FUNCTION DESCRIPTION:

General information:

The function provides a feedback about the actual camshaft position relative to the engine position measured with the crankshaft sensor. The signals of one, two or four camshaft sensors are treated (intake and/or exhaust camshaft on one or two cylinder banks).

The actual engine position is captured with every camshaft signal edge. The camshaft position is calculated as the difference between the captured engine position, and the engine position measured on the respective camshaft. The difference may be due to tolerances, or due to an intentional displacement by a camshaft phasing system (VVTI).

Two different adaptive learning algorithms eliminate the tolerances, in order to measure exactly the VVTI displacement.

The reference position adaptation is done for all signal edges. It is performed on all intake camshafts as long as LV_DI_AD_REF_CAM_IVVT_IN = 0. It is performed on all exhaust camshafts as long as LV_DI_AD_REF_CAM__IVVT_EX = 0. The camshafts are then situated in their respective VVTI passive positions. After the completion of the adaptation LV_AD_END_CAM_IN(EX)[i] is set and PSN_AD_CAM_IN(EX)[i] is calculated as the mean value of all adaptated signal edges. The reference edge has the index 1. It is the first electrical falling edge of the camshaft signal after TDC0.

The position of other signal edges is adapted continuously relative to the reference signal edge, in order to always deliver a coherent position information.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Both adaptation algorithms are performed only at a limited dynamic variation of the camshaft position measured at the reference edge.
The logical calibration bit LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] is set if the VVTI system is inhibited on the corresponding camshafts. The respective camshafts will be treated like being constantly in the VVTI passive position. If an engine has more camshaft sensors then VVTI actuators, then NLC_IVVT_IN(EX) = 0 indicates that VVTI is not existing on intake or on exhaust camshafts.

4.57.1 Engine Position Determination from Camshaft signal

General information:

As soon as camshaft is self-synchronized, the actual engine position is calculated at every camshaft signal edge from theorical position plus adaptation value for the actual signal edge index.
i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Recurrence : *every CAM active edge*

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]
PSN_ENG_CAM_IN(EX)[i] (n) = NC_PSN_EDGE_CAM_IN(EX)[z][i] +
PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) +
ID_CAM_PHA_COR

4.57.2 Camshaft Position Output

Application conditions:

Activation:
LV_VLD_PSN_CAM_IN(EX)[i] = 1 **And** LV_SYN_VLD = 1
Recurrence: *every update of IDX_EDGE_CAM_IN(EX)[i]*
Initialization:
PSN_CAM_IN(EX)[i] = 0
PSN_EDGE_CAM_IN(EX)[z][i] = 0

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]
PSN_EDGE_CAM_IN(EX)[z][i] = PSN_ENG_ENSD - PSN_ENG_CAM_IN(EX)[i]
In the following calculations, the resolution has to be converted:
PSN_CAM_IN(EX)[i] = PSN_EDGE_CAM_IN(EX)[z][i]
PSN_DIF_EDGE_CAM_IN(EX)[i] = PSN_ENG_ENSD (n) - PSN_ENG_ENSD (n-1)
T_DIF_EDGE_CAM_IN(EX)[i] = T_SEG_CAM_IN(EX)[i]

4.57.3 Camshaft Position Adaptation

4.57.3.1 Reference Position Adaptation

General information:

The reference position adaptation is done whenever it is not disabled by the corresponding flag from VVTI, or if there is no VVTI on that camshaft, and if the condition for limited dynamic variation of the camshaft position is true. A flag is set to signal successful adaptation.

The flag is reset when the adaptation inhibit conditions become false.

If LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1

Then LV_AD_END_CAM_IN(EX)[i] = 0

The camshaft position output value should be zero in VVTI passive position. At each ocurrence of the reference camshaft signal edge, a portion of the position deviation is added to the previous adaptation value, as long as adaptation conditions are true, this is done for all the camshaft signal edges.

If the conditions stay true for a number of revolutions, then the flag for successful end of adaptation is set (LV_AD_END_CAM_IN(EX)[i] = 1).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN(EX)_I =1 **And** LV_SYN_VLD = 1

And

LV_DI_AD_REF_CAM_IVVT_IN(EX) = 0 **Or** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 1 **Or** NLC_IVVT_IN(EX) = 0

Recurrence: every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)

Initialization:

LV_AD_END_CAM_IN(EX)[i] = 0

CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] are initialized to 0)

PSN_AD_CAM_IN(EX)[i] = Sum **(** PSN_EDGE_AD_CAM_IN(EX)[z][i]
for z = 1...NC_NR_EDGE_CAM_IN(EX) **)** /NC_NR_EDGE_CAM_IN(EX)
(resolution conversion)

LV_CAM_AD_SAVE_IN(EX)[i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, LV_CAM_AD_SAVE_IN(EX)[i] is initialized to 0)

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

At reset: CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

(All these adaptive values has to be reset in case of cam/crk mechanical change (Chain change, camshaft sensor change...))

Formula section:

If |PSN_EDGE_CAM_IN(EX)[1][i] (n) - PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| < C_GRD_AD_REF_MAX_CAM_IN(EX)

Then increment CTR_REV_AD_REF_CAM_IN(EX)[i]

The adaptation values are calculated for all indexes (for z = 1...NC_NR_EDGE_CAM_IN(EX))

PSN_EDGE_AD_CAM_IN(EX)[z][i] (n) = PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_REF_CAM_IN(EX) * PSN_EDGE_CAM_IN(EX)[z][i]

Else CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

Endif

If CTR_REV_AD_REF_CAM_IN(EX)[i] >= C_NR_REV_AD_REF_CAM_IN(EX)

Then CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

PSN_AD_CAM_IN(EX)[i] = Sum **(** PSN_EDGE_AD_CAM_IN(EX)[z][i]
for z = 1...NC_NR_EDGE_CAM_IN(EX) **)** /NC_NR_EDGE_CAM_IN(EX)
(resolution conversion)

If LV_CAM_AD_SAVE_IN(EX)[i] = 1
Then **If** |CAM_PSN_LST_REF_AD_IN(EX)[i] - PSN_EDGE_AD_CAM_IN(EX)[1][i]| < C_TOL_TOOTH_OFF_CAM_IN(EX)
Then CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

Else nothing
Endif
LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 1 *(to allow the ONE_TOOTH_OFF diagnosis only if a reference adaptation has been done after the very first one)*
Else **If** C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0
Then CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

LV_CAM_AD_SAVE_IN(EX)[i] = 1 *(set at the end of the very first reference adaptation)*
Else nothing
Endif
Endif
LV_AD_END_CAM_IN(EX)[i] = 1
Else
LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 0
Endif

If LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1
Then CTR_REV_AD_REF_CAM_IN(EX)[i] = 0
Endif

4.57.3.2 Continuous Edge Position Adaptation

The continuous position adaptation is enabled at a limited dynamic variation of the camshaft position measured at the reference signal edge.
The difference of the actual camshaft position measured at the reference edge, and the actual camshaft position measured at any other signal edge, is calculated once per camshaft revolution. That difference is multiplied with a cofficient (<<1) and added to the previous adaptation value to form the new adaptation value, which is applied in the following camshaft revolution. This way the camshaft position output value calculated at any signal edges will approach the camshaft position output value calculated at the reference signal edge.

Application conditions:

Activation:
LV_VLD_PSN_CAM_IN[i] = 1 **And** LV_SYN_VLD = 1
And
LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1 **And** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 0 **And** NLC_IVVT_IN(EX) = 1
Recurrence: *every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)*
Initialization:
PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] is initialized to 0)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

Formula section:

For the following equations, the index z of the camshaft signal edges equals IDX_EDGE_CAM_IN(EX)[i] (z=1 for reference edge). The adaptation values are calculated for all indexes from 2 to NC_NR_EDGE_CAM_IN(EX).

If |PSN_EDGE_CAM_IN(EX)[1][i] (n) - PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| < C_GRD_AD_MAX_CAM_IN(EX)
Then PSN_EDGE_AD_CAM_IN(EX)[z][i] (n) = PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_CAM_IN(EX) * (PSN_EDGE_CAM_IN(EX)[z][i] - PSN_EDGE_CAM_IN(EX)[1][i])
Endif

4.57.3.3 Reference adaptive values save authorization at Powerlatch

Before saving the adaptive values in NVMY during PWL, it is important to check if they are correct. Even if the REF_CRK_CAM error is not set, the calculated adaptive values can be wrong (for example, the error flag could have been reset on a quick key 0 to 1 transition).

Application conditions:

Activation:
ECU_STATE = PWL
Recurrence: *once during PWL, for all camshaft edges of all present camshaft sensors, before saving the NVMY adaptive values*
Initialization:
LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0

Formula section:

If PSN_EDGE_AD_CAM_IN(EX)[z][i] < - C_TOL_REF_CRK_CAM_IN(EX)
or PSN_EDGE_AD_CAM_IN(EX)[z][i] > C_TOL_REF_CRK_CAM_IN(EX)
Then LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1
Else
If LV_CAM_AD_SAVE_IN(EX)[i] = 1
And
CAM_PSN_LST_REF_AD_IN(EX)[i] <> PSN_EDGE_AD_CAM_IN(EX)[1][i]
And
C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0
Then LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1
Else *nothing, (if LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] has been set to 1 due to anyone of the camshaft edges, it must stay to 1 and the adaptive will not be saved. Contrary, if all the camshaft edges are correct, adaptive values can be saved, LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] must stay at 0)*
Endif
Endif

end

4.58.2 Dynamic engine conditions for canister purge

General information:

The limited dynamic condition for a variable exist if the current value stays inside a tolerance window. If the values of n & maf (homogeneous) rsp. n, tqi_sp_s and lamb_sp_s (stratified) stay within a window around the moving mean value of this variable for a certain time, limited dynamic is detected. C_FAC_LAM_CP_DYW should be always greater than C_FAC_LAM_DIF_MAX_CP.

Application conditions

Initialisation:

```
at RST or IGKON
   N_DYW_CP         = 0

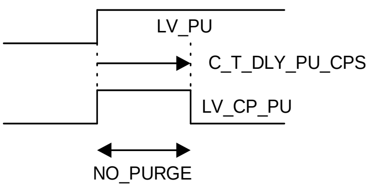
4.58.3 Trailling throttle information for canister purge

General information:

In case of trailling throttle condition LV_PU, the fuel coming from the purge could be important compared to the fuel injected. To prevent any malfunction we need to close immediatly the purge valve during a delay C_T_DLY_PU_CPS. During this time the flag LV_CP_PU is set to 1.



Application conditions

Initialisation: at RST or IGKON
  LV_CP_PU = 0
  T_DLY_CP_PU_TMP = 0

Recurrence: *called by superior block*

Activation: *called by superior block*

Deactivation: - -

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula section:

if LV_PU 0 1
then T_DLY_CP_PU_TMP = C_T_DLY_PU_CPS
else T_DLY_CP_PU_TMP = **max** (0, T_DLY_CP_PU_TMP - TA)
endif
LV_CP_PU = [*T_DLY_CP_PU_TMP* > 0]
end

4.58.4 Canister purge prohibition after "trailing fuel cut off"

After a fuel cut off phase (PUC) the engine needs a ceratain time to stabilize the air fuel ratio. During this phase the lambda controller has a deviation. To prevent that this deviation has an influence on the CL calculation, canister purge will be disabled after a PUC phase.

Application conditions

Initialisation: `at RST or IGKON`
`LV_CP_PUC = 0`
`T_DLY_CP_PUC_TMP = 0`

Recurrence: *called by superior block*

Activation: *called by superior block*

Deactivation: – –

Formula section:

if LV_PUC = 1
then T_DLY_CP_PUC_TMP = C_T_DLY_PUC_CP
else T_DLY_CP_PUC_TMP = **max** (0, T_DLY_CP_PUC_TMP - TA)
endif
LV_CP_PUC = [*T_DLY_CP_PUC_TMP* > 0]
end

4.58.5 Lambda control limitation reached

General information:

When the lambda control reaches a minimum or maximum value, the information LV_FAC_LAM_LIM_MIN rsp. LV_FAC_LAM_LIM_MAX is set. As soon as the lambda control value is again in its limits, the bit information is reset. In order to memorize this information and to wait for a lambda control value stabilized, an information is managed LV_LAM_LIM_CP.
This value is set to TRUE as long as any lambda control limit is exceeded and reset after a delay C_T_LAM_LIM_CP after the lambda control is within its limits again.

Application conditions

Initialisation: `at RST or IGKON`
`LV_LAM_LIM_CP = 0`
`T_DLY_LAM_LIM_CP_TMP = 0`
Recurrence: `called by superior block`

Activation: *called by superior block*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula section:

if LV_FAC_LAM_LIM_MIN [i] = 1 at least one bench
or LV_FAC_LAM_LIM_MAX [i] = 1 at least one bench
then T_DLY_LAM_LIM_CP_TMP = C_T_LAM_LIM_CP
else T_DLY_LAM_LIM_CP_TMP = **max** (0, T_DLY_LAM_LIM_CP_TMP - TA)
endif
LV_LAM_LIM_CP = [T_DLY_LAM_LIM_CP_TMP > 0]
end

4.58.6 Lambda control within functional window

General information:

Parallel to the observation of lamba control limits using the flags LV_FAC_LAM_LIM_MIN and LV_FAC_LAM_LIM_MAX coming from the lambda controller, the canister purge strategy provides two independent limits C_FAC_LAM_CP_BOL & C_FAC_LAM_CP_TOL.
As long as at least one lambda controller is not running in a window defined by [C_FAC_LAM_CP_BOL, C_FAC_LAM_CP_TOL] an information is set to TRUE and reset after a delay C_T_DLY_LAM_CP after all lambda controllers are within [C_FAC_LAM_CP_BOL, C_FAC_LAM_CP_TOL] again.

Application conditions

Initialisation: `at RST or IGKON`
`LV_LAM_OUT_CP = 0`
`T_DLY_LAM_OUT_CP_TMP = 0`

Recurrence: *called by superior block*

Activation: *called by superior block*

Deactivation: - -

Formula section:

if FAC_LAM_MV_MMV_CP [i] <= C_FAC_LAM_CP_BOL at least one bench
or FAC_LAM_MV_MMV_CP [i] >= C_FAC_LAM_CP_TOL at least one bench
then T_DLY_LAM_OUT_CP_TMP = C_T_DLY_LAM_CP
else T_DLY_LAM_OUT_CP_TMP = **max** (0, T_DLY_LAM_OUT_CP_TMP - TA)
endif
LV_LAM_OUT_CP = [*T_DLY_LAM_OUT_CP_TMP* > 0]
end

4.58.7 Commutation interruption management

General information:

Before a combustion commutation, the CPS valve may be closed to purge the intake manifold. A delay will be added to wait for lambda stabilisation and manifold purge. During the commutation the evaporative emission control is in state NO_PURGE

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

4.58.9 Calculation of PRS_CPS

General information:

PRS_CPS is the pressure drop over the CP system, i.e. the difference between ambient air pressure and intake manifold pressure

Application conditions

Initialisation: `at RST or IGKON`
`PRS_CPS = 0`

Recurrence: *called by superior block*

Activation: *called by superior block*

Deactivation: - -

Formula section:

```
if      LC_PRS_CPS_EXT
then PRS_CPS   = PRS_CPS_EXT
else  PRS_CPS  = AMP - MAP
end
```

4.58.10 Preselection of the canister purge state

General information:

After activation of the function (LV_CP_ACT=1) there is a continuous check of the activation conditions.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. <u>Conditions for manual mode:</u>

1. Test mode activated
   (LC_STATE_CDN_CP_MAN = 1)
   // in this case the conditions below are no more checked

STATE_CDN_CP = C_STATE_CDN_CP_MAN

<u>Conditions for immediate switch to NO_PURGE (without ramp):</u>

1. Fuel cut off active
   (LV_FCUT_IND = 1) **or**
2. Trailing throttle operation started
   (LV_CP_PU = 1) **or**
3. Prohibition after PUC
   (LV_CP_PUC = 1) **or**
4. Deactivation due to high engine speed /CPU load
   (LV_N_MAX_CP = 1) **or**
5. Difference pressure intake manifold-environment below threshold
   (relevant for supercharger engine or high engine load)
   (PRS_CPS < C_PRS_MAX_CPS_2) **or**
6. Request for fast closing from appl.inc. module
   (LV_INH_CP_FAST = 1)

STATE_CDN_CP = CDN_NO_FAST

<u>Conditions for NO_PURGE:</u>

(closing of the CPS required)

1. Conditions for NO_FAST are not fulfilled **and**
2. {canister purge manually forced to NO_PURGE
   (LC_CP_INH_MAN=1) **or**

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

3. Application incidences flag to inhibit canister purge and switch to NO_PURGE
(LV_INH_CP=1) **or**
4. NO_PURGE locked for a certain time by EVAC control
(STATE_LOCK_CP = NO_PURGE) **or**
5. Request to close CPS from OBD2 sequenceur
(LV_CP_CLOSE_REQ=1) **or**
6. Difference pressure intake manifold-environment below threshold
(relevant for supercharger engine)
(PRS_CPS < C_PRS_MAX_CPS) **or**
7. Idle speed active and ambient air temperature below threshold
(acoustic problems with the CPS at low ambient temperatures)
[(LV_IS=1) **and** (TIA_THR < C_TIA_MIN_CP)] **or**
8. Combustion commutation and stabilization
(LV_CP_CMU_CMB=1) **or**
9. Engine operation point outside CP window and NO_PURGE selected for this event
[(LV_CP_WIN = 0) **and** (C_STATE_WIN_CP_NOT = NO_PURGE)] **or**

1. Lambda controller reached limits and no purge state is desired

[(LV_LAM_LIM_CP = 1) **and** (C_STATE_LAM_LIM_CP = NO_PURGE)] **or**
11. Catalyst purge requests state NoPurge
[(LV_CP_CAT_PURGE = 1
and (LC_CP_CAT_PURGE_OFF = 1 or LV_CL_MDL_END_CAT_PURGE = 1)] **or**

STATE_CDN_CP = CDN_NO_PURGE

<u>Conditions for MIN_PURGE:</u>

1. *"hard" conditions for MIN_PURGE:*

The "hard" condtitions for MIN_PURGE force MIN_PURGE, i.e. no usage of the canister load model is possible.

LV_CP_CDN_MIN_PURGE_FAST =
1. {closed loop canister purge (“normal puge”) manually deactivated
(LC_CP_CLL_INH_MAN=1) **or**
2. Application incidences flag to inhibit normal purge and switch to MIN_PURGE
(LV_INH_CP_CLL=1) **or**
3. MIN_PURGE locked for a certain time by EVAC control
(STATE_LOCK_CP = MIN_PURGE) **or**
4. Trailing throttle
(LV_PU = 1) **or**
5. Switch for not allowing NORMAL_PURGE in stratified set
(LV_HOM_ACT=0 **and** LC_CP_CLL_S_INH=1) **or**
6. Engine operation point outside CP window and MIN_PURGE selected for this event
[(LV_CP_WIN = 0) **and** (C_STATE_WIN_CP_NOT = MIN_PURGE)] } **or**
7. Catalyst purge requests open loop
[(LV_CP_CAT_PURGE = 1) and (LC_CP_CAT_PURGE_OPL = 1)]

1. *combination of all conditions for MIN_PURGE:*

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. [Any of the "hard" conditions for MIN_PURGE is given (LV_CP_CDN_MIN_PURGE_FAST = 1) **or**
4. Lambda control in open-loop state in homogeneous mode
(LV_HOM_ACT=1 **and** LV_LAM_LSCL[i] = 0)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

(at least one bank) **or**

5. Lambda control stopped in homogeneous mode
(LV_HOM_ACT=1 **and** LV_LAM_STOP[i] = 1 **and** LV_LAM_STOP_SHO_PER[i] = 0)
(at least one bank, both conditions has to be true for one bank) **or**
6. Lambda controller reached limits and min purge state is desired
[(LV_LAM_LIM_CP=1) **and** (C_STATE_LAM_LIM_CP = MIN_PURGE)]

STATE_CDN_CP = CDN_MIN_PURGE

Conditions for RAMP_OPEN:

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. Conditions for MIN_PURGE are not fulfilled **and**
4. Limited dynamics for canister purge fulfilled
(LV_CP_DYW=1) **and**
5. [Lambda control in defined limits in homogeneous mode
(LV_HOM_ACT=1 **and** LV_LAM_OUT_CP=0) **or**
6. Lambda setpoint within defined limits in stratified mode
[LV_HOM_ACT=0 **and** (C_LAMB_SP_S_CP_BOL < LAMB_SP_S <C_LAMB_SP_S_CP_TOL)]
] **and**
7. Engine operation within CP window (LV_CP_WIN = 1)

STATE_CDN_CP = CDN_RAMP_OPEN

Conditions for RAMP_OPEN_FAST :

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. Conditions for MIN_PURGE are not fulfilled **and**
4. Limited dynamics for canister purge fulfilled
(LV_CP_DYW=1) **and**
5. [Lambda control in defined limits in homogeneous mode
(LV_HOM_ACT=1 **and** LV_LAM_OUT_CP=0) **or**
6. Lambda setpoint within defined limits in stratified mode
[LV_HOM_ACT=0 **and** (C_LAMB_SP_S_CP_BOL < LAMB_SP_S <C_LAMB_SP_S_CP_TOL)]
]

STATE_CDN_CP = CDN_RAMP_FAST

(the only difference between conditions for RAMP_OPEN and for RAMP_OPEN_FAST is the engine operation window.)

if none of the above conditions are fulfilled
STATE_CDN_CP = NO_CDN

The calculation of STATE_CDN_CP is done in the following order:

if Conditions for manual mode fulfilled
then STATE_CDN_CP = C_STATE_CDN_CP_MAN
elseif Conditions for NO_FAST fulfilled
then STATE_CDN_CP = CDN_NO_FAST
elseif Conditions for NO_PURGE fulfilled
then STATE_CDN_CP = CDN_NO_PURGE
elseif Conditions for MIN_PURGE fulfilled
then STATE_CDN_CP = CDN_MIN_PURGE
elseif Conditions for RAMP_OPEN fulfilled
then STATE_CDN_CP = CDN_RAMP_OPEN
elseif Conditions for RAMP_OPEN_FAST fulfilled

FUNCTION DESCRIPTION:

General information:

The purpose of introducing multiplexed segment-synchronous variables is to be able to watch several online-values (segment-synchronous) via only one variable during calibration. This way the number of used online-variables can be reduced during measurements while still having the possibility to measure the data of all cylinders.

Description:

E.g.: The variable IGA_0_5 shows the ignition angle of the currently firing cylinder as online-output-data by writing the different succeeding IGA-values (firing order) into the respective segments of the variable.

Action definition

ACTION_COMM_SEND_CHAL_CAN_TRIG ()	Mode: O
-	

ACTION_INTC_NO_VECH_REQ ()	Mode: O
When this action is called the service "Anfrage:Fahregestellnummer" is requested.	

General information:

The basis of this CAN communication is the specification for "BN 2000" integration revision 6.3.0 (E65) and 4.1.0 (E60). All messages are transmitted as a complete frame, that means every label which is not defined will be transmitted with its "invalid" value (not initialization value!!).

The network management is done by the standard core, so it isn t described in that document.

The allocation of the messages to the two CAN- controller follows the BMW- Excel- Sheet Verteilung_ CAN_Kanäle_2CANController.xls from 25-06-2003. The messages which are according to this sheet transmitted in channel 0 ... 13, Basic 1 and Basic 2 are sent via CAN- controller 1. The messages in channel 14 ... 27, Basic 3 and Basic 4 are sent via CAN- controller 2.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

4.60.3 Enable conditions for BN 2000 diagnosis

General information:

The CAN diagnosis for BN input messages is only to be enabled if the variant has been recognized. In case of a modul (e.g. TCS) which is not a variant but implemented in every vehicle the diagnosis is always enabled.
If BN diagnosis for message XXX is enabled (conditions see table below) then the conditions for activating the BN diagnosis have to be checked: only if LV_CDN_DIAG_BN_XXX =1 then the BN diagnosis is to be activated. For activation conditions see Chapter BN2000 diagnosis .
In the following the input messages, their keywords, the symptoms which have to be dectected (timeout, alive, checksum) and the enable conditions for each diagnosis are described.
The XXX in the Chapter BN2000 diagnosis have to be replaced by the respective keyword in the table below.
As soon as an TOUT/CKS/TCC-symptom is detected the last CAN-signals of the corresponding message are freezed until the LV_ERR_BN_xxx is debounced, no more new values are taken over. After the LV_ERR_BN_xxx is debounced the signals are set to default-values.
The diagnosis of the symptoms TOUT/CKS/TCC can be inhibited by setting the corresponding calibration constant C_CTR_DIAG_TOUT/CKS/TCC_CAN_MAX_xxx to 0. In this case the CAN-signals will be taken over.

Table of BN input messages

4.60.4 Input messages

General information:

The handling of default-values in case of a CAN-error is as follows: if one of the symptoms (timeout, alive or checksum) is detected the last received value should be freezed until the error is debounced. After debounce the respective default-value should be used until rebounce.

4.60.4.1 ACC-Modul

T_INH_ACK_IGK_OFF >= C_T_MAX_INH_ACK_IGK_OFF
Then STATE_ACK_IGK_OFF= 1
Else STATE_ACK_IGK_OFF= 0
Endif

NOTE : Bit LV_OBD_SCAN_REQ is supplied via network layer. Purpose of this part is to make sure that Kl15 will be deactivated only by pressing START/STOP button once OBD scan tool has been connected to vehicle and one of the messages in table below was sent. Switching off KL15 by power managment is not possible in this state.

Requirements for LV_OBD_SCAN_REQ :
- is initialised with "0" at reset
- after disconnecting OBD scan tool Kl15 can be switched off by pressing START/STOP button.
- is set when OBD scan tool is connected to vehicle can and one of the messages listed in table has been sent successfully once.

CAN identifier (hex)	Description
7DF	CAN identifier for functionally addressed request messages sent by the external test equipment.
7E0	Physical request CAN identifier from the external test equipment to ECU #1
7E1	Physical request CAN identifier from the external test equipment to ECU #2
7E2	Physical request CAN identifier from the external test equipment to ECU #3
7E3	Physical request CAN identifier from the external test equipment to ECU #4
7E4	Physical request CAN identifier from the external test equipment to ECU #5
7E5	Physical request CAN identifier from the external test equipment to ECU #6
7E6	Physical request CAN identifier from the external test equipment to ECU #7
7E7	Physical request CAN identifier from the external test equipment to ECU #8

4.60.7 Check Sum Calculation

FUNCTION DESCRIPTION:

The check sum calculation is additional to the "alive counter" a further possibility to supervise the data transmitted via CAN. From all safety relevant controllers, the ECU included, a check sum over all sent data including his own CAN-ID (11 bit) is calculated and sent together with the data frame. The receiver of the data frame can calculate the check sum over the received data and compare it with the received check sum. If both check sums are not the same a transmission error occured. For check sum calculation see newest BN 2000 specification.
The check sums CKS_CLC_TQ_DCC, CKS_CLC_CAS, CKS_CLC_TQ_TCS, CKS_CLC_TQ_ETCU, CKS_CLC_TQ_AMT, CKS_CLC_MSW, CKS_CLC_LDM, CKS_CLC_TQ_PSTE_3, CKS_CLC_PBR, CKS_CLC_ETCU, CKS_CLC_TQ_TCT
CKS_CLC_TQ_PBR are calculated with received data (see description below).

CKS_CLC_ECU1, CKS_CLC_ECU2 and CKS_CLC_ECU3, CKS_CLC_TQ_WHEEL_1, CKS_CLC_TQ_WHEEL_2, CKS_CLC_GS_IDC are calculated with sent data from ECU.

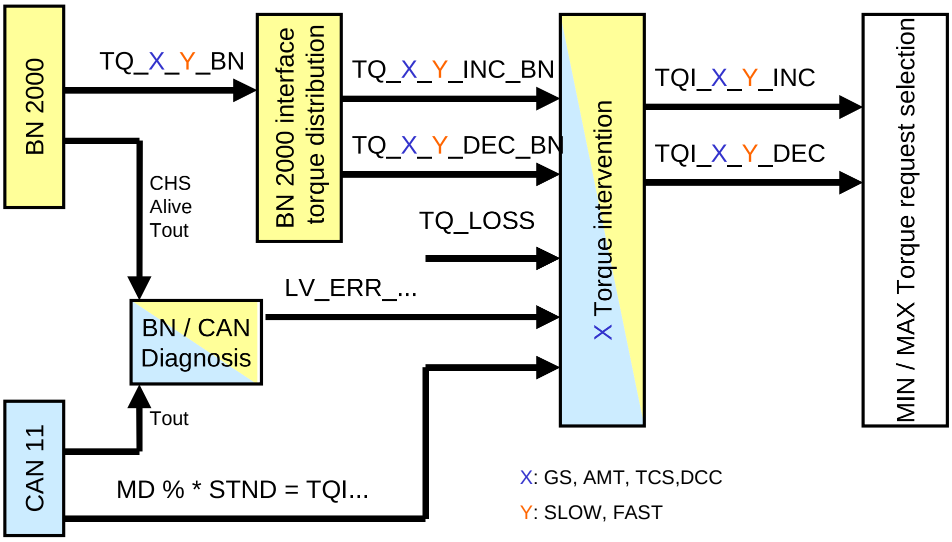
FUNCTION DESCRIPTION:

General information:

Copyright (C) Continental AG,2007

Some functions of BN 2000 contain a torque request. For the torque structure interfaces it's necessary to define the direction of torque request as increased or decreased. The BN delivers just one torque request and an additional direction information bit. This module combines the direction information bit of BN with the torque request and supported the torque structure interfaces.

Signal flow diagram:



Application conditions

Initialisation:

*TQ_**X** _FAST_DEC_BN = 1023.97Nm*
*TQ_**X** _SLOW_DEC_BN = 1023.97Nm*
*TQ_**X** _FAST_INC_BN = -1024 Nm*
*TQ_**X** _SLOW_INC_BN = -1024 Nm*
TQ_WHEEL_LDM_INC_DEC_BN = -32000 Nm
LV_RST_T_TQ_DCC_CS = 1
T_TQ_DCC_CS = 0
LV_ERR_SYM_TQ_DCC_CS = 0

Recurrence: *10ms*

Activation: *LV_VAR_BN = 1 and LV_IGK = 1*

Description:

INDEX	Functionality				
Customer	EGS	DSC	SSG	ACC	LDM
Y	ETCU	TCS	AMT	DCC	LDM
X_INC	GS_INC	MSR	AMT_INC	DCC_INC	LDM_INC _DEC
X_DEC	GS_DEC	ASR	AMT_DEC	-	-
Z	GS	TCS	AMT	DCC	LDM

(The DCC function delivers only an increased Torque request. By using this template the initialisation of LV_TQ_DCC_DEC_REQ with 0 is necessary.) Beside of this, it is necessary that under defined conditions the torque request of the DCC is controlled by the ECU.

4.62 CAN messages gateway

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_STMIN_ECU	-	0... FFH	0... 255	1	ms
STMIN for gateway from EGS to tester					

Description:

ECU is in case of 11hex gateway between EGS on PT-CAN and Tester on Lo-CAN (e.g reprogramming via tester). The table below describes the way of routing the named diagnosis messages. Routing by hardware means that the controller is used (no application software involved). Routing by software means that the related message is received and if necessary modified and than sent to designated receiver (e.g. tester).

Messages	ID	Routing by ..	Sent from..	Sent to..
Diagnosis-Messages	6F0-6FF	Hardware	Tester	EGS
Diagnosis-Messages	618	Software	EGS	Tester

Formula section:

Rule for software routing:

receive message (buffer byte 0-7)
If byte 1 of received message == 30hex (FlowControl)
Then **if** byte 3 of received message < C_STMIN_ECU (STMIN)
Then byte 3 = C_STMIN_ECU
Endif
Endif
send message (buffer byte 0-7)

4.63 Synchronisation determination in camshaft limp home

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CAM_LIH_EXT_ENA	O/V	0... 1H	0 ...1	1	-
Camshaft limp home with external help enabled					
LV_SEG_NR_UPD_REQ	O/V	0... 1H	0 ...1	1	-
SEG_NR update request					
LV_SYN_VLD_CAM_LIH	O/V	0... 1H	0 ...1	1	-
Engine synchronization determined in camshaft limp home mode					

Input data:

INH_INJ {p. 2295}	LV_VS_RUN {p. 1176}	N {p. 1525}	N_GRD {p. 1525}
NC_CAM_LIH_SWI {p. 638}	SEG_CTR {p. 1525}	SEG_NR {p. 1525}	TCO_CMN {p. 642}
VB_CMN {p. 642}			

FUNCTION DESCRIPTION:

General information:

This functions aims at initializing the variables used by ENSD or others aggregates in case no camshaft limp home method has been selected.

Description:

Application conditions

Initialisation: *none*

Recurrence: *at reset*

Activation: *NC_CAM_LIH_SWI = None*

Deactivation: *NC_CAM_LIH_SWI None*

Formula section:

LV_SYN_VLD_CAM_LIH = 0
LV_CAM_LIH_EXT_ENA = 0
LV_SEG_NR_UPD_REQ = 0

Remark: as this module is only a stub, N, N_GRD, SEG_CTR, LV_VS_RUN, INH_INJ, TCO_CMN, VB_CMN and SEG_NR are not used.

General information:

From the 6 different basic operating states only 1 can be active at the same time. So this function can be realised as a state machine. This specification describes the transition conditions.

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Initialisation:	`RST, ERU2ES, ES2ERU`
Recurrence:	`10MS, SEG`
Activation:	`10MS: always` `SEG: always`
Deactivation:	`never`

Function description:

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LV_ES is the operating state which is set during ECU initialisation.
The engine operating state Engine Stopped (LV_ES) is characterized by N_32 < NC_N_MIN. In this engine operating state, the functions are assigned to initialisation values.
The entire scope of diagnosis and actuator control is accessible.

5.2.1.1 Initilisation of Variables at Reset

LV_ES is the operating state which is set during ECU initialisation

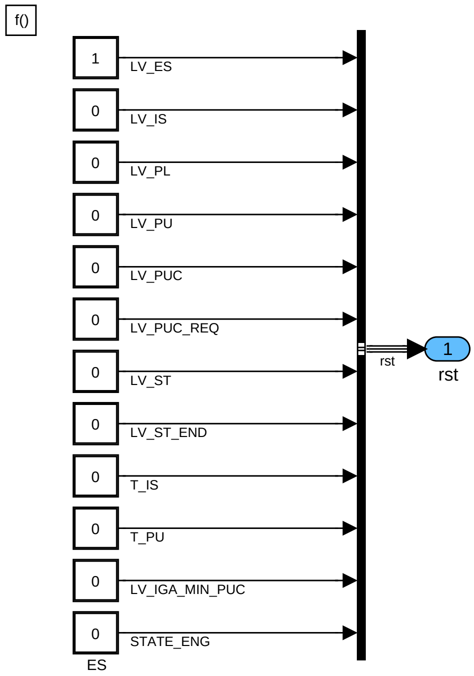

Figure 5.2.2: :

5.2.2.3.1.1 Calculation of Engine States

The State variables are calculated.
Additional calculation of LV_ST_END: The engine operating state Start (LV_ST) (cold start and hot start) is detected from all engine operating states via means of engine speed. The boolean LV_ST_END displays the transition from start to running engine .

5.2.2.3.1.1.1.1.1 Calculation of Transition Condition

Engine operating state : Idle Speed (LV_IS)The Transition condition for various To facilitate this documentation, N_SP_IS and N_DIF_MMV are described in the chapter System Variables . The following states are calculated in this part
Exit to LV_PL : Part Load, Exit to LV_PU : Trailing Throttle
states are calculated below.

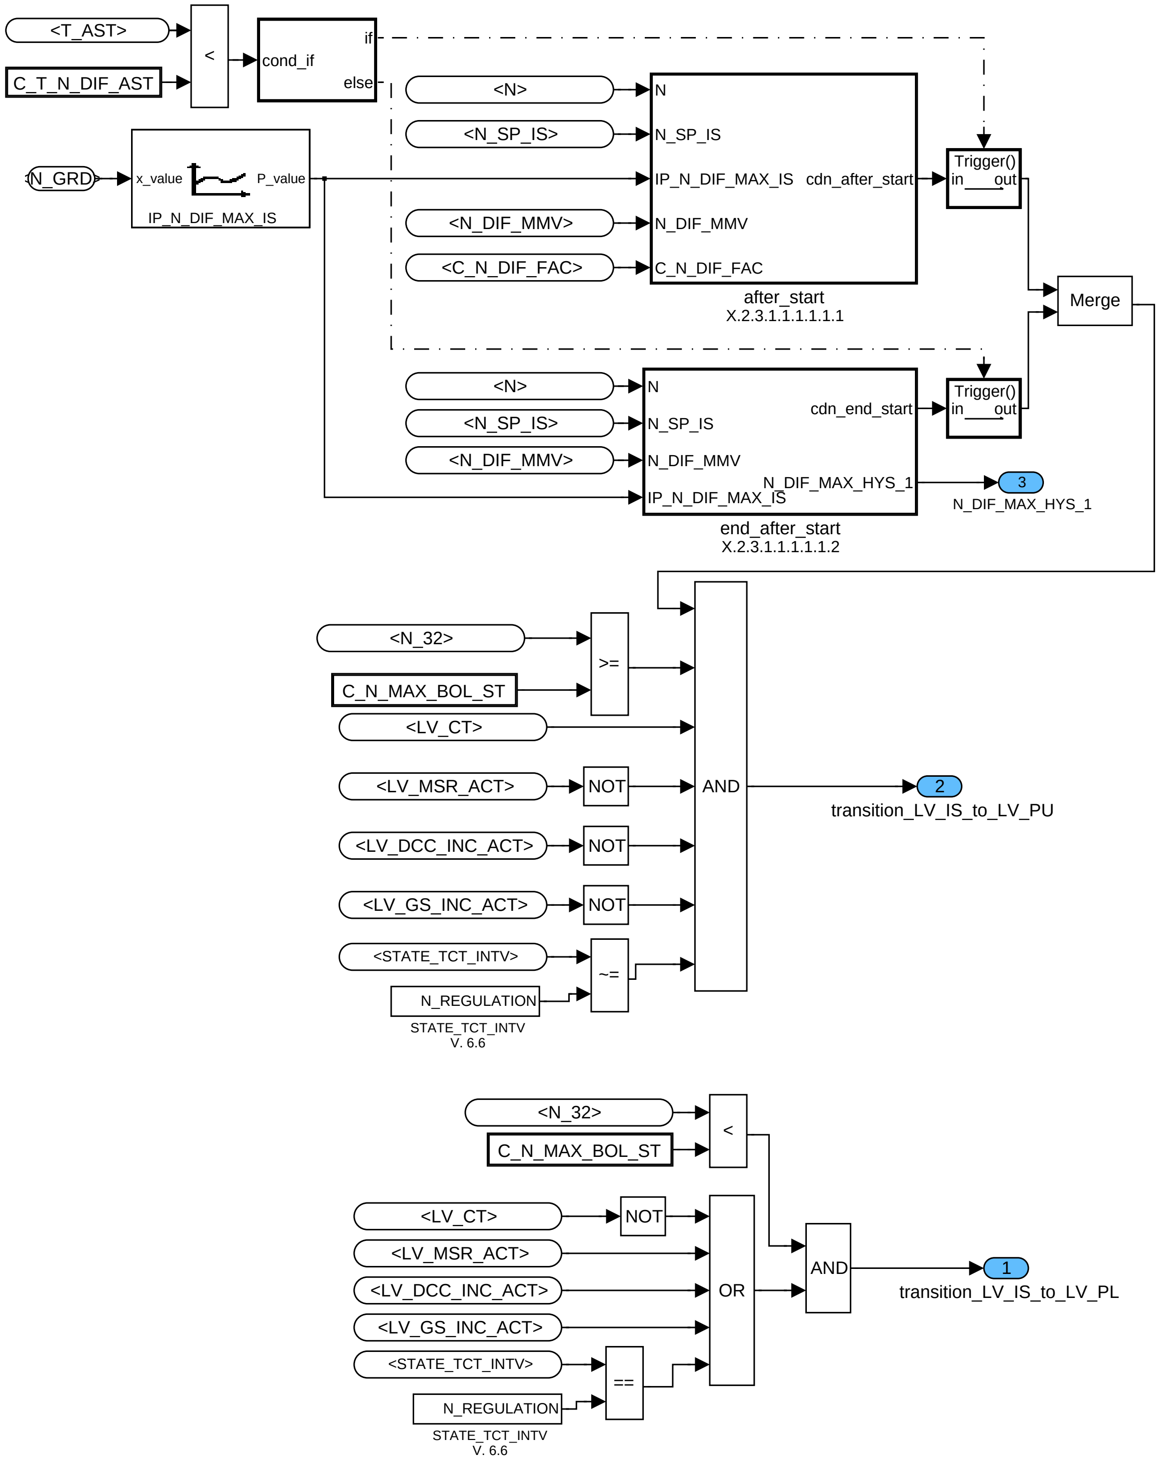

Figure 5.2.17: :

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.2.2.3.1.1.1.1.1.1 Condition 1

This condition represents AFTER START

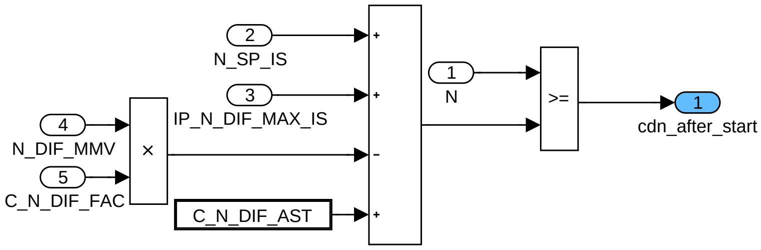

Figure 5.2.18: :

5.2.2.3.1.1.1.1.1.2 Condition 2

This condition represents END AFTER START

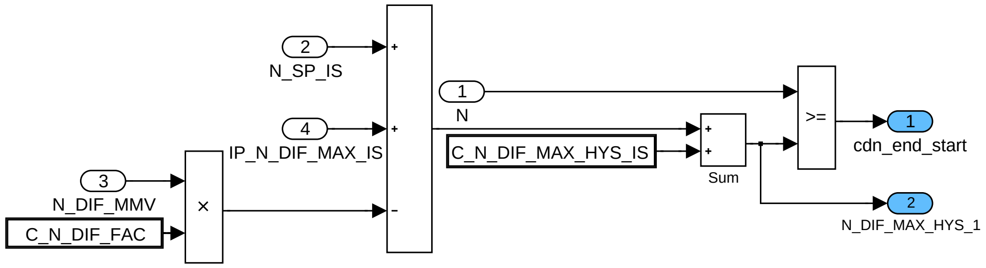

Figure 5.2.19: :

5.2.2.3.1.1.1.1.2 Engine operating state : "Part Load" (LV_PL)

To facilitate this documentation, N_SP_IS is described in the chapter System Variables . The following states are calculated in this subchapter Exit to LV_IS : Idle Speed, Exit to LV_PU : Trailing Throttle.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

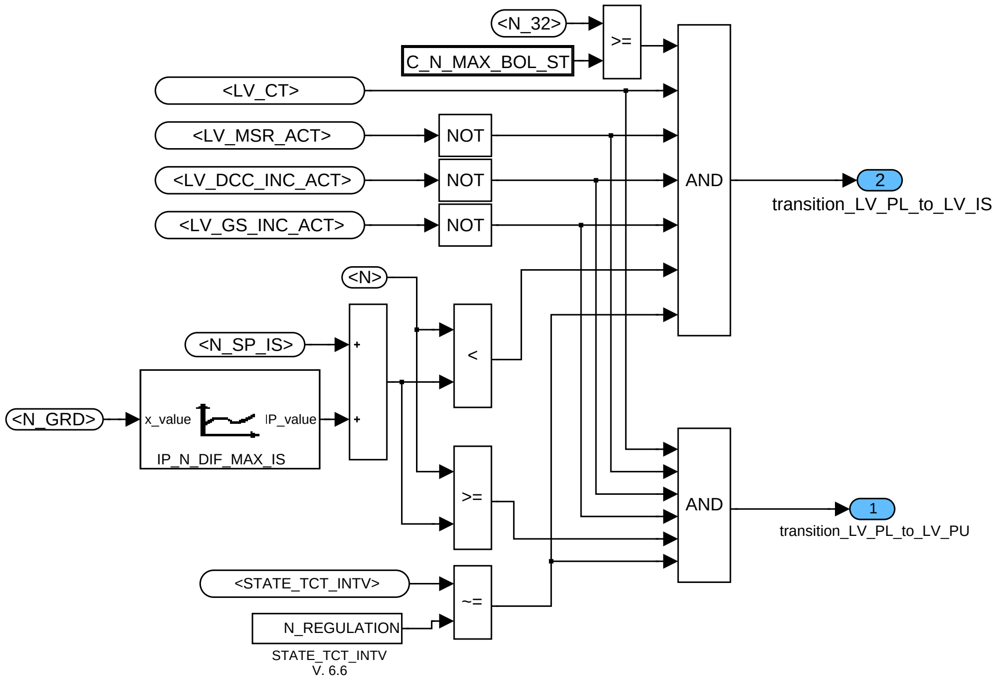

Figure 5.2.20: :

5.2.2.3.1.1.1.1.3 Engine operating state : "Trailing Throttle" (LV_PU)

To facilitate this documentation, N_GRD and N_SP_IS are described in the chapter System Variables . The following state transitions are calculated - Exit to LV_PL : Part Load, Exit to LV_IS : Idle Speed

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

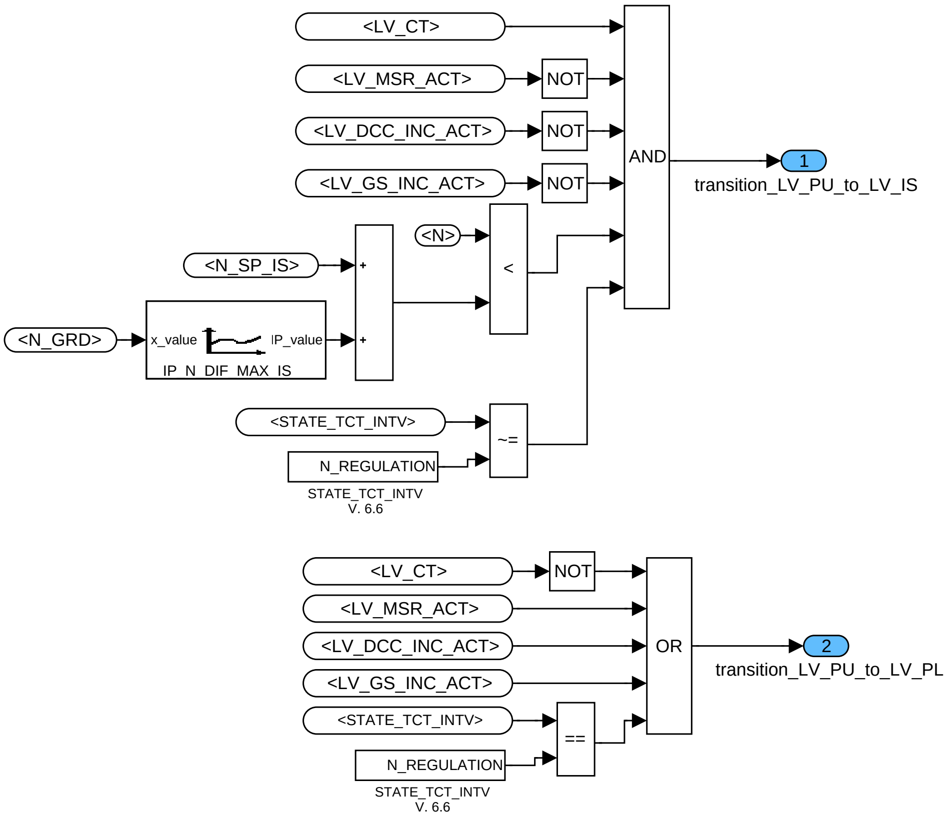

Figure 5.2.21: :

5.2.2.3.1.1.1.1.4 Exit to LV_PUC : Trailing Throttle Fuel Cut Off

After active MSR function a delay time for entrance into PUC is started to suppress a jittering of MSR function.
T_PU_MSR started at LV_MSR_ACT 1 to 0

In order to avoid a sudden entry in PUC especially for TCT variant the flag LV_CS_PUC in dependence of STATE_ETCU_CLU is defined. The driveability in stop and go conditions is improved by using a delayed clutch switch for entry in PUC.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.2.2.3.1.3 Calculation of N_HYS variables

To facilitate this documentation, N_SP_IS is described in the chapter   System Variables .
To facilitate this documentation, N_SP_IS is described in the chapter   System Variables .
The engine speed threshold for termination of PUC (reactivation of injection at decreasing engine speed) is the reactivation engine speed N_MIN_PUC. It is dependant from TCO, gear ratio, vehicle type (trans-

mission) and TQ_LOSS_ADD (additional torque losses). ARS and PSTE torque request maps remain preserved to keep the opportunity of separate treatment.

Function 'LV_PUC Hysteresis':
To avoid toggling PUC <- -> PU or PUC <- -> IS there is a hysteresis for the engine speed threshold which determines this transition. Transition from PUC when N < threshold (N_MIN_PUC); transition to PUC when N > threshold + hysteresis (N_MIN_PUC + N_HYS_ACT_PUC).
When entering Trailing Throttle Fuel Cut Off (LV_PUC), the engine speed hysteresis is set to a larger value, ID_N_HYS_MAX_PUC__GR_xx (xx = MT, AT), and a cycle counter is loaded with an adjustable number, C_CYCNR_HYS_PUC. The cycle counter is decremented once per program cycle in any engine operating state except 'Trailing Throttle Fuel Cut Off' (LV_PUC).
When the counter has reached its lower limit 0, the engine speed hysteresis is reset to the value ID_N_HYS_MIN_PUC__GR_xx. This value depends on gear GR_xx and vehicle speed VS and is the minimum engine speed hysteresis for LV_PUC. The hysteresis is reset to this minimum value also, if during counter decrementation the engine operating state changes to partload and this reset is enabled by calibration switch LC_N_HYS_CYL_CUT_OFF_xx_CONF.
If the coolant temperature is below the threshold C_TCO_MIN_PUC_ST when the engine is started, then the engine speed hysteresis for the detection of LV_PUC is increased to an adjustable value ID_N_HYS_PUC_ST__GR_xx, for an adjustable number of cycles C_CYCNR_HYS_PUC_ST. This results in faster catalyst heat-up during trailing throttle operation.
For the customer request LV_INH_PUC_CUS = 1, the engine operating state LV_PUC is inhibited.

FUNCTION DESCRIPTION:

General information:
This module is used for administration of runtime reduction and calculation optimization steps.
Pay Attention! This module has to be placed in the operating system immediately after the calculation of N_32 and SEG_NR, which are calculated by the ENSD aggregate. All aggregates, which are affected by calculation optimization, have to be calculated afterwards.

5.3.1 Runtime reduction

Application conditions

Activation : *every engine state*

Deactivation : -

Initialization:
```
at reset:  STATE_CLC_RED = NC_STATE_CLC_RED_SEG_1
CTR_CYL_NR_ST_CLC = 0
CTR_CYL_NR_STOP_CLC = (NC_CYL_NR - 1)
CTR_CBK_IN_NR_ST_CLC = 1                    (physical meaning)
CTR_CBK_IN_NR_STOP_CLC = NC_CBK_IN_NR
CTR_CBK_EX_NR_ST_CLC = 1                    (physical meaning)
CTR_CBK_EX_NR_STOP_CLC = NC_CBK_EX_NR
```

Recurrence :
```
LV_ST_END = 0:  10 ms
LV_ST_END = 1:  segment synchronous
```

This chapter describes runtime reduction steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to the intake or exhaust bank, which is allocated to the related cylinder by NC_IN_REF and NC_LAMB_REF.

5.4.1 Full Load: (LV_FL)

FUNCTION DESCRIPTION:

General information:
Main parameter for full load is an engine speed dependent load threshold. Additional parameters to disable full load are several failure conditions, coolant temperature, engine speed and vehicle speed. After fullfillment of all other conditions, the state LV_FL can be suppressed for a certain time.

Application conditions

Activation : at every engine operating state

Deactivation : -

Initialization : LV_FL and LV_FL_RAW = 0
LV_FL_1 and LV_FL_2 and LV_FL_3 = 0

Update rate : 10 ms

Formula section:

Intermediary values:
check pedal value for full load request, including hysteresis:

```
            increment timerT_TI_DLY_FL
      else    reset timer T_TI_DLY_FL
            LV_FL  =  0
      endif
else        LV_FL        =  0
endif
```

5.4.2 Intercept function : (LV_INF)

FUNCTION DESCRIPTION:

General information:

In the engine operating states trailing throttle (LV_PU) or trailing throttle fuel cut off (LV_PUC), the **intercept function(LV_INF)** can be enabled below an engine speed threshold IP_N_MAX_INF.

For this purpose, the engine speed gradient N_GRD is monitored.

If the negative engine speed gradient exceeds the adjustable constant C_N_GRD_MIN during trailing throttle fuel cut off the injection will be reactivated to counteract the high negative engine speed gradient.

Application conditions

Activation : at every engine operating state

Initialization : LV_INF = 0

Update rate : every segment

Formula section:

```
If          LV_CT          =  1              and
            N_32           <  IP_N_MAX_INF   and
            N_GRD          <  C_N_GRD_MIN
then        LV_INF     =  1
else        LV_INF     =  0
```

FUNCTION DESCRIPTION:

General Information:
Via tester an operation mode (e.g. homogenous) can be requested. This is necessary e.g. for end of line tests. This information is used in this module, to switch between several calibratable operation modes. The generated information word OPM_EXT_REQ is send to the customer software via layer.

5.6.1 Cycle counter CYC_CAST

FUNCTION DESCRIPTION:

General information:

1. CYC_CAST shows the number of 120°crk cycles that have elapsed during the actual start phase (LV_ST=1). The start value is either zero or limited by the constant C_CYC_CAST_MAX_ST_ES (if start break off was detected).
2. During actual after start phase (LV_AST from 0 to 1), the counter is reseted and restarts counting the number of cycles after start. When LV_AST is finished CYC_CAST remains at its last value.

Application conditions

Activation: *LV_ST = 1 or LV_AST = 1*

Deactivation: *LV_ST = 0 and LV_AST = 0*

Initialization: CYC_CAST = 0 at ECU-reset

Recurrence: Every TDC

Formula section:

If LV_AST 0 => 1
then CYC_CAST = 0
else if LV_ST or LV_AST is 1 and CYC_CAST $<$ 65535
then $CYC\_CAST_n = CYC\_CAST_{n-1} + 1$
else $CYC\_CAST_n = CYC\_CAST_{n-1}$
if LV_ST_ES = 1
then if CYC_CAST $>$ C_CYC_CAST_MAX_ST_ES
then CYC_CAST = C_CYC_CAST_MAX_ST_ES
endif
endif

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.6.2 Start Break off LV_ST_ES

Description:

Activation:

For *engine stall during start phase*, i.e. transition from LV_ST to LV_ES before N_32 reaching IP_N_MAX_TOL_ST__TCO, the flag **LV_ST_ES** is set to 1, if LV_ST was active for a minimum number of cycles C_CYC_CAST_MIN_ST_ES. (Hint: At the same time the counter CYC_CAST will be frozen to its actual value).

Deactivation and application:

Case 1 (start after C_T_MIN_ECU_REST elapsed or powerlatch ended):

A timer T_ST_ES is started at the transition from LV_ST to LV_ES. If the timer elapses before a new start takes place (T_ST_ES   C_T_MIN_ECU_REST), LV_ST_ES is reset and CYC_CAST is set to zero in the next start.

Application conditions

Initialisation: T_ST_ES = 0 at ECU reset

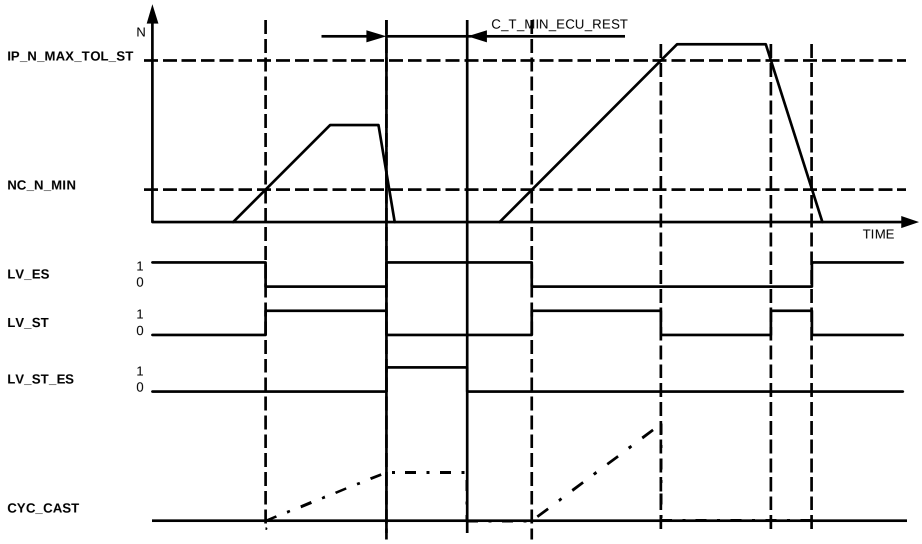
Recurrence: 100 ms

Formula section:

If transition LV_ST → LV_ES
and LV_ST_END = 0 ; eng.op.state Start *not left*
and CYC_CAST   C_CYC_CAST_MIN_ST_ES
then LV_ST_ES = 1
endif
If LV_AST   0 => 1
and LV_ST   1 => 0
or T_ST_ES   C_T_MIN_ECU_REST
then LV_ST_ES = 0
endif

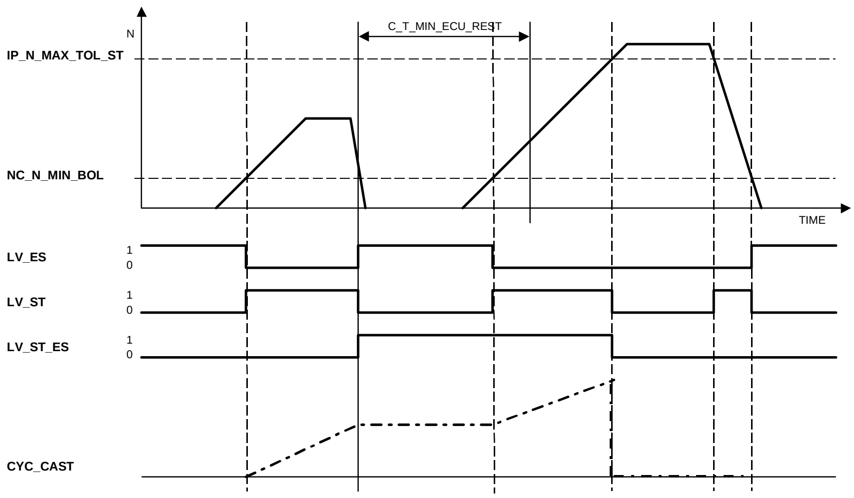
If LV_ST_ES = 1 **and** LV_ES=1
then T_ST_ESn = T_ES_STn-1 + 1
If T_ST_ES >= C_T_MIN_ECU_REST
then LV_ST_ES = 0
CYC_CAST = 0
endif
else T_ST_ES = 0
endif

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Case 2 (start within C_T_MIN_ECU_REST):

If a new start takes place before the timer has elapsed (T_ST_ES < C_T_MIN_ECU_REST), LV_ST_ES remains set until the engine operation state start is exited to part load or idle,
In this case the counter CYC_CAST starts with the previous frozen CYC_CAST-value *limited to a adjustable maximum value (see definition of CYC_CAST).*



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Remark :

If C_T_MIN_ECU_REST > C_T_MAX_ECU (power latch time) and powerlatch-phase ended the value of CYC_CAST is reseted to zero for the next engine start after “start break off”-event.

5.6.3 Restart function detection (LV_REST)

FUNCTION DESCRIPTION:

General information:

The re-start function is requested as an injection time correction during start.

- If the CAN clock timing is available LV_T_REL_CAN_REG=1 the re-start factor is calculated by TCO_STOP, T_AST_REST and T_ES (see “Fuel mass setpoint and pre-injection time calculation”).
- If the CAN clock timing is not available LV_T_REL_CAN_REG=0 the re-start factor is calculated as a substitue from IP_TI_ST_REST.

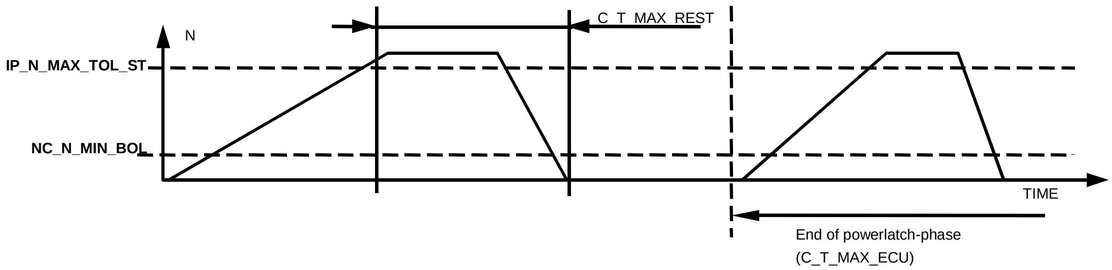
Application conditions:

Activation:
After transition from engine start (LV_ST = 1) to engine stop (LV_ES = 1) LV_REST is checked to the end of the powerlatch-phase. As the engine was operated in part load or idle before engine stop, the next start is considered as a restart if following conditions are fullfilled:

If TCO_REST $<$ FFH (no flash-error)
and TCO TCO_REST - C_TCO _DIF_MAX_REST

then LV_REST = 1
else LV_REST = 0

Therefore the restart-flag LV_REST is set to **1** before the next start, if the start happens before the end of the powerlatch-phase and the coolant temperature did not drop too much.
The calculation of start injection time deactivation factor will start with CYC_CAST = 0.



Deactivation:
A counter T_AST is started at transition LV_ST → (LV_IS or LV_PL) .
If the engine operating state engine stopped (LV_ES) is detected before the counter has reached its maximum value C_T_MAX_REST, the related coolant temperature is stored :
(TCO → TCO_REST) in a non volatile memory.

Recurrence: segment

5.6.4 Engine stall detection LV_STALL

General information:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

Engine stall detection is used for injection and CRK diagnosis.

If engine is stopped with ignition-key-on there are two different possibilities:

- Engine is stalling
- CRK error is active

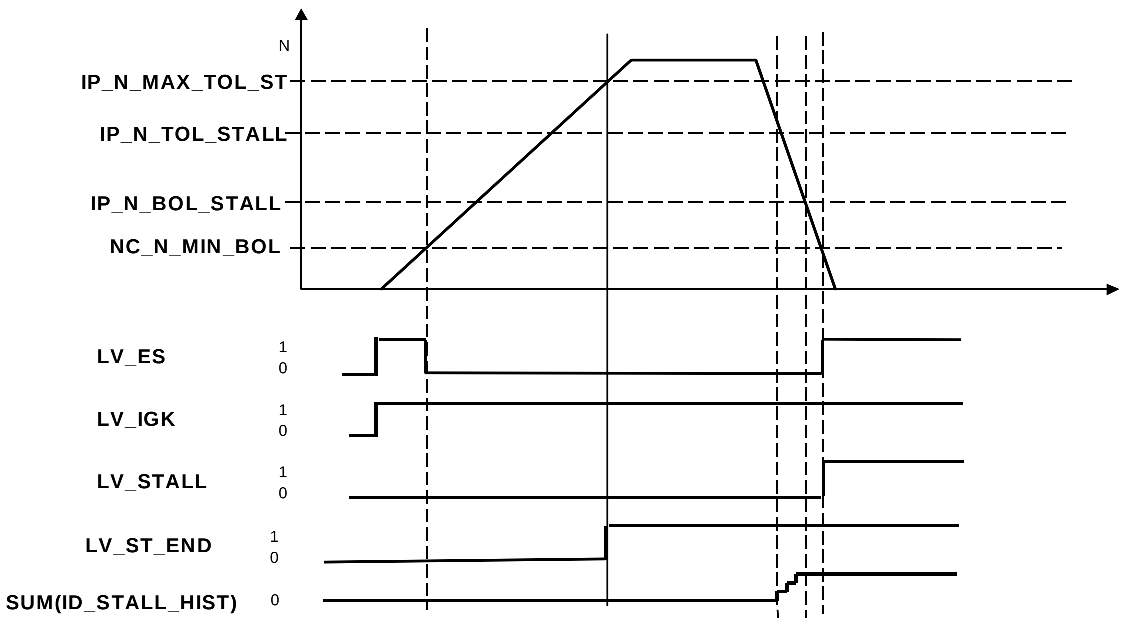
In order to detect a real engine stalling the engine speed value N_TOOTH_CUS is monitored. The reason for monitoring N_TOOTH_CUS instead of N is that N_TOOTH_CUS is calculated with a recurrency of 10ms, whereas N is calculated segment-syncronous. With engine-speed-values of $<$ 1500 rpm the segment-time increases, the resulting update-rate of N is not precise enough for the different cases of engine-stall-detection.
If a CRK error occurs N_TOOTH_CUS is set to 0. If the engine is stalling N_TOOTH_CUS is passing a defined stalling-window.

Description:

ID_STALL_HIS is a buffer for the 32 last update rates (= 320ms History).

If N_TOOTH_CUS is between IP_N_TOL/BOL_STALL then the value in the buffer is set to 1 (=true-event).
After transition from engine running (LV_ST_END = 1) to engine stop (LV_ES = 1) with **turned on ignition** (LV_IGK = 1), it is checked if the sum of true-events in the buffer is bigger then a stalling - threshold.

Signal flow diagram:



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions

Initialisation: *LV_STALL is restored out of NVMY*

Recurrence: *10ms*

Copyright (C) Continental AG,2007

Activation: *N_TOOTH_CUS < C_N_MAX_CDN_STALL* **and** *LV_ST_END = 1*

Formula section:

Reset of event-counter and ring-buffer after activation:
ID_STALL_HIS = 0
CTR_N_WIN_STALL = 0

Caclulation of LV_STALL:
if IP_N_BOL_STALL < N_TOOTH_CUS < IP_N_TOL_STALL
then ID_STALL_HIS = 1
CTR_N_WIN_STALL ++ *(stop ++ if FFH is reached)*
else ID_STALL_HIS = 0
CTR_N_WIN_STALL = 0
endif

If LV_ES 0 => 1
and LV_ST_END = 1
and LV_IGK = 1
and SUM(ID_STALL_HIS) > C_CTR_N_WIN_STALL
then LV_STALL = 1
endif

Reset LV_STALL
if LV_ST_END 0 => 1
then LV_STALL = 0
endif

5.6.5 After-Start function : (LV_AST)

FUNCTION DESCRIPTION:

General information:

The after-start function serves to supply the extra injection quantity required after start by the cold walls of the combustion chamber.
The after-start function (**LV_AST**) is requested whenever the engine exits the operating state start (LV_ST) and is executed simultaneously with other engine operating states, except engine stopped (LV_ES) and start (LV_ST).
The value of T_AST when engine stopped (LV_ES=1) - after LV_ST_END = 1 has reached once - detected is transfered in T_AST_REST and safed in the non volatile memory at the end of the powerlatch - phase.

The variable T_AST indicates the time after leaving start-state. After reaching it's maximum value, T_AST is frozen. Reset occurs with every new start (Transition from LV_ST = 0 to 1).

T_AST_DIAG is calculated from T_AST to satisfy OBD requirements: recurrency must be 500ms for input signal aquisition/diagnosis.

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Activation:

The state **LV_AST** is activated as soon as the engine operating state start (LV_ST) is exited to go to the engine operating states idle speed (LV_IS) or part load (LV_PL).

Deactivation:

TI_CAST = 0 (refer to Chapter : “ Injection “).

Recurrence:

Segment (LV_AST), 100ms (T_AST/T_AST_REST), 500ms (T_AST_DIAG)

Formula section:

If LV_ES = 0 **AND** LV_ST = 0
then
if T_AST $<$ max. Value
then increment T_AST
endif
endif
T_AST_DIAG = T_AST (physical meaning)

If LV_ES = 1 **or** LV_ST = 1 **or** LV_AST_END = 1
Then LV_AST = 0
Else LV_AST = 1
Endif

If LV_ST_END$_n$ = 0 and LV_ST_END$_{n-1}$ = 1000 **and**
LV_ES$_n$ = 1 and LV_ES$_{n-1}$ = 0
Then T_AST_REST = T_AST
Endif

5.6.6 State warm up

FUNCTION DESCRIPTION:

General information:

Calculation of state warm up. When end of warm up phase and catalyst heating is detected, LV_WUP_CAN is set to 1.

Application conditions

Initialisation: *0*

Recurrence: *100 ms*

Formula section:

IF T_AST $>$ IP_T_AST_SWI_WUP__CTR_KM_CAN **or**
TCO $>$ C_TCO_SWI_WUP
THEN LV_WUP_CAN = 1 (catalyst heating ended indication, engine at operating temperature)
ELSE LV_WUP_CAN = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.6.7 Cumulated time since engine start for OBD scan tool (PID1F)

FUNCTION DESCRIPTION:

General information:

Time after start is needed for OBD scan tool (PID1F)

Application conditions

Initialisation: `at reset or transition LV_DC = 1->0 set T_AST_SAE = 0 s`

Recurrence: *1s*

Activation: *LV_ST_END = 1*

Deactivation: *LV_ST_END = 0*

Formula section:

T_AST_SAEn = T_AST_SAEn-1 + 1s

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.7.1 Catalyst Heating functions

General information:

Logical catalyst heating variables that have been used up to now are set depending on STATE_CH.

Application conditions

Initialisation: *all outputs = 0 at ECU initialization*
Recurrence: *100 ms*
Activation: *at every engine operating state*
Deactivation: –

Formula section:

If STATE_CH = 1
Then
LV_TI_CH = 1
Else
LV_TI_CH = 0
Endif

IF STATE_CH = 1 **OR** 2
Then
LV_CH_N_SP_IS = 1
Else
LV_CH_N_SP_IS = 0
endif

5.7.2 Warm-up function : (LV_WUP)

FUNCTION DESCRIPTION:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

The injection is corrected with the warm-up enrichment.
The states warm-up (LV_WUP) and catalyst heating (LV_TI_CH) are used parallel.

Application conditions

Initialisation : LV_WUP = 1

Recurrence : once per segment (720 °crk / NC_CYL_NR)

Activation : at all engine operating states

Deactivation : TI_WUP_1_ADD = 0 (refer to chapter : " Injection "). Is activated again at STATE_ENG = LV_ES

Formula section:

```
if    LV_ES = 1
   then      LV_WUP  =  1
endif

if    LV_WUP = 1
    then     if       TI_WUP_1_ADD > 0
                  then          LV_WUP   unchanged   (stays at value 1)
                  else                   LV_WUP   =   0
                endif
    else     LV_WUP   unchanged   (stays at value 0)
endif
```

Activation of manual setting of state of cat. heating					

General Information

This module has to be calculated before any other catalyst heating module.
In this module the decision is made if catalyst heating after start, in low load or for desulfation is active.
STATE_CH indicates the actual status and triggers other modules.

Application Conditions

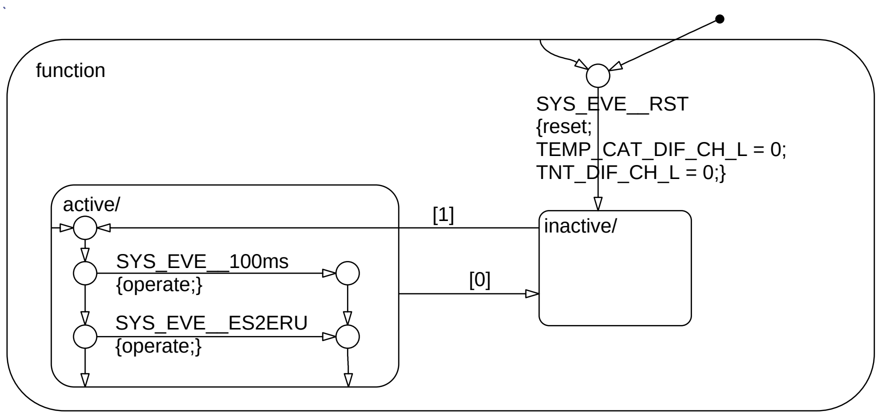

Figure 5.8.1: : Path: EXTC_ISPCLCHC0/APP_CDN/Chart

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

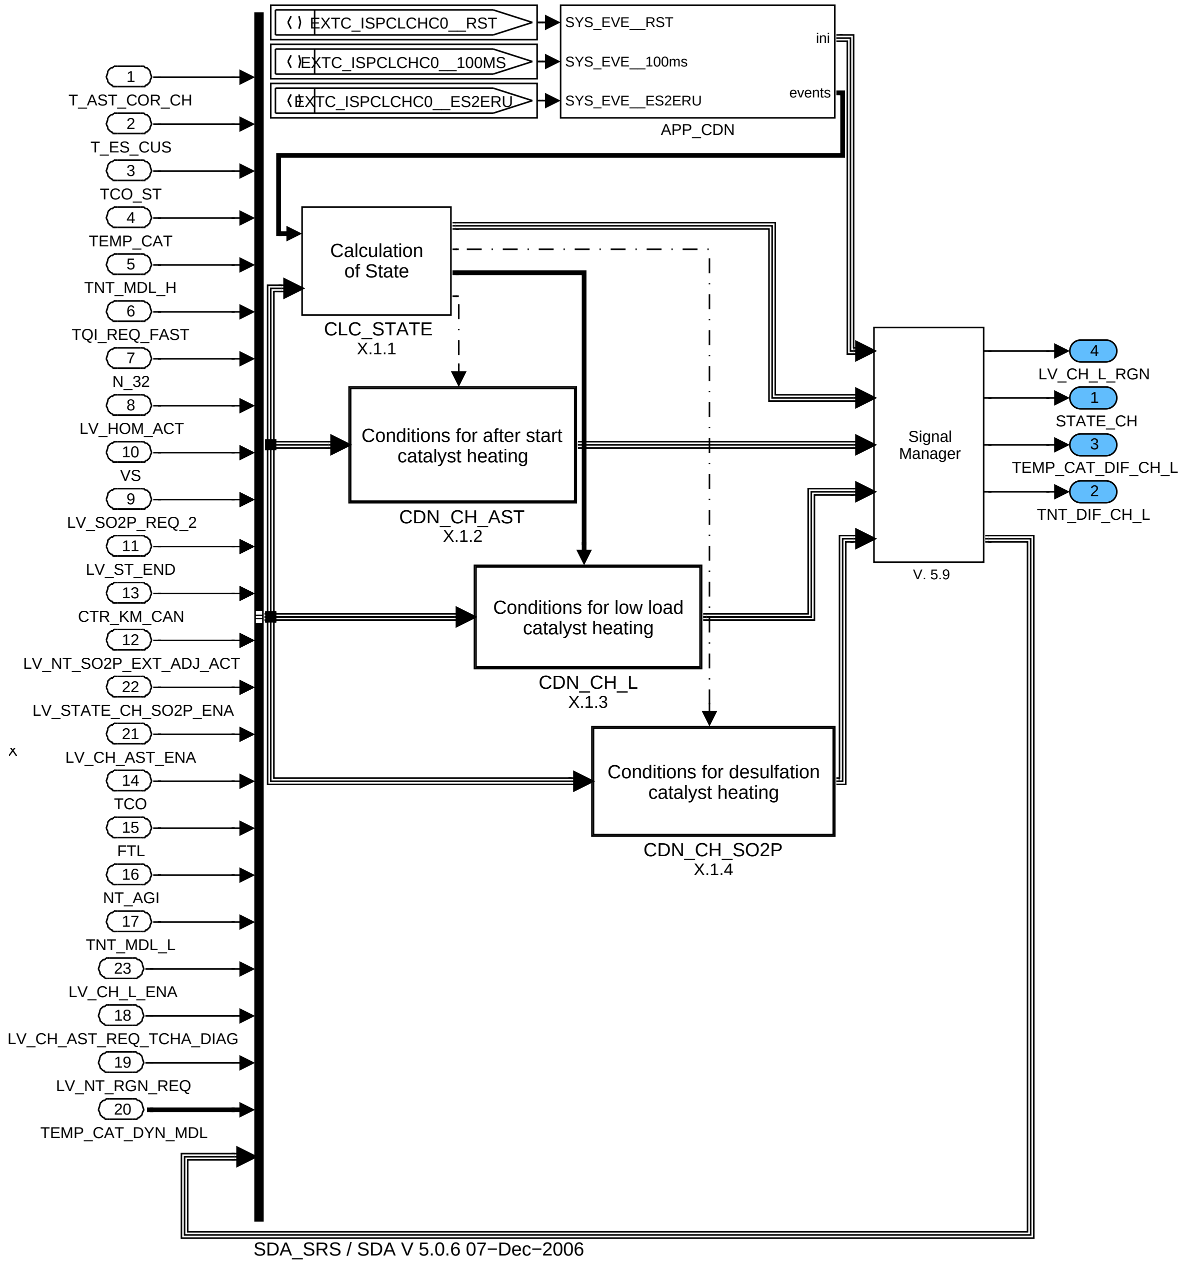

Figure 5.8.2: : Path: EXTC_ISPCLCHC0

5.8.1 State machine

5.8.1.1 State machine - Subsystem

The conditions for activation of several catalyst heating measures are not calculated if another measure is active see stateflow chart.

With to LC_STATE_CH_MAN_ACT it is possible to switch STATE_CH manually.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

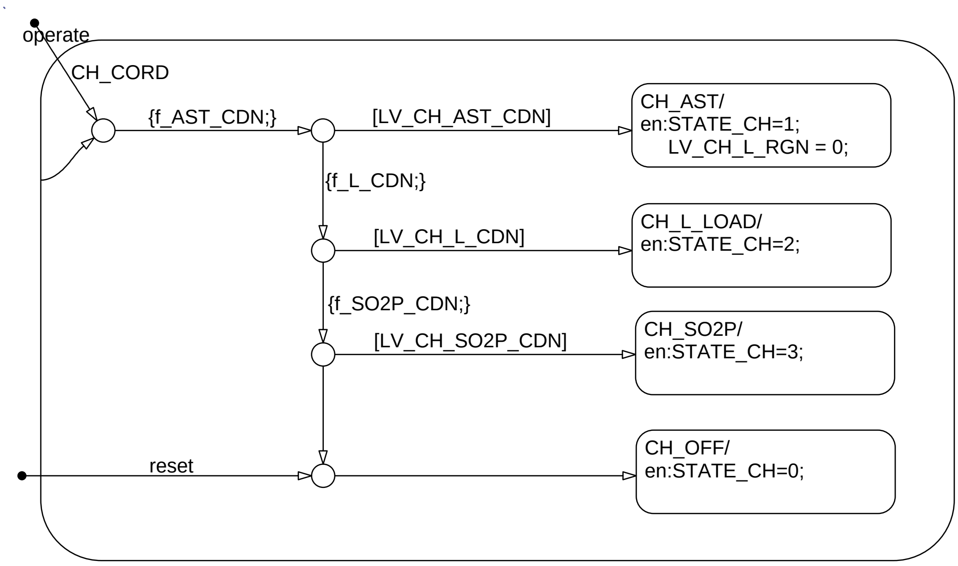

Figure 5.8.4: : Path: EXTC_ISPCLCHC0/CLC_STATE/SUB/state_machine

5.8.2 Conditions for after start heating

5.8.2.1 Conditions for after start heating - Subsystem

T_ES_CUS is the time with stopped engine. If one of the conditions stops catalyst heating, it only can be re-activated after next start.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

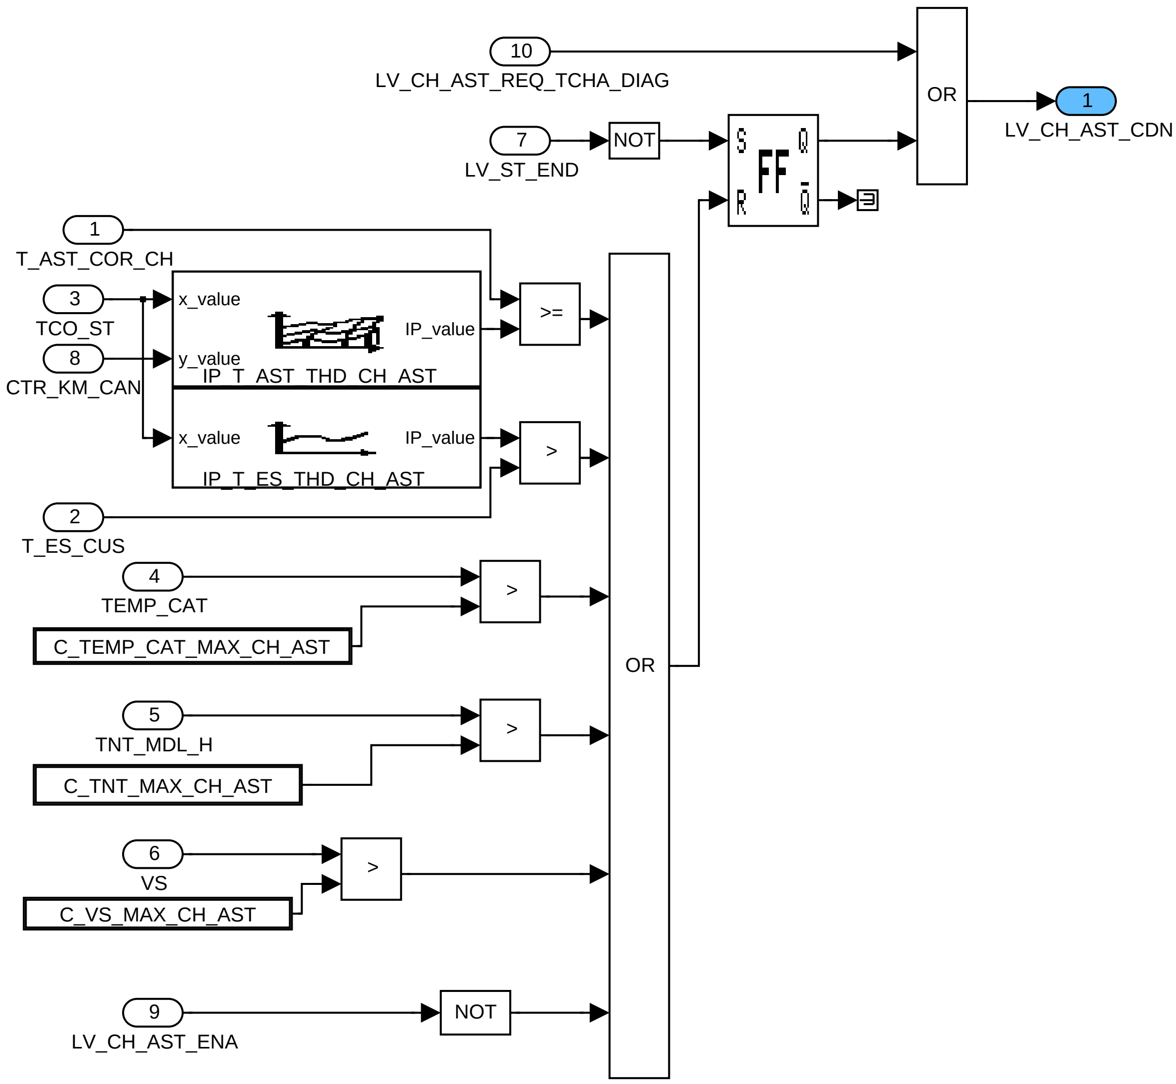

Figure 5.8.5: : Path: EXTC_ISPCLCHC0/CDN_CH_AST/SUB

5.8.3 Conditions for low load heating

5.8.3.1 Conditions for low load heating - Subsystem

TNT_MDL_L can be adjusted depending on NOx-trap aging.
Low load catalyst heating can be activated due to low temperatures in NOx-Trap or Pre-catalyst ('CH_L_CDN') or after regeneration of NOx-trap. In 2nd case the lambda-split function is activated (LV_CH_L_RGN = 1).
The differences between the actual temperatures and the thresholds TNT_DIF_CH_L and TEMP_CAT_DIF_CH_L are used as mapinputs in the setpoint calculation modules e.g. for torque reserve.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

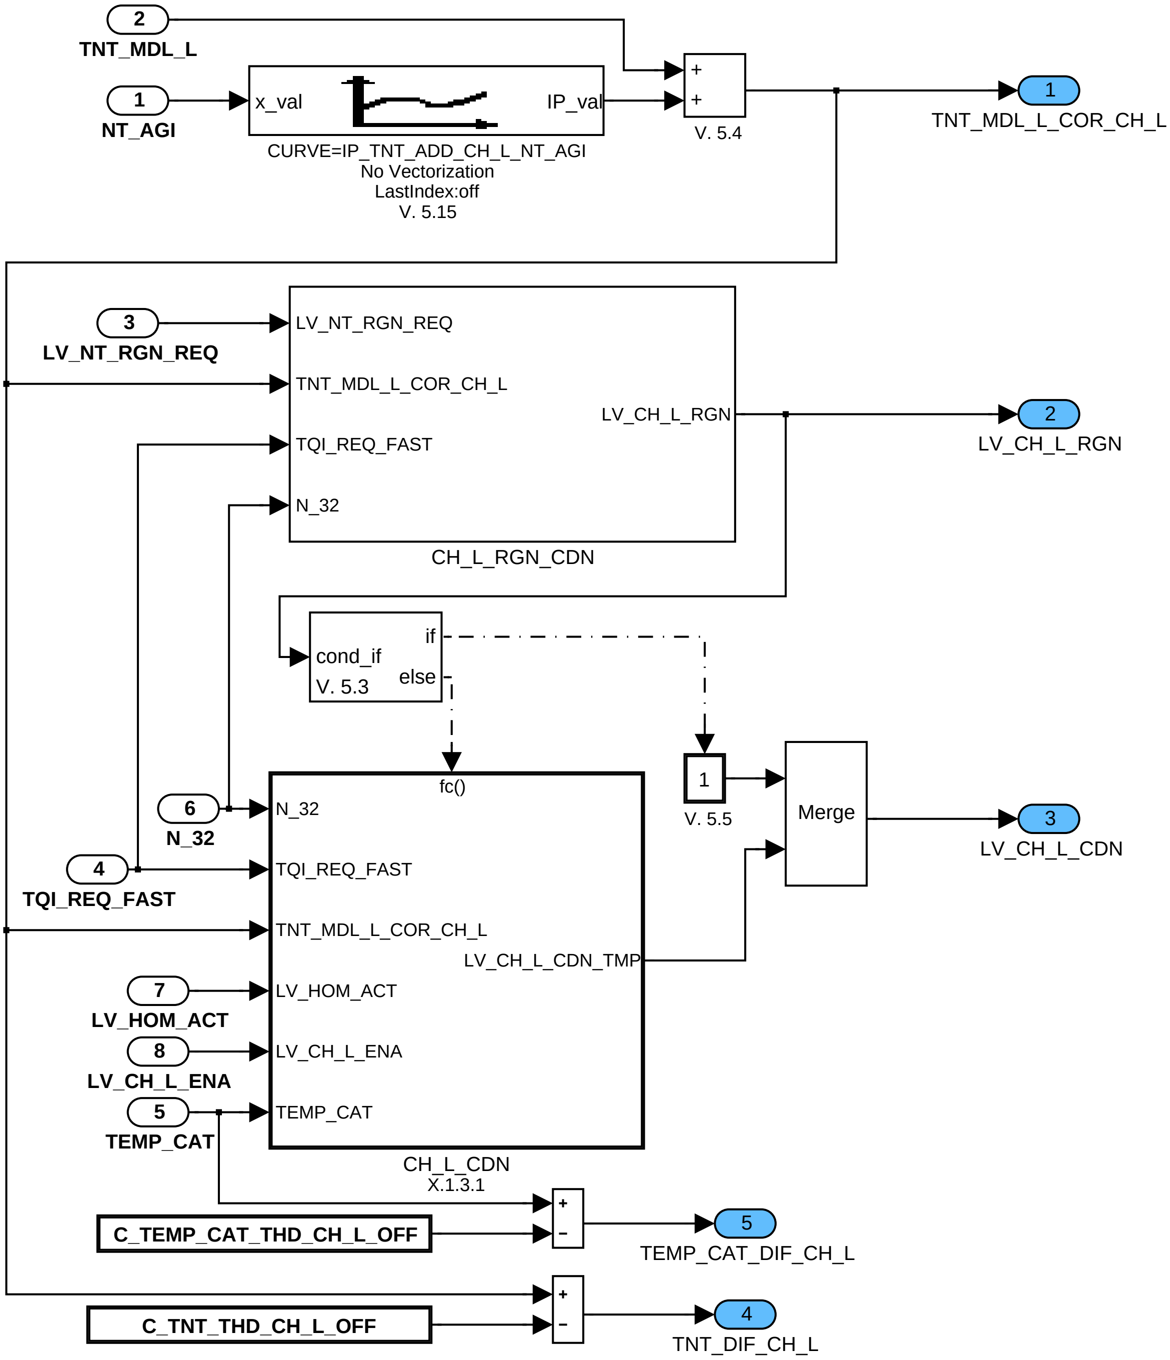

Figure 5.8.6: : Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB

5.8.3.1.1 Conditions for low load heating - Subsystem

For torque, engine speed and temperature there are each two thresholds for hysteresis application. For homogenous and stratified mode there are several activation thresholds for catalyst temperature. Attention: In low load catalyst heating one measure is to request homogeneous mode at too low temperatures! (See "Catalyst heating low load strategy"). These temperature thresholds have to be calibrated cohesive.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

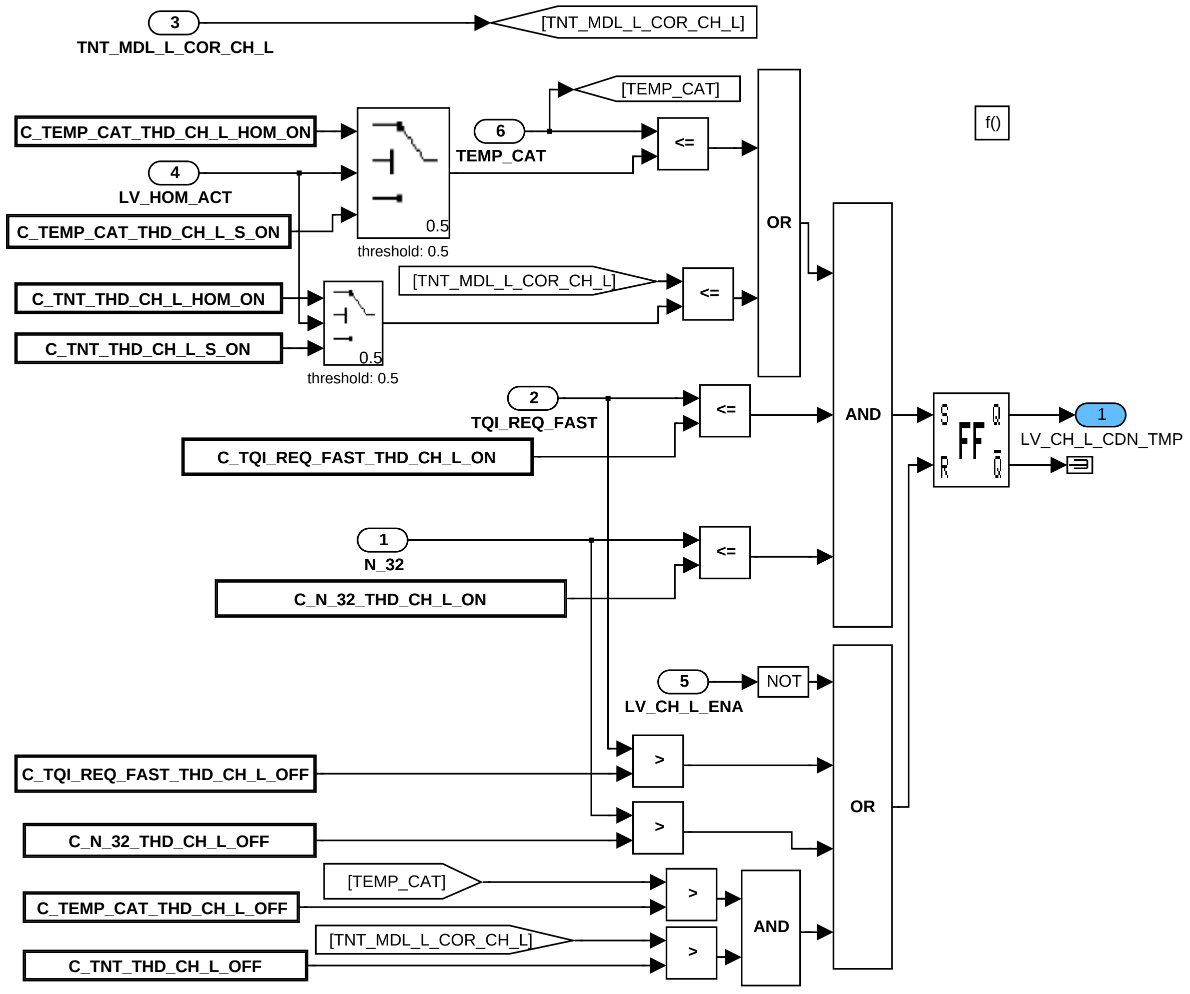

Figure 5.8.7: : Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB/CH_L_CDN

5.8.3.1.2 Conditions for low load heating after regeneratin (lambda split function)

LV_NT_RGN_REQ is 1 at active regeneration. The function can be deactivated depending on load-, temperature- or time threshold.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

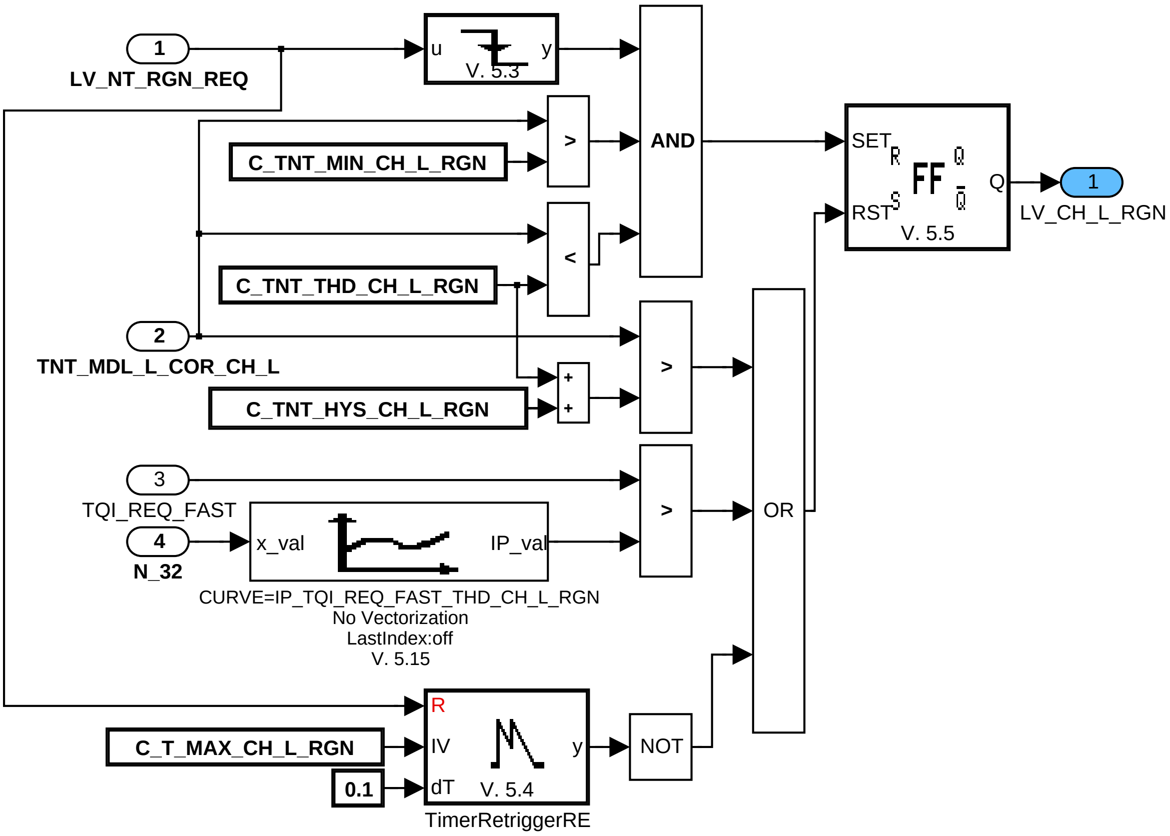

Figure 5.8.8: : Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB/CH_L_RGN_CDN

5.8.4 Conditions for desulfation catalyst heating

5.8.4.1 Conditions for desulfation catalyst heating - 1st part

Vehicle speed and requested torque are filtered to avoid often on and off switching. TCO and FTL thresholds can only be re-set at engine off.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.9.2.2 Calculation of timer and counter - for desulfation catalyst heating

CTR_CH_SO2P counts the ineffective tryings to heat up the catalyst. T_CH_SO2P_ACT is the time, the catalyst is heated without started desulfation (temperature for desulfation not reached).DIST_SO2P_END are the kilometres that have been driven since the last successful desulfation. DIST_CH_SO2P_INH are the kilometres that have been driven since the time- or counter-threshold was reached. After C_DIST_CH_SO2P_INH_MAX is reached, the timer and the counter are initialized and the catalyst is heated again.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

This modul merges the STATE_.. values from after start and low load catalyst heating.

Application Conditions

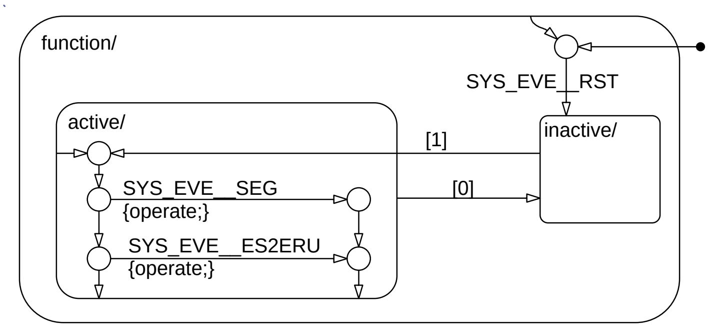

Figure 5.10.1: : Path: EXTC_REQCOMOD0/APP_CDN/Chart

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

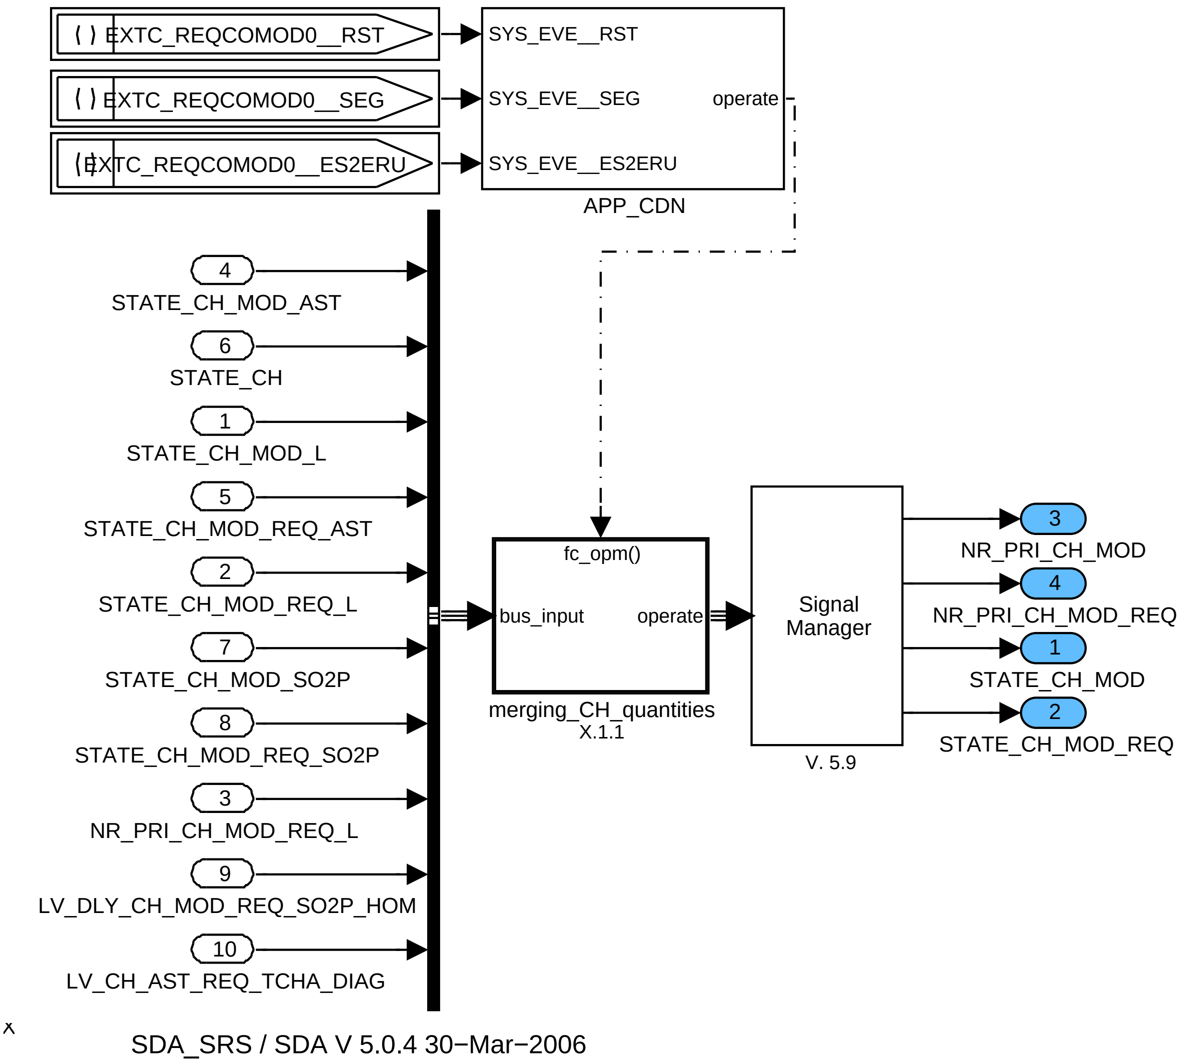

Figure 5.10.2: : Path: EXTC_REQCOMOD0

5.10.1 Operate Subsystem

5.10.1.1 Generation of STATE_CH_MOD

STATE_CH indicates the actual active catalyst heating state CH_AST, CH_L_LOAD or CH_SO2P. STATE_CH_MOD is set to the corresponding value.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

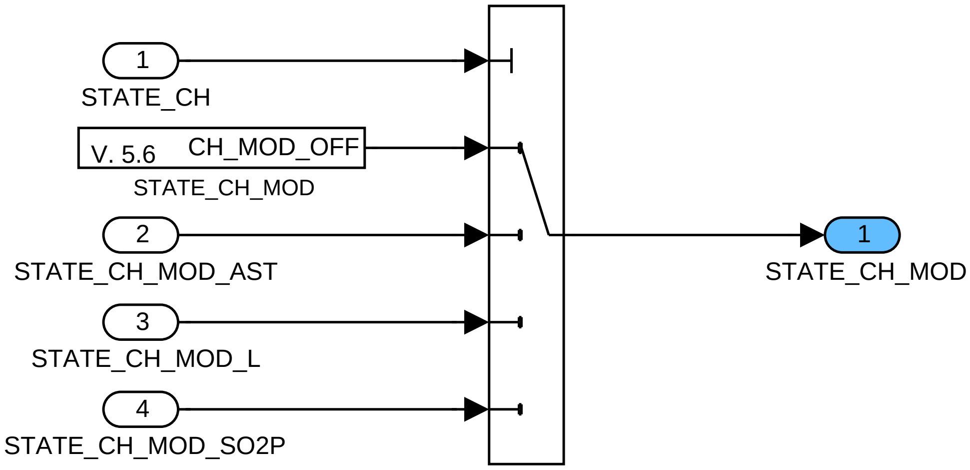

Figure 5.10.3: : Path: EXTC_REQCOMOD0/merging_CH_quantities/CLC_STATE_CH_MOD

5.10.1.2 Generation of STATE_CH_MOD_REQ

Same procedere as for STATE_CH_MOD. At LV_DLY_CH_MOD_REQ_SO2P_HOM = 1, it is possible that STATE_CH_MOD_REQ requests homogeneous mode although STATE_CH is CH_OFF. At LV_CH_AST_REQ_TCHA_DIAG = 1, MPLH is requested.

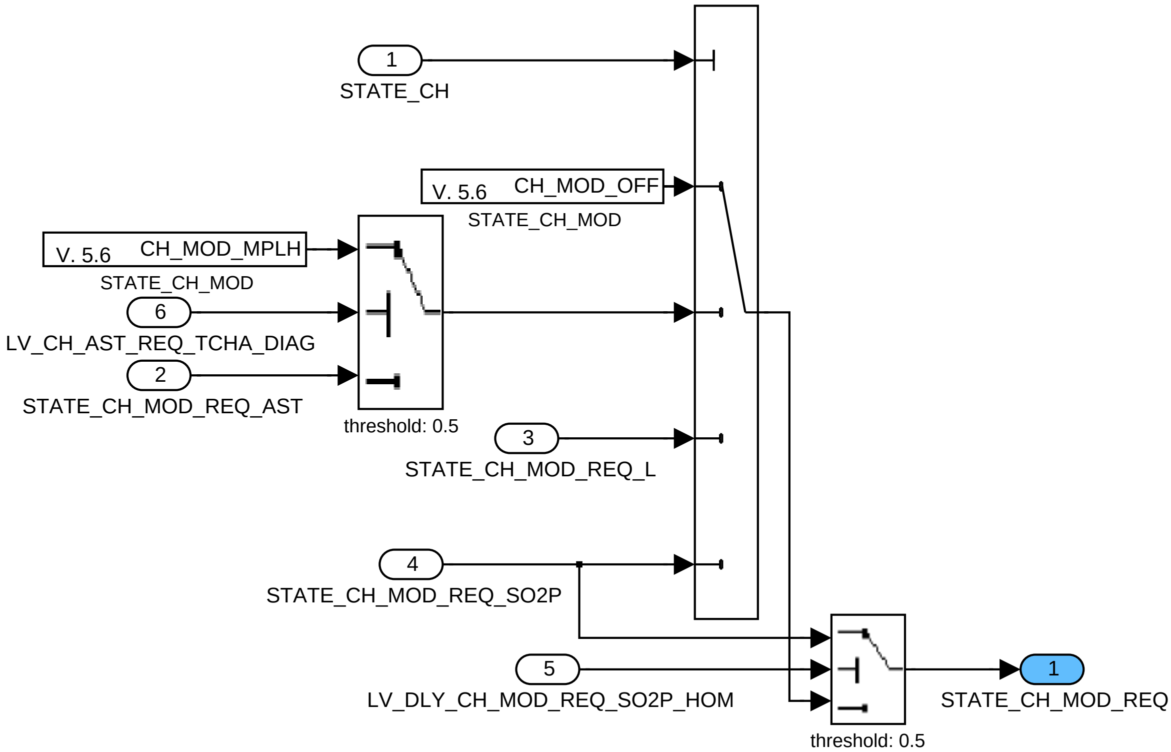

Figure 5.10.4: : Path: EXTC_REQCOMOD0/merging_CH_quantities/CLC_STATE_CH_MOD_REQ

5.10.1.3 Generation of priority for operation mode requests

At active turbo diagnosis a separate value is used.

Activation of manual setting of catalyst heating strategy					

General Information

The engine states during catalyst heating can be homogeneous (HOM), homogeneous with multiple injection (MPLH), stratified with post injection (MPLP) and homogeneous-stratified (HOMS). STATE_CH_MOD_AST, generated in this module, contains the information which catalyst heating strategy is active and is used for CH-setpoint calculation (for example fuel mass setpoint or lambda). Further the request which combustion mode is the most efficient for catalyst heating is generated in this module.

Application Conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.11.2 Actual combustion mode for after start catalyst heating

5.11.2.1 No title given

STATE_CH_MOD_AST is set according to the bit-variables that show the actual mode (HOM, MPLH, HOMS or MPLP). If no mode is requested for catalyst heating (STATE_CH_MOD_REQ_AST = 0) also the actual mode is set to 0. It is also possible to set STATE_CH_MOD_AST manually.

5.11.3.1.1 clc_of_resulting_request

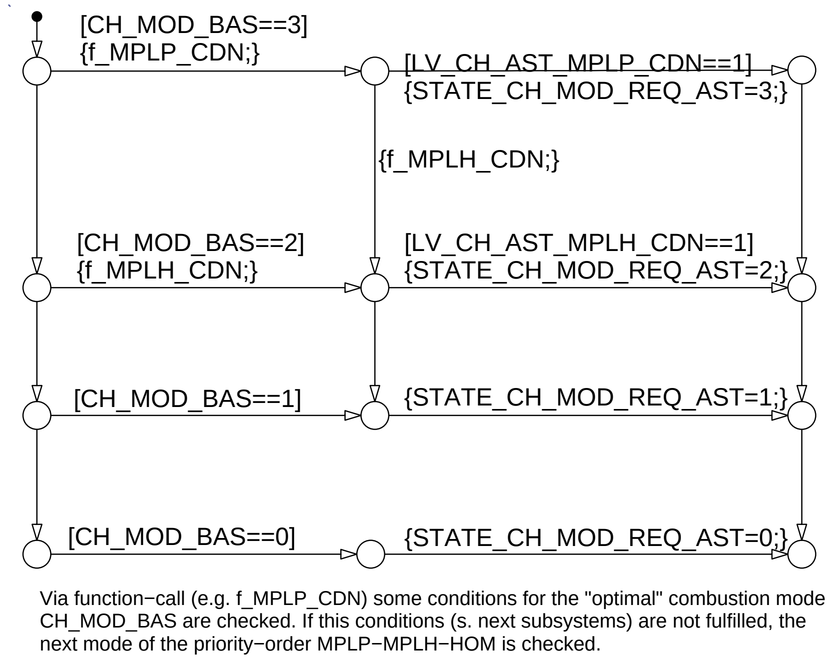

Figure 5.11.6: : Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/clc_of_resulting_request

5.11.3.1.2 Conditions for homogenous mode with multiple injection

LV_CH_AST_MPLH_CDN indicates if conditions for MPLH for catalyst heating are fulfilled. It is set to 0 if the engine speed is not in-between a calibratable range, LV_HOM_ENA is 0 or the pedal value exceeds C_PV_MAX_MPLH_CH for a certain time (C_T_MIN_PV_THD_MPLH_CH_DEAC). The bit LV_CH_AST_MPLH_CDN can only be set to 1 again after next engine start.

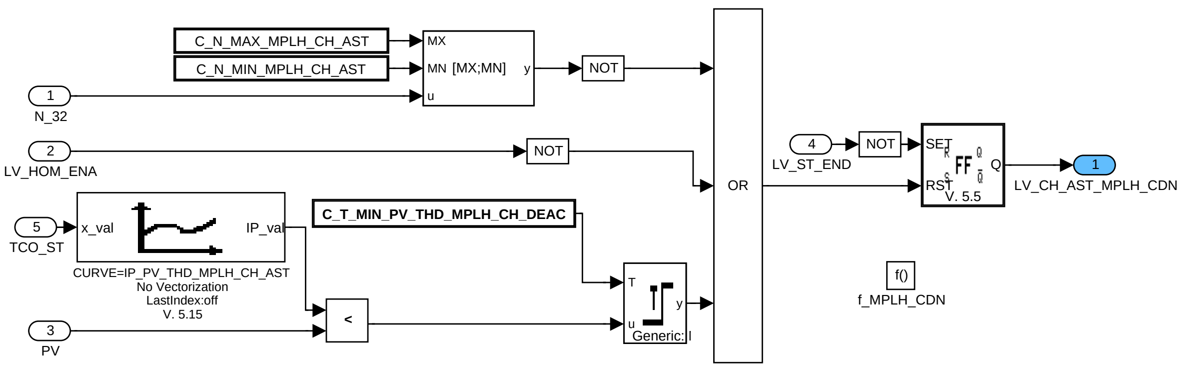

Figure 5.11.7: : Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/MPLH_CDN

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.11.3.1.3 Conditions for stratified mode

For stratified mode with post injection the torque request and the engine speed has to be in-between a calibratable range, the vehicle speed must be below a limit and LV_S_ENA must indicate that stratified mode is enabled.

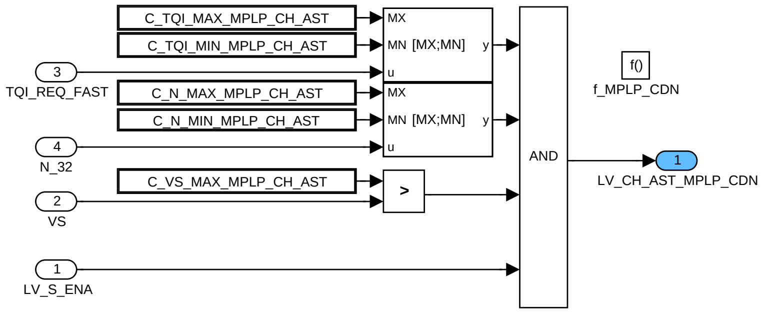

Figure 5.11.8: : Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/MPLP_CDN

Below this NOx trap temperature the homogeneous stratified mode is requested for low load catalyst heating					

General information

This module has to be calculated after Catalyst heating coordination and Catalyst heating after start strategy and before any other catalyst heating module.

The output STATE_CH_MOD_L will be merged in Catalyst heating strategy into STATE_CH_MOD. This value is used to trigger setpoint calculation modules. STATE_CH_MOD_REQ_L will be merged into STATE_CH_MOD_REQ.

Application Condition

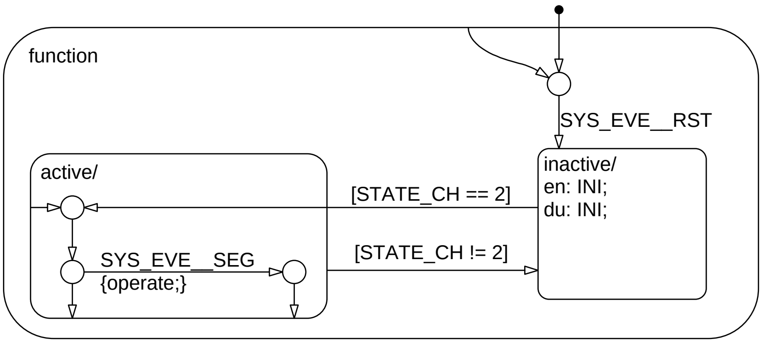

Figure 5.12.1: EXTC_ISPCLmodll0/APP_CDN/Chart

Function Description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

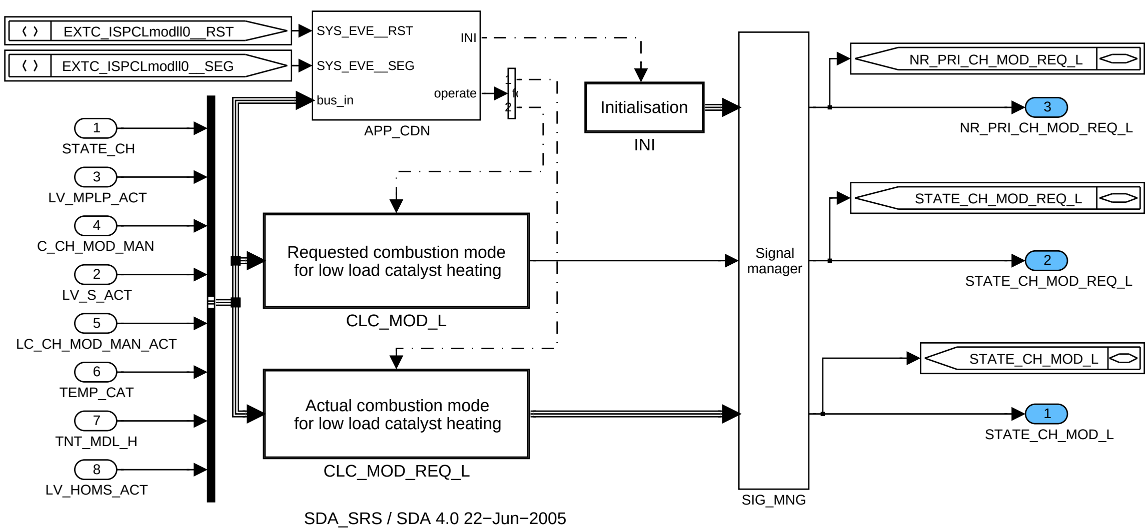

Figure 5.12.2: EXTC_ISPCLmodll0

5.12.1 Initialization

All outputs are set to 0 at reset and deactivated function.

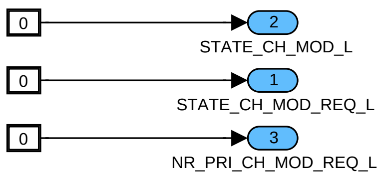

Figure 5.12.3: EXTC_ISPCLmodll0/INI/INI_SUB

5.12.2 Actual combustion mode for low load catalyst heating

Depending on the actual active combustion mode, STATE_CH_MOD_L is set to HOMS, MPLP or HOM. With (L)C_CH_MOD_MAN(_ACT) it is possible to set it manually.

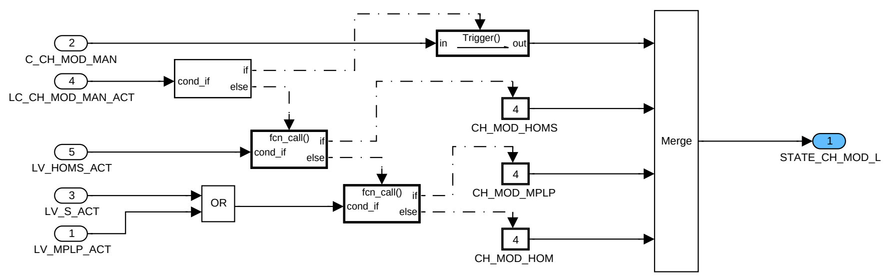

Figure 5.12.4: EXTC_ISPCLmodll0/CLC_MOD_L/CLC_MOD_L_SUB

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

5.12.3 Requested combustion mode for low load catalyst heating

If catalyst or NOxTrap temperature falls below C_TEMP_CAT_MIN_SWI_HOMS_CH_L or C_TNT_MIN_SWI_HOMS_CH_L the HOMS - mode is requested to inhibit that the catalyst cools down under the working temperature. If one of the temperatures falls even below C_TEMP_CAT_MIN_SWI_HOM_CH_L or C_TNT_MIN_SWI_HOM_CH_L homogenous mode is requested. NR_PRI_CH_MOD_REQ_L is increased via C_NR_PRI_CH_MOD_REQ_L_ACT if the request shell be active.

Requested combustion mode for desulfation catalyst heating					
LC_STATE_CH_MOD_SO2P_MAN_ACT	-	0... 1H	0 ...1	1	-
Activation of manual setting of catalyst heating strategy for desulfation					

General Information

This module has to be calculated after Catalyst heating coordination , Catalyst heating after start strategy , Catalyst heating low load strategy and before any other catalyst heating module.

The engine states during catalyst heating for desulfation can be homogeneous (HOM) and homogeneous with multiple injection (MPLH). STATE_CH_MOD_SO2P, generated in this module, contains the information which catalyst heating strategy is active and is used for CH-setpoint calculation (for example fuel mass setpoint or lambda). It will be merged in Catalyst heating strategy into STATE_CH_MOD. STATE_CH_MOD_REQ_SO2P will be merged into STATE_CH_MOD_REQ. Further a request is generated that contains the most efficient combustion mode for desulfation catalyst heating.

Application Conditions

Initialization: RST
Activation: 100MS: STATE_CH == 3
SEG: STATE_CH == 3
Deactivation: STATE_CH != 3 & & STATE_CH_MOD_REQ_SO2P == 0

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 5.13.1 Initialisation

5.13.1.1 Initialisation - Subsystem

The outputs are initialised at reset and function deactivation.

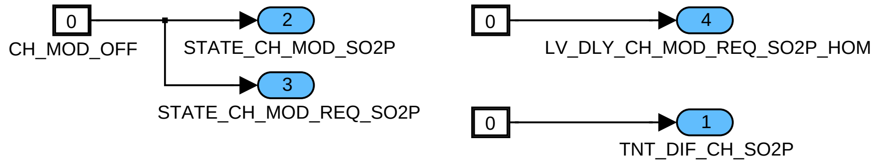

Figure 5.13.2: : Path: EXTC_ISPCLMODSO0/INI/SUB

5.13.2 100 ms - Task

5.13.2.1 100 ms - Task - Subsystem

At deactivation of desulfation catalyst heating due to torque or vehicle speed threshold (STATE_CH == 0 and LV_STATE_CH_SO2P_ENA=1) there is the possibility to request homogenous mode for a calibratable time.

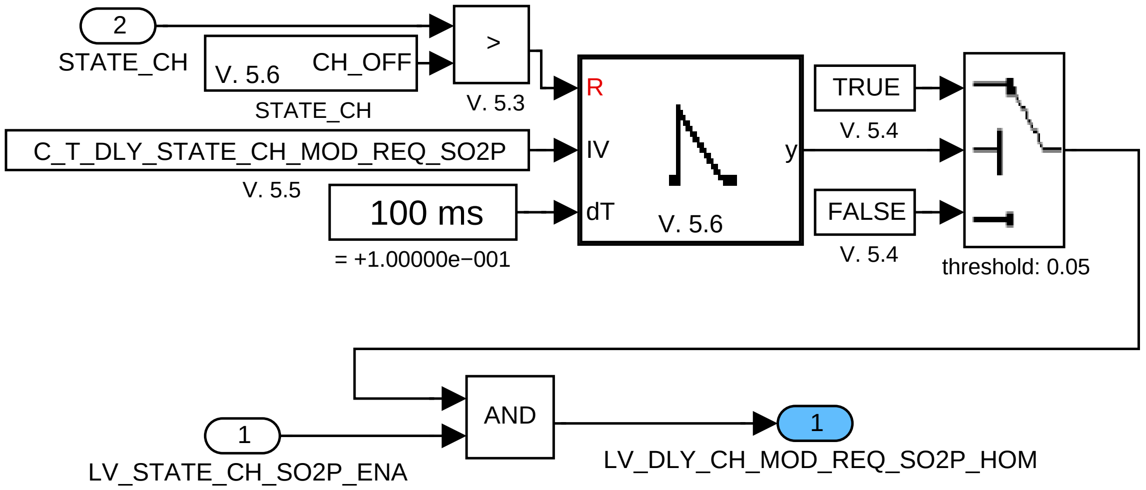

Figure 5.13.3: : Path: EXTC_ISPCLMODSO0/operate_100ms/SUB

5.13.3 Segment synchronous task

5.13.3.1 Segment synchronous task - Subsystem

TNT_DIF_CH_SO2P is the difference between the NOx-trap temperature setpoint and the actual value. It is negative if there is necessity to heat. The ID and the calibration data for manual setting have other physical meaning as the output of the spec because for catalyst heating for desulfation only HOM and MPLH can be used.

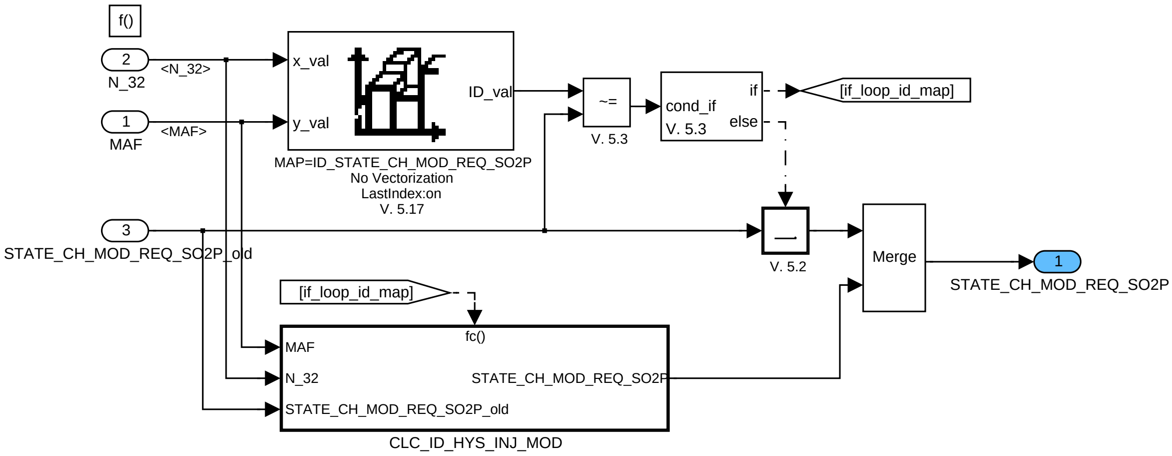

Figure 5.13.5: : Path: EXTC_ISPCLMODSO0/operate_SEG/SUB/CLC_ID_HYS

5.13.3.1.1.1 Change of injection mode

The basic for the changing of the injection mode is the hysteresis of N_32 and MAF to avoid the toggle between the injection modes. The actual values of N_32 and MAF are detected by the corresponding breakpoints. These indexes are going to the map ID_STATE_CH_MOD_REQ_SO2P. The hysteresis is calculated with the value of the corresponding breakpoint and the calibration constant. The changing of the injection mode is only possible after reaching the maximum threshold of the hysteresis. Example: Actual engine speed is 3000rpm. Corresponding breakpoint is 1632rpm. Calibration value is 200rpm. Result of the hysteresis is 1632rpm + 200rpm = 1832rpm. The calculation of MAF is the same.

Switch between Layer and internal calculatiopn of LAMB_SP_S					

FUNCTION DESCRIPTION:

General information:

The lambda LAMB_SP_S in stratified has to be limited to a minimum lambda value. If the lambda setpoint LAMB_SP_S is below the minimum threshold LAMB_MIN_S then the stratified combustion is not authorized.

Description:

Application conditions

Activation: *LV_S_CLC = 1*

Deactivation: *LV_S_CLC = 0*

Initialization:
```
at reset:
    LAMB_SP_S(n-1) = C_LAMB_SP_S_INI
    at the transition of LV_S_CLC from 0 to 1:
    LAMB_SP_S_RAW has to be calculated for the initialization.
    LAMB_SP_S(n-1) = LAMB_SP_S_RAW.
```

Update rate: 10 ms

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FUNCTION DESCRIPTION:

There are several project specific requests to inhibit the stratified and AFL mode. Within this function all these requests lead to the bits LV_INH_S and LV_INH_AFL to simpify the combustion manager.

To reduce the processor load all stratified mode related modules shall no longer be calculated, if LV_S_CLC = 0. All AFL-mode relevant modules including the combustion manager shall no longer be calculated, if LV_AFL_CLC = 0.

Application conditions

Initialisation:

```
at reset:    LV_INH_S = 1
         LV_INH_AFL = 1
         LV_S_CLC = 1
         LV_AFL_CLC = 1
```

Recurrence: *10 ms*

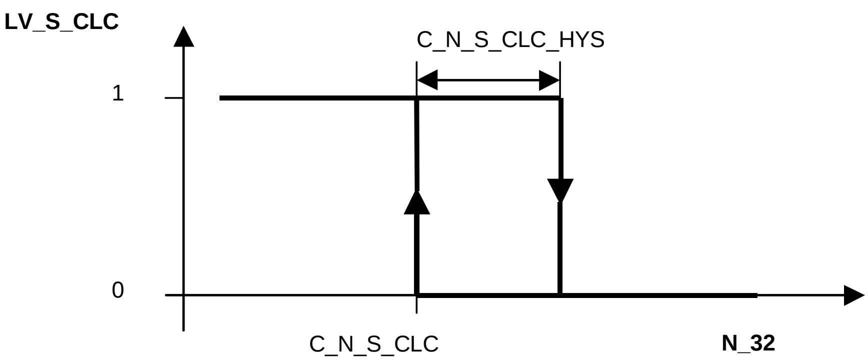
Activation: *every engine state*

Deactivation: -

Formula section:

Definition of LV_S_CLC:

This calculation will only be done if the STATE_CMB_CTL = HOM_AFS.



Definition of LV_AFL_CLC:

This calculation will only be done if the STATE_CMB_CTL = HOM_AFS.

5.16 Run time optimization by recurrency switch

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CLC_2SEG	O/V	0... 1H	0 ...1	1	-
Toggle-Bit for activation/deactivation of the segment synchronously calculation					
LV_CLC_2SEG_ENA	O/V	0... 1H	0 ...1	1	-
Activation flag for correction modes for non segment synchronously calculation					

Input data:

N_32 {p. 1525}			

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_N_SEG_2_ENA	V	0... FFH	0... 8160	32	rpm
engine speed threshold for the activation of the calculation recurrence change to every second segment					

General information

At a high engine speed, run time problems may occur. Overstepping a certain engine speed threshold, the Toggle-Bit created in this module can evoke modules calculated segment synchronuously to switch to a recurrency of every second segment.

Application conditions:

Initialisation: `LV_CLC_2SEG = 0; LV_CLC_2SEG_ENA = 0`

Activation: `every other engine state`

Deactivation: `engine stopped or engine start detected: LV_ES = 1 or LV_ST = 1`

Recurrence: `every segment`

Function description:

Formula section:

Activation of Toggle-Bit:

As soon as the engine speed exceeds a threshold C_N_SEG_2_ENA, the Toggle-Bit LV_CLC_2SEG gets activated and changes its value from zero to one the next segment and back to zero again the subsequent segment.

Activation of Correction-Bit:

At the same time, the bit LV_CLC_2SEG_ENA is set to one. This bit enables calculation corrections in files that use a segment counter or have to be corrected by any other influences caused by a calculation recurrence only every second segment.

Deactivation:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The deactivation of both bits is done as soon as the engine speed threshold is underspent again.

```
if   N_32 >   C_N_SEG_2_ENA
then      LV_CLC_2SEG_ENA     =  1
          LV_CLC_2SEG         =  0 → 1→ 0 → 1 → 0 → 1 →0 → ...(toggling)
else      LV_CLC_2SEG_ENA = 0
          LV_CLC_2SEG   = 0
endif
```

6.1.1 IGSP_M6001

General information:

This module coordinates different ignition angle requests and calculates the ignition angles IGA_AV_H_RNG[x] and IGA_AV_H_RNG_S[x].

IGA_SP is the output from the torque management functions to realize the torque setpoint. IGA_SP is limited to IGA_MIN the minimum ignition angle which can be applied to the engine.

IGA_BAS_COR is the corrected basic igniton angle which is realized normally if no other requests like knock control or torque requests (via IGA_SP) requires a retarded ignition angle.

The reference ignition angle IGA_REF_COR is a theoretical ignition angle at maximum engine torque. It is the reference value to all ignition angles to calculate the ignition angle differences (IGA_DIF_xxx) for the calculation of EFF_IGA_xxx values.

According to application choice (through logical application incidence flag LC_IGA_ST_ENA) the ignition angle during start phase is not managed through the torque but by the specific value IGA_ST. In this case, the corresponding ignition efficiencies are set to 1. At the end of start phase the transition from IGA_ST to the set point ignition delivered by torque calculation IGA_AV_1[x] is approached through a gradient limitation (the ignition gradient step is calibrateable).

This module delivers the homogeneus ignition angle IGA_AV_H_RNG[x] and the stratified ignition angle IGA_AV_H_RNG_S[x] for the MSD70 project in IGRE. For the MSV70, the stratified ignition angle is a copy of the homogeneus one. Therefore, this HOM /S switch is also visible in MSV70, but effectiv.

6.2.1 Ignition angle efficiency

The ignition efficiency values EFF_IGA_AV (actual efficiency), EFF_IGA_BAS_COR (basic efficiency), EFF_IGA_BAS_COR_KNK_FIL (efficiency with mean knock correction) and EFF_IGA_MIN (minimum efficiency due to IGA_MIN) provide the link from an ignition angle to a torque efficiency. They are used in different torque modules to calculate the actual indicated engine torque, basic indicated engine torque values or the minimum indicated engine torque.
The efficiency calculation follows always the same strategy:
calculation of all specific delta ignition angle IGA_DIF...
calculation of efficiencies using engine mode depending function "EFF_IGA(IGA_DIF...)".

Dwell time correction versus battery voltage and engine speed					

6.3.1 Dwell time calculation

FUNCTION DESCRIPTION:

The dwell time raw value calculation is based on the simulation done by the HW-group. At any time an adaptation or correction factor has to be multiplied or added in this chapter.
The dwell time open-loop control value is stored in terms of a battery voltage and engine speed related characteristics.

Application conditions

Initialisation: *TD = C_TD_INI* at reset

Recurrence: *10 ms*

Activation: at every engine state ***if*** *LV_HOM_RUN = 1*

Formula section

If LV_TD_AD_H == 1
Then TD = IP_TD_S(VB, N_32) * TD_FAC + C_TD_S_AS
Else TD = IP_TD(VB, N_32) * TD_FAC + C_TD_AS
Endif

FUNCTION DESCRIPTION:

General information:
The output data could be only TD_FAC. All other factors should be only visible values.
The dwell time factor regroups all adjustment factors as coil temperature factor or a boost factor for start. Here the boost factor is not taken into account as we use for MSD8X project an adaptation of Dwell Time at hight current target at start.

Initialisation : at reset
TD_FAC = 1
TD_FAC_TCO = 1
Recurrence: 10 ms

Formula section:

TD_FAC_TCO = IP_TD_FAC_TCO
TD_FAC = TD_FAC_TCO

6.5 Dwell time period for stratified mode

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TD_S	O/V	0... FFFFH	0... 262.14	0,004	ms
Dwell time for stratified mode					

Input data:

LDPM_N_32_1_IGRE	LDPM_VB_1_IGRE	LV_S_RUN {p. 8137}	N_32 {p. 1525}
TD_FAC {p. 1874}	VB {p. 1185}		

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_TD_S_AS	-	F800... 7F0H	-8.192 ...8.128	0.004	ms
Application intervention for stratified mode (typ. Value : 0 ms)					
C_TD_S_INI	-	0... FFFF H	0... 262.14	0.004	ms
Init. value for dwell time control (same for homogeneous and stratified mode)					
IP_TD_S	V	0... FFFFH	0... 262.14	0,004	ms
LDPM_VB_1_IGRE	8	0... FFH	0... 26	0,102	V
LDPM_N_32_1_IGRE	8	0... FFH	0... 8160	32	rpm
Dwell time correction versus battery voltage and engine speed for stratified mode					

FUNCTION DESCRIPTION:

The following function is similar to the dwell time calculation for homogeneous combustion. Only the calibration data should be adapted to stratified combustion.
The dwell time value calculation is based on the simulation done by the HW-group. The dwell time open-loop control value is stored in terms of a battery voltage-related characteristic.

Application conditions

Initialisation: *TD_S* = *C_TD_S_INI* at reset

Recurrence: *10 ms*

Activation: *LV_S_RUN* = *1*

Deactivation: LV_S_RUN = 0

Formula section:

TD_S = IP_TD_S(VB,N_32) * TD_FAC + C_TD_S_AS

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

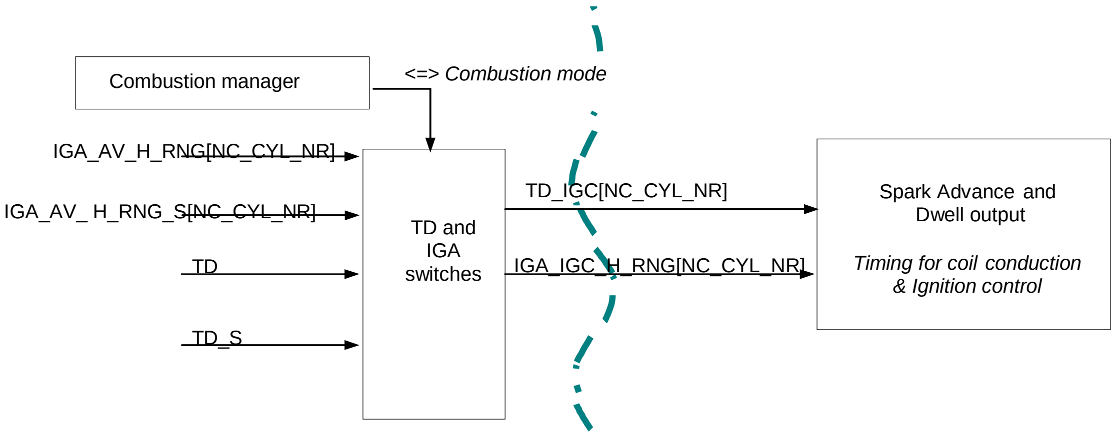
FUNCTION DESCRIPTION:

This module should cover all necessary switches between the different dwell times and ignition angles to ensure two outputs, TD_IGC[NC_CYL_NR] and IGA_IGC_H_RNG[NC_CYL_NR].

Initialisation: at reset
TD_IGC[NC_CYL_NR] = TD + TD_AD[NC_CYL_NR]
IGA_IGC_H_RNG[NC_CYL_NR] = IGA_AV_H_RNG[NC_CYL_NR]

For x = 0 **to** NC_CYL_NR - 1
ACTION_INFR_SetIgnDwell(x,TD_FAC_MIN,TD_IGC[x],TD_FAC_MAX)
ACTION_INFR_SetIgnAngle(x,IGA_IGC_H_RNG[x])
Endfor

Signal flow diagram:



Choice between homogeneous inputs and stratified inputs

The switch between homogeneous and stratified combustion mode could not be realised between TD_ON[NC_CYL_NR] and TD_OFF[NC_CYL_NR].
Switching is only possible if there's no action on the cylinder.
The switch has to be synchronised with the injection switch. The combustion manager managed by INJR does this synchronisation. The switch has to work per cylinder. Some inputs on this signal flow diagram are in fact use by the synchronization module of INJR.

6.6.1 Update of Ignition angle if homogeneous mode is selected

Application conditions

Activation: *LV_ST_END = 1: Engine synchronized*

Recurrence: 10ms

Formula section:

For x = 0 **to** NC_CYL_NR - 1
If INJ_MOD[x] == 'SNGH' **And** INJ_MOD_SP[x] == 'SNGH'
Or **[** INJ_MOD[x] == 'MPLH' **And** INJ_MOD_SP[x] == 'MPLH' **And** LV_IGN_INJ_SYN_DEAC = 1 **]**

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Or **[** INJ_MOD[x] == 'MPLH+PLS3' **And** INJ_MOD_SP[x] == 'MPLH+PLS3' **And** LV_IGN_INJ_SYN_DEAC = 1 **]**
Then IGA_IGC_H_RNG[x] = IGA_AV_H_RNG[x]
ACTION_INJR_IgnUpdate (x, IGA_IGC_H_RNG[x]**)**
ACTION_INFR_SetIgnAngle (x, IGA_IGC_H_RNG_ACT[x]**)**
Endif
Endfor

6.6.2 TD_LIM_MAX calculation

Application conditions

Activation: `Engine synchronized`

Recurrence: `10ms`

Initialisation: `at reset`

Formula section:

If VB < C_VB_TD_MAX_LIM_L
Then TD_LIM_MAX = NC_TD_LIM_MAX_H
Endif

If VB > C_VB_TD_MAX_LIM_H
Then TD_LIM_MAX = NC_TD_LIM_MAX_L
Endif

In every case: TD_IGC[x] * TD_FAC_MAX <= TD_LIM_MAX
TD_IGC[x] * TD_FAC_MIN >= NC_TD_LIM_MIN

NC_TD_LIM_MIN is defined for dwell time protection in case of advance ignition changes during the dwell time application. If the dwell time is equal to this minimal limit value, the advance ignition could be not guaranteed

NC_TD_LIM_MAX is defined for the maximum dwell time in case of advance ignition changes during the dwell time application. If the dwell time is equal to this maximal limit value, the advance ignition could be not guaranteed

Note: In any case, TD_FAC_MIN has to be smaller than 1 and TD_FAC_MAX greater than one to be sure to respect the requested dwell and avoid inconsistencies

care has to be taken with the setting of NC_TD_LIM_MAX_L and NC_TD_LIM_MAX_H in order to avoid Dwell Time /coil charging recovery:
Dwell time can start at the earliest at 288°CRK before the TDC.
NC_TD_LIM_MAX_L and NC_TD_LIM_MAX_H should be tuned in consequence to respect coil charging time no recovery and coil capacity

*TD MAX = min(TD_IGC[x] * TD_FAC_MAX , TD_LIM_MAX)*
*TD MIN = max(TD_IGC[x] * TD_FAC_MIN, NC_TD_LIM_MIN)*

6.6.3 Dwell time switch Ignition Actuator Tests Diagnosis

Application conditions

Activation:

```
[ LV_ES = 1              // Actuator tests activation
  and   LV_IGK        = 1
  and   LV_FIRST_VLD_TOOTH = 0
  and   LV_INH_IGC[x] = 0
```

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. ```
and      at least one LV_IGC _EXT_ADJ[x] = 1]
```

Deactivation:

```
[ LV_ES  = 0          // Actuator tests deactivation
  or        LV_IGK        = 0
  or      LV_FIRST_VLD_TOOTH = 1
or     LV_INH_IGC[x]  = 1
  or        at least one LV_IGC_EXT_ADJ[x] = 0]
```

Recurrence: `On transition of IGC_EXT_ADJ[x] from 0 to 1`

System description:

For ignition coil actuator tests purpose, the Dwell Time has to be applied and transmitted to BSW via action. A specific service is used for those tests purposes.

Formula section:

If (INJ_MOD[x] & NC_INJ_MOD_MASK_1) != NC_INJ_MOD_HOM *// Stratified mode for cyl. _x*
Then TD_IGC[x] = TD_S
Else TD_IGC[x] = TD
Endif

For x = 0 **to** NC_CYL_NR - 1
If LV_IGC _EXT_ADJ[x] = 1
Then On transition of IGC _EXT_ADJ[x] from 0 to 1
And LV_FIRST_VLD_TOOTH = 0
ACTION_INFR_SetIgcDwellTest(x,TD_IGC[x])
ElseIf LV_FIRST_VLD_TOOTH = 1
ACTION_INFR_SetIgcDwellTest(x,0) *// immediate cut of tests on engine running*
EndIf
EndFor

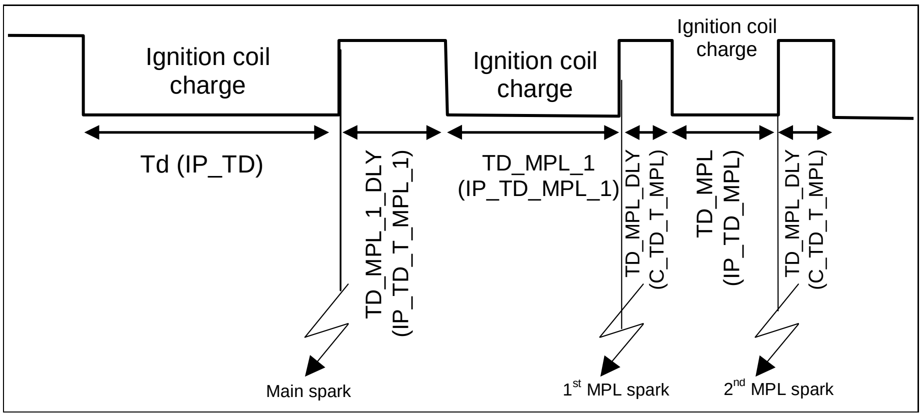
6.7.1 Calculation of parameters for multiple spark

FUNCTION DESCRIPTION:

With this function several subsequent sparks could be created. The delay time to create a spark and the time to reload the coil are defined in tables depending on battery voltage and on engine speed.
At start and for the following application conditions, the ignition is controlled by means of multiple sparks.
After an adjustable combustion period, the ignition coil is loaded with a specific dwell time to create successive sparks. The number of successive sparks is defined as IGN_MPL_NR.
The multiple sparks ignition can also be activated by the input flag LV_TD_MPL_SPC_IGN_ACT. In this case, the 1^{st} MPL spark (e.g. the first spark after the main spark) is controlled by specific calibration data IP_TD_MPL_1 and IP_TD_T_MPL_1 (see the picture below for more explanation).
If LV_TD_MPL_SPC_IGN_ACT is inactive, the 1^{st} MPL spark takes the same parameters than the other MPL sparks.



The MPL Sparks are maintained during a time (C_T_CTR_TD_MPL_AST or C_T_CTR_TD_MPL) after the end of the activation condition, before exiting this MPL procedure (*Application Multiple Spark Maintenance for a time before Exit Case*)
We use an estimated coil temperature to limit the number of multiple sparks and then protect ignition coil.
We also increase the number of multiple sparks in case of misfiring.
Priority is given to the protection of ignition coil, according to the estimated temperature coil compared to a maximum value: C_TEMP_MDL_IGC_MAX.

Application conditions

Initialisation:

```
IGN_MPL_NR = 0
    TD_MPL          = 0
TD_MPL_1        = 0
    TD_MPL_DLY     = 0
    TD_MPL_1_DLY  = 0
T_CTR_TD_MPL       = 0          At reset and in deactivation
condition
```

6.8.2 Recurrence 100ms

6.8.2.1 Calculation of cooling temperature for temperature model (recurrence 100ms)

The cooling temperature is calculated as the sum of the influence of the ambient temperature and TOIL or TCO. The customer wants the LC to choose between TOIL and TCO because he is not sure which one is correct. In a future version the selection will be removed.

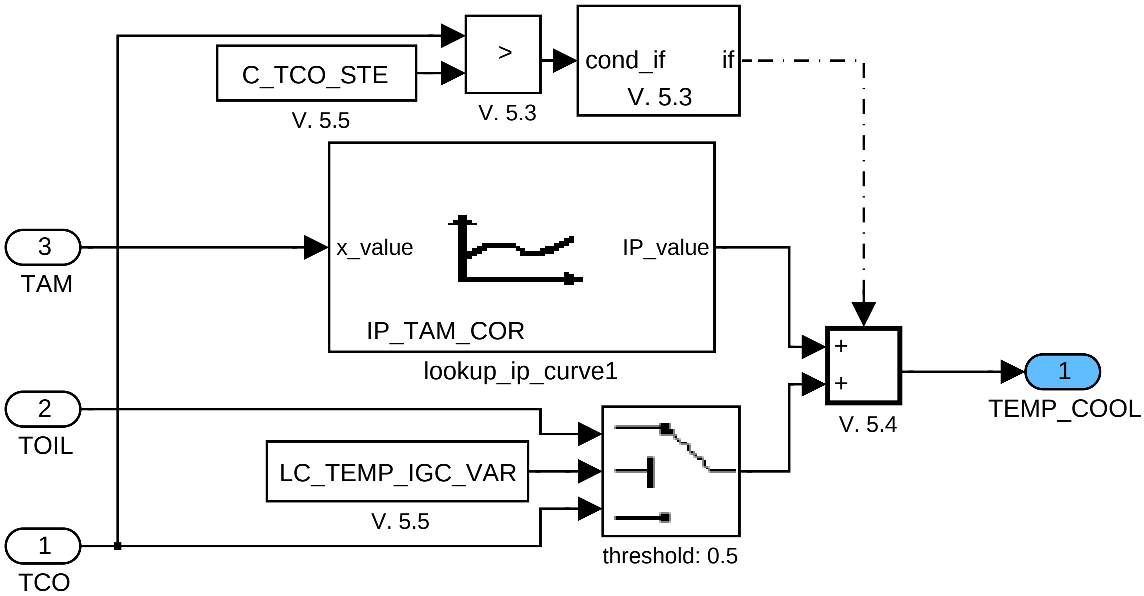

Figure 6.8.6: : Path: IGRE_M602J/OPM_100MS/TEMP

6.8.3.1.1.2 Calculation of model-temperature

The model temperature of the ignition coils gets calculated in this function. Based on the heat-energy, the cooling temperature, and the last calculated model temperature the cooling-energy and the new model temperature get calculated. C_ALFA_A_IGC is the product of the heat-transfer-c fficient and the area of the coils and C_CP_M_IGC the product of the heat-capacity and the mass of the coils. The integrator-block generates the temperature.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

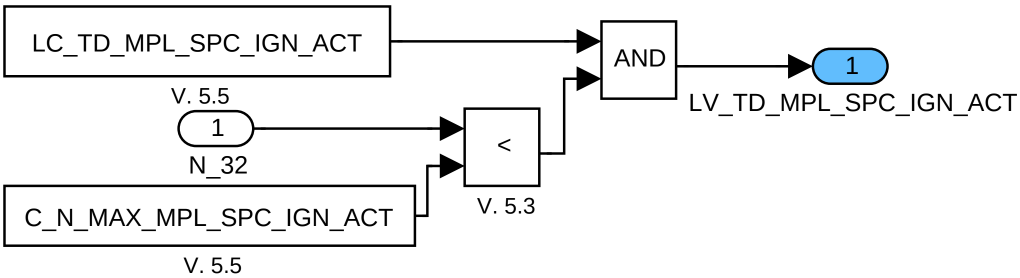

Figure 6.8.11: : Path: IGRE_M602J/OPM_10MS/MPL_SPC_IGN_ACT

6.8.3.4 Individual raise of Multiple Spark in case of misfiring

The purpose of this function is to set a calibrated number of multiple spark on a specific cylinder in case of misfiring.
The selection of cylinder is done by a word: STATE_MPL_CYL_IGN. Each bit codes a cylinder, the first cylinder is code by the lowest bit. If the bit is set to 1, there is misfiring and we set the number of MPL for this cylinder to a calibrated value. If it's set to 0, the number of MPL in this specifications will be set to 0 and will be replace in the generic specifications by an appropriate value based on a interpolation table depending on engine speed and battery voltage.

6.8.3.4.1 Set INJ_MOD_MPL to NC_INJ_MOD_S

6.9.1 Normal Mode Activation

FUNCTION DESCRIPTION:

As there could be different possibilities to deactivate the ignition system an **OR-Junction** is done in this chapter. The output of this or-junction has to be INH_IGC.
The Inputs can come from the ignition diagnosis, from the injection chapter, from the Misfire Generator or from any other function requesting ignition cut-off.

Application conditions

Initialisation: `at reset`

Recurrence:
```
if LV_ST_END = 1and LV_IGN_INJ_LOCK_REQ = 0:
                     segment synchronous (every TDC)
 if LV_ST_END = 0 or LV_IGN_INJ_LOCK_REQ = 1:
       10 ms
```

Activation: `LV_SYN_ENG = 1`

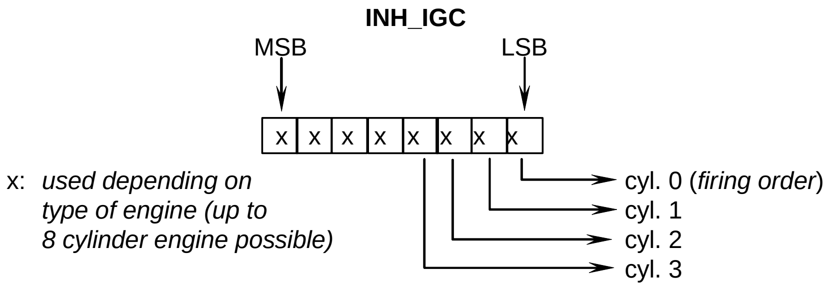
Deactivation: `LV_SYN_ENG = 0`

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Output driver deactivation

The decision to inhibit an ignition stage is taken for each output before the turn on at TD_ON[x]. This means that no Disable /cut-off can be set on a coil while charging
INH_IGC is the bit wise OR of all inputs requesting an ignition cut-off.
LV_INH_IGC[x] sets the INH_IGC for the corresponding cylinder to 1.
When one bit within INH_IGC is set to 1, the corresponding ignition output is performed as soon as possible. The ignition output remains inhibited while the INH_IGC is unchanged.



- *Calculation of CTR_CYCNR_IGA_ES*

IF (LV_IGK$_n$= 0 **and** LV_IGK$_{n-1}$ = 1)
or (LV_STST_STOP_REQ$_n$ = 1 **and** LV_STST_STOP_REQ$_{n-1}$ = 0)

THEN CTR_CYCNR_IGA_ES$_n$ = C_CYCNR_IGA_ES

ELSE **IF** (LV_IGK$_n$ = 0 **and** LV_IGK$_{n-1}$ = 0)
or (LV_STST_STOP_REQ$_n$ = 1 **and** LV_STST_STOP_REQ$_{n-1}$ = 1)

THEN CTR_CYCNR_IGA_ES$_n$ = CTR_CYCNR_IGA_ES$_{n-1}$ -1

ELSE CTR_CYCNR_IGA_ES$_n$ = CTR_CYCNR_IGA_ES$_{n-1}$

ENDIF

ENDIF

- *Inhibition for ignition system of cylinder x*

IF LV_LOCK_IMOB = 1
or LV_IGN_INJ_LOCK_REQ = 1
or LV_FIRST_VLD_TOOTH = 0
or (CTR_CYCNR_IGA_ES = 0 **and** LV_IGK = 0)
or (CTR_CYCNR_IGA_ES = 0 **and** LV_STST_STOP_REQ = 1)

THEN INH_IGC = $2^{NC\_CYL\_NR}$- 1 (ignitions on all the cylinders are inhibited)
ELSE

FOR x = 0 to NC_CYL_NR-1
IF LV_INH_IGC[x] = 1
or bit x of INH_IGC_MIS_GEN = 1
THEN the corresponding bit /Cylinder x of INH_IGC is set to 1
ELSE the corresponding bit /Cylinder x of INH_IGC is set to 0
ENDIF
ENDFOR

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

ENDIF

FOR x = 0 to NC_CYL_NR-1
ACTION_INFR_SetIgnEnable(x, not(corresponding bit x of INH_IGC))
ENDFOR

Note:

1. For DI engine it is strongly recommended to enable Ignition only after Validated synchronisation, *ie.* activation of this function on LV_SYN_VLD = 1 only instead of LV_SYN_ENG
2. No deactivation is possible on a charging coil, *ie.* after TD_ON[x] event: if Dwell Time has started on a stage, this charging will be elapsed to its end
   Refer to module 200X for more details

Ambient pressure correction of the basic ignition angle at start at operation mode 2					

6.10.1 IGSP_M6004

FUNCTION DESCRIPTION:
General information:
The ignition angle at start is basically dependent on the engine speed N and coolant temperature TCO determined by the map IP_IGA_ST_BAS. Additionally a map dependent on the ambient pressure AMP corrects this basic ignition angle. To avoid backfiring due to the fast increase of the combustion chamber temperature a second correction dependent on the cycle counter CYC_ST and the coolant temperature is added. A further map consideres influences of the inrake air temperature TIA.
The switch LV_IGA_ST_OPM_SEL is used to determine if either the basic ignition angle at start for operation mode 1 or the basic ignition angle at start for operation mode 2 is calculated.
In case of MSA start (engine start stop automatic) there is an additive correction dependent on the relative engine position PSN_ENG_REL_ST for the first ignition.

Application conditions :
Activation : LV_ST = 1 or (LV_ES = 1 and LV_SYN_ENG = 1)
Deactivation : LV_ST = 0 and (LV_ES = 0 or LV_SYN_ENG = 0)
Update rate : every 10 ms and every TDC
Initialisation: at reset : *IGA_ST = 0*
LV_IGA_ST_PSN_ENG_COR_STST = 0
LV_PSN_ENG_REL_TMP = 0

Remark: if LV_IGA_ST_OPM_SEL = 1 only the upper part has to be executed (IP....OPM_2), else only the lower part has to be executed (IP....OPM_1).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FUNCTION DESCRIPTION:

General information:

Homogeneous mode:
In homogeneous mode, if EGR function is active, the basic ignition angle IGA_BAS_IVVT is improved by the additive EGR correction value IGA_BAS_EGR_COR. This value depends from N_32, MAF, TCO, EGR_RATIO_SP and LAMB_SP.

Stratified mode:

In stratified mode, if EGR function is active, the basic ignition angle IGA_BAS_S is improved by the additive EGR correction value IGA_BAS_EGR_COR. IGA_BAS_EGR_COR is calculated from the coolant temperature TCO (IP_IGA_EGR_S).

Application conditions

Activation: LV_EGR_ACT = 1

Deactivation: LV_EGR_ACT = 0

Update Rate: 10 ms

Initialization: IGA_BAS_EGR_COR = 0

Signal flow diagram:

Compiler switch for specific minimum IGA after start phase enabled					

FUNCTION DESCRIPTION:

The minimum ignition angle is the minimum allowable ignition angle which is possible to apply to the engine. The basic minimum ignition angle determined through a calibration map is corrected by a temperature dependent additive term. Furthermore there are additive influences by cat heating and engine operating mode like throttled or unthrottled.In some special engine running states, the minimal ignition angle calibrated in this function can be limited by external request to avoid too strong spark retards during those states.Hence, in all practical cases IGA_DIF_MIN_H_RNG is a negative value which is the maximum allowable spark retard determined by a calibration map. It includes the coolant temperature correction (*for engine protection, pollution condition, etc...*).

6.12.1 IGA_DIF_MIN_H_RNG calculation with extra spark retard for torque intervention and after start management

General information:

In case of a strong fast torque intervention requested (*ie. if IGA_DIF_SP_H_RNG hence requested by torque intervention becomes lower than IGA_DIF_MIN_0_H_RNG*) then a specific over-retard (*IGA_DIF_MIN_DELTA_H_RNG*) is authorised on minimum ignition angle for a while. It permits to manage a strongest response from the engine to a torque reduction request. IGA_DIF_MIN_0_*H_RNG* is just an intermediate variable introduced here for clarification of explanations. IGA_DIF_MIN_0_*H_RNG* is just the result of the interpolation map without other affects. This over-retard is only allowed for a given time (*C_IGA_DIF_MIN_DELTA_TEMP_ENA*). In case of a rising edge of the flag for enabling extra-retard (LV_IGA_DIF_MIN_DELTA_ACT= 0->1) the active counter is reseted to C_IGA_DIF_MIN_DELTA_TEMP_ENA. If torque intervention by spark retard is active as well as homogeneous ignition angle and injection parameters are applied to the engine (LV_TQ_IGA_ACT=1 and LV_HOM_ACT=1) the active counter is decremented to 0, otherwise it is incremented back to C_IGA_DIF_MIN_DELTA_TEMP_ENA. The counter for extra-retard is set to avoid exhaust gas over-heating and thus protect the exhaust branch. At the end of this counter, this over-retard on IGA_DIF_MIN_H_RNG goes back up to 0 with a limited gradient (*C_IGA_DIF_MIN_DELTA_LGRD*_H_RNG) for its come-back law. This limited gradient for come-back is necessary to avoid the changes on ignition angle applied can be felt on-board the car. At the end of this gradient limited come-back, such an other kind of extra retard is inhibited during a while (*C_IGA_DIF_MIN_DELTA_TEMP_ENA*) just to be sure to avoid any problems of exhaust gas over-heating. This functionality aims to deal with thermal exchange effects. So, the timer are in time units (*sec.*) and the calibration map here defined for extra retard is related to LDP of temperature.

Application conditions

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Initialisation: IGA_DIF_MIN_H_RNG = 0° CRK at reset
IGA_DIF_MIN_0_H_RNG = 0 °CRK
IGA_DIF_MIN_AST_H_RNG = 0 °CRK

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Discrete SuperBlock	Sample Period	Sample Skew	Inputs	Outputs	Enable Signal
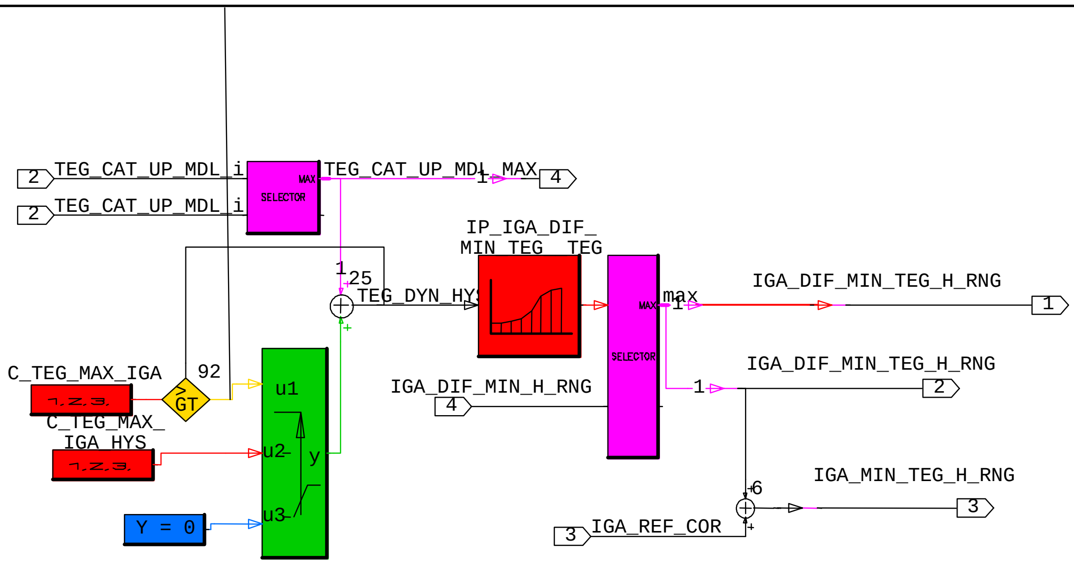
IGA_MIN_for_TEG	1.	0.	4	4	Parent



General information:

The minimum ignition angle IGA_MIN is the minimum allowable ignition angle that is possible to apply to the engine. Hencce, it only includes the combustion stability concern. It does not take into account any thermal effect. It should be used during the torque intervention phases in order to produce a fast reduction of the torque.

Applying IGA_MIN as actual ignition angle results in efficiency losses that should lead to an exhaust gas overheating and/or engine damages.

In order to avoid overheating of the components in the exhaust-system branch, minimum spark retard has to be limited in accordance with the actual exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR].

Moreover to determine the maximum possible torque reserve for catalyst heating, the torque reserve co-ordination module needs the minimum ignition angle efficiency and the minimum ignition angle with exhaust branch protection efficiency in order to limit and choose the different torque reserve requests.

Hence another minimum spark retard difference have to be calculated IGA_DIF_MIN_TEG_H_RNG which takes into account the exhaust gas system protection. It is the maximum between the one calculated versus the maximal exhaust gases temperature (TEG_CAT_UP_MDL_MAX) and the basic one IGA_DIF_MIN_H_RNG.

Classically IGA_DIF_MIN is calculated from a basic value of the minimum ignition angle corrected with a temperature dependent additive term. The basic minimum spark advance is here extracted from a calibration map.

To calculate the minimum spark retard limitation according to the exhaust gas temperature the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG is used. TEG_DYN_HYS is used as input for this map. This intermediate variable TEG_DYN_HYS represents the exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] increased by an hysterisis in order to anticipate the exhaust-system branch overheat.

The influence of the ignition angle on the exhaust gas temperature results from the ignition angle efficiency. Thus - in order to calibrate easily the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG - one should use the efficiencies resulting from IGA_DIF_MIN_H_RNG values with the map IP_EFF_IGA__IGA_DIF and limit these efficiencies according to the actual exhaust gas temperature to avoid exhaust-system branch overheat. Then, thanks to the reverse map IP_IGA_DIF__EFF or thanks to the torque model for ignition angle efficiency, it is possible to calculate the value of the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG.

So, in all practical cases IGA_DIF_MIN_H_RNG is a negative value that is the maximum allowable spark retard for engine stable running and pollutant conditions. It includes the coolant temperature correction. The exhaust gas temperature limitation is then taken into account in IGA_DIF_MIN_TEG_H_RNG:

The actual exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] can be either measured by a sensor on the exhaust-system branch or calculated from an exhaust gas temperature model.

For engines with multiple cylinder bamks, this temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] of exhaust gas before catalyst is defined and dedicated for each cylinder banks individualy. Since here the limitation of IGA_MIN is just a protective function versus the catalyst overheating, only the maximal value from all those cylinder bank related TEG_CAT_UP_MDL[NC_CBK_EX_NR] temperature will be taken into account.

Note: Two different update rates are used in the following calculations: for everything related to TEG only 1000ms rate is used to update calculation in synchronisation with TEG updates; for calculations related to ignition angle a 10 time faster update rate of 100ms.

These calculations are only performed when engine is running (*not stalled*) in homogenous mode after the end of start phase.

Application conditions

Activation: LV_HOM_RUN = 1 **and** LV_ST = 0 **and** LV_ES = 0

active only in homogenous mode after the end of start phase before engine stall

Deactivation: LV_HOM_RUN = 0 **or** LV_ST = 1 **or** LV_ES = 1

Initialisation:
IGA_MIN_TEG_H_RNG = -90 °CRK
IGA_DIF_MIN_TEG_H_RNG = -180 °CRK
IGA_DIF_MIN_TEG_1_H_RNG = -180 °CRK
TEG_DYN_HYS = 0 at reset

Update Rate:
TEG_DYN_HYS => 1000ms
and synchronised with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates.
IGA_DIF_MIN_TEG_H_RNG => 100ms
IGA_MIN_TEG_H_RNG => 100ms
EFF_IGA_MIN_TEG => 100ms

Formula section:

Maximal cylinder bank exhaust gas temperature determination:

every 1000ms

in synchronisation with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates

$$TEG\_CAT\_UP\_MDL\_MAX = \underset{0}{\overset{NC\_CBK\_NR-1}{Max}}\left(TEG\_CAT\_UP\_MDL\_i\right)$$

Hysteris function on exhaust gas temperature for ignition effects anticipation:

every 1000ms

in synchronisation with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates

If $TEG\_DYN\_HYS_{n-1} > C\_TEG\_MAX\_IGA$
Then $TEG\_DYN\_HYS_{n} = TEG\_CAT\_UP\_MDL\_MAX_{n} + C\_TEG\_MAX\_IGA\_HYS$
Else $TEG\_DYN\_HYS_{n} = TEG\_CAT\_UP\_MDL\_MAX_{n}$
Endif

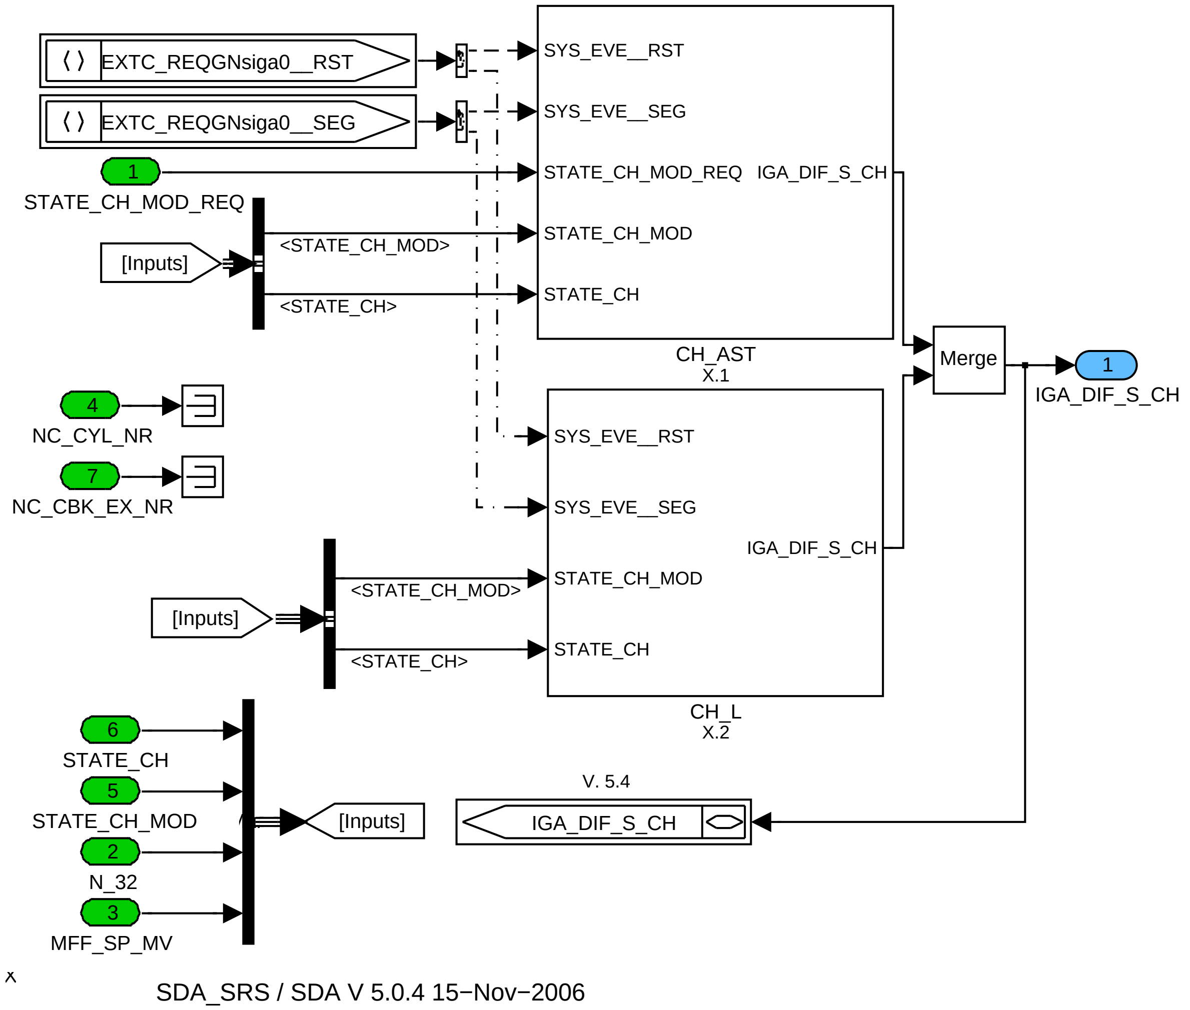

Figure 6.14.1: : Path: EXTC_REQGNsiga0

General Information

For catalyst heating in stratified mode possibly with post injection there is an increase of exhaust gas temperature due to retarding the ignition angle. In this module a difference of the ignition angle is generated.
The function is divided into two parts: After start and low load catalyst heating.

6.14.1 Catalyst heating after start

Setpoint spark retard for torque intervention					

FUNCTION DESCRIPTION:

General information:

For homogeneous (*LV_HOM_RUN = 1*) the module ignition angle setpoint delivers IGA_DIF_SP_H_RNG as an output which depends on the torque setpoint TQI_SP_CBK[NC_CBK_EX_NR]. For the calculation of the setpoint of ignition efficiency EFF_IGA_SP the actual cylinder fuel cut-off efficiency EFF_SCC_AV, the Exhaust Gas Re-circulation efficiency and the actual lambda efficiency EFF_LAMB_AV are considered which are multiplied with the reference torque value TQI_REF.
By evaluation of the standardised ignition characteristic the spark retard value IGA_DIF_SP_H_RNG is calculated (*a negative value*) and will be applied on the reference ignition angle to define the ignition angle setpoint for torque interventions. In a system with variable valve lift the standardised ignition characteristic depends on the actual engine mode. Two modes are distinguished: load control via inlet valve lift and load control via the main throttle. To pay this different load controls attention the basic standardised ignition characteristic given by IP_IGA_DIF_SP_H_RNG is corrected with engine mode depending factor FAC_IGA_DIF.
Hereafter, it is determined if a fast torque intervention request implies a spark retard for its application through the logical flag LV_TQ_IGA_REQ.
If EFF_IGA_SP >= EFF_IGA_BAS_COR then no torque intervention is necessary and LV_TQ_IGA_ACT is set to 0 since there is no spark retard requested by torque. In this case IGA_DIF_SP_H_RNG is set to the passive value which is the maximum value for difference ignition angle *(=0 °CRK*). Then IGA_DIF_SP_H_RNG is not a limitation for the basic ignition angle in any case.
If EFF_IGA_SP < (EFF_IGA_BAS_COR - Threshold) then a significant spark retard resulting from a torque request has to be applied. For this LV_TQ_IGA_REQ is set to 1.
The value of the Threshold used here depends on both if an anti-jerk intervention is activated and if the engine is in idle speed phase. In normal condition (*no anti-jerk nor idle speed*) the threshold is Threshold = C_EFF_IGA_THD_1. In case of Anti-Jerk intervention a specific threshold will be used (*Threshold_1 = C_EFF_IGA_THD_AJ*) ; in idle speed also another specific threshold (*Threshold_2 = C_EFF_IGA_THD_IS*) instead of the normal one. Finally, the minimal threshold between both preceding is retained to be *applied (Threshold = Min(Threshold_1,Threshold_2)*).
IGA_DIF_SP_H_RNG is deduced from EFF_IGA_SP and is added (*negative value*) to the reference ignition angle to get the ignition angle setpoint for torque intervention.
The main reason for the existence of these two cases is to reduce ignition angle jitters if torque values are jittering (TQI_SP_CBK[NC_CBK_EX_NR] *and TQI_REF*). If no significant torque intervention is recognised then IGA_DIF_SP_H_RNG is set to the passive value 0°CRK. In this case the torque

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Copyright (C) Continental AG,2007

controlled ignition angle setpoint has definitely no impact any more to the applied ignition angle which is then only determined from the basic ignition angle and knock control.
This functionality allows choosing what parameter (*Ignition, Injection, ETC, etc...*) will be impacted first by a fast torque intervention and how this torque reduction request will be handled.
IGA_SP_CAN_H_RNG is calculated like IGA_SP_H_RNG only with calculations depending on TQI_SP_CAN.

Application conditions:

Activation: LV_HOM_RUN = 1
Deactivation: LV_HOM_RUN = 0
Initialisation: IGA_SP_CBK_H_RNG[NC_CBK_EX_NR] = IGA_SP_H_RNG = 60°CRK **and** IGA_SP_CBK_CAN_H_RNG[NC_CBK_EX_NR] = IGA_SP_CAN_H_RNG = 60°CRK **and** LV_TQ_IGA_ACT = 0 at reset
Update Rate: 10 ms

Formula section:

IF EFF_SCC_AV > 0
then EFF_IGA_SP_CBK_1[NC_CBK_EX_NR] = TQI_SP_CBK[NC_CBK_EX_NR] /(TQI_REF * EFF_SCC_AV * EFF_LAMB_AV_CBK[NC_CBK_EX_NR])
else EFF_IGA_SP_CBK_1[NC_CBK_EX_NR] =TQI_SP_CBK[NC_CBK_EX_NR]/(TQI_REF* EFF_LAMB_AV_CBK[NC_CBK_EX_NR])
endif
EFF_IGA_SP_CBK_1_CAN[NC_CBK_EX_NR] = TQI_SP_CAN /(TQI_REF * EFF_SCC_AV * EFF_LAMB_AV_CBK[NC_CBK_EX_NR])
note: if division by 0 then set EFF_IGA_SP_CBK_1 to maximum Hexa value.

EFF_IGA_SP_CBK[NC_CBK_EX_NR]=Min(EFF_IGA_SP_CBK_1[NC_CBK_EX_NR] , 1.0)
EFF_IGA_SP_CBK_CAN[NC_CBK_EX_NR]=Min(EFF_IGA_SP_CBK_1_CAN[NC_CBK_EX_NR] , 1.0)
Those preliminary calculations have to be done all the time whatever should be the value of LV_TQ_IGA_ACT.

Fast torque intervention request determination
Preliminary calculations for threshold:
If LV_ACT_AJ = 1
Then Threshold_1 = C_EFF_IGA_THD_AJ
Else Threshold_1 = C_EFF_IGA_THD_1
Endif
If LV_REQ_ISC = 1
Then Threshold_2 = C_EFF_IGA_THD_IS
Else Threshold_2 = C_EFF_IGA_THD_1
Endif
And Threshold = Min(Threshold_1,Threshold_2)
Threshold, Threshold_1, Threshold_2 here are only an intermediate variable to clarify those choices on the Torque intervention.
Fast Torque Intervention request determination upon Threshold
(Reduction to a global variable instead of cylinder bank selective approach):
If (EFF_IGA_SP_CBK[CBK_1]<(EFF_IGA_BAS_COR_CBK[CBK_1] - Threshold) **Or** (EFF_IGA_SP_CBK[CBK_2]<(EFF_IGA_BAS_COR_CBK[CBK_2] - Threshold))
Then LV_TQ_IGA_REQ = 1
Elseif EFF_IGA_SP_CBK[CBK_1] >= EFF_IGA_BAS_COR_CBK[CBK_1]
Or

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. EFF_IGA_SP_CBK[CBK_2] >= EFF_IGA_BAS_COR_CBK[CBK_2]
then LV_TQ_IGA_REQ = 0
else $LV\_TQ\_IGA\_REQ_{n}$ = $LV\_TQ\_IGA\_ACT_{n-1}$
Endif

//LV_TQ_IGA_ACT determination:
If C_TQ_IGA_INH = 0
Then LV_TQ_IGA_ACT = LV_TQ_IGA_ENA
Else **If** C_TQ_IGA_INH = 1
Then LV_TQ_IGA_ACT = 0
Else **If** LV_TQ_IGA_ENA = 1 **and** LV_TQ_IGA_REQ = 1
Then LV_TQ_IGA_ACT = 1
Else LV_TQ_IGA_ACT = 0
Endif
Endif
Endif

Setpoint spark retard calculation (for visual purposes, [C] =[NC_EX_CBK_NR] in the following concerning _CBK_ variables):
If LV_TQ_IGA_ACT = 1
Then EFF_IGA_INV_COR_CBK*[C]* = **(**100 - EFF_IGA_SP_CBK*[C]**100**)** /FAC_EFF_IGA
EFF_IGA_INV_COR_CBK_CAN*[C]* = **(**100 - EFF_IGA_SP_CBK_CAN*[C]**100**)** /FAC_EFF_IGA

IGA_DIF_SP_CBK_H_RNG*[C]* = IP_IGA_DIF_SP_H_RNG(EFF_IGA_INV_COR_CBK*[C]*)

IGA_DIF_SP_CBK_CAN_H_RNG*[C]* = IP_IGA_DIF_SP_H_RNG (EFF_IGA_INV_COR_CBK_CAN*[C]*)

IGA_SP_CBK_H_RNG*[C]* = IGA_REF_COR_CBK*[C]* + IGA_DIF_SP_CBK_H_RNG*[C]*

IGA_SP_CBK_CAN_H_RNG*[C]* = IGA_REF_COR_CBK*[C]* + IGA_DIF_SP_CBK_CAN_H_RNG*[C]*
Else IGA_SP_CBK_H_RNG*[C]* = IGA_SP_CBK_CAN_H_RNG*[C]* = 60°CRK
Endif

Calculation of Arithmetic Mean Values:
IGA_SP_H_RNG = mean(IGA_SP_CBK_H_RNG*[C]*)
IGA_DIF_SP_H_RNG = mean(IGA_DIF_SP_CBK_H_RNG*[C]*)
IGA_SP_CAN_H_RNG = mean(IGA_SP_CBK_CAN_H_RNG*[C]*)
IGA_DIF_SP_CAN_H_RNG = mean(IGA_DIF_SP_CBK_CAN_H_RNG*[C]*)

Number of freeze frame datasets for storing operation point and cylinder number for excursion limit analysis					

6.16.1 Inhibition of knock control

General information:

To activate the knock control, a macro function (KNK_CTL_DIS) is executed which checks if knock control is disabled due to malfunctions. If KNK_CTL_DIS = 0 the conditions are fulfilled and the knock control is enabled.

Application conditions

Initialisation:
```
at reset or LV_ES 0->1:
If LV_ERR_CRK = 0 and LV_ERR_KNKS[NC_NR_SENS_KNK] =
0 and LV_ERR_SPI_KNK = 0
Then KNK_CTL_DIS = 0
```

Recurrence: *every segment*

Activation: *LV_ES = 0*

Formula section:

If LV_ERR_CRK = 1 **or**
LV_ERR_KNKS[NC_NR_SENS_KNK] = 1 **or**
LV_ERR_SPI_KNK = 1
Then KNK_CTL_DIS = 1
Endif

6.16.2 Excursion Limit Analysis

FUNCTION DESCRIPTION:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

General information:

'Control Excursion Limit' in the 'Knock Control' module is used to limit the difference of the ignition adjustment angle through knock control of the single cylinders to a certain value.
When a limitation on one cylinder is done, LV_IGA_DIF_MAX_KNK is set in order to give this information to the 'Excursion Limit Analysis' functionality.
Here the values for the concerning cylinder and actual operation point are stored.

Graphical interpretation:

- Cylinder individual counter CTR_IGA_DIF_MAX_KNK[NC_CYL_NR]

```
input   |_CTR_|
- -> |______|   (for CYL_ID_KNK = 0)

N.B.: i represents identification index of stored info data set
(shifting in 'For' loop has not to be executed, if NC_NR_FRF_KNK_RTD = 1)
(efficiency of CPU load could be optimized, if only 'filled' freeze frames are shifted)

6.16.3 Pre-Ignition Analysis

FUNCTION DESCRIPTION:

General information:

'Normal Operation Pre-Ignition' in the 'Knock Control' module is used to cut off injection of a single cylinder in case of pre-ignition detection. LV_KNK_PRE_DET is set and gives this information to the 'Pre-Ignition Analysis' functionality. Here the values for the concerning cylinder and actual operation point are stored. Also the number of pre window (CTR_0_...) and main window (CTR_1...) events when pre-ignition is detected is monitored.

Graphical interpretation:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

6.16.4 Knock Control Measurement CAN-Interface

General information:

This chapter is used as interface between the variables on the local CAN bus of the knock control measurement with CAN-interface and the system variables.
The process is as followed:
a.) start the output of systemvalues
b.) output of the systemvalue
c.) stop the output of systemvalues

6.16.4.1 CAN Protocol

Description:

The following control units participate to CAN-communication:
DME: Engine management system
IAV: Measurement equipment from BMW

Baudrate: 500 kBaud

The IAV sends for starting its measurement values on CAN Messages the ID = **700H.**

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The DME sends its measurement concerning the IAV interface on CAN Messages with the ID = **701H and 702H.**
The IAV sends for stopping its measurement values on CAN Messages   the ID = **70AH.**

6.16.4.2 Send messages by DME ID 701H and ID702H

ID 701H

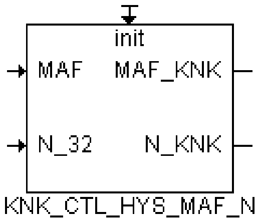
6.17.1 Pre-processing

6.17.1.1 Hysteresis Function for MAF and N_32



General information:

Hysteresis functions for engine speed and air-mass changes are defined for the tables relevant for the knock control in order to avoid steps recognisable for the driver due to small changes of the operation point.

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization: *MAF_KNK = N_KNK = 0 at reset and engine running to engine stop*

Update Rate: *every segment*

Formula section:

if **|(N_32 - N_KNK)| >= C_N_IGA_HYS_KNK**
N_KNK = N_32
else
N_KNK remains unchanged
end if

if **|(MAF - MAF_KNK)| >= C_MAF_IGA_HYS_KNK**
MAF_KNK = MAF
else
MAF_KNK remains unchanged
end if

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 6.17.1.2 Knock Control Enable

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization:
LV_KNK_CTL_ENA = 0 at reset and engine running to engine stop
LV_KNK_CTL_PRE_ENA = 0 at reset and engine running to engine stop
LV_CTR_KNK_CMB = 0 reset and engine running to engine stop
CTR_KNK_CMB = 0 reset and engine running to engine stop

Update Rate: *every segment*

Formula section:

knock control enable:
if (LV_ST = 1 or LV_IGK = 0)
then LV_KNK_CTL_ENA = 0
else
if (MAF_KNK >= IP_MAF_MIN_KNK__N__TCO)
LV_KNK_CTL_ENA = 1
else
LV_KNK_CTL_ENA = 0
end if
end if

knock control pre-ignition enable:
if LV_KNK_CTL_ENA = 1 **and** MAF_KNK >= IP_MAF_MIN_KNK_PRE
then LV_KNK_CTL_PRE_ENA = 1
else LV_KNK_CTL_PRE_ENA = 0
end if

inhibit knock control pre-ignition:
if N_32 > C_N_KNK_CTL_PRE_INH
then LV_KNK_CTL_PRE_INH = 1
else LV_KNK_CTL_PRE_INH = 0
end if

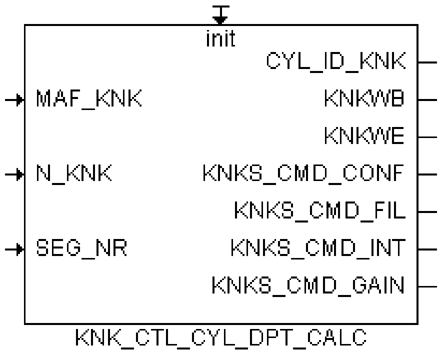
Copyright (C) Continental AG,2007

If the relevant air-mass is below the air-mass threshold (LV_KNK_CTL_ENA = 0), only the noise value calculation is executed.
An additional air-mass threshold exists for enabling cylinder cut off algorithm (LV_KNK_CTL_PRE_ENA).
A complete inhibition of pre-window calculation and consideration is forced (LV_KNK_CTL_PRE_INH = 1), when pre-window is initialized with 0 (see IRS); especially when engine speed is above a calibratable threshold.

6.17.1.3 Cylinder Dependent Calculations



6.17.1.3.1 Cylinder Number for Knock Control

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

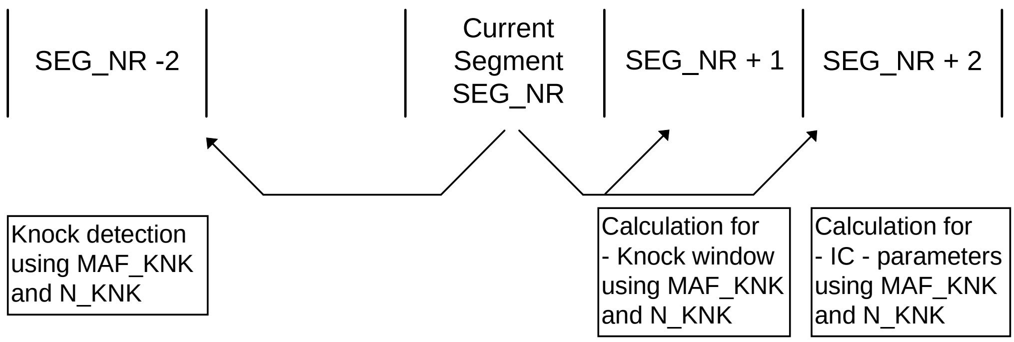
Initialization: *CYL_ID_KNK = 0 at reset and engine running to engine stop*

Update Rate: *every segment*

Formula section:

CYL_ID_KNK = SEG_NR - 2

Description:



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

6.17.1.3.2 Knock Measurement Window

General information:

The knock detection is performed for cylinder-individually defined measurement windows since knock-typical oscillations only occur for certain crankshaft angles. The measurement windows (crank angle of beginning and end) are specified as function of the engine speed and load.
If the estimated 'End of the Knock Measurement Window' is lower or equal compared to the 'Beginning of the Knock measurement Window', both values are initialized.

The crank angle for the beginning of the knock measurement window is taken for each cylinder from the respective table IP_KNKWB[x] according to the firing order.
The crank angle for the end of the knock measurement window is taken for each cylinder from the respective table IP_KNKWE[x] according to the firing order.

Apart from window settings for AFS (stoichiometric) separate windows are existing in operation mode AFL (lean) and S (stratified).

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization:
```
at reset and engine running to engine stop
 KNKWB[0 to NC_CYL_NR] = NC_KNKWB_INI
 KNKWE[0 to NC_CYL_NR] = NC_KNKWE_INI
 KNKWB_PRE[0 to NC_CYL_NR] = NC_KNKWB_PRE_INI
 KNKWE_PRE[0 to NC_CYL_NR] = NC_KNKWE_PRE_INI
```

Update Rate: *every segment*

Formula section:

Definition of cylinder dependent knock window ranges:
RNG_WB = (720° /NC_CYL_NR) - 12°
RNG_WB_HEX = HEX(RNG_WB /0.375°)
RNG_WE = (720° /NC_CYL_NR) - 6°
RNG_WE_HEX = HEX(RNG_WE /0.375°)

endif

call action interface for pre and normal window

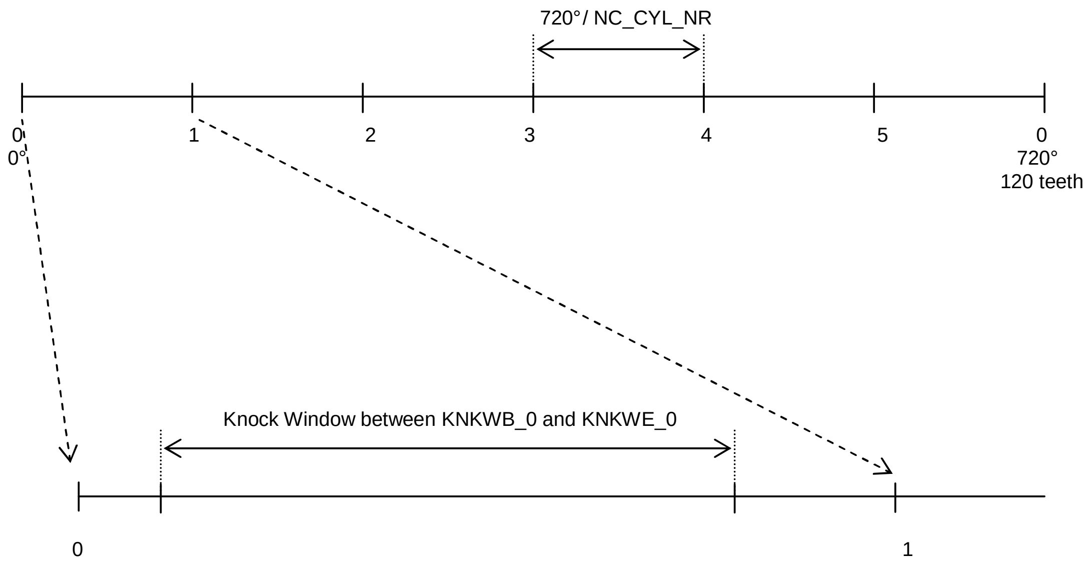
ACTION_INFR_*SetKnkWindow*(IN <Knkwb>, IN <Knkwd>, IN <Cyl>, IN <Win>)
Sets knock window for cylinder *cyl*

N.B.: x represents current SEG_NR + 1

Important information for calibration:
In order to have the possibility of two windows (pre- and main) in one segment, BSW is calculating with double number of segments with half of the original length. Every window begin (pre- or main) must lie within one of such doubled segments. The beginning of a segment for the main window is fixed in BSW to 2°CRK after TDC. Due to that the main knock window KNKWB[x] must be calibrated not before 2°CRK.
IP_KNKWE_PRE_GAP calibration must be done before KNKS_PRE signal parameter calibration (window, gain, filter frequency, integration time constant), in order to assure right calculated and transferred values from the knock IC and not to have different values because of new window length after changing this restriction. The duration of the gap between KNKWE_PRE and KNKWB is determined by the SPI bus communication. During the gap the integrator value of the pre-window has to be read and the ATIC62 device has to be programmed with the main window parameters (window, gain, filter frequency, integration time constant). The required duration has to be determined system individually by the BSW SW department.
Special restrictions must be considered, if distance between 0°CRK (minimum possible value for pre-window begin and end; also when set inactive a activation peak is remaining) and main window begin should be smaller than this determined gap or a smaller gap in general should be used. Then especially the same parametrisation for pre- and main window is required and no inhibition for pre-window calculation is allowed. Thus in BSW right parameters for main window are already set during pre-window parametrisation.
To have low CPU load, the knock pre-ignition window can be set to 0 by LV_KNK_CTL_PRE_INH = 1. This is done either above a calibratable engine speed threshold or at implausibility, when pre-window end is earlier than pre-window begin. KNKWB_PRE and KNKWE_PRE values are initialized with the NC values 0. Then no parametrisation and knock IC processing is executed (see IRS). Also the detection algorithm and KNK_THR_PRE aren't executed any longer.

Description:
(example for NC_CYL_NR=6; TDC offset = 0°CRK)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



6.17.1.3.3 Assignment of cylinder number to Knock sensor diagnosis

FUNCTION DESCRIPTION:

The physically defined cylinder number is defined in firing oder 1 5 3 6 2 4 for a in-line 6 cyl. engine. There is the possibility to define especially for the knock sensor diagnosis which cylinder should be used for the knock sensor diagnosis via the help of the calibration constants C_KNKS_1/_2_DIAG. Only 'loud' cylinders should be used to detect a malfunktion of the Knock sensor signal.
The maximum possible number of cylinders is defined with NC_KNKS_CONF. Only cylinders can be used which are assigned for the knock detection of the individual knock sensor.
e.g. in-line 6 cyl. engine:

logically:	0	1	2	3	4	5	
physically:	1	5	3	6	2	4	
assignment KR	0	1	0	1	0	1	NC_KNKS_CONF = 2A hex
assignment KNKS1	1	0	1	0	1	0	C_KNK_1_DIAG = 15 hex
assignment KNKS2	0	1	0	1	0	1	C_KNK_2_DIAG = 2A hex

Application conditions

Initialisation: `all = 0 at reset and engine running to engine stop`

Recurrence: `segment synchronous`

Activation: `all engine states except LV_ES`

6.17.1.3.4 Calibration of ATIC62 device

FUNCTION DESCRIPTION:

General information:
The knock control in the engine management works with the ATIC62 device. The output value of the integrator after the end of the measurement window is fed as Knock Value KNKS through an analogue channel to the control algorithm.
(Further information may be obtained in "Applications Guide to ATIC62 ".)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Apart from parameters for AFS (stoichiometric) separate sets of parameters are existing in operation mode AFL (lean) and S (stratified).

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization:
```
KNKS_CMD_INT[0 to NC_CYL_NR]      =   0
 KNKS_CMD_FIL[0 to NC_CYL_NR]          =      0
 KNKS_CMD_GAIN[0 to NC_CYL_NR]        =      0
 KNKS_CMD_INT_PRE[0 to NC_CYL_NR]     =     0
 KNKS_CMD_FIL_PRE[0 to NC_CYL_NR]     =     0
 KNKS_CMD_GAIN_PRE[0 to NC_CYL_NR] =     0
 KNKS_CMD_CONF[0 to NC_CYL_NR]      =      value of configuration
bit at position x
                  in NC_KNKS_CONF
   at reset and engine running to engine stop
```

Update Rate: *every segment*

Formula section:

If OPM_AV = "AFS"

Then KNKS_CMD_INT[x] = ID_ITC_KNK[x]

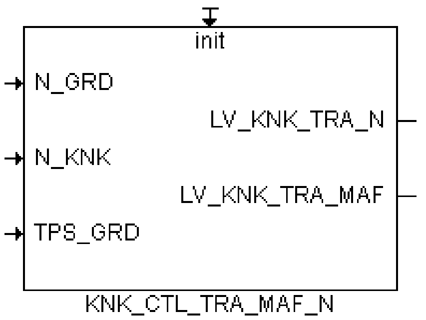
Note: These calibration data have to be adjusted if the processor sampling rate is changed.

6.17.1.4 Load and Speed Dynamics



6.17.1.4.1 Speed Dynamics Function

FUNCTION DESCRIPTION:

General information:
In order to keep track with the noise values for large engine speed gradients (LV_KNK_TRA_N = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA.
Care needs to be given to the absolute function evaluation, so that there is no difference in the treatment of positive and negative speed gradients.
Furthermore the values of Knock -Adaptation-circuits 1 + 2 are only read at active speed dynamics.

Application conditions

Activation: *at every engine state except engine stop*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

else

LV_KNK_TRA_N = 0

end if

6.17.1.4.2 Load Dynamics Function

FUNCTION DESCRIPTION:

General information:

In order to keep track with the noise values for large (positive) load gradients (LV_KNK_TRA_MAF = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA. After the triggering of the load dynamics the special filtering constant C_NL_CRLC_TRA is applied for the number of ID_CYCNR_FAC_TRA_KNK__N cycles. In addition, at active load dynamics function, the knock detection (KNK_THD[x]) is made less sensitive with the help of the factor C_FAC_TRA_KNK.
The values from the knock adaptation-circuits 1 + 2 are only read.

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization: *LV_KNK_TRA_MAF = 0 at reset and engine running to engine stop*

Update Rate: *every segment*

Formula section:

if **LV_IGA_TRA_KNK 0 -> 1**

LV_KNK_TRA_MAF = 1 for ID_CYCNR_FAC_TRA_KNK__N cycles

else

if **(ID_CYCNR_FAC_TRA_KNK__N has elapsed)**

LV_KNK_TRA_MAF = 0

6.17.2.4.2 Normal Operation Pre-Ignition

FUNCTION DESCRIPTION:

General information:
Surface ignition, before the regular ignition is triggered, is called pre-ignition. This kind of autoignition is caused by a hot spot, generated by prolonged, heavy spark knock. It is known as knock-induced pre-ignition. This is the most damaging side effect of spark knock.
Knock-induced pre-ignition is detected by following algorithm, that is observing normal knocking (normal knock window) and pre-ignition (pre-knock window). Both windows are evaluated to detect occuring pre-ignition events. If either many knock events are detected in the normal knock window or in the pre-knock window or in the normal knock window plus the pre-knock window during a certain number of firing events, autoignition is detected and the protection function of the engine is activated. Then the injection of the concerned cylinder is shut off for a calibratable number of firing events, which can be increased in case of multiple detection events during one driving cycle, in order to prevent engine damage.
(No execution, if not (LV_KNK_CTL_PRE_ENA = 1))

Detection algorithm:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 6.17.2.4.3 Normal Operation

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FUNCTION DESCRIPTION:

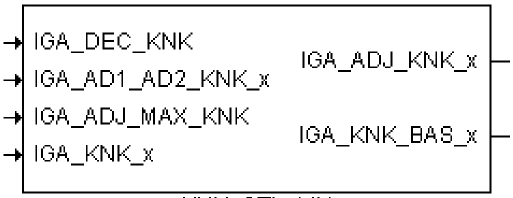
General information:

The spark retard is calculated cylinder-individual at every firing event. The spark retard due to the knock control system is determined by the spark retard due to knocking combustion (IGA_KNK[NC_CYL_NR]). The sum of these retard components is limited to a maximum spark retard.
In case of knock free operation (LV_KNK=0) and LV_KNK_CTL_ENA = 1 the Ignition retard due to knock control is re-set to zero (Controlled reset at Knock-free operation).
The controlled ignition-timing reset remains active until either the map ignition timing (IGA_KNK_BAS[x] = 0) is reached or until knocking occurs.

Formula section:

if (LV_KNK = 1)
then IGA_KNK_BAS[x] = IGA_KNK[x] - IGA_DEC_KNK
else Controlled reset at Knock-free operation
  if (LV_IGA_TRA_KNK = 0)
  then IGA_KNK_BAS[x] = IGA_KNK[x] + IP_IGA_INC_KNK__N
  else IGA_KNK_BAS[x] = IGA_KNK[x]
  end if
end if
N.B.: x represents current CYL_ID_KNK

6.17.2.4.4 Limp Home Operation



KNK_CTL_LIH

FUNCTION DESCRIPTION:

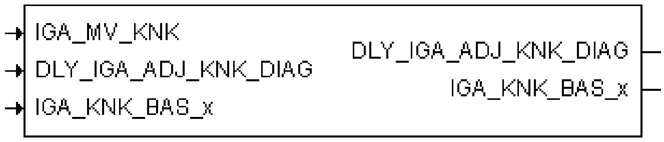
General information:
After an diagnosis error on the knock control system is detected (KNK_CTL_DIS = 1) the limp home spark retard level is achieved via spark retard Intensity 1 (IGA_DEC_KNK).

Formula section:

Check if limphome spark retard level is already reached
if IGA_KNK[x] - IGA_DEC_KNK < IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard
then
  IGA_KNK_BAS[x] = IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
Limphome spark retard level not yet reached
else
  IGA_KNK_BAS[x] = IGA_KNK[x] - IGA_DEC_KNK
end if

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

6.17.2.4.5 Control Exursion limit



KNK_CTL_CTL_EX_LIM

FUNCTION DESCRIPTION:

General information:

The control excursion limit is used to limit the difference of the ignition adjustment angle through knock-control of the single cylinders to a certain value. All 720 °CRK the arithmetic mean value of the cylinder ignition adjustment angles IGA_KNK_BAS[NC_CYL_NR] is calculated:

All 720/Cyl. °CRK a test will be done, to see whether the ignition adjustment angle of the just calculated cylinder is more retarded or advanced than

IGA_MV_KNK - C_IGA_ DIF_MIN_MAX_KNK. In this case the knock control adjustment angle is limited to the control excursion limit.

In case that ignition angle retard reaches the maximum limit, LV_IGA_DIF_MAX_KNK is set in order to give this information to the 'Excursion Limit Analysis' functionality, where the values for concerning cylinder and actual operation point are stored.

Formula section:

Case Differentiation:

Analysis trigger reset:

LV_IGA_DIF_MAX_KNK = 0

if IGA_KNK_BAS[x] IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK

advance limitation:

then IGA_KNK_BAS[x] = IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK

else

if IGA_KNK_BAS[x] IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK

retard limitation:

then IGA_KNK_BAS[x] = IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK

Analysis trigger for cylinder individual counter, freeze of Cyl_ID_KNK and operation point:

LV_IGA_DIF_MAX_KNK = 1

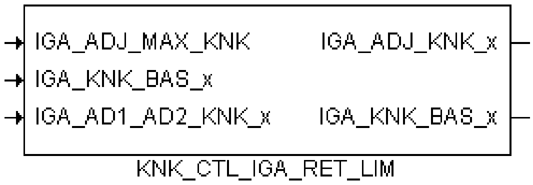
endif

end if

N.B.: x represents current CYL_ID_KNK

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

6.17.2.4.6 Limitation of total ignition retard

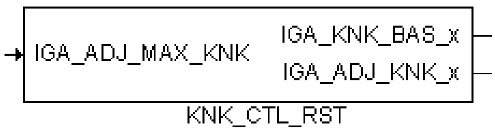


Formula section:

if LV_HOM_ACT = 1
then
check if limphome spark retard level is already reached
if IGA_KNK_BAS[x] < IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard
then
IGA_KNK_BAS[x] = IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
endif
endif
IGA_KNK[x] = IGA_KNK_BAS[x]
IGA_ADJ_KNK[x] = IGA_KNK_BAS[x]

N.B.: x represents current CYL_ID_KNK

6.17.2.4.7 Reset of Knock control



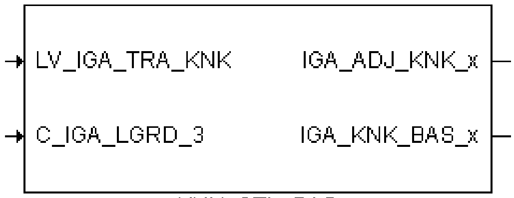
Formula section:

IGA_KNK_BAS[x] = 0°CRK
IGA_ADJ_KNK[x] = IGA_ADJ_MAX_KNK - IGA_WOUT_KNK

N.B.: x represents current CYL_ID_KNK

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

6.17.2.5 Knock control passiv (Reset after abandoning the Knock-Operating-Limit)



KNK_CTL_PAS

FUNCTION DESCRIPTION:

General information:
If the operating limit falls below (LV_KNK_CTL_ENA = 0;), then the ignition adjustment angle IGA_KNK_BAS[x] is re-set to 0, with the change limitation C_IGA_LGRD_3 - however referring to 720° CRK -, in order to reach the map ignition timing.

Formula section:

if (LV_IGA_TRA_KNK = 0)
then
IGA_ADJ_KNK[x] = IGA_ADJ_KNK[x]$_{(N-1)}$ + C_IGA_LGRD_3
IGA_KNK_BAS[x] = 0
else
IGA_ADJ_KNK[x] = IGA_ADJ_KNK[x]$_{N-1)}$ (remains unchanged)
IGA_KNK_BAS[x] = 0
end if

6.17.2.6 Knock Control in Stratified Mode

FUNCTION DESCRIPTION:

General information:
Knock detection and knock control is also active in stratified combustion mode. As ignition retard is not usable in stratified mode and may lead to problems at combustion mode changes, the spark retard variables IGA_ADJ_KNK and IGA_KNK_BAS are set to zero during stratifed. If stratified mode is left, the spark retard has to start at 0 °CRK when knock is recognized.

Formula section:

if OPM_AV = ’S’ (stratified combustion, 1H)
then
call action interface for acquisition of knks signal for pre and normal window

ACTION_INFR_*GetVKnks*(OUT <V_knks>, IN <Cyl>, IN <Win>)
Gets the formatted knock noise raw signal

IGA_ADJ_KNK[x] = 0 °CRK
IGA_KNK_BAS[x] = 0 °CRK

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

if (KNKSx >= KNK_THD[x])
then LV_KNK = 1
else LV_KNK = 0
endif
if (KNKS_PRE[x] ≥ KNK_THD_PRE)
then LV_KNK_PRE = 1
else LV_KNK_PRE = 0
end if
CYCNR_KNK_PRE_DET = 0 (reset of counter for observation period)
CTR_KNK_PRE_DET[x] = 0 (reset of detection counter)
CTR_KNK_PRE_DET_0[x] = 0 (reset of pre window counter)
CTR_KNK_PRE_DET_1[x] = 0 (reset of main window counter)
LV_KNK_PRE_DET = 0 (reset of bit for detected pre-ignition)
CYCNR_INH_IV_KNK_PRE_DET[x] = 0 (reset of injection shut off counter)
set all bits in INH_IV_KNK = 0 (reset of pre-ignition inhibit bits)
else
IGA_ADJ_KNK[x] is calculated as described in the previous chapters
IGA_KNK_BAS[x] is calculated as described in the previous chapters
end if

Hints:
Due to former changes IGA_KNK[x] is now identical to IGA_KNK_BAS[x].
At transition from stratified combustion mode to normal operation mode of knock control, NC_CYL_NR cycles have to be elapsed for spark retard.

6.17.3 Post-processing

6.17.3.1 Meanvalues of knock-control ignition adjustment

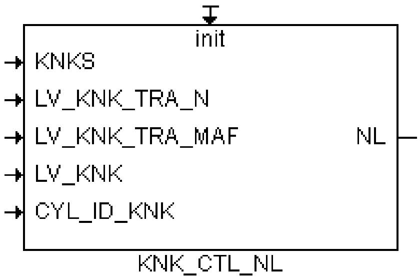
6.17.3.2 Noise Value



FUNCTION DESCRIPTION:

The noise value is cylinder-individually calculated as sliding average from the knock values. The averaging constant is either taken from ID_NL_CRLC, if no knock control transient function is active (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0) or C_NL_CRLC_TRA, when a knock control transient function is active (LV_KNK_TRA_N = 1 or LV_KNK_TRA_MAF = 1).

Application conditions

Activation: *at every engine state except engine stop*

Deactivation: *at engine stop*

Initialization: NL[0 to NC_CYL_NR] = C_KNK_THD_MAX
at reset or engine running to engine stop

Update Rate: *every segment*

Formula section:

if **(LV_KNK_TRA_N or LV_KNK_TRA_MAF)**
then if **OPM_AV = "AFS"**
then **NL[x] = NL[x] + (KNKS[x] - NL[x]) * C_NL_CRLC_TRA**
else **NL[x] = NL[x] + (KNKS[x] - NL[x]) * C_NL_CRLC_TRA_AFL**
end if

elseif **LV_CTR_KNK_CMB = 1**
then **NL[x] = NL[x] + (KNKS[x] - NL[x]) * C_NL_CRLC_CMB**

else **NL[x] = NL[x] + (KNKS[x] - NL[x]) * ID_NL_CRLC**
end if

NL[NC_CYL_NR] shows always the measured noise value from the ATIC62 device. The noise value is calculated always (independant from detection of knocking combustion).

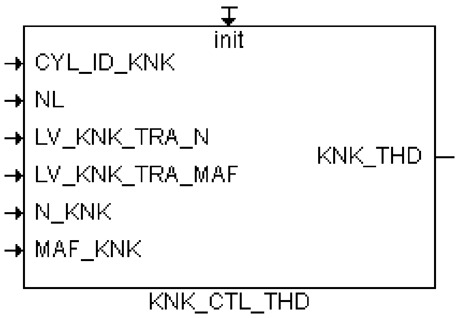
In transient condition, if knocking combustions are detected (LV_KNK = 1) after knock-free operation, the first noise value is used weighted ((KNKS[x] / IP_FAC_THD_KNK) * C_FAC_KNK_TRA instead of simply use of KNKS[x]) to calculate the noise level, the second and the following are taken into consideration for normal transient calculation of noise level again.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Else, if KNKS[x] $\geq$ IP_FAC_NL_UPD_DEAC * KNK_THD[x] (signal near threshold)
AND LV_KNK_PAS_TRAN_ACT = 1 (**delay cycles elapsed after passive or limp-home)**
AND LV_CTR_KNK_CMB = 0 (**delay counter elapsed after combustion mode switch), the first and the second noise value isn‘t used to calculate the noise level (NL[NC_CYL_NR] remains unchanged), the third and the following are taken into consideration for calculation of noise level. NL[NC_CYL_NR] remains unchanged for this time.**

N.B.: x represents current CYL_ID_KNK

6.17.3.3 Relative and Absolute Knock Threshold



FUNCTION DESCRIPTION:

General information:
The knock threshold (KNK_THD[NC_CYL_NR]) is the limit for the knock values (KNKSx), which are used for knock decision. If the knock values are greater or equal to the knock threshold, then knocking is recognised (LV_KNK = 1) and an ignition timing retardation follows. If the knock values are smaller, knocking is not detected (LV_KNK = 0) and the relevant KNK-ignition-angle is reset ($\rightarrow$ Knock-free Operation after Knocking).

The knock threshold is calculated for each cylinder separately and depends on the cylinder-individual noise value. Calculation of the knock threshold occurs with help from the cylinder-individual knock factors IP_FAC_THD_KNK[NC_CYL_NR] and knock summand IP_ADD_KNK__N.

If the noise value is above the minimum threshold C_NL_MIN, the knock threshold is calculated on the basis of the cylinder-individually noise value NL[NC_CYL_NR]. If the noise value is below C_NL_MIN this value is used as noise value for calculation of the knock threshold. If the knock threshold is above ID_THD_MAX_KNK this value is used as knock threshold (Limitation).
C_THD_MAX_KNK stays preserved as initialisation value for NL and NL_0_5 (in multiplexer specification).

N.B.: The actual knock value KNKS[x]$_n$ is not used in the calculation of the actual knock threshold KNK_THD[x]$_n$ but in the calculation of the next threshold KNK_THD[x]$_{n+1}$. So the decision knocking combustion yes/no is done with using the knock threshold KNKS[x]$_{n-1}$.

Application conditions

Activation: *at every engine state except engine stop*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

Deactivation: *at engine stop*

Initialization: KNK_THD[0 to NC_CYL_NR] = KNK_THD_PRE = 5V
at reset and engine running to engine stop

Update Rate: *every segment*

Formula section:

The lower absolute threshold is one value for all cylinders and is represented by the constant C_NL_MIN.

```
If      NL[x] < C_NL_MIN
        NL_LIM = C_NL_MIN
else
        NL_LIM = NL[x]
end if

if      OPM_AV = "AFS"
        if      (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0)
                KNK_THD[x] = ( NL_LIM + IP_KNK_THD_ADD_N ) * IP_FAC_THD_KNK[x]
        else
                KNK_THD[x] = ( NL_LIM + IP_KNK_THD_ADD_N ) * IP_FAC_THD_KNK[x] *
                                C_FAC_TRA_KNK
        end if
else
        if      (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0)
                KNK_THD)[x] = ( NL_LIM + IP_KNK_THD_ADD_N_AFL ) *
                                IP_FAC_THD_KNK_AFL[x]
        else
                KNK_THD)[x] = ( NL_LIM + IP_KNK_THD_ADD_N_AFL ) *
                                IP_FAC_THD_KNK_AFL[x] * C_FAC_TRA_KNK
        end if
end if
```

The knock threshold is generally limited to KNK_THD_MAX

```
KNK_THD_MAX = IP_KNK_THD_MAX
If  (KNK_THD[x] > KNK_THD_MAX)
     KNK_THD[x] = KNK_THD_MAX
end if

If  LV_KNK_CTL_PRE_INH = 0
     KNK_THD_PRE = ID_KNK_THD_MAX_PRE
end if
```

N.B.: x represents current CYL_ID_KNK

(*) The correction factor **C_FAC_TRA_KNK** is part of the KNK-load dynamics function and is effective after recognised load dynamics **ID_CYCNR_FAC_TRA_KNK__N** cycles.

The knock factor is the multiplicative part used for calculation of the knock threshold from the noise value.
The knock summand is an additive correction of the knock noise value. Thereby the knock threshold can be moved, dependent on the speed, in a positive or negative direction.

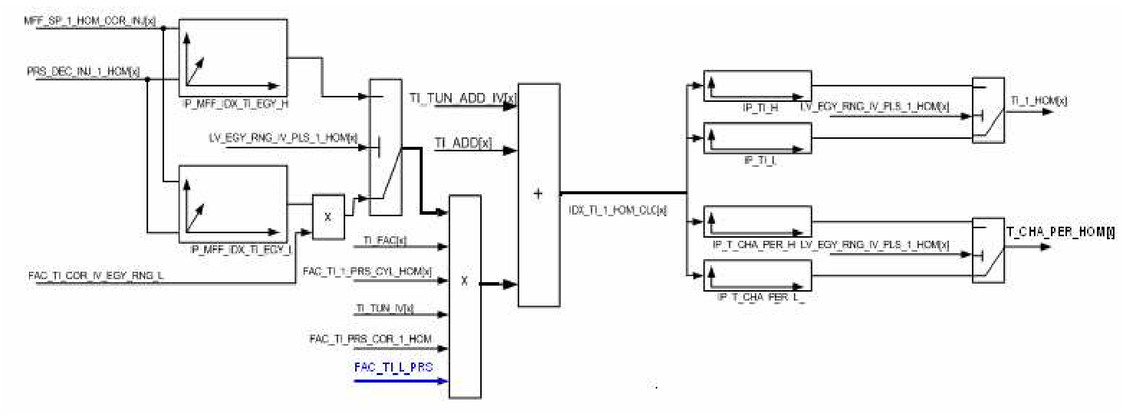
Overview:

Calculation of the cylinder individual injection times for homogeneous mode:

First pulse:
This module calculates the cylinder individual injection times TI_1_HOM[x], which are applied at the injectors.
The injection time can be set manually. If the switch LC_TI_1_HOM_MAN_ACT is set to one, the constant C_TI_1_HOM_MAN is applied.

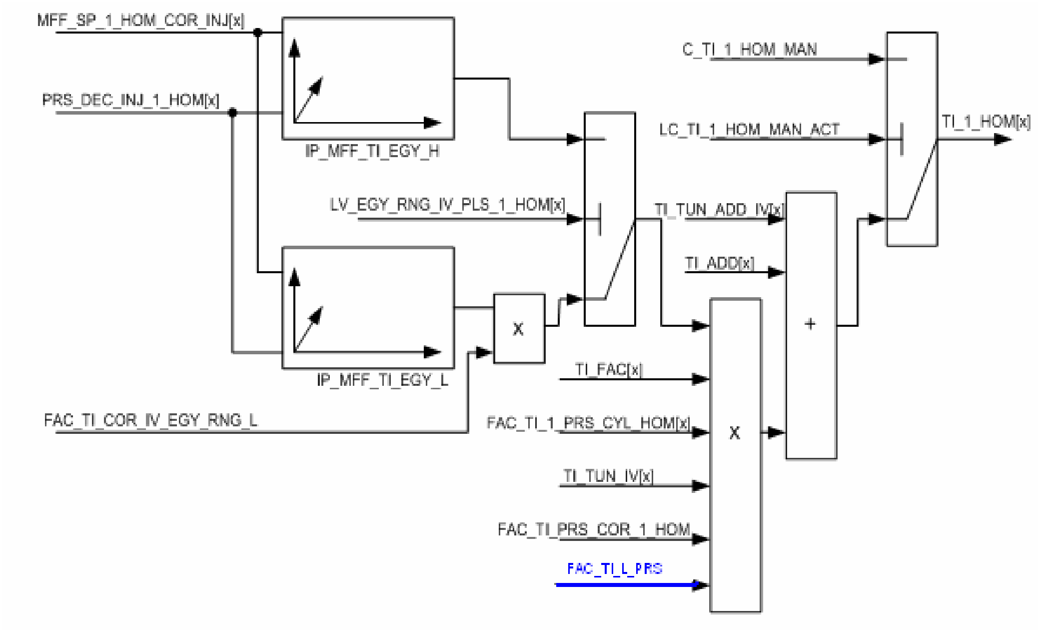
If homogeneous lean mode is active (STATE_CMB_CTL = HOM_AFL) and TI_1_HOM[x] is smaller than (TI_MIN + C_TI_MIN_OFS), the combustion mode changes to homogeneous mode. This is indicated if the flag LV_AUTH_TI_MIN_AFL is set to zero. Switching back to homogeneous lean mode is allowed at the earliest if the delay time C_T_AUTH_TI_MIN_AFL has elapsed. Then the flag LV_AUTH_TI_MIN_AFL is set back to zero.

Overview for calculation of the first pulse in homogenous mode with active current shaping (LC_CUR_SHP_INJ_ENA = 1):



Overview for calculation of the first pulse in homogenous mode with inactive current shaping (LC_CUR_SHP_INJ_ENA = 0):

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



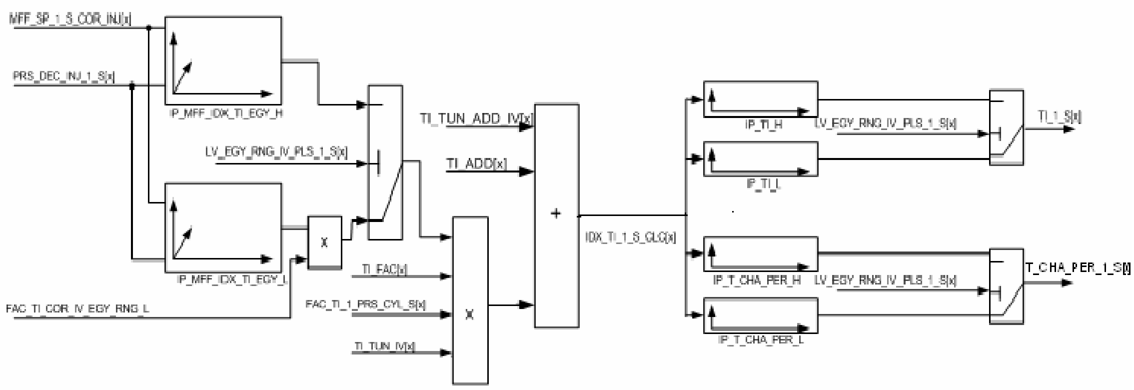
Second pulse:
If double injection is active (STATE_INJ_MOD_HOM_REQ = MPLH), then TI_2_HOM[x] is calculated.

Third pulse:
If triple injection is active (STATE_INJ_MOD_HOM_REQ = MPLH+PLS3), then TI_3_HOM[x] is calculated.

Calculation of the cylinder individual injection times for stratified mode:

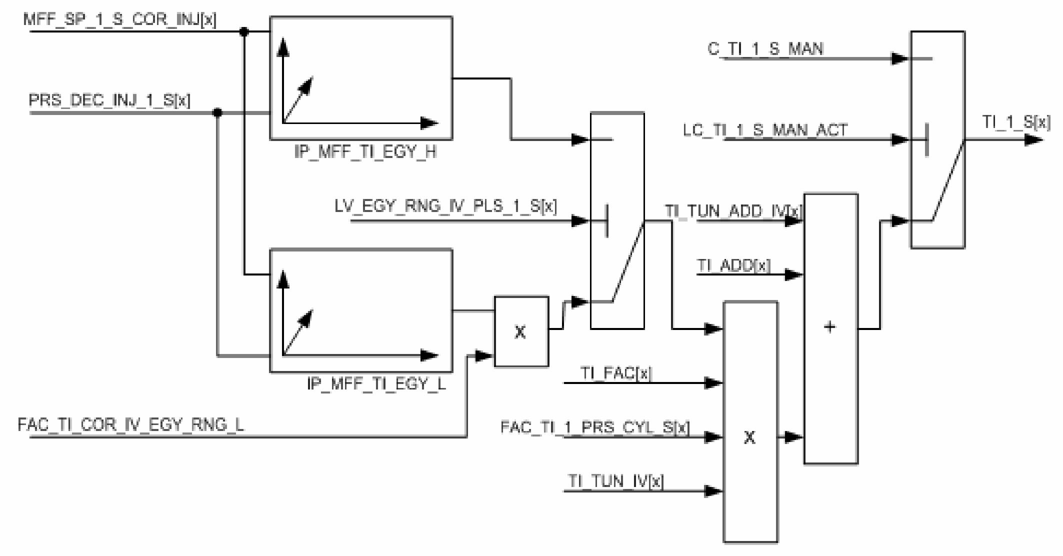
First pulse:
The injection time TI_1_S[x] can be set manually. If the switch LC_TI_1_S_MAN_ACT is set to one, the constant C_TI_1_S_MAN is applied.

Overview for calculation of the first pulse in stratified mode with active current shaping (LC_CUR_SHP_INJ_ENA = 1):



Overview for calculation of the first pulse in stratified mode with inactive current shaping (LC_CUR_SHP_INJ_ENA = 0):

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Second pulse:
If double injection is active (STATE_INJ_MOD_S_REQ = MPLS), then TI_2_S[x] is calculated.

The injection time TI_2_S[x] can be set manually. If the switch LC_TI_2_S_MAN_ACT is set to one, the constant C_TI_2_S_MAN is applied.

Third pulse:
If triple injection is active (STATE_INJ_MOD_S_REQ = MPLS+PLS3), then TI_3_S[x] is calculated.

The injection time TI_3_S[x] can be set manually. If the switch LC_TI_3_S_MAN_ACT is set to one, the constant C_TI_3_S_MAN is applied.

FUNCTION DESCRIPTION:

7.1.1 Segment synchronous tasks

Application conditions

Activation: every engine state

Deactivation: –

Initialization:

```
at reset:  TI_3_HOM_CLC_MIN   = 65.535 ms

```

Recurrence:
```
 LV_ST_END = 0:  10 ms
LV_ST_END = 1:     segment synchronous
```

Formula section:

For loop for runtime optimization:
In this specification the for loop
FOR i = 0, i < NR_CYL_CLC_RED_INJ **DO**
x = CTR_CYL_NR_ST_CLC_INJR + i
(1a)**IF** x >= NC_CYL_NR
(1a)**THEN**
x = x - NC_CYL_NR
(1a)**ENDIF**
<**loop content**>
ENDFOR
is substituted by
FOR cylinder_start to cylinder_stop **DO**
<**loop content**>
ENDFOR
Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

7.1.1.1 Calculation of the cylinder individual injection times for homogeneous mode

7.1.1.1.1 Calculation of the minimal applied injection time

TI_MIN_HOM is used to for deactivation of air fuel lean mode.
(1)IF LV_AFL_CLC = 1
(1)THEN
TI_MIN_HOM = IP_TI_MIN_HOM
... (Input data for IP_TI_MIN_HOM is
PRS_DEC_INJ_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[0]])
(1)ENDIF

7.1.1.1.2 First pulse (main pulse)

Correction of fuel pressure pulsations for homogeneous single injection mode:
(1)IF STATE_INJ_MOD_HOM_REQ = "SNGH"
AND LC_PRS_COR_SNGH_ENA = 1
AND LV_PRS_COR_SNGH_ENA = 1
(1)THEN

7.1.6.2 Subroutines

This chapter describes the sub functions which are called from the main sections.

7.1.6.2.1 Calculate Pulse timing parameters

This section calculates the pulse timing parameters (Charge Time, TI) for the given counting factor index and needle lift.
Input parameters: PRM_LV_EGY_RNG_IV, PRM_IDX_TI_CLC
Output parameters: PRM_T_CHA_PER, PRM_TI
Parameter description:

PRM_LV_EGY_RNG_IV	IN	0...1H	0...1	1	[-]
Injector needle lift.					
PRM_IDX_TI_CLC	IN	0...FFFFH	0...65535	1	[-]
Counting factor index					
PRM_T_CHA_PER	OUT	0...7FFFH	0...3276.7	0.1	[µs]
Injector charge periode					
PRM_TI	OUT	0...FFFFH	0...65.535	0.001	[ms]
Injection time					

Calculate_Pulse_timing_parameters(IN <PRM_LV_EGY_RNG_IV>,
IN <PRM_IDX_TI_CLC>, OUT <PRM_T_CHA_PER>, OUT <PRM_TI>)
(1)IF PRM_LV_EGY_RNG_IV = 1
(1)THEN - high injector needle lift
PRM_TI = IP_TI_H(PRM_IDX_TI_CLC)
PRM_T_CHA_PER = IP_T_CHA_PER_H(PRM_IDX_TI_CLC)
(1)ELSE - low injector needle lift
PRM_TI = IP_TI_L(PRM_IDX_TI_CLC)
PRM_T_CHA_PER = IP_T_CHA_PER_L(PRM_IDX_TI_CLC)

7.1.7 Time synchronous tasks

Application conditions

Activation: every engine state

Deactivation: –

Initialization: at reset: LV_AUTH_TI_MIN_AFL = 1

Recurrence: 10 ms

Calculation of LV_AUTH_TI_MIN_AFL:

If homogeneous lean mode is active (STATE_CMB_CTL = HOM_AFL) and the electrical injection time is smaller than (TI_MIN_HOM + C_TI_MIN_OFS), the combustion mode changes to homogeneous stochiometric mode. Switching back to homogeneous lean mode is allowed at the earliest if the delay time C_ T_AUTH_TI_MIN_AFL has elapsed.

1. **IF**

LV_AFL_CLC = 0

1. **THEN**

LV_AUTH_TI_MIN_AFL = 1
T_AUTH_TI_MIN_AFL = 0
(1) ELSE
(2) IF
LV_AUTH_TI_MIN_AFL = 1
AND
STATE_CMB_CTL = 'HOM_AFL' (homogeneous lean mode)
AND
TI_1_HOM_CLC_MIN < (TI_MIN_HOM + C_TI_MIN_OFS)
(2) THEN
LV_AUTH_TI_MIN_AFL = 0
T_AUTH_TI_MIN_AFL = C_ T_AUTH_TI_MIN_AFL
(2) ELSE
(3) IF
T_AUTH_TI_MIN_AFL (n) > 0.01s (0H)
(3) THEN
T_AUTH_TI_MIN_AFL (n+1) = T_AUTH_TI_MIN_AFL (n) - 0.01 [s]
(3) ELSE
LV_AUTH_TI_MIN_AFL = 1
(3) ENDIF
(2) ENDIF
(1) ENDIF

Output variable for LACO:
(4) IF (STATE_INJ_MOD_REQ = 'SNGH') **OR** (STATE_INJ_MOD_REQ = 'MPLH')
OR (STATE_INJ_MOD_REQ = 'MPLH+PLS3')
(4) THEN
CRK_DIF_SOI_IGN = CRK_DIF_SOI_IGN_HOM
(4) ELSE
CRK_DIF_SOI_IGN = CRK_DIF_SOI_IGN_S

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
INJ_UPD_ACK [NC_CYL_NR]	V	0... FFH	0... 255	1	-
Actual applied update mode; returned by I/O software					
LV_CTR_PBK_IV_INI_INC	V	0... 1H	0 ...1	1	-
Flag to trigger another injection power stage initialization after init failed.					
LV_CUR_CHA_OFS_INI	V	0... 1H	0 ...1	1	-
Flag to indicate that offset cancellation current is initialized for all power banks.					
LV_EGY_RNG_IV_PLS_1_ACK [NC_CYL_NR]	O/V	0... 1H	0 ...1	1	-
Cylinder individual flag to indicate that the first injection pulse was executed with high injector needle lift (1 = high).					
LV_EGY_RNG_IV_PLS_1_ACT [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag for the injector energy range of the first pulse (0 = low range, 1 = high range); for injection update calculations					
LV_IGN_INJ_COPL_HOM_ACT [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag to indicate that ignition injection coupling is active during HOM mode.					
LV_IGN_INJ_UPD_WIN	V	0... 1H	0 ...1	1	-
Flag to indicate that an injection mode switch or update is possible					
LV_INH_INJ [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag that indicates if cylinder shut off is active or not					
LV_INH_INJ_OLD	-	0... 1H	0 ...1	1	-
Flag that indicates if cylinder shut off was active or not. It contains the information from previous calculation run.					
LV_INH_INJ_UPD_MOD_UPD [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag to indicate an inhibitation of update mode update					
LV_INJ_DEAC_BACK_ENG	V	0... 1H	0 ...1	1	-
Flag to indicate deactivated injection due to backward rotation of engine					
LV_INJ_MOD_UPD	V	0... 1H	0 ...1	1	-
Flag to indicate that the possibility of an injection mode data update (1) or mode switch (0) has to be checked					
LV_INJ_MPLP_CYL [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Logical variable for enabling post injection, cylinder individual					
LV_INJ_REST_ENA	V	0... 1H	0 ...1	1	-
Flag to indicate a possible restart of injection during running engine					
LV_INJ_UPD_CLC_ENA	V	0... 1H	0 ...1	1	-
Flag to enable injection update calculations					
LV_IV_MES_VLD	O/V	0... 1H	0 ...1	1	-
The flag indicates if the measurements for charge and voltage of the piezo injector is valid					
LV_IV_PLS_MES_VLD [NC_NR_IV_PLS]	V	0... 1H	0 ...1	1	-
Flag to indicate valid measurement of charge and voltage of each injection pulse.					
LV_SOI_ACT_SWI [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag to indicate the use of start of injection angle for injection mode switch calculations					
LV_SOI_ACT_UPD [NC_CYL_NR]	V	0... 1H	0 ...1	1	-
Flag to indicate the use of start of injection angle for injection mode update calculations					
LV_ST_INJ	O/V	0... 1H	0 ...1	1	-
Flag which indicates that the injection has started after engine synchronization

TI_ACT_UPD [NC_CYL_NR]	V	0... FFFFH	0... 65.535	0.001	ms
Injection time for injection mode data update calculations					
TI_ADD_PULSE_MIN	O/V	0... FFFFH	0... 65.535	0.001	ms
Minimum injection time for additive injection pulse					
TI_POST_MES [NC_CYL_NR]	O/V	0... FFFFH	0... 65.535	0.001	ms
Actual performed cylinder individual injection time, post injection pulse					
V_ADC_REF_MES_INJ	V	0... FFFFH	0... 9.9998474121093	152.587e-6	V
Filtered ADC reference calibration voltage.					
V_ADC_REF_MES_INJ_RAW	V	0... FFFFH	0... 9.9998474121093	152.587e-6	V
Raw ADC reference calibration voltage.					
V_IV_1_MES [NC_CYL_NR]	O/V	0... 7FFFH	0... 639.98046875	0.01953125	V
Actual measured voltage of a carried out first pulse on the piezo injector, cylinder individual					
V_IV_2_MES [NC_CYL_NR]	O/V	0... 7FFFH	0... 639.98046875	0.01953125	V
Actual measured voltage of a carried out second pulse on the piezo injector, cylinder individual					
V_IV_POST_MES [NC_CYL_NR]	O/V	0... 7FFFH	0... 639.98046875	0.01953125	V
Actual measured voltage of a carried out post pulse on the piezo injector, cylinder individual					
VBOOST_PBK_IV_MES [NC_NR_DCDC_INJ]	V	0... 7FFFH	0... 639.98046875	0.01953125	V
Actual measured voltage of the DCDC converter for the injection valve power stage banks

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Action definition

ACTION_INJR_IgnUpdate (**IN**<PRM_IGA_IGC_H_RNG>,**IN**<PRM_CYL>)	Mode: O
This action sets the cylinder individual ignition angle for mode switch and data update of <Cyl> to <Iga_Igc_H_Rng>..	

Parameter	Type	Hex.Limits	Phys.Limits	Resol.	Unit
PRM_IGA_IGC_H_RNG	in	FA60... 5A0H	-90 ...90	0.0625	°CRK
This parameter defines the new ignition angle for homogeneous single injection mode.					
PRM_CYL	in	0... 7H	0 ...7	1	-
This action affects the injection mode of cylinder Cyl.					

Import actions:

The purpose of this module is the transfer of injection related data to IO-Software under real time conditions. The most important thing is to maintain the data consistency. The figure 1 shows the general flow of data:

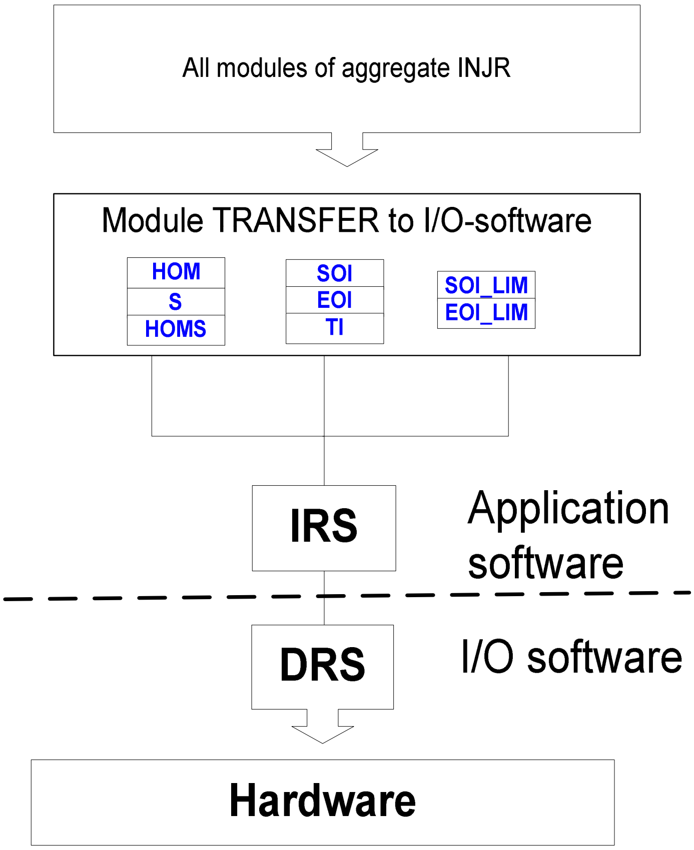

Figure 7.2.1: overview Interface to I/O-software

Control of piezo injector needle lift

To control the needle lift of the piezo injector the energy loaded into the actuator is set by the number of energy packets. In the actual version are two possible setting: High lift and low lift. The data is an input data from module needle lift. The variables are T_CHA_PER_xxx and T_DCHA_PER_xxx, which describe the charge and discharge time.

7.2.15 Crash signal reaction of injection driver

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

General information:

This chapter describes the behavior of the injection driver during vehicle crash. Under crash conditions, all selected injectors (NC_IV_CRASH) are open for a predefined period, to drain off the fuel from the rail into the cylinder. This will reduce the danger of fire or explosion, if the rail will be damaged.
Definition of STATE_INJ_CRASH_ACT:
00H = no request received;
    The injection driver works under normal conditions.
01H = vehicle crash reaction request received by LV_INJ_CRASH_ACT = 1;
    The injection driver will be shut down.
02H = injection driver crash reaction acknowledged;
    The selected injectors are opened for NC_TI_CRASH period.
03H = injection driver crash reaction finished;
    All working injectors are closed. The driver is under hold conditions.

Application conditions:

Initialisation: at reset: T_INJ_CRASH_ACT = 0
STATE_INJ_CRASH_ACT = 00H

Activation: every engine state

Deactivation: –

Recurrence: 10 ms

Function description:

Formula section:

7.2.16 Time synchronous tasks (1s)

General information:

This chapter describes time synchronous tasks with the recurrence of 1 second.
Here, the voltage setpoint for the DCDC converter is set depending on the temperature of the ECU. The DCDC voltage is transferred via PWM value.

Application conditions:

Initialisation: –

Activation: at every engine state

Deactivation: –

Recurrence: 1 s

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Function description:

Formula section:

```
Calculate DCDC converter setpoint and send it to basic software:
PWM_DCDC_SP = IP_PWM_DCDC_PCTL(TECU)

Limit DCDC converter setpoint to maximum and minimum value to prevent power stage
destruction:
PWM_DCDC_SP = MAX(PWM_DCDC_SP, NC_PWM_DCDC_SP_MIN)
PWM_DCDC_SP = MIN(PWM_DCDC_SP, NC_PWM_DCDC_SP_MAX)
FOR  d = 0 TO  (NC_NR_DCDC_INJ - 1) DO:
ACTION_INFR_SetInjDcdc(IN Dcdc_nr= d, IN Dcdc_ducy= PWM_DCDC_SP)
ENDFOR

Get measured reference calibration voltage and calculate ADC voltage reference
calibration:
The measured voltage NC_V_ADC_REF_INJ is more accurate then the ADC reference
voltage.  By calculating a correction factor for all ADC measurement values,
this accuracy can be transferred to all ADC measurements.  This feature exists
only for certain injection hardware drivers.
#IF  NC_PBK_IV_TYP = 1
#THEN
ACTION_INFR_GetInjMesURef(OUT V_ADC_REF_MES_INJ_RAW= Voltage)
#ENDIF

Voltage reference calibration is activated by LC switch and a positive plausibility
check of the raw value.
IF  NC_PBK_IV_TYP = 1                                             AND

7.2.17.4 Update injection data

The CSERS_TEST variables show the injection set points which will be activated if CSERS multiple injection diagnosis demo mode is activated and catalyst heating is active. They are also calculated out of demo mode in order to enable a control of the demo mode set points before activating the demo mode.
Be aware that bad calibration of injection pulses, e.g. injection pulse during / after ignition may harm components of the test vehicle.

Calculation of CSERS_INIJ_DIAG test timing and phasing outputs for visibility

FUNCTION DESCRIPTION:

This function reads the ECU end of line trimming values for piezo injector energy measurement. A check against the complementary values is done as well as a plausibility check.

General information:

The pizo injector energy measurement consists of a voltage measurement and a charge measurement. Both kinds of measurement have to be calibrated at the end of production line (EOL trimming) to improve measurement accuracy. The results of the EOL trimming are one correction factor for voltage measurement and one correciton factor for charge measurement for each injection driver ATIC.

Signal flow diagram:

-

Copyright (C) Continental AG,2007

Description:

If the functionality is activated by LC, each values are checked against their complementary values which are also stored within the ECU at end of produciton line. After that, a plausibility check is done by using an upper and a lower threshold. If the complementary check or the plausibility check fails or if the functionality is deactivated by LC, the trimming factors are set to 1.

Application conditions

Initialisation: –

Recurrence: *only once at reset*

Activation: *every engine state*

Deactivation: –

Formula section:

(1) IF LC_FAC_IV_MES_PBK_ENA = 1

Considering the shut off time for re start calculation					

7.4.1 FMSP_M7003

FUNCTION DESCRIPTION:
General information:
In order to improve restarts, a correction factor of mass fuel flow during preinjection and start injection is calculated. This factor is multiplicative and decreases the mass fuel flow. In order to prevent, that no calculation of T_ES was done, the T_ES calculation task is called.

Deactivation factor of post start enrichment at low fuel pressure					

7.6.1 FMSP_M7009

FUNCTION DESCRIPTION:
General information:
This enrichment takes place just after start in order to ensure the first combustions in cold conditions.
CYC_CAST is first the number of cycles (segments) at start. At the transition to after start, the counter is reset and represents then the number of afterstart cycles during LV_AST=1.
Depending on fuel pressure FUP the functionality weighs up 2 cold post start injection times. Both injection times are calculated continuously and depending on a factor based on fuel pressure a interpolation between high and low pressure path estimates the executed after start injection TI_CAST.

Application conditions:
Initialisation: all outputs = 0 at ECU reset
Recurrence: segmentsynchronous
Activation: Post start auxiliary function (LV_AST) activated (exit from LV_ST to LV_IS or LV_PL) and (LV_CLC_2SEG = 1 or LV_CLC_2SEG_ENA = 0)
Deactivation: not Activation

TI_CAST_SWI

There are two input values TI_CAST_H_PRS and TI_CAST_LIH_L_PRS. Each input value belongs to the fuel pressure. Moreover FUP indicates which path is more weighted. It is ensured that a continuous

Copyright (C) Continental AG,2007

crossfading in the range TI_CAST_H_PRS and TI_CAST_LIH_L_PRS is active in the after start time interval. The algorithms are calculated until LV_AST drops.

7.7.1 FMSP_M700A

FUNCTION DESCRIPTION:
General information:
To cover the increased fuel requirement while the engine is cold, injection is corrected via the warm up enrichment.
The function splits up 2 warmup enrichment parts intermediate value (applied for 2 different fuel pressure modes). In accordance with the received fuel pressure FUP the warm up injection represents the weighted enrichment parts.
Application conditions:
Activation : at every engine operating state, when
(LV_CLC_2SEG = 1 **or** LV_CLC_2SEG_ENA = 0)
Deactivation : **not** Activation
Initialization : at ECUInitialisation, LV_ES = 0 >1, LV_ST = 0 > 1:
TI_WUP, TI_TEMP and FAC_TI_WUP_FUP = 1,0
TI_WUP_1 = 1,000061, TI_WUP_1_ADD = 0,000061
Update rate : 1/segment

The input values TI_WUP_1_H_PRS and TI_WUP_1_LIH_L_PRS are calculated for the fuel high pressure and the fuel limp home low pressure mode. Each input value belongs to a fuel pressure mode. Depending on FUP a factor indicates which path is executed as a result of the interpolation.

FUNCTION DESCRIPTION:

7.8.1 Definition of the injection range

Application conditions

Activation: `at reset`

Deactivation: –

Initialization: –

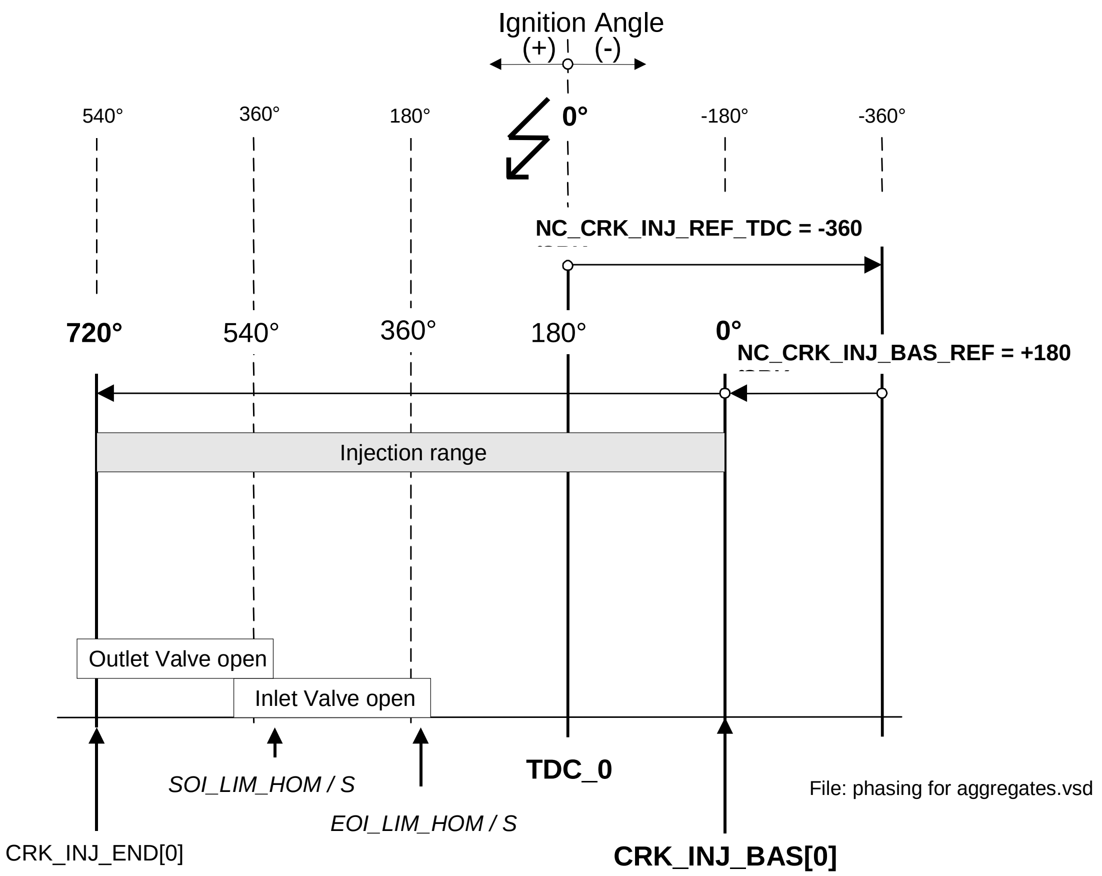
Recurrence: `once at reset`

The fuel can be injected over a range of 720 °CRK. The cylinder individual zero position of this range is defined via the constants NC_CRK_INJ_REF_TDC and NC_CRK_INJ_BAS_REF with reference to the ignition TDC of cylinder 0, see figure below.

Formula section:

Related to tdc cylinder 0:
FOR x = 0 **TO** (NC_CYL_NR-1) **DO**:
CRK_INJ_BAS[x] = NC_CRK_INJ_REF_TDC + NC_CRK_INJ_BAS_REF - x * (720 /NC_CYL_NR)
ENDFOR

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Definition of the non calibrateable constants:

NC_CRK_INJ_REF_TDC = -360°CRK
NC_CRK_INJ_BAS = 180 °CRK

For loop for runtime optimization:
In this specification the for loop
FOR i = 0, i < NR_CYL_CLC_RED_INJ **DO**
  x = CTR_CYL_NR_ST_CLC_INJR + i
  (1a)**IF** x >= NC_CYL_NR
  (1a)**THEN**
    x = x - NC_CYL_NR
  (1a)**ENDIF**
  <**loop content**>
ENDFOR
is substituted by
FOR cylinder_start to cylinder_stop **DO**
  <**loop content**>
ENDFOR
Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.8.2 Injection phasing at start

Application conditions

Activation: LV_ST_END = 0
Deactivation: –
Initialization: –
Recurrence: 10ms

Formula section:

All calculations are related to CRK_INJ_BAS[NC_CYL_NR].

EOI_LIM_HOM = 0
(1) IF (single injection)
INJ_MOD_HOM_REQ = NC_INJ_MOD_SINGLE (if single injection is requested)
(1) THEN

LC_T_DLY_2_3_S_EXT_MAN_ENA	-	0... 1H	0 ...1	1	-
Switch to enable manual setpoint for time interval between second and third pulse of stratified injection					

FUNCTION DESCRIPTION:

In this part, the conversion of injection phasing from customer nomenclature to supplier nomenclature is done.
For calculation order purposes, the specification is divided in two parts. The part that calculates the delay times for stratified combustion mode must be calculated before the task "Final injection timing", the part that calculates the rest of the phasing must be calculated after.

For loop for runtime optimization:
In this specification the for loop
FOR i = 0, i < NR_CYL_CLC_RED_INJ **DO**
x = CTR_CYL_NR_ST_CLC_INJR + i
(1a)**IF** x >= NC_CYL_NR
(1a)**THEN**
x = x - NC_CYL_NR
(1a)**ENDIF**
<**loop content**>
ENDFOR
is substituted by
FOR cylinder_start to cylinder_stop **DO**
<**loop content**>
ENDFOR
Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

7.15.1 Calculation of pulse delay times for stratified combustion mode

Note: This task must be calculated **before** the task "Final injection timing"!

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

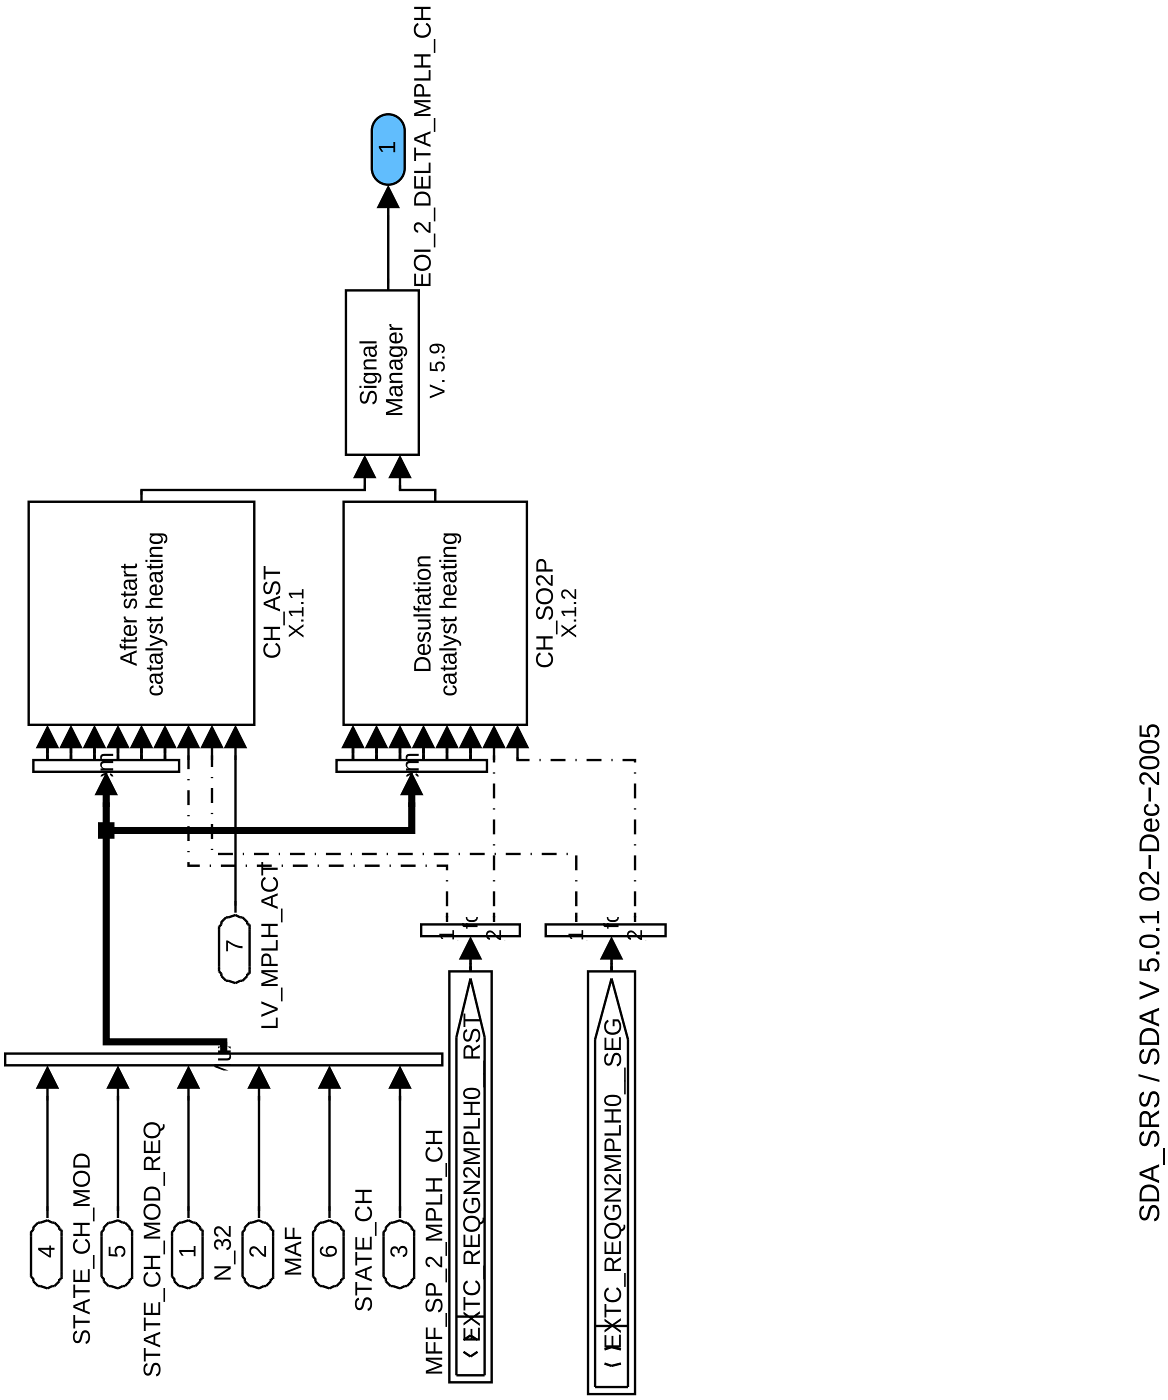

Figure 7.18.1: : Path: EXTC_REQGN2MPLH0

General Information

For catalyst heating in homogeneous split mode an additional injection pulse is generated. This module contains the phasing of this pulse.
EOI_2_DELTA_MPLH_CH therefore is defined as crankshaft angle difference between end of injection of 2nd pulse and ignition angle.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

To heat up the catalyst a 2nd fuel mass pulse is injected in homogeneous mode short time before ignition. In this module the mass of this pulse is generated.

Copyright (C) Continental AG,2007

The ignition angle is being retarded to increase the exhaust temperature. The 2nd injection mass MFF_SP_2_MPLH_CH should be calculated depending on ignition angle. That is done through IGA_AV_MV_H_RNG.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

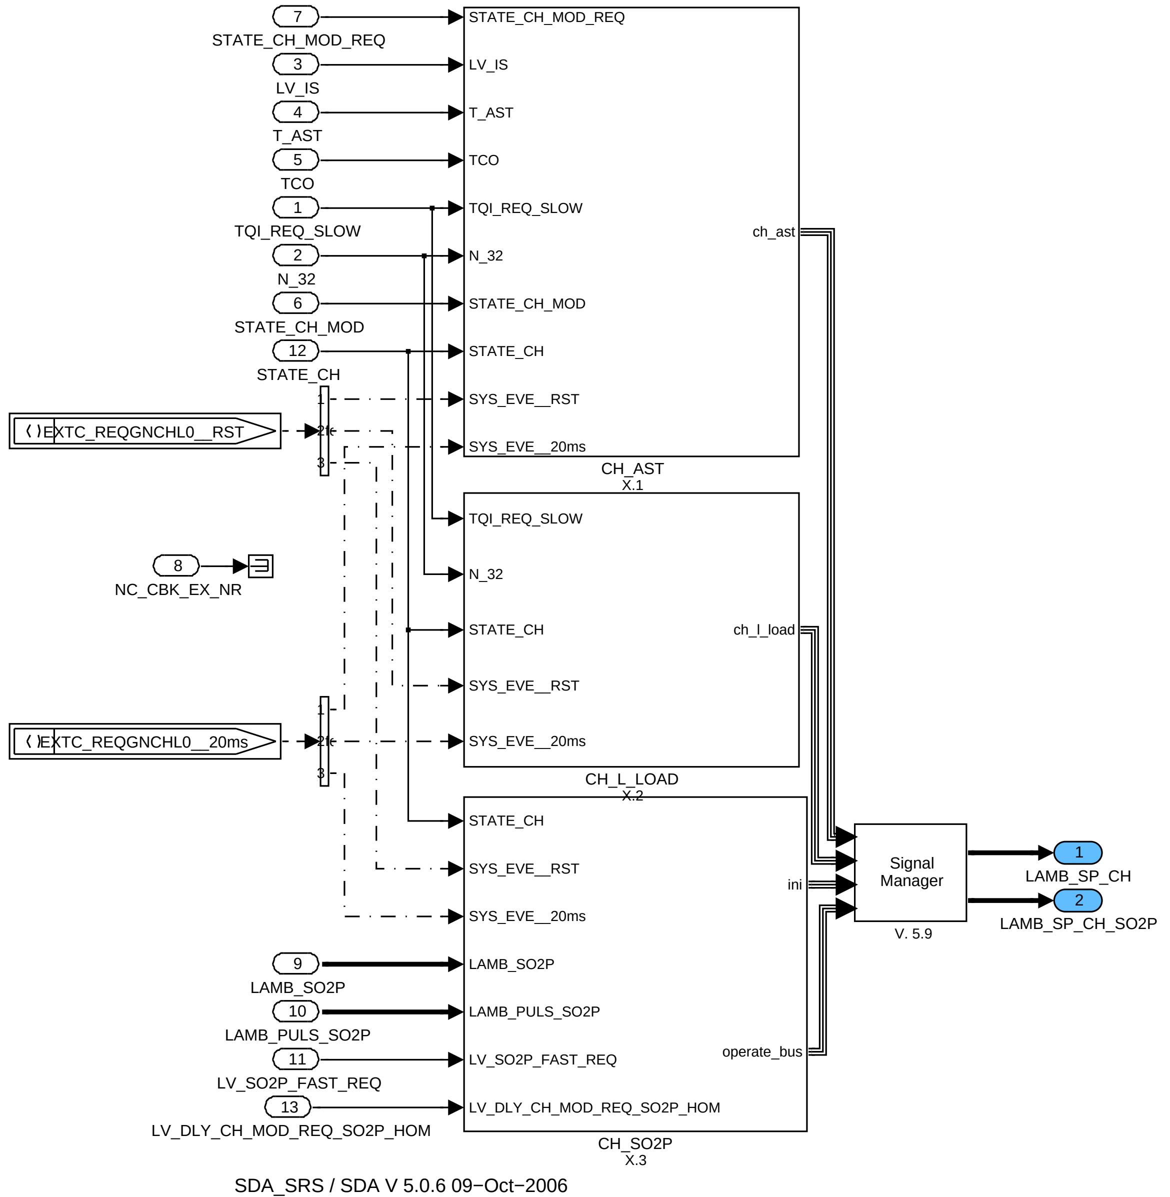

Figure 7.20.1: : Path: EXTC_REQGNCHL0

General Information

In this module a lambda-setpoint for homogeneous catalyst heating is generated.

7.20.1 After start catalyst heating

In stratified mode the lambda setpoint is also calculated if homogenous (split) mode is requested by STATE_CH_MOD_REQ.

Application Conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.20.2 Low load catalyst heating

Low load catalyst heating is activated after regeneration. With this function it is possilble to apply different lambda-setpoints for each bank. The function can only be used with Y exhaust-systems because the exhaust gases of the lean and the rich cylinder banks are mixed upstream the NOx-trap and cause exothermic reaction.

Application Conditions

7.20.3.1 Initialisation

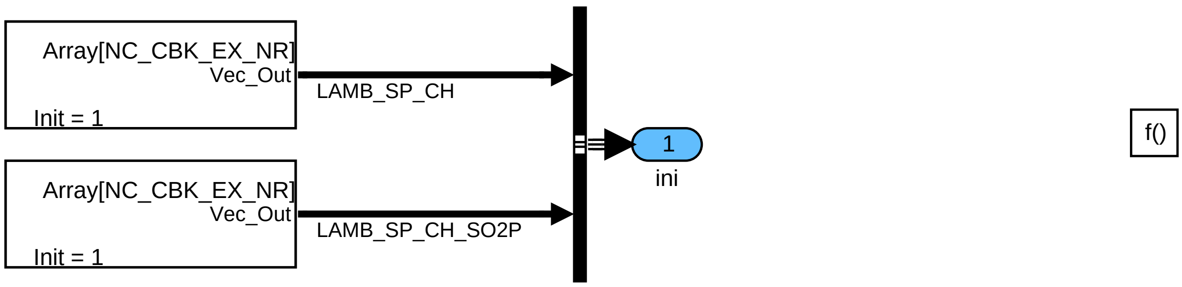

Figure 7.20.12: : Path: EXTC_REQGNCHL0/CH_SO2P/INI

7.20.3.2 Function: Desulfation catalyst heating

The basic lambda value for catalyst desulfation catalyst heating is applicatable for single or splitted injection. A temperature-depending factor weighs the difference between this basic-value and lambda=1. The resulting lambda setpoint is used for both cylinder banks. LAMB_SP_CH is used during catalyst heating phase, LAMB_SP_CH_SO2P is used during desulfation if there was catalyst heating active before. Due to C_LAMB_SP_CH_MAN it is possible to set the lambda setpoint cylinder individual.

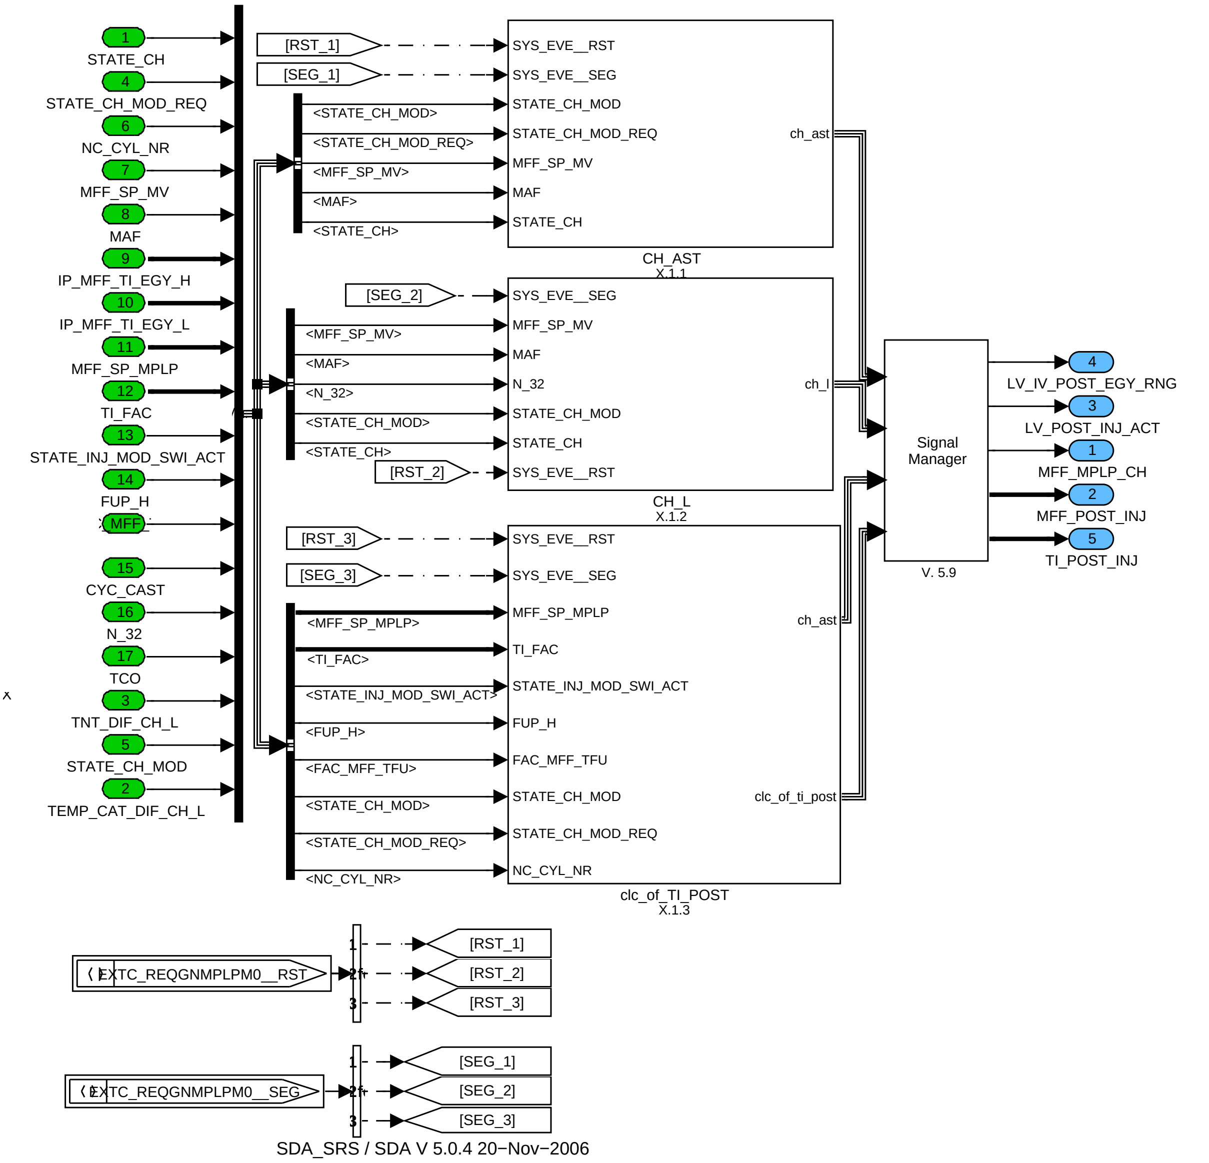

Figure 7.21.1: : Path: EXTC_REQGNMPLPM0

General Information

For catalyst heating an additional fuel mass pulse is injected after the stratified injected main combustion has occurred. In this module the mass of this so called post injection is generated.
The module has to be calculated before Injection phase of post injection for catalyst heating , MAF correction for catalyst heating in stratified mode and Ignition angle difference for catalyst heating with post injection .

Overview

Copyright (C) Continental AG,2007

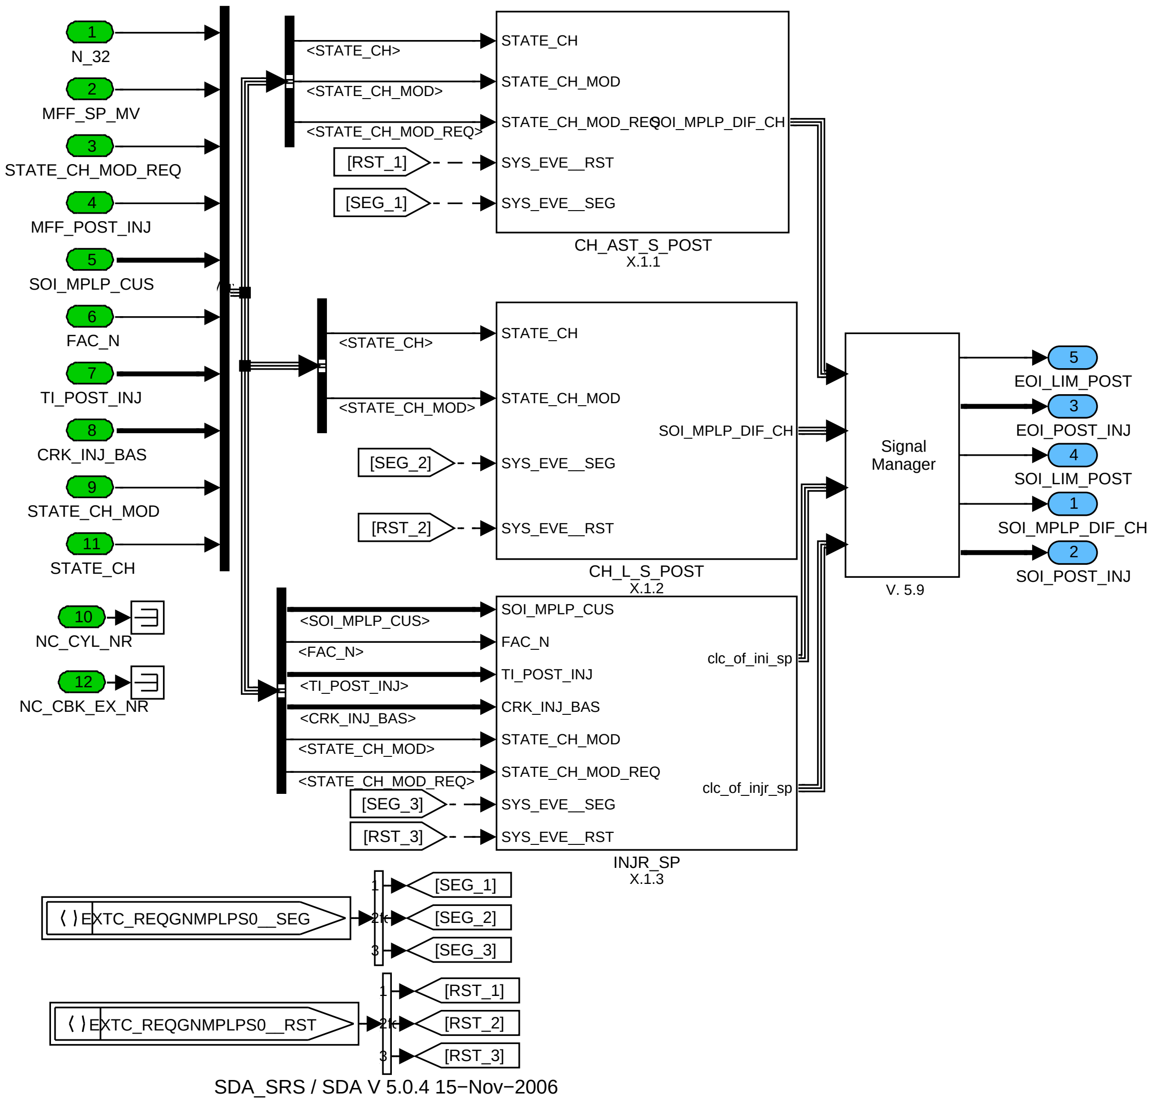

Figure 7.22.1: : Path: EXTC_REQGNMPLPS0

General Information

For catalyst heating an additional fuel mass pulse is injected after the stratified injected main combustion has occurred. This will increase the temperature in the exhaust system, especially in the catalyst. In this module the injection phase of this so called post injection is generated.
The function is splitted into 3 parts: the phasing for after start catalyst heating, the phasing for low load heating and the calculation of further setpoints for the INJR aggregate.
SOI_MPLP_DIF_CH is an input for BMWfunctions where SOI_3_S_CUS is the (eventually changed) output. SOI_POST_INJ and EOI_POST_INJ are the actually phasings.

SOI_MPLP_DIF_CH means the difference crankshaft angle between the ignition angle and the start of the post injection.

7.22.1 Post injection for after start catalyst heating

FUNCTION DESCRIPTION:

Application conditions:

Recurrence: every 1 s.
Initialisation: at reset LAMB_COP_CUS_i = C_LAMB_COP_PAS
Activation: If LV_ST_END = 1
Deactivation: -

General information:

If the temperature in the exhaust line exceeds a certain limit, the catalytic converter or even the exhaust line can be destroyed. To reduce the temperature the lambda is ramped down.
The exhaust line of a gasoline direct injection engine consists of a precatalyst and a NO_x-trap catalyst. The actual temperatures upstream (TEG_CAT_UP_MDL_i) and downstream of the precatalyst (TEG_CAT_DOWN_MDL_i or TEG_PCAT_DOWN_i, respectively) and the temperature in the NO_x-trap (TNT_MDL_H_i) are compaired to thresholds, separate for each temperature. The difference between an actual temperature and a threshold is input for an I-controller. Three different I-controllers are working in parallel.
Descriptions of LAMB_COP_i is the output LAMB_COP_CUS_i

In the following, **xx** serves as substitute for specification purposes. This is in detail:
xx = TEG_CAT_UP_MDL for I-controller 1 (temperature upstream of the precatalyst)
xx = TEG_CAT_DOWN for I-controller 2 (temperature downstream of the precat.)
xx = TNT_MDL_H for I-controller 3 (temperature in the NO_x-trap catalyst)

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.23.1 Maximal selection between model or sensor based temperatur downstream the precatalyst

If a temperature sensor downstream the precatalyst is available the maximum value between the sensor based temperature TEG_PCAT_DOWN_i and the the model based temperature TEG_CAT_DOWN_MDL_i is choosen.

TEG_CAT_DOWN_i = MAX (TEG_PCAT_DOWN_i, TEG_CAT_DOWN_MDL_i)

Note:

If no temperature sensor downstream the precatalyst is available the variable has to be initialized as follows:
TEG_PCAT_DOWN_i = 0

7.23.2 Activation and Deactivation of the Controller

A single controller is activated (LV_xx_COP_i = 1) if the temperature xx_i exceeds its threshold C_xx_THD_COP. A singel controller is deactivated (LV_xx_COP_i = 0) if the temperature xx_i is below the threshold C_xx_THD_MIN_COP or if the temperature xx_i is below the threshold C_xx_THD_COP after the lambda was ramped up and has reached the the basic lambda setpoint LAMB_BAS_i.
All controllers are deactivated if one of the following logical variables is set to one:
LV_AST, LV_PUC, LV_SCC_i.
For that case the lambda for catalyst overheat protection LAMB_COP_i is set to the passive value C_LAMB_COP_PAS.

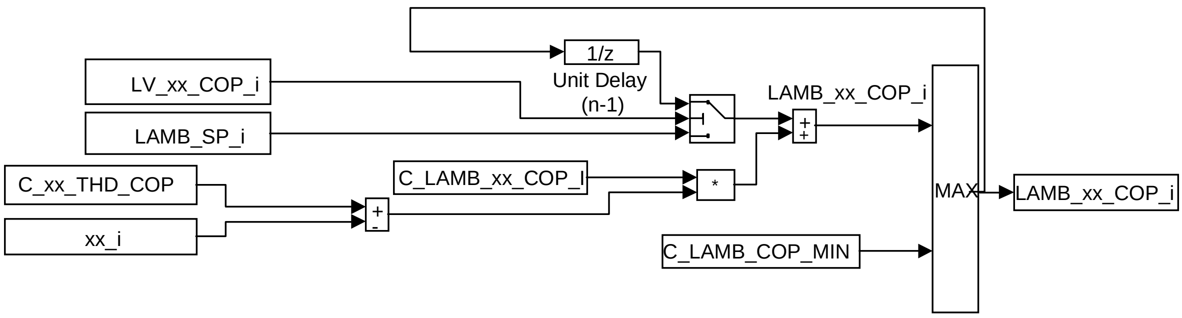
```
(1) If              LV_AST = 1 or LV_PUC = 1or LV_SCC_i = 1
(1) then              LV_xx_COP_i = 0
  1. else
          (2) if              xx_i >= C_xx_THD_MIN_COP
          (2) then
            (3) if               xx_i >= C_xx_THD_COP
            (3) then               LV_xx_COP_i = 1
            (3) else
                  (4) if               LAMB_xx_COP_i > LAMB_BAS_i
                  (4) then               LV_xx_COP_i = 0
                  (4) endif
            (3) endif
          (2) else              LV_xx_COP_i = 0
          (2) endif
  1. endif
```

At transition LV_xx_COP_i = 0 -> 1 the variable LAMB_xx_COP_i is initialized with LAMB_SP_i .

7.23.3 Controller Equations

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007



If LV_xx_COP_i = 1 ...... (controller active)
then
LAMB_xx_COP_i (n) = LAMB_xx_COP_i (n-1) + C_LAMB_xx_COP_I * (C_xx_THD_COP - xx_i)
else LAMB_xx_COP_i = C_LAMB_COP_PAS ...... (controller inactive)
endif

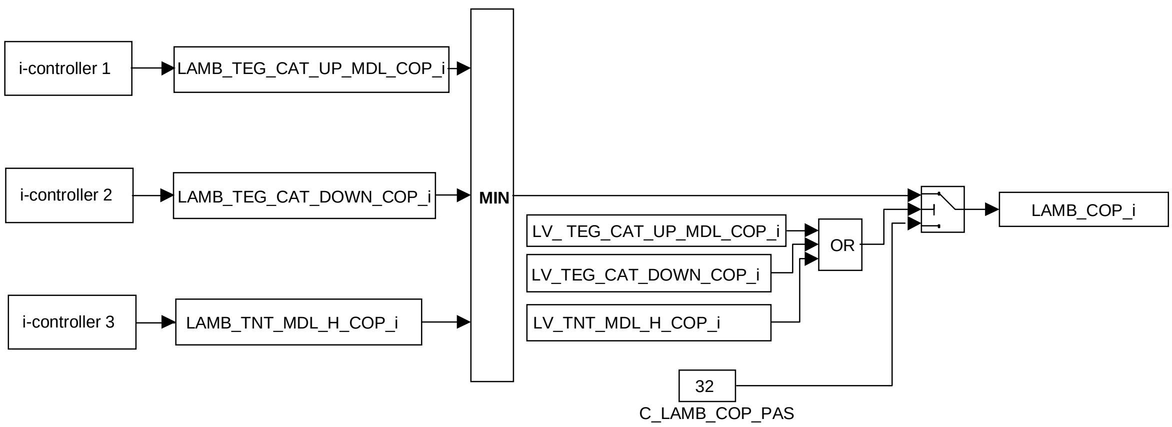
Application Hint: The passive value C_ LAMB_COP_PAS shoud be set to 32.

The value LAMB_xx_COP_i can not be smaller than the minimum allowed lambda value C_LAMB_ COP_MIN:

LAMB_xx_COP_i = MAX (LAMB_xx_COP_i, C_LAMB_COP_MIN)

7.23.4 Calculation of LAMB_COP (Resulting lambda request)

System flow diagramm:



If at least one controller is active (LV_xx_COP_i = 1) the minimum controller output is selected for LAMB_COP_i:

if LV_TEG_CAT_UP_MDL_COP_i = 1
or
LV_TEG_CAT_DOWN_COP_i = 1
or
LV_TNT_MDL_H_COP_i = 1
then LAMB_COP_i = MIN (LAMB_xx_COP_i)
LV_LAMB_COP_i = 1
else LAMB_COP_i = C_LAMB_COP_PAS

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

LV_LAMB_COP_i = 0

endif

If one of the temperatures **xx_i** exceeds the maximum threshold C_xx_THD_MAX_COP, the lambda enrichment is set to the minimum allowed lambda value C_LAMB_COP_MIN immediately.

If

TEG_CAT_UP_MDL_i >= C_TEG_CAT_UP_MDL_THD_MAX_COP

or

TEG_CAT_DOWN_MDL_i >= C_TEG_CAT_DOWN_THD_MAX_COP

or

TNT_MDL_H_i >= C_TNT_MDL_H_THD_MAX_COP

then LAMB_COP_i = C_LAMB_COP_MIN

endif

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LC_PRS_COR_1_HOM_CMP_ENA	-	0... 1H	0 ...1	1	-
Flag to enable fuel pressure correction with compression influence for 1st pulse homogeneous mode					

FUNCTION DESCRIPTION:

General information:

The module calculates a correction factor to compensate the influence of the cylinder counter pressure at the injector (here: MAP) and the influence of the fuel temperature on the injected fuel mass. Also, the pressure difference at the injector is calculated.

Application conditions

Activation: every engine state

Deactivation: –

Initialisation: at reset: FAC_TI_1_PRS_CYL_HOM[ ] = 1 // all NC_CYL_NR elements

Update rate: LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Formula section:

FOR m = 0 **TO** NC_CBK_HPP_NR - 1 **DO**
Check, if fuel bank m has to be calculated:
(1)IF Bit m of LF_PRS_COR_HPP_ENA = 1
(1)THEN
(1a)IF LV_ST_END = 0 **OR** LC_PRS_COR_1_HOM_CMP_ENA = 0

(2)ENDIF
(2a)ENDIF

A rough injection duration angle CRK_INJ_1_HOM is estimated from TI_1_PRS_HOM_SP_TMP and engine speed (FAC_N):
From the manifold pressure MAP_INJ[m], the end of injection and the rough injection angle a mean counter pressure within the cylinder during the injection is calculated.
The pressure difference at the injector is calculated from fuel rail pressure and the manifold pressure.
The correction factor FAC_TI_1_PRS_CYL_HOM is used to compensate the influence of the cylinder counter pressure on the injector needle lift.

CRK_INJ_1_HOM = TI_1_PRS_HOM_SP_TMP * FAC_N

PRS_INJ_MV_1_HOM = MAP_INJ[m] * IP_PRS_INC_CMP
(Input data for IP_PRS_INC_CMP is

```

Calculation of the counter pressure within the cylinder:

A rough injection duration angle CRK_INJ_2_HOM is estimated from TI_2_PRS_HOM_SP_TMP and engine speed (FAC_N):

From the manifold pressure MAP, the end of injection EOI_2_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]] and the rough injection angle a mean counter pressure within the cylinder during the injection is calculated.

The pressure difference at the injector is calculated from fuel rail pressure and the mean counter pressure.

The total correction factor results from the map IP_FAC_TI_PRS_CYL.
For low injector needle lift, a separate map IP_FAC_TI_PRS_CYL_L is used.

```
CRK_INJ_2_HOM = TI_2_PRS_HOM_SP_TMP * FAC_N

TI_1_PRS_S_SP_TMP = IP_TI_L(IDX_TI_1_PRS_S_SP_TMP)
(3)ENDIF
(2a)ELSE // current shaping is inactive; classic TI calculation applied
(3a)IF LV_EGY_RNG_IV_PLS_1_S[IDX_PRS_COR_CYL_CLC_S[m]] = 1
(3a)THEN
TI_1_PRS_S_SP_TMP = IP_MFF_TI_EGY_H(
(MFF_SP_1_S[IDX_PRS_COR_CYL_CLC_S[m]]*(1 +
FAC_MFF_DIF_S[IDX_PRS_COR_CYL_CLC_S[m]])*FAC_MFF_TFU);
PRS_DEC_INJ_1_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1))
* FAC_TI_1_PRS_CYL_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1)
(3a)ELSE
TI_1_PRS_S_SP_TMP = IP_MFF_TI_EGY_L(
(MFF_SP_1_S[IDX_PRS_COR_CYL_CLC_S[m]]*(1 +
FAC_MFF_DIF_S[IDX_PRS_COR_CYL_CLC_S[m]])*FAC_MFF_TFU);
PRS_DEC_INJ_1_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1))
* FAC_TI_COR_IV_EGY_RNG_L[m]
* FAC_TI_1_PRS_CYL_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1)
(3a)ENDIF
(2a)ENDIF

A rough injection duration angle CRK_INJ_1_S is estimated from TI_1_PRS_S_SP_TMP and engine speed:

From the manifold pressure MAP_INJ[m], the end of injection EOI_1_S[IDX_PRS_COR_CYL_CLC_S[m]] and the rough injection angle a mean counter pressure within the cylinder during the injection is calculated.

CRK_INJ_1_S = TI_1_PRS_S_SP_TMP * FAC_N

PRS_INJ_MV_1_S = MAP_INJ[m] * IP_PRS_INC_CMP_S
(EOI_1_S[IDX_PRS_COR_CYL_CLC_S[m]]; CRK_INJ_1_S)

The pressure difference at the injector is calculated from fuel rail pressure and the mean counter pressure.
If the engine is not running in stratified mode (LV_IGA_AND_INJ_SWI = 1), for a correct calculation of the pressure correction the FUP_H_SP_S_INJ[m] has to be used instead of the actual FUP_H_INJ[m], because the actual FUP_H_INJ[m] is tuned for a different combustion mode than stratified.

(4)IF LV_IGA_AND_INJ_SWI = 1
(4)THEN
FUP_PRS_COR[m] = FUP_H_SP_S_INJ[m]
(4)ELSE
FUP_PRS_COR[m] = FUP_H_INJ[m]
(4)ENDIF
PRS_DEC_INJ_1_S_TMP = FUP_PRS_COR[m] - PRS_INJ_MV_1_S

The total correction factor results from the map IP_FAC_TI_PRS_CYL.
For low injector needle lift, a separate map IP_FAC_TI_PRS_CYL_L is used.
(4a)IF LV_EGY_RNG_IV_PLS_1_S[IDX_PRS_COR_CYL_CLC_S[m]] = 1
(4a)THEN
FAC_TI_1_PRS_CYL_S_TMP = IP_FAC_TI_PRS_CYL(PRS_INJ_MV_1_S)
(4a)ELSE

A rough injection duration angle CRK_INJ_3_S is estimated from TI_3_PRS_S_SP_TMP and engine speed:
Note: TI_3_PRS_S_SP_TMP is calculated with the pressure correction information of the previous calculated injector pressure difference PRS_DEC_INJ_3_S[IDX_PRS_COR_CYL_CLC_S[m]].

From the manifold pressure MAP_INJ[m], the end of injection EOI_3_S[IDX_PRS_COR_CYL_CLC_S[m]] and the rough injection angle a mean counter pressure within the cylinder during the injection is calculated.

The pressure difference at the injector is calculated from fuel rail pressure and the mean counter pressure.

The total correction factor results from the map IP_FAC_TI_PRS_CYL.
For low injector needle lift, a separate map IP_FAC_TI_PRS_CYL_L is used.

CRK_INJ_3_S = TI_3_PRS_S_SP_TMP * FAC_N

PRS_INJ_MV_3_S = MAP_INJ[m] * IP_PRS_INC_CMP_S

General information

The large signal capacity of the piezo stack rises with temperature. This dependency can be used to determine the piezo temperature out of its capacity. Since the capacity is also influenced by forces acting on the piezo stack the fuel pressure has to be taken into account. This dependency is described by the map IP_TEMP_CAPA_IV_NOM supplying a temperature for a certain nominal (mean) capacity and fuel pressure level. The map IP_CAPA_IV_NOM describes the inverse relationship supplying a capacity for a given temperature and fuel pressure. The lookup curve IP_CAPA_COR_EGY_IV accounts for the dependency of the capacity on the energy stored in the piezo stack and provides an additive correction for the capacity value.
The capacity value deviates from one stack to another due to manufacturing variations, aging effects etc.. Therefore the offset of each injector to the nominal capacity has to be determined at a reference temperature.(Fig. 1)

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

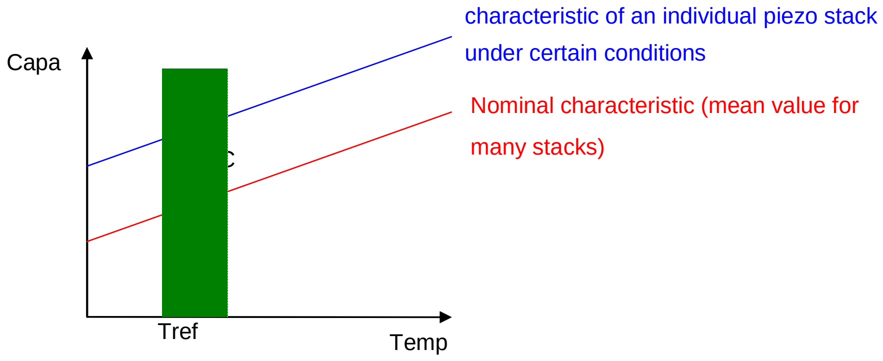

Figure 7.35.1: : capacity temperature relationship for piezo stacks

The capacity offset of each injector is stored in the nonvolatile memory (NVMY). Once the capacity offset is available the individual capacity can be shifted to the nominal characteristic allowing for a determination of the piezo temperature (Fig. 2).

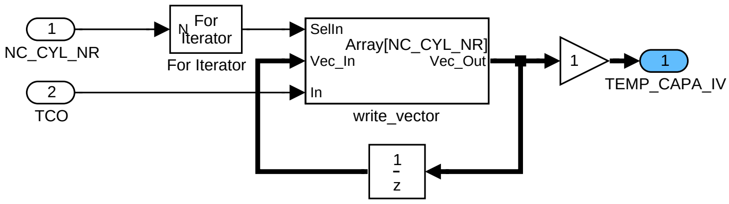

Figure 7.35.7: INJR_ISPCLCAPA0/init1/For_Iterator

7.35.3 Plausibility check of engine off time and calculation of substitute value for TEMP_CAPA_IV

A new adaptation value of the capacity offset is calculated if the engine offtime is plausible and greater than a calibratable constant. If both conditions are true the bit LV_T_ES_CAPA_TEMP_VLD is set. For the first engine start at end-of-line the capacity offset adaptation is always done. At the first engine start LV_TEMP_CAPA_IV_EOL is zero. It is set to one if the capacity offset is adapted and will be stored in the nonvolatile memory. Furthermore an substitute value for the piezo-capacity temperature is determined via engine off-time, coolant-temperature and the mean value of the piezo-temperatures of the last driving cycle.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

While the segment counter is lower than a calibratable constant the temperature of the piezo stacks is set to the substitute value TEMP_CAPA_IV_SUB. When the SEG_CTR exceed this threshold the temperature is extracted from the map IP_TEMP_CAPA_IV_NOM accounting for each stack's individual capacity offset to the nominal value.

Filtering of piezo capacity

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The large signal capacity is calculated out of measured charge and voltage value. Since the signal is noisy it has to be low pass filtered. The filter constant can be applied via C_FAC_FIL_CAPA_IV. The filtered capacity is used for the further calculations. At first entry the filtered capacity is set to the measured capacity value via reset (R) and intial value (IV) input ports. The filter is enabled if the measured voltage and charge values are valid (LV_IV_MES_VLD), if the measured injection time is greater than a calibratable constant and if high energy range is used (LV_EGY_RNG_IV_PLS_1_ACT).

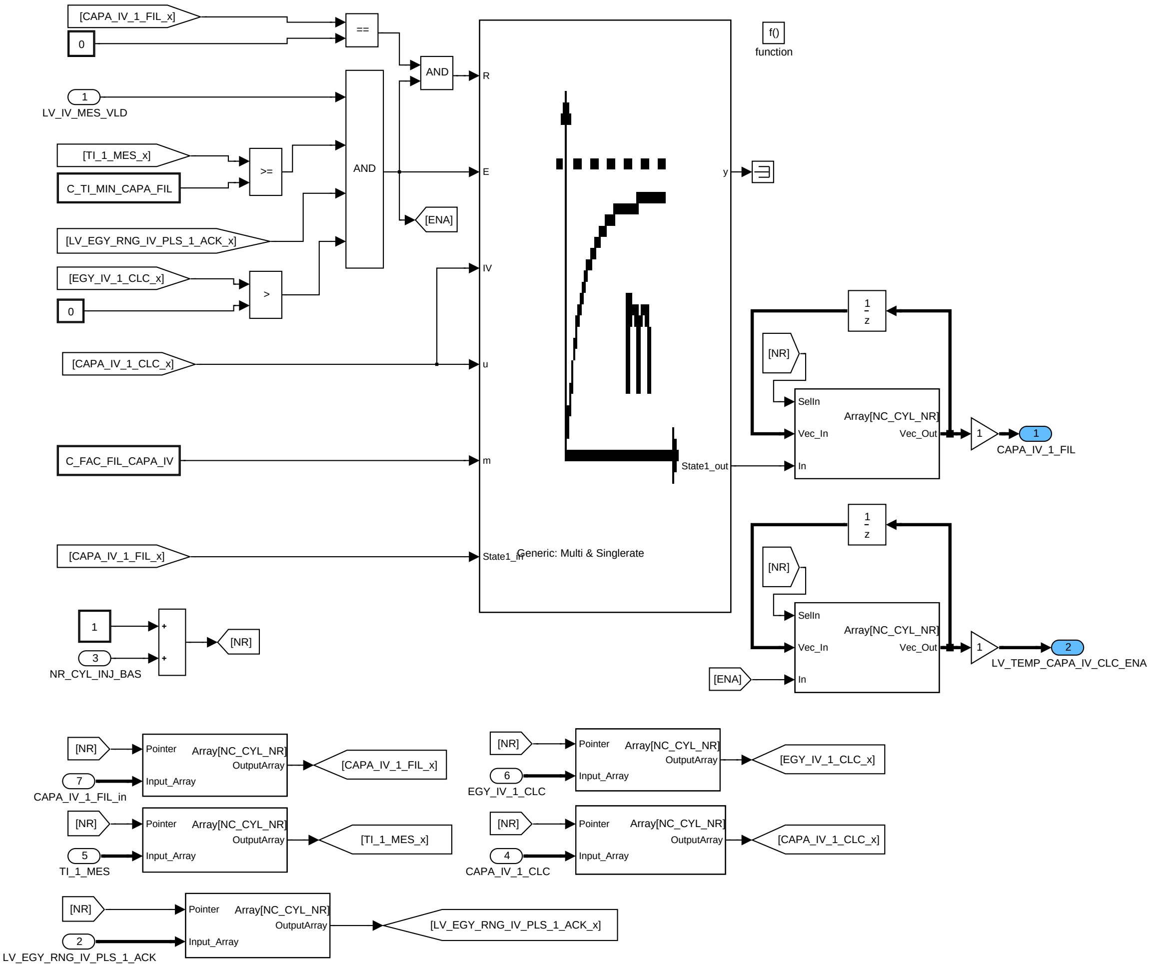

Figure 7.35.17: INJR_ISPCLCAPA0/operate/Capa_Filter

Calculation of capacity offset

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The capacity offset of each injector is stored in the nonvolatile memory. A new adaptation value is calculated if the engine offtime T_ES is plausible and greater than a calibratable constant (LV_T_ES_CAPA_TEMP_VLD = TRUE). Then the coolant temperature TCO is used as the reference temperature. The calculation of the offset value is triggered as soon as the segment counter exceeds a calibratable level. The capacity offset is limited to C_CAPA_IV_DIF_NOM_LIM. The calculation of capacity offset can be inhibited if catalyst heating is active. For the first engine start the end-of-line flag LV_TEMP_CAPA_IV_EOL is set if adaptation was done.

Switch to disable cylinder individual injector needle lift					

DESCRIPTION:

General information:

This functionality switches between two different base energy ranges for PIEZO injectors. Starting with these base ranges, specific energy levels are calculated for each cylinder depending on the cylinder balancing injection valve energy level.

Application conditions

Initialization: at reset and at first valid tooth:

LF_EGY_RNG_IV_1_HOM_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_2_HOM_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_3_HOM_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_1_S_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_2_S_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_3_S_REQ = (2^NC_CYL_NR) - 1

Activation: every engine state

Deactivation: -

Formula section:

For loop for runtime optimization:
In this specification the for loop
FOR i = 0, i < NR_CYL_CLC_RED_INJ **DO**
x = CTR_CYL_NR_ST_CLC_INJR + i
(1a)**IF** x >= NC_CYL_NR
(1a)**THEN**
x = x - NC_CYL_NR
(1a)**ENDIF**
<**loop content**>
ENDFOR
is substituted by
FOR cylinder_start to cylinder_stop **DO**
<**loop content**>
ENDFOR
Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

7.36.1 Cylinder individual adjustment of the energy level

This function calculates cylinder individual charge and discharge gradients depending on the cylinder balancing injection valve energy level. Should the unlimited gradient value run out of the lower/upper limits, the gradient variable shall be limited to the maximum or minimum threshold - dependently on engine operation mode (homogenous or stratified) - and the energy-level-difference factor shall be converted in the MFF-difference factor.

7.36.2 Selection of injector energy range

7.36.2.1 Basis calculations

The minimum fuel mass setpoint for stratified mode is determined from the pulses with a fuel mass setpoint greater than zero. The corresponding minimum injection time is calculated and if the injection time is greater than a threshold or homogeneous mode is selected, high energy range will be selected for the injector, pulse individual.
The energy range can also be clipped to low range by dynamic injector needle lift selection (bit field LFT_L_IV_S_REQ).
Important note: For better readability of the specification, the LSB of the bit field LFT_L_IV_S_REQ, which corresponds to the physically first injection pulse, is referred to as bit 1 (**not** bit 0 as it would be in SW). The next bit would be bit 2 etc.

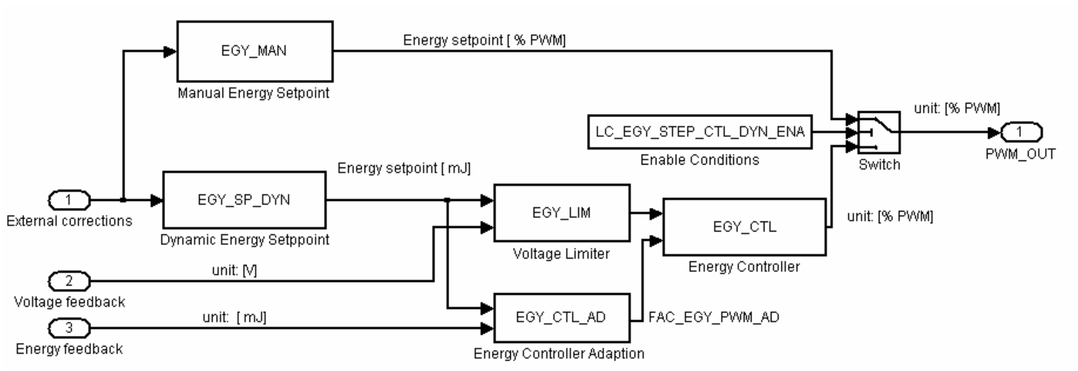
Symbolic constant for usage of high energy range of PIEZO injection valve					

Exported actions:

ACTION_INJR_**SetFacEgyPwmAd** (IN <Cyl>, IN <Fac>)
Sets the cylinder individual conversion factor FAC_EGY_PWM_AD of cylinder <Cyl> to value <Fac>.

7.37.1 Controller concept overview



There are several modes to operate the piezo energy controller unit.
If **LC_EGY_STEP_CTL_DYN_ENA** is FALSE, the manual set point calculation with direct feed through to the PWM output is active.
Otherwise the dynamic set point calculation and voltage limiter are activated.
For the voltage limiter are proper feedback conditions necessary.
The adaption of the conversion factor FAC_EGY_PWM_AD is calculated, if switched ON only, and if proper feedback is granted.

Value of NC_EGY_RNG_H = 1.

7.37.1.1 Description for ACTION_INJR_SetFacEgyPwmAd

ACTION_INJR_SetFacEgyPwmAd (IN <Cyl>, IN <Fac>)					
Sets the cylinder individual conversion factor FAC_EGY_PWM_AD of cylinder <Cyl> to value <Fac>.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0...7 H	0...7	1	1
This action affects the conversion factor FAC_EGY_PWM_AD of cylinder Cyl.					
Fac	IN	0...FFFFH	0...1.99996948	3.05176 E-5	%/mJ
This parameter defines the new value of FAC_EGY_PWM_AD.					

Formula Section for ACTION_INJR_SetFacEgyPwmAd:

FAC_EGY_PWM_AD[Cyl] = Fac

General information

This module generates an external cylinder individual set point for the piezo energy controller. EGY_ SP_IV_EXT. Furthermore an additive piezo energy correction is supplied. It is taken into account for the energy set point calculation.

Application Condition

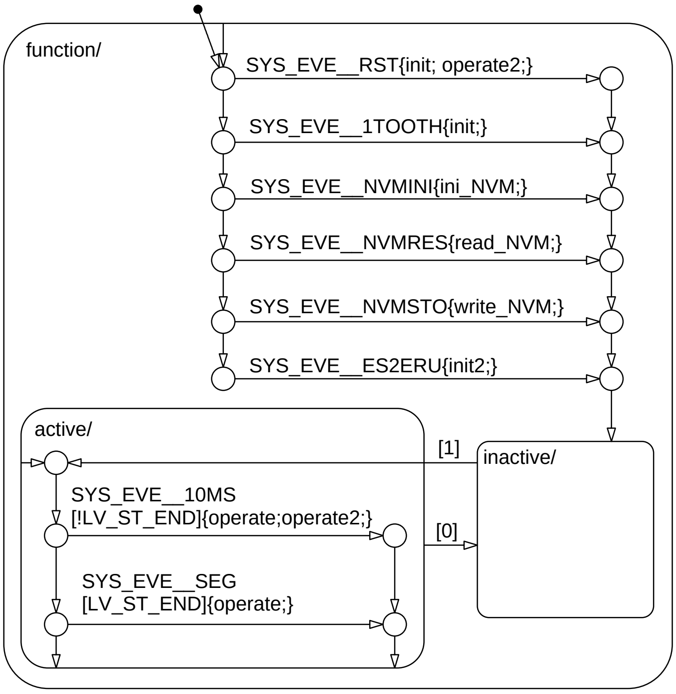

Figure 7.38.1: INJR_ISPCLEGYAI0/APP_CDN/Chart

Function Description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

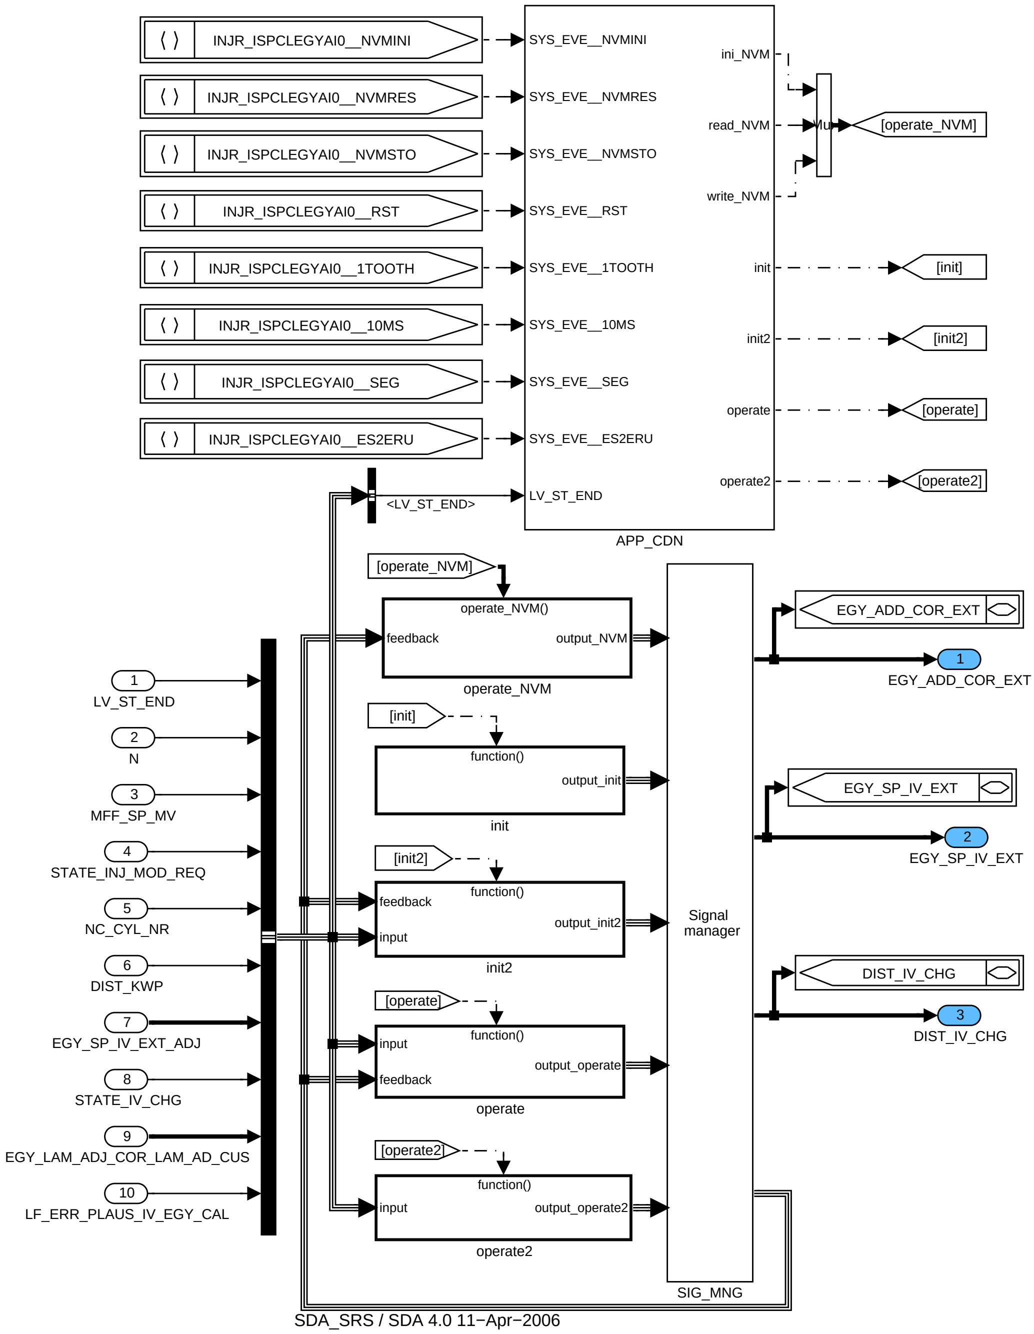

Figure 7.38.2: INJR_ISPCLEGYAI0

7.38.1 Nonvolatile memory operations

The accumulated driving distance at injector change DIST_IV_CHG is stored in the nonvolatile memory (NVM). It is read from and written to the NVM before/after each complete driving cycle.
Please note: DIST_IV_CHG has to be allocated in that part of the NVM-RAM which is not erased during reflashing of ECU.

7.38.2 Initialization at reset and first valid tooth

At reset and fist valid tooth the additive energy correction is set to 0.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

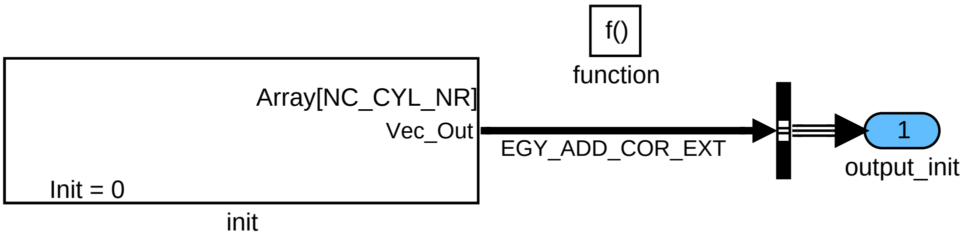

Figure 7.38.3: INJR_ISPCLEGYAI0/init

7.38.3 Calculation at engine stop to engine run

At ES2RUN it is determined whether an injection valve was changed: STATE_IV_CHG is provided by the keywordprotocol KWP and supplies a bit coded information: If the bit on position x is set the injector was changed. DIST_IV_CHG is the cylinder individual driving distance when the injector was changed. It is stored in the nonvolatile memory.

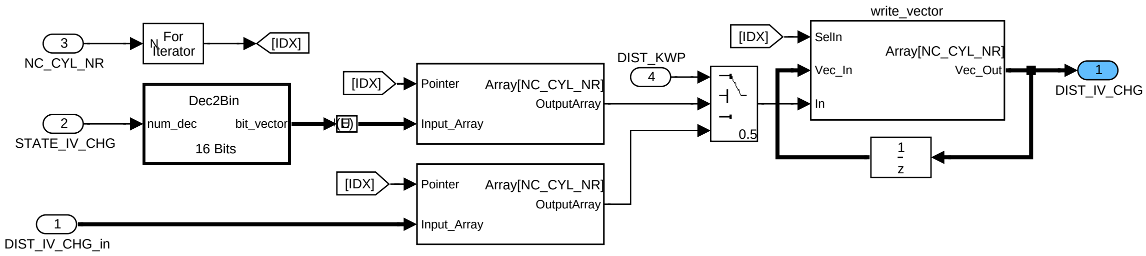

Figure 7.38.4: INJR_ISPCLEGYAI0/init2/ForIterator

7.38.4 Calculation of additive energy correction

An additive piezo energy correction depending on engine speed and load is supplied. Depending on the requested combustion modes (homogeneous, homogeneousstratified and stratified) different maps are used. Furthermore an additive correction accounting for aging effects of the piezo injection valve is supplied cylinder individually. The accumulated driving distance is used as an indicator for aging. It is given by the difference of the actual driving distance and the driving distance at the last injector change. EGY_LAM_ADJ_COR_LAM_AD_CUS accounts for the long term lambda adaptation.

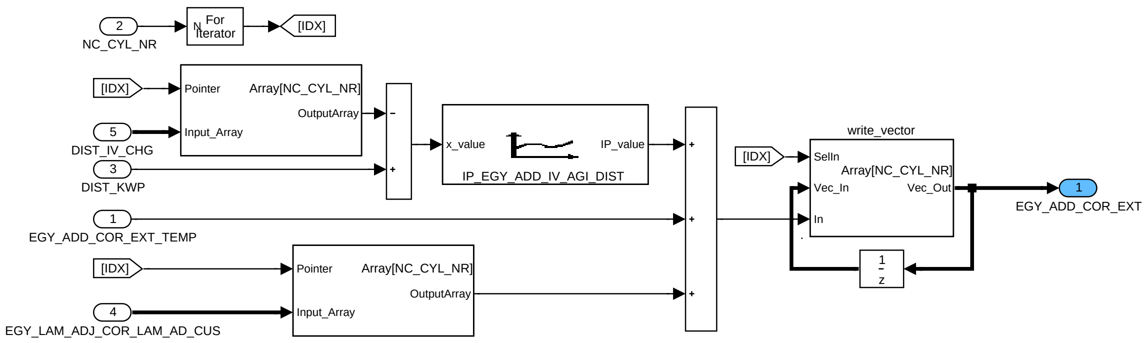

Figure 7.38.6: INJR_ISPCLEGYAI0/operate/ForIterator

7.38.5 External energy setpoint for energy controller

This functionality supplies a cylinder individual injection valve energy set point for the energy controller. It is set to EGY_SP_IV_EXT_ADJ given by the KWP if the cylinder individual values are plausible (bit x is zero in bit-mask LF_ERR_PLAUS_IV_EGY_CAL for logical cylinder x) and if LC_EGY_SP_IV_EXT_ADJ_ENA is set. Otherwise cylinder individual values can be supplied manually via the calibration constant C_EGY_SP_IV_EXT_ADJ.

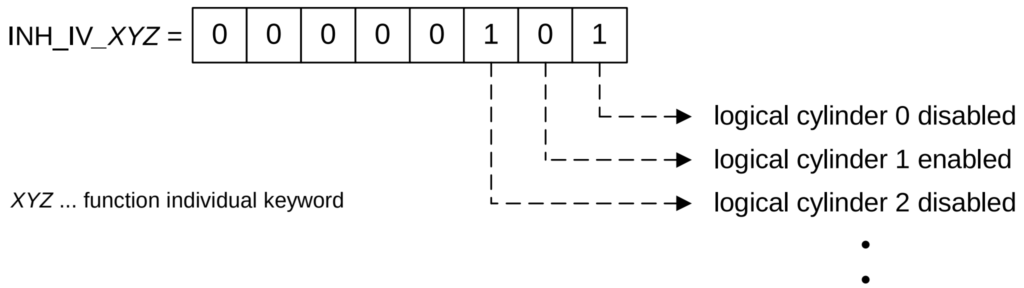
Cylinder shut off pattern for dynamic cylinder shut off					
LC_SWI_MOD_INH_IV_DYN	-	0... 1H	0 ...1	1	-
Mode switch between different dynamic fuel shut off algorithm					

General information

Static fuel shut off:

In several engine operating- and system states and in case of malfunctions of the injection or ignition system the fuel injection must be disabled at individual cylinders. All the shut off requirements are coordinated, hence these requirements have to have the same structure as described below:



Dynamic fuel shut off:

The information which cylinder has to be shut off static, is coded within a byte (with the length of 8 bit) at the cylinder corresponding position.

In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.

Injections, which are already started, will not be stopped.

FUNCTION DESCRIPTION:

Application conditions

Activation: every engine state

Deactivation: –

Initialization: –

Reccurence: if LV_ST_END = 0: 10 ms
if LV_ST_END = 1: segment synchronous

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.39.2 Dynamic fuel shut off

In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.

Injections, which are already started, are not stopped.

The map ID_INH_SWI_IV contains (2 * NC_CYL_NR + 1) different pattern with calibrate able shut off sequences. Every pattern is allocated to an index NR_PAT (mapping points).
There are two requirements for “Dynamic fuel shut off” to this module:
NR_PAT_SEL_CYL is an index defined by the module “Sequential fuel cut off and restart fuel feed”.
NR_PAT_SCC is an index defined by the module “Torque based pattern calculation”.
NR_PAT is the index corresponding to the highest shut off level (number of cylinders disabled) of these both requirements. A certain pattern is repeated until this index changes.
NR_PAT_OLD = NR_PAT
NR_PAT = MAX (NR_PAT_SEL_CYL, NR_PAT_SCC)
INH_SWI_IV = ID_INH_SWI_IV
For example a map ID_INH_SWI_IV for an 8-cylinder engine with different shut off sequences (8 next injections):

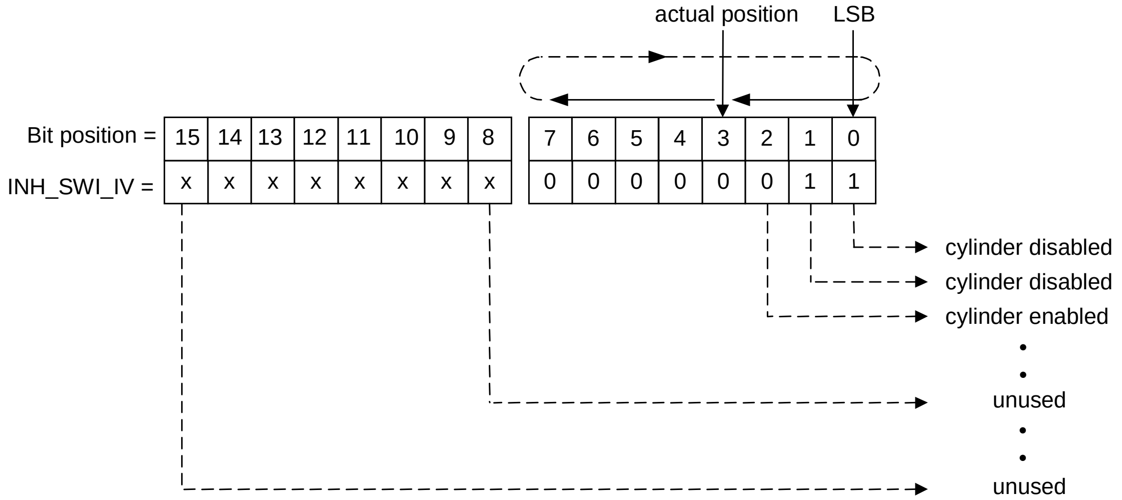
15	xxxxxxxx 00000011
16	xxxxxxxx 00000001

Note:

To guarantee that the algorithm works correct, the table ID_INH_SWI_IV has to be applied as follows: The higher the index NR_PAT, the higher the number of cylinders deactivated.

INH_SWI_IV is defined as follows:



(e.g. NC_INJ_INH_SWI_IV_SHIFT_NR = 8, actual bit position = 4):

If the bit at a bit position = 1 → cylinder disabled
If the bit at a bit position = 0 → cylinder enabled

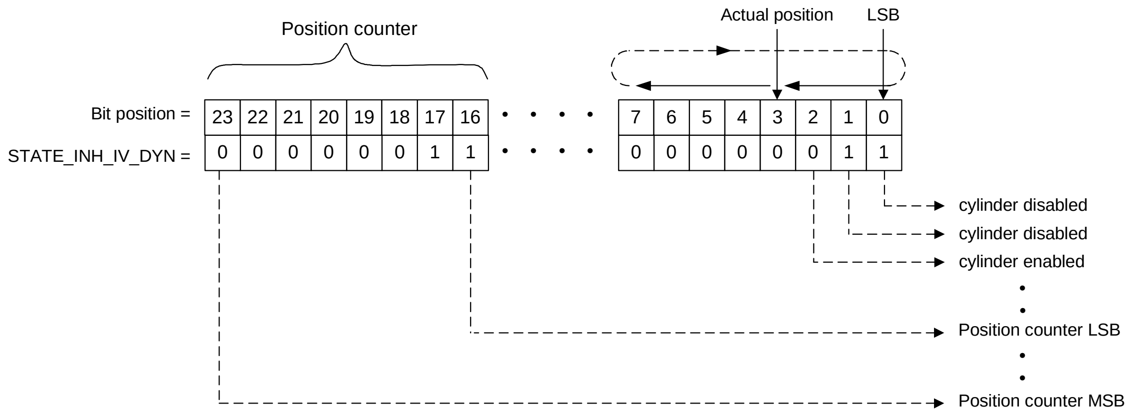
Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The length of the pattern is 16 bit. NC_INJ_INH_SWI_IV_SHIFT_NR defines how many bits are used for the shut off sequence.

NC_CYL_NR < = NC_INJ_INH_SWI_IV_SHIFT_NR < = 16

Calculation of STATE_INH_IV_DYN:

Definition of STATE_INH_IV_DYN:



Note! The position counter data field inside STATE_INH_IV_DYN will be updated at TRIG_EOI_LIM[x].
It contains the 'Actual position' inside the shut off pattern sequence.
Select between two different algorithm for STATE_INH_IV_DYN calculation:
(1) IF LC_SWI_MOD_INH_IV_DYN = 0
(1) THEN Classic mode: If NR_PAT increases, then STATE_INH_IV_DYN starts always with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the 'Actual position' stays unchanged and a new shut off pattern - or the old one - is used based on INH_SWI_IV - see picture above.

(2) IF NR_PAT > NR_PAT_OLD
(2) THEN
Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(2) ELSE
Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:
STATE_INH_IV_DYN = STATE_INH_IV_DYN **AND** 0xFFFF0000 ...bitwise
OR ...bitwise
INH_SWI_IV **AND** 0x0000FFFF ...bitwise
Note! Pay attention of data consistency of STATE_INH_IV_DYN.
(2) ENDIF

(1) ELSE Modern mode: Only if NR_PAT was zero and increases, then STATE_INH_IV_DYN starts with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the 'Actual position' stays unchanged and a new shut off pattern - or the old one - is used based on INH_SWI_IV - see picture above.

(3) IF (NR_PAT_OLD = 0) **AND** (NR_PAT > NR_PAT_OLD)
(3) THEN

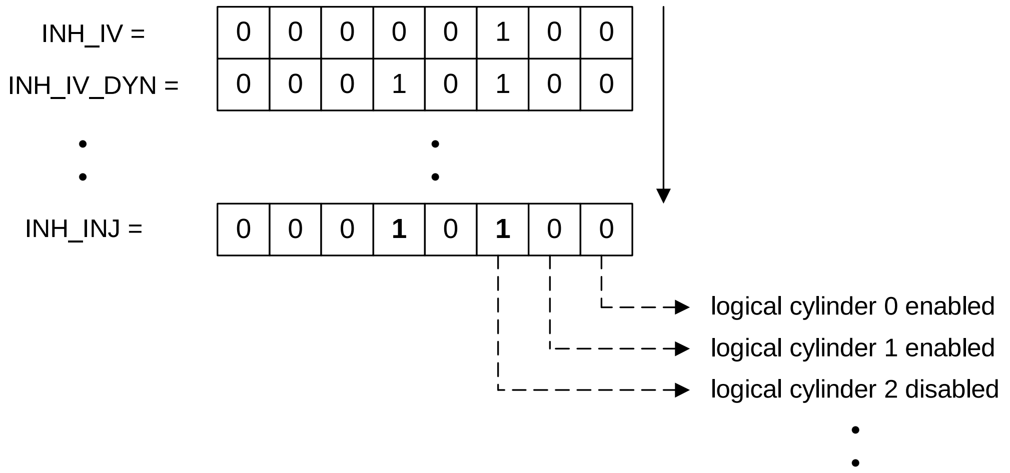
Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(3) ELSE
Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:
STATE_INH_IV_DYN = STATE_INH_IV_DYN **AND** 0xFFFF0000 ...bitwise
OR ...bitwise
INH_SWI_IV **AND** 0x0000FFFF ...bitwise
Note! Pay attention of data consistency of STATE_INH_IV_DYN.
(3) ENDIF
(1) ENDIF

7.39.3 Coordination of shut off information for basic software (INH_INJ)

The output pattern INH_INJ is the bitwise OR of the pattern INH_IV and INH_IV_DYN, linked with a mask ((2 $^{NC\_CYL\_NR}$) -1).
As an example see below:



Note! Pay attention of data consistency of INH_IV.

7.39.4 Shut Off Status Information

SUM_INH_IV .... sum of INH_IV
SUM_INH_IV_CBK_i .... sum of those bits within INH_IV which are allocated to exhaust cylinderbank i, with i = 1 for exhaust cylinderbank 1 and i = 2 for exhaust cylinderbank 2.
SUM_INH_IV_DYN ..... sum of INH_IV_DYN
SUM_INH_INJ ..... sum of INH_INJ
Note! Pay attention on data consistency of SUM_INH_INJ and SUM_INH_IV_DYN

Note:

The allocation between physical cylinders and exhaust cylinderbank 1 and 2 is defined by the pattern NC_LAMB_REF. For example an 8 cylinder engine:

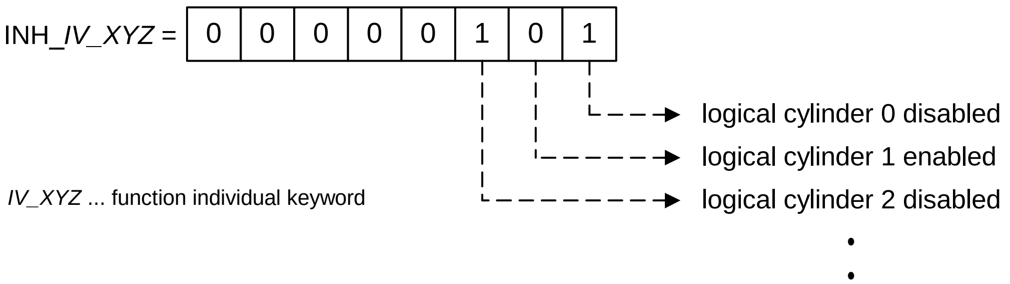
Formula section:

7.40.1.1 General



In several engine operating- and system states and in case of malfunctions the fuel injection must be disabled at individual cylinders. All the shut off requirements are coordinated, hence these requirements have to have the same structure as described below:

The information which cylinder has to be shut off static, is coded within a byte (with the length of 8 bit) at the cylinder corresponding position.

7.40.1.2 Static Fuel Shut Off Requirements

7.40.1.2.1 Inhibit by manual switch

Logical variable to inhibit LV_DT impact on jerk minimal sequential fuel cut-off activation					

FUNCTION DESCRIPTION:

General information:
At transition from trailing throttle to trailing throttle fuel cut off, torque jumps generally occur at trailing throttle fuel cut off which are noticeable as jerks in the vehicle. To reduce the torque at this transition, the ignition timing is retarded and the combustion air is adjusted to small values.
These procedures however do not always achieve the required torque reduction, because ignition timing and combustion air can only be reduced that far, that jerk free engine operation is still possible.
To support the above mentioned torque reduction measurement, it is possible that the injection is switched on and/or switched off for individual cylinders within a defined number of engine cycles (on and/or deactivation) incase of PUC and reentry into Idle.
The engine speed gradient is monitored in order to cancel the selective reentry idle at rapid engine speed drops. If the engine speed gradient is below the threshold C_N_GRD_MIN_SEL_RIS or N_DIF_COR is greater than or equal to C_N_DIF_MAX_SEL_RIS then all cylinders are immediately activated (-> CASE 2). The same happens if during selective reentry there is a significant increase of torque request, e.g. TQI_SP_SLOW_DIF is higher than C_TQI_SP_SLOW_DIF_MAX (-> CASE 2 and 3).

7.41.1 Calculation of TQI_SP_SLOW dynamic

Description:

This value is needed for fast restart of fuel feed.

Application conditions

Initialisation: *TQI_SP_SLOW_DIF = 0*
Recurrence: *20ms*
Activation: *at every engine state*
Deactivation: –

Formula section:

TQI_SP_SLOW_DIF = TQI_SP_SLOW(n) - TQI_SP_SLOW(n-1)

7.41.2 NR_PAT_SEL_CYL calculation

Recurrence: Segment-synchronous

7.41.2.1 Calculation of T_OSC_DT:

if LV_AT = 0

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

then T_OSC_DT = ID_T_OSC_DT(GEAR)
else T_OSC_DT = 0
endif

Description (Example for 4-cylinder engines)

At a transition LV_PU → LV_PUC,. LV_PUC → LV_IS and LV_PUC → LV_PL , 32 cycles (8 x 720°CRK) in case of a 4-cylinder can be influenced. To realize this, a table ID_PAT_SEL_CYL contains the sequences of injection patterns (0...7), predefined in the table ID_PAT_IND. “ NR_SEL_CYL “ means the logical number in the shut off sequence (1...8).

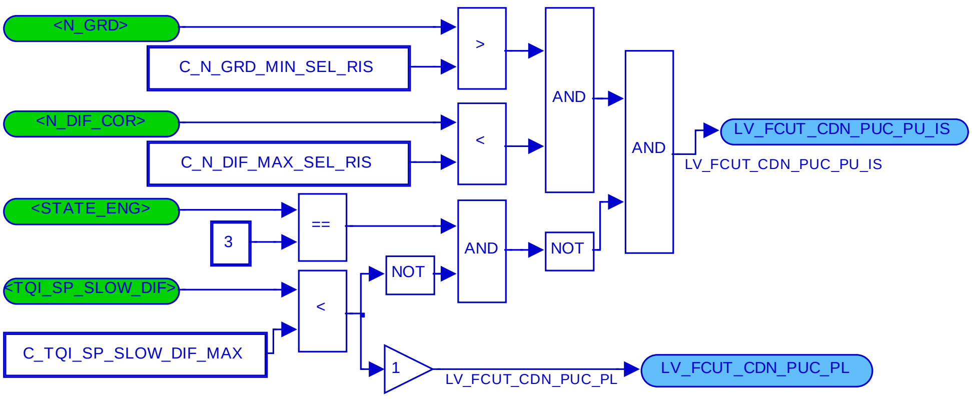
Application conditions:

Activation:

At active cylinder specific transitions LV_SEL_CYL =1

7.41.2.2 Calculation of exit conditions for running sequences (CASE 2 and CASE 3)

These bits are needed to terminate running sequences.



7.41.2.3 Transition from PU ? PUC (CASE 1)

The entrance in the transition pattern for PUC follows, when all conditions for PUC are fulfilled.

```
if LC_ENA_FCUT_AJ = 0 or LV_AT = 1
        then if (LV_DT = 0 and LC_INH_DT_PU = 0)
                then    NR_SEL_CYL = 8
                        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                else    NR_SEL_CYL starts from 1 and is incremented every 720 °KW
                        until its maximum value. In case of deactivation NR_SEL_CYL
                        is reset to 1.
        else
        if (LV_DT = 0 and LC_INH_DT_PU = 0)
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                T_FCUT_AJ is initialized with T_OSC_DT /2
        else    NR_SEL_CYL = C_NR_SEL_CYL_1
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                LV_SEL_CYL = 1
                if T_FCUT_AJ - T_SEG_AV = 0
                then    NR_SEL_CYL = 8
                        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
```

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

```
                    T_FCUT_AJ is initialized with T_OSC_DT /2
                    LV_SEL_CYL = 0
            else    NR_SEL_CYL_n = NR_SEL_CYL_n-1
                    T_FCUT_AJ is decremented
                    end
      end
end
```

The transition is completed, when the last of the 32 transition cycles has run out. The pattern index applied as last one has to be the highest used for the cut-off strategy , that means all cylinders are cut off. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern or while the time sequence an engine operating state change to PU, PL or IS happens, all cylinders are switched on immediatedly (pattern index : “0”), NR_SEL_CYL is reset to 1.

7.41.2.4 Transition from PUC ? IS or PUC ? PU (CASE 2)

The entrance in the transition pattern for RIS (reactivation idle speed) follows, when all conditions for IS resp. PU are fulfilled.

```
 if LC_ENA_FCUT_AJ = 0 or LV_AT = 1
then    if (LV_DT = 0 and LC_INH_DT_PU = 0) or LV_FCUT_CDN_PUC_PU_IS = 0
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
        else    NR_SEL_CYL starts from 1 and is incremented every 720 °KW
                until its maximum value.

else
        if (LV_DT = 0 and LC_INH_DT_PU = 0) or LV_FCUT_CDN_PUC_PU_IS = 0
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                T_FCUT_AJ is initialized with T_OSC_DT /2
        else    NR_SEL_CYL = C_NR_SEL_CYL_2
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                LV_SEL_CYL = 1
                if T_FCUT_AJ - T_SEG_AV = 0
                then    NR_SEL_CYL = 8
                        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                        T_FCUT_AJ is initialized with T_OSC_DT /2
                        LV_SEL_CYL = 0
                else    NR_SEL_CYL_n = NR_SEL_CYL_n-1
                        T_FCUT_AJ is decremented
                end
        end
end
```

The transition pattern is completed, when the last cycle of the 32 transition cycles has run out. The pattern number applied as last one has to be „0” , that means all cylinders are switched on. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern or while time sequence a engine operating state change to PUC happens, the transition pattern or time sequence for RIS runs out to its end and after that the transition pattern for PUC starts, if required.

If the function is deactivated (see deactivation conditions), all cylinders are switched on immediatedly. In case of deactivation NR_SEL_CYL is reset to 1.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.41.2.5 Transition from PUC ? PL (CASE 3)

The entrance in the transition pattern for RPL (reactivation part load) follows, when all conditions for PL are fulfilled.

```
 if LC_ENA_FCUT_AJ = 0 or LV_AT = 1
then    if (LV_DT = 0 and LC_INH_DT_PU = 0) or LV_FCUT_CDN_PUC_PL = 0
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
        else    NR_SEL_CYL starts from 1 and is incremented every 720 °KW
                until its maximum value. In case of deactivation NR_SEL_CYL
                is reset to 1.

else
        if (LV_DT = 0 and LC_INH_DT_PU = 0) or LV_FCUT_CDN_PUC_PL = 0
        then    NR_SEL_CYL = 8
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                T_FCUT_AJ is initialized with T_OSC_DT /2
        else    NR_SEL_CYL = C_NR_SEL_CYL_3
                NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                LV_SEL_CYL = 1
                if T_FCUT_AJ - T_SEG_AV = 0
                then    NR_SEL_CYL = 8
                        NR_PAT_SEL_CYL = ID_PAT_SEL_CYL(NR_SEL_CYL)
                        T_FCUT_AJ is initialized with T_OSC_DT /2
                        LV_SEL_CYL = 0
                else    NR_SEL_CYL_n = NR_SEL_CYL_n-1
                        T_FCUT_AJ is decremented
                end
        end
end
```

The transition pattern is completed, when the last cycle of the 32 transition cycles has run out. The pattern number applied as last one has to be „0" , that means all cylinders are switched on. NR_SEL_CYL is reset to 1.

If in the course of the transition pattern a engine operating state change to PUC happens, the transition pattern for reentry PL runs out to its end and after that the transition pattern for PUC starts, if required. If the function is deactivated, all cylinders are switched on immediatedly.

Deactivation:
- LV_ES = 1 **or**
- LV_ST = 1 **or**
- LV_IGK = 0 **or**
- Pattern completed

At passive cylinder specific transitions:
LV_SEL_CYL = 0 and NR_SEL_CYL = 1
T_FCUT_AJ is initialized with T_OSC_DT /2

Transition tables

The transition pattern indexes are adjustable in the table ID_PAT_SEL_CYL. There are 8 fade out patterns which are applicable per transition table (definition of patterns see chapter 7, "Cylinder shut off with pattern").

The following cases are distinguished in ID_PAT_SEL_CYL:

CASE 1: Trailing throttle fuel cut off (PUC)
CASE 2: Restart IS (RIS)
CASE 3: Restart PL (RPL)

Example for shut-off sequences with 8 levels and a shut off pattern for the 4 next injections (4-cylinder)

CASE_SEL_CYL■ NR_SEL_CYL →

	1	***2***	***3***	***4***	***5***	***6***	***7***	***8***
1	1	1	2	2	3	3	4	4
2	5	5	5	6	6	7	7	0
3	5	6	6	7	0	0	0	0

According shut off sequences: (0 : Injection, 1: no injection)

Case 1	1 0 0 0	1 0 0 0	1 0 1 0	1 0 1 0	1 0 1 1	1 0 1 1	1 1 1 1	1 1 1 1
Case 2	0 1 1 1	0 1 1 1	0 1 1 1	0 1 0 1	0 1 0 1	0 0 0 1	0 0 0 1	0 0 0 0
Case 3	0 1 1 1	0 1 0 1	0 1 0 1	0 0 0 1	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0

Formula section:

NR_PAT_SEL_CYL = ID_PAT_SEL_CYL

Application assistances

Handling of reactivation functions (out of PUC):
Injection (Reactivation fuel feed) : To ensure, that all cylinders get at least once the same amount of TI_ADD_REAC, TI_ADD_REAC is not decremented as long as sequential transition PUC → IS resp. PUC → PL is ongoing.
Ignition: The according reactivation functions are not concerned by sequential transition functions.
Handling of engine states:
The detection of PU, PUC, PL and IS is not concerned by sequential transition functions.

7.42 O2 sensor (lin, up) signal compensation and conversion

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_CYC_T_WAIT_OFS_ADJ_RED [NC_CBK_EX_NR]	V	0... FFH	0... 255	1	-
Counter of cycles for application of reduced repetition rate for offset adjustment during engine warm-up					
CTR_ERR_LSL_IF_SPI_OFS_ADJ_SAVE [NC_CBK_EX_NR]	V	0... FFH	0... 255	1	-
Storage variable for SPI communication error counter value of WRAF controller					
CTR_VLS_MV_LSL_NR_SAMPLE [NC_CBK_EX_NR]	V	0... FFH	0... 255	1	-
Sample counter for mean value calculation					
IPLSL_COR [NC_CBK_EX_NR]	O/V	8000... 7FFFH	-12.596... 12.59561	384e-6	mA
Compensated nominal pumping current (after sensor /sensor dispersion compensation for new /aged sensor)					
LAMB_LS_UP [NC_CBK_EX_NR]	O/V	0... 7FFFH	0... 31.99902	976.599e-6	-
Lambda signal value of the WRAF sensor					
LAMB_LS_UP_MIN	O/V	0... 7FFFH	0... 31.99902	976.599e-6	-
Minimum lambda in multiple-branched exhaust gas lines					
LAMB_LS_UP_MV	O/V	0... 7FFFH	0... 31.99902	976.599e-6	-
Mean value of lambda in multiple-branched exhaust gas lines					
LAMB_LS_UP_MV_TMP	-	0... FFFFFFFFH	0... 4194303.99902	976.599e-6	-
Temporary storage for calculation of mean value of lambda in multiple-branched exhaust gas lines					
LV_LAMB_PLS_SWI_OFF [NC_CBK_EX_NR]	V	0... 1H	0 ...1	1	-
Indicator for need to switch off forced lambda stimulation					
LV_LAMB_STI_OFF_LSL_OFS_ADJ [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Request for disabling of forced lambda stimulation, or keeping it disabled, resp.					
LV_LSL_OFS_ACT_AST [NC_CBK_EX_NR]	V	0... 1H	0 ...1	1	-
Switch to chose activation conditions directly after engine start					
LV_LSL_OFS_ADJ_ACT [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
State of the offset measurement (active /not active)					
LV_LSL_OFS_ADJ_IS [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Offset measurement carried out during current idle phase					
LV_LSL_OFS_GAIN_SWI_CYC [NC_CBK_EX_NR]	V	0... 1H	0 ...1	1	-
Boolean flag indicating active Ip gain range for alternating offset adjustment					
LV_LSL_UP_SHO_PER_REQ [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Trigger the short period stop mode of Lambda controller during offset adjustment and gain switching					
LV_SWI_CLC_LSL_OFS_ADJ [NC_CBK_EX_NR]	V	0... 1H	0 ...1	1	-
Logical variable for switching of lambda calculation routines

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SWI_GAIN_LSL_IF [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag configuring the WRAF sensor interface gain-selection for Ip measurement (0 = g8, 1 = g16)					
LV_VLS_OFS_ADJ_CMPL [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag indicating successful completion of offset adjustment cycle					
LV_VLS_OFS_ADJ_ENA_LSL_IF [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag requesting enabling of offset adjustment mode of WRAF sensor interface for lambda signal output voltage					
LV_VLS_OFS_LIM_LSL [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag indicating limitation of output voltage offset adjustment value for Ip gain16					
LV_VLS_OFS_LIM_LSL_L_GAIN [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag indicating limitation of output voltage offset adjustment value for Ip gain8					
STATE_LSL_OFS_ADJ [NC_CBK_EX_NR]	V	0H 1H 2H 3H 4H	WAIT PREPARE ADJUST_H ADJUST_L RETURN	-	-
State of WRAF controller lambda output voltage offset adjustment					
T_DLY_LAMB_STI_OFF_OFS_ADJ [NC_CBK_EX_NR]	V	0... FFFFH	0... 655.35	0.01	s
Wait timer to allow for lambda signal settling upon deactivation of forced stimulation					
T_DLY_LSL_OFS_ADJ [NC_CBK_EX_NR]	V	0... FFH	0... 2.55	0.01	s
Wait timer to delay acquisition of measurement values upon activation of adjustment					
T_DLY_LSL_OFS_ADJ_IS [NC_CBK_EX_NR]	V	0... FFH	0... 2.55	0.01	s
Wait timer to delay activation of offset adjustment upon entering engine state idle speed					
T_DLY_LSL_OFS_ADJ_PUC_END [NC_CBK_EX_NR]	V	0... FFFFH	0... 655.35	0.01	s
Wait timer to delay activation of offset adjustment after leaving fuel cut-off phase					
T_INI_DLY_LSL_SIG_ACQ [NC_CBK_EX_NR]	V	0... FFH	0... 2.55	0.01	s
Delay of aquisition after freeze of signal. Assures that segment synchronous meanvalue calc has reached final value.					
T_WAIT_LSL_OFS_ADJ [NC_CBK_EX_NR]	V	0... FFFFH	0... 655.35	0.01	s
Wait timer to define minimum interval between two subsequent offset adjustment cycles					
VLS_COR_H_RES_LSL [NC_CBK_EX_NR]	V	0... FFFFH	0... 9.99984	152.6e-6	V
Compensated output signal of lambda sensor with extended resolution					
VLS_COR_MV_LSL [NC_CBK_EX_NR]	V	0... FFFFH	0... 9.99984	152.6e-6	V
Optional average over two samples of compensated output signal of lambda sensor					
VLS_COR_TMP_LSL [NC_CBK_EX_NR]	V	0... FFFFH	0... 9.99984	152.6e-6	V
Temporary storage value of compensated output signal of lambda sensor

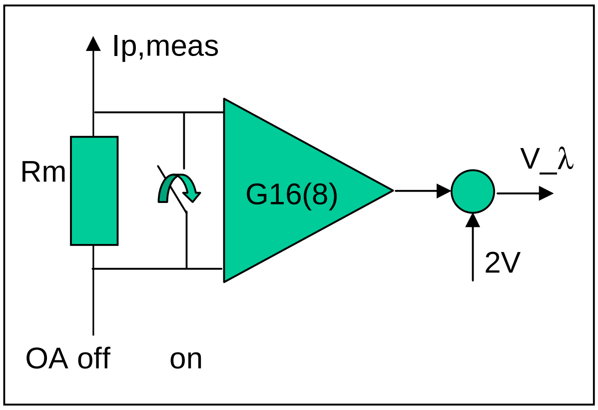
LC_VLS_COR_MV_LSL_ACT	-	0... 1H	0 ...1	1	-
Switch for (de)activation of averaging of VLS_COR_H_RES_LSL[i] prior to conversion					
LC_VLS_UP_THD_SWI_GAIN_AFL_ACT	-	0... 1H	0 ...1	1	-
Boolean flag for activation of Ip gain switching due to possible VLS_UP_RAW[i] lean side signal saturation					
LC_VLS_UP_THD_SWI_GAIN_AFR_ACT	-	0... 1H	0 ...1	1	-
Boolean flag for activation of Ip gain switching due to possible VSL_UP_RAW[i] rich side signal saturation					

FUNCTION DESCRIPTION:

OA = Offset adjustment.
Based on short circuiting of Ip measurement amplifier input.



Ip measurement gain16 = High Gain ('1')
Ip measurement gain8 = Low Gain ('0')

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Use cases				
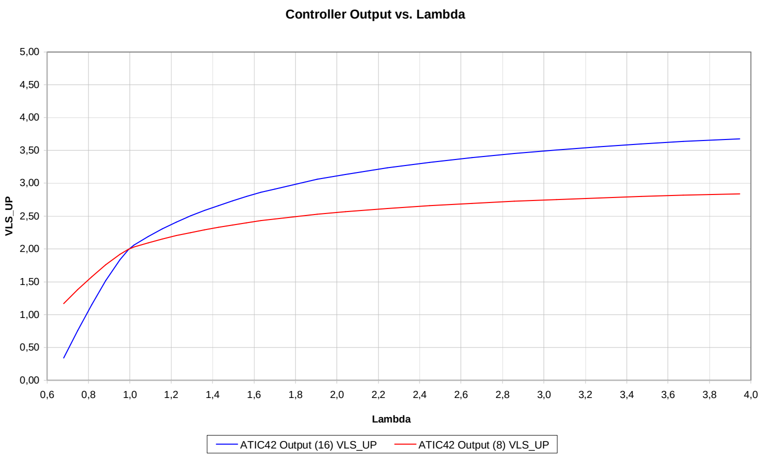
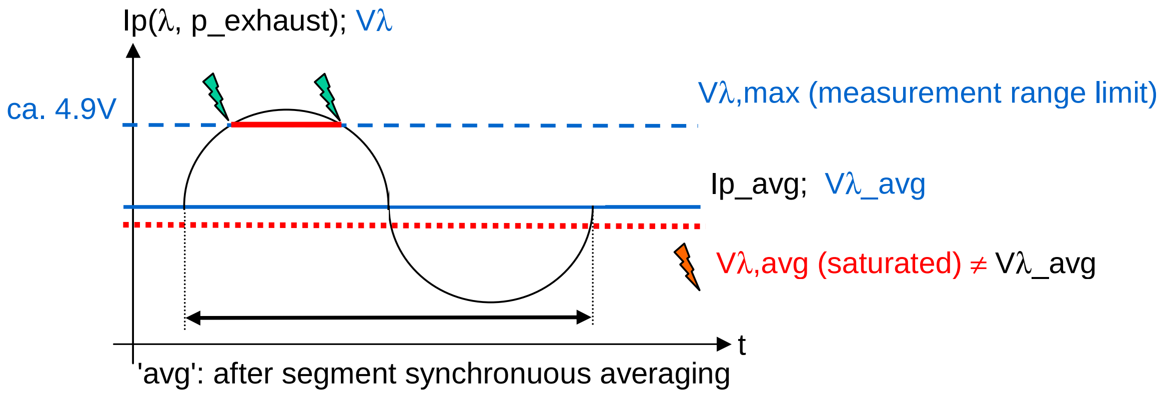
LOGICAL CONSTANT Effect ('0' / '1')	gain16 only	gain8 only	gain16&8 simultane ously	gain16/8 alternating
LC_LSL_OFS_ADJ_GAIN_SEL Defines default Ip measurmement gain	1	0	1	1
LC_LSL_OFS_ADJ_H_L_GAIN OA in default gain only (second range is approximated) / for both gains	0	0	1	1
LC_LSL_OFS_GAIN_SWI_CYC Simultaneous / alternating OA for both gains	0	0	0	1
LC_IPLSL_GAIN_SWI_ACT Gain switching during Ip measurement active	0 / 1	0 / 1	0 / 1	0 / 1



Ip measurement range vs. resolution (exemplary).



Range switching triggered by /V thresholds to avoid saturation effects of Ip measurement.

Switching thresholds/hysteresis

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned
(NC_CBK_EX_NR = 2), then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions

Initialisation: The following variable initialisation shall take place at **LV_IGK 0->1, afterRESET**, or **upon erase of error management:**

VLS_UP_COR[i] = 0
VLS_COR_H_RES_LSL[i] = 0

7.43 O2 sensor (lin, up) signal compensation and conversion (Appl. Inc.)

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_LSL_OFS_ADJ [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag indicating that upstream oxygen sensor Ip offset adjustment shall be inhibited					
T_HOM_ACT_OFS_ADJ	O/V	0... FFFFH	0... 655.35	0.01	s
Time in homogenous mode for enabling offset adjustment					

Input data:

C_T_DLY_TTIP_MES_ OBD_LSH_UP {p. 5440}	C_T_DLY_TTIP_RES_ OBD_LSH_UP {p. 5440}	LV_HOM_ACT {p. 8136}	LV_LAM_AD_INJ_ACT {p. 3348}
STATE_LSL_IF_SPI_RD [NC_CBK_EX_NR] {p. 956}			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned
(NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The Boolean flag LV_INH_LSL_OFS_ADJ[i] shall indicate whether the upstream oxygen sensor Ip offset adjustment shall be permitted to take place.
When set, Ip offset adjustment shall be inhibited.

Description:

Application conditions:

Initialisation:
The following initialisation shall be carried out **after RESET**, **after engine start**, or **upon erase of error management**.
LV_INH_LSL_OFS_ADJ [i] = 0
T_HOM_ACT_OFS_ADJ = max phys. value

Recurrence:
T_SAMPLE = 10ms

Activation:
LV_ST_END == 1

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Deactivation:
- -

Formula section:

IF LV_HOM_ACT = 0
THEN T_HOM_ACT_OFS_ADJ = 0
ELSE increment T_HOM_ACT_OFS_ADJ (timer shall saturate at max phys. limit)
ENDIF

If STATE_LSL_IF_SPI_RD[i] *bit* LSL_ENA == 0
or LV_LAM_AD_INJ_ACT = 1
or (T_HOM_ACT_OFS_ADJ <= (C_T_DLY_TTIP_MES_OBD_LSH_UP + C_T_DLY_TTIP_RES_OBD_LSH_UP))
then LV_INH_LSL_OFS_ADJ[i] = 1
else LV_INH_LSL_OFS_ADJ[i] = 0
endif

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.44 O2 sensor (up) operability detection

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LAMB_DE_INT_LS_UP_READY [NC_CBK_EX_NR]	V	0... FFFFH	0... 63.9990234	97.6563e3	-
Value as a measure of the sensor signal variation vs. time

Test switch to check function behaviour at revocation of dew point					

FUNCTION DESCRIPTION

General information:

This is a particular **version for linear oxygen sensors to be used if the oxygen sensor ceramic temperature is determined by internal resistance measurement of the Nernst cell**. It requires that the oscillator can be switched on and off depending on LV_LS_UP_READY_RAW[i] which is determined in this function.

The operability check for the lambda sensor shall detect the moment at which the sensor reaches principal ability to generate plausible output signals (once pump current control loop has successfully been activated!). It shall analyse the sensor signal and distinguish between two stages of operative readiness. The criterion for raw sensor operability may be the variation of the sensor signal as well as the crossing of a maximum or minimum threshold by the sensor signal or simply when a delay has been exceeded. When the raw operative readiness has been sensed, the full operative readiness shall be determined by waiting until the minimum oxygen sensor ceramic temperature for safe sensor operation has been reached.

The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then

i = 1, for exhaust cylinder bank 1

i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)

i = 1, for single exhaust cylinder bank.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Signal flow diagram:

Description:

The function shall be activated with the following conditions being fulfilled:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Engine start is left, i.e. "exit START" (LV_ST_END = 1) *and*
Upstream heater has left the batteryvoltage protection mode (STATE_LSH_UP[i]   LSH_VB_PROT) *and*
Upstream heater is <u>not</u> in off mode (STATE_LSH_UP[i]   LSH_OFF) *and*
Threshold value of MAF integral is <u>not</u> exceeded during PUC.
The function shall be deactived once any one of these conditions is not fulfilled anymore.
Function restart shall also take place upon erase of error management.
Precondition for starting the operability check is that the delay time ID_T_DLY_CHK_LS_UP_READY has expired.

The sensor is subsequently recognized as being <u>fully</u> operable (LV_LS_UP_READY[i] = 1) if

(

the value LAMB_DE_INT_LS_UP_READY[i] exceeds the threshold C_LAMB_DE_INT_THD_LS_UP_READY once
OR if the sensor output signal LAMB_LS_UP[i] exceeds the window defined by the limiting values C_LAMB_THD_MIN_LS_UP_READY and C_LAMB_THD_MAX_LS_UP_READY

< This state is called <u>raw</u> sensor operability (LV_LS_UP_READY_RAW[i] = 1) >

AND

the value for ceramic temperature is valid (LV_TTIP_MES_VLD_LS_UP[i] = 1)
AND the value of the reference voltage is valid (LV_V_REF_VLD_R_IT_LS_UP[i] = 1)
AND the temperature of the sensor is higher than a threshold (TTIP_MES_LS_UP[i] > C_TTIP_MIN_LS_UP_READY)

AND

the dew point was exceeded (LV_TEMP_DEW_LS_UP[i] = 1)
OR LC_TEG_MIN_DEAC = 1 (only for test purpose in conjunction with forced sensor heating prior to engine start!)

AND

LC_TEG_MIN_THD_DEAC_TEST = 0

)

OR

the timer for forced activation has expired (T_TOUT_LS_UP_READY[i] = 0)
AND dew point was exceeded (LV_TEMP_DEW_LS_UP[i] = 1) for certain time delay (LV_TEG_MIN_DLY[i] = 1)
< This state is called <u>forced</u> sensor operability (LV_LS_UP_READY_CDN[i] = 1) >

The logical value LV_LS_UP_READY_RAW[i] detects changes in sensor signal as basis for recognition of the raw sensor operability.

<u>REMARK:</u> The CARB has defined that the sensor must be recognized as being operable after a certain time upon engine start. This requirement is realized using the timer T_TOUT_LS_UP_READY[i].

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

If the timer has expired the sensor will be set operable (LV_LS_UP_READY[i] = 1) and in addition the conditional readiness bit (LV_LS_UP_READY_CDN[i]) will be set to 1 , initializing the forced activation of sensor.

The flag LV_LSL_UP_ERR_SUSP[i] indicates that a fault may be present in the sensor, which is not yet debounced but may lead to wrong lambda measurement. It may be used to restrict the usage of the sensor signal by functions like lambda control or adaptation or diagnosis functions. The detection of these conditions is effectively masked with LV_LSL_UP_SUSP_ENA[i], which ensures that LV_LSL_UP_ERR_SUSP[i] is not set during sensor warmup.

FUNCTION DESCRIPTION:

General information:

The purpose of this function is the management of supply of pumped reference current (Icp), and pump current (Ip) control for ATIC42 WRAF sensor interface.
The Icp current is required by certain WRAF sensor types to provide a pumped oxygen reference for the Nernst cell sensing portion, as this is not provided by venting air into a chamber within the sensor. The value of the Icp current is programmed according to certain operating states of the WRAF system, and the Icp current is enabled or disabled.
Ip current is a measure of lambda. The Ip controller shall be required to meet stringent sensor protection requirements. For certain critical operating states of WRAF sensor, it may be undesirable to have the Ip control active and hence the function shall enable /disable the Ip control as required.
Both danger of implausible lambda measurement, e.g. due to signal saturation effects, and physical sensor destruction have to be detected and appropriate measures are taken.
Ip control is activated with a repeated pulse routine to avoid excessive pumping voltage (Vp) supply at point of activation. During activation, some of the provided sensor protection mechanisms are inhibited because they would produce inappropriate results due to transient behaviour.
Validity of pumping current signal is jugded depending on current state of WRAF system. Certain operating conditions lead to temporary revocation of validity flag, e.g. danger of increased heater-coupling on Ip signal circuit due to longer term battery undervoltage.
In case of pumping voltage (Vp) across sensor pump cell violating certain bounds or of reverse Icp cut-off, Ip control also has to be inhibited to avoid physical destruction of sensor element, i.e. by blackening effect of zirconia dioxyde ceramic.
Two logical variables stating short term profound reliability of measured lambda signal, and signal accuracy level (regular /limited), resp., shall be provided.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Description:

The function shall be activated once the transition from engine start to engine run has taken place and once the initialisation of the WRAF sensor 'ASW<=>BSW' interface has successfully been carried out. It shall stay active up to the end of ECU power latch.

Alternative activation of certain chapters shall take place in case of forced sensor pre-heating prior to engine start.

The function is split into ten main sections:

1. Activation of pumped reference current (Icp)
2. Value of pumped reference current (Set Icp programming value)

Copyright (C) Continental AG,2007

3. Determination of Icp cut-off conditions (Overvoltage at sensor Vn pin)
4. Determination of required status of pump current (Ip) control loop
5. Activation of pump current (Ip) control loop
6. Possibility of increased heater-coupling due to permanent battery undervoltage
7. Validity of pump current (Ip)
8. Pumping voltage (Vp) limitation strategy
9. Provision of a cumulative logical variable LV_LAMB_LS_UP_VLD_i for judgement of short term reliability of WRAF system lambda output signal.
10. Indication of regular /limited accuracy of measurement signal.

Remark: Below description of functional units within WRAF sensor control module aims to provide a general survey on physical backgrounds of sensor behaviour and derived actions for operational strategy. For related **variable names** please respect corresponding diagrams provided within **formula section**.

1. Activation of pumped reference current

This section shall provide the Icp enable and appropriate programming value information to the WRAF sensor interface and indicate whether the pumped reference has been filled via corresponding validity flag.

Should the sensor type being used not have a pumped oxygen reference or a general WRAF sensor error has occured, then this section shall be disabled, i.e. status flag for Icp validity is revoked, Icp is programmed to its minimum value, and Icp supply is deactived.

If none of these two conditions is present, this section behaves as follows:

During pulsed Ip control activation only programming value of Icp is evaluated and no other change in Icp supply conditions is performed.

In case of permanent operation of Ip loop with no SPI fault present, sufficiently high battery voltage for accurate operation of ATIC42, and no Vn overvoltage in conjuction with under-run of rich lambda setpoint threshold present (occurence is limited to rich atmosphere, forced Icp cut-off is automatically performed by ATIC42 HW), routine waits for successful mirroring of latest Icp status and programming value commands sent via SPI bus.

Once command transfer has been successful, Icp flow is requested, sensor element temperature has exceeded calibratible threshold, counter limit for filling time of pumped reference is determined. Latter condition can be replaced by OBD2 heater fault present in conjunction with operative sensor readiness (-> tip temperature not reliable), or in case of conditional operative readiness (-> forced sensor activation).

If repeated evaluation of corresponding index table (which depends on sensed element temperature and Icp programming value) leads to a higher value than adjusted before and pumped reference has not been filled completely yet, counter limit is increased. To force initial determination of counter limit this action is also performed when entering the condition with a filling counter value of zero.

Once Icp counter limit is reached the Icp valid flag is set, otherwise counter for Icp filling status is incremented.

General Icp activation is treated depending on engine condition (Icp active with engine running), status of forced sensor heating, and value of power latch delay timer. Latter provides for extended Icp supply after engine stop.

Next Subroutine Value of pumped reference current is executed to determine appropriate Icp programming value.

Should any of the following conditions hold true, filling status of pumped reference has to be verified: SPI command transfer fault, low battery voltage, Vn overvoltage in conjunction with under-run of rich lambda setpoint threshold, revocation of Icp activation, tip temperature drop below threshold.

If pumped reference area has been judged to be completely filled before, Icp counter limit is set to calibratable threshold which represents delay for emptying prior to revocation of 'Icp valid' status bit - to take into account for transient disturbances without immedate reset. Revocation takes place once counter has been decremented to zero.

In case of forced sensor pre-heating prior to engine start, simplified filling procedure of pumped reference is applied which bypasses certain conditions.

1. Value of pumped reference current

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Icp value to be programmed is determined for four different operating states taking into account dependency of provided reference pumping current on (estimated) exhaust lambda and on sensor element temperature:

- Power Latch phase (engine stalled and forced sensor pre-heating inactive): Exhaust system filled with air; Ip control loop disabled. Icp supply is limited to calibratable delay time.
- Ip control active or pulsed activation thereof: Exhaust lambda provided by WRAF sensor.
- Ip control inactive, cold sensor: Exhaust lambda derived from combustion lambda setpoint (LAMB_SP[i]) and additional secondary air flow (SAF_KGH). For calibration it has to be taken into account that LAMB_SP[i] does not represent composition of exhaust atmosphere present at linear oxygen sensor during activation of secondary air; under these conditions lean conditions prevail at sensor mounting location regardless of LAMB_SP[i]!
- Ip control inactive, warm sensor, or OBD2 heater fault present in conjunction with operative sensor readiness (-> tip temperature not reliable), or in case of conditional operative readiness (-> forced sensor activation): same as above.

The influence of secondary air on exhaust lambda at sensor mounting position is taken into account for disabled Ip control loop.
Current status of Ip control loop is judged by evaluation of corresponding ATIC42 interface bit.
Distinction between cold and warm sensor is made by evaluation of calibratable ceramic temperature threshold.
As long as Ip control is in disabled state, Electromagnetic force (EMF) across sensor nernst cell adjusts itself in a range between 0 ... 1V depending on surrounding exhaust gas atmosphere - comparable to the behaviour of a binary type oxygen sensor. With enabled loop, EMF is controlled to be approx. -0mV constantly.
As a rule of thumb for conversion of Icp programming value to actual value of Icp current provided by ATIC42 (which is split between sensor nernst cell and shunt resistance within ATIC42 module which serves as voltage limitation for cold sensor) the following formula can be applied:
Icp = (k + 1) * 5uA with k: Icp programming value.

1. Determination of Icp cut-off conditions

Under worst case tolerances and rich conditions, the potential at sensor pin VN may exceed the threshold up to which Icp generation can be guaranteed for sensors of pumped reference type. Under such circumstances the Icp may temporarily be reduced or even cut-off by ATIC42 protection mechanism. This may lead to lean Ip misindication and also to sensor damage.
ATIC42 2^{nd} silicon provides for automatic Icp cut-off in case of Vn overvoltage and signals the presence of such a condition through its interface.
Hence when Icp cut-off is signaled to occur by ATIC42, Ip control shall be disabled reducing the potential Vp across the pump cell and thereby also reducing the potential at pin Vn.
The voltage Vp across the pump cell shall be modelled by multiplying the measured pump current Ip with the pump cell internal DC resistance obtained from the relationship between the internal resistance of the Nernst cell and the pump cell.
The pump cell DC internal resistance (Rip) shall be obtained from a mapping dependent on value of nernst cell inner resistance (Ri, representing sensor temperature), and lambda setpoint. Both internal resistances are linked by sensor temperature and design. Additionally the pump cell resistance is dependent on the sensor lambda environment, hence the lambda setpoint dependence. Preliminary Rip value is then multiplied by a factor and a constant is added. Both parameters permit the dependency of the resistances to be modified to take worst case ageing into account.
The pump cell voltage Vp shall be calculated by multiplying modelled Rip by corrected value of pump current Ip.
Providing that WRAF sensor is of pumped reference type, the function shall determine whether Icp cut-off conditions are already active. If true, then the condition shall only be deemed to no longer persist when Rip is less than the value stored once Icp cut-off conditions were determined (i.e. sensor elememt got hotter), or lambda setpoint is greater than (i.e. leaner) than the value stored once Icp cut-off conditions were determined. Or, if maximum duration of active Vp limitation is calibrated to be non-zero, when the internal timer TIMER_2 has expired. In addition, for all three cases, VN overvoltage shall no longer be indicated by ATIC42. If all this holds true, then TIMER_2 shall be stopped, the stored Rip and

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

lambda setpoint values shall be reset and the Ip control inhibition flag revoked. Otherwise TIMER_2 is decremented.

If the Icp cut-off conditions are inactive, and pulsed Ip control activation has been completed, calculated Vp voltage shall be compared to a minimum threshold. If this rich threshold is exceeded or Vn overvoltage is sensed by ATIC42 and rich environment is present at sensor (i.e. rich lambda setpoint threshold is under-run), Icp cut-off conditions may occur. Should they be present for longer than estimated emptying delay of pumped reference, TIMER_2 shall be initialized, the current Rip and lambda setpoint values shall be stored, and Ip control inhibition flag shall be set.

1. Determination of required status of pump current (Ip) control loop

This section shall collect the various requests for activation /deactivation of the Ip control loop and provide the information to the WRAF sensor interface.

The function shall provide for manual switching of the Ip control loop by means of logical constants. If manual activation is requested, subroutine Activation of pump current control loop is executed.

In case of automatic switching, no general WRAF sensor error present and running engine (or with activated forced sensor pre-heating), the function checks if pumped reference of a sensor requiring Icp is not completely filled yet, or if Icp cut-off or Vp limitation sensor protection routine is active (and forced sensor pre-heating is inactive). Either one of these conditions leads to Ip passivation by resetting corresponding ATIC42 interface bit. At the same time all variables needed for next Activation of pump current control loop are initialized.

Next the function shall determine whether the conditional operative readiness is set or pulsed Ip control activation is running. If so then the evaluation of further conditions related to sensor readiness and tolerated lambda setpoint range for Ip activation shall be skipped and Activation of pump current control loop shall be executed.

If former condtions are not present, then the function shall determine whether operative readiness is set (or forced sensor pre-heating is activated). If not, then the Ip control loop shall be deactivated.

Once oxygen sensor ceramic temperature is greater or equal to a calibratable threshold, Ip loop shall be enabled once lambda setopint is located within calibratable bounds, or secondary air is active (providing for lean exhaust gas atmosphere), and Ip offset adjustment is not pending. The same action is taken once OBD2 heater fault ist present (-> tip temperature not reliable). Otherwise Ip loop shall stay disabled.

Thus pumping voltage saturation because of high pumping current requirements for << >> 1 can be avoided at point of Ip control loop activation. During secondary air phase, output signal of WRAF sensor is used for monitoring purposes. Thus Ip loop has to be activated even at very lean surrounding atmosphere which is present at that time. In general pumping voltage saturation in lean direction is not critical for WRAF sensor operation in conjunction with ATIC42 as it is for rich atmosphere.

1. Activation of pump current (Ip) control

In order to avoid excessive supply of pumping voltage Vp to WRAF sensor during switch-on of Ip control loop (which might lead to sensor destruction due to blackening effect for applied rich voltages Vp < 2V), a pulsed activation with PWM-behaviour is provided.

For a calibratable number of cycles, ON- and OFF- phases of variable length are applied to WRAF sensor interface. Calibration can also be used to skip sensor protection mechanisms during one-time Ip switch-on for a certain time. In this case OFF-phase is of zero length.

1. Indication of possibility for increased heater-coupling due to permanent battery undervoltage

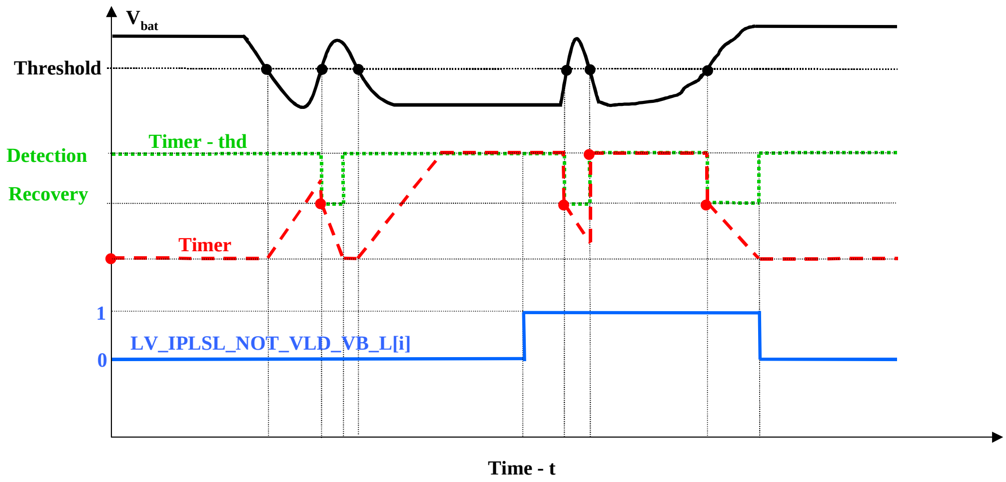
For the linear oxygen sensor BOSCH LSU4.9, up to and including Äp3.1, there is a danger that for longer term battery undervoltage in combination with maximum heater PWM, increased heater-coupling to the pumping current signal circuit of the sensor might appear.

This effect is related to ion migration within the sensor element due to long term application of a certain ion activation potential to negative sensor heater electrode which is of active low type.

Once regular battery voltage conditions are restored the exaggerated heater coupling vanishes within several seconds and returns to regular values.

A timer based detection strategy for possibility of increased heater coupling has been developed and is depticted in below figure.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Once the critical battery undervoltage condition is met for a certain delay time after leaving engine start - usually also leading to high PWM values - pumping current validity shall be revoked.
Since detection and recovery might be linked to different delay times, timer threshold is switched depending on presence of battery undervoltage condition.
If recovery delay time is interrupted by repeated undervoltage condition the delay timer is set to and kept at detection threshold value.
Should time based thresholds for detection and recovery be calibrated identically, latter ist incremented for one step to avoid ambiguities within algorithm execution.

1. Validity of pump current (Ip)

This section shall model the basic validity of the Ip current. For short term reliability of ATIC42 lambda output signal a special indicator bit is introduced in chapter 9.
The function shall check if a general WRAF sensor error is present or if a SPI error has occurred since the last function recurrence. Latter information is retrieved by comparison of corresponding error counter with its previously stored value. If the values differ from each other then current value shall be stored for next comparison, the internal timer TIMER_1 and the Ip validity flag shall be reset.
If sufficient battery voltage for power supply of ATIC42 is available, function shall wait for the sent Ip control enable /disable information to be mirrored by comparing to ATIC42 SPI response byte.
In case of forced sensor pre-heating additional delay time **after engine start** can be calibrated. If corresponding timer threshold is calibrated to be zero, validity of pump current shall also be detectable prior to engine start.
Next the function checks if pulsed activation of pump current control loop is active. If so, Ip validity is revoked.
If not, the function shall determine whether the Ip control loop has been requested to be active. In addition the danger of increased heater coupling due to permanent battery undervoltage has to be excluded.
If all validation conditions hold true, a delay shall be exceeded prior to setting the Ip validity flag. If false, then the internal timer TIMER_1 and the Ip validity flag shall be reset.

1. Pumping voltage (Vp) limitation strategy

Since it is crucial for pumping voltage (Vp) across WRAF sensor pump cell not to exceed certain bounds depending on sensor temperature and ehxaust lambda (roughly $|Vp| \leq 2V$ for sensor at operating temperature, less during sensor warm-up), compliance with these limits has to be ensured under all operating conditions. Exceeding these limits may lead to physical sensor destruction by blackening of zirconia sensor element especially under rich conditions.
Sensor ageing (increase in pump cell inner resistance), insufficient sensor operating temperature, or high pressure conditions, resp., may lead to restriction of measurable lambda range within permitted pumping voltage range.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Since physical Vp threshold for WRAF sensors can be extended to Vp > 2V in lean area, HW based analog Vp limitation provided by ATIC42 offers sufficient protection. For rich area, evaluation of digital limitation threshold LV_LSL_VP_LIM_i enables strict limitation of Vp to fixed threshold of Vp = -2V also under dynamic conditions by means of SW intervention on status of Ip control loop.
Gradual increase in limitation of operational lambda range in rich environment due to long term effects shall lead to adaptation of corresponding threshold which is stored in non-volatile ECU memory.
Once digital Vp limitation is indicated by ATIC42, and rich lambda setpoint limitation threshold is under-run, and secondary air /pulsed Ip control activation both are not active, current measured lambda value is temporarily stored as new threshold for reactivation of Ip control. Since digital limitation might already limit pumping current, measured lambda value is equal or greater actual lambda which provides additional security margin for reactivation of Ip control loop.
Should Lambda signal be indicated not to be reliable at that time, current lambda setpoint value is adopted as new temporary threshold.
To guarantee minimum operational range in rich direction, e.g. for Ip activation during sensor warm-up, a calibratable maximum value for Vp limitation lambda threshold has to be respected in addition.
Vp limitation threshold is assigned with either latter value or previously determined temporary threshold.
Upon storage of Vp limitation threshold, Ip control is inhibited by setting corresponding flag and Vp limitation status bit is set thus preventing second evaluation of limitation threshold during current Vp limitation phase.
Should Vp limitation not be indicated any longer, but Vp limitation still be active, lambda setpoint is crosschecked with actual Vp limitation threshold. Once setpoint value exceeds latter, Vp limitation status is reset and inhibition of Ip control loop is revoked.
With Vp limitation inactive and reliable lambda value exceeding limitation threshold in rich direction an improvement in WRAF sensor behaviour is detected (due to sensor change or vanishing of temporary effects which led to an increase in Vp requirements, like e.g. elevated exhaust pressure or decreased sensor temperature) and Vp limitation threshold is relaxed.

1. Logical variable for judgement of WRAF sensor lambda signal reliability

Various conditions for operative readiness of WRAF system, consisting of WRAF sensor (including heater) & WRAF controller, have to be fullfilled and no diagnostic contraindications are allowed to be present to judge WRAF lambda signal as being *completely* reliable (for details see formula section). Evaluation of this variable has to take place at start of Vp limitation check.

1. Logical variable for judgement of lambda sensor signal accuracy level

Certain environmental conditions or functional limitations might lead to decrease in signal accuracy level (regular -> limited) due to need for additional compensative measures which are subject to tolerances, or limited functional performance.
Presence of any of these conditions is indicated by cumulative flag.

Application conditions

Initialisation:

The following initialisation shall take place for each newly-flashed ECU or upon detection of EEPROM error:
LAMB_THD_VPLSL_LIM[i] = 0

The following initialisation shall take place directly after RESET:
ICPLSL_LSL_IF[i] = 0
T_IPLSL_NOT_VLD_VB_L_THD[i] = C_T_IPLSL_NOT_VLD_VB_L_INC
T_IPLSL_NOT_VLD_VB_L[i] = 0

The following initialisation shall take place after ECU RESET, at LV_IGK = 0->1, or upon erase of error management:
R_IT_IPLSL[i] = 16383.75 (i.e. FFFFH)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

VPLSL[i] = 0
CTR_ICPLSL[i] = 0
CTR_ICPLSL_MAX[i] = 0
T_ICPLSL_DLY_PWL[i] = 0
LV_ICPLSL_VLD[i] = 0

R_IT_IPLSL[i] ***Store*** = 16383.75 (i.e. FFFFH)
LAMB_SP[i] ***Store*** = 0
Reset internal timers T_DLY_IPLSL_CTL_ENA[i] & T_DLY_VPLSL_LIM_ACT [i]

Recurrence:
T_SAMPLE = 10ms.

Activation:
For chapters 3. /6. /8. /9.: Transition from engine start to run and SPI initialisation complete.
LV_LSL_IF_SPI_RST_END[i] == 1
and LV_ST_END == 1

For chapters 1. /2. /4. /5. /7. **/10.**: Extended supply of pumped reference current and activation of Ip control loop prior to engine start in case of forced sensor pre-heating.

LV_LSL_IF_SPI_RST_END[i] == 1
and **(** LV_ST_END == 1
or LV_LSH_UP_MAN_ACT[i] == 1 **)**

Deactivation:
At the end of ECU power latch.

LC_MAP_PUC_LIM_REQ_LSL_GAIN_AD	-	0... 1H	0 ...1	1	-
Enable request to torque management for limitation of MAP during PUC					

FUNCTION DESCRIPTION:

During fuel cut-off the engine purges the exhaust line with air. This condition is the best suitable engine operating condition to check the WRAF sensor's static gain.
The function comprises:

1. the recognition of a condition to be stable enough for a significant pumping current measurement.
2. pumping current correction due to interfering impacts as: exhaust pressure etc.
3. current acquisition and averaging during fuel cut.
4. evaluation of adaptation conditions
5. WRAF sensor gain adaptation

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions

Activation: at LV_IGK = 1
Deactivation: at LV_IGK = 0

Initialization **at first ECU run** :
FAC_LSL_GAIN_AD[i] = 1
IPLSL_MMV_VLD_FCUT[i] = C_IPLSL_NOM_PURGE
IPLSL_VARI_VLD_FCUT[i] = 0
LV_LSL_FIRST_GAIN_AD[i] = 1

Initialization at every transition **LV_IGK = 0 ->** 1, **ECU Reset, or upon erase of error management**:
STATE_IPLSL_AD_FCUT[i] = INIT

7.46.1 Conditions for WRAF Sensor fuel cut-off Ip determination

FUNCTION:

These conditions must be verified the whole time during the fuel cut-off Ip determination.
Request of MAP limitation during next PUC phase by any arbitrary exhaust cylinder bank shall lead to corresponding request to torque management.

Recurrence: T_SAMPLE = 100ms.

Perform prior to execution of FOR loop depending on [i].
If LV_PUC == 0
then LV_MAP_PUC_LIM_REQ_LSL_GAIN_AD = 0
endif
Fuel cut-off Ip determination is requested only:
If (LV_LS_UP_READY [i] == 1

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

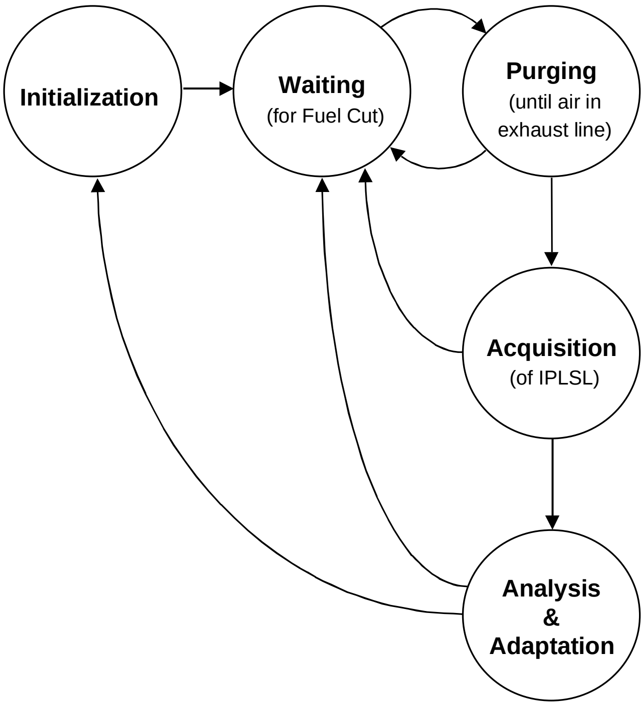
7.46.3 Sequence for fuel cut-off Ip determination:

FUNCTION:

Recurrence: T_SAMPLE = 100 ms.

Remark: Index ‘n’ is linked to T_SAMPLE = 100ms.



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.46.3.1 State INIT :

Actions:

LV_LSL_GAIN_AD_REQ[i] = 0
LV_LSL_FCUT_MES_REP_INH[i] = 0
LV_LSL_FCUT_MES_NOT_PLAUS[i] = 0
LV_LSL_GAIN_AD_FCUT_NOT_OK[i] = 0
LV_IPLSL_COR_MMV_FCUT_VLD[i] = 1
T_DLY_IPLSL_COR_MMV_FCUT_VLD[i] = 0

Transition to state “WAIT”:

Conditions:
none
Actions during transition:
STATE_IPLSL_AD_FCUT[i] = WAIT

7.46.3.2 State WAIT :

STATE_IPLSL_AD_FCUT[i] remains in this wait state as long as the conditions for fuel cut Off Ip determination are not fulfilled or not fulfilled anymore. Furthermore it is taken care that only one measurement per fuel cut is done.

Actions:

If LV_PUC == 0
then LV_LSL_FCUT_MES_REP_INH[i] = 0
endif

Transition to state “PURGE":

Conditions:

If LV_LSL_GAIN_AD_REQ[i] == 1
and LV_LSL_FCUT_MES_REP_INH[i] == 0
(LV_LSL_FCUT_MES_REP_INH[i] == 1 prevents a second measurement during the same fuel cut)
and **(** LV_MAP_PUC_LIM_ACT_LSL_GAIN_AD == 1
or LC_MAP_PUC_LIM_ACT_NOT_VLD == 1 **)**
and LV_SWI_GAIN_LSL_IF[i] == LC_IPLSL_GAIN_SEL_LSL_GAIN_AD

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.46.3.3 State: PURGE :

During fuel cut STATE_IPLSL_AD_FCUT[i] waits until the exhaust system is purged and the pumping current is stable. The stability is reached if:

1. the gradient of the averaged pumping current is below a threshold
2. and the absolute pumping current is higher than a given threshold.

Actions:

none

Transition to state "WAIT":

Conditions:

If LV_LSL_GAIN_AD_REQ[i] == 0
then *" transition to WAIT "*
endif

Actions during transition:

STATE_IPLSL_AD_FCUT[i] = WAIT

Transition to state "Acquisition":

Conditions:

If LV_LSL_GAIN_AD_REQ[i] == 1
and (IPLSL_COR_MMV_FCUT[i]$_n$ - IPLSL_COR_MMV_FCUT[i]$_{n-1}$)

IPLSL_VARI_PURGE[i] = 0
T_ACQ_IPLSL_PURGE[i] = 0
IPLSL_COR_BEG_PURGE[i] = IPLSL_COR_MMV_FCUT[i]

7.46.3.4 State Acquisition :

As input the pumping current (IPLSL_COR_MMV_FCUT[i]) is compensated for actual impacts of:

1. ambient pressure
2. engine speed
3. MAF_KGH
4. (and WRAF sensor TTIP_MES_LS_UP[i])

Afterwards the real current (IPLSL_PURGE[i]) is calculated by division with the actual compensation factor (FAC_LSL_GAIN_AD[i]).

During the acquisition time (C_T_ACQ_IPLSL_PURGE) the actual real current (at fuel cut and at purged exhaust line) is averaged (IPLSL_MV_PURGE[i]) and its variance (IPLSL_VARI_PURGE[i]) is calculated. At the end of the acquisition a final compensation of residual gas purging is done by multiplying with IP_FAC_COR_IPLSL_CHG_PURGE with the latter depending on the Ip change from start to end of acquisition.

Actions:

If LV_IPLSL_COR_MMV_FCUT_VLD[i] = 1
then **If** T_ACQ_IPLSL_PURGE[i] $<$ C_T_ACQ_IPLSL_PURGE
then IPLSL_PURGE[i] = IPLSL_COR_MMV_FCUT[i]
* IP_FAC_COR_IPLSL_MAF_KGH * IP_FAC_COR_IPLSL_N_32 /
FAC_LSL_GAIN_AD[i]

Transition to state “ADAPT":
Conditions:
If LV_LSL_GAIN_AD_REQ[i] == 1
and LV_LSL_FCUT_MES_REP_INH[i] == 1
then *" transition to ADAPT "*
endif
Actions during transition:
STATE_IPLSL_AD_FCUT[i] = ADAPT

7.46.3.5 State ADAPT :

The fuel cut pumping current sample is checked for sensor operability and stability during the previous acquisition phase. Therefore the variance of the output must be between allowed limits. If this condition or the conditions for “fuel cut-off Ip determination” are not fulfilled anymore the STATE_IPLSL_AD_FCUT[i] switches back to “WAIT”.
If the conditions are fulfilled it will be declared as “valid sample”. Next a MMV value and the variance of the valid Ip samples are calculated.
If the gain adaptation takes place for the first time (in case of a new sensor or new ECU) the MMV value is initialized with the mean-value of the first measurement. The variance stays on the initial value (zero) in this case. The calculation of MMV and variance is started as soon as one successful gain adaptation was carried out (by setting LV_FIRST_GAIN_AD = 0).
A new adaptive factor (FAC_LSL_GAIN_AD[i]) for the WRAF sensor’s gain is calculated if the following conditions for adaptation are fulfilled:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

1. Variance of previous valid samples in permitted range.
2. Adaptive factor (FAC_LSL_GAIN_AD[i]) in permitted range

Since the new adaptive factor is calculated based on the MMV value of the valid samples it follows the average of the last measurements and not direct every particular fuel cut sample. The response time of the adaptation is defined by the correlation constant (C_CRLC_IPLSL_MV_VLD).

Actions:

If LV_IPLSL_VLD_FCUT[i] == 0
(LV_IPLSL_VLD_FCUT[i] == 1 prevents a second evaluation and updating of IPLSL_MMV_VLD_FCUT[i] during the same fuel cut)
and C_IPLSL_VARI_THD_MIN_PURGE $<=$ IPLSL_VARI_PURGE[i]
$<$ C_IPLSL_VARI_THD_MAX_PURGE
then LV_LSL_FCUT_MES_NOT_PLAUS[i] = 0
LV_IPLSL_VLD_FCUT[i] = 1

Average of recent valid fuel cuts & Variance of recent valid fuel cuts:
If (LV_LSL_FIRST_GAIN_AD[i] == 1 **and** LC_LSL_FIRST_GAIN_AD == 1)
then IPLSL_MMV_VLD_FCUT[i]$_i$ = IPLSL_MV_PURGE[i]$_i$
IPLSL_VARI_VLD_FCUT[i]$_i$ = IPLSL_VARI_VLD_FCUT[i]$_{i-1}$

else IPLSL_MMV_VLD_FCUT[i]$_i$ = IPLSL_MMV_VLD_FCUT[i]$_{i-1}$
+ C_CRLC_IPLSL_MV_VLD * (IPLSL_MV_PURGE[i]

- IPLSL_MMV_VLD_FCUT[i]$_{i-1}$)

IPLSL_VARI_VLD_FCUT[i]$_i$ = IPLSL_VARI_VLD_FCUT[i]$_{i-1}$
+ C_CRLC_IPLSL_MV_VLD * ((IPLSL_MV_PURGE[i]
- IPLSL_MMV_VLD_FCUT[i]$_i$) ^2 - IPLSL_VARI_VLD_FCUT[i]$_{i-1}$)

end

Adaptation conditions
If IPLSL_VARI_VLD_FCUT[i] $>$ C_IPLSL_MV_VLD_VARI_MAX
then STATE_IPLSL_GAIN_AD[i] = 3 *(impossible)*
(adaptation impossible due variance limit of valid fuel cut measurements exceeded)
else **If** (C_IPLSL_NOM_PURGE /IPLSL_MMV_VLD_FCUT[i])

FUNCTION DESCRIPTION:

General information:

If one of the below mentioned conditions is not fulfilled, the inhibit bit interrupts the WRAF sensor gain adaptation at fuel cut-off.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)

i = 1, for single exhaust cylinder bank.

Application conditions

Initialisation: *at every LV_IGK = 0 ⇒ 1 and reset all output variables are initialized with 0*

Recurrence: *T_SAMPLE = 100 ms.*

Activation: *at LV_IGK = 1*

Deactivation: *at LV_IGK = 0*

FUNCTION DESCRIPTION:

General information:

If two separate cylinder banks are concerned, then
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2
The heater control shall be realised by use of a state machine. Each upstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

Lambda probe heating after engine start (normal case)

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account.
The function shall permit oxygen sensor heating under open and closed loop control.
Signal flow:

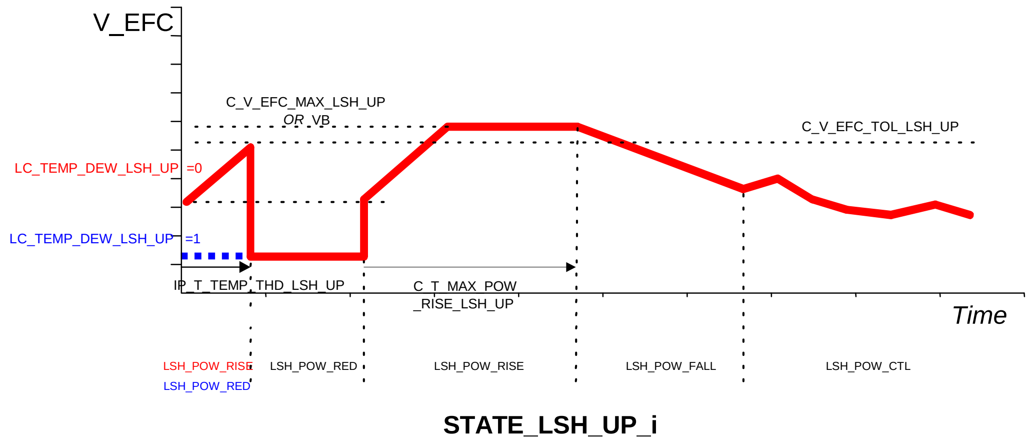

Figure 7.48.1: : Course of effective heater voltage over time /state

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated if not otherwise required (see sub chapter "forced lambda probe heating before engine start").

In the normal case (no forced heating before engine start) heating shall be started when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the correspopnding bank is not set (LV_INH_LSH_UP[i] = 0). Depending on the lambda sensor requirement specification following two methods of initial lambda sensor heating are possible as judged by calibration of LC_TEMP_DEW_LSH_UP (see figure 1). This is due to the fact that for lambda sensors until dew point recognition either a certain temperature limit or a defined voltage limit must not be exceeded as the lambda sensor may be damaged by water splash or excessive temperature gradient otherwise. Depending on the setting of LC_TEMP_DEW_LSH_UP the heater management state machine shall thus switch from LSH_OFF to LSH_POW_RISE (LC_TEMP_DEW_LSH_UP = 0) or to LSH_POW_RED (LC_TEMP_DEW_LSH_UP = 1). In case of direct dew point recognition after hot restart the state machine shall switch to LSH_POW_RISE.

1.) Transition from LSH_OFF to LSH_POW_RED before dew point recognition

In case of transition from LSH_OFF to LSH_POW_RED the initial heater power is set by setting the effective heater voltage to C_V_EFC_RED_LSH_UP. The reduced heating state where water splash may occur shall persist until the dew point in the exhaust gas system has been recognized, i.e. until LV_TEMP_DEW_LS_UP[i] = 1, at which point the heater state shall switch to LSH_POW_RISE.

The effective heater voltage shall be set to the effective heater voltage as determined by IP_V_EFC_INI_LSH_UP, which may be modified by the calibration data C_V_EFC_STEP_LSH_UP, and may further be incremented with a gradient of C_V_EFC_INC_LSH_UP without danger of damaging the oxygen sensor. Additionally the timer T_POW_RISE_LSH_UP[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_UP determined at function start.

2.) Transition from LSH_OFF to LSH_POW_RISE before dew point recognition

In case of transition from heater state LSH_OFF to LSH_POW_RISE the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_UP[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_ LSH_UP. In the state LSH_POW_RISE, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_UP. The continuation of the heating gradient shall depend on whether the dew point at sensor location has been recognized.

Should the dew point not have been exceeded (LV_TEMP_DEW_LS_UP[i] = 0) but timer T_POW_RISE_LSH_UP[i] has equalled or exceeded IP_T_TEMP_THD_LSH_UP, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the

Copyright (C) Continental AG,2007

heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_UP. In this case, the heater state shall be set to LSH_POW_RED (see above).

The reduced heating state shall persist until the dew point in the exhaust gas system has been recognized, i.e. until LV_TEMP_DEW_LS_UP[i] = 1, at which point the heater state shall return to LSH_POW_RISE. For further operation please refer to case 1.)

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEMP_DEW_LS_UP[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Dependent on whether closed loop control is permitted, the heater management shall enter either LSH_POW_CTL or LSH_POW_FALL. Should closed loop be permitted (LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0) and the ceramic temperature reference be valid (LV_V_REF_VLD_R_IT_LS_UP[i] = 1) and ceramic temperature exceed the set temperature (TTIP_MES_LS_UP[i]   C_TTIP_SP_LS_UP[i]) then the state machine shall change to LSH_POW_CTL and the timer shall be frozen. This state change shall permit the controller to take over heating when the operative readiness has been detected in order to prevent under- & overshoot of the ceramic temperature. Should the conditional operative readiness be set (LV_LS_UP_READY_CDN[i] = 1) then the state machine shall also enter state LSH_POW_CTL and stop the timer. This shall permit the heater stability diagnosis to be carried out even when the heater is sufficiently defective to prevent the set temperature from being reached. Should the closed loop controller be inhibited or the ceramic temperature calibration be faulty, and T_POW_RISE_LSH_UP[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_UP (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_UP until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_UP alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_UP * IP_FAC_V_EFC_TEG_LSH_UP. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

Should, however, the Boolean flag LV_TEMP_DEW_LS_UP[i] be reset whilst in the state LSH_POW_FALL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage may be carried out in open loop or closed loop mode. Unless either the closed loop control inhibit bit (LV_INH_LSH_CTL_CLL_LSH_UP[i]) is set or the reference voltage validity bit (LV_V_REF_VLD_R_IT_LS_UP[i]) is reset, the effective heater voltage shall be controlled in closed loop mode. Closed loop control conditions met shall be indicated by setting LV_LSH_CTL_CLL_LSH_UP[i]. Should at any time one of the above conditions no longer be met, the heater controller shall revert to open loop control, reset the closed loop variables and reset LV_LSH_CTL_CLL_LSH_UP[i].

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_UP and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_UP) may be required for the reasons outlined above.

In the closed loop heater control mode, a PI controller, that affects the open loop effective heater voltage in an additive manner, shall regulate the effective heater voltage such that the temperature specified by C_TTIP_SP_LS_UP[i] is maintained. The closed loop control may be further described as follows:

The current temperature of the oxygen sensor (TTIP_MES_LS_UP[i]) shall be obtained and the difference between this temperature and the set temperature computed to obtain the input variable to the controller (TTIP_MES_DIF_LS_UP[i]). Note that this variable shall be computed in both open and closed loop control modes but shall only be used in the closed loop control mode.

The controller shall then determine the appropriate additive voltage (V_EFC_CTL_ADD_LSH_UP[i]) by computing the P and I terms separately and then adding the two terms.

The P term (V_EFC_CTL_P_LSH_UP[i]) shall calculate a voltage proportional to the temperature difference and thus converting a temperature delta into voltage. The P term shall only be calculated when the

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

absolute temperature difference (TTIP_MES_DIF_LS_UP[i]) equals or exceeds a constant (C_TTIP_DIF_MIN_CTL_P_LS_UP). This shall be achieved via the map IP_FAC_xxx_P_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_P_LSH_UP shall permit global parameter changes to be made.

The I term (V_EFC_CTL_I_LSH_UP[i]) shall calculate an integral of a voltage that shall be proportional to the temperature difference and thus converting a temperature delta into voltage. This shall be achieved via the map IP_FAC_xxx_I_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_I_LSH_UP shall permit global parameter changes to be made.

Once the additive voltage has been determined, this shall then be added to the open loop control voltage along with a calibration system constant (C_V_EFC_AS_LSH_UP) to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_UP[i]) shall be computed from the open loop value, the closed loop additive term and the global correction value.

The closed loop control computations shall be suspended should either the Boolean flag LC_LSH_CTL_CLL_INH_LSH_UP[i] be set or the ceramic temperature no longer be valid, for example due to an active reference voltage measurement, as indicated by LV_TTIP_MES_VLD_LS_UP[i] being reset. This shall freeze the P and I terms at their last calculated value. Upon revoking the suspension, the controller shall continue to compute from where the point immediately prior to the suspension, i.e. shall not start anew. Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_UP[i] & LV_V_EFC_LIM_MAX_LSH_UP[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEMP_DEW_LS_UP[i] be reset whilst in the state LSH_POW_CTL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_UP, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_UP[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_UP. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0, T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_DYN_LS_UP[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_DYN_MAX_LSH_UP, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending closed loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL,

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open /closed loop control. The closed loop controller shall not be started anew. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_UP[i] equal or exceed the threshold C_V_EFC_TOL_LSH_UP.

In this instance, the timer T_V_EFC_TOL_LSH_UP[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_UP, timer T_V_EFC_LIM_LSH_UP[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_UP[i] should fall below the threshold C_V_EFC_TOL_LSH_UP at any time, LV_V_EFC_LIM_TOL_LSH_UP[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_UP[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_UP[i]. Once the timer T_V_EFC_LIM_LSH_UP[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_UP, both timers shall be reset and timer T_V_EFC_TOL_LSH_UP[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_UP again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_UP[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_UP, C_V_EFC_MAX_ST_LSH_UP or VB dependent on the value of T_POW_RISE_LSH_UP[i].

If T_POW_RISE_LSH_UP[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_UP STEP or conditions regarding T_AST and STATE_LSH_UP[i] then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

If T_POW_RISE_LSH_UP[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_UP then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_UP[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_UP[i] shall be the lower of the values V_EFC_CLC_LSH_UP[i] & C_V_EFC_LIM_LSH_UP otherwise V_EFC_LSH_UP[i] shall be set to V_EFC_CLC_LSH_UP[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_UP[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_UP & NC_LSHPWM_BOL_LSH_UP. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_UP.

Should at any time an inhibit flag be set (LV_INH_LSH_UP[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_UP[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_UP[i]. On a transition of the inhibit bit LV_INH_LSH_UP[i] from 1 0, the heater function shall start from anew.

Forced lambda probe heating before engine start (for application purpose)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Additionally to normal sensor heating after engine start setting LC_LSH_UP_MAN_ACT[i] = 1 allows forced pre-heating of the lambda sensor before engine start. The aim is to ramp up the sensor element to operating temperature in order to achieve a reliable lambda sensor signal already at the time when the engine is started. It has to be emphasized that this method covers a high risk for sensor damage by water splash as operating temperature is already reached before dew-point recognition. Therefore this feature shall only be used for application purpose.

If forced heating is activated, i.e. condition 15 being fulfilled, the state machine shall enter the state LSH_POW_RISE and a heater voltage C_V_EFC_INI_LSH_UP_MAN_ACT shall be applied. Before engine start no forced convection and consequently no lambda sensor cooling by the exhaust gas is present. Therefore the initial heater voltage may be reduced to C_V_EFC_INI_LSH_UP_MAN_ACT in order to prevent excessive temperature gradients and overheating. Additionally the STATE_LSH_UP[i] shall be set to LSH_POW_RISE, the timer T_POW_RISE_LSH_UP[i] shall be incremented and the status flag LV_LSH_UP_MAN_ACT[i] indicating activated forced heating shall be set. Forced pre-heating activation by evaluating the transition of LC_LSH_UP_MAN_ACT[i] from 0 to 1 ensures that forced heating may not become active in field application even if LC_LSH_UP_MAN_ACT[i] remains 1 for the final series data.

In the state LSH_POW_RISE the lambda sensor heater voltage shall further be increased with the same voltage ramp as for inactive forced heating. It should be considered that too high ramp values may lead to excessive temperature gradients. The heater voltage during this initial phase is limited to C_V_EFC_MAX_LSH_UP_MAN_ACT. Resetting LC_LSH_UP_MAN_ACT[i] shall also reset LV_LSH_UP_MAN_ACT[i]. If T_POW_RISE_ LSH_UP[i] exceeds the threshold C_T_MAX_CDN_LSH_UP_MAN_ACT the state machine shall change to state LSH_POW_CTL.

In the state LSH_POW_CTL while forced heating is active the element temperature shall be controlled in open loop. The corresponding effective heater voltage is derived from the same map IP_V_EFC_CTL_LSH_UP as for inactive forced heating, reduced by the factor C_FAC_V_EFC_LSH_UP_MAN_ACT. If forced heating is activated the lambda sensor protection states LSH_VB_PROT and LSH_TEMP_PROT may be reached. Should the corresponding conditions no longer be met, the state LSH_POW_RISE shall be re-entered.

Application conditions:

Activation:

At any engine operating state.

Deactivation:

-

Time recurrence:

The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms.

The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms.

Initialisation:

The following variable initialisation shall take place at LV_IGK = 0→1:

STATE_LSH_UP[i] = LSH_OFF
T_POW_RISE_LSH_UP[i] = 0
T_V_EFC_TOL_LSH_UP[i] = 0
T_V_EFC_LIM_LSH_UP[i] = 0
LSHPWM_UP[i] = 0
V_EFC_CTL_P_LSH_UP[i] = 0
V_EFC_CTL_I_LSH_UP[i] = 0
V_EFC_CTL_ADD_LSH_UP[i] = 0
V_EFC_LSH_UP[i] = 0
V_EFC_CLC_LSH_UP[i] = 0
LV_LSH_CTL_CLL_LSH_UP[i] = 0
LV_LSH_UP_MAN_ACT[i] = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

IN LSHPWM_UP[i])

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_UP[i] & LV_INH_LSH_CTL_CLL_LSH_UP[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater closed loop control function respectively

Formula section:

The following formula shall be evaluated before the state machine is calculated:
If LC_LSH_UP_MAN_ACT[i] = 1→0
then LV_LSH_UP_MAN_ACT[i] = 0
endif

7.48.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.
Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.48.3 Oxygen sensor heater driver duty cycle computation

The PWM duty cycle for the appropriate heater driver shall continually be calculated in all heater states at the specified recurrence.

If (STATE_LSH_UP[i] = LSH_OFF **&** LC_LSH_UP_MAN_ACT[i] = 0)
then LSHPWM_UP[i] = LSHPWM_EXT_LS_UP[i]
else **If** (VB C_VB_MAX_PROT_LSH_UP)
then LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 1
LSHPWM_UP[i] = C_V_EFC_PROT_VB_LSH_UP^2 *100 /VB$_N{}^2$
else LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0
LSHPWM_UP[i] = V_EFC_LSH_UP[i]$_N{}^2$ *
C_FAC_V_EFC_AS_LSH_UP *100 /VB$_N{}^2$
If LSHPWM_UP[i] NC_LSHPWM_TOL_LSH_UP
then LSHPWM_UP[i] = NC_LSHPWM_TOL_LSH_UP
else **If** LSHPWM_UP[i] NC_LSHPWM_BOL_LSH_UP
then LSHPWM_UP[i] = NC_LSHPWM_BOL_LSH_UP
else LSHPWM_UP[i] = LSHPWM_UP[i]
endif
endif
endif
endif.
ACTION_INFR_SetPwmLshUp(
IN i
IN LSHPWM_UP[i])

The value C_FAC_V_EFC_AS_LSH_UP is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinderbanks.

i = 1 ... NC_CBK_EX_NR

Description:

The Boolean constant LC_LSH_UP[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_UP[i] shall be reset. When reset, LV_INH_LSH_UP[i] shall be set.
The Boolean flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall indicate whether closed loop heating shall be inhibited or not. Should either the Boolean constant LC_LSH_UP_CLL_CTL[i] be reset or one of several upstream
sensor error bits be set then the Boolean inhibit flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be set (open loop heater control), otherwise LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be reset (closed loop heater control permitted).

7.50.1 Signal evaluation

FUNCTION DESCRIPTION:

General information:

The function shall evaluate the oxygen sensor signal voltage and compute a number of resultant values that may be used by other functions. These values shall include:

1. Moving mean of sensor voltage first derivative, i.e. average signal gradient
2. Minimum value of moving mean of sensor voltage first derivative in lean phase
3. Absolute maximum of sensor voltage first derivative over defined number of previous samples, i.e. measure of sensor voltage stability
4. Moving mean value of lean sensor voltage
5. Moving mean value of rich sensor voltage.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

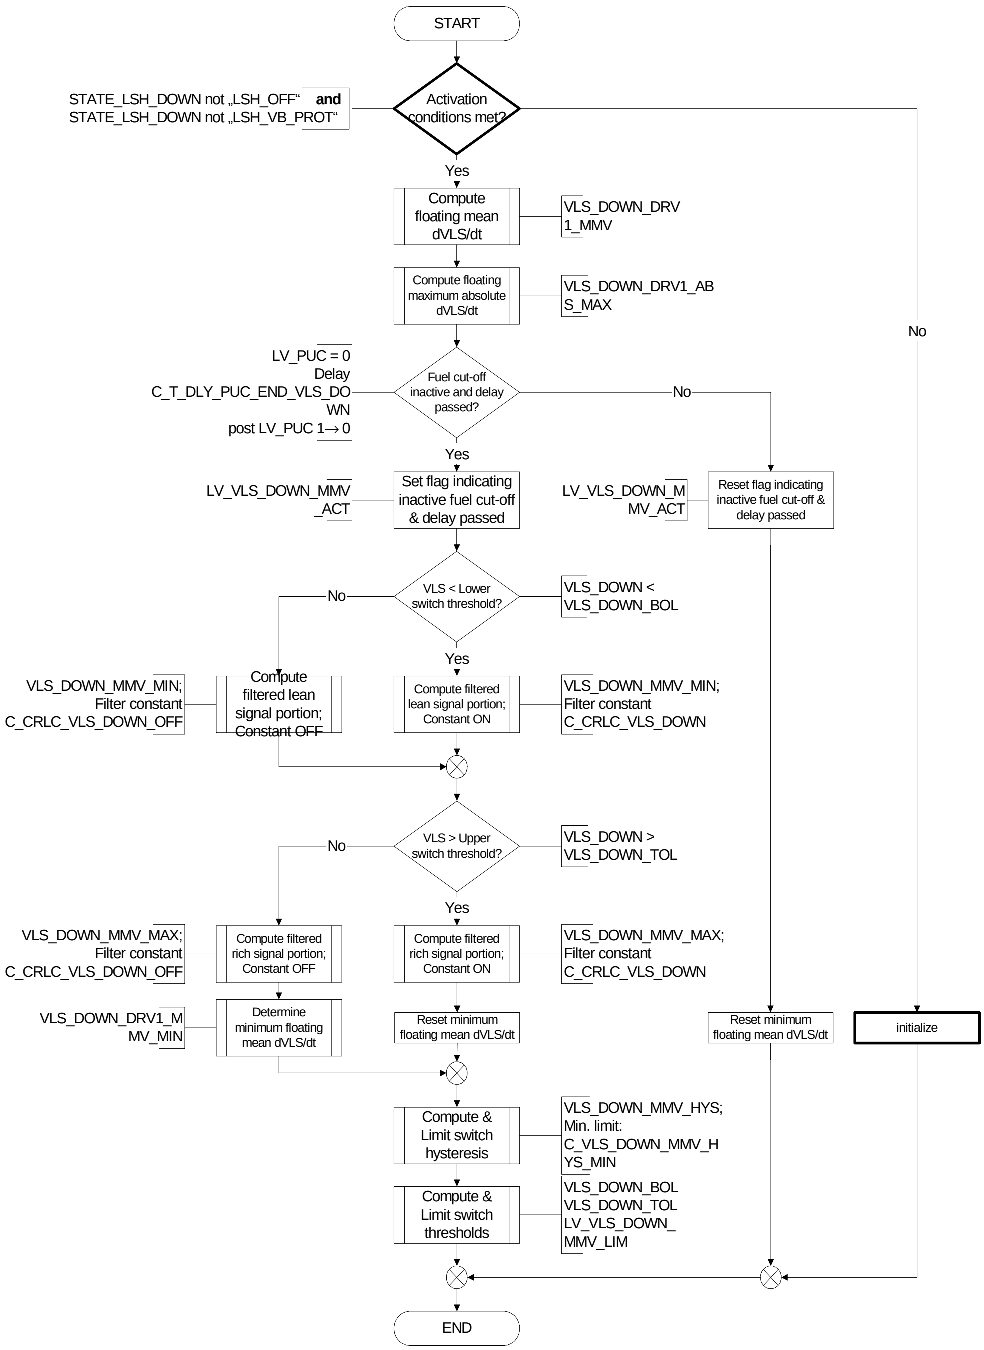

Figure 1 Function flow chart, Signal evaluation

Description:

The function shall evaluate the downstream oxygen sensor signal VLS_DOWN and VLS_DOWN_H_RES[i] and provide variables quantifying the signal characteristics: Floating mean gradient, Floating maximum signal deviation between samples, Filtered mean rich signal voltage & Filtered mean lean signal voltage (voltage will deviate from stable level signal with ageing of the catalyst). This shall be carried out as follows:

The function shall be active when the heater state is not "off" or "overvoltage protection".

Once the activation conditions have been met the function may be described in the following blocks:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

1. Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]: The moving mean value of oxygen sensor signal voltage first derivative VLS_DOWN_DRV1_MMV[i] shall be computed by averaging the last differences between consecutive VLS_DOWN_H_RES[i] samples, i.e. the most current difference (VLS_DOWN_H_RES[i]$_N$ - VLS_DOWN_H_RES[i]$_{N-1}$) and the previous C_CTR_VLS_DOWN_BUF differences. This shall indicate a measure for the signal gradient.
2. Computation of absolute maximum of first derivative VLS_DOWN_DRV1_ABS_MAX[i]: The absolute maximum of the oxygen sensor voltage first derivative VLS_DOWN_DRV1_ABS_MAX[i] shall be computed by taking the maximum of the absolute values of the last differences between consecutive VLS_DOWN_H_RES[i] samples, i.e. the most current difference (VLS_DOWN_H_RES[i]$_N$ - VLS_DOWN_H_RES[i]$_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal stability.
3. Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]: The computation of the moving mean value of lean and rich sensor voltages, associated switch thresholds and switch hysteresis shall only be carried out when the overrun fuel cut-off flag is reset (LV_PUC = 0) and the time C_T_DLY_PUC_END_VLS_DOWN has passed since the deactivation of the last occurring engine state PUC (i.e. LV_PUC 1 0). The lean and rich mean signal voltages shall be implemented by use of first order low pass filtering and floating switching thresholds. For example:

Should the VLS_DOWN[i] signal exceeds the threshold VLS_DOWN_TOL[i], the rich mean signal voltage VLS_DOWN_MMV_MAX[i] shall be computed by filtering the VLS_DOWN [i] signal with filter constant C_CRLC_VLS_DOWN. This shall continue until threshold VLS_DOWN_TOL[i] is no longer exceeded, after which VLS_DOWN_MMV_MAX[i] shall be computed by filtering with filter constant C_CRLC_VLS_DOWN_OFF. This constant is much smaller than C_CRLC_VLS_DOWN and the effect is to cause the VLS_DOWN_MMV_MAX[i] to follow the rich peaks. The OFF constant shall permit the VLS_DOWN_MMV_MAX[i] signal to follow the VLS_DOWN[i] signal for sudden decreases in signal amplitude, i.e. maximum VLS_DOWN[i] lower than VLS_DOWN_TOL[i].

The same procedure shall be carried out for the computation of VLS_DOWN_MMV_MIN[i], i.e. where VLS_DOWN[i] falls below VLS_DOWN_BOL[i], VLS_DOWN_MMV_MIN[i] shall be computed with filter constant C_CRLC_VLS_DOWN and where VLS_DOWN[i] no longer falls below VLS_DOWN_BOL[i], the filter constant C_CRLC_VLS_DOWN_OFF shall be used.

4. Determination of the minimum value of the moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]: The same conditions as for the computation of VLS_DOWN_MMV_xxx[i] shall apply. Should VLS_DOWN[i] fall below or equal VLS_DOWN_TOL[i], VLS_DOWN_DRV1_MMV_MIN[i]$_N$ shall be equal to the lower of VLS_DOWN_DRV1_MMV_MIN[i]$_{N-1}$ & VLS_DOWN_DRV1_MMV[i]. When VLS_DOWN[i] exceeds VLS_DOWN_TOL[i], the LV_PUC condition in conjunction with delay C_T_DLY_PUC_END_VLS_DOWN is not met or the function is deactivated, VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.
5. Compute & limit switch hysteresis: The value of the hysteresis, VLS_DOWN_MMV_HYS[i], used to determine the switching thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be made proportional using factor C_FAC_VLS_DOWN_MMV_HYS to the oxygen sensor signal amplitude, as determined by taking the absolute difference of the moving mean lean /rich variables. The hysteresis shall also be limited so that it may not fall below the calibrateable threshold C_VLS_DOWN_MMV_HYS_MIN.
6. Compute & limit switch thresholds: The function shall limit the minimum amplitude of the difference between the moving mean lean /rich variables (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) to twice that of the switch hysteresis, VLS_DOWN_MMV_HYS[i].

Should the amplitude of the aforementioned difference fall below the said threshold, both the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be set to the average of the moving mean lean /rich variables, the moving mean lean /rich variables are recalculated based on the limited switching thresholds and hysteresis and the flag LV_VLS_DOWN_MMV_LIM[i] shall be set to indicate that switch threshold limiting is active.

Should no limiting be required, the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be calculated based on the switch hysteresis, moving mean lean variable and moving mean rich variable respectively. The flag LV_VLS_DOWN_MMV_LIM[i] shall be reset to indicate that no switch threshold limiting is being carried out.

The above blocks shall be cycled through once every function recurrence.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions:

Recurrence:
The function shall be carried out once every oxygen sensor acquisition, i.e. every 10 ms.
Initialisation:
The following initialisation shall be carried out at RESET and when the function is inactive (or at least once when the function becomes inactive).

VLS_DOWN_MMV_MIN[i] = C_VLS_DOWN_INI_MIN
VLS_DOWN_MMV_MAX[i] = C_VLS_DOWN_INI_MAX
VLS_DOWN_BOL[i] = C_VLS_DOWN_INI_MAX

VLS_DOWN_MMV_HYS[i] = C_VLS_DOWN_MMV_HYS_MIN
LV_VLS_DOWN_MMV_LIM[i] = 0
LV_VLS_DOWN_MMV_ACT[i] = 0
VLS_DOWN_DRV1_MMV[i] = 0
VLS_DOWN_DRV1_MMV_MIN[i] = 0
VLS_DOWN_DRV1_ABS_MAX[i] = 0
Buffer contents from which VLS_DOWN_DRV1_MMV[i] & VLS_DOWN_DRV1_ABS_MAX[i] computed = 0.
Activation:
STATE_LSH_DOWN[i] **not** LSH_OFF **and**
STATE_LSH_DOWN[i] **not** LSH_VB_PROT
Deactivation:
STATE_LSH_DOWN[i] = LSH_OFF **or**
STATE_LSH_DOWN[i] = LSH_VB_PROT

Formula section:

The following function shall be carried out in the order listed and as indicated by the function flow chart:
Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]

$$\mathrm{VLS\_DOWN\_DRV1\_MMV[i]} = \frac{\sum_{x=0}^{\mathrm{C\_CTR\_VLS\_DOWN\_BUF-1}} \left(\mathrm{VLS\_DOWN\_H\_RES[i]}_{N-x} - \mathrm{VLS\_DOWN\_H\_RES[i]}_{N-(x+1)}\right)}{\mathrm{C\_CTR\_VLS\_DOWN\_BUF} * 10\mathrm{ms}}$$

The above may be facilitated for example by use of a C_CTR_VLS_DOWN_BUF value ring buffer. The most current difference, (VLS_DOWN_H_RES[i]$_{N}$ - VLS_DOWN_H_RES[i]$_{N-1}$), would overwrite the oldest difference in the buffer, (VLS_DOWN_H_RES[i]$_{N-5}$ - VLS_DOWN_H_RES[i]$_{N-6}$), and the average of the buffer contents recalculated.
Computation of absolute maximum of first derivative number of previous samples VLS_DOWN_DRV1_ ABS_MAX[i]

$$\mathrm{VLS\_DOWN\_DRV1\_ABS\_MAX[i]} =$$

$$\mathrm{MAXIMUM}\left|_{x=0}^{\mathrm{C\_CTR\_VLS\_DOWN\_BUF-1}} \left(\mathrm{VLS\_DOWN\_H\_RES[i]}_{N-x} - \mathrm{VLS\_DOWN\_H\_RES[i]}_{N-(x+1)}\right)\right|$$

The above may be facilitated for example by use of the same C_CTR_VLS_DOWN_BUF value ring buffer, as proposed above for the computation of VLS_DOWN_DRV1_MMV[i]. The function would calculate the absolute values of the buffer contents and take the maximum of these values.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]

If (LV_PUC = 0) **&**
(delay since last LV_PUC 1 0 transition C_T_DLY_PUC_END_VLS_DOWN)
then LV_VLS_DOWN_MMV_ACT[i] = 1
If (VLS_DOWN[i] $<$ VLS_DOWN_BOL[i])
then *Compute moving mean lean signal, filter constant ON*
else *Compute moving mean lean signal, filter constant OFF*
endif
If (VLS_DOWN[i] $>$ VLS_DOWN_TOL[i])
then *Compute moving mean rich signal, filter constant ON*
VLS_DOWN_DRV1_MMV_MIN[i] = 0
else *Compute moving mean rich signal, filter constant OFF*
Determine minimum of moving mean of first derivative
endif
Compute & limit switch hysteresis
Compute & limit switch thresholds
else LV_VLS_DOWN_MMV_ACT[i] = 0
Reset timer used for delay C_T_DLY_PUC_END_VLS_DOWN
VLS_DOWN_DRV1_MMV_MIN[i] = 0
endif.

Compute moving mean lean signal, filter constant ON

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

VLS_DOWN_MMV_MIN[i]$_N$ = VLS_DOWN_MMV_MIN[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN) + VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN

Compute moving mean lean signal, filter constant OFF

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

VLS_DOWN_MMV_MIN[i]$_N$ = VLS_DOWN_MMV_MIN[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN_OFF) + VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN_OFF

Compute moving mean rich signal, filter constant ON

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

VLS_DOWN_MMV_MAX[i]$_N$ = VLS_DOWN_MMV_MAX[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN) + VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN

Compute moving mean rich signal, filter constant OFF

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

VLS_DOWN_MMV_MAX[i]$_N$ = VLS_DOWN_MMV_MAX[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN_OFF) + VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN_OFF

Determine minimum of moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]

The determination of the minimum of VLS_DOWN_DRV1_MMV[i] shall take place when the condition VLS_DOWN[i] VLS_DOWN_TOL[i] has been met. In this case:

VLS_DOWN_DRV1_MMV_MIN[i] = MIN(VLS_DOWN_DRV1_MMV_MIN[i], VLS_DOWN_DRV1_MMV[i])

Should the above condition no longer met, the LV_PUC with delay condition not be met or the initial activation conditions not be met then VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.

Compute & limit switch hysteresis

VLS_DOWN_MMV_HYS[i] = | (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) | *

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The operative readiness of the downstream oxygen sensor(s) shall be determined by this function to allow other functions to act accordingly dependent upon the readiness.

Description:

The operative readiness shall only be determined for a downstream oxygen sensor which is not operatively ready. The oxygen sensor shall be set as inoperable after a ECU reset, in the state *Engine Stop*, when during PUC the MAF integral exceeds a calibrated threshold or when the dew point LV_TEMP_DEW_LS_DOWN[i] switches back to 0.
The operative readiness shall be determined by analysing the downstream oxygen sensor voltage (VLS_DOWN[i]) and determining whether the voltage has left a pre-determined voltage band after the lambda probe heater state machine has reached LSH_POW_CTL.
A second condition shall permit the forced operative readiness state, should the voltage level condition not be met, by assuming that when the modelled exhaust gas temperature at lambda probe position has reached a pre-determined threshold, that the downstream oxygen sensor is also at operating temperature and functioning. The forced readiness detection may additionally be delayed until dew point detection or even longer until the calibratable threshold C_T_MIN_TEMP_DEW_LS_DOWN has been reached, depending on its calibration.
Should the sensor's operative readiness be reset due to a sufficiently long fuel cut-off phase or reset of dew-point recognition a certain mass air flow integral threshold after leaving fuel cut-off shall be awaited until operability detection is started again. This shall ensure that the sensor heater has sufficient time to raise the temperature up to normal operating conditions prior to start of readiness detection in order to increase its reliability.
The operative readiness of the downstream oxygen sensor(s) shall be recorded in the variable LV_LS_DOWN_READY[i].

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account. The function shall permit oxygen sensor heating under open loop control.

Signal flow:

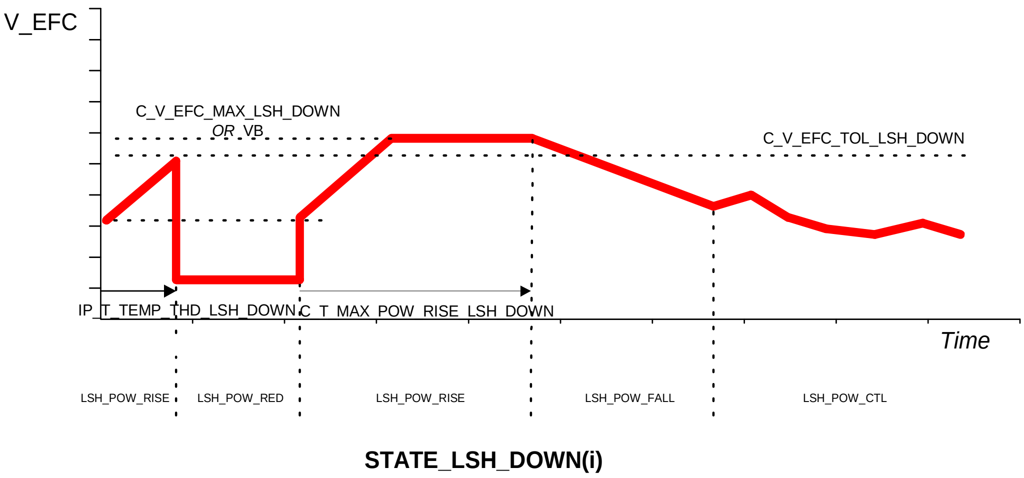

Figure 7.52.1: : Course of effective heater voltage over time /state

Description:

The heater control shall be realised by use of a state machine. Each downstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated.

Heating shall commence should the activation conditions listed below be met. i.e. when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the corresponding bank is not set (LV_INH_LSH_DOWN[i] = 0). The appropriate heater state shall change to LSH_POW_RISE and the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_DOWN[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_LSH_DOWN.

In the state LSH_POW_RISE, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_DOWN.

The continuation of the heating gradient shall depend on whether the dew point at the sensor location has been determined to have been exceeded, i.e. the temperature of the inner manifold wall at the sensor location has exceeded the temperature threshold where water in the exhaust gas may condense, as determined by LV_TEMP_DEW_LS_DOWN[i].

Should the dew point not have been exceeded (LV_TEMP_DEW_LS_DOWN[i] = 0) but timer T_POW_RISE_LSH_DOWN[i] has equalled or exceeded IP_T_TEMP_THD_LSH_DOWN, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_DOWN. In this case, the heater state shall be set to LSH_POW_RED.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The reduced heating state shall persist until the dew point in the exhaust gas system has been determined to have been exceeded, i.e. until LV_TEMP_DEW_LS_DOWN[i] = 1, at which point the heater state shall return to LSH_POW_RISE. The effective heater voltage shall be set to the same effective heater voltage as determined at start (IP_V_EFC_INI_LSH_DOWN), which may be modified by the calibration data C_V_EFC_STEP_LSH_DOWN, may be further incremented with a gradient of C_V_EFC_INC_LSH_DOWN without danger of damaging the oxygen sensor and the timer T_POW_RISE_LSH_DOWN[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_DOWN determined at function start.

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEMP_DEW_LS_DOWN[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Should T_POW_RISE_LSH_DOWN[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_DOWN (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_DOWN until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_DOWN alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_DOWN * IP_FAC_V_EFC_TEG_LSH_DOWN. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

Should, however, the Boolean flag LV_TEMP_DEW_LS_DOWN[i] be reset whilst in the state LSH_POW_FALL, the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage is carried out in open loop mode.

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_DOWN and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_DOWN) may be required for the reasons outlined above.

To the open loop control voltage a calibration system constant (C_V_EFC_AS_LSH_DOWN) can be added to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_DOWN[i]) shall be computed from the open loop value and the global correction value.

Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_DOWN[i] & LV_V_EFC_LIM_MAX_LSH_DOWN[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEMP_DEW_LS_DOWN[i] be reset whilst in the state LSH_POW_CTL, then the open loop controller terms shall be reset, the Boolean flags to indicate open loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_DOWN, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_DOWN. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0, T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i]

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_DYN_MAX_LSH_DOWN, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending open loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL, the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open loop control. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i] shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_DOWN[i] equal or exceed the threshold C_V_EFC_TOL_LSH_DOWN.

In this instance, the timer T_V_EFC_TOL_LSH_DOWN[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN, timer T_V_EFC_LIM_LSH_DOWN[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_DOWN[i] should fall below the threshold C_V_EFC_TOL_LSH_DOWN at any time, LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_DOWN[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_DOWN[i]. Once the timer T_V_EFC_LIM_LSH_DOWN[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_DOWN, both timers shall be reset and timer T_V_EFC_TOL_LSH_DOWN[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_DOWN[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_DOWN, C_V_EFC_MAX_ST_LSH_DOWN or VB dependent on the value of T_POW_RISE_LSH_DOWN[i].

If T_POW_RISE_LSH_DOWN[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN or conditions regarding T_AST and STATE_LSH_DOWN[i] then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

If T_POW_RISE_LSH_DOWN[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_DOWN[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_DOWN[i] shall be the lower of the values V_EFC_CLC_LSH_DOWN[i] & C_V_EFC_LIM_LSH_DOWN otherwise V_EFC_LSH_DOWN[i] shall be set to V_EFC_CLC_LSH_DOWN[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_DOWN[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_DOWN & NC_LSHPWM_BOL_LSH_DOWN. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_DOWN.
Should at any time an inhibit flag be set (LV_INH_LSH_DOWN[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_DOWN[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_DOWN[i]. On a transition of the inhibit bit LV_INH_LSH_DOWN[i] from 1 0, the heater function shall start from anew.

Application conditions:

Activation:
At any engine operting state.
Deactivation:
-
Time recurrence:
The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms. T_SAMPLE_1 = 100ms
The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms. T_SAMPLE_2 = 10ms
Initialisation:
The following variable initialisation shall take place at the beginning of a new driving cycle:
STATE_LSH_DOWN[i] = LSH_OFF
T_POW_RISE_LSH_DOWN[i] = 0
T_V_EFC_TOL_LSH_DOWN[i] = 0
T_V_EFC_LIM_LSH_DOWN[i] = 0
LSHPWM_DOWN[i] = 0
V_EFC_LSH_DOWN[i] = 0
V_EFC_CLC_LSH_DOWN[i] = 0
LV_V_EFC_LIM_BOL_LSH_DOWN[i] = 0
LV_V_EFC_LIM_TOL_LSH_DOWN[i] = 0
LV_V_EFC_LIM_MAX_LSH_DOWN[i] = 0
LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

At reset:

ACTION_INFR_SetPwmLshDown(
IN i
IN LSHPWM_DOWN[i])

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_DOWN[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater open loop control function respectively

Formula section:

7.52.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

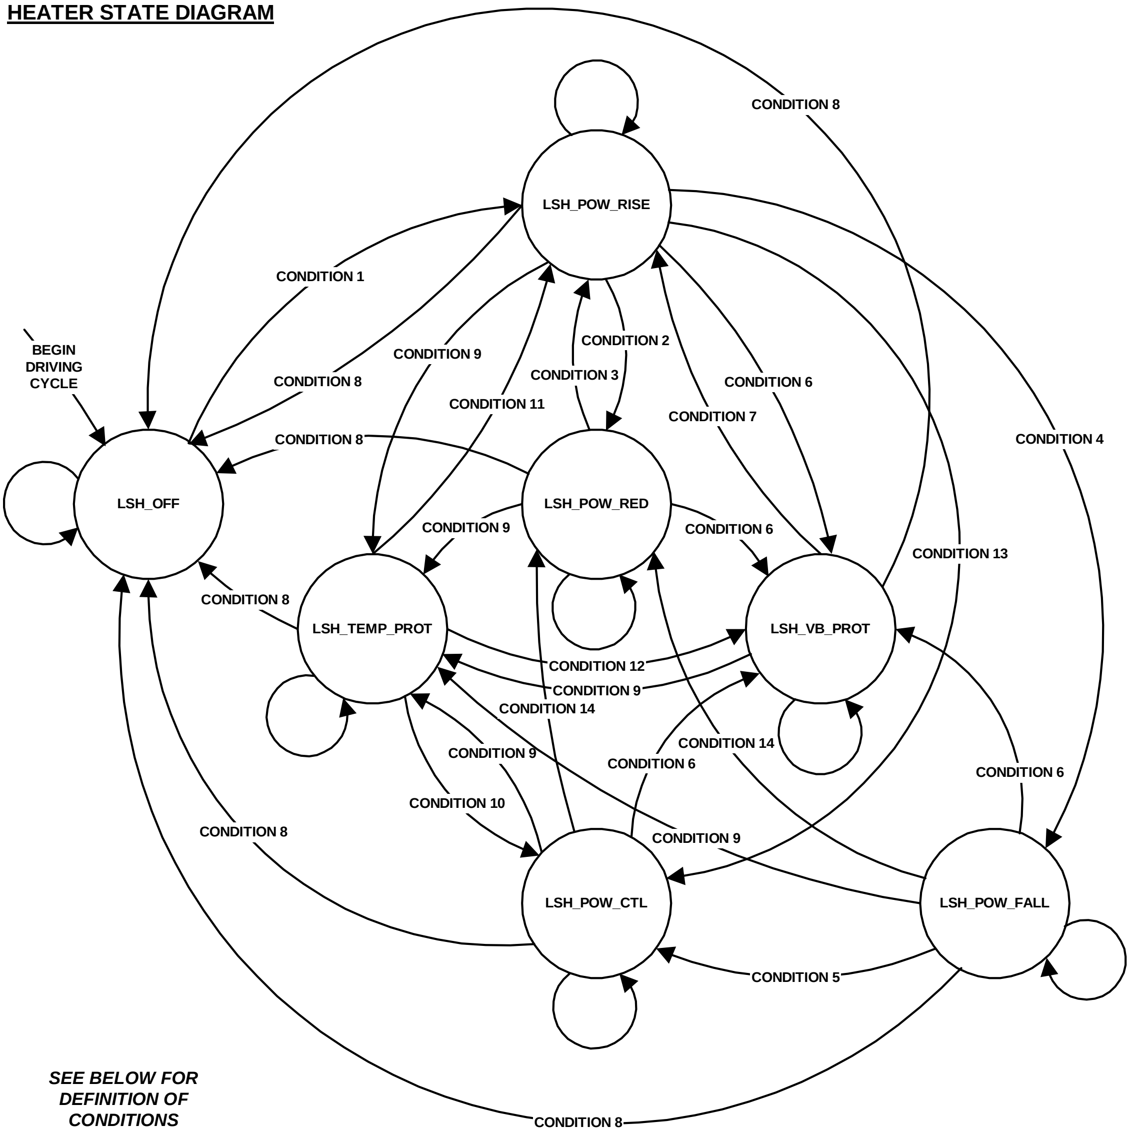

Figure 2: Heater management state diagram

else LSHPWM_DOWN[i] = LSHPWM_DOWN[i]
endif
endif
endif
endif.
ACTION_INFR_SetPwmLshDown(
IN **i**
IN **LSHPWM_DOWN[i])**

The value C_FAC_V_EFC_AS_LSH_DOWN is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.53 O2 sensor (bin, down) heater management (Appl. Inc.)

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LSHPWM_EXT_LS_DOWN [NC_CBK_EX_NR]	O/V	0... FFH	0... 99.60937	0.390625	%
Downstream heater PWM duty cycle preset from external tester					
LV_INH_LSH_DOWN [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Boolean flag indicating project specific application conditions for heating not met					
TEMP_INI_LS_DOWN [NC_CBK_EX_NR]	O/V	8000... 7FFFH	-2048... 2047.9375	0.0625	°C
Oxygen sensor temperature at start					

Input data:

LSHPWM_DOWN_EXT_ADJ [NC_CBK_EX_NR] {p. 7431}	LV_IGK {p. 906}	LV_LSHPWM_DOWN_EXT_ADJ [NC_CBK_EX_NR] {p. 7434}	LV_VAR_LSH_DOWN {p. 656}
NC_CBK_EX_NR {p. 1829}	NC_LSHPWM_BOL_LSH_DOWN {p. 2423}	TEG_WALL_CAT_DOWN_MDL [NC_CBK_EX_NR] {p. 8236}	

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_LSH_DOWN [NC_CBK_EX_NR]	-	0... 1H	0 ...1	1	-
Boolean variable to enable oxygen sensor heating					

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The Boolean constant LC_LSH_DOWN[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_DOWN[i] shall be reset. When reset, LV_INH_LSH_DOWN[i] shall be set.
The oxygen sensor temperature at start TEMP_INI_LS_DOWN[i] shall be obtained from the input variable TEG_WALL_CAT_DOWN_MDL[i] (this is the exhaust duct temperature downstream) every time an engine start is finished.
All actions beside the initialisation routine are done only, if the variant with monitor lambda sensors is on the table.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions

Activation: *LV_IGK = 1*

Deactivation: *LV_IGK = 0*

Recurrence: *1 s*

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle:

LV_INH_LSH_DOWN[i] = 0
LSHPWM_EXT_LS_DOWN[i] = 0
TEMP_INI_LS_DOWN[i] = 0 °C

Formula section:

```
IF          LV_LSHPWM_DOWN_EXT_ADJ[i] = 0
THEN
     if      LV_VAR_LSH_DOWN = 0
     then       LV_INH_LSH_DOWN[i]   =   1
            LSHPWM_EXT_LS_DOWN[i]   = NC_LSHPWM_BOL_LSH_DOWN
     else       LV_INH_LSH_DOWN[i]   =  ! LC_LSH_DOWN[i]
            LSHPWM_EXT_LS_DOWN[i]   =   0
ELSE        LV_INH_LSH_DOWN[i]   =   1
            LSHPWM_EXT_LS_DOWN[i]   = LSHPWM_DOWN_EXT_ADJ[i]
ENDIF
```

Once at every function activation:

TEMP_INI_LS_DOWN[i] = TEG_WALL_CAT_DOWN_MDL[i]

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.54 O2 sensor lambda setpoint intervention

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LAMB_SP_DIAG_LS_UP_DOWN [NC_CBK_EX_NR]	O/V	0... 7FFFH	0... 31.99902	976.599e-6	-
Lambda set point for active plausibility test					
LV_LAMB_SP_REQ_DIAG_ACT [NC_CBK_EX_NR]	O/V	0... 1H	0 ...1	1	-
Lambda coordination request to change set point for active plausibility test					

Input data:

LAMB_SP_DIAG_OC_ LSL_UP [NC_CBK_EX_NR] {p. 4300}	LAMB_SP_DIAG_OPL_ LS_UP_DOWN [NC_CBK_EX_NR] {p. 5387}	LAMB_SP_OSC_CHK [NC_CBK_EX_NR] {p. 5214}	LV_ST_END {p. 1720}

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function provides an internal coordination of lambda setpoint requests from functions within EGCP.

Description:

The function shall perform a priority ranking for several lambda setpoint requests established inside the EGCP aggregate and forward one request to functions outside EGCP. The flag LV_LAMB_SP_REQ_DIAG_ACT[i] shall indicate that at least one setpoint request is active. No check should be performed whether the setpoint is reached, nor should a request for open or closed loop lambda control be output. The possible sources of lambda setpoint requests are:

- plausibility check of upstream and downstream O2 sensor,
- monitor for downstream O2 sensor during oscillation check,
- monitor for upstream O2 sensor during open circuit check.

Application conditions

Initialisation:

At LV_IGK = 0 to 1, reset or at clearing error memory initialize all variables and bits with 0, with the expection of:
LAMB_SP_DIAG_LS_UP_DOWN[i] which is initialized with 1.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Figure 7.55.1: : Definition of   dwell times

Description:

The logical variable LV_AFL_i that indicates a lean air fuel ratio (lambda set point is lean) is calculated based on the output of the forced lambda stimulation. In case of a positive LAMB_PLS[i] the flag is set to one. The lean dwell time T_AFL_CYC[i] is calculated in that case. If LAMB_PLS[i] is negative or zero LV_AFL[i] is 0. In that case the rich dwell time T_AFL_CYC[i] is calculated.
When LV_AFL[i] switches from 0 to 1 T_AFL_CYC[i] is reset. When LV_AFL[i] switches from 1 to 0 T_AFR_CYC[i] is reset and the current value of T_AFL_CYC[i] is stored in the variable T_AFL_CYC_HLD[i]
The function is only active when the forced lambda stimulation is active (LV_LAMB_PLS_ACT[i] = 1). For further explanation see Figure 1.
T_SUM_AFL_AFR_CYC[i] is the period time of the forced lambda stimulation. It is updates each rising edge of LV_AFL[i].

Application conditions

Initialisation: at engine start (LV_ST_END = 0 -> 1) and at each function activation:

```
LV_AFL[i] = 0
        LV_AFL_OLD_1_EGCP[i] = 0
        CTR_AFL_CYC[i] = 0
        T_AFR_CYC[i] = T_SAMPLE
        T_AFL_CYC[i] = T_SAMPLE
        T_AFL_CYC_HLD[i] = T_SAMPLE
        T_SUM_AFL_AFR_CYC[i] = T_SAMPLE
```

Recurrence: *T_SAMPLE = 10 ms*

Activation: *LV_LAMB_PLS_ACT[i] = 1*

7.56.1 Detection of dew point

FUNCTION DESCRIPTION:

General information:

The exhaust gas temperature model has been removed from supplier side and is now modelled in the BMW objects. This module does satisfy the open interfaces of the dew point recognition between supplier and BMW.

Application conditions

Initialisation:

```
IF  (there are no adaptation values stored OR  the EEPROM
does not work)
            THEN
      CTR_COLD_ST_UP = 0 (default value is set)
      CTR_COLD_ST_DOWN = 0 (default value is set)

ELSE        CTR_COLD_ST_UP = CTR_COLD_ST_UP
      CTR_COLD_ST_DOWN = CTR_COLD_ST_DOWN
      (previously stored values are assigned)

          END
          At transition LV_ES = 1 -> 0
          INT_TEG_MAF = 0         (Mass flow integral for dew
point detection)
          LV_TEG_MIN_THD = 0         (State:  dew point not
passed)
          LV_TEG_CAT_DOWN_MIN_THD = 0 (State:  dew point downstream
of cat.  not passed)
```

Recurrence: 1000ms

Activation: LV_ES and LV_ST = 0 (after leaving the engine state ST)

Deactivation: LV_ES = 1 (engine state ES is active)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula section:

Calculation of the number of cold starts up-/downstream:

After leaving the engine state ST the value of CTR_COLD_ST_UP/DOWN is incremented by the increment one.
The value CTR_COLD_ST_UP/DOWN is a measure of the number of cold-start tests and has to be stored in the flash-memory when the engine is switched off (LV_IGK = 0). After a new start of the engine CTR_COLD_ST_UP/DOWN is initialized with the stored value.

IF LV_ST_END= 0 -> 1
THEN CTR_COLD_ST_UP = CTR_COLD_ST_UP + 1
CTR_COLD_ST_DOWN = CTR_COLD_ST_DOWN +1
ENDIF

Calculation of INT_TEG_MAF

IF LV_PUC = 0 **AND** (LV_TEG_MIN_THD = 0 **OR** LV_TEG_CAT_DOWN_MIN_THD = 0)
% For PUC active no increment of INT_TEG_MAF$_N$
THEN
INT_TEG_MAF$_N$ = INT_TEG_MAF$_{N-1}$ + MAF_KGH$_N$ * 1000ms

END

Dew point upstream of catalyst:
T_ES_DEW = T_ES_CUS

MAF_INT_TEG_THD = IP_INT_TEG_THD(TCO_ST, TIA)
MAF_DEW_ADD_UP = IP_MAF_ADD_DEW_UP(T_ES_DEW, TAM)
FAC_DEW_CTR_COLD_ST_UP = (1 + (CTR_COLD_ST_UP - 1) * C_CTR_COLD_ST_UP)

MAF__INT_DEW_END_UP_SP = **(**MAF_INT_TEG_THD + MAF_DEW_ADD_UP) * FAC_DEW_CTR_COLD_ST_UP

IF INT_TEG_MAFN >**=**MAF_INT_DEW_END_UP_SP
THEN
LV_TEG_MIN_THD = 1 % dew point passed
ENDIF

Reset of cold start counter CTR_COLD_ST_UP:

IF LV_TEG_MIN_THD = 1
THEN
CTR_COLD_ST_UP = 0 % reset of cold start counter upstream
ENDIF

Dew point downstream of catalyst:

MAF_INT_TEG_CAT_DOWN_THD = IP_INT_TEG_CAT_DOWN_THD(TCO_ST, TIA)

7.57.1 Mean value calculations for the TEG model

General information:

The TEG model is calculated at the recurrence of 500 ms. For this it is nessesary to calculate mean values by high frequency influency variables. The sampling of the input datas are 10 ms.

Application conditions

Initialisation: –

Recurrence: 10ms

Activation: LV_IGK = 1

Deactivation: –

FUNCTION DESCRIPTION:

Cylinder shut off regionisation:
This function shows bank selective the mean value of shut off cylinders about 500 ms. After this time the sampling is starting again.

General information:

This function
- manages the stop modes of the linear lambda controller,
- defines non stationary conditions,
- calculates the crankshaft difference between start of fuel injection and the position where the sensor detects the exhaust gas,
- detects whether lambda closed loop control was active at least once during the actual driving cycle and
- evaluates the fuel system status.

The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension _i is used in the model instead of [i] as found in the textual description.

The lambda-controller is in the stop-mode (LV_LAM_STOP[i] = 1) if one of the conditions
a) the offset-adjustment of the lambda-sensor is active
(LV_LSL_OFS_ADJ_ACT[i] = 1)
b) Switching of the pump current measurement range (gain-switching) of the lambda-sensor is currently taking place (LV_VLS_UP_INIT[i] = 1)
c) Ip gain-switch of the lambda-sensor is not yet confirmed by the hardware (LV_SWI_GAIN_LSL_IF[i] STATE_LSL_IF_SPI_RD[i] (bit SWI_GAIN))
d) OBDI signal failed (LV_LSL_DEAC[i] = 1)
e) one cylinder at least is cut off (LV_FCUT_IND = 1)
f) the engine state LV_PUC is active
g) lambda controller stop mode request (LV_LAM_STOP_REQ[i] = 1)
is fulfilled.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Additionally LV_LAM_STOP_SHO_PER[i] is set to 1 in case that condition a), b), c) or d) is true (short period stop mode).
LV_LAM_STOP_SHO_PER[i] is set to 0 if condition e), f) or g) is true (nominal stop mode). These latter conditions have the higher priority if a) or b) are fulfilled too.
If condition a) and b) are not fulfilled anymore the timer T_LAM_REAC[i] is to start. If this timer exceeds a calibration threshold, LV_LAM_STOP[i] and LV_LAM_STOP_SHO_PER[i] are set both to 0.
If condition e), f) and g) are not fulfilled anymore the integral MAF_INT_LAM_REAC[i] is calculated. If this integral exceeds a calibration threshold and the controller difference FAC_DIF_LAM_IN[i] is below a threshold while a time out threshold is not exceeded, LV_LAM_STOP[i] is set to 0.

For the calcuation of the air mass flow integral the unit conversion:
[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600
has to be considered.

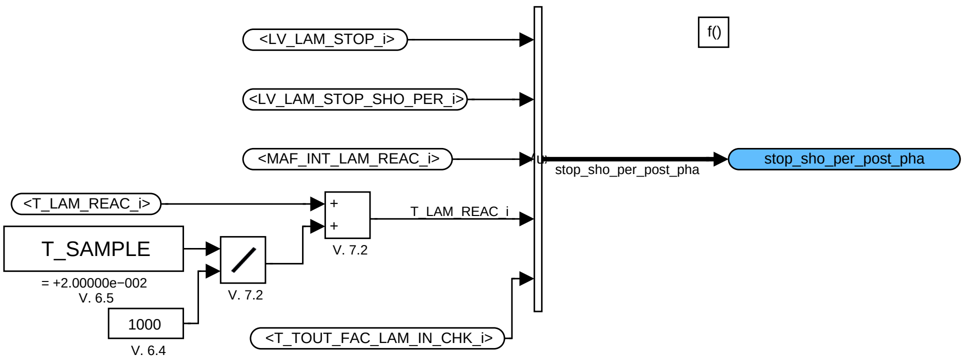

Figure 7.58.11: :

7.58.2.1.1.2 Calculation of CRK_DIF_SOI_LSL_POS[i]

The value of CRK_DIF_SOI_LSL_POS[i] corresponds to the crankshaft angle difference between the start of injection and the end of the exhaust cycle of the engine. This value is required for the calculation of the gas delay needed for the linear lambda controller. The distance between start of injection and top dead center where the injected fuel is ignited is defined by CRK_DIF_SOI_IGN (see injection phase for homogeneous and stratified mode). The distance from the mentioned top dead center to the point where the exhaust valves close is defined by 360°CRK plus current position of exhaust camshaft (CAM_EX[i]; is always negative) minus half of the opening period. So the opening timing edge of the exhaust valve is met.

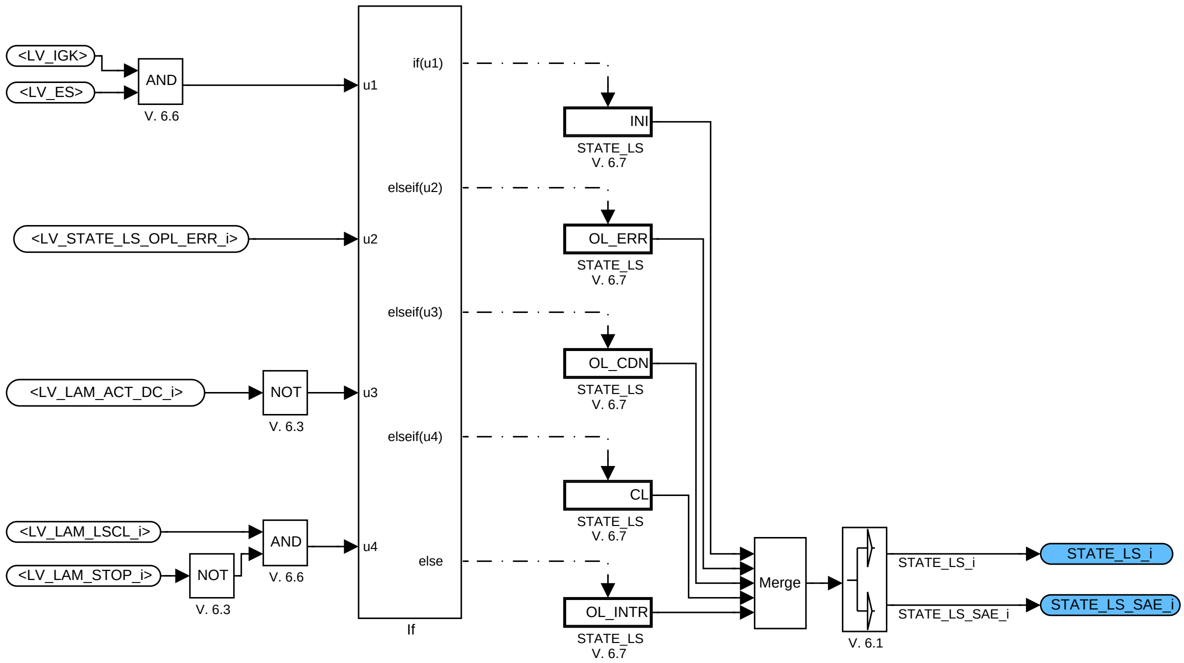

Figure 7.58.15: :

7.58.2.2 Definition of non stationary conditions

To avoid big controller excursion under non stationary conditions like wall film the output limitation of the lambda controller can be restricted. Therefore the flag LV_LAM_NOT_STAT_CDN is set if the neutral value FAC_NEUT_NOT_STAT_CDN exceeds the calibration minimum or maximum. The limitation itself (reaction on this flag) is executed in the module linear lambda control.
If the sum of the wall film is lower than this calibration threshold a counter is decreased. If the counter is 0 then the lambda-controller works without the limitation again.

7.58.2.2.1 Definition of non stationary conditions

To avoid big controller excursion under non stationary conditions like wall film the output limitation of the lambda controller can be restricted. Therefore the flag LV_LAM_NOT_STAT_CDN is set if the neutral value FAC_NEUT_NOT_STAT_CDN exceeds the calibration minimum or maximum. The limitation itself (reaction on this flag) is executed in the module linear lambda control.
If the sum of the wall film is lower than this calibration threshold a counter is decreased. If the counter is 0 then the lambda-controller works without the limitation again.

General information:

By means of a Pad approximation the delayed lambda set point LAMB_SP_FIL_HOM[i] (for homogeneous mode) and LAMB_SP_FIL_S[i] (for stratified mode) is calculated. All other variables which are output of these sub-systems are only necessary to realize the functionality with the desired accuracy. The behavior of the delay is described by an all-pass filter (Pad approximation of 2nd order). Its principle is shown here below.

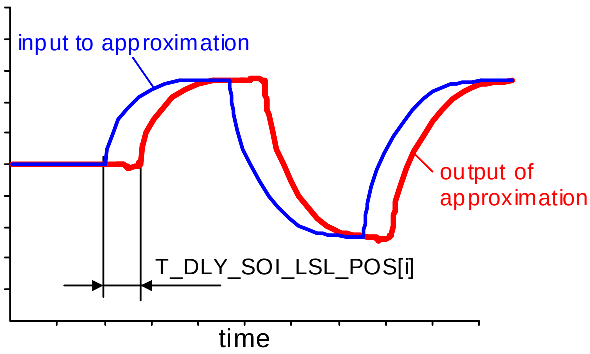

Figure 7.59.1: :

Gas delay approximation (2nd order Pad approximation)

The following formula describes the Pad approximation in its mathematical representation:

$$f_1 = \frac{T\_DLY\_SOI\_LSL\_POS[i]}{T\_SAMPLE},$$

7.59.1.1.1.1 Calculation of pre control lambda set point

In case of homogeneous mode the pre control lambda set point is the static set point LAMB_SP_HOM[i] added with the forced stimulation output LAMB_PLS[i]. Furthermore LAMB_SP_DELTA_LAM[i] is subtracted to consider a trim control lambda shift. This latter variable is assigned in the application incidences.
The pre control correction FAC_LAM_PCTL[i] is then calculated by inverting LAMB_SP_PCTL[i].
In case of stratified mode (LV_HOM_ACT[i] = 0) both outputs are initialized

7.59.3.1.1.1 Activation and state machine

The sub-system ACT_LAM desribes the activation of the lambda sontroller.

State machine of lambda contoller:
If LV_LAM_LSCL[i] is 0 then state "0:OFF" is applied. Otherwise then three different states are to distinguish.
State "1:ON" is applied when the controller is not stopped by the flag LV_LAM_STOP[i]. In that case the controller is in normal operation mode.
If LV_LAM_STOP[i] is set to 1 either state "2:STOP_SHO_PER" or state "3:STOP" is applied depending on LV_LAM_STOP_SHO_PER[i].

7.59.3.1.1.1.1 STATE_LAM

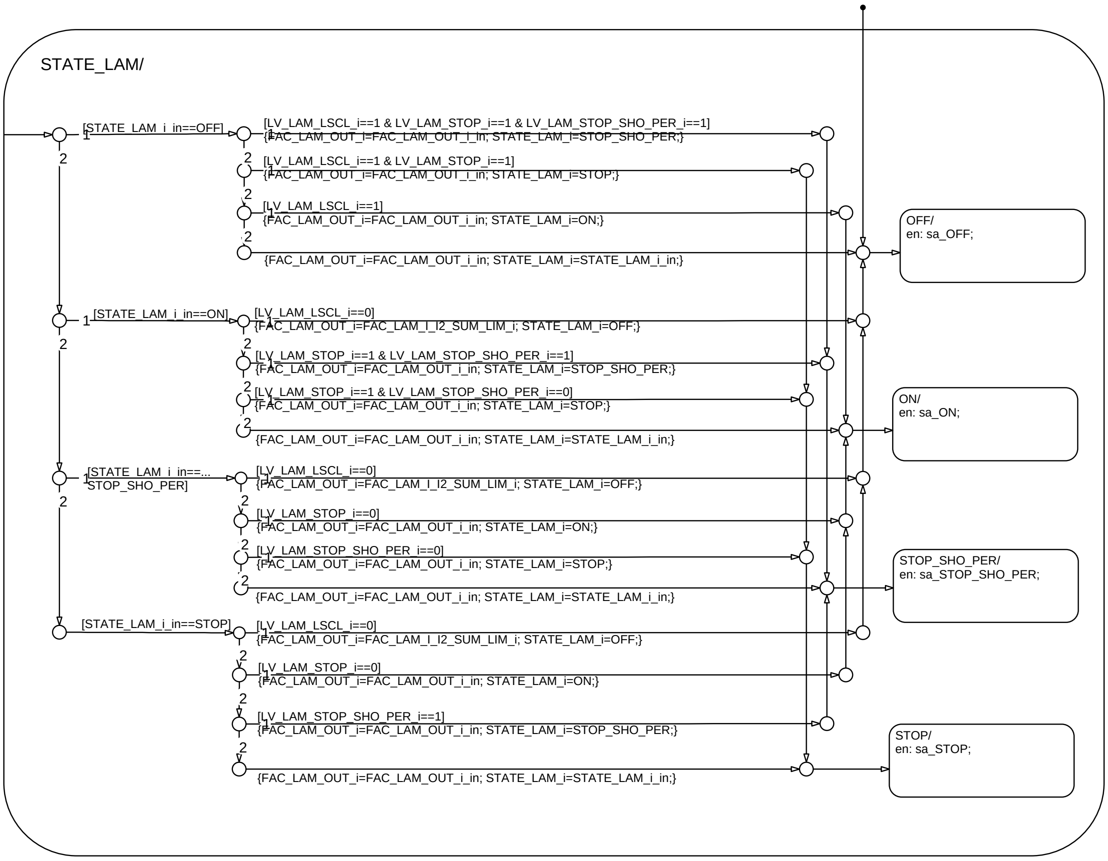

Figure 7.59.32: :

7.59.3.1.1.1.2 Controller activation /deactivation

Independent of the lambda controller state (STATE_LAM[i]) the evaluation of controller activation / deactivation is calculated.

The controller is activated by the flag LV_LAM_LSCL[i] = 1. This flag is set if the following conditions are fulfilled:

- inhibit flag not set (LV_INH_LSCL[i] = 0)
- no request from OBD function to inhibit lambda controller (LV_LAM_DI_REQ[i] = 0)
- WRAF sensor operability recognised (LV_LS_UP_READY[i] = 1)
- engine speed above threshold (N_32 > C_N_MIN_LAM_LSCL)
- time after start threshold expired (T_AST > ID_T_AST_MIN_LSCL_ACT)
- coolant temperature exceeds threshold

(in idle speed TCO > ID_TCO_MIN_LAM_LSCL_IS
otherwise TCO > ID_TCO_MIN_LAM_LSCL)
or the time ID_T_MAX_LSCL_ACT_TCO is expired

LV_T_MAX_LSCL_ACT_TCO[i] is permanently set to 1 if the controller was activated by the time condition instead of activation by the corresponding TCO condition. Otherwise LV_T_MAX_LSCL_ACT_TCO[i] is set to 0. If one of the conditions above is not fulfilled the flag LV_LAM_LSCL[i] is set to 0 and the controller is not activated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

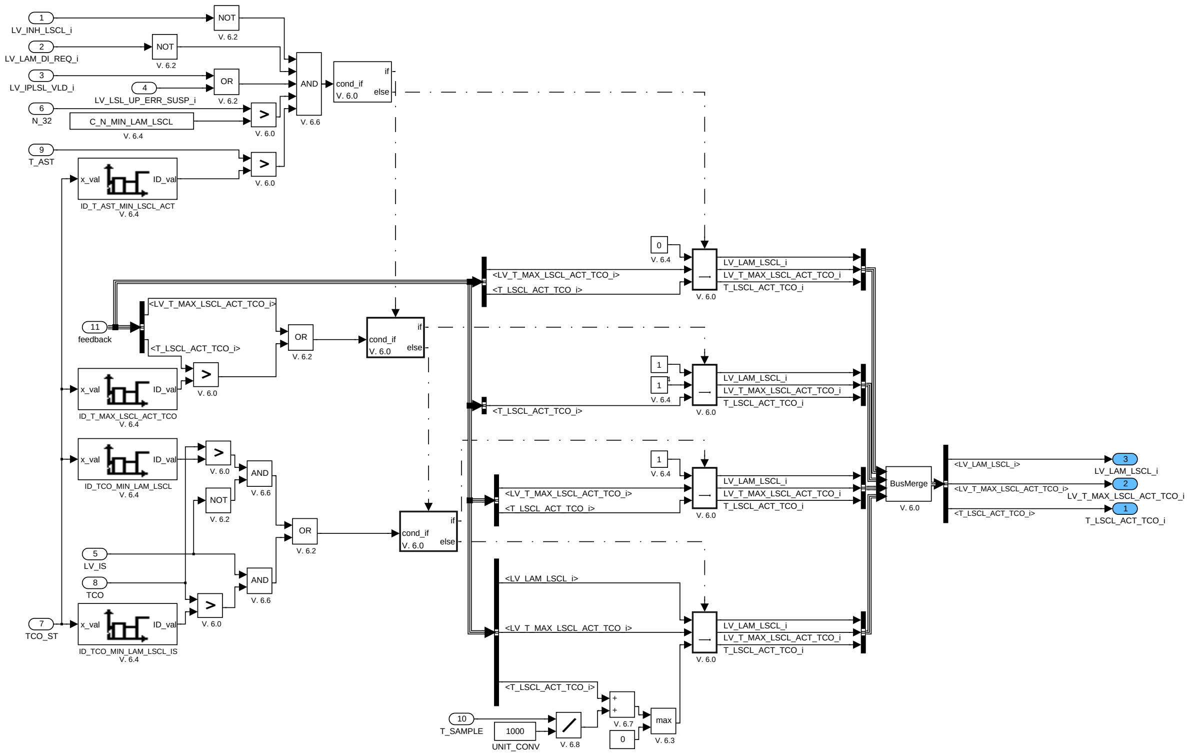

Figure 7.59.33: :

7.59.3.1.1.1.3 STATE_LAM: "0:OFF"

In state "0:OFF" this calibration flag LC_LAM_I2_ACT is copied in the variable LV_LAM_I2_ACT that means a switch between PID and PII2D controller can only be applied in this state.

The reset of internal state variables and output values (Sub-System: RST__IT_STATE_VALUE_OUT_VALUE_CBK_SPC) is carried out.

FAC_LAM_OUT[i] is set to the current offset (I + I2 share) when entering this state and then ramped down to zero (RAMP_DOWN__FAC_LAM_OUT).

The controller difference FAC_DIF_LAM_IN[i] is calculated (Sub-System: CLC__FAC_DIF_LAM) as difference of the inverted lambda set point (LAMB_SP_FIL_HOM[i])-1 and the inverted measured lambda signal corrected by the trim control influence (LAMB_LS_UP[i] + LAMB_AV_DELTA_LAM[i])-1. Therefore FAC_DIF_LAM_IN[i] represents a richness. LAMB_AV_DELTA_LAM[i] is assigned in the application incidences. A moving mean value of the controller difference (FAC_DIF_LAM_IN_MMV[i]) is calculated in order to realise a shift of I and I2 share based on downstream signal evaluation.

A moving mean value of the downstream sensor signal voltage (VLS_DOWN_LAM_MMV[i]) is calculated (Sub-System: DET__VLS_DOWN_AFL_AFR). Based on this moving mean value a too lean (100% O2 loading of the catalyst) or too rich (0% O2 loading of the catalyst) mixture is detected. The respective flags LV_VLS_DOWN_THD_AFL_LAM[i] or LV_VLS_DOWN_THD_AFR_LAM[i] is set to 1.

7.59.3.1.1.1.4.9 Calculation of the I and I2 share

The calculation of the I and I^2 share depends on the flag LV_LAM_I2_ACT. If it is set to 1 then the lambda controller is calculated as an PII^2D controller. Otherwise a PID controller is applied.

PII^2D controller: The control differences are summed up in the variable FAC_DIF_SUM_LAM_IN[i]. A shift of the I and I2 share based on downstream signal evaluation is realised by shifting FAC_DIF_SUM_LAM_IN[i]. This variable is then multiplied with the I share gain FAC_GAIN_I_LAM[i] and the sample time. The result is stored in the variable FAC_LAM_I[i] which represents the unlimited I share. In case of anti wind up limitation of FAC_LAM_I[i] to its maximum or minimum possible range FAC_DIF_SUM_LAM_IN[i] has to be limited "backwards". FAC_DIF_SUM_LAM_IN[i] is input to the calculation of the I^2 share too. Therefore a multiplication with T_SAMPLE^2 and FAC_GAIN_I2_LAM[i] is necessary. If the product of FAC_DIF_SUM_LAM_IN[i], T_SAMPLE^2 and FAC_GAIN_I2_LAM[i] leads to zero result while FAC_DIF_SUM_LAM_IN[i] is not zero (FAC_GAIN_I2_LAM[i] is never 0 when using a PII^2D controller) then the I^2 share is increased or decreased by the resolution of FAC_LAM_I2[i]. By means of FAC_LAM_DELTA_I_I2_SHIFT[i] the shift of the I share is realised. If the shift should be applied if this variable is not equal to 0 for one sample step. With C_TOUT_I_I2_SHIFT_VLD an time out for the shift can be applied.

PID controller: The I^2 share FAC_LAM_I2[i] is always set to 0. The I share is calculated with an internal variable that has a higher resolution than FAC_LAM_I[i] (see formula section).

For both controllers the calculation of the I share is only executed if no limitation is applied (LV_FAC_LAM_LIM_MAX[i] = 0 and LV_FAC_LAM_LIM_MIN[i] = 0). If the injected fuel mass is not on its minimum value (indicated by LV_TI_1_HOM_MIN = 1) or LV_FAC_LAM_LIM_MIN[i] = 0 then the I share is only calculated if the controller difference is above 0. If LV_FAC_LAM_LIM_MAX[i] = 0 then the controller difference must be above 0. For the I^2 share calculation FAC_DIF_SUM_LAM_IN[i] must be above or below 0 in the same way in case of the mentioned limitations.

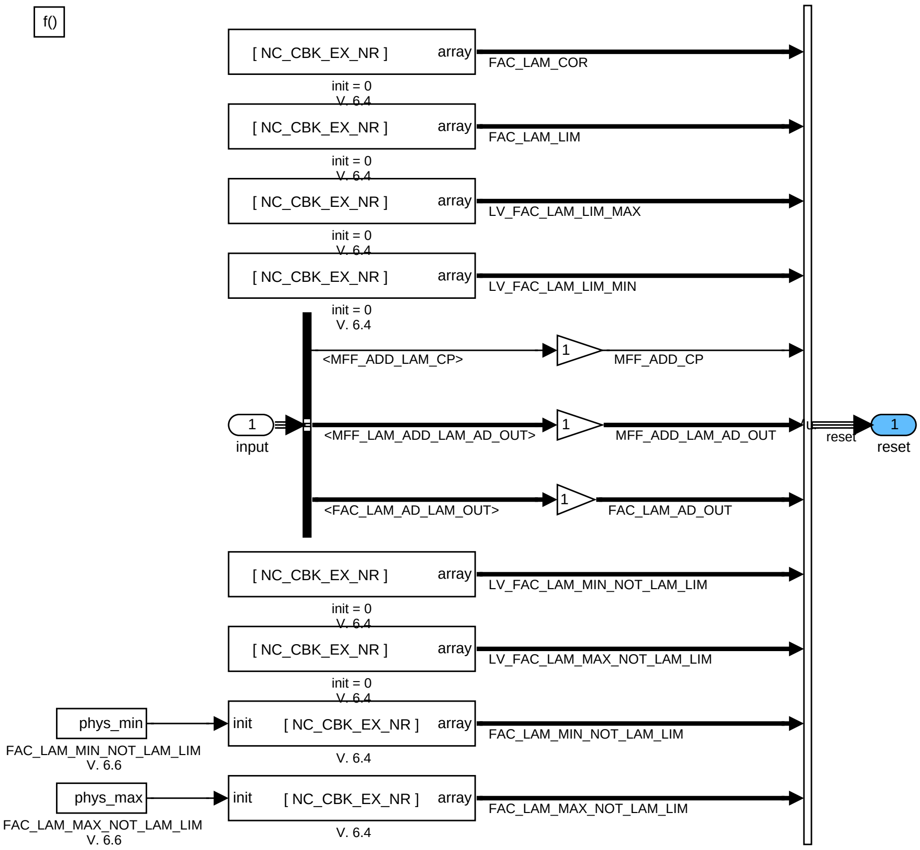

Figure 7.59.113: :

7.59.5 Calculation of air fuel ratio changes counter

General information:

At each change of LV_AFL[i] the counter of air fuel ratio changes CTR_RAF_CHG[i] has to be incremented.
The counter CTR_RAF_CHG[i] can overflow.

NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application conditions:

FUNCTION DESCRIPTION:

General information:

This module defines the project specific activation conditions and necessary output variables for the linear lambda controller.
The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions

Initialisation:

```
at ECU reset:

Formula section:

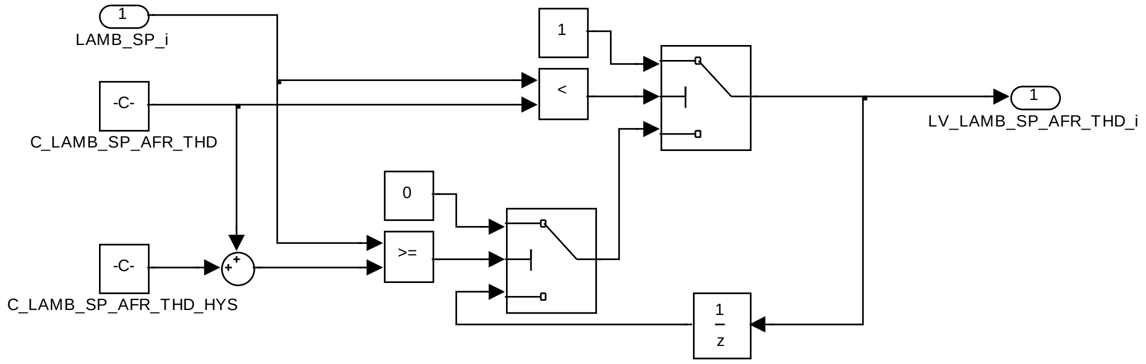
7.60.1 Calculation of LV_INH_LSCL[i]

7.60.1.1 Inhibition of the lambda feedback control circuit

If(1) LAMB_SP[i] < C_LAMB_SP_AFR_THD
% lambda setpoint value is less than the rich air-fuel mixture threshold
Then(1) LV_LAMB_SP_AFR_THD[i] = 1
Else(1)
If(2) LAMB_SP[i] C_LAMB_SP_AFR_THD + C_LAMB_SP_AFR_THD_HYS
Then(2) LV_LAMB_SP_AFR_THD[i]= 0
Endif(2)
Endif(1)
If(1) LAMB_SP[i] > C_LAMB_SP_AFL_THD lambda setpoint value is greater than the lean air-fuel mixture threshold
Then(1) LV_LAMB_SP_AFL_THD[i] = 1
Else(1)
If(2) LAMB_SP[i] ≤ C_LAMB_SP_AFL_THD - C_LAMB_SP_AFL_THD_HYS
Then(2) LV_LAMB_SP_AFL_THD[i] = 0
Endif(2)
Endif(1)
(signal flow is analogous LV_LAMB_SP_AFR_THD[i] , see above)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007



If(1) MAF $<$ IP_LAM_MAF_MIN
Then(1) LV_LAM_MAF_MIN = 1
Else(1)
If(2) MAF IP_LAM_MAF_MIN + C_LAM_MAF_MIN_HYS
Then(2) LV_LAM_MAF_MIN = 0
Endif(2)
Endif(1)

7.60.1.2 Inhibition due to present error

If ERR_INH_LSCL[i] $>$ 0
Then LV_STATE_LS_OPL_ERR[i] = 1
Else LV_STATE_LS_OPL_ERR[i] = 0
Endif

7.60.1.3 Summary of all inhibition conditions for activation of lambda controller

If LV_STATE_LS_OPL_ERR[i] = 1 **or** (present error)
LV_LAMB_SP_AFR_THD[i] = 1 **or** (lambda setpoint to rich)
LV_LAMB_SP_AFL_THD[i] = 1 **or** (lambda setpoint to lean)
LV_LAM_MAF_MIN = 1 **or** (minimum maf not fulfilled)
(LC_LAMB_COP_OFF = 1 **and**
LV_LAMB_COP[i] = 1**) or** (catalyst overheat prevention)
LV_ACT_SA_EOL = 1 **or** (EOL test SA is active)
(LC_LAM_OFF_SAWUP=1**and**
LV_SA_END = 0**) or** (secondary air is active)
LV_INH_LAM_KWP = 1 (disable Controller via Tester)
Then LV_INH_LSCL[i] = 1
Else LV_INH_LSCL[i] = 0
Endif

7.60.1.4 Calculation of LV_LAM_STOP_REQ[i]

The request to stop the lambda-controller (LV_LAM_STOP_REQ[i] = 1), if one of the conditions

1. stratified charge mode (LV_HOM_ACT=0) **and** LC_HOM_ACT_COMP = 0 **or**
2. secondary air is active (LV_SA_END = 0) **and** LC_LAM_OFF_SAWUP = 1

is fulfilled.

If (LV_HOM_ACT = 0 **and**
LC_HOM_ACT_COMP = 0) **or**
LV_INH_LSCL_CUS[i] = 1 **or**

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

(LV_SA_END = 0 **and**
LC_LAM_OFF_SAWUP = 1**)**
Then LV_LAM_STOP_REQ[i] = 1
Else LV_LAM_STOP_REQ[i]= 0
Endif

7.60.1.5 Setting of LV_LAM_GAIN_SWI

The gain of the lambda controller is different between idle speed and part load. Therefore, the gain is switched in case of active idle speed controller.
If (LV_REQ_ISC = 1 **and** LC_LAM_GAIN_SWI = 1)
or (LV_LAM_AD_INJ_ACT = 1 **and** LC_LAM_GAIN_SWI_LAM_AD_INJ = 1)
Then LV_LAM_GAIN_SWI = 1
Else LV_LAM_GAIN_SWI = 0
Endif

7.60.1.6 Assignment of LAMB_SP_DELTA_LAM[i]

The output of the trim controller (P and I share) is distributed as follows as corrective intervention on the lambda set point and on the measured lambda signal:

If STATE_LAM_GAIN_REQ_LS_DIAG = DYN_DIAG
Then LAMB_DELTA_DYN_DIAG[i] = IP_LAMB_DELTA_DYN_DIAG (FAC_
COMP_MV_DIAG_DYN_SENS_MDL [i])
Else LAMB_DELTA_DYN_DIAG[i] = 0
Endif
LAMB_SP_DELTA_LAM[i] = LAMB_DELTA_LAM_ADJ[i]
+ DELTA_LAMB_SP_O2L_MDL[i]
+ LAMB_DELTA_DYN_DIAG[i]

7.60.1.7 Assignement of LAMB_AV_DELTA_LAM[i]

FAC_IPT_SENS_MDL_OPT[i] = 0
endif

7.60.1.10 Calculation of air massflow integral during S/HOMS operation mode

If LV_HOM_ACT = 1 -> 0
Then MAF_INT_S_ACT = 0
Elseif LV_HOM_ACT = 0
Then MAF_INT_S_ACT = MAF_INT_S_ACT + MAF_CYL [kg/h] * T_SAMPLE [ms] * 1/3600 [(g*h) /(kg*ms)]
Elseif LV_HOM_ACT = 1
Then hold MAF_INT_S_ACT
Endif

7.60.2 Calculations in 10ms

General information:

The lambda controller plant model is determined depending on STATE_SENS_MDL. It can be chosen between a lean2rich, a rich2lean and a default model.
The default sensor plant model is used e.g. if forced adaptation is off and gradient based switching is off or during the dynamic diagnosis to have a defined reference.

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

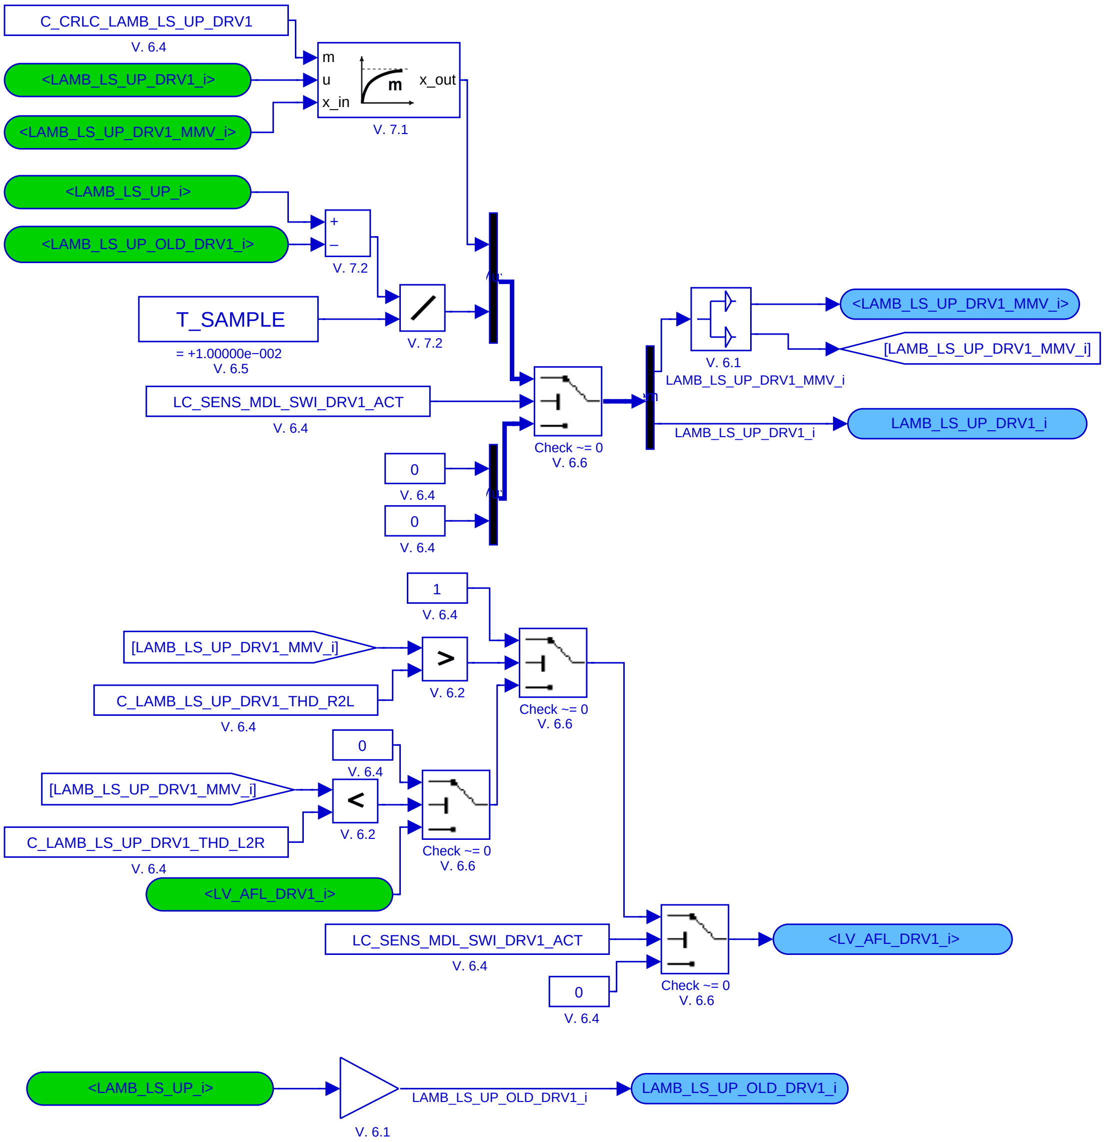
7.60.2.2 1.2.3 Calculation of first derivate detection of lean Air-Fuel mixture when set



7.60.2.3 1.2.4 Determination T1 and T-delay times for lambda controller plant model in-case of ageing

FAC_COMP_MV_DIAG_DYN_SENS_MDL[i] is given by EGCP to indicate the assymetric aged sensor behaviour. (e.g. -1.5=L2Rslow, 1.5=R2Lslow and 0=nominal).Depending on this value additional T1- and T-delay-times (separate ones for R2L & L2R) can be determined. These times are taken into account in the lambda controller plant model while the R2L or L2R model is active

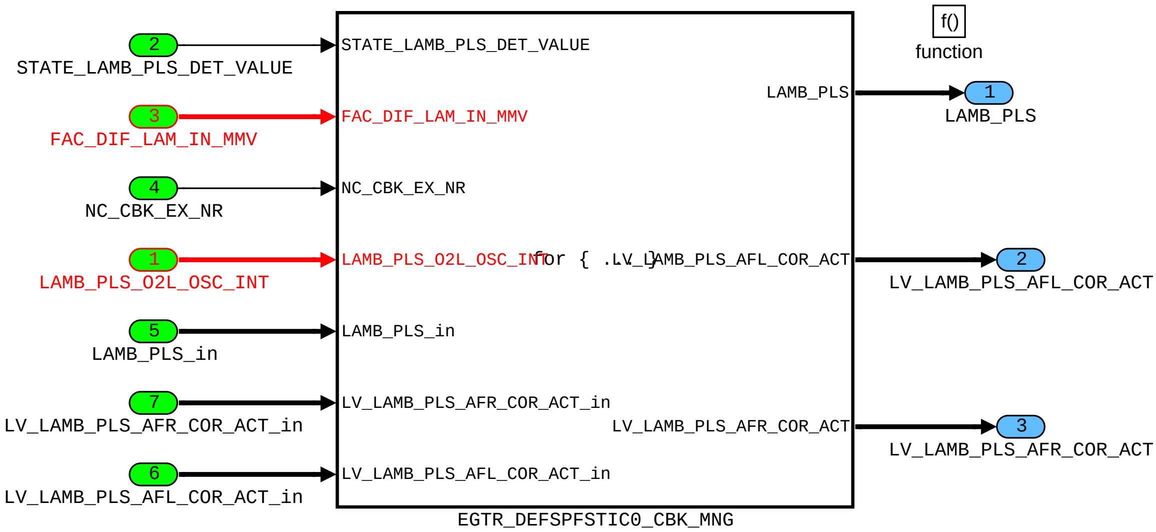

Figure 7.61.3: EGTR_DEFSPFSTIC0/operate

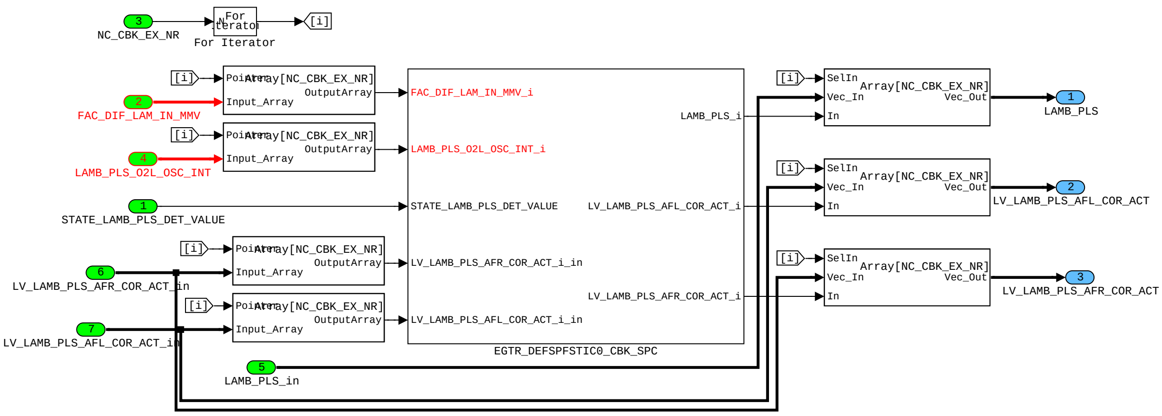

Figure 7.61.4: EGTR_DEFSPFSTIC0/operate/EGTR_DEFSPFSTIC0_CBK_MNG

Corrective action depending on lambda cotnroller difference

Depending on the lambda control difference FAC_LAM_DIF_IN[i] a corrective intervention on the lambda pulse can be applied. In case of too lean mixture the lean deviation can be suppressed and in case of too rich mixture the rich deviation can be suppressed. Activation and deactivation of the corrective intervention is realised with different thresholds in order to apply a hysteresis.
With LC_LAMB_PLS_COR_ACT_IS this corective action can also be applied in idle speed.

General Information

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The forced lambda stimulation generates an output signal that causes lean and rich deviations of the air fuel ratio from the lambda controller set point. By means of the stimulation parameters (set point deviation, period time and gradient) a well defined O2 load for the catalyst can be calibrated. So the catalyst efficiency can be increased.
Furthermore the forced lambda stimulation is used by diagnosis functions for the up stream lambda sensor and by the catalyst efficiency diagnosis.
The recurrence time is defined by T_SAMPLE in 20 ms.
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

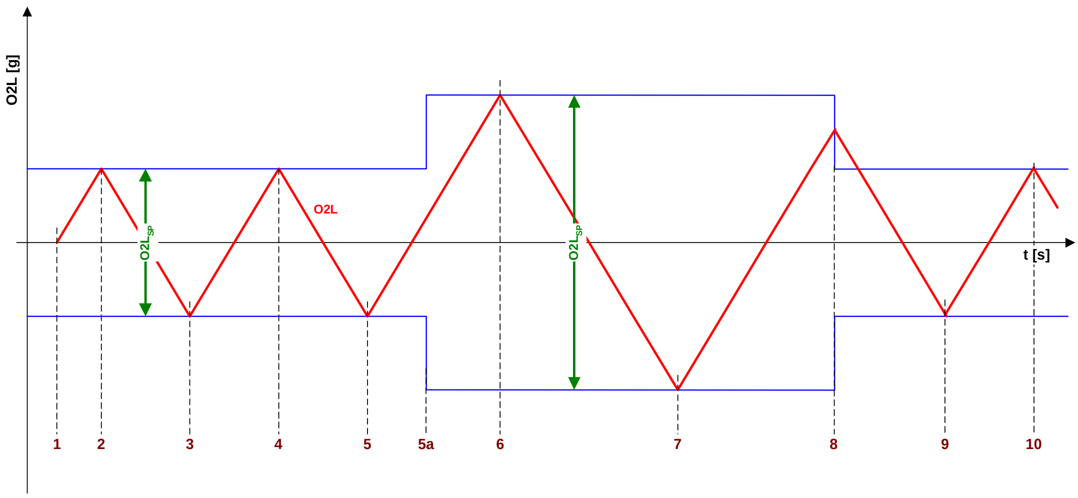
7.62.1.1.1 Execution of state machine:

In state OFF the output of the forced lambda stimulation is 0. This state is active if LV_LAMB_PLS_ACT[i] is not set.
In case of LV_LAMB_PLS_ACT[i] = 1 either state AFL or state AFR is active. In state AFL the set point deviation is increased stepwise to the calibrated set point deviation. In state AFR the set point deviation is decreased. The transition between both states depend on the O2 loading calculated in both states (CLC_O2L_LAMB_PLS). When the current O2 loading reaches the current set point (O2L_SP_NEW_LAMB_PLS[i]) then the transition to the opposite state takes place. The O2 loading is calculated with the formula:

$$m_{O_2} = 23\% \cdot \int \left(1 - \tfrac{1}{1+\Delta\lambda_{SP}}\right) \cdot \dot{m}_{air} \, dt$$

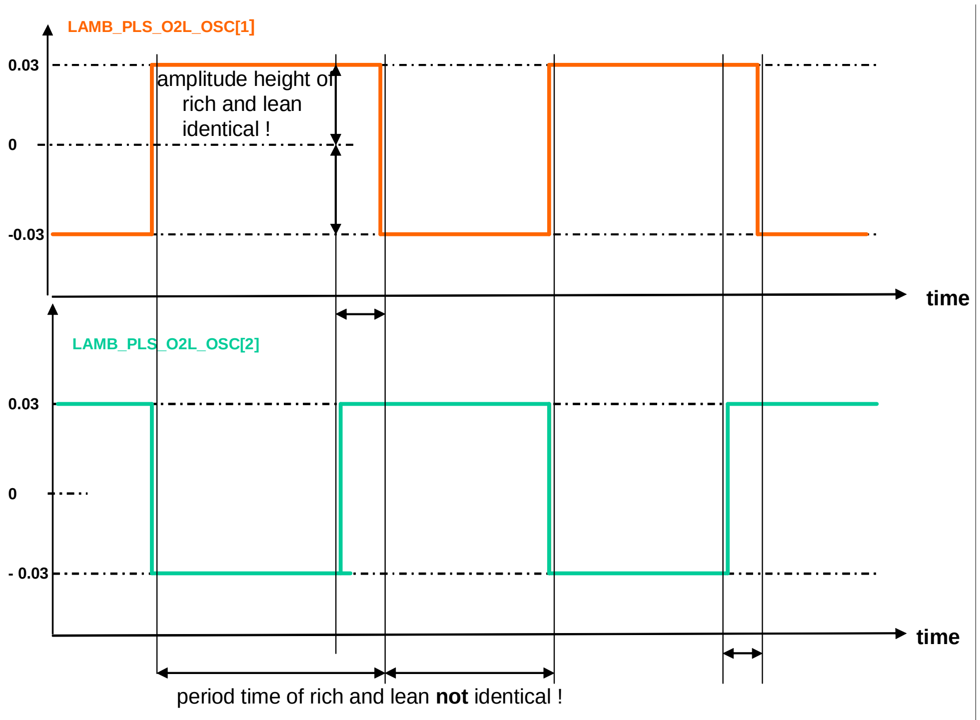
In order to realise synchronisation of both banks two flags are defined. LV_LAMB_PLS_MST_CBK_ACT is a common flag that defines whether forced stimulation is already active for one bank. Master bank is the bank that has set the flag LV_LAMB_PLS_MST_CBK_ACT; this is also indicated by the bank selective flag LV_LAMB_PLS_MST_CBK[i] which must be set to 1 for the master bank and to 0 for the slave bank.
The second flag to synchronise both banks is LV_LAMB_PLS_SYN_CBK. This flag is set by the master when the transition from state AFR to AFL occurs in order to inform the slave to execute the desired transition.

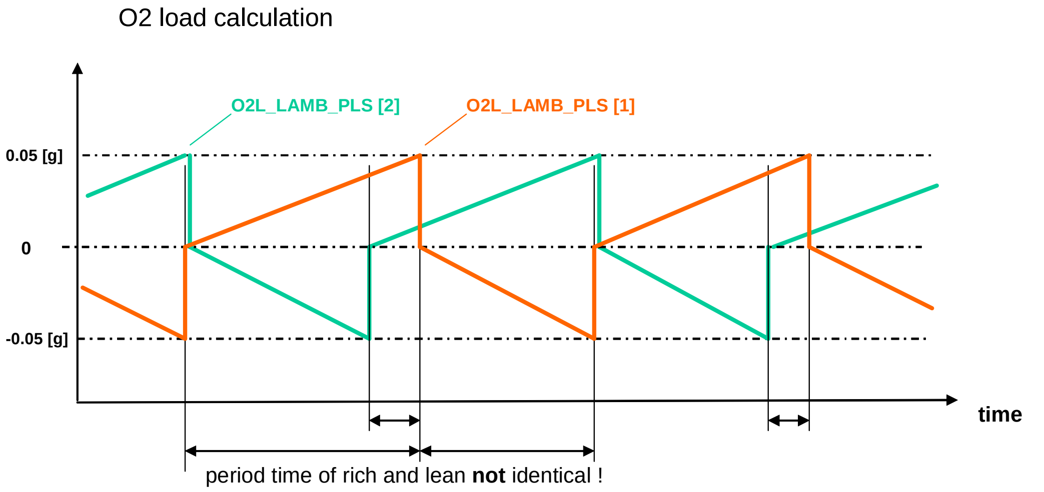


If the set point from Determination of forced lambda stimuation parameters (O2L_SP_PLS) changes the O2 loading set point that is adjusted switches for the next half wave to an intermedieate value and the next but one half wave will be the target value.
Asynchronous or synchronous operation:
The master bank changes from lean to rich or from rich to lean, if the O2 threshold O2L_SP_NEW_PLS is reached. The synchronization pulse LV_LAMB_PLS_SYN_CBK is set at the end of the rich phase.
In case of asynchronous forced stimulation (LC_O2L_PLS_CBK_SYN=0) the slave changes from lean to rich at synchronization pulse and from rich to lean, if the O2 threshold is reached.
In case of synchronous forced stimulation (LC_O2L_PLS_CBK_SYN=1) the slave changes from rich to lean at synchronization pulse and from lean to rich, if the O2 threshold is reached.
Timesynchronous operation:
Due to the formula for O2 load calculation the time duration of the lean part of the forced stimulation period is slightly longer than the rich part.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

During the bankwise asynchronous operation mode (LC_O2L_PLS_CBK_SYN=0), this fact leads to small overlapping phases, where both banks are in the same STATE_LAMB_PLS = RICH or LEAN.

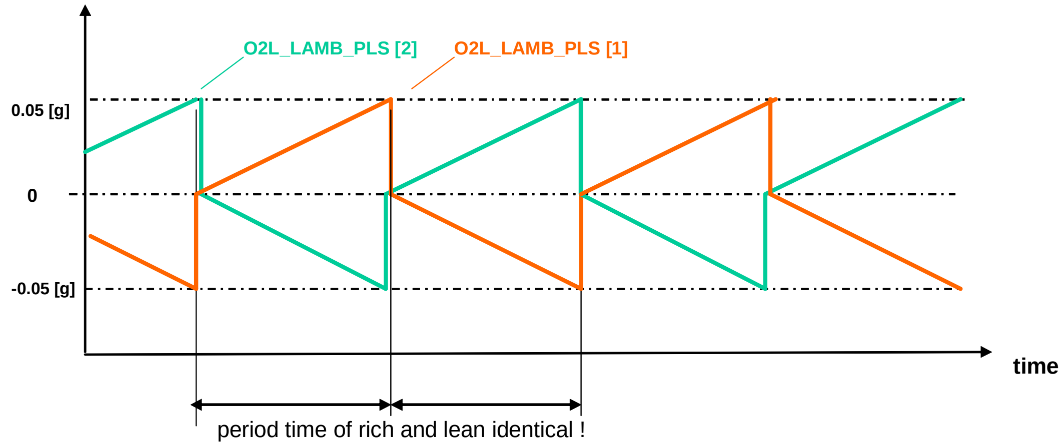




To prevent this behaviour and achieve a duration of the rich and lean phase of exact the same length, the amplitude of the forced stimulation LAMB_PLS_O2L_OSC can be corrected during the lean or during the rich phase (STATE_LAMB_PLS = AFL or AFR).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

O2 load calculation



COR_AFL:
To switch on the timesynchronous operation with correction of the amplitude in STATE_LAMB_PLS=AFL set C_STATE_LAMB_PLS_O2L_OSC_COR = 1 (COR_AFL) .
As a consequence the amplitude LAMB_PLS_O2L_OSC is no more symmetric on the lean and rich side.
LAMB_PLS_O2L_OSC is limited to the calibrated value on the rich side and will be corrected to a slightly higher value on the lean side.
The correction factor on the lean side is calculated as follows:

$$m_{O_2}\_lean = -m_{O_2}\_rich$$

$$\frac{LAMB\_PLS\_O2L\_OSC(lean)}{1+LAMB\_PLS\_O2L\_OSC(lean)} = -\frac{LAMB\_PLS\_O2L\_OSC(rich)}{1+LAMB\_PLS\_O2L\_OSC(rich)}$$

$$LAMB\_PLS\_O2L\_OSC(lean) = -\frac{LAMB\_PLS\_O2L\_OSC(rich)}{1+2*LAMB\_PLS\_O2L\_OSC(rich)}$$

COR_AFR :
To switch on the timesynchronous operation with correction of the amplitude in STATE_LAMB_PLS=AFR set C_STATE_LAMB_PLS_O2L_OSC_COR = 2 (COR_AFR).
LAMB_PLS_O2L_OSC is then limited to the calibrated value on the lean side and will be corrected to a slighly lower value on the rich side.
The correction factor is on the rich side calculated as follows:

$$LAMB\_PLS\_O2L\_OSC(rich) = -\frac{LAMB\_PLS\_O2L\_OSC(lean)}{1+2*LAMB\_PLS\_O2L\_OSC(lean)}$$

COR_OFF:
If timesynchronous operation is not requested, it is possible to enable normal operation mode with symmetric amplitude hight by setting C_STATE_LAMB_PLS_O2L_OSC_COR = 0 (COR_OFF).

7.62.1.1.1.2 Calculation of O2 loading:

The O2 loading is calulated with the already mentioned formula. If the O2 loading that is to added each sample step is smaller than its resolution then the O2 loading is increased or decreased (depending on the sign) by the resolution value.

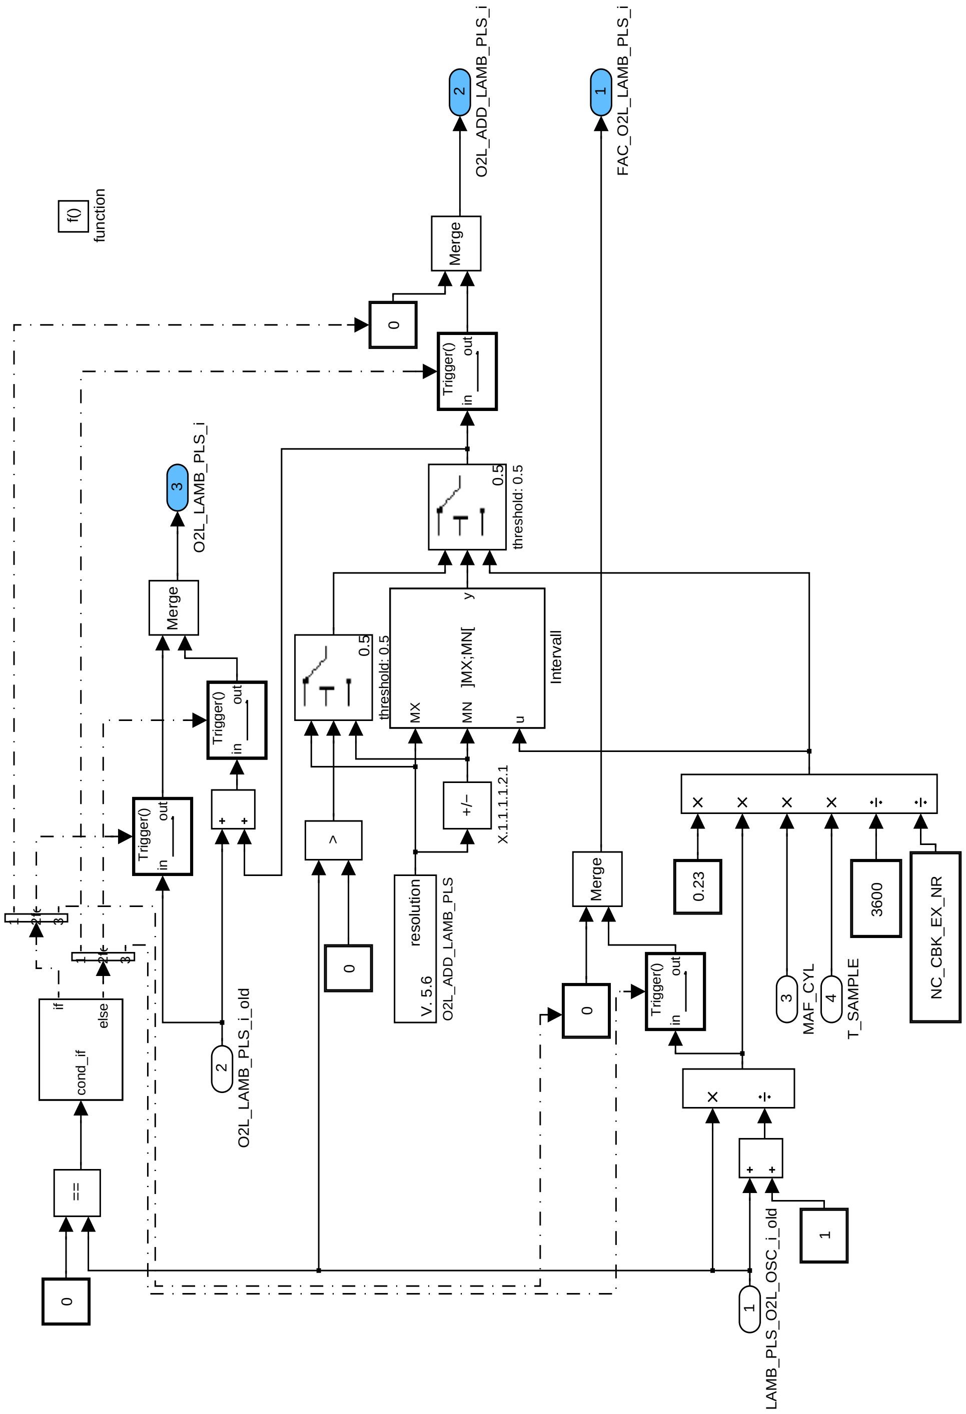

Figure 7.62.7: : Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/ EGTR_DEFSPFSTI0_CBK_SPC/CLC_O2L_LAMB_PLS

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.62.1.1.1.3 STATE "AFL":

In that state the lambda set point deviation LAMB_PLS_O2L_OSC[i] is increased step wise by LAMB_DELTA_MAX_PLS and limited to LAMB_SP_DE_PLS.
If timesynchronous operation mode is activated with C_STATE_LAMB_PLS_O2L_OSC_COR = 1, the lambda set point deviation is not symmetric. The rich half wave is limited to LAMB_SP_DE_PLS, but the lean half wave is corrected to a slightly higher value.
If the LAMB_PLS_O2L_OSC[i] becomes positive (indicated by rising edge of LV_LAMB_PLS_O2L_POS[i]) the sign of the current O2 loading changes in order adjust the right O2 loading (given by the set point).

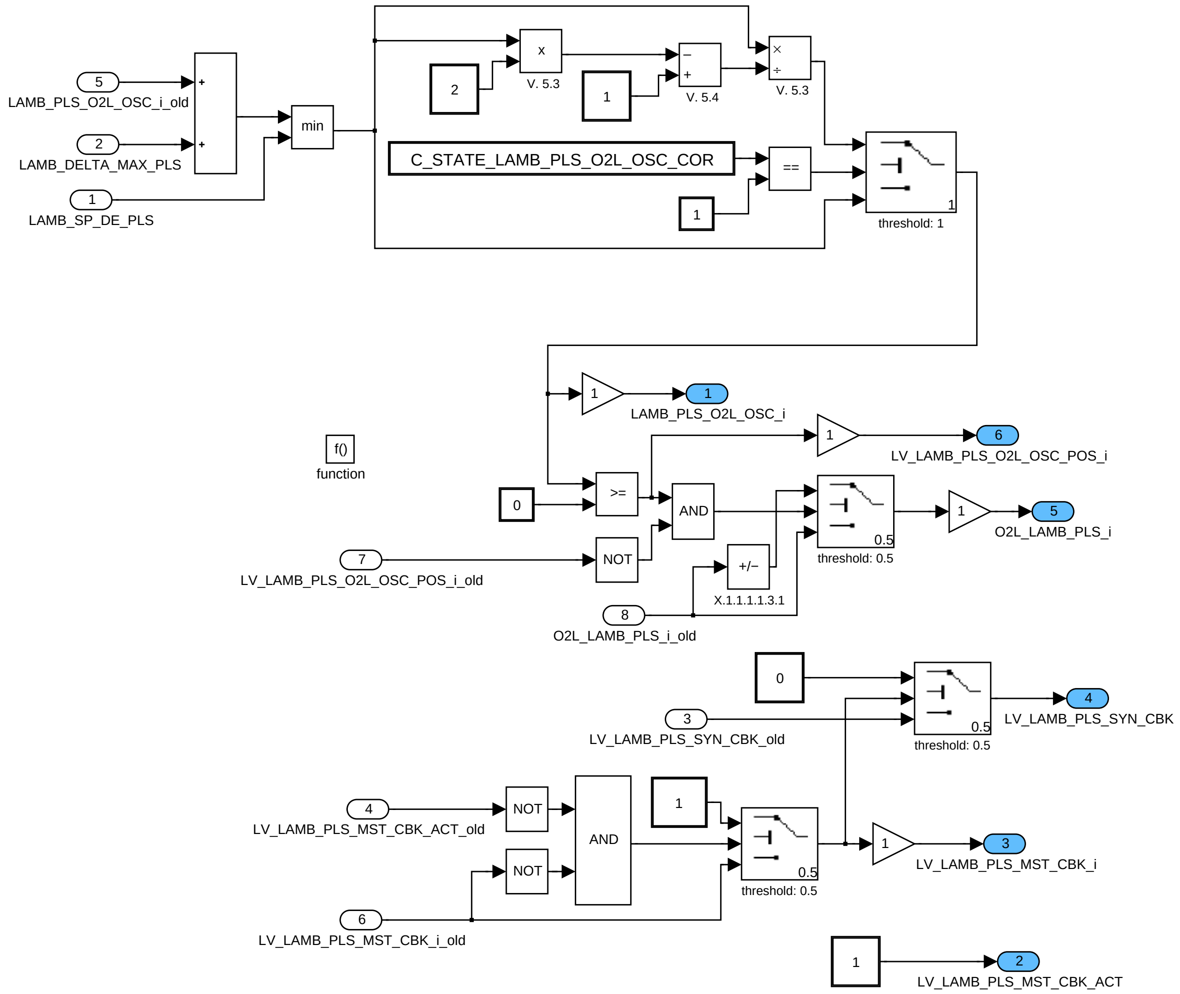

Figure 7.62.8: : Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC/STATE_LAMB_PLS__AFL

7.62.1.1.1.4 STATE "AFR":

In that state the lambda set point deviation LAMB_PLS_O2L_OSC[i] is decreased step wise by LAMB_DELTA_MAX_PLS and limited to minus LAMB_SP_DE_PLS.
If timesynchronous operation mode is activated with C_STATE_LAMB_PLS_O2L_OSC_COR = 2, the lambda set point deviation is not symmetric. The lean half wave is limited to LAMB_SP_DE_PLS, but the rich half wave is corrected to a slightly lower value.
If the LAMB_PLS_O2L_OSC[i] becomes negative (indicated by falling edge of LV_LAMB_PLS_O2L_POS[i]) the sign of the current O2 loading changes as in state AFL .

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

When the O2 loading set point is reached the master bank sets the synchronization flag.

7.64.1 LACO_ISPCLMVLDC0

This function calculates only differences between base values and their moving means values. These differences or deltas are to be used within the function that needs limited dynamic conditions. The evaluation of the limited dynamic bit is part of the function that need this flag. So the mean value calculation is concentrated in this function.

NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

Copyright (C) Continental AG,2007

Function Description

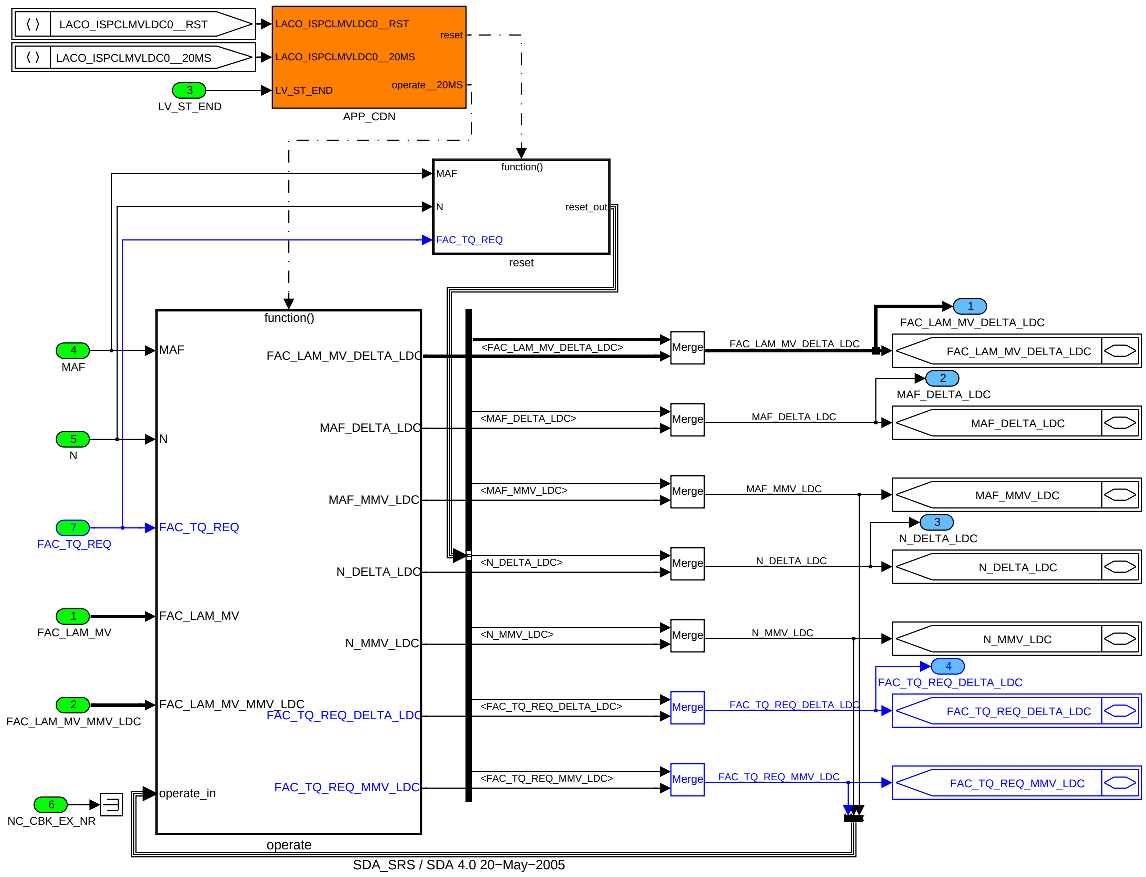

Figure 7.64.2: LACO_ISPCLMVLDC0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.64.1.1 SUBFUNCTION: reset

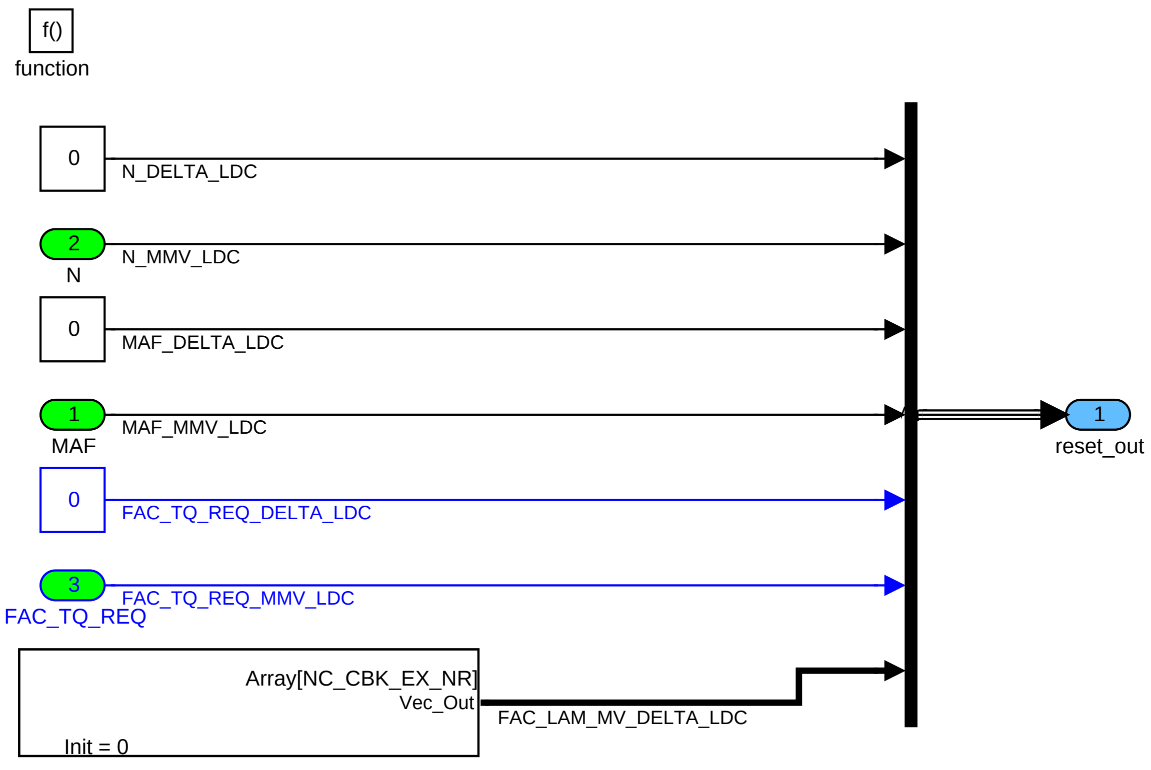

Figure 7.64.3: LACO_ISPCLMVLDC0/reset

7.64.1.2 operate

This function calculates for the detection of the limited dynamics the moving mean values of engine speed (N and N_MMV_LDC), air mass flow (MAF and MAF_MMV_LDC) and degree of activation of the accelerator pedal (PV and PV_AV_MMV_LDC). Furthermore the difference between these input values and the moving mean values is calculated.

For the lambda control output only the difference is evaluated because the moving mean value calculation is located in the lambda control module itself because of easier realisation of shift operations of the moving mean value (FAC_LAM_MV_MMV_LDC[i]).

Remark: The difference calculation of lambda control output is a vector operation.

General information:

The trim controller causes a shift of the WRAF sensor signal (upstream of the catalyst) or/and a shift of the lambda set point (in opposite direction). The output components (P share, I share, the sum of both or the adaptation value) of the trim controller can be linked in the application incidence for the lambda controller to corresponding inputs of the lambda controller. A compensation of ageing effects of the WRAF sensor as well as a better observance of the catalyst window is reached because of these shifts.
The control value is composed of P, I and D shares. All are determined depending on the trim control sensor signal (binary signal). The difference of the sensor voltage from set point value is the basic characteristic. The set point value can be applied depending on the operating point, so that the dynamic lambda can be adjusted according to the operating range.

The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application conditions:

Initialisation:	`RST`
Recurrence:	`20MS`
Activation:	`LV_ST_END == 1`
Deactivation:	`if activation not true`

Function description:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.65.2 Operation at 20ms

7.65.2.1 For loop (for i = 1 to NC_CBK_EX_NR)

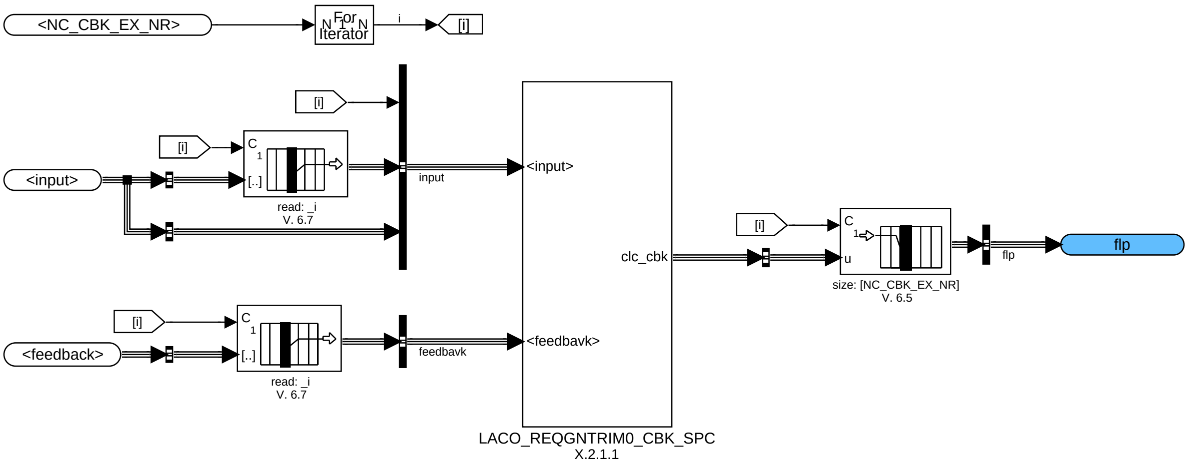

Figure 7.65.2: :

7.65.2.1.1 Calculation of for loop

7.65.2.1.1.1 Activation /deactivation of trim control (part I)

The trim controller is activated when the following conditions are fulfilled:
- no general inhibition
- the trim sensor is ready for operation
- the catalyst enrichment function is not active
- the lambda controller must be active
- the lambda controller must not be in short term in stop mode
- no output limitation of the lambda controller is active
- the catalyst is at operating temperature
- the catalyst efficiency is in the valid area
- the lambda set point must lie within calibration range
- no overheating protection with rich lambda is active

Before verifying the condition for P, I and/or D share activation, an air mass flow integral must exceed the threshold applied thresholds. These thresholds can be calibrated independently for P share, I share and D share activation. Depending on the deactivation reason different air mass flow integral thresholds can be applied. In case of hot start indicated by T_AST below limit and TCO above threshold the P share can be activated immediately if no other above mentioned activation condition is not fulfilled. The activation is realised by setting the MAF integral threshold for the P share to 0.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

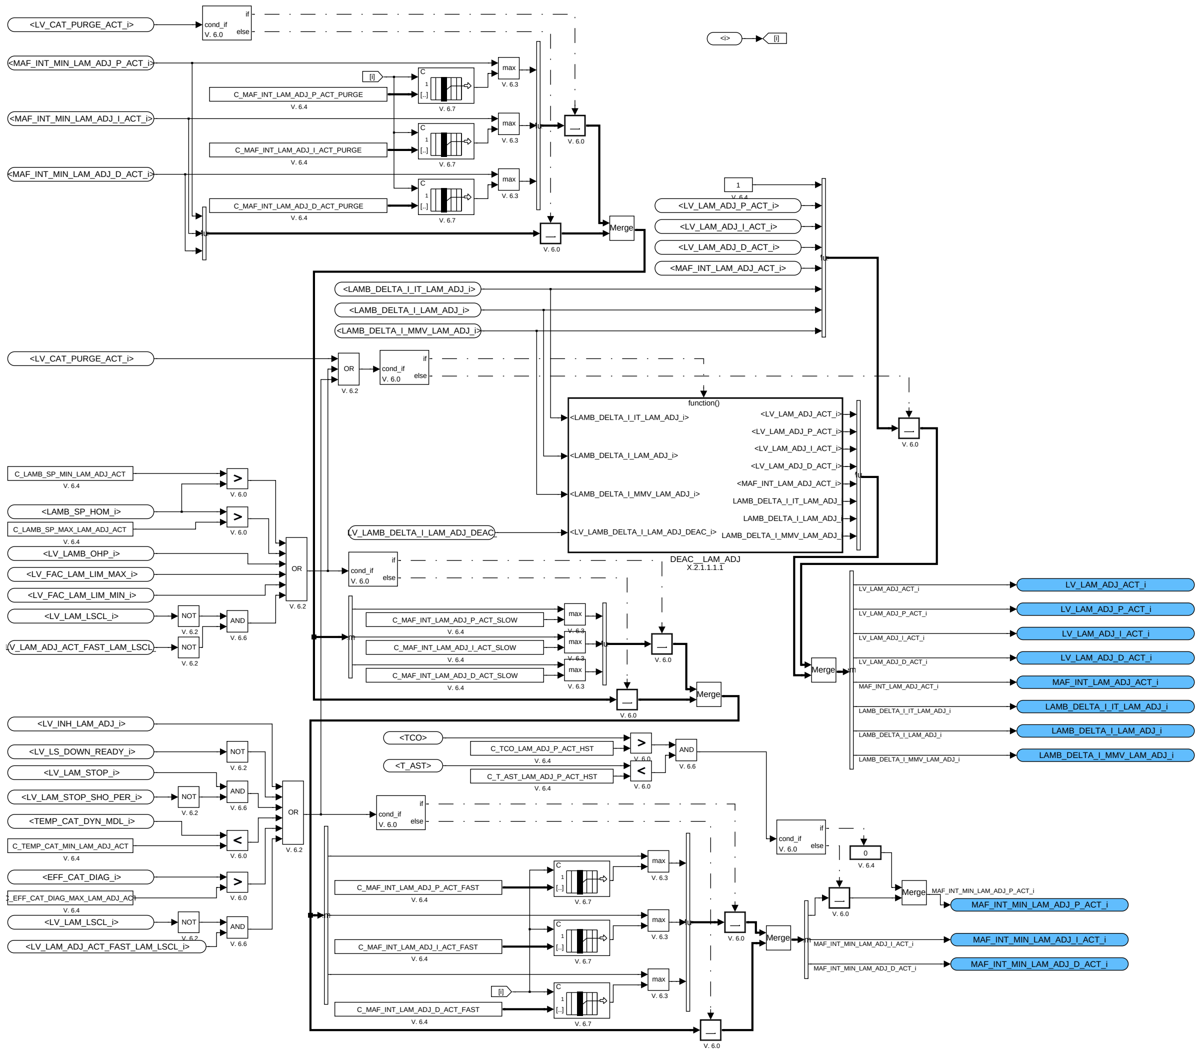

Figure 7.65.3: :

7.65.2.1.1.1.1 Deactivate trim controller

When deactivating the trim controller the P share and D share will get 0 and the I share remain fix (by deactivating the calualtion). If LV_LAMB_DELTA_I_LAM_ADJ_DEAC[i] was set to 0 (in the application incidences) then the I share is set to 0.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

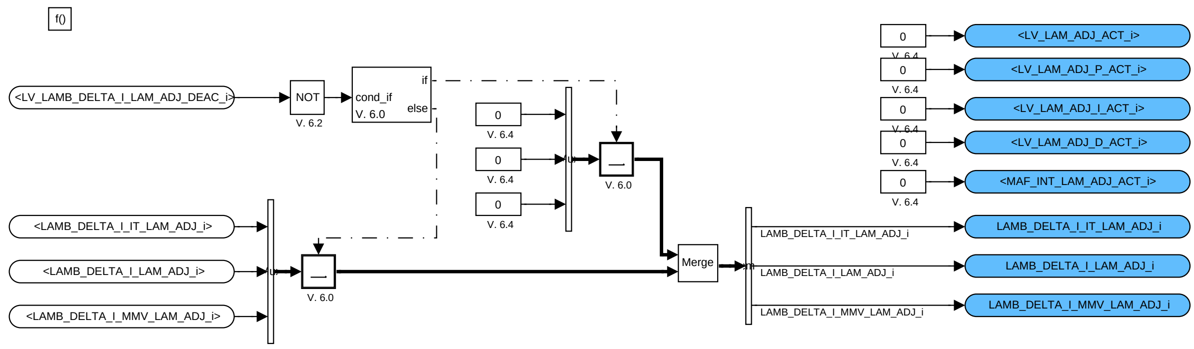

Figure 7.65.4: :

7.65.2.1.1.2 Activation /deactivation of trim control (part II)

When all conditions to activate the trim controller are fulfilled an air mass integral is started and the conditions for P, I and D share are checked separately.

For the calcuation of the air mass flow integral the unit conversion:
[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600
has to be considered.

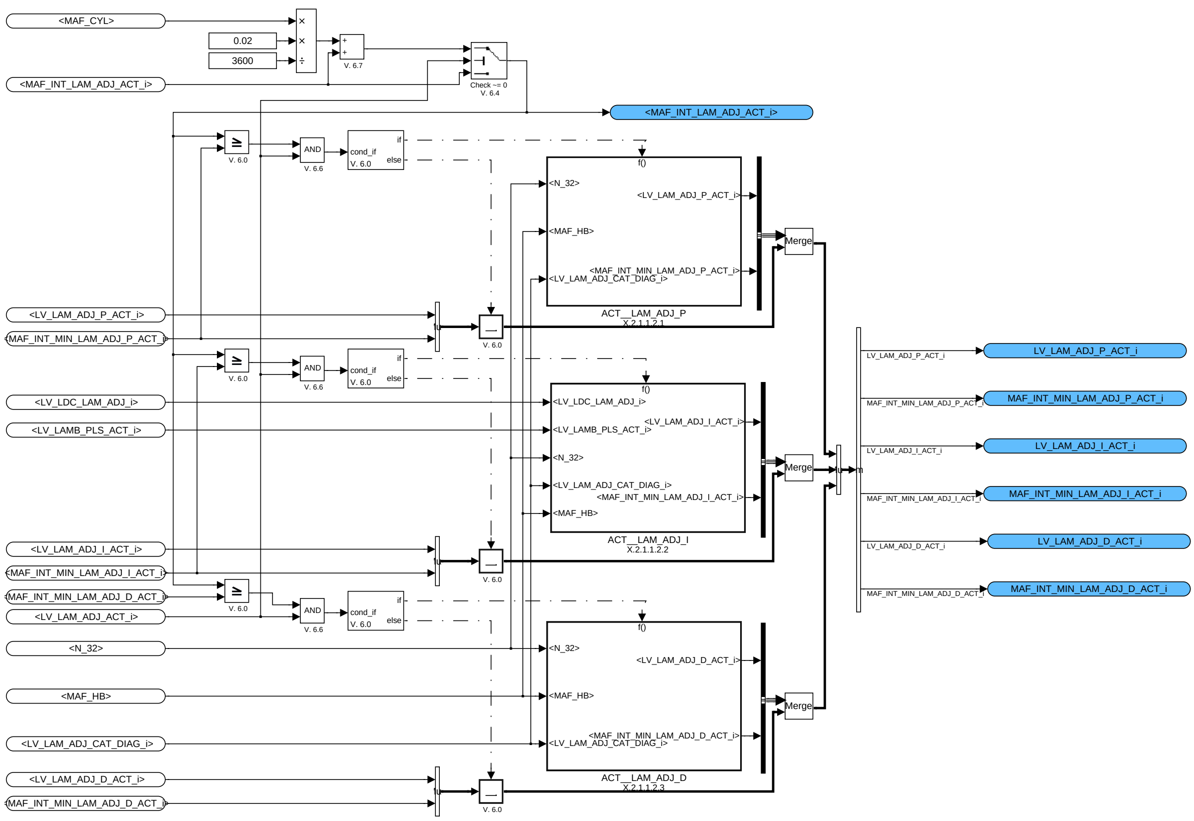

Figure 7.65.5: :

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.65.2.1.1.2.1 Check P share activation conditions

The P share calculation gets active (indicated by LV_LAM_ADJ_P_ACT[i] after the P share MAF integral threshold is exceeded - only in applied N and MAF areas or when catalyst efficiency diagnosis or CYBL homogeneous activity is active.

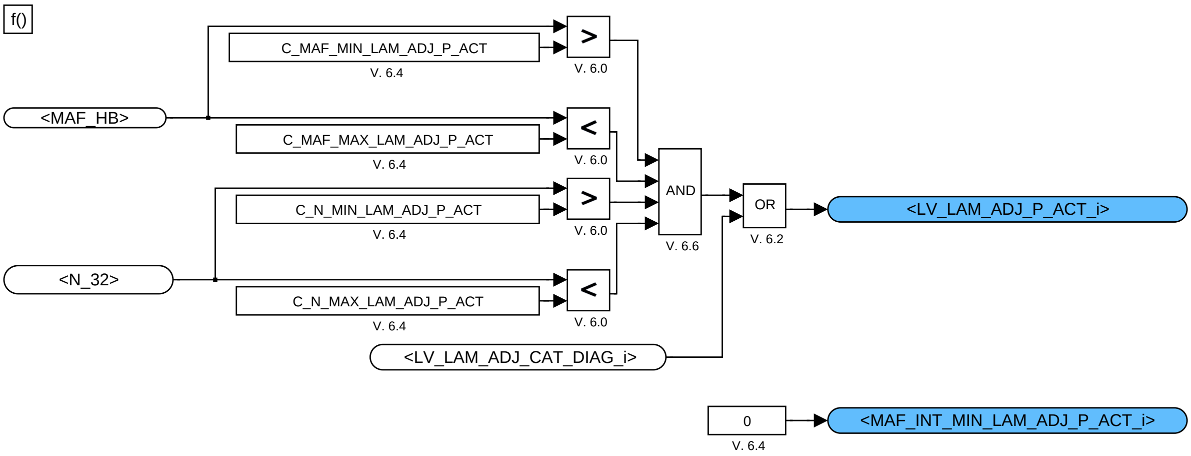

Figure 7.65.6: :

7.65.2.1.1.2.2 Check I share activation conditions

The I share calculation gets active (indicated by LV_LAM_ADJ_I_ACT[i]) after the I share MAF integral threshold is exceeded - in applied MAF areas when the limited dynamics conditions are fulfilled and when the forced lambda stimulation is active. Both latter conditions can be inhibited by means of calibration flags. During active cat efficiency diagnosis or CYBL homogeneous activity the I share is always active after exceeding the MAF integral threshold.

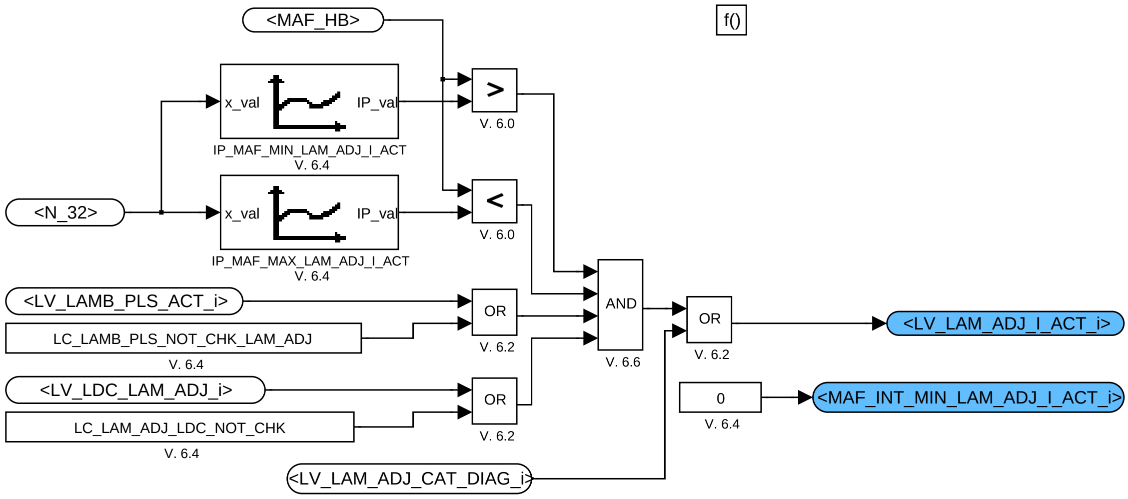

Figure 7.65.7: :

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.65.2.1.1.2.3 Check D share activation conditions

The D share calculation gets active (indicated by LV_LAM_ADJ_D_ACT[i] after the D share MAF integral threshold is exceeded - only in applied N and MAF areas and when the catalyst efficiency diagnosis is not active or when CYBL homogeneous activity is active.

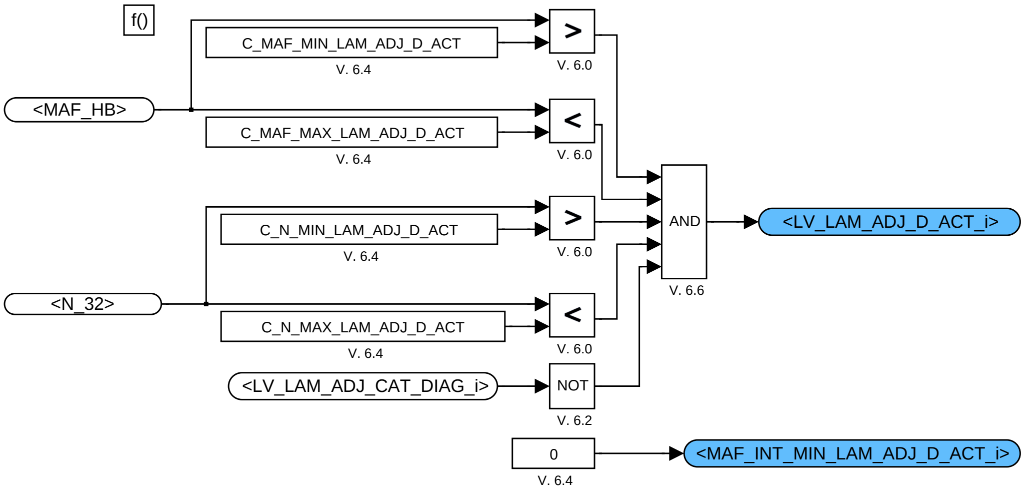

Figure 7.65.8: :

7.65.2.1.1.3 Calculation of controller difference

The controller deviation is defined by the difference of the set point of the sensor output voltage IP_VLS_SP_LAM_ADJ[i] and the actual value VLS_AV_LAM_ADJ[i]. The setpoint can be shifted by IP_VLS_SP_DELTA_LAM_ADJ depending on catalyst ageing to take into account stringent NOx increase with catalyst ageing.
VLS_AV_LAM_ADJ[i] is calculated in the application incidences and can be directly the measured trim sensor signal or the filtered and shifted signal in case of Catalyst diagnosis (depending on project requirements). The actual value can also inlude an external adjustment.

Copyright (C) Continental AG,2007

7.65.2.1.1.4 P share calculation

The P share is calculated when LV_LAM_ADJ_P_ACT[i] is 1. Otherwise the P share is 0. In case of active catalyst diagnosis an own P share gain characteristic line is used.

7.65.2.1.1.4.1.5 P share calculation in case of normal state

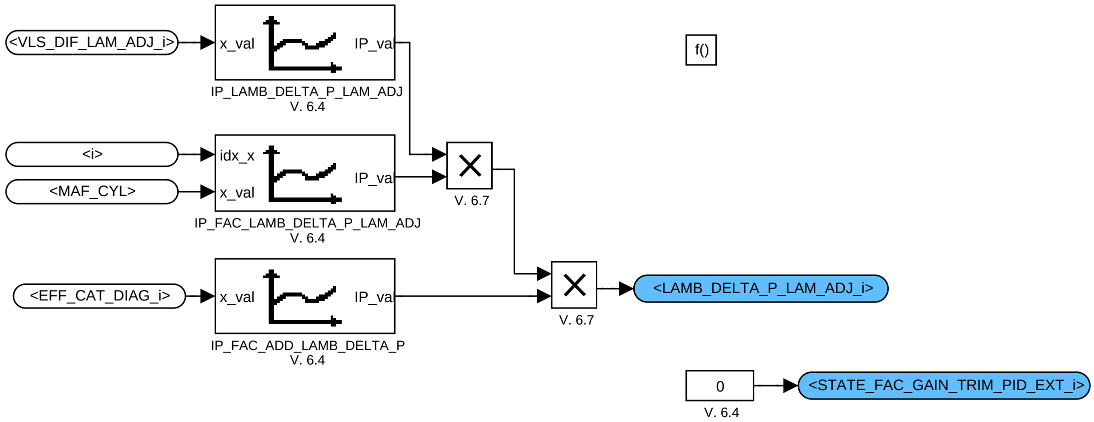

Figure 7.65.16: :

7.65.2.1.1.5 I share calculation management

The I share itself is calculated internally with a higher resolution than the output variable LAMB_DELTA_I_LAM_ADJ[i]. The variable LAMB_DELTA_I_IT_LAM_ADJ[i] is used. A limitation of calibration thresholds (C_LAMB_DELTA_I_MIN_LAM_ADJ and C_LAMB_DELTA_I_MAX_LAM_ADJ) is applied at the end of the calculation. Both variables are initialised with the adaptation value LAMB_DELTA_AD_LAM_ADJ[i].
The I share is only calculated when LV_LAM_ADJ_I_ACT[i] is 1. The calculation is the summation of IP_LAMB_DELTA_I_LAM_ADJ * IP_CRLC_LAMB_DELTA_I_LAM_ADJ. This latter map is for MAF_CYL weighting. If the I share is not calculated it remains fix.
A moving mean value of the I share LAMB_DELTA_I_MMV_LAM_ADJ[i] (needed for WRAF sensor characterisitc line adaptation) is calculated.
In case of active catalyst diagnosis and sensor dynamic diagnosis own parameters are applied (IP_LAMB_DELTA_I_LAM_ADJ_DIAG multiplied by IP_CRLC_LAMB_DELTA_I_LAM_ADJ) and the moving mean value of the I share is not calculated. When cat diagnosis gets active the I share is stored. It is written back to the corresponding variable at the end of the diagnosis only in case that LC_LAM_ADJ_I_SAVE_CAT_DIAG is set to 1.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.65.2.1.1.6 D share calculation

The D share is calculated when LV_LAM_ADJ_D_ACT[i] is 1. The D share is calculated by evaluating the voltage difference between the control difference and its moving mean value. The filter parameter for moving mean value is MAF_CYL and EFF_CAT_DIAG depending to take into account longer needed duration of D-share at low MAF_CYL and shorter due to OSC deterioring due to catalyst ageing This voltage difference is then input to a characteristic line IP_LAMB_DELTA_D_LAM_ADJ that is weighted by MAF_CYL and EFF_CAT_DIAG[i].

LC_VAR_EX_CUS	-	0... 1H	0 ...1	1	-
Switch to an exhaust gas configuration with 2 linear and 1 binary O2 sensor (LC = 1)					

General information:

There are many errors which make it necessary to stop the trim control when they occure.
The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank

basic characteric line shift of WRAF sensor					

General Information

This function adapts the WRAF sensor characterisic line by observing the I share of the trim control function. A basic (load depending) lambda shift of the WRAF sensor can be corrected by means of an additional offset. This offset can change due to ageing of the sensor.

The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Conditions

Initialization: RST, NVMINI, NVMRES, NVMSTO
Recurrence: 100MS
Activation: LV_ST_END == 1
Deactivation: never

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.67.1.2 Initialization of non volatile memory

7.67.1.3 Read non volatile memory

7.67.1.4 Store non volatile memory

7.67.2 Operation at 100ms

7.67.2.1 For loop

7.67.2.1.1 Basic WRAF sensor characteristic line shift

7.67.2.1.1.1 Conditions check for WRAF sensor characteristic line adaptation

By means of IP_LAMB_DELTA_BAS_LAM_ADJ[i] the basic sensor characteristic line shift is defined MAF and N dependent. In idle speed the calibration data C_LAMB_DELTA_BAS_LAM_ADJ_IS[i] is applied. Together with the adaptive correction LAMB_DELTA_AD_LAM_ADJ[i] (stored as non volatile data) the total shift LAMB_DELTA_SUM_LAM_ADJ_AD[i] is defined.

When the conditions for activating the adaptation are fulfilled the subsystem CLC_AD_CDN_OK is executed. Otherwise the subsystem CLC_AD_CDN_NOT_OK is called where no action is executed.

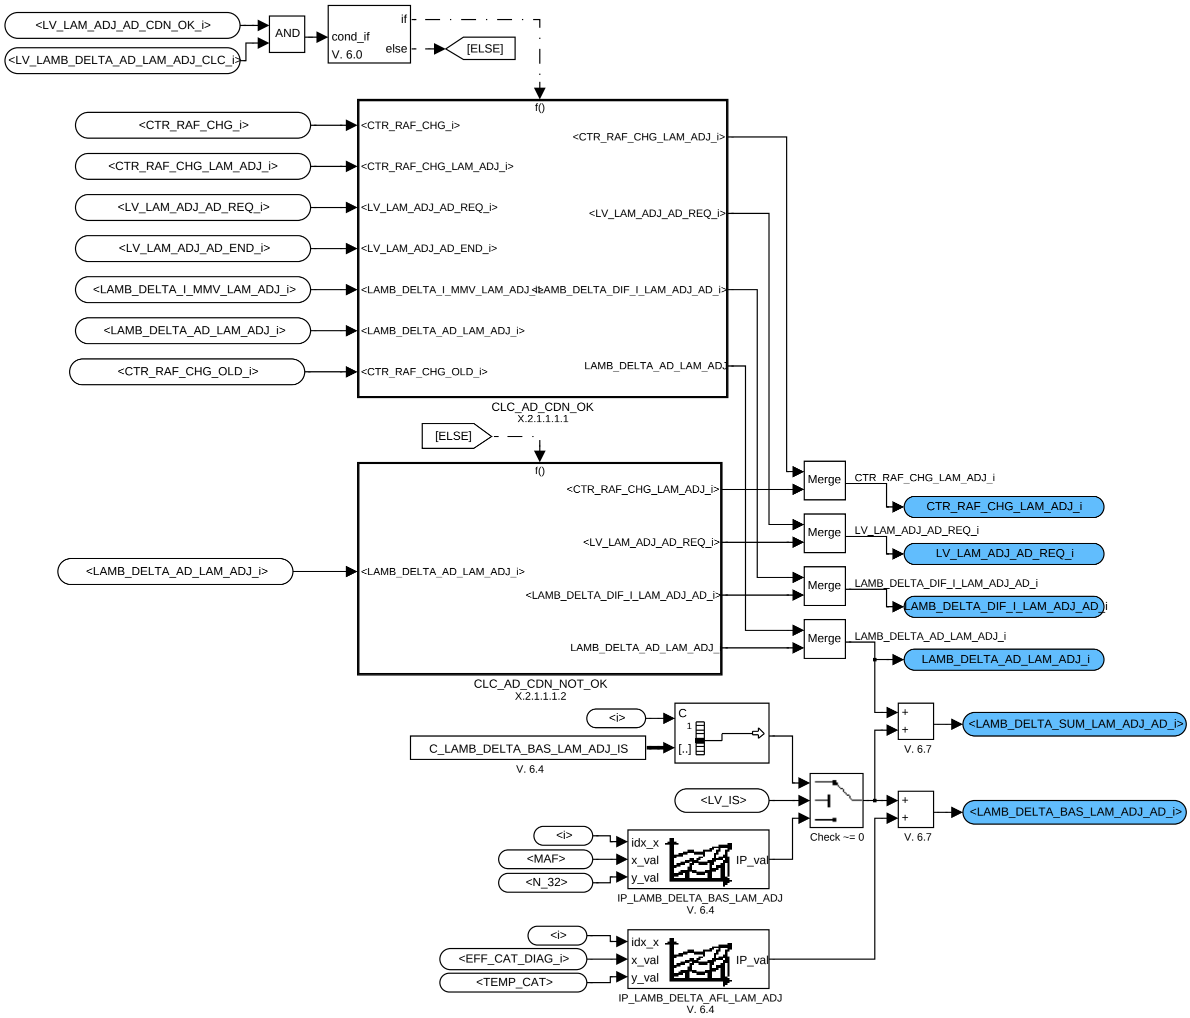

Figure 7.67.2: :

7.67.2.1.1.1.1 Adaptation of WRAF sensor characteristic line offset

The function waits a certain number of lean rich air fuel ratio changes (C_NR_RAF_CHG_WAIT_LAM_ADJ) between 2 adaptation cycles. Then the current I share of the trim controller is shifted step by step into the adaptation value. Furthermore this latter value is limited on a calibration maximum and minimum.

7.68.1 LACO_REQGNTRCDN0

This function checks several conditions that must be fulfilled in order to start the WRAF sensor characteristic line adaption. These conditions shall define a stable state of the downstream sensor signal used by trim control.

The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.

Check conditions

If all the following conditions are fulfilled an air mass flow integral is calulated:

Catalyst efficiency diangnosis not active

limited dynamics (LV_LDC_LAM_ADJ[i]) are fulfilled

I share of trim control is active

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

forced lambda stimulation is active
canister purge valve is closed
air mass flow is in a valid range
engine speed is in a valid range
P share of trim contol must be very low (absolute value)
I share of trim control must be stable
(difference between I share and moving mean value must be small)

When the air mass flow integral exceeds a calibration threshold the flag LV_LAM_ADJ_AD_CDN_OK[i] indicating that the adaptation can be started is set.

For the calcuation of the air mass flow integral the unit conversion:
[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600
has to be considered.

FUNCTION DESCRIPTION:

General information:

For a two bank exhaust gas configuration the calculation of the limited dynamic condition LV_LDC_DLY[i] is calculated for each bank separately. To differentiate variables and calibration data the index i is used.

i = 1, for cylinder bank 1
i = 2, for cylinder bank 2

The limited dynamic conditions LV_LDC_DLY[i] for dynamic fuel trim is detected if engine speed, mass air flow, FAC_LAM_MV[i] and the factor torque request gradient are within the correspondent dynamic window. Once this condition is met, an integral of the air flow is incremented until the calibrated threshold exceeds. After this point the flag LV_LDC_DLY[i] is set to indicate the trim controller, that the engine is running under limited dynamic conditions.

Application conditions

Initialisation:
```
at reset:
 LV_LDC_DLY[i] = 0
 MAF_INT_LDC_DLY[i] =  0
```

Recurrence: 20ms

Activation:
```
 LV_VAR_LSH_UP = 1  and  LV_ST_END = 1  and  LV_IGK = 1
```

Deactivation:
```
LV_VAR_LSH_UP = 0  or   LV_ST_END = 0  or  LV_IGK = 0
   Initialisation at deactivation:
 LV_LDC_DLY[i] = 0
 LV_N_LDC_DLY = 0
 LV_MAF_LDC_DLY = 0
 MAF_INT_LDC_DLY[i] =  0
   N_MMV_DLY          =    N
   MAF_MMV_DLY        =   MAF
 FAC_LAM_MV_MMV_DLY[i]  = FAC_LAM_MV[i]
 FAC_TQ_REQ_GRD_SUM_DLY   =  0
```

Formula section:

7.69.1 Calculation of the factor torque request gradient FAC_TQ_REQ_GRD

At every recurrence the variable FAC_TQ_REQ shall be written into a ring buffer containing the last four FAC_TQ_REQ values. The gradient of FAC_TQ_REQ (FAC_TQ_REQ_GRD) is calculated based on the FAC_TQ_REQ difference between the values contained in the first and last position of the ring buffer.

7.69.2 Limited engine speed (N) dynamics

The floating mean value N_MMV_DLY is computed using the averaging constant C_N_CRLC_DLY. The limited dynamics condition only exist while the engine speed N lies within the dynamics window around N_MMV_DLY.
If the above limited dynamics condition is violated, the floating mean value N_MMV_DLY is set to the current engine speed in order to reach the limited dynamics condition faster:

N_MMV_DLY = N_MMV_DLY * (1 - C_N_CRLC_DLY) + C_N_CRLC_DLY * N

IF | N - N_MMV_DLY | < C_N_DYW_DLY
  THEN LV_N_LDC_DLY = 1
  ELSE LV_N_LDC_DLY = 0
    N_MMV_DLY = N
ENDIF

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.69.3 Limited mass air flow (MAF) dynamics

The floating mean value MAF_MMV_DLY is computed using the averaging constant C_MAF_CRLC_DLY. The limited dynamics condition only exist while the air mass MAF stays within the dynamics window around MAF_MMV_DLY.
If the above limited dynamics condition is violated, the floating mean value MAF_MMV_DLY is set to the current air-mass value in order to reach the limited dynamics condition faster:

IF LV_N_LDC_DLY = 1
THEN
MAF_MMV_DLY = MAF_MMV_DLY * (1 - C_MAF_CRLC_DLY) +
C_MAF_CRLC_DLY * MAF

IF | MAF - MAF_MMV_DLY | $<$ C_MAF_DYW_DLY
THEN LV_MAF_LDC_DLY = 1
ELSE LV_MAF_LDC_DLY = 0
MAF_MMV_DLY = MAF
ENDIF
ELSE
MAF_MMV_DLY = MAF
LV_MAF_LDC_DLY = 0
LV_LDC_DLY[i] = 0
MAF_INT_LDC_DLY[i] = 0
ENDIF

7.69.4 Limited requested torque factor gradient (FAC_TQ_REQ_GRD) dynamics

The FAC_TQ_REQ_GRD reflects the dynamic of the actual driver's demand prior to the corrections and is calculated with the recurence T_SAMPLE in [ms].
If C_FAC_TQ_REQ_GRD_SUM_MIN is larger than C_FAC_TQ_REQ_GRD_SUM_MAX the FAC_TQ_REQ gradient summation FAC_TQ_REQ_GRD_SUM_LDC_DLY will be no condition to determine the limited dynamic bit LV_LDC_DLY[i].

IF(3) LV_MAF_LDC_DLY = 1
THEN(3)

ENDIF(3)
```

7.69.5 Limited mean lambda controller output (FAC_LAM_MV[i]) dynamics

The floating mean value of the mean lambda controller output FAC_LAM_MV_MMV_DLY[i] is computed by using the averaging constant C_FAC_LAM_MV_CRLC_DLY. The limited dynamics condition is present while FAC_LAM_MV[i] stays within the dynamics window around FAC_LAM_MV_MMV_DLY[i]. If this condition violated, the correspondent flag is reset indicating a dynamic condition is present and the floating mean value FAC_LAM_MV_MMV_DLY[i] is set to the current value in order to reach the limited dynamics condition faster.

```
IF LV_FAC_TQ_REQ_LDC_DLY    =    1
THEN
  FAC_LAM_MV_MMV_DLY[i]   =
               FAC_LAM_MV_MMV_DLY[i] * (1 - C_LAM_MV_CRLC_DLY) +
                                           C_LAM_MV_CRLC_DLY * FAC_LAM_MV[i]

  IF | FAC_LAM_MV[i] - FAC_LAM_MV_MMV_DLY[i] | < C_LAM_MV_DYW_DLY
  THEN  LV_LAM_MV_LDC_DLY[i] = 1
  ELSE  LV_LAM_MV_LDC_DLY[i] = 0
              FAC_LAM_MV_MMV_DLY[i]   = FAC_LAM_MV[i]
```

General Information

In order to compensate serial production tolerances of components, an adaptive correction is calculated (one additive and two multiplicative) based on the filtered lambda controller output.
The additive and multiplicative adaptation corrections are used for calculating the injection time for all engine operating states, except at engine stop and engine start .
Lambda adaptation, for precision reason, needs to be performed at lambda equal 1 conditions. The function itself is activated by the corresponding LV_LAM_AD_ACT[i].
Depending on load and engine speed three different adaptation fields (one offset and two factor areas) are observed.

Adaptation field diagram

According to project philosophy homogeneous mode and suitable conditions can be forced by setting:
LC_MFF_ADD_RNG_AFS_REQ_LAM_AD,
LC_FAC_L_RNG_AFS_REQ_LAM_AD and /or
LC_FAC_H_RNG_AFS_REQ_LAM_AD.

Furthermore this function is used by the lambda adaptation in warmup phase to provide an unique interface to lambda controller and fuel mass set point calculation.

NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

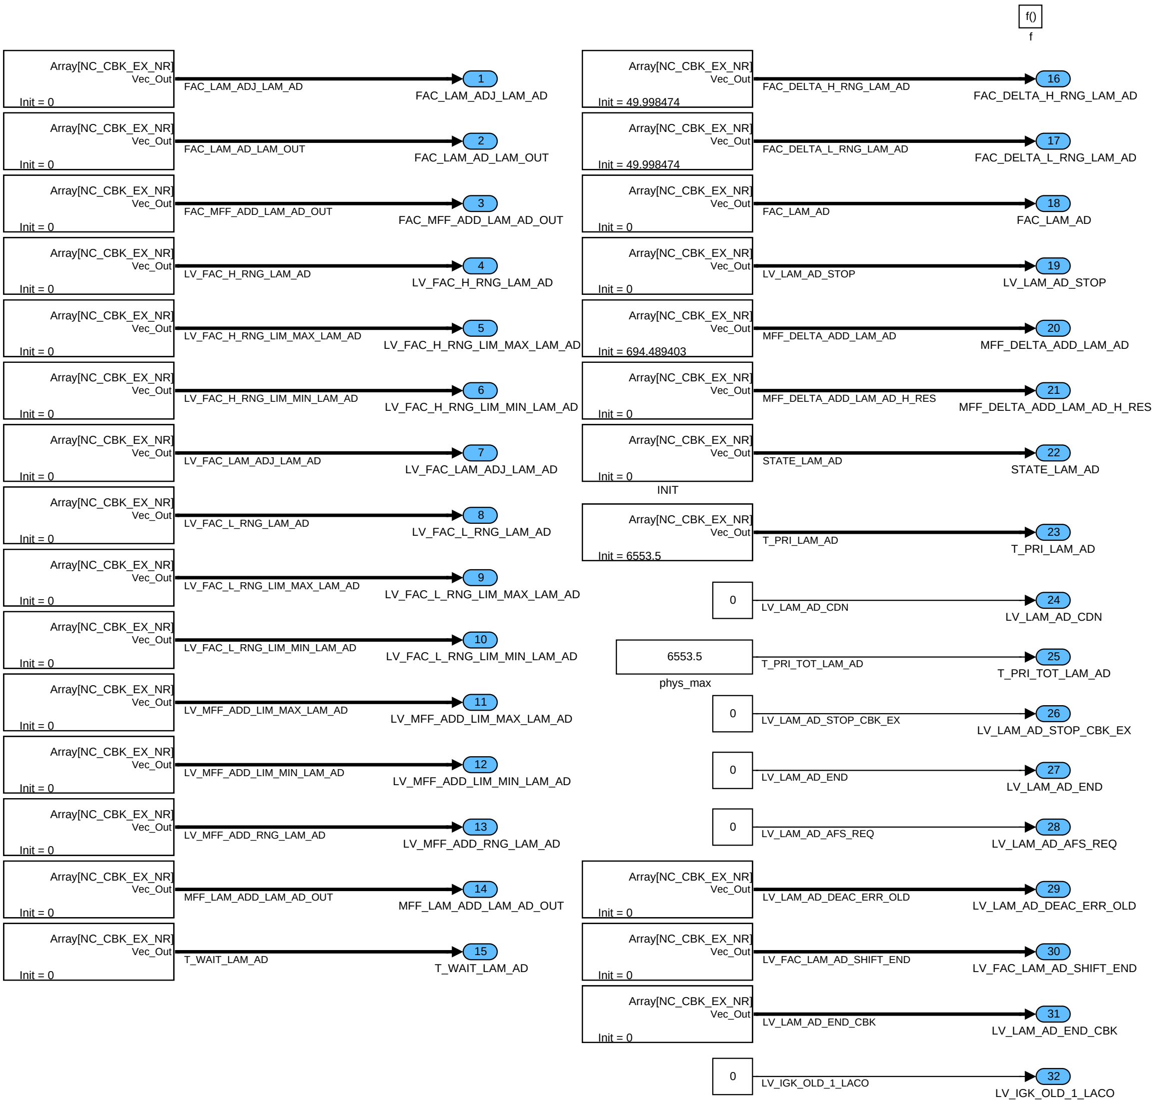

Figure 7.70.3: LACO_ISPCLADA0/INI/RST

Non Volatile Memory Data

MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i], FAC_H_RNG_LAM_AD[i] and FAC_MFF_ADD_FAC_LAM_AD[i] are stored in the NVMY (at the end of PWL phase) and read out at ECU reset.
If the ECU is brand new or in case of EEPROM error these data are set to the default value 0.
Furthermore the variables MFF_ADD_LAM_AD_TMP[i], FAC_L_RNG_LAM_AD_TMP[i] and FAC_H_RNG_LAM_AD_TMP[i] are used to store the initial values of MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i] and FAC_H_RNG_LAM_AD[i] during the whole driving cycle for potential use.
If the low range or the high adaptation value is zero indicating that the adaptation value was not yet learned since the last reset of the NVMY data, LV_FAC_L_RNG_LAM_AD_INI[i] respectively LV_FAC_H_RNG_LAM_AD_INI[i] are set to one.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.70.2 Formula Section

The main functionality is executed by means of a FOR loop over the number of exhaust banks. Only the determination of the priority information for the priority manager between canister purge and lambda adaptation is independent of the number of exhaust banks and executed after the FOR loop.

For Loop over Number of Exhaust Banks

Initialization of FOR Loop

Set Variables

Before executing the for loop variables are initialized.

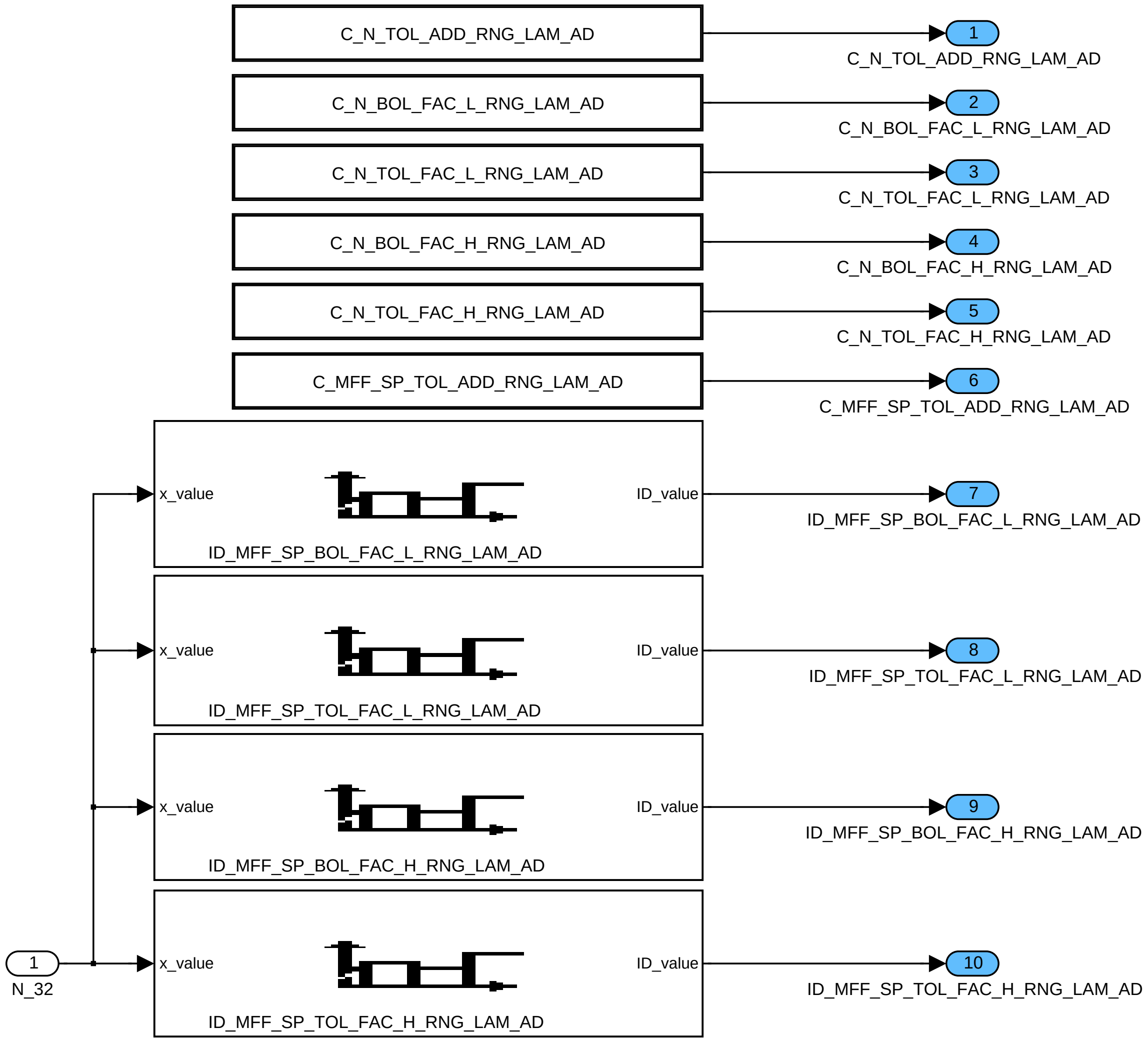

Figure 7.70.5:
LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/DET_STATE_LAM_AD/SET_CAL_VALUE

State Machine

If the lambda adaptation is not active the state INIT is applied.
If the engine is not running in one of the adaptation fields the state WAIT is applied.
Depending on fuel mass flow and engine speed limits the respective states are entered.
If the respective condition bit LV_LAM_AD_CDN_ADD; LV_LAM_AD_CDN_L_RNG or LV_LAM_AD_CDN_H_RNG is set, the adaptation state ADAPT_ADD, ADAPT_FAC_L or ADAPT_FAC_H is applied.
Otherwise one of the condition states is applied (CDN_ADD, CDN_FAC_L or CDN_FAC_H).
Furthermore at each transition to one of the adaptation sates the counter CTR_RAF_CHG_LAM_AD[i] is set to 0.

The following flags are set in any state.
LV_LAM_AD_CDN is indicating that the conditions for adaptation are fulfilled (used by priority manager between canister purge and lambda adaptation).
LV_LAM_AD_END sets the temporary end of lambda adaptation (to indicate to the priority manager that the priority for lambda adaptation is low).
LV_LAM_AD_AFS_REQ (if set to 1) requests stoichiometric mixture.
LV_MFF_ADD_RNG_LAM_AD[i], LV_FAC_L_RNG_LAM_AD[i] and LV_FAC_H_RNG_LAM_AD[i] are indicating that the lambda adaptation is active and running in the respective adaptation field.

State INIT

Set Variables

The general flags are set to 0. All other variables remain unchanged.

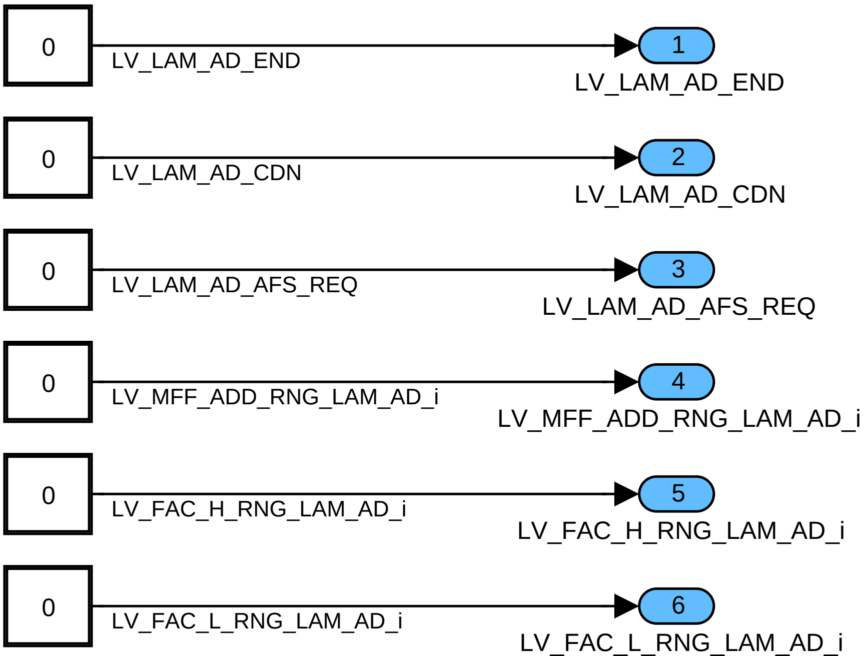

Figure 7.70.7:
LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/STATE_ACTION/INI/SET_VALUE

State WAIT

Set Variables

The general flags are set to 0. The time T_PRI_LAM_AD[i] is set to the maximum value of the 3 adaptation fields. All other variables remain unchanged.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

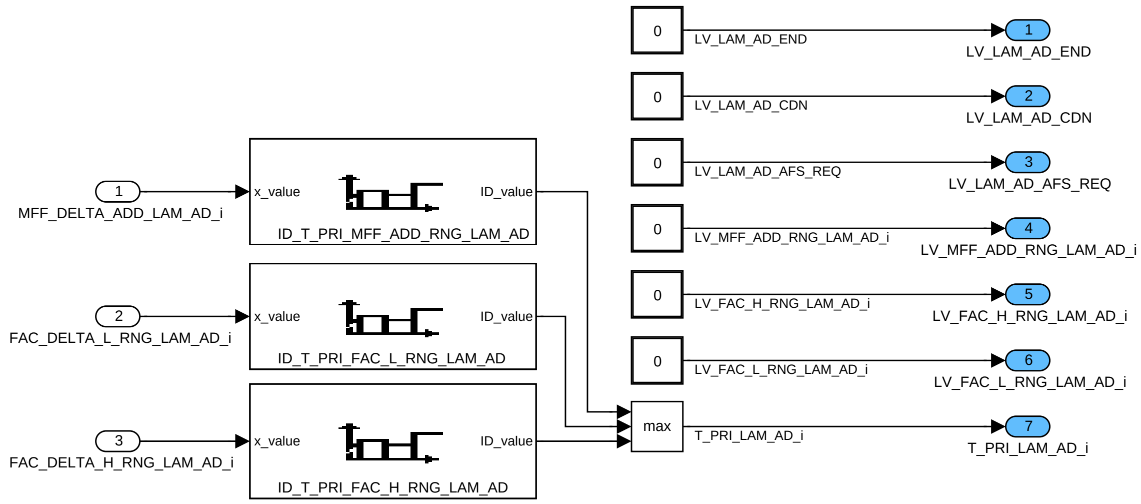

Figure 7.70.8:
LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/STATE_ACTION/WAIT/SET_VALUE

State CDN_ADD

Set Variables

LV_LAM_AD_CDN is set to 1 as the load conditions for adaptation are fulfilled.
If LV_LAM_AD_ENA is set by the priority manager and stoichiometry request is allowed for offset adaptation by means of the respective calibration flag LV_LAM_AD_AFS_REQ is set to 1.
T_PRI_LAM_AD[i] is set depending on the last learned value in this adaptation field.
The other general flags are set to 0 and all other variables remain unchanged.

Wait Timer threshold reached

Calculation of lambda controller shift

In order to apply the lambda controller shift with the same amount as the lambda adaptation shift FAC_LAM_ADJ_LAM_AD[i] is calculated based on the lambda controller output and a correlation constant (defined in application incidences) The respective lambda adaptation shift is calculated (with high resolution by the internal variable MFF_DELTA_ADD_LAM_AD_H_RES[i]) by multiplying FAC_LAM_ADJ_LAM_AD[i] with the fuel mass flow set point. The result is assigned to MFF_DELTA_ADD_LAM_AD[i] which is the lambda adaptation shift that is finally applied.
The variable MFF_DELTA_ADD_LAM_AD[i] will be 0 as long as the absolute value of MFF_DELTA_ADD_LAM_AD_H_RES[i] is below the resolution of MFF_DELTA_ADD_LAM_AD[i]

Shift of adaptation values by external function

External functions might require an inverse step change in the Lambda adaptation value. The control of the value shift takes place in the external function and is indicated by the flags LV_FAC_LAM_AD_SHIFT[i].

The Lambda adaptation is shifted if the condition LV_FAC_LAM_AD_SHIFT[i] = 1 is valid. This variable is to be reset if the Lambda adaptation shift was carried out. That requires a confirmation of the executed controller shift. The confirmation is done by setting the variable LV_FAC_LAM_AD_SHIFT_END[i] to 1.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

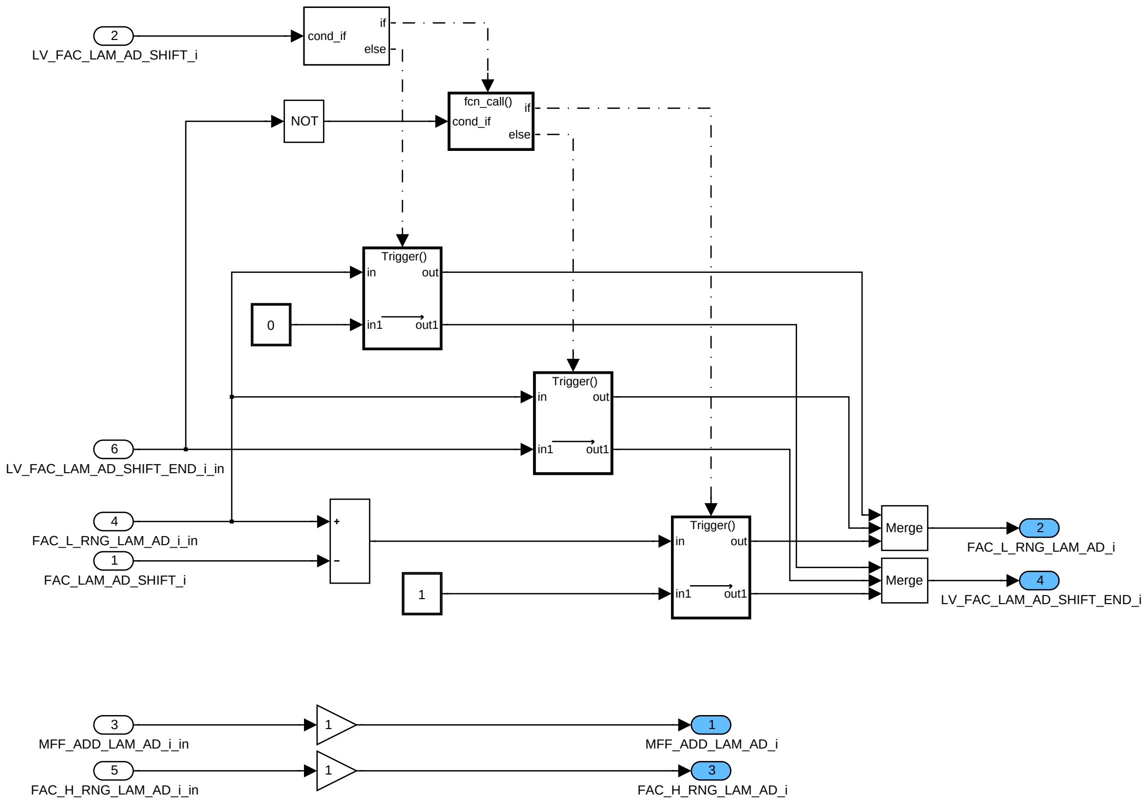

Figure 7.70.35: LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/CLC_CMN/SHIFT_LAM_AD

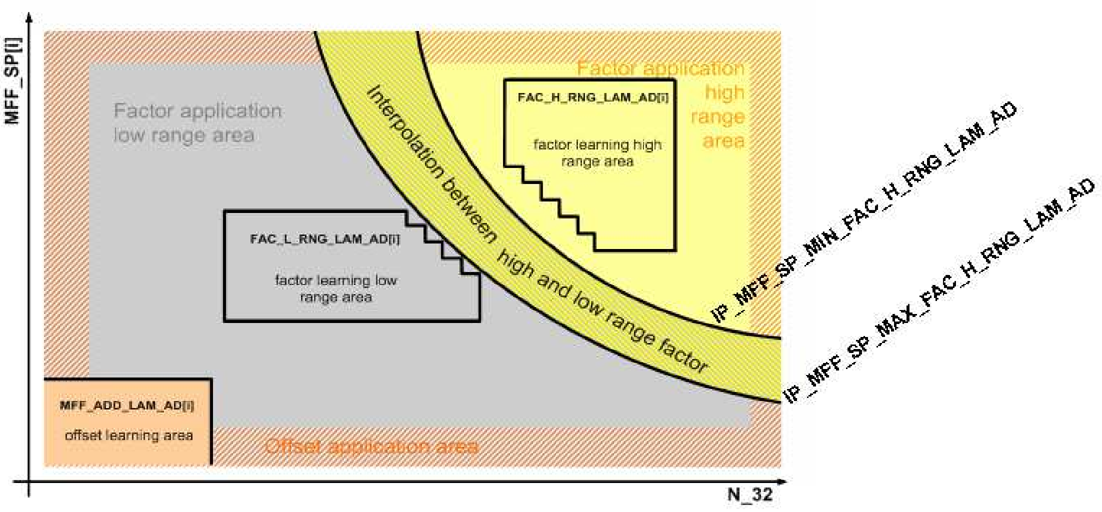
Determination of Interpolated Lambda Adaptation Factor

In order to meet the physical behaviour of engine components (especially the air mass flow sensor), the actual multiplicative factor is calculated out of the two determined factors by interpolation at every state. Interpolation is applied between the borders
IP_MFF_SP_MAX_FAC_H_RNG_LAM_AD (lower border) and
IP_MFF_SP_MIN_FAC_H_RNG_LAM_AD (upper border)
as shown in the figure.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Interpolation of adaptation factors

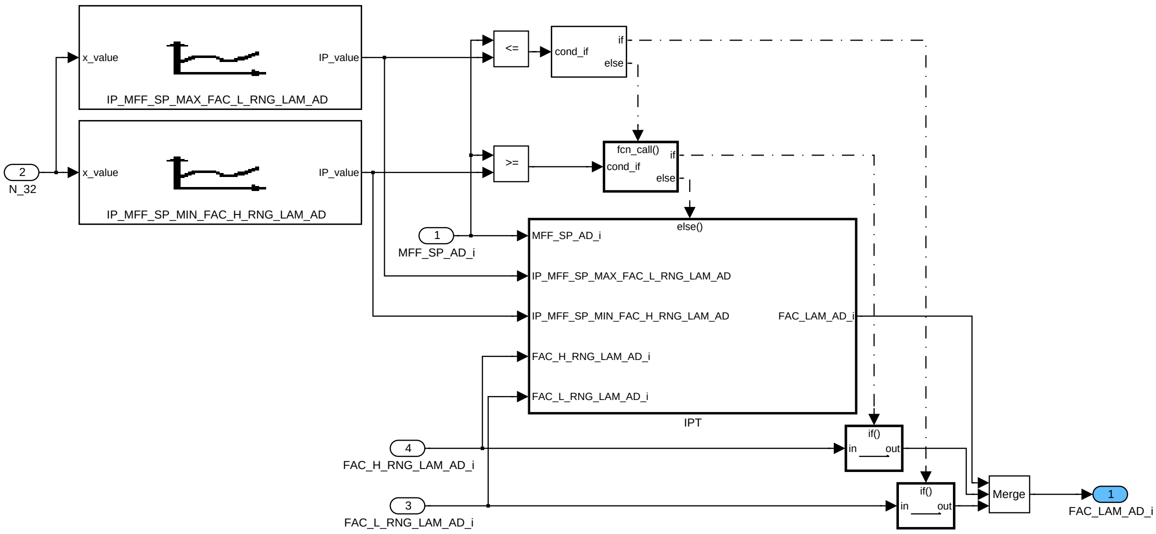


Figure 7.70.36:
LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/CLC_CMN/CLC_FAC_LAM_AD

Calculation of Output Signals for Fuel Mass Flow Set Point Correction

In order to avoid mixture problems when the engine has not reached its service temperature (warm up), lambda adaptation factors and their corresponding relative intermediate results can be decreased versus TCO and their own value (which is applied when the engine has its service temperature).
This is performed by weighting the adaptive factors as long as the lambda adaptation is disabled due to TCO C_TCO_MIN_LAM_AD (see: "application incidences").
The quotient of the additive relative factor is determined. The values MFF_LAM_ADD_LAM_AD_OUT[i] and MFF_SP[i] should be conditioned so, that FAC_MFF_ADD_LAM_AD_OUT[i] does not exceed the physical range of +/100 %!
The relative lambda adaptation FAC_MFF_ADD_FAC_LAM_AD[i] as long term adaptation is calculated out of both adaptation factors.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

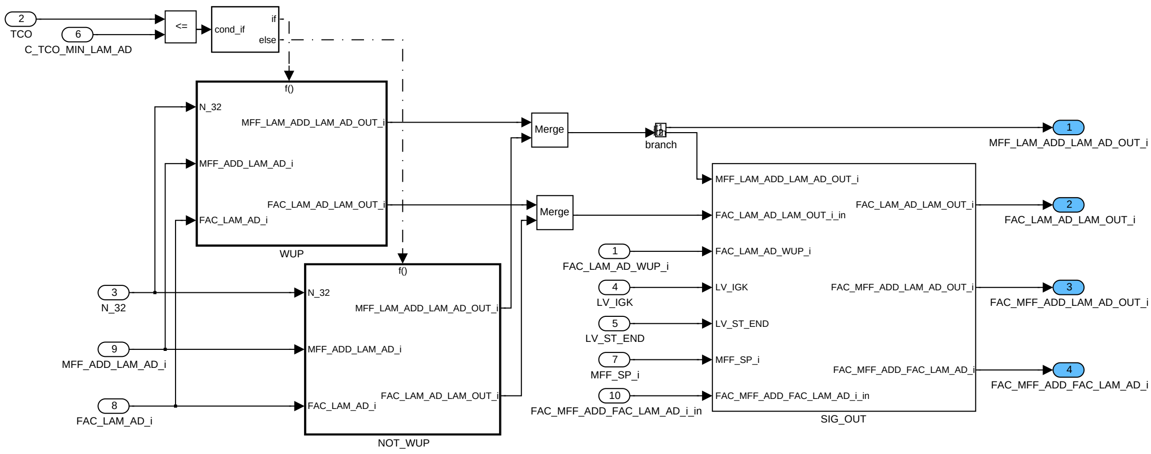

Figure 7.70.37: LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/CLC_CMN/CLC_SIG_OUT

Apply Weighting Factors

A factor depending on engine speed can be applied if the lambda adaptation correction must not be applied by 100% in the whole engine speed range.

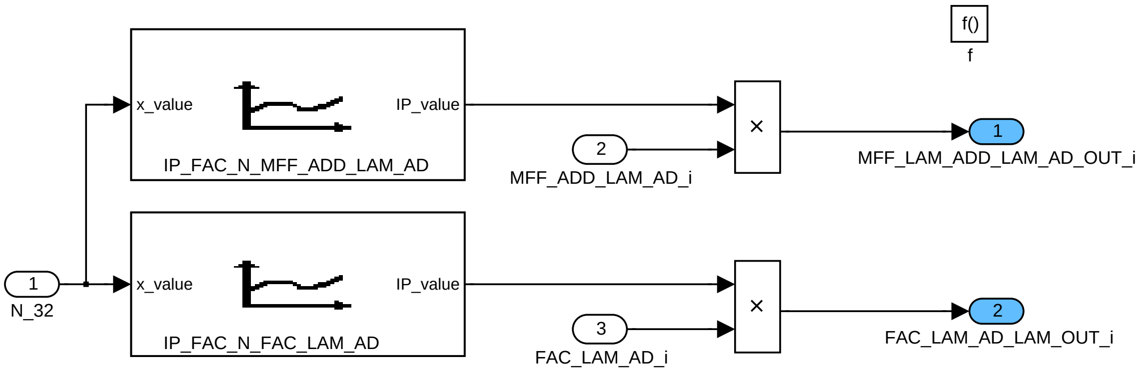

Figure 7.70.38:

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

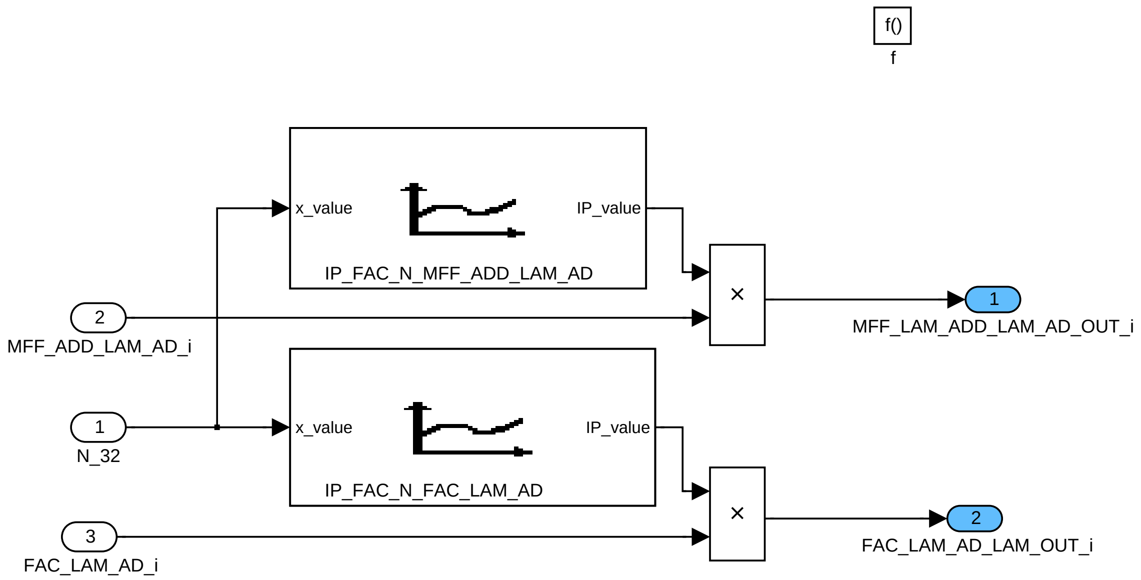

Figure 7.70.39:
LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/CLC_CMN/CLC_SIG_OUT/WUP

Final Output

FAC_MFF_ADD_LAM_AD_OUT[i] is the additive correction related to the fuel mass flow set point in order to have the same definition as for the multiplicative correction. When the engine is running this value is added to the multiplicative correction; so with the variable FAC_MFF_ADD_FAC_LAM_AD[i] the whole lambda adaptation correction is expressed.
If the lambda adaptation in warmup phase (external module) is active the respective output of this function FAC_LAM_AD_WUP[i] is not zero and added here to the over all lambda adaptation multiplicative correction.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

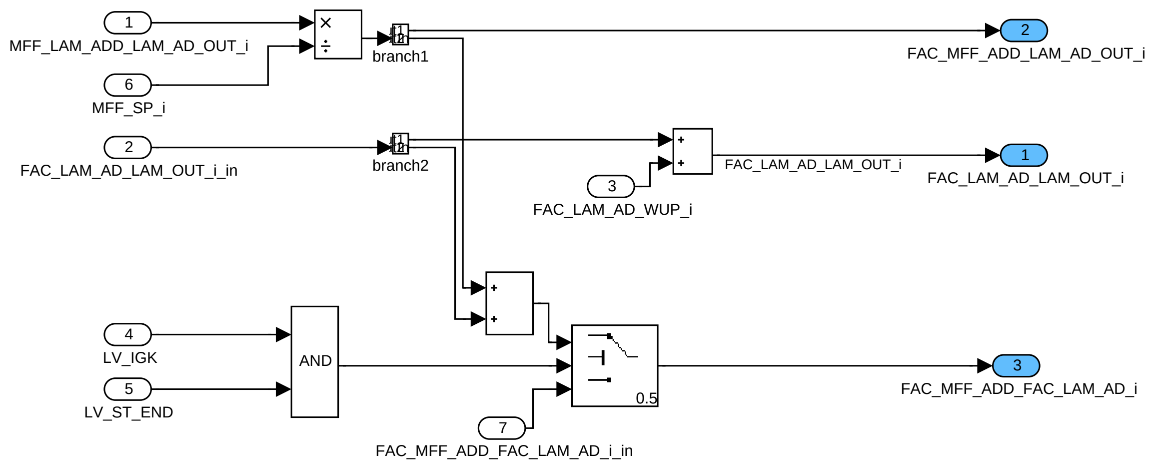

Figure 7.70.40:

Interface to Lambda Controller

Interfacing Lambda Adaptation (this function)

A shift of the lambda controller output after the calculation of a valid adaptation value by FAC_LAM_ADJ_LAM_AD[i] is required in order to avoid rapid changes in the air fuel ratio caused by the lambda adaptation. FAC_LAM_ADJ_LAM_AD[i] is calculated in the states "ADAPT_ADD", "ADAPT_FAC_L" and "ADAPT_FAC_H".
The shift of the lambda controller output is not carried out, if the lambda controller is stopped. To avoid a loss of adaptation values in that case, the lambda controller shall confirm the successful lambda controller shift.
If the lambda controller does not confirm the controller shift by FAC_LAM_ADJ_LAM_AD[i] by setting LV_FAC_LAM_ADJ_LAM_AD_END[i] to 1, the lambda adaptation stops further calculations (LV_LAM_AD_STOP[i] is set to 1) until the controller shift is confirmed. FAC_LAM_ADJ_LAM_AD[i] shall be set to 0 and LV_FAC_LAM_ADJ_LAM_AD[i] and LV_LAM_AD_STOP[i] are reset, if at a stopped lambda adaptation the deactivating conditions are fulfilled.

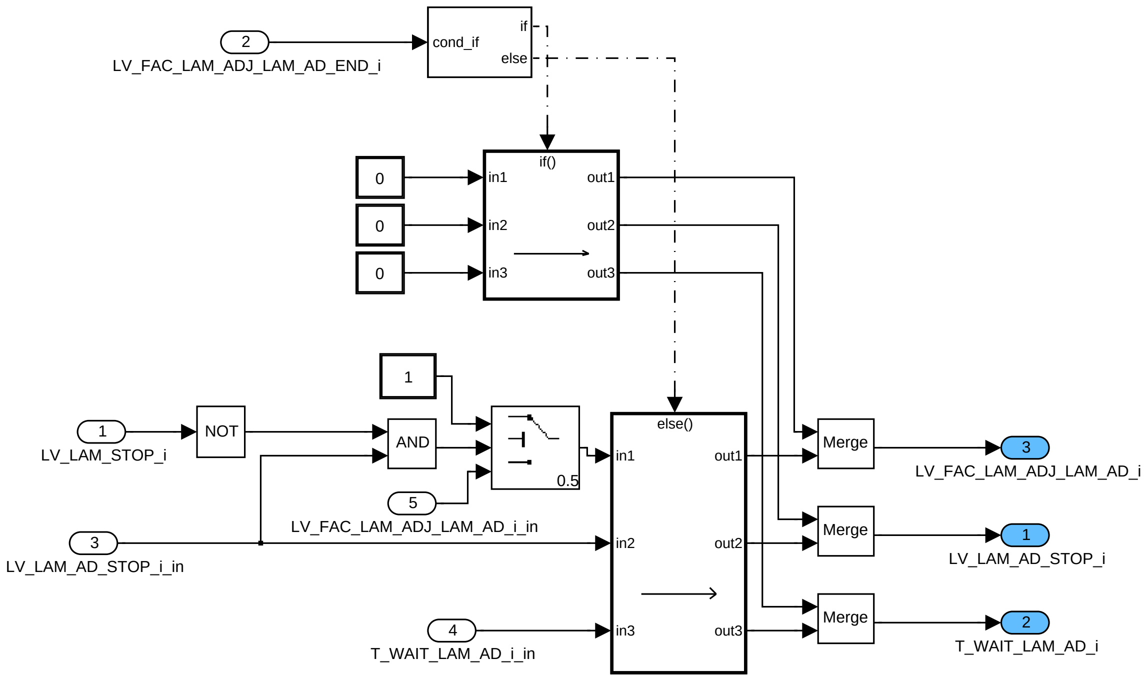

Figure 7.70.41: LACO_ISPCLADA0/OPM_20MS/CBK_MNG/CBK_FLP/CLC_CMN/LAM_IF/LAM_AD

Interfacing Lambda Adaptation in Warm up phase (external module)

If TCO is below C_TCO_MIN_LAM_AD, any required shift by the warmup lambda adaptation is taken into account. Above this threshold lambda adaptation is active and any shift of this function is taken into account. As both adaptation function cannot be active at the same time the request flag LV_FAC_LAM_ADJ_LAM_AD[i] is used for both.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Check of Requirements for Time Scheduler

In order to observe the priority of further lambda adaptations, the differences between the old and the new adapted factors are observed. According to the observed deviations the new maximum time for next adaptation is calculated regarding the present conditions.
The output value for the time scheduler T_PRI_TOT_LAM_AD is not bank selective and represents the minimum time of all cylinder banks. In case of single exhaust cylinder bank T_PRI_TOT_LAM_AD is equal to T_PRI_LAM_AD[i] of this single bank.
If at least for one exhaust bank LV_LAM_AD_STOP[i] is set then the auxiliary flag LV_LAM_AD_STOP_CBK_EX is set to 1.
If the Lambda adaptation priority of any bank is below a limit (that means that the priority time is above a calibration threshold), the bank selective temporary Lambda adaptation end flag is set. When T_PRI_LAM_AD[i] exceeds C_T_PRI_MAX_LAM_AD the flag LV_LAM_AD_END_CBK[i] is set.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.71.1 LACO_ISPCLADAW0

The Lambda adaptation in warmup phase enhances the Lambda adaptation functionality to obtain a more precise correction at low temperatures ($<$ 50°C). The adaptive correction is applied to compensate serial production tolerances of components at low.
TCO dependent correction factors (%/°C) are learned in five temperature ranges. The correction factors are derived from the Lambda controller output. They are learned in an adaptation field specified by MFF_SP[i] and N_32. They are, however, to correct the injection time for all engine states. Learning of these factors requires that the Lambda controller is in the state 'ON'.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks. For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

7.71.1.1 SUBFUNCTION: operate

Calculation of the uncorrected Lambda controller output

To obtain the actual load on the Lambda controller, the controller output without adaptation is calculated. This is the sum of FAC_LAM_LIM[i] and applied adaptive correction in the warmup phase. The actual load is then filtered to have a smoother signal. In case of a not yet activated Lambda controller the value is set to zero. This is necessary in order to facilitate the detection of end of the transient phase after the start of the Lambda controller.

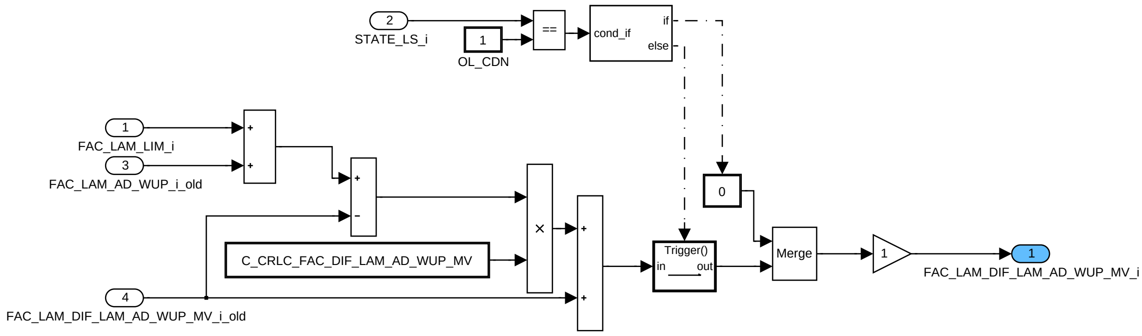

Figure 7.71.3: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/FAC_LAM_DIF_LAM_AD_WUP_MV

Correlation constant for updating of adaptation factors

In the update process of the adaptation factor a correlation constant is taken into account. Typically this value will be less then one to reduce the impact of outlier.
In case of a brand new ECU the cold adaptation values need to be shifted, if they are learned before the warm adaptation values are learned. The shift value amounts to the adaptation factor in the low range area. During this shift process no correlation constant is considered. Hence, in case of a brand new ECU the correlation constant is set to 1. Otherwise the auto shift value will not correspond to the corresponding value learned in the cold adaptation.

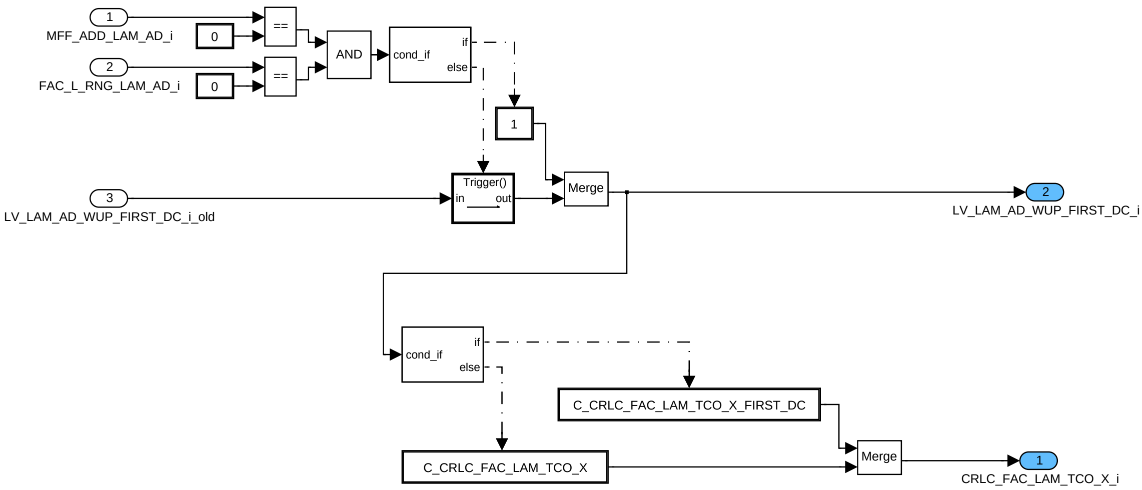

Figure 7.71.4: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/CLC_CRLC_LAM_TCO_X

Determination of valid partial load phase

To enable learning of the adaptation factor the conditions for valid learning have be fulfilled for at least the calibratable time C_T_MAX_LAM_AD_WUP_LDC.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The conditions are:
Limited dynamics of the Lambda adaptation are fulfilled.
Lambda controller is active.
Lambda controller is not in the stop mode.
N_32 is below a threshold, but above another threshold.

- MFF_SP[i] is below a threshold, but above another threshold.

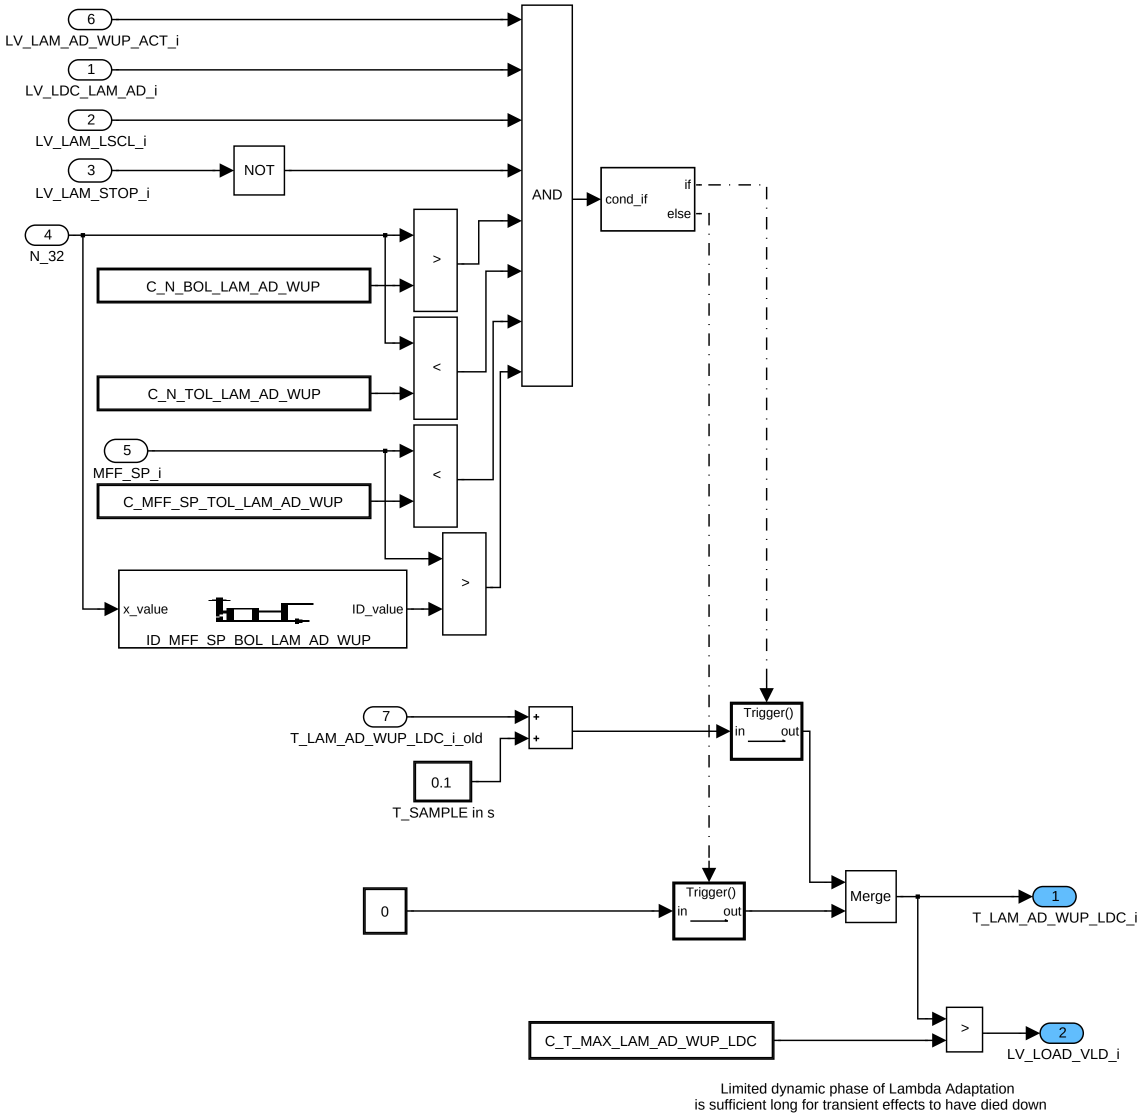

Figure 7.71.5: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/TCO_MIN_INTER_LAM_AD_WUP/CLC_T_LAM_AD_WUP_LDC

Determination of minimum temperature valid for learning in current driving cycle

To enable learning in the current driving cycle for the first time the following conditions must be satisfied:
The counter as well as the timer criteria are fulfilled, thus is transient phase is over.
The global activation conditions are fulfilled.
Limited dynamics are given, the Lambda controller is in state on and engine operating point is within the required mass air flow and speed range (see also definition of LV_LOAD_VLD[i]).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The coolant temperature is within the temperature range of the lowest and highest interpolation points.

If above conditions are fulfilled, then the flag indicating the detection of TCO_MIN_INTER is set.

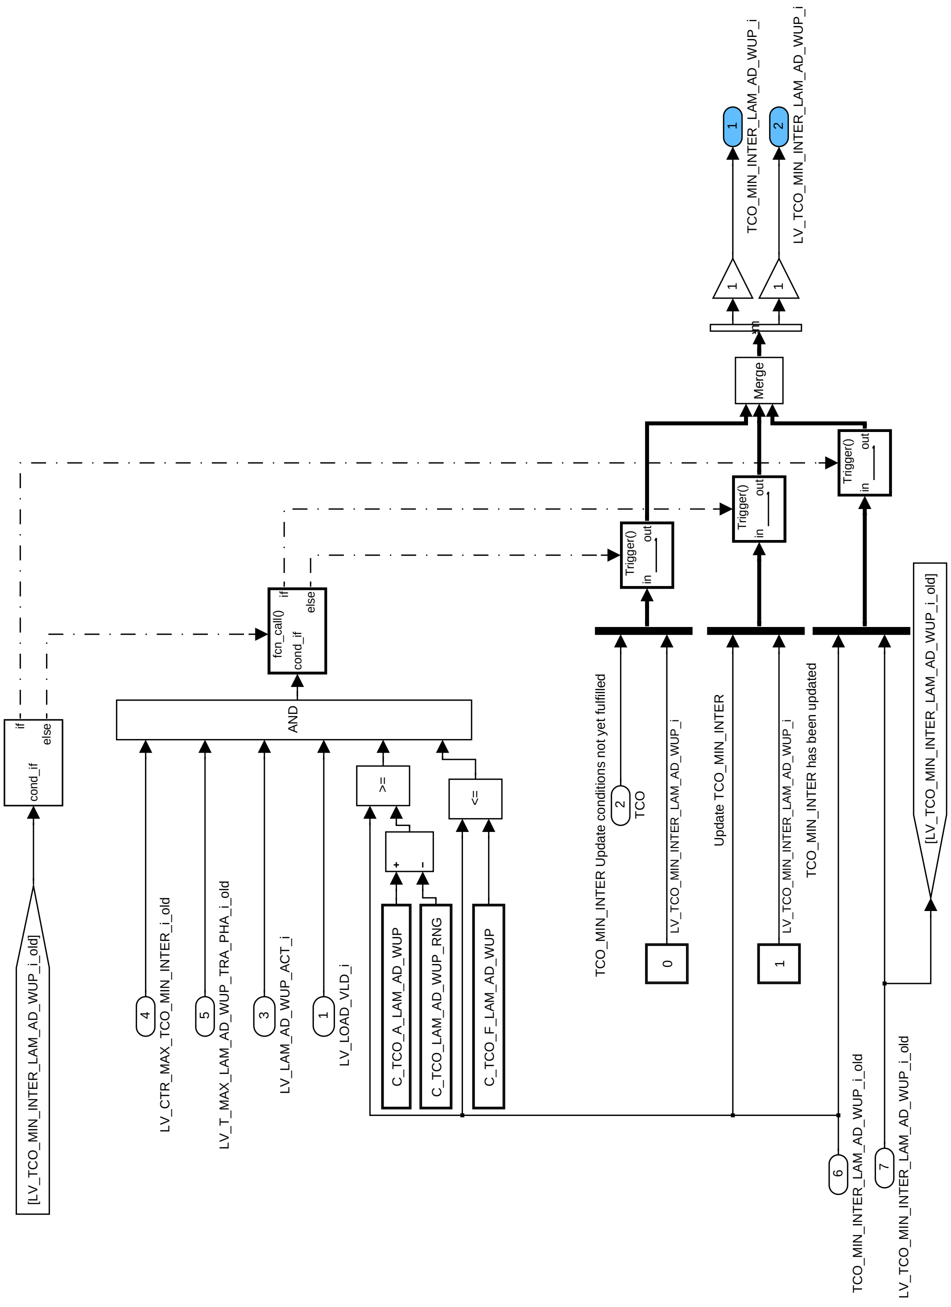

Figure 7.71.6:
LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/FAC_LAM_AD_WUP_CBK_SPC/

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Determination of end of transient phase

Two different criteria can be used to determine the end of the transient phase:
Timer criteria:

When the Lambda controller enters the state ON a timer is incremented. If this timer exceeds a threshold, it is assumed that the transient is over. This criterion is very simple, but not very accurate.

Counter criteria:

The counter is incremented when the uncorrected Lambda controller moves towards the zero percent line or stays unchanged. In case it moves away from the zero percent line, the counter is decremented. The counter cannot be decremented below zero. If the counter exceeds a certain threshold, the end of the transient phase is detected. This criterion was found to be very accurate.

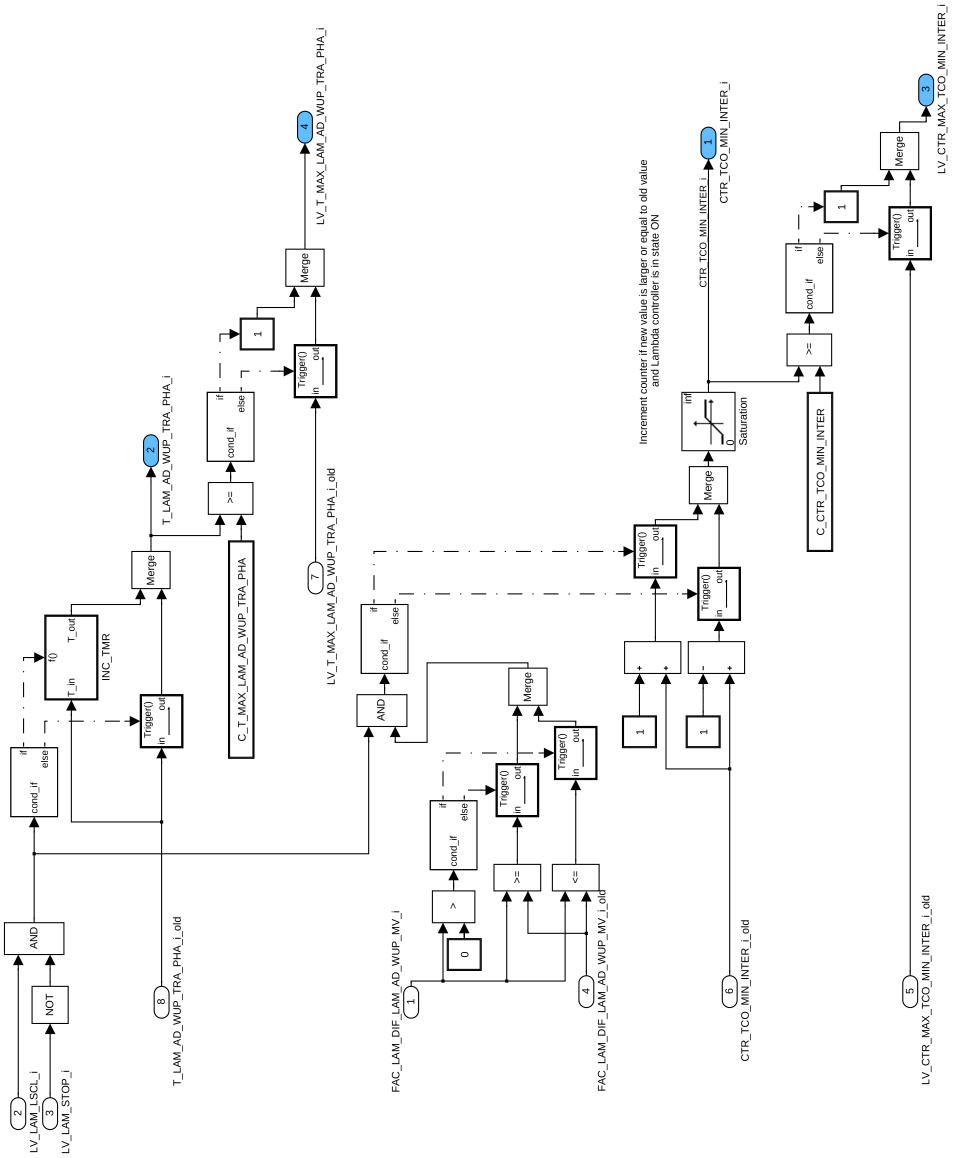

Figure 7.71.7: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/TCO_MIN_INTER_LAM_AD_WUP/CLC_CTR_TCO_MIN_INTER

Auto shift functionality - correction of adaptation value with warm adaptation value

In each driving cycle it is checked whether the fuel quality has changed to the worse. This check is done once per driving cycle at the time when the conditions for learning are fulfilled for the first time. A change of fuel quality is detected if the uncorrected Lambda controller output has shifted by at least

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

a calibratable threshold towards lean. The threshold is specified in a map with TCO as an input. This allows taking into account the TCO dependent deterioration effect of poor fuel quality.
Once fuel of low quality is detected, a flag indicating that detection was done in the current driving cycle is set to one. Furthermore, the difference in the uncorrected Lambda controller output (which led to this detection) is normalized. The normalization is done using a TCO dependent map. The same map is used later on to shift all adaptation values. Therefore, the map has to represent the qualitative course of the additional enrichment demand caused by the poor fuel quality.

Detection of change in fuel quality

In each driving cycle it is checked whether the fuel quality has changed to the worse. This check is done once per driving cycle at the time when the conditions for learning are fulfilled for the first time. A change of fuel quality is detected if the uncorrected Lambda controller output has shifted by at least a calibratable threshold towards lean. The threshold is specified in a map with TCO as an input. This allows taking into account the TCO dependent deterioration effect of poor fuel quality.

Once fuel of low quality is detected, a flag indicating that detection was done in the current driving cycle is set to one. Furthermore, the difference in the uncorrected Lambda controller output (which led to this detection) is normalized. The normalization is done using a TCO dependent map. The same map is used later on to shift all adaptation values. Therefore, the map has to represent the qualitative course of the additional enrichment demand caused by the poor fuel quality.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

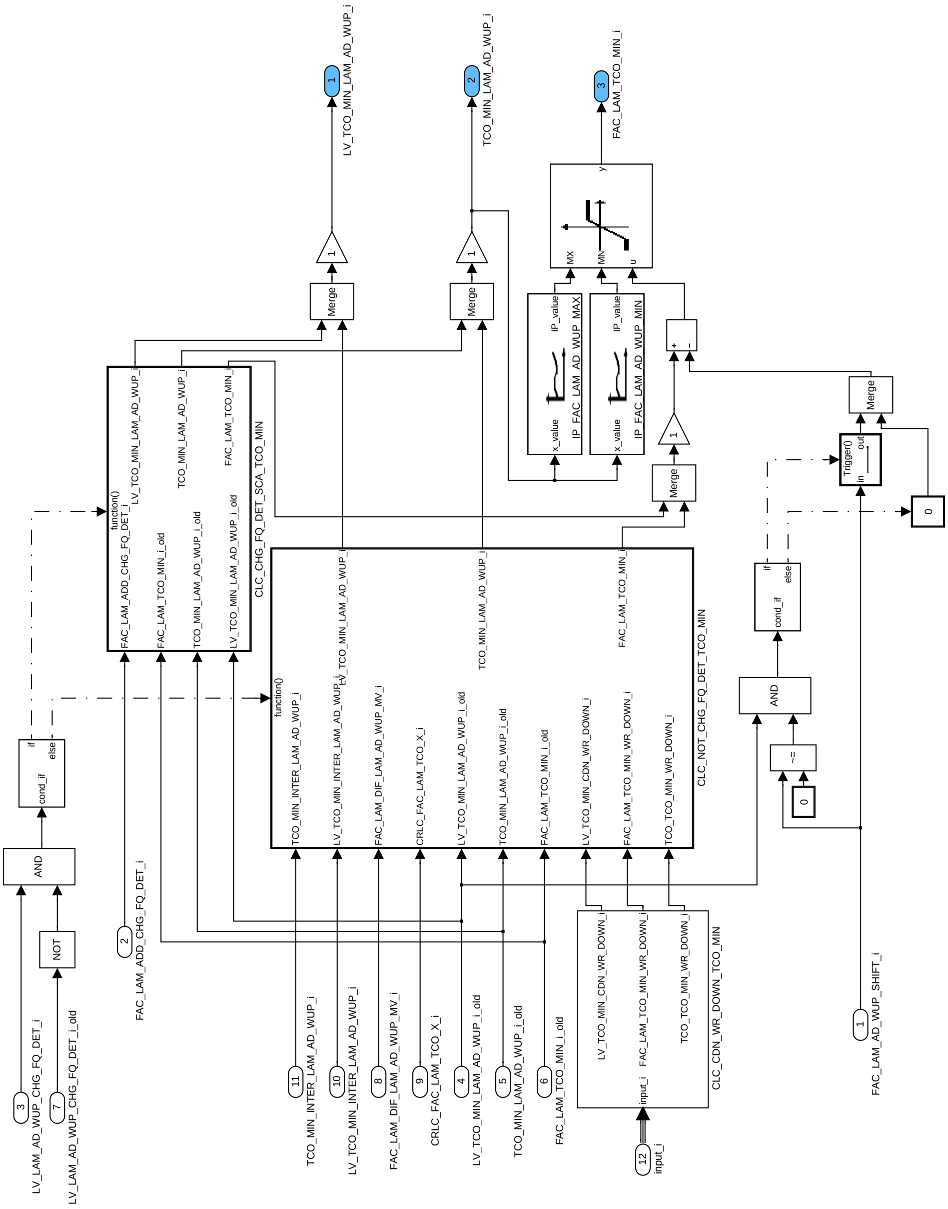

Figure 7.71.10: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/TCO_MIN_LAM_AD_WUP

Determination of adaptation value during detection of change in fuel quality

First it is checked whether the adaptation factor is different from zero to confirm, that it has been updated at some point in the past. If this is not the case no shift is realized at this particular interpolation point. For shifting the normalized shift value is multiplied by a TCO dependent weighting factor and then added to the old adaptation factor. The weighting factor takes into account that the negative effects of the low quality fuel disappear with rising temperature. Hence, the weighting factor should be around 1 for the lowest interpolation point and at around zero for the highest temperature.

If a change in fuel quality is detected the normal update process of the adaptation factor is inhibited. The auto shift value is always zero with the exception of the calculation recurrence during which the shift is executed. Furthermore, if the adaptation factor was not updated in this driving cycle (LV_TCO_X_LAM_AD_WUP[i]), then the auto shift correction is not applied.

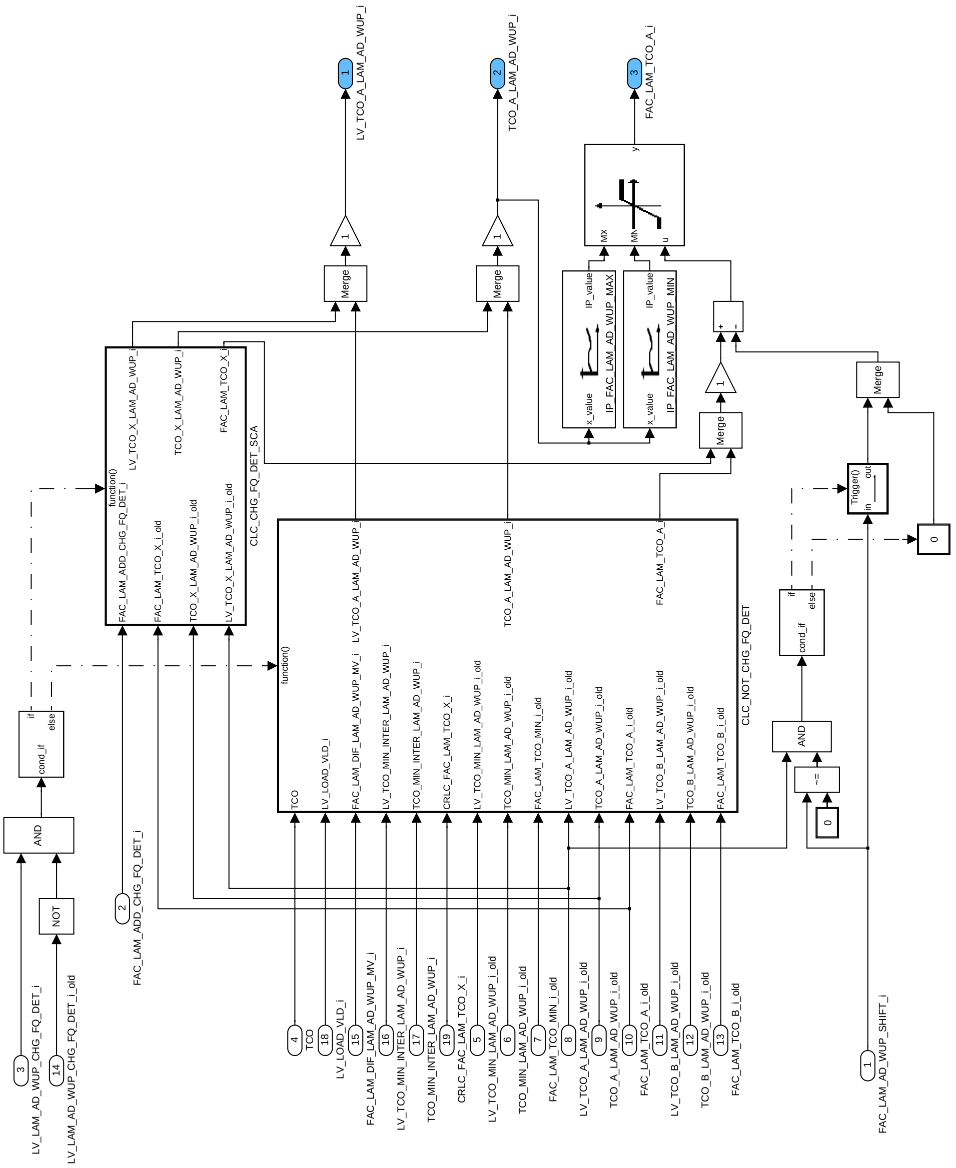

Figure 7.71.15: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/FAC_LAM_AD_WUP_CBK_SPC/TCO_LAM_AD_WUP/CLC_FAC_LAM_TCO_A

Determination of adaptation value during detection of change in fuel quality

First it is checked whether the adaptation factor is different from zero to confirm, that it has been updated at some point in the past. If this is not the case no shift is realized at this particular interpolation point.

For shifting the normalized shift value is multiplied by a TCO dependent weighting factor and then added to the old adaptation factor. The weighting factor takes into account that the negative effects of the low quality fuel disappear with rising temperature. Hence, the weighting factor should be around 1 for the lowest interpolation point and at around zero for the highest temperature.

TCO_LAM_AD_WUP/CLC_FAC_LAM_TCO_A/CLC_CHG_FQ_DET_SCA

Determination of adaptation value during normal operation

Four different states shall be distinguished:

1.) Conditions to update are not yet fulfilled. Indicator flag remains zero and the factor and the temperature at the interpolation point are not updated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

2.) The adaptation factor the corresponding temperature are updated once the following conditions are met:
 TCO is within the temperature window
 End of transient phase has been detected, thus TCO_MIN_INTER[i] is set
 The conditions for valid learning are fulfilled sufficiently long (LV_LOAD_VLD[i])
 The difference to the previously stored value is sufficiently large
If all above conditions are met, the adaptation factor is updated with the uncorrected Lambda controller output (in this process a correlation factor is considered) and the corresponding temperature is updated with the current TCO. Additionally the indicator flag is set to one.
3.) If TCO_MIN[i] is updated (the lowest ever learnt temperature is reduced) and it is larger than the temperature of the interpolation point, then the adaptation value is updated with factor belonging to TCO_MIN[i]. The corresponding temperature is not updated in this state. This update procedure can be restricted in such that TCO_MIN[i] needs to be within temperature of point of A and point B plus size of the temperature window.
4.) Update was already done in this driving cycle: No actions are undertaken.

The calculation at point B to E proceed analogous. At interpolation point F the correction factor is fixed at zero, in order to fade out the correction smoothly.

Parameters for slope equation

Here the parameters which are required to solve the slope equation are arranged.

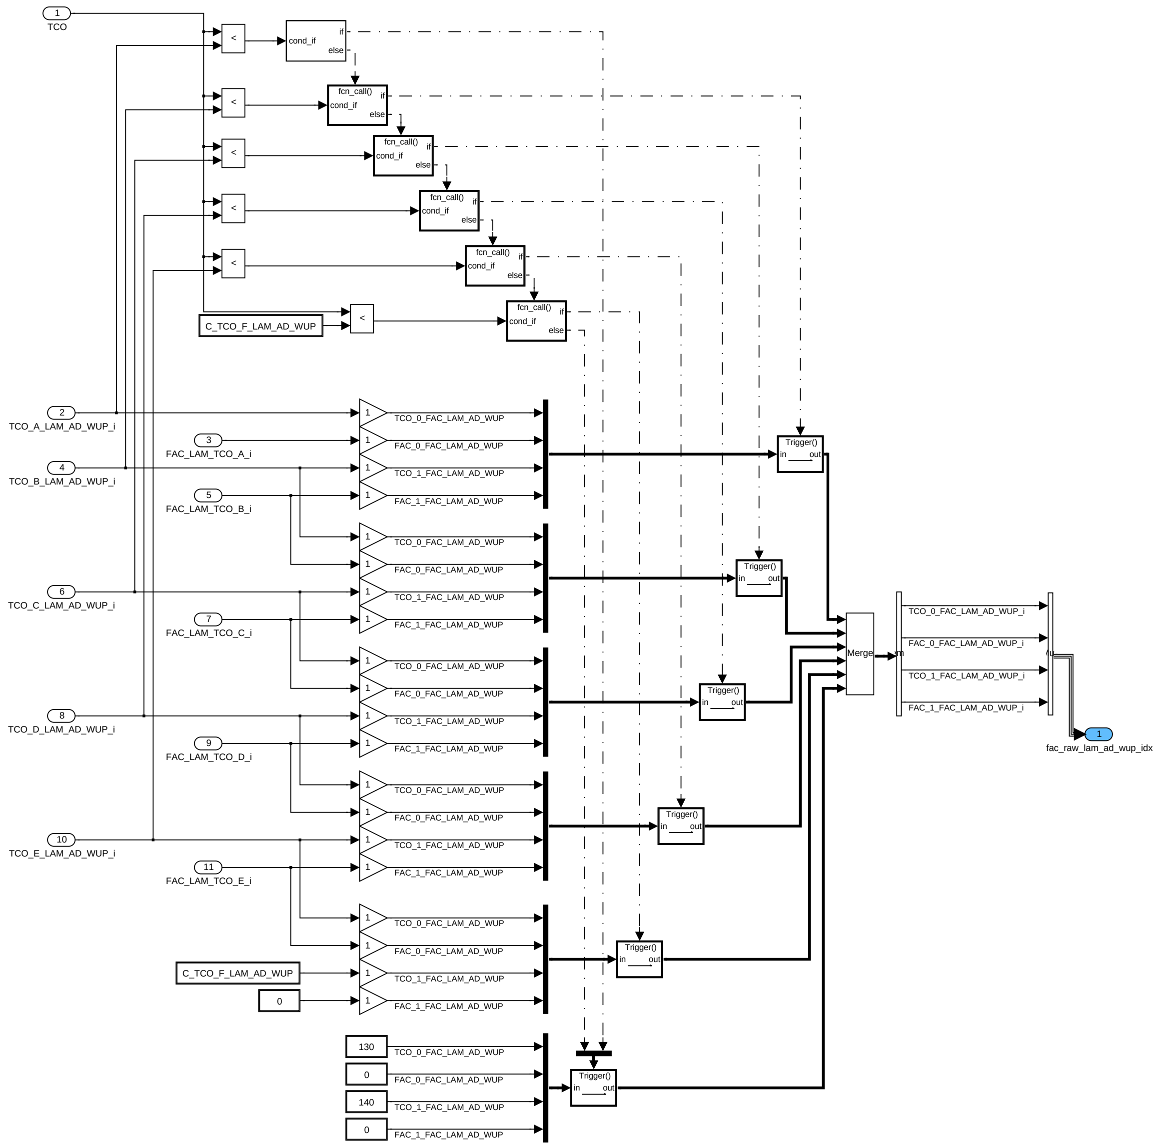

Figure 7.71.31: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/CLC_FAC_LAM_AD_WUP/FAC_RAW_LAM_AD_WUP_IDX

Calculation of the Lambda adaptation factor in the warm up phase

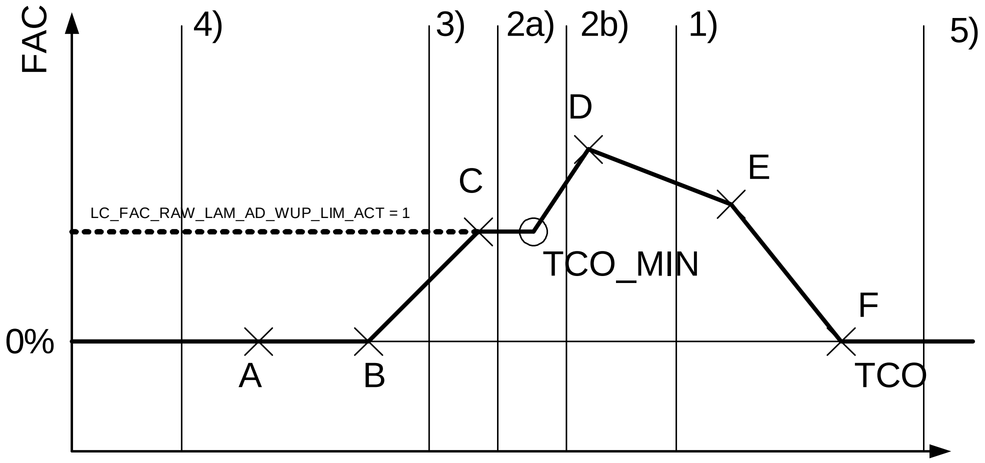
The respective adaptation factor in warmup phase is derived from slope equation with TCO as an input. Five different cases for the calculation of FAC_RAW_LAM_AD_WUP must be distinguished:

1.) The momentary TCO is between two interpolation points with TCO_MIN *smaller* than the lower interpolation point: Solving the slope equation with the two interpolation points and TCO as an input will yield FAC_RAW_LAM_AD_WUP.

2.) The momentary TCO is between two interpolation points with TCO_MIN *larger* than the lower interpolation point: Between the lower interpolation point and TCO_MIN, the output is fixed to FAC_LAM_TCO_MIN. Between TCO_MIN and the upper interpolation point, the slope equation made up from TCO_MIN and the upper interpolation point shall be used to calculate FAC_RAW_LAM_AD_WUP.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

3.) TCO is smaller than TCO_MIN and TCO_MIN is larger than the next higher interpolation point. If LC_FAC_RAW_LAM_AD_WUP_LIM_ACT is set to one, the output value is fixed to FAC_LAM_TCO_MIN; otherwise it shall be obtained by solving the slope equation.
4.) TCO is smaller than temperature at point A:
If LC_FAC_RAW_LAM_AD_WUP_LIM_ACT is set to one, the output value is fixed to FAC_LAM_TCO_MIN, otherwise it is zero.
5.) TCO is larger than temperature of point F: the output is zero.



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FAC_LAM_AD_WUP_CBK_SPC/CLC_FAC_LAM_AD_WUP/FAC_RAW_LAM_AD_WUP

Limitation of adaptation factor

Three different limitations of the Lambda adaptation factor in warmup phase can be applied. If the conditions to go closed loop Lambda control are not yet fulfilled (STATE_LS == 0) C_FAC_LAM_AD_WUP_MAX/MIN_LSCL_OFF is applied. In the transient phase until TCO_MIN_INTER is detected C_

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FAC_LAM_AD_WUP_MAX/MIN_INTER is the relevant limitation. After detection of TCO_MIN_INTER the limitation are specified by IP_FAC_LAM_AD_WUP_MAX/MIN.
With C_FAC_LAM_AD_WUP_DELTA the shifts in the Lambda adaptation factor in warmup phase can be smoothed by specifying the maximum step value. It has been observed that for large changes in the adaptation value that Lambda controller output is not reduced as fast as the adaptation value increases (due to transient effects). This causes unwanted deviation of the Lambda value, which can be avoided by specifying a smooth transition between different values of the adaptation factor.

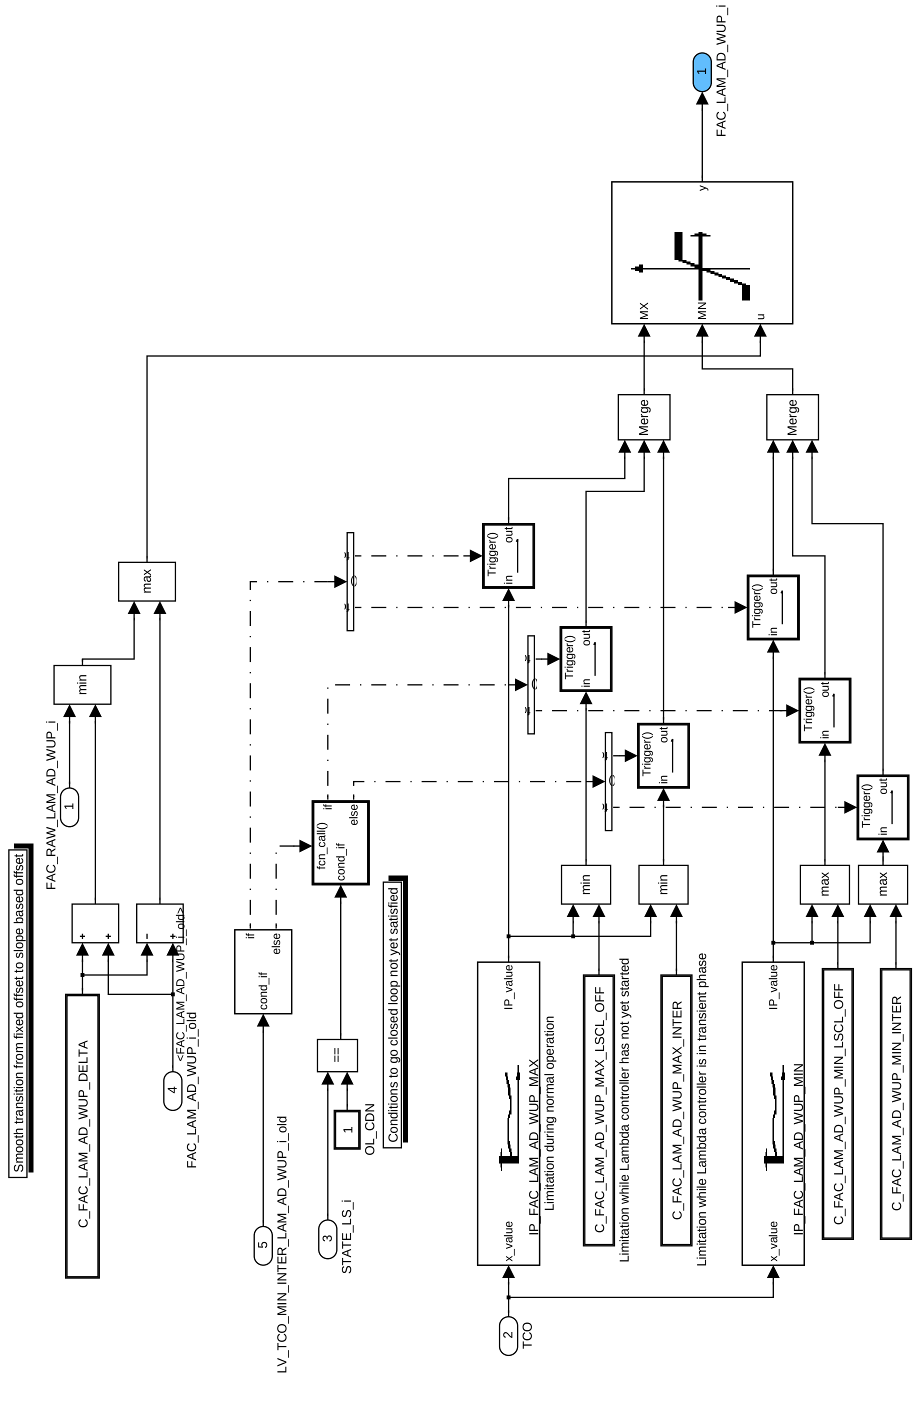

Figure 7.71.33: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/
FAC_LAM_AD_WUP_CBK_SPC/CLC_FAC_LAM_AD_WUP/FAC_LAM_AD_WUP_LIM

Copyright (C) Continental AG,2007

Shift of the Lambda controller

A shift of the Lambda controller output is required if the value of FAC_LAM_AD_WUP[i] has changed since the last calculation recurrence in order to avoid large Lambda controller excursions.

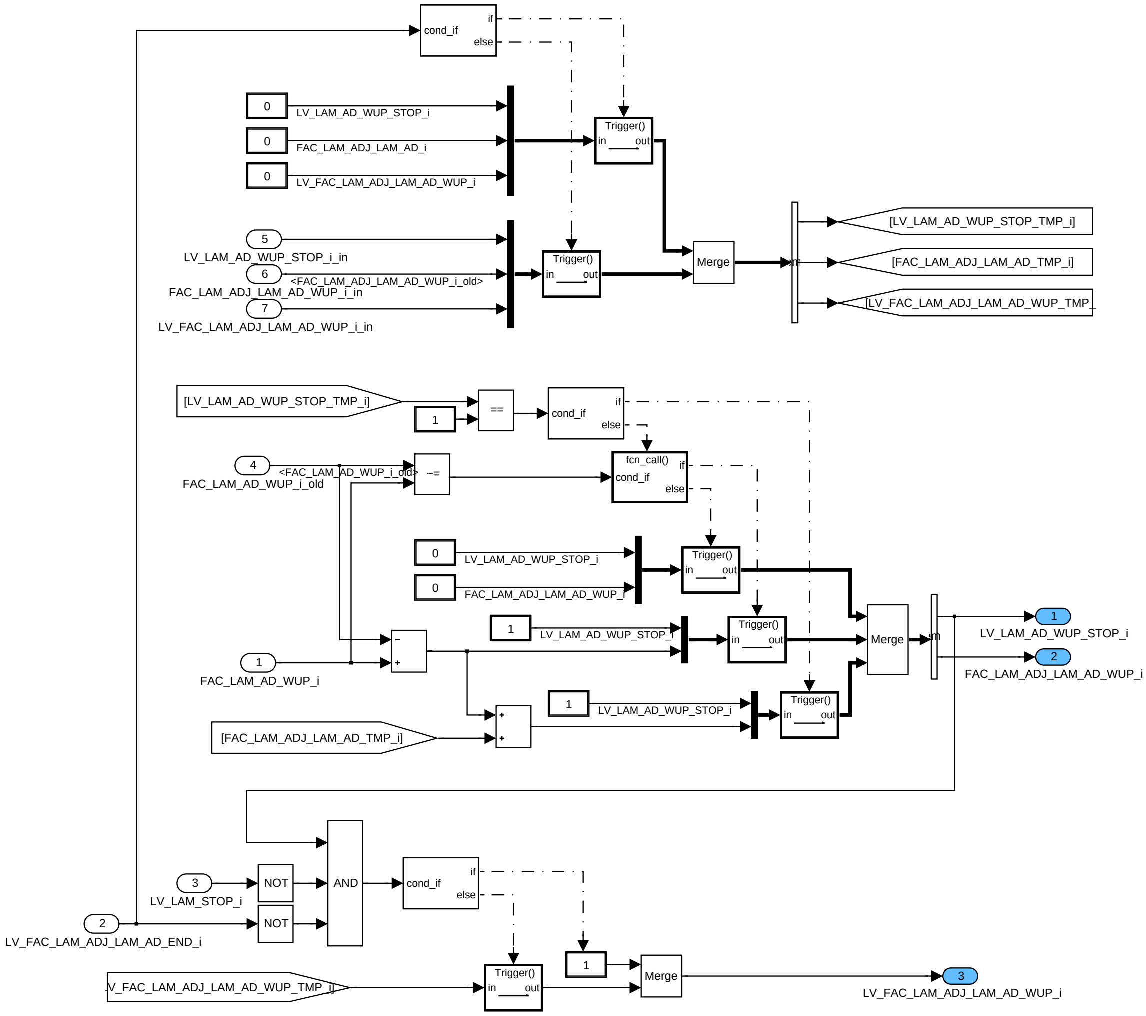

Figure 7.71.34: LACO_ISPCLADAW0/operate/FAC_LAM_AD_WUP_CBK_MNG/

Rewriting of adaptation correction in warm up phase with non volatile stored values

In case of Lambda adaptation relevant errors (see application incidences) the values of the data to be stored in the nonvolatile memory must be rewritten with the values stored at the end of the last driving cycle.

C_TCO_MAX_LAM_AD_WUP	-	0... FEH	-48... 142.5	0.75	°C
maximum coolant temperature for Lambda adaptation in warm-up phase					
C_TCO_MAX_T_AST_INH_LAM_AD	-	0... FEH	-48... 142.5	0.75	°C
Max. TCO to allow time window to inhibit lambda adaption					
C_TCO_MIN_LAM_AD	-	0... FEH	-48... 142.5	0.75	°C
minimum coolant temperature for adaptive learning					
C_TCO_MIN_LAM_AD_WUP	-	0... FEH	-48... 142.5	0.75	°C
minimum coolant temperature for Lambda adaptation in warm-up phase					
C_TIA_MAX_LAM_AD	-	0... FEH	-48... 142.5	0.75	°C
maximum air temperature for adaptive learning					
C_WGPWM_MIN_LAM_AD	-	0... FFFFH	0... 99.99847	1.5259e-3	%
Minimum waste gate signal for lambda adaptation at active driving cycle					
LC_LAM_AD_INH_STOP_OIL	-	0... 1H	0 ...1	1	-
Logical constant to inibit the lambda adaptation when LV_INH_FSD_STOP_OIL is set.					
LC_LAM_AD_WUP_ADD_RNG_CDN	-	0... 1H	0 ...1	1	-
Logical switch to require previous adaptation in ADD Range					
LC_LAM_AD_WUP_DEAC [NC_CBK_EX_NR]	-	0... 1H	0 ...1	1	-
logical calibration to disable Lambda adaptation in warm-up pahse					
LC_LAM_AD_WUP_INH_STOP_OIL	-	0... 1H	0 ...1	1	-
Logical constant to inibit the lambda adaptation WUP when LV_INH_FSD_STOP_OIL is set.					
LC_LAM_AD_WUP_L_RNG_CDN	-	0... 1H	0 ...1	1	-
Logical switch to require previous adaptation in FAC_L Range					
LC_WGPWM_INH_LAM_AD_ENA	-	0... 1H	0 ...1	1	-
Logical constant to enable inhibition of the lambda adaptation below a wastegate PWM value					

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks. For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The activation conditions of the lambda adaptation depends on:

- coolant temperature thresholds,
- temperature of intake air into manifold threshold,
- air mass flow threshold,
- secondary air function including diagnosis finished
- lambda setpoint thresholds
- and several error flags that must be zero

If all activation conditions are fulfilled, during the warm-up phase LV_LAM_AD_WUP_ACT[i] is set and during normal warm conditions LV_LAM_AD_ACT[i] is set to 1. That means that the lambda adaptation can get active if no other inhibition defined in the lambda adaptation module is set.

The detection of the limited dynamics is calculated based on the current engine speed, air mass flow and filtered lambda control output. The input to this function is the difference between each of the mentioned base values and its moving mean values. If one of those differences exceeds a calibrated threshold, an air mass flow integral is started to be calculated until a calibrated MAF threshold is reached. During the calculation the limited dynamics are defined to be not fulfilled (LV_LDC_LAM_AD[i] = 0). In order to reset the difference between base value and moving mean value after each threshold exceeding, an offset variable is introduced (see formula section).
Furthermore the correlation constant for calculation of adaptive values and the distance between two adaptations are determined dependent on the different adaptation ranges.

Application conditions

Initialisation: *at ECU reset:*

LV_LAM_AD_ACT[i] = 0
LV_LAM_AD_WUP_ACT[i] = 0
LV_LAM_AD_ACT_ERR[i] = 0
CRLC_LAM_AD[i] = 0
T_WAIT_MAX_LAM_AD[i] = 0
LV_LDC_LAM_AD[i] = 0
N_OFS_LDC_LAM_AD[i] = 0 rpm
MAF_OFS_LDC_LAM_AD[i] = 0 mg/ stk
FAC_LAM_MV_OFS_LDC_LAM_AD[i] = 0 %
MAF_INT_LDC_LAM_AD[i] = 0 g
LV_LAM_AD_DEAC_ERR[i] = 0
LV_LAM_AD_CDN_H_RNG[i] = 0
LV_LAM_AD_CDN_L_RNG[i] = 0
LV_LAM_AD_CDN_ADD[i] = 0
MFF_SP_AD[i] = MFF_SP_HOM_BAS_MV

At transition LV_IGK = 1 -> 0:

LV_LAM_AD_ACT[i] = 0
LV_LAM_AD_WUP_ACT[i] = 0

Recurrence: *T_SAMPLE = 20 ms*

Activation: *LV_IGK = 1*

Deactivation: *LV_IGK = 0*
