_IVVTPWM_IN(_EX) = IP_FAC_VB_IVVTPWM *
IP_FAC_TMAG_IVVTPWM_IN(_EX)

IVVTPWM_ADC(_RTD)_IN = C_IVVTPWM_ADC(_RTD)_IN

If CONF_CAM_VVT_EX = 1

then IVVTPWM_ADC(_RTD)_EX = C_IVVTPWM_ADC(_RTD)_EX

else IVVTPWM_ADC(_RTD)_EX = 0 [%]

Recurrence: 100 ms

Activation: In every engine state

Formula section:

FAC_COR_IVVTPWM_IN(_EX) = IP_FAC_VB_IVVTPWM *
IP_FAC_TMAG_IVVTPWM_IN(_EX)

IVVTPWM_ADC(_RTD)_IN = C_IVVTPWM_ADC(_RTD)_IN *
FAC_COR_IVVTPWM_IN

If CONF_CAM_VVT_EX = 1

then IVVTPWM_ADC(_RTD)_EX = C_IVVTPWM_ADC(_RTD)_EX *
FAC_COR_IVVTPWM_EX

else IVVTPWM_ADC(_RTD)_EX = 0 [%]

FUNCTION DESCRIPTION:

General information:

As obvious from its name there should be no actuator movement if it is energized by the holding pulse width modulation. If it is not fulfilled, e.g. due to component tolerances, ageing effects, etc., deviations of the camshaft position from the setpoint can occur. The deviation adaptation determines a correction leading to proper holding pulse width modulation.

Description:

Let us assume the following situation: The setpoint remains almost the same after its change. It is indicated by LV_CAM_SP_DYW_IVVT_IN(_EX)_i = 1. The controller needs some time to get the camshaft position to the setpoint. If there is a deviation from the setpoint after this time, an improper value in the map IP_IVVTHPWM is assumed. Possible reasons are the solenoid valve tolerances, deviations of the actual temperature of the solenoid valve from the modeled one, ageing effects, etc.

The adaptation is requested formally if there is a change of the setpoint that lead to a control adjustment. After the change, if the conditions for the adaptations are fulfilled the adaptation is started.

The first phase of the adaptation is waiting for the controller fading away. It is counted in the adaptation cycles. One adaptation cycle is the period between two used camshaft edges. The controller fading away IP_CYC_MIN_DE_AD_IVVT must be over at first. Short before this event (IP_CYC_MIN_DE_AD_IVVT * C_FAC_RED_CYC_MIN_DE_AD_IVVT) a filtering of the camshaft deviation starts. The camshaft position deviation (absolute value) must not be bigger than C_CAM_HYS_DE_AD_IVVT. Otherweise, a failure is assumed in this case. The adaptation is terminated and a diagnosis (for enduring position deviation) is enabled. Vice versa, the adaptation is disabled while the adaptation is active.

The priciple of the adaptation is as follows. The holding pulse width modulation is being changed by means of IVVTHPWM_DE_AD_IN(_EX)_i. This quantity is increased or decreased so that the deviation is diminishing. If the deviation becomes smaller than C_CAM_HYS_DE_AD_END_IVVT or the position crosses the setpoint the adaptation is finished successfully. The resulting contribution IVVTHPWM_DE_AD_IN(_EX)_i to the holding pulse width modulation is limited to C_IVVTHPWM_HYS_DE_AD and assigned into IVVTHPWM_DE_AD_SAVE_IN(_EX)_i. This quantity is then saved into an adaptation table, see "IVVT Holding PWM Adaptation Manager".

If the engine operation remains steady after the adaptation the camshaft position deviation is integrated, CAM_DIF_INT_DE_AD_IVVT_IN(_EX)_i. If this quantity reaches the threshold C_CAM_DIF_INT_DE_AD_REST_IVVT the adaptation is restarted. This restarting must be enabled by LC_ENA_DE_AD_REST_IVVT. Another reason for the adaptation request is a change of the TMAG_IVVT breaking point in the map IP_IVVTHPWM.

If the maximum number of the adaptation cycles is reached the adaptation is terminated without any saving into the adaptation table.

No adaptation is activated if the oil temperature is too high and the engine speed too low. The oil pressure might not be sufficient for the adaptation. The adaptation results might not be reliable.

Application conditions:

Initialization:

At reset: LV_DE_AD_REQ_IVVT_IN(_EX)_i = 1
LV_DE_AD_END_IVVT_IN(_EX)_i = 1

At deactivation: LV_DE_AD_REQ_IVVT_IN(_EX)_i = 1
LV_DE_AD_END_IVVT_IN(_EX)_i = 1
IVVTHPWM_DE_AD_IN(_EX)_i = 0
CAM_DIF_INT_DE_AD_IVVT_IN(_EX)_i = 0

Recurrence: At each used camshaft edge, see "IVVT Scheduler"

Activation: LV_ACT_IND_IVVT_IN(_EX)_i = 1
and (TOIL <= C_TOIL_MAX_IVVTHPWM_AD
or N_32 >= C_N_32_MIN_IVVTHPWM_AD)

FUNCTION DESCRIPTION:

General information:

The drift adaptation is a fine tuning of the holding pulse width modulation.

Description:

The adaptation procedure is activated if STATE_CTL_IVVT_IN(_EX)_i changes from "HLD_DLY" to "HLD_ADAP". The current camshaft position is saved and a time measurement is started.

Formally, the next step is the drift calculation. The state STATE_CTL_IVVT_IN(_EX)_i is still "HLD_ADAP", also, no calculation is carried out. The time measurement continues, i.e., the adaptation is not aborted, while conditions for the drift adaptation are fulfilled.

The drift velocity is calculated when "HLD_ADAP" has been held for IP_CYC_MIN_DRIFT_AD_IVVT drift adaptation cycles at least and has been left due to an adjustment, i.e., STATE_CTL_IVVT_IN(_EX)_i becomes "ADJ". The holding pulse width modulation correction IVVTHPWM_DRIFT_AD_SAVE_IN(_EX)_i is calculated from ID_IVVTHPWM_COR_DRIFT_AD dependent on the velocity drift. The sign of the velocity drift determines the sign of the correction so that the drift becomes smaller.

No adaptation is activated if the oil temperature is too high and the engine speed too low. The oil pressure might not be sufficient for the adaptation. The adaptation results might not be reliable.

Application conditions:

Initialization:

At reset:

CAM_DRIFT_AD_ST_IVVT_IN(_EX)_i = C_CAM_INI_IN(_EX)

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

Activation:

```
        LV_ACT_IND_IVVT_IN(_EX)_i = 1
and     (       TOIL <= C_TOIL_MAX_IVVTHPWM_AD
        or      N_32 >= C_N_32_MIN_IVVTHPWM_AD)
```

Formula section:

Drift adaptation kick-off:

```
if              LV_DRIFT_AD_ACT_IVVT_IN(_EX)_i = 0
        and     STATE_CTL_IVVT_IN(_EX)_i(n-1) = "HLD_DLY"

FUNCTION DESCRIPTION:

General information:

The contributions of the two holding pulse width modulation adaptations, i.e., deviation and drift adaptation, are saved into the adaptation table IVVTHPWM_AD_IN(_EX)_i[…] in this manager.

Description:

The properties of the adaptation table IVVTHPWM_AD_IN(_EX)_i[…] are specified by means of the dummy ID_IVVTHPWM_AD_IN(_EX)_i, see "Calibration data". The index of the adaptation map is independent from IP_IVVTHPWM(_EX) The adapted values are saved dependent on the solenoid valve temperature TMAG_IVVT(_EX). The "[...]" part of the indentifier expresses saving into the cell belonging to the current TMAG_IVVT(_EX).

After the adaptation end the variables IVVTHPWM_DE_AD_SAVE_IN(_EX)_i and IVVTHPWM_DRIFT_AD_SAVE_IN(_EX)_i do not change till the next adaptation kick-off. They are set 0 at this moment, see the adaptation procedures.

The values in the table cannot exceed the limits C_IVVTHPWM_AD_MIN and C_IVVTHPWM_AD_MAX.

Application conditions:

FUNCTION DESCRIPTION:

General information:

Particles in the oil control valve of the IVVT system can disturb the system performance. These debris do not affect the oil control valve operation if they are away from the oil flow control area. This can be achieved by movements of the valve control piston between its stop positions. Such procedure is called oil control solenoid valve cleaning.

Description:

The cleaning is done if the engine is stopped. If it is before the engine start (LV_ES = 1 and LV_IGK = 1) there is the delay C_T_DLY_ST_CLE_SLV_IVVT before cleaning. The start (LV_ES = 1 $\rightarrow$ 0) usually follows the transition LV_IGK = 0 $\rightarrow$ 1 very quickly. The cleaning would be interrupted soon after its beginning. If delay C_T_DLY_ST_CLE_SLV_IVVT with LV_IGK = 1 is reached it is to assume that the driver will wait some time before starting.

The engine is not running in the power latch (LV_ES = 1 and LV_IGK = 0). The oil pressure may be high at the power latch beginning, especially at low oil temperatures. As the actuator might move during the cleaning, there is the delay C_T_DLY_PWL_CLE_SLV_IVVT.

The basic unit of the cleaning is a cycle. The cycle consists of 2 * C_CTR_STEP_CLE_SLV_IVVT steps. The first cycle half has high level pulse width modulation, the second half has low level PWM. There can be C_CTR_CYC_CLE_SLV_IVVT cycles in one driving cycle. The cleaning signal is specified by ID_IVVTPWM_CLE_SLV. It is possible to create a smoothed signal in order to limit possible noise at the cleaning. The solenoid valve temperature and the battery voltage are taken into account by the correction factor FAC_COR_IVVTPWM_IN(_EX).

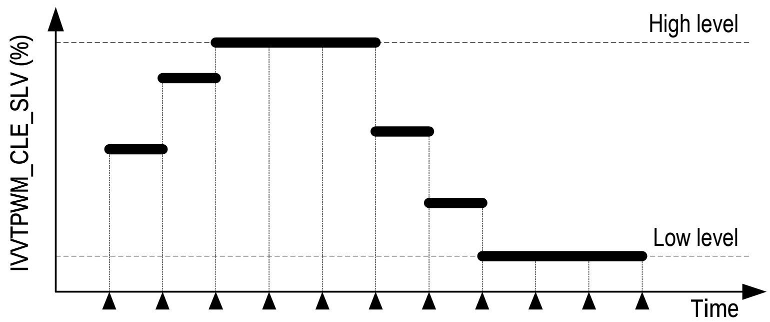

Figure: "Oil control solenoid valve cleaning cycle"

The cleaning can be disabled by LV_DI_CLE_SLV_IVVT (application incidence).

The oil control solenoid valve cleaning occurs in the power-latch too. The power-latch is to hold while the cleaning is active.

Input data:

STATE_ACR_TEST_IVVT	LV_ES	CONF_CAM_VVT_EX	

FUNCTION DESCRIPTION:

General information:

An actuator test is done by means of a special PWM signal.

Description:

An actuator test function can request 1 Hz 50 % PWM signal for each individual camshaft. This is indicated by STATE_ACR_TEST_IVVT. The test function guarantees that some conditions are fulfilled when requesting tests. Those relevant for the IVVT system are that the solenoids can be energised and that the engine speed is 0.

The 1 Hz 50 % PWM test signal is generated by means of 100 % PWM 0.5 s lasting and 0 % PWM lasting 0.5 s with the frequency of the holding energisation.

Application conditions:

CTR_ABC_CAM_STAT_IVVT_IN_i	CTR_ABC_CAM_STAT_IVVT_EX_i		

FUNCTION DESCRIPTION:

General information:

It might be advantageous to disable the reference position adaptation under certain conditions. E.g., a new reference position can be adapted at very high engine speed due to huge centrifugal forces and camshaft sensor dirft. Such operating state usually outlasts only for short time, and the newly learnt reference position is not suitable for the most operating states.

Description:

The adaptation is disabled if the engine load is over C_MAF_HB_MAX_AD_REF_DI_IVVT, the engine speed is outside of the range C_N_32_MIN(_MAX)_AD_REF_DI_IVVT and the oil temperature is outside of the range C_TOIL_MIN(_MAX)_AD_REF_DI_IVVT.

The adaptation is also disabled if IVVT is under error conditions, such as electrical, deviation (stuck, plausibility) and short trip.

Application conditions:

Initialization:

At reset, at deactivation:

LV_CAM_SP_REF_AD_DI_IVVT = 1

Recurrence:

100 ms

Activation:

At every engine state

Formula section:

if MAF_HB > C_MAF_HB_MAX_AD_REF_DI_IVVT

or N_32 < C_N_32_MIN_AD_REF_DI_IVVT
or N_32 > C_N_32_MAX_AD_REF_DI_IVVT

9.75 IVVT Lock at Transition to Engine Stop

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
LV_CAM_LOCK_IVVT_IN_i	O/V	0...1H	0...1	1	-
1 = actuator locked at transition to engine stop, 0 = not locked; inlet					
LV_CAM_LOCK_IVVT_EX_i	O/V	0...1H	0...1	1	-
1 = actuator locked at transition to engine stop, 0 = not locked; exhaust					

Input data:

FUNCTION DESCRIPTION:

General information:

The ENSD aggregate needs the information whether the actuator locking system was locked at the transition to engine stop or not at the next engine start.

Description:

LV_CAM_LOCK_IVVT_IN(_EX)_i is handled as if the actuator were never locked at the transition to engine stop.

Application conditions:

Initialisation: LV_IGK = 0-->1

LV_CAM_LOCK_IVVT_IN(EX)=1

Recurrence: At each used camshaft edge, see "IVVT Scheduler"

Activation: At every engine state

Formula section:

LV_CAM_LOCK_IVVT_IN(EX) = 1 (always remain 1)

9.76.2 CHRG_DEFSPPUT0/OPM

9.76.2.1 CHRG_DEFSPPUT0/OPM/CLC_OPM

The regular pressure upstream throttle setpoint is low passed filtered in case of torque limitation for turbo charger protection. The result may be overwritten by a manual value.

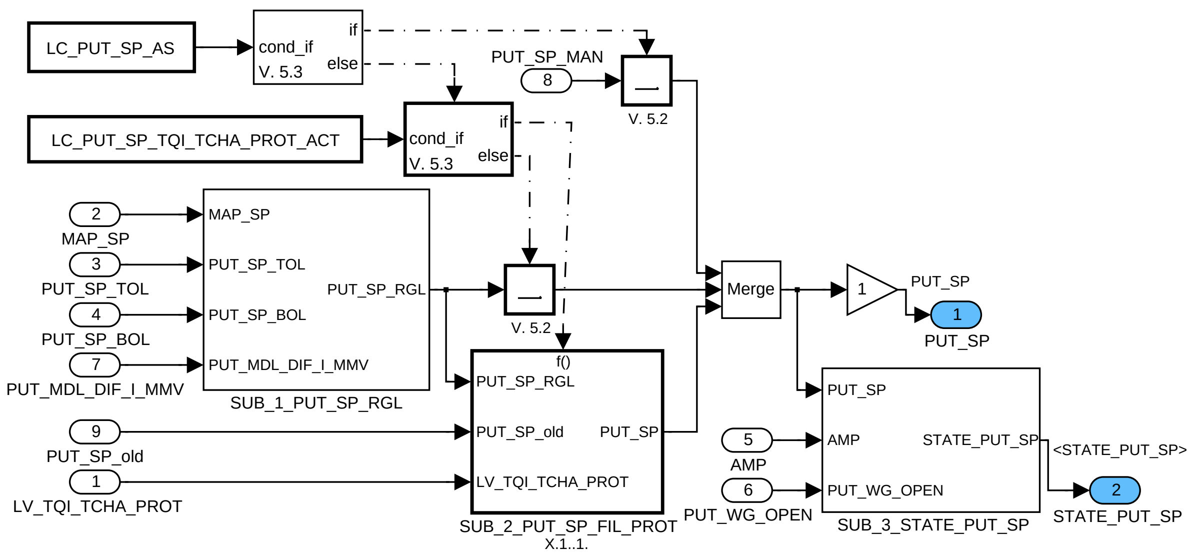

Figure 178:
Path: CHRG_DEFSPPUT0/OPM/CLC_OPM

9.76.2.1.1 No title given for this section

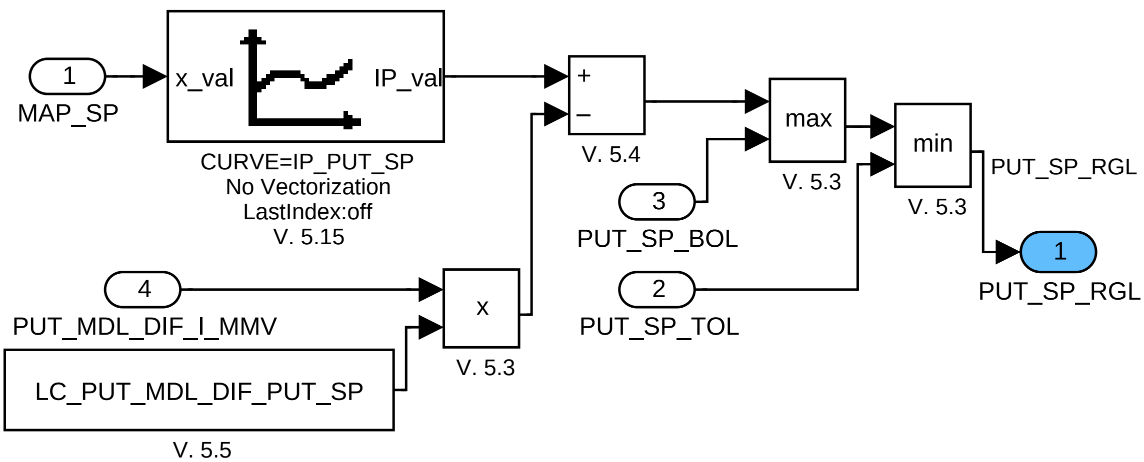

Figure 179:

9.76.2.1.2 CHRG_DEFSPPUT0/OPM/CLC_OPM/SUB_2_PUT_SP_FIL_PROT

When engine torque limitation for turbo charger protection is active (LV_TQI_TCHA_PROT = 1) PUT_SP is not allowed to increase as rapidly as MAP_SP in order to stabilize the turbo charger operation setpoint. In this case PUT_SP is low pass filtered.

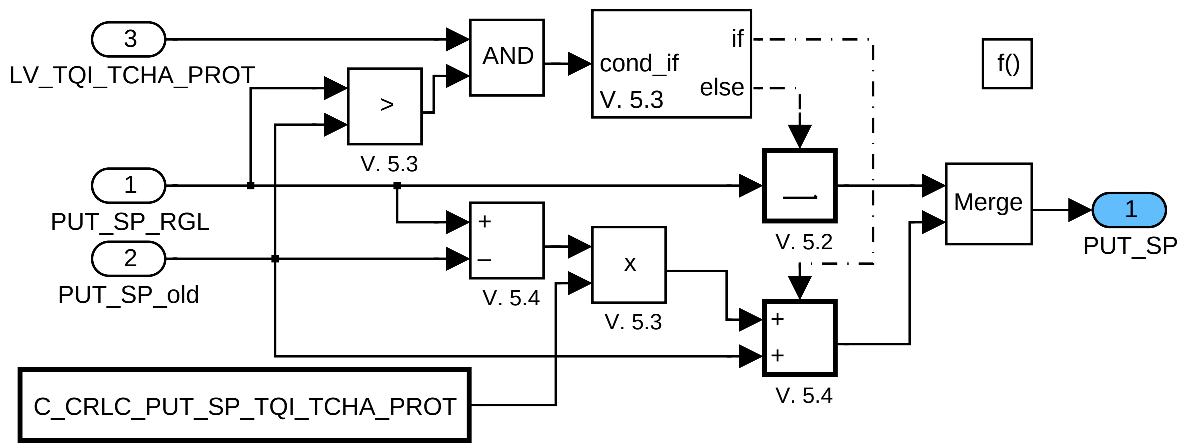

Figure 180:
Path: CHRG_DEFSPPUT0/OPM/CLC_OPM/SUB_2_PUT_SP_FIL_PROT

9.76.2.1.3 CHRG_DEFSPPUT0/OPM/CLC_OPM/SUB_3_STATE_PUT_SP

STATE_PUT_SP shows whether PUT_SP is below ambient pressure (= 0), between ambient pressure and basic charge air pressure (= 1) or above basic charge air pressure (= 2).

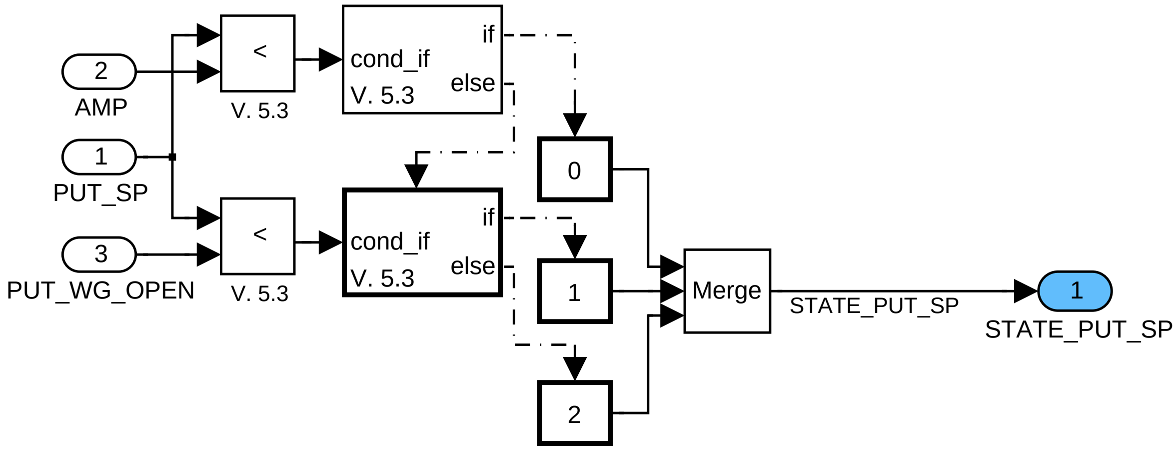

Figure 181:
Path: CHRG_DEFSPPUT0/OPM/CLC_OPM/SUB_3_STATE_PUT_SP

9.78.1 CHRG_ISPCLCHAEN0

This module calculates the conditions at the charger, the intercooler and the air cleaner at the desired setpoint.

In this 1st step it is assumed that the recirculation path will be closed when the charge air pressure control is active. Therefore the mass air flow through air cleaner, charger intercooler and engine at the set point are equal.

indicated torque setpoint reduction factor for turbocharger protection (turbocharger speed gradient)					

9.79.1 CHRG_REQGNPROT0

FUNCTION DESCRIPTION:

To protect the turbo charger from overspeed (N_TCHA) or in case of:

failure detected on the wastegate

failure detected on the recirculation valve (only if “RCL close” failure state detected)

a torque reduction can be applied.

In case those torque reductions do not show the wanted effect, there are constants for absolute maximum (not applied in case of RCL failure) which cause an immediate complete opening of the wastegate or an immediate torque setpoint reduction.

General information:

The physical limits are the maximum turbine temperature and the turbo charger rotational speed. They depend on the turbine and housing material and usually are among 900°C to 1050°C respectively 160 000rpm to 250 000rpm. The first way to decrease the exhaust gas temperature without loosing engine torque is to enrich the air/fuel ratio. Second step is to decrease the torque request and third step is to open the bypass (waste gate) of the turbine immediately. The first two measures are located in EXTC, the third in the present module. Decreasing the torque setpoint and opening the waste gate are also appropriate solutions if too high rotational speed of the turbo charger is detected.

Decreasing the torque setpoint is also appropriate solution if a failure is detected on the wastegate or on the recirculation valve (remark: for the recirculation valve, it is necessary to decrease torque only if “RCL close” failure state is detected). .

Function description:

The variable N_TCHA_MAX_DIF is the input into an PI-controller. If N_TCHA > C_N_TCHA_MAX_SP the TQI_N_TCHA_MAX_I is ramped down to decrease the turbo charger speed. In case of too high turbo charger speed gradients the temporary torque reduction value is decreased again by multiplying with an turbo charger speed gradient dependent factor. If the turbo charger speed finally drops below the calibratable threshold C_N_TCHA_MAX_SP then TQI_N_TCHA_MAX_I is ramped up again until TQI_ADD_ACT is reached. If TQI_ADD_ACT is reached, TQI_N_TCHA_MAX is set to its passive value of 7FFFh 1023.97Nm again.

The value of the torque request cannot underspend the calibratable constant C_TQI_MIN_TCHA_PROT.

CHRG_REQGNPROT0/OPM/CLC_OPM/CLC_STATE_TCHA_PROT

STATE_TCHA_PROT collects all the information about limited turbo charger performance because of extreme operating conditions. Each limit corresponds to one bit of STATE_TCHA_PROT:

Bit 15 = 32768 = Permanent torque limitation because of load-TPS-error

Bit 14 = 16384 = Permanent torque limitation because of too high exhaust gas temperature

Bit 13 = 8192 = Permanent torque limitation because of wastegate driver error

Bit 12 = 4096 = Permanent torque limitation because of too high charger speed

Bit 11 = 2048 = Permanent torque limitation because of charger control/pressure implausibility

Bit 10 = 1024 = Any permanent torque limitation

Bit 9 = 512 = Temporary torque limitation because of high charger speed

Bit 8 = 256 = Operation at maximum charger pressure ratio

Bit 7 = 128 = Operation at maximum absolute charge air pressure setpoint

General Information

This module is valid for a binary recirculation actuator. The controller must be "Digital type" (ON/OFF) (i.e.: NC_PSN_RCL_CTL = 1).

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: LC_TCHA_CONF
Deactivation: !LC_TCHA_CONF

9.80.2 SUBFUNCTION: operate_10ms

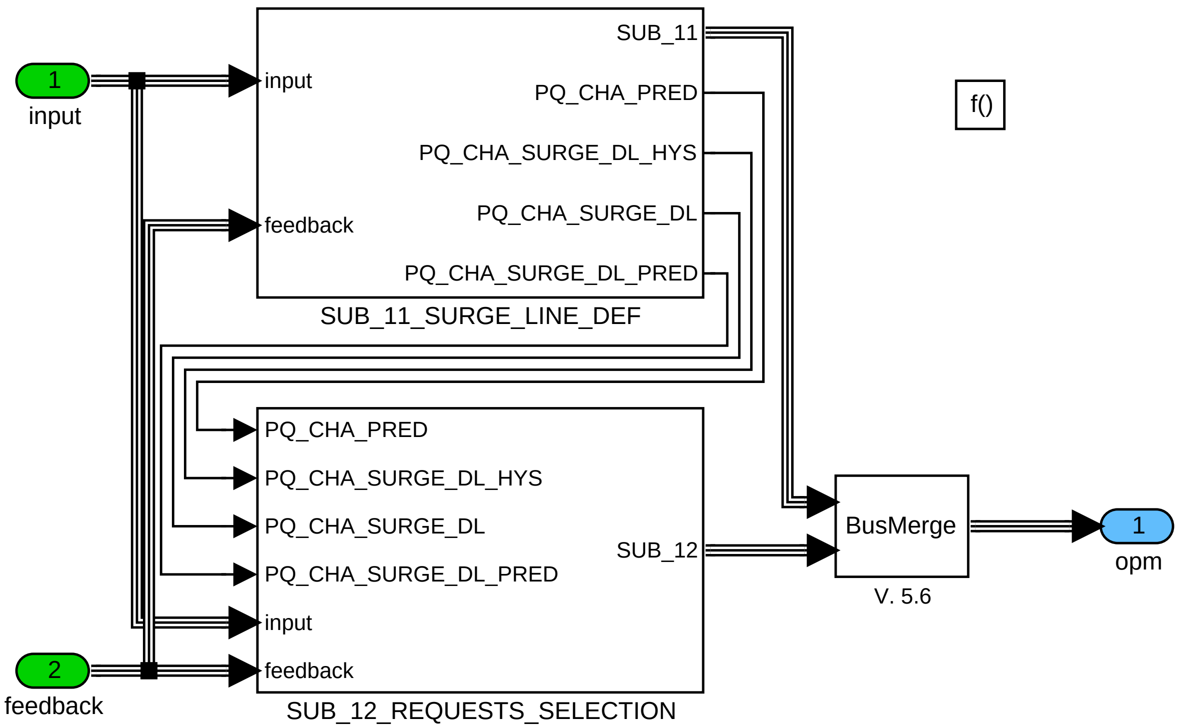

Figure 210:
Path: CHRG_ISPCLPSNRC0/OPM

9.80.2.1 Surge line definition with prediction based on RCL actuator response time:

The RCL activation response time is defined based on pressure conditions. Activation times are determined separately for activation and deactivation.
Surge is detected both based on current volume flow and pressure ratio PQ_CHA_MV and VOL_FLOW_CHA_UP_RED and on predicted pressure ratio PQ_CHA_PRED and VOL_FLOW_CHA_UP_RED_PRED. The prediction horizon is defined as equal to the response time of the RCL actuator. For a bi turbo system surge is determined on average values of the inlet branches.

9.80.2.1.1.2 RCL Actuator Response Delay Time:

When RCL opening command has just been reset (LV_CMD_RCL_OPEN = 0 and LV_CMD_RCL_OPEN_OLD_RCL_SP = 1) T_RESP_RCL_ON is copied to T_DLY_RESP_RCL_ON. Otherwise T_DLY_RESP_RCL_ON is decremented. After a reset of LV_CMD_RCL_OPEN (LV_CMD_RCL_OPEN = 0 and T_DLY_RESP_RCL_ON = 0) T_RESP_RCL_ON stays active.

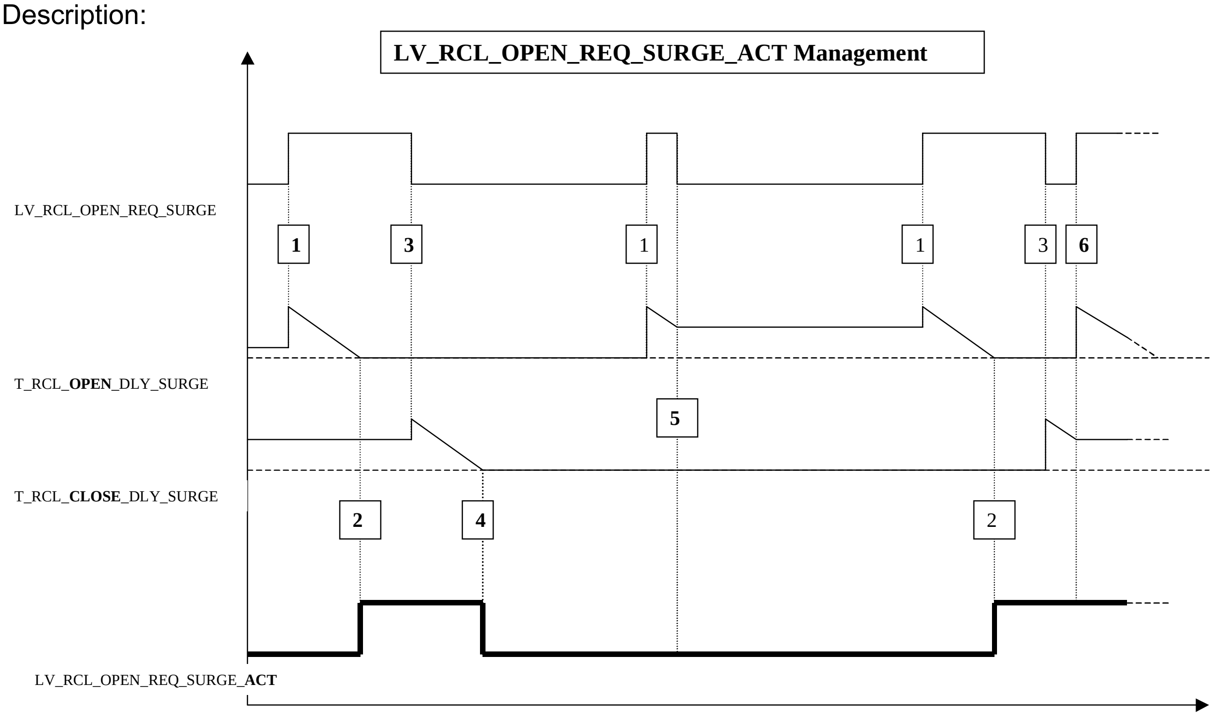
9.80.2.2 Different Requests Selection:

Different conditions may occur which lead to the demand of an open recirculation actuator.
The recirculation actuator can be opened if:
. surge protection is active (refer to LV_SURGE, LV_SURGE_PRED definitions) or
. overpressure protection is active (refer to LV_IN_PROT in 30904301) or
. turbo charger protection functionality is active (refer to LV_TCHA_PROT_ACT) or
. the pedal [in case of no torque intervention] is quickly released or
. the throttle [in case of torque intervention] is quickly closed or
. the engine is either in trailing throttle or trailing throttle fuel cut off state (this can be deactivated by application) or
. a request is generated via service tool (end of line test) or application system.
The RCL is forced closed when cruise control is active.
Description:



1: Transition of LV_RCL_OPEN_REQ_SURGE = 0 to 1 (Timer T_RCL_OPEN_DLY_SURGE is initialized with C_T_RCL_OPEN_DLY_SURGE
From 1 to 2: T_RCL_OPEN_DLY_SURGE is decreased as long as LV_RCL_OPEN_REQ_SURGE = 1

2: Timer T_RCL_OPEN_DLY_SURGE has elapsed (LV_RCL_OPEN_REQ_SURGE_ACT is set to 1
3: Transition of LV_RCL_OPEN_REQ_SURGE = 1 to 0 And LV_RCL_OPEN_REQ_SURGE_ACT = 1 (Timer T_RCL_CLOSE_DLY_SURGE is initialized with IP_T_RCL_CLOSE_DLY_SURGE
From 3 to 4: T_RCL_CLOSE_DLY_SURGE is decreased as long as LV_RCL_OPEN_REQ_SURGE = 0
4: Timer T_RCL_CLOSE _DLY_SURGE has elapsed (LV_RCL_OPEN_REQ_SURGE_ACT is set to 0
5: Transition of LV_RCL_OPEN_REQ_SURGE = 1 to 0 (Timer T_RCL_OPEN_DLY_SURGE is frozen and LV_RCL_OPEN_REQ_SURGE_ACT remains unchanged
Timer T_RCL_CLOSE_DLY_SURGE is not initialized as LV_RCL_OPEN_REQ_SURGE_ACT = 0 (ie: no need to plan to close the actuator which is already closed !)
6: Transition of LV_RCL_OPEN_REQ_SURGE = 0 to 1 (Timer T_RCL_CLOSE_DLY_SURGE is frozen and LV_RCL_OPEN_REQ_SURGE_ACT remains unchanged

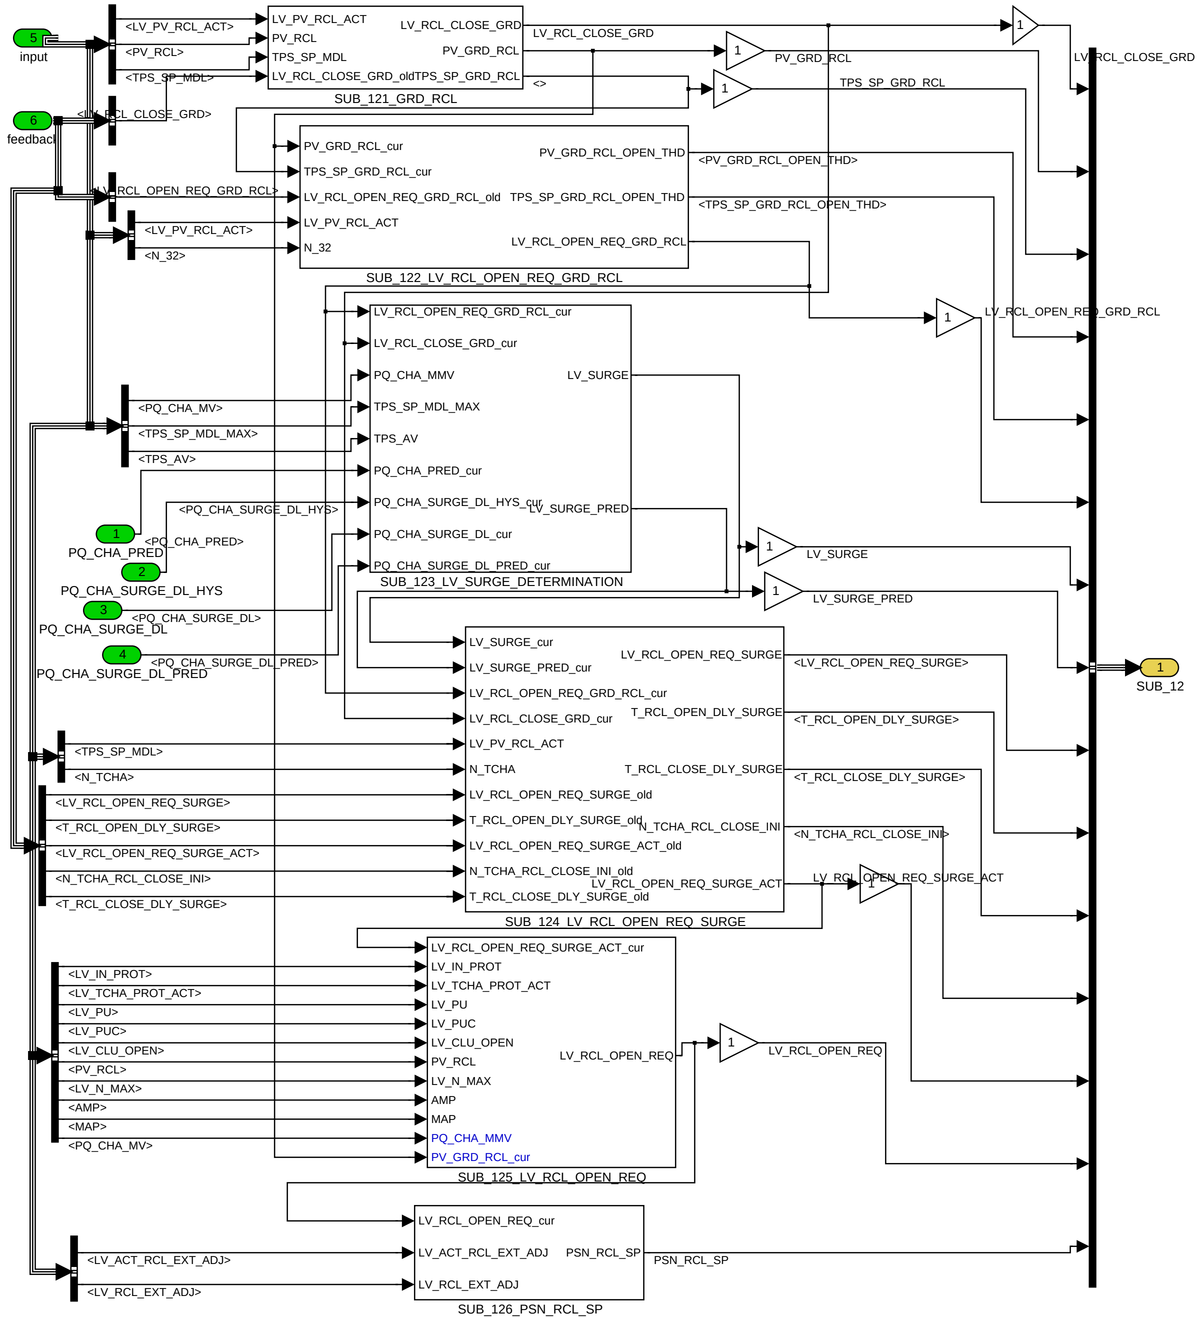


Figure 217:

Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION

9.80.2.2.1 RCL Actuator Closing Request:

LV_PV_RCL_ACT determines whether pedal value PV_RCL (= 1) or throttle opening setpoint TPS_SP_MDL (= 0) controls the recirculation actuator (refer to module Recirculationactuator set point determination Appl. Inc.).

If the torque request by the driver increases pedal value PV_RCL and/or throttle opening setpoint TPS_SP_MDL increase. If both pedal value PV_RCL and/or throttle opening setpoint TPS_SP_MDL and their gradients PV_GRD_RCL and TPS_SP_GRD_RCL exceed activation thresholds then the recirculation actuator is requested to closed (LV_RCL_CLOSE_GRD = 1). If the gradients fall below deactivation thresholds this request is reset (LV_RCL_CLOSE_GRD = 0).

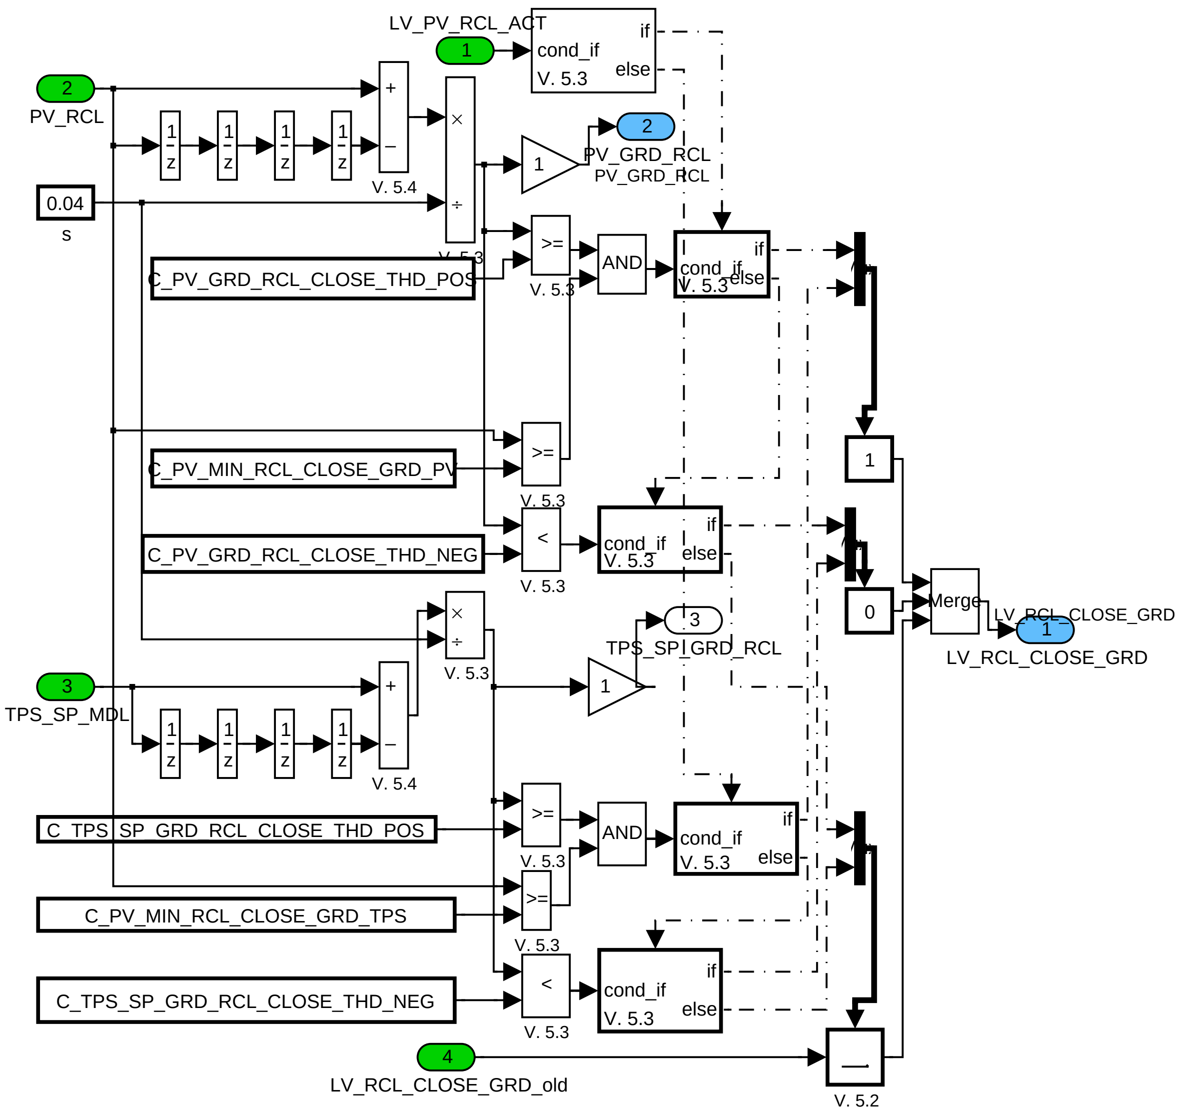

Figure 218:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_121_GRD_RCL

9.80.2.2.2 RCL Actuator Opening Request:

LV_PV_RCL_ACT determines whether pedal value PV_RCL (= 1) or throttle opening setpoint TPS_SP_MDL (= 0) controls the recirculation actuator.
If the torque request by the driver decreases pedal value PV_RCL and/or throttle opening setpoint TPS_SP_MDL decrease. If pedal value gradient PV_GRD_RCL and/or throttle opening setpoint gradient TPS_SP_GRD_RCL fall below activation thresholds then the recirculation actuator is requested to open (LV_RCL_OPEN_REQ_GRD_RCL = 1). If the gradients increase again by a hysteresis C_PV_GRD_RCL_OPEN_HYS then this request is reset (LV_RCL_OPEN_REQ_GRD_RCL = 0).

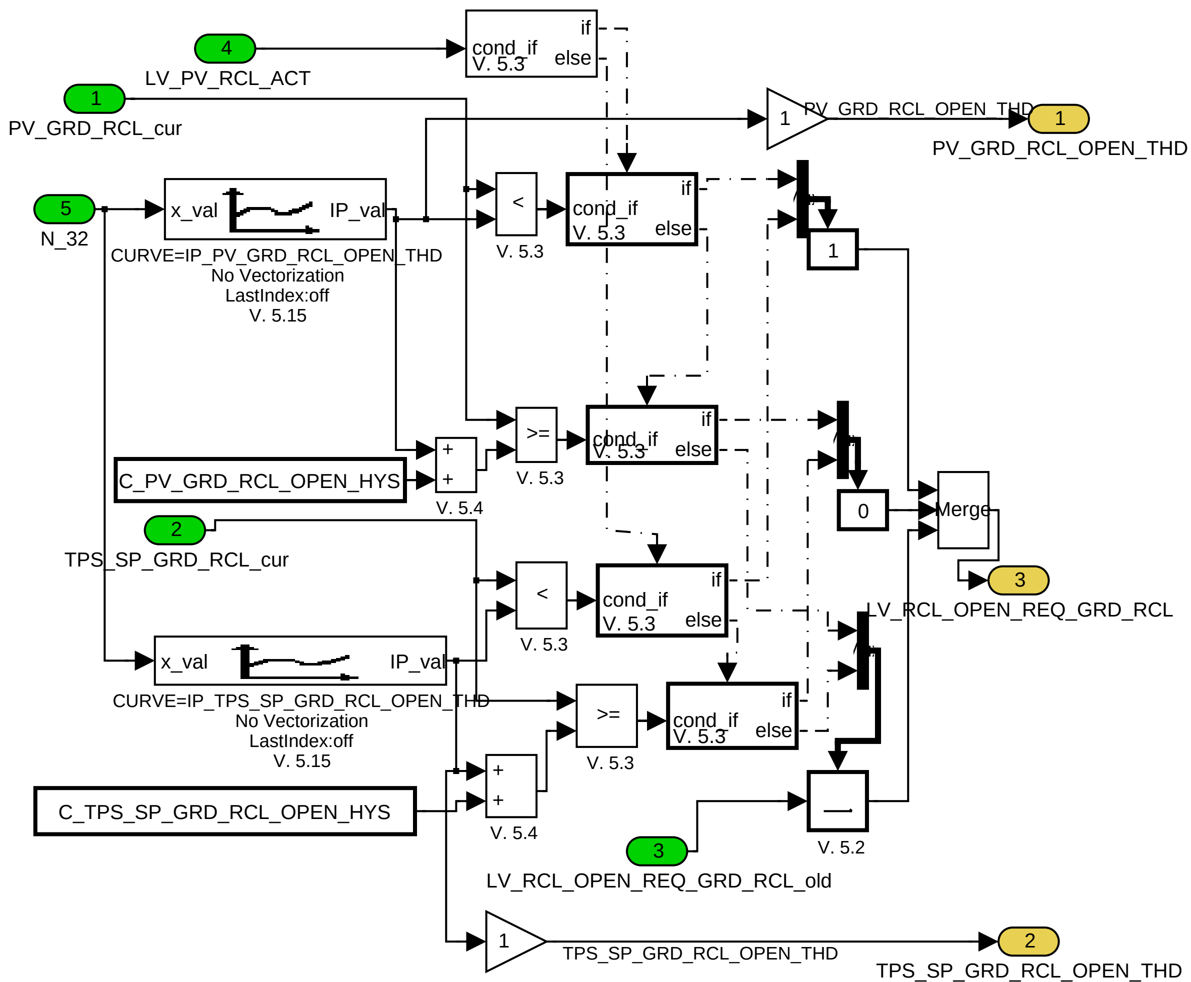

Figure 219:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_122_LV_RCL_OPEN_REQ_GRD_RCL

9.80.2.2.3 Surge Line and Surge line predicted definition:

Surge is detected if the actual throttle opening TPS_AV is close to its maximum possible value TPS_SP_MDL and either the current compressor pressure ratio PQ_CHA_MV is greater than the current surge limit PQ_CHA_SURGE_DL or the predicted compressor pressure ratio PQ_CHA_PRED is greater than the predicted surge limit PQ_CHA_SURGE_DL_PRED or (switchable) recirculation actuator opening is requested via PV/TPS gradient condition.

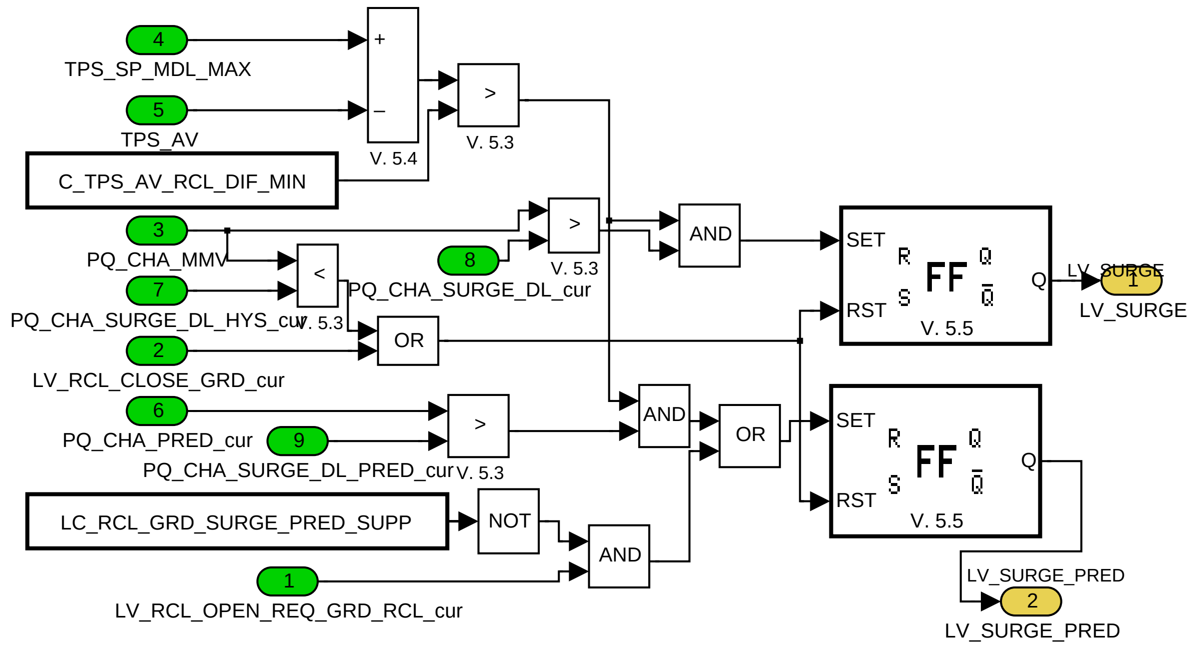

Figure 220:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_123_LV_SURGE_DETERMINATION

9.80.2.2.4 RCL Open request surge:

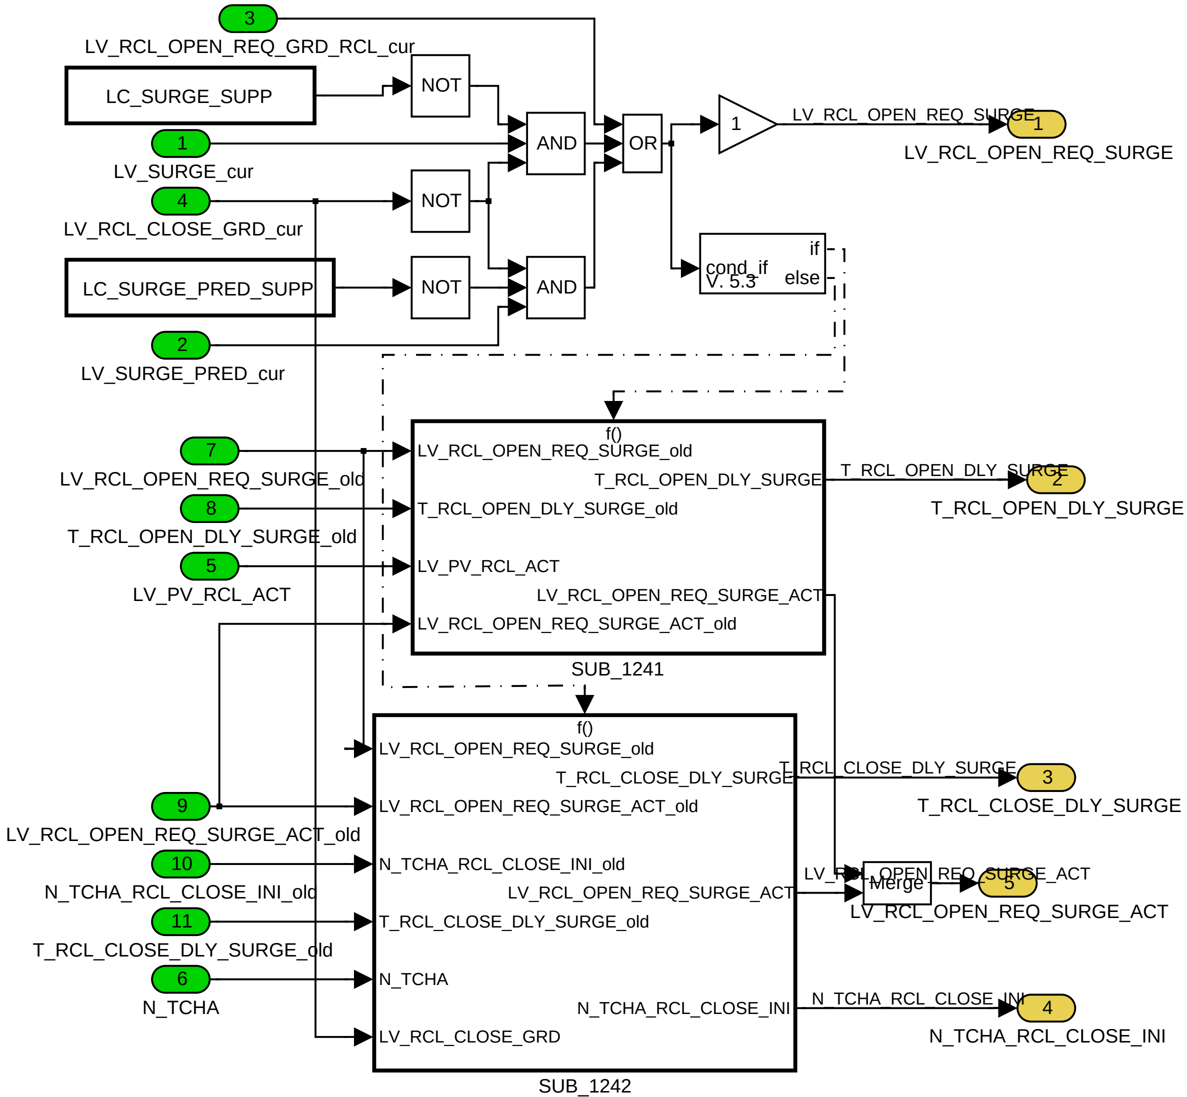

Figure 221:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_124_LV_RCL_OPEN_REQ_SURGE

9.80.2.2.4.1 RCL Opening delay time for activation

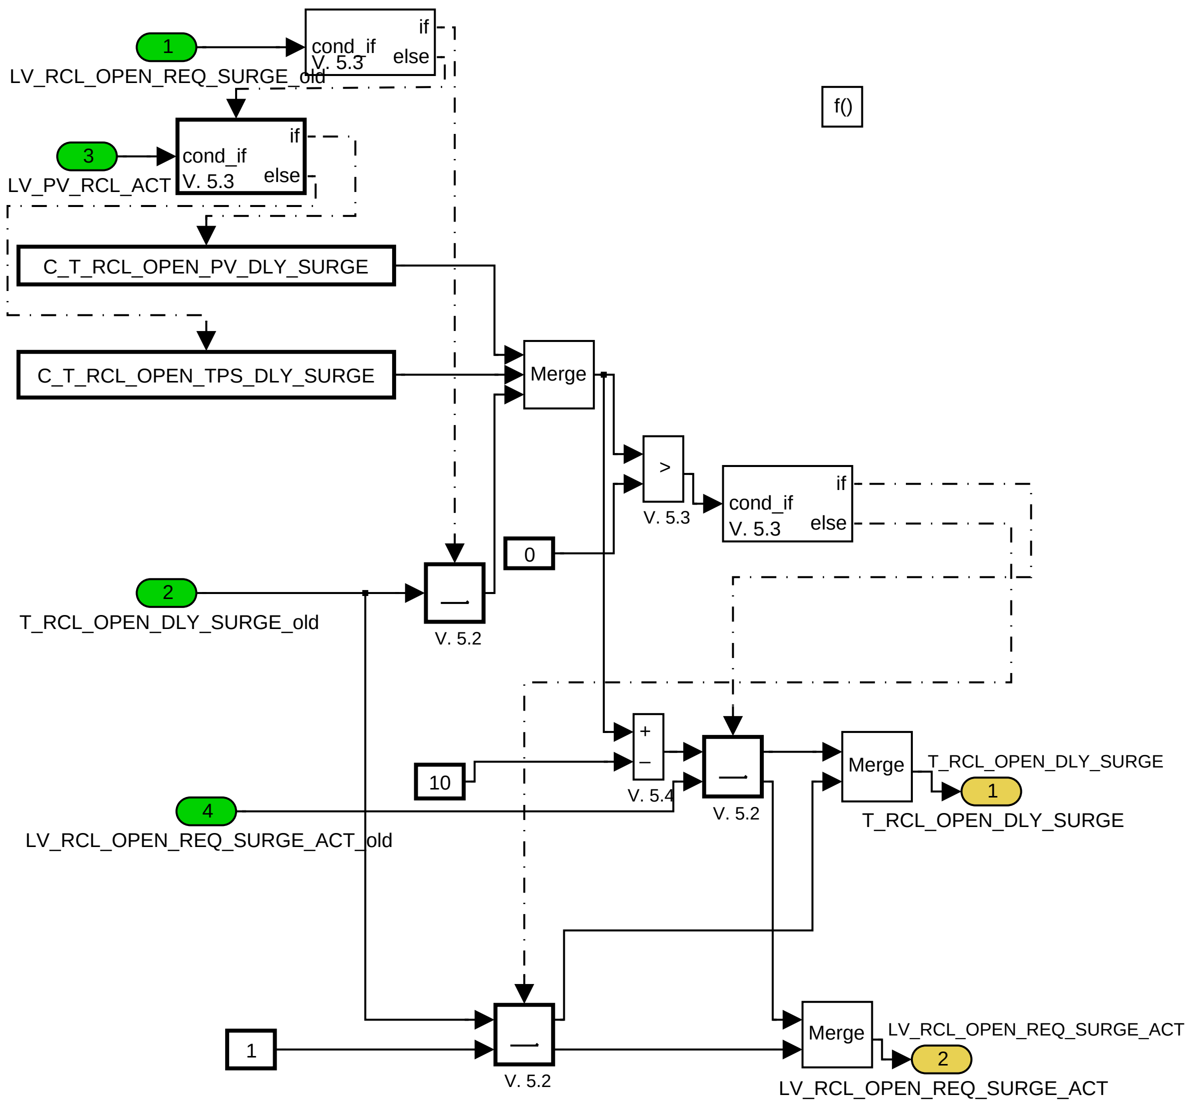

Figure 222:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_124_LV_RCL_OPEN_REQ_SURGE/SUB_1241

9.80.2.2.4.2 RCL closing delay time for activation

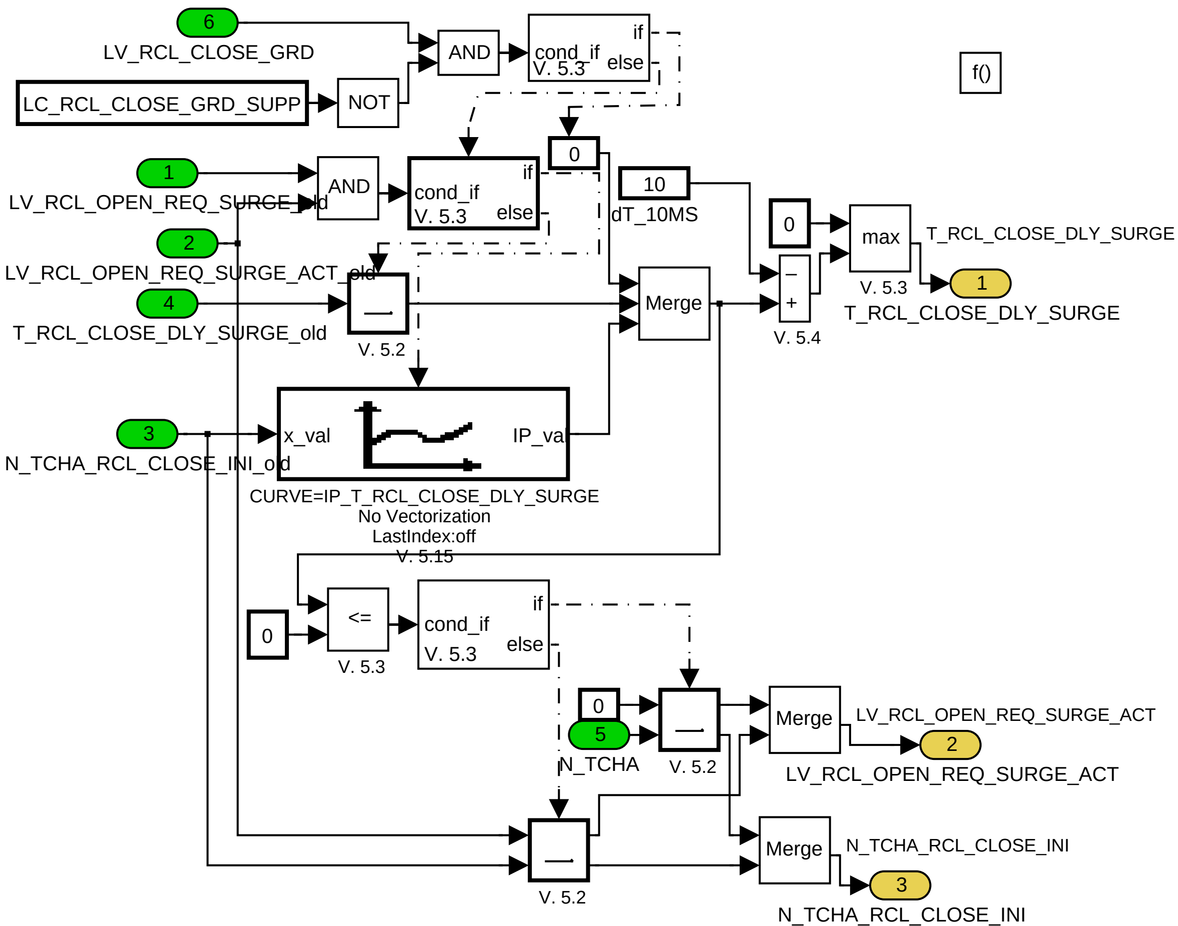

Figure 223:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_124_LV_RCL_OPEN_REQ_SURGE/SUB_1242

9.80.2.2.5 RCL Actuator opening request:

Opening and closing requests for the recirculation actuator are coordinated here. Highest priority for have the opening request because of turbo charger protection LV_TCHA_PROT_ACT, opening request because of intake manifold protection LV_IN_PROT and (switchable) opening request because of non charged engine operation. Opening requests because of PU/PUC (switchable), because of engine speed limitation (switchable), because of surge detection (with pedal value minimum threshold) and because of opened clutch (switchable) have second priority. Second priority requests are blocked if the pedal value is greater than a threshold C_PV_RCL_CLOSE_BOL and the clutch is open (gear shift for fast acceleration). Additionally, to reduce the turbo lag out of low load, it is also possible to open the recirculation valve for a certain time until the turbocharger starts to compress the intake air. The goal of this is to reduce the pressure losses during this time by bypassing the charger.
To activate the RCL opening the gradient for the pedal value has to pass the threshold C_PV_GRD_RCL_OPEN_SET. Moreover the pressure quotient of the charger has to be under the calibrateable value C_PQ_CHA_RCL_OPEN_SET. If the pressure quotient exceeds this threshold the recirculation valve closes again, not to limit the boost pressure in a negative way.

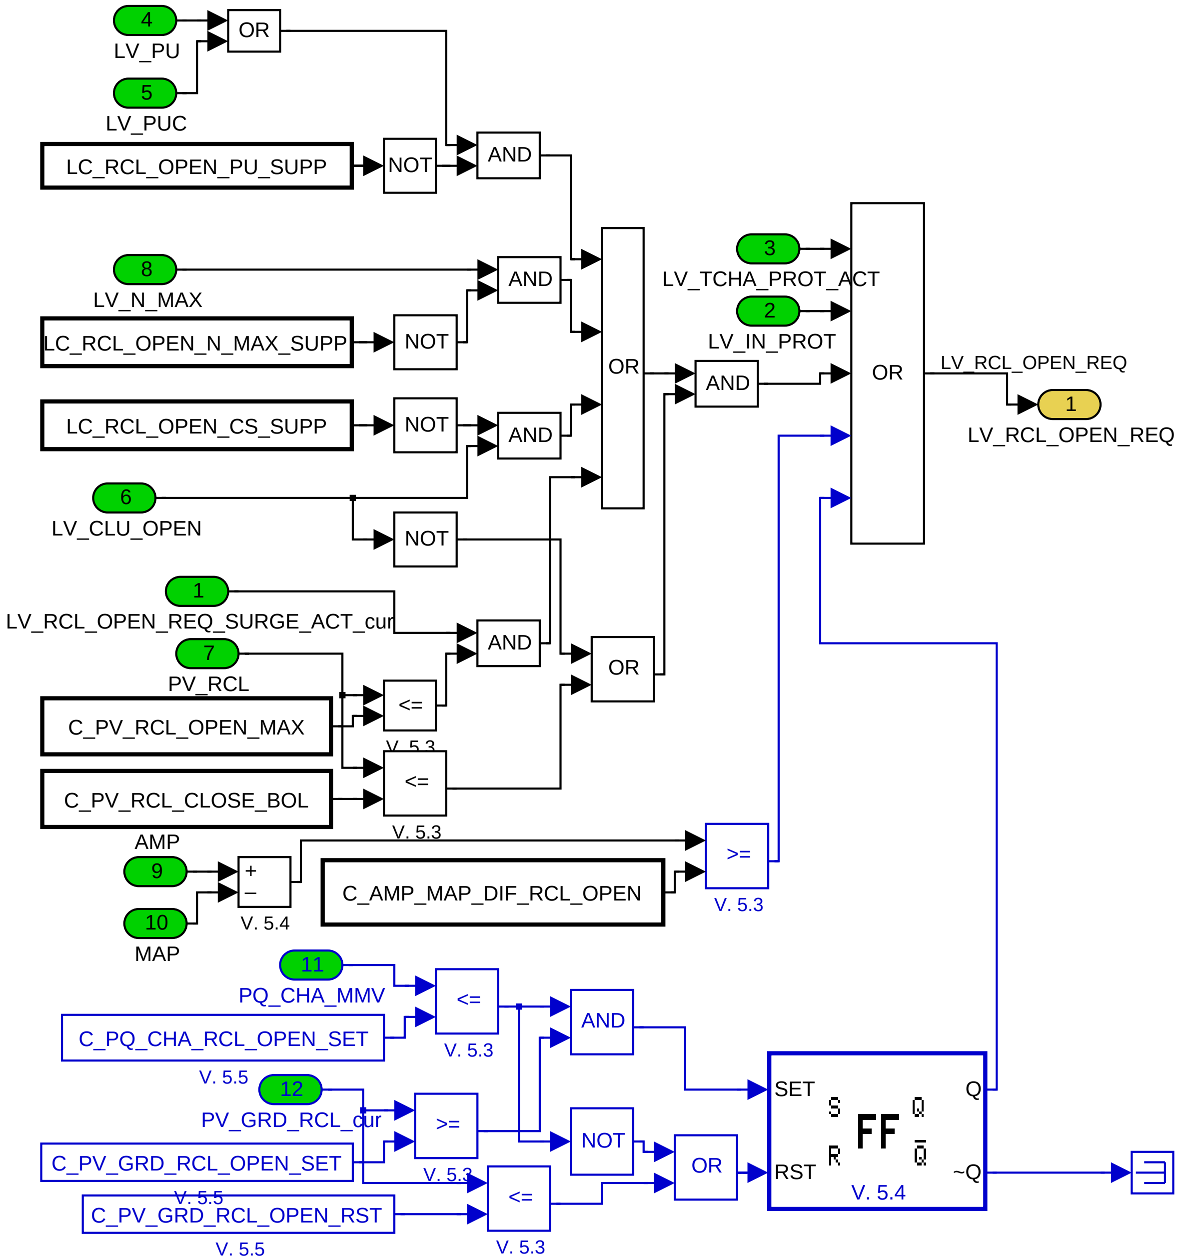

Figure 224:
Path: CHRG_ISPCLPSNRC0/OPM/SUB_12_REQUESTS_SELECTION/SUB_125_LV_RCL_OPEN_REQ

9.80.2.2.6 RCL Actuator position set point:

9.81.1 CHRG_ISPCLPRCAI0

The pedal value used for recirculatioin actuator position control and the condition when recirculation actuator control is based on pedal value, when on throttle position can vary for different engines. These calculations are done here project specifically.

The pedal value used for recirculation actuator position control can be the measured pedal value or a reconstructed pedal value including torque several interventions.

General Information

The purpose of the present PUT controller is to minimize the deviation between the pressure upstream throttle setpoint (PUT_SP) and the actual pressure upstream throttle. When in charged engine operation the throttle is fully opened this PUT controller deviation determines the correspondence of MAF and MAF_SP as well as TQI and TQI_SP accordingly.

Application Conditions

Initialization: RST
Recurrence: 10MS

general specification

The I share of the PUT controller is activated only when both the general PUT controller activation conditions are fulfilled and when PUT is greater than the basic charge pressure PUT_WG_OPEN.

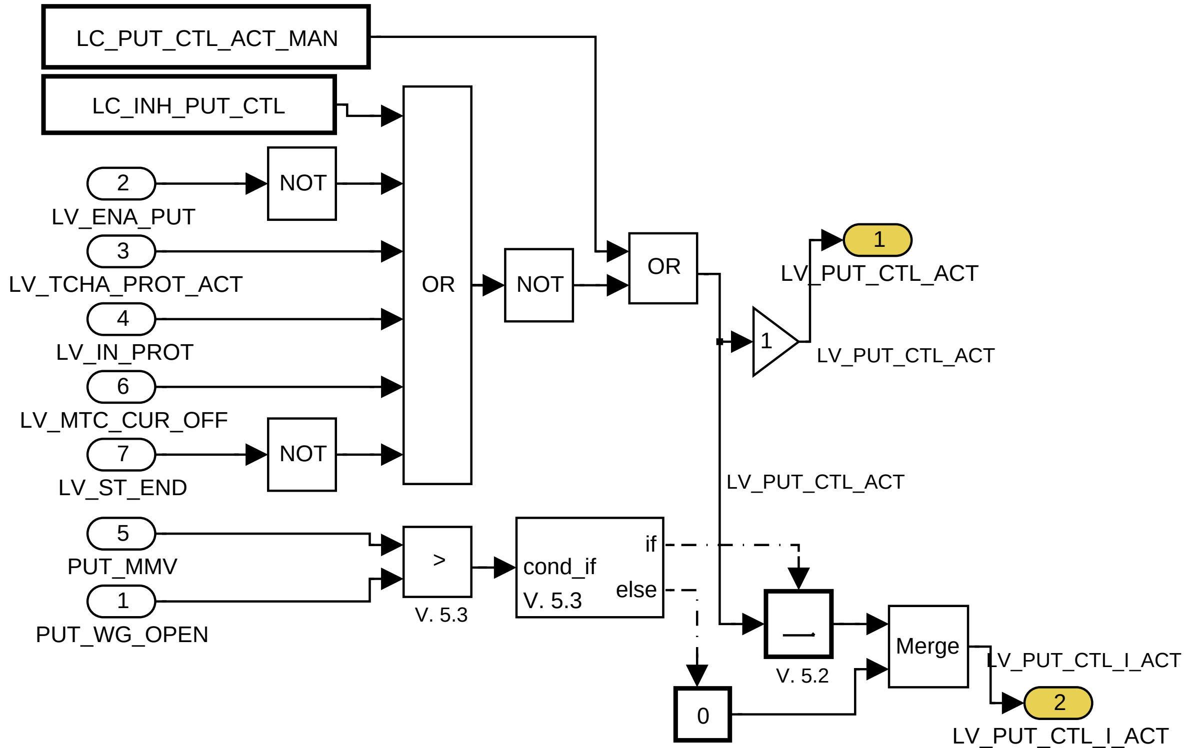

Figure 232:

9.82.2.2 CHRG_REASPPUT0/OPM/SUB_2_PUT_CTL_STAT

Recognition of stationary PID controller operation
Stationary charge air pressure controller operation is recognized if either
- PUT_DIF enters a window [C_PUT_DIF_Min_STAT_ACT, C_PUT_DIF_MIN_STAT_ACT] or
- PUT_DIF_MMV_STAT or PUT_MMV_STAT gradient changes its sign.

Non stationary charge air pressure controller operation is recognized if either
- PUT_DIF gets higher than C_PUT_DIF_MAX_STAT_DEAC or
- PUT_DIF gets smaller than C_PUT_DIF_MIN_STAT_DEAC.

9.82.2.4 CHRG_REASPPUT0/OPM/SUB_5_PID_CTLR

PID-Controller

The pressure up throttle controller is configured as a PID-controller in which the D-Part is inactive at steady state conditions. Each controller factor can be calibrated by a manual value instead of the

interpolation maps. The controller is stopped during engine torque limitation for turbo charger protection.
The controller gain depend on an auxiliary rotational speed N_PUT_CTL. By means of C_N_PUT_CTL_SRC can be chosen whether this rotational speed is engine speed N (= 0), actual charger speed N_TCHA (= 1) or charger speed setpoint N_CHA_SP (= 2).

9.82.2.4.2 CHRG_REASPPUT0/OPM/SUB_5_PID_CTLR/SUB_52_PID_RGL_GAIN

There are three sets of controller gains
- one for stationary operation
- one for non stationary operation with manual transmission
- one for non stationary operation with automatic transmission.

There is an additional factor for the I gain. In non stationary operation the I share can work symmetrically (C_FAC_PUT_CTL_I_COR_POS = 1) for both negative and positive PUT_DIF. To prevent PUT overshoots it can be limited to work for negative PUT_DIF (i.e. PUT_SP > PUT_MMV) only (C_FAC_PUT_CTL_I_COR_POS = 1). To prevent PUT overshoots for PUT_SP jumps which do not trigger non stationary operation, the I share is deactivated for PUT_MMV gradients bigger than C_PUT_MMV_GRD_MAX_PUT_CTL_I.

FUNCTION DESCRIPTION:

General information:

An adaptation is carried out to compensate series tolerances. The values of map PRS_DIF_WG_ACR_SP_AD are saved in EEPROM during power latch phase and reread at ECU reset. The indices IDX_PRS_PUT_AD and IDX_FLOW_PUT_AD are used to address PRS_DIF_WG_ACR_SP_AD and the axes LDPM_PRS_1_CHRG and LDPM_FLOW_1_CHRG.

Application conditions:

Initialisation: at ECU reset:

MAF_MMV_PUT_AD = 0
N_MMV_PUT_AD = 0
PUT_DIF_MMV_PUT_AD = 0
MAF_SP_MMV_PUT_AD = 0
PRS_PUT_AD = 1013 hPa
FLOW_PUT_AD = 0
PRS_DIF_WG_ACR_SP_AD_ADD = 0
CTR_PUT_AD = 0
PRS_DIF_WG_ACR_PUT_AD = 0
T_DLY_PUT_AD = C_T_DLY_PUT_AD_INI

if (checksum error) **or** LC_AD_CLR_PUT_CTL **then**
PRS_DIF_WG_ACR_SP_AD [...][...] = 0
endif

Activation: LC_TCHA_CONF = 1 **and** LV_ST_END = 1

Deactivation: LC_TCHA_CONF = 0 **or** LV_ST_END = 0

Formula section:

Read adaptation value

// PRS_DIF_WG_ACR_SP_AD [...] [...] is the value from the adaptation map
// IP_PRS_DIF_WG_ACR_SP_AD (PRS_PUT_AD, FLOW_PUT_AD),
// which is defined as a dummy IP in the calibration data.

PRS_DIF_WG_ACR_SP_AD_ADD =
PRS_DIF_WG_ACR_SP_AD (PRS_EX_PRS_WG_ACR_SP, FLOW_WG_SP)

Adaptation of PRS_DIF_WG_ACR_SP_AD

By means of the tables ID_PRS_PUT_AD_MIN and ID_PRS_PUT_AD_MAX several adaptation-windows (indexed by idx) ID_PRS_PUT_AD_MIN [idx] < LDPM_PRS_1_CHRG [idx] < ID_PRS_PUT_AD_MAX [idx]. If PRS_PUT_AD is in one of these windows, that is ID_PRS_PUT_AD_MIN [idx] <= PRS_PUT_AD <= ID_PRS_PUT_AD_MAX [idx] for a given index idx, an adaptation of the map PRS_DIF_WG_ACR_SP_AD at LDPM_PRS_1_CHRG [idx] is possible. If such a window can be found at the index idx, we set IDX_PRS_PUT_AD = idx, otherwise IDX_PRS_PUT_AD is set to FFh.
The search for the window is performed by means of the data-point-search implemented in the Software-library: For a given PRS_PUT_AD, the data point search for the axis LDPM_PRS_1_CHRG returns an index idx_sw such that LDPM_PRS_1_CHRG [idx_sw] <= PRS_PUT_AD < LDPM_PRS_1_CHRG [idx_sw+1]. If PRS_PUT_AD is smaller or bigger than any value of the axis, idx_sw is set to the first or last index respectively.

By means of the tables ID_FLOW_PUT_AD_MIN and ID_FLOW_PUT_AD_MAX several adaptation-windows (indexed by idx) ID_FLOW_PUT_AD_MIN [idx] < LDPM_FLOW_1_CHRG [idx] < ID_FLOW_PUT_AD_MAX [idx]. If FLOW_PUT_AD is in one of these windows, that is ID_FLOW_PUT_AD_MIN [idx] <= FLOW_PUT_AD <= ID_FLOW_PUT_AD_MAX [idx] for a given index idx, an adaptation of the map PRS_DIF_WG_ACR_SP_AD at LDPM_FLOW_1_CHRG [idx] is possible. If such a window can be found at the index idx, we set IDX_FLOW_PUT_AD = idx, otherwise IDX_FLOW_PUT_AD is set to FFh.
The search for the window is performed by means of the data-point-search implemented in the Software-library:: For a given FLOW_PUT_AD, the data point search for the axis LDPM_FLOW_1_CHRG returns an index idx_sw such that LDPM_FLOW_1_CHRG [idx_sw] <= FLOW_PUT_AD < LDPM_FLOW_1_CHRG [idx_sw+1]. If FLOW_PUT_AD is smaller or bigger than any value of the axis, idx_sw is set to the first or last index respectively.

9.85.1 CHRG_ISPCLFLOWG0

General information:

In the exhaust manifold the exhaust gas flow through the outlet valves of the engine is divided into turbine flow, wastegate flow and the flow for external exhaust gas recirculation. The wastegate flow setpoint FLOW_WG_SP depends on the other three flows. In stationary operation (i.e. FLOW_ENG_TCHA has reached its setpoint FLOW_ENG_SP after a FLOW_ENG_SP jump) FLOW_WG_SP must be calculated based on FLOW_WG_SP in order not to have a positive feedback which leads to growing engine flow and charged pressure oscillations. Just after a FLOW_ENG_SP jump FLOW_WG_SP must be calculated based on FLOW_ENG_TCHA (< FLOW_ENG_SP at this moment) because otherwise the wastegate opens too early. The transition from FLOW_ENG_TCHA to FLOW_ENG_SP as base for FLOW_WG_SP calculation is done when either FLOW_ENG_MMV reaches its setpoint FLOW_WG_SP or when engine flow swings back before reaching its setpoint.

For a biturbo system all FLOW_xx represent the flows for one turbo charger.

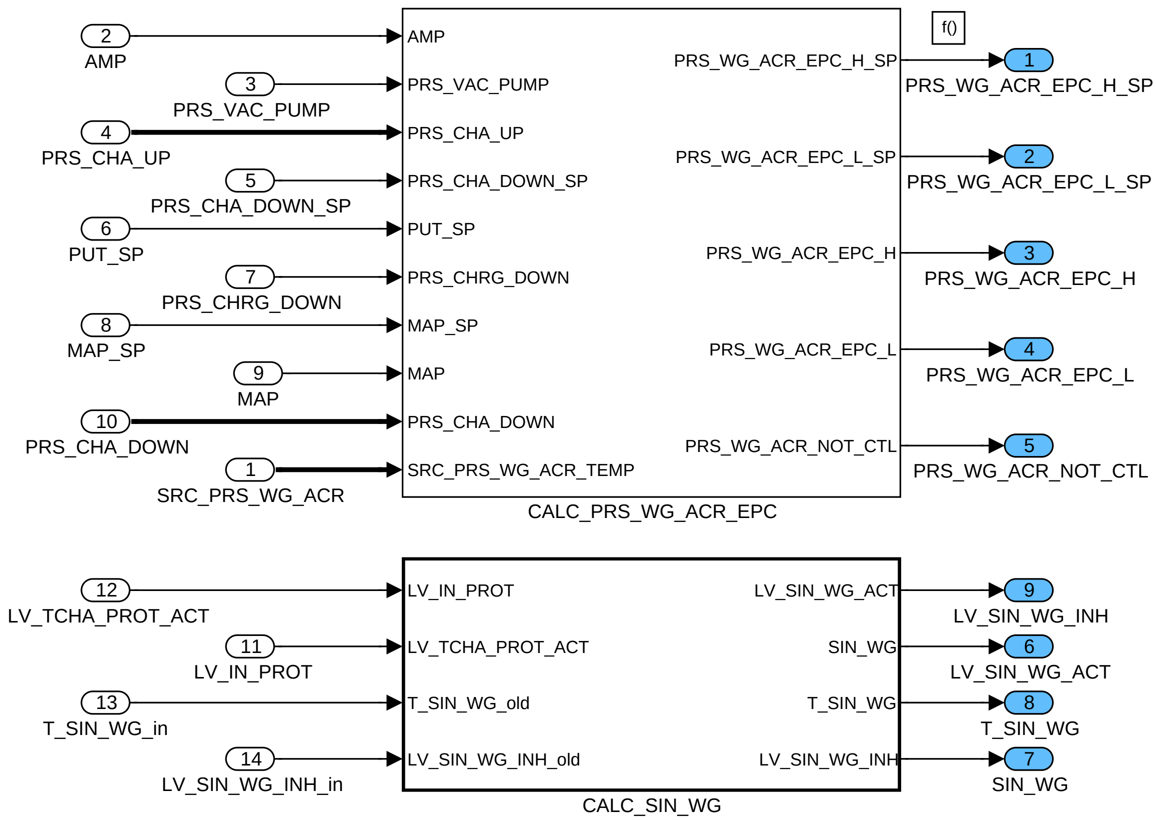

Figure 268 CHRG_ACCTLWGAI0/ operate_10ms

CHRG_ACCTLWGAI0/OPERATE_10MS/CALC_PRS_WG_ACR_EPC

The pressure in either of the two chambers of the pneumatic wastegate actuator can be controlled by means of an electropneumatic converter (EPC). Depending on which pressure is controlled, there can be different pressures at the high pressure and low pressure side of the EPC. These choices are defined here. Any of the input pressures can be copied to any output pressure. Because the configuration settings are checked only after ECU reset, these settings can not be changed during engine run.

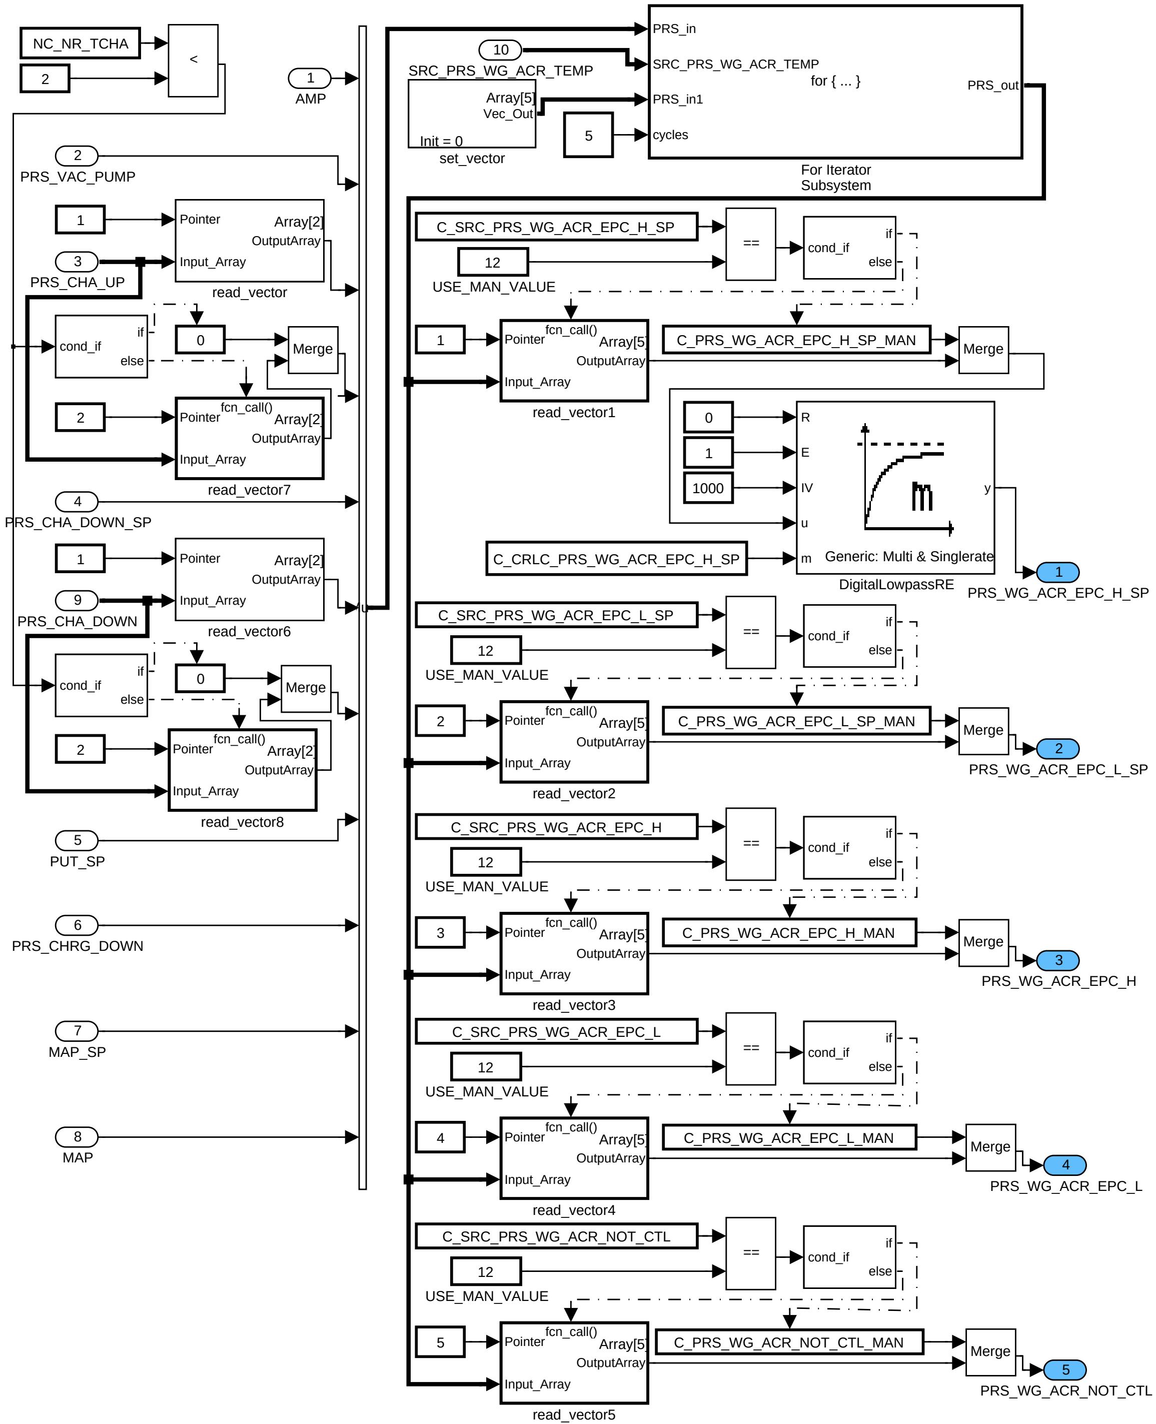

Figure 269 CHRG_ACCTLWGAI0/ operate_10ms/ CALC_PRS_WG_ACR_EPC

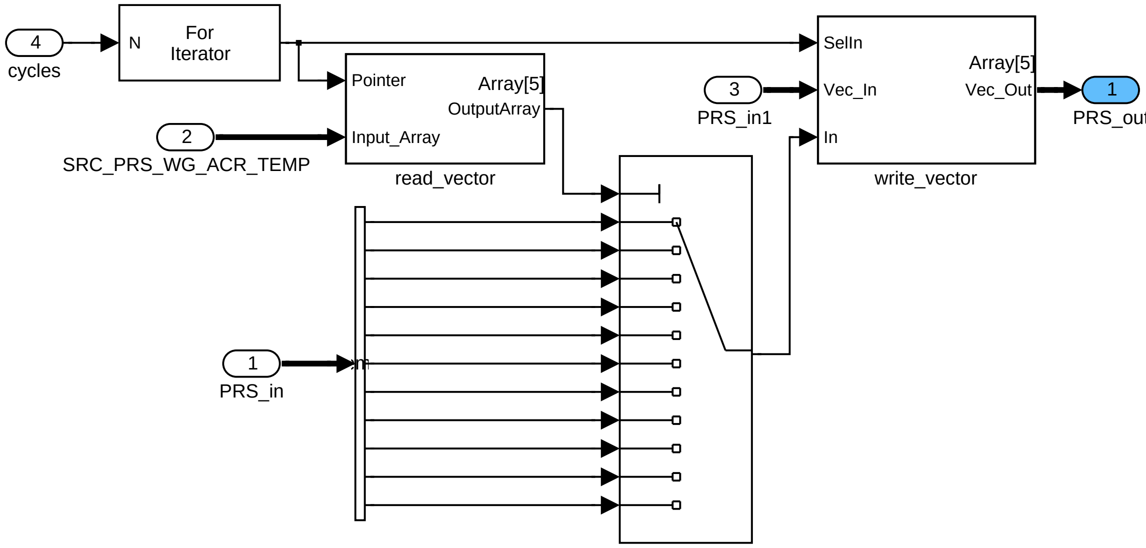

Figure 270CHRG_ACCTLWGAI0/ operate_10ms/ CALC_PRS_WG_ACR_EPC/ For Iterator

Subsystem

CHRG_ACCTLWGAI0/OPERATE_10MS/CALC_SIN_WG

System identification of the turbocharger can be performed by means of a sinusoidal excitation signal applied to the wastegate control signal or the wastegate opening setpoint. This sine signal with a tuneable frequency C_FRQ_SIN_WG is calculated here. It has no dimension, it has to be multiplied with the appropriate amplitude wherever it is used.

In IP_SIN_WG one quarter of the sine wave is stored, any angle is transformed into the first quadrant.

Whenever one of the flags LV_IN_PROT or LV_TCHA_PROT_ACT is set to 1 signaling dangerous conditions for the turbocharger or for the intake manifold the sine signal generation is stopped and can be resumed only after LC_SIN_WG_RST has been set for some time and reset again.

waste gate position setpoint					

9.88.1 CHRG_ISPCLPSNWG0

FUNCTION DESCRIPTION:

General information:

This module calculates the waste gate position setpoint and the torque at the waste gate caused by the exhaust gas pressure difference at the waste gate.

In this 1st step the reduced area setpoint is input, in later versions the flow setpoint through the waste gate, the pressure upstream and downstream the waste gate will be inputs.

Description:

The waste gate position setpoint is calculated dependent on the reduced area setpoint of the waste gate. The map IP_PSN_WG_SP represents this relationship. 0% means WG is closed (reduced area = 0) and 100% means WG is open (maximum reduced area).

The torque caused by gas forces depends on the force on the gate and the effective lever arm. The force depends on the exhaust gas pressure difference and the effective gate area. A positive value means a torque which opens the waste gate.

The influence of the effective area and the lever arm of the gate are summarised in the map IP_FAC_TQ_WG_PRS_EX_SP, because both depend on the waste gate position. The map represents the product of effective lever arm and effective gate area.

General Information

Turbine flow setpoint and turbine pressure setpoint for turbo charger precontrol are defined here.
For bi turbo systems all values describe one average exhaust bank.
Using the inverse turbine model the exhaust pressure upstream turbine PRS_EX_TCHA is calculated.

Application Conditions

Initialization: RST, ES2ERU
Recurrence: 10MS
Activation: LC_TCHA_CONF
Deactivation: !LC_TCHA_CONF

Function description

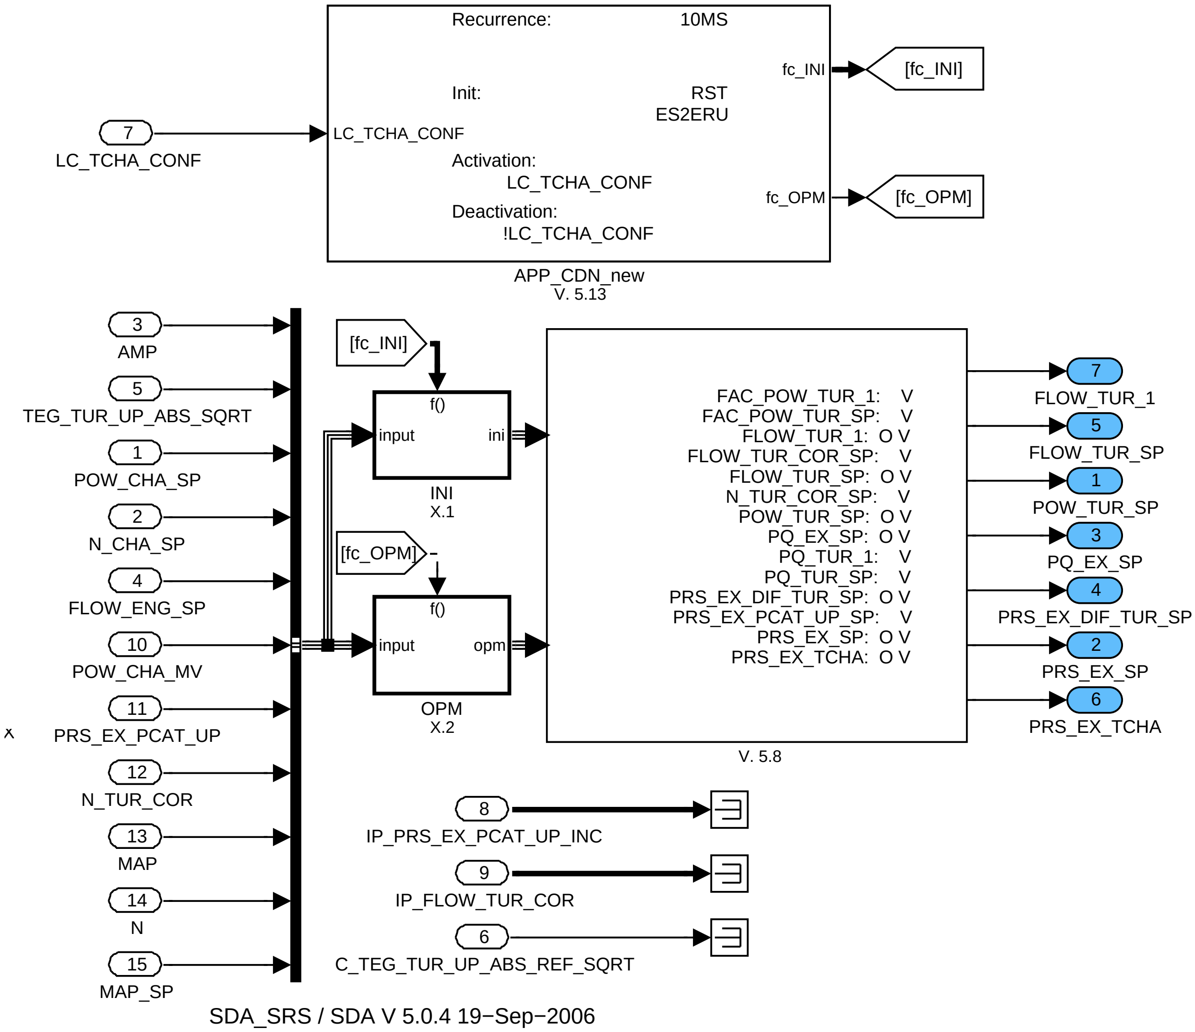

Figure 277:
Path: CHRG_ISPCLTUR0

9.89.1 Calculation at reset and engine stop to engine run

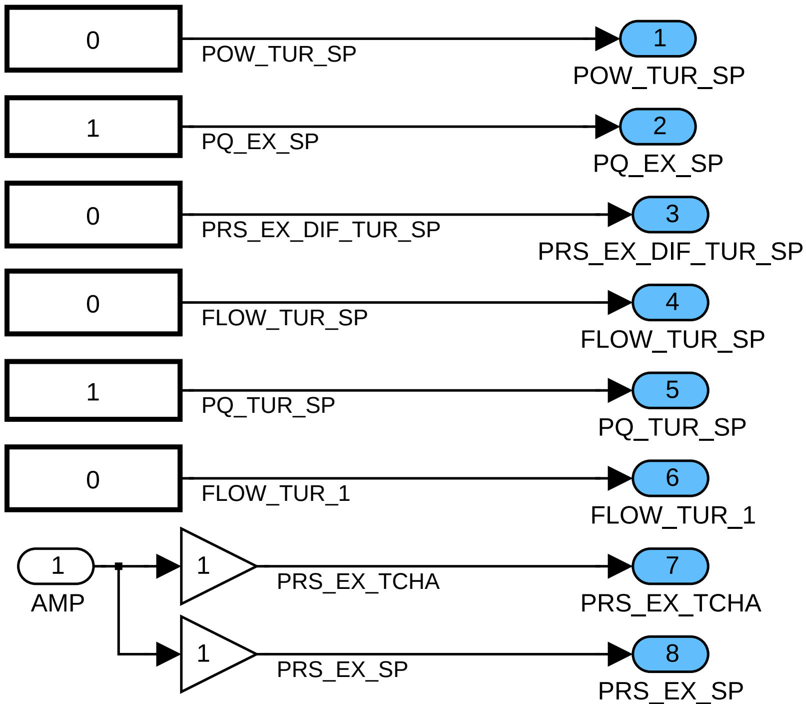

Figure 278:
Path: CHRG_ISPCLTUR0/INI/INI

9.89.2 Recurrence 10 ms

9.89.2.1 Calculation of turbine flow

9.89.2.1.1 Overview of calculation of actual turbine flow

9.89.2.1.1.1 Calculation of actual turbine flow

Exhaust pressure upstream turbine PRS_EX_TCHA is calculated using the inverse turbine model. Current engine operation conditions are corrected to reference conditions. In the turbine maps IP_PQ_TUR_SP and IP_FLOW_TUR_COR the behaviour of the turbine is stored. Additionally the map IP_FAC_PLS_COR_PQ_TUR_SP was introduced to consider a correction term on PQ_TUR due to pulsations which improve the turbine efficiency

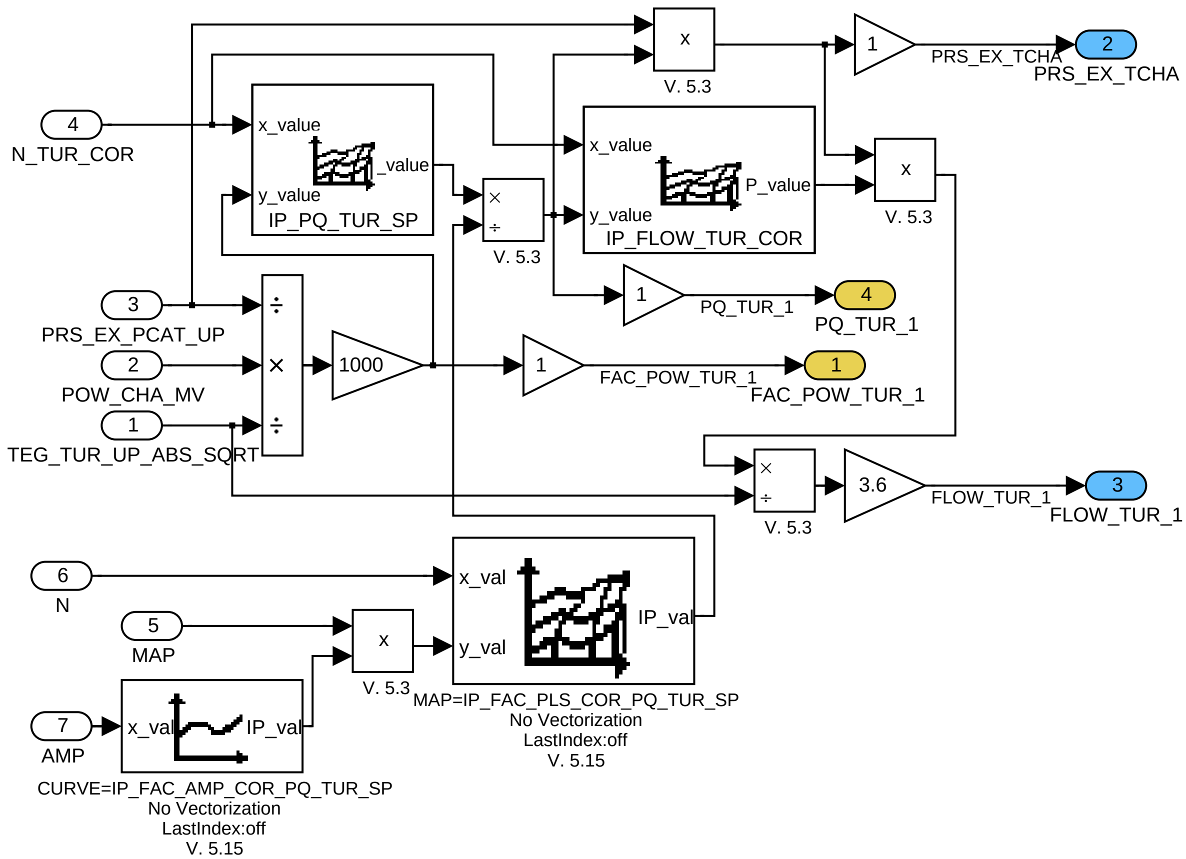

Figure 279:
Path: CHRG_ISPCLTUR0/OPM/CLC_OPM/CALC_FLOW_TUR_1/CLC_FLOW_TUR_1

9.89.2.1.2 Overview of calculation of turbine flow setpoint

9.89.2.1.2.1 Calculation of turbine flow setpoint

Current engine operation conditions are corrected to reference conditions. In the turbine maps IP_PQ_TUR_SP and IP_FLOW_TUR_COR the behaviour of the turbine is stored. Additionally a map for a correction term on PQ_TUR_SP was introduced (IP_FAC_PLS_COR_PQ_TUR_SP) which considers any pulsation effects that improves the turbine efficiency. Turbine pressure ratio and turbine flow setpoints can be replaced by manual settings.

A.1.2 Ordered by error name

For generation of the readiness-codes all diagnosis are connected with a CARB status (CARB_CC failures are only considered if they are calibrated as Emission relevant, see "Failure class"):

- CARB_CC Comprehensive component, continuous test
- CARB_MIS Misfire monitoring, continuous test
- CARB_FSD Fuel system monitoring, continuous test
- CARB_CAT Catalyst monitoring, sequential test
- CARB_HC Heated catalyst monitoring, sequential test
- CARB_EVAP Evaporative system monitoring, sequential test
- CARB_SA Secondary air monitoring, sequential test
- CARB_AC A/C system refrigerant monitoring, sequential test
- CARB_LS Oxygen sensor monitoring, sequential test
- CARB_LSH Oxygen sensor heater monitoring, sequential test
- CARB_EGR EGR system monitoring, sequential test

Calibration of C_ERR_CLAS_x (in HEX):

00 h: Diagnosis not active
10 h: Non CARB/EOBD Failure with medium priority, no MIL activation
43 h: emission relevant Failure with low priority, MIL activation
63 h: emission relevant Failure with high priority, MIL activation
93 h: emission relevant failure with high priority, MIL activation (in 1st DC)

A.2 Anti-bounce algorithms

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_PREV_XX	-	0...FH	0...15	1	[-]
Previous value of ERR_SYM_XX when the diagnosis conditions are fulfilled					
CTR_ABC_XX	V/O/S	0...FFH	0...255	1	[-]
anti bounce counter of diagnosis XX					
CTR_ABC_END_DIAG_XX	V	0...FFH	0...255	1	[-]
Counter for end of diagnosis XX generation					
LV_END_DIAG_XX	V	0...1H	0...1	1	[-]
Diagnostic done completely at least one time					
LV_CDN_DIAG_XX	V	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_XX	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	0	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					

Remark : The present failure and the anti-bounce counter may be saved or not (see 'Calculation of the Anti-bounce')

Input data:

LV_IGK	LV_DC	LV_ABC_INH	

Import actions:

#IF NC_ERR_DET_UPD = 1
ACTION_ERRM_UpdErrDet (IN<XX>)
This action indicates each occurrence of the detected error
#ENDIF

Export actions:

Name
ACTION_ERRM_FilterSymptom(IN< XX >, IN< lv_cdn_diag_XX >, IN< err_sym_XX >, IN< C_ABC_INC_XX >, IN< C_ABC_DEC_XX >, IN< C_ABC_MAX_XX >, OUT< LV_ERR_XX >)
This action computes the elementary anti-bounce filter for one failure treatment and returns filter result
ACTION_ERRM_NoFilterSymptom(IN< XX >, IN< lv_cdn_diag_XX >, IN< err_sym_XX >, IN< lv_err_set_XX >, IN< lv_err_reset_XX >, IN< lv_end_diag_XX >, OUT< LV_ERR_XX >)
This action computes the elementary treatment case no filtering is used
ACTION_ERRM_AbcFilterSymptomEnd(IN< XX >, IN< C_ABC_MAX_XX>, OUT< LV_ERR_XX >)
This action erases diagnostic failure and sets the end of diagnostic in case of antibounce filter type
ACTION_ERRM_NoFilterSymptomEnd(IN< XX >, OUT< LV_ERR_XX >)
This action erases diagnostic failure and sets the end of diagnostic in case of no filter
ACTION_ERRM_AbcFilterReset(IN< XX >, OUT< LV_ERR_XX >)
This action resets data filter in case of antibounce filter type
ACTION_ERRM_NoFilterReset(IN< XX >, OUT< LV_ERR_XX >)
This action resets data filter in case of no filter
ACTION_ERRM_GetLvErr(IN< XX >, OUT< LV_ERR_XX >)
This action is used to get LV_ERR_XX value
ACTION_ERRM_GetLvEndDiag(IN< XX >, OUT< LV_END_DIAG_XX >)
This action is used to get LV_END_DIAG_XX value
ACTION_ERRM_GetLvCdnDiag(IN< XX >, OUT< LV_CDN_DIAG_XX >)
This action is used to get LV_CDN_DIAG_XX value
ACTION_ERRM_GetErrSym(IN< XX >, OUT< ERR_SYM_XX >)
This action is used to get ERR_SYM_XX value

ERR_SYM_XX is defined like output data for each diagnosis as following :

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
ERR_SYM_XX	O/V	0..0FH	All combination	1	-
		0H	NO_SYM		
		1H	SYM_0		
		2H	SYM_1		
		4H	SYM_2		
		8H	SYM_3		
		FH	BENCH_MODE		
Symptom : failure without filtering of diagnosis XX					

It is possible to combine several symptoms.

FUNCTION DESCRIPTION:

General information:

The filtering algorithm (anti-bounce or statistic) is used usually for the simple diagnosis (e.g. : usually OBD1 diagnosis). If there is another need, diagnosis manages itself the filtering and the end of diagnosis (e.g. : usually OBD2 diagnosis).

The filtering is used to filter the detected failure. The failure becomes present after filtering.

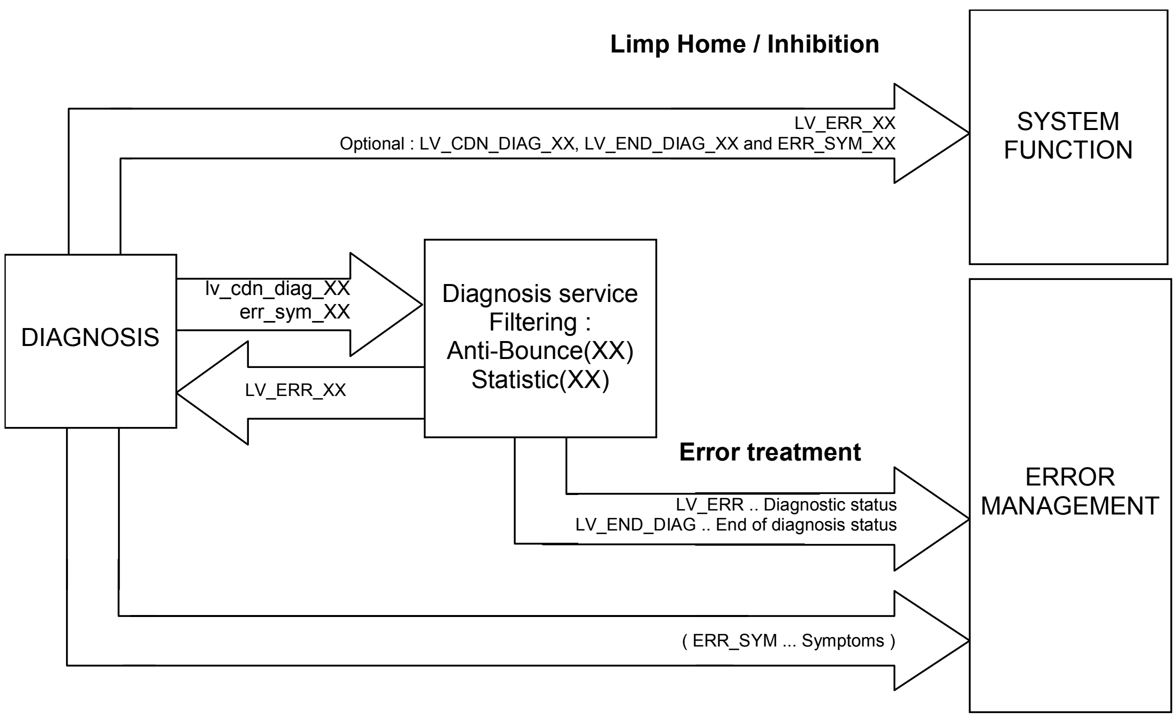
The end of diagnosis definition is realised after a time defined as the minimum time to detect a present failure.

The filtering algorithm (anti-bounce or statistic) uses one counter to check failure detection threshold and one counter to manage the end of diagnosis (Diagnostic result available).

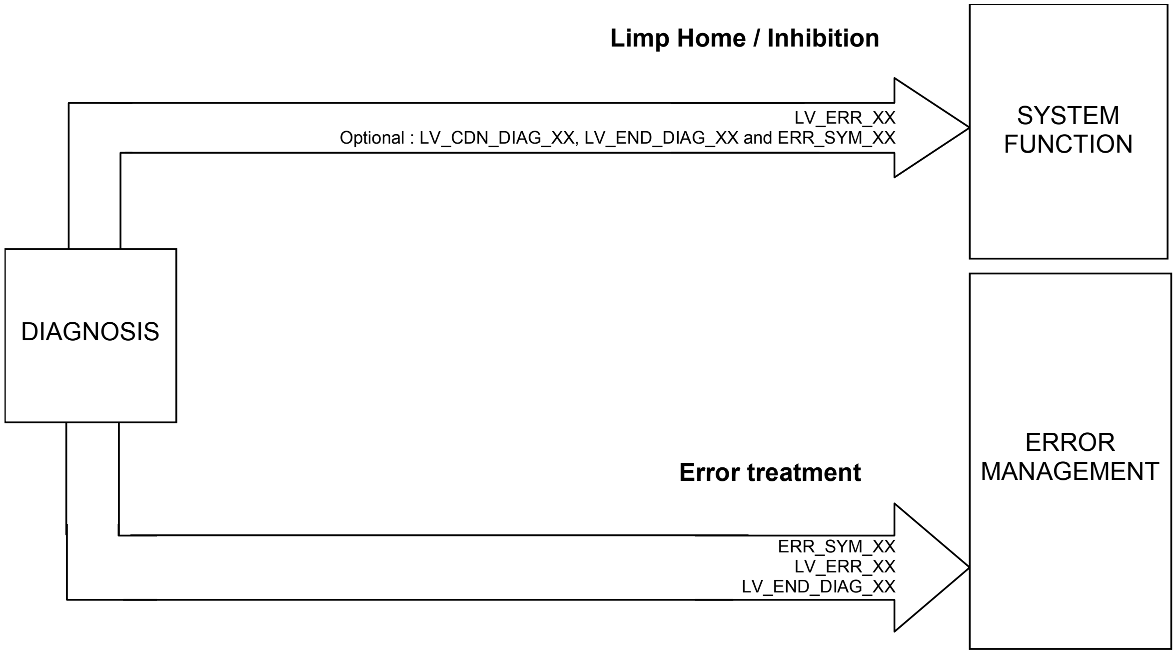
Filter choice selection : according to the diagnostic filtering configuration the filtering algorithm used is the anti-bounce filtering (NLC_ABC_STC_XX = 0) or the standard statistical filtering (NLC_ABC_STC_XX=1)

Signal flow diagram :

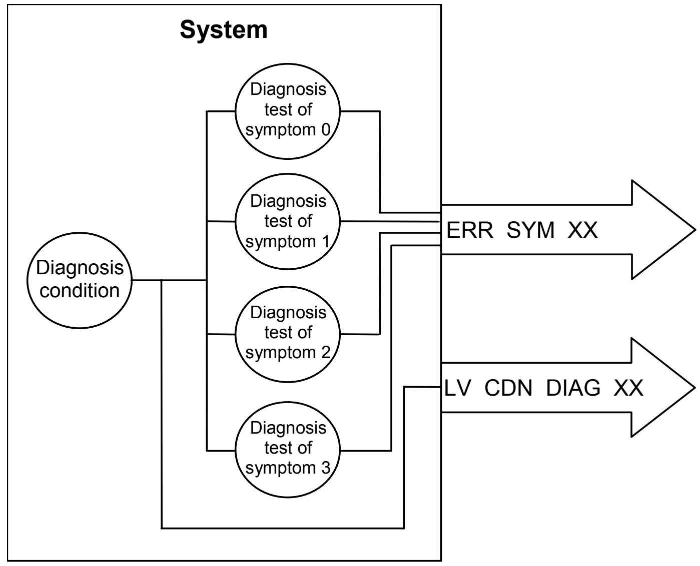
Diagnosis with an anti-bounce algorithm :



Diagnosis without anti-bounce algorithm :



The symptoms are evaluated when diagnosis conditions are fulfilled :



A.2.1 Initialisation of anti-bounce, statistical and multi-conditions filters

This paragraph is dedicated to the initialisation of main data, at the following events:

- ECU reset
- LV_IGK 0 → 1 transition before the end of the power-latch phase
- LV_DC 1 → 0 transition

A.2.1.1 At ECU reset

Management of NVMY

```
If      NVMY not corrupted and not first ECU power-up
Then
        CTR_ABC_ XX is restored from NVMY
        LV_ERR_XX is restored from NVMY
        ERR_SYM_XX is restored from NVMY
Else
        CTR_ABC_ XX = 0
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif

LV_CDN_DIAG_XX = 0
CTR_ABC_END_DIAG_XX = 0
LV_END_DIAG_XX = 0

If      NLC_ABC_NOT_SAVE_XX = 1
Then
        { case of STD_INI, MEM and STC configurations }
        CTR_ABC_XX = 0
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif
```

Configuration evaluation

```
If      NLC_ABC_INI_VALUE_XX = 1
Then
        { case of MEM_INI configuration }
        If      LV_ERR_XX = 1
        Then
                CTR_ABC_XX = C_ABC_MAX_XX - C_ABC_INC_XX
        Else
                CTR_ABC_XX = 0
        Endif
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif
```

A.2.1.2 At LV_IGK 0 → 1 transition, without ECU reset

```
If      NLC_ABC_NOT_SAVE_XX = 1 and NLC_ABC_INI_IGK_XX = 1
Then
        CTR_ABC_ XX = 0
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif

LV_CDN_DIAG_XX = 0

If      NLC_ABC_NOT_SAVE_XX = 0
        and NLC_ABC_INI_VALUE_XX = 1
        and NLC_ABC_INI_IGK_XX = 1
Then
        { case of MEM_INI configuration }
        If      LV_ERR_XX = 1
        Then
                CTR_ABC_XX = C_ABC_MAX_XX - C_ABC_INC_XX
        Else
                CTR_ABC_XX = 0
        Endif
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif

If      NLC_ABC_INI_DC_END_DIAG = 0
Then
        CTR_ABC_END_DIAG_XX = 0
        LV_END_DIAG_XX = 0
Endif
```

A.2.1.3 At LV_DC 1 → 0 transition

```
If      NLC_ABC_INI_DC_END_DIAG = 1
Then
        CTR_ABC_END_DIAG_XX = 0
        LV_END_DIAG_XX = 0
Endif

If      LV_ERR_XX = 0 and NLC_ABC_INI_VALUE_XX = 0
Then
        { all cases excepted MEM_INI configuration }
        CTR_ABC_XX = 0
        ERR_SYM_XX = 0
Endif
```

A.2.2 Recurrence

The recurrence is always managed by the diagnosis recurrence.

A.2.3 Filtering algorithm description

A.2.3.1 Description:

Syntax : ACTION_ERRM_FilterSymptom(IN<XX>, IN<lv_cdn_diag_XX>, IN< err_sym_xx>, IN<C_ABC_INC_XX>, IN<C_ABC_DEC_XX>,IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)

Parameter(in) :	XX	Type: index to identify the Diagnostic
	lv_cdn_diag_XX	Type: Diagnostic condition
	err_sym_XX	Status of failure
	C_ABC_INC_XX	Anti-bounce counter increment
	C_ABC_DEC_XX	Anti-bounce counter decrement
	C_ABC_MAX_XX	Maximum value of anti-bounce counter
Parameter(out) :	LV_ERR_XX	Type: Boolean (=1 when failure)

Short Description : This action returns the filter result on symptoms detected at each diagnostic recurrence

A.2.3.2 Antibounce algorithm filtering type

A.2.3.2.1 Calculation of the anti-bounce counter

Description:

Anti-bounce operation:

If the system failure is detected and the diagnosis conditions are fulfilled (LV_CDN_DIAG_XX = 1) then the failure is detected (ERR_SYM_XX ≠ 0) and the anti-bounce counter is incremented. In this case an action is called to manage some functionality (eg : to visualise the sporadic error of all diagnosis using this anti-bounce algorithm).

If the system failure isn't detected and the diagnosis conditions are fulfilled (LV_CDN_DIAG_XX = 1) then the failure isn't detected (ERR_SYM_XX = 0) and the anti-bounce counter is decremented.

If the diagnosis conditions aren't fulfilled (LV_CDN_DIAG_XX = 0) then the detected failure is unchanged ($ERR\_SYM\_XX_{(N)} = ERR\_SYM\_XX_{(N-1)}$) and the anti-bounce counter is unchanged.

The present failure is set when the anti-bounce counter has reached its MAX (unequal to zero).

The configuration allows:

- to save or not the present failure and the anti-bounce counter
- to initialise or not the present failure and the anti-bounce counter at transition LV_IGK 0 → 1
- to manage the decrement of the anti-bounce counter or not (the anti-bounce counter remains at the maximum value)
- to calibrate or not the decrement of the anti-bounce counter.

Anti-bounce bench mode:

To make easier the development phase, it may be interesting to force the LV_ERR_XX flag (present failure) and the associated symptoms in order to free the diagnosis and to test only the error management and/or the application incidence (limp home or inhibition) associated to the present failure. This mode is active only if the LC_ABC_BENCH and NLC_BENCH_MODE flags are set.

To set LV_ERR_XX to one and ERR_SYM_XX = FH (all detected error symptoms) :

Set the C_ABC_INC_XX calibration to the maximum value (FFH).

To set LV_ERR_XX to zero and ERR_SYM_XX = 0 (no detected error symptom) :

Set the C_ABC_INC_XX calibration to zero.

Note:

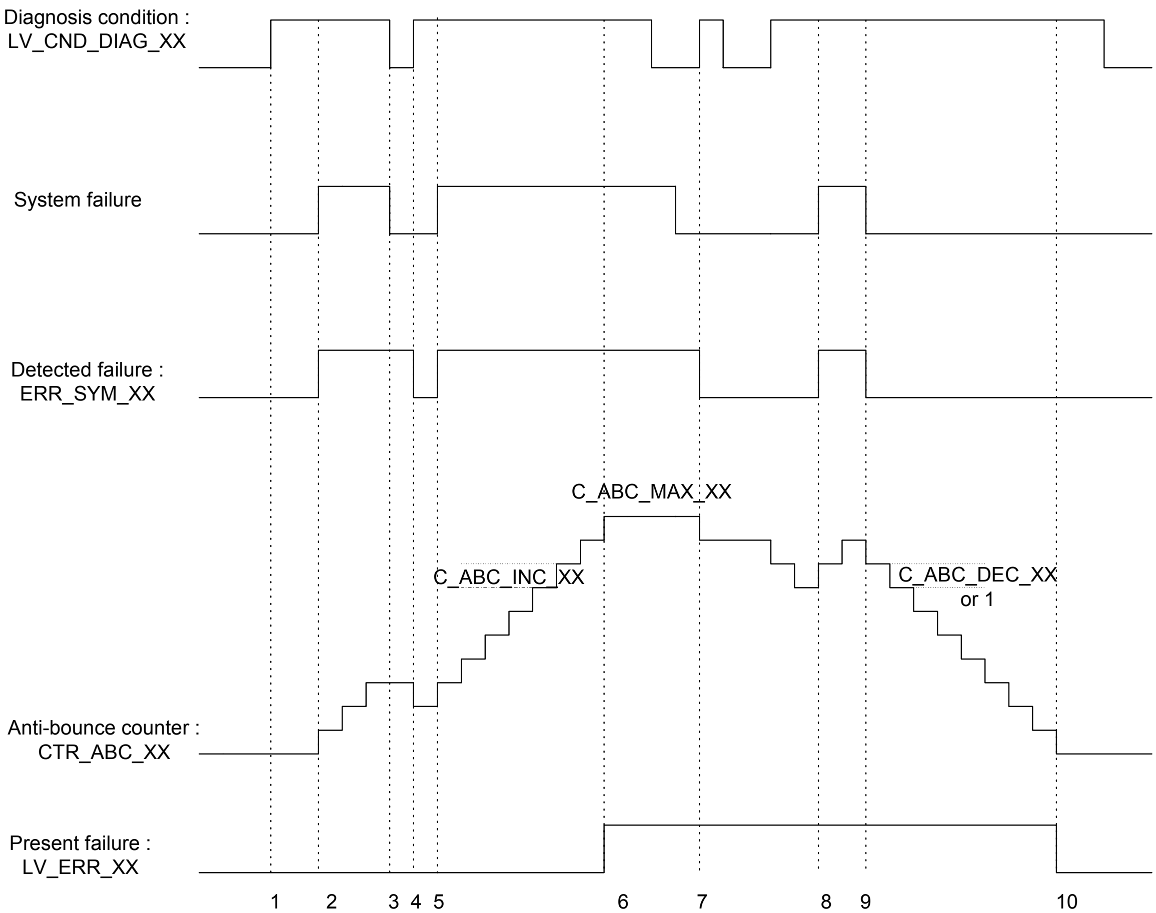
In this mode, the diagnosis condition (LV_CDN_DIAG_XX) and the end of diagnosis (LV_END_DIAG_XX) are set to 1 (LV_CDN_DIAG_XX = 1 means the ERR_SYM_XX is valid and LV_END_DIAG_XX = 1 means the LV_ERR_XX flag is valid).

Anti-bounce inhibition:

For specific needs, the anti-bounce filtering calculation (anti-bounce operation and anti-bounce bench mode) may be inhibited, with LV_ABC_INH inhibition flag.

Signal flow diagram:

1 -The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0):



1: The diagnosis conditions are fulfilled but the failure isn't detected
LV_CDN_DIAG_XX = 1,
ERR_SYM_XX = 0.

➔ CTR_ABC_XX remains at the value 0.
LV_ERR_XX = 0.

2: The diagnosis conditions are fulfilled and the failure is detected.
LV_CDN_DIAG_XX = 1,
ERR_SYM_XX <> 0.

➔ CTR_ABC_XX = 0 + C_ABC_INC_XX
LV_ERR_XX = 0.

3: The diagnosis conditions aren't fulfilled
and the failure remains detected. → CTR_ABC_XX is frozen
LV_CDN_DIAG_XX = 0, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

.

4: The diagnosis conditions are fulfilled again
and the failure is no more detected. → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 0.

5: The diagnosis conditions are still fulfilled
and the failure is detected again → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 0.

6: The diagnosis conditions are still fulfilled,
the failure is still detected
and the failure becomes present. → CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

7: The diagnosis conditions are fulfilled,
the failure isn't detected
and the failure remains present. → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 1.

8: The diagnosis conditions are still fulfilled,
the failure is detected again
and the failure remains present. → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 1.

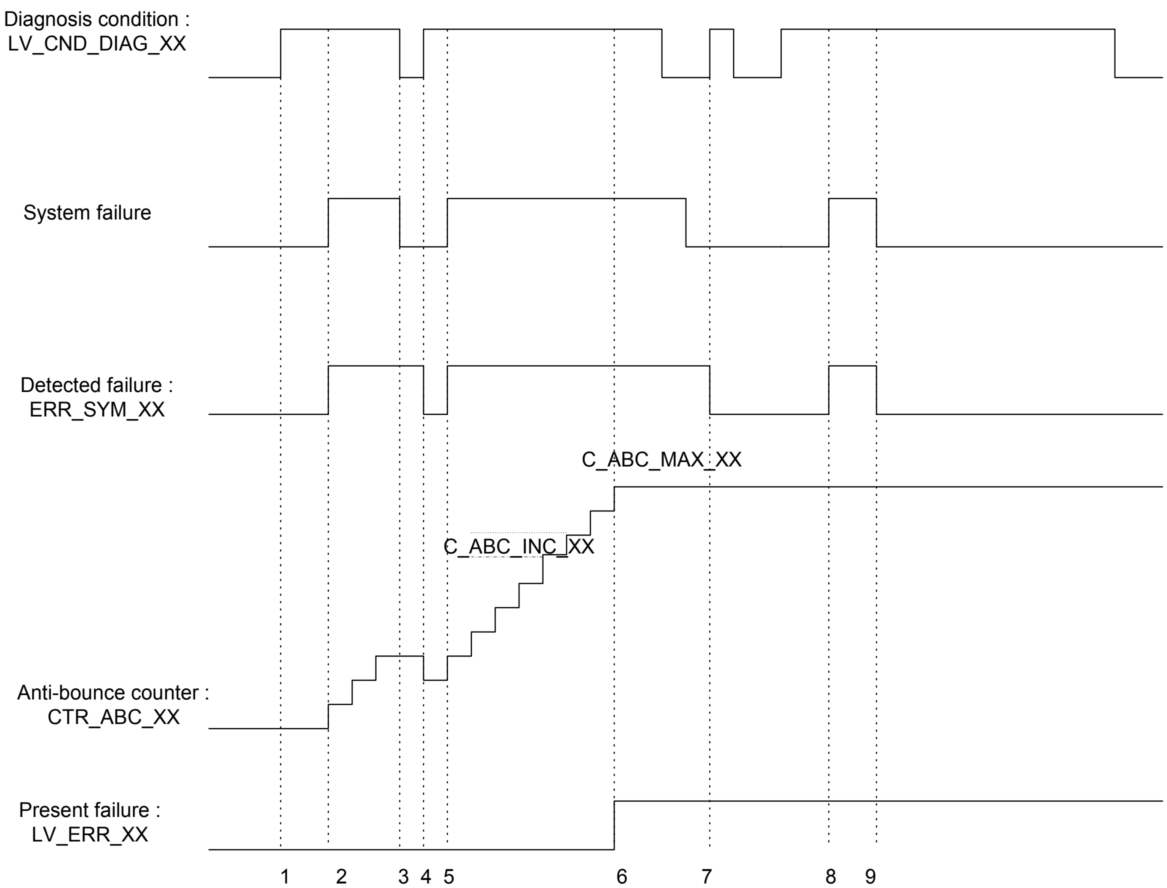
9: The diagnosis conditions are still fulfilled,
the failure isn't detected
and the failure remains present. ➔ CTR_ABC_XX = CTR_ABC_XX – decrement
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX = 0.

10: The diagnosis conditions are still fulfilled,
the failure isn't detected
and the failure is no more present. ➔ CTR_ABC_XX = 0
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX = 0.

Remark

- Decrement value = 1 if NLC_ABC_CAL_DEC_XX bit = 0
- Decrement value = C_ABC_DEC_XX if NLC_ABC_CAL_DEC_XX bit = 1.

2-The anti-bounce counter isn't decremented (NLC_ABC_NOT_DEC_XX = 1):



1: The diagnosis conditions are fulfilled but the failure isn't detected
LV_CDN_DIAG_XX = 1,
ERR_SYM_XX = 0.
➔ CTR_ABC_XX remains at the value 0.
LV_ERR_XX = 0.

2: The diagnosis conditions are fulfilled and the failure is detected.
LV_CDN_DIAG_XX = 1,
ERR_SYM_XX <> 0.
➔ CTR_ABC_XX = 0 + C_ABC_INC_XX
LV_ERR_XX = 0.

3: The diagnosis conditions aren't fulfilled
and the failure remains detected. → CTR_ABC_XX is frozen
LV_CDN_DIAG_XX = 0, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

4: The diagnosis conditions are fulfilled again
and the failure is no more detected. → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 0.

5: The diagnosis conditions are still fulfilled
and the failure is detected again → CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 0.

6: The diagnosis conditions are still fulfilled,
the failure is still detected
and the failure becomes present. → CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

7: The diagnosis conditions are fulfilled,
the failure isn't detected
and the failure remains present. → CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, (counter not decrement)
ERR_SYM_XX = 0. LV_ERR_XX = 1.

.

8: The diagnosis conditions are still fulfilled,
the failure is detected again
and the failure remains present. → CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

.

.9: The diagnosis conditions are still fulfilled,
the failure isn't detected
and the failure remains present. ➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, (counter not decrement)
ERR_SYM_XX = 0. LV_ERR_XX = 1.

Remark

- Decrement value = 1 if NLC_ABC_CAL_DEC_XX bit = 0
- Decrement value = C_ABC_DEC_XX if NLC_ABC_CAL_DEC_XX bit = 1.

Application conditions:

Initialization: See "Initialisation of anti-bounce, statistical and multi-conditions filters" paragraph

Recurrence: The recurrence is managed by the diagnosis.

Activation: The activation is managed by the diagnosis for the anti-bounce operation or the anti-bounce bench mode.

Deactivation: LV_ABC_INH = 1

Formula section:

Anti-bounce bench mode :

If(1) (LC_ABC_BENCH = 1 **and** NLC_BENCH_MODE=1) **and** ((C_ABC_INC_XX = 0) **or** (C_ABC_INC_XX = FFH))

        Endif(1b)
    Endif(1a)
```

A.2.3.2.2 Calculation of the end of diagnosis

Description:

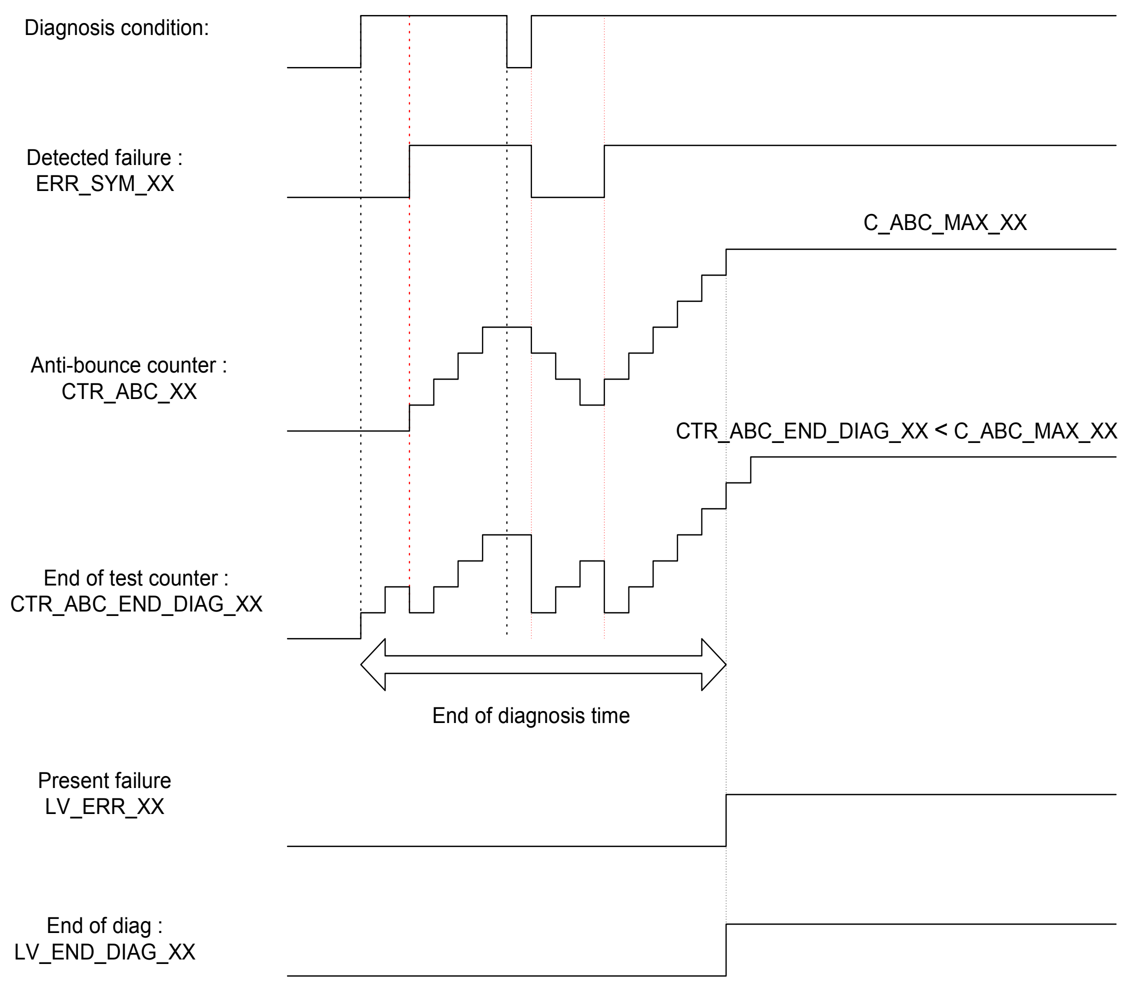
The end of diagnosis definition is set after a time defined like being the time necessary to evaluate the failure (present or not).

Signal flow diagram:

End of diagnosis algorithm illustration in standard case :

The end of diagnosis counter is reset at each transition of the detected failure.

When the failure becomes present : the end of diagnosis is set.

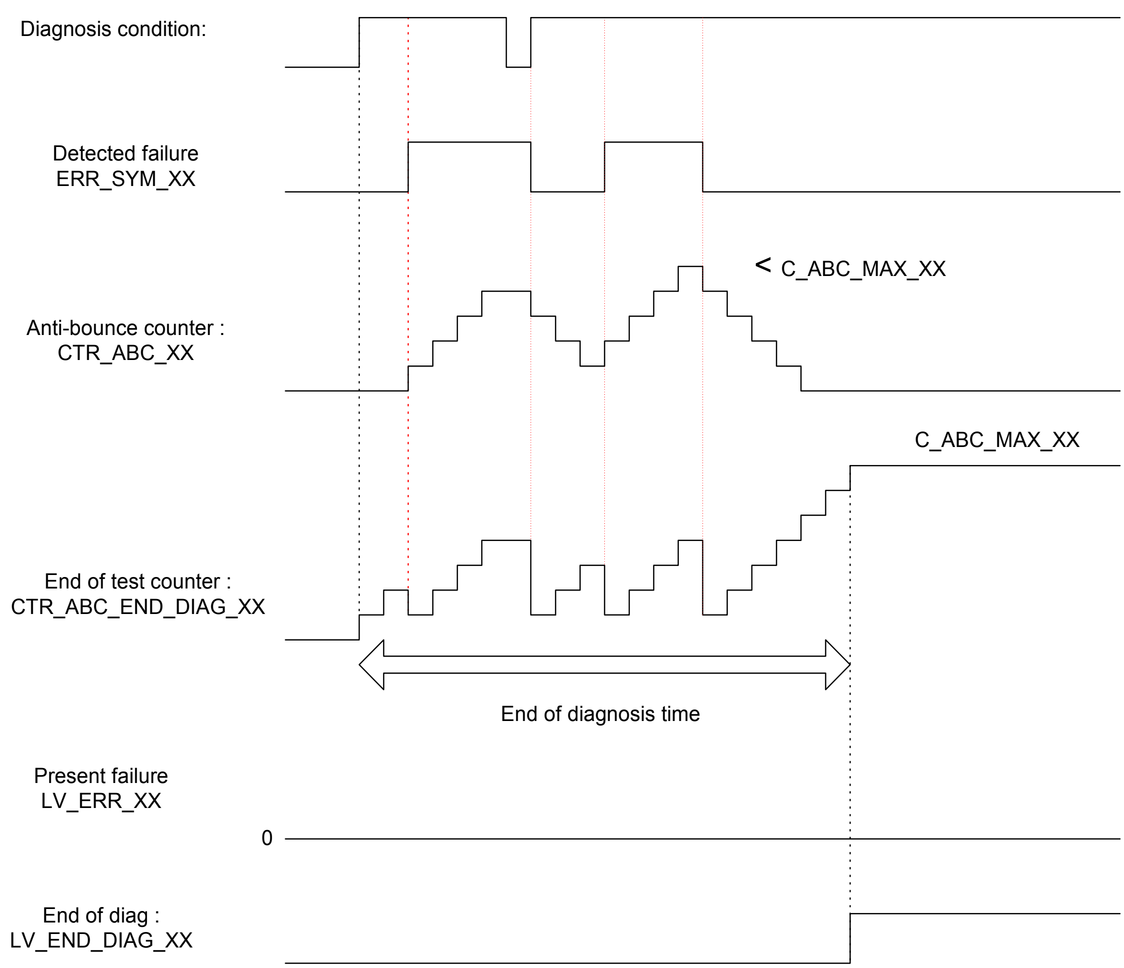


The detected failure will disappear and the anti-bounce counter won't reach the maximum value then the failure won't become present.

The end of diagnosis counter is reset at each transition of the detected failure.

When the detected failure is stable : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

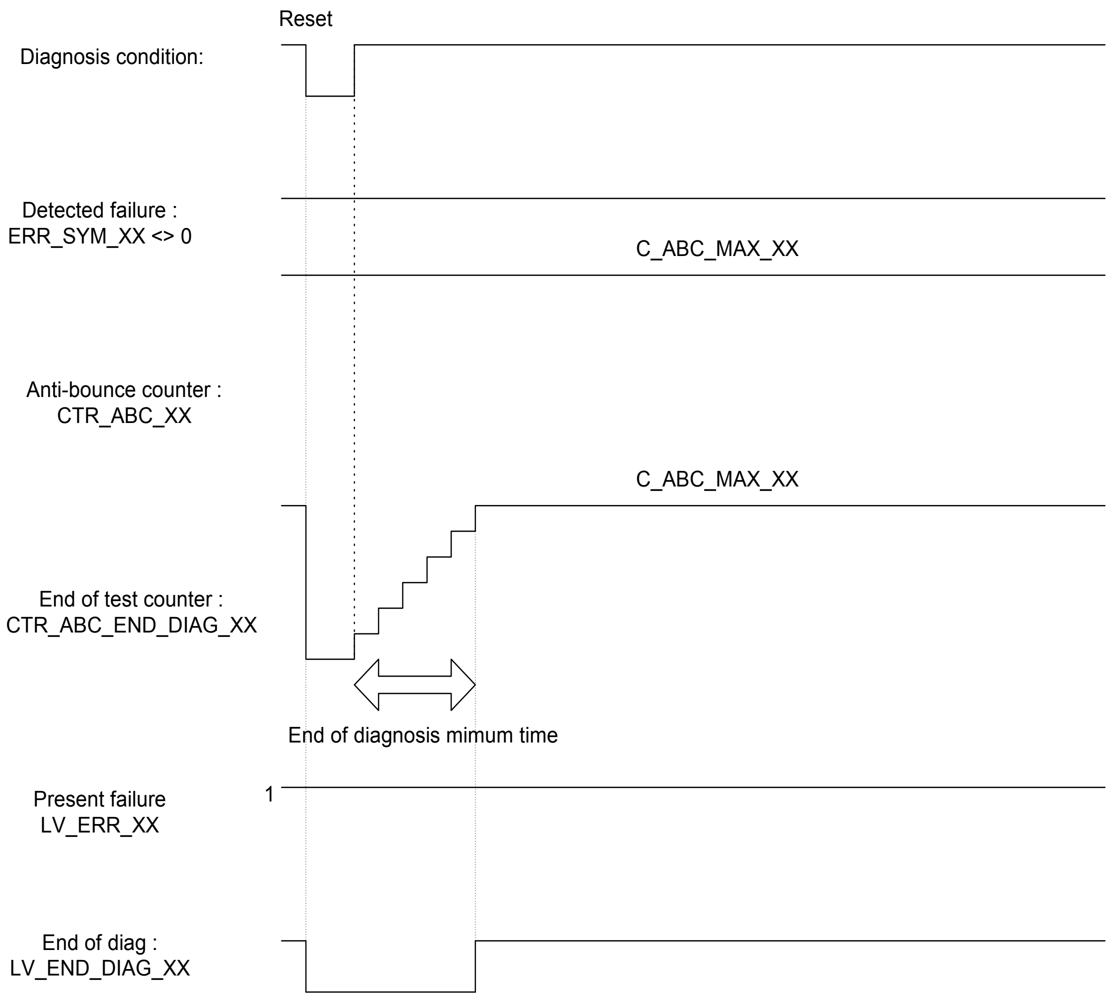


End of diagnosis algorithm illustration in case of reset event :

After the reset event, the detected failure remains present (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

The failure has been present and remains present after reset.



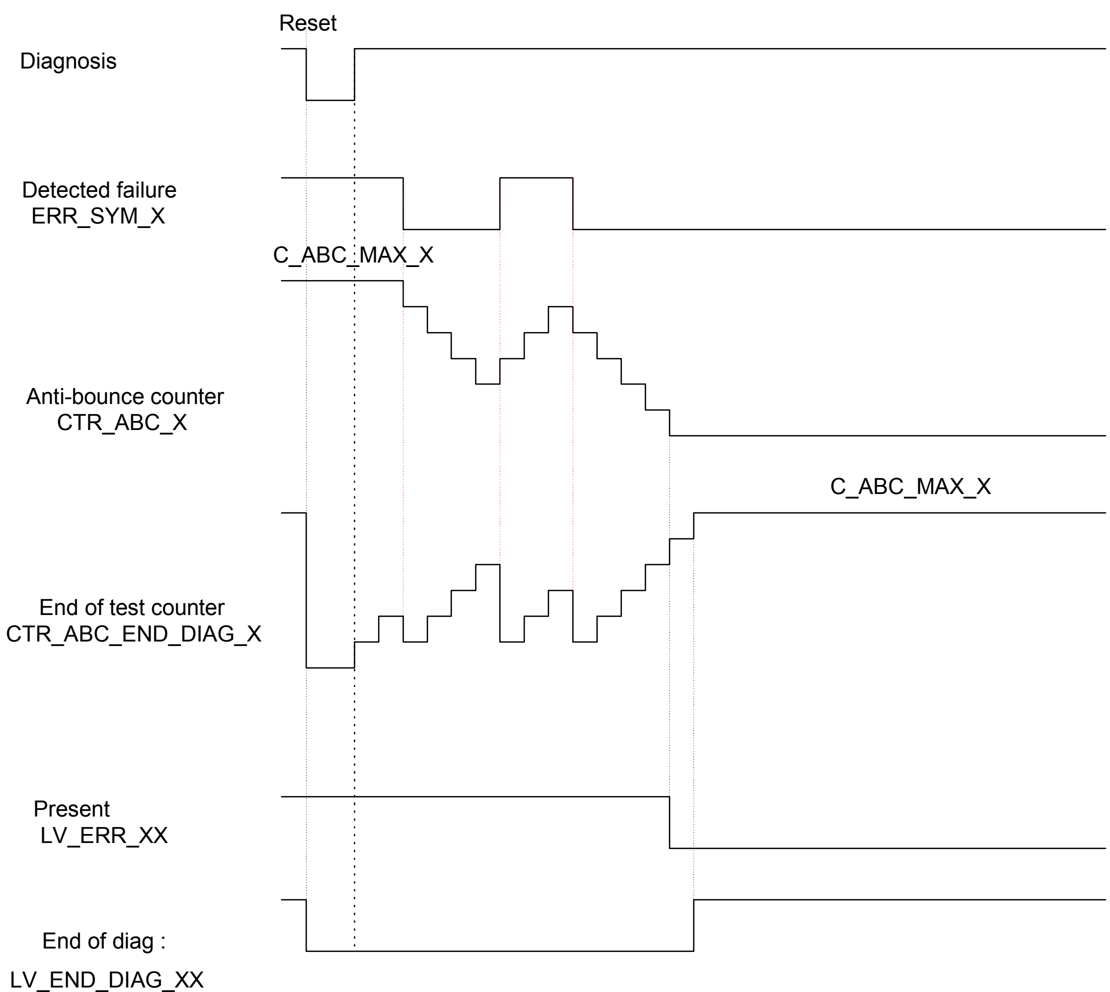
Before the reset, the failure was detected until the failure became present.

After the reset, the detected failure appears during a glitch so the end of diagnosis counter is reset at each transition of the detected failure,

When the detected failure disappears after all (stable) then

- the present failure disappears
- the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

  When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

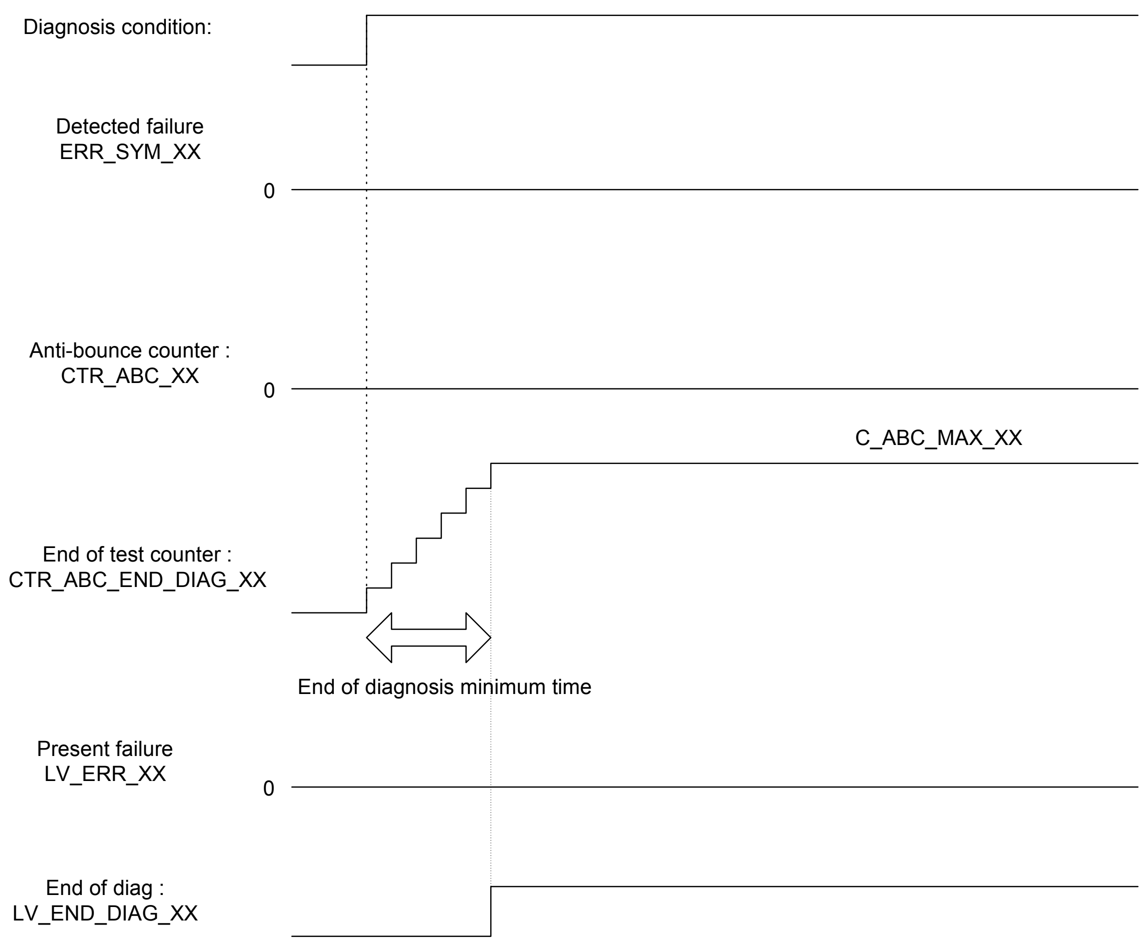


End of diagnosis algorithm illustration when the time to reach the end of diagnosis is minimum

The failure isn't detected (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

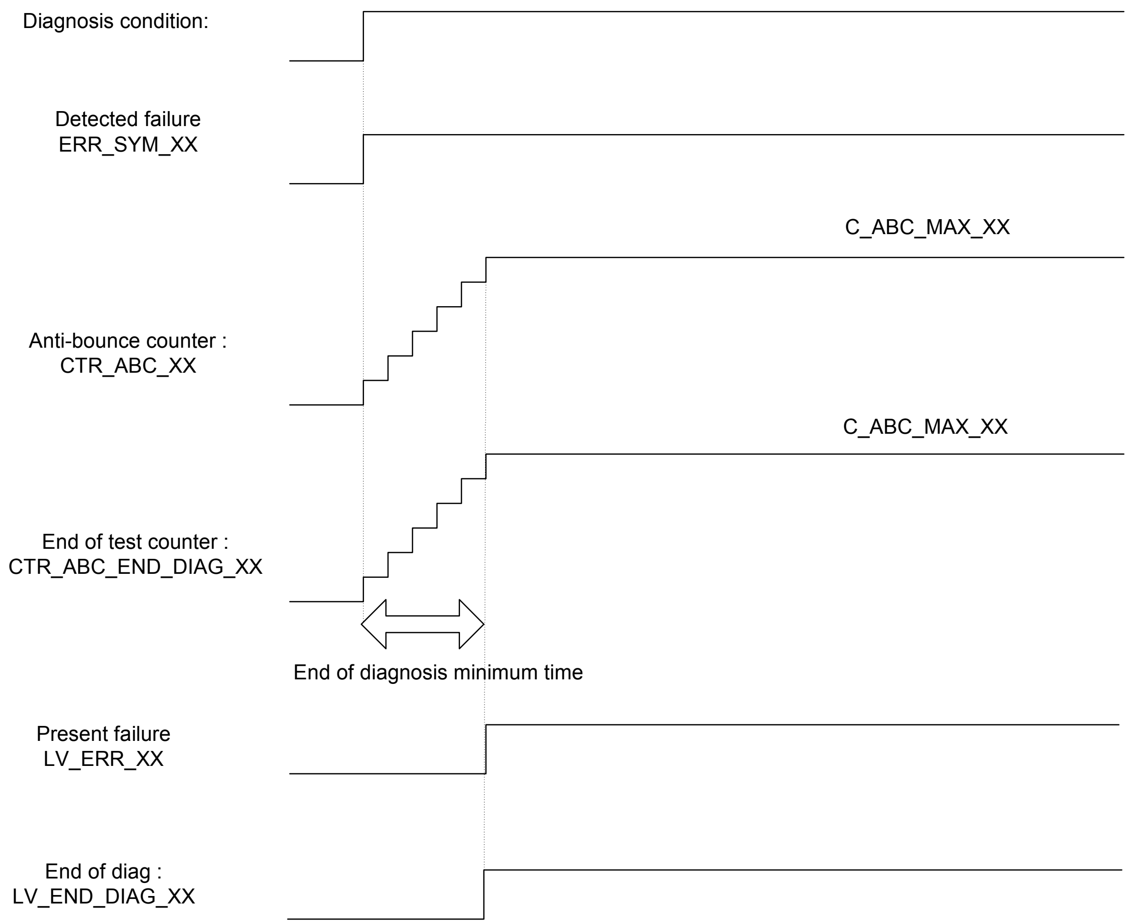
The end of diagnosis appears after the minimum time (the detected failure doesn't appear).



The failure is detected unchangingly (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the failure becomes present : the end of diagnosis is set.

The end of diagnosis and the failure appears after the minimum time (the detected failure is permanent).



Application conditions:

Initialization: See "Initialisation of anti-bounce, statistical and multi-conditions filters" paragraph

Recurrence: The recurrence is managed by the diagnosis.

Activation: The activation is managed by the diagnosis for the anti-bounce operation or the anti-bounce bench mode.

Deactivation: -

Formula section:

If(0) LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*

Then(0)

End of diagnosis in the bench mode:

If(1) (LC_ABC_BENCH = 1 **and** NLC_BENCH_MODE=1) **and** ((C_ABC_INC_XX = 0) **or** (C_ABC_INC_XX = FFH))

Endif(1)

Else(0)

{Inhibition of anti-bounce filtering}

If(1) (LV_CDN_DIAG_XX = 1
or
((LC_ABC_BENCH = 1 **and** NLC_BENCH_MODE=1)
and (C_ABC_INC_XX = 0) **or** (C_ABC_INC_XX = FFH))

Then(1)

{ERR_SYM_PREV_XX is updated at each diagnosis recurrence even during the inhibition, so that when the inhibition is removed ERR_SYM_PREV_XX is updated with the value calculated at the last diagnosis recurrence of the inhibition phase.}

ERR_SYM_PREV_XX = ERR_SYM_XX

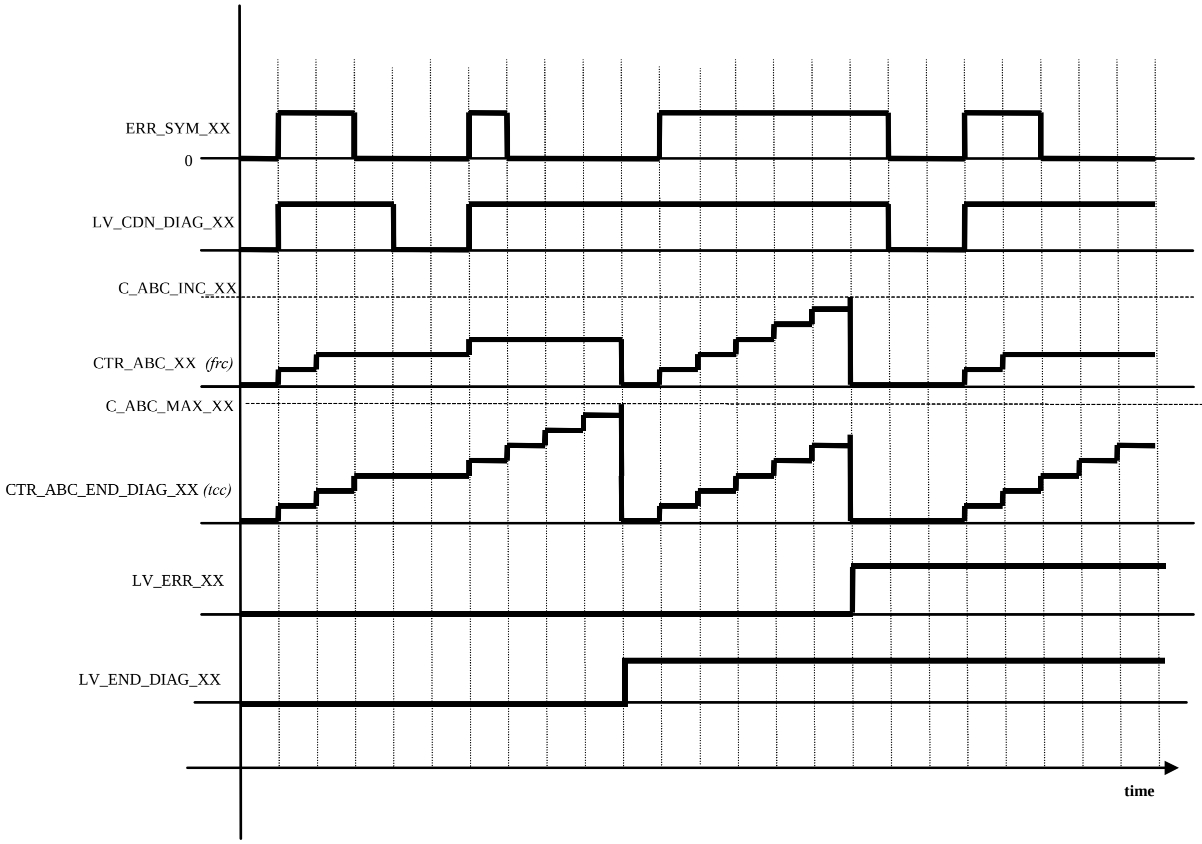
Endif(1)

Endif(0)

A.2.3.3 Standard statistical filtering type

General information:

The purpose is to make an error detection by statistical evaluation.
An error is only detected, if a symptom is active for C_ABC_INC_XX times within the test period C_ABC_MAX XX, with test symptom condition fulfilled (LV_CDN_DIAG_XX = 1).



In this chapter,

- the data CTR_ABC_XX represents the frequency counter
- the calibration C_ABC_INC_XX represents the maximum for frequency counter of the processed symptom
- the data CTR_ABC_END_DIAG_XX represents the period counter increment
- the calibration C_ABC_MAX_XX represents the maximum for test counter of the processed symptom

The calibration C_ABC_MAX_XX must be greater than C_ABC_INC_XX.

Formula section:

Anti-bounce in the bench mode :

```
If      (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1)
        and
        ((C_ABC_INC_XX = 0) or (C_ABC_INC_XX = FFH))
Then
        If      C_ABC_INC_XX = 0
        Then
                ERR_SYM_XX = 0
                LV_ERR_XX = 0
                CTR_ABC_XX = 0
        Else
                If      C_ABC_INC_XX = FFH
                Then
                        ERR_SYM_XX = 0FH
                        LV_ERR_XX = 1
                        CTR_ABC_XX = C_ABC_INC_XX
                Endif
        Endif
Endif
```

Frequency counter increment:

If LV_CDN_DIAG_XX = 1
and ERR_SYM_XX ≠ 0
and C_ABC_INC_XX ≠ 0
Then
  If NC_ERR_DET_UPD = 1
  and LC_ERR_DET_UPD = 1
  Then
   ACTION_ERRM_UpdErrDet(IN<XX>, SYNCHRONIZATION<CALL>)
  Endif
  CTR_ABC_XX = CTR_ABC_XX + 1
Endif

Period counter increment:

If LV_CDN_DIAG_XX = 1
Then
  CTR_ABC_END_DIAG_XX = CTR_ABC_END_DIAG_XX + 1
Endif

Detection of the error state for the current symptom:

If CTR_ABC_XX >= C_ABC_INC_XX
Then
  LV_ERR_XX = 1
  { The current symptom is entered to failure memory }
Endif

Detection of the error free symptom:

If CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
and CTR_ABC_XX < C_ABC_INC_XX
Then
  LV_ERR_XX = 0
Endif

End of the diagnostic period for statistic symptom:

If CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
or CTR_ABC_XX = C_ABC_INC_XX
Then
  CTR_ABC_XX = 0
  CTR_ABC_END_DIAG_XX = 0
  { End of diagnostic period for statistic symptom is reached }
  LV_END_DIAG_XX=1
Endif

A.2.4 Description for ACTION_ERRM_NoFilterSymptom :

Syntax :	ACTION_ERRM_NoFilterSymptom(IN<XX>, IN<lv_cdn_diag_XX>, IN<err_sym_XX>, IN<lv_err_set_XX>, IN<lv_err_reset_XX>, IN<lv_end_diag_XX>, OUT<LV_ERR_XX>)	
Parameter(in) :	XX	Type: index to identify the Diagnostic
	lv_cdn_diag_XX	Type: Diagnostic condition
	err_sym_XX	Status of failure
	lv_err_set_XX	Type: Boolean to set the failure
	lv_err_reset_XX	Type: Boolean to reset the failure
	lv_end_diag_XX	Type: Boolean (=1 when result available)
Parameter(out) :	LV_ERR_XX	Type: Boolean (=1 when failure)
Short Description :	This action returns the result on symptoms detected at each diagnostic recurrence, when no filter is used.	

A.2.5 System Description:

This action is used in case of diagnostics which don’t need any filtering will use the “NO type” filter.

LV_ERR_XX is managed as a **STD** anti-bounce filtering type (saved in NVMY at end of power latch, ...).

LV_END_DIAG_XX is managed by error management (reset at DC transition, ...).
ERR_SYM_XX is updated at each diagnostic recurrence, to fulfil the diagnostic result.

Formula section :

If LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*
Then

    If lv_end_diag_XX = 1
    Then
        LV_END_DIAG_XX = 1
    Endif

    If lv_err_set_XX = 1
    Then
        LV_ERR_XX = 1
    Endif

    If lv_err_reset_XX = 1
    Then
        LV_ERR_XX = 0
    Endif

    If lv_cdn_diag_XX =1

Then

LV_CDN_DIAG_XX = 1
ERR_SYM_XX = err_sym_xx

Else

LV_CDN_DIAG_XX = 0
{ ERR_SYM_XX is unchanged }

Endif

Endif

A.2.6 Description for ACTION_ERRM_AbcFilterSymptomEnd:

Syntax:	ACTION_ERRM_AbcFilterSymptomEnd(	IN<XX>, IN< C_ABC_MAX_XX>, OUT< LV_ERR_XX >)
Parameter(in):	XX	Type: index to identify the Diagnostic
	C_ABC_MAX_XX	Maximum value of anti-bounce counter
Parameter(out):	LV_ERR_XX	Type: Boolean

Short Description: This action erases diagnostic failure and sets immediately the end of diagnostic information in case of anti-bounce filter (STD, STD_INI, STC, MEM and MEM_INI)

Formula section :

If LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*
Then

LV_CDN_DIAG_XX = 1
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX = 1
CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX

Endif

A.2.7 Description for ACTION_ERRM_NoFilterSymptomEnd:

Syntax:	ACTION_ERRM_NoFilterSymptomEnd(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean

Short Description: This action erases diagnostic failure and sets immediately the end of diagnostic information in case of no filter (NO)

Formula section :

If LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*
Then

LV_CDN_DIAG_XX = 1
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0

LV_END_DIAG_XX = 1
Endif

A.2.8 Description for ACTION_ERRM_AbcFilterReset:

Syntax: ACTION_ERRM_AbcFilterReset(IN<XX>, OUT<LV_ERR_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_ERR_XX Type: Boolean

Short Description: This action resets data filter in case of ABC filter type

Formula section :

If LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*

Then

LV_CDN_DIAG_XX = 0
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX is unchanged
CTR_ABC_END_DIAG_XX is unchanged

Endif

A.2.9 Description for ACTION_ERRM_NoFilterReset:

Syntax: ACTION_ERRM_NoFilterReset(IN<XX>, OUT<LV_ERR_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_ERR_XX Type: Boolean

Short Description: This action resets data filter in case of no filter usage

Formula section :

If LV_ABC_INH = 0 *{No inhibition of anti-bounce filtering}*

Then

LV_CDN_DIAG_XX = 0
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
LV_END_DIAG_XX is unchanged

Endif

A.2.10 Description for ACTION_ERRM_GetLvErr:

Syntax: ACTION_ERRM_GetLvErr(IN<XX>, OUT<LV_ERR_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_ERR_XX Type: Boolean

Short Description: This action returns the failure status for the diagnostic XX.

Formula section :

LV_ERR_XX = failure status for the diagnostic XX

A.2.11 Description for ACTION_ERRM_GetLvEndDiag:

Syntax: ACTION_ERRM_GetLvEndDiag(IN<XX>, OUT<LV_END_DIAG_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_END_DIAG_XX Type: Boolean

Short Description: This action returns the end of diagnostic flag for the diagnostic XX.

Formula section :

LV_END_DIAG_XX = end of diagnostic flag for the diagnostic XX

A.2.12 Description for ACTION_ERRM_GetLvCdnDiag:

Syntax: ACTION_ERRM_GetLvCdnDiag(IN<XX>, OUT<LV_CDN_DIAG_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_CDN_DIAG_XX Type: Boolean

Short Description: This action returns the condition status for the diagnostic XX.

Formula section :

LV_CDN_DIAG_XX = condition status for the diagnostic XX

A.2.13 Description for ACTION_ERRM_GetErrSym:

Syntax: ACTION_ERRM_GetErrSym(IN<XX>, OUT<ERR_SYM_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): ERR_SYM_XX Status of failure

Short Description: This action returns the symptoms for the diagnostic XX.

Formula section :

ERR_SYM_XX = symptoms for the diagnostic XX

A.2.14 CPU load optimisation mechanisms

General information:

This section describes the mechanism of optimisation. The principle is to suspend the filter algorithm execution when it is not necessary.

Formula section:

If NLC_BENCH_MODE = 0
Then
{ the bench mode isn't available whatever LC_ABC_BENCH value }
the CPU load is reduced
Else
{ the bench mode is available if LC_ABC_BENCH = 1 }
less CPU load reduction than with NLC_BENCH_MODE = 0
Endif

Case 1 : the diagnostic uses an anti-bounce filtering algorithm

If LV_ERR_XX = 0
and LV_END_DIAG_XX = 1
and ERR_SYM_XX = 0
and CTR_ABC_XX = 0
Then
{ it is not necessary to call the Error Management (including the filtering) }
LV_END_DIAG_XX = 1 *{ unchanged }*
LV_ERR_XX = 0 *{ unchanged }*
Endif

Case 2 : the diagnostic doesn't use an anti-bounce filtering algorithm

If (LV_ERR_XX = 0 **and** LV_END_DIAG_XX = 1 **and** ERR_SYM_XX = 0)
Then
{ it is not necessary to call the Error Management }
LV_END_DIAG_XX = 1 *{ unchanged }*
LV_ERR_XX = 0 *{ unchanged }*
Endif

A.2.15 Synchronisation between Anti-bounce algorithm and Error Management

General information:

This section describes the mechanism of synchronisation of the failure filtering with the Error Management core. The principle is to call the Error Management upon events.

LV_END_DIAG_XX 0 → 1 transition

LV_ERR_XX 0 → 1 transition

LV_ERR_XX 1 → 0 transition

This mechanism is followed whatever the filter (type STD, STD_INI, DEC_CAL, MEM, MEM_INI, STC) but also for diagnoses which don't use any filter (type NO).

A.2.16 Configuration and calibration data

NC_ABC_CONF_FCT_DIAG_XX :

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 | | | | | | | └─>  bit 0 : NLC_ABC_NOT_SAVE_XX
 | | | | | | └───>  bit 1 : NLC_ABC_INI_IGK_XX
 | | | | | └─────>  bit 2 : NLC_ABC_INI_VALUE_XX
 | | | | └───────>  bit 3 : NLC_ABC_NOT_DEC_XX
 | | | └─────────>  bit 4 : NLC_ABC_CAL_DEC_XX
 | | └───────────>  bit 5 : NLC_ABC_STC_XX
 | └─────────────>  bit 6 : Not used
 └───────────────>  bit 7 : Not used
```

Bits definition

- NLC_ABC_NOT_SAVE_XX : if this bit is set to 0 the anti-bounce context (CTR_ABC_XX and LV_ERR_XX) is saved at the end of power latch, only when the failure is in dynamic memory, and restored at the event Reset.
Limitation : the saved configuration is only available if the NVMY manager take into account the filter environment data (LV_ERR_XX, CTR_ABC_XX).

- NLC_ABC_INI_IGK_XX : LV_ERR_XX and CTR_ABC_XX are reset at the transition LV_IGK 0 -> 1 and at the event reset.

- NLC_ABC_INI_VALUE_XX : if this bit is set to 1 then the anti-bounce counter is initialised with C_ABC_MAX_XX – C_ABC_INC_XX if there was a failure between the last and this initialisation (NLC_ABC_NOT_SAVE_XX = 0 to test the failure before this initialisation) else the anti-bounce counter is initialised with 0 value.

- NLC_ABC_NOT_DEC_XX : if this bit is set to 0 then the anti-bounce counter can be decremented if the condition for decrement are fulfilled. If this bit is set to 1 then the anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains (the anti-bounce counter can be decremented anymore) until a transition LV_IGK 0 → 1 or reset following the NLC_ABC_INI_IGK_XX bit configuration (If the NLC_ABC_NOT_DEC_XX bit is set to 1 then NLC_ABC_NOT_SAVE_XX must be set to 1).

- NLC_ABC_CAL_DEC_XX : if this bit is set then the anti-bounce decrement is calibratable, the calibration is named C_ABC_DEC_XX else the anti-bounce decrement is equal to 1 and there isn't calibration.

- NLC_ABC_STC_XX : if this bit is set then the filter used is the statistical filter else the filter used is the anti-bounce filter (Standard configuration).

Predefined filter type :

	NLC_ABC_STC_XX	NLC_ABC_CAL_DEC_XX	NLC_ABC_NOT_DEC_XX	NLC_ABC_INI_VALUE_XX	NLC_ABC_INI_IGK_XX	NLC_ABC_NOT_SAVE_XX
STD_INI	0	0	0	0	1	1
STD	0	0	0	0	0	0
MEM	0	0	1	0	1	1
MEM_INI	0	0	1	1	1	0
DEC_CAL	0	1	0	0	0	0
STC	1	0	0	0	1	1
NO	0	0	0	0	0	0

The **standard configuration with initialisation (STD_INI)** is
NC_ABC_CONF_FCT_DIAG_XX = 3H (default configuration)

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0).
The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).
The filter used is the Anti-bounce (NLC_ABC_STC_XX = 0).

The **statistical configuration (STC)** is NC_ABC_CONF_FCT_DIAG_XX = 23H

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the frequency counter (CTR_ABC_XX) is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The filter used is the statistical (NLC_ABC_STC_XX = 1).

The **standard configuration (STD)** is NC_ABC_CONF_FCT_DIAG_XX = 0H

The data CTR_ABC_XX and LV_ERR_XX are saved (NLC_ABC_NOT_SAVE_XX = 0, NLC_ABC_INI_IGK_XX = 0, NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decrement (NLC_ABC_NOT_DEC_XX = 0).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **memory configuration (MEM)** is NC_ABC_CONF_FCT_DIAG_XX = BH

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains until a transition LV_IGK 0 → 1 or reset (NLC_ABC_NOT_DEC_XX = 1).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **memory configuration (MEM_INI)** is NC_ABC_CONF_FCT_DIAG_XX = EH

The data CTR_ABC_XX and LV_ERR_XX are initialised at the transition LV_IGK 0 → 1 and reset (NLC_ABC_INI_IGK_XX = 1). The anti-bounce counter is initialised to the C_ABC_MAX_XX – C_ABC_INC_XX value (NLC_ABC_INI_VALUE_XX = 1) only if there was a failure between the last and this initialisation (NLC_ABC_NOT_SAVE_XX = 0 to test the failure before this initialisation) else the anti-bounce counter is initialised with 0 value. The data LV_ERR_XX is initialised with 0 value.

The anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains until a transition LV_IGK 0 → 1 or reset (NLC_ABC_NOT_DEC_XX = 1).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **decrement calibratable configuration (DEC_CAL)** is set with NC_ABC_CONF_FCT_DIAG_XX = 10H

The data CTR_ABC_XX and LV_ERR_XX are saved (NLC_ABC_NOT_SAVE_XX = 0, NLC_ABC_INI_IGK_XX = 0, NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decrement (NLC_ABC_NOT_DEC_XX = 0).

The decrement value is calibratable (NLC_ABC_CAL_DEC_XX = 1).

The standard configuration is NLC_ABC_INI_DC_END_DIAG = 0 and NC_ERR_DET_UPD = 0 (default configuration).

Some functionalities (e.g. : to visualise the sporadic error of all diagnosis using this anti-bounce algorithm) aren't used when the failure is detected.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ABC_BENCH	1	0...1H	0...1	1	[-]
Logical constant to manage the anti-bounce bench mode					
LC_ERR_DET_UPD	1	0...1H	0...1	1	[-]
Logical constant to manage some functionality as the visualisation of the sporadic error					
C_ABC_DEC_XX	1	0...FFH	0...255	1	[-]
Anti-bounce counter decrement for XX diagnosis					
C_ABC_INC_XX	1	0...FFH	0...255	1	[-]
XX diagnosis anti-bounce counter increment (for anti-bounce filtering) or frequency counter maximum value (for statistical filtering)					
C_ABC_MAX_XX	1	1...FFH	1...255	1	[-]
XX diagnosis anti-bounce counter maximum value (for anti-bounce filtering) or threshold of period counter for failure detection (for statistical filtering)					

Remark :

The standard calibration is LC_ABC_BENCH = 0 **and** NLC_BENCH_MODE=0 (default calibration) then the bench mode isn't managed.

If the diagnosis doesn't manage calibratable decrement then the C_ABC_DEC_XX calibration isn't defined in calibration data (NLC_ABC_CAL_DEC_XX = 0).

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ABC_CONF_FCT_DIAG_XX	1	0...FFH	0...255	1	[-]

Export actions:

ACTION_ERRM_UpdErrDet (IN <XX>)
This action is used to visualize intermittent failures
ACTION_ERRM_IntmClr(IN < PRM_IDX_DYN >)
This action is used to clear one single Intm failure

FUNCTION DESCRIPTION:

General information:

The purpose of this function is the visualization of those diagnosis instances that show intermittent failures (ERR_SYM_XX ≠ 0) but do not enter into the dynamic error management structure, because the antibounce counter does not reach its maximum value.
If a failure of a diagnosis whitout using the anti-bounce algorithm is detected or if CTR_ABC_xx of a diagnosis using the anti-bounce algorithm is incremented for the 2nd time, it is stored in the array ERR_INTM_DIAG_INST[NC_NR_ERR_INTM] and its symptom is stored in the array ERR_INTM_SYM[NC_NR_ERR_INTM]. This is done for every new failure as long as the maximum number of entries NC_NR_ERR_INTM of this structure has not been reached.
If a new failure is stored, it is displayed also in ERR_INTM_DIAG_INST_ACT. If the antibounce counter of a failure reaches its maximum value it will be additionally stored in dynamic error memory.

The ERR_INTM_ENVD_... values refer to the same logic as ENVD_... of the normal FMY. The Information is stored if CTR_ABC_xx of a diagnosis using the anti-bounce algorithm is incremented for the 2nd time or if the failure flag is set for any kind of diagnosis.

A.3.1.1 Storage of intermittent failures and their frequency of appearance

Description:

Syntax : ACTION_ERRM_UpdErrDet (IN <XX>)

Parameter (in) : *Function_Name* Type: index to identify the function

Parameter (out) : *No parameter*

Short description : This action is used to store intermittent failures

Application conditions:

Initialization: -

Recurrence: At action call

Activation: NC_ERR_DET_UPD = 1 **and** LC_ERR_DET_UPD = 1

Formula section:

```
If    ERR_SYM_XX ≠ 0  {at the first time for failures not using anti-bounce algorithm and
                       at the 2nd increment of CTR_ABC_XX for diagnosis using
                       anti-bounce algorithm }
Then  If    diagnosis instance XX is not yet stored
            in ERR_INTM_DIAG_INST[ 0 ... NC_NR_ERR_INTM –1 ]
      Then  If    CTR_ERR_INTM_NR < NC_NR_ERR_INTM
            Then  ERR_INTM_DIAG_INST[ CTR_ERR_INTM_NR ] = XX
                  ERR_INTM_SYM[ CTR_ERR_INTM_NR ] = ERR_SYM_XX
                  ERR_INTM_DIAG_INST_ACT = XX
                  CTR_ERR_INTM_NR = CTR_ERR_INTM_NR + 1
                  ERR_INTM_ENVD_CUS_SET_CMN = ENVD_CONF_CUS_SET_CMN
                  ERR_INTM_ENVD_CUS_SET_SPC = ID_ERR_ENVD_XX
            Endif
      Else  If    transition LV_ERR_XX 0 ->1                  or
                  ( transition LV_END_DIAG_XX 0 ->1 and LV_ERR_XX =1 )
            Then  ERR_INTM_ENVD_CUS_SET_CMN = ENVD_ CONF_CUS_SET_CMN
                  ERR_INTM_ENVD_CUS_SET_SPC = ID_ERR_ENVD_XX
            Endif
      Endif
Endif
```

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_ERR_INTM	1	1...FFH	1...255	1	[-]
Maximum number of diagnosis instances to be listed in ERR_INTM_DIAG_INST NC_NR_ERR_INTM = 10					

A.3.1.2 Clear a single intermittent failure corresponding to dynamic entry (PRM_IDX_DYN)

Description:

Syntax : ACTION_ERRM_IntmClr (IN < PRM_IDX_DYN >)

Parameter (in) : *Function_Name* Type: index to identify the corresponding PRM_IDX_DYN

Parameter (out) : *No parameter*

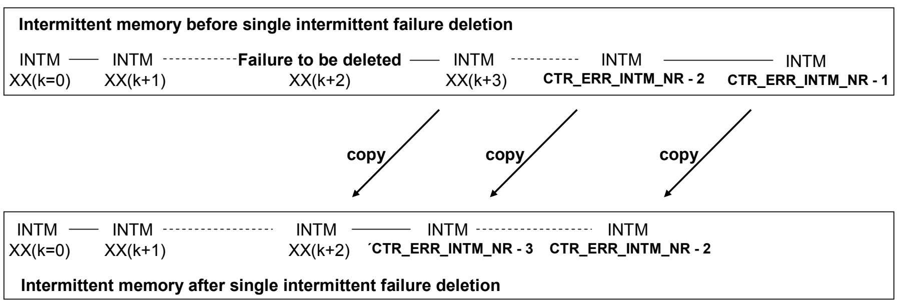
Short description : This action is used to erase a single intermittent failure corresponding to failure entry in Dynamic layer (PRM_IDX_DYN)

Application conditions:

Initialization: -

Recurrence: At action call

Activation:



Formula section:

IF (*NLC_ERR_DET_UPD = 1* **and** *LC_ERR_DET_UPD = 1)*

For i = 0 to CTR_ERR_INTM_NR -1

IF ERR_INTM_DIAG_INST[i] = = DIAG_INST[PRM_IDX_DYN]

Remove corresponding intermittent failure, corresponding intermittent symptom and corresponding Intermittent FrF (CUS_SET_CMN and CUS_SET_SPC)

Sort intermittent array:
- ERR_INTM_DIAG_INST
- ERR_INTM_SYM
- ERR_INTM_ENVD_CUS_SET_CMN
- ERR_INTM_ENVD_CUS_SET_SPC

End For

End If

A.3.1.3 Clear array of intermittent failures

Description:

By setting the calibration bit LC_ERR_INTM_CLR from 0 to 1 all failure entries are reset.

The array of intermittent failures is also initialised on other system events. This depends on the configuration C_ERR_INTM_CLR_INI

Application conditions:

Initialisation: -

Recurrence: -

Activation: at ECU reset, if bit 0 of C_ERR_INTM_CLR_INI = 1

at LV_IGK 0->1, if bit 1 of C_ERR_INTM_CLR_INI = 1

at Error Management cleared, if bit 2 of C_ERR_INTM_CLR_INI = 1

at transition LC_ERR_INTM_CLR 0→1 (recurrence is 1 second)

on failure erase service received

Formula section:

Reset array of intermittent failures:

ERR_INTM_DIAG_INST[0 ... NC_NR_ERR_INTM –1] = 0

ERR_INTM_SYM[0 ... NC_NR_ERR_INTM –1] = 0

CTR_ERR_INTM_NR = 0

ERR_INTM_DIAG_INST_ACT = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ERR_INTM_CLR	1	0...1H	0...1	1	[-]
reset array of intermittent failures					
C_ERR_INTM_CLR_INI	1	0...7H	0...7	1	[-]
control of different init possibilities of array of intermittent failures bit 0: clear of array at ECU reset bit 1: clear of array at LV_IGK 0->1 bit 2: clear of array, if Error management is cleared (initialisation active, if bit = 1)					

A.3.2 Anti-bounce filtering inhibition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ABC_INH	V/O	0...1H	0...1	1	[-]
Anti-bounce filterings inhibition					

Export actions:

ACTION_ERRM_InhibitFiltering (IN<InhibitFilter>)
This action shall be used to inhibit anti-bounce filtering calculations

Description:

Important note: Usage of the API is under project responsibility. By default, the inhibition is not set.

In addition, LV_ABC_INH flag must be securised to avoid any undesired inhibition.

To avoid failure recording during specific ECU phases (e.g. reprogramming,...), diagnoses are inhibited. To realize this inhibition, anti-bounce filtering calculations are frozen.

This inhibition is generally used during reprogramming phase.

Syntax: ACTION_ERRM_InhibitFiltering (IN <InhibitFilter>)

Parameter(in): InhibitFilter filter inhibition

Parameter(out: No parameter

Short Description: This API permits to activate or deactivate the anti-bounce calculation.

Application conditions:

Initialisation: *at ECU reset*

LV_ABC_INH = 0

(default value : Anti-bounce calculation is not inhibited)

Recurrence: -

Activation: at action request

Formula section:

If InhibitFilter = ON
Then
LV_ABC_INH = 1
Else
LV_ABC_INH = 0
Endif

A.4 Multi-condition debounce algorithm

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
CTR_ABC_XX	O/V/S	0...FFH	0...255	1	[-]
anti bounce counter of diagnosis XX					
CTR_ABC_END_DIAG_XX	O/V	0...FFH	0...255	1	[-]
Counter for end of diagnosis XX generation					
CDN_DIAG_PREV_XX	O/V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Diagnostic condition of last failure symptom					

Input data:

LC_ABC_BENCH	NC_ABC_CONF_FCT_DIAG_XX	NLC_ABC_INI_DC_END_DIAG	NC_ERR_DET_UPD
LC_ERR_DET_UPD	LV_IGK	LV_ABC_INH	NLC_BENCH_MODE

Import actions:

#IF NC_ERR_DET_UPD = 1 and NLC_ENA_MULTI_CDN = 1
ACTION_ERRM_UpdErrDet (IN<XX>)
This action indicates each occurrence of the detected error
#ENDIF

Export actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result
ACTION_ERRM_MultiFilterSymEnd(IN< XX >, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)
This action erases diagnostic failure and sets the end of diagnostic in case of multi-conditions filter type
ACTION_ERRM_MultiFilterReset(IN< XX >,OUT<LV_ERR_XX>)
This action resets data filter in case of multi-conditions filter type

General information:

Description:

According the diagnosis condition information CDN_DIAG_XX and the diagnosis symptom (raw value) information the symptom calculation ERR_SYM_XX is performed. Then the failure symptom is debounced to set the present failure LV_ERR_XX.

A special readiness calculation is done to set the end of diagnosis information. LV_END_DIAG_XX is set only if there was enough time to make a diagnosis of all symptoms or a failure gets present.

Note:

To set the LV_END_DIAG_XX is necessary to have the conditions for all symptoms at the same time for a given time.

Restrictions:

In case of multiple symptoms at the same time, only one symptom will be taken into account according the following priority rule: SYM_0 ==> SYM_3 ; Priority max ==> Priority Min

Only the last symptom present will be taken into account in this algorithm, so in case of symptom change, only the last symptom will be used to increment and decrement the counters.

Application conditions:

Initialization: *At ECU reset and LV_IGK 0 → 1 transition*

CDN_DIAG_PREV_XX = 0

Other data initialization

ERR_SYM_XX = *Refer to “Antibounce algorithms” chapter for initialization*
CTR_ABC_XX = *Refer to “Antibounce algorithms” chapter for initialization*
LV_ERR_XX = *Refer to “Antibounce algorithms” chapter for initialization*
CTR_ABC_END_DIAG_XX = *Refer to “Antibounce algorithms” chapter for initialization*

A.4.1 Multi-condition anti-bounce filter algorithm description

Description for ACTION_ERRM_FilterMulticondition:

Syntax : ACTION_ERRM_FilterMulticondition (IN<XX>, IN<CDN_DIAG_XX>, IN<ERR_DIAG_XX>, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)

Parameter(in):	XX	Type: index to identify the Diagnostic
	CDN_DIAG_XX	Type: Byte carrier (Each symptom condition)
	ERR_DIAG_XX	Type: Byte carrier (Raw value symptom)
	C_ABC_INC_XX	Type: Calibration byte for the increment value
	C_ABC_MAX_XX	Type: Calibration byte for the maximum value
Parameter(out):	LV_ERR_XX	Type: Boolean (=1 when failure)

Short Description: This action returns information necessary for the diagnostic and the error management.

Formula section:

Anti-bounce bench mode :

```
If(0) LV_ABC_INH = 0
Then
If(1) (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1) and ((C_ABC_INC_XX = 0) or
(C_ABC_INC_XX = FFH))
Then(1)
        If(2)   C_ABC_INC_XX = 0
        Then(2)
                {Case force no failure}
                LV_ERR_XX = 0
                ERR_SYM_XX =  0
                CTR_ABC_XX = 0
                LV_END_DIAG_XX = 1
                CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX

Endif(0)
```

A.4.2 Description for ACTION_ERRM_MultiFilterSymEnd :

Syntax: ACTION_ERRM_MultiFilterSymEnd(IN<XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)

Parameter(in): XX Type: index to identify the Diagnostic
C_ABC_MAX_XX Type: Calibration byte for the maximum value

Parameter(out): LV_ERR_XX Type: Boolean

Short Description: This action erases diagnostic failure and sets immediately the end of diagnostic information in case of multi-conditions filter (MPL_STD_INI)

Formula section :

LV_CDN_DIAG_XX = 1
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX = 1
CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX

A.4.3 Description for ACTION_ERRM_MultiFilterReset:

Syntax: ACTION_ERRM_MultiFilterReset(IN<XX>, OUT<LV_ERR_XX>)

Parameter(in): XX Type: index to identify the Diagnostic

Parameter(out): LV_ERR_XX Type: Boolean

Short Description: This action resets data filter in case of Multiconditions filter type

Formula section :

LV_CDN_DIAG_XX = 0
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX is unchanged
CTR_ABC_END_DIAG_XX is unchanged

A.4.4 Synchronization between multi-condition algorithm & Error Management

General information:

This section describes the mechanism of synchronisation of the failure filtering with the Error Management core. The principle is to call the Error Management upon events.

LV_END_DIAG_XX 0 → 1 transition
LV_ERR_XX 0 → 1 transition
LV_ERR_XX 1 → 0 transition

A.4.5 Mechanism for CPU load optimisation

General information:

This section describes the mechanism of optimisation. The principle is to suspend the filter algorithm execution when is not necessary. When the bench mode is used for a diagnostic XX the mechanism of CPU load optimisation is disabled for this instance.

Formula section:

If LV_ERR_XX = 0
and LV_END_DIAG_XX = 1
and ERR_SYM_XX = 0
and CTR_ABC_XX = 0
Then
It is not necessary to call error management (including filtering)
LV_END_DIAG_XX = 1 {unchanged}
LV_ERR_XX = 0 {unchanged}
Endif

A.4.6 Configuration data

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_SYM_XX	1	1...FH	1...15	1	[-]
Available symptom(s) for XX diagnostic					

Configuration data detailed description:

Symptoms 0 and 1 available: 03H
Symptoms 0, 1 and 2 available: 07H (typical value)
Symptoms 0, 1, 2 and 3 available: 0FH

Predefined filter type:

	NLC_ABC_STC_XX	NLC_ABC_CAL_DEC_XX	NLC_ABC_NOT_DEC_XX	NLC_ABC_INI_VALUE_XX	NLC_ABC_INI_IGK_XX	NLC_ABC_NOT_SAVE_XX
MPL_STD_INI	0	0	0	0	1	1

The **standard configuration with initialisation (MPL_STD_INI)** is NC_ABC_CONF_FCT_DIAG_XX = 3H (default configuration)

The data CTR_ABC_XX and LV_ERR_XX are Reset at the transition LV_IGK 0 → 1 and Reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0).
The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).
The filter used is the Anti-bounce (NLC_ABC_STC_XX = 0).

A.5 Upstream oxygen sensor heater OBDI diagnosis

Output data:

CDN_DIAG_LSH_UP[NC_CBK_EX_NR]	V	0...7H	0...7	1	-
Diagnosis condition for each symptom of upstream heater diagnosis OBD I					

Input data:

LV_ST_END	STATE_LSH_UP[NC_CBK_EX_NR]	**LV_VB_CDN_OBD_1**	TEG_DYN
LSHPWM_UP[NC_CBK_EX_NR]	LV_LSH_OC_LSH_UP[NC_CBK_EX_NR]	LV_LSH_SCP_LSH_UP[NC_CBK_EX_NR]	LV_LSH_SCG_LSH_UP[NC_CBK_EX_NR]
LV_INH_DIAG_LSH_UP[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_IGK	LV_DC

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

All symptoms of the current error code are handeled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

Description:

The error detection is effected via the ECU hardware.

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements.

The function is intended for use in a hardware configuration where the heater driver shall carry out the electrical fault diagnosis and provide the electrical status via status flags.

- *Short circuit to Vbatt by Over-temperature* ***or*** *Overcurrent* (**SCP**)
- *Short circuit to GND* (SCG)
- *Open load* (**OC**)

The electrical status flags for each heater driver shall be read out via SPI and decoded by the appropriate function typically every 10 ms and made available to the Application SW in the form of driver and fault specific flags. The flags shall only be set by the appropriate function and may only be reset by the diagnosis function. These flags are:

- **SCP** LV_LSH_SCP_LSH_UP[i]
- SCG LV_LSH_SCG_LSH_UP[i]
- **OC** LV_LSH_OC_LSH_UP[i]

The heater drivers named are capable of detecting an **OC** and **SCP** fault when in the ON state and only capable of detecting a SCG fault in the OFF state. As the heater power is controlled by a PWM signal, the driver will be placed alternately in an ON and then OFF state.

The diagnosis shall be activated should the following conditions be met:

- Engine leaving the engine start state as denoted by LV_ST_END = 1
- Battery voltage falls between pre-set thresholds to protect against false errors at battery voltage extremes as indicated by **LV_VB_CDN_OBD_1**.
- LSHPWM signal greater or equal to or lower or equal to specific calibrateable value. Should the PWM be set to 100 %, no SCG fault can be recognised (e.g. for ATIC39 & ATM3x min. of 250 µs required). Similarly for the **OC** / **SCP** fault, a fault can only be detected when the ON time is longer than a minimum threshold (e.g. for ATM3x for **OC** min. 250 µs). The exact HW thresholds are dependent upon the characteristics of the external circuitry.
- Inhibit flag not set (LV_INH_DIAG_LSH_UP[i])

In exceptionally rare extreme environmental conditions for certain system configurations, it is possible that the heater driver may be driven into over-temperature during initial oxygen sensor heating. In this case, the driver automatically turns off the output stage in self-protection and sets the **SCP** electrical fault bit. In order to mask an incorrect oxygen sensor heater **SCP** fault, the function shall only allow the **SCP** to set a fault during the initial heater phase, if the exhaust gas temperature has exceeded a pre-determined calibrateable threshold.

The oxygen sensor heater fault detection shall be debounced by use of an anti-bounce counter. This shall be handled by the Dynamic Error Management.

Each of the above listed faults shall be described individually below:

Otherwise the diagnosis has to be suppressed (CDN_DIAG_LSH_UP[i] = 0). This is managed within the “Diagnosis condition calculation.

Application conditions:

Activation : every engine state

Deactivation: -

Initialization: all variables (except LV_END_DIAG_xx) are initialised with 0 at every LV_IGK = 0 ->1 and reset
LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 and at Reset

NOTE: The input flags LV_LSH_SCP_LSH_UP[i], LV_LSH_SCG_LSH_UP[i] & LV_LSH_OC_LSH_UP[i] shall be initialised to 0 at the beginning of a new driving cycle by the appropriate BSW function.

Recurrence: 1 s

NOTE: The heater PWM frequency shall be at least 2 times faster than the diagnosis frequency to ensure that an oversampling effect does not occur!

Formula section:

CDN_DIAG_LSH_UP[i] = 0

If LV_ST_END = 1
and **LV_VB_CDN_OBD_1** = 1
and LV_INH_DIAG_LSH_UP[i] = 0
then **If** LSHPWM_UP[i] ≥ C_LSHPWM_MIN_DIAG_LSH_UP
and [(STATE_LSH_UP[i] <> LSH_POW_RISE
and STATE_LSH_UP[i] <> LSH_POW_RED)
or TEG_DYN ≥ C_TEG_DYN_MIN_DIAG_LSH_UP]
then bit 0 of CDN_DIAG_LSH_UP[i] = 1 *(**SCP** can be detected))*
endif
If LSHPWM_UP[i] ≤ C_LSHPWM_MAX_DIAG_LSH_UP
then bit 1 of CDN_DIAG_LSH_UP[i] = 1 *(**SCG** can be detected)*
endif
If C_LSHPWM_MIN_DIAG_LSH_UP ≤ LSHPWM_UP[i]
≤ C_LSHPWM_MAX_DIAG_LSH_UP
then bit 2 of CDN_DIAG_LSH_UP[i] = 1 *(**OC** can be detected)*
endif
endif

Error Symptom calculation (raw value from I/O SW)

ERR_DIAG_LSH_UP[i] = 0

If	LV_LSH_SCP_LSH_UP[i] = 1
then	bit 0 of ERR_DIAG_LSH_UP[i] = 1
endif	
If	LV_LSH_SCG_LSH_UP[i] = 1
then	bit 1 of ERR_DIAG_LSH_UP[i] = 1
	LV_LSH_SCG_ACT_LSH_UP[i] = 1
endif	
If	*abc-counter* = 0
then	LV_LSH_SCG_ACT_LSH_UP[i] = 0
endif	
If	LV_LSH_OC_LSH_UP[i] = 1
then	bit 2 of ERR_DIAG_LSH_UP[i] = 1
endif	

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_LSH_UP[i] and ERR_DIAG_LSH_UP[i].

This algorithm determines:

ERR_SYM_LSH_UP[i]	(= raw value ERR_DIAG_LSH_UP[i] filtered with CDN_DIAG_LSH_UP[i], detected error symptom for lambda sensor heater upstream [i] diagnosis)
LV_ERR_ LSH_UP[i]	(Error flag for debounced error of for lambda sensor heater upstream [i])
LV_CDN_DIAG_ LSH_UP[i]	(Diagnosis condition information)
LV_END_DIAG_ LSH_UP[i]	(End of diagnosis information)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

A.5.1 Application incidences for upstream oxygen sensor heater OBDI diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_LSH_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Inhibit flag for upstream oxygen sensor heater OBDI diagnosis					

Input data:

LV_ST_END	NC_CBK_EX_NR	NLC_LSH_RLY_EFP	LV_EFP
LV_ERR_RLY_EFP	CONF_LAM		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks. In case of two separate catalyst systems (NC_CBK_EX_NR = 2) i = 1 for exhaust bank 1, i = 2 for exhaust bank 2.

Description:

In some systems the supply voltage of the O2-Sensor heater may be connected to the electrical fuel pump relay (NLC_LSH_RLY_EFP = 1). In this case, if the electrical fuel pump is switched off or if the fuel pump relay is defective, no heating would occur and the heater driver will recognize an incorrect heater fault. Hence the OBD I heater diagnosis shall be inhibited if LV_EFP = 0 or if LV_ERR_RLY_EFP = 1.

Application conditions:

Initialisation: LV_INH_DIAG_LSH_UP[i] shall be reset at transition LV_ST_END 0 → 1

Recurrence: The function shall be carried out once every 1 s.

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

If NLC_LSH_RLY_EFP = 1
then *(O2-Sensor Heater supplied via EFP relay)*
  If LV_EFP = 0 *(EFP relay not active)*
  or LV_ERR_RLY_EFP = 1 *(error at EFP relay)*
  or CONF_LAM = 0 *(open loop lambda control)*
  then LV_INH_DIAG_LSH_UP[i] = 1
  else LV_INH_DIAG_LSH_UP[i] = 0
else *(O2-Sensor Heater supplied via EFP relay)*
  if CONF_LAM = 0 *(open loop lambda control)*
  then LV_INH_DIAG_LSH_UP[i] = 1
  else LV_INH_DIAG_LSH_UP[i] = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_DIAG_LSH_UP	1	0...FFH	0...255	1	-
Anti-bounce counter increment for upstream O2-sensor heater diagnosis.					
C_ABC_MAX_DIAG_LSH_UP	1	1...FFH	1...255	1	-
Maximum value of the anti-bounce counter for upstream O2-sensor heater diagnosis.					

Configuration for diagostic symptoms:

Diagnostic	Symptom Description	Symptom	Filter type
Upstream oxygen sensor heater OBDI diagnosis Bank 1, Sensor 1	*Short circuit to battery*	SYM_0	*STD*
	Short circuit to GND	SYM_1	
	Open circuit	SYM_2	
LSH_UP_1		SYM_3	

List of Environmental Data to store in Failure Memory: TCO_ST
LSHPWM_UP_1
R_IT_LS_UP_1_ENVD_H
R_IT_LS_UP_1_ENVD_L

Application assistances:

Recommendation: The Application assistances shall be maintained for the remaining duration of the driving cycle.

- Evaporative emission system
  Control - Activation of Minimum Operation
  System diagnosis - Inhibit
- Lambda control (Only for exhaust gas temperatures lower than O2 sensor lowest operating temperature)
  Control - Return to open-loop mode (Bank selectively)
  NOTE: Closed loop control may be permitted if the signal voltage excursion is large enough
  Adaptation - Inhibit (Bank selectively)
  Downstream trim regulation - Inhibit (Bank selectively)
- Oxygen sensor / Lambda controller diagnosis:
  O2 sensor upstream voltage excursion diagnosis - Inhibit (Bank selectively)
  O2 sensor upstream response time diagnosis - Inhibit (Bank selectively)
  O2 sensor control limit diagnosis - Inhibit (Bank selectively)
  O2 sensor frequency diagnosis - Inhibit (Bank selectively)
  O2 sensor upstream signal voltage diagnosis (Bank selectively)
  O2 sensor upstream signal plausibility diagnosis (Bank selectively)
  O2 sensor downstream response time diagnosis (Bank selectively)
  O2 sensor downstream signal voltage diagnosis (Bank selectively)
  O2 sensor downstream PUC end diagnosis (Bank selectively)
- Idle speed adaptation - Inhibit
- Knock adaptation - Inhibit
- MAF / TPS-Plausibility diagnosis - Inhibit
- Fuel system diagnosis - Inhibit (indirectly via LV_LSCL)
- Catalyst efficiency diagnosis - Inhibit (Bank selectively) (indirectly via LV_LSCL)
- O2 sensor upstream heater OBD II diagnosis - Inhibit (Bank selectively)

A.6 Downstream oxygen sensor signal monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]	V/O	0...01H	0...1	1	-
Boolean error flag, electrical fault currently present on downstream oxygen sensor signal					

Input data:

LV_ERR_SCG_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	LV_ERR_SCP_LS_DOWN[NC_CBK_EX_NR]	LV_ERR_OC_LS_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

The VLS_DOWN[i] value used for diagnosis purposes shall not be affected should the sensor be “pumped”. The value prior to pumping shall be used until the sensor returns to normal operation (no pumping).
Once an electrical fault has been detected and debounced, the plausibility diagnosis shall not be carried out until the electrical fault has been diagnosed as being no longer present. The electrical diagnosis shall remain unaffected by the state of the plausibility diagnosis.
Once an electrical fault has been diagnosed and debounced, the application assistances (Functions that are defined to be affected by the state of the oxygen sensor signal) shall remain active for the remainder of the driving cycle. The restarting of the affected functions during the next driving cycle shall be carried out according to the project philosophy.
The measurement of the oxygen sensor voltage shall not be affected by the detection of a signal fault unless explicitly deactivated.

Description:

The oxygen sensor signal electrical diagnosis shall detect the following faults:

A. Short circuit of the oxygen sensor signal line to GND
B. Short circuit of the oxygen sensor signal line to Vbatt
C. Open circuit (line break) in the connection to oxygen sensor element

Each fault may set the boolean flag (LV_ERR_SCG_LS_DOWN[i]; LV_ERR_SCP_LS_DOWN[i]; LV_ERR_OC_LS_DOWN[i]) to signal that the particular fault is currently active. Should one of the electrical fault flags (A-C) be set, then a global error flag (LV_ERR_EL_LS_DOWN[i]) shall be set to indicate that an electrical fault currently exists on the particular oxygen sensor.
Each of the above listed erro shall be described individually in further detail below.

Application conditions:

Initialisation: all variables shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Recurrence: 100ms

Activation:

If LV_IGK = 1

Deactivation:

If LV_IGK = 0

Formula section:

If LV_ERR_SCG_LS_DOWN[i] = 1
or LV_ERR_SCP_LS_DOWN[i] = 1
or LV_ERR_OC_LS_DOWN[i] = 1
then LV_ERR_EL_LS_DOWN[i] = 1
else LV_ERR_EL_LS_DOWN[i] = 0
endif

A.6.1 Short circuit of oxygen sensor signal to GND.

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_SCG_LS_DOWN[NC_CBK_EX_NR]	V/O	0...01H	0...1	1	-
Boolean error flag, short to ground fault currently present on downstream oxygen sensor signal					
ERR_SYM_SCG_LS_DOWN[NC_CBK_EX_NR]	V/O	0H 2H	NO_SYM SYM_1	1	-
Boolean symptom flag, short to ground fault currently present on downstream oxygen sensor signal					
LV_CDN_DIAG_SCG_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Status conditions of oxygen sensor short to ground downstream diagnosis

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_DC	LV_IGK	LV_INH_DIAG_SCG_LS_DOWN[NC_CBK_EX_NR]
R_IT_LS_DOWN[NC_CBK_EX_NR]	CTR_CYCNR_R_IT_LS_DOWN_VLD[NC_CBK_EX_NR]		MAF_KGH

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

In order to determine the electrical fault, short circuit to GND, the oxygen sensor signal voltage is compared to a calibrateable threshold (C_VLS_THD_DIAG_SCG_LS_DOWN) in conjunction with certain activation conditions.
Should a hard short to GND (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to 0 V. This condition may also occur should the air-fuel mixture (AFR) become lean due to a fault in the injection system, due to an air leak, intentional or not, or due to a normal operating conditions. Hence the following additional fault conditions shall be required:
The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_SCG_LS_DOWN[i]).

Each time that timer T_ACT_PLS_DIAG_SCG_LS_DOWN[i] exceeded the minimum duration (C_T_DLY_DIAG_SCG_LS_DOWN) for the first time, e.g. first time after engine start or after timer T_ACT_PLS_DIAG_SCG_LS_DOWN[i] has been reset, the

CTR_R_UPD_DIAG_SCG_LS_DOWN[I] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.
It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_R_UPD_DIAG_SCG_LS_DOWN[I] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_R_UPD_DIAG_SCG_LS_DOWN[I] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. If this conditions and all the above conditions be met, the diagnosis shall be considered to be active.
Should the diagnosis be determined to be active, the oxygen sensor signal voltage shall be compared to the threshold. Should the voltage fall below the threshold and the resistance condition R_IT_LS_DOWN[i] less than threshold be met, a pre - detection counter is incremented. The counter is reseted to 0 if the above mentioned conditions are no more fulfilled. If the pre – detection counter counter reached the maximum value then the active check is triggered or if finished the error “Short to GND” is detected.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory.

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

LV_DIAG_ACT_REQ_LS_DOWN[i] was deleted from the formula section but it should be initialised by 0 and held as output.

Recurrence: T_SAMPLE = 100ms

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_INH_DIAG_SCP_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	LV_DC

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

Should a hard short to Vbatt (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to Vbatt and the analogue digital converter value will tend to 5 V. This effect does not occur under normal conditions as the sensor delivers typically 1 V for rich AFR at the sensor location and may be used for short to Vbatt detection.

In order to determine the electrical fault, short circuit to Vbatt, the oxygen sensor signal voltage (VLS_DOWN[i]) is compared to a calibrateable threshold (C_VLS_THD_DIAG_SCP_LS_DOWN) in conjunction with the herein mentioned activation conditions.
The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_SCP_LS_DOWN[i]).
Should the oxygen signal voltage exceed the said threshold, a signal short to Vbatt shall be determined to be present and the debounce counter shall be incremented otherwise the debounce counter shall be decremented.
The error flag LV_ERR_SCP_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_SCP_LS_DOWN) shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

LV_END_DIAG_SCP_LS_DOWN is initialised with 0 at every (LV_IGK = 0 ->1 and LV_DC = 0) or reset or at clearing the error memory

STATE_LSH_DOWN[NC_CBK_EX_NR]	LV_INH_DIAG_OC_LS_DOWN[NC_CBK_EX_NR]	CTR_CYCNR_R_IT_LS_DOWN_VLD[NC_CBK_EX_NR]	R_IT_LS_DOWN[NC_CBK_EX_NR]
LV_LS_DOWN_READY[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_DC	

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

Should a complete open circuit occur in the oxygen sensor signal or return line, the measured voltage at the input to the microcontroller will tend to the voltage determined by the operative readiness potential divider (approx. 450 mV) and the measured internal resistance will be abnormally high.
In order to determine an open circuit electrical fault, the oxygen sensor internal resistance (R_IT_LS_DOWN[i]) is compared to a calibrateable threshold (C_R_IT_MIN_DIAG_OC_LS_DOWN) in conjunction with certain activation conditions shown below:
The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_OC_LS_DOWN[i]).

The sensor shall be determined to be in a state of operative readiness (LV_LS_DOWN_READY[i] = 1, possibly thorough forced activation) and the temperature operating conditions of the sensor shall be determined to be sufficient to permit normal operation, i.e. No fault shall be determined to be present in the appropriate downstream oxygen sensor heater (LV_ERR_LSH_DOWN[i] = 0) or if so that the operating temperature be determined to be sufficient for sensor operability (TEG_CAT_DOWN_MDL[i] > C_TEG_CAT_MIN_DIAG_OC_LS_DOWN), and the appropriate heater shall be determined to being controlled normally (STATE_LSH_DOWN[i] = LSH_POW_CTL).
Should the above initial conditions be met, a timer (T_ACT_PLS_DIAG_OC_LS_DOWN[i]) shall be incremented. Should the conditions no longer be met, both timers shall be reset and flag LV_T_CDN_DIAG_OC_LS_DOWN[i] reset.
The oxygen sensor signal shall be determined to lie in a calibrateable voltage band (C_VLS_AFL_THD_DIAG_OC_LS_DOWN < VLS_DOWN[i] < C_VLS_AFR_THD_DIAG_OC_LS_DOWN).
Should the above listed pre-activation conditions be determined to have been met, a timer T_CDN_DIAG_OC_LS_DOWN[i] shall be started. The timer shall be required to equal or exceed a minimum calibrateable duration (C_T_CDN_DIAG_OC_LS_DOWN). When no longer met, T_CDN_DIAG_OC_LS_DOWN[i] and LV_T_CDN_DIAG_OC_LS_DOWN[i] shall be reset.
Each time that the T_CDN_DIAG_OC_LS_DOWN[i] has exceeded the minimum duration for the first time, e.g. first time after engine start or after the T_CDN_DIAG_OC_LS_DOWN[i] has been reset, the CTR_R_UPD_DIAG_OC_LS_DOWN[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.
It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_R_UPD_DIAG_OC_LS_DOWN[i] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_R_UPD_DIAG_OC_LS_DOWN[i] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i] and a flag LV_R_IT_VLD_DIAG_OC_LS_DOWN[I] be set, thus indicating that the voltage lies within the set band and that a new resistance value is available.
If either LV_T_CDN_DIAG_OC_LS_DOWN[i] is set or T_ACT_PLS_DIAG_OC_LS_DOWN[i] equals or exceeds threshold C_T_DLY_DIAG_OC_LS_DOWN, the diagnosis shall be considered to be available.
Should the diagnosis be determined to be available and the condition LV_R_IT_VLD_DIAG_OC_LS_DOWN[I] has been met, the oxygen sensor internal resistance shall be compared to the said threshold. Should the resistance exceed the threshold, a signal open circuit shall be determined to be present and the debounce counter shall be incremented otherwise the debounce counter shall be decremented.
The error flag LV_ERR_OC_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum and reset should the anti-bounce counter reach 0.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the PUC_LS_DOWN[i] and the Rate-Based Monitoring statistics is defined with STATE_RBM_PUC_LS_DOWN[i] data.

Within STATE_RBM_PUC_LS_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_PUC_LS_DOWN[i] = 0 at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_PUC_LS_DOWN[i] = 1

The pending status of the following failures has to be checked only once:

For ETC and non_ETC variants:

Dependence	Error			
	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_VCC_PVS_2	LV_ERR_EL_CPS	LV_ERR_MEC_OPEN_CPS
	LV_ERR_MAF_SCG_OC	LV_ERR_MAF_SCP	LV_ERR_EL_MAP	LV_ERR_MAP_PLAUS
NC_CBK_EX_NR	LV_ERR_OBD_LSH_DOWN[i]	LV_ERR_SWT_LS_DOWN[i]	LV_ERR_PUE_LS_DOWN[i]	LV_ERR_LSH_DOWN[i]
	LV_ERR_SCG_LS_DOWN[i]	LV_ERR_SCP_LS_DOWN[i]	LV_ERR_OC_LS_DOWN[i]	
	LV_ERR_FSD[i]	LV_ERR_FSD_LAM_LIM[i]		

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_PUC_LS_DOWN[i] = 0
and LV_END_DIAG_PUC_LS_DOWN[i] = 1
Then bit 0 of STATE_RBM_PUC_LS_DOWN[i] = 1
Endif

If bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 0
and LV_INH_DIAG_RBM_PUC_LS_DOWN[i] = 1
Then bit 1 of STATE_RBM_PUC_LS_DOWN[i] = 1
Endif

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_PUC_LS_DOWN_1 = 0
then RATE_RBM_PUC_LS_DOWN_1 = FFFFH
else RATE_RBM_PUC_LS_DOWN_1
= (CTR_COMP_RBM_PUC_LS_DOWN_1 / CTR_CDN_RBM_PUC_LS_DOWN_1)
endif

A.7.3 Variables for fleet monitoring

Output data:

VLS_DOWN_MIN_TOT_DC	V/O/S	0...3FFH	0...4.995	0.0049	V
Former / current driving cycle minimum downstream oxygen sensor voltage					
VLS_DOWN_MAX_TOT_DC	V/O/S	0...3FFH	0...4.995	0.0049	V
Former / current driving cycle maximum downstream oxygen sensor voltage					

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_IGK		

Description:

Application conditions:

Initialisation: - at first ECU power up and non-volantile memory lost:

VLS_DOWN_MIN_TOT_DC = 3FFH

VLS_DOWN_MAX_TOT_DC = 0H

- otherwise: restored from non-volantile memory

Recurrence: 10ms

Activation: LV_IGK = 1

Deactivation: -

Formula section:

If VLS_DOWN[1] < VLS_DOWN_MIN_TOT_DC

Then VLS_DOWN_MIN_TOT_DC = VLS_DOWN[1]

Endif

If VLS_DOWN[1] > VLS_DOWN_MAX_TOT_DC

Then VLS_DOWN_MAX_TOT_DC = VLS_DOWN[1]

Endif

A.8 Signal plausibility monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DIAG_CDN_PLAUS_LS_DOWN[NC_CBK_EX_NR]	V	0...1H	0...1	1	[-]
Boolean flag, plausibility check on downstream oxygen sensor signal possible					
LV_ERR_PLAUS_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Boolean flag, error plausibility check on downstream oxygen sensor signal					

Input data:

LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]	LV_LS_DOWN_READY[NC_CBK_EX_NR]	LV_ERR_LSH_DOWN[NC_CBK_EX_NR]	LV_ERR_PUC_LS_DOWN[NC_CBK_EX_NR]
NC_CBK_EX_NR	STATE_LSH_DOWN[NC_CBK_EX_NR]	LV_IGK	LV_ERR_FL_LS_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

Due to possible oxygen sensor defects (e.g. reference air poisoning) or faults in the injection system (e.g. leaking fuel injector), the oxygen sensor may not provide the expected lean or rich AFR signal level during overrun fuel cut-off (PUC) or full load (FL) condition. Hence, the oxygen sensor signal shall be checked for plausibility during this engine operating states.

Description:

If the following conditions are met, then the general conditions for plausibility check are determined to be present:

A. Ignition key shall be determined to be on (LV_IGK = 1)
B. No electrical oxygen sensor fault shall be determined to be present on the sensor being diagnosed (LV_ERR_EL_LS_DOWN[i] = 0).
C. Sensor shall be in a state of operative readiness (LV_LS_DOWN_READY[i] =1).
D. The sensor shall be determined to be at operating temperature (STATE_LSH_DOWN[i] = LSH_POW_CTL & LV_ERR_LSH_DOWN[i] = 0).

The corresponding flag LV_DIAG_CDN_PLAUS_LS_DOWN[i] shall then be set.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits to 0

Recurrence: **T_sample 10 ms**

Activation / Deactivation:

If	LV_IGK = 1
and	LV_ERR_EL_LS_DOWN[i] = 0
and	LV_LS_DOWN_READY[i] = 1
and	LV_ERR_LSH_DOWN[i] = 0
and	STATE_LSH_DOWN[i] = LSH_POW_CTL
then	**“Diagnosis available”**
	LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1
else	**“Diagnosis NOT available”**
	LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 0
endif	

Formula section:

If	LV_ERR_PUC_LS_DOWN[i] = 1
or	LV_ERR_FL_LS_DOWN[i] = 1
then	LV_ERR_PLAUS_LS_DOWN[i] = 1
else	LV_ERR_PLAUS_LS_DOWN[i] = 0
endif	

A.8.1 Overrun fuel cut-off (PUC) oxygen sensor signal plausibility

Mode 6 value describing last VLS_DOWN PUC plausibility result					

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_PUC	MAF_INT_PUC_ACT	LV_DIAG_CDN_PLAUS_LS_DOWN[NC_CBK_EX_NR]
LV_INH_DIAG_PUC_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	NC_CBK_EX_NR	MAF_KGH
	LV_DC		

FUNCTION DESCRIPTION:

General information:

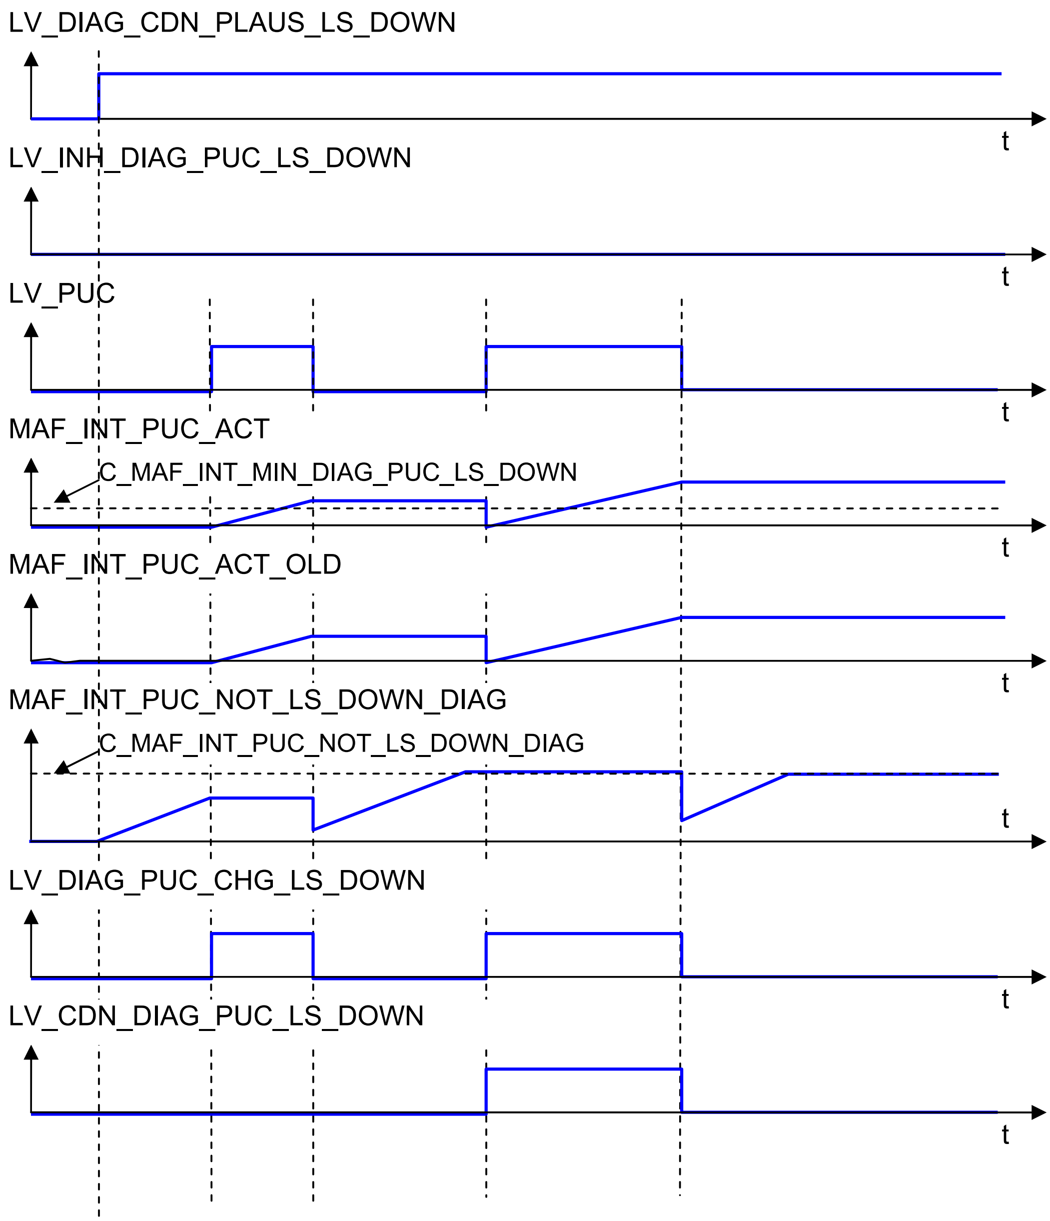
Description:

Should the oxygen sensor signal voltage (VLS_DOWN[i]) exceed the calibrateable thresholds (C_VLS_MIN_DIAG_PUC_LS_DOWN) during engine operating state PUC and the following additional conditions are met, then a fault shall be determined to be present:

A. The appropriate inhibit flag shall not be set (LV_INH_DIAG_PUC_LS_DOWN[i]).
B. Plausibility check set to be possible (LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1)
C. The PUC state (LV_PUC = 1) shall be determined to be stable, as determined by comparing the mass air flow integral calculated after activation (MAF_INT_PUC_ACT) with the threshold range (C_MAF_INT_MIN_VLS_DOWN_DIAG; C_MAF_INT_MAX_VLS_DOWN_DIAG).
D. The energy transfer from the exhaust gas to the oxygen sensor shall exceed the calibratable threshold (C_MAF_INT_PUC_NOT_LS_DOWN_DIAG).
E. The reset of the MAF integral from the last fuel cut off phase must have taken place before activating the diagnosis. Otherwise there is a risk to set the conditions to 1 right at the beginning of the fuel cut off phase. At this time, the lambda sensor voltage downstream is still high and the error symptom would be set for one recurrence.
F. Prior to the PUC phase the VLS_DOWN[i] must have exceeded the voltage thresholds C_VLS_DOWN_PUC_PLAUS_VLD and C_VLS_DOWN_PUC_AFR_VLD.

The error flag LV_ERR_PUC_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.



Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits (except LV_END_DIAG_xx) to 0, except VLS_DOWN_PUC_SAVE. VLS_DOWN_PUC_SAVE[i] shall be initialised to 0 at new ECU and in case of NVMY checksum errors. In normal case, VLS_DOWN_PUC_SAVE shall be initialised to its saved value. Reset only at clearing error memory.

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

Recurrence: **T_sample 100ms**

Activation / Deactivation: -

LV_INH_DIAG_FL_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	NC_CBK_EX_NR	LV_DC

FUNCTION DESCRIPTION:

General information:

Description:

Should the oxygen sensor signal voltage (VLS_DOWN[i]) exceed the calibrateable thresholds (C_VLS_MAX_DIAG_FL_LS_DOWN) during engine operating state FL and the following additional conditions are met, then a fault shall be determined to be present:

A. The appropriate inhibit flag shall not be set (LV_INH_DIAG_FL_LS_DOWN[i]).
B. Plausibility check set to be possible (LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1)
C. The FL state (LV_FL = 1) shall be determined to be stable, as determined by comparing the mass air flow integral calculated after activation (MAF_INT_FL) with the threshold range (C_MAF_INT_MIN_DIAG_FL_LS_DOWN; C_MAF_INT_MAX_DIAG_FL_LS_DOWN).

The error flag LV_ERR_FL_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits (except LV_END_DIAG_xx) to 0

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

Recurrence: **T_sample 100ms**

Activation / Deactivation:

If LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1
and LV_INH_DIAG_FL_LS_DOWN[i] = 0
and LV_FL = 1
and C_MAF_INT_MAX_DIAG_FL_LS_DOWN > MAF_INT_FL

A.8.3 Calculation of MAF_INT_FL

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_INT_FL	V/O	0...FFFFH	0...1820.42	2.78E-02	[g]
integral of air mass flow while FL active					

Input data:

LV_FL	MAF_CYL	LV_ST_END	LV_IGK

FUNCTION DESCRIPTION:

General information:

Description:

The calculation of MAF_INT_FL expires in 20ms raster as long as the operation status FL is fulfilled even when the application conditions for plausibility check function are not fulfilled. MAF_INT_FL_i is limited to the maximum value if necessary in case of a longer FL phase.
The value of MAF_INT_FL should reset to 0 if the transition LV_FL = 1 -> 0 takes place.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1 or reset reset of all variables and bits to 0

Recurrence: **Tsample = 20ms**

Activation / Deactivation:

If LV_ST_END = 1

then *calculation enabled*

else *calculation disabled*

endif

Formula section:

If LV_FL = 1

then

$MAF\_INT\_FL_n$ [g] = $MAF\_INT\_FL_n$ [g] + MAF_CYL * T_SAMPLE [ms] * 1/3600 [(g*h) / (kg*ms)]

else

MAF_INT_FL = 0

endif

A.9 Downstream oxygen sensor heater OBDI diagnosis

LV_INH_DIAG_LSH_DOWN[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_IGK	LV_DC

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

All symptoms of the current error code are handeled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

Description:

The error detection is effected via the ECU hardware.

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements.

The function is intended for use in a hardware configuration where the heater driver shall carry out the electrical fault diagnosis and provide the electrical status via status flags.

- *Short circuit to Vbatt by Over-temperature* ***or*** *Overcurrent* (**SCP**)
- *Short circuit to GND* (SCG)
- *Open load* (**OC**)

The electrical status flags for each heater driver shall be read out via SPI and decoded by the appropriate function typically every 10 ms and made available to the Application SW in the form of driver and fault specific flags. The flags shall only be set by the appropriate function and may only be reset by the diagnosis function. These flags are:

- **SCP** LV_LSH_SCP_LSH_DOWN[i]
- SCG LV_LSH_SCG_LSH_DOWN[i]
- **OC** LV_LSH_OC_LSH_DOWN[i]

The heater drivers named are capable of detecting an **OC** and **SCP** fault when in the ON state and only capable of detecting a SCG fault in the OFF state. As the heater power is controlled by a PWM signal, the driver will be placed alternately in an ON and then OFF state.

The diagnosis shall be activated should the following conditions be met:

- Engine leaving the engine start state as denoted by LV_ST_END = 1
- Battery voltage falls between pre-set thresholds to protect against false errors at battery voltage extremes as indicated by **LV_VB_CDN_OBD_1**.
- LSHPWM signal greater or equal to or lower or equal to specific calibrateable value. Should the PWM be set to 100 %, no SCG fault can be recognised (e.g. for ATIC39 & ATM3x min. of 250 µs required). Similarly for the **OC** / **SCP** fault, a fault can only be detected when the ON time is longer than a minimum threshold (e.g. for ATM3x for **OC** min. 250 µs). The exact HW thresholds are dependent upon the characteristics of the external circuitry.
- Inhibit flag not set (LV_INH_DIAG_LSH_DOWN[i])

In exceptionally rare extreme environmental conditions for certain system configurations, it is possible that the heater driver may be driven into over-temperature during initial oxygen sensor heating. In this case, the driver automatically turns off the output stage in self-protection and sets the **SCP** electrical fault bit. In order to mask an incorrect oxygen sensor heater **SCP** fault, the function shall only allow the **SCP** to set a fault during the initial heater phase, if the exhaust gas temperature has exceeded a pre-determined calibrateable threshold.

The oxygen sensor heater fault detection shall be debounced by use of an anti-bounce counter. This shall be handled by the Dynamic Error Management.

Each of the above listed faults shall be described individually below:

Otherwise the diagnosis has to be suppressed (CDN_DIAG_LSH_DOWN[i] = 0). This is managed within the “Diagnosis condition calculation.

Application conditions:

Activation : every engine state

Deactivation: -

Initialization: all variables (except LV_END_DIAG_xx) are initialised with 0 at every LV_IGK = 0 ->1 and reset
LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 and at reset

NOTE: The input flags LV_LSH_SCP_LSH_DOWN[i], LV_LSH_SCG_LSH_DOWN[i] & LV_LSH_OC_LSH_DOWN[i] shall be initialised to 0 at the beginning of a new driving cycle by the appropriate BSW function.

Recurrence: 1 s

NOTE: The heater PWM frequency shall be at least 2 times faster than the diagnosis frequency to ensure that an oversampling effect does not occur!

Formula section:

CDN_DIAG_LSH_DOWN[i] = 0

If LV_ST_END = 1
and **LV_VB_CDN_OBD_1** = 1
and LV_INH_DIAG_LSH_DOWN[i] = 0
then **If** LSHPWM_DOWN[i] ≥ C_LSHPWM_MIN_DIAG_LSH_DOWN
and [(STATE_LSH_DOWN[i] <> LSH_POW_RISE
and STATE_LSH_DOWN[i] <> LSH_POW_RED)
or TEG_CAT_DOWN_MDL[i] ≥ C_TEG_CAT_MDL_DOWN_MIN_LSH_DOWN]
then bit 0 of CDN_DIAG_LSH_DOWN[i] = 1 *(**SCP** can be detected))*
endif
If LSHPWM_DOWN[i] ≤ C_LSHPWM_MAX_DIAG_LSH_DOWN
then bit 1 of CDN_DIAG_LSH_DOWN[i] = 1 *(**SCG** can be detected)*
endif
If C_LSHPWM_MIN_DIAG_LSH_DOWN ≤ LSHPWM_DOWN[i] ≤ C_LSHPWM_MAX_DIAG_LSH_DOWN
then bit 2 of CDN_DIAG_LSH_DOWN[i] = 1 *(**OC** can be detected)*
endif
endif

Error Symptom calculation (raw value from I/O SW)

ERR_DIAG_LSH_DOWN[i] = 0

If LV_LSH_SCP_LSH_DOWN[i] = 1
then bit 0 of ERR_DIAG_LSH_DOWN[i] = 1
endif
If LV_LSH_SCG_LSH_DOWN[i] = 1
then bit 1 of ERR_DIAG_LSH_DOWN[i] = 1
endif
If LV_LSH_OC_LSH_DOWN[i] = 1
then bit 2 of ERR_DIAG_LSH_DOWN[i] = 1
endif

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_LSH_DOWN[i] and ERR_DIAG_LSH_DOWN[i].

This algorithm determines:

ERR_SYM_LSH_DOWN[i] (= raw value ERR_DIAG_LSH_DOWN[i] filtered with CDN_DIAG_LSH_DOWN[i], detected error symptom for lambda sensor heater upstream [i] diagnosis)

LV_ERR_ LSH_DOWN[i] (Error flag for debounced error of for lambda sensor heater upstream [i])

LV_CDN_DIAG_ LSH_DOWN[i] (Diagnosis condition information)

LV_END_DIAG_ LSH_DOWN[i] (End of diagnosis information)

Input data:

LV_ST_END	NC_CBK_EX_NR	NLC_LSH_RLY_EFP	LV_EFP
LV_ERR_RLY_EFP	CONF_LAM	CONF_CAT_EFF	

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks. In case of two separate catalyst systems (NC_CBK_EX_NR = 2) i = 1 for exhaust bank 1, i = 2 for exhaust bank 2.

Description:

In some systems the supply voltage of the O2-Sensor heater may be connected to the electrical fuel pump relay (NLC_LSH_RLY_EFP = 1). In this case, if the electrical fuel pump is switched off or if the fuel pump relay is defective, no heating would occur and the heater driver will recognize an incorrect heater fault. Hence the OBD I heater diagnosis shall be inhibited if LV_EFP = 0 or if LV_ERR_RLY_EFP = 1.

Application conditions:

Initialisation: LV_INH_DIAG_LSH_DOWN[i] shall be reset at transition LV_ST_END 0 → 1

Recurrence: The function shall be carried out once every 1 s.

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

If NLC_LSH_RLY_EFP = 1
then *(O2-Sensor Heater supplied via EFP relay)*
  If LV_EFP = 0 *(EFP relay not active)*
  or LV_ERR_RLY_EFP = 1 *(error at EFP relay)*
  or CONF_LAM = 0 *(open loop lambda control)*

Application assistances:

Recommendation: The Application Assistances shall be maintained for the remaining duration of the driving cycle.

- Lambda control (Only for exhaust gas temperatures lower than O2 sensor lowest operating temperature):
  Downstream trim regulation - Inhibit (Bank selectively)
- Oxygen sensor / Lambda controller diagnosis:
  O2 sensor downstream signal diagnosis – Inhibit (Bank selectively, OC & SCB)
  O2 sensor downstream response time diagnosis – Inhibit (Bank selectively)
  O2 sensor downstream PUC end diagnosis – Inhibit (Bank selectively)
- Catalyst efficiency diagnosis - Inhibit (Bank selectively) (indirectly via LV_LSCL)

A.10 ETC position sensor diagnosis

FUNCTION DESCRIPTION:

General information:

The following TPS diagnosis can be distinguished:

- Diagnosis of the admissible voltage ranges V_TPS_1 and V_TPS_2
  To avoid engine stall during chattering TPS_1or 2 signal the diagnosis threshold at idle can be calibrated lower with two constants C_V_TPS_X_MIN/MAX_IS. So the time to reach the error threshold can be reduced. (HMC bad signal contact test procedure)
- In case of high deviations between TPS_AV_1 and TPS_AV_2, a plausibility check with the main load signal (MAF_TPS_MES) is activated and the faulty TPS channel is searched.
- In the case of one defective TPS channel, the plausibility check of the error-free sensor with the main load signal (MAF_TPS_MES) is activated (second TPS error). The monitoring of the error-free channel runs continuously.

A.10.1 Diagnosis of the admissible voltage ranges V_TPS_1 and V_TPS_2

Output data:

MAF_TPS_MES	MAF_TPS_EXT	LV_INH_DIAG_TPS_MAF	LV_ERR_MAF
LV_ERR_MAP	N_32	PUT	TIA_THR
TCO	LV_DC		

FUNCTION DESCRIPTION:

General information:

In the case of an error-free system, the throttle position TPS_AV_1 and TPS_AV_2 must not differ by more than C_TPS_RATIO_HYS. If the threshold C_TPS_RATIO_HYS is exceeded, the TPS error detection is done through plausibility with MAF_TPS_MES.

Description:

Detection of the implausible channel in the case of a comparison error within the admissible voltage ranges. To perform this plausibility check, the variables MAF_TPS_SUB_x are calculated on the basis of the throttle position values TPS_AV_x .

The absolute amount of the differences between MAF_TPS_SUB_x and the mass air flow measured are determined, normalized with IP_MAF_TPS_DIF_DIAG and integrated over the period C_T_TPS_MAF_ERR_INT.

After the integration period the TPS channel which has the highest error sum is declared as faulty. The other channel is also declared as faulty, if it’s error sum exceeds the threshold C_TPS_MAF_ERR_INT. If both error sums are identical (threshold not exceeded), TPS channel 1 is declared as faulty.

Above the limitation IP_TPS_MAX_DIAG the value MAF_TPS_SUB_X has no longer a practical relationship to TPS_AV. In this case, no error detection is performed (only first error detection, TPS ratio check).

The variable LV_ERR_TPS_RATIO isn’t subject to the error management and is set, if a TPS ratio error occurs.

Error symptoms are defined for this diagnosis function as:

ERR_SYM_TPS_MAF_1:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘

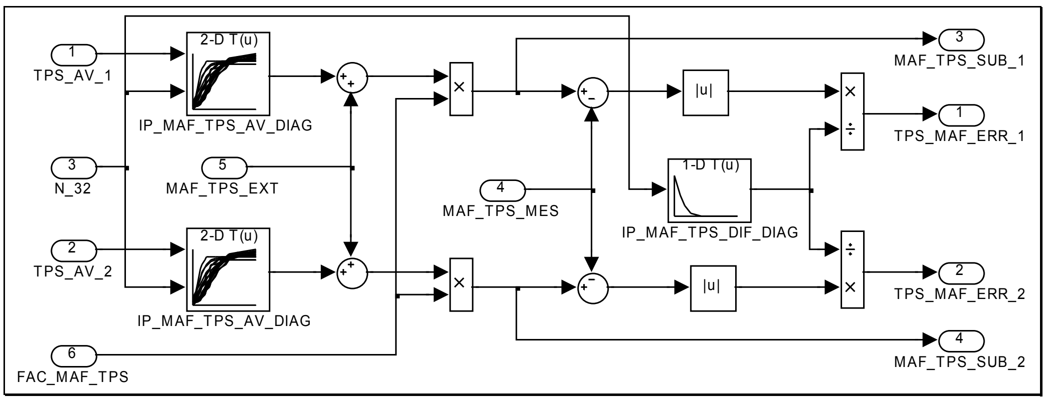
A.10.2.3 Calculation of TPS – MAF deviation

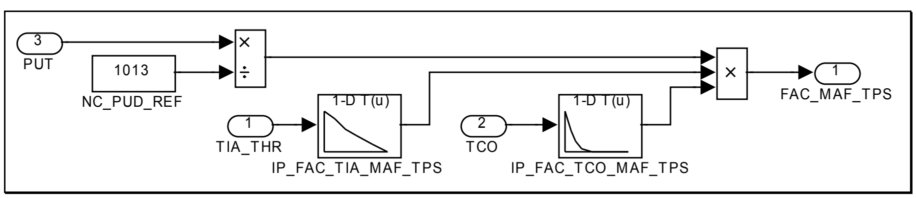
General information:

This function calculates the substitute air mass flow MAF_TPS_SUB_X for both TPS channels based on TPS_AV_X and engine speed. The module supports air mass flows as a result of charging and a correction depend on environment conditions (FAC_MAF_TPS). The variable MAF_TPS_EXT is defined in the corresponding diagnostic applications incidence.
The result of the calculation are the errors between MAF sensor and substitute air mass flow MAF_TPS_SUB_X.

Signal flow diagram:



Calculation of MAF_TPS_SUB and TPS – MAF deviation



Consideration of the environment conditions

Application conditions:

Initialisation: at LV_IGK = 0 → 1 **or** reset :
MAF_TPS_SUB_x = TPS_MAF_ERR_x = 0

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

Calculation of MAF_SUB_X: *{calculation for channel 1 and 2 separate}*

if LV_CDN_DIAG_TPS_MAF_X
and LV_ERR_MAF = 0
and LV_ERR_MAP = 0
then Consideration of the environment conditions

FAC_MAF_TPS = IP_FAC_TIA_MAF_TPS * IP_FAC_TCO_MAF_TPS ...
* (PUT / NC_PUD_REF)

Calculation of the substitute air mass flow depend on TPS

{TPS - Breakpoints for IP_MAF_TPS_AV_DIAG: TPS_AV_x}
MAF_TPS_SUB_x = [IP_MAF_TPS_AV_DIAG(N_32, TPS_AV_x) ...
+ MAF_TPS_EXT] * FAC_MAF_TPS

Calculation of the normalized TPS – MAF error:

$$TPS\_MAF\_ERR\_x = \frac{|MAF\_TPS\_SUB\_x - MAF\_TPS\_MES|}{IP\_MAF\_TPS\_DIF\_DIAG}$$

else

MAF_TPS_SUB_x = 0
TPS_MAF_ERR_x = 0

endif

A.10.2.4 Diagnosis of a first TPS error, TPS ratio error

FUNCTION DESCRIPTION:

General information:

Detection of the implausible channel in the case of a poti comparison error !

Description:

The substitute values MAF_TPS_SUB_X are used for the plausibility check while the engine is running. The differences between the measured mass air flow and the substitute values are normalized and integrated over a period C_T_TPS_MAF_ERR_INT.
The plausibility check cannot be performed when a mass air flow signal is missing, in this case, the channels are declared as faulty.

Application conditions:

Initialisation: at LV_IGK = 0 → 1 **or** reset :
TPS_MAF_ERR_INT = 0;
integration timer t_tps_maf_err_int and t_tps_maf_err_int_2 = 0

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

```
if      STATE_TPS_DIAG_STEP == "RATIO_CHK"    and
        LV_CDN_DIAG_TPS_MAF_1                 and
        LV_CDN_DIAG_TPS_MAF_2

then    Start integration timer C_T_TPS_MAF_ERR_INT
        t_tps_maf_err_int + = 10 ms

        Calculation of TPS_MAF_ERR_INT_X:     {calculation for channel 1 and 2 separate}
        TPS_MAF_ERR_INT_X(k)  = TPS_MAF_ERR_INT_X(k-1) + TPS_MAF_ERR_X

Error detection, integration timer is expired
        if      t_tps_maf_err_int >= C_T_TPS_MAF_ERR_INT
        then    if      TPS_MAF_ERR_INT_1  >= TPS_MAF_ERR_INT_2
                then    ERR_SYM_TPS_MAF_1 = SYM_2

Input data:

LV_IGK	LV_ST	LV_ES	C_CONF_MAF
MAF_KGH_MES	MAP_MES	EFF_VOL_SLOP	EFF_VOL_OFS_SUM

FUNCTION DESCRIPTION:

General information:

This module provides a external substitute air mass flow based on engine charging or recirulation flap (and so on) for the corresponding TPS plausibility check with main load sensor (MAF_TPS_MES).

The flags LV_INH_DIAG_TPS_MAF permit to deactivate the corresponding diagnostic.

Application conditions:

Initialisation: at LV_IGK = 0 → 1 or reset,
MAF_TPS_EXT = 0 *{ no charging or recirulation flap }*
MAF_TPS_MES = 0

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

{ Inhibition conditions for the TPS – MAF plausibility – check }

```
LV_INH_DIAG_TPS_MAF = ( LV_ES          or
                        LV_ST          or
                        LV_TPS_AD_REQ  or
                        LV_ERR_TPS_VCC )
```

End of diagnosis MTC_DR					

Input data:

LV_IGK	LV_INH_DIAG_MTC_DR	LV_DC	

FUNCTION DESCRIPTION:

General information:

The error detection is effected via the ECU hardware (MTC H-bridge IC).

Description:

The following errors symptoms leads to an error. They can not be distinguished by the software:

- Undervoltage
- Overcurrent
- Overtemperature
- H-bridge hardware disable

Error-symptoms are defined to this diagnosis function as following :

```
[ | | | ]
 |  |  |  └─> -                        (= SYM_0)
 |  |  └───> -                         (= SYM_1)
 |  └──────> -                         (= SYM_2)
 └─────────> ETC power stage error     (= SYM_3)
```

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) are initialised with 0 at every LV_IGK = 0 ->1 and reset
LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 and at reset

Recurrence: 10 ms

Activation:

if LV_IGK **and**
LV_INH_DIAG_MTC_DR == 0
then LV_CDN_DIAG_MTC_DR = 1
else LV_CDN_DIAG_MTC_DR = 0
endif

Deactivation: When the activation condition is not fulfilled.

Formula section:

Call BSW routine to read out the error state lv_mtc_dr_sf of the power stage !

if lv_mtc_dr_sf *{ MTC H-bridge error detected }*
then ERR_SYM_MTC_DR = SYM_3
LV_ERR_MTC_DR = 1 *{ after debounce, set for this DC }*
else ERR_SYM_MTC_DR = NO_SYM
endif

Calculation end of diagnosis:

LV_END_DIAG_MTC_DR is calculated by error management.

A.12 ETC power stage diagnosis (appl. inc.)

Output data:

Debounce time counter for system deviation check					
T_TPS_DIF_SP	V	0h...FFh	0...2.55	0.01	s
Time counter for constant TPS setpoint					
T_END_DIAG_MTC_CTL	V	0h...FFh	0...2.55	0.01	s
Time counter for end of diagnosis					
MTCPWM_MMV	V	0h ... 7FFFh	0...99.997	0.00305	%
Moving mean value of the position controller output					
TPS_SP_ST_DIAG	-	0h...3FFFh	0...119.5	0.0073	°TPS
TPS setpoint at start of constant setpoint detection					

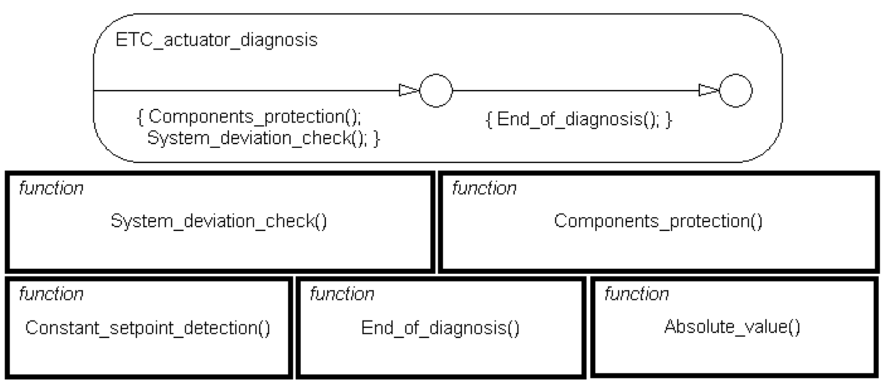
Input data:

LV_IGK	LV_INH_DIAG_MTC_CTL	TPS_SP	TPS_DIF
VB_MMV	MTCPWM	LV_DC	

General information:

The task of this diagnosis is to detect a throttle valve error or a jammed ETC actuator. The diagnosis observes the ETC position controller system deviation TPS_DIF in small and large signal range. The adjustment speed of the ETC actuator depends strongly on the operating voltage, therefore the debounce diagnosis time counter T_TPS_DIF_DIAG is a function of it.

Additionally the PWM output of the digital position controller is monitored by a diagnosis function. A high current of the rotor circuit over a long time can destroy the ETC components.



Statechart: ETC actuator diagnosis

Description:

The following errors symptoms can be distinguished :

- PWM error of the ETC system
- Error in small signal detection
- Error in large signal detection

Error-symptoms are defined to this diagnosis function as following :

```
□□□□
│ │ │ └─> PWM outside range          (= SYM_0)
│ │ └───> -                          (= SYM_1)
│ └─────> small signal detection     (= SYM_2)
└───────> large signal detection     (= SYM_3)
```

Indicated error-symptoms are saved at the end of the software module. Only the last error entry is saved in the generic error management. The error symptom SYM_0 has lower priority than the other symptoms. Only one symptom can be active at a time.

Application conditions:

Initialisation: at LV_IGK = 0 → 1 **or** reset:

All error variables ...MTC_CTL, T_TPS_DIF_DIAG, TPS_SP_ST_DIAG, MTCPWM_MMV and lv_tps_dif_dir to zero
(except LV_END_DIAG_MTC_CTL); T_TPS_DIF_SP = C_T_TPS_DIF_SP

LV_END_DIAG_MTC_CTL is initialised with 0
at every LV_DC = 0 → 1 **or** reset

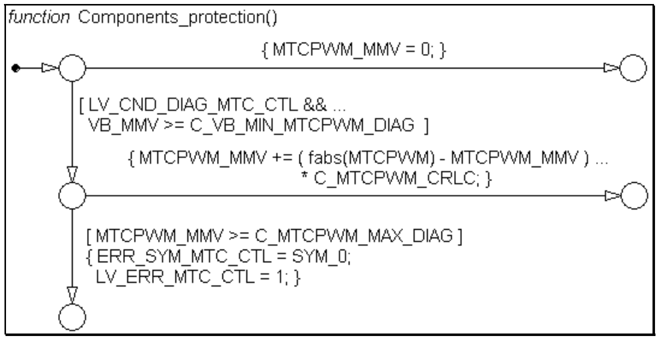
Recurrence: 10 ms

Activation:

if	LV_IGK	**and**
	LV_ERR_MTC_CTL == 0	**and**
	LV_INH_DIAG_MTC_CTL == 0	
then	LV_CDN_DIAG_MTC_CTL = 1	
else	LV_CDN_DIAG_MTC_CTL = 0	
endif		

Components protection

The following function monitors the absolute value of the digital position controller output. If the moving mean value exceeds the diagnosis threshold than an error will be indicated. The calculation of the moving mean value is done by low pass first order. The corresponding correlation factor specifies the speed of whose calculation.



Function: Protection of the ETC components

Formula section:

if LV_CDN_DIAG_MTC_CTL **and** (VB_MMV >= C_VB_MIN_MTCPWM_DIAG)

then *{ Calculation of the MTCPWM moving mean value by a low pass filter first order ! }*

MTCPWM_MMV += [| MTCPWM | - MTCPWM_MMV] * C_MTCPWM_CRLC

{ MTCPWM diagnostic condition depend on moving mean value }

if MTCPWM_MMV >= C_MTCPWM_MAX_DIAG

then ERR_SYM_MTC_CTL = SYM_0 *{ PWM outside range }*

LV_ERR_MTC_CTL = 1 *{ set for this DC }*

endif

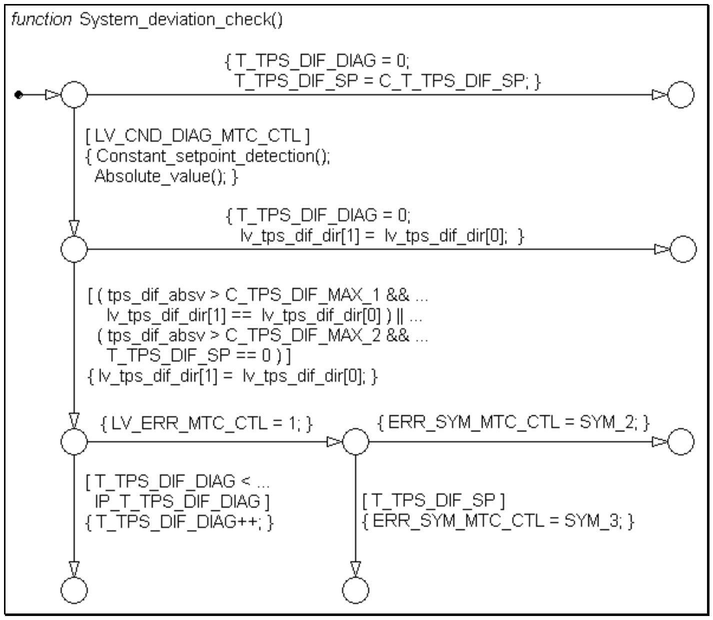
else *{ reset of the moving mean value }*

MTCPWM_MMV = 0

endif

System deviation check

This functionality monitors the absolute value of the system deviation. The algorithm is split in a small and a large signal range detection. The small signal range detection of the system deviation is only active after constant throttle position setpoint detection. The large signal range detection is done when the system deviation exceeds a upper threshold and its sign doesn't change.



Function: System deviation check

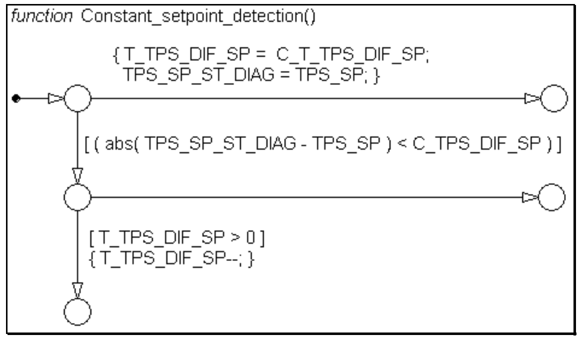
Formula section:

if LV_CDN_DIAG_MTC_CTL
then call Constant_setpoint_detection() *{ function for constant setpoint detection }*
call Absolute_value() *{ function for absolute value determination }*
if [tps_dif_absv > C_TPS_DIF_MAX_1 **and**
lv_tps_dif_dir(k-1) == lv_tps_dif_dir(k)] **or**
[tps_dif_absv > C_TPS_DIF_MAX_2 **and**
T_TPS_DIF_SP == 0]
then *{ save direction information for the next calculation step }*
lv_tps_dif_dir(k-1) = lv_tps_dif_dir(k)
if T_TPS_DIF_DIAG < IP_T_TPS_DIF_DIAG(VB_MMV)
then T_TPS_DIF_DIAG += 1 H
else LV_ERR_MTC_CTL = 1 *{ set for this DC }*
if T_TPS_DIF_SP
then ERR_SYM_MTC_CTL = SYM_3 *{ large signal detection }*
else ERR_SYM_MTC_CTL = SYM_2 *{ small signal detection }*
endif
endif
else *{ timer is reset }*
T_TPS_DIF_DIAG = 0
{ save direction information for the next calculation step }
lv_tps_dif_dir(k-1) = lv_tps_dif_dir(k)
endif
else *{ timers are reset }*
T_TPS_DIF_DIAG = 0
T_TPS_DIF_SP = C_T_TPS_DIF_SP

endif

Function for constant TPS setpoint detection

This function detects a constant throttle position setpoint. The small signal range detection will be started with constant setpoint recognition, otherwise the functionality is set to passive.



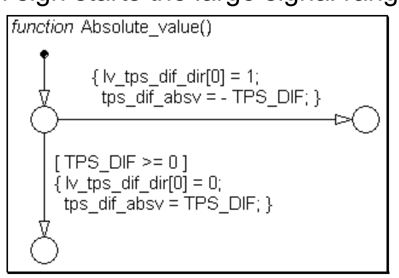
Function: Constant setpoint determination

Formula section:

if | TPS_SP_ST_DIAG – TPS_SP | < C_TPS_DIF_SP
then **if** T_TPS_DIF_SP > 0
then T_TPS_DIF_SP – = 1 H
endif
else *{ timer is reset }*
T_TPS_DIF_SP = C_T_TPS_DIF_SP
TPS_SP_ST_DIAG = TPS_SP
endif

Function for the absolute value determination

This function calculates the absolute value and indicates the sign of the system deviation. A change of the system deviation sign starts the large signal range detection newly again.



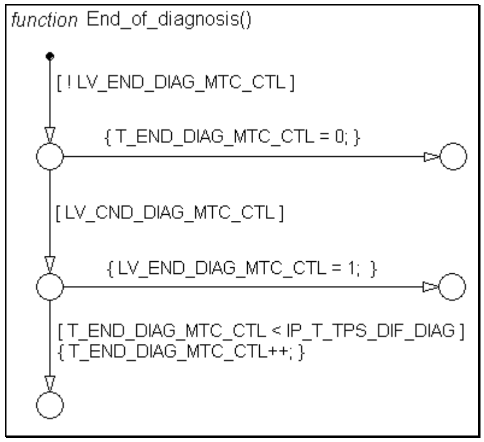
Function: Determination of absolute value

Formula section:

if TPS_DIF >= 0
then *{ set direction information }*
lv_tps_dif_dir(k) = 0
tps_dif_absv = TPS_DIF
else *{ set direction information and absolute value }*
lv_tps_dif_dir(k) = 1

```
        tps_dif_absv        = - TPS_DIF
endif
```

End of diagnosis, System deviation check



Function: End of diagnosis

Formula section:

if LV_END_DIAG_MTC_CTL == 0
then **if** LV_CDN_DIAG_MTC_CTL
    then **if** T_END_DIAG_MTC_CTL < IP_T_TPS_DIF_DIAG(VB_MMV)
        then T_END_DIAG_MTC_CTL += 1 H
        else LV_END_DIAG_MTC_CTL = 1 *{ set for this DC }*
        endif
    else T_END_DIAG_MTC_CTL = 0
    endif
endif

Calibration data:

FUNCTION DESCRIPTION:

General information:

The throttle position is determined by a two-channeled sensor. Both channels deliver inverse dispersing voltage signals. In order to reduce the measurement inaccuracy, the two signal voltages will be referenced to their supply voltage. After the initial engine start and component change the sensor characteristic is learnt within an adaptation routine. The learned values for the limp-home position, the lower mechanical stop and the TPS 1 amplification are stored at the end of the driving cycle as „non-volatile“.

A.15.1 Initialisation of TPS adaptation and start check

Description:

At start of the TPS adaptation or start check the following initialisation is necessary. *{ This whole chapter is initialisation, it has to be done before initialisation functions of other ETC modules. }*

Application conditions:

Initialisation: at reset **or** LV_IGK = 0 ⇒ 1 **or** LV_TPS_AD_ACT = 0 ⇒ 1 **or**
LV_TPS_AD_REQ _ST_CHK == 1 *{ re-initialisation after start check request}* **or**
LV_TPS_AD_REQ_VB_LOW == 1 *{re-initialisation after VB low during adaptation}*

```
{ Nominal slope of TPS 1 and 2 }
TPS_SLOP                    = C_TPS_SLOP
{ Is an adaptation demanded ? }
if    LV_TPS_AD_REQ == 0
then  { initialisation of time counter }
      t_max_tps_ad          = C_T_MAX_TPS_LIH_CHK
      { Initialisation of the inhibition condition for the amplified TPS 1 channel }
      if    LC_TPS_AD_GAIN_ENA == 1
      then  LV_INH_TPS_GAIN_1 = 0
      else  LV_INH_TPS_GAIN_1 = 1
      endif
```

{ next adaptation step }
TPS_AD_STEP = ST_CHK_LIH
{ Initialization value of the limp-home position }
TPS_LIH_INI = $0.5 \cdot [\mathrm{TPS\_LIH\_1} + \mathrm{TPS\_LIH\_2}]$

else *{ Set inhibition condition for the selection of the amplified TPS 1 channel }*
LV_INH_TPS_GAIN_1 = 1
{ initialisation of the adaptation values }
V_TPS_AD_LIH_X = C_V_TPS_SP_LIH_X
V_TPS_AD_BOL_X = C_V_TPS_AD_BOL_INI_X
V_TPS_GAIN_AD_BOL = C_V_TPS_GAIN_AD_BOL_INI
{ Initialization value of the limp-home position }
TPS_LIH_INI = ...

$$0.5 \cdot \mathrm{TPS\_SLOP} \cdot [\mathrm{C\_V\_TPS\_SP\_LIH\_1} - \mathrm{C\_V\_TPS\_SP\_LIH\_2} \ldots - \mathrm{C\_V\_TPS\_AD\_BOL\_INI\_1} + \mathrm{C\_V\_TPS\_AD\_BOL\_INI\_2}]$$

TPS_LIH_X = TPS_LIH_INI
{ amplification value of the measuring amplifier }
TPS_AD_SLOP_GAIN_1 = C_TPS_AD_SLOP_GAIN_INI
{ initialisation of time counter }

A.15.2 Diagnosis conditions and error symptom definition

Description:

The diagnosis condition for the TPS adaptation is true as long as the adaptation is active and the diagnosis condition for the TPS start check is also true as long as the start check is active.

The end of diagnosis in error free case is set on the end of the TPS start check / adaptation or latest, if a error is set.

The error symptoms are defined for this diagnosis as:

ERR_SYM_TPS_AD (TPS adaptation)

```
□□□□
│ │ │ └─> adaptation conditions exceeded              (= SYM_0)
│ │ └───> limp-home adaptation outside range          (= SYM_1)
│ └─────> adaptation of the amplifier not possible    (= SYM_2)
└───────> lower mec. stop adaptation outside range    (= SYM_3)
```

ERR_SYM_TPS_AD_SPR (TPS adaptation)

```
□□□□
│ │ │ └─> lower position not reached                  (= SYM_0)
│ │ └───> error lower return spring check             (= SYM_1)
│ └─────> upper position not reached                  (= SYM_2)
└───────> error upper return spring check             (= SYM_3)
```

ERR_SYM_TPS_AD_GAIN (TPS adaptation)

```
□□□□
│ │ │ └─> adapted amplification too low               (= SYM_0)
│ │ └───> adapted amplification too high              (= SYM_1)
│ └─────> -                                           (= SYM_2)
└───────> -                                           (= SYM_3)
```

ERR_SYM_TPS_ST_CHK (TPS start check)

```
□□□□
│ │ │ └─> error in spring check                       (= SYM_0)
│ │ └───> error in limp-home check                    (= SYM_1)
│ └─────> -                                           (= SYM_2)
└───────> -                                           (= SYM_3)
```

Application conditions:

Initialisation: at reset **or** LV_IGK = 0 ⇒ 1 **or** LV_TPS_AD_ACT = 0 ⇒ 1 :

Set all error variables ..._TPS_AD... and ..._TPS_ST_CHK to zero !

Recurrence: 5ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn't fulfilled.

Formula section:

{ The diagnosis conditions are calculated in front of the adaptation or start check algorithm ! }

```
if      LV_TPS_AD_ACT == 1
then    { Wait C_T_DLY_TPS_AD ms after ignition on to get a plausible battery voltage. The global
        time delay can be finished when ECM3 pre drive check is done and after defined time delay ! }
        if      T_DLY_TPS_AD >=  C_T_DLY_TPS_AD          or

      endif
endif
```

A.15.3 Co-ordination of the adaptation functions

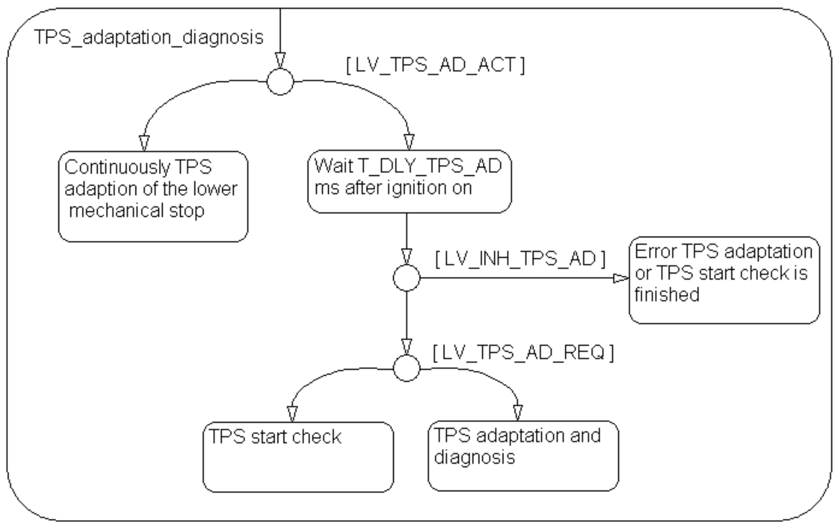
Description:

The adaptation of the throttle position includes two sections: the start routine and adaptation routine. The start routine is a part of the adaptation routine with owns thresholds and is carry out at every switch-on of the engine control unit. The adaptation routine starts only if the adaptation is requested.

The actual adaptation condition LV_TPS_AD_ACT and the adaptation request LV_TPS_AD_REQ are defined in the corresponding application incidence.

To get a plausible battery voltage the check of adaptation or start check is delayed T_DLY_TPS_AD after control unit is switched on.

Signal flow diagram:



Application conditions:

Initialisation: see above

Recurrence: 5 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn't fulfilled.

Formula section:

```
if      LV_TPS_AD_ACT
then    { Wait C_T_DLY_TPS_AD ms after ignition on to get a plausible battery voltage. The global
        time delay can be finished when ECM3 pre drive check is done and after defined time delay ! }
        if      T_DLY_TPS_AD >=  C_T_DLY_TPS_AD           or
                ( STATE_DR_MU_MC ==  ENABLE       and
                  T_DLY_TPS_AD >=  C_T_DLY_MIN_TPS_AD )
        then    { Inhibition bit for TPS adaptation, is set in the corresponding application incidence }
                if      LV_INH_TPS_AD
                then    { Is an adaptation requested ? }
                        if    LV_TPS_AD_REQ
                        then    { Error TPS adaptation, inhibition bit is set }
                                ERR_SYM_TPS_AD = SYM_0
                                LV_ERR_TPS_AD = 1     {set for DC without debounce}
                        else    { Start check is finished ! }
                                TPS_AD_STEP            = ST_CHK_END

Comment: The continuously lower mechanical stop adaptation is now executed !

endif

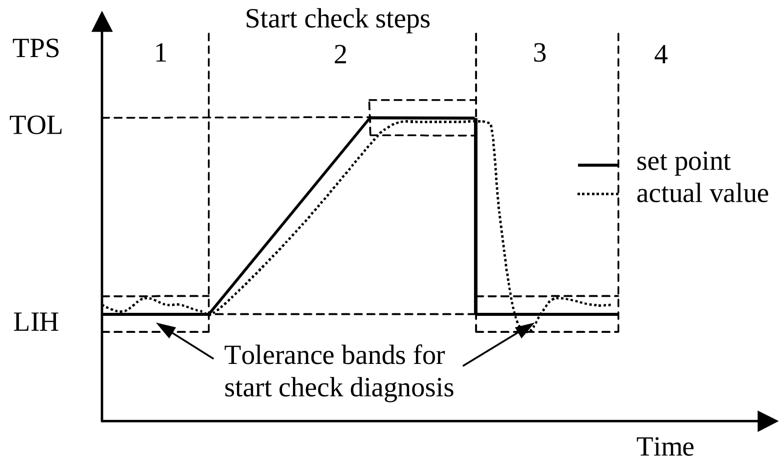
A.15.4 TPS start check and diagnosis

Description:

The Start routine is carried out with every switch-on of the engine control unit (LV_IGK = 1). The TPS-adaptation bit is active initialised (LV_TPS_AD_ACT =1) for the start-check or adaptation-routine. The routine includes the following:

- Limp-home position check
- Adaptation of the limp-home position
- Upper return spring check

The start check is only carried out when the adaptation conditions are maintained otherwise it will be ignored without error entry.



The state variable TPS_AD_STEP indicates the following start check steps:

Adap. area	TPS_AD_STEP	Note
1	ST_CHK_LIH	Check and adaptation of the limp-home position
2	ST_GO_TOL	throttle flap goes into a upper position
3	ST_SPR_CHK	Upper return spring and limp-home check
4	ST_CHK_END	End of start check

Formula section:

```
start_check( )
    switch( TPS_AD_STEP )
        case ST_CHK_LIH:        call function st_chk_lih( )
                                break
        case ST_GO_TOL:         call function st_go_tol( )
                                break
        case ST_SPR_CHK:        call function st_spr_chk( )
                                break
        default:                { TPS start check successful finished }
                                TPS_AD_STEP             = ST_CHK_END
                                { set new ETC setpoint }
                                TPS_SP_AD               = TPS_LIH_1
                                { switch on request ETC power stage }
                                LV_TPS_AD_CUR_OFF       = 0
                                { enable injection for all cylinder }
                                INH_IV_TPS_AD           = 0
    end switch
end function
```

A.15.4.1 function st_chk_lih, check of the limp-home position

Description:

When checking the limp-home position the throttle valve is staying without current hold by spring power in the limp-home position. The actual sensor-signals are compared with their adaptations in the non-volatile memory.

If the actual voltage values during the time interval are outside the hysteresis then no agreement is recognised and a new adaptation is necessary or an engine start must be cancelled.

Formula section:

```
st_chk_lih()
    if      t_max_tps_ad
    then    t_max_tps_ad - = 5 ms
            if      | V_TPS_x – V_TPS_AD_LIH_x | ≤ C_V_TPS_LIH_CHK_HYS
            then    check of the LIH position
                    t_step_tps_ad + = 5 ms
                    if      t_step_tps_ad > C_T_DYW_TPS_LIH_CHK
                    then    Limp-home check was successful !
                            CTR_ST_CHK_LIH_OK + = 1 h
                            { initialisation for the next adaptation step }
                            t_step_tps_ad          = 0
                            t_max_tps_ad           = C_T_MAX_TPS_SP_RST_CHK
                            { enable injection for all cylinder }
                            INH_IV_TPS_AD          = 0
                            { switch on request ETC power stage }
                            LV_TPS_AD_CUR_OFF      = 0
                            { next adaptation step }
                            TPS_AD_STEP            = ST_GO_TOL

A.15.4.2 function st_go_tol, throttle flap goes into upper position

Description:

This function is used to positioning the throttle flap into a position above limp-home. The position controller is switched on and the setpoint is increased by change limitation until the setpoint for testing the retracting spring is reached.

Now a timer is started. The actual value of the throttle position has to reach the setpoint within the hysteresis within a limit maximum of time.

Formula section:

st_go_tol()

```
    { engine start without start delay in case of injection is enable }
    if     ( LV_ST == 0 ) or INH_IV_TPS_AD
    then   if     TPS_SP_AD < C_TPS_SP_RST_CHK_BAS

    endif
end function
```

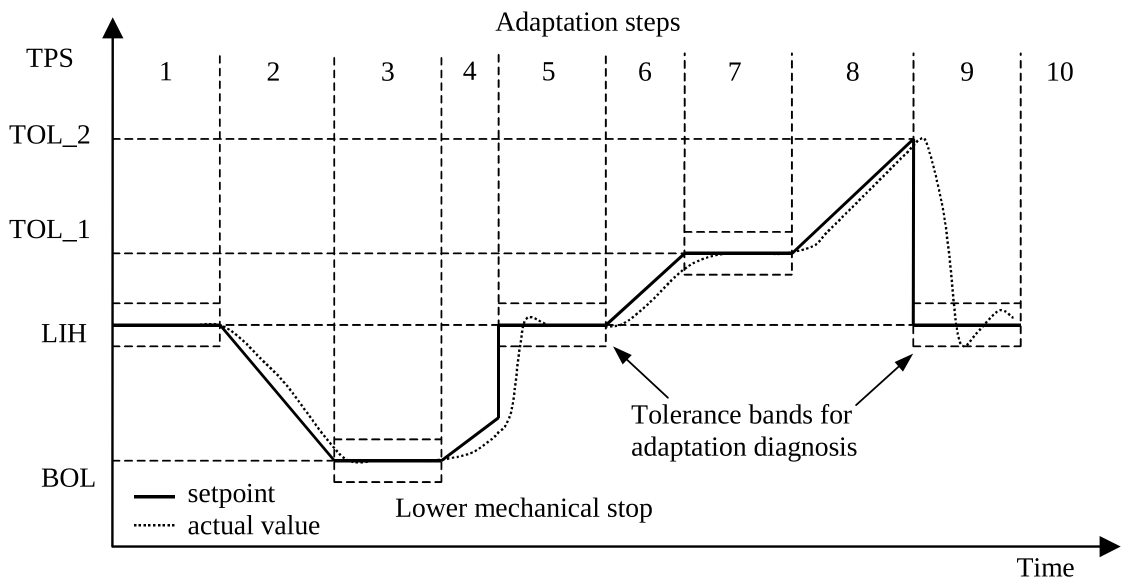
A.15.5 TPS adaptation and diagnosis

Description:

Due to the electrical and the mechanical tolerances of the throttle position system, the sensor characteristic has to be learnt. The adaptation and diagnosis of the lower mechanical stop and limp-home position occurs within the adaptation routines. The adapted lower mechanical stop and the upper check position are used for the calculation of the amplification of the amplified TPS 1 channel. The upper mechanical stop is not learned. During the TPS adaptation no limitation of the throttle position setpoint is active. The learned value for the limp-home position, the lower mechanical stop and the TPS 1 amplification are stored at the end of the driving cycle as „non-volatile".

The TPS adaptation includes the following functions:

- Adaptation and check of the limp-home position
- Adaptation and check of the lower mechanical stop
- Lower return spring check
- Adaptation of the amplifier amplification (TPS 1 channel)
- Upper return spring check



The state variable TPS_AD_STEP indicates the following adaptation steps:

Steps	TPS_AD_STEP	Note
1	AD_LIH_POS	Adaptation and check of the limp-home position
2	AD_GO_BOL	Throttle flap drives in the lower mechanical stop
3	AD_BOL_POS	Adaptation and check of the lower mechanical stop
4	AD_GO_LIH	Throttle flap drives in a position below throttle flap LIH
5	AD_SPR_CHK_1	Check of the lower return spring
6	AD_GO_TOL_1	Throttle drives in a position above throttle flap LIH
7	AD_TOL_POS	Adaptation position of the measuring amplifier
8	AD_GO_TOL_2	Throttle drives in a position above throttle flap LIH
9	AD_SPR_CHK_2	Check of the upper return spring
10	AD_END	Successful adaptation end

Formula section:

tps_adaptation( )

end function

A.15.5.1 Function ad_lih_pos(), adaptation of the limp-home position

Description:

The first step is the adaptation of the limp-home position. The actuator is without current and is forced by the spring power in the limp home position.

During the adaptation all the voltage values must be in the adaptation windows. A hysteresis band is set up around each of the first recorded values (TPS 1 and 2). If all the values lie in this hysteresis band during an adjustable time then the adaptation values are determined from each first and last value. If the TPS - value lies outside the hysteresis band then the process is newly started for both TPS. The learning algorithm is limited by the maximum time. This procedure is the same for the Limp home position and the lower mechanical stop. Just the calibration values are different. An error is detected if the adaptation could not be carried out during the maximum time C_T_MAX_TPS_AD.

Formula section:

```
ad_lih_pos()
    if      t_max_tps_ad
    then    t_max_tps_ad - = 5 ms
            if      | V_TPS_X – C_V_TPS_SP_LIH_X | ≤ C_V_TPS_AD_WIN_LIH

```

$$V\_TPS\_AD\_LIH\_x = \frac{v\_tps\_x\_buf + V\_TPS\_x}{2}$$

A.15.5.2 Function ad_go_bol(), throttle flap goes into lower mechanical stop

Description:

This function is used to drive the throttle flap into the lower mechanical stop. The position controller is switched-on and the setpoint is decreased by change limitation.

Formula section:

```
ad_go_bol ()
    if      TPS_SP_AD > 0
    then    TPS_SP_AD - = C_TPS_SP_BOL_LGRD
    else    { initialisation for the next adaptation step }
            t_max_tps_ad       = C_T_MAX_TPS_AD
            t_step_tps_ad      = 0
            v_tps_x_buf        = V_TPS_X
            v_tps_gain_1_buf   = V_TPS_GAIN_1
            { next adaptation step }
            TPS_AD_STEP        = AD_BOL_POS
    endif
end function
```

A.15.5.3 Function ad_bol_pos(), adaptation of the lower mechanical stop

Description:

As soon as the mechanical stop is reached, the adaptation of the lower mechanical stop for all TPS input channels is started.

During the adaptation all the voltage values must be in the adaptation windows. A hysteresis band is set up around each of the first recorded values (TPS 1 and 2). If all the values lie in this hysteresis band during an adjustable time then the adaptation values are determined from each first and last value. If the TPS - value lies outside the hysteresis band then the process is newly started for both TPS. The learning algorithm is limited by the maximum time. If the maximum adaptation time is exceeded, a adaptation error is indicated.

Formula section:

```
ad_bol_pos()
    if      t_max_tps_ad
    then    t_max_tps_ad - = 5 ms
            if      | V_TPS_X – C_V_TPS_SP_BOL_ | ≤ C_V_TPS_AD_WIN_BOL
            { If the difference of one of the two sensors is greater than C_V_TPS_AD_HYS ! }
            then    if      | v_tps_x_buf – V_TPS_x | > C_V_TPS_AD_HYS
                    then    { reinitialisation of v_tps_..._buf }
                            v_tps_x_buf        = V_TPS_X
                            v_tps_gain_1_buf   = V_TPS_GAIN_1
                            { reset time counter }
                            t_step_tps_ad      = 0
                    endif
                    t_step_tps_ad + = 5 ms
                    if      t_step_tps_ad > C_T_TPS_AD_HYS
                    then    { Calculation of lower mechanical stop and TPS amplification }
```

```
                    call function calculate_AD_values( )
                    { initialisation for the next adaptation step }
                    t_max_tps_ad      = C_T_MAX_TPS_SP_RST_CHK
                    { next adaptation step }
                    TPS_AD_STEP       = AD_GO_LIH
               endif
          else { reset time counter }
               t_step_tps_ad          = 0

          endif
     else { lower mechanical stop adaptation outside range }
          ERR_SYM_TPS_AD = SYM_3
          LV_ERR_TPS_AD  = 1                    {set for DC without debounce}
     endif
end function
```

A.15.5.3.1 Function calculate_AD_values( )

Description:

This function calculates the adaptation values of the lower mechanical stop and limp-home position for both throttle position sensors. The throttle position sensor slope TPS_SLOP is set to the nominal slope C_TPS_SLOP.

Application conditions:

Activation: *Is called from function ad_bol_pos( )*

Formula section:

calculate_AD_values( )

{ Nominal slope of TPS 1 and 2 }

$$TPS\_SLOP = C\_TPS\_SLOP$$

{ Lower mechanical stop of TPS 1 and 2 }

$$V\_TPS\_AD\_BOL\_x = \frac{v\_tps\_x\_buf + V\_TPS\_x}{2}$$

{ Lower mechanical stop of amplified TPS 1 channel }

$$V\_TPS\_GAIN\_AD\_BOL = \frac{v\_tps\_gain\_1\_buf + V\_TPS\_GAIN\_1}{2}$$

{ Calculation of the limp-home position for TPS 1, 2 and the default value }

$$TPS\_LIH\_1 = [V\_TPS\_AD\_LIH\_1 - V\_TPS\_AD\_BOL\_1]... \cdot TPS\_SLOP$$

$$TPS\_LIH\_2 = [V\_TPS\_AD\_BOL\_2 - V\_TPS\_AD\_LIH\_2]... \cdot TPS\_SLOP$$

$$TPS\_LIH\_INI = 0.5 \cdot [TPS\_LIH\_1 + TPS\_LIH\_2]$$

{ Set temporary electrical adaptation values }

```
V_TPS_AD_EL_BOL_1     = V_TPS_AD_BOL_1
V_TPS_AD_EL_BOL_2     = V_TPS_AD_BOL_2
V_TPS_GAIN_AD_EL_BOL  = V_TPS_GAIN_AD_BOL
```

end function

A.15.5.4 Function ad_go_lih(), throttle flap goes below LIH into position

Description:

This function is used to positioning the throttle flap into a position between lower mechanical stop and limp-home. The position controller is switched-on and the setpoint is increased by change limitation until the setpoint for testing the lower return spring is reached.

The throttle flap has to reach the requested position in a defined time limit and hysteresis window, otherwise an error will be indicated.

Formula section:

```
ad_go_lih ()
    if      TPS_SP_AD < C_TPS_SP_SPR_CHK_UP
    then    TPS_SP_AD + = C_TPS_SP_RST_CHK_LGRD
            if      TPS_SP_AD > C_TPS_SP_SPR_CHK_UP
            then    TPS_SP_AD = C_TPS_SP_SPR_CHK_UP
            endif

end function
```

A.15.5.6 Function ad_go_tol_1(), throttle flap goes into upper position

Description:

After the adaptation of the lower mechanical stop and the limp-home position the adaptation routine goes on with the upper spring test and the adaptation of the amplification from the TPS measuring amplifier. This function is used to positioning the throttle flap into a position above limp-home. The position controller is switched-on and the setpoint is increased by change limitation until the setpoint for the adaptation of the measuring amplifier is reached.

The throttle flap has to reach the requested position in a defined time limit and hysteresis window, otherwise an error will be indicated.

Formula section:

```
ad_go_tol_1()
     if     TPS_SP_AD < C_TPS_SP_RST_CHK
     then   TPS_SP_AD += C_TPS_SP_RST_CHK_LGRD

LV_ERR_TPS	LV_ERR_TPS_ST_CHK	LV_MTC_CUR_OFF	LC_TPS_AD_GAIN_ENA

FUNCTION DESCRIPTION:

A.16.1 Set adaptation state and request

Description:

The adaptation demand is checked every time the control unit is switched on. The TPS adaptation is necessary in the following cases:

- In initial start (first engine run or control unit exchange), that means no adaptation values are stored in the non volatile memory
- After a component exchange , if the TPS values are lie outside the tolerance window (LV_TPS_AD_REQ_ST_CHK)
- Check sum error (NVMY – error) is current
- Initiated by the tester (LV_TPS_AD_ACT_EXT_ADJ)
- Adaptation request bit LV_TPS_AD_REQ is set

Each of these points ends with a new adaptation request.

Application conditions:

Initialisation: at reset **or** LV_IGK = 0 ⇒ 1

LV_TPS_AD_ACT = 1 *{ initiate TPS adaptation or start check }*
LV_TPS_AD_REQ is initialised with the value from the non-volatile memory !
T_DLY_TPS_AD_VB_LOW = 0
LV_TPS_AD_VB_LOW = 0
LV_TPS_AD_REQ_VB_LOW = 0

```
if    ( Initial start      or        { first engine run or control unit exchange }
        Check sum error  )
then  { set a new adaptation request }
      LV_TPS_AD_REQ = 1
endif
```

Recurrence: 5 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn't fulfilled.

Formula section:

```
{ The TPS adaptation or start check are finished or stopped ! }
if    LV_TPS_AD_ACT
then  { TPS adaptation or start check successful finished }
      if    ( TPS_AD_STEP == ST_CHK_END     or
              TPS_AD_STEP == AD_END           )
      then  { Reset of the current adaptation or start check }
            LV_TPS_AD_ACT   = 0
            LV_TPS_AD_REQ_VB_LOW = 0
            if     LV_ERR_TPS_AD_GAIN == 0
            then   { Reset of the adaptation request }
                   LV_TPS_AD_REQ  = 0
            endif
      endif
      { TPS adaptation or start check is stopped in case of errors ! }
      if    ( LV_ERR_TPS_AD == 1            or
              LV_ERR_TPS_AD_SPR == 1         )
      then  { Stop of the current adaptation or start check }

if      ( LC_TPS_AD_REQ = 0 ⇒ 1             or      { request via calibration system }
          LC_TPS_AD_GAIN_ENA = 0 ⇒ 1        or      { request via system configuration }
          LV_TPS_AD_REQ_ST_CHK               )      { request from TPS start check }
then    { Set a new adaptation request, at the end of the DC the adaptation request is saved in the
          non-volatile memory ! }
        LV_TPS_AD_REQ = 1
endif
{ If the TPS start check requests a new TPS adaptation, the TPS adaptation is started at once ( the
activation information LV_TPS_AD_ACT == 1 is still available ) }
```

A.16.2 Inhibition of the TPS adaptation

Description:

After the activation of the adaptation routine the following conditions are requested until LV_TPS_AD_ACT == 0. The inhibition information are used for the TPS adaptation and the TPS start check.

Application conditions:

Initialisation: at reset **or** LV_IGK = 0 ⇒ 1 **or** LV_TPS_AD_ACT = 0 ⇒ 1:
LV_INH_TPS_AD = 0
LV_MTC_CUR_ERR = 0
ctr_mtc_cur_err = 0

Recurrence: 5 ms

Activation: LV_TPS_AD_ACT == 1

Deactivation: When the activation condition isn't fulfilled.

Formula section:

{ Comparison between requested and actual ETC power stage state (switch-on or -off) ! In the constant C_MTC_CUR_TPS_AD the power stage state for every adaptation step is coded. }

```
if      ( 0x01 h & [ C_MTC_CUR_TPS_AD >> TPS_AD_STEP ] ) == LV_MTC_CUR_OFF

FUNCTION DESCRIPTION:

General information:

The ETC management observes and coordinates all functions of the electrical throttle flap, these are the following functions: throttle position determination, throttle position control, actuator adaptation and the corresponding diagnosis.

Furthermore it checks the presence of ETC or PVS related errors which cause a limp home reaction opf the system such as Power Limitation, Engine Speed Limitation, Forced Idle or Engine Shut-Down.

If such a limp home is activated then an additional limp home error is entered to inform the service technician about the type of limp home reaction.

The module is directly calculated after the following diagnosis:

- Throttle position sensor diagnosis
- ETC power stage diagnosis
- ETC position controller diagnosis

A.17.1 TPS state manager

General information:

The TPS state manager coordinates all possible TPS errors (see below), indicates the state of the TPS diagnosis for the determination of the throttle position and requests a engine torque reduction in case of TPS errors. The module is calculated after the TPS diagnosis and indicates in STATE_TPS_DIAG the following states:

STATE_TPS_DIAG	Note	Fault reaction
TPS_NO_ERROR	no faults in sensor system	sensor 1 is active, no fault reaction
TPS_1_ERROR	sensor 1 is faulty	sensor 2 is active, engine torque reduction
TPS_2_ERROR	sensor 2 is faulty	sensor 1 is active, engine torque reduction
TPS_MAX_ACT	compare error	max. selection between sensor 1 & 2
TPS_DBL_ERROR	both sensors are faulty	limp-home request, ETC currentless

Possible TPS errors:

TPS errors	Note
LV_ERR_TPS_VCC	sensor supply voltage
LV_ERR_TPS_1	electrical diagnosis, range check, sensor 1
LV_ERR_TPS_2	electrical diagnosis, range check, sensor 2
LV_ERR_TPS_RATIO	compare error between TPS 1 and TPS 2
LV_ERR_TPS_MAF_1	plausibility error between TPS 1 and MAF
LV_ERR_TPS_MAF_2	plausibility error between TPS 2 and MAF

Signal flow diagram:

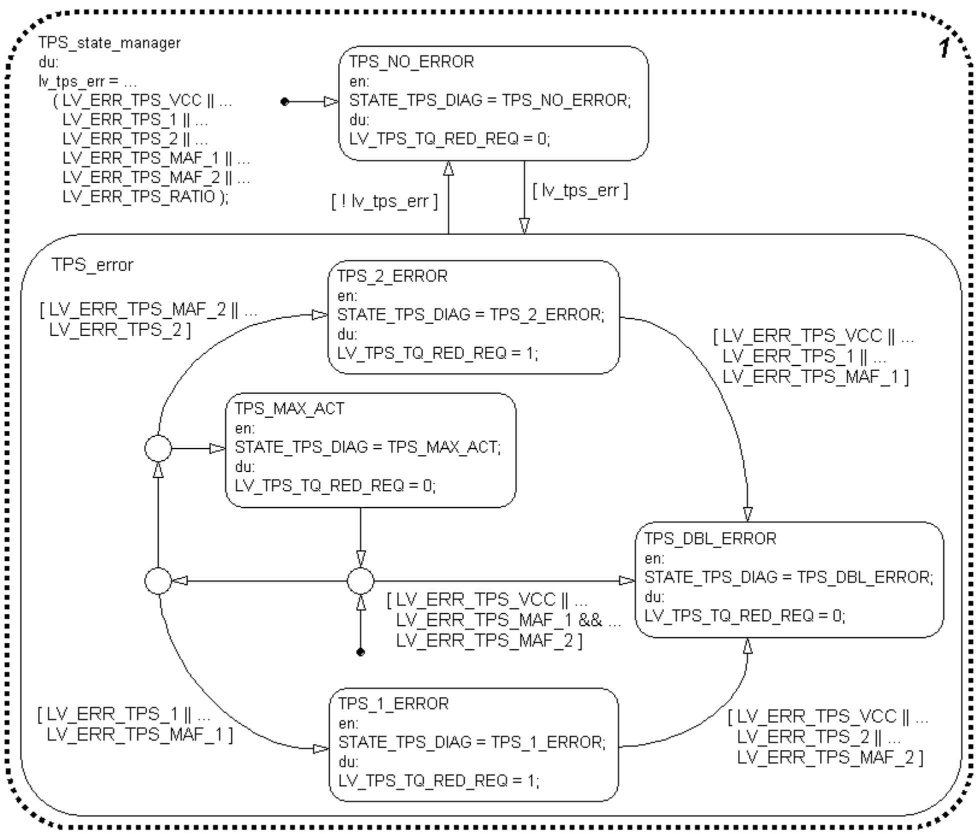

Figure 1: TPS state manager

Application conditions:

Initialisation: at LV_IGK = 0 → 1 **or** reset
STATE_TPS_DIAG = TPS_NO_ERROR
LV_TPS_TQ_RED_REQ = 0

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

```

```

A.17.2 General information:

The ETC limp-home manager observes all TPS and ETC diagnosis functions. In case of sefaty critical errors, the ETC limp-home manager switchs off the ETC power stage via disable line or requests a ETC limp-home setpoint for control limp-home position (in case of broken upper return spring, the power stage is enable) and demands a engine speed limitation. The manager distinguishs two modes of engine speed limitation :

Mode	STATE_N_LIM_ETC_REQ	Note
0	N_NOT_LIM	engnie speed limitation isn't demanded
1	N_LIM_CON	a constant engine speed limitation is demanded
2	N_LIM_PVS	a variable engine speed limitation is demanded, the limitation speed is a function of PVS

{ In case of engine speed limitation, the logical variable LV_N_LIM_ETC_LIH is always set ! }

Signal flow diagram:

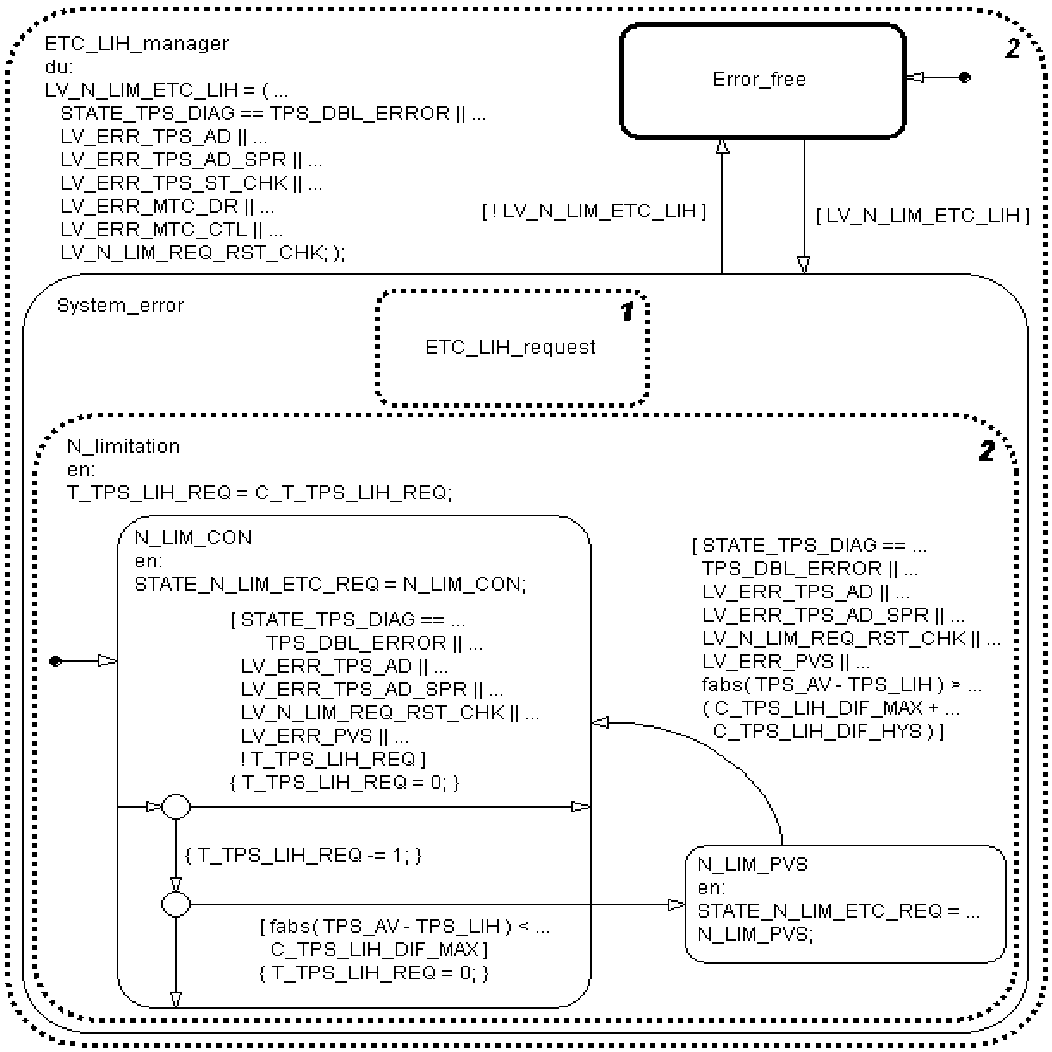

Figure 2: ETC limp-home manager

Application conditions:

Initialisation: at LV_IGK = 0 → 1 **or** reset :

```
LV_N_LIM_ETC_LIH         = 0
LV_MTC_CUR_OFF_REQ       = 0
LV_TPS_SP_LIH_REQ        = 0
STATE_N_LIM_ETC_REQ      = N_NOT_LIM
```

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

A.17.3 Global error bit of the ETC system

General information:

The local variable LV_ERR_TPS is defined as global error bit and is provided as input variable for other functions. She isn't subject to the error management and is set, if a ETC fault occurs.

Application conditions:

Initialisation: LV_ERR_TPS = 0 at LV_IGK = 0 → 1 **or** reset

Recurrence: 10 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition is not fulfilled.

Formula section:

```
if    LV_ERR_TPS_VCC          or   { error TPS supply voltage }
      LV_ERR_TPS_1            or   { error TPS 1, electrical diagnosis }
      LV_ERR_TPS_2            or   { error TPS 2, electrical diagnosis }
      LV_ERR_TPS_MAF_1        or   { TPS 1 isn't plausible to MAF }
      LV_ERR_TPS_MAF_2        or   { TPS 2 isn't plausible to MAF }
      LV_ERR_TPS_AD           or   { error TPS adaptation, LIH + BOL }
      LV_ERR_TPS_AD_SPR       or   { error TPS adaptation, spring check }
      LV_ERR_TPS_ST_CHK       or   { error TPS start check }
      LV_ERR_MTC_DR           or   { error in power stage }
      LV_ERR_MTC_CTL               or   { error position control }

endif

endif

A.18.2 Diagnosis general inhibition in case of engine backwards rotation detection

General information:

Inhibits cam/crk diagnosis when a reverse engine rotation has been detected until confirmation/nullification.

Application conditions:

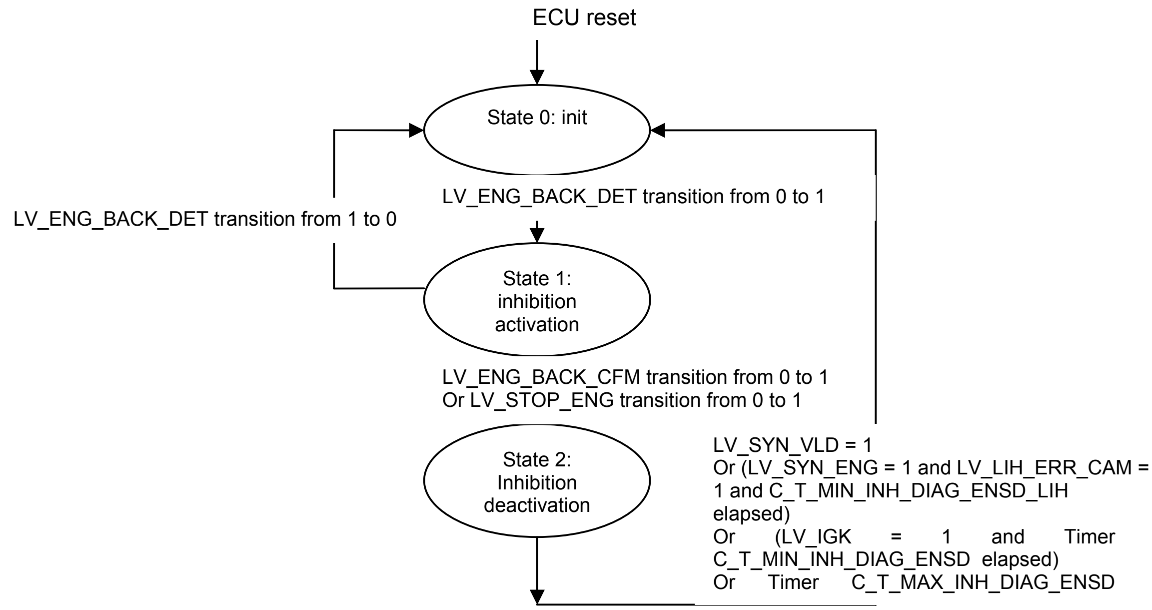
Initialisation: no initialization value.

Recurrence: 10ms **and** transition from 1 to 0 of LV_IGK **and** every update of LV_ENG_BACK_DET or LV_ENG_BACK_CFM **and** transition from 0 to 1 of LV_SYN_VLD **and** transition from 0 to 1 of LV_STOP_ENG **and** transition from 0 to 1 of LV_SYN_ENG in case of camshaft limp_home mode (LV_LIH_ERR_CAM = 1)

Activation: LC_ENG_BACK_INH = 0

Deactivation: when application conditions are not fulfilled

Formula section:



State 0: Initialisation

Input conditions:

External event:	ECU reset
From state 1:	LV_ENG_BACK_DET transition from 1 to 0
From state 2:	LV_SYN_VLD = 1
	Or (LV_IGK = 1 and timer C_T_MIN_INH_DIAG_ENSD elapsed)
	Or timer C_T_MAX_INH_DIAG_ENSD elapsed
	Or (LV_SYN_ENG = 1 and LV_LIH_ERR_CAM = 1 and timer C_T_MIN_INH_DIAG_ENSD_LIH elapsed)

Output conditions:

To state 1:	LV_ENG_BACK_DET transition from 0 to 1
	And Timer C_T_DLY_REST_IGK stopped

Action in the state:

Set timer to C_T_MIN_INH_DIAG_ENSD

Set timer to C_T_MAX_INH_DIAG_ENSD

Set timer to C_T_MIN_INH_DIAG_ENSD_LIH

Transition action:

None

State 1: Inhibition activation

Input conditions:

From state 0: LV_ENG_BACK_DET transition from 0 to 1

Output conditions:

To state 0: ECU reset

Or LV_ENG_BACK_DET transition from 1 to 0

To state 2: LV_ENG_BACK_CFM transition from 0 to 1

Or LV_STOP_ENG transition from 0 to 1

Action in the state: LV_INH_DIAG_ENSD = 1

LV_IGN_INJ_LOCK_REQ = 1

Stop timer C_T_MIN_INH_DIAG_ENSD if on-going

Stop timer C_T_MAX_INH_DIAG_ENSD if on-going

Stop timer C_T_MIN_INH_DIAG_ENSD_LIH if on-going

Transition action:

To state 0: LV_INH_DIAG_ENSD = 0

LV_IGN_INJ_LOCK_REQ = 0

To State 2: Start timer C_T_MAX_INH_DIAG_ENSD

Start timer C_T_MIN_INH_DIAG_ENSD if LV_IGK = 0

Start timer C_T_MIN_INH_DIAG_ENSD_LIH

State 2: Inhibition deactivation

Input conditions:

From state 1: LV_ENG_BACK_CFM transition from 0 to 1

Or LV_STOP_ENG transition from 0 to 1

Output conditions:

To state 0: ECU reset

Or LV_SYN_VLD = 1

Or (LV_IGK = 1 and timer C_T_MIN_INH_DIAG_ENSD elapsed)

Or timer C_T_MAX_INH_DIAG_ENSD elapsed

Or (LV_SYN_ENG = 1 and LV_LIH_ERR_CAM = 1

and timer C_T_MIN_INH_DIAG_ENSD_LIH elapsed)

Action in the state: Start timer C_T_MIN_INH_DIAG_ENSD
on transition of LV_IGK from 1 to 0

Transition action:

To state 0: LV_INH_DIAG_ENSD = 0

LV_IGN_INJ_LOCK_REQ = 0

Remark: if C_T_MIN_INH_DIAG_ENSD = 0, then timer is started at transition of LV_IGK from 1 to 0 and considered as elapsed immediately.

A.18.3 Diagnosis Manager

General information:

One purpose of the diagnosis manager is to provide a summary of diagnostic information, in order to facilitate taking the necessary actions in case of a failure, e.g. switch to limp-home mode. The corresponding outputs are crankshaft limp-home request a general camshaft error flag for IVVT, and a general camshaft error for synchronization.

The other purpose is to avoid getting multiple error codes and freeze frames for the same failure. The corresponding outputs are the inhibit flags for the various diagnosis functions.

i = 1...NC_NR_CAM_CBK

Application conditions:

Initialisation: no initialization value.

Recurrence: every change in the error flags of one of the diagnostic functions

or when error memory is cleared

Activation:

Deactivation:

Formula section:

Setting of LV_ERR_CRK

if LV_ERR_CRK_SYN = 1
or LV_ERR_CRK_TOOTH_PER = 1
or LV_ERR_CRK_TOOTH = 1
or LV_ERR_CRK_PLAUS = 1
or LV_ERR_CRK_OC = 1
then LV_ERR_CRK = 1

if LV_ERR_CRK_SYN = 0
and LV_ERR_CRK_TOOTH_PER = 0
and LV_ERR_CRK_TOOTH = 0
and LV_ERR_CRK_PLAUS = 0
and LV_ERR_CRK_OC = 0
then LV_ERR_CRK = 0

If LV_ERR_CRK = 1 then all other diagnoses on the crankshaft signal will be inhibited via the interfaces LV_INH_DIAG_CRK_SYN, LV_INH_DIAG_CRK_TOOTH, LV_INH_DIAG_CRK_TOOTH_PER, LV_INH_DIAG_CRK_PLAUS and LV_INH_DIAG_CRK_OC, except the one that detected the failure.

Setting of LV_ERR_CAM_IN(EX)[i]

```
if    LV_ERR_SYN_CAM_IN[i] = 1
            or      LV_ERR_PER_CAM_IN [i] = 1
            or      LV_ERR_PLAUS_CAM_IN [i] = 1
            or      LV_ERR_REF_CRK_CAM_IN [i] = 1
            or      LV_ERR_SYN_CRK_CAM_IN [i] = 1
            or      LV_ERR_TOOTH_OFF_IN [i] = 1
            then    LV_ERR_CAM_IN [i] = 1
endif

if    LV_ERR_SYN_CAM_IN [i] = 0
            and     LV_ERR_PER_CAM_IN [i] = 0
            and     LV_ERR_PLAUS_CAM_IN [i] = 0
            and     LV_ERR_REF_CRK_CAM_IN [i] = 0
            and     LV_ERR_SYN_CRK_CAM_IN [i] = 0
            and     LV_ERR_TOOTH_OFF_IN [i] = 0
then        LV_ERR_CAM_IN [i] = 0
endif

If(1)       CONF_CAM_VVT_EX = 0    (no exhaust Camshaft sensor / VVT present)
then(1)     LV_ERR_CAM_EX[i] = LV_ERR_CAM_IN [i]
            LV_INH_DIAG_SYN_CAM_EX[i] = 1
            LV_INH_DIAG_PER_CAM_EX[i] = 1
            LV_INH_DIAG_PLAUS_CAM_EX[i] = 1
            LV_INH_DIAG_REF_CRK_CAM_EX[i] = 1
            LV_INH_DIAG_TOOTH_OFF_EX[i] = 1
else(1)     (exhaust Camshaft sensor / VVT present)
    if      LV_ERR_SYN_CAM_EX [i] = 1
    or      LV_ERR_PER_CAM_EX [i] = 1
    or      LV_ERR_PLAUS_CAM_EX [i] = 1
    or      LV_ERR_REF_CRK_CAM_EX [i] = 1
    or      LV_ERR_SYN_CRK_CAM_EX [i] = 1
    or      LV_ERR_TOOTH_OFF_EX [i] = 1
    then    LV_ERR_CAM_EX [i] = 1
```

```
        endif
        if      LV_ERR_SYN_CAM_EX [i] = 0
        and     LV_ERR_PER_CAM_EX [i] = 0
        and     LV_ERR_PLAUS_CAM_EX [i] = 0
        and     LV_ERR_REF_CRK_CAM_EX [i] = 0
        and     LV_ERR_SYN_CRK_CAM_EX [i] = 0
        and     LV_ERR_TOOTH_OFF_EX [i] = 0
        then    LV_ERR_CAM_EX [i] = 0
        endif
    endif(1)
```

If LV_ERR_CAM_IN(EX)[i] = 1 then other diagnoses on the same camshaft signal will be inhibited via the interfaces LV_INH_DIAG_SYN_CAM_IN(EX)[i], LV_INH_DIAG_PER_CAM_IN(EX)[i], LV_INH_DIAG_PLAUS_CAM_IN(EX)[i], LV_INH_DIAG_REF_CRK_CAM_IN(EX)[i],and LV_INH_DIAG_TOOTH_OFF_IN(EX)[i], except the one that detected the failure.

Setting of LV_ERR_CAM_TOT

VVT actuators existing in the system are given by a logical combination of the configuration data NLC_IVVT_IN(EX) and the calibration data LC_NOT_ADJ_CAM_IVVT_IN(EX)[i].

LV_ERR_CAM_TOT = 1 if LV_ERR_CAM_IN(EX)[i] = 1 for one of the sensors on camshafts with IVVT actuator.

LV_ERR_CAM_TOT = 0 if LV_ERR_CAM_IN(EX)[i] = 0 for all sensors on camshafts with IVVT actuator.

A.18.4 Inhibition of camshaft sensor diagnosis for crankshaft synchronization

General information:

Calculation of the inhibition flag of camshaft sensor diagnosis for crankshaft synchronization in case of possible reverse rotation.

I = 1...NC_NR_CAM_CBK

Application conditions:

Initialisation: LV_INH_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0 at ECU reset **and** 0 to 1 transition of LV_IGK

Recurrence: 10ms **and** transition from 0 to 1 of LV_STOP_ENG **and** transition from 0 to 1 of LV_SYN_VLD

Activation: -

Deactivation: -

Formula section:

If LV_SYN_ENG = 0

A.19.1.1 Camshaft Segment Period Diagnosis

FUNCTION DESCRIPTION:

General information:

Camshaft signal acquisition validates the segment period by minimum limits derived from the maximum engine speed. The diagnostic state indicates when a segment period was too short, e.g. due to supplementary signal transitions. The camshaft signal acquisition will filter out such signal transitions as far as possible. If there are too many additional pulses however, the camshaft signal acquisition may not be able to synchronize any more, or the accuracy of camshaft position measurement may be degraded.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined for this diagnostic function as following:

```
□□□□
│ │ │ └─> Camshaft segment period too short "CAM_PER"   (= SYM_0)
│ │ └───> (not used)                                     (= SYM_1)
│ └─────> (not used)                                     (= SYM_2)
└───────> (not used)                                     (= SYM_3)
```

Application conditions:

Initialisation:
LV_CDN_DIAG_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_ERR_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
ERR_SYM_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*

Recurrence: every camshaft signal edge

Activation: *for inlet camshaft*

LV_ACT_CAM_IN[i] = 1 AND LV_INH_DIAG_PER_CAM_IN[i] = 0 AND LV_INH_DIAG_ENSD = 0 AND LV_INH_CDN_PER_CAM_IN[i] = 0

A.19.1.2 Camshaft Synchronization Diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect camshaft sensor failure. Each time the camshaft signal synchronization algorithm fails, it will set the diagnostic flag LV_ORNG_RATIO_CAM_IN(EX)[i] for the appropriate camshaft.

The camshaft signal acquisition will filter out supplementary signal transitions as far as possible. If there are too many additional pulses however, the camshaft signal acquisition will not be able to synchronize any more. Synchronization may also be impossible due to missing or inaccurate signal transitions of the sensor.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined for this diagnostic function as following:

```
□□□□
│ │ │ └─> Camshaft synchronization failure "SYNC_LOSS"     (= SYM_0)
│ │ └───> (not used)                                        (= SYM_1)
│ └─────> (not used)                                        (= SYM_2)
└───────> (not used)                                        (= SYM_3)
```

Application conditions:

Initialisation:

A.20.1 Camshaft position diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect when the camshaft reference position is outside of the designed range relative to the engine position from crankshaft. This allows to detect engine misbuilds (wrong assembly of the valve train), camshaft drive defects, or sensor failures that are not detected by the normal signal diagnosis.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Error-symptoms are defined for this diagnostic function as following:

```
□□□□
│ │ │ └─> Camshaft to crankshaft reference violated "REF_CRK_CAM"   (= SYM_0)
│ │ └───> (not used)                                               (= SYM_1)
│ └─────> (not used)                                               (= SYM_2)
└───────> (not used)                                               (= SYM_3)
```

Application conditions

Application conditions:

Initialisation:

A.20.3 Camshaft Sensor Diagnosis (Appl. Inc.)

FUNCTION DESCRIPTION:

This is the definition of DTC (P-codes) for the different diagnostic functions of the camshaft signal.

Input data:

LV_ERR_REF_CRK_CAM_IN_i	LV_ERR_PER_CAM_IN[NC_NR_CAM_CBK]	LV_ERR_SYN_CAM_IN_i	
LV_ERR_SYN_CRK_CAM_IN_i	LV_ERR_PLAUS_CAM_IN_i		

Application condition :

Recurrence: At the update of each one of the camshaft sensor diagnostic flags

*** Application Assistance:**

Limp home functions:
- KNK limp home value calculation
- No preinjection performed

The following control functions are inhibited:
- Knock control
- Anti-jerk function
- Engine overheating protection at VS = 0
- Gear ratio calculation
- Downstream fuel trim regulation

The following adaptation functions are inhibited:
- Knock adaptation
- Catalyst heating adaptation (indirect)
- Segment time adaptation

The following diagnosis functions are inhibited:
- Camshaft sensor diagnosis
- Knock sensor diagnosis
- O2-sensor downstream signal voltage diagnosis (only SCG)
- Misfire detection (ER-calculation)
- O2-sensor upstream switching time diagnosis
- O2-sensor upstream frequency diagnosis
- Catalyst efficiency diagnosis
- O2-sensor downstream switching time diagnosis
- O2-sensor downstream OBDII puc-end diagnosis
- Crankshaft oscillation detection

Result available of crankshaft diagnosis with loss of synchronization					

Input data:

LV_CRK_SYN	LV_RUN_ENG	LV_ORNG_TOOTH_PER_CRK	LV_ORNG_NR_TOOTH_CRK
LV_LOST_SYN_CRK	LV_INH_DIAG_CRK_SYN	LV_INH_DIAG_CRK_TOOTH	LV_INH_DIAG_CRK_TOOTH_PER
LV_LIH_ERR_CRK	LV_INH_DIAG_ENSD	LV_STOP_ENG	N_32

General information:

The purpose of the function is to detect failures on the crankshaft signal while the system is synchronized.

The diagnosis is divided in three different parts: tooth number error, implausible tooth period, and loss of synchronization on crankshaft signal.

A.21.1.1 Crankshaft Sensor Diagnosis with Tooth Number Error

FUNCTION DESCRIPTION:

General information:

The number of teeth per crankshaft revolution is monitored by the crankshaft signal acquisition. The algorithm may tolerate a number of missing/additional teeth per revolution without loosing synchronization, depending on the used target wheel and on configuration data. The bit LV_ORNG_NR_TOOTH_CRK indicates wrong tooth number during the most recent crankshaft revolution.

If a tooth was missing or added during one revolution, then all variables based on teeth counting will be produced with an error. This concerns for example spark advance, segment time, misfire segments, camshaft position, etc. The purpose of the function is to provide information when the crankshaft signal is inaccurate, in order to take the necessary actions.

Description:

Error-symptoms are defined for this diagnostic function as following:

```
□□□□
│ │ │ └─> Incorrect crankshaft tooth number "TOOTH_NUMBER"     (= SYM_0)
│ │ └───> (not used)                                           (= SYM_1)
│ └─────> (not used)                                           (= SYM_2)
└───────> (not used)                                           (= SYM_3)
```

Application conditions

Initialisation:

LV_CDN_DIAG_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
LV_ERR_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
ERR_SYM_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*

Recurrence: *once per crankshaft revolution, after detection of the reference gap, except in the first revolution after synchronization*

Activation: LV_CRK_SYN = 1
And LV_INH_DIAG_CRK_TOOTH = 0
And LV_INH_DIAG_ENSD = 0
And N_32 > C_N_32_MAX_DIAG_CRK_TOOTH

When the activation conditions are fulfilled then LV_CDN_DIAG_CRK_TOOTH = 1.

Deactivation:

When the activation conditions are not fulfilled then LV_CDN_DIAG_CRK_TOOTH = 0.

Formula Section

Symptoms calculation:

If LV_ORNG_NR_TOOTH_CRK = 0

Then ERR_SYM_CRK_TOOTH = NO_SYM

Else ERR_SYM_CRK_TOOTH = "SYM_0" {Detection of symptom TOOTH_NUMBER}

Endif

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

Apply filter on current symptoms
If filtering result available (after debounce)
Then
LV_ERR_CRK_TOOTH = filtering result
LV_END_DIAG_CRK_TOOTH = 1
Deliver the result to Error Management
Endif

Configuration for diagnostic symptoms :

		SYM_1	
		SYM_2	
		SYM_3	

Calculation of missing/added tooth information for misfire

Initialisation:

LV_INH_MIS_CRK = 0 at reset and at engine stalling (LV_STOP_ENG transition from 0 to 1).

Recurrence: *once per crankshaft revolution, after detection of the reference gap, except in the first revolution after synchronization*

Activation: LV_CRK_SYN = 1

Deactivation: LV_CRK_SYN = 0

Formula Section

Symptoms calculation:

If LV_ORNG_NR_TOOTH_CRK = 0

Then LV_INH_MIS_CRK = 0

Else LV_INH_MIS_CRK = 1

Endif

LV_ORNG_NR_TOOTH_CRK is reset after reading at the reference gap

A.21.1.2 Crankshaft Sensor Diagnosis with implausible Tooth Period

FUNCTION DESCRIPTION:

General information:

Crankshaft signal acquisition validates the tooth period by limits derived from the current engine speed.

Before synchronization, LV_ORNG_TOOTH_PER_CRK indicates implausible gradient of the tooth period. This flag is also set if a reference gap occurs during valid teeth phase or when the first reference gap cannot be detected.

After synchronization, LV_ORNG_TOOTH_PER_CRK is set if spikes are detected outside the crankshaft window acceptance window.

Description:

Error-symptoms are defined for this diagnostic function as following:

```
[ | | | ]
 | | | └─> Implausible crankshaft tooth period "TOOTH_PERIOD"   (= SYM_0)
 | | └───> (not used)                                          (= SYM_1)
 | └─────> (not used)                                          (= SYM_2)
 └───────> (not used)                                          (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
LV_ERR_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
ERR_SYM_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*

Recurrence: if LV_CRK_SYN = 1: every reference gap
If LV_CRK_SYN = 0: when LV_ORNG_TOOTH_PER_CRK is set

Activation: LV_RUN_ENG= 1
And LV_LIH_ERR_CRK = 0
And LV_INH_DIAG_CRK_TOOTH_PER = 0
And LV_INH_DIAG_ENSD = 0

When the activation conditions are fulfilled then LV_CDN_DIAG_CRK_TOOTH_PER = 1.

Deactivation:

When the activation conditions are not fulfilled then LV_CDN_DIAG_CRK_TOOTH_PER = 0.

Formula Section

Symptoms calculation:

Before crankshaft synchronization (LV_CRK_SYN = 0)

If LV_ORNG_TOOTH_PER_CRK = 0

Then ERR_SYM_CRK_TOOTH_PER = NO_SYM

Else ERR_SYM_CRK_TOOTH_PER = “SYM_0" {Detection of symptom TOOTH_PERIOD}

Endif

After crankshaft synchronization (LV_CRK_SYN = 1)

If LV_ORNG_TOOTH_PER_CRK = 1 set at a tooth event or end of tolerance window

Then ERR_SYM_CRK_TOOTH_PER = “SYM_0" {Detection of symptom TOOTH_PERIOD}

Endif

LV_ORNG_TOOTH_PER_CRK is reset after reading

If LV_ORNG_TOOTH_PER_CRK = 0 at the reference gap

Then ERR_SYM_CRK_TOOTH_PER = NO_SYM

Endif

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

Apply filter on current symptoms

		SYM_3	

A.21.1.3 Crankshaft Sensor Diagnosis with Loss of Synchronization

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect crankshaft failure when the system looses synchronization on the crankshaft signal.

Synchronization will be lost if the reference gap is not detected at the correct position plus/minus a tolerance of missing/additional teeth, depending on the used target wheel and on configuration data.

If the signal fails completely (no more crankshaft signal edges are detected), then no error will be detected by this diagnosis, since the condition is similar to stopped engine. A failure then may be detected by the crankshaft sensor plausibility diagnosis (e.g. test against the camshaft signal).

Description:

Error-symptoms are defined for this diagnostic function as following:

```
□□□□
│ │ │ └─> Loss of synchronization "SYNC_LOSS"     (= SYM_0)
│ │ └───> (not used)                              (= SYM_1)
│ └─────> (not used)                              (= SYM_2)
└───────> (not used)                              (= SYM_3)
```

Application conditions:

A.22.1.1 Diagnosis of crankshaft sensor

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect a failure if synchronization on crankshaft signal cannot be achieved.

One of the available camshaft signals is selected for crankshaft synchronization by setting one of the flags LV_ACT_SYN_CRK_CAM_IN[i] in the engine position control function. The signal edge counter of that camshaft is observed while the crankshaft is not synchronized. If the count reaches a calibrated number, and the system is still not synchronized with the crankshaft signal, then crankshaft sensor plausibility error is set without further debouncing. If valid crankshaft teeth have already been detected, the symptom will be “implausible signal”, otherwise it will be “missing signal”.

i = 1...NC_NR_CAM_CBK

In case of CONF_CAM_VVT_EX = 0 the exhaust camshaft is not taken into account for the diagnosis.

Description:

Error-symptoms are defined to this diagnostic function as following:

```
┌─┬─┬─┬─┐
│ │ │ └─> Signal missing        (= SYM_0)
│ │ └───> Signal implausible    (= SYM_1)
│ └─────> (not used)            (= SYM_2)
└───────> (not used)            (= SYM_3)
```

Application conditions:

Initialisation:	LV_CDN_DIAG_CRK_PLAUS = 0 at reset
	LV_END_DIAG_CRK_PLAUS = 0 at reset
	ERR_SYM_CRK_PLAUS = NO_SYM at reset
	LV_ERR_CRK_PLAUS = 0 at reset
Recurrence:	every update of CTR_EDGE_CAM_IN(EX)[i]
	And 0 to 1 transition of LV_STOP_ENG
Activation:	LV_ACT_CRK = 1
	And LV_INH_DIAG_CRK_PLAUS = 0
	And LV_INH_DIAG_ENSD = 0

When the activation condition is fulfilled then LV_CDN_DIAG_CRK_PLAUS = 1.

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_CRK_PLAUS = 0.

Formula Section

Symptoms calculation:

A.22.1.3 Camshaft Sensor Diagnosis for Crankshaft Synchronization

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect a failure of the camshaft information for crankshaft synchronization.

Up to four camshaft signals may be available in the system (intake and/or exhaust on one or two cylinder banks). The Engine Position Control selects one camshaft for synchronization by activating the corresponding operating mode. The camshaft signal acquisition will indicate "camshaft signal out of range for crankshaft synchronization" by setting LV_ORNG_CAM_SYN_CRK, which has to be reset by the diagnosis after treatment. A counter is incremented at every recurrence if LV_ORNG_CAM_SYN_CRK is set. The error is detected when the counter reaches a calibrated maximum.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined to this diagnostic function as following:

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │ │ │ └─> Camshaft signal  not valid for crankshaft synchronization     (= SYM_0)
 │ │ └───> (not used)                                                    (= SYM_1)
 │ └─────> (not used)                                                    (= SYM_2)
 └───────> (not used)                                                    (= SYM_3)
```

Application conditions:

Input data:

LV_IGK	LV_INH_DIAG_CRK_OC		

FUNCTION DESCRIPTION:

General information:

This dummy file replaces the MCPS circuit diagnosis for systems with ACPS. A circuit diagnosis for ACPS is not considered neceessary, since with any of the three lines open or short-circuited, the signal will be constantly high or low. The failure will then be detected by the functional diagnosis.

Application conditions:

Activation: LV_IGK = 1
And LV_INH_DIAG_CRK_OC = 0

When the activation condition is fulfilled then LV_CDN_DIAG_CRK_OC = 1.

Desactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_CRK_OC = 0.

Formula section:

ERR_SYM_CRK_OC = 0

LV_ERR_CRK_OC = 0

LV_END_DIAG_CRK_OC = 1

A.22.3 Crankshaft Sensor Diagnosis (Appl. Inc.)

FUNCTION DESCRIPTION:

This is the definition of DTC (P-codes) for the different diagnostic functions of the crankshaft signal.

Input data:

LV_ERR_CRK_SYN	LV_ERR_CRK_TOOTH	LV_ERR_CRK_PLAUS	LV_ERR_CRK_TOOTH_PER

Application condition :

Recurrence: At the update of each one of the crankshaft sensor diagnostic flags

*** Application Assistance:**

Limp home functions:
- KNK limp home value calculation
- No preinjection performed
- Engine speed limitation to C_N_MAX_CRK_LIH (only if CRK limp-home is active)-

The following control functions are inhibited:
- Knock control
- Anti-jerk function
- Engine overheating protection at VS = 0
- Gear ratio calculation
- Downstream fuel trim regulation

The following adaptation functions are inhibited:
- Knock adaptation
- Catalyst heating adaptation (indirect)
- Segment time adaptation

The following diagnosis functions are inhibited:
- Camshaft sensor diagnosis
- Knock sensor diagnosis
- O2-sensor downstream signal voltage diagnosis (only SCG)
- Misfire detection (ER-calculation)
- O2-sensor upstream switching time diagnosis
- O2-sensor upstream frequency diagnosis
- Catalyst efficiency diagnosis
- O2-sensor downstream switching time diagnosis
- O2-sensor downstream OBDII puc-end diagnosis
- Crankshaft oscillation detection

A.23 Extended Diagnosis for MWSS

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_MWSS	O/V	0...1H	0..1	1	-
logical variable for wheelspeed sensor failure after debouncing					
LV_ERR_PRES_MWSS	O/V	0...1H	0..1	1	-
logical variable for wheelspeed sensor failure currently present before debouncing					
V_DIF_MWSS_DIAG	O/V	0...FFH	0..5	19.6e-3	V
difference between max and min voltage of a sample periode					
V_DIF_MAX_MWSS_DIAG	O/V/S	0...FFH	0..5	19.6e-3	V
maximum difference between max and min voltage of a sample periode					
V_MIN_MWSS_DIAG	V	0...FFH	0..5	19.6e-3	V
minimum voltage of a sample periode					
V_MAX_MWSS_DIAG	V	0...FFH	0..5	19.6e-3	V
maximum voltage of a sample periode					
NR_MWSS_DIAG_SAMPLE	V	0...FFH	0...255	1	-
Current value of sample counter					

Input data:

MWSS_DIAG_BAS	LV_CDN_VB_OBD1	VS	CONF_VS

FUNCTION DESCRIPTION:

General information:

With short circuit or open load of one of the sensor lines of a magnetic wheel speed sensor, the input circuitry might still produce an output signal which may trigger the rough road detection algorithm and thus inhibit misfire detection. The purpose of this function is to detect such failures by monitoring the bias node voltage of the input circuitry.

Under normal conditions, there is a DC voltage at the bias node voltage with relatively large tolerances which has a relatively small AC voltage superimposed due to unsymmetric parasitic capacities of the wiring harness.

If the input circuit toggles with a faulty sensor, the superimposed AC voltage will be larger than the noise at o.k. system. This is used as a signal for sensor failure. The hardware should be designed in a way to have a sufficient margin for the detection threshold.

At zero speed it is checked if the limits of the DC voltage for normal operation are exceeded. This allows to detect a short circuit to ground or to battery before the vehicle begins to move.

Description:

The voltage MWSS_DIAG_BAS is sampled by an analog input of the CPU or via analog-multiplexer at a rate which may be inferior to the signal frequency, e.g. every 1 ms to 10 ms. The AC amplitude is then calculated as the difference between maximum and minimum value of a number of samples.

As soon as C_NR_MWSS_DIAG_SAMPLE samples are completed, the maximum and the minimum voltage of this sampling period is available in V_MAX_MWSS_DIAG and V_MIN_MWSS_DIAG. The difference of both is V_DIF_MWSS_DIAG. It equals approximately the peak - to peak - voltage of the sampling periode.

Depending on the vehicle speed at the end of the sampling periode, the values of V_MAX_MWSS_DIAG, V_MIN_MWSS_DIAG or V_DIF_MWSS_DIAG are compared to the respective thresholds to set an error bit and start the debouncing algorithm.

Application conditions:

Activation: The function is active only if CONF_VS = "WHEEL" and **LV_CDN_VB_OBD1 = 1.**

Conditions to detect a failure:

If VS > 0
    and V_DIF_MWSS_DIAG > C_V_THD_MWSS
then LV_ERR_PRES_MWSS = 1
the debounce counter is incremented with C_ABC_INC_MWSS
else if VS = 0
    and (V_MIN_MWSS_DIAG < C_V_THD_MIN_MWSS
or V_MAX_MWSS_DIAG > C_V_THD_MAX_MWSS)
then LV_ERR_PRES_MWSS = 1
the debounce counter is incremented with C_ABC_INC_MWSS
else LV_ERR_PRES_MWSS = 0
    if LV_ERR_MWSS = 0
    then *the debounce counter is decremented*
    endif
endif

If the debounce counter has reached C_ABC_MAX_MWSS
then LV_ERR_MWSS = 1
endif

Error Healing:

If LV_ERR_MWSS = 1
and VS > C_VS_MIN_MWSS_CNL
and LV_ERR_PRES_MWSS = 0
then a delay time C_T_MWSS_MIN_CNL is running

If the delay time C_T_MWSS_MIN_CNL has run out
then LV_ERR_MWSS = 0 *(the debounce counter is set to zero)*

Remark: The time delay C_T_MWSS_MIN_CNL is frozen when one of the conditions mentioned above is currently not present (exceptLV_ERR_PRES_MWSS=1). When all conditions are present again, the counter continues. The time delay starts a new when LV_ERR_PRES_MWSS = 1 is detected.

Emergency operation :

* Limp Home : **none**

* Application Incidence : **none**

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_V_THD_MWSS	1	0...FFH	0..5	19.6e-3	V
threshold for peak-to-peak voltage to detect a failure at moving vehicle					
C_V_THD_MIN_MWSS	1	0...FFH	0..5	19.6e-3	V
threshold minimum bias node voltage to detect a failure at stopped vehicle					
C_V_THD_MAX_MWSS	1	0...FFH	0..5	19.6e-3	V
threshold maximum bias node voltage to detect a failure at stopped vehicle					
C_NR_MWSS_SAMPLE	1	0...FFH	0...255	1	-
number of samples per sample period					
C_ABC_INC_MWSS	1	0...FFH	0...255	1	-
Increment of anti-bounce-counter					
C_ABC_MAX_MWSS	1	1...FFH	1...255	1	-
Maximum of anti-bounce-counter					
C_VS_MIN_MWSS_CNL	1	0...FFH	0...255	1	km/h
Vehicle speed threshold for healing of MWSS error					
C_T_MWSS_MIN_CNL	1	1...FFFFH	0.1...655.35	0.01	sec
Time delay to heal MWSS error					

Note: For calibration and validation of the thresholds, the maximum value for the peak-to-peak-voltage V_DIF_MWSS_DIAG is stored in the EEPROM with the name V_DIF_MAX_MWSS_DIAG. It will be reset only when the error memory is erased.

Application hint:

C_NR_MWSS_SAMPLE should be set to 20 minimum for a stable V_DIF_MWSS_DIAG.
The delay C_T_MWSS_MIN_CNL must be longer than the maximum time necessary to complete a sample periode.
Set C_VS_MIN_MWSS_CNL to the highest speed that is reached regularly for at least the duration of C_T_MWSS_MIN_CNL.

A.23.1 Application assistances for the extended MWSS diagnosis

Present failure for segment time adaptive values					
LV_END_DIAG_T_SEG_ER	V	0...1H	0...1	1	[-]
Diagnosis end of segment time adaptive values					

Input data:

LV_DC	LV_INH_MIS_CRK	LV_INH_DIAG_T_SEG_ER	

FUNCTION DESCRIPTION:

The purpose of this error is to diagnose synchronisation errors on engine roughness segments measurement.
An error symptom "*Missing/Adding 1 tooth or more on engine roughness segment acquisition*" is detected when a crankshaft synchronisation error caused by 1 or 2 missing/additional tooth occurs on one crankshaft revolution.

Application conditions:

Initialisation: *at ECU reset or KEY OFF/KEY ON event*

LV_CDN_DIAG_T_SEG_ER = 0

ERR_SYM_T_SEG_ER = *Refer to filtering configuration for the initialisation value*

LV_ERR_T_SEG_ER = *Refer to filtering configuration for the initialisation value*

LV_END_DIAG_T_SEG_ER = *Refer to filtering configuration for the initialisation value*

Recurrence: each 360°Crk at segment task

Activation/Deactivation:

If LV_DC = 1

And LV_INH_DIAG_T_SEG_ER = 0

Then LV_CDN_DIAG_T_SEG_ER = 1 *diagnosis is active*

Else LV_CDN_DIAG_T_SEG_ER = 0 *diagnosis is passive*

EndIf

Formula section:

Error detection

If LV_INH_MIS_CRK = 1

Then ERR_SYM_T_SEG_ER = SYM_1

(symptom "Missing/Adding 1 or 2 teeth on engine roughness segment acquisition" is active, ABC counter starts to increment)

LV_ERR_T_SEG_ER = 1 *(after anti-bounce)*

Else ERR_SYM_T_SEG_ER = NO_SYM

(no symptom is declared, ABC counter starts to decrement)

LV_ERR_T_SEG_ER = 0 *(after anti-bounce)*

EndIf

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Present failure for ER segment time adaptive values					
LV_END_DIAG_SEG_AD_ER	V	0...1H	0...1	1	[-]
Diagnosis end of ER segment time adaptive values					

Input data:

LV_SEG_AD_ER	LV_SEG_AD_LIM_ER	LV_INH_DIAG_SEG_AD_ER	LV_SEG_AD_AVL_ER

Description:

The purpose is to diagnose the ER segment adaptive values.

If during or at the end of the segment adaptive values learning process *(LV_SEG_AD_ER = 1 or LV_SEG_AD_ER = 1 –> 0)*, at least one of the engine roughness segment adaptation values is at the limit (LV_SEG_AD_LIM_ER = 1), the error symptom SEG_AD_ER "engine roughness segment adaptation values at the limit" is detected.

Application conditions:

Initialisation: *at ECU reset or KEY OFF/KEY ON event*

LV_CDN_DIAG_SEG_AD_ER = 0

ERR_SYM_SEG_AD_ER = *Refer to filtering configuration for the initialisation value*

LV_ERR_SEG_AD_ER = *Refer to filtering configuration for the initialisation value*

LV_END_DIAG_SEG_AD_ER = *Refer to filtering configuration for the initialisation value*

Recurrence: segment task

Activation/Deactivaton:

A.25 Vehicle Speed Signal Diagnosis (VS)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_VS	V/S/O	0...1H	0...1	1	-
Boolean for error currently present on vehicle speed signal acquisition.					
T_VS_MIN_DIAG	V/O	0…FFFFH	0 …655.35	0.01	S
Timer for error symptom VS plausibility present					

Input data:

MAF	LV_CDN_VB_OBD1	N	N_MAX_THD
VS		LV_IGK	N_32
TCO	LV_IND_FCUT	LV_AT	LV_ERR_MAF
			LV_ERR_MAP

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the frequent input signal (VS) on the microcontroller.
The application recurrence is **10 msec**.
The diagnosis takes place only if **LV_CDN_VB_OBD1 = 1.**

Application conditions:

Detection:

* Plausibility Check

If LV_IGK **=** 1 (Active)
and VS **=** 0
and N >= C_N_VS_MIN_DIAG(_AT)
and N < N_MAX_THD – C_N_VS_MAX_HYS_DIAG
and MAF >= C_MAF_VS_MIN_DIAG(_AT)
and LV_IND_FCUT **=** 0
and TCO > C_TCO_VS_MIN_DIAG
and LV_ERR_MAF = 0
and LV_ERR_MAP = 0
then the time counter T_VS_MIN_DIAG is incremented

If the time counter C_T_VS_MIN_DIAG(_AT) seconds has run out
then ERR_SYM_VS = 1H (SYM_1) 'Invalid Signal' is detected
and LV_ERR_VS **=** 1

Remark: The time delay C_T_VS_MIN_DIAG(_AT) is frozen when one of the above-mentioned diagnosis conditions is currently not present (except VS = 0).
When all conditions are present again, the counter continues.
As soon as VS > 0 is detected the time counter is reset immediately.

Error healing:

If LV_IGK = 1
and VS > 0 **for more than** C_T_VS_MIN_DIAG(_AT) seconds

then LV_ERR_VS = 0

Emergency operation:

* Limp Home: no limp home

Formula section:

* Error Signalling :

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_TCO_VS_MIN_DIAG	-	0...FEH	-48...142.5	0.744	°C
Minimum coolant temperature to perform vehicle speed diagnosis.					
C_N_VS_MIN_DIAG(_AT)	1	0...FFH	0...8160	32	rpm
Engine speed threshold for implausible signal condition detected on VS signal. Depending on LV_AT

A.26.2 Application assistance:

- TCO Limp Home Calculation modified
- Coolant Temperature initialization modified (only if additionally TCO-Error detected)
- Evaporative Emission Control - Activation of MIN_PURGE instead of MAX_PURGE
- The following Adaptation Functions are inhibited:
  - Lambda Adaptation
  - Knock Adaptation
  - Idle Speed Adaptation
- The following Diagnosis Functions are inhibited:
  - Differential tank pressure sensor plausibility diagnosis (noisy signal)
  - Differential tank pressure sensor plausibility diagnosis (signal constant)
  - O2-Sensor downstream signal voltage diagnosis (only SCG)
  - MAP/TPS Plausibility Diagnosis
  - Evaporative System Diagnosis
  - Fuel System Diagnosis
  - Thermostat Diagnosis

A.26.3 RBM interface for the "TIA_DYN" diagnosis

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
STATE_RBM_TIA_DYN	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor of TIA Signal Stuck diagnosis for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_TIA_DYN	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of TIA Signal Stuck diagnosis, for application purposes					

Input data:

LV_END_DIAG_DYN_TIA[NC_SENS_NR_TIA]	CTR_COMP_RBM_TIA_DYN	CTR_CDN_RBM_TIA_DYN	LV_DC
LV_ERR_TCO_EL	LV_ERR_TCO_PLAUS	LV_ERR_TCO_GRD	
CTR_ERR_DYN_NR	LV_ERR_TCO_STUCK_H	LV_ERR_TCO_STUCK	
LV_ERR_VS	LV_ERR_MWSS		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TIA_DYN monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TIA_DYN data.

Within STATE_RBM_TIA_DYN, three different informations are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)

  (no intrusive operation, no short trip)

  (general information depending on monitor could be added)
- Monitor disabled because of system malfunction (bit 1)

  (depending on failure status: pending)

  (general information depending on monitor could be added)
- Monitor individual RBM conditions encountered within this DC (bit 2)

  (general information depending on monitor could be added)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TIA_DYN = 0

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_TIA_DYN = 0

on failure memory reset :

bit 1 of STATE_RBM_TIA_DYN = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL, LV_ERR_TCO_PLAUS, LV_ERR_TCO_GRD, LV_ERR_TCO_STUCK, LV_ERR_TCO_STUCK_H, LV_ERR_VS, LV_ERR_MWSS

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_TIA_DYN = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_TIA_DYN = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_TIA_DYN = 0

Then

If LV_END_DIAG_TIA_DYN = 1

Then

bit 0 of STATE_RBM_TIA_DYN = 1

Endif

Endif

If bit 1 of STATE_RBM_TIA_DYN = 0

Then

If LV_ERR_TCO_EL = 1 **or**

LV_ERR_TCO_GRD = 1 **or**

LV_ERR_TCO_PLAUS = 1 **or**

LV_ERR_TCO_STUCK = 1 **or**

LV_ERR_TCO_STUCK_H = 1 **or**

LV_ERR_VS = 1 **or**

LV_ERR_MWSS = 1 **or**

Then

bit 1 of STATE_RBM_TIA_DYN = 1

Endif

Endif

No specific condition for TOIL_STUCK :

bit 2 of STATE_RBM_TIA_DYN always equal to 1

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_TIA_DYN = 0
then RATE_RBM_TIA_DYN = FFFFH
else RATE_RBM_TIA_DYN
= (CTR_COMP_RBM_TIA_DYN / CTR_CDN_RBM_TIA_DYN)
endif

A.27 Electrical Failure Monitoring:

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_EL_TIA[NC_SENS_NR_TIA]	O/V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	-

Minimum time after start value for Short Cut to Plus or Open Circuit detection condition					
C_VP_TIA_MAX_DIAG_EL[NC_SENS_NR_TIA]	1	0...7FFFH	0...4.999847	1.52588E-4	V
VP_TIA voltage threshold value for Short Cut to Plus or Open Circuit: one value for each TIA sensor of AIRT					
C_VP_TIA_MIN_DIAG_EL[NC_SENS_NR_TIA]	1	0...7FFFH	0...4.999847	1.52588E-4	V
VP_TIA voltage threshold value for Short Cut to Ground: one value for each TIA sensor of AIRT					

A.27.1 General:

NC_AIRT_TIA_SENS has been defined depending on the TIA hardware definition (NC_TIA_CONF value).

The **Electrical Diagnosis** has to be performed for the NC_SENS_NR_TIA sensors.

(See “Loop For m = 1 to NC_SENS_NR_TIA” below).

Initialization of ERR_SYM_EL_TIA, LV_CDN_DIAG_EL_TIA, LV_END_DIAG_EL_TIA, LV_ERR_EL_TIA depends on the type of anti bounce chosen by the project.

General information:

The purpose is to diagnose the voltage value V_TIA from the air temperature sensor(s) and to detect an electrical failure. 2 symptoms are distinguished:

SCP (Short Cut to Plus),

SCG (Short Cut to Ground) or OC (Open Circuit).

Only one symptom can be active at the same time.

NC_SENS_NR_TIA	VS	MAF_THR	

A.28.1 Intermittent Failure Monitoring (“INTM”):

The purpose is to detect intermittent failure in order to avoid sudden calculation transitions for any function based on a sensor temperature value. Failure is detected when the difference between the raw value and the mean value of TIA_MES overpasses a calibrateable threshold.

NOTE:

- after debouncing, LV_ERR_INTM_TIA[m] and LV_END_DIAG_INTM_TIA[m] are automatically managed.

- in order to avoid wrong detections, very high filtering on TIA_MES_MMV[m] is required.

- as this diagnosis is based on the measured value TIA_MES[m], an uncorrect calibration of the conversion table could lead wrong error detections.

Application conditions :

For m = 1 **to** NC_SENS_NR_TIA

Initialization:

According to the type of the anti-bounce :
LV_CDN_DIAG_INTM_TIA[m] = 0,
LV_ERR_INTM_TIA[m] = 0,
LV_END_DIAG_INTM_TIA[m] = 0,
ERR_SYM_INTM_TIA[m] = NO_SYM

At Reset
TIA_MES_DIF_DIAG_INTM[m] = 0°C

Recurrence: **100ms**

Activation: **If** LV_IGK = 1
And LV_CDN_VB_MIN_DIAG = 1
And LV_INH_DIAG_INTM_TIA[m] = 0
And CTR_ABC_EL_TIA[m] = 0
Then LV_CDN_DIAG_INTM_TIA[m] = 1
Endif

Deactivation: **If** one of the Activation condition is not fulfilled
Then LV_CDN_DIAG_INTM_TIA[m] = 0
Endif

End for m

Formula section:

For m = 1 **to** NC_SENS_NR_TIA

TIA_MES_DIF_DIAG_INTM[m] = |TIA_MES[m] - TIA_MES_MMV[m]|

If LV_CDN_DIAG_INTM_TIA[m] = 1
Then **If** TIA_MES_DIF_DIAG_INTM[m] > C_TIA_MES_DIF_DIAG_INTM
Then ERR_SYM_INTM_TIA[m] = “SYM_0”
And anti-bounce counter is incremented
Else ERR_SYM_INTM_TIA[m] = “NO_SYM”
And anti-bounce counter is decremented
Endif
Else *ERR_SYM_INTM_TIA[m] and the anti-bounce counter remain unchanged*
Endif

End for m

A.28.2 Stuck Signal Failure Monitoring (“DYN”):

Application conditions:

For m = 1 **to** NC_SENS_NR_TIA

Initialization:

According to the type of the anti-bounce :
LV_CDN_DIAG_DYN_TIA[m] = 0,
LV_ERR_DYN_TIA[m] = 0,
LV_END_DIAG_DYN_TIA[m] = 0,
ERR_SYM_DYN_TIA[m] = NO_SYM

At Reset
TIA_MES_DIF_DIAG_DYN[m] = 0°C
TIA_MES_MAX_DIAG_DYN = TIA_MES_ST[m]
TIA_MES_MIN_DIAG_DYN = TIA_MES_ST[m]
LV_CDN_DYN_TIA_LOAD = 0
T_DYN_TIA_DEC = 0
T_DYN_TIA_INC = 0

Recurrence: **100ms**

Activation:

If LV_IGK = 1
And LV_ST_END = 1
And LV_CDN_VB_MIN_DIAG = 1
And LV_INH_DIAG_DYN_TIA[m] = 0
And ERR_SYM_EL_TIA[m] = 0
And LV_ERR_EL_TIA[m] = 0
And ERR_SYM_INTM_TIA[m] = 0
And LV_ERR_INTM_TIA[m] = 0
And C_TIA_MIN_DIAG_DYN < TIA[m] < C_TIA_MAX_DIAG_DYN
And TCO >= C_TCO_MIN_DIAG_DYN
And |TCO_ST - TCO_STOP| >= C_TCO_DIF_TIA_DIAG_DYN
(rem: TCO_STOP is the value of TCO for the latest transition LV_ES = 0 to 1)
And |TCO_ST – TIA_MES_ST[m]| <= C_TEMP_ST_DIF_MAX_DIAG_DYN
And LV_CDN_DYN_TIA_LOAD = 1 (MAF_THR, VS condition for diag)
And LV_END_DIAG_DYN_TIA[m] = 0
(rem: in this way, the diagnosis is performed only once per Driving Cycle)
Then LV_CDN_DIAG_DYN_TIA[m] = 1
Endif

Deactivation:

If one of the Activation condition is not fulfilled
Then LV_CDN_DIAG_DYN_TIA[m] = 0
Endif

End for m

Formula section:

For m = 1 **to** NC_SENS_NR_TIA

Minimum time after start value for electrical TAM sensor diagnosis condition					

A.30 Ambient air temperature sensor diagnosis from CAN

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
ERR_SYM_TAM_CAN	V/O	0H 1H 2H 4H	NO_SYM SYM_0 SYM_1 SYM_2	1	[-]
Symptom of TAM failure from CAN					
LV_CDN_DIAG_TAM_CAN	V	0...1H	0...1	1	[-]
Conditions for TAM diagnosis from CAN: 0 = not fulfilled, 1 = fulfilled					
LV_END_DIAG_TAM_CAN	V	0...1H	0...1	1	[-]
Result of TAM diagnosis from CAN					
LV_ERR_TAM_CAN	V/O	0H 1H	PASSIVE ACTIVE	1	[-]
Boolean for CAN_ERR on ambient temperature TAM_CAN					

Input data:

STATE_ERR_TAM_CAN	LV_TAM_CAN_FIRST_VLD	LV_IGK	LV_ERR_CAN_BUS_OFF
CONF_TAM			

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to read the CAN error flags of the TAM message from CAN and to transform them in signals necessary for the ECU and ERRM and the calculation of TAM.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
┌─┬─┬─┐
│ │ │ │
└─┴─┴─┘
 │  │  └─> not valid          (= SYM_0)
 │  └────> short circuit      (= SYM_1)
 └───────> open circuit       (= SYM_2)
```

Application conditions:

Initialisation: *LV_IGK = 0 -> 1 and reset initialise all output variables with 0H.*

Recurrence: *100 ms*

Activation: *CONF_TAM = 1*

Formula section:

Conditions calculation:

If LV_TAM_CAN_FIRST_VLD = 1
And LV_ERR_CAN_BUS_OFF = 0
And LV_IGK = 1
Then LV_CDN_DIAG_TAM_CAN = 1
Else LV_CDN_DIAG_TAM_CAN = 0
Endif

Symptoms calculation:

If LV_CDN_DIAG_TAM_CAN = 1
Then **If** STATE_ERR_TAM_CAN = 0H *(no SYM)*
Then ERR_SYM_TAM_CAN = 0H
Elseif STATE_ERR_TAM_CAN = 1H *(TAM signal from CAN not valid)*
Then ERR_SYM_TAM_CAN = 1H
Elseif STATE_ERR_TAM_CAN = 2H *(Short circuit)*
Then ERR_SYM_TAM_CAN = 2H
Else ERR_SYM_TAM_CAN = 4H *(Open circuit)*
Endif
Else ERR_SYM_TAM_CAN = 0H *(no SYM)*
Endif

Calculation of LV_END_DIAG_TAM_CAM and LV_ERR_TAM_CAN

LV_ERR_TAM_CAN — Calculated by error management : CTR_ABC_TAM_CAN reach maximum

LV_END_DIAG_TAM_CAN — Calculated by error management

Configuration for diagnostic symptoms :

Diagnostic TAM	*Symptom description*	Symptom	Filter type
Range ambient temperature from CAN diagnosis	*not valid*	*SYM_0*	*STD_INI*
	Short circuit	*SYM_1*	
	Open circuit	*SYM_2*	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_TAM_CAN	1	0...FFH	0...255	1	-
Increment debounce counter for failure TAM from CAN					
C_ABC_MAX_TAM_CAN	1	1...FFH	1...255	1	-
Maximum value debounce counter failure TAM from CAN					

A.31 TAM range check

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_ORNG_TAM	V/O	0...1H	0...1	1	[-]
Present failure TAM range					
ERR_SYM_ORNG_TAM	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Symptom of TAM range failure					

Input data:

General information:

Application conditions:

Initialization: **At Reset:** LV_ERR_ORNG_TAM = 0
ERR_SYM_ORNG_TAM = “NO_SYM”

Recurrence: no (the outputs are just calculated once)

Activation: always active

Deactivation: -

Formula section:

Calibration data:

A.32 Error flags for TAM, TIA_THR, TIA_IM and TIA_CYL

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TAM	V/O	0...1H	0...1	1	[-]
Boolean for error currently present which might affect temperature TAM (after debounce)					
LV_ERR_TIA_CYL	V/O	0...1H	0...1	1	[-]
Boolean for error currently present which might affect temperature TIA_CYL (after debounce)					
LV_ERR_TIA_IM	V/O	0...1H	0...1	1	[-]
Boolean for error currently present which might affect temperature TIA_IM (after debounce)					
LV_ERR_TIA_THR	V/O	0...1H	0...1	1	[-]
Boolean for error currently present which might affect temperature TIA_THR (after debounce)					
LV_ERR_EL_TIA_THR	V/O	0...1H	0...1	1	[-]
Result of electrical diagnosis on one TIA sensor(s) which might affect temperature TIA_THR					
LV_END_DIAG_EL_TIA_THR	V/O	0...1H	0...1	1	[-]
Result of electrical diagnosis on one TIA sensor(s) which might affect temperature TIA_THR					

Input data:

LV_ERR_EL_TIA[NC_SENS_NR_TIA]	LV_ERR_DYN_TIA[NC_SENS_NR_TIA]	LV_ERR_INTM_TIA[NC_SENS_NR_TIA]	LV_ERR_PLAUS_TIA[NC_SENS_NR_TIA]
LV_ERR_TIA_CHRG_DOWN	LV_ERR_TIA_CHRG_UP	NC_TIA_CONF	NC_IDX_TIA_AM_CHRG
NC_IDX_TIA_CHRG_THR	NC_IDX_TIA_IM_CYL	LV_ERR_EL_TAM	NC_SENS_NR_TIA
LV_END_DIAG_EL_TIA[NC_SENS_NR_TIA]	LV_ERR_PLAUS_TAM	LV_ERR_TAM_CAN	LV_ERR_ORNG_TAM
CONF_TAM			

A.32.1 General information [Version for : NC_CHRG_CONF<>0 And NC_TIA_CONF=10,11,12,13,21,22,23,24,30]

- For each TIA sensor, 3 Error Flags are defined (in Chapter Diagnosis):

LV_ERR_**EL**_TIA,
LV_ERR_**INTM**_TIA,
LV_ERR_**DYN**_TIA,
LV_ERR_**PLAUS**_TIA.

- For each TAM sensor (if available), 2 Error Flags are defined (in Chapter Diagnosis):

LV_ERR_**ORNG**_TAM,
LV_ERR_**PLAUS**_TAM.

Based on these values we are now defining 1 Error Flag associated to each temperature TAM, TIA_THR, TIA_IM and TIA_CYL. They are named:

LV_ERR_TAM,
LV_ERR_TIA_THR,
LV_ERR_TIA_IM,
LV_ERR_TIA_CYL,
LV_ERR_TAM , LV_ERR_TIA_THR, LV_ERR_TIA_IM and LV_ERR_TIA_CYL are defined as Output of AIRT Aggregate.

- Additionnaly LV_ERR_EL_TIA_THR and LV_END_DIAG_EL_TIA_THR are defined for other Aggregate diagnosis based on TIA_THR

Application conditions:

Initialisation : **At** Reset

LV_ERR_TIA_THR, LV_ERR_TIA_IM, LV_ERR_TIA_CYL must be initialized with formula section.

Recurrence : **see below**

Activation : At all Engine States

Deactivation: -

Formula section:

A.32.2 LV_ERR_TAM definition:

Recurrence : **1 s**

A value for NC_TIA_CONF is defined for each hardware definition (see specification Air Temperature Sensor(s) Configuration)

Depending on NC_TIA_CONF, the values of LV_ERR_TAM is defined.

```
If    CONF_TAM <> 0
Then        If   LV_ERR_TAM_CAN=1
            Or LV_ERR_ORNG_TAM=1
            Or LV_ERR_PLAUS_TAM=1
            Or LV_ERR_EL_TAM = 1
            Then LV_ERR_TAM = 1
            Else  LV_ERR_TAM = 0
            Endif
Else        #If NC_TIA_CONF = 10
            #Then  LV_ERR_TAM = LV_ERR_z_TIA[NC_IDX_TIA_IM_CYL]
            #Endif
            #If NC_TIA_CONF = 13 Or 21
            #Then  LV_ERR_TAM = LV_ERR_z_TIA[NC_IDX_TIA_CHRG_THR]
            #Endif
            #If NC_TIA_CONF = 12 Or 24
            #Then  LV_ERR_TAM = LV_ERR_z_TIA[NC_IDX_TIA_CHRG_UP]
            #Endif
            #If NC_TIA_CONF = 11 Or 22 Or 23 Or 30
            #Then  LV_ERR_TAM = LV_ERR_z_TIA[NC_IDX_TIA_AM_CHRG]
            #Endif
Endif
```

A.32.3 LV_ERR_TIA_THR, LV_ERR_TIA_IM and LV_ERR_TIA_CYL definition:

Recurrence : **100 ms.**

In the same way, depending on NC_TIA_CONF value, the values of LV_ERR_TIA_THR, LV_ERR_TIA_IM and LV_ERR_TIA_CYL are defined.

NC_TIA_CONF	10	11	13, 22
LV_ERR_TIA_THR LV_ERR_TIA_IM LV_ERR_TIA_CYL	LV_ERR_**z**_ TIA[NC_IDX_TIA_IM_CYL]	LV_ERR_**z**_ TIA[NC_IDX_TIA_AM_CHRG]	LV_ERR_**z**_ TIA[NC_IDX_TIA_CHRG_THR]

NC_TIA_CONF	12
LV_ERR_TIA_THR LV_ERR_TIA_IM LV_ERR_TIA_CYL	LV_ERR_TIA_CHRG_DOWN

NC_TIA_CONF	23, 24	21, 30
LV_ERR_TIA_THR	LV_ERR_TIA_CHRG_DOWN	LV_ERR_**z**_ TIA[NC_IDX_TIA_CHRG_THR]
LV_ERR_TIA_IM LV_ERR_TIA_CYL	LV_ERR_**z**_ TIA[NC_IDX_TIA_IM_CYL]	

Example: for NC_TIA_CONF = 21:

From column "20" of the first table we define:

- For LV_ERR_TIA_THR:

LV_ERR_TIA_THR is defined based on LV_ERR_**z**_TIA[NC_IDX_TIA_CHRG_THR] as follow:

If LV_ERR_**EL**_TIA[NC_IDX_TIA_CHRG_THR] = 0
And LV_ERR_**INTM**_TIA[NC_IDX_TIA_CHRG_THR] = 0
And LV_ERR_**DYN**_TIA[NC_IDX_TIA_CHRG_THR] = 0
And LV_ERR_**PLAUS**_TIA[NC_IDX_TIA_CHRG_THR] = 0
Then LV_ERR_TIA_THR = 0
Else LV_ERR_TIA_THR = 1
Endif

- For LV_ERR_TIA_IM and LV_ERR_TIA_CYL:

LV_ERR_TIA_IM and LV_ERR_TIA_CYL are defined based on LV_ERR_**z**_TIA[NC_IDX_TIA_IM_CYL] as follow:

If LV_ERR_**EL**_TIA[NC_IDX_TIA_IM_CYL] = 0
And LV_ERR_**INTM**_TIA[NC_IDX_TIA_IM_CYL] = 0
And LV_ERR_**DYN**_TIA[NC_IDX_TIA_IM_CYL] = 0
And LV_ERR_**PLAUS**_TIA[NC_IDX_TIA_IM_CYL] = 0
Then LV_ERR_TIA_IM = LV_ERR_TIA_CYL = 0
Else LV_ERR_TIA_IM = LV_ERR_TIA_CYL = 1
Endif

1st Exception: for the case: ***NC_TIA_CONF = 12***

For these cases, only the Error flag LV_ERR_TIA_CHRG_DOWN is delivered by the Charger Aggregate. Also, LV_ERR_TIA_THR, LV_ERR_TIA_IM, LV_ERR_TIA_CYL are defined as follow:

LV_ERR_TIA_THR = LV_ERR_TIA_IM = LV_ERR_TIA_CYL = LV_ERR_TIA_CHRG_DOWN

2nd Exception: for the 2 cases: ***NC_TIA_CONF = 23 Or 24***

For the same raison, LV_ERR_TIA_THR, LV_ERR_TIA_IM, LV_ERR_TIA_CYL are defined as follow:

- For LV_ERR_TIA_THR:

LV_ERR_TIA_THR = LV_ERR_TIA_CHRG_DOWN

- For LV_ERR_TIA_IM and LV_ERR_TIA_CYL

If LV_ERR_**EL**_TIA[NC_IDX_TIA_IM_CYL] = 0
And LV_ERR_**INTM**_TIA[NC_IDX_TIA_IM_CYL] = 0

And LV_ERR_**DYN**_TIA[NC_IDX_TIA_IM_CYL] = 0
And LV_ERR_**PLAUS**_TIA[NC_IDX_TIA_IM_CYL] = 0
Then LV_ERR_TIA_IM = LV_ERR_TIA_CYL = 0
Else LV_ERR_TIA_IM = LV_ERR_TIA_CYL = 1
Endif

A.32.4 LV_ERR_EL_TIA_THR and LV_END_DIAG_EL_TIA_THR definition:

Recurrence : **100 ms.**

#If NC_TIA_CONF = 10
#Then LV_ERR_EL_TIA_THR = LV_ERR_EL_TIA[NC_IDX_TIA_IM_CYL]
LV_END_DIAG_EL_TIA_THR = LV_END_DIAG_EL_TIA[NC_IDX_TIA_IM_CYL]
#Endif
#If NC_TIA_CONF = 11
#Then LV_ERR_EL_TIA_THR = LV_ERR_EL_TIA[NC_IDX_TIA_AM_CHRG]
LV_END_DIAG_EL_TIA_THR = LV_END_DIAG_EL_TIA[NC_IDX_TIA_AM_CHRG]
#Endif
#If NC_TIA_CONF = 13 **Or** 21 **Or** 22 **Or** 30
#Then LV_ERR_EL_TIA_THR = LV_ERR_EL_TIA[NC_IDX_TIA_CHRG_THR]
LV_END_DIAG_EL_TIA_THR = LV_END_DIAG_EL_TIA[NC_IDX_TIA_CHRG_THR]
#Endif
#If NC_TIA_CONF = 12 **Or** 23 **Or** 24
#Then LV_ERR_EL_TIA_THR = 0 (just to fullfill interfaces)
LV_END_DIAG_EL_TIA_THR = 1 (just to fullfill interfaces)
#Endif

A.33 Error Flags for Charge Air Temperature

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TIA_CHRG_UP	O	0...1H	0...1	1	-
Present failure on one TIA sensor(s) which might affect temperature TIA_CHRG_UP					
LV_ERR_TIA_CHRG_DOWN	O	0...1H	0...1	1	-
Present failure on one TIA sensor(s) which might affect temperature TIA_CHRG_DOWN					

Input data:

NC_TAM_CAN_USE	NC_TIA_CONF	LV_ERR_TIA_THR	LC_TCHA_CONF

A.33.1 CHRG_FCTDGTAIR0

Description:

The aim is to define the errors flags LV_ERR_TIA_CHRG_UP [respectively _DOWN] associated to the temperatures TIA_CHRG_UP [respectively _DOWN]. These two flags are made available to the other Aggregates.

Application Condition

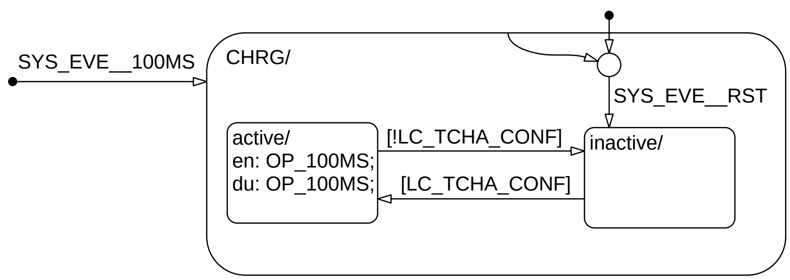

Figure 1 CHRG_FCTDGTAIR0/ APP_CDN/ Chart

"Maximum vehicle speed " time in percent since engine start					
LV_CDN_ENA_RATIO_T_AST	V	0...1H	0...1	1	[-]
Boolean for ratio time after engine start enable condition					

Input data:

LV_IS	LV_PUC	MAF_KGH	VS
TAM			

FUNCTION DESCRIPTION:

General information:

The coolant temperature increase after engine start is most dependent on the ambient- and the engine operating conditions. To avoid monitoring failures within the diagnosis functions related to the coolant temperature behaviour, the influence of critical engine driving conditions must be taken into consideration. To allow a comparison to the time elapsed since engine start, the activation time of the critical driving conditions are calculated in percent of the elapsed time. The percentage values are used in several diagnosis functions to cancel monitoring in order to avoid failures.

Application conditions:

Initialisation at Exit start (EXIT_ST):

LV_CDN_ENA_RATIO_T_AST = 1

all other output data are set to “0” [phys]

Initialisation at Engine run to Engine stop (ERU_to_ES):

LV_CDN_ENA_RATIO_T_AST = 0

T_DIAG_AST = 0 s

Recurrence: 1000 ms

Activation: LV_CDN_ENA_RATIO_T_AST = 1

Deactivation: LV_CDN_ENA_RATIO_T_AST = 0

Formula section:

Calculation of the after start time for diagnosis functions:

If T_DIAG_AST < 65535 s

then $T\_DIAG\_AST_{(n)} = T\_DIAG\_AST_{(n-1)} + 1$ s

else $T\_DIAG\_AST_{(n)} = T\_DIAG\_AST_{(n-1)}$

endif

Calculation of the "idle speed" period after start:

If LV_IS = 1

then $T\_IS\_AST_{(n)} = T\_IS\_AST_{(n-1)} + 1$ s

else $T\_IS\_AST_{(n)} = T\_IS\_AST_{(n-1)}$

endif

RATIO_T_IS_AST = (T_IS_AST / T_DIAG_AST) * 100 %

Calculation of the " trailing throttle fuel cut-off " period after start:

If LV_PUC = 1

then $T\_PUC\_AST_{(n)} = T\_PUC\_AST_{(n-1)} + 1$ s

else $T\_PUC\_AST_{(n)} = T\_PUC\_AST_{(n-1)}$

endif

RATIO_T_PUC_AST = (T_PUC_AST / T_DIAG_AST) * 100 %

Calculation of the "low load" period after start:

If MAF_KGH <= IP_MAF_KGH_LOAD_MIN_AST

then $T\_LOAD\_MIN\_AST_{(n)} = T\_LOAD\_MIN\_AST_{(n-1)} + 1$ s

else $T\_LOAD\_MIN\_AST_{(n)} = T\_LOAD\_MIN\_AST_{(n-1)}$

endif

RATIO_T_LOAD_MIN_AST = (T_LOAD_MIN_AST / T_DIAG_AST) * 100 %

Calculation of the "low vehicle speed" period after start:

If VS <= C_VS_THD_VS_MIN_AST

then $T\_VS\_MIN\_AST_{(n)} = T\_VS\_MIN\_AST_{(n-1)} + 1$ s

else $T\_VS\_MIN\_AST_{(n)} = T\_VS\_MIN\_AST_{(n-1)}$

endif

RATIO_T_VS_MIN_AST = (T_VS_MIN_AST / T_DIAG_AST) * 100 %

Calculation of the "high vehicle speed" period after start:

If VS > C_VS_THD_VS_MAX_AST

then $T\_VS\_MAX\_AST_{(n)} = T\_VS\_MAX\_AST_{(n-1)} + 1$ s

else $T\_VS\_MAX\_AST_{(n)} = T\_VS\_MAX\_AST_{(n-1)}$

endif

RATIO_T_VS_MAX_AST = (T_VS_MAX_AST / T_DIAG_AST) * 100 %

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_THD_VS_MIN_AST	1	0...FFH	0...255	1	[km/h]
Minimum vehicle speed threshold for “low vehicle speed” period calculation after start					
C_VS_THD_VS_MAX_AST	1	0...FFH	0...255	1	[km/h]
Maximum vehicle speed threshold for “high vehicle speed” period calculation after start					
IP_MAF_KGH_LOAD_MIN_AST	4	0...FFFFH	0...2047.96875	0.03125	[kg/h]

Boolean for end of coolant temperature signal gradient diagnosis					
TCO_MES_LIM_GRD	V	0...FEH	-48...142.5	0.75	[°C]
Limited measured coolant temperature for signal gradient diagnosis					

Input data:

TCO_MES	LV_ERR_TCO_STUCK	LV_ERR_TCO_STUCK_H	LV_ERR_TCO_PLAUS
LV_ERR_TCO_STUCK_RNG	TIA_THR	T_DIAG_AST	LV_IGK
LV_INH_DIAG_TCO_EL	LV_CDN_VB_MIN_DIAG	CTR_ABC_TCO_EL	CTR_ABC_TCO_GRD
LV_INH_DIAG_TCO_GRD	VP_TCO [NC_NR_TCO_SENS]	NC_NR_TCO_SENS	

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis function is to detect electrical failures as defined by OBD I and OBD II requirements. The coolant temperature raw sensor voltage (VP_TCO[0]) is measured with use of an A/D converter by the ECU hardware. The modified sensor signal is converted then into a measured temperature value (TCO_MES). Each by the ECU hardware measured raw sensor value is checked as well as the converted temperature signal.

Application conditions:

See separate chapters:

A.35.1 Global coolant temperature failure

FUNCTION DESCRIPTION:

General information:

A global coolant temperature error is set without debounce as soon as an electrical-, or signal gradient-, or stuck signal-, or plausibility- error is detected. All separate diagnosis functions are performed all the time if the diagnosis conditions are fulfilled. The deactivation of diagnosis functions with use of configuration switches is not possible.

In addition a preliminary coolant temperature error is set as soon as debouncing of an electrical-, or signal gradient- symptom occurs or in case of a plausibility-, or stuck signal-error. The preliminary coolant temperature error will be stored in the non-volatile memory during the ECU's self-holding phase to be available at the beginning of the next driving cycle.

Application conditions:

Initialisation at Reset:

LV_ERR_TCO = 0
LV_CDN_ENA_TCO_PREL = 1
LV_ERR_TCO_PREL = LV_ERR_TCO_PREL_DET *(NVMY)*
LV_ERR_TCO_PREL_DET = LV_ERR_TCO_PREL_DET *(NVMY)*
(NVMY: stored in the non-volatile memory)

Initialisation at Engine stop to Engine run (ES_to_ERU):

LV_ERR_TCO_PREL_DET = 0
LV_CDN_ENA_TCO_PREL = 0

Initialisation at FMY clear:

LV_ERR_TCO = 0
LV_ERR_TCO_PREL = 0
LV_ERR_TCO_PREL_DET = 0

Recurrence: 100 ms
Activation: at every engine operating state

Formula section:

If	LV_ERR_TCO_EL = 1	**or**
	LV_ERR_TCO_GRD = 1	**or**
	LV_ERR_TCO_STUCK = 1	**or**
	LV_ERR_TCO_STUCK_H = 1	**or**
	LV_ERR_TCO_STUCK_RNG = 1	**or**
	LV_ERR_TCO_PLAUS = 1	**or**
then	LV_ERR_TCO = 1	(without debounce)
else	LV_ERR_TCO = 0	
endif		

A.35.1.1 Preliminary coolant temperature failure (at ES after RESET)

Application conditions:

Recurrence:	100 ms
Activation:	LV_CDN_ENA_TCO_PREL = 1
Deactivation:	LV_CDN_ENA_TCO_PREL = 0

Formula section:

If	CTR_ABC_TCO_EL > 0	**or**
	CTR_ABC_TCO_GRD > 0	**or**
	LV_ERR_TCO_PREL_DET = 1	
then	LV_ERR_TCO_PREL = 1	(without debounce)
else	LV_ERR_TCO_PREL = 0	
endif		

A.35.1.2 Preliminary coolant temperature failure (at ERU / at ES after ERU_to_ES)

Application conditions:

Recurrence:	100 ms
Activation:	LV_CDN_ENA_TCO_PREL = 0
Deactivation:	LV_CDN_ENA_TCO_PREL = 1

Formula section:

A.35.2 Coolant temperature signal range diagnosis (TCO_EL)

FUNCTION DESCRIPTION:

General information:

The purpose of the signal range- or electrical diagnosis is to detect electrical errors in the input circuit of the coolant temperature sensor. The analog sensor input signal is converted into a digital value with use of an A/D converter. All symptoms of the error code are handled by anti-bouncing. Only one symptom can be active at a time.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> Short circuit to  Vbatt or Open Circuit "SCP_OC"      (= SYM_0)
 │  │  └────> Short circuit to Ground "SCG"                        (= SYM_1)
 │  └───────> (not used)                                           (= SYM_2)
 └──────────> (not used)                                           (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_EL	=	*Refer to filtering configuration for the initialisation*
LV_END_DIAG_TCO_EL	=	*Refer to filtering configuration for the initialisation*
LV_CDN_DIAG_TCO_EL	=	*Refer to filtering configuration for the initialisation*
ERR_SYM_TCO_EL	=	*Refer to filtering configuration for the initialisation*

Recurrence:	100 ms	
Activation:	LV_IGK = 1	**and**
	LV_CDN_VB_MIN_DIAG = 1	**and**
	LV_INH_DIAG_TCO_EL = 0	
Deactivation:	Activation condition not true	
	At Deactivation: LV_CDN_DIAG_TCO_EL = 0	

Formula section:

Error detection:

endif (2)

endif (1)

End of diagnosis:

For the calculation of LV_END_DIAG_TCO_EL see "Anti-bounce Algorithm, calculation of the end of diagnosis".

A.35.3 Coolant temperature signal gradient diagnosis (TCO_GRD)

FUNCTION DESCRIPTION:

General information:

The purpose of the signal gradient diagnosis is to detect a not plausible gradient on the measured coolant temperature sensor signal. The monitoring is based on a comparison between the actual measured and the last measure coolant temperature value. The symptom of the error code is handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                                            (= SYM_0)
 │  │  └────> -                                            (= SYM_1)
 │  └───────> -                                            (= SYM_2)
 └──────────> Coolant temperature signal gradient error    (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_GRD = *Refer to filtering configuration for the initialisation*
LV_END_DIAG_TCO_GRD = *Refer to filtering configuration for the initialisation*
LV_CDN_DIAG_TCO_GRD = *Refer to filtering configuration for the initialisation*
ERR_SYM_TCO_GRD = *Refer to filtering configuration for the initialisation*

Initialisation at Reset:

$TCO\_MES\_LIM\_GRD_{(n)} = TCO\_MES\_LIM\_GRD_{(n-1)} = TCO\_MES$

Recurrence: 100 ms

Activation:

If LV_IGK = 1 **and**
LV_CDN_VB_MIN_DIAG = 1 **and**
LV_INH_DIAG_TCO_GRD = 0
then LV_CDN_DIAG_TCO_GRD = 1
else LV_CDN_DIAG_TCO_GRD = 0
$TCO\_MES\_LIM\_GRD_{(n)} = TCO\_MES\_LIM\_GRD_{(n-1)} = TCO\_MES$
endif

Formula section:

Error detection:

Input data:

LV_IGK	LV_INH_DIAG_IV	PREV_STATE_IV	NC_CYL_NR
LV_CDN_VB_OBD1	LV_ST_END	LV_FL	LV_ES
N_32	LV_DC		

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.
STATE_ERR_IV is the general error bit after debouncing for limp-home reactions without entry in Error-memory.
It has to be assured that all cylinders had been injected in the cycle before.

All symptoms of the current error code are handeled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

Description:

The error detection is effected via the ECU hardware.

A valid diagnosis of all failures can only be detected when the injector was operated at least one time since the last changes and the filter times are observed. A short circuit to battery (SCB) and an open circuit (OC) can be detected only when the injector is “ON”. A short circuit to ground (SCG) can be detected only when the injector is “OFF”. Otherwise the diagnosis has to be suppressed (CDN_DIAG_IV [x] = 0). This is managed within the “Diagnosis condition calculation.

Application conditions:

Activation : every engine state

Deactivation: -

Initialization: at reset and at transition LV_IGK 0 -> 1:
all outputs (except LV_END_DIAG_IV) = 0

at reset and at transition LV_DC 0 -> 1:

LV_END_DIAG_IV = 0

Recurrence: 300 ms

Formula section:

(1) FOR x = 0 **TO** (NC_CYL_NR-1) **DO**: (Diagnosis condition calculation)

CDN_DIAG_IV [x] = 0

(2) IF LV_INH_DIAG_IV = 0
and
LV_IGK = 1
and
LV_CDN_VB_OBD1 = 1
and
LV_ES = 0

(2) THEN

(3) IF Bit x of PREV_STATE_IV = 1
and
if hardware valid flag is set

(3)THEN bit 0 of CDN_DIAG_IV [x] = 1 *(SCB can be detected))*

MAF	TCO	N_32	LV_ERR_CAM_IN[NC_NR_CAM_CBK]
NL_x	LV_ERR_CRK	ECU_DIAG_SF	IP_MAF_MIN_KNK__N_32__TCO
KNKS_x			

FUNCTION DESCRIPTION:

General information:

The purpose is to observe the analog input signal (KNKS) from the ATM40 device to the microcontroller.

The signal is checked continuously by a range check of the signal and with two algorithms, which observe the signal bandwidth. A Slave (BBINT) and a Master (BBSW) algorithm is used. Both algorithms have to show the same state to increment the ABC counter.

Range check:

The absolute noise value of the ATM40 device is checked if it is inside the normal operating range, C_NL_MIN_DIAG < NL_x < C_NL_MAX_DIAG. An out of range error can be detected in this way.

The Master algorithm (BBSW):

The bandwidth (│NL - KNKS│) of the signal is evaluated for cylinder 2 and 3. In case of short to ground, short to battery or open load the bandwidth is smaller than during normal operation. To monitor the bandwidth of the signal the magnitude is compared with a calibratable threshold C_DYW_MIN_KNKS_DIAG. If the bandwidth magnitude of cylinder 2 and 3 does not exceed C_DYW_MIN_KNKS_DIAG the cycle counter CYCNR_DYW_KNKS_DIAG is incremented by 1 every 360°CRK. This cycle counter is reset as soon as the KNKS value of cylinder 2 or 3 exceeds the threshold C_DYW_MIN_KNKS_DIAG. If the cycle counter reaches C_CYCNR_KNKS_DIAG, a knock sensor failure can be detected if the slave algorithm confirms the failure also. After the failure has been detected the counter CYCNR_DYW_KNKS_DIAG is decremented by 5 if the bandwidth of cyl. 2 or 3 exceeds the threshold C_DYW_MIN_KNKS_DIAG and the state of the ‘Slave algorithm’ is void.

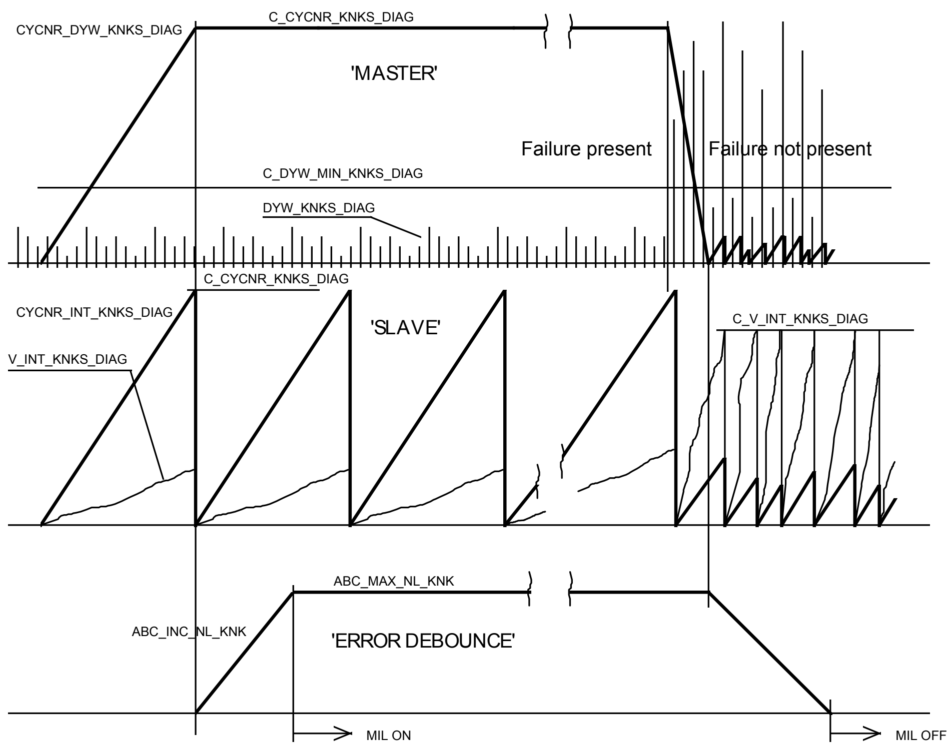
The Slave algorithm (BBINT):

This algorithm uses the bandwidth of the signal as well. The bandwidths of cylinder 2 and 3 are accumulated via an integration method. The accumulated voltage value is compared every revolution with the calibratable threshold C_V_INT_KNKS_DIAG. As soon as the threshold C_V_INT_KNKS_DIAG is reached the cycle counter CYCNR_INT_KNKS_DIAG (incremented every 360°CRK) is reset. If the cycle counter CYCNR_INT_KNKS_DIAG reaches the threshold C_CYCNR_KNKS_DIAG before the voltage threshold is reached the failure is confirmed by the slave algorithm.

If both algorithms detect a failure, the debounce starts (ABC counter is incremented). In this way a unplausible signal can be detected.

After the detection of the failure (ABC = ABC_MAX_NL_KNK) the master algorithm only is used to observe the bandwidth of the signal. If at least one value of the bandwidths exceeds the threshold C_DYW_MIN_KNKS_DIAG the counter CYCNR_DYW_KNKS_DIAG is decremented by 5 every 360°CRK. As soon as the counter CYCNR_DYW_KNKS_DIAG reaches 0 the ABC counter is decremented by 1 every 720°CRK.

Description:



Application conditions:

Recurrence: Crankshaft Synchronous (see details in formula section)

Activation:

- LV_ES = 0 **and** LV_ST = 0 **and** LV_PU = 0 **and** LV_PUC = 0 **and**
- [MAF > IP_MAF_MIN_KNK__N_32__TCO **and**
  MAF > C_MAF_MIN_KNKS_DIAG] **and**
- N_32 > C_N_MIN_KNKS_DIAG **and**
- LV_ERR_CRK = 0 **and**
- LV_ERR_CAM_IN_i = 0 **and**
- No communication failure (SPI bus) is present
  ('ATIC62_SPI_ERR' bit of ECU_DIAG_SF = 0)
  => LV_KNKS_DIAG_ENA **=** 1
  => LV_CDN_DIAG_KNKS_1 **=** 1

Deactivation:

- one of the conditions above not fulfilled
  => LV_KNKS_DIAG_ENA **=** 0
  => LV_CDN_DIAG_KNKS_1 **=** 0

Formula section:

- Every 180° crankshaft :

If NL_x < C_NL_MIN_DIAG
or NL_x > C_NL_MAX_DIAG
then LV_ERR_KNKS_1_RNG = 1
ERR_SYM_KNKS_1 = SYM_0 # Signal out of range
else LV_ERR_KNKS_1_RNG = 0

- Every 360° crankshaft :

Slave algorithm (BBINT) :

$V\_INT\_KNKS\_DIAG_i = V\_INT\_KNKS\_DIAG_{i-1} + DYW\_KNKS\_DIAG\_2 + DYW\_KNKS\_DIAG\_3$

With : $DYW\_KNKS\_DIAG\_2 = |NL\_2 - KNKS\_2|$

$DYW\_KNKS\_DIAG\_3 = |NL\_2 - KNKS\_3|$

$CYCNR\_INT\_KNKS\_DIAG_i = CYCNR\_INT\_KNKS\_DIAG_{i-1} + 1$

If V_INT_KNKS_DIAG >= C_V_INT_KNKS_DIAG
then **If** CYCNR_INT_KNKS_DIAG < C_CYCNR_KNKS_DIAG
then LV_ERR_KNKS_1_SLAVE = 0
and reset (V_INT_KNKS_DIAG, CYCNR_INT_KNKS_DIAG)
else LV_ERR_KNKS_1_SLAVE = 1 -> SLAVE Error is detected
and reset (V_INT_KNKS_DIAG, CYCNR_INT_KNKS_DIAG)

Master algorithm (BBSW) :

If [|KNKS_2 - NL_2| > C_DYW_MIN_KNKS_DIAG **or**
|KNKS_3 - NL_3| > C_DYW_MIN_KNKS_DIAG]

then CYCNR_DYW_KNKS_DIAG = 0

else CYCNR_DYW_KNKS_DIAG = CYCNR_DYW_KNKS_DIAG + 1

If CYCNR_DYW_KNKS_DIAG >= C_CYCNR_KNKS_DIAG
and LV_ERR_KNKS_1_SLAVE **=** 1 (SLAVE Error is detected)

then LV_ERR_KNKS_1_DYW **=** 1 -> MASTER Error is detected
if ERR_SYM_KNKS_1 = NO_SYM
then ERR_SYM_KNKS_1 = SYM_1 # Unplausible signal

Error debounce :

If LV_ERR_KNKS_1_RNG **=** 1

or LV_ERR_KNKS_1_DYW **=** 1 (MASTER_ERROR is detected)

then $ABC_i = ABC_{i-1}$ + ABC_INC_NL_KNK with: i =720°CRK

If ABC >= ABC_MAX_NL_KNK

then LV_ERR_KNKS_1 = 1 (Knock sensor failure dectected)

If after the failure has been debounced and |KNKS_2 - NL_2| > C_DYW_MIN_KNKS_DIAG or |KNKS_3 - NL_3| > C_DYW_MIN_KNKS_DIAG, then the cycle counter CYCNR_DYW_KNKS_DIAG is decremented by 5. As soon as the cycle counter equals 0 and no LV_ERR_KNKS_1_RNG currently present the ABC - Counter is decremented by 1.

If LV_ERR_KNKS_1_DYW = 0 **and** LV_ERR_KNKS_1_RNG = 0

then ERR_SYM_KNKS_1 = NO_SYM

Formula section:

** Debounce :*

Increment value for debounce counter : C_ABC_INC_NL_KNK
Maximum value for debounce counter : C_ABC_MAX_NL_KNK

Emergency operation :

** Limp Home : In the case of a knock sensor error LV_ERR_KNKS_1 = 1 and consequently KNK_CTL_DIS = 1 indicating a knock control relavant error; this in turn triggers the application of the limp home ignition angle retard IGA_KNK_CTL_DIS in the knock control module.*

Input data:

LV_IGK	LV_CDN_VB_OBD1	CONF_ACC	LV_RLY_MAIN_EXT_ADJ
C_T_DLY_RLY_MAIN_DIAG	LV_DC		

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the air condition relay signal.

The diagnosis is only active if “Vehicle with ACC” is learnt.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
|_|_|_|_|
 |  |  |  └─> Short circuit to Vbatt (SCB)      (= SYM_0)
 |  |  └───> Short circuit to GND (SCG)         (= SYM_1)

Anti bounce counter for ATIC62 SPI line diagnosis					

Input data:

LV_PRDR_ACT	STATE_DR_MU_MC	ERR_COD_MC_SAVE	NC_ETC_CONF

FUNCTION DESCRIPTION:

General information:

The purpose of the test is the check of ram areas and communication connections. In the stored ECU-failure bytes the error location is specified more detailed. Most of the checks are performed during system start-up.

ECU selftest error (= SYM_0)

Application conditions:

Initialization :

At first ECU power up, Loss of NVMY or NVMY reset

ECU_DIAG_SF_SAVE = 0

At reset,

ECU_DIAG_SF = 0

ABC_SPI_ATIC39 = 0

ABC_SPI_ATIC62 = 0

ECU_DIAG_SF_SAVE = restored from NVMY

At FMY clear,

ECU_DIAG_SF_SAVE = 0

Before saving ECU_DIAG_SF_SAVE in NVMY,

ECU_DIAG_SF_SAVE = ECU_DIAG_SF_SAVE **or** ECU_DIAG_SF ...bitwise

Fomular section :

a) Watch-dog failure detection at reset

If 'Software watchdog reset status' of ECU_RST_STATUS_HW is set

then Set 'WDT_ERR' bit of ECU_DIAG_SF

endif

b) Coherence failure detection between ECU software and calibration at reset

If reference number of ECU software <> reference number of calibration

then Set 'REF_ERR' bit of ECU_DIAG_SF

endif

c) RAM failure detection at reset (for non-ETC system)

If RAM failure is detected

then Set 'RAM_ERR' bit of ECU_DIAG_SF

endif

In non-ETC system, RAM failure detection at reset should be executed before application system detection (CCP) to avoid CCP RAM failure detection at ECU without CCP RAM.

d) SPI communication diagnosis every 10 ms

```
% ATIC39 SPI line diagnosis %
If      (NC_ETC_CONF = 1 and LV_PRDR_ACT = 0 and STATE_DR_MU_MC = ENABLE)
    or  NC_ETC_CONF = 0
Then    If      ATIC39 SPI communication line is failed
        then    ABC_SPI_ATIC39 = ABC_SPI_ATIC39 + C_ABC_INC_SPI
                If      ABC_SPI_ATIC39 >= C_ABC_MAX_SPI
                then    ABC_SPI_ATIC39 = C_ABC_MAX_SPI
                        Set 'ATIC39_SPI_ERR' bit of ECU_DIAG_SF
                endif
        else    ABC_SPI_ATIC39 = ABC_SPI_ATIC39 - 1
                If      ABC_SPI_ATIC39 = 0
                then    Clear 'ATIC39_SPI_ERR' bit of ECU_DIAG_SF
                endif
        endif
endif
```

e) SPI communication diagnosis every 10 ms

```
% ATIC62 SPI line diagnosis(Knock sensor) %
If      ATIC39 SPI communication line is failed
then    ABC_SPI_ATIC62 = ABC_SPI_ATIC62 + C_ABC_INC_SPI
        If      ABC_SPI_ATIC62 >= C_ABC_MAX_SPI
        then    ABC_SPI_ATIC62 = C_ABC_MAX_SPI
                Set 'ATIC62_SPI_ERR' bit of ECU_DIAG_SF
        endif
else    ABC_SPI_ATIC62 = ABC_SPI_ATIC62 - 1
        If      ABC_SPI_ATIC62 = 0
        then    Clear 'ATIC62_SPI_ERR' bit of ECU_DIAG_SF
        endif
endif
```

f) RAM failure detection at 10 ms (for ETC system)

```
If      ERR_COD_MC_SAVE = 0x0C
then    Set 'RAM_ERR' bit of ECU_DIAG_SF
```

endif

g) Checksum diagnosis every 100 ms

If Each checksum of customer boot, ECU software and calibration data area is not correct

then Set 'CKS_xxx_ERR' bit of ECU_DIAG_SF % xxx ; customer boot, ECU software and calibration data according to area %

endif

RAM failure diagnosis is done only once and diagnosis result is not reversible.

Detection :

Main ECU diagnosis accoding to ECU_DIAG_SF

Recurrence : 10 ms

If ECU_DIAG_SF <> 0

then LV_CDN_DIAG_ECU = 1

ERR_SYM_ECU = SYM_0

A.43.1 VIM power stage diagnosis (ATIC 39)

General information:

The VIM is driven by the ECU via ATIC 39. The failure detection is done by ECU Hardware. The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39” (static).

Error-symptoms: are defined to this diagnosis function as following

```
┌─┬─┬─┬─┐
│ │ │ └─> Short circuit to Vbatt        (= SYM_0)
│ │ └───> Short circuit to GND          (= SYM_1)
│ └─────> Open load                     (= SYM_2)
└───────> -                             (= SYM_3)
```

Application conditions:

Initialisation: at LV_IGK 0 → 1 **or** reset **or** clear failure memory

LV_INH_DIAG_VIM = 0

CDN_DIAG_VIM = 0

Recurrence: 100ms

Activation: CONF_VIM > 0

Formula section:

if	LV_IGK = 1	**and**
	LV_ES = 0	**and**
	LV_ST = 0	**and**
	LV_CDN_VB_OBD1 = 1	**and**
	LV_ERR_ECU = 0	
then	LV_INH_DIAG_VIM = 0	
else	LV_INH_DIAG_VIM = 1	
endif		

ABC-Type: use multi -condition debounce algorithm (MPL_STD_INI).

A.43.2 Diagnosis of VIM adaptation

Description:

For diagnosis the adaptation, the switching time and the electrical value of the feed back potentiometer can be used.

The diagnosis of adaptation (see chapter “adaptation of lower and higher of VIM ”).
Failure symptom:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                        (= SYM_0)
 │ │ └───> -                        (= SYM_1)
 │ └─────> -                        (= SYM_2)
 └───────> adaptation failure       (= SYM_3)
```

Application conditions:

Initialisation:	with LV_IGK = 0 --> 1 **or** reset **or** clear failure memory
	LV_CDN_DIAG_VIM_AD = 0
	LV_END_DIAG_VIM_AD = 0
	LV_ERR_VIM_AD = 0
	ERR_SYM_VIM_AD = NO_SYM
Recurrence:	20 ms
Activation:	CONF_VIM = 2 **and** LC_VIM_AD_DIAG_ENA = 1

Formula section:

```
If      STATE_VIM_AD > 0h (VIM_AD_PUC_TIMER)     and
        LV_END_DIAG_VIM_AD = 0
then    LV_CDN_DIAG_VIM_AD    = 1
else    LV_CDN_DIAG_VIM_AD    = 0
endif
 If     LV_CDN_DIAG_VIM_AD    = 1     and
        STATE_VIM_AD = VIM_AD_ERR
then    LV_ERR_VIM_AD = 1        (failure entry without debouncing)
        ERR_SYM_VIM_AD = SYM_3
endif
If      (STATE_VIM_AD = VIM_AD_ERR  or  STATE_VIM_AD = VIM_AD_OK)
then    LV_END_DIAG_VIM_AD = 1
endif
```

ABC Type: No

A.43.3 VIM stuck check

Description:

Usually the VIM switches from open to closed and reverse in a very short time. If the pneumatic system is not o.k. or the VIM has too much friction or even stucks, the switching time becomes too long or the VIM does not switch at all. This leads to a failure entry with symptom “mechanical failure”, “upper stop not reached” or “lower stop not reached”.

Failure symptom up:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> mechanical failure (upper stop not reached)     (= SYM_0)
 │ │ └───>                                                 (= SYM_1)
 │ └─────>                                                 (= SYM_2)
 └───────>                                                 (= SYM_3)
```

Failure symptom down:

```
[ | | | ]
 |  |  |  └─>                                                     (= SYM_0)
 |  |  └───> mechanical failure (lower stop not reached)          (= SYM_1)
 |  └──────>                                                      (= SYM_2)
 └─────────>                                                      (= SYM_3)
```

Application conditions:

Initialisation: with LV_IGK = 0 --> 1 or reset clear of failure memory
T_VIM_DIAG_MEC_LONG = C_T_VIM_DIAG_MEC_LONG
T_VIM_DIAG_MEC_SHO = C_T_VIM_DIAG_MEC_SHO
Following variables are initialized according filter type:
LV_CDN_DIAG_VIM_MEC_LONG
LV_CDN_DIAG_VIM_MEC_SHO
LV_ERR_VIM_MEC_LONG
LV_ERR_VIM_MEC_SHO
LV_END_DIAG_VIM_MEC_LONG
LV_END_DIAG_VIM_MEC_SHO
ERR_SYM_VIM_MEC_LONG
ERR_SYM_VIM_MEC_SHO

Recurrence: 20 ms

A.43.6 Variables for fleet monitoring

A.43.7 - Monitoring of T_VIM_DIAG_MEC_LONG(_SHO):

Initialisation: - at first ECU power up and non-volantile memory lost:
T_VIM_SWI_MEC_LONG(_SHO)_MAX_TOT_DC = 0H
- otherwise: restored from non-volantile memory

Recurrence: *20 ms*

Activation: *LV_CDN_DIAG_VIM_MEC_LONG = 1*

Deactivation: -

Formula section:

If C_T_VIM_DIAG_MEC_LONG(_SHO) - T_VIM_DIAG_MEC_LONG(_SHO) >
T_VIM_SWI_MEC_LONG(_SHO)_MAX_TOT_DC

Then T_VIM_SWI_MEC_LONG(_SHO)_MAX_TOT_DC =
C_T_VIM_DIAG_MEC_LONG(_SHO) - T_VIM_DIAG_MEC_LONG(_SHO)

Endif

A.43.8 RBM Interface for VIM mechanical failure short position

FUNCTION DESCRIPTION:

General information:

With this module the interface between the monitor VIM_MEC_SHO and the Rate-Based Monitoring statistics is defined with STATE_RBM_VIM_MEC_SHO data.

Within STATE_RBM_VIM_MEC_SHO three different information are defined:

Information about bit 0 of STATE_RBM_VIM_MEC_SHO:

Conditions for monitoring are met long enough to detect malfunction (no intrusive operation, no short trip)

Information about bit 1 of STATE_RBM_VIM_MEC_SHO:

Monitor disabled because of system malfunction (depending on failure status: pending)

Information about bit 2 of STATE_RBM_VIM_MEC_SHO:

Monitor individual RBM conditions encountered within this DC

Application conditions:

Initialisation:

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_VIM_MEC_SHO = 0
LV_INH_DIAG_RBM_VIM_MEC = 0

at LV_DC 0 -> 1 transition :
bit 0, bit 1 of STATE_RBM_VIM_MEC_SHO = 0
bit 2 of STATE_RBM_VIM_MEC_SHO = 1

On failure memory reset :
bit 1 of STATE_RBM_VIM_MEC_SHO = 0

Recurrence: 1s

Activation: CONF_VIM = 2 **and** LV_DC 0 -> 1 transition **and** LV_DC = 1

Formula section:

{ definition of LV_INH_DIAG_RBM_VIM_MEC }

If LV_ERR_VCC_SENS_SUB = 1 **or**
LV_ERR_VIM = 1 **or**
LV_ERR_VIM_FB_EL = 1 **or**
then LV_INH_DIAG_RBM_VIM_MEC = 1

endif

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once:

LV_ERR_VCC_SENS_SUB

LV_ERR_VIM

LV_ERR_VIM_FB_EL

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_VIM_MEC_SHO = 0 **do**

with each VIM failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_VIM_MEC_SHO = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_VIM_MEC_SHO = 0

Then

If LV_END_DIAG_VIM_MEC_SHO = 1

Then bit 0 of STATE_RBM_VIM_MEC_SHO = 1

Endif

Endif

If bit 1 of STATE_RBM_VIM_MEC_SHO = 0

Then

A.44.1 Electrical diagnosis of VIM feed-back

Description:

The feed-back value of the potentiometer can be obeserved if it is within sensefull electrical range.

Failure symptom:

```
□□□□
│ │ │ └─> short cut to battery / open loop      (= SYM_0)
│ │ └───> short cut to ground                   (= SYM_1)
│ └─────> -                                     (= SYM_2)
└───────> -                                     (= SYM_3)
```

Application conditions:

Initialisation: with LV_IGK = 0 --> 1 or reset clear of failure memory

Recurrence: 20 ms

Activation: LV_ST = 0 and CONF_VIM = 2

Formula section:

Short cut to battery/ Short cut to ground or open loop

```
If      LV_IGK              = 1   And
        LV_CDN_VB_OBD1      = 1   And
        LV_ERR_VCC_SENS_SUB = 0
Then    LV_CDN_DIAG_VIM_FB_EL = 1
        If    V_VIM > C_V_VIM_MAX_DIAG
        Then  ERR_SYM_VIM_FB_EL = SYM_0            ; Short cut to battery
        Else  If    V_VIM < C_V_VIM_MIN_DIAG
              Then  ERR_SYM_VIM_FB_EL = SYM_1      ;Short cut to ground or open loop
              Else  ERR_SYM_VIM_FB_EL = NO_SYM
              Endif
        Endif
Else    LV_CDN_DIAG_VIM_FB_EL = 0
Endif
```

The LV_END_DIAG-Bit and LV_ERR-Bit is managed by the error memory.

ABC Type: STD_INI

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be the detection of electrical faults and not plausible conditions. Therefore the following error-checks are performed:

- Signal range check high
- Signal range check low
- Ratio check
- High resistance check (only for potentiometer systems)
- Move check
- Plausibility brake / PVS

For freeze frame, DTC, error code number, symptom number, emission error type, successive error management, data for MIL-management and anti-bounce configuration see chapters for general diagnosis information and application incidences.

PVS1 out of range check high error symptoms :

```

Signal flow diagram:

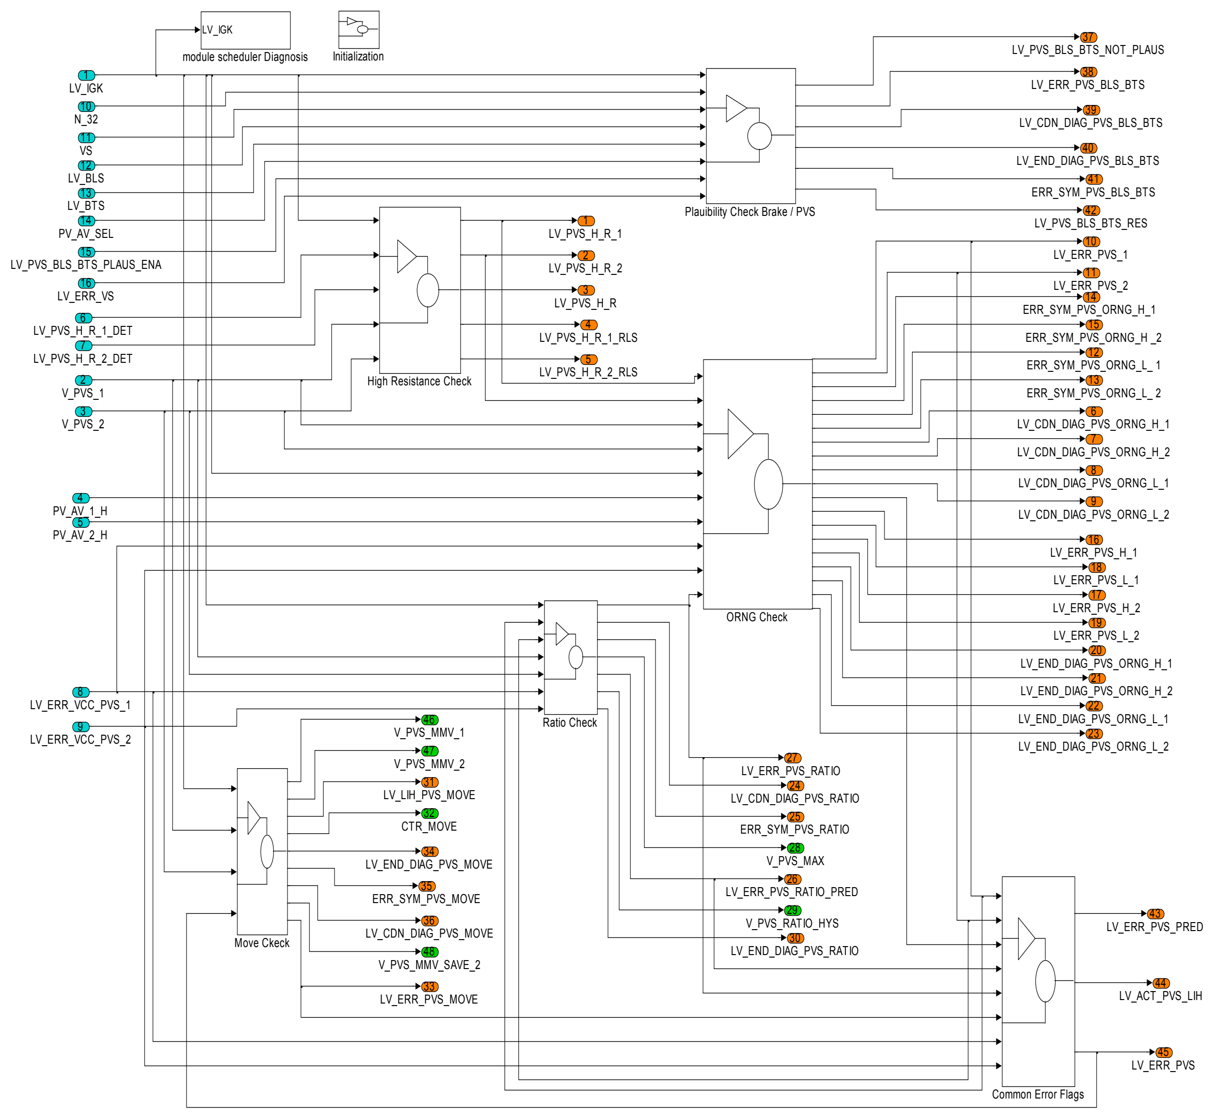

Figure 1: Diagnosis of Pedal Value Sensor (PVS)

Description:

Module scheduler:

The module „Diagnosis of Pedal Value Sensor (PVS)“ is executed at function call CLC_PVS_DIAG__10MS and initialized at CLC_PVS_DIAG__RST.
Each function part is calculated according to the corresponding function call which order is organized in the module scheduler shown below.

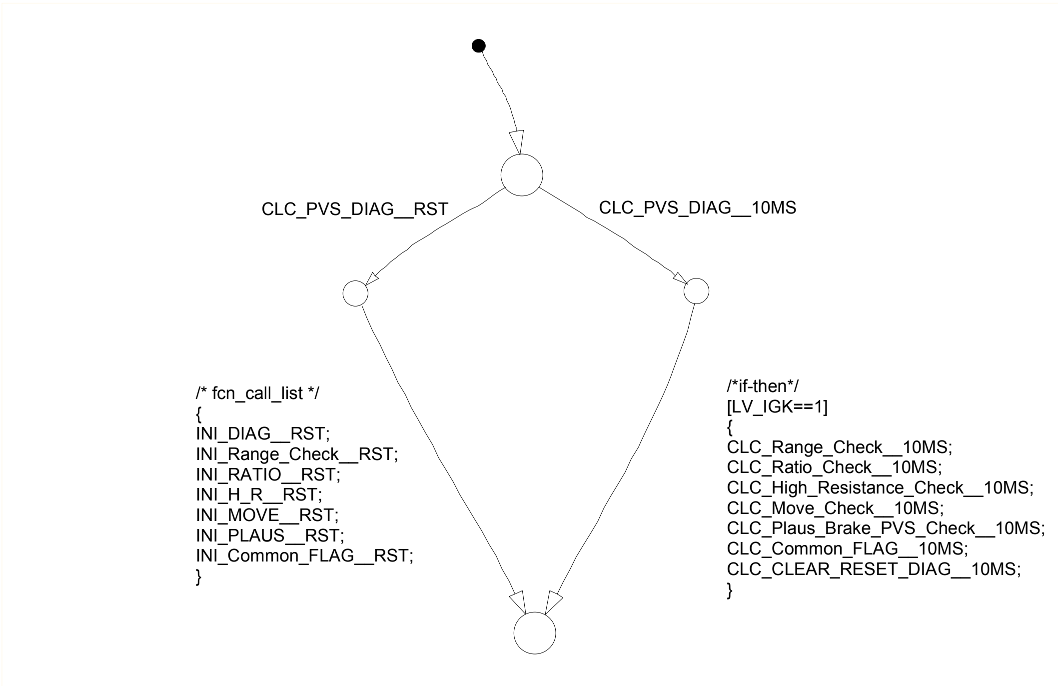

Figure 2: module scheduler Diagnosis

Module calculation order **at** Initialization

1. INITIALIZATION	on fcn-call INI_DIAG__RST
2. ORNG Check	on fcn-call INI_Range_Check_RST
3. Ratio Check	on fcn-call INI_RATIO__RST
4. High Resistance Check	on fcn-call INI_H_R__RST
5. Move Check	on fcn-call INI_MOVE_RST
6. Plausibility Check Brake / PVS	on fcn-call INI_PLAUS__RS
7. Common Error Flags	on fcn-call INI_Common_FLAG__RST

Module calculation order **after** Initialization

1. ORNG check	on fcn-call CLC_Range_Check__10MS
2. Ratio Check	on fcn-call CLC_Ratio_Check__10MS
3. High Resistance Check	on fcn-call CLC_High_Resistance_Check__10MS
4. Move Check	on fcn-call CLC_Move_Check__10MS
5. Plausibility Check Brake / PVS	on fcn-call CLC_Plaus_Brake_PVS_Check__10MS
6. Common Error Flags	on fcn-call CLC_Common_FLAG__10MS
7. INITIALIZATION	on fcn-call CLC_CLEAR_RESET_DIAG__10MS

Initialization:

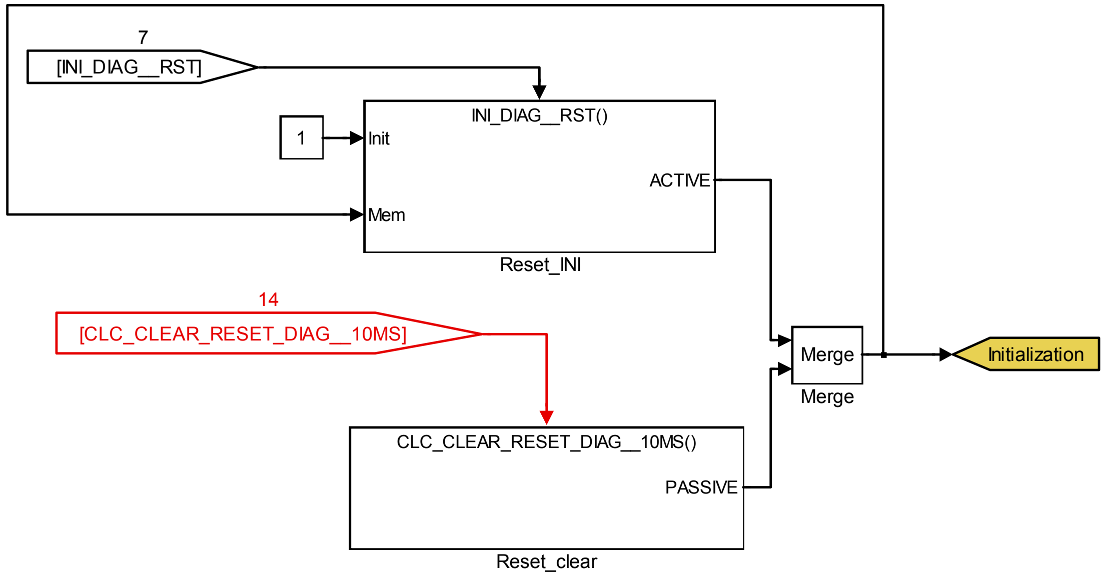

Figure 3: Initialization

At function call **INI_DIAG__RST** INITIALIZATION is set to **active**.
It is set to **passive** again at the end of the next regular calculation cycle at function call **CLC_CLEAR_RESET_DIAG__10MS.**

A.45.1 Out of range check (ORNG)

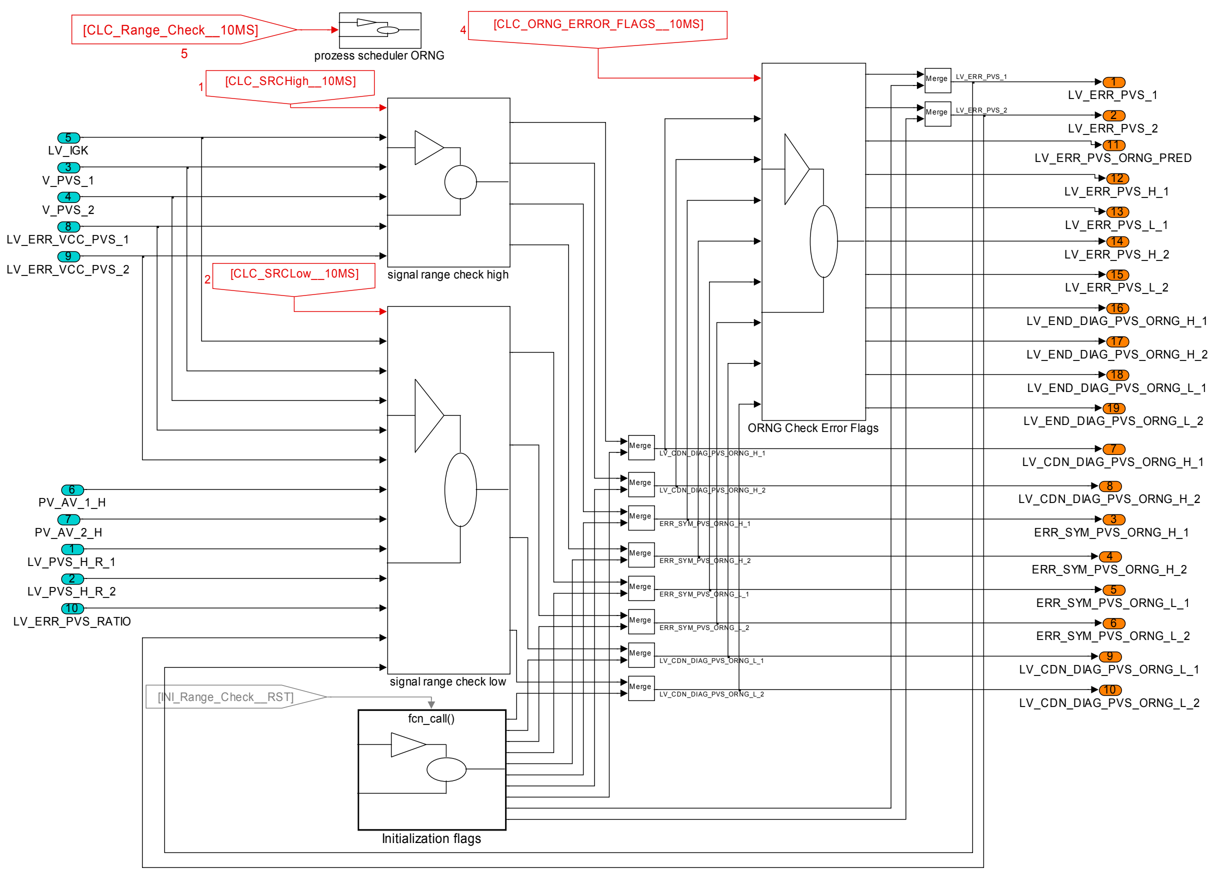

Figure 4: ORNG check

Description:

During normal operation, the output voltages of the PVS-sensors must lie within a permitted range.

If a signal voltage is detected as out of range (above or below), the bit LV_ERR_PVS_ORNG_PRED will be set during debouncing. The bit will be reset, if

– the setting conditions are not fulfilled anymore (diagnosis condition flag + symptom) or

– after the error is debounced, LV_ERR_PVS_x = 1

In order to re-examine, whether a range violation has caused a Ratio-error, the debouncing times of both signal range checks (high / low) have to be selected smaller than the debouncing time of the Ratio-check.

Calculation order:

1. Signal Range Check High — on fcn-call CLC_SRCHigh__10MS
2. Signal Range Check Low — on fcn-call CLC_SRCLow__10MS
3. ORNG Check Error Flags — on fcn-call CLC_ORNG_ERROR_FLAGS__10MS

A.45.1.1 Signal range check high

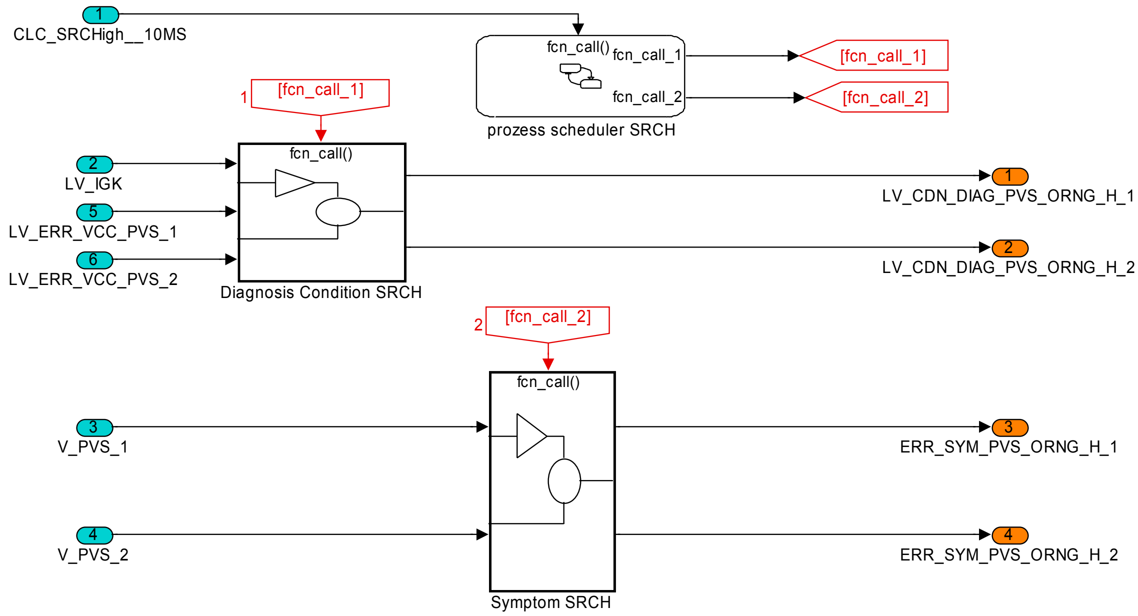

Figure 5: Signal range check high

Description:

In an error-free system, the sensor voltages must lie below the limits C_V_PVS_MAX_DIAG_x.

Calculation order:

1. Diagnosis Condition SRCH on fcn_call_1
2. Symptom SRCH on fcn_call_2

Formula section:

Diagnosis Condition SRCH:

IF LV_IGK == 1 **AND** LV_ERR_VCC_PVS_1 = 0
THEN LV_CDN_DIAG_PVS_H_1 = 1 (Diagnosis channel 1 active)
ELSE LV_CDN_DIAG_PVS_H_1 = 0 (Diagnosis channel 1 passive)
ENDIF

IF LV_IGK == 1 **AND** LV_ERR_VCC_PVS_2 = 0
THEN LV_CDN_DIAG_PVS_H_2 = 1 (Diagnosis channel 2 active)
ELSE LV_CDN_DIAG_PVS_H_2 = 0 (Diagnosis channel 2 passive)
ENDIF

Symptom SRCH_1:

IF V_PVS_1 > C_V_PVS_MAX_DIAG_1
THEN ERR_SYM_PVS_H_1= 1H (short to plus)
//anti-bounce counter (PVS_H_1) + C_ABC_INC_PVS_ORNG_1, only one increment per activated time condition, LV_ERR_PVS_H_1 = 1 after debounced
ELSE ERR_SYM_PVS_H_1= 0H (no symptom)
ENDIF

Filtering:

APPLY filter on current symptom

IF filtering result available (after debounce)

THEN LV_ERR_PVS_H_1 = filtering result

LV_END_DIAG_PVS_H_1 = 1

Deliver the result to Error Management

END

Symptom SRCH_2:

IF V_PVS_2 > C_V_PVS_MAX_DIAG_2
THEN ERR_SYM_PVS_H_2 = 1H (short to plus)
//anti-bounce counter (PVS_H_2) + C_ABC_INC_PVS_ORNG_2, only one increment per activated time condition, LV_ERR_PVS_H_2 = 1 after debounced
ELSE ERR_SYM_PVS_H_2 = 0H (no symptom)
ENDIF

Filtering:

APPLY filter on current symptom

IF filtering result available (after debounce)

THEN LV_ERR_PVS_H_2 = filtering result

LV_END_DIAG_PVS_H_2 = 1

Deliver the result to Error Management

END

A.45.1.2 Signal Range Check Low (SRCL)

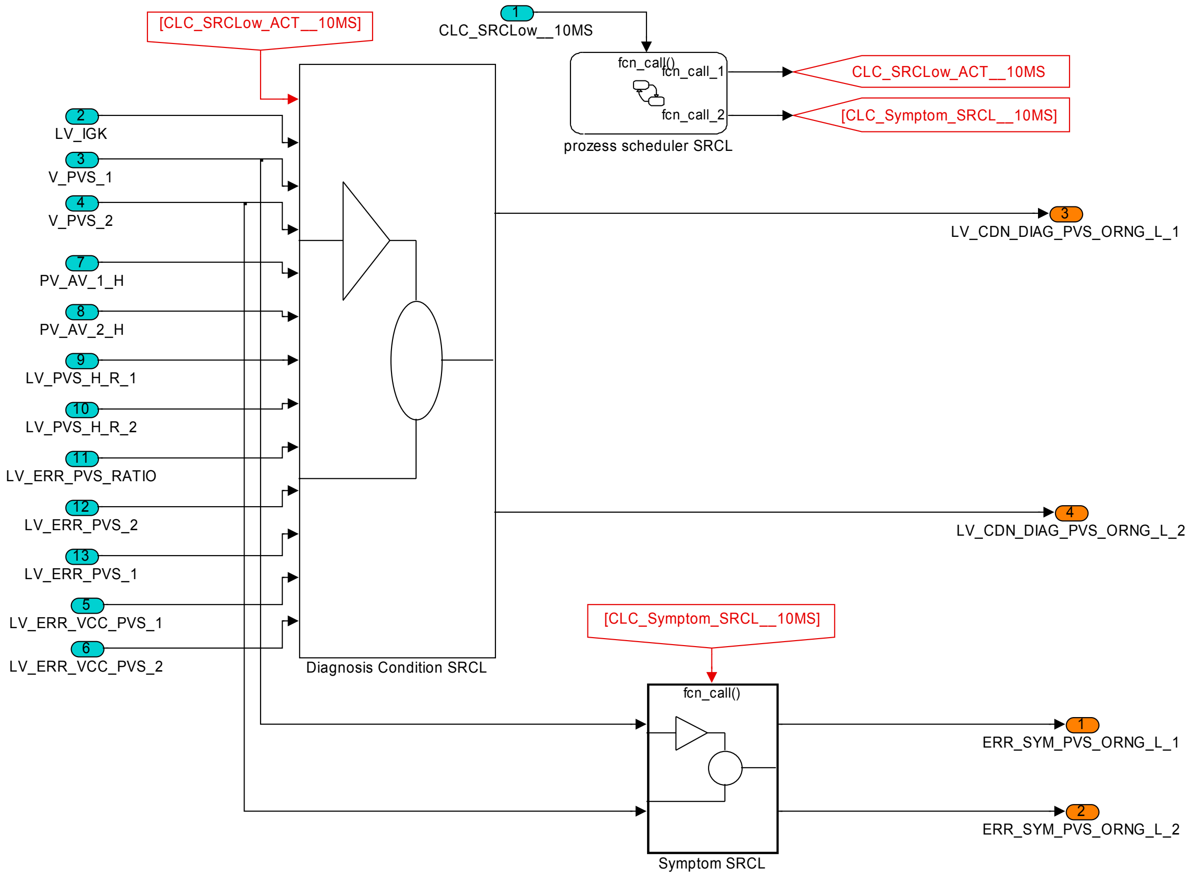

Figure 6: Signal Range Check Low

Description:

Calculation order:

1. Diagnosis Condition SRCL — on fcn-call CLC_SRCLow_ACT__10MS
2. Symptom SRCL — on fcn-call CLC_Symptom_SRCL__10MS

A.45.1.2.1 Diagnosis Condition SRCL:

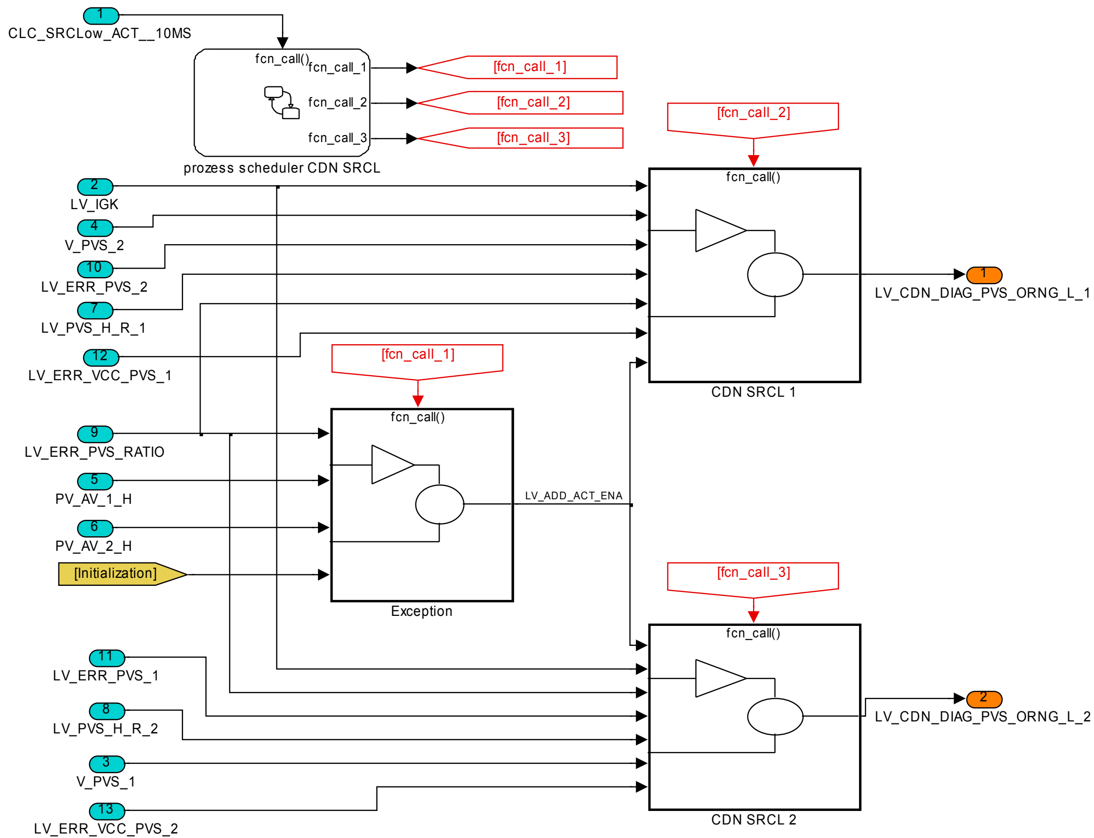

Figure 7: Diagnosis Condition Signal Range Check Low

Description:

The diagnosis conditions of the signal range check low on channel 1 and 2 depend on different conditions for each channel respectively and a common exception condition for both. If the diagnosis conditions are fulfilled, the flag LV_CDN_DIAG_PVS_ORNG_L_x =1.

Calculation order:

1. Exception on fcn_call_1
2. CDN SRCL 1 on fcn_call_2
3. CDN SRCL 2 on fcn_call_3

Exception

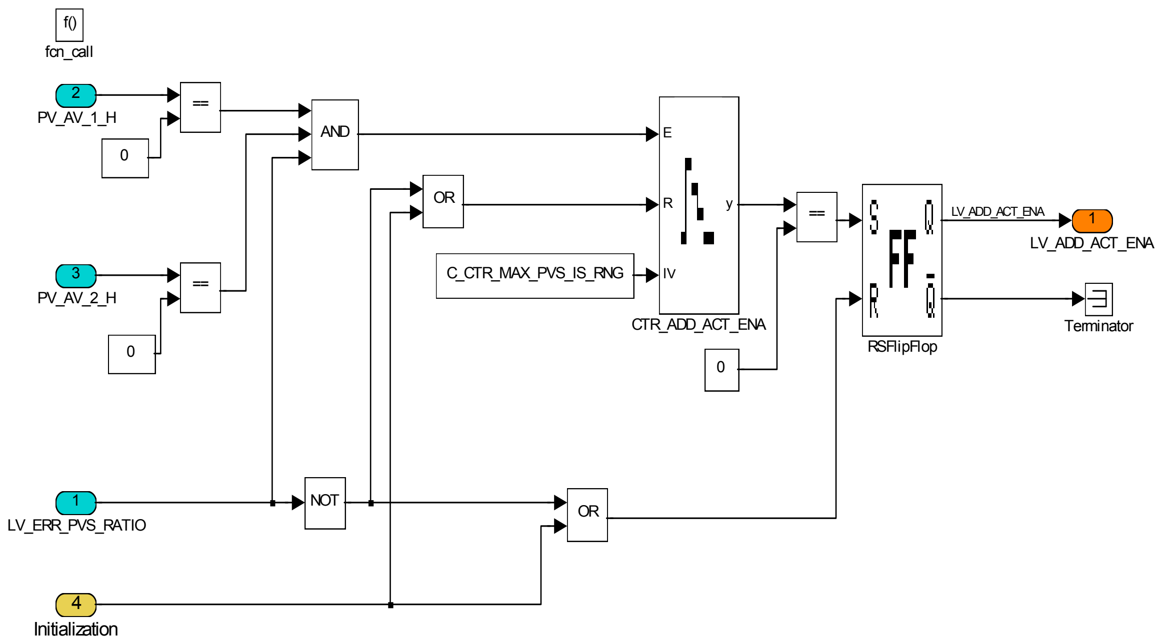

Figure 8: Exception

Description:

If a Ratio-Error is already debounced, the SRCL diagnosis conditions are not fulfilled until both pedal values PV_AV_1_H and PV_AV_2_H have been 0 % for the adjustable time C_CTR_MAX_PVS_IS_RNG. If the exception condition is fulfilled, LV_ADD_ACT_ENA will be set for the whole driving cycle and the SRCL can also be performed even if there is a high resistance and ratio-error.

Example:

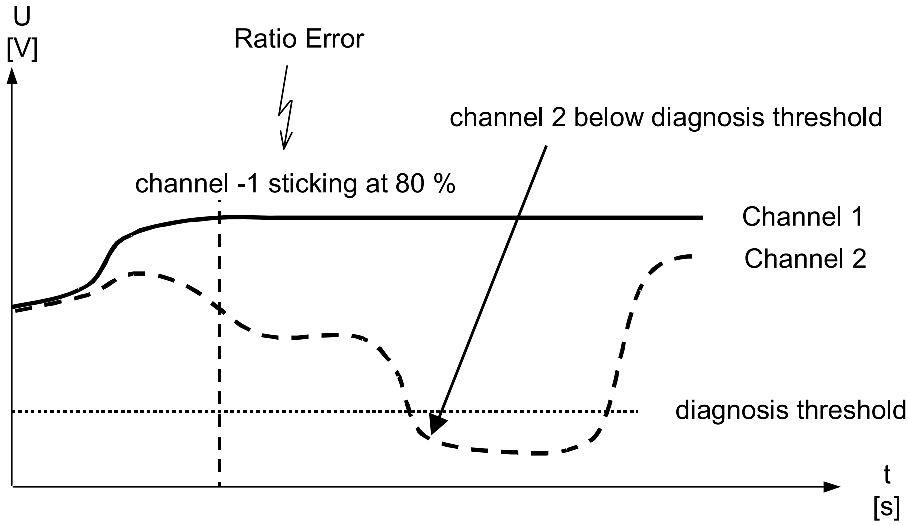

Figure 9: Example

If there is a Ratio-Error debounced **only**, (e.g. due to a sticking channel 1 to PV_AV_1_H = 80 %), there is no information about which channel is faulty.

To avoid a activation and debouncing of Signal Range Check Low if channel 2 underspends the diagnosis threshold as a result of high resistance (after a Ratio Error is already debounced), both channels have to be detected at idle PV_AV_1_H = 0% and PV_AV_2_H = 0% for an adjustable durance to enable.

Formula section:

```
IF          LV_ERR_PVS_RATIO        == 1                                   AND
            INITIALIZATION          == passive
THEN
    IF      PV_AV_1_H == 0                                                 AND
            PV_AV_2_H == 0                                                 AND

          ENDIF

    ENDIF
ENDIF
```

A.45.1.2.2 Symptom SRCL:

Description:
In an error-free system, the sensor voltages must lie above the limits C_V_PVS_MIN_DIAG_x.

Formula section:

Error Symptom Channel 1:

```
IF      V_PVS_1 < C_V_PVS_MIN_DIAG_1
THEN    ERR_SYM_PVS_L_1 = 2H   (short to ground or open line)
        //anti-bounce counter (PVS_L_1) + C_ABC_INC_PVS_ORNG_1, only one increment
        per activated time condition, LV_ERR_PVS_L_1 = 1 after debounced
ELSE    ERR_SYM_PVS_L_1 = 0H   (NO_SYM)
ENDIF
```

Filtering:

APPLY filter on current symptom

IF filtering result available (after debounce)

THEN LV_ERR_PVS_L_1 = filtering result

LV_END_DIAG_PVS_L_1 = 1

Deliver the result to Error Management

END

Error Symptom Channel 2:

```
IF      V_PVS_2 < C_V_PVS_MIN_DIAG_2
THEN    ERR_SYM_PVS_L_2 = 2H   (short to ground or open line)
        //anti-bounce counter (PVS_L_2) + C_ABC_INC_PVS_ORNG_2, only one increment
        per activated time condition, LV_ERR_PVS_L_2 = 1 after debounced
ELSE    ERR_SYM_PVS_L_2 = 0H   (NO_SYM)
ENDIF
```

Filtering:

APPLY filter on current symptom

IF filtering result available (after debounce)

THEN LV_ERR_PVS_L_2 = filtering result

LV_END_DIAG_PVS_L_2 = 1

Deliver the result to Error Management

END

A.45.1.3 ORNG Check Error Flags

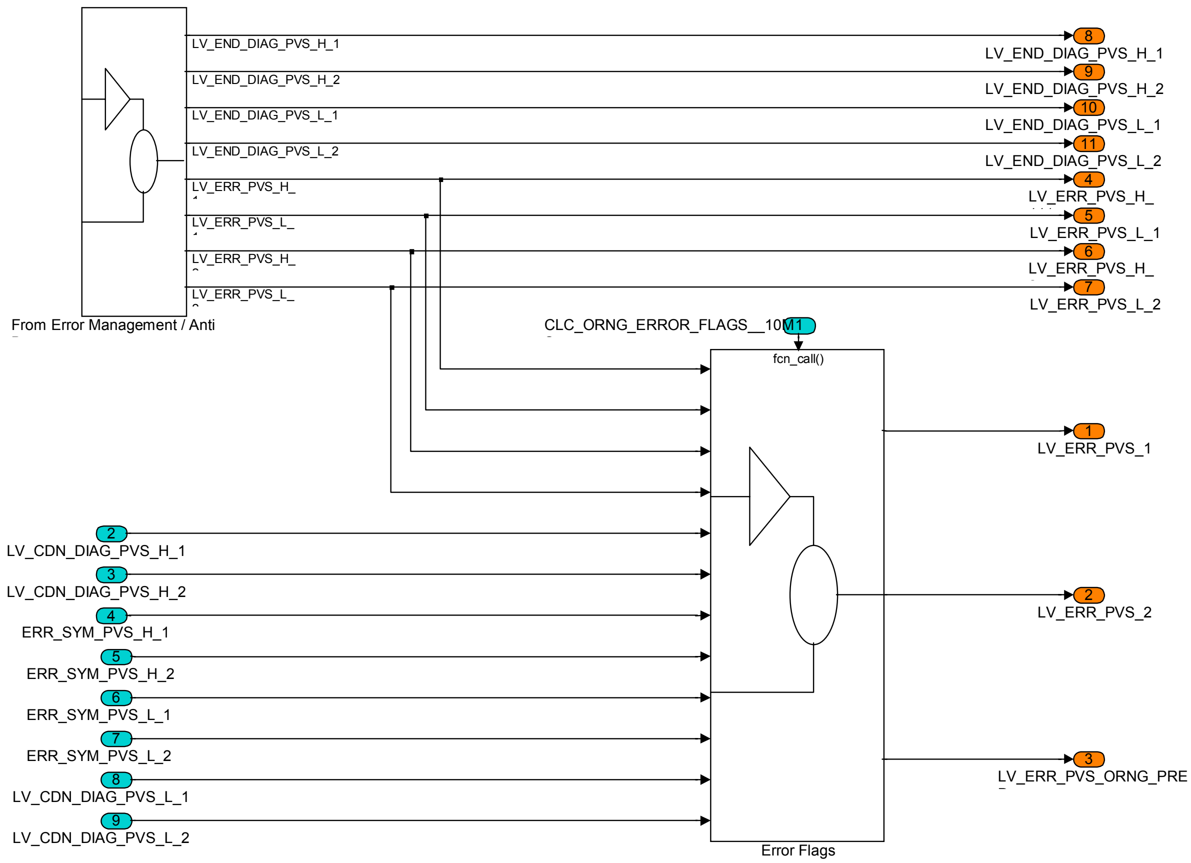

Figure 12: ORNG Check Error Flags

Description:

After debouncing the following error flags are set for the whole driving cycle:

LV_ERR_PVS_H_1

LV_ERR_PVS_H_2

LV_ERR_PVS_L_1

LV_ERR_PVS_L_2

The end of diagnosis flags are set when, the diagnosis result is available or the present error is debounced. They are reset at initialization.

LV_END_DIAG_PVS_H_1

LV_END_DIAG_PVS_H_2

LV_END_DIAG_PVS_L_1

LV_END_DIAG_PVS_L_2

Error Flags

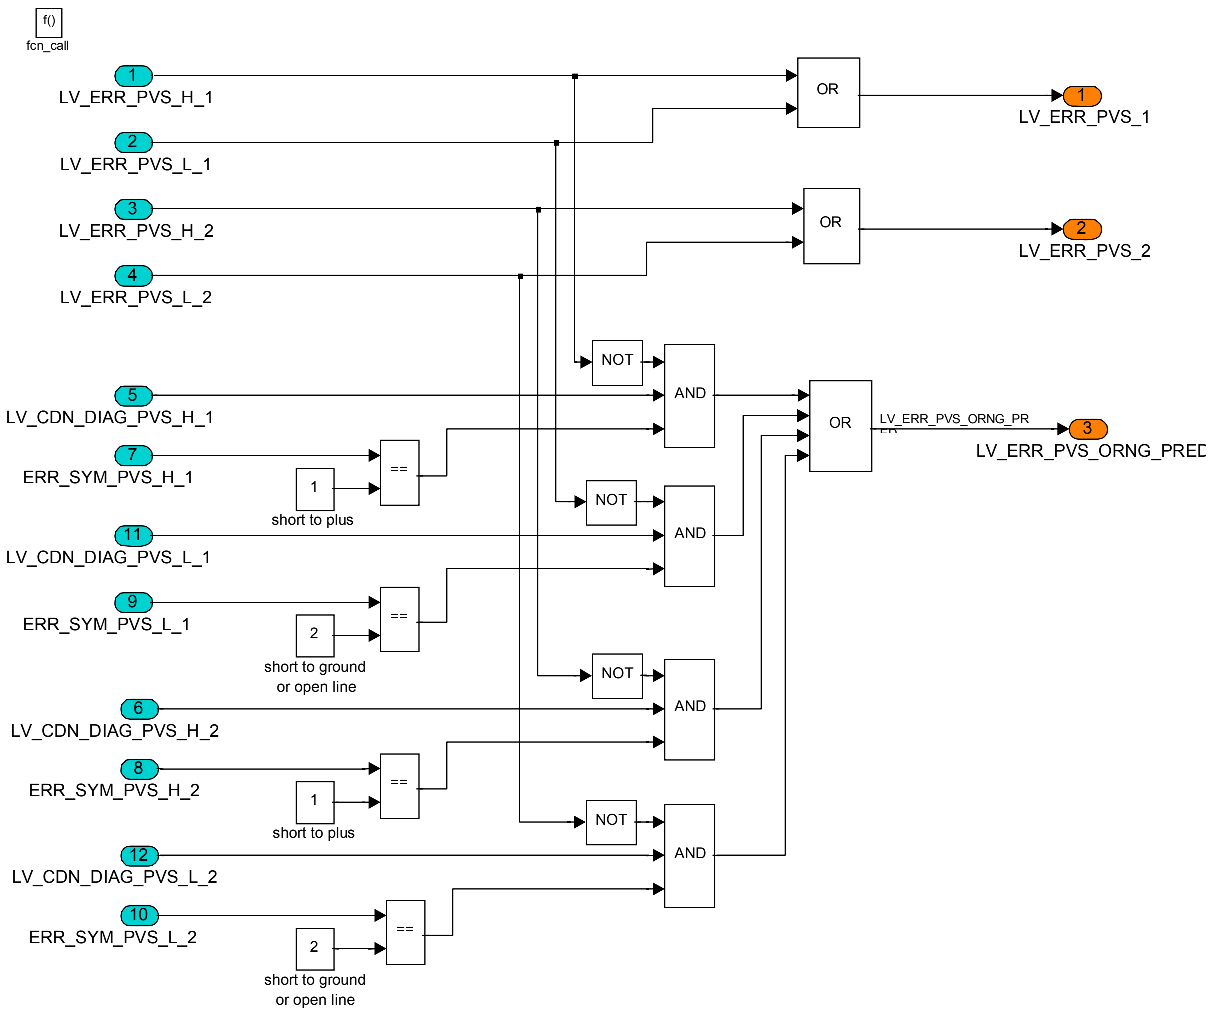

Figure 13: Errors ORNG

The error flags of SRCH and SRCL are combined to build the ORNG error status of each channel.

If a signal voltage is detected as out of range (symptom short to plus or to ground) and the diagnosis is active (LV_CDN_DIAG_PVS_ORNG_x_x ==1), the bit LV_ERR_PVS_ORNG_PRED will be set during debouncing. The bit will be reset, if

– the setting conditions are not fulfilled anymore (diagnosis condition + symptom) or
– after the error is debounced, LV_ERR_PVS_x = 1

Formula section:

ORNG Error debounced on PVS 1:

```
IF      LV_ERR_PVS_H_1 == 1     OR
        LV_ERR_PVS_L_1 == 1
THEN    LV_ERR_PVS_1 = 1
ENDIF
```

ORNG Error debounced on PVS 2:

```
IF      LV_ERR_PVS_H_2 == 1     OR
        LV_ERR_PVS_L_2 == 1
THEN    LV_ERR_PVS_2 =1
ENDIF
```

ORNG Error Predicted

```
IF      [       LV_CDN_DIAG_PVS_H_1 ==1         and
                ERR_SYM_PVS_H_1 == 1H and
          NOT(LV_ERR_PVS_H_1 ==1)                       ]       OR
        [       LV_CDN_DIAG_PVS_L_1 ==1         and
                ERR_SYM_PVS_L_1 == 2H and
          NOT(LV_ERR_PVS_L_1 ==1)                       ]       OR
        [       LV_CDN_DIAG_PVS_H_2 ==1         and
                ERR_SYM_PVS_H_2 == 1H and
          NOT(LV_ERR_PVS_H_2 ==1)                       ]       OR
        [       LV_CDN_DIAG_PVS_L_2 ==1         and
                ERR_SYM_PVS_L_2 == 2H and
          NOT(LV_ERR_PVS_L_2 ==1)                       ]
THEN    LV_ERR_PVS_ORNG_PRED = 1
ELSE    LV_ERR_PVS_ORNG_PRED = 0
ENDIF
```

A.45.2 Ratio Check

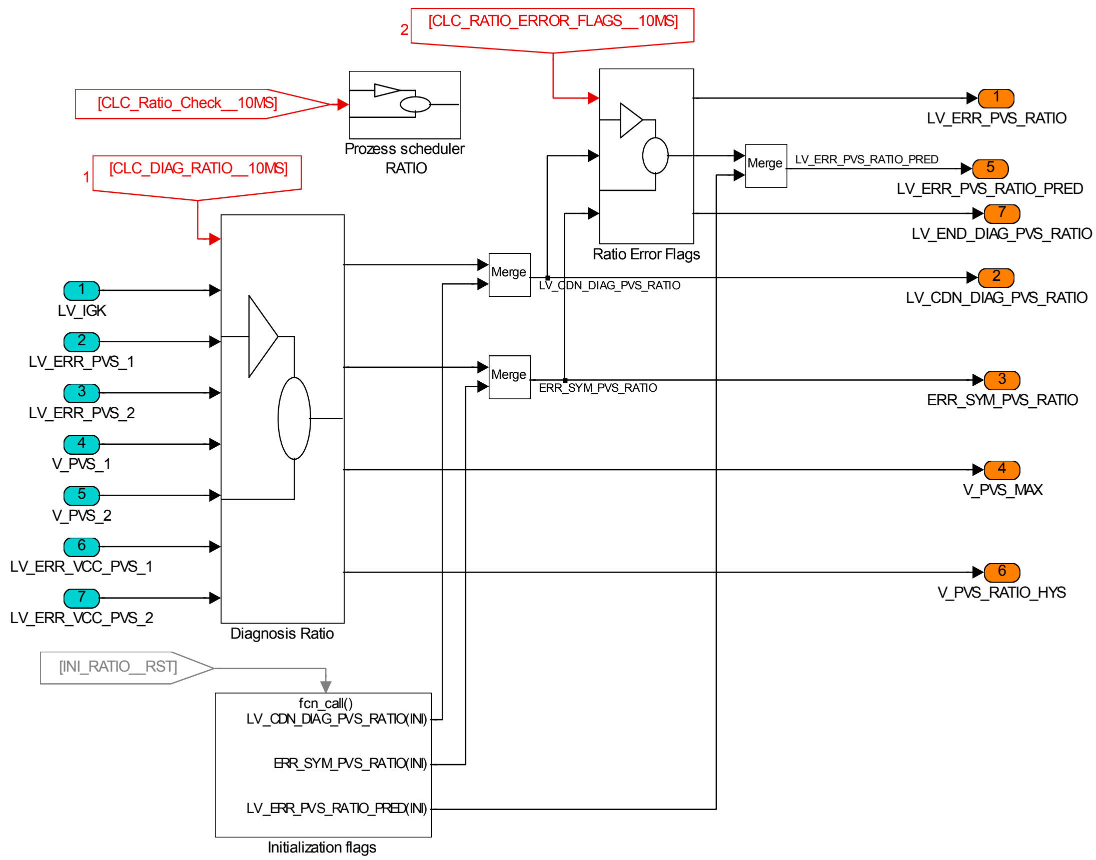

Figure 14: Ratio Check

Description:

The objective of the Ratio Check is to detect a relative deviation of the two PVS voltages.

If the voltages differ more than a permitted hysteresis, the bit LV_ERR_PVS_RATIO_PRED will be set during debouncing. The bit will be reset if:

- the setting conditions are not fulfilled anymore or
- the error is debounced, LV_ERR_PVS_RATIO = 1

In order to re-examine whether a range violation has caused a ratio error, the debounce time of the Ratio Check has to be higher than the debouncing time of the signal range checks (high / low).

Calculation order:

1. Diagnosis Ratio — on fcn-call CLC_DIAG_RATIO__10MS
2. Ratio Error Flags — on fcn-call CLC_RATIO_ERROR_FLAGS__10MS

A.45.2.1 Diagnosis Ratio

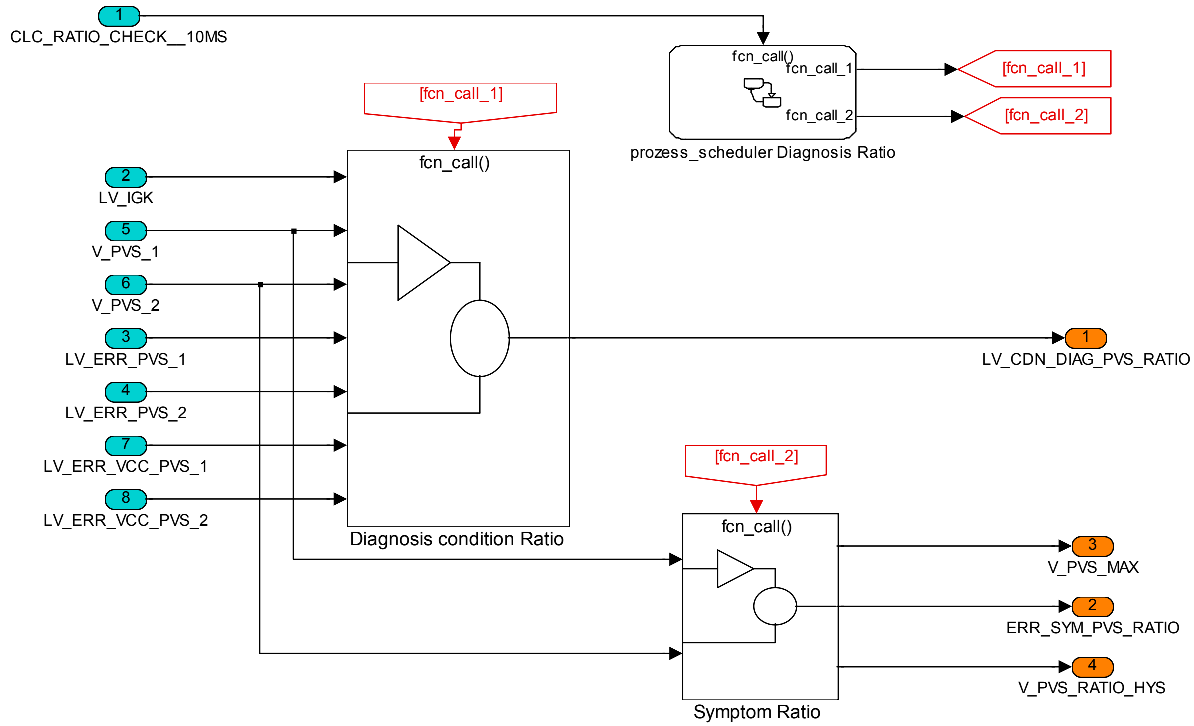

Figure 15: Diagnosis Ratio

Description:

Calculation order:

1. Diagnosis condition Ratio on fcn_call_1
2. Symptom Ratio on fcn_call_2

A.45.2.1.1 Diagnosis condition Ratio

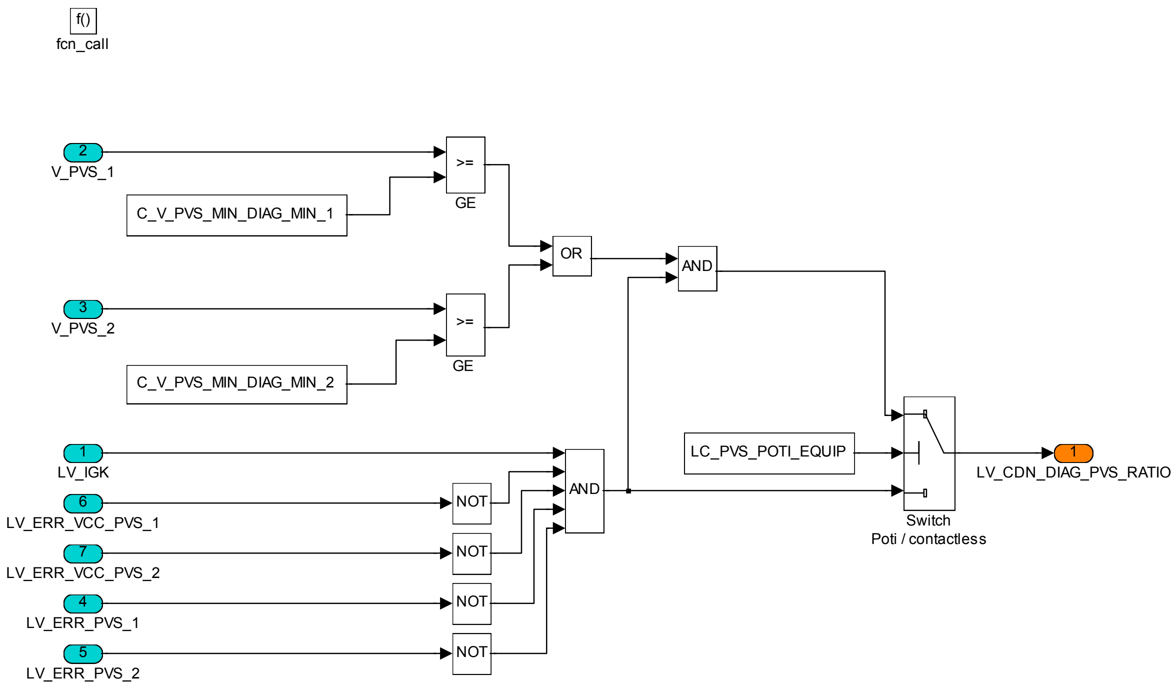

Figure 16: Diagnosis condition Ratio

Description:

As a consequence of different sensor system (potentiometer or contactless), different diagnosis conditions have to be taken into account.

For potentiometer systems (LC_PVS_POTI_EQUIP == 1)

At the lower reversing point a potentiometer may get disposits which lead to high contact resistances (high resistance). This may implicate that a sensor voltage drops.

Therefore the condition for Ratio Check is only fulfilled, if both channels are faultlessly and at least one sensor voltage V_PVS_x is greater or equal C_V_PVS_MIN_DIAG_MIN_x.

For contactless systems (LC_PVS_POTI_EQUIP == 0)

The condition is fulfilled if both channels are faultlessly.

Formula section:

```
IF    LV_IGK == 1                                         AND
      LV_ERR_PVS_1 == 0                                   AND
      LV_ERR_PVS_2 == 0                                   AND
      LV_ERR_VCC_PVS_1 == 0                               AND
      LV_ERR_VCC_PVS_2 == 0                               AND
THEN
      IF    LC_PVS_POTI_EQUIP == 0
      THEN  LV_CDN_DIAG_PVS_RATIO = 1
      ELSE
            IF    [   V_PVS_1 >= C_V_PVS_MIN_DIAG_MIN_1 or
                      V_PVS_2 >= C_V_PVS_MIN_DIAG_MIN_2   ]
            THEN  LV_CDN_DIAG_PVS_RATIO = 1
            ELSE  LV_CDN_DIAG_PVS_RATIO = 0
            ENDIF
      ENDIF
ELSE        LV_CDN_DIAG_PVS_RATIO = 0
ENDIF
```

A.45.2.1.2 Symptom Ratio

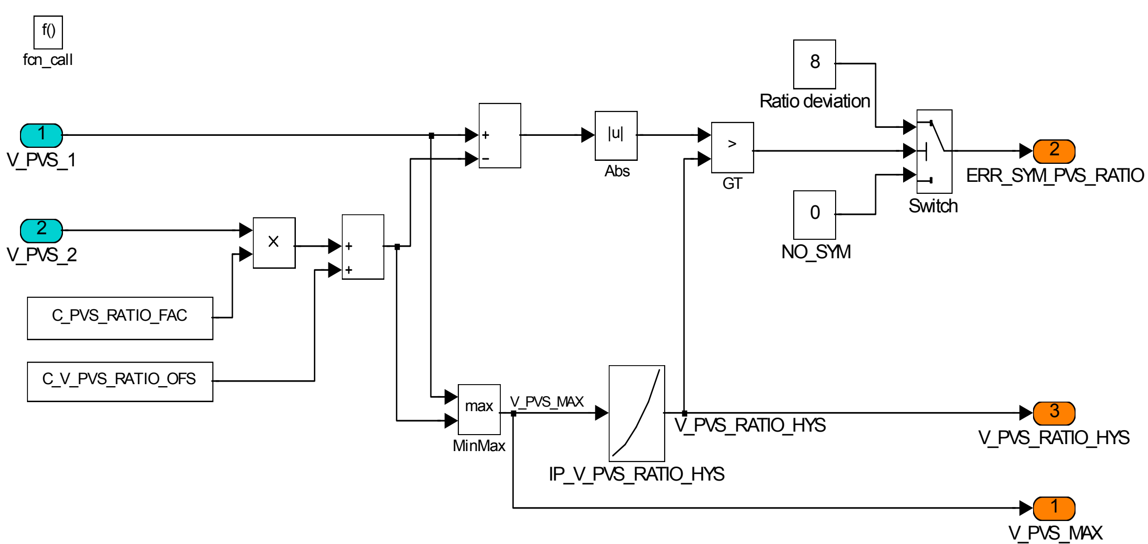

Figure 17: Symptom Ratio

Description:

At an error free system, the sensor voltages may not differ more than an allowed hysteresis depending on the actual gas pedal position. If the deviation of (V_PVS_1 and V_PVS_2 nominal) is higher than the allowed value the symptom “Ratio deviation” is detected.

To avoid that a Ratio Error will be debounced due to a high resistance at upper reversing point, the 1-dimensional map has to be calibrated in conformity with this effect.

Formula section:

V_PVS_MAX = **MAX (**V_PVS_1, (V_PVS_2 * C_PVS_RATIO_FAC +
C_V_PVS_RATIO_OFS)**)** {intermediate results are *0xFFFF* hex size}
{no overflow}

V_PVS_RATIO_HYS = IP_PVS_RATIO_HYS (V_PVS_MAX)

IF ABS **[** V_PVS_1- (V_PVS_2 * C_PVS_RATIO_FAC + C_V_PVS_RATIO_OFS)**]**
> V_PVS_RATIO_HYS {intermediate results are *0xFFFF* hex size}
{no overflow}

THEN ERR_SYM_PVS_RATIO = 8H (Ratio deviation)
//anti-bounce counter (PVS_RATIO) + C_ABC_INC_PVS_RATIO, only one increment per activated time condition, LV_ERR_RATIO = 1 after debounced

ELSE ERR_SYM_PVS_RATIO = 0H (NO_SYM)

Filtering:

APPLY filter on current symptom

IF filtering result available (after debounce)

THEN LV_ERR_PVS_RATIO = filtering result
LV_END_DIAG_PVS_RATIO = 1
Deliver the result to Error Management

A.45.2.2 Ratio Error Flags

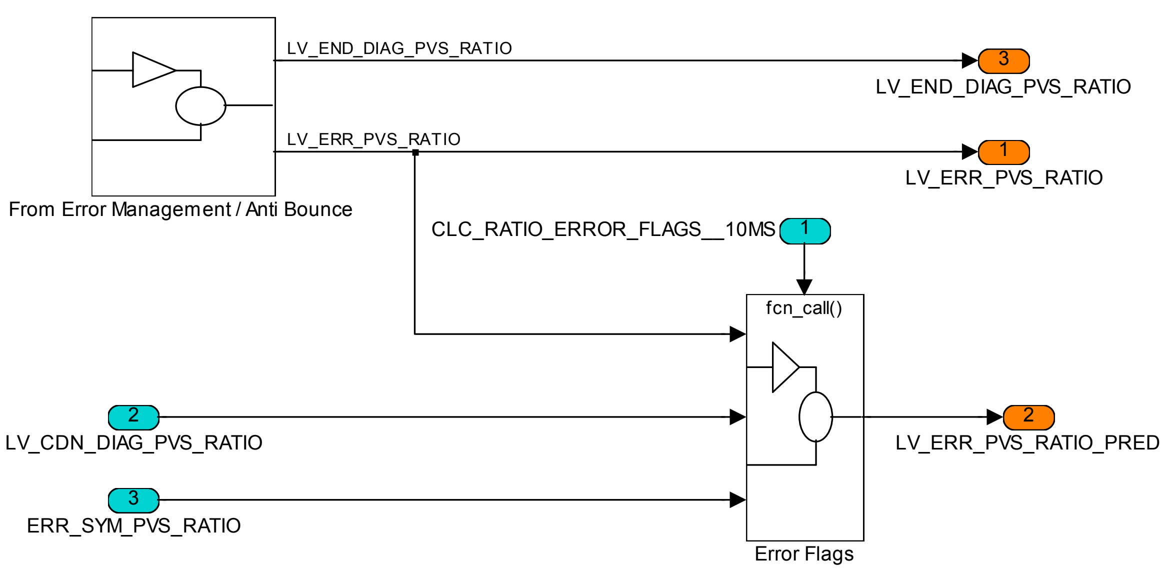

Figure 18: Ratio Error Flags

Description:

After debouncing the error flag LV_ERR_PVS_RATIO is set for the whole driving cycle

The end of diagnosis flag LV_END_DIAG_PVS_RATIO is set when,

- the diagnosis result is available
- the error is debounced

They are reset at initialization.

Error Flags

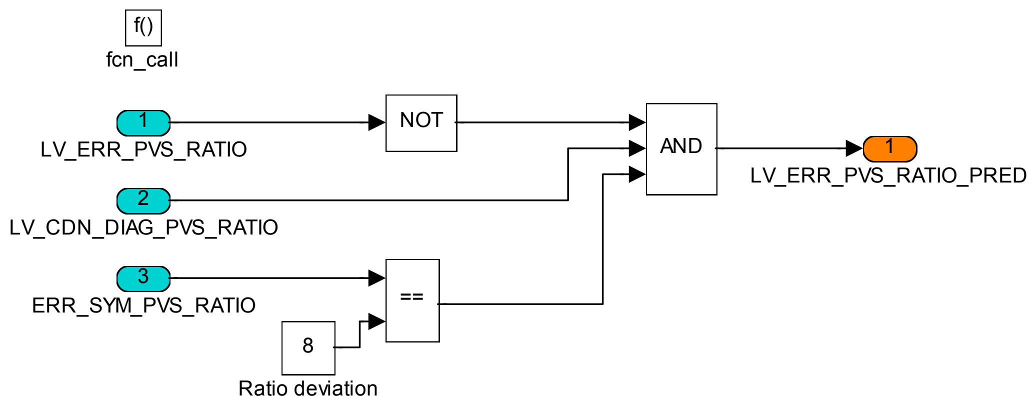

Figure 19: Error Flags

If the symptom is detected and the diagnosis is active (LV_CDN_DIAG_PVS_RATIO == 1), the bit LV_ERR_PVS_RATIO_PRED will be set during debouncing. The bit will be reset, if

- the setting conditions are not fulfilled anymore or
- after the error is debounced, LV_ERR_PVS_RATIO = 1

Formula section:

IF	LV_CDN_DIAG_PVS_RATIO == 1	**AND**
	ERR_SYM_PVS_RATIO == 8H	**AND**
	NOT (LV_ERR_PVS_RATIO==1)	
THEN	LV_ERR_PVS_RATIO_PRED = 1	
ELSE	LV_ERR_PVS_RATIO_PRED = 0	
ENDIF		

A.45.3 High Resistance Check

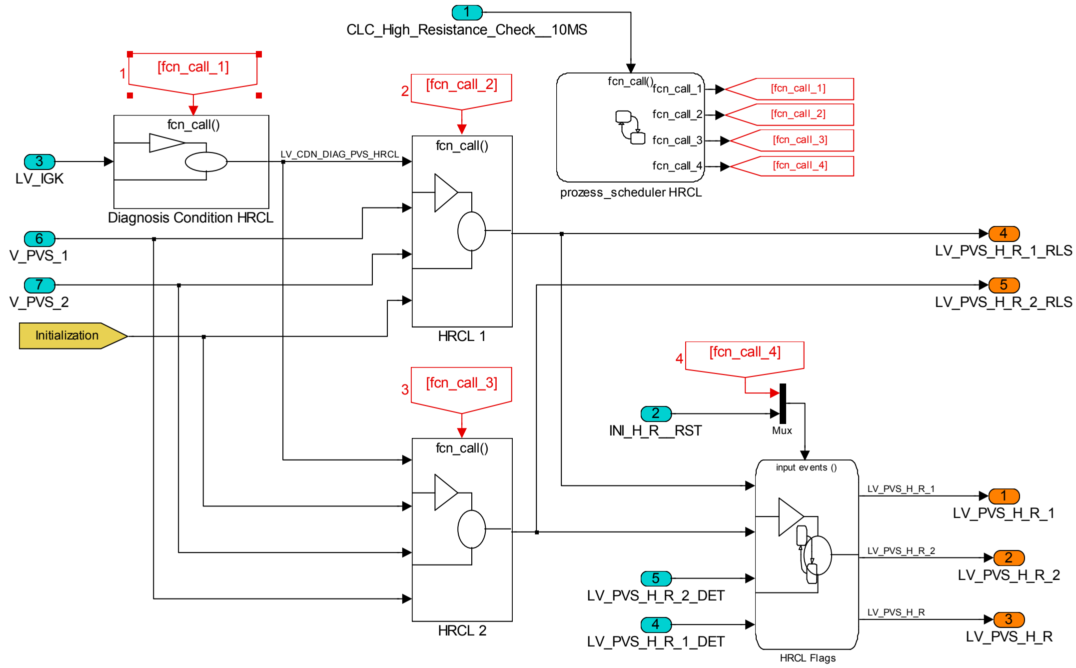

Figure 20: High Resistance Check

Description:

A potentiometer system may get high contact resistances at upper and lower reversing points as a result of settled abrasions.

The intend of this diagnosis function is to detect high resistance at the lower reversing points to differentiate a voltage drop due to

- high resistance or
- other faults (out of range or ratio)

to prevent an unintentional error recognition.

If a contactless PVS sensor is applied, this function can be disabled setting LC_PVS_POTI_EQUIP == 0

If a high resistance is recognized on channel x, the bit LV_PVS_H_R_x is set. The bit LV_PVS_H_R_x_RLS is set additionally to have an information in the next driving cycle whether a high resistance was detected in the previous (calculation of LV_PVS_H_R_x_DET at initialization on the basis of LV_PVS_H_R_x_RLS in last driving cycle).

If a high resistance is recognized on both channels, LV_PVS_H_R is set.

Calculation order:

1. Diagnosis Condition HRCL (High Resistance Check Low) on fcn_call_1
2. HRCL 1 (High Resistance Check Channel 1) on fcn_call_2
3. HRCL 2 (High Resistance Check Channel 2) on fcn_call_3
4. HRCL Flags on fcn_call_4

A.45.3.1 Diagnosis Condition HRCL (High Resistance Check Low)

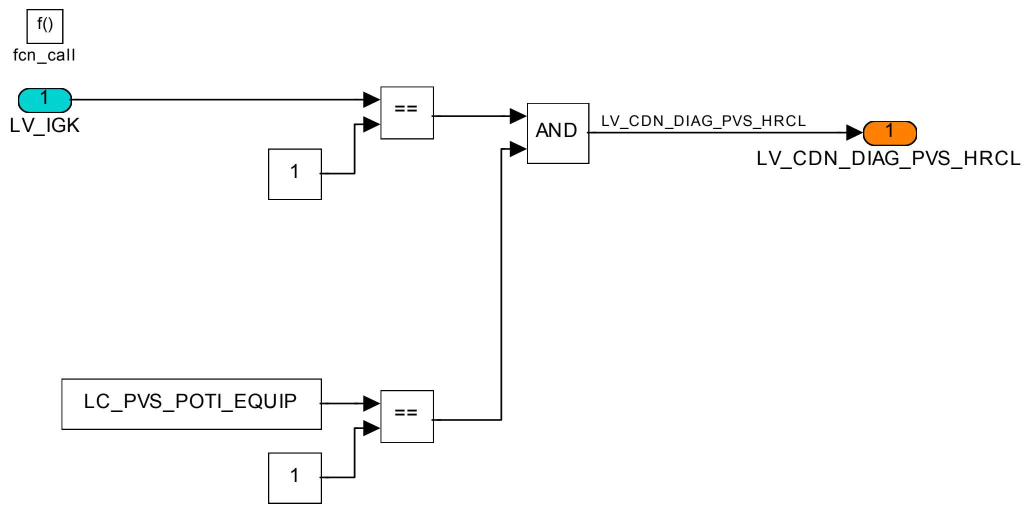

Figure 21: Diagnosis Condition HRCL

Description

The diagnosis condition is fulfilled if LV_IGK == 1 and the logical constant LC_PVS_POTI_EQUIP == 1. The High Resistance Check is performed **only** if the diagnosis condition is true (LV_CDN_DIAG_PVS_HRCL == 1).

Formula section:

IF LV_IGK == 1 **AND**
LC_PVS_POTI_EQUIP == 1
THEN LV_CDN_DIAG_PVS_HRCL = 1
ELSE LV_CDN_DIAG_PVS_HRCL = 0
ENDIF

A.45.3.2 HRCL 1 (High Resistance Check Channel 1)

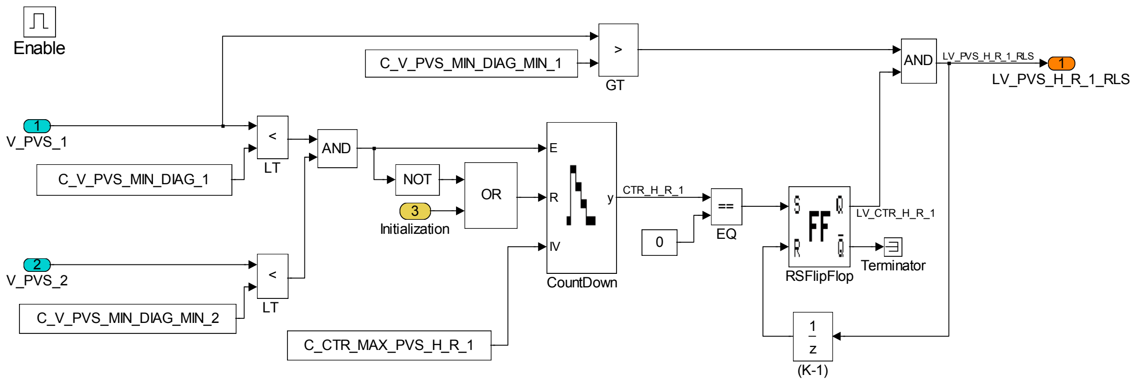

Figure 22: HRCL 1

Description:

If the signal voltage of channel 1 underspends the threshold C_V_PVS_MIN_DIAG_1 while channel 2 is underneath C_V_PVS_MIN_DIAG_MIN_2 the counter is decremented. If channel 1 exceeds the threshold C_V_PVS_MIN_DIAG_MIN_1 after counter has reached 0, a high contact resistance has been recognized (high resistance).

Formula section:

IF **NOT (**V_PVS_1 < C_V_PVS_MIN_DIAG_1 **and**
V_PVS_2 < C_V_PVS_MIN_DIAG_MIN_2**)** **OR**
Initialization
THEN CTR_H_R_1$_{(K)}$ = C_CTR_MAX_PVS_H_R_1
ELSE

IF CTR_H_R_1 $_{(K-1)}$ > 0
THEN CTR_H_R_1$_{(K)}$ = CTR_H_R_1 $_{(K-1)}$ – [update rate]
ENDIF

ENDIF

IF LV_PVS_H_R_1_RLS$_{(K-1)}$ == 0
THEN

IF CTR_H_R_1 $_{(K)}$ == 0
THEN LV_CTR_H_R_1 = 1
ENDIF

ELSE LV_CTR_H_R_1 = 0
ENDIF

IF LV_CTR_H_R_1 = =1 **AND**
V_PVS_1 > C_V_PVS_MIN_DIAG_MIN_1
THEN LV_PVS_H_R_1_RLS$_{(K)}$ = 1
ELSE LV_PVS_H_R_1_RLS$_{(K)}$ = 0
ENDIF

A.45.3.3 HRCL 2 (High Resistance Check Channel 2)

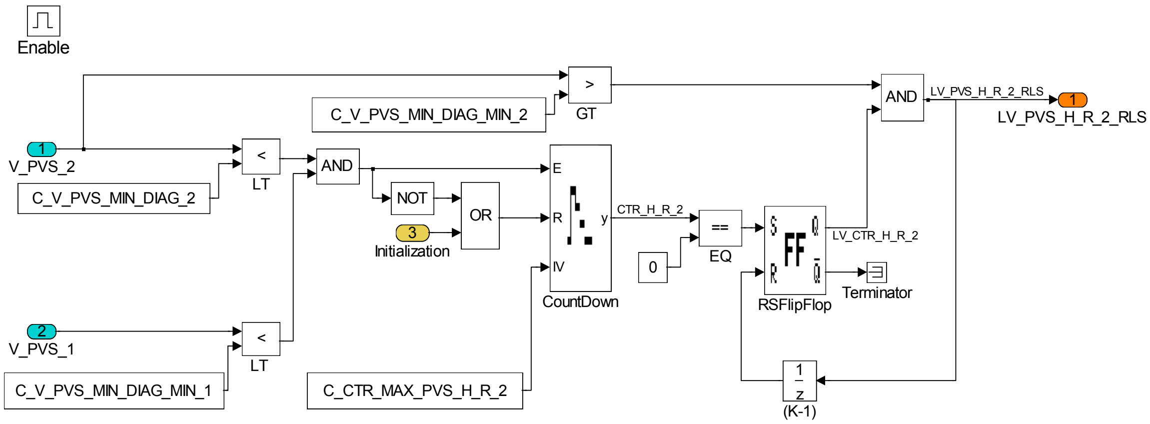

Figure 23: HRCL 2

Description:

If the signal voltage of channel 2 underspends the threshold C_V_PVS_MIN_DIAG_2 while channel 1 is underneath C_V_PVS_MIN_DIAG_MIN_1 the counter is decremented. If channel 2 exceeds the threshold C_V_PVS_MIN_DIAG_MIN_2 after counter has reached 0, a high contact resistance has been recognized (high resistance).

Formula section:

IF **NOT (**V_PVS_2 < C_V_PVS_MIN_DIAG_2 **and**
V_PVS_1 < C_V_PVS_MIN_DIAG_MIN_1**)** **OR**
Initialization
THEN CTR_H_R_2$_{(K)}$ = C_CTR_MAX_PVS_H_R_2
ELSE

IF CTR_H_R_2 $_{(K-1)}$ > 0
THEN CTR_H_R_2$_{(K)}$ = CTR_H_R_2 $_{(K-1)}$ – [update rate]
ENDIF

ENDIF

IF LV_PVS_H_R_2_RLS$_{(K-1)}$ == 0
THEN

IF CTR_H_R_2 $_{(K)}$ == 0
THEN LV_CTR_H_R_2 = 1
ENDIF

ELSE LV_CTR_H_R_2 = 0
ENDIF

IF LV_CTR_H_R_2 = =1 **AND**
V_PVS_2 > C_V_PVS_MIN_DIAG_MIN_2
THEN LV_PVS_H_R_2_RLS$_{(K)}$ = 1
ELSE LV_PVS_H_R_2_RLS$_{(K)}$ = 0
ENDIF

A.45.3.4 HRCL Flags

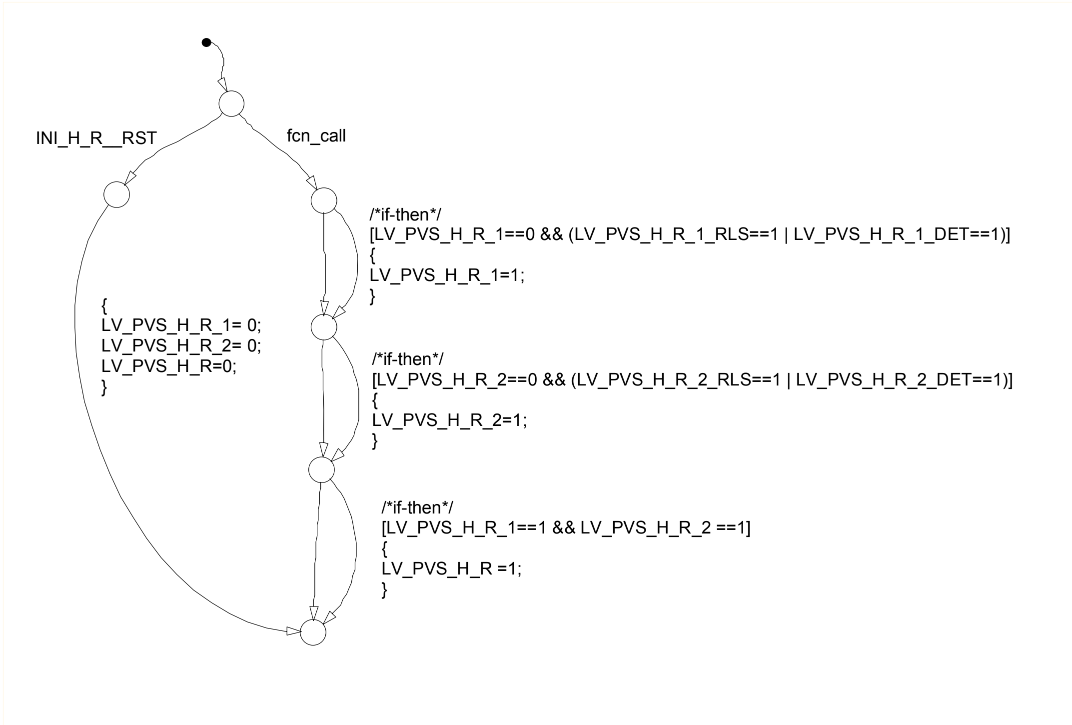

Figure 24: HRCL Flags

Description:

At Initialization the bits LV_PVS_H_R_1, LV_PVS_H_R_2, LV_PVS_H_R are set = 0.

Regular calculation is done as shown above. If a high contact resistance is recognized actually (LV_PVS_H_R_x_RLS == 1) or has been detected in the last driving cycle (LV_PVS_H_R_x_DET ==1), the bit LV_PVS_H_R_x is set respectively. If high resistance is recognized on **both** channels, LV_PVS_H_R is set additionally.

A.45.4 Move Check

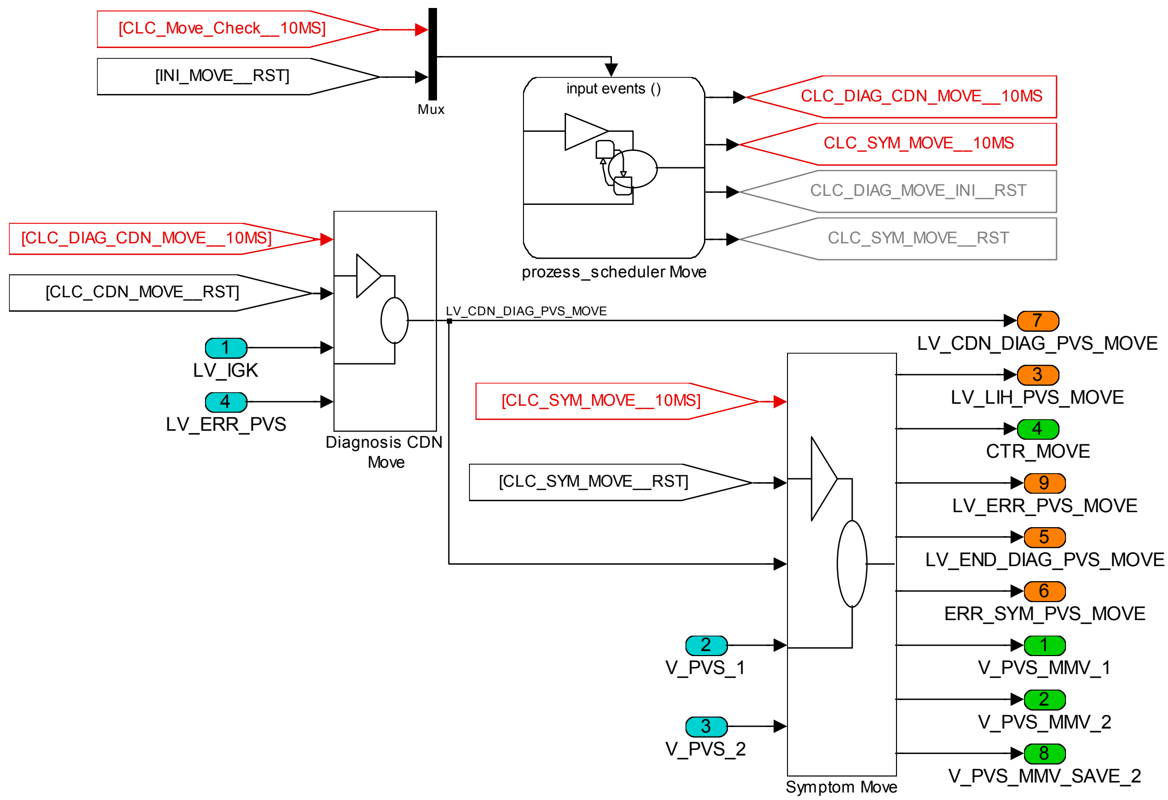

Figure 25: Move Check

Description:

The Move Check is based on the fact that both pedal value sensors are located on one shaft. A change of one channel is tied to the other one. If a motion of only one channel is detected LV_LIH_PVS_MOVE is set temporary. A counter is incremented at every recognition. If the counter reaches the maximum value LV_ERR_PVS_MOVE and LV_LIH_PVS_MOVE are set to 1 permanently.

Calculation order:

1. Diagnosis CDN Move — on fcn-call CLC_DIAG_CDN_MOVE__10MS
2. Symptom Move — on fcn-call CLC_SYM_MOVE__10MS

Initialization order:

1. Diagnosis CDN Move — on fcn-call CLC_CDN_MOVE__RST
2. Symptom Move — on fcn-call CLC_SYM_MOVE__RST

A.45.4.1 Diagnosis CDN Move

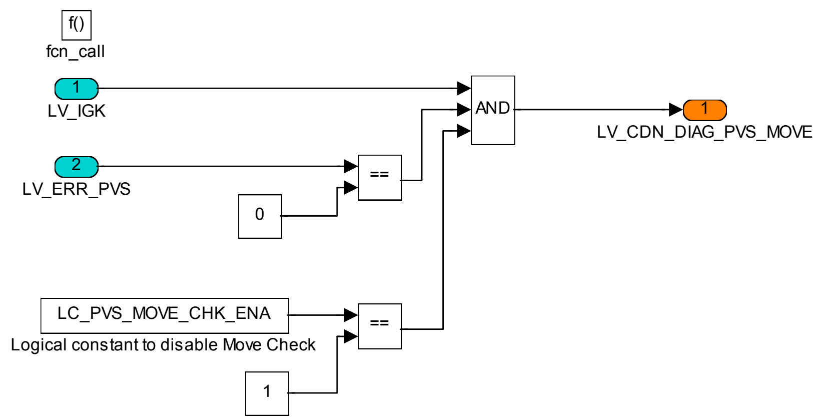

Figure 26: Diagnosis Condition Move

Description:

Regular calculation:

The Move Check is **only** executed (LV_CDN_DIAG_PVS_MOVE = 1) if, LV_IGK = 1, no PVS error is already debounced LV_ERR_PVS = 0 and LC_PVS_MOVE_CHK_ENA = 1.

At Initialization LV_CDN_DIAG_PVS_MOVE is set = 0.

A.45.4.2 Symptom Move

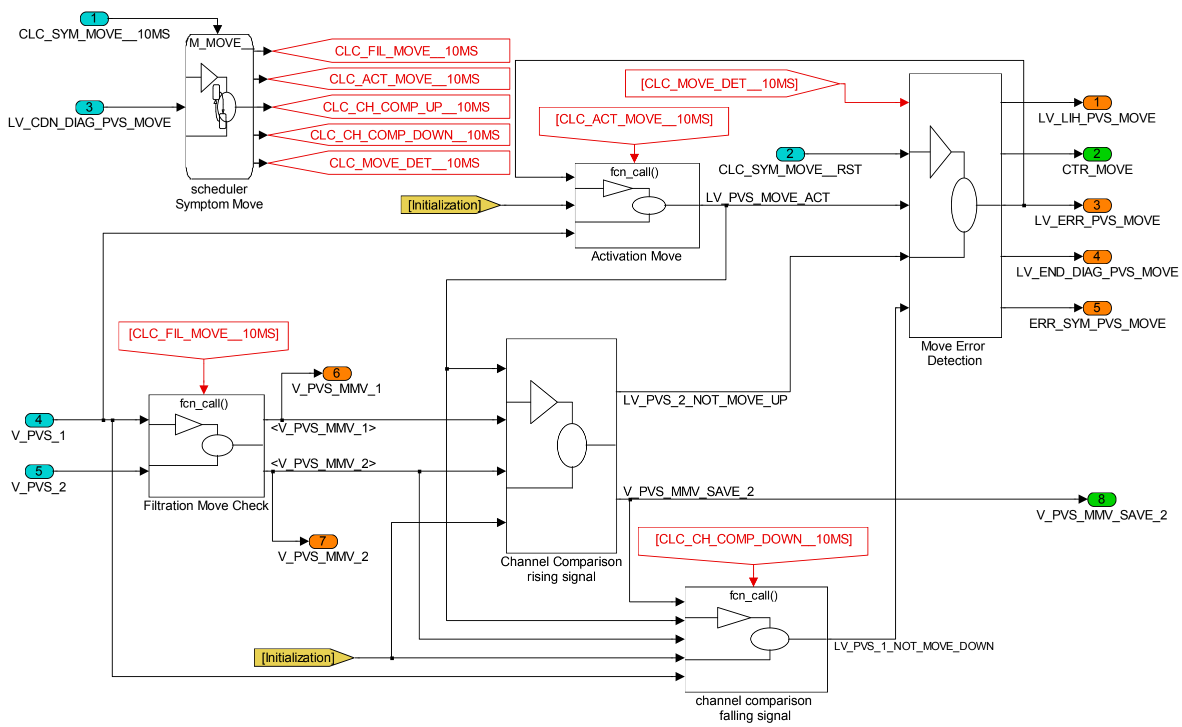

Figure 27: Symptom Move

Description:

Calculation order:

1. Filtration Move Check — on fcn-call CLC_FIL_MOVE__10MS
2. Activation Move — on fcn-call CLC_ACT_MOVE__10MS
3. Channel comparison rising signal — on fcn-call CLC_CH_COMP_UP__10MS
4. Channel comparison falling signal — on fcn-call CLC_CH_COMP_DOWN__10MS
5. Move Error Detection — on fcn_call CLC_MOVE_DET__10MS

A.45.4.2.1 Filtration Move Check

Description:

In order to consider of dynamic behavior, the sensor voltages have to be filtered.

$$V\_PVS\_MMV\_1_{(K)} = V\_PVS\_MMV\_1_{(K-1)} * (1 - C\_CRLC\_PVS\_1\_MOVE) + V\_PVS\_1 * C\_CRLC\_PVS\_1\_MOVE$$

$$V\_PVS\_MMV\_2_{(K)} = V\_PVS\_MMV\_2_{(K-1)} * (1 - C\_CRLC\_PVS\_2\_MOVE) + V\_PVS\_2 * C\_CRLC\_PVS\_2\_MOVE$$

A.45.4.2.2 Activation Move

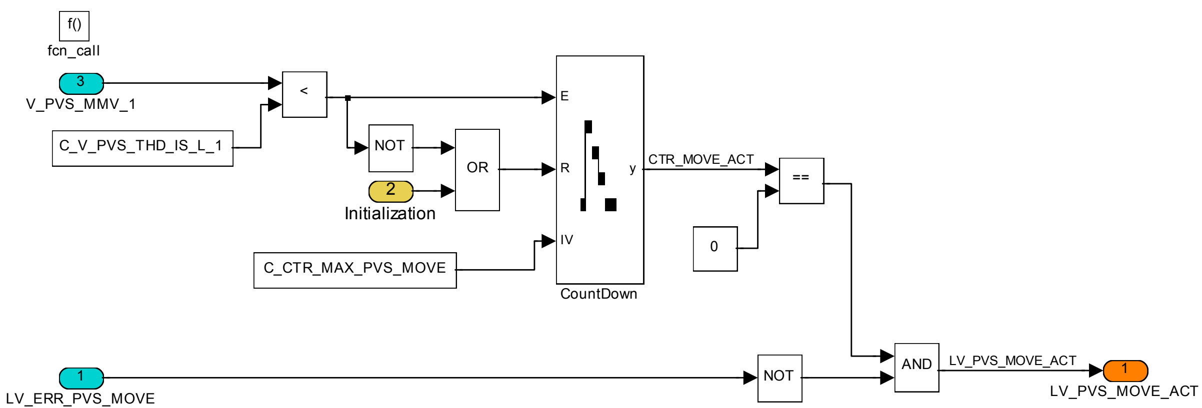

Figure 28: Activation Move

Description:

For activation or re-activation of the diagnosis, the filtered voltage of channel 1 has to be recognized underneath the idle speed threshold C_V_PVS_THD_IS_L_1 for C_CTR_MAX_PVS_MOVE and <u>no</u> Move Error is already debounced.

Formula section:

IF **NOT** (V_PVS_MMV_1 < C_V_PVS_THD_IS_L_1) **OR**
Initialization
THEN CTR_MOVE_ACT$_{(K)}$ = C_CTR_MAX_PVS_MOVE
ELSE

  IF CTR_MOVE_ACT$_{(K-1)}$ > 0
  THEN CTR_MOVE_ACT$_{(K)}$ = CTR_MOVE_ACT$_{(K-1)}$ – [update rate]
  ENDIF

ENDIF

IF CTR_MOVE_ACT$_{(K)}$ == 0 **AND**
NOT (LV_ERR_PVS_MOVE==1)
THEN LV_PVS_MOVE_ACT = 1
ELSE LV_PVS_MOVE_ACT = 0
ENDIF

A.45.4.2.3 Channel comparison rising signal

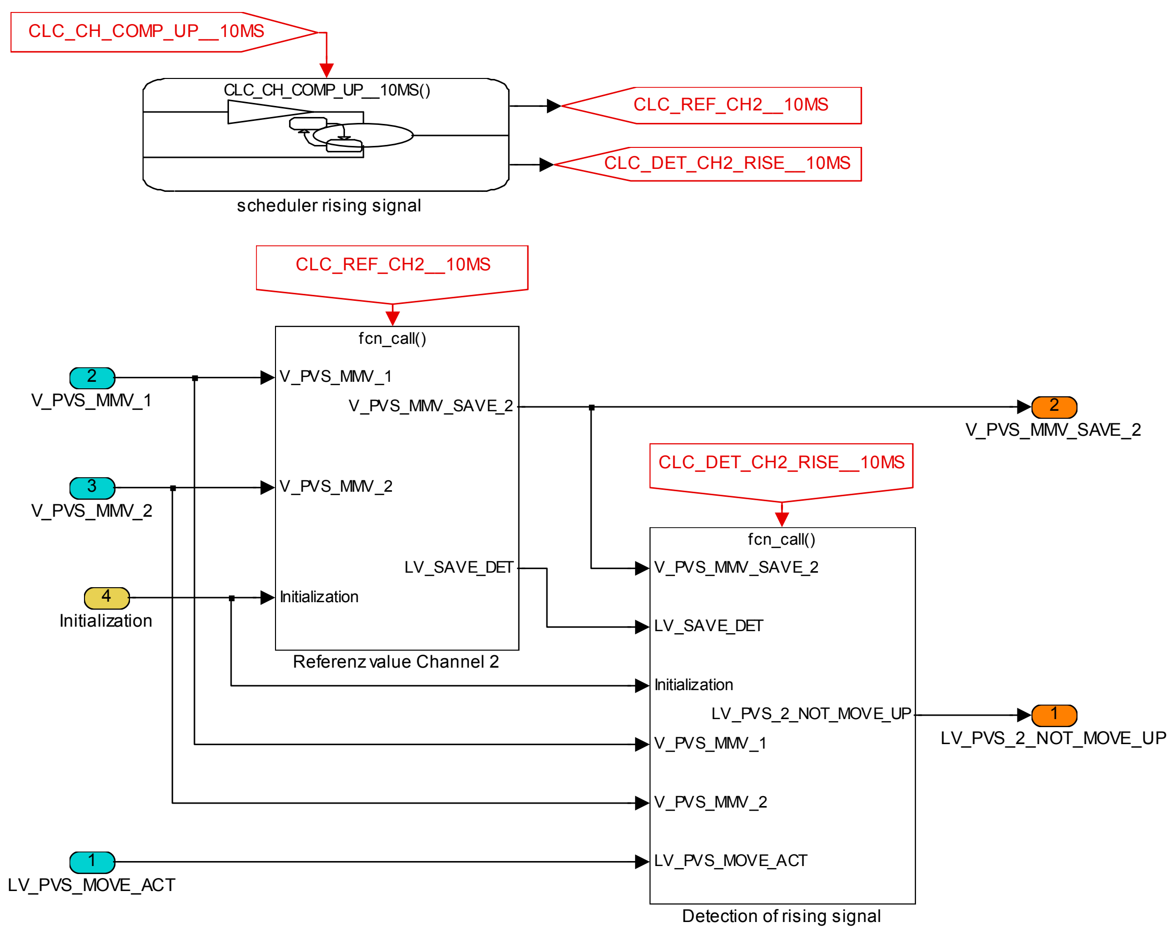

Figure 29: Channel comparison rising signal

Description:

Calculation order:

1. Referenz value Channel 2 on fcn-call CLC_REF_CH2__10MS
2. Detection of rising signal on fcn-call CLC_DET_CH2_RISE__10MS

Referenz value Channel 2:

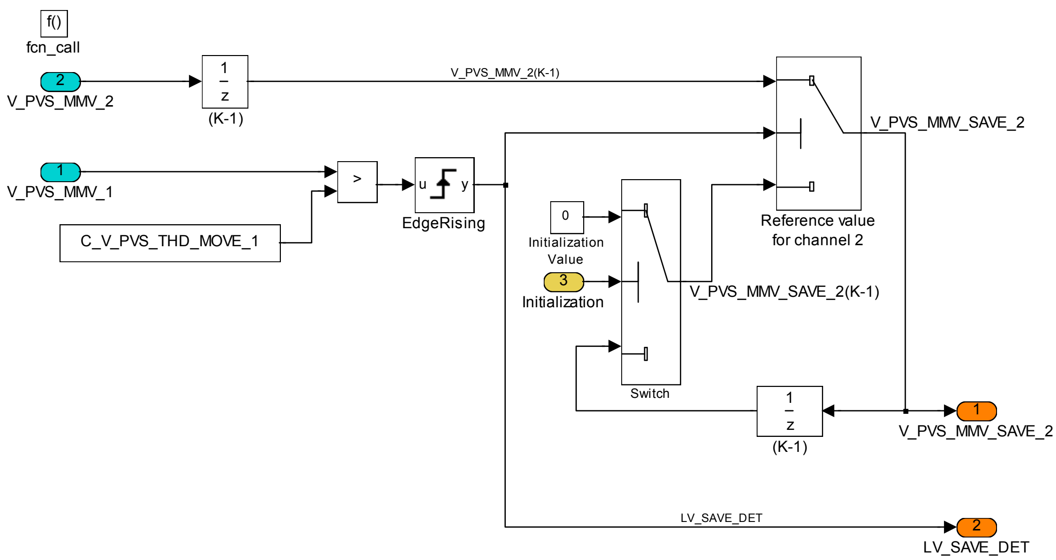

Figure 30: Referenz value channel 2

If PVS-Channel 1 has moved from idle speed position and the filtered voltage V_PVS_MMV_1 exceeds C_V_PVS_THD_MOVE_1, the previous filtered voltage $V\_PVS\_MMV\_2_{(k-1)}$ of channel 2 is saved to V_PVS_MMV_SAVE_2.

Formula section:

At Initialization $V\_PVS\_MMV\_SAVE\_2_{(K-1)} = 0$; V_PVS_MMV_2 = 0

IF $(V\_PVS\_MMV\_1_{(K-1)} <= C\_V\_PVS\_THD\_MOVE\_1)$ **AND**
$(V\_PVS\_MMV\_1_{(K)} > C\_V\_PVS\_THD\_MOVE\_1)$

THEN $V\_PVS\_MMV\_SAVE\_2_{(K)} = V\_PVS\_MMV\_2_{(k-1)}$
LV_SAVE_DET = 1

ELSE $V\_PVS\_MMV\_SAVE\_2_{(K)} = V\_PVS\_MMV\_SAVE\_2_{(K-1)}$
LV_SAVE_DET = 0

ENDIF

Detection of rising signal:

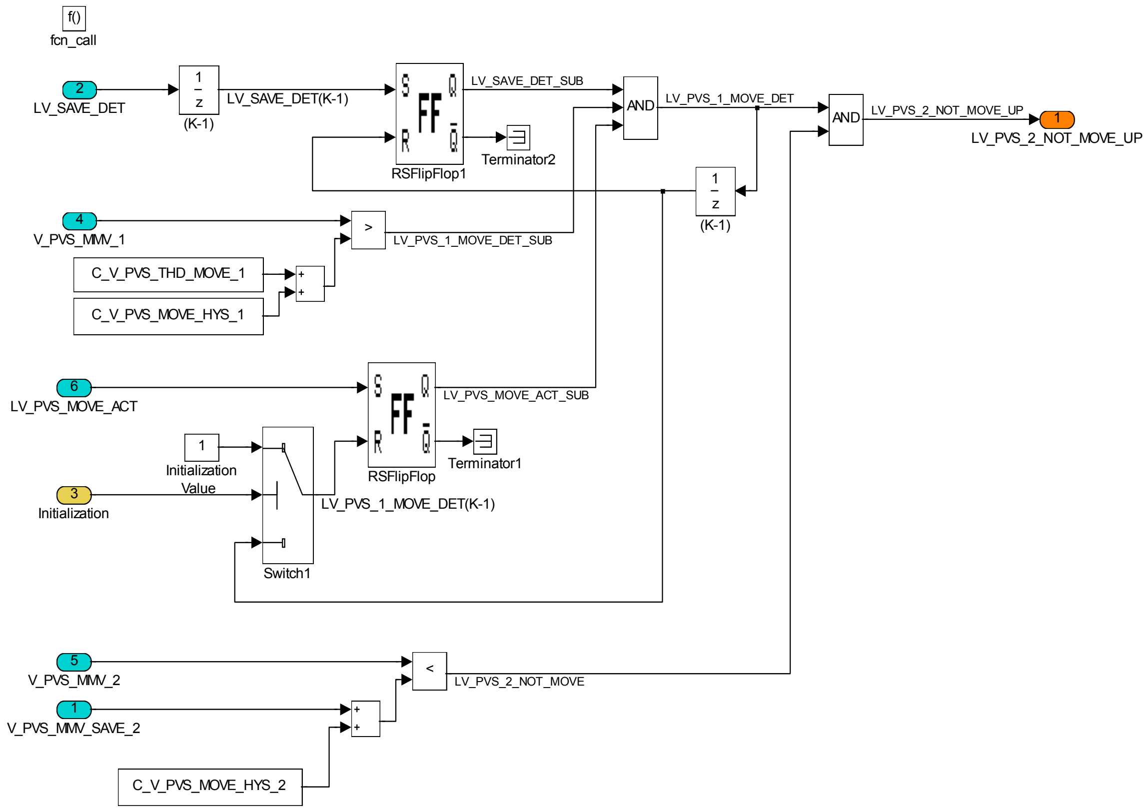

Figure 31: Detection of rising signal

If PVS-Channel 1 exceeds C_V_PVS_THD_MOVE_1 + C_V_PVS_MOVE_HYS_1, Channel 2 must have exceed V_PVS_MMV_SAVE_2 + C_V_PVS_MOVE_HYS_2, too (LV_PVS_2_NOT_MOVE_UP=0). Otherwize a fault would be detected (LV_PVS_2_NOT_MOVE_UP = 1).

The comparison is only executed or executed again if a referenz value was saved before (LV_SAVE_DET_INTER = 1) and the activation condition has been fullfiled (LV_PVS_MOVE_ACT_SUB = 1).

Formula section:

At Initialization LV_PVS_1_MOVE_DET$_{(K-1)}$ = 0

IF LV_PVS_1_MOVE_DET$_{(K-1)}$ == 0
THEN
  IF LV_PVS_MOVE_ACT == 1
  THEN LV_PVS_MOVE_ACT_SUB = 1
  ENDIF
  IF LV_SAVE_DET$_{(K-1)}$ == 1
  THEN LV_SAVE_DET_SUB = 1
  ENDIF
ELSE LV_PVS_MOVE_ACT_SUB = 0
  LV_SAVE_DET_SUB = 0
ENDIF

IF	LV_SAVE_DET_SUB == 1	**AND**
	LV_PVS_MOVE_ACT_SUB == 1	**AND**
	(V_PVS_MMV_1 > C_V_PVS_THD_MOVE_1 + C_V_PVS_MOVE_HYS_1)	
THEN	LV_PVS_1_MOVE_DET = 1	
ELSE	LV_PVS_1_MOVE_DET = 0	
IF	LV_PVS_1_MOVE_DET = 1	**AND**
	V_PVS_MMV_2 < V_PVS_MMV_SAVE_2 + C_V_PVS_MOVE_HYS_2	
THEN	LV_PVS_2_NOT_MOVE_UP = 1	
ELSE	LV_PVS_2_NOT_MOVE_UP = 0	
ENDIF		

A.45.4.2.4 Channel comparison falling signal

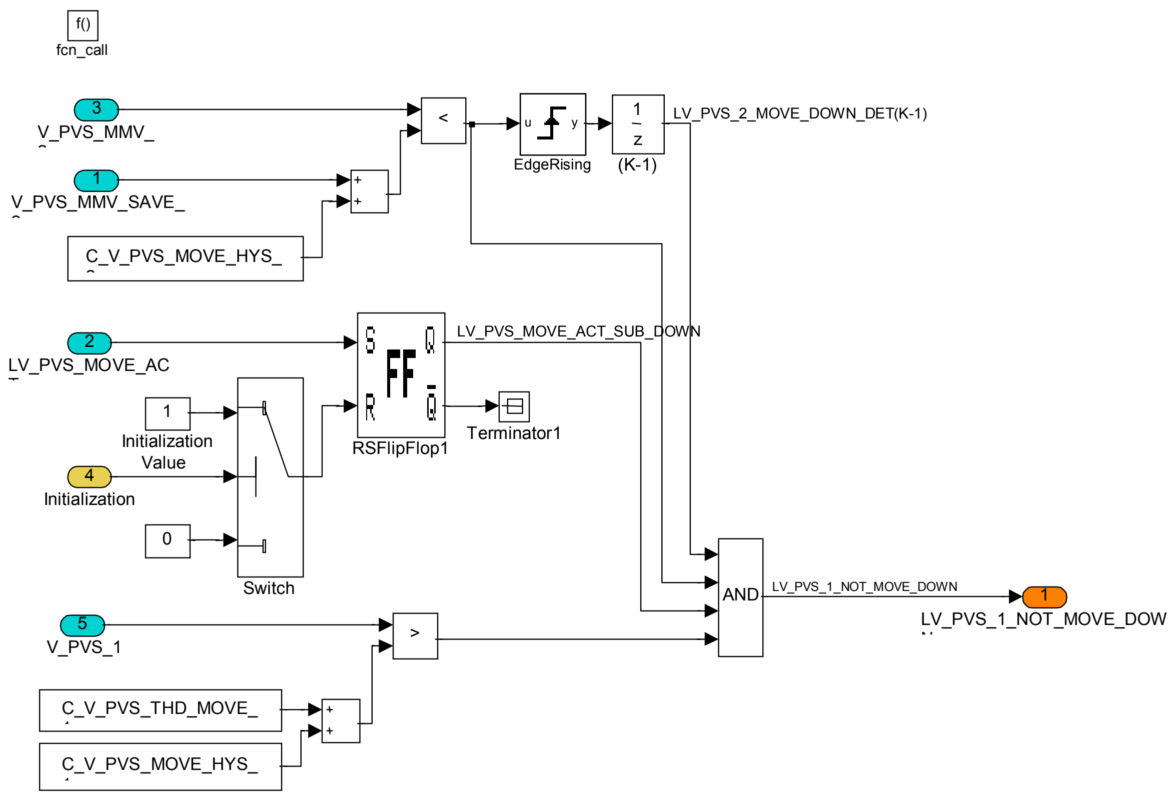

Figure 32: Channel comparison falling signal

Description:

If the filtered channel 2 signal falls below the previously saved value V_PVS_MMV_SAVE_2 (Channel comparison rising signal) + C_V_PVS_MOVE_HYS_2 again, channel 1 must be underneeth C_V_PVS_THD_MOVE_1 + C_V_PVS_MOVE_HYS_1, too. Otherwize a fault would be detected (LV_PVS_1_NOT_MOVE_DOWN$_{(K)}$ = 1).

The comparison is only executed if the activation condition has been fullfiled once (LV_PVS_MOVE_ACT).

Formula section:

At Initialization LV_PVS_MOVE_ACT_SUB_DOWN = 0

```
IF          Initialization
THEN        LV_PVS_MOVE_ACT_SUB_DOWN = 0
ELSE
    IF      LV_PVS_MOVE_ACT == 1
    THEN    LV_PVS_MOVE_ACT_SUB_DOWN = 1
    ENDIF
ENDIF
```

IF V_PVS_MMV_2$_{(K-1)}$ > V_PVS_MMV_SAVE_2 + C_V_PVS_MOVE_HYS_2 **AND**
V_PVS_MMV_2$_{(K)}$ < V_PVS_MMV_SAVE_2 + C_V_PVS_MOVE_HYS_2
THEN LV_PVS_2_MOVE_DOWN_DET = 1
ELSE LV_PVS_2_MOVE_DOWN_DET = 0
ENDIF

IF LV_PVS_2_MOVE_DOWN_DET$_{(K-1)}$ == 1 **AND**
V_PVS_MMV_2$_{(K)}$ < V_PVS_MMV_SAVE_2 + C_V_PVS_MOVE_HYS_2 **AND**
LV_PVS_MOVE_ACT_SUB_DOWN == 1 **AND**
V_PVS_1 > C_V_PVS_THD_MOVE_1 + C_V_PVS_MOVE_HYS_1
THEN LV_PVS_1_NOT_MOVE_DOWN = 1
ELSE LV_PVS_1_NOT_MOVE_DOWN = 0
ENDIF

A.45.4.2.5 Move Error Detection

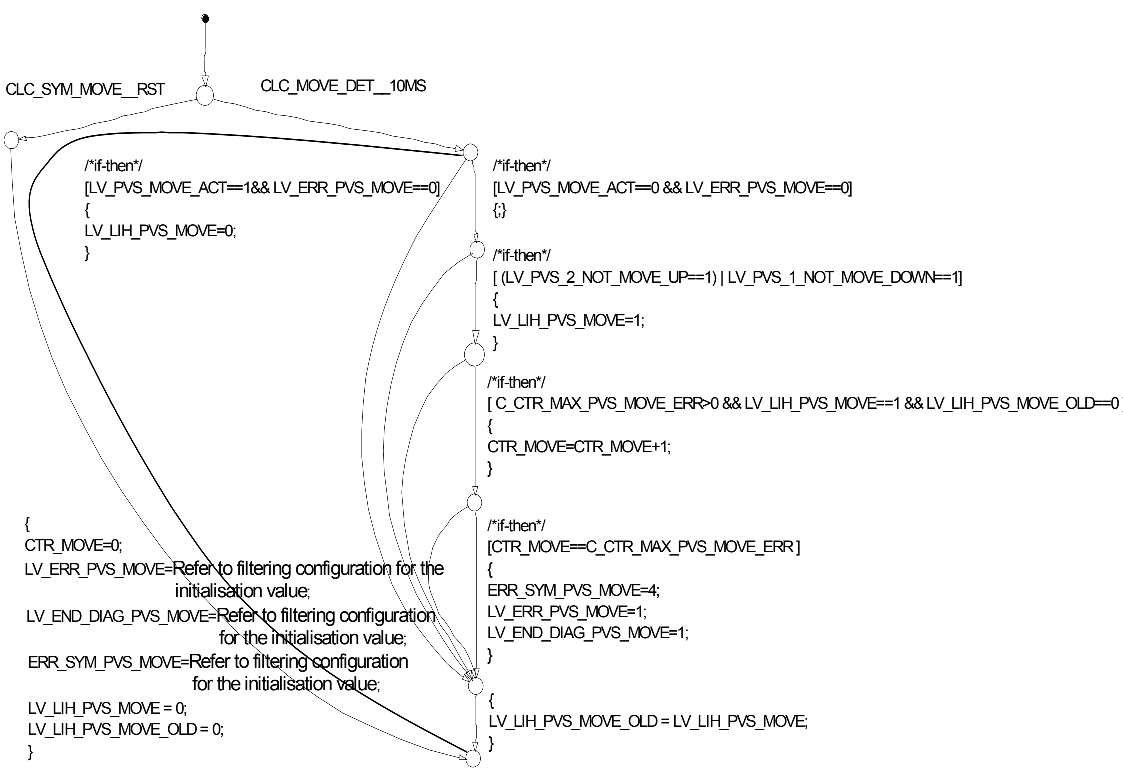

Figure 33: Move Error Detection

Description:

At Initialization following settings are done (on fcn-call CLC_SYM_MOVE__RST):
- CTR_MOVE = 0
- LV_ERR_PVS_MOVE = 0
- LV_END_DIAG_PVS_MOVE = 0
- ERR_SYM_PVS_MOVE = 0H (NO_SYM)
- LV_LIH_PVS_MOVE = 0
- LV_LIH_PVS_MOVE$_{(K-1)}$ = 0

During regular operation (on fcn-call CLC_MOVE_DET__10MS), calculation is done as shown below. If the symptom is detected the first time, LV_LIH_PVS_MOVE will be set and a counter is incremented by 1.
The bit is reset if LV_PVS_MOVE_ACT = 1 and LV_ERR_PVS_MOVE is not already debounced. After setting LV_LIH_PVS_MOVE several times,
- LV_ERR_PVS_MOVE =1
- ERR_SYM_PVS_MOVE = 4H (MOVE_MAX)
- LV_END_DIAG_PVS_MOVE = 1 are set,
- The flag LV_LIH_PVS_MOVE will be kept set.

The debouncing of LV_ERR_PVS_MOVE can be disabled setting C_CTR_MAX_PVS_MOVE_ERR = 0.

A.45.5 Plausibility Check Brake /PVS

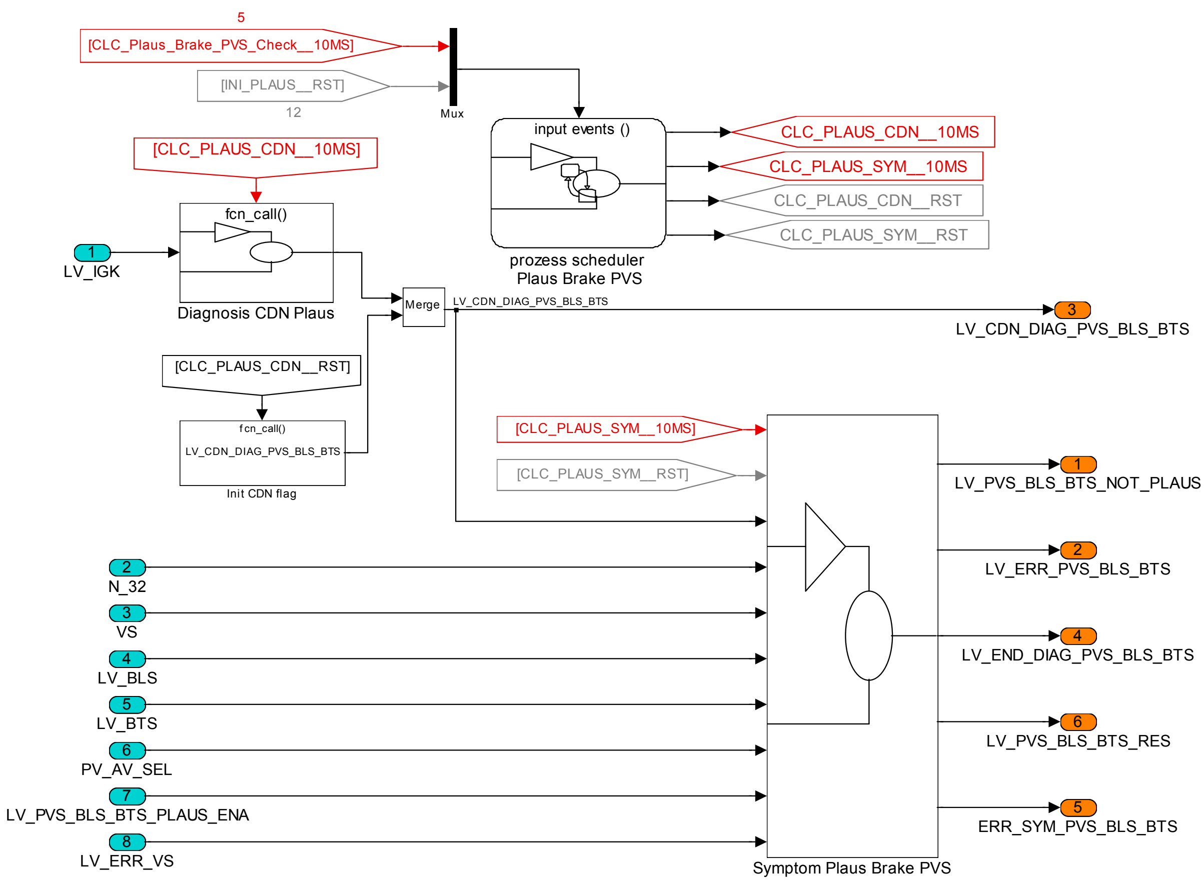

Figure 34: Plausibility Check Brake / PVS

Description:

The intend of this diagnosis function is to detect an undesired gas pedal activation against the drivers demand e.g. due to a mechanically clamping pedal.

If this state is detected, the bit LV_PVS_BLS_BTS_NOT_PLAUS will be set to decrease engine torque. After setting the bit C_CTR_MAX_PVS_BLS_BTS_PLAUS_ERR times, the bit LV_ERR_PVS_BLS_BTS will be set.

The debouncing of the bit LV_ERR_PVS_BLS_BTS can be disabled setting C_CTR_MAX_PVS_BLS_BTS_PLAUS_ERR = 0.

This function can be disabled setting LC_PVS_BLS_BTS_PLAUS_ENA = 0.

Calculation order:

1. Diagnosis CDN Plaus — on fcn-call CLC_PLAUS_CDN__10MS
2. Symptom Plaus Brake / PVS — on fcn-call CLC_PLAUS_SYM__10MS

Initialization order:

1. Diagnosis CDN Plaus — on fcn-call CLC_PLAUS_CDN__RST
2. Symptom Plaus Brake / PVS — on fcn-call CLC_PLAUS_SYM__RST

A.45.5.1 Diagnosis CDN Plaus

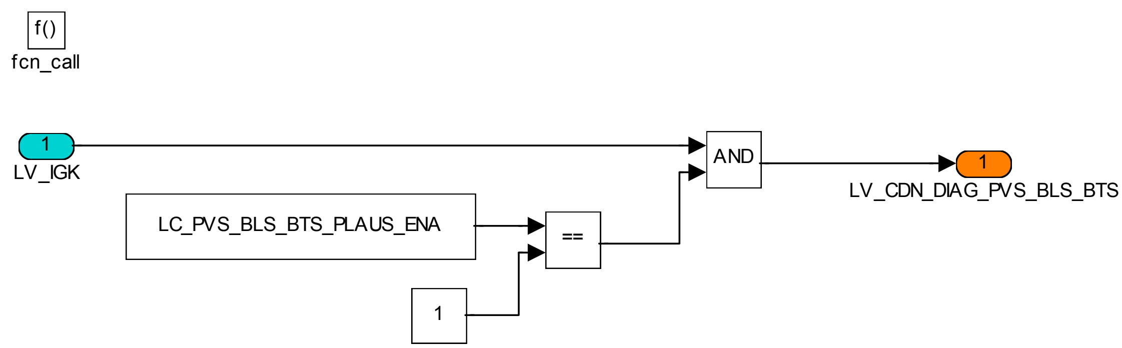

Figure 35: Diagnosis CDN Plaus

Description:

The Plausibility Check is **only** executed if LV_IGK == 1 and the enable bit LC_PVS_BLS_BTS_PLAUS_ENA ==1.

A.45.5.2 Symptom Plaus Brake / PVS

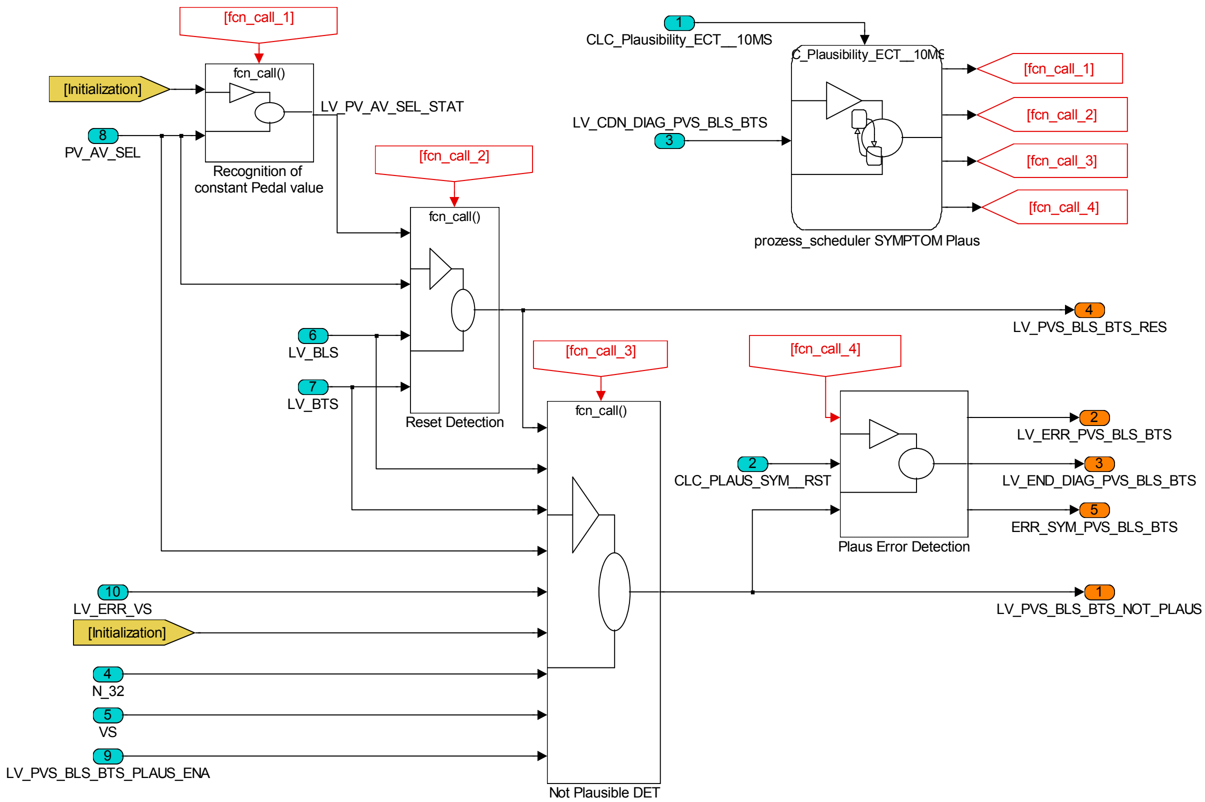

Figure 36: Symptom Plaus Brake / PVS

Description:

Calculation order:

1. Recognition of constant pedal value on fcn_call_1
2. Reset detection on fcn_call_2
3. Not Plausible DET on fcn_call_3
4. Plaus Error Detection on fcn_call_4

A.45.5.2.1 Recognition of constant pedal value

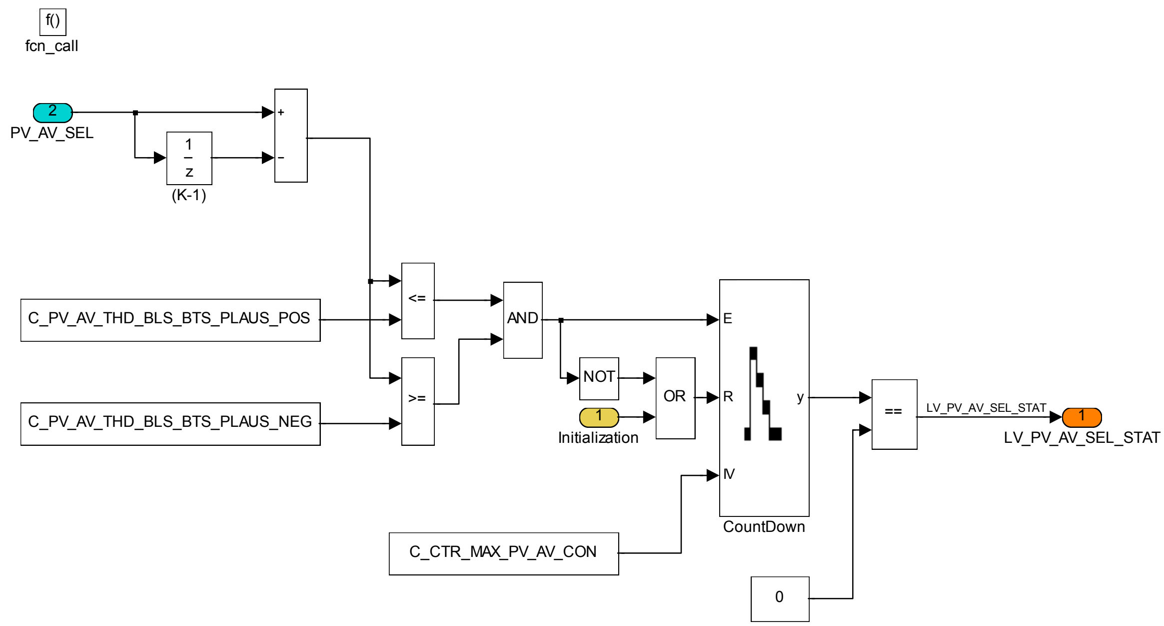

Figure 37: Recognition of constant pedal value

Description:

The gas pedal is recognized as constant LV_PV_AV_SEL_STAT = 1, if the pedal value does not differ more than a permitted value up- and downwards for the time C_CTR_MAX_PV_AV_CON.

Formula section:

IF NOT{(PV_AV_SEL$_{(K)}$ – PV_AV_SEL$_{(K-1)}$ <= C_PV_AV_THD_BLS_BTS_PLAUS_POS) **and**
(PV_AV_SEL$_{(K)}$ – PV_AV_SEL$_{(K-1)}$ >= C_PV_AV_THD_BLS_BTS_PLAUS_NEG)**}** **OR**
Initialization
THEN CTR_PVS_STAT$_{(K)}$ = C_CTR_MAX_PV_AV_CON
ELSE
IF CTR_PVS_STAT$_{(K-1)}$ > 0
THEN CTR_PVS_STAT$_{(K)}$ = CTR_PVS_STAT$_{(K-1)}$ – [update rate]
ENDIF
ENDIF
IF CTR_PVS_STAT$_{(K)}$ == 0
THEN LV_PV_AV_SEL_STAT = 1
ELSE LV_PV_AV_SEL_STAT = 0
ENDIF

A.45.5.2.2 Reset detection

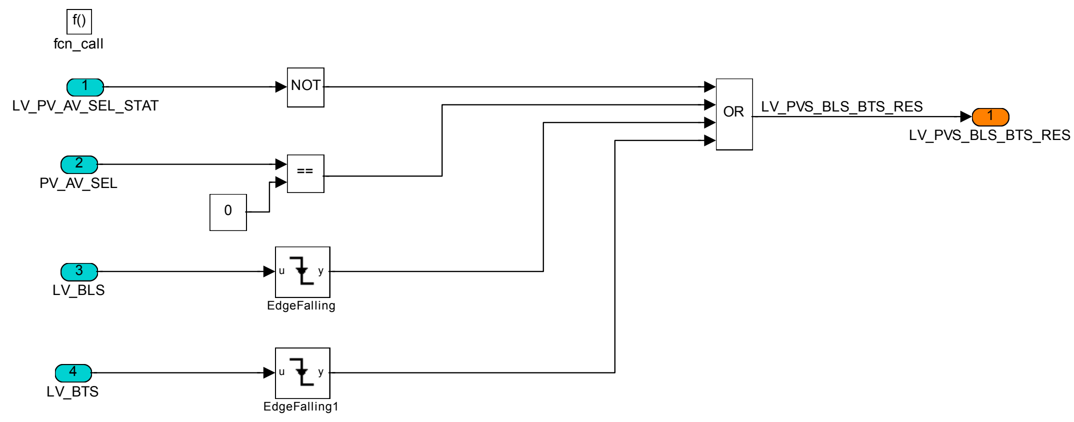

Figure 38: Reset detection

Description:

A recognized implausibility of brake and gas pedal is being reset (LV_PVS_BLS_BTS_RES = 1), if

- the gas pedal is recognized as not constant (LV_PV_AV_SEL_STAT = 0), or
- the actual pedal value PV_AV_SEL = 0 (driver intend is idle), or
- the brake recognition changes to inactive LV_BLS = 1 → 0 or
- the brake recognition changes to inactive LV_BTS = 1 → 0

Formula section:

IF	LV_PV_AV_SEL_STAT == 0	**OR**
	PV_AV_SEL == 0	**OR**
	{LV_BLS$_{(K-1)}$ == 1 **and** LV_BLS$_{(K)}$ == 0**}**	**OR**
	{LV_BTS$_{(K-1)}$ == 1 **and** LV_BTS$_{(K)}$ == 0**}**	
THEN	LV_PVS_BLS_BTS_RES = 1	
ELSE	LV_PVS_BLS_BTS_RES = 0	
ENDIF		

A.45.5.2.3 Not Plausible DET

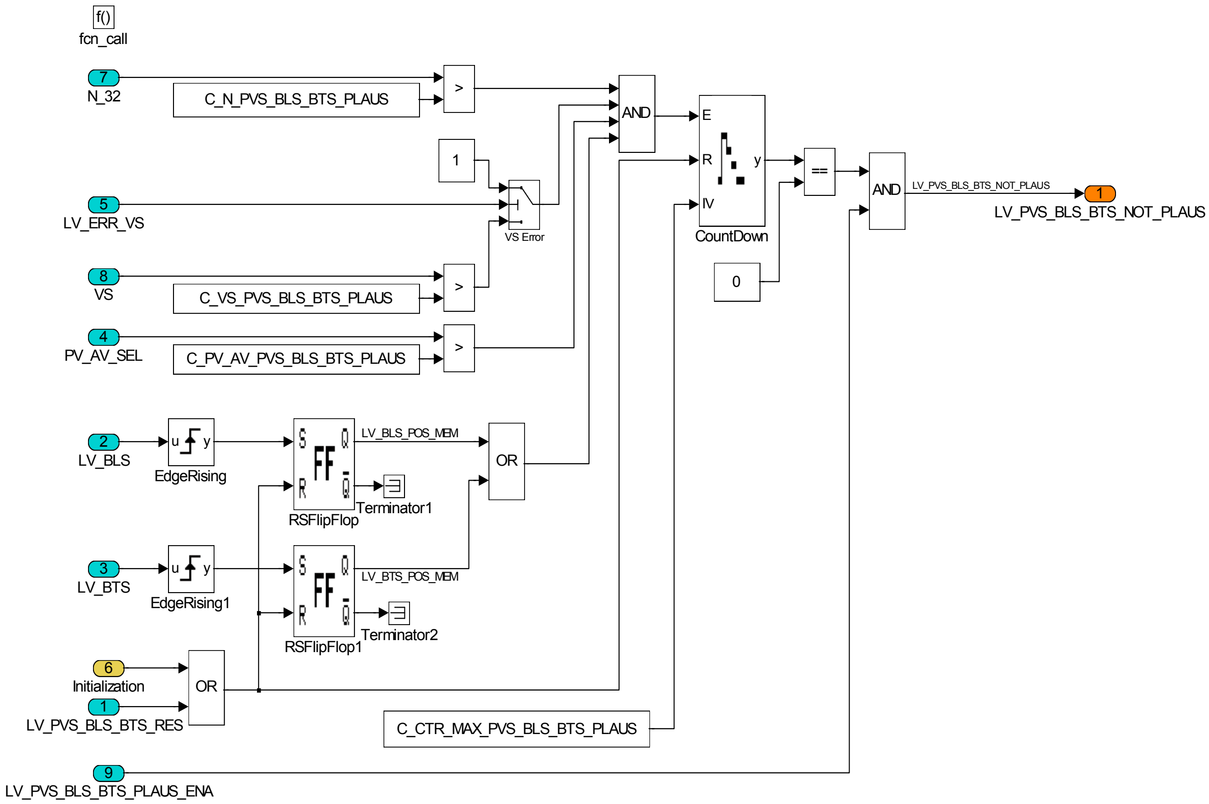

Figure 39: Not Plausible Detection

Description:

An undesired gas pedal activation against the driver demand (e.g. clamping pedal) is detected by using the break information LV_BLS / LV_BTS.

If an activation of the brake is detected **after** the gas pedal has already been activated and

N_32 is above C_N_PVS_BLS_BTS_PLAUS and

VS is above C_VS_PVS_BLS_BTS_PLAUS (not if VS signal is faulty LV_ERR_VS==1)and

PV_AV_SEL is above C_PV_AV_PVS_BLS_BTS_PLAUS

a counter will be decremented. If the counter reaches 0 after the time C_CTR_MAX_PVS_BLS_BTS_PLAUS and LV_PVS_BLS_BTS_PLAUS_ENA = 1, an implausible state of brake and gas pedal will be detected (LV_PVS_BLS_BTS_NOT_PLAUS = 1).

Formula section:

IF	LV_PVS_BLS_BTS_RES ==1 **OR** Initialization	
THEN	CTR_NOT_PLAUS$_{(K)}$ = C_CTR_MAX_PVS_BLS_BTS_PLAUS LV_BLS_POS_MEM = 0 LV_BTS_POS_MEM = 0	
ENDIF		
IF	**(**LV_BLS$_{(K-1)}$ == 0 **and** LV_BLS$_{(K)}$ == 1**)**	
THEN	LV_BLS_POS_MEM = 1	
IF	**(**LV_BTS$_{(K-1)}$ == 0 **and** LV_BTS$_{(K)}$ == 1**)**	
THEN	LV_BTS_POS_MEM = 1	
IF	**(**LV_BLS_POS_MEM ==1 **or** LV_BTS_POS_MEM == 1**)**	**AND**
	N_32 > C_N_PVS_BLS_BTS_PLAUS	**AND**
	{ [VS > C_VS_PVS_BLS_BTS_PLAUS and LV_ERR_VS==0**]** or LV_ERR_VS==1**] }**	**AND**
	PV_AV_SEL > C_PV_AV_PVS_BLS_BTS_PLAUS	**AND**
	CTR_NOT_PLAUS$_{(K)}$ > 0	
THEN	CTR_NOT_PLAUS$_{(K)}$ = CTR_NOT_PLAUS$_{(K-1)}$ – [update rate]	
ENDIF		
IF	CTR_NOT_PLAUS$_{(K)}$ == 0	**AND**
	LV_PVS_BLS_BTS_PLAUS_ENA ==1	
THEN	LV_PVS_BLS_BTS_NOT_PLAUS = 1	
ELSE	LV_PVS_BLS_BTS_NOT_PLAUS = 0	
ENDIF		

A.45.5.2.4 Plaus Error Detection

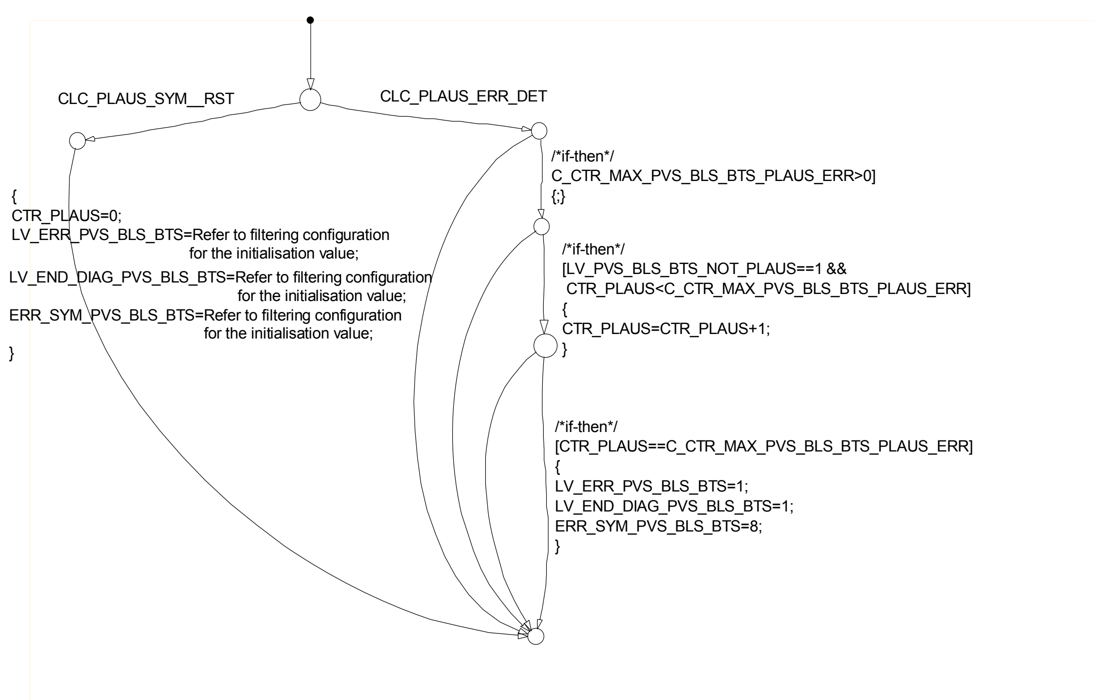

Figure 40: Plaus Error Detection

Description:

At Initialization following settings are done:

- CTR_PLAUS = C_CTR_MAX_PVS_BLS_BTS_PLAUS_ERR
- LV_ERR_PVS_BLS_BTS = 0
- LV_END_DIAG_PVS_BLS_BTS = 0
- ERR_SYM_PVS_BLS_BTS = 0H (NO_SYM).

During normal operation calculation is done as shown below. Each detection the counter is increment by one. After C_CTR_MAX_PVS_BLS_BTS_PLAUS_ERR times,

- LV_ERR_PVS_BLS_BTS = 1
- ERR_SYM_PVS_BLS_BTS = 8H (PLAUS_MAX)
- LV_END_DIAG_PVS_BLS_BTS = 1.

The debouncing of LV_ERR_PVS_BLS_BTS can be disabled setting C_CTR_MAX_PVS_BLS_BTS_PLAUS_ERR = 0.

A.45.6 Common Error Flags

Description:

At Initialization following settings are done:

- LV_ACT_PVS_LIH = 0
- LV_ERR_PVS = 0
- LV_ERR_PVS_PRED = 0

During normal operation calculation is done as shown below.

While a ratio error or out of range error is predicted (LV_ERR_PVS_ORNG_PRED or LV_ERR_PVS_RATIO_PRED), the common flag LV_ERR_PVS_PRED will be set.

If an error is debounced by ratio check or out of range check or supply voltage diagnosis (LV_ERR_PVS_RATIO or LV_ERR_PVS_x or LV_ERR_VCC_PVS_x), the flag LV_ACT_PVS_LIH for PVS limp home coordination will be set.

If LV_ACT_PVS_LIH is set or an error is debounced by the Move Check (LV_ERR_PVS_MOVE), the common error flag LV_ERR_PVS will be set.

LV_PVS_H_R_1_SAVE	V/O/S	0...1H	0...1	1	-
PVS 1 high resistance information stored in EEPROM					
LV_PVS_H_R_2_SAVE	V/O/S	0...1H	0...1	1	-
PVS 2 high resistance information stored in EEPROM					
LV_PVS_BLS_BTS_PLAUS_ENA	O/V	0...1H	0...1	1	-
Plausibility check PVS/BLS/BTS enable					

Input data:

LV_PVS_H_R_1_RLS	LV_PVS_H_R_2_RLS	LV_IGK	

General information:

The application incidences describe the anti-bounce mechanism and error treatment of the module ‘Diagnosis of pedal value sensor’.

Since it is a two-channel system, the letter ‘x’ is for channel 1 or channel 2, in order to simplify the description.

All conditions flags and error symptoms mentioned in “Error treatment” are only used to describe the configuration of the anti bounce mechanism. They have no functional use here and are therefore not enumerate as inputs.

Application conditions:

Activation: LV_IGK = 1

Deactivation: otherwise

Initialisation: **IF** LV_PVS_H_R_x_SAVE == 1

{High resistance information was stored in non volatile memory}

THEN LV_PVS_H_R_x_DET = 1

{High resistance of channel X was detected in last driving cycle}

LV_PVS_H_R_x_SAVE = 0

{Error information deleted in non volatile memory}

ELSE LV_PVS_H_R_x_DET = 0

ENDIF

LV_PVS_BLS_BTS_PLAUS_ENA = 0

Recurrence: *every 10 ms*

General Description:

The Application Incidences are executed at function call CLC_PVS_DIAG_APPL_INC__10MS and initialized at CLC_PVS_DIAG_APPL_INC__RST.

A.46.1 Initialization conditions

Description:

The application condition for the initialization of e.g. the error bits, the anti-bounce counters and other variables of the modules:

- Diagnosis of Pedal Value Sensor
- Diagnosis of Pedal Value Sensor (Application Incidences) are commonly defined here.

The error bits, anti-bounce-counters and other variables or bits are initialized at reset, at transition from LV_IGK = 0 to 1 and at clearing of the failure memory.

A.46.2 Error treatment

High resistance check:

IF LV_PVS_H_R_x_RLS == 1

{High resistance of channel x detected in current driving cycle}

THEN LV_PVS_H_R_x_SAVE = 1

{High resistance information is stored in the non volatile memory at the end of the driving cycle to be used as information in next driving cycle }

ENDIF

A.46.3 General application incidences

Enable of PVS/BLS/BTS plausibility check:

An ESP-intervention can activate the Brakelight- or Braketest-switch. In this case the check must be disabled by setting the LV_PVS_BLS_BTS_PLAUS_ENA = 0 during ESP or ASR intervention.

IF LC_PVS_BLS_ESP_CHK_ENA = 1 (ESP is able to disable the BLS)

THEN LV_PVS_BLS_BTS_PLAUS_ENA = 0

ELSE LV_PVS_BLS_BTS_PLAUS_ENA = 1

FUNCTION DESCRIPTION:

General information:

The purpose of this diagnosis function is to detect all major failures, which can happen between ECU output and ignition coils.

This function is adaptable on every engine but the type of spark plugs and ignition coils must be taken into account.

The diagnosis is performed separate for each ignition coil. The feedback signal from the specific ignition coil (following the firing order) is evaluated by the microcontroller.

A.47.1 Short circuit to plus: SCP

Description:

In some Hard ware driver the ignition powerstage is not protected against short circuit to ground and they are not able to withstand an overload current for a long time so it is necessary to switch off the powerstage by software.

For ignition coil actuator tests purpose, the SCP diagnostic function has to be enabled, activated and monitored upon the tests requests

The same case and comments (see before) apply here also.

The Ignition output diagnosis function detects short circuit to battery and sets LV_IGC_SCP[x]. It cuts off the ignition driver after a delay time which is defined in the IGBT Protection function. In the ignition diagnosis function the error is debounced.

Application conditions:

1. **Normal Engine Running mode**

Initialisation: all output variables of the function have to be set to 0 at reset ECU *(except saved error flag)*

Recurrence: if NC_IGN_DIAG_TYP =ATM46 every segment

if NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Activation: **If** LV_INH_IGC[x] = 0

And LV_ERR_CAM = 0

And N_32 > C_N_32_MIN_SCP_IGC_DIAG

And IGN_MPL_NR = 0

And if NC_IGN_DIAG_TYP =ATIC29
Failure information for current cylinder
from ATIC29 is valid

endif

Then LV_CDN_DIAG_IGC_SCP[x] = 1

Else LV_CDN_DIAG_IGC_SCP[x] = 0

Endif

2. **Ignition Actuator Tests mode**

Initialisation: all output variables of the function have to be set to 0 at reset ECU *(except saved error flag)*

Recurrence: **if** NC_IGN_DIAG_TYP =ATM46
On transition of IGC_x_EXT_ADJ from 1 to 0
for reading the SCP failure status

Activation: For x = 0 to NC_CYL_NR – 1

If LV_INH_IGC[x] = 0
And LV_ERR_CAM = 0

[And LV_ES = 1 // *Actuator tests activation*

And LV_IGK = 1

And LV_IGC_x_EXT_ADJ = 1]

Then LV_CDN_DIAG_IGC_SCP[x] = 1
Else LV_CDN_DIAG_IGC_SCP[x] = 0
Endif
EndFor

Formula section:

If LV_CDN_DIAG_IGC_SCP =1

Then **If** LV_SCP_IGC[x] = 1

Then ERR_SYM_IGC_SCP[x] = 1H

else ERR_SYM_IGC_SCP[x] = 0H

Else No action on the antibounce counter

Endif

Debounce:

Anti - bounce counter increment: C_ABC_INC_IGC_SCP

Maximum value of anti - bounce counter: C_ABC_MAX_IGC_SCP

If LV_CDN_DIAG_IGC_SCP[x] =1

Then **If** ERR_SYM_IGC_SCP[x] = 1H

Then the antibouce counter is started (see anti bounce counter)

Else The antibounce counter is decremented

Endif

Endif

Ignition cut off conditions:

If C_ABC_MAX_IGC_SCP delay is reached

then LV_INH_IGC[x] = 1

Endif

Ignition restart after cut off:

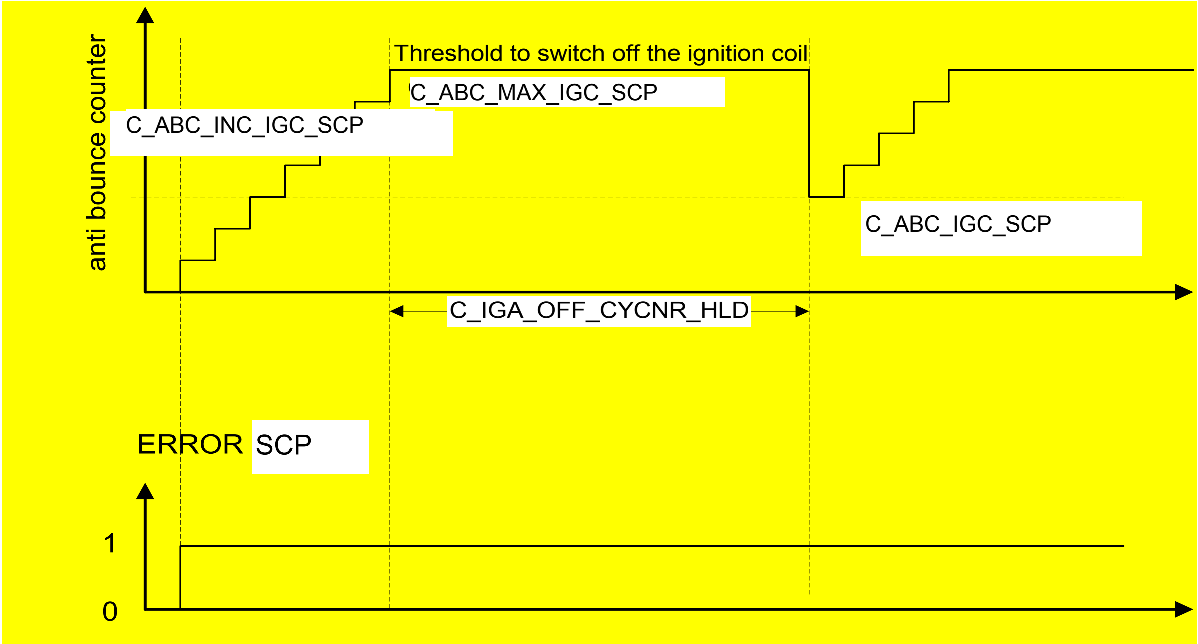
To regenerate the power stage the diagnosis will be switched off (LV_INH_IGC[x] = 1) for C_IGA_OFF_CYCNR_HLD recurrence number (see graphic, failure reaction in case of error).

After the refreshing cycle the debounce counter is set to C_ABC_IGC_SCP (see graphic below) and the ignition will be switched on to test the operating stage again. In case of error it will be debounced again.

This procedure is executed C_SUM_IGC_SCP times before the coil is absolutely switched off, until reset for ATM46 not for ATIC29

In next engine cycle the error is kept present. To take sure that the vehicle is able to restart the ignition will be switched on, till the diagnosis conditions are fulfilled and the diagnosis restarts.

Failure reaction in case of error



Anti bounce configuration data:

Diagnosis	Symptom	SYM	ABC type
Ignition diagnosis for SCP	SCP	*0*	STD
LV_ERR_IGC_SCP			

Application hint:

Some driver as ATM46 does not cut itself in case of SCP failure. For better Driver protection The counter threshold C_ABC_IGC_SCP mustn't exceed 4 cycles For the same reason the counter C_ABC_MAX_IGC_SCP must be set below 12 cycles.
The function can be disabled by the 'enable byte' C_ESB_IGN_CUT_DIAG.

A.47.2 OL / SCG diagnosis

Description

The diagnosis is based on the OL and SCG information from the ignition output diagnosis function.

Application conditions:

Initialisation: all outputs variables have to be set to "0" at reset

Recurrence: if NC_IGN_DIAG_TYP =ATM46 every segment

if NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Activation: **If** LV_ES = 0

And LV_ST = 0

And N_32 > C_N_32_MIN_OL_SCG_IGC_DIAG

And TCO > C_TCO_MIN_IGC_DIAG

And LV_INH_IGC[x] = 0

And LV_ERR_CAM = 0

And No low voltage battery (LV_CDN_VB_OBD1 = 1)

And Counter Number of recurrence > NC_IGC_DLY

And IGN_MPL_NR = 0

And if NC_IGN_DIAG_TYP =ATIC29
Failure information for current cylinder
from ATIC29 is valid
endif

Then LV_CDN_DIAG_IGC_SCG[x] =1

LV_CDN_DIAG_IGC_OL[x] =1

Else LV_CDN_DIAG_IGC_SCG[x] = 0

LV_CDN_DIAG_IGC_OL[x] = 0

Endif

Formula section:

If LV_CDN_DIAG_IGC_SCG[x] =1

And LV_CDN_DIAG_IGC_OL[x] =1

Then **If** LV_OL_IGC[x] = 1

Then ERR_SYM_IGC_OL[x] = 4H

Else ERR_SYM_IGC_OL[x] = 0H

Endif

Else No action on the antibounce counter

Endif

If LV_CDN_DIAG_IGC_SCG[x] =1

And LV_CDN_DIAG_IGC_OL[x] =1

Then **If** LV_SCG_IGC[x] = 1

Then ERR_SYM_IGC_SCG[x] = 2H

Else ERR_SYM_IGC_SCG[x] = 0H

Endif

Else No action on the antibounce counter

Endif

Debounce:

Anti - bounce counter increment: C_ABC_INC_IGC_OL

C_ABC_INC_IGC_SCG

Maximum value of anti - bounce counter:C_ABC_MAX_IGC_OL
C_ABC_MAX_IGC_SCG

If LV_CDN_DIAG_IGC_SCG[x] =1
And LV_CDN_DIAG_IGC_OL[x] =1
Then **If** ERR_SYM_IGC_OL[x] = 4H
Then the antibouce OL counter is started (see anti bounce counter)
Else The antibounce OL counter is decremented
Endif
Endif

If LV_CDN_DIAG_IGC_SCG[x] =1
And LV_CDN_DIAG_IGC_OL[x] =1
Then **If** ERR_SYM_IGC_SCG[x] = 2H
Then the antibouce SCG counter is started (see anti bounce counter)
Else The antibounce SCG counter is decremented
Endif
Endif

Anti bounce configuration data:

Ignition diagnosis for OL and SCG	OL	*2*	STD
	SCG	*1*	
LV_ERR_IGC_OL LV_ERR_IGC_SCG			

A.47.3 Or of ignition failure

Initialisation: all outputs variables have to be set to "0" at reset

Recurrence: Every 100 ms

Formula section:

LV_ERR_IGC = LV_ERR_IGC_SCP[x] **OR** LV_ERR_IGC_SCG[x] **OR** LV_ERR_IGC_OL[x]

A.47.4 Unfiltered ignition error information for misfire detection

Application conditions:

Initialisation: IGC_DIAG_MIS = 0 at reset ECU

Recurrence: if NC_IGN_DIAG_TYP =ATM46 every segment
if NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Formula section:

If LV_SCP_IGC[x] = 1
or LV_OL_IGC[x] = 1
or LV_SCG_IGC[x] = 1
Then set the bit for the actual cylinder in IGC_DIAG_MIS = 1
Else reset the bit for the actual cylinder in IGC_DIAG_MIS = 0
Endif

Description:

The error information of the ignition system should not be filtered. The different error detection are linked by a wired "OR". As soon as an ignition error is detected the information should be available as output cylinder individually in the byte IGC_DIAG_MIS.

IGC_DIAG_MIS

FUNCTION DESCRIPTION:

General information:

The crankshaft to camshaft reference violation means that the defined phasing has been changed, e.g., due to incorrect engine repair. If this mistake does not lead to damage of the engine it is detected by a diagnosis by ENSD during the activation adaptation of the reference position.

There can be a jump of the chain/belt during the engine. It can be recognized if the camshaft position leaves the possible adjustment range operation by the crankshaft to camshaft mechanics violation diagnosis.

Description:

The crankshaft to camshaft mechanics violation diagnosis is enabled if the crankshaft to camshaft reference violation diagnosis (ENSD) has not detected errors, i.e., the activation adaptation has finished successfully, and the engine is running.

Error-symptoms are defined to this diagnostic function as follows:

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │  │  │  └─> (not used)                          (= SYM_0)

FUNCTION DESCRIPTION:

General information:

A jammed or a slow-response actuator is detected by means of a comparison of the camshaft position and the setpoint and quantities derived from them. Two cases are distinguished: detection at steady setpoint and at changing setpoint.

Description:

In order to avoid wrong error detections by the camshaft position deviation diagnosis, the diagnosis is enabled only in certain IVVT operation range.

Camshaft position deviation diagnosis at steady setpoint:

There is a strong coherence with the deviation adaptation of the holding pulse width modulation. The deviation adaptation is started after a setpoint change at first. The diagnosis is started after the adaptation. If the camshaft position deviation after a setpoint change is bigger than a threshold the adaptation is omitted and the diagnosis is started immediately.

If the setpoint reaches the reference position the deviation adaptation is inactive. The diagnosis has to be disabled for some time till the camshaft reaches the reference position. It is realized by means of CTR_CAM_SP_NEUT_IVVT_IN(_EX)_i.

The principle of the diagnosis is based on two integrators. The first one, CAM_DIF_INT_DIAG_IVVT_IN(_EX)_i, integrates the absolute value of the deviation in time if the deviation is bigger than the threshold C_CAM_HYS_DE_DIAG_IVVT_IN(_EX). If the deviation is smaller than this threshold the first integrator is set to 0 and the second one, CAM_DIF_INT_DIAG_RST_IVVT_IN(_EX)_i, integrates the threshold C_CAM_HYS_DE_DIAG_IVVT_IN(_EX) in time. If one of the integrators reaches the diagnosis threshold C_CAM_DIF_INT_MAX_DIAG_IVVT_IN(_EX) the symptom ERR_SYM_CAM_STAT_IVVT_IN(_EX)_i can be set. If it is the integrator CAM_DIF_INT_DIAG_IVVT_IN(_EX)_i the symptom is set to failure. If it is the integrator CAM_DIF_INT_DIAG_RST_IVVT_IN(_EX)_i the symptom is set inactive.

This diagnosis principle is not sensitive for short stochastical temporary camshaft position deviations.

CAM_DIF_INT_DIAG_IVVT_IN(_EX) shows the last diagnostic result. It is to compare with C_CAM_DIF_INT_MAX_DIAG_IVVT_IN(_EX). If the integrated value is greater than or equal to the calibration datum it indicates a failure. The opposite case indicates a faultless performance. The saved value is actually zero.

Camshaft position deviation diagnosis at changing setpoint:

The setpoint has to be stable for certain time before starting the dynamic diagnosis. One possibility is that the IVVT system was inactive, i.e. the reference position was the target. Or the setpoint was within the time moving dynamic window IP_CAM_SP_DYW_DIAG_IVVT_IN(_EX) at least C_DLY_MIN_DIAG_DYN_IVVT. The time moving dynamic window means that after the time C_T_CAM_SP_DYW_DIAG_IVVT the current setpoint is taken for the next window. Thus, the diagnosis can work with some setpoint gradient and jitter.

If the setpoint leaves the dynamic window the previous setpoint, the setpoint change direction and the current camshaft position are assigned into dynamic diagnosis start variables. A time counter is started and the diagnosis becomes active. If the setpoint change keeps its mean direction, i.e. there is no strong opposite change and there is a setpoint gradient greater than a minmum required one, the time counting continues. If the timer T_MIN_DIAG_DYN_IVVT_IN(_EX)_i = IP_T_MIN_DIAG_DYN_ADC(_RTD)_IVVT_IN(_EX) elapses the setpoint change over the diagnosis has to be bigger than C_CAM_SP_DIF_DIAG_DYN_IVVT_IN(_EX). These calibration data depend among each other. Then it is possible to evaluate the camshaft position change over the diagnosis. If it is greater than C_CAM_DIF_DIAG_DYN_IVVT_IN(_EX) there is no failure, otherwise a jammed or slow-responsing actuator is assumed.

CAM_DIF_DIAG_DYN_SAVE_IN(_EX)_i shows the last diagnostic result. It is to compare with C_CAM_DIF_DIAG_DYN_IVVT_IN(_EX). If the saved value is greater than or equal to the calibration datum it indicates a faultless performance. The opposite case indicates a failure.

Error-symptoms definition:

Error-symptoms are defined to this diagnostic function as follows:

LV_ERR_CAM_STAT_IVVT_IN(_EX)_i:

```
□□□□
│ │ │ └─> (not used)                    (= SYM_0)
│ │ └───> (not used)                    (= SYM_1)
│ └─────> (not used)                    (= SYM_2)
└───────> CAM_STAT_IVVT_IN(_EX)_i       (= SYM_3)
```

LV_ERR_CAM_DYN_IVVT_IN(_EX)_i:

```
□□□□
│ │ │ └─> (not used)                    (= SYM_0)

FUNCTION DESCRIPTION:

General information:

A jammed or a one-side slow-response actuator is detected by means of a comparison of the camshaft position and the setpoint and quantities derived from them.

Description:

In order to avoid wrong error detections by the camshaft position partial deviation diagnosis, the diagnosis is enabled only in certain IVVT operation range.

Camshaft position partial deviation diagnosis at steady setpoint:

There is a strong coherence with the deviation adaptation of the holding pulse width modulation. The deviation adaptation is started after a setpoint change at first. The diagnosis is started after the adaptation. If the camshaft position partial deviation after a setpoint change is bigger than a threshold the adaptation is omitted and the diagnosis is started immediately.

If the setpoint reaches the reference position the deviation adaptation is inactive. The diagnosis has to be disabled for some time till the camshaft reaches the reference position. It is realized by means of CTR_CAM_SP_NEUT_IVVT_IN(_EX)_i.

The principle of the diagnosis is based on two integrators. The first one, CAM_INT_PAS_DIAG_IVVT_IN(_EX)_i, integrates the absolute value of the deviation in time if the deviation is bigger than the threshold C_CAM_HYS_PAS_DIAG_IVVT_IN(_EX). If the deviation is smaller than this threshold the first integrator is set to 0 and the second one, CAM_INT_PAS_DIAG_RST_IVVT_IN(_EX)_i, integrates the threshold C_CAM_HYS_PAS_DIAG_IVVT_IN(_EX) in time. If one of the integrators reaches the diagnosis threshold C_CAM_INT_MAX_PAS_IVVT_IN(_EX) while the other integrator does not reach the diagnosis threshold C_CAM_INT_MIN_PAS_IVVT_IN(_EX), the one-side slow response symptom ERR_SYM_CAM_PAS_IVVT_IN(_EX)_i can be set. If it is the integrator CAM_INT_PAS_DIAG_IVVT_IN(_EX)_i the symptom is set to failure. If it is the integrator CAM_INT_PAS_DIAG_RST_IVVT_IN(_EX)_i the symptom is set inactive.

This diagnosis principle is not sensitive for short stochastical temporary camshaft position partial deviations.

CAM_INT_PAS_SAVE_IVVT_IN(_EX)_i shows the last diagnostic result. It is to compare with C_CAM_INT_MAX_PAS_IVVT_IN(_EX). If the saved value is greater than or equal to the calibration datum it indicates a failure. The opposite case indicates a faultless performance. The saved value is actually zero.

Error-symptoms definition:

Error-symptoms are defined to this diagnostic function as follows:

LV_ERR_CAM_PAS_IVVT_IN(_EX)_i:

```
| | | | |
 │  │  │  └─> (not used)                         (= SYM_0)
 │  │  └────> (not used)                         (= SYM_1)
 │  └───────> (not used)                         (= SYM_2)
 └──────────> CAM_PAS_IVVT_IN(_EX)_i             (= SYM_3)
```

Application conditions:

Initialization:

LV_CDN_DIAG_CAM_PAS_IVVT_IN(_EX)_i = 0

LV_END_DIAG_CAM_PAS_IVVT_IN(_EX)_i = 0
Refer to filtering configuration for the initialization value

LV_ERR_CAM_PAS_IVVT_IN(_EX)_i = 0
Refer to filtering configuration for the initialization value

ERR_SYM_CAM_PAS_IVVT_IN(_EX)_i = NO_SYM
Refer to filtering configuration for the initialization value

At activation:

If LV_ACT_IND_SAVE_PAS_IVVT_IN(_EX)_i = 0

and LV_ACT_IND_IVVT_IN(_EX)_i = 1

then CAM_INT_PAS_DIAG_IVVT_IN(_EX)_i = 0

and CAM_INT_PAS_SAVE_IVVT_IN (_EX)_i = 0

and CAM_INT_PAS_ADC_IVVT_IN(_EX)_i = 0

and CAM_INT_PAS_RTD_IVVT_IN(_EX)_i = 0

and CAM_INT_PAS_DIAG_RST_IVVT_IN(_EX)_i = 0

and CAM_INT_PAS_RTD_SAE_IVVT_IN_i = 0

and CAM_INT_PAS_ADC_SAE_IVVT_EX_i = 0

endif

LV_END_CAM_PAS_0_IVVT_IN(_EX)_i = 0

LV_ERR_CAM_PAS_0_IVVT_IN(_EX)_i = 0

At deactivation:

LV_CDN_DIAG_CAM_PAS_IVVT_IN(_EX)_i = 0

At failure memory reset:

LV_CDN_DIAG_CAM_PAS_IVVT_IN(_EX)_i = 0

LV_ERR_CAM_PAS_IVVT_IN(_EX)_i = 0

CAM_INT_PAS_DIAG_IVVT_IN(_EX)_i = 0

CAM_INT_PAS_DIAG_RST_IVVT_IN(_EX)_i = 0

LV_END_CAM_PAS_0_IVVT_IN(_EX)_i = 0

LV_ERR_CAM_PAS_0_IVVT_IN(_EX)_i = 0

At failure memory reset, in case of checksum error:

CAM_INT_PAS_RTD_SAE_IVVT_IN_i = 0

CAM_INT_PAS_ADC_SAE_IVVT_EX_i = 0

Recurrence:

At each used camshaft edge, see "IVVT Scheduler"

FUNCTION DESCRIPTION:

General information:

The interface between the monitor (non-continuous camshaft deviation diagnosis CAM_DE_IVVT_IN(_EX)_i) and the Rate-Based Monitoring statistics is defined with STATE_RBM_CAM_STAT_IVVT_IN(_EX)_i and STATE_RBM_CAM_DYN_IVVT_IN(_EX)_i

Description:

The Rate-Based Monitoring statistics for the IVVT function specifies additional conditions which have to be fulfilled for having the specified driving cycle. The function has to be activited twice at least or it is activated for 10 seconds at least. Further, no RBM statistics is updated if the diagnosis is done during the IVVT short trip LV_TRIP_ACT_IVVT_IN(_EX) = 1 (external triggering possible, e.g. as a garage test).

These two conditions are realized as follows. The setpoint has to leave the reference position and cross the threshold C_CAM_SP_THD_RBM_2_IVVT_IN(_EX) twice at least or it has to be over C_CAM_SP_THD_RBM_10_IVVT_IN(_EX) for 10 seconds at least.

Application conditions:

Initialization:

At reset:

STATE_RBM_CAM_STAT_IVVT_IN(_EX)_i = 0

STATE_RBM_CAM_DYN_IVVT_IN(_EX)_i = 0

STATE_RBM_CAM_PAS_IVVT_IN(_EX)_i = 0

At failure memory reset:

Bit 1 of STATE_RBM_CAM_STAT_IVVT_IN(_EX)_i = 0

Bit 1 of STATE_RBM_CAM_DYN_IVVT_IN(_EX)_i = 0

Bit 1 of STATE_RBM_CAM_PAS_IVVT_IN(_EX)_i = 0

Recurrence: 100 ms

Activation: LV_DC = 1

Formula section:

CONF_CAM_VVT_EX			

Import actions:

ACTION_ERRM_FilterMulticondition(IN < xx >, IN < Cdn_Diag_xx >, IN < Err_Diag_xx >, IN < C_Abc_Inc_xx >, IN < C_Abc_Max_xx >, OUT < Lv_Err_xx >)
This action computes the elementary antibounce filter for one failure treatment and returns filter result
ACTION_INFR_GetElDiagSlvVvt(IN < Vvt > OUT < Cdn_Diag >, OUT < Err_Diag >)
This action reads the failure and condition information for a symptom of the SLV VVT power stage of camshaft Vvt

FUNCTION DESCRIPTION:

General information:

The IVVT solenoid valve is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

The diagnosis of all failures (SCP, SCG and OC) of the IVVT solenoid power stage is possible if the energisation is not too close to 0 % and to 100 %. The minimum and the maximum duty cycle necessary for the complete diagnosis results from the hardware properties (solenoid resistance and inductivity) and frequency used. The duty cycles used by the IVVT control algorithm (calibration data) have to be within this range. It is possible if the adjustment velocity at PWM little bit greater than the minimum diagnosis PWM equals approximately the velocity at 0 %. Similarly, if the adjustment velocity at PWM little bit smaller than the maximum diagnosis PWM equals approximately the velocity at 100 %.

As described in the control algorithm the holding duty cycle (~40-60 %) can be replaced by a time limited ~10 % or ~90 % energisation. If this energisation is short (never longer than 5 ms - recommended maximum calibration value) then 0 % is used instead of ~10 % and 100 % instead of ~90 %. It means that the deviation of the camshaft position from the setpoint is small. This can occur on every used camshaft edge. The recommended calibration is that the time between two used edges is 10 ms at least. Also, there is 5 ms of the holding duty cycle between the 0 % and 100 % energisations. There is at least one "on" and one "off" period at the frequency 200 Hz and higher (300-400 Hz is usually used for holding). This fits to the recurrence of reading of the diagnostic information every 10 ms even if the 10 ms diagnostic recurrence and the camshaft edges are asynchronous. The detection of a failure can be delayed by ~10 ms, but this is negligible.

An external solenoid valve energisation is possible, i.e., independent on the IVVT control algorithm. Then, the external source must fully manage its impacts on the output signal diagnosis, e.g. inhibition by LV_INH_DIAG_SLV_IVVT_IN(_EX)_i.

After conditions for the diagnosis activation are met the diagnosis is delayed for NC_DLY_PSD_SLV_IVVT recurences in order to avoid usage of wrong infrastructure information.

This diagnosis is called for each configured camshaft, see "IVVT Scheduler".

Application conditions:

Initialisation:

LV_ERR_SLV_IVVT_IN(_EX)_i are initialised according to Filter-type

At reset:

CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0

Recurrence: 100 ms

Activation: Inlet: *At every engine state*

Exhaust: CONF_CAM_VVT_EX = 1

Formula section:

xx = SLV_IVVT_IN(_EX)_i

yy = VVT_IN(_EX)_i

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_SLV_IVVT_IN(_EX)_i and basic diagnosis conditions CDN_DIAG_SLV_IVVT_IN(_EX)_i) received from the infrastructure:

```
if      LV_IVVTPWM = 1
    and LV_INH_DIAG_SLV_IVVT_IN(_EX)_i = 0
    and LV_CDN_VB_OBD1 = 1
then    Diagnosis active
        ACTION_INFR_GetElDiagSlvVvt(
        IN               yy
        OUT              CDN_DIAG_xx,
        OUT              ERR_DIAG_xx,
        SYNCRONIZATION   CALL)
        Basic diagnosis conditions are set according to infrastructure information:
        CDN_DIAG_SLV_IVVT_IN(_EX)_i. Failure symptoms (raw value) are set
        according to infrastructure information: ERR_DIAG_SLV_IVVT_IN(_EX)_i
        if    "This query was reached for NC_DLY_PSD_SLV_IVVT diagnosis
              recurrences at least"
        then  Additional diagnosis conditions
              if    0
              then  Conditions that disable SYM_0 detection
                    bit 0 of CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0
                    { Diagnosis of SYM_0 is not possible }
              endif
              if    0
              then  Conditions that disable SYM_1 detection
                    bit 1 of CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0
                    { Diagnosis of SYM_1 is not possible }
              endif
              if    0
              then  Conditions that disable SYM_2 detection
                    bit 2 of CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0
                    { Diagnosis of SYM_2 is not possible }
              endif
        else  CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0
        endif
else    CDN_DIAG_SLV_IVVT_IN(_EX)_i = 0
endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_SLV_IVVT_IN(_EX)_i and ERR_DIAG_SLV_IVVT_IN(_EX)_i.

```
ACTION_ERRM_FilterMulticondition(
IN               xx,
IN               CDN_DIAG_xx,
IN               ERR_DIAG_xx,
IN               C_ABC_INC_xx,
IN               C_ABC_MAX_xx,
OUT              LV_ERR_xx,
SYNCRONIZATION   CALL)
```

This algorithm determines:

ERR_SYM_SLV_IVVT_IN(_EX)_i	(detected error symptom for SLV_IVVT_IN(_EX)_i diagnosis)
LV_ERR_SLV_IVVT_IN(_EX)_i	(Error flag for debounced error of SLV_IVVT_IN(_EX)_i)
LV_CDN_DIAG_SLV_IVVT_IN(_EX)_i	(Diagnosis condition information)
LV_END_DIAG_SLV_IVVT_IN(_EX)_i	(End of diagnosis information)

CAM_AV_IVVT_IN_i	CAM_AV_IVVT_EX_i		
LV_CAM_SP_DFCT_IVVT_IN_i	LV_CAM_SP_DFCT_IVVT_EX_i		

FUNCTION DESCRIPTION:

General information:

Two-bank engines having IN_1 & IN_2 and/or EX_1 & EX_2 phasing can have failures (enduring camshaft position deviation or electrical failure leading to maximum adjustment position) that lead to different camshaft positions in the individual banks. It is possible to manage a balancing of the banks by means of setting the individual setpoint of the running camshaft dependent on the actual position of the faulty, e.g. jammed, actuator. The IVVT state is to set "Limp home" but it is necessary to keep concerned camshafts activated.

If an actuator failure is emulated the concerned camshaft must remain active in order to have the position control active.

A.58.1 IVVT Individual Error Check for Bank Balancing

Description:

This subfunction is active only for 2-bank systems. It is realized in the scheduler.

Individual errors are checked for keeping concerned camshafts active.

The evaluation of the electrical failure is done by means of C_CAM_HYS_REF_SLV_ERR_IVVT. If an electrical error is detected, what lasts some time, and the camshaft is near the reference position it is a "non-balancing" electrical error.

Application conditions:

Initialization:

Recurrence:

360 °CRK

Activation:

LV_ERR_LIH_IVVT = 1

Deactivation:

Not activation

Formula section:

if LV_ERR_REF_CRK_CAM_IN(_EX)_i = 1
 or LV_ERR_MEC_IVVT_IN(_EX)_i = 1
 or (LV_ERR_SLV_IVVT_IN(_EX)_i = 1
  and Inlet:
  CAM_AV_IVVT_IN_i >
  C_CAM_INI_IN - C_CAM_HYS_REF_SLV_ERR_IVVT
  Exhaust:
  CAM_AV_IVVT_EX_i <
  C_CAM_INI_EX + C_CAM_HYS_REF_SLV_ERR_IVVT)

then

LV_ERR_BAL_NOT_IVVT_IN(_EX)_i = 1

else

LV_ERR_BAL_NOT_IVVT_IN(_EX)_i = 0

endif

A.58.2 IVVT Individual Camshaft Activation

Description:

The best reaction on the following "non-balancing" errors is to inactivate the whole IVVT system:
LV_ERR_CRK
LV_ERR_CAM_TOT
LV_ERR_LIH_EXT_IVVT
LV_ERR_REF_CRK_CAM_IN(_EX)_i
LV_ERR_MEC_IVVT_IN(_EX)_i
LV_ERR_SLV_IVVT_IN(_EX)_i leading to reaching of the reference position

The effects of the error LV_ERR_CAM_DE_IVVT_IN(_EX)_i and of LV_ERR_SLV_IVVT_IN(_EX)_i, which leads to reaching of the maximum adjustment position, can be reduced by the bank balancing.

If there is a "balancing" error and then a "non-balancing" error is detected the whole IVVT system is inactivated. It is assumed that the probability of such case is very small.

The emulation of an actuator failure is indicated by LV_CAM_SP_DFCT_IVVT_IN(_EX)_i = 1. When the failure leads to an error detection the IVVT system becomes inactive. But the concerned camshaft remains active in order to have the position control active for the failure emulation.

A special case can occur. E.g. there is a camshaft sensor error and the actuator failure emulation is active (LV_CAM_SP_DFCT_IVVT_IN(_EX)_i = 1). Then, the individual camshaft remains active. This function is a tuning one, also it is managed by application. The application monitors the engine operation. In such case the real failure is to fix and then the failure emulation can continue.

This special case does not occur at effective 2-bank adjustment configuration (camshafts are inactivated even if failure emulation active) because the indvidual activation algorithm allows this easily. To do it for all configurations would require a complex algorithm.

Application conditions:

Initialization:

At transition "engine run" → "engine stop":

LV_ACT_IND_IVVT_IN(_EX)_i = 0

LV_ACT_TOT_IVVT_IN(_EX) = 0

Recurrence:

360 °CRK

Activation:

At every engine state

Formula section:

or (CONF_TOIL_MDL =! 0 **and** LV_ERR_TCO = 1)
then LV_ERR_LIH_EXT_IVVT = 1
else LV_ERR_LIH_EXT_IVVT = 0
endif

A.60 Cooling fan diagnosis

FUNCTION DESCRIPTION:

General information:

Because of a RLY/PWM-fan configuration [NC_ECF_CONF = 2] it is possible to choose the wanted fan diagnosis strategy during ECU runtime with use of a logical constant (CONF_CFA) in combination with project specific requirements. Either the diagnosis function for RLY-fan(s) or the diagnosis function for PWM-fan(s) is activated. It is strongly prohibited to enable both functions in parallel.

For each RLY fan stage as well as each PWM value, a signal at the ECU output has to be generated by the infrastructure to control the available cooling fan(s) (hardware component) at the vehicle. A diagnosis function is necessary in both cases. As soon as the RLY-fan diagnosis function is activated, all PWM-fan diagnosis output data are set to neutral values and vice versa.

A global electronically controlled cooling fan error is set without debounce as soon as the corresponding diagnosis function is detecting an electrical cooling fan failure by one of the available cooling fan stage(s) (RLY or PWM controlled).

A.60.1 Cooling fan diagnosis (RLY version)

Input data:

LV_IGK	LV_CDN_VB_OBD1	LV_DC	

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the cooling fan relay signal (low and high).

A global electronically controlled cooling fan error is set without debounce as soon as the diagnosis function is detecting an electrical cooling fan failure by one of the available cooling fan(s).

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following:

```

Input data:

LV_IGK	LV_CDN_VB_OBD1	LV_DC	

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the electronical cooling fan.

A global electronically controlled cooling fan error is set without debounce as soon as the diagnosis function is detecting an electrical cooling fan failure by one of the available cooling fan(s).

The input signal is a modulated control pulse (PWM).

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.
The diagnosis condition calculation is done according **“Limited”** duty cycle, thus no definition of the PWM diagnosis windows is necessary.

Error-symptoms are defined to this diagnosis function as following:

```
□□□□
│ │ │ └─> Short circuit to Vbatt (SCB)          (= SYM_0)

Diagnosis condition for each symptom					

Input data:

LV_IGK	LV_CDN_VB_OBD1	LV_DC	

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the electric fuel pump relay signal.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
□□□□
| | | └─> Short circuit to Vbatt (SCB)      (= SYM_0)
| | └───> Short circuit to GND (SCG)        (= SYM_1)
| └─────> Open load (OL)                    (= SYM_2)
└───────> -                                 (= SYM_3)
```

Application conditions:

Initialisation: all variables (except LV_END_DIAG_RLY_EFP) are initialised with 0 at every LV_IGK = 0 ->1 and reset
LV_END_DIAG_xx is initialised with 0 at every (LV_IGK = 0 ->1 and LV_DC = 0) and at reset

Recurrence: 300 ms

Activation: *at every engine operating state*

Formula section:

IF LV_IGK = 1 **AND**
LV_CDN_VB_OBD1 = 1
THEN LV_INH_DIAG_RLY_EFP = 0
ELSE LV_INH_DIAG_RLY_EFP = 1
ENDIF

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_RLY_EFP	1	0...FFH	0...255	1	-
Debounce counter increment RLY_EFP diagnosis					
C_ABC_MAX_RLY_EFP	1	01...FFH	1...255	1	-
Debounce counter maximum value – RLY_EFP diagnosis					

A.62.1 Application incidences for electric fuel pump diagnosis

Configuration for diagnostic symptoms :

Diagnostic	Symptom Description	Symptom	Filter type

A.63 Air Conditioning pressure signal diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_ACP	V/S/O	0H...1H	0...1	1	-
Error currently present on AC pressure signal acquisition (after debounce)					
ERR_SYM_ACP	O/V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	-
Error symptom for ACP diagnosis					
LV_CDN_DIAG_ACP	O/V	0H...01H	0...1	1	-
Diagnosis condition for ACP diagnosis					

Input data:

V_ACP_MES	STATE_ACP	CONF_ACP	CONF_ACC
LV_ERR_VCC_SENS_SUB			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the analog input signal (V_ACP_MES) from Air conditioning transducer pressure sensor to the micro-controller via the multiplexed.

Application conditions:

The error detection is only performed if the vehicle is equippted with air condition control (CONF_ACC = 1), the air conditioner option has been recognized (CONF_ACP has been set to 1) and if no failure is present on senor supply voltage (LV_ERR_VCC_SENS_SUB = 0).

Recurrence: **100 ms**

Formula section:

If V_ACP_MES < C_ACP_MIN_DIAG

then *`Short to Ground´ or `Line Break´ is detected.*

and the anti-bounce counter is incremented with C_ABC_INC_ACP_DIAG

If V_ACP_MES > C_ACP_MAX_DIAG

then *`Short to Battery Voltage´ is detected.*

and the anti-bounce counter is incremented with C_ABC_INC_ACP_DIAG

If the anti-bounce counter reaches C_ABC_MAX_ACP_DIAG

Then LV_ERR_ACP = 1

If the anti-bounce counter reaches 0

Then LV_ERR_ACP = 0

* Debounce :

Anti - bounce counter increment : C_ABC_INC_ACP_DIAG
Maximum value of anti - bounce counter : C_ABC_MAX_ACP_DIAG

Emergency operation :

AC-Pressure state set to high in case of ACP-Error (Spec xx400Dyy.zzz)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ACP_MIN_DIAG	1	0...3FFH	0...5	0.0195	V
Air conditionning transducer pressure raw acquisition threshold for short detection to ground					
C_ACP_MAX_DIAG	1	0...3FFH	0...5	0.0195	V
Air conditionning transducer pressure raw acquisitioshold for short detection to battery voltage or line break					
C_ABC_INC_ACP_DIAG	1	0...FFH	0...255	1	-
Anti – bounce counter increment for Air conditionning transducer pressure sensor diagnosis					
C_ABC_MAX_ACP_DIAG	1	0...FFH	0...255	1	-
Maximum value of the anti - bounce for Air conditionning transducer pressure sensor diagnosis					

A.63.1 Air Conditioning Pressure sensor diagnosis (Appl. Inc.)

Input data:

LV_ERR_ACP	LV_ACCIN	LV_RLY_ACCOUT	V_ACP_MES_ENVD_H
V_ACP_MES_ENVD_L			

Error treatment:

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> short circuit to battery (SCB)                    (= SYM_0)
 │ │ └───> short circuit to ground (SCG) or open circuit (OC) (= SYM_1)
 │ └─────> -                                                 (= SYM_2)
 └───────> -                                                 (= SYM_3)
```

Configuration for diagnostic symptoms :

Diagnostic	Symptom Description	Symptom	Filter type
A/C pressure sensor diagnosis	Short circuit to battery (SCB)	SYM_0	*STD*
	Short circuit to ground (SCG) or open circuit (OC)	SYM_1	
		SYM_2	
ACP		SYM_3

End of diagnosis for Ambient pressure sensor diagnosis					

Input data:

VP_AMP	LV_INH_DIAG_AMP	NC_IDX_DIAG_AMP	VP_AMP_MAX_DIAG
VP_AMP_MIN_DIAG			

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_AMP	1	0...FFH	0...255	1	-
Increment debounce counter					
C_ABC_MAX_AMP	1	1...FFH	1...255	1	-
Maximum value debounce counter					

Import actions:

ACTION_ERRM_FilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <ABC_INC>, IN <ABC_DEC>, IN <ABC_MAX>, OUT <LV_ERR>)
This action computes the elementary anti-bounce filter
ACTION_ERRM_GetErrSym(IN <IDX_DIAG>, OUT <ERR_SYM>)
Action that returns the symptom of the failure
ACTION_ERRM_GetLvCdnDiag(IN <IDX_DIAG>, OUT <LV_CDN_DIAG>)
Action that returns the diagnostic condition
ACTION_ERRM_GetLvEndDiag(IN <IDX_DIAG>, OUT <LV_END_DIAG>)
Action that returns the status of the failure availability

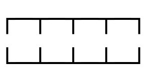
A.64.1 General information:

The purpose of the diagnosis shall be to detect electrical faults as defined by OBD I requirements.

The signal of the altitude pressure sensor on the A/D-input of the microcontroller is checked.

Description:

Error-symptoms are defined to this diagnosis function as following:



| | | └─> Short circuit to battery "SCP" (= SYM_0)
| | └──> Short circuit to Ground "SCG" (= SYM_1)
| └────> - (= SYM_2)
└─────> - (= SYM_3)

Remark: Depending on the Hardware, Open Circuit "OC" is assigned to SYM_0 or to SYM_1.

Error debounce:

- Debounce counter increment: C_ABC_INC_AMP
- Debounce counter decrement: 1
- Debounce counter maximum value: C_ABC_MAX_AMP

Threshold value VP_MAP_MV to detect Short circuit in signal wire to earth or wire break					

A.69.1 General Information:

Definition of the thresholds to detect either short circuit in signal wire to battery or short circuit in signal wire to ground or wire break:

Short circuit in signal wire to VB

VP_MAP_MAX_DIAG = C_VP_MAP_MAX_DIAG

Short circuit in signal wire to ground or wire break

VP_MAP_MIN_DIAG = C_VP_MAP_MIN_DIAG

Inhibition:

Depending on projects specific requirements, the manifold air pressure sensor diagnosis needs can be inhibited by setting LV_INH_DIAG_EL_MAP = 1.

LV_INH_DIAG_EL_MAP is a bit which contains the project- specific activation/deactivation condition.

Import actions:

ACTION_ERRM_FilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <ABC_INC>, IN <ABC_DEC>, IN <ABC_MAX>, OUT <LV_ERR>)
This action computes the elementary anti-bounce filter
ACTION_ERRM_GetErrSym(IN <IDX_DIAG>, OUT <ERR_SYM>)
Action that returns the symptom of the failure
ACTION_ERRM_GetLvErr(IN <IDX_DIAG>, OUT <LV_ERR>)
Action that returns the status of the debounced failure

A.70.1 General Information :

Analog input signal in the A/D-Input from the Microprocessor.

Description

Error - symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> Signal Line Short to Battery Voltage        (= SYM_0)
 │  │  └───> Signal Line Short to Ground or Open load     (= SYM_1)
 │  └─────> -                                             (= SYM_2)
 └───────> -                                              (= SYM_3)
```

Error debounce:

- Debounce counter increment: C_ABC_INC_MAF_SCP
- Debounce counter decrement: 1
- Debounce counter maximum value: C_ABC_MAX_MAF_SCP

- Debounce counter increment: C_ABC_INC_MAF_SCG_OC
- Debounce counter decrement: 1
- Debounce counter maximum value: C_ABC_MAX_MAF_SCG_OC

A.70.1.4 SUBFUNCTION: visualizationERRMdata

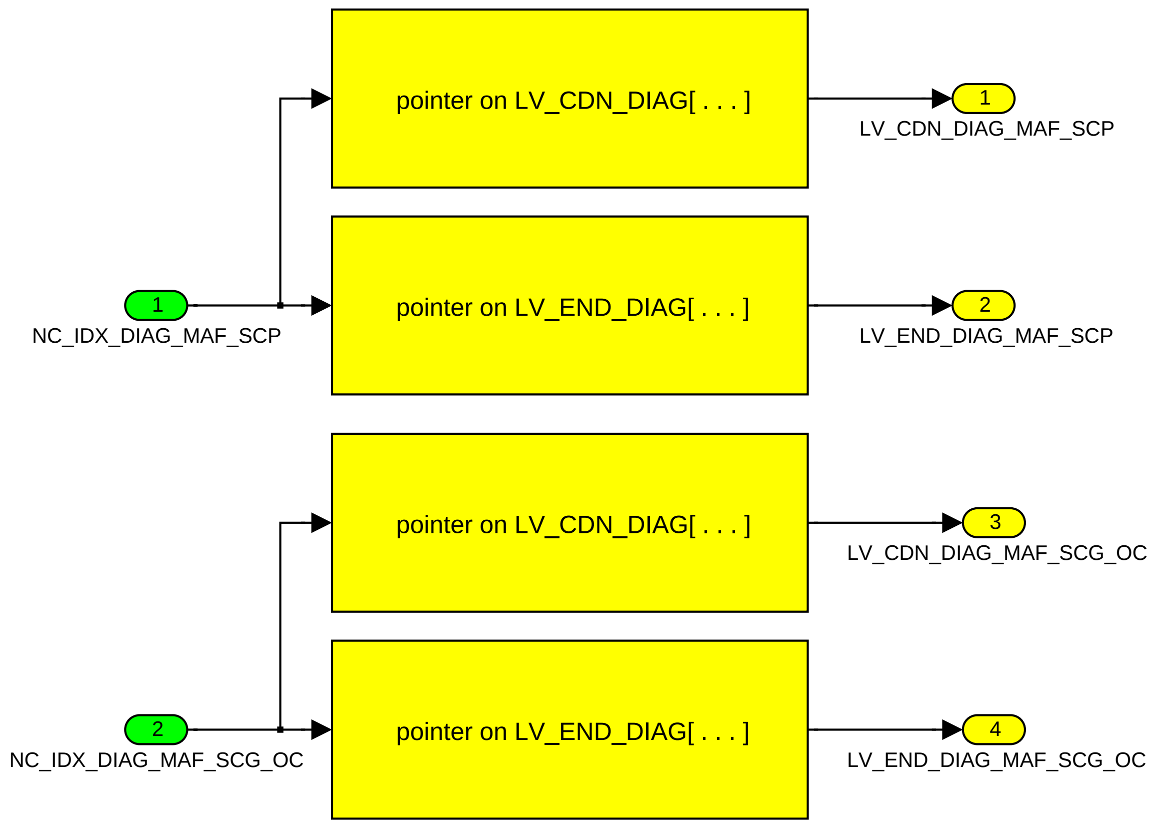

Figure 56 INSY_SIG_DMAF0/ visualizationERRMdata

A.71 Mass air flow sensor diagnosis (App. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_MAF_DIAG	O/V	0...1H	0...1	1	-
Flag to stop the Mass air flow sensor diagnosis					
LV_INH_MAF_SCG_DIAG	O/V	0...1H	0...1	1	-
Flag to inhibit the Mass air flow sensor diagnosis in case of SCG					
T_DLY_IGK_MAF_DIAG	-	0...FFH	0...2.55	0.01	s
Delay time after LV_IGK = 0 -> 1 for MAF diagnosis inhibition					

Input data:

LV_DC	LV_PWL	LV_ERR_RLY_EFP	LV_EFP
LV_MAF_SWI	T_AST	LV_CDN_VB_OBD1	LV_IGK
ERR_SYM_ISA_2	ERR_SYM_ISA_1		

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DLY_IGK_MAF_DIAG	1	0...FFH	0...2.55	0.01	s
Delay time after LV_IGK = 0 -> 1 for MAF diagnosis inhibition					
C_T_DLY_MAF_DIAG	1	0...FFH	0...25.5	0.1	s
Delay time after start for MAF diagnosis inhibition					

A.71.1 General information:

Depending on projects specific requirements, the mass air flow sensor diagnosis needs can be inhibited by setting LV_INH_MAF_DIAG = 1.

LV_INH_MAF_DIAG is a bit which contains the project-specific activation/deactivation condition.

The flag LV_INH_MAF_SCG_DIAG deactivates the diagnosis in case of short cut to ground (SCG) symptom appears.

A.71.2 Application assistances

- **Emergency operation:**

- with an ABC-value unequal to 0 the intake manifold model will not be corrected anymore via the MAF sensor signal to avoid engine stall during the debouncing phase (before final error detection)

- **Application Assistance:**

Limp home functions:
- TPS limp home (calculation modified)
- Engine speed limitation
- Set state torque intervention to max. state (=3)
- EVAP-control activation of MIN-operation

The following control functions are inhibited:
- Downstream Fuel Trim Regulation
- Catalyst Heating
- Torque intervention for gear shift

The following adaptation functions are inhibited:
- Lambda adaptation
- Knock adaptation
- Idle speed adaptation
- Reduced area adaptation learning (indirect)
- Catalyst heating adaptation (indirect)
- Segment time adaptation
- Ambient pressure adaptation

The following diagnosis functions are inhibited:
- Ignition diagnosis
- ISA-plausibility diagnosis
- O2-sensor downstream signal voltage diagnosis (only SCG)
- Differential tank pressure sensor plausibility diagnosis (Noisy signal)
- Differential tank pressure sensor plausibility diagnosis (Signal constant)
- load/TPS-plausibility diagnosis
- Misfire detection (ER-calculation)
- EVAP-diagnosis
- Fuel system diagnosis
- O2-sensor upstream switching time diagnosis
- O2-sensor upstream frequency diagnosis
- Catalyst efficiency diagnosis
- O2-sensor downstream switching time diagnosis
- O2-sensor downstream OBDII puc-end diagnosis
- Thermosthat diagnosis

A.72 Reference voltage diagnosis (VCC_PVS_1_DIAG , VCC_PVS_2_DIAG , TPS_VCC_DIAG and VCC_SENS_SUB_DIAG)

Inhibition of diagnosis					
LV_ERR_VCC	V/O	0...1H	0...1	1	-
Failure state currently present on 1 of the 4 reference voltages VCC_PVS_1 or VCC_PVS_2 or VCC_TPS or VCC_SENS_SUB					

Input data:

VCC_PVS1_DIAG_BAS	VCC_PVS2_DIAG_BAS	VCC_TPS_DIAG_BAS	VCC_SENS_SUB_DIAG_BAS
LV_RLY_MAIN_EXT_ADJ	C_T_DLY_RLY_MAIN_DIAG	LV_IGK	

FUNCTION DESCRIPTION:

General information:

If the supply voltage is invalid, the sensors depending on it would deliver wrong values and could be detected as faulty. Therefore the reference voltages are acquired from the Hardware I/O System and monitored. The diagnosis voltage delivered from HW is half of the real supply voltage.

Acquisition of Diagnosis Voltage :

VCC_PVS_1_DIAG = VCC_PVS1_DIAG_BAS * 2

VCC_PVS_2_DIAG = VCC_PVS2_DIAG_BAS * 2

VCC_TPS_DIAG = VCC_TPS_DIAG_BAS * 2

VCC_SENS_SUB_DIAG = VCC_SENS_SUB_DIAG_BAS * 2

Application conditions:

Initialisation: *at the transition LV_IGK = 0 to 1, at reset event and clear error memory*

LV_INH_DIAG_VCC_PVS_1 = 0

LV_INH_DIAG_VCC_PVS_2 = 0

LV_INH_DIAG_TPS_VCC = 0

LV_INH_DIAG_VCC_SENS_SUB = 0

LV_ERR_VCC_PVS_1 = 0

LV_ERR_VCC_PVS_2 = 0

LV_ERR_TPS_VCC = 0

LV_ERR_VCC_SENS_SUB = 0

Activation: **If** LV_IGK = 1

And LV_INH_DIAG_VCC_PVS_1 = 0

Then LV_CDN_DIAG_VCC_PVS_1 = 1

Else LV_CDN_DIAG_VCC_PVS_1 = 0 (*Deactivation)*

If LV_IGK = 1
And LV_INH_DIAG_VCC_PVS_2 = 0
Then LV_CDN_DIAG_VCC_PVS_2 = 1
Else LV_CDN_DIAG_VCC_PVS_2 = 0 (*Deactivation)*

If LV_IGK = 1
And LV_INH_DIAG_TPS_VCC = 0
Then LV_CDN_DIAG_TPS_VCC = 1
Else LV_CDN_DIAG_TPS_VCC = 0 (*Deactivation)*

If LV_IGK = 1
And LV_INH_DIAG_VCC_SENS_SUB = 0
Then LV_CDN_DIAG_VCC_SENS_SUB = 1
Else LV_CDN_DIAG_ VCC_SENS_SUB = 0 (*Deactivation)*

For VCC_PVS_2 and TPS_VCC the inhibition bit is always set to 0 (LV_INH_DIAG_VCC_PVS_2 = 0 / LV_INH_DIAG_TPS_VCC = 0)

Recurrence: 10 ms

Formula section:

If C_T_DLY_RLY_MAIN_DIAG has run out after LV_RLY_MAIN_EXT_ADJ = 1-> 0
and LV_RLY_MAIN_EXT_ADJ = 0
Then LV_INH_DIAG_VCC_PVS_1 = 0

A.73 Battery voltage diagnosis

A.73.1 Battery voltage range diagnosis

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_ERR_VB	V/O	0...1H	0...1	1	-
Boolean for error currently present on system voltage					

Input data:

VB	LV_IGK	LV_ES	LV_ST
	VS	LV_RLY_MAIN_EXT_ADJ	C_T_DLY_RLY_MAIN_DIAG

FUNCTION DESCRIPTION :

General information:

The purpose is to diagnose the system voltage which has to guarantee to perform diagnosis functions.

The diagnosis takes place with a recurrence of 1 sec.

Application conditions :

** Conditions to perform the diagnosis :*

if LV_IGK = 1
and LV_ES = 0
and LV_ST = 0
and *C_T_DLY_RLY_MAIN_DIAG has run out after LV_RLY_MAIN_EXT_ADJ = 1->0* *(Delay after Actuator Test)*
and *LV_RLY_MAIN_EXT_ADJ = 0* *(No Main Relay Actuator Test)*
and VS > C_VS_MIN_VB_DIAG

** Failure detection :*

if VB **<** C_VB_L_DIAG
then the Anti-Bounce counter is incremented with C_ABC_INC_VB
else the Anti-Bounce counter is decremented with 1

If the Anti-Bounce counter reaches C_ABC_MAX_VB, LV_ERR_VB is set to 1.

if VB **>** C_VB_H_DIAG
then the Anti-Bounce counter is incremented with C_ABC_INC_VB
else the Anti-Bounce counter is decremented with 1

If the Anti-Bounce counter reaches C_ABC_MAX_VB, LV_ERR_VB is set to 1.

Failure treatment :

* Debouce :

Anti-bounce counter increment: C_ABC_INC_VB

Maximum value of anti-bounce counter: C_ABC_MAX_VB

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_VB	1	0...FFH	0..255	1	-
. Anti-bounce counter increment for VB					
C_ABC_MAX_VB	1	1...FFH	1...255	1	-
Maximum value of antibounce counter for VB					
C_VS_MIN_VB_DIAG	1	0...FFH	0...255	1	Km/h
Minimum vehicle speed to perform Battery Voltage monitoring					
C_VB_L_DIAG	1	0...6CH	0...10.97	0.1	V
Battery voltage threshold for low battery voltage					
C_VB_H_DIAG	1	0...FFH	0...25.8984	26/256	V
Battery voltage threshold for high battery voltage					

A.73.2 Battery Voltage open circuit diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_VB_OC	V/O	0...1H	0...1	1	-
Boolean for open circuit on Battery voltage VB					
ERR_SYM_VB_OC	V	0H 1H 2H 4H	NO_SYM SYM_0 SYM_1 SYM_2	1	-
Error symptom for VB_OC					
LV_CDN_DIAG_VB_OC	V	0...1H	0...1	1	-
Conditions for VB_OC diagnosis fulfilled					
LV_END_DIAG_VB_OC	V	0...1H	0...1	1	-
End of VB_OC diagnosis					

Input data:

VB_MES	V_IGK_MES	ENG_STATE	V_IGK
T_AST_ENVD	VS	LV_IGK	C_T_DLY_RLY_MAIN_DIAG
LV_RLY_MAIN_EXT_ADJ	V_IGK_BAS	NC_KEY_OFF_THR	

FUNCTION DESCRIPTION:

General information:

Purpose of this diagnosis is to check if the ECU is correctly supplied from battery via VB-Pin. In case of incorrect supply the ECU is still running with risk of hardware damage.

Application conditions:

Initialisation: at transition LV_IGK = 0 to 1 and at ECU reset

Recurrence: 10 ms

Activation: **If** LV_IGK = 1

and V_IGK_BAS > NC_KEY_OFF_THR

and C_T_DLY_RLY_MAIN_DIAG has run out after LV_IGK = 0 --> 1 *(to ensure main relay had enough time to switch on after key on)*

CONF_IMOB	LV_ERR_COM_RESP_IMOB	CONF_IMOB_VER	

A.74.1 SMARTRA fault

Description:

The purpose is to diagnose the SMARTRA and its communication.
Following failures during transmission may occur :

- SMARTRA receives error code 01h: Antenna error
- SMARTRA receives no response message within the max. communication time
- Communication timing not correct (P1MAX, P2MAX, or P4MAX)
- Received byte has wrong address or the size of the checksum is not correct

Application conditions :

Activation: *CONF_IMOB_VER =1*

During authentication and key teaching process

Deactivation : After good authentication
LV_ERR_IMOB_SMARTRA_ANT = **false**
LV_ERR_IMOB_MSG = **false**
LV_ERR_IMOB_RESP = **false**

Formula section:

If SMARTRA responds with error code 01h (Antenna coil error)
then an internal counter is increased, and try again untill internal counter is 3 in same DC
After **three** times negative response received from SMARTRA, the flag
LV_ERR_IMOB_SMARTRA_ANT = **true** with **SYM_0**

If { Inter-byte time for immobilizer request exceeds P1MAX }
LV_ERR_COM_P1MAX_IMOB = **true**
or
{ Inter-byte time for EMS request exceeds P4MAX }
LV_ERR_COM_P4MAX_IMOB = **true**
or
{ Address or the size or the checksum is not correct }
LV_ERR_COM_RESP_IMOB = **true**
Then an internal counter is increased
After **three** times bad communication during key authentication, the flag
LV_ERR_IMOB_ MSG = **true** with **SYM_0** **// SMARTRA**

If {the time-out delay for communication has elapsed}
LV_ANS_NOT_IMOB = **true**
or
{ No received byte within P2MAX }
LV_ERR_COM_P2MAX_IMOB = **true**
then
If auto-variant learning(auto-detection) has not been done yet
Then wait 1.5 second for response from immobilizer unit
If there is no response from SMARTRA within 1.5 sec
Else LV_ERR_IMOB_RESP = **true** with **SYM_0** **// SMARTRA**
Else an internal counter is increased
After **three** times bad communication during key authentication, the flag
LV_ERR_IMOB_RESP = **true** with **SYM_0** **// SMARTRA**

If CONF_IMOB_SMARTRA = 2 **// SMARTRA3 Only**
Then

If {EMS send 4Bh}
{SMARTRA response with the state byte 02h}
Then an internal counter is increased
After counter reaches three, the flag
LV_ERR_IMOB_SMARTRA3 = 1
ERR_SYM_IMOB_SMARTRA3 = "SYM_0"

If {EMS send 4Bh}
{SMARTRA response with the state byte 03h}
Then an internal counter is increased
After counter reaches three, the flag
LV_ERR_IMOB_SMARTRA3 = 1
ERR_SYM_IMOB_SMARTRA3 = "SYM_1"

Rev.C :
Adding SMT3 Error symptom

If { EMS send 4Bh}
{SMARTRA response with the state byte 01h with an invalid ERN}
Or { EMS send 54h}
{SMARTRA response with the 03h messege (Incorect Password for learnt smartra during key teaching procedure(69 02 03 CS) }

Then an internal counter is increased
After counter reaches three, the flag
LV_ERR_IMOB_SMARTRA3 = 1
ERR_SYM_IMOB_SMARTRA3 = "SYM_2"

If { EMS send 4Bh}
{ Locked SMARTRA response negative response 15h with error code 05h}
Then an internal counter is increased
After counter reaches three, the flag
LV_ERR_IMOB_SMARTRA3 = 1
ERR_SYM_IMOB_SMARTRA3 = "SYM_3"

<u>Emergency operation :</u>

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.2 Smart-Key Communication Fault

Description:

The purpose is to diagnose communication with Smart-Key.
Following failures during transmission may occur :

- EMS receives no response message within the max. communication time
- Communication timing not correct (P1MAX, P2MAX, or P4MAX)
- Received byte has wrong address or the size of the checksum is not correct

Application conditions :

Activation: *CONF_IMOB_VER = 2* ***or*** *CONF_IMOB_VER = 3*
During communication

Deactivation : After good authentication
LV_ERR_IMOB_MSG = **false**
LV_ERR_IMOB_RESP = **false**

Formula section:

If { Inter-byte time for immobilizer request exceeds P1MAX }
LV_ERR_COM_P1MAX_IMOB = **true**
or
{ Inter-byte time for EMS request exceeds P4MAX }
LV_ERR_COM_P4MAX_IMOB = **true**
or
{ Address or the size or the checksum is not correct }
LV_ERR_COM_RESP_IMOB = **true**
Then an internal counter is increased
If C_MAX_DLY_ACT_IMOB elapsed after LV_IGK = 0 -> 1
Or An internal counter > C_MAX_ACK_IMOB_SMK
Then LV_ERR_IMOB_ MSG = **true** with **SYM_1** **// Smart-Key**
EndIf
EndIf

LV_ERR_IMOB_MSG error is detected, when authentification error [Invalid SMART-KEY (with wrong VIN) send "Positive response" with wrong VIN code] in SMART-KEY learnt state.

If {the time-out delay for communication has elapsed}
LV_ANS_NOT_IMOB = **true**
or
{ No received byte within P2MAX }
LV_ERR_COM_P2MAX_IMOB = **true**
Then an internal counter is increased
If C_MAX_DLY_ACT_IMOB elapsed after LV_IGK = 0 -> 1
Or An Internal counter > C_MAX_ACK_IMOB_SMK
Then LV_ERR_IMOB_RESP = **true** with **SYM_1** **// Smart-Key**
EndIf
EndIf

Emergency operation :

* Limp Home : No Limp-Home

A.74.3 Transponder fault

Description:

The purpose is to diagnose the signal from Transponder.

Following failure during transmission may occur :

- SMARTRA code 02h received : invalid Transponder data
  Corrupted Tp data, or more than one Tp in the field or no Tp in the field
- SMARTRA code 04h received : passive mode invalid
  Tp not in password mode, or Tp transport data has been changed
- SMARTRA code 11..17h received : Transponder programming error
  Transponder programming error

Application conditions :

Activation: *CONF_IMOB_VER = 1*
During authentication and key teaching process

Deactivation : After good authentication
LV_ERR_IMOB_TP_PROG = **false**
LV_ERR_IMOB_TP_DAT = **false**
LV_ERR_IMOB_TP_MOD = **false**

Formula section:

If SMARTRA responds with error code 02h

Then an internal counter is increased

After **three** times negative response received from SMARTRA,
The flag LV_ERR_IMOB_TP_DAT = **true** with **SYM_0**

If SMARTRA responds with error code 04h

Then an internal counter is increased

After **three** times negative response received from SMARTRA,

The flag LV_ERR_IMOB_TP_MOD = **true** with **SYM_0**

If SMARTRA responds with error code 11h, 12h, 13h, 14h, 15h, 16h, 17h

Then an internal counter is increased

After **three** times negative response received from SMARTRA,

The flag LV_ERR_IMOB_TP_PROG = **true** with **SYM_0**

Emergency operation :

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.4 Invalid Key fault

General information :

The purpose is to indicate that invalid data are sent by SMARTRA.
Following failure during transmission may occur:
- 3 times wrong code is received from key during authentication
- 3 times detection of a "VIRGIN" transponder at a "LERNT" EMS

Application conditions :

Activation: *CONF_IMOB_VER = 1*
During authentication and key teaching process

Deactivation : After good authentication LV_ERR_IMOB_AUTH = **false**

Formula section:

If { wrong code is received from key during authentication }
LV_ANS_ERR_IMOB = **true**

then an internal counter is increased
After three times wrong code received,
LV_ERR_IMOB_AUTH = **true** with **SYM_0**

Emergency operation :

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.5 EMS fault

Description:

The purpose is to diagnose an invalid request from EMS to the SMARTRA device.
Following failure may occur :
- SMARTRA code 03h received : invalid request from EMS or corrupted data
- The maximum number of (32) of "twice IGN ON" in virgin EMS is exceeded

Application conditions :

Activation: During authentication and key teaching process

Deactivation : After good authentication
LV_ERR_IMOB_TWICE_IGN_ON= **false**
LV_ERR_IMOB_EMS_REQ = **false**

Formula section:

```
If      CONF_IMOB_VER = 1
And     SMARTRA responds with error code 03h
Then    an internal counter is increased
        After three times negative response received from SMARTRA,
        The flag LV_ERR_IMOB_EMS_REQ = true with SYM_0
EndIf

If   LC_ENA_DIAG_IMOB_TWICE_IGN_ON =1
Then If      CONF_IMOB_VER = 1                               // Smartra
         and CTR_KEY_FAST_IMOB = NC_CTR_KEY_FAST_IMOB
     Then    LV_ERR_IMOB_TWICE_IGN_ON = true
             ERR_SYM_IMOB_TWICE_IGN_ON  = 1H      (SYM_0)
     Else    If      CONF_IMOB_VER = 2                       // Smart-Key 1
                 and CTR_KEY_FAST_IMOB = NC_CTR_KEY_FAST_IMOB
             Then    LV_ERR_IMOB_TWICE_IGN_ON = true
                     ERR_SYM_IMOB_TWICE_IGN_ON  = 2H   (SYM_1)
             Else    If     CONF_IMOB_VER = 3                // Smart-Key 2
                        and CTR_KEY_FAST_IMOB = NC_CTR_KEY_FAST_IMOB_SMK_2
                     Then   LV_ERR_IMOB_TWICE_IGN_ON = true
                            ERR_SYM_IMOB_TWICE_IGN_ON  = 2H    (SYM_1)
                     Else   LV_ERR_IMOB_TWICE_IGN_ON = false
                            ERR_SYM_IMOB_TWICE_IGN_ON  = 0H    (NO_SYM)
EndIf
```

Emergency operation :

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.6 EMS internal permanent memory fault

Description:

The purpose is to diagnose if incorrect immobilizer data are stored in flash:

The error flag (LV_ERR_IMOB_MEM) is set if one of the following error happens :
- at least one of the three data sets stored in the flash EPROM has wrong checksum.
- an impossible Immobilizer status is set

Application conditions :

Activation: After reset

Deactivation : -

Formula section:

If Checksum and data read out from flash EPROM does not fit together

or an impossible Immobilizer status is set

then LV_ERR_IMOB_MEM = **true** with **SYM_0**

Emergency operation :

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.7 Tester fault

Description:

The purpose of this diagnosis is to detect if incorrect or invalid data are sent by service-tester.

The error flag /LV_ERR_IMOB_TESTER) is set if one of the following error happens:

- Invalid message from tester (e.g. wrong length of data)

Application conditions :

Activation: CONF_IMOB_VER = 1
And LC_ENA_DIAG_IMOB_TESTER = 1
during tester communication

Deactivation : After error memory reset (by tester): LV_ERR_IMOB_TESTER = **false**

Formula section:

If message with wrong length from tester

then LV_ERR_IMOB_TESTER = **true** with **SYM_0**

EndIf

Emergency operation :

* Limp Home : start possible if certain conditions fulfilled
(see Immobilizer specification)

A.74.8 Immobilizer Configuration Fault

Description:

The purpose of this diagnosis is to detect if a Non-immobilizer EMS is build in a vehicle that is equipped with a SMARTRA device or Smart-Key.

The error flag (LV_ERR_IMOB_CONF) is set if the following error happens:

- A Non-immo EMS detects a SMARTRA connected on the serial communication line.

Application conditions :

Activation: CONF_IMOB = 0
And LC_ENA_DIAG_IMOB_CONF = 1
a test communication on the immobilizer line is started after ignition ON.

Deactivation: **If** configuration is changed to immobilizer (CONF_IMOB = 1) then LV_ERR_IMOB_CONF = **false**

Formula section:

If CONF_IMOB = 0

and ignition is switched ON

then a test communication on immobilizer line is started.

If a SMARTRA device is detected *{positive response from SMARTRA}*

then LV_ERR_IMOB_CONF = **true** with **SYM_0** // SMARTRA

If a Smart-Key device is detected {Positive response from Smart-Key}

Then LV_ERR_IMOB_CONF = **true** with **SYM_1** // Smart-Key

Calibration data:

LV_ERR_EL_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean error flag, fault currently present on upstream oxygen sensor signal					

Input data:

LV_ERR_SCG_LS_UP[NC_CBK_EX_NR]	LV_IGK	LV_ERR_SCP_LS_UP[NC_CBK_EX_NR]	LV_ERR_OC_LS_UP[NC_CBK_EX_NR]
NC_CBK_EX_NR	LV_ERR_READY_LS_UP[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

General information:

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Description:

The oxygen sensor signal electrical diagnosis shall detect the following faults:

A. Short circuit of the oxygen sensor signal line to GND
B. Short circuit of the oxygen sensor signal line to Vbatt
C. Open circuit (line break) in the connection to oxygen sensor element
D. Delayed readiness of the sensor

Should one of the electrical fault flags be set, then a global error flag (LV_ERR_EL_LS_UP[i]) shall be set to indicate that an electrical fault currently exists on the particular oxygen sensor.

Each of the above listed faults shall be described individually in further detail below.

Application conditions:

Initialisation: all variables shall be initialised to 0 at LV_IGK = 0 -> 1 or reset or by clearing the error memory.

Recurrence:

This diagnosis shall be carried out every *100 ms* provided no debounced fault has been detected and unless specifically noted otherwise in the relevant section.

Activation / Deactivation:

If LV_IGK = 1

Formula section:

If LV_ERR_SCP_LS_UP[i] = 1

or LV_ERR_SCG_LS_UP[i] = 1

or LV_ERR_OC_LS_UP[i] = 1

or LV_ERR_READY_LS_UP[i] = 1

then LV_ERR_EL_LS_UP[i] = 1

else LV_ERR_EL_LS_UP[i] = 0

endif

A.76.1 Short circuit of oxygen sensor signal to GND

Output data:

VLS_DOWN[NC_CBK_EX_NR]	CTR_CYCNR_R_IT_LS_UP_VLD[NC_CBK_EX_NR]	LV_DC	

Description:

In order to determine the electrical fault, short circuit to GND, the oxygen sensor signal voltage shall be compared to a calibratable threshold (C_VLS_MIN_DIAG_SCG_LS_UP) in conjunction with certain activation and additional conditions.

Should a hard short to GND (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to 0 V. This condition may also occur should the air-fuel mixture (AFR) become lean due to operating conditions or due to an air leak, intentional or not. Hence the following additional fault conditions shall be required:

The initial conditions shall reasonably ensure that no false air is being admitted into the system. One possible source of false air may be due to an open or a faulty Canister Purge Solenoid (CPS). Should a fault be determined to exist in the Evaporative Emissions System (LV_ERR_EL_CPS, LV_ERR_DIAG_CPS), then no further SCG diagnosis shall take place. An additional criterion shall only permit diagnosis to take place above a limiting thresholds of MAF_KGH value (C_MAF_KGH_MIN_DIAG_SCG_LS_UP) as the effect of an air leak is far greater at low engine loads.

In order to discriminate against a lean AFR due to the current engine / driving conditions and a possible short to GND, the lambda controller shall be taken into account: A fault may prevail if the lambda controller is active (LV_LAM_LSCL[i] = 1) and has reached the enriched limit (FAC_LAM_MAX[i]). Should the above activation conditions be met and the lambda controller be active, a timer (T_ACT_PLS_DIAG_SCG_LS_UP[i]) shall be started. If any of the initial conditions are no longer met, all timers and flag LV_LAM_MAX_DIAG_SCG_LS_UP[i] shall be reset and the request for CPS closure revoked (LV_DIAG_SCG_REQ_LS_UP[i]).

On reaching the lambda controller limit, the diagnosis function shall start a timer (T_LAM_LIM_DIAG_SCG_LS_UP[i]). Should the lambda controller remain limited uninterrupted for a pre-determined amount of time (C_T_LAM_LIM_DIAG_SCG_LS_UP), then the closure of the CPS shall be requested (LV_DIAG_SCG_REQ_LS_UP[i]) and state of the Evaporative Emissions System shall be checked. Should the lambda controller fall below the max. limit or the above initial conditions not be met, the timers shall be reset, any requested closure of the CPS revoked and the flag indicating controller limitation & CPS closed or inactive (LV_LAM_MAX_DIAG_SCG_LS_UP[i]) shall be reset. This shall prevent the diagnosis from blocking normal or minimum operation of the Evaporative Emissions System.

In order to discriminate against a lean AFR due to air via the Activated Charcoal Filter (ACF) canister, the state of the Evaporative Emissions System shall be checked as stated above. The steady closed state of the CPS shall be determined via EVAP Control state variables (LV_CP_CLOSE_ACT). Once the CPS has been determined to be closed, a mass air flow integral shall be started (MAF_INT_CPS_CLOSE_VLS_UP_MIN[i]). Should all above conditions continue to be met for a pre-determined threshold (C_MAF_INT_CPS_DIAG_SCG_LS_UP).

Each time that the MAF_INT_CPS_CLOSE_VLS_UP_MIN[i] exceeded the minimum duration (C_MAF_INT_CPS_DIAG_SCG_LS_UP) for the first time, e.g. first time after engine start or after the T_LAM_LIM_DIAG_SCG_LS_UP[i] has been reset, the CTR_R_UPD_DIAG_SCG_LS_UP[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_UP_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_R_UPD_DIAG_SCG_LS_UP[i] with that of CTR_CYCNR_R_IT_LS_UP_VLD[i]. Should the counters be unequal, then a new value is available and CTR_R_UPD_DIAG_SCG_LS_UP[i] shall be updated with CTR_CYCNR_R_IT_LS_UP_VLD[i]. If this conditions and all the above conditions be met, the diagnosis shall be considered to be active. LV_LAM_MAX_DIAG_SCG_LS_UP[i] shall then be set.

Should at any time the state of the CPS change from being closed, the diagnosis shall reset LV_LAM_MAX_DIAG_SCG_LS_UP[i] and the mass MAF_INT_CPS_CLOSE_VLS_UP_MIN[i] only.

The diagnosis condition shall be considered to be available if all the following conditions are met:

1) Activation time ellapsed (T_ACT_PLS_DIAG_SCG_LS_UP[i] > C_T_ACT_PLS_DIAG_SCG_LS_UP)
2) A new internal resistance exists (LV_R_MES_VLD_DIAG_SCG_LS_UP[i] = 1)
3) Either the lambda controller is not in limitation or the lambda controller is in limitation and the flag LV_LAM_MAX_DIAG_SCG_LS_UP[i] = 1 is set (*CPS closed and MAF delay ellapsed).*

If the diagnosis is available, the oxygen signal voltage fall below the threshold (VLS_UP[i] < C_VLS_MIN_DIAG_SCG_LS_UP) and the condition R_IT_LS_UP[i] under threshold be met and downstream voltage is over a threshold and lambda controller is still in the limit, a signal short to GND shall be determined to be present and the debounce counter incremented.

If the voltage not fall below the said threshold or the condition R_IT_LS_UP[i] under threshold is no longer met, then either the limiting of the lambda controller may be assumed to be being caused by something other than a short to ground on the oxygen sensor signal or a glitch has caused the voltage to temporarily exceed the SCG voltage threshold. In this case, should the debounce counter be determined to be zero, the timers shall be reset and any request of closure of the CPS shall be revoked otherwise the debounce counter shall be decremented.
It should be noted that the debounce counter shall only be decremented when the debounce counter is not zero, should the voltage or R_IT_LS_UP[i] under threshold criteria not be met.
The error flag LV_ERR_SCG_LS_UP[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

<u>Application conditions:</u>

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 at LV_IGK = 0 -> 1 or reset or by clearing the error memory

Input data:

VLS_UP[NC_CBK_EX_NR]	LV_IGK	LV_INH_DIAG_SCP_LS_UP[NC_CBK_EX_NR]	LV_DC

Description:

Should a hard short to Vbatt (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to Vbatt and the analog digital converter value will tend to 5 V. This

effect does not occur under normal conditions as the sensor delivers typically 1 V for rich AFR at the sensor location and may be used for short to Vbatt detection.
In order to determine the electrical fault, short circuit to Vbatt, the oxygen sensor signal voltage (VLS_UP[i]) is compared to a calibratable threshold (C_VLS_MAX_DIAG_ SCP_LS_UP) in conjunction with the aforementioned activation conditions.
If the oxygen signal voltage exceeds the said threshold, a signal short to Vbatt shall be determined to be present and the debounce counter incremented otherwise the debounce counter shall be decremented.
The error flag LV_ERR_SCP_LS_UP[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Application conditions:

LV_INH_DIAG_OC_LS_UP[NC_CBK_EX_NR]	LV_IGK	R_IT_LS_UP[NC_CBK_EX_NR]	STATE_LSH_UP[NC_CBK_EX_NR]
CTR_CYCNR_R_IT_LS_UP_VLD[NC_CBK_EX_NR]	LV_DC		

Description:

Should a complete open circuit in the oxygen sensor signal or return line occur, the measured voltage at the input to the microcontroller will tend to the voltage determined by the operative readiness potential divider (approx. 450 mV).
In order to determine the electrical fault, open circuit, the oxygen sensor signal voltage is compared to two calibratable thresholds in conjunction with certain activation and additional conditions. The following additional conditions shall be required:

- No fault in the appropriate upstream oxygen sensor heater circuit has been detected (LV_ERR_LSH_UP[i] = 0) or should a fault be present, that the operating temperature has been determined to be sufficient for sensor operability (TEG_CAT_UP_MDL[I] > C_TEG_CAT_MDL_DIAG_OC_LS_UP).

- The appropriate heater shall be determined to being controlled normally (STATE_LSH_UP[i] = LSH_POW_CTL)
- The lambda controller shall be active (LV_LAM_LSCL[i] = 1, possibly through forced activation).

Should the above conditions and the activation conditions have be met, then the oxygen sensor signal voltage shall be analysed to determine whether it lies within a calibratable voltage band (C_VLS_AFL_DIAG_OC_LS_UP < VLS_UP[i] < C_VLS_AFR_DIAG_OC_LS_UP). A counter (CTR_DIAG_OC_LS_UP[i]) shall keep track of the time that the signal voltage lies within this band since the above additional conditions have been determined to be true. Should the timer equal or exceed a minimum calibratable threshold (C_CTR_DIAG_OC_LS_UP), then a signal open circuit shall be determined to be present and the debounce counter shall be incremented. Should the initial conditions be met but the voltage condition not met, then the debounce counter shall be decremented.
The counter shall be reset if either the signal voltage leaves the threshold band or if the initial conditions listed above are no longer met.

Depending on the calibration of LC_R_IT_CHK_DIAG_OC_LS_UP aside monitoring lambda sensor voltage also the internal resistance value of the lambda probe shall be considered or not. If set, this provides an additional safety margin for the diagnosis for the case that lambda probe is cooling down significantly during long fuel cut-off phases or if operating temperature is not yet reached after engine start.
Note: In case of LC_R_IT_CHK_DIAG_OC_LS_UP = 1 the incrementation of CTR_DIAG_OC_LS_UP and CTR_ABC_OC_LS_UP depends on the updarate of CTR_R_UPD_DIAG_OC_LS_UP (~1 s not T_SAMPLE = 100 ms)!

It should be noted that the debounce counter shall only be incremented or decremented should the initial conditions be met. In all other cases, the debounce counter shall remain frozen.
The error flag LV_ERR_OC_LS_UP[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 at LV_IGK = 0 -> 1 ot reset or by clearing the error memory

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

LV_T_TOUT_LS_UP_READY[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_DC	

Description:

The diagnosis shall monitor if the lambda sensor gets ready in time, if it was disabled due to operating conditions as defined in the operative readiness determination. It evaluates two flags defined there. LV_LS_UP_READY[i] is set while suitable operating conditions are met and the sensor is operational, while LV_T_TOUT_LS_UP_READY[i] is set if suitable operating conditions are present for a certain time. An error is determined to be present if the second flag is set but the first one is not.

No filtering shall be applied to the symptoms.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 at LV_IGK = 0 -> 1 or reset or by clearing the error memory

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

Recurrence: ***T_sample = 100ms***

Activation / Deactivation:

LV_DC			

Description:

Due to possible oxygen sensor defects or faults in the injection system (e.g. leaking fuel injector), the oxygen sensor may not provide the expected lean AFR signal level during an overrun fuel cut-off (PUC) condition.

Hence, in order to determine the signal fault, the oxygen sensor signal shall be checked for plausibility during the engine operating state PUC. The oxygen sensor signal voltage (VLS_UP[i]) shall be required to exceed the calibratable threshold (C_VLS_MIN_DIAG_PUC_LS_UP), and the following activation conditions shall be met::

- No electrical fault shall be present on the O_2 sensor under test (LV_ERR_EL_LS_UP[i] = 0)
- Sensor shall be in a state of operative readiness (LV_LS_UP_READY[i] =1).
- The sensor shall be determined to be at operating temperature (STATE_LSH_UP[i] = LSH_POW_CTL & LV_ERR_LSH_UP[i] = 0) or should a fault exist in the heater circuit of the particular sensor under test, then a minimum Exhaust Gas Temperature (EGT) shall be exceeded (TEG_CAT_UP_MDL[i] > C_TEG_CAT_MDL_DIAG_OC_LS_UP).
- The engine state PUC (overrun fuel cut-off) shall be determined to be active (LV_PUC = 1) and stable, as determined by comparing the mass air flow integral calculated after PUC activation (MAF_INT_PUC) within the thresholds (C_MAF_INT_MIN_DIAG_PUC_LS_UP; C_MAF_INT_MAX_DIAG_PUC_LS_UP).

If the above listed conditions and the voltage condition are met then an implausible oxygen sensor signal PUC voltage shall be determined to be present and the debounce counter incremented. Should the activation conditions be met but the voltage condition not be met then the debounce counter shall be decremented. Should any of the activation conditions not be met, then the debounce counter shall remain frozen.

The error flag LV_ERR_PUC_LS_UP[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 at LV_IGK = 0 -> 1 ot reset or by clearing the error memory

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

NC_CBK_EX_NR	LV_IGK	LV_DC	

Description:

Should the oxygen sensor internal resistance be too high or a leakage resistance exist to either GND or Vbatt on the oxygen sensor signal line, the signal voltage excursion may not be sufficient to guarantee correct lambda control.

In order to determine the signal fault, voltage excursion implausible, the difference in the measured voltage between rich AFR (VLS_UP_MMV_MAX[i]) and lean AFR (VLS_UP_MMV_MIN[i]) is compared to a calibratable threshold (C_VLS_STK_DIAG_STK_LS_UP) in conjunction with the following activation conditions.

- No electrical fault shall be present on the O_2 sensor under test (LV_ERR_EL_LS_UP[i] = 0)
- The sensor shall be determined to be at operating temperature (STATE_LSH_UP[i] = LSH_POW_CTL & LV_ERR_LSH_UP[i] = 0) or should a fault exist in the heater circuit of the particular sensor under test, then a minimum Exhaust Gas Temperature (EGT) shall be exceeded (TEG_CAT_UP_MDL[i] > C_TEG_CAT_MDL_DIAG_OC_LS_UP).
- A minimum number of lambda controller P-jumps (C_CTR_LAM_P_DIAG_STK_LS_UP) since each activation of the lambda controller shall have been executed. The P-jump counter shall be reset whenever the lambda controller values VLS_UP_MMV_MAX[i] & VLS_UP_MMV_MIN[i] are reset. This shall ensure that the values used in the voltage condition are and remain current.
- No lambda limit present. That shall exclude a failure entry in case of low amplitude because of lambda limit or electrical error of upstream O2 sensor (SCG or OL).
- The cycle time counters T_AFL_CYC[i] and T_AFR_CYC[i] must not exceed a calibratable threshold. This is to prevent a stroke error entry due to the diminishing moving mean value for long cycle times.

If the above listed conditions and the voltage condition are met then an implausible oxygen sensor signal voltage excursion shall be determined to be present and the debounce counter incremented. Should the activation conditions be met but the voltage condition not be met then the debounce counter shall be decremented. Should any of the activation conditions not be met, then the debounce counter shall remain frozen.

The error flag LV_ERR_STK_LS_UP[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The variables shall be defined in accordance with the exhaust gas system for [i] = 1 to NC_CBK_EX_NR.

Application conditions:

Initialisation: all variables (except LV_END_DIAG_xx) shall be initialised to 0 at LV_IGK = 0 -> 1 ot reset or by clearing the error memory

LV_END_DIAG_xx is initialised with 0 at every LV_DC = 0 ->1 or reset or at clearing the error memory

VLS_UP_MMV_DIF_SAVE[i] shall be initialized with its saved value. Reset only at clearing error memory.

Recurrence: ***T_sample = 1000 ms***

Activation / Deactivation:

FUNCTION DESCRIPTION:

General information:

According the exhaust gas system shall the variables be defined from [i]=1 to NC_CBK_EX_NR.

Description:

The application incidences is applicable to each upstream oxygen sensor signal monitoring diagnosis function.

Note: The status of the Emissions Testing LV_ET_ACT shall be taken into account, altough this is not explicitly included in the formula section in order to make this specification more flexible. Should an emissions test be determined to be active, then no further STK diagnosis shall take place as false air is introduced into the system and may cause a lean mixture at the oxygen sensor location to be measured.

Application conditions:

Initialisation: *All inhibition flags shall be initialised to 1 (inhibit diagnosis until conditions met) at the beginning of a new driving cycle.*

Recurrence: *100ms*

Activation / Deactivation: **if** LV_IGK = 1

then *enable corresponding diagnosis*

else *disable corresponding diagnosis*

FUNCTION DESCRIPTION:

General information:

With this module the interface between the O2 sensor signal excursion plausability and the Rate-Based Monitoring statistics is defined with STATE_RBM_STK_LS_UP[1] data.

Within STATE_RBM_STK_LS_UP[1], three different informations are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
  (general information depending on monitor could be added)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
  (general information depending on monitor could be added)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (general information depending on monitor could be added)

Application conditions:

Initialisation :

at ECU reset: bit 0, bit 1 and bit 2 of STATE_RBM_STK_LS_UP[1] = 0

at transition LV_DC 0 → 1: bit 0, bit 1 and bit 2 of STATE_RBM_STK_LS_UP[1] = 0

on failure memory reset : bit 1 of STATE_RBM_STK_LS_UP[1] = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_SCP_LS_UP[1], LV_ERR_SCG_LS_UP[1], LV_ERR_OC_LS_UP[1]

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1) **While** bit 1 of STATE_RBM_STK_LS_UP[1] = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2) bit 1 of STATE_RBM_STK_LS_UP[1] = 1

Endwhile

Else(1) { the dynamic failure memory is empty }

No action

Every 1 s :

If bit 0 of STATE_RBM_STK_LS_UP[1] = 0

Then **If** LV_END_DIAG_STK_LS_UP[1] = 1

Then bit 0 of STATE_RBM_STK_LS_UP[1] = 1

If bit 1 of STATE_RBM_STK_LS_UP[1] = 0

Then **If** LV_ERR_SCP_LS_UP[1] = 1 **or**

LV_ERR_SCG_LS_UP[1] = 1 **or**

LV_ERR_OC_LS_UP[1] = 1

Then bit 1 of STATE_RBM_STK_LS_UP[1] = 1

No specific condition for STK_LS_UP[1] :

bit 2 of STATE_RBM_STK_LS_UP[1] always equal to 1

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_STK_LS_UP[1]_DIAG = 0

then RATE_RBM_STK_LS_UP[1] = FFFFH

else RATE_RBM_STK_LS_UP[1] = (CTR_COMP_RBM_STK_LS_UP[1] / CTR_CDN_RBM_STK_LS_UP[1])

A.78.1.3 RBM interface for the O2 sensor signal plausability in Fuel Cut-Off

Output data:

Input data:

LV_IGK	VB	CONF_DIAGCP	LV_ST_END
LV_DC			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the shut off valve signal from the driver which controls the shut off valve.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
[ | | | ]
 │  │  │  └─> Short circuit to Vbatt    SCP     (= SYM_0)
 │  │  └────> Short circuit to GND      SCG     (= SYM_1)
 │  └───────> Open load                 OL      (= SYM_2)
 └──────────> -                                 (= SYM_3)
```

Application conditions:

Initialisation: At reset or at LV_IGK = 0->1 or at clearing FMY:

- all (except LV_END_DIAG_xx) 0
- LV_INH_DIAG_SOV = 1

At reset or at LV_DC = 0->1 or at clearing FMY:

- LV_END_DIAG_xx = 0

Recurrence: 300 ms

Activation: at every engine operating state

Deactivation: activation condition not fulfilled

Formula section:

If LV_IGK = 1
and VB < C_VB_MAX_DIAG_SOV
and VB > C_VB_MIN_DIAG_SOV
and CONF_DIAGCP > 0
and LV_ST_END = 1
then LV_INH_DIAG_SOV = 0
else LV_INH_DIAG_SOV = 1
endif

- LV_INH_DIAG_SOV is used in chapter “Electrical diagnosis of power stage outputs” to activat/deactivate the ATIC39 diagnosis for SOV
- SOV diagnosis pulse time (noise treatment)

  To reduce SOV activation noise during SOV closed state, SOV diagnosis pulse time will be changed according to SOV status.

  1. SOV activation frequency at every SOV status : 7.6 Hz
  2. Normal SOV open state : Diagnosis pulse time 0.45 ms
  3. Normal SOV closed state (for EVAP, FUC_MISS_1) : Diagnosis pulse time 0 ms
  4. Electrical error at SOV closed : Diagnosis pulse time 0.45 ms

Short circuit to Vbatt:

If ERR_SYM_SOV = 1H (SYM_0)
and LV_ERR_SOV
then LV_ERR_SCP_SOV = 1
else LV_ERR_SCP_SOV = 0
endif

Short circuit to Vbatt:

If ERR_SYM_SOV = 2H (SYM_1)

and LV_ERR_SOV

then LV_ERR_SCG_SOV = 1

else LV_ERR_SCG_SOV = 0

endif

Open load:

If ERR_SYM_SOV = 4H (SYM_2)

and LV_ERR_SOV

then LV_ERR_OC_SOV = 1

else LV_ERR_OC_SOV = 0

endif

Global error bit LV_ERR_SOV:

If one of the symptoms is detected faulty after debounce, LV_ERR_SOV is set to 1. Else LV_ERR_SOV is set to 0.

Calculation of LV_END_DIAG_SOV and antibounce counter:

- see chapter "Anti-bounce Algorithm: Calculation of the end of diagnosis"

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Maximum Battery voltage threshold for SOV diagnosis					

A.79.1 SOV diagnosis (Appl. Inc.)

Configuration for diagnostic symptoms :

Diagnostic	Symptom Description	Symptom	Filter type
Evap. system leak errors	SCB	SYM_0	*STD*
	SCG	SYM_1	
	OL	SYM_2	
SOV		SYM_3	

List of Environmental Data to store in Failure Memory:: TAM
CPPWM_ENVD
DTP_ENVD
CP_STATE

Application assistance:

In case of the function is declared damaged by the diagnosis then the impacted function or diagnosis must be taken into account (applied a correction or a limp home for the concerned function and inhibed the concerned diagnosis).

List of impacted function and diagnosis :

In case of STG only:

- Evaporative system control (NO_PURGE)
- Evaporative system monitoring
- Downstram fuel trim regulation
- Lambda adaptation
- Idle speed adaptation
- Segment time adaptation
- ISA plausibilty diagnosis
- DTP sensor diagnosis
- Lambda limit diagnosis
- Catalist efficiency diagnosis
- O2-sensor diagnosesFuel system diagnosis
- MAP/TPS rationality check

Whatever the symptom, is disabled:
- Evaporative system monitoring

FUNCTION DESCRIPTION:

General information:

Engine speed deviation from the nominal engine speed is monitored when the vehicle is stopped and the throttle is settled after closing.

If the difference to the nominal idle speed keeps too high or too low in spite of an activated idle speed controller, an idle speed control plausibility error is detected.

A second diagnosis is available for cold start idle monitoring.

Application conditions:

Initialization: *transition* LV_IGK 0 → 1 or reset
LV_ERR_ISC = 0
LV_ERR_ISC_CST = 0

ERR_SYM_ISC = NO_SYM
ERR_SYM_ISC_CST = NO_SYM

FUNCTION DESCRIPTION:

General information:

These application incidences give the possibility to define customer specific conditions for inhibiting the diagnosis of the idle speed.

Application conditions:

Initialisation: LV_INH_DIAG_ISC = 1

Recurrence: 100 ms

Activation: LV_IGK = 1

Formula section:

If LV_ERR_CAM_DE_IVVT_IN_i = 1 or
LV_ERR_CAM_DE_IVVT_EX_i = 1 or
LV_ERR_CRK = 1 or
LV_ERR_MAF = 1 or
LV_ERR_MAP = 1 or
LV_ERR_CPS = 1 or
LV_ERR_MEC_CPS =1 or

	LV_ERR_SLV_IVVT_IN_i = 1	or
	LV_ERR_SLV_IVVT_EX_i = 1	or
	LV_ERR_ISA_i = 1	or
	LV_ERR_FSD_i = 1	or

	LV_ERR_LS_UP[NC_CBK_EX_NR] = 1	
Then	LV_INH_DIAG_ISC_= 1	
Else	LV_INH_DIAG_ISC = 0	
Endif		

Error treatment:

Error-symtoms are defined to this diagnosis function as following :

```
□□□□
│ │ │ └─> Idle Control System RPM higher than expected  (= SYM_0)
│ │ └───> Idle Control System RPM lower than expected   (= SYM_1)
│ └─────> -                                             (= SYM_2)
└───────> -                                             (= SYM_3)
```

Application Assistances :

The following diagnosis functions are inhibited :

- MAF / TPS Plausability
- DTP Noisy signal diagnosis
- EVAP diagnosis

Configuration for diagnostic symptoms :

Diagnostic	Symptom Description	Symptom	Filter type
Idle speed control diagnosis ERR_ISC	RPM higher than expected	SYM_0	*STD_INI*
	RPM lower than expected	SYM_1	
		SYM_2	
		SYM_3	

Diagnostic	Symptom Description	Symptom	Filter type

		SYM_3	

A.82 Main Relay Diagnosis (RLY_MAIN)

A.82.1 Main Relay not switched on / not switched off Diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_RLY_MAIN	O/V	0...1h	0...1	1	-
Boolean for error detected at the main relay.					
T_RLY_MAIN_DIAG	V	0...FFh	0...2550	10	ms
Time window to perform the main relay diagnosis.					

Input data:

LV_IGK	V_IGK	VB	LV_RLY_MAIN_EXT_ADJ
LV_ACT_RLY_MAIN_EXT_ADJ			

FUNCTION DESCRIPTION:

General information:

The Main Relay Diagnosis is performed to detect if the Main Relay has switched and remains on after Key-On and if it has switched off after the Power Latch Phase.

Description:

The diagnosis is delayed for C_T_DLY_RLY_MAIN_DIAG to allow the relay to switch on/off. After this the actual VB is compared with a diagnostic threshold. If the error conditions are fulfilled the error is debounced.

If an error is detected after the Power Latch Phase the ECU is switched off after T_RLY_MAIN_DIAG has ellapsed.

Error-symtoms are defined to this diagnosis function as following :

```
□□□□
│ │ │ └─> Main relais has not switched off     (= SYM_0)
│ │ └───> Main relais has not switched on      (= SYM_1)
│ └─────> -                                    (= SYM_2)
└───────> -                                    (= SYM_3)
```

Application conditions:

Initialisation: restored out of the NVMY

Recurrence:

The application recurrence for the Diagnosis is **10 msec**;
The „Main Relay Off"-Detection is performed only once after power latch.

Activation: *see Formula section*

Formula section:

Detection if Main Relay is on during Key-On:

If(1) LV_RLY_MAIN_EXT_ADJ = 0

Then(1) **If(2)** LV_IGK = 1 **and**

V_IGK > C_V_IGK_RLY_MAIN_DIAG

(direct connection to the battery,
to ensure a battery voltage that would be able to switch the relay)

Then(2) start time: C_T_DLY_RLY_MAIN_DIAG
(time to allow the relay to switch, set only once. For continuos diagnosis set to 0)

If(3) C_T_DLY_RLY_MAIN_DIAG has run out *(if started, see above)*

Then(3) **If(4)** VB < C_VB_RLY_MAIN_DIAG
(connection to battery via main relay)

Then(4) LV_ERR_RLY_MAIN = 1 (after debounce)

Else(4) LV_ERR_RLY_MAIN = 0 (after rebounce)

Endif(4)

Else(3) C_T_DLY_RLY_MAIN_DIAG is still running

Endif(3)

Else(2) no Diagnosis

Endif(2)

Else(1) no Diagnosis; the main relay is controlled by LV_ACT_RLY_MAIN_EXT_ADJ

Endif(1)

<u>Detection if Main Relay is off after Power Latch Phase:</u>

If(1) Power Latch Phase has run out after Key-Off

Then(1) start time: C_T_DLY_RLY_MAIN_DIAG
(time to allow the relay to switch)

If(2) LV_IGK is still 0

Then(2) start T_RLY_MAIN_DIAG with C_T_RLY_MAIN_DIAG

(start the time window during which the diagnosis is performed)

If(3) T_RLY_MAIN_DIAG is still running **and**

VB > C_VB_RLY_MAIN_DIAG
(connection to battery via main relay)

Then(3) LV_ERR_RLY_MAIN = 1 (after debounce)

Else(3) LV_ERR_RLY_MAIN = 0 (after rebounce)

Endif(3)

Else(2) no switched off Diagnosis

Endif(2)

Else(1) no Diagnosis

Endif(1)

End of Diagnosis RLY_MAIN_DLY					

Input data:

LV_IGK	V_IGK	VB	LV_RLY_MAIN_EXT_ADJ

FUNCTION DESCRIPTION:

General information:

The main relay diagnosis is performed at reset to detect if the main relay has been switched on within the correct timing. This diagnostic is comparable to main relay switch on, but is separated for having faster reaction time.

Once no failure has been found, diagnosis is then disabled.

Description:

The diagnosis starts after LV_IGK 0->1. After this the actual VB is compared with a diagnostic threshold. If the error conditions are fulfilled the error is debounced.

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
│ │ │ └─> -                                   (= SYM_0)

C_TCO_TH_OPEN_DIAG_TH			

FUNCTION DESCRIPTION:

General information:

The purpose of this diagnosis is to detect a stuck oil temperature signal.

The diagnostic function checks whether after a variation of the calculated oil temperature TOIL_MDL_FSD also a variation of the measured oil temperature TOIL_MES is detected.

The diagnosis is performed only once per driving cycle.

Error-symtoms are defined to this diagnosis function as following :

```
|_|_|_|_|
 |  |  |  └─> -                        (= SYM_0)
 |  |  └────> -                        (= SYM_1)
 |  └───────> Sensor signal stuck  (= SYM_2)
 └──────────> -                        (= SYM_3)
```

Application conditions:

Initialisation (after initialisation of TOIL_MDL_FSD and TOIL_MES):

TOIL_MES_MIN_DIAG = TOIL_MES_MAX_DIAG = TOIL_MES

TOIL_MDL_MIN_DIAG = TOIL_MDL_MAX_DIAG = TOIL_MDL_FSD

FUNCTION DESCRIPTION:

General information:

To be sure that some diagnosis functions are not disabled by unplausible TOIL value (i.e. Camshaft control deviation is disabled in case of high or low TOIL), this diagnosis function check if :

- TOIL_MES is not unplausibly low when TOIL_MDL_FSD is high
- TOIL_MES is not unplausibly high when TCO is low (and no relevant failure)

Error-symtoms are defined to this diagnosis function as following :

```
| | | └─> Sensor signal unplausible low   (= SYM_0)
| | └───> -                               (= SYM_1)
| └─────> -                               (= SYM_2)
└───────> -                               (= SYM_3)
```

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │  │  │  └─> -                                  (= SYM_0)
 │  │  └────> Sensor signal unplausible high     (= SYM_1)
 │  └───────> -                                  (= SYM_2)
 └──────────> -                                  (= SYM_3)
```

Application conditions:

A.83.4.4 RBM interface for the "TOIL Signal Stuck" diagnosis

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
STATE_RBM_TOIL_STUCK	O/V	0 ... 7H	0 ... 7H	1	-
Interface of monitor of TOIL Signal Stuck diagnosis for the rate based monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					
RATE_RBM_TOIL_STUCK	V	0...FFFFH	0....7,99572	0,000122	-
Actual RBM rate of TCO Signal Stuck diagnosis, for application purposes					

Input data:

LV_END_DIAG_TOIL_STUCK	CTR_COMP_RBM_TOIL_STUCK	CTR_CDN_RBM_TOIL_STUCK	LV_DC
LV_ERR_TCO_EL	LV_ERR_TCO_PLAUS	LV_ERR_TCO_GRD	
CTR_ERR_DYN_NR	LV_ERR_TOIL	LV_ERR_TCO_STUCK	
LV_ERR_TOIL_PLAUS_L	LV_ERR_TOIL_PLAUS_H		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TOIL_STUCK monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TOIL_STUCK data.

Within STATE_RBM_TOIL_STUCK, three different informations are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
  (general information depending on monitor could be added)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
  (general information depending on monitor could be added)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (general information depending on monitor could be added)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TOIL_STUCK = 0

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_TOIL_STUCK = 0

on failure memory reset :

bit 1 of STATE_RBM_TOIL_STUCK = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL, LV_ERR_TCO_PLAUS, LV_ERR_TCO_GRD, LV_ERR_TCO_STUCK, LV_ERR_TOIL, LV_ERR_TOIL_PLAUS_L, LV_ERR_TOIL_PLAUS_H

If(1) { CPU optimization at LV_DC 0 → 1 transition }

CTR_ERR_DYN_NR <> 0 { the dynamic failure memory isn't empty }

Then(1)

While bit 1 of STATE_RBM_TOIL_STUCK = 0 **do**

with each XX failure of the above list :

ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>, SYNCHRONIZATION<CALL>)

If(2) XX has a pending status

Then(2)

bit 1 of STATE_RBM_TOIL_STUCK = 1

Endif(2)

Endwhile

Else(1)

{ the dynamic failure memory is empty }

No action

Endif(1)

Every 1 s :

If bit 0 of STATE_RBM_TOIL_STUCK = 0
Then
If LV_END_DIAG_TOIL_STUCK = 1
Then
bit 0 of STATE_RBM_TOIL_STUCK = 1
Endif
Endif

If bit 1 of STATE_RBM_TOIL_STUCK = 0
Then
If LV_ERR_TCO_EL = 1 **or**
LV_ERR_TCO_GRD = 1 **or**
LV_ERR_TCO_PLAUS = 1 **or**
LV_ERR_TCO_STUCK = 1 **or**
LV_ERR_TOIL = 1 **or**
LV_ERR_TOIL_PLAUS_L = 1 **or**
LV_ERR_TOIL_PLAUS_H = 1 **or**
Then
bit 1 of STATE_RBM_TOIL_STUCK = 1
Endif
Endif

No specific condition for TOIL_STUCK :

bit 2 of STATE_RBM_TOIL_STUCK always equal to 1

Calculation of actual RBM rate (for application purposes)

If CTR_CDN_RBM_TOIL_STUCK = 0
then RATE_RBM_TOIL_STUCK = FFFFH
else RATE_RBM_TOIL_STUCK
= (CTR_COMP_RBM_TOIL_STUCK / CTR_CDN_RBM_TOIL_STUCK)
endif

A.84 Differential Tank Pressure Sensor Diagnosis (DTP)

A.84.1 General activation condition

Input data:

C_CONF_DIAGCP			

Application conditions:

Activation: C_CONF_DIAGCP ≠ 0

Deactivation: C_CONF_DIAGCP = 0

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the differential tank pressure sensor output signal. Additional to a short circuit or a line break it could occur that the chip inside the pressure sensor fails and the signal which is then provided at the sensor output could be in the valid range, but it is not fluctuating anymore. To detect this failure the plausibility of the signal is checked by looking at the maximum fluctuation.

The DTP diagnosis is performed by three errors**.**

Electrical error:

"DTP Short to Ground" :**MIN_DTP (ABC)**

"DTP Short to Plus or line break" :**MAX_DTP (ABC)**

Plausibility error:

"DTP signal not plausible" :**PLAUS_DTP (STC)**

Noisy error:

"DTP signal Noisy":**NOISE_DTP (STC)**

Freeze frame, DTC, error code number, symptom number, recurrence, CARB-Info, Successive error management and data for MIL-management see chapters for general diagnosis informations.

A.84.2 DTP electrical diagnosis and SOV stuck diagnosis:

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_DTP_EL	V/O	0...1H	0...1	1	-
Boolean for error currently present on differential tank pressure sensor (Electrical Diagnosis).

Diagnosis condition for electrical diagnosis (DTP_MIN and DTP_MAX)					
ERR_SYM_DTP_EL	V/O	0H 1H 2H	NO_SYM SYM_0 SYM_1	1	-
Detected error symptom DTP_EL diagnosis					
LV_END_DIAG_DTP_EL	V/O	0...1H	0...1	1	-
End of electrical diagnosis (DTP_MIN and DTP_MAX) diagnosis					

Input data:

CONF_DIAGCP	LV_CDN_VB_OBD2	LV_IGK	V_DTP
DTP			LV_ERR_VCC_SENS_SUB

Description:

Error-symtoms are defined to this diagnosis function as following :

Short circuit to Vbatt or open line (= SYM_0)
Short circuit to GND (= SYM_1)

Remark: Calculation of LV_END_DIAG_DTP_EL see generic calculation “End of diagnosis” in anti bounce algorithm.

Application conditions:

Initialisation: at new DC

- LV_ERR_DTP_EL = 0
- LV_ERR_MEC_SOV = 0

Recurrence:

- 40ms,

Activation:

If LV_IGK = 1
and LV_CDN_VB_OBD2 = 1
and CONF_DIAGCP > 0
and LV_ERR_VCC_SENS_SUB = 0
and LV_ERR_MEC_SOV = 0

then the diagnosis for the symptoms ´**MIN_DTP**´ and ´**MAX_DTP**´ is **available**

else the diagnosis for the symptoms ´**MIN_DTP**´ and ´**MAX_DTP**´ is **not available**

Symptom 'Signal Line Short to Battery voltage' or 'Signal line break' ***MAX_DTP****:*

If V_DTP > C_V_DTP_MAX_DIAG

then 'Signal line short to battery voltage' or 'Signal line break' is detected

and Symptom **MAX_DTP** is active, anti bounce counter is incremented

and ERR_SYM_DTP_EL = SYM_0

and LV_ERR_DTP_EL = 1 (after debounce)

Symptom 'Signal line short to ground' ***MIN_DTP****:*

elseif V_DTP < C_V_DTP_MIN_DIAG

then 'Signal line short to ground' is detected

and symptom **MIN_DTP** is active, anti bounce counter is incremented

and ERR_SYM_DTP_EL = SYM_1

and LV_ERR_DTP_EL = 1 (after debounce)

else

then symptom **MAX_DTP** and **MIN_DTP** are inactive

and ERR_SYM_DTP_EL = NO_SYM

and LV_ERR_DTP_EL = 0 (after rebounce)

endif

Remark : For the calibration data for SOV stuck, refer to 'Charcoal-canister shutoff valve (SOV) stuck' chapter

- If no symptom is active, anti bounce counter is decremented

Anti-bounce counter increment: C_ABC_INC_DTP_EL
Maximum value of anti-bounce counter: C_ABC_MAX_DTP_EL

Calibration data:

LV_CDN_VB_OBD1	LV_ERR_TAM	LV_END_DIAG_VAP_LEAK_10	LV_END_DIAG_FUC_MISS

Description:

Error-symtoms are defined to this diagnosis function as following :

DTP signal not plausible (= SYM_0)
DTP signal not plausible high (= SYM_1)
DTP signal not plausible low (= SYM_2)

Remark: Calculation of LV_END_DIAG_DTP_PLAUS(_H/_L) see generic calculation "End of diagnosis"

Application conditions:

Initialisation: at new DC

- LV_ERR_DTP_PLAUS = 0
- LV_ERR_DTP_PLAUS_H = 0
- LV_ERR_DTP_PLAUS_L = 0
- LV_DTP_PLAUS_READY = 0 (DTP Plausibility runs every DC)
- LV_DTP_PLAUS_H_READY = 0
- LV_DTP_PLAUS_L_READY = 0

Recurrence: 1 sec

After engine start both the minimum and the maximum value of V_DTP are monitored. If all conditions for the Plausibility Diagnosis are fulfilled, the difference between the minimum and the maximum value of V_DTP is compared with a threshold.

- Determination of signal fluctuation:

1. Initialization: (at ECU reset) V_DTP_MAX_DIAG = 0V (0 hex)
V_DTP_MIN_DIAG = 4.995V (3FF hex)

2.Initialization: (one second after ECU reset) V_DTP_MAX_DIAG = V_DTP
V_DTP_MIN_DIAG = V_DTP

All following calculations must only be done after 2. Initialisation of V_DTP_MIN/MAX_DIAG.

- MIN / MAX determination of V_DTP:

If V_DTP_n > V_DTP_MAX_DIAG
then V_DTP_MAX_DIAG = V_DTP_n

If V_DTP_n < V_DTP_MIN_DIAG
then V_DTP_MIN_DIAG = V_DTP_n

Activation 1 : for DTP stuck

If LV_DTP_PLAUS_READY = 0

then **If** LV_ST_END = 1

and CONF_DIAGCP > 0

Input data:

LV_ST_END	CRU_SWI_DRIV_STATE	LV_IGK	CRU_BAS
STATE_CRU	CONF_CRU		

FUNCTION DESCRIPTION:

General Information:

The purpose of the diagnosis is to detect faults in the cruise switches. The signal of the cruise switches are checked for stuck position of the button for the SET/COAST and RES/ACC switches. Invalid voltage ranges and short circuit to positve, are also checked on the LAV since the switches are directly wired to the ECU.

Description:

The bits carrying the error-symptom is described in "Table of failure chapter" as well as the ABC counter type.

Application conditions:

Initialisation: by ERRM: all 0 according filter type

Recurrence: 100ms

Activation: (LV_IGK = on (key on) **and** LV_ST_END = 1 (out of start phase)
and LC_ERR_CRU_SWI_AUTH = 1 **and** CONF_CRU = 1)

Deactivation: LV_IGK = off (key off)
at deactivation: LV_CDN_DIAG_CRU_SWI_1/2/3 = 0

Formula section:

Input data:

LV_IGK	LV_IM_CS_PN	N_32	LV_AT
MAF	VS	C_VS_MIN_RUN	LV_ERR_MWSS
LV_ERR_VS	LV_ST	LV_ES	CONF_CRU

FUNCTION DESCRIPTION:

General information:

This module performs the diagnosis of the clutch switch. This is valid only in case of manual transmission and if vehicle is equiped with cruise-control.

The diagnosis is based on the verification of the presence of the expected clutch action to shift the gears necessary to bring the vehicle to a certain speed. It is highly improbable that the vehicle is accelerated several consecutive times to a certain speed with the clutch always depressed or never depressed.

Description:

If there's a a change in LV_IM_CS_PN, the CS is diagnosed as error-free and the diagnosis is switched off if end of diagnosis is reached.

If there's no change in LV_IM_CS_PN then each time the vehicle is stopped, the diagnosis is enabled. Until the vehicle gets to a certain speed, LV_IM_CS_PN is monitored for value change (clutch pedal actuation). If, for several times (Anti bounce is inrementing by one inrement per diagnosis cycle) the vehicle gets to speed and the clutch switch state has never changed (always 0 or 1) then a failure is recognized.

Depending of status LV_IM_CS_PN 0/1 at beginning of monitoring period there is the symtom OL/SCB or SCG.

Application conditions:

Initialisation: according filter type: ***"STD-INI",***
all other outputs 0 at LV_IGK 0->1 **or** reset **or** at clearing error memory

Recurrence: 1s (10 ms for LV_IM_CS_PN detection)

Activation:

If	LV_IGK = 0	**or**	
	LV_ES = 1	**or**	
	LV_ST = 1	**or**	
	LV_AT = 1	**or**	
	CONF_CRU = 0	**or**

Import actions:

ACTION_ERRM_FilterMulticondition(IN <XX>, IN <cdn_diag_XX>, IN <err_diag_XX>, IN <c_abc_inc_XX>, IN <c_abc_max_XX>, OUT <lv_err_XX>)
This action computes the elementary anti-bounce filter for one failure treatment and returns filter result
ACTION_ERRM_GetErrSym(IN <XX>, OUT <err_sym_XX>)
This action returns the error-symptom
ACTION_INFR_GetElDiagEl_rcl_acr(OUT <CDN_DIAG_EL_RCL_ACR>, OUT <ERR_DIAG_EL_RCL_ACR>)
This action reads the failure and the conditions information for each symptom from the infrastructure

A.88.1 General information

The RCL actuator is driven by the ECU via an output driver. The failure detection is done by ECU hardware. The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_EL_RCL_ACR executions, to avoid the usage of wrong infrastructure information.

Error-symptoms and conditions are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> SYM_0: Short circuit to battery (SCP)
 │ │ └───> SYM_1: Short circuit to ground (SCG)
 │ └─────> SYM_2: Open circuit (OC)
 └───────> SYM_3
```

Configuration for diagnostic symptoms:

Diagnostic **RCL Actuator**	**Symptoms**	**Nb**	**Filter type**
RCL actuator diagnosis	SCP	*0*	*MPL_STD_INI*
	SCG	*1*	
	OC	2	
		3	

The data LV_END_DIAG_EL_RCL_ACR and LV_CDN_DIAG_EL_RCL_ACR are not present in output data, since they are not used by other functions. Nevertheless; they are provided in error management and always visible.

The error management variables are initialized according to filter type.

- The antibounce type may be changed by the project.
- The recommended P-code value may be the P-code defined by the Carb. The project may changed this parameter if the customer or the project decides to take into account others values.
- The failure class parameter allows to configure the behaviour of the error management for this failure. This value may be recommended and the customer or the project decides to take into account others values.
- The failure class are described in the specification Failure Class.

Application assistance:

In case of the function is declared damaged by the diagnosis then the impacted function or diagnosis must be taken into account (applied a correction or a limphome for the concerned function and inhibed the concerned diagnosis).

List of impacted functions and diagnoses :

A.89.3 RBM interface for RCL Plausibilty - stucked close - diagnosis:

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the RCL plausibility - stuck close - monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_PLAUS_CLOSE_RCL data.

Within STATE_RBM_PLAUS_CLOSE_RCL, three different informations are defined:

_ Conditions for monitoring are met long enough to detect malfunction (bit 0)
(no intrusive operation, no short trip)
_ Monitor disabled because of system malfunction (bit 1)
(depending on failure status: pending)
_ Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_CLOSE_RCL = 0
at LV_DC 0 → 1 transition :
bit 0, bit 1 and bit 2 of STATE_RBM_PLAUS_CLOSE_RCL = 0
on failure memory reset :
bit 1 of STATE_RBM_PLAUS_CLOSE_RCL = 0

Recurrence: **1 s**

Activation: LC_TCHA_CONF =1 **And** (LV_DC 0 → 1 transition **Or** LV_DC = 1)

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

{ Specific, the project shall list hereafter all failures that can inhibit the RCL plausibility - stuck close - monitor }
