DESCRIPTION:

General information:

if$^{(1)}$ two separate cylinder banks are concerned
then
i = 1, for cylinder bank 1 (x = 0, 2, 4, ...)
i = 2, for cylinder bank 2 (x = 1, 3, 5, ...)
else$^{(1)}$
i = 1 (x = 0 ... 3 or 4)
endif$^{(1)}$

Description of index "[i]" and "[x]":

x: logical cylinder
*use **NC_CYL_NR** : number of engine cylinders - index "[x]"*
*use **LF_LS_CBK_EX_LAM_CYL_SEL_CONF**: pattern for allocation of physical cylinders to exhaust bank - index "[i]"*

The purpose of this function is detection and control the cylinder to cylinder air-fuel ratio deviation in an internal combustion engine using an observer to estimate the deviation of each cylinder that is not measurable and a controller for each cylinder separately. In this connection the periodic signal of the WRAF sensor is reconstructed using a sensor model and adapted to the measured value. The estimated state describes the deviation in percentage for each cylinder. The mentioned value is an input to a control system that balances the air- /fuel ratio in each cylinder separately (Figure 1).

Figure 1: Structure of the cylinder individual lambda control for a 3-cylinder-exhaust-bank

Formula section:

7.73.6 Signal evaluation (segment synchronous)

The aim of signal evaluation with a low sampling rate is the precise dividing of the lambda sensor output signal into the identified cylinder. Therefore, the sampling moment shall be computed, depending on the engine operating state, precisely. The Sampling moment is influenced by phase displacement predetermined by IP_CRK_SYN[i]. The value of the phase shift is given in CRK.

7.73.6.1 Calculation of the segment period

Depending on the engine speed the segment period is simply computed by

if$^{(1)}$ two separate exhaust banks are concerned, **then**

$$TA = 2 * \frac{2 * 60}{N * NC\_CYL\_NR}$$

(1.5.1.1)

else$^{(1)}$

$$TA = \frac{2 * 60}{N * NC\_CYL\_NR}$$

(1.5.1.2)

endif$^{(1)}$

7.73.6.2 Calculation of the phase displacement

The phase shift - caused by system delayed response - is computed once per combustion cycle using the map IP_CRK_SYN[i], adjusted by C_CRK_CYL_LAM[x], PHA_SHIFT_CAM_EX[i] and DELTA_CRK_CYL_LAM[i]. It shall be determined at the beginning of the combustion cycle (SEG_NR = 0). That applies to the first and ensuing segments.

if$^{(1)}$ SEG_NR = 0
then
CRK_CYL_LAM[x] = IP_CRK_SYN[i] + C_CRK_CYL_LAM[x] +
PHA_SHIFT_CAM_EX[i] + DELTA_
CRK_CYL_LAM[i] +

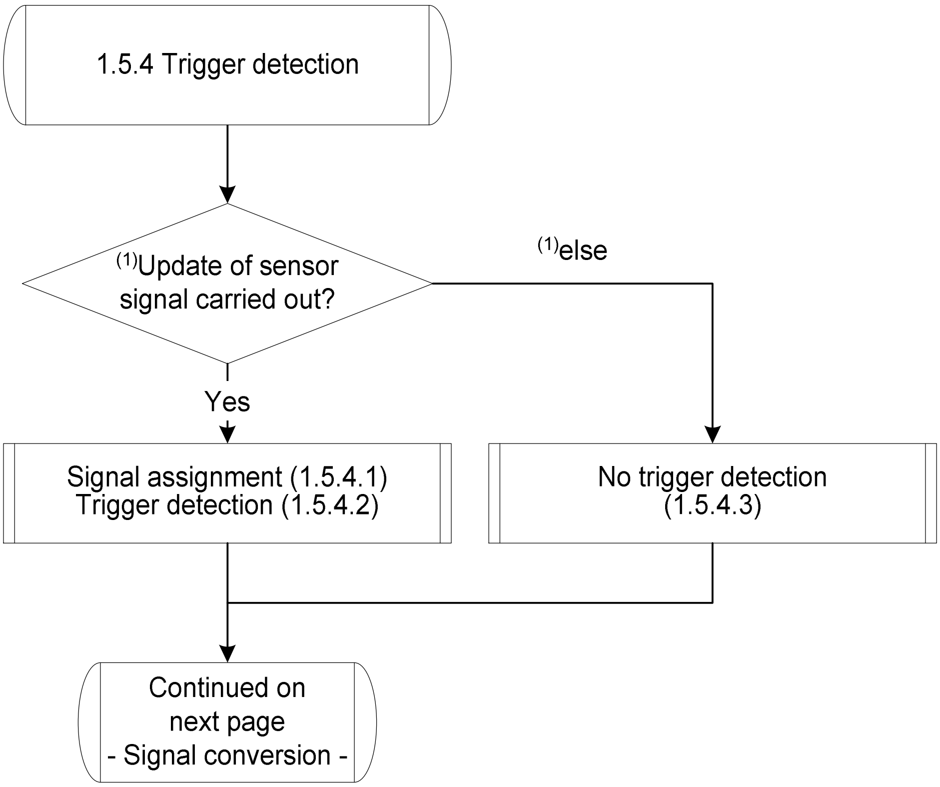
7.73.6.4 Trigger detection

The trigger for the corresponding segment is created if the state of the variable VLS_CYL_TRIG[x] changes. At the same time the value of VLS_CYL[x] shall be transferred to VLS_CYL_SEL[x].



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

if$^{(1)}$ VLS_CYL_TRIG[x] VLS_CYL_TRIG[x]$_{k-1}$
then
VLS_CYL_SEL[x] = VLS_CYL[x]

(1.5.4.1)

LV_TRIG[x] = 1

(1.5.4.2)

else(1)

LV_TRIG[x] = 0

(1.5.4.3)

endif(1)

7.73.7 Signal conversion

The voltage value of VLS_CYL_SEL[x] shall be converted to Lambda using the characteristic curve IP_LAMB_CYL$_x$ and has to be shifted by its mean value. The resulting value represents the global AFR deviation. Calculation and shifting the mean value shall be carried out in segment step.

if(1) LV_TRIG[x] =1

then

LAMB_CYL_SEL[x]= IP_LAMB_CYL (VLS_CYL_SEL[x])

(1.6.1)

$$\text{DELTA\_LAMB\_AV[i]} = \text{LAMB\_CYL\_SEL[x]} - \frac{1}{\alpha}\sum_{k=1}^{\alpha}\text{LAMB\_CYL\_SEL[x]};$$

α :number of cylinders per bank

(1.6.2)

7.73.8 Calculation of time lag of the lambda-sensor model

T1_LAMB_CYL_SEL[i] = IP_T1_LAMB_CYL_SEL[i]

(1.7.1)

7.73.9 Calculation of the estimation-error

Estimation error represents the difference between the measured value, DELTA_LAMB_AV[i], and the estimated value, DELTA_LAMB_MDL[i].

DELTA_LAMB_ERR_RAW[i] = DELTA_LAMB_AV[i] -
DELTA_LAMB_MDL[i][x(n-1)] **(1.8.1)**

Remark: Software shall guarantee a segment synchronous comparison, i.e. the value of DELTA_LAMB_AV[i] at the segment-time x shall be compared with that DELTA_LAMB_MDL[i] which was calculated in segment x during the last combustion cycle [x(n-1)].

7.73.10 Weighting the estimation-error

Depending on T1_LAMB_CYL_SEL[i], the error shall be weighted. This is carried out by means of a characteristic curve. A non-linear dependent weighting function might be considered for late come out.

DELTA_LAMB_ERR[i] = DELTA_LAMB_ERR_RAW[i] * IP_FAC_ERR_LAM_SEL

(1.9.1)

7.73.11 Signal splitting /Calculation of the cylinder selective AFR /Signal merge

Splitting procedure shall be implemented in order the weighted error signal to be allocated to an internal state, which describes the current estimated value of air -/fuel ratio in each cylinder respectively (Figure 2).

DELTA_LAMB_ERR_CYL_SEL[x] = DELTA_LAMB_ERR[i]

(1.10.1)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

An adaptation mechanism, including an integral-action element for each cylinder - corrected by exhaust-manifold-port factor C_CRLC_EXV_FAC[x], adjusts the estimated value to the actual one. The adjusted value of the cylinder individual deviation is calculated by the equation

DELTA_LAMB_CYL[x]$_k$ = (DELTA_LAMB_CYL[x]$_{k-1}$ + DELTA_LAMB_ERR_CYL_SEL[x]$_k$*TA)* C_CRLC_EXV_FAC[x] **(1.10.2)**

In order to avoid rounding error that leads to zero-readout of the gradient term in aforementioned equation, following scan shall be made:

if$^{(2)}$ (DELTA_LAMB_ERR_CYL_SEL[x]$_k$*TA = 0 **and** DELTA_LAMB_ERR_CYL_SEL[x]$_k$ $>$ 0)

then

increment(DELTA_LAMB_ERR_CYL_SEL[x]$_k$*TA) **(1.10.3)**

else$^{(2)}$

if$^{(3)}$(DELTA_LAMB_ERR_CYL_SEL[x]$_k$*TA = 0 **and** DELTA_LAMB_ERR_CYL_SEL[x]$_k$$<$ 0)

then

decrement (DELTA_LAMB_ERR_CYL_SEL[x]$_k$*TA) **(1.10.4)**

endif$^{(3)}$

endif$^{(2)}$

In accordance with the ignition sequence signal-reassembling procedure shall be carried out in order to get the divided signals together. DELTA_LAMB_CYL_SEL[i] is input of the sensor model for the current segment.

DELTA_LAMB_CYL_SEL[i]$_k$ = DELTA_LAMB_CYL[x]$_k$ **(1.10.5)**

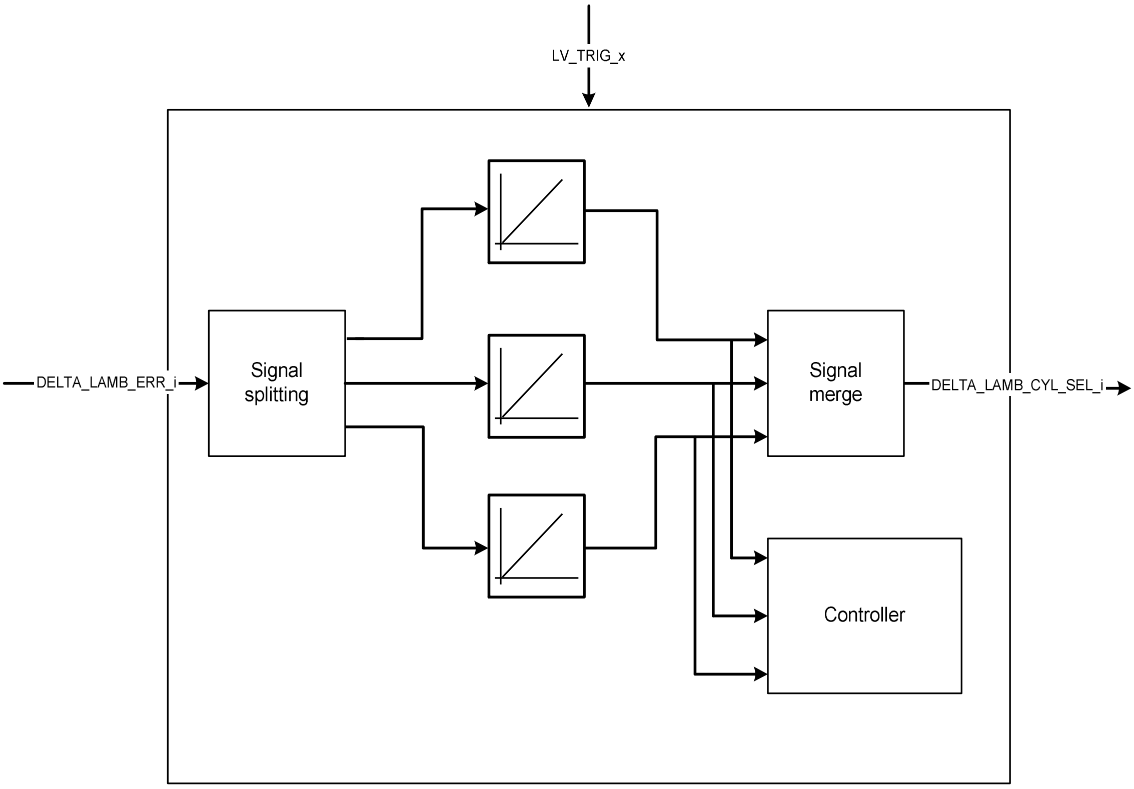

Figure 7.73.9: : Signal splitting, adjustment and signal merge

7.73.12 Sensor model

The dynamic behaviour of WRAF sensor is described by a sensor model, first order low-pass-filter. This is characterised by a time lag, T1_LAMB_CYL_SEL[i]. Furthermore, the effect of the delay is considered by choice of an adequate sampling time relevant to crankshaft angle. This is depicted in 0 ... 720 CRK range.
The approximated model is theoretically defined in time range as

$$y(t) = 1 - e^{-t/T}$$

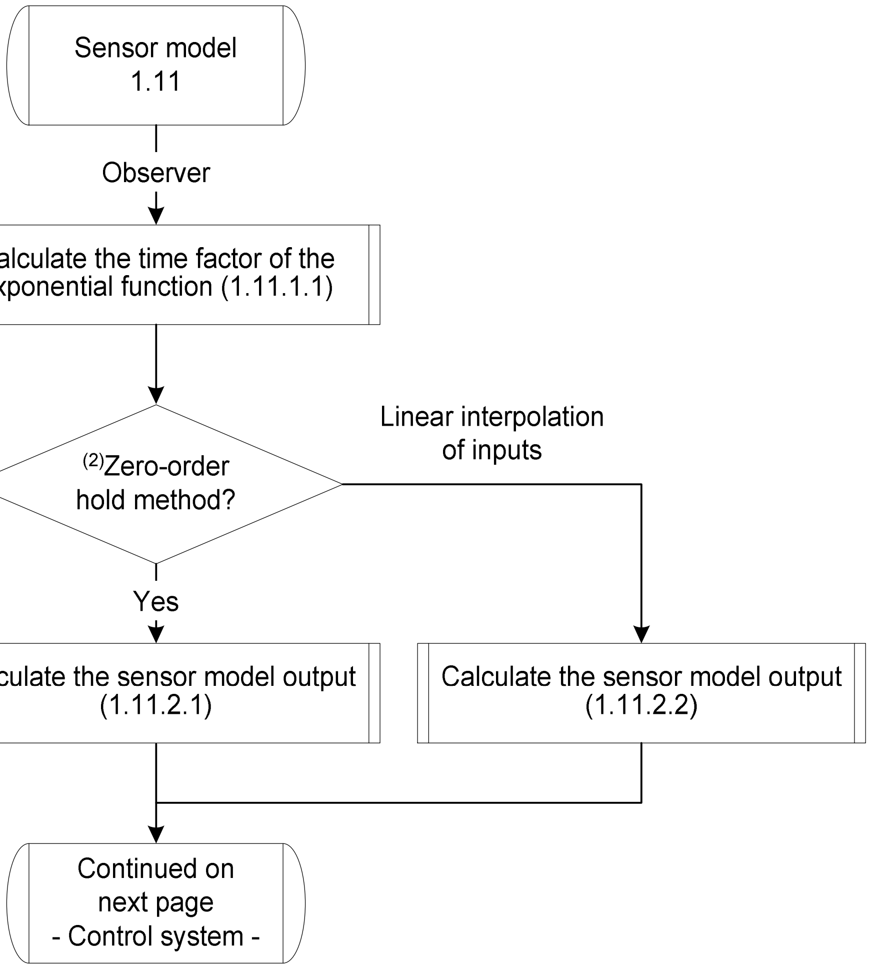
and described in frequency range as continuous-time model

$$G(s) = \frac{1}{1 + sT}$$

with T = T1_LAMB_CYL_SEL[i]

Conversion of continuous-time model to discrete-time model with sample time TA can be made using either ’zoh’- or ’foh’-method.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



7.73.12.1 Calculation of model parameters

$$FAC\_T[i] = \frac{T1\_LAMB\_CYL\_SEL[i]}{TA}$$

(1.11.1.1)

- Zero-order hold on the inputs ’zoh’ - recommended method

(LC_LAMB_DELTA_MDL_HLD = 0)

calibration maps are

$$IP\_EXP\_LAMB\_MDL[i] = e^{-\frac{1}{FAC\_T[i]}},$$

IP_N1_FAC_LAMB_MDL[i] = 1 - IP_EXP_LAMB_MDL[i] and
IP_N2_FAC_LAMB_MDL[i] = 0

- Linear interpolation of inputs ’foh’ (LC_LAMB_DELTA_MDL_HLD = 1)

calibration maps are

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

$$IP\_EXP\_LAMB\_MDL[i] = e^{-\frac{1}{FAC\_T[i]}},$$

IP_N1_FAC_LAMB_MDL[i] = 1 - FAC_T[i]$_*$ (1 - IP_EXP_LAMB_MDL[i]) and
IP_N2_FAC_LAMB_MDL[i] = FAC_T[i] - (1 + FAC_T[i])$_*$ IP_EXP_LAMB_MDL[i]

7.73.12.2 Calculation of the sensor model output

The output of sensor model is governed by DELTA_LAMB_MDL[i].

if$^{(2)}$LC_LAMB_DELTA_MDL_HLD = 0
then
DELTA_LAMB_MDL[i]$_k$ = IP_EXP_LAMB_MDL[i]*DELTA_LAMB_MDL[i]$_{k-1}$ + IP_N1_FAC_LAMB_MDL[i]*DELTA_LAMB_CYL_SEL[i]$_k$
(1.11.2.1)
else$^{(2)}$
DELTA_LAMB_MDL[i]$_k$ = IP_EXP_LAMB_MDL[i]*DELTA_LAMB_MDL[i]$_{k-1}$ + IP_N1_FAC_LAMB_MDL[i]*DELTA_LAMB_CYL_SEL[i]$_k$ + IP_N2_FAC_LAMB_MDL[i]*DELTA_LAMB_CYL_SEL[i]$_{k-1}$
(1.11.2.2)
endif$^{(2)}$

Attention:

Precise allocation required. For segment x, DELTA_LAMB_MDL[i]$_{k-1}$ and DELTA_LAMB_CYL_SEL[i]$_{k-1}$ are buffered variables that were calculated in the segment x -1 for one bank system and x - 2 for two bank system.

7.73.13 Control system

A cylinder individual AFR regulation is carried out (Figure 3).

7.73.13.1 Control deviation

The tracking error for corresponding cylinder is defined as DELTA_LAMB_DIF_CYL[x].

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.73.13.2 Calculation of proportional-action controller (P-Component)

The P-Component can be switched off using an on-off switch

if$^{(3)}$ LC_FAC_CYL_LAM_P_SWI = 1
then
FAC_CYL_LAM_P[x]= IP_FAC_GAIN_P_LAM_CYL_SEL* DELTA_LAMB_DIF_CYL[x]*IP_CRLC_P_NEUT_RNG **(1.12.2.1)**
else$^{(3)}$
FAC_CYL_LAM_P[x]= 0 **(1.12.2.2)**
endif$^{(3)}$

7.73.13.3 Calculation of integral-action controller (I-Component)

Tracking step disturbances with zero steady state error requires integration of the tracking error. Integral action can be incorporated by defining an internal state FAC_CYL_LAM_INT[x] that represents the integrated tracking error. This state is governed by FAC_CYL_LAM_INT[x]. For the injection systems being not adapted the integral action can be switched to the fast control parameter. The action is then triggered by LV_LAM_CYL_SEL_CTL_FAST_REQ.

if$^{(3)}$ LV_LAM_CYL_SEL_CTL_FAST_REQ = 1
then
FAC_CYL_LAM_INT[x]$_k$= FAC_CYL_LAM_INT[x]$_{k-1}$ + IP_CRLC_INT_FAST_CYL_LAM*DELTA_LAMB_DIF_CYL[x]$_k$* IP_CRLC_I_NEUT_RNG **(1.12.3.1)**
else$^{(3)}$
FAC_CYL_LAM_INT[x]$_k$= FAC_CYL_LAM_INT[x]$_{k-1}$ + IP_CRLC_CYL_LAM*DELTA_LAMB_DIF_CYL[x]$_k$* IP_CRLC_I_NEUT_RNG **(1.12.3.2)**
endif$^{(3)}$

In order to avoid rounding error that leads to zero-readout of the gradient term in aforementioned equation, following scan shall be made:

7.73.13.9 Update of cylinder individual lambda adaptation values

The computation of the cylinder individual lambda adaptation shall be updated in the time-cycle C_T_LAM_CYL_ADJ_CST/C_T_LAM_CYL_ADJ. When the computation was carried out, then the initial value of cylinder individual lambda-controller, FAC_CYL_LAM_INT[x], and low pass filter, FAC_LAM_CYL_SEL_ADJ_FIL[x]/FAC_LAM_CYL_SEL_ADJ_CST_FIL[x] shall be shifted. On the deactivation condition all cylinder individual filter outputs, FAC_LAM_CYL_SEL_ADJ_FIL[x] and the timer CTR_T_LAM_CYL_ADJ[i] shall be set to zero.

7.73.16 Detection of observer divergence

In order to detect the observer divergence in closed-loop operation and stop the adaptation process consequently, virtual limitation (C_FAC_CYL_LAM_VIRT_MIN/MAX) is defined. As soon as the single controller output (FAC_CYL_LAM[x]) passes the virtual limit over, the value of CILC- Characteristic Quantity (CQ- value as a measure for the observer behaviour) for the concerned exhaust bank is stored. Should one of the concerned exhaust-bank members (cylinders) reach the actual limit (LV_FAC_CYL_

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LAM_LIM_MIN/MAX[x] = 1) the current CQ- value has to be compared with the stored value at virtual limit transition. A positive ascent of characteristic value (CQ- value) in current activation cycle (STATE_LAMB_CYL_SEL_CQ_SLOP[i] = 2) is interpreted as for unstable behaviour of CILC and shall involve inhibition of adaptation process.

Phase Shift Adaptation

FUNCTION DESCRIPTION:

General information:

This module enables an adaptation of phase shift, which might be influenced by ageing effect of wide range A/F sensor or even calibration-error for instance.

if(1) two separate exhaust banks are concerned
then

i = 1, for cylinder bank 1 (x = 0, 2, 4, ...)
i = 2, for cylinder bank 2 (x = 1, 3, 5, ...)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

else(1)

i = 1 (x = 0 ... 3 or 4)

endif(1)

Description of index "[i]" and "[x]":

x: logical cylinder
*use **NC_CYL_NR** : number of engine cylinders - index "[x]"*
*use **LF_LS_CBK_EX_LAM_CYL_SEL_CONF**: pattern for allocation of physical cylinders to exhaust bank - index "[i]"*

Time recurrence: every TDC

7.74.1 Initialization (at reset)

The following initialization shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

7.74.8 Detection of Cylinder Individual lambda Control Instability - based on CILC- controller output:

For detection of unstable state of CILC the controller output of adjacent cylinders are considered. Should two of the cylinders be at the opposite limit and a drift-away behaviour of cylinder individual lambda control be detected, thus the unstable behaviour of CILC is assumed.

if$^{(4)}$ **[{**(LV_FAC_CYL_LAM_LIM_MIN[x] = 1 **and** LV_FAC_CYL_LAM_LIM_MAX[x+1] = 1) **or** (LV_FAC_CYL_LAM_LIM_MAX[x] = 1 **and** LV_FAC_CYL_LAM_LIM_MIN[x+1] = 1)**} and** LV_LAM_CYL_SEL_CTL_DRIFT_PRED[i] = 1**]** [*Remark: the index x and x+1 relate to the in succession firing cylinders on the same exhaust bank]*

General Information

The module serves as a check box for application conditions of the function cylinder individual lambda control . If several conditions are fulfilled the flag LV_LAM_CYL_ENA is set to 1. This flag is an input to the cylinder individual lambda control.

Description of index "[i]" and "[x]":

x: logical cylinder
use NC_CYL_NR: number of engine cylinders index "[x]"
use LF_LS_CBK_EX_LAM_CYL_SEL_CONF: pattern for allocation of physical cylinders to exhaust bank index "[i]"

Application Conditions

Initialization: RST
Activation: SEG: always
100MS: always
Deactivation: never

7.75.1 Initialisation Overview

7.75.1.1 Initialisation at Reset

Check if CLF_LS_CBK_EX_LAM_CYL_SEL_CONF is calibrated in a valid way (0 or NC_LAMB_REF). If not, LV_LS_CBK_LAM_CYL_SEL_CONF_VLD indicates that the calibration is wrong and LV_LAM_CYL_ENA[NC_CBK_EX_NR] can not be set to 1.
So CILC is deactivated when calibration is wrong

7.75.2.1.5 Calculation of Variable Phase shift

Regarding the influence of variable position of exhaust camshaft on phase shift, a variable phase shift, PHA_SHIFT_CAM_EX[i] is defined.
For a six-cylinder engine with a variable valve timing for instance, the variable phase shift is governed by the following calculation.

Dynamic window of engine speed for detection of limited dynamics (cylinder individual lambda control)					

General information

The condition limited dynamics LV_LAM_CYL_SEL_LDC[i] for cylinder individual lambda control is detected if the engine speed, mass air flow and the mean value of lambda controller output are within the corresponding dynamic window. Once all of the conditions are fulfilled, the integral of the mass air flow is calculated. The limited dynamics is then detected (LV_LAM_CYL_SEL_LDC[i] = 1) if the value of mass air flow integral reaches the calibrated threshold.

Application conditions:

Initialisation: **at reset, LV_IGK = 0 →1 and clear error memory:**

```
LV_LAM_CYL_SEL_LDC[i] = 0
MAF_INT_LDC_LAM_CYL_SEL[i] = 0
```

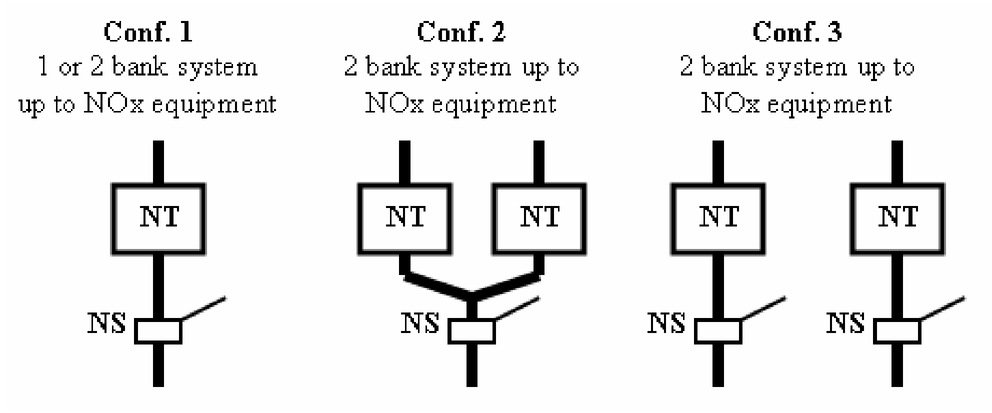
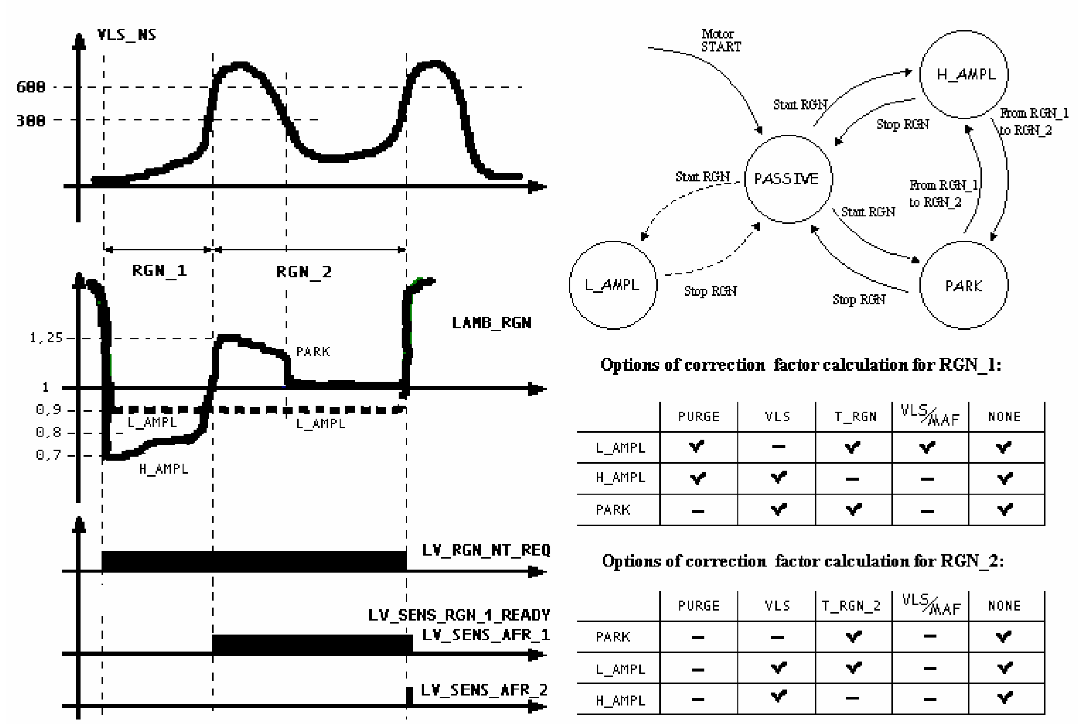
General Information

The requirement of NOxstorage catalyst regeneration is the engine is operated with a rich mixture. This is the lambda setpoint for catalyst regeneration edition for single- and twin-branched exhaust lines, also for the Y configuration with two NOx-Traps (NT) and one NOx-Sensor (Conf 2). In this case the lambda setpoint of the already regenerated NT is set to the park value C_LAMB_PARK_BAS. The covered exhaust gas configurations are shown in the picture below:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



The regeneration curves, state flow and correction options for example configuration shows the picture:



Options of correction factor calculation for RGN_1:

	PURGE	VLS	T_RGN	VLS/MAF	NONE
L_AMPL	✓	–	✓	✓	✓
H_AMPL	✓	✓	–	–	✓
PARK	–	✓	✓	–	✓

Options of correction factor calculation for RGN_2:

	PURGE	VLS	T_RGN_2	VLS/MAF	NONE
PARK	–	–	✓	–	✓
L_AMPL	–	✓	✓	–	✓
H_AMPL	–	✓	–	–	✓

NC_CBK_EX_NR is the number of exhaust gas lines. Therefore
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2.
NC_NOX_SENS_CONF is the number of NOx-Sensors. Therefore
NC_NOX_SENS_CONF = 0, for no NOx-Sensor
NC_NOX_SENS_CONF = 1 (n = 1), for one NOx-Sensor
NC_NOX_SENS_CONF = 2 (n = i), for two NOx-Sensors
NC_NT_NR is the number of NOx Catalysts. Therefore
NC_NT_NR = 1 (k = 1), for one NOx Catalyst
NC_NT_NR = 2 (k = i), for two NOx Catalysts

7.77.1 INITIALIZATION AT RESET, ACTIVATION AND DEACTIVATION

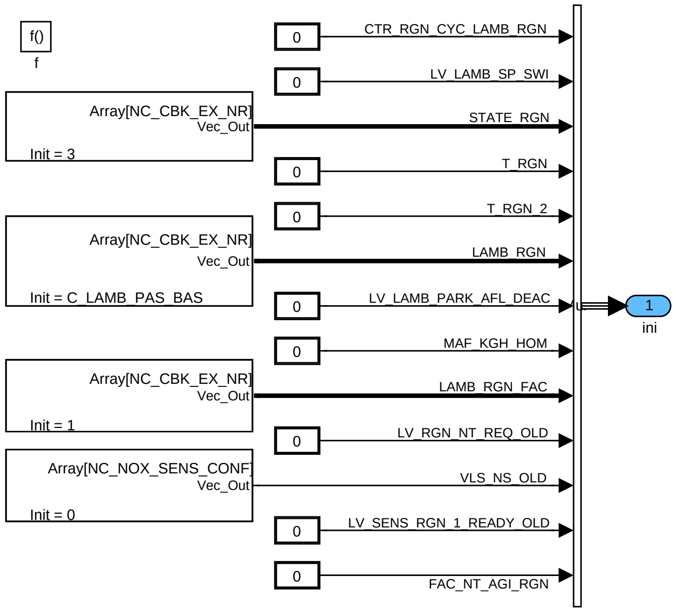

Figure 7.77.3: :

7.77.2 FORMULA SECTION

The function consists of two main sections:

SECTION 1: Initialization of the Regeneration State at start of the regeneration, calculation of the regeneration time and of the lambda basis for the low amplitude regeneration

SECTION 2: Calculation of the Regeneration State and the Regeneration Lambda Setpoint

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.77.2.1 SECTION 1: Initialization of Regeneration State at start of the regeneration, calculation of regeneration time and lambda basis for the low amplitude regeneration

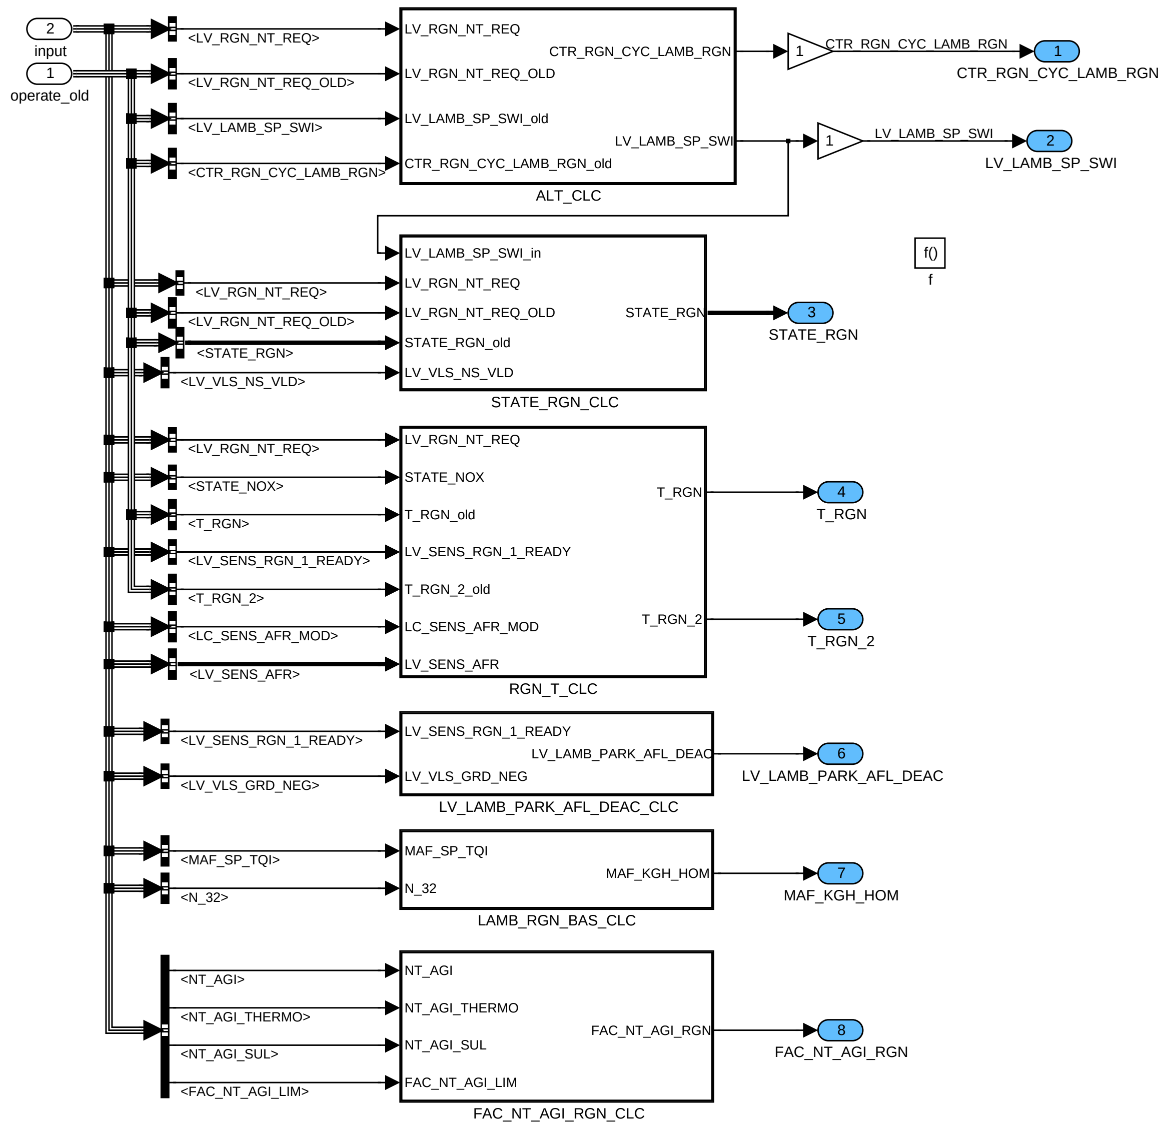

Figure 7.77.5: :

7.77.2.1.1 Calculation of regeneration counter and alternate flag

The regeneration counter is incremented at entering in regeneration. The alternate flag is used for switching of initialization values for the STATE_RGN between both banks. The interval between switching is set by the C_CTR_RGN_SWI_DEAC (alternate flag is not active) and by the C_CTR_RGN_SWI_ACT (alternate flag is active).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

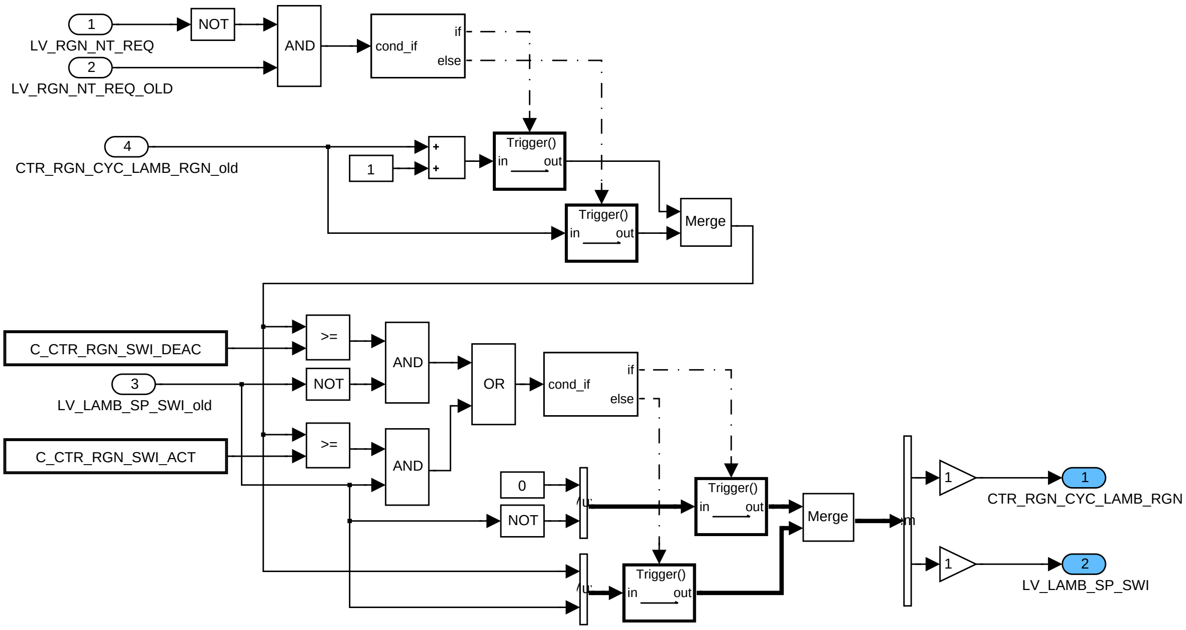

Figure 7.77.6: :

7.77.2.1.2 Initialization of regeneration state

The regeneration strategy for all banks is set at start of regeneration. The regeneration state is initialized depending on alternate flag.

7.78.1 EGTR_DEFSPCENRD0

This function determines the oxygen loading for different catalyst enrichment (purge) cases that is to be relased during pre cat purge. The oxygen loading to be released during main cat purge is defined in the main function based on the oxygen loading for the pre catayst. Furthermore a priorization of the different cases is included.

The different enrichment cases after lean air fuel mixture condition, that are described within this function, are catalyst purge

after trailing throttle fuel cutoff phase (PUC),

after secondary air injection (SA),

after hot start (HST) and

after catalyst heating (CH) with lean air fuel mixture condition.

after cylinder cutoff at gear shifting (GS_SCC).

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

Different catalyst purge cases

If LV_CAT_PURGE_ACT[i] is or gets 0 and STATE_CAT_PURGE[i] is not changing (compared to one sample step before) then the state is set to CAT_PURGE_OFF .
When one of the different cat purge cases gets active the flag LV_CAT_PURGE_ST[i] is set for one sample step to inform the main function.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

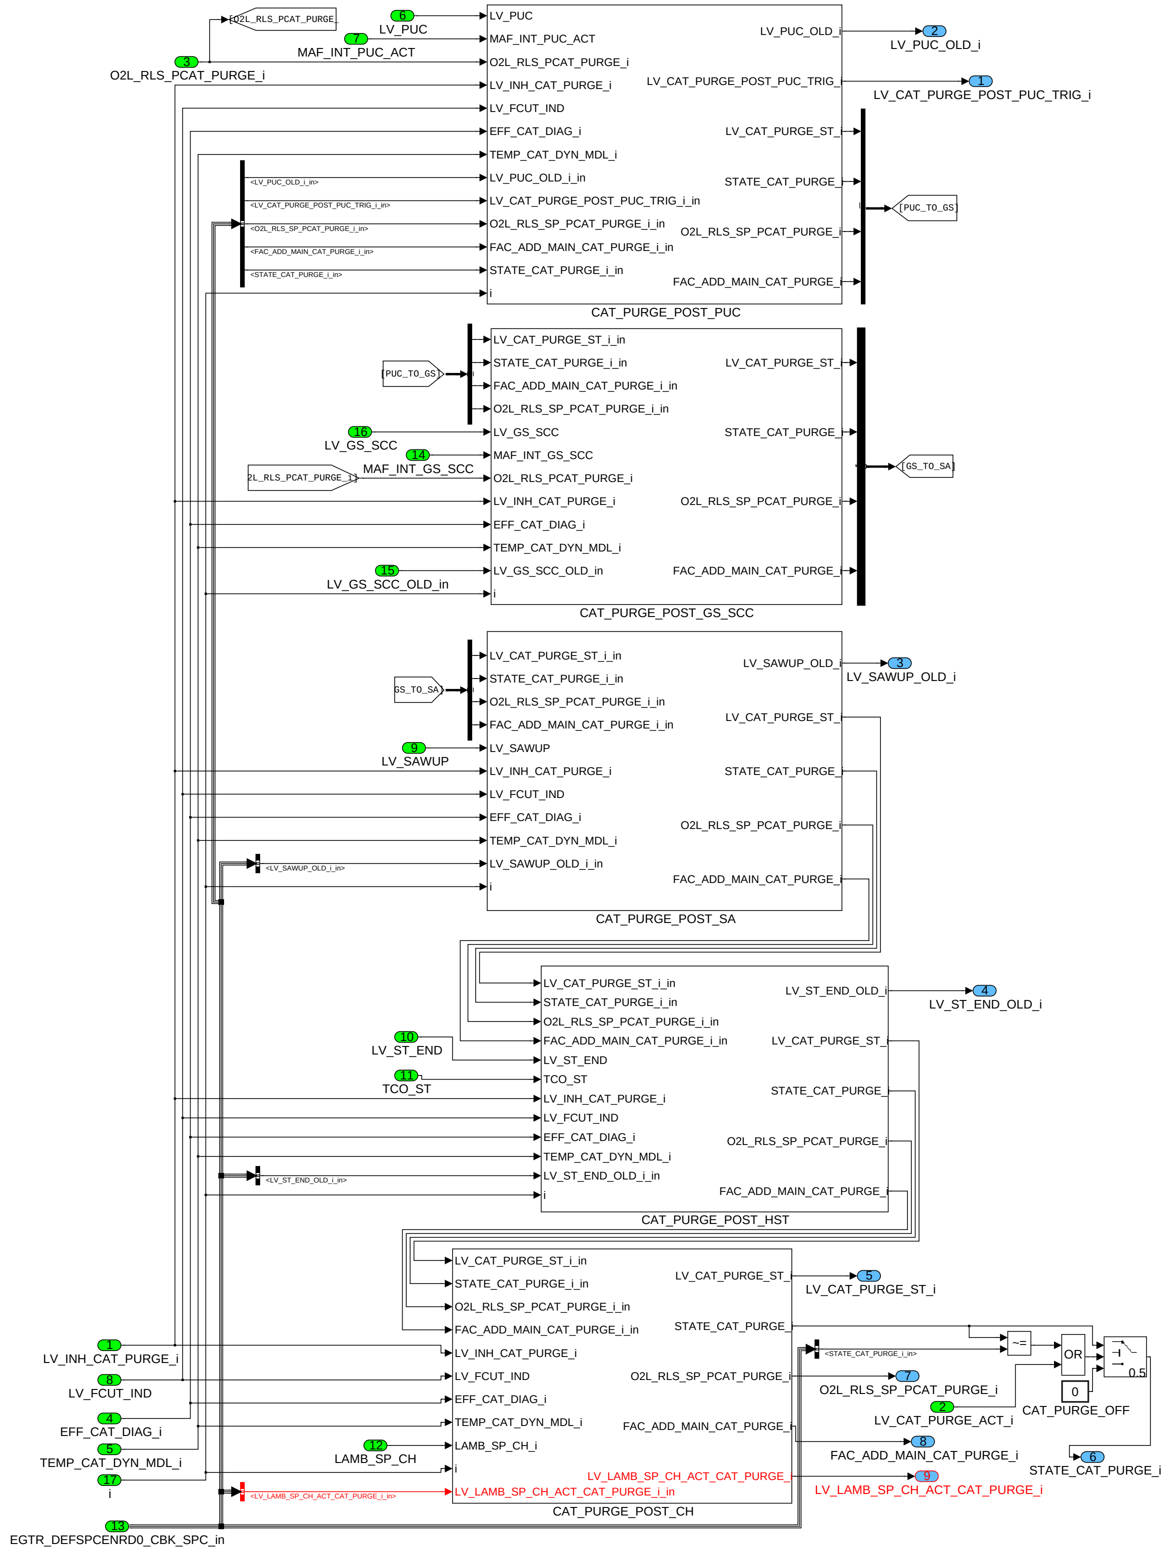

Figure 7.78.5: EGTR_DEFSPCENRD0/operate/EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC

Catalyst purge after catalyst heating with lean air fuel mixture condition

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Cat purge after catayst heating is activated at falling edge of LV_LAMB_CH. Cat purge after trailing throttle fuel cutoff phase must not be active, no cylinder must be shut off and the inhibition flag must not be set.
The cat purge state is set to CAT_PURGE_CH .
The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_CH multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_CH.

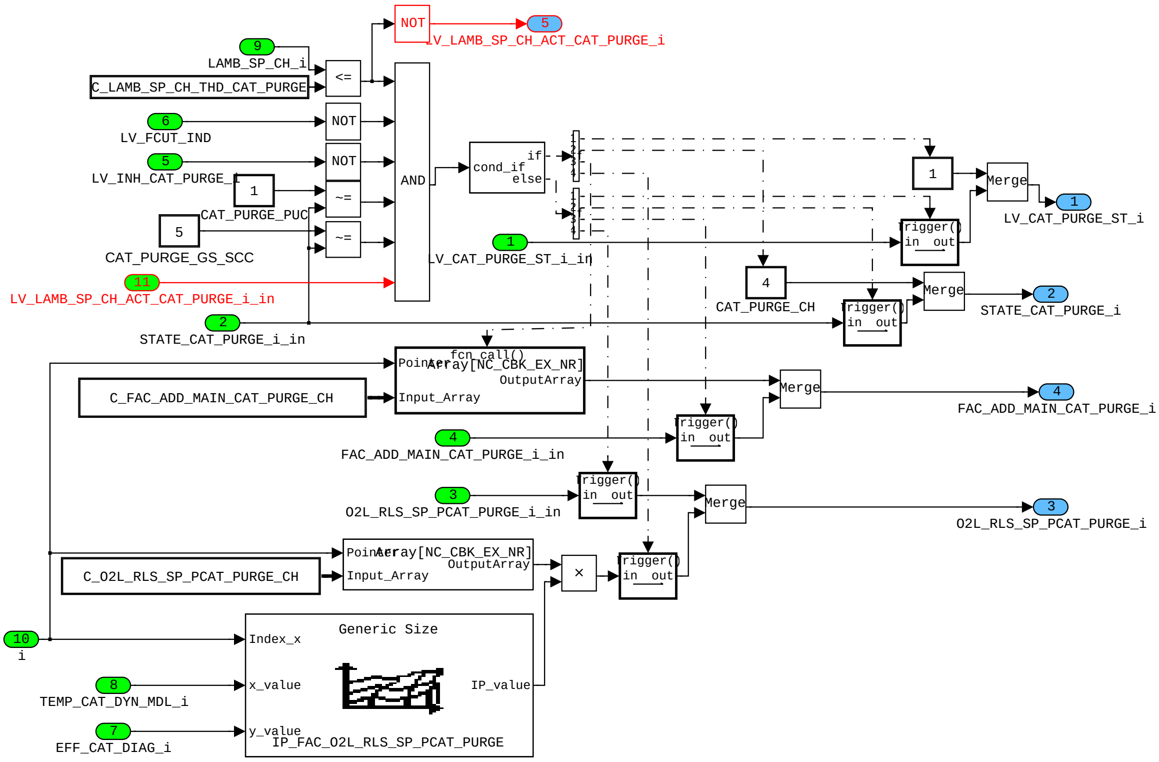

Figure 7.78.6: EGTR_DEFSPCENRD0/operate/EGTR_DEFSPCENRD0_CBK_MNG/
EGTR_DEFSPCENRD0_CBK_SPC/CAT_PURGE_POST_CH

Catalyst purge after cylinder cut off at gear shifting

Cat purge after cylinder cutoff at gear shifting is activated by a falling edge of LV_GS_SCC. It is similar to purge after PUC and has the same priority.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

EGTR_DEFSPCENRD0_CBK_SPC/CAT_PURGE_POST_GS_SCC

Catalyst purge after hot start

Cat purge after hot start is activated at rising edge of LV_ST_END when the cooling temperature at start (TCO_ST) is above a calibration threshold. No other cat purge case must be active, no cylinder must be shut off and the inhibition flag must not be set.

The cat purge state is set to CAT_PURGE_HST .

The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_HST multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_HST.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

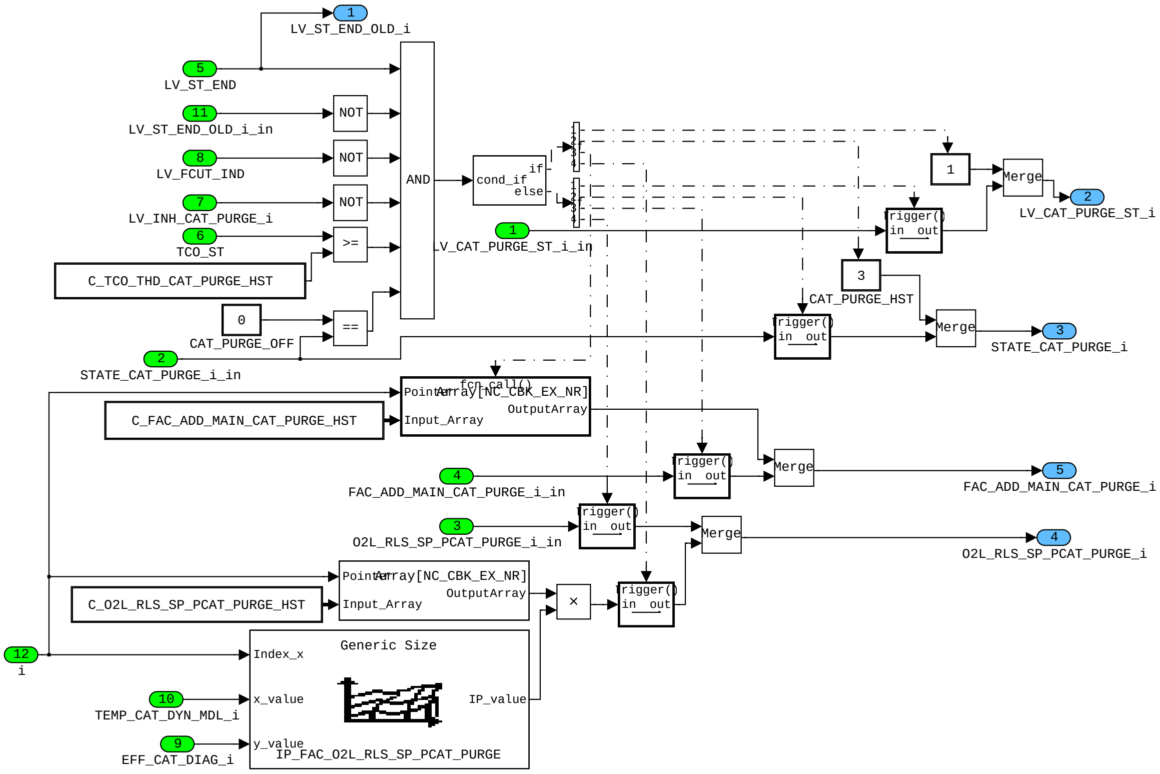

Figure 7.78.8: EGTR_DEFSPCENRD0/operate/EGTR_DEFSPCENRD0_CBK_MNG/
EGTR_DEFSPCENRD0_CBK_SPC/CAT_PURGE_POST_HST

Catalyst purge after trailing throttle fuel cut off phase

Cat purge after trailing throttle fuel cutoff (PUC) is activated at falling edge of LV_PUC. The inhibition flag must not be set and the air mass that was integrated during PUC must be above a minimum threshold or during last cat purge the pre cat purge was not finished (O2L_RLS_PCAT_PURGE[i] $>$ 0).

If at least one cylinder is shut off (LV_FCUT_IND = 1) when the conditions above are fulfilled then the start of cat purge is delayed till no cylinder is shut off any more. This is realized by means of the auxiliary flag LV_CAT_PURGE_POST_PUC_TRIG[i].

The cat purge state is set to CAT_PURGE_PUC .

The oxygen loading to be relased during pre catalyst purge is defined by IP_O2L_RLS_SP_PCAT_PURGE_PUC multiplied by a catayst temperature and efficiency depending factor. The result is limited to the maximum oxygen loading of the pre catalyst defined by C_O2L_RLS_MAX_PCAT_PURGE. The additional factor to calculate the main catayst loading is set to 1.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

EGTR_DEFSPCENRD0_CBK_SPC/CAT_PURGE_POST_PUC

Catalyst purge after secondary air injection

Cat purge after secondary air is activated at falling edge of LV_SAWUP. Cat purge after trailing throttle fuel cutoff phase must not be active, no cylinder must be shut off and the inhibition flag must not be set.

The cat purge state is set to CAT_PURGE_SA .

The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_SA multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_SA.

General Information

The catalyst purge function realizes fast adjustment of optimized conditions for a high catalyst efficiency after a transition from trailing throttle fuel cut-off phase or other lean air fuel mixture conditions to stoichiometric conditions. That requires a fuel enrichment in order to reduce the oxygen content inside the catalyst. The degree of the fuel enrichment depends on the oxygen and the NOx content in the catalyst.
The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

Application Conditions

Initialization: RST
Recurrence: 20MS
Activation: always
Deactivation: never

7.79.2.1 Introduction of multiple bank system

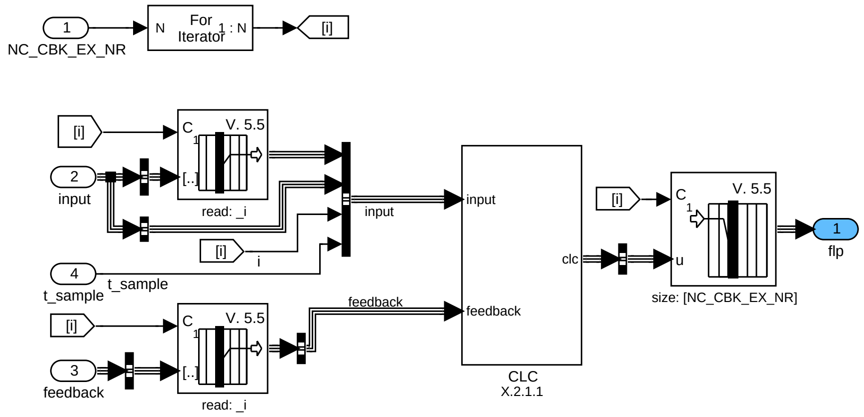

Figure 7.79.4: :

7.79.2.1.1 Formula section

7.79.2.1.1.1 Management of catalyst purge initialization and pre and main catalyst purge

If LV_CAT_PRUGE_ST[i] is set by the function Oxygen loading determination for catalyst enrichment function the initialization sub-system (INI_CAT_PURGE) is called. The flag is set only for one sample step.
Depending on LV_CAT_PURGE_PCAT[i] and LV_CAT_PURGE_MAIN_CAT[i] one of the sub-systems PRE_CAT_PURGE or MAIN_CAT_PURGE is called.
If LV_PUC or the inhibition flag is set no cat purge is executed or an active cat purge is interrupted (sub-system NOT_CAT_PURGE is called).
The cat purge activity flag LV_CAT_PURGE[i] is set to 1 if pre or main cat purge is active.

7.79.2.1.1.1.2 Calculation of CAT_PURGE

7.79.2.1.1.1.2.1 Initialization of catalyst purge (fc_INI_CAT_PURGE)

Pre cat purge is activated by setting the respective flag. Main cat purge is deactivated.
The oxygen loading release integral for pre cat purge O2L_RLS_PCAT_PURGE[i] is initialised by O2L_RLS_SP_PCAT_PURGE[i]. The oxygen loading release integral for main cat purge is calculated by multiplying the one for pre cat purge with a factor map and with the additional factor defined in the function Oxygen loading determination for catalyst enrichment function . The rest oxygen loading release and the total oxygen loading release is the sum of the one for pre cat purge and main cat purge.

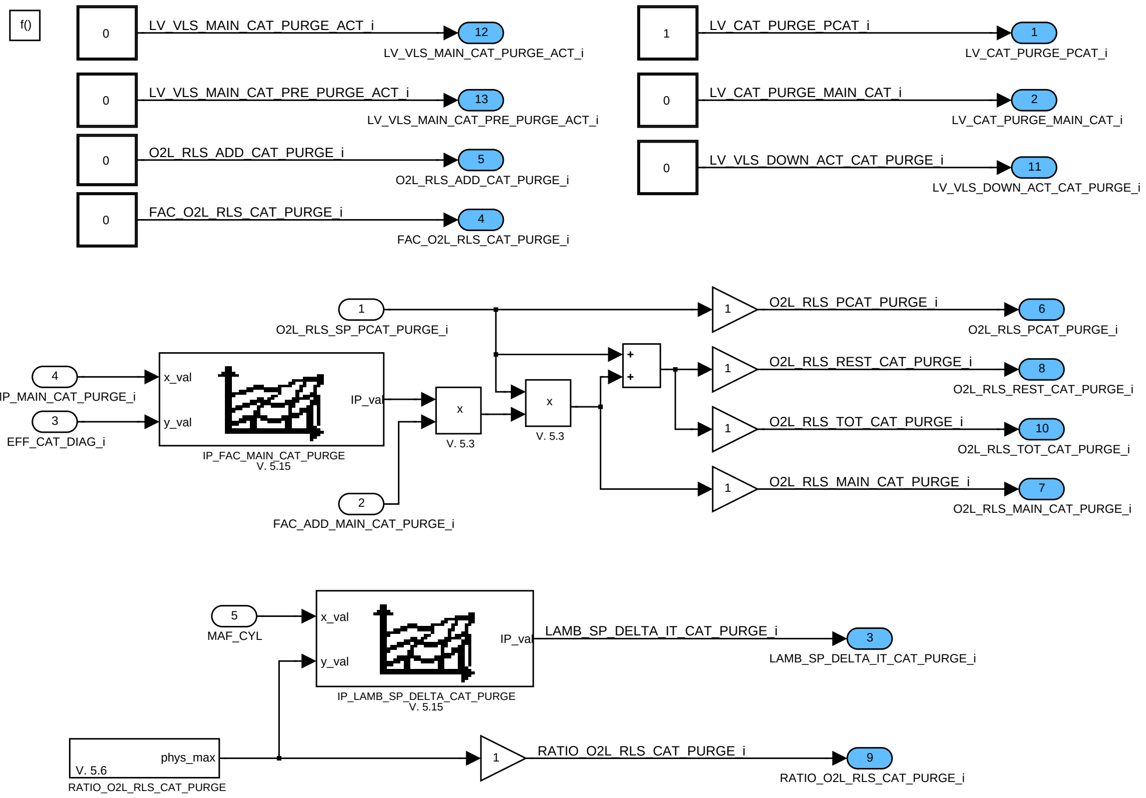

Figure 7.79.6: :

7.79.2.1.1.1.2.2 Main catalyst purge (fc_MAIN_CAT_PURGE)

If the oxygen loading for the main catalyst is released (O2L_RLS_MAIN_CAT_PURGE[i] <= 0) the end of main cat purge is detected and the respective sub-system MAIN_CAT_PURGE_END is triggered. Otherwise the sub-system MAIN_CAT_PURGE_CLC is called.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Figure 7.79.10: :

7.79.2.1.1.1.3.2 Pre catalyst purge (fc_PRE_CAT_PURGE)

If the oxygen loading for the pre catalyst is released (O2L_RLS_PCAT_PURGE[i] <= 0) and the lean to rich diagnosis isn t active (LV_DIAG_PUE_LS_DOWN_ADD_ACT = 0) or the downstream sensor signal exceeds a calibration threshold the end of pre cat purge is detected and the respective sub-system is triggered. The downstream signal is only evaluated if no error at the downstream sensor is present and the heater state is in LSH_POW_CTL . Furthermore the downstream signal must have been below the calibration threshold.
If the above mentioned conditions are not fulfilled the sub-system PRE_CAT_PRUGE_CLC is called.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.79.2.1.1.1.3.2.1 Calculation of LV_VLS_MAIN_CAT_PURGE_ACT

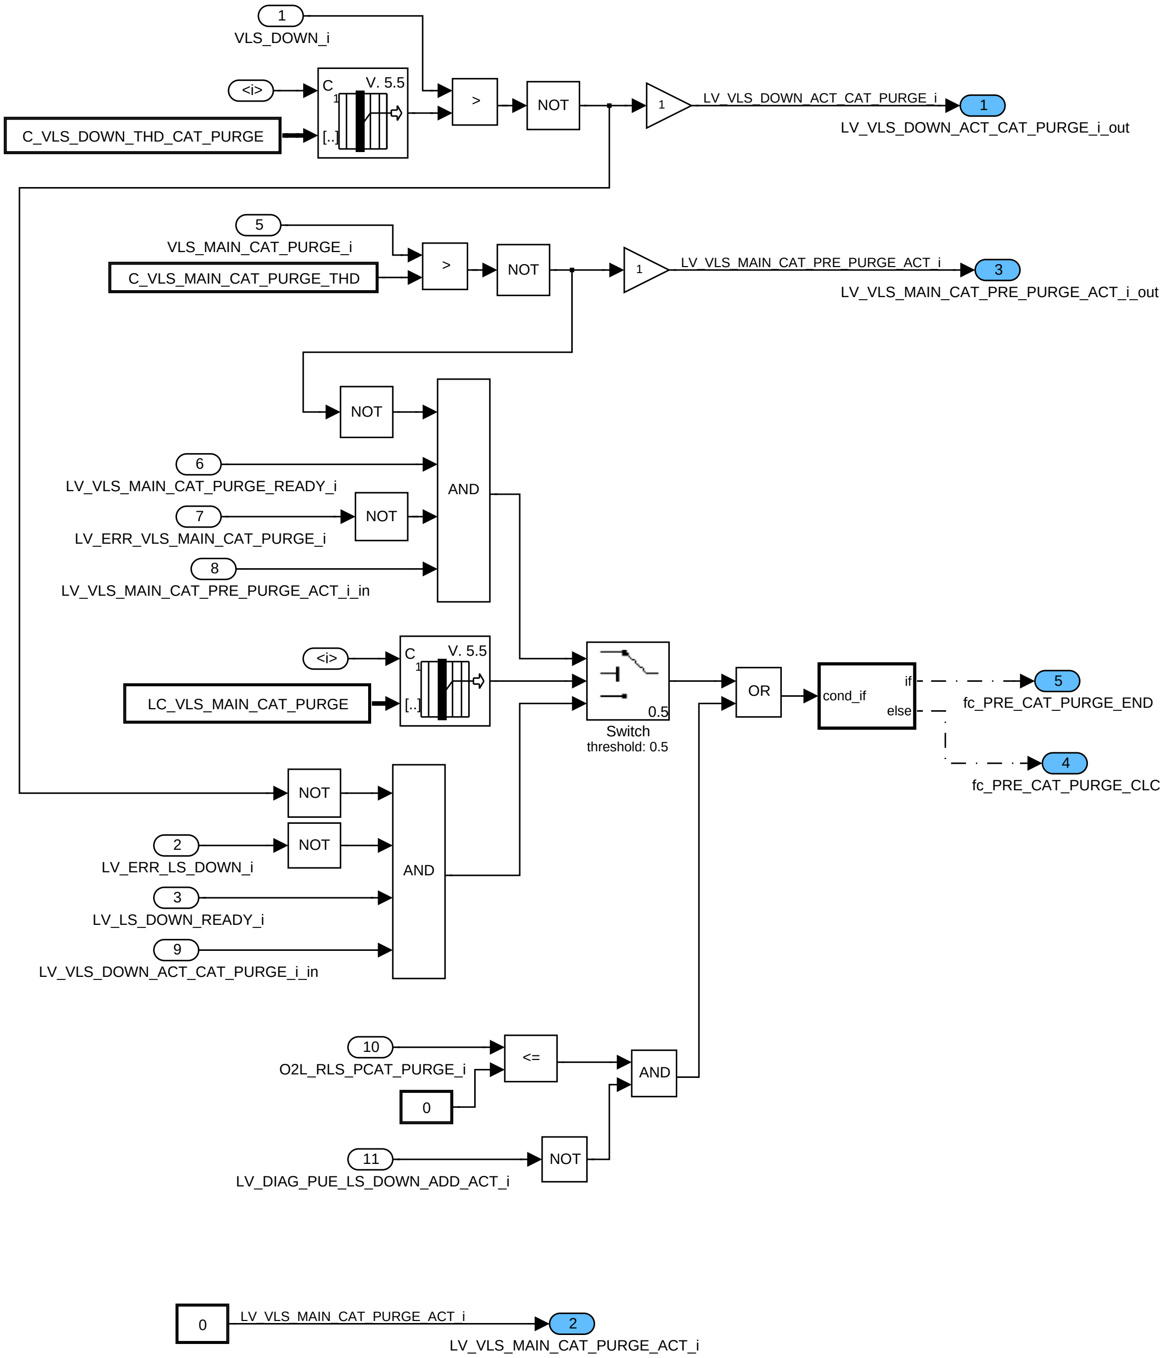

Figure 7.79.11: :

7.79.2.1.1.1.3.2.2 End of pre catalyst purge (cdn_true)

Main cat purge is activated by setting the respective flag. Pre cat purge is deactivated.
By newly evaluating the map IP_FAC_MAIN_CAT_PURGE the oxygen loading to be released during main cat purge is updated. The rest and total oxygen loading release is renewed and the quotient: rest /total oxygen loading release is also updated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

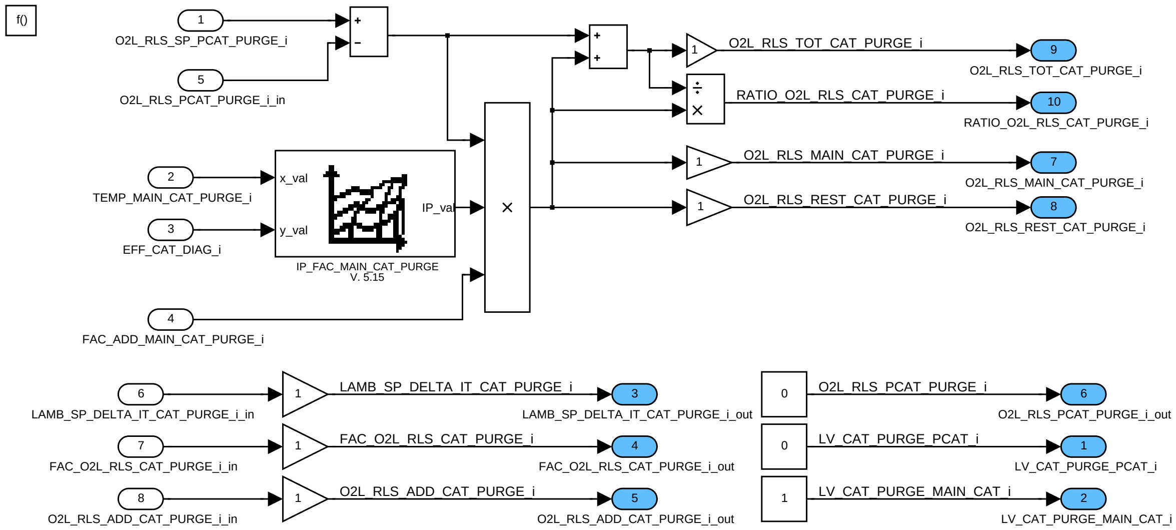

Figure 7.79.12: :

7.79.2.1.1.1.3.2.3 Calculation of pre catalyst purge oxygen loading release (cdn_false)

The rich shift of the lambda set point is taken from the respective map. The oxygen loading release is calculated by the following formula:

$$m_{O_2} = 0.23 \cdot \int \frac{-\Delta\lambda_{SP}}{1-\Delta\lambda_{SP}} \cdot \dot{m}_{air}\, dt$$

The remaining oxygen loading release (O2L_RLS_REST_CAT_PURGE[i]) is renewed and the quotient (RATIO_O2L_RLS_CAT_PURGE[i]): rest /total oxygen loading release is calculated.
For the calculation of the oxygen loading the unit conversion:
[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600
has to be considered.
The fraction of the formula above is minimized to the resolution of its variable (FAC_O2L_RLS_CAT_PURGE[i]). The oxygen loading that is added each sample step is also minimized to the resolution of its variable (O2L_RLS_ADD_CAT_PURGE[i]).

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

General Information

This function defines the general inhibition of catalyst purge and the temperature of the main catalyst by means of a temperature gradient.
NC_CBK_EX_NR defines the number of exhaust banks.

Additionally, MAFintegrals from INSY (MAF_INT_PUC_ACT and MAF_INT_PUC_NOT_ACT) and an MAFintegral for gear shifting with cylinder cutoff (MAF_INT_GS_SCC) are included.
An additionally interface to NOXM for cat purge after lean operation is included.

Application Conditions

Initialization: RST
Activation: 20MS: always
SEG: always
Deactivation: never

7.81.2 Formula section:Calculation at every 20ms

7.81.2.1 LV_INH_CAT_PURGE and TEMP_MAIN_CAT_PURGE

LC_CAT_PURGE_INH[i] can inhibit each exhaust bank separately, while the threshold conditions of MAF_CYL, N_32 and TCO is valid for both banks in the same way. A vector operation must be applied. The temperatur gradient calculation for the main catalyst is a vector operation too.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.81.2.2 Introduction of multiple bank system

7.81.2.2.1 Calculation of LAMB_SP

7.81.2.2.1.1 LAMB_SP_DELTA_ADD_CAT_PURGE

This cat purge interface to NOXM is used after lean operation.
Vector size of input signals depend from NC_NT_NR and NC_NOX_SENS_CONF. Vector size of output signal depends from NC_CBK_EX_NR. Therefore the input signals have to be used dependend on different exhaust gas configurations. Especially, if NC_CBK_EX_NR is greater than the number of NOx sensors or NOx traps only the signal of the first bank have to be used for calculation of both banks.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.81.2.3 MAF_INT_PUC_ACT and MAF_INT_PUC_NOT_ACT

Calculation of MAF integrals is done depending on LV_PUC, the reset of the integrals is done depending on edges of LV_PUC.

These edges will be detected in the synchronous segment loop and stored in LV_PUC_CHG_L_H or _H_L, to avoid loosing edges at high speed. After reset of an integral the edge memory flag will be cleared.

C_TEMP_CAT_MIN_LAMB_PLS_ACT	-	0... 7FFFH	-273.15... 1774.7875	0.0625	°C
minimum value of the catalyst temperature for the activation of the forced stimulation					

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

The recurrence time is defined by T_SAMPLE in [ms].
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

Application Conditions

Initialization: RST
Recurrence: 20MS
Activation: LV_ST_END==1
Deactivation: LV_ST_END==0

Function description

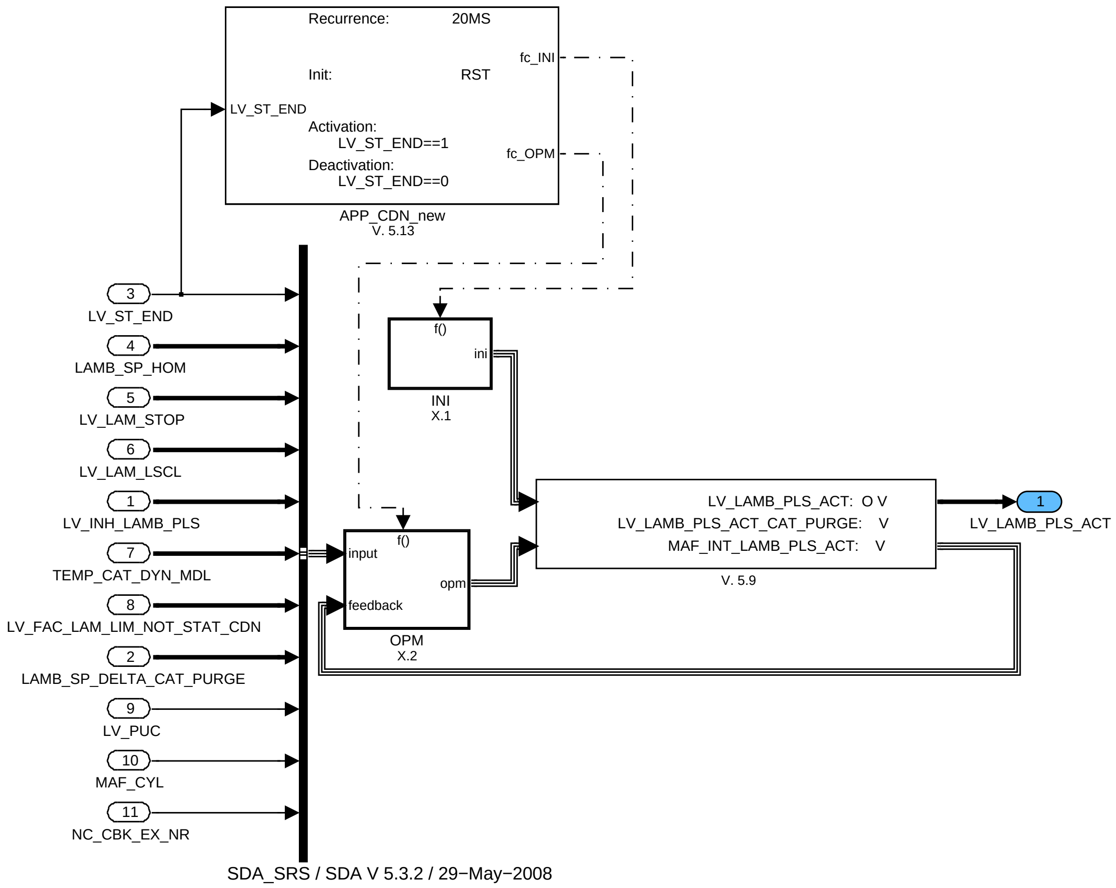

Figure 7.82.1: :

7.82.1 Initialisation

All variables are initialized with "0"

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.82.2 Introduction multiple bank system

7.82.2.1 Bank specific calculations

7.82.2.1.1 Check lambda set point delta and request for heater diagnosis

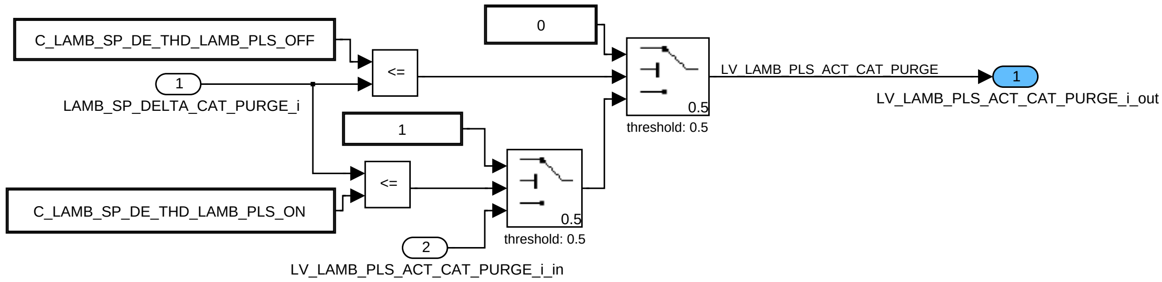

Figure 7.82.2: :

7.82.2.1.2 Check lambda and lambda controller conditions

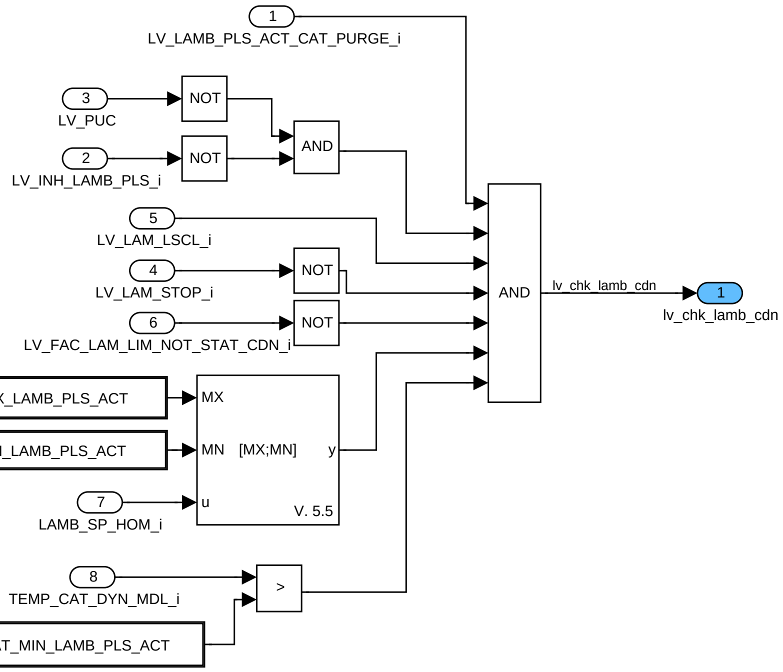

Figure 7.82.3: :

7.82.2.1.3 Calculation request for cat forced stimulation

For the activation the following conditions must be fulfilled:
- engine state pull fuel cut off is inactive
- no inhibition from application incidences
- lambda controller is activated and not in stop mode
- no lambda controller limitation under non stationary operating conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

- lambda set point deviation from catalyst purge is below calibration limit including hysteresis consideration (LV_LAMB_PLS_ACT_CAT_PURGE[i]); this flag is evaluated each time when the activation conditions are checked
- the lambda set point is in a valid range
- the catalyst temperature value exceeds a calibration threshold

If these conditions above are all fulfilled a mass air flow integral is calculated. The forced stimulation will be finally activated when the integral exceeds a calibration limit.

For the calculation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600

has to be considered.

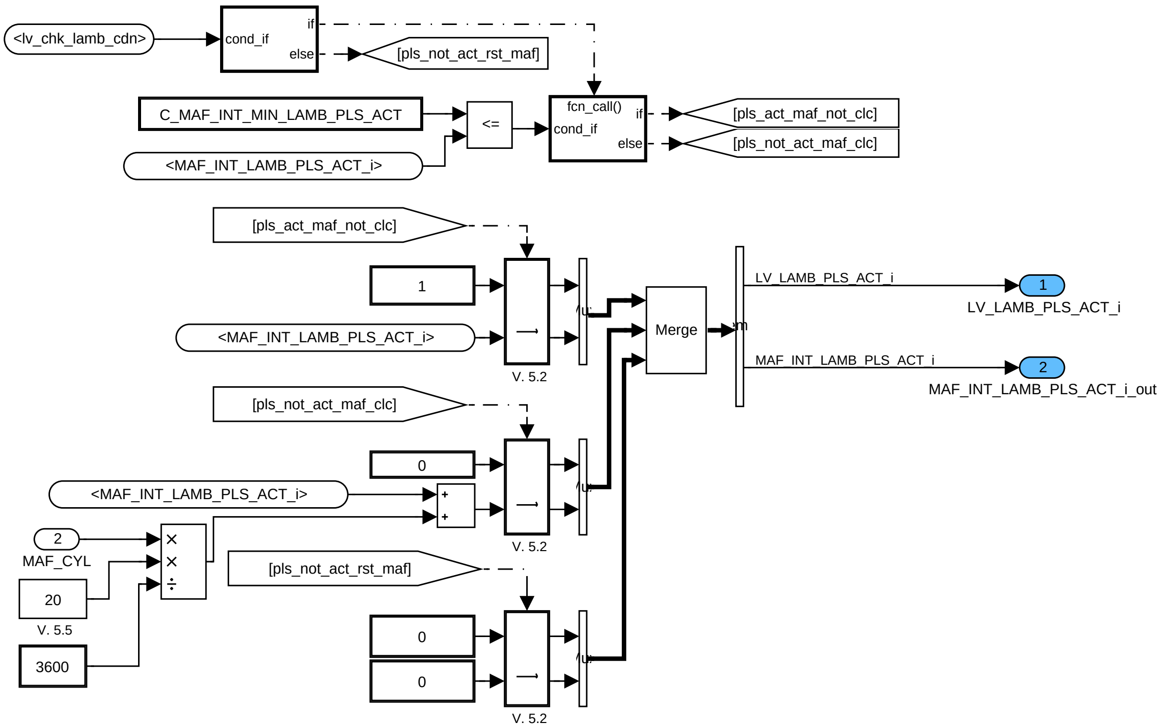

Figure 7.82.4: :

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

This module calculates the NOx engine out emission mass flow at homogeneous-stratified mode. This module guesses also a predicted value, if the homogeneous-stratified mode would become active at the actual conditions.
The calculations consist of an basis calibration, depending on fuel mass, motor speed and ambient temperature. This value will be corrected by several factors, which depend from the deviation of state variables compared to the basis calibration.

Logical value: lambda1 or richer operation is requested or active					
LV_CAT_PURGE_REQ_POST_AFL [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
request for cat purge from NOx management					
LV_MDL_AFR	O/V	0... 1H	0 ...1	1	-
Model rich exhaust gas (stop of regeneration)					
LV_NOX_SENS	O/V	0... 1H	0 ...1	1	-
Logical Variable for the existence of a NOx-Sensor					
LV_NOX_SENS_NOX_VLD_RGN_ST [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
flag: NOx sensor NOx signal validity at the moment the NOx sensor rgn request is set					
LV_NOX_SENS_RGN	O/V	0... 1H	0 ...1	1	-
Regeneration request only due to NOx sensor (loading model blocked)					
LV_NT_ACT	O/V	0... 1H	0 ...1	1	-
Flag for NOx catalyst function activation					
LV_NT_AFS_REQ	O/V	0... 1H	0 ...1	1	-
Request of lambda = 1 operation mode					
LV_NT_AFS_REQ_PRED	V	0... 1H	0 ...1	1	-
Prediction result for request of homogeneous stoichiometric operation					
LV_NT_HOM_INI	O/V	0... 1H	0 ...1	1	-
flag: NOx trap initialised due to sufficient hom. stoic. operation (accumulation effects eliminated)					
LV_NT_RGN_2_NOT_VLD	V	0... 1H	0 ...1	1	-
Regeneration of second bank not successful					
LV_NT_RGN_2_NOT_VLD_SET	V	0... 1H	0 ...1	1	-
Set condition for Regeneration of second bank not successful					
LV_NT_RGN_STOP_PUC	O/V	0... 1H	0 ...1	1	-
Indicator, that a NOx regeneration was broken by engine state PUC

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_NTL_DEC_INT_AFR	V	0... 1H	0 ...1	1	-
Rich detection by NTL_DEC_INT ratio at the end of the regeneration of the second bank					
LV_NTL_DEC_INT_STOP_RGN	V	0... 1H	0 ...1	1	-
Ratio of NTL_DEC_INT reached to cancel the regeneration of the second bank					
LV_RGN_AGI [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
Flag used for communication with aging function					
LV_RGN_AGI_VLD [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
Flag used for communication with aging function					
LV_RGN_CDN	O/V	0... 1H	0 ...1	1	-
Flag for testing whether or not regeneration conditions are given					
LV_RGN_NT_REQ	O/V	0... 1H	0 ...1	1	-
Logical Variable for NOx trap regeneration phase request					
LV_RGN_REQ_NOX_SENS	O/V	0... 1H	0 ...1	1	-
Regeneration request caused by the NOx-Sensor signal					
LV_RGN_REQ_NOX_SENS_TMP [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
Bench-selective regeneration request caused by the NOx-Sensor signal					
LV_RGN_REQ_NTLD	O/V	0... 1H	0 ...1	1	-
Logical value for regeneration phase request because of the NOx trap loading degree					
LV_RGN_REQ_NTLD_AFS	O/V	0... 1H	0 ...1	1	-
Logical value for regeneration phase request before switching to stoichiometric operation or rich operation					
LV_RGN_STOP_MDL	O/V	0... 1H	0 ...1	1	-
Flag indicating: Stop of Rgn out of model enabled					
LV_RGN_STOP_SENS	O/V	0... 1H	0 ...1	1	-
Flag indicating: Stop of Rgn by sensor enabled					
LV_RGN_STOP_TOUT	O/V	0... 1H	0 ...1	1	-
Flag indicating: Stop of Rgn by time counter enabled					
LV_SENS_AFR [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
downstream sensor measures rich exhaust gas (stop of regeneration)					
LV_SENS_AFR_TRIM	O/V	0... 1H	0 ...1	1	-
downstream sensor sees rich exhaust gas (homogeneous detection threshold)					
LV_SENS_AFR_TRIM_TMP [NC_NT_NR]	O/V	0... 1H	0 ...1	1	-
downstream sensor measures rich exhaust gas (homogeneous detection threshold) (bench-selective value)					
LV_SENS_RGN_1_READY	O/V	0... 1H	0 ...1	1	-
End of first regeneration					
LV_T_AFL_MIN	O/V	0... 1H	0 ...1	1	-
flag: minimum lean time for setting a request elapsed					
LV_TOUT_AFR	O/V	0... 1H	0 ...1	1	-
rich exhaust gas after timeout (stop of regeneration)					
LV_TRIG_AFR_AFL	O/V	0... 1H	0 ...1	1	-
Logical value for triggering a transition of rich to lean operation					
LV_VLS_GRD_NEG	O/V	0... 1H	0 ...1	1	-
Negative gradient of VLS_NOX_SENS_1 between first and second regeneration					

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Filtered corrected NOx concentration after catalyst					
NOX_CONC_RAW	O/V	0... FFFFH	0... 65535	1	ppm
NOx concentration engine out					
NOX_CONC_RED	O/V	0... FFFFH	0... 65535	1	ppm
corrected NOx concentration in catalyst (incl. SSR)					
NOX_CONC_RED_MMV	O/V	0... FFFFH	0... 65535	1	ppm
filtered corrected NOx concentration in catalyst (incl. SSR)					
NOX_CONC_RED_MMV_RGN_ST	O/V	0... FFFFH	0... 65535	1	ppm
filtered corrected NOx concentration in catalyst (incl. SSR) at NOx regeneration start					
NOX_COR	V	0... FFFFH	0... 1023.98437	0.015625	mg/s
raw engine out NOx emission					
NOX_COR_INT	V	0... FFFFH	0... 10485.6	0.16	mg
Integral of modelled NOx raw emissions (pre NOx catalyst) at current lean operation phase					
NOX_COR_RED	O/V	0... FFFFH	0... 1023.98437	0.015625	mg/s
corrected engine out NOx emission (incl. SSR)					
NOX_COR_RED_MMV	O/V	0... FFFFH	0... 1023.98437	0.015625	mg/s
Moving mean value of corrected engine out NOx emission (incl. SSR)					
NOX_FLOW	V	0... FFFFH	0... 1023.98437	0.015625	mg/s
NOx emission flow which is stored in the catalyst					
NOX_HOMS_PRED_HYS	V	0... FFFFH	-1024... 1023.96875	0.03125	mg/s
NOx hysteresis for reset of Lambda = 1.0 operation request - homogeneous lean prediction					
NOX_HOMS_PRED_THD	V	0... FFFFH	0... 1023.98437	0.015625	mg/s
NOx threshold for set of Lambda = 1.0 operation request - homogeneous lean prediction					
NOX_NS_AD_RGN_ST [NC_NT_NR]	O/V	0... 05DCH	0... 1500	1	ppm
downstream NOx concentration, measured by NOx sensor at start of regeneration					
NOX_NS_AD_TMP [NC_NOX_SENS_CONF]	V	0... 05DCH	0... 1500	1	ppm
temporary internal NOx sensor NOx value for regeneration request calculation					
NOX_OUT_INT_TMP [NC_NOX_SENS_CONF]	V	0... FFFFH	0... 10485.6	0.16	mg
temporary internal NOx out integral value for NOx sensor regeneration request calculation

FUNCTION DESCRIPTION:

General information:

The NOx catalyst management can handle single branch and twin branch exhaust gas lines with the configuration data NC_NT_NR.
If NC_NT_NR = 1, just one NOx catalyst is taken into account, if NC_NT_NR = 2, the software calculates the twin branch version concerning NOx catalysts.
with i = 1 ... NC_NT_NR
typical values of NC_NT_NR = 1; 2

If two or more separate cylinder banks are concerned, then
m = 1, for cylinder bank 1
m = 2, for cylinder bank 2
with m = 1 ... NC_CBK_EX_NR
typical values of NC_CBK_EX_NR = 1;2

NC_NOX_SENS_CONF considers the number of NOx sensors in the system
with k = 1 ... NC_NOX_SENS_CONF
typical values of NC_NOX_SENS_CONF = 1;2

In some passages logical expressions are calculated using information of different branches (example: A_1 and A_2). If this module is compiled for single branched exhaust lines, only the first expression (here: A_1) should be taken into consideration.

In case of LV_NT_STST = 1 all calculations of this module shall be inhibited. That's valid for all used recurrences (10ms, 20ms, 100ms, 1000ms).

Application conditions

Initialisation: *- -*

Recurrence: *defined at each subchapter of this module, basic recurrence of this module is 10 ms*

Activation: *LV_NT_STST = 0*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Deactivation: LV_NT_STST = 1

7.86.1 NOx catalyst management - catalyst states

FUNCTION DESCRIPTION:

Application conditions

Initialisation: – –

Recurrence: *10 ms*

Activation: – –

Deactivation: – –

7.86.1.1 State transition manager

FUNCTION DESCRIPTION:

General information:

The NOx catalyst state manager should be initialized with the STATE_NOX = PASSIVE.
In order to keep the state manager as simple as possible without loss of functionality, the state STOP contains all engine states based on stoichiometric operation except the regeneration. Such possible states are besides the ordinary lambda=1 operation the desulfation, the catalyst heating (see lambda=1-request chapter). Due to lambda oscillations in lambda=1 operation, the consideration of LV_NT_AFS_REQ is necessary in order to prevent an undesired leave of STOP.
The flag LV_RGN_AGI_i is set to 1 when the regeneration just starts (STATE_NOX switches from LOAD to REGENERATION) and the starting regeneration was requested by the modelled loading degree (LV_RGN_REQ_NTLD=1). It is reset, when the regeneration is stopped by a downstream sensor signal (see Sub-chapter: STATE_NOX = STOP).
STATE_NOX has to be initialised with PASSIVE
The states of the NOx Trap function are:

- ***PASSIVE*** : Initialisation of NOx catalyst management
- ***WARMUP***: Sensors ready, waiting for suitable catalyst temperature
- ***LOAD*** : storage of NOx (and oxygen) during lean burn phases
- ***REGENERATION*** : NOx-regeneration of the catalyst during a rich burn phase
- ***STOP*** : Lambda=1 operation
- ***WAIT***: During Fuel Cut Off, only oxygen crosses the catalyst

7.86.1.2 STATE_NOX = PASSIVE

FUNCTION DESCRIPTION:

General information:

The state PASSIVE is active during engine stop, engine start, after start, warming up and inactivated NOx catalyst function.
The values of the variables listed below are their initialisation values.
If regeneration stop mode is model , NTL has to be initialised with a suitable high value in order to prevent the state manager to leave first regeneration (after function start) due to low model load.

(1 - C_CRLC_NOX_CONC_OUT_MDL)
NOX_OUT_MDL_INT= NOX_OUT_MDL_INT$_{n-1}$ + NOX_OUT_MDL
% NOX_OUT_MDL_INT has to be internally treated as a longint.

The factor C_NOX_CONC_COR consists of the following chemical constants:
C_NOX_CONC_COR = molmass air /molmass NO2 * (1/factor for transformation kg/h- -> kg/s) = 29 /46 * 3600 = 2269.565
This value should be the initialization value of the calibration data.
Due to possible small values of NOX_OUT_MDL, NOX_OUT_MDL_INT has to be internally treated as a longint.

7.86.1.4.2 NOx trap storage capacity and loading degree

General information:

The basic catalyst storage capacity is worked out by a map depending on the raw NOx concentration NOX_CONC and on the modelled NOx-trap temperature mean value. The aging factor NT_AGI_NTLD is delivered from the module NOx catalyst aging and reduces the basic storage capacity with the present aging state depending on catalyst temperature.
The current load of the NOx storage catalyst is worked out by the NOx mass flow actually available to be stored in the catalyst NOX_FLOW and the NOx trap efficiency NT_EFF.
The NOx trap loading degree is the ratio of the NOx trap absolute loading and the NOx storage capacity.
The increase of NTLD is limited to C_NTLD_LGRD per time step.

Signal flow diagram:

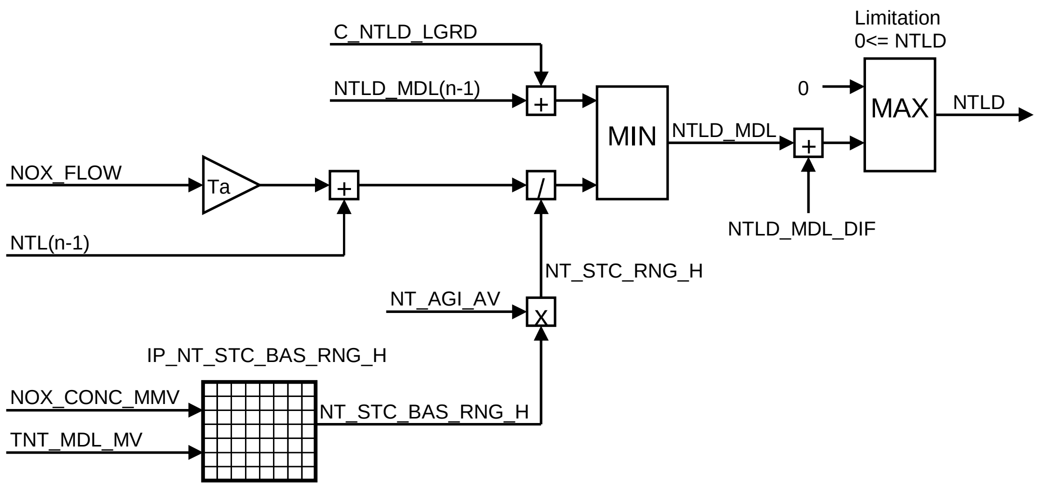

Figure 7.86.3: : NOx catalyst storage capacity, absolute loading and loading degree

Formula section:

NT_STC_BAS_RNG_H = IP_NT_STC_BAS_RNG_H (NOX_CONC_MMV, TNT_MDL_MV))
NT_AGI_AV = IP_NT_AGI_RGN_FRQ (NT_AGI_NTLD, TNT_MDL_MV)

7.86.1.6.3 Calculation of NTL_DEC and NTL_DEC_INT

General information:

For the regeneration of the NOx trap a rich mixture is required.
NTL_DEC_i represents the lack of oxygen during regeneration. This lack of oxygen corresponds to the reducing agent mass. The unit of NTL_DEC therefore is [mg O2 /time step].
NTL_DEC_INT_i represents the integral of the NTL_DEC_i during regeneration. It is calculated during the regeneration phase.
NTL_DEC_INT_SWI represents the NTL_DEC_INT up to the moment the downstream sensor switches from lean to rich. This value may be used for several adaptation purposes.
Due to possible small values of NTL_DEC (defined as a longint), NTL_DEC_INT has to be internally treated as a longint.

Formula section:

if (155) NC_NT_NR = 2

NTL_DEC_SUM = NTL_DEC[1]

endif (155)

The factor C_O2_FLOW_COR_FAC consists of the following constants:
C_O2_FLOW_COR_FAC = (0.21* molmass(O2)) /molmass(air) * factor for transformation of MAF_FG_CYL (kg/h) to (mg/s)) = 0.21 * 32 /29 * 10^6 /3600 = 64.37
This value should be the initialization value of the calibration data.

NTL_DEC_INT has to be internally treated as a longint.

7.86.1.6.4 Decrementation of the NOx trap absolute loading of NOx and O2

General information:

During the regeneration phase the reducing agent is used for both, the reduction of the stored NOx and the stored O2. This is taken into account by using a share factor FAC_RGN_DEC_SHAR for the decrement of the NTL and the O2L. This share factor is calculated using the ratio of stored O2 to the sum of stored O2 and NOx.
C_FAC_O2_EQU and C_FAC_COR_O2L are based on the chemical equation of the regeneration phase.

1. C_FAC_O2_EQU should be calibrated with 1.25 to be neutral.
2. C_FAC_COR_O2L should be calibrated with 1 to be neutral.

The constant C_O2_FLOW_COR_FAC and is also defined in oxygen storage subchapter of STATE_NOX=LOAD chapter.

Signal flow diagram:

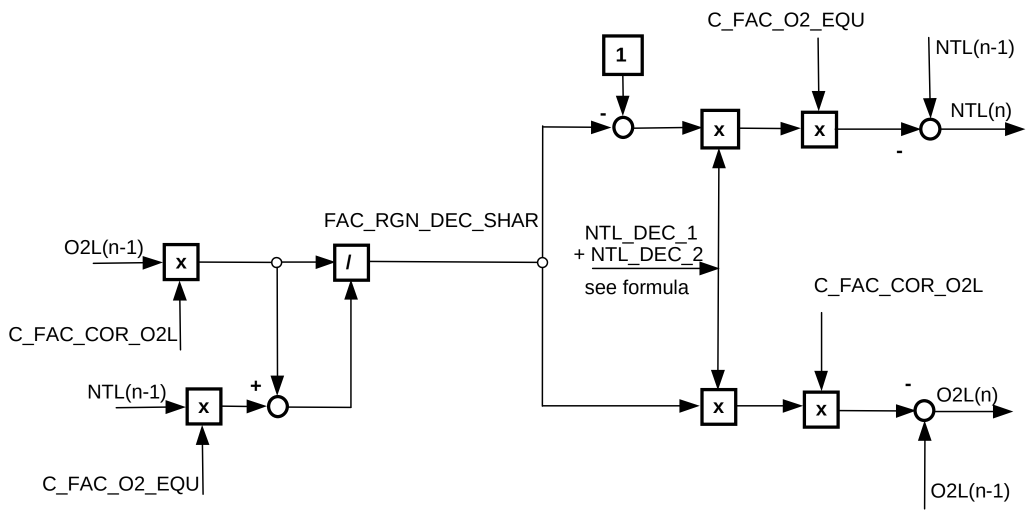

Figure 7.86.7: : NOx trap loading decrement during regeneration phase

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula section:

FAC_RGN_DEC_SHAR = O2L(n-1) * C_FAC_COR_O2L /
(O2L(n-1) * C_FAC_COR_O2L + NTL(n-1) * C_FAC_O2_EQU)

NTL_n = **max** [NTL_MIN, NTL_{n-1} - (1-FAC_RGN_DEC_SHAR) * NTL_DEC_SUM * C_FAC_O2_EQU]
NTL_H_n = **max** [NTL_MIN, NTL_H_{n-1} - (1-FAC_RGN_DEC_SHAR) * NTL_DEC_SUM * C_FAC_O2_EQU]
Attention!
- Observe different resolutions and value ranges of NTL, NTL_H and NTL_MIN.
- NTL and NTL_H should be internally calculated as longint.

O2L(n) = **max** (0, O2L (n-1) - FAC_RGN_DEC_SHAR * NTL_DEC_SUM * C_FAC_COR_O2L)
NTLD_MDL = NTL /NT_STC_RNG_H
NTLD = max (0, NTLD_MDL + NTLD_MDL_DIF)

7.86.1.7 STATE_NOX = STOP

FUNCTION DESCRIPTION:

General information:

When STATE_NOX remains in STOP (e.g. due to Lambda=1-engine operation), NTL_MIN can change due to trap temperature changes.
When the system remains in STATE_NOX = STOP for a longer time after a lean operation phase then the catalyst purge functionality is activated. The catalyst purge functionality is controlled by an own state machine.

7.86.2.2 General, definition of slow flags

FUNCTION DESCRIPTION:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

This block is executed in any STATE_NOX

The switch LC_NOX_SENS and the logical variable LV_NOX_SENS indicate the existence of a NOx-Sensor in the exhaust system.

The regeneration of the NOx catalyst can be started by the NOx-Sensor signal or by the NOx trap loading degree model. With LV_NOX_SENS_RGN, generated by the code word LC_NOX_SENS_RGN, it is possible to decide whether only the NOx sensor should be able to request a regeneration or both, model and sensor are able to request:

- LV_NOX_SENS_RGN = 1: The regeneration is started exclusively by the NOx sensor signal. The loading degree model is blocked (the regeneration request before switching to lambda 1 is not affected).
- LV_NOX_SENS_RGN = 0: The regeneration starts when the NOx catalyst loading degree exceeds a threshold or by the signal of the NOx-Sensor (which comes first)

If the system is not equipped with a NOx-Sensor, LV_RGN_REQ_NOX_SENS is permanently set to zero.

endif (48)

7.86.2.4 General, definition of fast flags

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX except PASSIVE.
At the beginning of a regeneration phase LV_TRIG_AFR_AFL must be 0. In order to trigger the transition from rich to lean operation the logical value LV_TRIG_AFR_AFL is set to 1 if the NTL becomes lower than C_NTL_TRIG_AFR_AFL.
Every time when a regeneration phase is finished the value SUM_NTL_CYC is incremented by 1. SUM_NTL_CYC has to be stored in the nonvolatile memory. SUM_NTL_CYC can be set to the specific value C_SUM_NTL_CYC_SP using the logical constant LC_SUM_NTL_CYC_NEW.
When either the binary lambda sensor or the NOx sensor indicates a rich exhaust gas downstream NOx trap, the logical variable LV_SENS_AFR_i is set to 1.
The mode of stopping a regeneration can be controlled by C_STATE_RGN_CTL. Thereby, it is possible to stop the regeneration only by the model, only by the sensor signal (LV_SENS_AFR) or by either model or sensor. In addition, a stop of regeneration after a constant regeneration time is possible. If a special regeneration (e.g. for adaptation purposes) was requested by LV_RGN_REQ_AD, the stop of the regeneration is forbidden until the adapting module re-enables it.

7.86.2.4.1 Rich mode calculation of binary NOx-Senor signal

FUNCTION DESCRIPTION:

General information:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.86.3 Rich mode calculation of binary NOx-Sensor signal (named NOXY_VL-SAFCLC110 in Figure 10)

The function sets the status flag LV_SENS_AFR_1 to rich mode and parallel sets the end of first regeneration flag LV_SENS_RGN_1_READY when the binary NOx-Sensor signal goes up for the first time over a threshold and sets the status flag LV_SENS_AFR_2 to rich mode in three ways (see Figure 9 below):

a) when the same binary signal goes up for the second time over a threshold (see Figure 9a).

b) when the binary NOx-Sensor signal goes for the first time over the threshold, then it goes not down enough and finally goes up (see Figure 9b).

c) when the binary NOx-Sensor signal goes for the first time over the threshold and then goes not down and the maximal time is over (see Figure 9c).

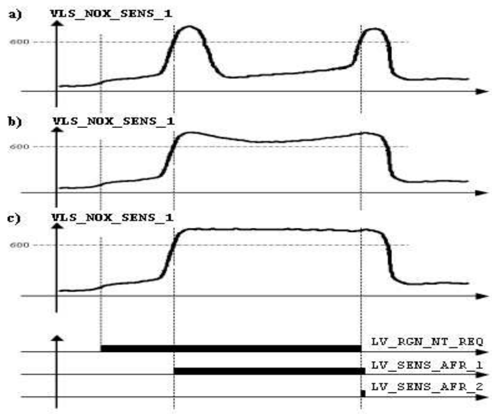

Figure 9: Signals during a NOx regeneration

This specification is special designed for systems with two banks (including two NOx-Traps) and Y-configuration of the exhaust gas system.

7.86.3.1 Request of a regeneration phase

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = LOAD

A request of a regeneration of the NOx catalyst can be made by the following conditions:

1. from the model by a high loading degree LV_RGN_REQ_NTLD
2. by the signal of the post-trap NOx-Sensor LV_RGN_REQ_NOX_SENS
3. before switching to lambda=1 or richer operation LV_RGN_REQ_AFS
4. by the diagnosis /adaptation module LV_RGN_REQ_AD

In order to guarantee a minimum duration of the lean phase the value IP_T_AFL_MIN has to be exceeded by the counter T_AFL before any regeneration request can be set.

In order to limit the regeneration frequency, T_AFL has to exceed C_T_AFL_RGN_REQ_NTLD before a regeneration request can be made by the loading degree model.

After a regeneration it is prohibited to generate a new regeneration request by the NOx sensor (LV_RGN_REQ_NOX_SENS_TMP_i = 1) for the time C_T_NOX_SENS_VLD. The time C_T_NOX_SENS_

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

VLD is controlled by the timer T_AFL. T_AFL has to exceed C_T_NOX_SENS_VLD before a regeneration can be requested by the NOx sensor.
In case of active auxiliary functionalities module, a regeneration request by the loading degree model or by the NOx sensor may be inhibited by the flag LV_INH_RGN_AD.
When switching from lean conditions to lambda=1 or richer operation a regeneration can be required. The request of this regeneration phase depends on the maximum NOx-trap loading degree for stoichiometric operation IP_NTLD_MAX_AFS_MT /IP_NTLD_MAX_AFS_AT. The check for this maximum loading degree for stoichiometric operation is carried out ever when switching to homogeneous Lambda=1 or richer engine operation which should indicated by LV_AFL_NOT=1.
A regeneration can only be requested if various conditions for allowing a regeneration are fulfilled. In this case, the logical variable LV_RGN_CDN is set to 1.

7.86.3.1.2 NOx sensor based regeneration request

This block is executed when called

General information:

If the system has only 1 cylinder bank then the variable LV_RGN_REQ_NOX_SENS_TMP_1 generates directly the value of the logical variable LV_RGN_REQ_NOX_SENS.
If the system is equipped with 2 cylinder banks, a regeneration request is set LV_RGN_REQ_NOX_SENS = 1, if at least one cylinder bank requests a regeneration LV_RGN_REQ_NOX_SENS_TMP_i = 1.
With LV_NOX_SENS_NOX_VLD_k is indicated that the signal NOX_NS_AD[k] is valid. In this case NOX_NS_AD[k] can be used for the generation of a regeneration request. Otherwise the regeneration request can not be generated by using NOX_NS_AD[k].
A NOx regeneration request can be generated by different methods. These are:

- the NOx concentration, which is measured downstream of NOx catalyst, exceeds a threshold
- the downstream measured NOx integral exceeds a threshold
- the ratio of downstream measured NOx integral to mileage exceeds a threshold
- the ratio of downstream measured NOx integral to upstream modelled NOx integral exceeds a threshold

Recurrence: called by superior chapter

Signal flow diagram:

7.86.3.2 Request of a NOx catalyst purge

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = LOAD
If there is no request for a regeneration before switching from lean burn condition to lambda=1 or richer mixture a NOx catalyst purge request is set dependent on the amount of stored NOx and O2 (NTL + O2L). The request is reset under the same conditions a regeneration is reset **or** when lambda exceeds C_LAMB_RGN.
The check for setting the request is only to be carried out if the request is yet unset.
LV_ACT_INT_PUC_AFL is passed to the *catalyst enrichment function (cat-purge function for continuous lambda control)* where a displacement of the lambda-controller setpoint will be done.

7.86.3.3 Reset of regeneration and purge requests

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = REGENERATION

A regeneration phase is stopped under the following conditions:

1. The modelled loadings of NOx and O2L both fall below a threshold
2. All downstream sensors detect a rich mixture LV_SENS_AFR
3. A constant time period is exceeded
4. an engine state with higher priority is activated. These higher prior engine states can be fuel cut-off (PUC) or full load (FL).

The regeneration stopping conditions are valid under the following circumstances:

1. A stop out of the model is possible if LV_RGN_STOP_MDL is set to 1.
2. A stop by the sensor signal is possible if LV_RGN_STOP_SENS is set to 1.
3. A stop by the time counter is possible if LV_RGN_STOP_TOUT is set to 1.
4. Also a combination of sensor stop and model stop is possible.

The priority of the engine states fuel cut-off (PUC) and full load (FL) in relation to a running NOx regeneration are selectable by C_NT_RGN_STOP_PUC_SEL and C_NT_RGN_STOP_FL_SEL. It can be chosen:

C_NT_RGN_STOP_PUC_SEL =

0 ... the NOx catalyst control functionality does not react on the engine state fuel cut-off (PUC)

1 ... a running NOx regeneration is broken, when the air mass flow at PUC exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN_NT_RGN_STOP

2 ... a running NOx regeneration is broken, when the air mass flow at PUC exceeds a threshold and the clutch is closed;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN_NT_RGN_STOP

C_NT_RGN_STOP_FL_SEL =

0 ... the NOx catalyst control functionality does not react on the engine state full load or a high engine load near full load.

1 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is broken, when the air mass flow at full load exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN

2 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is broken, when the air mass flow at full load exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN_NT_RGN_STOP

3 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is not broken

Calibration hint:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The maps IP_NTL_MIN and IP_NTL_MIN_RGN_STOP should be calibrated on identical values.

7.86.3.4 Request of lambda =1 operation

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX except PASSIVE.
Depending on various conditions the lean operation of the engine can be forbidden using LV_NT_AFS_REQ. This flag is an input to the combustion manager. There, it forces the combustion manager to switch to lambda=1 homogeneous mode.
All conditions leading to stoichiometric homogeneous operation of all modules of the NOx trap functions (including NOx catalyst aging and NOx catalyst desulfation) are handled by this subroutine in order to get only one flag as interface to the combustion manager. These conditions are:

1. catalyst temperature too high
2. catalyst temperature too low
3. aging state too bad
4. desulfation introduced
5. other reasons considered in the corresponding application incidences module

Application conditions

Use LV_VLS_NS_VLD for calculation of LV_INH_RGN_REQ					

7.87.1 Inhibiting the NOx catalyst management

FUNCTION DESCRIPTION:

Number of NOx sensors: NC_NOX_SENS_CONF k = 1...NC_NOX_SENS_CONF
Number of lambda sensors: NC_CBK_EX_NR i = 1...NC_CBK_EX_NR

Typical configurations:
[NC_CBK_EX_NR:NC_NOX_SENS_CONF] =[1:1], [2:2], [2:1]

Description:

The timer T_IPLSL_VLD_DLY is limited to its maximum value. An overflow is not allowed.

Application conditions

Initialisation: at reset
LV_INH_NT_ACT = 0
T_IPLSL_VLD_DLY = 0

Recurrence: *100 ms*

Activation: *at every engine state*

Deactivation: –

Formula section:

if LV_IPLSL_VLD[i] = 0 *% valid if at least one [i] = 0*
then T_IPLSL_VLD_DLY(n) = T_IPLSL_VLD_DLY(n-1) + Recurrence
else T_IPLSL_VLD_DLY = 0
endif

if **((** LV_IPLSL_VLD[i] = 0 *% valid if at least one [i] = 0*
(readiness of upstream oxygen sensor)
and T_IPLSL_VLD_DLY >= C_T_IPLSL_VLD_DLY
)
or LV_ERR_TCO = 1
(error currently present on error location coolant temperature sensor)
or LV_ERR_MAF = 1
(error currently present on mass air flow acquisition)
or LV_ERR_CAM = 1
(global error on camshaft sensor)
)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. LC_VLS_NS_VLD_INH_RGN_ENA = 0**)**
then LV_INH_RGN_REQ = 0
endif
endif

7.87.3 Inhibiting the regeneration request due to modeled loading degree

FUNCTION DESCRIPTION:

This is a dummy file provided for project-specific reasons to disable regeneration request due to high loading degree. Contrary to the previous subchapter, this new inhibition flag does not inhibit a regeneration due to a switch to homogeneous operation due to torque request by driver.

Application conditions

Initialisation: at reset
LV_INH_RGN_REQ_NTLD = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Recurrence: *100 ms*

Activation: *LV_NT_ACT = 1*

Deactivation: *LV_NT_ACT = 0*

Formula section:

if LC_INH_RGN_REQ_NTLD = 1 **OR**
(LV_NOX_NS_AUTH[k] = 1 **AND** *% valid if all [k] = 1*

then LV_INH_RGN_REQ_NTLD = 1
else LV_INH_RGN_REQ_NTLD = 0
endif

7.87.4 Inhibiting the lean operation (manual request of air/fuel stoichiometric)

FUNCTION DESCRIPTION:

The logical value LV_INH_NT_AFL allows to force a Lambda = 1.0 operation due to project specific requirements. Lambda = 1.0 operation is forced by an error of the NOx-Sensor or manual setting.

Application conditions

Initialisation: at reset
LV_INH_NT_AFL = 0

Recurrence: *100 ms*

Activation: *every time*

Deactivation: -

Formula section:

if (LV_ERR_NS_CAN_BOFF = 1
or LV_ERR_NS_CAN_MSG_LOST[k] = 1 *% valid if at least one [k] = 1*
or LV_ERR_NS_OBD_1[k] = 1 *% valid if at least one [k] = 1*
or (STATE_ERR_NS_OBD_2[k] **bitwise AND** C_ERR_NS_NT_AFL_BIT_SEL) != 0 *% valid if at least one [k] = 1*
or LV_ERR_LS_UP[i] = 1 *% valid if at least one [i] = 1*
or LV_INH_NT_AFL_NS_READY = 1
or LC_INH_NT_AFL = 1
)
and LC_INH_NT_AFL_OFF = 0
then LV_INH_NT_AFL = 1

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

else LV_INH_NT_AFL = 0
endif

7.87.5 Change to model when invalid NOx-Sensor Signal flow diagram

FUNCTION DESCRIPTION:

If the function is active (LC_INH_REQ_NOX_SENS_OFF = 0) and the NOx signal is not valid during the NOx catalyst loading phase the mode of the NOx regeneration request is switched from "SENSOR" to "MODEL". The NOx regeneration request by NOx sensor is as long as forbidden until the NOx sensor OBDII diagnosis is carried out and no error is appeared.

Application conditions

Initialisation: at reset, at deactivation:
LV_INH_RGN_REQ_NOX_SENS = 0
LV_INH_NOX_SENS_RGN = 0
LV_NTLD_ADJ = 0
STATE_RGN_REQ = SENSOR

Recurrence: *100ms.*

Activation: *LC_INH_REQ_NOX_SENS_OFF = 0*

Deactivation: *LC_INH_REQ_NOX_SENS_OFF = 1*

Formula section:

Default State:
STATE_RGN_REQ = SENSOR

Transitions:

STATE_RGN_REQ: **SENSOR to MODEL**

if STATE_NOX = LOAD
and (LV_NOX_NS_VLD[k] = 0
and T_NOX_NS_HLD[k] >= C_T_NOX_SENS_VLD_STATE_RGN_REQ)
% valid if at least one condition for [k] = true
and LV_T_NS_VLD = 1

if LV_ERR_EGR_2 = 1
then LV_ADJ_NOX_SENS_RGN = 1
else LV_ADJ_NOX_SENS_RGN = 0
endif

7.87.8 Calculation of full load air mass flow integral

General information:

The air mass flow integral MAF_INT_FL_ACT is used for detection of short and long full load phases or high engine load phases inside of NOx catalyst management functionality. This classification of full load phases or high engine load phases is required for the decision whether a running NOx regeneration is terminated because of higher full load priority or not.

Description:

The constant NC_FAC_MAF_INT_FL includes the recurrence and converts the physical unit of MAF_KGH from [kg/h] to [g/ms].
NC_FAC_MAF_INT_FL = Recurrence/3.6
Note! The calculation of MAF_INT_FL_ACT shall be stopped if the maximum value of value range is reached. An overflow is not allowed.

Application conditions

Initialisation: at reset, at deactivation:
MAF_INT_FL_ACT = 0
LV_LOAD_H = 0

Recurrence: *100ms*

Activation: *LV_NT_ACT = 1*

Deactivation: *LV_NT_ACT = 0*

Formula section:

if TQI_SP_MAF > IP_TQI_SP_MAF_LOAD_H(N_32)
then LV_LOAD_H = 1
else
if TQI_SP_MAF < IP_TQI_SP_MAF_LOAD_H(N_32) - C_TQI_SP_MAF_LOAD_H_HYS

General information:

The engine system is able to start with lean engine operation without a ready NOx sensor for NOx emission control. In this case the NOx emission control runs completely model controlled. The aim of this section is the limitation of this system state by requesting Lambda=1.0 engine operation up to the NOx sensor reaches its operation readiness.

Description:

Application conditions

Initialisation: at reset, at deactivation:
LV_INH_NT_AFL_NS_READY = 0

Switch to enable calculation of NOx tailpipe emission					

FUNCTION DESCRIPTION:

LV_ERR_NS_OBD_2[NC_NOX_SENS_CONF]

General information

The NOx signal of the NOx sensor is used to calculate the NOx tailpipe emission during lean operation mode.
The NOx concentration measured behind the NOx catalyst is converted into a mass flow. This NOx mass flow is integrated up to the absolute NOx tailpipe emission during a lean phase.

NC_NOX_SENS_CONF is the number of NOx sensors within the system. Therefore the index i represents:

i = 1 ... signals based on NOx sensor 1, which is mounted at cylinder bank 1 or at a summary tailpipe section of a Y exhaust line configuration

i = 2 ... signals based on NOx sensor 2, which is mounted at cylinder bank 2

Application conditions

Initialisation:

```
at reset
NOX_OUT_MES_INT[i] = 0
NOX_OUT_MES[i] = 0
```

Recurrence:

Action definition

ACTION_NOXM_CleanNTAdaptAgi ()	Mode: O
Initialization of NOx trap adaptation values of aging module	

ACTION_NOXM_WriteAgingExtAdj ()	Mode: O
New external values for aging calculation available	

General information

The NOx catalyst aging function can handle single branched and twin branched exhaust gas lines with the configuration data NC_NT_NR defined in the NOx catalyst management module.
If NC_NT_NR=1, just one exhaust line is taken into account, if NC_NT_NR=2, the software calculates the twin branch version.
i characterises the variable of branches which can be counted up

The NOx storage catalyst looses its storage capacity due to thermal aging and sulfur poisoning.
The aging is determined by the NOx-signal of a NOx-sensor, mounted downstream the NOx catalyst. The information, which kind of sensor is installed is included in LV_NOX_SENS.
The aging state of the catalyst is evaluated by an aging factor NT_AGI_SNG_i. The value of this factor is 1 in the case of a fresh catalyst, a value near zero indicates a destroyed catalyst. The resulting aging factor NT_AGI is the minimum of all existing NT_AGI_SNG_i.
The aging factors NT_AGI_SNG_i mainly will be decreased by the aging determination in this routine. Due to desulfation, the aging state of the catalyst can be improved (storage capacity increases). This increase is calculated by the desulfation function and passed to the aging function by NT_AGI_INC_SO2P. This value is set to 0 if no desulfation is active, otherwise it includes the incremetation of the aging factor per time step. This increment is added to the aging factor at every call of the aging function.
Handling of the aging states
When the resulting aging factor NT_AGI falls below the threshold C_NT_AGI_1 the desulfation request bit LV_SO2P_REQ_1 is set.
When the aging factor falls below the threshold C_NT_AGI_2 the desulfation request bit LV_SO2P_REQ_2 is set, this means an active catalyst heating is required.
When the aging factor falls below the threshold C_NT_AGI_3 a desulfation is requested. If this desulfation is not successful lean operation has to be forbidden, the request bit LV_NT_AFS_REQ_AGI for lambda=1 operation due to aging state is set.
The request for a desulfation or for operation in lambda=1 mode can be manually reseted by LC_NT_AGI_INI_MAN, in this case NT_AGI_SNG_i is initialized with C_NT_AGI_INI_i.
The values NT_AGI, NT_AGI_i have to be stored in the non-volatile memory.
Calculation of the base aging factor
The basis aging factor is determined by the NOx-signal of the NOx-Sensor NOX_PPM_i and the calculated reduced NOx raw emissions NOX_CONC_RED. In the moment the first NOx-Sensor detects

an inadmissible high NOx concentration downstrem the NOx catalyst and as a consequence LV_RGN_REQ_NOX_SENS is switched from 0 to 1, the actual storage capacity is calculated and compared with the base storage capacity of a fresh catalyst. The aging factor is calculated using the ratio of the actual storage capacity and the base storage capacity NT_STC. The calculation is carried out once when the regeneration starts.

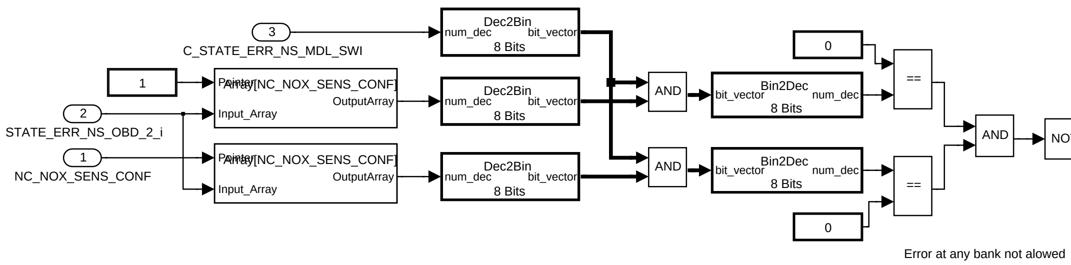

Figure 7.90.17: NOXM_MODUL703P/operate/MAIN/CBK/CLC_LV_SWI/BITWISE_AND

MAIN (for each NOx trap)

The following calculation will be done for each NOx trap, controlled by NC_NT_NR.

Aging calculation will only be done if a rising edge of the trigger signal LV_AGI_AD_TRIG occurs and the NOx sensor reaches a threshold at start of regeneration.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Condition to enable aging factor calculation

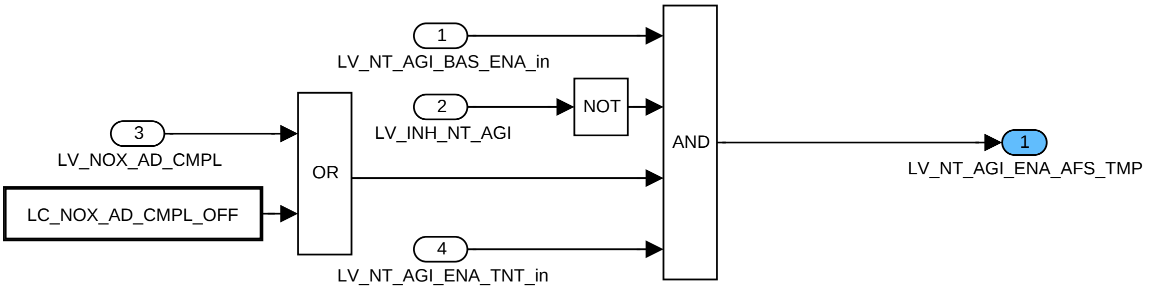

Figure 7.90.26: NOXM_MODUL703P/operate/ENABLING_FLAGS/CLC2

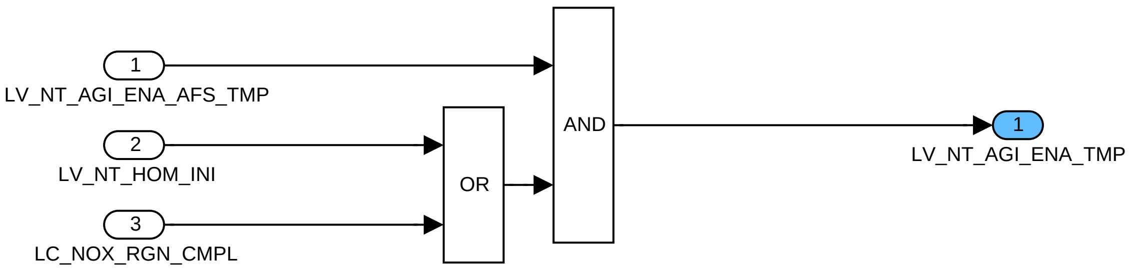

Figure 7.90.27: NOXM_MODUL703P/operate/ENABLING_FLAGS/CLC3

The T_AFL condition uses only lean phases whith LV_NT_AGI_ENA given at the beginning of the lean phase; aim is to prevent a closing of the EGR valve in the middle of a lean phase due to aging adaptation conditions given starting there as well as performing an adaptation after a lean phase with adaptation condition given only temporary.
CTR_NT_AGI_AD and CTR_NT_AGI_AD_CMPL have physical limits from 0 to 254 whereas the corresponing threshold constants C_CTR_NT_AGI_AD_MAX & C_CTR_NT_AGI_AD_CMPL_MAX have physical limits from 0 to 255. Thus by setting the constants to their maximum value the condition CTR $<$ thd is always true and no limitation of the adaptation attemps /adaptation cycles will occur

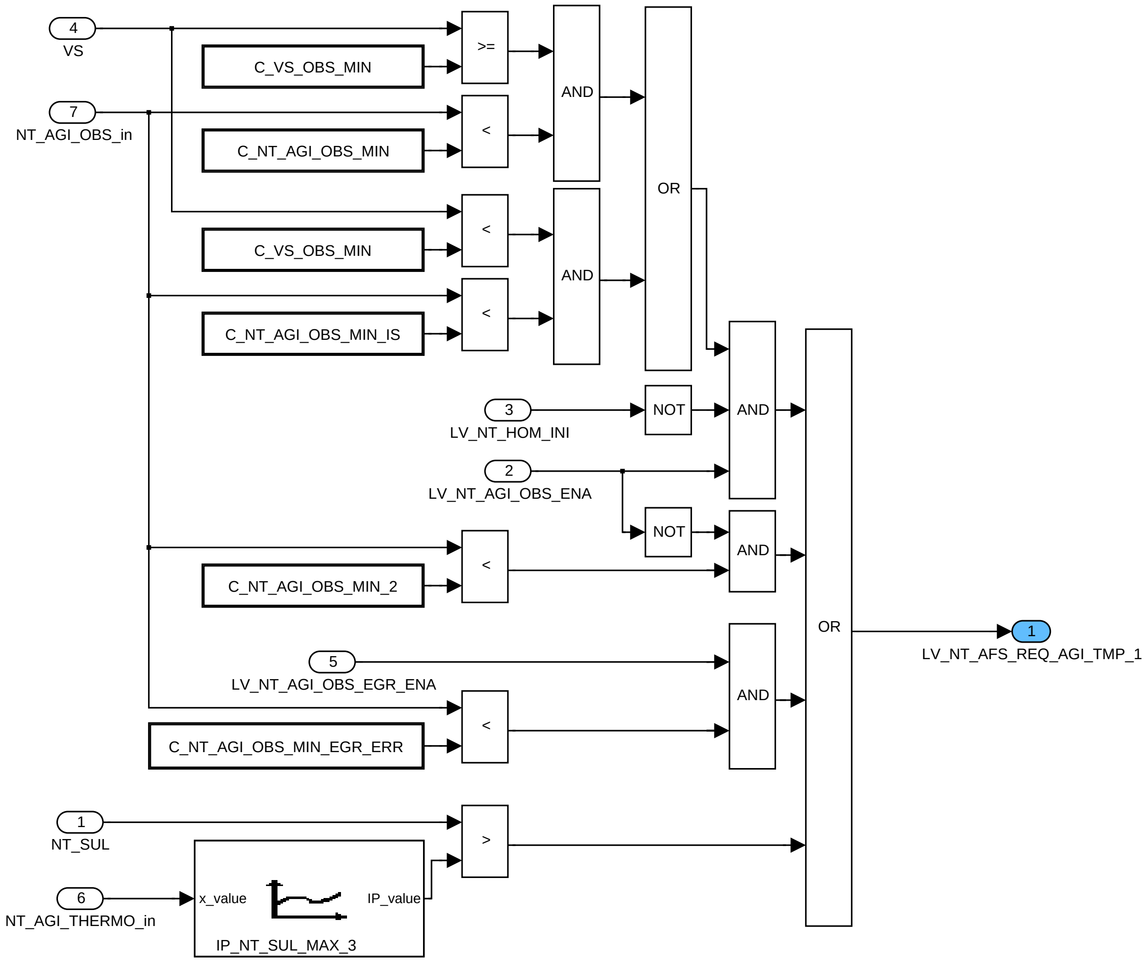

Figure 7.90.42: NOXM_MODUL703P/operate/DESULFATION/CLC3

Structure of fuel quality check

If the thermal aging factor reaches the third threshold, then the fuel quality check will be started. In that case a desulfation will be requested and the sulfur model will be calculated with higher sulfur ratio, controlled by FAC_SU_CONC_FUEL.
After desulfation (LV_SO2P_REQ_1=0) the prohibition of stratified mode (LV_NT_AFS_REQ_AGI_TMP_2) will be canceled.
Either the aging factor is OK and the fuel check will be finished immediately (sub-system OK) or after a calibratable number of cycles a decicion will be made (sub-system END) whether the NOx trap is OK or not. If OK the fuel quality check will be finished, if not the lambda=1 mode will be forced (LV_NT_AFS_REQ_AGI_TMP_3=1) because the trap is defect.

7.91.1 Activation Conditions for NOx catalyst aging

FUNCTION DESCRIPTION:

General information:

This flag deactivates the NOx catalyst aging adaptation when errors occure which must not stop the lean operation and the NOx catalyst management, but can cause an inaccuracy in the model, which must not be adapted.
With the calibration data LC_INH_NT_AGI_MAN it is possible to deactivate the NOx trap aging adaptation manually.
With the calibration data LC_INH_NT_AGI_OFF it is possible to make the adaptation allways working.
These bits are useful for the calibration phase.
Number of NOx catalyst: NC_NT_NR i = 1...NC_NT_NR
Number of NOx sensors: NC_NOX_SENS_CONF k = 1...NC_NOX_SENS_CONF
Number of lambda sensors: NC_CBK_EX_NR m = 1...NC_CBK_EX_NR

Typical configurations:

Action definition

ACTION_NOXM_CleanNTAdaptSul ()	Mode: O
Initialization of NOx trap adaptation values of sulfur module	

ACTION_NOXM_WriteSulfurExtAdj ()	Mode: O
New external values for sulfur model available	

7.92.1 NOx catalyst sulphur model (NOXM modul 704G)

General information:
The NOx catalyst sulphur model can handle single branched and twin branched exhaust gas lines with the configuration data NC_NT_NR defined in the NOx catalyst management module.
If NC_NT_NR=1, just one exhaust line is taken into account, if NC_NT_NR=2, the software calculates the twin branch version.
i belongs to NC_NT_NR.

Description:

The NOx catalyst sulphur model calculates the NOx catalyst sulphur loading.

The sulphur loading is increased only in lean burn phase (-> STATE_NOX = LOAD). The sulphur loading increment is calculated out of the fuel sulphur concentration and converted to a NOx mass loading equivalent (sulphur load in NO2 mass loading equivalent is loss of NOx storage capacity).
When the desulfation is active, the sulphur which is chemically stored in the NOx-trap is released depending on the NOx-trap monolith temperature, lambda, the modeled sulphur load NT_SUL on the corresponding layer and the value of NT_AGI_THERMO.

During the desulfation the NOx-trap sulphur load is decremented until it reaches 0.

C_CRLC_SU_NOX includes
- the factor for transformation of MFF_SP * N_32 {mg/stk * 1/min} to a fuel mass flow
{mg /TA} =0,1s /2 /60s = 1 /1200)
- and the factor for number of cylinders and number of NOx traps
= NC_CYL_NR /NC_NT_NR
- and the factor for transformation of C_SU_CONC_FUEL {ppm} to mass part sulphur
in fuel {mg S/mg fuel} = 1E-6
- and the factor for transformation of sulphur load {mg S} to sulphur load NO2 equivalent
{mg NO2} = 2 * 46 /32 = 2,875.

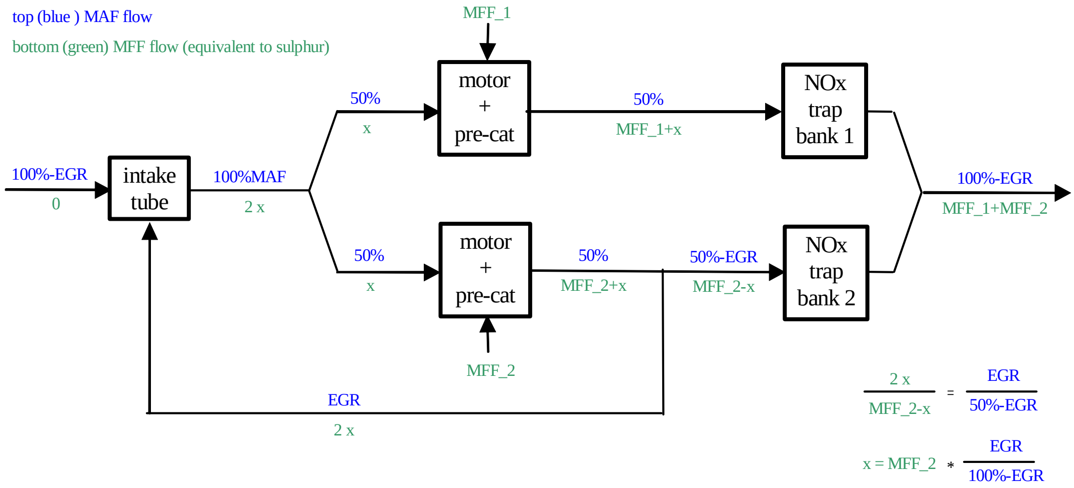
Example values:
- four cylinder and one NOx trap: 9,5833 E-9
- six cylinder and two NOx traps: 7,1875 E-9

Calculation inside this function is done by high resolution variable NT_SUL_32. Valid output to other functions is low resolution variable NT_SUL.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Unsymmetrical EGR branch

If the exhaust gas recirculation is unsymmetrical (exaust gas is taken from one bank and added to the intake air for both banks) then the different sulfur loading of the NOx traps will be considered by setting C_STATE_EGR_CBK to the bank with the EGR branch. In a symmetrical or a one-bank-system C_STATE_EGR_CBK have to be set to 0.
The splitting of the sulfur to both NOx traps is shown in the following picture. The sulphur is proportional to the fuel flow and the fuel split is controlled by the air flow, which depends from the EGR ratio.



Application Condition

NOXM_MODUL704G/ACTIONDEF_NOXM_WriteSulfurExtAdj/ACTION_NOXM_WriteSulfurExtAdj

7.92.1.3 OPERATE

Calculation before MAIN

Before the MAIN part, which is calculated for each bank, the difference of the fuel due to the unsymmetrical EGR will be calculated. It will be added or subtracted inside MAIN to both banks.

(If MFF_SP_2 is not existing caused by NC_CBK_EX_NR = 1, but access demanded by other variables depending on other indices of bigger size, then MFF_SP_1 is used.)

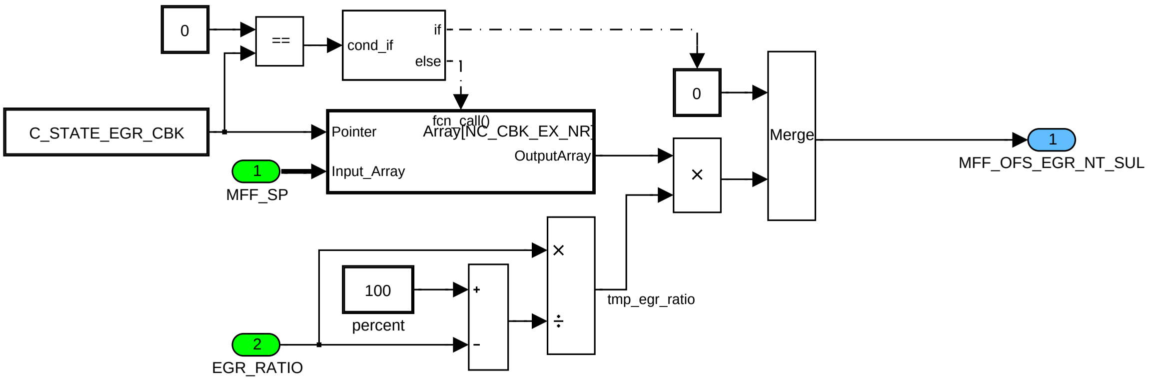

Figure 7.92.7: NOXM_MODUL704G/operate/BEFORE_MAIN

MAIN (for each NOx trap)

The function consists of the following parts
- manual initialization
- sulphur load update (from NOx catalyst aging)
- sulphur loading during LOAD phase
- sulphur release during desulfation
(splitted in two parts: before and after T_SO2P_DLY)

The for loop of the MAIN part is controlled by the number of NOx traps

NC_NT_NR = 1 means one NOx trap (calculation for i = 1)
NC_NT_NR = 2 means two NOx traps (calculation for i = 1 and 2)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

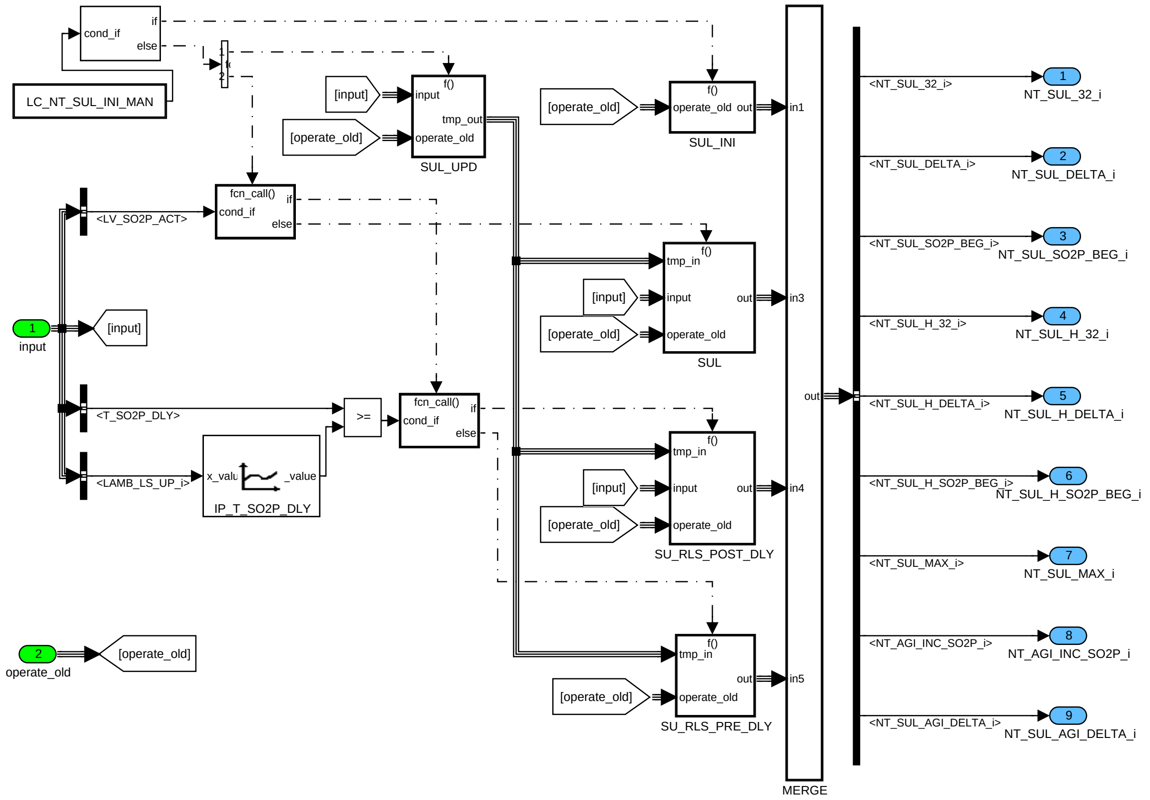

Figure 7.92.8: NOXM_MODUL704G/operate/CBK_MNG/MAIN

Manual initialization

If LC_NT_SUL_INI_MAN ist set, then the sulfur load of the NOx traps will be initialized with C_NT_SUL_INI.

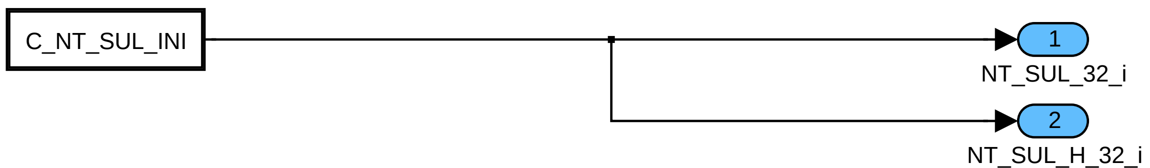

Figure 7.92.9: NOXM_MODUL704G/operate/CBK_MNG/MAIN/SUL_INI/CLC

Sulphur load update

The update value NT_SUL_UPD comes from the aging modul. The update takes place if the value is new and not zero.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

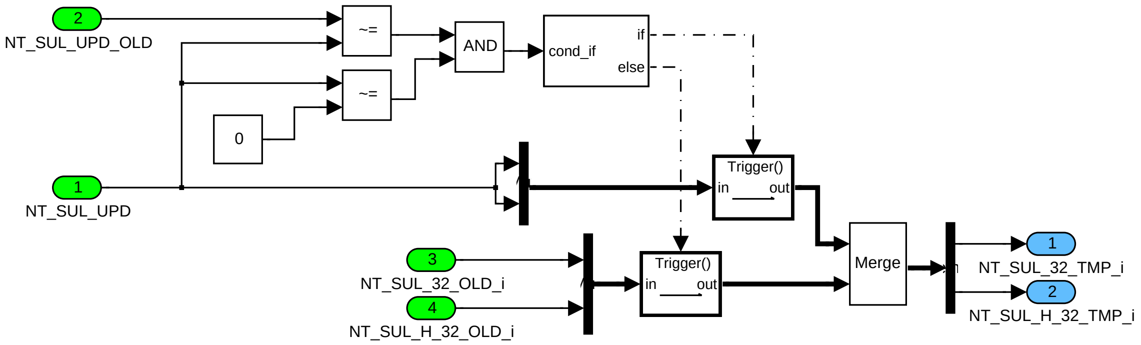

Figure 7.92.10: NOXM_MODUL704G/operate/CBK_MNG/MAIN/SUL_UPD/CLC

Calculation of sulphur loading increment

The offset of the EGR depending fuel will be added to the bank without EGR branch and subtracted to the bank with EGR. C_STATE_EGR_CBK selects the bank with EGR branch. From these corrected fuel values the sulphur increment for the NOx traps will be calculated.
The temporary variable mff_sp_tmp_i has the same resolution and limits as MFF_SP.
(If MFF_SP_2 is not existing caused by NC_CBK_EX_NR = 1, but access demanded by other variables depending on other indices of bigger size, then MFF_SP_1 is used.)

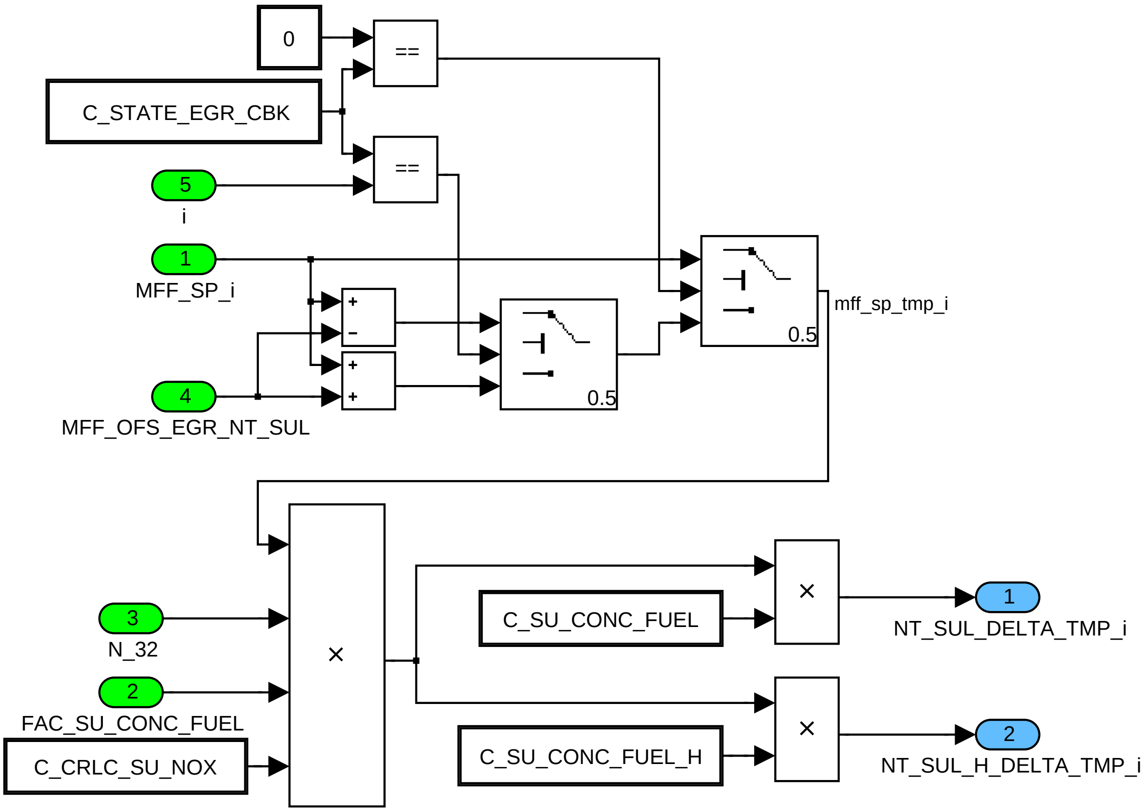

Figure 7.92.11: NOXM_MODUL704G/operate/CBK_MNG/MAIN/SUL/CLC/CLC1

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Selection of sulphur loading increment

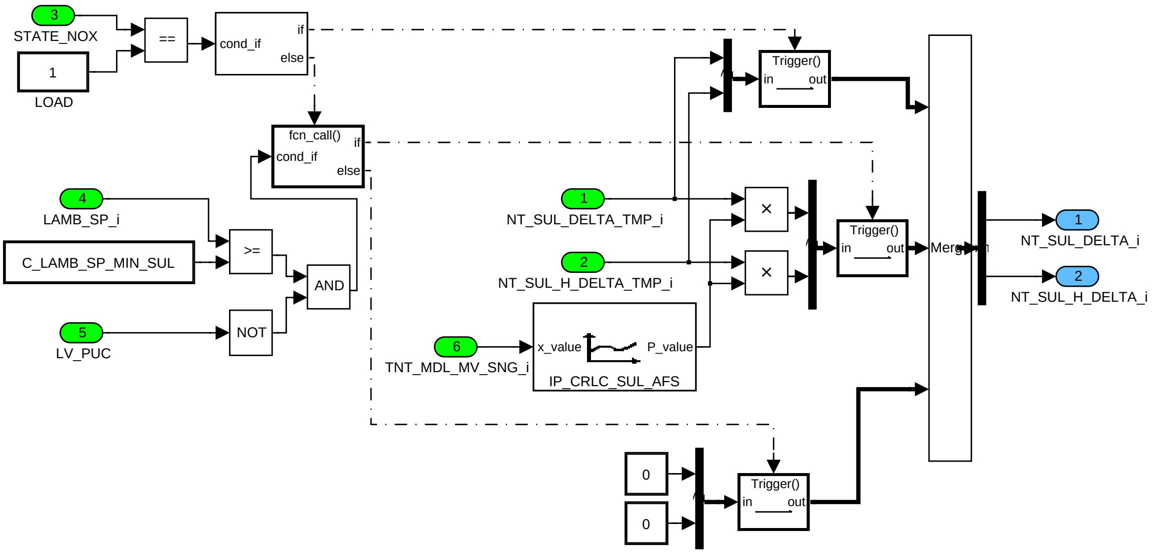

Figure 7.92.12: NOXM_MODUL704G/operate/CBK_MNG/MAIN/SUL/CLC/CLC2

Integral of sulphur

The sulphur increments will be added until a temperature dependent maximum. The limitation may be disabled. by LC_NT_SUL_LIM_NOT.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

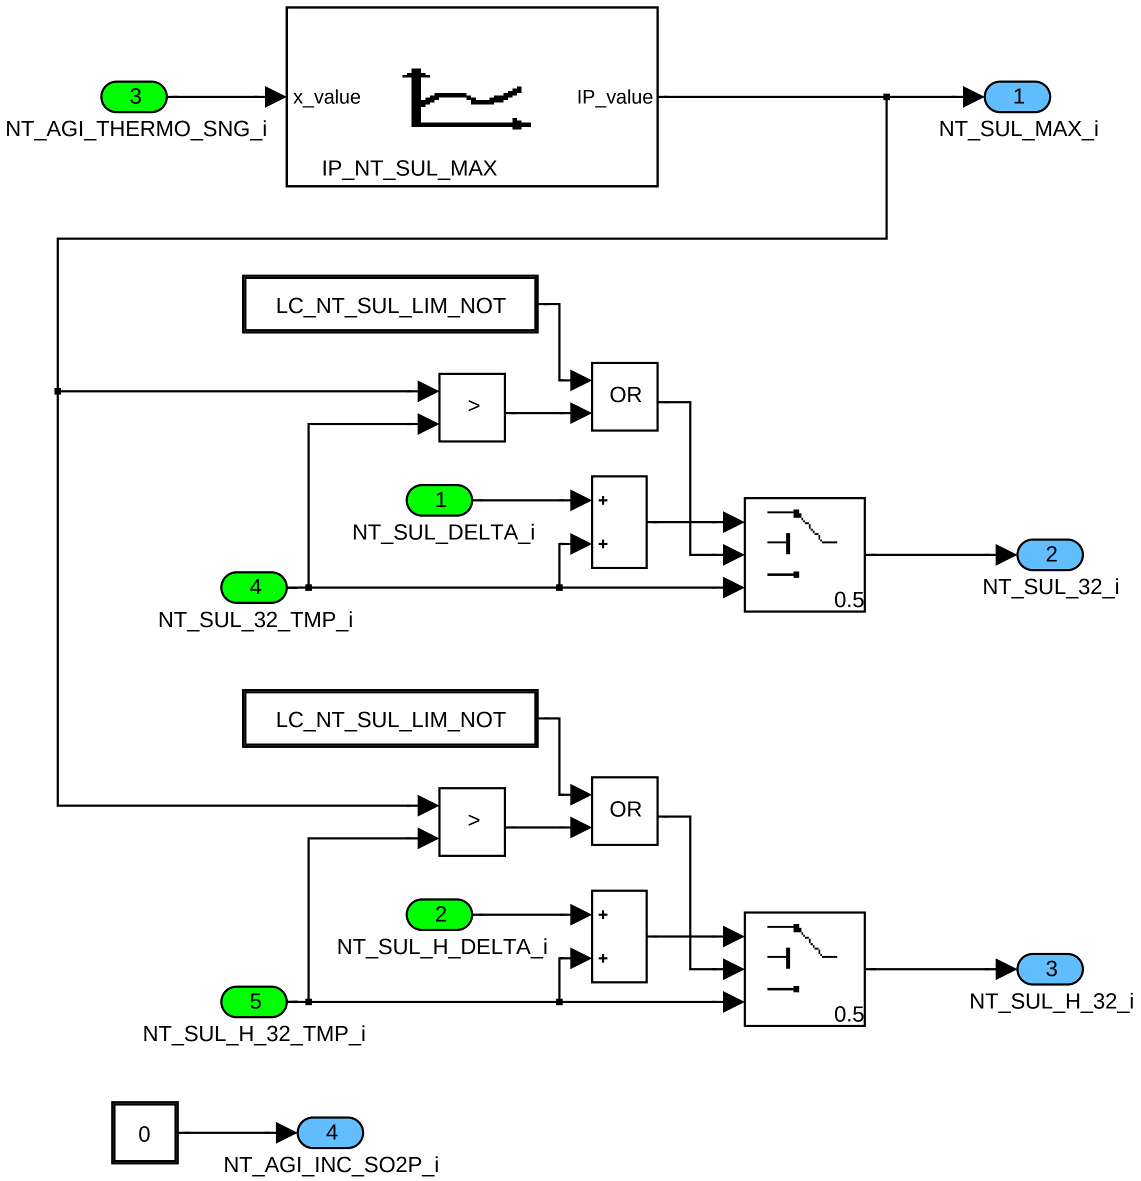

Figure 7.92.13: NOXM_MODUL704G/operate/CBK_MNG/MAIN/SUL/CLC/CLC3

Sulphur release phase post after delay time

The decrement of sulfur during release phase will be calculated by maps. The downward integration is limited to zero.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

Gasoline contains sulphur, which is chemically stored in the NOx catalyst. Due to this sulphur compounds, the NOx trap storage capacity and the NOx trap efficiency will decrease. The sulphates can be decomposed under high temperature with rich mixture. This catalyst state (high temperature, rich exhaust gas composition) is called NOx catalyst desulfation.
If a desulfation request is set, the function is able to request catalyst heating. When an enough high monolith-temperature is reached the desulfation is started by switching to a suitable lambda value. This desulfation lambda depends on the actual minimum monolith temperature and on the desulfation mode.
Two desulfation modes are implemented: a fast way with a single, rich lambda value or a way with a lambda alternating around lambda=1 and thereby with two main lambda values, a lower rich value and an upper lean value. This way permits low H2S emissions.
The decision, which desulfation process is chosen, is made dependent on the vehicle speed or a manual application.
It can't be guaranteed the setting of a lambda request is followed immediately by a change of lambda. For this reason, this function contents a detection of a desulfating atmosphere (that means a high temperature level and a rich exhaust gas composition.

Application Conditions

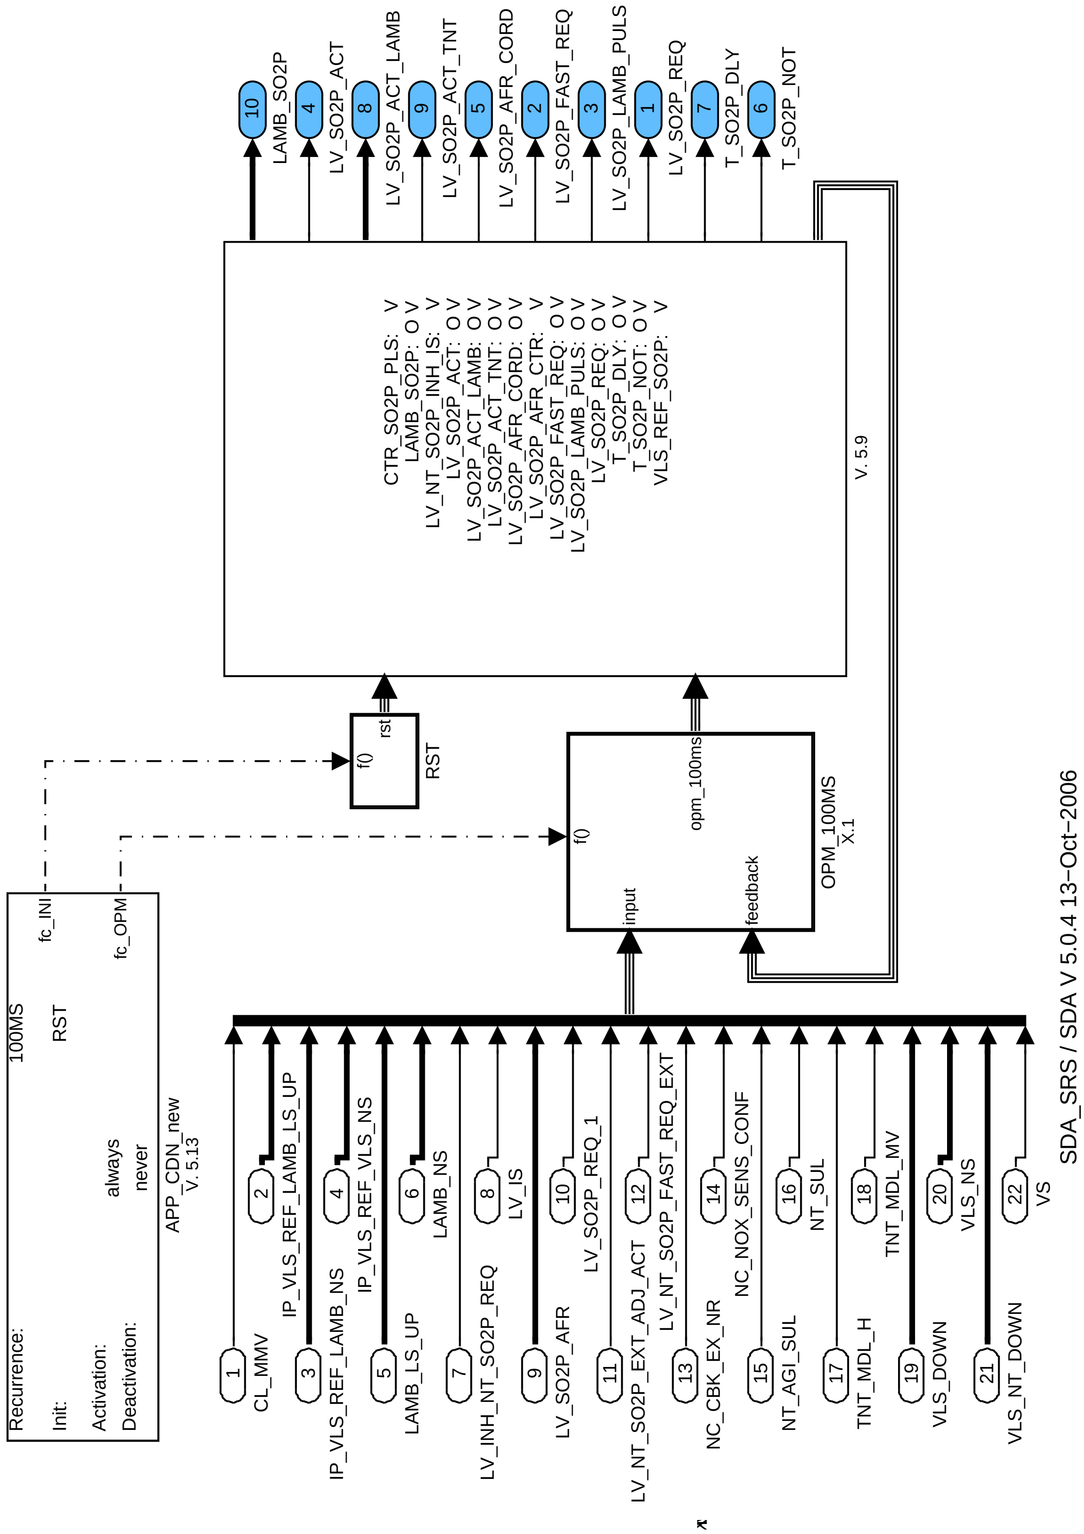

Figure 7.93.1: : Path: NOXM_REQGNNTD0

7.93.1 FORMULA SECTION

The bank specific and bank not specific calculations are done separately.

First the bank specific calculations are done (SO2P_ACT_MNG). This section contains detection of the desulfation atmosphere.
Bank not specific and bank diagonal calculations are included in subsystem REQ_CLC. In this section the request for desulfation is calculated.

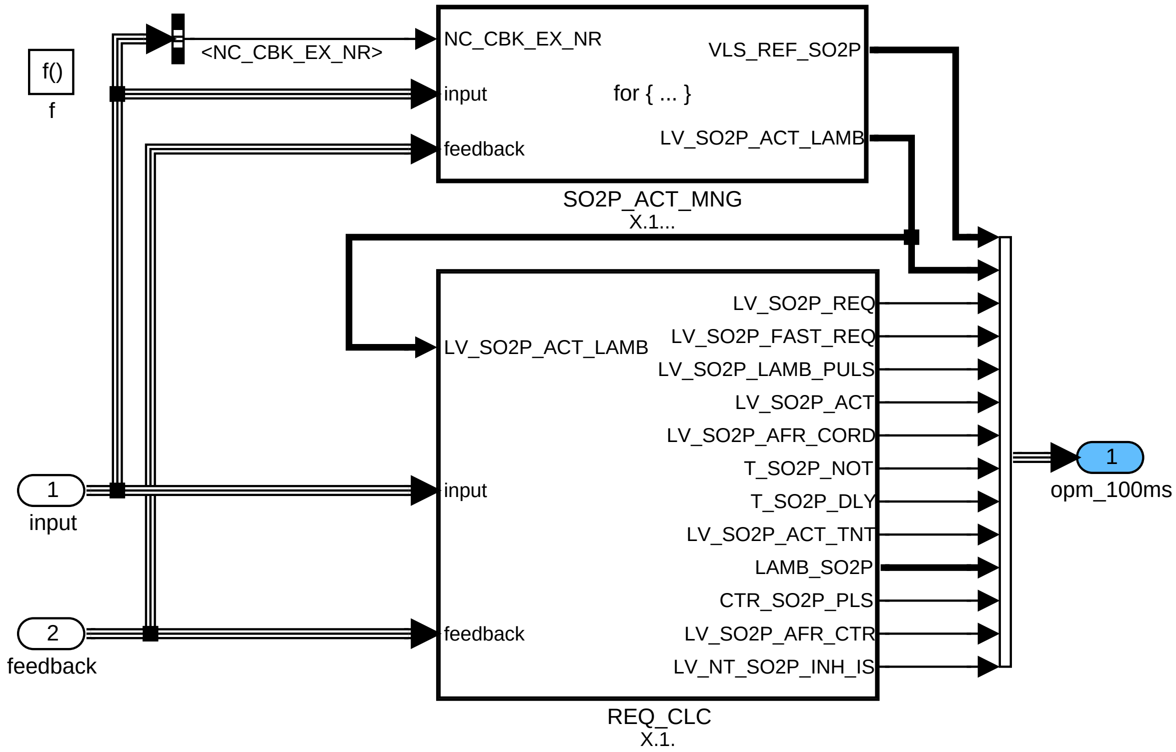

Figure 7.93.2: : Path: NOXM_REQGNNTD0/OPM_100MS

7.93.1.1 BANK SPECIFIC CALCULATIONS

7.93.1.1.1 Management of different exhaust gas configurations

Index "k" corresponds to number of NOx Sensors in the system. Supported is only configuration where number of NOx Sensors is less or equal to number of exhaust banks. If one NOx Sensor and two banks exist then for both banks shall be taken the same NOx Sensor voltage signal

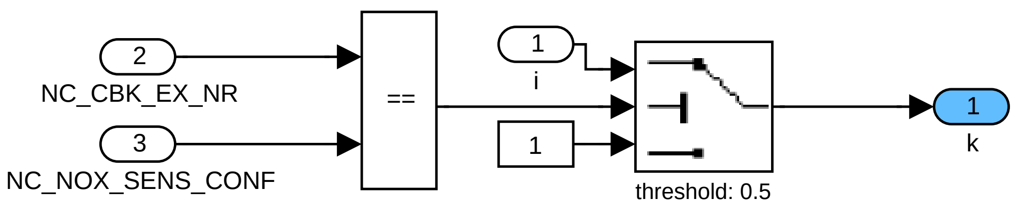

Figure 7.93.3: : Path: NOXM_REQGNNTD0/OPM_100MS/SO2P_ACT_MNG/CLC_k

7.93.1.1.2 Detection of a desulfating or non-desulfating atmosphere

For the detection of the exhaust gas composition one of available signals is chosen and converted to binary voltage value of lambda if needed. After that the desulfation atmosphere can be detected using Lambda value.

ACTION_NOXM_StartCatHeatDesu()					
Start catalyst heating for desulfation without any limitation due to fuel consumption					
Parameter	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**

If LV_SO2P_REQ_2 = 1 % catalyst heating already requested
Then LV_CH_SO2P_WOUT_LIM = 1 % fuel consumption not limited for CH
End If

Description for ACTION_NOXM_StopCatHeatDesu

ACTION_NOXM_StopCatHeatDesu()					
Stop catalyst heating for desulfation without any limitation due to fuel consumption					
Parameter	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**

LV_CH_SO2P_WOUT_LIM = 0 % fuel consumption limited for CH

Application conditions:

This module controls the desulfation that is forced by an external request.
Initialization : reset all values from output table except LV_CH_SO2P_WOUT_LIM to zero
Recurrence : **100** ms

Formula section:

Catalyst heating without limitations due to fuel consumptions
If LV_SO2P_REQ_2 = 0 % desulfation successful finished
Then LV_CH_SO2P_WOUT_LIM = 0 % fuel consumption limited for CH
End If

State machine for desulfation by scan tool

General information

The sub function *Desulfation controlled lambda alternation* allows a desulfation with an alternating lambda value controlled by the output voltage of the downstream sensor. The deviation of the basic lambda setpoint will only be carried out, if the lambda setpoint is in the range of 1. Alternation is defined by the maximum rich rsp. lean lambda shift, the p-jump and the delay time at rich or lean side befor p-jump. Gradients are defined according to engine conditions.

Definition of lambda deviation for lambda controller:

7.95.2 FORMULA SECTION

The function contains of two main Sections:
SECTION 1: Detection of lean/rich mixture
SECTION 2: Realization of lambda controller deviation

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

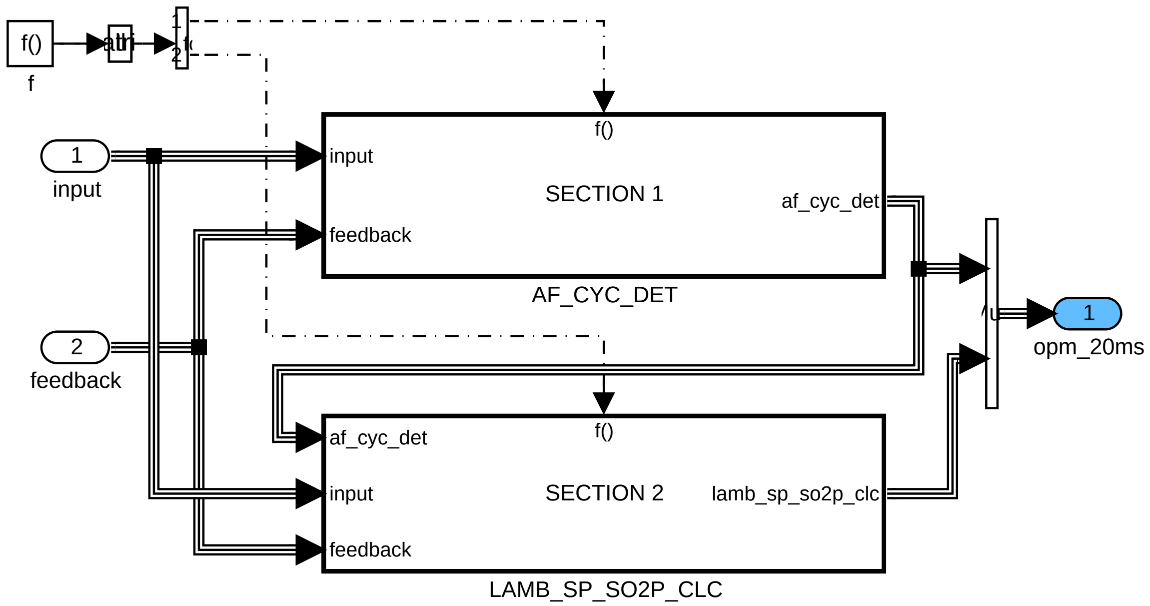

Figure 7.95.5: NOXM_DEFSPNTDLS0/OPM_20MS

SECTION 1: Detection of lean/rich mixture

The function shall provide an indication of the current Air-Fuel mixture ratio at LS downstream position, i.e. mixture lean or rich, and determine the lean and rich cycle time separately for further evaluation by other functions. This shall be carried out as follows:
AF transition detection:
There are several possibilities as reference for oxygen signal depending on existing sensors and their provided signals: NOx-sensor or binary oxygen sensor. The choosen output signal is scaled if necessary to the reference signal VLS_DOWN_REF.
The function shall detect a change in AF mixture from lean to rich or vice versa ignoring possible jitter in the sensor signal. This shall be facilitated by the following method: If the timer T_AFL_DOWN_LOCK falls below the threshold IP_T_AFL_DOWN_LOCK_xxx, the timer shall be incremented and the transition flag LV_VLS_DOWN_TRA shall be reset. Should, during following recurrence cycles, the timer equal or exceed the threshold and if the AF mixture flag is currently indicating lean, the function shall observe the VLS_DOWN_i signal for a change to rich as indicated by VLS_DOWN_i exceeding the threshold C_VLS_DOWN_AFR. Once this has occurred, the LV_VLS_DOWN_AFL flag shall be changed to indicate a rich mixture (LV_VLS_DOWN_AFL = 0), the counter CTR_VLS_DOWN_AFL_CYC shall be incremented to indicate the number of complete AF cycles since the last activation of the lambda controller, the timer T_AFL_DOWN_LOCK shall be reset and LV_VLS_DOWN_TRA is set to indicate the AF mixture transition. The same procedure, except increment of counter CTR_VLS_DOWN_AFL_CYC, applies for a currently rich mixture. A transition to a lean mixture shall be detected by VLS_DOWN falling below threshold C_VLS_DOWN_AFL.
Remark: The timer T_AFL_DOWN_LOCK and associated engine operating point dependent threshold IP_T_AFL_DOWN_LOCK_xxx reduce the effect of rapid oxygen sensor signal changes, noise generated by cylinder to cylinder AF mixture deviations, that would cause the lambda controller to execute a P-jump. The mapped lock-out time represents the delay between injection of the AF mixture and the burnt AF mixture reaching and being detected by the downstream oxygen sensor. The lock-out time shall not exceed the exhaust gas delay for any particular engine operating point otherwise the lambda controller frequency will be affected. Downstream oxygen sensor signal changes occurring within this delay time may not be considered to be due to the change in controlled lambda but from noise and shall be ignored.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Timer /counter incrementation:

The function shall increment the respective timer dependent on the current state of the AF mixture, as determined by LV_VLS_DOWN_AFL (lean mixture; increment T_VLS_DOWN_CYC_AFL. rich mixture; increment T_VLS_DOWN_CYC_AFR). Should at any time the desulfation control be deactivated, the function shall reset the counter CTR_VLS_DOWN_AFL_CYC.

As calibrateable back up solution a switch of LV_VLS_DOWN_AFL can also be forced by exceeding the time counter threshold for the corresponding cycle time (C_T_VLS_DOWN_CYC_AFL/AFR_MAX)

Increment T_VLS_DOWN_CYC_AFL /Increment T_VLS_DOWN_CYC_AFR

The timers T_VLS_DOWN_CYC_AFL and T_VLS_DOWN_CYC_AFR shall be incremented according to their specified conditions until they reach a maximum value of FFFFH at which point they shall no longer be incremented.

Increment CTR_VLS_DOWN_AFL_CYC

The Air-Fuel cycle counter CTR_VLS_DOWN_AFL_CYC shall be incremented for every lean to rich AF mixture transition, to indicate that a complete AF cycle has passed. The counter shall be incremented in such manner until it reaches a maximum value of FFFFH at which point it shall no longer be incremented.

Increment T_AFL_DOWN_LOCK

The timer T_AFL_DOWN_LOCK shall be incremented according to the specified conditions until it reaches a maximum value of FFFFH at which point it shall no longer be incremented.

SECTION 2: Realization of lambda controller deviation

The lambda control correction adjusts the fuel-air mixture to richness 1 in average. The lambda controller uses a PI strategy. It is adjusted to produce a leaner or a richer mixture according to the oxygen sensor information.
If LAMB_PULS_SO2P exceeds the limitations C_DELTA_LAMB_AFL/AFR_SO2P then LAMB_PULS_SO2P is limited to those values.
The calibration constants C_T_LAM_DLY_SO2P_POS and C_T_LAM_DLY_SO2P_NEG are provided for the pre-control of the P-jump delay. The IP_LAM_XX_YY maps have common data points.
The last calculated LAMB_PULS_SO2P value before the corresponding Lambda transition from lean to rich and from rich to lean remains constant until the delay time T_LAM_DLY_SO2P has come to an end, i.e. I component is frozen. LAMB_PULS_SO2P can not be changed or reset during this time.
To provide best performance (drivability, interface to other functions as e.g. desulfation) all banks reaching lean status wait with P-jump to rich side until last bank also has reached lean status (common P-jump to rich side).
High resolution variable LAMB_PULS_SO2P_H_RES_i shall be used for internal calculation. LAMB_PULS_SO2P_i with low resolution shall be the relevant output for other functions.
Remark: The transition flag LV_VLS_DOWN_TRA is just set during one recurrence of the corresponding specification. It has to be ensured that this spike is noticed by this part.
This SECTION contains of two main chapters:
SECTION 2.1: Calculation of activation condition and check of all banks (not for loop)
SECTION 2.2: Lambda deviation calculation (for loop)

SECTION 2.1: Calculation of activation condition and check of all banks (not for loop)

Activation condition for desulfation

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.96 NOx catalyst desulfation - lambda stimulation (Appl. Inc.)

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_LAMB_PULS_SO2P	O/V	0... 1H	0 ...1	1	-
flag inhibiting the NOx catalyst desulfation - lambda stimulation					

Input data:

LV_ERR_LS_DOWN [NC_CBK_EX_NR] {p. 5449}			

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_INH_LAMB_PULS_SO2P_MAN	-	0... 1H	0 ...1	1	-
Codeword for the manual setting of the inhibiting bit NOx trap desulfation by lambda stimulation					
LC_INH_LAMB_PULS_SO2P_OFF	-	0... 1H	0 ...1	1	-
Codeword for the deactivation of inhibiting the NOx trap desulfation by lambda stimulation					

Description:

This flag deactivates the NOx catalyst desulfation with lambda stimulation.
With the calibration data LC_INH_LAMB_PULS_SO2P_MAN it is possible to deactivate the NOx trap desulfation with lambda stimulation.
With the calibration data LC_INH_ LAMB_PULS_SO2P_OFF it is possible to make the NOx trap desulfation with lambda stimulation allways working.

Application conditions

Initialisation: 0 at reset

Recurrence: 100ms

Activation:

```
at every engine state
If          LC_INH_LAMB_PULS_SO2P_OFF = 1
then     LV_INH_LAMB_PULS_SO2P = 0       % no further calculation
necessary
```

endif

Formula section:

```
If          LV_ERR_LS_DOWN[i] = 1              // at least one
   or     LC_INH_LAMB_PULS_SO2P_MAN = 1
then     LV_INH_LAMB_PULS_SO2P = 1
else     LV_INH_LAMB_PULS_SO2P = 0
endif
```

FUNCTION DESCRIPTION:

General information:

The oxygen storage capacity adaptation allowes an adaptation of the NOx catalyst oxygen storage capacity which will decrease within time due to thermal aging effects.

Copyright (C) Continental AG,2007

The adaptation can be taken into consideration as factor or as offset value; this module offers both possibilities.
The main adaptation value is the factor, the offset is calculated using the factor.

Description:

Application conditions

Initialisation:

```
If          there are no stored values or checksum error
has occured or scantool reset
then        NT_O2_STC_AD = 1; LV_NT_O2_STC_LIM = 1, set all
other default values (=0)
else        use previously stored values
```

endif

Recurrence: 1000 ms

Activation: at every engine state

Formula section:

```
If      LC_NT_O2_STC_AD_MAN=1
then    LV_NT_O2_STC_REQ = 0
        LV_NT_O2_STC_VLD = 1
        NT_O2_STC_AD = C_NT_O2_STC_AD_MAN
        NT_O2_STC_OFS = (NT_O2_STC_AD-1) * NT_O2_STC_BAS
else    % O2_STC request coordination
        If      (DIST_NT - DIST_O2_STC_OLD) >= C_DIST_O2_STC
        or      LC_NT_O2_STC_REQ = 1
        then    LV_NT_O2_STC_REQ = 1
        endif
        If      [(DIST_NT - DIST_O2_STC_OLD) < C_DIST_O2_STC_VLD
        and     LV_NT_O2_STC_LIM = 0]
        or      LC_NT_O2_STC_VLD = 1
        then    LV_NT_O2_STC_VLD = 1
        else    LV_NT_O2_STC_VLD = 0

EGY_DEW_NT_STOP = C_EGY_DEW_NT_STOP % initialization via tester service job

7.99.1 Dew point determination

Application conditions

Activation: `LV_ST = 0 and LV_ES = 0`

Deactivation: `LV_ES = 1`

Recurrence: `100 ms`

Initialisation:

Initialisation at engine start: transition LV_ES = 1 -> 0
LV_TNT_MIN_THD_2 = 0
LV_TNT_MIN_THD_READY_2 = 0

Initialisation at engine stop: transition LV_ES = 0 -> 1
LV_TNT_MIN_THD_READY_2 = 0
LV_TNT_MIN_THD_2 = 0 % for a system with a NOx-sensor, the sensor
% heating is activated by LV_TNT_MIN_THD_2.
% Hence for a stopped engine the bit must be
% initialized
% Initialisation is done after calculation of EGY_DEW_NT_STOP

Function description:

On engine start, the calculated manifold wall temperature is compared to the reference value IP_TEG_WALL_TNT_DOWN_ST. If that temperature is higher than the reference value, it is assumed that no condensed water condenses from the exhaust gas. The status regarding reaching the dew point is represented by the bit LV_TNT_MIN_THD_2.
If the manifold wall temperature calculated is lower than the reference value (end of dew point not reached LV_TNT_MIN_THD_2 = 0), an additional amount of heat must be introduced into the exhaust-system branch. If the wall temperature exceeds the reference temperature or the amount of energy introduced into the exhaust system exceeds a certain threshold, end of dew point reached (LV_TNT_MIN_THD_2 = 1).
LV_TNT_MIN_THD_READY_2 is an internal flag to detect the first readyness after function start. To trigger the heater management function depending on low wall temperature (long PUC phase) the dew point detection is reseted below C_TEG_WALL_TNT_RED.
To set the dew point again, the hysteresis C_TEG_WALL_TNT_HYS must be passed.
To ensure, that values for TEG_WALL_NT_DOWN_MDL and TEG_WALL_NT_DOWN_MDL_ST are valid, the dew point detection is delayed by C_DLY_DEW_NT.

Formula section:

End of dew point after start:
If(1) T_AST > C_DLY_DEW_NT

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.99.2 Calculation of the NOx catalyst monolith temperature (sensor input)

Formula section:

TEG_PCAT_DOWN_COR[NC_CBK_EX_NR]
= TEG_PCAT_DOWN[NC_CBK_EX_NR] +TEG_PCAT_DOWN_ADD

7.99.2.1 Calculation of number of cold starts for Nox catalyst

After leaving the engine state ST the value of CTR_COLD_ST_NT is incremented by the increment one. At the same time dew point state detection is initialized LV_TNT_MIN_THD_2 = 0, i.e. the exhaust gas temperature is less than the temperature that characterizes the dew point.
The value CTR_COLD_ST_NT is a measure of the number of cold-start tests and has to be stored in the flash-memory when the engine is switched off (LV_IGK = 0). After a new start of the engine CTR_COLD_ST_NT is initialised with the stored value.
CTR_COLD_ST_NT is set to zero when the dew point of Temp_Model_2 is passed (LV_TNT_MIN_THD_2 = 1). The initialisation depends on Temp_Model_2 since it takes the longest for the second part of the Nox catalyst monolith to pass the dew-point.
In that way CTR_COLD_ST_NT is incremented for each engine start if the dew point of Temp_Model_2 was not passed before.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions

Initialisation: *from nonvolatile memory or = 0 if not possible*

Recurrence: *only once per engine run* *%CTR_COLD_ST_NT is only incremented per engine run*

Activation: *LV_ES =0*

Copyright (C) Continental AG,2007

Formula section:

If LV_TNT_MIN_THD_2 = 0 % at each transition from LV_ES = 1 -> 0
then CTR_COLD_ST_NT ++ % CTR_COLD_ST_NT is incremented; if there is a
else CTR_COLD_ST_NT = 0 % a transition of LV_TNT_MIN_THD = 0 -> 1 within the
endif % same DC, CTR_COLD_ST_NT has to be set to 0

7.99.3 Increasing the required energy

Function description:

On each restart, the amount of condensed water first increases and then decreases until the dew point is reached. To this effect, the energy introduced into the exhaust system EGY_DEW_END_NT_INT is calculated from the start and saved in the non-volatile memory at "engine stop" and after the latching phase has elapsed.
The amount of energy that has been brought into the exhaust system is weighted with FAC_EGY_DEW_NT_STOP, a factor dependent on the ambient temperature and the ratio of EGY_DEW_END_NT_INT and the threshold EGY_DEW_END_NT.
The result of this whole calculation is stored as EGY_DEW_NT_STOP in non volatile memory.
If the dewpoint is passed, EGY_DEW_NT_STOP is set to 0.

Application conditions

Initialisation: *at reset: from nonvolatile memory or = 0 if not possible*

Recurrence: only once after transition from LV_ES 0 ->1
Activation: at transition from LV_ES 0->1

Formula section:

RATIO_EGY_DEW_NT = EGY_DEW_END_NT_INT /EGY_DEW_END_NT
FAC_EGY_DEW_NT_STOP = IP_FAC_EGY_DEW_END_NT_STOP
If LV_TNT_MIN_THD_2 = 0
then if FAC_EGY_DEW_NT_STOP >= 0
then EGY_DEW_NT_STOP$_{(new)}$ = EGY_DEW_NT_STOP$_{(last)}$
+ IP_EGY_DEW_END_NT * FAC_EGY_DEW_NT_STOP
else EGY_DEW_NT_STOP$_{(new)}$ = EGY_DEW_NT_STOP$_{(last)}$
+ EGY_DEW_NT_STOP$_{(last)}$* FAC_EGY_DEW_NT_STOP
endif
else EGY_DEW_NT_STOP$_{(new)}$ = 0
endif

7.99.4 Integration of energy brought into the exhaust system

Function description:

For dew point detection of the NOX-Trap, the energy, that is brought into the exhaust system, has to be integrated.

Application conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Initialisation: *EGY_DEW_END_NT_INT = 0 at transition LV_ES 1 -> 0*

Recurrence: *200ms*

Activation: *LV_ST_END= 1 and LV_ES = 0*

Deactivation: LV_ES =1

Formula section:

EGY_DEW_END_NT_INT = EGY_DEW_END_NT_INT$_{(n-1)}$ + EGY_DEW_NT_DOWN * 0,2s

7.99.5 Calculation of the total energy until end of dew point

Application conditions

Activation: LV_CHECK_MDL_ST = 1

Deactivation: LV_ES = 1

Recurrence: 100ms

Initialisation:

Initialisation at engine start: transition LV_ES = 1 -> 0
EGY_DEW_END_NT = FFFFFFFFH
CTR_EGY_DEW_NT = 0

Function description:

To enable detection end of dew point, the necessary energy that has to be introduced into the exhaust system must be calculated first.

The value for the missing amount of energy is obtained from the map IP_EGY_DEW_END_NT. Input for this map is TEG_WALL_NT_DOWN_MDL_ST and TCO_ST.

ID_MAF_KGH_MIN_EGY_DEW_NT is a curve versus the wall temperature TEG_WALL_NT_DOWN_MDL which describes the minimum mass air flow, that has to exceeded to trigger the incrementing of CTR_EGY_DEW_NT.

MAF_KGH and of CTR_EGY_DEW_NT are inputs for IP_FAC_EGY_DEW_END_NT which will provide another factor for decreasing EGY_DEW_END_NT.

Formula section:

MAF_KGH_MIN_EGY_DEW_NT = ID_MAF_KGH_MIN_EGY_DEW_NT

If MAF_KGH > MAF_KGH_MIN_EGY_DEW_NT
Then CTR_EGY_DEW_NT ++ *% increment by 0.1*
Else CTR_EGY_DEW_NT = 0 *% reset counter*

FAC_EGY_DEW_END_NT = IP_FAC_EGY_DEW_END_NT
FAC_EGY_DEW_END_NT_TAM_T_ES = IP_FAC_EGY_DEW_END_NT_TAM_T_ES

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

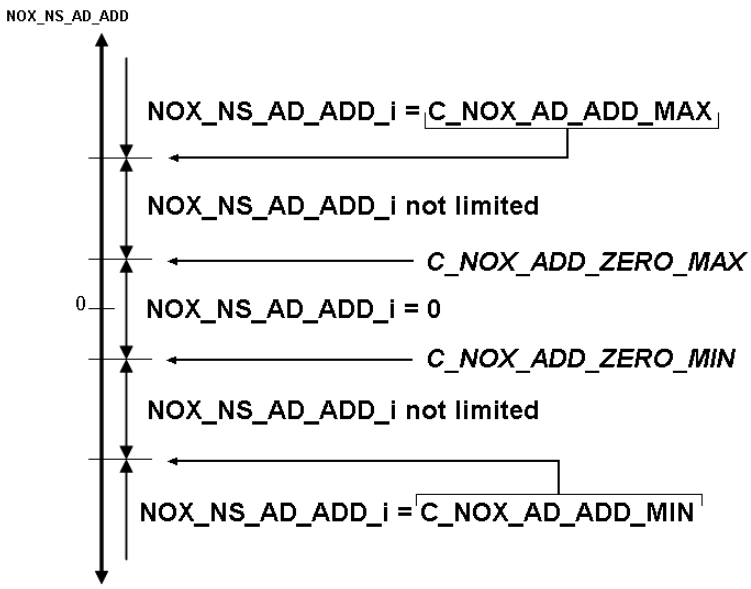
7.103.1 NOx signal offset adaptation

NOx signal offset adaptation can be done at PUC phase. At PUC phase NOx signal is influenced by the humidity cross-sensitivity of NOx-Sensor. The NOx signal is a combination out of signal offset and humidity cross-sensitivity.
Another possibility for NOx signal offset adaptation is after the start of a new NOx catalyst LOAD phase. At this time the NOx catalyst stores the NOx so that the NOx emissions are nearly to 0 [ppm]. Hence the NOx signal is dominated by signal offset. Attention! After an incompletely NOx regeneration or when the NOx catalyst has got a high sulphur load this offset adaptation must be inhibited.
This NOx signal offset adaptation calculates all offset values. Which offset value is used for the NOx signal offset adaptation, is possible to calibrate.
The NOx signal NOX_NS_i is compared with C_NOX_OFS_PUC_MAX before a new adaptation value (NOX_OFS_PUC_i) is calculated. This check is for prevention of adaptation failures.
C_NOX_OFS_PUC_MAX is the sum of the maximum humidity cross-sensitivity and the maximum positive NOx signal offset according to the sensor specification.
The calibration constant C_NT_HOM_INI_USE is used for independent configuration of offset calculation at PUC and of offset calculation after start of LOAD phase .

C_NT_HOM_INI_USE	**Description**
Bit B0	The offset calculation at PUC considers LV_NT_HOM_INI at offset determination (1...on/ 0...off).
Bit B1	The offset calculation after start of “LOAD” phase considers LV_NT_HOM_INI at offset determination (1...on/ 0...off).
Bit B2	not used
Bit B3	not used
Bit B4	not used
Bit B5	not used
Bit B6	not used
Bit B7	not used

The final NOx signal offset adaptation value NOX_NS_AD_ADD _i arises out of PUC offset value (NOX_OFS_PUC_i), LOAD offset value (NOX_OFS_LOAD_i) or manual offset value (C_ NOX_NS_AD_ADD_i). The used value is selected by C_NOX_OFS_SEL.
After the calculation of NOX_NS_AD_ADD_i it is limited (see below).



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

Setting NOX_NS_AD_ADD_i to 0 within the gap C_NOX_ADD_ZERO_MIN < NOX_NS_AD_ADD_i < C_NOX_ADD_ZERO _MAX was implemented in order to switch off the NOx signal offset adaptation if the calculated offset value is within the specified NOx signal tolerance (see NOx-Sensor specification).
NOX_NS_AD_i is the measured signal which is corrected by the signal offset NOX_NS_AD_ADD_i.
The calculation of NOX_NS_AD_i is done with a recurrence, which is in accordance with the NOx catalyst regeneration request calculation.
Additional information:
Suffix "_cur" is an abbreviation of current and means that the value is calculated in the same recurrence not first time.
Suffix "_old" means that this value is calculated last time in previous recurrence.

7.103.2 NOx sensor valid flag after regeneration

After regeneration it is prohibited to generate a new regeneration request by the NOx sensor (LV_RGN_REQ_NOX_SENS_i = 1) if the signal is not valid. This can be triggered by observation of the signal gradient or the time C_T_NOX_SENS_VLD. The gradient has to be permanently within a certain range for a continuous time. The time C_T_NOX_SENS_VLD is controlled by the timer T_AFL. T_AFL has to exceed C_T_NOX_SENS_VLD before regeneration can be requested by the NOx sensor.

Application Condition

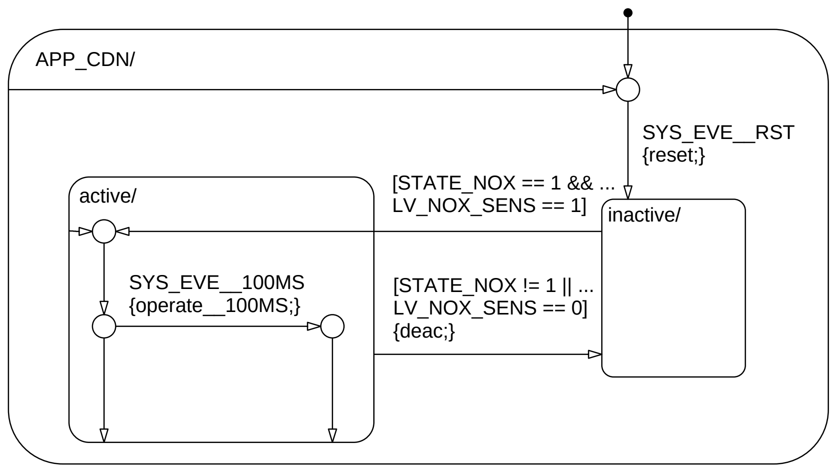

Figure 7.103.29: NOXD_MDLADNSFCN0/VLD_LV/APP_CDN/Chart

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. General information

This module coordinates the adaptation and application of the correction factors calculated by the functions "Cylinder Balancing via ER" and "Cylinder Balancing via Lambda Sensor".

The module "Cylinder Balancing via Lambda Sensor" calculates the adaptation values only in homogenous modes (lean or stochiometric), while the module "Cylinder Balancing via ER" calculates the adaptation values only in stratified mode. it is possible to apply manually the calculated adaptation values either in homogeneous or stratified or in both combustion modes with a calibration constant.

With use of a calibration constant a manual adjustment of the used injector energy level calculation is possible. The complete energy level calculation is disabled and the corresponding output values for the injection path are set to zero if the switch is set to "Disable".

Two different algorithms are existing for the injection valve energy level calculation. While the manual switch is set to "Adjustment", the calculation is based on a step by step approximation until a stable

Copyright (C) Continental AG,2007

energy level is reached. In case the manual switch is set to "Control", the energy level is calculated by a converter.

Both calculation routines can be activated in parallel while the manual switch is set to "AJD/CTL". The common energy level then is a summary of the adjustment value with the controller value.

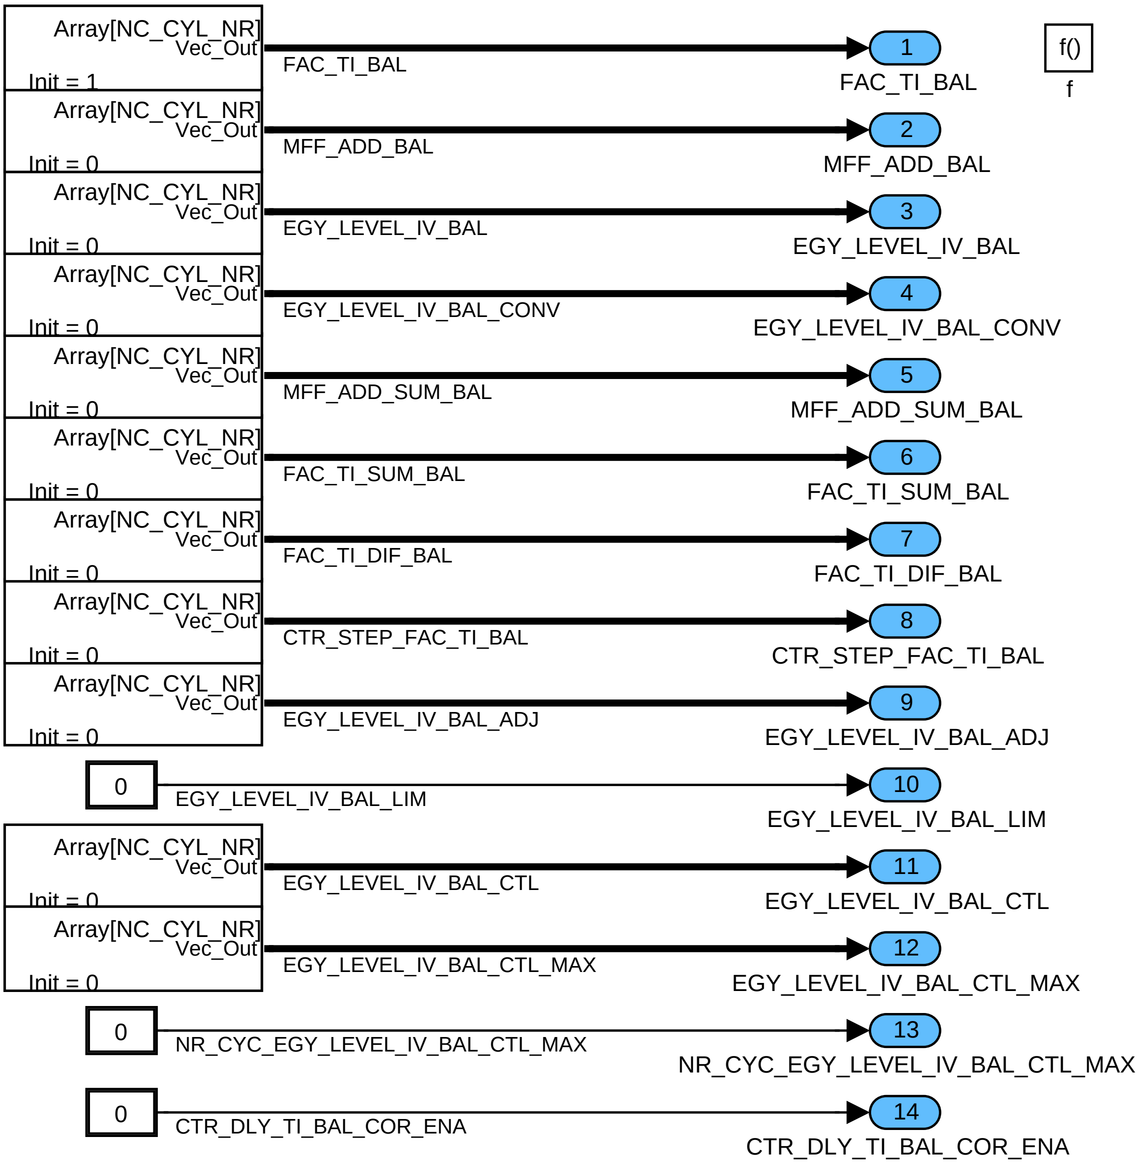

Figure 7.104.6: CYBL_M30704P01/OPM/OPERATE_100MS/OPERATE_100MS

Calculation of overall correction factors for cylinder balancing at engine stop

The formula section is only activated if the switch for a manual reset is set to "0". In case of a manual reset (refer:" Manual Reset of cylinder balancing correction values"), the calculations are stopped at once.

The calculation of the total cylinder balancing correction output values takes place at engine stop and engine start in fixed time steps. The output values are used to adjust the wanted cylinder individual corrections. All total cylinder correction values (for every cylinder) are calculated within one time step during this period.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

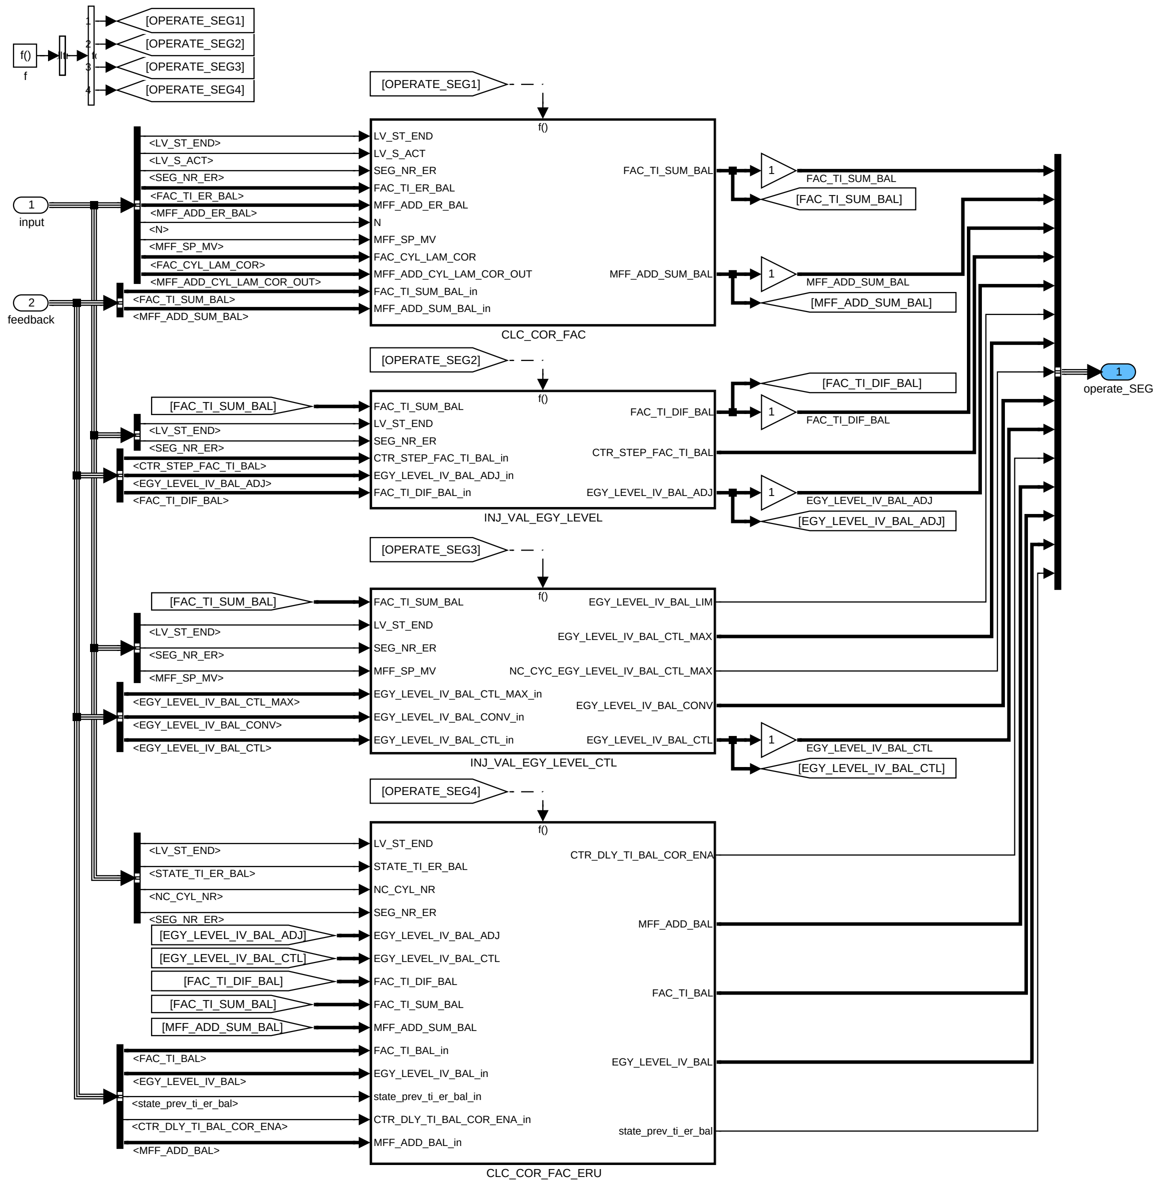

Figure 7.104.12: CYBL_M30704P01/OPM/OPERATE_SEG

Calculation of correction factors for cylinder balancing

The formula section is only activated if the switch for a manual reset is set to "0". In case of a manual reset (refer: "Manual Reset of cylinder balancing correction values"), the calculations are stopped at once.

The cylinder balancing correction factors for homogenous and stratified combustion mode are built from the input values of the different cylinder balancing adaptation functions. With a manual calibration constant it is possible to adjust the adaptation values at different combustion modes.

Short description of possible settings:

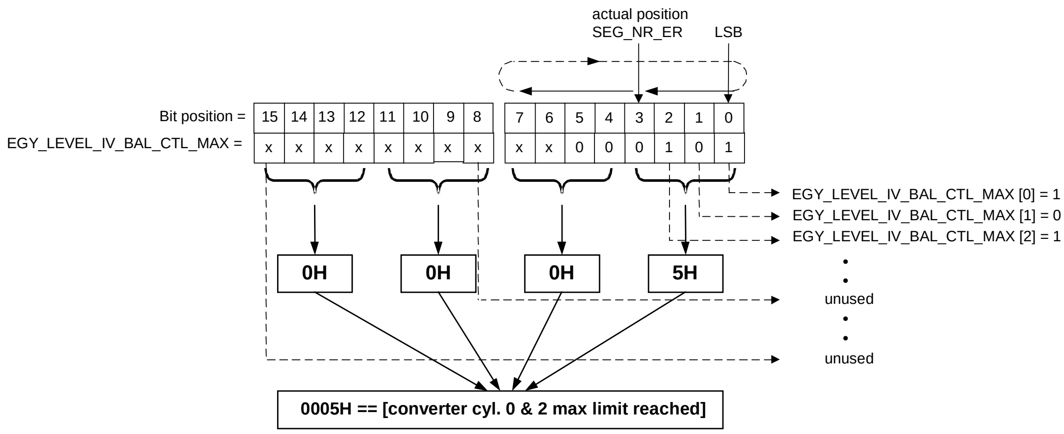
Cylinder balancing injection valve energy level control

The formula section is only activated if the switch for a manual reset is set to "0". In case of a manual reset (refer: "Manual Reset of cylinder balancing correction values"), the calculations are stopped at once.

The energy level conversion is only enabled while the manual switch for injection valve energy level calculation is set to "Control" or "ADJ& CTL".

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Signalization of converter maximum output value reached



Note: always the complete WORD (16BIT) is displayed as visible value

As soon as an energy level conversion of one cylinder is reaching its maximum, a corresponding value is set to "1" to indicate the related cylinder. To save memory resources, the information for all cylinders is located within one output date (WORD). Each BIT information within the WORD is used to indicate one cylinder. It is possible to handle up to 16 cylinders with this method.

For a description more in detail please have a look to the signal flow diagram above. As example, a sixcylinder engine with two converters, which have reached the limits is shown.

Cylinder balancing injection valve energy level control OPERATE_SEG CASE_THEN

("Calculation of the converter part enabled")

Task of this section is to convert the multiple correction factor provided by the cylinder balancing functions into a corresponding energy level value. The energy level signal is used to adjust the injector needle lift.

The outputs of the converter are limited to a calibrateable threshold. If one converter output has reached the limit a flag is set to one and the corresponding segment number is displayed.

The final converter outputs are corrected with a multiple factor out of an interpolation table to compensate different conversion rates for the energy levels at all engine operating areas.

Calculation of overall correction factors for cylinder balancing at engine run

The formula section is only activated if the switch for a manual reset is set to "0". In case of a manual reset (: "Manual Reset of cylinder balancing correction values"), the calculations are stopped at once.

Finally, the calculation of the total cylinder balancing correction output values takes place. The output values are used to adjust the wanted cylinder individual corrections. All injection valve correction values are calculated at any engine operating area depending of the chosen control strategy.

To avoid high cylinder to cylinder torque differences, especially at first activation after engine start and at cylinder balancing via ER activation, all total cylinder correction values are calculated within one segment. Later on, only the correction values of the current valid segment is calculated. The control is realized by a calibrateable forloop with adjustable "start" and "stop" parameters.

General information

This application incidence module is used as interface module between the project specific key word protocol (KWP) and the generic cylinder balancing functionality. The KWP provides for every piezo injector and absolute MFF value, which is determined at end of injector production line and imported to the ECU at vehicle production.

To take the aging of each injector into consideration, the distance since the last injector change is calculated. The determined distance is basic for an additive MFF offset value out of an interpolation table.

It is possible to adjust default values provided by a constant array instead of the input values from the key word protocol (KWP). For this purpose a separate switch (logical constant) is existing to manage the absolute MFF setpoint values. In serial production, always the KWP values have to be used.

General information

The calculation of the additive correction or adaptation values is performed, depending on the settings of the corresponding logical activation variable. LV_MFF_ADD_ER_BAL_ENA is used to enable the correction path, while LV_MFF_ADD_AD_ER_BAL_ENA enables the adaptation path. As soon as the corresponding logical value is set to 1 in combination with additional activation conditions, the calculation is started.

The calculated additive adaptation value MFF_ADD_AD_ER_BAL[NC_CYL_NR] for each cylinder is stored in the nonvolatile memory to be available for initialization issues at next engine run.

With use of the manual reset it is possible to initialize the additive correction or adaptation values with zero at any time. In this case, the flags which indicate the exceeding of a controller output limitation are set to zero as well (refer: Initialization at Manual Reset)

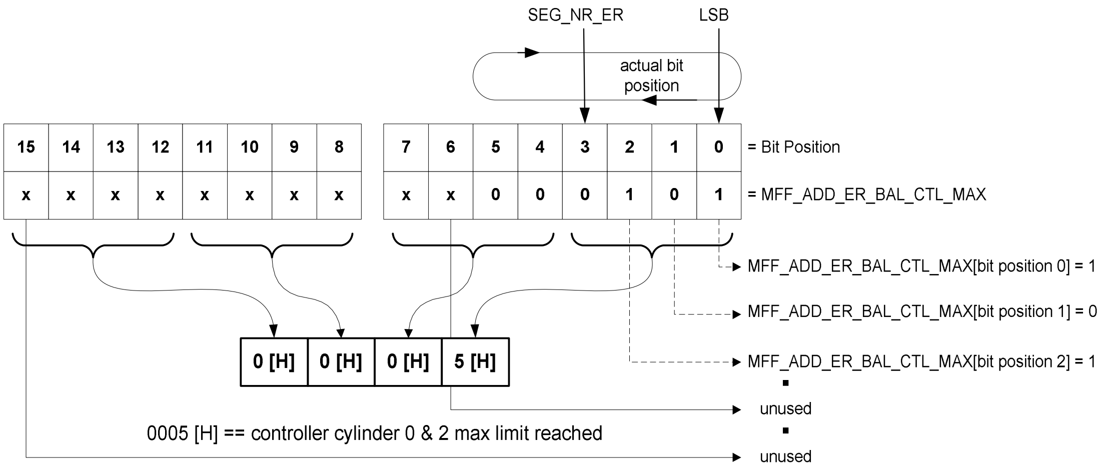
Calculation of the additive injection time correction values

The calculation of the additive injection time correction values are only performed if the corresponding enable bit LV_MFF_ADD_ER_BAL_ENA is set to logical 1 in combination with additional activation conditions. In this case, a separate correction value for each cylinder is determined with use of a PIcontroller.
As soon as a PIcontroller of one cylinder is reaching its maximum, a corresponding value is set to 1 to indicate the related cylinder. To save memory resources, the information for all cylinders is located within one output data (WORD). Each BIT information within the WORD is used to indicate one cylinder. It is possible to handle up to 16 cylinders with this method.
For a description more in detail please have a look to the signal flow diagram below. As example, a sixcylinder engine with two PIcontrollers, which have reached the limits is shown.
Signal flow diagram:

Signalization of controller max. output value reached for additive path



Note: always the complete WORD (16 BIT) is displayed as visible value

Controller Equataions

For the additive correction mode, a separate set of NC_CYL_NR controllers exists operating in parallel (one controller for each cylinder).
The computation of the output values is carried out every C_CYCNR_MFF_ADD_ER_BAL engine cycles (= calibrateable number of engine cycles).
Only in case of C_CYCNR_MFF_ADD_ER_BAL = 1, the calculation of the additive path is done without interruption. At every segment the corresponding cylinder specific correction value is built.
If the computation is not done at every engine cycle (C_CYCNR_MFF_ADD_ER_BAL > 1), the trigger of the controller output calculation is always related to SEG_NR_ER = 0.

Correction of limited controller output values with adaptation values

The limited controller output values are corrected with the currently available adaptive correction values, which are saved in the NVMY and updated at Activation or Deactivation of the additive adaptation path (LV_MFF_ADD_AD_ER_BAL_ENA)

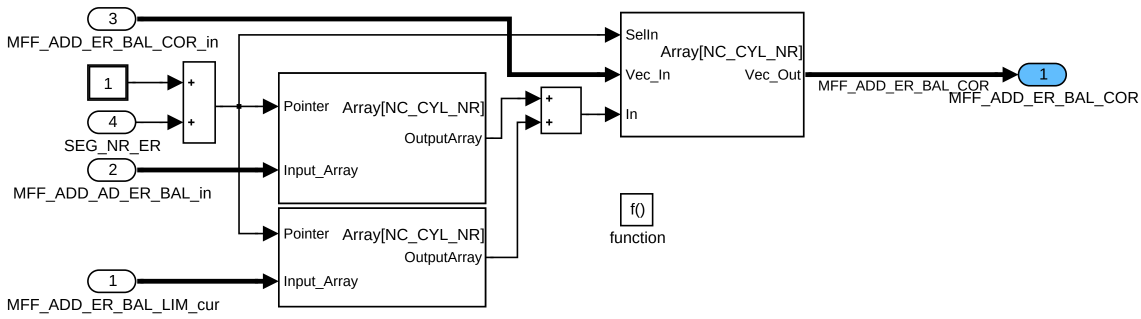

Figure 7.106.25: CYBL_M30708501/OPM/operate_SEG/CLC_OPERATE_SEG/ CLC_ADD_INJ_T_COR_VALUE/COR_LIM_CTL_OUT_VALUE

Observation of corrected controller output values for OBD issues

The additive correction values out of the correction path are observed for OBD purposes. As soon as the minimum or maximum diagnosis threshold is exceeded, a corresponding flag for the related cylinder is set. In this case the OBD system is indicated to handle the further failure treatment. The diagnosis thresholds have always to be less or equal to the absolute minimum or maximum controller output limits.

Calculation of the additive injection time adaptation values

The corrected NC_CYL_NR controller output values are adjusted dependent on the corresponding segment number SEG_NR_ER. During the function is activated, at every new segment the corresponding MFF_ADD_ER_BAL value is updated. Due to this correction the sum of all adaptation output values remains zero to guarantee that the overall injection spreading stays unchanged.

General information:

The calculation of the multiple correction or adaptation values is performed, depending on the settings of the corresponding logical activation variable. LV_FAC_TI_ER_BAL_ENA is used to enable the correction path, while LV_FAC_TI_AD_ER_BAL_ENA enables the adaptation path. As soon as the corresponding logical value is set to "1" in combination with additional activation conditions, the calculation is started.
The calculated additive adaptation value FAC_TI_AD_ER_BAL[NC_CYL_NR] for each cylinder is stored in the nonvolatile memory to be available for initialization issues at next engine run.
With use of the manual reset it is possible to initialize the multiple correction or adaptation values with zero at any time. In this case, the flags which indicate the exceeding of a controller output limitation are set to zero as well (refer: "Initialization at Manual Reset")

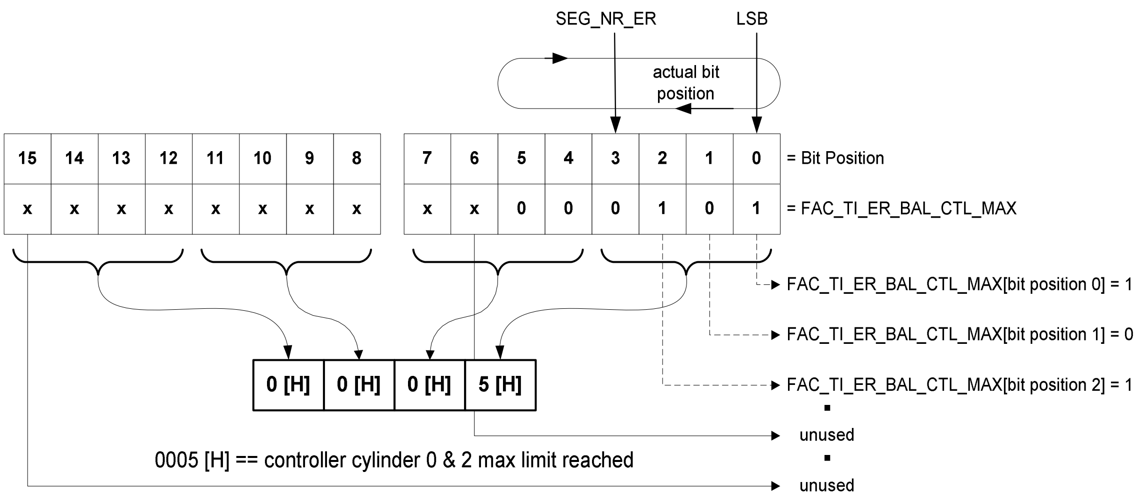
Structure of the multiple injection time correction values

The calculation of the multiple injection time correction values are only performed if the corresponding enable bit LV_FAC_TI_ER_BAL_ENA is set to logical "1" in combination with additional activation conditions. In this case, a separate correction value for each cylinder is determined with use of a PIcontroller.
As soon as a PIcontroller of one cylinder is reaching its maximum, a corresponding value is set to "1" to indicate the related cylinder. To save memory resources, the information for all cylinders is located within one output data (WORD) is used to indicate one cylinder. It is possible to handle up to 16 cylinders with this method.
For a description more in detail please have a look to the signal flow diagram below. As example, a sixcylinder engine with two PIcontrollers, which have reached the limits, is shown.
Signal flow diagram:
Signalization of controller max. output value reached for multiple path



Note: always the complete WORD (16 BIT) is displayed as visible value

Controller Equations

For the multiple correction mode, a separate set of NC_CYL_NR controllers exists operating in parallel (one controller for each cylinder).
The computation of the output values is carried out every C_CYCNR_FAC_TI_ER_BAL engine cycles (= calibrateable number of engine cycles).
Only in case of C_CYCNR_FAC_TI_ER_BAL = 1, the calculation of the additive path is done without interruption. At every segment the corresponding cylinder correction value is built.
If the computation is not done at every engine cycle (C_CYCNR_FAC_TI_ER_BAL > 1), the trigger of the controller output calculation is always related to SEG_NR_ER = 0.

Correction of limited controller output values with adaptation values

The limited controller output values are corrected with the currently available adaptive correction values, which is saved in NVMY and updated at Activation or Deactivation of the multiple adaptation path (LV_FAC_TI_AD_ER_BAL_ENA)

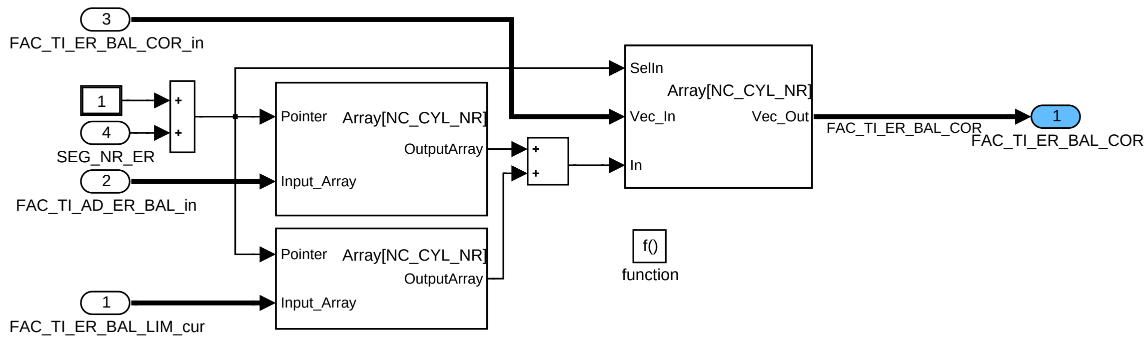

Figure 7.107.25: CYBL_M30707Q01/OPM/operate_SEG/CLC_OPERATE_SEG/ CLC_MPL_TI_COR_VALUE/COR_LIM_CTL_OUT_VALUE

Observation of corrected controller output values for OBD issues

The multiple correction values out of the correction path are observed for OBD purposes. As soon as the minimum or maximum diagnosis threshold is exceeded, a corresponding flag for the related cylinder is set. In this case the OBD system is indicated to handle the further failure treatment. The diagnosis thresholds have always to be less or equal to the absolute minimum or maximum controller output limits.

CLC_MPL_TI_COR_VALUE/COR_CTL_OUT_VALUE_OBD

Calculation of the multiple injection time adaptation values

The corrected NC_CYL_NR controller output values are adjusted dependent on the corresponding segment number SEG_NR_ER. During the function is activated, at every new segment the corresponding FAC_TI_ER_BAL value is updated. Due to this correction the sum of all adaptation output values remains zero to guarantee that the overall injection spreading stays unchanged.

This action sets the cylinder individual bit <Cyl> of STATE_INJ_UPD_ENA to <State_Inj_Upd_Ena>.

FUNCTION DESCRIPTION:

General information:

This specification is for project specific adaptations.

7.108.1 Runtime reduction

Description:

This chapter describes runtime reduction steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to that intake or exhaust bank, which is allocated to the related cylinder by NC_ IN_REF and NC_LAMB_REF. The control variables for cylinder and bank dependent calculations will be imported via CTR_CYL_NR_xxx and CTR_CBK_xxx data.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions

Activation : `every engine state`

Deactivation : –

Initialization: –

Recurrence :
```
LV_ST_END = 0:  10 ms
LV_ST_END = 1:  segment sychronous
```

Formula Section :

For loop for runtime optimization:
In this specification the for loop
FOR i = 0, i < NR_CYL_CLC_RED_INJ **DO**
x = CTR_CYL_NR_ST_CLC_INJR + i
(1a)**IF** x >= NC_CYL_NR
(1a)**THEN**

Copyright (C) Continental AG,2007

x = x - NC_CYL_NR
(1a)**ENDIF**
<**loop content**>
ENDFOR
is substituted by
FOR cylinder_start to cylinder_stop **DO**
<**loop content**>
ENDFOR
Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

Determine cylinder and bank numbers for follow up calculations

R_S/V as well as the unit conversions (1hPa = 100N/m^2 and 1rpm = 30stk/h) is included in C_FAC_MAP_TCYL_MDL (C_FAC_MAP_TCYL_MDL = R_S/(V*3000)).

MAP_INJ[0] = MAF_CYL * TCYL_MDL_CUS * C_FAC_MAP_TCYL_MDL /N

(6)ELSE

MAP_INJ[0] = MAP

(6)ENDIF

7.108.18 Compensation of missing residual-gas amount after PUC

Description:

This chapter describes the compensation of missing residual-gas amount at restart of fuel feed. This is caused by a inhibit of injection in the past. At restart of fuel feed for the first combustion residual-gas amount is missing. Therfore the calculated fuel amount is wrong. This functionality should compensate this effect.

Application conditions

Activation : *LV_ST_END = 0*
Deactivation : –
Initialization: –
Recurrence : *10 ms*

Formula Section :

FOR x = 0 **TO** NC_CYL_NR-1
MFF_ADD_REAC[x] = 0
END FOR

Application conditions

Activation : *LV_ST_END = 1*
Deactivation : –
Initialization: –
Recurrence : *segment sychronous*

Formula Section :

(1)IF LC_MFF_ADD_REAC_ENA = 1
(1)THEN
FOR cylinder_start to cylinder_stop **DO**
IF (Bit-Nr x of PREV_STATE_IV = 0)
THEN

7.108.19 Injector test mode

Application conditions

Activation: *LV_ES = 1*

Deactivation: –

Initialization: –

Recurrence: 1 s

This chapter describes the necessary interfaces to the procedure for actuator tests by diagnostic tester.

7.108.19.1 Formula Section:

LV_IV_TEST_MOD_AUTH = 0
NR_CYL_IV_TEST_MOD = 0
(1) FOR x = 0 **TO** (NC_CYL_NR -1)
CTR_TEST_MOD_IV_EXT[x] = CTR_TEST_MOD_IV[x]
(1) END FOR
Please note! This for-loop should be realized in SW with a #define. CTR_TEST_MOD_IV_EXT[NC_CYL_NR] has to be realized also as a #define for CTR_TEST_MOD_IV to preserve resources.

7.108.20 Crash signal reaction of injection driver

Application conditions

Activation: *every engine state*

Deactivation: –

Initialization: –

Recurrence: 10 ms

This chapter describes the necessary interfaces to customer signals to react on a vehicle crash.

7.108.20.1 Formula Section:

(1) IF STATE_EFP_CRASH_CAN = 2H

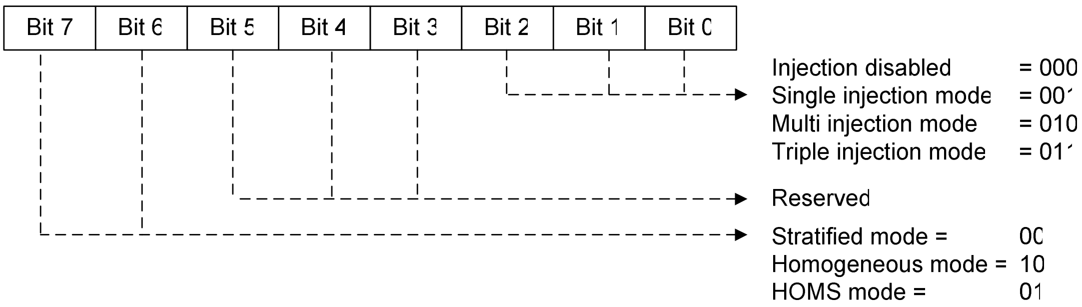
Description:

This section determines the actual set injection mode request.

Byte definition

Definitions bit masks for injection modes: STATE_INJ_MOD_REQ, STATE_INJ_MOD_HOM_REQ, STATE_INJ_MOD_S_REQ and STATE_INJ_MOD_HOMS_REQ



Example: homogenous multi injection mode (MPLH)

1	0	0	0	0	0	1	0

The mapping of the information about injector needle lift selection is done from a bit field as input to bit field as output. Here, the conversion from customer pulse numeration to supplier numeration is done.
Important note: For better readability of the specification, the LSB of each bit field, which corresponds to the physically first injection pulse, is referred to as bit 1 (**not** bit 0 as it would be in SW). The next bit would be bit 2 etc.

Definition of NC constants

NC_INJ_MOD_SINGLE = 0x01H

LV_EGY_RNG_HOM_EXT_ENA = 0
(1)ENDIF

Calculate variables used by other functionalities (stable interface):

INJ_MOD_GLOBAL = STATE_INJ_MOD_REQ
(1)FOR cylinder_start to cylinder_stop **DO**
(1)IF INJ_MOD_SP[x] $\neq$ INJ_MOD[x]
(1)THEN
Bit x of STATE_INJ_MOD_SWI_ACT = 1
(1)ELSE
Bit x of STATE_INJ_MOD_SWI_ACT = 0
(1)ENDIF
(1)ENDFOR

7.108.22 Calculation of injection fixed update window and ignition update window

Application conditions

Activation : every engine state

Deactivation : –

Initialization: at reset : **calculate Formula Section**

Recurrence : 1s

Description:

This section calculates the crank windows for ignition and injection update. The initialization routine at reset is the same as the time synchronous routine (1s)!

Formula Section :

CRK_PSN_STAT_WIN_ST = C_CRK_PSN_STAT_WIN_ST
(1)IF CRK_PSN_STAT_WIN_ST >= ((720°/NC_CYL_NR)*1.1)
(1)THEN
CRK_PSN_STAT_WIN_ST = ((720°/NC_CYL_NR)*1.1)
CRK_PSN_STAT_WIN_END = 720°
(1)ELSE
CRK_PSN_STAT_WIN_END = 720° - ((720°/NC_CYL_NR)*1.1
- CRK_PSN_STAT_WIN_ST)
(1)ENDIF
CRK_PSN_STAT_IGN_UPD_ST = C_CRK_PSN_STAT_IGN_UPD_ST
CRK_PSN_STAT_IGN_UPD_END = C_CRK_PSN_STAT_IGN_UPD_END

Copy calibratable needle lift set point during MFMA to aggregate interface:
LF_EGY_RNG_HOM_EXT = CLF_EGY_RNG_LAM_AD_INJ
Note: Bit 0 of CLF_EGY_RNG_LAM_AD_INJ represents the needle lift of the first pulse, bit 1 the lift of the second and bit 2 the lift of the third pulse!

(1) THEN

FAC_TI_L_PRS = (IP_FAC_TI_FUP_L_PRS(FUP_H_INJ) * IP_FAC_TI_TEMP_L_PRS(TFU_INJ, TAM)) + 1

/* FUP_H_INJ and TFU_INJ must be calculated before the calculation of FAC_TI_L_PRS */

(1) ELSE

FAC_TI_L_PRS = 1

(1) ENDIF

7.108.24 Description of exported actions

7.108.24.1 Description of ACTION_INJR_SetStateInjUpdEna

ACTION_INJR_SetStateInjUpdEna(IN <Cyl>, IN <State_Inj_Upd_Ena>)					
This action sets the cylinder individual bit <Cyl> of STATE_INJ_UPD_ENA to <State_Inj_Upd_Ena>.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	-
Number of logical cylinder.					
State_Inj_Upd_Ena	IN	0 ... 1	0 ... 1	1	-
Logical value for setting or resetting the corresponding cylinder value.					

Formula Section:

Bit Cyl of STATE_INJ_UPD_ENA = State_Inj_Upd_Ena
Note: The LSB of STATE_INJ_UPD_ENA is referred to as Bit 0 (zero based indication)!

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Copyright (C) Continental AG,2007

This module handles the activation for the upper and lower temperature range for the lambda adaptation via injection mode and the engine speed controller, the lambda controller and the misfire detection are monitored during the adaptation.

Application Conditions

Initialization: RST, IGKON, NVMINI, NVMRES, NVMSTO
Activation: 20MS: always
SEG: always
ES2ERU: always
Deactivation: never

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 7.109.1 Initialization

Initialization of the variables at ignition on and reading and writing of the variables stored in the non volatile memory.

7.109.1.1 Initialization of the online variables at reset

All variables are initialized with 0 at reset.

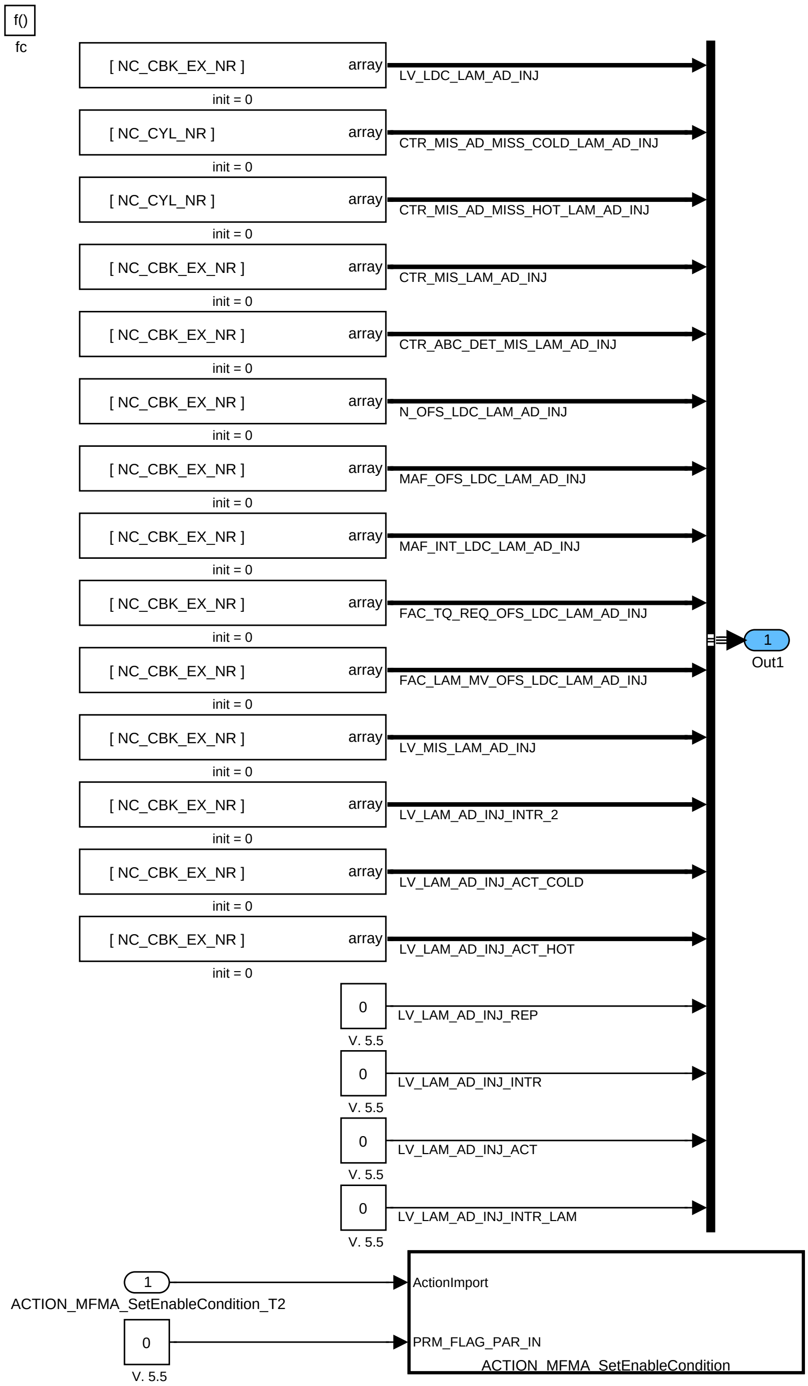

Figure 7.109.2: :

7.109.1.4 Writing of non volatile memory variables

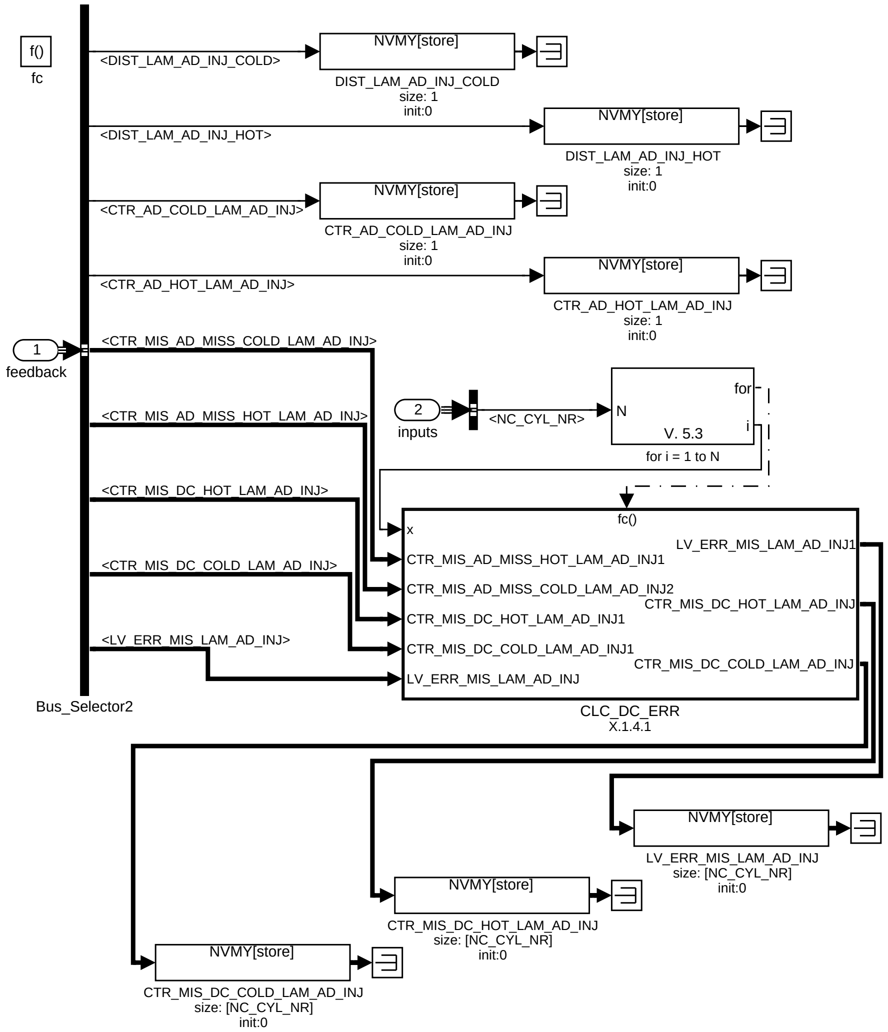

Figure 7.109.5: :

7.109.1.4.1 Calculation of driving cycle counter and creation of error flags

For each cylinder the number of driving cycles with missed adaptation due to misfire are counted. If the counter exceeds a threshold, the error flag will be set at the end of a driving cycle.

7.109.1.4.1.1 Calculation of driving cycle counter and error flags

If the number of missed adaptation cycles due to misfire in a driving cycle exceeds the threshold C_CTR_MIS_LAM_DC_MIN_LAM_AD_INJ, the counter for driving cycles with missed adaptation is increased. If the number of driving cycles with failed adaptations reaches the threshold C_CTR_MAX_DC_LAM_AD_INJ, the error flag for the depending cylinder is set.

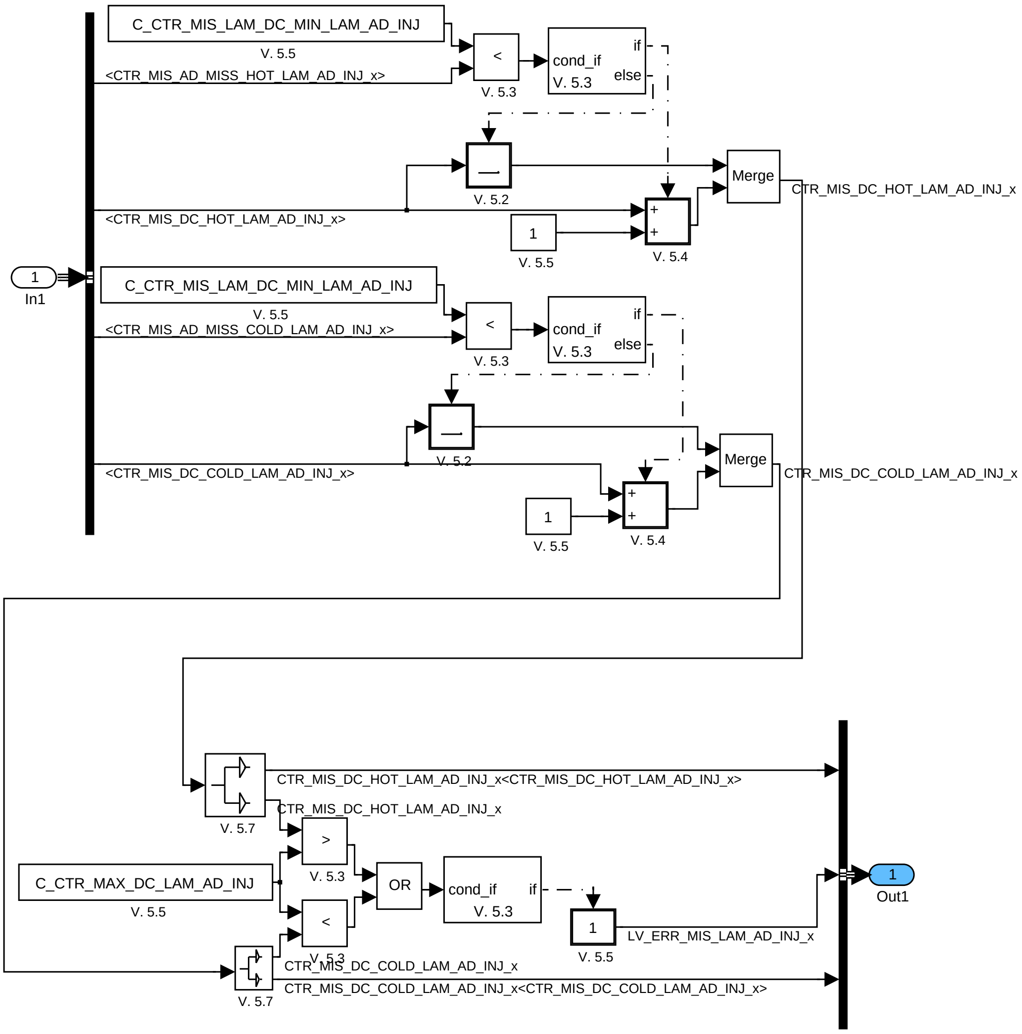

Figure 7.109.6: :

7.109.1.5 NVMY initialization

The distance counter is initialized at non volatile memory initialization with the sum of the mileage counter and the output of the map IP_DIST_LAM_AD_INJ_HOT/COLD. With this calculation the first adaptation after NVMY initialization will start after a mileage distance defined in the map. All other values are initialized with zero.

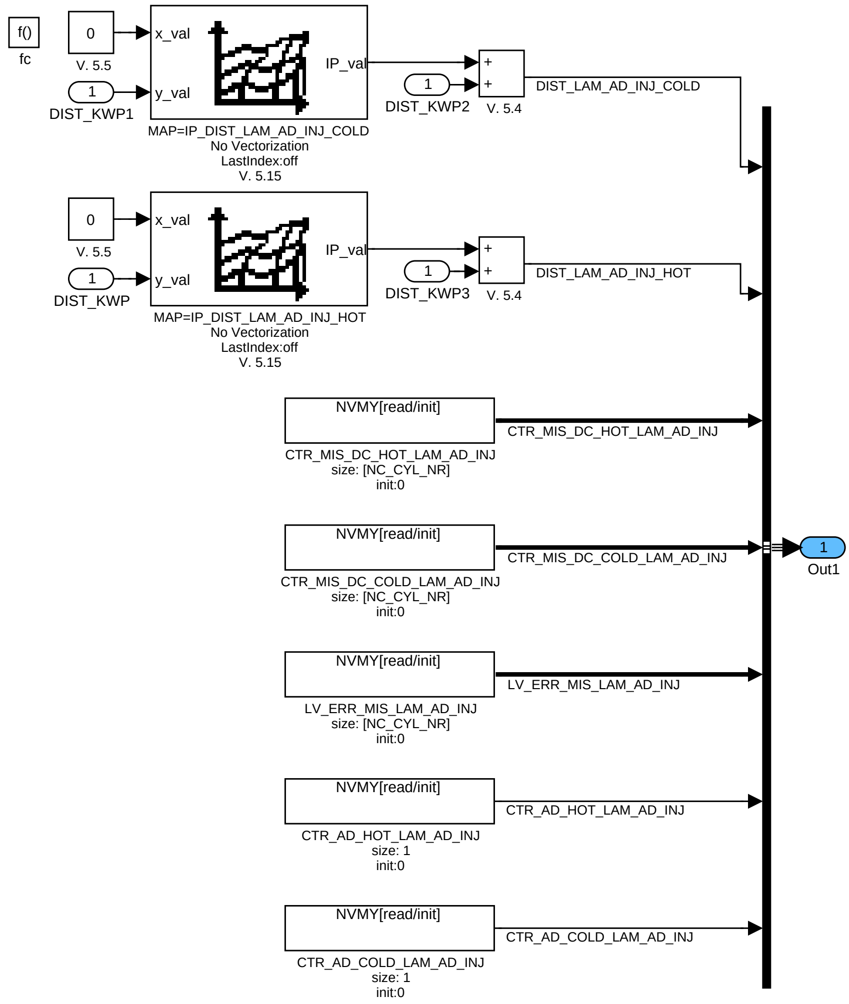

Figure 7.109.7: :

7.109.2 Determination of the adaptation conditions

The determination of adaptation conditions is divided into bank specific and bank independent calculations.

7.109.2.1 Bank independent calculations

The bank independent calculations are divided in general calculations, temperature calculations and the clearance of interruption and repeat flags.

7.109.2.1.1 General activation conditions

For activation of the adaptation the fuel mass flow and the engine speed has to be inside limitations. Also a certain time after engine start has to be passed.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

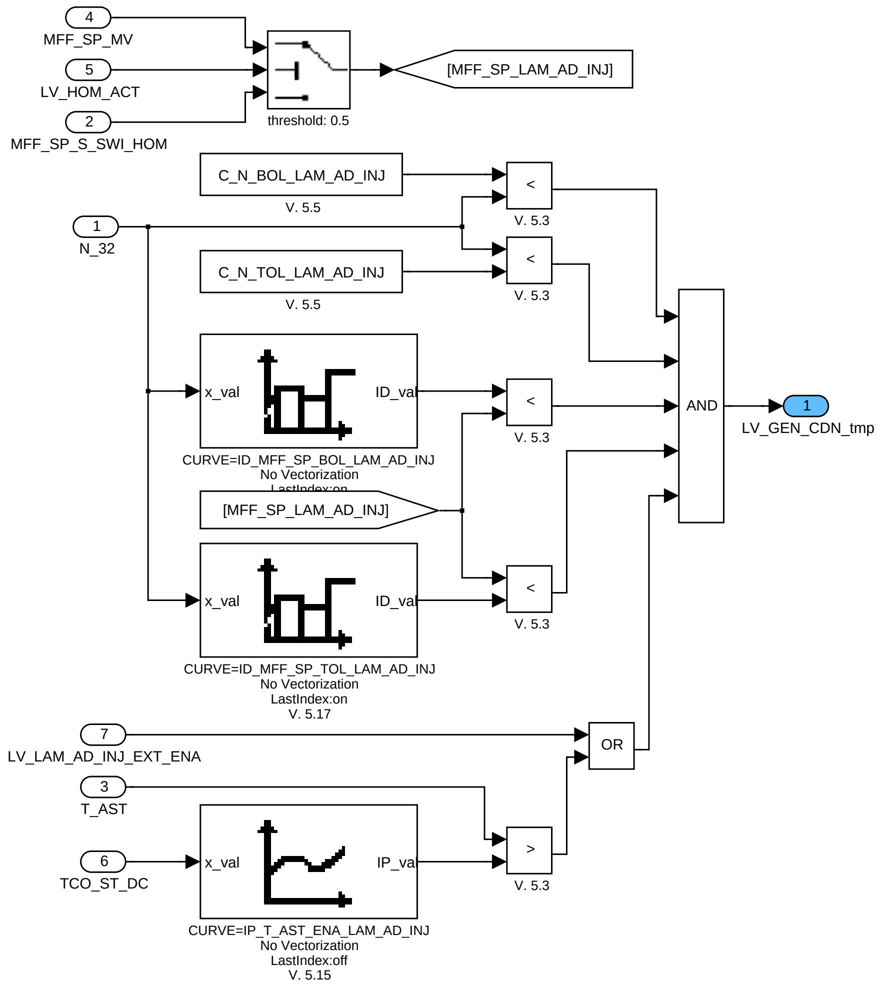

Figure 7.109.8: :

7.109.2.1.2 Temperature range activation conditions

To activate the adaptation for cold and hot adaptation range the depending temperature can bee chosen between coolant temperature and fuel temperature. For activation the temperature has to be inside limitations, the general conditions has to be fulfilled, the cylinder individual lambda controller has to be ready and the condition for the mileage counter has to be fulfilled. Also the maximum number of adaptation cycles in the driving cycle has not to be reached.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.109.2.1.4 Reset of LV_LAM_AD_INJ_EXT_ENA

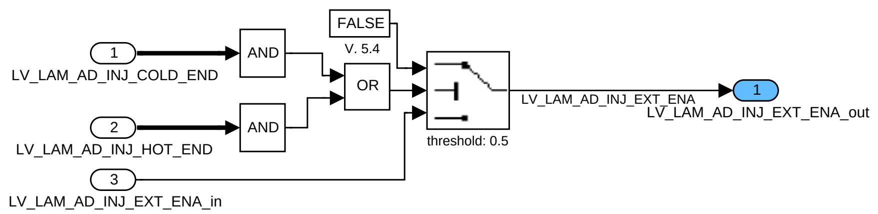

Figure 7.109.14: :

7.109.2.2 Bank specific calculations

The following calculations are done for all cylinder banks. Inside the model the bank specific values are denoted with the suffix _i whereas in the textual description they are referenced via [i].

7.109.2.2.1 Limited dynamics determination

The flag LV_LDC_LAM_AD_INJ[i] is calculated using N, MAF; FAQ_TQ_REQ and FAC_LAM_MV conditions. During multiple injections the monitoring of FAC_LAM_MV can be changed by using different thresholds.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

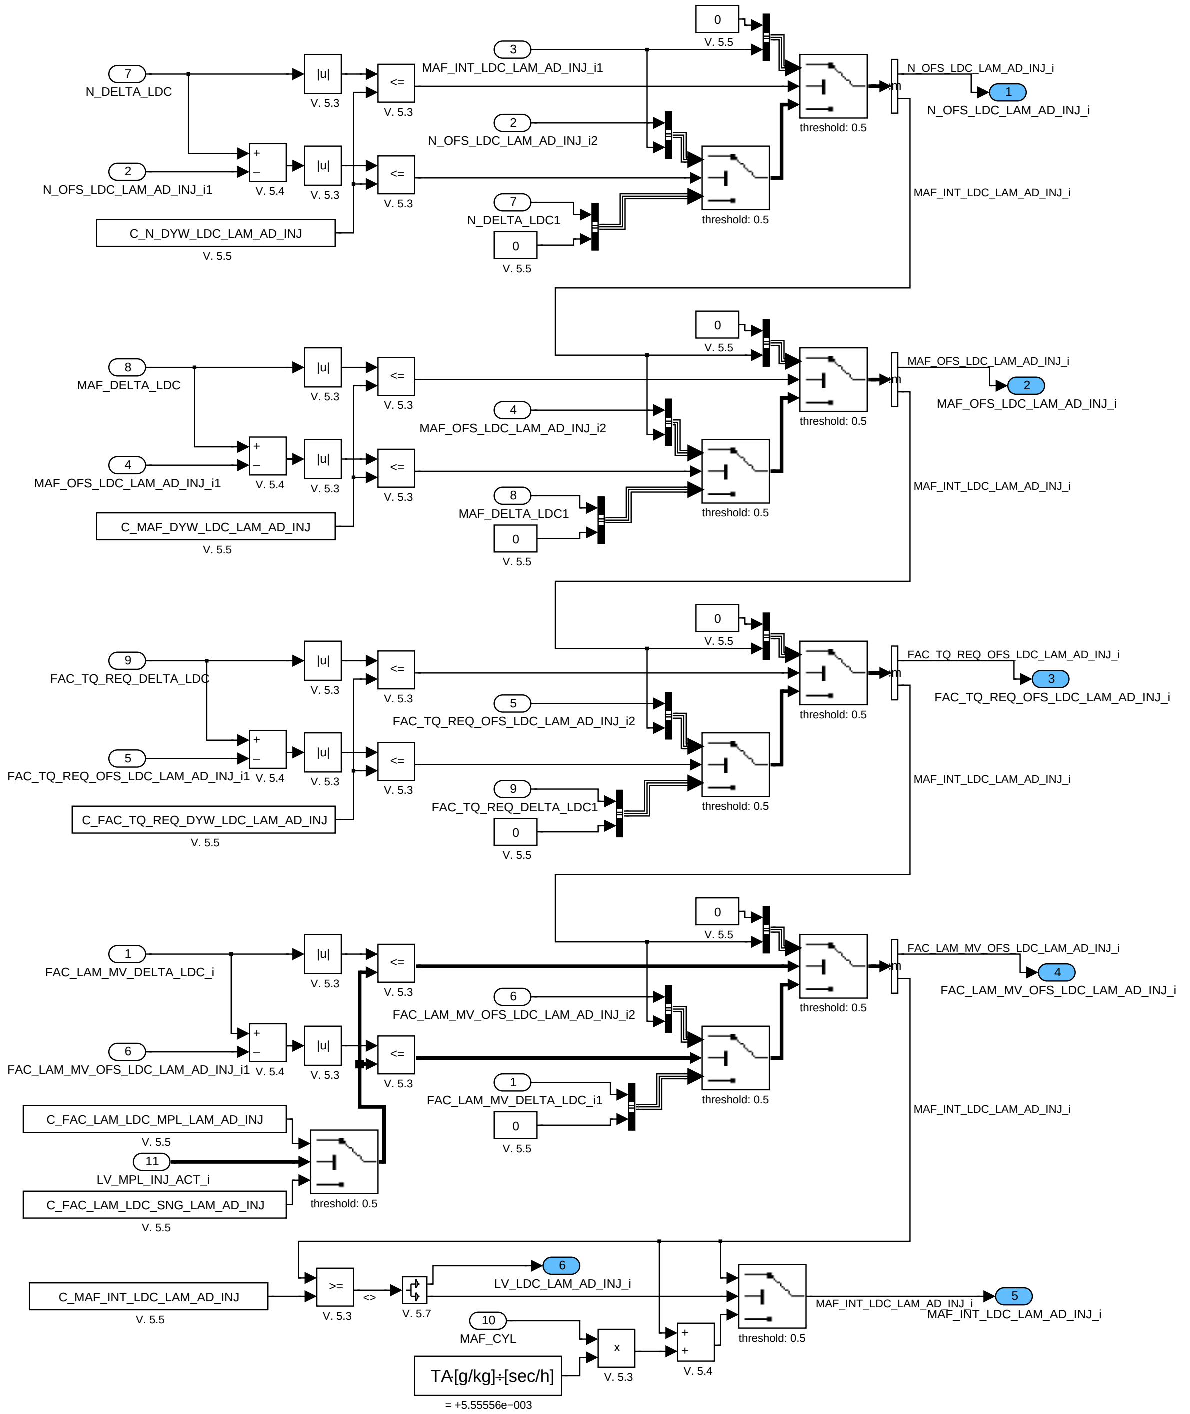

Figure 7.109.15: :

7.109.2.2.2 Determination of adaptation conditions for upper or lower temperature range

If the limited dynamics are given and the lambda controller operates within defined limits, depending on the temperature conditions the adaptation for the upper or lower temperature range is enabled, if all banks fulfil these conditions and the catalyst temperature has to be below a threshold. Or the adaptation can be activated manually via calibration value.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

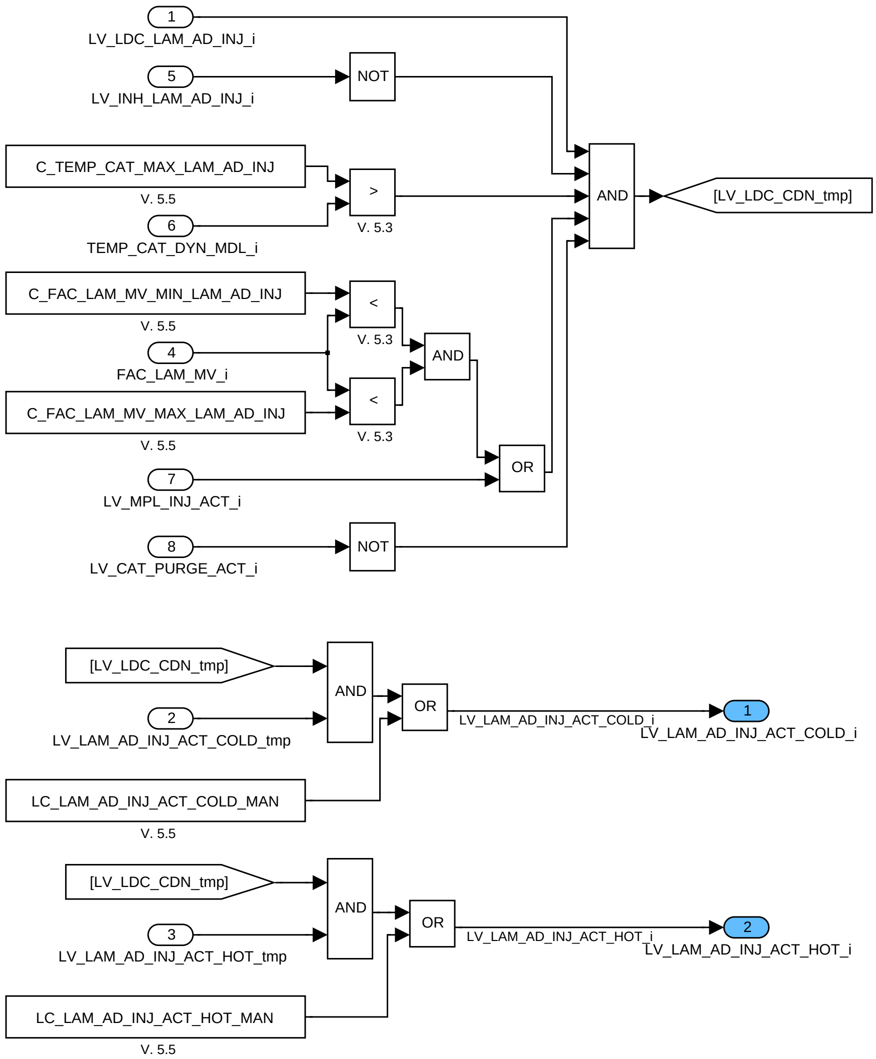

Figure 7.109.16: :

7.109.2.2.3 Monitoring of ENSC, LACO and MISF

During the multiple injection phase the output of the engine speed controller, the lambda controller and the misfire detection are monitored.At a certain number of misfire events or at a certain deviation in the lambda controller output the adaptation is interrupted immediately and the adaptation is repeated.For a deviation in the engine speed controller, the adaptation is at first finished and then repeated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.109.2.2.3.3 Calculate counter for misfire handling

This calculation are done, if a misfire during multiple injection is detected. At misfire the misfire counter is incremented an the interruption flag is set, which leads to a repeat of the adaptation. If the maximum number of repeated adaptation due to misfire are reached, a second interruption flag is set, a counter is incremented and the adaptation is continued with all left cylinders.

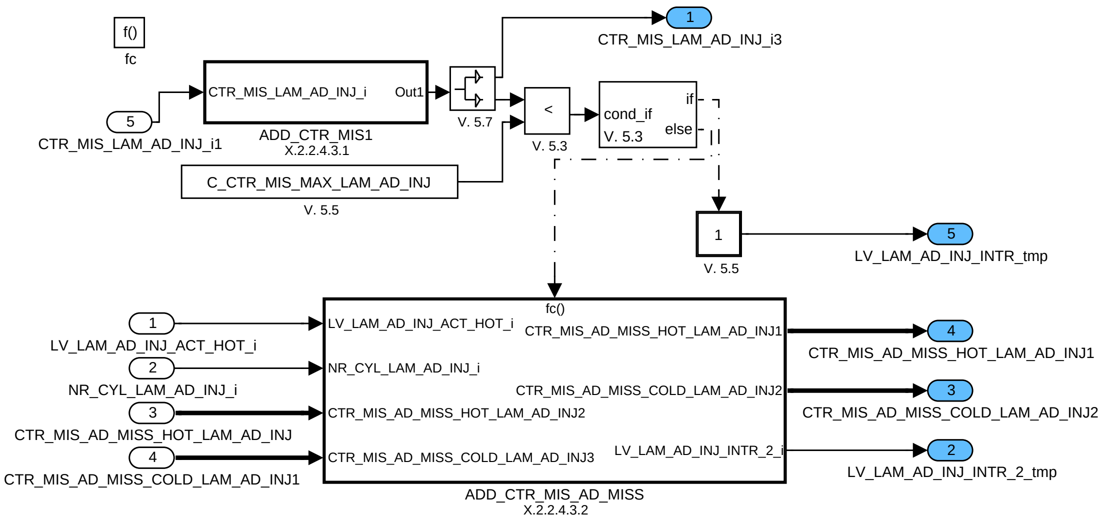

Figure 7.109.21: :

7.109.2.2.3.3.1 Incrementation of CTR_MIS_LAM_AD_INJ

The counter is incremented and limited.

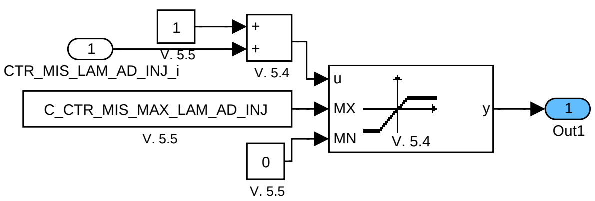

Figure 7.109.22: :

7.109.2.2.3.3.2 Incrementation of of CTR_MIS_AD_MISS_COLD/HOT_LAM_AD_INJ

Depending on the temperature range the counters are incremented.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

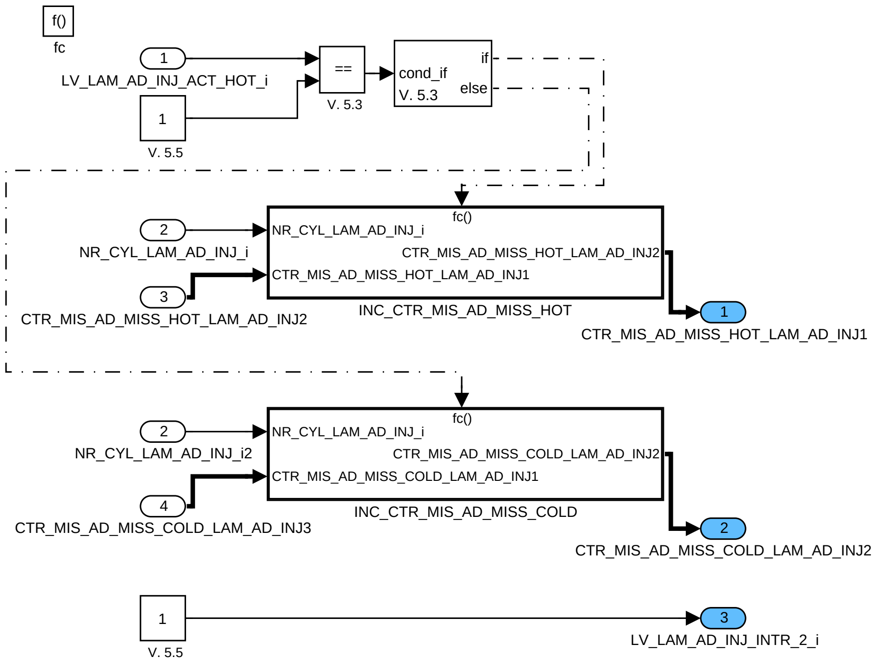

Figure 7.109.23: :

7.109.2.2.3.4 Conditions for interruption due to lambda conditions

If the lambda controller output exceeds the limitations, the adaptation is interrupted.

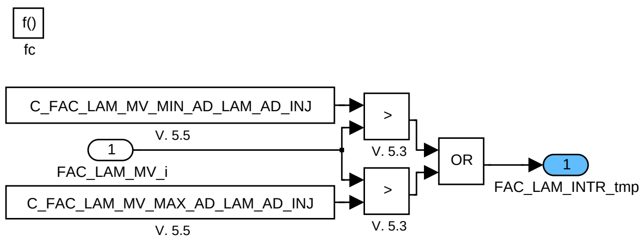

Figure 7.109.24: :

7.109.2.2.3.5 Conditions for interruptions due to ENSC controller output deviation

For a big difference in the idle speed controller in single and multiple injection, the adaptation will be finished and repeted.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

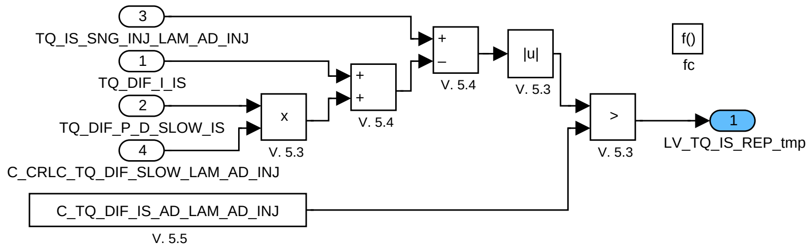

Figure 7.109.25: :

7.109.2.3 Calculation of general activation flag and update of the distance counter

The general activation flag is set if the bank specific condition for hot or cold conditions are given. Also the update of the mileage threshold is updated.

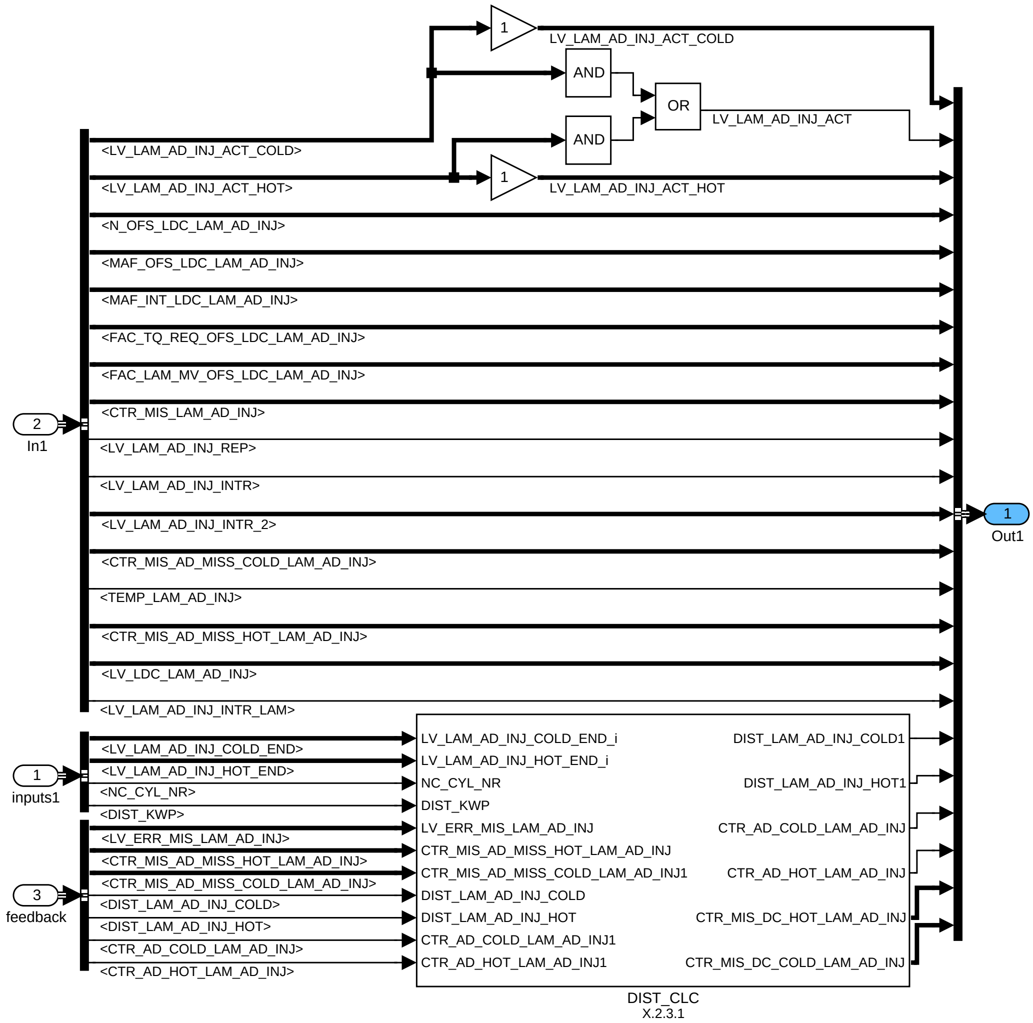

Figure 7.109.26: :

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.109.2.3.1 Update of the mileage threshold

The mileage threshold is separately updated for hot and cold adaptation if the adaptation is finished successfully for all cylinders and no repeat of adaptation due to misfire is necessary.

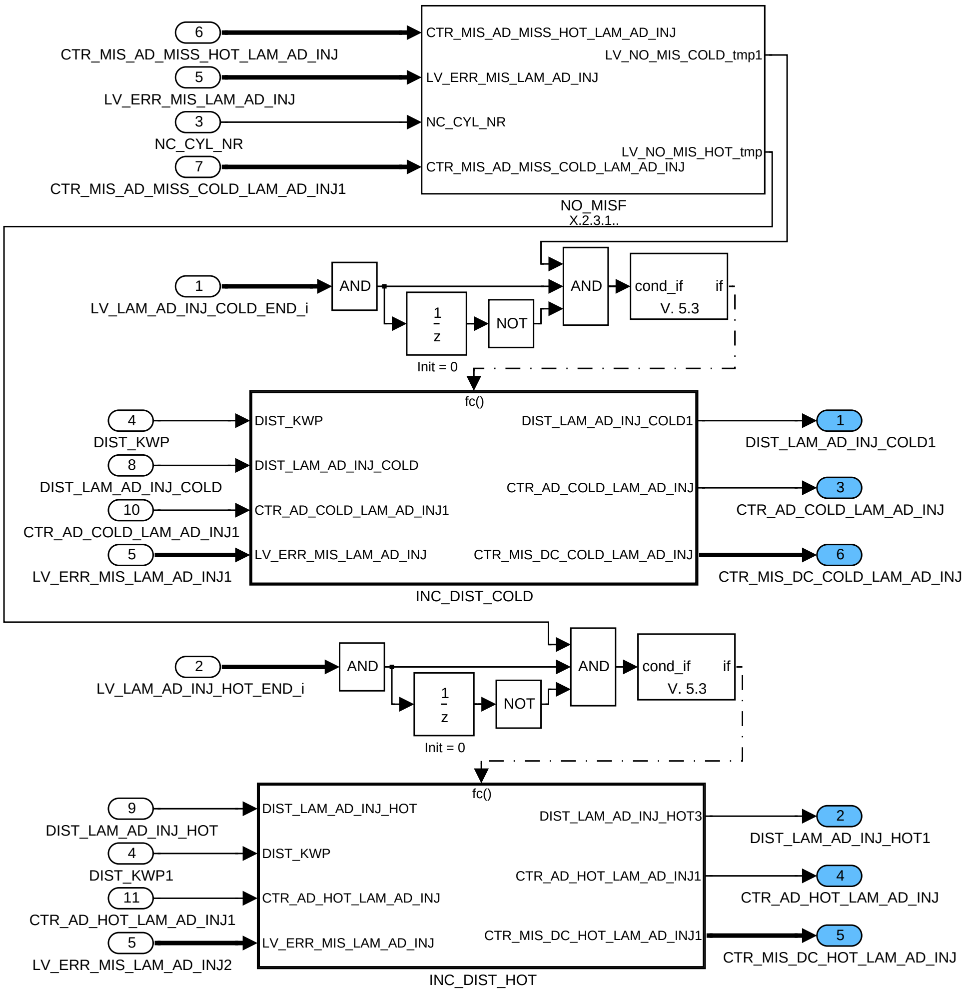

Figure 7.109.27: :

7.109.2.3.1.1 Distance threshold incrementation for cold adaptation

At successful adaptation the distance counter will be incremented; the CTR_AD_COLD_LAM_AD_INJ will be incremented and if no error is present and the LC_CTR_MIS_DC_LAM_AD_INJ_CLR is set the CTR_MIS_DC_COLD_LAM_AD_INJ is cleared.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

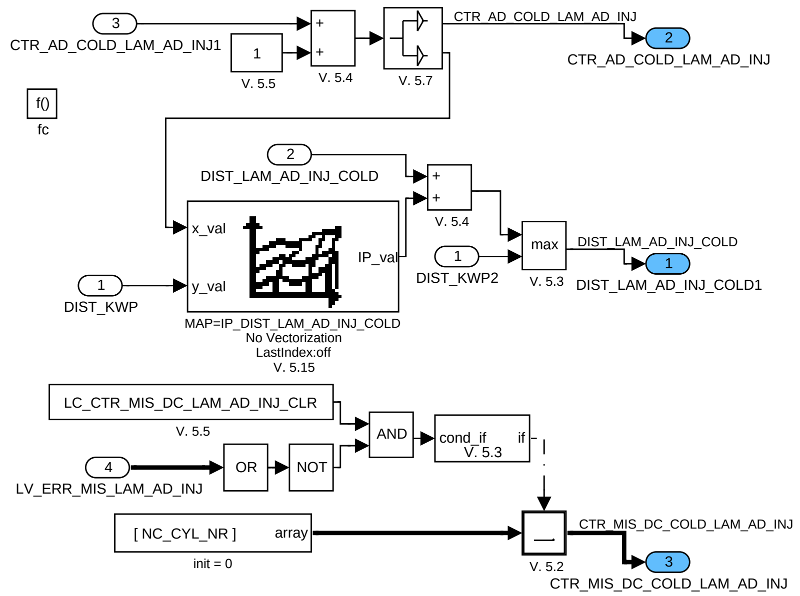

Figure 7.109.28: :

7.109.2.3.1.2 Distance threshold incrementation for hot adaptation

At successful adaptation the distance counter will be incremented; the CTR_AD_HOT_LAM_AD_INJ will be incremented and if no error is present and the LC_CTR_MIS_DC_LAM_AD_INJ_CLR is set the CTR_MIS_DC_HOT_LAM_AD_INJ is cleared.

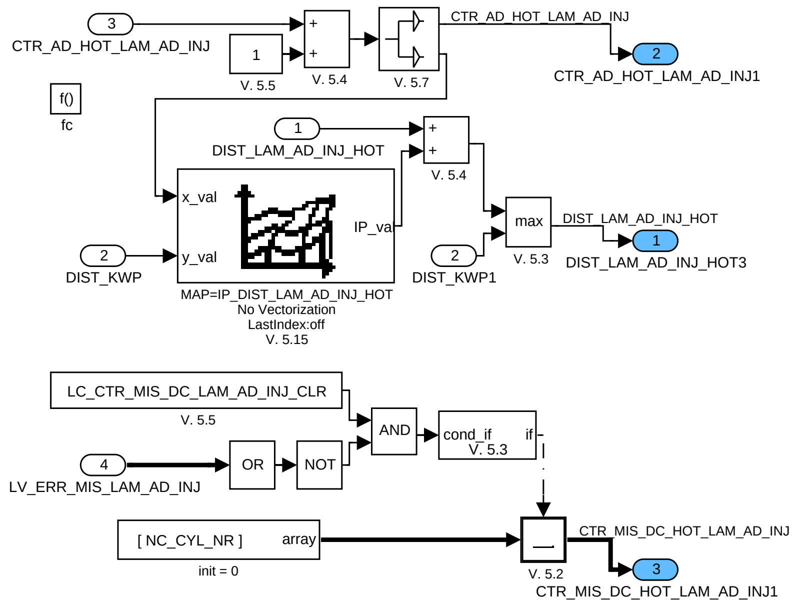

Figure 7.109.29: :

7.109.2.3.1.3 No misfire condition for mileage threshold update

The mileage threshold can be updated, if the condition "no misfire" is present for all cylinders.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

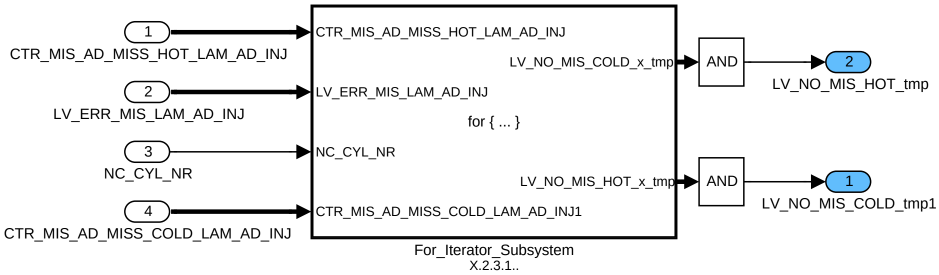

Figure 7.109.30: :

7.109.2.3.1.3.1 No misfire condition

For each cylinder it tested, if no misfire was present or the error for misfire is already present.

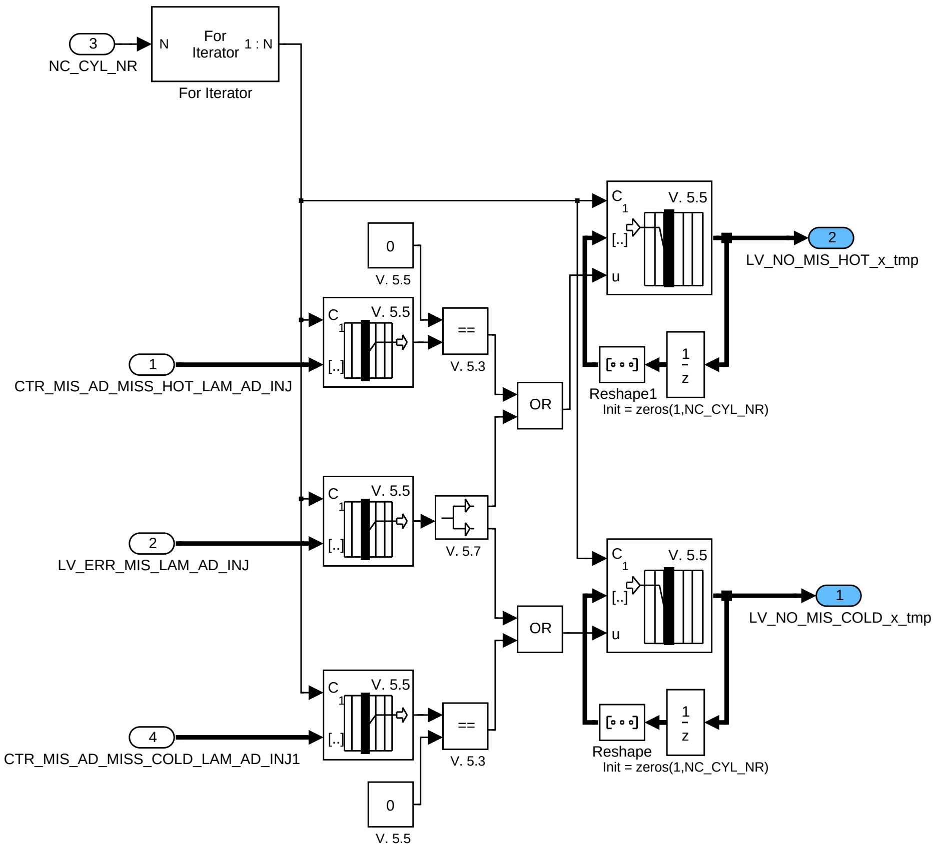

Figure 7.109.31: :

7.109.3 Segment synchronous calculations to detect misfire

Calculations to detect misfire with the same recurrence as the misfire calculations. Misfire will be detected only at multiple injection phase, represented by STATE_LAM_AD_INJ_ACT $>$ 2 (single injection)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.109.3.1 Detection of misfire

If misfire is detected for the cylinder with multiple injections, a misfire counter is incremented. The flag indicating misfire is set, if the counter reach a threshold.

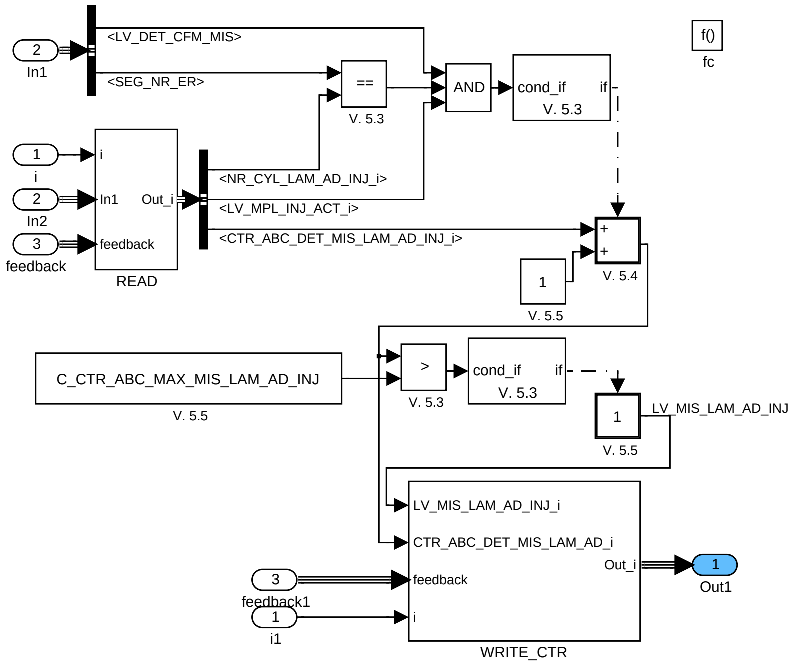

Figure 7.109.32: :

7.109.4 Calculations at event engine stop to engine run

Cylinder individual calculations to clear the error flags.

7.109.4.1 Clear error flags, distance threshold and counters

At a change of an injector, the CTR_AD_HOT/COLD_LAM_AD_INJ and the error flags and counter are cleared. The distance threshold and the error can also be cleared by calibration data.
If a resetting of the NVMY data via service tester is requested with the flag LV_LAM_AD_INJ_CLR_AD_EXT, the counters and the distance thresholds are cleared.

General Information

This module coordinates the usage of single and multiple injections for lambda adaptation via injection mode.

Application Conditions

Initialization: RST, IGKON, NVMRES, NVMINI, NVMSTO
Activation: 20MS: always
ES2ERU: always
Deactivation: never

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2 Bank specific calculations

All calculations are done for every bank. The value for the specific bank is denoted in the graphical model with the suffix _i whereas in the textual description the bank specific values are referred to with [i].

Copyright (C) Continental AG,2007

7.110.2.1 Preliminary calculations

7.110.2.1.1 Calculation of LV_LAM_AD_INJ_ACT_COLD_MEM, LV_WAIT_LAM_AD_INJ_END and LV_STATE_LS_LAM_AD_INJ_CLL

The flag LV_WAIT_LAM_AD_INJ_END is set if the adaptation signals the end of the mean value calculation for both banks. The values of LV_LAM_AD_INJ_ACT_COLD are memorized in LV_LAM_AD_INJ_ACT_COLD_MEM as this is used for determination of the phase numbers NR_PHA_LAM_AD_INJ_COLD/HOT. To get a bank synchronous switching of the state machine, the activation conditions for the lambda controller are checked for all banks and stored in LV_STATE_LS_LAM_AD_INJ_CLL.

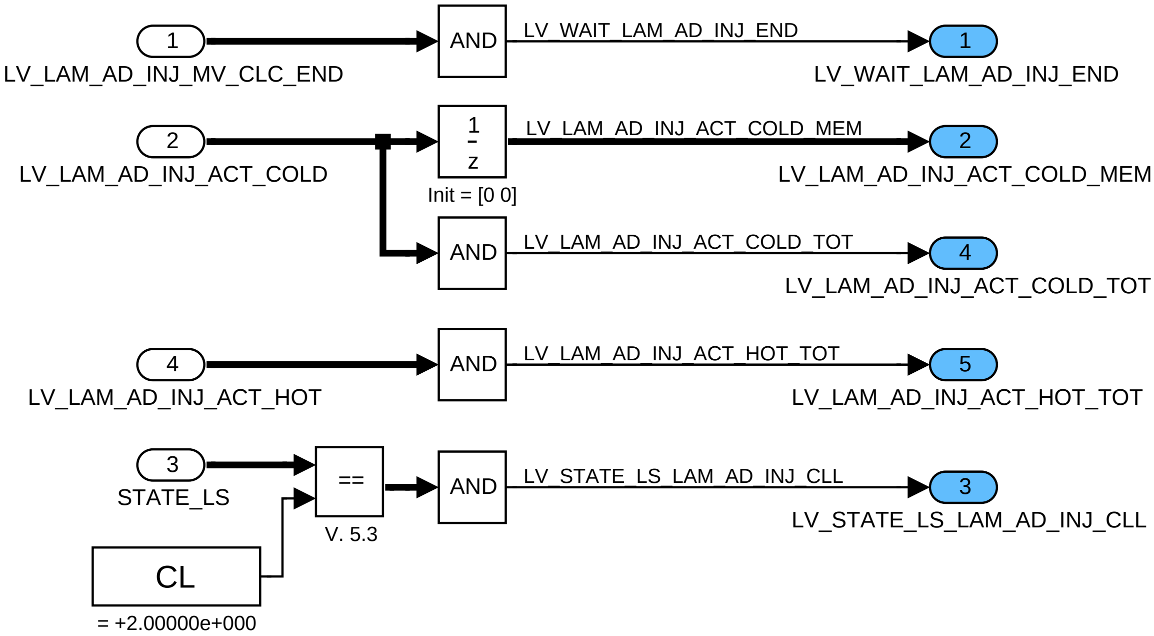

Figure 7.110.5: : Path: MFMA_REQCOAIMM0/OPM/CLC_MEM/CLC

7.110.2.2 Adaptation manager

The adaptation manager consists of three states STATE_LAM_AD_INJ[i]:
NOT_ACT: inactive state
CLC_CYL_STATE: intermediate state to determine single/multiple injection-mode for the next adaptation phase
WAIT_LAM_AD_INJ: the adaptation enabled for the injection-mode defined in the previous state

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

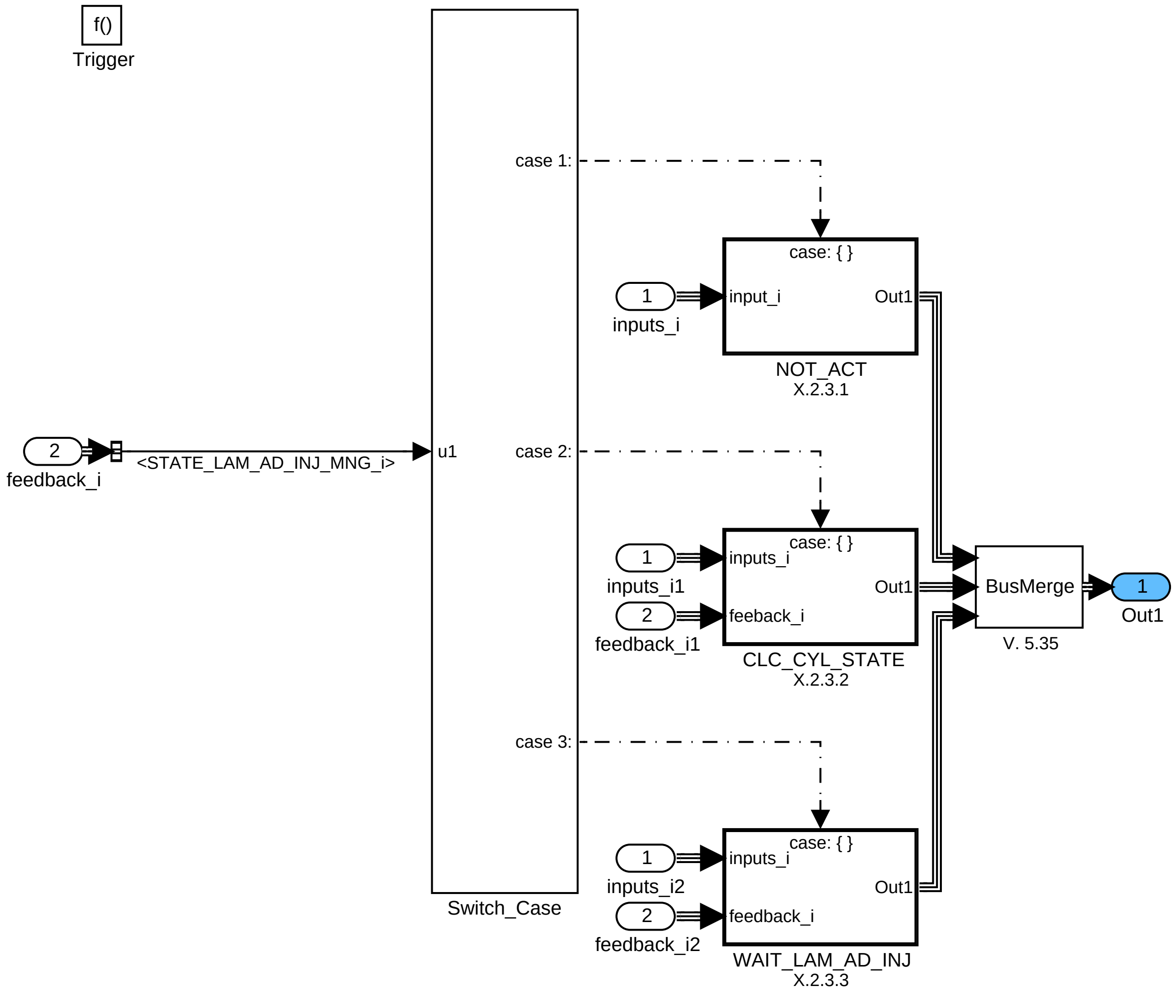

Figure 7.110.6: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG

7.110.2.2.1 NOT_ACT

In this state the adaptation is inactive. If the conditions for the adaptation in the upper or lower temperature range apply, the injection mode control is requested by setting the state STATE_LAM_AD_INJ_ACT[i] different from zero.

7.110.2.2.1.1 Transition conditions

If the adaptation conditions apply the injection mode control is requested and the state is left if it is granted (LV_LAM_AD_INJ_CUS_ACK = 1).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

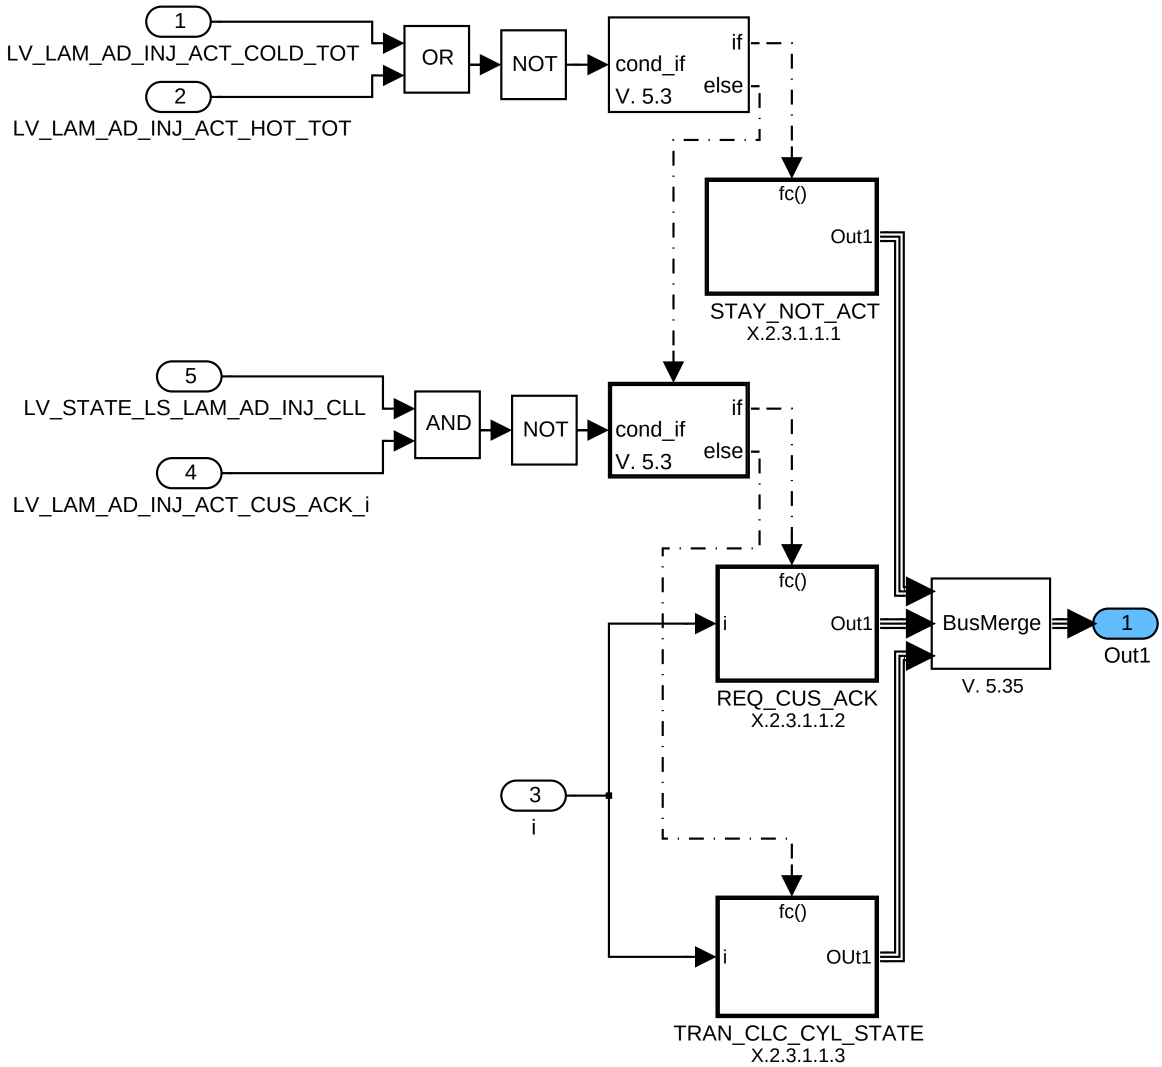

Figure 7.110.7: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC

7.110.2.2.1.1.1 Remaining in NOT_ACT

7.110.2.2.1.1.1.1 Reset of the request for the injection mode control

The request is reset if the conditions are no more fulfilled.

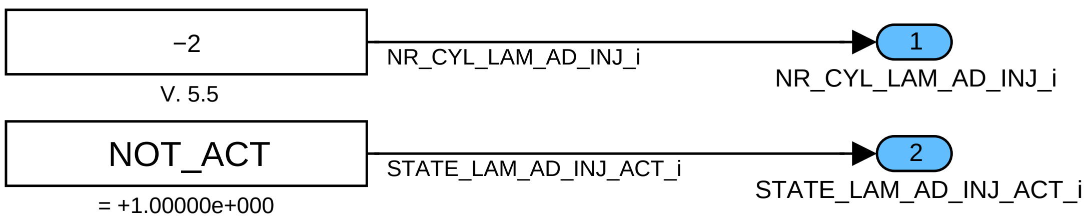

Figure 7.110.8: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/STAY_NOT_ACT/CLC

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.1.1.2 Start of injection mode control handshake

The injection mode for the bank is requested.

7.110.2.2.1.1.2.1 Request for injection mode control

The control of the injection mode is requested by setting the STATE_LAM_AD_INJ_ACT[i] to the first element of ID_NR_CYL_LAM_AD_INJ[i], which should be set to one or two to request single injections.

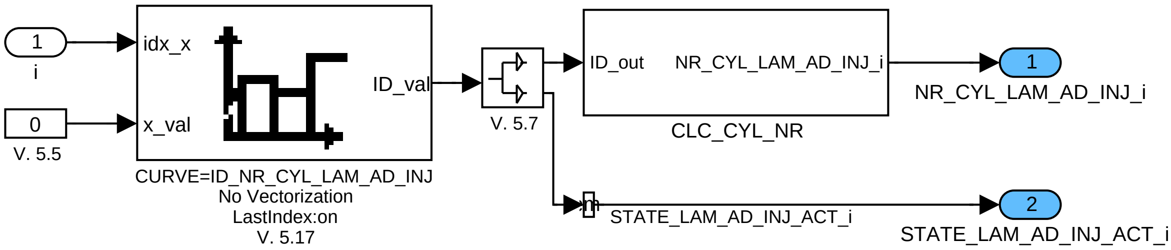

Figure 7.110.9: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/REQ_CUS_ACK/CLC

7.110.2.2.1.1.3 Injection mode control granted

7.110.2.2.1.1.3.1 Transition to CLC_CYL_STATE

If the acknowledge bit for injection mode control LV _LAM_AD_INJ_CUS_ACK is set, the state is left towards CLC_CYL_STATE.

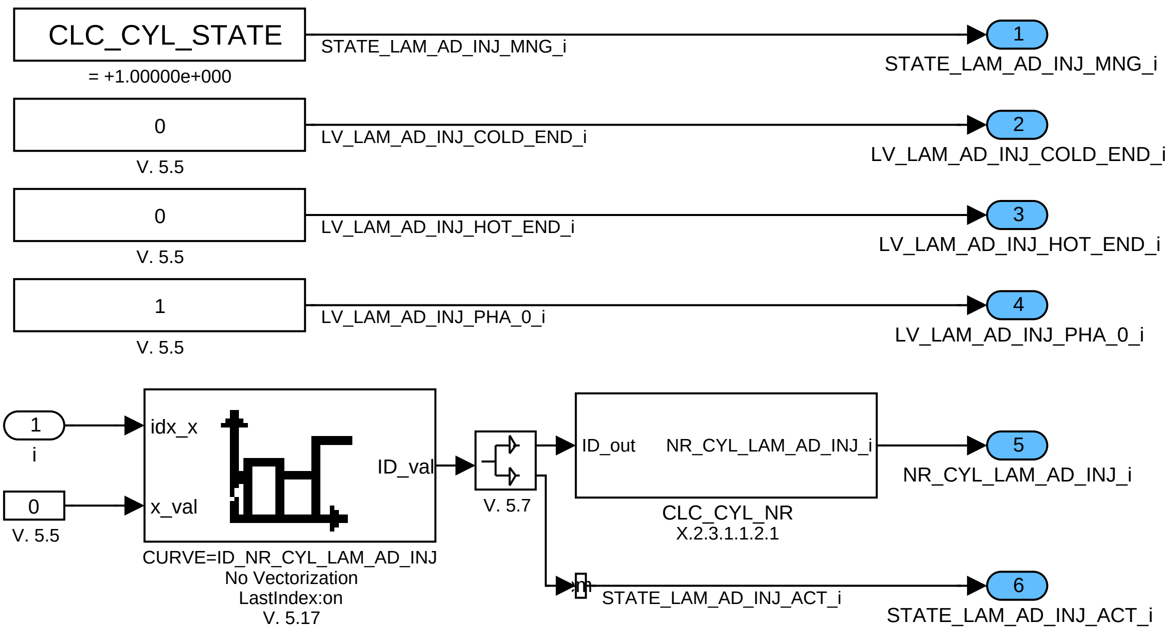

Figure 7.110.10: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/TRAN_CLC_CYL_STATE/CLC

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.1.1.3.1.1 Calculation of the cylinder number from STATE_LAM_AD_INJ_ACR

The conversion from ID_out[i] to NR_CYL_LAM_AD_INJ[i] can be done in the code as follows:
NR_CYL_LAM_AD_INJ[i] = (signed)((ID_out+1) >> 1) - 2;
Therewith the conversion should be done as follows:

ID_OUT	NR_CYL_LAM_AD_INJ
0	-2
1	-1
2	-1
3	0
4	0
...	...
18	7

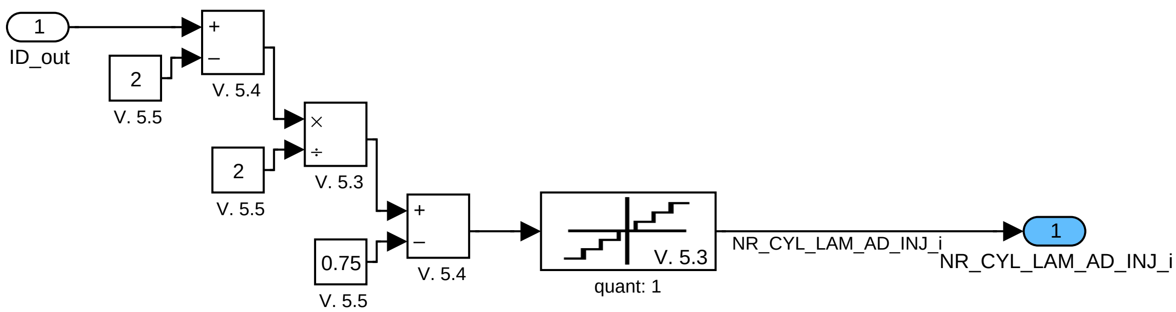

Figure 7.110.11: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/
TRAN_CLC_CYL_STATE/CLC/CLC_CYL_NR

7.110.2.2.2 CLC_CYL_STATE

This state is used for determination of the injection mode for the next adaptation phase.

7.110.2.2.2.1 Transition conditions

If the cylinder number of the current bank NR_CYL_LAM_AD_INJ[i] is equal to -2, the current adaptation is assumed to be finished and the state is left to NOT_ACT. If the adaptation is interrupted due to the lack of the necessary conditions, a transition to NOT_ACT is performed, too. Otherwise the state changes to WAIT_LAM_AD_INJ.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

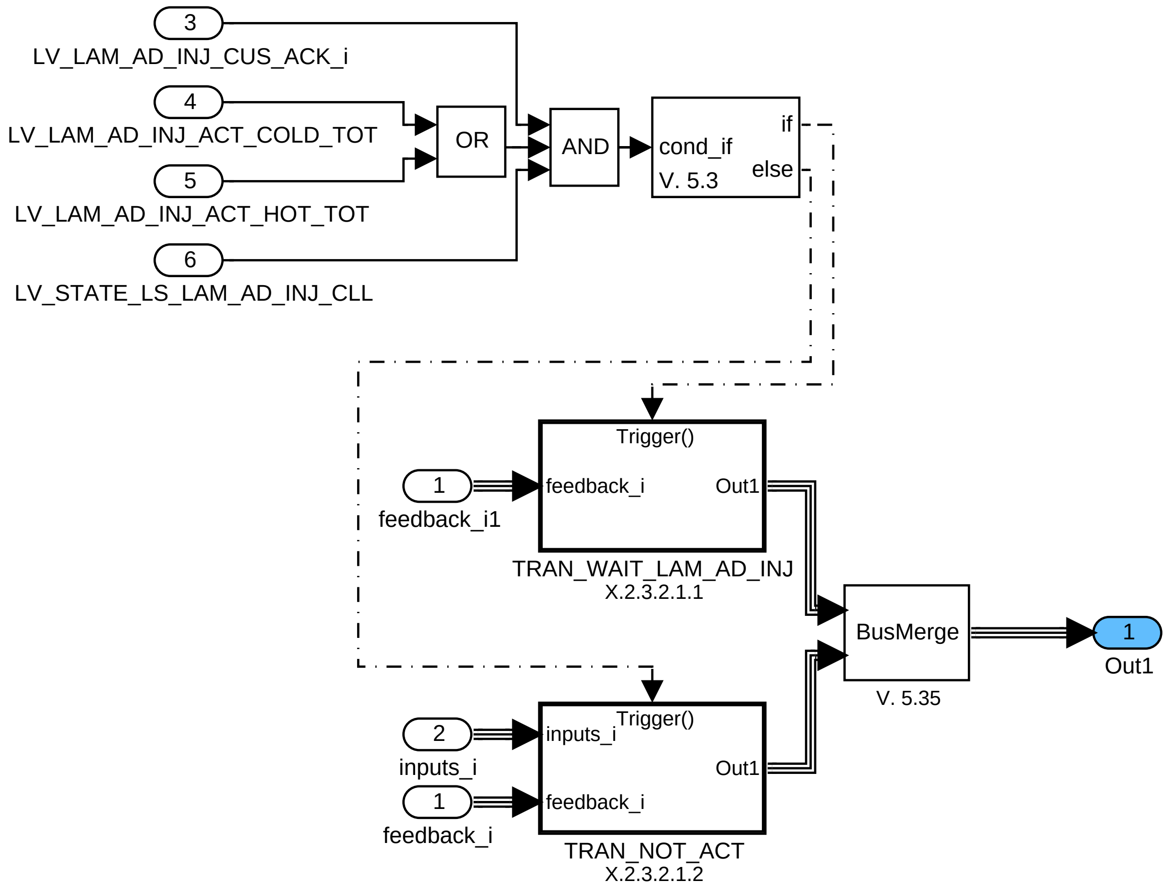

Figure 7.110.12: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC

7.110.2.2.2.1.1 Transition to WAIT_LAM_AD_INJ

7.110.2.2.2.1.1.1 Setting of LV_SNG/MPL_ACT

If the STATE_LAM_AD_INJ_ACT[i] is bigger than 2, multiple injections for this cylinder number are requested and therefore LV_MPL_INJ_ACT[i] is set. Otherwise LV_SNG_INJ_ACT[i] is set to enable the corresponding adaptation.

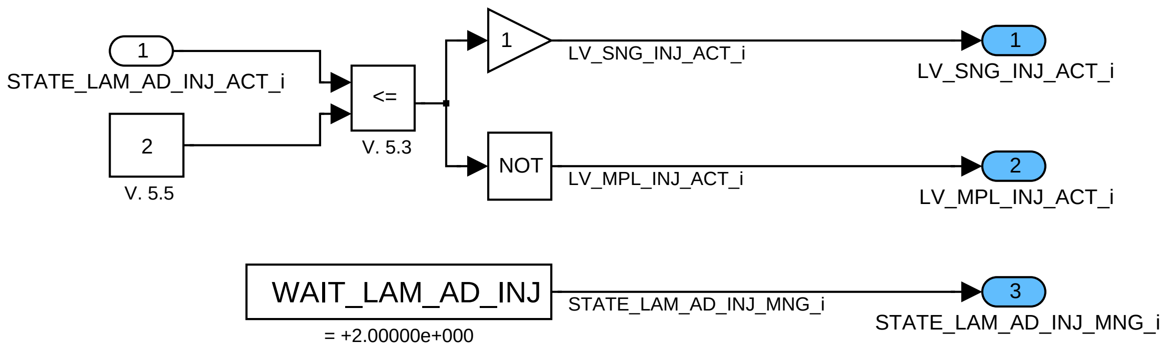

Figure 7.110.13: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC/TRAN_WAIT_LAM_AD_INJ/CLC

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.2.1.2 Transition to NOT_ACT due to interruption

7.110.2.2.2.1.2.1 Saving of the last completed phase number

If the adaptation is interrupted, the last completed adaptation phase number is stored in NR_PHA_LAM_AD_INJ_COLD/HOT[i], to make sure the adaptation is continued with the correct phase number if the conditions apply again and therefore all cylinders are adapted.

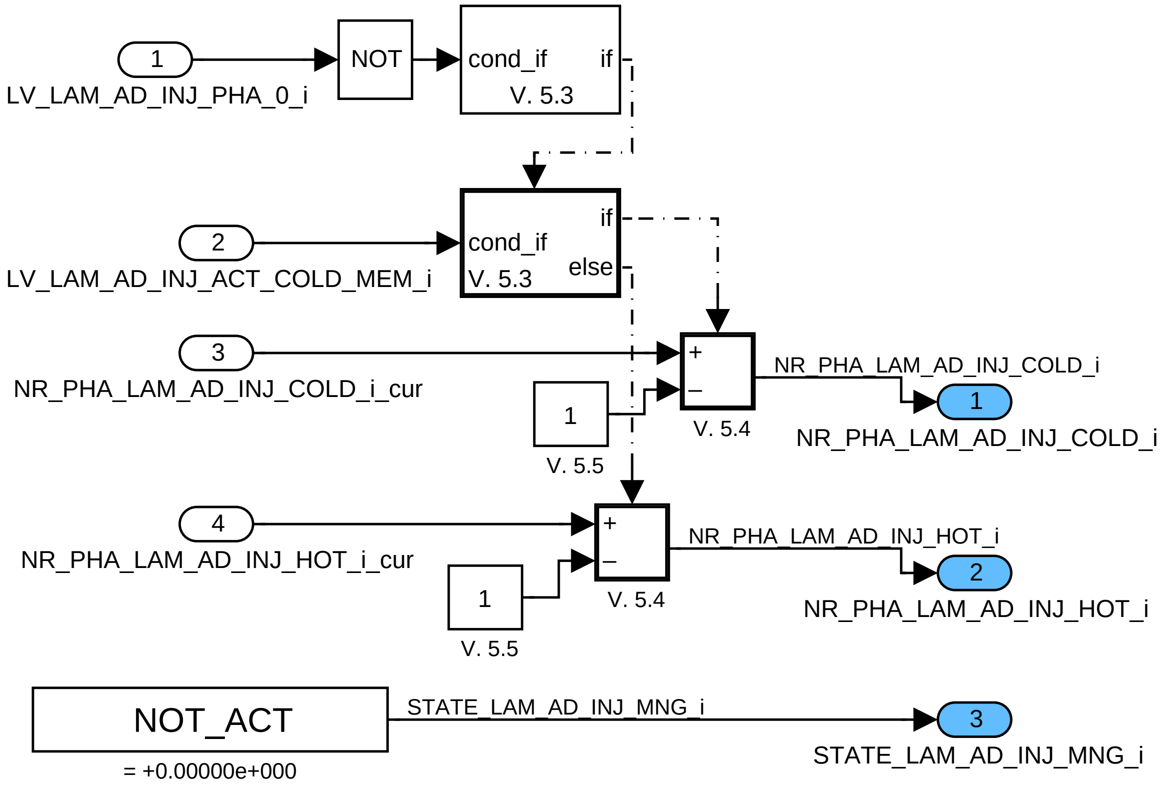

Figure 7.110.14: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC/TRAN_NOT_ACT/CLC

7.110.2.2.3 WAIT_LAM_AD_INJ

This state waits for the current adaptation phase to be completed or the adaptation conditions to be stopped.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.3.1 Transitions conditions

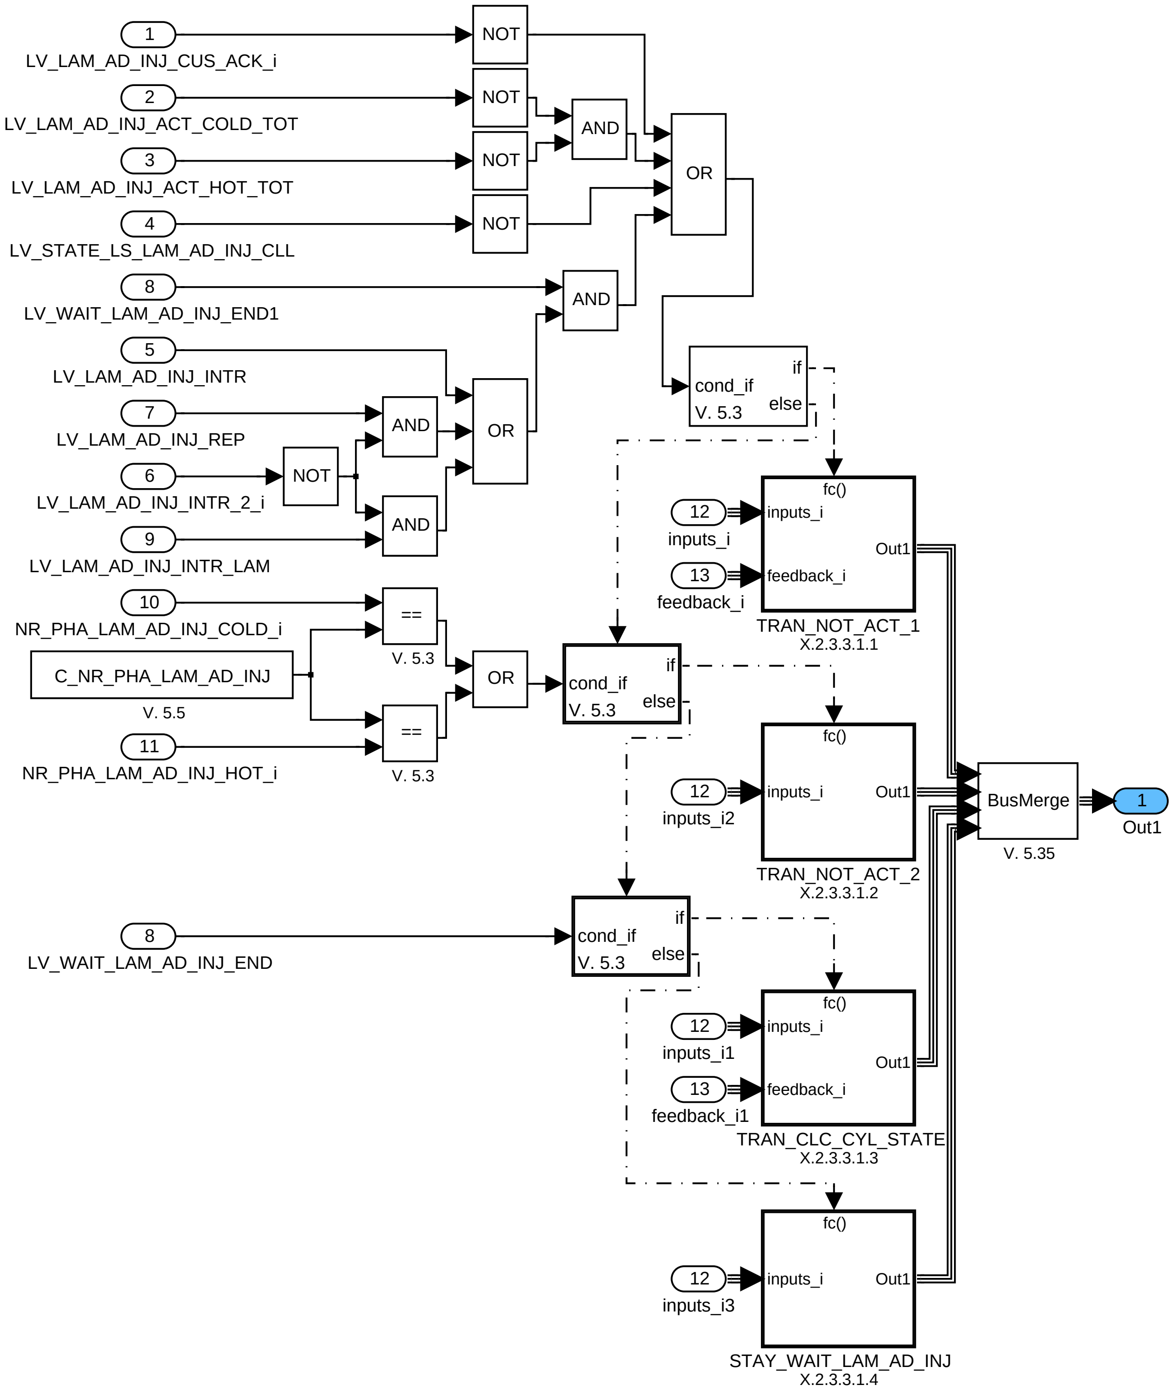

Figure 7.110.15: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.3.1.1 Transition to NOT_ACT due to interruption

7.110.2.2.3.1.1.1 Saving of the last completed phase number

If the adaptation is interrupted, the last completed adaptation phase number is stored in NR_PHA_LAM_AD_INJ_COLD/HOT[i], to make sure the adaptation is continued with the correct phase number if the conditions apply again and therefore all cylinders are adapted.
Furthermore the activation flags LV_SNG/MPL_ACT[i] are reset, to ensure that the current adaptation phase is stopped.

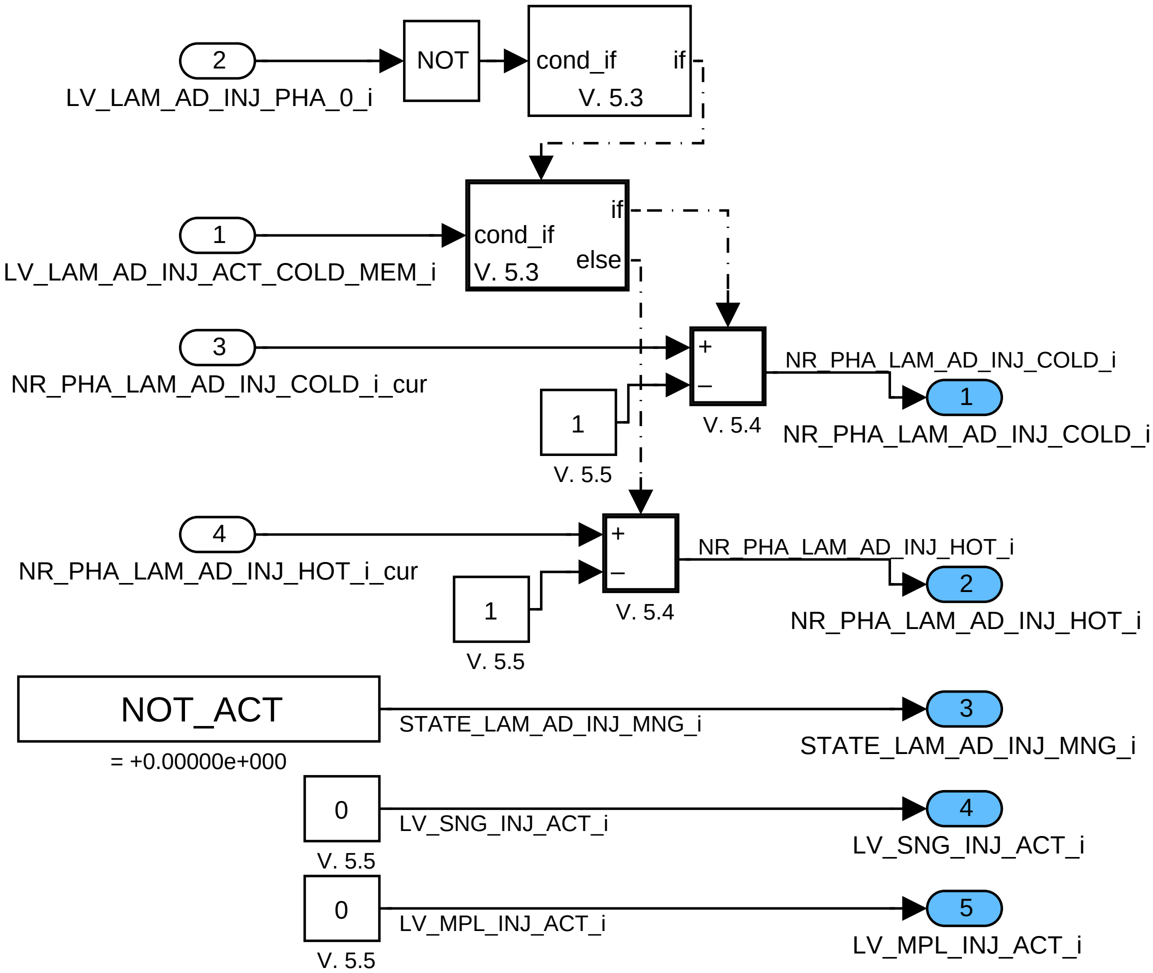

Figure 7.110.16: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_NOT_ACT_1/CLC

7.110.2.2.3.1.2 Transition to NOT_ACT due to finished adaptation

7.110.2.2.3.1.2.1 Setting of LV_LAM_AD_INJ_COLD/HOT_END

As the adaptation for the current temperature range is finished, the corresponding end-flag is set and the corresponding phase number NR_PHA_LAM_AD_INJ_COLD/HOT[i] is reset to 0. Therefore the adaptation starts from the beginning if the conditions apply for the next time.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

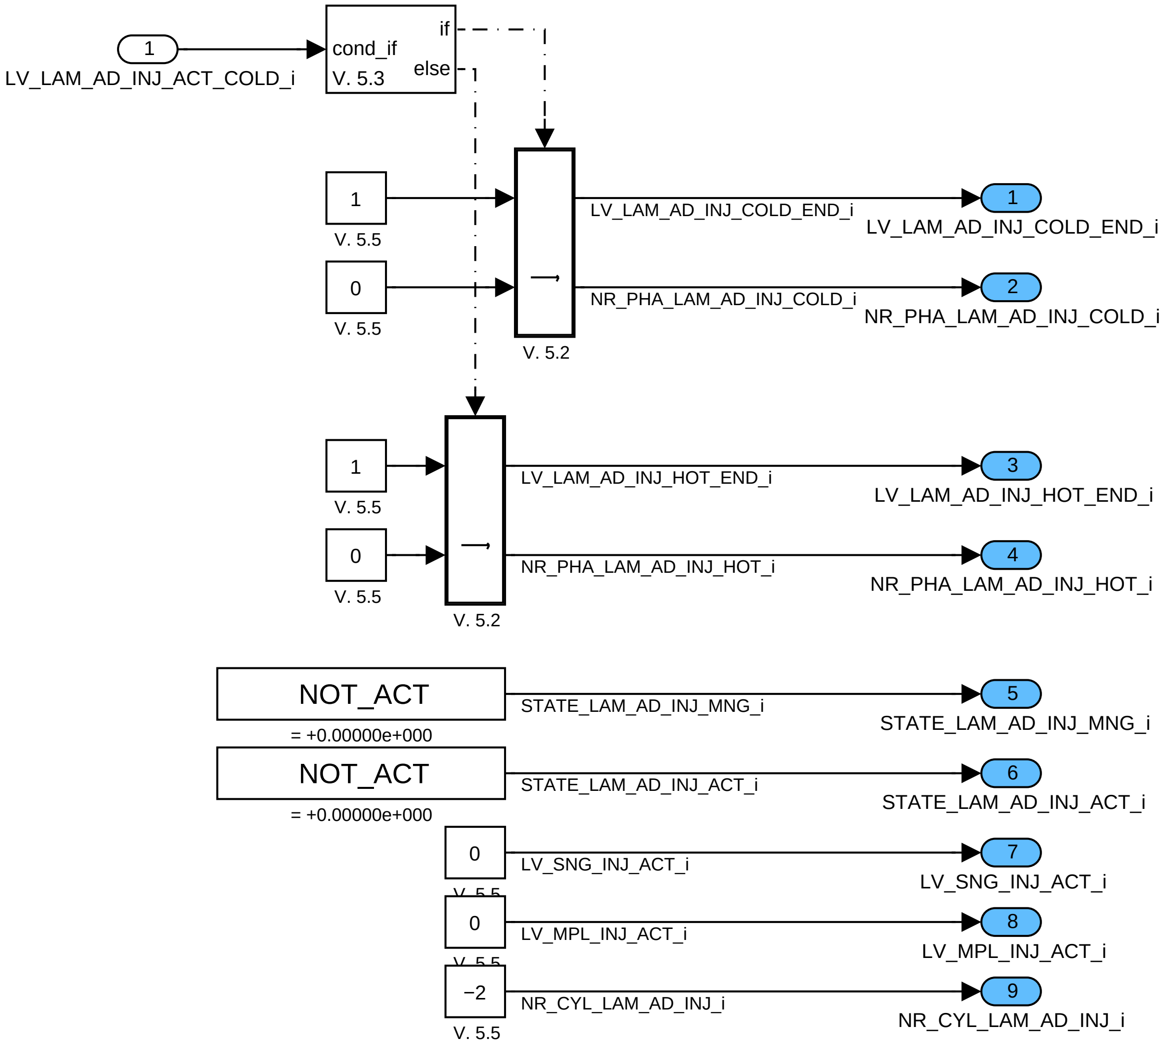

Figure 7.110.17: : Path:
MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_NOT_ACT_2/CLC

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.3.1.3 Transition to CLC_CYL_STATE

7.110.2.2.3.1.3.1 Determination of the injection mode for the next adaptation phase

The injection mode for the next adaptation phase is determined from the map ID_NR_CYL_LAM_AD_INJ[i] and requested via STATE_LAM_AD_INJ_ACT[i]. If multiple injections for one cylinder of the current bank is requested, the corresponding cylinder number is stored in NR_CYL_LAM_AD_INJ[i]. Otherwise -1 (single injection) or -2(end of adaptation) is used.

Copyright (C) Continental AG,2007

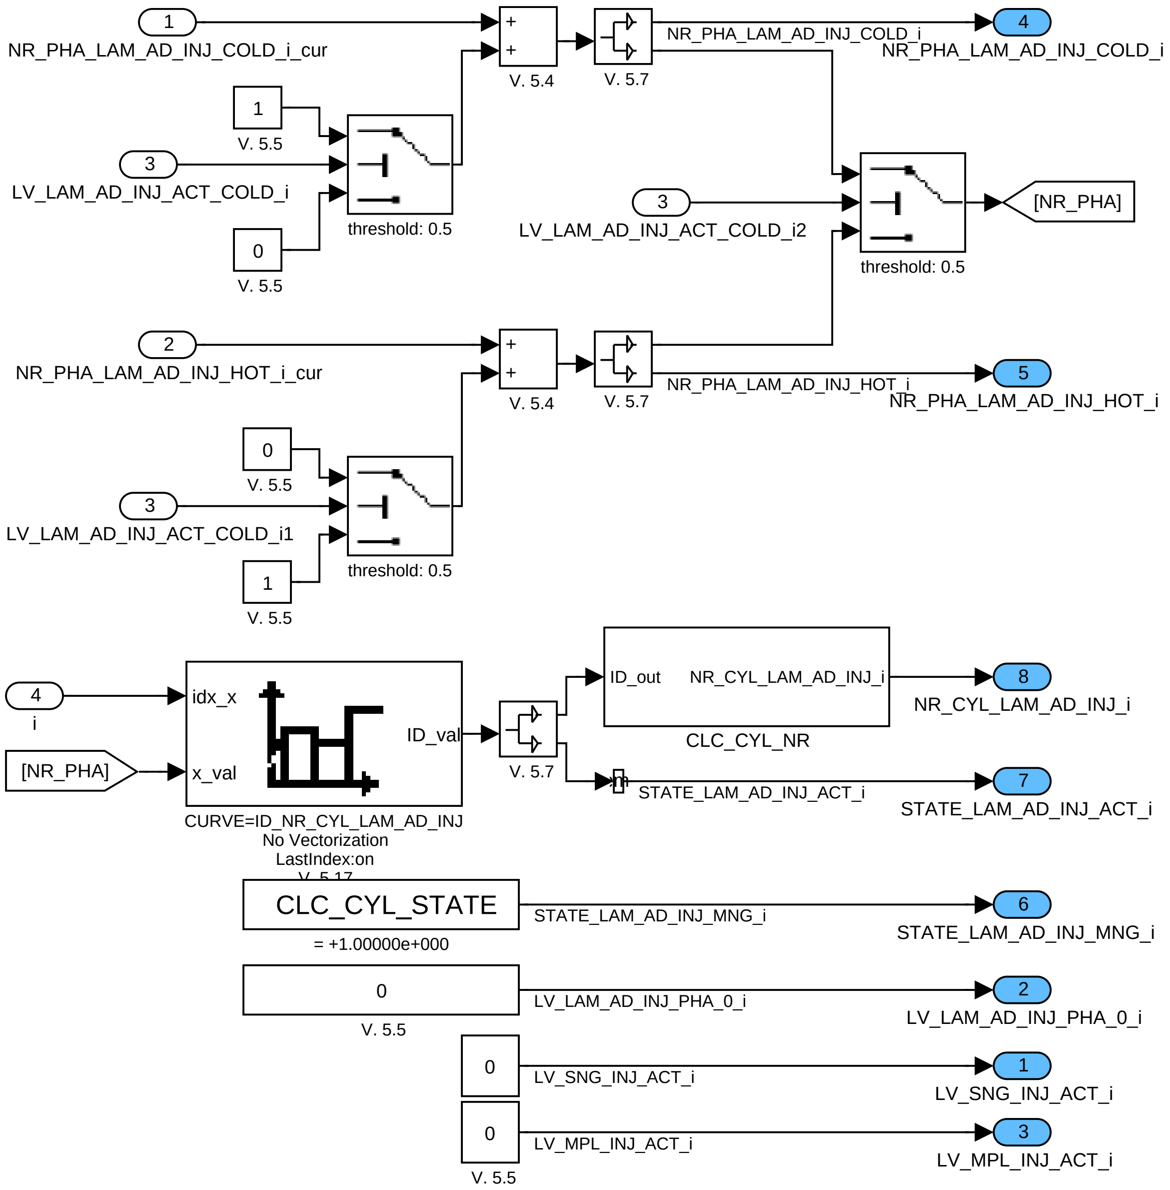

Figure 7.110.18: : Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_CLC_CYL_STATE/CLC_1

7.110.2.2.3.1.3.2 Cancelling of multiple injection due to misfire error

If the flag LV_ERR_MIS_LAM_AD_INJ[x] (where x denotes the current cylinder number) is set, i.e. a repeated misfire error is detected, the request for multiple injections is cancelled and another single injection phase will be started to continue with the adaptation of the other cylinders.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.2.2.3.1.4 Waiting for the end of the current adaptation cycle

7.110.2.2.3.1.4.1 Resetting of LV_SNG/MPL_INJ_ACT

If one bank signals the end of its adaptation phase (LV_LAM_AD_INJ_MV_CLC_END[i]), the corresponding activation flags LV_SNG/MPL_INJ_ACT[i] are reset. If the flag LV_LAM_AD_INJ_INTR_2[i] is set, repeated misfire is detected on the current cylinder and therefore single injection is requested.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.110.3 Operations at transition engine stop to engine run

7.110.3.1 Resetting of the phase numbers

If a resetting of the NVMY data via service tester is requested with the flag LV_LAM_AD_INJ_CLR_AD_EXT, the phase numbers of both banks for the upper and lower temperature range are reset to 0.

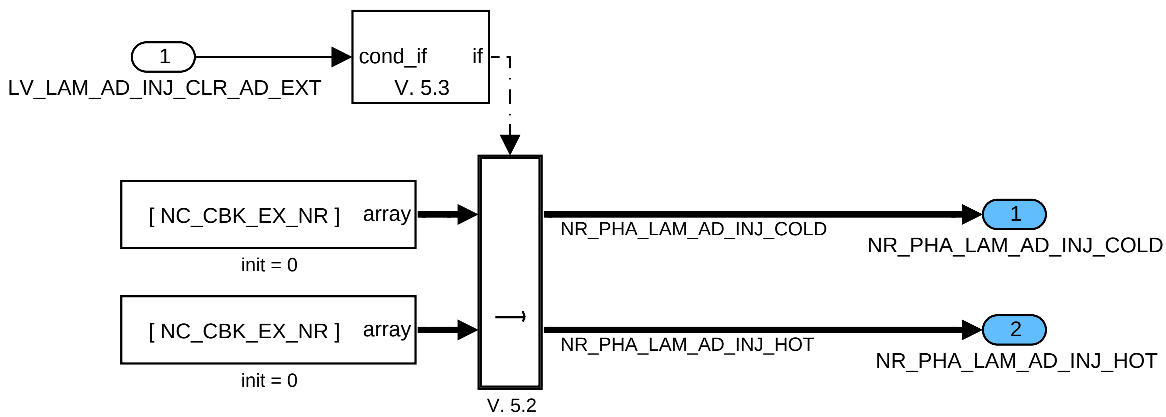

Figure 7.110.21: : Path: MFMA_REQCOAIMM0/ES2ERU/CLC

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_LAM_AD_INJ_INH	-	0... 1H	0 ...1	1	-
Manual inhibition of lambda adaptation via injection mode					

General Information

In the application incidence module the inhibition flag LV_INH_LAM_AD_INJ[i] for every exhaust cylinder bank is calculated.

Application Conditions

Initialization: RST, IGKON
Recurrence: 20MS
Activation: always
Deactivation: never

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

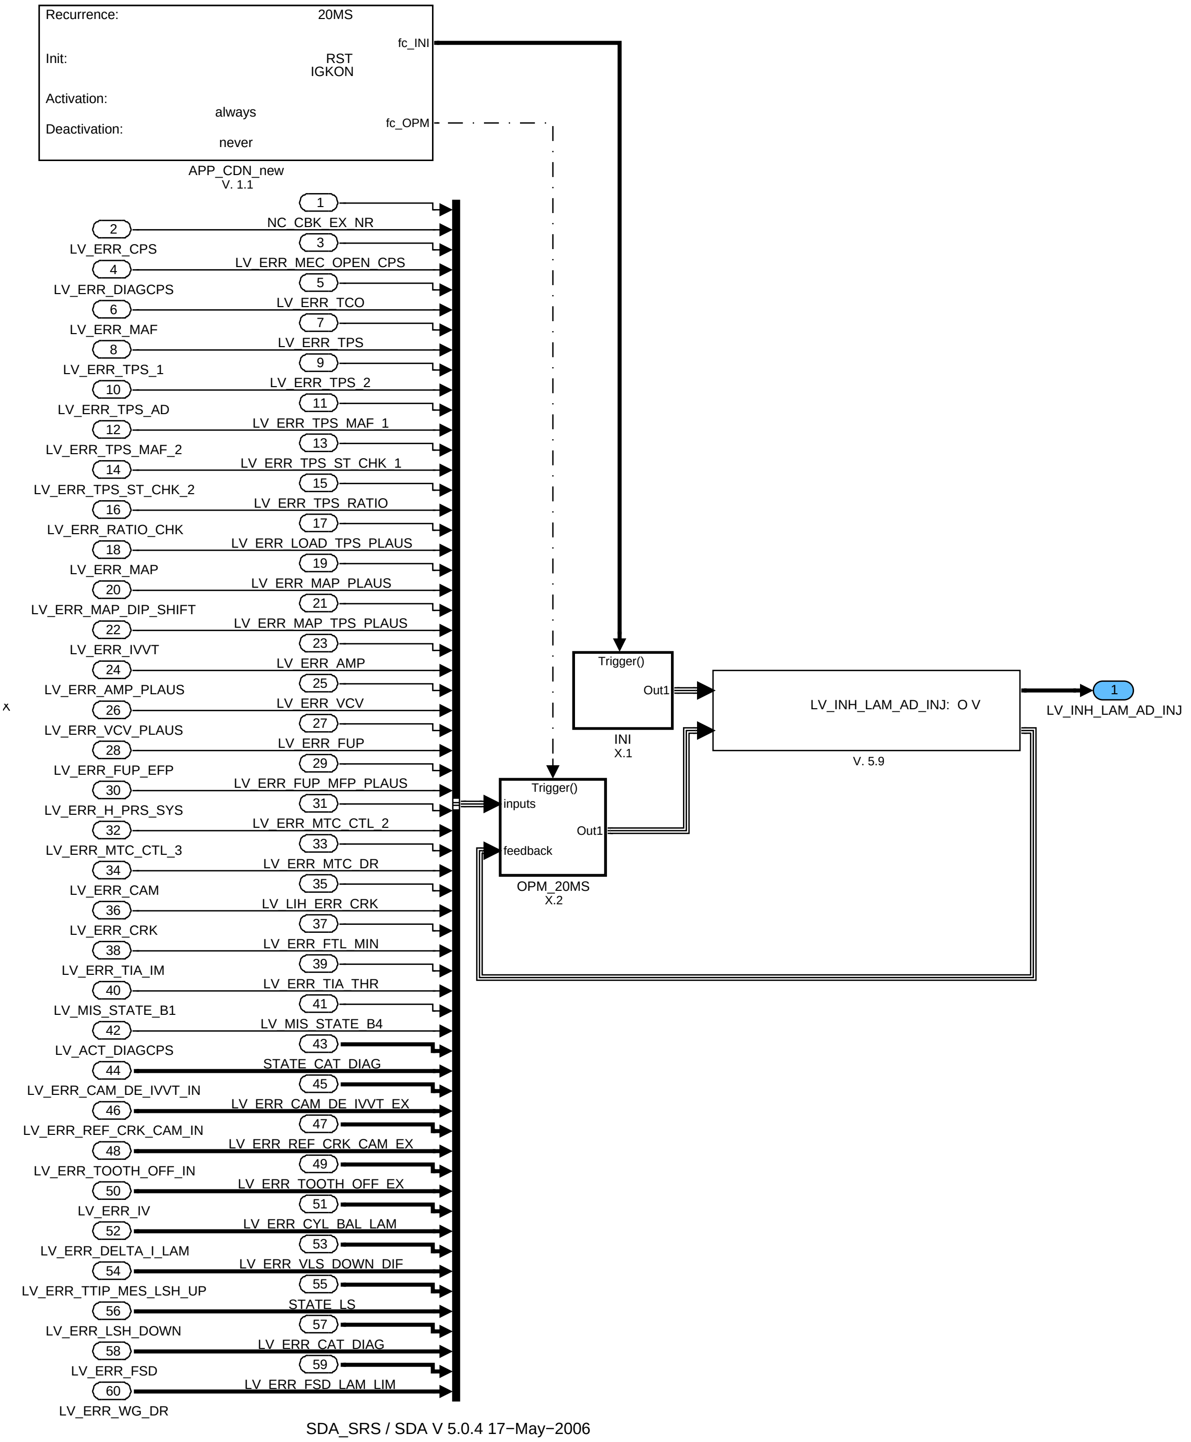

Figure 7.111.1: : Path: MFMA_ISPCLAIMI0

7.111.1 Initialization

The inhibition flag is initialized at reset and at ignition key on.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

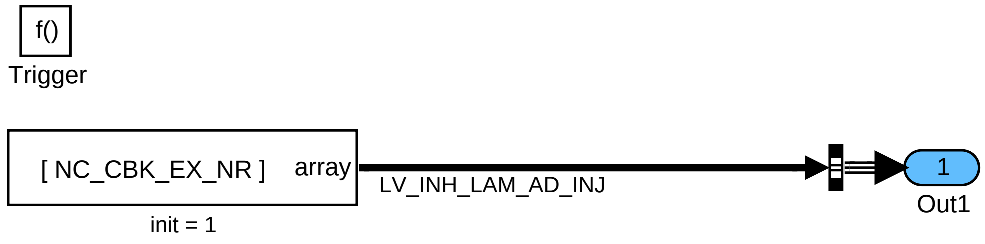

Figure 7.111.2: : Path: MFMA_ISPCLAIMI0/INI

7.111.2 Inhibition conditions calculation

The inhibition conditions calculation is divided into two parts. The first part consists of conditions, which do not depend on a specific exhaust cylinder bank, and therefore any of the conditions will inhibit the adaptation of all banks. The second part consists only of conditions, which depend on a specific bank and will inhibit only the adaptation on the corresponding bank.

7.111.2.1 Bank independent conditions

The bank independent conditions are also split in two parts, where the first part uses all scalar conditions/ error flags and the second part uses the non-scalar (array) conditions.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

7.111.2.1.2 Non-scalar conditions

In this block the all conditions whose dimension can be bigger than 1 are used for the calculation of the inhibition flag. The OR-blocks with only one input return true of at least one index of the array is set to 1.

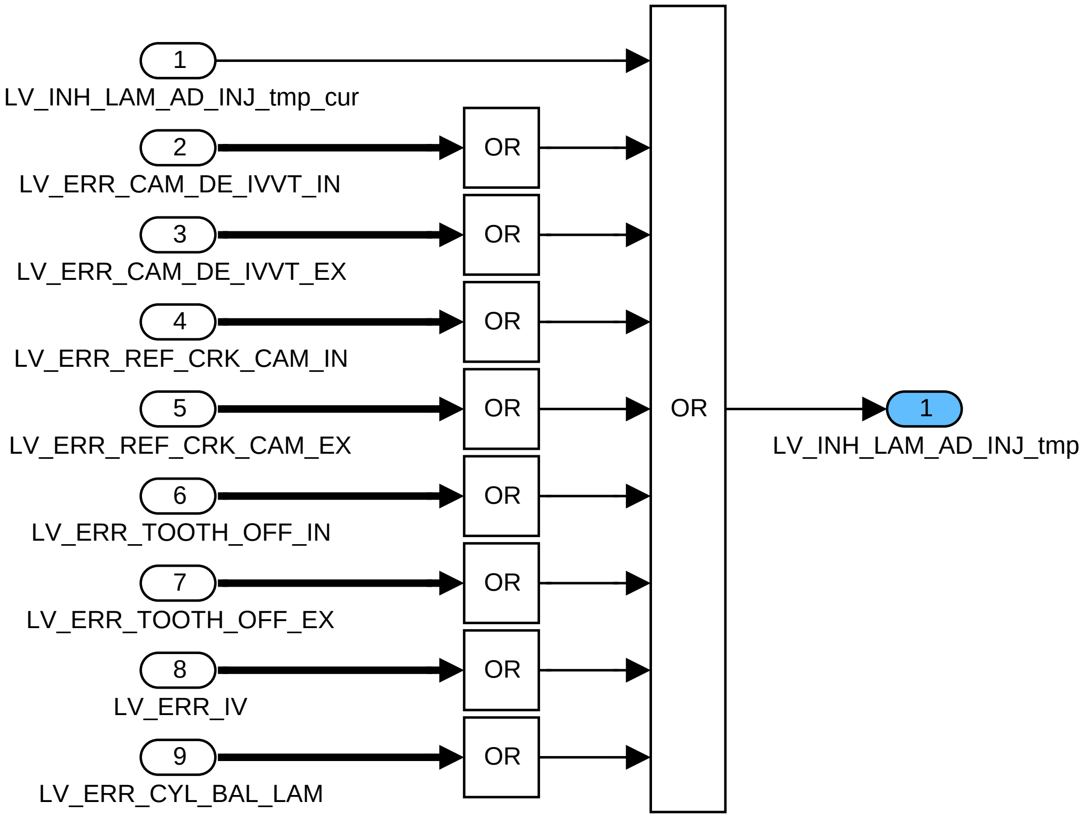

Figure 7.111.4: : Path: MFMA_ISPCLAIMI0/OPM_20MS/BANK_INDEP_CLC/CLC_2

7.111.2.2 Bank specific calculations

The bank specific calculations are done for every exhaust cylinder bank (1...NC_CBK_EX_NR). The index of the current cylinder bank is denoted with the suffix _i in the model whereas in the text square brackets are used (e.g. LV_INH_LAM_AD_INJ[i]).

7.111.2.2.1 Bank selective inhibition conditions

If one of the bank selective conditions applies, only the adaptation of the corresponding bank is inhibited. If LV_INH_LAM_AD_INJ_tmp (bank independent condition) is set, both banks will be inhibited.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General Information

The adaptation of the additional fuel mass at minimum fuel mass injection is divided in a time slice with single injection and with multiple injections. At the beginning of each phase a certain time is waited in a transient phase for system stabilization. In a second phase the lambda mean value is calculated. At the end of the phase with multiple injections, the additional fuel at minimum injection is calculated from the lambda controller output difference of the single and multiple injection phase.

Application Conditions

Initialization: RST, IGKON, NVMRES, NVMSTO, NVMINI
Activation: 20MS: always
1S: always
ES2ERU: always
Deactivation: never

7.112.2.1.1 State transitions

7.112.2.1.1.1 State selection

7.112.2.1.1.1.1 NOT_ACT

If the next adaptation cycle starts (either with single or multiple injections), the state is left towards TRA_PHA.

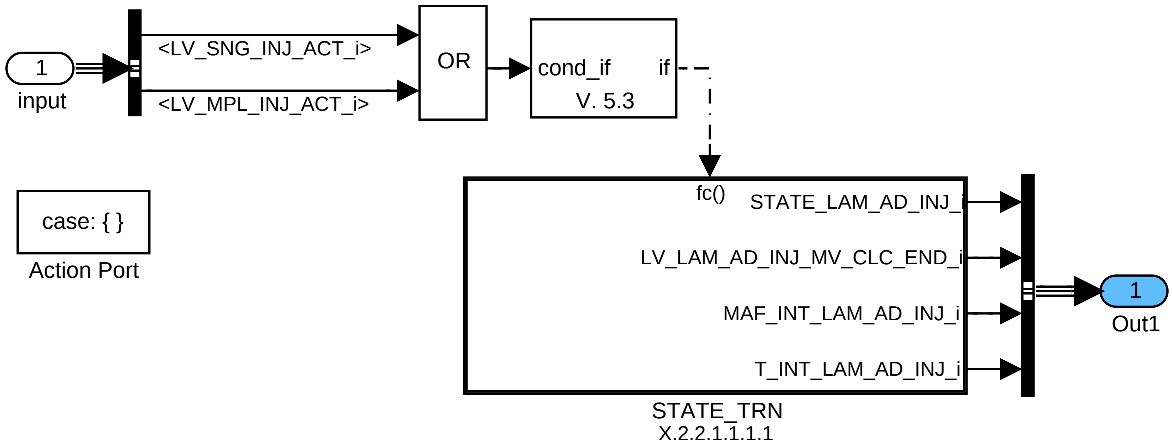

Figure 7.112.5: : Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/NOT_ACT

7.112.2.1.1.1.1.1 Transition to TRA_PHA

On the transition to TRA_PHA the MAF and time integrals are set to 0 and furthermore the end flag used in the manager module is reset.

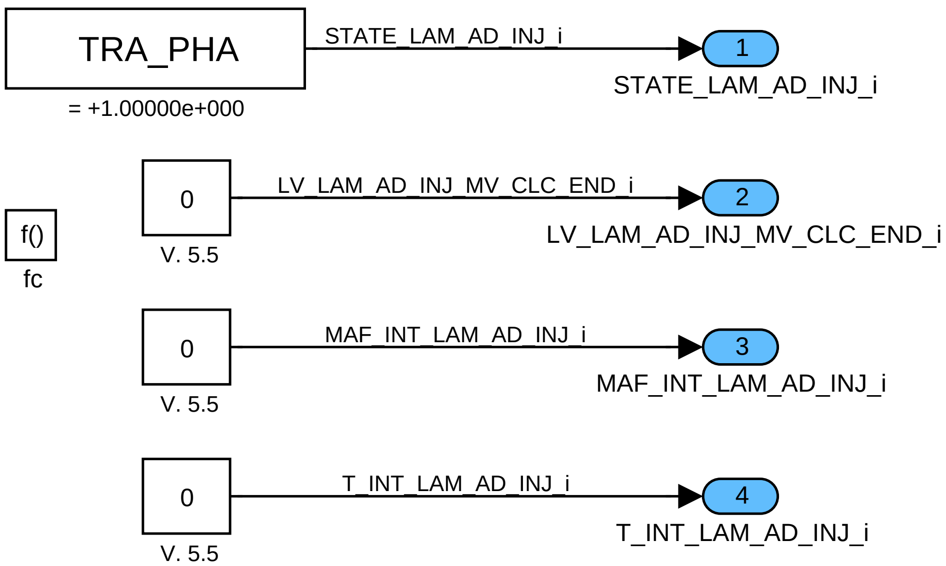

Figure 7.112.6: : Path:
MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/NOT_ACT/STATE_TRN

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.112.2.1.1.1.2 TRA_PHA

The state TRA_PHA is usually left towards MV_CLC, but if the adaptation is interrupted, the state will change back to NOT_ACT.

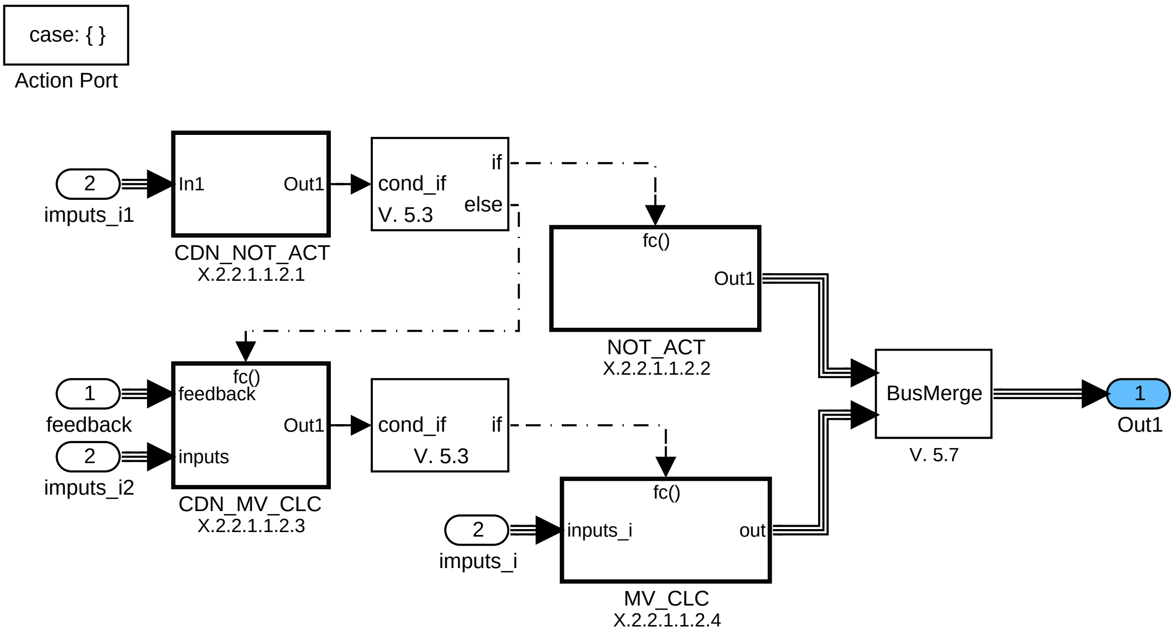

Figure 7.112.7: : Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA

7.112.2.1.1.1.2.1 Conditions for NOT_ACT

If none of the flags LV_SNG/MPL_INJ_ACT is set, the state is left towards NOT_ACT.

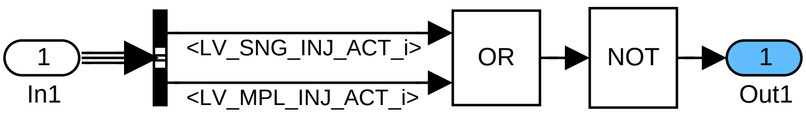

Figure 7.112.8: : Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/CDN_NOT_ACT

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

7.112.2.1.1.1.2.4 Transition to MV_CLC

On transition to MV_CLC the MAF and time integrals are reset.

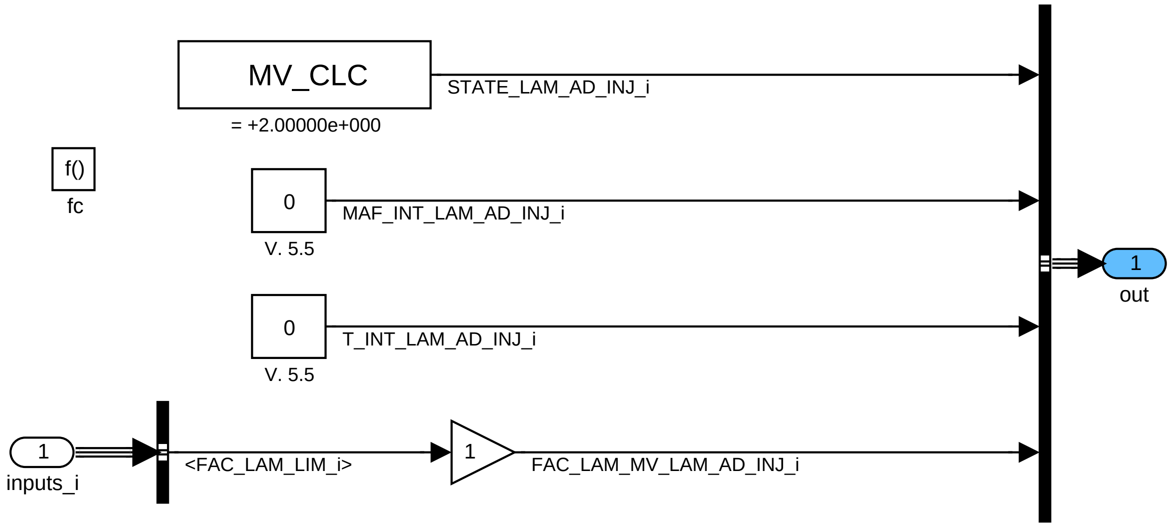

Figure 7.112.11: : Path:
MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/MV_CLC

7.112.2.1.1.1.3 MV_CLC

The state MV_CLC is usually left towards NOT_ACT after a single injection adaptation phase or due to interruption, and towards LAM_AD after a multiple injection adaptation phase.

7.112.2.1.1.1.3.1 Interruption of the mean-value calculation

If neither single nor multiple injection adaptation is allowed anymore, the state is left towards NOT_ACT.

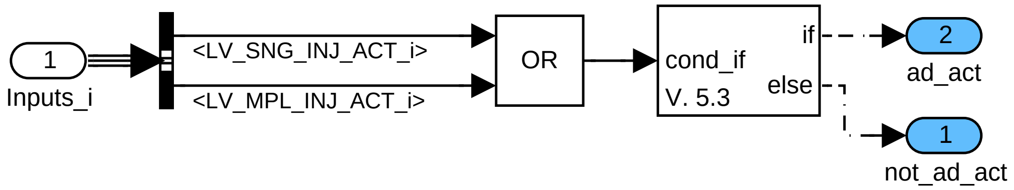

Figure 7.112.12: : Path:
MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/CDN_AD_ACT

7.112.2.1.1.1.3.2 Conditions for normal end of MV_CLC

If the MAF and time integrals reach a threshold, the state is left to NOT_ACT after single injections and to LAM_AD after multiple injections. If misfire is detected or the lambda controller had reached its limitations, the state is also left immediately.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. LC_FAC_COR_SLOP_CHA_CAL_ENA	-	0... 1H	0 ...1	1	-
Actives the correction of the mesaured charge in relation to a a reference charge					

Exported actions:

ACTION_INJR_SetOfsCurIni(IN <Bank>, IN <OfsCurIni>)
This action initializes the bank individual offset cancellation current of bank <Bank> with the value <OfsCurIni>.

FUNCTION DESCRIPTION:

General information:

The value of the piezo charge is determined by an analog integration of the piezo current over time. The integrator output can be converted into a charge value via A/D conversion.
Due to integrator offset currents and drift of integrator gain, the accuracy of the measured charge may differ. Therefore those two effects have to be corrected.
The offset current is corrected by a variable current source. The integrator gain error is measured by applying a known amount of charge (reference charge) to the integrator and by correcting the differences between reference charge and measured charge with use of a correction factor.
This procedure is applied for each electrical bank.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Note: The local variables I_PI_TMP and PI_PI_TMP as well as the static nonvisible variable I_PI_CTL_CUR_CHA_OFS_CNL should be 32-bit and should have the resolution 1e-6 A (that is, their resolution should be 256-times finer than the one of the output variable CUR_CHA_OFS_CNL_OUT).

Signal flow diagram:

Description:

Application conditions

Initialisation:

```
at reset:
   CHR_TRIM_DIF_0_FIL[ ] = 0 // all NC_PBK_IV_NR elements
  (1)IF  LC_CUR_SLOP_COR_CHR_REF = 1
  (1)THEN
     CHR_TRIM_DIF_1_FIL[ ] = NC_CHR_INJ_REF
     // all NC_PBK_IV_NR elements
  (1)ELSE
     CHR_TRIM_DIF_1_FIL[ ] = C_CHR_INJ_REF
                               // all NC_PBK_IV_NR elements
 (1)ENDIF
   FAC_COR_SLOP_CHA_CAL[ ] = 1     // all NC_PBK_IV_NR elements
   CUR_CHA_OFS_CNL_OUT[ ] = 0 // all NC_PBK_IV_NR elements
   I_PI_CTL_CUR_CHA_OFS_CNL[ ] = 0   // all NC_PBK_IV_NR
     elements
   CTR_PLAUS_CUR_OFS_TOT = 0
   CTR_PLAUS_CUR_OFS = 0
   CTR_PLAUS_CHA_CAL = 0
   RATIO_PLAUS_CUR_OFS = 0
   RATIO_PLAUS_CHA_CAL = 0
```

Recurrence: *1 s*

Activation:

```
LC_CUR_OFS_CNL_CHA_CAL_ENA = 1
AND  STATE_PBK_IV_INI = "INIT_FINISHED"
 AND STATE_ERR_PBK_IV = 0
 AND NC_PBK_IV_TYP = 1 (for ATIC88)
 AND N > C_N_MIN_OFS_CNL_CHA_CAL
 AND PREV_STATE_IV = (2^NC_CYL_NR) - 1
 AND INH_INJ = 0
```

Deactivation: *If activation conditions are **not** fulfilled, function must be deactivated.*

Formula section:

(1)FOR m = 0 **TO** NC_PBK_IV_NR - 1 **DO**

The compensation of the remaining charge (Offset Cancellation) and the analog integrator gain correction are carried out for each electrical bank.

Low pass filter for measured trim pulses:

Two PT1-filters are applied to the difference of the measured voltage values CHA_TRIM_1 - CHA_TRIM_0 and to the difference of the measured voltage values CHA_TRIM_3 - CHA_TRIM_2. The factor of the filter is defined by C_FAC_FIL_CHR_TRIM = 1 - exp(-2*pi*fs*Ts), where Ts=1 s (recurrence of the block) and fs is the cut off frequency of the filter.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

7.113.1 PI-controller for applied offset cancellation current:

Plausibility check:
To track errors within the trimming system and the A/D conversion, a plausibility check of the analogue measured charge values is done. For visualization purposes, the ration between plausible values and the total number of values is calculated for offset cancellation and gain calibration separately.

CTR_PLAUS_CUR_OFS_TOT = CTR_PLAUS_CUR_OFS_TOT + 1
(4)IF LC_CUR_CHA_OFS_CNL_ENA = 1
(4)THEN
 Plausibility check:
 (4a)IF (CHR_INJ_TRIM_0[m] < C_CHR_TRIM_MAX_PLAUS_BEG
  AND CHR_INJ_TRIM_0[m] > C_CHR_TRIM_MIN_PLAUS_BEG
  AND CHR_INJ_TRIM_1[m] < C_CHR_TRIM_MAX_PLAUS_BEG
  AND CHR_INJ_TRIM_1[m] > C_CHR_TRIM_MIN_PLAUS_BEG)
 (4a)THEN
  Increment plausibility counter and calculate ratio:
  CTR_PLAUS_CUR_OFS = CTR_PLAUS_CUR_OFS + 1
  RATIO_PLAUS_CUR_OFS = CTR_PLAUS_CUR_OFS
   /CTR_PLAUS_CUR_OFS_TOT
  Filter input signal:
  CHR_TRIM_DIF_0_FIL[m] = (C_FAC_FIL_CHR_TRIM *
   ((CHR_INJ_TRIM_1[m] - CHR_INJ_TRIM_0[m])
   - CHR_TRIM_DIF_0_FIL[m](n-1))) + CHR_TRIM_DIF_0_FIL[m](n-1)
  I_PI_TMP = I_PI_CTL_CUR_CHA_OFS_CNL[m](n-1)
   - CHR_TRIM_DIF_0_FIL[m] * C_KI_PI_CTL_CUR_CHA_OFS_CNL * 1 s
  I_PI_TMP = **MIN**(I_PI_TMP, C_CUR_CHA_OFS_PI_CTL_I_LIM_MAX)

7.114 NOx catalyst aging model

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_NT_AGI_MDL	O/V	0... FFFFFFFFH	0... 0.99999	232.8e-12	-
Modeled aging of NT					
FAC_NT_AGI_MDL_THERMO	O/V	0... FFFFH	0... 0.99998	15.3e-6	-
Converted modeled aging factor to thermo aging factor					

Action definition

ACTION_NOXM_CleanNTAdaptAgiMdl ()	Mode: O
External service for Initiaöization of Modelled Aging values	

ACTION_NOXM_WriteAgiMExtAdj ()	Mode: O
Reset of NSC modelled value using external value	

FUNCTION DESCRIPTION:

General information:

This modul has no functionality. It provides only all existing interfaces for other moduls.

Application conditions

Initialisation: *at reset set all output values to 1 (means new NOx catalyst)*

Recurrence:no
Activation:

Action definition:

Both actions have no functionality.

Local actions:

ACTION_ENSC_OPERATION_MANAGER(IN <IN1>, IN <IN2>, OUT <OUT>, OUT <TQ_DIF_OPM_1>, OUT <TQ_DIF_OPM_2>)
Operation manager

Overview

The controller consists of three parts:

PD-part
PD-part separation into slow and fast path
I-part

An operation mode manager splits up each controller part (applied for 2 different operation modes) in accordance with the received interpolation factor FAC_TQ_ADD_IS_OPM_SEL.
The operation manager for idle speed control operates with the operation mode parameters used in the module *Idle speed torque reserve*.

Application Condition

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Function Description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

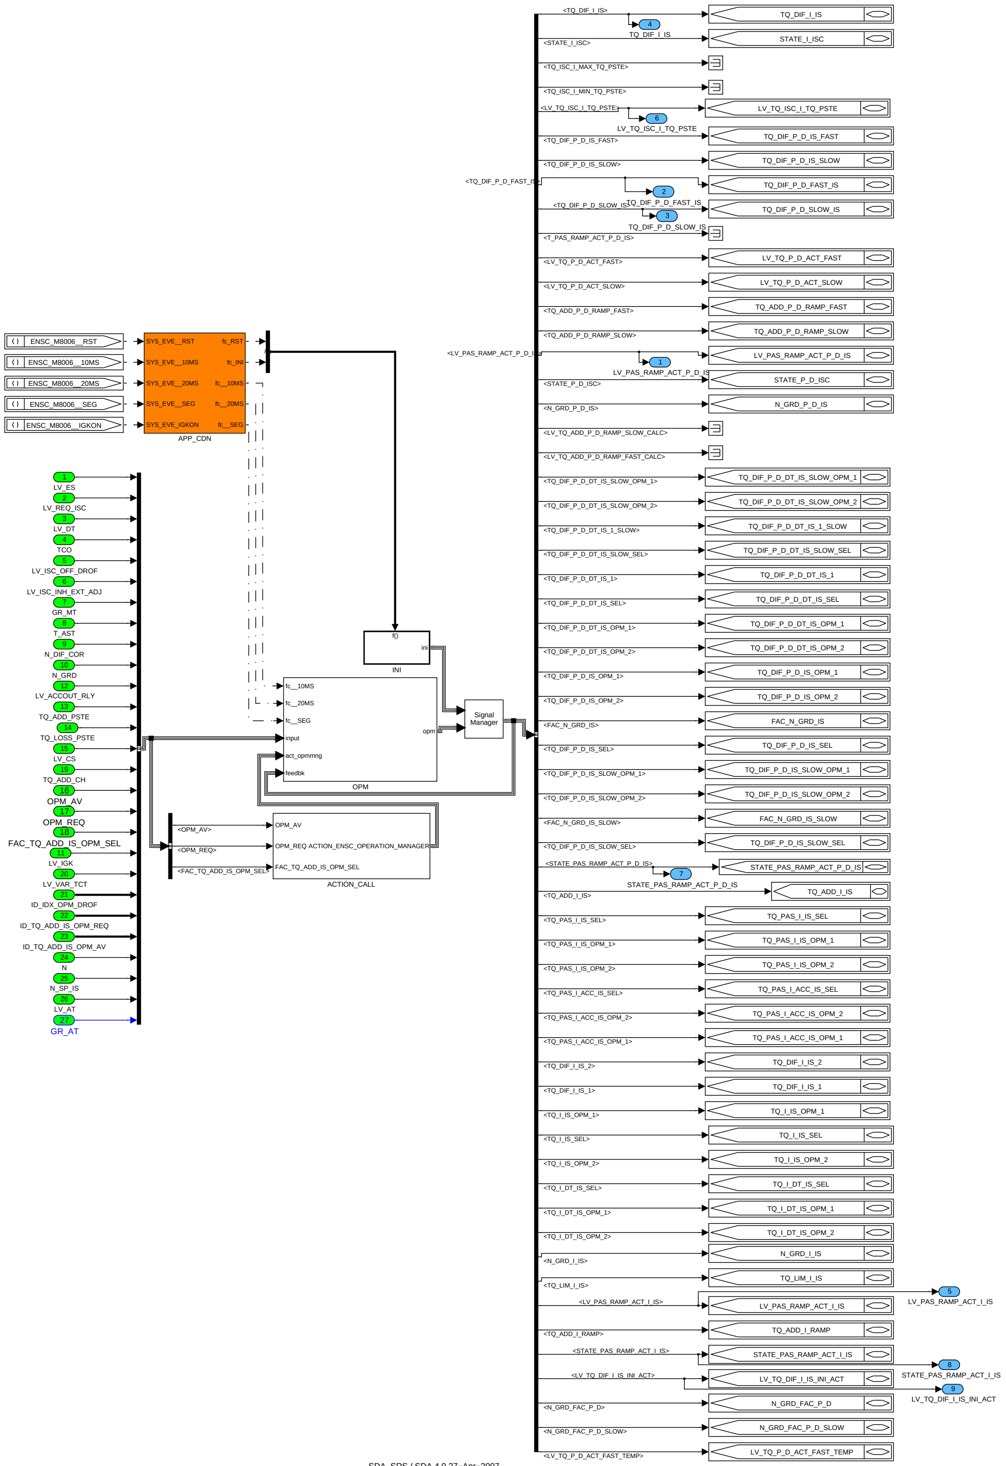

Figure 8.2.2: ENSC_M8006

8.2.1 Operation mode manager

There are two input values IN_1, IN_2. Each input value belongs to a special operation mode OPM_1, OPM_2. Moreover the value OPM_SEL_AV indicates the active and OPM_SEL_REQ indicates the requested operation mode. The aim of the operation manager is to create an output value depending

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

on the active operation mode. If there is a switch from one mode to another a smooth changeover from one input value to the other is possible by using the interpolation factor FAC_OPM_SEL.
A special logic takes care that the needed part is calculated only. That means if OPM_1 is active and there is no switch requested then the output value of the operation manager = IN_1 and some part of the algorithm for IN_2 are not calculated anymore. In this case the bit LV_OPM_SEL_1=1 indicates that only the calculation of the IN_1-path is done.
The information of the actual and the requested operation mode can be changed by interpretations maps ID_...OPM_SEL. The effect of this is, that by calibration the operation mode 1 can be wired to the input 2. That means the belonging for a operation mode to an input value is flexible.

The following tables defines the local variables described above:

Common variables:

OPM_AV (from Layer)	OPM_AV	Input	Actual operation mode
OPM_REQ (from Layer)	OPM_REQ	Input	Requested operation mode
-	OPM_SEL_AV	Internal value	Actual active operation mode after interpretation
-	OPM_SEL_REQ	Internal value	Requested operation mode after interpretation
FAC_TQ_ADD_IS_OPM_SEL (from Layer)	FAC_OPM_SEL	Input	Interpolation factor
LV_TQ_DIF_IS_OPM_SEL_1	LV_OPM_SEL_1	Output	Operation mode 1 active
LV_TQ_DIF_IS_OPM_SEL_2	LV_OPM_SEL_2	Output	Operation mode 2 active
LV_TQ_DIF_IS_OPM_RLS	LV_OPM_RLS	Output	Operation mode within valid range
ID_TQ_ADD_IS_OPM_AV	ID_OPM_AV	cal	Mapping of active operation mode
ID_TQ_ADD_IS_OPM_REQ	ID_OPM_REQ	cal	Mapping of requested operation mode

Controller parameter:

P_D_SLOW:

TQ_DIF_P_D_IS_SLOW_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_DIF_P_D_IS_SLOW_OPM_2	IN_2	Input	Input value for operation mode 2
TQ_DIF_P_D_IS_SLOW_SEL	OUT	Output	Result of interpolation

P_D_FAST:

TQ_DIF_P_D_IS_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_DIF_P_D_IS_OPM_2	IN_2	Input	Input value for operation mode 2
TQ_DIF_P_D_IS_SEL	OUT	Output	Result of interpolation

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

8.2.4 Formula section

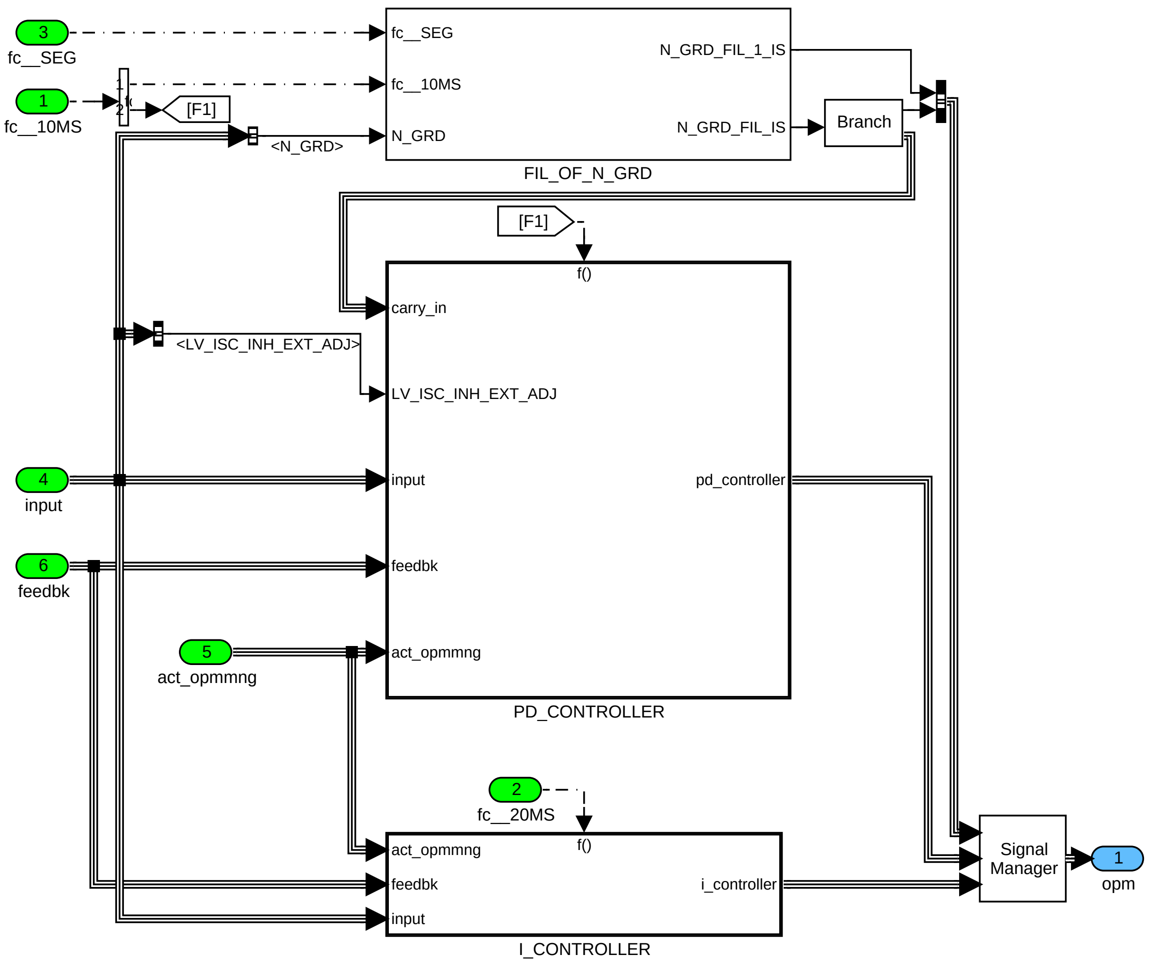

Figure 8.2.14: ENSC_M8006/OPM

Filtering of N_GRD

General information:
In order to be able to smooth the gradient for the idle speed control, there are 2 options for filtering the raw engine speed gradient N_GRD:
1) with ring buffer with 1 ... 6 buffers (calibrateable)
2) with 1^{st} order low-pass filter.

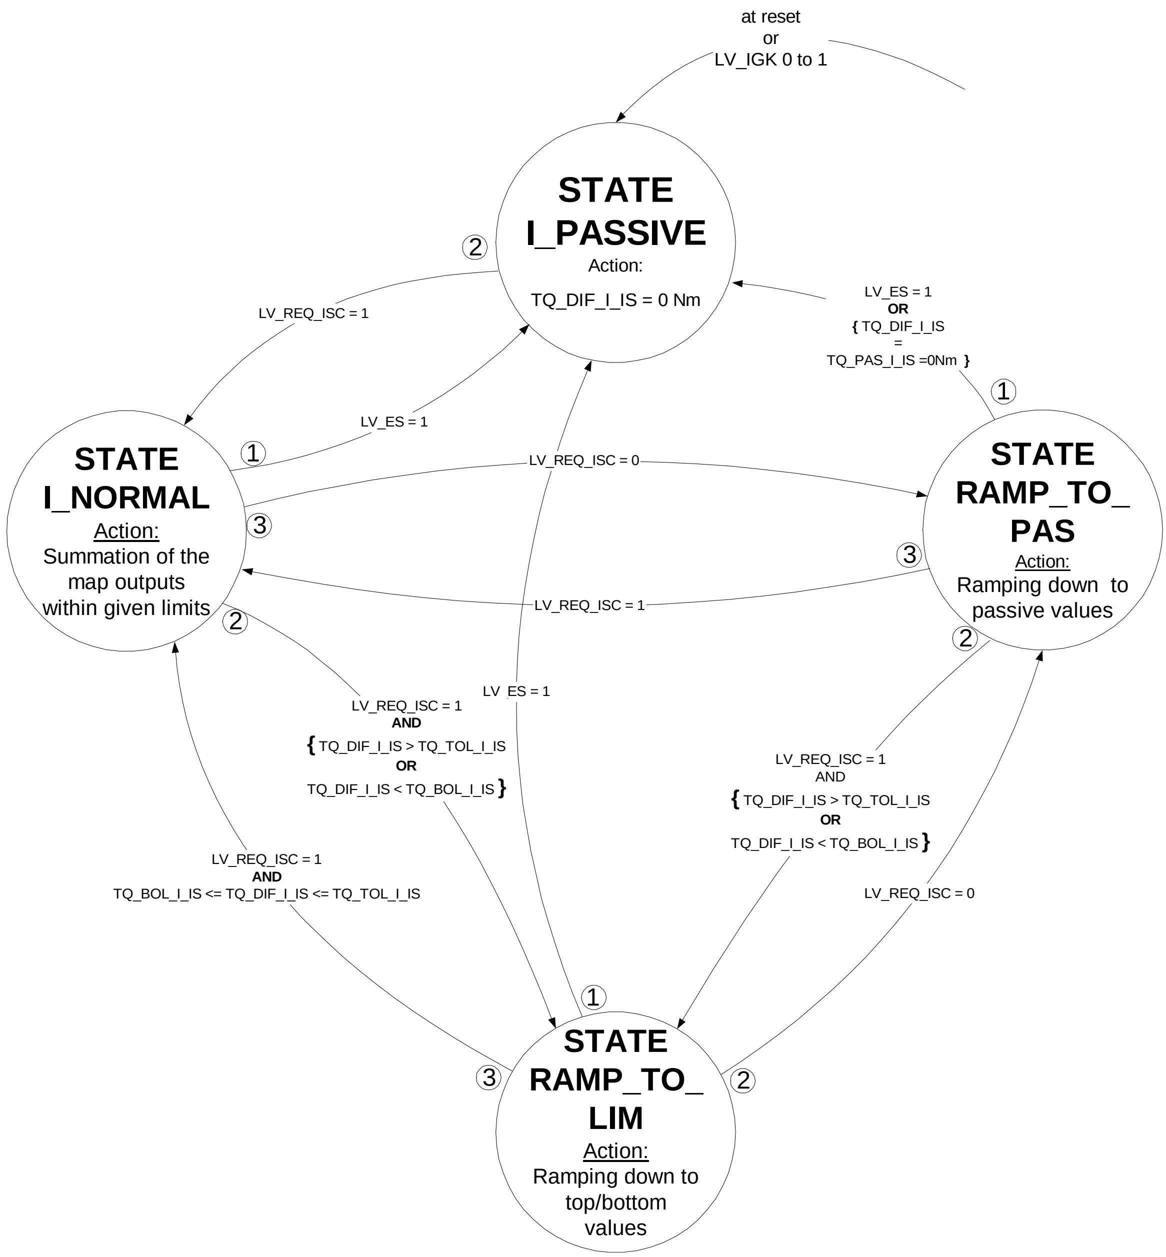

Figure 8.2.18: : State diagram of the integral part

The integral part is devided into four states:

STATE_I_ISC = I_PASSIVE:

Initialization (at reset or when LV_IGK = 0   1; from all other states in case of LV_ES = 1)

STATE_I_ISC = I_NORMAL:

In   this state the evaluation of the controller maps and the "normal" integration takes place.

STATE_I_ISC = RAMP_TO_LIM:

Ramp to limits; in this state the integral part is ramped down to the calibratible top/bottom limit values.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

STATE_I_ISC = RAMP_TO_PAS:
Ramp to passive value 0 Nm; in this state the integral part is ramped down to zero in case LV_REQ_ISC = 0.

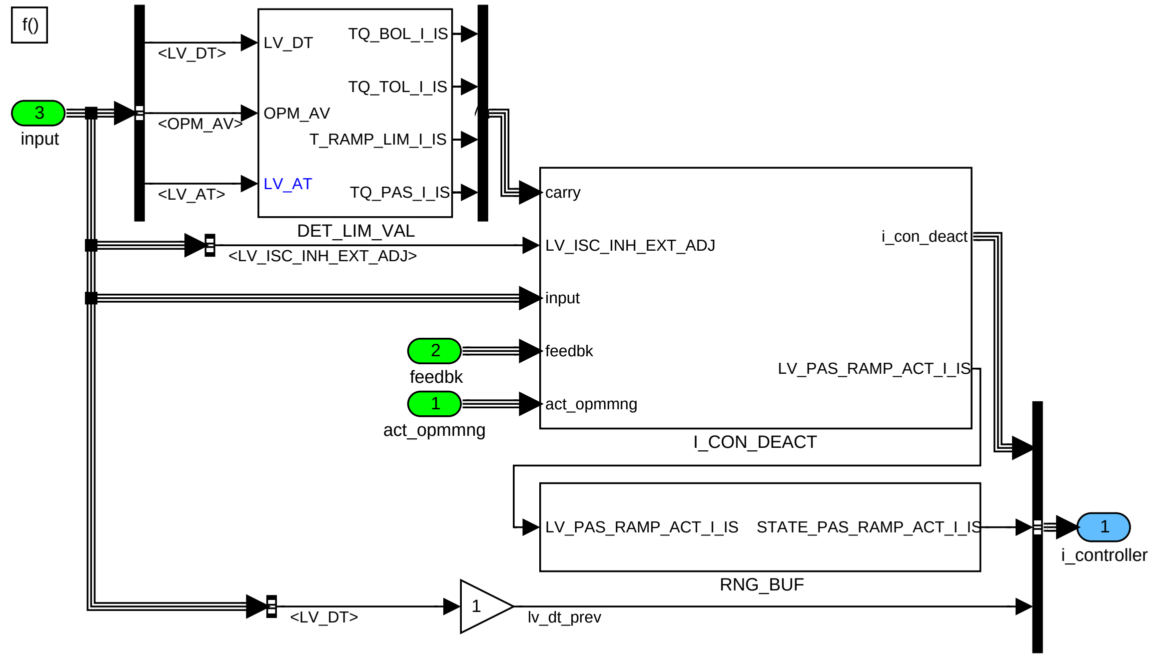

Figure 8.2.19: ENSC_M8006/OPM/I_CONTROLLER

Determination of the top/bottom limit values:

The passive value **(target value)** of the ramp operation is 0 Nm.
TQ_PAS_I_IS = 0Nm

Calculation when there is no transition from passive or "ramp to pas" to normal state.

Condition check on LV_DT and determination of TQ_ADD_I_IS

In STATE I_NORMAL, see figure 5, the "normal" integration takes place. A torque difference TQ_ADD_I_IS is determined in dependence of the speed deviation N_DIF_COR and the speed gradient N_GRD_I_IS (for LV_DT = 0) and only in dependance of the speed deviation N_DIF_COR for LV_DT = 1 and in addition depending on time after start T_AST, figure 6.
Considering the operation mode manager there are included separated paths in the functionality for the calculation of the idle speed controller I-share. This enables a proper engine running in throttled and unthrottled mode. Also in after start an additional factor is used for each mode.
To reach two important targets, TQ_ADD_I_IS should be calibrated as follows:

compensation of a speed offset
automatic precalibration of the integral part: if there is a load active after the driver released the gas pedal (ACC, power steering, etc), then speed falls with a higher gradient into idle range than in comparision to the situation without load. This means, that the integral part should carry higher (positive) values to intercept speed. That means, that with the help of the gradient dependancy in the integral part an automatic precalibration of the TQ_ADD_I_IS (so TQ_DIF_I_IS) can be reached, which is load dependant. It must be said, that this interception function must be synchronized with the PD-part calibration. With the correct calibration, the passive values are not needed any more.

The integration takes place within calibratible boundaries, figure 7.

At deactivation of ISC the integrator output is controlled to a passive-value by ramp limit activation. The determination of the ramp takes place in the same way as described before for the top/bottom limit ramps.

Actions:

The ramp limit operation starts at deactivation of the ISC. The necessary increment (**TQ_ADD_I_RAMP**) to reach the required ramp-slope **is only calculated once while transitioning into this state**. This value is valid until deactivation of the ramp limit operation.

While transition into this state, so while the ramp is active, there could be a change in TQ_PAS_I_IS. If in this case TQ_ADD_I_RAMP is negative for example and the passive value is higher than the actual value, then the new requested passive value can never be reached, because TQ_ADD_I_RAMP is only calculated once. Therefore TQ_PAS_I_IS is fixed while transition into this state to prevent a wrong comparison in the following condition:

FUNCTION DESCRIPTION:

Figure 2: *State of the PD-part*

The PD-part is devided into three states:

Copyright (C) Continental AG,2007

STATE_P_D_ISC = P_D_PASSIVE:
Initialization (at reset or from LV_IGK = 0   1; from all other states in case of LV_ES = 1)

STATE_P_D_ISC = P_D_NORMAL:
In   this state the evaluation of the controller maps takes place.

STATE_P_D_ISC = RAMP_TO_ZERO:
Ramp to passive value, which is always zero for the PD-part; in this state the PD-part is ramped down to zero in case of deactivation of the PD-part

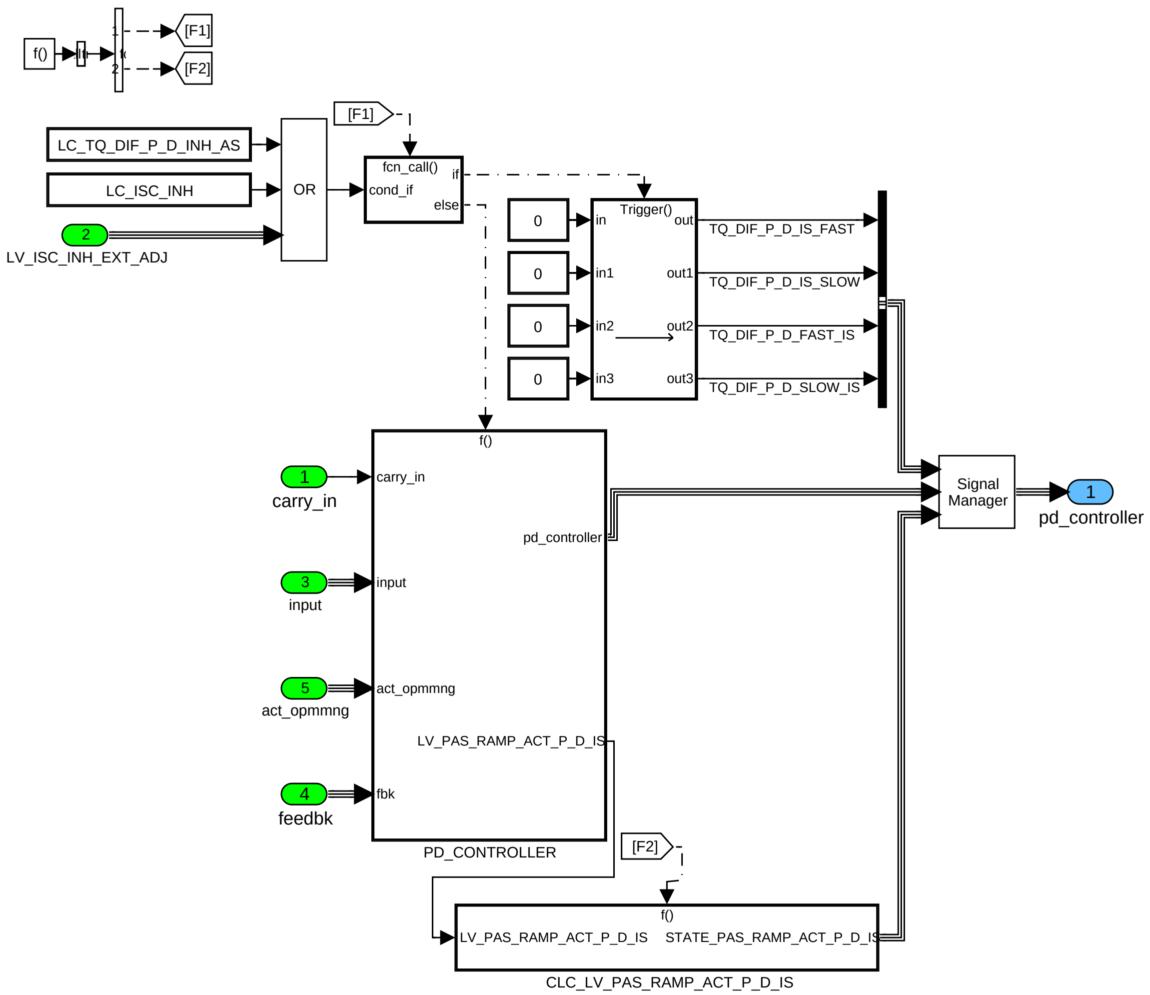

Figure 8.2.52: ENSC_M8006/OPM/PD_CONTROLLER

Application conditions

Activation:

```
IF   LC_ISC_ACT_CDN_SWI == 1
   THEN
        Use these application incidences
   ELSE IF LV_AMT_CRAWL_ON = 1
          THEN        LV_REQ_ISC  =  0
     ELSE              LV_REQ_ISC  =  LV_IS
                         ENDIF
ENDIF
At reset:                STATE_REQ_ISC = ISC_PASSIVE
    T_CTR_PU_ISC_ACT = C_T_DLY_ISC_ACT_PU
```

Update rate: 10 ms

At deactivation: T_CTR_PU_ISC_ACT = C_T_DLY_ISC_ACT_PU

8.3.1 General

The activation of the idle speed controller depends on different driving situations. Five states are distinguished. The actual status of the idle speed activation is stored in STATE_REQ_ISC.

State 0: Idle speed controller is passive **(STATE_REQ_ISC = ISC_PASSIVE)**.

State 1: Activation of the ISC after start **(STATE_REQ_ISC = AFTER_START)**.

State 2: "Normal activation": Activiation of the ISC in case of LV_IS = 1 **(STATE_REQ_ISC = NORMAL)**

State 3: Activation of the ISC if speed remains stationary at a certain value in trailing throttle state **(STATE_REQ_ISC = TRAILING_THR)**.

State 4: Activation of the ISC in part load, in case of underspeed. **(STATE_REQ_ISC = PART_LOAD)**.

Formula section:

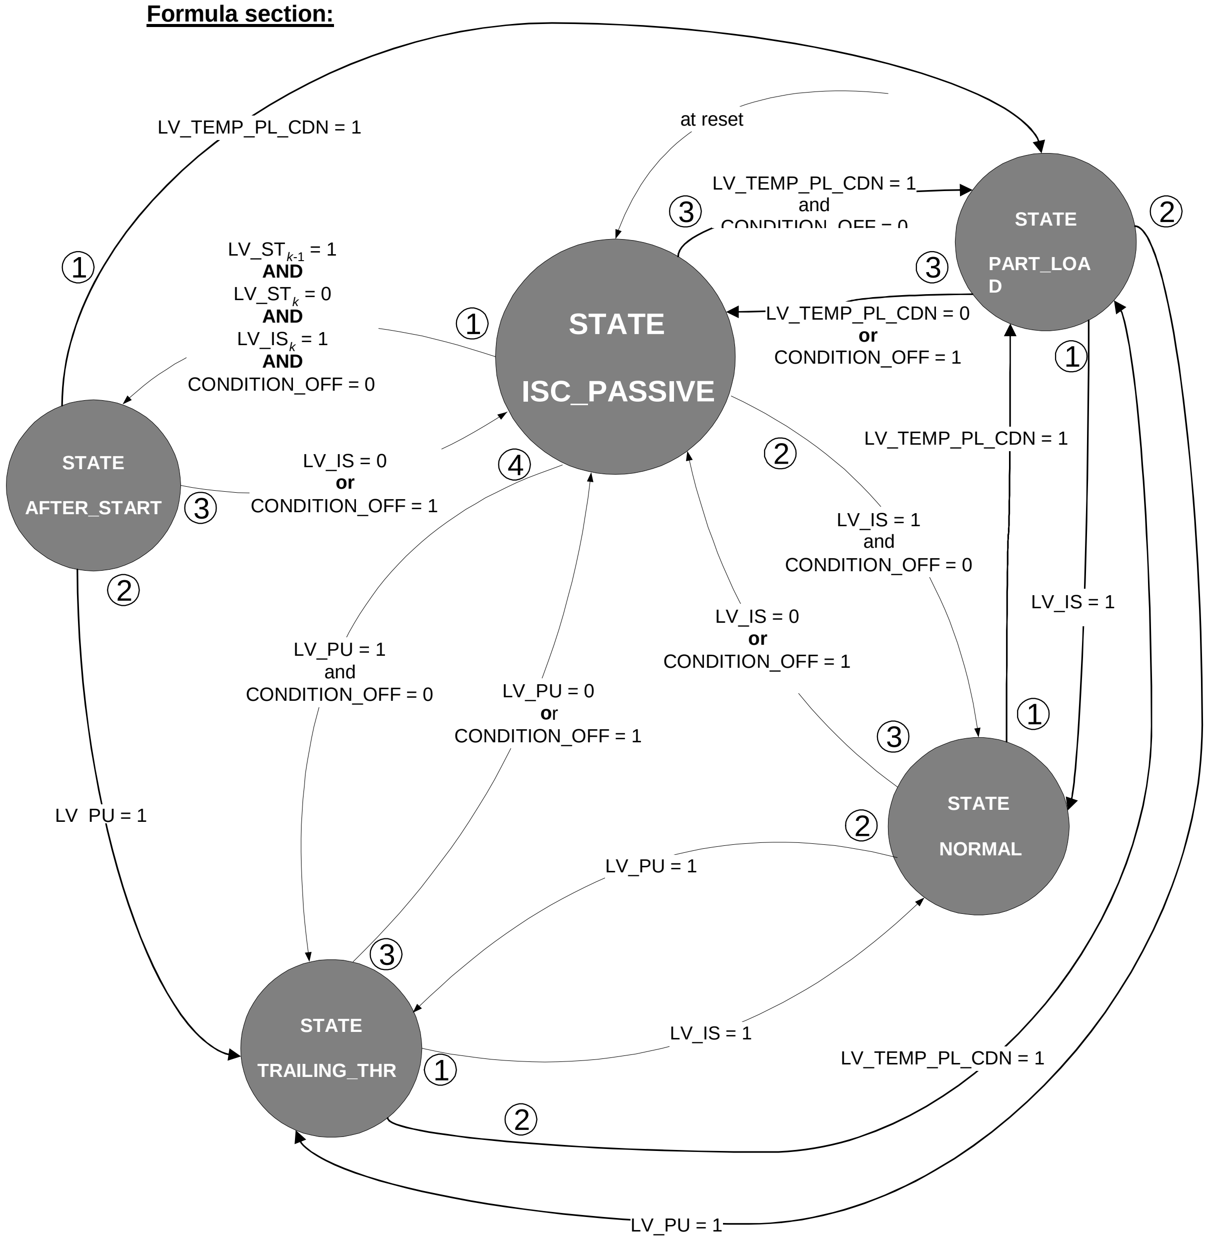

Figure 8.3.1: : State diagram of the ISC activation.

The numbers at different transitions of one state to another represent the priority in which the transitions have to be checked.

8.3.2 ISC Passive (STATE ISC_PASSIVE)

FUNCTION DESCRIPTION:

This state is the idle speed controller passive state. The controller is deactivated if there is a transition to this state.

Formula section:

Action: LV_REQ_ISC = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Transition: see figure 1

Action during transition to AFTER_START: LV_NEG_N_GRD_FIL_MEM = 0
N_GRD_FIL_ISC_ACT_AST = 0

8.3.3 Checking ISC activation conditions after start (Entry into IS after ST, STATE AFTER_START)

FUNCTION DESCRIPTION:

After transition from engine state ST to IS, the activation of the ISC is requested if speed reaches a calibratible offset from N_SP_IS with a negative gradient N_GRD, figure 2. If speed does not reach this offset after decreasing and increasing again, the controller is also activated.

Transition: see figure 1

Action:

IF LC_ISC_ACT_AST_CDN_SWI == 1
THEN
LV_REQ_ISC = 1
ELSE
{
% Calculation of a filtered gradient for after start activation

$N\_GRD\_FIL\_ISC\_ACT\_AST_k = N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1} + C\_CRLC\_N\_GRD\_FIL\_ISC\_ACT\_AST \; \{N\_GRD_k - N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1}\}$

% If N reaches the calibratible offset N_SP_IS + C_N_DIF_ISC_ACT_AST
% with a negative gradient, then the controller is activated. If
% speed increases again *before* reaching N_SP_IS + C_N_DIF_ISC_ACT_AST,
% then the controller is activated, too. The falling gradient
% is layed up in LV_NEG_N_GRD_FIL_MEM.

IF N_GRD_FIL_ISC_ACT_AST $<$ 0
THEN
LV_NEG_N_GRD_FIL_MEM = 1

IF **{** N $<$ N_SP_IS + C_N_DIF_ISC_ACT_AST **}**
THEN
LV_REQ_ISC =1
ENDIF

ELSEIF **{** N_GRD_FIL_ISC_ACT_AST $>=$ 0 **}AND**
{ LV_NEG_N_GRD_FIL_MEM == 1**}**

THEN
LV_REQ_ISC =1

ENDIF

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Figure 3: *Activation of the ISC in case of LV_IS = 1*

Formular section:

Transition:see figure 1

Action:

IF(LV_AT = 1)
THEN IF (LV_DT = 0)
THEN LV_REQ_ISC = 1
ELSEIF (N_GB $<$ N - C_N_GB_DIF_N **OR** N_GRD $<$ IP_N_GRD_N_SP_IS_RATIO **OR** N_DIF_COR $>$0)
THEN LV_REQ_ISC = 1

ELSE LV_REQ_ISC = 1;

8.3.5 ISC activation in case of low engine speed decrease in trailing throttle state (LV_PU = 1, STATE TRAILING_THR)

If speed decrease in trailing throttle state is very low or speed does not decrease, the idle speed controller is activated after a calibratible time *C_T_DLY_ISC_ACT_PU*. The condition for that is a standing vehicle (VS=0). The counter is started when entering PU (LV_PU_{k-1} = 0 LV_PU_k = 1). The counter is reinitialized with C_T_DLY_ISC_ACT_PU when leaving PU. See figure 4.

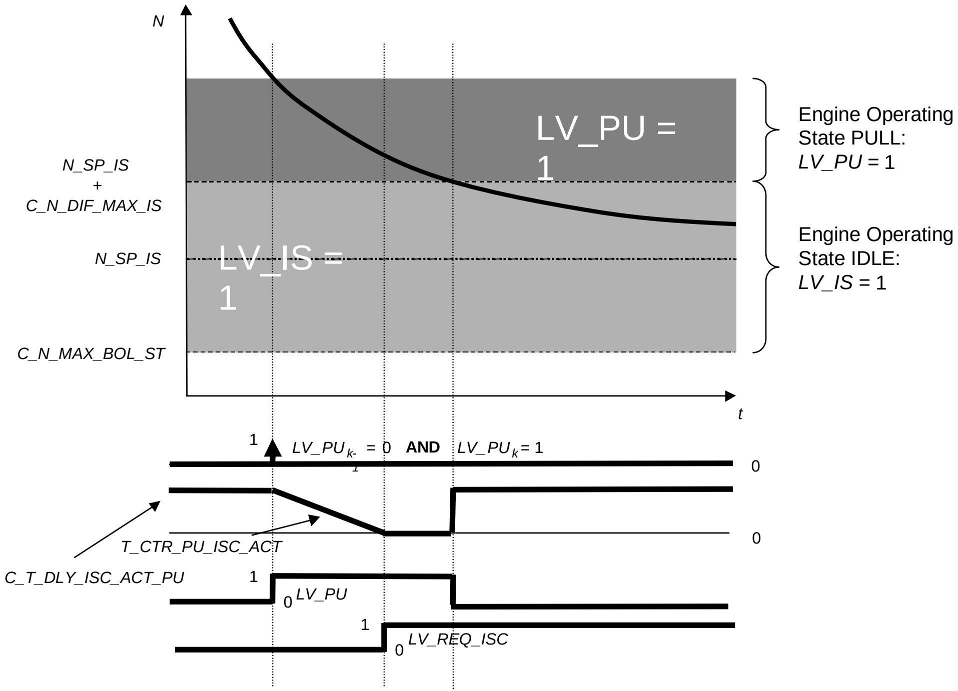

Figure 8.3.3: : Activation of the ISC in PU in case the speed decrease is too low and ***the vehicle does not move (VS = 0)***. *The counter starts from a tunable value C_T_DLY_ISC_ACT_PU and stops at zero.*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formular section:

Transition: see figure 1

Action: start toramp down *T_CTR_PU_ISC_ACT* when entering PU
(the initialization of *T_CTR_PU_ISC_ACT* was already done before)

IF **{** VS == 0 **OR** LV_DT == 0 **}** **AND** **{** T_CTR_PU_ISC_ACT == 0 **}**
THEN
LV_REQ_ISC = 1
ELSE
LV_REQ_ISC = 0
ENDIF

Reinitialize *T_CTR_PU_ISC_ACT* with C_T_DLY_ISC_ACT_PU when leaving state TRAILING_THR

8.3.6 Conditions for ISC part load activation (STATE PART_LOAD)

In part load, the driver or cruise control torque request can be so small, that the idle speed setpoint N_SP_IS cannot be held and speed is decreasing. In this case, the idle speed controller is used to guaranty N N_SP_IS. The conditions for activating the ISC in this case depend on the speed and a calibratible hysteresis, figure 5.

UNSUPPORTED IMAGE FORMAT

Figure 5: Activating the ISC in part load

Formula section:

Transition: see figure 1

Action: LV_REQ_ISC = 1

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

8.3.7 Checking ISC inhibit interfaces

During AMT shift intervention Phase 1 (LV_AMT_CRAWL_ON = 1) an additional Converter torque is calculated; during this time the ISC is looked State "PASSIVE".

All inhibit interfaces lead to CONDITION_OFF which is used in the state diagram (figure 1).

IF LV_AMT_CRAWL_ON = 1
THEN CONDITION_OFF = 1
ELSE CONDITION_OFF = 0
ENDIF

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

8.4 Idle speed adaptation

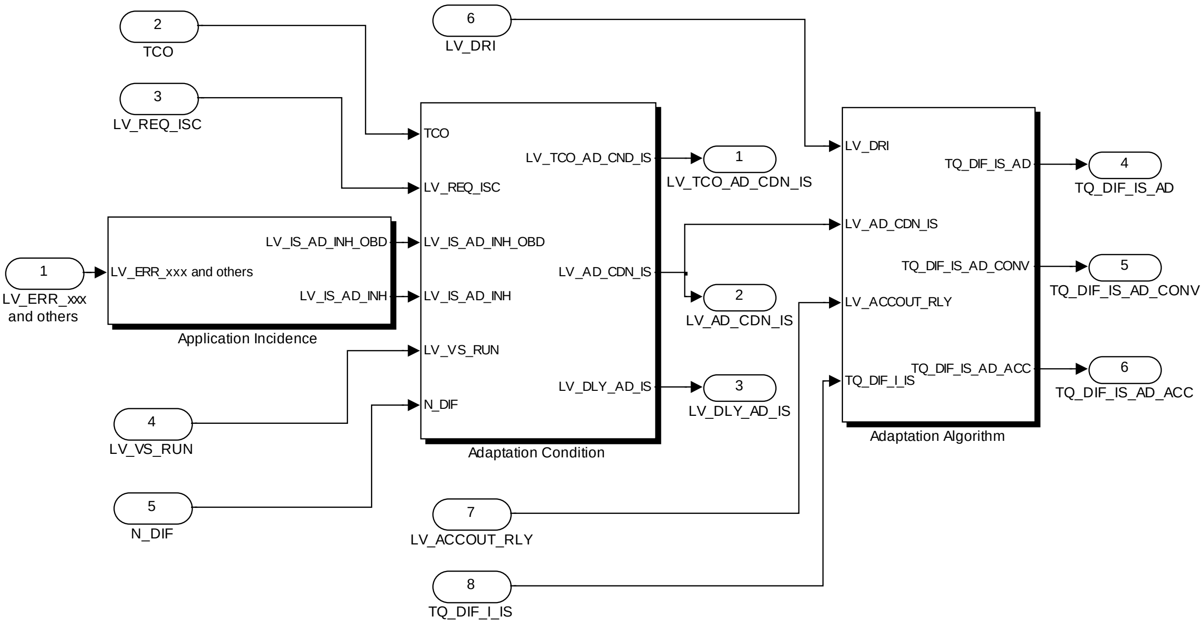

Figure 8.4.1: : Idle Speed Adaptation, Overview

Functional Description:

The present adaptation is introduced to compensate spread and series variation of engine, air conditioning compressor and hydraulic converter torque losses. It is calculated during idle speed, using the integral part of the idle speed controller for the adaptation of three different parameters:

TQ_DIF_IS_AD is the adaptation of the basic engine torque losses, without taking the drivetrain into account (disengaged gear),
TQ_DIF_IS_AD_CONV is an adaptation of the hydraulic converter torque request at idle speed (for automatic transmission only),
TQ_DIF_IS_AD_ACC is an adaptation value which consideres two adaptation cases depending on the actual situation:

air conditioning compressor and converter active at the same time
only air conditioning compressor active

The function consists of the following blocks:

Application Incidence: Checks whether a relevant error has occurred.
Adaptation Condition: Checks whether the adaptation conditions are fulfilled.

- Adaptation Algorithm: Calculation of the specific adaptation parameters.

These parameters are integrated directly in the specific functions, i.e. the adaptation of the converter torque TQ_DIF_IS_AD_CONV is used in the function "Converter torque" ...

Time after start during which idle speed adaptation is disabled					

General information

The idle speed adaptation is inhibited if on of the errors described in the formula section occur. Additionally it is possible to inihibit the idle speed adaptation for a certain time after start dependent on the start temperature.

Description:
If one of these error bits is set, LV_IS_AD_INH_OBD = 1 and LV_IS_AD_INH = 1.
Adaptation is not allowed see application conditions.

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. FUNCTION DESCRIPTION:
The complete function is calculated every 100ms independent of the status of the adaptation condition. If the adaptation conditions are fulfilled (LV_AD_CDN_IS = 1), the corresponding adaptation value is fed by the I-gain of the idle speed controller value TQ_DIF_I_IS :

The adaptation of ACC and CONV (TQ_DIF_IS_AD_ACC_CONV) is calculated if the gear is engaged (LV_DRI = 1) and the air conditioning compressor is switched on (LV_ACCOUT_RLY = 1).
The adaptation of ACC and CONV with neutral control active (TQ_DIF_IS_AD_ACC_NEUT) is calculated if the gear is engaged (LV_DRI = 1), neutral control active (LV_AT_NEUT_CTL = 1) and the air conditioning compressor is switched on (LV_ACCOUT_RLY = 1).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

If LV_ACCOUT_RLY = 1 and LV_DRI = 0, the adaptation of the air conditioning compressor is calculated (TQ_DIF_IS_AD_ACC_1).
The Hydraulic converter torque adaptation with neutral control passive (TQ_DIF_IS_AD_CONV_1) is calculated if LV_DRI = 1, LV_AT_NEUT_CTL = 0 and LV_ACCOUT_RLY =0.
The Hydraulic converter torque adaptation with neutral control active (TQ_DIF_IS_AD_CONV_NEUT) is calculated if LV_DRI = 1, LV_AT_NEUT_CTL = 1 and LV_ACCOUT_RLY =0.
The basic adaptation of the idle speed controller (TQ_DIF_IS_AD) is calculated if the gear is disengaged (LV_DRI = 0) and the air conditioning compressor is switched off (LV_ACCOUT_RLY = 0).

Therefore, a fraction of the integral part of the idle speed controller (FAC_TQ_DIF_IS_AD * TQ_DIF_I_IS) is added at each cycle to the concerned adaptation parameter, whose value is limited through a min/max limiter. The adaptation parameters are stored, even after deactivation of the function. These values are used as start values after re-entering into the same adaptation path.
The outputs of the different adaptation paths are always covered with values of the last adaptation, even if the adaptation conditions are not fulfilled or the engine is not in idle. But these values will only be adapted (changed) if the certain adaptation path is activated and they are certainly only considered in the single modules (Torque Loss and Lead for ACC , Converter Torque) in conformance with the actual situation (ACC on, drivetrain engaged). Only the basic torque losses (TQ_DIF_IS_AD) are always considered in the module Torque Losses .
TQ_DIF_IS_AD_CONV is considered in the converter torque calculation module, TQ_DIF_IS_AD_ACC in the calculation of the air conditioning compressor losses. TQ_DIF_IS_AD is added in the torque losses.

The integration is done with high resolution values (long signed word).
At the end of the integration the conversion from high resolution (signed long word) to normal resolution (signed word) is done. Only the high word is taken from the signed long word value.

Application conditions:

8.7.3 Functional overview of the adaptation algorithm

Depending of the status of several logical variables (LV_DRI, LV_ACCOUT_RLY, LV_AT_NEUT_CTL) and the automatic gearbox clutch information STATE_MOD_GB the different adaptation paths are cho-

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

sen. With the help of the logical field STATE_MOD_GB the logical variable LV_AT_NEUT_CTL is created.
A filter first order is used to smooth the adaptation value changes in case of engaging/disengaging the drive w/o neutral control active and/or switching on/off the AC.

8.7.3.1 Setting of LV_AT_NEUT_CTL

With the help of the logical field STATE_MOD_GB the logical variable LV_AT_NEUT_CTL is created. Depending on that information a separate set of adaptation values is chosen.

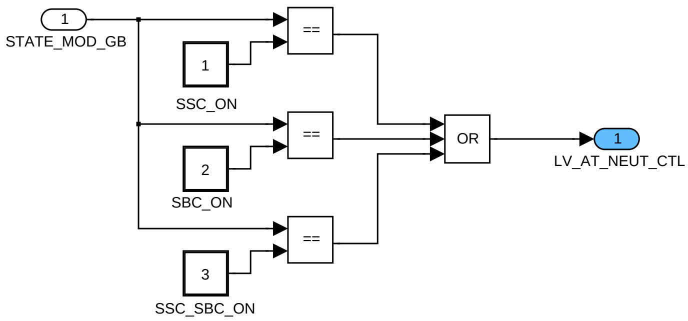

Figure 8.7.16: :

8.7.3.2 Calculation of the different adaptation values TQ_DIF_IS_AD_XXX

Depending of the status of several logical variables (LV_DRI, LV_ACCOUT_RLY, LV_AT_NEUT_CTL) the different adaptation paths are chosen.
To ensure that the adaptation values don't change during the transition from OPM_1 to OPM_2 and vice versa the flags LV_OPM_SEL_TQ_IS_AD_1/_2 are taken into account. Only if LV_OPM_SEL_TQ_IS_AD_1 is set or LV_OPM_SEL_TQ_IS_AD_2 is set the corresponding integrator out value is routed through.
IP_FAC_TQ_DIF_IS_AD_VS is used to consider the vehicle speed in the adapted torque losses of external devices (ACC, torque converter, SSC and SBC). This factor is not applied to the adapted engine torque losses TQ_DIF_IS_AD.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Figure 8.7.17: :

8.7.3.2.1 Creation of the function calls for the several adaptation values

Depending on the logical status of the flags LV_DRI, LV_AT_NEUT_CTL and LV_ACCOUT_RLY the corresponding subsystem is triggered. So in total 6 different combinations are possible.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

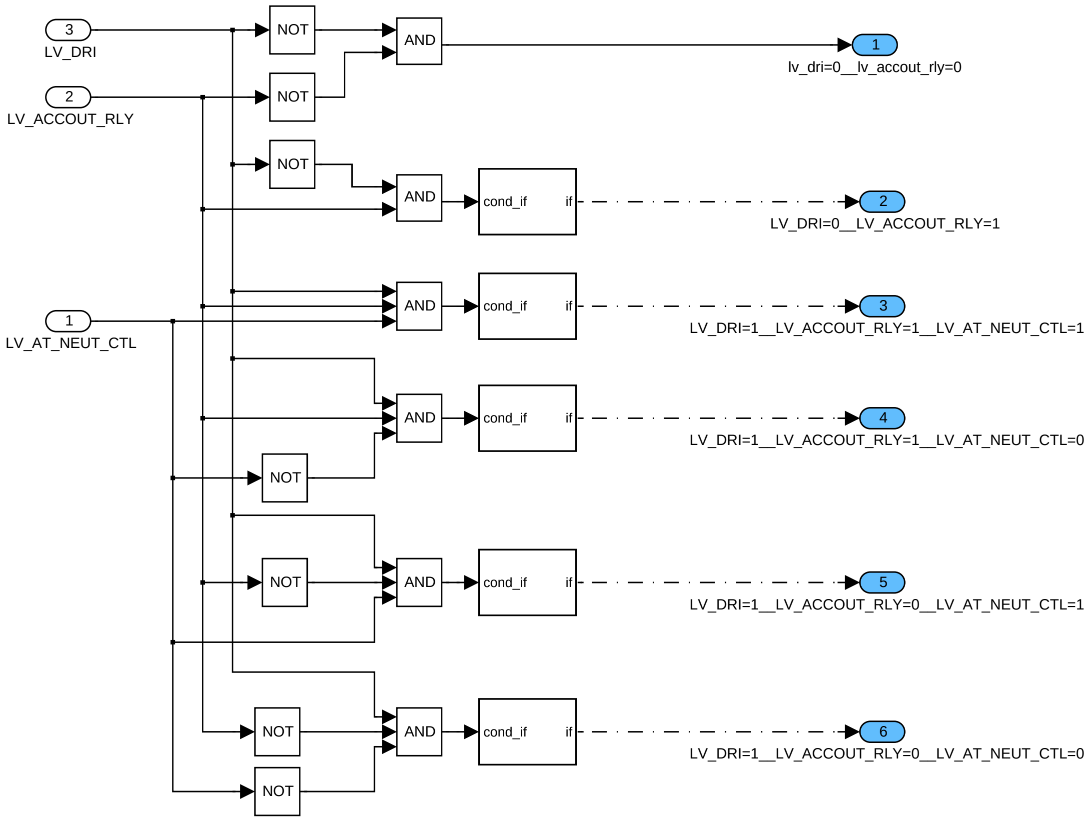

Figure 8.7.18: :

8.7.3.2.2 Input for adaptation algorithm TQ_DIF_I_IS

The adaptation algorithm is fed by the I-gain of the idle speed controller. Due to the fact that the whole function is calculated continuously the input into the adaptation algorithm is controlled via the enable flag LV_AD_CDN_IS. If the adaptation condition is not fulfilled the passive value 0 Nm is routed into the adaptation algorithm. Thus no adaptation value change takes place.

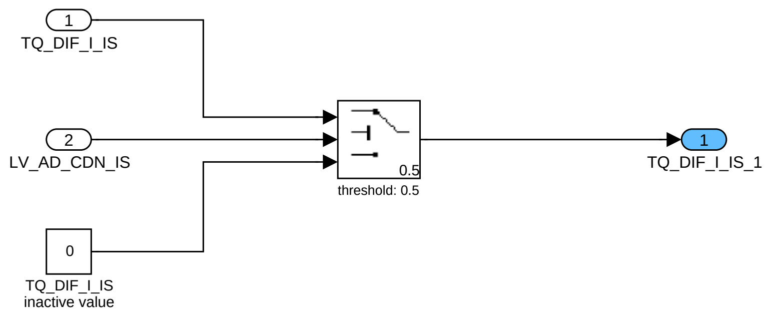

Figure 8.7.19: :

8.7.3.2.3 Basic adaptation value (TQ_DIF_IS_AD)

This adaptation value is applied for a MT or AT vehicle with drive not engaged.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The speed of the adaptation process is defined through the calibration parameter The speed of the adaptation process is defined through the parameter FAC_TQ_DIF_IS_AD and the function s update rate. This factor is calculated in the map IP_FAC_TQ_DIF_IS_AD, which is depend on the absolut value of TQ_DIF_I_IS. This provides a fast or a slow adaptation.
The sign of the input in the integrator function will be inverted because the output of the Subsystem is coordinated into TQ_LOSS [neg....0] Nm .

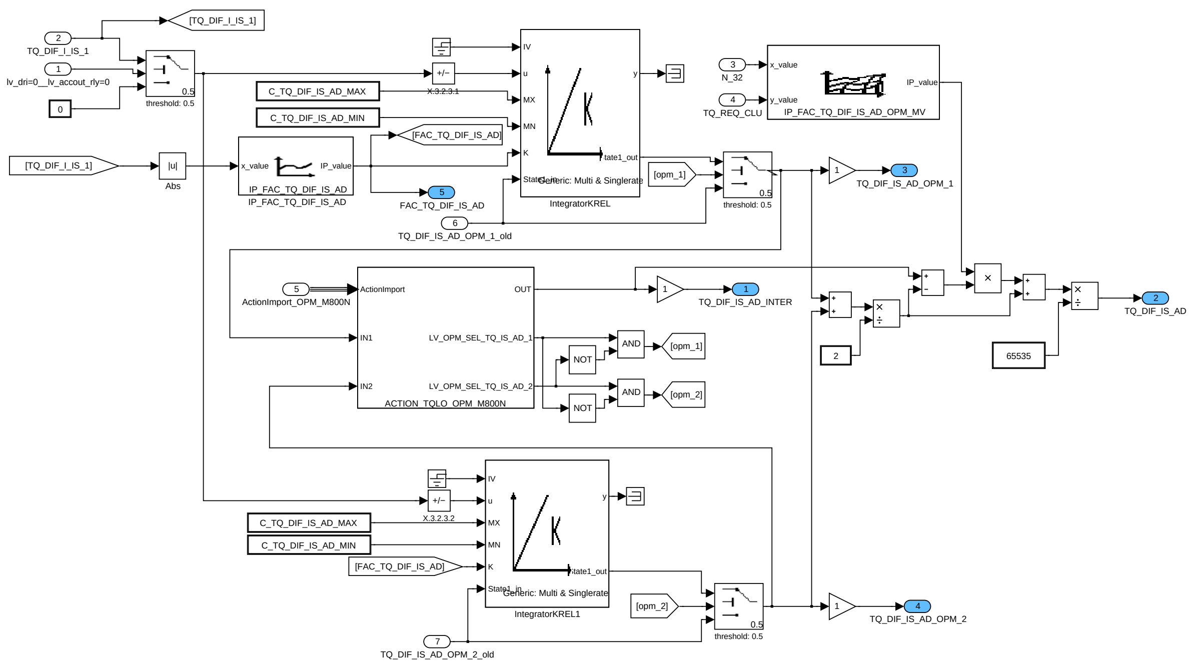

Figure 8.7.20: :

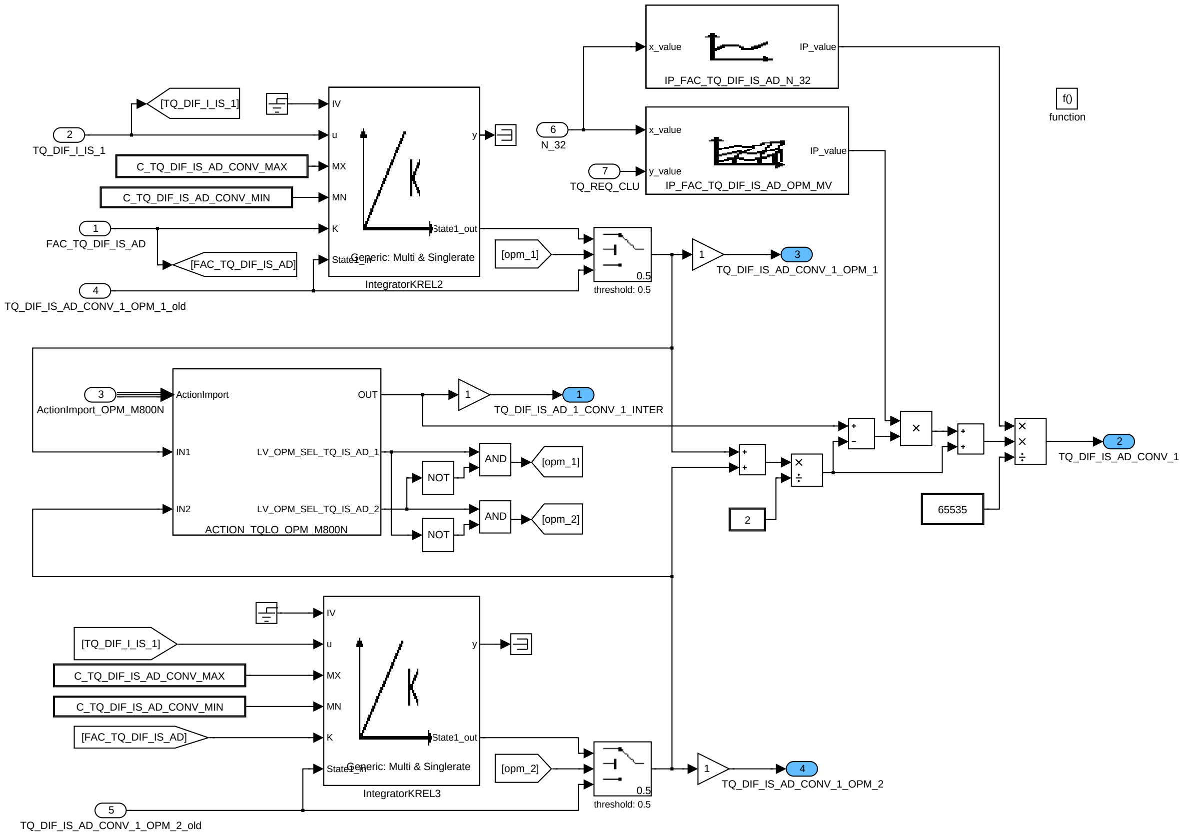

Figure 8.7.25: :

8.7.3.3 Filtering of the adaptation values

In order to be able to use one input for the ACC torque losses module and one adaptation value for the converter torque calculation module, switches are introduced to change between TQ_DIF_IS_AD_ACC_1, TQ_DIF_IS_AD_ACC_CONV and TQ_DIF_IS_AD_ACC_NEUT in dependency of the status of the logical inputs. To prevent abrupt changes in TQ_DIF_IS_AD_ACC (in case of switching between TQ_DIF_AD_IS_ACC_CONV to TQ_DIF_AD_IS_ACC_NEUT or the TQ_DIF_IS_AD_ACC_1), the output value of the final switch is smoothed by a low pass filter. The same strategy is applied in case of a change of the status of the neutral control. The change between TQ_DIF_IS_AD_CONV_NEUT and TQ_DIF_IS_AD_CONV_1 is also routed via a low pass filter.
During the first ACC adaptations, TQ_DIF_IS_AD_ACC may be erroneous and should therefore be limited to small values.

Additive torque reserve at idle at VVT mode (mode1)					

Function description

General Information:
The module   Idle Speed Torque Reserve   consists of two parts:
1. Idle speed torque reserve due to low engine speed
2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves

1. Idle speed torque reserve due to low engine speed
Depending on the predicted engine speed difference N_DIF_PRED a torque reserve by increasing the load is calculated. If actual engine speed falls it is possible to increase load before the actual engine speed is below the engine speed setpoint for idle speed. At the same time a spark retard compensates the supposed torque increase. So a quick torque incraease by spark advance can be realized to stabilize engine speed at its setpoint.
For negative gradients of TQ_ADD_IS_BOL_SEL a PT1filter for TQ_ADD_IS_BOL calculation is applied to avoid torque jumps caused by fast changes of ignition angle. For positive gradients of the input TQ_ADD_IS_BOL_SEL the output value TQ_ADD_IS_BOL is identical to the input.

2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves
At high torque reserve requests (ex.: catalyst heating) the ignition angle can be retarded down to the minimum ignition angle IGA_MIN. This may cause problems with idle speed stability. In order to prevent speed from oscillating in case the actual ignition angle is in the near of IGA_MIN caused by high torque reserves, the maximum availible torque reserve must be limited. In order to reach this, a tunable calibration constant C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is introduced. C_TQ_DIF_ADD_IS_TOL_OPM_1/2 has the same influence than TQ_ADD_IS_BOL: while the last defines a minimum torque reserve, C_TQ_DIF_ADD_IS_TOL_OPM_1/2 takes influence on the maximum torque reserve in idle. The availible torque reserve range is shown in figure 1.

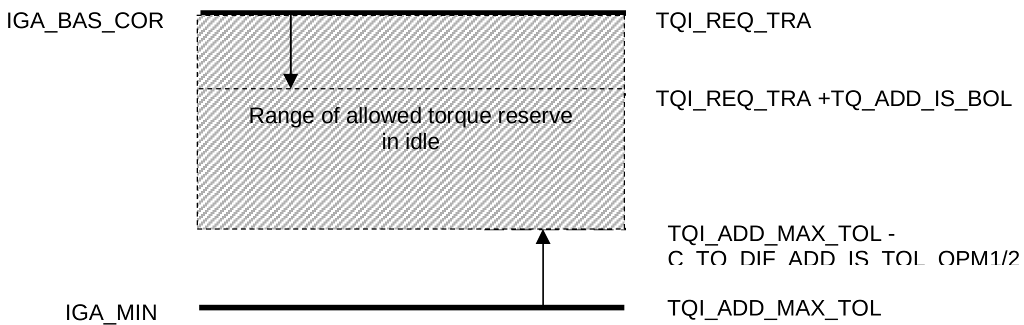

Figure 8.8.1: : Availible torque reserve range after limiting:

TQI_ADD_MAX_TOL   C_TQ_DIF_ADD_IS_TOL_OPM_1/2 defines the max. idle torque reserve

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Since C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is a calibratable constant, this may cause a conflict situation as shown in figure 2.

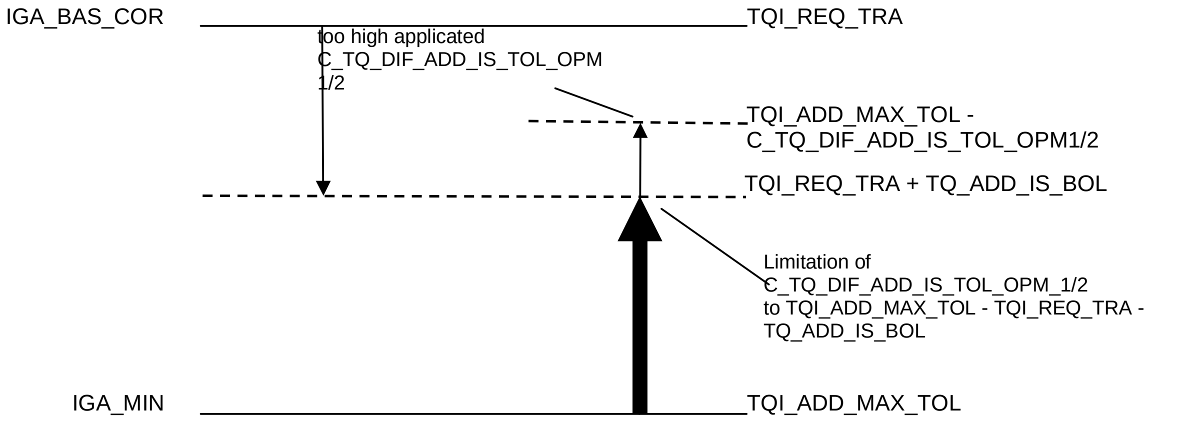

Figure 8.8.2: : Limiting C_TQ_DIF_ADD_IS_TOL_OPM_1/2 in case of a conflict

In this case TQ_ADD_IS_BOL has a higher priority than C_TQ_DIF_ADD_IS_TOL_OPM_1/2, since the possibility of moving the ignition angle in direction spark advance by building up a torque reserve is more essential than keeping it at a certain point from IGA_MIN, which „only“ causes irregular running. The condition for a non-critical situation, figure 1, is

TQI_REQ_TRA+TQ_ADD_IS_BOL<= TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL_OPM_1/2 (1)

Solving this relation leads to

C_TQ_DIF_ADD_IS_TOL_OPM_1/2<=TQI_ADD_MAX_TOL - TQI_REQ_TRA - TQ_ADD_IS_BOL (2)

If relation (2) is not fulfilled, C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is limited, figure 3.

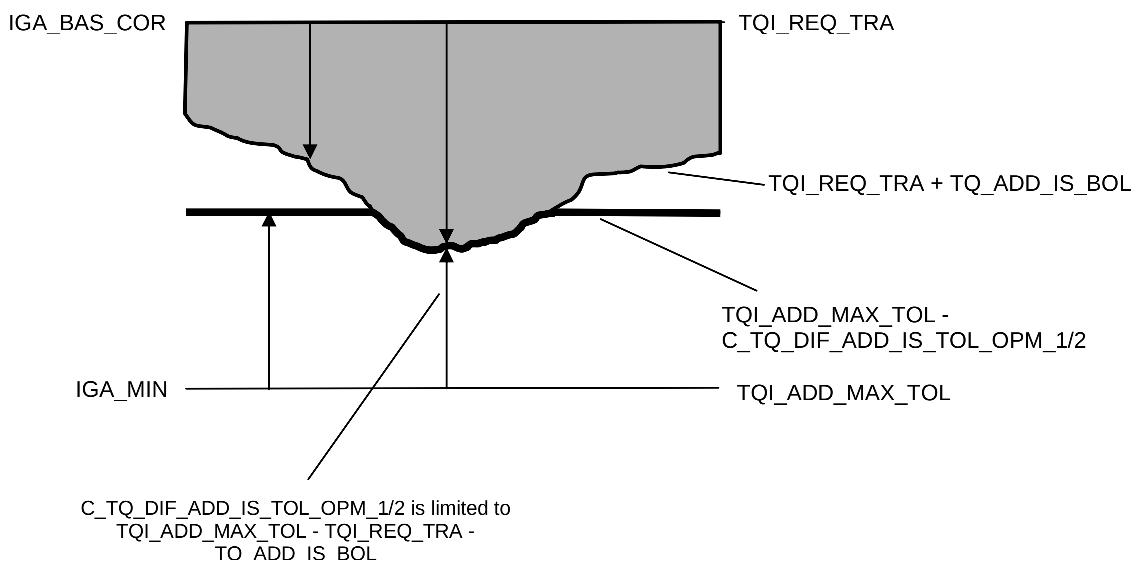

Figure 3: Limiting C_TQ_DIF_ADD_IS_TOL_OPM_1/2 in case TQI_REQ_TRA + TQ_ADD_IS_BOL is greater than TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL_OPM_1/2

Activation

Operation mode manager

There are two input values IN_1, IN_2. Each input value belongs to a special operation mode OPM_1, OPM_2. Moreover the value OPM_SEL_AV indicates the active and OPM_SEL_REQ indicates the requested operation mode. The aim of the operation manager is to create an output value depending on the active operation mode. If there is a switch from one mode to another a smooth changeover from one input value to the other is possible by using the interpolation factor FAC_OPM_SEL.
A special logic takes care that the needed part is calculated only. That means if OPM_1 is active and there is no switch requested then the output value of the operation manager = IN_1 and some part of the algorithm for IN_2 are not calculated anymore. In this case the bit LV_OPM_SEL_1=1 indicates that only the calculation of the IN_1path is done.
The information of the actual and the requested operation mode can be changed by interpretations maps ID_...OPM_SEL. The effect of this is, that by calibration the operation mode 1 can be wired to the input 2. That means the belonging for a operation mode to an input value is flexible.

The following table defines the local variable described above:

TQ_ADD_IS_BOL_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_ADD_IS_BOL_OPM_2	IN_2	Input	Input value for operation mode 2
OPM_AV (from Layer)	OPM_AV	Input	Actual operation mode

8.9 Torque reserve for canister purge at idle

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_CP	O/V	8000... 7FFFH	-1024... 1023.96875	0.03125	Nm
Torque reserve for canister purge at idle					

Input data:

CL_MMV {p. 3698}	LV_HOM_RUN {p. 8136}	LV_IS {p. 1720}	STATE_CP {p. 3637}

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_CRLC_TQ_ADD_CP	-	0... FFH	0... 0.99609	3.91e-3	-
Filter constant for canister purge torque reserve					
IP_TQ_ADD_CP	-	0... FFFFH	-1024... 1023.96875	0.03125	Nm
LDP_CL_MMV_IP_TQ_ADD_CP	8	0... FFH	0... 1.99218	0.0078125	-
Map for determination of TQ_ADD_CP in dependence of CL_MMV					

Configuration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_TQ_ADD_CP_INH	-	0... 1H	0 ...1	1	-
Logical variable for inhibiting the torque reserve for canister purge in idle					

Input data table order: External inputs - Inputs from other EVAC modules

General Information:

The torque reserve for canister purge in idle should be active, when the canister purge function is in a controlled mode, so if STATE_CP = MAX_PURGE.
By increasing the engine load without increasing the torque output, a higher purge rate is possible.

Signal flow diagram:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

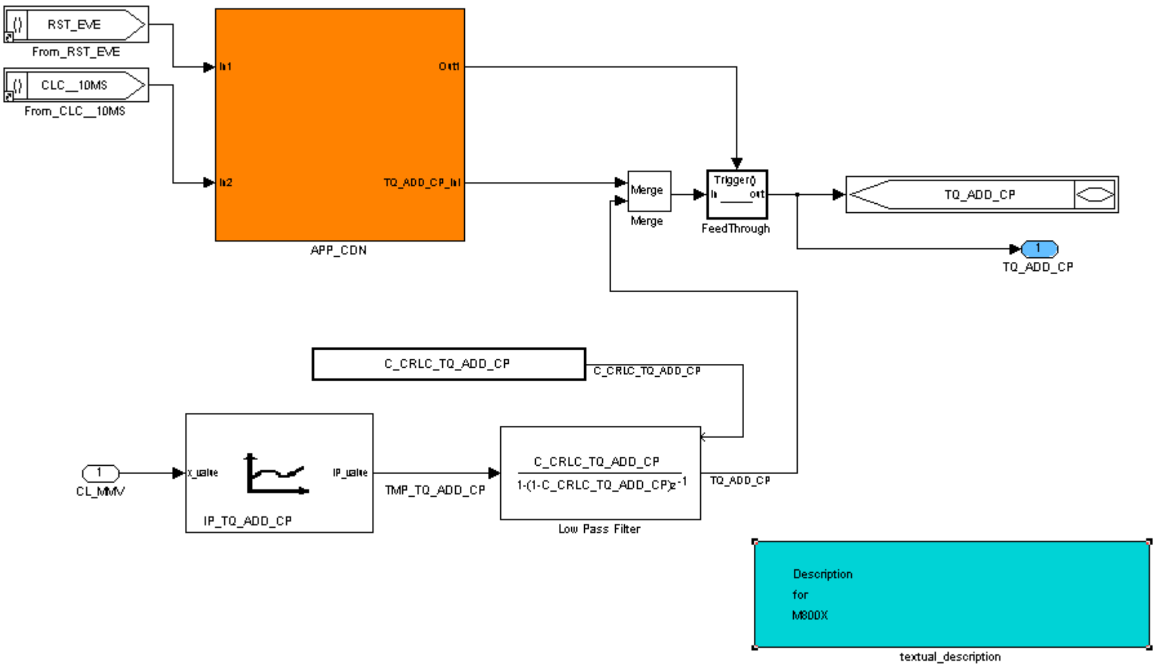

Figure 8.9.1: : Torque reserve for canister purge at idle

FUNCTION DESCRIPTION:

General information:

Activation:

LV_IS = 1
and STATE_CP = MAX_PURGE
and LC_TQ_ADD_CP_INH = 0
and LV_HOM_RUN = 1

Deactivation:

LV_IS = 0
or STATE_CP MAX_PURGE
or LC_TQ_ADD_CP_INH = 1
or LV_HOM_RUN = 0

Initialization: at reset or deactivation

TQ_ADD_CP = 0

Recurreny: **20** ms

Formula section:

TMP_TQ_ADD_CP = IP_TQ_ADD_CP (CL_MMV)

TQ_ADD_CP$_n$= // filtered value of *TMP_TQ_ADD_CP*

TQ_ADD_CP$_{n-1}$+ C_CRLC_TQ_ADD_CP * (*TMP_TQ_ADD_CP* - TQ_ADD_CP$_{n-1}$)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

For catalyst heating an increased idle speed is needed. In this modul there is a setpointcalculation for each strategy which is only calculated if actually needed.

N_SP_IS_CH is initialized with 0 because N_SP_IS is generated by a maximum-selection.

8.10.1 After start catalyst heating

There are several maps for engaged gear and not engaged. Via LC it is possible to use this dependency also for manual transmission.

Application Conditions

Function description

8.10.1.1 Operate subsystem: after start catalyst heating

For Gear > 0 there are several maps. With LC_DRI_ACT_MT it is possible to use the duplicated maps also for manual transmission. If these maps are used once they will be used until next engine start.

C_OPG_SP_MIN_ACR	-	0... FFFH	0... 99.9756	0.02441	%
Lower limitation threshold of the actuator position setpoint					

General information

This module describes the generation of the actuator valve position setpoint for closed - loop digital position control. All setpoint requests delivered from the remaining software system are gathered, co-ordinated and filially limited in the physical limits of the actuator valve. At the end of the module the position setpoint is provided for the digital position controller directly.

Application Condition

Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information

The following module shall provide all remaining actuator valve position setpoint requests for all engine operating states. At the end of the function the power stage activation condition according to position setpoint request is calculated.

Copyright (C) Continental AG,2007

Application Condition

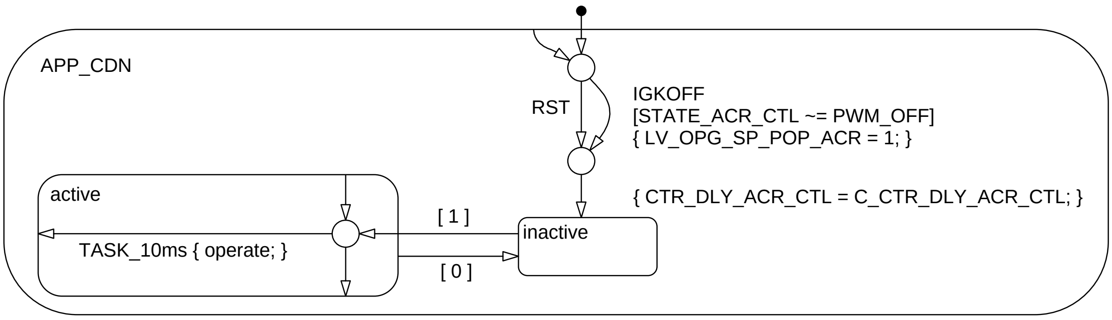

Figure 9.2.1: ACRC_setpoint_selection_ai/APP_CDN/APP_CDN

Function Description

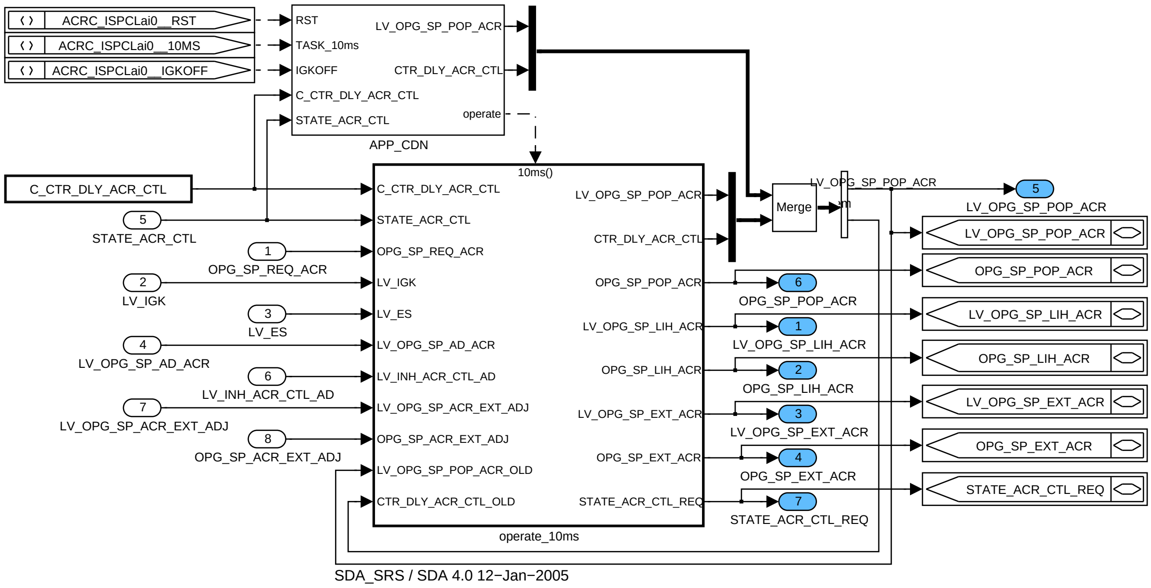

Figure 9.2.2: ACRC_setpoint_selection_ai

9.2.1 Setpoint generation

The module defines the following setpoint requests: Limp home position setpoint request active with deactivated power stage, external position setpoint request made with the calibration system and the setpoint request setpoint during post operating phase after ignition off. During the post operating phase the setpoint is set to C_OPG_SP_POP_ACR and will be removed first after a defined calibration time.
At the end of the function the power stage activation request is performed. In normal operating the transition between active and passive closed loop control is calculated here. Closed loop control will be finished after a defined delay time and position setpoint requests lower than C_OPG_SP_EXT_ACR. With passive closed loop control it is possible to deactivate the power stage via disable line or to close the actuator valve with output of a constant PWM duty cycle. The decision will be done with the logical configuration constant LC_PWM_ACR_OFF_ENA !

General information

This module describes the digital position controller used for the closedloop control of an electrical actuator. The position controller is carried out as a digital robust position controller. Calibration data are determined according to SiemensVDO internal position controller design algorithms. The controller algorithm is split in a 2 ms functionality for closedloop position control and a 10 ms functionality for static preload, battery voltage correction and position setpoint rate limitation.

Application Condition

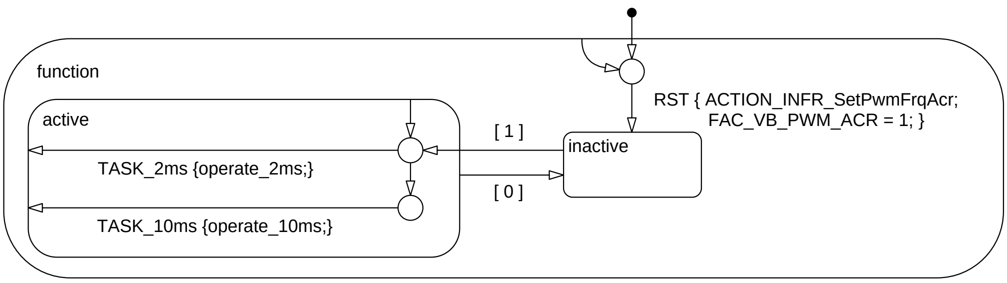

Figure 9.3.1: ACRC_position_controller/APP_CDN/APP_CDN

Function Description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

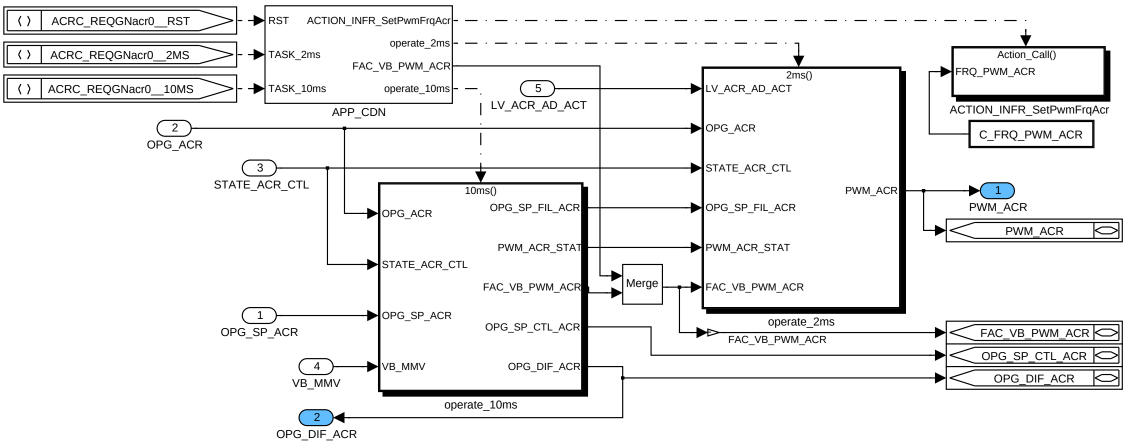

Figure 9.3.2: ACRC_position_controller

9.3.1 Functional part of 10ms

The 10 ms functionality of the position controller is only calculated if the closedloop position control has been requested. Closedloop position control will be indicated by the state PWM_CTL (= 2) of the state variable STATE_ACR_CTL.

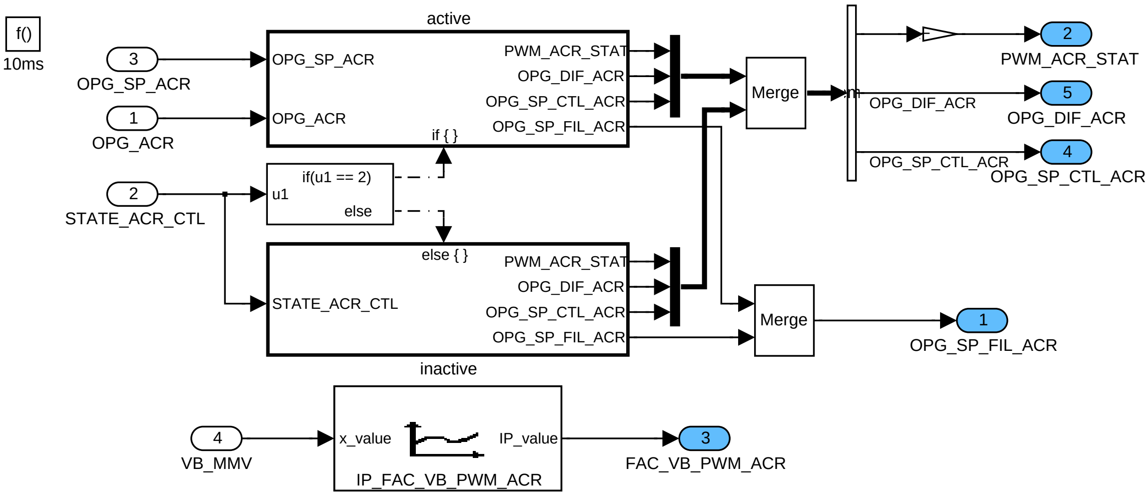

Figure 9.3.3: ACRC_position_controller/operate_10ms

ACR position controller

This function part contains the calculation of the battery correction factor, the static pre load of the position controller output and a final position setpoint filter function as a part of the closed loop position control. In the inactive state of the position control algorithm the battery voltage correction factor is set to 1, the static preload is set to C_PWM_ACR_CLOSE and all other values are set to zero.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

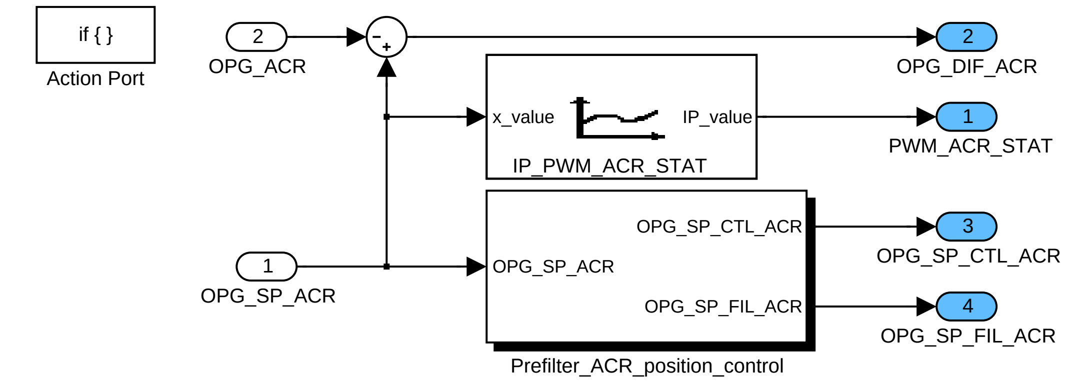

Figure 9.3.4: ACRC_position_controller/operate_10ms/active

Pre-filter functionality

The position setpoint filter function consists of a rate limitation functionality and a weighting between the described setpoint rate limitation and the direct setpoint request. The weighting can be chosen by the calibration constant C_FAC_OPG_SP_ACR. Finally the setpoint request for the digital position controller is corrected by the static transfer amplification factor C_FAC_K_FIL_ACR_CTL of the position controller filter function.

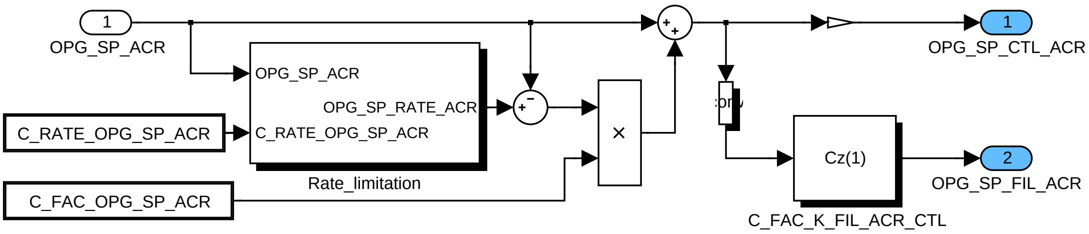

Figure 9.3.5: ACRC_position_controller/operate_10ms/active/Prefilter_ACR_position_control

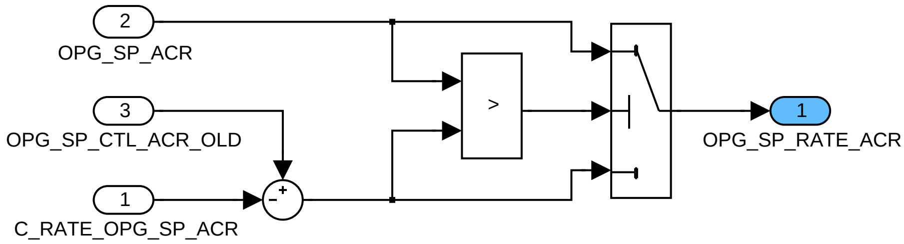

Figure 9.3.8: ACRC_position_controller/operate_10ms/active/Prefilter_ACR_position_control/Rate_limitation/Close_direction

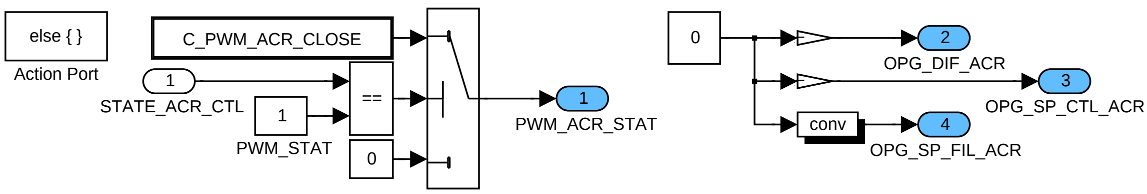

Note: The state variable OPG_SP_RATE_ACR_OLD from the active part is also set to zero !

Figure 9.3.9: ACRC_position_controller/operate_10ms/inactive

9.3.2 Functional part of 2ms

The 2 ms functionality of the position controller is only calculated if the closedloop position control has been requested. Closedloop position control will be indicated by the state PWM_CTL (= 2)of the state variable STATE_ACR_CTL.
After the calculation of the position controller the static preload and the battery voltage correction are considered. Finally the PWM dutycycle of the position controller output will be limited between 100 % and 100 %.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

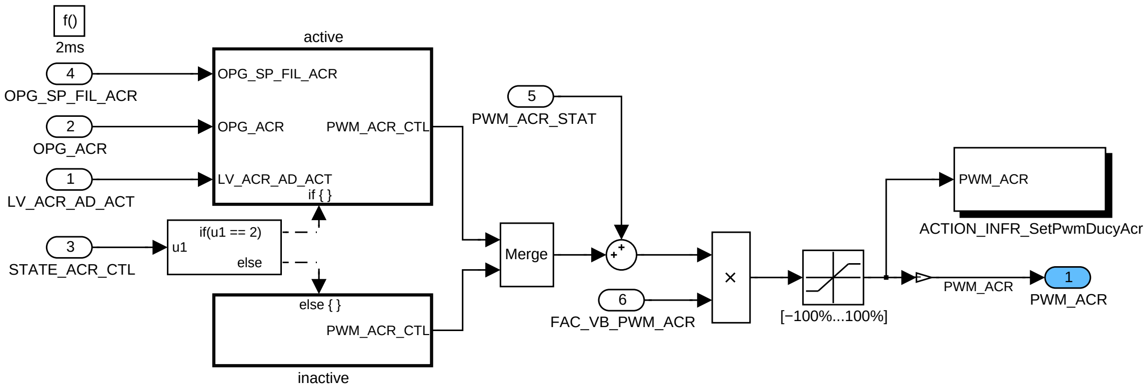

Figure 9.3.10: ACRC_position_controller/operate_2ms

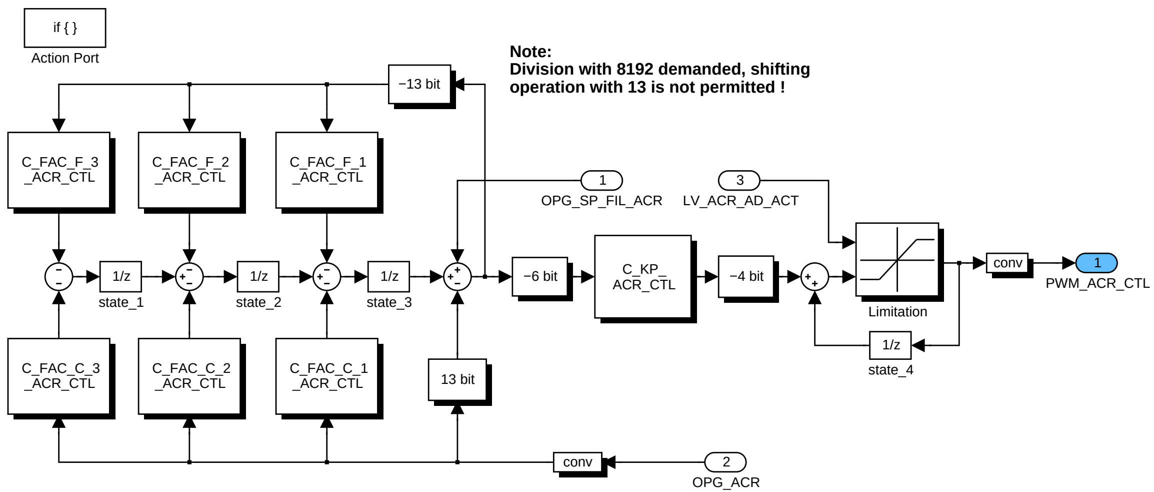
ACR position controller

The position control algorithm is a robust digital position controller and based on the pole placement design. The position controller consists of a filter function third order in backwards direction and a amplification factor with integrated integrator in forward direction. The output of the integrator is limited between a lower and upper limitation threshold. In the inactive state of the controller algorithm all state variables (state_x, x = 1...4) and the controller output are set to zero.
Calibration data are determined according to SiemensVDO internal position controller design algorithms.



PWM_ACR = KP * z / (z − 1) * [C(1) / F(1) * OPG_SP_ACR − C(z) / F(z) * OPG_ACR]

C_FAC_x_y_ACR_CTL : HEX = 8000...7FFFH, DEC = −4...4, RES = 2^−13 = 1.2207e−4

C_KP_ACR_CTL : HEX = 0...400H, DEC = 0...64, RES = 2^−4 = 0.0625

Import actions:

ACTION_INFR_DisableAcrDr ()
ACTION_INFR_EnableAcrDr ()

General information

The propose of this module is to coordinate all states of closed - loop position control. The state variable STATE_ACR_CTL indicates the current state of the actuator systems. The operating can be divided in the power stage is deactivated via disable line, the actuator is controlled means of static PWM dutycycle for active valve closing and the closed - loop position control.

ACTION_INFR_SetACCOUT (**IN**<lv_accout_rly>)

9.5.1 Enabling the activation of the ACC-relay

FUNCTION DESCRIPTION:

General information:

The activation of the ACC-relay is controlled by the logical value LV_ACCOUT_RLY which is handled by this module. The A/C-ECU requests to switch the ACC-relay by LV_ACCIN. Under certain conditions the activation will be suppressed (LV_ACCOUT_RLY_ENA = 0). These conditions are
- engine stopped or start
- during time after transition from start
- during time after detecting high torque request when vehicle speed is low
- during time after last ACC-relay switch off
- CAN-Timeout (CAN11H) INSTR3-message: LV_ERR_TOUT_ICL_3
- CAN-Timeout (BN2000) IHKA-message: LV_ERR_BN_ACC
- CAN-Busoff

Activation : at every engine operating state
Deactivation : -
Initialization : LV_ACCOUT_RLY_ENA = 0 at reset
Update rate : 10 ms

Formula section:

a) If LV_ES = 1 or LV_ST = 1, then LV_ACCOUT_RLY_ENA = 0
b) If T_AST C_ACCIN_DLY_4 then LV_ACCOUT_RLY_ENA = 0
c) **If** PV_AV becomes C_PVS_FL_ACCIN when VS C_VS_MAX_ACCIN
then LV_ACCOUT_RLY_ENA = 0 for the time C_ACCIN_DLY_1 **and**
a timer (C_ACCIN_DLY_1_LOCK_FL) is started;
a renewed triggering of ACC-suppression due to condition c) is not possible:

- during the time C_ACCIN_DLY_1_LOCK_FL
- if time C_ACCIN_DLY_1_LOCK_FL has passed but the state FL has not been exited since last triggering due to c)

d) If time after last ACC-relay switch off C_ACCIN_DLY_5
then LV_ACCOUT_RLY_ENA = 0
This condition d) is not valid, if a blocking due to condition c) ends.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

h) If LV_ERR_BN_ACC = 1 then LV_ACCOUT_RLY_ENA = 0

i) If LV_ERR_TOUT_ICL_3 = 1 then LV_ACCOUT_RLY_ENA = 0

j) If LV_ERR_CAN_BOFF = 1 then LV_ACCOUT_RLY_ENA = 0

In all other cases : LV_ACCOUT_RLY_ENA = LV_ACCIN

9.5.2 Turn-On-/Turn-Off-Delay ACC-relay

Note: The imported actions are defined in the HVAC - IRS (infrastructure requirement specification).

FUNCTION DESCRIPTION:

General information:

If the enabling conditions for activating the ACC-relay are fulfilled (LV_ACCOUT_RLY_ENA = 01) then the ACC-relay is activated (LV_ACCOUT_RLY = 01) via a turn-on-delay. The same way the ACC-relay is deactivated (LV_ACCOUT_RLY = 10) via a turn-off-delay if LV_ACCOUT_RLY_ENA = 10.
If LV_SUPP_ACCIN_DIAGCPS = 1 due to functional check CPS then the state of LV_ACCOUT_RLY is freezed.
For test purpose at assembling line or workshop the ACC-relay can be switched by a serial communication tool, if available (external adjustment). These switchings are done without the turn-on-delay, so the engine speed will show a clear reaction.

Activation : at every engine operating state
Deactivation : -
Initialization : LV_ACCOUT_RLY = 0 at reset
LV_TOUT_ACC = 1
T_ACC = FFFFH
T_ACC_DLY = FFH

Update rate : 10 ms

Constant to switch to manual ECFPWM_ECF activation					

Configuration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
NC_ECFPWM_ECF_SUB_DIAG	-	0... FFH	0... 99.60937	0.390625	%
Configuration constant for ECFPWM in case of active failure					

9.7.1 Control of ECFPWM[NC_ECF_NR] with ignition key on

FUNCTION DESCRIPTION:

General information:

The electric fan is controlled with a 100 Hz PWM signal to regulate its rotational speed. The calculated pulse width modulation depends on various components which are handled by the BMW “Wärmeman-agementkoordinator”.

Application conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

Initialisation: `all = 0 at reset`
`T_N_PERC_ECF_ACT = C_T_N_PERC_ECF_ACT`

Recurrence: *200ms*

Activation: *LV_IGK = 1*

(see: "*ENTE scheduler*")

9.7.1.1 Calculation of PWM-signal for the electric cooling fan

Description:

All calculations which are necessary for the computation of the overall cooling fan speed are done by the BMW "Wärmemanagementkoordinator". Via layer BMW hands over the final cooling fan speed N_PERC_ECF which is already standardized to percentage.

Self-diagnosis runs each time the electric fan is switched on. The electric fan should be operated with constant, low speed stage for this.

If N_PERC_ECF > C_N_PERC_ACT_ECF **and**
T_N_PERC_ECF_ACT > 0 sec.
Then T_N_PERC_ECF_ACT is decremented
ECFPWM[0] = C_N_PERC_ACT_ECF
Else ECFPWM[0] = N_PERC_ECF
Endif

Formula section:

If (1) LV_ERR_ECF[0] = 1
then (1) ECFPWM[0] = NC_ECFPWM_ECF_SUB_DIAG
else (1)
if (2) LV_ECFPWM_ECF_EXT_ADJ = 1
then (2) ECFPWM[0] = ECFPWM_ECF_EXT_ADJ
else (2)
if (3) LC_ECFPWM_ECF_MAN = 1
then (3) ECFPWM[0] = C_ECFPWM_ECF_MAN
endif (3)
endif (2)
endif (1)
Default-value for NC_ECFPWM_ECF_SUB_DIAG = 2.37%

9.7.2 Control with ignition key off up to detection of ES and in the self-holding phase

General information:

With ignition key off until ES and in the self-holding phase of the control unit, the control frequency is switched over to 10Hz and a pulse width modulation ECFPWM_IGK_OFF is set. The power latch time is defined in Chapter Basic Software Inputs and Outputs.

Application conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Recurrence: 100 ms

Activation:

```
  ECU_STATE = PWL
If          T_PWL < C_T_ECFPWM_PWL
then      ECFPWM_IGK_OFF = N_PERC_ECF
else     ECFPWM_IGK_OFF = 0
```

endif

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Time delay for EGR active after start					
C_TCO_MIN_EGR	-	0... FEH	-48... 142.5	0.75	°C
Minimum temperature for EGR-control active					
LC_ACR_CTL_ENA	-	0... 1H	0 ...1	1	-
Logical constant for the activation of actuator position control					

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

The EGR-Control is activated (LV_ACR_CTL_ENA = 1), if the coolant temperature TCO is higher than a threshold value C_TCO_MIN_EGR and the engine is running at part load or idle speed (LV_FL=0). If idle speed is detected the EGR-function is activated after the time T_AST> C_T_AST_EGR.

Application conditions

Initialisation: *at RST set LV_ACR_CTL_ENA to zero !*

Recurrence: *20ms*

Activation: *at all engine operating states*

Deactivation: *no deactivation*

Formula section:

```
if      TCO > C_TCO_MIN_EGR                      and

9.9.3 Operation mode request

9.9.3.1 Calculation

Depending on STATE_CH the calculation is separated for after start, low load and desulfation catalyst heating.

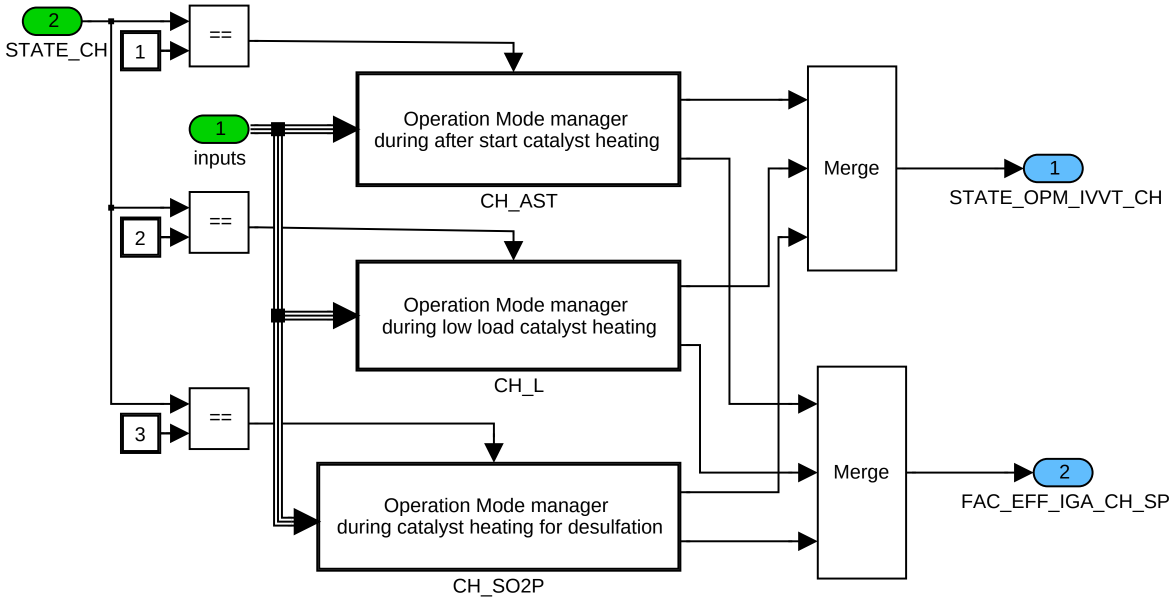

Figure 9.9.7: : Path: EXTC_REQGNcam0/OPM_REQ/SUB

9.9.3.1.1 EXTC_REQGNCAM0/OPM_REQ/SUB/CH_AST

9.9.3.1.1.1 Operation Mode manager during after start catalyst heating

FAC_EFF_IGA_CH_SP = 0 means that emission-optimal settings are to be chosen. FAC_EFF_IGA_CH_SP = 1 means that engine-roughness-optimal settings of camshafts shell be chosen. This setpoint value shell result in FAC_EFF_IGA_CH which is used for interpolation betweet emission- and engine-roughness-optimal maps. STATE_OPM_IVVT_CH contains the same information in logical way. 2 means emission-optimum, 1 means engine-roughness-optimum, 0 means no request from catalyst heating side.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Fuel pressure setpoint for catalyst heating					

General Information

During homogeneous mode with double injection (MPLH mode) it is necessary to use a higher fuel pressure due to the 2nd "stratified" injection.

Application Conditions

Initialization: RST
Recurrence: 20MS
Activation: always
Deactivation: never

Function description

9.10.1 Operate Subsystem

If catalyst heating in MPLH-mode is active STATE_CH_MOD OR STATE_CH_MOD_REQ = 2 = CH_ MOD_MPLH the IP values are used. This can be during after start catalyst heating or catalyst heating for desulfation. In all other cases the passive value C_FUP_SP_CH_PAS is used.

Number of the exhaust flaps in system					

Import actions:

ACTION_INFR_SetEf (**IN**<ef_nr>,**IN**<Lv_ef>)

General information:

To optimize the vehicle noise behaviour, an exhaust flap can be activated depending on the engine speed (N_EF) and the load (FAC_TQ_REQ). The exhaust flap is closed below a FAC_TQ_REQ value threshold, it is opened above the threshold.
The exhaust flap activation is only activated after the time C_T_EF_AST after the transition from Start.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The switching threshold (FAC_TQ_EF_THD) is depending on enginespeed (N_EF), the selected gear (GEAR_EF), the transmission (manuell or automatic) and the convertible top (LV_CTOP = 0 closed, or LV_CTOP = 1 open).

To prevent the exhaust flap from switching continuously during constant driving at the switching threshold, two hysteresises (C_N_EF_HYS and C_FAC_TQ_EF_THD_HYS) are introduced for the switching process.
The closing of the exhaust flap is delayed depending on the enginespeed (N_32).

During catalyst heating with increased idle speed setpoint, the state of the exhaust flap is adjustable by C_STATE_CH_EF.

At low vehicle speeds the state of the exhaust flap is adjustable by C_STATE_VS_MIN_EF_xx, but C_STATE_CH_EF has higher priority as C_STATE_VS_MIN_EF_xx (xx = MT/AT).
For MSD85 is NC_EF_NR=2 and for all other projects is NC_EF_NR=1.

General information:

This function is used to control an open loop, 2- or 3-stage variable intake manifold. The output VIM_AV is generated to be used for the volumetric efficiency of the engine which is influenced by the VIM position. For a 2-stage variable intake manifold VIM_AV should be set to 0% /100% in order to facilitate the application of the volumetric efficiency.
For test purpose at assembling line or workshop the VIM can be switched by a serial communication tool, if available (external adjustment).

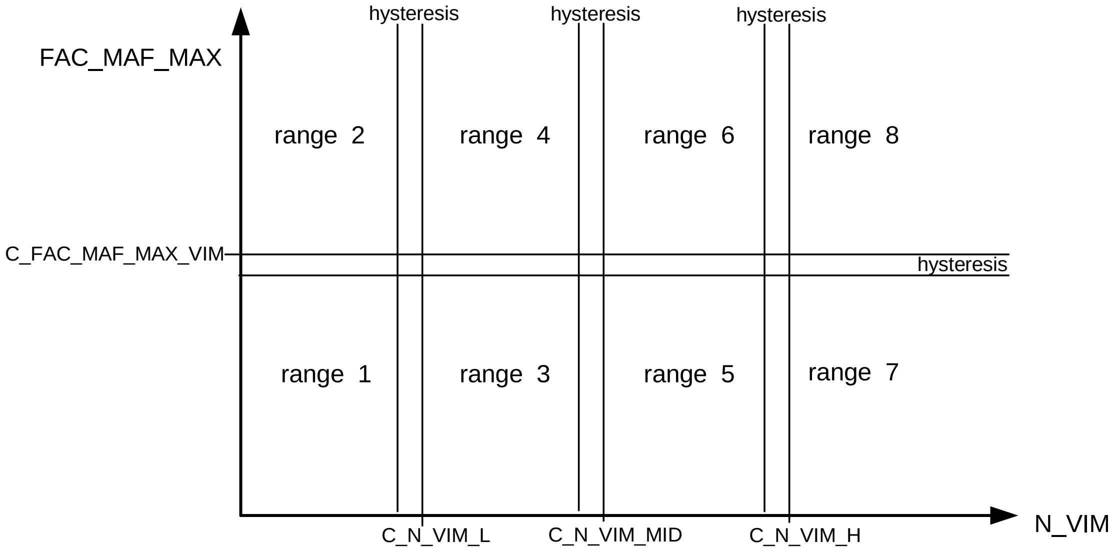

Diagram is valid if external adjustment is inactive.

Application conditions

Initialisation: VIMPWM_1 = C_VIMPWM_PAS at ECU initialisation VIMPWM_2 = C_VIMPWM_PAS and at function deactivation
VIM_AV = C_VIM_AV_1
T_OPEN_VIM_DEAC = C_T_OPEN_VIM_DEAC
all others: physical 0
at LV_IGK 0->1 or at reset : LV_VIM_RLS_TMP = 0

Recurrence: *10 ms*

Activation: *at every engine operating state*

Deactivation: –

Formula section:

Condition for release of VIM function

If LV_ST_END = 1 **and**
C_VB_MIN_VIM ≤ VB ≤ C_VB_MAX_VIM **and**
ID_STATE_RLS_VIM = 1 **and**
LV_ERR_VIM_1 = 0 **and**
LV_ERR_VIM_2 = 0
then LV_VIM_RLS = 1
else LV_VIM_RLS = 0
endif

Corrected engine speed for VIM function:

If LV_VIM_RLS = 1
then N_VIM = N * IP_FAC_N_VIM * IP_FAC_TIA_N_VIM
endif

Hysteresis for switching thresholds:
Valid for all 4 thresholds, C_N_VIM_L, C_N_VIM_MID, C_N_VIM_H and C_FAC_MAF_MAX_VIM: when increasing the input value (N_VIM /FAC_MAF_MAX) then switch at
input value > threshold ,
when decreasing the input value then switch back at
input value < threshold - hysteresis .

threshold	C_N_VIM_L / -_MID / -_H	C_FAC_MAF_MAX_VIM
hysteresis	C_N_VIM_HYS	C_FAC_MAF_MAX_VIM_HYS

Determination of desired flap position

Configuration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_FAC_FLOW_SP_MIN_PURGE	-	0... 1H	0 ...1	1	-
switch to activate /deactiate "intelligent MIN_PURGE"					

DI version
Input data table order: External inputs - Inputs from other EVAC modules

General information:

This module provides the flow setpoint for MIN_PURGE and the FUEL_FLOW setpoint for closed loop purge (“normal purge”).

Application conditions

Initialisation: *on activation and on deactivation:*
```
FLOW_CPS_SP_MIN_PURGE   = 0
RATIO_FUEL_SP_MAX_PURGE   = 0
MFF_MAX_CP              = 0
FLOW_MAX_CPS            = 0
FLOW_MAX_PHY_CPS   = 0
```

Recurrence: *100 ms*

Activation: *LV_CP_ACT = 1*

Deactivation *LV_CP_ACT = 0*

Formula section:

// Flow setpoint for MIN_PURGE & fuel flow ratio for closed loop

case selection of STATE_OPM_ENG_CP

Import actions:

ACTION_EVAM_Purge ()

Should be calculated before LACO calculation!
Input data table order: External inputs - Inputs from other EVAC modules
Hint: For each operating point, the corresponding value of IP_FLOW_MAX_OPEN_CPS and IP_FLOW_MAX_OPEN_CPS_2 must not exceed the corresponding value of IP_FLOW_MAX_CPS.

General information

General information:

The evaporative emissions of the fuel tank system are stored in an activated charcoal filter ACF to prevent an escape of the gas to the environment. The loading capacity of the filter is limited, so the filter must be purged temporarily. Therefore the canister purge solenoid CPS. that is positioned between the charcoal filter and the intake manifold is opened by the engine management system. To prevent driveability and emission problems, the opening of the CPS and so the purge flow MFF_CP must be controlled.
With the Evaporative Emission Control function, the opening of the CPS is controlled in dependence with the fuel mass stored in the canister. Therefore the canister load cl is calculated using the measured mass air flow MAF, the deviation of the lambda-control when the CPS is opened, the mass flow through the CPS and the stoichiometric constant of the fuel (14.7). The opening of the CPS is controlled in dependence with the canister load CL.

9.14.1 State machine

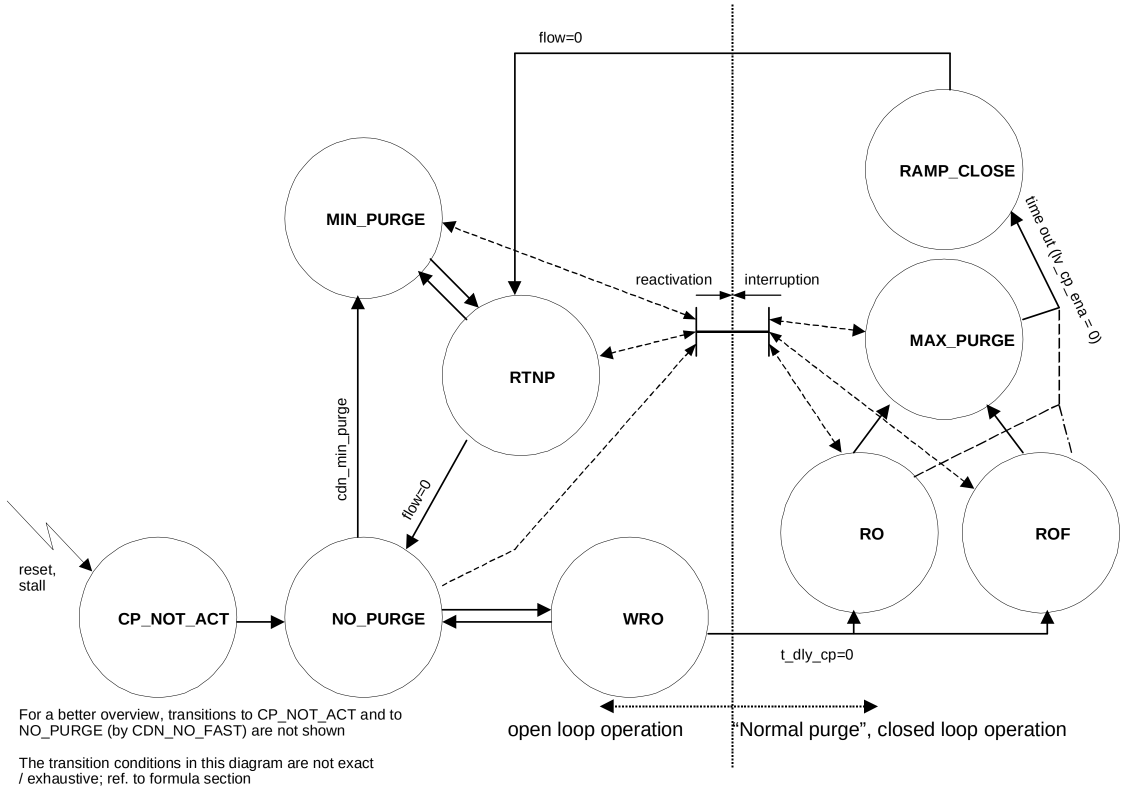

Figure 9.14.3: : State machine (simplified)

The canister purge control has the following states:

- CP_NOT_ACT function inactive, initial state
- NO_PURGE Valve closed, no purging.
- RAMP_TO_NO_PURGE Flow is currently ramped down from purging level to zero
- MIN_PURGE open loop purge with low flow
- WAIT_RAMP_OPEN waiting for lambda control stabilisation before leaning mode
- RAMP_OPEN Slow opening of the valve, learning mode
- RAMP_OPEN_FAST Faster opening of the valve; cl known from previous purge
- MAX_PURGE Controlled canister purge with high flow through the ACF
- RAMP_CLOSE Closing of the valve at the end of controlled operation

9.14.1.1 Brief description of the activation conditions of the different states

General information:

In the following, a brief description of the conditions of each state is given, this description is only for information and is not precise. In general, if the conditions below are met, the state described will be active.
The detailed conditions for transitions from each state to each other possible state and the actions to be done on the transitions are described in the next chapter "State Transitions".

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The “controlled states” are RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE & RAMP_CLOSE.
The “non-controlled states” are NO_PURGE, RAMP_TO_NO_PURGE, MIN_PURGE and WAIT_RAMP_OPEN.

NORMAL_PURGE Operation (closed loop operation)
If the conditions for NORMAL_PURGE are fulfilled, the NORMAL_PURGE operation is proceeded in the following sequences:

	RAMP_OPEN	MAX_PURGE	RAMP_CLOSE
or	RAMP_OPEN_FAST	MAX_PURGE	RAMP_CLOSE

These sequences can change, if one of the phases is disabled for a short time and the interrupt is not longer than an applicable time constant

- C_T_DI_RAMP_OPEN_CP_0/_1 (STATE_CLL_DEAC_CP = RAMP_OPEN_DEAC) **or**
- C_T_DI_MAX_CP_0/_1 (STATE_CLL_DEAC_CP = MAX_PURGE_DEAC) **or**
- C_T_DI_RAMP_FAST_CP_0/_1 (STATE_CLL_DEAC_CP = RAMP_FAST_DEAC)

If RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE operation was interrupted (any non-controlled state active) and the interruption time is lower than the adjustable times C_T_DI_RAMP_OPEN_CP_0/_1, C_T_DI_RAMP_FAST_CP_0/_1 rsp. C_T_DI_MAX_CP_0/_1, RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE operation starts immediately with the values which were stored when the operation was interrupted.
When the interruption times are longer than the corresponding constants, NORMAL_PURGE states are re-started with a new RAMP_OPEN /RAMP_OPEN_FAST phase. (FLOW_CTL_CPS starts with zero.)

CP_NOT_ACT
Function inactive, initial state

1. Engine stopped or stalled
2. coolant temperature threshold not once exceeded

NO_PURGE
Valve closed, no purging.

1. STATE_CDN_CP = CDN_NO_PURGE or CDN_NO_FAST **and**
2. [Fast shut-off necessary **or**
3. ramp from purge states to NO_PURGE finished]

RAMP_TO_NO_PURGE
Flow is currently ramped down from purging level to zero
If fast shut-off is necessary, the state machine will directly switch to NO_PURGE (immediate valve closing without ramp), otherwise, RAMP_TO_NO_PURGE will be active as long as the valve is closed by a ramp

1. STATE_CDN_CP = CDN_NO_PURGE **and**
2. Fast shut-off not necessary **and**
3. Ramp from purge states to NO_PURGE not finished **and**
4. [Previous state was MIN_PURGE or WAIT_RAMP_OPEN **and** time out from time scheduler LV_CP_ENA = 0]

An immediate switch to NO_PURGE without ramp is requested by STATE_CDN_CP = CDN_NO_FAST. In this case, FLOW_CTL_CPS is directly set to 0, no ramping down will occur.

MIN_PURGE
No controlled purge possible, open loop purge with low flow, thus low disturbance of lambda contro.

1. STATE_CDN_CP = CDN_MIN_PURGE **or**
2. Empty canister detected at the end of RAMP_OPEN

RAMP_OPEN
Slow opening of the valve, canister load not known, will be learned during RAMP_OPEN

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

1. STATE_CDN_CP = CDN_RAMP_OPEN **and**
2. Long time since the last MAX_PURGE (old cl value no more useable) **and**
3. The time delay for lambda control stabilization is elapsed or not necessary (due to MAX_PURGE or RAMP_OPEN disabling).

RAMP_OPEN_FAST

Faster opening of the valve than in RAMP_OPEN; cl known from previous normal purge operation

1. STATE_CDN_CP = CDN_RAMP_FAST **and**
2. Short time since the last MAX_PURGE (old cl value still useable) **and**
3. The time delay for lambda control stabilization is elapsed or not necessary (due to MAX_PURGE or RAMP_OPEN disabling)

MAX_PURGE

Controlled canister purge with high flow through the ACF

1. NO_PURGE /RAMP_TO_NO_PURGE /MIN_PURGE not requested **and**
2. RAMP_OPEN or RAMP_OPEN_FAST normally finished **and**
3. Can be directly reached from the non-controlled states, if MAX_PURGE was previously disabled and disabling time was lower than a threshold (STATE_CLL_DEAC_CP = MAX_PURGE_DEAC)
4. Can be entered at catalyst purge with canister load model running

RAMP_CLOSE

Closing of the valve at the end of controlled operation

1. NO_PURGE /RAMP_TO_NO_PURGE /MIN_PURGE not requested **and**
2. Canister purge time slice elablsed /Lambda adaption time active

9.14.1.2 Preliminary calculations

```
LV_CP_CDN_RAMP_OPEN_FAST =
        { [        T_DLY_MAX_CP > 0                        // cl from prev. purge useable

<u>No RO possible:</u>
imagine: turn on engine and stay in idle for a long time; STATE_CDN_CP = CDN_RAMP_OPEN_FAST (idle), but only RAMP_OPEN possible as no RO occurred before; we would never purge anything as we would wait in NoPurge.

New: Possibility to switch to min_purge in this case (configurable).
Ref. to Thäder-mail 29.04.02
no consideration of lambda control (LV_LSCL_i = 1, both benches) necessary, as STATE_CDN_CP will be cdn_min_purge anyway, if at least one lambda controller is not active

NO_CDN-management:
As STATE_CDN_CP=NO_CDN is quite new, this state was previously not considered everywhere. If STATE_CDN_CP = NO_CDN, NO_PURGE is not forced and NORMAL_PURGE is not possible (except the re-entry in maxpurge after deac), so we may switch to MIN_PURGE (configurable)

```
elseif          {[STATE_CDN_CP = CDN_RAMP_FAST        // No RO possible
             and        LC_CP_TRA_MIN_RAMP_OPEN_DIS ]
       or    [ STATE_CDN_CP = NO_CDN                  // NO_CDN-management
             and        LC_CP_TRA_MIN_PURGE_DFT_ENA ]}
       and   (!LV_CP_CAT_PURGE or !LC_CP_CAT_PURGE_MDL_ACT)
then         call  "INITIALIZATION-VALUES on leaving NO_PURGE"
             call  "INITIALIZATION-VALUES on entering MIN_PURGE"
             STATE_CP        = MIN_PURGE

else         STATE_CP        = NO_PURGE                // default
endif
end
```

9.14.1.5 RAMP_TO_NO_PURGE

```
if           LV_CP_ACT       = 0
then         STATE_CP        = CP_NOT_ACT

elseif          STATE_CDN_CP = CDN_NO_FAST
or           FLOW_CTL_CPS = 0                          // flow reduction finished
then         call  "INITIALIZATION-VALUES on leaving RAMP_TO_NO_PURGE"
             call  "INITIALIZATION-VALUES on entering NO_PURGE"
             STATE_CP        = NO_PURGE
```

if flow_ctl_cps reaches 0 in the same moment than a switch to min_purge would be possible, the switch to no_purge has now priority. In the next recurrence, a switch from no_purge to min_purge will occur. This 20ms delay is seen as neglectable. (The high-end solution would be to check the flow_ctl_cps condition only if STATE_CDN_CP = cdn_no_purge)

9.14.1.12 INITIALIZATIONS on transitions

The following submodules are called on transitions between the different states of canister purge control

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

9.14.1.12.1 Storage of Values for OBDII EVAP-System Monitoring (RO, ROF, MaxP)

This submodule is called, if RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE is left due to purge time elapsed (LV_CP_ENA = 0).
In this case, the last calculated value of the canister load CL_MMV is stored as CL_MMV_CLC_END before RAMP_CLOSE operation starts. This value is used as input for the OBDII EVAP-System Monitoring.
In addition, this subroutine may be called if MAX_PURGE is left due to a valve closing request from OBD II function.

CL_MMV_CLC_END = CL_MMV
end

9.14.1.12.2 INITIALIZATION-VALUES on entering NO_PURGE

This submodule is called at every possible transition from any state to NO_PURGE except the transition CP_NOT_ACT NO_PURGE.
On entering NO_PURGE, the initialisations listed below are done.

// Initialisation of the time counter for lambda controller stabilisation
FLOW_GRD_CPS = 0
FLOW_TAR_CPS = 0
FLOW_CTL_CPS = 0
LV_CP_CLL = 0
LV_STATE_MEM_CP_CLL = 0
PQ_CP_SP = 1 // In this mode no forced PQ is required
end

9.14.1.12.3 INITIALIZATION-VALUES on leaving NO_PURGE

If the NO_PURGE operation is left towards any other state, the following initialisations are done.
- –
end

9.14.1.12.4 INITIALIZATION-VALUES on entering RAMP_TO_NO_PURGE

This submodule is called at every possible transition from any state to RAMP_TO_NO_PURGE.
On entering RAMP_TO_NO_PURGE, the initialisations listed below are done.
As cl is not updated during RAMP_TO_NO_PURGE, it’s sufficient to define the correction factor for closing speed FLOW_FAC_CP on transition from any state to RAMP_TO_NO_PURGE.
The start value of FLOW_CTL_CPS for the ramp has to be defined.

LV_CP_CLL = 0
FLOW_TAR_CPS = 0
FLOW_CTL_CPS = **min** [FLOW_CTL_CPS, FLOW_MAX_CPS]
PQ_CP_SP = 1 // In this mode no forced PQ is required
if STATE_CP = MIN_PURGE
then FLOW_FAC_CP = 1 // ramp decrement cor. factor
else FLOW_FAC_CP = IP_FLOW_FAC_CP (CL)
endif
end

9.14.1.12.5 INITIALIZATION-VALUES on leaving RAMP_TO_NO_PURGE

If the RAMP_TO_NO_PURGE operation is left towards any other state, the following initialisations are done.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

- –
end

9.14.1.12.6 INITIALIZATION-VALUES on entering MIN_PURGE

This submodule is called at every possible transition from any state to MIN_PURGE.
On entering MIN_PURGE, the initialisations listed below are done.
The start value of FLOW_CTL_CPS for the ramp has to be defined.

LV_CP_CLL = 0
FLOW_CTL_CPS = **min** [FLOW_CTL_CPS, FLOW_MAX_CPS]
PQ_CP_SP = 1 // In this mode no forced PQ is required
end

9.14.1.12.7 INITIALIZATION-VALUES on leaving MIN_PURGE

If the MIN_PURGE operation is left towards any other state, the following initialisations are done.

- –
end

9.14.1.12.8 INITIALIZATION-VALUES on entering WAIT_RAMP_OPEN

This submodule is called at every possible transition from any state to WAIT_RAMP_OPEN.
On entering WAIT_RAMP_OPEN, the initialisations listed below are done.
The only way to enter WRO is from NO_PURGE, so FLOW_CTL_CPS, LV_CP_CLL & PQ_CP_SP have not to be set on the entrance of this state

T_DI_CP = 0 // reset of time counter for disabled normal purge
STATE_CLL_DEAC_CP = CP_NO_DEAC
T_DLY_CP = C_T_CP_PURGE_TUBE+ IP_T_DLY_CP(MAF_KGH_FG_PRED_COR_CP) * C_FAC_T_DLY_PURGE_TUBE_CP
MAF_INT_CP = 0
T_MAF_INT_CP = 0
The only scenario of having state_cll_deac_cp <> no_deac on entry of wait_ramp_open is the following:
A ROF was disabled; during the disabling time, the time T_DLY_MAX_CP reaches 0, so in the following only RO is possible. So although LV_CDN_RAMP_OPEN may be given, no entry in deactivated RO or ROF will occur; then, the state machine will switch to WRO; to have STATE_CLL_DEAC_CP on a reasonable value after WRO & RO, it has to be reset here
end

9.14.1.12.9 INITIALIZATION-VALUES on leaving WAIT_RAMP_OPEN

If the WAIT_RAMP_OPEN operation is left towards any other state, the following initialisations are done.

end

9.14.1.12.10 INITIALIZATION-VALUES on entering RAMP_OPEN

This submodule is called at every possible transition from any state to RAMP_OPEN.
If the RAMP_OPEN operation was disabled (Conditions for RAMP_OPEN were not fulfilled) for a time < C_T_DI_RAMP_OPEN_CP_0/_1 (T_DI_CP > 0, STATE_CLL_DEAC_CP = RAMP_OPEN_DEAC), initialisations for disabled RAMP_OPEN are done, otherwise the standard initialisations for RAMP_OPEN are done.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

      if    STATE_OPM_ENG_CP = ENG_MODE_0
      then T_DI_CP                    = C_T_DI_RAMP_FAST_CP_0
      else T_DI_CP                    = C_T_DI_RAMP_FAST_CP_1
      endif
endif
end
```

9.14.1.12.14 INITIALIZATION-VALUES on entering MAX_PURGE

This submodule is called at every possible transition from any state to MAX_PURGE.
On entering MAX_PURGE, the initialisations listed below are done.
If the MAX_PURGE operation was disabled (Conditions for MAX_PURGE were not fulfilled) for a time t < C_T_DI_MAX_CP_0/_1 (T_DI_CP > 0, STATE_CLL_DEAC_CP = MAX_PURGE_DEAC), the initialisations for disabled MAX_PURGE are done additionally to the standard initialisations for MAX_PURGE.

```
if    STATE_CLL_DEAC_CP      = MAX_PURGE_DEAC
then  FLOW_CTL_CPS            = MIN (FLOW_CTL_CPS_DI;
                             FLOW_MAX_CPS * C_FAC_FLOW_MAX_INI_CP;
                             MFF_SP_MV * C_MFF_RATIO_FLOW_INI_CP
                             * [N_32 * NC_CYL_NR * 3) /10^5 ] / CL_MMV)
                             // [mg/stk] -> [kg/h]
else  ACTION_EVAM_Purge ()
endif
// standard initialisations
LV_CP_CLL                     = 1
STATE_CLL_DEAC_CP             = CP_NO_DEAC
T_DI_CP                       = 0
if          STATE_CP = RAMP_OPEN
then        T_DLY_REQ_CP_TMP        = C_T_DLY_REQ_CP
elseif            STATE_CP = NO_PURGE
            and   LV_CP_CAT_PURGE = 1
            and   LV_CL_MDL_ENA = 1
then        LV_CL_MDL_CAT_PURGE_ACT_CP = 1
            FLOW_CTL_CPS       = MIN (FLOW_MAX_CPS * C_FAC_FLOW_MAX_INI_CP;
                             MFF_SP_MV * C_MFF_RATIO_FLOW_INI_CP
                             * [N_32 * NC_CYL_NR * 3) /10^5 ] / CL_MMV)
                             * C_FAC_FLOW_CAT_PURGE_INI_CP
                             // [mg/stk] -> [kg/h]
endif

// Additionnal initialization in case of RAMP_OPEN_FAST to MAX_PURGE transition:
if    STATE_CP = RAMP_OPEN_FAST
then  FLOW_CPS_OLD_1          = FLOW_CPS
      FLOW_CPS_OLD_2          = FLOW_CPS
      FLOW_DLY_OLD_1_CP       = FLOW_CPS
      FLOW_DLY_OLD_2_CP       = FLOW_CPS
endif
end
```

9.14.1.12.15 INITIALIZATION-VALUES on leaving MAX_PURGE

If the MAX_PURGE operation is disabled or ends, the following actual values for FLOW_CTL_CPS_DI are stored before the interruption of the operation:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. ```

9.14.1.12.16 INITIALIZATION-VALUES on entering RAMP_CLOSE

This submodule is called at every possible transition from any state to RAMP_CLOSE.
On entering RAMP_CLOSE, the initialisations listed below are done.
The Initialization value of FLOW_CTL_CPS for RAMP_CLOSE is the last calculated value of min (FLOW_CTL_CPS, FLOW_MAX_CPS) if the preceding operation was MAX_PURGE. If the RAMP_OPEN operation was preceding the Initialization value is the last calculated value of FLOW_CTL_CPS of the RAMP_OPEN operation.
The only way to enter RC is from another normal_purge state, so LV_CP_CLL has not to be set on the entrance of this state

```
STATE_CLL_DEAC_CP       = CP_NO_DEAC
T_DI_CP                 = 0
PQ_CP_SP                = 1              // In this mode no forced PQ is required
FLOW_TAR_CPS            = 0
if     STATE_CP         = MAX_PURGE
then  FLOW_CTL_CPS      = min [FLOW_CTL_CPS, FLOW_MAX_CPS]
endif
end
```

9.14.1.12.17 INITIALIZATION-VALUES on leaving RAMP_CLOSE

If the RAMP_CLOSE operation is left towards any other state, the following initialisations are done.
LV_STATE_MEM_CP_CLL = 1
end

9.14.2 Canister purge management states

9.14.2.1 NO_PURGE

General information:

In the NO_PURGE state of the Evaporative Emission Control no calculation of the CPS flow set point flow_ctl_cps, the fuel flow from the activated charcoal filter (ACF) MFF_CP, the Canister Load cl and the additive fuel flow for injection correction will be done.

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

call “Time counter for disabled RAMP_OPEN or MAX_PURGE”
end

9.14.2.2 RAMP_TO_NO_PURGE

Formula section:

FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV) * FLOW_FAC_CP
if LV_CP_CMU_CMB
then FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_CMU_CP
elseif LV_CP_CLOSE_1
then FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_1_CP

then FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_2_CP
endif
call “FLOW_CTL_CPS ramping”
call “Time counter for disabled RAMP_OPEN or MAX_PURGE”
end

9.14.2.3 MIN_PURGE

General information:

In the MIN_PURGE state, the CPS flow is calculated from calibration datas depending on combustion mode.
FLOW_TAR_CPS = FLOW_CPS_SP_MIN_PURGE * FAC_FLOW_TAR_COR_CP
if FLOW_CTL_CPS$_{n-1}$ $>$ FLOW_TAR_CPS // actual value higher than SP
then FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV)// decreasing flow
else **if** LV_HOM_ACT = 1
then FLOW_GRD_CPS = IP_FLOW_INC_CP (MFF_SP_MV)
* IP_FLOW_INC_COR_HOM_CP (MAF_CYL) // increasing flow
else FLOW_GRD_CPS = IP_FLOW_INC_CP (MFF_SP_MV) // increasing flow
endif
LV_STATE_MEM_CP_CLL = 0 // transition from normal purge finished
endif
call “FLOW_CTL_CPS ramping”
call “Time counter for disabled RAMP_OPEN or MAX_PURGE”
end

9.14.2.4 WAIT_RAMP_OPEN

General information:

The WAIT_RAMP_OPEN state is reached if the conditions for normal entry in RAMP_OPEN or RAMP_OPEN_FAST are given but the time counter for lambda controller stabilisation is not yet elapsed or CPS adaptation is active. It can only be reached by NO_PURGE.
To speed up the reaction of the lambda sensor in RAMP_OPEN or RAMP_OPEN_FAST, the purge tube may be purged itself for a short instance in WAIT_RAMP_OPEN. Using this functionality, the purge valve is opened rapidly and wide for a very short time to purge the diluted gas in the tubes and fill the purge tubes with "fresh" gas from the ACF.
For the calcuation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) /(kg*ms)] /3600
has to be considered.

Formula section:

if LV_CPS_AD_ACT = 0
then
MAF_INT_CP = MAF_INT_CP + (MAF_CYL * TA /3600) // MAF Integral for Lambda controller stabilisation
T_MAF_INT_CP = T_MAF_INT_CP + TA // Total time of the MAF integration for min/max limitation
T_DLY_CP = **max** [T_DLY_CP$_{n-1}$ - TA, 0] // Purge tube time counter
// "purging the purge tube"
endif
if T_MAF_INT_CP $<$ C_T_CP_PURGE_TUBE
then
FLOW_TAR_CPS = C_FLOW_CPS_SP_PURGE_TUBE
FLOW_GRD_CPS = C_FLOW_CPS_GRD_PURGE_TUBE
else
FLOW_TAR_CPS = 0
FLOW_GRD_CPS = C_FLOW_CPS_GRD_PURGE_TUBE_CLOSE
endif
call "FLOW_CTL_CPS ramping"
end

9.14.2.5 RAMP_OPEN

General information:

After a reset, an engine stall or if a certain time since the last MAX_PURGE operation has passed, the load cl of the canister is considered as not known. In this case the canister load value cl is initialized to a constant value c_cl_st_cp and the CPS is opened slowly, using a ramp function. So a high deviation of the lambda control shall be prevented.
The RAMP_OPEN operation is finished when the fuel flow MFF_CP is greater than a maximum value MFF_MAX_CP or when the CL_MMV value stay in a dynamic window. Then the MAX_PURGE operation starts, if the cl is above a threshold, otherwise the reaction of the system is configurable.
At the end of the RAMP_OPEN operation the remaining time of purge is reevaluated versus Canister Load cl is reevaluated.

Formula section:

call "calculation of PQ_CP_SP" (common)
call "calculation of the flow setpoint" (common)
end

9.14.2.6 RAMP_OPEN_FAST Operation

General information:

After a short interruption of the MAX_PURGE operation the load cl of the ACF stay around the last value calculated. In this case the flow_ctl_cps is calculated as a function of the actual FLOW_CTL_CPS value and the objective value.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

The RAMP_OPEN_FAST operation is finished. when one of the following conditions is set:

- FLOW_CTL_CPS is greater or equal to the value FLOW_TAR_CPS
- The fuel flow MFF_CP is greater than a maximum value MFF_MAX_CP

Then the MAX_PURGE operation starts. If the purge time is elapsed (LV_CP_ENA=0), the RAMP_OPEN_FAST operation ends. the RAMP_CLOSE operation starts immediately.
At the end of the RAMP_OPEN_FAST operation the purge time is reevaluated (see chapter "time scheduler").

Formula section:

PQ_CP_SP =1 // In this mode no forced PQ is required by canister purge
call "calculation of the flow setpoint" (common)
end

9.14.2.7 MAX_PURGE Operation

General information:

The MAX_PURGE operation is started when the RAMP_OPEN operation or the RAMP_OPEN_FAST operation is finished.
The MAX_PURGE operation ends when the purge time is elapsed. Then the RAMP_CLOSE operation starts.
During MAX_PURGE, the time counter T_DLY_MAX_CP is initialised to C_T_DLY_MAX_CP_0/_1. When the MAX_PURGE operation ends or when the MAX_PURGE is disabled, the time T_DLY_MAX_CP starts to count backwards down to 0.

Calculation of FLOW_CTL_CPS for MAX_PURGE
The value of FLOW_CTL_CPS during MAX_PURGE operation is calculated as a function of the filtered canister load CL_MMV and the maximum allowable fuel flow from the CPS MFF_MAX_CP (see flow setpoints module).

Formula section:

call "calculation of PQ_CP_SP" (common)
call "Calculation of LV_T_DLY_REQ_CP"
FLOW_TAR_CPS = **min** [MFF_MAX_CP /CL_MMV, FLOW_MAX_CPS] * FAC_FLOW_TAR_COR_CP
if FLOW_CTL_CPS$_{n-1}$ $>$ FLOW_TAR_CPS // actual value higher than SP
then FLOW_GRD_CPS = IP_FLOW_CPS_DEC (MFF_SP_MV) // decreasing flow
else **if** LV_HOM_ACT = 1
then FLOW_GRD_CPS = IP_FLOW_CPS_INC (MFF_SP_MV) * IP_FLOW_INC_COR_HOM_CP (MAF_CYL)// increasing flow
else FLOW_GRD_CPS = IP_FLOW_CPS_INC (MFF_SP_MV) // increasing flow
endif
endif
(gradient limitation moved here from flow calculation chain)
call "FLOW_CTL_CPS ramping"
Should be limited by ip_..._inc; as mff_max_cp is now moved to flow_sp spec, it may be at a very high value on entrance of a disabled max_purge; in addition, a reasonable fuel_flow_max_cp will we available after latest 100ms (recurrence changed), so for this first 100ms, we should not have flow_ctl_cps being unreasonably high
end

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. 9.14.2.7.1 Calculation of LV_T_DLY_REQ_CP

This management is usefull esssentially during an emision cycle. The aim is to stop the purge in case of request from the catalyst diagnosis (or an other OBD2 diagnosis), one time during the cycle.
LV_T_DLY_REQ_CP is set C_T_DLY_REQ_CP seconds after a Ramp_Open and stay to 1 until next trip or engine stalling.
The flag is set after having been for a time C_T_DLY_REQ_CP in an un-interrupted MAX_PURGE coming from RAMP_OPEN and stay to 1 until next trip or engine stalling .
When coming from any other state than RAMP_OPEN, the flag is not calculated.

Signal flow diagram:

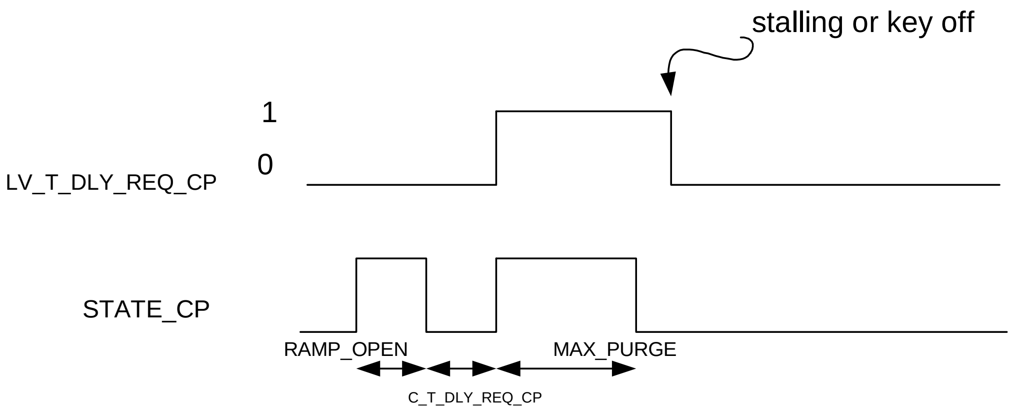

Figure 9.14.4: : LV_T_DLY_REQ_CP

Formula section:

if T_DLY_REQ_CP_TMP > 1h
then T_DLY_REQ_CP_TMP = **max** (1h, T_DLY_REQ_CP_TMP - TA)
endif
if T_DLY_REQ_CP_TMP = 1h
then LV_T_DLY_REQ_CP = 1
endif
end

9.14.2.8 RAMP_CLOSE Operation

General information:

The RAMP_CLOSE operation starts if the purge time is elapsed.
The RAMP_CLOSE operation ends when the value of FLOW_CTL_CPS is equal to 0.

Calculation of FLOW_CTL_CPS for RAMP_CLOSE
When the RAMP_CLOSE operation is activated FLOW_CTL_CPS is decremented. The decrement value depends on the map values of IP_FLOW_DEC_CP. The closing speed of the CPS is so controlled by the mass fuel flow setpoint MFF_SP_MV.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula section:

FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV) * IP_FLOW_FAC_CP (CL)
call "FLOW_CTL_CPS ramping"
end

9.14.3 Common submodules

The keywords in brackets at the end of the headline of each following submodule indicates, by which STATE_CP the corresponding submodule is called. If STATE_CP = CP_NOT_ACT, none of the following submodules is called. The following abbreviations are used:

NP NO_PURGE
RTNP RAMP_TO_NO_PURGE
MinP MIN_PURGE
WRO WAIT_RAMP_OPEN
RO RAMP_OPEN
ROF RAMP_OPEN_FAST
MaxP MAX_PURGE
RC RAMP_CLOSE

9.14.3.1 Time counter for disabled RAMP_OPEN or MAX_PURGE (NP, RTNP, MinP)

General information:

This calculation is called in NO_PURGE, RAMP_TO_NO_PURGE and MIN_PURGE.
If the RAMP_OPEN or the MAX_PURGE operation was interrupted (NO_PURGE, RAMP_TO_NO_PURGE or MIN_PURGE active) and the time counter T_DI_CP is greater than zeor which means that the interrupt-time is lower than the adjustable times C_T_DI_RAMP_OPEN_CP_0/_1 (RAMP_OPEN) or C_T_DI_MAX_CP_0/_1 (MAX_PURGE), a direct switch back to the previous state RAMP_OPEN or MAX_PURGE is possible, if the conditions for this previous state are once again given.
Otherwise (time counter T_DI_CP reached zero), NORMAL_PURGE has to restart with RAMP_OPEN.
TA = recurrence

Formula section:

If (LV_CP_NEW_RAMP_OPEN = 0
and LV_CP_NEW_RAMP_OPEN_FAST = 0
then T_DI_CP$_n$ = **max** [0, T_DI_CP$_{n-1}$ - TA]
else T_DI_CP = 0
endif
T_LOCK_CP$_n$ = **max** [0, T_LOCK_CP$_{n-1}$ - TA]
if T_DI_CP = 0
then STATE_CLL_DEAC_CP = CP_NO_DEAC
endif
if T_LOCK_CP = 0
then STATE_LOCK_CP = UNLOCKED
endif
end

9.14.3.2 Calculation of PQ_CP_SP (RO, MaxP)

General information:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

This calculation is called only in Ramp_Open and MAX_PURGE, and available only in stratified and homogeneous lean burn modes.
In this mode a forced PQ is required by canister purge in order to increase PRS_CPS and to purge with more efficiency. IP_PQ_CP_SP is depending on engine speed and torque setpoint.

Formula section:

if [(LV_HOM_ACT = 0)
or (LV_HOM_AFL_ACT = 1 **and** LC_PQ_SP_CP_HOM_AFL=1)]
then if (CL_MMV $>$ C_CL_MMV_PQ)
then PQ_SP_CP_TMP = IP_PQ_CP_SP (N_32, TQI_SP_S)
else PQ_SP_CP_TMP = 1
endif
PQ_CP_SP$_n$ = PQ_CP_SP$_{n-1}$ +
(PQ_SP_CP_TMP - PQ_CP_SP$_{n-1}$) * C_CRLC_PQ_SP_CP
else PQ_CP_SP$_n$ = 1
endif

9.14.3.3 Calculation of the flow setpoint (RO, ROF)

General information:

This calculation is called in RAMP_OPEN and RAMP_OPEN_FAST.
Old spec: “An additional delay is performed if a linear O2 sensor is used.”
Not defined in SW and spec; should an c_offset be defined?

The opening of the CPS is controlled by the value of FLOW_CTL_CPS. This value describes the flow requested through the CPS. So a too high deviation of the lambda control at transient engine operation should be avoided. The opening sequence is as follows:

- When entering RAMP_OPEN or RAMP_OPEN_FAST, FLOW_CTL_CPS is initialised
- After start or re-start of RAMP_OPEN or RAMP_OPEN_FAST, the system waits for the gas transfer time between CPS valve and upstream lambda sensor (IP_T_DLY_CP).
- When this delay is elapsed or when using a binary lambda control and a transition rich to lean occurs, the next period of increment steps starts. The number of increment steps for this phase is defined from ID_FLOW_INC_NR_CP. This number is defined once at the beginning of the phase. For each increment the FLOW_CTL_CPS increase is fixed by IP_FLOW_INC_CP corrected by IP_FLOW_FAC_CP. The opening speed of the CPS is so controlled by the mass air flow MAF_CYL and the load CL of the activated charcoal canister ACF to avoid lambda regulation deviation.
- After the increment steps are carried out, the function waits again for gas transfer time or binary lambda sensor rich-lean transition.
- FLOW_CTL_CPS is limited to FLOW_TAR_CPS, the target flow setpoint.

The Pjump used depends of the bank selected (see canister load and lambda deviation module). The Pjump is related to gas enrichment.
The aim is to increase the FLOW_CTL_CPS with incremented values to prevent unexpected lambda deviation due to the lambda controller.
The increment number ID_FLOW_INC_NR_CP carried out is tuneable and depending on engine speed.
The time delay will allow to synchronize the flow variation, the gas transfer and the lambda control. As long as the maximum flow FLOW_TAR_CPS is not reached the sequence will start over.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited.          endif
         // T_DLY_CP_OPEN will be set to IP_T_DLY_CP /10
         LV_CP_AFL_IT                   = 1                           // lean
         FLOW_GRD_CPS        = 0
```

This line is not needed: with lc_lam_lin_cps, the variable is always =1 (is initialised to 1 at entry of ro, rof), so no transition can occur.

With lc_lam_lin_cps=0 and lambda control lean lv_cp_afl_it=1; if at the exit of this passage (flow incrementation) lv_cp_afl_it=0, a direct jump again to flow incrementation will occur; not critical as this can just appear with empty canister (otherwise lambda control rich)

Intake manifild model Rbg,. empty canister: lambda control at lean side, perhaps better to wait for 1xrich side, 1x lean side

endif
end

9.14.3.4 FLOW_CTL_CPS ramping

The ramping up and down of the internal flow setpoint FLOW_CTL_CPS is defined by the target (final setpoint to be reached) FLOW_TAR_CPS and the flow gradient (increment rsp. decrement) FLOW_GRD_CPS.

This calculation is applied in all states with any flow ramps.

if FLOW_CTL_CPS$_{n-1}$ $>$ FLOW_TAR_CPS // actual value higher than target
then FLOW_CTL_CPS$_n$ = // decreasing flow
max [FLOW_TAR_CPS, FLOW_CTL_CPS$_{n-1}$ - FLOW_GRD_CPS]

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

T_DLY_CL_MDL$_n$ = T_DLY_CL_MDL$_{n-1}$
Endif

if LV_CP_NEW_RAMP_OPEN = 1
then T_DLY_MAX_CP = 0
endif

if T_DLY_MAX_CP = 0
then LV_CL_CLC_VLD = 0 // switch off int. MIN_PURGE
endif
end

9.14.4.2 Default values for disabled calculations

When the maximum engine speed limitation is reached (LV_N_MAX_CP) some of the calculations for the injection correction must be stopped to decrease the CPU load. If LV_N_MAX_CP is active then the normal calculations of the following variables are not done and the values of these variables are set to 0.

Formula section:

FLOW_SP_CPS = 0
FLOW_COR_CPS = 0
FLOW_CPS = 0
FLOW_TOT_CPS = 0
MAF_CPS = 0
end

9.14.4.3 OBD2 diagnosis activation

General information:
In order to manage the priority between canister purge and catalyst diagnosis or between canister purge and O2 sensor diagnosis, the bit information LV_CP_ACT_REQ will be sent to the diagnosis OBD2 manager. Two cases are possible :

- first of all, when the conditions to purge are set in order to learn the canister load (RAMP_OPEN phase).
- when LV_T_DLY_REQ_CP=1 if the canister load (CL_MMV) is greater than a calibrated value C_CL_MMV_REQ.

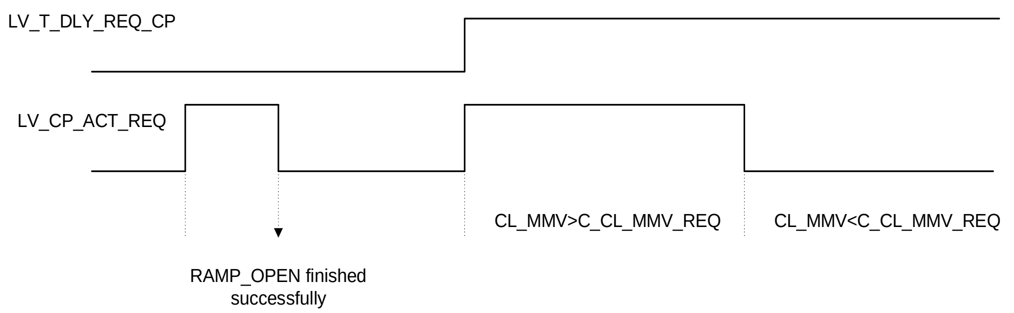

Figure 9.14.6: : LV_CP_ACT_REQ

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LV_CP_ACT_REQ =
[LV_T_DLY_REQ_CP **and** (CL_MMV > C_CL_MMV_REQ)]
or STATE_CP = RAMP_OPEN
end

9.14.4.4 Calculation of FLOW_CPS and FLOW_COR_CPS

The setpoint of the mass flow through the CPS (FLOW_COR_CPS) is calculated using the actual calculated values of FLOW_CTL_CPS, a ramp gradient depending on MAF_CYL and the correction factors on ambient pressure and ambient temperature.
If the OBD II evaporative system monitoring (vaccum method) function is active (LV_DIAGCP_CPS_ACT=1), the opening of the CPS is controlled by the value of FLOW_SP_CPS_EVAP (see chapter OBDII functions).
The opening of the CPS can also be controlled by the application system using the switch LC_FLOW_CPS_AS and C_FLOW_CPS_AS.
The calculation of FLOW_SP_CPS is limited using a gradient value.
In RAMP_OPEN, RAMP_OPEN_FAST, NO_PURGE and RAMP_TOP_NO_PURGE, the gradient limitation is no more applied.
The flow request through the CPS is limited by the physical maximum flow at fully openend valve defined in FLOW_MAX_PHY_CPS (depending on pressure difference ambient air - intake manifold)
The value FLOW_TOT_CPS permits to measure the quantity of flow during an emission cycle.

Signal flow diagrams:

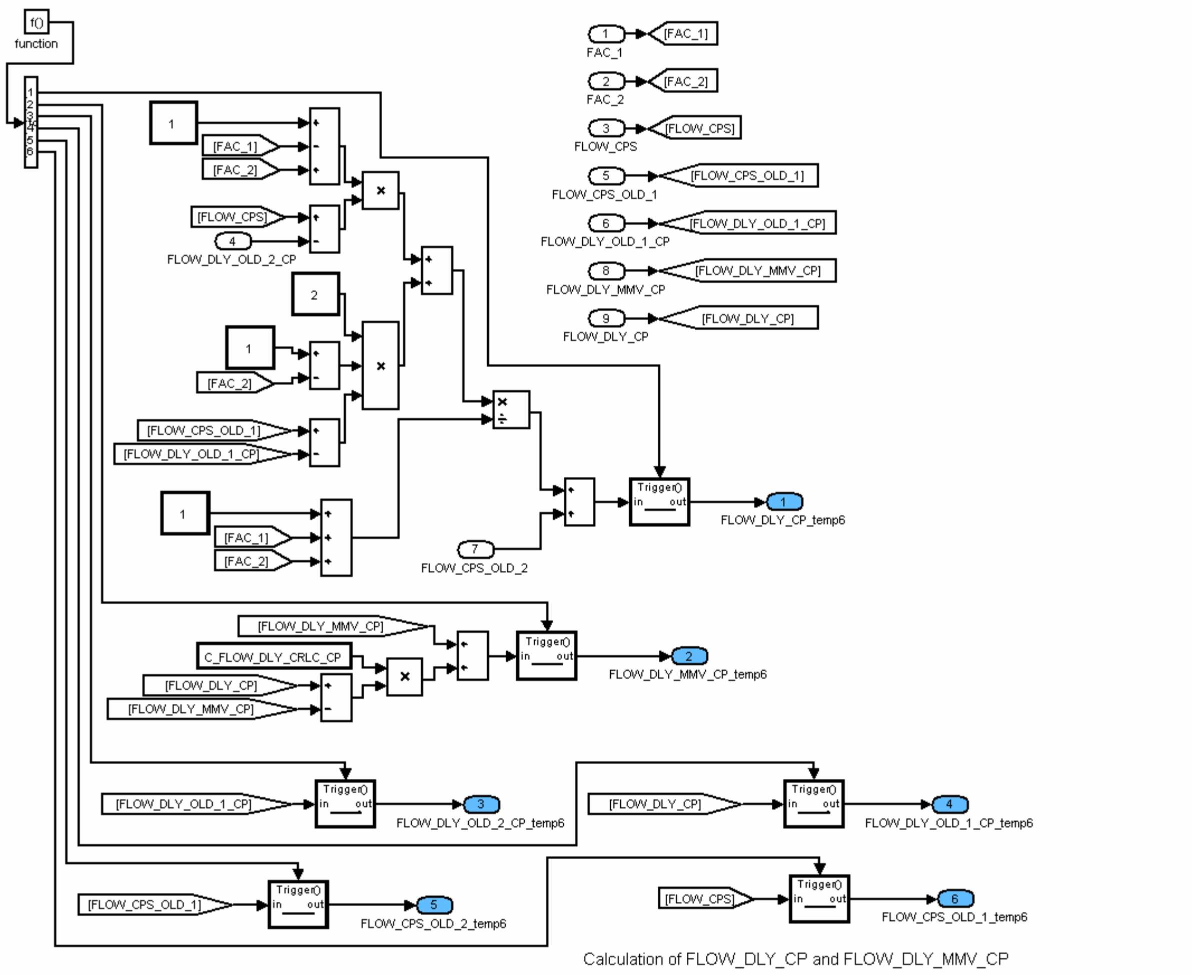

Figure 9.14.8: : calculation of FLOW_DLY_CP and FLOW_DLY_MMV_CP

the calc. of MAF_DLY_CP and MAF_DLY_MMV_CP is done following the same scheme

Formula section:

Padefilter-parameters

if STATE_OPM_ENG_CP = ENG_MODE_0
then FAC_1 = IP_T_DLY_CP (MAF_KGH_FG_PRED_COR_CP)
else FAC_1 = IP_T_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP)
FAC_2 = FAC_1 * FAC_1 /3

Calculation of FLOW_DLY_CP and FLOW_DLY_MMV_CP:
// Pade-filter
FLOW_DLY_CP=
1 /(1 + FAC_1 + FAC_2)
* (1 - FAC_1 + FAC_2)
* (FLOW_CPS - FLOW_DLY_OLD_2_CP)
+ 2 * (1 - FAC_2) * (FLOW_CPS_OLD_1 - FLOW_DLY_OLD_1_CP)
+ FLOW_CPS_OLD_2

// Low pass-filter

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FLOW_DLY_MMV_CP$_n$= FLOW_DLY_MMV_CP$_{n-1}$ +
(FLOW_DLY_CP$_n$ - FLOW_DLY_MMV_CP$_{n-1}$) * C_FLOW_DLY_CRLC_CP

// memorization for next recurrence
FLOW_DLY_OLD_2_CP = FLOW_DLY_OLD_1_CP
FLOW_DLY_OLD_1_CP = FLOW_DLY_CP
FLOW_CPS_OLD_2 = FLOW_CPS_OLD_1
FLOW_CPS_OLD_1 = FLOW_CPS

Calculation of MAF_CP, MAF_DLY_CP and MAF_DLY_MMV_CP:
MAF_CP = MAF_THR + MAF_CPS
Better: MAF_CP, only visible, no output

// Pade-filter
MAF_DLY_CP(n)=
1 /(1 + FAC_1 + FAC_2)
* (1 - FAC_1 + FAC_2)
* (MAF_CP$_n$- MAF_DLY_OLD_2_CP)
+ 2 * (1 - FAC_2) * (MAF_CP_OLD_1 - MAF_DLY_OLD_1_CP)
+ MAF_CP_OLD_2

// Lowpass-filter
MAF_DLY_MMV_CP$_n$= MAF_DLY_MMV_CP$_{n-1}$ +
(MAF_DLY_CP$_n$- MAF_DLY_MMV_CP$_{n-1}$) * C_MAF_DLY_CRLC_CP

// memorization for next recurrence
MAF_DLY_OLD_2_CP = MAF_DLY_OLD_1_CP
MAF_DLY_OLD_1_CP = MAF_DLY_CP
MAF_CP_OLD_2 = MAF_CP_OLD_1
MAF_CP_OLD_1 = MAF_CP

Calculation of MAF_DLY_CPS and MAF_DLY_MMV_CPS:
// Pade-filter
MAF_DLY_CPS(n)=
1 /(1 + FAC_1 + FAC_2)
* (1 - FAC_1 + FAC_2)
* (MAF_CPS$_n$- MAF_DLY_OLD_2_CPS)
+ 2 * (1 - FAC_2) * (MAF_CPS_OLD_1 - MAF_DLY_OLD_1_CPS)
+ MAF_CPS_OLD_2

// Lowpass-filter
MAF_DLY_MMV_CPS$_n$= MAF_DLY_MMV_CPS$_{n-1}$ +
(MAF_DLY_CPS$_n$- MAF_DLY_MMV_CPS$_{n-1}$) * C_MAF_DLY_CRLC_CPS

// memorization for next recurrence
MAF_DLY_OLD_2_CPS = MAF_DLY_OLD_1_CPS
MAF_DLY_OLD_1_CPS = MAF_DLY_CPS
MAF_CPS_OLD_2 = MAF_CPS_OLD_1
MAF_CPS_OLD_1 = MAF_CPS
end

9.15.1 Project specific definition for "Time after start"

General information:

T_AST_CP has to be written in general with T_AST. Only special configurations, e.g. for stop-start functionality, T_AST_CP has to be written with other values (e.g. T_AST_DC).

Application conditions

Initialisation: *T_AST_CP = 0 after reset*

Recurrence: *100ms*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

Activation: `all engine states`

Deactivation: `- -`

Formula section:

T_AST_CP = T_AST

9.15.2 Activation of the Evaporative Emission Control Function

General information:

The Evaporative Emission Control function is activated (LV_CP_ACT=1), if the time after start exceeds IP_T_ST_AST_TCO_ST_CPS_MIN, which depends on coolant temperature after start. The function is active during all engine operating states except the following states:

- engine stopped (LV_ES=1)
- engine start (LV_ST=1)

For the MSA stop/start functionality it is necessary to calculate a seperat T_AST_CP, which represents the time after first start in an driving cycle.

Application conditions

Initialisation: `LV_CP_ACT = 0 after reset or stalling`

Recurrence: `20ms`

Activation:

Deactivation: `- -`

Formula section:

LV_CP_ACT =
[T_AST_CP > IP_T_ST_AST_TCO_ST_CPS_MIN(TCO_ST)
and LV_ES = 0
and LV_ST = 0
and [LV_AST = 0 **or** LC_CP_AST_ACT = 0]
and LC_CP_ACT = 1]

9.15.3 Cross-locking table

General information:

This chapter describes the evaporative emission control inhibition.

9.15.4 Project specific factor for MIN purge flow

General information:

With this function, the MIN_PURGE flow can be varied by a factor from 0 to 4 for vehicles without catalyst and lambda sensors or in case of using different engine operation modes (STATE_OPM_ENG_CP).

Application conditions

Initialisation: FAC_FLOW_COR_CP_EXT = 1 *at reset* FAC_FLOW_COR_CP_MIN_PURGE = 1 *at reset*

Recurrence: *100ms*

Activation: *LV_ST_END = 1*

Deactivation: *LV_ST_END = 0*

Formula section:

If (1) LV_VAR_LSH_UP = 1
Then (1)
If (2) STATE_OPM_ENG_CP = 0
Then (2) FAC_FLOW_COR_CP_MIN_PURGE = 1
Else (2) FAC_FLOW_COR_CP_MIN_PURGE = IP_FAC_REL_FLOW_CPS_WOUT_CAT
Endif (2)
FAC_FLOW_COR_CP_EXT = 1
Else (1) FAC_FLOW_COR_CP_EXT = IP_FAC_REL_FLOW_CPS_WOUT_CAT
FAC_FLOW_COR_CP_MIN_PURGE = 1
Endif (1)

9.15.5 External calculations

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

With this function, it is possible to supply the Evaporative emission control variables function with a measured canister purge differential preasure. For further information on the use of this external differential preasure please refer to chapter Evaporative emission control variables .

Application conditions

Initialisation:	*PRS_CPS_EXT= 0 at reset*
Recurrence:	*20ms*
Activation:	*LV_ST_END = 1*
Deactivation:	*LV_ST_END = 0*

Formula section:

PRS_CPS_EXT = MAP_DIP_MES_BAS_2SEG

9.15.6 Management of LV_CP_CLOSE_CP_x with no OBD sequencer

General information:

This chapter describes the recommendations for evaporative emission control inhibition when no OBD sequencer is used. In this case the flags LV_CP_CLOSE_1, LV_CP_CLOSE_2, and LV_CP_CLOSE_3 must be managed within this module.
Examples that need to close purge are OBD diagnostics for leak detection and catalyst monitor.
Normally the flags LV_CP_CLOSE_CP_x are managed and defined by the OBD sequencer, if there is no sequencer it is recommended to set LC_TLDV_NOT_SEQ =1 and define and calculate these flags in the application inc. spec.
C_STATE_CONF_TLDV_CP and C_STATE_CONF_CAT_CP are used to configure the closing ramp of the CPS valve to inhibit purge during an OBD test.
Values of C_STATE_CONF_TLDV_CP and C_STATE_CONF_CAT_CP:
0: Canister purge remains active, no request to close the valve
1: Canister purge closed with highest speed closing ramp
2: Canister purge closed with medium speed closing ramp
3: Canister purge closed with normal speed closing ramp

Application conditions

Initialisation:
```
at reset or power loss:
 LV_CP_CLOSE_1 = 0  (never changed after initialisation)
 LV_CP_CLOSE_2 = 0  (never changed after initialisation)
 LV_CP_CLOSE_3 = 0  (never changed after initialisation)
```
Recurrence: *only initialisation*

9.15.7 Selection of STATE_OPM_ENG_CP in case of engine operation mode change (OPM_AV)

General information:

This chapter describes the canister purge behaviour in case of changing engine operation mode (OPM_AV).

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Application conditions

Initialisation: *at reset or power loss STATE_OPM_ENG_CP = 0*

Recurrence: 100 ms

Activation: *every engine state*

Formula Section:

STATE_OPM_ENG_CP = ID_STATE_OPM_ENG_CP
Setting of the flag LV_STATE_OPM_CHG_HOM_CP to detect the engine mode change from homogenious (ENG_MODE_0) to stratified (ENG_MODE_1/2) and vice versa and the flag LV_STATE_OPM_CHG_S_CP to detect the schange of the stratified engine mode (ENG_MODE_1 to ENG_MODE_2 and vice versa.

if [(STATE_OPM_ENG_CP$_n$ = ENG_MODE_0
and STATE_OPM_ENG_CP$_{n-1}$!= ENG_MODE_0)

endif

9.15.8 end

9.15.9 Flow Reduction near engine operation mode switch

General information:

The two thresholds for an engine operating mode change is given by the two input values. Around this fuel mass point the flow through the CPS valve is reduced, to prevent disturbences at engine mode change by canister purge.

Application conditions

Initialisation: all values = 0 at reset

Recurrence: 20 ms

Activation: *every engine state*

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Formula Section:

NC_NR_CP_BUF	-	0... FFH	0... 255	1	-
Size of the fuel buffer FUEL_FLOW_ADD_BUF					

Input data table order: External inputs - Inputs from other EVAC modules

General information:

When the Evaporative Emission Control is active, the fuel injection is corrected by an additive value MFF_ADD_LAM_CP to avoid emission and driveability problems caused by the fuel flow through the CPS. This correction is done all the time.
During RAMP_OPEN when the lambda control is shifted the buffer will be initialized to the last MFF_ADD_CP_KGH value.
The MFF_BUF_CP value is calculated to take into account the distance between the CPS VALVE and the injectors.
The value MFF_ADD_LAM_CP is added with a minus sign to the total formula of the injection calculation (see chapter INJECTION).
The value MFF_TOT_CP allow to measure the quantity of fuel during an emission cycle.
After the initialization phase the buffer must be calculated all the time, in order to have the buffer empty when the evaporative function is stopped.

Application conditions

Initialisation:
```
at reset and engine stop
   MFF_TOT_CP                    = 0
```

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

```
 at reset, engine stop and deactivation
MFF_ADD_BUF[all]                   = 0
 MFF_BUF_CP                        = 0
 MFF_ADD_LAM_CP                    = 0
 MFF_CPS                           = 0
 MFF_ADD_CYL_CP                    = 0
 TQI_ADD_CP                        = 0

9.16.2 Handling of the ring buffer

The recurrence of this subchapter is configurable by LC_FLOW_CPS_CAL:
if LC_FLOW_CPS_CAL=0 then reccurency **20** ms
if LC_FLOW_CPS_CAL=1 then reccurency **40** ms
The buffer MFF_ADD_BUF has NC_NR_CP_BUF elements
IDX_CP, IDX_RD_CP and IDX_STEP_CP are pointers within the ring buffer; they have to be checked for exceeding the limits of the ring buffer.
IDX_CP is the current position within the ring buffer MFF_ADD_BUF. This position is incremented every 20 rsp. 40 ms, depending on LC_FLOW_CPS_CAL

Formula section:

Correction of MAF_KGH_FG_PRED (MAP and TIA)

```
If      STATE_OPM_ENG_CP = ENG_MODE_0
        Then MAF_KGH_FG_PRED_COR_CP = MAF_KGH_FG_PRED *                 IP_
MAF_KGH_PRED_COR_MAP_TIA(MAP,TIA)
        Else  MAF_KGH_FG_PRED_COR_CP = MAF_KGH_FG_PRED *               IP_
MAF_KGH_PRED_COR_MAP_TIA_2(MAP,TIA)
```

// The overflow handling of the buffer indices is not described here and has to be done software-internal

```
// reading
If LC_MAF_COR_ACT_CP = 0
then
        if      STATE_OPM_ENG_CP = ENG_MODE_0
        then    IDX_RD_CP       = IDX_CP - IP_MFF_DLY_CP (MAF_CYL)
        else    IDX_RD_CP       = IDX_CP - IP_MFF_DLY_CP_2 (MAF_CYL)
        endif
else
        if      STATE_OPM_ENG_CP = ENG_MODE_0
                then        IDX_RD_CP       = IDX_CP -
                IP_MFF_DLY_CP (MAF_KGH_FG_PRED_COR_CP)
        else    IDX_RD_CP       = IDX_CP -
           IP_MFF_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP)
        endif
endif
```

BUF_OUT_CP = MFF_ADD_BUF[IDX_RD_CP] * MAF * N_32 * NC_CYL_NR * 3 / 10^5

```
// writing   IDX_STEP_CP elements are filled
if      MFF_ADD_CP_KGH = 0
then    BUF_INP_CP = 0
else    BUF_INP_CP      = MFF_ADD_CP_KGH /
              (max(MAF_THR,C_MAF_THR_MIN_BUF_CP) + MAF_CPS)
endif
if      LV_FAC_LAM_SHIFT_CP =1
        then  MFF_ADD_BUF [all]     = BUF_INP_CP
              BUF_OUT_CP            = MFF_ADD_CP_KGH
              MFF_BUF_CP            = MFF_ADD_CP_KGH
```

```
        else   if STATE_OPM_ENG_CP = ENG_MODE_0
               then IDX_STEP_CP    = IP_IDX_STEP_CP (MAF_KGH_FG_PRED_COR_CP)
               else  IDX_STEP_CP    =
                IP_IDX_STEP_CP_2 (MAF_KGH_FG_PRED_COR_CP)
               endif
               for k = IDX_CP to IDX_CP + IDX_STEP_CP do
                      MFF_ADD_BUF[k] = BUF_INP_CP
               endfor
        endif
// moving the position index
IDX_CP = IDX_CP + IDX_STEP_CP + 1

// final filtered buffer output
    MFF_BUF_CP_n     = [MFF_BUF_CP_n-1 + IP_CRLC_MFF_BUF_CP (MAF_CYL)
                            * (BUF_OUT_ CP - MFF_BUF_CP_n-1)]
 end
```

calibration hint:

If a modification of the recurrence of the ring buffer is done (modification on LC_FLOW_CPS_CAL), the delay times, which are calibrated as index, have to be updated according to the new recurrence.

9.16.3 Injection correction calculation

This correction is applied for homogeneous mode only. In stratified mode, correction is applied by torque (see next paragraph)

init of TQI_ADD_CP for robustness reasons

is engine speed check for >0 necessary? if engine speed = 0, canister purge will be deactivated!

```
if      N_32 > 0
then  MFF_ADD_LAM_CP    = (MFF_BUF_CP * 10^5) /(N_32 * NC_CYL_NR * 3)
else  MFF_ADD_LAM_CP    = 0
endif
MFF_ADD_CYL_CP = MFF_ADD_LAM_CP
TQI_ADD_CP             = 0
end
```

9.16.4 Torque Correction calculation

During stratified combustion, the impact of the premixed fuel flow coming from the CPS has to be compensated in an alternative way. It was demonstrated that the torque increase due to canister purge is dependent on the mass fuel flow from the CPS, the engine speed, and, additionally, on the mass flow of fuel that originates from the injector. The corrective torque will be calculated in the project spezific Torque coordination.

Formula section:

```
if      N_32 > 0
then  MFF_CPS            = MFF_BUF_CP * 10^5 /(N_32 * NC_CYL_NR * 3)
else  MFF_CPS = 0
endif
MFF_ADD_CYL_CP = MFF_CPS
```

DI version

Input data table order: External inputs - Inputs from other EVAC modules

General information:

This module calculates the lambda deviation caused by the opening of the CPS valve and a canister load value using the lambda deviation value. The canister load is the concentration of fuel vapors within the mixture flow coming from the ACF.
The opening period cppwm of the CPS is controlled in dependence with the canister load CL.

Application conditions

Initialisation:

```
at RST, IGKON or deactivation
   all values = 0
   CL          = C_CL_ST_CP
   CL_MMV  = C_CL_ST_CP
   At first initialisation or NVMY error:  LAMB_MMV_0_GRD_
CP= 1
```

Recurrence: *20 ms*

Activation: *LV_CP_ACT = 1*

Deactivation: *LV_CP_ACT = 0*

9.17.1 INITIALIZATION of AMP_ST_PRS_MEM_CP

Save the first valid ambient preasure AMP once after reset:

Application conditions

Initialisation: *AMP_ST_PRS_MEM_CP = 0 at RST*
Recurrence: ***100*** *ms*
Activation: – –
Deactivation: – –

if LV_ERR_AMP = 0 **and** LV_END_DIAG_AMP = 1 **and** AMP_ST_PRS_MEM_CP = 0
then AMP_ST_PRS_MEM_CP = AMP
end

9.17.2 INITIALIZATIONS on STATE_CP transitions

The following submodules are to be calculated on transitions between the different states of canister purge control.
To follow a transition in CP control module, STATE_CP and STATE_CLL_DEAC_CP have to be memorised in this module.
At the case of STATE_OPM_ENG_CP != MODE_0 the intialization value for CL and CL_MMV is corrected in the direction of the last known CL_MMV. The correction can be weighted and limited.
Problem: in cp-ctrl spec, STATE_CLL_DEAC_CP is reset after performing the inits of the entered state, so this reset of STATE_CLL_DEAC_CP will occur before the check of STATE_CLL_DEAC_CP in cl-spec. Therefore, a local copy of STATE_CLL_DEAC_CP   STATE_DEAC_CP_MEM is needed!

Formula section:

if STATE_CP   STATE_CP_MEM // transition detected
then **if** STATE_CP_MEM = RAMP_OPEN
then **call** “INITIALIZATION-VALUES on leaving RAMP_OPEN”
if STATE_CP = MAX_PURGE
and FAC_LAM_DIF_CP $>$ 0

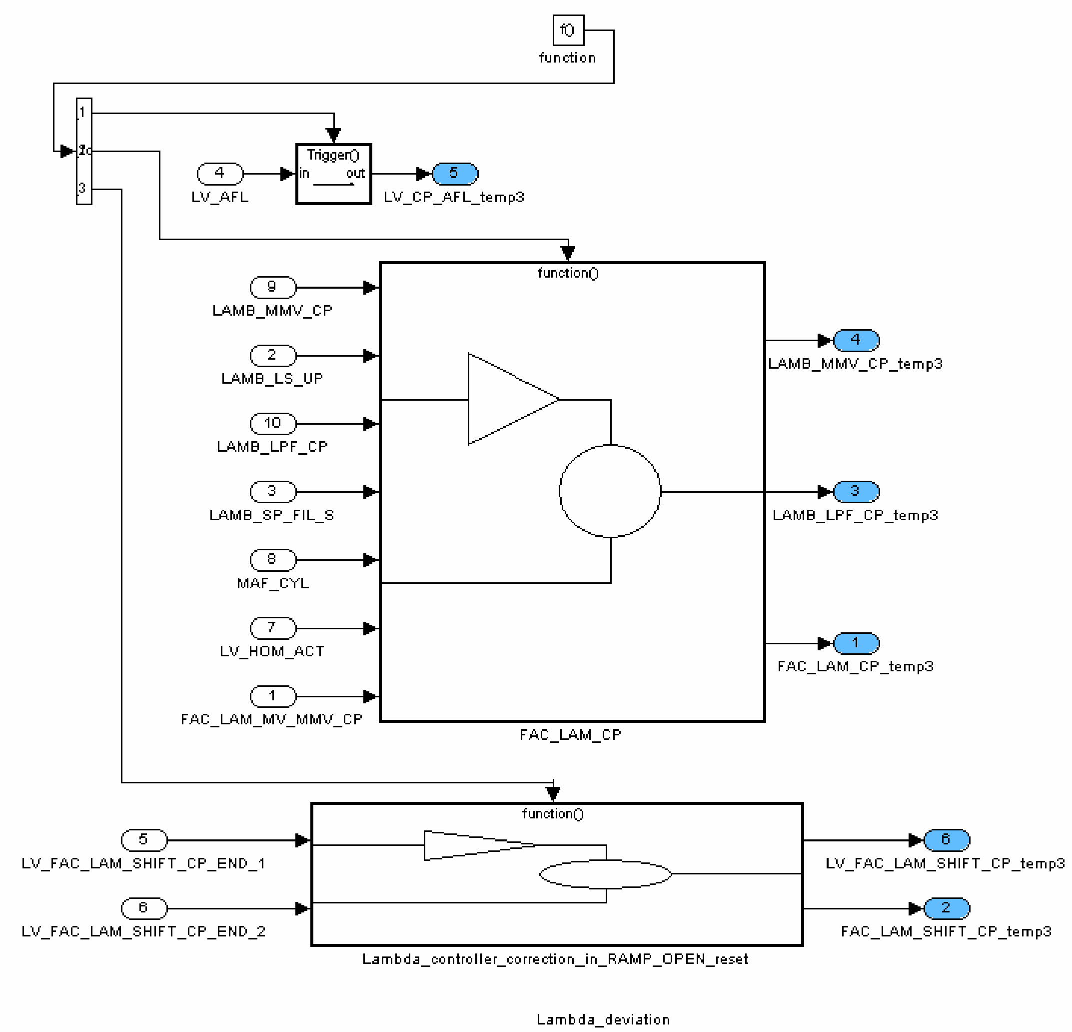
9.17.3 Lambda deviation

In case of two bank exhaust line configuration, the master-exhaust bank for evaporative emission control has to be defined using LC_LAM_CBK_CPS.
The additive constant C_FAC_LAM_DIF_CP_AS should be set to 0 in normal operation; it is only provided for validation purposes
The calculation of the filtered mean value of lambda controller output FAC_LAM_MV_MMV_CP is done inside LACO aggregate. Indeed, the filter constant for this calculation - CRLC_FAC_LAM_MV_MMV_CP - is provided by this module, depending on the STATE_CP.
In open loop, a strong filtering is desired to obtain a stable value for FAC_LAM_0_CP on entering the closed loop. Within the closed loop operation, the filtering should be less severe in order to enable a quick learning of CL and fast reactions on lambda deviations caused by canister purge.



Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

9.17.3.2 Lambda controller correction in RAMP_OPEN (reset)

The flag requesting a shift of the lambda controller LV_FAC_LAM_SHIFT_CP is reset after all acknowledge flags from lambda controller are received.

Formula section:

if LV_FAC_LAM_SHIFT_CP_END [i] = 1 // all benches have to be =1
then LV_FAC_LAM_SHIFT_CP = 0
FAC_LAM_SHIFT_CP = 0
endif
end

9.17.4 Calculation of MFF_CP

General information:

This calculation is calculated in RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE and RAMP_CLOSE. The fuel flow from the ACF when the CPS is opened causes a deviation of the lambda control. This fuel flow can be calculated as a function of the difference of the lambda control values with closed /opened CPS, the mass air flow MAF_DLY_MMV_CP, the lambda value LAMB_LPF_CP and a constant taking into account the stoiciometric ratio C_RAF_CLC_CP.
The mass air flow MAF_DLY_MMV_CP is the filtered value of maf_cp using a Pade-filter and a moving mean value calculation to consider the delay time between the mass air flow maf_cp and the FAC_LAM_CP calculation. The fuel flow calculation MFF_LAM_CP is the result of the lambda control deviation.
The additive adaptive fuel mass flow MFF_ADD_CP_KGH caused by the canister purge is also regarded in the calculation.
When the deviation of the lambda control FAC_LAM_DIF_CP exceeds C_FAC_LAM_DIF_MAX_CP during RAMP_OPEN operation or when the RAMP_OPEN operation is finished successfully, the fuel injection time is corrected by an additive correction value and the lambda controller value FAC_LAM_CP is corrected by the value of FAC_LAM_DIF_CP. FAC_LAM_DIF_CP is then set to 0 because the lambda deviation is corrected.
During MAX_PURGE. RAMP_OPEN_FAST and RAMP_CLOSE operation there is a continuous additive adaptive correction of the fuel. The additive fuel flow MFF_ADD_CP_KGH is calculated from the calculated mass flow through the CPS FLOW_CPS and the filtered canister load CL_MMV.
During RAMP_OPEN, the MFF_ADD_CP_KGH is updated as soon as FAC_LAM_DIF_CP exceeds the threshold C_FAC_LAM_DIF_MAX_CP and a last time on the transition RAMP_OPEN to MAX_PURGE, so MFF_ADD_CP_KGH will change periodically during RAMP_OPEN. If RAMP_OPEN is disabled for a short time, the current value of MFF_ADD_CP_KGH is stored in MFF_ADD_CP_OLD on leaving RAMP_OPEN and restored on re-entering RAMP_OPEN (see initialisations).

Formula section:

endif
end

9.17.5 Calculation of the Canister Load CL, CL_MMV

General information:

This calculation is called in RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE and RAMP_CLOSE.
The load CL of the ACF is calculated as the ratio of the fuel flow MFF_LAM_CP and the flow FLOW_DLY_MMV_CP added to the ratio of the fuel flow MFF_ADD_CP_KGH and the flow FLOW_CPS.
The flow FLOW_DLY_MMV_CP is the filtered value of FLOW_CPS using a Pade-filter and a moving mean value calculation to consider the delay between the FLOW_CPS and the MFF_LAM_CP calculation. Those calculations are described in a separate chapter.
The minimum and maximum values of this ratio are limited by 0 and C_CL_MAX_CP. The value of CL is filtered using a moving mean value calculation. The value of CL is only calculated when the engine is operated at limited dynamics (LV_CP_DYW=1).

Note: All values of IP_CL_CRLC_INI have to be bigger than the highest value of IP_CL_CRLC; otherwise, the filter constant CRLC_CL will be unstable.

9.17.5.3 CL value conformity check :

General information:

This calculation is called in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE.
When the calculation of the canister load create a high difference between the previous value CL_{n-1} and the new value CL_n a transition to MIN_PURGE is requested by setting of LV_CL_GRD_CHK_MAX.

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LV_CL_GRD_CHK_MAX = [**abs** [CL$_{n-1}$ - CL$_{n}$] $>$ C_CL_DYW_MAX_CP]
end

9.17.6 CL_MMV evaluation for homogeneous engine operation mode request

Homogeneous lambda one combustion is requested by setting of the bit information LV_LAMB_AFS_CP (see chapter "Calculation of LV_LAMB_AFS_CP"). Two possibilities are given. If the canister load CL_MMV is greater then the threshold IP_CL_MMV_HOM_PRS_UP_CP. The threshold is taken from a map depending on the difference between the ambient preasure at reset and the actual ambient preasure. The bit information is reset if the canister load falls below the threshold IP_CL_MMV_HOM_PRS_DOWN_CP. The setting and reseting of the bit LV_LAMB_AFS_CP is debounced by the counters ABS_LAMB_AFS_CP.
The other possibility is given for lower CL_MMV values, if the vehicle drives not in the city. There is the increasement for purge flow much bigger then driving in the city. During driving in the city the fuel consumption increase is too high to request homogenious mode.

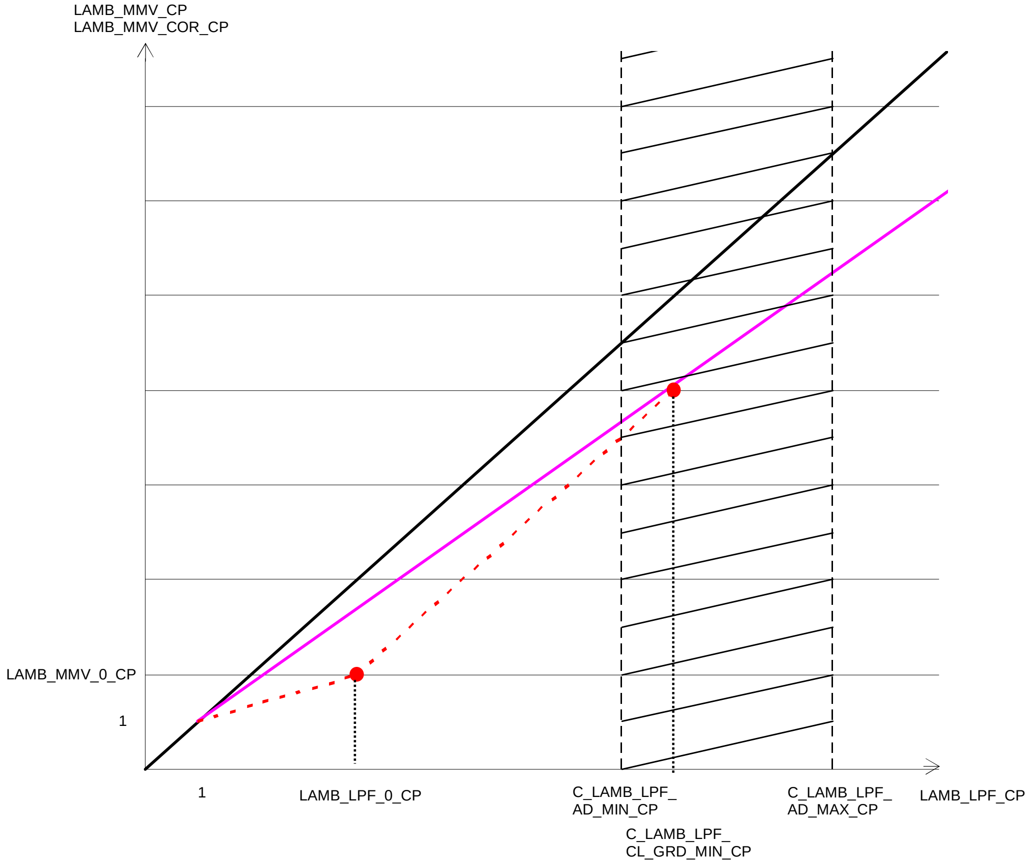
9.17.7 Adaptation of FAC_LAM_0_CP in stratified mode

In stratified mode it is necessary to adapt the start value of the lambda deviation concerning to the lambda setpoint during canister purge. The deviation between lambda setpoint and measured lambda value is component specific. Therefor a straigt line is approximated at everv start of RO or ROF. If the lambda setpount is in a defined window, the straight line will be adapted to the actual start value. Out of this straight line, a corrected lambda value LAMB_MMV_COR_CP will be calculated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



9.17.7.1 Initalisation at RO and ROF for FAC_LAM_0_CP correction at stratified mode

At initialization of RO or ROF the filtered lambda and lambda setpoint are stored.

LAMB_MMV_0_CP = LAMB_MMV_CP
LAMB_LPF_0_CP = LAMB_LPF_CP
T_CP_PER_RUN_CP = 0

9.17.7.2 Calculation of the straight line for LAMB_MMV_COR_CP

If LAMB_LPF_CP is in the window of C_LAMB_LPF_AD_MIN_CP and C_LAMB_LPF_AD_MAX_CP the straight line will be learned. The straight line is defined by the sampling point [LAMB_LPF_CP=1; LAMB_MMV_CP=1] and the gradient LAMB_MMV_0_GRD_CP.
if ((LAMB_LPF_CP $>$ C_LAMB_LPF_AD_MIN_CP)
and (LAMB_LPF_CP $<$ C_LAMB_LPF_AD_MAX_CP))
then

// new gradient calculated by the sampling points 1;1
and LAMB_MMV_0_CP; LAMB_LPF_0_CP //
LAMB_MMV_0_GRD_NEW_CP = (LAMB_MMV_CP-1)/(LAMB_LPF_CP-1)

// Filter for the gradient of the straight line //
LAMB_MMV_0_GRD_CP$_n$= LAMB_MMV_0_GRD_CP$_{n-1}$+
(LAMB_MMV_0_GRD_NEW_CP- LAMB_MMV_0_GRD_CP$_{n-1}$)
*C_CRLC_ LAMB_MMV_0_GRD_CP

T_LAMB_MMV_COR_UPD_CP = 0

endif

9.17.7.3 Calculation of corrected FAC_LAM_0_CP in stratified

In stratified mode the value FAC_LAM_0_CP has to be corrected if the lambda setpoint changes. The calculation of the straight line depends on LAMB_LPF_CP and the start value LAMB_LPF_0_CP. If the start value is bigger then C_LAMB_LPF_AD_MIN_CP, the LAMB_MMV_COR_CP value will be on the solid line. If the start value is smaller then C_LAMB_LPF_AD_MIN_CP the value LAMB_MMV_COR_CP will be on the dotted line for LAMB_LPF_CP smaller then > C_LAMB_LPF_CLC_GRD_MIN_CP.

```
if      LC_FAC_LAM_0_COR_ACT_CP = 1
then
        if      (LAMB_LPF_0_CP   > C_LAMB_LPF_AD_MIN_CP or
                  LAMB_LPF_CP > C_LAMB_LPF_CLC_GRD_MIN_CP)
        then            // LAMB_MMV_COR_CP is on the solid straight line //
                LAMB_MMV_COR_CP = 1 + [LAMB_MMV_0_GRD_CP *(LAMB_LPF_CP - 1)]
                // linear equation with the sampling points 1;1 and the gradient
                // LAMB_MMV_0_GRD_CP
        elseif LAMB_LPF_CP > LAMB_LPF_0_CP
        then  LAMB_MMV_0_TMP_CP =
                        1+ [LAMB_MMV_0_GRD_CP * (C_LAMB_LPF_CLC_GRD_MIN_CP - 1)]
                // y-value for the sampling point C_LAMB_LPF_CLC_GRD_MIN_CP,
                // needed for the calculation of the dotted straight line
                LAMB_MMV_COR_CP = LAMB_MMV_0_CP +
                                [(LAMB_MMV_0_TMP_CP - LAMB_MMV_0_CP) *
                                (LAM_LPF_CP - LAMB_LPF_0_CP)/
                                (C_LAMB_LPF_CLC_GRD_MIN_CP - LAMB_LPF_0_CP)]
                // linear equation with the sampling points LAMB_LPF_0_CP;LAMB_MMV_0_CP
                // and C_LAMB_LPF_CLC_GRD_MIN_CP; LAMB_MMV_0_TMP_CP
                else   LAMB_MMV_COR_CP =
                        1 + [(LAMB_MMV_0_CP-1) * (LAMB_LPF_CL-1) /(LAMB_LPF_0_CP-1)]
                // linear equation with the sampling points 1;1 and
                // LAMB_LPF_0_CP;LAMB_MMV_0_CP
                endif
        endif
        FAC_LAM_0_CP = (LAMB_MMV_COR_CP - LAMB_LPF_CP) /LAMB_LPF_CP
else   FAC_LAM_0_CP = (LAMB_MMV_0_CP - LAMB_LPF_0_CP) /LAMB_LPF_0_CP
endif
```

9.17.7.4 Time management for valid FAC_LAM_0_CP at stratified mode

The run time of the current purge period is measured in T_CP_PER_RUN_CP. This time is compared with a thereshold caculated on the time since the last adaption of the straight line T_LAMB_MMV_COR_UPD_CP and the difference between the lambda setpoint at start of the purge period and the current setpoint. The threshold is weighted with a factor depending on the canister load.

```
T_CP_PER_RUN_CP = T_CP_PER_RUN_CP + 0.2
LAMB_LPF_DIF_IT_CP = ABS(LAMB_LPF_0_CP - LAMB_LPF_CP)
if      (LV_HOM_ACT = 0)
        & (T_CP_PER_RUN_CP >
        (IP_T_CP_PER_END_CP(LAMB_LPF_DIF_IT_CP,T_LAMB_MMV_COR_UPD_CP)
        *IP_T_CP_PER_END_COR_CP(CL_MMV)))
then   LV_CP_PER_END_REQ_S_CP = 1
else   LV_CP_PER_END_REQ_S_CP = 0
endif
```

9.17.8 Open loop calculations

Formula section:

In NO_PURGE, & WRO, lv_state_mem_cp_cll=0, in min_purge, it is reset when the transition is finished, rtnp itself is left to no_purge, when the transition is finished

if LV_CL_MDL_ACT = 1
then CL_MMV_n = CL_MDL
else CL_MMV_n = CL_MMV_{n-1}
endif
if LV_STATE_MEM_CP_CLL
or LV_CL_MDL_ACT = 1
then MFF_ADD_CP_KGH = CL_MMV * FLOW_CPS
else MFF_ADD_CP_KGH = 0
endif
CL_n = CL_{n-1} // no calculation
if LV_CL_MDL_ACT = 1
then MFF_CP = MFF_ADD_CP_KGH
else MFF_CP = 0
endif
(moved to lambda deviation)
LV_CL_GRD_CHK_MAX = 0
FAC_LAM_DIF_CP = 0
LV_CP_PER_END_REQ_S_CP = 0
end

9.17.9 Calculation of LV_LAMB_AFS_CP

General information:

A commutation to homogeneous lambda one combustion with the flag LV_LAMB_AFS_CP is requested if a short circuit to the ground of the CPS is detected, if the CL-MMV evaluation or the CPS adaptation request this mode. As CL_MMV is only evalutated in closed loop operation, there is the risk of getting stuck in homogeneous operation. Therefore timers limit the request for both criteria (T_AST and AMP) to an applicable time after which a homogeneous request is cancelled.

Application conditions

Initialisation: *all values = 0* *at RST or IGKON*
Recurrence: ***20*** *ms*
Activation: *- - (called by superior block)*
Deactivation: *- - (called by superior block)*

Formula section:

// Timer calculation
T_LAMB_AFS_T_AST = **max**[T_LAMB_AFS_T_AST - TA, 0]
T_LAMB_AFS_AMP_VLD_CP = **max[**T_LAMB_AFS_AMP_VLD_CP - TA, 0**]**
T_LAMB_AFS_T_AST_VLD_CP = **max[**T_LAMB_AFS_T_AST_VLD_CP - TA, 0**]**

if (LV_LAMB_AFS_T_AST_CP = 1 **and** VS $>$ C_VS_MIN_LAMB_AFS)

(T_LAMB_AFS_T_AST > 0 **and** T_LAMB_AFS_T_AST_VLD_CP > 0**)]**

end

9.17.10 Engine operating point window

General information:

If the operating point (N,MFF) has a big distance to the operating point stored at entering RO or ROF at stratified engine mode, it is useful to start a new purge phase, due to imprecision in the lambda signal. If the engine operating point will exceed a small window (window_1), the CL-model will be activated, if the CL-model is not valid, a new RO or ROF will be requested. If the operating point will exceed a large window (window_2), a new RO or ROF will be requested.

Formula section:

General information:

The evaporative emissions of the fuel tank system are stored in an activated charcoal filter ACF to prevent an escape of the gas to the environment. The loading capacity of the filter is limited, so the filter must be purged temporarily. Therefore the canister purge solenoid CPS. that is positioned between the charcoal filter and the intake manifold is opened by the engine management system. To prevent driveability and emission problems, the opening of the CPS and the purge flow MFF_CP must be controlled.
With the canister load modelling function (CL-Model), the continuity of the CL factor over time during phases of disturbed calculation is guarantied. Therefore the canister load CL will be substituted with the output of a SIMULINK model, which is a calculation result of a normalized exponential function.

9.18.3 Canister Load modelling

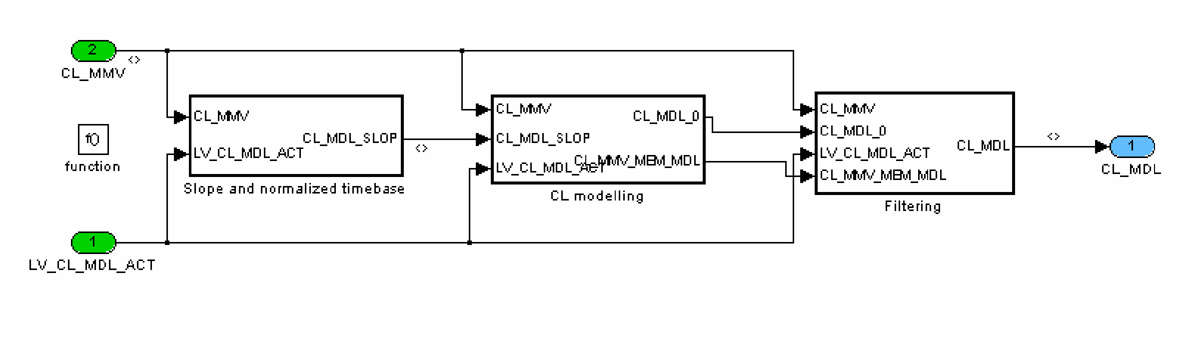

Figure 9.18.1: : structure of the canister load model

Formula section:

call “Slope and normalized timebase”
call “Modelling and output of CL_MDL”
call “Evaluation CL versus CL_MDL”
end

Calculation information:

The overview shows that the complete function is divided into three submodules, the used inputs are the recurrence time described in chapter Application conditions, the logical value LV_CL_MDL_VALUE_ ACT indicating instationary driving conditions it is the result of the Data Type Conversion block with STATE_CDN_CL_MDL as input and the value of Canister Load.
The outgoing CL_MDL value is chosen via a switch block between either the Canister Load during stationary driving conditions at the one hand and the modelled Canister Load Load during instationary driving conditions at the other hand indicated by the variable LV_CL_MDL_VALUE_ACT.

9.18.3.1 Slope and normalized timebase

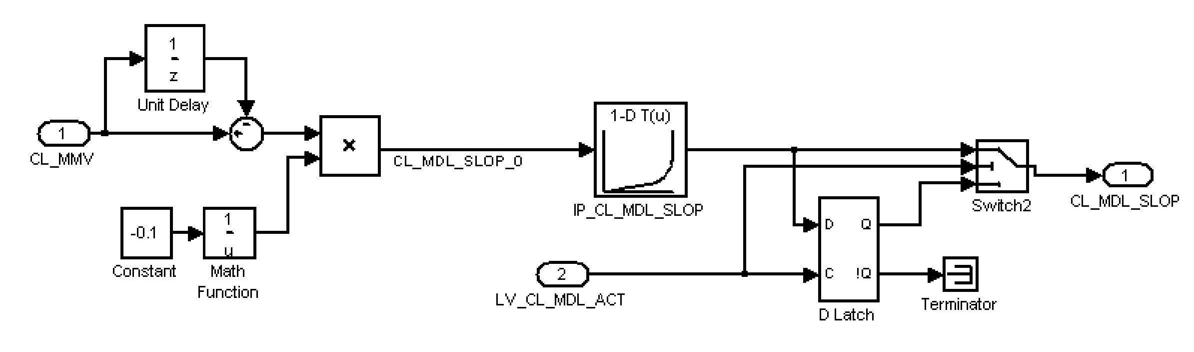

Figure 9.18.2: : slope and normalized timebase

This submodule calculates the (inverted) slope of CL_MMV by building the difference CL_MMV$_n$ minus CL_MMV$_{n-1}$. The slope is used with the Map IP_CL_MDL_SLOP to read out the normalized time

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

constant CL_MDL_SLOP which indicates the time position on a exponential function using the slope as an input. The outgoing CL_MDL_SLOP value is frozen when LV_CL_MDL_ACT=1.

Formula section:

if LV_CL_MDL_ACT = 0
then CL_MDL_SLOP_0 = -(CL_MMV_MEM_CL_MDL-CL_MMV_MEM_CL_MDL_OLD)
CL_MDL_SLOP = IP_CL_MDL_SLOP (CL_MDL_SLOP_0)
else CL_MDL_SLOP_n = CL_MDL_SLOP_{n-1}
endif
end

9.18.3.2 Modelling and output of CL_MDL

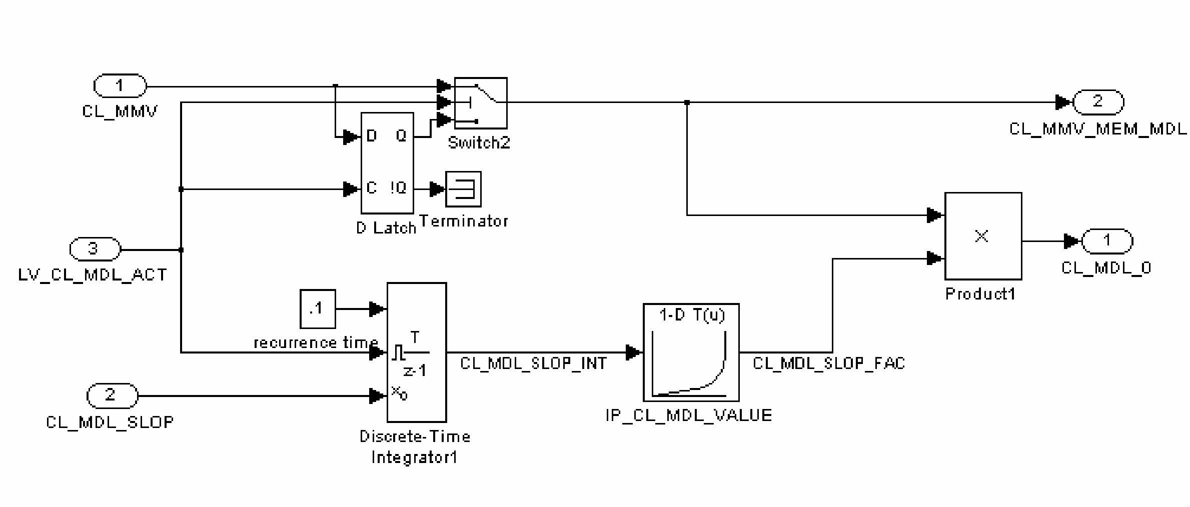

Figure 9.18.3: : modelling and output of CL_MDL

The output of IP_CL_MDL_VALUE is the normalized value of CL_MDL over $\text{CL\_MDL\_SLOP}_{integral}$. The input of IP_CL_MDL_VALUE is calculated with the Discrete-Time Integrator block. The starting point of integration is CL_MDL_SLOP.

Formula section:

if LV_CL_MDL_ACT = 0
then CL_MDL_0 = CL_MMV_MEM_CL_MDL
CL_MMV_MEM_MDL = CL_MMV_MEM_CL_MDL
CL_MDL_SLOP_INT = 0
else CL_MDL_SLOP_INT = $\text{CL\_MDL\_SLOP\_INT}_{n-1}$ + CL_MDL_SLOP
CL_MDL_SLOP_FAC = IP_CL_MDL_VALUE (CL_MDL_SLOP_INT)
CL_MDL_0 = CL_MMV_MEM_MDL * CL_MDL_SLOP_FAC
end

9.18.3.3 Evaluation CL_MMV versus CL_MDL

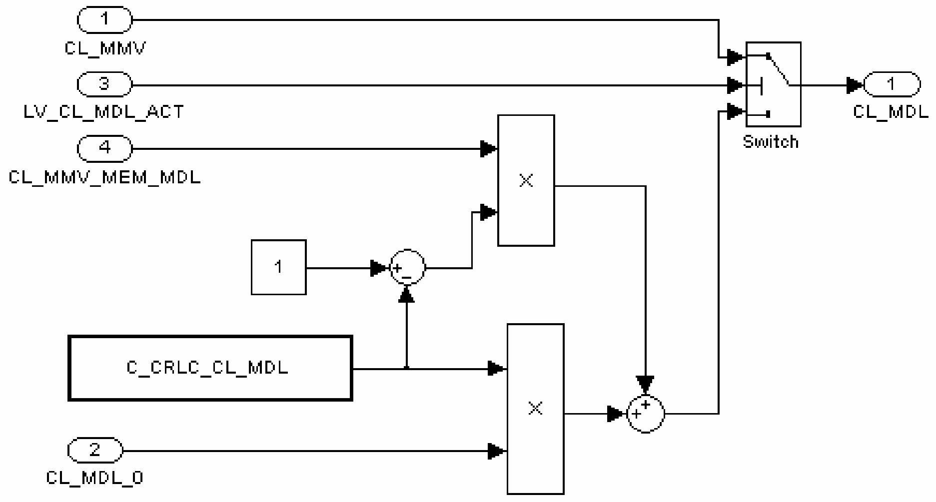

Figure 9.18.4: : evaluation CL versus CL_MDL

This submodul evaluates the CL_MMV_MEM_MDL value (frozen if LV_CL_MDL_ACT) versus the CL_ MDL_0 value by using the filter constant C_CRLC_CL_MDL.

Formula section:

if LV_CL_MDL_ACT = 0
then CL_MDL = CL_MMV
else CL_MDL = CL_MDL_0 * C_CRLC_CL_MDL
+ CL_MMV_MEM_MDL * (1-C_CRLC_CL_MDL)

end

Input data table order: External inputs - Inputs from other EVAC modules

General information:

Lambda adapation and canister purge both use a lambda deviation for their purposes. Indeed, as the canister purge itself causes a certain lambda deviation, both functions can not work simultaneous. As a consequence, a time management has to be installed partitioning the engine opertating time and enabling either canister purge or lambda adaptation while disabling the other function.

Signal flow diagram:

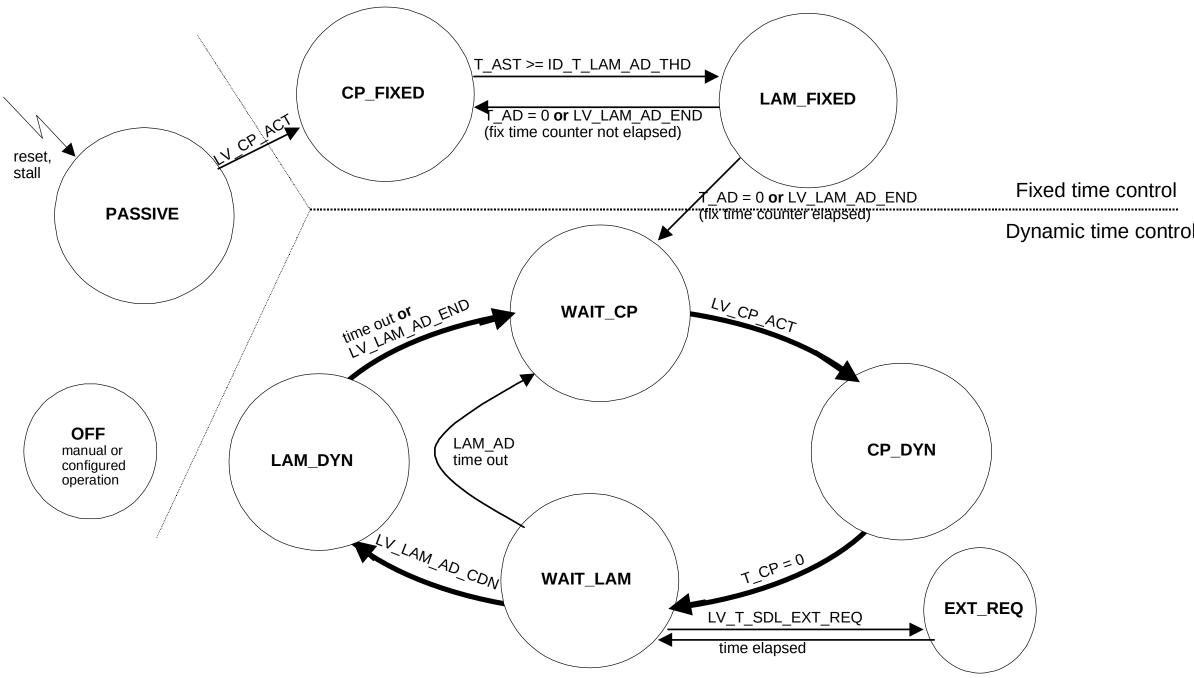

Figure 9.19.1: : time scheduler state diagram

The state diagram above only contains the recent transitions; all possible transitions are listed in the formula section below.
The following table indicates whether canister purge or lambda adapatation is enabled/disabled depending on the state STATE_T_SDL_CP of the time scheduler.

configurable C
Lambda adaptation is enabled in the corresponding states after the CPS is closed
CP is enabled in WAIT_LAM for a calibratable time

Figure 9.19.2: : enabling of canister purge or lambda adaptation depending on state

In general the time control is splited into two main parts:

- At leaving start the time split between lambda adaption and canister purge is defined by a certain number of fixed time frames. The number of these fixed time frames is given by NC_NR_CP_LAM_AD -1 (last defines the start of dynamic time slices).
- After performing the fixed time frames, the time periods of canister purge and lambda adaption are depending on canister load and the necessity of lambda adaption, indicated by their corresponding functions, so dynamic time frames will be applied.
- For Hybrid and Stop/Start configurations the timers for the dynamic time slices are stopped during engine off time.

After the start phase has ended and canister purge is possible (LV_CP_ACT = 1), the manager starts with a time slice depending on TCO. For very cold condition, the dynamic time slices will be performed immediatily. For a mid range temperature, the fixed slices defined in ID_T_SET_T_AST_LAM_CP are done and for a high temperature at first one fixed canister purge time frame will perfaomed. After a defined time the manager will switch to the dynamic time slices.
During CP_FIXED period the canister purge is possible if the conditions for the function are fulfilled. If they're not fulfilled, neither canister purge nor lambda adaptation will be active.
During LAM_FIXED period the canister purge is disabled and the lambda adaptation is enabled. During this period and after the canister purge valve is closed, the lambda adaptation is possible if the conditions for the function are fulfilled. If they're not fulfilled, neither canister purge nor lambda adaptation will be active.
If the lambda adaptation sends its ready bit LV_LAM_AD_END, the lambda adaptation time will immediately end and the state switches to CP_FIXED.
This sequence (canister purge /lambda adapation) is repeated until ID_T_SET_T_AST_LAM_CP defines dynamic slices; for each period, the start time is defined by the corresponding value of the indexiation table ID_T_SET_T_AST_LAM_CP.
The dynamic time frames start with WAIT_CP after the fixed time frames are elapsed, see description of the different states below.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Description of the different time control states

PASSIVE
After each reset or engine stalling the time control starts with state PASSIVE and switches to CP_FIXED or WAIT_CP depending on TCO and when canister purge starts to be active, i.e. LV_CP_ACT = 1 is fulfilled. Lambda adaptation can be activated during this state (configurable)

CP_FIXED
Only canister purge is enabled. This state is active as long as no lambda adaptation is triggered by the corresponding time threshold. If a lambda adaptation is urgently requested, LAM_FIXED is selected.

LAM_FIXED
Only lambda adaption is enabled. This state is left, if the adaptation is finished or the next fixed or dynamic slice starts. If immediate lambda adpatation is requested via the flag LV_STATE_T_SDL_CP_LAM_AD_EXT, this state is not left until these flags have been reset. Afterwards, the fixed time slices are resumed.

CP_DYN
Canister purge is enabled. This state is left, if the timecounter T_CP elapses or an urgent lambda adaptation is requested.

LAM_DYN
Lambda adaption is enabled. To leave this state, a time counter initialised when detecting an empty canister has to have elapsed. The state is left, if the standard adaptation time counter has elapsed and no adaptation is currently ongoing or if the end of an adaptation cycle is signaled by lambda adaptation itself.

WAIT_LAM
Within WAIT_LAM, canister purge is enabled; this enabling may expire after a calibratable time. As soon as the conditions for a lambda adaptation are given, this state is left towards LAM_DYN and lambda adaptation starts. If the time counter for lambda adaptation C_T_MFF_AD_MAX is elapsed, WAIT_CP is selected and canister purge is enabled.

WAIT_CP
Within WAIT_CP, lambda adaptation is enabled. As soon as canister purge function is active (LV_CP_ACT = 1), this state is left towards CP_DYN and canister purge is enabled.

EXT_REQ
If functions other than canister purge and lambda adaptation request a certain time slice with both, lambda adaptation and canister purge deactivated, the time scheduler may switch to the state EXT_REQ for a calibratable time.

In all states with enabled lambda adaptation, the enabling starts when the canister purge valve is closed (LV_CP_CLOSE_ACT = 1).
At the “regular” entry of MAX_PURGE (i.e. not a re-entry after a short deactivation but an entry after finishing canister load learning phases RAMP_OPEN or RAMP_OPEN_FAST) the time slices for CP and lambda adaptation are re-evaluated; remaining time for canister purge is the minimum of IP_T_MAX_CP (depending on canister load) and the lambda adaption priorisation time T_PRI_TOT_LAM_AD. A small time T_PRI_TOT_LAM_AD from lambda adaptation is related to a high priority for lambda adaptation as the canister purge time will be decreased.
Three cases are handled:

High canister load
If the canister is detected full at the end of the learning phase the time control gives priority to the evaporative emission control by increasing the remaining purge time in order to decrease the canister load. The purge time IP_T_MAX_CP is used to purge the canister.

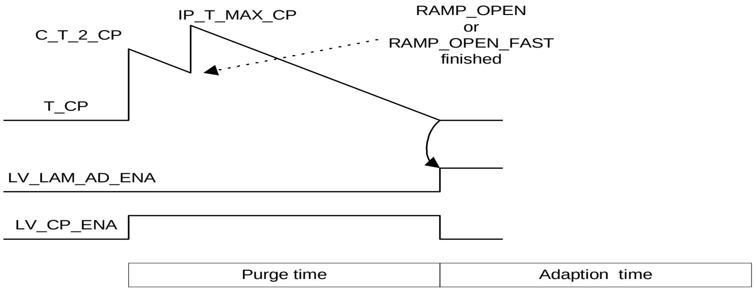

Figure 9.19.3: : canister purge time at high canister load

Medium canister load

If the canister is detected with a medium load, the purge time is calculated as the minimum value between the needs of the lambda adaption and canister purge using the lambda adaption priorisation time T_PRI_TOT_LAM_AD. A small time T_PRI_TOT_LAM_AD from lambda adaptation is related to a high priority for lambda adaptation as the canister purge time will be decreased.

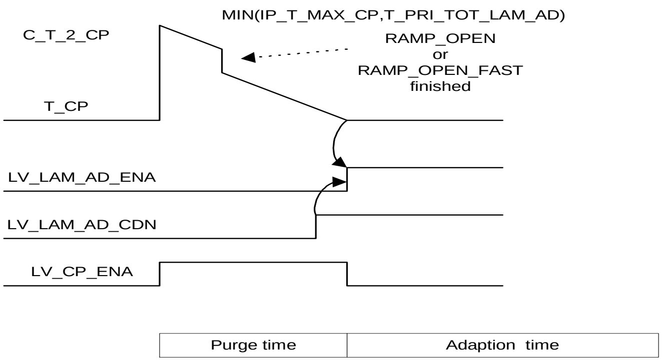

Figure 9.19.4: : canister purge time at medium canister load

Empty canister

If the canister is detected empty at the end of the learning phase, the canister purge is disabled for a time C_T_DI_CP and the lambda adaption is enabled.

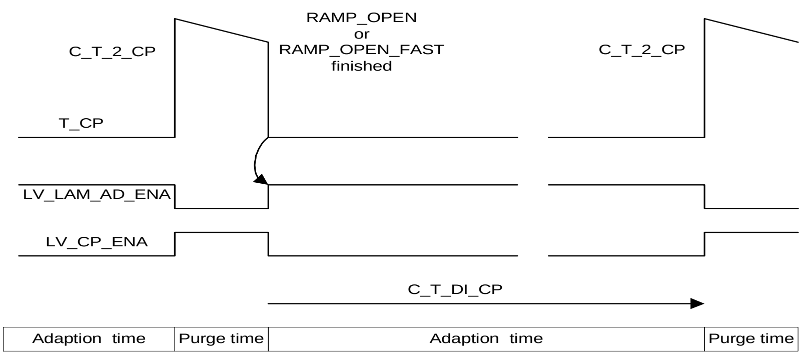

Figure 9.19.5: : canister purge time at low canister load

Input data table order: External inputs - Inputs from other EVAC modules

General information:

The PWM-setpoint to control the opening of the canister purge valve CPPWM is calculated from a map as a function of the flow setpoint and the pressure difference. This flow setpoint is deliverd from evapoarative emission control module.
The influence of the battery voltage VB on the opening of the CPS is corrected by the additive value IP_CPPWM_VB_1_ADD or IP_CPPWM_VB_2_ADD and multiplicative value IP_CPPWM_VB_FAC.
Two frequencies of the CPS are possible; the selection of the current frequency is dependent on engine speed and valve opening.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

An additional PWM offset can be applied using C_CPPWM_AS (the offset) and LC_CPPWM_AS (the switch to turn the consideration of the offset on).
The term CPPWM_ADD_AD includes the valve adaptation value delivered from the canister purge valve characteristic adapation function (if included).
An external setpoint CPPWM_EXT_ADJ is applied, if LV_CPPWM_EXT_ADJ is true.
If a fault is detected on the canister purge valve (LV_ERR_EL_CPS=1), the opening of the CPS is controlled by the value of CPPWM_LIH (see chapter OBDI functions).
In case of high CPU load /high engine speed (LV_N_MAX_CP=1), the regular control of the valve is stopped to save CPU load.
The physical range for the frequency request FRQ_REQ_CP is 5 to 32 Hz.

Application conditions

Initialisation: *LV_CP_CLOSE_ACT=1 and all other values =0 at reset or stalling*

Recurrence: ***20*** *ms*

Activation: every engine state

Deactivation - -

General information

The purpose of the CPS_AD function is to find the STO(starttoopenpoint) of the canisterpurgesolenoid (CPS): The PWMvalue (valid for the default frequency C_FRQ_MIN_CPS_AD) at which the CPS (canisterpurgesolenoidvalve) has reached the end of it s mechatronical delay time and starts to open (STO). Therefore the CPS is opened using a ramp, meanwhile monitoring the lambdaadaptation (FAC_LAMB) to detect a deviation caused by fuel purged through the CPS. Due to the fact that at a low canisterload (CL_MMV) the adaptation is getting less accurate or even impossible the purgemassflow during adaptation can be increased by rising the frequency (to have more openingperiods per second). The frequency is calculated according to CL_MMV. For PWM is a relative value (valid only for a special frequency) all PWMvalues have to be corrected after computing the frequency.

The function CPS_AD (CPSadaptation) is part of the EVACaggregate. To allow a fast purge of the ACF the PWMramp for opening the CPS has to start at the STO.

APP_CDN:
This chart is the function s internal statemachine.

When the conditions (i.e. engine speed, canister load) are sufficient (checked by the function START_CDN_OK), the state active (substate adaptation) is entered.

For transparency the conditions are split into the flags: LV_CPS_AD_ST_CDN_OK, LV_CPS_AD_RUN_CDN_OK, LV_ENG_OK_CPS_ AD, LV_CPS_OK_CPS_AD, LV_T_OK_CPS_ AD, LV_CL_OK_CPS_ AD, LV_CTR_OK_CPS_AD. For details see APP_CDNblock.

The function LEARN_STO ist triggered during state active (by triggering the containing subsystem LEARN_STO). The output value STATE_CPS_AD_REQ is used to control the function s internal state while STATE_CPS_AD is the reporting value from the function. After an interrupt or failed adaptation the flag LV_ERR_CPS_AD is set. After that in state closing the valve is closed and in state waiting there is time to compensate any lambdadeviation caused by the function.
The value LC_CPS_AD_CHK allws an override of the CPS_ADconditions.

Copyright (C) Continental AG,2007

If maybe once a LEARN_SLOPEfunction will be added, the state active will have to be divided into the substates LEARN_STO_active and LEARN_SLOPE_active.
At abortion (to avoid a lambdastep by suddenly closing the CPS) the function has to be shutdown by entering state CLOSE. This can be caused by changing conditions like N or by flags like LV_CPS_AD_INH. In this case the function goes into state CLOSING to prevent any further influence on the engine.
A decreasing CL_MMV value during adaptation is normal but - after a sufficient CLvalue has been assured before function start - does not require a shutdown; the value LV_CPS_AD_RUN_CDN_OK is still 1.

If all conditions for CPS adaptation are met but the engine is not in homogeneous operation mode, this mode is requested via the flag LV_CPS_AD_HOM_REQ.
This request is hold up for the time C_T_CPS_AD_HOM_REQ or if the engine mode changes until the adaptation is finished or was interrupted. After a nonsuccessful request or after the adaptation is finished /was interrupted, for the time C_T_DLY_CPS_AD_HOM_REQ no request for homogeneous operation mode is allowed.
After a nonsuccessful request or after the adaptation is finished/was interrupted, for the time C_T_DLY_CPS_AD_HOM_REQ no requests for homogeneous mode are allowed.
Per driving cycle only C_CTR_CPS_AD_HOM_REQ requests are allowed, afterwards CPS adaptation can only take place if the engine is in homogeneous operation mode due to other conditions.

9.21.1 SUBFUNCTION: LEARN_STO

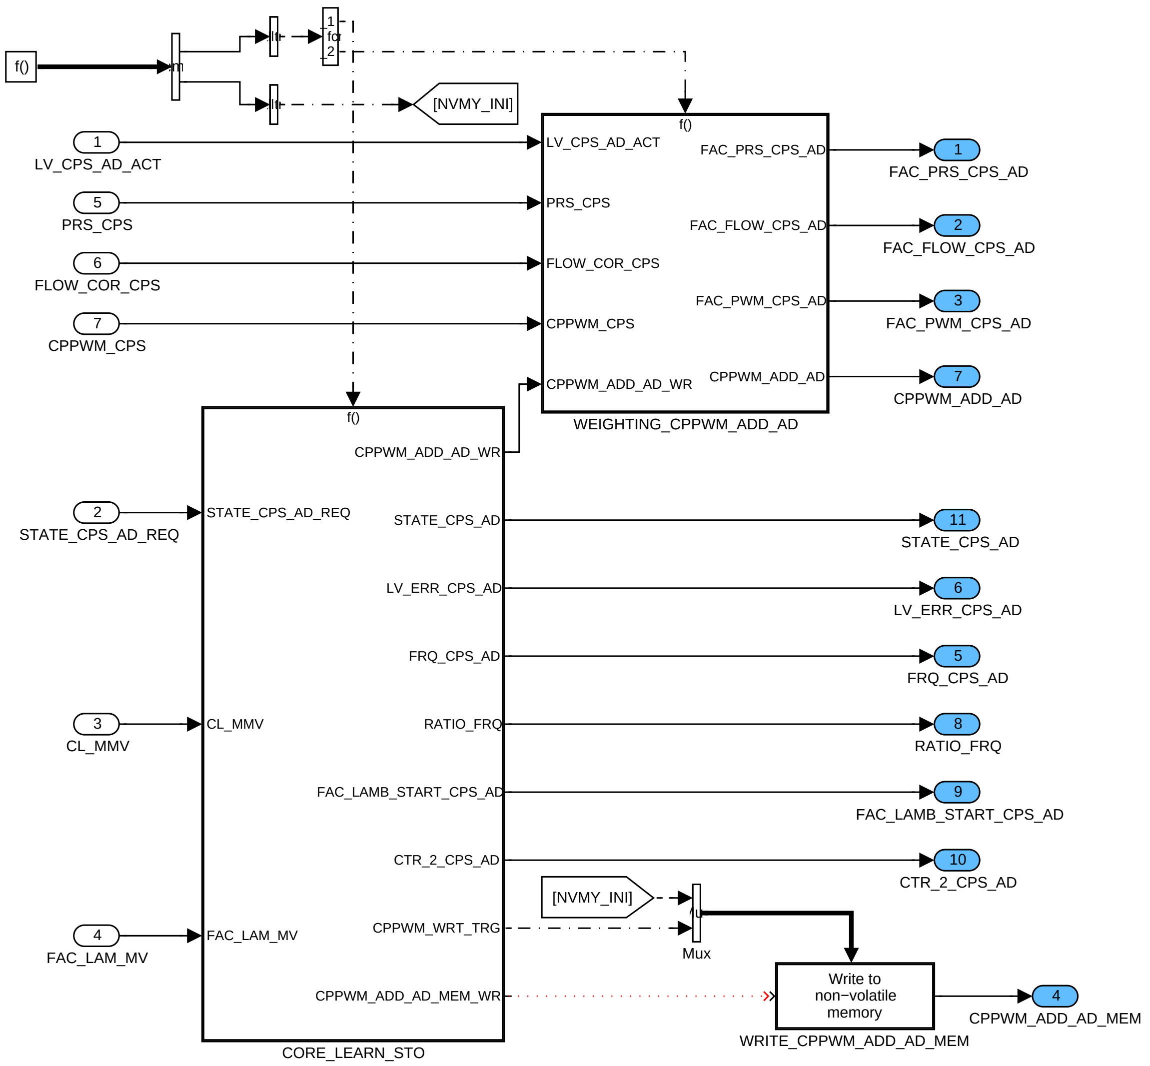

Figure 9.21.10: EVAC_CPS_AD/LEARN_STO

EVAC_CPS_AD/LEARN_STO/CORE_LEARN_STO

This chart is the core of the CPS_ADfunction. The states are:

Entry:
When entering the chart outputs are set to default values.
In case of a CPPWM_ADD_AD_MEM > maximum threshold (danger of engine disturbance) the memory value is set to minimum threshold.

CHECK_CONDITIONS:
This first substate is to prevent a new initialisation (state INIT) of the chart at the last trigger before it s state machine (APP_CDN) is leaving the state active. If PWMadaptation is demanded by APP_CDN, the state CHECK_CONDITION will be left because of STATE_CPS_AD_REQ==2.

INIT_WAIT:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

STATE_CPS_AD is set to 1 eporting that the function is in a waitstate (to allow manipulations during implementation using T_WAIT or provide some additional time for lambda recreation after any disturbance in the past).
CPPWM_ADD_AD_MEM_WR (output variable for CPPWM_ADD_AD_MEM in the nonvolatile memory) is set to the last known value of CPPWM_ADD_AD_MEM.

calculations:
FAC_LAMB_START is the memory for the current FAC_LAMBvalue to calculate a lambdadeviation caused by the function eliminating a constant lambdaoffset.
To minimize the measuring error during STOadaptation the adaptation has to be done at highest possible frequency to measure the highest possible fuel massflow. This is the frequency where the lambdadeviation caused by the openingincrement (CPPWM_INC_AD) is just small enough not to disturb the engine. CPPWM_INC_AD just as several other values are here adapted to the new frequency, using RATIO_FRQ which is calculated using the canister load CL_MMV.
Before entering INCREASE_PWM STATE_CPS is set to 7 reporting that PWMadaptation is in process.
The two junctions are to avoid a calculated FRQ which is above C_FRQ_MAX_MEC_CPS.

IMPORTANT:

The code *{FRQ=abs(...* is paid to a stateflow-bug for *abs(* in stateflow is really *abs(fix(* and there aint't no *fix(* in stateflow. The correct mathematical expression here is *{FRQ=fix(...* to cut out the comma.

INCREASE_PWM:
Here the STO is detected. Frequent entering of the junction beside allows the monitoring of the lambdadeviation while opening the CPS. The time delay C_T_DLY_FAC_LAMB is to let the lambdasensor detect the HC purged into the manifold.
If the function is interrupted (STATE_CPS_AD_REQ==4), the state ist left to go directly to CLOSE.

CLOSE:
The state CLOSE can be reached from INCREASE_PWM via regular (success) or errortransition. Here the measured value is checked against calibrationthresholds. Each transition reports via STATE_CPS. The successtransition calculates the memorized STO (for FRQ_MIN_CPS_AD) and mixes it with the old one using C_CPPWM_AD_RATIO.
The CPS is closed using a ramp until STO is reached (assuming a massflow=0 at STO), then the CPS is completely closed.

WAIT_CLOSE:
This stat is to provide a time delay (time increment) for the closing ramp.
WAIT_LAMB_RGN:
The state gives the engine some time to recover (C_T_WAIT_LAMB_RGN) from the lambdadeviation caused by the adaptation, i.e. to preserve a calm idlestate for the next adaptation cycle.

WRITE_CPPWM_ADD_AD_MEM:
This block defines the writetononvolatilememory of CPPWM_ADD_AD_MEM.

Due to change requirements the INTERNAL value CPPWM_ADD_AD has been deleted in this chart; there rests only the output CPPWM_ADD_AD_WR which is now replacing CPPWM_ADD_AD in the internal calculations.
At NVMY_INI, i.e. when the ECU is flashed with a new software, the adaptation value CPPWM_ADD_AD_MEM is initialized with the value C_CPPWM_ADD_AD_MEM_NVMY_INI and this value is written to the nonvolatile memory. By this it can be assured that a reasonable starttoopen point is used for the purging cycles before the first CPS adaptation could be done.

For correct processing, the check of CPPWM_ADD_AD_MEM has been transferred from state CHECK_CONDITIONS to chart entry.

At NVMY_INI, i.e. when the ECU is flashed with a new software, the adaptation value CPPWM_ADD_AD_MEM is initialized with the value C_CPPWM_ADD_AD_MEM_NVMY_INI and this value is written to the nonvolatile memory. By this it can be assured that a reasonable starttoopen point is used for the purging cycles before the first CPS adaptation could be done.

This submodule does a weighting of the STO CPPWM_ADD_AD_WR to calculate the output CPPWM_ADD_AD. The PRS_CPS-weighting is to pay respect to a nonlinear behaviour of the CPS (to be defined by manufacturer, used for calibration of IP_CPPWM_OPEN_CPS). The FLOW- and PWM-weighting is to 'softly' eliminate the factor when reaching an operating state where STO is of almost no influence.

9.22.1 Main relay control

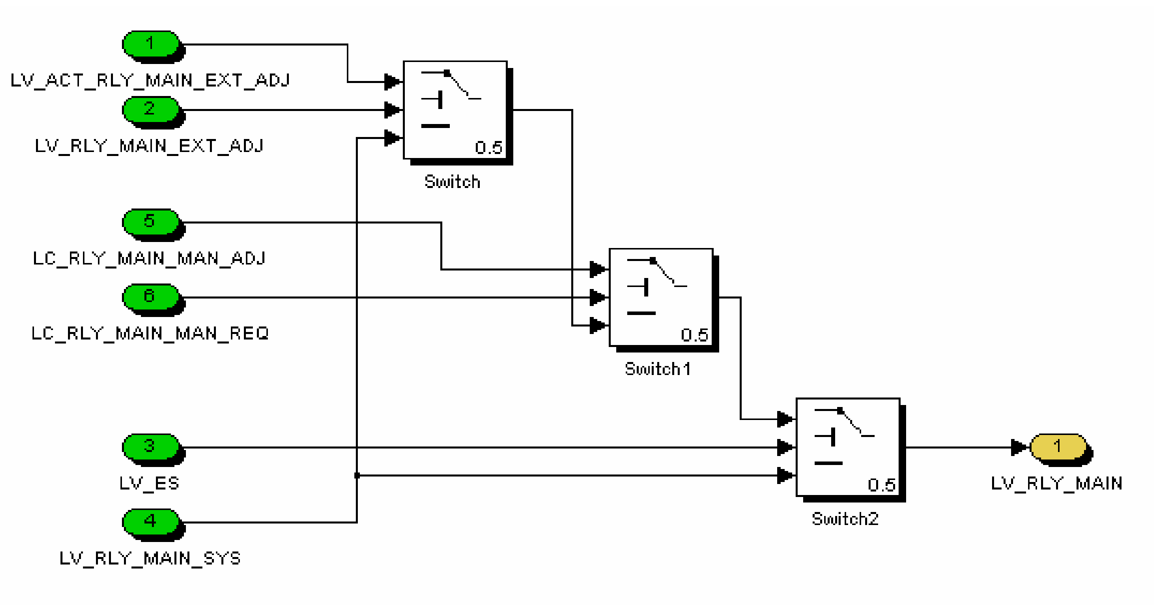
FUNCTION DESCRIPTION:

General information:

Purpose of this module is to get an entry point to switch on or off the main relay and get a status of the control command through LV_RLY_MAIN.
Upon ignition key transition from OFF to ON, the ECU voltage regulator is set to ON and the core microprocessor is reset. Then, so as to power up the system (system = ECU + actuators + sensors), the main relay has to be switched ON (most of actuators are supplied by the main relay).
Upon ignition key transition from ON to OFF, the ECU enters in the post-operating phase. At its end, the system shutdown is obtained by disabling the power supply on sensors and actuators. For that it is necessary to switch off the main relay. Then, the ECU can be switched off too.
To summarize, the main relay is switched on as soon as the ignition key is turned in the ON position and it remains ON until the ECU voltage regulator is switched off.

The system depending switching state is stored in the flag LV_RLY_MAIN_SYS. This request can be overruled by the request of the calibration system or tester (serial communication). To prevent destruction of components (actuators which are supplied via main relay), switching is only allowed when engine stopped (LV_ES =1). While engine is running, always the system depending switching state is used.

Signal flow diagram:



Application conditions

Initialisation: `all 0`

Recurrence: `10 ms`

Activation: `at reset`

Formula section:

IF (ECU_STATE = WAKE_UP **and** LV_CUR_VCV_CTL_PRE_RUN = 0) **or**

9.23 Power latch management

Data definition:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_PWL_TRAN_ES_EL	O/V	0... 1H	0 ...1	1	-
flag active in shutdown-phase: IGK on is not accepted without reset					
LV_PWL_ACT	O/V	0... 1H	0 ...1	1	-
power latch phase active (Do not use as Output)					
PWL_LOCK_CDN	O/V	0... FFFFH	0... 65535	1	-
Power latch extension by project-specific configuration:see configuration-values in bitmask NC_PWL_LOCK_CDN_XXX					
T_PWL	O/V	0... FFFFH	0... 6553.5	0.1	s
incrementing timer during PWL phase active					

Input data:

LV_DIAG_END_RLY_ MAIN_DLY {p. 4933}	NC_PWL_LOCK_CDN_ XXX	STATE_LRN_ECU {p. 657}	

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_T_MAX_PWL	-	0... FFFFH	0... 6553.5	0.1	s
maximum power-latch time for ECU switch off (if reached => not saved data will be lost)					
C_T_MIN_PWL	-	0... FFFFH	0... 6553.5	0.1	s
minimum power-latch time for ECU switch off					

Action definition

ACTION_FCTM_ClrPwlLockCdn (**IN**<Param1>)	Mode: O
Clear related flag at pwl_lock_cdn	

ACTION_FCTM_SetPwlLockCdn (**IN**<Param1>)	Mode: O
Set related flag at pwl_lock_cdn	

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FUNCTION DESCRIPTION:

Initialisations:

T_PWL = 0 at RST **or** EXIT_PWL
LV_PWL_ACT = 0
LV_PWL_ACT = 1 at TO_PWL

Recurrence: 100 ms
Activation: LV_PWL_ACT = 1

General information:

The relevant informations for setting PWL_LOCK_CDN are transferred with the help of the action call.

The ECU keeps active for a minimum time after entering the powerlatch-phase.
The minimum ECU power latch time (C_T_MIN_PWL) can only be extended by other functions locking a PWL-resource using the bitword PWL_LOCK_CDN (see project specifc list of PWL configuration data (definition of NC_PWL_LOCK_CDN_XXX)). If the maximum powerlatch time C_T_PWL_MAX is reached the ECU will be shut down and all not saved data will be lost.

Bit-position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PWL_LOCK_CDN																

Each other function is responsible itself to lock /unlock its own PWL-resource at entering /leaving the powerlatch-phase !

Formula section:

T_PWL = T_PWL + 100ms

If **(**T_PWL > C_T_MIN_PWL **and** PWL_LOCK_CDN = 0**)**
Or **(**T_PWL > C_T_MAX_PWL **and** atPWL_LOCK_CDN no NVMY Bit is set**)**
Or LV_INH_PWL_TRAN_ES_EL = 1 (already in shut down)
Then activate shut-down mechanism
Else do nothing
Endif

Actions for shut-down mechanism:

reactivation by switching IGK on is forbidden

- LV_INH_PWL_TRAN_ES_EL = 1
- disable Monitoring-unit (MU)
- wait until MU-disable is confirmed **or** Communication with MU failed **or** LV_DIAG_END_RLY_MAIN_DLY = 0
- all function specific initializations with end of power latch phase are done.
- The power-supply-pin of the ECU is switched off.
- Call 5V reset detection.

Requirements for ACTION_FCTM_SetPwlLockCdn(<param>):

param: NC_PWL_LOCK_CDN_xxx (see Appl. INCI)

Function description

General information:
The objective of this function is to protect the engine against overspeed and therefore to control the engine speed. A PI controller is used to hold the engine speed at the engine speed limit setpoint, which derives from the module 'Engine speed limit coordination' from chapter 4. Engine overspeed mainly is controlled by reduction of engine torque. The output value of this module is TQI_N_MAX, which is an input in the torque coordination module. Different tasks are designed in this module:
prediction of engine speed to avoid great engine speed overshoots, especially in the first phase of controlling
activation of speed limit controller due to speed deviation between predicted engine speed and engine speed limit
PI controller
activation of fuel cut off for exceeding the engine speed limit for more than a calibratable difference

9.25.2 Formula section

Calculation of predicted engine speed
The engine speed prediction shall activate the engine speed limitation controller before the real engine speed reaches the threshold N_MAX_THD. Therefore the complete controller has a PID behaviour at activation, to prevent high engine speed overshoot.
The prediction is deactivated, if the controller has stopped the engine speed increase. During the following period the PI controller can guarantee the engine speed limitation up to N_MAX_THD without predicting the engine speed.
Due to a bad resolution of N_GRD, the prediction is only calculated, if a clear high engine speed gradient is detected. This is possible by comparing the gradient N_GRD with an engine speed depending threshold IP_N_GRD_THD__N_32.
The prediction is stopped latest, if the real engine speed is no longer increasing
(N_GRD =< 0).
To prevent sudden changes for the engine speed limit controller input at activation or deactivation, it is necessary to have a PT1 filter for the engine speed controller input. So a negative feed back of the controller output to the real engine speed is prevented.

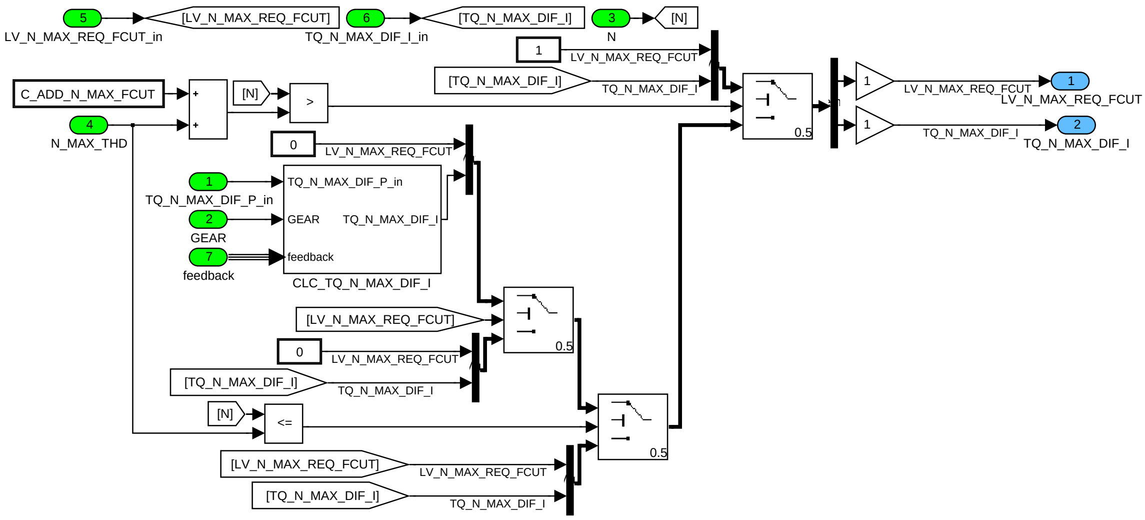

Figure 9.25.9: ENSL_M901E/OPM/CLC_LV_N_MAX/ACT_FUEL_CUT_OFF

Initialisation of N MAX integrator.

Calculation of TQ_N_MAX_DIF_I

The integrator has to be initialized for the transition of LV_N_MAX from 0 to 1 and for the transition of LV_N_MAX_REQ_FCUT from 1 to 0. In the first case the integrator output is set to zero and in the second case the integrator output has to ensure that the TQI_N_MAX does not show a step (during LV_N_MAX_REQ_FCUT active the TQI_N_MAX is set to zero).

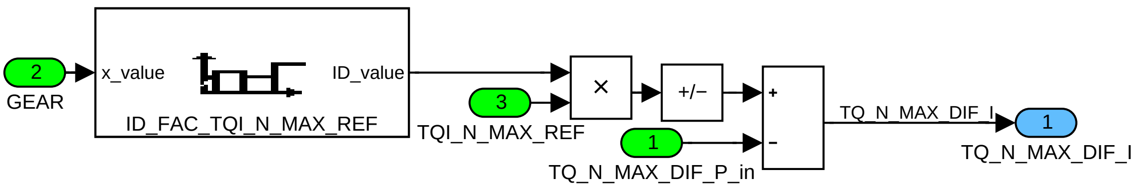

Figure 9.25.10: ENSL_M901E/OPM/CLC_LV_N_MAX/ACT_FUEL_CUT_OFF/

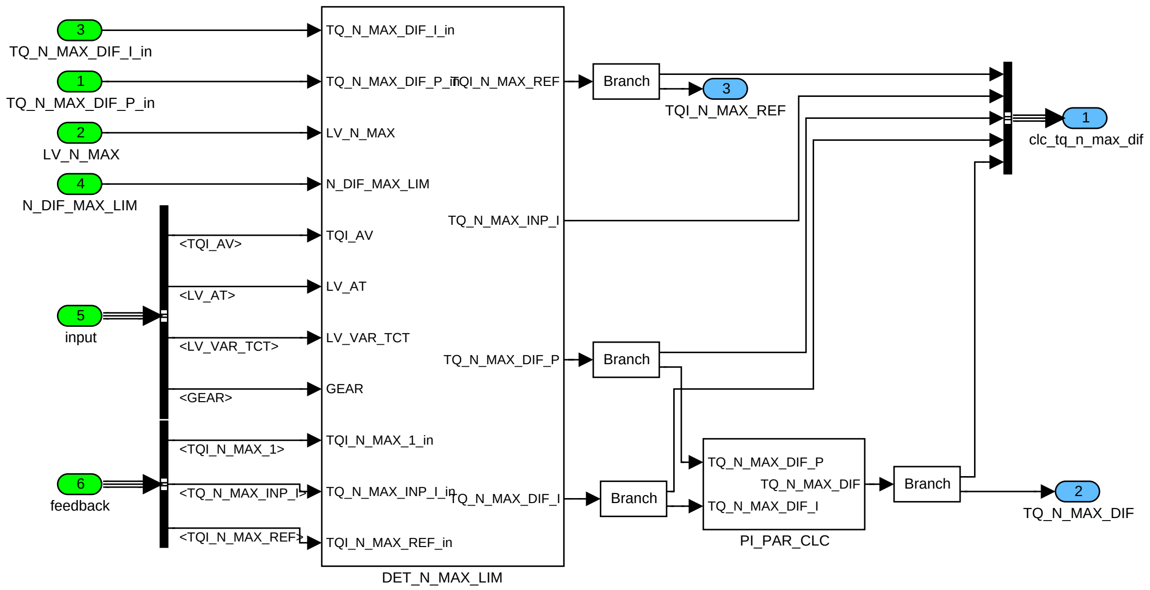

Figure 9.25.11: ENSL_M901E/OPM/CLC_TQ_N_MAX_DIF

Determination of TQ_N_MAX_REF, TQ_N_MAX_DIF_P, TQ_N_MAX_DIF_I and TQ_N_MAX_INP_I

The integrator input has to be set to zero, when the TQ_N_MAX_1 is smaller than zero and the calculated input TQ_N_MAX_INP_1 is smaller than or equal to zero. This avoids a steadily decrease of the integrator output which could cause problems when re entering the controller.
TQ_N_MAX_REF, TQ_N_MAX_DIF_P, TQ_N_MAX_DIF_I and TQ_N_MAX_INP_I are calculated here.

Switch for manual FUP_EFP_SP					

General information:

The module fuel pressure setpoint of electrical fuel pump delivers a fuel setpoint to the module fuel pressure control.

The fuel pressure setpoint of the low pressure pump is normally taken out of a map depending on engine speed and injected fuel mass. Exemptions are power latch phase of the electrical fuel pump and the pull mode. Additionally a testbench function is included. In order to avoid to big fuel pressure setpoint gradients a certain gradient limitation is included.

Application conditions:

Initialisation: RST
Recurrence: 100MS
Activation: always
Deactivation: never

Duration time for the actuator test at EFPPWM = 100 % till switch off (value: 5 s)					

General information:

The electrical fuel pump is controlled by the EFPPWM.
The PI-controller is used to compensate deviations from the nominal fuel pressure after the fuel pump. If no sensor is applied the EFPPWM is only calculated with the help of the precontrol map, which corresponds to the pump data.
In order to control also deviations caused by external influences or aging two adaptation strategies are applied. One adaptation is used in a nominal operating point where the I-part of the controller is taken as an adaptive I-part. The other adaptation gives the minimum EFPPWM for ensuring the correct fuel pressure for the jet pumps without increasing the fuel pressure to the level where the overpressure release valve opens.

Application conditions:

Initialisation:	`RST, NVMRES, NVMINI, NVMSTO`
Recurrence:	`10MS, SEG`
Activation:	`always`
Deactivation:	`never`

9.28.2.2.5.3 Calculation

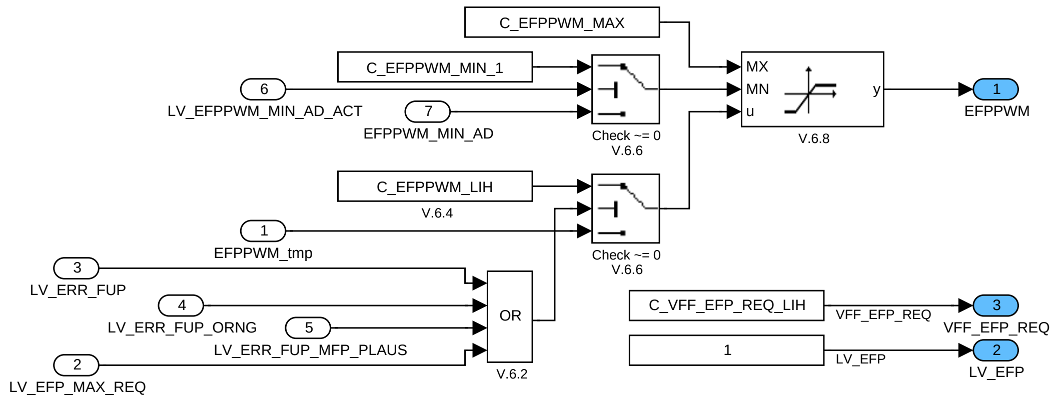

Figure 9.28.17: :

9.28.2.2.6 Electrical fuel pump off

9.28.2.2.6.1 Calculation of the controller in state "off"

If no fuel delivery is required the ECU has to give a minimum EFPPWM. The only operating point where this rule can not be applied is at request from the independent car heater. At this point the adapted minimum PWM is applied to the pump.

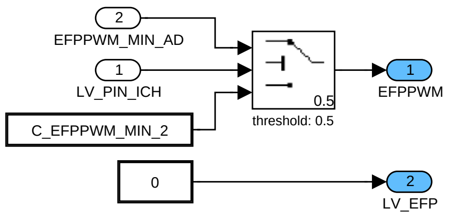

Figure 9.28.18: :

9.28.2.2.7 Electrical fuel pump on

Calculation of the Controller in state "on"
The functionality for the electrical fuel pump in status "on" is given here. It is split into a precontrol calculation part, a limitation signal generating part (mainly for PUC), an EFPPWM calculation part and the controller output part.

9.28.2.2.7.1 Electrical fuel pump on pre-control

Calculation of the precontroller
The precontrol part calculated the precontroller value out of the required fuel mass for the injection. Within the given two maps the basic controller output is calculated.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Switch to define if limp home of EFP pump is requested on raw error symptom of fuel low pressure sensor, additionally					

General information:

The electrical fuel pump is controlled by the EFPPWM.
The PI-controller is used to compensate deviations from the nominal fuel pressure after the fuel pump.
In this module the switching conditions for the main module are calculated. This includes also limp home and crash reactions. Application Condition

Application conditions:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Initialisation:	`RST, NVMRES, NVMINI, NVMSTO`
Recurrence:	`10MS, SEG`
Activation:	`always`
Deactivation:	`never`

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

The actual fuel consumption value (FCO_AV_1) is calculated from MFF_SP (incl. Lambdaadaptation) or MFF_SP_BAS (without Lam-ad) and several factors. During NOx regeneration additional FCO_AV_2 is calculated. This is not the real fuel mass, but it is used to avoid strong peaks in the FCO_AV signal. If NOx regeneration, desulfurization or the idle speed controller during stratifid mode is active, FCO_AV is additional filtered to avoid high gradients in the FCO signal. To ensure that the integrated fuel consumption (FCO) is still correct despite of the filtering and the use of FCO_AV_2 (-> FCO_FIL_DIF = 0), a balance controller (C_FCO_DIF_GAIN) is activated to balance FCO over a certain time.

Application conditions

Initialisation: `at reset or LV_IGK 0->1: all = 0, except FCO_DMTL = 0 only at reset and FCO_FIL_DIF =0 only at reset`

Recurrence: `every segment, except calculation of T_RAMP_FCO_FIL and FCO_FIL_DIF_FB, 10ms recurrence`

Activation: `LV_ES = 0`

Formula section:

// calculate FCO_AV_1
If LC_FCO_MFF_ADD_CYL_CP = 1 *// use Canister fuel flow for FCO calculation?*
then FCO_MFF_ADD_CYL_CP = MFF_ADD_CYL_CP

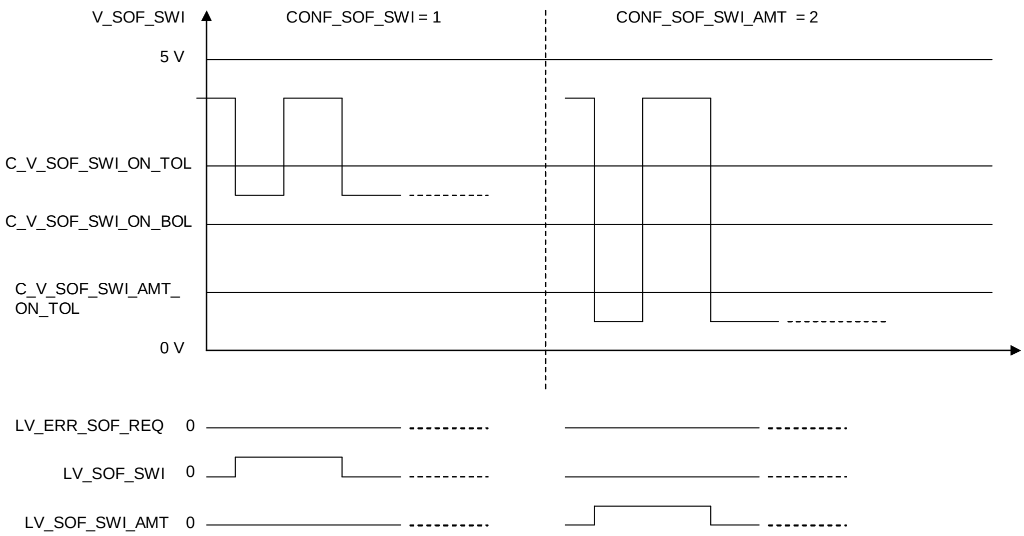
9.32.1 Acquisition of sport-mode-switch

General information:

Calculation of the sport-mode request by taking the voltage of the sport-mode-switch.
The request acts according to the rising egde of the voltage signal.
There must be for 3 cyles the same result of LV_SOF_SWI(_AMT) to accept the level.

Signal flow diagram:



In case of failure LV_ERR_SOF_REQ =1 inhibitation of LV_SOF_SWI(_AMT):

Application conditions

Initialisation:

9.32.2 Acquisition of sound-flap

General information:

To optimize the vehicle noise behaviour, an sound flap can be activated depending on the engine speed (N_SOF) and the load (FAC_TQ_REQ). The sound flap is closed below a FAC_TQ_REQ threshold, it is opened above the threshold.
The sound flap is only activ after the time C_T_SOF_AST after the transition from Start.
The switching threshold (FAC_TQ_SOF_THD) is depending on enginespeed (N_SOF), the selected gear (GEAR_EF), the transmission (manuell or automatic) and the convertible top (LV_CTOP = 0 closed, or LV_CTOP = 1 open).

To prevent the sound flap from switching continuously during constant driving at the switching threshold, two hysteresises (C_N_SOF_HYS and C_FAC_TQ_SOF_THD_HYS) are introduced for the switching process.
The closing of the sound flap is delayed depending on the engine speed (N_32). The opening of the sound flap is delayed depending on the engine speed (N_SOF), the selected gear (GEAR_EF), the transmission (manuell or automatic) and the convertible top (LV_CTOP = 0 closed, or LV_CTOP = 1 open).

At low vehicle speeds the state of the sound flap is adjustable by C_STATE_VS_MIN_SOF_xx (xx = MT/AT).

The sound flap can be tested via KWP protocol at EOL or at service station by setting LV_SOF_EXT_ADJ = 1.

PWM output signal for the electronic controlled thermostat in case of a failure					

9.33.1 Adjustment of the pulse width modulated output signal (ECTPWM)

FUNCTION DESCRIPTION:

General information:

For calibration issues and service tool operations the calculated pulse width modulated signal (ECT-PWM_CLC) has to be adjusted manually before it is sent to the power stage of the electronic controlled thermostat (ECTPWM). Two possibilities for the manual adjustment are existing. With the logical constant LC_ECTPWM_MAN it is possible to adjust the calibratable value C_ECTPWM_MAN to the PWM output with use of the calibration system. The service tool allows the adjustment of the PWM signal as

well. In this case the logical variable LV_ECTPWM_EXT_ADJ is set from logical low (0) to logical high (1) and the adjustable value ECTPWM_EXT_ADJ is used as output signal (ECTPWM).
As soon as the thermostat failure algorithm detects a electrical thermostat failure, the PWM output signal is set to a calibratable value (NC_ECTPWM_SUB_DIAG) at once and the ECT control state "LIH" is activated.

Application conditions

Initialisation:

```
 all 0 at reset,
   Except:  T_ECTPWM_AST :
at reset or at transition LV_ES 0 - -> 1:   T_ECTPWM_AST =
0
 // the time condition C_T_ECTPWM_AST is reset each time
 the engine state "engine stop" is reached or ecu is reset
```

Recurrence: *1000 ms*

Activation: *at every engine operating state*

Deactivation: –

Endif(4)
Endif(3)
Endif (2)
Endif (1)

9.33.2 Limitation of the pulse width modulated output signal (ECTPWM)

FUNCTION DESCRIPTION:

General information:

The limits of the pulse width modulated output signal for the electronic controlled thermostat are fixed to NC_ECTPWM_MIN for the lower and NC_ECTPWM_MAX for the upper value. The controller output signal must be limited as soon as the amount of the controller is reaching the limits.
The power stage output signal for the electronic controlled thermostat is limited to a minimum and a maximum value to guarantee a continuous working electrical diagnosis of the power stage.

Application conditions

Initialisation: *all 0 at reset*
Recurrence: *1000 ms*
Activation: *at every engine operating state*
Deactivation: –

Cooling fan power output of all available fan(s) at the vehicle					

Input data:

ECFPWM [NC_ECF_NR] {p. 3596}	ECFPWM_IGK_OFF {p. 3596}	LV_ERR_ECF_EL [NC_ECF_NR] {p. 4507}	NC_ECF_CONF {p. 576}
NC_ECF_NR {p. 576}			

FUNCTION DESCRIPTION:

General information:

This manager specifies the sequencing of project specific ENTE tasks.

Description:

Within the aggregate ENTE, the cooling fan functions (acquisition, control, diagnosis, torque loss) are handled project specific with use of HOOK modules. Because different projects use different update rates for the functions, it is necessary to handle the function calls specific within this module.

Application conditions

Recurrence: see formula section below

Activation: at every engine operating state

Deactivation: –

Formula section:

Switch for manual setting of ECRASPWM					

FUNCTION DESCRIPTION:

Description:

This modul consists of three parts.

- End of line Sytem test functionality
- Calculation of ECRASPWM
- Setting of STATE_ECRAS_SYS

EOL-System test: the system test is activated by LV_ACT_ECRAS_EOL_EXT_ADJ which is set by tester (see "Services for EOL tests" chapter). During this EOL test several ECRASPWM will be set for a certain time. This allows that every possible failure can be detected by the ECRAS feedback diagnosis.
Calculation of ECRASPWM: The ECRAS PWM signal will be claculated. ECRASPWM requests will be prioritised.
Setting of STATE_ECRAS_SYS: A State STATE_ECRAS_SYS is created which displays specific information about the whole ECRAS system (eg. diagnosis, EOL etc.).

Application conditions

Initialisation: *reset* ***or*** *LV_IGK = 0 -> 1 all 0, except ECRASPWM = C_ECRASPWM_DIAG*

Recurrence: *100 ms*

Activation: *always*

Deactivation: *none*

Formula section:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. General Information

There are maps for homogeneous mode and stratified mode according to the variable, which shows the actual engine mode. In PU and PUC a different map for the fuel pressure setpoint is selected.

Additionally a testbench function is also included. In order to avoid too big fuel pressure setpoint gradients a certain gradient limitation is included. That limitation is consisting out of a increment and decrement limitation. For PU and PUC a different limitation for increment and decrement is selected.

Application Conditions

Initialization: RST, ERU2ES
Recurrence: SEG activated if LV_ST_END==1
10MS activated if LV_ST_END==0
Deactivation: !LV_ST_END

9.36.2.1 Fuel pressure setpoint calculation overview

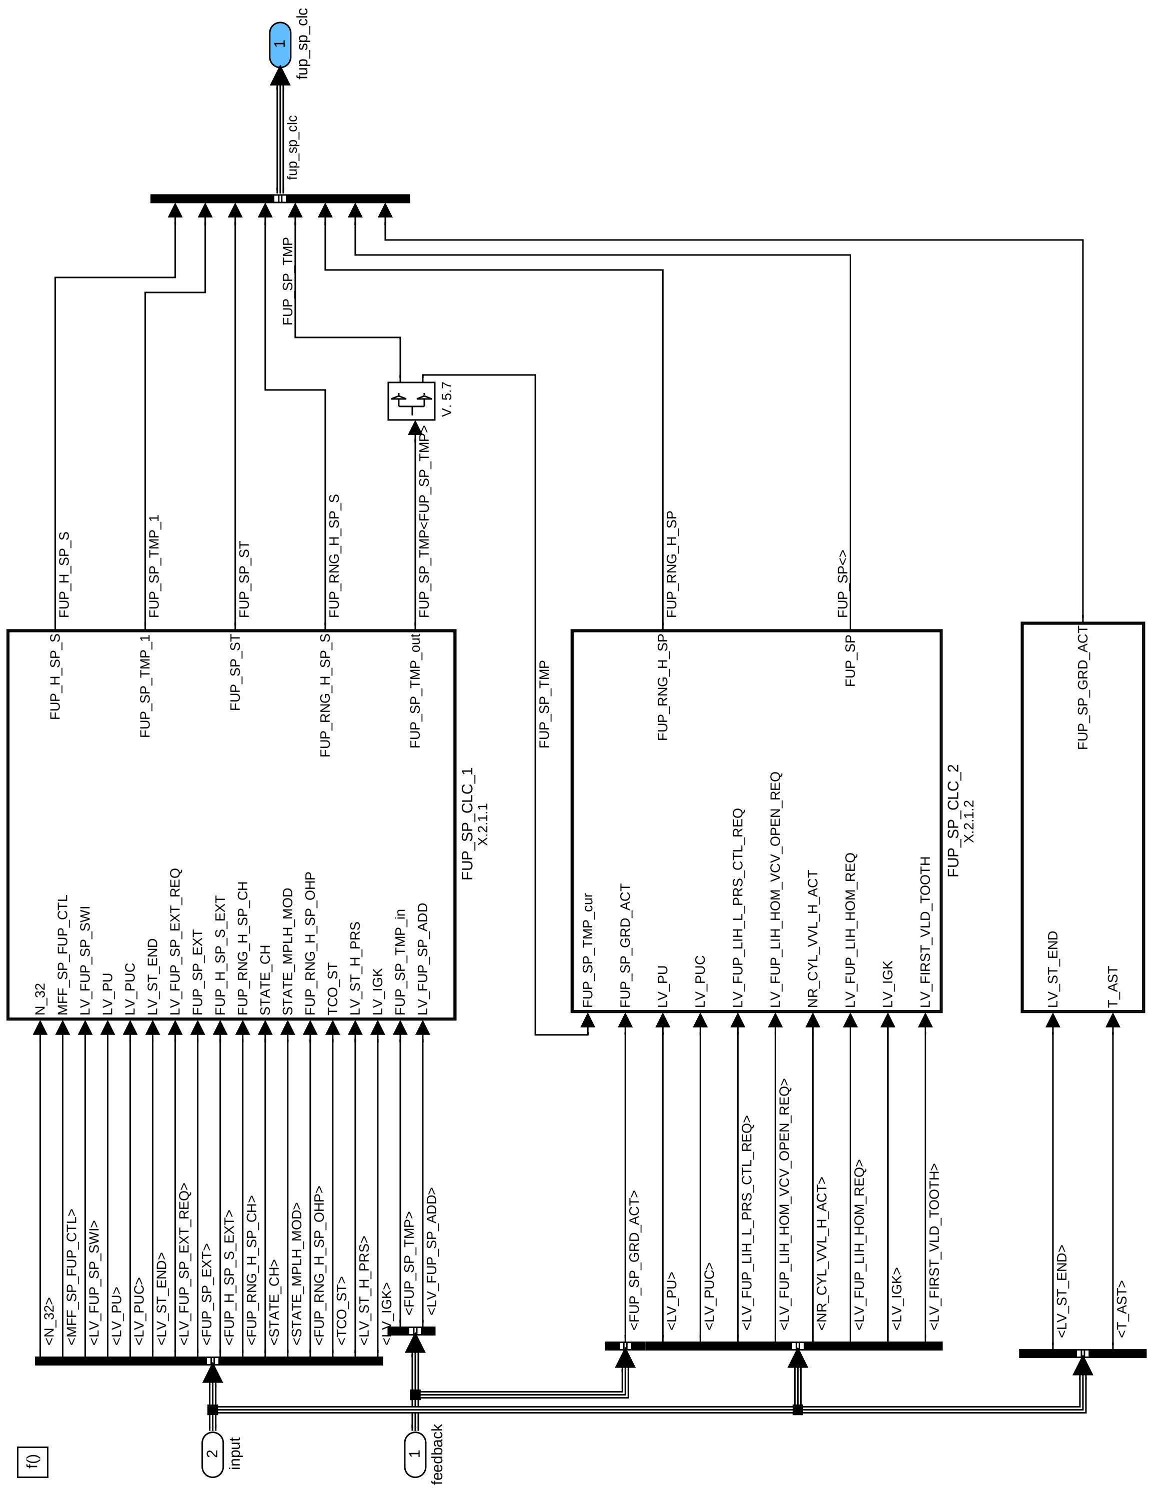

Figure 9.36.7: : Path: FUSL_M904A/OPM/FUP_SP_CLC

9.36.2.1.1 Calculation of fuel pressure high setpoint

The actual fuel pressure setpoint is taken out the two maps. Only for PU and PUC mode different fuel pressure setpoints can be selected due to injector requirement.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

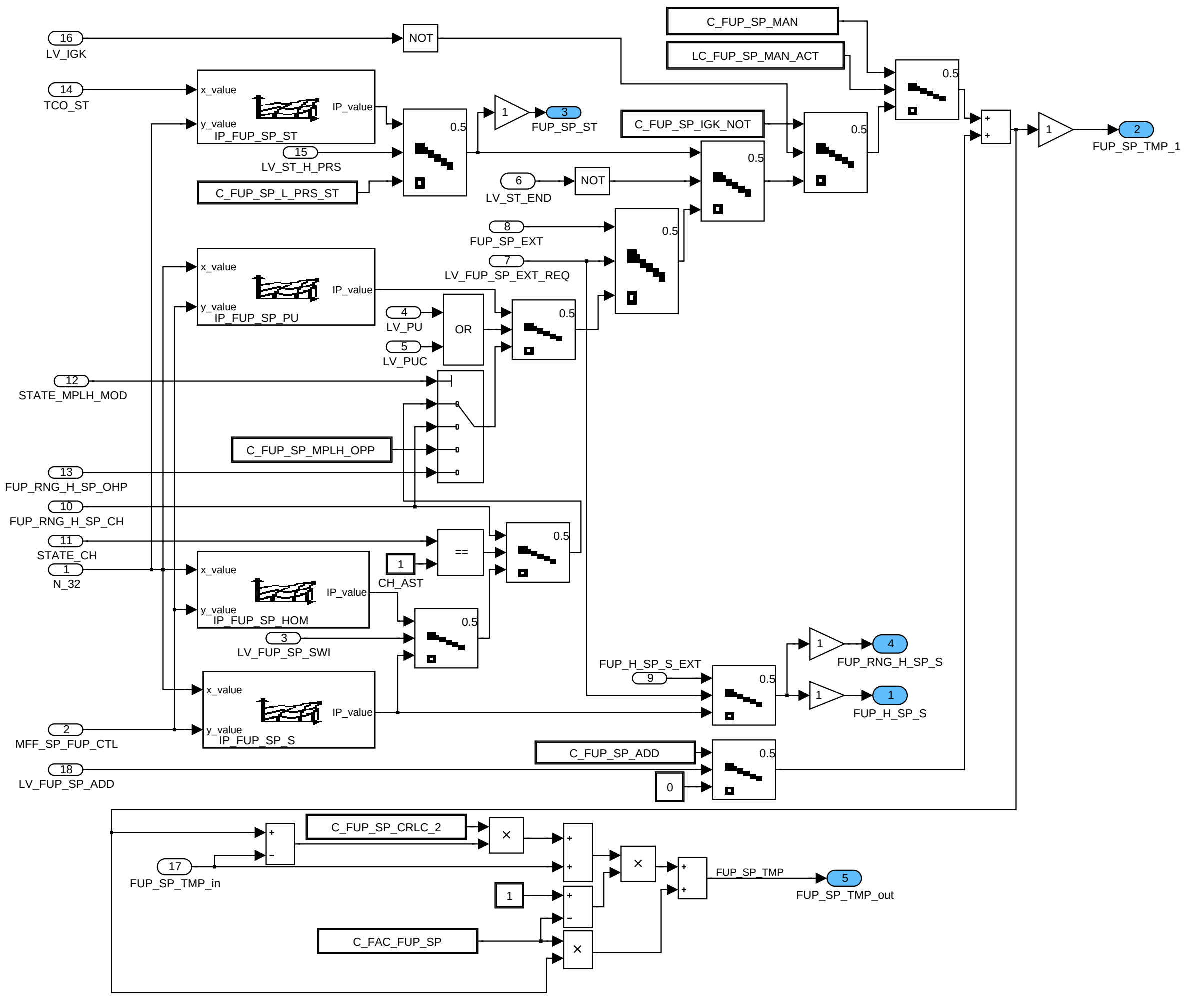

Figure 9.36.8: : Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_1

9.36.2.1.2 Calculation of fuel pressure setpoint

For the gradient limitation the calibration should be started with the highest value for all gradient limitations. The values should be lowered by applying jumps the FUP_SP via manual intervention.

The internal value in the difference limiter has to be initialised with FUP_SP_TMP at reset.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

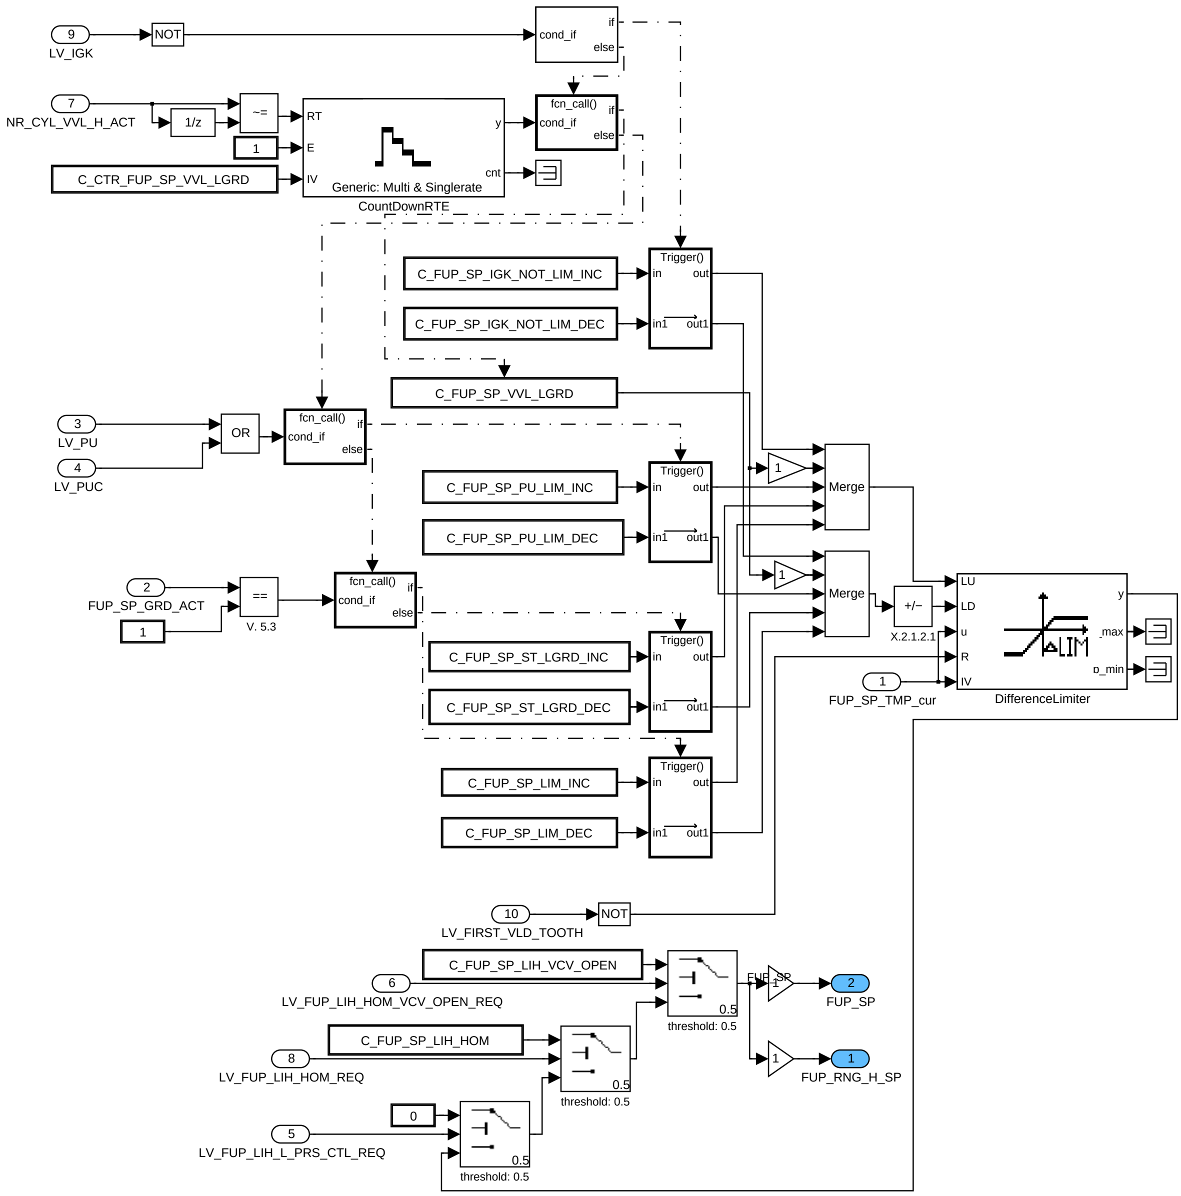

Figure 9.36.9: :   Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_2

9.36.2.1.3 Fuel pressure setpoint gradient calculation

The gradient limitation out the start phase will be stopped until the FUP_SP is reached.

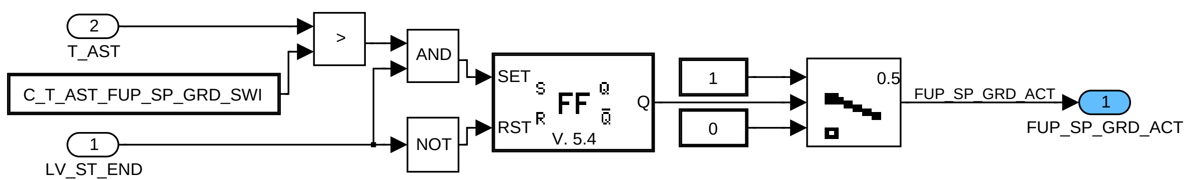

Figure 9.36.10: :   Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_3

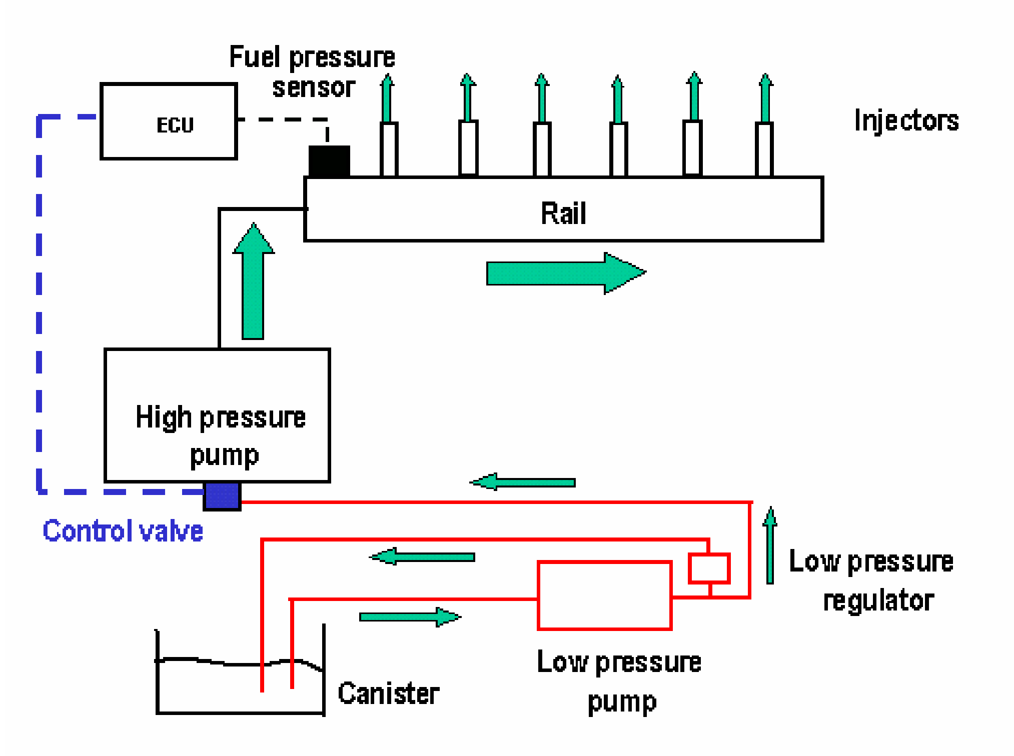
General Information

A variant of the fuel pressure control system is a threewayvalve as a control mode, which combines the volume control valve and the regulator functionality. In that case the regulator is obsolete.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



General scheduling

Segment synchronious tasks:

1. Fuel pressure of low pressure pump
2. Fuel pressure
3. {Injection related parts of SW}
4. Electrical fuel pump control (Appl. Inc.)
5. Electrical fuel pump
6. Fuel supply general
7. Fuel pressure setpoint calculation
8. Fuel pressure control
9. High pressure pump control

1 ms tasks:

1. Fuel pressure of low pressure pump

10 ms tasks:

1. Fuel pressure of low pressure pump
2. Fuel pressure
3. {Injection related parts of SW}
4. Electrical fuel pump control (Appl. Inc.)
5. Electrical fuel pump
6. Fuel pressure setpoint calculation
7. Fuel pressure control (Appl. Inc.)
8. Fuel pressure control

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

9. High pressure pump control (Appl. Inc.)
10. High pressure pump control

20 ms tasks:

1. Fuel system pressure diagnosis for low pressure (Appl. Inc)
2. Fuel system pressure diagnosis for low pressure
3. Fuel system pressure diagnosis (Appl. Inc.)
4. Fuel system pressure diagnosis

40 ms tasks:

1. Fuel pressure sensor diagnosis for low pressure (Appl. Inc.)
2. Fuel pressure sensor diagnosis for low pressure
3. Fuel pressure sensor diagnosis (Appl. Inc.)
4. Fuel pressure sensor diagnosis

100 ms tasks:

1. Electrical diagnosis of fuel pressure actuator (Appl. Inc.)
2. Electrical diagnosis of fuel pressure actuator
3. Fuel pressure setpoint of electrical fuel pump
4. Fuel pressure control (Appl. Inc.)
5. Fuel pressure control
6. High pressure pump control
7. Fuel supply general

1000 ms tasks:
Fuel pressure actuator temperature calculation

Management of the pressure and flow controlers in the intervention mode

Condition VFF_VCV under the C_VFF_SWI_THD

In idle speed:

Reset of the I part of the flow controller
Set of the I part of the pressure controller
No reset of the I part of the pressure controller
No Execution of the adaptations

In PUC:

No reset of the I part of the flow controller
Set of the I part of the pressure controller
Reset of the I part of the pressure controller depending on the reset LC's
Alternative execution of the pressure /leakage adaptations

In PU:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

Copyright (C) Continental AG,2007

No reset of the I part of the flow controller
Set of the I part of the pressure controller
Reset of the I part of the pressure controller depending on the reset LC's
No Execution of the adaptations.

9.37.1 Function description of 100MS task

Application Conditions

Initialization: RST
Recurrence: 100MS
Activation: always
Deactivation: never

Function description

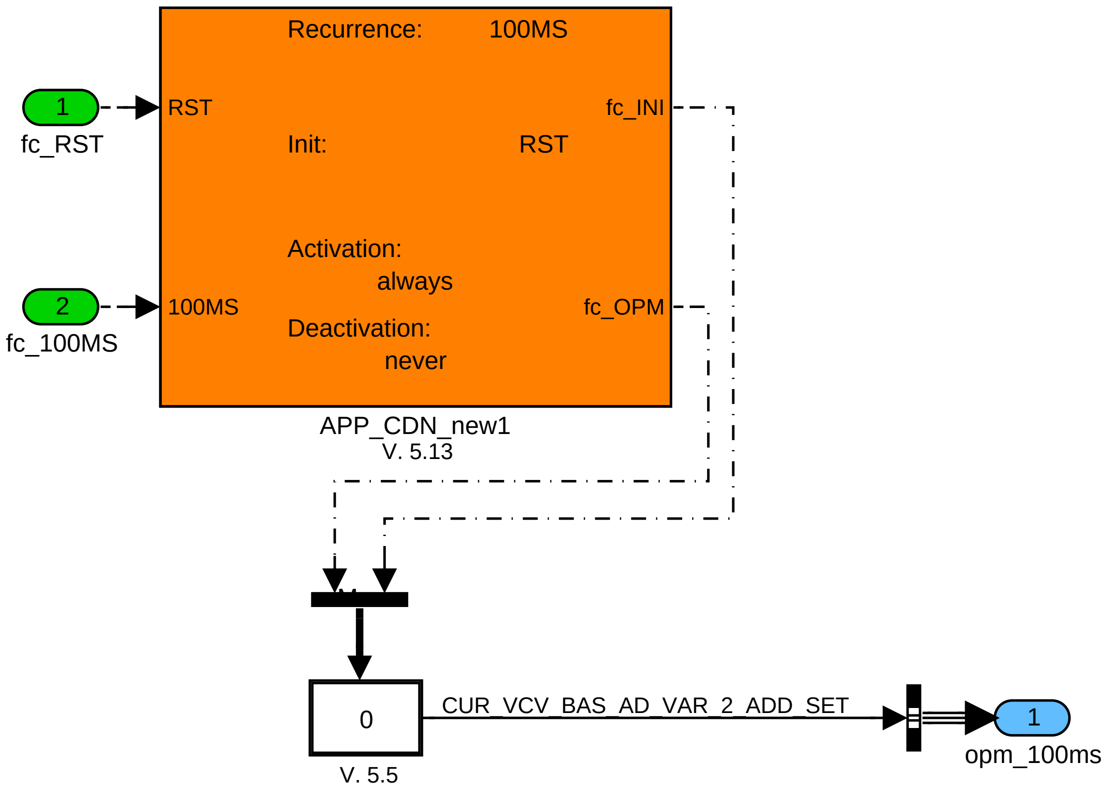


Figure 9.37.2: : Path: FUSL_M9049/OPM_100MS

9.37.2 Function Description of segment synchronous task

The fuel supply general organizes the different fuel pressure control possiblities. It can be achieved an automatic mode where the flow control and pressure control mode is chosen by the flow through the volume control valve. Also only flow control or pressure control can be selected. The pressure control part can be divided into pressure control with or without flow precontrol and the flow control can be combined with or without pressure control.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. General information:

The control algorithm can be used for all kind of flow controlled pump. This function is the interface of the fuel pressure acquisition and the fuel pressure setpoint calculation to the fuel pump control.

It calculates basically a requested fuel mass to be delivered into the fuel rail by the HP pump. This calculation is based on the fuel pressure setpoint, measrured fuel pressure, the fuel mass flow setpoint and the feedback of the pump interface, which is the fuel mass delivered by the pump. Additionally there is the input fuel temperature, which is needed to correct the calculation of the fuel mass in the rail.

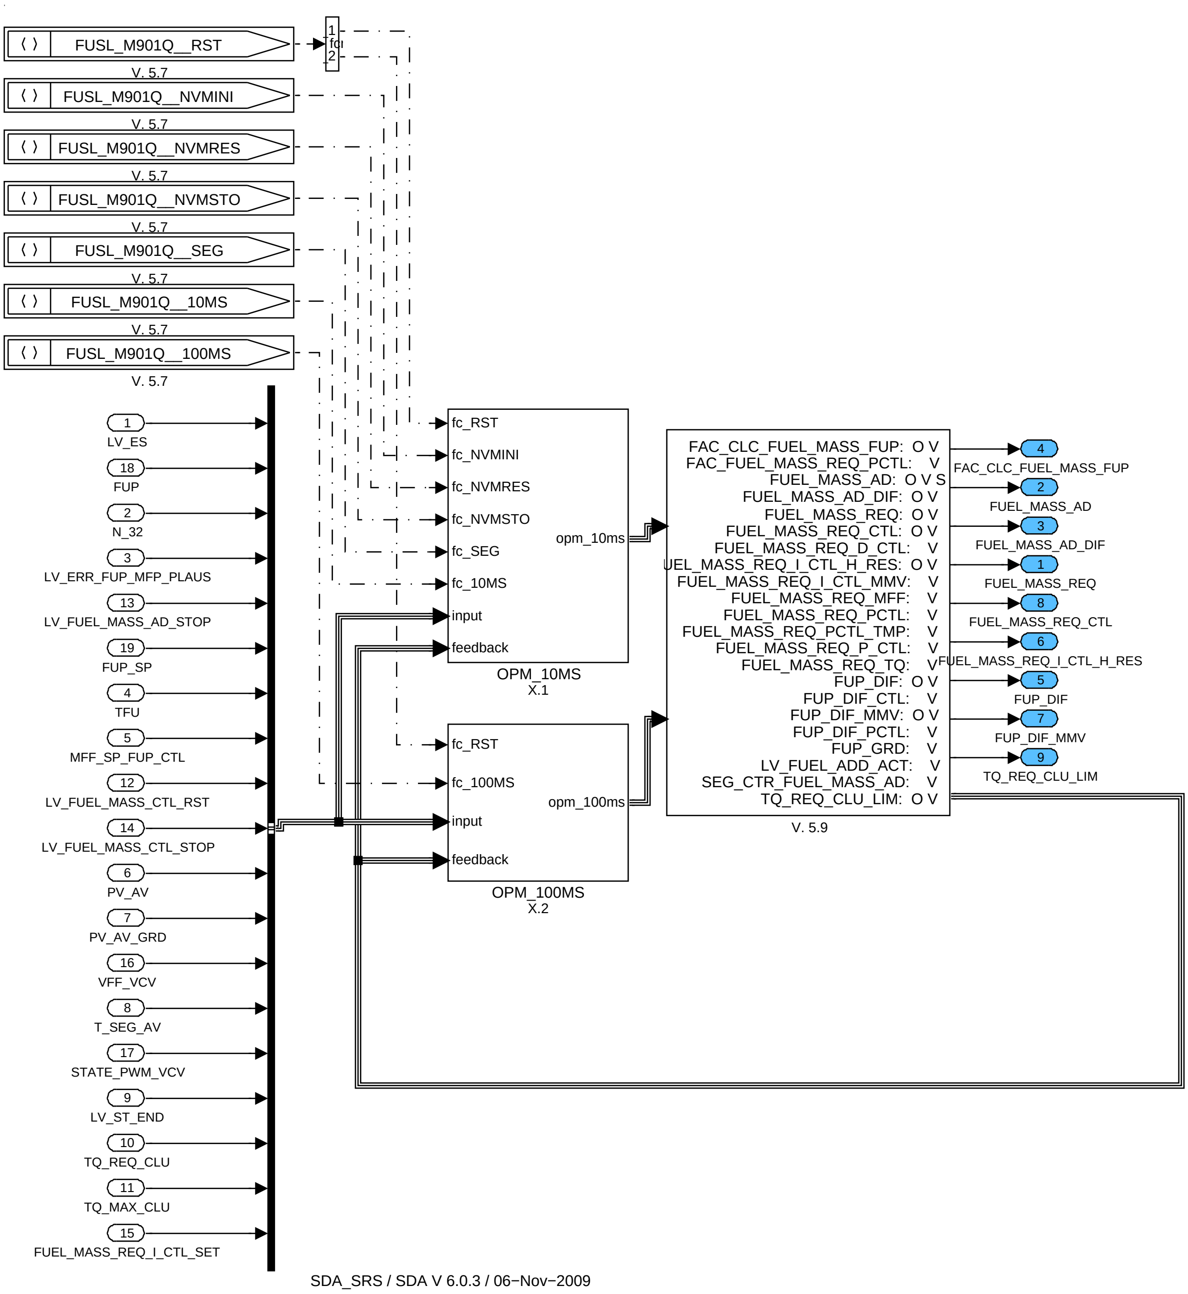

Figure 9.38.1: :

9.38.1 Function Description of 10MS

General information:

The functionality is split into several parts. First part is the precalcualtion of the fuel mass. In this module first the deviation between the fuel pressure setpoint and the measured fuel pressure is calculated. This deviation is the basis for the calculation of the requested fuel mass from the precontroller. This input will be corrected by a weighting factor and a conversion factor, which includes the density of the fuel and the compressibility of the rail and the fuel.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

To get a correct input for the mass fuel flow this will be corrected within the module mass fuel flow setpoint for fuel pressure control with the effective fuel cut off ratio.

The controller is split into the fuel mass adaptation and the actual controller. The calculated fuel mass adaptation takes as a basis the old value to the adaptive fuel mass and uses a actual calculated fuel mass adapation deviation. The adaptive fuel mass is min/max limited. The fuel mass adapation deviation is only calculated if the engine speed and the pump fuel mass is within certain limits. Another criteria is a segment counter, which allows the adaptation only after a certain amount of segments with stable conditions. The basis for the adapation is a filtered I-part of the controller.

The input of the actual controller is also a fuel pressure deviation. This time the deviation is calculated out of the measured fuel pressure fuel pressure setpoint. Out of this deviation the P part and the I part of the controller is calculated out of maps. After that calculation the P part can be reseted by certain conditions. The I part taken out of the map will be added up with the old value. This value can be 'frozen or reseted. Anyway there is limitation to min/max values. The I part and the P part are finally added up to the controller output.

With this controller output, the precalculation and the corrected mass fuel flow setpoint value the requested fuel mass is calculated.

Application conditions:

Initialisation:	`RST, NVMINI, NVMRES, NVMSTO`
Recurrence:	`SEG, 10MS`
Activation:	`SEG: LV_ES == 0 && LV_ST_END == 1 10MS: LV_ES == 0 && LV_ST_END == 0`
Deactivation:	`LV_ES == 1`

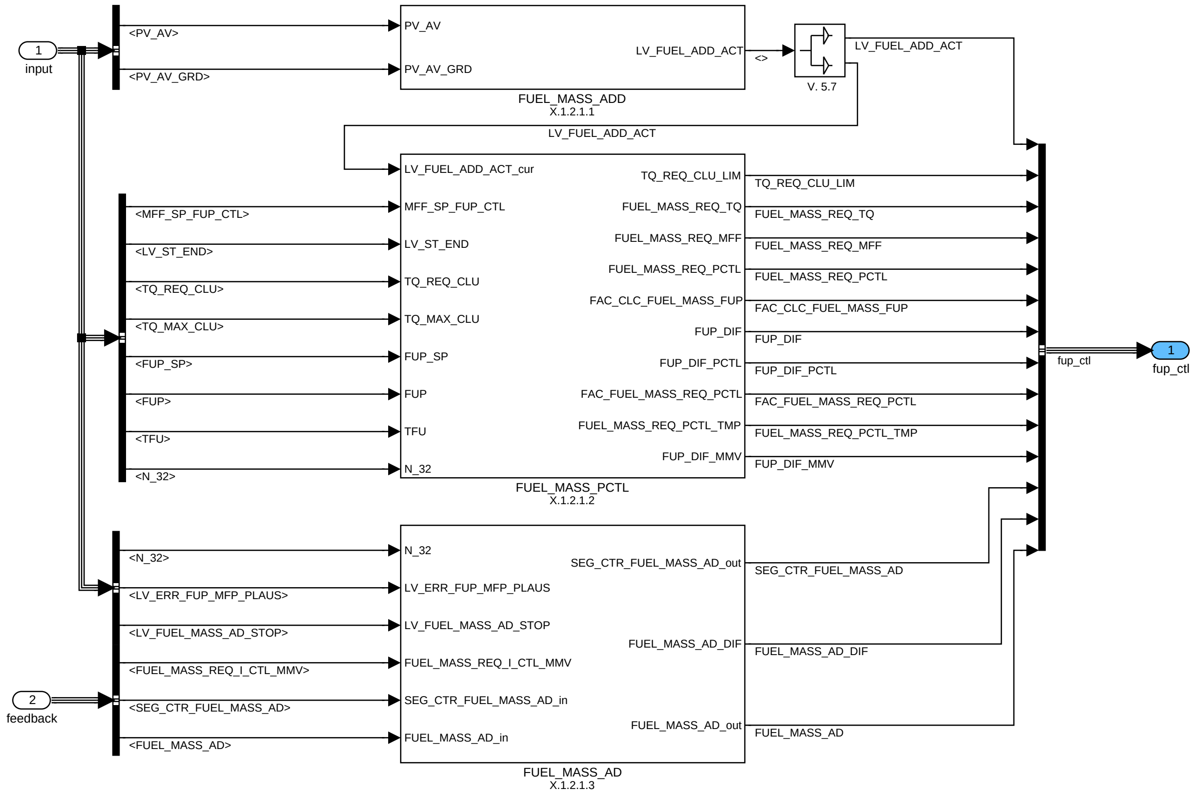

Figure 9.38.9: :

9.38.1.2.1.1 Additional fuel mass active

Depending on the pedal value and the pedal value gradient a fuel mass is added to the precontroller for a certain amount of cycles. This is indicated by a flag.

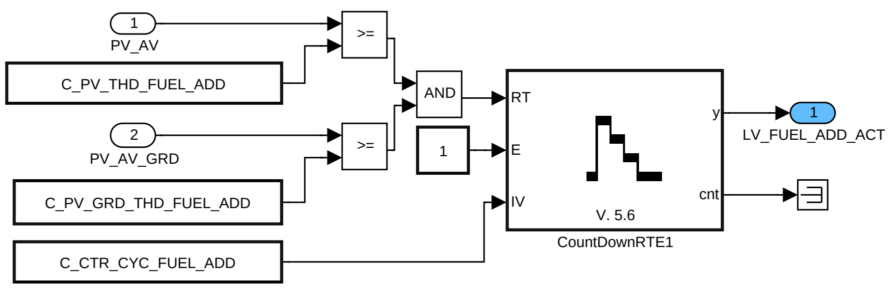

Figure 9.38.10: :

9.38.1.2.1.2 Calculation

Out of the fuel pressure deviation related to the used fuel pressure the precontrol value is calculated. This value can be modified by the weighting factor given by the map. Out of this calculated precontrol fuel pressure value a precontrol fuel mass must be chosen. This is done by the second map. Additionally to that a fuel mass can be added to the precontrol.

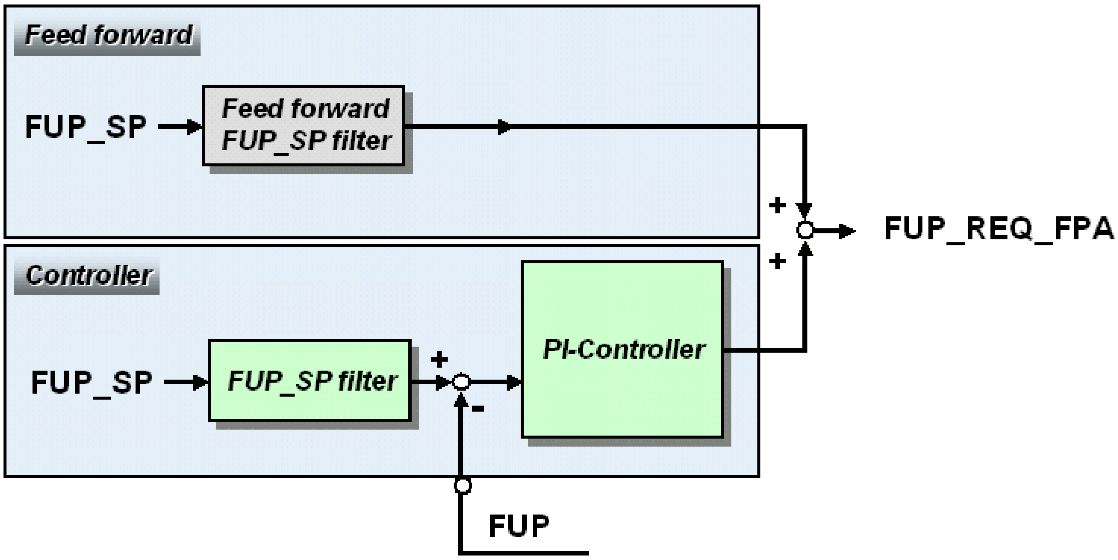
General Information

Application hint: NC_CLC_FUEL_PUMP_CTL = 1 for inlet controlled multi piston pump

The fuel pressure control (Appl. Inc.) provides a fuel pressure demand for the regulator. It is depending on fuel pressure setpoint and the fuel pressure. The structure is constiting out of a feed forward and a controller part.



Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: 1
Deactivation: 0

Function description

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

9.39.2 Formula Section

The functionality is consiting mainly out of transistion calculation part and a controller part.

The transistion are calculated out of several external inputs and the controller is taken into account this external influences.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

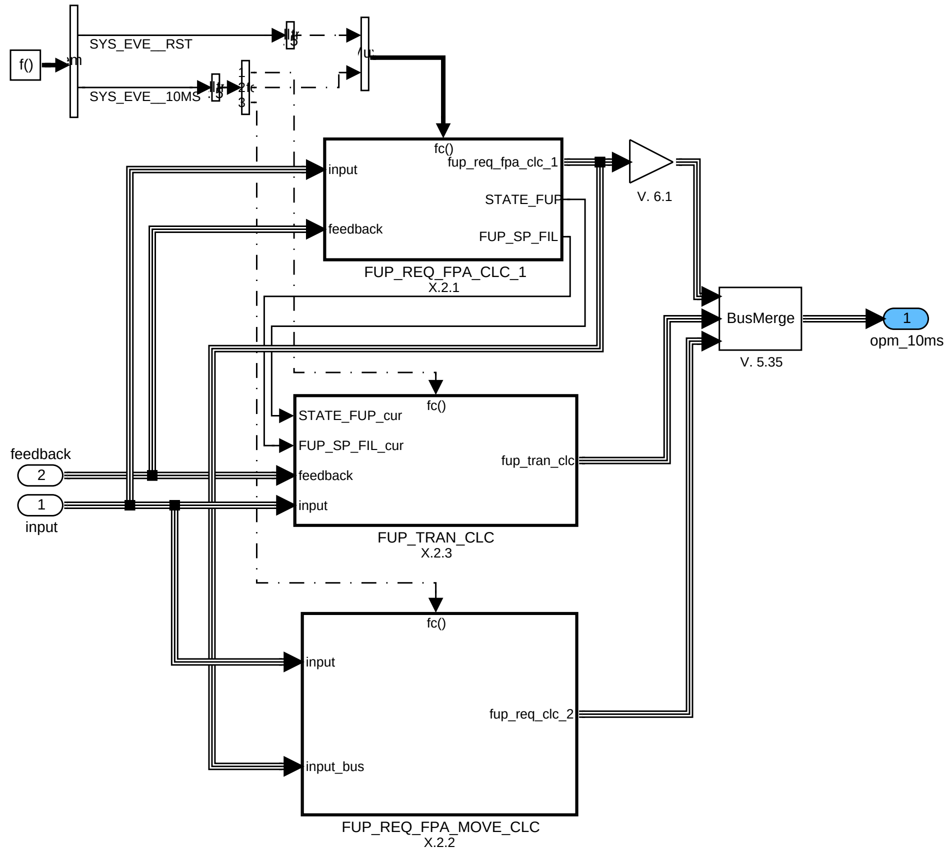

Figure 9.39.4: : Path: FUSL_M903W/OPM_10MS

9.39.2.1 Calculation

Out of the result of the state diagram a certain PWM is calculated within that subblocks.

The state diagram is corresponding to the different states of the controller. All the transition conditions are defined in the application incidence of fuel pressure control.

In Low pressure state the FPAPWM signal has minimum value. Also all the initialization is done in this state. Then in order to reach the fuel pressure setpoint the transition is done to Fast pressure increase . In this state the regulator has its maximum FPAPWM value in order to ensure the maximum pressure increase. In the state Pressure control the feed forward controller and the PIcontroller are active. The state Overpressure is selected when the pressure in the rail is too high. Here the FPAPWM signal has minimum value. In the state Limp home the control loop is opened and only the feed forward controller is active.

When a low pressure start is required the controller starts in Low pressure state until STATE_FUP_ TRAN = 2. This variable is defined in application incidences. After the start phase the fuel pressure should reach the setpoint in state Fast pressure increase . After fulfilling STATE_FUP_TRAN = 3 (setpoint is reached) the state Pressure control will be entered.

In case of a high pressure start the controller remains in Low pressure state until STATE_FUP_TRAN = 2 (starter relay is activated). This is done for security reasons in order to protect the regulator for overheating. In state Fast pressure increase the fasted pressure increase is performed. After fulfilling STATE_FUP_TRAN = 3 (setpoint is reached) the state Pressure control will be activated.

9.39.2.1.1.2.3 Calculation

Withing that two blocks the adaptation and the fuel pressure request for the FPA are calculated.

The calculation of the I and Ppart is done with the help of the fuel pressure deviation and two maps. The Ipart is not allowed to be outside of certain limits. Out of the precontrol, Ipart and Ppart the final fuel pressure demand for the high pressure pump control is generated.

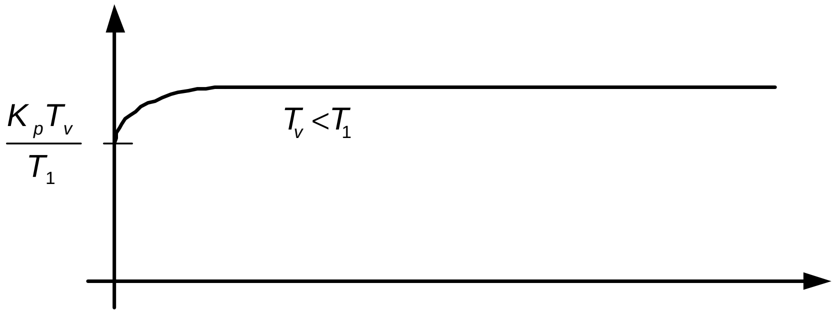
9.39.2.1.2 Set point calculation

Within this subblock the filtered fuel pressure setpoint and the precontroller is calculated.

The aim of the precontroller is to prevent overshoots or undershoots of the fuel pressure at big fuel pressure setpoint slopes. This whole block is basically representing a PPT1block.

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.



Source: PPT1-response.vsd

The factor KpTv/T1 ist represented by FAC_FUP_SP_PCTL. This factor is depending on the FUP_SP change. This factor will be multiplicated with FUP_SP, which is the basis for the FPAPWM value. The FUP_SP value is also filtered with a modified PT1filter.

9.39.2.3.2.4 Timer Calculation

This timer is observing to overpressure and gives signals to the state diagram.

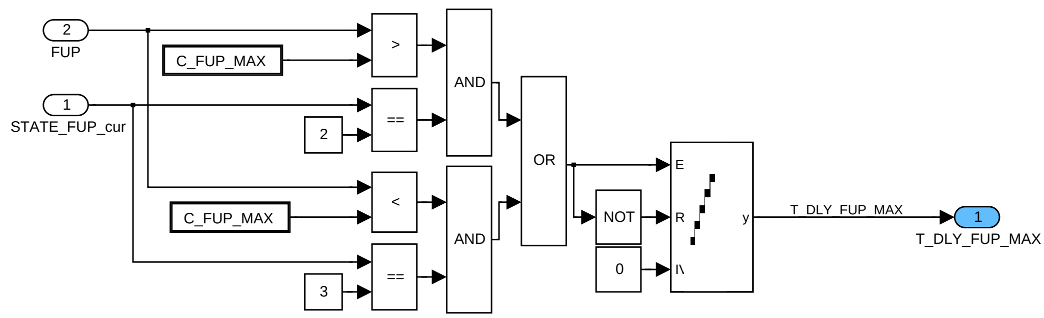

Figure 9.39.27: : Path:
FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL/T_DLY_FUP_MAX_CLC

9.39.2.3.3 Calculation

Due to complexibility of the transition calculation this function part is split into three parts.

In the first part the crash state will be achieved in case of crash event. When the engine stops the low pressure state will be selected. In case of overpressure more than a certain time the overpressure state should be reached. After disappearing of the overpressure more than a certain time this state will be left. In case of fuel pressure sensor failure the open loop state should be selected.

The second part gives possiblities to reach close state. This state might be not valid due to external influences at the actual actuator control done in high pressure pump control.

In the third part mainly start conditions are mentioned. In case of required high pressure start the high request for the FPA control is given as soon as the starter relay has closed. Otherwise a certain engine speed has to be reached.

Calibration data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_CRLC_FUP_CUR_VCV_MIN_AD	-	0... FFH	0... 0.99609375	3.90625e-3	-
Correlation constant for the MMV calculation of FUP for the adaptation					
C_CRLC_VB_VCV_MMV	-	0... FFH	0... 0.99609375	3.90625e-3	-
Averaging constant of VB filter for VCV control					
C_CRLC_VFF_VCV_MIN_BAS_MMV	-	0... FFH	0... 0.99609375	3.90625e-3	-
Filter constant for moving mean value calculation of the VFF_VCV_MIN_BAS					
C_CRLC_VFF_VCV_MIN_MMV	-	0... FFH	0... 0.99609375	3.90625e-3	-
Filter constant for moving mean value calculation of the VFF_VCV_MIN					
C_CTR_CUR_VCV_AST_MOVE_ACT	-	0... FFH	0... 255	1	-
Number of CUR pulses to move the VCV after engine stop					
C_CTR_CUR_VCV_BAS_AD_VAR_2_MAX	-	0... FFH	0... 255	1	-
Counter for the second variant of the flow control adaptation					
C_CTR_CUR_VCV_CTL_STOP	-	0... FFFFH	0... 65535	1	-
Counter for stopping the VCV current control in intervention mode					
C_CTR_CUR_VCV_MAX	-	0... FFH	0... 255	1	-
Calibration for Counter in Operation max mode					
C_CTR_CUR_VCV_MIN_AD_MAX	-	0... FFH	0... 255	1	-
Counter for the pressure control part adaptation					
C_CTR_MIN_VFF_VCV_MIN_AD_INI	-	0... FFH	0... 255	1	-
Constant for initialisation of counter for frequency of the lekage adaptation					
C_CTR_MIN_VFF_VCV_MIN_AD_SWI	-	0... FFH	0... 255	1	-
Constant deciding the frequency of the lekage adaptation					
C_CUR_BAS_CUR_VCV_CTL_MAX	-	0... FFFFH	0... 65.535	1e-3	A
Maximum current to enable VCV current controler					
C_CUR_BAS_CUR_VCV_CTL_MIN	-	0... FFFFH	0... 65.535	1e-3	A
Minimun current to enable VCV current controler					
C_CUR_VCV_AD_CORD_2	-	0... FFFFH	0... 0.0000999984	1.52588e-9	A/hPa
Correlation constant for transfering the I-part into the PWM_VCV_BAS curve					
C_CUR_VCV_AD_VAR_2_CORD_1	-	0... FFFFH	0... 0.049999237	762.939e-9	A/mg
Correlation constant for transfering the I-part into the flow control curve for second variant of the VCV flow adaptation					
C_CUR_VCV_AST_MOVE	-	0... FFFFH	0... 65.535	1e-3	A
PWM for moving the VCV after engine stop

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_CUR_VCV_AST_MOVE_MIN	-	0... FFFFH	0... 65.535	1e-3	A
VCV current threshold to activate the VCV after engine stop movement wthout LV_ERR_FUP_STOP					
C_CUR_VCV_BAS_AD_VAR_2_ADD_INI	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Initialisation value for the additive component ot the second variant of the VCV flow adaptation					
C_CUR_VCV_BAS_AD_VAR_2_ADD_MAX	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Maximum value for the additive component in the second variant of the VCV flow adaptation					
C_CUR_VCV_BAS_AD_VAR_2_ADD_MIN	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Minimum value for the additive component in the second variant of the VCV flow adaptation					
C_CUR_VCV_CRASH	-	0... FFFFH	0... 65.535	1e-3	A
CUR for VCV in CRASH					
C_CUR_VCV_CTL_AD_MAX	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Maximum allowed current deviation to enable PWM adaption					
C_CUR_VCV_DIF_REL_PRE_RUN_MIN	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Deviation of the VCV current controler to enable VCV_PRE_RUN					
C_CUR_VCV_LIH	-	0... FFFFH	0... 65.535	1e-3	A
CURfor VCV in limphome					
C_CUR_VCV_LIM_INC	-	0... FFFFH	0... 65.535	1e-3	A
Gradient limitation for increment of CUR_VCV					
C_CUR_VCV_MAN	-	0... FFFFH	0... 65.535	1e-3	A
Manual CURsignal for the VCV					
C_CUR_VCV_MIN_AD_1_INI	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Initialisation value CUR_VCV first point of pressure control part					
C_CUR_VCV_MIN_AD_1_MAX	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Maximum value for the adaptation of point 1 of the pressure control part					
C_CUR_VCV_MIN_AD_1_MIN	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Minimum value for the adaptation of point 1 of the pressure control part					
C_CUR_VCV_MIN_AD_2_INI	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Initialisation value CUR_VCV second point of pressure control part					
C_CUR_VCV_MIN_AD_2_MAX	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Maximum value for the adaptation of point 2 of the pressure control part					
C_CUR_VCV_MIN_AD_2_MIN	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Minimum value for the adaptation of point 2 of the pressure control part					
C_CUR_VCV_MIN_AD_MAX	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Maximum value for the adaptation of the pressure control part					
C_CUR_VCV_MIN_AD_MIN	-	8000... 7FFFH	-32.768 ...32.767	1e-3	A
Minimum value for the adaptation of the pressure control part					
C_CUR_VCV_MIN_OPL	-	0... FFFFH	0... 65.535	1e-3	A
Minimum CURsignal for the VCV in open loop (at engine stop)					
C_CUR_VCV_MIN_TOL	-	0... FFFFH	0... 65.535	1e-3	A
Maximum value for CUR_VCV_MIN					
C_CUR_VCV_PRE_RUN	-	0... FFFFH	0... 65.535	1e-3	A
Current for VCV_PRE_RUN

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
C_CUR_VCV_SP_MAX	-	0... FFFFH	0... 65.535	1e-3	A
Maximum allowed current for VCV					
C_CUR_VCV_VFF_VCV_MIN_AD	-	0... FFFFH	0... 65.535	1e-3	A
CUR value for the leakage adaptation					
C_FAC_CUR_VCV_AD_VAR_2_CORD_2	-	1... FFH	0.000392157 ...0.100000035	392.157e-6	1/mg
Correlation constant for transfering the I-part into the CUR_VCV_BAS curve for second variant of the VCV flow adaptation					
C_FAC_CUR_VCV_BAS_AD_2_TMP_INI	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Initialisation value for the temporary variable for the multiplicative component ot the second variant of the VCV flow adaptation					
C_FAC_CUR_VCV_BAS_AD_VAR_2_MAX	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Maximum value for the multiplicative component of the second variant of VCV flow adaptation					
C_FAC_CUR_VCV_BAS_AD_VAR_2_MIN	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Minimum value for the multiplicative component of the second variant of VCV flow adaptation					
C_FAC_CUR_VCV_CTL_MAX	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Maximum output of VCV current controller					
C_FAC_CUR_VCV_CTL_MIN	-	8000... 7FFFH	-2... 1.99993896484	61.0352e-6	-
Minimum output of VCV current controller					
C_FAC_PWM_VCV_MIN	-	0... FFH	0... 9.9609375	0.0390625	-
Correction factor for the PWM_VCV_MIN by the flow through the regulator part					
C_FRQ_PWM_VCV_OPL	-	0... 3FFH	0... 1023	1	Hz
Required frequency for the VCV for open position (typical 10 - 1023 Hz); Initialisation with 100Hz					
C_FRQ_PWM_VCV_PRE_RUN	-	0... 3FFH	0... 1023	1	Hz
Required frequency for the VCV for pre run (typical 10 - 1023 Hz); Initialisation with 100Hz					
C_FRQ_REQ_VCV_AST_MOVE	-	0... 3FFH	0... 1023	1	Hz
Required frequency for moving the VCV after engine stop (typical 10 - 1023 Hz)					
C_FUP_CUR_VCV_MIN_AD_1	-	0... FFFFH	0... 347776	5.3067216	hPa
Mean fuel pressure for adaptation of point 1 of pressure control part					
C_FUP_CUR_VCV_MIN_AD_1_INI	-	0... FFFFH	0... 347776	5.3067216	hPa
Initialisation value for the fuel pressure first adaptation point pressure control part					
C_FUP_CUR_VCV_MIN_AD_2	-	0... FFFFH	0... 347776	5.3067216	hPa
Mean fuel pressure for adaptation of point 2 of pressure control part					
C_FUP_CUR_VCV_MIN_AD_2_INI	-	0... FFFFH	0... 347776	5.3067216	hPa
Initialisation value for the fuel pressure second adaptation point pressure control part					
C_FUP_CUR_VCV_MIN_HYS_1	-	0... FFFFH	0... 347776	5.3067216	hPa
Hysteresis of fuel pressure for adaptation of point 1 of pressure control part					
C_FUP_CUR_VCV_MIN_HYS_2	-	0... FFFFH	0... 347776	5.3067216	hPa
Hysteresis of fuel pressure for adaptation of point 2 of pressure control part					
C_FUP_DIF_CUR_VCV_AD	-	0... FFFFH	0... 347776	5.3067216	hPa
Max. fuel pressure deviation to allow adaptation

General information:

The fuel pressure in the rail can be controlled by an volume control valve at the inlet side. Depending on the requested fuel mass to be delivered by the fuel pump the inlet valve to the pump has to be controlled.

Copyright (C) Continental AG,2007

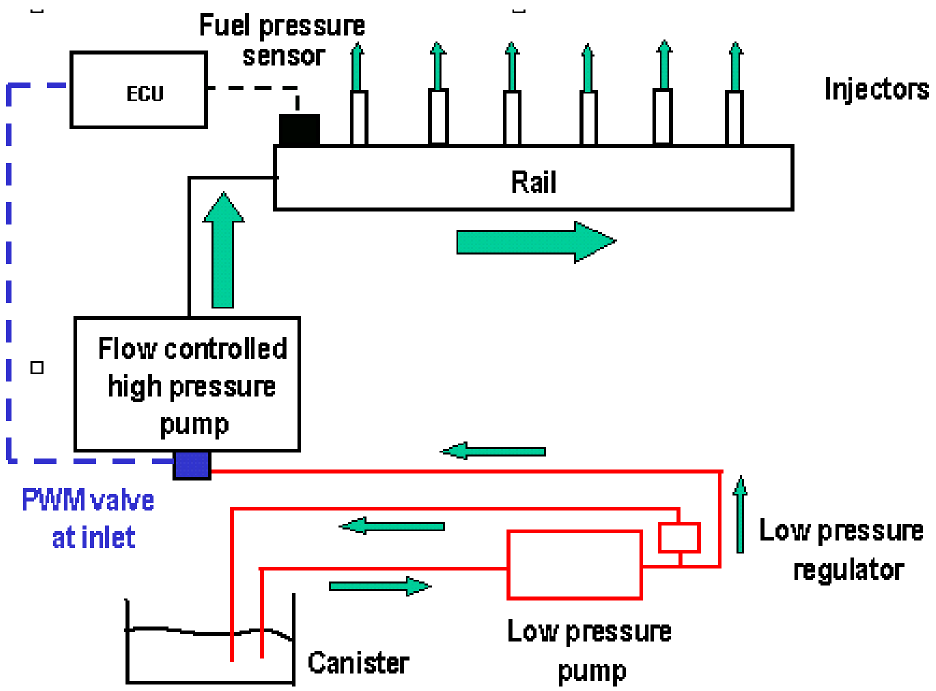

Figure 9.40.1: :

In case of checksum error or new ECU initial values are taken for the corresponding variables. Otherwise the stored values are taken. All adapted values can be cleared by the variable LC_HPP_CTL_AD_CLR.

Use ACTION_INFR_SetPwmVcv(IN<ducy>)
ACTION_INFR_SetFrqPwmVcv(IN<frq>)
IF NC_V_CUR_VCV_MES > 0 (Shunt for VCV current is present in ECU)

9.40.1.1.1.1 Check of C_IDX_TRIM and range check

Here the trim-ID is checked additonal a range check of the trim values is done. In the case that the trim values are out of a defined range the use of the trim-values is inhibited (via LV_V_CUR_VCV_BOOT_NOT_VLD). Via LV_V_CUR_VCV_BOOT_NOT_VLD also an error entry can be triggered.

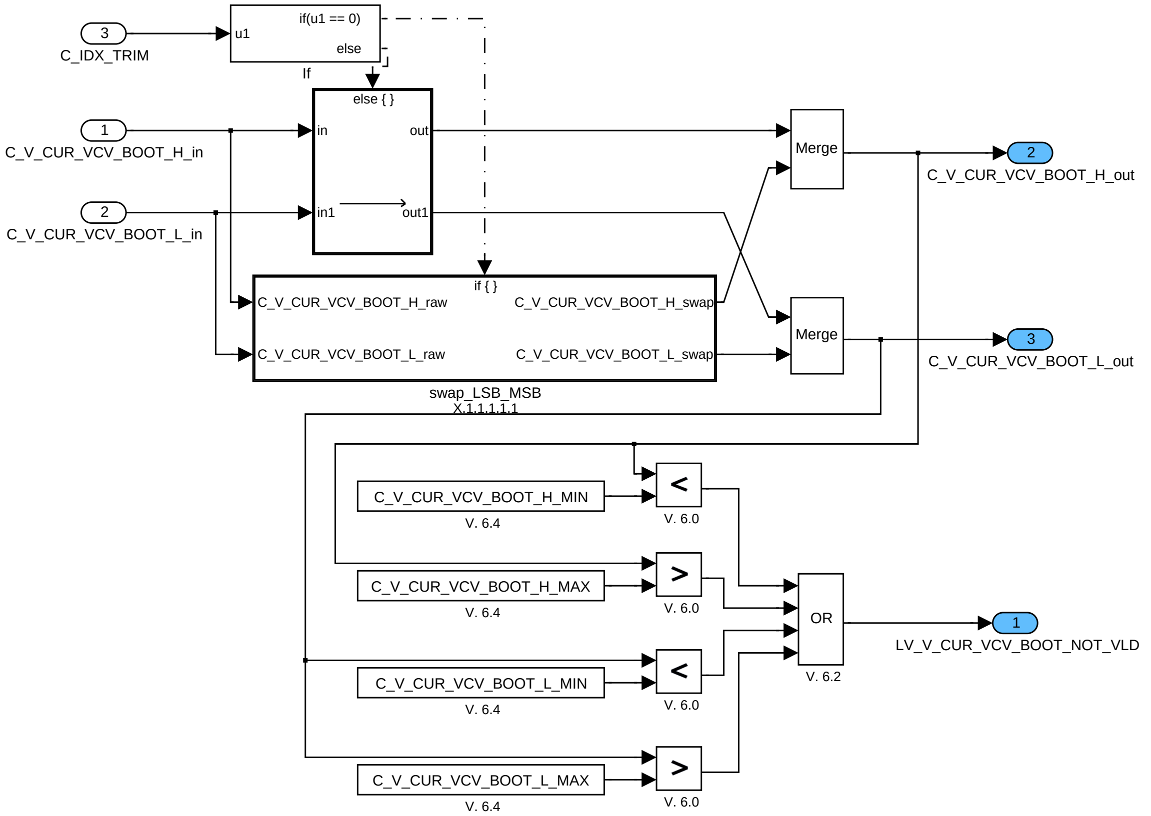

Figure 9.40.6: :

9.40.1.1.1.1.1 Swap of lower and upper bytes

LSB_MSB_swap and the Trim ID C_IDX_TRIM
C_V_CUR_VCV_BOOT_H/L are voltages that are measured during production phase and stored along with their complements in the logistic area. They are the trim values for the volume control valve (VCV) of the high preassure pump. The ASW reads those values during initialisation. The values are stored in HEX-format. For MSD87-6 there are different ways the HEX values are stored (order of MostSignificantByte/LeastSignificatByte). To distingush the different HEX-conventions used during trim process a trim ID was indroduced. It has the label name C_IDX_TRIM.

Example:
analog voltages are digitised
3,1061V=20356digits
(hint: HexValue 4F84 in Microsoft- Windows Calculator;
the value which is stored in the logistic area in the MSD80 project is 844F)

the value which is stored in the logistic area in the MSD87-6 project differs depending on the Trim ID C_IDX_TRIM
ECUs with TrimmID 0 use the format 4F84
ECUs with TrimmID 1 use the format 844F

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

The ASW has to take care of the LSB/MSB_order of the HEX values when it reads them back. LSB/MSB need to be swapped or not, depending on the trimID. Complement values use the same format as the trim values that is why the LSB_MSB swap has only to be done for the calculation in the formula section.

see also 'logistic concept for production line test'
Trim_VCV order:
0x00 =
(only sample production)
adr. n = MSB,
adr (n+1)=LSB
0x01 =
(serial production)
adr. n = LSB,
adr (n+1)=MSB

General information:

In this module the limphome bits for the high pressure pump control are calculated.

Application conditions:

Initialisation: `all outputs to zero at RST`
Recurrence: `10MS`
Activation: `always`
Deactivation: `never`

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LC_MFF_ADD_ER_BAL_ENA	-	0... 1H	0 ...1	1	-
Logical constant to enable additive MFF intervention out of idle					

General information:

Cylinder balancing via TI intervention means a correction of the cylinder individual injection time values to achieve a balancing of the indicated torque between the single cylinders based on engine roughness calculation. Target is to achieve a smooth engine running.
The "Balancing Manager" is realized with a state machine. Different states with a defined setting of corresponding output variables are existing as well as clear conditions to change from one state to another. The calculation of adaptation values is controlled by the states of the state machine.
By means of the logical constant LC_MFF_ADD_ER_BAL_ENA it is possible to enable (LC_MFF_ADD_ER_BAL_ENA = 1) or disable (LC_MFF_ADD_ER_BAL_ENA = 0) the additive adaptation in part load. At idle speed the additive adaptation is always enabled.
In order to compensate torque differences, e.g. caused by manufacturing tolerances of the injection valves, either an additive or a multiple adaptation correction of the injection times is carried out at state "Cylinder Balancing" depending on the current mass fuel flow setpoint.
The additive adaptation value, which influences the offset of the injection valve characteristic line is learned at low mass fuel flow values. The multiple adaptation factor however, which influences the slop of the injector characteristic line, is learned at higher mass fuel flow values (refer: figure).

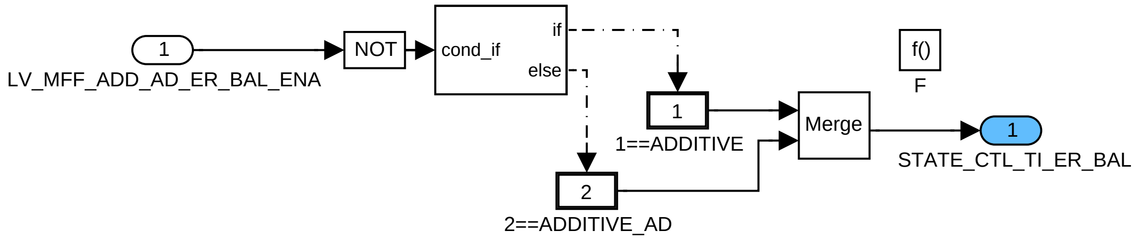

Figure 9.43.13: CYBL_M30907L03/OPERATE_SEG/STATE_CYBL_CTL_TI_INTV/ELSE/THEN

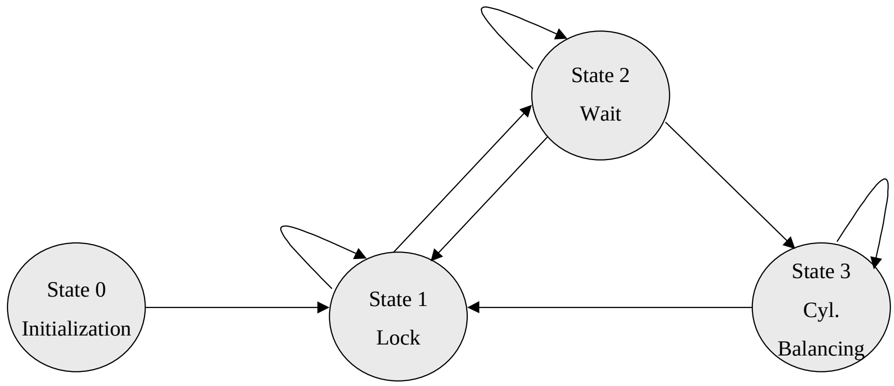
Description of the Cylinder Balancing Manager

State diagram:



Cylinder Balancing Manager: State 0H - Initialization

At reset the state of cylinder balancing changes at once to state "Initialization". The state "Initialization" is active for one recurrence (first segment after reset). As soon as the next segment (second segment after reset) is valid, the state changes immediately to state "Lock".

Cylinder Balancing Manager: State 1[H] - Lock

The algorithm stays in this state until the flags LV_TI_ER_BAL_ENA is set to 1 . This flag is set when certain conditions for controlling and adaptation are fulfilled.

Cylinder Balancing Manager: State 2[H] - Wait

The counter CTR_TI_ER_BAL_ENA starts to run. It counts down from its calibrate able initial value IP_CTR_TI_ER_BAL_ENA_INI to zero (decrease of 1 every engine cycle).

Furthermore the input values ER_STND_MMV_BAL[SEG_NR_ER] and ER_STD_MMV_BAL[SEG_NR_ER] have to below a certain limit:

Cylinder Balancing Manager: State [3] - Cylinder Balancing

The input values ER_STND_MMV_BAL[SEG_NR_ER] and ER_STD_MMV_BAL[SEG_NR_ER] have to below a certain limit (analogue to state 2).

General information

The Appl. Inc. module is used to keep the cylinder balancing functions modular. Therefore the activation conditions for the signal preparation functions, the balancing manager and the cylinder balancing adaptation functions are set within this module. The cylinder balancing functions are activated as soon as the corresponding activation condition is enabled (=1).

With the logical variable LV_MFF_COR_ER_BAL_ENA_EXT it is possible to adapt the main enable condition (to start cylinder balancing via TI intervention) with additional external requirements. The flag is used as input signal for the cylinder balancing manager.

With the logical variable LV_MFF_ADD_AD_ER_BAL_ENA_EXT it is possible to adapt the main adaptation condition (to start cylinder balancing additive adaptation) with additional external requirements. The flag is used as input signal for the cylinder balancing manager.

A logical calibration constant is available to stop all cylinder balancing interventions at once. In case of LC_TI_ER_BAL_STOP_MAN = 1, several activation conditions for the cylinder balancing functions are disabled (=0). If the logical constant is enabled (=1), a reinitialisation ("0"[hex]) of all output values occurs.

Basic condition to enable cylinder balancing manager calculations

LV_ER_FDOUT (flag for engine roughness fade out condition)
LV_ENA_ER (calculation of engine roughness (ER) values valid)
LV_SEG_AD_AVL_ER (segment adaptation process achieved at least one time)
LV_SEG_AD_LIM_ER (engine roughness (ER) adaptation values not out of range)
LV_STATE_RR (no rough road detected)

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LV_ERR_CRK (no failure present on crankshaft sensor)
LV_ERR_CAM (no failure present on camshaft sensor)
LV_ERR_TPS (flag for throttle position error)
LV_ERR_TCO (flag for TCO sensor error)
LV_ERR_VCV (flag for voltage supply error)
LV_ERR_FUP (flag for fuel pressure sensor error)
LV_ERR_FUP_ST (flag for "fuel pressure at start to low" error)
LV_ERR_FUP_ORNG (flag for "fuel pressure out of range" error)
LV_ERR_FUP_MFP_PLAUS (flag for "FUPmass fuel pump relation" error)
LV_ERR_H_PRS_SYS (flag for abnormal fuel pressure error)
LV_ERR_LOAD_TPS_PLAUS (flag for "LOADthrottle position relation" error)
LV_ERR_T_SEG_ER (flag for "segment time adaptive value" error)
LV_ERR_SEG_AD_ER (flag for "ER segment time adaptation" error)
LV_ERR_CYL_BAL_ER[x] (flag for cylinder balancing error, AND condition over all cylinders
[x] is representing each cylinder separately [1...NC_CYL_NR])
LV_ERR_CAT_DIAG[i] (flag for cat diagnosis error, AND condition over all exhaust banks
[i] is representing each exhaust bank separately [1...NC_CBK_EX_NR])
LV_INH_BAL_CUS (customer request to inhibit the function]
LV_ERR_MAP_TPS_PLAUS (flag for MAPthrottle position plausibility error)
LV_DET_MIS (status for actual detected misfire)
LV_MIIS_STATE_A (no CARB A[200 CRK] misfire failure present)
LV_MIS_STATE_B4 (no CARB B4[1000 CRK] misfire failure present)
LV_FCUT_IND (flag for cylinder shut off)
STATE_ERR_IV (error pattern for injection valve failure)

FUNCTION DESCRIPTION:

General information:

This manager specifies the sequencing of all CYBL tasks.

Description:

Within the cylinder balancing package (CYBL), all functions for Cylinder balancing via engine roughness" (CYBL_ER) are included. This scheduler has to manage the coordination of all involved parts.

Application conditions

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

FUNCTION DESCRIPTION:

General information:

Task of the cylinder balancing coordination is to observe the balancing adaptation functions at end of line test and to set a readiness information as soon as a defined adaptation limit for each adaptation has been reached.

Application conditions

Initialization at first Engine run or NVMY-error:

```
LV_CYL_BAL_LAM_AD_EOL = 0                 (first initialization)
LV_CYL_BAL_LAM_SEL_AD_COLD_EOL = 0        (first initialization)
LV_CYL_BAL_LAM_SEL_AD_HOT_EOL = 0         (first initialization)
LV_CYL_BAL_ER_AD_FAC_EOL = 0              (first initialization)
LV_CYL_BAL_ER_AD_ADD_EOL = 0              (first initialization)
FOR m = 0 to NC_CBK_EX_NR - 1
```

```
    LV_CYL_BAL_LAM_SEL_AD_COLD[m] = 0          (first initialization)
    LV_CYL_BAL_LAM_SEL_AD_RNG_L[m] = 0         (first initialization
    LV_CYL_BAL_LAM_SEL_AD_RNG_H[m] = 0         (first initialization
    LV_CYL_BAL_LAM_AD_FAC[m] = 0               (first initialization
    LV_CYL_BAL_LAM_AD_ADD[m] = 0               (first initialization
END FOR
```

Initialization at Reset:

```
LV_CYL_BAL_LAM_AD_EOL = LV_CYL_BAL_LAM_AD_EOL          (NVMY)
LV_CYL_BAL_ER_AD_FAC_EOL = LV_CYL_BAL_ER_AD_FAC_EOL    (NVMY)
LV_CYL_BAL_ER_AD_ADD_EOL = LV_CYL_BAL_ER_AD_ADD_EOL    (NVMY)
LV_CYL_BAL_LAM_SEL_AD_COLD_EOL = LV_CYL_BAL_LAM_SEL_AD_COLD_
EOL (NVMY)
LV_CYL_BAL_LAM_SEL_AD_HOT_EOL = LV_CYL_BAL_LAM_SEL_AD_HOT_
EOL (NVMY)
```

FOR m = 0 to NC_CBK_EX_NR - 1

LV_CYL_BAL_LAM_SEL_AD_COLD[m] = LV_CYL_BAL_LAM_SEL_AD_COLD[m] *(NVMY)*
LV_CYL_BAL_LAM_SEL_AD_RNG_L[m] = LV_CYL_BAL_LAM_SEL_AD_RNG_L[m] *(NVMY)*

9.46.1 External adjustment of cylinder balancing readiness at end of line (EOL):

FUNCTION DESCRIPTION:

General information:

In case of an external adjustment (request from key word protocoll) the readiness bits for all cylinder balancing adaptation functions at EOL are set to zero. While the external adjustment is activated, all following subchapters within the module "Cylinder balancing coordination at EOL" are deactivated and the corresponding "Initialization at Deactivation" process for this chapters is blocked during the period.

Application conditions

Recurrence: *100 ms*

Activation: *LV_CYL_BAL_AD_EOL_EXT_ADJ = 1*

Deactivation: *LV_CYL_BAL_AD_EOL_EXT_ADJ = 0*

Formula section:

LV_CYL_BAL_LAM_AD_EOL = 0

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

LV_CYL_BAL_LAM_SEL_AD_COLD_EOL = 0
LV_CYL_BAL_LAM_SEL_AD_HOT_EOL = 0
LV_CYL_BAL_ER_AD_FAC_EOL = 0
LV_CYL_BAL_ER_AD_ADD_EOL = 0
FOR m = 0 to NC_CBK_EX_NR - 1
    LV_CYL_BAL_LAM_SEL_AD_COLD[m] = 0
    LV_CYL_BAL_LAM_SEL_AD_RNG_L[m] = 0

    LV_CYL_BAL_LAM_AD_FAC[m] = 0
    LV_CYL_BAL_LAM_AD_ADD[m] = 0
END FOR

9.46.2 Manual reset of cylinder balancing readiness at end of line (EOL):

FUNCTION DESCRIPTION:

General information:

In case of a manual reset it is possible to adjust the exported output data to a wanted value to make the function test and handling more easier. While the manual function reset is activated, all following subchapters within the module "Cylinder balancing coordination at EOL" are deactivated and the corresponding "Initialization at Deactivation" process for this chapters is blocked during the period.

9.46.4 Calculation of cylinder balancing engine roughness adaptation readiness (EOL):

FUNCTION DESCRIPTION:

Transmittal, reproduction, dissemination and/or editing of this document as well as utilisation of its contents and communication thereof to others without expressed authorisation are prohibited. Offenders will be held liable for payment of damages. All rights created by patent grant or registration of a utility model or design patent are reserved.

General information:

After activation of the corresponding adaptation function (multiple or additive) at stratified combustion mode, a timer is started to observe the filtered engine roughness values used as input for the adaptation controllers. As soon as all controller input values are within a defined range for a specific time interval, readiness is indicated. The function is controlled by a state machine.

Application conditions:

Initialization at Reset **or** *Deactivation*

9.46.6 Calculation of cylinder balancing lambda adaptation readiness (EOL):

FUNCTION DESCRIPTION:

General information:

After activation of the corresponding adaptation function at homogenous combustion mode, a timer is started to observe the deviation between the actual and the last learned lambda deviation value. As soon as the deviation values are within a defined range for a specific time interval, readiness is indicated. The function is controlled by a state machine.

Application conditions:

Initialization at Reset **or** *Deactivation*

FOR m = 0 to NC_CBK_EX_NR - 1
  LV_STATE_CYL_BAL_LAM_CHG_WAIT[m] = 0
  CTR_CYL_BAL_LAM_CBK_AD[m] = 0
END FOR
T_CYL_BAL_LAM_AD = 0.00[s]
LV_STATE_CYL_BAL_LAM_CHG_AD = 0
STATE_CYL_BAL_LAM_AD_EOL = "Ready" (0[**H**])

Recurrence: 20 ms

Activation:
LC_CYL_BAL_AD_EOL_RST = 0 **and**
LV_CYL_BAL_AD_EOL_EXT_ADJ = 0 **and**
LC_CYL_BAL_CORD_EOL_STOP_MAN = 0 **and**
LV_CYL_BAL_LAM_AD_EOL = 0

Deactivation:
LC_CYL_BAL_AD_EOL_RST = 0 **and**
LV_CYL_BAL_AD_EOL_EXT_ADJ = 0 **and**
[LC_CYL_BAL_CORD_EOL_STOP_MAN = 1 **or**
LV_CYL_BAL_LAM_AD_EOL = 1 **]**
