The memory area of all output data variables of this module is not permanently RAM tested, the memory area of this module is not cyclic ROM tested.

Description:

Since the different faults can occur in a successive way, they are stored in different locations of the error memory.

All faults LV_ERR_XX_MON_1 are stored in separate locations, in order to be able to analyze a scenario of successive faults. If more than one errors stored in one location, then it will be detected by different error symptoms.

The information whether a warning lamp (ETC MIL) is switched on in case of an error can be found in the general OBD error code table.

Application conditions:

Activation: at every engine state
Deactivation: -
Initialization:
- for condition see ‘Application Incidences of Process Monitoring chapter 1.1’

-ACTION_ERRM_NoFilterReset(IN<CONV_MON>, OUT<LV_ERR_CONV_MON_1>)
-ACTION_ERRM_NoFilterReset(IN<N_32_MON>, OUT<LV_ERR_N_32_MON_1>)
-ACTION_ERRM_NoFilterReset(IN<TPS_MON>, OUT<LV_ERR_TPS_MON_1>)
-ACTION_ERRM_NoFilterReset(IN<PVS_MON>, OUT<LV_ERR_PVS_MON_1>)
-ACTION_ERRM_NoFilterReset(IN<CRU_INH_MON>, OUT<LV_ERR_CRU_INH_MON_1>)

(these actions erases filter data (LV_CDN_DIAG_xx = 0, LV_ERR_xx = 0, ERR_SYM_xx = NO_SYM

- For LV_ERR_N_MAX_MON_SAVE = 0, if a power up is recognized. A power up is detected, if the variables in the reset safe RAM are not consitend.

Update Rate: 40 ms

11.29.1 Error memory management of LV_ERR_CONV_MON_1

Formula section:

```
LV_CDN_DIAG_CONV_MON_1 = 1

If    (LV_ERR_CONV_MON = 1
Then
      lv_err_reset_CONV_MON_1 = 0;
      lv_err_set_CONV_MON_1 = 1;                {failure detected}
      ERR_SYM_CONV_MON_1 = SYM_3;
      LV_END_DIAG_CONV_MON_1 = 1;
Else
      lv_err_set_CONV_MON_1 = 0;
      lv_err_reset_CONV_MON_1 = 1;    {no failure detected}
      ERR_SYM_CONV_MON_1 = NO_SYM;
      If { delay 520ms } then
      /* After the level2 fault reaction time of 500ms the errors are updated */
            LV_END_DIAG_CONV_MON_1 = 1;
      Endif
Endif
```

For error management treatment the following action is called:

ACTION_ERRM_NoFilterSymptom(IN<CONV_MON>, IN<LV_CDN_DIAG_CONV_MON_1>, IN<ERR_SYM_CONV_MON_1>, IN<lv_err_set_CONV_MON_1>, IN<lv_err_reset_CONV_MON_1>, IN<LV_END_DIAG_CONV_MON_1>, OUT<LV_ERR_CONV_MON_1>)

11.29.2 Error memory management of LV_ERR_N_32_MON_1

Formula section:

```
LV_CDN_DIAG_N_32_MON_1 = 1

If    (LV_ERR_N_32_MON = 1
Then
      lv_err_reset_N_32_MON_1 = 0;
      lv_err_set_N_32_MON_1 = 1;                {failure detected}
      ERR_SYM_N_32_MON_1 = SYM_3;
```

```
        LV_END_DIAG_N_32_MON_1 = 1;
    Else
        lv_err_set_N_32_MON_1 = 0;
        lv_err_reset_N_32_MON_1 = 1;      {no failure detected}
        ERR_SYM_N_32_MON_1 = NO_SYM;
        If { delay 520ms } then

            LV_END_DIAG_CRU_INH_MON_1 = 1;
      Endif
Endif
```

For error management treatment the following action is called:

ACTION_ERRM_NoFilterSymptom(IN<CRU_INH_MON>, IN<LV_CDN_DIAG_CRU_INH_MON_1>, IN<ERR_SYM_CRU_INH_MON_1>, IN<lv_err_set_CRU_INH_MON_1>, IN<lv_err_reset_CRU_INH_MON_1>, IN<LV_END_DIAG_CRU_INH_MON_1>, OUT<LV_ERR_CRU_INH_MON_1>)

11.29.6 Error memory management of LV_ERR_TQI_AV_MON_1

Formula section:

```
If        LV_TQI_MON_ACT_MON = 1
Then      LV_CDN_DIAG_TQI_AV_MON_1 = 1;

If   (LV_ERR_TQI_AV_MON = 1)
Then
    lv_err_reset_TQI_AV_MON_1 = 0;
    lv_err_set_TQI_AV_MON_1 = 1;               {failure detected}
    ERR_SYM_TQI_AV_MON_1 = SYM_3;
    LV_END_DIAG_TQI_AV_MON_1 = 1;
Else
    lv_err_set_TQI_AV_MON_1 = 0;
    lv_err_reset_TQI_AV_MON_1 = 1;             {no failure detected}
    ERR_SYM_TQI_AV_MON_1 = NO_SYM;
    If { delay 520ms } then
    /* After the level2 fault reaction time of 500ms the errors are updated */
                LV_END_DIAG_TQI_AV_MON_1 = 1;
    Endif
Endif
```

For error management treatment the following action is called:

ACTION_ERRM_NoFilterSymptom(IN<TQI_AV_MON>, IN<LV_CDN_DIAG_TQI_AV_MON_1>, IN<ERR_SYM_TQI_AV_MON_1>, IN<lv_err_set_TQI_AV_MON_1>, IN<lv_err_reset_TQI_AV_MON_1>, IN<LV_END_DIAG_TQI_AV_MON_1>, OUT<LV_ERR_TQI_AV_MON_1>)

11.29.7 Error memory management of LV_ERR_TQI_N_MAX_MON_1

The error LV_ERR_TQI_N_MAX_MON_1 triggers the redundant switch off path (see "Fault Reaction of Process Monitoring") during the actual duty cycle. This finally leads to a reset after debouncing (see "Processor Monitoring"). The entry into the error memory has to be performed past reset. Therefore it is needful to store the error information reset safe; LV_ERR_TQI_N_MAX_MON_1_SAVE is located in the reset safe RAM area. The entry into the error memory is done past reset by evaluation of the information stored before reset.

Application conditions:

Initialisation: LV_ERR_TQI_N_MAX_MON_1_SAVE = 0
only after power up, no initialization after reset

Formula section:

```
If          LV_IGK = 1 and
            VB > C_VB_MIN_MON_DIAG
Then        LV_CDN_DIAG_TQI_N_MAX_MON_1 = 1;

If(1)       (LV_ERR_TQI_N_MAX_MON_1_SAVE = 1)/* error detected last duty cycle */
Then(1)
   /* error not jet passed to ERRM =>  transfer error information to ERRM*/
   lv_err_reset_TQI_N_MAX_MON_1 = 0;
   lv_err_set_TQI_N_MAX_MON_1 = 1;
   ERR_SYM_TQI_N_MAX_MON_1 = SYM_3;
   /* environment data are already reset safe stored before reset */
   LV_END_DIAG_TQI_N_MAX_MON_1 = 1;
   /* avoid more than one entry into error memory */
   if (2) {delay 120ms}
   Then(2)
     /* this delay time periode depends on Processor Monitoring */
     /* After this time periode the reset has to be carried out */
     LV_ERR_TQI_N_MAX_MON_1_SAVE = 0;
   Endif(2)
Else(1)     /* error not detected last duty cycle */
     If (3)(LV_ERR_TQI_N_MAX_MON_1 = 1)
     Then(3)        /* error was stored last recurrence */
            lv_err_reset_TQI_N_MAX_MON_1 = 0;
            lv_err_set_TQI_N_MAX_MON_1 = 1;
            ERR_SYM_TQI_N_MAX_MON_1 = SYM_3;
```

```
            LV_END_DIAG_TQI_N_MAX_MON_1 = 1;
        Else(3)
            lv_err_set_TQI_N_MAX_MON_1 = 0;
            lv_err_reset_TQI_N_MAX_MON_1 = 1;          {no failure detected}
            ERR_SYM_TQI_N_MAX_MON_1 = NO_SYM;
          If (4){ delay 520ms }
          Then(4)
            /* After the level2 fault reaction time of 500ms the errors are updated */
            LV_END_DIAG_TQI_N_MAX_MON_1 = 1;
          Endif(4)
        Endif(3)
    Endif(1)
    If(5) (LV_ERR_TQI_N_MAX_MON = 1)
    Then(5)   /* error detected in actual duty cycle */
        If(6)   (LV_ERR_TQI_N_MAX_MON_1_SAVE = 0)

Endif
```

For error management treatment the following action is called:

ACTION_ERRM_NoFilterSymptom(IN<TQ_EXT_MON>,
IN<LV_CDN_DIAG_TQ_EXT_MON_1>, IN<ERR_SYM_TQ_EXT_MON_1>,
IN<lv_err_set_TQ_EXT_MON_1>, IN<lv_err_reset_TQ_EXT_MON_1>,
IN<LV_END_DIAG_TQ_EXT_MON_1>, OUT<LV_ERR_TQ_EXT_MON_1>)

11.29.12 Diagnosis for AFS request by monitoring (Diagnostic file – STD_INI filter)

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
CTR_SWI_AFS_MON	V/O/S	0...FFH	0...255	1	[-]
Reset resistant counter for number of AFS requests by monitoring					
LV_ERR_SWI_AFS_MON	O/V	0...1H	0...1	1	[-]
Indicator: maximum number of AFS request by MFF-monitoring has been reached					
LV_END_DIAG_SWI_AFS_MON	V/O	0...1H	0...1	1	[-]
Diagnostic of AFS request by monitoring performed at least one time					
LV_CDN_DIAG_SWI_AFS_MON	V/O	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_SWI_AFS_MON	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					

Input data:

		LV_TQI_MON_ACT_MON	LV_SWI_AFS_MFF_MAX_MON

FUNCTION DESCRIPTION:

General information:

CTR_SWI_AFS_MON needs to be saved reset resistant AND in NVMY !

Description:

The MFF-monitoring-functionality is able to send requests for switching the engine to AFS-mode in case of detected unplausibilities in non-AFS-modes.

In order to gain information about the number of interventions of the MFF-monitoring-functionality during vehicle/ECU-lifetime, this diagnosis has been introduced.

The flag LV_SWI_AFS_MFF_MAX_MON represents that the maximum allowed number of requests by MFF-monitoring to switch to AFS-mode has been reached.

CTR_SWI_AFS_MON is used to count these events.

Additionally, the indicator flag LV_ERR_SWI_AFS_MON is set. It is used to call the ERRM and store the indicator with environmental data (e.g. with the value of CTR_SWI_AFS_MON) for further examination.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> LV_SWI_AFS_MFF_MAX_MON detected        (= SYM_0)
 │ │ └───> not used                               (= SYM_1)
 │ └─────> not used                               (= SYM_2)
 └───────> not used                               (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_SWI_AFS_MON = STD_INI
LV_END_DIAG_SWI_AFS_MON = STD_INI
LV_ERR_SWI_AFS_MON = STD_INI
ERR_SYM_SWI_AFS_MON = STD_INI

at first power up/on saved RAM lost (or reprogramming): *CTR_SWI_AFS_MON = 0*

at reset: CTR_SWI_AFS_MON = restored from NVMY

Recurrence: 40ms

Activation:

```
If      LV_TQI_MON_ACT_MON = 1
Then    LV_CDN_DIAG_SWI_AFS_MON = 1
Endif
```

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_SWI_AFS_MON = 0.

Formula section:

Symptoms calculation :

```
If      LV_SWI_AFS_MFF_MAX_MON changes from 0→1
Then
        ERR_SYM_SWI_AFS_MON = SYM_0
        CTR_SWI_AFS_MON = CTR_SWI_AFS_MON +1

Else
    ERR_SYM_SWI_AFS_MON = NO_SYM    { No failure has been detected }
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

LV_TQ_WHEEL_LDM_REQ	LV_ERR_MFF_MON	LV_ERR_TPS_MON

FUNCTION DESCRIPTION:

General information:

For every fault, the environmental conditions are stored in the environmental data variables. The error symptom is used for encoding the type of the fault if more than one level 2 error could nead to the errror. The variables are chosen such that the fault scenario can be analyzed.

The memory area of all output data variables of this module is not cyclical RAM tested,
the memory area of this module is not cyclic ROM tested.

Application conditions:

Initialization: -

Activation: *according to "Error Memory management of Process Monitoring"*

Update Rate: *according to "Error Memory management of Process Monitoring"*

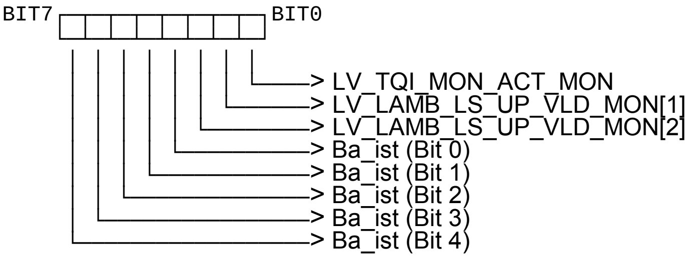
Formula section:

Since the different faults can occur in a successive way, they are stored in different locations of the failure memory.

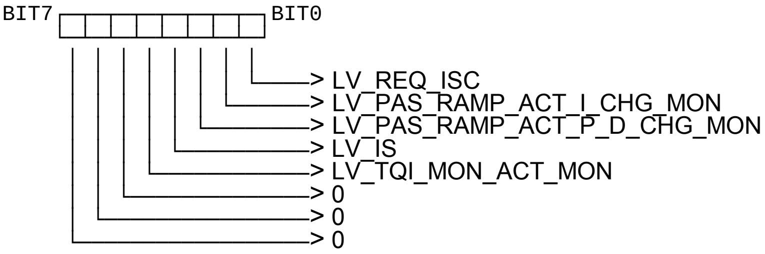
11.30.1 Definition of Statusbytes

The bit values for the ENVD of each error (that actually uses bit values within its ENVD) are represented by a statusbyte. The definition of these statusbytes is listed below.

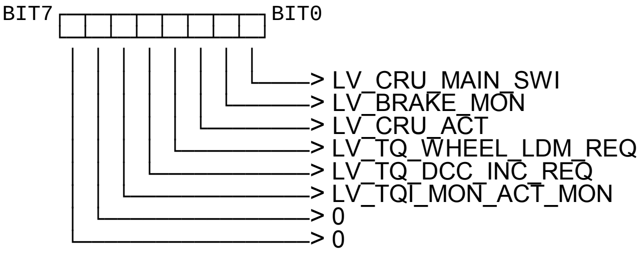
STATE_LV_ERR_MFF_MON_1 :



STATE_LV_ERR_TQ_DIF_ISC_MON_1 :



STATE_LV_ERR_CRU_INH_MON_1 :



11.30.2 Definition of non volantile ENVD for LV_ERR_TQI_N_MAX_MON_1

As the error LV_ERR_TQI_N_MAX_MON leads to a reset of the ECU, its environmental data need to be stored reset save before the reset. Therefore the ENVD of this error is copied to reset save labels. This is only done one time when the error occurs (refer to "ERRM of process monitoring": ERRM of LV_ERR_TQI_N_MAX_MON_1).

N_32_MON_SAVE = N_32_MON

PREV_STATE_IV_SAVE = PREV_STATE_IV

STATE_TQI_N_MAX_MON_1_1_SAVE :

```
BIT7 ┌┬┬┬┬┬┬┬┐ BIT0
     └┴┴┴┴┴┴┴┘
      │││││││└──────> LV_ERR_TQI_AV_MON
      ││││││└───────> LV_IGK_MON
      │││││└────────> LV_ERR_TPS
      ││││└─────────> LV_ERR_PVS

      ││└───────────> (PV_AV_MON = 0)
      │└────────────> LV_N_LIM_ETC_LIH
      └─────────────> (LV_ERR_TQ_LOSS_MON=1 OR LV_ERR_TQ_MIN_CLU_MON=1 OR
                       LV_ERR_TQ_MAX_CLU_MON=1)
```

STATE_TQI_N_MAX_MON_1_2_SAVE :

```
BIT7 ┌┬┬┬┬┬┬┬┐ BIT0
     └┴┴┴┴┴┴┴┘
      │││││││└──────> LV_ERR_CONV_MON
      ││││││└───────> LV_ERR_MSR_INH_MON
      │││││└────────> LV_ERR_N_32_MON
      ││││└─────────> (LV_ERR_TQ_DIF_P_D_IS_MON=1 OR LV_ERR_TQ_DIF_I_IS_MON=1)
      │││└──────────> LV_ERR_PVS_MON
      ││└───────────> LV_ERR_TPS_MON
      │└────────────> LV_ERR_MFF_MON
      └────────────--> 0
```

To save some locations in failure memory some of the level 2 errors collect in one error ,location as different symtoms, this is shown in the next table. In addition to the information above, for every fault environmental data is stored. This datas are tuneable. The following table is only a recommendation of enviromental datas.

Error	SYM	Error Cause	Recommendation of environmental data

The information whether a warning lamp (ETC MIL) is switched on in case of an error can be found in the general OBD error code table.

In case of more than one error cause occurs, always the first error (according to the table above; see BIT 0...4 of first Byte for the order) is taken into account.

11.30.3 List of error codes and symptoms

The list of error codes and the list of error symptoms can be found in the chapter "Table of failures".

12.1 ECM3 - MC requirements to infrastructure

Export actions:

ACTION_INFR_McChkCks(OUT <lv_mc_cks_ok>)
Check whether the checksum of the current communication was correctly transmitted.
ACTION_INFR_McChkPar(OUT <lv_mc_par_ok>)
Check whether the parity bits in the current communication are correctly set.
ACTION_INFR_McGetHd(OUT <state_mu>)
Get the header byte from the current communication.
ACTION_INFR_McGetErrByte(OUT <lf_mu_err_byte>)
Get error byte (containing error code and indication) from the current communication.
ACTION_INFR_McGetCompNr(OUT <nr_mu_comp>)
Get compatibility number transferred from the MU in the current communication.
ACTION_INFR_McGetVersNr(OUT <nr_mu_hw_vers>)
Get HW version number transferred from the MU in the current communication.
ACTION_INFR_McGetRstCtr(OUT <ctr_rst_mu>)
Get the reset counter of the MU transferred in the current communication.
ACTION_INFR_McGetConfData(OUT <lf_mu_conf_byte>)
Get the configuration data transferred from the MU in the current communication.
ACTION_INFR_McGetOvdFlag(OUT <lv_v_h_det_mu>)
This action returns the over-voltage detection flag sent by the MU.
ACTION_INFR_McGetUvdFlag(OUT <lv_v_l_det_mu>)
This action returns the under-voltage detection flag sent by the MU.
ACTION_INFR_McGetPfmByte(OUT <lf_mc_rcv_pfm_byte>)
Get the PFM data sent by the MU.
ACTION_INFR_McGetFsistIdx(OUT <idx_test_rcv_mc_fct_spc_ist>)
Get the FS-IST question sent by the MU.
ACTION_INFR_McGetFsistAbcVal(OUT <abc_rcv_mc_fct_spc_ist>)
Get the FS-IST anti-bounce counter value sent by the MU.
ACTION_INFR_McGetIgkMu(OUT <lv_mu_ign_key>)
Get the ignition key signal transmitted by the MU in the current communication.
ACTION_INFR_GetAnDigMonValMu(OUT <vp_mu_an_dig_mon>)
Get value of A/D conversion sent from the MU in the current communication.
ACTION_INFR_GetAnDigMonValMc(OUT <vp_mc_an_dig_mon>)
Get value of A/D conversion performed on the MC.
ACTION_INFR_McRestart()
Trigger a reset of the MC.
ACTION_INFR_McGetNdis0(IN <lv_mu_di_out_0>)
Read value of the NDIS_OUT0 pin sent by the MU.
ACTION_INFR_McGetNdis1(OUT <lv_mu_di_out_0>)
Read value of the NDIS_OUT1 pin sent by the MU.
ACTION_INFR_McStartCom(IN <state_mc>)
Trigger communication according to the given state.
ACTION_INFR_McRomChkReady(OUT <lv_mc_rom_chk_ready>)
This action returns a flag indicating whether the level 1 ROM check is ready or not.
ACTION_INFR_McRomChkOk(OUT <lv_mc_rom_chk_ok>)
This action returns a flag indicating whether the level 1 ROM check was completed successfully or not.
ACTION_INFR_McGetDiagPws0(OUT <state_mc_sopc_dr_0>)
This action returns status information of the power stage 0 (whether it is enabled (=1) or disabled (=0), or undefined (=3)).
ACTION_INFR_McGetDiagPws1(OUT <state_mc_sopc_dr_1>)
This action returns status information of the power stage 1 (whether it is enabled (=1) or disabled (=0), or undefined (=3)).
ACTION_INFR_McSendConfData(IN <lv_mu_mod>, IN <lv_mu_ign_key_acq>, IN <lv_mu_pow_off_trm_ena>, IN < lv_mu_inj_off_trm_ena >)
This action sends the configuration data to the infrastructure for transmission to the MU.
ACTION_INFR_McSendCompNr(IN <nr_mc_comp>)

This action sends the compatibility number of the MC to the infrastructure for transmission to the MU.
ACTION_INFR_McSendIgk(IN <lv_igk>)
This action sends the ignition key signal to the infrastructure for transmission to the MU.
ACTION_INFR_McSendErrInfo(IN <ctr_rst_mc>, IN <err_cod_mc>, IN <state_err_idc_mc>)
This action sends the error information (reset counter, error code & indication) to the infrastructure for transmission to the MU.
ACTION_INFR_McSendDrOff(IN <lv_mc_dr_off>)
This action sends the flag for the redundant switch-off path to the infrastructure for transmission to the MU.
ACTION_INFR_McSendPfmResp(IN <lf_mc_resp_pfm>)
This action sends the PFM response of the MC to the infrastructure for transmission to the MU.
ACTION_INFR_McSendFsistResp(IN <idx_resp_trm_mc_fct_spc_ist>)
This action sends the FS-IST answer of the MC to the infrastructure for transmission to the MU.
ACTION_INFR_McChkStack(OUT <PRM_LV_CHK_OK>)
This action returns the result of the stack check performed by the infrastructure.
ACTION_INFR_StartMuReadyChk()
This action triggers the start of the check for readiness of MU.
ACTION_INFR_MuReady(OUT <PRM_LV_MU_READY>)
This action fetches the result of the check for readiness of MU.

ACTION_INFR_McGetCompNr(nr_mu_comp)

This action reads a byte containing compatibility information of the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
nr_mu_comp	OUT	0...3H	0...3	1	[-]

Compatibility number sent by the MU

ACTION_INFR_McGetVersNr(nr_mu_hw_vers)

This action reads a byte containing compatibility information of the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
nr_mu_hw_vers	OUT	00...1FH	0...31	1	[-]

HW version number sent by the MU

ACTION_INFR_McGetRstCtr(ctr_rst_mu)

This action reads the reset counter of the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
ctr_rst_mu	OUT	0...FH	0...15	1	[-]

Reset counter of MU sent in the current communication

ACTION_INFR_McGetConfData(lf_mu_conf_byte)

This action reads a byte encoding configuration data received from the MU in the current communication.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lf_mu_conf_byte	OUT	00...FFH	0...255	1	[-]

Byte sent by the MU containing configuration information

ACTION_INFR_McGetOvdFlag(lv_v_h_det_mu)

This action reads the flag sent by the MU indicating whether over-voltage had been detected

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_v_h_det_mu	OUT	0...1H	0...1	1	[-]

Flag indicating whether over-voltage has been detected by the MU

ACTION_INFR_McGetUvdFlag(lv_v_l_det_mu)

This action reads the flag sent by the MU indicating whether under-voltage had been detected

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_v_l_det_mu	OUT	0...1H	0...1	1	[-]

Flag indicating whether under-voltage has been detected by the MU

ACTION_INFR_McGetPfmByte(lf_mc_rcv_pfm_byte)

This actions reads the program flow monitoring byte sent by the MU in the current communication.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lf_mc_rcv_pfm_byte	OUT	00...FFH	0...255	1	[-]

PFM byte sent by MU in the current communication: either an updated synchronisation byte or status information of MU PRM anti-bounce counters

ACTION_INFR_McGetFsistIdx(idx_test_rcv_mc_fct_spc_ist)

This action reads the MU question for the FS-IST.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
idx_test_rcv_mc_fct_spc_ist	OUT	00...3FH	0...63	1	[-]

FS-IST question sent by MU in the current communication

ACTION_INFR_McGetFsistAbcVal(abc_rcv_mc_fct_spc_ist)

This action reads the MU question for the FS-IST.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
abc_rcv_mc_fct_spc_ist	OUT	0...FH	0...15	1	[-]

FS-IST anti-bounce counter sent by MU in the current communication

ACTION_INFR_McGetIgkMu(lv_mu_ign_key)

This value reads the ignition key signal transmitted by the MU in the current communication.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mu_ign_key	OUT	0...1H	0...1	1	[-]

Value of the ignition key (as obtained via the IGN_IN pin on the MU) sent from the MU in the current communication

ACTION_INFR_GetAnDigMonValMc(vp_mc_an_dig_mon_tmp)

This action reads the new value from the A/D conversion on the MC from the infrastructure.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
vp_mu_an_dig_mon_tmp	OUT	8000...7FFFH	-5...4.99984	0.1526e-3	[V]

Value of A/D conversion on the MC

ACTION_INFR_GetAnDigMonValMu(vp_mu_an_dig_mon)

This action reads the new value from the A/D conversion on the MU from the infrastructure.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
vp_mc_an_dig_mon	OUT	0...7FFFH	0...4.99984	0.1526e-3	[V]

Value of A/D conversion on the MU

ACTION_INFR_McRestart()

This action triggers a reset of the MC.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit

ACTION_INFR_McGetNdis0(lv_mu_di_out_0)

This action reads the value of the NDIS_OUT0 pin sent from the MU

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mu_di_out_0	OUT	0...1H	0...1	1	[-]

Actual value of the NDIS_OUT0 pin

ACTION_INFR_McGetNdis1(lv_mu_di_out_1)

This action reads the value of the NDIS_OUT1 pin sent from the MU

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mu_di_out_1	OUT	0...1H	0...1	1	[-]

Actual value of the NDIS_OUT1 pin

ACTION_INFR_McRomChkReady(lv_mc_rom_chk_ready)

This action returns a flag indicating whether the level 1 ROM check has been completed.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mc_rom_chk_ready	OUT	0...1H	0...1	1	[-]

Flag indicating whether the level 1 ROM check has been completed

ACTION_INFR_McRomChkOk(lv_mc_rom_chk_ok)

This action returns a flag indicating whether the level 1 ROM check has been completed successfully or not.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mc_rom_chk_ok	OUT	0...1H	0...1	1	[-]

Flag indicating whether the level 1 ROM check has been completed successfully

ACTION_INFR_McGetDiagPws0(state_mc_sopc_dr_0)

This action returns status information about power stage 0 required for the switch-off path check.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
state_mc_sopc_dr_0	OUT	0...3H	0...3	1	[-]

State indicating whether power stage 0 is enabled or disabled, or whether the diagnostic is not finished/unstable

ACTION_INFR_McGetDiagPws1(state_mc_sopc_dr_1)

This action returns status information about power stage 1 required for the switch-off path check.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
state_mc_sopc_dr_1	OUT	0...3H	0...3	1	[-]
State indicating whether power stage 1 is enabled or disabled, or whether the diagnostic is not finished/unstable					

ACTION_INFR_McSendConfData(lv_mu_mod, lv_mu_ign_key_acq, lv_mu_pow_off_tmr_ena, lv_mu_inj_off_tmr_ena)

This action sends the configuration data to the infrastructure; from there, they are transmitted to the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mu_mod	IN	0...1H	0...1	1	[-]
Mode of MU (0 = EMS, 1 = TCU)					
lv_mu_ign_key_acq	IN	0...1H	0...1	1	[-]
Mode for ignition key acquisition on MU (0 = SW, 1 = HW)					
lv_mu_pow_off_tmr_ena	IN	0...1H	0...1	1	[-]
Enable flag for power-off timer on MU					
lv_mu_inj_off_tmr_ena	IN	0...1H	0...1	1	[-]
Enable flag for injection-off timer on MU					

ACTION_INFR_McSendCompNr(nr_mc_comp)

This action sends the compatibility number of the MC to the infrastructure; from there, it is transmitted to the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
nr_mc_comp	IN	0...3H	0...3	1	[-]
Compatibility number of MC					

ACTION_INFR_McSendIgk(lv_igk)

This action sends the ignition key signal to the infrastructure; from there, it is transmitted to the MU

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_igk	IN	0...1H	0...1	1	[-]
Value of ignition key signal on MC					

ACTION_INFR_McSendErrInfo(ctr_rst_mc, err_cod_mc, state_err_idc_mc)

This action sends the error informarion on the MC to the infrastructure; from there, it is transmitted to the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
ctr_rst_mc	IN	0...FH	0...15	1	[-]
Reset counter on MC					
err_cod_mc	IN	00...1FH	0...31	1	[-]
Error code on MC					
state_err_idc_mc	IN	0...3H	0...3	1	[-]
Error indication on MC					

ACTION_INFR_McSendDrOff(lv_mc_dr_off)

This action sends the flag for the redundant switch-off path to the infrastructure; from there, it is transmitted to the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_mc_dr_off	IN	0...1H	0...1	1	[-]
Flag indicating whether the redundant switch-off path was triggered or not					

ACTION_INFR_McSendPfmResp(lf_mc_resp_pfm)

This action sends the current PFM response on the MC to the infrastructure; from there, it is transmitted to the MU.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lf_mc_resp_pfm	IN	00...7FH	0...127	1	[-]
PFM response on the MC					

ACTION_INFR_McSendFsistResp(idx_resp_trm_mc_fct_spc_ist)					
This action sends the FS-IST answer on the MC to the infrastructure; from there, it is transmitted to the MU.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
idx_resp_trm_mc_fct_spc_ist	IN	00...3F	0...63	1	[-]
FS-IST answer on the MC					

ACTION_INFR_McStartCom(state_mc)					
This actions triggers a communication corresponding to the state given as argument.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
state_mc	IN	00...FFH	0...255	1	[-]
Header byte sent from MC					

ACTION_INFR_McChkStack(PRM_LV_CHK_OK)					
This actions triggers a communication corresponding to the state given as argument.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_LV_CHK_OK	OUT	0...1H	0...1	1	[-]
Result of stack check performed by infrastructure (1=OK, 0=NOK)					

ACTION_INFR_StartMuReadyChk()					
This action starts the check for MU readiness.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**

ACTION_INFR_MuReady(PRM_LV_MU_READY)					
This action fetches the result of the check for MU readiness.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_LV_MU_READY	OUT	0...1H	0...1	1	[-]
Result of MU readiness check performed by infrastructure (1=OK, 0=NOK)					

FUNCTION DESCRIPTION:

General information:

This document specifies the requirements of the processor monitoring ASW implemented on the main controller (MC) to the infrastructure: the requirements deal with the communication interface between the MC and MU (from the point of view of the MC) and the interface to the hardware.

Requirements for ACTION_INFR_McChkCks:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

This action shall incorporate requirements R44_3 and R44_4 of the following function.

12.1.1 G44 Communication checksum monitoring

R44_1: All transmitted data shall be protected by an XOR checksum of header byte and data bytes.

R44_2: The checksum shall always be the last data to be transmitted.

R44_3: The XOR checksum of the received data shall be checked.

R44_4: In case of a checksum error, this shall be indicated to the application SW by setting the return value lv_mc_cks_ok to 0.

Coincidence requirements: -

Requirements for ACTION_INFR_McChkPar:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

This action shall incorporate the following requirements.

12.1.2 G45 Parity-bit checking

R45_1:The most sensitive data shall be protected by a parity bit (these shall be the second and third byte in CONFIG and DISABLE communications).

R45_2: Sensitive data shall be checked for even parity.

R45_3: In case of a parity bit error, this shall be indicated to the application SW by setting the return value lv_mc_par_ok to 0.

Coincidence requirements: -

Requirements for ACTION_INFR_McRestart:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

The action shall trigger a system reset, including a reset of the MU.

Coincidence requirements: -

Requirements for ACTION_INFR_McGetDiagPws0:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

During the switch-off path check (SOPC), the current status (enabled/disabled) of the power stage is inspected by Processor Monitoring on the MC to check if the MU or the MC can disable the power stage. This leads to several requirements described in the following function.

12.1.3 G48 Requirements to IRS actions for switch-off path check

R48_1: The SOPC requires interfaces indicating the status of monitoring-relevant power stage(s) at certain times depending on the interaction of several Processor Monitoring functions.

R48_2: The status information shall be provided in a way independent from the actually used HW drivers for these monitoring-relevant power stage(s).

R48_3: The status information shall be acquired by calling the actions ACTION_ECM3_McGetDiagPws0() and ACTION_ECM3_McGetDiagPws1() inside the Processor Monitoring function "Switch-Off Path Check."

R48_4: Each of the two action calls shall return a three-valued status of the corresponding power stage: a return value of NC_STATE_RESP_DR_ENA (=1) shall mean " enabled", NC_STATE_RESP_DR_DI (=0) shall mean "disabled", NC_STATE_RESP_DR_DFT (=3) shall mean "undefined."

R48_5: If the status information for a power stage is unavailable, unclear, or unstable when requested, the returned status shall indicate "undefined"; this shall also be the default value after an acquisition of the status via one of the action calls (internal reset of the status to "undefined").

R48_6: Regardless of the way of its acquisition, the information status of a power stage indicated by the flag returned by any of the actions shall not be older than 20ms for GS/DS and 8ms for TCU when the interface is called (corresponding to the length of two communication cycles of Processor Monitoring for EMS or TCU mode); this may well have consequences on the frequency of SPI line checks and other mechanisms.

R48_7: It shall be possible to perform the switch-off path check at any time, regardless of the used power stage(s) and the current state of the system; in particular, this means that calling the function for retrieving the value of the power stage should be possible any time without disrupting the system's behaviour.

Coincidence requirements: -

Requirements for ACTION_INFR_McGetDiagPws1:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

During the switch-off path check, the current status (enabled/disabled) of the power stage is inspected by Processor Monitoring on the MC to check if the MU or the MC can disable the power stage. This leads to several requirements described in the following function.

G48 Requirements to IRS actions for switch-off path check

(see above)

Coincidence requirements: -

Requirements for ACTION_INFR_GetAnDigMonValMc:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment

Diagnosis:

The action shall incorporate the following requirements.

12.1.4 G53 Requirements to infrastructure interface for acquisition of values of A/D conversions on MC

R53_1: Directly after the end of each communication between MC and MU, an A/D conversion (of the same signal which is connected to the A/D converter of the MU) shall be performed.

R53_2: The result of the conversion shall be stored as value and complement until it is fetched via ACTION_INFR_GetAnDigMonValMc().

R53_3: When the action ACTION_INFR_GetAnDigMonValMc() is called, the stored value shall be checked for consistency with the stored complement:
R53_3.1: if value and complement are consistent, the actual converted value shall be returned;
R53_3.2: if value and complement are inconsistent, the constant NC_VP_MC_AN_DIG_MON_CPL_ERR shall be returned instead of the actual converted value.

Coincidence requirements: -

Requirements for ACTION_INFR_StartCom:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment

Diagnosis:

The action shall incorporate the following requirements.

12.1.5 G61 Requirements to infrastructure interface for triggering a communication with the MU

R61_1: This action shall incorporate the requirements R44_1 and R44_2 of the function "G44 Communication checksum monitoring" described above.

R61_2: Based on the state information passed as argument, parity bits shall be set for the appropriate data bytes (see description of the communication protocol) to achieve even parity (cf. "G45 Parity-bit checking" above).

R61_3: When the action is called, it shall invalidate the previous header-byte sent by the MU by copying NC_STATE_MC_NOT_VLD in its place.

R61_4: The state information passed as argument shall be included in the outgoing message to the MU.

R61_5: The action shall ensure that a communication with the MU is eventually performed (whether that means that a communication is triggered directly or just scheduled).

Coincidence requirements: -

Requirements for ACTION_INFR_SendConfData:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

The action shall incorporate the following functional requirements.

12.1.6 G46 Complement of configuration data

R46_1: In the CONFIG and PREDRIVE communication, the configuration data sent by the MC shall be protected by also sending the bit-wise complement of the configuration information (see specification of the communication protocol).

Coincidence requirements: -

Requirements for ACTION_INFR_McChkStack:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

The action shall incorporate the following functional requirements.

12.1.7 G50 Requirements to infrastructure interface for stack check

R50_1: The stack check shall have the ability to detect static stuck-at errors (like the standard RAM check).

R50_2: While the stack check is performed, interrupts shall be suppressed; consequently, there is an upper bound on the time available for the stack check (<= 2µs).

R50_3: The stack check shall test that slice of memory which would be used for saving the content of the registers used inside level 2 when an interrupt occurs during its execution.

R50_4: For the call and the execution of the stack check itself, no stack shall be used.

Coincidence requirements: -

Requirements for ACTION_INFR_StartMuReadyChk:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

The action shall incorporate the following functional requirements.

12.1.8 G58 Requirements to infrastructure interface for start of MU readiness check

R58_1: The check for readiness of MU shall be performed by sending a communication with more than 48bit length to the MU (the MU simply discards such communications).

R58_2: When the action is called, such a special communication shall be prepared and scheduled.

R58_3: When the action is called, it shall invalidate the previous header-byte sent by the MU by copying NC_STATE_MC_NOT_VLD in its place.

R58_4: The communication shall be completed at most NC_T_MC_COM_CYC ms later so that the result can be evaluated.

Coincidence requirements: -

Requirements for ACTION_INFR_MuReady:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

The action shall incorporate the following functional requirements.

12.1.9 G59 Requirements to infrastructure interface for evaluation of MU readiness check

R59_1: When the action is called, the MU response to the special communication used for the readiness check (cf. G58) shall be evaluated.

R59_2: The return value of the action shall be 1 if the MU response is different from only constant '0' and only constant '1' (i.e., at least two bits in the MU response are not equal to each other).

R59_3: Otherwise (i.e., all bits in the MU response are equal to '0' or all bits are equal to '1') it is assumed that the MU is not yet ready and the return value of the action shall be 0.

Note: also HW problems (shortcuts to ground or supply) of the SPI connection might lead to the MU being seen as not ready.

Coincidence requirements: -

12.1.10 Requirements to infrastructure interface for Standard ROM check on MC

FUNCTION DESCRIPTION:

General information:

In order to detect static ROM faults, the Standard ROM check is performed once after each power-up.

Description:

The function shall incorporate the following requirements:

G55 Requirements to infrastructure interface for Standard ROM check on MC

R55_1: For computing the checksum, the CRC algorithm shall be used.

R55_2: The areas checked by the Standard ROM check include all code, constant, and calibration areas with the exception of such ROM areas which might be changed during runtime (e.g., EEPROM simulation in the FLASH memory); furthermore excluded is the area where the expected checksum is stored.

R55_3: There shall be a configuration switch in the infrastructure routine for the ROM check with the effect that a ROM error in the calibration data area does not result in reporting an unsuccessful ROM check: this is done in order to prevent ROM check errors (and a subsequent fault reaction) while calibrations are performed.

R55_4: The Standard ROM check shall be computed at least once per driving cycle; this means if it has been completed once, it need not be restarted again for the driving cycle (in particular not after a reset); however, if it is interrupted by a reset while not yet completed, it shall be restarted after the reset.

12.1.11 Requirements to infrastructure interface for Standard RAM check on MC

FUNCTION DESCRIPTION:

General information:

The standard RAM check is performed after each power-up or reset.

By writing specific bit patterns to the RAM cells, static faults can be detected.

Description:

The action shall incorporate the following functional requirements.

G56 Requirements to infrastructure interface for Standard RAM check on MC

R56_1: During each start-up (after reset or power-up), all RAM areas shall be tested.

R56_2: The Standard RAM check shall at least provide the option to be destructive or non-destructive, as is appropriate for the tested areas; in case of destructive testing, the RAM cells shall afterwards be initialised to 0.

R56_3: The RAM check shall be able to detect static "stuck to 0" and "stuck to 1" errors in each of the tested RAM cells.

12.2 ECU-selftest

FUNCTION DESCRIPTION:

General information:

The purpose of the test is the check of differents memories (RAM, Flash, NVMY).

Remark:
- If failures are detected there are not-defined system reactions possible!
- If there is a failure in the Boot-software it it possible to have a passive ECU without error entry.

12.2.1 Flash test

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_ECU_CKS	V/O	0...1H	0...1	1	[-]
Present ECU checksum error					
LV_CDN_DIAG_ECU_CKS	V/O	0...1H	0...1	1	[-]
ECU Diagnosis active (=1)					
ERR_SYM_ECU_CKS	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected Symptom ECU					
LV_END_DIAG_ECU_CKS	V/O	0...1H	0...1	1	[-]
End of ECU Diagnosis					

Description:

The following three areas are checked by calculating the checksum:

- Boot software
- Applicative software
- Calibration data

For error healing one diagnosis cyle is necessary. If there is only transition key-ON / key OFF without end of diagnosis is reached then the error remains active.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Error in Boot - SW                (= SYM_0)
 │ │ └───> Error in Applic - SW              (= SYM_1)
 │ └─────> Error in Calibration data range   (= SYM_2)
 └───────> -                                 (= SYM_3)
```

Application conditions:

Initialisation: all 0 at reset **or** clearing error memory

Recurrence: Boot software test is applied once, recurrency of applicative software and calibration data test is depending on length of each test (some minutes possible).

Activation: at system start up after ignition-key-ON

(applicative software and calibration-data test remains active for the engine run)

Formula section:

Setting of condition diag.

LV_CDN_DIAG_ECU_CKS = 1 at reset

Error detection

```
If      one error symptom is detected
Then    ERR_SYM_ECU_CKS = SYM_0 or SYM_1 or SYM_2
        LV_ERR_ECU_CKS = 1                    //no debounce
        LV_END_DIAG_ECU_CKS = 1
Else    ERR_SYM_ECU_CKS = NO_SYM
        LV_ERR_ECU_CKS = 0
Endif
```

End of diagnosis with no error detection

after finishing each test once: LV_END_DIAG_ECU_CKS = 1

12.2.2 RAM test

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_ECU_RAM	V/O	0...1H	0...1	1	[-]
Present ECU RAM error					
LV_CDN_DIAG_ECU_RAM	V/O	0...1H	0...1	1	[-]
ECU Diagnosis RAM active (=1)					
ERR_SYM_ECU_RAM	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected Symptom ECU RAM					
LV_END_DIAG_ECU_RAM	V/O	0...1H	0...1	1	[-]
End of ECU Diagnosis RAM					

Description:

The following two areas are tested by ECU internal test routine:

- Internal - RAM
- Timing processing unit – RAM

- External -RAM

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> RAM error                    (= SYM_0)
 │  │  └────> -                            (= SYM_1)
 │  └───────> -                            (= SYM_2)
 └──────────> -                            (= SYM_3)
```

Remark: LV_ERR_ECU_RAM will only deliver a valid result if Level 3 (processor monitoring) is not implemented yet. Otherwise Level 3 will detect a failed RAM-test thru LV_ERR_MON_3 and the corresponding symptom: ERR_SYM_MON_3 = SYM_1 (RAM error on MC).

Application conditions:

Initialisation: all 0 at reset **or** clearing error memory

Recurrence: once

Activation: at reset

Formula section:

Setting of condition diag.

LV_CDN_DIAG_ECU_RAM = 1 at reset

Error detection

```
If      one error symptom is detected          (RAM test error detected by L1)
Then    ERR_SYM_ECU_RAM = SYM_0
        LV_ERR_ECU_RAM = 1                     (error is set for this engine run, no debounce)
        LV_END_DIAG_ECU_RAM = 1
Else    after finishing each test once LV_END_DIAG_ECU_RAM = 1
Endif
```

12.2.3 NVMY test

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_ECU_NVMY	V/O	0...1H	0...1	1	[-]
Present ECU NVMY error

Input data:

PWL_LOCK_CDN	LV_WARM_RST	ECU_STATE	V_IGK
C_VB_MIN_OBD1			

Description:

The NVMY blocks are restored after each reset during the initialization phase after start up. If one block is detected as faulty (see “Non volatile data” in chapter Basic SW general operation) only this datas are initialized.

Error symptoms are defined for this diagnosis function as:

```
☐☐☐☐
 │ │ │ └─> NVMY error             (= SYM_0)
 │ │ └───> -                      (= SYM_1)
 │ └─────> -                      (= SYM_2)
 └───────> -                      (= SYM_3)
```

Application conditions:

Initialisation: all 0 at reset **or** clearing error memory

Recurrence: 40 ms (see formula section)

Activation: at reset

Formula section:

at reset:

Error detection

```
If      V_IGK < C_VB_MIN_OBD1                                   or

Endif
```

12.3 Overview of Processor Monitoring

12.3.1 System Overview

Based on the recommendations of the VDA (as expressed in the version 2.0 of the paper of the VDA ETC working group "Arbeitskreis EGAS"), the monitoring concept for electronic control units (ECUs) uses three levels; this document provides a more detailed description of the *processor monitoring* level (level 3 in VDA terms).

Based on the VDA guidelines, the processor monitoring level consists of two *separate* hardware components: the main controller (MC) and the monitoring unit (MU). The former is generally realised by a micro controller (µC), while the latter might just as well be realised by an application-specific integrated circuit (ASIC), i.e., some specifically designed piece of hardware; this MU is almost exclusively used for processor monitoring functionality (the only exception is the A/D converter on the MU which is used for the monitoring of the A/D conversion on the MC; this functionality is as such not part of the processor monitoring but of the process monitoring, or "level 2" in VDA terms).

The monitoring concept described here is *generic* in the sense that it works regardless of how the MU is realised in terms of actual hardware (µC vs. ASIC), and for both engine management systems (EMSs) for gasoline/diesel engines and transmission control units (TCUs).

The two system components, MC and MU, *mutually* monitor each other (just to be clear about the fact that not only the MU monitors the MC). For instance, assume that there is a failure in the calculations of the ALU (arithmetic logic unit) of the MC. This could produce potentially dangerous results: e.g., due to a faulty calculation, the ECU might increase the engine speed too much for the driver to control the car. Additionally, the MC itself might not be able to detect such a fault and react appropriately (e.g., perform a reset, or switch off the engine): after all, it cannot even be guaranteed that the processor notices the fault, a (from the external point of view) faulty processor might ‘internally’ believe that the system, including itself, is functioning correctly.

In order to be able to detect such a case, the MU provides an *independent* (hardware) instance which can judge (as far as it is safety-relevant) whether the behaviour of the MC is appropriate according to actual environment conditions and demands (like the driver’s wish expressed, e.g., in terms of pushing the accelerator pedal); the behaviour of the MU, in turn, is then monitored by the MC in order to ascertain that the MU is still able to perform its monitoring duties.

All of these mutual monitoring activities are achieved by means of a repeated ‘*question and answer*’ (Q&A) game: the MU sends questions to the MC, and the MC sends back the respective answers. Based on the quality of the sent questions and received answers, *both* components can tell whether the respective other component is still working correctly.

If there are faults detected while the ECU is running (by whatever means available), appropriate fault reactions are carried out, either by the MC or by the MU, whichever detects the error. As most of the monitored functionalities are safety-critical, such fault reactions or processor monitoring necessitate (at least temporarily) disabling of the safety-relevant power stages in order to reach the so-called *safe state*. In order to be able to perform this type of fault reaction, there have to be corresponding connections (‘*switch-off paths*’) on the hardware level between MC/MU and the relevant power stages (e.g., H-bridge and injectors for gasoline engines). Note that, if the MU detects a fault on the MC, disables the power stages, and triggers a reset of the MC (the standard fault reaction), this reset is then fed back from the MC to the MU so that the *complete* system is restarted (potentially utilising external components like, e.g., power supply).

It should be stressed at this point that, as far as safety is concerned, the **primary goal** of the **fault reaction** is to **disable the power stages**: this prevents an error to result in an undesired acceleration of the car (or, correspondingly, unwanted shifting of gears or erroneous opening/closing of the clutch in TCU applications). The fact that (up to a certain maximal number) a reset is triggered after this disabling is only done in order to increase the **availability** of the car (i.e., to potentially enable the driver to continue his driving relatively undisturbed without having to use the ignition key)!

Coming back to the main task of processor monitoring, in order to set up the aforementioned Q&A game, the two components need to exchange data: this *communication interface* is usually implemented in the form of the S*erial* P*eripheral* I*nterface* (SPI). In this way, MC and MU *synchronise* their progress and, in doing so, can monitor the performed actions.

As an immediate consequence of the separation on the hardware level, since each component has its own parameter memory for variables and is running its own algorithms (in case the MU is realised by an ASIC, this refers to the circuitry that is hard-wired into the chip), variables on the MU are, a priori, not visible (i.e., available) on the MC, and vice versa, unless they are specifically transferred to the other component via the communication interface: variables are *local* to the MU or the MC. Moreover, even after being transmitted from one component to the other, variables on the MC and the MU will usually have different names since the communication is based on *values*, not *names* (despite ‘containing’ the same values!), and variable names reflect the content of the variables, which can very well be different on MC and MU.

It should furthermore be noted that any value exchanged between MC and MU can always only be a *snapshot* of a variable since it can only contain the actual value of the variable *at the time of the transmission*: consider the case a variable X is sent from the MU to the MC at a certain time t; if the variable is changed on the MU at time t+1, this update stays *local to the MU* in the sense that the MC only notices it if the changed X is re-transmitted to the MC after the update.

From a functional point of view, the main purpose of the processor monitoring is to monitor the proper functioning of the MC, thereby, continuing the layer-approach of the over-all system design (level 1 contains engine control functions and their diagnoses, level 2 monitors these functions and diagnoses by re-calculating the necessary values in an independent way to provide a means of judging their plausibility), in particular and most importantly, ensuring the proper functioning of the process monitoring. From this approach, the following main objectives of processor monitoring are derived:

- *memory checks on MC* (both RAM and ROM);
- *memory checks on MU* (RAM and ROM); this depends on the hardware realisation of the MU; on an ASIC, a RAM check shall be performed as usual; however, in place of a ROM check, there shall be a built-in self test (BIST) which tests the proper functioning of certain parts of the circuitry (mostly those parts responsible for triggering a fault reaction);
- *switch-off path check*: after each (re-)initialisation of the system, it must be checked whether the switch-off paths of the system work properly, viz., whether they can actually switch off the safety-relevant power stages should there be the need to do so later on;

- *program flow monitoring (PFM)*: it shall be checked that (monitoring-relevant) tasks (of level 2) on the MC are performed in the correct order and with the correct timing; here, “task” refers to a given and fixed sequence of modules running in the same nominal time grid (i.e., functionally connected parts of processor monitoring);
- *function-specific instruction set test (FS-IST)*: it shall be tested whether the processor correctly performs the (monitoring-relevant) calculations needed for the process monitoring on the MC; this shall be achieved by performing a number of *test calculations*; in order to avoid any effects of these (additional) test calculations on the actual monitoring functionality (and in line with VDA requirements), these test calculations are performed by a *copy* of some of the (monitoring-relevant) parts of the process monitoring located in separate memory on the MC which (being a copy of level 2 functionality) is also known as ”*level 2’*” (L2’).

Note that PFM and the FS-IST complement each other to achieve as complete a monitoring of the processor functionality as possible: while PFM checks whether the necessary tasks are executed in the *correct order* and with the *correct timing*, the FS-IST additionally checks that the required *calculations are performed correctly* (so that the tasks can properly execute and calculate the ‘right’ result - provided the employed algorithm is correct and correctly implemented: both PFM and L2’ can only achieve ‘formal’ or ‘syntactic’ correctness, ‘semantic’ correctness lies in the hands of the developer and cannot be tested (in this way)!).

A schematic overview of the system is presented in the following figure “Sketch of processor monitoring with two power stages,” including the required disable lines from the MC and the MU to the power stages; note that this picture does not include the redundant analogue input signal based on which the A/D conversion on the MU is performed and then sent to the MC in order to determine proper functioning of the A/D converter on the MC (by comparing the conversion result sent by the MU with the result obtained on the MC).

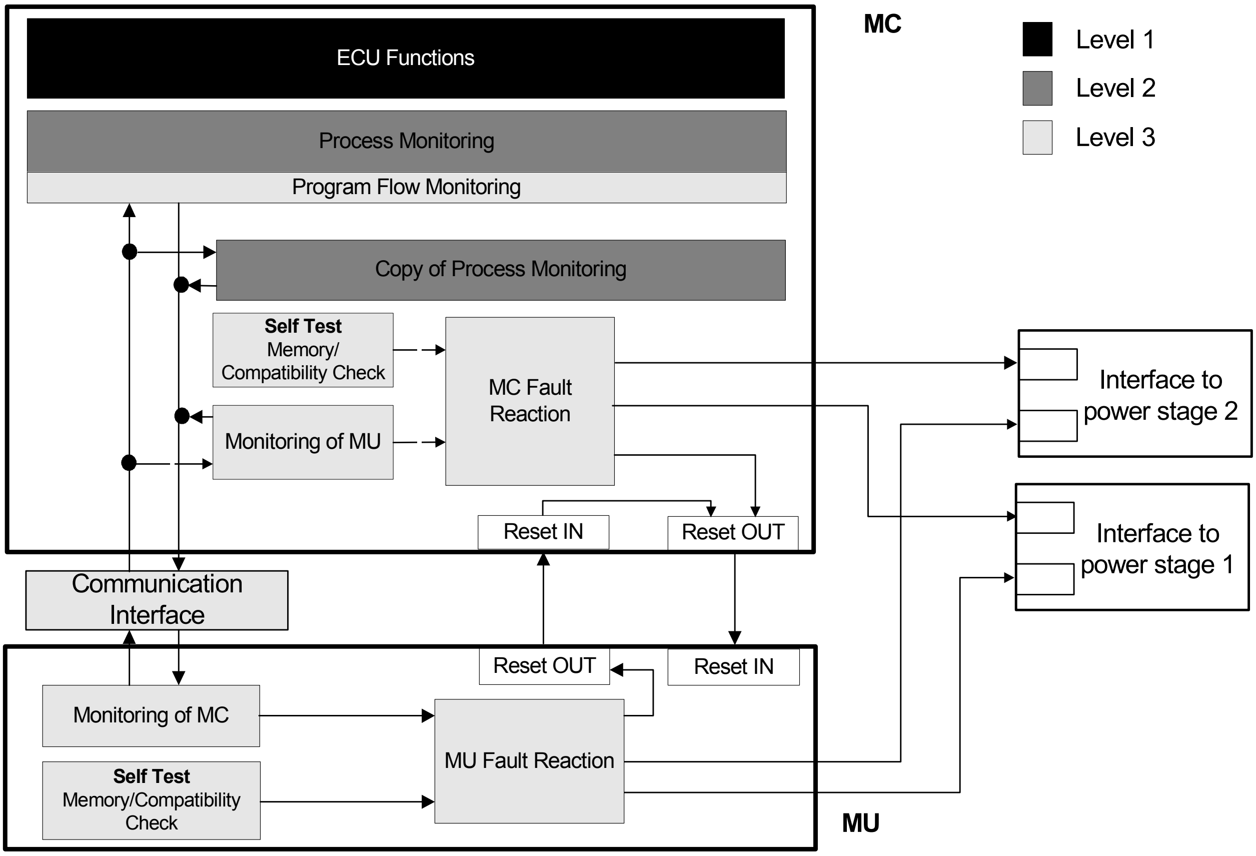

Figure 1: Sketch of processor monitoring with two power stages

12.3.2 States of the Components

The behavior of both components of the processor monitoring (i.e., MC and MU) is described by two *autonomous* state machines, reflecting the fact that both constitute separate components of a distributed system and as such should really have a separate state space.

Even so, the structure of the two state machines is basically identical, mostly because the two components have a common task, viz., perform the processor monitoring. Nevertheless, as the two parts run independently of each other, both could be in mismatching states; it is the task of the communication interface to prohibit such cases by ensuring that the components *synchronously* progress through their states in the correct order. The exception to this rule is the DISABLE state which is entered after a fault was detected (on the component which detected the fault); this knowledge can then only be propagated to the other component by means of a communication, e.g., it can be the case that, for one communication cycle, the MU is in DISABLE while the MC is still in NORMAL (after the next communication, the MC will also go to DISABLE).

The basic layout of the two state machines is described the figure “State machine layout.” The figure contains the basic transitions sequence through the different states. We shall now describe the actions which are performed in each of the states (for the time being without distinguishing between which actions are performed on MC and MU, respectively). Communications between MC and MU are an integral part of the system’s functionality and, in any case, information about the current state of a component is always part of the data exchanged by the communications.

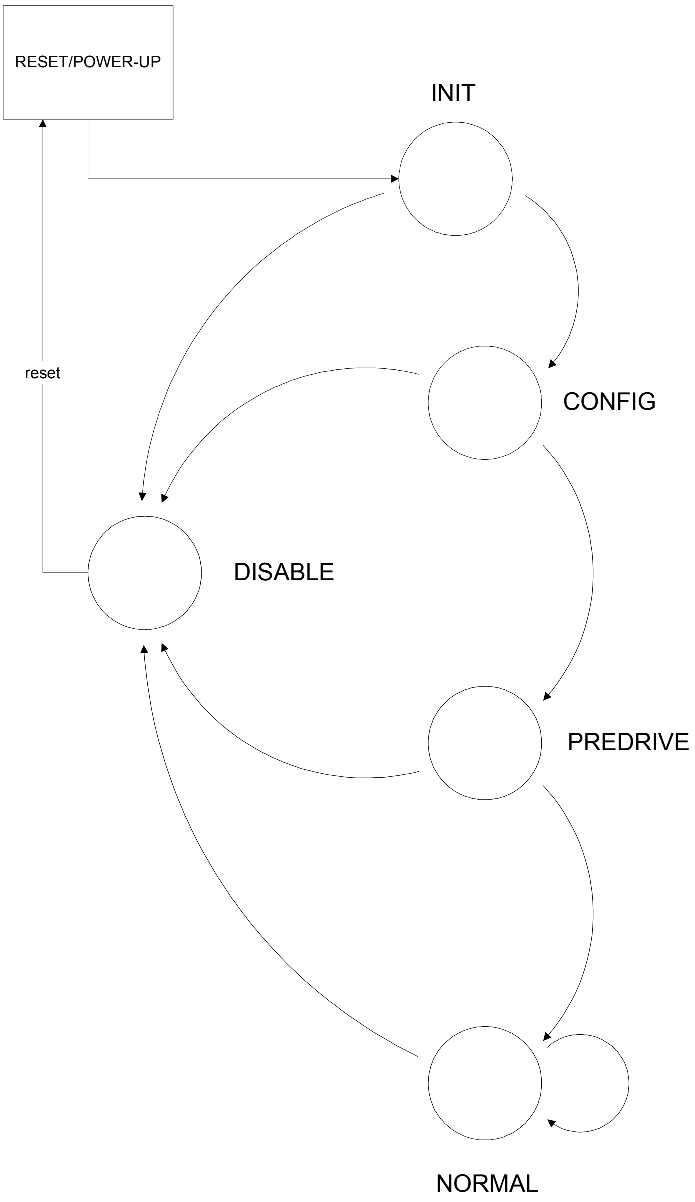

Figure 2: State machine layout

12.3.2.1 The INIT state

As indicated by its name, the INIT state is the initial state of the state machine, i.e., always after power-up or a reset, ‘start-up’ tasks like data initialisation and several self tests on both MC and MU are performed in INIT. Note that there is *no* communication performed while the two components are in their respective INIT states.

12.3.2.2 The CONFIG state

In the error free case, the next state is the CONFIG state which is mainly used to prepare and perform the first communication between MC and MU; consequently, the tasks carried out in this state are to prepare the communication, wait for it, and afterwards evaluate the received data. The exchanged data include error codes and reset counters, together with configuration and compatibility data; this communication is usually referred to as the

"CONFIG communication" because if everything is working normally, both components will be in their respective CONFIG states.

12.3.2.3 The PREDRIVE state

In the PREDRIVE state, another communication (the "PREDRIVE communication") is performed which serves the purpose to initialise the PFM (see section "Program Flow Monitoring" for both MC and MU) and the FS-IST (see module "Function-Specific Instruction Set Test" on both MC and MU) with the necessary data; also the configuration data transferred in the previous communication is sent back in order to double-check correct reception; additionally, from this state onwards, the monitored A/D conversion values are transferred from the MU to the MC so that the value obtained on the MC can be checked against the conversion values (of the same signal!) from the MU.

12.3.2.4 The NORMAL state

The NORMAL state is the state which is reached when all the previous actions (including communications) were performed successfully; it represents a properly functioning system. Since there are several tasks which have to be continuously performed (e.g., PFM, FS-IST), there are ongoing communications ("NORMAL communication") in the NORMAL state which continue the exchange of the necessary data for such continuous tasks.

12.3.2.5 The DISABLE state

The DISABLE state is reached if an error occurs during any the actions in the other states, see Figure 2; such errors include communication errors or errors detected during the Switch-off Path Check (see section "Switch-Off Path Check"). Consequently, since the system is malfunctioning, *the power stages are disabled*, by the component that enters its respective DISABLE state. In a corresponding communication ("DISABLE communication"), error information (like reset counters and error codes) are then exchanged.

12.3.3 Communication protocol between MC and MU

In the following, the communication protocol between MC and MU shall be described where the communications in each state are described on after the other.

The description for each communication is given in such a way that always the data flow in both directions (MC to MU, and MU to MC) is depicted in a separate column.

Note that in following description of the communication protocol, all variables are named as they are known on the MC, the MU is regarded as a black-box.

A row in the tables corresponds to one byte, and where more than one data is sent in one byte together this indicated accordingly (e.g., in the CONFIG state communication, ERR_COD_MC and STATE_ERR_IDC_MC are sent in a combined form as byte1 of the data sent from the MC to the MU).

The first byte of each communication in both directions is always a header byte reflecting the internal state of the sending component.

The last byte of each communication in both directions is always the (XOR) checksum of the previous 5 bytes (incl. header-byte) to detect communication errors.

12.3.3.1 CONFIG state communication

MC → MU	MU → MC

NC_STATE_MC_CONF	NC_STATE_MC_CONF
STATE_ERR_IDC_MC, ERR_COD_MC **(P)**	ERR_COD_MU, STATE_ERR_IDC_MU **(P)**
CTR_RST_MC **(P)**	LV_V_L_DET_MU, LV_V_H_DET_MU CTR_RST_MU **(P),**
Configuration data 1: NLC_MU_MOD NLC_MU_IGN_ACQ NLC_MU_INJ_OFF_TRM_ENA NLC_MU_POW_OFF_TRM_ENA Configuration data 2: 0 **(P)**	NR_MU_COMP, NR_MU_HW_VERS
Complement of configuration data 1 and 2 **(P)**	Empty (0x00)
Checksum	Checksum

(P) = Due to the high importance of the information, these data bytes are protected by a parity bit. A parity error (odd instead of even parity) is regarded as a communication error, see "G45 Parity-bit checking."

- MC and MU exchange error codes, error indications, and reset counters (the error code and error indication of the MU are sent as LF_MU_ERR_BYTE and then "decoded" to ERR_COD_MU and STATE_ERR_IDC_MU).
- The flags LV_V_L_DET_MU and LV_V_H_DET_MU are set if under- or over-voltage, respectively, has been detected on the MU.
- Based on the compatibility information NC_MU_COMP and HW version NC_MU_HW_VERS which is sent by the MU, the MC can check whether its software is compatible to the MU.
- By sending configuration data 1 and 2 during the CONFIG communication, the MU is configured by the MC: monitoring an EMS or a TCU; the acquisition of the ignition key signal can be configured to HW or SW mode; the IOT and POT functionality can be enabled; the 0 in Configuration data 2 stands for not performing EOLT.

12.3.3.2 PREDRIVE state communication

MC → MU	**MU → MC**
NC_STATE_MC_PRDR	NC_STATE_MC_PRDR
NR_MC_COMP	LF_MC_RCV_PFM_BYTE
Empty (0x00)	LV_MU_DI_OUT_0, LV_MU_DI_OUT_1, IDX_TEST_RCV_MC_FCT_SPC_IST
Configuration data 1: NLC_MU_MOD, NLC_MU_IGN_ACQ, NLC_MU_INJ_OFF_TRM_ENA, NLC_MU_POW_OFF_TRM_ENA Configuration data 2: 0 **(P)**	LV_MU_IGN_KEY, LF_MU_CONF_BYTE_PRDR (combining Configuration data 1 and Configuration data 2)
Complement of configuration data 1 and 2 **(P)**	VP_MU_AN_DIG_MON
Checksum	Checksum

(P) = Due to the high importance of the information, these data bytes are protected by a parity bit. A parity error (odd instead of even parity) is regarded as a communication error, see "G45 Parity-bit checking."

- The MU sends the first PFM synchronisation byte LF_MC_RCV_PFM_BYTE, the first FS-IST question IDX_TEST_RCV_MC_FCT_SPC_IST, and the converted analogue value VP_MU_AN_DIG_MON.
- The configuration data 1 and 2 are confirmed by the MC: now the MU is completely configured.
- To ensure that the MU is always working in the correct mode, it reads back all of its internally stored configuration data and sends it back to the MC as LF_MU_CONF_BYTE_PRDR.
- Based on the compatibility information NR_MC_COMP sent by the MC, the MU can check whether it is compatible to the MC.
- The MU shall send the status of its disable outputs in LV_MU_DI_OUT_0 and LV_MU_DI_OUT_1.

- The MU sends the latched valued of its input for the ignition key signal as LV_MU_IGN_KEY (regardeless of whether it was configured for SW or HW acquisition of said signal).

12.3.3.3 NORMAL state communication

MC → MU	MU → MC
NC_STATE_MC_NORM	NC_STATE_MC_NORM
LF_MC_RESP_PFM	LF_MC_RCV_PFM_BYTE
LV_MC_DR_OFF, LV_IGK, IDX_RESP_TRM_FCT_SPC_IST	LV_MU_DI_OUT_0, LV_MU_DI_OUT_1, IDX_TEST_RCV_MC_FCT_SPC_IST
Empty (0x00)	LV_MU_IGN_KEY, LF_MU_CONF_BYTE_NORM, ABC_RCV_MC_FCT_SPC_IST
Empty (0x00)	VP_MU_AN_DIG_MON
Checksum	Checksum

- The MU keeps on sending FS-IST questions IDX_TEST_RCV_MC_FCT_SPC_IST, and additionally the FS-IST anti-bounce counter ABC_RCV_MC_FCT_SPC_IST, and the monitored analogue value VP_MU_AN_DIG_MON.
- LF_MC_RCV_PFM_BYTE is either an updated PFM synchronisation byte or a status byte where a set bit indicates that the corresponding PFM anti-bounce counter on the MU has value >0.
- The MC sends the PFM answer byte LF_MC_RESP_PFM and the FS-IST answer IDX_RESP_TRM_FCT_SPC_IST.
- Additionally, it is indicated whether wrong FS-IST answers are sent because the redundant switch off path is activated via the flag LV_MC_DR_OFF.
- As the information whether the ignition key is switched on or off is important information, as it is used to determine whether the injection will be switched off (via the IOT), the MC sends its information LV_IGK to the MU.
- If the ignition key is connected to the CAN bus, the state of the ignition key cannot be acquired by the MU. In this case the IGK acquisition of the MU must be configured to software acquisition, i.e., LV_IGK is used to determine whether the IOT or the POT has to be started.

- To ensure that the MU is always working in the correct mode, it reads back its internally stored configuration data 1 and sends it back to the MC in the form of LF_MU_CONF_BYTE_NORM.
- The MU shall send the status of its disable outputs in LV_MU_DI_OUT_0 and LV_MU_DI_OUT_1.

- The MU sends the latched valued of its input for the ignition key signal as LV_MU_IGN_KEY (regardeless of whether it was configured for SW or HW acquisition of said signal).

12.3.3.4 DISABLE state communication

MC → MU	**MU → MC**
NC_STATE_MC_DI	NC_STATE_MC_DI
STATE_ERR_IDC_MC ERR_COD_MC **(P)**	LF_MU_ERR_BYTE **(P)** (Combining ERR_COD_MU and STATE_ERR_IDC_MU)
LV_IGK CTR_RST_MC **(P)**	CTR_RST_MU **(P)**
Empty (0x00)	LV_MU_IGN_KEY
Empty (0x00)	VP_MU_AN_DIG_MON
Checksum	Checksum

(P) = Due to the high importance of the information, these data bytes are protected by a parity bit. A parity error (odd instead of even parity) is regarded as a communication error, see "G45 Parity-bit checking."

- MC and MU exchange error codes, error indications, and reset counters (the error code and error indication of the MU are sent as LF_MU_ERR_BYTE and then "decoded" to ERR_COD_MU and STATE_ERR_IDC_MU).
- The MC sends its value of the ignition key signal, so does the MU.
- The MU sends the monitored analogue value VP_MU_AN_DIG_MON.

12.3.4 Table of error codes of MC and MU

The following table shows the meanings of the different error codes of MC in order to make it easier to analyse them in case of an error detected by Processor Monitoring.

Value	ERR_COD_MC	ERR_COD_MU
0	No error	No error
1	Header-byte error detected on MC	Header-byte error detected on MU
2	Checksum error detected on MC	Checksum error detected on MU
3	Parity error detected on MC	Parity error detected on MU
4	Wrong configuration data sent by MU	Wrong configuration data sent by MC
5	Error in switch-off path check	Error in complement check of configuration data
6	Error in compatibility check on MC	Error in compatibility check on MU
7	Error in Standard ROM check	Communication maximum time-out monitoring
8	Error in Standard RAM check	Communication minimum time-out monitoring
9	Error in Level 2 ROM check	Error detected by ignition key monitoring on MU
10	Error in Level 2 RAM check	NORMAL instead of EOLT header received
11	FS-IST: MU sent wrong question	FS-IST: MC sent wrong answer
12	FS-IST: MU does not react to deliberately wrong answer	Redundant switch-off path hsa been triggered
13	FS-IST: MU does not decrease its FS-IST anti-bounce counter	MU has detected under-voltage
14	Error in check of MU readiness	MU has detected over-voltage
15	- *(not used)*	MU has detected under- and over-voltage
16	PFM: MU does not toggle PFM bit 0 in time	PFM task 0 executed to slowly on MC
17	PFM: MU does not toggle PFM bit 1 in time	PFM task 1 executed to slowly on MC
18	PFM: MU does not toggle PFM bit 2 in time	PFM task 2 executed to slowly on MC
19	PFM: MU does not toggle PFM bit 3 in time	PFM task 3 executed to slowly on MC
20	PFM: MU does not toggle PFM bit 4 in time	PFM task 4 executed to slowly on MC
21	PFM: MU does not toggle PFM bit 5 in time	PFM task 5 executed to slowly on MC
22	PFM: MU does not toggle PFM bit 6 in time	PFM task 6 executed to slowly on MC
23	Invalid state transition or undefined state on MC	Invalid state transition or undefined state on MU
24	PFM: MU does not react to deliberately wrong PFM bit 0	- *(not used)*
25	PFM: MU does not react to deliberately wrong PFM bit 1	- *(not used)*
26	PFM: MU does not react to deliberately wrong PFM bit 2	- *(not used)*
27	PFM: MU does not react to deliberately wrong PFM bit 3	- *(not used)*

28	PFM: MU does not react to deliberately wrong PFM bit 4	- *(not used)*
29	PFM: MU does not react to deliberately wrong PFM bit 5	- *(not used)*
30	PFM: MU does not react to deliberately wrong PFM bit 6	- *(not used)*
31	- *(not used)*	- *(not used)*

12.4 MC Processor Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Export actions:

ACTION_ECM3_McChangeState(IN <PRM_STATE_MC_NEW>)
This action changes the state of the MC to the given new state; when already in DISABLE, nothing is done.
ACTION_ECM3_WriteChkCpl(INOUT <PRM_VAR>, OUT <PRM_VAR_CPL>, IN <PRM_VALUE>)
This action writes the value into the RAM and cross-checks the written value; the complement is generated, stored, and the corresponding variable is returned.
ACTION_ECM3_ChkCpl(IN <PRM_VAR>, IN <PRM_VAR_CPL>)
This action compares the value of var with its complement var_CPL.
ACTION_ECM3_ReadChkCpl(OUT <PRM_RESULT>, IN <PRM_VAR>, IN <PRM_VAR_CPL>)
This action checks that var and var_CPL are a valid value-complement pair, and if yes, stores the value in result so that the value can be used in successive calculations.

ACTION_ECM3_McReadChkCpl(OUT <PRM_RESULT>, IN <PRM_VAR>, IN <PRM_VAR_CPL>, IN <PRM_DFT_VALUE>)
This action checks that var and var_cpl are a valid value/complement pair; if no returns the supplied default value and triggers a fault reaction.
ACTION_ECM3_McChkStack()
This action triggers a check of the appropriate stack area by the infrastructure and evaluates its result.
ACTION_ECM3_McReadChkState (OUT <PRM_STATE_MC_TMP>)
This action checks the current state for being valid.
ACTION_ECM3_McResetRomChkFlags()
This action resets the flags for the Standard ROM check in case this becomes necessary.

Description for actions:

ACTION_ECM3_McChangeState(PRM_STATE_MC_NEW)

Change STATE_MC to new state.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_STATE_MC_NEW	IN	0...FFH	0...255	1	[-]
Representation of state to be entered					

ACTION_ECM3_WriteChkCpl(PRM_VAR, PRM_VAR_CPL, PRM_VALUE)

see description in section "RAM check service actions of Processor Monitoring on MC"

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_VAR	INOUT	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR_CPL	OUT	*any*		*any*	*any*
Variable for the complement of PRM_VAR					
PRM_VALUE	IN	*any*	*any*	*any*	*any*
Value to be stored					

ACTION_ECM3_ChkCpl(PRM_VAR, PRM_VAR_CPL)

see description in section "RAM check service actions of Processor Monitoring on MC"

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_VAR	IN	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR_CPL	IN	*any*		*any*	*any*
Variable for the complement of PRM_VAR					

ACTION_ECM3_ReadChkCpl(PRM_RESULT, PRM_VAR, PRM_VAR_CPL)

see description in section "RAM check service actions of Processor Monitoring on MC"

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_RESULT	OUT	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR	IN	*any*		*any*	*any*
Variable for the complement of PRM_VAR					
PRM_VAR_CPL	IN	*any*	*any*	*any*	*any*
Value to be stored					

ACTION_ECM3_McReadChkCpl(PRM_RESULT, PRM_VAR, PRM_VAR_CPL, PRM_DFT_VALUE)					
see description in section "RAM check service actions of Processor Monitoring on MC"					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_RESULT	OUT	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR	IN	*any*		*any*	*any*
Variable for the complement of PRM_VAR					
PRM_VAR_CPL	IN	*any*	*any*	*any*	*any*
Value to be stored					
PRM_DFT_VALUE	IN	*any*	*any*	*any*	*any*
Default value for PRM_VAR in case an inconsistency is detected					

ACTION_ECM3_McChkStack()					
The action triggers a stack check via an infrastructure action and evaluates the result of the check.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**

ACTION_ECM3_McReadChkState(<PRM_STATE_MC_TMP>)					
The action reads the internal representation of the current state (STATE_MC) and checks it for validity; in case of an inconsistency, the return value shall be NC_STATE_MU_DI (the representation for DISABLE state) and a fault reaction shall be triggered.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_MC_TMP	OUT	0...FFH	0...255	1	[-]
Short description of the given parameter					

ACTION_ECM3_McResetRomChkFlags()					
This action resets the flags LV_MC_ROM_CHK_READY and LV_MC_ROM_CHK_OK; this is used by DISABLE requests.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**

FUNCTION DESCRIPTION:

General information:

This module describes the main function of processor monitoring on the MC, in particular the state machine.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ERR_SWI_MC_LEVEL_2_CAL	1	0...FFH	0...255	1	[-]
Switch to disregard ROM errors in the level 2 calibration data (when set to NC_ERR_SWI_MC_LEVEL_2_CAL)					
C_ERR_SWI_MC_LEVEL_2_COD	1	0...FFH	0...255	1	[-]
Switch to disregard ROM errors in the level 2 code (when set to NC_ERR_SWI_MC_LEVEL_2_COD)					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ERR_SWI_MC_LEVEL_2_CAL	1	0...FFH	0...255	1	[-]
Value for the switch which allows to disregard ROM errors in the level 2 calibration area					
NC_STATE_MC_INI	1	0...FFH	0...255	1	[-]
Internal representation for INIT state					
NC_STATE_MC_CONF	1	0...FFH	0...255	1	[-]
Internal representation (and header byte) for CONFIG state					
NC_STATE_MC_PRDR	1	0...FFH	0...255	1	[-]
Internal representation (and header byte) for PREDRIVE state					
NC_STATE_MC_NORM	1	0...FFH	0...255	1	[-]
Internal representation (and header byte) for NORMAL state					
NC_STATE_MC_DI	1	0...FFH	0...255	1	[-]
Internal representation (and header byte) for DISABLE state					
NLC_MU_MOD	1	0...1H	0...1	1	[-]
Configuration of MU mode (monitoring of EMS=0 or TCU=1)					
NLC_MU_IGN_KEY_ACQ	1	0...1H	0...1	1	[-]
Configuration for acquisition of IGK signal on the MU (by software=0 or hardware=1)					
NLC_MU_POW_OFF_TMR_ENA	1	0...1H	0...1	1	[-]
Configuration of MU for enabling/disabling the power-off timer					
NLC_MU_INJ_OFF_TMR_ENA	1	0...1H	0...1	1	[-]
Configuration of MU for enabling/disabling the injection-off timer					
NC_NR_MC_COMP	1	0...7H	0...7	1	[-]
Compatibility information of MC					
NC_VP_MC_AN_DIG_MON_CPL_ERR	1	8000...7FFFH	-5...4.99984	0.1526e-3	[V]
Constant indicating a complement error of the value of the A/D conversion on the MC acquired in the infrastructure					
NC_ERR_SWI_MC_LEVEL_2_COD	1	0...FFH	0...255	1	[-]
Value for the switch which allows to disregard ROM errors in the level 2 code					
NC_STATE_MC_NOT_VLD	1	0...FFH	0...255	1	[-]
Internal representation for invalid state					

12.4.1 State machine on MC

FUNCTION DESCRIPTION:

General information:

This function represents the main control flow in the MC; based on the current state of the MC, other modules/functions are activated or deactivated. The internal state machine of the MC governs which actions on the MC shall be performed, e.g.:

- which data are sent to the MU;
- which actions should be taken upon receiving data, in particular, whether the received data are acceptable and the MU is still in sync with the MC;
- whether the power stages should be disabled or enabled.

As described schematically in the signal flow diagram, given a state, there are only a certain number of other states reachable.

Signal flow diagram:

The following diagram shows the state machine of the MC with all the possible transitions.

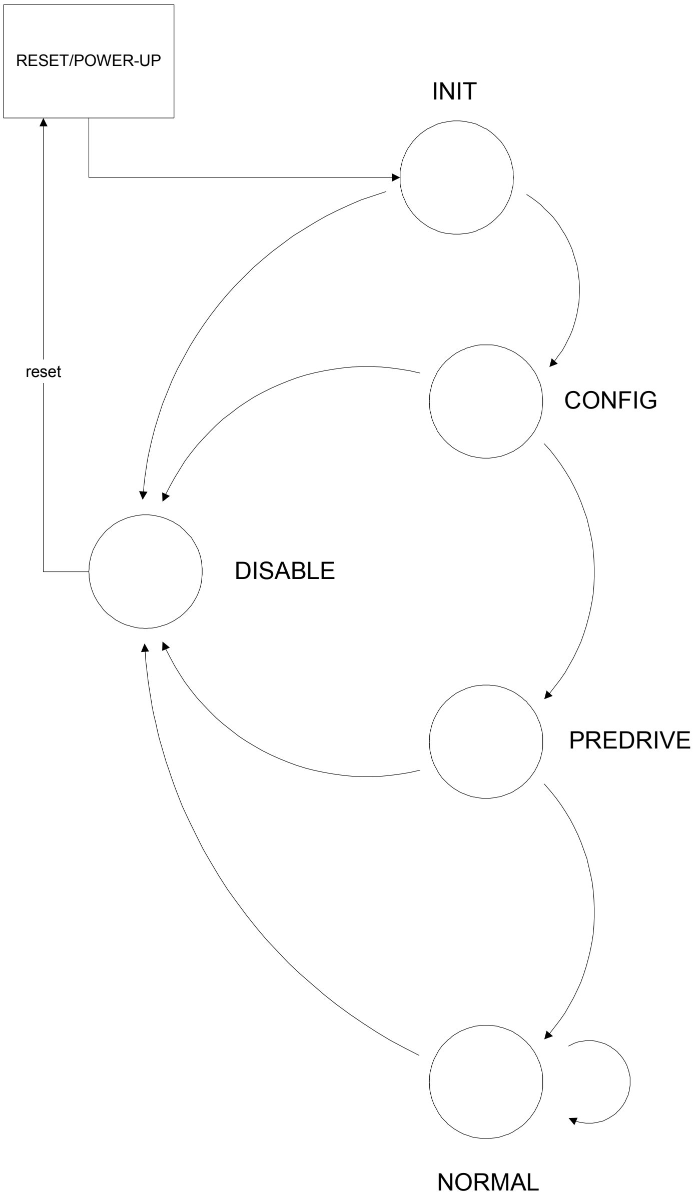

Figure 3 State machine of the MC

Description:

This function shall incorporate the following requirements:

G51 State machine on MC

R51_1: All state changes shall be performed using the action ACTION_ECM3_McChangeState().

R51_2: The possible state changes are described in the signal flow diagram above; no other transition between the states shall be performed.

R51_3: A valid transition from one state to the other (according to the signal flow diagram) shall be performed when all tasks of the given state are finished; an exception is the transition to DISABLE state: this shall be performed immediately when a transition condition is given (e.g., when a fault reaction on the MC is carried out, or when the MU sends a DISABLE header).
Note: a rough sequencing of tasks and state transitions can be given as follows

- evaluation of data from previous communication
- state transition (if necessary)
- preparation of new communication
- triggering of new communication

R51_4: The internal representations of states/header bytes shall be chosen in such a way that the minimum of the pair-wise hamming distances is as high as possible, i.e., in order to change from one valid representation of a state into another valid representation of a different state, several bits have to toggle at once.

R51_5: The same bit patterns shall be used for internal representation of states and for the corresponding header bytes sent to the MU.

R51_6: Concerning the transition from INIT to CONFIG:
R51_6.1: there shall be a project-specific transition condition (cf. G52);
R51_6.2: the transition shall only be performed if all tasks in INIT have been completed (cf. activation conditions) AND LV_MU_READY = 1 AND the project-specific condition is satisfied.
Note: the actual state change from INIT to CONFIG can be performed by the function G52 evaluating the project-specific transition condition; however, R51_6.2 then has to be ensured by the control flow (e.g., the project-specific condition is only evaluated if all other conditions like LV_MU_READY = 1 are already satisfied).

Description for ACTION_ECM3_McChangeState:

ACTION_ECM3_McChangeState(PRM_STATE_MC_NEW)					
Change STATE_MC to new state.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_MC_NEW	IN	0...FFH	0...255	1	[-]
Representation of state to be entered					

Formula section:

```
/* When already in DISABLE, no transition shall be possible: see signal flow diagram */
IF (STATE_MC <> NC_STATE_MC_DI)
THEN
    STATE_MC = PRM_STATE_MC_NEW;
```

FI

Application conditions:

Initialisation: *`/* Has the reset counter exceeded its threshold: if so, perform start-up in DISABLE; otherwise in INIT (note: also CTR_RST_MC_CPL has to be checked, using the actions from "RAM check service actions of processor monitoring on MC") */`*

```
STATE_MC = NC_STATE_MC_INI;
IF (CTR_RST_MC > NC_CTR_RST_MC_THD)
THEN
    STATE_MC = NC_STATE_MC_DI;
ELSE
```

Recurrence: The **initialisation** performed **after each power-up or reset**.

Afterwards, the function is **called**.

Activation: -

Deactivation: -

12.4.2 Monitoring of state machine

FUNCTION DESCRIPTION:

Description:

This function shall incorporate the following requirements:

G9 Monitoring of state machine

R9_1: The state machine on the MC shall be monitored in by testing whether STATE_MC is still valid (i.e., that it is equal to one of NC_STATE_MC_INI, NC_STATE_MC_CONF, NC_STATE_MC_PRDR, NC_STATE_MC_NORM, NC_STATE_MC_DI).

R9_2: If it is detected that the MC is an undefined state:
R9_2.1: it shall be assumed to be in DISABLE state;
R9_2.2: an immediate fault reaction shall be performed by calling ACTION_ECM3_McFaultReaction() with error location NC_ERR_COD_MC_NOT_VLD_TRAN.

R9_3: The function shall be incorporated into the action ACTION_ECM3_McReadChkState() as described in the formula section below.

Description for ACTION_ECM3_McReadChkState:

ACTION_ECM3_McReadChkState(<PRM_STATE_MC_TMP>)					
The action reads the internal representation of the current state (STATE_MC) and checks it for validity; in case of an inconsistency, the return value shall be NC_STATE_MU_DI (the representation for DISABLE state) and a fault reaction shall be triggered.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_MC_TMP	OUT	0...FFH	0...255	1	[-]
Short description of the given parameter					

Formula section:

```
IF ("STATE_MC is valid") /* see R9_1 */
THEN
    PRM_STATE_MC_TMP = STATE_MC
ELSE /* invalid state */
    PRM_STATE_MC_TMP = NC_STATE_MC_DI;
    ACTION_ECM3_McFaultReaction (IN        NC_ERR_COD_MC_NOT_VLD_TRAN);
FI
```

Application conditions:

Initialisation: -

Recurrence: The function is called via ACTION_ECM3_McReadChkState().

Activation: -

Deactivation: -

12.4.3 ROM checks of processor monitoring on MC

FUNCTION DESCRIPTION:

General information:

On the MC, there are two different ROM checks:

- the *standard ROM check* which checks the *whole* ROM (code, constants, calibration data with the exception of areas which can be changed during runtime like FLASH or EEPROM);
- the *cyclic ROM check for process monitoring* which checks the ROM of process monitoring (consisting of the code, constants, and calibration data of process monitoring, plus the code of all library functions called in the code of process monitoring).

The difference between the two ROM checks is the fact that the standard ROM check is performed only *once* after power-up (after reset only if the reset occurred before its successful completion) while the ROM check for process monitoring is *cyclic*, i.e., it is restarted after completion.

12.4.3.1 Standard ROM check on MC

FUNCTION DESCRIPTION:

General information:

This sub-function describes the standard ROM check (a.k.a. "level 1 ROM check") on the MC which is performed once per driving cycle directly after power-up or reset.

The two actions ACTION_ECM3_McLockPwlResource() and ACTION_ECM3_McUnlockPwlResource() are used to ensure that the ECU is not powered down before the ROM check has been completed at least once in the corresponding driving cycle.

Description:

The function incorporates the following requirements:

G8.1 Standard ROM check on MC

R8.1_1: Every 1000ms:
R8.1_1.1: the action ACTION_INFR_McRomChkReady() shall be called;
R8.1_1.2: its return value shall be stored in the flag LV_MC_ROM_CHK_READY (indicating whether the Standard ROM check has been finished or not); the flag shall be stored in a reset-safe manner and together with a complement, LV_MC_ROM_CHK_READY_CPL which shall also be stored in a reset-safe manner; LV_MC_ROM_CHK_READY shall be accessed (read/write) using the actions ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() defined in the section "RAM check service actions of processor monitoring on MC"; its default value in case of a RAM error shall be 0;
R8.1_1.3: if LV_MC_ROM_CHK_READY = 1:
R8.1_1.3.1: the corresponding power-latch resource shall be unlocked by calling ACTION_ECM3_McUnlockPwlResource();
R8.1_1.3.2: the action ACTION_INFR_McRomChkOk() shall be called;
R8.1_1.3.3: its return value shall be stored in the flag LV_MC_ROM_CHK_OK (indicating whether the checksum calculated by the standard ROM check is equal to the expected one);
R8.1_1.3.4: if LV_MC_ROM_CHK_OK = 0:
R8.1_1.3.4.1: LV_MC_ROM_CHK_READY shall be reset to 0 using the RAM check service actions;
R8.1_1.3.4.2: an immediate fault reaction shall be performed by calling ACTION_ECM3_McFaultReaction() with error code NC_ERR_COD_MC_ROM_LEVEL_1.

R8.1_2: This function shall be under PFM control using the 1000ms PFM task (note that this does only refer to the processor monitoring function which only evaluates the result of the standard ROM check; the actual checksum calculation itself is part of the infrastructure and as such cannot be controlled by PFM).

Description for ACTION_ECM3_McResetRomChkFlags:

ACTION_ECM3_McResetRomChkFlags()					
This action resets the flags LV_MC_ROM_CHK_READY and LV_MC_ROM_CHK_OK; this is used by DISABLE requests.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**

Formula section:

LV_MC_ROM_CHK_OK = 0;

/ Using the RAM check service actions */*

LV_MC_ROM_CHK_READY = 0;

Application conditions:

Initialisation: After power-up:

/ Using the RAM check service actions */*
LV_MC_ROM_CHK_READY = 0;
/ Lock power-latch resource */*
ACTION_ECM3_McLockPwlResource();

After power-up or reset:

LV_MC_ROM_CHK_OK = 0;
/ Lock power-latch resource */*
ACTION_ECM3_McLockPwlResource();

Recurrence: Every 1000ms

Activation: (STATE_MC <> NC_STATE_MC_DI) **AND**
(LV_MC_ROM_CHK_READY = 0)
/ using the RAM check service actions */*
(not in DISABLE state and not yet completed)

Deactivation: otherwise;
at deactivation, call ACTION_ECM3_McUnlockPwlResource()
/ after transition to DISABLE or after completion of ROM check: unlock power-latch resource */*

12.4.3.2 Cyclic ROM check on MC for process monitoring

FUNCTION DESCRIPTION:

General information:

The cyclic ROM check for process monitoring ("level 2 ROM check") checks all level 2 ROM areas, which are different from the level 1 ROM areas, as well as the corresponding constant and calibration data, very much like the standard ROM check for the level 1 ROM areas. However, there are two differences between the two ROM checks.

First of all, while the level 1 ROM check is only executed *once* per driving cycle, the level 2 ROM check is performed cyclically, i.e., once it is finished, it starts again.

Secondly, the level 2 ROM check also takes into account all library functions (e.g., from the mathematics library) which might potentially called from within any level 2 function.

This can be achieved, e.g., by performing a *complete* check of those external libraries or by the use of so-called *inline functions* where only the code of those functions *which are actually called* is tested: the code of inline functions is directly copied to the place where the function is called, instead of performing a function call; concretely, the code of an inline function from the mathematics library called from a level 2 function thus becomes part of the level 2 code and is consequently tested by the level 2 code ROM check.

Note that the two mentioned ways to check external library functions were just chosen as examples: there might very well be other ways to include such libraries in the level 2 ROM check, it just has to be ensured that **each function called inside a level 2 function is included in the level 2 ROM check** (one way or another).

Description:

The function incorporates the following requirements:

G8.2 Cyclic ROM Check on MC for Process Monitoring

R8.2_1: The checksum shall be calculated by an addition checksum.

R8.2_2: Both the calculated checksum and its expected value shall be unsigned values obtained by adding unsigned values.

R8.2_3: The areas to be checked are comprised of the **level 2 code** area, the **level 2 constant data**, the **level 2 calibration data**, and the **code of all functions from external libraries contained in the level 2 code**.

R8.2_4: For the level 2 code area, the following special mechanism shall be used:
R8.2_4.1: there shall be two sections of level 2 code;
R8.2_4.2: for one of the sections, there shall be a calibration switch C_ERR_SWI_MC_LEVEL_2_COD which, **for application software only**, allows ignoring errors in the level 2 code area if its value is set to NC_ERR_SWI_MC_LEVEL_2_COD; **for production software, this switch must be ignored!**
R8.2_4.3: for the second section of the code area, C_ERR_SWI_MC_LEVEL_2_COD must not have any effect: a checksum error in this section shall always lead to a fault reaction;
R8.2_4.4: the ROM areas where C_ERR_SWI_MC_LEVEL_2_COD and the expected checksum for the code area are stored shall not be part of the level 2 ROM check.

R8.2_5: For the level 2 calibration area, the following special mechanism shall be used:
R8.2_5.1: there shall be a calibration switch C_ERR_SWI_MC_LEVEL_2_CAL which, **for application software only**, allows ignoring errors in the level 2 calibration ROM area if its value is set to NC_ERR_SWI_MC_LEVEL_2_CAL; **for production software, this switch must be ignored!**
R8.2_5.2: the ROM areas where C_ERR_SWI_MC_LEVEL_2_CAL and the expected checksum for the calibration data area are stored shall not be part of the level 2 ROM check.

R8.2_6: In case a level 2 ROM error is detected, i.e., in case the calculated checksum does not agree with the expected one:
R8.2_6.1: the redundant switch-off path shall be triggered by calling the action ACTION_ECM3_RedSwitchOffPath();

R8.2_6.2: an immediate fault reaction shall be performed by calling the action ACTION_ECM3_McFaultReaction() with the error code NC_ERR_COD_MC_ROM_LEVEL_2;
R8.2_6.3: the flag LV_MC_ROM_CHK_READY shall be reset (using the RAM check service actions).

R8.2_7: The level 2 ROM check shall run in a fixed time grid and shall be called every **10ms**; the meaning of "running in a fixed time grid" is that the level 2 ROM check is activated with a fixed recurrence; when activated, it continues where it left off when called the time before, i.e., this does not mean that it has to be finished between two calls but simply that it is continued when called for the next time.

R8.2_8: One level 2 ROM check cycle shall be finished:
R8.2_8.1: in **EMS** mode, within the time for temporary disabling of power stages (see "G22 Disabling of power stages");
R8.2_8.2: in **TCU** mode, within 500ms.

R8.2_9: The cyclic ROM check for process monitoring shall be under PFM control (viz., the 40ms PFM task with task number 5)

Application conditions:

Initialisation:	The checksum shall be set to a configurable initial value.
Recurrence:	The **initialisation** shall be performed **after each power-up or reset** and **after one cycle has been completed**. The **function itself** shall be calculated **every 10ms**.
Activation:	-
Deactivation:	-

12.4.4 RAM checks of processor monitoring on MC

FUNCTION DESCRIPTION:

General information:

Several RAM checks have to be performed on the MC to test the integrity of the RAM:

- there shall be a non-destructive RAM check for those data that have to be stored in a reset-safe way, and those RAM areas that are shared between BOOT and ECU software;
- for all remaining RAM areas, there shall be a destructive RAM check which also performs an initialisation to 0;
- additionally, there shall be a cyclic RAM check for the level 2 RAM areas and for some of the RAM areas of the processor monitoring: this is done by storing those variables as pair of value and complement and performing consistency checks when accessing the variables;
- in order to prevent faults due to interrupt handling while level 2 is active, also a stack check is implemented which checks the relevant memory area on the stack where the level 2 register content will be stored in case of an interrupt.

The first two kinds of RAM checks have to be performed in such a way as to be able to detect static errors like stuck bits/cells. The last two kinds of RAM check are used to detect dynamic errors like a bit toggling during runtime or one (process/processor monitoring) module corrupting the memory area of another one, or problems with the stack memory.

12.4.4.1 Standard RAM check on MC

FUNCTION DESCRIPTION:

General information:

Those variables which are to be stored in the reset-safe RAM area have to checked without destroying their contents.

Description:

The function incorporates the following requirements:

G6 Standard RAM check on MC (destructive/non-destructive)

R6_1: In case an error has been detected during the Standard RAM check, an immediate fault reaction shall be performed; however, the Standard RAM check is active at a time when calling ACTION_ECM3_McFaultReaction() with the error code NC_ERR_COD_MC_RAM_LEVEL_1 is not possible; therefore, the effect of the action shall be mimicked as much as possible (increase reset counter, set error code, trigger reset if reset counter has not yet passed a certain threshold etc.).

Application conditions:

Initialisation:	-
Recurrence:	Once before all other functions are started
Activation:	activated by the Standard RAM check
Deactivation:	-

12.4.4.2 RAM check service actions of processor monitoring on MC

FUNCTION DESCRIPTION:

General information:

In addition to the RAM checks described above which are only executed after power-up/reset, the processor monitoring on the MC also provides RAM check functionality which is used to protect data which is repeatedly used in both process and processor monitoring.

The functionality of the process monitoring (level 2) is calculated cyclically. The calculation and the storage of intermediate results of the process monitoring functions is performed using the registers of the processor as far as possible. The registers are tested by the function-specific instruction set test (see “MC function-specific instruction set test”).

Description:

The function, via the exported actions, incorporates the following requirements:

G7 RAM check service actions of processor monitoring on MC

R7_1: All variables of the process monitoring which are located in the RAM and used in the next recurrence of a task (e.g. anti-bounce-counters) or in a different successive task are stored as pairs consisting of the value and its complement.

R7_2: After execution of a level 2 module, its results have to be copied from registers into variables located in the RAM. After storing a value from an internal register in the RAM, together with its complement in a variable of the name var_CPL if the original variable was named var (example: LV_OFF_IV_MON_CPL contains the complement of LV_OFF_IV_MON), the value is read back from the RAM and compared with the original value of the register. This procedure is performed by the action ACTION_ECM3_WriteChkCpl() described below.

R7_3: At the beginning of the following recurrence of the task, the two complementary variables are checked for plausibility. Also intermediate results, which cannot be completely handled by the internal registers, are stored in value-complement pairs and checked for plausibility. This is done at the beginning of a level 2 module using the action ACTION_ECM3_ChkCpl() or ACTION_ECM3_ReadChkCpl(); the difference between these two actions is that the action ACTION_ECM3_ChkCpl() only performs a plausibility check for a variable and its complement variable without loading the actual value into a register, while ACTION_ECM3_ReadChkCpl() also loads a register with the value of the given variable.

R7_4: If a RAM fault is detected by these functions, an immediate fault reaction shall be performed via ACTION_ECM3_McFaultReaction(), using the error code NC_ERR_COD_MC_RAM_LEVEL_2.

R7_5: Additionally, there is also a variant of the level 2 RAM check service action ACTION_ECM3_ReadChkCpl() named ACTION_ECM3_McReadChkCpl() used for variables of processor monitoring; the difference to the level 2 service action is the presence of a default return value which shall be returned in case an inconsistency is detected (this is only meaningful for those variables which are stored in the reset-safe area, the others are initialised by the reset following the fault reaction).

R7_6: All RAM check service actions have to be implemented as macros to avoid function calls in the code of level 2 and processor monitoring.

R7_7: All RAM check service actions have to be implemented in such a way that they are universally usable, in particular regardless of the type of their parameters.

Description for ACTION_ECM3_WriteChkCpl

ACTION_ECM3_WriteChkCpl(PRM_VAR, PRM_VAR_CPL, PRM_VALUE)					
see description in section "RAM check service actions of Processor Monitoring on MC"					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_VAR	INOUT	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR_CPL	OUT	*any*		*any*	*any*
Variable for the complement of PRM_VAR					
PRM_VALUE	IN	*any*	*any*	*any*	*any*
Value to be stored					

Formula section:

```
PRM_VAR = PRM_VALUE;
PRM_VAR_CPL = complement(PRM_VALUE);
IF (PRM_VAR != PRM_VALUE)
THEN
    ACTION_ECM3_McFaultReaction(
            IN      NC_ERR_COD_MC_RAM_LEVEL_2);
FI
```

Description for ACTION_ECM3_ChkCpl

ACTION_ECM3_ChkCpl(PRM_VAR, PRM_VAR_CPL)					
see description in section "RAM check service actions of Processor Monitoring on MC"					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_VAR	IN	*any*	*any*	*any*	*any*
Variable to be checked					
PRM_VAR_CPL	IN	*any*		*any*	*any*
Variable for the complement of PRM_VAR					

Formula section:

```
IF (PRM_VAR != complement(PRM_VAR_CPL))
THEN
            ACTION_ECM3_McFaultReaction(
                    IN      NC_ERR_COD_MC_RAM_LEVEL_2);
FI
```

Description for ACTION_ECM3_ReadChkCpl

ACTION_ECM3_ReadChkCpl(PRM_RESULT, PRM_VAR, PRM_VAR_CPL)					
see description in section "RAM check service actions of Processor Monitoring on MC"					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_RESULT	OUT	*any*	*any*	*any*	*any*
Variable to be checked

PRM_VAR_CPL	IN	*any*	*any*	*any*	*any*
Value to be stored					
PRM_DFT_VALUE	IN	*any*	*any*	*any*	*any*
Default value for PRM_VAR in case an inconsistency is detected					

Formula section:

```
IF (PRM_VAR != complement(PRM_VAR_CPL))
THEN
            PRM_RESULT = PRM_DFT_VALUE;
            ACTION_ECM3_McFaultReaction(
                    IN      NC_ERR_COD_MC_RAM_LEVEL_2);
ELSE
            PRM_RESULT = PRM_VAR;
FI
```

Application conditions:

Initialisation:	Before the first test of the complementary variables, all appropriate variables must be initialized properly using the action ACTION_ECM3_WriteChkCpl().
Recurrence:	All the actions in this function are called.
Activation:	-
Deactivation:	-

12.4.4.3 Stack check service action of processor monitoring on MC

FUNCTION DESCRIPTION:

General information:

In addition to the RAM checks described above (the start-up checks described in G6 and the cyclic level 2 RAM check described in G7), there is another memory test to ensure the integrity of memory areas used by the stack. The motivation for the function is as follows.

While a process monitoring (level 2) module is executed, an interrupt might occur. Prompted by the interrupt, the current content of the registers, plus "logistic" data like a return address, are stored on the stack. Once the interrupt handling is finished, the register content is restored from the stack and program execution continues where it left off before the interrupt (the address is also determined from the data saved on the stack).
However, if the used stack memory is corrupted, the level 2 register content might be corrupted without being detected; this could either lead to a dormant fault (level 2 might not catch an existing error) or reduce the availability of the vehicle (a level 2 fault reaction might get triggered unnecessarily).
Finally, if the return address is corrupted by being stored on the stack, the level 2 module might not be completed (leading to a problem with program flow monitoring (PFM), again reducing availability), or some code passages of the level 2 module might be omitted (again leading to a dormant fault).
Consequently, at the beginning of each level 2 module, the relevant stack areas have to be checked so that in case of an interrupt during the execution of the module, the necessary data can be correctly stored and recovered.

Description:

The function incorporates the following requirements:

G49 Stack check service action of processor monitoring on MC

R49_1: The interface to level 2 shall be provided via the exported action ACTION_ECM3_McChkStack().

Remark:

- the action shall be called at the very beginning of each level 2 module in order to ensure that the relevant stack area is OK in case the level 2 module is interrupted;
- the action shall be "sandwiched" in between two PFM actions in order to ensure that the stack check action is entered and left properly since its code might not be completely ROM-checked.

R49_2: When ACTION_ECM3_McChkStack() is called, the infrastructure action ACTION_INFR_McChkStack() shall be called in order to perform the stack check; the requirements to this action shall be described in the IRS of Processor Monitoring.

R49_3: ACTION_INFR_McChkStack() shall return a flag indicating whether the stack check was successful or not.

R49_4: If ACTION_INFR_McChkStack() indicates that the stack check was unsuccessful, an immediate fault reaction shall be performed via ACTION_ECM3_McFaultReaction(), using the error code NC_ERR_COD_MC_RAM_LEVEL_2.

R49_5: The call and the execution of ACTION_ECM3_McChkStack() shall use no stack.

Application conditions:

Initialisation: -

Recurrence: The function is called via ACTION_ECM3_McChkStack().

Activation: -

Deactivation: -

12.4.5 Configuration of MU

FUNCTION DESCRIPTION:

General information:

The MU can be configured in various ways, e.g., whether it is used for monitoring of EMS or TCU application (a choice which has implications on timing etc.). The act of configuring is one of the tasks of the MC which sends these data in the first communication to the MU (and re-sends them in the second so that the data can be rendered plausible on the MU).

Since the configuration has far-reaching influences on the behaviour of the MU and the whole system (e.g., by enabling or disabling the injection-off timer) and each configuration information is simply a bit information, the MU keeps on sending its configuration to the MC in NORMAL communications so that a change in the configuration of the MU can be detected as quickly as possible.

Description:

The function incorporates the following requirements:

G10 Configuration of MU by MC

R10_1: In the CONFIG communication, the MC sends configuration information to the MU; the MU can be configured with respect to:
- general mode (EMS or TCU, NLC_MU_MOD)
- hardware (via the dedicated input pin) or software (only via information received from the MC) acquisition of ignition key signal (NLC_MU_IGN_KEY_ACQ)
- power-off timer enabled or disabled (NLC_MU_POW_OFF_TMR_ENA)
- injection-off timer enabled or disabled (NLC_MU_POW_OFF_TMR_ENA)
- end-of-line test enabled or not (always disabled)

This is achieved by calling the action ACTION_INFR_McSendConfData() with the above arguments; note that the end-of-line test configuration is not part of the argument list since it is always disabled.

R10_2: In the PREDRIVE communication, the MC shall re-send these data in order to confirm the previously sent data (note that, in case a discrepancy between the two sets of configuration data is detected, an immediate fault reaction on the MU shall be the consequence); since the arguments have already been sent to the infrastructure, there is no need to re-send them.

R10_3: The MC shall obtain the complete set of configuration information (including the end-of-line test configuration) from the MU after the PREDRIVE communication so that the MC knows what the MU believes to be configured for; the information shall be stored in LF_MU_CONF_BYTE acquired by calling the action ACTION_INFR_McGetConfData(), and compared to the data from R10_1 and R10_2; note that LF_MU_CONF_BYTE is a compressed representation where the bit values for the configuration data have to be extracted from.

R10_4: The MC shall obtain the configuration information (excluding the end-of-line test configuration) from the MU after NORMAL communications; the information shall again be stored in LF_MU_CONF_BYTE acquired by calling the action ACTION_INFR_McGetConfData(), and compared to the data from R10_1 and R10_2.

R10_5: In case a configuration mismatch is detected on the MC:
R10_5.1: in PREDRIVE, there shall be an immediate fault reaction by calling ACTION_ECM3_McFaultReaction() with error code NC_ERR_COD_MC_CONF_DIF;
R10_5.2: in NORMAL, there shall be a debounced fault reaction, using the anti-bounce counter NC_ABC_MC_CONF_DIF, the error code NC_ERR_COD_MC_CONF_DIF, and the two actions ACTION_ECM3_McIncAbc() and ACTION_ECM3_McDecAbc().

Application conditions:

Initialisation:	LF_MU_CONF_BYTE = 0;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. R10_1 shall be executed before the CONFIG communication is triggered; R10_2 does not require any activity; R10_3 shall be executed after the PREDRIVE communication and the corresponding communication monitoring function; R10_4 shall be executed after NORMAL communications and the corresponding communication monitoring function; R10_5 shall be executed after R10_3 and R10_4, as appropriate.
Activation:	For R10_3 and R10_4, LV_MC_COM_ERR = 0 must hold *(they are only executed if no communication error was detected; note that a consistency check with LV_MC_COM_ERR_CPL is necessary)*
Deactivation:	Otherwise

12.4.6 Version compatibility check

FUNCTION DESCRIPTION:

General information:

This functions describes when and how compatibility information is exchanged between MC and MU.

Description:

This function incorporates the following requirements:

G11 Version compatibility check

R11_1: After the CONFIG communication, if communication monitoring has not found an error, i.e., if LV_MC_COM_ERR = 0 (note that a consistency check with LV_MC_COM_ERR_CPL is necessary), the MC shall obtain the compatibility information sent by the MU (NR_COMP_MU; the hardware version NR_MU_HW_VERS is only sent for information purposes) by calling the actions ACTION_INFR_McGetCompNr() and ACTION_INFR_McGetVersNr().

R11_2: If the compatibility information from the MU does not match the information on the MC (NC_NR_MC_COMP), an immediate fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction with error code NC_ERR_COD_MC_COMP_NR.

R11_3: In the PREDRIVE communication, the MC shall send compatibility information the MU (NC_NR_MC_COMP) by calling the action ACTION_INFR_McSendCompNr() before the PREDRIVE communication is triggered.

Application conditions:

Initialisation:	NR_MU_COMP = 0; NR_MU_HW_VERS = 0;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. R1 shall be executed after the CONFIG communication is completed and no communication error was detected; R2 shall be executed after R1, if necessary; R3 shall be executed before the PREDRIVE communication is triggered.
Activation:	For R1, LV_MC_COM_ERR = 0 must hold *(only executed if no communication error was no detected; note that a consistency check with LV_MC_COM_ERR_CPL is necessary)*
Deactivation:	Otherwise

12.4.7 Acquisition of values of A/D conversions

FUNCTION DESCRIPTION:

General information:

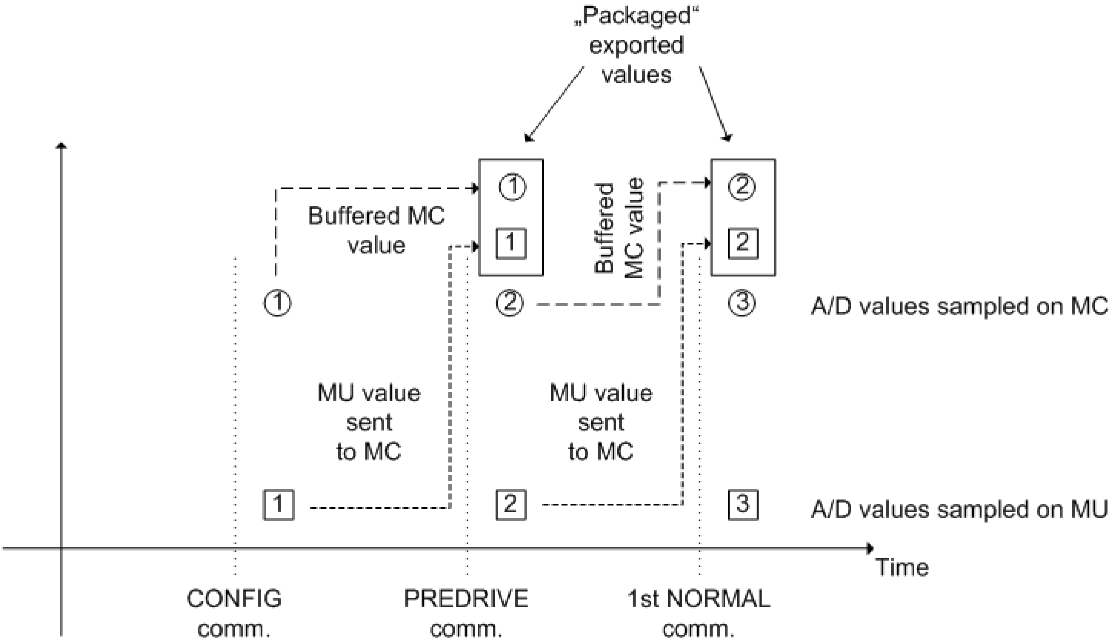
This functions describes when and how the result of the A/D conversions (both on MC and MU) shall be acquired and how it is exported to process monitoring.

A/D conversions are performed on both MC and MU, in both cases after a communication, starting with the end of the CONFIG communication.

However, since the value acquired on the MU can only be transmitted to the MC in the next communication, the data have to be synchronised: for example, the value acquired on the MU after the CONFIG communication is only transmitted to the MC in the PREDRIVE communication and hence only available on the MC after the end of the PREDRIVE communication; in the meantime, the MC also has acquired A/D values after the CONFIG and PREDRIVE communications; so it has to be ensured that the value from the MU sampled after the CONFIG communication is exported ("packaged") together with the value sampled on the MC after the CONFIG communication.

This can easily be achieved by simply buffering the value sampled on the MC until after the next communication (see signal flow diagram).

Signal flow diagram:



Description:

This function incorporates the following requirements:

G23 Acquisition of values of A/D conversions

R23_1: After each communication:
R23_1.1: the buffered A/D value VP_MC_AN_DIG_MON_TMP shall be copied into VP_MC_AN_DIG_MON;
R23_1.2: VP_MC_AN_DIG_MON_TMP and VP_MC_AN_DIG_MON shall be stored together with their complements VP_MC_AN_DIG_MON_TMP_CPL and VP_MC_AN_DIG_MON_CPL and only be accessed using the actions ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC";
R23_1.3: their default values in case of a RAM error shall be 0.

R23_2: After storing the buffered value into the actual interface, the new value of the A/D conversion on the MC shall be fetched from the infrastructure by calling the action ACTION_INFR_GetAnDigMonValMc(), storing the result in VP_MC_AN_DIG_MON_TMP.

R23_3: If VP_MC_AN_DIG_MON_TMP is equal to NC_VP_MC_AN_DIG_MON_CPL_ERR:
R23_3.1: VP_MC_AN_DIG_MON_TMP shall be reset to 0 (using the RAM check actions);
R23_3.2: an immediate fault reaction shall be performed via ACTION_ECM3_McFaultReaction(), using the error code NC_ERR_COD_MC_RAM_LEVEL_2;
R23_3.3: otherwise, no action shall be performed.

R23_4: After each successful PREDRIVE, NORMAL, and DISABLE communication (i.e., LV_MC_ERR_COM = 0):

R23_4.1: the freshly transmitted value of the A/D conversion on the MU shall be fetched from the infrastructure via the action ACTION_INFR_GetAnDigMonValMu(), storing the result in VP_MU_AN_DIG_MON;
R23_4.2: VP_MU_AN_DIG_MON shall be stored together with its complement VP_MU_AN_DIG_MON_CPL and only be accessed using the actions ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC";
R23_4.3: its default value in case of a RAM error shall be 0.

Note: the MU value VP_MU_AN_DIG_MON is only updated after a *successful* communication while the MC value is acquired after *each* communication; in the extreme case of no successful communications, the MU value will therefore freeze to the value obtained after the last correct communication, eventually leading to a fault reaction (of process monitoring, where the MC and MU values are compared); however, unsuccessful communications will (much faster) lead to a fault reaction of processor monitoring (by the communication monitoring functions).

Application conditions:

Initialisation: */* Using the RAM check service actions */*

VP_MC_AN_DIG_MON = 0;
VP_MU_AN_DIG_MON = 0;
VP_MC_AN_DIG_MON_TMP = 0;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** shall be executed **after the communication monitoring functions**.

Activation: For R23_1, R23_2, R23_3:

Always.

For R23_4:

((STATE_MC = NC_STATE_MC_PRDR) **OR**
(STATE_MC = NC_STATE_MC_NORM) **OR**
(STATE_MC = NC_STATE_MC_DI)) **AND**
(LV_MC_COM_ERR = 0)
(active in PREDRIVE, NORMAL, and DISABLE state but only if the preceding communication was successful; note that a consistency check with LV_MC_COM_ERR_CPL is necessary)

Deactivation: Otherwise

12.4.8 Exchange of ignition key information between MC and MU

FUNCTION DESCRIPTION:

General information:

This function describes when and how information regarding the state of the ignition key is exchanged between MC and MU.

Description:

This function incorporates the following requirements:

G25 Exchange of ignition key information between MC and MU

R25_1: In each NORMAL and DISABLE communication, the MC sends the value of LV_MC_IGN_KEY to the MU; this is achieved by calling ACTION_INFR_McSendIgk() with argument LV_MC_IGN_KEY before the corresponding communications are triggered.

R25_2: If the MU is configured for hardware acquisition of the ignition key signal, after each PREDRIVE, NORMAL, and DISABLE communication, the value of the ignition key input IGK_IN on the MU shall be acquired by calling the action ACTION_INFR_McGetIgkMu(), storing the result in LV_MU_IGN_KEY, but only if no communication error was detected, i.e., LV_MC_COM_ERR = 0 (note that a consistency check with LV_MC_COM_ERR_CPL is necessary).

Application conditions:

Initialisation:	LV_MU_IGN_KEY = 0;
Recurrence:	The **initialisation** shall be performed **after each reset or power-up**. The **function** shall be **executed after the communication monitoring functions**.
Activation:	((STATE_MC = NC_STATE_MC_PRDR) **OR** (STATE_MC = NC_STATE_MC_NORM) **OR** (STATE_MC = NC_STATE_MC_DI)) *(only active in PREDRIVE, NORMAL, and DISABLE state)*
Deactivation:	Otherwise

Note: data with mode "S" shall only be stored in a reset-safe manner, not in NVMY!

Input data:

STATE_MC	NC_STATE_MC_INI	NC_STATE_MC_CONF	NC_STATE_MC_PRDR
NC_STATE_MC_NORM	NC_STATE_MC_DI	LV_MC_ROM_CHK_READY	LV_MC_ROM_CHK_READY_CPL
LV_MC_SOPC_ACT	LV_MC_COM_ERR	LV_MC_COM_ERR_CPL	LV_MC_PFM_WRG_RESP_ACT_6
NLC_MU_INJ_OFF_TMR_ENA	LV_MU_IGN_KEY		

Export actions:

ACTION_ECM3_McFaultReaction(IN <err_cod>)
This action immediately performs the central fault reaction storing the given error code.
ACTION_ECM3_McIncAbc(IN <abc_id>, IN <err_cod>)
This action increases the value of the indicated anti-bounce counter by its corresponding increment; if the maximal value is reached, a fault reaction is triggered with the given error code as parameter.
ACTION_ECM3_McDecAbc(IN <abc_id>)
This action decreases the value of the indicated anti-bounce counter by 1.
ACTION_ECM3_RedSwitchOffPath()
This action sets the flag LV_MC_DR_OFF and, in doing so, activates the redundant switch-off path.
ACTION_ECM3_DisableReq(OUT<flag>)
This action changes the state of processor monitoring on both MC and MU into DISABLE state without triggering a restart of the ECU (exported to ASW); the flag returns "false" in case the request has not been completed (with or without error).
ACTION_ECM3_ShutDown(OUT <flag>)
This action changes the state of processor monitoring on both MC and MU into DISABLE state, eventually triggering a restart of the ECU (exported to ASW) ; the flag returns "false" in case the request has not been completed (with or without error).

Import actions:

ACTION_ECM3_WriteChkCpl(INOUT <>, OUT <>, IN <>)

FUNCTION DESCRIPTION:

General information:

This module contains several functions related to the fault reaction of processor monitoring on the MC.
Note that several functions might change the value of several of the output variables (e.g., the value of the reset counter of the MC, CTR_RST_MC, is changed by both the central fault reaction and the healing of reset counter and error information) but that always, at any given time, only **one** of the sub-functions is active so the variables simply have the value of the last update that they received (thereby acting as a kind of “merge” block).

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CTR_RST_MC_THD	1	0...FH	0...15	1	[-]
Threshold for reset counter on MU, RST_CTR_MC, the reaching of which shall prompt the MU to irreversibly (for the current driving cycle) disable the power stages					
NC_ERR_COD_MC_NOT_ERR	1	0...1FH	0...31	1	[-]
Error code for "no error"					
NC_ERR_COD_MC_HD	1	0...1FH	0...31	1	[-]
Error code for "header byte invalid or disallowed transition					
NC_ERR_COD_MC_CKS	1	0...1FH	0...31	1	[-]
Error code for "checksum of received data is wrong"					
NC_ERR_COD_MC_PAR	1	0...1FH	0...31	1	[-]
Error code for "parity error in received data"					
NC_ERR_COD_MC_CONF_DIF	1	0...1FH	0...31	1	[-]
Error code for "configuration data different from previously sent data"					
NC_ERR_COD_MC_SOPC	1	0...1FH	0...31	1	[-]
Error code for "error in switch-off path check"					
NC_ERR_COD_MC_COMP_NR	1	0...1FH	0...31	1	[-]

Maximal value for anti-bounce counter corresponding to MU not reacting to wrongly transmitted PFM bit of task 2					
NC_ABC_MC_PFM_3_RESP_MAX	1	0...FH	0...15	1	[-]
Maximal value for anti-bounce counter corresponding to MU not reacting to wrongly transmitted PFM bit of task 3					
NC_ABC_MC_PFM_4_RESP_MAX	1	0...FH	0...15	1	[-]
Maximal value for anti-bounce counter corresponding to MU not reacting to wrongly transmitted PFM bit of task 4					
NC_ABC_MC_PFM_5_RESP_MAX	1	0...FH	0...15	1	[-]
Maximal value for anti-bounce counter corresponding to MU not reacting to wrongly transmitted PFM bit of task 5					
NC_ABC_MC_PFM_6_RESP_MAX	1	0...FH	0...15	1	[-]

Maximal value for anti-bounce counter corresponding to MU not reacting to wrongly transmitted PFM bit of task 6					
NC_CTR_COM_CYC_MC_DEC_RST_INI	1	0...3FFH	0...1023	1	[-]
Initial value for communication cycle counter for healing of reset counter and error information					
NC_CTR_MU_DI_MAX	1	0...FH	0...15	1	[-]
Maximal value for counter for disable request					
NC_CTR_RST_MC_DI	1	0...FH	0...15	1	[-]
Value of reset counter to be sent to MU in case of a disable request					
NC_CYCNR_MC_DR_DI_TMP	1	1...FFH	1...255	1	[-]
Number of communication cycles (<>0) for temporary disabling after the PREDRIVE communication					
NC_ERR_COD_MC_MU_READY	1	0...1FH	0...31	1	[-]
Error code for "MU not ready"					
NC_ERR_COD_MU_V_L	1	0...1FH	0...31	1	[-]
Error code for "MU has detected under-voltage"					
NC_ERR_COD_MU_V_H	1	0...1FH	0...31	1	[-]
Error code for "MU has detected over-voltage"					
NC_ERR_COD_MU_V_L_H	1	0...1FH	0...31	1	[-]
Error code for "MU has detected both under- and over-voltage"					
NC_ERR_COD_MU_FCT_SPC_IST	1	0...1FH	0...31	1	[-]
Error code for "MU has detected a wrong FS-IST answer"					

Note: The last four error codes are MU error codes and are only used in connection with error memory and the under-/over-voltage flags sent from the MU (see section "Acquisition of under-/over-voltage flags").

12.5.1 Central fault reaction

FUNCTION DESCRIPTION:

General information:

This function contains the central fault reaction of processor monitoring on the MC. Since this function is not activated with a fixed recurrence but only called when an error has actually occurred, the complete functionality is encapsulated in the action ACTION_ECM3_McFaultReaction() which can be imported and called by other functions, should they require to trigger an immediate fault reaction (debounced fault reactions are handled via G21 "Debounce mechanism").

In order to avoid recursive calls of the fault reaction:

- **no monitoring of state machine shall be performed**
- **no complement checks shall be performed, only the complements shall be written**
- **for all calls of external functions (e.g. for disabling power stages), it has to be ensured that they cannot lead to recursive calls of the fault reaction**

Description:

The function, via the action ACTION_ECM3_McFaultReaction(), incorporates the following requirements:

G1 Central fault reaction

R1_1: Concerning the activation of the fault reaction:

- **a fault reaction shall only be performed in a state different from DISABLE (i.e., STATE_MC <> NC_STATE_MC_DI);**
- **if STATE_MC = NC_STATE_MC_DI when the fault reaction is triggered, nothing shall be done;**

- **therefore, the following requirements only refer to the case that the fault reaction is actually performed (i.e., STATE_MC <> NC_STATE_MC_DI).**

R1_2: The action ACTION_ECM3_McCancelSopc() shall be called in order to ensure that the power stages can be disabled.

R1_3: The power stages shall be disabled, see G22 "Disabling of power stages"; **this shall only be done if the fault reaction was activated in a state different from DISABLE (i.e., STATE_MC <> NC_STATE_MC_DI) to avoid recursive calls to the fault reaction (via ACTION_ECM2_LockPws())**.

R1_4: A transition into the DISABLE state shall be performed, using ACTION_ECM3_McChangeState(); this shall be done before the power stages are disabled (due to R22_8, the power stages will anyway be disabled in DISABLE, even if there is a problem during the execution of the fault reaction).

R1_5: If the reset counter CTR_RST_MC on the MC is strictly less than the threshold NC_CTR_RST_MC_THD:
R1_5.1: the reset counter shall be incremented by 1; this value shall be stored with complement CTR_RST_MC_CPL in a reset-safe area; the default value for CTR_RST_MC shall be NC_CTR_RST_MC_THD + 1 (in case of data corruption, assume permanent disabling).
R1_5.2: an MC error code which corresponds to the error location shall be stored, together with the indicator ”ECU restart request”; this value shall be stored in a reset-safe area.
R1_5.3: There shall be an attempt to restart the ECU, using the action ACTION_INFR_McRestart().

R1_6: If the reset counter is greater than or equal to the threshold NC_CTR_RST_MC_THD:
R1_6.1: the reset counter shall be set to NC_CTR_RST_MC_THD + 1; this value shall be stored with complement CTR_RST_MC_CPL in a reset-safe area; the default value for CTR_RST_MC shall be NC_CTR_RST_MC_THD + 1 (in case of data corruption, assume permanent disabling).
R1_6.2: an MC error code which corresponds to the error location shall be stored, together with the indicator ”DISABLE request”; this value shall be stored in a reset-safe area.
R1_6.3: the update flag for MC error memory information shall be set by calling ACTION_ECM3_McSetErrmUpdateFlag(1).
R1_6.4: there shall be no attempt to restart the MC.

R1_7: No monitoring of state machine or complement checks using the RAM check service actions shall be performed in order to avoid recursive calls of the fault reaction; for complements, the check shall be performed manually and in case of inconsistency, the default value shall be used.

R1_8: The power latch resource for the Standard ROM check shall be unlocked by calling ACTION_ECM3_McUnlockPwlResource().

Description of ACTION_ECM3_McFaultReaction

Description:

Syntax:	ACTION_ECM3_McFaultReaction(IN <err_cod>)	
Parameter (IN):	err_cod	error code indicating the cause of the fault reaction
Short description:	This action performs the central fault reaction of processor monitoring on MC (as specified in "G1 Central fault reaction" above).	

Application conditions:

Initialisation: /* Using the RAM check actions (where applicable) */

CTR_RST_MC = 0;
ERR_COD_MC = NC_ERR_COD_MC_NOT_ERR;

Recurrence: The **initialisation** shall be **performed after each power-up**.

The **function** itself is **called when required**.

Activation: -

Deactivation: -

12.5.2 Healing of reset counter and error information

FUNCTION DESCRIPTION:

General information:

If the MC is in NORMAL state (which indicates that there is no error present) for a certain time (4s), then the reset counter is decreased by 1 since the system has been stable long enough to assume that there is currently no problem present; if this decreasing results in a reset counter of 0, also the error code and the error indication shall be cleared.

Description:

This function incorporates the following requirements:

G2 Healing of reset counter and error code

R2_1: The reset counter shall be decreased by 1 after 4000ms have passed.

R2_2: If the reset counter is decremented to 0, the error code shall be cleared, i.e., set to 0, and the error indication shall be changed to “no error present.”

R2_3: The function shall only be active in NORMAL state, and if LV_MC_ROM_CHK_READY is set (i.e., after the standard ROM check has been completed and no reset or transition to DISABLE has occurred, hence the ROM check must have been successful); LV_MC_ROM_CHK_READY has to be accessed together with its complement LV_MC_ROM_CHK_READY_CPL, using the actions from "RAM check service actions of processor monitoring on MC."

R2_4: The time measurement shall be performed by counting communication cycles, rather than actually measuring elapsed time, counting backwards starting from NC_CTR_COM_CYC_MC_DEC_RST_INI (see initialisation below).

R2_5: Additionally, the healing shall only take place if LV_MC_PFM_WRG_RESP_ACT_6 is set to one indicating that the wrong response test for PFM task 6 has been performed at least once (to avoid endless resets due to wrong PFM in task 6).

R2_6: While LV_MC_SOPC_ACT = 1, no healing shall take place (to prohibit healing while the SOPC has not yet been completed).

Application conditions:

Initialisation:	*/* Initialise communication cycle counter */* CTR_COM_CYC_MC_DEC_RST = NC_ CTR_COM_CYC_MC_DEC_RST_INI;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. The **function itself** shall be **activated after the data from NORMAL communications have been evaluated successfully**.
Activation:	(STATE_MC = NC_STATE_MC_NORM) **AND** (LV_MC_ROM_CHK_READY = 1) **AND** (LV_MC_PFM_WRG_RESP_ACT_6 = 1) **AND** (LV_MC_SOPC_ACT = 0) *(only active in NORMAL AND after standard ROM check was completed AND wrong response test for PFM task 6 has been performed once AND SOPC has been completed)*
Deactivation:	Otherwise

12.5.3 State of fault reaction and up-to-dateness of error code

FUNCTION DESCRIPTION:

General information:

The error indication describes the current state of the fault reaction in the sense that, if the fault reaction is triggered and it is decided that the ECU should be restarted, the error indication is set to “ECU restart request”, while an (irreversible for the current driving cycle) DISABLE request leads to the error indication “DISABLE request” (the decision between these two choices depends of the value of the reset counter CTR_RST_MC, see section “Central fault reaction”).

Description:

This function incorporates the following requirements.

G3 State of fault reaction and up-to-dateness of error code

R3_1: In addition to the error code, there shall be the error indication STATE_ERR_IDC_MC which indicates the state of the fault reaction and the up-to-dateness of the error code:

- “No error present” shall be indicated while no error is present (including the case that the reset counter is being decremented);
- “ECU restart request” shall be indicated if fault reaction currently requests ECU restart (i.e., the reset counter has not yet reached a certain defined value);
- “DISABLE request” shall be indicated if fault reaction requests DISABLE instead of ECU restart (i.e., the reset counter has reached the defined value);
- “ECU restart was requested” (“previous restart request”) shall be indicated after ECU has been restarted due to an ECU restart request from the fault reaction.

R3_2: The error indication shall be stored in a reset-safe RAM area.

R3_3: After a reset but not after power-up, if the current error indication is “ECU restart request,” this shall be changed to “ECU restart was requested”: a restart must have actually been performed because otherwise the INIT state could not have been reached (see initialisation below).

R3_4: In INIT (i.e., STATE_MC = NC_STATE_MC_INI), the update flag for MC error memory information shall always be set by calling ACTION_ECM3_McSetErrmUpdateFlag(1); this shall be done after the potential change of the error indication described by R3_3.

R3_5: Once the CONFIG communication has been prepared, i.e., after ACTION_INFR_McSendErrInfo() has been called, if the state of the fault reaction on the MC indicated "ECU restart was requested", it shall be changed to "No error present" by setting STATE_ERR_IDC_MC to NC_STATE_ERR_IDC_MC_NOT_PRES.

Application conditions:

Initialisation: After power-up:

/ After power-up, initialise the error indication to "no error present" */*

```
STATE_ERR_IDC_MC =
        NC_STATE_ERR_IDC_MC_NOT_PRES;
```

After reset:

/ After reset, if "ECU restart request" is indicated, this shall be changed to "restart was requested": the restart request has been carried out successfully, see R3_3 above */*

```
IF (STATE_ERR_IDC_MC =
    NC_STATE_ERR_IDC_MC_REST_REQ)
THEN
    STATE_ERR_IDC_MC =
        NC_STATE_ERR_IDC_MC_PREV_REST;
FI
```

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** shall be **called**.

Activation: -

Deactivation: -

12.5.4 Transmission of error information from MC to MU

FUNCTION DESCRIPTION:

General information:

This function describes how the error information (reset counter, error code, and error indication) are sent from MC to MU.

Description:

This function incorporates the following requirements:

G4.1 Transmission of error information from MC to MU

R4.1_1: The MC shall send reset counter, error code, and error indication to the MU in the communications in the states CONFIG and DISABLE using the action call ACTION_INFR_McSendErrInfo(), before the respective communications are triggered, with arguments ERR_COD_MC, STATE_ERR_IDC_MC, and CTR_RST_MC.

R4.1_2: When preparing the data for a DISABLE communication, i.e., if STATE_MC = NC_STATE_MC_DI, and LV_MU_DI_ACT is set (i.e., if a disable request for the MU is still active, see "Disable request by external software"), the value NC_CTR_RST_MU_DI shall be used as one argument to ACTION_INFR_McSendErrInfo(), instead of CTR_RST_MC; NC_CTR_RST_MU_DI must be different from 0.

Application conditions:

Initialisation:	-
Recurrence:	The **function** shall be **executed before a communication is triggered**.
Activation:	(STATE_MC = NC_STATE_MC_CONF) **OR** (STATE_MC = NC_STATE_MC_DI) *(only active in CONFIG and DISABLE state)*
Deactivation:	Otherwise

12.5.5 Evaluation of error information from MU on MC

FUNCTION DESCRIPTION:

General information:

This function describes when and how the error information (reset counter, error code, and error indication) sent from the MU is evaluated on the MC.

Description:

This function incorporates the following requirements:

G4.2 Evaluation of error information from MU on MC

R4.2_1: In CONFIG and DISABLE, if communication monitoring indicates no error, i.e., LV_MC_COM_ERR = 0 (and its complement LV_MC_COM_ERR_CPL=1):
R4.2_1.1: the MC shall obtain the reset counter CTR_RST_MU of the MU using the action ACTION_INFR_McGetRstCtr();
R4.2_1.2: the MC shall obtain the error code ERR_COD_MU of the MU using the action ACTION_INFR_McGetErrCode();
R4.2_1.3: the MC shall obtain the error indication STATE_ERR_IDC_MU of the MU using the action ACTION_INFR_McGetErrIdc().

R4.2_2: The update flag for MU error memory information shall be set by calling ACTION_EMC3_McSetErrmUpdateFlag(0).

Application conditions:

Initialisation:	*/* Initialise MU error information */* CTR_RST_MU = 0;

ERR_COD_MU = NC_ERR_COD_MC_NOT_ERR;
STATE_ERR_IDC_MU = NC_STATE_ERR_IDC_MC_NOT_PRES;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** shall be executed **after the communication monitoring functions** and **after G5.1 "Disable request by MU."**

Activation: ((STATE_MC = NC_STATE_MC_CONF) **OR**
(STATE_MC = NC_STATE_MC_DI)) **AND**
(LV_MC_COM_ERR = 0)
(only active after CONFIG or DISABLE communications, and if no communication error was detected)

Deactivation: Otherwise

12.5.6 Disable request by MU

FUNCTION DESCRIPTION:

General information:

This function deals with the case when the MU sends a DISABLE header. Receiving a DISABLE header from the MU always causes a transition to DISABLE and disabling of power stages.

Description:

This function incorporates the following requirements:

G5.1 Disable request by MU

R5.1_1: If the MC is in a state different from DISABLE (i.e., STATE_MC <> NC_STATE_MC_DI) and a DISABLE header is received from the MU (i.e., ACTION_ECM3_McGetHd() returns NC_STATE_MC_DI):
R5.1_1.1: a transition into DISABLE shall be performed, using ACTION_ECM3_McChangeState();
R5.1_1.2: the power-latch resource for the Standard ROM check shall be unlocked by calling ACTION_ECM3_McUnlockPwlResource();
R5.1_1.3: **for production SW**, if the MU sends the error indication "ECU restart request" (i.e., if ACTION_ECM3_McGetErrIdc() returns NC_STATE_ERR_IDC_MC_REST_REQ), the MC shall attempt to restart the ECU by calling the action ACTION_INFR_McRestart() (the error indication expresses that the MU has performed a fault reaction which should have triggered a reset but the reset was not performed); **for development SW**, no restart shall be attempted.

R5.1_2: If the value of MU_DI_STATE is different from "MU_DI_ERR", it shall be set to "MU_DI_OK" (if a corresponding disable request had already timed out, this shall not be masked by the MU finally responding with a DISABLE header).

R5.1_3: No monitoring of state machine shall be performed (since anyway a change into DISABLE is the consequence).

Application conditions:

Initialisation: -

Recurrence: The **function** shall be **executed after the communication monitoring functions**.

Activation: always

Deactivation: -

12.5.7 Disable request by external software

FUNCTION DESCRIPTION:

General information:

This function provides an interface for the application software in order to force both MC and MU into DISABLE state (in particular to be able to re-program the ECU without having to worry about time-out monitoring, PFM, FS-IST etc.).

Description:

This function incorporates the following requirements:

G5.2 Disable request by external software

R5.2_1: Processor monitoring shall export an interface to the application software in order to force a transition of the processor monitoring on the MC into DISABLE state using ACTION_ECM3_McChangeState(); if already in DISABLE, the MC shall stay there.

R5.2_2: The MC shall clear its error information, i.e., CTR_RST_MC, ERR_COD_MC, and STATE_ERR_IDC_MC.

R5.2_3: The disable request has four different states, recorded in MU_DI_STATE:
- "MU_DI_NOT_REQ" meaning "no disable request"
- "MU_DI_BUSY" meaning "MU has not yet responded, the request is still busy"
- "MU_DI_ERR" meaning "MU response has timed out"
- "MU_DI_OK" meaning "MU has responded in time"

R5.2_4: The interface shall be provided in the form of the action call ACTION_ECM3_DisableReq()
R5.2_4.1: when ACTION_ECM3_DisableReq() is called, and MU_DI_STATE is equal to "MU_DI_NOT_REQ", it shall be set to "MU_DI_BUSY"; *hence, if MU_DI_STATE is different from "MU_DI_NOT_REQ", it shall remain unchanged*;
R5.2_4.2: the flag LV_MU_DI_ACT shall be set (prompting sending NC_CTR_RST_MU_DI instead of the value of CTR_RST_MC (which is 0, see R2) to the MU in subsequent DISABLE communications, see "Transmission of error information from MC to MU" R3);
R5.2_4.3: ACTION_ECM3_DisableReq() shall return "false" in case MU_DI_STATE is equal to "MU_DI_BUSY" and true otherwise.

R5.2_5: After each subsequent communication, in case the MU has not responded with a DISABLE header (which leads to MU_DI_STATE being set to "MU_DI_OK", see "Disable request by MU" R2), i.e., if MU_DI_STATE is equal to "MU_DI_BUSY", the counter CTR_MU_DI shall be increased by one.

R5.2_6: When the counter CTR_MU_DI reaches the value NC_CTR_MU_DI_MAX, this shall be considered as a time-out, i.e., STATE_MU_DI shall be set to "MU_DI_ERR" (which also counts as the disable request being finished, however unsuccessfully).

R5.2_7: The action ACTION_ECM3_McResetRomChkFlags() shall be called (resetting the flags for the Standard ROM check).

R5.2_8: In CONFIG, just before triggering the CONFIG communication, MU_DI_STATE shall be changed from "MU_DI_OK" (the initialisation value) to "MU_DI_NOT_REQ"; in this way, as long as the transition from INIT to CONFIG has not yet been performed, the return value of ACTION_ECM3_DisableReq() will be 1 (instead of 0, cf. R5.2_4.1 and R5.2_4.3).

R5.2_9: In case ACTION_ECM3_DisableReq() is called, the power-latch resource for the Standard ROM check shall be unlocked by calling ACTION_ECM3_McUnlockPwlResource().

Description of ACTION_ECM3_DisableReq

Description:

Syntax:	ACTION_ECM3_DisableReq()
Parameter (OUT):	flag Indication whether the disable request has been completed (perhaps with error, cf. R5.2_4.3 above)
Short description:	This action implements the disable request as specified above in "G5.2 Disable request by external software."

Application conditions:

Initialisation:	MU_DI_STATE = "MU_DI_OK"; CTR_MU_DI = 0; LV_MU_DI_ACT = 0;
Recurrence:	The **initialisation** shall be **performed after each power-up or reset**. The **function itself** shall be **called via ACTION_ECM3_DisableReq()**.
Activation:	-
Deactivation:	-

12.5.8 Shutdown request by external software

FUNCTION DESCRIPTION:

General information:

This function provides an interface for the application software in order to restart the ECU.

Description:

This function incorporates the following requirements:

G5.3 Shutdown request by external software

R5.3_1: Processor monitoring shall export an interface to the application software in order to force restart of the ECU via the MU.

R5.3_2: The interface shall be provided in the form of the action call ACTION_ECM3_ShutDown().

R5.3_3: It behaves exactly like ACTION_ECM3_DisableReq() with the one exception that the flag LV_MU_DI_ACT is not set, i.e., in subsequent DISABLE communications, the real value of CTR_RST_MC (which is 0 since it has been reset by the shutdown/disable request) is sent; this will first force the MU into DISABLE, clearing its error information in the process, and eventually to restart the ECU (unless the MU has not detected an error on its own, and also the state of the ignition key plays a role in how the MU reacts to the request).

Description of ACTION_ECM3_ShutDown

Description:

Syntax:	ACTION_ECM3_ShutDown()
Parameter (OUT):	flag Indication whether the shutdown request has been finished (with or without error, cf. R5.2_4.3 above)
Short description:	This action requests a restart of the ECU via the MU as specified above in "G5.3 Shutdown request by external software" (whether this is actually done depends on the internal state of the MU).

Application conditions:

Initialisation:	-
Recurrence:	The **function itself** shall be **called via ACTION_ECM3_ShutDown()**.
Activation:	-
Deactivation:	-

12.5.9 The redundant switch-off path

FUNCTION DESCRIPTION:

General information:

In case process or processor monitoring on the MC detect a fatal error and attempt to disable the safety-relevant power stages, they can also use the switch-off paths on the monitoring unit to redundantly perform the switching-off. This is done via an action call (from within process monitoring) which sets a flag in the processor monitoring that forces the MC to deliberately send wrong FS-IST answers to the MU which in turn, potentially after some debouncing, leads to a fault reaction on the MU and in particular to disabling the safety-relevant power stages (hence the name “redundant switch-off path” as the MU is eventually prompted to also disable the power stages).

Description:

This function incorporates the following requirements:

G20 Redundant switch-off path

R20_1: There shall be an interface between process and processor monitoring which, when used, causes the processor monitoring on the MC to permanently send wrong FS-IST answers to the MU, in this way eventually (after debouncing) resulting in a fault reaction of the MU.

R20_2: This interface shall be realised by providing the action call ACTION_ECM3_RedSwitchOffPath() to process monitoring which shall set the flag LV_MC_DR_OFF; LV_MC_DR_OFF shall be stored as together with its complement LV_MC_DR_OFF_CPL and shall only be accessed via the actions ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from "RAM check service actions of processor monitoring on MC"; its default value in case of a RAM error shall be 1, indicating that the redundant switch-off path has been triggered.

Description of ACTION_ECM3_RedSwitchOffPath

Description:

Syntax:	ACTION_ECM3_RedSwitchOffPath()
Short description:	This action triggers the redundant switch-off path by setting the flag LV_MC_DR_OFF using the action ACTION_ECM3_WriteChkCpl() (see “RAM check service actions of processor monitoring on MC”).

Application conditions:

Initialisation:	*/* Using the RAM check service actions */* LV_MC_DR_OFF = 0;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. The **function itself** shall be called via ACTION_ECM3_RedSwitchOffPath().
Activation:	-
Deactivation:	-

12.5.10 Debounce mechanism

FUNCTION DESCRIPTION:

General information:

Debouncing is a very common task for many functions of processor monitoring. Hence this module exports actions which perform the two necessary tasks to do with debouncing: increasing one of these anti-bounce counters by a predefined increment, and decreasing such a counter with a predefined decrement. Note that increasing an anti-bounce counter can trigger a fault reaction (viz., if its maximal value is reached).

Note that values of anti-bounce counters are not exported directly!

Description:

In the following, let xxx range over all possible identifiers for anti-bounce counters which are used on the MC (e.g., one possible value is HD for header-byte monitoring). The function incorporates the following requirements:

G21 Debounce mechanism

R21_1: If an error has been detected the anti-bounce counter of the corresponding error location shall be increased by the corresponding increment NC_ABC_MC_xxx_INC without creating an overflow; this shall be achieved by calling ACTION_ECM3_McIncAbc().

R21_2: If the anti-bounce counter reaches a corresponding maximum value NC_ABC_MC_xxx_MAX a fault reaction shall be triggered.

R21_3: If no error is detected and the anti-bounce counter of the corresponding error location is greater than 0, the anti-bounce counter shall be decreased by the corresponding decrement NC_ABC_MC_xxx_DEC without creating an underflow; this shall be achieved by calling ACTION_ECM3_McDecAbc().

R21_4: In general, if not specified otherwise, the following configuration shall be used: NC_ABC_MC_xxx_INI = 0, NC_ABC_MC_xxx_INC = 2, NC_ABC_MC_xxx_DEC = 1, NC_ABC_MC_xxx_MAX = 6.

R21_5: After a reset, in INIT state, i.e., STATE_MC = NC_STATE_MC_INI:
R21_5.1: if any anti-bounce counter of communication monitoring (xxx=HD, CKS, CONF_DIF) is greater than 0, the flag LV_ABC_MC_ERR_COM shall be set to 1, otherwise it shall be set to 0;
R21_5.2: if any anti-bounce counter of PFM **except for task 6** (xxx=PFM_*k*_TOG, PFM_*k*_RESP **for 0 <=*k*<= 5**) is greater than 0, the flag LV_ABC_MC_ERR_PFM shall be set to 1, otherwise it shall be set to 0;
R21_5.3: if one of the two anti-bounce counters PFM_6_TOG or PFM_6_RESP **for task 6** is greater than 0, the flag LV_ABC_MC_ERR_PFM_6 shall be set to 1, otherwise it shall be set to 0;
R21_5.4: if any anti-bounce counter of FS-IST is greater than 0 (xxx=WRG_IDX, WRG_RESP) or greater than 2 (in case of xxx=NOT_DEC), the flag LV_ABC_MC_ERR_FCT_SPC_IST shall be set to 1, otherwise it shall be set to 0;
R21_5.5: after evaluation, the anti-bounce counters shall be initiatialised to their corresponding INI values NC_ABC_MC_xxx_INI.

Description of ACTION_ECM3_McIncAbc

Description:

Syntax:	ACTION_ECM3_McIncAbc(IN <abc_id>, IN <err_cod>)	
Parameter (IN):	abc_id	identifier for the anti-bounce counter to be increased
Parameter (IN):	err_cod	error code for a potential fault reaction
Short description:	This action increases the value of the specified anti-bounce counter by the corresponding increment without creating an overflow; if the corresponding maximal value is reached, a fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction().	

Description of ACTION_ECM3_McDecAbc

Description:

Syntax: ACTION_ECM3_McDecAbc(IN <abc_id>)

Parameter (IN): abc_id identifier for the anti-bounce counter to be increased

Short description: This action decreases the value of the specified anti-bounce counter by 1 without creating an underflow.

Application conditions:

Initialisation: After each power-up:

All anti-bounce counters are initialised to their corresponding INI values.

After each power-up and reset:

LV_ ABC_MC_ERR_COM = 0;
LV_ ABC_MC_ERR_PFM = 0;
LV_ ABC_MC_ERR_PFM_6 = 0;
LV_ ABC_MC_ERR_FCT_SPC_IST = 0;

Recurrence: The **initialisation** shall be performed **after each power-up and reset** (see above).

Afterwards, **increasing** or **decreasing** of anti-bounce counters shall be done **via action calls**.

Activation: in all states *(in particular in in INIT state!)*

Deactivation: -

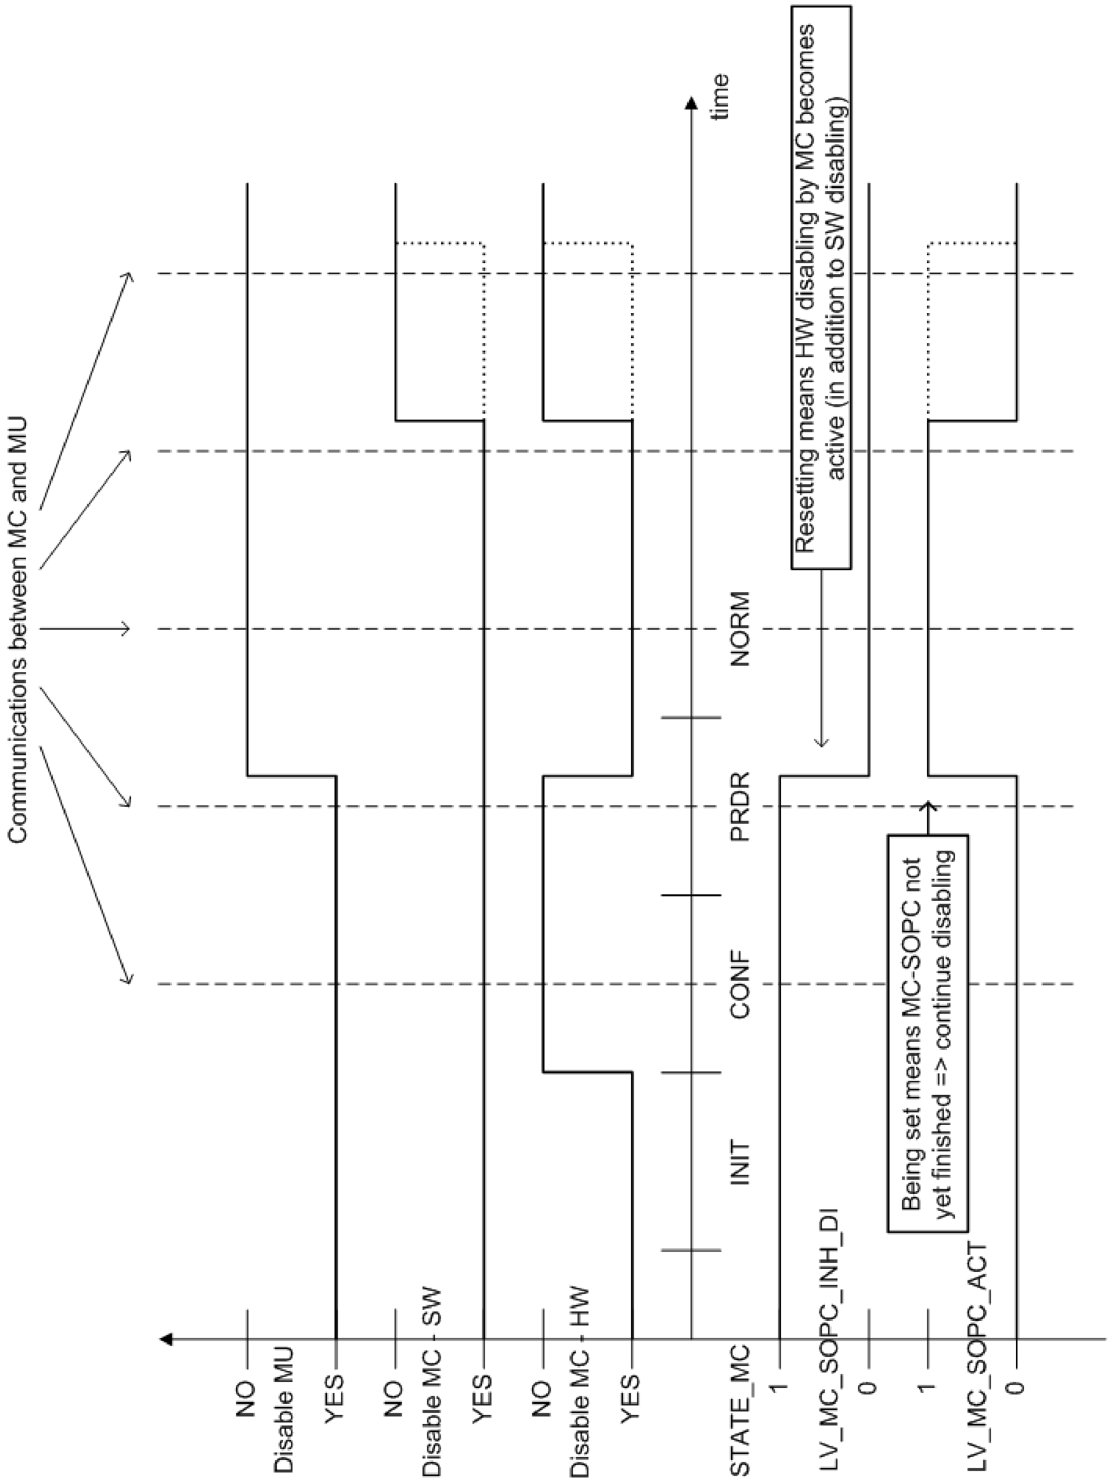
12.5.11 Disabling of power stages

FUNCTION DESCRIPTION:

General information:

This function describes how and when the MC disables the power stages it is connected to, separately for each state.
The phrase "enabling of power stages" shall be used to denote the fact that the MC no longer *disables*; however, this does not imply anything regarding *actively using* the power stages.
Note that on the MC, there are two ways of disabling: one is by SW done via flags which lead to no active signals being generated (e.g., no injection patterns); the second one is via HW where dedicated HW lines are used to disable power stages (the MU only has such HW disable lines).

Signal flow diagram:



Note that the diagram only shows the case when no temporary disabling is performed; the distinction between SW and HW disabling on the MC is managed by the switch-off path check.

Description:

The complete function satisfies the following requirements:

G22 Disabling of power stages

R22_1: The MC shall:
R22_1.1: permanently disable the power stages by setting LV_ERR_MU_MC = 1 (it has to be ensured that LV_ERR_MU_MC, after being set once, is not reset again), plus additionally calling ACTION_ECM2_LockPws() (in order to ensure that process monitoring also disables the power stages);
R22_1.2: temporarily disable the power stages by setting LV_ERR_TMP_MU_MC = 1, plus additionally calling ACTION_ECM2_LockPws() (in order to ensure that process monitoring also disables the power stages);
R22_1.3: enable the power stages by setting LV_ERR_TMP_MU_MC = 0 and LV_ERR_MU_MC = 0 (cf. remark above!), plus additionally calling the action ACTION_ECM2_ResetErrorFlags() (in order to ensure that process monitoring also stops disabling the power stages if appropriate).

R22_2: Both error flags shall be stored together with their respective complements, LV_ERR_MU_MC_CPL and LV_ERR_TMP_MU_MC_CPL, and shall be accessed using the imported RAM check service actions ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() (see "RAM check service actions of processor monitoring on MC"); their default values in case of a RAM error shall be 1, i.e., indicating that the power stages shall be disabled.

R22_3: The power stages shall be disabled depending on the reset counters of both MC and MU, and the current state of the monitoring concept.

R22_4: In INIT, the MC shall temporarily disable the power stages.

R22_5: In CONFIG, the MC shall temporarily disable the power stages.

R22_6: In PREDRIVE:
R22_6.1: the MC shall temporarily disable the power stages;
R22_6.2: before the PREDRIVE communication, if any of the two reset counters (CTR_RST_MC, or CTR_RST_MU) is > 1, the MC shall set CTR_COM_CYC_MC_DR_DI_TMP to NC_CYCNR_MC_DR_DI_TMP (this counter shall be used to temporarily disable the power stages until in total NC_CYCNR_MC_DR_DI_TMP + 2 communication cycles have been performed).

R22_7: In NORMAL:
R22_7.1: if CTR_COM_CYC_MC_DR_DI_TMP is not active (i.e., = 0), the MC shall enable the power stages (see signal flow diagram); this only holds if no pre-condition of any other requirement is satisfied (cf. in particular R22_9 and R22_10).
R22_7.2.: if CTR_COM_CYC_MC_DR_DI_TMP is active (i.e., <> 0):
R22_7.2.1: the MC shall temporarily disable the power stages;
R22_7.2.2: CTR_COM_CYC_MC_DR_DI_TMP shall be decreased by one without creating an underflow.

R22_8: In DISABLE, the MC shall permanently and temporarily disable the power stages.

R22_9: In PREDRIVE and NORMAL, the MC shall consider the status of the disable outputs of the MU regarding disabling the power stages:
R22_9.1: the MC shall call the actions ACTION_INFR_McGetNdisOut0() and ACTION_INFR_McGetNdisOut1() to obtain the status informationand store the results in LV_MU_DI_OUT_0 and LV_MU_DI_OUT_1 (note that disabling means status = 0, enabling means status = 1);

R22_9.2: the information about the status of the MU disable outputs shall be used as follows:
R22_9.2.1: if LV_MU_DI_OUT_0 = 0 and LV_MU_DI_OUT_1 = 1 and LV_MU_IGN_KEY = 0 and NLC_MU_INJ_OFF_TMR_ENA = 1, the injection-off timer (IOT) in the MU shall be assumed to be active; hence, the following assignment shall be performed:

- LV_INJ_OFF_TMR_INJ_ENA_TMP = 0 *(IOT active, no enabling of injection)*;

R22_9.2.2: if LV_MU_DI_OUT_0 = 0 and LV_MU_DI_OUT_1 = 0, the MU disables both its disable outputs; hence, the following assignment shall be performed:

- LV_ERR_TMP_MU_MC = 1 *(temporary disabling)*

R22_9.2.3: if LV_MU_DI_OUT_0 = 1 and LV_MU_DI_OUT_1 = 1, the MU enables its disable outputs; hence, the IOT must be inactive and the following assignment shall be performed:

- LV_INJ_OFF_TMR_INJ_ENA_TMP = 1 *(IOT inactive, enabling of injection)*;

R22_9.2.4: otherwise, the following assignment shall be performed:

- LV_ERR_TMP_MU_MC = 1 *(temporary disabling)*

R22_10: In NORMAL, while LV_MC_SOPC_ACT = 1 (i.e., the MC-part of the SOPC has not yet been finished), the MC shall temporarily disable the power stages.

R22_11: In PREDRIVE and NORMAL, if the MU indicates disabling any of its power stages (i.e., LV_MU_DI_OUT_0 or LV_MU_DI_OUT_1 = 0), the flag LV_MC_INH_SOPC shall be set to 1; otherwise, it shall be set to 0; the flag being set consequently indicates that the MU still disables the power stages (and therefore prompts a delay the MC-part of the SOPC).

Application conditions:

Initialisation: *(/* Initialise communication cycle counter for temporary disabling to "no temporary disabling" */)*

CTR_COM_CYC_MC_DR_DI_TMP = 0;

/ Delay of MC-part of SOPC (not yet) necessary */*

LV_MC_INH_SOPC = 0;

/ Using the RAM check service actions: temp. disabling */*

LV_ERR_MU_MC = 0;
LV_ERR_TMP_MU_MC = 1;
LV_MU_DI_OUT_0 = 0;
LV_MU_DI_OUT_1 = 0;

/ Power stages disabled after reset */*

LV_INJ_OFF_TMR_ENA_INJ_TMP = 0;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** is **active in all states**.

Activation: always

Deactivation: -

12.5.12 Acquisition of under-/over-voltage flags

FUNCTION DESCRIPTION:

General information:

The MU contains detection mechanisms for both under- and over-voltage conditions in case its voltage leaves its operating range.
This is, amongst others, prompts a reset (which is held for as long as either condition persists) of MC and MU.
If the under- or over-voltage condition is present long enough, one of the flags LV_V_L_DET_MU or LV_V_H_DET_MU (as appropriate) is set. Once the voltage returns to its normal range, the system starts up and the two flags (which have been stored in a reset-safe area) are sent to the MC.

Description:

The function incorporates the following requirement:

G24 Acquisition of under-/over-voltage flags

R24_1: If no errors were detected in the CONFIG communication, i.e., if LV_MC_COM_ERR = 0 (and its complement LV_MC_COM_ERR_CPL = 1), the flags LV_V_L_DET_MU and LV_V_H_DET_MU shall be assigned the values sent by the MU, using the actions ACTION_INFR_McGetUvdFlag() and ACTION_INFR_McGetOvdFlag(), respectively.

Application conditions:

Initialisation:	LV_V_H_DET_MU = 0; LV_V_L_DET_MU = 0;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. The **function itself** shall be executed **after the communication monitoring functions.**
Activation:	(STATE_MC = NC_STATE_MC_CONF) **AND** (LV_MC_COM_ERR = 0) *(only active in CONFIG and if no communication error was detected)*
Deactivation:	Otherwise

12.6 MC Communication Monitoring between MC and MU

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MC_CKS_OK	-	0...1H	0...1	1	[-]
Local variable: flag indicating whether the (XOR) checksum of the data received from the MU is correct					
LV_MC_CKS_OK_CPL	-	0...1H	0...1	1	[-]
Local variable: complement of LV_MC_CKS_OK					
LV_MC_HD_OK	-	0...1H	0...1	1	[-]
Local variable: flag indicating whether the received header was correct or not					
LV_MC_HD_OK_CPL	-	0...1H	0...1	1	[-]
Local variable: complement of LV_MC_HD_OK					
LV_MC_PAR_OK	-	0...1H	0...1	1	[-]
Local variable: flag indicating whether the data received from the MU had the correct (even) parity					
LV_MC_PAR_OK_CPL	-	0...1H	0...1	1	[-]
Local variable: complement of LV_MC_PAR_OK					
STATE_MU_TMP	V/O/S	0...FFH	0...255	1	[-]
Header byte of MU as sent to MC (stored in reset-safe manner)					
LV_MC_COM_ERR	V/O	0...1H	0...1	1	[-]
Error flag indicating any communication error (checksum, header, or parity)					
LV_MC_COM_ERR_CPL	V/O	0...1H	0...1	1	[-]
Complement of LV_MC_COM_ERR					
LV_MU_READY	V/O	0...1H	0...1	1	[-]
Flag indicating whether MU is ready (=1) or not (=0)					
CTR_MU_READY	-	0...FFH	0...255	1	[-]
Local variable: counter for attempts of check of MU readiness					
STATE_MU_TMP_CPL	O/S	0...FFH	0...255	1	[-]
Complement of STATE_MU_TMP (stored in reset-safe manner)					

Input data:

STATE_MC	NC_STATE_MC_CONF	NC_STATE_MC_PRDR	NC_STATE_MC_NORM
NC_STATE_MC_DI	NC_ERR_COD_MC_CKS	NC_ERR_COD_MC_HD	NC_ERR_COD_MC_PAR
NC_ABC_MC_CKS	NC_ABC_MC_HD	NC_STATE_MC_INI	NC_ERR_COD_MC_MU_READY
NC_STATE_MC_NOT_VLD			

Import actions:

ACTION_ECM3_McFaultReaction(IN <>)
ACTION_ECM3_McIncAbc(IN <>, IN <>)
ACTION_ECM3_McDecAbc(IN <>)
ACTION_ECM3_WriteChkCpl(INOUT <>, OUT <>, IN <>)
ACTION_ECM3_ChkCpl(IN <>, IN <>)
ACTION_ECM3_ReadChkCpl(OUT <>, IN <>, IN <>)
ACTION_ECM3_McReadChkCpl(OUT <>, IN <>, IN <>, IN <>)
ACTION_ECM3_McReadChkState(OUT <>)
ACTION_INFR_McStartCom(IN <>)
ACTION_INFR_McChkCks(OUT <>)
ACTION_INFR_McGetHd(OUT <>)
ACTION_INFR_McChkPar(OUT <>)
ACTION_INFR_StartMuReadyChk()
ACTION_INFR_MuReady(OUT <>)

FUNCTION DESCRIPTION:

General information:

This module describes all functions related to monitoring of communications on the MC.

The complete function is split according to the states where the communication occurs, and also there is a second split between triggering a communication, and monitoring the data from a preceding communication; functions for communication monitoring are triggered after the communication between MC and MU is finished.

Note that header-byte monitoring, in case a DISABLE header is received from the MU, only performs the consecutive parity-bit checking; the transition to DISABLE, which is also a consequence of the received header, is specified in the function "G5.1 Disable request by MU" (cf. R5.1_1.1).

A noteworthy point for communications in the states NORMAL and DISABLE is that the preparation of the next communication needs to be performed at a certain point *when all the necessary other functions have been executed and completed* as they prepare the data to be sent in the next communication; this can be contrasted to the two functions for CONFIG and PREDRIVE which are essentially triggered by state changes (with the additional point that certain data have to be sent to the infrastructure so that the correct values are transmitted to the MU).

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_T_MC_COM_CYC	1	0...FFH	0...255	1	[-]
Time between triggering two communications					
NC_CTR_MU_READY_MAX	1	0...FFH	0...255	1	[-]
Maximal number how often the check for MU readiness shall be performed before triggering a fault reaction					

12.6.1 Check of MU readiness

FUNCTION DESCRIPTION:

General information:

The start-up on MC and MU is done asynchronously, so potentially the MC could already be willing to trigger the first communication while the MU has not yet completed its start-up. A communication error would be the consequence, even if the communication itself was performed without any problem – the MU simply was not yet ready and had, e.g., not yet properly prepared the data for the first communication.

In order to avoid such situations, the MC – as the master of the communication – shall first check whether the MU is ready. If the MU is ready, the first communication shall be triggered. Otherwise, the MU readiness check shall be repeated for a certain number of times, and if the MU is still not ready after a configurable number of attempts, a fault reaction shall be performed.

The configuration can be adjusted in such a way that the readiness check shall be performed forever without ever becoming actually ready; this is intended for such situations where no MU is available in the HW.

Description:

The function shall incorporate the following requirements:

G57 Check of MU readiness

R57_1: The MC shall trigger the readiness check by calling the action ACTION_INFR_StartMuReadyChk().

R57_2: In the next recurrence, the MC shall fetch the result of the MU readiness check by calling the action ACTION_INFR_MuReady() with argument LV_MU_READY.

R57_3: If LV_MU_READY = 1, the MU is ready; this information is used as one of the conditions for enabling the transition from INIT to CONFIG (where the first communication will then be triggered, cf. G12).

R57_4: If LV_MU_READY = 0, CTR_MU_READY shall be increased by 1.

R57_5: If CTR_MU_READY > NC_CTR_MU_READY_MAX, the central fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction() with argument NC_ERR_COD_MC_MU_READY.

R57_6: If CTR_MU_READY <= NC_CTR_MU_READY_MAX, the sequence shall be started again from R57_1 onwards, i.e., calling ACTION_INFR_StartMuReadyChk() still in the same recurrence.

Application conditions:

Initialisation:	LV_MU_READY = 0; CTR_MU_READY = 0;
Recurrence:	The **initialisation** shall be performed **after each power-up or reset**. The **function itself** shall be executed **every NC_T_MC_COM_CYC ms**.
Activation:	(STATE_MC = NC_STATE_MC_INI) **AND** (LV_MU_READY <> 1) *(only active in INIT state and when the check has not yet been finished)*
Deactivation:	Otherwise

12.6.2 Trigger CONFIG communication

FUNCTION DESCRIPTION:

General information:

This function describes the triggering of the CONFIG communication by the MC.

Description:

The function incorporates the following requirements:

G12 Trigger CONFIG communication

R12_1: In the CONFIG communication, the following data are sent from the MC to the MU:

- error code;
- error indication;
- reset counter;
- configuration data for MU (plus their complements).

(See the description of the communication protocol; further note that these data are *not* imported here because sending them to the infrastructure so that they are available for the communication is the task of the corresponding modules where the data are exported)

R12_2: The communication is triggered by the MC once these data have been sent to the infrastructure by the responsible modules ("Central fault reaction", "State of fault reaction and up-to-dateness of error code", "Configuration of MU"); this shall be achieved by calling the action ACTION_INFR_McStartCom() with argument STATE_MC.

Application conditions:

Initialisation:	-
Recurrence:	The **function** shall be **activated after the relevant data** (see R12_1 above) **have been transported to the infrastructure**.
Activation:	STATE_MC = NC_STATE_MC_CONF *(only active in CONFIG state)*
Deactivation:	Otherwise

12.6.3 Communication monitoring in CONFIG state

FUNCTION DESCRIPTION:

General information:

This function describes how the CONFIG communication is monitored on the MC in the CONFIG state. Note that this really only refers to communication monitoring but not to evaluation of the received data: in case an error was encountered, an error flag (LV_MC_COM_ERR) shall be set which is subsequently exported to other processor monitoring functions so that those do not get activated in case of a communication error.

Description:

The function incorporates the following requirements:

G13 Communication monitoring in CONFIG state

R13_1: The sequence of checks shall be communication checksum monitoring, followed by communication header-byte monitoring, and finally parity-bit checking.

R13_2: For communication checksum monitoring:
R13_2.1: the action ACTION_INFR_McChkCks() shall be called returning the flag LV_MC_CKS_OK (which is set if the checksum was correct);
R13_2.2: the variable LV_MC_CKS_OK shall be stored together with its complement LV_MC_CKS_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0;
R13_2.3: in case of a checksum error:

R13_2.3.1: an immediate fault reaction shall be carried out by calling ACTION_ECM3_McFaultReaction() with error code NC_ERR_COD_MC_CKS;
R13_2.3.2: LV_MC_COM_ERR shall be set;
R13_2.3.3: no further communication monitoring shall be performed.

R13_3: For communication header-byte monitoring:
R13_3.1: the action ACTION_INFR_McGetHd() shall be called returning the header byte STATE_MU_TMP sent by the MU in the preceding communication; STATE_MU_TMP shall be stored together with its complement STATE_MU_TMP_CPL; both variables shall be stored in a reset-safe manner;
R13_3.2: the only acceptable header bytes are CONFIG and DISABLE;
R13_3.3: in case a CONFIG header is received, LV_MC_HD_OK shall be set and the communication monitoring shall continue (with parity-bit checking);
R13_3.4: in case a DISABLE header is received, the flag LV_MC_HD_OK shall be set and parity-bit checking shall be performed as for DISABLE communications (see section "Communication monitoring in DISABLE state" R4);
R13_3.5: in case of receiving a header-byte other than CONFIG or DISABLE:
R13_3.5.1: an immediate fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction with error code NC_ERR_COD_MC_HD;
R13_3.5.2: the flag LV_MC_HD_OK shall be reset;
R13_3.5.3: LV_MC_COM_ERR shall be set;
R13_3.5.4: no further communication monitoring shall be performed;
R13_3.6: the variable LV_MC_HD_OK shall be stored together with its complement LV_MC_HD_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0.

R13_4: For parity-bit checking:
R13_4.1: the action ACTION_INFR_McChkPar() shall be used which returns the flag LV_MC_PAR_OK (which is set of the parity was correct);
R13_4.2: the variable LV_MC_PAR_OK shall be stored together with its complement LV_MC_PAR_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0;
R13_4.3 in case of a parity error:
R13_4.3.1: an immediate fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction with error code NC_ERR_COD_MC_PAR;
R13_4.3.2: LV_MC_COM_ERR shall be set.

R13_5: The variable LV_MC_COM_ERR shall be stored together with its complement LV_MC_COM_ERR_CPL and accessed using the actions ACTION_ECM3_WriteChkCpl(),ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC"; its default value shall be 1.

Application conditions:

Initialisation: *\/* After each power-up *\/*

STATE_MU_TMP = NC_STATE_MC_INI;

/ After each power-up or reset, using the RAM check service actions */*

LV_MC_CKS_OK = 0;

LV_MC_HD_OK = 0;
LV_MC_PAR_OK = 0;
LV_MC_COM_ERR = 0;

Recurrence: The **initialisation** shall be performed **after each power-up or reset (as indicated above)**.

The **function itself** shall be triggered **after the communication between MC and MU is finished**.

Activation: STATE_MC = NC_STATE_MC_CONF *(only active in CONFIG state)*

Deactivation: Otherwise

12.6.4 Trigger PREDRIVE communication

FUNCTION DESCRIPTION:

General information:

This function describes the triggering of the PREDRIVE communication by the MC.

Description:

The function incorporates the following requirements:

G14 Trigger PREDRIVE communication

R14_1: In the PREDRIVE communication, the following data are sent from the MC to the MU:

- compatibility number;
- configuration data for MU (plus their complements).

(See the description of the communication protocol; further note that these data are *not* imported here because sending them to the infrastructure so that they are available for the communication is the task of the corresponding modules where the data are exported)

R14_2: The communication is triggered by the MC once these data have been sent to the infrastructure by the responsible modules ("Version compatibility check", "Configuration of MU"); this shall be achieved by calling the action ACTION_INFR_McStartCom() with argument STATE_MC.

Application conditions:

Initialisation: -

Recurrence: The **function** shall be **activated after the relevant data** (see R1 above) have **been transported to the infrastructure** and **if NC_T_MC_COM_CYC ms have passed since the last communication**.

Activation: STATE_MC = NC_STATE_MC_PRDR *(only active in PREDRIVE state)*

Deactivation: Otherwise

12.6.5 Communication monitoring in PREDRIVE state

FUNCTION DESCRIPTION:

General information:

This function describes how the PREDRIVE communication is monitored on the MC in the PREDRIVE state. Note that this really only refers to communication monitoring but not to evaluation of the received data: in case an error was encountered, an error flag (LV_MC_COM_ERR) shall be set which is subsequently exported to other processor monitoring functions so that those do not get activated in case of a communication error.

Description:

The function incorporates the following requirements:

G15 Communication monitoring in PREDRIVE state

R15_1: The sequence of checks shall be communication checksum monitoring, followed by communication header-byte monitoring.

R15_2: For communication checksum monitoring:
R15_2.1: the action ACTION_INFR_McChkCks() shall be called returning the flag LV_MC_CKS_OK (which is set if the checksum was correct);
R15_2.2: the variable LV_MC_CKS_OK shall be stored together with its complement LV_MC_CKS_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0;
R15_2.3: in case of a checksum error:
R15_2.3.1: an immediate fault reaction shall be carried out by calling ACTION_ECM3_McFaultReaction with error code NC_ERR_COD_MC_CKS;
R15_2.3.2: LV_MC_COM_ERR shall be set;
R15_2.3.3: no further communication monitoring shall be performed.

R15_3: For communication header-byte monitoring:
R15_3.1: the action ACTION_INFR_McGetHd() shall be called returning the header byte STATE_MU_TMP sent by the MU in the preceding communication; STATE_MU_TMP shall be stored together with its complement STATE_MU_TMP_CPL; both variables shall be stored in a reset-safe manner;
R15_3.2: the only acceptable header bytes are PREDRIVE and DISABLE;
R15_3.3: in case a PREDRIVE header is received, LV_MC_HD_OK shall be set and communication monitoring is finished;
R15_3.4: in case a DISABLE header is received, LV_MC_HD_OK shall be set and parity-bit checking shall be performed as for DISABLE communications (see section "Communication monitoring in DISABLE state" R19_4);
R15_3.5: in case of receiving a header-byte other than PREDRIVE or DISABLE:
R15_3.5.1: an immediate fault reaction shall be triggered by calling ACTION_ECM3_McFaultReaction with error code NC_ERR_COD_MC_HD;
R15_3.5.2: the flag LV_MC_HD_OK shall be reset;
R15_3.5.3: LV_MC_COM_ERR shall be set;
R15_3.5.4: no further communication monitoring shall be performed;
R15_3.5.5: the variable LV_MC_HD_OK shall be stored together with its complement LV_MC_HD_OK_CPL and it shall be accessed using the actions from section "RAM check

service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0.

R15_4: The variable LV_MC_COM_ERR shall be stored together with its complement LV_MC_COM_ERR_CPL and accessed using the actions ACTION_ECM3_WriteChkCpl(),ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC."

Application conditions:

Initialisation:	*/* Using the RAM check actions */* LV_MC_COM_ERR = 0;
Recurrence:	The **initialisation** shall be performed **before the PREDRIVE communication is triggered**. The **function itself** shall be triggered **after the communication between MC and MU is finished**.
Activation:	STATE_MC = NC_STATE_MC_PRDR *(only active in PREDRIVE state)*
Deactivation:	Otherwise

12.6.6 Trigger NORMAL communication

FUNCTION DESCRIPTION:

General information:

This function describes the triggering of the NORMAL communication by the MC.

Description:

The function incorporates the following requirements:

G16 Trigger NORMAL communication

R16_1: In the NORMAL communication, the following data are sent from the MC to the MU:
- the PFM response;
- the FS-IST response;
- the value of the ignition key;
- the flag for the redundant switch-off path.

(See the description of the communication protocol; further note that these data are *not* imported here because sending them to the infrastructure so that they are available for the communication is the task of the corresponding modules where the data are exported)

R16_2: The communication is triggered by the MC once these data have been sent to the infrastructure by the responsible modules ("Post-processing of PFM response before communications", "Post-processing of the FS-IST data on MC for transmission to MU", "Exporting the value of the ignition key", "The redundant switch-off path"); this shall be achieved by calling the action ACTION_INFR_McStartCom() with argument STATE_MC (note that the function can be called either shortly after the transition PREDRIVE→NORMAL, or after all other functions in NORMAL have been executed in case the NORMAL state is not left).

Application conditions:

Initialisation: -

Recurrence: The **function** shall be **activated after the relevant data** (see R16_1 above) **have been transported to the infrastructure** and **if NC_T_MC_COM_CYC ms have passed since the last communication**.

Activation: STATE_MC = NC_STATE_MC_NORM *(only active in NORMAL state)*

Deactivation: Otherwise

12.6.7 Communication monitoring in NORMAL state

FUNCTION DESCRIPTION:

General information:

This function describes how the NORMAL communications are monitored on the MC in the NORMAL state. Note that this really only refers to communication monitoring but not to evaluation of the received data: in case an error was encountered, an error flag (LV_MC_COM_ERR) shall be set which is subsequently exported to other processor monitoring functions so that those do not get activated in case of a communication error.

Description:

The function incorporates the following requirements:

G17 Communication monitoring in NORMAL state

R17_1: The sequence of checks shall be communication checksum monitoring, followed by communication header-byte monitoring.

R17_2: For communication checksum monitoring:
R17_2.1: the action ACTION_INFR_McChkCks() shall be called which returns the flag LV_MC_CKS_OK (which is set if the checksum was correct);
R17_2.2: the variable LV_MC_CKS_OK shall be stored together with its complement LV_MC_CKS_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0;
R17_2.3: in case of a checksum error, a debounced fault reaction shall be carried out:
R17_2.3.1: in case the checksum is wrong, the corresponding anti-bounce counter shall be increased (potentially triggering a fault reaction) by calling ACTION_ECM3_McIncAbc() with anti-bounce counter identifier NC_ABC_MC_CKS and error code NC_ERR_COD_MC_CKS;
R17_2.3.2: LV_MC_COM_ERR shall be set;
R17_2.3.3: no further communication monitoring shall be performed;
R17_2.4: in case the checksum is correct, the corresponding anti-bounce counter shall be decreased by calling ACTION_ECM3_McDecAbc() with anti-bounce counter identifier NC_ABC_MC_CKS.

R17_3: For communication header-byte monitoring:
R17_3.1: the action ACTION_INFR_McGetHd() shall be called returning the header byte STATE_MU_TMP sent by the MU in the preceding communication; STATE_MU_TMP shall be stored together with its complement STATE_MU_TMP_CPL; both variables shall be stored in a reset-safe manner;
R17_3.2: the only acceptable header bytes are NORMAL and DISABLE;
R17_3.3: in case a NORMAL header is received, LV_MC_HD_OK shall be set and communication monitoring is finished;
R17_3.4: in case a DISABLE header is received, LV_MC_HD_OK shall be set and parity bit checking shall be performed as for DISABLE communications (see section "Communication monitoring in DISABLE state" R19_4);
R17_3.5: in case of receiving a header-byte different from NORMAL or DISABLE, a debounced fault reaction shall be carried out:
R17_3.5.1: in case the header-byte is wrong, the corresponding anti-bounce counter shall be increased (potentially triggering a fault reaction) by calling ACTION_ECM3_McIncAbc() with anti-bounce counter identifier NC_ABC_MC_HD and error code NC_ERR_COD_MC_HD;
R17_3.5.2: the flag LV_MC_COM_ERR shall be set;
R17_3.5.3: no further communication monitoring shall be performed;
R17_3.5.4: the flag LV_MC_HD_OK shall be reset (in case the fault reaction is not correctly performed);
R17_3.6: in case the header-byte is NORMAL, the corresponding anti-bounce counter shall be decreased by calling ACTION_ECM3_McDecAbc() with anti-bounce counter identifier NC_ABC_MC_HD;
R17_3.7: the variable LV_MC_HD_OK shall be stored together with its complement LV_MC_HD_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0.

R17_4: The variable LV_MC_COM_ERR shall be stored together with its complement LV_MC_COM_ERR_CPL and accessed using the actions ACTION_ECM3_WriteChkCpl(),ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC."

Application conditions:

Initialisation:	*/* Initialise LV_MC_COM_ERR using the RAM check actions */* LV_MC_COM_ERR = 0;
Recurrence:	The **initialisation** shall be performed **before a NORMAL communication is triggered**. The **function itself** shall be triggered **after the communication between MC and MU is finished**.
Activation:	STATE_MU = NC_STATE_MU_NORM *(only active in NORMAL state)*
Deactivation:	Otherwise

12.6.8 Trigger DISABLE communication

FUNCTION DESCRIPTION:

General information:

This function describes the triggering of the DISABLE communication by the MC.

Description:

The function incorporates the following requirements:

G18 Trigger DISABLE communication

R18_1: In the DISABLE communication, the following data are sent from the MC to the MU:
- error code;
- error indication;
- reset counter;
- the value of the ignition key;

(See the description of the communication protocol; further note that these data are *not* imported here because sending them to the infrastructure so that they are available for the communication is the task of the corresponding modules where the data are exported)

R18_2: The communication is triggered by the MC once these data have been sent to the infrastructure by the responsible modules ("Exporting the value of the ignition key", "The redundant switch-off path"); this shall be achieved by calling the action ACTION_INFR_McStartCom() with argument STATE_MC (note that the function can be called either shortly after the transition into DISABLE from a different state, or after all other functions in DISABLE have been executed in case the DISABLE state is not left).

Application conditions:

Initialisation:	-
Recurrence:	The **function** shall be acti**vated after the relevant data** (see R18_1 above) **have been transported to the infrastructure** and **if NC_T_MC_COM_CYC ms have passed since the last communication**.
Activation:	STATE_MC = NC_STATE_MC_DI *(only active in DISABLE state)*
Deactivation:	Otherwise

12.6.9 Communication monitoring in DISABLE state

FUNCTION DESCRIPTION:

General information:

This function describes how the DISABLE communication is monitored on the MC in the DISABLE state. Note that this really only refers to communication monitoring but not to evaluation of the received data: in case an error was encountered, an error flag (LV_MC_COM_ERR) shall be set which is subsequently exported to other processor monitoring functions so that those do not get activated in case of a communication error.

Description:

The function incorporates the following requirements:

G19 Communication monitoring in DISABLE state

R19_1: The sequence of checks shall be communication checksum monitoring, followed by communication header-byte monitoring, and finally parity-bit checking.

R19_2: For communication checksum monitoring:
R19_2.1: the action ACTION_INFR_McChkCks() shall be called which returns the flag LV_MC_CKS_OK (which is set if the checksum was correct);
R19_2.2: the variable LV_MC_CKS_OK shall be stored together with its complement LV_MC_CKS_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0;
R19_2.3: in case of a checksum error, no fault reaction shall be carried out, only LV_MC_COM_ERR shall be set and no further communication monitoring shall be performed.

R19_3: For communication header-byte monitoring:
R19_3.1: the action ACTION_INFR_McGetHd() shall be called returning the header byte STATE_MU_TMP sent by the MU in the preceding communication; STATE_MU_TMP shall be stored together with its complement STATE_MU_TMP_CPL; both variables shall be stored in a reset-safe manner;
R19_3.2: the only acceptable header bytes is DISABLE;
R19_3.3: in case a DISABLE header is received, LV_MC_HD_OK shall be set and the communication monitoring shall continue (with parity-bit checking);
R19_3.4: in case of receiving a header-byte different from DISABLE, no fault reaction shall be carried out, only LV_MC_COM_ERR shall be set and no further communication monitoring shall be performed; furthermore, also the flag LV_MC_HD_OK shall be reset;
R19_3.5: the variable LV_MC_HD_OK shall be stored together with its complement LV_MC_HD_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring" ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl(); its default value shall be 0.

R19_4: For parity-bit checking:
R19_4.1: the action ACTION_INFR_McChkPar() shall be used which returns the flag LV_MC_PAR_OK (which is set of the parity was correct);
R19_4.2: the variable LV_MC_PAR_OK shall be stored together with its complement LV_MC_PAR_OK_CPL and it shall be accessed using the actions from section "RAM check service actions of Processor Monitoring"; its default value shall be 0 ACTION_ECM3_WriteChkCpl(), ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl();
R19_4.3: in case of a parity error, no fault reaction shall be triggered, only LV_MC_COM_ERR shall be set, and no further communication monitoring shall be performed.

R19_5: The variable LV_MC_COM_ERR shall be stored together with its complement LV_MC_COM_ERR_CPL and accessed using the actions ACTION_ECM3_WriteChkCpl(),ACTION_ECM3_ChkCpl(), ACTION_ECM3_ReadChkCpl(), and ACTION_ECM3_McReadChkCpl() from section "RAM check service actions of processor monitoring on MC."

Application conditions:

Initialisation: *`/* Initialise LV_MC_COM_ERR using the RAM check actions */`*

LV_MC_COM_ERR = 0;

Recurrence: The **initialisation** shall be performed **before a DISABLE communication is triggered**.

The **function itself** shall be triggered **after the communication between MC and MU is finished**.

Activation: STATE_MU = NC_STATE_MU_DI *(only active in DISABLE state)*

Deactivation: Otherwise

12.7 MC Switch-Off Path Check

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MC_SOPC_INH_DI	V/O	0...1H	0...1	1	[-]
Flag indicating to other functions not to disable the power stages via HW disable lines because the MU-part of the SOPC is active

Local variable: final result of the SOPC					
LV_MC_SOPC_ACT	V/O	0...1H	0...1	1	[-]
Flag indicating whether MC SOPC is still active (=1, i.e., not finished) or not (=0)					
IDX_STATE_SOPC	V/O/S	0...FH	0...15	1	[-]
Index into lookup table to determine the final result of the SOPC (stored in reset-safe manner)					
IDX_STATE_SOPC_CPL	O/S	0...FH	0...15	1	[-]
Complement of IDX_STATE_SOPC (stored in reset-safe manner)					

Note: mode "S" shall mean storage in reset-safe, but not necessarily non-volatile memory.

Input data:

CTR_RST_MC	CTR_RST_MC_CPL	LV_MC_INH_SOPC	NC_STATE_MC_INI
NC_STATE_MC_CONF	NC_STATE_MC_PRDR	NC_STATE_MC_NORM	NC_STATE_MC_DI
STATE_MC			

Export actions:

ACTION_ECM3_McCancelSopc()
This action cancels the SOPC.

Description for actions:

ACTION_ECM3_McCancelSopc()

When called, this action resets LV_MC_SOPC_INH_DI in order to ensure that the power stages can be properly disabled by the MC; this is used inside G1 "Central Fault Reaction" which could be activated while the SOPC is not yet finished.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit

FUNCTION DESCRIPTION:

General information:

The switch-off path check (SOPC, previously also known as "Predrive Check") is part of the standard monitoring duties performed by the processor monitoring functions.

Its objective is to determine whether the system's *switch-off paths*, i.e., dedicated physical connections with the purpose to disable the safety-relevant power stages are fully functional, in case an error should necessitate this action,.

Both MC and MU can have up to two such switch-off paths each connected to MC and MU.

The check itself is performed during the system's start-up (see signal flow diagram below).

The principle idea of the check is that one of the two system components (MC or MU) attempts to disable the power stages it is connected to and then, after obtaining status information from the power stages, it is judged whether they are indeed disabled.

The status of the power stages during the SOPC shall be collected on the MC, simply because the MU cannot read back the status of the power stages.

It is clear that the SOPC has to be synchronised between the MC and the MU in order to avoid conflicts stemming from the need to unequivocally decide whether a given switch-off path works or not (e.g., the MC and MU paths must not be tested at the same time because it might not be possible to determine which component is actually responsible for the disabling or, should the disabling fail, which switch-off path to which component is broken).

Since communications constitute the main synchronisation mechanism between MC and MU, the SOPC is synchronised according to different communications between MC and MU.

This specification describes the generic procedure; any project-specific deviation or extension shall be specified in the application incidences, function "G27 Configuration for switch-off path check."

Signal flow diagram:

The sequencing of the switch-off path check with respect to the different communications is shown in the following diagram (note that the diagram only shows the case when no temporary disabling is performed):

Description:

The function shall incorporate the following requirements (always refer to the signal flow diagram):

G26 Switch-off path check

R26_1: The status information of a power stage shall be retrieved using the actions ACTION_INFR_McGetDiagPws0() and ACTION_INFR_McGetDiagPws1(); the requirements to these actions are described in the section "ECM3 - MC requirements to infrastructure interface."

R26_2: For the check of the MU switch-off paths:
R26_2.1: it shall be performed after the transition from INIT to CONFIG but before triggering the PREDRIVE communication (since, under regular circumstances, the MU stops disabling the power stages after the PREDRIVE communication, see signal flow diagram);
R26_2.2: if any of the two actions returns "undefined" as status information from a power stage, it shall be assumed that the corresponding switch-off path is not working;
R26_2.3: the result of the SOPC for the MU paths shall be stored as the two lower bits in the 4-bit vector IDX_STATE_SOPC, which shall be stored together with its complement IDX_STATE_SOPC_CPL (see "RAM check service actions of processor monitoring on MC"), its default value being NC_IDX_STATE_SOPC_DFCT (= no switch-off path working);
R26_2.4: the diagnostic result for power stage 0 shall be the MSB of the two bits reserved for the MU results;
R26_2.5: a set bit shall indicate that the switch-off path is working;
R26_2.6: when storing the two MU results, the upper two bits shall be reset (since IDX_STATE_SOPC is stored in reset-safe memory, these might still contain old data from a previous SOPC).

R26_3: The flag LV_MC_SOPC_INH_DI shall be handled as follows:
R26_3.1: it shall be set for the duration of the MU-part of the SOPC (from initialisation to shortly before the PREDRIVE communication);
R26_3.2: it shall be reset after the MU-part of the SOPC **but before the PREDRIVE communication**;
R26_3.3: it shall be stored together with its complement LV_MC_SOPC_INH_DI_CPL pair and accessed using the actions from "RAM check service actions of processor monitoring on the MC", with default value 0, indicating inactive SOPC.

R26_4: For the check of the MC switch-off paths:
R26_4.1: it shall be performed at some point after triggering the PREDRIVE communication (under regular circumstances, the MU then no longer disables the power stages);
R26_4.2: if any of the two actions returns "undefined" as status information from a power stage, it shall be assumed that the corresponding switch-off path is not working;
R26_4.3: the result of the SOPC for the MC paths shall be stored as the two upper bits in the 4-bit vector IDX_STATE_SOPC, which shall be stored together with its complement IDX_STATE_SOPC_CPL (see "RAM check service actions of processor monitoring on MC"), its default value being NC_IDX_STATE_SOPC_DFCT (= no switch-off path working);
R26_4.4: the diagnostic result for power stage 0 shall be the MSB of the two bits reserved for the MC results;
R26_4.5: a set bit shall indicate that the switch-off path is working.

R26_5: As for the exact timing of the MC-part of the SOPC:

R26_5.1: after the MU-part of the SOPC **but before the PREDRIVE communication**, LV_MC_SOPC_ACT shall be set to 1 in order to indicate that the MC-part of the SOPC has not yet been completed (this prompts disabling of power stages by the MC, cf. R22_10);
R26_5.2: the MC-part of the SOPC can only be performed if LV_MC_INH_SOPC = 0 (this indicates that the power stages are no longer temporarily disabled and that the MU no longer disables the power stages); under regular circumstances, this leaves time between after the PREDRIVE communication and before triggering the second NORMAL communication (cf. R22_7.1 and R22_9) to perform the check;
R26_5.3: otherwise, if LV_MC_INH_SOPC = 1, the MC-part of the SOPC has to be postponed until R26_5.2 becomes applicable (note that LV_MC_SOPC_ACT remains set!);
R26_5.4: after the MC-part of the SOPC has been finished, LV_MC_SOPC_ACT shall be reset (allowing the power stages to be enabled, cf. R22_10).

R26_6: By the previous requirements R26_2 and R26_4, the index IDX_STATE_SOPC for the lookup in one of the result tables is generated by concatenating the results of MC and MU paths as depicted below:

Bit 3	Bit 2	Bit 1	Bit 0
MC result PSW0	MC result PWS1	MU result PWS0	MU result PWS1

R26_7: For determining the final result of the SOPC, depending on the value of CTR_RST_MC (for which a consistency check with its complement CTR_RST_MC_CPL using ACTION_ECM3_ReadChkCpl() has to be performed), the following cases shall be distinguished:
R26_7.1: if CTR_RST_MC < NC_CTR_RST_MC_THD_SOPC, the final result of the switch-off path check STATE_MC_RESP_SOPC shall be obtained by a lookup in the table NC_RESP_SOPC_1[] at index IDX_STATE_SOPC;
R26_7.2: if CTR_RST_MC ≥ NC_CTR_RST_MC_THD_SOPC, the final result of the switch-off path check STATE_MC_RESP_SOPC shall be obtained by a lookup in the table NC_RESP_SOPC_2[] at index IDX_STATE_SOPC;
R26_7.3: the configuration of the lookup tables shall be described in the application incidences; in this way, the number of switch-off paths are connected to each component can be taken into account by putting dummy values into the lookup tables at appropriate positions.

R26_8: For the final result STATE_MC_RESP_SOPC:
R26_8.1: it shall be obtained by a lookup in one of the two tables NC_RESP_SOPC_x as described in R26_7;
then shall determine the behaviour of the system as a reaction to the SOPC results; it shall be stored as a value/complement pair and be accessed by the actions from "RAM check service actions of processor monitoring on MC", its default value being NC_STATE_RESP_SOPC_DFCT (indicating a complete failure of the SOPC); the two simple cases are: allowing the engine to start-up as usual in case the result is NC_STATE_RESP_SOPC_OK (the switch-off path check was completely successful); performing the central fault reaction of processor monitoring in case NC_STATE_RESP_SOPC_DFCT (in case the status of the switch-off paths would not permit reaching the safe state of the system in case of a safety-critical error); since other reactions might be desired, there can be up to 256 different values which (potentially) could correspond to 256 different engine start-up behaviours (but it should be noted that there are only up to 16 different configurations of the status information of the power stages); the considered values (in addition to the default cases NC_STATE_RESP_SOPC_DFCT and NC_STATE_RESP_SOPC_OK), plus the corresponding reactions, are also described in the application incidences.

R26_9: In DISABLE, the SOPC shall be cancelled; this means that LV_MC_SOPC_INH_DI shall be reset to 0 (and its complement set to 1) to indicate the end of the MU-part, and that LV_MC_SOPC_ACT shall be reset to 0 to indicate the end of the MC-part.

R26_10: If LV_MC_INH_SOPC performs a transition from 0 to 1 during the MC-part of the SOPC (including the determination of the result), the MC-part has to be restarted (see R26_5; the MC-part can only start anew when LV_MC_INH_SOPC = 0).

Description for action ACTION_ECM3_McCancelSopc:

ACTION_ECM3_McCancelSopc()

When called, this action resets LV_MC_SOPC_INH_DI in order to ensure that the power stages can be properly disabled by the MC; this is used inside G1 "Central Fault Reaction" which could be activated while the SOPC is not yet finished.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit

Formula section:

/* NOT using the RAM check service actions (to avoid recursion in fault reaction)! */

LV_MC_SOPC_INH_DI = 0;
LV_MC_SOPC_INH_DI_CPL = complement(0);

Application conditions:

Initialisation: **After each power-up:**

/ Using the RAM check service actions */*

IDX_STATE_SOPC = NC_IDX_STATE_SOPC_DFCT;

After each power-up or reset:

/ Using the RAM check service actions */*

LV_MC_SOPC_INH_DI = 1;
STATE_MC_RESP_SOPC = NC_STATE_RESP_SOPC_DFCT;

/ MC-part of the SOPC not yet active, cf. R26_5.1*/*

LV_MC_SOPC_ACT = 0;

Recurrence: The **initialisation** shall be performed **after each power-up or reset (see above)**.

The **function itself** is **spread over the states INIT, CONFIG, PREDRIVE, and NORMAL**, as depicted in the signal flow diagram.

Activation: STATE_MC <> NC_STATE_MC_DI *(inactive in DISABLE state)*

Deactivation: STATE_MC = NC_STATE_MC_DI *(inactive in DISABLE state)*

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

FUNCTION DESCRIPTION:

General information:

Program flow monitoring (PFM) is one of the ways in which the processor monitoring functionality monitors whether the MC-SW, most importantly the process monitoring, is still executed “properly.” From the perspective of PFM, “properly” means that the safety-relevant functions of process monitoring are executed with the correct recurrence and in the correct sequence. The basic algorithm of PFM works as follows.

The MU sends a bit pattern, the so-called *PFM synchronisation byte*, to the MC: this synchronisation byte contains one bit for each of 7 *PFM tasks* (numbered from 0 to 6) to be monitored. Here, “PFM task” denotes a collection of software modules (=functions), in particular of process monitoring, which have to be executed in a defined order and which have to be executed in the same time grid. There can be up to 30 "inspection points" in each of the monitored tasks (e.g., if 3 inspections per module are performed, this means up to 10 modules per task).

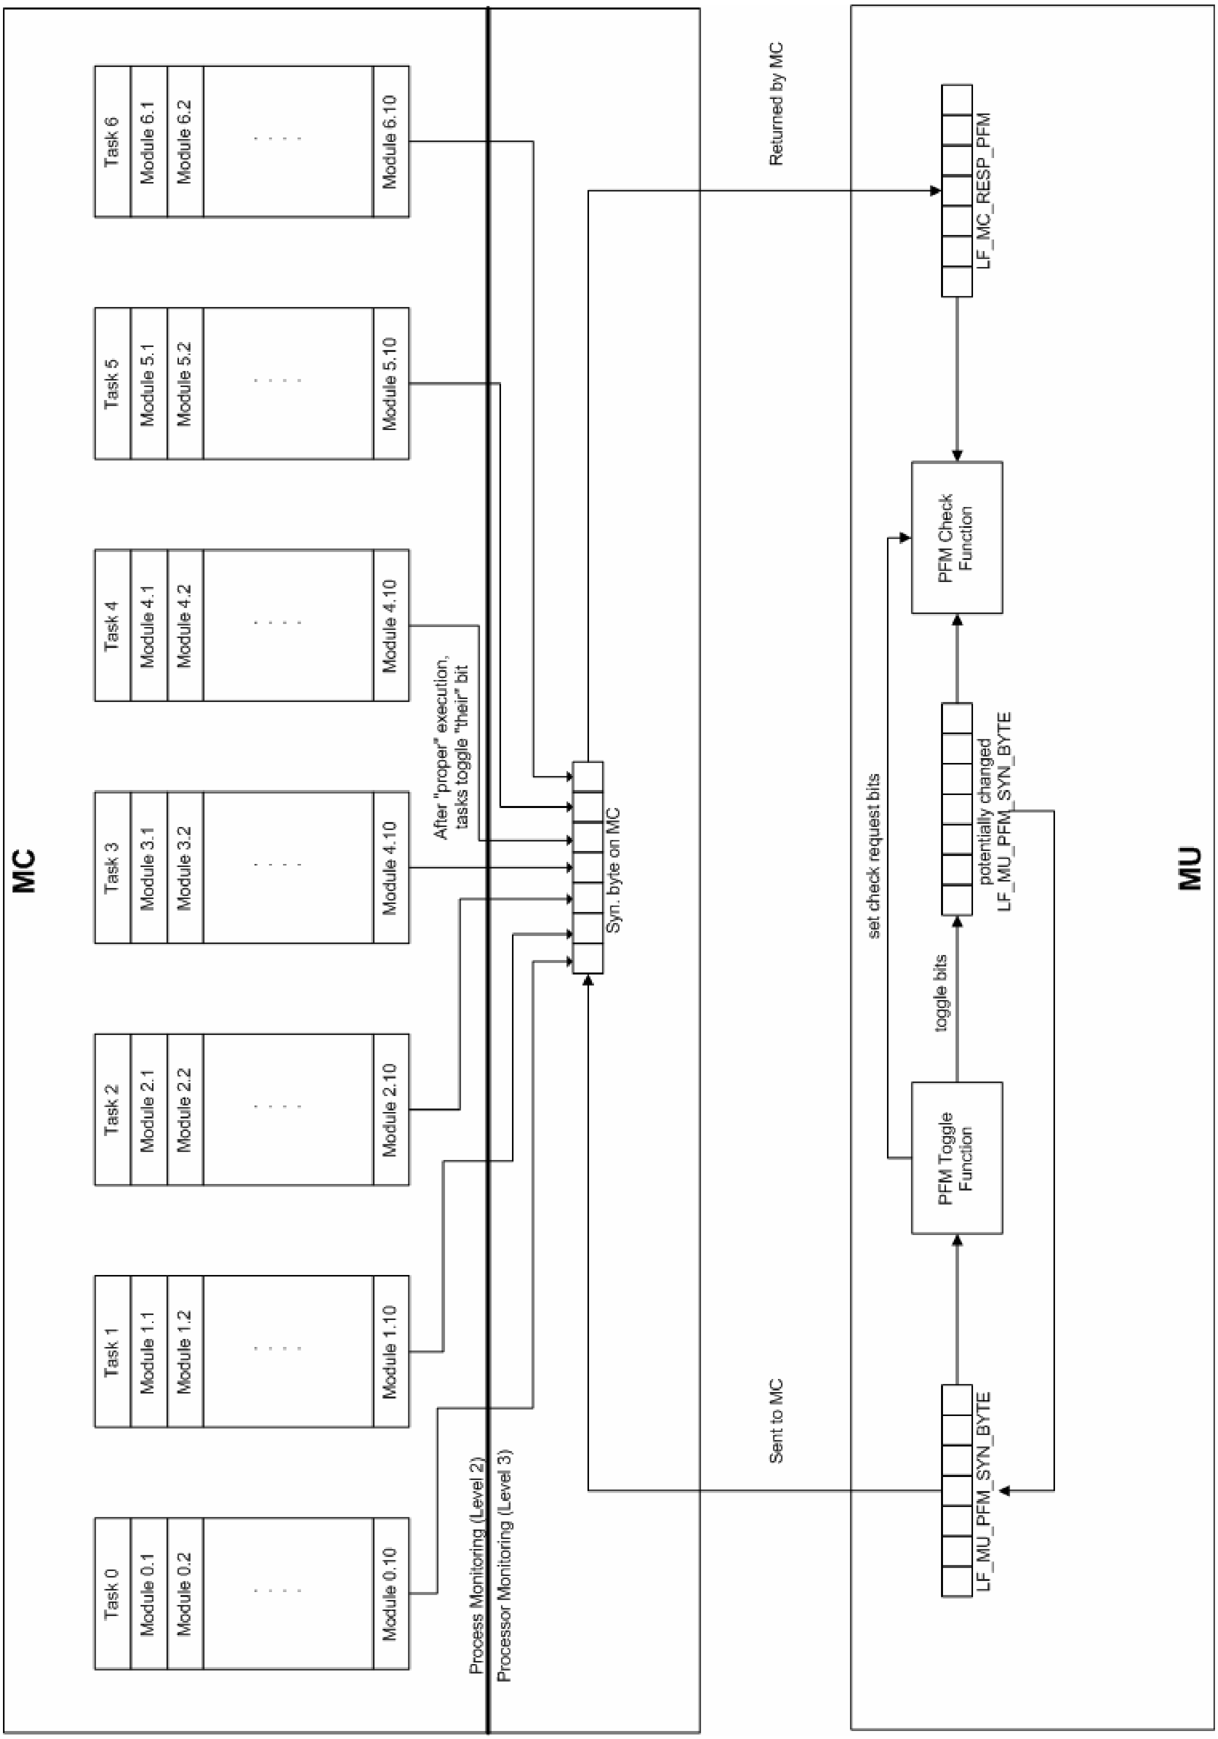
Having been received by the MC, the synchronisation byte is used to obtain the so-called *PFM response byte*: if the monitored modules (of process monitoring or others) from one task *are executed* and, furthermore, if they are *executed in the correct order* (note that these are two different constraints!), they manipulate the bit in the response byte corresponding to ‘their’ task in such a way that it is finally toggled. The (thus potentially updated) response byte is sent back to the MU. In how far the sent response byte (MC → MU) differs from the originally transmitted synchronisation byte (MU → MC) depends solely on which monitored modules were executed until the communication where the response byte was transmitted.

It should be noted that the MU sends two kinds of information: synchronisation bytes and status bytes, and that there is at least one status byte sent between two synchronisation bytes because of the toggle frequency on the MU. Such a status byte contains information about PFM anti-bounce counters on the MU: a set bit indicates that the corresponding counter has value > 0.

Meanwhile, on the MU, the synchronisation byte that was previously sent to the MC, is also manipulated: specific bits are toggled in a way in line with what is expected from the MC in terms of toggling the bits, assuming that the process monitoring tasks are executed “properly” in the sense explained above. When the PFM response of the MC (= a potential update by the MC of the original synchronisation byte) is received, it can thus be compared with the (now also on the MU manipulated) synchronisation byte on the MU.

Since the way the MU manipulates the synchronisation byte is the reference for how the MC should do the same task, a mismatch between the synchronisation byte and the PFM response of the MC indicates that the program execution on the MC is not performed in the prescribed way; as a consequence, a debounced fault reaction will be performed, using separate anti-bounce counters for each of the 7 tasks.

Signal flow diagram:



Description:

The PFM on the MC has the following main tasks:

1. decoding of PFM byte sent by the MU;
2. PFM service actions;
3. monitoring of timely updates of the synchronisation byte by the MU;
4. test MU reaction to wrong PFM responses;
5. post-processing of PFM response before communications.

These sub-tasks of PFM shall, in the following, be represented as the sub-functions of this module.

A special case arises for the first sub-function. It is possible that the monitored functionality (e.g., process monitoring) is running asynchronously to the communications between MC and MU. Therefore, the sub-function must be split in two: one function running synchronously with the communications dealing with testing the MU responses (timely updates and reaction to deliberately wrong responses); another one running synchronously with the fastest monitored task acquiring the synchronisation byte for toggling by the PFM service actions in the same time grid as the modules under PFM inspection.

The last sub-function which is responsible for preparing the PFM response sent to the MU only takes into account that synchronisation byte which used for the service actions since only this can provide the information which modules of the monitored tasks have been executed.

The sequencing of these sub-functions shall also be described (which is basically in the order in which they are presented above with the exception of the service actions which are independently executed by the modules/tasks which are put under the supervision of PFM).

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_MC_PFM	1	0...FFH	0...255	1	[-]
Number of PFM tasks					
NC_NR_MC_PFM_TCC	1	0...FFH	0...255	1	[-]
Size of arrays TCC_MC_PFM_TOG[] and NC_TCC_MC_PFM_TOG_MAX[]					
NC_TCC_MC_PFM_TOG_MAX[NC_NR_MC_PFM_TCC]	1	0...FFH	0...255	1	[-]
Array containing the maximal number of communication cycles for the MU to perform the timely toggling of PFM bits for PFM tasks 0...NC_NR_MC_PFM_TCC					
NC_TCC_MC_PFM_TOG_6_MAX	1	0...FFFFH	0...65535	1	[-]
Maximal number of communication cycles for the MU to perform the toggling of the PFM bit for task 6					
NLF_MC_PFM_SYN_BYTE_INI	1	0...7FH	0...127	1	[-]
Initial value for the PFM synchronisation byte used for toggling by the service actions					

12.8.1 Decoding of PFM byte sent by the MU used for monitoring of MU

FUNCTION DESCRIPTION:

General information:

This sub-function describes how the "raw" data received from the MU (via the infrastructure interface) are pre-processed for PFM on the MC.

Note that this sub-function deals with that instance of the synchronisation byte which is only evaluated to detect whether the MU is still processing its PFM functions properly.

Description:

The function incorporates the following requirements:

G28 Decoding of PFM byte sent by the MU used for monitoring of MU

R28_1: In PREDRIVE, i.e., STATE_MC = NC_STATE_MC_PRDR, in case no communication error was detected (i.e., LV_MC_COM_ERR = 0 and its complement LV_MC_COM_ERR_CPL = 1, checked using the RAM check service actions):
R28_1.1: the "raw" PFM data sent by the MU are obtained by calling the action ACTION_INFR_McGetPfmByte() and the return value shall be stored in the variable LF_MC_RCV_PFM_BYTE_MON;
R28_1.2: since the MU always sends a synchronisation byte as the first PFM byte, bits 0...6 of LF_MC_RCV_PFM_BYTE_MON shall be copied to the synchronisation byte on the MC, LF_MC_PFM_SYN_BYTE_MON.

R28_2: In NORMAL, i.e., STATE_MC = NC_STATE_MC_NORM, in case no communication error was detected (i.e., LV_MC_COM_ERR = 0 and its complement LV_MC_COM_ERR_CPL = 1, checked using the RAM check service actions):
R28_2.1: the "raw" PFM data sent by the MU are obtained by calling the action ACTION_INFR_McGetPfmByte() and stored in the variable LF_MC_RCV_PFM_BYTE_MON.
R28_2.2: the change marker LF_MC_PFM_SYN_BYTE_CHG is saved in LF_MC_PFM_SYN_BYTE_CHG_OLD.
R28_2.3: depending on the value of the MSB (Most Significant Bit) of LF_MC_RCV_PFM_BYTE_MON, two cases arise:
R28_2.3.1: **MSB = 0** means the MU has sent an (updated) *synchronisation byte* as bits 0...6 of LF_MC_RCV_PFM_BYTE_MON.
R28_2.3.1.1: the change marker LF_MC_PFM_SYN_BYTE_CHG is updated, setting bit *k* if bit *k* in LF_MC_PFM_SYN_BYTE_MON <> bit *k* in LF_MC_RCV_PFM_BYTE_MON, and clearing bit *k* otherwise;
R28_2.3.1.2: bits 0...6 of LF_MC_RCV_PFM_BYTE_MON shall be copied to LF_MC_PFM_SYN_BYTE_MON;
R28_2.3.1.3: LF_STATE_ABC_PFM_MU shall not be updated.
R28_2.3.2: **MSB = 1** means the MU has sent a *status byte* of the PFM anti-bounce counters on the MU: bit 0 <= *k* <= 6 in LF_MC_RCV_PFM_BYTE_MON being set indicates that the value of the anti-bounce counter for PFM task *k* on the MU is strictly greater than 0.
R28_2.3.2.1: the change marker LF_MC_PFM_SYN_BYTE_CHG shall be reset to 0;
R28_2.3.2.2: bits 0...6 of LF_MC_RCV_PFM_BYTE_MON shall be copied to LF_STATE_ABC_PFM_MU.
R28_2.3.2.3: LF_MC_PFM_SYN_BYTE_MON shall not be updated.

Note:
Requirement R28_2.3.2.1 is based on the following equivalence:

any of the two "change markers" LF_MC_PFM_SYN_BYTE_CHG and LF_MC_PFM_SYN_BYTE_CHG_OLD is equal to 0

if and only if

the PFM byte from the corresponding communication (either the current one or the one before that) was a status byte.

This holds because the MU sends a PFM synchronisation byte *only if* it was actually updated, compared to the previously sent synchronisation byte: at least one bit must have changed and hence, in turn, at least one set bit in the corresponding change marker would have to be set on the MC.

Application conditions:

Initialisation:	*LF_MC_RCV_PFM_BYTE_MON = 0;* *LF_MC_PFM_SYN_BYTE_MON = 0;* *LF_STATE_ABC_PFM_MU = 0;* *LF_MC_PFM_SYN_BYTE_CHG = 0;* *LF_MC_PFM_SYN_BYTE_CHG_OLD = 0;* *CTR = 0;*
Recurrence:	*The **initialisation** shall be **executed after each power-up or reset.*** *The **function itself** shall be **executed after the modules** "Communication monitoring in PREDRIVE state" or "Communication monitoring in NORMAL state", depending on the current state* (i.e., synchronously to the communications between MC and MU).
Activation:	*((STATE_MC = NC_STATE_MC_PRDR) **OR*** *(STATE_MC = NC_STATE_MC_NORM)) **AND*** *(LV_MC_COM_ERR = 0)* (active in both PREDRIVE and NORMAL, but only if no communication error was detected)
Deactivation:	*Otherwise*

12.8.2 Decoding of PFM byte sent by the MU used for toggling by the PFM service actions

FUNCTION DESCRIPTION:

General information:

This sub-function describes how the "raw" data received from the MU (via the infrastructure interface) are pre-processed for PFM on the MC when used for the PFM service actions.

The function shall be executed **synchronously to, but before** the fastest monitored task: in case there has been an update of the synchronisation byte just before the execution of the monitored task, the PFM service actions will use the updated value of the synchronisation byte when determining the relevant bits in the PFM response LF_MC_RESP_PFM sent to the MU.

Since this function potentially runs asynchronously to the communications between MC and MU, it is necessary to perform the necessary communication monitoring (checksum, header-byte) specifically inside this function. In case an error is detected, no fault reaction shall be carried out, only the received data shall be ignored: eventually the "standard" communication monitoring will be performed and will detect the error and perform the defined reaction.

Description:

The function incorporates the following requirements:

G60 Decoding of PFM byte sent by the MU used for toggling by the PFM service actions

R60_1: In NORMAL, i.e., if MC_STATE = NC_STATE_MC_NORM:
R60_1.1: for **communication checksum monitoring**, the action ACTION_INFR_McChkCks() shall be called returning the flag LV_MC_CKS_OK_PFM (which is set if the checksum was correct);
R60_1.2: in case of a checksum error:

R60_1.2.1: no further communication monitoring shall be performed;
R60_1.2.2: no update of LF_MC_RCV_PFM_BYTE_TOG shall be performed;
R60_1.3: in case of correct checksum, for **communication header-byte monitoring**, the action ACTION_INFR_McGetHd() shall be called returning the header byte STATE_MU_TMP_PFM sent by the MU in the latest communication.
R60_1.4: If STATE_MU_TMP_PFM <> NC_STATE_MC_NORM, no update of LF_MC_RCV_PFM_BYTE_TOG shall be performed.
R60_1.5: If STATE_MU_TMP_PFM = NC_STATE_MC_NORM, the action ACTION_INFR_McGetPfmByte() shall be called and the return value shall be stored in the variable LF_MC_RCV_PFM_BYTE_TOG.
R60_1.6: Depending on the value of the MSB (Most Significant Bit) of LF_MC_RCV_PFM_BYTE_TOG, two cases arise:
R60_1.6.1: **MSB = 0** means the MU has sent an (updated) *synchronisation byte* as bits 0...6 of LF_MC_RCV_PFM_BYTE_TOG, which shall hence be copied to LF_MC_PFM_SYN_BYTE_TOG;
R60_1.6.2: **MSB = 1** means the MU has sent a *status byte* of the PFM anti-bounce counters on the MU, hence no update of LF_MC_PFM_SYN_BYTE_TOG shall be performed.

Application conditions:

Initialisation: *LF_MC_PFM_SYN_BYTE_TOG = NLF_MC_PFM_SYN_BYTE_INI;*
LF_MC_RCV_PFM_BYTE_TOG = 0;
STATE_MU_TMP_PFM = 0;
LV_MC_CKS_OK_PFM = 0;
Recurrence: *The **initialisation** shall be **executed after each power-up or reset.***
*The **function itself** shall be **executed synchronously to but before the fastest monitored task*** (i.e., potentially asynchronously to the communications between MC and MU).
Activation: *(STATE_MC = NC_STATE_MC_NORM)* (only active in NORMAL)
Deactivation: *Otherwise*

12.8.3 PFM service actions

FUNCTION DESCRIPTION:

General information:

This sub-function describes the services to supervise the program flow in relevant modules/tasks (in particular those of process monitoring).

Description:

The function incorporates the following requirements:

G29 PFM service actions

In general, PFM works by providing "markers" in the form of actions to be called at certain points in the supervised modules/tasks, thus enabling the PFM function to analyse the correctness of the program flow inside those modules/tasks.

In the following, let *k* always range over 0 to 6, with the intended meaning that *k* corresponds to one of the 7 different PFM tasks, and let *j* range over 0 to 29, for maximally 30 "inspection points" spread over (the modules in any of) the 7 tasks.

The PFM inspection for a fixed task *k* works as follows.

There is a *PFM control byte* STATE_MC_PFM_CTL_BYTE[*k*] which, before the first PFM synchronisation byte is transmitted from the MU to the MC (in the PREDRIVE communication), is initialised to *nc_ctl_ini* (one initial value for the control bytes of all tasks).

The PFM service actions ACTION_ECM3_Service*j*TaskPfm(*k*) and ACTION_ECM3_ServicePfm(*k*) subsequently manipulate STATE_MC_PFM_CTL_BYTE[*k*], allowing the PFM function to track the program flow in the supervised tasks.

The idea behind the actions ACTION_ECM3_Service*j*TaskPfm(*k*) is to record the correct sequencing inside a task: STATE_MC_PFM_CTL_BYTE[*k*] is manipulated such that

STATE_MC_PFM_CTL_BYTE[*k*] = *nc_ctl_end_k*
if and only if
all "inspection points" in the task were reached in their correct sequence *j* = 0,1,2,...,*max*
(*max* <= 29 and depends on the supervised task)

This yields the following error cases:

- **"inspection points" were reached in an incorrect order (e.g., 0,1,3,2,...),**
- **"inspection points" were skipped (e.g., 0,2,3,...),**
- **"inspection points" were reached repeatedly (e.g., 0,1,1,2,...),**
- **or arbitrary combinations thereof.**

In all of these cases, the control byte shall have a value different from *nc_ctl_end_k*, indicating an incorrect program flow in task *k*.

The action ACTION_ECM3_ServicePfm(*k*) shall implement a "*end of task*" marker by checking the current value of STATE_MC_PFM_CTL_BYTE[*k*] for equality with the expected end value *nc_ctl_end_k*.

This implies that this action must be executed *after all "inspection point" actions of task k have been executed,* i.e., it must be *the last PFM-relevant activity of the task k* under supervision; usually, it really is the last activity before the end of the task.

If the test is positive, i.e., all "inspection points" inside task *k* have been reached exactly once and in the correct sequence, bit *k* in the *PFM response* LF_MC_RESP_PFM shall be set to the negated value of bit *k* in the current synchronisation byte LF_MC_PFM_SYN_BYTE_TOG. Consequently, since the PFM response will eventually be transmitted to the MU, the MU will receive a bit which is toggled when compared to its original value in the synchronisation byte as sent from the MU.

If the test is negative, bit *k* in the synchronisation byte LF_MC_PFM_SYN_BYTE_TOG shall simply be copied to bit *k* in the PFM response (since the MU expects to receive this bit in its toggled state, this will eventually prompt a reaction by the MU).

Regardless of the test result, the control byte for task *k* shall be re-initialised to its start value *nc_ctl_ini* in order to prepare a new execution of task *k*.

Note: the common start value *nc_ctl_ini* and the individual end values *nc_ctl_end_k* for each of the control bytes are configurable so that they can be adapted to project-specific needs and NOT declared here.

Note: the PFM response is exclusively determined from the instance of the PFM synchronisation byte LF_MC_PFM_SYN_BYTE_TOG acquired synchronously with the fastest monitored task since only this instance should record the effect of any monitored modules being executed.

Description of ACTION_ECM3_Service(j)TaskPfm

Description:

Syntax:	ACTION_ECM3_Service(j)TaskPfm(IN <k>)
Parameter (IN):	k task number
Short description:	This action manipulates the control byte STATE_MC_PFM_CTL_BYTE[*k*] of task *k* in order to indicate the fact that the *j*-th "inspection point" in the task has been reached

Description of ACTION_ECM3_ServicePfm

Description:

Syntax:	ACTION_ECM3_ServicePfm(IN <k>)
Parameter (IN):	k task number
Short description:	This action provides an "*end of task*" marker, see formula section.

Formula section:

```
IF (STATE_MC_PFM_CTL_BYTE[k] = nc_ctl_end_k)
THEN /* all "inspection points" reached correctly, stored inverted bit in PFM response */
        LF_MC_RESP_PFM.k = invert(LF_MC_PFM_SYN_BYTE_TOG.k)
ELSE /* wrong program flow, store un-inverted bit in PFM response */
        LF_MC_RESP_PFM.k = LF_MC_PFM_SYN_BYTE_TOG.k
FI
/* Reset control byte for task k */
STATE_MC_PFM_CTL_BYTE[k] = nc_ctl_ini;
```

Application conditions:

Initialisation: /* Set control bytes to their common start value */

```
FOR k = 0 TO NC_NR_MC_PFM
DO
        STATE_MC_PFM_CTL_BYTE[k] =      nc_ctl_ini;
OD
```

Recurrence: *The **initialisation** shall be **performed after each power-up or reset**.*
*The **actions** shall be **called from inside the supervised modules**.*

Activation: -

Deactivation: -

12.8.4 Monitoring of timely updates of the synchronisation byte by the MU

FUNCTION DESCRIPTION:

General information:

This sub-function describes the mechanism by which the MC monitors whether the MU sends, in the corresponding intervals of time, synchronisation bytes where specific bits have been toggled at the right rate.
In this way it is possible to detect whether the MU is still running in "real-time" compared to the MC (in some ways, this is the dual of PFM which serves the purpose to detect whether the modules/tasks of process monitoring still run in "real-time").

Description:

The function incorporates the following requirements:

G30 Monitoring of timely updates of the synchronisation byte by the MU

R30_1: From the point of view of the MC, the MU is supposed to send updated synchronisation bytes at certain rates; the rate is determined by the bit toggling function on the MU, additionally influenced by the communication recurrence.

R30_2: In order to check whether this toggling process on the MU still works correctly, there is the array TCC_MC_PFM_TOG[] (of size 6) plus TCC_MC_PFM_TOG_6 (for PFM task 6 which, due to its low recurrence, needs higher resolution), on the MC, for counting communication cycles between two updates of the corresponding bit in the synchronisation bytes sent by the MU.

R30_3: For each of the counters, there is a corresponding maximal value contained in the array NC_TCC_MC_PFM_TOG_MAX[], plus NC_TCC_MC_PFM_TOG_6_MAX, which is used for detecting whether an update of the synchronisation byte by the MU was performed too late.

Application conditions:

Initialisation: /* Initialise the required data */

```
FOR CTR = 0 TO NC_NR_MC_PFM_TCC
DO
    TCC_MC_PFM_TOG[CTR] = 0;
OD
TCC_MC_PFM_TOG_6 = 0;
```

Recurrence: *The **initialisation** shall be **performed after each power-up or reset.** The **formula section** shall be **executed after the PFM sub-function "Decoding of PFM byte sent by MU used for monitoring of MU."***

Activation: *(STATE_MC = NC_STATE_MC_NORM)* (only performed in NORMAL after the PFM byte sent from the MU has been decoded; in PREDRIVE, the check does not make sense since there, the MU sends a synchronisation byte for the first time)

Deactivation: -

Formula section:

```
FOR CTR = 0 TO 5
DO
    /* Has the bit in the synchronisation byte been updated? */
```

```
        IF (LF_MC_PFM_SYN_BYTE_CHG.CTR = 1)
    THEN /* Yes: check value of test cycle counter */
            IF (TCC_MC_PFM_TOG[CTR] <
                NC_TCC_MC_PFM_TOG_MAX[CTR])
            THEN /* Bit toggled in time: decrease corresponding anti-bounce counter; reset test
            cycle counter*/
                ACTION_ECM3_McDecAbc(
                        IN      NC_ABC_MC_PFM_[CTR]_TOG);
                TCC_MC_PFM_TOG[CTR] = 0;
            ELSE /* Bit not toggled in time: debounced fault reaction; reset test cycle counter */
                ACTION_ECM3_McIncAbc(
                    IN      NC_ABC_MC_PFM_[CTR]_TOG,
                    IN      NC_ERR_COD_MC_PFM_[CTR]_TOG);
                TCC_MC_PFM_TOG[CTR] = 0;
            FI
      /* Bit not updated; has the test cycle counter reached its maximal value? */
    ELSEIF (TCC_MC_PFM_TOG[CTR] ≥
                        NC_TCC_MC_PFM_TOG_MAX[CTR])
      THEN /* Yes: debounced fault reaction; reset test cycle counter */
            ACTION_ECM3_McIncAbc(
                IN      NC_ABC_MC_PFM_[CTR]_TOG,
                IN      NC_ERR_COD_MC_PFM_[CTR]_TOG);
            TCC_MC_PFM_TOG[CTR] = 0;
    ELSE /* No: increase test cycle counter */
            TCC_MC_PFM_TOG[CTR] = TCC_MC_PFM_TOG[CTR] +1;
      FI
OD
/* Perform the same algorithm for task 6, using TCC_MC_PFM_TOG_6 and
NC_TCC_MC_PFM_TOG_6_MAX */
```

12.8.5 Test MU reaction to wrong PFM responses

General information:

If a correctly working MU receives a wrong PFM response (i.e., at least one bit in the PFM response sent by the MC is different from the corresponding bit in the synchronisation byte kept on the MU), it performs a debounced fault reaction: it increases its corresponding anti-bounce counter and, if the maximal value for that counter is reached, triggers a fault reaction. This sub-function aims at testing this mechanism by, under the appropriate circumstances, *deliberately* sending a wrong PFM response to the MU and the checking the eventual reaction to the wrong response. This presupposes the presence of a mechanism on the MC to "notice" the fact that the MU has increased a PFM anti-bounce counter after a wrong PFM response. Furthermore, the robustness of the system must not be affected by a deliberately wrong PFM response, in particular such a wrong answer must not trigger a fault reaction.
For implementing this mechanism, it is crucial that the MU, whenever its synchronisation byte has not changed, sends status bytes establishing which of its PFM anti-bounce counters have value 0 and which do not. It follows that those with value 0 can be tested because (very importantly) there, a wrong answer is *guaranteed* not to trigger a fault reaction (for the others, this need not be true) and, equally important, the next time a status byte is sent, it can be checked whether the anti-bounce counter is still equal to 0 (meaning that the MU has *not* reacted to the wrong response) or not (meaning that the MU has increased the corresponding anti-bounce counter and hence reacted to the wrong response).
Note that this check cannot detect an anti-bounce counter on the MU which is stuck to a value between 0 and the maximal value: the status byte will always indicate that the anti-bounce counter

is different from 0 so that there will never be a deliberately wrong PFM response for the corresponding task.

Description:

The function incorporates the following requirements:

G31 Test MU reaction to wrong PFM responses

The algorithm is described in the formula section the following points should be pointed out (note that these considerations do not take into account the presence of communication errors).

When activated for the first time (after the first NORMAL communication), the initial status byte of the MU anti-bounce counters has just been received: in the PREDRIVE communication, the MU always sends the initial synchronisation byte; consequently, in the first NORMAL communication, the current status of the PFM anti-bounce counters on the MU is transmitted to the MC.

Moreover, LF_MC_PFM_SYN_BYTE_CHG_OLD currently has value 0 since, after the PREDRIVE communication, LF_MC_PFM_SYN_BYTE_CHG is initialised to 0 and this value is stored in LF_MC_PFM_SYN_BYTE_CHG_OLD after the first NORMAL communication.

Consequently, the first condition is false for every *k*, and nothing happens until the test of LF_STATE_ABC_PFM_MU. If bit *k* of LF_STATE_ABC_PFM_MU is set, we do nothing (anti-bounce counter on MU not equal to 0, cannot risk sending a wrong response as this might trigger a fault reaction). If bit *k* is not set, this means that the anti-bounce counter on the MU for task *k* has value 0 so we activate sending wrong responses; this will result in a wrong bit in the PFM response in the next communication (in this case: the second NORMAL communication) sent out after the post-processing function has been executed. So a set bit in LF_MC_WRG_RESP_PFM_ACT indicates that a wrong response was sent or will be sent, depending on when the value is observed.

Now assume that normal operation has continued for some time. When the function gets activated, the same test as described above is performed, viz., it is checked whether the corresponding bit in LF_MC_WRG_RESP_PFM_ACT is set, which implies that in the previous communication, a wrong response has been sent out, and whether in the previous communication an updated synchronisation byte was transmitted by the MU; so the status of an MU anti-bounce counter is only checked after a bit was toggled on the MU and sent to the MC.

This test being successful implies that in the current communication, a status byte was sent and so it can be checked whether the status of the MU anti-bounce counter for a task *k* is not equal to 0.

If this is the case the previously sent wrong response was detected by the MU (since a wrong response is only sent out if the anti-bounce counter is equal to 0) and the corresponding anti-bounce counter on the MC can be decreased. However, if the value of the MU anti-bounce counter is equal to 0, this means that the previously sent wrong response was not detected and consequently, the corresponding anti-bounce counter on the MC must be increased, eventually leading to a debounced fault reaction.

If this increase of the MC anti-bounce counter has not yet triggered a fault reaction, it is then checked whether the MU anti-bounce counter status indicates a value of 0. If that is the case (i.e., either when really no error is present on the MU or when previously a wrong answer was sent out but the MU has not (yet) reacted to the wrong response), the flag corresponding bit in LF_MC_WRG_RESP_PFM_ACT is set in order to send a wrong PFM response.

Note that this implies sending a wrong PFM response until one communication after the MU next updates its synchronisation byte and sends it to the MC because before that it is not possible to de-activate sending of wrong responses, unless the MU anti-bounce counter is no longer equal to 0 which also implies that the MC must have updated its synchronisation byte.

Sending a wrong response for any task is done for the first time as soon as the corresponding status byte received from the MU indicates that the MU anti-bounce counter has value 0. Due to its slow recurrence and the described algorithmic pre-condition, a long time has to elapse before the wrong response test for task 6 can be performed (also due to the fact that the corresponding anti-bounce counter is initialised to a non-zero value to speed up fault detection for this task). On the other hand, the reset counter on the MC heals after a certain time period which should last longer than the duration all possible diagnostic tests inside Processor Monitoring. Consequently, the healing can only be performed after the wrong response test for PFM task 6 has been performed at least once. This is fact shall be indicated to the function "Healing of reset counter and error code" (G2) by the flag LV_MC_PFM_WRG_RESP_ACT_6: it shall be set when sending a wrong PFM response for task 6 is activated.

Application conditions:

Initialisation: /* Deactivate sending wrong PFM responses for all tasks */
LF_MC_WRG_RESP_PFM_ACT = 0;
LV_MC_PFM_WRG_RESP_ACT_6 = 0;
Recurrence: *The* ***initialisation*** *shall be* ***performed after each power-up or reset****.*
The ***formula section*** *shall be* ***executed after the PFM sub-function "Decoding of PFM byte sent by MU used for monitoring of MU."***
Activation: *(STATE_MC = NC_STATE_MC_NORM)* (only performed in NORMAL after the PFM byte sent from the MU has been decoded)
Deactivation: *Otherwise*

Formula section:

```
FOR CTR = 0 TO NC_NR_MC_PFM
DO /* Check whether sending of wrong responses for task k is active and whether the last communication, the bit for task k was toggled (=in the last communication, a synchronisation byte was sent so that now a status byte must have been received) */
        IF ((LF_MC_WRG_RESP_PFM_ACT.CTR = 1) AND
        (LF_MC_PFM_SYN_BYTE_CHG_OLD.CTR = 1))
        THEN /* Has MU-anti-bounce counter reacted to wrong response? */
                IF (LF_STATE_ABC_PFM_MU.CTR = 1)
                THEN /* Yes: decrease MC anti-bounce counter */
                        ACTION_ECM3_McDecAbc(
                                IN      NC_ABC_MC_PFM_[CTR]_RESP);
                        IF (CTR = 6)
                        THEN /* Sending of wrong responses for task 6 has been performed at least once: indicate this to the function "Healing of reset counter and error code" (G2) */
                                LV_MC_PFM_WRG_RESP_ACT_6 = 1;
                        FI
                ELSE /* No: increase MC anti-bounce counter */

12.8.6 Post-processing of PFM response before communications

General information:

This sub-functions sets the value of the PFM response to be sent to the MU in the following (NORMAL) communication.

Description:

The function incorporates the following requirements:

G32 Post-processing of PFM response before communications

Before the new PFM response can be sent to the MU, some post-processing of its current value might be necessary, viz., if sending of wrong PFM responses is active for a certain task, it must be ensured that the effect of the service actions (which, if executed properly, would result in a correct PFM response for the corresponding task) is overridden and explicitly a wrong bit in the PFM response is set.

By the way the checking mechanism on the MU works, this means that the bit in the PFM response has to be *equal* to the value of the respective in the current synchronisation byte on the MC (as the MU expects this bit to be sent back with its value *toggled*).

Finally, the (potentially modified) PFM response LF_MC_PFM_RESP has to be sent to the infrastructure so that it can be transmitted to the MU when the next communication is triggered.

To ensure this behaviour is precisely the task of this sub-function.

Application conditions:

Initialisation: *LF_MC_RESP_PFM = 0;*
Recurrence: *The **initialisation** shall be **performed after each power-up or reset**.*
*The **formula section** shall be **executed just before the next communication is triggered**.*
Activation: *(STATE_MC = NC_STATE_MC_NORM)* (active in NORMAL state)
Deactivation: *Otherwise*

Formula section:

```
FOR CTR = 0 TO 6
DO /* Shall a wrong response bit shall be sent for task k? */
    IF (LF_MC_WRG_RESP_PFM_ACT.CTR = 1)
        THEN /* Yes: set value of the bit in PFM response to the value of the corresponding bit in
        the current synchronisation byte used for toggling by PFM service actions */
                LF_MC_RESP_PFM.CTR = LF_MC_PFM_SYN_BYTE_TOG.CTR;
    FI /* Otherwise leave bit in PFM response as it is */
DO
ACTION_INFR_McSendPfmResp(IN        LF_MC_RESP_PFM);
```

FUNCTION DESCRIPTION:

General information:

The function-specific instruction set test (FS-IST) complements the program flow monitoring (PFM) functionality in an effort to obtain as complete a monitoring of the proper functioning of the main controller (MC) as possible. The goal of the FS-IST is to check whether the MC is capable of correctly performing the calculations necessary for the most important safety-relevant functions in the *process monitoring* ("VDA level 2") - hence the name *function-specific* instruction-set test: only computations with relevance for the monitoring concept (the ‘function’ under consideration) are tested, as opposed to a complete instruction-set test.
As already stated, the FS-IST checks whether certain safety-relevant calculations are performed correctly. These so-called test calculations are performed by a copy of the relevant modules of process monitoring (so as not to ‘disturb’ the action process monitoring by the test calculations); these copied level 2 modules constitute the so-called copy of process monitoring, or level 2’. Although conceptually part of processor monitoring, the level 2’ are in practise more closely associated to process monitoring than to processor monitoring: each change of a process monitoring module a copy of which is part of level 2’ has to be carried out also for the corresponding level 2’ module.
Since the test calculations are also performed on the MC, i.e., by the same processor that performs the actual (level 2) calculations, the monitoring unit (MU) is used to initiate the FS-IST and check whether the calculations arrive at the correct results (otherwise no reasonable way of detecting faults is possible).
Concretely, the FS-IST is performed in the following way (there are some points to note about the timing which will be explained after the description of the basic algorithm):

- on the MU, there exists an array of test indices, or questions; these questions are simply bit patterns which are cyclically sent to the MC, i.e., at the beginning, the first entry of the array is sent, then the second, and so on (in the error-free case, the case of errors will be described later); for these question, there are corresponding answers, or responses, which are also stored in an array on the MU
- these test indices, once they have been received by the MC-part of processor monitoring, are then sent to the level 2’ via an interface which, depending on the question from the MU, determines the starting values (i.e., values of inputs, etc.) for the level 2’ modules;
- using this chosen starting values, level 2’ calculates according to the modules, depending on the ability of the processor, yielding a specific actual output value that is then forwarded to the MC-part of processor monitoring, again via the interface, together with the expected result for this particular test index;
- the MC-part of processor monitoring then determines (by comparing the actual with the expected output value) whether the test calculation was performer successfully before sending a response, or answer, back to the MU; note that this answer is also influenced by other factors (e.g., if a fault by the MC-side of processor monitoring was detected, this answer is forced to be false from the expected answer on the MU)
- the MU receives the answer of the MC-part of processor monitoring and compares that to the entry in its array of expected results at the position corresponding to the sent test index;
- if this comparison has a positive result, and anti-bounce counter shall be decreased (without creating an underflow, i.e., if its value is already 0 nothing shall happen, see “G21 Debounce mechanism”) and the procedure shall continue as described before;
- if the comparison shows that a wrong answer has been received, an anti-bounce counter shall be increased; upon reaching its maximal value, the central fault reaction (“G1

central fault reaction”) shall be triggered; if the maximal value is not reached when increasing the anti-bounce counter, the particular question that was wrongly answered shall be re-sent to the MC for as long as the anti-bounce has not reached 0, i.e., if a question was answered wrongly and the value of the anti-bounce counter has value 4, the same question is sent (at least) 4 times before the next question is sent.

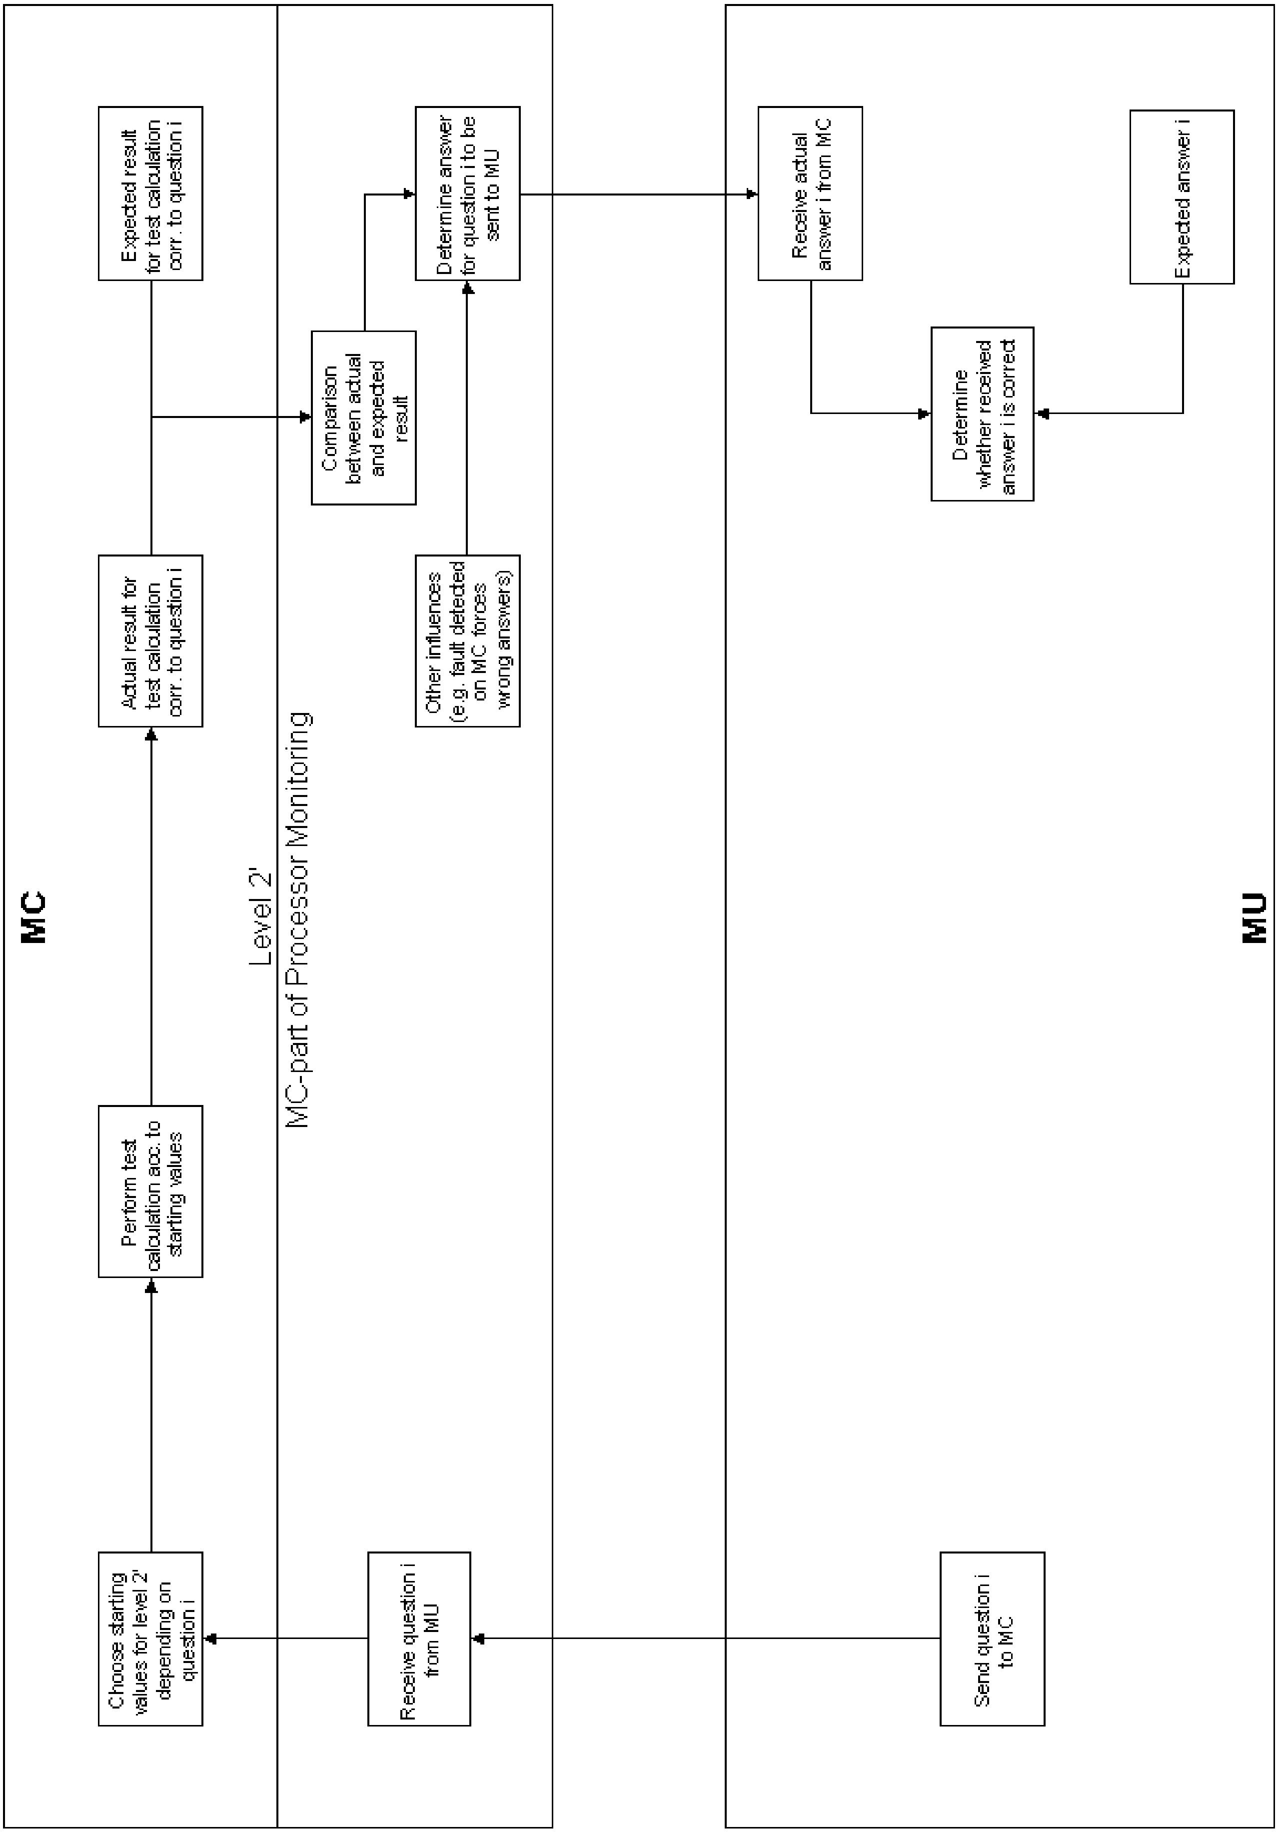
Note the possibility to distinguish between questions and question numbers: in this way, the algorithm for obtaining the new test index can be very simple, viz., the question number simply needs to be increased by with every correct answer (or set to if all possible numbers have been run through), while the actual bit patterns denoting the questions (to be found in a predefined array) can be chosen in such a way as to decrease (if not completely eliminate) the probability of corruption during the communication and also to be able to distinguish between question and answers in EMS and TCU mode of the MU. As stated before, some words regarding timing are necessary at this point:

- when the MU is used for monitoring of EMSs, the level 2’ answers are only checked every second communication cycle;
- when the MU is used for monitoring of TCUs, the level 2’ answers are checked every communication cycle;
- in NORMAL state, whenever the MU sends any question to the MC, the response received in that very communication (regardless of the chosen variant, EMS or TCU) is the answer corresponding to a previous question, i.e., in order to find out whether a question has been answered wrongly, the freshly received answer must be compared to the stored answer corresponding to the previous question;
- if an answer was wrong, the previously described timing situation leads to the fact that, before repeating the wrongly answered question, there will be one transmission of a new question (viz., in the communication where the wrong answer was received); for instance, assuming that both questions and question numbers are simply 0,1,2,... and question 3 is permanently answered wrongly by the MC, the following sequence of questions arises: 0,1,2,3,4,3,3,3... trigger “G1 Central fault reaction”, i.e., question 3 repeated until increasing the anti-bounce counter triggers a fault reaction; the answer to question 4 is simply ignored because the fact that the answer to question 3 was wrong only becomes apparent after question 4 has already been transmitted to the MC.

On the MC, for sending the response, there is a similar split into "answer" and "answer number" in order to facilitate the distinction between the responses from level 2' and for the MU.

Signal flow diagram:

A schematic overview of the FS-IST functionality is given in the following diagram (note that the picture only depicts the control flow, one should not forget that time passes when the communications are performed, the level 2’ calculations are performed etc.):



MC
Level 2'
MC-part of Processor Monitoring
MU
Choose starting values for level 2' depending on question i
Perform test calculation acc. to starting values
Actual result for test calculation corr. to question i
Expected result for test calculation corr. to question i
Comparison between actual and expected result
Determine answer for question i to be sent to MU
Other influences (e.g. fault detected on MC forces wrong answers)
Receive question i from MU
Receive actual answer i from MC
Expected answer i
Determine whether received answer i is correct
Send question i to MC

12.9.1 Pre-processing of the FS-IST data received from MU

FUNCTION DESCRIPTION:

General information:

This function pre-processes the data sent by the MU.

In PREDRIVE and NORMAL communications, the MU sends an FS-IST question and, only in NORMAL communications, additionally also the value of the anti-bounce counter for wrong FS-IST answers on the MU (it is not necessary to send that value in PREDRIVE because then its value is 0).

Description:

The function incorporates the following requirements:

G33 Pre-processing of the FS-IST data received from MU

The inputs to this function are IDX_TEST_RCV_MC_FCT_SPC_IST, the question as it was sent from the MU (via the infrastructure) and, in NORMAL communications, ABC_RCV_MC_FCT_SPC_IST, the value of the anti-bounce counter on the MU used for debouncing wrongly answered FS-IST questions.

Since the first MU anti-bounce counter value is only sent in NORMAL communications but the initial value of 0 is already known and used in PREDRIVE, it is necessary to use the local identifier ABC_LID_MC_FCT_SPC_IST to be used in all other MC FS-IST functions both in PREDRIVE and NORMAL; this variable is initialised to 0 before the PREDRIVE communication and then updated with the actual value sent by the MU after NORMAL communications.

As for the question sent by the MU, it is more efficient to instead use the corresponding *question number* (which is nothing but the appropriate index into the array NC_IDX_TEST_MC_FCT_SPC_IST[] of questions on the MC), in particular to simplify handing data to level 2'. Therefore, a decode step has to be taken after received the question on the MC: the received question IDX_TEST_RCV_MC_FCT_SPC_IST is simply compared to all entries in the array NC_IDX_TEST_MC_FCT_SPC_IST[] in order to find whether the transmitted question does indeed correspond to a known index on the MC, which is then stored in IDX_NR_LID_MC_FCT_SPC_IST; in order to detect when this decoding step fails, IDX_NR_LID_MC_FCT_SPC_IST is initialised to a specific value, NC_IDX_NR_WRG_MC_FCT_SPC_IST, indicating an invalid question number, and if no corresponding question number is found, this remains the value of IDX_NR_LID_MC_FCT_SPC_IST.

In this way, after both PREDRIVE and NORMAL communication(s), all data are always present for the other FS-IST functions.

Application conditions:

Initialisation: */* Initialise the value of the MU anti-bounce counter sent by the MU */*

ABC_RCV_MC_FCT_SPC_IST = 0;

/ Initialise the value of the MU anti-bounce counter on the MC */*

ABC_LID_MC_FCT_SPC_IST = 0;

/ Initialise question number for question sent by MU to wrong number */*

IDX_NR_LID_MC_FCT_SPC_IST = NC_IDX_NR_WRG_MC_FCT_SPC_IST;

/ Initialise index number */*

IDX_NR = 0;

/ Initialise question sent by MU */*

IDX_TEST_RCV_MC_FCT_SPC_IST = 0;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **formula section** shall be **executed after the functions “Communication monitoring and evaluation of received data in PREDRIVE state” and “Communication monitoring and evaluation of received data in NORMAL state” have been finished**.

```

12.9.2 Test of MU reaction to wrong FS-IST answers

FUNCTION DESCRIPTION:

General information:

This sub-function, under certain conditions, indicates (to the post-processing sub-function) a deliberate sending of wrong FS-IST answers to the MU, similar to PFM, with the goal to test whether the MU, after an appropriate delay, reacts to the received wrong answer by sending an increased anti-bounce counter and repeating the wrongly answered question.

This sub-function is executed after the pre-processing function.

Description:

The function incorporates the following requirements:

G34 Test of MU reaction to wrong FS-IST answers

After the data received from the MU have been decoded and pre-processed, the newly received information (in particular about the value of the FS-IST anti-bounce counter on the MU) is used to determine whether it is possible to send a deliberately wrong FS-IST answer in the current system state.

In addition to the anti-bounce counter information from the MU, this system state includes the value of a test cycle counter TCC_MC_FCT_SPC_IST_WRG_RESP counting the number of times the function gets activated. There are two significant values of this counter, viz., NC_TCC_MC_IST_WRG_RESP_REQ and NC_TCC_MC_IST_WRG_RESP_CHK: the former means that sending a wrong answer is requested (this will eventually prompt setting a flag influencing the post-processing sub-function to export a bad answer); the latter value means that it is time to check whether the MU has reacted to a previously sent deliberately wrong answer (one has to allow for some delay because the MU only sends a new question every second communication cycle; consequently, the two values must necessarily be different). If the counter reaches a certain number then it is re-started, eventually triggering a new cycle of another wrong answer, check MU reaction to that and so on.

The sub-function consists of several sequential sub-tasks:

1. find out whether the MU anti-bounce counter sticks to a non-zero value (deploying a saved copy of its previous value);
2. test whether the MU has reacted (i.e., increased the anti-bounce counter accordingly) if the test cycle counter has reached value NC_TCC_MC_IST_WRG_RESP_CHK; this test also checks whether the MU anti-bounce counter sticks to 0 (complementing the previous test);
3. initiate sending a deliberately wrong FS-IST answer if the test cycle counter has reached value NC_TCC_MC_IST_WRG_RESP_REQ;
4. increase the value of the test cycle counter (including re-starting the counter when it is has reached its end value).

These sub-tasks shall be performed in this order; note that the second and third task cannot be activated at the same time anyway because their activation conditions are that the test cycle counter reaches two distinct values. As a consequence, they will be specified in one common formula section.

Note that for sub-task 3, (potentially) initiating the sending of a wrong FS-IST answer to the MU, is only performed of the MU anti-bounce counter is equal to 0, much like in the corresponding PFM functionality: sending a deliberately wrong answer must not trigger fault reaction. As a consequence, if the test cycle counter indicates that the MU should have reacted to a wrong answer (sub-task 2), it is tested whether the MU anti-bounce counter has value 2 which corresponds to exactly one increase of the MU anti-bounce counter (caused by the *deliberately* wrong answer).

It should furthermore be noted that, if during sub-task 2, it is found that the anti-bounce counter does not have the expected value, a wrong answer shall again be sent (this is achieved by setting the flag LV_MC_FCT_SPC_IST_WRG_RESP_ACT) and the test cycle counter shall be decrease by 1; the latter action is done because in sub-task 4, the test cycle counter is *unconditionally* increase by 1 so in the mentioned error case, the counter will, after the increase, still have value NC_TCC_MC_IST_WRG_RESP_CHK, i.e., after the next activation of the FS-IST, it will again be checked whether the MU has reacted to the wrong answer.

Application conditions:

Initialisation: *[/* FS-IST to be activated */]*

```
/* FS-IST to be activated */
LV_MC_FCT_SPC_IST_ACT = 1;
/* Initialise saved value of MU anti-bounce counter */
ABC_LID_MC_FCT_SPC_IST_OLD = 0;
```

/ Initially deactivate sending of wrong responses */*

LV_MC_FCT_SPC_IST_WRG_RESP_ACT = 0;

/ Initially set test cycle counter to requesting a wrong response */*

TCC_MC_FCT_SPC_IST_WRG_RESP =
NC_TCC_MC_IST_WRG_RESP_REQ

Recurrence: The **initialisation** shall be **performed after each power-up or reset**.

The **formula section** shall be **executed after the FS-IST sub-function "Pre-processing of FS-IST data received from MU" has been finished.**

Activation: (LV_MC_FCT_SPC_IST_ACT = 1) **OR** ("MU configured for TCU mode")

Deactivation: Otherwise

Formula section:

    /* Sub-task 4: increase test cycle counter (including re-starting the counter) */
    TCC_MC_FCT_SPC_IST_WRG_RESP =
                        (TCC_MC_FCT_SPC_IST_WRG_RESP + 1)
                MOD     NC_TEST_REC_IDX_MAX_MON2 + 4;
    /* Note that still LV_MC_FCT_SPC_IST_ACT = 1, i.e., the FS-IST is still active! */
```

12.9.3 Monitoring of FS-IST questions sent by MU

FUNCTION DESCRIPTION:

General information:

This sub-function monitors the sending of questions by the MU by comparing the question number corresponding to the actually sent question (in case it could be decoded) with a *predicted* question number (obtained as a function of the previous question number, plus the current and the saved state of the MU anti-bounce counter). In case of a discrepancy, a debounced fault reaction will be the result.

Description:

The function incorporates the following requirements:

G35 Monitoring of FS-IST questions sent by MU

After the data received from the MU have been pre-processed, in particular the newly sent question has been translated (if possible) into the matching question number on the MC, this function first predicts the expected question number; inputs for this are the previous, saved question number IDX_NR_LID_MC_FCT_SPC_IST_OLD, the current state of the MU anti-bounce counter ABC_LID_MC_FCT_SPC_IST, and the saved value ABC_LID_MC_FCT_SPC_IST_OLD of the MU anti-bounce counter, and the result of the prediction is stored in IDX_NR_LID_MC_FCT_SPC_IST_PRED.

Once the predicted question number has been obtained, a range check is performed for this decoded question number; in case it is found to be out of range (which means that the decode process detected an invalid question to which no matching question number could be found), a debounced fault reaction shall be performed and the *predicted* question number shall be saved (it is no use to save the invalid question number because the next prediction has to be based on a valid question number; moreover, the predicted question number is the one that should have been sent in the first place).

If the range check was successful, the predicted question number is compared with the decoded question number. If the two numbers disagree, a debounced fault reaction shall be performed, using the actions ACTION_ECM3_McIncAbc and ACTION_ECM3_McDecAbc, the anti-bounce counter NC_ABC_MC_WRG_IDX and (potentially) the error code NC_ERR_COD_MC_WRG_IDX. The difference to the previous case with the failed range check is the fact that in this case, the decoded question number will, despite not being the expected one, still be used as the basis for the next prediction: after all, it is a valid question number sent by the MU and it reflects the internal state of the MU (at least from the point of view of FS-IST). If the prediction for the next question number is to have any chance of being accurate, the decoded value has to be used because also the MU bases its internal calculation on it.

Note that the saved question number is initialised to the maximal question number because then it is only necessary to increase it by 1 (modulo the maximal question number, i.e., 0) to obtain the predicted question number in case the MU anti-bounce counter has current value 0 - as is the case in PREDRIVE when the function is active for the first time, and so the initial case does not require special treatment but can be handled just like any other case.

Now back to the calculation of the predicted question number. There are several cases, all distinguished by the interplay between saved value (ABC_LID_MC_FCT_SPC_IST_OLD) and newly transmitted value (ABC_LID_MC_FCT_SPC_IST) of the MU anti-bounce counter:

1. **ABC_LID_MC_FCT_SPC_IST ≤ 1:**

   Then no error is present on the MU, hence the MU should send the next question, i.e.,

   IDX_NR_LID_MC_FCT_SPC_IST_PRED =
   (IDX_NR_LID_MC_FCT_SPC_IST_OLD + 1)
   MOD NC_TEST_REC_IDX_MAX_MON2,

   as always during normal operation (the modulo-operation is necessary to avoid overflows of the predicted question number); the fact that less than or equal to 1 is tested is connected to the fact that the MU repeats a wrongly answered question until this condition for its FS-IST anti-bounce counter is satisfied;

2. **(ABC_LID_MC_FCT_SPC_IST_OLD = 0) AND (ABC_LID_MC_FCT_SPC_IST = 2):**

   This case expresses the fact that an error was detected on the MU between the last and the current activation of the FS-IST on the MC; consequently, it is expected that the MU simply repeats the wrongly answered question number, i.e.,

   IDX_NR_LID_MC_FCT_SPC_IST_PRED =
   (IDX_NR_LID_MC_FCT_SPC_IST_OLD - 1)
   (for IDX_NR_LID_MC_FCT_SPC_IST_OLD > 0)

   and

   IDX_NR_LID_MC_FCT_SPC_IST_PRED =
   NC_TEST_REC_IDX_MAX_MON2 - 1;
   (for IDX_NR_LID_MC_FCT_SPC_IST_OLD = 0)

   repeating the wrongly answered question means expecting the predecessor of the current question number because of the timing of fault detection in the FS-IST: in a certain communication, the MU receives an FS-IST answer *A(i)* from the MC to a question *Q(i)* with number *i* and, due to the bidirectional nature of the communication interface between MC and MU, in the very same communication it sends out the next question *Q(i+1)* (as the MU must assume that the received answer is correct because of system robustness issues); consequently, after the next activation of the FS-IST functions on the MC after this communication, *i+1* is stored in IDX_NR_LID_MC_FCT_SPC_IST_OLD; in the meantime, the MU has detected that *A(i)* was wrong: a debounced fault reaction is the consequence (responsible for the checked increase of the MU anti-bounce counter from 0 to 2), and in the next communication, the MU will repeat the question *Q(i)*, i.e., exactly as expressed in the formula for the predicted question number above;

3. **Otherwise (meaning that the current value is >1 and the saved value is >0):**

   This means that the MU will repeat the same question number as the saved one, i.e., IDX_NR_LID_MC_FCT_SPC_IST_PRED = IDX_NR_LID_MC_FCT_SPC_IST_OLD, and the explanation is similar to the previous case: the constellation of saved and current value for the MU anti-bounce counter can only be present if there has been an error on the MU but not in the last communication because otherwise, the save value of the MU anti-bounce counter would be 0 (the previous case); consequently, the MU has already started to repeat a wrongly answered question, and *will continue to do so* until its anti-bounce counter reaches 1 (cf. the first case); hence it is expected to receive the same question number as in the communication before.

Application conditions:

Initialisation: *\/* Initialise predicted question number *\/*

IDX_NR_LID_MC_FCT_SPC_IST_PRED = 0;

/ Initialise saved question number to last question number (see above) */*

IDX_NR_LID_MC_FCT_SPC_IST_OLD =
NC_TEST_REC_IDX_MAX_MON2;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function** shall be performed **after the function "Pre-processing of FS-IST data received from MU" has been finished** *(it may run in parallel to the test whether the MU reacts to wrongs FS-IST answers)*.

Activation: (LV_MC_FCT_SPC_IST_ACT = 1) **OR** ("MU configured for TCU mode")

Deactivation: Otherwise

12.9.4 Export of the question number to level 2'

FUNCTION DESCRIPTION:

General information:

This sub-function provides the question number to level 2' after all the required sub-functions have been activated; before calling level 2', a range check for the to-be-exported data is performed, and level 2' is not called in case the range check fails.

Description:

This sub-function incorporates the following requirements:

G36 Export of the question number to level 2'

R36_1: The current value ABC_LID_MC_FCT_SPC_IST of the MU anti-bounce counter shall be saved as ABC_LID_MC_FCT_SPC_IST_OLD for the next FS-IST activation.

R36_2: The current question number IDX_NR_LID_MC_FCT_SPC_IST shall be assigned to the variable TEST_REC_IDX_MON2 to be exported to level 2'.

R36_3: A range check on the latter value shall be performed (in order to avoid an invalid value to be exported to level 2', in particular if it was not possible to decode the question sent by the MU; cf. G33).

R36_4: If the range check was successful, TEST_REC_IDX_MON2 shall be handed over to level 2', otherwise nothing is done: level 2' need not be activated with an invalid value (unnecessary computations), and there is no default value for it either (it is not clear what the MU expects in answer to a corrupted question).

Application conditions:

Initialisation: */* Initialise exported question number to invalid value */*

TEST_REC_IDX_MON2 = NC_IDX_NR_WRG_MC_FCT_SPC_IST;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**

. The **function itself** shall be performed **after both FS-IST functions "Test of MU reaction to wrong FS-IST answers" and "Monitoring of FS-IST questions sent by MU" have been finished**.

Activation: (LV_MC_FCT_SPC_IST_ACT = 1) **OR** ("MU configured for TCU mode")

Deactivation: Otherwise

12.9.5 Export of the question number to level 2' (second calculation)

FUNCTION DESCRIPTION:

General information:

This sub-function provides the question number to level 2' after all the required sub-functions have been activated; before calling level 2', a range check for the to-be-exported data is performed, and level 2' is not called in case the range check fails.

Description:

This sub-function incorporates the following requirements:

G62 Export of the question number to level 2' (second calculation)

R62_1: The current question number IDX_NR_LID_MC_FCT_SPC_IST shall be assigned to the variable TEST_REC_IDX_MON2 to be exported to level 2'.

R62_2: A range check on the latter value shall be performed (in order to avoid an invalid value to be exported to level 2', in particular if it was not possible to decode the question sent by the MU; cf. G33).

R62_3: If the range check was successful, TEST_REC_IDX_MON2 shall be handed over to level 2', otherwise nothing is done: level 2' need not be activated with an invalid value (unnecessary computations), and there is no default value for it either (it is not clear what the MU expects in answer to a corrupted question).

Application conditions:

Initialisation:	-
Recurrence:	The **function** shall be executed **after both FS-IST functions "Test of MU reaction to wrong FS-IST answers" and "Monitoring of FS-IST questions sent by MU" have been finished (even if they were not activated)**.
Activation:	(LV_MC_FCT_SPC_IST_ACT = 0) **AND** ("MU not configured for TCU mode") */* note that this function is executed in those recurrences of Processor Monitoring where G36 is **not** executed */*
Deactivation:	Otherwise

12.9.6 Decoding of the result of the level 2' test calculation

FUNCTION DESCRIPTION:

General information:

This sub-function decodes the result of the test calculation from level 2' (a 16bit value) into an answer number that can then be used for generating the actual FS-IST answer sent to the MU (a 6bit value).

Description:

The sub-function incorporates the following requirements:

G37 Decoding of the result of the level 2' test calculation

R37_1: After finishing, the test calculation of level 2' shall export its result in the 16bit value RESP_MON2 (note: this is an *answer*, not an *answer number*, similar to the distinction between question and question number; RESP_MON2 cannot be sent to the MU directly: the 16bit value would not fit into the 6bit reserved in the communication protocol for the FS-IST answer from the MC; consequently, a decoding process, like the decoding of the MU question, has to be performed before the actual FS-IST answer can be obtained).

R37_2: The decoding process is performed utilising the 'conversion table' ID_RESP_MON2 and its axis LDPM_TEST_REC_IDX_MON2:
R37_2.1: the answer number IDX_NR_RESP_MC_FCT_SPC_IST shall be initialised to the invalid number NC_IDX_NR_WRG_MC_FCT_SPC_IST;
R37_2.2: then IDX_NR_RESP_MC_FCT_SPC_IST runs through the table ID_RESP_MON2 (using LDPM_TEST_REC_IDX_MON2) and an index is sought such that a lookup at that index in the conversion table ID_RESP_MON2 yields RESP_MON2 as the result;
R37_2.3: in this way, if an index into ID_RESP_MON2 corresponding to RESP_MON2 is found, IDX_NR_RESP_MC_FCT_SPC_IST is assigned this value or, if the level 2' response could not be decoded (i.e., if there is no matching table entry), IDX_NR_RESP_MC_FCT_SPC_IST is not updated and keeps the invalid number NC_IDX_NR_WRG_MC_FCT_SPC_IST as value (this information can then be used in the subsequent post-processing sub-function).

Application conditions:

Initialisation: */* Initialise answer number to wrong number */*

IDX_NR_RESP_MC_FCT_SPC_IST =
NC_IDX_NR_WRG_MC_FCT_SPC_IST;

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** shall be executed **after the FS-IST sub-function "Export of the question number to level 2'" has been finished**.

Activation: (LV_MC_FCT_SPC_IST_ACT = 1) **OR** ("MU configured for TCU mode")

Deactivation: Otherwise

12.9.7 Decoding of the result of the level 2' test calculation (second calculation)

FUNCTION DESCRIPTION:

General information:

This sub-function decodes the result of the test calculation from level 2' (a 16bit value) into an answer number that can then be used for generating the actual FS-IST answer sent to the MU (a 6bit value).

This is done for the "second calculation" with the same question number. It is necessary to store whether the result was correct or not; for this, we have to ensure that

TEST_REC_IDX_MON2 is valid since otherwise level2' would not have been activated (hence we have to perform a range check on TEST_REC_IDX_MON2).

Description:

The sub-function incorporates the following requirements:

G63 Decoding of the result of the level 2' test calculation (second calculation)

R63_1: After finishing, the test calculation of level 2' shall export its result in the 16bit value RESP_MON2 (note: this is an *answer*, not an *answer number*, similar to the distinction between question and question number; RESP_MON2 cannot be sent to the MU directly: the 16bit value would not fit into the 6bit reserved in the communication protocol for the FS-IST answer from the MC; consequently, a decoding process, like the decoding of the MU question, has to be performed before the actual FS-IST answer can be obtained).

R63_2: The decoding process is performed utilising the 'conversion table' ID_RESP_MON2 and its axis LDPM_TEST_REC_IDX_MON2:
R63_2.1: the answer number IDX_NR_RESP_MC_FCT_SPC_IST shall be initialised to the invalid number NC_IDX_NR_WRG_MC_FCT_SPC_IST;
R63_2.2: then IDX_NR_RESP_MC_FCT_SPC_IST runs through the table ID_RESP_MON2 (using LDPM_TEST_REC_IDX_MON2) and an index is sought such that a lookup at that index in the conversion table ID_RESP_MON2 yields RESP_MON2 as the result;
R63_2.3: in this way, if an index into ID_RESP_MON2 corresponding to RESP_MON2 is found, IDX_NR_RESP_MC_FCT_SPC_IST is assigned this value or, if the level 2' response could not be decoded (i.e., if there is no matching table entry), IDX_NR_RESP_MC_FCT_SPC_IST is not updated and keeps the invalid number NC_IDX_NR_WRG_MC_FCT_SPC_IST as value (this information can then be used in the subsequent post-processing sub-function).

R63_3: After the decoding, if

- TEST_REC_IDX_MON2 is in range *(level 2' has in fact been activated with a defined question number)*, **AND**
- IDX_NR_RESP_MC_FCT_SPC_IST <> TEST_REC_IDX_MON2 *(the answer number from level 2' does not correspond to current (valid!) question, e.g., if the level2' answer RESP_MON2 could not be found in ID_RESP_MON2)*, **AND**
- IDX_NR_ERR_MC_FCT_SPC_IST is out of range, i.e., it has a value not between 0 and NC_TEST_REC_IDX_MAX_MON2-1 *(no "second calculation" has failed previously; this is done to repeat the* first *wrongly answered "second calculation")*,

IDX_NR_ERR_MC_FCT_SPC_IST shall be set to TEST_REC_IDX_MON2 *(storing the (valid!) question number for which the second calculation failed for later reference; by the previous conditions, this is the smallest/earliest question number for which the "second calculation" failed)*; otherwise, nothing shall be done *(in particular, if IDX_NR_ERR_MC_FCT_SPC_IST is in range, it shall stay unchanged in order to remember the* first *question number for which the "second calculation" failed)*

Application conditions:

Initialisation: *\/* Initialise index for wrong second calculation to invalid number *\/*

```
IDX_NR_ERR_MC_FCT_SPC_IST =
        NC_IDX_NR_WRG_MC_FCT_SPC_IST;
```

Recurrence: The **initialisation** shall be performed **after each power-up or reset**.

The **function itself** shall be executed **after the FS-IST sub-function "Export of the question number to level 2' (second calculation)" has been finished**.

Activation: (LV_MC_FCT_SPC_IST_ACT = 0) **AND** ("MU not configured for TCU mode") */* note that this function is executed in those recurrences of Processor Monitoring where G37 is **not** executed */*

Deactivation: Otherwise

12.9.8 Post-processing of the FS-IST data on MC for transmission to MU

FUNCTION DESCRIPTION:

General information:

This sub-function performs the necessary post-processing steps regarding the FS-IST on the MC, most importantly sending of a wrong answer if this has previously been requested (whether deliberately, because the redundant switch-off path was triggered, or because any of the decoding steps has failed), and toggling the activation condition for the FS-IST (which is only activated every second communication cycle).

Description:

The sub-function incorporates the following requirements:

G38 Post-processing of the FS-IST data on MC for transmission to MU

R38_1: If any of the following errors is active:
- the redundant switch-off path has been triggered (LV_MC_DR_OFF = 1, LV_MC_DR_OFF_CPL = 0, checked using the RAM check service actions), or
- a deliberately wrong answer shall be sent to the MU (LV_MC_FCT_SPC_IST_WRG_RESP_ACT = 1), or
- the current MU question could not be decoded properly (TEST_REC_IDX_MON2 = NC_IDX_NR_WRG_MC_FCT_SPC_IST), or
- the current level 2' answer could not be decoded properely (IDX_NR_RESP_MC_FCT_SPC_IST = NC_IDX_NR_WRG_MC_FCT_SPC_IST), or
- the current question has been answered wrongly during the last "second calculation" (IDX_NR_RESP_MC_FCT_SPC_IST = IDX_NR_ERR_MC_FCT_SPC_IST),

then a wrong answer shall be sent to the MU, calling the infrastructure action ACTION_INFR_McSendFsistResp() with NC_IDX_RESP_WRG_MC_FCT_SPC_IST as parameter.

R38_2: Otherwise, in case no error has been detected, the corresponding entry in the "answer array" NC_IDX_RESP_MC_FCT_SPC_IST[] shall be sent to the MU, calling the infrastructure action ACTION_INFR_McSendFsistResp() with NC_IDX_RESP_MC_FCT_SPC_IST[IDX_NR_RESP_MC_FCT_SPC_IST] as parameter.

R38_3: Finally, the active flag LV_MC_FCT_SPC_IST_ACT shall be toggled so that a new answer is only sent in the communication after the next communication cycle.

R38_4: The value of LV_MC_DR_OFF shall be written to the infrastructure using the action ACTION_INFR_McSendDrOff() so that it can be transmitted to the MU in NORMAL communications.

R38_5: The flag LV_MC_FCT_SPC_IST_WRG_RESP_ACT shall be reset to stop deliberately sending a wrong response.

R38_6: If IDX_NR_ERR_MC_FCT_SPC_IST = IDX_NR_RESP_MC_FCT_SPC_IST, IDX_NR_ERR_MC_FCT_SPC_IST shall be re-set to NC_IDX_NR_WRG_MC_FCT_SPC_IST *(a wrong answer for the previously "remembered" question number where the "second calculation" failed shall be sent to MU so the question will be repeated by the MU and hence the "marker" can be re-set to its initial value)*.

Application conditions:

Initialisation:	-
Recurrence:	The **function** shall be **executed after all other FS-IST sub-functions have been finished**.
Activation:	(LV_MC_FCT_SPC_IST_ACT = 1) **OR** ("MU configured for TCU mode")
Deactivation:	Otherwise

12.10 MC Error Memory Management of Processor Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_RST_ERR_MEM_ACT	V/S	0...FFH	0...255	1	[-]
Local variable: current value of reset counter for error memory management, plus potentially additional information					
CTR_RST_ERR_MEM_OLD	V/S	0...FFH	0...255	1	[-]
Local variable: old value of reset counter for error memory management, plus potentially additional information					
ERR_COD_ERR_MEM_ACT	V/S	0...1FH	0...31	1	[-]
Local variable: current value of error code for error memory management					
LV_MC_CPT_ERR_MEM_ACT	V/S	0...1H	0...1	1	[-]
Local variable: flag indicating whether the current error code for error memory management belongs to MC (=1) or MU(=0)					
ERR_COD_ERR_MEM_OLD	V/S	0...1FH	0...31	1	[-]
Local variable: old value of error code for error memory management					
LV_MC_CPT_ERR_MEM_OLD	V/S	0...1H	0...1	1	[-]
Local variable: flag indicating whether the old error code for error memory management belongs to MC (=1) or MU(=0)					
STATE_ERR_IDC_ERR_MEM_ACT	V/S	0...3H	0...3	1	[-]
Local variable: current error indication for error memory management

NC_STATE_MC_PRDR	NC_STATE_MC_NORM	NC_STATE_MC_NOT_VLD	LV_ABC_MC_ERR_COM
LV_ABC_MC_ERR_PFM	LV_ABC_MC_ERR_FCT_SPC_IST	LV_ABC_MC_ERR_PFM_6	

Export actions:

ACTION_ECM3_McSetErrmUpdateFlag(IN <cpt>)
This action sets the update flag LV_MC_UPD_ERR_MEM_cpt (=0 means MU, =1 means MC) for error memory information.

Import actions:

ACTION_ECM3_ReadChkCpl(OUT <>, IN <>, IN <>)
ACTION_ECM3_McReadChkCpl(OUT <>, IN <>, IN <>, IN <>)
ACTION_ECM3_WriteChkCpl(INOUT <>, OUT <>, IN <>)
ACTION_ECM3_ChkCpl(IN <>, IN <>)
ACTION_ECM3_McReadChkState(OUT <>)
ACTION_ECM3_McErrmService(IN <>, IN <>, IN <>, IN <>, IN <>, IN <>, IN <>, IN <>)

Note: the last action is defined in the application incidences and hence its functional content can be adjusted to project-specific needs/requirements.

FUNCTION DESCRIPTION:

General information:

This module serves as the interface between the processor monitoring and the error memory management: as such, it provides an action call by which the current error information (error code, error indication, reset counter, and whether the data stem from MC or MU) get stored in a history-like fashion; furthermore, an action is imported (from the application incidences of processor monitoring to allow project-specific adaptations to different error memory concepts) and called after the saved values have been updated; this imported action performs the actual triggering of the error memory management with the current failure state.

Description:

The module provides the action ACTION_ECM3_McSetErrmUpdateFlag() which sets one of the update flags LV_MC_UPD_ERR_MEM_MC and LV_MC_UPD_ERR_MEM_MU, depending on the value of its argument.

This flag then, in turn, serves as (one of) the activation condition(s) for the functions described here, which then create/continue an error history using the variables in the output table.

The error history records which component has triggered the update of error memory information: the MC in INIT and after a fault reaction leading to permanent disabling of the power stages; the MU after a successful CONFIG communication and after receiving a DISABLE header from the MU in a state different from DISABLE.

The history stores the current value of reset counter, error code, error indication, and component (MC or MU), plus the corresponding old values (the length of the history is only two).

After the history is potentially updated, the project-specific function ACTION_ECM3_McErrmService(), which is imported from the application incidences (where it is defined), shall be called; this is taken care of by another sub-function, since the action shall be called *always* even when none of the update functions is actually executed due to unsatisfied activation conditions: this is necessary to inform the error memory management not only in the case that an error is present but also in the case that no error is present.

Description of ACTION_ECM3_McSetErrmUpdateFlag

Description:

Syntax:	ACTION_ECM3_McSetErrmUpdateFlag (IN <cpt>)	
Parameter (IN):	cpt	Component: 0 means MU, 1 means MC
Short description:	This action sets one of the two flags LV_MC_UPD_ERR_MEM_MU (if cpt = 0) or LV_MC_UPD_ERR_MEM_MC (if cpt = 1); note that only setting the flag is prompted by other modules, the actual update of the data is done in this module (using the flags as activation conditions).	

Application conditions:

Initialisation: After power-up:

/ Initialise the information for error memory management */*

```
CTR_RST_ERR_MEM_ACT = 0;
CTR_RST_ERR_MEM_OLD = 0;
ERR_COD_ERR_MEM_ACT = NC_ERR_COD_MC_NOT_ERR;
ERR_COD_ERR_MEM_OLD = NC_ERR_COD_MC_NOT_ERR;
STATE_ERR_IDC_ERR_MEM_ACT =
                              NC_STATE_IDC_MC_NOT_PRES;
STATE_ERR_IDC_ERR_MEM_OLD =
                              NC_STATE_IDC_MC_NOT_PRES;
LV_MC_CPT_ERR_MEM = 0;
LV_MC_CPT_ERR_MEM_OLD = 0;
LV_MC_UPD_ERR_MEM_MC = 0;
LV_MC_UPD_ERR_MEM_MU = 0;
```

After reset:

/ No initialisation of error memory data necessary, update will be performed, if necessary, by means of an action call */*

```
LV_MC_UPD_ERR_MEM_MC = 0;
LV_MC_UPD_ERR_MEM_MU = 0;
```

Recurrence: The **initialisation** shall be **performed after each power-up or reset**.

Activation: -

Deactivation: -

12.10.1 Update of error memory information with MU data

FUNCTION DESCRIPTION:

General information:

This sub-function describes when and how the error history for the error memory gets updated with new data from the MU.

There are two cases for this:

1. after a successful CONFIG communication, when the error information sent from the MU have been evaluated on the MC (including the treatment of under- and over-voltage having been detected on the MU);
2. after a successful communication in which the MU sent a DISABLE header while the MC was (prior to the communication) not yet in DISABLE, and the error information sent from the MU has been evaluated on the MC.

Since the subsequent actions are slightly different and would only lead to complicated case distinctions, the two cases will be represented by two sub-functions.

12.10.1.1 Update of error memory information with MU data after CONFIG communication

FUNCTION DESCRIPTION:

General information:

This sub-function describes how the error memory gets updated with new data from the MU after a successful CONFIG communication, taking into account potentially set under-/over-voltage flags.

Description:

The function incorporates the following requirements:

G39 Update of error memory information with MU data after CONFIG communication

R39_1: If

- **LV_MC_V_L_DET_MU =1** or **LV_MC_V_L_DET_MU =1** *(i.e., a voltage monitoring error has been detected by the MU before the previous reset)*, and
- the _ACT-variables *(describing the most recently stored error)* indicate an error which is **different from the same (combination of) voltage monitoring error(s) as currently detected by the MU** (*i.e., LV_MC_CPT_ERR_MEM_ACT <> 0 or ERR_COD_ERR_MEM_ACT not equal to NC_ERR_COD_MU_V_L, NC_ERR_COD_MU_V_H, or NC_ERR_COD_MU_V_L_H, respectively, depending on the three possible combinations where at least one of the two flags is set)*:

R39_1.1: the values of the _ACT-variables of error memory information shall be saved in the corresponding _OLD-variables;
R39_1.2: ERR_COD_ERR_MEM_ACT shall be set to NC_ERR_COD_MU_V_L, NC_ERR_COD_MU_V_H, or NC_ERR_COD_MU_V_L_H, respectively, depending on the three possible combinations where at least one of the two flags is set;
R39_1.3: CTR_RST_ERR_MEM_ACT shall be set to 0;
R39_1.4: STATE_ERR_IDC_ERR_MEM_ACT shall be set to NC_STATE_IDC_MC_NOT_PRES;
R39_1.5: LV_MC_CPT_ERR_MEM_ACT shall be set to 0, i.e., the active component shall be set to MU.

R39_2: If R39_1 does not apply but:

- **LV_MC_CPT_ERR_MEM_ACT <> 0** *(most recently stored error not an MU error)*, or
- **ERR_COD_ERR_MEM_ACT <> ERR_COD_MU** *(most recently stored error has different error code)*, or
- **CTR_RST_ERR_MEM_ACT (four LSBs) > CTR_RST_MU** *(most recently stored reset counter greater than current reset counter on MU, i.e., even though potentially the same error has occurred again, the decreased actual value of the reset counter indicates that the reset counter must have healed in between)*:

R39_2.1: the values of the _ACT-variables of error memory information shall be saved in the corresponding _OLD-variables;
R39_2.2: the values of ERR_COD_MU, STATE_ERR_IDC_MU, and CTR_RST_MU shall be saved to the _ACT-variables, and the active component shall be set to MU, i.e., LV_MC_CPT_ERR_MEM_ACT shall be set to 0.

R39_3: If R39_1 and R39_2 both do not apply but **CTR_RST_ERR_MEM_ACT (four LSBs) < CTR_RST_MU** *(i.e., the same MU error has occurred at least one more time which led to the increment of the reset counter since the storage)*, then the _ACT-variables shall be updated with the values of ERR_COD_MU, STATE_ERR_IDC_MU, and CTR_RST_MU, and LV_MC_CPT_ERR_MEM_ACT shall be set to 0, i.e., the active component shall be set to MU.

R39_4: The update flag LV_MC_UPD_ERR_MEM_MU shall be reset.

Application conditions:

Initialisation:	-
Recurrence:	The function shall be executed after the function "Evaluation of error information from MU on MC" (when potentially new data from the MU are available on the MC).
Activation:	(STATE_MC = NC_STATE_MC_CONF) **AND** (LV_MC_UPD_ERR_MEM_MU = 1) **AND** ((STATE_ERR_IDC_MU <> NC_STATE_ERR_IDC_MC_NOT_PRES) **OR** (LV_V_L_DET_MU = 1) **OR** (LV_V_H_DET_MU = 1)) *(only active in CONFIG if update flag for MU is set and if any of the following conditions is true: the error indication of the MU is different from "no error present"; the UVD flag is set; the OVD flag is set)*
Deactivation:	Otherwise

12.10.1.2 Update of error memory information with MU data after DISABLE communication

FUNCTION DESCRIPTION:

General information:

This sub-function describes how the error memory gets updated with new data from the MU after a successful communication in which the MU sent a DISABLE header but the MC was, prior to the communication, not in DISABLE state (meanwhile, it is also in DISABLE).

Description:

The function incorporates the following requirements:

G40 Update of error memory information with MU data after DISABLE communication

R40_1: If
- **LV_MC_CPT_ERR_MEM_ACT <> 0** *(most recently stored error not an MU error)*, or
- **ERR_COD_ERR_MEM_ACT <> ERR_COD_MU** *(most recently stored error has different error code)*, or
- **CTR_RST_ERR_MEM_ACT (four LSBs) > CTR_RST_MU** *(most recently stored reset counter greater than counter on MU, i.e., even though potentially the same error has occurred again, the decreased actual value of the reset counter indicates that the reset counter must have healed in between)*

R40_1.1: the values of the _ACT-variables of error memory information shall be saved in the corresponding _OLD-variables;
R40_1.2: the values of ERR_COD_MU, STATE_ERR_IDC_MU, and CTR_RST_MU shall be saved to the _ACT-variables, and the active component shall be set to MU, i.e., LV_MC_CPT_ERR_MEM_ACT shall be set to 0.

R40_2: If R40_1 does not apply, but **CTR_RST_ERR_MEM_ACT (four LSBs) < CTR_RST_MU** *(i.e., the same MU error has occurred at least one more time which led to the increment of the reset counter since the storage)*, then the _ACT-variables shall be updated with the values of ERR_COD_MU, STATE_ERR_IDC_MU, and CTR_RST_MU, and LV_MC_CPT_ERR_MEM_ACT shall be set to 0, i.e., the active component shall be set to MU.

R40_3: The update flag LV_MC_UPD_ERR_MEM_MU shall be reset.

Application conditions:

Initialisation: -

Recurrence: The function shall be executed after the function "Evaluation of error information from MU on MC" (when potentially new data from the MU are available on the MC).

Activation: (STATE_MC = NC_STATE_MC_DI) **AND**
(LV_MC_UPD_ERR_MEM_MU = 1) **AND**
(STATE_ERR_IDC_MU <> NC_STATE_ERR_IDC_MC_NOT_PRES)
(only active in DISABLE if update flag for MU is set and error indication different from "no error present")

Deactivation: Otherwise

12.10.2 Update of error memory information with MC data

FUNCTION DESCRIPTION:

General information:

This sub-function describes when and how the error history for the error memory gets updated with new data from the MC.

There are two cases for this:
1. in INIT (potentially after the error indication has been changed from "ECU restart request" to "ECU restart was requested");
2. after a fault reaction on the MC leading to permanent disabling (i.e., CTR_RST_MC = NC_CTR_RST_MC_THD + 1, error indication "disable request").

In the first case, the update function is only called if the error indication is different from "no error present". Note that this condition is also satisfied in the second case, and in both cases, the update flag LV_MC_UPD_ERR_MEM_MC has been set by the corresponding modules ("State of fault reaction and up-to-dateness of error code" and "Central fault reaction", respective).

Consequently, the activation conditions for the function are that LV_MC_UPD_ERR_MEM_MC is set and that the error indication is different from "no error present."

Description:

The function incorporates the following requirements:

G41 Update of error memory information with MC data

R41_1: If
- **LV_MC_CPT_ERR_MEM_ACT <> 1** *(most recently stored error not an MC error)*, or
- **ERR_COD_ERR_MEM_ACT <> ERR_COD_MC** *(most recently stored error has different error code)*, or
- **CTR_RST_ERR_MEM_ACT (four LSBs) > CTR_RST_MC** *(most recently stored reset counter greater than counter on MC, i.e., even though potentially the same error has occurred again, the decreased actual value of the reset counter indicates that the reset counter must have healed in between)*:

R41_1.1: the values of the _ACT-variables of error memory information shall be saved in the corresponding _OLD-variables;
R41_1.2: the values of ERR_COD_MC, STATE_ERR_IDC_MC, and CTR_RST_MC (after a consistency check with its complement CTR_RST_MC_CPL using ACTION_ECM3_ReadChkCpl()) shall be saved to the _ACT-variables, and the active component shall be set to MC, i.e., LV_MC_CPT_ERR_MEM_ACT shall be set to 1;
R41_1.3: if ERR_COD_MC = NC_ERR_COD_MC_SOPC *(i.e., an error in the switch-off path check was detected)*, IDX_STATE_SOPC shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs); IDX_STATE_SOPC shall be accessed using the RAM check service actions (complement check with IDX_STATE_SOPC_CPL);
R41_1.4: if ERR_COD_MC = NC_ERR_COD_MC_HD *(i.e., an invalid header-byte has been sent by the MU)*, the value of STATE_MU_TMP shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs); the value encoded in CTR_RST_ERR_MEM_ACT shall be as shown in the following table:

Value of STATE_MU_TMP	Encoded value (dec.)
NC_STATE_MC_CONF	1
NC_STATE_MC_PRDR	2
NC_STATE_MC_NORM	3
NC_STATE_MC_DI	4
NC_STATE_MC_NOT_VLD	5
00H	6
FFH	7

R41_1.5: if ERR_COD_MC <> NC_ERR_COD_MC_SOPC and ERR_COD_MC <> NC_ERR_COD_MC_HD *(i.e., neither an SOPC nor a header error has occurred)*, the flags LV_ABC_MC_ERR_COM, LV_ABC_MC_ERR_PFM, LV_ABC_MC_ERR_PFM_6 and LV_ABC_MC_ERR_FCT_SPC_IST shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs) as follows:

Bit 3	Bit 2	Bit 1	Bit 0
LV_ABC_MC_ERR_FCT_SPC_IST	LV_ABC_MC_ERR_PFM_6	LV_ABC_MC_ERR_PFM	LV_ABC_MC_ERR_COM

R41_2: If R41_1 does not apply but **CTR_RST_ERR_MEM_ACT (four LSBs) < CTR_RST_MC** *(i.e., the same MC error has occurred at least one more time which led to the increment of the reset counter since the storage)*:
R41_2.1: the _ACT-variables shall be updated with the values of ERR_COD_MC, STATE_ERR_IDC_MC, and CTR_RST_MC (after a consistency check with its complement CTR_RST_MC_CPL using ACTION_ECM3_ReadChkCpl()), and LV_MC_CPT_ERR_MEM_ACT shall be set to 1, i.e., the active component shall be set to 1;
R41_2.2: if ERR_COD_MC = NC_ERR_COD_MC_SOPC *(i.e., an error in the switch-off path check was detected)*, IDX_STATE_SOPC shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs); IDX_STATE_SOPC shall be accessed using the RAM check service actions (complement check with IDX_STATE_SOPC_CPL);
R41_2.3: if ERR_COD_MC = NC_ERR_COD_MC_HD *(i.e., an invalid header-byte has been sent by the MU)*, the value of STATE_MU_TMP shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs); the value encoded in CTR_RST_ERR_MEM_ACT shall be as shown in above table;

R41_2.4: if ERR_COD_MC <> NC_ERR_COD_MC_SOPC and ERR_COD_MC <> NC_ERR_COD_MC_HD *(i.e., neither an SOPC nor a header error has occurred)*, the flags LV_ABC_MC_ERR_COM, LV_ABC_MC_ERR_PFM, LV_ABC_MC_ERR_PFM_6 and LV_ABC_MC_ERR_FCT_SPC_IST shall be encoded into the four MSBs of CTR_RST_ERR_MEM_ACT (CTR_RST_MC uses only the four LSBs) as shown in the table above.

R41_3: The update flag LV_MC_UPD_ERR_MEM_MC shall be reset.

Application conditions:

Initialisation:	-
Recurrence:	After the functions "State of fault reaction and up-to-dateness of error code" and "Central fault reaction"
Activation:	(LV_MC_UPD_ERR_MEM_MC = 1) **AND** (STATE_ERR_IDC_MC <> NC_STATE_ERR_IDC_NOT_PRES)
Deactivation:	Otherwise

12.10.3 Activation of project-specific function calling the error memory management

FUNCTION DESCRIPTION:

General information:

This sub-function simply calls the project-specific function ACTION_ECM3_McErrmService() which uses hands error history to the error memory management and sets the necessary diagnosis flags.

The action shall be called every time when potentially an update of the error history could have been performed, regardless of an actual update; this is done because the error memory also needs to be informed of the case where *no* error is present/detected.

Description:

The sub-function incorporates the following requirements:

G42 Activation of project-specific function calling the error memory management

R42_1: The project-specific action ACTION_ECM3_McErrmService() shall be called in CONFIG or DISABLE with the complete error history after any of the update functions above has been called ***regardless of whether the update function actually was activated***.

R42_2: In DISABLE, ACTION_ECM3_McErrmService() shall only be called once.

Application conditions:

Initialisation: -

Recurrence: The function shall be called each time after one of the update functions could be have been activated, regardless of the actual activation of the update function.

Activation: (STATE_MC = NC_STATE_MC_CONF) **OR**
(STATE_MC = NC_STATE_MC_DI) **OR**
("LV_MC_UPD_ERR_MEM_MC or LV_MC_UPD_ERR_MEM_MU were previously set")
(activated only in CONFIG and DISABLE after an update function could have been called)

Deactivation: -

12.11 MC Processor Monitoring (Application Incidences)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_MON_3	O/V	0...1H	0...1	1	[-]
Error detected by processor monitoring					
LV_CDN_DIAG_MON_3	V	0...1H	0...1	1	[-]
Diagnosis condition for processor monitoring error					
LV_END_DIAG_MON_3	V	0...1H	0...1	1	[-]
Indicates that diagnosis has been finished					
ERR_SYM_MON_3	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Error symptom extracted from ERR_COD_MC and ERR_COD_MU					
ENVD_0_MON_3	O/V/S	0...FFH	0...255	1	[-]
Environmental data 0 for general processor monitoring error					
ENVD_1_MON_3	O/V/S	0...FFH	0...255	1	[-]
Environmental data 1 for general processor monitoring error

12.11.1 Generic configuration – Value assignment for configuration data

FUNCTION DESCRIPTION:

General information:

This section describes the value assignment for the generic (i.e., project-independent) configuration data of Processor Monitoring (e.g., header-bytes, error codes etc.) for engine management systems (EMSs).

THESE ASSIGNMENTS CANNOT BE CHANGED BY PROJECTS!

Value assignment for configuration data of processor monitoring on MC:

```
/* State machine */

NC_STATE_MC_INI = 241;        /* F1H */
NC_STATE_MC_CONF = 146;   /* 92H */
NC_STATE_MC_PRDR = 199;   /* C7 */
NC_STATE_MC_NORM = 173;  /* ADH */
NC_STATE_MC_DI = 59;          /* 3BH */
NC_STATE_MC_NOT_VLD = 2; /* 02H */

/* Compatibility information of MC */

NC_NR_MC_COMP = 0;

/* Value for calibration switch so that no fault reaction will be performed after a ROM error for
level 2 calibration data (NOT TAKEN INTO ACCOUNT IN PRODUCTION SOWFTARE!) */

NC_ERR_SWI_MC_LEVEL_2_CAL = 165 /* A5H */

/* Value for calibration switch so that no fault reaction will be performed after a ROM error for
level 2 code (NOT TAKEN INTO ACCOUNT IN PRODUCTION SOWFTARE!) */

NC_ERR_SWI_MC_LEVEL_2_COD = 165 /* A5H */

/* Threshold for reset counter for irreversibly disabling of power stages */

NC_CTR_RST_MC_THD = 7;

/* Error codes on MC*/

12.11.2 Project-specific configuration – Value assignment for configuration data

<u>FUNCTION DESCRIPTION:</u>

<u>General information:</u>

This section describes the value assignment for the project-specific configuration data of Processor Monitoring (e.g., configuration information for MU, etc.).

<u>Value assignment for configuration data of Processor Monitoring:</u>

/ Configuration */*

NLC_MU_MOD = 0; */* EMS */*
NLC_MU_IGN_KEY_ACQ = 1; */* HW acquisition */*
NLC_MU_POW_OFF_TMR_ENA = 0; */* POT inactive */*
NLC_MU_INJ_OFF_TMR_ENA = 1; */* IOT active */*

/ Common threshold for reset counter of MU and MC determining when error memory information shall be updated */*

NC_CTR_RST_THD_ERR_MEM = 1;

/ Maximal value for counter in check of MU readiness */*

NC_CTR_MU_READY_MAX = 3;

12.11.3 Project-specific configuration – Configuration of switch-off path check

<u>FUNCTION DESCRIPTION:</u>

<u>General information:</u>

This "sub-function" describes the configuration of the switch-off path check.

Description:

The function incorporates the following requirements:

G27 Configuration of switch-off path check

R27_1: The following system configuration is assumed:

- the **MC is only connected to power stage 1 (H-bridge)**; the check result for its switch-off path to power stage 0 (injection) shall always be 0;
- the **MU is connected to both power stages 0 and 1**.

R27_2: There are two final results:

- "**no engine start**" with representation NC_STATE_RESP_SOPC_DFCT (00H = 0) which shall simply trigger a fault reaction of processor monitoring by calling ACTION_ECM3_McFaultReaction() with error code NC_ERR_COD_MC_SOPC
- "**engine start**" with representation NC_STATE_RESP_SOPC_OK (FFH = 255) which shall prompt no reaction, i.e., the system starts up as usual.

R27_3 : The SOPC threshold NC_CTR_RST_MC_THD_SOPC for the reset counter is set to 0: the lookup for the final result shall always be performed in NC_RESP_SOPC_2[].

R27_4: The values in the array NC_RESP_SOPC_2[] shall correspond to the following start-up behaviour:

Index	**MC**		**MU**		**Result**
	PWS0	**PWS1**	**PWS0**	**PWS1**	
0	0	0	0	0	**no start**
1	0	0	0	1	**no start**
2	0	0	1	0	**no start**
3	0	0	1	1	**no start**
4	0	1	0	0	**no start**
5	0	1	0	1	**no start**
6	0	1	1	0	**start**
7	0	1	1	1	**start**
8	1	0	0	0	**no start**
9	1	0	0	1	**no start**
10	1	0	1	0	**no start**
11	1	0	1	1	**no start**
12	1	1	0	0	**no start**
13	1	1	0	1	**no start**
14	1	1	1	0	**no start**
15	1	1	1	1	**no start**

In the above table, the first column represents the index IDX_STATE_SOPC, while the next 4 columns represent the feedback from the two power stages (in the way that they are used to obtain IDX_STATE_SOPC), and the last column described the entry in NC_RESP_SOPC_2[] at index IDX_STATE_SOPC.

R27_5: The MU-SPOC result for power stage 0 obtained before triggering the PREDRIVE communication has to be re-checked before triggering the first NORMAL communication: the status of this particular disable line can only be determined unequivocally if tested when disabled and enabled; this does not cause any conflict with the MC-part of the SOPC since the MC is not connected to power stage 0. The

final check result of power stage 0 for the MU has to take into account both checks: only if the first result was "disabled" and the second was "enabled", the complete check was successful.

Value assignment for configuration data of SOPC:

/ Size of arrays for switch-off path check */*
NC_NR_RESP_SOPC = 16;
/ always use NC_RESP_SOPC_2, never NC_RESP_SOPC_1 for lookup of the final result */*
NC_CTR_RST_MC_THD_SOPC = 0;
/ SOPC result: no engine start possible */*
NC_STATE_RESP_SOPC_DFCT = 0;
/ SOPC result regular engine start possible */*
NC_STATE_RESP_SOPC_OK= 255;
/ not used: all entries are equal to NC_STATE_RESP_SOPC_DFCT */*
NC_RESP_SOPC_1[NC_NR_RESP_SOPC] = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
/ see table and NCs for results above */*
NC_RESP_SOPC_2[NC_NR_RESP_SOPC] = [0, 0, 0, 0, 0, 0, 255, 255, 0, 0, 0, 0, 0, 0, 0, 0]
/ Default value for IDX_STATE_SOPC: no switch-off path working */*
NC_IDX_STATE_SOPC_DFCT = 0;
/ Diagnostic result from power stage "driver disabled" */*
NC_STATE_RESP_DR_DI = 0;
/ Diagnostic result from power stage "driver enabled" */*
NC_STATE_RESP_DR_ENA = 1;
/ Default diagnostic result from power stage ("status undefined") */*
NC_STATE_RESP_DR_DFT = 3;

Application conditions:

Initialisation:	*/* Using the RAM check service actions */* LV_MC_ST_LIH_SOPC = 0;
Recurrence:	The **initialisation** shall be **executed after each power-up or reset**.

12.11.4 Project-specific configuration – Error memory service function

General information:

The function incorporates the following requirements:

G43 Error memory service function

The action ACTION_ECM3_McErrmService() shall be called when all the necessary information is available. When the action is called, it is first tested whether an update of the error history was performed right before the action was called. Since this is only done in case there currently is an error present, this means if no update was done the error symptom ERR_SYM_MON_3 can be set to "NO_SYM"; ERR_SYM_MON_3 consists of four bits:

Bit3 (SYM_3)	Bit2 (SYM_2)	Bit1 (SYM_1)	Bit0 (SYM_0, LSB)
8	4	2	1
FS-IST error on MU	SOPC error/ unspecific level 3 error	RAM error on MC	ROM error on MC

For every fault, environmental conditions are stored in the environmental data variables ENVD_x_MON_3; the stored content is chosen to help analysing the fault scenario afterwards; more information can be found in the formula section below.

Application conditions:

Initialisation: */* Initialise the interfaces to ERRM */*

LV_ERR_MON_3 = 0;
LV_CDN_DIAG_MON_3 = 0;
LV_END_DIAG_MON_3 = 0;
ERR_SYM_MON_3 = NO_SYM */* No symptom */*;
ENVD_0_MON_3 = 0;
ENVD_1_MON_3 = 0;
ENVD_2_MON_3 = 0;
ENVD_3_MON_3 = 0;

Recurrence: The **initialisation** shall be **performed after each power-up and reset** and **at FMY reset**.

Activation: This **sub-function** is **called**.

Description of ACTION_ECM3_McErrmService

Description:

Syntax: ACTION_ECM3_McErrmService(

IN <cpt_act>,
IN <err_cod_act>,
IN <err_idc_act>,
IN <ctr_rst_act>,
IN <cpt_old>,
IN <err_cod_old>,
IN <err_idc_old>,
IN <ctr_rst_old>
)

Parameter (IN):	cpt_act	component for current error information (1=MC, 0=MU)
Parameter (IN):	err_cod_act	current error code
Parameter (IN):	err_idc_act	current error indication
Parameter (IN):	ctr_rst_act	current value of reset counter
Parameter (IN):	cpt_old	component for previous error information (1=MC, 0=MU)
Parameter (IN):	err_cod_old	previous error code
Parameter (IN):	err_idc_old	previous error indication

Parameter (IN): ctr_rst_old previous value of reset counter

Short description: This action receives the current error history and provides the interface to the error memory management.

Formula section:

```
IF ( (ctr_rst_act > 0) OR ((cpt_act = 0) AND ("err_cod_act indicates voltage monitoring
error")) ) /* reset counter of current error greater than 0 OR current error is an MU error and
the current error is a voltage monitoring error */

     /* Set environmental data, see table for exact bit positions */

     ENVD_0_MON_3 = "combine cpt_act, err_idc_act and err_cod_act into one byte";
     ENVD_1_MON_3 = ctr_rst_act; /* this could include encoded additional information */
     ENVD_2_MON_3 = "combine cpt_old, err_idc_old and err_cod_old into one byte";
     ENVD_3_MON_3 = ctr_rst_old; /* this could include encoded additional information */
```

	Bit 7	**Bit 6**	**Bit 5**	**Bit 4**	**Bit 3**	**Bit 2**	**Bit 1**	**Bit 0**
ENVD_0_MON_3	Current error: 0 for MU error 1 for MC error	Current error: error indication 0 = no error 1 = restart request 2 = DISABLE request 3 = restart was requested		Current error: error code (see tables in "Processor monitoring general")				
ENVD_1_MON_3	Current error: additional information (test results of switch-off paths, encoded wrong header byte, ABC status, cf. G41 "Update of error memory information with MC data")				Current error: reset counter			
ENVD_2_MON_3	Old error: 0 for MU error 1 for MC error	Old error: error indication 0 = no error 1 = restart request 2 = DISABLE request 3 = restart was requested		Old error: error code (see tables in "Processor monitoring general")				
ENVD_3_MON_3	Old error: additional information (test results of switch-off paths, encoded wrong header byte, ABC status, cf. G41 "Update of error memory information with MC data")				Old error: reset counter			

```
  FI

  LV_CDN_DIAG_MON_3 = 1;

  LV_END_DIAG_MON_3 = 1;                 { Diagnosis is finished }

  Deliver the result to Error Management;
```

Configuration for diagnostic symptoms:

Diagnostic MON_3	Symptom description	Symptom	Filter type
Diagnoses of Processor Monitoring	ROM error on MC	*SYM_0*	NO
	RAM error on MC	*SYM_1*	
	SOPC or unspecific error	*SYM_2*	
	FS-IST error on MU	*SYM_3*	

Note: it is recommended to configure MON_3 to "CARB CC"
Note: it is recommended to calibrate ENVD_x_MON_3 to be stored in the error memory when a MON_3 error occurs (ID_ERR_ENVD_MON_3).

12.11.5 Project-specific configuration – Initialisation of power stages after disabling by Processor Monitoring

FUNCTION DESCRIPTION:

General information:

Not used since this is done via polling in the relevant functions.

12.11.6 Project-specific configuration – Project-specific transition condition for the transition from INIT to CONFIG state

FUNCTION DESCRIPTION:

General information:

In order to prevent a start of Processor Monitoring SW while the "environmental condition" inside the ECU (e.g., the supply voltage for the H-bridge, which is supplied via the main relay) are not yet in a defined state, the transition from INIT to CONFIG (where the first communication is performed) can only be performed under specific conditions.

This functions describes a project-specific condition for the transition to be possible; other (generic) conditions might be defined in other specifications.

Description:

This function incorporates the following requirements:

G52 Project-specific transition condition for the transition from INIT to CONFIG state

R52_1: If LV_DIAG_END_RLY_MAIN_DLY = 1 **AND** LV_RLY_MAIN_DLY_ERR = 0, the transition from INIT to CONFIG shall be possible.

R52_2: Otherwise, the transition shall not be possible.

Application conditions:

Initialisation: -

Recurrence: The **function** shall be **called by G51 "State machine on MC" for deciding if the transition from INIT to CONFIG can be performed**.

Activation: STATE_MC = NC_STATE_MC_INI *(only active in INIT state)*

Deactivation: Otherwise

12.11.7 Project-specific configuration – Acquisition of ignition key information on MC

FUNCTION DESCRIPTION:

General information:

In each NORMAL and DISABLE communication, the MC sends information about the status of the ignition key signal to the MU.

Usually, the ignition key information on the MC is available in LV_IGK; however, in some instances, a pre-processing step could possible/necessary (e.g., if the signal is available redundantly, it can be checked for plausibility and then the monitored value can be sent to the MU; another application could be to return the MU value in HW acquisition mode back to the MU so that only the pin value on the MU will determine the MU-internal ignition key information).

To support any such pre-processing, this project-specific function allows to freely define the value of LV_MC_IGN_KEY before it is sent to the MU.

Description:

This function incorporates the following requirements:

G54 Acquisition of ignition key information on MC

R54_1: The value of LV_MC_IGN_KEY shall be obtained by copying LV_MU_IGN_KEY.

Application conditions:

Initialisation: LV_MC_IGN_KEY = 0

Recurrence: The **initialisation** shall be **performed after each power-up and reset**.

The **function itself** shall be activated before G25 in NORMAL and DISABLE.

Activation: (STATE_MC = NC_STATE_MC_NORM) **OR**
(STATE_MC = NC_STATE_MC_DI)
(active in NORMAL and DISABLE state)

Deactivation: *Otherwise*

Formula section:

/ send back MU value to MU to avoid problems with wrong detection thresholds */*

LV_MC_IGN_KEY = LV_MU_IGN_KEY

12.11.8 Project-specific configuration – Extension of power-latch phase for Standard ROM check

FUNCTION DESCRIPTION:

General information:

Since the Standard ROM check (G8.1) is calculated in the background, it is not pre-determined how long it will take to complete; however, there is the requirement that the ROM check has to be completed at least once per driving cycle. Consequently, in order to fulfil the mentioned requirement, the power latch phase (the phase after the ignition has been switched off, KL15 = 0, but before the ECU is switched off) shall be extended variably for (at least) as long the duration of one complete checksum calculation.

Description:

This function incorporates the following requirements:

G64 Extension of power-latch phase for Standard ROM check

Application conditions:

Initialisation: -

Recurrence: The **function itself** shall be activated via the action exported calls ACTION_ECM3_McLockPwlResources() and ACTION_ECM3_McUnlockPwlResources().

Description of ACTION_ECM3_McLockPwlResource

Description:

Syntax: ACTION_ECM3_McLockPwResource()

Formula section:

"set power-latch lock condition corresponding to NC_PWL_LOCK_CDN_ROM_CHK in PWL_LOCK_CDN"

Description of ACTION_ECM3_McUnlockPwlResource

Description:

Syntax: ACTION_ECM3_McUnlockPwResource()

Formula section:

"reset power-latch lock condition corresponding to NC_PWL_LOCK_CDN_ROM_CHK in PWL_LOCK_CDN"

12.11.9 Project-specific configuration – Handling of injection-off timer functionality

FUNCTION DESCRIPTION:

General information:

The injection-off timer inside the MU can disable the injection power stage. This fact shall be indicated to other SW parts via the flag LV_INJ_OFF_TMR_INJ_ENA.

Description:

This function incorporates the following requirements:

G65 Handling of injection-off timer functionality

R65_1: The value of LV_INJ_OFF_TMR_INJ_ENA shall be obtained by checking a 0->1 transition of LV_MU_IGN_KEY between the last two recurrences, see formula section below (*due to unreliable disable information from the MU, the only reliable decision base is the ignition key information*).

NOTE: the ignition key signal is already low while the timer is active but not yet disabling the injection so the injection will be disabled immediately after the 1->0 transition of the ignition key signal!

NOTE: this is only a temporary solution and should be changed once the latest version of the MU is consistently used in the HW; then it will be sufficient to copy the value of LV_INJ_OFF_TMR_ENA_INJ_TMP to LV_INJ_OFF_TMR_ENA_INJ!

Application conditions:

Initialisation:	LV_INJ_OFF_TMR_ENA_INJ = 0 LV_MU_IGN_KEY_OLD = 0
Recurrence:	The **initialisation** shall be **performed after each power-up and reset**. The **function itself** shall be activated after G22.
Activation:	(STATE_MC = NC_STATE_MC_CONF) **OR** (STATE_MC = NC_STATE_MC_PRDR) **OR** (STATE_MC = NC_STATE_MC_NORM) */* only active in CONFIG; PREDRIVE, or NORMAL state */*
Deactivation:	otherwise */* inactive in INIT and DISABLE state: here, LV_ERR_TMP_MU_MC is set anyway and so the power stages are disabled regardless of the IOT */*

Formula section:

/ Enable injection if value of ignition key signal on MU, LV_MU_IGN_KEY, of current and last recurrence is high because then the IOT has been reliably reset inside the MU (wait-state needed due to delay stemming from SPI communication) */*

LV_INJ_OFF_TMR_INJ_ENA = LV_MU_IGN_KEY_OLD **AND** LV_MU_IGN_KEY;

/ Save current value for next recurrence */*

LV_MU_IGN_KEY_OLD = LV_MU_IGN_KEY;

Import action

void klann_clrad(void)

FUNCTION DESCRIPTION:

General information:

Non volatile datas are stored in the E2PROM. Non volatile datas are:

- All adaptation values
- The debounced errors in the dynamic error memory (max. 10)
- Some datas from the last engine run

This specification describes the non volatile data handling in connection with the E2PROM and how to initialize those values by calibration system.
The input values for Linear-Lambda functions and Error memory (see:"Selective adaptation ranges") are not considered in the Input data above.

Application conditions:

Initialisation: see "READ Non-Volatile-Data to the E2PROM"

Recurrence: at state READ: Once
at state WRITE: Once

	at state	DELETE:	1s
Activation:	at state	READ:	after ECU reset
	at state	WRITE:	ECU_STATE = PWL
	at state	DELETE:	LV_IGK = 1

13.1.1 READ Non-Volatile-Datas from the E2PROM

Description:

The update of the non-volatile-datas will be executed at the system startup after Ignition-key-ON.

Every functionality will be read seperately from the E2PROM. If a checksum fault or a fail of hardware communication (SPI) occurs, then all non-volatile-datas will be initialized (Adaptation values with default or calibratable values and all debounced and active errors with 0).

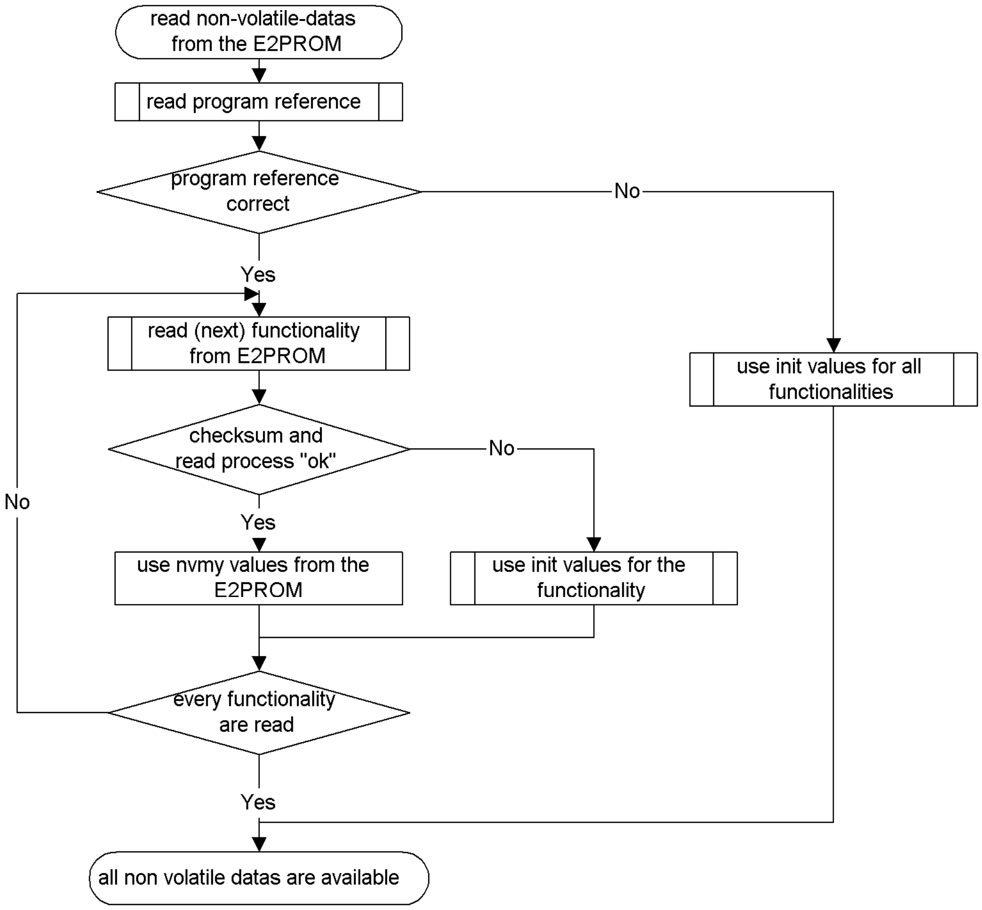

Figure 1 flow chart of the READ process

13.1.2 WRITE Non-Volatile-Datas to the E2PROM

Description:

The write process to the E2PROM starts at the end of the PWL (power latch phase).

Every individual functionality will be saved seperately with the current values for the non-volatile-datas in the E2PROM. Moreover a checksum will be calculated, which will also be stored. The actual program reference will be saved in the same way.

13.1.3 INITIALIZE Non-Volatile-Datas

Description:

Non-volatile-datas can be initialized by calibration system.

The following Non-Volatile-Datas can be initialized by a calibration constant:

- All Non-Volatile-Datas and all Adaptation-Values
- Selective adaptive range values

The initialization will be executed once per transition, if the calibration constant transits from 0 -> 1.

Remark: The following variables can not be initialized by a calibration constant:

TRT (Total runtime counter)

VS_MAX_SEL_EXT_REQ (Request of maximum vehicle speed limitation)

Formula section:

Initialize all Adaptation-Datas:

```
If      LC_AD_CLR = 1
Then    All Selective Adaptive Range Values and all Non-Volatile-Datas are initialized (without Error memory)
Endif
```

Initialize selectiv Non-Volatile-Datas:

```
If      LC_AD_CLR_XXXX = 1      (XXXX = selective adaptation range)
Then    Selective adaptive values are initialized
Endif
```

Clear KLANN-Adaptation values:

```
If      LC_AD_CLR_LACO 0 -> 1
Then    call klann_clrad(void)
Endif
```

13.1.4 Selective adaptation ranges

Description:

The following adaptation values/datas from the last engine run are considered in selective adaptation ranges:

Adaptation range:		Initialization:

13.2 Non Volatile Data Management – General Functionality

13.2.1 Introduction

This document specifies the high level SW specification of the NVMY function. It allows storing and restoring some data manipulated by the Engine Control Unit as adaptative values, error flags for the diagnosis, and engine environments on several driving cycles in case of failure.

The non volatile data management shall provide:

- a common interface between the aggregates in the ECU and the function NVMY i.e. the mechanism to access to the memory for writing and reading stored data,
- different services provided to the aggregates,
- a safety data storage

13.2.2 Abbreviations and terms

HW	HardWare
SW	SoftWare
ECU	Engine Control Unit
CRC	Cyclic Redundancy Checksum
EEPROM	Electrically Erasable PROM
NVMY	Non Volatile MemorY

FLASH EEPROM emulation means that NVMY data are stored into the flash device.

In the rest of this document the term memory designs either EEPROM or FLASH EEPROM emulation.

13.2.3 General description

Usually the manager provides the capability to initialise, memorize and restore data. The NVMY manager shall ensure the NVMY data recording, and also secure the NVMY data integrity.

The NVMY manager shall support:

- a scheduler to handle the priority of the tasks,
- a supervisor, called regularly by the operating system, handles the real time,
- an executor of the services,
- the return of error cases to the others aggregates,
- the initialisation of the data and the integrity of the data in the memory structure.

13.2.4 Hardware constraints

The NVMY manager is hardware independent and shall administrate the NVMY data on EEPROM and/or FLASH EEPROM emulation.

EEPROM:

Writing of NVMY data could be done “in live” (write on "fly") while the ECU is running. This operation must be limited in order to save the EEPROM life duration regarding the hardware write/erase cycles.

Also, the application needs to take in account the EEPROM size capability.

FLASH EEPROM emulation:

Both accesses to flash data are available regarding flash hardware definition:

- One bank: the operating system is blocking while erase/write operation. The write/erase operation has to ensure that the SW is in a safe ECU mode (shutdown phase). Application has to guaranty that all NVMY data must be store at shutdown phase.
- Dual banks: the operating system is not blocking while erase/write operation. There is the possibility to store NVMY data while applicative SW is running.

Two specific flash segments are requested (at least).

Recommendation:

The writing of NVMY data on "fly" must be limited to one per ECU cycle in order to save the memory life duration.

Pre-emptive operation:

Application must ensure to not perform operation on memory while it is used by the NVMY manager.

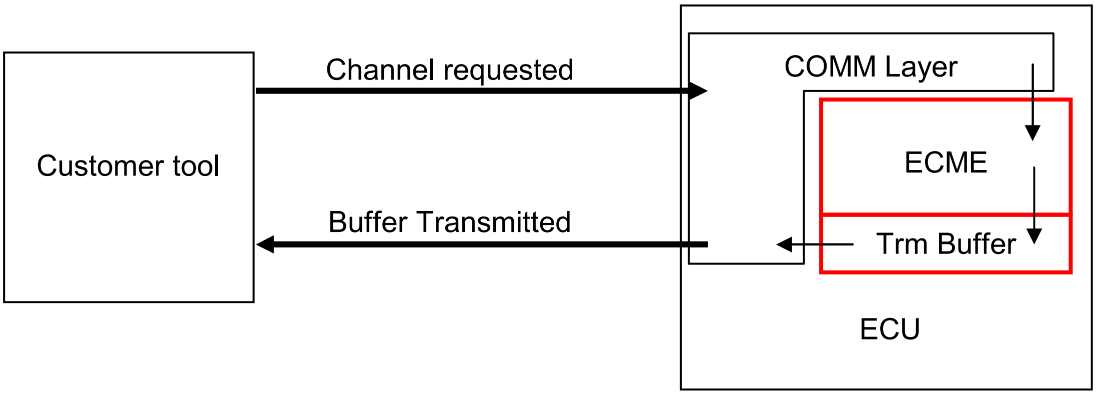
13.2.5 NVMY system events

Three related system events are defined:

- NVMRES: read-out (restore) non volatile data from the memory. It happens before the reset event. In case of error, NVMINI happens afterwards
- NVMINI: initialize the non-volatile data with defined default values. It happens after NVMRES and before the reset event in case of error during NVMRES
- NVMSTO: store the non-volatile data into the memory. It happens in a safe ECU mode (ECU shutdown). By extension, the write on "fly" functionality uses the same system event.

13.2.6 Flight recorder on customer tool request

On special communication request, a configured channel can be sent to a customer tool.



Via the communication media, the tool first asks for one specific channel.

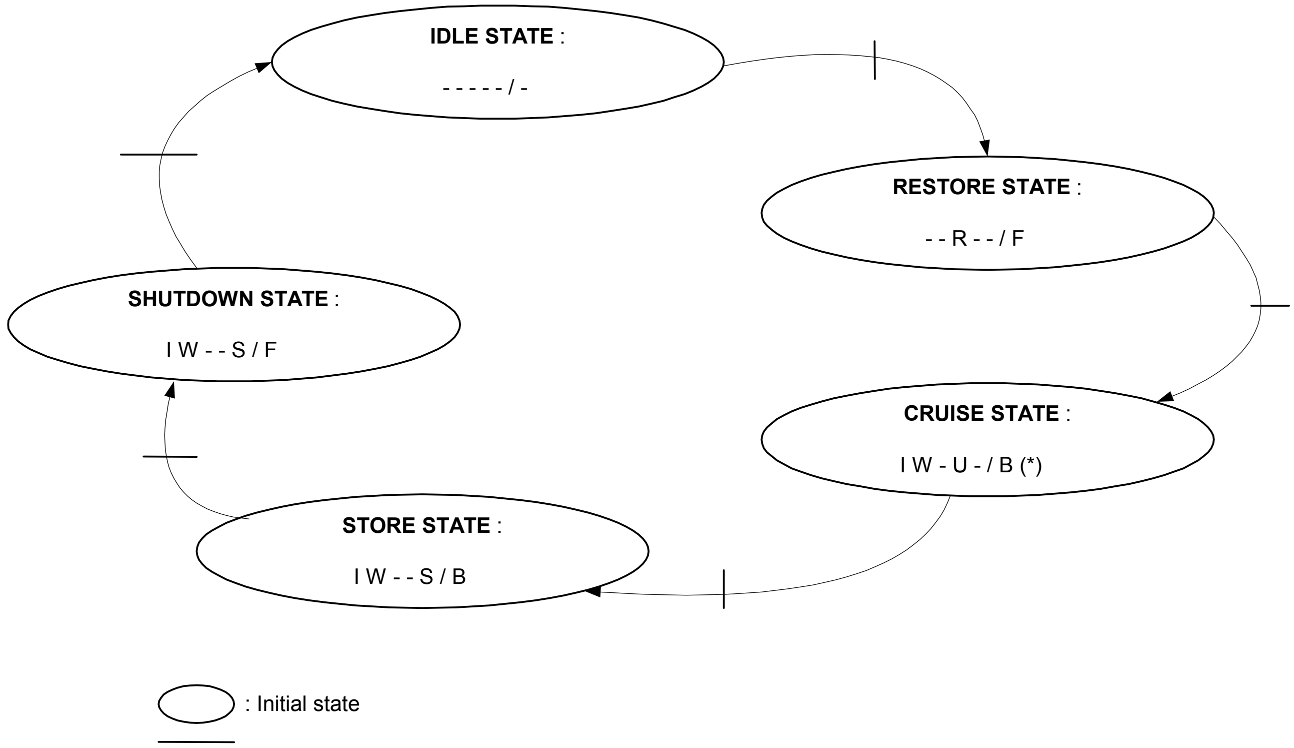
On reception of this message, ECME scheduler will prepare itself to read out the asked channel. As soon as the channel is available, a transmission buffer to the communication media is filled. After this, the channel can be sent to the customer tool.

13.3 Non Volatile Memory – Manager description

Basically, this module contains the scheduler and the supervisor related to NVMY functionality.
The supervisor is a state machine that contains the way that NVMY channel's operation are performed in addition to the type of operations enabled depending on the current state.
Furthermore, the supervisor only decides when NVMY operations should be performed.
Indeed, depending on the state of engine control management, the NVMY operations are performed either in BACKGROUND or FOREGROUND mode.
Foreground mode means that ECME's aggregate keeps "hand" till operation is finished.
On the contrary, BACKGROUND mode intends that NVMY operations are performed step by step while engine maybe running.

13.3.1 NVMY Manager

The picture below, presents all manager states :



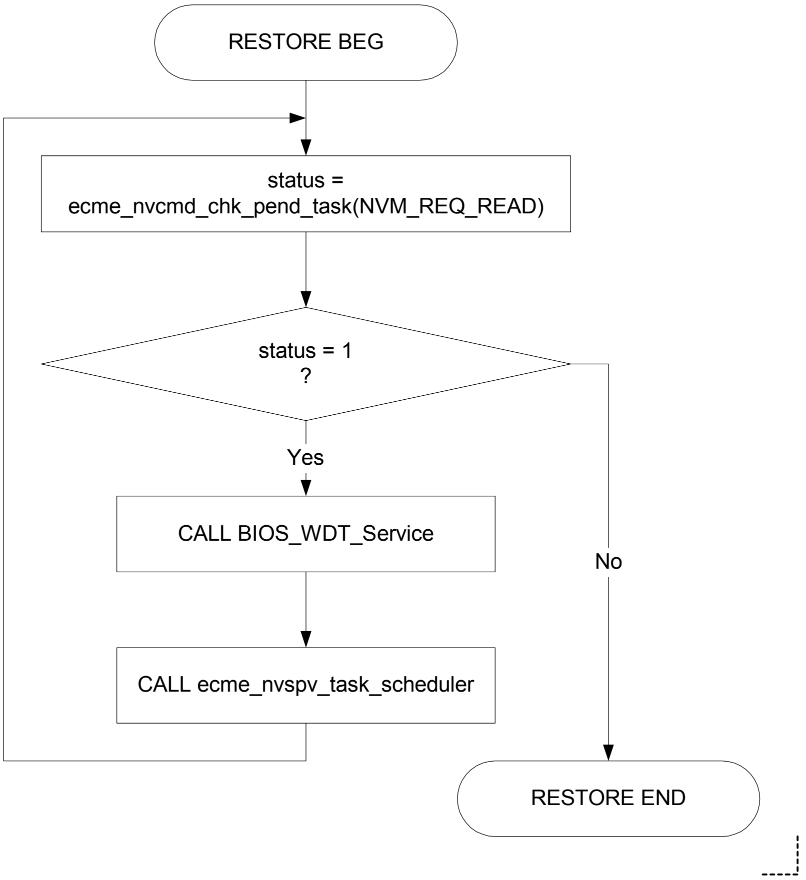
Active tasks :
- : disabled
I : Init task enabled
W : Write task enabled
R : Read task enabled
U : Update task enabled
S : Synchronisation task enabled

Operation mode :
F : Foreground
B : Background

13.3.2 STATES description

- IDLE state
  The supervisor simply does nothing.

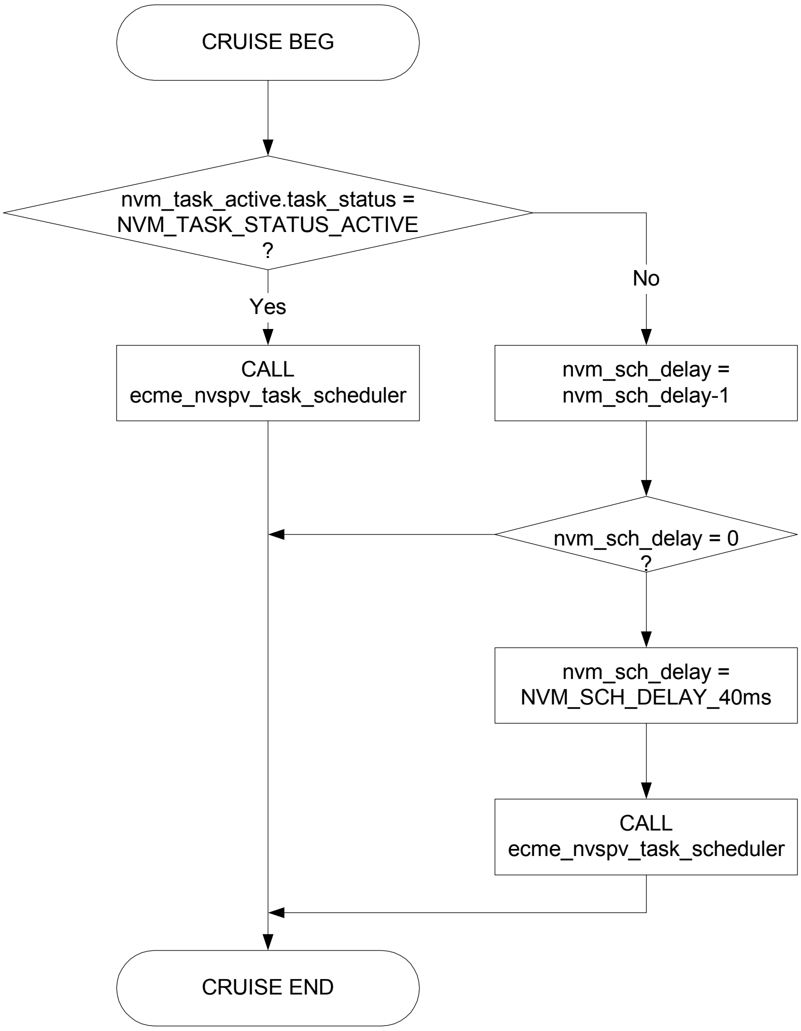
- RESTORE state :



This state is working in FOREGROUND. the NVMY scheduler is called till READ requests do not remain. As a complete RESTORE may take a long time, the Watchdog shall be rearmed periodically.

- CRUISE state :

This state is working in BACKGOUND. Each NVMY task should be performed step by step. The time base of 5ms for calling the supervisor is the good compromise according to the FLASH and EEPROM hardware data sheets.
Nevertheless, a new NVMY task shall be started 40ms after the end of the previous one, in order to minimize the load on SPI bus since engine maybe running.
Concerning watchdog, it is rearmed within OS operation.



- STORE state :

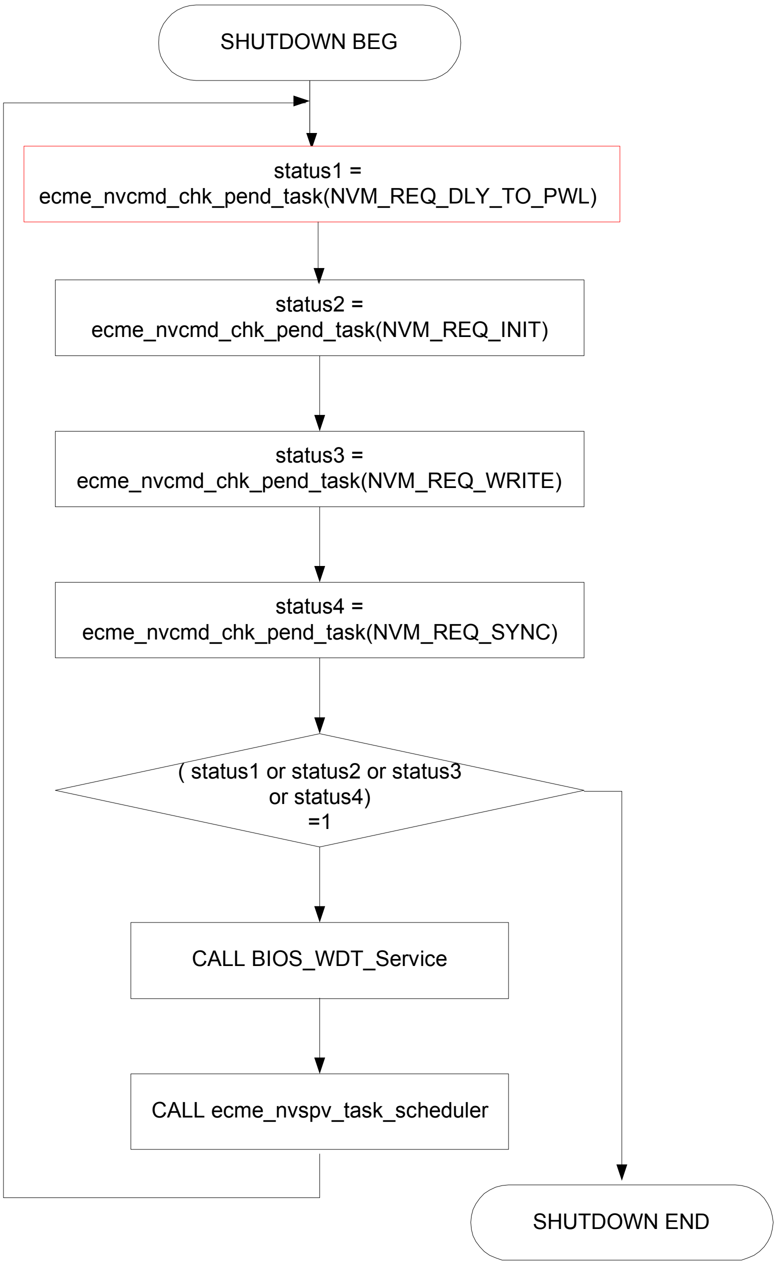
The NVMY scheduler (ecme_nvspv_task_scheduler) is simply called within this state.

REMARK :

Though this state is no more than a call, it may be found useless. Nevertheless, it might be used in future release of NVMY, in the case that STORE operations are started at the beginning of the power-latch.

- SHUTDOWN STATE

This state is working in FOREGROUND. This state is mainly used to complete STORE operations. The scheduler is either called till WRITE requests or INIT requests or SYNCHRONISATION requests are not pending.
As RESTORE operations, SHUTDOWN may take a long time. Therefore, Watchdog shall be periodically rearmed.



13.4 Non Volatile Data Management – Services Definition

This module especially contains all services offered to external aggregate.
These services are used to request operation from outside ECME aggregate

13.4.1 RESTORE service (FOREGROUND)

This service is in charge to restore a list of channels defined by parameter.
In addition, it may proceed with different kind of initialisation:

- First power on initialization
- Tuning initialization

This service is only available during RESTORE state according to NVMY supervisor.
It implies that it acts in Foreground only during ECU start-up. That is to say, OS is not active.

Therefore, it must be used during ECU start-up only.

13.4.1.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_RESTORE_LST				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	list_name	U8 *	-	list name
OUTPUT	-	void	-	-

13.4.2 CLEAR INIT request (FOREGROUND)

This service is in charge to cancel an INIT request if the concerned channel is detected as corrupted at RESTORE stage.

It only acts in foreground during ECU’s start-up.

13.4.2.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_CLEAR_INIT_REQ				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	nvmsetname	-	-	channel name
OUTPUT	-	void	-	-

13.4.3 READ service (FOREGROUND)

This service is in charge to read a single channel defined by parameter.
It only acts in foreground during ECU’s start-up.

13.4.3.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_READ_CH				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	nvmsetname	-	-	channel name
OUTPUT	-	void	-	-

13.4.4 READ FOR DIAG service (BACKGROUND)

This service is in charge to read a single channel when a diagnosis tool requires it.
It only acts in background during ECU's cruise operation.
It is only supported by specific channel configuration.

13.4.4.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_READ_FOR_DIAG_CH				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	nvmsetname	-	-	channel name
OUTPUT	-	void	-	-

13.4.5 WRITE service (BACKGROUND)

This service is in charge to write a single channel defined by parameter.
It only acts in foreground during ECU's cruise operation.

However, it may not work with flash that does not support basic operation while CPU fetches code (example: flash with simple bank). In this case the write operation is delay to the STORE ECME operation (done in the power latch).

Moreover, NVMY channel writing execution is delayed to running state, if writing is ordered during ECU start-up.

13.4.5.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_WRITE_CH				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	nvmsetname	-	-	channel name
OUTPUT	-	void	-	-

13.4.6 STORE service (BACKGROUND)

This service is in charge to prepare the store of all channels.
This service only acts in background during ECU's store operation.

13.4.6.1 Implementation

ECME_NVCMD				
ecme_nvcmd_write_ch_req				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	-	-	-	-
OUTPUT	-	-	-	-

13.4.7 SHUTDOWN service (FOREGROUND)

This service is in charge to store all channels.
This service only acts in background during ECU's shutdown operation.

13.4.7.1 Implementation

ECME_NVCMD				
ecme_nvcmd_shutdown				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	-	-	-	-
OUTPUT	-	-	-	-

13.4.8 NVMY coherency error services (FOREGROUND)

ECME aggregate provides two services for the NVMY coherency check functionality in order to set or clear coherency error.

These services are based on two macros defined below. Basically, these macros respectively set nvm_sw_coherency_err to 1 or 0.

13.4.8.1 Implementation

ECME_NVCMD				
ECME_NVMCMD_VLD_CHK_OK				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	-	-	-	-
OUTPUT	-	-	-	-

ECME_NVCMD				
ECME_NVMCMD_VLD_CHK_NOK				
Parameters	**Name**	**Type**	**Value(s)**	**Comment**
INPUT	-	-	-	-
OUTPUT	-	-	-	-

13.5 Non Volatile Memory – Mechanisms for Data initialization

These section deals with all cases of NVMY channel initialization.

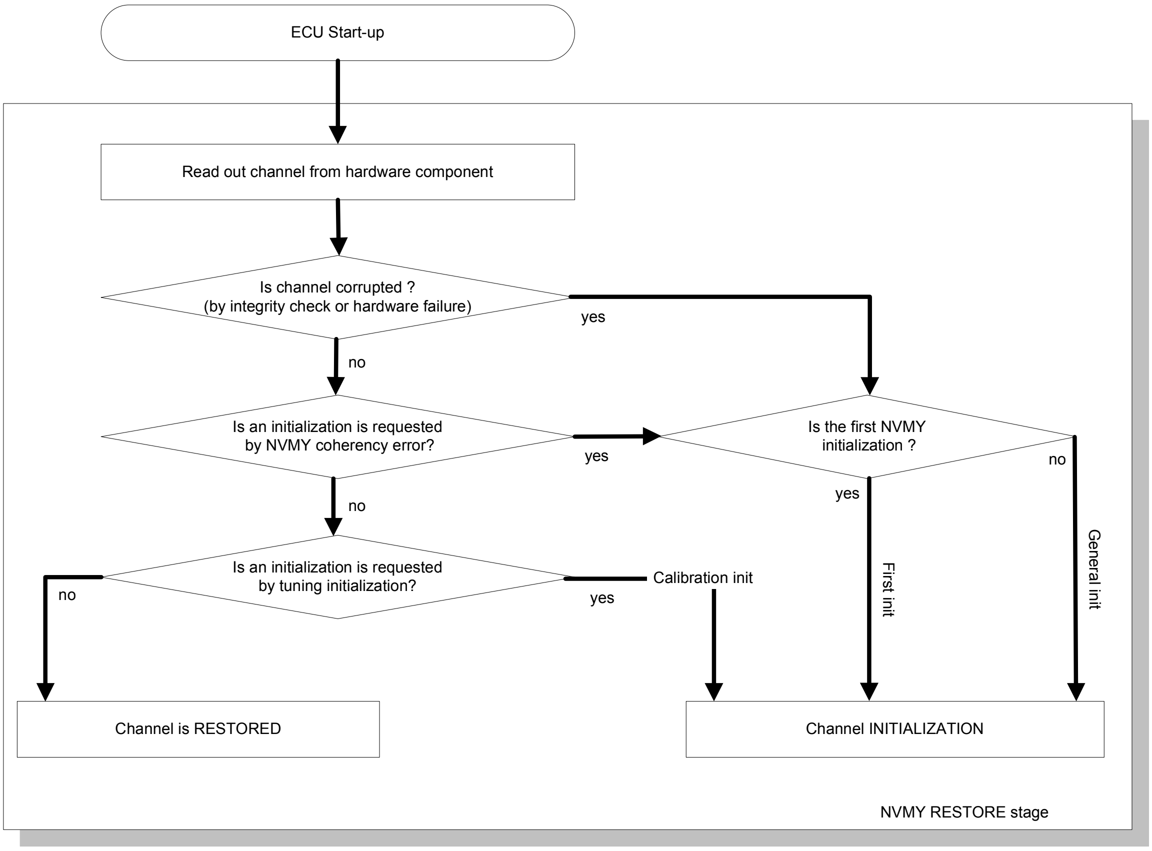
The initialization consists in initializing channel(s) with their default values.

The Channels set may be either partially or completely initialized depending on the case.

In addition, we can distinguish 3 kind of initialization:
- First initialization
- General initialization
- Calibration initialization

NVMY data initialization is performed during the NVMY RESTORE stage.

The following diagram depicts all kind of NVMY channel initialization:



13.5.1 Initialization in case of corrupted channel

Basically, this initialization is requested by the NVMY executor in case of a reading error occurred toward a single channel. Reading failure can be generated by a hardware failure or integrity channel problem (according to the channel attribute configuration).

13.5.2 Initialization in case of NVMY coherency error

During RESTORE stage, NVMY functionality should ensure that restore data match with Applicative software functionalities, which are using NVMY data.

NVMY coherency mainly relies on a check at RESTORE stage in order to determine whether NVMY contents (all channels) is compatible or not with applicative software.
Usually, problem may occur if ECU is restarted after it has been previously reprogrammed, because channel definition may have change in between from one software version to another. Without coherency check, it may lead Applicative software to run with NVMY data that are not correct, so coherency check is mandatory before restoring whole NVMY contents.

<u>Strategy:</u>
The NVMY coherency check relies on two channels (named SWVER_FIX and SWVER), which contains data related to coherency check (ECU-SW coherence identifier).
In the same way, Applicative software contains the same data. At restore stage, both channels are read before applicative channel reading. If NVMY content doesn't fit with current applicative software, a status notification is sent to the NVMY manager.

The below picture defines the channel allocation.

SWVER_FIX is the first written channel.
SWVER is the last written channel.

13.5.3 Initialization in case of tuning request

NVMY function provides the possibility to force channel initialization during <u>RESTORE stage</u>. This is <u>only</u> restricted to the ECU development phase.

This kind of initialization is limited and can only be applied to a limited number of channels, pre-defined with configuration. Therefore channels are grouped according to 3 possible levels of initialization.

Tuning calibration:

The following calibrations are defined under DDS and allow channel initialization:

Calibration name	Value	Purpose
lc_req_ini_nvm	PASSIVE	No request for initialization
	ACTIVE	Initialization is required
c_req_ini_nvm_grp	0	unused
	1	channels that belong to group level 1 should be initialized
	2	channels that belong to group level 2 should be initialized
	3	channels that belong to group level 3 should be initialized
	4	reserved for future purpose
	5	reserved for future purpose
	6	reserved for future purpose
	7	reserved for future purpose

13.5.4 Initialization in case of "First power-on"

In case of brand new ECU, the initialization of all channels with their default values is called initialization "first power-on".

Usually, this kind of initialization may occur only one time during ECU's lifetime.

This procedure relies on one channel (named ECME_1_FIX), which contains data related to the first power-on detection. Since this data is not set, all channels are supposed to be initialized. It implies that this data is false when ECU is delivered at the customer.

13.5.5 Hard initialization

Hardware means that channel is initialized with default values within hardware component.
Since these initialization may be performed during engine running (ECME CRUISE stage), it saves up writing time at the end of the power-latch.
Though this task is applied to EEPROM and FLASH, this initialization is only relevant for EEPROM.

13.6 Non Volatile Data Management, configuration

This section gives a summary of ECME features in order to advise you in the way that you define your data into channels organisation.

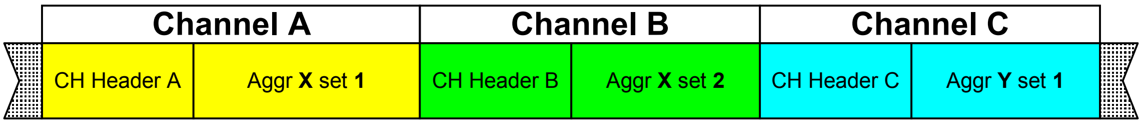
Each aggregate that want to use some Non Volatile data must create a channel containing all data to be saved.

13.6.1 Channel organisation

The NVMY is divided into channels that physically represent a part of the hardware component.

Each channel is divided into two parts. The first part so-called Header contains the data related to the saving criteria. In other words, the data that ensures saving data integrity. The second part only contains the saved data that belongs to the same aggregate.

Basically, the contents of non-volatile memory looks like as follow:



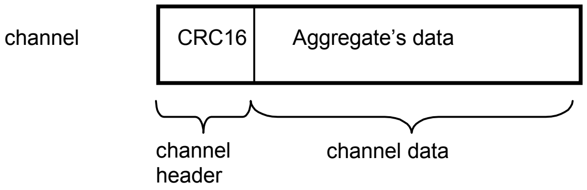
Each aggregate (or function) can define one or several channels depending on its requirements. Nevertheless two different Aggregates could not share their channel.

One aggregate can hold one or more channels but can not share any channel with a different Aggregate

13.6.2 Saving criteria

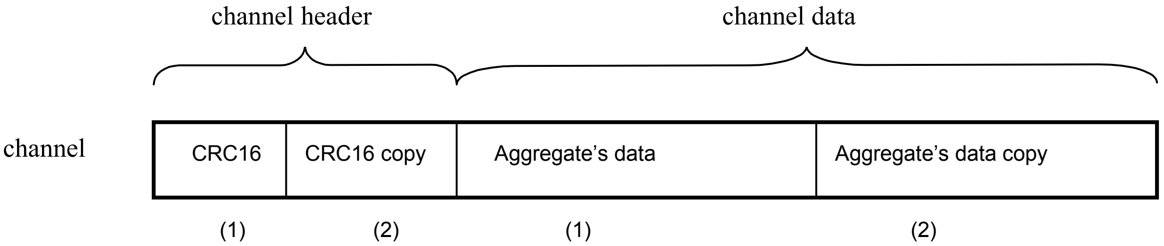
Data that belongs to the same channel are secured by a single saving criterion taken from the list below:

CRC 16 : channel integrity is covered by checksum calculation CRC16



If the CRC16 coherency check with the aggregate's data is failed, the channel is declared as corrupted: initialization needs to be performed.

MASTER and COPY : aggregate's data and CRC16 are duplicated in a zone called COPY



(1) master block
(2) copy block

Process of restoration:

Master check block (*)	Copy block check (*)	Result block	comment
ok	ok	master	last updated information
ok	nok	master	last updated information
nok	ok	copy	last updated information
nok	nok	initialization has to be done	both blocs are corrupted

(*) master/copy check block is ok means that CRC16 coherency check is coherent with the aggregate's data

This method is only available for EEPROM hardware component.

NONE: there is not saving criterion to guaranty the channel data integrity.

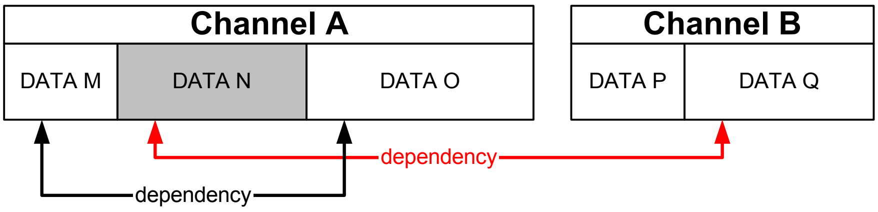
Non volatile memory data that should be secured with two different criteria can not share the same channel. Nevertheless, you may take the strongest criteria in order to group these data.

NVMY data within a channel are secured with the same saving criteria

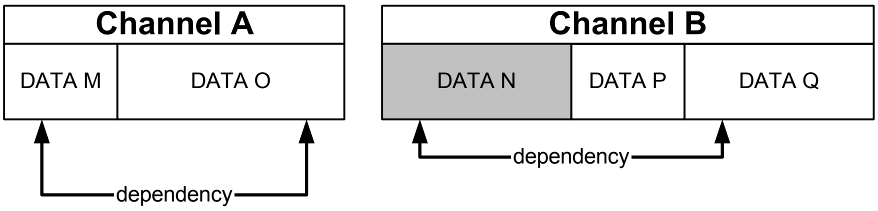
13.6.3 NVMY data coherency

As NVMY channels are separately handled by ECME aggregate, you should take care in the way you group data. Indeed, you should not separate data that are linked together. That is to say data that might be initialised at the same time in case of failure.

WRONG ORGANIZATION



CORRECT ORGANIZATION



DATA of the same Aggregate that are functionally linked should be grouped in the same channel.

13.6.4 Channel management

13.6.4.1 STANDARD channel

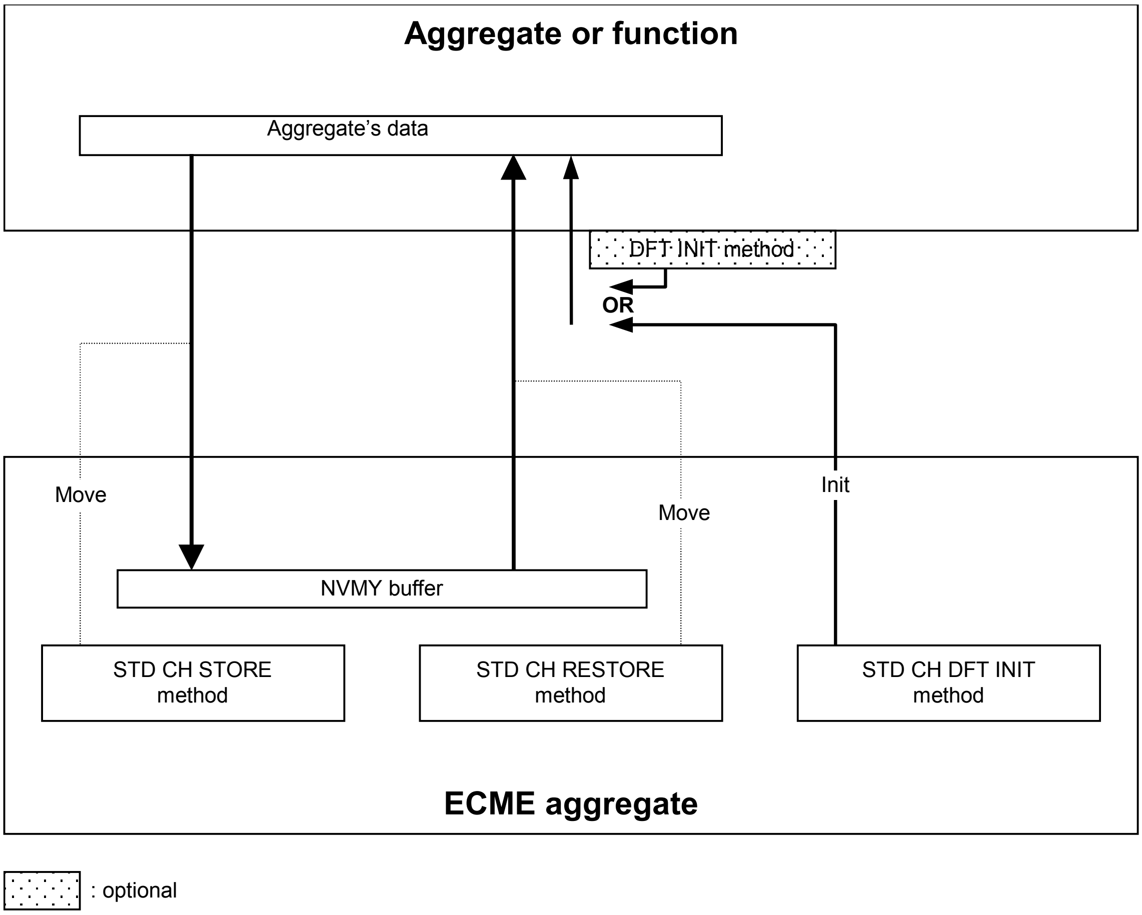
Aggregate do not have to provide any routine for NVMY data management except an initialisation routine if the default value does not match the Aggregate requirement (*).

In this case, the Aggregate relies on the ECME services for following purposes:

RESTORE
from Hardware component to Aggregate's data
STORE
from Aggregate's data to Hardware component

- DEFAULT INITIALIZATION [**optional** *]

The following picture describes the way that non-volatile data are managed in case of a STANDARD channel:



REMARK:

Aggregate's data memory location is known by the method boxes.
Accordingly, ECME aggregate should know of Aggregate's data declaration.

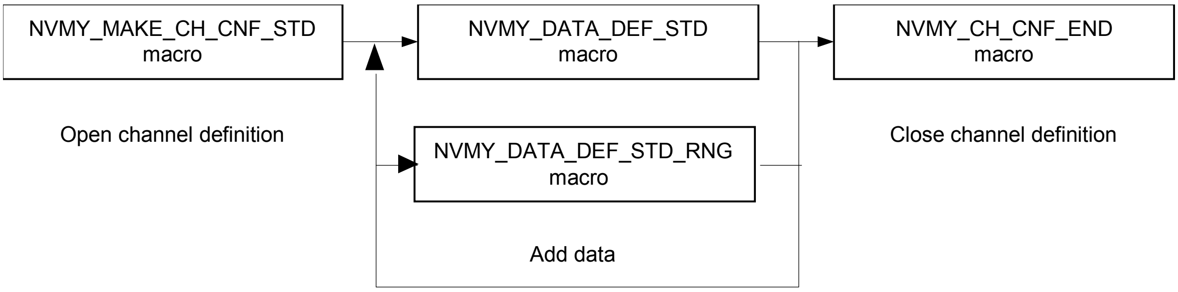
The use of STANDARD channel should be limited in order to avoid constant management overhead.

STANDARD Channel should be used for a few data only. Therefore, you should consider that a STANDARD channel can not hold more than 10 data.

13.6.4.1.1 Channel configuration

An ECME aggregate provides several MACROs that help the designer in order to define Channel configuration.
This configuration takes place into the ECME_ANVM.CFG component that is described in later section of this document.

Standard channels are defined according to the following scheme:



13.6.4.1.2 MACROs description

NVMY_MAKE_CH_CNF_STD (CH_ID,
TGT_ID,
VERSION_CHK,
TUNING_LVL,
SAVING_METH,
DFT_INIT_METH)

This macro opens a standard channel definition.
Besides, it helps to define all channel characteristics.

Parameters definition:

Parameter	**Value**	**Purpose**	**Comment**
CH_ID	NAME_N[_FIX] **(1)**	Channel identifier	Used to order ECME operation on a channel
TGT_ID	E2P	EEprom is the Preferred hardware location for storing this channel.	**This channel is stored to Eeprom if component is available. Otherwise, it will be stored to FLASH.**
	SIM_E2P	FLASH is the Preferred hardware location for storing this channel.	**This channel is stored to Eeprom if component is available. Otherwise, it will be stored to EEPROM.**
VERSION_CHK	CHK	Channel is sensitive to NVMY coherency check	If the NVMY contents coherency checking failed, the channel's data should be initialized with default values
	NO_CHK	Channel is not sensitive to NVMY coherency check	Channel's data is not initialized even if NVMYcontents coherency checking failed
TUNING_LVL	LV0 **(2)**	Channel is part of level 0 group for tuning initialization	Protected group : ECME's Tuning calibration has no effect on this group
	LV1	Channel is part of level 1 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 1
	LV2	Channel is part of level 2 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 2
	LV3	Channel is part of level 3 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 3
ORE	NO_STRQ (4)	Synchronization for store operation	Copy data from previous block and don't take in account data from current driving cycle.
	NO_SYNC (5)	No operation done at Store phasis	Synchronisation and write operation is forbidden.
	END_PWL	Store at the end of Powerlatch	END_PWL and BEG_PWL do the same operations : store is done at the end of powerlatch
	BEG_PWL	Store at the beginning of powerlatch	
SAVING_METH	CRC16	CRC16 method	Channel's data are secured with CRC16 method
	MACOPY	MACOPY method	Channel's data are secured with MACOPY method
	NONE	NONE method	Channel's data are secured with NONE method
DFT_INIT_METH	NVMY_DATA_INIT_DFT	Aggregate uses the ECME's default init method	Channel data are initialized by ECME's method in case of troubles.
	Default Init **function name (3)**	specific method provided by Aggregate	Aggregate provides a method in order to initialize channel's data.

Remarks:

(1) : According to the “C coding guideline”, the channel identifier name is limited to **17** characters.
For convenience, **NAME** shall refer to Aggregate’s short name.
N is a digit that may be used in the case that Aggregates holds more than one channel.
The **FIX** may be added to channel identifier name if channel is not sensitive to NVMY data coherency checking.

(2) : This level is basically used to protect channels against tuning initialisation.
For instance, the channel dedicated to NVMY data coherency is protected.

(3): Basically, this field refers to the function name defined by Aggregate.

(4) : The channels that have the NO_STRQ parameter are only synchronized at powerlatch. For the first powerlatch, they are stored but in the case that the first powerlatch is interrupted the channels are not stored and will be initialized at every power on until they are stored into flash. The aggregate should take this into account and store the channel separately in case of initialization.

(5) : The channels that have NO_SYNC parameter are never stored nor synchronized to memory. The aggregate should take this into account and store the channel separately.

NVMY_DATA_DEF_STD(nvmy_data)

This macro helps to add a single data to the channel.
The nvmy_data corresponds to the real name of the NVMY data.
The name of the data must be limited to 15 characters.

NVMY_DATA_DEF_STD_RNG(name, address, size)

This macro helps to add a data to the channel.
The name must be limited to 15 characters.
Address corresponds to the NVMY data address begin.
Size is the length of the NVMY data in byte and must be limited in order to not increase the channel size excessively.

NVMY_CH_CNF_END(CH_ID)

This macro closes a standard channel definition.

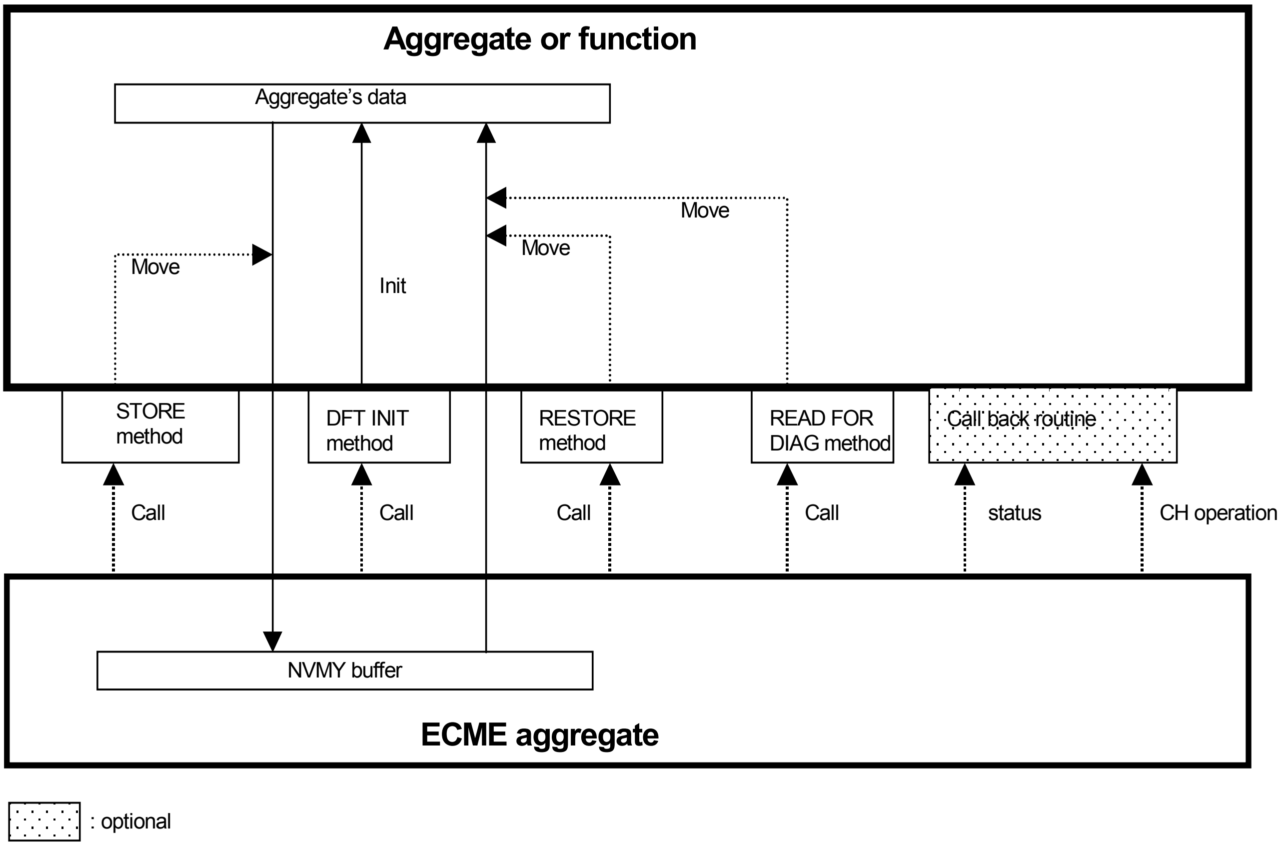
CH_ID is the same as the one defined by NVMY_MAKE_CH_CNF_STD macro.

13.6.4.2 SPECIFIC channel

Aggregates provide all methods for NVMY data management as follows:

RESTORE
from Hardware component to Aggregate's data
STORE
from Aggregate's data to Hardware component
DEFAULT INITIALIZATION
Aggregate's data initialization with default value

- CALLBACK routine [optional]
  Call back routine called by ECME aggregate after a store operation in order to get its status.
- READ FOR DIAGNOSIS
  From hardware component to the data used by the Read for diagnosis service



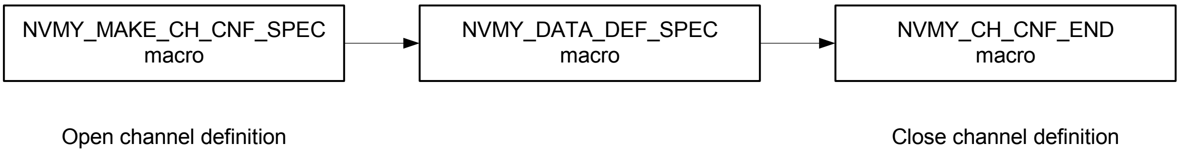
REMARK:

Aggregate's data memory location is known by the method boxes.
Thus, ECME aggregate does not have to know Aggregate's data memory location.

13.6.4.2.1 Channel configuration

An ECME aggregate provides several MACROs that help the designer in order to define Channel configuration.
This configuration takes place into the ECME_ANVM.CFG component that is described in later section of this document.

Standard channel are defined according to the following scheme:



13.6.4.2.2 MACROs description

```
NVMY_MAKE_CH_CNF_SPEC (   CH_ID,
                          TGT_ID,
                          VERSION_CHK,
                          TUNING_LVL,
                          SAVING_METH,
                          STORE_METH,
                          RESTORE_METH,
                          CBACK_METH,
                          DFT_INIT_METH,
                          READ_FOR_DIAG_METH)
```

This macro opens a standard channel definition.
Besides, it helps to define all channel characteristics.

Parameters definition:

Parameter	Value	Purpose	Comment
CH_ID	NAME_N[_FIX] **(1)**	Channel identifier	Used to order ECME operation on a channel
TGT_ID	E2P	EEprom is the Preferred hardware location for storing this channel.	**This channel is stored to Eeprom if component is available. Otherwise, it will be stored to FLASH.**
	SIM_E2P	FLASH is the Preferred hardware location for storing this channel.	**This channel is stored to Eeprom if component is available. Otherwise, it will be stored to EEPROM.**
VERSION_CHK	CHK	Channel is sensitive to NVMY coherency check	If the NVMY contents coherency checking failed, the channel's data should be initialized with default values
	NO_CHK	Channel is not sensitive to NVMY coherency check	Channel's data is not initialized even if NVMYcontents coherency checking failed
TUNING_LVL	LV0 **(2)**	Channel is part of level 0 group for tuning initialization	Protected group : ECME's Tuning calibration has no effect on this group
	LV1	Channel is part of level 1 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 1
	LV2	Channel is part of level 2 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 2
	LV3	Channel is part of level 3 group for tuning initialization	Channel's contents may be initialized with default values if tuning calibration is set to level 3

Parameter	Value	Purpose	Comment
ORE	NO_STRQ (4)	Synchronization for store operation	Copy data from previous block and don't take in account data from current driving cycle.
	NO_SYNC (5)	No operation done at Store phasis	Synchronisation and write operation is forbidden.
	END_PWL	Store at the end of Powerlatch	END_PWL and BEG_PWL do the same operations : store is done at the end of powerlatch
	BEG_PWL	Store at the beginning of powerlatch	
SAVING_METH	CRC16	CRC16 method	Channel's data are secured with CRC16 method
	MACOPY	MACOPY method	Channel's data are secured with MACOPY method
	NONE	NONE method	Channel's data are secured with NONE method
STORE_METH	Store **function name** **(3)**	specific method provided by Aggregate	Aggregate provides a method in order to copy NVMY data from ram to nvmy buffer (ECME)
RESTORE_METH	Restore **function name** **(3)**	specific method provided by Aggregate	Aggregate provides a method in order update its NVMY data thanks to NVMY buffer
CBACK_METH	NVMY_DFT_CBACK	ECME call-back default method	Call back is not active for this channel.
	call back **function name** **(3)**	specific method provided by Aggregate	Aggregate provides a method that will be called by ECME in case of writing on fly
DFT_INIT_METH	NVMY_DATA_INIT_DFT	Aggregate uses the ECME's default init method	Channel data are initialized by ECME's method in case of troubles.
	Default Init **function name** **(3)**	specific method provides by Aggregate	Aggregate provides a method in order to initialize channel's data.
READ_FOR_DIAG_METH	NVMY_DFT_READ_FOR_DIAG	Aggregate uses the ECME's Read For Diag default method	Read For Diagnosis is not active for this channel
	Read for diag **function name** **(3)**	specific method provides by Aggregate	Aggregate provides a method in order to Read For Diagnosis channel's data.

Remarks:

(1): According to the "C coding guideline", the channel identifier name is limited to **17** characters.
For convenience, **NAME** shall refer to Aggregate's short name.
N is a digit that may be used in the case that Aggregates holds more than one channel.
The **FIX** may be added to channel identifier name if channel is not sensitive to NVMY data coherency checking.

(2): This level is basically used to protect channels against tuning initialisation.
For instance, the channel dedicated to NVMY data coherency is protected.

(3): Basically, this field refers to the function name defined by Aggregate.

(4): The channels that have the NO_STRQ parameter are only synchronized at powerlatch. For the first powerlatch, they are stored but in the case that the first powerlatch is interrupted the channels are not stored and will be initialized at every power on until they are stored into flash. The aggregate should take this into account and store the channel separately in case of initialization.

(5): The channels that have NO_SYNC parameter are never stored nor synchronized to memory. The aggregate should take this into account and store the channel separately.

NVMY_DATA_DEF_SPEC(aggr_typedef_struct)

This macro is used to add a package of NVMY data to channel.
This package is defined through the typedef structure provided by Aggregate

NVMY_CH_CNF_END(CH_ID)

This macro closes a specific channel definition.

CH_ID is the same as the one defined by NVMY_MAKE_CH_CNF_SPEC macro.

13.6.5 Tuning Initialisation

This section treats all tuning aspects related to NVMY functionality.
During life of project, developers may need to initialise some channels with their default values.
In this way ECME provides 2 calibrations that are used in this purpose.

Nevertheless, channels should be correctly configured. That is to say, channel’s level should be defined according to the way that developers intend to use tuning calibrations.

Afterwards, these calibrations may be used to initialise a set of channels defined by the user.

Besides, ECME provides a safe way for channel initialisation. Indeed, initialisations are made during ECU’s start-up only.

13.6.5.1 Calibration description

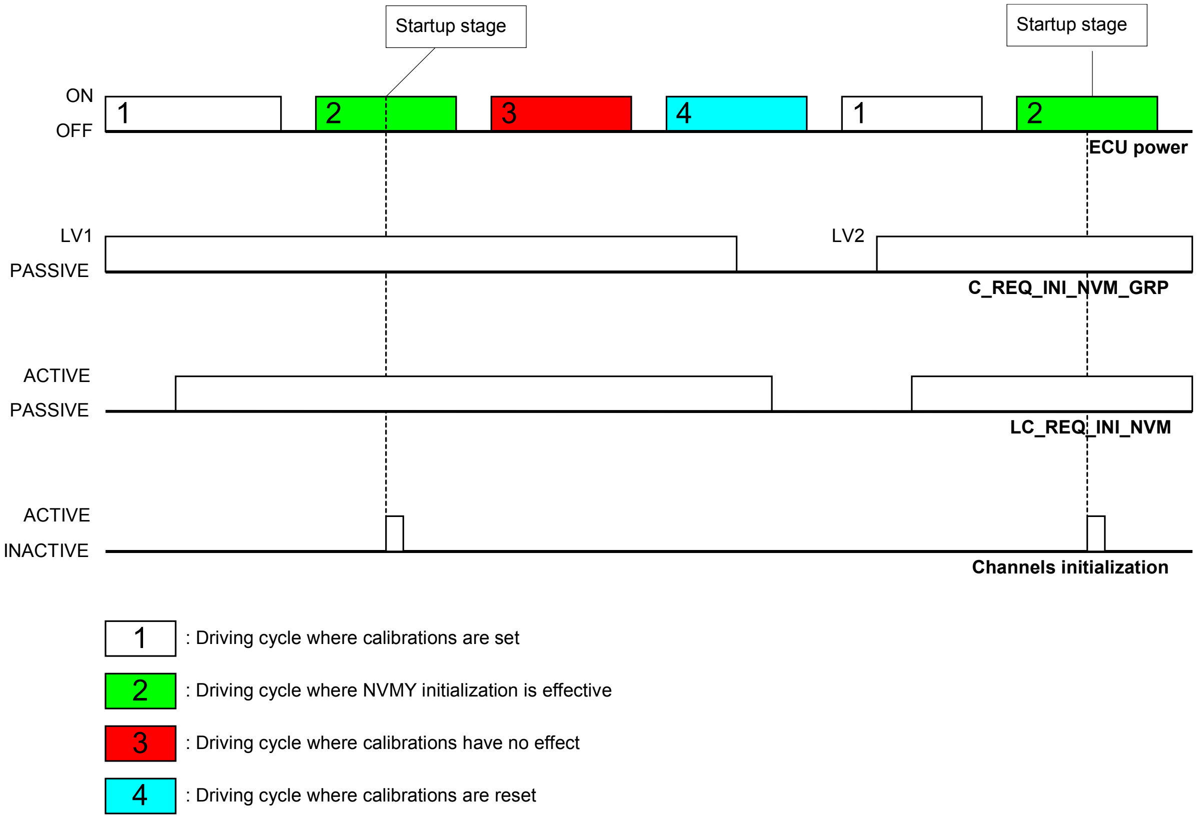
From SAM 2000 point of view, these calibrations belong to the ECME_NVM_DEV group.
In addition, the values are given according to SAM view.

Calibration name	Value	Purpose
lc_req_ini_nvm	PASSIVE	No request for initialization
	ACTIVE	Initialization is required
c_req_ini_nvm_grp	0	unused
	1	channel that belong to group level 1should be initialized
	2	channel that belong to group level 2should be initialized
	3	channel that belong to group level 3 should be initialized

Lc_req_ini_nvm is the trigger for NVMY initialisation, whereas c_req_ini_nvm_grp is used to identify the channel group.

You should notice that initialisation is only effective when lc_req_ini_nvm is set is changed from PASSIVE to ACTIVE. In addition, Initialisations are only done at start-up.

These calibrations should be used according to the following diagram:



13.6.5.2 First Power On

After the first power on, the Non Volatile Memory must operate its own initialisation.

So, an important delay may occur between the first power on of the Ecu and the availability of the whole NVMY strategy.

In consequence, all aggregate using NVMY functionality must first wait for the end of this first initialisation.

13.7 Aggregate ECME adaptation

13.7.1 Outputs for BMW functions which are not defined as ECME exported data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
B_pwf	V/O	0...1	0...1	1	-
0: reading of customer adaptation block in the E2PROM was successful // 1: not sucessful					

Input data:

LV_NVMY_CUS_WRG			

FUNCTION DESCRIPTION:

General information:

There are customer provided adaptation values stored in the E2Prom. Therefore the information has to be created whether the re-loading of this values out of the NVMY was successful or not. The bit B_pwf is containing this information (0 = upload was successful // 1 = upload failed).

Application conditions:

Initialisation: B_pwf = 0 at reset

Recurrence: once after up-loading of the adaptation values out of the E2Prom

Activation: after up-loading the customer adaptation values out of the E2Prom

Deactivation: after set of B_pwf

Formula section:

B_pwf = LV_NVMY_CUS_WRG if non-volatile stored data of storage class .Nvram (all customer adaptation values) could not be re-loaded error free out of the E2PROM

14 ECU Operation

Export actions:

ACTION_SetRstInfo_ECM3	

Action sets reset information of ecm3 security system

Import actions:

ACTION_INFR_GetBiosAdcStatus (OUT <Bios_adc_status >)
This action provides the digitized status of analogous signals

General information:

The goal is to memorise the number and the reason of irregular ECU-resets (not at the normal power-up !!), in order to support the ECU-development.
The reset-information will NOT be saved in E^{2}PROM for evaluation at the car-service-station.
Related hardware: TC1796 / system Units32-Bit / Single-Chip Microcontroller

The new debug driver is called by debug events which are typically resets. After a debug event it is necessary to ensure that the event- and the diagnosis-information is stored.

In case of E2PROM error or standby function call all informations are cleared.

The following figures show, which different values and additional info can be evaluated and stored for later access:

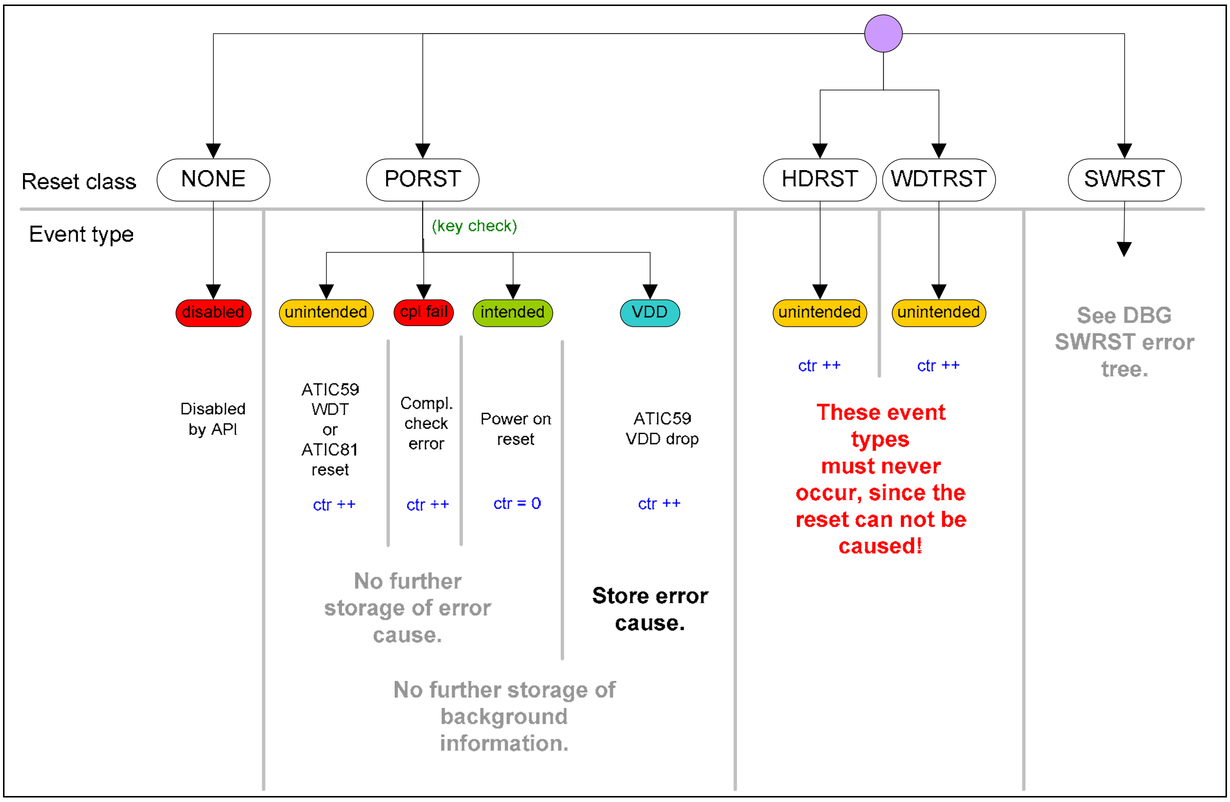

Figure1: DBG main reset class

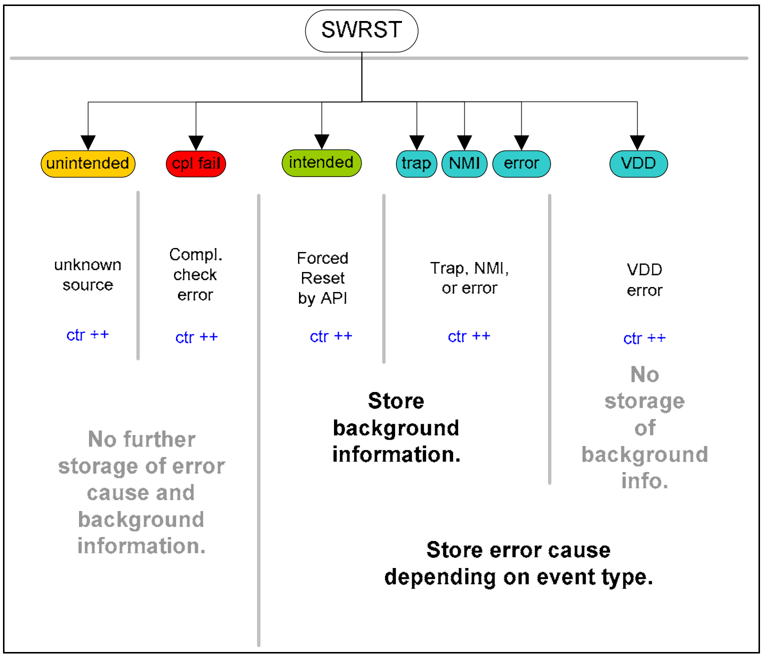

Figure 2: DBG SWRST reset tree

As described in figure1 the reset class represents a main category of reset types and the described event. The type represents a more detailed description of an occured reset, only the event type is used here as RST_TYP.

The error cause is more detailled or is set to 0 if not valid. It is used here as RST_INFO_ADD.

The background information is only stored/updated for event types as shown above. Only some backtrace information is provided at the moment, named RST_DBG_BACKTRACE_ADDRESS. The information is marked valid or invalid through RST_DBG_BACK_INFO_VLD. The complete info is set to 0 if not valid.

In a further step a warm/cold-Reset-detection is done by following mechanism:
A reset-save key which is written at ECU power-up and destroyed at regular ECU power-down. Checking this key against its init-value allows to detect a warm-reset.
By comparing the debug driver and the reset-save key it is possible to distinguish between internal or external MC-resets.

Reset-detection is done by evaluating low level functionality at startup:

RST_TYP
This value represents, whether an intended Power-on reset (cold start, 12h) or any other reset is detected at startup.

Hex-val	Description
01h	Error at evaluation (ERROR_TYPE)
02h	Driver disabled (DISABLED_TYPE)
10h	Unintended Power-On Reset (WDT or ATIC81, PORST_TYPE_UNINTENDED)
11h	Complement error at Power-On Reset (PORST_TYPE_CPL_FAIL)
12h	Intended Power-On Reset (Cold Start, PORST_TYPE_INTENDED)
13h	VDD Error at Power-On Reset (PORST_TYPE_VDD_ERROR)
20h	Hardware Reset (HDRST_TYPE_UNINTENDED)
30h	Watchdog Reset (WDTRST_TYPE_UNINTENDED)
40h	Unintended Software Reset (SWRST_TYPE_UNINTENDED)
41h	Complement error at Software Reset (SWRST_TYPE_CPL_FAIL)
42h	Intended Software Reset (SWRST_TYPE_INTENDED)
43h	VDD Error at Software Reset (SWRST_TYPE_VDD_ERROR)
44h	Trap (detected trap, SWRST_TYPE_TRAP)
45h	NMI (detected NMI/Trap class 7, SWRST_TYPE_NMI)
46h	Error at Reset (SWRST_TYPE_ERROR)

This value represents, whether a Power-on reset or any other reset is detected at startup.

RST_SEC
This value represents, whether the implemented security mechanism ECM3 has notified the module after restart through the interface ACTION_SetRstInfo_Ecm3 (see below) about an executed reset.

Hex-val	Description
00h	No additional Security info
01h	Additional Security info registered since last power-up

RST_INFO_CTR

Hex-val	Description
00h	Unspecified / Additional Reset info invalid
xxh	Number of atypical warm resets since last power-up

This value represents the number of atypical warm resets since last power-up, if additional reset info is valid. On Power-on reset this value is reset to 0.

Except for an intended Power-on reset (cold start, 12h) some additional informations may be provided as a list of the last detected resets. The list entry [0] represents the last/newest one, [1] that one before the last and so on up to the maximum size of the list with the length of NC_RST_DBG_LIST_SIZE. Before evaluating a new reset the whole list is shifted by one step and therefore the oldest list entry [NC_RST_DBG_LIST_SIZE-1] is lost.

Information lists are defined as arrays:
NC_RST_DBG_LIST_SIZE (see module configuration data: e.g. MSx80=2, MSD85=1)
NC_RST_DBG_BACKTRACE_SIZE = 10

RST_CLAS_TYP[NC_RST_DBG_LIST_SIZE]

This list value represents the same value as RST_TYP (see above), if reset differs from an intended Power-on reset at startup.

RST_CLAS_SEC[NC_RST_DBG_LIST_SIZE]

This list value represents the same value as RST_SEC (see above), if reset differs from an intended Power-on reset at startup.

RST_INFO_ADD[NC_RST_DBG_LIST_SIZE]

This list value represents an additional info on the cause of the reset.

RST_INFO_ADD at RST_CLAS_TYP = 42h (Intended Software Reset)

If an intended software reset is triggered by the following cases, the equivalent value is stored:

Hex-val	Description
00000000h	no info available
00000100h	Caused by Immobilizer (IMOB)
00000200h	Caused by Reprogr. (REPROG learn)
00000201h	Caused by Reprogr. (REPROG kwp)
00000300h	Caused by Security Control (SEC_MC)
00000400h	Caused by Memory Support (SUPRAM)
00000401h	Caused by Memory Support (NVMY)
00000402h	Caused by ADC driver (BIOS_ADC)
00000404h	Caused by injection (INJR)
00000500h	Caused by VIgk Peak (VDD_IGK)

RST_INFO_ADD at RST_CLAS_TYP = 44h (Trap)

If a software reset by trap occured, the equivalent value is stored in format:

Hex-val	Description
xxxx0000h	Trap value (high word)
0000yyyyh	Tin value (low word)

The trap classes represent more in detail, which type of trap occurred.

A trap occurs as a result of an event such as a Non-Maskable Interrupt (NMI), an instruction exception, memory-management exception or an illegal access. Traps are always active; i.e. they cannot be disabled by software action.
The TriCore architecture specifies general classes for traps. Each class has its own trap handler, accessed through a trap vector of 32 bytes per entry, indexed by the hardware-defined trap class number.

Hex-val	Description
00FFh	No trap deteced
0000h	memory management unit
0001h	Internal Protection Traps
0002h	Instruction Error
0003h	Context Management
0004h	System bus and peripherals error
0005h	Assertion traps

Within each trap class, specific traps are distinguished by a Trap Identification Number (TIN) that is loaded by hardware into a register before the first instruction of the trap handler is executed.

Note: The TC1796 does not include a MMU, no traps in class 0 will be generated.

The following Tin information is available depending on the trap class:

Info TIN in trap class 0

Hex-val	Description
FFh	no tin deteced
00h	Virtual Address Fill
01h	Virtual Address Protection

Info TIN in trap class 1

Hex-val	Description
FFh	no tin deteced
01h	Privileged Instruction
02h	Memory Protection: Read Access
03h	Memory Protection: Write Access
04h	Memory Protection: Execution Access
05h	Memory Protection: Peripheral Access
06h	Memory Protection: Null Address
07h	Global Register Write Protection

Info TIN in trap class 2

Hex-val	Description
FFh	no tin deteced
01h	Privileged Instruction
02h	Memory Protection: Read Access
03h	Memory Protection: Write Access
04h	Memory Protection: Execution Access
05h	Memory Protection: Peripheral Access
06h	Memory Protection: Null Address
07h	Global Register Write Protection

Info TIN in trap class 3

Hex-val	Description
01h	Free context list depleted (FCX == LCX)
02h	Call depth overflow
03h	Call depth underflow
04h	Free context list underflow (FCX == 0)
05h	Call stack underflow (PCX == 0)
06h	Context type error (PCXI.UL wrong)
07h	Nesting error: RFE with non-zero call depth

Info TIN in trap class 4

Hex-val	Description
01h	Program fetch bus error
02h	Data load bus error
03h	Data store bus error

Info TIN in trap class 5

Hex-val	Description
01h	Arithmetic overflow
02h	Sticky arithmetic overflow

RST_INFO_ADD at RST_CLAS_TYP = 45h (NMI)

If an NMI is the reason one of the following cases with their equivalent value is stored:

Hex-val	Description
00000100h	External NMI
00000200h	NMI caused by WDT
00000300h	PLL loss of lock
00000400h	Parity error in DMI memory

00000401h	Parity error in SPRAM or Instruction cache
00000402h	Parity error in PMI memory
00000403h	Parity error in DMU memory
00000404h	Parity error in PCP RAM memory
00000405h	Parity error in PCP ROM memory
00000406h	Parity error in CAN memory

RST_DBG_BACK_INFO_VLD[NC_RST_DBG_LIST_SIZE]

If additional background information is available, this info shows, whether these info is valid. In other cases 0.

Hex-val	Description
00h	Additional Background infos invalid
01h	Additional Background infos valid

RST_DBG_BACKTRACE_ADDRESS[NC_RST_DBG_LIST_SIZE][NC_RST_DBG_BACKTRACE_SIZE]

If additional background information is valid, a list of NC_RST_DBG_BACKTRACE_SIZE 32-bit values is provided for further investigation purposes.

Hex-val	Description
xxxxxxxxh	Backtrace address 0
yyyyyyyyh	Backtrace address 1
zzzzzzzzh	...

These additional background informations are stored, but not provided at the moment:

RST_DBG_LAST_UPPER_CONTEXT[NC_RST_DBG_LIST_SIZE][15]

RST_DBG_PROC_STATUS[NC_RST_DBG_LIST_SIZE][9]

RST_DBG_ENVIRONMENT[NC_RST_DBG_LIST_SIZE][23]

Before a SW-reset is explicitely executed, it is ensured that the debug driver is activated by calling the DBG routine. This enables the storage of the following bytes in the reset safe memory as valid debug informations.

All additional reset-debug-informations are saved in EEPROM and contain the cause for the last warm-resets.

Activation:

once, directly after each ECU-reset; before starting the operation-system

Formula section:

Evaluate controller information:

RST_TYP

```
RST_SEC = 0 (reset to 0)

If (1)    RST_TYP = 12h (Intended Power-On Reset)
Then (1)
    Power-On-Reset detected
    LV_WARM_RST = 0
Else (1)
    warm-Reset detected
    RST_INFO_CTR = Reset Counter from Debug driver
    Shift all list entries by one, eg.              (first in first out of stored informations)
    RST_CLASS_TYP[NC_RST_DBG_LIST_SIZE-2]
            -> RST_CLASS_TYP[NC_RST_DBG_LIST_SIZE-1]
                    ->
    RST_CLASS_TYP[0]
            -> RST_CLASS_TYP[1]
    Erase newest list entries, eg.
    RST_CLASS_TYP[0] = 0
    Evaluate and store actual values in list
    RST_CLASS_TYP[0] = RST_TYP
    RST_INFO_ADD[0] = Cause from Debug driver     (Additional Info)
    CPU_LOAD_MAX_RST_DET[0] = CPU_LOAD_MAX at reset
    N_CPU_LOAD_MAX_RST_DET[0] = N_MAX at CPU_LOAD_MAX
    CPU_LOAD_RST_DET[0] = CPU_LOAD at reset
    N_RST_DET[0] = N at reset
    DIST_RST_DET[0] = DIST at reset
    TRT_RST_DET[0] = TRT at reset
    If (2) RST_CLASS_TYP[0] = 42h (Intended Software Reset)
            RST_LPRC_RESET_ADDRESS[0] = Last  LPRC caller address
    Else (2)
            RST_LPRC_RESET_ADDRESS[0] = 0
    Endif (2)
    RST_DBG_BACK_INFO_VLD[0] = Validation info from Debug driver
    If (2) RST_DBG_BACK_INFO_VLD[0] = 1
            RST_DBG_BACKTRACE_ADDRESS[0][ ] = Backtrace from Debug driver
            RST_DBG_BACK_UPPER_CONTEXT[ ] = Context from Debug driver
            RST_DBG_BACK_PROC_STATUS[ ] = Processor status from Debug driver
            RST_DBG_BACK_ENVIRONMENT[ ] = Environment from Debug driver
    Endif (2)
    LV_WARM_RST = 1
    LV_ RST_DET = 1
```

Endif (1)

Later notification from security system:

Activation: **Action at notification from ECM3 (ACTION_SetRstInfo_Ecm3)**

Formula section:

LV_RST_DET_DISP = 0 (reset flag until error reported)
RST_SEC = 1 (add ECM3 security info)

The safety-concept will submit the information after a reset, when rst-information from the MU is available. As it is not known, whether or when such a reset can be detected by security system, the trap reset can set error SYM_0 before it will be set to SYM_1 by security system.

Clearing of stored data can be done on demand:

Activation: **Action at clearing FMY (e.g. by service-tester)**

Formula section:

RST_TYP = 0
RST_INFO_CTR = 0 Clear Reset counter from Debug driver also
RST_SEC = 0
LV_RST_DET_DISP = 0
LV_RST_DET = 0
LV_WARM_RST = 0

Clear all list entries, eg.
RST_CLASS_TYP[NC_RST_DBG_LIST_SIZE-2] = 0
...
RST_CLASS_TYP[0] = 0

Activation: **Action for status ADC from interface (ACTION_GetBiosAdcStatus)**

called every 10ms

Hint:
The Adc_watchdog_timeout describes the timeout of ADC interface in BIOS.

When the Adc_watchdog_timeout >= NC_MAX_ADC_OUT the interface is detected as out of operation and debug driver is called.

Formula section:

NC_MAX_ADC_OUT = 50 (Configuration BIOS: adc_watchdog_max_timeout)

```
NC_CTR_MAX_ADC_OUT = 50

ACTION_INFR_GetBiosAdcStatus (Bios_adc_status)

set counter CTR_ADC_OUT according STD_INI

IF      ACTION_INFR_GetBiosAdcStatus delivers ADC error
THEN    CTR_ADC_OUT$_n$ = CTR_ADC_OUT$_{n-1}$ + 1
ELSE    IF CTR_ADC_OUT$_n$ >0
        THEN CTR_ADC_OUT$_n$ = CTR_ADC_OUT$_{n-1}$ – 1
        ELSE CTR_ADC_OUT$_n$ = 0
        END
END

IF              CTR_ADC_OUT >= NC_CTR_MAX_ADC_OUT
THEN            call Reset Debug driver    (execute Reset caused by ADC interface)
                CTR_ADC_OUT = 0
END
```

14.1.1 Handling of ECU-Reset detection in error management

FUNCTION DESCRIPTION:

The following section describes the mechanism of failure handling in error management. Related to the reset type the error management carries out a failure symptom.

Application conditions:

after each ECU-reset
As information from the safety concept is only available late after restart, it has to be checked cyclic for changes (see later). So it is supposed first, that errors will be cleared first.

An entry in error management has occurred if the reset counter RST_INFO_CTR is incremented.

In this case actually the byte RST_CLAS_TYP[0] which include the causes of resets is additionally sent to error management.

Error symptoms are defined to this diagnosis function as follows:

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> -   Intended software reset (SWRST)    (= SYM_0)
 │  │  └────> -   Reset by safety-concept            (= SYM_1)
 │  └───────> -   Reset unintended by software       (= SYM_2)
 └──────────> -   Reset unintended by hardware       (= SYM_3)
```

at clearing FMY

The error is present until clearing FMY by application constant or flash. Additionally an information about current presence of failure is performed.

Hint: As described also in ASW the CPU_LOAD_MAX is reset with LC_CPU_LOAD_MAX_RST.

cyclic data collection

recurrency: 10 ms

In the warm-reset memory several data are cyclic saved every 10ms. CPU_LOAD_RST_DET is updated with CPU_LOAD. In case of an occured warm-reset the memory is read at initialisation of ECU. CPU_LOAD_RST_DET represents the CPU_LOAD at warm-reset. N_RST_DET is the related engine speed at this warm-reset. The CPU_LOAD_MAX_RST_DET is the occured maximum and saved in non-volatile memory. It gives information about several cycles. N_CPU_LOAD_MAX_RST_DET is the related engine speed at this maximum.

Related to warm-reset memory DIST_RST_DET represents the distance and TRT_RST_DET represents the total runtime at the last occured warm-reset.

By preparing the freeze frame it is necessary to hand over the relevant values. So the configured freeze frame is read out of warm-reset memory.

The data listed in the table are enabled to configure in freeze frame as environment data.
If a reset occurs and send to error-management the freeze frame is saved. Via tester the data are readable on the diagnostic communication line.

The anti-bounce-algorithm is not used. The sympton is set and reset immediately.

14.2 ECOP – Requirements to infrastructure interface

Export actions:

ACTION_INFR_GetVpTecu (OUT < Vp_tecu_sens **>)**
This action provides the digitized voltage value of the ECU temperature sensor
ACTION_INFR_GetVTecuMc (OUT <V_tecu_mc_sens>)
This action provides the digitized voltage value of the microcontroller temperature sensor
ACTION_INFR_GetBiosAdcStatus (OUT <Bios_adc_status>)
This action provides the digitized status of analogous signals

Description for actions:

ACTION_INFR_GetVpTecu (Vp_tecu_sens**)**

This action provides the digitized voltage value of the ECU temperature sensor in a single value delivered from the infrastructure. The AD conversion is performed autonomously by the infrastructure. When the action is called the gathered information will be provided to the application software level.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Vp_tecu_sens	OUT	0...7FFFH	0...4.99984	0.1526e-03	V
ECU temperature sensor voltage value					

ACTION_INFR_GetVTecuMc (V_tecu_mc_sens**)**

This action provides the digitized voltage value of the microcontroller temperature sensor in a single value delivered from the infrastructure. The AD conversion is performed autonomously by the infrastructure. When the action is called the gathered information will be provided to the application software level.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
V_tecu_mc_sens	OUT	0...7FFFH	0...4.99984	0.1526e-3	V
Microcontroller temperature sensor voltage					

ACTION_INFR_GetBiosAdcStatus (Bios_adc_status**)**

This action provides the digitized status of analogous signals in a single value delivered from the infrastructure. The AD conversion is performed autonomously by the infrastructure. When the action is called the gathered information will be provided to the application software level.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Bios_adc_status	OUT	0...1H	0...1	1	[-]
Status ADC in BIOS					

FUNCTION DESCRIPTION:

General information:

The following action is used for the acquisition of the digitized voltage values of the adressed ECU temperature sensors in two single values. The action delivers the ECU temperature sensors voltages values to the application software level from the standard AD converter queue.

- The AD conversions are performed autonomously by the infrastructure, the returned values are not older than 500 ms (in case of TECU sensor) and 10 ms (in case of the TECU sensor of the microcontroller).
- The voltage values are gathered in the infrastructure until the application reads out the information by calling the action, old values are replaced by new values.

Requirements for ACTION_INFR_GetVpTecu:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Vp_tecu_sens			10 Bit	Vp_tecu_sens is digitized at point in time t_k. For the returned array the maximum allowed time periode $\| t_k - t_i \|$ must less than 500ms.	No comment

Diagnosis: no electrical diagnosis done here

Coincidence requirements: When calling this action, all returned voltages must be within the last 500 ms.

Requirements for ACTION_INFR_GetVTecuMc:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
V_tecu_mc_sens			10 Bit		

Diagnosis: no electrical diagnosis done here

Coincidence requirements: When calling this action, all returned voltages must be within the last 500 ms.

Requirements for ACTION_INFR_GetBiosAdcStatus:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Bios_adc_status			1 Bit		

Diagnosis: no electrical diagnosis done here

Coincidence requirements:

When calling this action, all returned results must be within the last **10 ms**.

14.3 ECU State Detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ECU_STATE	V/O	0H 1H 2H 3H 4H 5H 6H	ENG_STOP RUN_ENG SYN_ENG_IGK_ON SYN_ENG_IGK_OFF PWL ENG_LOCK WAKE_UP	0	[-]
information on ECU state					
FAST_ECU_TRAN_PWL_CTR	V	0...FFFFH	0...655.35	0.01	[s]
fast transition counter for transition from SYN_ENG_IGK_OFF to PWL despite of engine running					

Input data:

LV_INH_PWL_TRAN_ES_EL	ECU_LOCK_REQ	
LV_STOP_ENG	LV_IGK	LV_SYN_ENG
LV_FIRST_VLD_TOOTH	LV_RUN_ENG	LV_CS
T_DLY_RLY_MAIN_DIAG	LV_RLY_MAIN	VB
C_VB_RLY_MAIN_DIAG		

Application conditions:

Recurrence: If LV_ES = 1 → segment-synchronous

If LV_ES = 0 → 10ms

FUNCTION DESCRIPTION:

General information:

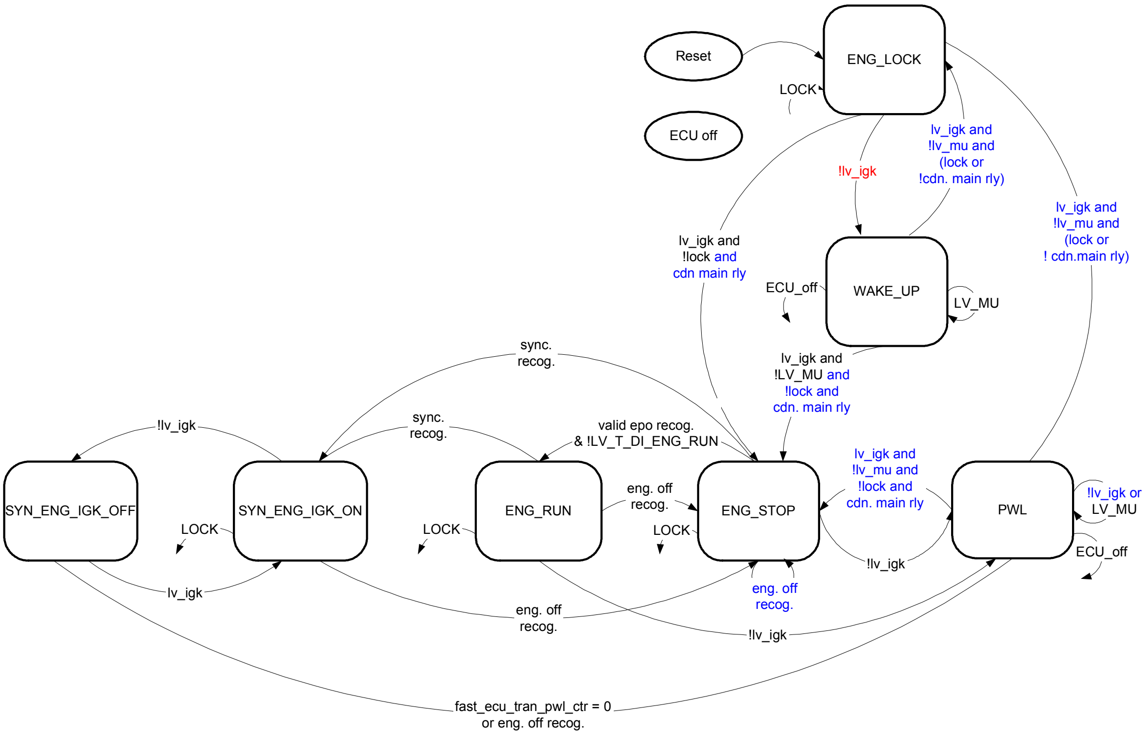
The function ECU-state manages detection of the operating states of the ECU and transitions between them referring to the main inputs key detection and crankshaft synchronization.

The ECU-state offers system events corresponding to those transitions that can be used by other functions (e.g. ignition function that asks for ignition reset on the transition engine running to engine stop).

Those actions are described in the specification chapter of the corresponding functions.

An important value to determine the ECU-state is the value ECU_LOCK_REQ. If it becomes 1, the ECU-state will become ENG_LOCK (exeption is PWL and WAKE_UP).

Signal flow diagram:



Details:
-> LOCK = ecu_lock_req
-> LV_MU = lv_inh_pwl_tran_es_el
-> eng. off recog. = lv_stop_eng
-> sync. recog. = lv_syn_eng
-> valid epo recog. = lv_run_eng and !lv_syn_eng
-> cdn. main rly = [lv_rly_main and (vb >= c_vb_rly_main_diag or t_dly_rly_main_diag = 0)]

Detection of first valid tooth:

If LV_STOP_ENG = 0 **and**

LV_FIRST_VLD_TOOTH 0 -> 1

Then offer an interface for project specific activities on this state transition

Endif

ENGINE LOCK (ENG_LOCK)

This state is dedicated to a special operating state (e.g. engine locked by immobilizer) where all essential outputs are inhibited. An interface for project specific activities on this state ENG_LOCK does exist. The ECU state is initialized with this state after reset.

ENG_LOCK => WAKE_UP

```
If      LV_IGK = 0
Then    ENG_LOCK => WAKE_UP
Endif
```

ENG_LOCK => ENG_STOP

```
If      ECU_LOCK_REQ = 0                and
        LV_IGK = 1                      and
        LV_RLY_MAIN = 1                 and
        (VB >= C_VB_RLY_MAIN_DIAG       or
        T_DLY_RLY_MAIN_DIAG = 0)
Then    offer an interface for project specific activities on this state transition
        ECU_STATE = ENG_STOP
Endif
```

ENGINE STOP (ENG_STOP)

The crankshaft does not turn (no valid crank- or cam-edges are recognized), ignition key is ON and no engine lock condition is set. An interface for project specific activities on this state does exist.

ENG_STOP => PWL

```
If      LV_IGK = 0
Then    offer an interface for project specific activities
        LV_T_DI_ENG_RUN  =  0
        ECU_STATE = PWL
Endif
```

ENG_STOP => ENG_LOCK

```
If      ECU_LOCK_REQ > 0        and
        LV_IGK = 1
Then    offer an interface for project specific activities
        ECU_STATE = ENG_LOCK
Endif
```

ENG_STOP => ENG_STOP

```
If          LV_STOP_ENG = 1
Then        offer an interface for project specific activities
            ECU_STATE = ENG_STOP
            Decrement  timer_disable_engine_run  till 0
            If      timer_disable_engine_run = 0
            Then    LV_T_DI_ENG_RUN  =  0
            Endif
Endif
```

ENG_STOP => ENG_RUN

```
If          LV_RUN_ENG = 1              and
            LV_SYN_ENG = 0              and
            LV_T_DI_ENG_RUN = 0
Then        offer an interface for project specific activities
            ECU_STATE = RUN_ENG
Endif
```

ENG_STOP => SYN_ENG_IGK_ON

```
If          LV_RUN_ENG = 1    and
            LV_SYN_ENG = 1
Then        offer an interface for project specific activities for transition of state RUN_ENG
            offer a second interface for project specific activities on the state transition in
            state SYN_ENG_IGK_ON
            ECU_STATE = SYN_ENG_IGK_ON
Endif
```

RUNNING ENGINE (ENG_RUN)

This state corresponds to a turning engine without synchronization on crankshaft.

An interface for project specific activities on this state does exist.

ENG_RUN => PWL

```
If          LV_IGK = 0
Then        offer an interface for project specific activities on this state transition.
            ECU_STATE = PWL
Endif
```

ENG_RUN => ENGINE LOCK

```
If      ECU_LOCK_REQ > 0
Then    offer an interface for projekt specific activities,
        ECU_STATE = ENG_LOCK
Endif
```

ENG_RUN => ENG_STOP

```
If      LV_STOP_ENG = 1
Then    offer an interface for project specific activities,
        ECU_STATE = ENG_STOP
Endif
```

ENG_RUN => SYN_ENG_IGK_ON

```
If      LV_SYN_ENG = 1
Then    offer an interface for project specific activities
        ECU_STATE = SYN_ENG_IGK_ON
Endif
```

SYNCHRON ENGINE: IGNITION KEY ON (SYN_ENG_IGK_ON)

This state corresponds to a synchronized engine and ignition key on.

SYN_ENG_IGK_ON => ENG_LOCK

```
If      ECU_LOCK_REQ > 0
Then    offer an interface for project specific activities
        ECU_STATE = ENG_LOCK
Endif
```

SYN_ENG_IGK_ON => ENGINE STOP

```
If      LV_STOP_ENG = 1
Then    offer an interface for project specific activities
        If      LV_CS = 1
        Then    start  timer_disable_engine_run  with C_T_DI_ENG_RUN
                LV_T_DI_ENG_RUN  =  1
        Endif
        ECU_STATE = ENG_STOP
Endif
```

SYN_ENG_IGK_ON => SYN_ENG_IGK_OFF

```
If      LV_IGK = 0
Then    offer an interface for project specific activities,
        ECU_STATE = SYN_ENG_IGK_OFF
Endif
```

Fast transition counter FAST_ECU_TRAN_PWL_CTR

The transition SYN_ENG_IGK_OFF => PWL FAST_ECU_TRAN_PWL_CTR is done if engine is stopped or if LV_IGK = 0 and fast transition counter FAST_ECU_TRAN_PWL_CTR = 0. The fast transition counter is started at transition from SYN_ENG_IGK_ON => SYN_ENG_IGK_OFF and is decremented at every recurrence by 10 ms.

```
If      transition ECU_STATE = SYN_ENG_IGK_OFF => ECU_STATE = PWL
Then    FAST_ECU_TRAN_PWL_CTR = FAST_ECU_TRAN_PWL_CTR - 10 ms
Else    FAST_ECU_TRAN_PWL_CTR = NC_FAST_TRAN_PWL
Endif
```

SYNCHRON ENGINE: IGNITION KEY OFF (SYN_ENG_IGK_OFF)

This state corresponds to a synchronized engine and ignition key off.

SYN_ENG_IGK_OFF => SYN_ENG_IGK_ON

```
If      LV_IGK = 1
Then    offer an interface for project specific activities
        ECU_STATE = SYN_ENG_IGK_ON
Endif
```

SYN_ENG_IGK_OFF => PWL

```
If      LV_STOP_ENG = 1                    or
        FAST_ECU_TRAN_PWL_CTR = 0
Then    offer an interface for project specific activities
        ECU_STATE = PWL
Endif
```

POWER LATCH (PWL)

Non volatile data are stored and ECU shutdown is prepared. An interface for project specific activities on this state does exist.

PWL => ENG_LOCK

```
If      LV_IGK = 1                      and
        LV_INH_PWL_TRAN_ES_EL = 0       and
        (ECU_LOCK_REQ > 0               or
        LV_RLY_MAIN = 0                 or
        (VB < C_VB_RLY_MAIN_DIAG        and
        T_DLY_RLY_MAIN_DIAG > 0))
Then    ECU_STATE = ENG_LOCK
Endif
```

PWL => ENG_STOP

```
If      LV_IGK = 1                      and
        LV_INH_PWL_TRAN_ES_EL = 0       and
        ECU_LOCK_REQ = 0                and
        LV_RLY_MAIN = 1                 and
        (VB >= C_VB_RLY_MAIN_DIAG       or
        T_DLY_RLY_MAIN_DIAG = 0)
Then    ECU_STATE = ENG_STOP
Endif
```

PWL => PWL

```
If      LV_ IGK=0                       or
        LV_INH_PWL_TRAN_ES_EL = 1
Then    The condition LV_INH_PWL_TRAN_ES_EL = 1 indicates that the monitoring
        unit disabled the powerstages of MTC and injection outputs. IGK ON recognition
        is not accepted without reset.
        ECU_STATE = PWL
Endif
```

WAKE UP MODE (WAKE_UP)

The Wake UP Mode can only be reached after ECU_Reset (Shut Down Mode).
This mode indicates that the LV_WAKE_UP was set and the Ignition Key is off.

WAKE_UP => ENG_LOCK

```
If      LV_IGK  = 1                  and
        LV_INH_PWL_TRAN_ES_EL = 0    and
        (ECU_LOCK_REQ > 0            or
        LV_RLY_MAIN = 0              or
        (VB < C_VB_RLY_MAIN_DIAG     and
        T_DLY_RLY_MAIN_DIAG > 0))
Then    ECU_STATE = ENG_LOCK
Endif
```

WAKE_UP => ENG_STOP

Import actions:

ACTION_INFR_GetVTecuMc(OUT <V_TECU_MC>)
This action provides the digitized voltage value of the microcontroller temperature sensor
ACTION_INFR_GetVpTecu(OUT <VP_TECU>)
This action provides the digitized voltage value of the ECU temperature sensor

14.4.1 ECU temperature TECU:

The ECU temperature is measured through an A/D converter. The software then is generating a modified sensor signal (VP_TECU), which is requested by the application software for further execution.

The conversion into physical values is made through the non-linear characteristic IP_TECU. In case of a present fault of the TECU-sensor a substitute value will be used.

By request (LC_TECU_SWI) the source for the TECU calculation can switch between IP_TECU(VP_TECU) and TECU_MC.

Configuration data

Here are listed the configuration data:

Data	**Value**
NC_TECU_MC_SLOP	190 °C/V *
NC_TECU_MC_OFS	231.9 °C

*Note: For SW calculation purposes NC_TECU_MC_SLOP = 0.028992584

15.1 ECU reprogramming, general functionality

15.1.1 Introduction

This document describes the flash reprogramming concept. The concept is always applied.

It is a generic specification. For the customer particular requirements another document called “ECU reprogramming, SW specification” describes the software specification of the reprogramming function.

In addition to this current document the customer specific parts (diagnosis protocol, logistics and historic field) have to be described in other files referring to this document.

This document does not describe the first programming of an ECU at the Siemens production line or the first programming of prototypes.

15.1.2 General description

The usage of suitable segmented flash memories, with the opportunity to delete and (re-) program parts of the module separately, enables the development of a strategy called reprogramming of the Flash memory at the customer.

The car manufacturers use this feature in order to delete the Calibration data and/or ECU-SW and to program them again. With this method it is possible to avoid the exchange of the ECU when functional changes or errors of the ECU-SW occur.

The result is a considerable decrease in expenses of the after-sales service for the customer and the supplier.

The activation of the function and the communication actions are done through a unique communication line (diagnosis line) without applying an external voltage to a specific pin of the ECU connector.

The ECU memory is divided into three principal and functional independent parts : Boot sector, ECU-SW sector and Calibration data sector.

The reprogramming function needs always an existing Boot-SW because all the software routines for a reprogramming session are located in the Boot sector (Boot-SW).

The fundamental restriction is that this sector is not erasable.

The effects resulting from the user actions during a reprogramming session (e.g. key off/key on, false use of the tool, manipulation) and external disruptions on the communication line are not predictable. So the ECU has to ensure that unauthorized actions or failures in the reprogramming session have no impact on the operation of the Boot-SW / ECU-SW.

The following principle requirements have to be taken into consideration for the implementation of the reprogramming function :

- The reprogramming function can be used for the end of line and the field programming.
- The routines for the programming / erasing of the flash memory must be executed from outside the Flash memory itself, because a read access to the flash memory is not possible during programming / erasing.
- For the activation of the reprogramming function and the communication during the session only one physical layer (e.g. K-line) is used.
- For the reprogramming function the customer specific diagnostic protocol is used.
- The software is divided into three independent parts (Boot-SW, ECU-SW, and Calibration data).
- Each part of the SW is protected with its own, separate checksum.
- The reprogramming function needs always an existing Boot-SW.
- For the customer it is not possible to reprogram the Boot-SW.
- Security concept to protect the ECUs against unauthorized manipulation.
- Security concept to avoid the “recycling ECUs” when the reprogramming is not correct.
- Check mechanism for compatibility between Boot-SW, ECU-SW and calibration data.
- Information about the reprogramming status of the ECU easily available for the tool.

15.1.3 Communication between reprogramming Tool and ECU

The communication between the reprogramming tool and the ECU is carried out through a unique bi-directional data link (in general K-line).

The reprogramming services are part of the diagnosis services. The basic services are listed below :

- Communication initialization,
- ECU identification (read logistics information),
- Reprogramming Tool identification (security access),
- Erase action (Calibration data sector and/or ECU-SW sector),
- Transfer actions (read / write Calibration data and/or ECU-SW),
- Reprogramming control and report (checksum, coherence Boot-SW / ECU-SW / Calibration data),
- Historic update (write bytes in Boot sector),
- End communication.

All the diagnostic services that are needed for a reprogramming session must be stored in the Boot-SW (non-erasable sector).

The performance (duration) of a reprogramming session depends on the performance of the communication protocol, except for the Flash memory erase sequence, that depends on the Flash memory type.

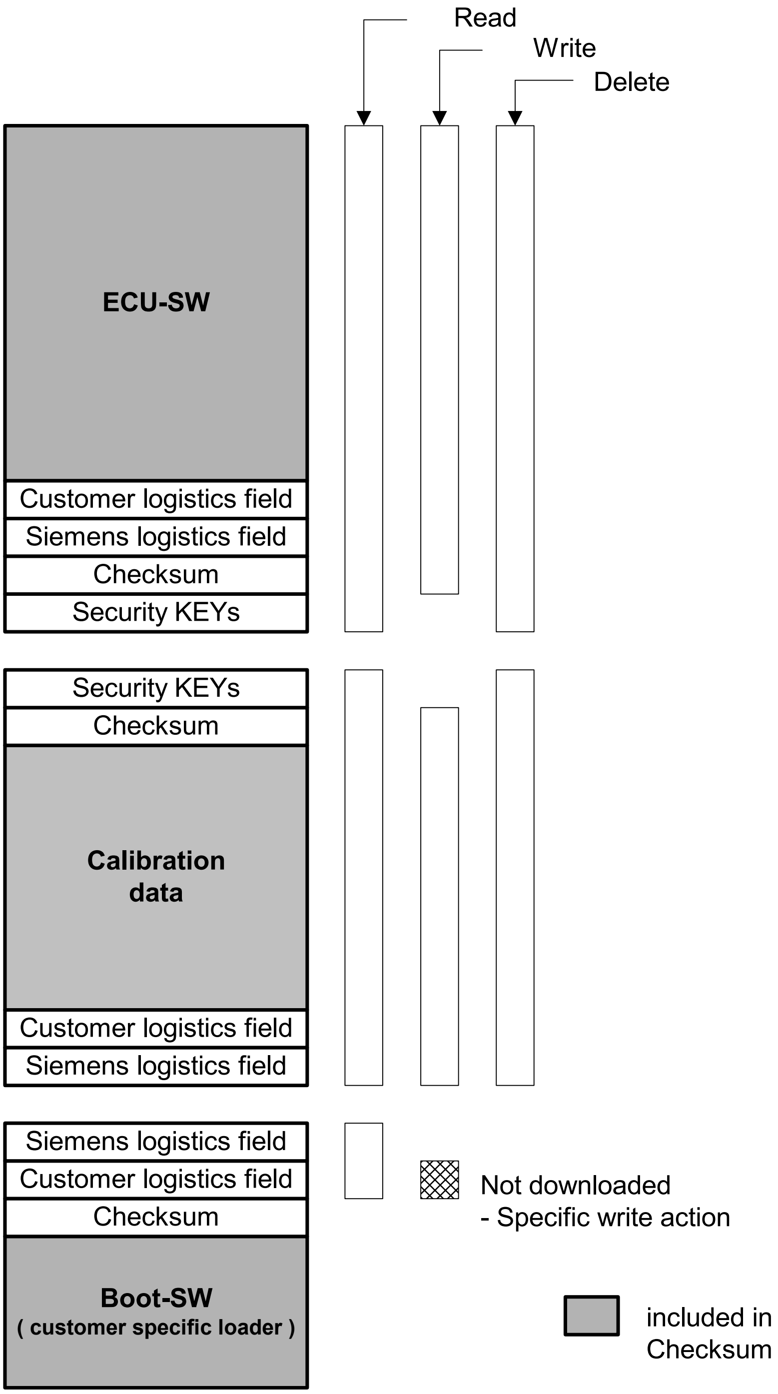
The diagnosis protocol and services have to be described in other documents.

15.1.4 Functional memory layout

The software is divided into three parts :

Boot-SW	cannot be reprogrammed through the customer protocol, size depends on the used flash memory.
ECU-SW	reprogrammable, size depends on the used flash memory.
Calibration data	reprogrammable, size depends on the used flash memory.

The following picture shows the principle architecture.



15.1.4.1 Boot-SW

This sector is not erasable through the customer protocol; it contains all routines used at start-up of the system and all diagnosis services for a reprogramming session.

A field is reserved for customer logistics information.

Contents :

- Interface for ECU-SW,
- Minimum operating system,
- RAM-Test,
- Key_on / Key_off recognition mechanism,
- Customer specific communication protocol layer,
- Diagnosis communication services for reprogramming and logistics,
- Reprogramming routines (delete, start, transfer, exit and check) for the flash memory (please report to chapter 15.1.7 -Reprogramming states),
- Flash access routines for erasing and reprogramming,
- Siemens logistics information field (test results of the Siemens production line, logistics data, identifiers, checksum),
- Customer logistics information field (e.g. the historic of the reprogramming actions stored at the end of reprogramming session),
- Security mechanisms (checksum calculation, coherence and security keys check),
- Seed / Key procedure.

15.1.4.2 ECU-SW

The ECU-SW size depends on the functional system requirements. The limitation to a maximum size depends on the used flash device.

This part contains all routines of the applicative SW of the system.

The reprogramming actions affect the complete area, except the security fields (please report to chapter 15.1.5 - Security mechanisms).

Contents :

- Interface for Boot-SW,
- Basic SW functions which are not necessary for the reprogramming,
- All I/O and applicative SW routines,
- Communication protocol routines,
- Seed / Key procedure,
- Security keys for ECU-SW which guarantee the correct reprogramming,
- Logistic information field (Siemens and Customer),
- Interrupt vector table.

The logistic information field of the ECU-SW, the checksum information and the interrupt vector table are located at fixed addresses in the same way as the interface table for the Boot-SW.

15.1.4.3 Calibration data

The calibration data contains all information for engine tuning.

The reprogramming actions affect the complete area, except the security fields (please report to chapter 15.1.5 -Security mechanisms).

Contents :

- All constants and calibration maps tuned via application tool,
- Security keys for the calibration data which guarantee the correct reprogramming,
- Identification field (comparable to logistic information field within the software),
- Customer logistics field (if necessary).

The checksum information has a definite size and is located at a fixed address within the calibration data.

15.1.5 Security mechanisms

The effects resulting from user actions during a reprogramming session or caused by unauthorized manipulation are not predictable. So a protection is necessary to avoid erroneous flash contents as a consequence of such an influence.

The SW has to ensure a high level of security so that the above mentioned cases have no impact on the operation of the ECU. Therefore special security mechanisms are implemented. Some for protection and the other for a safe detection if correct reprogrammed.

- Security keys in flash memory and RAM to secure the reprogramming session,
- Status word in RAM to guaranty the proper sequence of the reprogramming states,
- Seed/Key procedure (according to SAE J2186 / J2190) via the data link to allow a reprogramming session,
- When an ECU-SW reprogramming session is active, only reprogramming within the ECU-SW memory address range is allowed.
- When a calibration data session is active, only reprogramming within the calibration memory address range is allowed.
- ADD-ON programming for logistics data is only allowed, when no ECU-SW or Calibration data reprogramming is active.
- Checksum test to detect data transmission errors on the data link,
- Check mechanism using a coherence system,
- All logistics data in the BOOT-SW cannot be deleted over the lifetime of the ECU.
- As long as a reprogramming session is not successfully completed, the ECU remains in the reprogramming state (only activation of Boot-SW); this is necessary to avoid “recycling ECUs”.

15.1.5.1 Security Access

To avoid unauthorized manipulation (read / erase / write actions) of the ECU data, security accesses (Siemens / Customer) are implemented to allow / forbid access to the content of the flash memory.

It is not possible to reprogram the ECU-SW and/or the calibration data if the ECU is not unlocked by a successfully security access phase (according to SAE J2186) between the reprogramming tool and the ECU.

The access to higher security levels (or unlocked state) is realized by two successfully handshake messages (request / response) between the tool and the ECU. Thus the ECU certifies the tool.

15.1.5.2 Reprogramming Keys in RAM

To avoid unpredictable erase / write actions of the ECU data, the basic routines for erase and write actions are inhibited if the Reprogramming Keys are not initialized.

The Reprogramming Keys, 4 RAM bytes, are initialized at each erase / write request that concerns the reprogramming function. These keys are tested by the basic routines (erase / write).

At the end of each erase / write routine and on ECU reset, these bytes are set to 00h.

15.1.5.3 Checksum calculation

To guaranty the validity of the reprogrammed data transmitted through the communication line an independent checksum value is stored in each area (ECU-SW, Calibration data).

This checksum is tested at the end of a reprogramming session. If the calculated values do not fit with the stored values in ECU-SW area and Calibration data area, the applicative software is inhibited and there is no engine operation.

15.1.5.4 Coherence System

The Coherence System ensures that the three independent SW-parts fit together. The coherence identifiers are implemented in the Boot-SW, the ECU-SW and the Calibration data and are checked at the end of a reprogramming session and at start-up of the ECU.

If the three identifiers do not fit together, the applicative software is inhibited and there is no engine operation.

15.1.5.5 Security Keys in flash memory

To guaranty that a reprogramming session is successfully completed, a four bytes Security Key is implemented in each part, which can be reprogrammed (ECU-SW, Calibration data).

These keys are updated at the end of a reprogramming session, and tested at start-up of the ECU. If one of the Security Keys is not valid, the applicative software is inhibited and there is no engine operation.

Functional description of the Security Keys :

- After a reprogramming request, the Security Key is set to 00h.
- During the erase operation the Security Key is automatically set to default value of the flash.
- At the end of the reprogramming operation the checksum and the Coherence System are checked, in case of a proper reprogramming session the Security Key is set to a fixed value.

15.1.5.6 Reprogramming session status

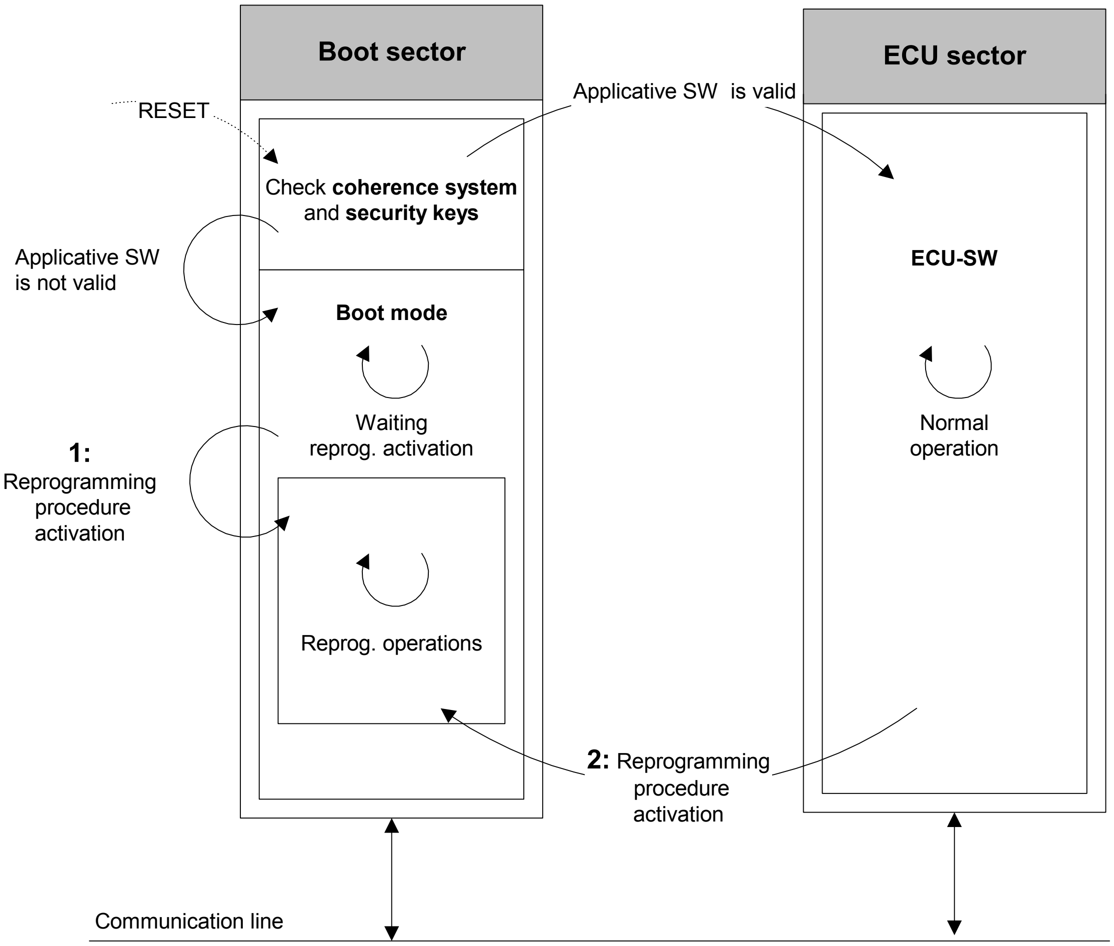
To guaranty the proper sequence of the reprogramming session, a session status is tested and updated in each basic action (please report to chapter 15.1.7 -Reprogramming states).

This mechanism avoids to skip a phase of the reprogramming states.

15.1.6 Reprogramming procedure activation

The following picture shows the principle mechanisms to activate a reprogramming session :

1. In that case, the applicative SW is inhibited; the Boot-SW controlled the communication line interface and the diagnosis services for the reprogramming activation.
2. In that case, ECU is in applicative mode. It should switch to Boot mode before to launch the reprogramming function.



The applicative SW is only activated if all parts are correct reprogrammed and fit together.
If one part is missing or not correct reprogrammed the system actives the Boot-SW.

The following conditions are possible at start-up (Key-On, Reset) of the system :

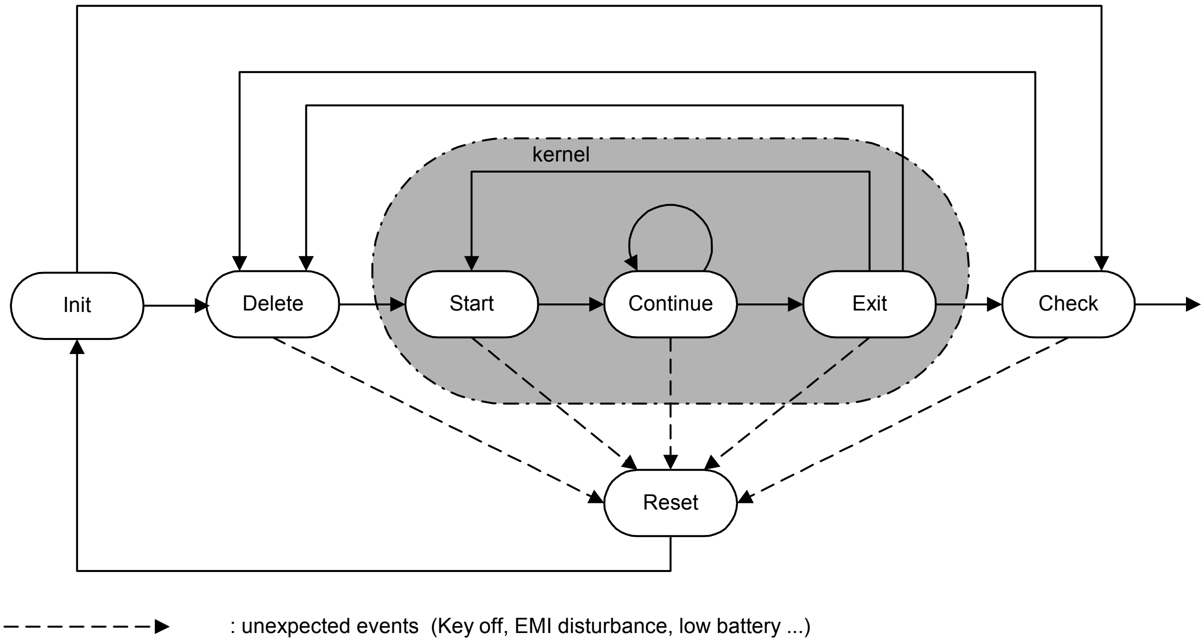
Boot-SW	ECU-SW	Calib. data	ECU action
X	[-]	[-]	ECU activates only Boot-SW, no engine operation
X	[-]	X	ECU activates only Boot-SW, no engine operation
X	[X]	X	ECU activates only Boot-SW, no engine operation
X	[X]	[X]	ECU activates only Boot-SW, no engine operation
X	X	[-]	ECU activates only Boot-SW, no engine operation
X	X	[X]	ECU activates only Boot-SW, no engine operation
X	X	X	ECU normal operation = engine operation

(X = available, [X] = wrong reprogrammed or coherence system value not correct, [-] = erased)

15.1.7 Reprogramming states

These reprogramming states are only possible when the ECU is unlocked by the tool.

REPROGRAMMING STATES



15.1.7.1 State “Init”

First step to the flash access, only necessary once during an ECU reprogramming session.

- Prepare a reprogramming session
    - The diagnostic session has to be opened.
    - The timings of the protocol have to be set to higher limits in order to reduce the reprogramming duration.
- Unlock ECU for a reprogramming session

15.1.7.2 State “Delete”

- The only action is to delete either calibration data or ECU-SW.
- This state also activates the Boot SW mode.

15.1.7.3 State "Start"

- Open a reprogramming session for calibration data or ECU-SW.
- No data are deleted.
- No reprogramming of data.
- Check if address area is allowed.

15.1.7.4 State "Continue"

- An active reprogramming session for calibration data or ECU-SW is continued.
- Reprogramming of data will be done.
- No data are deleted.

Note: If a session for reprogramming of calibration data is opened, reprogramming of ECU-SW is not possible and vice versa.

15.1.7.5 State "Exit"

- Close a reprogramming session for calibration data or ECU-SW.
- No checks are done.
- No reprogramming of data.

15.1.7.6 State "Check"

- The calibration data and ECU-SW are checked (coherence system, checksums).
- No reprogramming of data (except the Security Keys if necessary to write).
- Update of the reprogramming status word; please report to the chapter 15.1.8 - Reprogramming Status Word definition.

15.1.7.7 State "Reset"

- Reset the status information for reprogramming. Useful when the communication end or a break was detected.

15.1.8 Reprogramming Status Word definition

The Reprogramming Status Word informs users on the validity of the applicative SW.

This word content is a dynamic information (RAM) and is only valid if the check of reprogramming have been previously performed.

At reset this information is lost.

Bit #	Bit definition	Group definition
#15	Checksum of Calibration data is correct	Calibration data information
#14	Security Keys for Calibration data are not written	
#13	Security Keys for Calibration data are correct	
#12	Calibration data is correct	
#11	Checksum of ECU-SW is correct	ECU-SW information
#10	Security Keys for ECU-SW are not written	
#9	Security Keys for ECU-SW are correct	
#8	ECU-SW is correct	
#7	Reprogramming of ECU is successfully completed	General ECU information
#6	ECU is not at the end of reprogramming session	
#5	Coherence identifiers fit together	Coherence system information
#4	Calibration data does not fit to ECU-SW	
#3	ECU-SW does not fit to Boot-SW	
#2	Coherence identifier in Calibration data is erroneous	
#1	Coherence identifier in ECU-SW is erroneous	
#0	Coherence identifier in Boot-SW is erroneous	

When the bit definition is right, the bit value is set to 1.

e.g. just at the end of successful reprogramming session, the value is BBh A0h.

15.2 Flash reprogramming

15.2.1 The message flow of flash-reprogramming with the WinProF Tool (aftersales)

Index

16.1 EGCP Configuration Data

Input data:

NC_FAC_R_REF_LS_DOWN	NC_R_REF_LS_DOWN	NC_VLS_DOWN_CUR_PUMP_REF	NC_LSHPWM_BOL_LSH_DOWN
NC_LSHPWM_TOL_LSH_DOWN	NC_LSHPWM_BOL_LSH_UP	NC_LSHPWM_TOL_LSH_UP	NC_FAC_10_SAMPLE
NC_FAC_5_SAMPLE	NC_NR_BUF_SAMPLE_LEN	NC_NR_RAW_BUF_LEN	NC_N_MIN_VLS_UP_MV
NC_T_SEG_LEN_MIN	NC_NR_BUF_SUM_LEN	NC_PSD_DLY_LSH_UP	NC_PSD_DLY_LSH_DOWN

16.1.1 Global configuration data

Here are listed the configuration data specific for the projects using the Tricore processor and which can be used in other aggregates:

ATTENTION: NC_CBK_EX_NR has the value 2 for 4 and 6 cylinder engines. For N43 UL the second bank is virtual to fit the system.

Data	**Value**
NC_CBK_EX_NR	2
NC_STATE_LSL_UP_IF	1
NC_STATE_VLS_UP_SIG_ACQ	1
NC_FRQ_LSHPWM_UP	100 Hz
NC_FRQ_LSHPWM_DOWN	10 Hz
NC_PSD_DLY_LSH_UP	2
NC_PSD_DLY_LSH_DOWN	2
NC_FAC_R_REF_LS_DOWN	0.07957
NC_R_REF_LS_DOWN	3740 Ohm
NC_VLS_DOWN_CUR_PUMP_REF	3.22 V

16.1.2 Local configuration data

Here are listed the configuration data, which are used only in the EGCP aggregate.

Data	**Value**
NC_LSHPWM_BOL_LSH_DOWN	1 %
NC_LSHPWM_TOL_LSH_DOWN	99 %
NC_LSHPWM_BOL_LSH_UP	0 %
NC_LSHPWM_TOL_LSH_UP	97.265625 %
NC_FAC_10_SAMPLE	2
NC_FAC_5_SAMPLE	4
NC_NR_BUF_SAMPLE_LEN	12

Data	Value
NC_NR_RAW_BUF_LEN	10
NC_N_MIN_VLS_UP_MV	500 rpm
NC_T_SEG_LEN_MIN	0.01 s
NC_NR_BUF_SUM_LEN	24
NLC_LSH_RLY_EFP	0
NC_NR_CONF_LSH_RLY	0
NC_FAC_MAF_INT_20	20/3.6 msec

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CBK_EX_NR	1	1...4H	1...4	1	[-]
Number of exhaust cylinder banks					
NC_STATE_LSL_UP_IF	1	0...7H	0...7	1	[-]
Interface to lambda sensor linear upstream					
NC_STATE_VLS_UP_SIG_ACQ	1	0...7H	0...7	1	[-]
Configuration switch for optional signal acquisition					
NC_FRQ_LSHPWM_UP	1	0...FFFFH	0...4095.9375	0.0625	[Hz]
PWM frequency for the upstream oxygen sensor heater					
NC_FRQ_LSHPWM_DOWN	1	0...FFFFH	0...4095.9375	0.0625	[Hz]
PWM frequency for the downstream oxygen sensor heater					
NLC_LSH_RLY_EFP	1	0...1H	0...1	1	[-]
Configuration switch to indicate whether lambda sensor heater is connected to EFP or main relay					
NC_NR_CONF_LSH_RLY	1	0...7H	0...7	1	[-]
Numerical constant which describes the lambda sensor heater wiring					
NC_FAC_MAF_INT_20	1	0...FFFFH	0...0.89236	0.0136e-3	[s]
unit adaptation factor					

Notes:

- *The configuration switch NC_STATE_VLS_UP_SIG_ACQ denotes whether signal filtering shall be applied to the linear lambda sensor's raw signal provided by the BSW prior to further signal processing. If signal filtering shall be applied NC_STATE_VLS_UP_SIG_ACQ shall be set to 1. If not or if binary upstream sensor is used NC_STATE_VLS_UP_SIG_ACQ shall be set to 0.*

- *The PWM frequency for the oxygen sensor heater must be adjusted to values larger than 5Hz, i.e.* NC_FRQ_LSHPWM_UP >= 5Hz and NC_FRQ_LSHPWM_DOWN >= *5Hz. Usually no values larger than 100 Hz are applied, the exact value has to be derived from the corresponding sensor specification.*

16.2 EGCP - Requirements to Infrastructure Interface

Input data:

NC_CBK_EX_NR			

Export actions:

ACTION_INFR_CSetPwmLshUp(IN <i>, **IN** <ducy>**)**
This action sets the lambda heater upstream driver
ACTION_INFR_CSetPwmLshDown(IN <i>, **IN** <ducy>**)**
This action sets the lambda heater downstream driver
ACTION_INFR_CGetVAdcLsUp(IN <I>, **OUT** <v_adc>**)**
This action gets the raw value from the upstream oxygen sensor voltage
ACTION_INFR_CGetVAdcLsDown(IN <i>, **OUT** <v_adc>**)**
This action gets the oxygen sensor voltage downstream
ACTION_INFR_CGetVAdcTempLsUp(IN <i>, **OUT** <v_adc>**)**
This action gets the oxygen sensor voltage upstream
ACTION_INFR_CEnableCilc()
This action sets the activation of CILC (cylinder individuel lambda control)
ACTION_INFR_CDisableCilc()
This action sets the deactivation of CILC
ACTION_INFR_CGetCilc(IN <x>, **OUT** <v_adc, **OUT** <ctr>**)**
Signal acquisition for CILC
ACTION_INFR_CSetCilc(IN <x>, **IN** <crk>**)**
This action provide actual phase displacement for each cylinder
ACTION_INFR_CGetElDiagLshUp(IN <i>, **OUT** <cdn_diag>, **OUT** <err_diag>**)**
This action reads the failure and the conditions information for each symptom from the infrastructure
ACTION_INFR_CGetElDiagLshDown(IN <i>, **OUT** <cdn_diag>, **OUT** <err_diag>**)**
This action reads the failure and the conditions information for each symptom from the infrastructure
ACTION_INFR_CGetWrafControl(IN <i>, **OUT** <lv_lsl_deac>, **OUT** <state_err_vnlsl>, **OUT** <state_err_vglsl>, **OUT** <state_err_viplsl>, **OUT** <state_err_vrclsl>, **OUT** <state_err_iplsl>, **OUT** <state_err_lsl>, **OUT** <state_lsl_if_spi_rd>, **OUT** <state_lsl_if_conf_spi_rd>, **OUT** <frq_r_it_osc_lsl_if_spi_rd>, **OUT** <ctr_err_lsl_if_spi_wr>, **OUT** <ctr_err_lsl_if_spi_it_osc_ena>, **OUT** <lv_vplsl_lim>, **OUT** <lv_vnlsl_lim>**)**
This action reads the values from the WRAF controller
ACTION_INFR_CSetWrafControl(IN <i>, **IN** <state_lsl_if_spi_wr>, **IN** <state_lsl_if_conf_spi_wr>, **IN** <frq_r_it_osc_lsl_if_spi_wr>, **IN** <lv_lsl_if_rst>, **IN** <lv_lsl_up_spi_com_inh>, **IN** <lv_ctr_err_lsl_if_spi_man_inc>**)**
This action sets the values of the WRAF controller
ACTION_INFR_CSetCmdLsUp(IN <i>, **IN** <lv_swi_ls_up>**)**
This action starts the internal resistance determination by "pumping" the sensor.
ACTION_INFR_CSetCmdLsDown(IN <i>, **IN** <lv_swi_ls_down>**)**
This action starts the internal resistance determination by "pumping" the sensor.
ACTION_INFR_CSetHeatCoupling(IN <i>, **IN** <t_dly_trig_lsh_up>, **IN** <lamb_sp_fil_hom>**)**
This action sets the value of the WRAF controller for the heater coupling diagnosis.
ACTION_INFR_CGetHeatCoupling(IN <i>, **OUT** <lamb_sp_fil_delta_rise>, **OUT** <lamb_sp_fil_delta_fall>, **OUT** <vls_up_delta_rise>, **OUT** <vls_up_delta_fall>**)**
This action gets the value from the WRAF controller for the heater coupling diagnosis.

General information:

a) **i = NC_CBK_EX_NR** (Number of exhaust gas cylinder banks)

b) **x = NC_CYL_NR** (Number of engine cylinders)

Description for actions:

ACTION_INFR_CSetPwmLshUp(i, ducy **)**					
This action sets the lambda heater upstream driver					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
ducy	IN	0...FFH	0...99.609375	0.390625	%
Up Heater driver PWM duty cycle					

ACTION_INFR_CSetPwmLshDown(i, ducy **)**					
This action sets the lambda heater downstream driver					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
ducy	IN	0…FFH	0…99.609375	0.390625	%
Down Heater driver PWM duty cycle					

ACTION_INFR_CGetVAdcLsUp(i, v_adc **)**					
This action gets the raw value from the upstream oxygen sensor voltage.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
v_adc	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
Raw value of upstream oxygen sensor voltage					

ACTION_INFR_CGetVAdcLsDown(i, v_adc **)**					
This action gets the oxygen sensor voltage upstream					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
v_adc	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
Downstream oxygen sensor voltage					

ACTION_INFR_CGetVAdcTempLsUp(i, v_adc **)**					
This action sets the upstream lambda sensor temperature voltage					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
v_adc	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
Upstream lambda sensor temperature voltage					

ACTION_INFR_CEnableCilc()					
This action sets the activation of CILC (cylinder individuel lambda control)					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

ACTION_INFR_CDisableCilc()					
This action sets the deactivation of CILC					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

ACTION_INFR_CGetCilc(x, v_adc, ctr **)**					
Signal acquisition for CILC					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
x	IN	**0…7H**	**0…7**	**1**	**-**
logical index of cylinder to be acquired					
v_adc	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
upstream oxygen sensor acquisition (cylinder individual)					
Ctr	OUT	0…FFH	0…255	1	-
cylinder selective update counter for trigger event					

ACTION_INFR_CSetCilc(x, crk **)**					
This action provide actual phase displacement for each cylinder. Remark: The maximum angle delay which can be realized by the BSW is 720°CRK. Larger values shall be calculated beginning with 0°CRK.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
x	IN	**0…7H**	**0…7**	**1**	**-**
logical index of cylinder to be changed					
crk	IN	0…F0H	0…1440	6	°CRK
Value of phase displacement					

ACTION_INFR_CGetElDiagLshUp(i**,** cdn_diag, err_diag **)**					
This action reads the failure and the conditions information for each symptom from the infrastructure The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	**-**
Index of exhaust cylinder banks					
cdn_diag	OUT	0...7H	0...7	1	-
Bit 0: Set, if error symptom SCP (SYM_0) is detected Bit 1: Set, if error symptom SCG (SYM_1) is detected Bit 2: Set, if error symptom OC (SYM_2) is detected					
err_diag	OUT	0...7H	0...7	1	-
Raw value of error symptom. The relevant bit is set, if the error has been detected.					

ACTION_INFR_CGetElDiagLshDown(i**,** cdn_diag, err_diag **)**					
This action reads the failure and the conditions information for each symptom from the infrastructure The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	**-**
Index of exhaust cylinder banks					
cdn_diag	OUT	0...7H	0...7	1	-
Bit 0: Set, if error symptom SCP (SYM_0) is detected Bit 1: Set, if error symptom SCG (SYM_1) is detected Bit 2: Set, if error symptom OC (SYM_2) is detected					
err_diag	OUT	0...7H	0...7	1	-
Raw value of error symptom. The relevant bit is set, if the error has been detected.					

ACTION_INFR_CGetWrafControl(i, lv_lsl_deac, state_err_vnlsl, state_err_vglsl, state_err_viplsl, state_err_vrclsl, state_err_iplsl, state_err_lsl, state_lsl_if_spi_rd, state_lsl_if_conf_spi_rd, frq_r_it_osc_lsl_if_spi_rd, ctr_err_lsl_if_spi_wr, ctr_err_lsl_if_spi_it_osc_ena, lv_vplsl_lim, lv_vnlsl_lim **)**
This action reads the values from the WRAF controller.

Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
lv_lsl_deac	OUT	0...1H	0...1	1	-
Boolean flag indicating OBDI signal fault pending					
state_err_vnlsl	OUT	0H 1H 2H	NO_FAULT SCG SCB	1	[-]
Diagnosis status of the Nernst Cell positive pin.					
state_err_vglsl	OUT	0H 1H 2H	NO_FAULT SCG SCB	1	[-]
Diagnosis status of the Virtual Ground pin.					
state_err_viplsl	OUT	0H 1H 2H	NO_FAULT SCG SCB	1	[-]
Diagnosis status of the Pump Cell pin.					
state_err_vrclsl	OUT	0H 1H 2H	NO_FAULT SCG SCB	1	[-]
Diagnosis status of the Calibration Resistance pin.					
state_err_iplsl	OUT	0H 1H 2H	NO_FAULT CURRENT_LOW CURRENT_HIGH	1	[-]
Diagnosis status of the Pumping Current.					
state_err_lsl	OUT	0H 1H	NO_FAULT FAULT	1	[-]
OBDI General Status					
state_lsl_if_spi_rd	OUT	0...FFH	0...255	1	[-]
Bit-field, mapping verified contents of WRAF controller Configuration Register					
state_lsl_if_conf_spi_rd	OUT	0...FFH	0...255	1	[-]
Content of the configuration register comprising sensor disconnection time delay and Icp value					
frq_r_it_osc_lsl_if_spi_rd	OUT	0...7FH	0...127	1	[-]
Content of the configuration register comprising Ri-measurement frequency and bit for pin selective disabling					
ctr_err_lsl_if_spi_wr	OUT	0...FFH	0...255	1	[-]
Counter indicating number of invalid INIT_REG_x write validation cycles which have been detected					
ctr_err_lsl_if_spi_it_osc_ena	OUT	0...FFH	0...255	1	[-]
Counter indicating number of invalid transmissions of “R_IT_OSC_ENA” bit					
lv_vplsl_lim	OUT	0…1H	0…1	1	[-]
Boolean flag indicating that Pump Cell voltage has reached its limits					
lv_vnlsl_lim	OUT	0...1H	0...1	1	[-]
Boolean flag indicating overvoltage at Nernst Cell positive pin (reverse Icp cut-off)					

ACTION_INFR_CSetWrafControl(i, state_lsl_if_spi_wr, state_lsl_if_conf_spi_wr, frq_r_it_osc_lsl_if_spi_wr, lv_lsl_if_rst, lv_lsl_up_spi_com_inh, lv_ctr_err_lsl_if_spi_man_inc**)**

This action sets the values of the WRAF controller

Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
state_lsl_if_spi_wr	IN	0...FFH	0...255	1	-
Bit-field mapping of contents to be written to WRAF controller INIT_REG_1					
state_lsl_if_conf_spi_wr	IN	0...FFH	0...255	1	-
Bit-field mapping of contents to be written to WRAF controller INIT_REG_1					
frq_r_it_osc_lsl_if_spi_wr	IN	0...7FH	0...127	1	-
Mapping of contents to be written to WRAF controller INIT_REG_1					
lv_lsl_if_rst	IN	0...1H	0...1	1	-
Boolean flag to reset the WRAF controller					

lv_lsl_up_spi_com_inh	IN	0...1H	0...1	1	-
Inhibit bit for the SPI-communication related to electrical diagnosis on BSW level					
lv_ctr_err_lsl_if_spi_man_inc	IN	0...1H	0...1	1	-
BSW interface for manual increase of value of SPI communication error counter					

ACTION_INFR_CSetCmdLsUp(i, lv_swi_ls_up **)**					
This action starts the internal resistance determination by "pumping" the the sensor.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
lv_swi_ls_up	IN	0H 1H	Switch off Switch on	1	-
Digital command parameter for the setting of pump current for binary upstream lambda sensor Remark: Switch on equal to activation (high or low level)					

ACTION_INFR_CSetCmdLsDown(i, lv_swi_ls_down **)**					
This action starts the internal resistance determination by "pumping" the the sensor.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
lv_swi_ls_down	IN	0H 1H	Switch off Switch on	1	-
Digital command parameter for the setting of pump current for binary downstream lambda sensor Remark: Switch on equal to activation (high or low level)					

ACTION_INFR_CSetHeatCoupling(i, t_dly_trig_lsh_up, lamb_sp_fil_hom **)**					
This action sets the value of the WRAF controller for the heater coupling diagnosis.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
t_dly_trig_lsh_up	IN	0...FFH	0...0.255	0.001	s
Time delay for acquisition of oxygen sensor signal and lambda model					
lamb_sp_fil_hom	IN	0...7FFFH	0...1.999939	6.10351573229163 E-5	-
output signal of the WRAF sensor model for homogeneous mode					

ACTION_INFR_CGetHeatCoupling(i, lamb_sp_fil_delta_rise, lamb_sp_fil_delta_fall, vls_up_delta_rise, vls_up_delta_fall **)**					
This action gets the value from the WRAF controller for the heater coupling diagnosis.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
i	IN	0H 1H	1 2	1	-
Index of exhaust cylinder banks					
lamb_sp_fil_delta_rise	OUT	0...7FFFH	0...1.99993896484375	6.10351562E-5	-
Acquired lambda model value at the rising edge of heater PWM					
lamb_sp_fil_delta_fall	OUT	0...7FFFH	0...1.99993896484375	6.10351562E-5	-
Acquired lambda model value at the falling edge of heater PWM					
vls_up_delta_rise	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
Acquired oxygen sensor voltage at the rising edge of heater PWM					
vls_up_delta_fall	OUT	0...7FFFH	0...4.99984741	1.52588E-4	V
Acquired oxygen sensor voltage at the falling edge of heater PWM					

FUNCTION DESCRIPTION:

16.2.1 Control of the up- and downstream LSH Driver

General information:

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible.

Requirements for ACTION_INFR_CSetPwmLshUp:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
i				Index parameter i is related to parameter: ducy	
ducy	-	-	0.390625 %		. By the initialization the PWM value set to 0%.

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The Action has to be called synchronous (e.g. 10 ms) according the recurrences in the specification

Requirements for ACTION_INFR_CSetPwmLshDown:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
i				Index parameter i is related to parameter: ducy	
ducy	-	-	0.390625 %		By the initialization the PWM value set to 0%.

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The Action has to be called synchronous (e.g. 10 ms) according the recurrences in the specification

16.2.2 Exhaust gas composition – Requirements for up- and downstream lambda sensor voltage

General information:

Voltages of lambda sensors offered by Basic SW are transformed to application system specific variables.

Requirements for ACTION_INFR_CGetVAdcLsUp:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

i			1	Index parameter i is related to parameter: v_adc	
v_adc		0,1%	1.52588E-4 V		

Diagnosis:

Coincidence requirements: The AD conversion is performed autonomously by the infrastructure all 10 ms (state =0) or 1 ms (state=1)

Requirements for ACTION_INFR_CGetVAdcLsDown:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
i			1	Index parameter i is related to parameter: v_adc	
v_adc		0,1 %	1.52588E-4 V		

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The AD conversion is performed autonomously by the infrastructure all 10 ms.

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The AD conversion is performed autonomously by the infrastructure all 10 ms.

16.2.3 Signal acquisition for cylinder individual lambda control (CILC)

General information:

Additionally basic informaton about requirements for the infrastructure can be found in the module 201P with the title **" Signal acquisition for cylinder individual lambda control".**

```
if two separate cylinder banks are concerned, then
    i = 1, for cylinder bank 1 ( x = 0, 2, 4, ... )
    i = 2, for cylinder bank 2 ( x = 1, 3, 5, ... )
else
i = 1 ( x = 0 ... 3 or 4 )
end
x: logical cylinder (NC_CYL_NR)
```

The function shall serve as a detector for a precise signal acquisition of the Wide Range Air-Fuel (WRAF) sensor in accordance with the identified cylinder.

The calculation shall be done for x = 0 : NC_CYL_NR –1.

16.2.4 Upstream oxygen sensor heater OBDI diagnosis

General information:

The error detection is performed via the ECU hardware. Error informations are gathered until read out by the application software ASW. At the moment when ASW is reading data from I/O software, the I/O software data will be reset. (It is possible to have more than one electrical failure symptom reported to ASW.)
Following errors may be detected:

1. short cut to battery (scp)
2. short cut to ground (scg)
3. open curcuit (ol)

This action returns the result of the electrical diagnosis of the RCL Actuator Electrical Power Stage

- The device readout is performed autonomously by the Infrastructure. It has to be ensured that the infrastructure interface provides the result before the ASW readout which is defined by the diagnosis frequency.
- The error information are gathered in the Infrastructure until the Application reads out the information by calling ACTION_INFR_CGetElDiagLshUp() / ACTION_INFR_CGetElDiagLshDown().
- After having read out the information by calling ACTION_INFR_CGetElDiagLshUp() / ACTION_INFR_CGetElDiagLshDown(), the data inside the Infrastructure are reset.

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

All symptoms of the current error code are handeled by anti-bouncing.
The error detection is effected via the ECU hardware.

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements.

The function is intended for use in a hardware configuration where the heater driver shall carry out the electrical fault diagnosis and provide the electrical status via status flags. Usually the ASW diagnosis frequency is much lower than the HW diagnosis frequency for PWM signals. Therefore several symptoms may be provided to the ASW within one diagnosis cycle. In this case the following priorization shall be considered.

- *Short circuit to Vbatt by Over-temperature **or** Overcurrent* (**SCP**)
- *Short circuit to GND* (SCG)
- *Open load* (**OC**)

The electrical status flags for each heater driver shall be read out and decoded by the appropriate function and made available to the Application SW in the form of driver and fault specific flags. It must be considered that the PWM frequency shall be at least twice the diagnosis frequency to avoid oversampling

Requirements for ACTION_INFR_CGetElDiagLshUp:

Data acquisition

16.2.5 Wide Range Air-Fuel sensor interface (BSW)

General information:

Additionally basic informaton about requirements for the infrastructure can be found in the module 202V with the title **"Wide Range Air-Fuel sensor interface (BSW) for the ATIC42".**

general specification

The function shall describe the interface between the Wide Range Air-Fuel (WRAF) sensor, its controll device and ECU.

The following information can be requested by the ECU from the WRAF sensor:

- [Read from the two IC identity registers IDENT_REG_1[i] and IDENT_REG_2[i] – currently not implemented in generic SW!]
- Configuration and initialization of the 1-byte long **initialisation register**, to be taken from the corresponding BSW Specification
- Configure and initialise the **second configuration register** containing the 5 bit setting for the Icp-current value, and the 3-bit register for protection time prior to sensor disconnecting in case of electrical failure.
- Configure and initialise the 7-bit register containing Ri measurement frequency and the activation switch for selective pin disabling during sensor protection time.
- Read out the sensor pin electrical diagnostic register.
- Read out the general status register
- [Reset the WRAF controller – currently not implemented in generic SW!]

The individual timing requirements and the general description of the SPI may be found in the WRAF controller Component Specification and shall not be repeated here. Only those points that serve to clarify the interface between the WRAF controller and the microcontroller will be elaborated upon.

16.2.7 Acquisition of signal voltage and lambda model values for the Heater Coupling Diagnosis

General information:

Additionally basic informaton about requirements for the infrastructure can be found in the module 202Y with the title **"Acquisition of signal voltage and lambda model values for the Heater Coupling Diagnosis with UEGO Sensors and ATIC42"**

This function shall deliver the inputs needed by the heater coupling diagnosis and describe how the sensor signal and corresponding model values shall be acquired synchronously with the heater signal.

The BSW shall guarantee the edge detection of the PWM signal up to a PWM frequency of 100Hz.
Remarks:
- High and low phase of a PWM signal: minimum 2 ms (which corresponds to the current feasibility of BSW).
- The maximum delay time for edge detection must be equal to or smaller than 2 ms.
- Further requirements have to be clearified with BSW.

Acquired oxygen sensor voltage at the falling edge of heater PWM					

FUNCTION DESCRIPTION:

General information:

a) **i = NC_CBK_EX_NR** (Number of exhaust gas cylinder banks)

b) **x = NC_CYL_NR** (Number of engine cylinders)

Depending on the value of NC_CBK_EX_NR and the states of the variable **NR_CONF_CBK_EX** following rules are defined which have to be used for all actions.

The symbolic item param_list represents the complete dedicated action parameters, exept the explicitly given one.

RULE 1: *%% used in general for upstream SET-ACTION*
IF NC_CBK_EX_NR = 2
THEN

```
    Case selection      NR_CBK_EX
    = 1:
            for i = 1:  ACTION_INFR_Command(IN < i = 1 >, param_list) =
                                    ACTION_INFR_CCommand( IN < i = 1 >, param_list)
            for i = 2:  no ACTION activity
    = 2:
            ACTION_INFR_Command(IN <i>, param_list) =
                        ACTION_INFR_CCommand ( IN < i>, param_list)
# ELSE
    ACTION_INFR_Command(IN <i>, param_list) =
                ACTION_INFR_CCommand ( IN < i>, param_list)
# ENDIF
```

RULE 2: *%% used in general for downstream SET-ACTION*

```
# IF        NC_CBK_EX_NR = 2

has to be executed after all other functions of EGCP which have the same recurrence.

ACTION_INFR_SetWrafControl(...)

16.4.2 Descripton of the interaction between infrastruture and the WRAF controller

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

The function shall describe the interface between the Wide Range Air-Fuel (WRAF) sensor, its controll device, the ATIC42 in its final development step (2nd Silicon, B5), and ECU.

The digital control part of the interface is realised in hardware by means of a Serial Peripheral Interface (SPI) bus between the ECU and the ATIC42. Latter acts as slave while the microcontroller acts as master. Via the SPI it shall be possible to carry out the following tasks:

- [Read from the two IC identity registers IDENT_REG_1[i] and IDENT_REG_2[i] – currently not implemented in generic SW!]

- Configure and initialise the 1-byte long **initialisation register**, which comprehends the following switches:

bit position	description
0	Set Ip measurement gain (16 or 8)
1	Enable/disable pumping current (Ip) offset measurement
2	Enable/disable reference pumping current (Icp)
3	Enable/disable Ip controller
4	Enable/disable Nernst Cell inner resistance (Ri) calibration
5	Start/stop oscillator for Ri measurement
6	Enable/disable sensor
7	Set Ri measurement range (range2, range1)

- Configure and initialise the **second configuration register** containing the 5 bit setting for the Icp-current value, and the 3-bit register for protection time prior to sensor disconnecting in case of electrical failure.

- Configure and initialise the 7-bit register containing Ri measurement frequency and the activation switch for selective pin disabling during sensor protection time.

- Read out the sensor pin electrical diagnostic register.

- Read out the general status register

- [Reset the ATIC42 – currently <u>not</u> implemented in generic SW!]

The individual timing requirements and the general description of the SPI may be found in the ATIC42 Component Specification and shall not be repeated here. Only those points that serve to clarify the interface between the ATIC42 and the microcontroller will be elaborated upon.

16.4.3 BSW Description

General remark regarding handling of read (RD), and write (WR) variables of SPI interface: Access to status bits which are part of STATE_LSL_IF... SPI_*RD[*i] variables has to be realized by directly addressing the individual bit "STATE_LSL_IF ... SPI_*RD*[i].bitX". The contents of STATE_LSL_IF ... SPI_*WR[*i] variables can either be accessed directly via "STATE_LSL_IF ... SPI_*WR[*i].bitX" or by corresponding logical variables, e.g. LV_LSL_ENA_LSL_IF[i].

16.4.3.1 SPI command sequencing

Immediately after a HW-reset or after ECU RESET, the standard command sequence stated below shall be executed. All the initialization information shall be sent once. Afterwards the sequence is repeated at every recurrence of BSW, i.e. every T_SAMPLE, containing up-to-date control information (command identifiers according to ATIC42 specification dated 24/07/02 are stated in brackets):

RD_DIAG_1(M1) + RD_DIAG_2(M2)
+ WR_CONF_INIT_1(F) + WR_CONF_INIT_2(I)

+ WR_INIT_R_FRQ_1(K) + WR_INIT_R_FRQ_2(L)
+ WR_INIT_1(C) + WR_INIT_2(D)
[+ RD_IDENT_1(A1) “dummy” command]

In order to receive the answer to the last write command sent, which is evaluated for communication monitoring purposes, WR_INIT_2(D), a “dummy” read command - has been added to the sequence.
Remark: With transmission of command “n”, response to command “n-1” is received in communication cycle “n”.

WR_INIT_2(D) command is sent at the end of each communication cycle to allow for all configuration data to be updated before setting sensor status (enable/disable).

16.4.3.2 Deactivation of WRAFsensor

Decoupling of WRAF sensor due to presence of electrical fault is handled by ASW/BSW interface (Appl Inc), 403B.

With LV_LSL_UP_SPI_COM_INH[i] = 1, ATIC42 SPI-responses related to electrical diagnosis status (contents of General Status Register and Pin Diagnosis Register) are no longer used to update contents of corresponding interface variables STATE_ERR_xxx[i], LV_LSL_VP_LIM[i], and LS_VNLSL_LIM[i]. The value of these variables thus preserves OBDI error status at the very moment of successful error debouncing for the remainder of the current driving cycle.

16.4.3.3 Reading the identification registers (currently not implemented in generic SW!)

If required, the identification registers can be read via the commands RD_IDENT_1(A1) and RD_IDENT_2(A2).

The command RD_IDENT_2(A2) reads the 8 MSB of the IC code while the command RD_IDENT_1(A1) reads the 3 LSB of the IC code, the 2 bit supplier index, and the 3 bit IC version number. The received information could be placed in a 16-bit output variable STATE_LSL_IF_IC_INFO[i] (V, 0...FFFFH, 0...65535, 1, -).

16.4.3.4 Reading the diagnostic registers

Diagnostic information regarding electrical sensor failures can be retrieved with the command sequence RD_DIAG_1(M1) + RD_DIAG_2(M2) which addresses the ATIC42 status registers.

Upon reading the general status register contents , the contents of both diagnosis registers are deleted. Therefore the two commands have to be performed in the appropriate sequence specified above: first the single pin diagnosis status has to be evaluated (RD_DIAG_1(M1)), then the general status register can be read (RD_DIAG_2(M2)) - deleting all electrical diagnosis information the very same moment!

The pin diagnosis register DIAG_REG_1 contains information regarding the type and location of electrical sensor faults. The following failure categories can be detected and for each fault a diagnosis bit is latched:

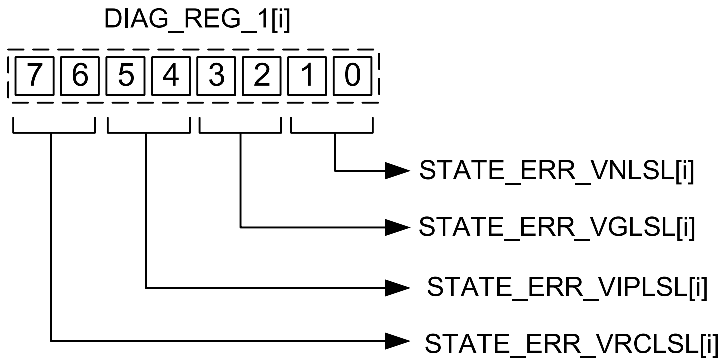
bit position	description
0	Short circuit to Ground (SCG) at pin RCD
1	Short circuit to Battery (SCB) at pin RCD
2	SCG at pin VIP
3	SCB at pin VIP
4	SCG at pin VG
5	SCB at pin VG
6	SCG at pin VN
7	SCB at pin VN

Two bits are associated with every sensor pin (RCD, VIP, VG, VN). Their combination provides four possible failure states (00 = no failure, 01 = SCG, 10 = SCB, 11 = presently not used).

DIAG_REG_2 contains information regarding general failure status, Pump Cell voltage and pumping current limit status, and overvoltage at VN pin. The following diagnoses can be evaluated :

1. General status of diagnosis.
2. Pump cell voltage at allowed limits. A special bit is set but not latched – as soon as the limitation is over, this bit is reset.
3. Pumping current (Ip) at its limits. A special bit is set but not latched – as soon as the violation disappears, this bit is reset.
4. Overvoltage at Nernst Cell positive pin which might impair voltage headroom for generation of reference pumping current. Therefore Icp generation is disabled by ATIC42 HW to prevent reverse Icp. Diagnosis bit is set but not latched.

As faults may occur while reading the diagnostic registers, it is advised to verify the contents of the diagnosis registers regularly. This shall be carried out by comparing the responses related to two consecutive RD_DIAG commands.



If after two consecutive RD_DIAG_x[i] command sequences a fault persists, the function shall decode the contents of both DIAG_REG_x[i] registers. The contents of the DIAG_REG_1[i] shall be placed in the appropriate output data variables, as it is shown in the picture above.

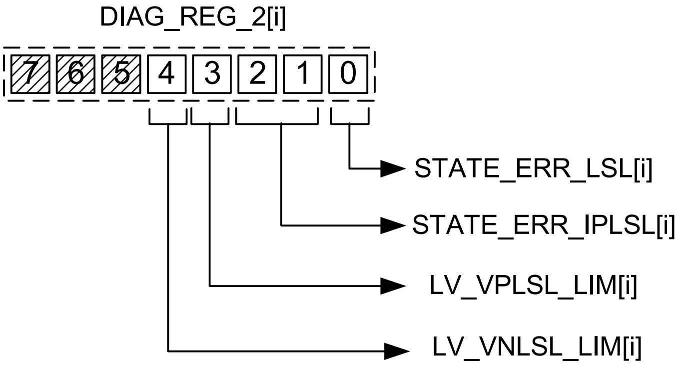
STATE_ERR_VNLSL[i] mirrors the diagnosis of Nernst cell positive pin, STATE_ERR_VGLSL[i] the diagnosis of virtual ground pin, STATE_ERR_VIPLSL[i] the diagnosis of Pump Cell positive pin, and STATE_ERR_VRCLSL[i] the diagnosis of the RCD pin.

The following diagnosis are decoded in each STATE-variable:

00H means no fault,

01H means short circuit to ground

02H means short circuit to battery.



The contents of the DIAG_REG_2[i] shall be placed in the appropriate output data variables:

STATE_ERR_LSL[i] gives the general status of the diagnosis in the ATIC42, where 00H means no fault and 01H means a fault is present. LV_VPLSL_LIM[i] shall be activated if the pump cell voltage reaches allowed bounds. STATE_ERR_IPLSL[i] gives a diagnosis when the pump cell current is out of range, where 00H means no fault, 01H means Ip current too low and 02H means Ip current too high. LV_VNLSL_LIM[i] signals detection of overvoltage at positive Nernst Cell pin which leads to disabling of reference pumping current in order to avoid reverse current flow.

Additionally, a Boolean flag LV_LSL_DEAC[i] shall be set if at any time a single valid RD_DIAG_x data byte returns an electrical fault at one sensor pin (excluding Pump Cell voltage at allowed bonds, VN overvoltage, and Ip limitation). The flag shall only be reset should the function receive two valid consecutive RD_DIAG command return data bytes indicating that the specific fault is no longer present.

16.4.3.5 Writing to the initialisation register (WR_INIT)

The application software (ASW) shall be permitted to write to both configuration registers of the ATIC42 to perform control of its different functionalities.

The interface to the ASW shall be facilitated by defining input data variables STATE_LSL_IF_SPI_WR[i], STATE_LSL_IF_CONF_SPI_WR[i], FRQ_R_IT_OSC_LSL_IF_SPI_WR[i] and the communication error counter CTR_ERR_LSL_IF_SPI_RD[i].

The BSW function shall service the ASW as follows:

The WRITE command sequence shall be carried out every recurrence, independently of any new information made available by the ASW via the interfaces STATE_LSL_IF_SPI_WR[i], STATE_LSL_IF_CONF_SPI_WR[i], FRQ_R_IT_OSC_LSL_IF_SPI_WR[i], and of the previous write command being incorrectly executed.

The function shall latch the current content of the three input data variables STATE_LSL_IF_xxx_SPI_WR[i](n) to STATE_LSL_IF_xxx_SPI_WR[i](n-1). Thus any further changes to the information during a WRITE cycle are prevented.

Next, the STATE_LSL_IF_xxx_SPI_WR[i](n-1) information shall be sent via the SPI to the ATIC42. The content written shall thereupon be verified via the corresponding answer which is received when sending the next command of the current SPI sequence.

Next, the STATE_LSL_IF_xxx_SPI_WR[i](n-1) information shall be sent via the SPI to the ATIC42. The content written shall thereupon be verified via the corresponding answer which is received when sending the next command of the current SPI sequence.

Should any WRITE command within current SPI transmission cycle be invalid or the written content not match the read content, the counter CTR_ERR_LSL_IF_SPI_WR[i] shall be incremented once.

For write validation procedure, sensor enable bit LV_LSL_ENA_LSL_IF[i] in the initialisation register is NOT considered because it is automatically reset by ATIC42 HW upon detection of an electrical sensor failure, regardless of the last transmitted SPI command. This asynchronuous change in bit value assignment does not represent a communication error.

In addition, bit6 of FRQ_R_IT_OSC_LSL_IF_SPI_xx[i] which represents the status of the “Pin Selective Disabling” feature shall also not be evaluated for SPI communication monitoring at present. Due to an ATIC42 HW error, command execution is performed but not monitored in ASIC response.

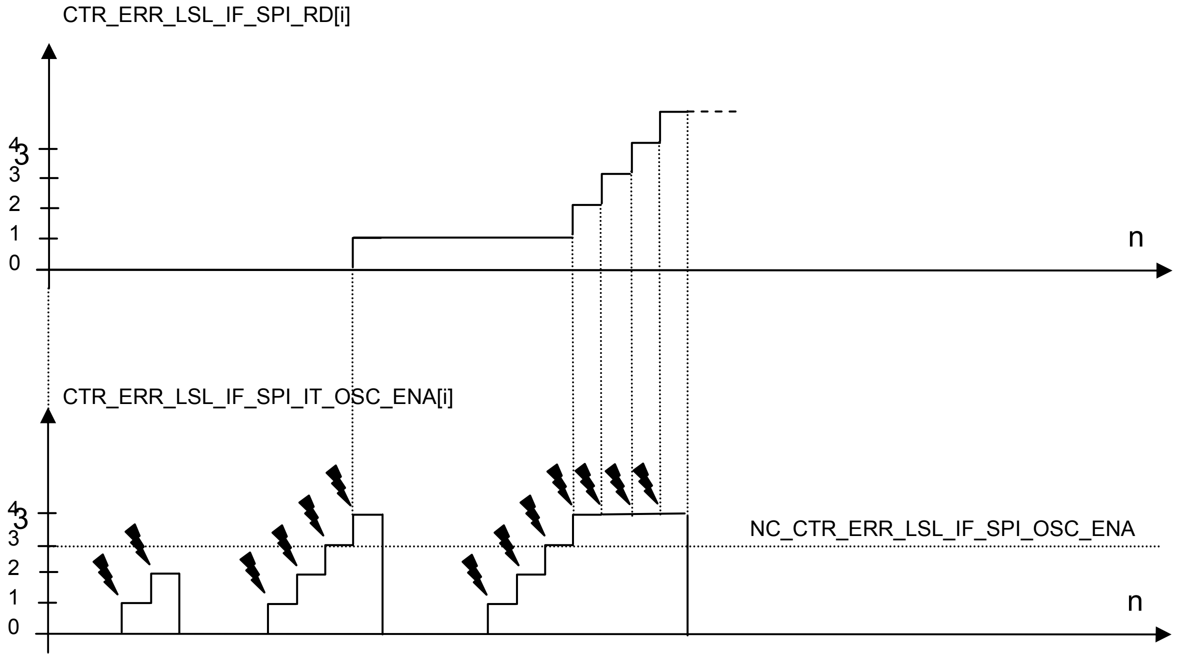
For manual increment of SPI communication error counter an interface to ASW (403B) is provided. This feature is introduced for purpose of SW test.

As the ATIC42 has a serial interface, the response to the currently transmitted command represents the answer to the previously executed command. As example, in the ATIC42 standard command sequence, the response received with command WR_CONF_INIT_1 corresponds to the answer to the preceding command RD_DIAG_2(M2). The BSW shall accordingly transfer the command responses to the correspondent output data variable (STATE_LSL_IF_SPI_RD[i], STATE_LSL_IF_CONF_SPI_RD[i], or FRQ_R_IT_OSC_LSL_IF_SPI _RD[i], resp.).

Up to ATIC42, 2nd Silicon, B5 step, a workaround for SPI transmission of “R_IT_OSC_ENA” bit has to be implemented. The ASIC shows random deviation between SPI request to set this bit and its physical reaction. If ATIC42 fails in switching on the oscillator for Ri determination, its ‘correct’ response does not fit the transmitted request.

Since this behaviour does not represent a communication error, its direct evaluation shall be excluded for the regular communication error counter CTR_ERR_LSL_IF_SPI_RD[i]. To be able to distinguish between HW based mismatch of request and response and SPI communication error, an additional cascaded error counter is introduced (CTR_ERR_LSL_IF_SPI_IT_OSC_ENA[i]) to deal with the “R_IT_OSC_ENA” bit. Its value is limited to NC_CTR_ERR_LSL_IF_SPI_OSC_ENA = 3. This threshold represents maximum number of sequential retries for setting “R_IT_OSC_ENA” bit before SPI communication error is recognized and reported to global error counter CTR_ERR_LSL_IF_SPI_RD[i].

Should transmission be successfull before supplementary counter reaches threshold value, it is reset. Once CTR_ERR_LSL_IF_SPI_IT_OSC_ENA[i] reaches threshold value, this value is kept until next successfull processing of “R_IT_OSC_ENA” bit and every additional erroneous transmission leads to direct incrementation of global error counter (see also Drawing 1).



Drawing 1: Relation between global and cascaded communication error counter

16.4.3.6 Performing a SW reset at the ATIC42 IC (currently not implemented in generic SW!)

The command RESET_IC(O) shall be executed if there exists a request to reset the ASIC via SW (LV_LSL_IF_RST[i] = 1). The activation of this flag as well as the priority definition should be handled in the “WRAF sensor interface (ASW-BSW)” Appl Inc, 403B. With the reset command the internal reset line is activated and all SPI registers are set to their default state provided by ATIC42 HW!

In order to deal with daisy chain communication comprehending multiple WRAF controllers (requiring identical number of commands provided to each controller but individual data contents), two alternative reset sequences can be thought of and should be discussed with the specific project prior to implementation:

- Repeated transmission of reset commands - equaling number of commands in regular sequence - to WRAF controller which is to be reset.
- Reset performance on all connected WRAF controllers.

<u>**Application conditions:**</u>

Initialisation:

NC_CTR_ERR_LSL_IF_SPI_OSC_ENA = 3

The following variable initialisation shall take place at the activation of the BSW:

CTR_ERR_LSL_IF_SPI_WR[i] = 0

CTR_ERR_LSL_IF_SPI_IT_OSC_ENA_i = 0

LV_LSL_DEAC[i] = 0

LV_VPLSL_LIM[i] = 0

LV_VNLSL_LIM[i] = 0

STATE_LSL_IF_SPI_RD[i] = 0

STATE_LSL_IF_CONF_SPI_RD[i] = 0

FRQ_R_IT_OSC_LSL_IF_SPI_RD[i] = 0

STATE_ERR_LSL[i] = NO FAULT (0H)

STATE_ERR_VNLSL[i] = NO FAULT (0H)

STATE_ERR_VGLSL[i] = NO FAULT (0H)

STATE_ERR_VIPLSL[i] = NO FAULT (0H)

STATE_ERR_VRCLSL[i] = NO FAULT (0H)

STATE_ERR_IPLSL[i] = NO FAULT (0H)

Note:

The interface variables STATE_LSL_IF_SPI_WR[i] and STATE_LSL_IF_CONF_SPI_WR[i] shall be initialized in the “WRAF sensor interface” (ASW – BSW). The corresponding ASW (“Oxygen sensor temperature”, 402A) shall do the initialization of FRQ_R_IT_OSC_LSL_IF_SPI_RD[i].

Recurrence:

T_SAMPLE = 10 ms.

Activation:

After every ECU RESET.

Deactivation:

--

Formula section:

```
If      LV_CTR_ERR_LSL_IF_SPI_MAN_INC[i] == 1
then    CTR_ERR_LSL_IF_SPI_WR[i] = CTR_ERR_LSL_IF_SPI_WR[i] + 1
endif
If      LV_CTR_ERR_LSL_IF_SPI_MAN_INC[i] == 1 -> 0
then    CTR_ERR_LSL_IF_SPI_WR[i] = 0
endif
```

Valid SPI-Commands:

The following SPI-commands consist of a 4 bit command plus 4 bit data partition each:

RD_IDENT_1(A1)	0H + 1H
RD_IDENT_2(A2)	0H + 2H
WR_INIT_1(C)	2H + D0D1D2D3 (see Table 3)

WR_INIT_2(D)	3H + D4D5D6D7 (see Table 3)
WR_CONF_INIT_1(F)	5H + D0D1D2D3 (see Table 4)
WR_CONF_INIT_2(I)	8H + D4D5D6D7 (see Table 4)
WR_ INIT_R_FRQ_1(K)	AH + D0D1D2D3
WR_ INIT_R_FRQ_2(L)	BH + D4D5D6D7
RD_DIAG_1(M1)	CH + 1H (read pin diagnosis register)
RD_DIAG_2(M2)	CH + 2H (read general status register)
RESET_IC(O)	FH + FH

Following a RD_IDENT_2(A2) command, the data byte of the returned message is defined as follows:

Bit Pos.	Bit Name	Description
0	STATE_LSL_IF_IC_INFO[i].bit_8	8 MSB of IC Code
1	STATE_LSL_IF_IC_INFO[i].bit_9	Ditto
2	STATE_LSL_IF_IC_INFO[i].bit_10	Ditto
3	STATE_LSL_IF_IC_INFO[i].bit_11	Ditto
4	STATE_LSL_IF_IC_INFO[i].bit_12	Ditto
5	STATE_LSL_IF_IC_INFO[i].bit_13	Ditto
6	STATE_LSL_IF_IC_INFO[i].bit_14	Ditto
7	STATE_LSL_IF_IC_INFO[i].bit_15	Ditto

Table 1: Data byte equivalence of the response to command RD_IDENT_2(A2) and the output variable STATE_LSL_IF_IC_INFO[i]

Similarly the answer to RD_IDENT_1(A1) is defined as:

Bit Pos.	Bit Name	Description
0	STATE_LSL_IF_IC_INFO[i].bit_0	Bits 0 through 2, 3 LSB of IC Code
1	STATE_LSL_IF_IC_INFO[i].bit_1	Ditto
2	STATE_LSL_IF_IC_INFO[i].bit_2	Ditto
3	STATE_LSL_IF_IC_INFO[i].bit_3	Bits 4 through 5, Supplier index
4	STATE_LSL_IF_IC_INFO[i].bit_4	Ditto
5	STATE_LSL_IF_IC_INFO[i].bit_5	Bits 6 through 7, Chip version number *)
6	STATE_LSL_IF_IC_INFO[i].bit_6	Ditto
7	STATE_LSL_IF_IC_INFO[i].bit_7	Ditto

Table 2: Data byte equivalence between the response to RD_IDENT_1 and STATE_LSL_IF_IC_INFO[i]

*) 000 for A1, A2, B1 samples; 001 for B2 samples!

Output data STATE_LSL_IF_SPI_RD[i] shall be defined to be a byte mirroring the content of the register INIT_REG_1, which represents a collection of individual bits as shown in the following table:

Bit Pos.	Bit Name	Description
D0	SWI_GAIN	Set Ip measurement gain to 8 (0) or 16 (1)
D1	VLS_OFS_ADJ_ENA	IP-offset-measurement (0) disable (1) enable
D2	ICPLSL_ENA	Icp current: (0) disable (1) enable
D3	IPLSL_CTL_ENA	Ip controller: (0) disable (1) enable
D4	R_IT_CAL_ENA	Ri calibration mode: (0) disabled, (1) enabled
D5	R_IT_OSC_ENA	Oscilator: (0) off, (1) on
D6	LSL_ENA	Enable / Disable linear lambda sensor
D7	R_IT_SWI_RNG	Ri measurement gain: (0) Range 1, (1) Range 2

***Table 3**:* Data byte for command WR_INIT_1(C) and WR_INIT_2(D)

Similarly the output data STATE_LSL_IF_CONF_SPI_RD[i] shall be defined to be a byte mirroring the content of the WR_CONF_INIT_1(F) and WR_CONF_INIT_2(I) as follows:

Bit Pos.	Bit Name	Description
0	ICPLSL[i].bit_0	Bits 0 through 4, Icp current
1	ICPLSL[i].bit_1	
2	ICPLSL[i].bit_2	
3	ICPLSL[i].bit_3	
4	ICPLSL[i].bit_4	
5	T_DLY_DI[i].bit_0	Bits 5 through 7, sensor protection time
6	T_DLY_DI[i].bit_1	
7	T_DLY_DI[i].bit_2	

Table 4: Data byte for command WR_CONF_INIT_1(F) and WR_CONF_INIT_2(I)

Following a RD_DIAG_1(M1) command, the data byte of the returned message is defined as follows:

Bit Pos.	Bit Name	Description
0	STATE_ERR_VNLSL[i].bit_0	VN -short circuit to gnd (0) no (1) yes
1	STATE_ERR_VNLSL[i].bit_1	VN -short circuit to battery (0) no (1) yes
2	STATE_ERR_VGLSL[i].bit_0	VG -short circuit to gnd (0) no (1) yes
3	STATE_ERR_VGLSL[i].bit_1	VG -short circuit to battery (0) no (1) yes
4	STATE_ERR_VIPLSL[i].bit_0	VIP -short circuit to gnd (0) no (1) yes
5	STATE_ERR_VIPLSL[i].bit_1	VIP -short circuit to battery (0) no (1) yes
6	STATE_ERR_VRCLSL[i].bit_0	RCD -short circuit to gnd (0) no (1) yes
7	STATE_ERR_VRCLSL[i].bit_1	RCD -short circuit to battery (0) no (1) yes

Table 5: Data byte equivalence between the register DIAG_REG_1[i] and the diagnosis output variables

Following a RD_DIAG_2(M2) command, the data byte of the returned message is defined as follows:

Bit Pos.	Bit Name	Description
0	STATE_ERR_LSL[i]	General diagnosis status: (0) no fault, (1) fault
1	STATE_ERR_IPLSL[i].bit_0	IP current low: (0) no (1) yes
2	STATE_ERR_IPLSL[i].bit_1	IP current high: (0) no (1) yes
3	LV_VPLSL_LIM[i]	VP at the allowed bounds: (0) no (1) yes
4	LV_VNLSL_LIM[i]	Overvoltage at VN pin: (0) no (1) yes

Table 6: Data byte equivalence between the register DIAG_REG_2[i] and the corresponding diagnosis output variables

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CTR_ERR_LSL_IF_SPI_OSC_ENA	-	0...FFH	0...255	1	[-]
Limit of counter indicating number of invalid transmissions of "R_IT_OSC_ENA" bit					

16.5 Exhaust gas composition – Requirements to I/O BSW

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VLS_UP_RAW[NC_CBK_EX_NR]	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Raw value of upstream oxygen sensor voltage					
VLS_DOWN[NC_CBK_EX_NR]	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Downstream sensor voltage measured					
V_TEMP_LS_UP[NC_CBK_EX_NR]	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Upstream lambda sensor temperature voltage					
VP_LS_UP_RAW	-	0...7FFFH	0...4.99984	0.1526e-3	[V]
Temporary storage for conversion of VLS_UP ADC value to resolution required in EGCP					
VP_LS_DOWN	-	0...7FFFH	0...4.99984	0.1526e-3	[V]
Temporary storage for conversion of VLS_DOWN ADC value to resolution required in EGCP					
VP_TEMP_LS_UP	-	0...7FFFH	0...4.99984	0.1526e-3	[V]
Temporary storage for conversion of V_TEMP_LS_UP ADC value to resolution required in EGCP					

Input data:

NC_CBK_EX_NR	LV_R_IT_REQ_LS_UP[NC_CBK_EX_NR]	LV_R_IT_REQ_LS_DOWN[NC_CBK_EX_NR]	NC_STATE_VLS_UP_SIG_ACQ
NC_STATE_LSL_UP_IF			

Import actions:

ACTION_INFR_GetVAdcLsUp(IN <i>, **OUT** <v_adc>**)**
Acquisition of the raw value from the upstream oxygen sensor voltage
ACTION_INFR_GetVAdcLsDown(IN <i>, **OUT** <v_adc>**)**
This action gets the oxygen sensor voltage downstream
ACTION_INFR_GetVAdcTempLsUp(IN <i>, **OUT** <v_adc>**)**
This action gets the oxygen sensor voltage upstream

FUNCTION DESCRIPTION:

General information:

Name	Acquisition recurrence	Acquisition precision	Notes
VLS_UP_RAW[i]	10ms	10bit	NC_STATE_VLS_UP_SIG_ACQ = 0
	1ms	10bit	NC_STATE_VLS_UP_SIG_ACQ = 1
V_TEMP_LS_UP[i]	10ms	10bit	-
VLS_DOWN[i]	10ms	10bit	-

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

If the lambda sensor signal shall be filtered prior to further processing NC_STATE_VLS_UP_SIG_ACQ has to be set to 1, otherwise to 0.

Description:

Voltages of lambda sensors offered by Basic SW are read from infrastructure in standard ECU06 resolution and transformed to application system specific variables.

Application conditions:

Activation: at every engine operating state
Deactivation: -
Update rate:
VLS_UP_RAW[i]: 10 ms for NC_STATE_VLS_UP_SIG_ACQ = 0
1 ms for NC_STATE_VLS_UP_SIG_ACQ = 1
VLS_DOWN[i] : 10 ms
V_TEMP_LS_UP[i]: 10 ms
Initialization: at reset: VLS_UP_RAW[i] = 0
VLS_DOWN[i] = 0
V_TEMP_LS_UP[i] = 0

Formula section:

```
# If      NC_STATE_LSL_UP_IF = 0          % Masking shall only be done for binary sensor
# then    If     LV_R_IT_REQ_LS_UP[i] = 0
          then   acquire VLS_UP_RAW[i]
                 ACTION_INFR_GetVAdcLsUp(
                             IN          i
                             OUT         VP_LS_UP_RAW)
                 VLS_UP_RAW[i] = VP_LS_UP_RAW
          else   $VLS\_UP\_RAW[i]_N = VLS\_UP\_RAW[i]_{N-1}$
          endif
# else    acquire VLS_UP_RAW[i]
          ACTION_INFR_GetVAdcLsUp(
                      IN          i
                      OUT         VP_LS_UP_RAW)
          VLS_UP_RAW[i] = VP_LS_UP_RAW
          acquire V_TEMP_LS_UP[i]
          ACTION_INFR_GetVAdcTempLsUp(
                      IN          i

then    acquire VLS_DOWN[i]
        ACTION_INFR_GetVAdcLsDown(
                IN      i
                OUT     VP_LS_DOWN)
        VLS_DOWN[i] = VP_LS_DOWN
else    $VLS\_DOWN[i]_{N} = VLS\_DOWN[i]_{N-1}$
endif
```

16.6 Acquisition of signal voltage and lambda model values for the Heater Coupling Diagnosis with UEGO Sensorsand ATIC42

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LAMB_SP_FIL_DELTA_RISE[NC_CBK_EX_NR]	O	0...7FFFH	0...1.99993	0.061e-3	[-]
Acquired lambda model value at the rising edge of heater PWM					
LAMB_SP_FIL_DELTA_FALL[NC_CBK_EX_NR]	O	0...7FFFH	0...1.99993	0.061e-3	[-]
Acquired lambda model value at the falling edge of heater PWM					
VLS_UP_DELTA_RISE[NC_CBK_EX_NR]	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Acquired oxygen sensor voltage at the rising edge of heater PWM					
VLS_UP_DELTA_FALL[NC_CBK_EX_NR]	O	0...3FFH	0...4.99511	4.8828e-3	[V]
Acquired oxygen sensor voltage at the falling edge of heater PWM					
VP_LS_UP_DELTA_RISE	-	0...7FFFH	0...4.99984	0.1526e-3	[V]
Temporary storage for conversion of VLS_UP ADC readout at PWM rise to resolution required in EGCP					
VP_LS_UP_DELTA_FALL	-	0...7FFFH	0...4.99984	0.1526e-3	[V]
Temporary storage for conversion of VLS_UP ADC readout at PWM fall to resolution required in EGCP					

Input data:

VLS_UP[NC_CBK_EX_NR]	LSHPWM_UP[NC_CBK_EX_NR]	LAMB_SP_FIL_HOM[NC_CBK_EX_NR]	NC_CBK_EX_NR
T_DLY_TRIG_LSH_UP[NC_CBK_EX_NR]	LV_LSL_DIAG_LSH_LSL_UP_DEAC		

Import actions:

ACTION_INFR_SetHeatCoupling(IN <i>, **IN** <t_dly_trig_lsh_up>, **IN** <lamb_sp_fil_hom>**)**
This action sets the value of the WRAF controller for the heater coupling diagnosis.
ACTION_INFR_GetHeatCoupling(IN <i>, **OUT** <lamb_sp_fil_delta_rise>, **OUT** <lamb_sp_fil_delta_fall>, **OUT** <vls_up_delta_rise>, **OUT** <vls_up_delta_fall>**)**
This action gets the value from the WRAF controller for the heater coupling diagnosis

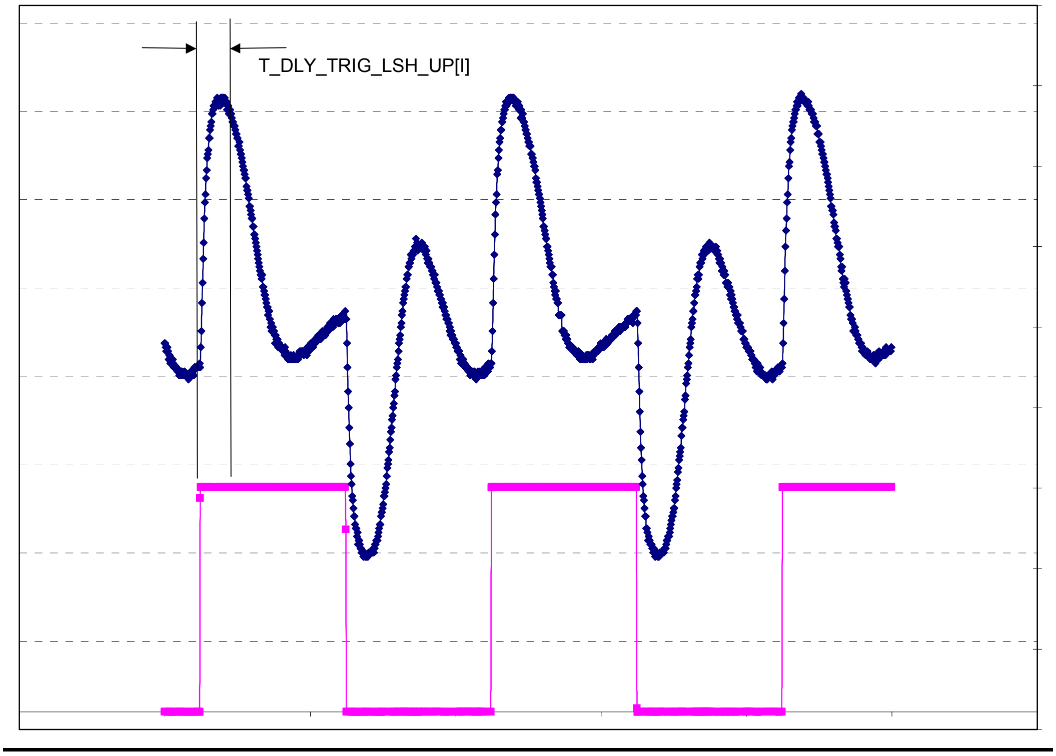
FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function shall deliver the inputs needed by the heater coupling diagnosis specific for UEGO Sensors controlled with the ATIC42. This functions describes how the upstream sensor signal and the lambda model shall be acquired synchronously with the heater signal.

Signal flow diagram:



Description:

In case a rising edge of the lambda sensor heater PWM is detected, the delay timer shall be started. After the delay timer expired its maximim value, the sensor signal VLS_UP[i] and the λ-model LAMB_SP_FIL[i] shall be acquired and transfered to the variables VLS_UP_DELTA_RISE[i] and LAMB_SP_FIL_DELTA_RISE[i] respectively.

Analogously, after a lambda sensor heater PWM falling edge occurred and the delay is expired the variables VLS_UP_DELTA_FALL[i] and LAMB_SP_FIL_DELTA_FALL[i] shall be updated.

The delay timer maximum value comprehends the value of T_DLY_TRIG_LSH_UP[i] updated at the last ***falling*** edge and shall be valid for one LSHPWM_UP[i] period at least. In case an edge comes before the time delay counter is expired, neither the lambda signal nor the lambda model shall be acquired. In this case the respective variables shall retain their old values until a new update is possible.

Also at the every falling edge the variables VLS_UP_DELTA_RISE[i], VLS_UP_DELTA_FALL[i], LAMB_SP_FIL_DELTA_RISE[i] and LAMB_SP_FIL_DELTA_FALL[i] shall be handed over to the ASW.

Application conditions:

Initialisation: at reset

VLS_UP_DELTA_RISE[i] = 0
VLS_UP_DELTA_FALL[i] = 0
LAMB_SP_FIL_DELTA_RISE[i] = 0
LAMB_SP_FIL_DELTA_FALL[i] = 0

Recurrence: 10 ms

Activation: **--**

Deactivation: **--**

Formula section:

Temporary storage for conversion of infrastructure data to resolution required in EGCP					

Input data:

CRK_CYL_LAM[NC_CYL_NR]	NC_CYL_NR	LV_LAM_CYL_ENA[NC_CBK_EX_NR]

Import actions:

ACTION_INFR_EnableCilc()
This action sets the activation of CILC (cylinder individuel lambda control)
ACTION_INFR_DisableCilc()
This action sets the deactivation of CILC
ACTION_INFR_GetCilc(IN <x>, **OUT** <v_adc, **OUT** <ctr>**)**
Signal acquisition for CILC
ACTION_INFR_SetCilc(IN <x>, **IN** <crk>**)**
This action provide actual phase displacement for each cylinder

FUNCTION DESCRIPTION:

General information:

The function shall serve as a detector for a precise signal acquisition of the Wide Range Air-Fuel (WRAF) sensor in accordance with the identified cylinder. Therefore, the phase displacement, CRK_CYL_LAM[x] shall be considered. Since for dual-bank engines, the signal acquisition is dual-port, the phase shift shall be allocated to the right cylinder and cylinder bank. The phase displacement CRK_CYL_LAM[x] is computed once every combustion cycle (ASW) and shall be considered for all cylinders.

The calculation shall be done for x = 0 : NC_CYL_NR –1.

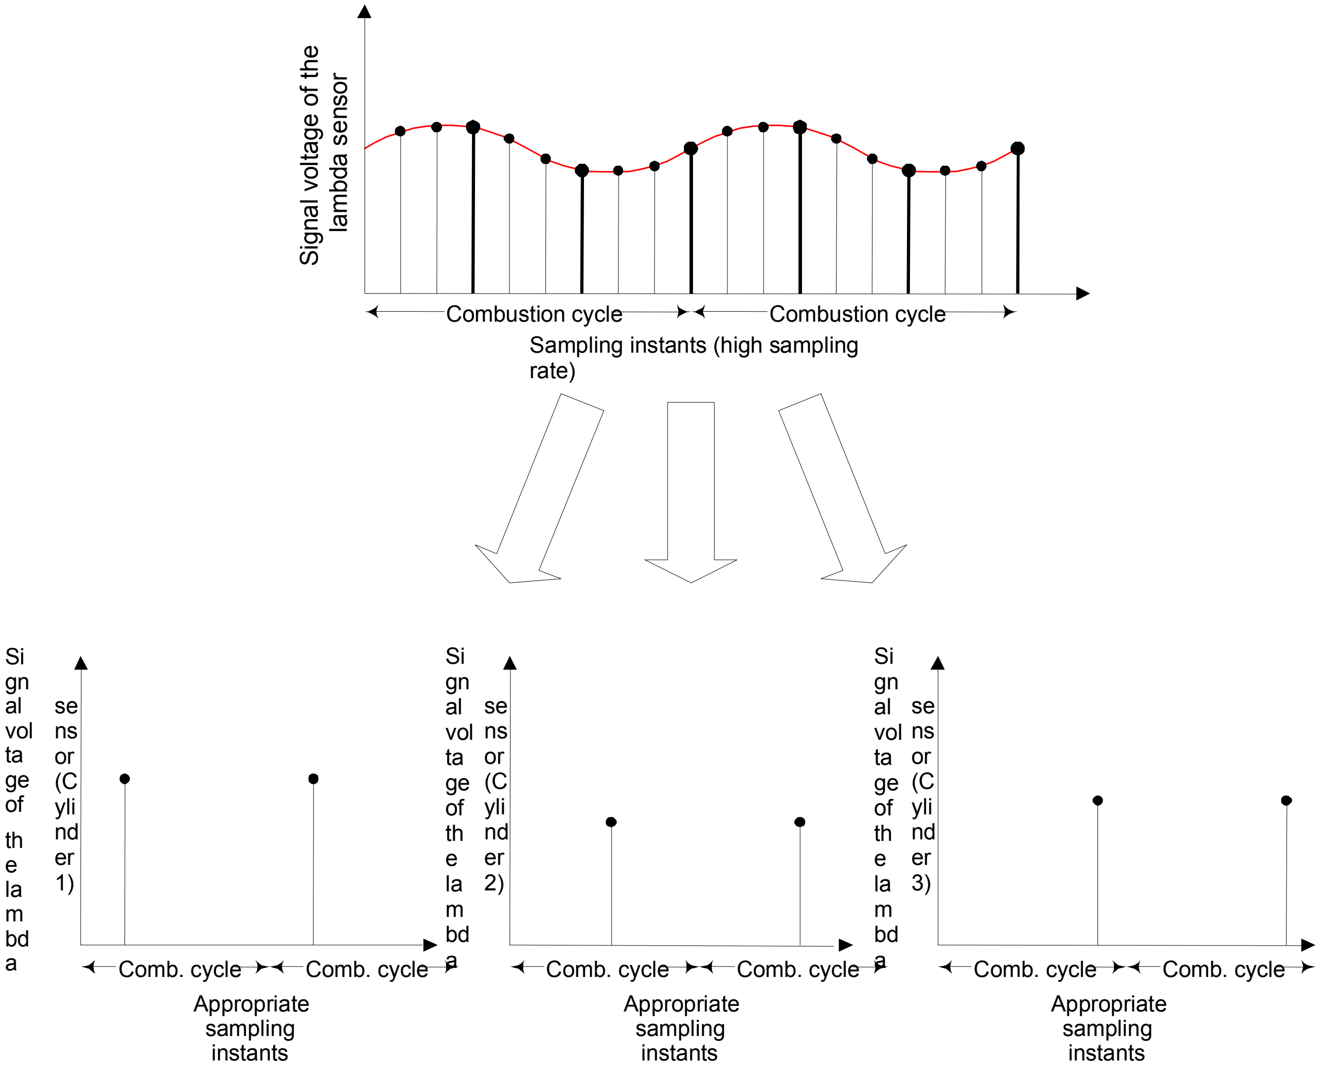

Figure 1: Cylinder individual signal acquisition of WRAF sensor

Application conditions:

Recurrence: segment synchronous, synchron to cylinder individual lambda control (ASW)

Activation: LV_LAM_CYL_ENA[i] = 0 -> 1

ACTION_INFR_EnableCilc()

Deactivation: LV_LAM_CYL_ENA[i] = 1 -> 0

ACTION_INFR_DisableCilc()

Formula section:

write data asynchronous to infrastructure

```
ACTION_INFR_SetCilc(
                IN      x
                IN      CRK_CYL_LAM[x])
```

get data asynchronous to infrastructure

```
ACTION_INFR_GetCilc(
                IN      x
                OUT     VP_LS_CYL_SEL
                OUT     CTR_VLS_UP_CYL_SEL_TRIG[x])
VLS_UP_CYL_SEL[x] = VP_LS_CYL_SEL
```

Description:

Signal acquisition and trigger event

In coordination with TDC the port selected signal voltage of the WRAF sensor shall be sampled (VLS_UP_CYL_SEL[x]) after the phase shift CRK_CYL_LAM[x] for each segment and the trigger counter for respective cylinder (CTR_VLS_UP_CYL_SEL_TRIG[x]) shall be incremented.

TDC **->** CRK_CYL_LAM[x] **->** VLS_UP_CYL_SEL[x] **->** CTR_VLS_UP_CYL_SEL_TRIG[x] ++

Remark:

For instance, see figure 2, which represents the sensor signal acquisition for a dual-bank engine (6 cylinders).

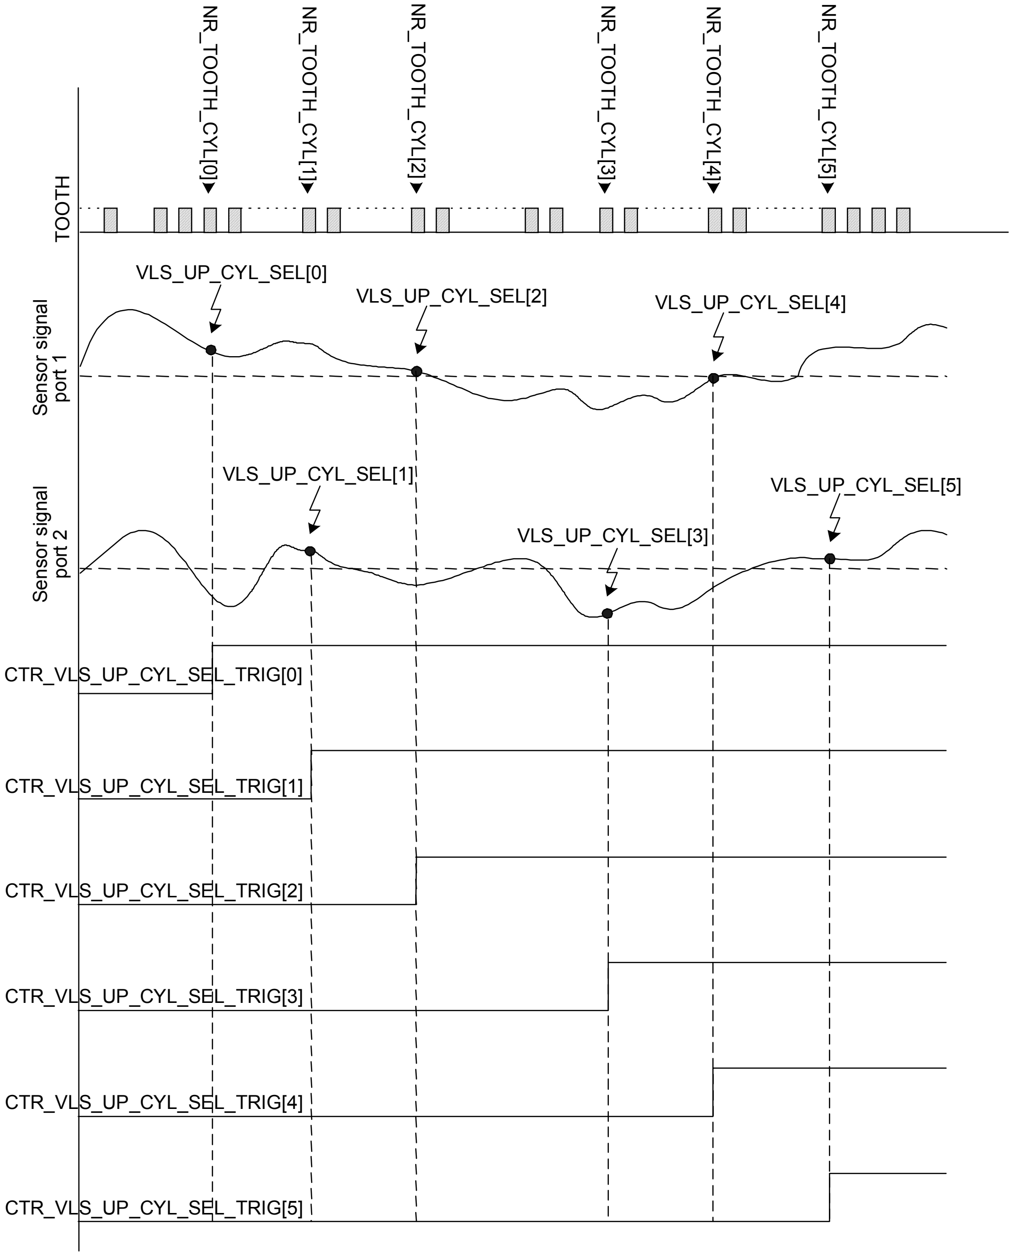

Figure 2: WRAF sensor signal acquisition of a dual-bank catalyst system (6 cylinders)

NC_CBK_EX_NR		

FUNCTION DESCRIPTION:

General information:

This function shall describe the interface between application software (ASW) and the basic software (BSW) that helps to initialise and to configure the ATIC42.

Furthermore, the function shall collect information about the status of the initialisations performed by itself and by other application software and send out a general status of the initialisation via the flag LV_LSL_IF_SPI_RST_END[i], which also indicates the readiness of the ATIC42.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

Description:

The function shall initialize the WRAF sensor interface **after RESET or upon erase of error management** by mirroring the contents of the calibration data C_STATE_LSL_IF_SPI_WR_INI into STATE_LSL_IF_SPI_WR[i] and C_STATE_LSL_IF_CONF_SPI_WR_INI into the variable STATE_LSL_IF_CONF_SPI_WR[i].

Table 1: Contents of the initialization variable C_STATE_LSL_IF_SPI_WR_INI

Bit	Bit Name	Meaning (value “1”/”0”)
0	SWI_GAIN	IP gain 16 / 8
1	VLS_OFS_ADJ_ENA	IP offset measurement ON / OFF
2	ICPLSL_ENA	Enable / disable Icp
3	IPLSL_CTL_ENA	Enable / disable Ip control loop (2nd silicon)
4	R_IT_CAL_ENA	Enable / disable Ri calibration
5	R_IT_OSC_ENA	Ri oscillator ON / OFF
6	LSL_ENA	Sensor enable / disable
7	R_IT_SWI_RNG	Ri measurement range 2 / range 1

After this the function shall bitwise compare the contents of STATE_LSL_IF_SPI_WR[i] and STATE_LSL_IF_SPI_RD[i], and of STATE_LSL_IF_CONF_SPI_WR[i] and STATE_LSL_IF_CONF_SPI_RD[i]. The function shall also check the initialization of the Ri-measurement frequency (done by the correspondent function) by bitwise comparing FRQ_R_IT_OSC_LSL_IF_SPI_WR[i] with FRQ_R_IT_OSC_LSL_IF_SPI_RD[i].

Remark:

For write validation procedure, sensor enable bit LV_LSL_IF_LSL_ENA_i in the initialisation register is NOT considered because it is automatically reset by ATIC42 HW upon detection of an electrical sensor failure, regardless of the last transmitted SPI command. This asynchronuous change in bit value assignment does not represent a communication error.

In addition, bit6 of FRQ_R_IT_OSC_LSL_IF_SPI_xx[i] which represents the status of the “Pin Selective Disabling” feature shall also not be evaluated for SPI communication monitoring at present. Due to an ATIC42 HW error, command execution is performed but not monitored in ASIC response.

Additionally the actual value of error counter CTR_ERR_LSL_IF_SPI_WR[i]$_{(N)}$ must be compared to its precedent value CTR_ERR_LSL_IF_SPI_WR[i]$_{(N-1)}$. If all comparisons show coincidence the flag LV_LSL_IF_SPI_RST_END[i] is set to 1.

The BSW function is defined elsewhere (Basic inputs & outputs, WRAF sensor interface). The BSW essentially observes the interface byte for changes. Should a change occur due to an ASW function, the new information is sent to the ATIC42 and the write cycle is then verified.

The function shall collect information from 8 logical variables and map these to the single byte variable STATE_LSL_IF_SPI_WR[i], which then acts as an interface to the BSW. The bit-field mapping is depicted in the following Table 2 and Figure 1.

Table 2: Bit-field mapping of contents of STATE_LSL_IF_SPI_WR[i]

Bit Pos.	Bit Name	Associated logical variable
0	SWI_GAIN	LV_SWI_GAIN_LSL_IF[i]
1	VLS_OFS_ADJ_ENA	LV_VLS_OFS_ADJ_ENA_LSL_IF[i]
2	ICPLSL_ENA	LV_ICPLSL_ENA_LSL_IF[i]
3	IPLSL_CTL_ENA	LV_IPLSL_CTL_ENA_LSL_IF[i]

4	R_IT_CAL_ENA	LV_R_IT_CAL_ENA_LSL_IF[i]
5	R_IT_OSC_ENA	LV_R_IT_OSC_ENA_LSL_IF[i]
6	LSL_ENA	LV_LSL_ENA_LSL_IF[i]
7	R_IT_SWI_RNG	LV_R_IT_SWI_RNG_LSL_IF[i]

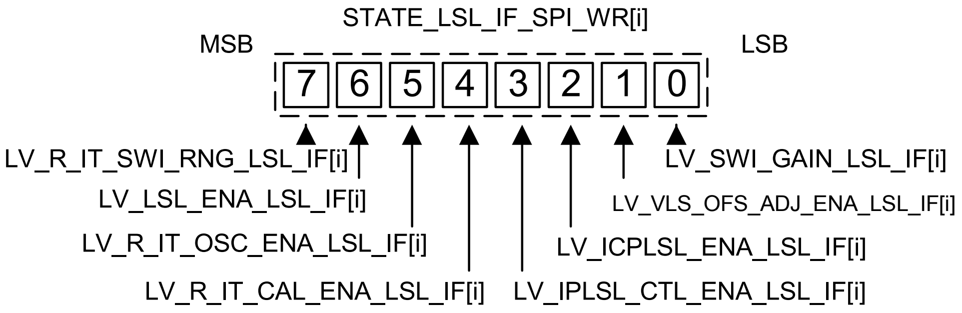

Figure 1: Bit-field mapping of contents of STATE_LSL_IF_SPI_WR[i]

Similarly the function shall also collect the value of the 5-bit variable ICPLSL_LSL_IF[i] and the value of the 3-bit variable T_DLY_DI_LSL_IF[i] and map these into the single byte variable STATE_LSL_IF_CONF_SPI_WR[i], which also acts as an interface to the BSW – see Figure 2.

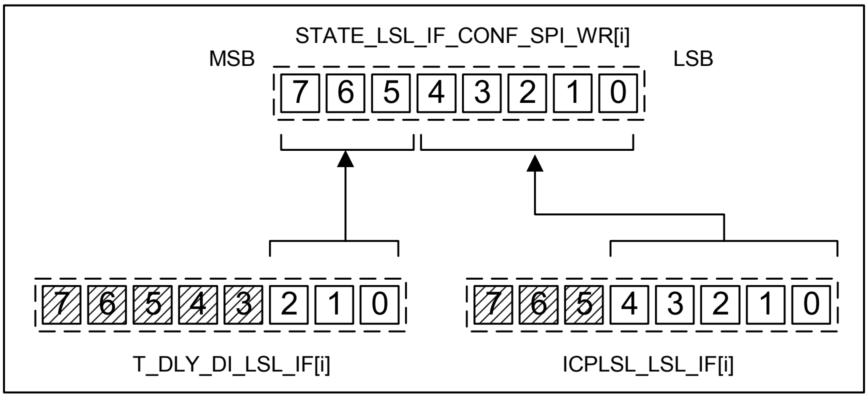

Figure 2: Bit-field mapping of contents of STATE_LSL_IF_CONF_SPI_WR[i]

<u>**Application conditions:**</u>

Initialization:

After a RESET or upon erase of error management the following initialization shall take place:
STATE_LSL_IF_SPI_WR[i] = C_STATE_LSL_IF_SPI_WR_INI
STATE_LSL_IF_CONF_SPI_WR[i] = C_STATE_LSL_IF_CONF_SPI_WR_INI
LV_LSL_IF_SPI_RST_END[i] = 0.
Store CTR_ERR_LSL_IF_SPI_WR_i$_{(N)}$ – 1.

Counter content is decremented at function initialization prior to storage to ensure that BSW is executed once the least before LV_LSL_IF_SPI_RST_END is set - and thus might falsely indicate execution of a successful write cycle for initialization. The simulated communication error (stored counter value differs from actual value) replaces time flow synchronization mechanism between ASW-BSW interface and BSW function which are executed at same recurrence rate. This workaround assures that BSW is able to perform one write cycle minimum regardless of contents of ATIC42 initialization registers.

Note: after a successfull initialization of the ATIC42 the flag LV_LSL_IF_SPI_RST_END shall be activated.

Recurrence:

T_SAMPLE = 10 ms.

Activation:

In all Engine States

Deactivation:

--

FUNCTION DESCRIPTION:

General information:

Specification defines and initializes variables and boolean flags not defined and initialized elsewhere.

In case of an electric fault (incl. Open Circuit) which is detected by WRAF sensor electric diagnosis, sensor is decoupled as long as corresponding error flags are present.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Description:

This function shall initialise the unused WRAF sensor interface flags.

Once OBDI sensor error is debounced (LV_ERR_EL_LSL_UP[i] == 1), WRAF sensor is decoupled (LV _LSL_ENA_LSL_IF [i] = 0) as long as error flag is present. Same action is taken once debounced OC failure is present (LV_ERR_OC_LSL_UP[i] == 1).

The following configuration data shall be used:

C_T_DLY_DI_LSL_IF = 010 = 2H (corresponds to 1ms)

Application conditions:

Initialisation:

The following variable initialisation shall take place *after RESET*.

T_DLY_DI_LSL_IF[i] = C_T_DLY_DI_LSL_IF

LV_LSL_IF_RST[i] = 0

LV_LSL_ENA_LSL_IF[i] = 1

The following variable initialisation shall take place *at LV_IGK = 0 -> 1, or upon erase of error management*.

LV_LSL_ENA _LSL_IF[i] = 1

NOTE: The logical variable LV_LSL_ENA_LSL_IF[i] is mapped in the interface byte STATE_LSL_IF_SPI_WR[i].
Its initialization shall be done according to the corresponding bit value of C_STATE_LSL_IF_SP_WR_INI in 'ATIC42 ASW<->BSW Interface', 4033.
T_DLY_DI_LSL_IF[i] is mapped in the configuration byte STATE_LSL_IF_CONF_SPI_WR[i].

Recurrence:

T_SAMPLE = 10ms

Activation:

In all engine states

FUNCTION DESCRIPTION:

General information:

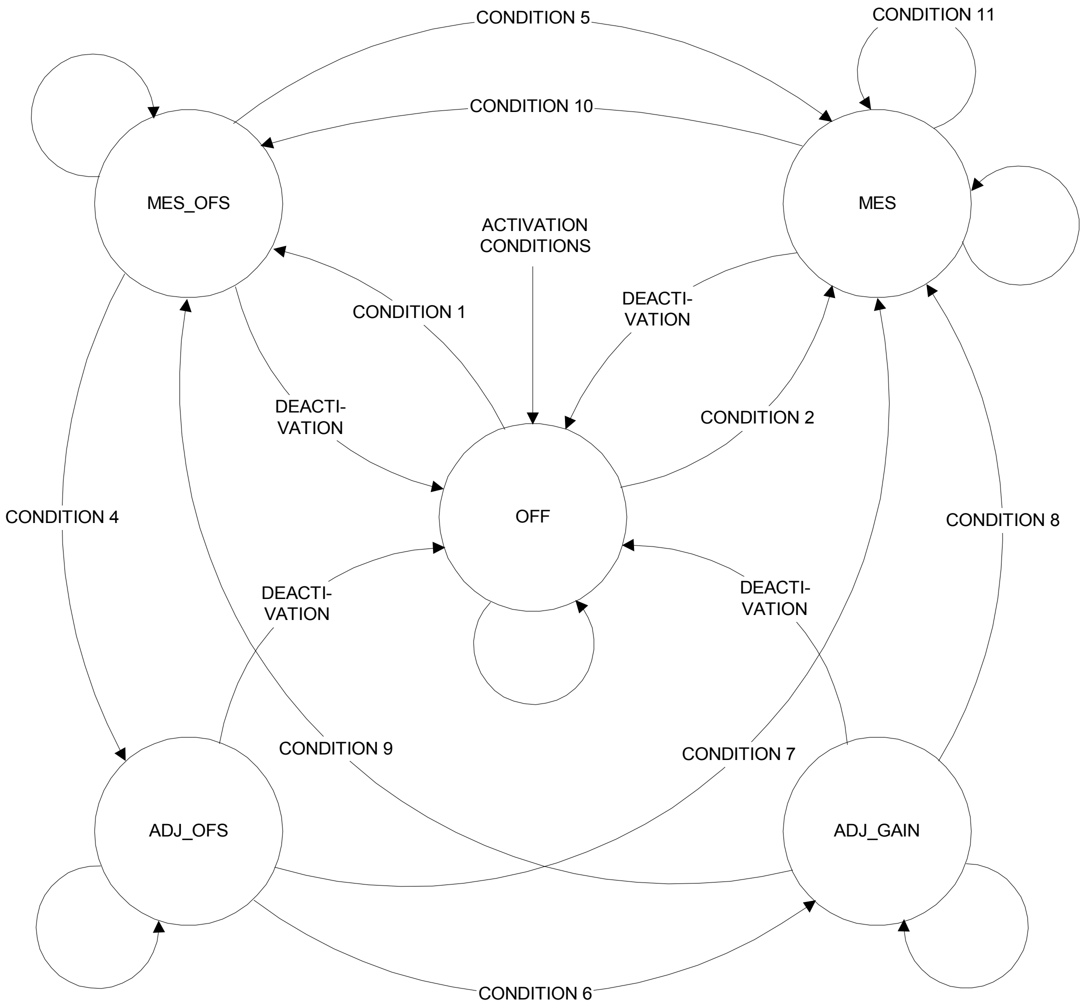
The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

The purpose of this function shall be to:

- Initialise the WRAF sensor interface with respect to all resistance determination parameters, i.e. switches and oscillator frequency.

- Switch between internal resistance ranges upon detection of operative readiness or when manually requested.
- Convert an acquired voltage (V_TEMP_LS_UP[i]) into an oxygen sensor element ceramic temperature and internal resistance.
- Periodically measure the offset and gain of the internal resistance determination circuit in order to minimise errors in the measured resistance and therefore ceramic temperature determination.

Signal flow diagram:



Description:

The function, once activated, shall provide the ceramic tip temperature of the oxygen sensor every 100 ms derived from the measured internal resistance. This temperature may then be used for temperature control and diagnosis purposes. In order to increase the system accuracy, the equation linking the measured voltage (measure of internal resistance) to the internal resistance may be compensated for drifts in offset and gain of the measurement circuit. The compensation shall be carried out periodically, when triggered by the input variable LV_LSL_OFS_ADJ_ACT[i] being set and when switching between internal resistance ranges. This former condition ensures that the oscillator, used to measure the internal resistance, is off when the lambda output offset measurement is carried out. The latter condition ensures that the different gain associated with the different range is re-measured.

The offsets shall be measured in both the measurement mode (oxygen sensor attached to WRAF sensor interface) and adjustment mode (reference calibration resistor attached to WRAF sensor interface) by switching the oscillator off and measuring the voltage output of the circuit. The gain shall be measured by switching to the adjust mode and taking the voltage reading with the calibration resistor in place. With reading and the knowledge of the value of the calibration resistor, stimulus resistor and previously measured offset in adjustment mode, the function shall compute the gain. This gain value of the internal amplifier is the same for both adjustment mode and measurement mode. However, the offsets may differ from one another due to CM (common mode) errors in the internal amplifier and due to the differing potentials at the VN amplifier input in adjustment mode (VGND) and measurement mode (VGND + VS). Hence the gain is calculated with the adjustment mode offset and the measured internal resistance is calculated with the measurement offset.

The **initialisation** of the function output data variables shall be carried out as follows:

- The SW initialisation of the WRAF sensor interface shall be carried out directly after a reset. FRQ_R_IT_OSC_LSL_IF_SPI_WR[i] shall be set to C_FRQ_R_IT_OSC_LSL_IF. The ASW interface function shall then determine whether the WRAF sensor interface has been successfully initialised by comparing the information returned from the WRAF interface ASIC with the corresponding initialisation request. Once all initialisations have been completed, the flag LV_LSL_IF_SPI_RST_END[i] is set indicating that the complete initialisation has been completed.
- The internal resistance R_IT_LS_UP[i] shall be initialised to its maximum value and the ceramic temperature TTIP_MES_LS_UP[i] to 0, i.e. cold sensor.
- The state machine shall be initialised to the OFF state and the temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be reset.
- The validity flags, LV_V_REF_VLD_R_IT_LS_UP[i], LV_V_OFS_MES_VLD_R_IT_LS_UP[i], LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i], LV_FAC_GAIN_H_VLD_R_IT_LS_UP[i] & LV_FAC_GAIN_L_VLD_R_IT_LS_UP[i] shall be initialised dependent on the state of activation logical constant LC_V_REF_R_IT_LS_UP. Should the function be set to be active via this constant, then the flags shall be initialised with 0. Hence should the function be set to be inactive, the flags shall be set to 1, i.e. show that the offset and gain measurements are valid. This permits the function to be disabled via LC_V_REF_R_IT_LS_UP without affecting the functions that use the ceramic temperature information.
- The test cycle and frequency counters used to measure the number of reference measurements carried out (TCC_...) and the number of reference measurements out of bounds (FRC_...) shall be initialised after completion of engine start.
- The offset variables V_OFS_MES_R_IT_LS_UP[i] & V_OFS_ADJ_R_IT_LS_UP[i] and gain variables FAC_GAIN_H_R_IT_LS_UP[i] & FAC_GAIN_L_R_IT_LS_UP[i] shall be initialised with the appropriate C_... constant.

Upon **deactivation** of the function, when the engine start flag is reset, the function shall indicate to other functions that the ceramic temperature is no longer valid by setting the STATE_TTIP_MES_LS_UP[i] to OFF, resetting the general validity flag LV_TTIP_MES_VLD_LS_UP[i], the internal resistance measurement oscillator shall be switched off, the internal resistance measurement mode set to normal measurement mode and the resistance range shall be set the value LC_R_RNG_REQ_LS_UP_LSL_IF.

The function shall be **activated** with LV_IGK = 1, no inhibition bit set (LV_INH_TTIP_LS_UP[i] == 1), no electrical OBD fault have been detected for the WRAF sensor which leads to sensor decoupling (STATE_LSL_IF_SPI_RD[i] (*bit* LSL_ENA) == 1), and either the raw or conditional operative readiness has been detected (LV_LS_UP_READY_RAW[i] = 1 or LV_LS_UP_READY_CDN[i] = 1), or forced sensor pre-heating has been activated (LV_LSH_UP_MAN_ACT[i] == 1).

It shall be **deactivated** for LV_IGK = 0, at presence of function inhibition through corresponding application incidence, upon detection of an electrical OBD fault for the WRAF sensor resulting in sensor decoupling, or the raw and conditional operative readiness be reset together with passivated forced sensor pre-heating.

The validity of the ceramic temperature measurement shall be computed every recurrence and indicated by the Boolean flag LV_V_REF_VLD_R_IT_LS_UP[i]. This flag shall be set when both offset measurements have been determined to be valid, as indicated by LV_V_OFS_MES_VLD_R_IT_LS_UP[i] and LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i], and when the gain has been determined to be valid, as indicated by LV_FAC_GAIN_H_VLD_R_IT_LS_UP[i] or LV_FAC_GAIN_L_VLD_R_IT_LS_UP[i] depending on the selected resistance range (LV_R_IT_SWI_RNG_LSL_IF[i]).

The function shall be implemented as a state machine with five states. The state of the state machine shall be indicated by the variable STATE_TTIP_MES_LS_UP[i]. The state machine may be described as follows:

STATE_TTIP_MES_LS_UP[i] = OFF

In state OFF, the ceramic temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be set to 0, indicating that the temperature shall not be used by other functions. The state machine may exit to one of either two states:

Exit to measurement mode offset measurement, **MES_OFS**: Shall occur when the SPI interface has been determined to have been initialised via flag LV_LSL_IF_SPI_RST_END[i] and should the calibration flag LC_V_REF_R_IT_LS_UP be set, thus permitting the calibration procedure to take place. Should these conditions be met, then *TIMER_1* & *TIMER_2* shall be reset, *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored, the state STATE_TTIP_MES_LS_UP[i] set to MES_OFS, the oscillator switched off via LV_R_IT_OSC_ENA_LSL_IF[i] = 0 and the measurement mode activated via LV_R_IT_CAL_ENA_LSL_IF[i] = 0.

Exit to normal resistance measurement mode, **MES**: Shall occur when the SPI interface has been determined to have been initialised via flag LV_LSL_IF_SPI_RST_END[i] and should the calibration flag LC_V_REF_R_IT_LS_UP be reset, thus preveting the calibration procedure from taking place. Should these conditions be met, then *TIMER_2* shall be reset, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored, the state STATE_TTIP_MES_LS_UP[i] set to MES, the oscillator switched on via LV_R_IT_OSC_ENA_LSL_IF[i] = 1 and the measurement mode activated via LV_R_IT_CAL_ENA_LSL_IF[i] = 0.

STATE_TTIP_MES_LS_UP[i] = MES_OFS

In state MES_OFS, the offset shall be determined as follows:

The function shall determine whether a fault in the SPI communication has occurred since the WRAF sensor interface control byte flags LV_R_IT_OSC_ENA_LSL_IF[i], LV_R_IT_CAL_ENA_LSL_IF[i], & LV_R_IT_SWI_RNG_LSL_IF[i] were programmed. This is facilitated by comparing the value of the SPI fault counter with the value stored prior to setting the flags. Additionally the status of the sensor coupling shall be determined. Should a communication fault have occurred either sending the information to the interface or should the information have changed in the interface control byte since programming, CTR_ERR_LSL_IF_SPI_WR[i] shall be incremented by the appropriate SPI communication function. This difference or the decoupling of the sensor, signalled by LV_LSL_DEAC[i] = 1 or STATE_LSL_IF_SP_RD[i].LSL_ENA = 0 shall cause the *TIMER_2* to be reset and the new value of the counter to be stored.

The SPI communication function operates an automatic retry strategy, thus if the desired contents could not be programmed or should the contents read back are not those programmed, then the SPI communication function shall continue to re-send the information until either it is successful or a debounced fault is recognised and further communication halted (check of FRQ_R_IT_OSC_LSL_IF_SP_RD[i]).

Should no SPI fault or decoupling of the sensor be determined to have occurred, the function shall verify that the desired contents have been programmed by reading the appropriate bits (IT_OSC_ENA, R_LS_CAL_ENA & R_LS_RNG) of the interface byte STATE_LSL_IF_SP_RD[i]. This byte mirrors the current contents of the WRAF sensor interface control byte. Due to the finite time that is required to program the WRAF sensor interface, the programming may not have taken place. In this instance the function shall await the next recurrence. If the programmed contents can be verified, the function shall wait until delay C_T_DLY_OFS_MES_R_IT_LS_UP has passed facilitated by *TIMER_2* and then take 4 V_TEMP_LS_UP[i] samples over the current and next 3 recurrences.

The absolute difference between the average of the 4 samples and the constant C_V_OFS_REF_R_IT_LS_UP shall then be compared to C_V_DIF_MAX_OFS_MES_R_IT_LS_UP to determine whether the measured offset is in bounds. If this is the case, the appropriate validity flag LV_V_OFS_MES_VLD_R_IT_LS_UP[i] set. If not the case, the frequency counter TCC_ERR_V_OFS_MES_R_IT_LS_UP[i] shall be incremented, indicating a faulty offset measurement, and LV_V_OFS_MES_VLD_R_IT_LS_UP[i] shall be reset. V_OFS_MES_R_IT_LS_UP[i] shall take on the value of the average, within bounds or not.

Test cycle counter TCC_V_OFS_MES_R_IT_LS_UP[i] shall be incremented, indicating that another measurement mode offset measurement has been carried out.

The state machine may exit to one of either two states:

Exit to adjustment mode offset measurement, **ADJ_OFS**: Shall occur when the offset measurement has been determined to have been completed. Should this condition be met, then the flag LV_R_IT_CAL_ENA_LSL_IF[i] shall be set, switching to adjust mode (calibration resistor), *TIMER_1* & *TIMER_2* shall be reset, *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored and the state STATE_TTIP_MES_LS_UP[i] set to ADJ_OFS.

Exit to normal resistance measurement mode, **MES**: Shall occur when the time limit C_T_MAX_V_OFS_MES_R_IT_LS_UP has been determined to have been exceeded, facilitated by *TIMER_1*. This provides a time out to ensure that the function does not lock up should SPI communication faults continuously prevent the offset measurement from being completed. Should these conditions be met, then the oscillator shall be switched on by setting flag LV_R_IT_CAL_ENA_LSL_IF[i], *TIMER_2* shall be reset, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored and the state STATE_TTIP_MES_LS_UP[i] set to MES.

STATE_TTIP_MES_LS_UP[i] = ADJ_OFS

In state ADJ_OFS, the offset shall be determined by exactly the same method as described for state MES_OFS, the only differences being:

- When checking that the programmed information has been correctly mirrored, bit STATE_LSL_IF_SP_RD[i].IT_OSC_ENA shall be 0, STATE_LSL_IF_SP_RD[i].R_LS_CAL_ENA shall be 1 and STATE_LSL_IF_SP_RD[i].R_LS_RNG shall equal LV_R_IT_SWI_RNG_LSL_IF[i].
- The *TIMER_2* delay shall be C_T_DLY_OFS_ADJ_R_IT_LS_UP.
- The absolute difference between the sample averages and constant C_V_OFS_REF_R_IT_LS_UP shall be compared to C_V_DIF_MAX_OFS_ADJ_R_IT_LS_UP.
- The adjustment mode offset variable shall be V_OFS_ADJ_R_IT_LS_UP[i], the validity flag shall be LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i], the frequency counter TCC_ERR_V_OFS_ADJ_R_IT_LS_UP[i] and test cycle counter TCC_V_OFS_ADJ_R_IT_LS_UP[i].

The state machine may exit to one of either two states:

Exit to adjustment mode gain measurement, **ADJ_GAIN**: Shall occur when the offset measurement has been determined to have been completed and the lambda offset calibration has been completed, thus ensuring that the oscillator being off does not disturb the lambda output. Should these conditions be met, then the flag LV_R_IT_OSC_ENA_LSL_IF[i] shall be set, switching the oscillator on, *TIMER_1* & *TIMER_2* shall be reset and *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored and the state STATE_TTIP_MES_LS_UP[i] set to ADJ_GAIN.

Exit to normal resistance measurement mode, **MES**: Shall occur when the time limit C_T_MAX_V_OFS_ADJ_R_IT_LS_UP has been determined to have been exceeded, facilitated by *TIMER_1* providing a time out as described and the lambda output offset compensation has been completed as determined by LV_LSL_OFS_ADJ_ACT[i] = 0. Should these conditions be met, then the oscillator shall be switched on by setting flag LV_R_IT_CAL_ENA_LSL_IF[i], the mode set to measurement mode by resetting LV_R_IT_CAL_ENA_LSL_IF[i], *TIMER_2* shall be reset, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored and the state STATE_TTIP_MES_LS_UP[i] set to MES.

STATE_TTIP_MES_LS_UP[i] = ADJ_GAIN

In state ADJ_GAIN, the gain shall be determined by similarly to the method as described for state MES_OFS, the only differences being:

- When checking that the programmed information has been correctly mirrored, bit STATE_LSL_IF_SP_RD[i].IT_OSC_ENA shall be 1, STATE_LSL_IF_SP_RD[i].R_LS_CAL_ENA shall be 1 and STATE_LSL_IF_SP_RD[i].R_LS_RNG shall equal LV_R_IT_SWI_RNG_LSL_IF[i].
- The *TIMER_2* delay shall be C_T_DLY_FAC_GAIN_R_IT_LS_UP.
- After having taken the 4 samples, the gain shall be computed using the equation in the formula section. The gain calculated and the constants used in the calculation shall depend on the selected resistance range.

- The absolute difference between the gain and constant C_GAIN_TEMP_LS_UP shall be compared to C_GAIN_TEMP_LS_UP_DIF.
- The adjustment mode gain variable shall be FAC_GAIN_H_R_IT_LS_UP[i], the validity flag shall be LV_FAC_GAIN_H_VLD_R_IT_LS_UP[i], the frequency counter TCC_ERR_FAC_GAIN_H_R_LS_UP[i] and test cycle counter TCC_FAC_GAIN_H_R_IT_LS_UP[i] or FAC_GAIN_L_R_IT_LS_UP[i], the validity flag shall be LV_FAC_GAIN_L_VLD_R_IT_LS_UP[i], the frequency counter TCC_ERR_FAC_GAIN_L_R_LS_UP[i] and test cycle counter TCC_FAC_GAIN_L_R_IT_LS_UP[i] dependent on the selected resistance range (LV_R_IT_SWI_RNG_LSL_IF[i]).

The state machine may exit to one of either two states:

Exit to normal internal resistance measurement mode, **MES**: Shall occur when the gain measurement has been determined to have been successfully completed (LV_V_REF_VLD_R_IT_LS_UP[i] = 1) or when the time limit C_T_MAX_FAC_GAIN_R_IT_LS_UP has been determined to have been exceeded, facilitated by *TIMER_1* providing a time out as described previously. Should these conditions be met, then the mode shall be set to measurement mode by resetting LV_R_IT_CAL_ENA_LSL_IF[i], *TIMER_2* shall be reset, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored and the state STATE_TTIP_MES_LS_UP[i] set to MES.

Exit to measurement mode offset measurement, **MES_OFS**: Shall occur should the gain measurement have been unsuccessfully completed (LV_V_REF_VLD_R_IT_LS_UP[i] = 0) or if the lambda output offset compensation be requested (LV_LSL_OFS_ADJ_ACT[i] = 1). Should either of these conditions be met, then the oscillator shall be switched off via LV_R_IT_OSC_ENA_LSL_IF[i] = 0 and the measurement mode activated via LV_R_IT_CAL_ENA_LSL_IF[i] = 0, *TIMER_1* & *TIMER_2* shall be reset, *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored, the state STATE_TTIP_MES_LS_UP[i] set to MES_OFS.

STATE_TTIP_MES_LS_UP[i] = MES

In state MES, the internal resistance shall be determined as follows:

The function shall determine whether a fault in the SPI communication or if the sensor has been decoupled as described previously. Should either of these conditions be true, the ceramic temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be reset, thus suspending further use of the temperature information, *TIMER_2* shall be reset and the new value of the counter to be stored.

Should no SPI fault or decoupling of the sensor be determined to have occurred, function checks for <u>rising</u> edge of ATIC42 pump current control enable bit. To avoid erroneous Ri readings due to electrical disturbance on Ri measurement circuit during Ip activation, Ri value is frozen for calibratable delay time C_T_DLY_R_IT_IPLSL_CTL_ACT triggered by rising edge detection. Same holds true for <u>falling</u> edge. During signal freeze LV_TTIP_MES_VLD_LS_UP[i] shall be reset.

Next the function shall verify that the desired control byte contents have been programmed by reading the appropriate bits (IT_OSC_ENA = 1, R_LS_CAL_ENA = 0, R_LS_RNG = LV_R_IT_SWI_RNG_LSL_IF[i]) of the interface byte STATE_LSL_IF_SP_RD. If not the case the function shall await the next recurrence. If the programmed contents can be verified, the function shall wait until delay C_T_DLY_CLC_R_IT_LS_UP has passed facilitated by *TIMER_2* and then compute the internal resistance from the measurement mode offset, V_OFS_MES_R_IT_LS_UP[i], the average of up to 8 V_TEMP_LS_UP[i] samples, the value of the stimulus resistor, C_R_IT_REF_LS_UP and dependent on the value of LV_R_IT_SWI_RNG_LSL_IF[i] either FAC_GAIN_H_R_IT_LS_UP[i] or FAC_GAIN_L_R_IT_LS_UP[i].

The ceramic temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be set and the ceramic temperature TTIP_MES_LS_UP[i] shall be determined from the map IP_TTIP_MES_LS_UP.

The state machine may exit to one state:

Exit to state, measurement mode offset measurement, **MES_OFS**: Shall occur should the calibration flag LC_V_REF_R_IT_LS_UP be set, thus permitting the calibration procedure to take place and either when the lambda offset correction has been determined to have been requested, LV_LSL_OFS_ADJ_ACT[i] = 1 or should the operative readiness be detected or finally should a manual switching of the gain be requested. The non-operative readiness condition ensures that should any of the time-outs occur in the states MES_OFS, ADJ_OFS or ADJ_GAIN, and the operative readiness not yet have been detected, then the function may restart the calibration process. Should these conditions be met, then, dependent on whether a manual range switch was requested, the resistance range shall be set to the Boolean constant LC_R_RNG_REQ_LS_UP_LSL_IF or to the negation of LV_LS_UP_READY[i], the ceramic temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be reset, the oscillator shall be switched off via LV_R_IT_OSC_ENA_LSL_IF[i] = 0, *TIMER_1* & *TIMER_2* shall be reset, *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored, the state STATE_TTIP_MES_LS_UP[i] set to MES_OFS.

Should the calibration flag LC_V_REF_R_IT_LS_UP be reset, thus disabling the calibration procedure to take place but the operative readiness be detected or should a manual switching of the gain be requested then , dependent on whether a manual range switch was requested, the resistance range shall be set to the Boolean constant LC_R_RNG_REQ_LS_UP_LSL_IF or to the negation of LV_LS_UP_READY[i], the ceramic temperature validity flag LV_TTIP_MES_VLD_LS_UP[i] shall be reset, *TIMER_1* & *TIMER_2* shall be reset, *TIMER_1* started. Additionally, the current value of the SPI fault counter CTR_ERR_LSL_IF_SPI_WR[i] shall be stored, but the state STATE_TTIP_MES_LS_UP[i] shall **remain in MES**.

In addition to the aforementioned state conditions, the state machine may **exit to state OFF from all other states**. This shall occur should the function be deactivated. In this case certain variables may be reset as described previously in the section regarding the initialisation.

Application conditions:

Initialisation:

The following initialisation shall take place directly **after RESET**:

FRQ_R_IT_OSC_LSL_IF_SPI_WR[i] = C_FRQ_R_IT_OSC_LSL_IF

The following variable initialisation shall take place **after RESET, at LV_IGK = 0 -> 1**, or **upon erase of error management**:

TTIP_MES_LS_UP[i] = 0

R_IT_LS_UP[i] = 16383.75 (i.e. FFFFH)

STATE_TTIP_MES_LS_UP[i] = OFF

LV_V_OFS_MES_VLD_R_IT_LS_UP[i] = **!** LC_V_REF_R_IT_LS_UP

LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i] = **!** LC_V_REF_R_IT_LS_UP

LV_FAC_GAIN_H_VLD_R_IT_LS_UP[i] = **!** LC_V_REF_R_IT_LS_UP

LV_FAC_GAIN_L_VLD_R_IT_LS_UP[i] = **!** LC_V_REF_R_IT_LS_UP

LV_TTIP_MES_VLD_LS_UP[i] = 0

LV_V_REF_VLD_R_IT_LS_UP[i] = ! LC_V_REF_R_IT_LS_UP

TCC_V_OFS_MES_R_IT_LS_UP[i] = 0

TCC_V_OFS_ADJ_R_IT_LS_UP[i] = 0

TCC_FAC_GAIN_H_R_IT_LS_UP[i] = 0

TCC_FAC_GAIN_L_R_IT_LS_UP[i] = 0

TCC_ERR_V_OFS_MES_R_IT_LS_UP[i] = 0

TCC_ERR_V_OFS_ADJ_R_IT_LS_UP[i] = 0

TCC_ERR_FAC_GAIN_H_R_LS_UP[i] = 0

TCC_ERR_FAC_GAIN_L_R_LS_UP[i] = 0

V_OFS_MES_R_IT_LS_UP[i] = C_V_OFS_REF_R_IT_LS_UP

V_OFS_ADJ_R_IT_LS_UP[i] = C_V_OFS_REF_R_IT_LS_UP

FAC_GAIN_H_R_IT_LS_UP[i] = C_FAC_GAIN_H_R_IT_LS_UP

FAC_GAIN_L_R_IT_LS_UP[i] = C_FAC_GAIN_L_R_IT_LS_UP

LV_R_IT_REQ_LS_UP[i] = 0

T_DLY_R_IT_IPLSL_CTL_ACT[i] = 0

Reset internal timers TIMER_1 & TIMER_2

Recurrence:

The function shall run at a recurrence of 10 ms.

The computation of a new internal resistance value shall be carried out once every 100 ms provided the applicable conditions have been met.

Activation:

The functions "*General validity of ceramic temperature measurement*", "*Reset statistical counters after diagnosis completion*" & "*State Machine*" shall be carried out according to the following conditions:

LV_INH_TTIP_LS_UP[i] == 0
and LV_IGK == 1
and STATE_LSL_IF_SPI_RD[i] (*bit* LSL_ENA) == 1

```
and     ( LV_LS_UP_READY_RAW[i] == 1
or      LV_LS_UP_READY_CDN[i] == 1
or      LV_LSH_UP_MAN_ACT[i] == 1 )
```

Deactivation:

```
        LV_INH_TTIP_LS_UP[i] ==1
or      LV_IGK == 0
or      STATE_LSL_IF_SPI_RD[i] ( bit LSL_ENA ) == 0
or      ( LV_LS_UP_READY_RAW[i] == 0
and     LV_LS_UP_READY_CDN[i] == 0
and     LV_LSH_UP_MAN_ACT[i] == 0 )
```

The following variable initialisation shall take place upon deactivation:

STATE_TTIP_MES_LS_UP[i] = OFF

LV_TTIP_MES_VLD_LS_UP[i] = 0

In addition upon deactivation, the following variables shall be conditionally initialised:

```
If      LV_LSL_IF_SPI_RST_END[i] == 1
then    LV_R_IT_CAL_ENA_LSL_IF[i] = 0
        LV_R_IT_OSC_ENA_LSL_IF[i] = 0
        If      LC_R_RNG_REQ_SWI_LS_UP_LSL_IF == 1
        then    LV_R_IT_SWI_RNG_LSL_IF[i] = LC_R_RNG_REQ_LS_UP_LSL_IF
        else    LV_R_IT_SWI_RNG_LSL_IF[i] = ! LV_LS_UP_READY[i]
        endif
endif
```

Formula section:

General validity of ceramic temperature measurement:

```
If      LV_R_IT_SWI_RNG_LSL_IF[i] == 0
then    LV_V_REF_VLD_R_IT_LS_UP[i]
        =       LV_V_OFS_MES_VLD_R_IT_LS_UP[i]
                &       LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i]
                &       LV_FAC_GAIN_H_VLD_R_IT_LS_UP[i]
else    LV_V_REF_VLD_R_IT_LS_UP[i]
        =       LV_V_OFS_MES_VLD_R_IT_LS_UP[i]
                &       LV_V_OFS_ADJ_VLD_R_IT_LS_UP[i]
                &       LV_FAC_GAIN_L_VLD_R_IT_LS_UP[i]
```

endif

State Machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Notes:
1. The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.
2. TIMER_1 & TIMER_2 refer to SW internal variables. TIMER_1 & TIMER_2 are not visible output variables.
3. The assignment store CTR_ERR_LSL_IF_SPI_WR[i]$_N$ denotes that the current counter value shall be noted by the SW until the next assignment occurs.

STATE_TTIP_MES_LS_UP[i] = “OFF”

Actions:

LV_TTIP_MES_VLD_LS_UP[i] = 0

Note: The above listed actions must be carried out at least once when the state has been entered for the first time or from any other state!

Condition 1: “OFF” to “MES_OFS”

LV_LSL_IF_SPI_RST_END[i] = 1 **&**
LC_V_REF_R_IT_LS_UP = 1

Transition actions:

Reset *TIMER_1*
Start *TIMER_1*
Reset *TIMER_2*
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = MES_OFS
LV_R_IT_OSC_ENA_LSL_IF[i] = 0
LV_R_IT_CAL_ENA_LSL_IF[i] = 0

Condition 2: “OFF” to “MES”

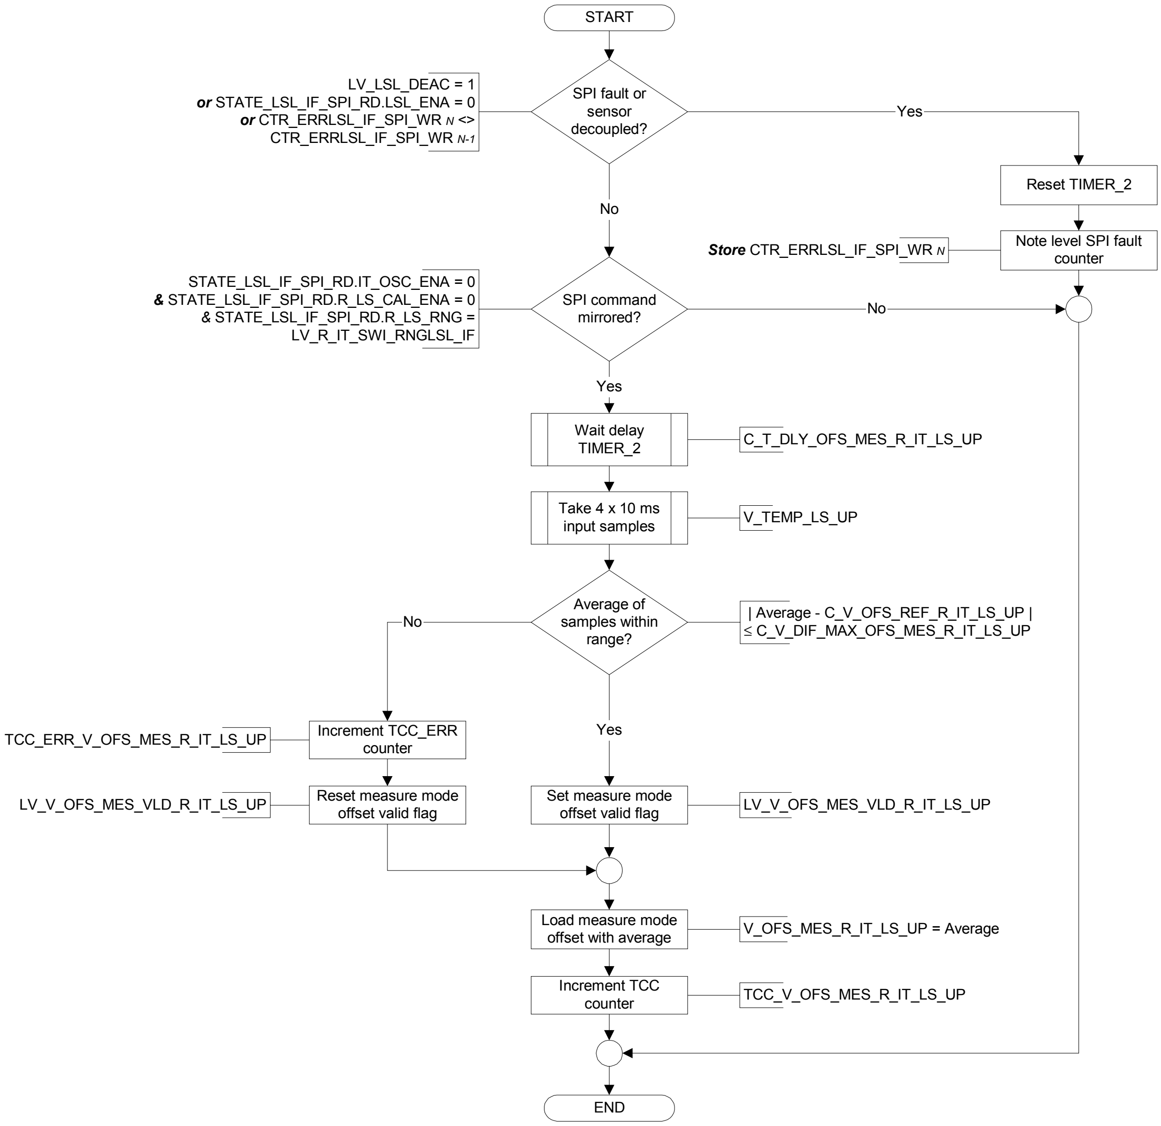
LV_LSL_IF_SPI_RST_END[i] = 1 **&**
LC_V_REF_R_IT_LS_UP = 0

Transition actions:

Reset *TIMER_2*
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = MES
LV_R_IT_OSC_ENA_LSL_IF[i] = 1
LV_R_IT_CAL_ENA_LSL_IF[i] = 0

STATE_TTIP_MES_LS_UP[i] = “MES_OFS”

Actions:



Note: TCC_V_OFS_MES_R_IT_LS_UP[i] & TCC_ERR_V_OFS_MES_R_IT_LS_UP[i] shall not be permitted to overflow.

Condition 4: *“MES_OFS” to “ADJ_OFS”*

MES_OFS procedure complete (valid or invalid)

Transition actions:

LV_R_IT_CAL_ENA_LSL_IF[i] = 1
Reset *TIMER_1*
Start *TIMER_1*
Reset *TIMER_2*
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = ADJ_OFS

Condition 5: *“MES_OFS” to “MES”*

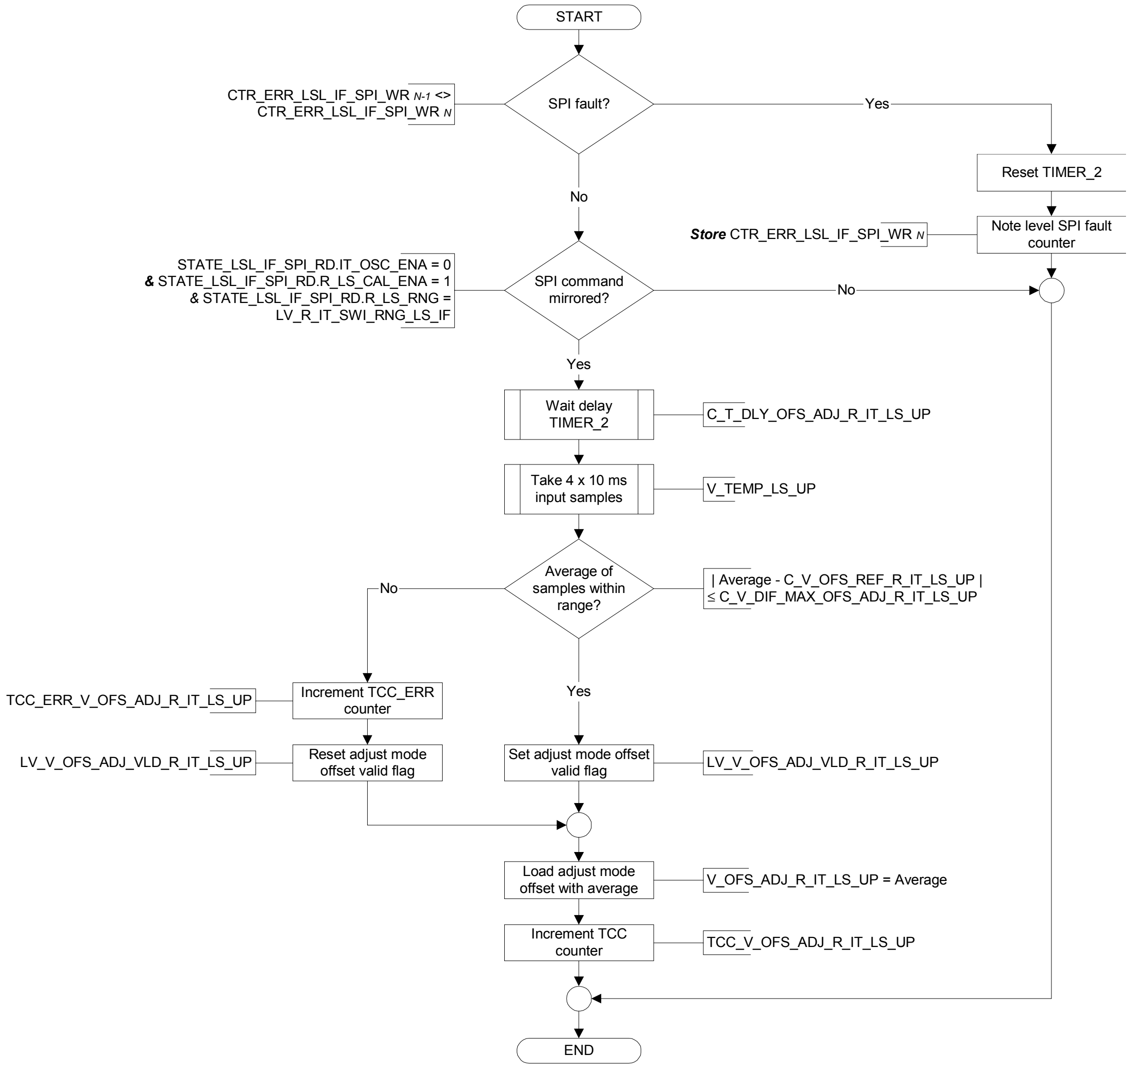
TIMER_1 ≥ C_T_MAX_V_OFS_MES_R_IT_LS_UP

Transition actions:

LV_R_IT_OSC_ENA_LSL_IF[i] = 1
Reset *TIMER_2*
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = MES

STATE_TTIP_MES_LS_UP[i] = “ADJ_OFS”

Actions:



Note: TCC_V_OFS_ADJ_R_IT_LS_UP[i] & TCC_ERR_V_OFS_ADJ_R_IT_LS_UP[i] shall not be permitted to overflow.

<u>Condition 6:</u> “ADJ_OFS” to “ADJ_GAIN”

ADJ_OFS procedure complete (valid or invalid) **&**
LV_LSL_OFS_ADJ_ACT[i] = 0

Transition actions:

LV_R_IT_OSC_ENA_LSL_IF[i] = 1
Reset *TIMER_1*
Start *TIMER_1*
Reset *TIMER_2*
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = ADJ_GAIN

<u>Condition 7:</u> “ADJ_OFS” to “MES”

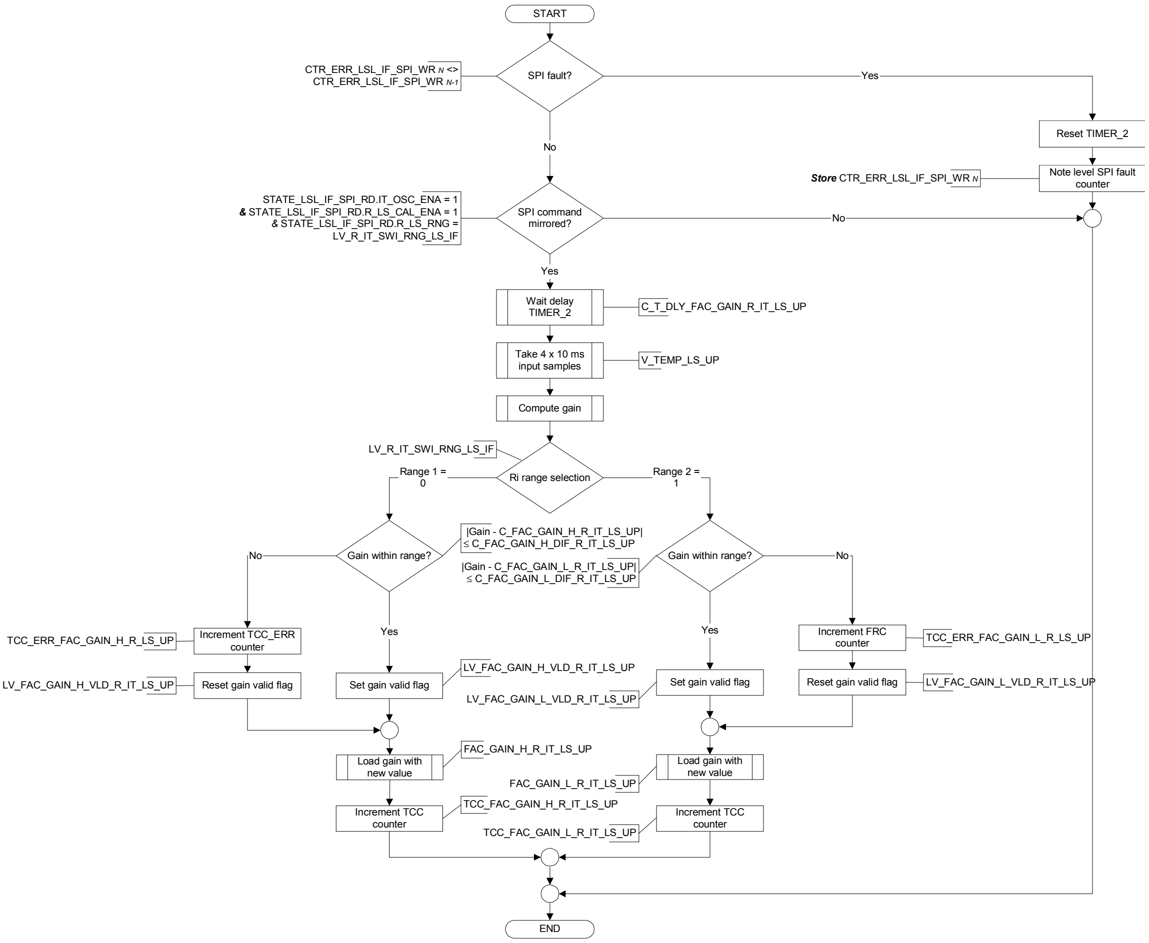
TIMER_1 ≥ C_T_MAX_V_OFS_ADJ_R_IT_LS_UP **&**
LV_LSL_OFS_ADJ_ACT[i] = 0

Transition actions:

```
LV_R_IT_OSC_ENA_LSL_IF[i] = 1
LV_R_IT_CAL_ENA_LSL_IF[i] = 0
Reset TIMER_2
Store CTR_ERR_LSL_IF_SPI_WR[i]_N
STATE_TTIP_MES_LS_UP[i] = MES
```

STATE_TTIP_MES_LS_UP[i] = “ADJ_GAIN”

Actions:



Note: TCC_FAC_GAIN_L_R_IT_LS_UP[i], TCC_ERR_FAC_GAIN_L_R_LS_UP[i], TCC_FAC_GAIN_H_R_IT_LS_UP[i] & TCC_ERR_FAC_GAIN_H_R_LS_UP[i] shall not be permitted to overflow.

Compute gain of internal resistance measurement circuit:

The gain shall be computed from the measurement circuit offset and the average of four (4) V_TEMP_LS_UP[i] samples in the adjustment mode using the following formula:

```
If      LV_R_IT_SWI_RNG_LSL_IF[i] == 0
then    FAC_GAIN_H_R_IT_LS_UP[i]
                = ( AV( V_TEMP_LS_UP[i] ) - V_OFS_ADJ_R_IT_LS_UP[i] )
                        * C_FAC_GAIN_R_IT_LS_UP
else    FAC_GAIN_L_R_IT_LS_UP[i]
                = ( AV( V_TEMP_LS_UP[i] ) - V_OFS_ADJ_R_IT_LS_UP[i] )
                        * C_FAC_GAIN_R_IT_LS_UP
endif
```

Where AV(V_TEMP_LS_UP[i]) is the average of the 4 previously samples taken at 10 ms intervals as shown in the appropriate flow chart.

Note: The difference in voltages (V_TEMP_LS_UP[i] – V_OFS_ADJ_R_IT_LS_UP[i]) shall be limited to 0 to prevent negative values.

Condition 9: "ADJ_GAIN" to "MES_OFS"

LV_LSL_OFS_ADJ_ACT[i] = 1 **or**
(ADJ_GAIN procedure complete **&**
LV_V_REF_VLD_R_IT_LS_UP[i] = 0)

Transition actions:

LV_R_IT_OSC_ENA_LSL_IF[i] = 0
LV_R_IT_CAL_ENA_LSL_IF[i] = 0
***Reset** TIMER_1*
***Start** TIMER_1*
***Reset** TIMER_2*
Store $\text{CTR\_ERR\_LSL\_IF\_SPI\_WR[i]}_N$
STATE_TTIP_MES_LS_UP[i] = MES_OFS

Condition 8: "ADJ_GAIN" to "MES"

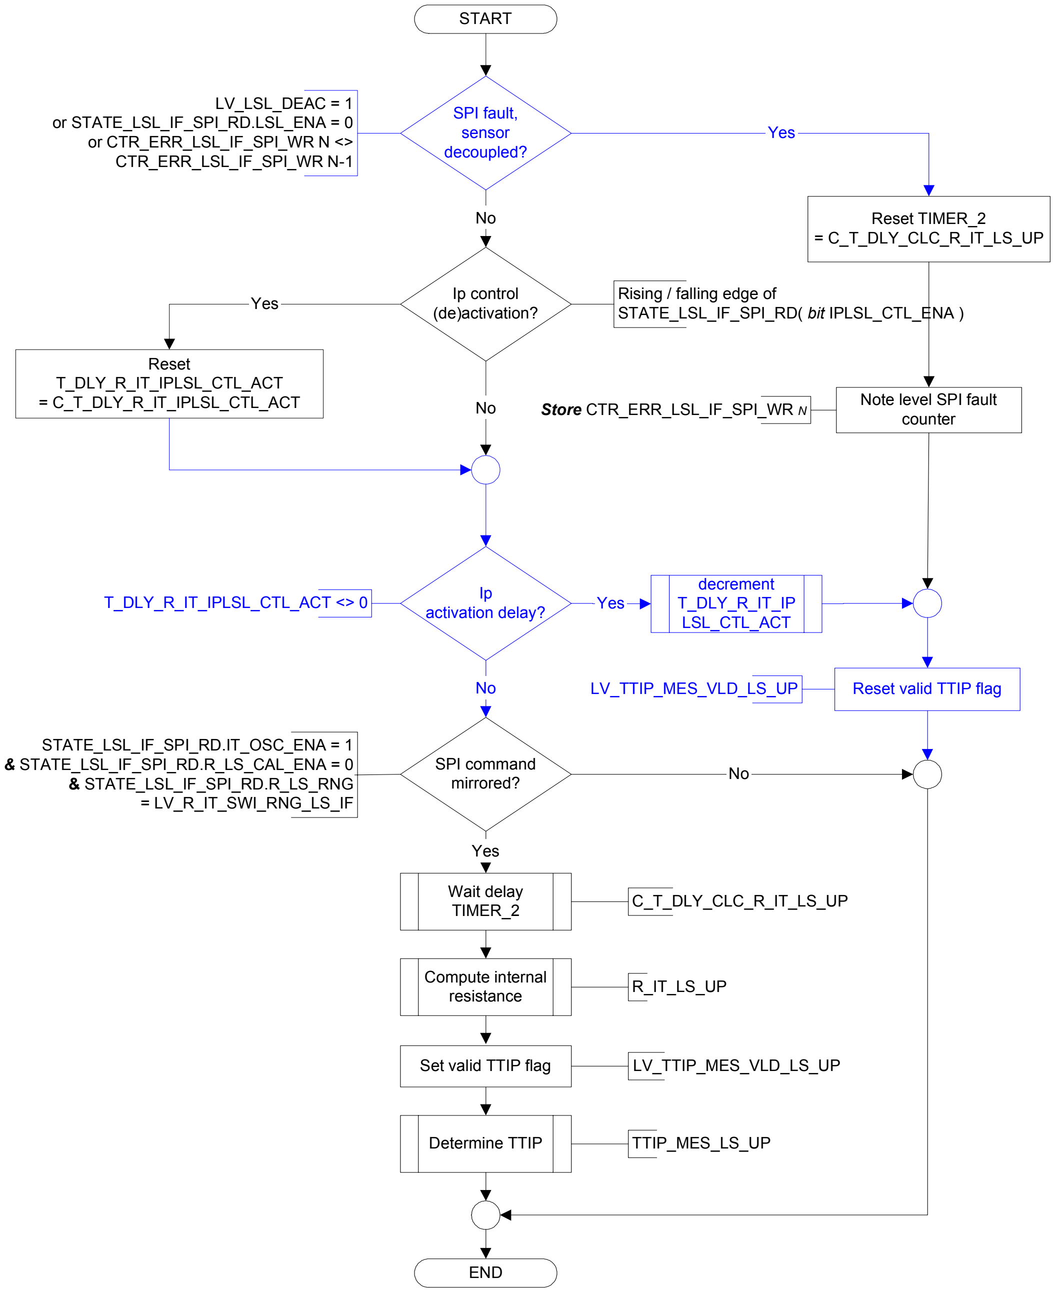
TIMER_1 ≥ C_T_MAX_FAC_GAIN_R_IT_LS_UP **or**
(ADJ_GAIN procedure complete **&**
LV_V_REF_VLD_R_IT_LS_UP[i] = 1)

Transition actions:

LV_R_IT_CAL_ENA_LSL_IF[i] = 0
***Reset** TIMER_2*
Store $\text{CTR\_ERR\_LSL\_IF\_SPI\_WR[i]}_N$
STATE_TTIP_MES_LS_UP[i] = MES

*STATE_TTIP_MES_LS_*UP[i] = *“MES”*

Actions:



Compute internal resistance of oxygen sensor element: (Deviating recurrence, see above)

The internal resistance shall be computed from the offset voltage determined in the measurement mode with the oscillator off, the measurement circuit gain determined in the adjust mode and AV(V_TEMP_LS_UP[i]). Once the active Ri determination conditions have been met as denoted above, the resistance shall be determined from the following formula.

```
If      LV_R_IT_SWI_RNG_LSL_IF[i] == 0
then    R_IT_LS_UP[i] = C_R_IT_REF_LS_UP
                * { AV( V_TEMP_LS_UP[i] ) - V_OFS_MES_R_IT_LS_UP[i] }
                / { 5V * FAC_GAIN_H_R_IT_LS_UP[i]
                        - ( AV( V_TEMP_LS_UP[i] ) - V_OFS_MES_R_IT_LS_UP[i] ) }
else    R_IT_LS_UP[i] = C_R_IT_REF_LS_UP
                * { AV( V_TEMP_LS_UP[i] ) - V_OFS_MES_R_IT_LS_UP[i] }
                / { 5V * FAC_GAIN_L_R_IT_LS_UP[i]
                        - ( AV( V_TEMP_LS_UP[i] ) - V_OFS_MES_R_IT_LS_UP[i] ) }
endif
```

Where AV(V_TEMP_LS_UP[i]) is either the average of the 8 previously samples taken at 10 ms intervals as shown in the appropriate flow chart or should the 100 ms task, in which the resistance is computed, be called before 8 samples could be taken then the latest V_TEMP_LS_UP[i] value shall be used. Should the timing be such that no current V_TEMP_LS_UP[i] are available then the resistance and hence ceramic temperature shall be calculated in the next 100 ms recurrence. Additionally, in this instance LV_TTIP_MES_VLD_LS_UP[i] would remain reset until the next recurrence.

Note: The difference in voltages (V_TEMP_LS_UP[i] – V_OFS_MES_R_IT_LS_UP[i]) shall be limited to 0 to prevent negative values.

Should internal resistance determination be suspended due to an adjustment measurement request, the value R_IT_LS_UP[i] shall be maintained at the value computed prior to suspension but the variable(s) used to compute the average shall be reinitialised.

Determine ceramic temperature from mapped characteristic oxygen sensor element temperature vs. internal resistance:

TTIP_MES_LS_UP[i] = IP_TTIP_MES_LS_UP (R_IT_LS_UP[i])

<u>*Condition 10:*</u> *“MES” to “MES_OFS”*

LC_V_REF_R_IT_LS_UP = 1 **&**
(LV_LSL_OFS_ADJ_ACT[i] = 1 **or**
LV_LS_UP_READY[i] *transition* 0 → 1 **or**
LC_R_RNG_REQ_SWI_LS_UP_LSL_IF *transition* 0 → 1)

Transition actions:

If (LC_R_RNG_REQ_SWI_LS_UP_LSL_IF = 1)

then

```
    LV_R_IT_SWI_RNG_LSL_IF[i] = LC_R_RNG_REQ_LS_UP_LSL_IF
else
    LV_R_IT_SWI_RNG_LSL_IF[i] = ! LV_LS_UP_READY[i]
endif.
LV_TTIP_MES_VLD_LS_UP[i] = 0
LV_R_IT_OSC_ENA_LSL_IF[i] = 0
Reset TIMER_1
Start TIMER_1
Reset TIMER_2
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
STATE_TTIP_MES_LS_UP[i] = MES_OFS
```

Condition 11: *“MES” to “MES”*

LC_V_REF_R_IT_LS_UP = 0 **&**
(LV_LS_UP_READY[i] *transition* 0 → 1 **or**
LC_R_RNG_REQ_SWI_LS_UP_LSL_IF *transition* 0 → 1)

Transition actions:

```
If (LC_R_RNG_REQ_SWI_LS_UP_LSL_IF = 1)
then
    LV_R_IT_SWI_RNG_LSL_IF[i] = LC_R_RNG_REQ_LS_UP_LSL_IF
else
    LV_R_IT_SWI_RNG_LSL_IF[i] = ! LV_LS_UP_READY[i]
endif.
LV_TTIP_MES_VLD_LS_UP[i] = 0
Reset TIMER_2
Store CTR_ERR_LSL_IF_SPI_WR[i]$_N$
```

Additional variable / constant definitions

FRQ_R_IT_OSC_LSL_IF_SPI_WR[i] and C_FRQ_R_IT_OSC_LSL_IF shall be defined as follows:

Bit 7	*Bit 6*	*Bit 5*	*Bit 4*	*Bit 3*	*Bit 2*	*Bit 1*	*Bit 0*
X	D6	D5	D4	D3	D2	D1	D0

Where:

X	denotes don’t care
D0 through D5	denotes the 6 bit coded oscillator frequency information. A value of 00H represents 2.0 kHz and each step 125 Hz. Hence 3F represents 9.875 kHz.
D6	denotes the bit used to selectively disable pins inside of the protection time under fault conditions. 0 pins will be decoupled after the protection time has passed. 1 the pin at which the fault is detected will immediately be decoupled, i.e. inside the protection time before the remaining pins are decoupled after the passing of the protection time.

16.10.1 Application specific conditions for oxygen sensor ceramic temperature

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_TTIP_LS_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Boolean flag indicating that upstream oxygen sensor ceramic temperature determination shall be inhibited					

Input data:

LV_DIAG_OC_IF_OSC_DI_LSL_UP[NC_CBK_EX_NR]	LV_ST_END	NC_CBK_EX_NR	LV_ES
STATE_LSL_IF_SPI_RD[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The Boolean flag LV_INH_TTIP_LS_UP[i] shall indicate whether the upstream oxygen sensor ceramic temperature determination shall be permitted to take place. When set, no temperature determination shall take place.

Description:

Application conditions:

Initialisation:

The following initialisation shall be carried out after RESET and upon leaving the engine state Engine Stop (LV_ES).

LV_INH_TTIP_LS_UP[i] = 0

Recurrence: 1s

Activation:

LV_ST_END == 1

Deactivation:

LV_ST_END == 0

Formula section:

```
If      LV_DIAG_OC_IF_OSC_DI_LSL_UP[i] == 1
or      STATE_LSL_IF_SPI_RD[i] bit LSL_ENA == 0
then    LV_INH_TTIP_LS_UP[i] = 1
else    LV_INH_TTIP_LS_UP[i] = 0
endif
```

Minimum segment time required for mean value calculation					

16.11.1 EGCP_SIGCVLSL3

The WRAF sensor’s signal is influenced by the pressure fluctuations in the exhaust manifold. The dynamic pressure peaks in exhaust gas results in momentary increase of oxygen concentration inside the reference cell of WRAF sensor & the same is refelected at the sensor output signal. Pressure fluctuation comes mainly from segment timing, quick open & close of exhaust valve, misfiring and may be some other parameter. Out of all these most dominant influence comes from segment timing. To remove segment timing influence from from the signal a mean value is evaluated.

The calculation shall be done for all exhaust cylinder banks.

NC_CBK_EX_NR defines the number of exhaust banks. For vector elements, the variable extension „_i“ is used in the model instead of „[i]“ as found in the textual description.

To evaluate segment synchronous mean value, the raw voltage signal is captured every 1 ms (from BSW) and stored in a ring buffer. The size of this ring buffer is defined by NC_NR_RAW_BUF_LEN and it is **fixed** at 10. All other calculations in this function is triggered soon after the 10th value is written in to the buffer. The segment time in m-sec is calculated every 10 ms.

In order to save the memory space, 2 intermediate sums is built out of the earlier 10 values and stored in a second ring buffer. At the same time, the number of samples taken for first intermediate sum calculation is stored in the third ring buffer. The number of samples required for mean value as well as intermediate sums is calculated dynamically based on the segment time.

The final mean value is calculated by reading the buffers filled with intermediate sums and corresponding number of samples. The values are filled in all the three ring buffers from bottom to top.

It is possible to switch off this function using the switch LC_VLS_UP_MV_ON, in which case only the raw sensor signal is delivered at 10 ms recurrence.

The ring buffer size for storing the intermediate sums and number of samples is calculated for a minimum engine speed of 500 rpm (Engine having 4 cyl and 2 exhaust bank – worst case). Hence the default values are

NC_N_MIN_VLS_UP_MV = 500 rpm

NC_NR_BUF_SAMPLE_LEN = 12

NC_NR_BUF_SUM_LEN = 2 * NC_NR_BUF_SAMPLE_LEN = 24

Application Condition

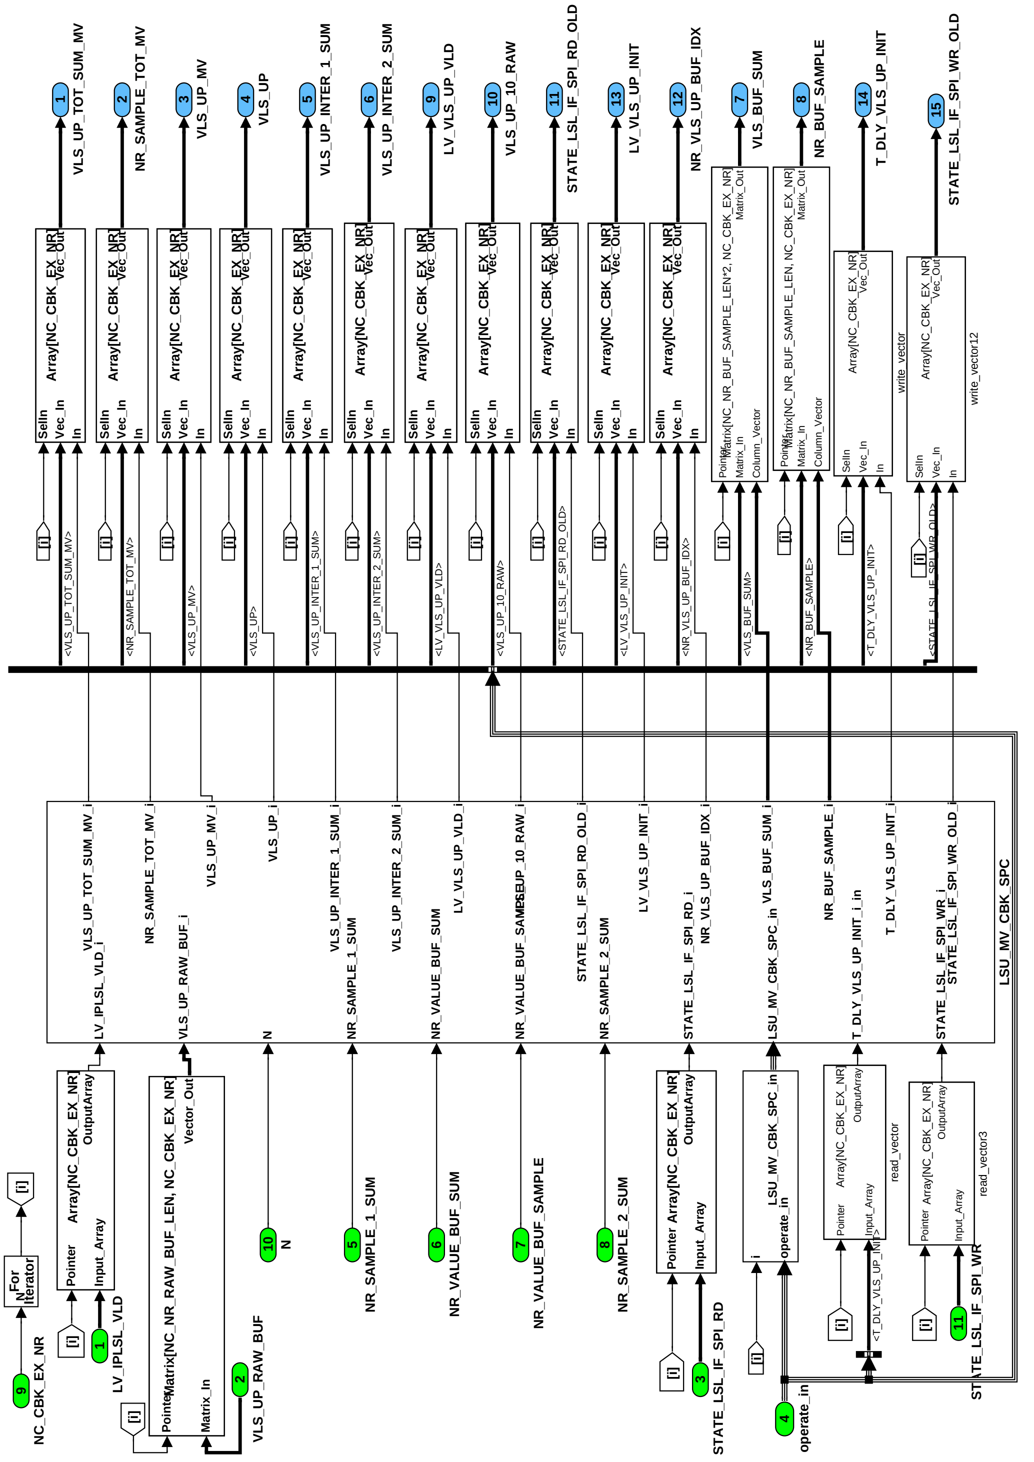

Figure 7 EGCP_SIGCVLSL3/ operate/ CLC_10MS/ LSU_MV_CBK_MNG

Re-initialisation of buffers

The raw signal voltage is always compared with limitting values and clipped if any. Accordingly the flag LV_VLS_UP_VLD is set.

The bit LV_VLS_UP_INIT is set to 1 whenever any one of the 2 LSBs of STATE_LSL_IF_SPI_WR toggles. T_DLY_VLS_UP_INIT is initialized to calibration value whenever any one of the 2 LSBs of STATE_LSL_IF_SPI_WR toggles. The bit LV_VLS_UP_INIT reset to 0 after expiry of timer T_DLY_VLS_UP_INIT.

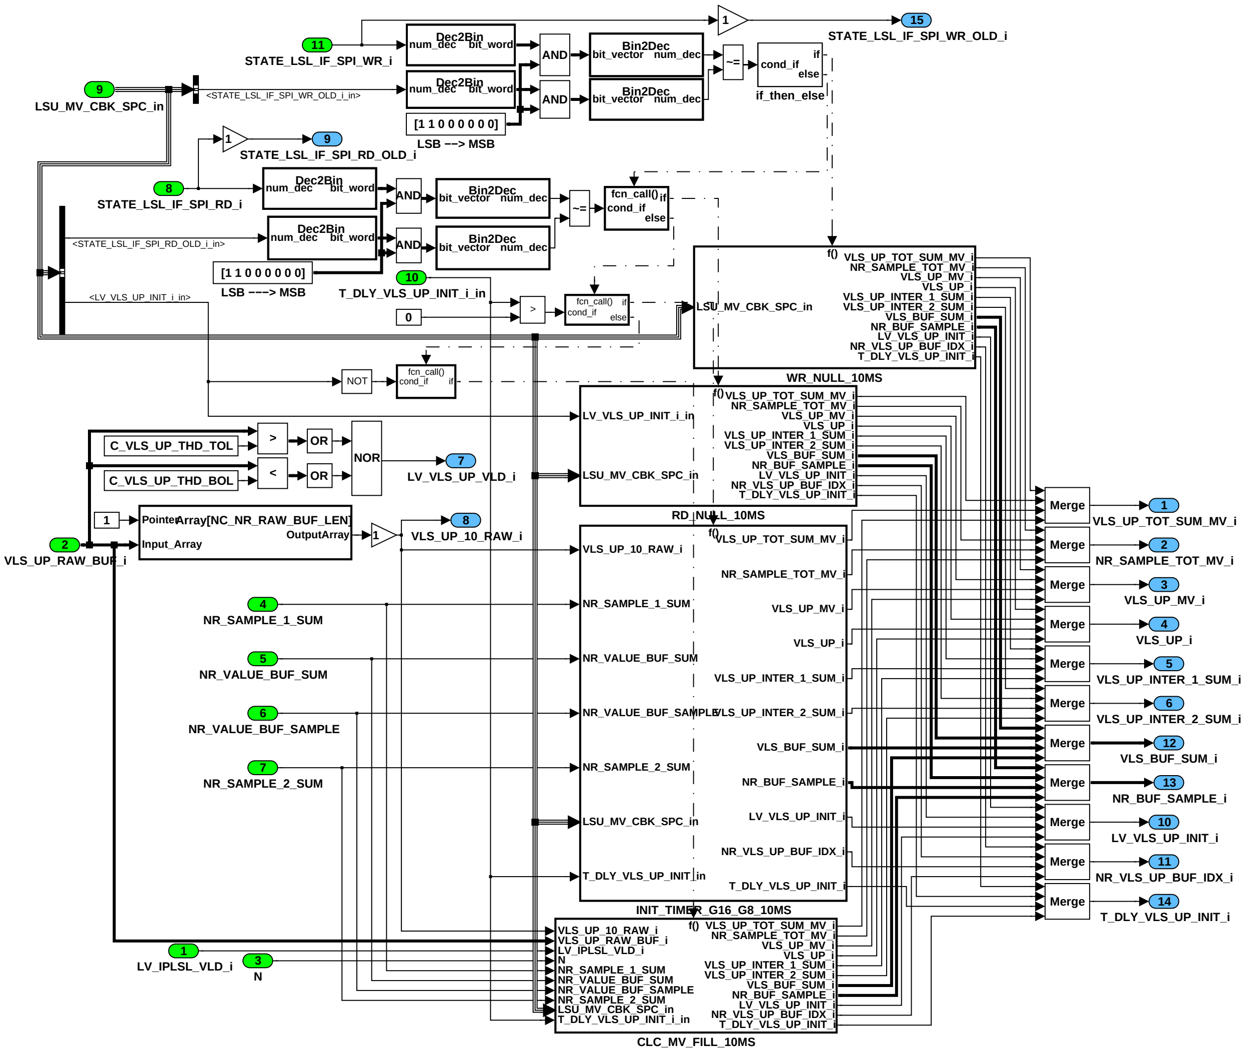

Figure 8 EGCP_SIGCVLSL3/ operate/ CLC_10MS/ LSU_MV_CBK_MNG/ LSU_MV_CBK_SPC

Filling ring buffers with current values

During engine starting, the buffers are filled with current sensor values till the conditions for mean value calculation are fulfilled. In this case, VLS_UP would be same as VLS_UP_10_RAW (every 10th raw signal value stored in VLS_UP_RAW_BUF).

Calculation of segment time and number of samples for mean value

The segment time will be calculated after every 10th raw signal value is written in to the buffer. The number of samples required for mean value calculation depend on the segment time. The minimum segment time is fixed using NC_T_SEG_LEN_MIN. If the measured segment time is less than the minimum, then number of samples will be calculated by corresponding multiplication factors.

The default values are

NC_T_SEG_LEN_MIN = 0.01 s

NC_FAC_10_SAMPLE = 2

NC_FAC_5_SAMPLE = 4

2 * 60 * 1000 * no_of_cyl_bank

T_SEG_LEN = --- (ms)

N_in_rpm * no_of_cyl

	NC_CBK_EX_NR		

Import actions:

ACTION_INFR_SetCmdLsDown(IN <i>, **IN** <lv_swi_ls_down>**)**
This action starts the internal resistance determination by "pumping" the sensor.
ACTION_INFR_GetVAdcLsDown(IN <i>, **OUT** <v_adc>**)**
This action sets the oxygen sensor voltage downstream

FUNCTION DESCRIPTION:

General information:

The function shall provide the output variable R_IT_LS_DOWN[i], the internal resistance of the oxygen sensor. The resistance is dependent on the operating temperature of the sensor and may be used for oxygen sensor diagnosis.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

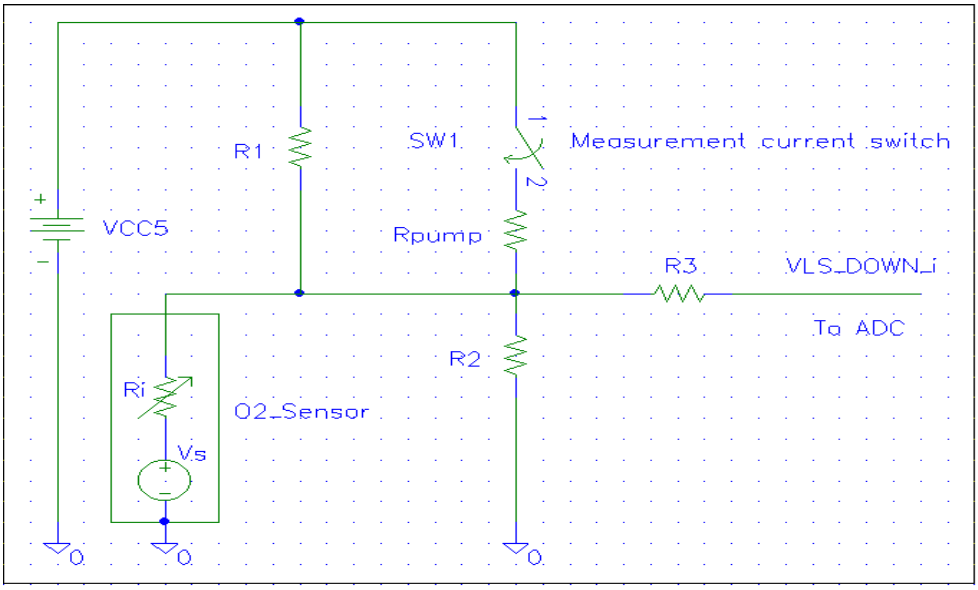

Figure 1 Simplified measurement circuit schematic, Internal resistance determination

Signal flow diagram:

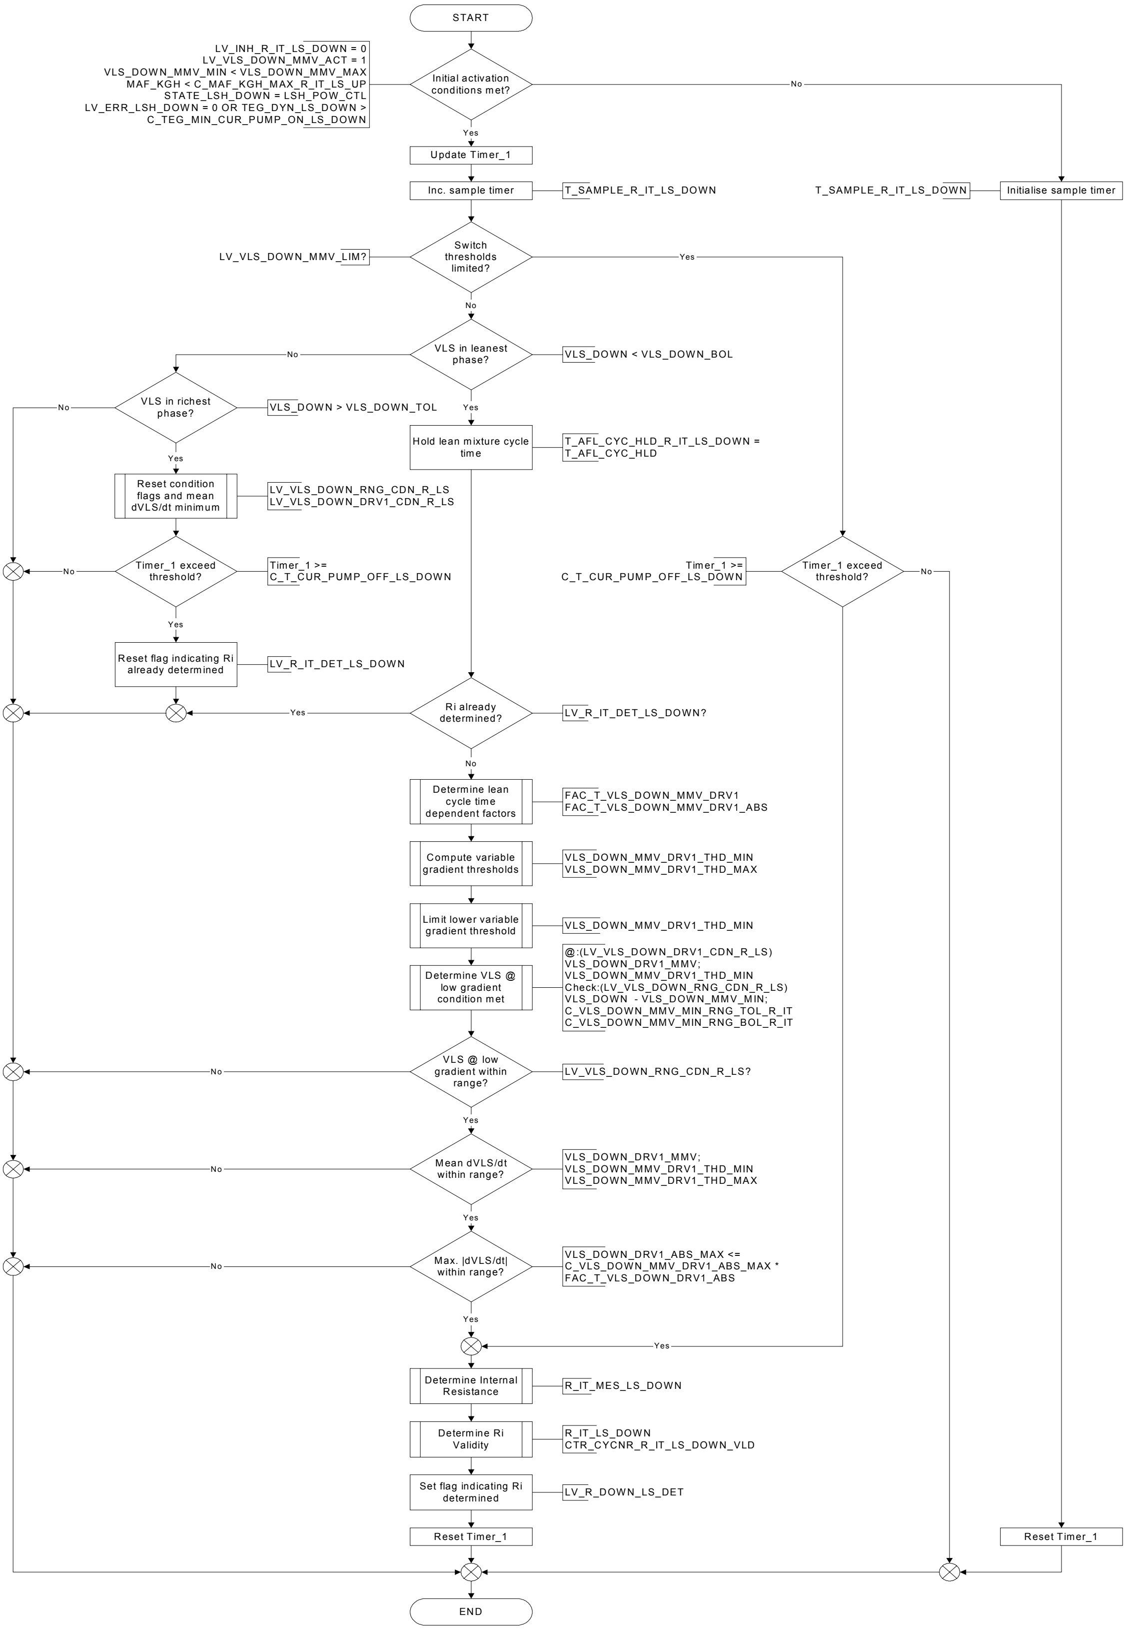

Figure 2 Function flow chart, Internal resistance determination

Description:

The internal resistance of the oxygen sensor shall be determined by use of the oxygen sensor interface circuit *Figure 1* (Capacitors not shown). The internal resistance provides information as to the tip temperature of the sensor and may be used for diagnosis purposes and operative readiness determination.

Under normal conditions, the switch SW1 shall be open and the oxygen sensor signal voltage (VLS_DOWN[i]) is measured by the microcontroller.

The potential divider (resistors R_1 & R_2) shall be permit the operation readiness of the oxygen sensor to be determined and enable electrical fault conditions to be detected.

Periodically, for a limited amount of time, the switch SW1 shall be closed and a voltage of approx. 4.8 V connected through resistor R_{pump} to the oxygen sensor signal connection. This shall cause current to flow into the sensor and through the internal resistance R_i, thereby “pumping” the sensor. The resultant voltage acquired at the microcontroller input shall permit the internal resistance of the sensor to be calculated by use of a formula shown in the formula section below.

Prior to permitting the determination of the internal resistance, a number of conditions shall be determined to be met:

The initial activation conditions shall require that: No function inhibit is requested (LV_INH_R_IT_LS_DOWN[i] = 0); Delay since deactivation since last overrun fuel cut-off passed (LV_VLS_DOWN_MMV_ACT); The initial post initialisation transients have passed for the VLS_DOWN_MMV_xxx[i] inputs (VLS_DOWN_MMV_MIN[i] < VLS_DOWN_MMV_MAX[i]); The engine load threshold has not been exceeded (MAF_KGH < C_MAF_KGH_MAX_R_IT_LS_DOWN); The oxygen sensor heater state LSH_POW_CTL has been reached; No heater OBDI error has been detected in the relevant heater driver (LV_ERR_LSH_DOWN[i]) or should a heater driver fault have been detected, the modelled exhaust gas temperature at downstream sensor position TEG_DYN_LS_DOWN[i] shall exceed the threshold C_TEG_MIN_CUR_PUMP_ON_LS_DOWN.

Once the above conditions have been met, an internal timer (*TIMER_1*) shall be started and timer T_SAMPLE_R_IT_LS_DOWN[i] shall be updated. The latter timer shall be initialised with its maximum value of 655.35 s. This ensures that the temperature limits for the validity function are correctly initialised. The further procedure shall depend on the status of the oxygen sensor signal, as determined by LV_VLS_DOWN_MMV_LIM. Should the VLS_DOWN_MMV_xxx[i] signals be limited, i.e. no or little oxygen sensor amplitude is present, the function shall determine the internal resistance every (C_T_CUR_PUMP_OFF_LS_DOWN + C_T_CUR_PUMP_ON_LS_DOWN + C_T_DLY_CUR_PUMP_LS_DOWN). Otherwise the oxygen sensor signal shall be determined to have significant amplitude and the internal resistance determination shall only be carried out in lean phases where the oxygen sensor signal is relatively flat and stable. This is achieved by the following conditions:

If the oxygen sensor signal is lean (VLS_DOWN[i] < VLS_DOWN_BOL[i]) and neither the resistance determination has been carried out yet in this lean phase nor the determination be locked out due to the minimum off time (LV_R_IT_DET_LS_DOWN[i] = 0) then the function shall determine the lean cycle time dependent factors FAC_T_VLS_DOWN_MMV_DRV1[i] & FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] from the appropriate maps IP_FAC_T_DRV1_VLS_DOWN_MMV & IP_FAC_T_VLS_DOWN_MMV_DRV1_ABS respectively. These factors shall be dependent on the held lean cycle time from the previous lean cycle (T_AFL_CYC_HLD_R_IT_LS_DOWN[i]). Should the cycle time decrease then it is intended that the factors shall increase and vice versa.

The thresholds for the gradient condition shall then be computed. These thresholds (VLS_DOWN_MMV_DRV1_THD_MAX[i] & VLS_DOWN_MMV_DRV1_THD_MIN[i]) are directly proportional to the amplitude of the difference between VLS_DOWN_MMV_xxx[i] signals. Furthermore, VLS_DOWN_MMV_DRV1_THD_MIN[i] shall be modified by factor FAC_T_VLS_DOWN_MMV_DRV1[i]. The factor FAC_T_VLS_DOWN_MMV_DRV1[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD_R_IT_LS_DOWN[i] is valid.

The variable threshold VLS_DOWN_MMV_DRV1_THD_MIN[i] shall be limited so that its value is not less than that of VLS_DOWN_DRV1_MMV_MIN[i] * C_FAC_VLS_DOWN_MMV_DRV1_THD_MIN.

The function shall then wait for the oxygen sensor signal gradient to exceed the minimum threshold (VLS_DOWN_DRV1_MMV[i] ≥ VLS_DOWN_MMV_DRV1_THD_MIN[i]) and then determine whether the absolute oxygen sensor signal voltage is within a particular range of the VLS_DOWN_MMV_MIN[i] signal (VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT ≤ VLS_DOWN[i] ≤ VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT). If this is the case, the VLS_DOWN[i] shall be considered to be consistent with previous lean phase amplitudes and resistance determination may be carried out. This condition shall only be carried out once per lean phase. i.e. at transition from rich to lean. The fulfilment of the gradient condition is indicated by LV_VLS_DOWN_DRV1_CDN_R_LS[i] and the fulfilment of the range condition by LV_VLS_DOWN_RNG_CDN_R_LS[i].

If the range condition has been met, the gradient is in a particular range (VLS_DOWN_MMV_DRV1_THD_MIN[i] ≤ VLS_DOWN_DRV1_MMV[i] ≤ VLS_DOWN_MMV_DRV1_THD_MAX[i]) and the oxygen sensor signal is determined to be stable in the short term (VLS_DOWN_DRV1_ABS_MAX[i] ≤ C_VLS_DOWN_MMV_DRV1_ABS_MAX * FAC_T_VLS_DOWN_MMV_DRV1_ABS[i]) then resistance determination is requested (LV_R_IT_REQ_LS_DOWN[i] = 1). The factor FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] shall be set to 1 unless C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN AF cycles have passed since the last lambda controller activation, as counted by CTR_AFL_CYC[i]. This ensures that T_AFL_CYC_HLD_R_IT_LS_DOWN[i] is valid.

Once internal resistance determination has been requested, the Basic SW shall take a single VLS_DOWN[i] sample and store as VLS_DOWN_CUR_PUMP_OFF[i]. SW1 shall be switched ON, at time C_T_CUR_PUMP_ON_LS_DOWN[i] and the VLS_DOWN[i] shall be masked. A second oxygen sensor signal voltage sample shall be taken and stored as VLS_DOWN_CUR_PUMP_ON[i]. SW1 shall then be switched OFF and masking shall continue for a time C_T_DLY_CUR_PUMP_LS_DOWN, after which the VLS_DOWN[i] shall return to normal following of the oxygen sensor signal voltage. Masking shall be discontinued if the oxygen sensor signal voltage exceeds VLS_DOWN_CUR_PUMP_ON[i] + C_VLS_HYS_R_IT_LS_DOWN during the time C_T_DLY_CUR_PUMP_LS_DOWN after switching off SW1. Adding the voltage hysteresis shall prevent the function to discard lambda sensor voltage masking if the first VLS_DOWN[i] value after switching off the pump current is larger than the last VLS_DOWN[i] value while pumping due to signal noise.

The internal resistance R_IT_MES_LS_DOWN[i] shall be determined using the formula stated with the main variables being oxygen sensor voltage prior to pumping, VLS_DOWN_CUR_PUMP_OFF[i], and signal voltage during pumping, VLS_DOWN_CUR_PUMP_ON[i].

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, a counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available.

NOTE: During the time where SW1 is switched on, (LV_R_IT_REQ_LS_DOWN[i]=1) the output voltage of the oxygen sensor (VLS_DOWN[i]) does not represent the true A/F ratio and is therefore invalid and shall not be used as such. The basic software shall mask the response of the sensor to pumping by keeping the voltage constant during this time by using the last VLS_DOWN[i] sample prior to activating SW1.

The internal resistance shall be calculated every time the oxygen sensor is pumped. For each new resistance value detected, the validity of the resistance shall be checked:

Should the validity function not be inhibited (LC_R_IT_VLD_INH_LS_DOWN = 0), then the tip temperature of the ceramic shall be determined from a map. TTIP_MES_LS_DOWN[i] represents the nominal temperature, TTIP_MES_TOL_LS_DOWN[i] represents the maximum temperature (R_IT_MES_LS_DOWN[i] * (1 – C_FAC_R_IT_ERR_NEG_LS_DOWN)), i.e. temperature for resistance with negative measurement error and TTIP_MES_BOL_LS_DOWN[i] represents the minimum temperature (R_IT_MES_LS_DOWN[i] * (1 + C_FAC_R_IT_ERR_NEG_LS_DOWN)), i.e. temperature for resistance with positive measurement error. A low pass filter shall then be applied to the upper and lower temperature limits to represent the maximum possible temperature gradient between resistance samples. Dependent on the direction of change of resistance between two measurements, either constant C_CRLC_TTIP_RISE_R_IT_LS_DOWN (rising temp.) or C_CRLC_TTIP_FALL_R_IT_LS_DOWN (falling temp.) shall be applicable. The final filter constant used, limited to a maximum of 1, shall be the aforementioned constant multiplied by the time between resistance samples (T_SAMPLE_R_IT_LS_DOWN[i]). This shall be to compensate for the irregular sample time.

Should then the ceramic tip temperature fall within the temperature limit bounds, the measured resistance shall be considered to be valid, shall be passed to the output variable R_IT_LS_DOWN[i], the counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented to indicate to other functions that a new resistance value is available and the T_SAMPLE_R_IT_LS_DOWN[i] shall be reset. If the above temperature condition is not met, R_IT_LS_DOWN[i] shall be maintained at its last value and the filtered temperature limits shall be reset to their previous values, i.e. the resistance value shall be ignored.

Should the validity function be inhibited then for each new resistance the R_IT_MES_LS_DOWN[i] shall be passed to R_IT_LS_DOWN[i] and the counter CTR_CYCNR_R_IT_LS_DOWN_VLD[i] shall be incremented.

In the case of significant oxygen sensor amplitude (LV_VLS_DOWN_MMV_LIM = 0) and the sensor signal be in the rich phase (VLS_DOWN[i] > VLS_DOWN_TOL[i]), the flags LV_VLS_DOWN_RNG_CDN_R_LS[i] & LV_VLS_DOWN_DRV1_CDN_R_LS[i] shall be reset. Furthermore, if these conditions have been met and the timer *TIMER_1* exceeds C_T_CUR_PUMP_OFF_LS_DOWN then LV_R_IT_DET_LS_DOWN[i] shall be reset, thereby permitting the internal resistance to be determined in the next cycle should the appropriate conditions be met.

For reference reasons of OBD II diagnosis the value R_IT_MDL_LS_DOWN_NEW[i] is calculated out of heating power, exhaust gas temperature and MAF_KGH.

Application conditions:

Recurrence: *T_SAMPLE_1 = 10 ms*

The function shall be carried out once every 10 ms. The internal resistance value shall only be calculated after “pumping” the oxygen sensor. See recurrence there. Reference internal rsistance shall be calculated with recurrence 1 s.

Initialisation:

at reset:

```
ACTION_INFR_SetCmdLsDown(
                        IN      i
                        IN      0)
```

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

R_IT_LS_DOWN[i] = 65535
R_IT_MES_LS_DOWN[i] = 65535
R_IT_MDL_LS_DOWN_NEW[i] = 65535
POW_MMV_LSH_DOWN[i] = 0
VLS_DOWN_CUR_PUMP_ON[i] = 0
VLS_DOWN_CUR_PUMP_OFF[i] = 0
CTR_CYCNR_R_IT_LS_DOWN_VLD[i] = 0
LV_VLS_DOWN_DRV1_CDN_R_LS[i] = 0
LV_VLS_DOWN_RNG_CDN_R_LS[i] = 0
LV_R_IT_REQ_LS_DOWN[i] = 0
LV_R_IT_DET_LS_DOWN[i] = 0
VLS_DOWN_MMV_DRV1_THD_MIN[i] = 0
VLS_DOWN_MMV_DRV1_THD_MAX[i] = 0
T_AFL_CYC_HLD_R_IT_LS_DOWN[i] = 0
FAC_T_VLS_DOWN_MMV_DRV1[i] = 0
FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] = 0
TTIP_REF_MDL_MMV_LS_DOWN[i] = 0
TTIP_MES_LS_DOWN[i] = 0
TTIP_MES_TOL_LS_DOWN[i] = 0
TTIP_MES_BOL_LS_DOWN[i] = 0
TTIP_MES_TOL_MMV_LS_DOWN[i] = 0
TTIP_MES_BOL_MMV_LS_DOWN[i] = 0
T_SAMPLE_R_IT_LS_DOWN[i] = 655.35

NOTE: All “N-1” variables shall also be initialised to the associated value specified above.

Activation / Deactivation:

```
If      LV_ST_END = 1
then    Function activated
else    Function deactivated
endif
```

Formula section:

```
If          LV_INH_R_IT_LS_DOWN[i] = 0
and         LV_VLS_DOWN_MMV_ACT = 1
```

```

Calculation of internal resistance reference:

% This calculation is carried out with the recurrence: T_SAMPLE_2 = 1 s.

POW_MMV_LSH_DOWN[i]$_n$ = POW_MMV_LSH_DOWN[i]$_{n-1}$ *
(1 - C_CRLC_POW_MMV_LSH_DOWN) +
C_CRLC_POW_MMV_LSH_DOWN *
V_EFC_LSH_DOWN[i]^2 * T_SAMPLE_2 * [W/(s*V$^{2)}$]

TTIP_REF_MDL_MMV_LS_DOWN[i]$_n$ = TTIP_REF_MDL_MMV_LS_DOWN[i]$_{n-1}$ *
(1 - IP_CRLC_TTIP_REF_MDL_LS_DOWN) +
IP_CRLC_TTIP_REF_MDL_LS_DOWN * TEG_DYN_LS_DOWN[i]
% IP (MAF_KGH)

R_IT_MDL_LS_DOWN_NEW[i] = IP_R_IT_MDL_LS_DOWN_NEW
% IP (POW_MMV_LSH_DOWN[i]; TTIP_REF_MDL_MMV_LS_DOWN[i])

Determine lean cycle time dependent factors:

```
If   (CTR_AFL_CYC[i] ≥ C_CTR_AFL_CYC_MIN_RI_IT_LS_DOWN)
then FAC_T_VLS_DOWN_MMV_DRV1[i] =
     IP_FAC_T_DRV1_VLS_DOWN_MMV (T_AFL_CYC_HLD_R_IT_LS_DOWN[i])
     FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] =
     IP_FAC_T_VLS_DOWN_MMV_DRV1_ABS (T_AFL_CYC_HLD_R_IT_LS_DOWN[i])
else FAC_T_VLS_DOWN_MMV_DRV1[i] = 1
     FAC_T_VLS_DOWN_MMV_DRV1_ABS[i] = 1
endif.
```

Compute variable gradient thresholds:

VLS_DOWN_MMV_DRV1_THD_MAX[i] = C_VLS_DOWN_MMV_DRV1_THD_MAX *
C_FAC_VLS_DOWN_MMV_DRV1_THD *
(VLS_DOWN_MMV_MAX[i] -
VLS_DOWN_MMV_MIN[i])

VLS_DOWN_MMV_DRV1_THD_MIN[i] = C_VLS_DOWN_MMV_DRV1_THD_MIN *
C_FAC_VLS_DOWN_MMV_DRV1_THD *
(VLS_DOWN_MMV_MAX[i] -
VLS_DOWN_MMV_MIN[i]) *
FAC_T_VLS_DOWN_MMV_DRV1[i]

Limit lower variable gradient threshold:

VLS_DOWN_MMV_DRV1_THD_MIN[i] = MAX(VLS_DOWN_MMV_DRV1_THD_MIN[i],
VLS_DOWN_DRV1_MMV_MIN[i] *
C_FAC_VLS_DOWN_MMV_DRV1_THD_MIN)

Determine VLS_DOWN at low gradient condition met:

```
If  (LV_VLS_DOWN_DRV1_CDN_R_LS[i] = 0) &
    (VLS_DOWN_DRV1_MMV[i] ≥ VLS_DOWN_MMV_DRV1_THD_MIN[i])
```

```
then LV_VLS_DOWN_DRV1_CDN_R_LS[i] = 1
     If  (VLS_DOWN[i] ≤
         (VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT) ) &
         (VLS_DOWN[i] ≥
         (VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT) )
     then LV_VLS_DOWN_RNG_CDN_R_LS[i] = 1
     else LV_VLS_DOWN_RNG_CDN_R_LS[i] = 0
     endif
endif.
```

NOTE: VLS_DOWN_MMV_MIN[i] + C_VLS_DOWN_MMV_MIN_RNG_TOL_R_IT shall not cause an overflow and VLS_DOWN_MMV_MIN[i] - C_VLS_DOWN_MMV_MIN_RNG_BOL_R_IT shall not cause an underflow.

Determine internal resistance:

Recurrence: T_SAMPLE_3 = 1 ms

```
If        LV_R_IT_REQ_LS_DOWN[i] = 1
then
```

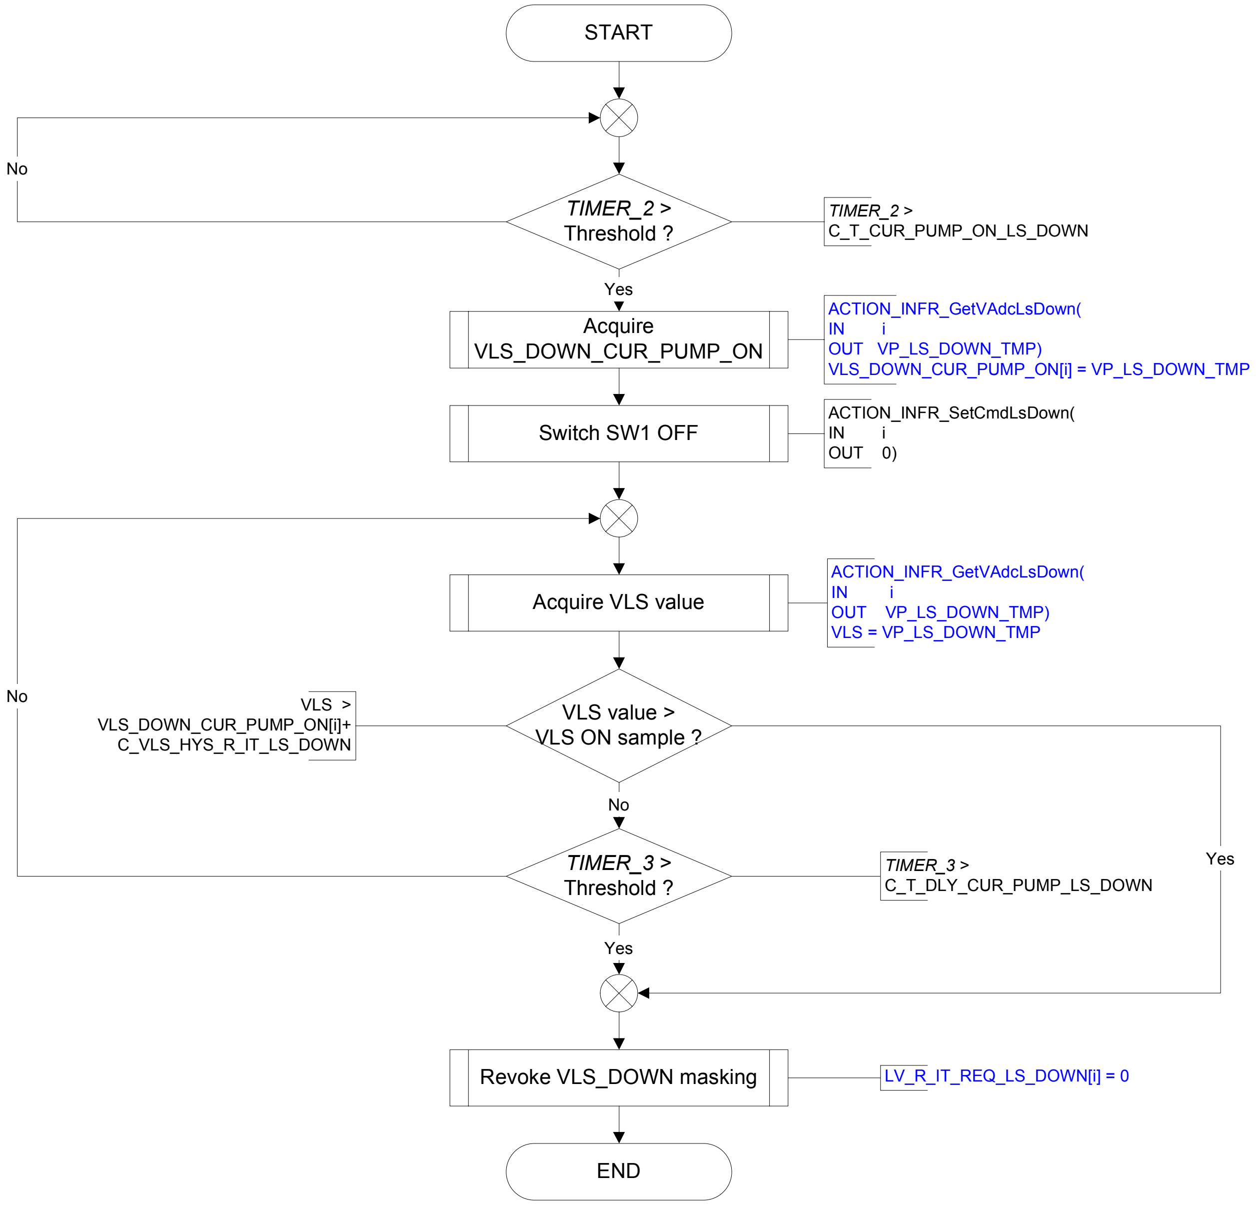

Figure 3 Function flow chart, Internal resistance determination

endif

Calculation of Internal resistance:

The internal resistance shall be determined as follows:

R_IT_MES_LS_DOWN[i] = NC_R_REF_LS_DOWN * (VLS_DOWN_CUR_PUMP_ON[i] - VLS_DOWN_CUR_PUMP_OFF[i]) / {NC_VLS_DOWN_CUR_PUMP_REF - (VLS_DOWN_CUR_PUMP_ON[i] - VLS_DOWN_CUR_PUMP_OFF[i])* NC_FAC_R_REF_LS_DOWN - VLS_DOWN_CUR_PUMP_ON[i]}

Determine internal resistance validity:

The following function shall be carried once out for every new resistance value determined.

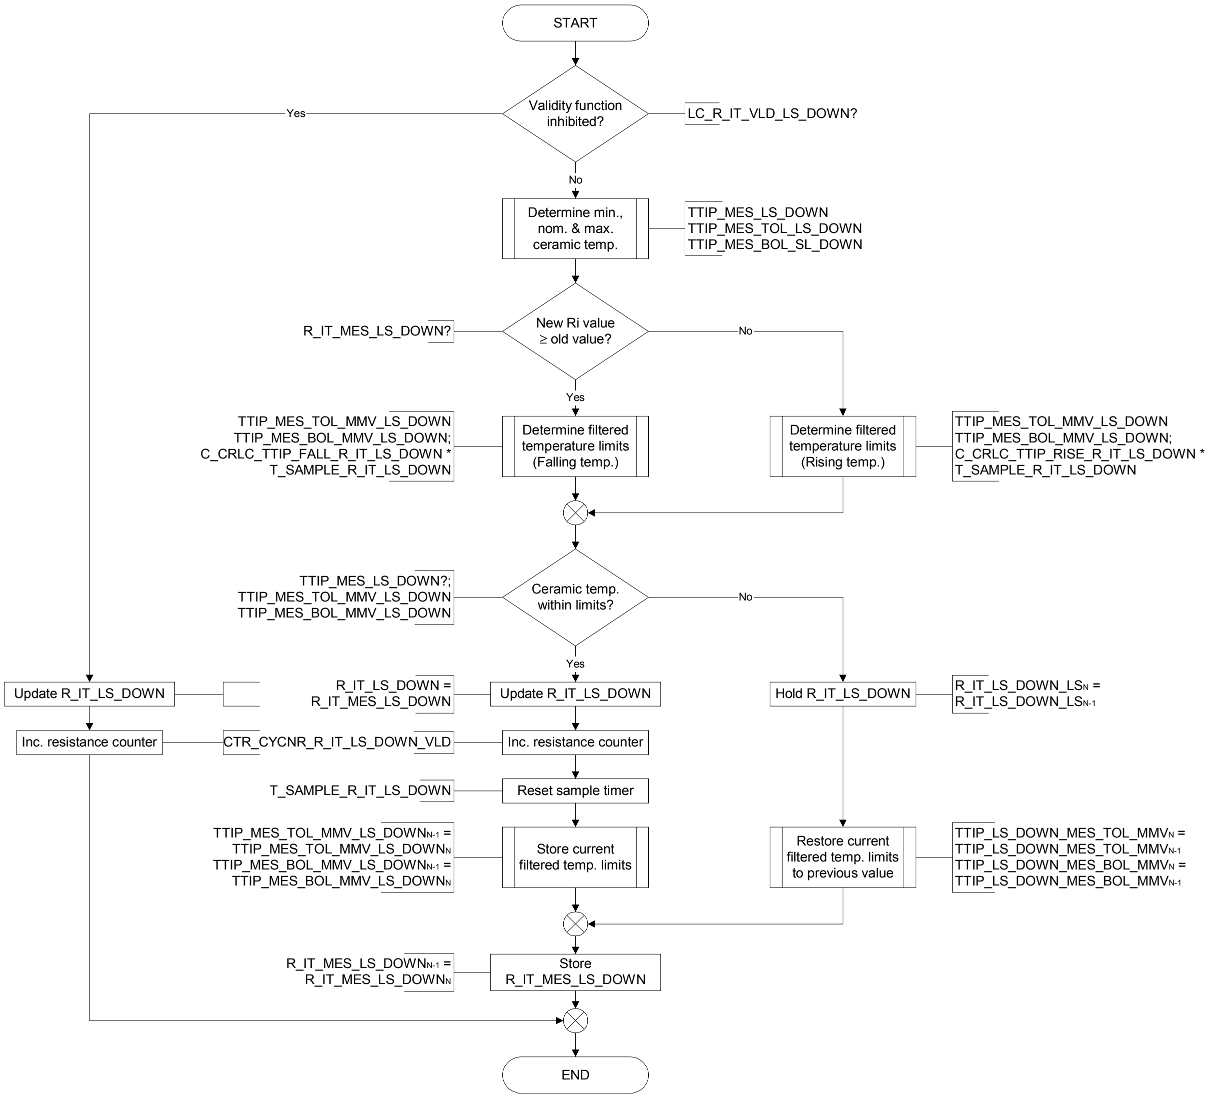

Figure 4 Function flow chart, Internal resistance validity determination

```
If (LC_R_IT_VLD_INH_LS_DOWN = 0)
then

16.12.1 Application specific conditions for oxygen sensor internal resistance

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	-
Boolean flag indicating that downstream sensor internal resistance determination shall be inhibited when set					

Input data:

NC_CBK_EX_NR	LV_ES	LV_VAR_LSH_DOWN	TCO

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.

The Boolean flag(s) LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR] shall indicate whether the downstream oxygen sensor internal resistance determination shall be permitted to take place. When set, no resistance determination shall take place.

Application conditions:

Initialisation: The following initialisation shall be carried out upon leaving the engine state Engine Stop (LV_ES).

LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR] = 0

Recurrence: 1s

Activation: at every engine operating state

Deactivation: -

Formula section:

```
If   LV_VAR_LSH_DOWN = 1   and   TCO > C_TCO_CUR_ON_LS_DOWN_MIN
  then    LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR]  =  0
  else    LV_INH_R_IT_LS_DOWN[NC_CBK_EX_NR]  =  1
endif
```

Calibration data:

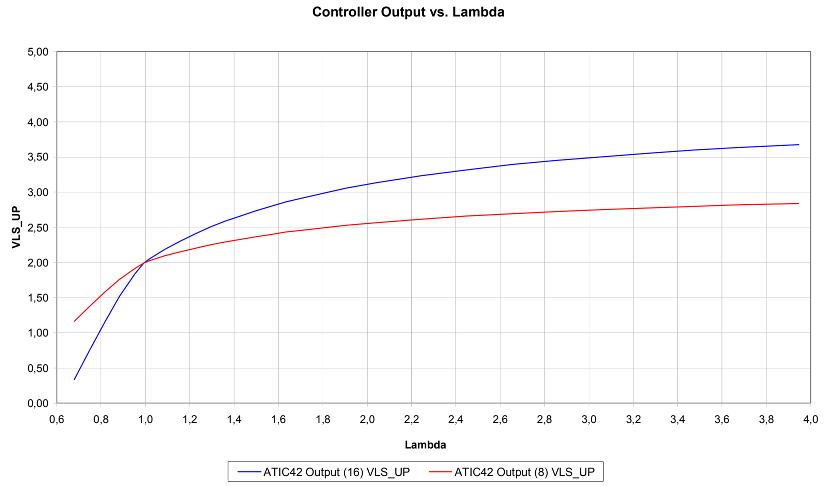
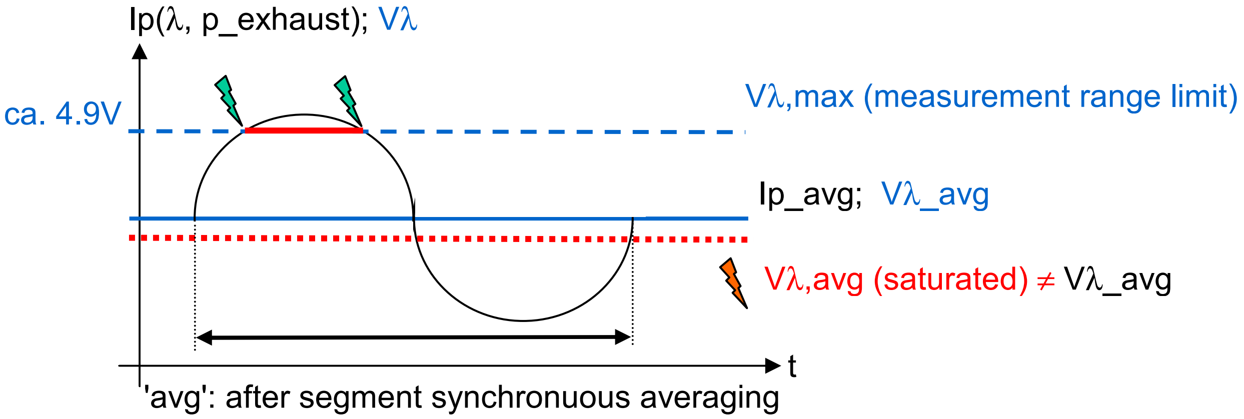
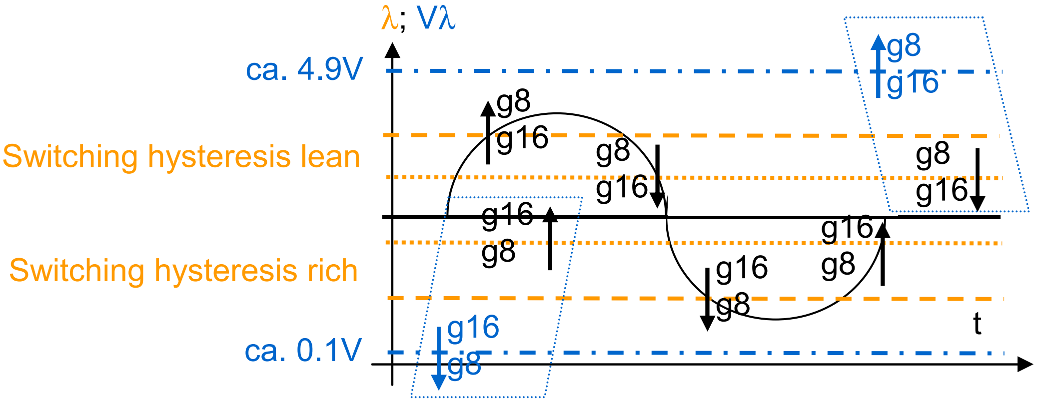
LOGICAL CONSTANT **Effect ('0' / '1')**	**gain16 only**	**gain8 only**	**gain16&8 simultaneously**	**gain16/8 alternating**
LC_LSL_OFS_ADJ_GAIN_SEL **Defines default Ip measurment gain**	**1**	**0**	**1**	**1**
LC_LSL_OFS_ADJ_H_L_GAIN **OA in default gain only (second range is approximated) / for both gains**	**0**	**0**	**1**	**1**
LC_LSL_OFS_GAIN_SWI_CYC **Simultaneous / alternating OA for both gains**	**0**	**0**	**0**	**1**
LC_IPLSL_GAIN_SWI_ACT **Gain switching during Ip measurement active**	**0 / 1**	**0 / 1**	**0 / 1**	**0 / 1**



Ip measurement range vs. resolution (exemplary).



Range switching triggered by λ / Vλ thresholds to avoid saturation effects of Ip measurement.



Switching thresholds/hysteresis

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned
(NC_CBK_EX_NR = 2), then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: The following variable initialisation shall take place at **LV_IGK 0->1**, **after RESET,** or **upon erase of error management**:

VLS_UP_COR[i] = 0

16.14 Application Incidences for ‘Offset adjustment of oxygen sensor (linear control)’

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_LSL_OFS_ADJ[NC_CBK_EX_NR]	O/V	0...1H	0...1	1	[-]
Boolean flag indicating that upstream oxygen sensor Ip offset adjustment shall be inhibited					
T_HOM_ACT_OFS_ADJ	O/V	0...FFFFH	0...655.35	0.01	[s]
Time in homogenous mode for enabling offset adjustment					

Input data:

STATE_LSL_IF_SPI_RD[NC_CBK_EX_NR]	LV_LAM_AD_INJ_ACT	C_T_DLY_TTIP_MES_OBD_LSH_UP	C_T_DLY_TTIP_RES_OBD_LSH_UP
LV_HOM_ACT			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned
(NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

The Boolean flag LV_INH_LSL_OFS_ADJ[i] shall indicate whether the upstream oxygen sensor Ip offset adjustment shall be permitted to take place.

When set, Ip offset adjustment shall be inhibited.

Description:

Application conditions:

Initialisation:

The following initialisation shall be carried out **after RESET**, **after engine start**, or **upon erase of error management**.

LV_INH_LSL_OFS_ADJ [i] = 0

T_HOM_ACT_OFS_ADJ = max phys. value

Recurrence:

T_SAMPLE = 10ms

Activation:

LV_ST_END == 1

Deactivation:

--

Formula section:

```
IF      LV_HOM_ACT = 0
THEN    T_HOM_ACT_OFS_ADJ = 0
ELSE    increment T_HOM_ACT_OFS_ADJ  (timer shall saturate at max phys. limit)
ENDIF

If      STATE_LSL_IF_SPI_RD[i] bit LSL_ENA == 0
or      LV_LAM_AD_INJ_ACT = 1
or      (T_HOM_ACT_OFS_ADJ <= (C_T_DLY_TTIP_MES_OBD_LSH_UP + C_T_DLY_TTIP_RES_OBD_LSH_UP))
then    LV_INH_LSL_OFS_ADJ[i] = 1
else    LV_INH_LSL_OFS_ADJ[i] = 0
endif
```

16.15 Operability detection for the linear lambda sensor

Output data:

16.15.1 FUNCTION DESCRIPTION

General information:

This is a particular **version for linear oxygen sensors to be used if the oxygen sensor ceramic temperature is determined by internal resistance measurement of the Nernst cell**. It requires that the oscillator can be switched on and off depending on LV_LS_UP_READY_RAW[i] which is determined in this function.

The operability check for the lambda sensor shall detect the moment at which the sensor reaches principal ability to generate plausible output signals (once pump current control loop has successfully been activated!). It shall analyse the sensor signal and distinguish between two stages of operative readiness. The criterion for raw sensor operability may be the variation of the sensor signal as well as the crossing of a maximum or minimum threshold by the sensor signal or simply when a delay has been exceeded. When the raw operative readiness has been sensed, the full operative readiness shall be determined by waiting until the minimum oxygen sensor ceramic temperature for safe sensor operation has been reached.

The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then

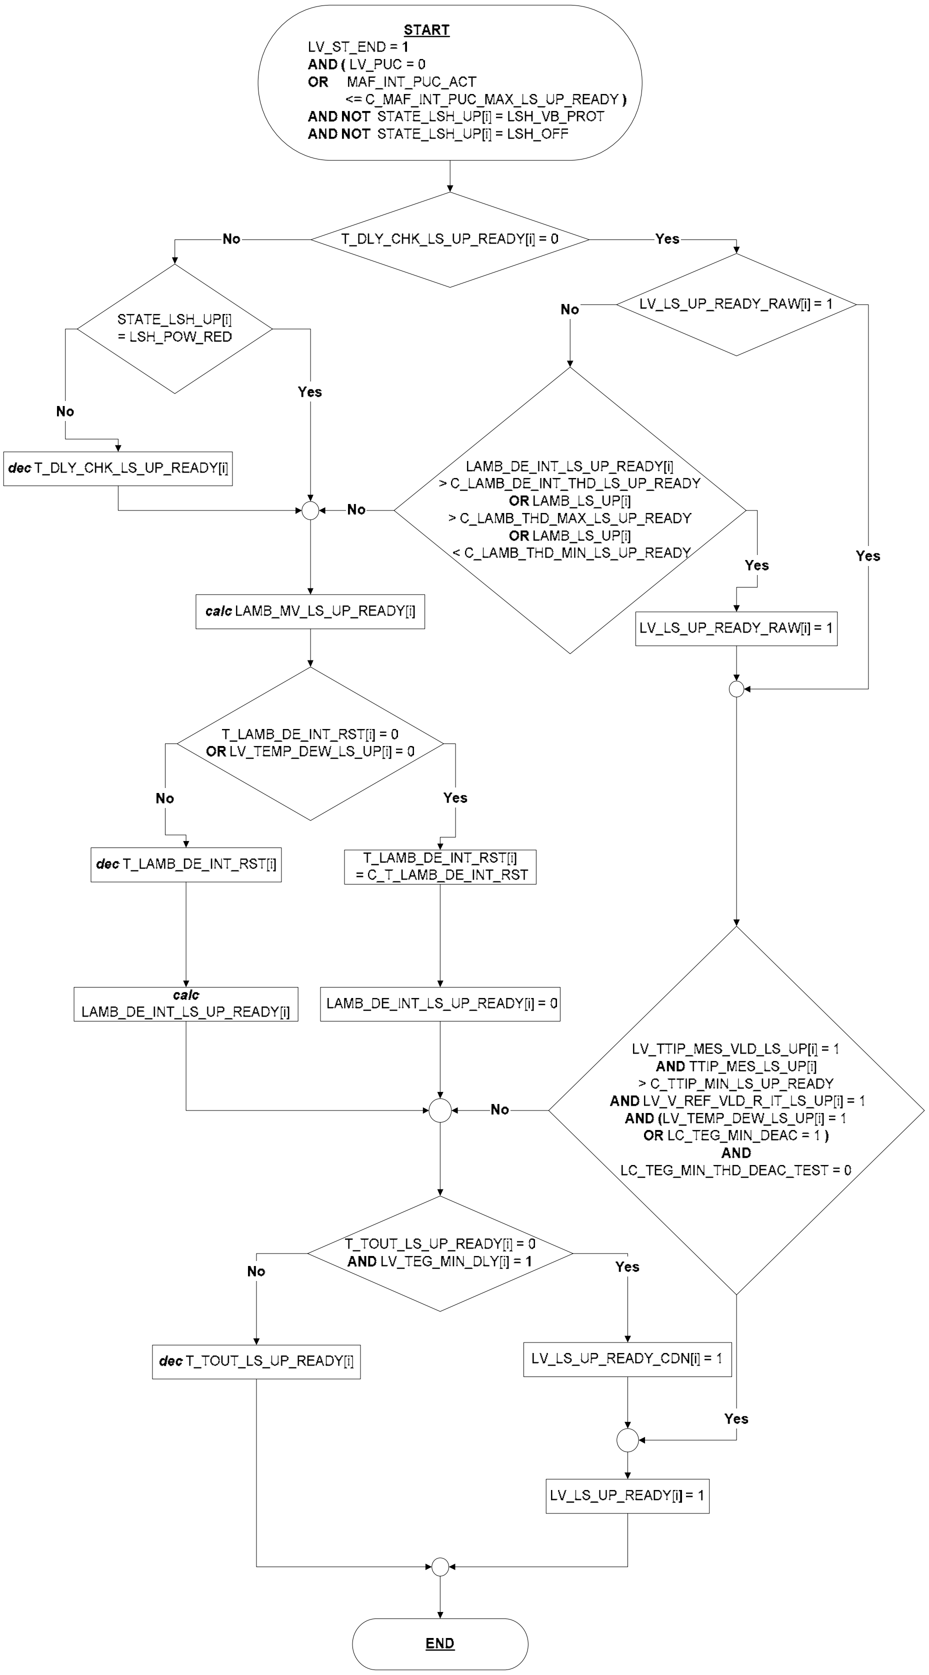
i = 1, for exhaust cylinder bank 1

i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)

i = 1, for single exhaust cylinder bank.

Signal flow diagram:



Description:

The function shall be activated with the following conditions being fulfilled:

Engine start is left, i.e. "exit START" (LV_ST_END = 1) *and*

Upstream heater has left the battery-voltage protection mode (STATE_LSH_UP[i] ≠ LSH_VB_PROT) *and*

Upstream heater is <u>not</u> in off mode (STATE_LSH_UP[i] ≠ LSH_OFF) *and*

Threshold value of MAF integral is <u>not</u> exceeded during PUC.

The function shall be deactived once any one of these conditions is not fulfilled anymore.

Function re-start shall also take place upon erase of error management.

Precondition for starting the operability check is that the delay time ID_T_DLY_CHK_LS_UP_READY has expired.

The sensor is subsequently recognized as being <u>fully</u> operable (LV_LS_UP_READY[i] = 1) if

(

the value LAMB_DE_INT_LS_UP_READY[i] exceeds the threshold C_LAMB_DE_INT_THD_LS_UP_READY once

OR if the sensor output signal LAMB_LS_UP[i] exceeds the window defined by the limiting values C_LAMB_THD_MIN_LS_UP_READY and C_LAMB_THD_MAX_LS_UP_READY

< This state is called <u>raw</u> sensor operability (LV_LS_UP_READY_RAW[i] = 1) >

AND

the value for ceramic temperature is valid (LV_TTIP_MES_VLD_LS_UP[i] = 1)

AND the value of the reference voltage is valid (LV_V_REF_VLD_R_IT_LS_UP[i] = 1)

AND the temperature of the sensor is higher than a threshold (TTIP_MES_LS_UP[i] > C_TTIP_MIN_LS_UP_READY)

AND

the dew point was exceeded (LV_TEMP_DEW_LS_UP[i] = 1)

OR LC_TEG_MIN_DEAC = 1 (only for test purpose in conjunction with forced sensor heating prior to engine start!)

AND

LC_TEG_MIN_THD_DEAC_TEST = 0

)

OR

the timer for forced activation has expired (T_TOUT_LS_UP_READY[i] = 0)

AND dew point was exceeded (LV_TEMP_DEW_LS_UP[i] = 1) for certain time delay (LV_TEG_MIN_DLY[i] = 1)

< This state is called forced sensor operability (LV_LS_UP_READY_CDN[i] = 1) >

The logical value LV_LS_UP_READY_RAW[i] detects changes in sensor signal as basis for recognition of the raw sensor operability.

REMARK: The CARB has defined that the sensor must be recognized as being operable after a certain time upon engine start. This requirement is realized using the timer T_TOUT_LS_UP_READY[i].

If the timer has expired the sensor will be set operable (LV_LS_UP_READY[i] = 1) and in addition the conditional readiness bit (LV_LS_UP_READY_CDN[i]) will be set to “1”, initializing the forced activation of sensor.

The flag LV_LSL_UP_ERR_SUSP[i] indicates that a fault may be present in the sensor, which is not yet debounced but may lead to wrong lambda measurement. It may be used to restrict the usage of the sensor signal by functions like lambda control or adaptation or diagnosis functions. The detection of these conditions is effectively masked with LV_LSL_UP_SUSP_ENA[i], which ensures that LV_LSL_UP_ERR_SUSP[i] is not set during sensor warmup.

FUNCTION DESCRIPTION:

General information:

The purpose of this function is the management of supply of pumped reference current (Icp), and pump current (Ip) control for ATIC42 WRAF sensor interface.

The Icp current is required by certain WRAF sensor types to provide a pumped oxygen reference for the Nernst cell sensing portion, as this is not provided by venting air into a chamber within the sensor. The value of the Icp current is programmed according to certain operating states of the WRAF system, and the Icp current is enabled or disabled.

Ip current is a measure of lambda. The Ip controller shall be required to meet stringent sensor protection requirements. For certain critical operating states of WRAF sensor, it may be undesirable to have the Ip control active and hence the function shall enable / disable the Ip control as required.

Both danger of implausible lambda measurement, e.g. due to signal saturation effects, and physical sensor destruction have to be detected and appropriate measures are taken.

Ip control is activated with a repeated pulse routine to avoid excessive pumping voltage (Vp) supply at point of activation. During activation, some of the provided sensor protection mechanisms are inhibited because they would produce inappropriate results due to transient behaviour.

Validity of pumping current signal is jugded depending on current state of WRAF system. Certain operating conditions lead to temporary revocation of validity flag, e.g. danger of increased heater-coupling on Ip signal circuit due to longer term battery undervoltage.

In case of pumping voltage (Vp) across sensor pump cell violating certain bounds or of reverse Icp cut-off, Ip control also has to be inhibited to avoid physical destruction of sensor element, i.e. by blackening effect of zirconia dioxyde ceramic.

Two logical variables stating short term profound reliability of measured lambda signal, and signal accuracy level (regular / limited), resp., shall be provided.

Description:

The function shall be activated once the transition from engine start to engine run has taken place and once the initialisation of the WRAF sensor 'ASW<=>BSW' interface has successfully been carried out. It shall stay active up to the end of ECU power latch.

Alternative activation of certain chapters shall take place in case of forced sensor pre-heating prior to engine start.

The function is split into ten main sections:

1. Activation of pumped reference current (Icp)
2. Value of pumped reference current ("Set Icp programming value")
3. Determination of Icp cut-off conditions ("Overvoltage at sensor Vn pin")
4. Determination of required status of pump current (Ip) control loop
5. Activation of pump current (Ip) control loop
6. Possibility of increased heater-coupling due to permanent battery undervoltage
7. Validity of pump current (Ip)
8. Pumping voltage (Vp) limitation strategy
9. Provision of a cumulative logical variable LV_LAMB_LS_UP_VLD_i for judgement of short term reliability of WRAF system lambda output signal.
10. Indication of regular / limited accuracy of measurement signal.

Remark: Below description of functional units within 'WRAF sensor control' module aims to provide a general survey on physical backgrounds of sensor behaviour and derived actions for operational strategy. For related **variable names** please respect corresponding diagrams provided within **formula section**.

1. Activation of pumped reference current

This section shall provide the 'Icp enable' and appropriate programming value information to the WRAF sensor interface and indicate whether the pumped reference has been filled via corresponding validity flag.

Should the sensor type being used not have a pumped oxygen reference or a general WRAF sensor error has occured, then this section shall be disabled, i.e. status flag for Icp validity is revoked, Icp is programmed to its minimum value, and Icp supply is deactived.

If none of these two conditions is present, this section behaves as follows:

During pulsed Ip control activation only programming value of Icp is evaluated and no other change in Icp supply conditions is performed.

In case of permanent operation of Ip loop with no SPI fault present, sufficiently high battery voltage for accurate operation of ATIC42, and no Vn overvoltage in conjuction with under-run of rich lambda setpoint threshold present (occurence is limited to rich atmosphere, forced Icp cut-off is automatically performed by ATIC42 HW), routine waits for successful mirroring of latest Icp status and programming value commands sent via SPI bus.

Once command transfer has been successful, Icp flow is requested, sensor element temperature has exceeded calibratible threshold, counter limit for filling time of pumped reference is determined. Latter condition can be replaced by OBD2 heater fault present in conjunction with operative sensor readiness (-> tip temperature not reliable), or in case of conditional operative readiness (-> forced sensor activation).

If repeated evaluation of corresponding index table (which depends on sensed element temperature and Icp programming value) leads to a higher value than adjusted before and pumped reference has not been filled completely yet, counter limit is increased. To force initial determination of counter limit this action is also performed when entering the condition with a filling counter value of zero.

Once Icp counter limit is reached the Icp valid flag is set, otherwise counter for Icp filling status is incremented.

General Icp activation is treated depending on engine condition (Icp active with engine running), status of forced sensor heating, and value of power latch delay timer. Latter provides for extended Icp supply after engine stop.

Next Subroutine “Value of pumped reference current” is executed to determine appropriate Icp programming value.

Should any of the following conditions hold true, filling status of pumped reference has to be verified: SPI command transfer fault, low battery voltage, Vn overvoltage in conjunction with under-run of rich lambda setpoint threshold, revocation of Icp activation, tip temperature drop below threshold.

If pumped reference area has been judged to be completely filled before, Icp counter limit is set to calibratable threshold which represents delay for emptying prior to revocation of 'Icp valid' status bit - to take into account for transient disturbances without immedate reset. Revocation takes place once counter has been decremented to zero.

In case of forced sensor pre-heating prior to engine start, simplified filling procedure of pumped reference is applied which bypasses certain conditions.

2. Value of pumped reference current

Icp value to be programmed is determined for four different operating states taking into account dependency of provided reference pumping current on (estimated) exhaust lambda and on sensor element temperature:

- Power Latch phase (engine stalled and forced sensor pre-heating inactive): Exhaust system filled with air; Ip control loop disabled. Icp supply is limited to calibratable delay time.
- Ip control active or pulsed activation thereof: Exhaust lambda provided by WRAF sensor.

- Ip control inactive, cold sensor: Exhaust lambda derived from <u>combustion</u> lambda setpoint (LAMB_SP[i]) and additional secondary air flow (SAF_KGH). For calibration it has to be taken into account that LAMB_SP[i] does not represent composition of exhaust atmosphere present at linear oxygen sensor during activation of secondary air; under these conditions lean conditions prevail at sensor mounting location regardless of LAMB_SP[i]!
- Ip control inactive, warm sensor, or OBD2 heater fault present in conjunction with operative sensor readiness (-> tip temperature not reliable), or in case of conditional operative readiness (-> forced sensor activation): same as above.

The influence of secondary air on exhaust lambda at sensor mounting position is taken into account for disabled Ip control loop.

Current status of Ip control loop is judged by evaluation of corresponding ATIC42 interface bit.

Distinction between “cold” and “warm” sensor is made by evaluation of calibratable ceramic temperature threshold.

As long as Ip control is in disabled state, Electromagnetic force (EMF) across sensor nernst cell adjusts itself in a range between 0 ... 1V depending on surrounding exhaust gas atmosphere – comparable to the behaviour of a binary type oxygen sensor. With enabled loop, EMF is controlled to be approx. 450mV constantly.

As a rule of thumb for conversion of Icp programming value to actual value of Icp current provided by ATIC42 (which is split between sensor nernst cell and shunt resistance within ATIC42 module which serves as voltage limitation for cold sensor) the following formula can be applied:

Icp = (k + 1) * 5uA with k: Icp programming value.

3. Determination of Icp cut-off conditions

Under worst case tolerances and rich conditions, the potential at sensor pin VN may exceed the threshold up to which Icp generation can be guaranteed for sensors of pumped reference type. Under such circumstances the Icp may temporarily be reduced or even cut-off by ATIC42 protection mechanism. This may lead to lean Ip misindication and also to sensor damage.

ATIC42 2nd silicon provides for automatic Icp cut-off in case of Vn overvoltage and signals the presence of such a condition through its interface.

Hence when Icp cut-off is signaled to occur by ATIC42, Ip control shall be disabled reducing the potential Vp across the pump cell and thereby also reducing the potential at pin Vn.

The voltage Vp across the pump cell shall be modelled by multiplying the measured pump current Ip with the pump cell internal DC resistance obtained from the relationship between the internal resistance of the Nernst cell and the pump cell.

The pump cell DC internal resistance (Rip) shall be obtained from a mapping dependent on value of nernst cell inner resistance (Ri, representing sensor temperature), and lambda setpoint. Both internal resistances are linked by sensor temperature and design. Additionally the pump cell resistance is dependent on the sensor lambda environment, hence the lambda setpoint dependence. Preliminary Rip value is then multiplied by a factor and a constant is added. Both parameters permit the dependency of the resistances to be modified to take worst case ageing into account.

The pump cell voltage Vp shall be calculated by multiplying modelled Rip by corrected value of pump current Ip.

Providing that WRAF sensor is of pumped reference type, the function shall determine whether Icp cut-off conditions are already active. If true, then the condition shall only be deemed to no longer persist when Rip is less than the value stored once Icp cut-off conditions were determined (i.e. sensor elememt got hotter), or lambda setpoint is greater than (i.e. leaner) than the value stored once Icp cut-off conditions were determined. Or, if maximum duration of active Vp limitation is calibrated to be non-zero, when the internal timer TIMER_2 has expired. In addition, for all three cases, VN overvoltage shall no longer be indicated by ATIC42. If all this holds true, then TIMER_2 shall be stopped, the stored Rip and lambda setpoint values shall be reset and the Ip control inhibition flag revoked. Otherwise TIMER_2 is decremented.

If the Icp cut-off conditions are inactive, and pulsed Ip control activation has been completed, calculated Vp voltage shall be compared to a minimum threshold. If this ‘rich’ threshold is exceeded or Vn overvoltage is sensed by ATIC42 and rich environment is present at sensor (i.e. rich lambda setpoint threshold is under-run), Icp cut-off conditions may occur. Should they be present for longer than estimated emptying delay of pumped reference, TIMER_2 shall be initialized, the current Rip and lambda setpoint values shall be stored, and Ip control inhibition flag shall be set.

4. Determination of required status of pump current (Ip) control loop

This section shall collect the various requests for activation / deactivation of the Ip control loop and provide the information to the WRAF sensor interface.

The function shall provide for manual switching of the Ip control loop by means of logical constants. If manual activation is requested, subroutine “Activation of pump current control loop” is executed.

In case of automatic switching, no general WRAF sensor error present and running engine (or with activated forced sensor pre-heating), the function checks if pumped reference of a sensor requiring Icp is not completely filled yet, or if Icp cut-off or Vp limitation sensor protection routine is active (and forced sensor pre-heating is inactive). Either one of these conditions leads to Ip passivation by resetting corresponding ATIC42 interface bit. At the same time all variables needed for next “Activation of pump current control loop” are initialized.

Next the function shall determine whether the conditional operative readiness is set or pulsed Ip control activation is running. If so then the evaluation of further conditions related to sensor readiness and tolerated lambda setpoint range for Ip activation shall be skipped and “Activation of pump current control loop” shall be executed.

If former condtions are not present, then the function shall determine whether operative readiness is set (or forced sensor pre-heating is activated). If not, then the Ip control loop shall be deactivated.

Once oxygen sensor ceramic temperature is greater or equal to a calibratable threshold, Ip loop shall be enabled once lambda setopint is located within calibratable bounds, or secondary air is active (providing for lean exhaust gas atmosphere), and Ip offset adjustment is not pending. The same action is taken once OBD2 heater fault ist present (-> tip temperature not reliable). Otherwise Ip loop shall stay disabled.

Thus pumping voltage saturation because of high pumping current requirements for λ << >> 1 can be avoided at point of Ip control loop activation. During secondary air phase, output signal of WRAF sensor is used for monitoring purposes. Thus Ip loop has to be activated even at very lean surrounding atmosphere which is present at that time. In general pumping voltage saturation in lean direction is not critical for WRAF sensor operation in conjunction with ATIC42 as it is for rich atmosphere.

5. Activation of pump current (Ip) control

In order to avoid excessive supply of pumping voltage Vp to WRAF sensor during switch-on of Ip control loop (which might lead to sensor destruction due to blackening effect for applied ‘rich’ voltages Vp < 2V), a pulsed activation with PWM-behaviour is provided.

For a calibratable number of cycles, ON- and OFF- phases of variable length are applied to WRAF sensor interface. Calibration can also be used to skip sensor protection mechanisms during one-time Ip switch-on for a certain time. In this case OFF-phase is of zero length.

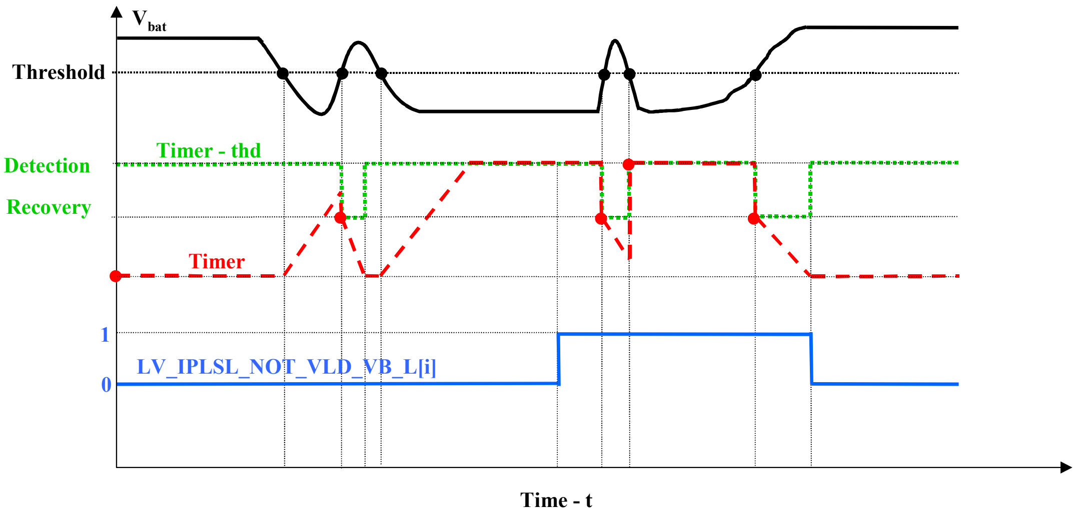
6. Indication of possibility for increased heater-coupling due to permanent battery undervoltage

For the linear oxygen sensor BOSCH LSU4.9, up to and including Äp3.1, there is a danger that for longer term battery undervoltage in combination with maximum heater PWM, increased heater-coupling to the pumping current signal circuit of the sensor might appear.

This effect is related to ion migration within the sensor element due to long term application of a certain ion activation potential to negative sensor heater electrode which is of ‘active low’ type.

Once regular battery voltage conditions are restored the exaggerated heater coupling vanishes within several seconds and returns to regular values.

A timer based detection strategy for possibility of increased heater coupling has been developed and is depticted in below figure.



Once the critical battery undervoltage condition is met for a certain delay time after leaving engine start - usually also leading to high PWM values – pumping current validity shall be revoked.

Since detection and recovery might be linked to different delay times, timer threshold is switched depending on presence of battery undervoltage condition.

If recovery delay time is interrupted by repeated undervoltage condition the delay timer is set to and kept at detection threshold value.

Should time based thresholds for detection and recovery be calibrated identically, latter ist incremented for one step to avoid ambiguities within algorithm execution.

7. Validity of pump current (Ip)

This section shall model the basic validity of the Ip current. For short term reliability of ATIC42 lambda output signal a special indicator bit is introduced in chapter 9.

The function shall check if a general WRAF sensor error is present or if a SPI error has occurred since the last function recurrence. Latter information is retrieved by comparison of corresponding error counter with its previously stored value. If the values differ from each other then current value shall be stored for next comparison, the internal timer TIMER_1 and the Ip validity flag shall be reset.

If sufficient battery voltage for power supply of ATIC42 is available, function shall wait for the sent Ip control enable / disable information to be mirrored by comparing to ATIC42 SPI response byte.

In case of forced sensor pre-heating additional delay time **after engine start** can be calibrated. If corresponding timer threshold is calibrated to be zero, validity of pump current shall also be detectable prior to engine start.

Next the function checks if pulsed activation of pump current control loop is active. If so, Ip validity is revoked.

If not, the function shall determine whether the Ip control loop has been requested to be active. In addition the danger of increased heater coupling due to permanent battery undervoltage has to be excluded.

If all validation conditions hold true, a delay shall be exceeded prior to setting the Ip validity flag. If false, then the internal timer TIMER_1 and the Ip validity flag shall be reset.

8. Pumping voltage (Vp) limitation strategy

Since it is crucial for pumping voltage (Vp) across WRAF sensor pump cell not to exceed certain bounds depending on sensor temperature and ehxaust lambda (roughly $|Vp| \leq 2V$ for sensor at operating temperature, less during sensor warm-up), compliance with these limits has to be ensured under all operating conditions. Exceeding these limits may lead to physical sensor destruction by “blackening” of zirconia sensor element especially under rich conditions.

Sensor ageing (increase in pump cell inner resistance), insufficient sensor operating temperature, or high pressure conditions, resp., may lead to restriction of measurable lambda range within permitted pumping voltage range.

Since physical Vp threshold for WRAF sensors can be extended to Vp > 2V in lean area, HW based analog Vp limitation provided by ATIC42 offers sufficient protection. For rich area, evaluation of digital limitation threshold LV_LSL_VP_LIM_i enables strict limitation of Vp to fixed threshold of Vp = -2V also under dynamic conditions by means of SW intervention on status of Ip control loop.

Gradual increase in limitation of operational lambda range in rich environment due to long term effects shall lead to adaptation of corresponding threshold which is stored in non-volatile ECU memory.

Once digital Vp limitation is indicated by ATIC42, and rich lambda setpoint limitation threshold is under-run, and secondary air / pulsed Ip control activation both are not active, current measured lambda value is temporarily stored as new threshold for reactivation of Ip control. Since digital limitation might already limit pumping current, measured lambda value is equal or greater actual lambda which provides additional security margin for reactivation of Ip control loop.

Should Lambda signal be indicated not to be reliable at that time, current lambda setpoint value is adopted as new temporary threshold.

To guarantee minimum operational range in rich direction, e.g. for Ip activation during sensor warm-up, a calibratable maximum value for Vp limitation lambda threshold has to be respected in addition.

Vp limitation threshold is assigned with either latter value or previously determined temporary threshold.

Upon storage of Vp limitation threshold, Ip control is inhibited by setting corresponding flag and Vp limitation status bit is set thus preventing second evaluation of limitation threshold during current Vp limitation phase.

Should Vp limitation not be indicated any longer, but Vp limitation still be active, lambda setpoint is crosschecked with actual Vp limitation threshold. Once setpoint value exceeds latter, Vp limitation status is reset and inhibition of Ip control loop is revoked.

With Vp limitation inactive and reliable lambda value exceeding limitation threshold in rich direction an 'improvement' in WRAF sensor behaviour is detected (due to sensor change or vanishing of temporary effects which led to an increase in Vp requirements, like e.g. elevated exhaust pressure or decreased sensor temperature) and Vp limitation threshold is relaxed.

9. Logical variable for judgement of WRAF sensor lambda signal reliability

Various conditions for operative readiness of WRAF system, consisting of WRAF sensor (including heater) & WRAF controller, have to be fullfilled and no diagnostic contraindications are allowed to be present to judge WRAF lambda signal as being *completely* reliable (for details see formula section). Evaluation of this variable has to take place at start of Vp limitation check.

10. Logical variable for judgement of lambda sensor signal accuracy level

Certain environmental conditions or functional limitations might lead to decrease in signal accuracy level (regular -> limited) due to need for additional compensative measures which are subject to tolerances, or limited functional performance.

Presence of any of these conditions is indicated by cumulative flag.

Application conditions:

Initialisation:

The following initialisation shall take place for each newly-flashed ECU or upon detection of EEPROM error:

LAMB_THD_VPLSL_LIM[i] = 0

The following initialisation shall take place directly after RESET:

ICPLSL_LSL_IF[i] = 0

T_IPLSL_NOT_VLD_VB_L_THD[i] = C_T_IPLSL_NOT_VLD_VB_L_INC

T_IPLSL_NOT_VLD_VB_L[i] = 0

The following initialisation shall take place after ECU RESET, at LV_IGK = 0->1, or upon erase of error management:

R_IT_IPLSL[i] = 16383.75 (i.e. FFFFH)

VPLSL[i] = 0

CTR_ICPLSL[i] = 0

CTR_ICPLSL_MAX[i] = 0

LAMB_SP[i] ***Store*** = 0

Reset internal timers T_DLY_IPLSL_CTL_ENA[i] & T_DLY_VPLSL_LIM_ACT [i]

Recurrence:

T_SAMPLE = 10ms.

Activation:

For chapters 3. / 6. / 8. / 9.: Transition from engine start to run and SPI initialisation complete.

LV_LSL_IF_SPI_RST_END[i] == 1
and LV_ST_END == 1

For chapters 1. / 2. / 4. / 5. / 7. **/ 10.**: Extended supply of pumped reference current and activation of Ip control loop prior to engine start in case of forced sensor pre-heating.

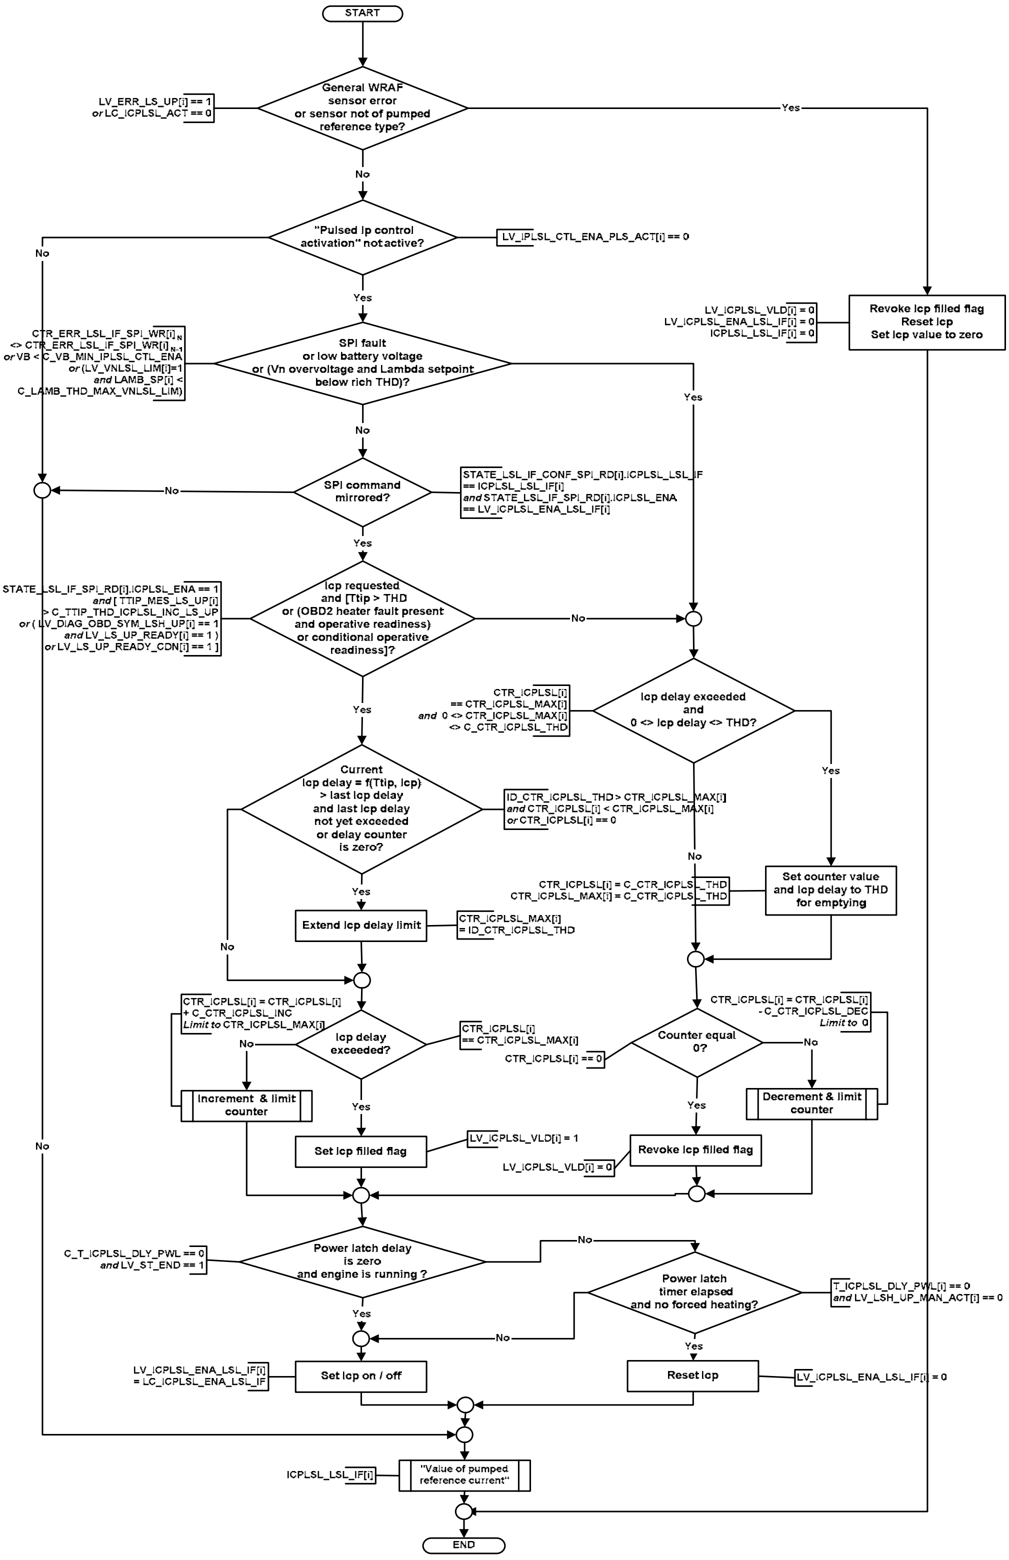
LV_LSL_IF_SPI_RST_END[i] == 1
and **(** LV_ST_END == 1
or LV_LSH_UP_MAN_ACT[i] == 1 **)**

Deactivation:

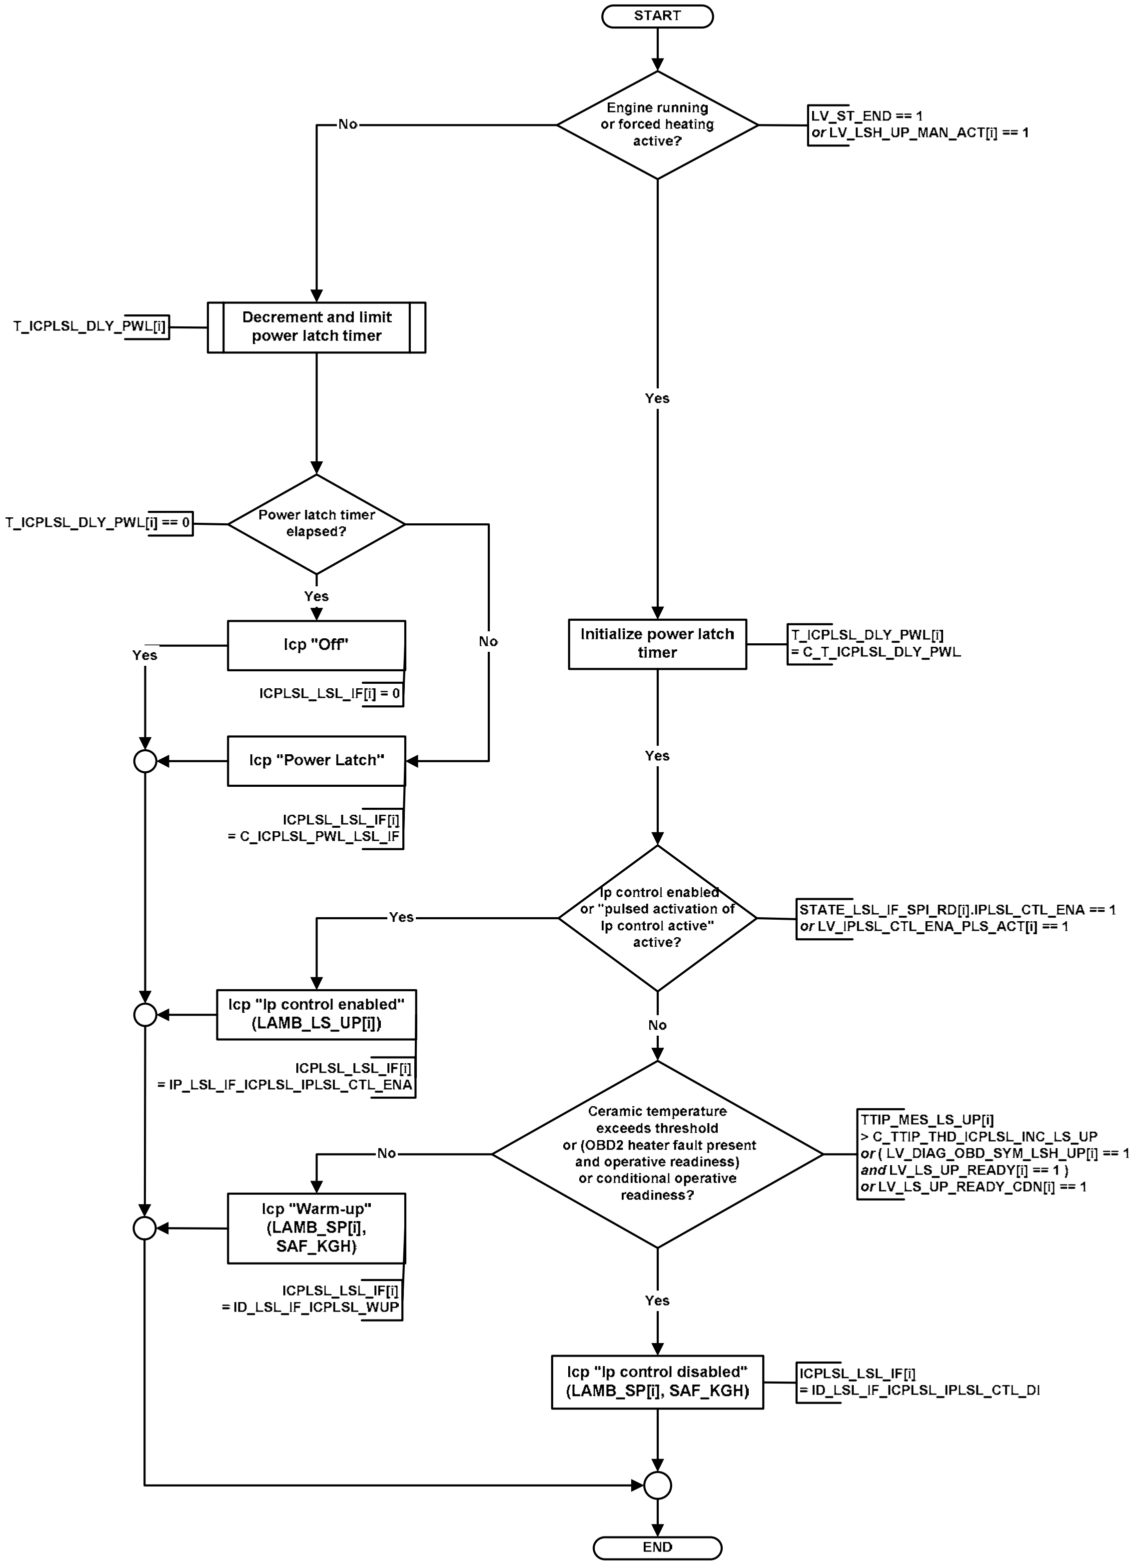
At the end of ECU power latch.

Formula section:

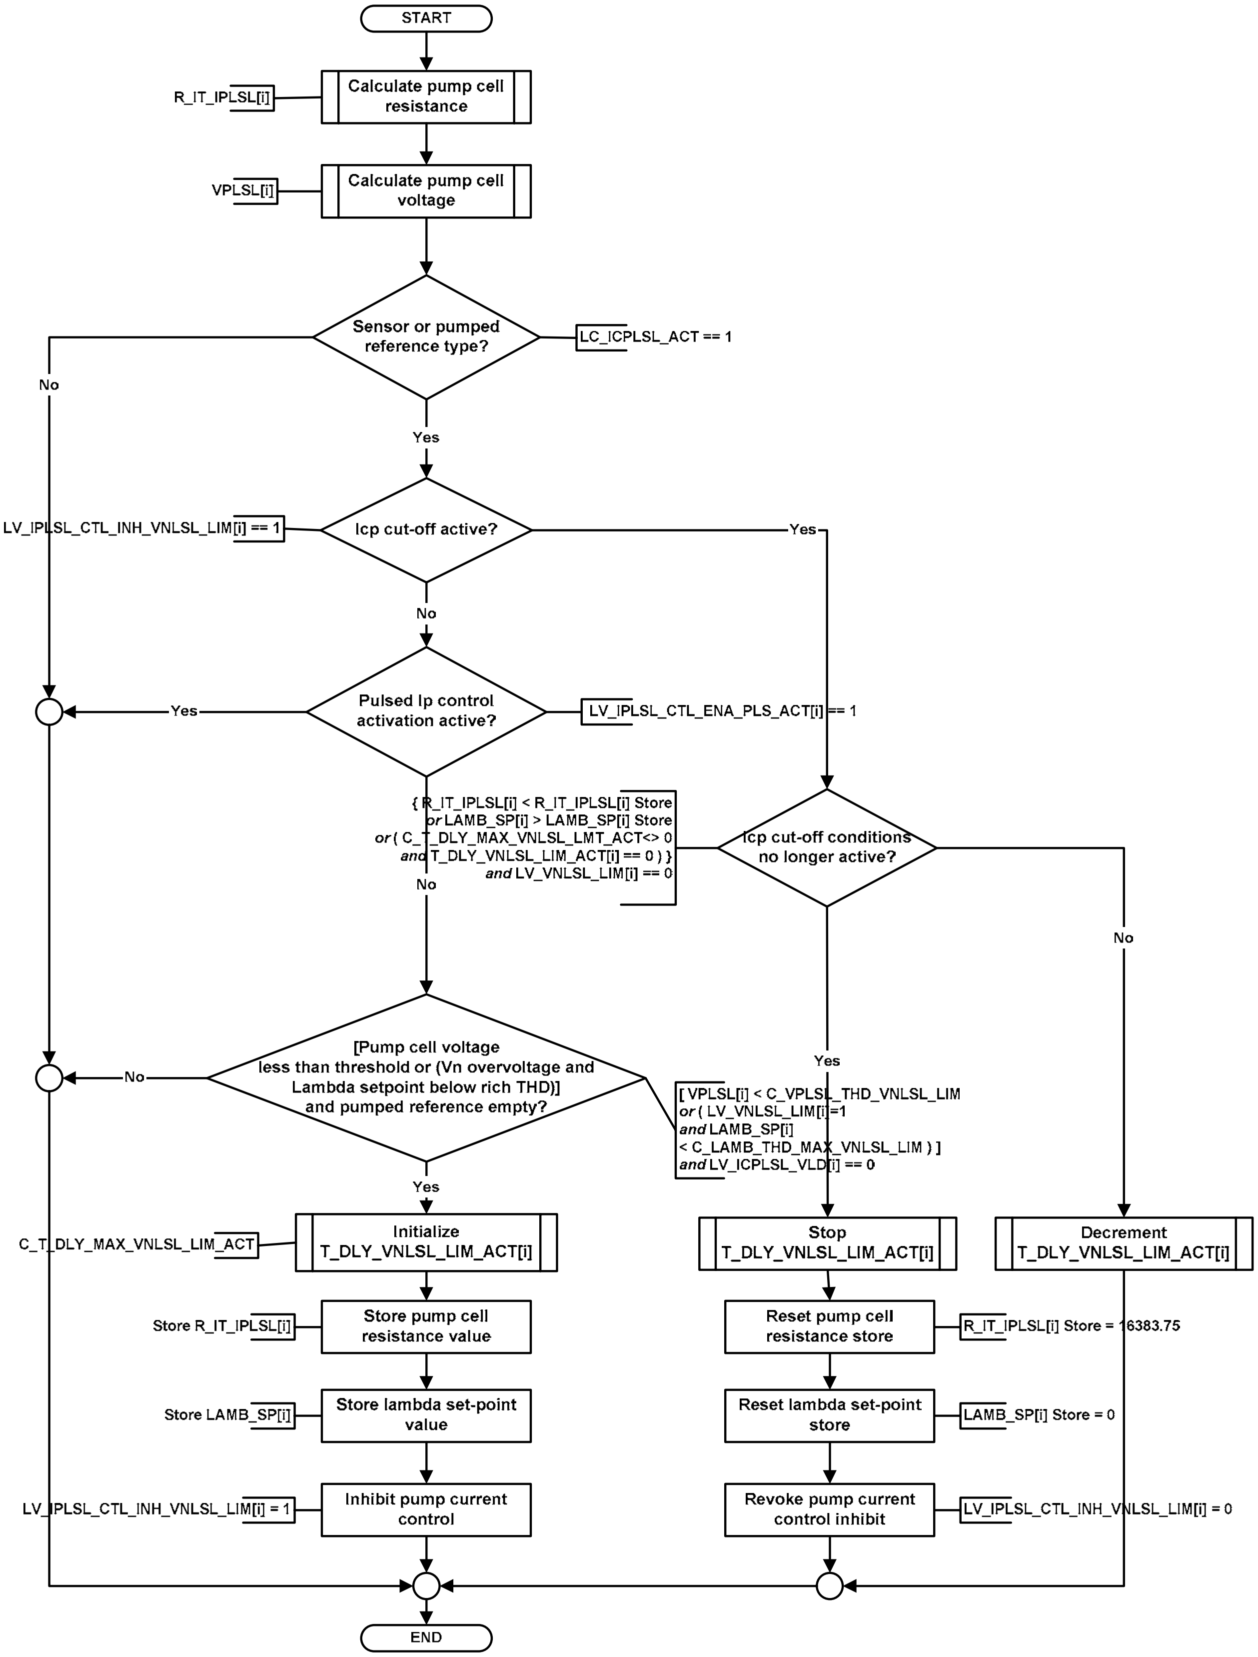
1. Activation of pumped reference current



2. Value of pumped reference current



3. Determination of Icp cut-off conditions



Calculation of modelled WRAF sensor pump cell DC resistance

See determination of Icp cut-off conditions above for use.

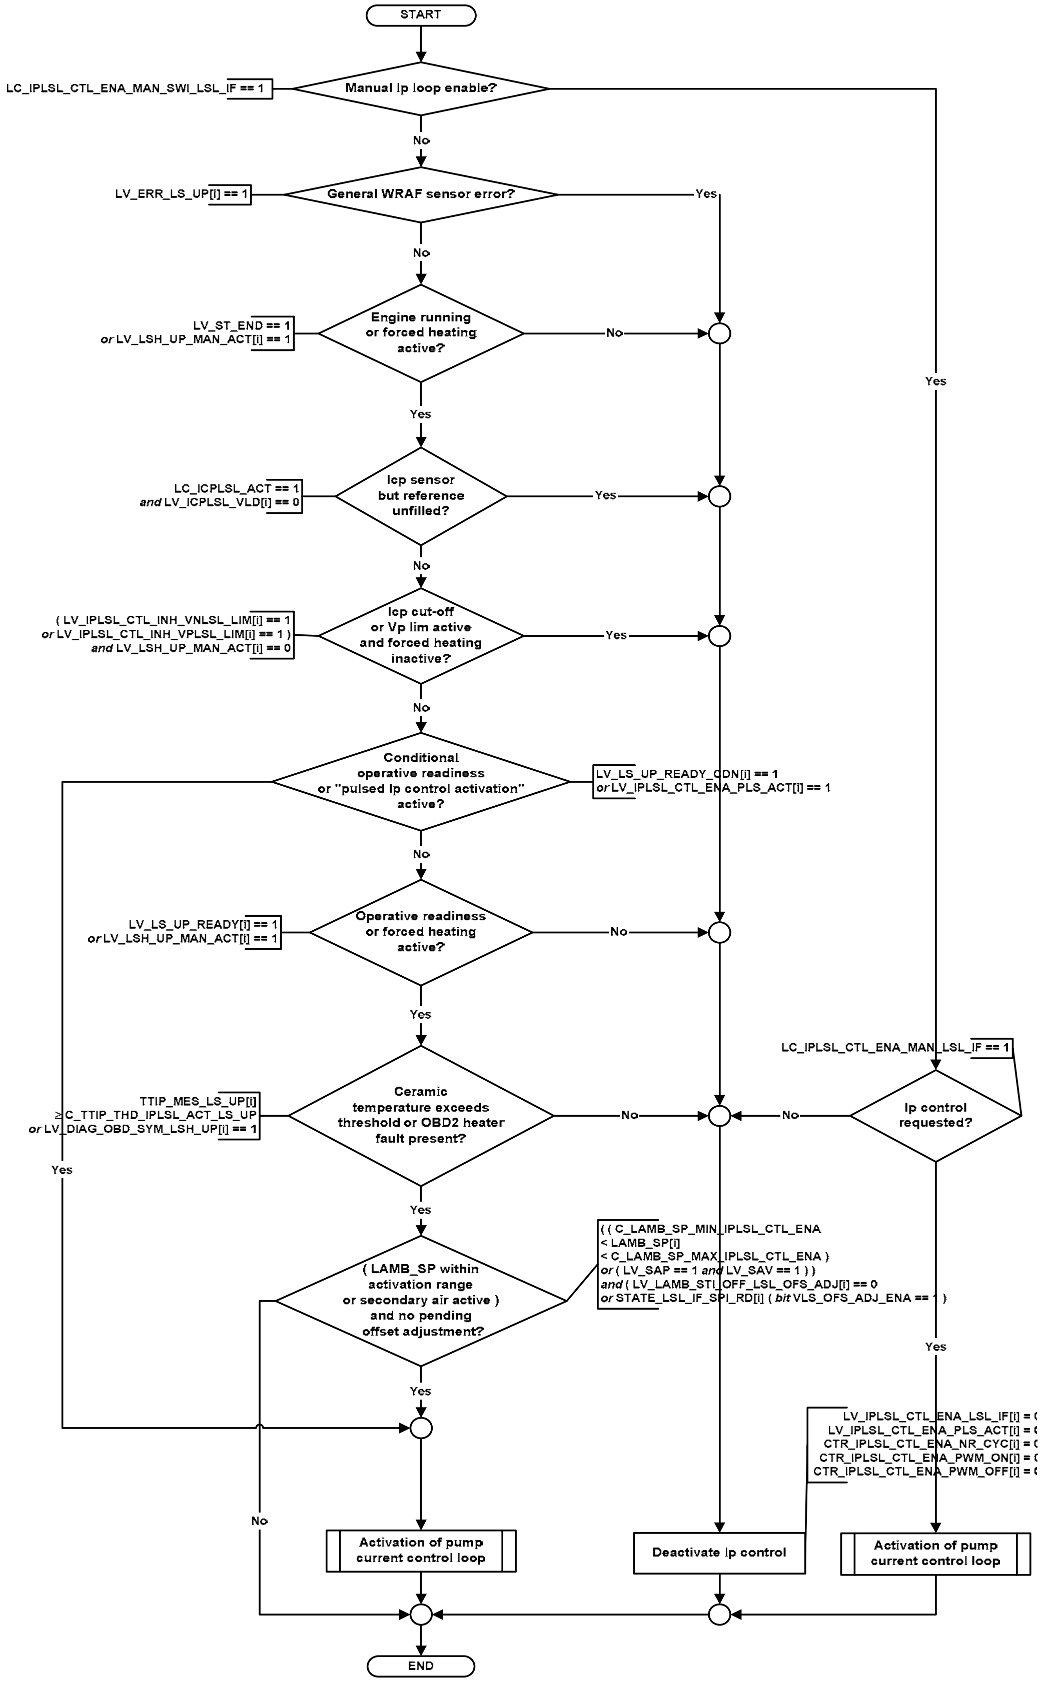
R_IT_IPLSL[i] = (IP_R_IT_IPLSL (R_IT_LS_UP[i], LAMB_SP[i]) * C_R_IT_IPLSL_AGI_FAC) + C_R_IT_IPLSL_AGI_ADD

Calculation of modelled voltage across WRAF sensor pump cell

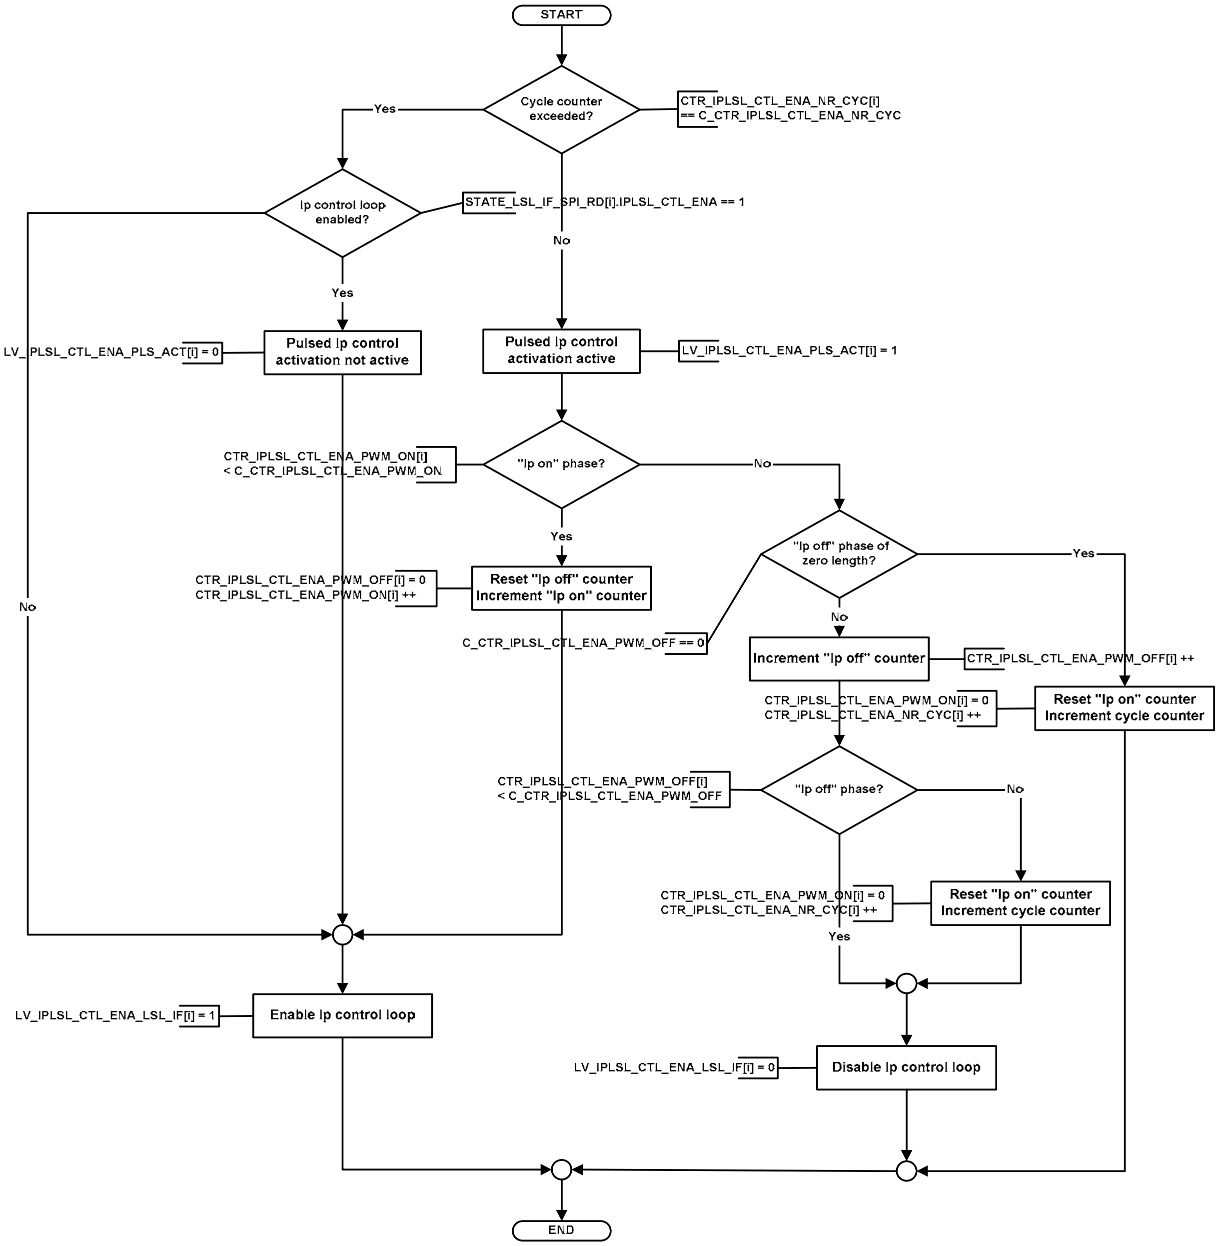
See determination of Icp cut-off conditions above for use.

VPLSL[i] = R_IT_IPLSL[i] * IPLSL_COR[i]

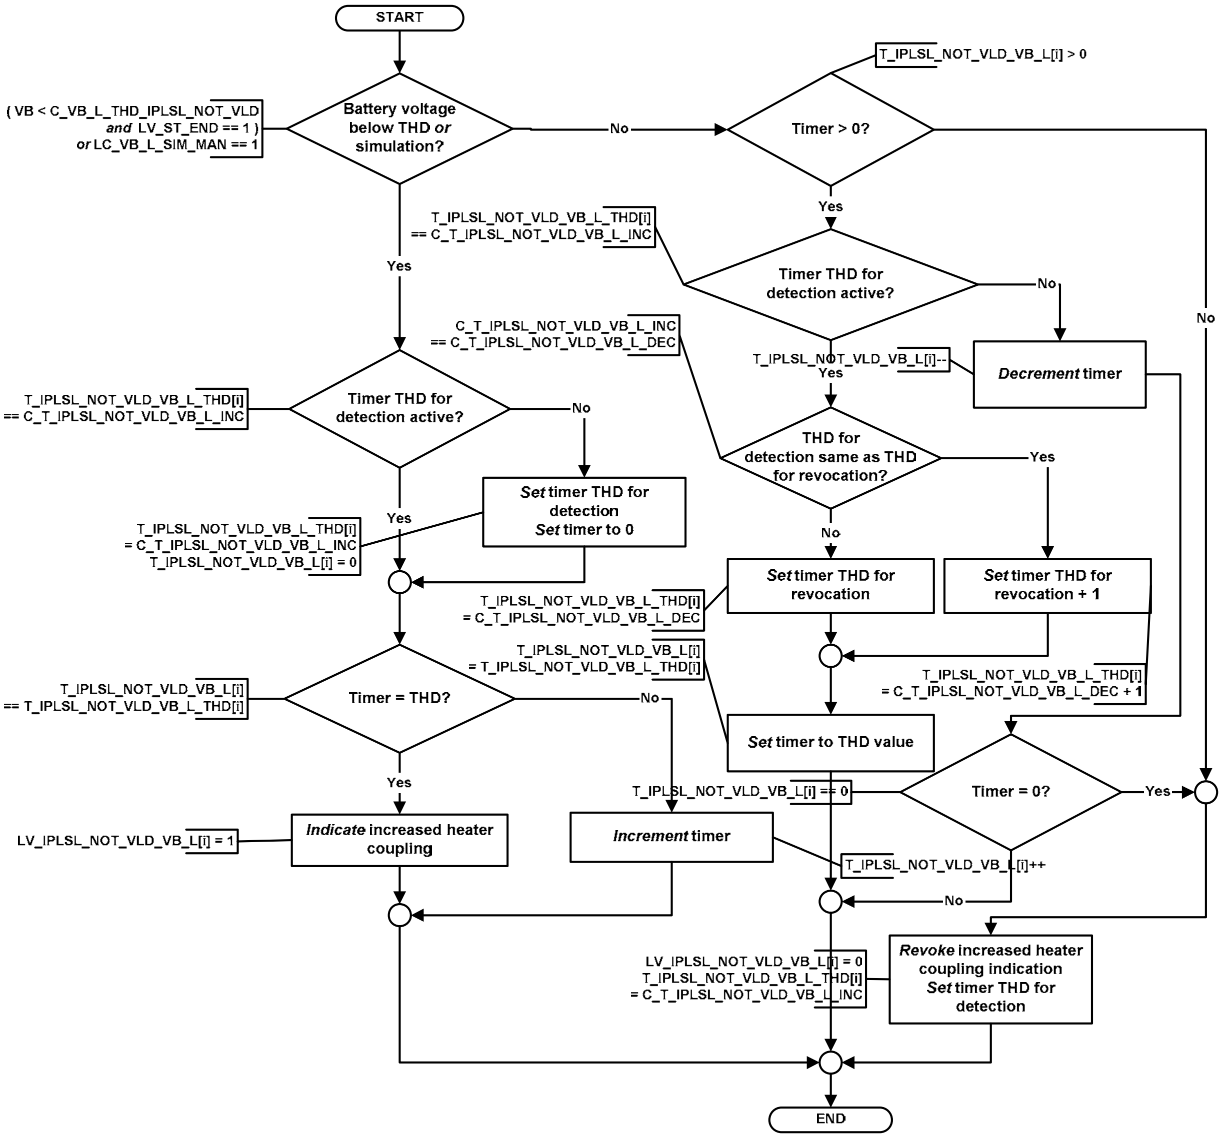
4. Determine required status of pump current (Ip) control loop



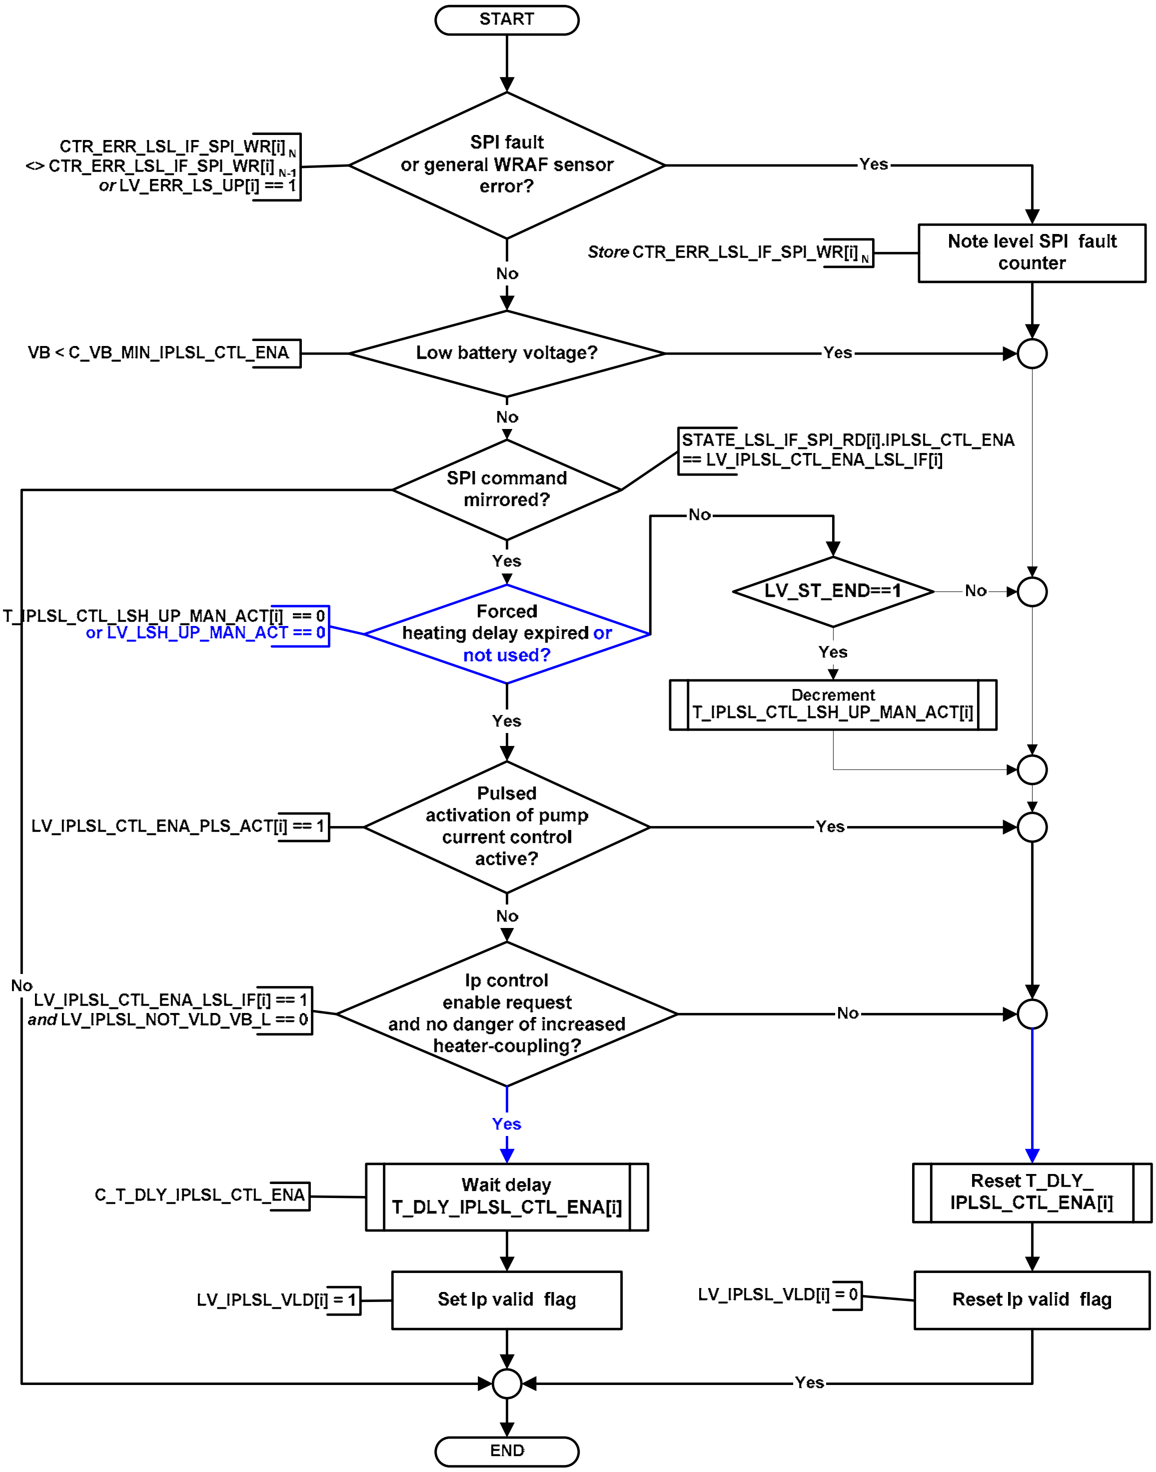
5. Activation of pump current (Ip) control loop



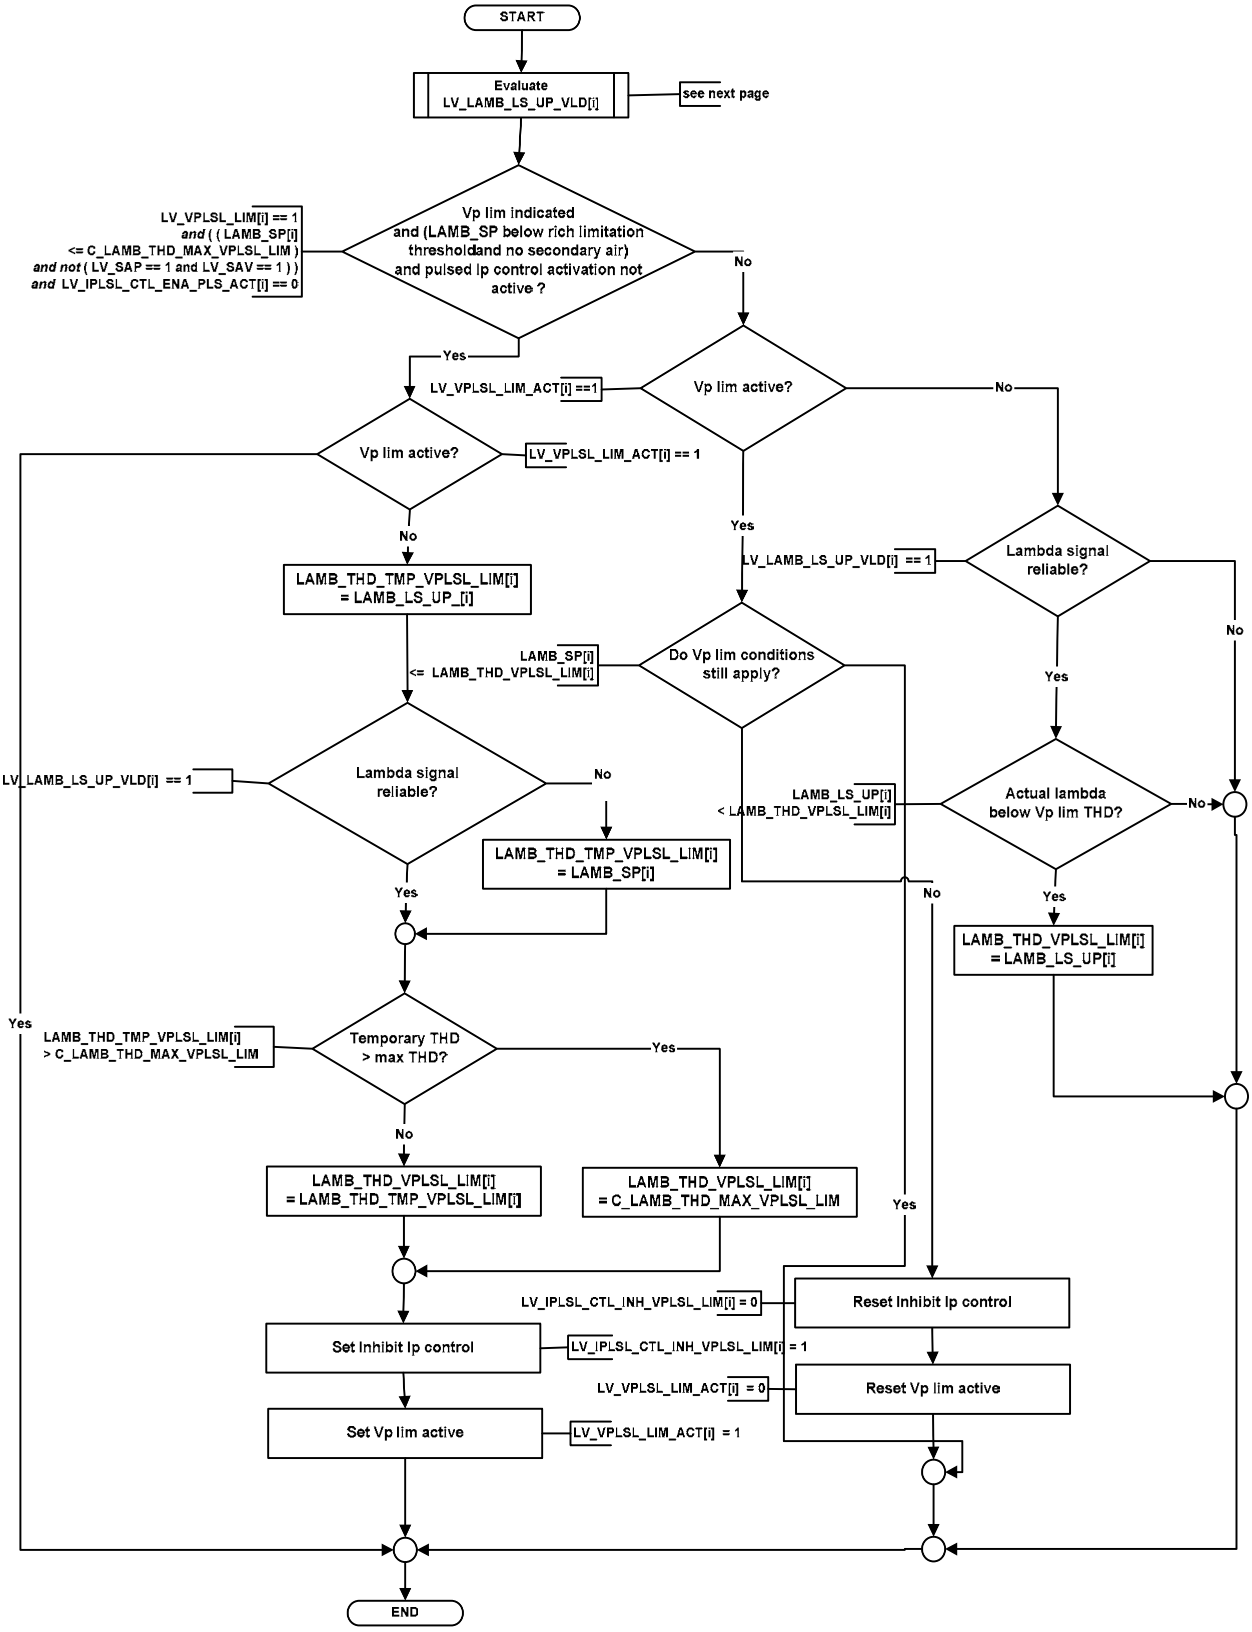
6. Indication of possibility for increased heater-coupling due to permanent battery undervoltage



7. Validity of pump current (Ip)



8. Pumping voltage (Vp) limitation strategy



9. Logical variable for judgement of short term WRAF sensor lambda signal reliability

```
If      LV_LS_UP_READY[i] == 1
        /* WRAF sensor full operative readiness detected */
and     LV_LSL_OFS_ADJ_ACT[i] == 0
and     LV_VLS_OFS_ADJ_ENA_LSL_IF[i] == 0
        /* WRAF controller electrical offset adjustment not active */
and     STATE_LSL_IF_SPI_RD[i] (bit LSL_ENA) == 1
        /* WRAF sensor coupled */
and     ( LV_ICPLSL_VLD[i] == 1 or LC_ICPLSL_ACT == 0 )
        /* Reference pumping current valid or sensor not of pumped reference type */
and     LV_IPLSL_VLD[i] == 1
        /* WRAF sensor pumping current valid */
and     LV_VLS_UP_VLD[i] == 1
        /* No clipping of ATIC42 output voltage present */
and     LV_VLS_UP_INIT[i] == 0

FUNCTION DESCRIPTION:

During fuel cut-off the engine purges the exhaust line with air. This condition is the best suitable engine operating condition to check the WRAF sensor’s static gain.
The function comprises:

1. the recognition of a condition to be stable enough for a significant pumping current measurement.
2. pumping current correction due to interfering impacts as: exhaust pressure etc.
3. current acquisition and averaging during fuel cut.
4. evaluation of adaptation conditions
5. WRAF sensor gain adaptation

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions

Activation: *at LV_IGK = 1*

Deactivation: *at LV_IGK = 0*

Initialization **at first ECU run :**

FAC_LSL_GAIN_AD[i] = 1

IPLSL_MMV_VLD_FCUT[i] = C_IPLSL_NOM_PURGE

IPLSL_VARI_VLD_FCUT[i] = 0

LV_LSL_FIRST_GAIN_AD[i] = 1

Initialization at every transition **LV_IGK = 0 ->** 1, **ECU Reset, or upon erase of error management**:

STATE_IPLSL_AD_FCUT[i] = INIT

16.17.1 Conditions for WRAF Sensor fuel cut-off Ip determination

FUNCTION:

These conditions must be verified the whole time during the fuel cut-off Ip determination.

Request of MAP limitation during next PUC phase by any arbitrary exhaust cylinder bank shall lead to corresponding request to torque management.

Recurrence: T_SAMPLE = 100ms.

Perform prior to execution of FOR loop depending on [i].

```
If      LV_PUC == 0
then    LV_MAP_PUC_LIM_REQ_LSL_GAIN_AD = 0
endif
```

Fuel cut-off Ip determination is requested only:

```
If      ( LV_LS_UP_READY [i] == 1
and     LV_IPLSL_VLD[i] == 1
and     LV_CP_CLOSE_ACT == 1

and     MAF_INT_PUC_ACT > MAF_INT_PUC_MIN_LSL_GAIN_AD[i]
then    " transition to ACQUISITION "
else    $IPLSL\_COR\_MMV\_FCUT[i]_{n-1}$ = $IPLSL\_COR\_MMV\_FCUT[i]_n$
        “ stay in PURGE ”
endif
```

Actions during transition:

STATE_IPLSL_AD_FCUT[i] = ACQUISITION

IPLSL_VARI_PURGE[i] = 0

T_ACQ_IPLSL_PURGE[i] = 0

IPLSL_COR_BEG_PURGE[i] = IPLSL_COR_MMV_FCUT[i]

16.17.3.4 State ”Acquisition” :

As input the pumping current (IPLSL_COR_MMV_FCUT[i]) is compensated for actual impacts of:

- ambient pressure
- engine speed
- MAF_KGH
- (and WRAF sensor TTIP_MES_LS_UP[i])

Afterwards the real current (IPLSL_PURGE[i]) is calculated by division with the actual compensation factor (FAC_LSL_GAIN_AD[i]).

During the acquisition time (C_T_ACQ_IPLSL_PURGE) the actual real current (at fuel cut and at purged exhaust line) is averaged (IPLSL_MV_PURGE[i]) and its variance (IPLSL_VARI_PURGE[i]) is calculated. At the end of the acquisition a final compensation of residual gas purging is done by multiplying with IP_FAC_COR_IPLSL_CHG_PURGE with the latter depending on the Ip change from start to end of acquisition.

Actions:

```
If      LV_IPLSL_COR_MMV_FCUT_VLD[i] = 1
then    If      T_ACQ_IPLSL_PURGE[i] < C_T_ACQ_IPLSL_PURGE
        then    IPLSL_PURGE[i] = IPLSL_COR_MMV_FCUT[i]
                        * IP_FAC_COR_IPLSL_MAF_KGH * IP_FAC_COR_IPLSL_N_32
                          / FAC_LSL_GAIN_AD[i]
                IPLSL_MV_PURGE[i]$_n$ = ( T_ACQ_IPLSL_PURGE[i]
                        * IPLSL_MV_PURGE[i]$_{n-1}$ + T_SAMPLE * IPLSL_PURGE[i] )
                        / ( T_ACQ_IPLSL_PURGE[i] + T_SAMPLE )
                IPLSL_VARI_PURGE[i]$_n$ =
                        ( T_ACQ_IPLSL_PURGE[i] * IPLSL_VARI_PURGE[i]$_{n-1}$
                        + T_SAMPLE * ( IPLSL_MV_PURGE[i] - IPLSL_PURGE[i] ) ^2 )
                        / ( T_ACQ_IPLSL_PURGE[i] + T_SAMPLE )
                T_ACQ_IPLSL_PURGE[i]$_n$  = T_ACQ_IPLSL_PURGE[i]$_{n-1}$ + T_SAMPLE
        endif
else    IPLSL_COR_BEG_PURGE[i] = IPLSL_COR_MMV_FCUT[i]

```
    STATE_IPLSL_AD_FCUT[i] = WAIT
```

Transition to state ”ADAPT":

Conditions:

```
If      LV_LSL_GAIN_AD_REQ[i] == 1
and     LV_LSL_FCUT_MES_REP_INH[i] == 1
then    " transition to ADAPT "
endif
```

Actions during transition:

```
STATE_IPLSL_AD_FCUT[i] = ADAPT
```

16.17.3.5 State ”ADAPT”:

The fuel cut pumping current sample is checked for sensor operability and stability during the previous acquisition phase. Therefore the variance of the output must be between allowed limits. If this condition or the conditions for ”fuel cut-off Ip determination” are not fulfilled anymore the STATE_IPLSL_AD_FCUT[i] switches back to ”WAIT”.

If the conditions are fulfilled it will be declared as ”valid sample”. Next a MMV value and the variance of the valid Ip samples are calculated.

If the gain adaptation takes place for the first time (in case of a new sensor or new ECU) the MMV value is initialized with the mean-value of the first measurement. The variance stays on the initial value (zero) in this case. The calculation of MMV and variance is started as soon as one successful gain adaptation was carried out (by setting LV_FIRST_GAIN_AD = 0).

A new adaptive factor (FAC_LSL_GAIN_AD[i]) for the WRAF sensor’s gain is calculated if the following conditions for adaptation are fulfilled:

1. Variance of previous valid samples in permitted range.
2. Adaptive factor (FAC_LSL_GAIN_AD[i]) in permitted range

Since the new adaptive factor is calculated based on the MMV value of the valid samples it follows the average of the last measurements and not direct every particular fuel cut sample. The response time of the adaptation is defined by the correlation constant (C_CRLC_IPLSL_MV_VLD).

Actions:

```
If      LV_IPLSL_VLD_FCUT[i] == 0
        ( LV_IPLSL_VLD_FCUT[i] == 1 prevents a second evaluation and
        updating of IPLSL_MMV_VLD_FCUT[i] during the same fuel cut )
and     C_IPLSL_VARI_THD_MIN_PURGE <= IPLSL_VARI_PURGE[i]
                < C_IPLSL_VARI_THD_MAX_PURGE
then    LV_LSL_FCUT_MES_NOT_PLAUS[i] = 0
        LV_IPLSL_VLD_FCUT[i] = 1

        Average of recent valid fuel cuts & Variance of recent valid fuel cuts:
        If      (LV_LSL_FIRST_GAIN_AD[i] == 1 and LC_LSL_FIRST_GAIN_AD == 1)
```

```
then    IPLSL_MMV_VLD_FCUT[i]$_{i}$ = IPLSL_MV_PURGE[i]$_{i}$
        IPLSL_VARI_VLD_FCUT[i]$_{i}$ = IPLSL_VARI_VLD_FCUT[i]$_{i-1}$

else    IPLSL_MMV_VLD_FCUT[i]$_{i}$ = IPLSL_MMV_VLD_FCUT[i]$_{i-1}$
        + C_CRLC_IPLSL_MV_VLD * ( IPLSL_MV_PURGE[i]
        –   IPLSL_MMV_VLD_FCUT[i]$_{i-1}$ )

        IPLSL_VARI_VLD_FCUT[i]$_{i}$ = IPLSL_VARI_VLD_FCUT[i]$_{i-1}$
        + C_CRLC_IPLSL_MV_VLD * (( IPLSL_MV_PURGE[i]
        - IPLSL_MMV_VLD_FCUT[i]$_{i}$ ) ^2 - IPLSL_VARI_VLD_FCUT[i]$_{i-1}$ )

end
```

FUNCTION DESCRIPTION:

General information:

If one of the below mentioned conditions is not fulfilled, the inhibit bit interrupts the WRAF sensor gain adaptation at fuel cut-off.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: at every LV_IGK = 0 ⇒ 1 and reset all output variables are initialized with 0

Recurrence: T_SAMPLE = 100 ms.

Activation: at LV_IGK = 1

Deactivation: at LV_IGK = 0

Formula section:

```

Import actions:

ACTION_INFR_SetPwmLshUp(IN <i>, IN <ducy>)
This action sets the lambda heater upstream driver

FUNCTION DESCRIPTION:

General information:

If two separate cylinder banks are concerned, then
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2

The heater control shall be realised by use of a state machine. Each upstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

Lambda probe heating after engine start (normal case)

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account.

The function shall permit oxygen sensor heating under open and closed loop control.

Signal flow:

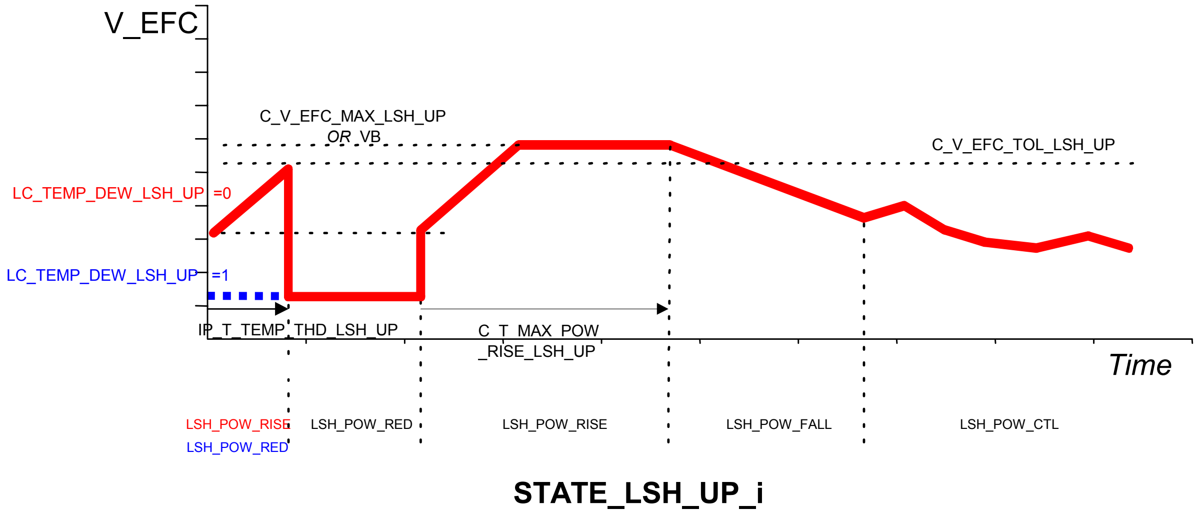

Figure 1: Course of effective heater voltage over time / state

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated if not otherwise required (see sub chapter "forced lambda probe heating before engine start").

In the normal case (no forced heating before engine start) heating shall be started when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the correspopnding bank is not set (LV_INH_LSH_UP[i] = 0). Depending on the lambda sensor requirement specification following two methods of initial lambda sensor heating are possible as judged by calibration of LC_TEMP_DEW_LSH_UP (see figure 1). This is due to the fact that for lambda sensors until dew point recognition either a certain temperature limit or a defined voltage limit must not be exceeded as the lambda sensor may be damaged by water splash or excessive temperature gradient otherwise. Depending on the setting of LC_TEMP_DEW_LSH_UP the heater management state machine shall thus switch from LSH_OFF to LSH_POW_RISE (LC_TEMP_DEW_LSH_UP = 0) or to LSH_POW_RED (LC_TEMP_DEW_LSH_UP = 1). In case of direct dew point recognition after hot restart the state machine shall switch to LSH_POW_RISE.

1.) Transition from LSH_OFF to LSH_POW_RED before dew point recognition

In case of transition from LSH_OFF to LSH_POW_RED the initial heater power is set by setting the effective heater voltage to C_V_EFC_RED_LSH_UP. The reduced heating state where water splash may occur shall persist until the dew point in the exhaust gas system has been recognized, i.e. until LV_TEMP_DEW_LS_UP[i] = 1, at which point the heater state shall switch to LSH_POW_RISE.

The effective heater voltage shall be set to the effective heater voltage as determined by IP_V_EFC_INI_LSH_UP, which may be modified by the calibration data C_V_EFC_STEP_LSH_UP, and may further be incremented with a gradient of C_V_EFC_INC_LSH_UP without danger of damaging the oxygen sensor. Additionally the timer T_POW_RISE_LSH_UP[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_UP determined at function start.

2.) Transition from LSH_OFF to LSH_POW_RISE before dew point recognition

In case of transition from heater state LSH_OFF to LSH_POW_RISE the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_UP[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_ LSH_UP. In the state LSH_POW_RISE, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_UP. The continuation of the heating gradient shall depend on whether the dew point at sensor location has been recognized.

Should the dew point not have been exceeded (LV_TEMP_DEW_LS_UP[i] = 0) but timer T_POW_RISE_LSH_UP[i] has equalled or exceeded IP_T_TEMP_THD_LSH_UP, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_UP. In this case, the heater state shall be set to LSH_POW_RED (see above).

The reduced heating state shall persist until the dew point in the exhaust gas system has been recognized, i.e. until LV_TEMP_DEW_LS_UP[i] = 1, at which point the heater state shall return to LSH_POW_RISE. For further operation please refer to case 1.)

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEMP_DEW_LS_UP[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Dependent on whether closed loop control is permitted, the heater management shall enter either LSH_POW_CTL or LSH_POW_FALL. Should closed loop be permitted (LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0) and the ceramic temperature reference be valid (LV_V_REF_VLD_R_IT_LS_UP[i] = 1) and ceramic temperature exceed the set temperature (TTIP_MES_LS_UP[i] ≥ C_TTIP_SP_LS_UP[i]) then the state machine shall change to LSH_POW_CTL and the timer shall be frozen. This state change shall permit the controller to take over heating when the operative readiness has been detected in order to prevent under- & overshoot of the ceramic temperature. Should the conditional operative readiness be set (LV_LS_UP_READY_CDN[i] = 1) then the state machine shall also enter state LSH_POW_CTL and stop the timer. This shall permit the heater stability diagnosis to be carried out even when the heater is sufficiently defective to prevent the set temperature from being reached. Should the closed loop controller be inhibited or the ceramic temperature calibration be faulty, and T_POW_RISE_LSH_UP[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_UP (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_UP until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_UP alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_UP * IP_FAC_V_EFC_TEG_LSH_UP. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

Should, however, the Boolean flag LV_TEMP_DEW_LS_UP[i] be reset whilst in the state LSH_POW_FALL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage may be carried out in open loop or closed loop mode. Unless either the closed loop control inhibit bit (LV_INH_LSH_CTL_CLL_LSH_UP[i]) is set or the reference voltage validity bit (LV_V_REF_VLD_R_IT_LS_UP[i]) is reset, the effective heater voltage shall be controlled in closed loop mode. Closed loop control conditions met shall be indicated by setting LV_LSH_CTL_CLL_LSH_UP[i]. Should at any time one of the above conditions no longer be met, the heater controller shall revert to open loop control, reset the closed loop variables and reset LV_LSH_CTL_CLL_LSH_UP[i].

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_UP and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_UP) may be required for the reasons outlined above.

In the closed loop heater control mode, a PI controller, that affects the open loop effective heater voltage in an additive manner, shall regulate the effective heater voltage such that the temperature specified by C_TTIP_SP_LS_UP[i] is maintained. The closed loop control may be further described as follows:

The current temperature of the oxygen sensor (TTIP_MES_LS_UP[i]) shall be obtained and the difference between this temperature and the set temperature computed to obtain the input variable to the controller (TTIP_MES_DIF_LS_UP[i]). Note that this variable shall be computed in both open and closed loop control modes but shall only be used in the closed loop control mode.

The controller shall then determine the appropriate additive voltage (V_EFC_CTL_ADD_LSH_UP[i]) by computing the P and I terms separately and then adding the two terms.

The P term (V_EFC_CTL_P_LSH_UP[i]) shall calculate a voltage proportional to the temperature difference and thus converting a temperature delta into voltage. The P term shall only be calculated when the absolute temperature difference (TTIP_MES_DIF_LS_UP[i]) equals or exceeds a constant (C_TTIP_DIF_MIN_CTL_P_LS_UP). This shall be achieved via the map IP_FAC_xxx_P_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_P_LSH_UP shall permit global parameter changes to be made.

The I term (V_EFC_CTL_I_LSH_UP[i]) shall calculate an integral of a voltage that shall be proportional to the temperature difference and thus converting a temperature delta into voltage. This shall be achieved via the map IP_FAC_xxx_I_LSH_UP_CTL, where xxx stands for either POS or NEG dependent on the sign of the temperature difference. The map values are dependent on engine speed and exhaust gas temperature. A further dimensionless constant C_FAC_CTL_I_LSH_UP shall permit global parameter changes to be made.

Once the additive voltage has been determined, this shall then be added to the open loop control voltage along with a calibration system constant (C_V_EFC_AS_LSH_UP) to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_UP[i]) shall be computed from the open loop value, the closed loop additive term and the global correction value.

The closed loop control computations shall be suspended should either the Boolean flag LC_LSH_CTL_CLL_INH_LSH_UP[i] be set or the ceramic temperature no longer be valid, for example due to an active reference voltage measurement, as indicated by LV_TTIP_MES_VLD_LS_UP[i] being reset. This shall freeze the P and I terms at their last calculated value. Upon revoking the suspension, the controller shall continue to compute from where the point immediately prior to the suspension, i.e. shall not start anew. Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_UP[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_UP[i] & LV_V_EFC_LIM_MAX_LSH_UP[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEMP_DEW_LS_UP[i] be reset whilst in the state LSH_POW_CTL, then the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_UP, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_UP[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_UP. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0, T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_DYN_LS_UP[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_DYN_MAX_LSH_UP, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending closed loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL, the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open / closed loop control. The closed loop controller shall not be started anew. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_UP[i] shall be reset, V_EFC_LSH_UP[i] shall be initialised to IP_V_EFC_INI_LSH_UP calculated after the start, the closed loop controller terms shall be reset, the Boolean flags to indicate closed loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_UP[i] equal or exceed the threshold C_V_EFC_TOL_LSH_UP.

In this instance, the timer T_V_EFC_TOL_LSH_UP[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_UP, timer T_V_EFC_LIM_LSH_UP[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_UP[i] should fall below the threshold C_V_EFC_TOL_LSH_UP at any time, LV_V_EFC_LIM_TOL_LSH_UP[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_UP[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_UP[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_UP[i]. Once the timer T_V_EFC_LIM_LSH_UP[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_UP, both timers shall be reset and timer T_V_EFC_TOL_LSH_UP[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_UP again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_UP[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_UP, C_V_EFC_MAX_ST_LSH_UP or VB dependent on the value of T_POW_RISE_LSH_UP[i].

If T_POW_RISE_LSH_UP[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_UP STEP or conditions regarding T_AST and STATE_LSH_UP[i] then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

If T_POW_RISE_LSH_UP[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_UP then V_EFC_CLC_LSH_UP[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_UP. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall be set and V_EFC_CLC_LSH_UP[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_UP otherwise LV_V_EFC_LIM_MAX_LSH_UP[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_UP[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_UP[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_UP[i] shall be the lower of the values V_EFC_CLC_LSH_UP[i] & C_V_EFC_LIM_LSH_UP otherwise V_EFC_LSH_UP[i] shall be set to V_EFC_CLC_LSH_UP[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_UP[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_UP & NC_LSHPWM_BOL_LSH_UP. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_UP.

Should at any time an inhibit flag be set (LV_INH_LSH_UP[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_UP[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_UP[i]. On a transition of the inhibit bit LV_INH_LSH_UP[i] from 1 → 0, the heater function shall start from anew.

Forced lambda probe heating before engine start (for application purpose)

Additionally to normal sensor heating after engine start setting LC_LSH_UP_MAN_ACT[i] = 1 allows forced pre-heating of the lambda sensor before engine start. The aim is to ramp up the sensor element to operating temperature in order to achieve a reliable lambda sensor signal already at the time when the engine is started. It has to be emphasized that this method covers a high risk for sensor damage by water splash as operating temperature is already reached before dew-point recognition. Therefore this feature shall only be used for application purpose.

If forced heating is activated, i.e. condition 15 being fulfilled, the state machine shall enter the state LSH_POW_RISE and a heater voltage C_V_EFC_INI_LSH_UP_MAN_ACT shall be applied. Before engine start no forced convection and consequently no lambda sensor cooling by the exhaust gas is present. Therefore the initial heater voltage may be reduced to C_V_EFC_INI_LSH_UP_MAN_ACT in order to prevent excessive temperature gradients and overheating. Additionally the STATE_LSH_UP[i] shall be set to LSH_POW_RISE, the timer T_POW_RISE_LSH_UP[i] shall be incremented and the status flag LV_LSH_UP_MAN_ACT[i] indicating activated forced heating shall be set. Forced pre-heating activation by evaluating the transition of LC_LSH_UP_MAN_ACT[i] from 0 to 1 ensures that forced heating may not become active in field application even if LC_LSH_UP_MAN_ACT[i] remains 1 for the final series data.

In the state LSH_POW_RISE the lambda sensor heater voltage shall further be increased with the same voltage ramp as for inactive forced heating. It should be considered that too high ramp values may lead to excessive temperature gradients. The heater voltage during this initial phase is limited to C_V_EFC_MAX_LSH_UP_MAN_ACT. Resetting LC_LSH_UP_MAN_ACT[i] shall also reset LV_LSH_UP_MAN_ACT[i]. If T_POW_RISE_LSH_UP[i] exceeds the threshold C_T_MAX_CDN_LSH_UP_MAN_ACT the state machine shall change to state LSH_POW_CTL.

In the state LSH_POW_CTL while forced heating is active the element temperature shall be controlled in open loop. The corresponding effective heater voltage is derived from the same map IP_V_EFC_CTL_LSH_UP as for inactive forced heating, reduced by the factor C_FAC_V_EFC_LSH_UP_MAN_ACT. If forced heating is activated the lambda sensor protection states LSH_VB_PROT and LSH_TEMP_PROT may be reached. Should the corresponding conditions no longer be met, the state LSH_POW_RISE shall be re-entered.

Application conditions:

Activation:

At any engine operating state.

Deactivation:

-

Time recurrence:

The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms.

The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms.

Initialisation:

The following variable initialisation shall take place at LV_IGK = 0→1:

STATE_LSH_UP[i] = LSH_OFF
T_POW_RISE_LSH_UP[i] = 0
T_V_EFC_TOL_LSH_UP[i] = 0
T_V_EFC_LIM_LSH_UP[i] = 0
LSHPWM_UP[i] = 0
V_EFC_CTL_P_LSH_UP[i] = 0
V_EFC_CTL_I_LSH_UP[i] = 0
V_EFC_CTL_ADD_LSH_UP[i] = 0
V_EFC_LSH_UP[i] = 0
V_EFC_CLC_LSH_UP[i] = 0
LV_LSH_CTL_CLL_LSH_UP[i] = 0
LV_LSH_UP_MAN_ACT[i] = 0
LV_V_EFC_LIM_BOL_LSH_UP[i] = 0
LV_V_EFC_LIM_TOL_LSH_UP[i] = 0
LV_V_EFC_LIM_MAX_LSH_UP[i] = 0
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0
TTIP_MES_DIF_LS_UP[i] = 0

At reset:

ACTION_INFR_SetPwmLshUp(

IN i

IN LSHPWM_UP[i])

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_UP[i] & LV_INH_LSH_CTL_CLL_LSH_UP[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater closed loop control function respectively

Formula section:

The following formula shall be evaluated before the state machine is calculated:

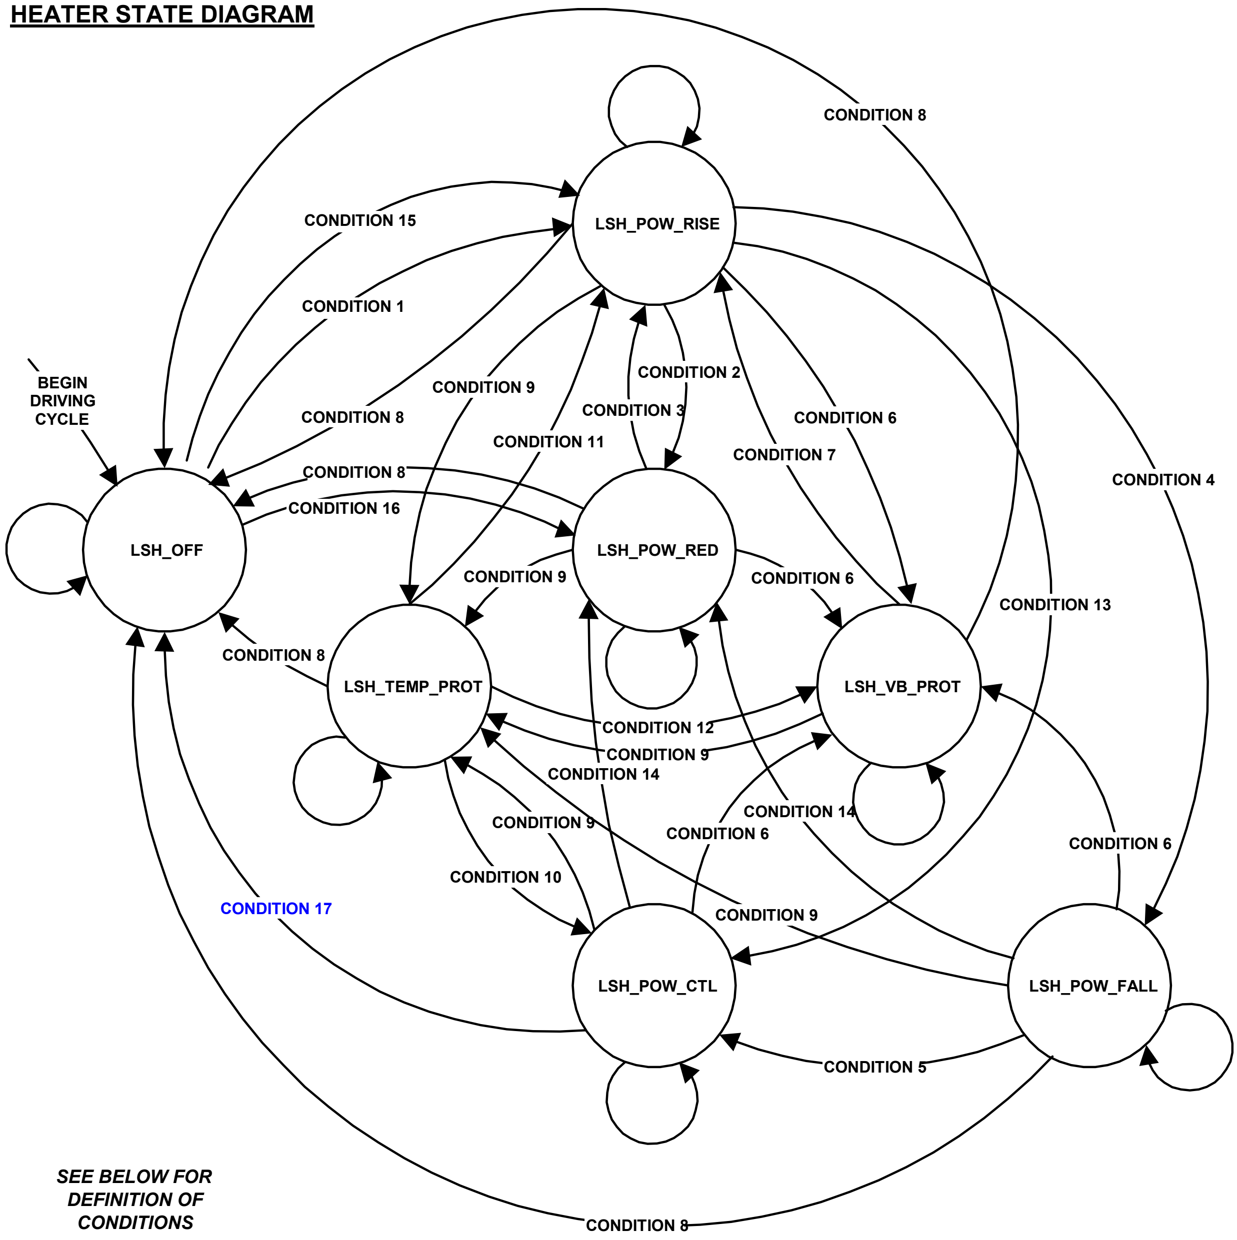
If LC_LSH_UP_MAN_ACT[i] = 1→0
then LV_LSH_UP_MAN_ACT[i] = 0
endif

16.19.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

HEATER STATE DIAGRAM



SEE BELOW FOR DEFINITION OF CONDITIONS

Figure 2: Heater management state diagram

STATE_LSH_UP[i] "LSH_OFF"

Actions:

T_POW_RISE_LSH_UP[i] = 0
T_V_EFC_TOL_LSH_UP[i] = 0
T_V_EFC_LIM_LSH_UP[i] = 0
V_EFC_CTL_P_LSH_UP[i] = 0
V_EFC_CTL_I_LSH_UP[i] = 0
V_EFC_CTL_ADD_LSH_UP[i] = 0
V_EFC_LSH_UP[i] = 0
V_EFC_CLC_LSH_UP[i] = 0
LV_LSH_CTL_CLL_LSH_UP[i] = 0
LV_LSH_UP_MAN_ACT[i] = 0
LV_V_EFC_LIM_BOL_LSH_UP[i] = 0
LV_V_EFC_LIM_TOL_LSH_UP[i] = 0
LV_V_EFC_LIM_MAX_LSH_UP[i] = 0
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0
TTIP_MES_DIF_LS_UP[i] = 0

Note: The above listed actions must be carried out at least once when the state has been entered for the first time or from any other state!

Condition 1:"LSH_OFF to LSH_POW_RISE"

LV_ST_END = 1 **&**
LV_INH_LSH_UP[i] = 0 **&**
(LV_TEMP_DEW_LS_UP[i] = 1 **or**
LC_TEMP_DEW_LSH_UP = 0)

Transition actions:

V_EFC_CLC_LSH_UP[i] = IP_V_EFC_INI_LSH_UP (TEMP_INI_LS_UP[i])
Timer T_POW_RISE_LSH_UP[i] shall be started
STATE_LSH_UP[i] = LSH_POW_RISE

Condition 16:"LSH_OFF to LSH_POW_RED"

LV_ST_END = 1 **&**
LV_INH_LSH_UP[i] = 0 **&**
LV_TEMP_DEW_LS_UP[i] = 0 **&**
LC_TEMP_DEW_LSH_UP = 1

Transition actions:

V_EFC_CLC_LSH_UP[i] = C_V_EFC_RED_LSH_UP

Condition 15: Forced transition "LSH_OFF to LSH_POW_RISE" before engine start.

LV_ES = 1 **&** LC_LSH_UP_MAN_ACT[i] = 0→1

Transition actions:

V_EFC_CLC_LSH_UP[i] = C_V_EFC_INI_LSH_UP_MAN_ACT
Timer T_POW_RISE_LSH_UP[i] shall be started
STATE_LSH_UP[i] = LSH_POW_RISE
LV_LSH_UP_MAN_ACT[i] = 1

STATE_LSH_UP[i] "LSH_POW_RISE"

Actions:

```
If      LV_LSH_UP_MAN_ACT[i] = 1 & LV_ST_END = 0
then    $V\_EFC\_CLC\_LSH\_UP[i]_{N} = MIN(V\_EFC\_CLC\_LSH\_UP[i]_{N-1} + C\_V\_EFC\_INC\_LSH\_UP * 100\ ms, C\_V\_EFC\_MAX\_LSH\_UP\_MAN\_ACT)$
else    $V\_EFC\_CLC\_LSH\_UP[i]_{N} = V\_EFC\_CLC\_LSH\_UP[i]_{N-1} + C\_V\_EFC\_INC\_LSH\_UP * 100\ ms$
endif
```

Note: See section "General oxygen sensor voltage protection" for notes on limiting the applied heater voltage.

Condition 8:"LSH_POW_RISE to LSH_OFF"

(LV_ST_END = 0 **&** LV_LSH_UP_MAN_ACT[i] = 0) **or** LV_INH_LSH_UP[i] = 1
Transition actions:

STATE_LSH_UP[i] = LSH_OFF
V_EFC_LSH_UP[i] = 0

Condition 9:"LSH_POW_RISE to LSH_TEMP_PROT"

TEG_DYN_LS_UP[i] > C_TEG_DYN_MAX_LSH_UP **&**
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0

Transition actions:

STATE_LSH_UP[i] = LSH_TEMP_PROT

Condition 6:"LSH_POW_RISE to LSH_VB_PROT"

LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 1

Transition actions:

STATE_LSH_UP[i] = LSH_VB_PROT

Condition 2:"LSH_POW_RISE to LSH_POW_RED"

(T_POW_RISE_LSH_UP[i] ≥ IP_T_TEMP_THD_LSH_UP (TEMP_INI_LS_UP[i]) **&**
LV_TEMP_DEW_LS_UP[i] = 0) **&** LV_LSH_UP_MAN_ACT[i] = 0

Transition actions:

STATE_LSH_UP[i] = LSH_POW_RED

Condition 13:"LSH_POW_RISE to LSH_POW_CTL"

(LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0 **&**
LV_V_REF_VLD_R_IT_LS_UP[i] = 1 **&**
TTIP_MES_LS_UP[i] ≥ C_TTIP_SP_LS_UP[i] - ID_TTIP_SP_DIF_LSH_UP **&**
LV_TTIP_MES_VLD_LS_UP[i] = 1) **or**
LV_LS_UP_READY_CDN[i] = 1 **or**
(LV_LSH_UP_MAN_ACT[i] = 1 **&**
T_POW_RISE_LSH_UP[i] ≥ C_T_MAX_CDN_LSH_UP_MAN_ACT)

Transition actions:

Stop timer T_POW_RISE_LSH_UP[i] and freeze value
STATE_LSH_UP[i] = LSH_POW_CTL

<u>Condition 4</u>:"LSH_POW_RISE to LSH_POW_FALL"

((LV_INH_LSH_CTL_CLL_LSH_UP[i] = 1 **or**
LV_V_REF_VLD_R_IT_LS_UP[i] = 0) **&**
T_POW_RISE_LSH_UP[i] ≥ C_T_MAX_POW_RISE_LSH_UP +
IP_T_TEMP_THD_LSH_UP (TEMP_INI_LS_UP[i])) **&** LV_LSH_UP_MAN_ACT[i] = 0

Transition actions:

Stop timer T_POW_RISE_LSH_UP[i] and freeze value
STATE_LSH_UP[i] = LSH_POW_FALL

STATE_LSH_UP[i] "LSH_POW_RED"

Actions:

V_EFC_CLC_LSH_UP[i] = C_V_EFC_RED_LSH_UP

<u>Condition 8</u>:"LSH_POW_RED to LSH_OFF"

(LV_ST_END = 0 **&** LV_LSH_UP_MAN_ACT[i] = 0) **or** LV_INH_LSH_UP[i] = 1

Transition actions:

STATE_LSH_UP[i] = LSH_OFF
V_EFC_LSH_UP[i] = 0

<u>Condition 9</u>:"LSH_POW_RED to LSH_TEMP_PROT"

TEG_DYN_LS_UP[i] > C_TEG_DYN_MAX_LSH_UP **&**
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0

Transition actions:

STATE_LSH_UP[i] = LSH_TEMP_PROT

<u>Condition 6</u>:"LSH_POW_RED to LSH_VB_PROT"

LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 1

Transition actions:

STATE_LSH_UP[i] = LSH_VB_PROT

<u>Condition 3</u>:"LSH_POW_RED to LSH_POW_RISE"

LV_TEMP_DEW_LS_UP[i] = 1

Transition actions:

V_EFC_CLC_LSH_UP[i] = IP_V_EFC_INI_LSH_UP (TEMP_INI_LS_UP[i]) *(same value as at start)* + C_V_EFC_STEP_LSH_UP
Re-initialise timer T_POW_RISE_LSH_UP[i] with IP_T_TEMP_THD_LSH_UP (TEMP_INI_LS_UP[i]) *(same value as at start)*
STATE_LSH_UP[i] = LSH_POW_RISE

Note: See section "General oxygen sensor voltage protection" for notes on limiting the applied heater voltage. The function shall prevent the effective heater voltage from becoming negative by limiting to 0 where necessary.

STATE_LSH_UP[i] "LSH_POW_FALL"

Actions:

$V\_EFC\_CLC\_LSH\_UP[i]_N = V\_EFC\_CLC\_LSH\_UP[i]_{N-1} - C\_V\_EFC\_DEC\_LSH\_UP * 100$ ms

Note: See section “General oxygen sensor voltage protection” for notes on limiting the applied heater voltage. The function shall prevent the effective heater voltage from becoming negative by limiting to 0 where necessary.

Condition 8:“LSH_POW_FALL to LSH_OFF”

(LV_ST_END = 0 **&** LV_LSH_UP_MAN_ACT[i] = 0) **or** LV_INH_LSH_UP[i] = 1

Transition actions:

STATE_LSH_UP[i] = LSH_OFF
V_EFC_LSH_UP[i] = 0

Condition 9:“LSH_POW_FALL to LSH_TEMP_PROT”

TEG_DYN_LS_UP[i] > C_TEG_DYN_MAX_LSH_UP **&**
LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 0

Transition actions:

STATE_LSH_UP[i] = LSH_TEMP_PROT

Condition 6:“LSH_POW_FALL to LSH_VB_PROT”

LV_V_EFC_LIM_PROT_VB_LSH_UP[i] = 1

Transition actions:

STATE_LSH_UP[i] = LSH_VB_PROT

Condition 14:“LSH_POW_FALL to LSH_POW_RED”

LV_TEMP_DEW_LS_UP[i] = 0

Transition actions:

T_V_EFC_TOL_LSH_UP[i] = 0
T_V_EFC_LIM_LSH_UP[i] = 0
V_EFC_CTL_P_LSH_UP[i] = 0
V_EFC_CTL_I_LSH_UP[i] = 0
V_EFC_CTL_ADD_LSH_UP[i] = 0
LV_LSH_CTL_CLL_LSH_UP[i] = 0
LV_V_EFC_LIM_BOL_LSH_UP[i] = 0
LV_V_EFC_LIM_TOL_LSH_UP[i] = 0
LV_V_EFC_LIM_MAX_LSH_UP[i] = 0
TTIP_MES_DIF_LS_UP[i] = 0
STATE_LSH_UP[i] = LSH_POW_RED

Condition 5:“LSH_POW_FALL to LSH_POW_CTL”

For Bank 1; i = 1

V_EFC_LSH_UP[i] ≤ IP_V_EFC_CTL_LSH_UP (N_32, TEG_DYN_LS_UP[i])

For Bank 2; i = 2

V_EFC_LSH_UP[i] ≤ IP_V_EFC_CTL_LSH_UP (N_32, TEG_DYN_LS_UP[i]) *
IP_FAC_V_EFC_TEG_LSH_UP

Transition actions:

STATE_LSH_UP[i] = LSH_POW_CTL

STATE_LSH_UP[i] “LSH_POW_CTL”

Actions:

Determine deviation between desired operating temperature and measured temperature:

TTIP_MES_DIF_LS_UP[i] = C_TTIP_SP_LS_UP[i] - TTIP_MES_LS_UP[i]

Note: TTIP_MES_DIF_LS_UP[i] shall be computed in both open loop and closed loop control modes.

Determine whether closed loop control permitted, if not revert to open loop control:

```
If   (LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0) &
     (LV_V_REF_VLD_R_IT_LS_UP[i] = 1)
then Closed loop control:
         LV_LSH_CTL_CLL_LSH_UP[i] = 1
         Case A: Closed loop control
else Open loop control:
         LV_LSH_CTL_CLL_LSH_UP[i] = 0

         PI controller shall be re-initialised, i.e.:
         V_EFC_CTL_P_LSH_UP[i] = 0
         V_EFC_CTL_I_LSH_UP[i] = 0
         V_EFC_CTL_ADD_LSH_UP[i] = 0
endif.
```

***Case A**: Closed loop control:*

Determine conditions for computation of closed loop control variables:

```
If   (LC_LSH_CTL_CLL_INH_LSH_UP[i] = 1) or
     (LV_TTIP_MES_VLD_LS_UP[i] = 0)
then General suspension and re-initialisation of closed loop control computation, i.e.:
         V_EFC_CTL_ADD_LSH_UP[i] = 0
         V_EFC_CTL_P_LSH_UP[i] = 0
         V_EFC_CTL_I_LSH_UP[i] = 0
else Normal closed loop control computation:
         Case B: Closed loop control & Not generally suspended:
endif.
```

***End Case A**: Closed loop control:*

***Case B**: Closed loop control & Not generally suspended:*

```
If   (TTIP_MES_LS_UP[i] > C_TTIP_SP_LS_UP[i])    i.e. Temperature difference negative
then     Compute I terms of controller:
         V_EFC_CTL_I_LSH_UP_TMP[i]$_{N}$ = V_EFC_CTL_I_LSH_UP[i]$_{N-1}$ +
         TTIP_MES_DIF_LS_UP[i] *
         IP_FAC_NEG_CTL_I_LSH_UP (N_32, TEG_DYN_LS_UP[i])*
         C_FAC_CTL_I_LSH_UP
         If      ( | TTIP_MES_DIF_LS_UP[i] | ≥ C_TTIP_DIF_MIN_CTL_P_LS_UP)
         then Compute P term of controller:
```

```
                V_EFC_CTL_P_LSH_UP_TMP[i] = TTIP_MES_DIF_LS_UP[i] *
                IP_FAC_NEG_CTL_P_LSH_UP (N_32, TEG_DYN_LS_UP[i])*
                C_FAC_CTL_P_LSH_UP
        else    V_EFC_CTL_P_LSH_UP_TMP[i] = 0
        endif
        if      (LV_V_EFC_LIM_BOL_LSH_UP[i] = 0) i.e. no lower limiting active
        then    V_EFC_CTL_I_LSH_UP[i]_N = V_EFC_CTL_I_LSH_UP_TMP[i]
                V_EFC_CTL_P_LSH_UP[i]_N = V_EFC_CTL_P_LSH_UP_TMP[i]
        else    V_EFC_CTL_I_LSH_UP[i]_N = MAX(V_EFC_CTL_I_LSH_UP[i]_N-1 ,
                                              V_EFC_CTL_I_LSH_UP_TMP[i])

        endif
endif
```

Note: In cases where the effective heater voltage has been limited as shown by the state of the Boolean flag LV_V_EFC_LIM_BOL_LSH_UP[i], the controller shall only be permitted to increase the effective voltage. In the case of limiting via Boolean flags LV_V_EFC_LIM_TOL_LSH_UP[i] & LV_V_EFC_LIM_MAX_LSH_UP[i] the closed loop control shall only be permitted to decrease the effective heater voltage. In all other cases, the controller shall effectively be suspended, i.e. P & I terms shall remain unchanged but applied, until the applicable limitation is revoked. Upon revoking the limitation, the function shall resume to compute the P & I terms according to the conditions specified above.

Combine P and I terms:
V_EFC_CTL_ADD_LSH_UP[i] =
V_EFC_CTL_P_LSH_UP[i] + V_EFC_CTL_I_LSH_UP[i]

Note: Although variables V_EFC_CTL_P_LSH_UP[i] and V_EFC_CTL_I_LSH_UP[i] are defined as words, the summation shall be carried out as a 16 bit addition and the resultant 16 bit value converted to an 8 bit value, by taking the high byte, and placed in V_EFC_CTL_ADD_LSH_UP[i]. This shall prevent controller from stopping short of the target temperature.

End Case B: *Closed loop control; Not suspended:*

Compute effective heater voltage from open loop control and closed loop delta voltages:

If LV_LSH_UP_MAN_ACT[i] = 1 **&** LV_ST_END = 0

then V_EFC_CLC_LSH_UP[i] = IP_V_EFC_CTL_LSH_UP (N_32, TEG_DYN_LS_UP[i]) *
C_FAC_V_EFC_LSH_UP_MAN_ACT

else

For Bank 1; i = 1

            endif
endif.
ACTION_INFR_SetPwmLshUp(
                    IN      i
                    IN      LSHPWM_UP[i])
```

The value C_FAC_V_EFC_AS_LSH_UP is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. ≥ 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinderbanks.

i = 1 ... NC_CBK_EX_NR

Description:

The Boolean constant LC_LSH_UP[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_UP[i] shall be reset. When reset, LV_INH_LSH_UP[i] shall be set.

The Boolean flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall indicate whether closed loop heating shall be inhibited or not. Should either the Boolean constant LC_LSH_UP_CLL_CTL[i] be reset or one of several upstream sensor error bits be set then the Boolean inhibit flag LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be set (open loop heater control), otherwise LV_INH_LSH_CTL_CLL_LSH_UP[i] shall be reset (closed loop heater control permitted).

Application conditions:

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Recurrence: 100 ms

Initialisation: LV_INH_LSH_UP[i] = 0

LV_INH_LSH_CTL_CLL_LSH_UP[i] = 0

LSHPWM_EXT_LS_UP[i] = 0%

V_EFC_LSH_UP_MAN = C_V_EFC_MAN

TEMP_INI_LS_UP[i] = TEG_WALL_CAT_UP_MDL[i]

Input data:

LV_ST_END	LV_ES	LV_PUC	NC_CBK_EX_NR
VLS_DOWN[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

The function shall evaluate the oxygen sensor signal voltage and compute a number of resultant values that may be used by other functions. These values shall include:

1. Moving mean of sensor voltage first derivative, i.e. average signal gradient
2. Minimum value of moving mean of sensor voltage first derivative in lean phase
3. Absolute maximum of sensor voltage first derivative over defined number of previous samples, i.e. measure of sensor voltage stability
4. Moving mean value of lean sensor voltage
5. Moving mean value of rich sensor voltage.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank

Signal flow diagram:

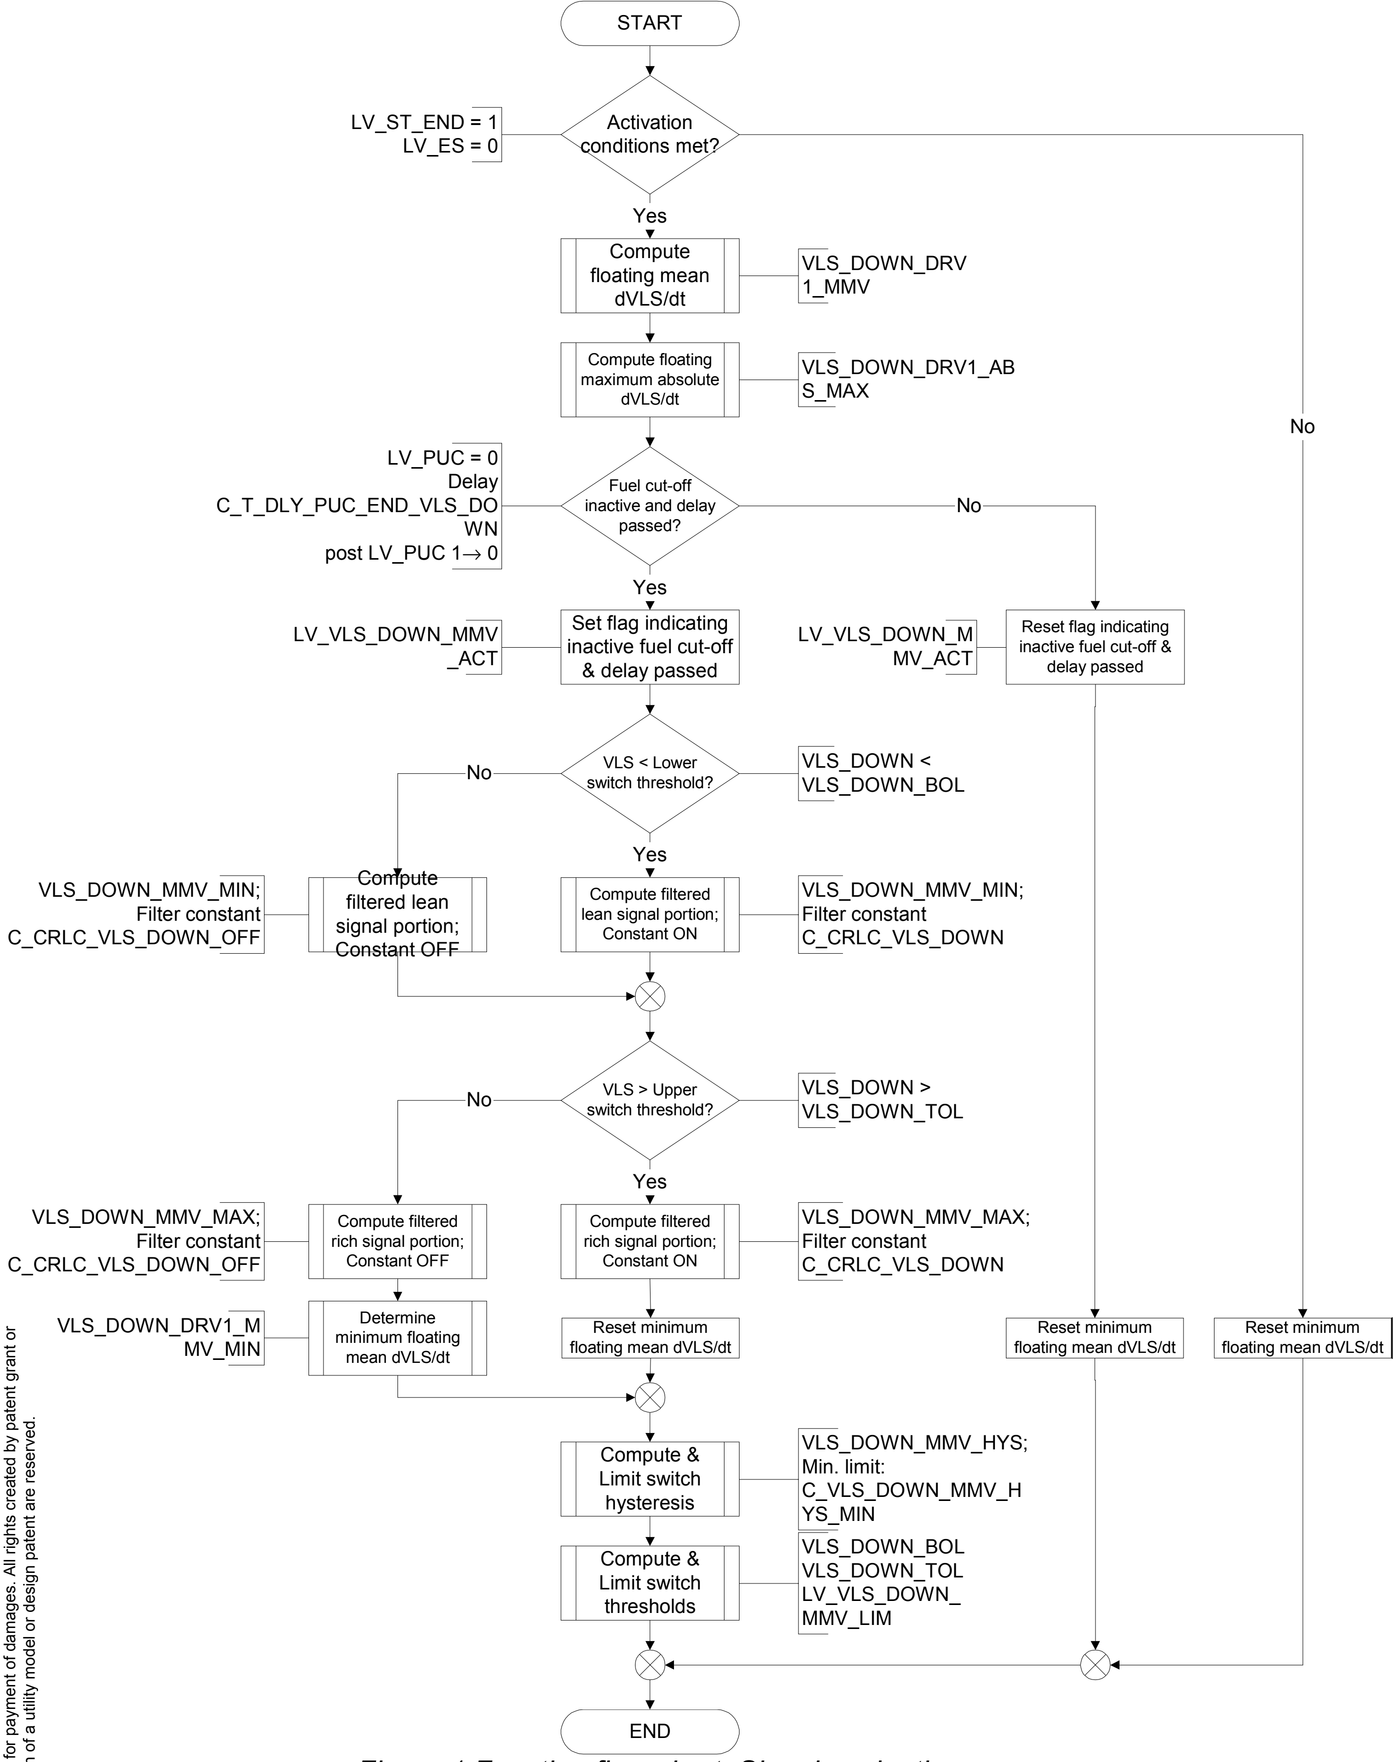

Figure 1 Function flow chart, Signal evaluation

Description:

The function shall evaluate the downstream oxygen sensor signal VLS_DOWN[i] and provide variables quantifying the signal characteristics: Floating mean gradient, Floating maximum signal deviation between samples, Filtered mean rich signal voltage & Filtered mean lean signal voltage (voltage will deviate from stable level signal with ageing of the catalyst). This shall be carried out as follows:

The function shall be activated should the engine state transition out of start (LV_ST_END = 1) and shall be deactivated should the engine stop state (LV_ES = 1) be entered.

Once the activation conditions have been met the function may be described in the following blocks:

1. Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]: The moving mean value of oxygen sensor signal voltage first derivative VLS_DOWN_DRV1_MMV[i] shall be computed by averaging the last differences between consecutive VLS_DOWN[i] samples, i.e. the most current difference (VLS_DOWN$[i]_N$ - VLS_DOWN$[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal gradient.

2. Computation of absolute maximum of first derivative VLS_DOWN_DRV1_ABS_MAX[i]: The absolute maximum of the oxygen sensor voltage first derivative VLS_DOWN_DRV1_ABS_MAX[i] shall be computed by taking the maximum of the absolute values of the last differences between consecutive VLS_DOWN[i] samples, i.e. the most current difference (VLS_DOWN$[i]_N$ - VLS_DOWN$[i]_{N-1}$) and the previous 5 differences. This shall indicate a measure for the signal stability.

3. Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]: The computation of the moving mean value of lean and rich sensor voltages, associated switch thresholds and switch hysteresis shall only be carried out when the overrun fuel cut-off flag is reset (LV_PUC = 0) and the time C_T_DLY_PUC_END_VLS_DOWN has passed since the deactivation of the last occurring engine state PUC (i.e. LV_PUC 1 → 0). The lean and rich mean signal voltages shall be implemented by use of first order low pass filtering and floating switching thresholds. For example:

Should the VLS_DOWN[i] signal exceeds the threshold VLS_DOWN_TOL[i], the rich mean signal voltage VLS_DOWN_MMV_MAX[i] shall be computed by filtering the VLS_DOWN[i] signal with filter constant C_CRLC_VLS_DOWN. This shall continue until threshold VLS_DOWN_TOL[i] is no longer exceeded, after which VLS_DOWN_MMV_MAX[i] shall be computed by filtering with filter constant C_CRLC_VLS_DOWN_OFF. This constant is much smaller than C_CRLC_VLS_DOWN and the effect is to cause the VLS_DOWN_MMV_MAX[i] to follow the rich peaks. The OFF constant shall permit the VLS_DOWN_MMV_MAX[i] signal to follow the VLS_DOWN[i] signal for sudden decreases in signal amplitude, i.e. maximum VLS_DOWN[i] lower than VLS_DOWN_TOL[i].

The same procedure shall be carried out for the computation of VLS_DOWN_MMV_MIN[i], i.e. where VLS_DOWN[i] falls below VLS_DOWN_BOL[i], VLS_DOWN_MMV_MIN[i] shall be computed with filter constant C_CRLC_VLS_DOWN and where VLS_DOWN[i] no longer falls below VLS_DOWN_BOL[i], the filter constant C_CRLC_VLS_DOWN_OFF shall be used.

4. Determination of the minimum value of the moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]: The same conditions as for the computation of VLS_DOWN_MMV_xxx[i] shall apply. Should VLS_DOWN[i] fall below or equal VLS_DOWN_TOL[i], VLS_DOWN_DRV1_MMV_MIN$[i]_N$ shall be equal to the lower of VLS_DOWN_DRV1_MMV_MIN$[i]_{N-1}$ & VLS_DOWN_DRV1_MMV[i]. When VLS_DOWN[i]

exceeds VLS_DOWN_TOL[i], the LV_PUC condition in conjunction with delay C_T_DLY_PUC_END_VLS_DOWN is not met or the function is deactivated, VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.

5. Compute & limit switch hysteresis: The value of the hysteresis, VLS_DOWN_MMV_HYS[i], used to determine the switching thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be made proportional using factor C_FAC_VLS_DOWN_MMV_HYS to the oxygen sensor signal amplitude, as determined by taking the absolute difference of the moving mean lean / rich variables. The hysteresis shall also be limited so that it may not fall below the calibrateable threshold C_VLS_DOWN_MMV_HYS_MIN.

6. Compute & limit switch thresholds: The function shall limit the minimum amplitude of the difference between the moving mean lean / rich variables (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) to twice that of the switch hysteresis, VLS_DOWN_MMV_HYS[i].

Should the amplitude of the aforementioned difference fall below the said threshold, both the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be set to the average of the moving mean lean / rich variables, the moving mean lean / rich variables are recalculated based on the limited switching thresholds and hysteresis and the flag LV_VLS_DOWN_MMV_LIM[i] shall be set to indicate that switch threshold limiting is active.

Should no limiting be required, the switch thresholds VLS_DOWN_BOL[i] & VLS_DOWN_TOL[i] shall be calculated based on the switch hysteresis, moving mean lean variable and moving mean rich variable respectively. The flag LV_VLS_DOWN_MMV_LIM[i] shall be reset to indicate that no switch threshold limiting is being carried out.

The above blocks shall be cycled through once every function recurrence.

Application conditions:

Recurrence:

The function shall be carried out once every oxygen sensor acquisition, i.e. every 10 ms.

Initialisation:

The following initialisation shall be carried out after a RESET and upon leaving the engine state Engine Stop (LV_ES).

VLS_DOWN_MMV_MIN[i] = C_VLS_DOWN_INI_MIN
VLS_DOWN_MMV_MAX[i] = C_VLS_DOWN_INI_MAX
VLS_DOWN_BOL[i] = C_VLS_DOWN_INI_MAX
VLS_DOWN_TOL[i] = C_VLS_DOWN_INI_MIN
VLS_DOWN_MMV_HYS[i] = C_VLS_DOWN_MMV_HYS_MIN
LV_VLS_DOWN_MMV_LIM[i] = 0
LV_VLS_DOWN_MMV_ACT = 0
VLS_DOWN_DRV1_MMV[i] = 0
VLS_DOWN_DRV1_MMV_MIN[i] = 0
VLS_DOWN_DRV1_ABS_MAX[i] = 0

Buffer contents from which VLS_DOWN_DRV1_MMV[i] & VLS_DOWN_DRV1_ABS_MAX[i] computed = 0.

Activation:

If LV_ST_END = 1

then ***Function activated***

endif.

Deactivation:

```
If  LV_ST_END = 0
    then  Function deactivated
        VLS_DOWN_DRV1_MMV_MIN[i] = 0
endif.
```

Formula section:

The following function shall be carried out in the order listed and as indicated by the function flow chart:

Computation of moving mean of first derivative VLS_DOWN_DRV1_MMV[i]

$$\text{VLS\_DOWN\_DRV1\_MMV[i]} = \frac{\sum_{x=0}^{5}\left(\text{VLS\_DOWN[i]}_{N-x} - \text{VLS\_DOWN[i]}_{N-(x+1)}\right)}{6 * 10\text{ms}}$$

The above may be facilitated for example by use of a 6 value ring buffer. The most current difference, (VLS_DOWN[i]$_{N}$ - VLS_DOWN[i]$_{N-1}$), would overwrite the oldest difference in the buffer, (VLS_DOWN[i]$_{N-5}$ - VLS_DOWN[i]$_{N-6}$), and the average of the buffer contents recalculated.

Computation of absolute maximum of first derivative number of previous samples VLS_DOWN_DRV1_ABS_MAX[i]

$$\text{VLS\_DOWN\_DRV1\_ABS\_MAX[i]} = \text{MAXIMUM}\left|{}_{x=0}^{5}\left(\text{VLS\_DOWN[i]}_{N-x} - \text{VLS\_DOWN[i]}_{N-(x+1)}\right)\right|$$

The above may be facilitated for example by use of the same 6 value ring buffer, as proposed above for the computation of VLS_DOWN_DRV1_MMV[i]. The function would calculate the absolute values of the buffer contents and take the maximum of these values.

Computation of moving mean value of lean and rich sensor voltages, VLS_DOWN_MMV_xxx[i]

```
If  (LV_PUC = 0) &

    If  (VLS_DOWN[i] > VLS_DOWN_TOL[i])
    then  Compute moving mean rich signal, filter constant ON
          VLS_DOWN_DRV1_MMV_MIN[i] = 0
    else  Compute moving mean rich signal, filter constant OFF
          Determine minimum of moving mean of first derivative
    endif
    Compute & limit switch hysteresis
```

```
        Compute & limit switch thresholds
else    LV_VLS_DOWN_MMV_ACT = 0
        Reset timer used for delay C_T_DLY_PUC_END_VLS_DOWN
        VLS_DOWN_DRV1_MMV_MIN[i] = 0
endif.
```

Compute moving mean lean signal, filter constant ON

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

VLS_DOWN_MMV_MIN[i]$_N$ = VLS_DOWN_MMV_MIN[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN) +
VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN

Compute moving mean lean signal, filter constant OFF

The moving mean of the lean signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

VLS_DOWN_MMV_MIN[i]$_N$ = VLS_DOWN_MMV_MIN[i]$_{N-1}$ *
(1-C_CRLC_VLS_DOWN_OFF) +
VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN_OFF

Compute moving mean rich signal, filter constant ON

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN.

VLS_DOWN_MMV_MAX[i]$_N$ = VLS_DOWN_MMV_MAX[i]$_{N-1}$ * (1-C_CRLC_VLS_DOWN) +
VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN

Compute moving mean rich signal, filter constant OFF

The moving mean of the rich signal voltage shall be realised by use of a 1st order low pass digital filter with the filter constant C_CRLC_VLS_DOWN_OFF.

VLS_DOWN_MMV_MAX[i]$_N$ = VLS_DOWN_MMV_MAX[i]$_{N-1}$ *
(1-C_CRLC_VLS_DOWN_OFF) +
VLS_DOWN[i]$_N$ * C_CRLC_VLS_DOWN_OFF

Determine minimum of moving mean of first derivative VLS_DOWN_DRV1_MMV_MIN[i]

The determination of the minimum of VLS_DOWN_DRV1_MMV[i] shall take place when the condition VLS_DOWN[i] ≤ VLS_DOWN_TOL[i] has been met. In this case:

VLS_DOWN_DRV1_MMV_MIN[i] = MIN(VLS_DOWN_DRV1_MMV_MIN[i],
VLS_DOWN_DRV1_MMV[i])

Should the above condition no longer met, the LV_PUC with delay condition not be met or the initial activation conditions not be met then VLS_DOWN_DRV1_MMV_MIN[i] shall be reset to 0.

Compute & limit switch hysteresis

VLS_DOWN_MMV_HYS[i] = | (VLS_DOWN_MMV_MAX[i] - VLS_DOWN_MMV_MIN[i]) | *
C_FAC_VLS_DOWN_MMV_HYS

```
If    (VLS_DOWN_MMV_HYS[i] < C_VLS_DOWN_MMV_HYS_MIN)
then  VLS_DOWN_MMV_HYS[i] = C_VLS_DOWN_MMV_HYS_MIN
endif.
```

Compute & limit switch thresholds

```

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

The operative readiness of the downstream oxygen sensor(s) shall be determined by this function to allow other functions to act accordingly dependent upon the readiness.

Description:

The operative readiness shall only be determined for a downstream oxygen sensor which is not operatively ready. The oxygen sensor shall be set as inoperable after a ECU reset, in the state *Engine Stop*, when during PUC the MAF integral exceeds a calibrated threshold or when the dew point LV_TEMP_DEW_LS_DOWN[i] switches back to 0.

The operative readiness shall be determined by analysing the downstream oxygen sensor voltage (VLS_DOWN[i]) and determining whether the voltage has left a pre-determined voltage band after the lambda probe heater state machine has reached LSH_POW_CTL.

A second condition shall permit the forced operative readiness state, should the voltage level condition not be met, by assuming that when the modelled exhaust gas temperature at lambda probe position has reached a pre-determined threshold, that the downstream oxygen sensor is also at operating temperature and functioning. The forced readiness detection may additionally be delayed until dew point detection or even longer until the calibratable threshold C_T_MIN_TEMP_DEW_LS_DOWN has been reached, depending on its calibration.

Should the sensor's operative readiness be reset due to a sufficiently long fuel cut-off phase or reset of dew-point recognition a certain mass air flow integral threshold after leaving fuel cut-off shall be awaited until operability detection is started again. This shall ensure that the sensor heater has sufficient time to raise the temperature up to normal operating conditions prior to start of readiness detection in order to increase its reliability.

The operative readiness of the downstream oxygen sensor(s) shall be recorded in the variable LV_LS_DOWN_READY[i].

Application conditions:

Initialisation:

At reset: reset all variables to 0

Recurrence: T_SAMPLE = 100 ms

Activation: In all engine states

Formula section:

% only relevant for Y configurations with one downstream sensor and 1 NOx sensor

%SW-hint: The following if-then-else calculation can be done outside the for-loop, since calculation is independent of exhaust bank.

Import actions:

ACTION_INFR_SetPwmLshDown(IN <i>, IN <ducy>)
This action sets the lambda heater downstream driver

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

The goal of the heater control shall be to control the oxygen sensor heating such that the optimal operating temperature is reached in the shortest time possible. At the same time, the maximum permissible temperature gradient (possible damage to ceramic due to thermal stress), the possible occurrence of water splash under the dew point (possible damage to ceramic due to thermal shock) and the absolute maximum ratings specified for the sensor shall be taken into account. The function shall permit oxygen sensor heating under open loop control.

Signal flow:

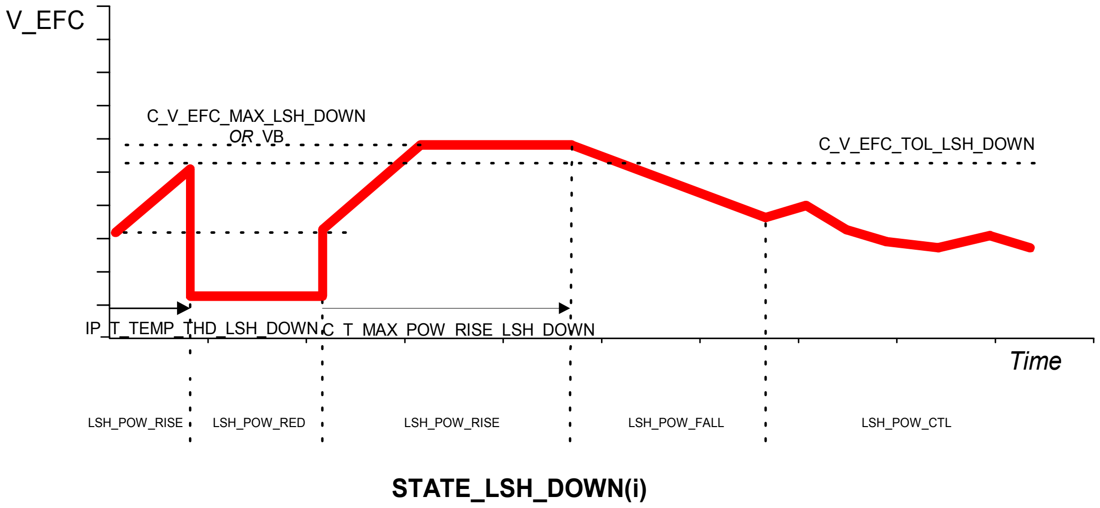

Figure 1: Course of effective heater voltage over time / state

Description:

The heater control shall be realised by use of a state machine. Each downstream oxygen sensor shall have its own state machine and each state machine shall run independently of the other.

The heater control shall be initialised to the LSH_OFF state at the start of a new driving cycle. Hence the oxygen sensor will not initially be electrically heated.

Heating shall commence should the activation conditions listed below be met. i.e. when the engine has transitioned from the start state (LV_ST_END = 1) and the heater management inhibit bit for the corresponding bank is not set (LV_INH_LSH_DOWN[i] = 0). The appropriate heater state shall change to LSH_POW_RISE and the initial value for the effective heater voltage shall be determined by obtaining the oxygen sensor temperature at start (TEMP_INI_LS_DOWN[i]) from input data. This shall then be used to obtain the appropriate effective heater starting voltage from map IP_V_EFC_INI_LSH_DOWN.

In the state LSH_POW_RISE, the effective heater voltage shall be incremented with the gradient of C_V_EFC_INC_LSH_DOWN.

The continuation of the heating gradient shall depend on whether the dew point at the sensor location has been determined to have been exceeded, i.e. the temperature of the inner manifold wall at the sensor location has exceeded the temperature threshold where water in the exhaust gas may condense, as determined by LV_TEMP_DEW_LS_DOWN[i].

Should the dew point not have been exceeded (LV_TEMP_DEW_LS_DOWN[i] = 0) but timer T_POW_RISE_LSH_DOWN[i] has equalled or exceeded IP_T_TEMP_THD_LSH_DOWN, it shall be assumed that condensed water splash at the oxygen sensor location may occur. In order to protect the oxygen sensor by keeping the temperature of the ceramic lower than the specified critical temperature, the heater power shall be reduced immediately by setting the effective heater voltage to C_V_EFC_RED_LSH_DOWN. In this case, the heater state shall be set to LSH_POW_RED.

The reduced heating state shall persist until the dew point in the exhaust gas system has been determined to have been exceeded, i.e. until LV_TEMP_DEW_LS_DOWN[i] = 1, at which point the heater state shall return to LSH_POW_RISE. The effective heater voltage shall be set to the same effective heater voltage as determined at start (IP_V_EFC_INI_LSH_DOWN), which may be modified by the calibration data C_V_EFC_STEP_LSH_DOWN, may be further incremented with a gradient of C_V_EFC_INC_LSH_DOWN without danger of damaging the oxygen sensor and the timer T_POW_RISE_LSH_DOWN[i] shall be reinitialised with the IP_T_TEMP_THD_LSH_DOWN determined at function start.

Should the initial exhaust gas temperature at start have been determined to exceed the dew point (LV_TEMP_DEW_LS_DOWN[i] = 1), the heater control shall not enter the reduced heater power state but continue to incrementally increase the heater power within the LSH_POW_RISE state.

Should T_POW_RISE_LSH_DOWN[i] be determined to have equalled or exceeded the value C_T_MAX_POW_RISE_LSH_DOWN (irrespective of the dew point having been exceeded or not), the heater state shall change to LSH_POW_FALL and the timer shall be frozen.

In the LSH_POW_FALL state, the effective heater voltage shall be reduced with a gradient of C_V_EFC_DEC_LSH_DOWN until such time that it falls below or equals the value set for the open loop control at the current engine operating point. For cylinder bank 1, this value is determined by map IP_V_EFC_CTL_LSH_DOWN alone. For cylinder bank 2, this value is determined by IP_V_EFC_CTL_LSH_DOWN * IP_FAC_V_EFC_TEG_LSH_DOWN. The latter factor shall be necessary to accommodate differences in heat transfer rates between cylinder banks at the oxygen sensor location, particularly for transversal mounted V6-engines. At such time the effective heater voltage falls below or equals the respective threshold, the heater state shall change to LSH_POW_CTL.

Should, however, the Boolean flag LV_TEMP_DEW_LS_DOWN[i] be reset whilst in the state LSH_POW_FALL, the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

The control of the effective heater voltage is carried out in open loop mode.

In the open loop heater control mode, the effective heater voltage shall be obtained from map IP_V_EFC_CTL_LSH_DOWN and is dependent upon the engine speed and the modelled exhaust gas temperature. For cylinder bank 2, an additional multiplicative factor (IP_FAC_V_EFC_TEG_LSH_DOWN) may be required for the reasons outlined above.

To the open loop control voltage a calibration system constant (C_V_EFC_AS_LSH_DOWN) can be added to permit a global change in the total effective heater voltage to be made. Thus the calculated effective heater voltage (V_EFC_CLC_LSH_DOWN[i]) shall be computed from the open loop value and the global correction value.

Furthermore should the sum of the components used to calculate the effective heater voltage be negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be set. This shall prevent the controller from decreasing the effective heater voltage further but not prevent it from increasing the voltage. When the sum of the components is no longer negative, LV_V_EFC_LIM_BOL_LSH_DOWN[i] shall be reset. Similarly, should either of the overvoltage limitation Boolean flags LV_V_EFC_LIM_TOL_LSH_DOWN[i] & LV_V_EFC_LIM_MAX_LSH_DOWN[i] be set, as described later, the controller shall be prevented from increasing the effective heater voltage further but not prevent it from decreasing the voltage. When the overvoltage flags are no longer set and the other applicable conditions are met, the controller shall resume normal operation.

Should, however, the Boolean flag LV_TEMP_DEW_LS_DOWN[i] be reset whilst in the state LSH_POW_CTL, then the open loop controller terms shall be reset, the Boolean flags to indicate open loop control and effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RED following the procedures outlined above.

Should at any time the battery voltage VB exceed the threshold C_VB_MAX_PROT_LSH_DOWN, as determined by the state of logical variable LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i], the oxygen sensor heater power shall be reduced by reducing the effective heater voltage used to calculate the driver duty cycle to C_V_EFC_PROT_VB_LSH_DOWN. The heater state shall change to LSH_VB_PROT on the next recurrence of the state machine and the effective heater voltage set to the aforementioned limit. This shall prevent damage to the sensor due to excessive heater voltages e.g. due to jump start from 24 V.

Should the battery voltage recover when in the state LSH_VB_PROT, as indicated by LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0, T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i] shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Short term voltage excursions shall cause the heater power to be limited but will only cause the state machine to change state should the voltage excursion persist until the next recurrence of the state machine. The state machine shall not be able to enter the LSH_VB_PROT state directly from LSH_OFF but shall be required to pass through LSH_POW_RISE.

The sensor shall also be protected from over-temperature. This shall be achieved by evaluating the value of the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] in all states other than LSH_OFF. Should the exhaust gas temperature exceed the threshold C_TEG_DYN_MAX_LSH_DOWN, the calculated effective heater voltage shall be reduced to 0, the state shall change to LSH_TEMP_PROT thus suspending open loop control, if active.

Should the exhaust gas temperature fall below the threshold, the state shall change dependent on the state active immediately prior to the over-temperature protection. If the state was LSH_POW_CTL, the state machine shall return to this state and the effective heater voltage shall take the new value as computed by the open loop control. If the state was any other than LSH_POW_CTL, the state shall change to LSH_POW_RISE. In this case T_POW_RISE_LSH_DOWN[i] shall be reset, V_EFC_LSH_DOWN[i] shall be initialised to IP_V_EFC_INI_LSH_DOWN calculated after the start, effective heater voltage limitation shall be reset and the heater control shall resume at state LSH_POW_RISE following the procedures outlined above.

Furthermore, in order to protect the sensor heater against long term high voltage stress it shall be necessary to limit the effective heater voltage should the value of V_EFC_CLC_LSH_DOWN[i] equal or exceed the threshold C_V_EFC_TOL_LSH_DOWN.

In this instance, the timer T_V_EFC_TOL_LSH_DOWN[i] shall be started. Should the overvoltage condition persist, such that this timer equals or exceeds the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN, timer T_V_EFC_LIM_LSH_DOWN[i] shall be started and the Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set. This flag shall prevent the controller from increasing effective the voltage further. If however the value of V_EFC_CLC_LSH_DOWN[i] should fall below the threshold C_V_EFC_TOL_LSH_DOWN at any time, LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be reset.

Once timer T_V_EFC_LIM_LSH_DOWN[i] has been started, Boolean flag LV_V_EFC_LIM_TOL_LSH_DOWN[i] shall be set or reset depending on the value of V_EFC_CLC_LSH_DOWN[i]. Once the timer T_V_EFC_LIM_LSH_DOWN[i] equals or exceeds threshold C_T_MAX_V_EFC_LIM_LSH_DOWN, both timers shall be reset and timer T_V_EFC_TOL_LSH_DOWN[i] must exceed the threshold C_T_MAX_V_EFC_TOL_LSH_DOWN again in order to permit further limiting to take place.

To prevent damage to the sensor, V_EFC_CLC_LSH_DOWN[i] shall not be permitted to exceed the lower of the values C_V_EFC_MAX_LSH_DOWN, C_V_EFC_MAX_ST_LSH_DOWN or VB dependent on the value of T_POW_RISE_LSH_DOWN[i].

If T_POW_RISE_LSH_DOWN[i] equals or exceeds the constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN or conditions regarding T_AST and STATE_LSH_DOWN[i] then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

If T_POW_RISE_LSH_DOWN[i] is lower then constant C_T_MAX_V_EFC_MAX_ST_LSH_DOWN then V_EFC_CLC_LSH_DOWN[i] shall be checked against VB & C_V_EFC_MAX_ST_LSH_DOWN. If either of the values is exceeded then Boolean flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be set and V_EFC_CLC_LSH_DOWN[i] limited to the lower of VB & C_V_EFC_MAX_ST_LSH_DOWN otherwise LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall be reset.

The flag LV_V_EFC_LIM_MAX_LSH_DOWN[i] shall prevent the controller from increasing effective the voltage further and permit the final effective heater voltage to be limited, as described later.

Should timer T_V_EFC_LIM_LSH_DOWN[i] be unequal to zero, i.e. overvoltage no longer tolerated as it has been present for certain time, V_EFC_LSH_DOWN[i] shall be the lower of the values V_EFC_CLC_LSH_DOWN[i] & C_V_EFC_LIM_LSH_DOWN otherwise V_EFC_LSH_DOWN[i] shall be set to V_EFC_CLC_LSH_DOWN[i].

Once the effective heater voltage has been determined throughout the various heater states other than LSH_OFF, it shall be used to compute the PWM duty cycle (LSHPWM_DOWN[i]) that shall control the appropriate heater driver. The heater power shall be corrected to take into account deviations in the measured battery voltage and limited to the range bounded by NC_LSHPWM_TOL_LSH_DOWN & NC_LSHPWM_BOL_LSH_DOWN. The evaluation of excess battery voltage shall be determined at the same recurrence as the computation of the duty cycle as described above. The PWM value may also be modified by use of constant C_FAC_V_EFC_AS_LSH_DOWN.

Should at any time an inhibit flag be set (LV_INH_LSH_DOWN[i] = 1), the corresponding oxygen sensor heater shall be switched off and the STATE_LSH_DOWN[i] set to LSH_OFF. This shall allow project specific application conditions to turn off oxygen sensor heating according to project philosophy. Should the heater function be inhibited, then the PWM duty cycle shall be set to input LSHPWM_EXT_LS_DOWN[i]. On a transition of the inhibit bit LV_INH_LSH_DOWN[i] from 1 → 0, the heater function shall start from anew.

Application conditions:

Activation:

At any engine operting state.

Deactivation:

-

Time recurrence:

The state machine, sensor protection and effective heater voltage definition shall be carried out once every 100 ms. T_SAMPLE_1 = 100ms

The determination of the oxygen sensor heater driver duty cycle and associated excessive battery voltage protection shall be carried out once every 10 ms. T_SAMPLE_2 = 10ms

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle:

STATE_LSH_DOWN[i] = LSH_OFF

T_POW_RISE_LSH_DOWN[i] = 0

T_V_EFC_TOL_LSH_DOWN[i] = 0

T_V_EFC_LIM_LSH_DOWN[i] = 0

LSHPWM_DOWN[i] = 0

V_EFC_LSH_DOWN[i] = 0

V_EFC_CLC_LSH_DOWN[i] = 0

LV_V_EFC_LIM_BOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_TOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_MAX_LSH_DOWN[i] = 0

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

At reset:

ACTION_INFR_SetPwmLshDown(

IN i

IN LSHPWM_DOWN[i])

NOTE: Projects not making use of the inhibit flags LV_INH_LSH_DOWN[i] shall ensure that they are initialised with and remain 0, thus never disabling the oxygen sensor heater function or thus never disabling the oxygen sensor heater open loop control function respectively

Formula section:

16.22.1 Heater management state machine

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

Note: The priorities of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropriate state as described below.

HEATER STATE DIAGRAM

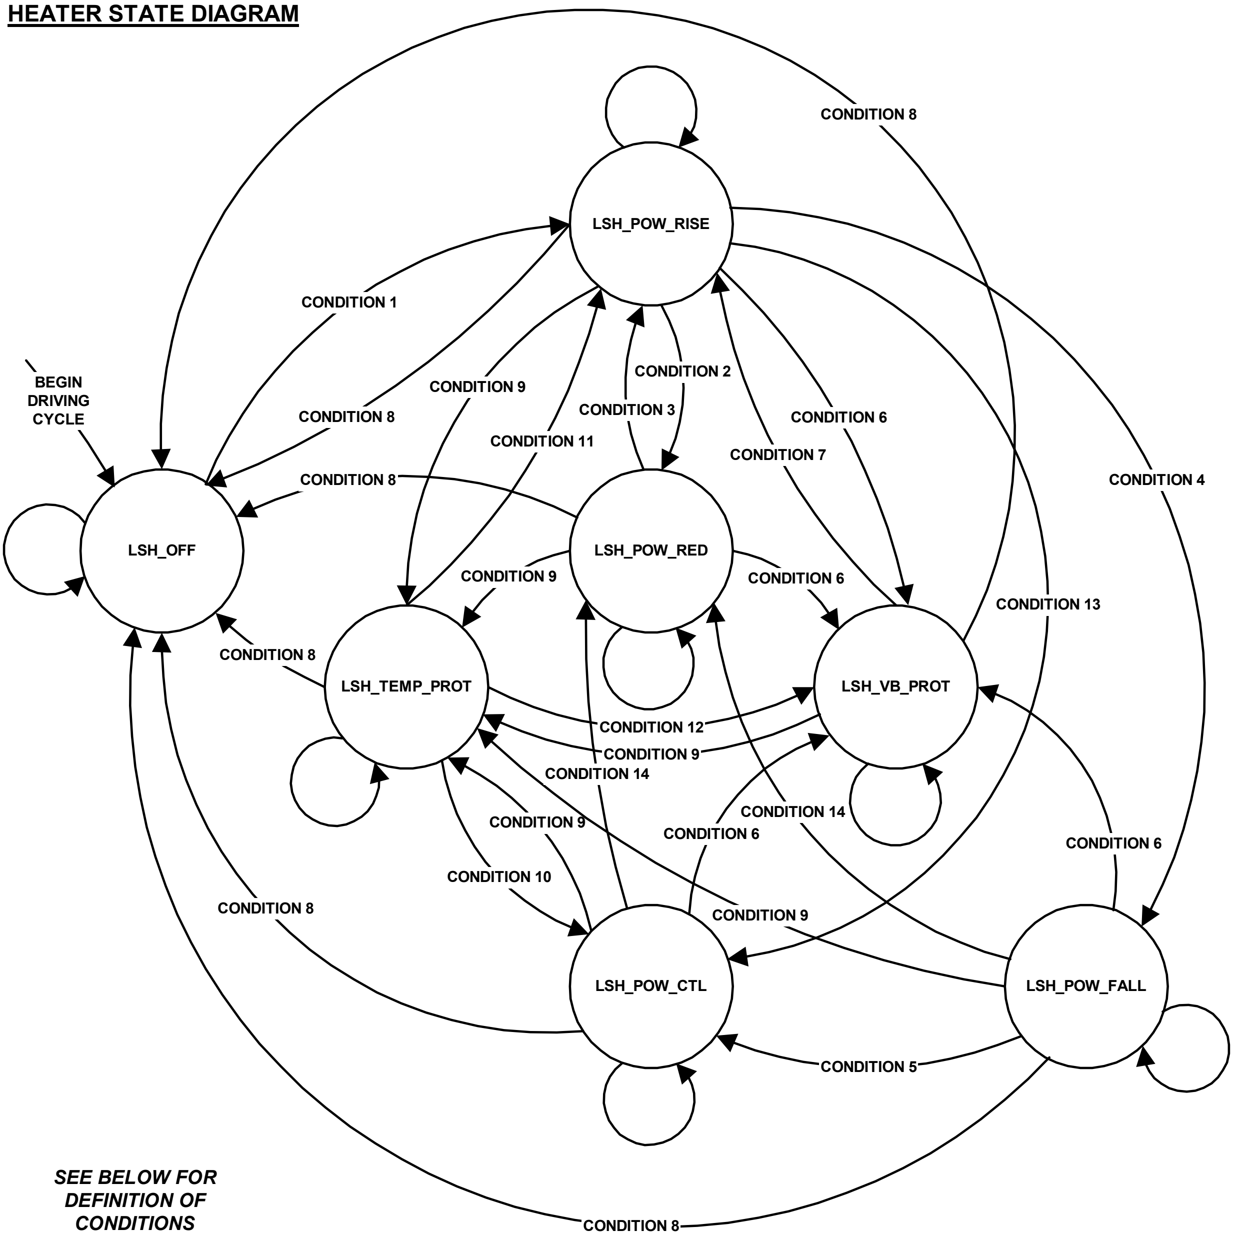

Figure 2: Heater management state diagram

STATE_LSH_DOWN[i] "LSH_OFF"

Actions:

T_POW_RISE_LSH_DOWN[i] = 0

T_V_EFC_TOL_LSH_DOWN[i] = 0

T_V_EFC_LIM_LSH_DOWN[i] = 0

V_EFC_LSH_DOWN[i] = 0

V_EFC_CLC_LSH_DOWN[i] = 0

LV_V_EFC_LIM_BOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_TOL_LSH_DOWN[i] = 0

LV_V_EFC_LIM_MAX_LSH_DOWN[i] = 0

LV_V_EFC_LIM_PROT_VB_LSH_DOWN[i] = 0

Note: The above listed actions must be carried out at least once when the state has been entered for the first time or from any other state!

<u>Condition </u>1:“LSH_OFF to LSH_POW_RISE”

LV_ST_END = 1 **&**

LV_INH_LSH_DOWN[i] = 0

Transition actions:

V_EFC_CLC_LSH_DOWN[i] = IP_V_EFC_INI_LSH_DOWN (TEMP_INI_LS_DOWN[i])

Timer T_POW_RISE_LSH_DOWN[i] shall be started

STATE_LSH_DOWN[i] = LSH_POW_RISE

STATE_LSH_DOWN[i] “LSH_POW_RISE”

Actions:

V_EFC_CLC_LSH_DOWN[i]$_{N}$ = V_EFC_CLC_LSH_DOWN[i]$_{N-1}$ + C_V_EFC_INC_LSH_DOWN

T_SAMPLE_1

Increment timer T_POW_RISE_LSH_DOWN[i]

Note: See section “Oxygen sensor heater voltage protection” for notes on limiting the applied heater voltage.

<u>Condition 8</u>:“LSH_POW_RISE to LSH_OFF”

LV_ST_END = 0 **or** LV_INH_LSH_DOWN[i] = 1

Transition actions:

STATE_LSH_DOWN[i] = LSH_OFF

                        endif
                endif
        endif
endif.
ACTION_INFR_SetPwmLshDown(
                IN      i
                IN      LSHPWM_DOWN[i])
```

The value C_FAC_V_EFC_AS_LSH_DOWN is a correction signal generated in the application system.

NOTE: The recurrence of the heater driving duty cycle shall occur at the same recurrence as the Vbatt acquisition. This shall prevent short duration voltage drop-outs during engine start

from causing long duration Vbatt corrections being made where the Vbatt has since recovered. This may otherwise cause excessive current to flow in the heater driver.

The computation of the duty cycle shall be checked to ensure that the result remains positive (i.e. $\geq$ 0) at all times and that now under- or overflows are caused by the values of the calibration system constants.

The multiplication of the corrected voltage ratio by 100 to obtain a unit of percent (%) may not necessarily be implemented in the SW but in the data bank definition of the variables.

LV_LSHPWM_DOWN_EXT_ADJ[NC_CBK_EX_NR]	LSHPWM_DOWN_EXT_ADJ[NC_CBK_EX_NR]	NC_LSHPWM_BOL_LSH_DOWN	

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The Boolean constant LC_LSH_DOWN[i] shall permit the appropriate oxygen sensor to be heated. When set, the Boolean inhibit flag LV_INH_LSH_DOWN[i] shall be reset. When reset, LV_INH_LSH_DOWN[i] shall be set.

The oxygen sensor temperature at start TEMP_INI_LS_DOWN[i] shall be obtained from the input variable TEG_WALL_CAT_DOWN_MDL[i] (this is the exhaust duct temperature downstream) every time an engine start is finished.

All actions beside the initialisation routine are done only, if the variant ‘with monitor lambda sensors’ is on the table.

Application conditions:

Activation:	LV_IGK = 1
Deactivation:	LV_IGK = 0
Recurrence:	1 s

Initialisation:

The following variable initialisation shall take place at the beginning of a new driving cycle:

LV_INH_LSH_DOWN[i] = 0
LSHPWM_EXT_LS_DOWN[i] = 0
TEMP_INI_LS_DOWN[i] = 0 °C

Formula section:

```
IF      LV_LSHPWM_DOWN_EXT_ADJ[i] = 0
THEN
    if      LV_VAR_LSH_DOWN = 0
    then    LV_INH_LSH_DOWN[i]  =  1
            LSHPWM_EXT_LS_DOWN[i]  = NC_LSHPWM_BOL_LSH_DOWN
    else    LV_INH_LSH_DOWN[i]  =  ! LC_LSH_DOWN[i]
            LSHPWM_EXT_LS_DOWN[i]  =  0
ELSE    LV_INH_LSH_DOWN[i]  =  1
        LSHPWM_EXT_LS_DOWN[i]  = LSHPWM_DOWN_EXT_ADJ[i]
ENDIF
```

Once at every function activation:

TEMP_INI_LS_DOWN[i] = TEG_WALL_CAT_DOWN_MDL[i]

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_LSH_DOWN[NC_CBK_EX_NR]	1	0...1H	0...1	1	[-]
Boolean variable to enable oxygen sensor heating					

16.23 O2 sensor Lambda set point intervention

Output data:

Lambda set point for active plausibility test					

Input data:

LAMB_SP_OSC_CHK[NC_CBK_EX_NR]	LAMB_SP_DIAG_OC_LSL_UP[NC_CBK_EX_NR]	LAMB_SP_DIAG_OPL_LS_UP_DOWN[NC_CBK_EX_NR]	LV_ST_END

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function provides an internal coordination of lambda setpoint requests from functions within EGCP.

Description:

The function shall perform a priority ranking for several lambda setpoint requests established inside the EGCP aggregate and forward one request to functions outside EGCP. The flag LV_LAMB_SP_REQ_DIAG_ACT[i] shall indicate that at least one setpoint request is active. No check should be performed whether the setpoint is reached, nor should a request for open or closed loop lambda control be output. The possible sources of lambda setpoint requests are:

- plausibility check of upstream and downstream O2 sensor,
- monitor for downstream O2 sensor during oscillation check,
- monitor for upstream O2 sensor during open circuit check.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset or at clearing error memory initialize all variables and bits with 0, with the expection of:
LAMB_SP_DIAG_LS_UP_DOWN[i] which is initialized with 1.

Recurrence:

This function shall be carried out every 100 ms.

Activation:

LV_ST_END = 1

Formula section:

```
% priority is open loop check > oscillation check > open circuit check
If    LAMB_SP_DIAG_OPL_LS_UP_DOWN[i] > 0
then
      LAMB_SP_DIAG_LS_UP_DOWN[i] = LAMB_SP_DIAG_OPL_LS_UP_DOWN[i]
      LV_LAMB_SP_REQ_DIAG_ACT[i] = 1

elseif        LAMB_SP_OSC_CHK[i] > 0
then
      LAMB_SP_DIAG_LS_UP_DOWN[i] = LAMB_SP_OSC_CHK[i]
      LV_LAMB_SP_REQ_DIAG_ACT[i] = 1

elseif        LAMB_SP_DIAG_OC_LSL_UP[i] > 0
and           LAMB_SP_DIAG_OPL_LS_UP_DOWN[i] = 0 for all i
then
      LAMB_SP_DIAG_LS_UP_DOWN[i] = LAMB_SP_DIAG_OC_LSL_UP[i]
      LV_LAMB_SP_REQ_DIAG_ACT[i] = 1

else
      LAMB_SP_DIAG_LS_UP_DOWN[i] = 1
      LV_LAMB_SP_REQ_DIAG_ACT[i] = 0
endif
```

Lean plus rich mixture cycle time; time of last forced lambda stimulation period					

Input data:

LV_ST_END	NC_CBK_EX_NR
LAMB_PLS[NC_CBK_EX_NR]	LV_LAMB_PLS_ACT[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Signal flow diagram:

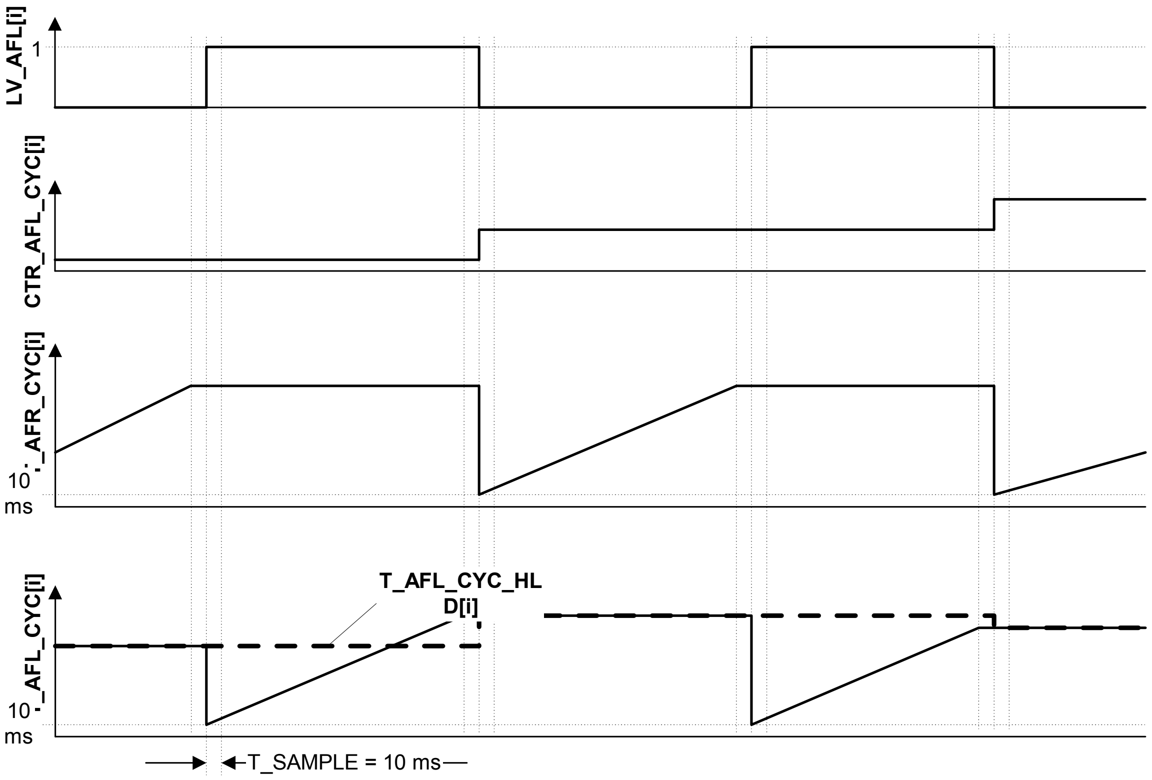

Figure 59: Definition of dwell times

Description:

The logical variable LV_AFL_i that indicates a lean air fuel ratio (lambda set point is lean) is calculated based on the output of the forced lambda stimulation. In case of a positive LAMB_PLS[i] the flag is set to one. The lean dwell time T_AFL_CYC[i] is calculated in that case. If LAMB_PLS[i] is negative or zero LV_AFL[i] is 0. In that case the rich dwell time T_AFL_CYC[i] is calculated.

When LV_AFL[i] switches from 0 to 1 T_AFL_CYC[i] is reset. When LV_AFL[i] switches from 1 to 0 T_AFR_CYC[i] is reset and the current value of T_AFL_CYC[i] is stored in the variable T_AFL_CYC_HLD[i]

The function is only active when the forced lambda stimulation is active (LV_LAMB_PLS_ACT[i] = 1). For further explanation see Figure 59.

T_SUM_AFL_AFR_CYC[i] is the period time of the forced lambda stimulation. It is updates each rising edge of LV_AFL[i].

Application conditions:

Initialisation: at engine start (LV_ST_END = 0 -> 1) and at each function activation:

LV_AFL[i] = 0
LV_AFL_OLD_1_EGCP[i] = 0
CTR_AFL_CYC[i] = 0
T_AFR_CYC[i] = T_SAMPLE
T_AFL_CYC[i] = T_SAMPLE
T_AFL_CYC_HLD[i] = T_SAMPLE
T_SUM_AFL_AFR_CYC[i] = T_SAMPLE

Recurrence: T_SAMPLE = 10 ms

Activation: LV_LAMB_PLS_ACT[i] = 1

Deactivation: -

Formula section:

```
IF LAMB_PLS[i] > 0    /* lean */
THEN
   LV_AFL[i] = 1
   IF LV_AFL_OLD_1_EGCP[i] = 0    /* rising edge LV_AFL[i] = 0 -> 1 */
   THEN
      T_SUM_AFL_AFR_CYC[i] = T_AFL_CYC_HLD[i] + T_AFR_CYC[i]
      T_AFL_CYC[i] = T_SAMPLE
   ELSE
      T_AFL_CYC[i] = T_AFL_CYC[i] + T_SAMPLE
   ENDIF
ELSE    /* rich */
   LV_AFL[i] = 0
   IF LV_AFL_OLD_1_EGCP[i] = 1    /* falling edge LV_AFL[i] = 1 -> 0 */
   THEN
      T_AFR_CYC[i] = T_SAMPLE
      T_AFL_CYC_HLD[i] = T_AFL_CYC[i]
      CTR_AFL_CYC[i] = CTR_AFL_CYC[i] + 1
   ELSE
      T_AFR_CYC[i] = T_AFR_CYC[i] + T_SAMPLE
   ENDIF
ENDIF

LV_AFL_OLD_1_EGCP[i] = LV_AFL[i]
```

16.25 Application Incidencies of the “WRAF sensor electric diagnosis”

16.25.1 Application Incidences of “Electrical Fault Detection”

Output data:

Maximum threshold of OBD-I Diagnosis debouncer counter					

Application assistances:

The following list shows the influenced functions if a failure is detected.

Direct error reactions:

The following functions have to be direct deactivated:

- catalyst efficiency diagnosis
- diagnosis of the canister purge system (flow rate diagnosis)
- secondary air diagnosis (flow rate)
- secondary air valve diagnosis (mechanical)
- secondary air pump
- upstream oxygen sensor temperature acquisition
- WRAF Sensor controller diagnosis
- WRAF Sensor Plausibility Diagnosis
- WRAF Sensor dynamic diagnosis
- WRAF Sensor not mounted diagnosis
- WRAF Sensor plausibility diagnosis during PUC
- WRAF Sensor false start diagnosis
- WRAF Sensor heater coupling diagnosis
- WRAF Sensor OBD2 heater diagnosis

The following function has to be activated :

- canister purge function (min. operation)

Diagnostic XX	Symptoms	Ref.	DTC Symptom CARB	DTC Symptom Customer	DTC Global CARB	DTC Global Customer	Failure class A/B	Readiness code

16.25.2 WRAF Sensor Pump Current Controller Diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_IPLSL_DIAG_INH_LSL_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Deactivation of "HW-Based Diagnosis with the CJ120"					

Input data:

LV_ST_END	NC_CBK_EX_NR	LV_IGK	LV_CDN_VB_OBD1

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Application conditions:

Initialization:

The flag shall be initialized as follow during the transition LV_IGK = 0 to 1.

LV_IPLSL_DIAG_INH_LSL_UP[i] = 0

Recurrence:

The function shall be carried out once every 10ms.

Activation:

Transition LV_IGK = 0 ->1

Deactivation:

Transition LV_IGK = 1 ->0. LV_IPLSL_DIAG_INH_LSL_UP[i] shall be set to 1.

Formula section:

```
If   LV_CDN_VB_OBD1 = 0
Then
    LV_IPLSL_DIAG_INH_LSL_UP[i] = 1
Else
    LV_IPLSL_DIAG_INH_LSL_UP[i] = 0
Endif
```

Input data:

LV_INH_DIAG_LSL_UP_IF[NC_CBK_EX_NR]	LV_IGK	LV_LSL_IF_SPI_RST_END[NC_CBK_EX_NR]	CTR_ERR_LSL_IF_SPI_WR[NC_CBK_EX_NR]
NC_CBK_EX_NR			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function shall detect an error during the initialization and/or operation of a WRAF sensor controller which uses a SPI comunication, like the CJ120 or ATIC42. For this task informations from the Basic Software (BSW) concerning the initialization and the communication between ASW and the controller are used to judge if the ASIC works properly.

After an ECU reset, the WRAF sensor controller is started and the diagnosis determines the time until the initialization of the ASIC has been performed (LV_LSL_IF_SPI_RST_END[i] = 1). If this doesn't happen after a certain time (C_T_RST_MAX_DIAG_LSL_UP_IF[I]) an error is present and the flag LV_ERR_LSL_UP_IF[i] shall be set. If the initialization occurs successfully, the difference is checked between the present error counter (CTR_ERR_LSL_IF_SPI_WR[i]) and the stored value of this error counter (CTR_ERR_SAVE_DIAG_LSL_UP_IF[i], stored at ECU reset, LV_IGK switch from 0 -> 1 or

at clearing error memory and also after each function call in case that a difference between both counters was found). If there is a difference, another counter is incremented.
If this counter is bigger than a threshold, a SPI communication error is entered.

In any case the flag LV_ERR_LSL_UP_IF[i] = 1 the operation of the WRAF sensor shall be inhibited.

Application conditions:

Initialisation:

At transition LV_IGK = 0 -> 1, at clearing error memory or at ECU reset,

LV_ERR_LSL_UP_IF[i] = 0
LV_END_DIAG_LSL_UP_IF[i] = 0
ERR_SYM_LSL_UP_IF[i] = 0
CTR_DELTA_LSL_UP_IF[i] = 0
CTR_ERR_SAVE_DIAG_LSL_UP_IF[i] = CTR_ERR_LSL_IF_SPI_WR[i]

Start TIMER_1 and TIMER_2

Recurrence:

The function shall run every 10 ms

Activation:

At LV_IGK=1 & LV_INH_DIAG_LSL_UP_IF[i]=0 the function shall be started and LV_CDN_DIAG_LSL_UP_IF[i] = 1

Deactivation:

The deactivation occures if the activation conditions above are not fulfilled.

Formula section:

```
If  LV_LSL_IF_SPI_RST_END[i] = 1        /init. of WRAF sensor controller done successfully
Then
    Stop TIMER_1

    If      CTR_ERR_LSL_IF_SPI_WR[i] =! CTR_ERR_SAVE_DIAG_LSL_UP_IF[i]
    then    CTR_DELTA_LSL_UP_IF[i]$_{n}$ = CTR_DELTA_LSL_UP_IF[i]$_{n-1}$ + 1
            CTR_ERR_SAVE_DIAG_LSL_UP_IF[i] = CTR_ERR_LSL_IF_SPI_WR[i]

		LV_DIAG_ACT_SHO_CDN_LSL_UP[NC_CBK_EX_NR]	

FUNCTION DESCRIPTION:

General information:

This function shall use some debounced OBD2 lambda sensor faults to evaluate if an open circuit in any of the four electric lines (VN, VG, VIP and VRc) is present. The matrix below shows reaction of sensor/controller to each open line.

Open Circuit on Line	Measured Sensor Temp	Lambda Sensor
VN	**V_Ri = 5 V (Ttip = 560 °C)**	**U_Lambda = 0 V** **(for NTK sensor only if R_I oscillator is turned off)**
VG	**V_Ri = 0 V (Ttip = 880 °C)** **(only applicable for some senosor types)**	**U_Lambda = 2.0 V** **(sensor stuck)**
VIP	**V_Ri plausible**	**U_Lambda = 2.0 V** **(sensor stuck)**
VRc	**V_Ri plausible**	**U_Lambda > 4.8 V in air**

This function shall run only if at least one of the following diagnoses has set its readiness bit: Activity Check, Plausibility during PUC and Sensor Heater OBD2. The function shall go to the state = “active” if one of the above diagnoses debounced a fault.

The end flag for this diagnosis is set if all the related diagnosis functions have set their end flags or after changing to the STATE “end” with detection of an open circuit error.

OC in the VN line (LSU and ZFAS-Ux sensors) or VG line (ZFAS-Ux only) cause an OBD2 heater symptom. Therefore an OC error is assumed if a heater symptom is accompanied by other indications of these OC errors. For OC in VN, a very low VLS_UP_DIAG[i] will occur (for ZFAS-Ux, only if the Ri measurement oscillator is turned off), while for OC in VG this value will be around 2.0V (i.e. stuck at lambda=1). These conditions are tested with an open loop lambda setpoint shift requested here, monitoring of VLS_UP_DIAG[i] is coordinated with the detection of shifted lambda setpoint and disabled Ri measurement oscillator. If the lambda shift request is not fulfilled, the diagnosis looks for an activity symptom instead to decide if the VG/VIP line is open, but this probably takes much more time.

If VLS_UP_DIAG[i] is stuck at 2.0V, as detected by the PUC plausibility or activity diagnoses, OC in VG or VIP may be present. In ZFAS-Ux sensors, OC in VG would also cause a heater symptom, so further fault isolation is possible using T_WAIT_SYM_OBD_2_LSH_UP[i] to wait for this symptom. If C_T_WAIT_SYM_OBD_2_LSH_UP is set to 0, all faults causing VLS_UP_DIAG[i]= 2.0V are regarded as OC in VIP, even if the test was triggered by an OBD2 heater symptom.

Quite independently, OC in VRC shows up as a VLS_H_OC symptom in the PUC plausibility diagnosis and is consumed here. It will be overridden however by any other OC fault.

If any open circuit symptom could be detected the flag LV_ERR_OC_LSL_UP[i] shall be set to 1.

If two separate catalyst systems are concerned, then
    i = 1, for cylinder bank 1
    i = 2, for cylinder bank 2,
else
    i = 1.

Description:

This action compute the elementary antibounce filter for one failure treatment and return filter result
ACTION_INFR_GetElDiagLshUp(IN <i>, OUT < cdn_diag>, OUT <err_diag>)
This action reads the failure and the conditions information for each symptom from the infrastructure

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

All symptoms of the current error code are handeled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

Description:

The error detection is effected via the ECU hardware.

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> Short circuit to battery (SCP)          (= SYM_0)
 │  │  └────> Short circuit to ground (SCG)           (= SYM_1)
 │  └───────> Open circuit (OC)               (= SYM_2)
 └──────────> -                                       (= SYM_3)
```

The function is intended for use in a hardware configuration where the heater driver shall carry out the electrical fault diagnosis and provide the electrical status via status flags.

- *Short circuit to Vbatt by Over-temperature* ***or*** *Overcurrent* (**SCP**)
- *Short circuit to GND* (SCG)
- *Open load* (**OC**)

The heater drivers named are capable of detecting an **OC** and **SCP** fault when in the ON state and only capable of detecting a SCG fault in the OFF state. As the heater power is controlled by a PWM signal, the driver will be placed alternately in an ON and then OFF state.

The diagnosis shall be activated should the following conditions be met:

- Engine leaving the engine start state as denoted by LV_IGK = 1
- Battery voltage falls between pre-set thresholds to protect against false errors at battery voltage extremes as indicated by **LV_VB_CDN_OBD_1**.
- CDN depending on duty cycle of LSHPWM_UP[i]
- Inhibit flag not set (LV_INH_DIAG_LSH_UP[i])

In exceptionally rare extreme environmental conditions for certain system configurations, it is possible that the heater driver may be driven into over-temperature during initial oxygen sensor heating. In this case, the driver automatically turns off the output stage in self-protection and sets the **SCP** electrical fault bit. In order to mask an incorrect oxygen sensor heater **SCP** fault, the function shall only allow the **SCP** to set a fault during the initial heater phase, if the exhaust gas temperature has exceeded a pre-determined calibrateable threshold.

The oxygen sensor heater fault detection shall be debounced by use of an anti-bounce counter. This shall be handled by the Dynamic Error Management.

Each of the above listed faults shall be described individually below:

Otherwise the diagnosis has to be suppressed (CDN_DIAG_LSH_UP[i] = 0). This is managed within the “Diagnosis condition calculation.

Application conditions:

Initialization: at reset CDN_DIAG_LSH_UP[i] = 0, ERR_DIAG_LSH_UP[i] = 0

All other variables are initialized according filter type

Activation : -

Deactivation: -

Recurrence: 100 ms

NOTE: The heater PWM frequency shall be at least 2 times faster than the diagnosis frequency to ensure that an oversampling effect does not occur!

Formula section:

```
If      LV_IGK = 1
and     LV_VB_CDN_OBD_1 = 1
and     LV_INH_DIAG_LSH_UP[i] = 0
then
```

Usage of the diagnosis information (failure symptoms (raw value) **ERR_DIAG_LSH_UP[i]** and basic diagnosis conditions **CDN_DIAG_LSH_UP[i]**) received from the infrastructure:

ACTION_INFR_GetElDiagLshUp(IN <i>, **OUT**<CDN_DIAG_LSH_UP[i]>, **OUT**<ERR_DIAG_LSH_UP[i]>**)**

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_LSH_UP[i]. Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_LSH_UP[i].

```
If      Activation conditions are met for the NC_PSD_DLY_LSH_UP recurrence
Then
        If      LSHPWM_UP[i] < C_LSHPWM_MIN_DIAG_LSH_UP
        or      [(STATE_LSH_UP[i] = LSH_POW_RISE
        or      STATE_LSH_UP[i] = LSH_POW_RED)
        and     TEG_DYN_LS_UP[i]< C_TEG_DYN_MIN_DIAG_LSH_UP]
        then    bit 0 of CDN_DIAG_LSH_UP[i] = 0 (SCP can not be detected))
        endif
        If      LSHPWM_UP[i] > C_LSHPWM_MAX_DIAG_LSH_UP
        then    bit 1 of CDN_DIAG_LSH_UP[i] = 0  (SCG can not be detected)
        endif
        if      LSHPWM_UP[i] < C_LSHPWM_MIN_DIAG_LSH_UP
        or      LSHPWM_UP[i]  > C_LSHPWM_MAX_DIAG_LSH_UP
```

```
                then    bit 2 of CDN_DIAG_LSH_UP[i] = 0  (OC can not be detected)
                endif
        Else
                CDN_DIAG_LSH_UP[i] = 0
        Endif
Else
                CDN_DIAG_LSH_UP[i] = 0
endif
```

Error Symptom calculation (raw value from I/O SW)

```
If      bit 1 of ERR_DIAG_LSH_UP[i] = 1
then    LV_LSH_SCG_ACT_LSH_UP[i] = 1
endif
```

```
If      abc-counter = 0
then    LV_LSH_SCG_ACT_LSH_UP[i] = 0
endif
```

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_LSH_UP[i] and ERR_DIAG_LSH_UP[i].

ACTION_ERRM_FilterMulticondition(IN <*XX*>, IN< CDN_DIAG_LSH_UP[i]>, IN< ERR_DIAG_LSH_UP[i]>, IN <C_ABC_INC_LSH_UP>, IN <C_ABC_MAX_LSH_UP>, OUT<LV_ERR_LSH_UP[i]>)

This algorithm determines:

ERR_SYM_LSH_UP[i]	(= raw value ERR_DIAG_LSH_UP[i] filtered with CDN_DIAG_LSH_UP[i], detected error symptom for lambda sensor heater upstream [i] diagnosis)
LV_ERR_ LSH_UP[i]	(Error flag for debounced error of for lambda sensor heater upstream [i])
LV_CDN_DIAG_ LSH_UP[i]	(Diagnosis condition information)
LV_END_DIAG_ LSH_UP[i]	(End of diagnosis information)

16.30.1 Application incidences for upstream oxygen sensor heater OBDI diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_LSH_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Inhibit flag for upstream oxygen sensor heater OBDI diagnosis					

Input data:

LV_ST_END	NC_CBK_EX_NR	LV_CDN_VB_OBD1	LV_ERR_SPI_MPS
LV_LS_UP_OBD_1_MAN_DEAC[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Description:

The diagnosis is inhibited due to low battery voltage, present error or if sensors are not learnt.

Application conditions:

Initialisation:	LV_INH_DIAG_LSH_UP[i] = 1 at reset
Recurrence:	The function shall be carried out once every 100 ms.
Activation:	LV_ST_END = 1
Deactivation:	LV_ST_END = 0 , set LV_INH_DIAG_LSH_UP[i] = 1

Formula section:

```
If      LV_CDN_VB_OBD1 = 0                    or
        LV_ERR_SPI_MPS = 1                    or
        LV_LS_UP_OBD_1_MAN_DEAC[i] = 1              //sensors not learnt
Then    LV_INH_DIAG_LSH_UP[i] = 1
Else    LV_INH_DIAG_LSH_UP[i] = 0
Endif
```

16.31 O2 sensor (bin, down) signal circuit diag

Output data:

LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Boolean error flag, electrical fault currently present on downstream oxygen sensor signal					

Input data:

LV_ERR_SCG_LS_DOWN [NC_CBK_EX_NR]	LV_IGK	LV_ERR_SCP_LS_DOWN[NC_CBK_EX_NR]	LV_ERR_OC_LS_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

The VLS_DOWN[i] value used for diagnosis purposes shall not be affected should the sensor be “pumped”. The value prior to pumping shall be used until the sensor returns to normal operation (no pumping).
Once an electrical fault has been detected and debounced, the plausibility diagnosis shall not be carried out until the electrical fault has been diagnosed as being no longer present. The electrical diagnosis shall remain unaffected by the state of the plausibility diagnosis.
Once an electrical fault has been diagnosed and debounced, the application assistances (Functions that are defined to be affected by the state of the oxygen sensor signal) shall remain active for the remainder of the driving cycle. The restarting of the affected functions during the next driving cycle shall be carried out according to the project philosophy.
The measurement of the oxygen sensor voltage shall not be affected by the detection of a signal fault unless explicitly deactivated.

Description:

The oxygen sensor signal electrical diagnosis shall detect the following faults:
A. Short circuit of the oxygen sensor signal line to GND
B. Short circuit of the oxygen sensor signal line to Vbatt
C. Open circuit (line break) in the connection to oxygen sensor element

Each fault may set the boolean flag (LV_ERR_SCG_LS_DOWN[i]; LV_ERR_SCP_LS_DOWN[i]; LV_ERR_OC_LS_DOWN[i]) to signal that the particular fault is currently active. Should one of the electrical fault flags (A-C) be set, then a global error flag (LV_ERR_EL_LS_DOWN[i]) shall be set to indicate that an electrical fault currently exists on the particular oxygen sensor.
Each of the above listed erro shall be described individually in further detail below.

Application conditions:

Initialisation: all variables shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Recurrence: 100ms

Activation:

If LV_IGK = 1

Deactivation:

If LV_IGK = 0

Formula section:

```
If      LV_ERR_SCG_LS_DOWN[i] = 1
or      LV_ERR_SCP_LS_DOWN[i] = 1
or      LV_ERR_OC_LS_DOWN[i] = 1
then    LV_ERR_EL_LS_DOWN[i] = 1
else    LV_ERR_EL_LS_DOWN[i] = 0
endif
```

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

In order to determine the electrical fault, short circuit to GND, the oxygen sensor signal voltage is compared to a calibrateable threshold (C_VLS_THD_DIAG_SCG_LS_DOWN) in conjunction with certain activation conditions.
Should a hard short to GND (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to 0 V. This condition may also occur should the air-fuel mixture (AFR) become lean due to a fault in the injection system, due to an air leak, intentional or not, or due to a normal operating conditions. Hence the following additional fault conditions shall be required:
The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_SCG_LS_DOWN[i]).

Each time that timer T_ACT_PLS_DIAG_SCG_LS_DOWN[i] exceeded the minimum duration (C_T_DLY_DIAG_SCG_LS_DOWN) for the first time, e.g. first time after engine start or after timer T_ACT_PLS_DIAG_SCG_LS_DOWN[i] has been reset, the CTR_R_UPD_DIAG_SCG_LS_DOWN[I] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_R_UPD_DIAG_SCG_LS_DOWN[i] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_R_UPD_DIAG_SCG_LS_DOWN[i] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. If this conditions and all the above conditions be met, the diagnosis shall be considered to be active.

Should the diagnosis be determined to be active, the oxygen sensor signal voltage shall be compared to the threshold. Should the voltage fall below the threshold and the resistance condition R_IT_LS_DOWN[i] less than threshold be met, a pre - detection counter is incremented. The counter is reset to 0 if the above mentioned conditions are no more fulfilled. If the pre – detection counter counter reached the maximum value then the active check is triggered or if finished the error “Short to GND” is detected. Additionally the triggered active diagnosis can be switched of with LC_DIAG_ACT_CHK_INH = 1.

<u>Application conditions:</u>

Initialisation: all variables shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Recurrence: T_SAMPLE = 100ms

Activation / Deactivation:

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_INH_DIAG_SCP_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

Should a hard short to Vbatt (i.e. approx. 0 Ω) exist on the oxygen sensor signal line, the signal voltage will tend to Vbatt and the analogue digital converter value will tend to 5 V. This effect does not occur under normal conditions as the sensor delivers typically 1 V for rich AFR at the sensor location and may be used for short to Vbatt detection.

In order to determine the electrical fault, short circuit to Vbatt, the oxygen sensor signal voltage (VLS_DOWN[i]) is compared to a calibrateable threshold (C_VLS_THD_DIAG_SCP_LS_DOWN) in conjunction with the herein mentioned activation conditions.

The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_SCP_LS_DOWN[i]).

Should the oxygen signal voltage exceed the said threshold, a signal short to Vbatt shall be determined to be present and the debounce counter shall be incremented otherwise the debounce counter shall be decremented.

The error flag LV_ERR_SCP_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

Application conditions:

Initialisation: all variables shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Recurrence: 100ms

Activation / Deactivation:

LV_LS_DOWN_READY[NC_CBK_EX_NR]	NC_CBK_EX_NR		

Description:

According the exhaust gas system shall the variables be defined for [i]=1 to NC_CBK_EX_NR.

Should a complete open circuit occur in the oxygen sensor signal or return line, the measured voltage at the input to the microcontroller will tend to the voltage determined by the operative readiness potential divider (approx. 450 mV) and the measured internal resistance will be abnormally high.
In order to determine an open circuit electrical fault, the oxygen sensor internal resistance (R_IT_LS_DOWN[i]) is compared to a calibrateable threshold (C_R_IT_MIN_DIAG_OC_LS_DOWN) in conjunction with certain activation conditions shown below:

The ignition key shall be determined to be on (LV_IGK = 1) and the appropriate inhibit flag shall not be set (LV_INH_DIAG_OC_LS_DOWN[i]).

The sensor shall be determined to be in a state of operative readiness (LV_LS_DOWN_READY[i] = 1, possibly thorough forced activation) and the temperature operating conditions of the sensor shall be determined to be sufficient to permit normal operation, i.e. No fault shall be determined to be present in the appropriate downstream oxygen sensor heater (LV_ERR_LSH_DOWN[i] = 0) or if so that the operating temperature be determined to be sufficient for sensor operability (TEG_DYN_LS_DOWN[i] > C_TEG_DYN_MIN_DIAG_OC_LS_DOWN), and the appropriate heater shall be determined to being controlled normally (STATE_LSH_DOWN[i] = LSH_POW_CTL).

Should the above initial conditions be met, a timer (T_ACT_PLS_DIAG_OC_LS_DOWN[i]) shall be incremented. Should the conditions no longer be met, both timers shall be reset and flag LV_T_CDN_DIAG_OC_LS_DOWN[i] reset.

The oxygen sensor signal shall be determined to lie in a calibrateable voltage band (C_VLS_AFL_THD_DIAG_OC_LS_DOWN < VLS_DOWN[i] < C_VLS_AFR_THD_DIAG_OC_LS_DOWN).

Should the above listed pre-activation conditions be determined to have been met, a timer T_CDN_DIAG_OC_LS_DOWN[i] shall be started. The timer shall be required to equal or exceed a minimum calibrateable duration (C_T_CDN_DIAG_OC_LS_DOWN). When no longer met, T_CDN_DIAG_OC_LS_DOWN[i] and LV_T_CDN_DIAG_OC_LS_DOWN[i] shall be reset.

Each time that the T_CDN_DIAG_OC_LS_DOWN[i] has exceeded the minimum duration for the first time, e.g. first time after engine start or after the T_CDN_DIAG_OC_LS_DOWN[i] has been reset, the CTR_R_UPD_DIAG_OC_LS_DOWN[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_R_UPD_DIAG_OC_LS_DOWN[i] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_R_UPD_DIAG_OC_LS_DOWN[i] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i] and a flag LV_R_IT_VLD_DIAG_OC_LS_DOWN[I] be set, thus indicating that the voltage lies within the set band and that a new resistance value is available.

If either LV_T_CDN_DIAG_OC_LS_DOWN[i] is set or T_ACT_PLS_DIAG_OC_LS_DOWN[i] equals or exceeds threshold C_T_DLY_DIAG_OC_LS_DOWN, the diagnosis shall be considered to be available.

Should the diagnosis be determined to be available and the condition LV_R_IT_VLD_DIAG_OC_LS_DOWN[I] has been met, the oxygen sensor internal resistance shall be compared to the said threshold. Should the resistance exceed the threshold, a signal open circuit shall be determined to be present and the debounce counter shall be incremented otherwise the debounce counter shall be decremented.

The error flag LV_ERR_OC_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum and reset should the anti-bounce counter reach 0.

Application conditions:

Initialisation: all variables shall be initialised to 0 with LV_IGK = 0 -> 1 or reset or at clearing the error memory

Recurrence: T_SAMPLE = *100ms*

Activation / Deactivation:

```
If      LV_IGK = 1

FUNCTION DESCRIPTION:

General information:

According the exhaust gas system the variables shall be defined from [i]=1 to NC_CBK_EX_NR.

Application conditions:

Initialisation: all variables are initialised to 1 at reset and every LV_IGK = 0→1

Recurrence: 100 ms

Activation: LV_IGK = 1 **and** LV_VAR_LSH_DOWN = 1

Deactivation: LV_IGK = 0 **or** LV_VAR_LSH_DOWN = 0

Before deactivation all variables shall be reset to 1.

Formula section:

16.32.1 Interface for Rate – Based - Monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the PUC_LS_DOWN[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_PUC_LS_DOWN[i] data.

Within STATE_RBM_PUC_LS_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation: *at ECU reset:*
bit 0, bit 1 and bit 2 of STATE_RBM_ PUC_LS_DOWN[i] = 0
LV_DC 0 ->1 transition:
bit 0 and bit 1 of STATE_RBM_ PUC_LS_DOWN [i] = 0
on failure memory reset:
bit 1 of STATE_RBM_STATE_RBM_ PUC_LS_DOWN [i] = 0

Recurrence: 1 s
Activation: LV_DC = 1

Formula section:

At LV_DC 0 ->1 transition

bit 2 of STATE_RBM_ PUC_LS_DOWN [i] = 1

The pending status of the following failures has to be checked only once :

LV_ERR_IV[NC_CYL_NR]	LV_ERR_FSD_LAM_LIM[NC_CBK_EX_NR]	LV_ERR_FUP
LV_ERR_FUP_MFP_PLAUS	LV_ERR_H_PRS_SYS	LV_ERR_VCV[NC_CBK_HPP_NR]

Boolean flag, plausibility check on downstream oxygen sensor signal possible					
LV_ERR_PLAUS_LS_DOWN[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Boolean flag, error plausibility check on downstream oxygen sensor signal					

Input data:

LV_ERR_EL_LS_DOWN[NC_CBK_EX_NR]	LV_LS_DOWN_READY[NC_CBK_EX_NR]	LV_ERR_LSH_DOWN[NC_CBK_EX_NR]	LV_ERR_PUC_LS_DOWN[NC_CBK_EX_NR]
NC_CBK_EX_NR	STATE_LSH_DOWN[NC_CBK_EX_NR]	LV_IGK	LV_ERR_FL_LS_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

Due to possible oxygen sensor defects (e.g. reference air poisoning) or faults in the injection system (e.g. leaking fuel injector), the oxygen sensor may not provide the expected lean or rich AFR signal level during overrun fuel cut-off (PUC) or full load (FL) condition. Hence, the oxygen sensor signal shall be checked for plausibility during this engine operating states.

Description:

If the following conditions are met, then the general conditions for plausibility check are determined to be present:

A. Ignition key shall be determined to be on (LV_IGK = 1)
B. No electrical oxygen sensor fault shall be determined to be present on the sensor being diagnosed (LV_ERR_EL_LS_DOWN[i] = 0).
C. Sensor shall be in a state of operative readiness (LV_LS_DOWN_READY[i] =1).
D. The sensor shall be determined to be at operating temperature (STATE_LSH_DOWN[i] = LSH_POW_CTL & LV_ERR_LSH_DOWN[i] = 0).

The corresponding flag LV_DIAG_CDN_PLAUS_LS_DOWN[i] shall then be set.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits to 0

Recurrence: **T_sample 10 ms**

Activation / Deactivation:

```
If      LV_IGK = 1
and     LV_ERR_EL_LS_DOWN[i] = 0
and     LV_LS_DOWN_READY[i] = 1
and     LV_ERR_LSH_DOWN[i] = 0
and     STATE_LSH_DOWN[i] = LSH_POW_CTL
then    "Diagnosis available"
        LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1
else    "Diagnosis NOT available"
        LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 0
endif
```

Formula section:

```
If      LV_ERR_PUC_LS_DOWN[i] = 1
or      LV_ERR_FL_LS_DOWN[i] = 1
then    LV_ERR_PLAUS_LS_DOWN[i] = 1
else    LV_ERR_PLAUS_LS_DOWN[i] = 0
endif
```

LV_INH_DIAG_PUC_LS_DOWN[NC_CBK_EX_NR]	LV_IGK	NC_CBK_EX_NR	MAF_KGH

FUNCTION DESCRIPTION:

General information:

Description:

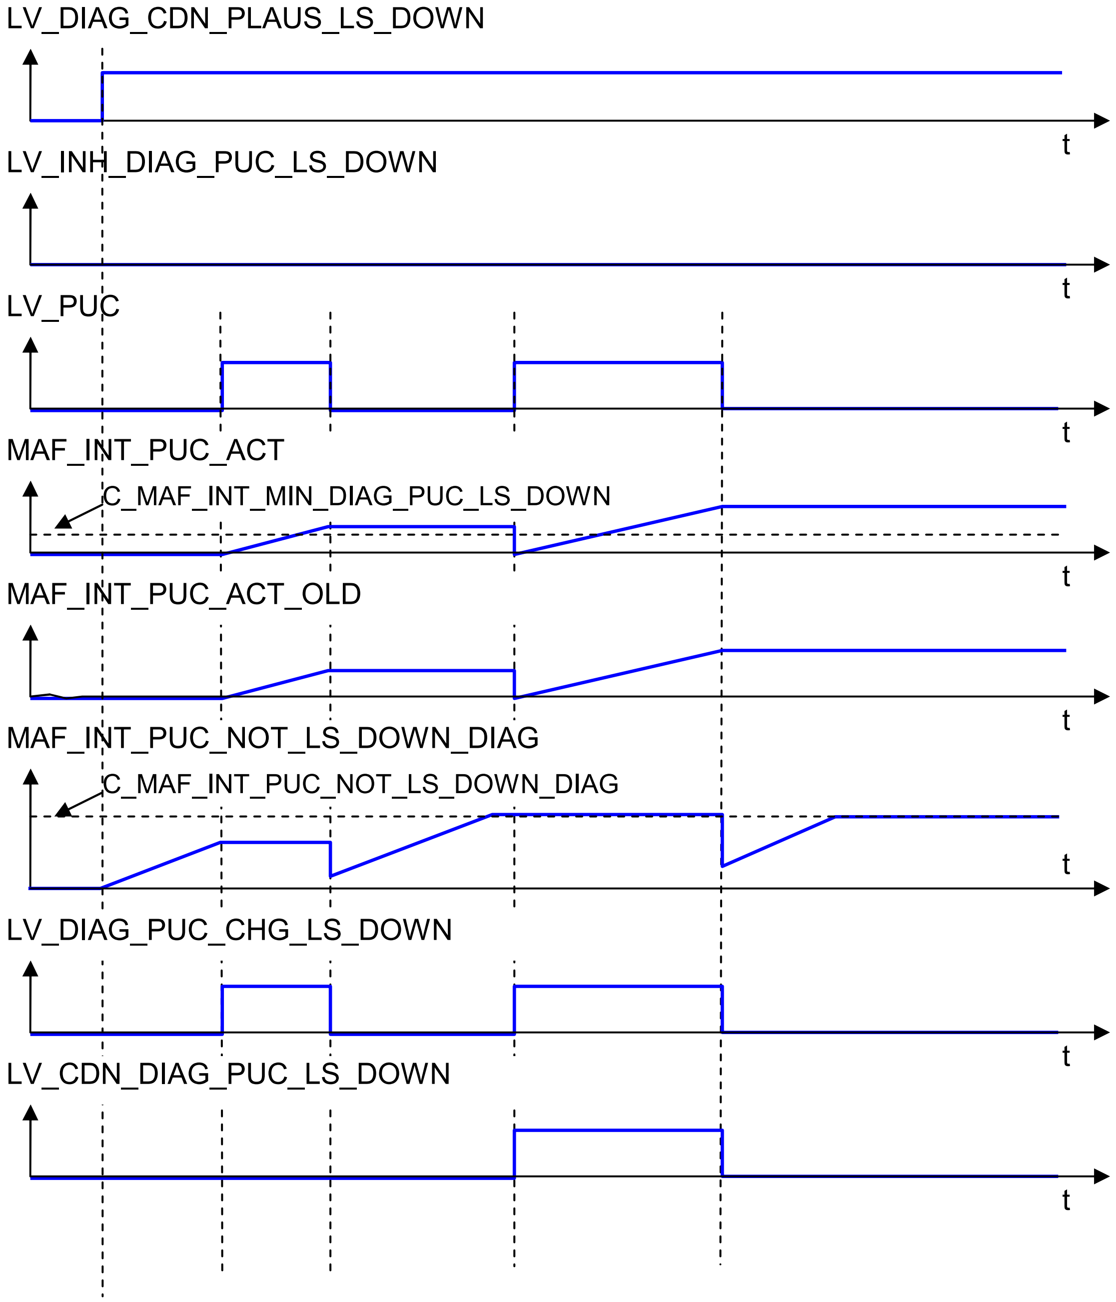
Should the oxygen sensor signal voltage (VLS_DOWN[i]) exceed the calibrateable thresholds (C_VLS_MIN_DIAG_PUC_LS_DOWN) during engine operating state PUC and the following additional conditions are met, then a fault shall be determined to be present:

A. The appropriate inhibit flag shall not be set (LV_INH_DIAG_PUC_LS_DOWN[i]).
B. Plausibility check set to be possible (LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1)
C. The PUC state (LV_PUC = 1) shall be determined to be stable, as determined by comparing the mass air flow integral calculated after activation (MAF_INT_PUC_ACT) with the threshold range (C_MAF_INT_MIN_VLS_DOWN_DIAG; C_MAF_INT_MAX_VLS_DOWN_DIAG).
D. The energy transfer from the exhaust gas to the oxygen sensor shall exceed the calibratable threshold (C_MAF_INT_PUC_NOT_LS_DOWN_DIAG).
E. The reset of the MAF integral from the last fuel cut off phase must have taken place before activating the diagnosis. Otherwise there is a risk to set the conditions to 1 right at the beginning of the fuel cut off phase. At this time, the lambda sensor voltage downstream is still high and the error symptom would be set for one recurrence.
F. Prior to the PUC phase the VLS_DOWN[i] must have exceeded the voltage thresholds C_VLS_DOWN_PUC_PLAUS_VLD and C_VLS_DOWN_PUC_AFR_VLD.

The error flag LV_ERR_PUC_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Correlation between MAF integrals MAF_INT_PUC_ACT, MAF_INT_PUC_ACT_OLD and MAF_INT_PUC_NOT_LS_DOWN_DIAG and diagnosis activation :



Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits to 0, except VLS_DOWN_PUC_SAVE. VLS_UP_PUC_SAVE[i] shall be initialised to 0 at new ECU and in case of NVMY checksum errors.

Recurrence: **T_sample 100ms**

Activation / Deactivation: -

LV_INH_DIAG_FL_LS_DOWN[NC_CBK_EX_NR]	MAF_INT_FL[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

General information:

Description:

Should the oxygen sensor signal voltage (VLS_DOWN[i]) exceed the calibrateable thresholds (C_VLS_MAX_DIAG_FL_LS_DOWN) during engine operating state FL and the following additional conditions are met, then a fault shall be determined to be present:

A. The appropriate inhibit flag shall not be set (LV_INH_DIAG_FL_LS_DOWN[i]).
B. Plausibility check set to be possible (LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1)
C. The FL state (LV_FL = 1) shall be determined to be stable, as determined by comparing the mass air flow integral calculated after activation (MAF_INT_FL[i]) with the threshold range (C_MAF_INT_MIN_DIAG_FL_LS_DOWN; C_MAF_INT_MAX_DIAG_FL_LS_DOWN).

The error flag LV_ERR_FL_LS_DOWN[i] shall be set once the anti-bounce counter has reached its maximum value and reset should the anti-bounce counter reach 0.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing the error memory, reset of all variables and bits to 0

Recurrence: **T_sample 100ms**

Activation / Deactivation:

```
If      LV_DIAG_CDN_PLAUS_LS_DOWN[i] = 1
and     LV_INH_DIAG_FL_LS_DOWN[i] = 0
and     C_MAF_INT_MAX_DIAG_FL_LS_DOWN > MAF_INT_FL[i]
        > C_MAF_INT_MIN_DIAG_FL_LS_DOWN
then    "Diagnosis available"
        LV_CDN_DIAG_FL_LS_DOWN[i] = 1
else    "Diagnosis NOT available"
        LV_CDN_DIAG_FL_LS_DOWN[i] = 0
endif
```

Formula section:

```
If      LV_CDN_DIAG_FL_LS_DOWN[i] = 1
then    If      VLS_DOWN[i] < C_VLS_MAX_DIAG_FL_LS_DOWN
        then    "FL signal plausibility fault present"
                ERR_SYM_FL_LS_DOWN[i] = sym_3 / "FL PLAUSIBILITY ERROR"
                /Error Manager shall debounce this symptom
        else
                ERR_SYM_FL_LS_DOWN[i] = "NO_SYM"

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_INT_FL[NC_CBK_EX_NR]	V/O	0...FFFFH	0...1820.42	0.0277778	[g]
integral of air mass flow while FL active					

Input data:

LV_FL	MAF_CYL	LV_ST_END	LV_IGK
VLS_UP[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

Description:

The calculation of MAF_INT_FL[i] expires in 20ms raster as long as either the operation status FL is fulfilled or VLS_UP[i] indicates rich conditions, depending on the setting of LC_MAF_INT_FL_CDN_AFR. The integral is calculated even when the application conditions for the plausibility check function are not fulfilled. MAF_INT_FL[i] is limited to the maximum value if necessary in case of a longer FL (or rich) phase.
The value of MAF_INT_FL[i] should reset to 0 if the transition LV_FL = 1 -> 0 takes place resp. if VLS_UP[i] no longer indicates rich.

Remarks:
Although the upstream sensor signal is used here if LC_MAF_INT_FL_CDN_AFR = 1, the calculation is still usable for both linear and binary upstream sensors. Only one of the calibrateable VLS_UP limits should be calibrated for a given type: the upper limit for linear sensors, and the lower limit for binary sensors. The other one is not meaningful and should be set to the physical limit.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1 or reset reset of all variables and bits to 0

Recurrence: **Tsample = 20ms**

Activation / Deactivation:

```
If      LV_ST_END = 1
then    calculation enabled
else    calculation disabled
endif
```

Formula section:

This action computes the elementary antibounce filter for one failure treatment and returns filter result
ACTION_INFR_GetElDiagLshDown(IN <i>, OUT < cdn_diag>, OUT <err_diag>)
This action reads the failure and the conditions information for each symptom from the infrastructure

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.
All symptoms of the current error code are handeled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

Description:

The error detection is effected via the ECU hardware.

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
☐☐☐☐
 │ │ │ └─> Short circuit to battery (SCP)          (= SYM_0)
 │ │ └───> Short circuit to ground (SCG)           (= SYM_1)
 │ └─────> Open circuit          (OC)          (= SYM_2)
 └───────> -                                       (= SYM_3)
```

The function is intended for use in a hardware configuration where the heater driver shall carry out the electrical fault diagnosis and provide the electrical status via status flags.

- *Short circuit to Vbatt by Over-temperature* ***or*** *Overcurrent* (**SCP**)
- *Short circuit to GND* (SCG)
- *Open load* (**OC**)

The heater drivers named are capable of detecting an **OC** and **SCP** fault when in the ON state and only capable of detecting a SCG fault in the OFF state. As the heater power is controlled by a PWM signal, the driver will be placed alternately in an ON and then OFF state.

The diagnosis shall be activated should the following conditions be met:

- Engine leaving the engine start state as denoted by LV_IGK = 1
- Battery voltage falls between pre-set thresholds to protect against false errors at battery voltage extremes as indicated by **LV_VB_CDN_OBD_1**.
- CDN depending on duty cycle of LSHPWM_DOWN[i]
- Inhibit flag not set (LV_INH_DIAG_LSH_DOWN[i])

In exceptionally rare extreme environmental conditions for certain system configurations, it is possible that the heater driver may be driven into over-temperature during initial oxygen sensor heating. In this case, the driver automatically turns off the output stage in self-protection and sets the **SCP** electrical fault bit. In order to mask an incorrect oxygen sensor heater **SCP** fault, the function shall only allow the **SCP** to set a fault during the initial heater phase, if the exhaust gas temperature has exceeded a pre-determined calibrateable threshold.

The oxygen sensor heater fault detection shall be debounced by use of an anti-bounce counter. This shall be handled by the Dynamic Error Management.

Each of the above listed faults shall be described individually below:

Otherwise the diagnosis has to be suppressed (CDN_DIAG_LSH_DOWN[i] = 0). This is managed within the “Diagnosis condition calculation.

Application conditions:

Initialization: at reset CDN_DIAG_LSHDOWN[i] = 0,

ERR_DIAG_LSH_DOWN[i] = 0

All other variables are initialized according filter type

Activation : -

Deactivation: -

Recurrence: 100 ms

NOTE: The heater PWM frequency shall be at least 2 times faster than the diagnosis frequency to ensure that an oversampling effect does not occur!

<u>**Formula section:**</u>

```
If      LV_IGK = 1
        And   LV_VB_CDN_OBD_1 = 1
        and   LV_INH_DIAG_LSH_DOWN[i] = 0
then
```

<u>Usage of the diagnosis information (failure symptoms (raw value)</u> **ERR_DIAG_LSH_DOWN[i]** <u>and basic diagnosis conditions</u> **CDN_DIAG_LSH_DOWN[i]**) <u>received from the infrastructure:</u>

ACTION_INFR_GetElDiagLshDown (IN <i>, **OUT**<CDN_DIAG_LSH_DOWN[i]>, **OUT**<ERR_DIAG_LSH_DOWN[i]>**)**

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_LSH_DOWN[i]. Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_LSH_DOWN[i].

```
    If      Activation conditions are met for the NC_PSD_DLY_LSH_DOWN recurrence
    Then
            If      LSHPWM_DOWN[i] < C_LSHPWM_MIN_DIAG_LSH_DOWN
            or      [(STATE_LSH_DOWN[i] = LSH_POW_RISE
            or      STATE_LSH_DOWN[i] = LSH_POW_RED)
            and     TEG_DYN_LS_DOWN[i] <
                    C_TEG_DYN_MIN_DIAG_LSH_DOWN]
            then    bit 0 of CDN_DIAG_LSH_DOWN[i] = 0 (SCP can not be detected))
            endif
            If      LSHPWM_DOWN[i] > C_LSHPWM_MAX_DIAG_LSH_DOWN
            then    bit 1 of CDN_DIAG_LSH_DOWN[i] = 0  (SCG can not be detected)
            endif
            If      LSHPWM_DOWN[i] < C_LSHPWM_MIN_DIAG_LSH_DOWN
            or      LSHPWM_DOWN[i]  > C_LSHPWM_MAX_DIAG_LSH_DOWN
            then    bit 2 of CDN_DIAG_LSH_DOWN[i] = 0  (OC can not be detected)
            endif
```

```
        Else
                CDN_DIAG_LSH_DOWN[i] = 0
        Endif
    Else
                CDN_DIAG_LSH_DOWN[i] = 0
    endif
```

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_LSH_DOWN[i] and ERR_DIAG_LSH_DOWN[i].

ACTION_ERRM_FilterMulticondition(IN <*XX*>, IN< CDN_DIAG_LSH_DOWN[i]>, IN< ERR_DIAG_LSH_DOWN[i]>, IN <C_ABC_INC_LSH_DOWN>, IN <C_ABC_MAX_LSH_DOWN>, OUT<LV_ERR_LSH_DOWN[i]>)

FUNCTION DESCRIPTION:

General information:

This function shall debounce OBD-I errors at the Wide Range Air/Fuel (WRAF) Sensor detected by the ATIC42 and define a variable containing the diagnosis register of the controller.

If the error is recognised as debounced, the function shall generate an error flag and inhibit the SPI-communication between basic software (BSW) and ATIC42. This is necessary, because in case an electrical failure, the ATIC42 disconnect and reconnect all the PINs of the sensor by itself every recurrence of the BSW, by reading of the Diagnosis-register. This is harmful for the sensor and must be prevented.

According the exhaust gas system the variable shall be defined from [i]=1 to NC_CBK_EX_NR.

Error Symptoms are defined as follows:

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │ │ │ └─> Short circuit to battery “SCP”   ( = SYM_0)
  │ │ └───> Short circuit to Ground “SCG”  ( = SYM_1)
  │ └─────> (not used)
  └───────> (not used)
```

Application conditions:

Initialisation:

The following variables, related to the diagnosis manager shall be initialized according to the filter type “MEM”.
(all 0 at LV_IGK 0->1 or at ECU reset or clearing error memory)

LV_ERR_EL_LSL_UP[i] = 0

LV_CDN_DIAG_EL_LSL_UP[i] = 0

LV_END_DIAG_EL_LSL_UP[i] = 0

ERR_SYM_EL_LSL_UP[i] = “NO_SYM”

The following data shall be set to 0 at LV_IGK 0->1 or at ECU reset or at clearing error memory

STATE_ERR_EL_LSL_UP[i] = ‘No Fault’

LV_LSL_UP_SPI_COM_INH[i] = 0

T_DLY_DIAG_EL_LSL_UP[i] = 0

Recurrence:

The function shall be carried out once every 10ms.

Activation / Deactivation:

If

LV_ST_END = 1 **and**
LV_ES = 0 **and**
LV_ERR_EL_LSL_UP[i] = 0 **and**
LV_LSL_IF_SPI_RST_END[i] = 1 **and**

```
     LV_INH_DIAG_EL_LSL_UP[i] = 0
Then
        LV_DIAG_ACT_EL_LSL_UP[i] = 1
        The diagnosis shall be carried out
Else
     LV_ DIAG_ACT_EL_LSL_UP[i] = 0
        The diagnosis shall be deactivated
Endif
```

Formula section:

The variable STATE_ERR_EL_LSL_UP[i] is usefull during the development phase of the ASIC and shall be built up by the failure-bits STATE_ERR_VNLSL[i], STATE_ERR_VGLSL[i], STATE_ERR_VIPLSL[i], STATE_ERR_VRCLSL[i], delivered from the BSW. This variable shall have one of the following values according to the following table:

STATE_ERR_ VRCLSL[i]	STATE_ERR_ VIPLSL[i]	STATE_ERR_ VGLSL[i]	STATE_ERR_ VNLSL[i]	Value for STATE_ERR_ EL_LSL_UP
0	0	0	0	0H
1	0	0	0	1H
0	**1**	0	0	2H
0	0	**1**	0	3H
0	0	0	**1**	4H
"1" in more then one Variable				5H
2	0	0	0	6H
0	**2**	0	0	7H
0	0	**2**	0	8H
0	0	0	**2**	9H
"2" in more then one Variable				AH

Setting the symptoms:

```
If (1)   LV_DIAG_ACT_EL_LSL_UP[i] = 1
Then (1)
     If (2) T_DLY_DIAG_EL_LSL_UP[i] > C_T_DLY_DIAG_EL_LSL_UP
     Then
          LV_CDN_DIAG_EL_LSL_UP[i] = 1
          If (3) 1H ≤ STATE_ERR_EL_LSL_UP[i] ≤ 5H
          Then (3)
             ERR_SYM_EL_LSL_UP[i] = sym_1  /% "Short to ground"
          Else (3)
             If  (4)
                        6H ≤ STATE_ERR_EL_LSL_UP[i] ≤ AH
             Then (4)
                       ERR_SYM_EL_LSL_UP[i] = sym_0   / % "Short to plus"
             Else (4)
                       ERR_SYM_EL_LSL_UP[i] = NO_SYM   /% no symptom
```

```
            Endif (4)
        Endif (3)
    Else (2)
      Increment T_DLY_DIAG_EL_LSL_UP[i]
    Endif (2)
Endif (1)
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

```
Apply filter on current symptoms
If filtering result available  (after debounce)
then
    LV_ERR_EL_LSL_UP[i] = filtering result
    LV_END_DIAG_EL_LSL_UP[i] = 1
    Delivery of the result to the Error Management
Endif
```

LV_LSL_UP_SPI_COM_INH[i] = LV_ERR_EL_LSL_UP[i]

FUNCTION DESCRIPTION:

General information:

This function shall monitor the *pump current controller* inside the WRAF sensor controller ATIC42 in order to protect the oxygen sensor against operation with high pump current (Ip) during excessive time which can be harmfull to the sensor.

High pump current for long time is allowed only during the warm up phase of the WRAF sensor, when its ceramic temperature not high enough, but the Ip controller activaton is needed to detect the sensor operability as fast as possible. To avoid false error messages this function shall run only after the sensor heater achieves its steady state after the warm up phase, when it starts to work in closed loop.

To avoid any double diagnostic it shall be monitored if no sensor electrical failure exists (short circuit to ground or to battery voltage) or if the heater management works properly. In both cases it is possible due to a failure to flow a high Ip current through the sensor. Similarly it must be asked if the sensor requires an *reference air pump current* and in positive case, if this is active.

If a *pump current controller* failure symptom is detected, the use of the sensor is not more possible and the lambda controller shall be deactivated immediately. Should this symptom be completely debounced, the sensor shall not be used for any purpose during the current driving cycle and also the *pump current controller* shall be deactivated in order to avoid any sensor damage.

Description:

This diagnosis serves to debounce the information concerning the conditions of the *pump current controller* which *is* the delivered by the ATIC42 via its Basic Software.
As long as the Ip current is at their bounds, which is defined *per* hardware [1], the ATIC42 limits the *pump current controller* output and writes in a warning message in its diagnosis register, indicating that Ip current is too low or too high. The Basic Software dedicated to the ATIC42 reads out every 10 ms the diagnosis register and save this information in the variable STATE_ERR_IPLSL[i]. This shall be evaluated here and in failure case the symptom debounced.

[1] For more informations please see the ATIC42 specification.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, by ECU-reset or at clearing the error memory shall all variables be reseted.

Recurrence:

The function shall be carried out once every 100ms.

Note: Altough the variable STATE_ERR_IPLSL[i] is updated every 10 ms, it is not necessary to evaluate it so frequently. The decision to stop the Ip controller must not be done with a resolution of miliseconds but seconds. It can be taken advantage to that point allowing to filter transient Ip-controller conditions.

Activation / Deactivation:

```
If      (LAMB_SP[i] < C_LAMB_SP_AFR_IPLSL_DIAG_LSL_UP  or
        LAMB_SP[i] > C_LAMB_SP_AFL_IPLSL_DIAG_LSL_UP)            and

16.36.1 Upstream O2 sensor final diagnosis

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function shall summarize the diagnostic status of the upstream oxygen sensor delivered from the OBD I & II functions (heater and sensor) through the flag LV_ERR_LS_UP[i].

The ultimate error flag LV_ERR_LS_UP[i] is a component error and no DTC shall be sended to the Error Management.

To reduce the number of variables to be checked by other diagnosis functions, the collecting flag LV_LS_UP_DIAG_END is introduced. It provides the possibility to combine the end flags from almost all the upstream linear lambda sensor diagnosis functions. By a bit mask variable it is calibratable which end flag contributes to the collecting end flag.

Note:
1. If two separate Banks are concerned, then i=1 for cylinder bank 1 and i=2 for cylinder bank 2.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

LV_ERR_LS_UP[i] = 0
LV_LS_UP_OBD_1_MAN_DEAC[i] = 0
LV_LS_UP_OBD_2_MAN_DEAC[i] = 0
LV_LS_UP_DIAG_END[i] = 0

Recurrence:

The function should be carried out once every 100 ms.

Activation/ Deactivation:

The diagnosis will be carried out if LV_ST_END = 1

Formula section:

```
If      LV_LS_UP_OBD_MAN_DEAC_EXT = 1
Then    LV_LS_UP_OBD_1_MAN_DEAC[i] = 1
        LV_LS_UP_OBD_2_MAN_DEAC[i] = 1
Else
```

```
              LV_LS_UP_OBD_1_MAN_DEAC[i] = LC_LS_UP_OBD_1_MAN_DEAC[i];
              LV_LS_UP_OBD_2_MAN_DEAC[i] = LC_LS_UP_OBD_2_MAN_DEAC[i];
Endif
```

The linear lambda sensor error flag shall be set under the following conditions:

```
IF
   LC_LS_UP_DIAG_ACT[i] = 1  % activation of final diagnosis                AND
  ( LV_ERR_EL_LSL_UP[i] = 1    % electrical failure                         OR
  LV_ERR_OC_LSL_UP[i] = 1   % open circuit failure                          OR
  LV_ERR_LSL_UP_IF[i] = 1     % linear sensor controller failure            OR

  LV_ERR_LSH_UP[i] = 1                  % heater electrical failure         OR
  LV_ERR_OBD_VLD_LSH_UP[i] = 1   % heater controller failure                OR
  LV_ERR_LSH_LSL_UP[i] = 1            % heater to sensor signal coupling failure   OR

  LV_ERR_AIR_LSL_UP[i] = 1   % sensor not mounted in exhaust pipe           OR
  LV_ERR_PUC_VLD_LS_UP[i]= 1      % sensor charact. line slope failure      OR
  LV_ERR_SHIFT_AFL_LSL_UP[i]= 1  % sensor charact. line shift to lean failure   OR
  LV_ERR_SHIFT_AFR_LSL_UP[i]= 1 % sensor charact. line shift to rich failure    OR

  LV_ERR_DYN_VLD_LS_UP[i]=1 & LC_ERR_DYN_VLD_LS_UP = 1                     OR
    % sensor dynamic failure (allowed by the project to stop closed loop control)
  LV_ERR_CHG_LS_UP =1 & LC_ERR_CHG_LS_UP = 1                               OR
    % sensor interchanged failure (allowed by the project to stop closed loop control)

   LC_LS_UP_ERR[i] = 1)          % manual activation of lambda sensor error
THEN
     LV_ERR_LS_UP[i] = 1
ELSE
     LV_ERR_LS_UP[i] = 0
ENDIF
```

The general end flag is created according to the following logic:

If the corresponding bit is one, the LV_END_DIAG_XX flag shall be considered for the final end flag.

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit mask variable (example) C_NR_END_DIAG_LSL_UP[i]	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1
	Not used	Not used	Not used	Not used	LV_END_DIAG_CHG_LS_UP	LV_END_DIAG_AIR_LSL_UP[i]	LV_END_DIAG_LSH_LSL_UP[i]	LV_END_DIAG_PUC_VLD_LS_UP[i]	LV_END_DIAG_SHIFT_AFR_LSL_UP[i]	LV_END_DIAG_SHIFT_AFL_LSL_UP[i]	LV_END_DIAG_DYN_VLD_LS_UP[i]	LV_END_DIAG_OBD_VLD_LSH_UP[i]	LV_END_DIAG_LSL_UP_IF[i]	LV_END_DIAG_OC_LSL_UP[i]	LV_END_DIAG_EL_LSL_UP[i]	LV_END_DIAG_LSH_UP[i]

For this proposal, the number would be 0000011111111111 binary = 2047 decimal. All end flags except the one from the interchanged diagnosis must be set to 1 to also set the final end flag to 1.

The bitmask shall be combined with the single end flags as follows:

If [(C_NR_END_DIAG_LSL_UP[i].bit 0 = 0 **or** LV_END_DIAG_LSH_UP[i] = 1)
and
(C_NR_END_DIAG_LSL_UP[i].bit 1 = 0 **or** LV_END_DIAG_EL_LSL_UP[i] = 1)
and

else
    LV_LS_UP_DIAG_END[i] = 0
endif
```

16.36.2 Downstream O2 sensor final diagnosis

FUNCTION DESCRIPTION:

General information:

This function shall summarize the diagnostic status of the downstream oxygen sensor delivered from the OBD I & II (heater and sensor) functions through the flag LV_ERR_LS_DOWN[i].

The ultimate error flag LV_ERR_LS_DOWN[i] is a System Error Flag. It should neither be saved in the Error Management nor a DTC code should be given.

To reduce the number of variables to be checked by other diagnosis functions, the collecting flag LV_LS_DOWN_DIAG_END is introduced. It provides the possibility to combine the end flags from almost all the downstream lambda sensor diagnosis functions. By a bit mask variable it is calibratable which end flag contributes to the collecting end flag.

Note:

1. If two separate Banks are concerned, then i=1 for cylinder bank 1 and i=2 for cylinder bank 2.
2. The diagnosis for interchanged lambda sensors is not included in the final error and end flag as this is mainly related to the End of Line test or to a final check after a repair in the garage.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

```
LV_ERR_LS_DOWN[i] = 0
LV_LS_DOWN_OBD_1_MAN_DEAC[i] = 0
LV_LS_DOWN_OBD_2_MAN_DEAC[i] = 0
LV_LS_DOWN_DIAG_END[i] = 0
```

Recurrence:

The function should be carried out once every 100 ms.

Activation / Deactivation:

The diagnosis will be carried out only if LV_ST_END = 1

Formula section:

```
If      LV_LS_DOWN_OBD_MAN_DEAC_EXT = 1
Then    LV_LS_DOWN_OBD_1_MAN_DEAC[i] = 1
        LV_LS_DOWN_OBD_2_MAN_DEAC[i] = 1
Else
    LV_LS_DOWN_OBD_1_MAN_DEAC[i] = LC_LS_DOWN_OBD_1_MAN_DEAC[i]
    LV_LS_DOWN_OBD_2_MAN_DEAC[i] = LC_LS_DOWN_OBD_2_MAN_DEAC[i]
Endif
```

Calculation of sum error bit for downstream oxygen sensor diagnosis

```
IF
    LC_LS_DOWN_DIAG_ACT[i] = 1     % final diagnosis active                  AND
    ( LV_ERR_EL_LS_DOWN[i]= 1      % electrical failure                      OR

    LV_ERR_SWT_LS_DOWN[i] = 1      % switching time rich-to-lean failure     OR
    LV_ERR_PUE_LS_DOWN[i] = 1      % sensor signal after PUC phase failure   OR

    LV_ERR_CHK_LS_DOWN[i] = 1      % error detected by the active test       OR
    LV_ERR_PLAUS_LS_DOWN[i] = 1  % error detected by the passive test
           OR

    LV_ERR_LSH_DOWN[i] = 1         % heater electrical failure               OR
    LV_ERR_OBD_LSH_DOWN[i] = 1   % heater obd2 failure                       OR
    ( LV_ERR_CHG_LS_DOWN = 1 & LC_ERR_CHG_LS_DOWN = 1 )                      OR
    % sensor interchanged failure

    LC_LS_DOWN_ERR[i] = 1 )        % manual activation of sensor error
THEN
     LV_ERR_LS_DOWN[i] = 1
```

```
ELSE
    LV_ERR_LS_DOWN[i] = 0
ENDIF
```

The general end flag is created according to the following logic:

If the corresponding bit is one, the LV_END_DIAG_XX flag shall be considered for the final end flag.

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit mask variable (example) C_NR_END_DIAG_LS_DOWN[i]	0	0	0	0	0	0	0	1	1	1	0	1	1	1	1	1
	Not used	Not used	Not used	Not used	Not used	LV_END_DIAG_CHG_LS_DOWN	LV_END_DIAG_PUE_LS_DOWN[i]	LV_END_DIAG_SWT_LS_DOWN[i]	LV_END_DIAG_CHK_LS_DOWN[i]	LV_END_DIAG_PUC_LS_DOWN[i]	LV_END_DIAG_FL_LS_DOWN[i]	LV_END_DIAG_OC_LS_DOWN[i]	LV_END_DIAG_SCG_LS_DOWN[i]	LV_END_DIAG_SCP_LS_DOWN[i]	LV_END_DIAG_OBD_LSH_DOWN[i]	LV_END_DIAG_LSH_DOWN[i]

For this proposal, the number would be 0000000111011111 binary = 479 decimal.

The bitmask shall be combined with the single end flags as follows:

```
If  [(C_NR_END_DIAG_LS_DOWN[i].bit 0 = 0 or LV_END_DIAG_LSH_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 1 = 0 or LV_END_DIAG_OBD_LSH_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 2 = 0 or LV_END_DIAG_SCP_LS_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 3 = 0 or LV_END_DIAG_SCG_LS_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 4 = 0 or LV_END_DIAG_OC_LS_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 5 = 0 or LV_END_DIAG_FL_LS_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 6 = 0 or LV_END_DIAG_PUC_LS_DOWN[i] = 1)
    and
    (C_NR_END_DIAG_LS_DOWN[i].bit 7 = 0 or LV_END_DIAG_CHK_LS_DOWN[i] = 1)
    and
```

```
        (C_NR_END_DIAG_LS_DOWN[i].bit 8 = 0 or LV_END_DIAG_SWT_LS_DOWN[i] = 1)
        and
        (C_NR_END_DIAG_LS_DOWN[i].bit 9 = 0 or LV_END_DIAG_PUE_LS_DOWN[i] = 1)
        and
        (C_NR_END_DIAG_LS_DOWN[i].bit 10 = 0 or LV_END_DIAG_CHG_LS_DOWN = 1)
    then
        LV_LS_DOWN_DIAG_END[i] = 1
    else
        LV_LS_DOWN_DIAG_END[i] = 0
    endif
```

FUNCTION DESCRIPTION:

Application conditions:

Initialisation:

At reset and LV_IGK 0 → 1 transition, do the following synchronization with ERRM:

ACTION_ERRM_GetLvErr (in OFS_LSL_UP_i,
out LV_ERR_OFS_LSL_UP[i])

ACTION_ERRM_GetLvEndDiag (in OFS_LSL_UP_i,
out LV_END_DIAG_OFS_LSL_UP[i])

ACTION_ERRM_GetLvErr (in CTL_LSL_UP_i,
out LV_ERR_CTL_LSL_UP[i])

ACTION_ERRM_GetLvEndDiag (in CTL_LSL_UP_i,
out LV_END_DIAG_CTL_LSL_UP[i])

When clearing the error memory, all ERRM related data shall be reset to 0.

Additionally, the following initialization shall be done on all these occasions:

CDN_DIAG_CTL_LSL_UP[i] = 0

ERR_DIAG_CTL_LSL_UP[i] = 0

CTR_OFS_ADJ_CMPL[i] = 0

T_DIAG_ACT_OFS[i] = 0

LV_LSL_OFS_ADJ_DIAG_OFS_OLD[i] = 0

For activation conditions and recurrences see the individual function blocks.

16.38.1 WRAF Controller Offset Diagnosis

General information:

This part of the function shall check the performance of the offset adjustment carried out by the WRAF controller. The measured offset should fall within a calibrateable band, and the time taken by an offset adjustment should be shorter than a calibrateable upper limit.

Error Symptoms are defined as follows:

```
  └─┴─┴─┴─┘
   │  │  │  └─> Limitation of offset correction in low gain         ( = SYM_0)
   │  │  └────> Limitation of offset correction in high gain        ( = SYM_1)
   │  └───────> Exceeded maximum duration of offset correction      ( = SYM_2)
   └──────────> (not used)
```

Recurrence:

The function shall be carried out once every 10ms.

Activation: LV_INH_DIAG_OFS_LSL[i] = 0 **and**
(LV_LSL_OFS_ADJ_DIAG_OFS_OLD[i] = 1 **or**
LV_LSL_OFS_ADJ_ACT[i] = 1)

Formula section:

```
If(1)      LV_LSL_OFS_ADJ_ACT[i] = 1
then(1)    Increment  T_DIAG_ACT_OFS[i]
else(1)    Reset  T_DIAG_ACT_OFS[i]
endif(1)
LV_LSL_OFS_ADJ_DIAG_OFS_OLD[i] = LV_LSL_OFS_ADJ_ACT[i]
```

Setting the symptoms:

```
if (1)    LV_VLS_OFS_ADJ_CMPL[i]  0 -> 1
then (1)     LV_CDN_DIAG_OFS_LSL_UP[i] = 1
          Reset T_DIAG_ACT_OFS[i]
          Increment CTR_OFS_ADJ_CMPL[i]
          if (2)  LV_VLS_OFS_LIM_LSL_L_GAIN[i] = 1
          then (2) ERR_SYM_OFS_LSL_UP[i] = SYM_0    % "offset correction limitation low gain"
          elseif (2) LV_VLS_OFS_LIM_LSL[i] = 1
          then (2) ERR_SYM_OFS_LSL_UP[i] = SYM_1  % "offset correction limitation high gain"
          else (2)  ERR_SYM_OFS_LSL_UP[i] = NO_SYM  % "offset correction works normal"
          endif (2)
elseif (1)   T_DIAG_ACT_OFS[i] >= C_T_DIAG_ACT_OFS_MAX
then (1)     LV_CDN_DIAG_OFS_LSL_UP[i] = 1
          ERR_SYM_OFS_LSL_UP[i] = SYM_2    % "offset correction maximum duration exceeded"
else (1)LV_CDN_DIAG_OFS_LSL_UP[i] = 0
endif (1)
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Calling the generic error management for anti-bounce filtering and update of the outputs:

```
ACTION_ERRM_FilterSymptom (      in     OFS_LSL_UP_i,
                                 in     LV_CDN_DIAG_OFS_LSL_UP[i],
                                 in     ERR_SYM_OFS_LSL_UP[i],
                                 in     C_ABC_INC_DIAG_OFS_LSL_UP[i],
                                 in     1,
                                 in     C_ABC_MAX_DIAG_OFS_LSL_UP[i],
                                 out    LV_ERR_OFS_LSL_UP[i])
ACTION_ERRM_GetLvEndDiag (       in     OFS_LSL_UP_i,
                                 out    LV_END_DIAG_OFS_LSL_UP[i])
```

16.38.2 WRAF Controller Limitation Diagnosis

General information:

This part of the function shall check the performance of the pump current controller and (if used) the reference pump current generator in the WRAF sensor controller. For this, the pump current, pump voltage and nernst overvoltage diagnostic flags read out from the controller by the BSW are checked.

Since the flags are also set if there is an open circuit in one or more of the sensor lines, the diagnosis must only operate under conditions that exclude an open circuit. Hence the checks for tip temperature and VLS_UP_DIAG limits.

To disable monitoring for the individual flags based on driving conditions, the corresponding bit in CDN_DIAG_CTL_LSL_INH[i] should be set. To turn off a monitor permanently, the bit in CDN_DIAG_CTL_LSL_DI[i] must be set instead, otherwise the diagnosis end bit will never be set.

Error Symptoms are defined as follows:

```
 |_|_|_|_|
  | | | └─> Limitation of pump current                             ( = SYM_0)
  | | └───> Limitation of pump voltage                             ( = SYM_1)
  | └─────> VN voltage too high for reference pump current generation  ( = SYM_2)
  └───────> (not used)
```

Recurrence:

The function shall be carried out once every 10ms.

Activation: LV_IPLSL_CTL_ENA_LSL_IF[i] = 1 **and**
(CDN_DIAG_CTL_LSL_INH[i].bit_x = 0 and
CDN_DIAG_CTL_LSL_DI[i].bit_x = 0) for any x = 0...2

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_OFS_LSL allows to deactivate the corresponding diagnostic.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

Description:

Application conditions:

Initialisation:
The following data shall be set to 0 at LV_IGK 0->1 or at ECU reset or at clearing error memory:
LV_INH_DIAG_OFS_LSL[i] = 0

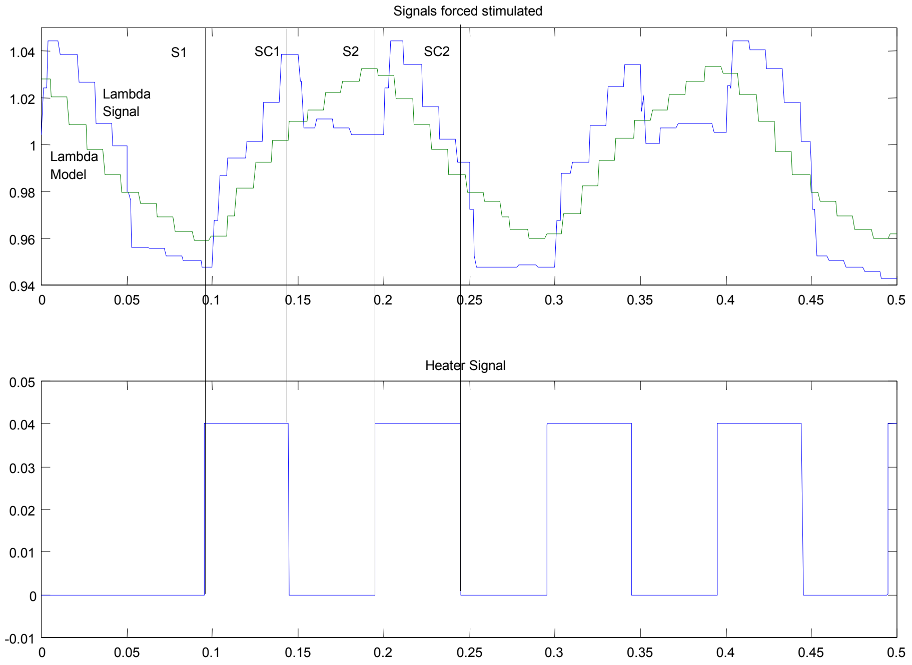
FUNCTION DESCRIPTION:

General information:

The diagnosis of heater coupling on the sensor signal shall detect an increase in the leakage current from heater to sensor circuit, which can be originated by the reduction of insulation resistance, and causes a crosstalk from the heater signal to the sensor circuit. Due to the heater coupling the measured signal of the wide range A/F sensor is perturbed and the lambda regulation influenced. The diagnosis criterion is the difference in the slope between measured sensor signal and model synchronised with the rising and falling edges of the heater PWM-signal. This is showed in the following picture, where a heater frequence of 10 Hz is admitted.

Sx … sampling of the Lambda value
SCx … sampling of the Lambda value and handover from Basic software



The values LAMB_SP_FIL_DELTA_FALL[i], LAMB_SP_FIL_DELTA_RISE[i], VLS_UP_DELTA_RISE[i] and VLS_UP_DELTA_FALL[i] are delivered from the BASIC-Software and represent the lambda model and the oxygen sensor voltage values acquired synchronised with the rising and falling edges of the heater PWM-signal.

Description:

At the beginning of every diagnosis period, the counter CTR_SYM_DIAG_LSH_LSL_UP[i] and the cycle counter CYCNR_DIAG_LSH_LSL_UP[i] shall be initialised by „0“.

After the hand over of VLS_UP_DELTA_RISE[i], VLS_UP_DELTA_FALL[i], LAMB_SP_FIL_DELTA_RISE[i] and LAMB_SP_FIL_DELTA_FALL[i] from the Basic-software (at the time SCx) this function has to start with the calculation of LAMB_DELTA_RISE/FALL[i].

For a better separation of the forced stimulation and the heater coupling (the forced stimulation has the same symptom as the heater coupling), it is necessary to include the sensor signal model in the diagnosis calculation. This will be realised by a subtraction from the relative deviation of the sensor signal model ($(\lambda_{SC1} - \lambda_{S1})_{model}$) and the relative deviation of sensor signal ($(\lambda_{SC1} - \lambda_{S1})_{meas}$). This results gets absolute value. Then it will be filtered by a first order lag element (for mean value). This values will be named to LAMB_DELTA_RISE_LPF[i] (calculated at time point S1 and SC1) and LAMB_DELTA_FALL_LPF[i] ($(\lambda_{SC1} - \lambda_{S2})_{model}$- $(\lambda_{SC1} - \lambda_{S2})_{meas}$).

This values will be compared with the threshold C_LAMB_DELTA_LPF_THD. Is the calculated value higher than the threshold, the error-counter (CTR_SYM_DIAG_LSH_LSL_UP[i]) will be incremented by “1”.

After a resumption of the diagnosis it must be guaranteed that LAMB_DELTA_FALL_LPF[i] contains a current value. If LAMB_DELTA_FALL_LPF[i] and LAMB_DELTA_RISE_LPF[i] are measured, then the cycle counter CYCNR_DIAG_LSH_LSL_UP[i] shall be incremented. If the necessary quantity of diagnosis for one cycle has been carried out, i.e. if CYCNR_DIAG_LSH_LSL_UP[i] > C_CYCNR_MAX_DIAG_LSH_LSL_UP is valid, the diagnosis result must be determined.

By the comparison of the diagnosis results to the limit value, the heater coupling is diagnosed, i.e. if CTR_SYM_DIAG_LSH_LSL_UP[i] > C_CTR_SYM_DIAG_LSH_LSL_UP is true, a heater coupling (ERR_SYM_LSH_LSL_UP[i] = 1) is recognised. If no error is diagnosed, than ERR_SYM_LSH_LSL_UP[i] = 0 is valid. After the reaching of the required number of diagnosis steps C_CYCNR_MAX_DIAG_LSH_LSL_UP, a new diagnosis cycle is started.
If an error could be detected, then the error flag LV_ERR_LSH_LSL_UP[i] = 1 is set, otherwise LV_ERR_LSH_LSL_UP[i] is set to 0.

Remark: The range of lambda sensor heater duty cycle must be limited, through the sampling of the wide range A/F sensor signal with an period of 10 ms. A heater coupling recognitionis possible only in a range of 15% up to 85% of the duty cycle.

At the function reactivation after LV_PUC=1 the MAF-integral shall be calculated. If the MAF-integral exceeds a defined threshold the heater coupling diagnosis starts.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset or at clearing error memory:

LV_IGK	LV_INH_DIAG_CHG_LS_UP	NC_CBK_EX_NR	LV_LAM_STOP_SHO_PER_CDN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

This function was written for exhaust gas systems having two banks, where a sensor interchange cannot be avoided by hardware measures. In case the upstream sensors were interchanged it is expected that both lambda signals will drift from the set point in different directions and the lambda controllers achieve their maximum.

A symptom can be detected if the lambda controller correction of one bank crosses the min threshold whereas the other one crosses the max threshold.

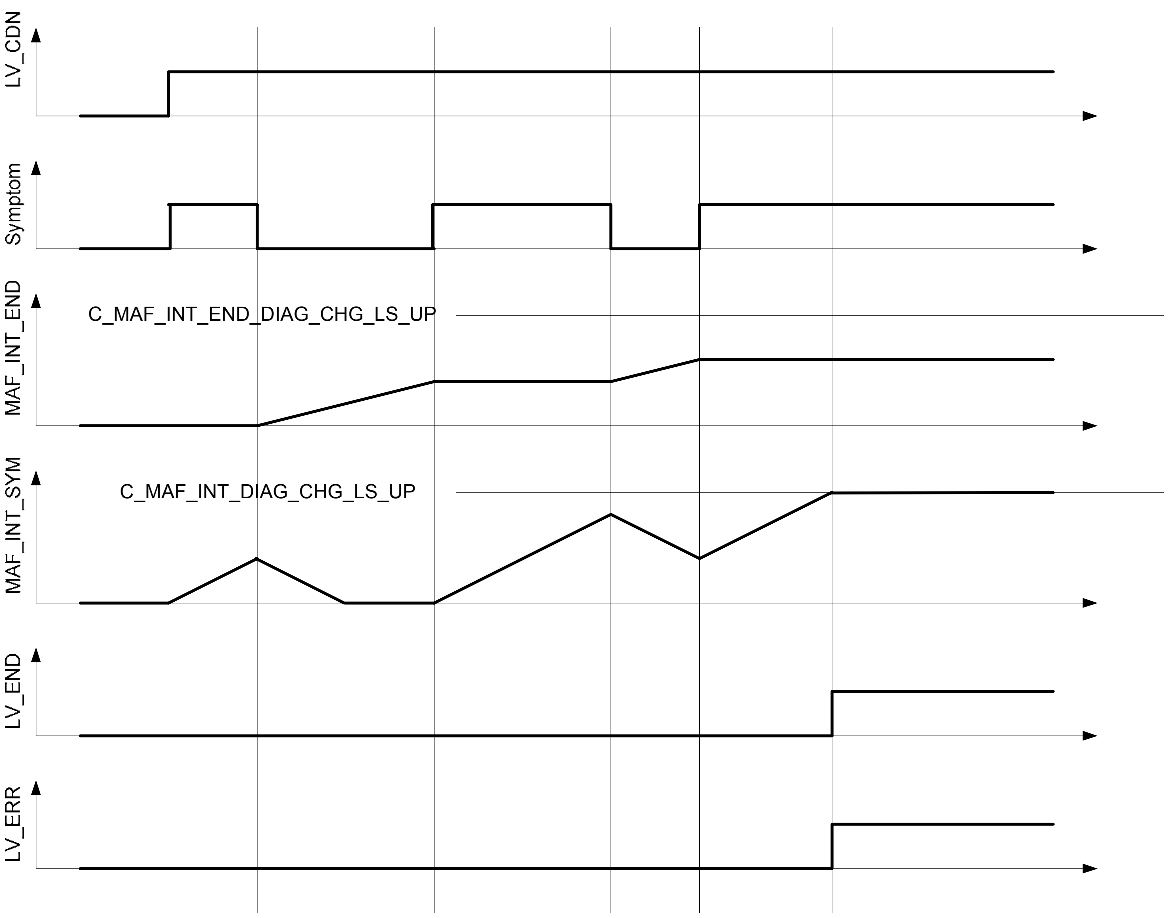

Figure 1: Basic principle of applied debounce algorithm.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 -> 1, reset or clearing error memory reset all variables.

Recurrence:

This function shall run every T_SAMPLE = 100 ms.

LV_INH_DIAG_AIR_LSL_UP[NC_CBK_EX_NR]	NC_CBK_EX_NR	LV_IGK	LV_DIAG_EOL_END_LS_UP_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Description:

This function shall detect a mechanically not attached sensor to the exhaust gas pipe. To do this the WRAF sensor output signal must be monitored during the engine operation , when power is generated. This shall be done by comparing the sensor signal VLS_UP_DIAG[i] with a threshold.
The function shall be activated during Partial Load or Full Load, if the sensor was recognised as operable, i.e. LV_IPLSL_VLD[i] = 1. A symptom shall be detected if the engine runs, i.e.

it generates power, and at the same time the sensor signal is very high, indicating a very lean combustion mixture.

Application Conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory reset all variables.

Recurrence:

The function shall be carried out every 100 ms.

Activation:

```

16.45.1.1 Interface for Rate – Based – Monitoring AIR_LSL_UP[i]

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the AIR_LSL_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_AIR_LSL_UP[i] data.

Within STATE_RBM_AIR_LSL_UP[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation: *at ECU reset:*

bit 0, bit 1 and bit 2 of STATE_RBM_AIR_LSL_UP[i] = 0

LV_DIAG_EOL_AIR_LSL_UP_DC[i] = 0

LV_DC 0 → 1 transition:

bit 0 and bit 1 of STATE_RBM_AIR_LSL_UP[i] = 0

LV_DIAG_EOL_AIR_LSL_UP_DC[i] = 0

on failure memory reset:

bit 1 of STATE_RBM_STATE_RBM_AIR_LSL_UP[i] = 0

LV_DIAG_EOL_AIR_LSL_UP_DC[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 -> 1 transition

bit 2 of STATE_RBM_AIR_LSL_UP[i] = 1

The pending status of the following failures has to be checked only once :

	LV_ERR_AMP	LV_ERR_LOAD_TPS_PLAUS

ACTION_ERRM_NoFilterReset(IN<IDX_DIAG>, OUT< LV_ERR_XX >)

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

This function shall evaluate the Linear Oxygen Sensor dynamic behaviour once per driving cycle by measuring the sensor output signal damping during the time, the forced stimulation is active with the special set of parameters for the Dynamic Diagnosis or for the Catalyst Efficiency Diagnosis. During this time the air-fuel ratio is stimulated with a defined amplitude and period.

The air-fuel oscillation observed with a new sensor and with the aged limit sensor shall be measured, using the above mentioned forced stimulation parameters in combination with the eventually shorter period time IP_T_DYN_DIAG. The results shall be saved in the maps IP_LAMB_AMPL_MIN_DYN_LSL_UP (for the aged limit sensor) and IP_LAMB_AMPL_MAX_DYN_LSL_UP (for a new sensor). The aged limit sensor has to be defined by the project in order to fulfil the legal emission requirements and/or to avoid the cross effect on any other function, for example on Catalyst Efficiency Diagnosis.

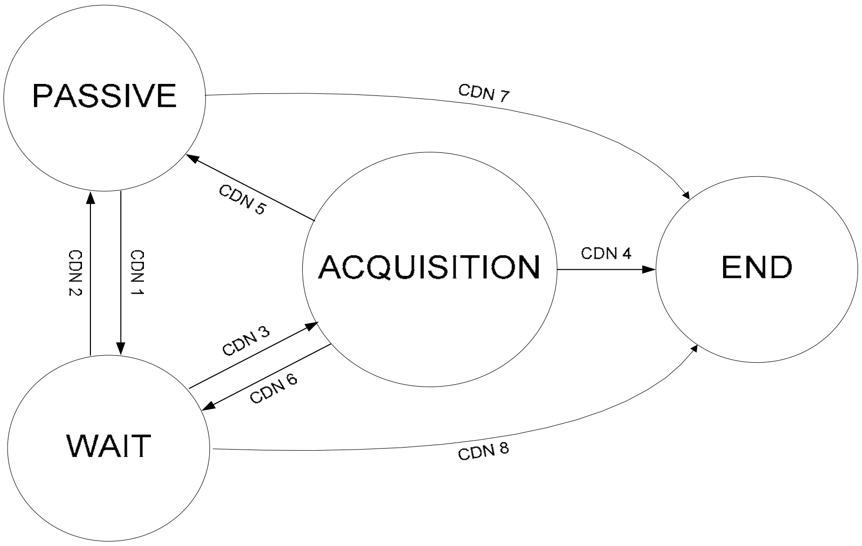
Once the diagnosis is active, after every forced stimulation period, the lambda sensor signal amplitude is calculated. This amplitude is normalised versus engine speed and load. After a calibrateable number of normalised amplitude values are available, a mean value is determined. The lambda amplitude mean value is transformed into the relative damping factor FAC_MV_DIAG_DYN_LSL_UP[i] by comparing with the amplitude of a new sensor with the value for the limit aged sensor.

Once the relative damping factor FAC_MV_DIAG_DYN_LSL_UP[i] is determined for the current driving cycle, it is compared with a calibrateable threshold. If the sensor dynamic response is considered to be over the acceptable limits, then LV_DIAG_DYN_SYM_LSL_UP[i] = 0, otherwise this flag is set to 1.

The factor FAC_MV_DIAG_DYN_LSL_UP[i] can also be used to adapt the sensor time constant model T1_LSL_UP[i] by setting the Boolean switch LC_T1_AD_DIAG_DYN_LSL_UP = 1. In that case a simple linear interpolation is done between the time constant for a new sensor and that for the aged limit sensor, which are saved in the correspondent maps IP_T1_LSL_UP_AGI_LIM[i] and IP_T1_LSL_UP[i]. For more information please refer to the function specification *Lambda control (Fuel mass).*

To help the calibration of this function a tuning guide is available.

Signal flow diagram:



Application conditions:

Initialisation:

At the transition LV_IGK = 0 ->1, by ECU reset, by clearing the Error Memory or by triggering the EOL test (transition LV_DIAG_EOL_DYN_LS_UP[i] = 0 -> 1) iinitialise the variables as indicated below:

- LAMB_MIN_DIAG_DYN_LSL_UP[i] = 32
- T_DYN_DIAG_AFL[i] = 1310.7
- T_DYN_DIAG_AFR[i] = 1310.7
- FAC_DIAG_DYN_LSL_UP[i] , FAC_DYN_LSL_DIAG_SAE[i] and FAC_DYN_LSL_DIAG_TOL_SAE[i] with the correspondent value saved on the non-volatile memory.
- all other variables with zero.

At the initialisation of new ECU or at a EEPROM checksum error, initialize

- FAC_DIAG_DYN_LSL_UP[i] with 0
- FAC_DYN_LSL_DIAG_SAE[i] with 0
- FAC_DYN_LSL_DIAG_TOL_SAE[i] with MAX

ACTION_ERRM_NoFilterReset(IN<NC_IDX_DIAG_ DYN_VLD_LS_UP[i]>, OUT<LV_ERR_ DYN_VLD_LS_UP[i]>)

Recurrence: 20 ms.

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: at every transition LV_IGK = 0->1or reset all variables shall be reset to 0.

at every transition LV_IGK = 1->0 LV_DIAG_DYN_INH_LSL_UP[i] = 1

Recurrence: the functions shall be carried out once every 1s.

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

16.47.1 Interface for Rate – Based - Monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the DYN_VLD_LS_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_DYN_VLD_LS_UP[i] data.

Within STATE_RBM_DYN_VLD_LS_UP[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation: *at ECU reset:*

bit 0, bit 1 and bit 2 of STATE_RBM_DYN_VLD_LS_UP[i] = 0
LV_DIAG_EOL_DYN_LS_UP_DC[i] = 0

LV_DC 0 ->1 transition:

bit 0 and bit 1 of STATE_RBM_DYN_VLD_LS_UP[i] = 0
LV_DIAG_EOL_DYN_LS_UP_DC[i] = 0

on failure memory reset:

bit 1 of STATE_RBM_STATE_RBM_DYN_VLD_LS_UP[i] = 0
LV_DIAG_EOL_DYN_LS_UP_DC[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 ->1 transition

bit 2 of STATE_RBM_DYN_VLD_LS_UP[i] = 1

The pending status of the following failures has to be checked only once :

LV_ERR_MEC_IVVT_IN[NC_NR_CBK_IVVT]	LV_ERR_MAF	LV_ERR_VLS_DOWN_DIF[NC_CBK_EX_NR]

16.48.1 EGCP_PLADGLSL6

This is an alternative diagnosis for the sensor dynamics of WRAF sensors in stratified combustion engines. It expects NOx trap regeneration or other short phases of homogenous combustion in a normally stratified or other lean engine operation. The function interprets the transition from homogenous to stratified mode as a step-like input to the sensor and monitors the sensor's signal response as it rises from around lambda=1 to higher values (typically above lambda=2).

The difference between this response and the modelled behaviour of a good sensor is integrated, start and end of the integral can be calibrated in terms of a MAF integral to focus on the parts of the signal trace that show large and reproducible differences between new and aged sensors. To get more even weighting of differences in the high and low lambda ranges, the modelled and measured lambda values are transformed into O_2 concentrations and the integrals are calculated with these concentrations. A map is used to correct for influences of mass air flow and engine speed on the sensor response.

Application Condition

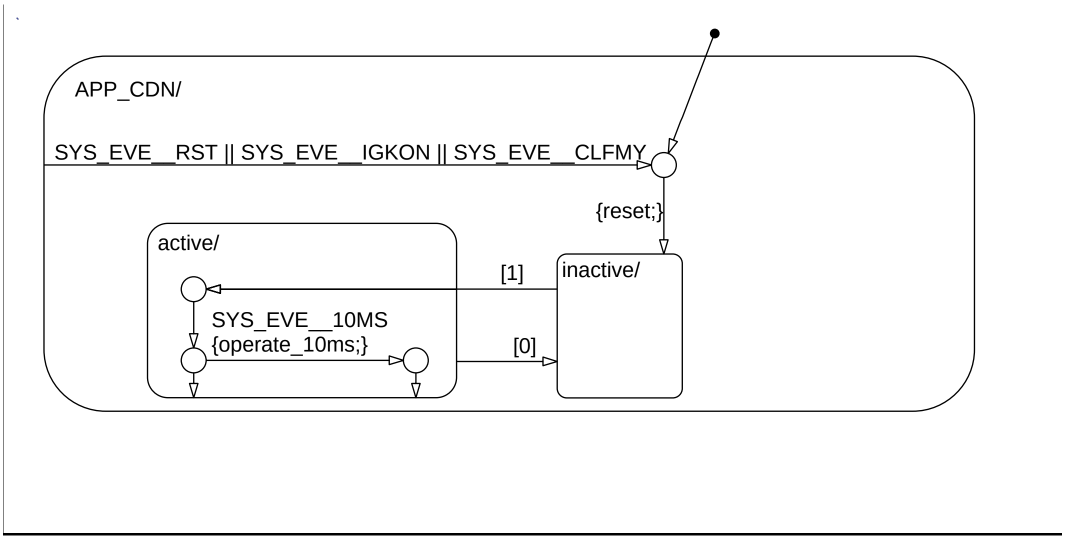

Figure 60 EGCP_PLADGLSL6/ APP_CDN/ Chart

Function Description

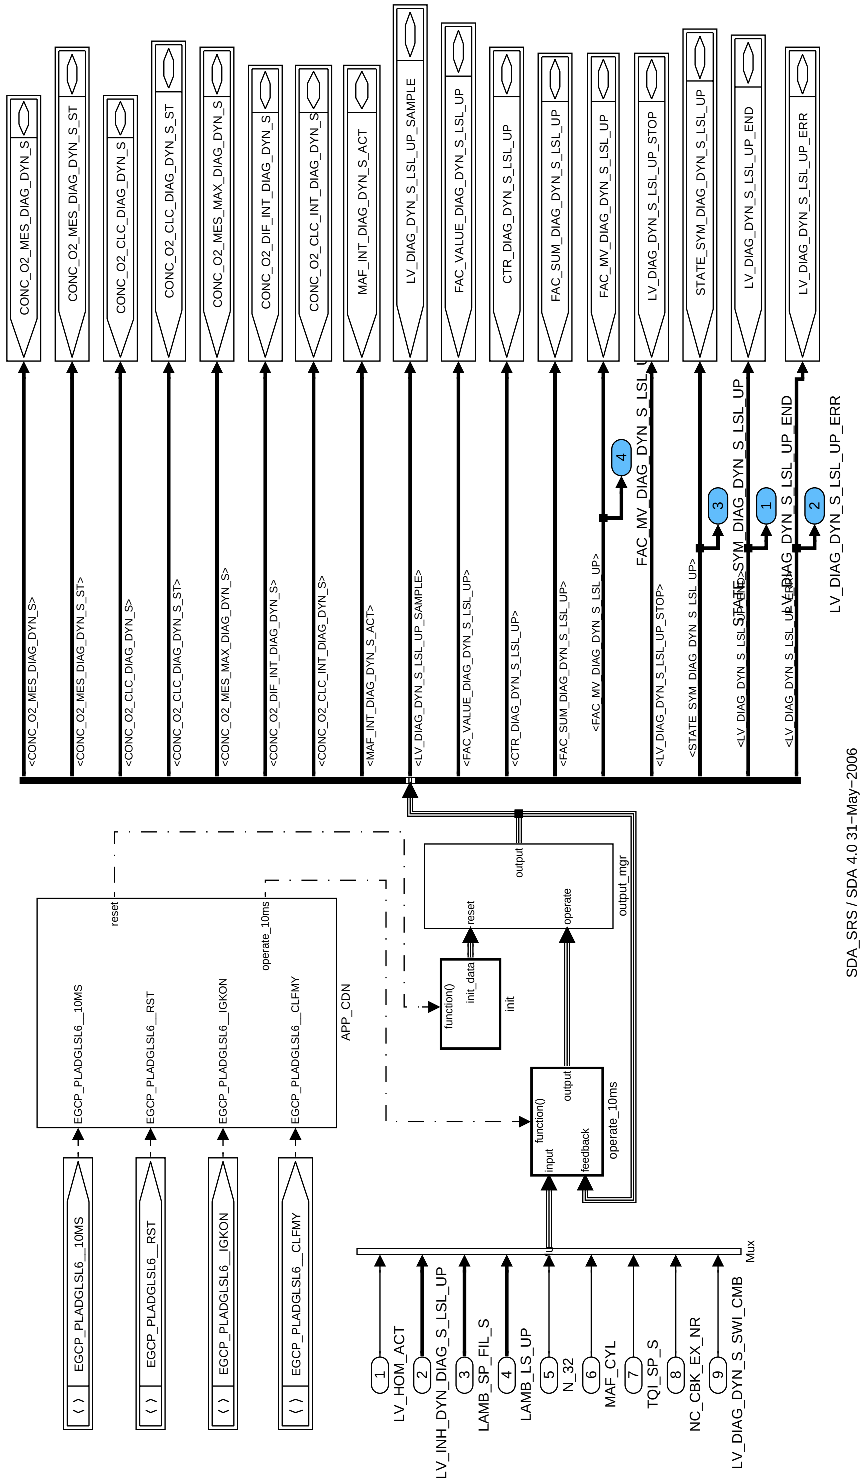

Figure 61 EGCP_PLADGLSL6

16.48.1.1 EGCP_PLADGLSL6/INIT

Initialization of the online data takes place at reset, when clearing the error memory and at the beginning of a driving cycle.

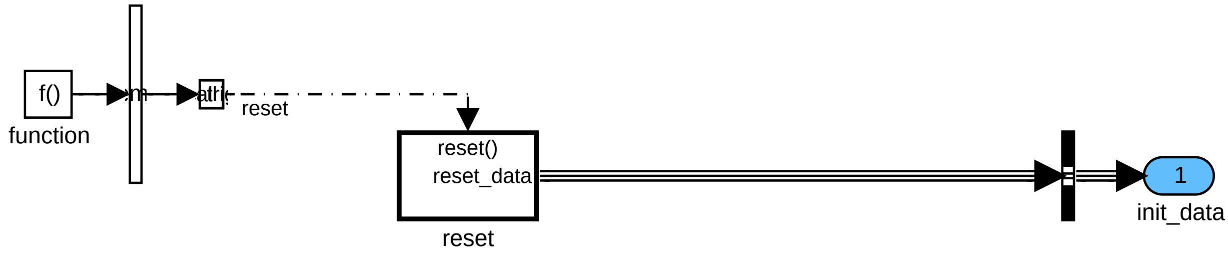

Figure 62 EGCP_PLADGLSL6/ init

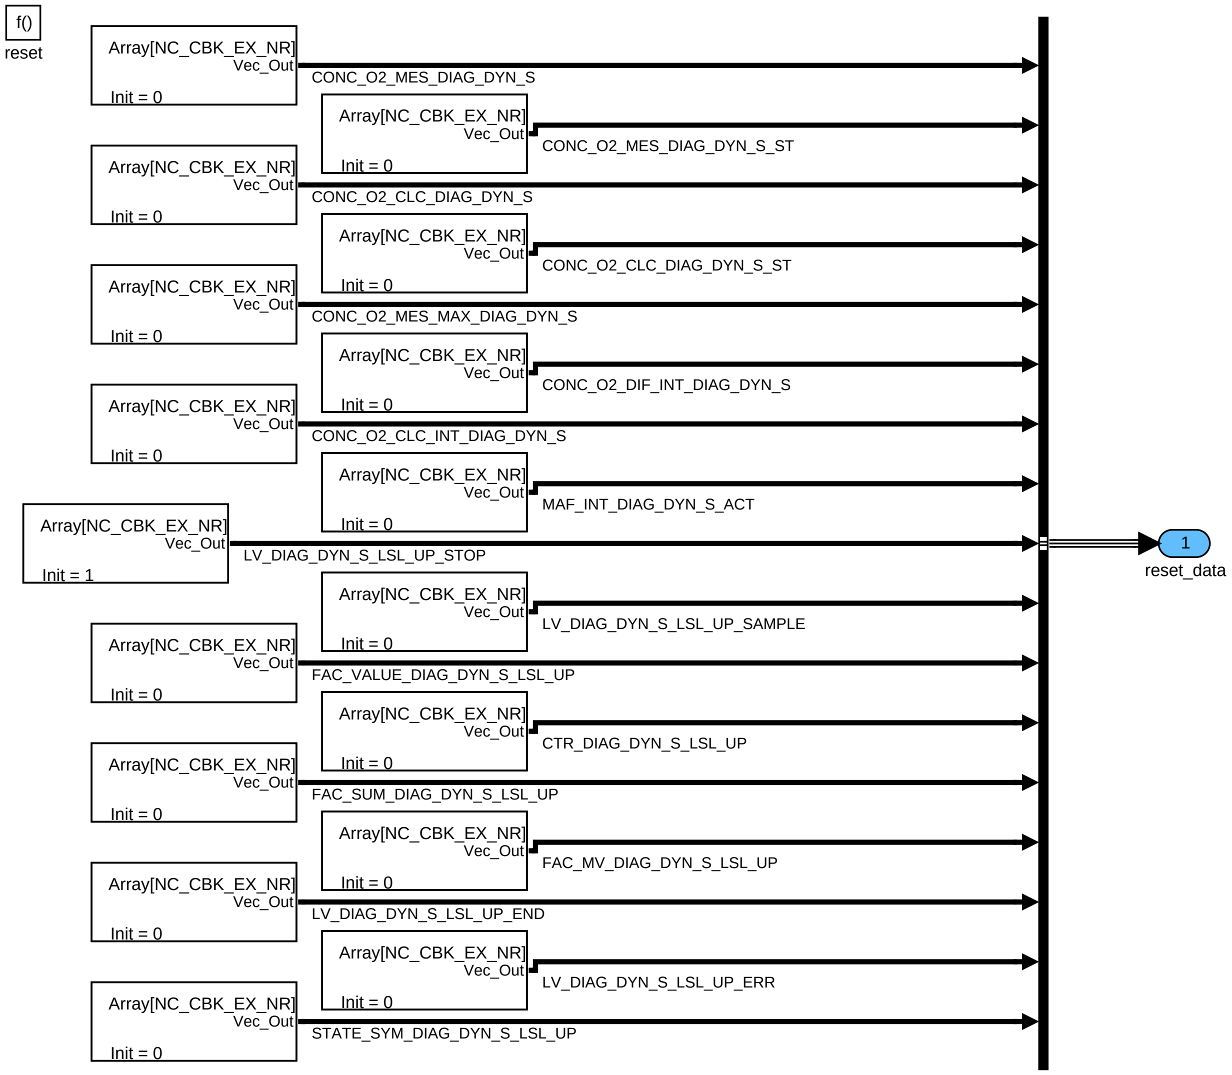

Figure 63 EGCP_PLADGLSL6/ init/ reset

16.48.1.2 SUBFUNCTION: operate_10ms

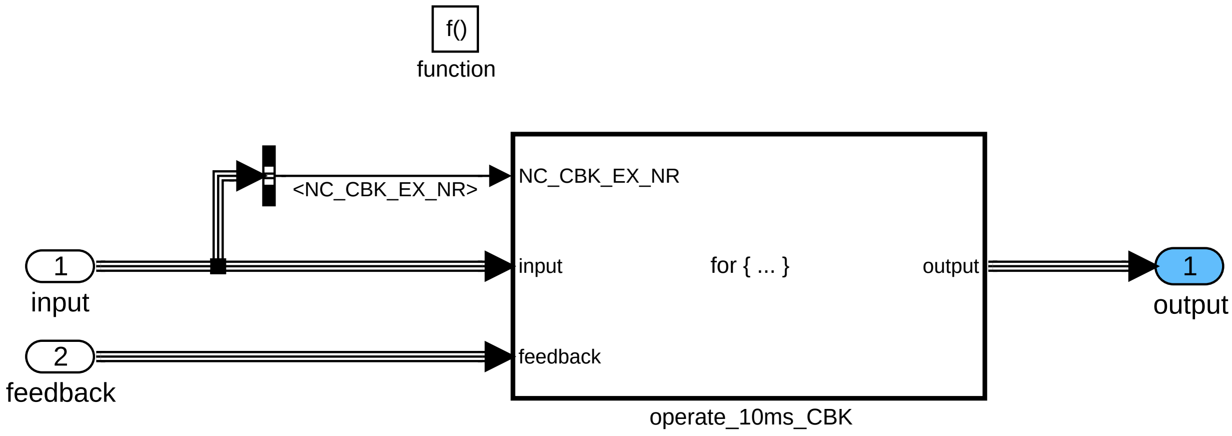

Figure 64 EGCP_PLADGLSL6/ operate_10ms

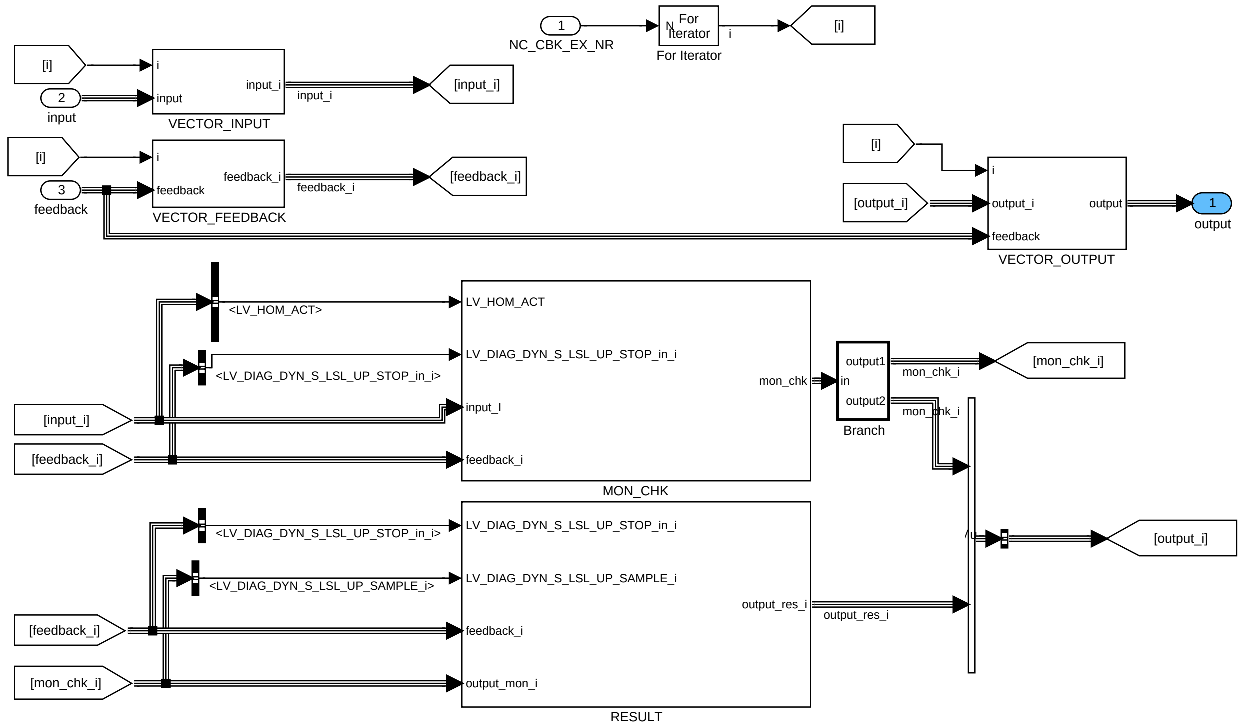

Figure 65 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK

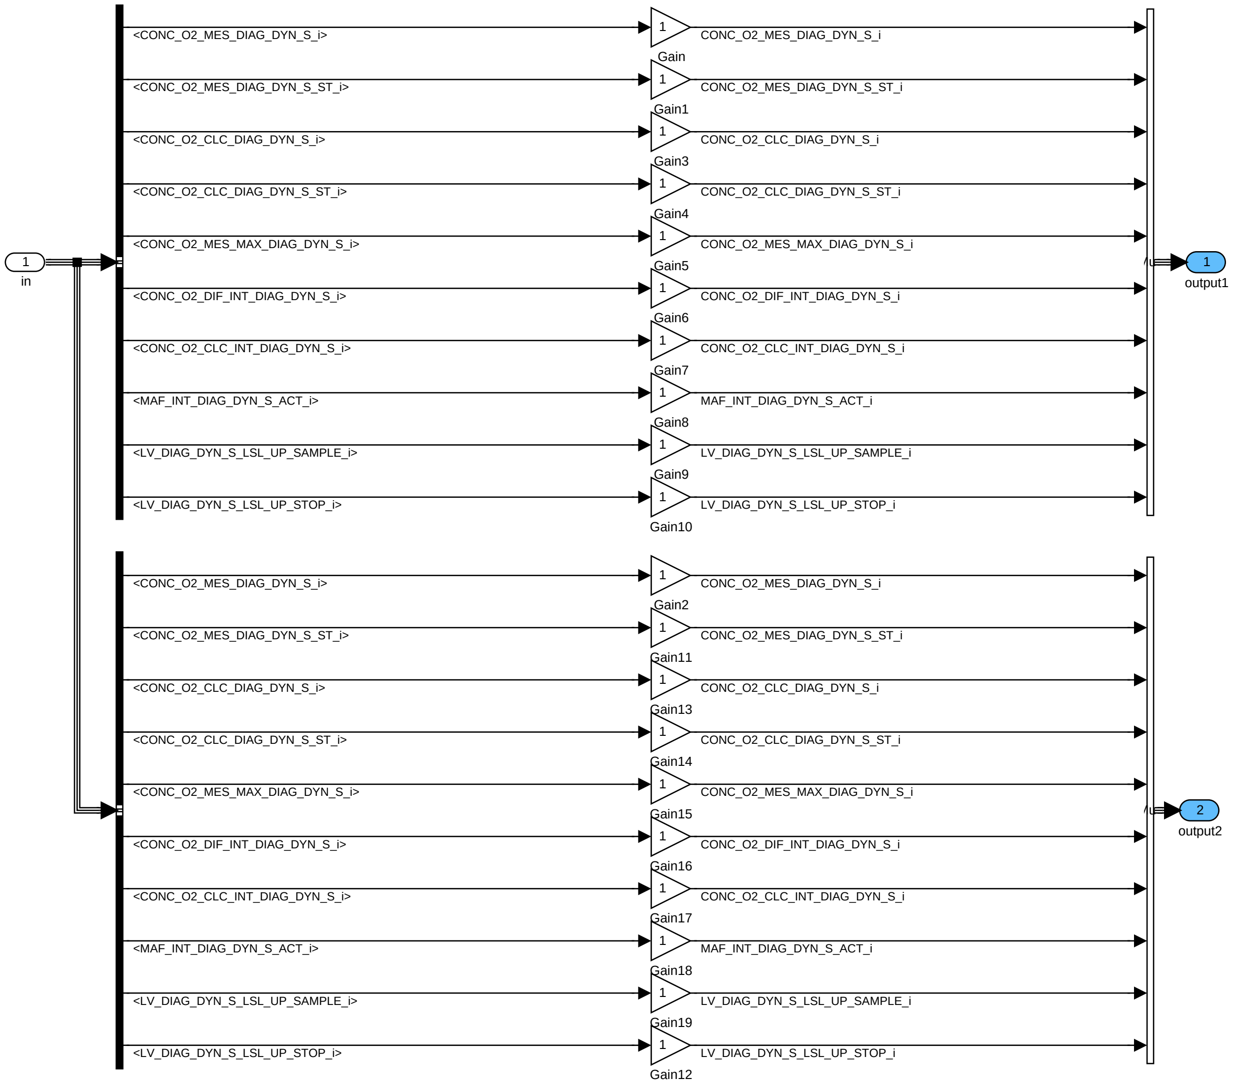

Figure 66 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ Branch

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/MON_CHK

This is the first part of the diagnosis, which continuously monitors the WRAF sensor signal and calculates several integrals (see below for further explanation). It starts if the engine is running in homogenous combustion mode and continues into the start of the following phase of stratified combustion until aborted or finished.

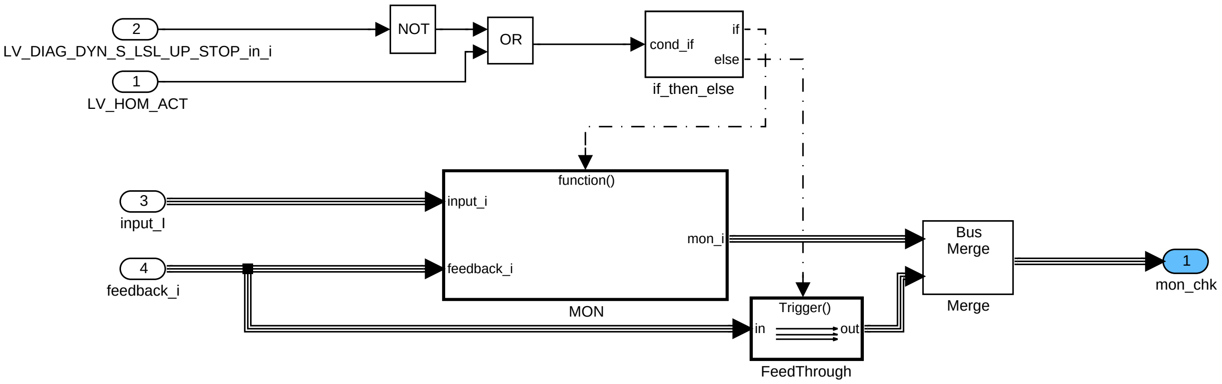

Figure 67 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK

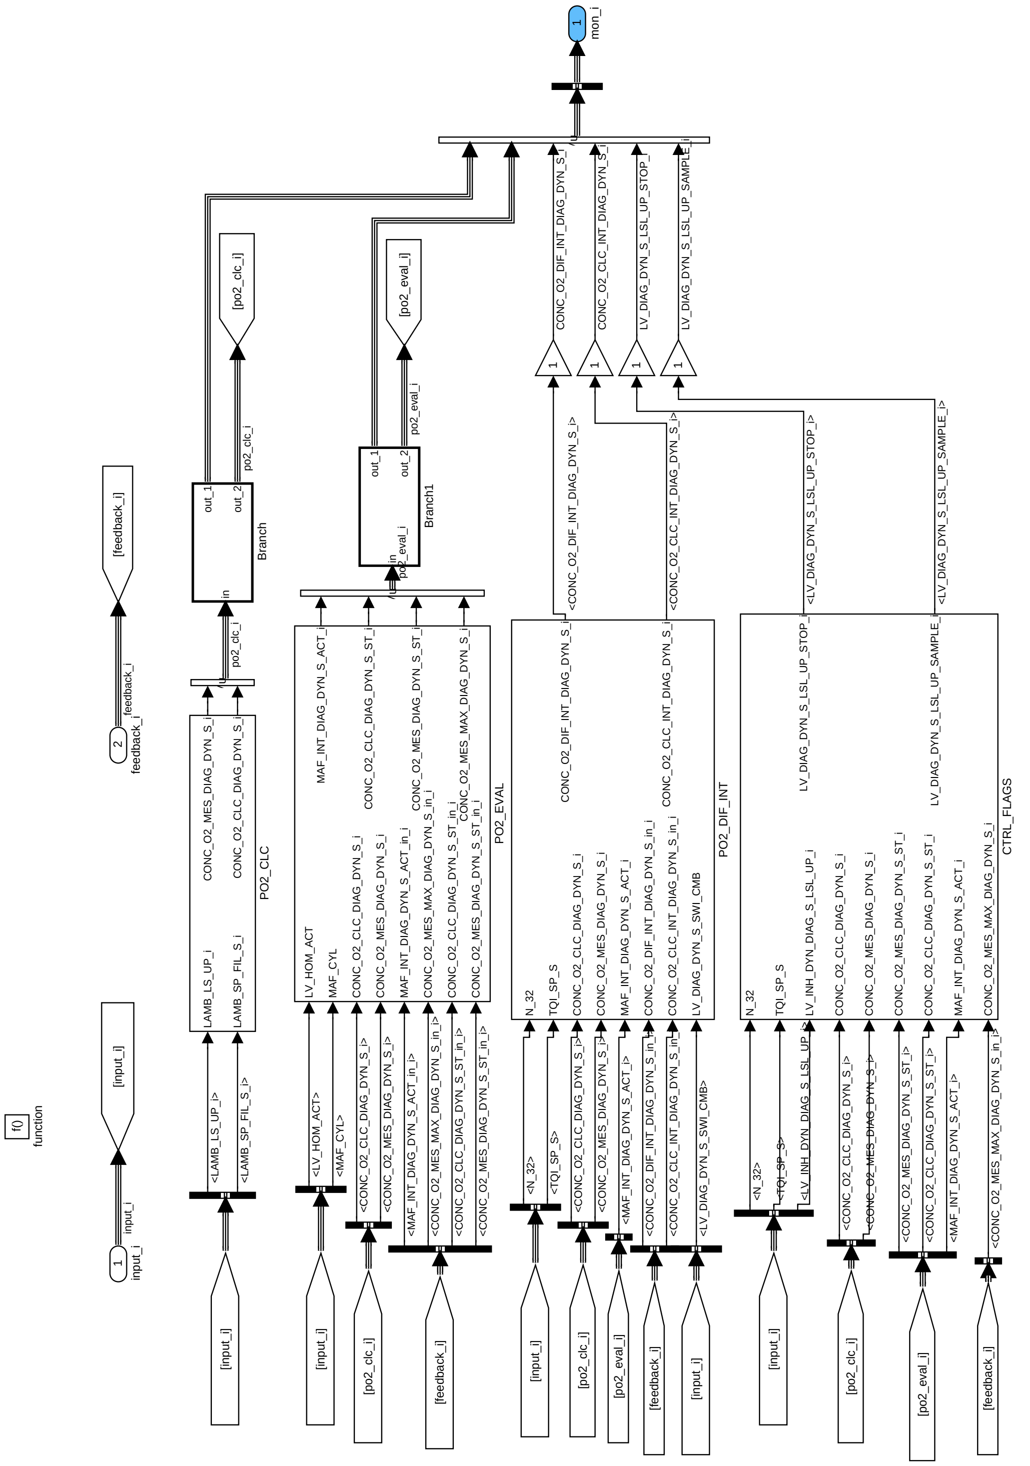

Figure 68 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON

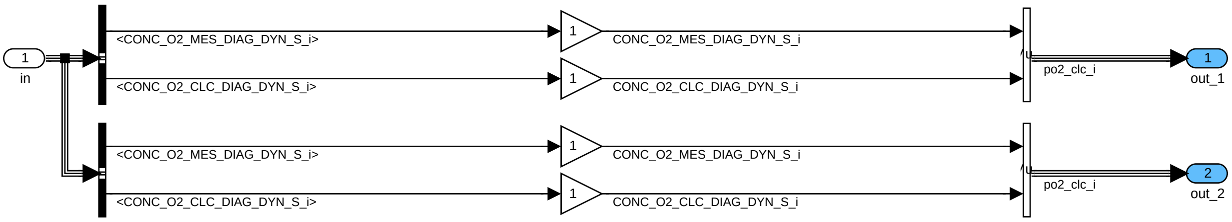

Figure 69 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ Branch

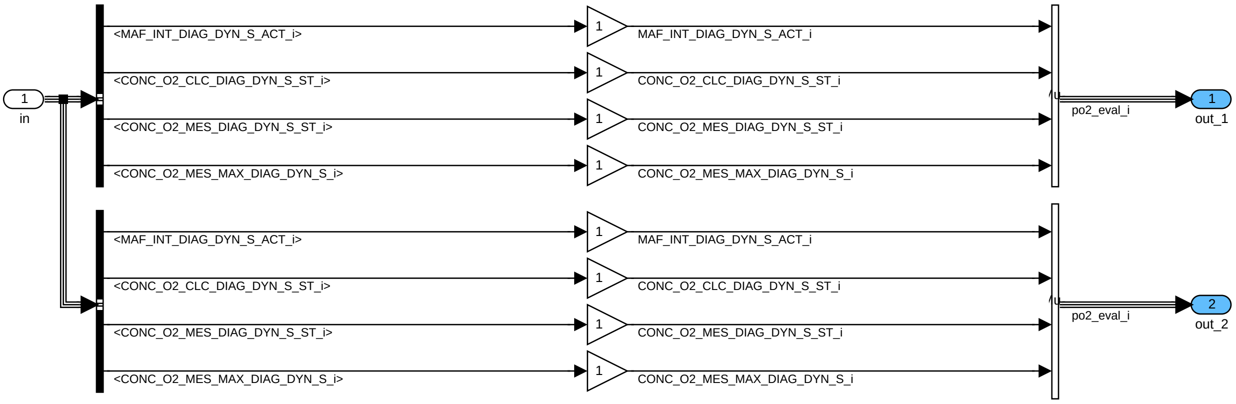

Figure 70 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ Branch1

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/MON_CHK/MON/CTRL_FLAGS

This section shall generate two flags. LV_DIAG_DYN_S_LSL_UP_SAMPLE[i] triggers the calculation of a result at the end of the current diagnostic cycle. It will be set to 1 in the last recurrence before the function deactivates itself, and reset to 0 at the start of the next cycle.

LV_DIAG_DYN_S_LSL_UP_STOP[i] is expected to be set to 0 during a homogenous combustion phase to indicate that a diagnostic cycle can be started at the next transition to stratified combustion. It will be set to 1 if the cycle should be stopped, either because a result is available or because required conditions are not fulfilled anymore.

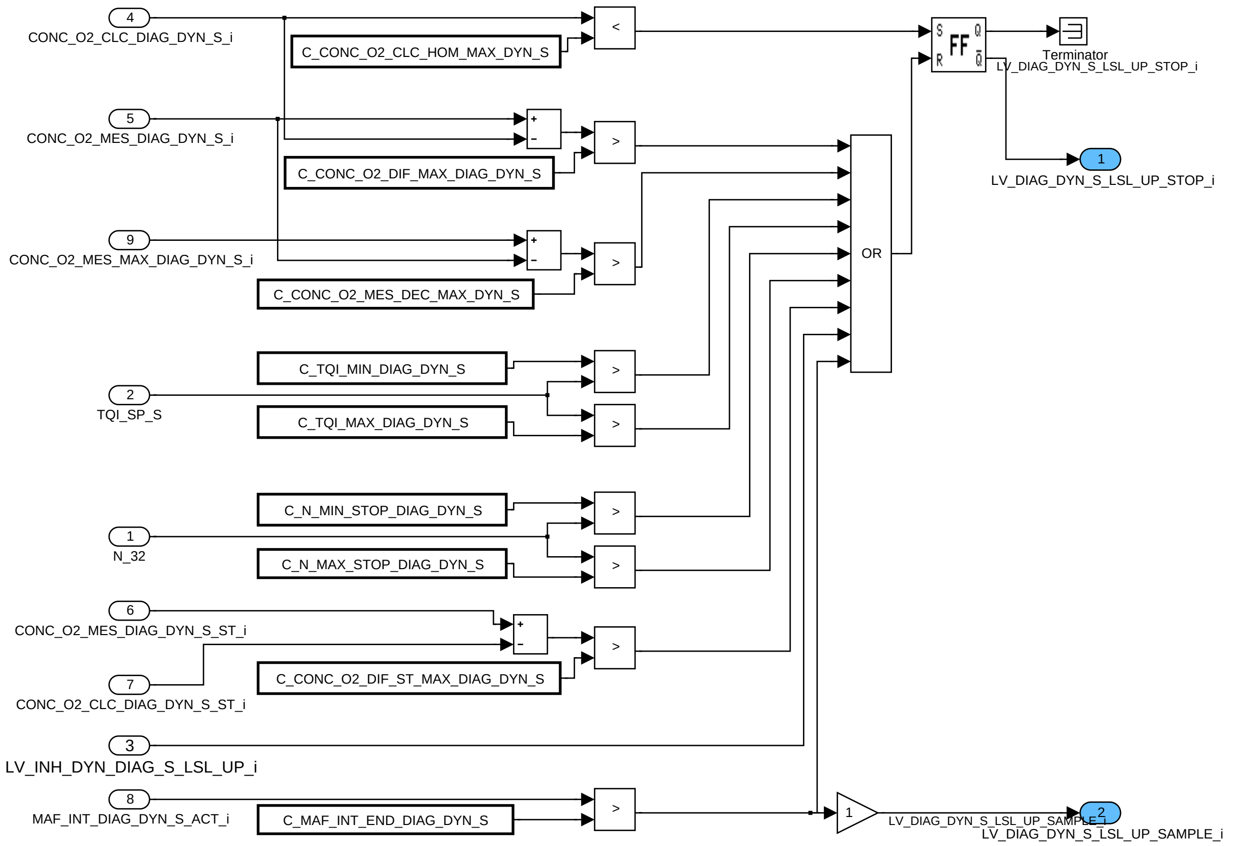

Figure 71 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ CTRL_FLAGS

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/MON_CHK/MON/PO2_CLC

This block calculates the O2 concentrations CONC_O2_MES_DIAG_DYN_S[i] from LAMB_LS_UP[i] and CONC_O2_CLC_DIAG_DYN_S[i] from LAMB_SP_FIL_S[i]. CONC_O2_MES_DIAG_DYN_S[i] can be scaled with a constant factor to improve diagnostic results for good sensors. The CONC_O2 values are used throughout the diagnosis because accuracy and dynamics are more similar across the different lambda ranges than for lambda itself.

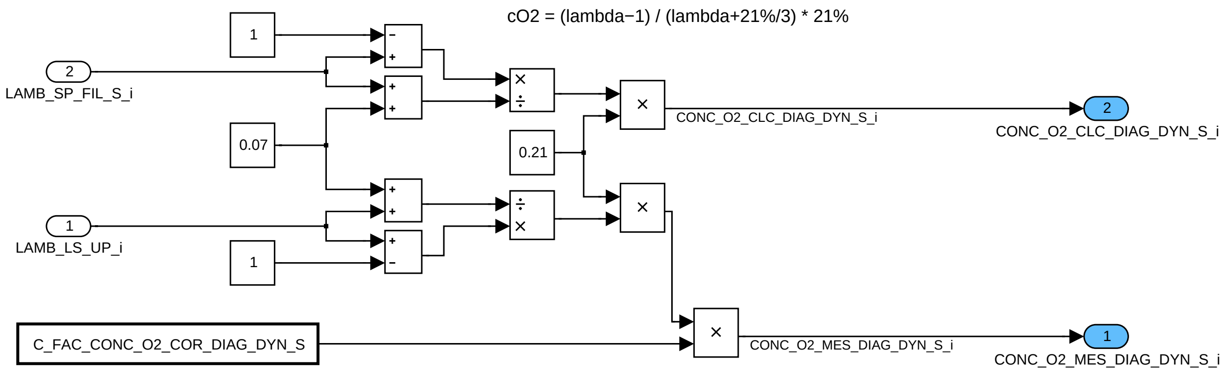

Figure 72 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ PO2_CLC

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/MON_CHK/MON/PO2_DIF_INT

Here, two integrals are produced which are used to calculate the diagnostic value. In CONC_O2_DIF_INT_DIAG_DYN_S[i] integrates the differences between modelled and measured O2 concentration, while CONC_O2_CLC_INT_DIAG_DYN_S[i] integrates the modelled oxygen concentration itself.

Both integrals start only after a calibrateable air mass has passed since the homogenous combustion mode was left. This can be used to avoid signal features shortly after the transition and to focus the diagnostic value on parts of the signal trace that show large and clear deviations between a modelled (fast) and a slow sensor. The integrals are stopped implicitly by calculating a result from them once after a certain air mass was consumed by the engine. After this, the function deactivates itself until the engine enters homogenous combustion mode again.

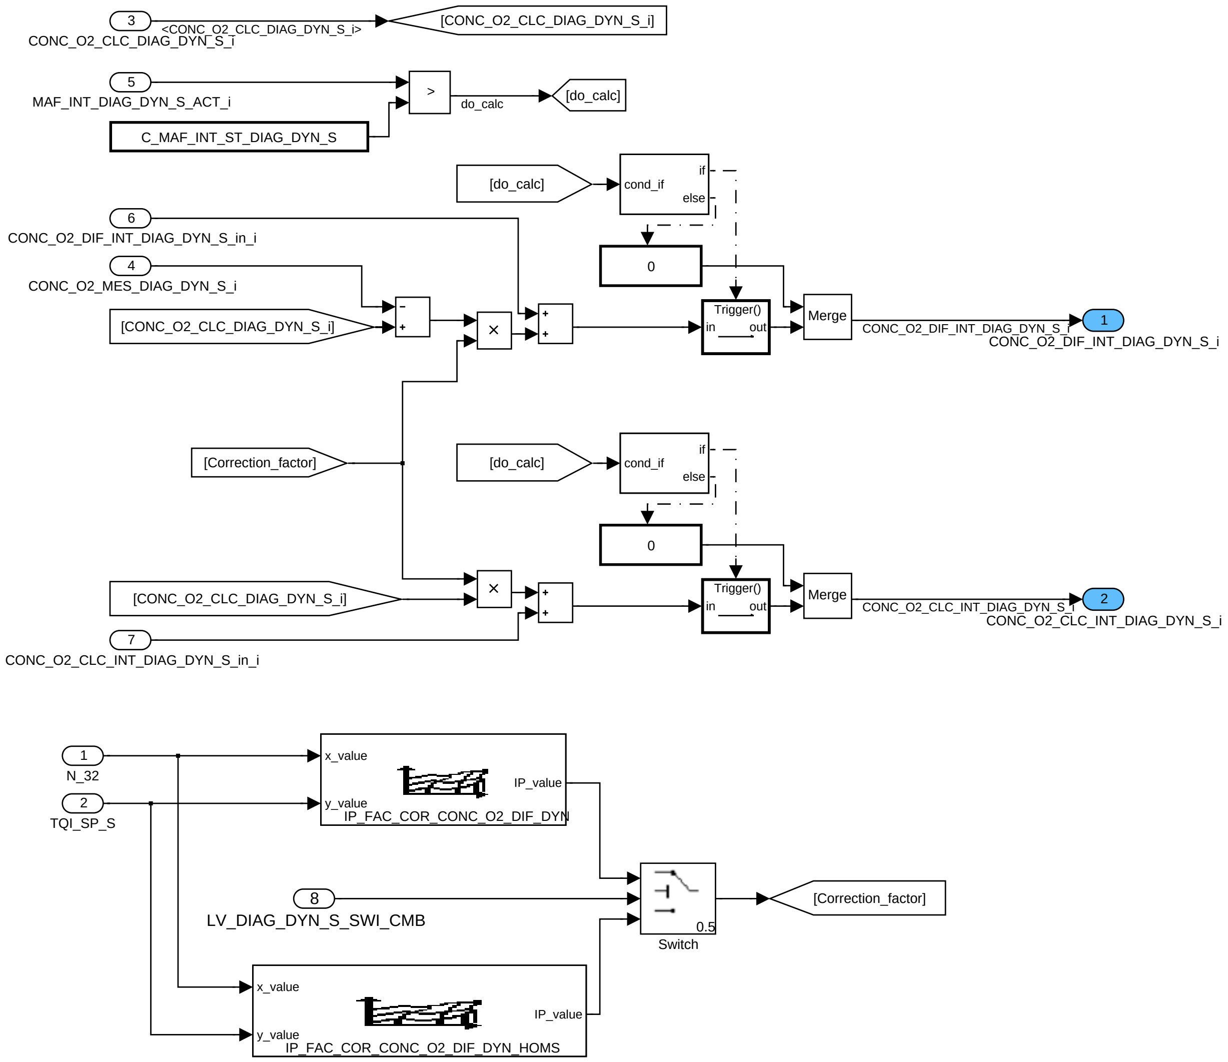

Figure 73 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ PO2_DIF_INT

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/MON_CHK/MON/PO2_EVAL

Here, a mass flow integral is calculated, which starts at the transition out of homogenous combustion and governs start and end points for the calculation of the diagnostic value. CONC_O2_MES_DIAG_DYN_S_ST[i] and CONC_O2_CLC_DIAG_DYN_S_ST[i] receive the values of CONC_O2_MES_DIAG_DYN_S[i] and CONC_O2_CLC_DIAG_DYN_S[i] at the time of the transition, they are used to calculate and validate the diagnostic result of the current transition. CONC_O2_MES_MAX_DIAG_DYN_S[i] is the highest O2 concentration found in the current diagnostic cycle, it is used in validation of the result.

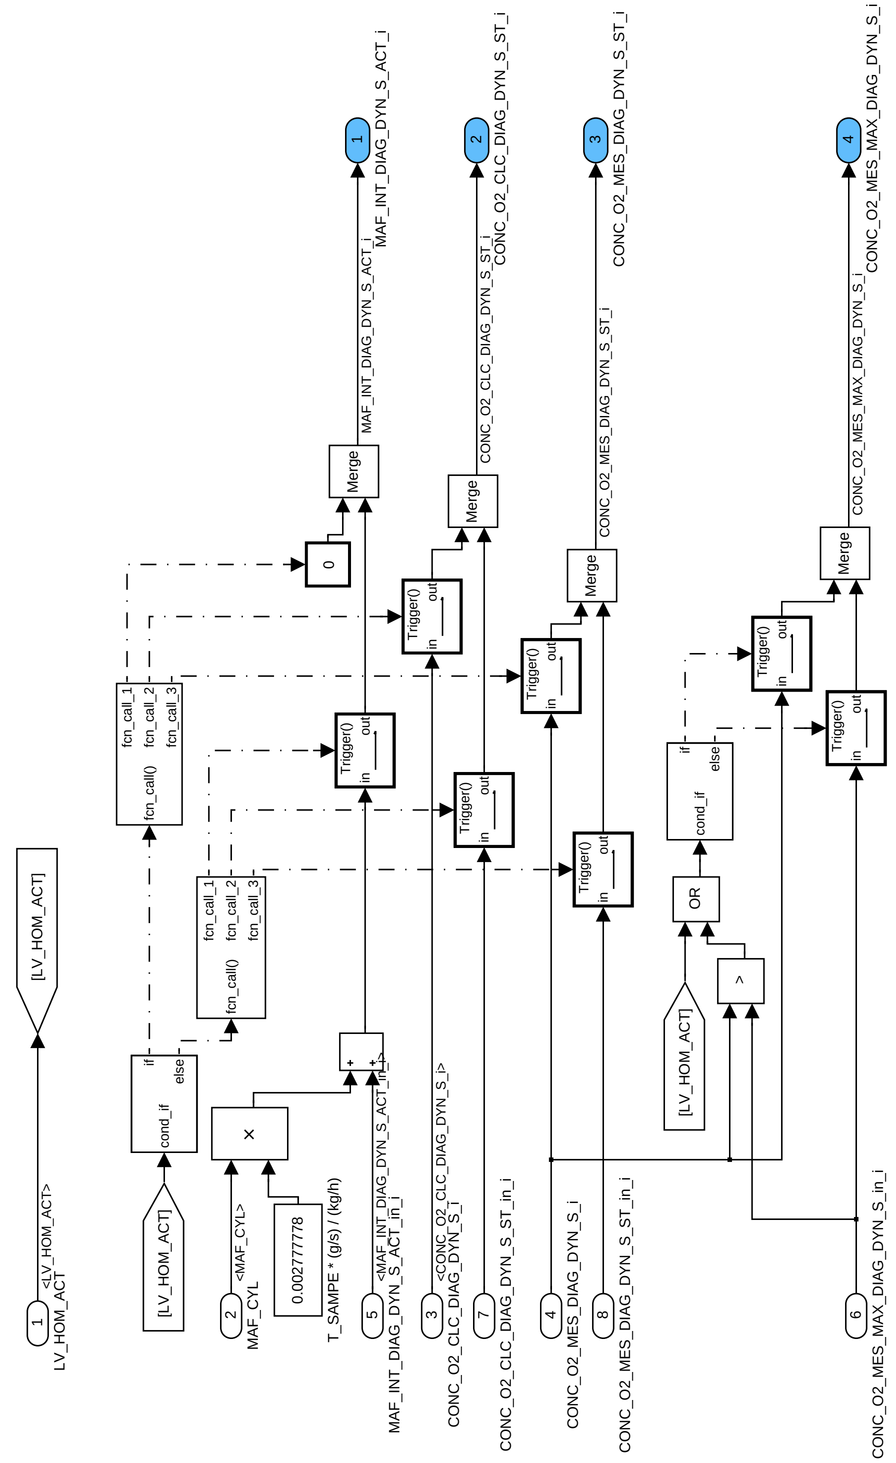

Figure 74 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ MON/ PO2_EVAL

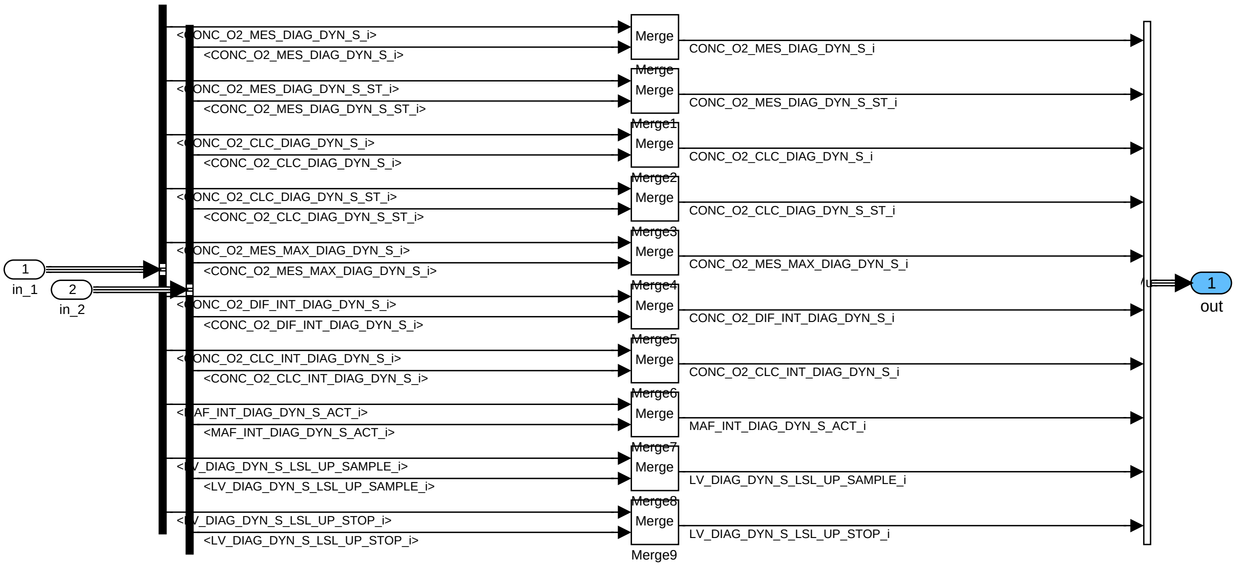

Figure 75 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ MON_CHK/ Merge

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/RESULT

The logic shown here triggers the calculation of a result once after a diagnostic cycle has completed successfully.

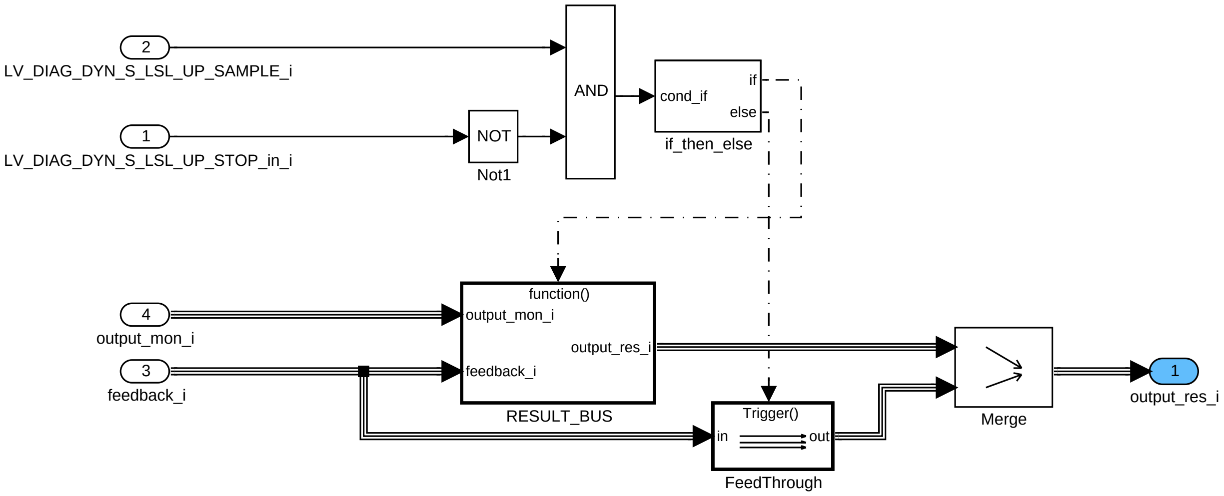

Figure 76 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT

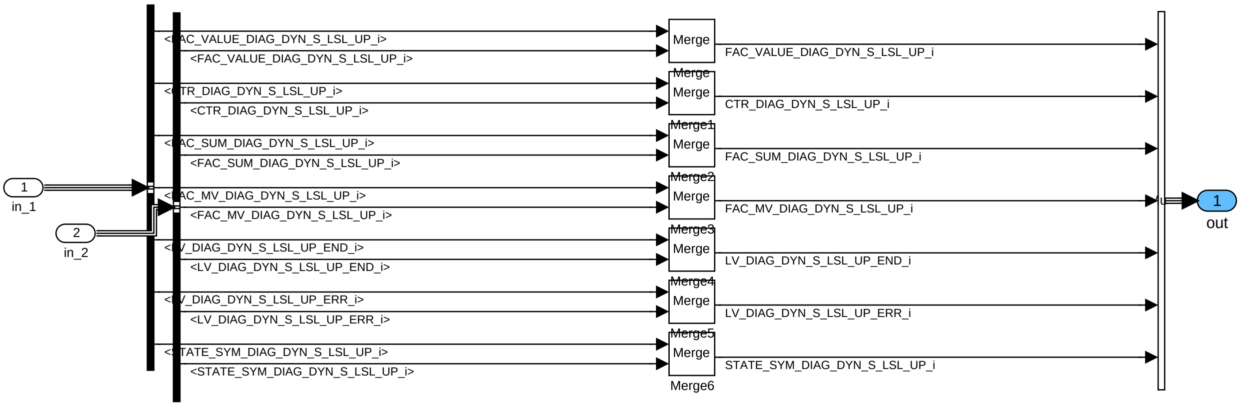

Figure 77 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ Merge

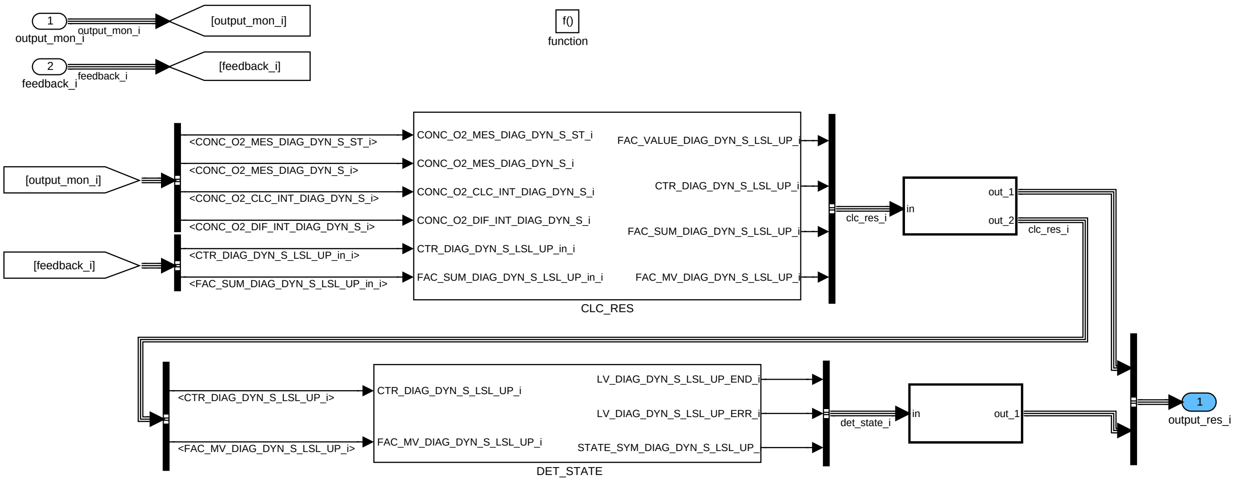

Figure 78 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ RESULT_BUS

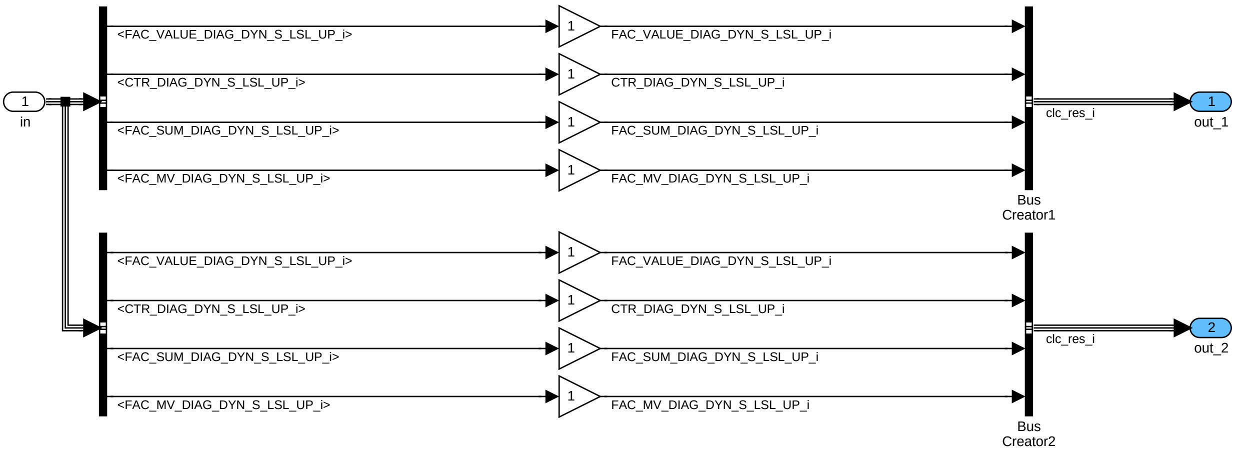

Figure 79 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ RESULT_BUS/ Branch

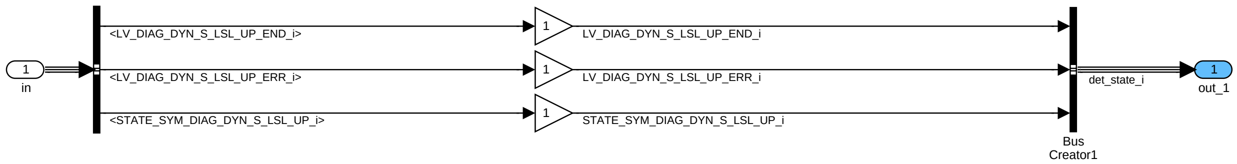

Figure 80 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ RESULT_BUS/ Branch1

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/RESULT/RESULT_BUS/CLC_RES

The result of one single diagnostic cycle is calculated in one of two ways and stored in FAC_VALUE_DIAG_DYN_S_LSL_UP[i]. It resembles the difference between modelled (i.e. "good") and actual sensor response to the lambda change in the transition from homogenous to lean combustion. If LC_DIAG_DYN_S_LSL_UP_MOD = 1, the difference is normalized to the signal change of the sensor and resembles the time constant of the sensor response. Otherwise it is normalized to the integrated signal change in the model, which makes the result more stable for slow sensors.

FAC_MV_DIAG_DYN_S_LSL_UP[i] is a cumulated average for the current driving cycle, whic is the basis for the decision whether the sensor is good or not.

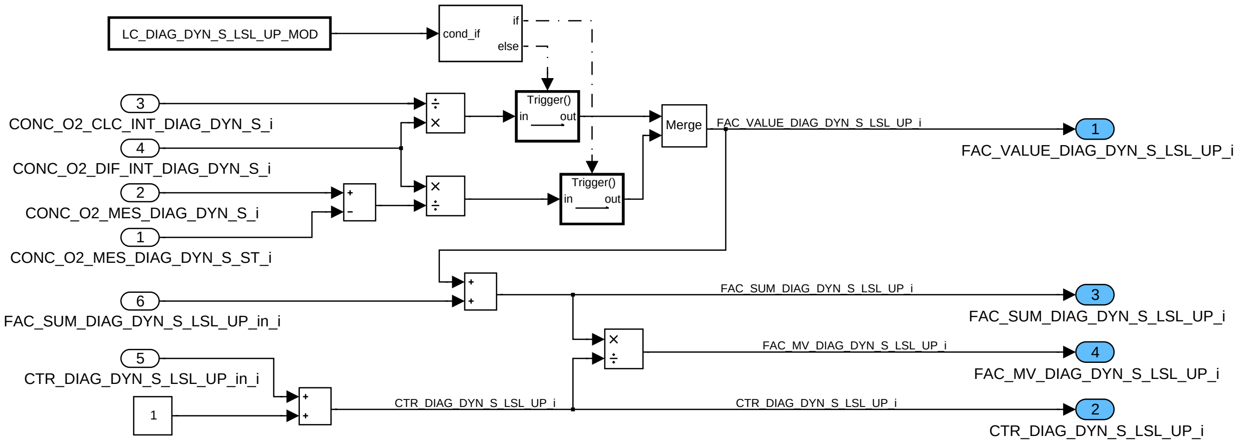

Figure 81 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ RESULT_BUS/ CLC_RES

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/RESULT/RESULT_BUS/DET_STATE

The block determines the diagnostic decision. With every cycle, the good/bad status in LV_DIAG_DYN_S_LSL_UP_ERR[i] and STATE_SYM_DIAG_DYN_S_LSL_UP[i] is updated, and if enough cycles have been completed, the end of diagnosis is indicated via LV_DIAG_DYN_S_LSL_UP_END[i]. This information is not transmitted to the error memory directly.

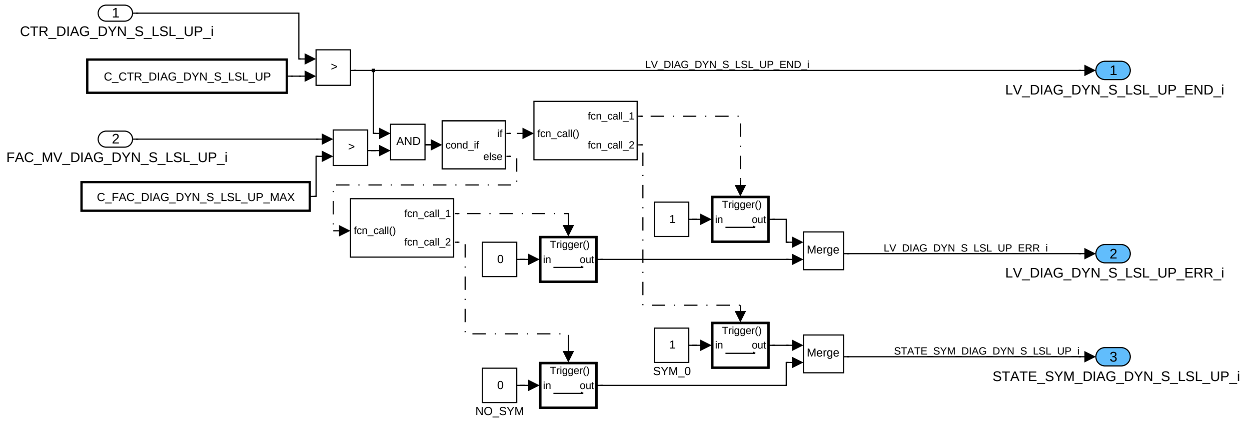

Figure 82 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ RESULT/ RESULT_BUS/ DET_STATE

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/VECTOR_FEEDBACK

This block selects required values from the last recurrence into a vector used in the functions for the current cylinder bank.

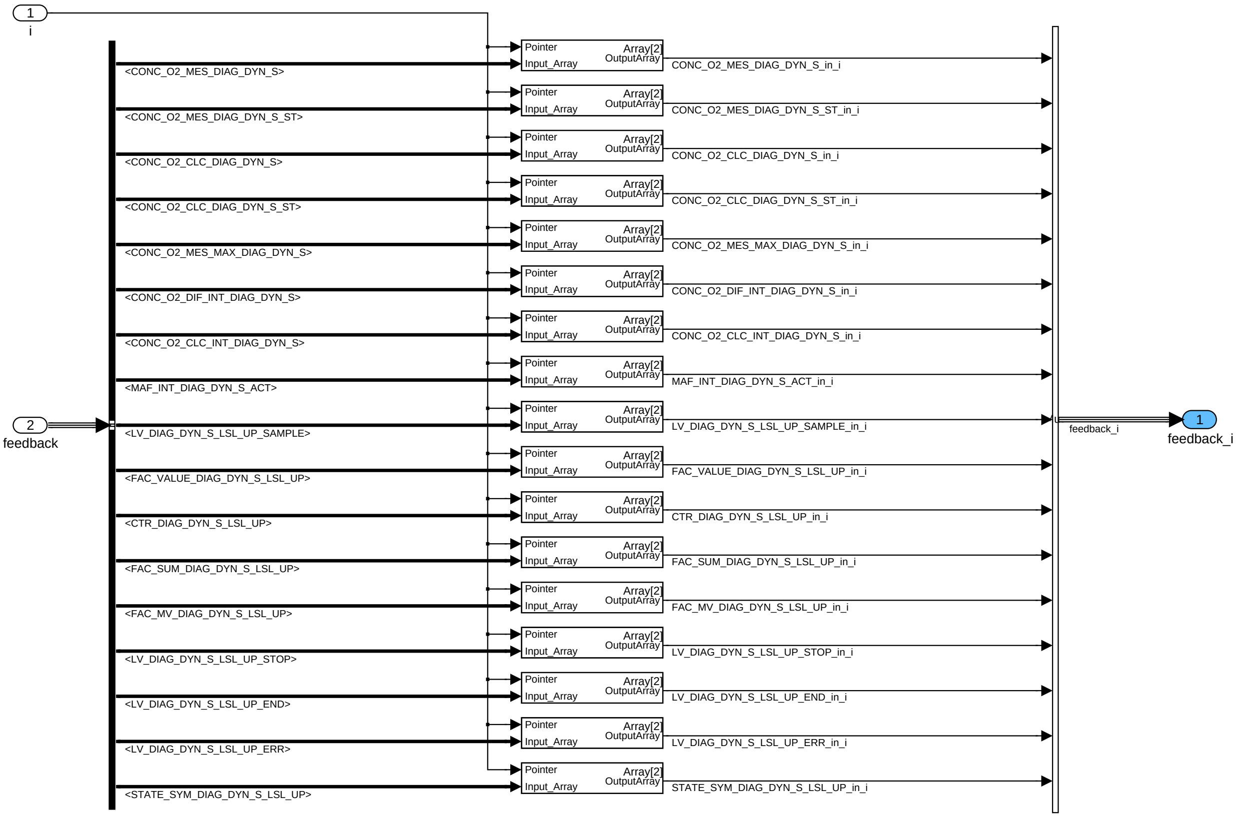

Figure 83 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ VECTOR_FEEDBACK

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/VECTOR_INPUT

The result of this block is a vector with the current input needed for the cylinder bank to be calculated.

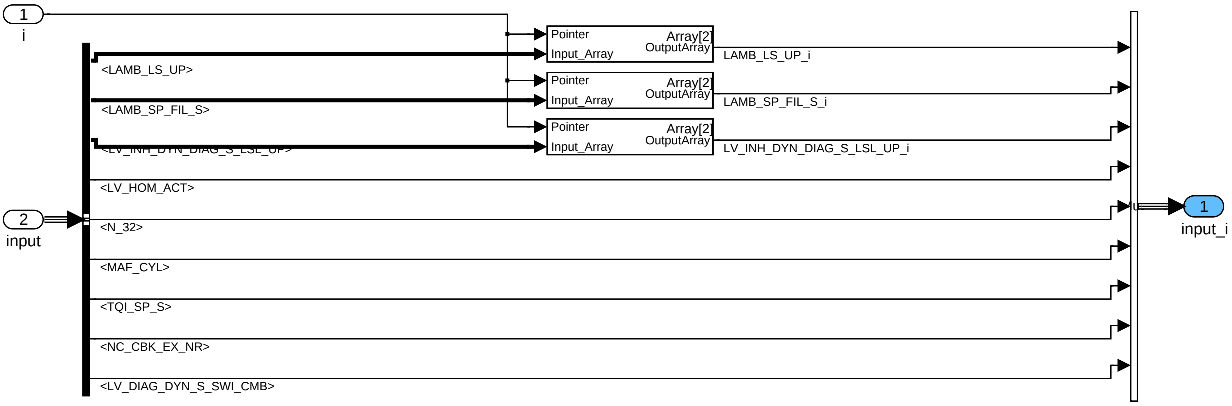

Figure 84 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ VECTOR_INPUT

EGCP_PLADGLSL6/OPERATE_10MS/OPERATE_10MS_CBK/VECTOR_OUTPUT

The output block assembles the model output vector from the results for the individual cylinder banks.

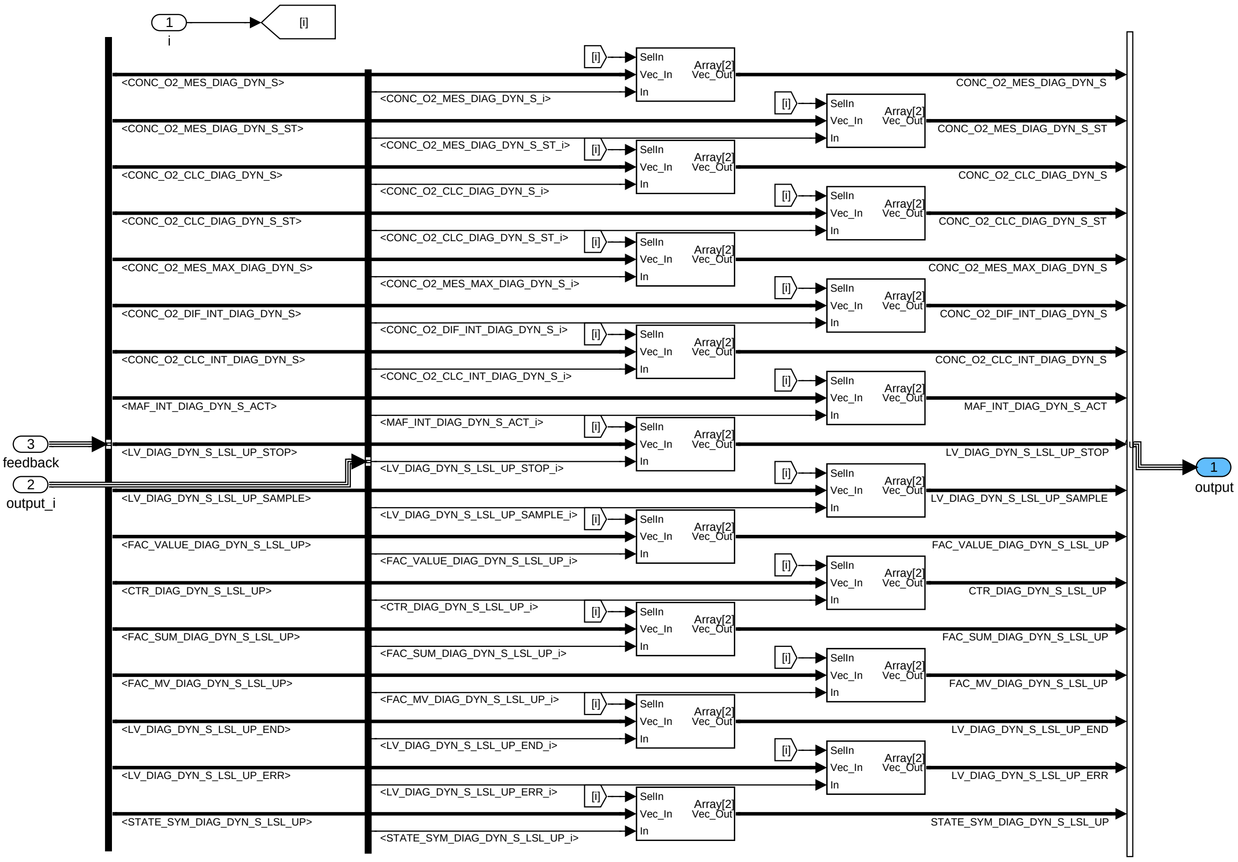

Figure 85 EGCP_PLADGLSL6/ operate_10ms/ operate_10ms_CBK/ VECTOR_OUTPUT

16.48.1.3 EGCP_PLADGLSL6/OUTPUT_MGR

The output manager merges the results of init and operate blocks into the functions' output vector.

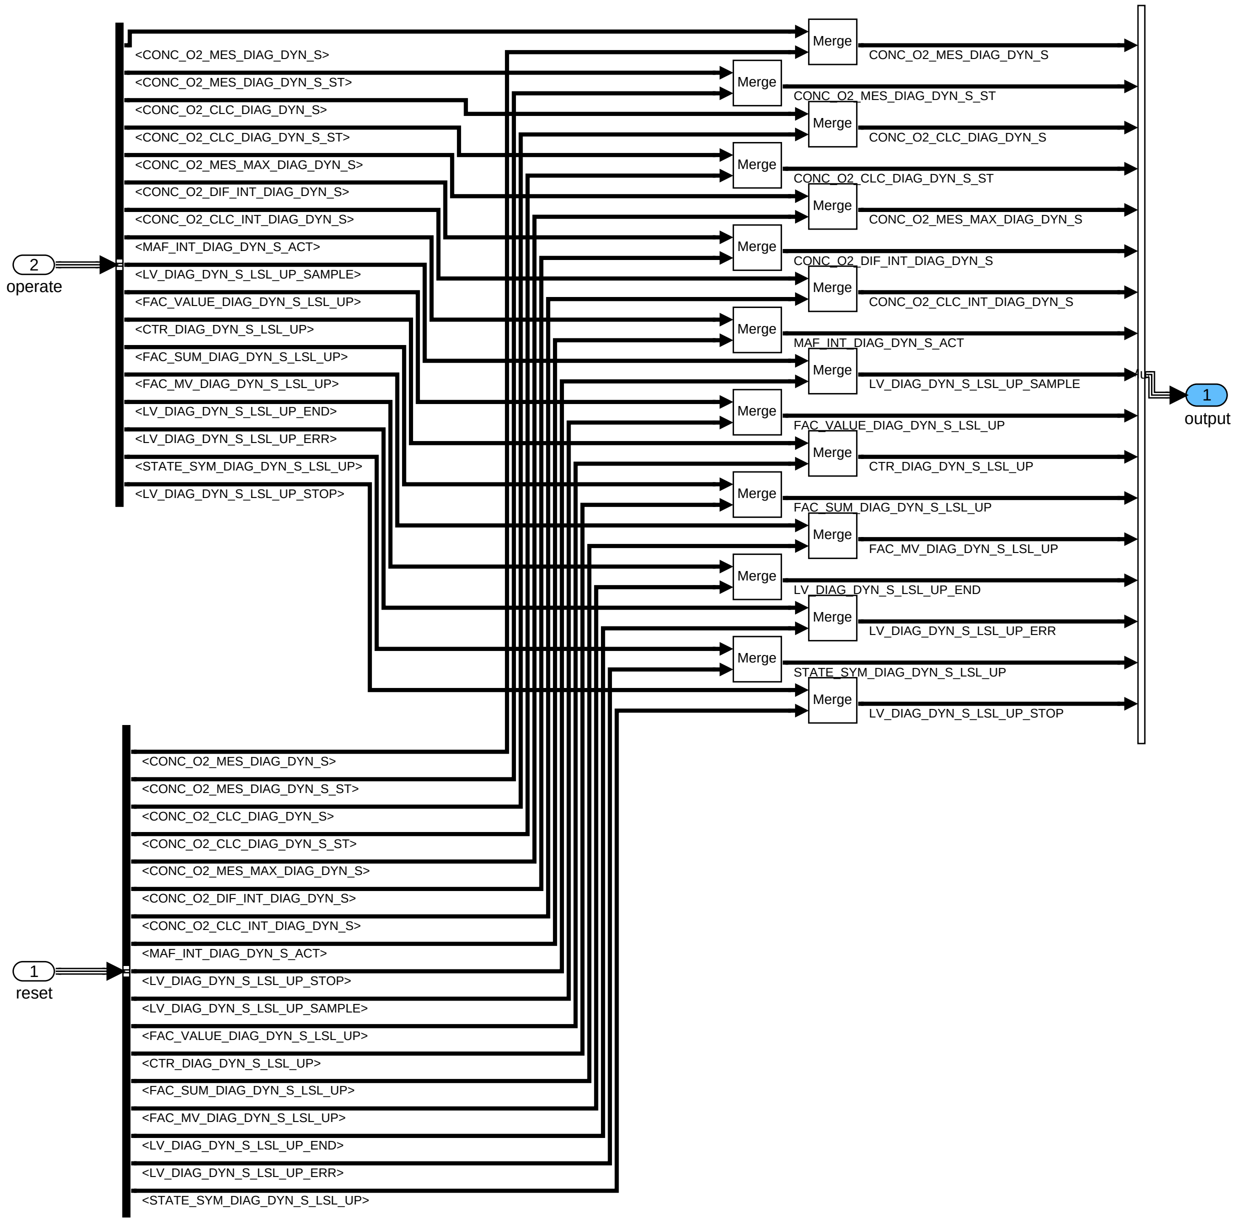

Figure 86 EGCP_PLADGLSL6/ output_mgr

16.49 Application Incidencies for “O2 sensor (lin, up) dyn diag after NOx trap regeneration"

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DYN_DIAG_S_LSL_UP[NC_CBK_EX_NR]	V/O	0...1H	0...1	1	[-]
Inhibition of linear lambda sensor dynamic diagnosis for stratified combustion					
LV_DIAG_DYN_S_SWI_CMB	O/V	0...1H	0...1	1	[-]
Logical variable to switch weighting factor depending on cumbustion mode					

Input data:

LV_DIAG_DYN_INH_LSL_UP[NC_CBK_EX_NR]	OPM_AV	LV_ST_END	LV_IGK

LV_ERR_CTL_LSL_UP[NC_CBK_EX_NR]			

16.49.1 General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

With C_DIAG_DYN_INH_CMB_TRAN the diagnosis can be interrupted due to switching of the combustion mode.

Interruption in case of:
Switching CBM from AFL to S and C_DIAG_DYN_INH_CMB_TRAN = 1
Switching CBM from S to AFL and C_DIAG_DYN_INH_CMB_TRAN = 2
Switching CBM from S to AFL and AFL to S and C_DIAG_DYN_INH_CMB_TRAN = 3

Application conditions:

Initialisation: At transition LV_IGK = 0 -> 1 or reset LV_INH_DYN_DIAG_S_LSL_UP[i] shall be set to 1.

Recurrence: 20ms.

Activation: -

Formula section:

Import actions:

ACTION_ERRM_NoFilterSymptom(IN<IDX_DIAG>, IN< LV_CDN_DIAG_XX >, IN< ERR_SYM_XX >, IN< LV_ERR_SET_XX >, IN< LV_ERR_RST_XX >, IN< LV_END_DIAG_XX >, OUT< LV_ERR_XX >)
ACTION_ERRM_NoFilterReset(IN<IDX_DIAG>, OUT< LV_ERR_XX >)

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

Description:

This function shall test the plausibility of the upstream sensor signal during the Pull Fuel Cut-off phase (PUC). The variable LV_DIAG_SYM_PUC_LSL_UP[i] indicates an open circit on Vg or Vip (“VLS_AFS_OC) or on Pin Vrc (“VLS_H_OC”). This variable is considered only as a symptom and therefore shall not be transmitted to the Error Management.

The failure flag LV_ERR_PUC_VLD_LS_UP[i] is directly transfered to the error management. The failure is entered, if the lambda sensor voltage during fuel cut off is higher than the voltage in case of Open Circuit on Pin Vg or Vip but lower than the standard voltage.

The variable VLS_UP_DIAG_SAVE_PUC_LSL_UP[i] shall retain its value until an updated one is present. It should be reset only in case the Error Management memory is deleted.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset, LV_DIAG_EOL_PUC_LSL_UP[i] = 0 -> 1 or at clearing error memory reset all variables. The variable saved in the non-volatile memory shall be reset only in case the error memory is cleared.
ACTION_ERRM_NoFilterReset(IN< NC_IDX_DIAG_PUC_VLD_LS_UP[i]>, OUT<LV_ERR_PUC_VLD_LS_UP[i]>)

Recurrence:

This function shall be executed every 100 ms.

Activation:

```
IF    LV_PUC = 1                                              AND

FUNCTION DESCRIPTION:

General information:

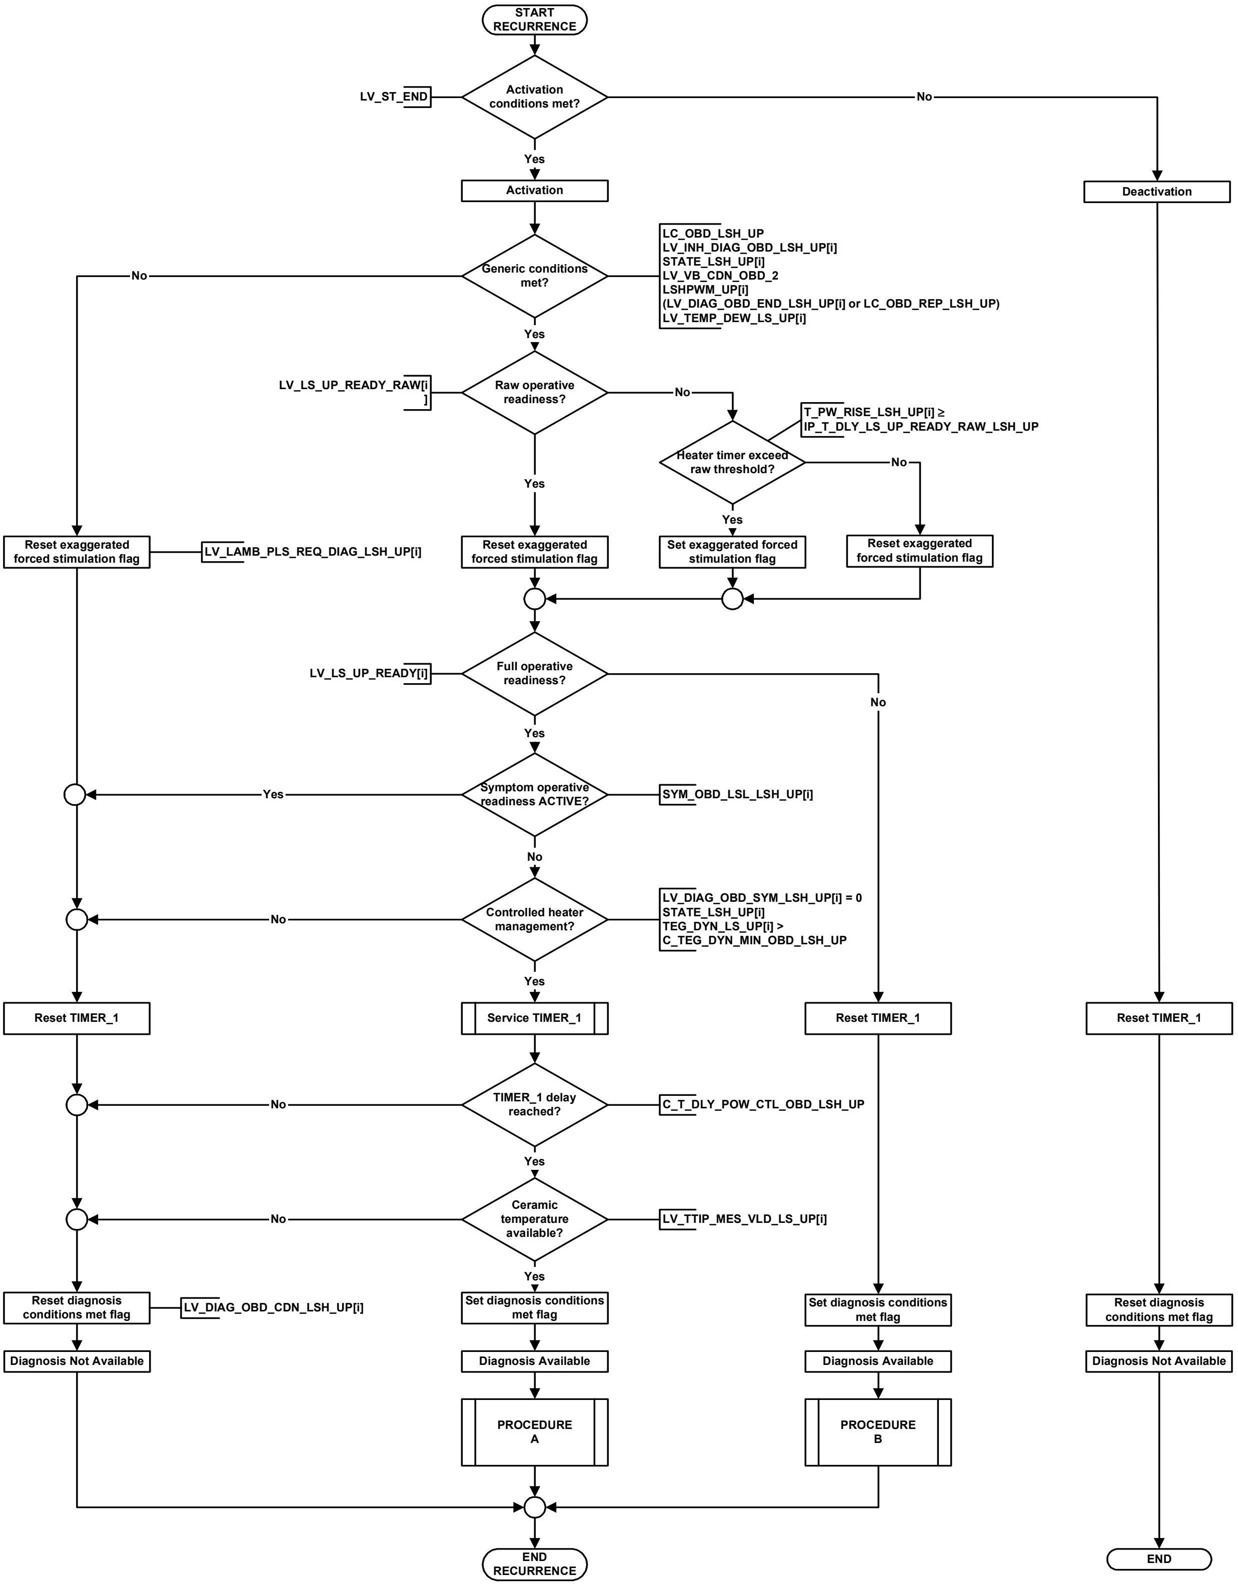
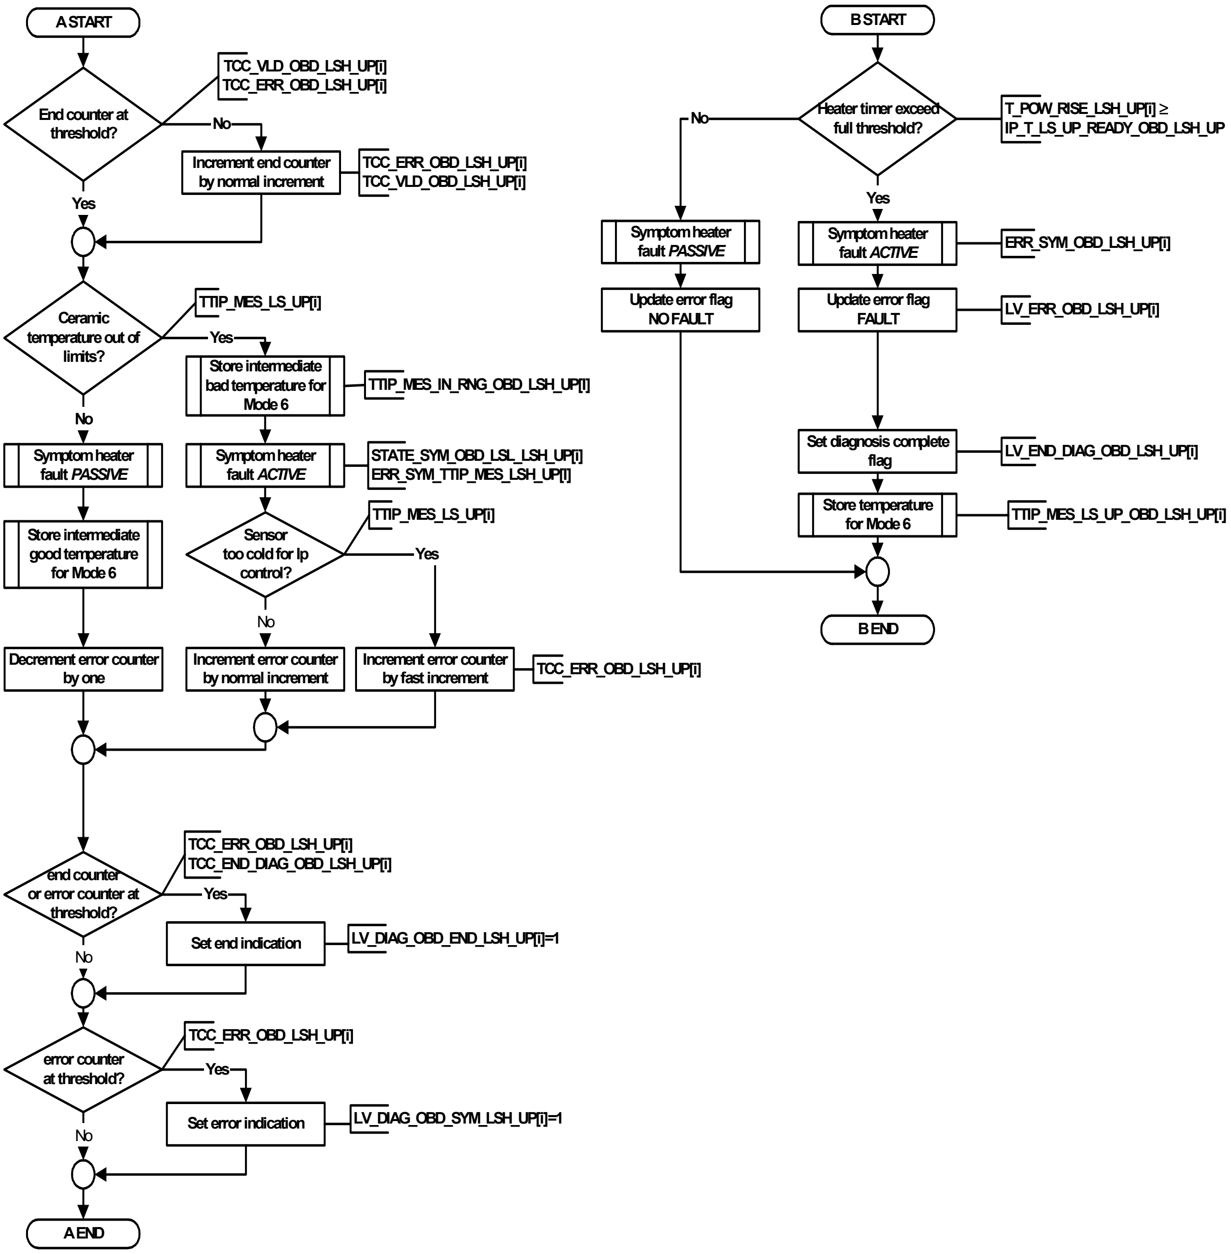
The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1, for exhaust cylinder bank 1
 i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1, for single exhaust cylinder bank.

This function shall facilitate the detection of oxygen sensor heater failures that would lead to an increase in emissions beyond the thresholds stated in the appropriate regulations. The diagnosis shall be carried out by determining whether the operative readiness of the sensor exceeds a time threshold or whether the measured oxygen sensor ceramic temperature exceeds or falls below set bounds over a number of measurement cycles, defined to be the actions carried out once per recurrence. The latter evaluation over the diagnosis cycle, defined to be after the completion of the set number of monitoring cycles, shall be carried out statistically.

Signal flow diagram:





Description:

Deviations in the oxygen sensor ceramic temperature or the oxygen sensor not being operatively ready in a timely manner can lead to an increase in emissions above the applicable standards or prevent the sensor signal from being used as a diagnostic system monitoring device.

The deviations may occur due to, for example, ageing of the heater element, defective wiring, increased heater circuit connector contact resistance, defective heater driver etc.

The hereafter mentioned diagnosis strategy is based on the detection via one of two methods, both cases being emissions relevant. Firstly the time to operative readiness shall be checked and secondly a statistical evaluation of the oxygen sensor ceramic temperature over a pre-defined number of monitoring cycles shall be carried out, whereby if the temperature should fall out of pre-set bounds a calibrateable number of times during the complete diagnosis cycle, a fault shall be detected as being present.

The oxygen sensor ceramic temperature shall be obtained indirectly via the measured internal resistance of the sensor.

The functionality of the diagnosis may be described in further detail below:

The diagnosis shall be carried out at least once per driving cycle or may be permitted to repeat, dependent on the status of flag LC_OBD_REP_LSH_UP. It shall be clear that only the temperature deviation detection method can repeat as the sensor warm-up phase is usually only carried out once per driving cycle. The diagnosis shall require a number of monitoring cycles to be carried out to permit statistical evaluation of the results. The function may set

The function shall be activated and deactivated dependent on the engine start state, denoted by flag LV_ST_END. Should the function be deactivated, the diagnosis conditions flags LV_DIAG_OBD_CDN_LSH_UP[i], LV_CDN_DIAG_OBD_VLD_LSH_UP[i] and LV_CDN_:DIAG_TTIP_MES_LSH_UP[i] and the SW internal timer *TIMER_1* shall be reset and the diagnosis shall be considered to be “Not Available”.

Additional application conditions shall be met prior to permitting monitoring cycles to take place:

- LC_OBD_LSH_UP shall permit the diagnosis to be enabled or disabled from within the calibration system.
- LV_INH_DIAG_OBD_LSH_UP[i] shall facilitate the interfacing of project specific application conditions.
- STATE_LSH_UP[i] shall neither be in LSH_OFF nor LSH_VB_PROT. See following description for explanation.
- VB shall remain within bounds as indicated by LV_VB_CDN_OBD_2. This shall provide the facility to ensure that the battery voltage is sufficient to carry out OBD II diagnosis.
- LSHPWM_UP[i] shall remain above or equal to C_LSHPWM_MIN_LSH_UP. This shall provide the facility to limit the performing of the diagnosis in a region where the sensor temperature can be controlled. No upper limit is given as should the heater become defective then the closed loop heater voltage controller will tend to drive the LSHPWM_UP[i] to its maximum limit.
- The condition (LV_DIAG_OBD_END_LSH_UP[i] = 0 **or** LC_OBD_REP_LSH_UP = 1) shall permit the diagnosis to be carried out once only per driving cycle (LC_OBD_REP_LSH_UP = 0) or continuously over the whole driving cycle (LC_OBD_REP_LSH_UP = 1).
- The dew point shall have passed as denoted by LV_TEMP_DEW_LS_UP[i] = 1.

The function shall determine whether the full operative readiness LV_LS_UP_READY[i] has been detected. If not, then the time to operative readiness detection method shall be carried out. Internal TIMER_1 shall be reset, the diagnosis conditions flag LV_DIAG_OBD_CDN_LSH_UP[i] shall be set and the diagnosis shall be declared as being “Available”. Timer T_POW_RISE_LSH_UP[i] shall be checked against threshold IP_T_DLY_LS_UP_READY_OBD_LSH_UP. Should it equal or exceed the threshold then the operative readiness has not been detected in a timely manner and the symptoms shall be set to READY_ERR, fault flag LV_DIAG_OBD_SYM_LSH_UP[i] and the error flags shall be set and the end of diagnosis flags shall be set. If T_POW_RISE_LSH_UP[i] does not equal or exceed the threshold then all fault indicators shall be reset.

In order to meet Mode 6 diagnosis requirements, the current oxygen sensor ceramic temperature shall be stored in TTIP_MES_LS_UP_OBD_LSH_UP[i]. (This is used for the detection of the full operative readiness and hence may be used to meet the requirements).

Once the full operative readiness has been detected, further conditions shall be met prior to determining whether the oxygen sensor temperature falls within bounds, i.e. detection method two.

The function shall determine whether a time to operative readiness fault has been detected by observing STATE_SYM_OBD_LSL_LSH_UP[i]. Provided no error symptom is active, the function shall then wait for STATE_LSH_UP[i] to reach LSH_POW_CTL. Additionally the exhaust gas temperature shall exceed the limit C_TEG_DYN_MIN_OBD_LSH_UP to ensure that in long PUC phases sensor cooling does not lead to false error detection. After this condition has been met, the function shall await the delay C_T_DLY_POW_CTL_OBD_LSH_UP. The delay provides the heater controller sufficient time to regulate the ceramic temperature to the set-point. Furthermore, this condition excludes states LSH_VB_PROT & LSH_TEMP_PROT. In both of these states, the heater power is reduced to prevent damage to the sensor. Under such conditions, it cannot be expected that the sensor temperature remain stable and hence OBDII heater diagnosis shall not be carried out in these instances. The SW internal timer used to await the delay shall be reset whenever STATE_LSH_UP[i] is no longer in LSH_POW_CTL or when the other above listed conditions are no longer met.

Additionally LV_TTIP_MES_VLD_LS_UP[i] shall be set, indicating that the ceramic temperature computation is active. This is the case when either the normal operative readiness has been detected via the raw operative readiness and validated via the ceramic temperature or the conditional operative readiness has been detected (forced operative readiness). These conditions permit the use of the measured ceramic temperature (TTIP_MES_LS_UP[i]) and not its initialised value (0 °C), i.e. the system tries to measure the ceramic temperature even if the heater fails sufficiently such that the normal operative readiness cannot be detected, where the oscillator used to measure the internal resistance and hence the ceramic temperature is only switched on when the sensor shows raw operative readiness. Note that during ceramic temperature reference measurements, the flag LV_TTIP_MES_VLD_LS_UP[i] will be revoked until the reference measurement cycle has been completed. The latter shall not cause TIMER_1 to be reset.

Once the application conditions have been met, this shall be indicated by setting the flag LV_DIAG_OBD_CDN_LSH_UP[i] and the function shall consider the diagnosis to be "Available". Should the conditions not be met, then LV_DIAG_OBD_CDN_LSH_UP[i] shall be reset and the diagnosis shall be considered to be "Not Available".

The function shall implement a statistical approach to detect a weak sensor heater: If the temperature is outside calibrateable limits, an error accumulator shall be incremented either with normal steps or with large steps, depending on the temperature being above or below a limit where the sensor is not functional. If the temperature is in range, the accumulator shall be decremented slowly. If the accumulator has reached a limit, the diagnosis shall indicate that an error is present. A second increment-only accumulator shall run in parallel to indicate that the diagnosis is done in the "good" case, i.e. that a fault would have been detected if it was permanently present. The diagnosis shall stop once an error has been detected. The last measured ceramic temperature shall be copied to a variable located in NVMY for Mode $06 scan tool output.

If the repeat flag LC_OBD_REP_LSH_UP_i is not set, the diagnosis shall stop as soon as the increment-only accumulator has reached or exceeded the required value and the end flag is set. If not, the diagnosis keeps running, but the result shall not change anymore once an error has been indicated.

Application conditions:

Initialisation:

The following variables shall be initialised after reset, at the transition of ignition key on (i.e. LV_IGK = 0 -> 1) and upon clearing of the error memory:

STATE_SYM_OBD_LSL_LSH_UP[i] = 0
LV_DIAG_OBD_SYM_LSH_UP[i] = 0
LV_DIAG_OBD_CDN_LSH_UP[i] = 0
LV_DIAG_OBD_END_LSH_UP[i] = 0
LV_LAMB_PLS_REQ_DIAG_LSH_UP[i] = 0
TCC_ERR_OBD_LSH_UP[i] = 0
TCC_END_DIAG_OBD_LSH_UP[i] = 0
LV_ERR_OBD_VLD_LSH_UP[i] = 0
ERR_SYM_OBD_VLD_LSH_UP[i] = “No symptom”
LV_CDN_DIAG_OBD_VLD_LSH_UP[i] = 0
LV_ERR_TTIP_MES_LSH_UP[i] = 0
ERR_SYM_TTIP_MES_LSH_UP[i] = “NO_SYM”
LV_CDN_DIAG_TTIP_MES_LSH_UP[i] = 0

***Reset** all timers*

NOTE: timers refer to internal SW timer and not to output data variable.

Recurrence:

The monitoring cycles shall occur every 100 ms providing the conditions are met.

Activation: "in all engine states"

16.53.1 Upstream sensor heater OBD2 diagnosis: Inhibition of diagnosis

Description:

This function shall evaluate the application conditions applicable to the oxygen sensor ceramic temperature OBDII monitoring and provide the result in a single boolean flag. This flag shall represent the interface to the main diagnosis function.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2), then
    i = 1, for cylinder bank 1
    i = 2, for cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank 1.

Application conditions:

Initialisation: at every transition LV_IGK = 0 -> 1or reset all variables shall be reset to 0, except STATE_RBM_OBD_VLD_LSH_UP[i] *//for init of this variable see section below*

at every transition LV_IGK = 1 -> 0

- LV_INH_DIAG_OBD_LSH_UP[NC_CBK_EX_NR] = 1

Recurrence: 1 s

Activation: LV_IGK = 1

Formula section:

```
If      LV_ERR_TTIP_MES_LSH_UP[i] = 1          or
        LV_ERR_LSL_UP_IF[i] = 1                or
        LV_ERR_AIR_LSL_UP[i] = 1               or

```

16.53.2 Upstream sensor heater OBD2 diagnosis: Interface for rate – based – monitoring

Description:

With this module the interface between the OBD_VLD_LSH_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_OBD_VLD_LSH_UP[i] data.

Within STATE_RBM_OBD_VLD_LSH_UP[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for heater diagnosis)

Application conditions:

Initialisation: *at ECU reset:*

bit 0, bit 1 and bit 2 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0

LV_DC 0 --> 1 transition:

bit 0 and bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0

bit 2 of STATE_RBM_OBD_VLD_LSH_UP[i] = 1

on failure memory reset:

bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 -->1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_AIR_LSL_UP[NC_CBK_EX_NR]	LV_ERR_EL_LSL_UP[NC_CBK_EX_NR]	LV_ERR_LSL_UP_IF[NC_CBK_EX_NR]
LV_ERR_CHG_LS_UP	LV_ERR_MIS[NC_CYL_NR]	LV_ERR_LSH_UP[NC_CBK_EX_NR]
LV_ERR_OC_LSL_UP[NC_CBK_EX_NR]	LV_ERR_OFS_LSL_UP[NC_CBK_EX_NR]	LV_ERR_CTL_LSL_UP[NC_CBK_EX_NR]
	LV_ERR_AIR_LSL_UP[NC_CBK_EX_NR]	

```
If(1)     { CPU optimization at LV_DC 0 --> 1 transition }
          CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
          While  bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0 do
```

```
                with each XX failure of the above list  (depending on configuration, see
                below):
                ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                SYNCHRONIZATION<CALL>)
                If(2)     XX has a pending status
                Then(2)        bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 1
                Endif(2)
            Endwhile
    Else(1)   { the dynamic failure memory is empty }      No action
    Endif(1)
```

Every 1 s :

```
If    bit 0 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0
Then
            If      LV_END_DIAG_OBD_VLD_LSH_UP[i] = 1
            Then    bit 0 of STATE_RBM_OBD_VLD_LSH_UP[i] = 1
            Endif
Endif
If    bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 0
Then
            If      LV_INH_DIAG_RBM_OBD_LSH_UP[i] = 1
            Then    bit 1 of STATE_RBM_OBD_VLD_LSH_UP[i] = 1
            Endif
Endif
```

LV_LS_DOWN_READY[NC_CBK_EX_NR]	VLS_DOWN[NC_CBK_EX_NR]		

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

This function shall facilitate the upstream sensor non-activity detection, which can be caused by a extremely cold sensors or an open circuit some ATIC42 or CJ125 lines.

Description:

In the first part of this test the sensor is assumed to have no activity if VLS_UP_DIAG remains stuck in a tight band around stoichiometric values. If this is true for C_CTR_RAW_ACT_SYM_LSL_UP recurrences, then the raw symptom flag LV_DIAG_RAW_ACT_SYM_LSL_UP is set.
Rate Based Monitoring (RBM) requires similar time spans for the diagnosis to come to an end with or without a failure present. Therefore, if VLS_UP_DIAG is not within the mentioned band (thus a failure is unlikely) the counter CTR_RAW_ACT_END_LSL_UP is incremented until the threshold C_CTR_RAW_ACT_END_LSL_UP is reached. At this point the end flag LV_DIAG_RAW_ACT_END_LSL_UP is set. VLS_UP_DIAG of a faultless sensor might pass through or come to lie within the critical band. In these cases the end counter is frozen and the incrementation is resumed, once the critical band is left again.
In the failure case CTR_RAW_ACT_SYM_LSL_UP is incremented until the threshold C_CTR_RAW_ACT_SYM_LSL_UP is reached, where the end flag and the raw symptom flag are set at the same instance. In case of intermittent faults, excursion from the critical band should not lead to an immediate reset of the raw symptom flag. Therefore, the raw symptom flag is taken back only if the raw symptom counter drops below C_CTR_RAW_ACT_RST_LSL_UP.

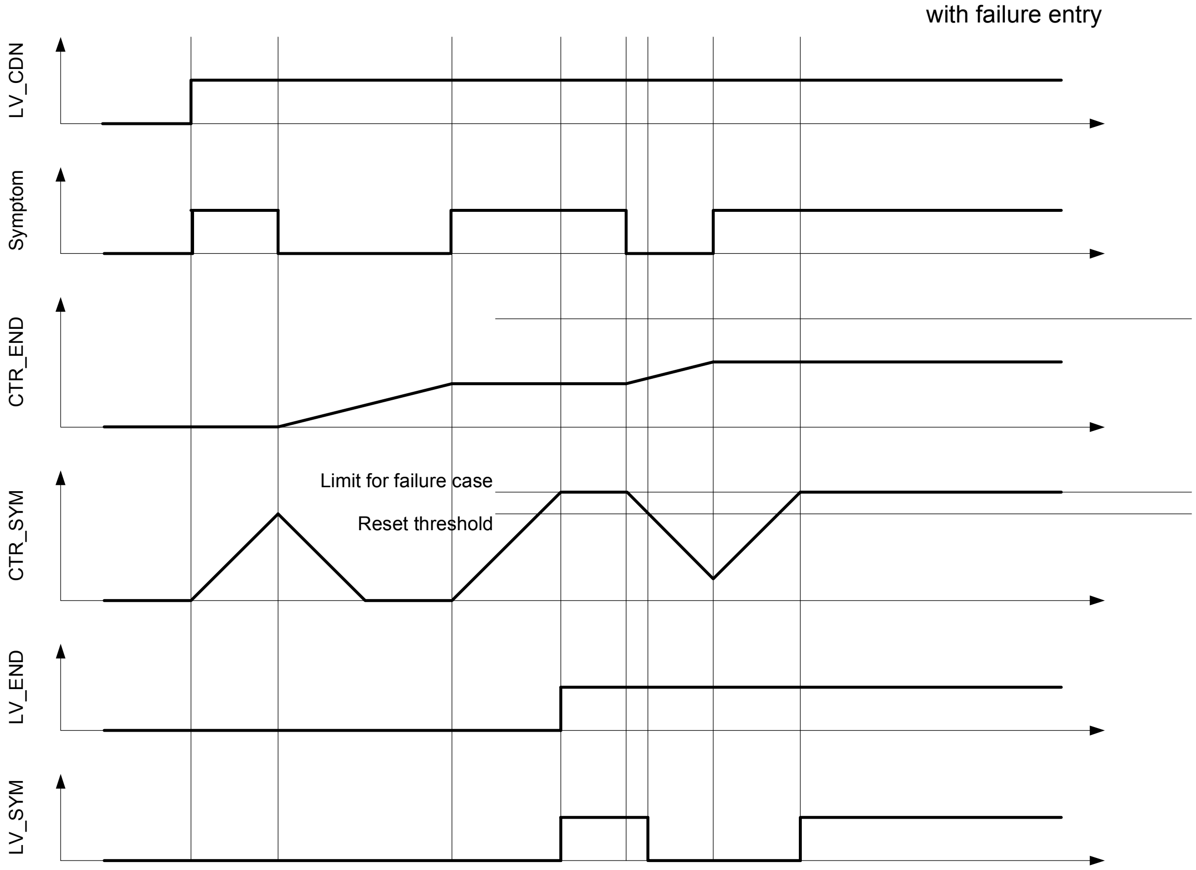

Figure 1: Basic principle of debounce algorithm for first part of activity check (LV_DIAG_RAW_ACT_END/SYM_LSL_UP)

The second part is started once the first part has come to an end and the following conditions are met: The forced stimulation is active and additionally engine speed, engine load, amplitude and period of the forced stimulation are sufficient to provoke the fluctuation of the sensor output. If these conditions are fulfilled then the following procedure is carried out. The difference between LAMB_LS_UP[i] and the moving mean value LAMB_MMV_ACT_LSL_UP[i] is calculated and integrated. After C_CTR_LAMB_DE_INT_ACT_LSL_UP forced stimulation periods the result is saved in the variable LAMB_DE_TOT_ACT_LSL_UP[i].
While integrating the difference between LAMB_LS_UP[i] and the moving mean value two different gain factors are taken into account. First, ID_LAMB_GAIN_LS_UP_DYN considers an aged sensor. Second, with ID_LAMB_GAIN_VLS_DOWN the speed of integration is reduced, if VLS_DOWN[i] shows either very rich or very lean conditions. The background here is that the combination of an upstream signal near stoichiometry and a very rich or very lean downstream signal strongly points to a not active upstream signal.
If the value of the deviation integral after C_CTR_LAMB_DE_INT_ACT_LSL_UP forced stimulation cycles is lower than the threshold C_LAMB_DE_TOT_ACT_LSL_UP, then the symptom counter shall be incremented, otherwise it shall be decremented. If the symptom counter has achieved the maximum C_CTR_SYM_MAX_ACT_LSL_UP cycles, then the symptom flag LV_DIAG_ACT_SYM_LSL_UP[i] is set, indicating that the sensor activity is very poor. This flag shall trigger the Open Circuit Diagnosis to narrow down the source of the failure. To have a valid end flag in case of a faultless sensor the counter C_CTR_END_ACT_LSL_UP is incremented once the end flag of the first part is set and no raw symptom was detected. The end flag of the Activity Check is set when the end counter reaches the sum of both loops needed for the fault detection.

Application conditions:

Initialisation:

At the transition LV_IGK = 0 to 1, reset or at clearing error memory reset all variables.

At the transition LV_DIAG_ACT_CDN_LSL_UP[i] = 0 -> 1 initialize as follow:

CTR_SYM_ACT_LSL_UP[i] = 0
CTR_END_ACT_LSL_UP[i] = 0
CTR_RAW_ACT_SYM_LSL_UP[i] = 0
CTR_RAW_ACT_END_LSL_UP[i] = 0

FUNCTION DESCRIPTION:

16.55.1 General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation:

at every transition LV_IGK = 0 -> 1or reset all variables shall be reset to 0.

at every transition LV_IGK = 1 -> 0 LV_DIAG_ACT_INH_LSL_UP[i] = 1

Recurrence:

The functions shall be carried out once every 1s.

Activation:

LV_IGK = 1

Deactivation:

LV_IGK = 0

Formula Section:

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)

i = 1, for single exhaust cylinder bank.

Description:

The plausibility check between the upstream oxygen sensor (WRAF sensor) and the downstream oxygen sensor (binary) signal is done once the expected driving conditions are fulfilled. A non-plausibility symptom detected by this diagnosis indicates that a failure is present in one of both sensors.

Two different symptoms can be detected:

- STATE_SYM_DIAG_PLAUS_LSL_UP[i] = *"SYM_0"*, if the upstream sensor indicates a rich lambda value, while the downstream sensor signal lean.
- STATE_SYM_DIAG_PLAUS_LSL_UP[i] = *"SYM_1"*, if the upstream sensor indicates a lean lambda value, while the downstream sensor signal rich.

Once the down- and upstream sensor signals are not mutual plausible first the mass flow integral MAF_SYM_RAW_PLAUS_LSL_UP[i] is calculated to take into account the delay time caused by the oxygen storage capability of the catalyst. If this integral reaches the threshold C_MAF_SYM_RAW_PLAUS_LSL_UP[i] the status in STATE_SYM_DIAG_PLAUS_LSL_UP[i] is set to the respective symptom. If either LV_DIAG_AFR_SYM_PLAUS_LSL_UP[i] or LV_DIAG_AFS_SYM_PLAUS_LSL_UP[i] disappears the MAF integral is decremented. When the integral reaches C_MAF_SYM_RAW_RST_PLAUS_LSL_UP[i] the status flag is taken back.

Second, after STATE_SYM_DIAG_PLAUS_LSL_UP[i] is set to the respective symptom the debounce algorithm is started. If both LV_DIAG_AFR/AFS_SYM_PLAUS_LSL_UP[i] and STATE_SYM_DIAG_PLAUS_LSL_UP[i] are active MAF_SYM_PLAUS_LSL_UP is integrated. In contrast if both symptom indicators are inactive (thus no failure is expected) the integral MAF_END_PLAUS_LSL_UP[i] is integrated. Should the status of flag differ from eachother, then both integrals are frozen. MAF_SYM_PLAUS_LSL_UP is reset when the status of STATE_SYM_DIAG_PLAUS_LSL_UP[i] changes. There is not reset condition for the end integral in order to have a valid end flag also in case of a jittering signal.

LV_DIAG_PLAUS_SYM_LSL_UP[i] is set to one once the symptom integral exceeds C_MAF_SYM_PLAUS_LSL_UP[i] is exceeded. LV_DIAG_PLAUS_END_LSL_UP[i] is set when the end integral exceeds sum of C_MAF_SYM_PLAUS_LSL_UP[i] and C_MAF_SYM_RAW_PLAUS_LSL_UP[i] or when the LV_DIAG_PLAUS_SYM_LSL_UP[i] is set.

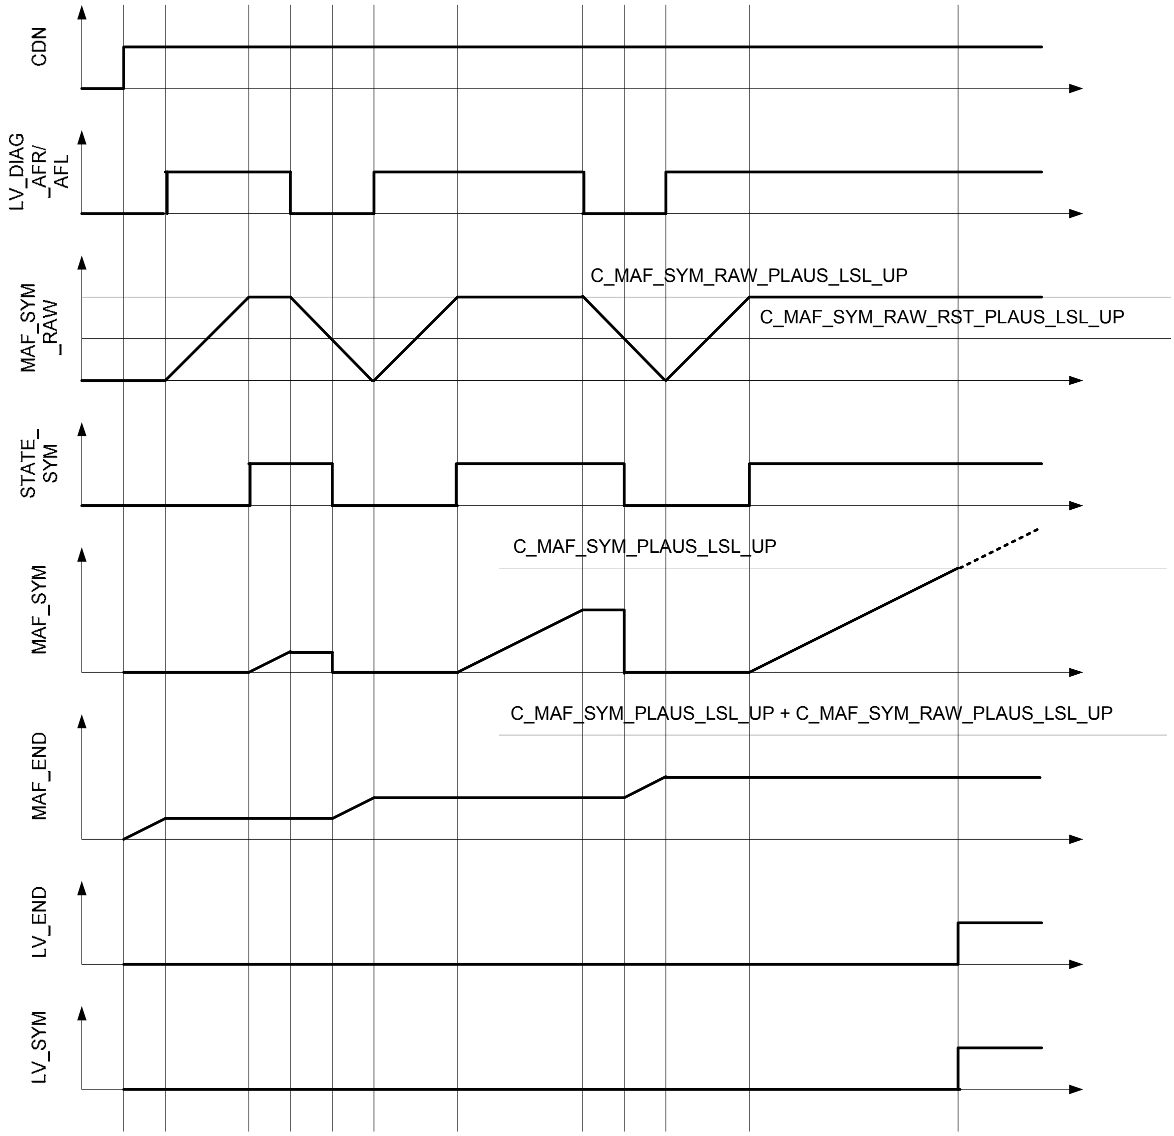

Figure 1: Basic principle of applied debounce algorithm.

The symptom flag LV_DIAG_PLAUS_SYM_LSL_UP is exported to *“Sensor Characteristic Line Shift to Lean”* and *“Shift to Rich”* functions to facilitate the detection of the faulty sensor and failure cause.

The calibration of this function is described in its Tunning Guide.

Application conditions:

Initialisation:

At transition LV_IGK = 0 to 1, reset or at clearing error memory reset all variables.

Recurrence: 100 ms

Activation:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: at every transition LV_IGK = 0->1or reset all variables shall be reset to 0.

at every transition LV_IGK = 1->0

LV_DIAG_PLAUS_INH_LSL_UP[NC_CBK_EX_NR] = 1

Recurrence: the functions shall be carried out once every 1s.

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

FUNCTION DESCRIPTION:

General information:

This function shall summarize the results of both dynamic fuel trim diagnosis specified in this module. Although this function has variable names which are according to the error management naming convention, it does not include an interface to the error manager.

Error Symptoms are defined as follows:

```
 ┌─┬─┬─┬─┐
 │ │ │ │ │
 └─┴─┴─┴─┘
  │  │  │  └─> AF too RICH      ( = SYM_0)
  │  │  └────> AF too LEAN      ( = SYM_1)
  │  └───────> (not used)
  └──────────> (not used)
```

Application conditions:

Initialisation: At transition LV_IGK = 0 to 1, ECU reset or at clearing error memory reset all variables to zero, except for the following:

T_SUM_RST_DELTA_I_LAM[i] = C_T_SUM_RST_MAX_DELTA_I_LAM[i]
T_SUM_END_DIAG_WIN_DELTA_I_LAM[i] = C_T_SUM_RST_MAX_DELTA_I_LAM[i]
T_SUM_END_READY_DELTA_I_LAM[i] = C_T_SUM_READY_DELTA_I_LAM[i]
LAMB_DELTA_I_SAVE_DIAG[i] shall not be initialized

Recurrence: 100 ms

Activation: -

Formula section:

```
If   LV_ERR_DELTA_I_LAM[i] = 1 or  LV_ERR_VLS_DOWN_DIF[i] = 1
Then
    If   (ERR_SYM_DELTA_I_LAM[i] = “SYM_0” &
          ERR_SYM_VLS_DOWN_DIF[i] <> “SYM_1”)
    Or   (ERR_SYM_DELTA_I_LAM[i] <> “SYM_1” &
          ERR_SYM_VLS_DOWN_DIF[i] = “SYM_0”)
    Then
            LV_ERR_LAM_ADJ[i]  = 1
            ERR_SYM_LAM_ADJ[i] = “SYM_0”
    Else
            If  (ERR_SYM_DELTA_I_LAM[i] = “SYM_1” &
                 ERR_SYM_VLS_DOWN_DIF[i] <> “SYM_0”)
```

```
                Or (ERR_SYM_DELTA_I_LAM[i] <> "SYM_0" &
                    ERR_SYM_VLS_DOWN_DIF[i] = "SYM_1")
                Then
                        LV_ERR_LAM_ADJ[i]  = 1
                        ERR_SYM_LAM_ADJ[i] = "SYM_1"
            Else
                        ERR_SYM_LAM_ADJ[i] = "NO_SYM"
                Endif
        Endif
    Endif

    If      LV_END_DIAG_DELTA_I_LAM[i] = 1 or
            LV_END_DIAG_VLS_DOWN_DIF[i]  = 1 or
        LV_DIAG_EOL_END_LS_UP_DOWN[i] = 1
    Then
        LV_END_DIAG_LAM_ADJ[i] = 1
    Endif
```

16.58.1 Monitoring trim controller I-Share

FUNCTION DESCRIPTION:

General information:

To fulfil the legal requirements of the OBDII lambda sensor diagnosis, the trim of the lambda control by the lambda sensor signal downstream of the catalytic converter must be monitored in addition to the diagnosis of the lambda sensor upstream of the catalytic converter. In the case of a trim control error, a plausibility check is performed to assign the faulty behavior to the control sensor or the monitoring sensor.
Faulty behavior of the lambda sensors upstream or downstream from the catalytic converter exists if one of the emission components exceeds the standard emissions in the emission test cycle by a certain factor.

Error Symptoms are defined as follows:

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │  │  │  └─> AF too RICH     ( = SYM_0)
  │  │  └───> AF too LEAN     ( = SYM_1)
  │  └─────> (not used)
  └───────> (not used)
```

Application conditions:

Initialisation: -- (see first chapter) --

Recurrence: 100ms

Activation / Deactivation:

```
If      LV_INH_DIAG_DLY_LAM[i] = 0
and     LV_CP_RAMP_OPEN_ACT  = 0
and     LV_LAM_ADJ_I_ACT[i] = 1
and     LV_ERR_DELTA_I_LAM[i] = 0
and     C_LAMB_DELTA_I_MAX_DIAG > C_LAMB_DELTA_I_MIN_DIAG
then    LV_CDN_DIAG_DELTA_I_LAM[i] = 1
           “diagnosis enabled”
else    LV_CDN_DIAG_DELTA_I_LAM[i] = 0
           “diagnosis disabled”
endif
```

Description:

16.58.2 Reset of time counters and set of end of diagnosis flags

After a calibrateable time during which the diagnosis has been activated and no error has been set, the timers for detection of too rich or lean system are reset or respectively reinitialised for the next diagnosis check. This must be done e.g. to avoid to sum up intermittend failures over a too long period.
Beside the items mentioned above the end of diagnosis flag can be set by two different time counters also. (T_SUM_END_DIAG_WIN_DELTA_I_LAM[i] and T_SUM_END_READY_DELTA_I_LAM[i])
After a calibrateable time during which the diagnosis has been activated the end of diagnosis flag is set. The flag of temporary end of diagnosis is a trigger for the similar conditions check and therefore always set after every completed DELTA_I_LAM cycle check (reset next recurrence).
At engine stop all time counters are reset respectively reinitialised.

Formula section:

```
If      LV_CDN_DIAG_DELTA_I_LAM[i] = 1
then    % Reset of time counters and set of end of diagnosis flags
        If      ERR_SYM_DELTA_I_LAM[i] = SYM_0 or SYM_1

                T_SUM_END_READY_DELTA_I_LAM[i] =
                                        C_T_SUM_READY_DELTA_I_LAM[i]
         endif
endif
```

16.58.3 Error detection for rich/lean A/F ratio deviation

If the total amount of I-share of the trim controller (LAMB_DELTA_I_LAM_ADJ[i] + LAMB_DELTA_AD_LAM_ADJ[i]) exceeds the diagnostic threshold C_LAMB_DELTA_I_MAX/MIN_DIAG[i], T_SUM_MAX/MIN_DELTA_I_LAM[i] is incremented as long as the diagnostic threshold is exceeded. If (LAMB_DELTA_I_LAM_ADJ[i] + LAMB_DELTA_AD_LAM_ADJ[i]) falls below the diagnostic threshold, then T_SUM_MAX/MIN_DELTA_I_LAM[i] is stopped. A failure is detected as soon as T_SUM_MAX/MIN_DELTA_I_LAM[i] is above the threshold C_T_SUM_MAX/MIN_MAX_DELTA_I_LAM[i]. Incrementation restarts, if the I-share of the trim controller exceeds the limit again.
If the engine is stopped the time counters shall be reset.

```
If      LV_CDN_DIAG_DELTA_I_LAM[i] = 1
then    % Error detection for rich/lean A/F ratio deviation
         If    ( LAMB_DELTA_I_LAM_ADJ[i] + LAMB_DELTA_AD_LAM_ADJ[i] ) >
                                              C_LAMB_DELTA_I_MAX_DIAG
         then       increment T_SUM_MAX_DELTA_I_LAM[i]
                    ERR_SYM_DELTA_I_LAM[i] = “SYM_1”       /AF too LEAN
         else       freeze T_SUM_MAX_DELTA_I_LAM[i]
                    If      ( LAMB_DELTA_I_LAM_ADJ[i] +
                     LAMB_DELTA_AD_LAM_ADJ[i] ) < C_LAMB_DELTA_I_MIN_DIAG
                    then    increment T_SUM_MIN_DELTA_I_LAM[i]

  then  LAMB_DELTA_I_SAVE_DIAG[i] = ( LAMB_DELTA_I_LAM_ADJ[i] +
                  LAMB_DELTA_AD_LAM_ADJ[i] )
  endif
```

Application hint: the data for each individual bank should fulfill the following conditions
1. C_T_SUM_RST_MAX_DELTA_I_LAM **>>** C_T_SUM_READY_DELTA_I_LAM
2. C_T_SUM_MIN_MAX_DELTA_I_LAM and C_T_SUM_MAX_MAX_DELTA_I_LAM **>>** C_T_SUM_MAX_ERR_DELTA_I_LAM

16.58.4 Monitoring of trim controller deviation

FUNCTION DESCRIPTION:

General information:

In order to get a fast decision of error location in case of oxygen sensor failure, trim controller input signal is monitored. Insufficient trim control over long period can be obtained out of this function. In conjunction with activity check of the up- and downstream sensors it is decided which sensor is damaged (up- or downstream).

Description:

The downstream sensor signal deviation to setpoint (VLS_DIF_LAM_ADJ[i]) is observed during trim controller diagnosis phase. This implements the activation of trim control.
If VLS_DIF_LAM_ADJ[i] exceeds either maximum or minimum voltage thresholds corresponding MAF integrals are started. As long as the diagnostic threshold is exceeded the MAF integral is incremented, else it is stopped. A failure is detected as soon as the MAF integral exceeds the threshold (MAF_INT_VLS_DIF_DLY_MAX/MIN). Then symptom flag LV_ERR_VLS_DOWN_DIF and the corresponding symptom (MIN or MAX) are set.
MAF_INT_RST_VLS_DOWN_DIF_DIAG[i] is incremented if no end flag is set so far, or if a symptom was detected at least once in the current diagnostic cycle, it seves two purposes: It causes a "good" diagnostic result if no symptom is detected after sufficient time has elapsed, and it aborts and restarts the diagnosis if a symptom was present, but occurs only rarely (e.g. due to dynamic driving conditions).

Error Symptoms are defined as follows:

```
 ┌──┬──┬──┬──┐
 └──┴──┴──┴──┘
  |  |  |  └─> AF too RICH     ( = SYM_0)
  |  |  └────> AF too LEAN     ( = SYM_1)

16.58.5 Limited dynamic for the function "Monitoring the Trim Controller Deviation"

FUNCTION DESCRIPTION:

General information:

As it is specified in the function "Monitoring Trim Controller Deviation" contained in this module, this shall be carried out every time the Trim Controller P-share is beeing calculated. This is active most of the time to maintain the the air fuel ratio inside the catalyst window also if any deviation happens. Under such unstable condition its not proper to carry out the trim controller diagnosis and this shall be inhibit until the system achieves the steady state. This shall be facilitated by the present function which shall summarize informations concerning the dynamic of engine speed, mass air flow and air fuel ratio.

Description:

The floating mean value N_MMV_VLS_DIF_DLY_LDC is computed using the averaging constant C_N_CRLC_LDC_VLS_DIF_DLY. The limited dynamics condition only exist while the engine speed N lies within the dynamics window around N_MMV_VLS_DIF_DLY_LDC.
If the above limited dynamics condition is violated, the floating mean value N_MMV_VLS_DIF_DLY_LDC is set to the current engine speed in order to reach the limited dynamics condition faster:

The floating mean value MAF_MMV_VLS_DIF_DLY_LDC is computed using the averaging constant C_MAF_CRLC_LDC_VLS_DIF_DLY. The limited dynamics condition only exist while the air mass MAF stays within the dynamics window around MAF_MMV_VLS_DIF_DLY_LDC. If the above limited dynamics condition is violated, the floating mean value MAF_MMV_VLS_DIF_DLY_LDC is set to the current air-mass value in order to reach the limited dynamics condition faster:

The floating mean value LAM_MMV_VLS_DIF_DLY_LDC[i] is computed using the averaging constant C_LAM_MV_CRLC_LDC_VLS_DIF_DLY. The limited dynamics condition continues to exist while the mean oxygen value FAC_LAM_MV[i] stays within the dynamics window around LAM_MMV_VLS_DIF_DLY_LDC[i]. If the above limited dynamics condition is violated, the floating mean value LAM_MMV_VLS_DIF_DLY_LDC[i] is set to the current mean oxygen value in order to reach the limited dynamics condition faster.

Application conditions:

Initialisation: -- (see first chapter) –

Recurrence: T_SAMPLE = 100ms

Activation: If (LV_IGK = 1 and LV_ST_END = 1)

Deactivation: *the above conditions are not fullfiled*

Initialization at deactivation:
N_MMV_VLS_DIF_DLY_LDC = N
MAF_MMV_VLS_DIF_DLY_LDC = MAF
LAM_MMV_VLS_DIF_DLY_LDC[i] = FAC_LAM_MV[i]

Formula section:

Limited engine speed (N) dynamics:

```
N_MMV_VLS_DIF_DLY_LDC =
            N_MMV_VLS_DIF_DLY_LDC * (1 - C_N_CRLC_LDC_VLS_DIF_DLY) +
                                       C_N_CRLC_LDC_VLS_DIF_DLY * N

IF | N - N_MMV_VLS_DIF_DLY_LDC | < C_N_LDC_VLS_DIF_DLY
THEN  LV_VLS_DIF_DLY_LDC_N = 1
ELSE  LV_VLS_DIF_DLY_LDC_N = 0
      N_MMV_VLS_DIF_DLY_LDC = N
ENDIF
```

Limited mass air flow (MAF) dynamics:

```
MAF_MMV_VLS_DIF_DLY_LDC =
         MAF_MMV_VLS_DIF_DLY_LDC * (1 - C_MAF_CRLC_LDC_VLS_DIF_DLY) +
                                       C_MAF_CRLC_LDC_VLS_DIF_DLY * MAF

IF | MAF - MAF_MMV_VLS_DIF_DLY_LDC | < C_MAF_LDC_VLS_DIF_DLY

THEN  LV_VLS_DIF_DLY_LDC_MAF = 1
ELSE  LV_VLS_DIF_DLY_LDC_MAF = 0
        MAF_MMV_VLS_DIF_DLY_LDC = MAF
ENDIF
```

Limited mean oxygen value (FAC_LAM_MV[i]) dynamics:

```
LAM_MMV_VLS_DIF_DLY_LDC[i]  =
           LAM_MMV_VLS_DIF_DLY_LDC[i] * (1 -
C_LAM_MV_CRLC_LDC_VLS_DIF_DLY)
                 +  C_LAM_MV_CRLC_LDC_VLS_DIF_DLY * FAC_LAM_MV[i]

IF | FAC_LAM_MV[i] - LAM_MMV_VLS_DIF_DLY_LDC[i] | <
                                            C_LAM_MV_LDC_VLS_DIF_DLY
THEN  LV_VLS_DIF_DLY_LDC_LAM_MV[i] = 1
ELSE  LV_VLS_DIF_DLY_LDC_LAM_MV[i] = 0
      LAM_MMV_VLS_DIF_DLY_LDC[i]  = FAC_LAM_MV[i]
ENDIF
```

Summarizing limited dynamic conditions:

```
IF      LV_VLS_DIF_DLY_LDC_N = 1   AND   LV_VLS_DIF_DLY_LDC_MAF = 1   AND
           LV_VLS_DIF_DLY_LDC_LAM_MV[i] = 1
THEN
      IF     MAF_INT_VLS_DIF_DLY_LDC[i] ≤  C_MAF_INT_MIN_VLS_DIF_DLY_LDC[i]
      THEN
           MAF_INT_VLS_DIF_DLY_LDC[i]$_n$ =

                      MAF_INT_VLS_DIF_DLY_LDC[i]$_{n-1}$

                      + MAF_KGH* T_SAMPLE [ms] * 1/3600 [(g*h) / (kg*ms)]
```

```
        ELSE
            freeze MAF_INT_VLS_DIF_DLY_LDC[i]
                LV_VLS_DIF_DLY_LDC[i] = 1
            ENDIF
    ELSE
            LV_VLS_DIF_DLY_LDC[i]                       =  0
            MAF_INT_VLS_DIF_DLY_LDC[i]                  =  0
    ENDIF
```

16.59.1 Inhibtion of “Dynamic fuel trim diagnosis”

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks. For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2), then:

i = 1 for exhaust cylinder bank 1
i = 2 for exhaust cylinder bank 2,
otherwise (NC_CBK_EX_NR = 1)
i = 1 for single exhaust cylinder bank.

Application conditions:

Initialisation: at reset all variables shall be set to zero;

at LV_IGK = 0 -> 1 all variables except *STATE_RBM_VLS_DOWN_DIF[i]* shall be set to zero;

at every LV_IGK = 1 -> 0 LV_INH_DIAG_DLY_LAM[i] = 1

Recurrence: 1 s

Activation: LV_IGK = 1

Dectivation: LV_IGK = 0

Formula section:

```
If      MAF_SCAV_EXT > C_MAF_SCAV_MAX_INH_DLY_LAM
then    MAF_INT_SCAV_NOT_ACT = C_MAF_INT_SCAV_NOT_ACT
else    MAF_INT_SCAV_NOT_ACT$_{n}$ =
        MAF_INT_SCAV_NOT_ACT$_{n-1}$
        - MAF_KGH* T_SAMPLE [ms] * 1/3600 [(g*h) / (kg*ms)]
endif
```

endif
```

16.59.2 Interface for Rate – Based – Monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the VLS_DOWN_DIF[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_VLS_DOWN_DIF[i] data.

Within STATE_RBM_VLS_DOWN_DIF[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for trim diagnosis)

Application conditions:

Initialisation:

at LV_DC 0 -> 1 transition:

bit 0 , bit 1 of STATE_RBM_VLS_DOWN_DIF[i] = 0

bit 2 shall be set to 1.

at ECU reset:

all bits of STATE_RBM_VLS_DOWN_DIF[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 -> 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_MAP_DIP_SENS	LV_ERR_MAP_DIP_PLAUS	LV_ERR_MAP_DIP_SHIFT
LV_ERR_SA_SAP	LV_ERR_SAP	LV_ERR_CAT_DIAG[NC_CBK_EX_NR]
LV_ERR_SA_SYS	LV_ERR_EL_CPS	LV_ERR_DIAGCPS
LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_PLAUS
LV_ERR_TCO_STUCK	LV_ERR_MAF	LV_ERR_MIS[NC_CYL_NR]
LV_ERR_AMP	LV_ERR_AMP_PLAUS	LV_ERR_DYN_VLD_LS_UP[NC_CBK_EX_NR]
LV_ERR_TPS	LV_MIS_STATE_A	LV_MIS_STATE_B

LV_ERR_FUP	LV_ERR_FUP_MFP_PLAUS	LV_ERR_H_PRS_SYS	LV_ERR_VCV
LV_ERR_FUP_ORNG	LV_ERR_FUP_ST	LV_ERR_TCO_STUCK_RNG	LV_ERR_TTIP_MES_LSH_UP[i]
LV_ERR_MAP_TPS_PLAUS			

```
If(1)     { CPU optimization at LV_DC 0 -> 1 transition }
          CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
          While  bit 1 of STATE_RBM_VLS_DOWN_DIF[i] = 0 do
                 with each XX failure of the above list  (depending on configuration, see
                 below):
                 ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                 SYNCHRONIZATION<CALL>)

                 If(2)        XX has a pending status
                 Then(2)      bit 1 of STATE_RBM_VLS_DOWN_DIF[i] = 1
                 Endif(2)
          Endwhile
Else(1)   { the dynamic failure memory is empty }      No action
Endif(1)
```

Every 1 s :

```
If    bit 0 of STATE_RBM_VLS_DOWN_DIF[i] = 0
Then
```

```
            If    LV_END_DIAG_VLS_DOWN_DIF[i] = 1
            Then  bit 0 of STATE_RBM_VLS_DOWN_DIF[i] = 1
            Endif
    Endif
    If    bit 1 of STATE_RBM_VLS_DOWN_DIF[i] = 0
    Then
            If    LV_INH_DIAG_RBM_DLY_LAM[i] = 1
            Then  bit 1 of STATE_RBM_VLS_DOWN_DIF[i] = 1
            Endif
    Endif
```

16.60.1 State machine

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Due to possible oxygen sensor defects (e.g. reference air poisoning) or faults in the injection system (e.g. leaking fuel injector), the oxygen sensors may not provide the expected lean or rich AF signal level during definite conditions (lean or rich). Hence, the oxygen sensor signals shall be checked for plausibility during this engine operating states. The handling is requested and results are utilized by a separate manager for oxygen sensors error.

Description:

If the following conditions are met, then the conditions for plausibility check at lean conditions are determined to be present:
A. The Fuel Trim Diagnosis has detected an error (transmitted by LV_DIAG_OPL_REQ_CBK[1]).
B. No general inhibition observed (LV_DIAG_ACT_INH_LS_UP_DOWN[i]) and no specific inihibition exists (LV_DIAG_AFR_AFL_INH_LS_UP_DOWN[i]= 0).
C. The lean state shall be determined to be stable, as determined by comparing the mass air flow integral calculated after activation (MAF_INT_DIAG_LS_UP_DOWN[i]) with the threshold range (C_MAF_INT_DIAG_LS_UP_DOWN[i]).
D. The lean condition will be maintained until a timer is elapsed or an error was found on the upstream sensor or in case of a 1 bank system also on the downstream sensor.

The rich check follows always the lean test. The procedure is analogous to the lean check.

In case of a two bank system and finished open loop test on bank 1 and if there was no upstream linear lambda sensor fault detected, the bank 2 will be checked (triggered by LV_DIAG_OPL_REQ_CBK[2] which is set in application incidences).

In case an EOL test the timers shall be initialized with a non-zero calibrateable value to reduce the minimum required time. The same is valid for the initialization of the MAF integral.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, by reset, by clearing error memory or by triggering the EOL test (LV_DIAG_EOL_REQ_LS_UP_DOWN[i] = 0 -> 1; while LV_DIAG_ACT_END_LS_UP_DOWN[i] = 0) initialise the variables as follows:

STATE_DIAG_ACT_LS_UP_DOWN[i] = 0
MAF_INT_DIAG_LS_UP_DOWN[i] = 0
LV_DIAG_ACT_END_LS_UP_DOWN[i] = 0
LV_DIAG_EOL_END_LS_UP_DOWN[i] = 0
LV_DIAG_AFR_CDN_LS_UP_DOWN[i] = 0
LV_DIAG_AFR_END_LS_UP_DOWN[i] = 0
LV_DIAG_AFL_CDN_LS_UP_DOWN[i] = 0
LV_DIAG_AFL_END_LS_UP_DOWN[i] = 0
LAMB_SP_BEG_DIAG_LS_UP_DOWN[i] = 1
LV_LAMB_SP_AFR_REQ_DIAG_ACT[i] = 0
LV_LAMB_SP_AFL_REQ_DIAG_ACT[i] = 0
T_DIAG_ACT_AFR_LS_UP_DOWN[i] = 0
T_DIAG_ACT_AFL_LS_UP_DOWN[i] = 0
LV_LAM_DI_REQ[i] = 0

Recurrence: *T_SAMPLE* = 100ms

> *Note:*
> *The functions contained in this module shall be carried out according the following sequence:*
> 1. *active test upstream sensor*
> 2. *active test downstream sensor*
> 3. *state machine*

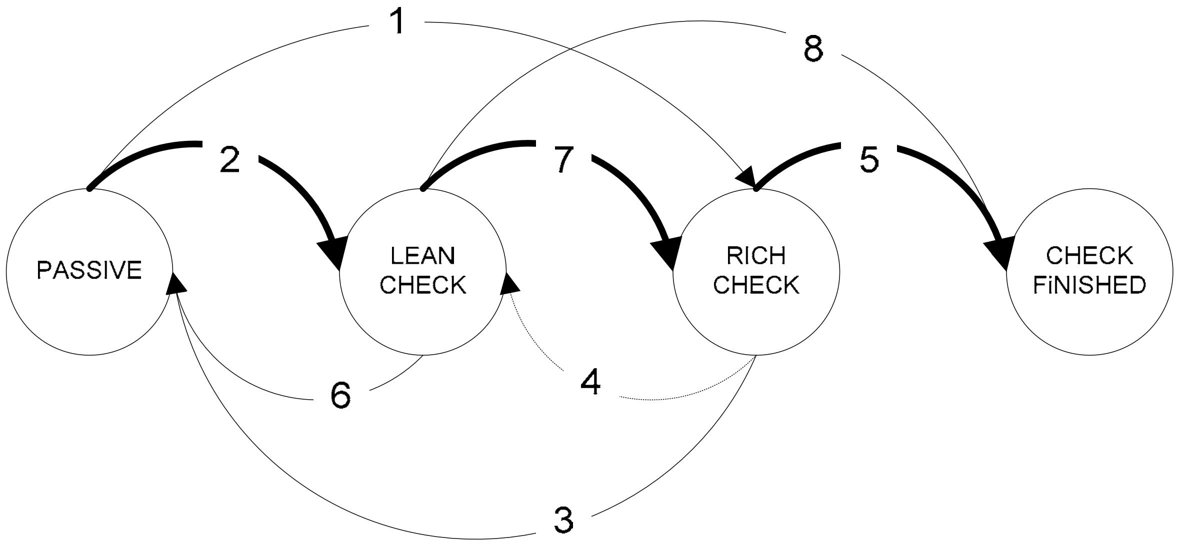
Activation:

LV_ST_END = 1

16.60.1.1 Sequence for check of signal plausibility monitoring (state machine)

The state machine shall remain in its current state and carry out the actions specified to occur within that state once per recurrence unless otherwise specified. The state machine shall only move to another state when one of the conditions has been determined to be met.

The priority of the conditions to change between states shall be defined by the order in which these conditions are listed within the appropiate state as described below.



STATE machine diagram:

    endif
```

16.60.1.3 State "RICH CHECK"

Description:

The MAF integral runs. After exceeding the calibrateable threshold for MAF the signal voltage is observed and the check is complete. The corresponding diagnosis flag is set in case of not sufficient voltage value.
The calculation of MAF_INT_DIAG_LS_UP_DOWN[i] expires in 100ms raster as long as the operation state is fulfilled. MAF_INT_DIAG_LS_UP_DOWN[i] is limited to the maximum value if necessary in case of a longer rich phase.

Actions:

```
If     LV_LAM_LSCL[i] = 0
and LAMB_SP[i]  > C_LAMB_AFR_MIN_DIAG_LS_UP_DOWN
and LAMB_SP[i]  < C_LAMB_AFR_MAX_DIAG_LS_UP_DOWN
then

16.60.1.5 State "CHECK FINISHED"

Action:

none

16.60.2 O2 Sensor (up) open loop diag

FUNCTION DESCRIPTION:

This function shall do a plausibility test of the upstream oxygen sensor after the lambda set point was shifted to rich and/or lean. The failure entry will be done by the O2 Sensor diagnosis management (characteristic shift down diagnosis). Consequently the flags LV_ERR_.... and LV_END_DIAG_... are defined there.

Description:

Application conditions:

Initialisation:

At LV_IGK change 0 -> 1, reset or at clearing error memory initialize the variables as follows:

LV_DIAG_AFR_CHK_SYM_LSL_UP[i] = 0
LV_DIAG_AFL_CHK_SYM_LSL_UP[i] = 0
LV_DIAG_ACT_CHK_CDN_LSL_UP[i] = 0
LV_DIAG_ACT_CHK_END_LSL_UP[i] = 0
CTR_SUM_RST_AFR_CHK_LSL_UP[i] = 0
CTR_SUM_RST_AFL_CHK_LSL_UP[i] = 0
CTR_AFR_CHK_LSL_UP[i] = 0
CTR_AFL_CHK_LSL_UP[i] = 0

Recurrence:

This function shall be carried out every 100 ms.

Activation:

```
If LV_DIAG_AFR_CDN_LS_UP_DOWN[i] = 1 or LV_DIAG_AFL_CDN_LS_UP_DOWN[i] = 1
then
    LV_DIAG_ACT_CHK_CDN_LSL_UP[i] = 1
    Activate function
Else
    LV_DIAG_ACT_CHK_CDN_LSL_UP[i] = 0
    Deactivate function
endif
```

Formula section:

```
If LV_DIAG_AFR_CDN_LS_UP_DOWN[i] = 1
And CTR_SUM_RST_AFR_CHK_LSL_UP[i] < C_CTR_SUM_RST_AFR_CHK_LSL_UP
then

    Endif
```

16.60.3 O2 sensor (down) open loop diag

FUNCTION DESCRIPTION:

General information:

This function shall do a plausibility test of the downstream oxygen sensor after the lambda set point was shifted to rich and/or lean. Once the test is complete on all cylinder banks, the symptoms are combined to produce appropriate error entries. The evaluation is different for 1 bank and 2 bank systems, more than 2 banks are not supported.

Here the dynamic error managemer is used to set the flags LV_ERR_.... and LV_END_DIAG_.... LV_DIAG_CYC_END_LS_DOWN[i] is defined as dummy for global interface reasons.

Description:

Error Symptoms are defined as follows:

```
ERR_SYM_CHK_LS_DOWN
  □□□□
   │ │ │ └─> downstream oxygen sensor too rich          ( = SYM_0)
   │ │ └───> downstream oxygen sensor too lean          ( = SYM_1)
   │ └─────> (not used)                                         ( = SYM_2)
   └───────> (not used)                                         ( = SYM_3)

ERR_SYM_CHG_LS_DOWN
  □□□□
   │ │ │ └─> (not used)                                         ( = SYM_0)
   │ │ └───> (not used)                                         ( = SYM_1)
   │ └─────> (not used)                                         ( = SYM_2)
   └───────> downstream oxygen sensors interchanged   ( = SYM_3)
```

Application conditions:

            and LV_INH_DIAG_CHG_LS_DOWN = 1)
then        LV_END_DIAG_CHK_LS_DOWN[i] = 1
endif
```

Hint: The constant C_T_END_DIAG_ACT_LS_DOWN[i] must be bigger equal
2* (C_T_MAX_DIAG_AFL_LS_UP_DOWN + C_T_MAX_DIAG_AFR_LS_UP_DOWN + maximum time for the MAF integral C_MAF_INT_DIAG_LS_UP_DOWN[i] times 2).
The reason is to be in line with Rate Based Monitoring requirements (duration of diagnosis in the no failure case not shorter than in the failure case).

16.60.4 Moving Lambda Set Point

FUNCTION DESCRIPTION:

This functions shall move the lambda set point to a calibratable value, in order to do a plausibility test with the upstream and the downstream oxygen sensors separately. To avoid a jump in the lambda value and consequently any problem concernig driving confort, the shift in the lambda set point should be done through a ramp function with calibratable slope. The slope is defined as the diference between desired lambda set point and its value before the active test divided by the number of recurrences to achieve the final set point value, which is calibratable.

While the function is moving the lambda set point the flag LV_LAMB_SP_REQ_DIAG_ACT[i] is active (set in module 708A) to import this new value with high priority to the lambda coordination. To avoid any unbounded value of LAMB_SP[i], it’s monitored while the movemnt occurs. As bounds for the lambda set point, it is used the desired AFR and AFL calibration data.

Description:

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset or at clearing error memory initialize all variables as follows:

LAMB_SP_DELTA_LS_UP_DOWN[i] = 0
LAMB_SP_DIAG_OPL_LS_UP_DOWN[i] = 0

Recurrence:

This function shall be carried out every 100 ms.

Activation:

This function shall be activated when
LV_LAMB_SP_AFR_REQ_DIAG_ACT[i] = 1 **or**
LV_LAMB_SP_AFL_REQ_DIAG_ACT[i] = 1

Otherwise this function shall be deactivated and *LAMB_SP_DIAG_OPL_LS_UP_DOWN[i]* shall be set to zero.

Formula section:

Manual inhibitation of symptom evaluation for downstream sensor interchanged error					

FUNCTION DESCRIPTION:

General information:

In this Appl. Incidence the execution order of the AF lean and rich active tests are defined. Also some criteria are defined, which must inhibit each test.
i = 1 ... NC_CBK_EX_NR

Application conditions:

Initialisation: **If** LV_IGK = 0→1 **or** reset **or** clearing the error memory **then**

LV_DIAG_ACT_INH_LS_UP_DOWN[i] = 0
LV_DIAG_AFR_AFL_INH_LS_UP_DOWN[i] = 0
LV_DIAG_OPL_REQ_CBK[i] = 0
LV_INH_DIAG_CHG_LS_DOWN = 0
LV_DIAG_ACT_INH_RBM_LS_UP_DOWN[i] = 0
LV_DIAG_EOL_REQ_LS_UP_DOWN[i] = 0

***If** LV_IGK = 1→0*
LV_INH_DIAG_CHG_LS_DOWN = 1
LV_DIAG_ACT_INH_LS_UP_DOWN[i] = 1

Recurrence: 100 ms

Activation: LV_IGK = 1

Deactivation: LV_DIAG_ACT_END_LS_UP_DOWN[i] = 1 or LV_IGK = 0

Formula section:

If the following conditions are true, the active test shall wait until the interferring functions are deactivated in the failure case.

```
If      CPPWM <> 0%        canister purge valve is open

then    LV_DIAG_AFR_AFL_INH_LS_UP_DOWN[i]  =  1
else    LV_DIAG_AFR_AFL_INH_LS_UP_DOWN[i]  =  0
endif
```

If the following errors/special mode are true the whole function shall be inhibited.

If LV_ERR_MAP_DIP_SENS = 1 **OR**
- LV_ERR_MAP_DIP_PLAUS = 1 **OR**
- LV_ERR_MAP_DIP_SHIFT = 1 **OR**

```
    -  LV_ERR_IVVT = 1                                                          OR

16.61.1 Interface for Rate – Based – Monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CHK_LS_DOWN[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_CHK_LS_DOWN[i] data.

Within STATE_RBM_CHK_LS_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for active- check)

Application conditions:

Initialisation:

at LV_DC 0 → 1 transition:

bit 0 , bit 1 of STATE_RBM_CHK_LS_DOWN[i] = 0

bit 2 of STATE_RBM_CHK_LS_DOWN[i] = 1

on failure memory reset:

bit 1 of STATE_RBM_CHK_LS_DOWN[i] = 0

at ECU reset all bits of STATE_RBM_CHK_LS_DOWN[i] shall be set to zero.

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_MAP_DIP_SENS	LV_ERR_MAP_DIP_PLAUS	LV_ERR_MAP_DIP_SHIFT

16.62.1 Delay time calculation after finishing fuel trim diagnosis without failure

FUNCTION DESCRIPTION:

General information:

This function shall deliver information in the no failure case, indicating that the sensor characteristic shift down diagnosis could have finished in the failure case.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

T_DLY_DIAG_SHIFT_DOWN[i] = 0
LV_T_DLY_DIAG_SHIFT_DOWN[i] = 0

Recurrence:

The function should be carried out once every 100 ms.

Activation / Deactivation:

The function will be carried out in case of

LV_ST_END = 1

Formula section:

```
If      T_DLY_DIAG_SHIFT_DOWN[i] >= C_T_DLY_DIAG_SHIFT_DOWN[i]
then    LV_T_DLY_DIAG_SHIFT_DOWN[i] = 1
else    If      LV_END_DIAG_LAM_ADJ[i] = 1
        and     LV_ERR_LAM_ADJ[i] = 0
        then    increment T_DLY_DIAG_SHIFT_DOWN[i]
        endif
endif
```

16.62.2 Sensor Characteristic Line Shift to Lean (CSD)

FUNCTION DESCRIPTION:

General information:

This function shall deliver information indicating that the sensor characteristic line has a shift to lean **(CSD)**, which shall be done by summarizing all similar failure symptoms of this kind.

It is assumed such deviation from the nominal behavior can be occur due to the poisoning of sensor reference air channel with fuel, but also due to a leak current inside the sensor, a very low reference air pump current (used in some types of wide range oxygen sensors) or a relatively high impedance short circuit to the battery voltage or ground in one of the four sensor lines.

In dependence of the shift strengh that are three different paths followed by this function:

1. Strong shift to lean: lambda controller go to its limit and the plausibility check recognises this error.
2. Middle strong shift to lean: the trim controller goes to its limit but the lambda controller not, the trim controller deviation diagnosis recognises that the system has a problem and the active test detects that the problem is in the upstream sensor, this showing a characteristic line shift to lean.
3. Mild shift to lean: the trim controller goes to its limit but the lambda controller not. The trim controller I-share runs to its limit, whereas the trim ctr. deviation diagnosis are not able to recognise that the system has a problem. The trim ctr I-share diagnosis triggers the active test which detects that the problem is in the upstream sensor, this showing a characteristic line shift to lean.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

```
ACTION_ERRM_NoFilterReset( IN<NC_IDX_DIAG_SHIFT_AFL_LSL_UP[i]>,
OUT<LV_ERR_SHIFT_AFL_LSL_UP[i]>)
```

Recurrence:

The function should be carried out once every 100 ms.

Activation / Deactivation:

The diagnosis will be carried out

```
If  LV_ST_END = 1 and LV_ERR_SHIFT_AFL_LSL_UP[i] = 0
Then
    LV_CDN_DIAG_SHIFT_AFL_LSL_UP[i] = 1        / activation
Else
    LV_CDN_DIAG_SHIFT_AFL_LSL_UP[i] = 0        / deactivation
Endif
```

Formula section:

```
IF   LV_DIAG_AFR_CHK_SYM_LSL_UP[i] = 1
     % failure detected during active test
     OR
     LV_DIAG_PLAUS_SYM_LSL_UP[i] = 1 &
     STATE_SYM_DIAG_PLAUS_LSL_UP[i] = “SYM_1 ” &
     LV_FAC_LAM_LIM_MAX[i] = 1
     % failure detected trhrough plausibility test and lambda ctr. in limitation
THEN
     LV_ERR_SHIFT_AFL_LSL_UP[i] = 1
     ERR_SYM_SHIFT_AFL_LSL_UP[i] = “SYM_0”
     LV_END_DIAG_SHIFT_AFL_LSL_UP[i] = 1
ELSE
     % normal driving cycle, no error detected
     IF     ( LV_T_DLY_DIAG_SHIFT_DOWN[i] = 1

16.62.3 Sensor Characteristic Line Shift to Rich

FUNCTION DESCRIPTION:

General information:

This function shall deliver information indicating that the sensor characteristic line has a shift to rich, which shall be done by summarizing all similar failure symptoms of this kind.

It is assumed such deviation from the nominal behavior can be occur due to a leak current inside the sensor, as well as a relatively high impedance short circuit to the battery voltage or ground in one of the four sensor lines.

In dependence of the shift strengh there are three different paths followed by this function:

4. Strong shift to rich: lambda controller go to its limit and the plausibility check recognises this error.
5. Middle strong shift to rich: the trim controller goes to its limit but the lambda controller not: The trim controller deviation diagnosis recognises that the system has a problem and the active test detects that the problem is in the upstream sensor showing a characteristic line shift to rich.
6. Mild shift to rich: the trim controller goes to its limit but the lambda controller not. The trim controller I-share runs to its limit, whereas the trim ctr. deviation diagnosis are not able to recognise that the system has a problem. The trim ctr I-share diagnosis triggers the active test which detects that the problem is in the upstream sensor, this showing a characteristic line shift to rich.

Application conditions:

Initialisation:

At LV_IGK = 0 to 1, reset **or** at clearing error memory:

ACTION_ERRM_NoFilterReset(IN< NC_IDX_DIAG_SHIFT_AFR_LSL_UP[i]>, OUT<LV_ERR_SHIFT_AFR_LSL_UP[i]>)

Recurrence:

The function should be carried out once every 100 ms.

Activation / Deactivation:

The diagnosis will be carried out

```
 If  LV_ST_END = 1 and LV_ERR_SHIFT_AFR_LSL_UP[i] = 0
Then
    LV_CDN_DIAG_SHIFT_AFR_LSL_UP[i] = 1         / activation
Else
    LV_CDN_DIAG_SHIFT_AFR_LSL_UP[i] = 0         / deactivation
Endif
```

Formula section:

```
IF    LV_DIAG_AFL_CHK_SYM_LSL_UP[i] = 1
    % failure detected during active test
    OR

16.63.1 Upstream sensor lean/rich – shift diagnosis: Interface for rate – based – monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the SHIFT_AFL_LSL_UP[i] and SHIFT_AFR_LSL_UP[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_SHIFT_AFL_LSL_UP[i] and STATE_RBM_SHIFT_AFR_LSL_UP[i] data.

Within STATE_RBM_SHIFT_AFL/AFR[i], three different informations are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for lean/rich shift diagnosis)

Application conditions:

Initialisation: *at ECU reset:*

bit 0, bit 1 and bit 2 of STATE_RBM_SHIFT_AFL_LSL_UP[i] = 0
bit 0, bit 1 and bit 2 of STATE_RBM_SHIFT_AFR_LSL_UP[i] = 0

LV_DC = 0 --> 1 transition:

bit 0 and bit 1 of STATE_RBM_SHIFT_AFL_LSL_UP[i] = 0
bit 0 and bit 1 of STATE_RBM_SHIFT_AFR_LSL_UP[i] = 0

bit 2 of STATE_RBM_SHIFT_AFL_LSL_UP[i] = 1
bit 2 of STATE_RBM_SHIFT_AFR_LSL_UP[i] = 1

on failure memory reset:

bit 1 of STATE_RBM_SHIFT_AFL_LSL_UP[i] = 0
bit 1 of STATE_RBM_SHIFT_AFR_LSL_UP[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Deactivation: LV_DC = 0

Formula section:

At LV_DC 0 --> 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_MEC_IVVT_IN	LV_ERR_MAF	LV_ERR_CHK_LS_DOWN[NC_CBK_EX_NR]

lambda setpoint requested by oscillation check for downstream lambda sensor					

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

This is a stub module to provide signals consumed in other EGCP modules.

Application conditions:

Initialisation: The output shall be set to the following values, which are never changed:
LV_ERR_OSC_CHK[i] = 0
LV_END_DIAG_OSC_CHK[i] = 1
LAMB_SP_OSC_CHK[i] = 0

Recurrence: *not applicable*

Activation: *not applicable*

FUNCTION DESCRIPTION:

General information:

The monitor sensor diagnosis consists of three separate tests. These tests are carried out at the beginning or at the end of the pull fuel cut-off (PUC) or after switching from stoichiometric to lean combustion. In detail there are the tests monitoring of the rich-lean switching time, monitoring of the signal voltage transition during PUC or after switching to lean combustion and monitoring of the signal voltage motion after PUC, the last one being complemented by an alternative function providing the error flags LV_DIAG_RGN_NT_LS_DOWN_ERR[i] and the completition flags LV_DIAG_RGN_NT_LS_DOWN_END[i]. The purpose of these tests is the recognition of emission relevant sensor errors caused by changes in the sensor behaviour or by electrical errors like open circuits.

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
  i = 1, for exhaust cylinder bank 1
  i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
  i = 1, for single exhaust cylinder bank.

endif
```

16.65.1 Monitoring the rich-lean switching times in the trailing throttle fuel cut-off

FUNCTION DESCRIPTION:

General information:

Changes in the dynamic behaviour of the monitor sensor can be detected by the recognition of the rich-lean switching time after fuel cut-off or after changing the combustion mode from homogenous mode to stratified mode.

Description:

After detection of the PUC engine operating state, the rich-lean switching time of the lambda sensor is determined and weighted depending upon the mass air flow in the intake system. The functioning of the sensor is diagnosed by comparison of the mean value of the weighted switching time with a limit. The functioning is guaranteed in this test if the switching time is below the limit.
The switching time diagnosis shall be finished for the current driving cycle, if C_CTR_SWT_DIAG_LS_DOWN valid switching times are calculated or if the alternative function indicates its completition via LV_DIAG_RGN_NT_LS_DOWN_END[i] = 1. Whenever one of the two functions completes, its diagnostic result is used for the current driving cycle and the result of the other function is ignored.
The rich-lean switching time of the sensor is determined in defined ranges of the mass air flow. A prerequisite for performing the diagnosis is that the voltage of the monitor sensor at the time of activating the trailing throttle fuel cut-off VLS_DOWN_TRAN_PUC[i] is above the threshold C_VLS_PUC_MIN_DIAG_SWT_LS_DOWN. The voltage value of the sensor at the time of trailing throttle fuel cut-off VLS_DOWN_TRAN_PUC[i] is required for the calculation of the dynamic limits for switching point determination and must be stored for the diagnostic period.
If the sensor voltage drops below the value C_FAC_VLS_MAX_DIAG_SWT_LS_DOWN * VLS_DOWN_TRAN_PUC[i], the switching time determination starts and the cycle counter CTR_SWT_ACT_LS_DOWN[i] has to be started. The counting process is ended if the limit C_FAC_VLS_MIN_DIAG_SWT_LS_DOWN * VLS_DOWN_TRAN_PUC[i] is exceeded downwards. The value of the cycle counter CTR_SWT_ACT_LS_DOWN[i] is a measure of the rich-lean switching time of the monitor sensor.
If a rich peak which exceeds C_VLS_HYS_DIAG_SWT_LS_DOWN occurs during determination of the switching time, its determination is interrupted and the relevant switching time is no longer further processed. The determination of the sensor switching times must also be interrupted if PUC is left.
Simultaneously to incrementation of CTR_SWT_ACT_LS_DOWN[i] the counter CTR_SWT_ACT_RBM_LS_DOWN[i] shall be incremented until the corresponding ratio CTR_QUO_SWT_RBM_LS_DOWN[i] exceeds the threshold for a defective lambda probe C_CTR_SWT_LS_DOWN. After this condition has been fulfilled the valid cycle counter CTR_SWT_LS_DOWN[i] shall be incremented. This procedure ensures that within each diagnostic cycle and after completion of the required total number of diagnostic cycles a probe malfunction can be detected as is demanded by ARB.
A valid value of the switching times for the monitor sensor must be weighted depending upon the minimum value for the mass flow during the determination of the switching time of the lambda sensor MAF_KGH_MIN_PUC. The weighting factor is determined via the map IP_FAC_CYCNR_MAX_LS_DOWN_ACT.
If for the determined switching time of the monitor sensor doesn't exceed the limit the sensor is diagnosed as functioning, otherwise as malfunctioning. Depending on LC_SWT_LS_DOWN_MV the average value of the switching time determination or the

respective minimum value shall be evaluated. The minimum or maximum measured diagnosis values are saved for the scantool SAE 1979 accordingly.

Application conditions:

Initialisation:

```
If      At LV_IGK 0->1 or reset or at clearing error memory
then    reset of all variables and bits to 0, except:
        MAF_KGH_MIN_PUC = "max phys. limit"
        CTR_SAVE_SWT_LS_DOWN[i] which shall be initialized with its saved
        Value.  Reset only at clearing error memory.
        CTR_QUO_SWT_LS_DOWN_MIN[i] which shall be initialized with its maximum
        value
endif
```

Recurrence: 20 ms

Activation / Deactivation:

```
If      ((LV_DIAG_MPL_CDN_LS_DOWN[i] =1
and        LV_INH_DIAG_SWT_LS_DOWN[i] = 0)
or        LV_DIAG_RGN_NT_LS_DOWN_END[i] = 1)
and     LV_END_DIAG_SWT_LS_DOWN[i] = 0
then    LV_CDN_DIAG_SWT_LS_DOWN[i] =1
else    LV_CDN_DIAG_SWT_LS_DOWN[i] =0
        (switching time check disabled)
        VLS_DOWN_TRAN_PUC[i] = 0
        LV_SWT_DIAG_VLD_LS_DOWN[i] = 0
        CTR_SWT_ACT_LS_DOWN[i] = 0
        CTR_SWT_ACT_RBM_LS_DOWN[i] = 0
        MAF_KGH_MIN_PUC = "max phys. limit"
        LV_DIAG_SWT_LS_DOWN_S_ENA[i] = 0
endif
```

Formula section:

% Ensure that either upstream or downstream sensor indicates rich conditions for a minimum contiguous air
% mass integral. After such conditions, leaner conditions are allowed for a limited time. The upstream criterion
% is preferred, because a slow downstream sensor could make it hard to detect short rich phases, thus
% inhibiting its own detection. Fuel cut is a blocking criterion on its own, because lambda setpoint is
% not a reliable indicator in this condition.

```

16.65.2 Monitoring the sensor voltage after leaving trailing throttle fuel cut-off

FUNCTION DESCRIPTION:

General information:

With level monitoring of the monitor sensor after leaving PUC unplausible voltage values due to short circuit to ground can be detected and a plausibility check upstream / downstream sensor can be made.

Description:

If the general conditions for activating the diagnostic function are fulfilled and If MAF_INT_PUC_NOT_ACT exceeds the value C_MAF_INT_DIAG_PUE_LS_DOWN, then the diagnosis must be made.

The maximum difference between the voltage value of the monitor sensor at the time of leaving PUC, VLS_DOWN_PUE[i] and the voltage value of the monitor sensor at the time at which the mass air flow MAF_INT_PUC_NOT_ACT exceeds the value C_MAF_INT_DIAG_PUE_LS_DOWN must be formed. Additionally the corresponding maximum and minimum values VLS_DIF_MIN_DIAG_PUE_LS_DOWN[i] and VLS_DIF_MAX_DIAG_PUE_LS_DOWN[i] shall be calculated. If the maximum difference lies below the limit C_VLS_DIF_MIN_DIAG_PUE_LS_DOWN, unplausible lambda sensor voltage of the post-Cat sensor after PUC is detected (ERR_SYM_PUE_LS_DOWN[i] = "SYM_3").
LV_ERR_PUE_LS_DOWN[i] = 1 as well as LV_END_DIAG_PUE_LS_DOWN[i] = 1 shall be set, if the counter reaches C_CTR_SYM_MAX_DIAG_PUE_LS_DOWN. Then also VLS_DIF_SAVE_DIAG_LS_DOWN[i] shall be set equal to VLS_DIF_MAX_DIAG_PUE_LS_DOWN[i].
If no unplausible lambda sensor voltage of the downstream sensor after PUC is detected ERR_SYM_PUE_LS_DOWN[i] = "NO_SYM" shall be set and the counter is decremented. After calibratable number of checks C_CTR_END_DIAG_PUE_LS_DOWN the end of diagnosis flag LV_END_DIAG_PUE_LS_DOWN[i] shall be set to 1 and VLS_DIF_SAVE_DIAG_LS_DOWN[i] equal to VLS_DIF_MIN_DIAG_PUE_LS_DOWN[i].

Application conditions:

Initialisation:

If At LV_IGK 0->1 **or** reset **or** at clearing error memory

then reset of all variables and bits to 0

except

- VLS_DIF_SAVE_DIAG_LS_DOWN which shall be initialized with its saved value. Reset only at clearing error memory.
- VLS_DIF_MIN_DIAG_PUE_LS_DOWN[i] = 4,99511V
- LV_DIAG_PUE_VLD_LS_DOWN[i] = 1

endif

Recurrence: 20 ms

Activation / Deactivation:

If LV_DIAG_MPL_CDN_LS_DOWN[i] =1

```
and     LV_INH_DIAG_PUE_LS_DOWN[i] = 0
and     LV_END_DIAG_PUE_LS_DOWN[i] = 0
then    LV_CDN_DIAG_PUE_LS_DOWN[i]  =1
        (leaving PUC check enabled)
else    LV_CDN_DIAG_PUE_LS_DOWN[i]  =0
        (leaving PUC check disabled)
        LV_DIAG_PUE_VLD_LS_DOWN[i] = 1
endif
```

Formula section:

```

Maximum allowed internal resistance of the downstream sensor for downstream dynamic diagnosis					

16.66.1 Inhibition of diagnosis of the monitor sensors

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then

i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

If one of the below mentioned conditions is not fulfilled, the inhibit bit interrupts the downstream oxygen sensor diagnosis.

Application conditions:

Initialisation: at every transition LV_IGK = 0 -> 1or reset all variables shall be reset to 0, except STATE_RBM_SWT_LS_DOWN[i] *//for init of this variable see section below*

16.66.3 RBM – Interface for monitor sensor diagnosis

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the SWT_LS_DOWN[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_SWT_LS_DOWN[i] data.

Within STATE_RBM_SWT_LS_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for SWT_LS_DOWN[i] diagnosis)

Application conditions:

Initialisation :

at ECU reset all bits of STATE_RBM_SWT_LS_DOWN[i] shall be initialized with 0

at LV_DC 0 ->1 transition :

bit 0 and bit 1 of STATE_RBM_SWT_LS_DOWN[i] = 0

bit 2 of STATE_RBM_SWT_LS_DOWN[i] = 1

on failure memory reset :

bit 1 of STATE_RBM_SWT_LS_DOWN[i] = 0

Recurrence: 1 s

Activation: LV_DC 0 -> 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 -> 1 transition

The pending status of the following failures has to be checked only once :

LV_LS_DOWN_READY[NC_CBK_EX_NR]	TCO	STATE_RGN[NC_CBK_EX_NR]	NC_CBK_EX_NR

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks.
For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
    i = 1, for exhaust cylinder bank 1
    i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
    i = 1, for single exhaust cylinder bank.

With level monitoring of the monitor sensor after leaving regeneration phase of NOx trap unplausible voltage values can be detected and a plausibility check of the sensor can be made.

Description:

If the general conditions for activating the diagnostic function are fulfilled and if during a regeneration phase either the state STATE_RGN[i] is set to L_AMPL or LC_STATE_RGN_L_AMPL_DEAC = 1 (withdrawal of monitoring STATE_RGN[i] depending on regeneration strategy) the lambda probe voltage and its previous value shall be stored.

Upon leaving the regeneration phase the previously measured voltage shall be compared to the threshold which, when exceeded, allows to activate the diagnosis as indicated by LV_DIAG_ACT_RGN_NT_LS_DOWN[i] = 1. Additionally the timer T_RGN_NT_END[i] and the mass air flow integral MAF_INT_RGN_NT_END[i] are calculated until the next stratified combustion mode is activated.

Provided that the stratified mode is activated before the timer T_RGN_NT_END[i] or the MAF integral MAF_INT_RGN_NT_END[i] exceed their respective threshold values monitoring the lambda probe voltage after leaving the regeneration phase shall be started and the MAF integral MAF_INT_RGN_NT_S_ACT[i] shall be calculated. After exceeding the MAF integral threshold C_MAF_INT_RGN_NT_S_ACT, i.e. if the stratified mode has been active long enough, the voltage difference between leaving the regeneration phase and exceeding the MAF integral threshold shall be calculated as expressed by VLS_DOWN_RGN_NT_DIF[i].

Comparison of the voltage difference to a threshold value allows to recognize a sensor malfunction. Each time the voltage comparison is made the counter for end of diagnosis recognition shall be increased. Provided that the measured voltage difference does not exceed its respective threshold C_VLS_DOWN_RGN_NT_DIF_THD the symptom counter CTR_SYM_DIAG_RGN_NT_LS_DOWN[i] shall be incremented by the calibratable increment C_CTR_INC_DIAG_RGN_NT_LS_DOWN and decremented otherwise with a decrement of 1.

The final diagnosis result is drawn after the end cycle counter has reached the calibratable minimum number of necessary diagnostic cycles C_CTR_END_DIAG_RGN_NT_LS_DOWN. In this case the end indication flag shall be set and the error indication flag shall be set following an n-out-of-m statistical evaluation for the case that the symptom counter has exceeded the corresponding threshold C_CTR_SYM_MAX_RGN_NT_ LS_DOWN. The result shall not be transmitted to the ERRM directly, since another diagnosis is expected to include it in its error and end state considerations.

Error-symptoms and conditions:

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │ │ │ └─> (not used)                                          (= SYM_0)

  │ └─────> (not used)                                          (= SYM_2)
  └───────> (lean voltage not reached after NOx cat. regeneration)  (= SYM_3)
```

Application conditions:

Initialisation:

At reset or the transition of LV_IGK = 0 -> 1 or at clearing the error memory all variables shall be reset to 0, except VLS_DOWN_RGN_NT_MES_SAE[i] and VLS_DOWN_RGN_NT_ MIN_SAE[i].

Initialisation in case of new ECU and NVMY checksum errors:
VLS_DOWN_RGN_NT_MES_SAE[i] = 0V

Initialisation in case of reset:

VLS_DOWN_RGN_NT_MIN_SAE[i] = C_VLS_DOWN_RGN_NT_DIF_THD

Recurrence: 20 ms

Activation: At any engine operating state

i = 2, for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

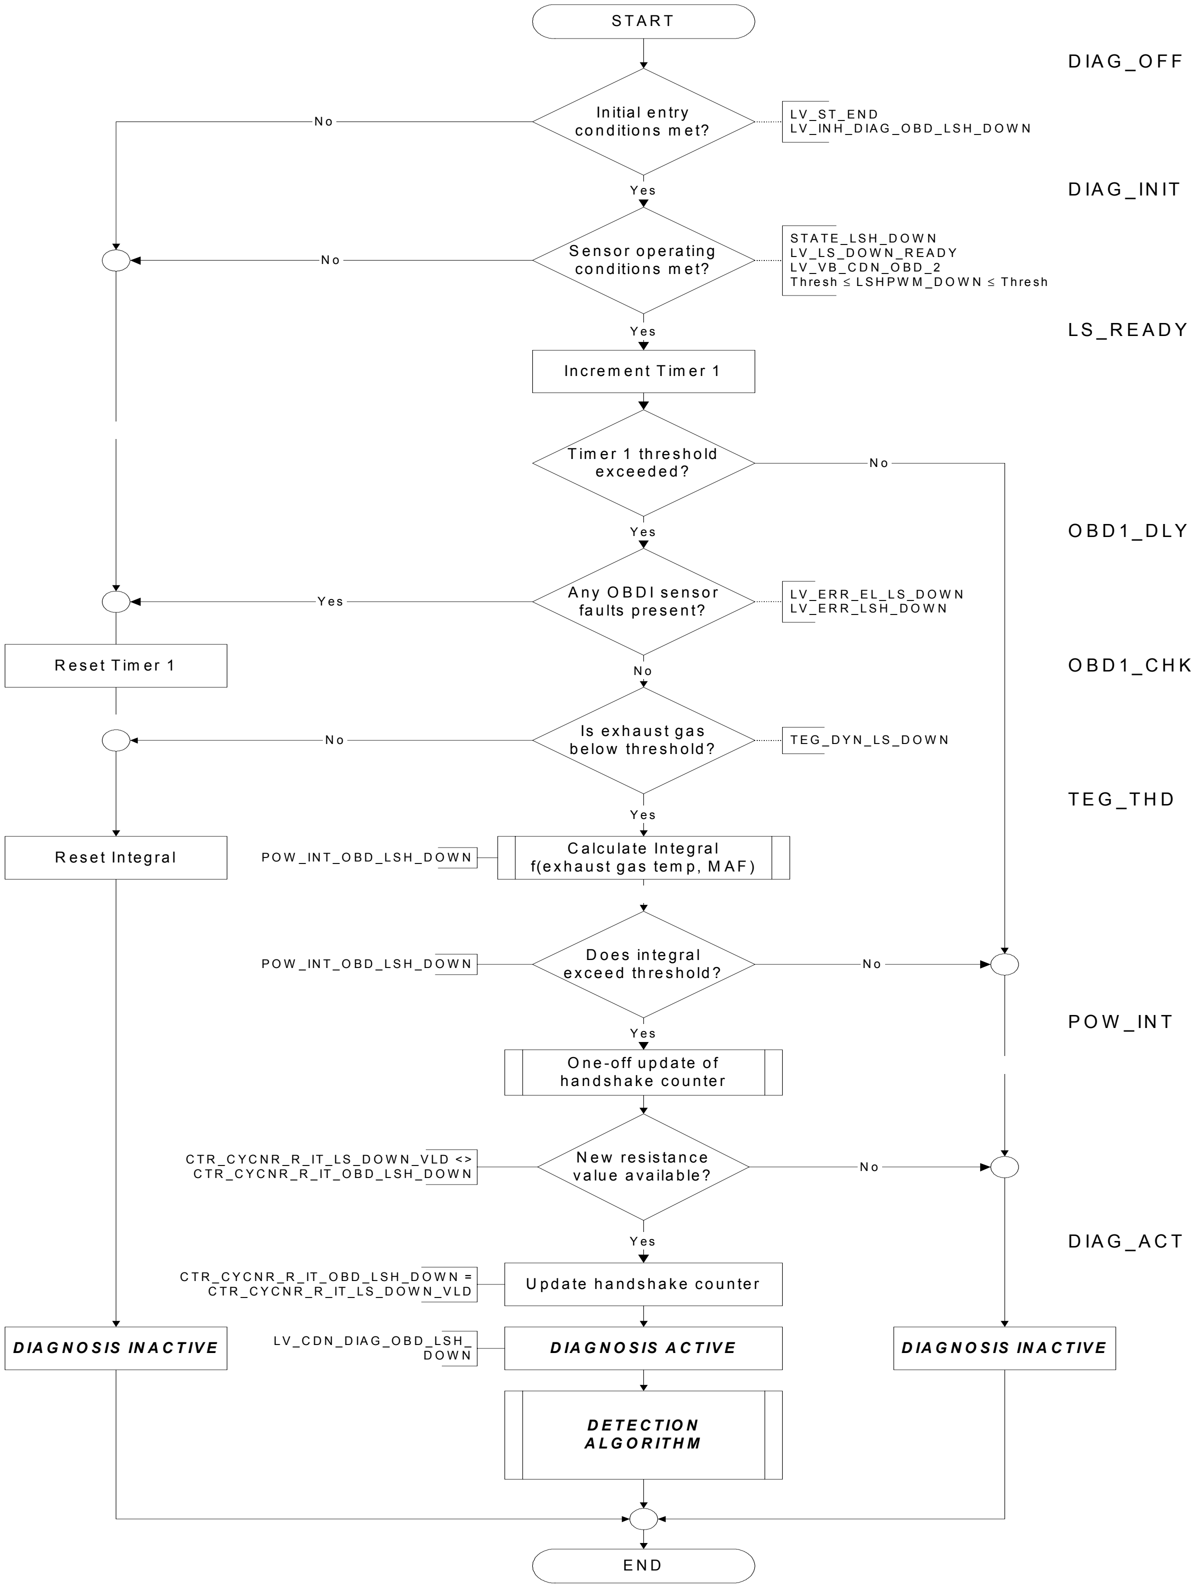
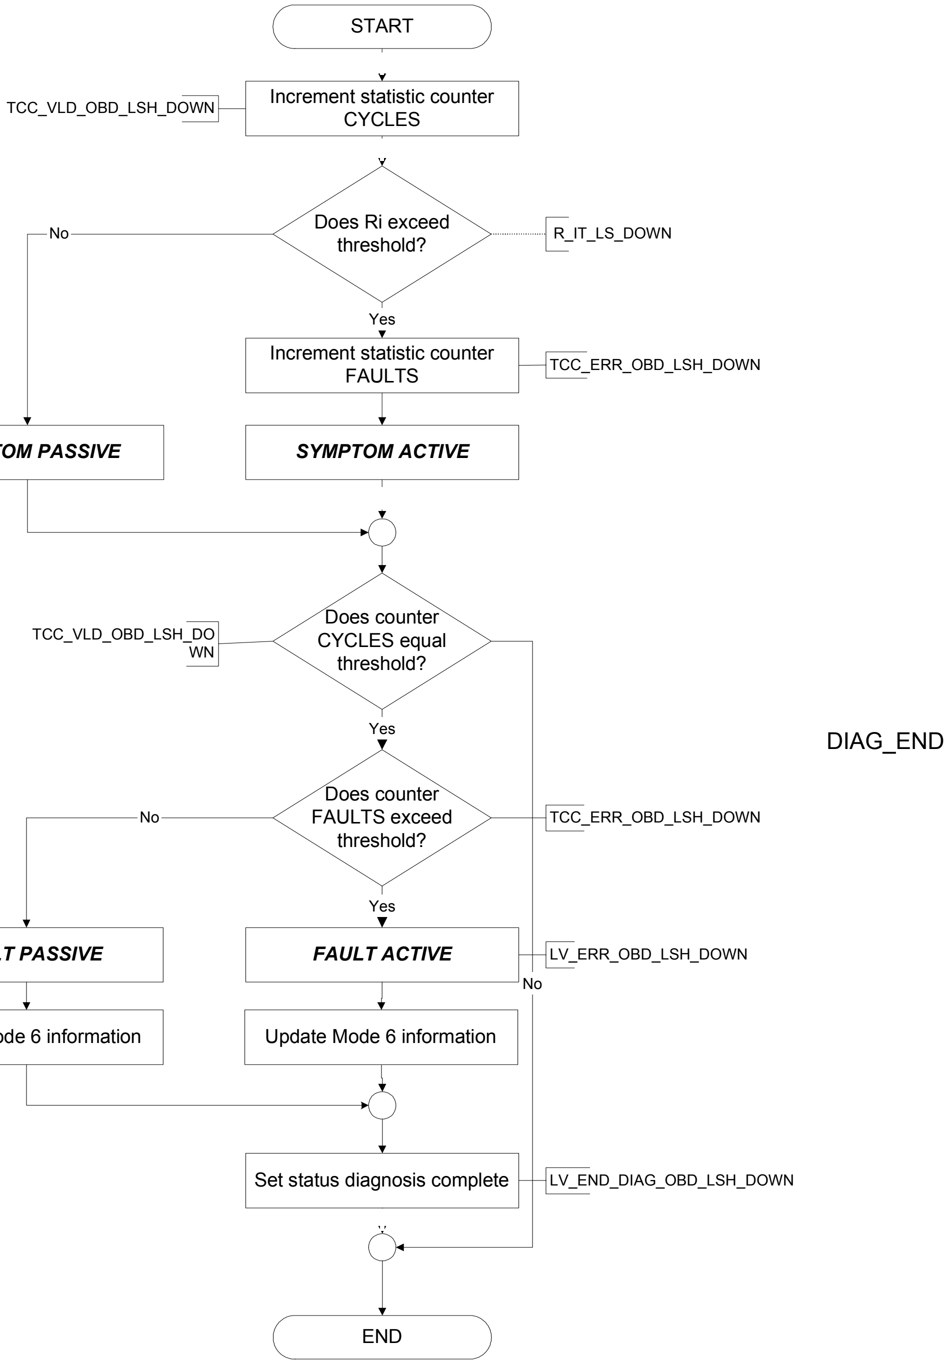
Signal flow diagram:

Activation conditions:



Detection Algorithm:



Description:

The downstream oxygen sensor heater circuit shall detect any loss in heater power that would cause a drop in the sensor operating temperature, thereby possibly causing exhaust gas emissions to rise above the applicable standards or prevent the sensor signal from being used as a diagnostic system monitoring device.

Losses in heater power may occur due to, for example, ageing of the heater element, defective wiring, increased heater cct. connector contact resistance, defective heater driver etc.

The hereafter mentioned diagnosis strategy is based on the comparison of the oxygen sensor internal resistance to an absolute threshold during operating conditions where the exhaust gas temperature has been determined to be sufficiently low as to cause the sensor ceramic temperature to fall outside normal operating levels, in cases where a power is insufficient.

The functionality of the diagnosis may be described in further detail below:

The initial diagnosis application condition; LV_ST_END shall ensure that the engine is running and has left the start phase but not yet entered the engine stop phase, LV_INH_DIAG_OBD_LSH_DOWN[i] shall ensure that the project specific application conditions (Application Incidences) have been met and LV_END_DIAG_OBD_LSH_DOWN[i] shall ensure that the diagnosis only be carried out once per driving cycle.

In order to ensure that the sensor has reached its normal operating temperature, the heater management state STATE_LSH_DOWN[i] shall be determined to be in the open loop control state LSH_POW_CTL, the sensor shall be determined to be in a state of operative readiness via LV_LS_DOWN_READY[i], the battery voltage VB shall be in a range determined to be fit for carrying out OBD2 diagnosis shown by LV_VB_CDN_OBD_2 and the heater duty-cycle LSHPWM_DOWN[i] shall be determined to be within calibrateable range C_LSHPWM_MIN_LSH_DOWN & C_LSHPWM_MAX_LSH_DOWN.

Should the above initial and operative conditions have been determined to be met, a timer, denoted herein as *TIMER_1*, shall be started. The timer shall run until the threshold T_DLY_OBD_LSH_DOWN_TMP is equalled or exceeded. Once this delay has passed, the status of the OBDI error bits LV_ERR_EL_LS_DOWN[i] & LV_ERR_LSH_DOWN[i] shall be read to ensure that no signal electrical or plausibility faults and no heater electrical faults are present in the sensor cct. under test. The delay shall ensure that sufficient time passes to permit completion of the OBDI monitoring prior to the start of OBDII monitoring.

Should no OBDI faults be present, the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] shall be compared to a calibrateable threshold C_TEG_DYN_MAX_OBD_LSH_DOWN. Due tolerances in the determination of the sensor internal resistance and in the case of a functional heater, the maximum resistance value may be given by a minimum tolerance sensor at a much lower temperature than for a maximum tolerance sensor at a higher temperature. Therefore, in the case of diagnosis based on an absolute internal resistance threshold, a certain temperature tolerance exists. The above mentioned temperature threshold shall lie below the minimum temperature determined from analysis of the internal resistance tolerances and be sufficient to cool the sensor ceramic element to below normal operating conditions, in the case of a heater fault.

Should the exhaust gas temperature be determined to equal or fall below the threshold, the monitoring strategy shall ensure that the sensor be cooled sufficiently long by the exhaust gas to enable differentiation between a functional and non-functional heater cct. (The time required is dependent on the thermal capacity of the system at the sensor location and the forced convection cooling of the sensor location). This shall be achieved by integrating the heat flux of the forced convection thermal transfer between sensor and exhaust gas, this being a measure for the cooling energy of the exhaust gas. The heat flux shall be calculated by determining the difference between the typical set sensor operating temperature C_TEMP_SP_OBD_LSH_DOWN and the modelled exhaust gas temperature TEG_DYN_LS_DOWN[i] and multiplying the result by the factor IP_FAC_MAF_OBD_LSH_DOWN representing the heat transfer coefficient and surface area concerned in the thermal transfer. As the heat transfer coefficient is a function of the velocity of the exhaust gas, the factor shall be mapped and dependent on the current mass airflow MAF_KGH.

The resultant integral POW_INT_OBD_LSH_DOWN[i] shall be compared to the threshold POW_INT_MIN_OBD_LSH_DOWN_TMP. Each time that the threshold be exceeded for the first time, e.g. first time after engine start or after the power integral has been reset, the CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated once only with the value CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. This shall ensure that only new internal resistance values be used for diagnosis purposes that have been determined since all the activation conditions have been met.

It shall be determined whether a new internal resistance has been determined by comparing the contents of counter CTR_CYCNR_R_IT_OBD_LS_DOWN[i] with that of CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. Should the counters be unequal, then a new value is available and CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated with CTR_CYCNR_R_IT_LS_DOWN_VLD[i]. If this conditions and all the above conditions be met, LV_CDN_DIAG_OBD_LSH_DOWN[i] shall be set and the diagnosis shall be considered to be active and the current monitoring cycle valid.

Once the current monitoring cycle has been determined to be valid, a counter TCC_VLD_OBD_LSH_DOWN[i] shall be incremented, denoting the number of valid monitoring cycles carried out to date. The internal resistance R_IT_LS_DOWN[i] shall be compared to a calibrateable threshold IP_R_IT_THD_OBD_LSH_DOWN according to modelled tip temperature of a new sensor (including safety margin). Should the resistance equal or exceed the threshold, a heater fault shall be determined to be present in the current cycle and a counter TCC_ERR_OBD_LSH_DOWN[i] shall be incremented, denoting the number of heater faults within the valid monitoring cycles carried out to date.

In order to comply with OBDII requirements, the current R_IT_LS_DOWN[i] value used shall be made available to an external tester. This information is Mode 6 information. Hence once the comparison to the threshold has been carried out, the latest measured internal resistance and threshold values (R_IT_L_MES_OBD_LSH_DOWN[i] and R_IT_L_REF_OBD_LSH_DOWN[i]) shall be copied to the respective Mode 6 interface variables R_IT_OBD_LS_DOWN[i] and R_IT_THD_OBD_LSH_DOWN[i] for the no error case. In the error case the variables R_IT_H_MES_OBD_LSH_DOWN[i] and R_IT_H_REF_OBD_LSH_DOWN[i] shall be handed out.

Once the number of valid monitoring cycles TCC_THD_OBD_LSH_DOWN_TMP has been determined to have been carried out, the diagnosis shall carry out a n-out-of-m statistical evaluation of the results. Should the number of determined heater faults exceed the threshold TCC_THD_ERR_OBD_LSH_DOWN_TMP, the oxygen sensor heater under test shall be considered to be faulty for the current driving cycle and flag LV_ERR_OBD_LSH_DOWN[i] shall be set.

If the number of faults does not exceed the threshold, LV_ERR_OBD_LSH_DOWN[i] shall be reset.

Once the statistical evaluation has been carried out, no further monitoring cycles shall be executed in the remaining driving cycle. This is achieved by setting LV_END_DIAG_OBD_LSH_DOWN[i].

Should, according to project philosophy, the diagnosis be activated for an end of line (EOL) test, specific threshold conditions for the diagnosis delay timer, the power integral, the required number of test and error indicating cycles may be chosen to shorten the time until recognition of diagnosis end.

NOTES:

A. The integral POW_INT_OBD_LSH_DOWN[i] shall be reset to 0 should the exhaust gas temperature exceed the applicable threshold. This would cause the sensor to be re-heated from the exhaust gas once again and a certain delay would be required prior to the sensor being cooled long enough to permit valid diagnosis to occur.

B. The timer *TIMER_1* and integral POW_INT_OBD_LSH_DOWN[i] shall be reset should any of the initial entry or operative readiness conditions no longer be met or an OBDI fault be detected in the sensor under test. This may cause the sensor to leave its normal operating conditions and the OBDII diagnosis shall be required to start from the beginning as the sensor operating conditions would require time to stabilise should the conditions be met again.

C. The statistic counters TCC_VLD_OBD_LSH_DOWN[i] and TCC_ERR_OBD_LSH_DOWN[i] shall <u>not</u> be reset by changing conditions and therefore shall only increment or remain frozen during any given monitoring cycle. The counters shall only be reset at the beginning of a new driving cycle.

D. Projects that provide for an internal statistical error management shall use their internal error management and apply this wherever reference to TCC_VLD_OBD_LSH_DOWN[i], TCC_ERR_OBD_LSH_DOWN[i], TCC_THD_OBD_LSH_DOWN_TMP & TCC_THD_ERR_OBD_LSH_DOWN_TMP is made.

E. The variable STATE_OBD_LSH_DOWN[i] shall indicate, at the end of the each monitoring cycle, the status of the diagnosis within that cycle. The following correlation of variable content to description shall apply:

0:	DIAG_OFF	Initialisation state; no conditions met
1:	DIAG_INIT	Initial conditions & application incidences met only
2:	LS_READY	Sensor operatively ready conditions met + 1,
3:	OBD1_DLY	OBDI monitoring completion delay exceeded + 1 & 2
4:	OBD1_CHK	No OBDI faults present +1, 2 & 3
5:	TEG_THD	Exhaust gas below threshold + 1, 2, 3 & 4
6:	POW_INT	Power integral exceeded + 1,2,3,4 & 5
7:	DIAG_ACT	***Diagnosis detection active***
8:	DIAG_END	***Diagnosis detection complete***

<u>Application conditions:</u>

Initialisation:

The following variables shall be initialised at reset, at the transition ignition key on (i.e. LV_IGK = 0 -> 1) and at clearing the error memory:

LV_CDN_DIAG_OBD_LSH_DOWN[i] = 0
ERR_SYM_OBD_LSH_DOWN[i] = 0
LV_ERR_OBD_LSH_DOWN[i] = 0
LV_END_DIAG_OBD_LSH_DOWN[i] = 0
STATE_OBD_LSH_DOWN[i] = 0
TEMP_DIF_OBD_LSH_DOWN[i] = 0
POW_INT_OBD_LSH_DOWN[i] = 0
TCC_VLD_OBD_LSH_DOWN[i] = 0
TCC_ERR_OBD_LSH_DOWN[i] = 0
CTR_CYCNR_R_IT_OBD_LS_DOWN[i] = 0
R_IT_L_MES_OBD_LSH_DOWN[i] = 0
R_IT_L_REF_OBD_LSH_DOWN[i] = 0
R_IT_H_MES_OBD_LSH_DOWN[i] = 0
R_IT_H_REF_OBD_LSH_DOWN[i] = 0

Reset *TIMER_1*

R_IT_OBD_LSH_DOWN[i] and R_IT_THD_OBD_LSH_DOWN[i] shall be initialised with the last value from the previous driving cycle stored in non-volatile memory after RESET.

NOTE: TIMER_1 refers to a program specific timer and is not intended to represent a variable name!

Recurrence:

The OBDII oxygen sensor heater diagnosis shall be carried out once per driving cycle. The diagnosis shall require a number of monitoring cycles to be carried out to permit statistical evaluation of the results. These monitoring cycles shall occur every 1 s, until a calibrateable number of valid diagnosis cycles has been exceeded.

Once this threshold has been completed, the OBDII oxygen sensor heater diagnosis shall no longer be carried out until a new driving cycle is initiated.

Should an OBDII heater fault be detected, the application assistances (Functions that are defined to be affected by the state of the oxygen sensor signal) shall remain active for the remainder of the driving cycle. The restarting of the affected functions during the next driving cycle shall be carried out according to the project philosophy.

then  „Diagnosis detection complete“
endif.
```

NOTES: The state variable STATE_OBD_LSH_DOWN[i] *shall only be validated at the completion of the current monitoring cycle, i.e. the state should not vary within the current 1 s monitoring cycle, but indicate at the end of the current cycle , the last state reached, dependant upon the branches.*

The variable CTR_CYCNR_R_IT_OBD_LS_DOWN[i] shall be updated with the current value of the input variable CTR_CYCNR_R_IT_LS_DOWN_VLD[i] on each occasion that the integral POW_INT_OBD_LSH_DOWN[i] exceeds the threshold for the first time. For further function calls where the integral condition is met, the one-off update shall not be carried out. This shall continue until the integral condition is no longer met.

Formula section:

Calculation of cooling energy integral:

Determine difference between typical sensor operating temperature and exhaust gas temperature:

TEMP_DIF_OBD_LSH_DOWN[i] = (C_TEMP_SP_OBD_LSH_DOWN - TEG_DYN_LS_DOWN[i])

(NOTE: Resolution of temperature difference is reduced from 0.0625 °C, resolution of the individual temperature variables, to 1 °C; The difference shall be limited to provide only positive values, i.e. ≥ 0)

The integral of heat flux (in Watts) provides a measure for the total cooling energy of the exhaust gas (in Joules):

POW_INT_OBD_LSH_DOWN[i]$_{(n)}$ = (POW_INT_OBD_LSH_DOWN[i]$_{(n-1)}$ + TEMP_DIF_OBD_LSH_DOWN[i] * IP_FAC_MAF_OBD_LSH_DOWN)

(NOTE: Integral shall be limited to its maximum hex limit, i.e. FFFFH or 65535 digits, to prevent overflow.)

Detection: (Assumes "Diagnosis detection active") **See also NOTE D above!**

FUNCTION DESCRIPTION:

General information:

LV_INH_DIAG_OBD_LSH_DOWN[NC_CBK_EX_NR] represents the influence by errors/conditions deactivating the O2 heater diagnosis. Additionally the interfaces for Rate Based Monitoring RBM are provided.

The calculation shall be done for all exhaust cylinder banks. For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
 i = 1 for exhaust cylinder bank 1
 i = 2 for exhaust cylinder bank 2
otherwise (NC_CBK_EX_NR = 1)
 i = 1 for single exhaust cylinder bank.

CTR_ERR_DYN_NR	

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the OBD_LSH_DOWN[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_OBD_LSH_DOWN[i] data.

Within STATE_RBM_OBD_LSH_DOWN[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset : bit 0, bit 1 and bit 2 of STATE_RBM_OBD_LSH_DOWN[i] = 0

at LV_DC 0 → 1 transition : bit 0 and bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0

on failure memory reset : bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

bit 2 of STATE_RBM_OBD_LSH_DOWN[i] = 1

The pending status of the following failures has to be checked only once:

LV_ERR_LSH_DOWN[NC_CBK_EX_NR]
LV_ERR_SCP_LS_DOWN[NC_CBK_EX_NR]
LV_ERR_SCG_LS_DOWN[NC_CBK_EX_NR]
LV_ERR_OC_LS_DOWN[NC_CBK_EX_NR]
LV_ERR_PUE_LS_DOWN[NC_CBK_EX_NR]
LV_ERR_CHK_LS_DOWN[NC_CBK_EX_NR]

```
If(1)     { CPU optimization at LV_DC 0 → 1 transition }
          CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
          While  bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0 do
                 ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                 SYNCHRONIZATION<CALL>)
                 with all XX failures of the above list.

                 If(2)        XX has a pending status
                 Then(2)
                              bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 1
                 Endif(2)
          Endwhile
Else(1)
          { the dynamic failure memory is empty }
          No action
Endif(1)
```

Every 1 s :

```
If        (bit 0 of STATE_RBM_OBD_LSH_DOWN[i] = 0     and
          LV_END_DIAG_OBD_LSH_DOWN[i] = 1)
Then      bit 0 of STATE_RBM_OBD_LSH_DOWN[i] = 1
Endif

If        (bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 0     and
          LV_INH_DIAG_RBM_OBD_LSH_DOWN[i] = 1)
```

```
Then    bit 1 of STATE_RBM_OBD_LSH_DOWN[i] = 1
Endif
```

MAF_CYL	LV_ACT_VLS_EOL_EXT_ADJ	OPM_REQ_CUS	C_OPM_EXT_REQ_VLS_EOL

FUNCTION DESCRIPTION:

General information:

This EOL test is to detect confused or wrong wired lambda sensors in order to prevent bad emmissions for a two cylinder bank system, therefore:

i = 1 for cylinder bank 1 and i = 2 for cylinder bank 2

Description:

This EOL-test is activated by customer-tool by setting LV_ACT_VLS_EOL_EXT_ADJ = 1. At the same time a switch to the correct engine operation mode (e.g. homogenous combustion mode) is triggered in another software module. The function goes to the state WAIT until the correct combustion mode is reached (indicated by OPM_REQ_CUS = C_OPM_EXT_REQ_VLS_EOL). Meanwhile a timer T_WAIT_VLS_EOL_OPM_SWI is incremented. If this timer exceeds the threshold C_T_WAIT_VLS_EOL_OPM_SWI, the switch to the correct engine operation mode failed. So the function goes to state TIMEOUT and the test is stopped. The test can only be restarted, when a stop command is sent from tester (LV_ACT_VLS_EOL_EXT_ADJ = 0) and the start command is sent again (LV_ACT_VLS_EOL_EXT_ADJ = 1).

When the engine is in correct operation mode, STEP-1 is started with shifting the Lambda-setpoint (bank 2 lean / bank 1 rich) for C_MAF_INT_MIN_VLS_EOL. After reaching the MAF integral there is the first freezing of VLS values. After this STEP-2 is started inverse (bank 2 rich / bank 1 lean). After reaching the MAF integral there is the second freezing of VLS values.
In STEP-3 it is checked, if the frozen values are valid. If YES the EOL result is calculated (resuming with STEP_4). If NO (the frozen values of the downstream sensors are in an undefined band between rich and lean), STEP_1 and STEP_2 are started again, to validate these values. The setting and checking of the flag LV_VLS_EOL_SHIFT_REP_INH makes sure, that this validation is done only one time and the test can not enter an endless loop of STEP_1 and STEP_2.

After this the EOL result STATE_VLS_EOL is calculated finally (STEP-4), by comparing the frozen values with calibratable thresholds.
The idea is, that at rich lambda setpoint LAMB_LS_UP and VLS_DOWN of the corresponding exhaust bank must show "rich" values. Analogous the same at lean lambda setpoint. If the frozen values are confused for bank 1 and 2 (lean value at rich setpoint and vice versa), then the corresponding sensors (upstream and/or downstream) are confused wired. If the frozen values do not cross the thresholds, the corresponding sensor signal is stucking.

The test is also used for failure analysis by the mechanics at the garage in the field.

Application conditions:

Initialisation: LAMB_SP_VLS_EOL[i] = 1 **and** remaining outputs = 0 at

initialization routine of start EOL test **or**

ECU reset **or**

Clearing error memory **or**

LV_IGK 0->1

Recurrence: 20ms

Activation:

If LV_ACT_VLS_EOL_EXT_ADJ 0 --> 1

Then Start function with WAIT

Else STATE_VLS_EOL = OFF

```
            Endif
Deactivation:     LV_ACT_VLS_EOL_EXT_ADJ = 0
      Action at deactivation: set LAMB_SP_VLS_EOL[i] = 1 and remaining outputs = 0
```

Formula section:

16.72 Acquisition of lambda sensor signal

16.72.1 O2 sensor (lin, up) SPI interface ASW – BSW

Initialisation of ATIC42 (= WRAF controller ASIC) status and configuration registers for SPI communication and control is basically handled within three modules: BSW (30202V01), ASW <-> BSW interface (403301), and corresponding Appl. Inc. (403B01). Configuration register for Ri measurement is initialised in 'O2 sensor (lin, up) element temperature determination' (402A01).

Certain calibration values depend on actual layout of generic ATIC42 HW module within target ECU and might be subject to change.

16.72.1.1 Calibration interfering functions

- Initialisation values for ATIC42 registers have to be chosen in accordance with calibration of 'O2 sensor (lin, up) operating strategy' (702Y01) regarding sensor warm-up behaviour, operation, and protection; chosen values have to comply with requirements and limits of specific sensor HW specification, ATIC42 HW module specification, and WRAF system operation guidelines.
- Cross dependencies / consistency with 'O2 sensor (lin, up) element temperature determination' (402A01), and 'O2 sensor (up) operability detection' (702O01) and have to be considered.

16.72.1.2 Calibration flowchart

There is no need to follow certain calibration sequence.

16.72.1.3 Calibration method

Supported SV ATIC42 WRAF System Configurations		
Configuration ID	**Combustion Principle**	**Sensor Type**

16.72.2.3 Calibration method

C_VLS_DOWN_MMV_HYS_MIN	Minimum hysteresis for the computation of the thresholds VLS_DOWN_TOL[i] and VLS_DOWN_BOL[i]. Compute & limit switch hysteresis. The hysteresis shall also be limited so that it may not fall below the calibrateable threshold C_VLS_DOWN_MMV_HYS_MIN (**e.g. 0,02 V**).
C_VLS_DOWN_INI_MIN	Lower initialisation value for VLS_DOWN_TOL[i]. VLS_DOWN_MMV_MIN[i] The value of VLS_DOWN_MMV_MIN[i] (moving mean of the lean signal voltage) is initialised by C_VLS_DOWN_INI_MIN (**e.g. 0,8 V**)
C_VLS_DOWN_INI_MAX	Upper initialisation value for VLS_DOWN_BOL[i]. VLS_DOWN_MMV_MAX[i] The value of VLS_DOWN_MMV_MAX[i] (moving mean of the rich signal voltage) is initialised by C_VLS_DOWN_INI_MAX (**e.g. 0,1 V**)
C_CRLC_VLS_DOWN	Filter constant for determination of VLS_DOWN_MMV_MIN[i]/ VLS_DOWN_MMV_MAX[i] values when respective threshold passed (**e.g. 0,02**).
C_CRLC_VLS_DOWN_OFF	Filter constant for determination of VLS_DOWN_MMV_MIN[i]/ VLS_DOWN_MMV_MAX[i] values when respective threshold not passed (**e.g. 0,002**)
C_FAC_VLS_DOWN_MMV_HYS	Multiplicative factor governing amplitude of hysteresis (**e.g. 0,25**)
C_T_DLY_PUC_END_VLS_DOWN	Delay between completion of engine state PUC and computation of VLS_DOWN_MMV_MIN[i]/ VLS_DOWN_MMV_MAX[i] (**e.g. 2 s**)

16.73 Lambda Sensor Operation and Parameter Calculation

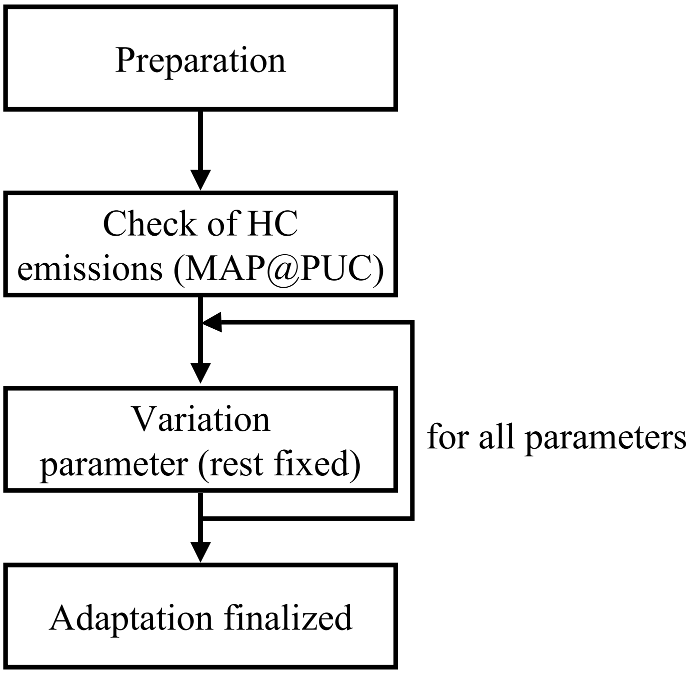
16.73.1 WRAF Sensor Gain Adaptation at Fuel Cut Off

16.73.1.1 Calibration interfering functions

- calculation of lambda value is affected in first order (part of offset adjustment - 702N)
- MAP limitation at PUC is handled at torque aggregate
- functionality's which have to be calibrated and running well in advance:
  - ❖ oxygen sensor temperature determination upstream
  - ❖ oxygen sensor heater management upstream
  - ❖ offset adjustment of oxygen sensor (linear control)
  - ❖ exhaust gas pressure calculation
- diagnosis's of oxygen sensor (heater and signal) are not mandatory to be activated (no direct impact for calibration)

16.73.1.2 Calibration flowchart

The sequence is also described by the order in calibration methods.



16.73.2 Calibration method

Preparation:

For preparation of the calibration all adaptation values have to be set to neutral values (=1), including the adaptation factor FAC_LS_GAIN_AD[i] = 1. All limiting thresholds should be set to minimum/maximum value to ensure non-impact.

general specification

The aim of gain adaptation calibration is to ensure best characteristic line of the linear oxygen sensor with focus on gain. Exerted influence on characteristic line by engine, environmental conditions and so on shall be reduced to a minimum. That increases accuracy and reliability.

C_TCO_MIN_LSL_GAIN_AD	<u>Description:</u> **Minimum coolant temperature to allow fuel cut Ip (pump current) determination** To ensure best and repeatable adaptation engine has to be at a warmed up status.
C_TAM_MAX_LSL_GAIN_AD	<u>Description:</u> **Maximum ambient temperature to allow fuel cut Ip (pump current) determination** To control impact of humidity (shift of characteristic due to absolute H_2O amount) the ambient temperature has to be limited for the adaptation
C_AMP_MIN_LSL_GAIN_AD	<u>Description:</u> **Minimum ambient pressure to allow fuel cut Ip (pump current) determination** To control impact of pressure at high altitude (shift of characteristic) the minimum ambient pressure has to be limited. Common conditions are supposed to be covered by exhaust gas pressure calculation as best as possible and correction within offset calculation. Therefore this is just a final threshold beyond which the inputs are not assumed to have suitable accuracy.
C_TTIP_MIN_LSL_GAIN_AD C_TTIP_MAX_LSL_GAIN_AD	<u>Description:</u> **Minimum/Maximum tip temperature to allow fuel cut Ip (pump current) determination** Within the defined range the heater management is assumed to run at controlled mode. Also shifts of signal characteristics are assumed to be quite low and can be handled within the correction applied at the adaptation (see IP_FAC_COR_IPLSL_TTIP_MES_LSL_UP below).
C_N_32_MIN_LSL_GAIN_AD C_N_32_MAX_LSL_GAIN_AD	<u>Description:</u> **Minimum/Maximum engine speed to allow fuel cut Ip (pump current) determination** Within the defined range the engine is running at common mode. Shifts of signal characteristics can be handled within the correction applied at the adaptation (see IP_FAC_COR_IPLSL_N_32 below).
C_N_32_BOL_LSL_GAIN_AD C_N_32_TOL_LSL_GAIN_AD	<u>Description:</u> **Additional minimum/maximum engine speed above/below which fuel cut Ip determination is allowed to take place.** Together with C_N_32_MIN_LSL_GAIN_AD and C_N_32_MAX_LSL_GAIN_AD the area within which gain adaptation is allowed can be shaped more flexible.
C_FAC_LSL_GAIN_AD_MAN_ADJ	<u>Description:</u> **Value for manual adjustment of WRAF sensor gain adaptation factor** Defined value for the adaptation factor, which can be set manually by calibration (see below).
LC_FAC_LSL_GAIN_AD_MAN_ADJ_ENA	<u>Description:</u> **Enable manual adjustment of WRAF sensor gain adaptation factor** Logical constant to set the adaptation factor to a defined value.
LC_LSL_GAIN_AD_ENA	<u>Description:</u> **Enable WRAF sensor gain adaptation** Logical constant to enable adaptation on principal. Can be used also as manual inhibition.

LC_LSL_GAIN_AD_ENA_TEST	**Description: Manual enable of LV_LSL_GAIN_AD_REQ[i] for test purposes** Logical constant to enable adaptation without respect to environmental conditions. The constant is used just for application purposes.
LC_MAP_PUC_LIM_REQ_LSL_GAIN_AD	**Description: Enable request to torque management for limitation of MAP during PUC** To ensure low HC evaporation into exhaust gas system during PUC phase MAP is increased via TQDR. This flag enables the announcement that this should be done.
LC_MAP_PUC_LIM_ACT_NOT_VLD	**Description: Flag to ignore activation of limitation of MAP during PUC by torque management** According to project philosophy adaptation can also take place even if TQDR does not limit MAP during PUC phase to ensure low HC emissions. This flag enables adaptation even without co-operation of TQDR.
LC_IPLSL_GAIN_SEL_LSL_GAIN_AD	**Description: Determines which Ip gain has to be active during execution of gain adaptation.** ' 0 ' = gain 8 ; ' 1 ' = gain 16.

Heck of HC emissions:

First of all HC emissions at fuel cut off (PUC) have to be checked. Depending on engine revolution maximum air mass flows must be determined, to limit HC emission out of engine (oil etc.) into exhaust gas system during PUC. High HC emission trouble the measurement (shift of characteristic). These maximum limits are handled by AGGR TQDR module D02V (Minimum indicated engine torque offset during PUC). For calibration please have a look there.

C_CTR_STOP_FSD_THD	**Description: Threshold for CTR_STOP_FSD to allow gain adaptation.** Caused by (unsuccessful) coldstarts in quick succession some amouts of fuel can reach into the oil. If the oil warms up the fuel may vaporise and additional HCs may be contained in the exhaust gas. This can lead to a wrong measurement of the pump current during PUC phase. The variable CTR_STOP_FSD (out of "fuel system diagnosis") is a measure for the dilution of the oil with fuel. Gain adaptation should be only allowed if CTR_STOP_FSD falls below a certain value.

Variation parameter:

In general based on a chosen base point, each of the parameters (TTIP; N_32, MAF, AMP) has to be varied on its own. The tests are proposed to run several times for each measurement point cycling between the observed PUC conditions (measurement) and PL conditions (long enough stabilisation phase). All other parameters are supposed to be fixed during variation of one parameter. Most corrections itself are quite small but may have influence if summed up. Please have a close look during calculation of the calibration parameters not to generate 1/factor instead of factor.

C_NR_GEAR_MIN_LSL_GAIN_AD	<u>Description:</u> **Minimum gear to allow fuel cut Ip (pump current) determination** Minimum gear to run the adaptation. Usually adaptations at lowest gear are not sufficient, as change of revolution during the acquisition is quite high. Valid adaptation therefore occurs quite rare.
C_CRLC_IPLSL_COR_FCUT	<u>Description:</u> **Correlation constant for filtering of corrected pumping current** The correlation constant ensures to smooth the signal in first order. Smoothing shouldn't be too much, not to extend the start of adaptation and to fulfil reasonable signal values.
C_IPLSL_NOM_PURGE	<u>Description:</u> **Nominal pumping current at fuel cut** This is the value the sensor should show at air. It is well defined by the specification of the sensor. For the calibration tests itself the actual signal value of the sensor used has to be checked (measurement at air) and calibrated here.
C_IPLSL_COR_GRD_THD_FCUT	<u>Description:</u> **Maximum gradient of low pass filtered pumping current to detect stable conditions (end of PURGE)** As one of the entry criteria for the start of an acquisition the gradient of the signal value has to be below a defined threshold. This guarantees stable, not increasing heavily signals.
C_FAC_IPLSL_COR_THD_FCUT	<u>Description:</u> **Factor for minimum threshold of the low pass filtered pumping current to detect stable conditions (end of PURGE)** As one of the entry criteria for the start of an acquisition the signal value has to reach at least a defined fraction of the nominal value. This guarantees not start adaptation to early and to dismiss low input signals, which might crawl and therefore would fulfil gradient criteria.
C_T_ACQ_IPLSL_PURGE	<u>Description:</u> **Duration of Ip (pump current) acquisition and averaging** The duration of the acquisition is being orientated towards the intended accuracy of the adaptation and the frequency and duration of PUC phases. The longer the acquisition takes place the better the factor is (less dispersion). The less and shorter PUC phases are expected the less valid adaptations will take place.
IP_FAC_COR_IPLSL_MAF_KGH	<u>Description:</u> **Factor for MAF correction** Map to realise the influence of the air mass flow. Usually this is the biggest impact on adaptation factors.
IP_FAC_COR_IPLSL_N_32	<u>Description:</u> **Factor for engine speed correction** Map to realise the influence of the engine revolution. Usually the impact on adaptation values is quite low.
IP_FAC_COR_IPLSL_TTIP_MES_LSL_UP	<u>Description:</u> **Factor for tip temperature correction** Map to realise the influence of the tip temperature. If the heater management is well calibrated the map will not have big impact as temperature stays near setpoint (nearly no deviation).
IP_FAC_COR_IPLSL_CHG_PURGE	<u>Description:</u> **Factor for residual gas after purging correction** The map is currently used to consider systematic shifts or failures. Therefore It can be calibrated after

	the primary calibration to bring adapted factors, which are stable but not near the neutral values (=1), to the neutral value.
IP_FAC_COR_IPLSL_AMP	**Description: Factor for AMP correction** Map to realise the influence of the ambient pressure. If the exhaust gas pressure model is well calibrated the map is superfluous and can be calibrated to neutral values (=1). Calibration can be done/checked far at the end at altitude trip/chamber.

Adaptation finalised:

After calibration phase of the signal values, some framework conditions have to be defined to ensure best accurate results of adaptation.

C_IPLSL_VARI_THD_MIN _PURGE C_IPLSL_VARI_THD_MAX _PURGE	**Description: Maximum variance of the low pass filtered pumping current to confirm stable conditions - Minimum variance of the low pass filtered pumping current to confirm that sensor is operable** After acquisition of the signal the quality is evaluated. One criterion is the variance. Being to high means a signal was not quite stable. Also being to low means the sensor might not be alive and just delivers constant values.
C_CRLC_IPLSL_MV_VLD	**Description: Correlation constant for filtering of valid Ip (pump current) samples (is also time constant for adaptation)** The correlation constant ensures to smooth the values (signal and variance) of all valid fuel cuts in first order. Smoothing shouldn't be too much, not to elongate taking into account a permanent step of signal at PUC (change of environmental conditions or real change of sensor behaviour). Also correlation should not be to fast to avoid consideration of just single spikes of signals.
C_IPLSL_MV_VLD_VARI _MAX	**Description: Maximum permitted variance of valid Ip (pump current) sample to allow adaptation** After acquisition of the signal the quality of calculated values is evaluated. One criterion is the variance. Being to high means the valid signals spreading too much for the last measurements, meaning they are not quite stable and therefore shouldn't be considered.
C_FAC_LSL_GAIN_AD_LIM _MIN C_FAC_LSL_GAIN_AD_LIM _MAX	**Description: Minimum/Maximum threshold for WRAF sensor gain adaptation** Within the defined range the adapted factors are taken into account. To low or to high factors are limited or even set to neutral value.
LC_FAC_LSL_GAIN_AD_LIM _RST	**Description: Switch for reset of adaptation factor to one when exceeding thresholds, or for adoption of threshold value, resp.** With this flag the factors can be reseted to neutral value (=1), if they exceed the defined range.
LC_FAC_LSL_GAIN_AD_ENA	**Description: Enable adoption of WRAF sensor gain adaptation factor** With this flag the adaptation can be finalised. The calculated and valid factor is taken into account. If not set the factor is set to neutral value (=1), meaning that the adaptation will not have any impact.

16.74 O2 sensor (lin, up) operability detection

16.74.1 Calibration interfering functions

16.74.1.1 Prerequisites

The following functions must be working before the operability detection can be calibrated:

- Engine operating functions with impact on exhaust temperature (e.g. ignition, catalyst heating)
- Upstream exhaust temperature model, including dew point detection
- Lambda sensor heater management (at least the precontrol part)
- Lambda sensor temperature determination
- WRAF sensor control and sensor signal acquisition must produce sensible lambda values around lambda=1. Pressure/temperature correction maps and gain switching are not needed yet.

16.74.2 Calibration flowchart

It is suggested to first set all data to the values given below and then verify if the function works correctly. If not, data must be changed according to the directions given for the individual labels and verification must be repeated.

16.74.3 Calibration method

16.74.3.1 Ressources

Most of the calibration may be done on the road side and/or on an engine dyno. Some data must be measured in the cold (cold trip or climate chamber), a weak heater limit sensor is required for this and it must be possible to set the battery voltage to the lowest acceptable value. A slow dynamic limit sensor may be useful to calibrate parts of the raw readiness detection.

16.74.3.2 Constraints

Legal requirements concerning closed loop lambda control may limit the applicable values for some of the labels:

- The sensor may be required to be ready after a certain time. The maximum possible delay from engine start to sensor activation is either the sum of C_T_DLY_LS_UP_READY_TEG_MIN and the time until the exhaust model temperature reaches the dew point or ID_T_TOUT_LS_UP_READY, whichever is larger.
- C_MAF_INT_PUC_MAX_LS_UP_READY and LC_TEG_MIN_DEAC provide ways to revoke sensor readiness in the middle of a driving cycle. If sensor readiness must be kept once it was established, these ways must be blocked by calibration either here or in the exhaust temperature model.

16.74.4 Calibrateable data

16.74.4.1 Readiness detection

There are two alternative paths to detect raw readiness: A lambda band which must be left by the sensor signal and a deviation integral which must exceed a certain threshold. Once the raw readiness was detected, full operative readiness is established when the measured tip temperature exceeds a limit. The function can be calibrated such that raw readiness is set unconditionally after a delay (see below) has elapsed.

ID_T_DLY_CHK_LS_UP_READY	**This delay timer runs while the sensor heater is not in state LSH_POW_RED, raw readiness detection is blocked until it has elapsed.** **Use 10s as a start.** **Must be greater than the initial LSH_POW_RISE**

	phase to avoid starting readiness detection before the dew point was passed.
C_LAMB_THD_MIN_LS_UP_READY **C_LAMB_THD_MAX_LS_UP_READY**	**The labels describe a band which must be left by the sensor signal for raw readiness to be detected.** **Set minimum to 0.98 and maximum to 1.02 for a start. Make the band narrower if it is not left by the signal of a good sensor, make it wider if the signal of a sensor with open Vip line leaves it.** **Set minimum to 2 and maximum to 0 to set raw readiness after the delay with no regard to sensor signal.**
C_CRLC_LAMB_LS_UP_READY **C_T_LAMB_DE_INT_RST** **C_LAMB_DE_INT_THD_LS_UP_READY**	**C_CRLC_LAMB_LS_UP_READY is a correlation constant for calculation of a moving mean value of the sensor signal. The deviations between signal and mean value are integrated for the duration of the timer C_T_LAMB_DE_INT_RST. If the integral exceeds C_LAMB_DE_INT_THD_LS_UP_READY, raw readiness is detected.** **Apply 0.05 for the CRLC, 5s for the timer and 0.002 for the threshold as a starting point.** **The integral must reliably exceed the threshold even for a slow sensor. With Open circuit in Vip, the integral must stay below the threshold. Lowering the CRLC constant and the threshold and rising the timeout will make raw readiness detection via this path easier, and vice versa. Do not set the timer higher than the timeout**
C_TTIP_MIN_LS_UP_READY	**If the tip temperature exceeds this limit, full sensor readiness is assumed. Must be coordinated with the activation limits for Ip control in the WRAF sensor control.**

16.74.4.2 Readiness timeout monitoring

These timers run rather independently. If readiness was not detected when both of them timed out, forced readiness is set and fault detection is triggered. The weak heater limit sensor is needed and the battery voltage should be lowered to the acceptable limit. Measurements should take place in the cold.

C_T_DLY_LS_UP_READY_TEG_MIN	**This time must pass after dew point detection before the sensor readiness is checked. 120s is a safe starting point.**

ID_T_TOUT_LS_UP_READY	**This timeout runs after engine start, 200s may be used as a starting point.** **Final values should be much lower, sensors usually take 10 to 20s to get ready once full heater power is supplied. Worst case must be measured with above mentioned conditions and limit parts, and some safety should be added. Only one of the timers needs to be calibrated, the other one may be left at 0.**

16.74.4.3 Readiness revocation

These data control readiness revocation in conditions where the exhaust gas is too cold. If readiness is revoked, readiness detection and timeout monitor will restart once the condition is relieved. The weak heater limit sensor is needed and the battery voltage should be lowered to the acceptable limit. Measurements should take place in the cold.

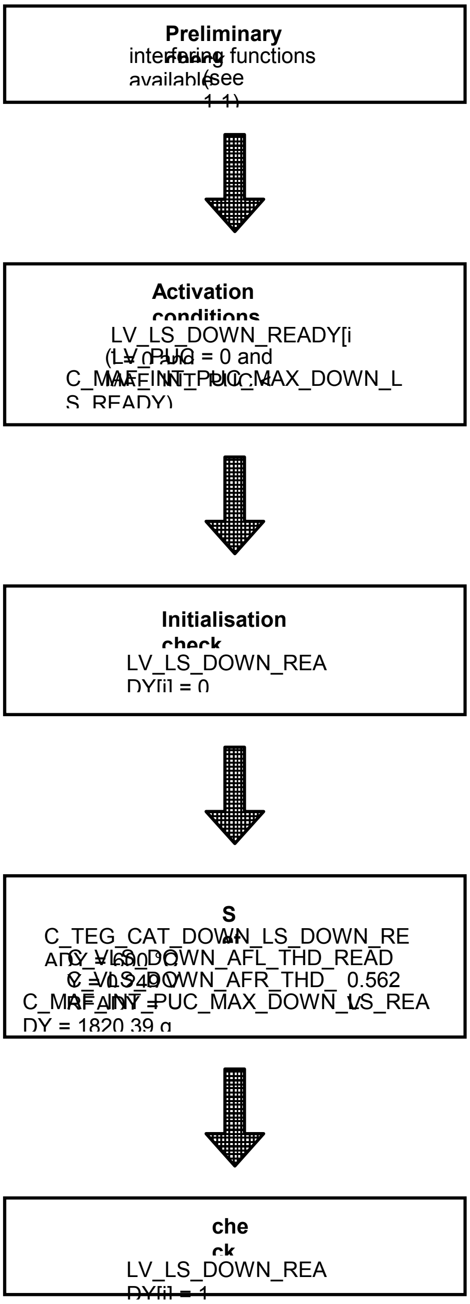
LC_TEG_MIN_THD_DEAC_TEST	**This is for test purposes only and must be set to 0**
LC_TEG_MIN_DEAC	**If set to 0, the readiness flag is revoked when the exhaust model temperature drops back below the dew point.**
C_MAF_INT_PUC_MAX_LS_UP_READY	**Minimum air mass which is sufficient to cool the sensor below minimum operating temperature during fuel cut off. Set to the maximum of 2912.67g, then check if the sensor becomes too cold during PUC and lower the value as required. Subtract a fair safety margin for cases like consecutive fuel cut off phases interrupted only by short part load phases (e.g. long descents in the mountains).** **Values far above 100g should be expected.** **Keep at maximum to disable the feature.**

16.75 Downstream oxygen sensor readiness detection

16.75.1 Calibration interfering functions

- Downstream oxygen sensor heater control
- Exhaust gas temperature model
- Lambda sensor voltage
- Catalyst purge

16.75.2 Calibration flowchart



16.75.3 Calibration method

_DOWN_READY	Temperature threshold above which O2 sensor recognised as operatively ready (**e.g. 600 °C**).
C_VLS_DOWN_AFL_THD_READY	Lean VLS_DOWN[i] threshold for operative readiness detection (**e.g. 0,249 V**)
C_VLS_DOWN_AFR_THD_READY	Rich VLS_DOWN[i] threshold for operative readiness detection (**e.g. 0,562 V**)
C_MAF_INT_PUC_MAX_DOWN_LS_READY	Maximum MAF integral during PUC for operability reset (**e.g. 1820,39 g** at the beginning).

16.76 Air-Fuel cycle evaluation

16.76.1 Calibration interfering functions

- Readiness detection of upstream oxygen sensor (LV_LS_UP_READY[NC_CBK_EX_NR])
- Lambda control (LV_LAM_LSCL[NC_CBK_EX_NR])
- Lambda sensor voltage (VLS_UP[NC_CBK_EX_NR])

16.76.2 Calibration flowchart

Preliminary check
interfering functions available (see 1.1)

Activation conditions
LV_ST_END = 1 and LV_ES = 0

Initialisation check
LV_AFL[i] = 0
T_AFL_CYC[i] = 0
T_AFL_CYC_HLD[i] = 0
T_AFR_CYC[i] = 0
T_AFL_LOCK[i] = 2.55 s (i.e. FFH)
CTR_AFL_CYC[i] = 0

Set
C_VLS_AFR_THD = 0,498 V
C_VLS_AFL_THD = 0,352 V
IP_T_AFL_LOCK = 0 all over

check for LV_LAM_LSCL[i] = 1

when VLS_UP[i] exceeds the threshold C_VLS_AFR_THD then the flag LV_AFL[i] shall be set to zero indicating that the air fuel mixture is rich. As long as LV_AFL[i] = 0 the timer T_AFR_CYC[i] has to be incremented. As soon as LV_AFL[i] changes from 1 to zero the timer T_AFR_CYC[i] shall be reset.

when VLS_UP[i] falls short of the threshold C_VLS_AFL_THD then the flag LV_AFL[i] shall be set to 1 indicating that the air fuel mixture is lean As long as LV_AFL[i] = 1 the timer T_AFL_CYC[i] has to be incremented. As soon as LV_AFL[i] changes from zero to 1 the timer T_AFL_CYC[i] shall be reset.

The Air-Fuel cycle counter CTR_AFL_CYC[i] shall be incremented for every lean to rich AF mixture transition (LV_AFL[i] 1 -> o), to indicate that a complete AF cyclehas passed.

Calibrate
IP_T_AFL_LOCK

16.76.3 Calibration method

The function shall detect a change in AF mixture from lean to rich or vice versa ignoring possible jitter in the oxygen sensor signal. This shall be facilitated by the following method: If the timer T_AFL_LOCK[i] falls below the threshold IP_T_AFL_LOCK, the timer shall be incremented and no further action shall take place in the current recurrence. Should, during following recurrence cycles, the timer equal or exceed the threshold and if the AF mixture flag is currently indicating lean, the function shall observe the VLS_UP[i] signal for a change to rich as indicated by VLS_UP[i] exceeding the threshold C_VLS_AFR_THD. Once this has occurred, the LV_AFL[i] flag shall be changed to indicate a rich mixture (LV_AFL[i] = 0), a counter CTR_AFL_CYC[i] shall be incremented to indicate the number of complete AF cycles since the last activation of the lambda controller, the output data T_AFL_CYC_HLD[i] shall be updated with T_AFL_CYC[i], the timer T_AFL_LOCK[i] shall be reset and a SW internal flag set to indicate the AF mixture transition. The same procedure, except incrementation of counter CTR_AFL_CYC[i], applies for a currently rich mixture. A transition to a lean mixture shall be detected by VLS_UP[i] falling below threshold C_VLS_AFL_THD.

C_VLS_AFR_THD	Threshold for detection of rich mixture (**e.g. 0,498 V**).
C_VLS_AFL_THD	Threshold for detection of lean mixture (**e.g. 0,352 V**).
IP_T_AFL_LOCK	LV_AFL[i] transition lock-out time after transition of AF mixture. The timer T_AFL_LOCK[i] and associated engine operating point dependent threshold IP_T_AFL_LOCK reduce the effect of rapid oxygen sensor signal changes, noise generated by cylinder to cylinder AF mixture deviations, that would cause the lambda controller to execute a P-jump. The mapped lock-out time represents the delay between injection of the AF mixture and the burnt AF mixture reaching and being detected by the oxygen sensor. The lock-out time shall not exceed the exhaust gas delay for any particular engine operating point otherwise the lambda controller frequency will be affected. Oxygen sensor signal changes occurring within this delay time may not be considered to be due to the change in controlled lambda but from noise and shall be ignored. (**e.g. see below**)

***Example for** IP_T_AFL_LOCK [s]*

16.77 Lambda Sensor Diagnosis OBDI

16.77.1 WRAF Sensor electrical diagnosis

16.77.1.1 Calibration interfering functions

16.77.1.2 Before start of the calibration of the electrical diagnosis, the following other functions must be calibrated:

Electrical diagnosis by ATIC 42 controller

- Signal Acquisition of linear lambda sensor (controller)

Pump Current Limitation

- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor

Open Circuit Diagnosis

- Basic Engine Tuning (Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control
- WRAF Sensor Plausibility Diagnosis during PUC
- WRAF Sensor Plausibility Diagnosis
- WRAF Sensor Activity Check
- WRAF Sensor Heater OBDII Diagnosis

16.77.1.3 Before calibration of the electrical diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.77.1.4 Calibration flowchart

The sequence is described by the order of constants and maps in the chapter “Calibration method” below.

16.77.1.5 Calibration method

Electrical Diagnosis by ATIC42 controller

C_T_DLY_DIAG_EL_LSL_UP	Time delay to start the electrical failure diagnosis; Check if there is any increment of the anti bounce counter in case of no delaytime. If nothing can be observed, choose 0 for this delaytime.

Pump Current Limitation

The purpose was to disable the IP loop for very rich or very lean A/F ratio to prevent a wrong A/F control in case of not reliable IP current. Due to the fact, that there is no MIL illuminated, its not possible to furthermore use this diagnosis. In fact it will not have any effect as the WRAF Sensor control no longer reacts to the symptom of this diagnosis. It will be changed or removed for some later revisions of this module. If there is really a problem on the pump current in an emission relevant operation area of the engine, it will lead to another failure entry (i.e. trim control setpoint deviation exceeded).

C_CTR_IPLSL_SYM_DIAG_LSL_UP	Max. error debounce counter; To prevent a wrong A/F ratio for a longer time due to unreliable IP current, the lambda control should be disabled within a few seconds. The function is processed all 100 ms. I.e. 30.
C_LAMB_SP_AFR_IPLSL_DIAG_LSL_UP	Max. rich lambda set point to activate the IP diagnosis; It must be significantly more rich than the richest AF ratio during emission test to not interfere into the emission test result. I.e. 0,8.
C_LAMB_SP_AFL_IPLSL_DIAG_LSL_UP	Min. lean lambda set point to activate the IP diagnosis; It must be significantly more lean than the leanest AF ratio during emission test to not interfere into the emission test result. I.e. 1,2.
LC_IPLSL_SYM_DIAG_LSL_UP	Logical variable to force IPLSL symptom flag (only for test purpose); Must be 0.

Open Circuit Diagnosis

Depending on the diagnosis functions which provide the INPUT for the Open Circuit diagnosis, it can be attempted to detect the Open Circuit in Idle Speed.
It´s important to check the timing during emission test.
The relevant failure cases are:
For each Pin (Vn, Vg, Vip, Vrc) test the failure entry in case that the open circuit happened

1. before the beginning of the driving cycle (damage of the wire during the night by an animal).
2. after operative readiness of the WRAF Sensor

Test case 1 and 2 in

- Idle Speed,
- Part Load,
- Dynamic Driving

and check out where the problems are to detect the open circuit.

In case of some WRAF Sensors, its not possible to distinguish open circuit on Vg and Vip, as the tip temperature measurement continues to work almost normal even with open circuit on Vg. That results in a failure entry "Open Circuit on Vip" even if in reality the line to

Vg is open. In this case, the waiting timer C_T_WAIT_SYM_OBD_2_LSH_UP can be calibrated to 1 sec.

C_VLS_UP_DIAG_MIN_OC_LSL_UP	LSL undervoltage threshold; Smaller than the smallest VLS_UP_DIAG for normal (rich) operation and bigger than 0 to cover some noise on the wire. I.e. 0,1 V.
C_T_VLS_UP_MIN_DIAG_OC_LSL_UP	Max allowed time for LSL undervoltage; As the reaction of VLS_UP in case of a real open circuit on Vn is very fast, this time can be short. I.e. 5 sec.
LC_DIAG_PUC_END_MAN_LSL_UP	Boolean switch to bypass activation of LV_DIAG_PUC_END_LSL_UP[i]; If there is no fuel cut off during the emission test cycle, a possible open circuit on Vrc would not be detected. The best way is to force fuel cut off as long as it is required to check the open circuit on Vrc. Otherwise, the authority must be informed that its not possible during emission test to perform the open circuit diagnosis on Vrc. To anyway set the end flag of the open circuit diagnosis even without fuel cut off, the flag could be set to 1.
C_T_WAIT_SYM_OBD_2_LSH_UP	Waiting time to check if OBD2 upstream heater error is present (to distinguish OC on Vip from Vg); Some seconds longer than C_TCC_THD_OBD_LSH_UP to be sure that a possible lambda sensor heater error could have been detected. E.g. 65 sec. In case of a WRAF Sensor which does not show a tip temperature error in case of open circuit on Vg, calibrate this time to 1 sec. (not 0 as there will occure another unwanted effect).
C_T_DIAG_OC_RST_OSC_DI	Time to reactivate oscillator for upstream tip temperature measurement; Must be longer than C_T_VLS_UP_MIN_DIAG_OC_LSL_UP.
C_T_DIAG_OC_LSL_UP	Timer to finish OC diagnosis in case of OBD2 upstream heater error symptom active and conditions for plausibility diagnosis fulfilled; It must be slightly longer than the time to debounce the “Sensor not active” check and the plausibility diagnosis: **(**IP_T_SYM_AFS_PLAUS + (1/10 * C_CTR_THD_DIAG_PLAUS_LSL_UP/ C_CTR_INC_DIAG_PLAUS_LSL_UP) + (C_CTR_SUM_RAW_ACT/(smallest value of ID_CTR_INC_RAW_ACT_LSL_UP * (1 sec / 20 ms))) + longest possible T_SUM_AFL_AFR_CYC[i] * (C_CTR_LAMB_DE_INT_ACT_LSL_UP + 1) * ((C_CTR_SYM_MAX_ACT_LSL_UP / C_CTR_SYM_INT_ACT_LSL_UP) + 1) **)**
C_T_DIAG_OC_LSL_UP_LSH_ERR	Timer to finish OC diagnosis in case of OBD2 upstream heater error symptom active and LAMB plausible; This is the time to ensure that LV_DIAG_RAW_ACT_SYM_LSL_UP could have been set to 1 in case of Open Circuit on Vg. It must be slighlty longer, i.e. 2 sec. more than (C_CTR_SUM_RAW_ACT/(smallest value of ID_CTR_INC_RAW_ACT_LSL_UP * (1 sec / 20 ms)).

16.77.2 WRAF Sensor controller diagnosis

16.77.2.1 Calibration interfering functions

16.77.2.1.1 Before start of the calibration of the WRAF Sensor controller diagnosis, following other functions must be calibrated:

- Signal Acquisition of linear lambda sensor (controller)

16.77.2.1.2 Before calibration of the electrical diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.77.2.2 Calibration flowchart

The sequence is described by the order of constants and maps in the chapter "Calibration method" below.

16.77.2.3 Calibration method

C_CTR_MAX_SPI_COM_LSL_UP[NC_CBK_EX_NR]	Max. allowed number of SPI communication errors; I.e. 5.
C_T_RST_MAX_DIAG_LSL_UP_IF[NC_CBK_EX_NR]	Max. waiting time for the initialization of the WRAF sensor controller; I.e. 130 sec.
C_T_END_DIAG_LSL_UP_IF[NC_CBK_EX_NR]	Time to diagnostic availability; I.e. same duration than C_T_RST_MAX_DIAG_LSL_UP_IF.

16.78 Lambda sensor downstream probe diagnosis (plausibility)

16.78.1 Calibration interfering functions

16.78.1.1 Before start of the calibration of the downstream lambda sensor plausibility diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (i.e. Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Basic Lambda Setpoint
- Full load correction
- Downstream lambda sensor heater calibration
-

16.78.1.2 Before calibration of the downstream lambda sensor plausibility diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.78.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.78.3 Calibration method

Plausibility Diagnosis during Fuel Cut Off

The calibration can be done on the road.
The calibration must be checked in emission test.
If no fuel cut off is allowed during emission test, the setting of the general end flag LV_LS_DOWN_DIAG_END must be adapted accordingly via C_NR_END_DIAG_LS_DOWN.

C_VLS_MIN_DIAG_PUC_LS_DOWN	VLS voltage threshold for PUC fault detection; This threshold must be smaller than the value for a sensor with open circuit minus tolerances (i.e. 0,37 V). And it must be bigger than the standard fuel cut off voltage plus tolerances. Besides the tolerances from ECU, the bigger part of the tolerances arise due to a weak heater, a cool sensor due to operation conditions or an engine which releases plenty of oil during fuel cut off. Take i.e. the voltage value from sensor specification for lambda = 1,10 or leaner. Take the Oxygen Sensor with limit low heater power and observe the sensor voltage during fuel cut off in all possible environment, especially very cold conditions (i.e. cold ambient temperature, fuel cut off right after operative readiness of the sensor). I.e. 100 mV.

C_MAF_INT_MAX_DIAG_PUC_LS_DOWN	Maximum threshold for MAF integral to end downstream PUC signal plausibility; Check the downstream lambda sensor voltage for long fuel cut off phases. Use the Oxygen Sensor with limit low heater power and a lifetime catalyst (i.e. 150 thousand miles aged for SULEV). Take a maximum maf integral which would lead to a significant voltage increase (i.e. 1/10 of the failure threshold) due to the cooling of the sensor. If no voltage change can be observed, the value can be as large than the MAF Integral for reset of the operative readiness of downstream Oxygen Sensor. Countercheck this calibration in very cold conditions.
C_MAF_INT_MIN_DIAG_PUC_LS_DOWN	Minimum threshold for MAF integral required to start downstream PUC signal plausibility; Air mass integral to purge the catalyst after start of fuel cut off. A catalyst with maximum O2 load is required (be careful with greening effect – better take a catalyst which was used for some hours). Measure the duration between start of fuel cut off and downstream signal voltage below C_VLS_MIN_DIAG_PUC_LS_DOWN. Multiply the measured time with a safety factor. This safety factor must cover a slow (aged) sensor which can still be used for trimming of A/F ratio and for catalyst diagnosis. Therefore its best to use a sensor which is already aged (i.e. artificially "aged" with small wholes in the protection tube), but still suitable for above mentioned functionality and to measure the delay with this sensor. To have no risk of wrong failure detection, anyway a safety factor should be considered. As there is the switching time diagnosis for the downstream oxygen sensor, the safety factor can be choosen large (i.e. above 100%). Check if the required duration of fuel cut off for a failure detection is shorter than the available fuel cut off time during emission test.
C_MAF_INT_PUC_NOT_LS_DOWN_DIAG	Minimum threshold for MAF integral out of PUC required to start downstream PUC signal plausibility; Useful for projects with a weak downstream O2 sensor heating. This MAF integral serves to prevent a wrong failure entry due to accumulated cooling energy in case of only briefly interrupted long fuel cut off phases. It goes in combination with a minimum MAF_KGH threshold, see C_MAF_KGH_MIN_LS_DOWN_DIAG. The MAF integral can be calibrated by cooling down the sensor during a long fuel cut off phase with high engine speed (worst case cooling). Another condition for the worst case is, that the whole exhaust line is still cool (start the measurements right after operative readiness - never going to high loads). Then go to part load and measure the time and the MAF integral until the sensor is warm enough (i.e. to show a lean signal). Make several measurements subsequently: long PUC until the sensor voltage increases in PUC (too cold), then PL for x sec. – increase the duration x for every measurement until the time in part load was long enough that the sensor is warmed up after it was cooled down.

	If the sensor does never cool down during long PUC phases, then calibrate this value to 0.
C_FAC_MAF_INT_LS_DOWN_DIAG	With this factor, it can be adjusted how big the impact of fuel cut off is to the lambda sensor temperature. If the sensor cools down very fast, the factor should be big. If the sensor almost never comes to a condition where it would be too cold, the factor should be small. If the factor is big, a short fuel cut off phase already requires a relatively long engine operation with positive torque generation afterwards to resume the diagnosis.
C_MAF_KGH_MIN_LS_DOWN_DIAG	The heat flow to the sensor is only considered, if the load is above this threshold.

<u>Full load (FL) oxygen sensor signal plausibility</u>

The calibration can be done on the road.
The diagnosis will in most vehicles not be active during the emission test as no full load occurs. In this case, the setting of the general end flag LV_LS_DOWN_DIAG_END must be independent from this diagnosis (calibration via C_NR_END_DIAG_LS_DOWN).

The sensor manufacturer gives just a guarantee for a rich voltage level which corresponds to a maximum aged lambda sensor.
In real life, the lambda sensors show this maximum guaranteed voltage already during standard operation at stoichiometric Air Fuel Ratio.

C_VLS_MAX_DIAG_FL_LS_DOWN	VLS voltage threshold for FL fault detection; There are two mainstreams which can be taken for calibration of this constant: 1. If the vehicle is rich mixture sensitive and the vehicle manufacturer agrees to change a sensor which shows still a voltage far over the specified minimum value in the sensor specification, then: Take a value which is significantly higher than the downstream fuel trim requires to decrement the fuel trim correction value. 2. If the vehicle manufacturer doesn´t agree to change a sensor which is still within the sensor specification, then: Take the guaranteed minimum rich voltage from sensor specification. In this case it must be checked if the sensor amplitude of such a sensor is enough for catalyst diagnosis malfunction detection. And it must be checked if for the vehicle lifetime the emission level can be kept. The vehicle manufacturer must agree.
C_MAF_INT_MAX_DIAG_FL_LS_DOWN	Maximum threshold for MAF integral to end downstream FL signal plausibility; The sensor signal is temperature dependent. In case of extended duration of full load it is possible that the sensor gets too hot and the sensor signal decreases. Take the oxygen sensor with maximum heater power. Stay in maximum full load and observe the voltage. If the voltage decreases although the lambda remains the same, then choose the mass air flow integral at this time to stop the diagnosis. E.g. 110 g.

C_MAF_INT_MIN_DIAG_FL_LS_DOWN	Minimum threshold for MAF integral required to start downstream FL signal plausibility; Air mass integral to purge the catalyst after start of full load. A catalyst with maximum O2 load is required. Measure the duration between start of Full Load (lowest full load possible) and downstream signal voltage above C_VLS_MAX_DIAG_FL_LS_DOWN. Multiply the measured time with a safety factor. This safety factor must cover a slow (aged) sensor which can still be used for trimming of A/F ratio and for catalyst diagnosis. Therefore its best to use a sensor which is already aged (i.e. artificially "aged" with small wholes in the protection tube), but still suitable for above mentioned functionality and to measure the delay with this sensor. To have no risk of wrong failure detection, anyway a safety factor should be considered. As there is the switching time diagnosis for the downstream oxygen sensor, the safety factor can be choosen large (i.e. above 200 %). Take care that the required duration of full load is reasonable during all day life operation. E.g. 20 g

16.79 Lambda Sensor Diagnosis OBDII

16.79.1 Active plausibility diagnosis

16.79.2 Calibration interfering functions

16.79.2.1 Before start of the calibration of active plausibility diagnosis, the following other functions must be calibrated:

- Basic Engine Tuning (i.e. Ignition, **Basic Injection**, Torque Model, Variable Valve Timing)
- **Intake Manifold Model (MAP System)**
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Basic Lambda Setpoint

16.79.2.2 Before calibration of the active plausibility diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.79.3 Calibration flowchart

The sequence is described by the order of constants and maps in the chapter “Calibration method” below.

16.79.4 Calibration method

Moving Lambda Setpoint

C_LAMB_SP_STEP_DIAG_LS_UP_DOWN	Number of recurrences to achieve the desired lambda set point; In case that the engine is robust against lambda changes, this value can be choosen quite small for a shorter duration of the whole test. I.e. 5. If time is not the matter, a lambda shift by 15 % within 1 second is reasonable -> then choose 10.
C_LAMB_SP_AFR_DIAG_LS_UP_DOWN	Lambda set point for rich fault detection; Two limits must be considered: 1. proper engine running must be ensured 2. enough margin for not perfectly balanced precontrol must be included Recommendation: at least 15 % rich if the engine runs proper at all operating points except FL or COP.
C_LAMB_SP_AFL_DIAG_LS_UP_DOWN	Lambda set point for lean fault detection; Two limits must be considered: 1. engine running without misfire must be ensured 2. enough margin for not perfectly balanced precontrol must be included Recommendation: 12 - 15 % lean if the engine is still running without misfire (under all operating points

except FL or COP)

State machine of active plausibility diagnosis

The calibration can be done on the road.
The calibration should be checked in emission test.
The failure can be caused i.e. by forcing a dynamic fuel trim diagnosis – too high difference between setpoint and actual downstream lambda sensor voltage :
adding + / - 10 % on IP_LAMB_LS_UP[i].
A new catalyst (not green but with maximum O2 load) is required.

The risk for this function is, that a wrong diagnosis result is found because of a wrong precontrol. It must be ensured, that the shift of the lambda setpoint always guarantees enough tolerance for precontrolled operation. The setpoint must be shifted strongly enough, to guarantee that a real rich or lean mixture is the result of the lambda setpoint shift.

The function makes sense if the fuel mass injection adaptation is disabled and reset to 0 at the time of starting the open loop test.

C_MAF_INT_DIAG_LS_UP_DOWN	Minimum threshold for MAF integral required to start active test; Choose an operation point with lowest engine speed / load area where the active test can run (slow reaction time of sensor). Measure the MAF integral until the downstream lambda sensor voltage shows the expected response to the lambda setpoint change.
C_MAF_INT_EOL_DIAG_LS_UP_DOWN	Initialization of MAF integral to reduce required minimum MAF value to start active test; Check the required MAF integral for the conditions of the EOL Test. Measure the MAF integral until the downstream lambda sensor voltage shows the expected effect to the lambda setpoint change.
C_LAMB_AFL_MIN_DIAG_LS_UP_DOWN	Min. lambda set point for lean fault detection; It is related to C_LAMB_SP_AFL_DIAG_LS_UP_DOWN and should be 2 % richer than this.
C_LAMB_AFL_MAX_DIAG_LS_UP_DOWN	Max. lambda set point for lean fault detection; In case that there is a leaner lambda setpoint due to any reason, the active test is interrupted by this lambda setpoint threshold. I.e. 2 % more than C_LAMB_SP_AFL_DIAG_LS_UP_DOWN.
C_LAMB_AFR_MIN_DIAG_LS_UP_DOWN	Min. lambda set point for rich fault detection; It is related to C_LAMB_SP_AFR_DIAG_LS_UP_DOWN and should be 2 % leaner than this.
C_LAMB_AFR_MAX_DIAG_LS_UP_DOWN	Max. lambda set point for rich fault detection; In case that there is a richer lambda setpoint due to any reason, the active test is interrupted by this lambda setpoint threshold. I.e. 2 % richer than C_LAMB_SP_AFR_DIAG_LS_UP_DOWN.
C_T_MAX_DIAG_AFR_LS_UP_DOWN	Timer threshold for plausibility test under rich AF conditions; Can be quite short as all waiting timers to get stable conditions have been waited for. I.e. 10 sec.
C_T_MAX_DIAG_AFL_LS_UP_DOWN	Timer threshold for plausibility test under lean AF conditions; Same than C_T_MAX_DIAG_AFR_LS_UP_DOWN.
C_T_DIAG_EOL_LS_UP	Initialization of timer in case of EOL to reduce the

_DOWN	required minimum activity test time; Check the available time during EOL test and don´t reduce the overall test time under rich or lean conditions below 5 seconds.
LC_DIAG_AUTH_CHK_LS_UP_DOWN	Boolean switch allowing the active test; 1 for activation of the active test.

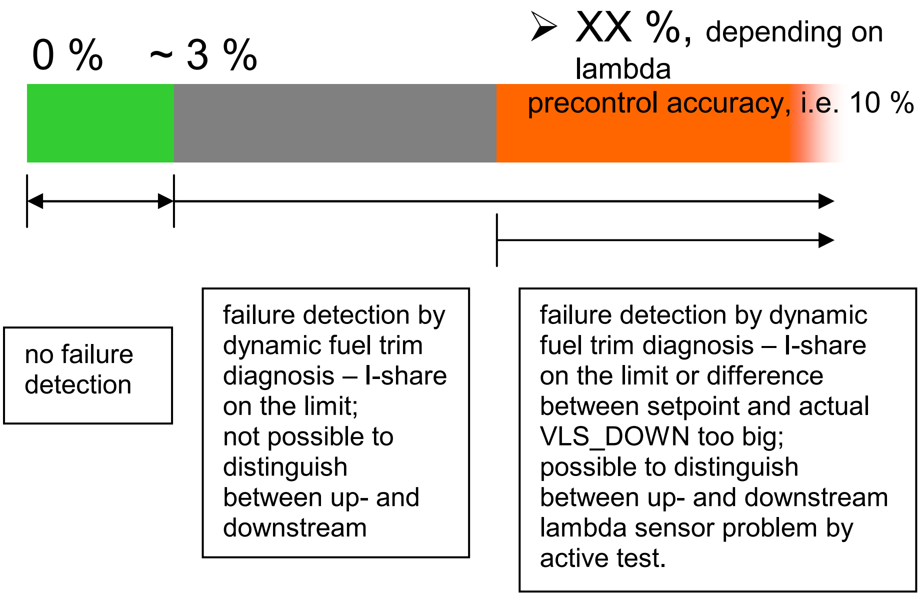
Active Test Upstream Sensor

C_LAMB_AFR_THD_DIAG_ACT_LSL_UP	Lambda value threshold for rich fault detection (upstream sensor); The closer this value is to lambda 1, the more deviation is possible for the precontrolled lambda to still detect a problem on the sensor. It must not be over the typical stoichiometric lambda setpoint. And it should not be smaller than the adjusted rich lambda setpoint during the active test plus the expected maximum deviation of real lambda from lambda setpoint. This value gives an additional opportunity to make the blind area (where no clear distinction between up- and downstream O2 Sensor error is possible) smaller than for the downstream O2 Sensor. The downstream O2 Sensor is always checked against its stoichiometric switching point, so just a big characteristic shift of C_LAMB_SP_AFR_DIAG_LS_UP_DOWN can be observed. Example: Fuel trim on the negative limit due to upstream O2 Sensor characteristic shift by – 10 % (-> LAMB_LS_UP = 1,1 in case of real lambda = 1,0). No failure detection by fuel system diagnosis or plausibility diagnosis. Lean test gives no problem for up- nor for downstream O2 Sensor. Rich test makes 15 % shift to rich. If the sensor would be able to follow this 15 % and the precontrol would be perfect, LAMB_LS_UP would be 0,95. If C_LAMB_AFR_THD_DIAG_ACT_LSL_UP was choosen to be 0,94 the problem will be detected. So the difference between C_LAMB_SP_AFR_DIAG_LS_UP_DOWN and C_LAMB_AFR_THD_DIAG_ACT_LSL_UP is approximately the characteristic shift over which an error could be detected. That also means, that at least between fuel trim limit and approximately 10% shift of characteristic its not possible to distinguish between up- and downstream lambda sensor error.
C_LAMB_AFL_THD_DIAG_ACT_LSL_UP	Lambda value threshold for lean fault detection (upstream sensor); See the explanation for C_LAMB_AFR_THD_DIAG_ACT_LSL_UP.
C_ABC_INC_CHK_LSL_UP	Increment for debounce algorithmus; C_ABC_MAX_CHK_LSL_UP / (C_ABC_INC_CHK_LSL_UP * 10 recurrences / sec) must be significantly shorter than the duration of the lean respectively the rich test (consider also the end

	of line active test duration which is even shorter : C_T_MAX_DIAG_AFL/AFR_LS_UP_DOWN – C_T_DIAG_EOL_LS_UP_DOWN).
C_ABC_MAX_CHK_LSL_UP	Maximum value for debounce algorithmus; See explanation for C_ABC_INC_CHK_LSL_UP.
C_CTR_SUM_RST_AFR_CHK_LSL_UP	Reset debounce counter for Rich test; Must be longer than the time to debounce an error via the anti bounce counter increment and maximum.
C_CTR_SUM_RST_AFL_CHK_LSL_UP	Reset debounce counter for Lean test; See explanation for C_CTR_SUM_RST_AFR_CHK_LSL_UP.

Active Test Downstream Sensor

C_VLS_AFR_THD_DIAG_ACT_LS_DOWN	VLS voltage threshold for rich fault detection (downstream sensor); Voltage slightly below the maximum guaranteed rich voltage of sensor supplier at lambda ~ 0,9 (see sensor specification).
C_VLS_AFL_THD_DIAG_ACT_LS_DOWN	VLS voltage threshold for lean fault detection (downstream sensor); Voltage slightly above the lean voltage at lambda 1,01.
C_T_MAX_CHK_LS_DOWN	Maximum time to debounce the error. It must be significantly shorter than the duration of the lean respectively the rich test. Consider also the end of line active test duration which is even shorter : C_T_MAX_DIAG_AFL/AFR_LS_UP_DOWN and C_T_DIAG_EOL_LS_UP_DOWN).
C_T_END_DIAG_ACT_LS_DOWN	Time for end of active test in case it was not triggered. It must be bigger or equal (C_T_MAX_DIAG_AFL_LS_UP_DOWN + C_T_MAX_DIAG_AFR_LS_UP_DOWN + twice the maximum time for the MAF integral C_MAF_INT_DIAG_LS_UP_DOWN). The reason is to be in line with Rate Based Monitoring requirements (duration of diagnosis in the no failure case not shorter than in the failure case).



0 %

~ 3 %

➢ XX %, depending on lambda precontrol accuracy, i.e. 10 %

no failure detection

failure detection by dynamic fuel trim diagnosis – I-share on the limit; not possible to distinguish between up- and downstream

failure detection by dynamic fuel trim diagnosis – I-share on the limit or difference between setpoint and actual VLS_DOWN too big; possible to distinguish between up- and downstream lambda sensor problem by active test.

16.80 Interchanged Lambda Sensor diagnosis

16.80.1 Calibration interfering functions

16.80.1.1 Before start of the calibration of the interchanged lambda sensor diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (i.e. Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed (also limits)
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control

16.80.1.2 Before calibration of the interchanged lambda sensor diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.80.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.80.3 Calibration method

Interchanged upstream lambda sensor diagnosis

The calibration can be done on the road.
The failure is created most easily by swapping the sensors.

C_FAC_LAM_LIM_MIN_CHG_LS_UP	Min. Threshold to detect an interchanged sensor; Smaller than lambda control limit.
C_FAC_LAM_LIM_MAX_CHG_LS_UP	Max. Threshold to detect a interchanged sensor; Smaller than lambda control limit.
C_MAF_INT_DIAG_CHG_LS_UP	Max. MAF integral value when ERR_SYM_... ≠ “NO_SYM”; To exclude short term events by dynamic driving. Bigger than required for short term events and smaller as the maximum possible time of active lambda control (or limited lambda control by wallfilm) during emission test. I.e. 150.

C_T_END_DIAG_CHG_LS_UP	Max. time to set LV_END_... = 1; Check how long it takes at lowest possible load to debounce the symptom. Add a few seconds.
C_FAC_INT_CHG_LS_UP	Gain factor for the MAF integral; 1

Interchanged Downstream Lambda Sensors

The calibration can be done on the road.
The failure is created most easily by swapping the sensors.
Different operating points must be checked.
Even the detection in Idle Speed can be checked.

C_VLS_DOWN_MAX_CHG_LS_DOWN	Max VLS_DOWN_i threshold; Exchange the Sensors and observe the "lowest" rich voltage for the bank which is on the rich side. Define the threshold slightly lower than this observed value. The voltage must be outside of the guaranteed rich voltage of the lambda sensor specification, as the guaranteed sensor rich voltage is already reached during normal operation with active trim control. So this diagnosis is not guaranteed for the sensor lifetime.
C_VLS_DOWN_MIN_CHG_LS_DOWN	Min VLS_DOWN_i threshold; Exchange the Sensors and observe the "highest" lean voltage for the bank which is on the lean side. Define the threshold slightly higher than this observed value.
C_MAF_INT_DIAG_CHG_LS_DOWN	MAF integral threshold; It must be smaller than the integral to debounce the error for the fuel trim diagnosis (vls_dif_dly - C_MAF_INT_VLS_DIF_DLY_MIN). Otherwise, the failure is not correctly located on sensors exchanged.
C_FAC_INT_CHG_LS_DOWN	Gain factor for the MAF integral; 1

16.81 Linear Oxygen Sensor plausibility diagnosis

16.81.1 Calibration interfering functions

16.81.1.1 Before start of the calibration of the plausibility diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control

16.81.1.2 Before calibration of the plausibility diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.81.2 Calibration flowchart

The sequence is described by the order of constants and maps in the chapter “Calibration method” below.

16.81.3 Calibration method

Plausibility Check

The calibration can be done on the road, except for calibration data to consider the catalyst delay. Here a chassis dynamometer is recommended.
A break out box is required.
The calibration must be checked in emission test.

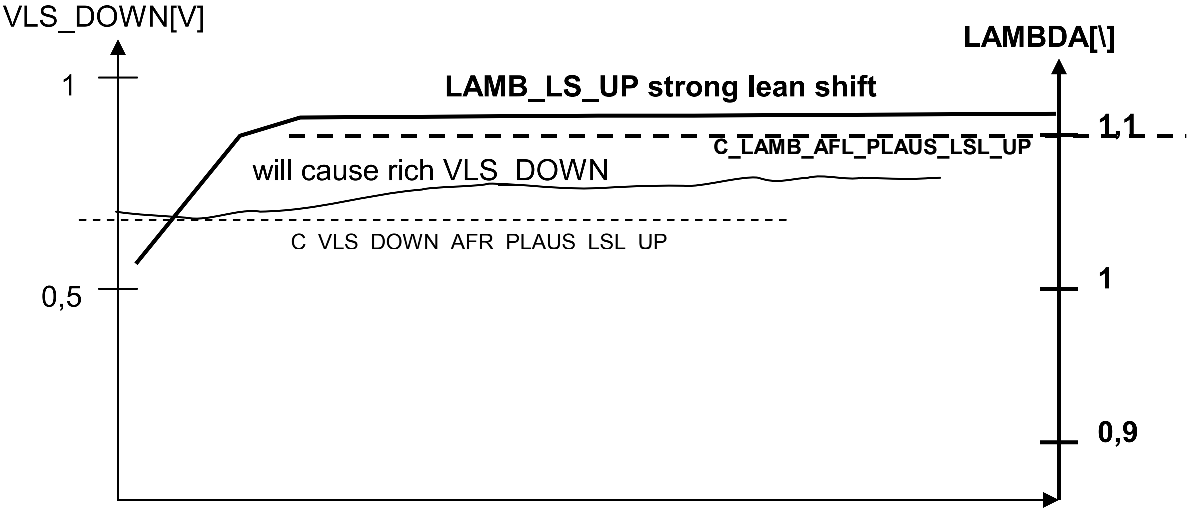
It's acceptable that the diagnosis runs only in Part load. The highest calibration level is reached, if the diagnosis works also in Idle Speed without risk of wrong failure detection.

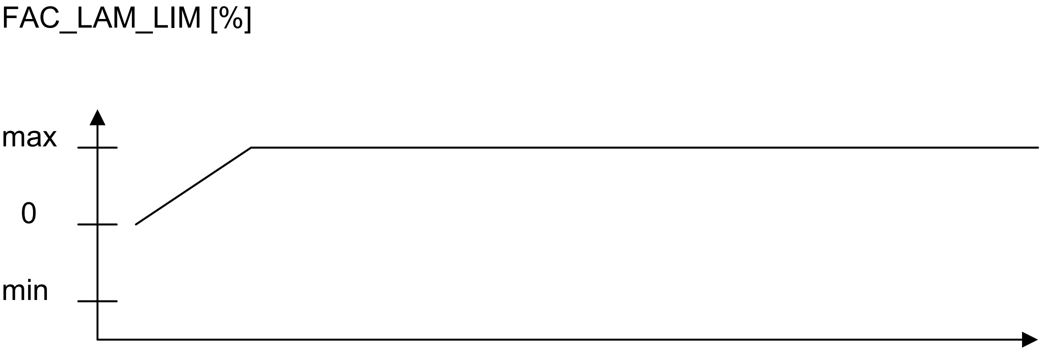
C_TEG_MIN_PLAUS_LSL_UP [NC_CBK_EX_NR]	Minimum temperature of the exhaust gas at the downstream sensor to carry out the plausibility check; The catalyst should be active to be able to smooth the downstream lambda sensor signal. I.e. 400 °C
C_TEG_MAX_PLAUS_LSL_UP[NC_CBK_EX_NR]	Maximum temperature of the exhaust gas at the downstream sensor to carry out the plausibility check; Deactivation threshold when the temperature of the

	exhaust line/exhaust gas is so hot, that the sensor signal is not anymore reliable. It might be a theoretical value in case that the sensor is reliable until the highest possible temperature. I.e. 900 °C
C_MAF_KGH_MIN_DIAG_PLAUS_LSL_UP	Minimum mass air flow to carry out the plausibility check; For very low load, the sensor signal could be like for an inactive sensor, so with this constant, low load can be excluded from the diagnosis range (i.e. IS at warm engine). i.e. 20 kg/h
C_MAF_KGH_MAX_DIAG_PLAUS_LSL_UP	Maximum mass air flow to carry out the plausibility check; To save runtime for high load. If this is not required, the threshold can be set to the max value. I.e. 500 kg/h
C_N_MIN_DIAG_PLAUS_LSL_UP	Lowest engine speed threshold to carry out the plausibility check; To define an rpm range above Idle Speed (in Idle Speed, the delay of the downstream catalyst A/F ratio is very long and the behaviour is hardly reproducible). I.e. 1000 rpm
C_TCO_MIN_DIAG_PLAUS_LSL_UP	Minimum threshold of the cooling-water temperature to activate the function; The precontrol of the engine will be better for higher TCO. As the plausibility check is however for quite strong characteristic shifts of the sensor, the TCO threshold can be chosen small, i.e. like the lambda control TCO activation threshold.
C_VLS_DOWN_AFL_PLAUS_LSL_UP[NC_CBK_EX_NR]	Lean-mixture threshold of the downstream sensor voltage; Voltage above 0 which can be easily reached even by an aged sensor.
C_VLS_DOWN_AFR_PLAUS_LSL_UP[NC_CBK_EX_NR]	Rich-mixture threshold of the downstream sensor voltage; Voltage slightly below the max. guaranteed rich voltage of sensor supplier at lambda ~ 0,9 (see sensor specification) I.e. 0,67 V
C_LAMB_AFL_PLAUS_LSL_UP[NC_CBK_EX_NR]	Lean-mixture threshold of the upstream sensor voltage; A significant rich value must be chosen, which is not met during emission test. I.e. 0,9
C_LAMB_AFR_PLAUS_LSL_UP[NC_CBK_EX_NR]	Rich-mixture threshold of the upstream sensor voltage; A significant lean value must be chosen which is not met during emission test. I.e. 1,1
C_MAF_SYM_PLAUS_LSL_UP[NC_CBK_EX_NR]	Second anti-bounce filter; In case of the need to speed up the diagnosis, this value can be reduced as it is a second debouncing filter.
C_MAF_SYM_RAW_PLAUS_LSL_UP[NC_CBK_EX_NR]	First anti-bounce filter: compensation of the catalyst delay, Force a mixture change (i.e. lambda = 0,90 to 1,10). Measure in steady state operation the delay time between sensor signal change upstream and downstream for different loads.

C_MAF_SYM_RAW_RST_PLAUS_LSL_UP[NC_CBK_EX_NR]	In case of intermittent failures, the raw symptom is not taken back immediately, but the first anti-bounce integral has to fall below this threshold.

Example for upstream lambda sensor lean shifted:





16.82 Linear Oxygen Sensor activity check

16.82.1 Calibration interfering functions

16.82.1.1 Before start of the calibration of the plausibility diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control

16.82.1.2 Before calibration of the plausibility diagnosis, the following modifications on the calibration data should be done:

Sensor activity check:

For the check of the sensor activity with a maximum slow sensor, all functions which would give additional stimulation to the lambda sensor activity should be switched off:

Lambda Adaptation

Trim Control

Canister Purge

Because the target is to find the minimum activity for the system without open circuit.

16.82.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the "Calibration method" section below.

Two loops at least are required to separate the failure case from the "No failure case".

1. Failure Case
(Open Circuit on Pin Vg / Vip)

2. Ensure no failure detection in the
"no open circuit" case especially for
- low load
- slow dynamic of sensor

16.82.3 Calibration method

No activity check

The calibration can be done on the road.
A break out box is required.

For low load it's difficult to distinguish the normal sensor from the sensor with open line on Pin Vg or Vip. Therefore, some fade out criteria exist to prevent wrong diagnosis entries.

C_VLS_UP_AFS_MIN _PLAUS_LSL_UP	Lower limit of upstream sensor signal window to detect the sensor non-activity; Lowest VLS_UP_DIAG voltage which occurs in the system after open circuit on Vg **or** Vip minus ~ 10 mV (since revision K of the plausibility check, the offset correction is already considered in VLS_UP_DIAG – so just the minimum VLS_UP_DIAG must be considered). In case, that through some peaks on VLS_UP_DIAG, the plausibility diagnosis is interrupted, increase the 10 mV to any value required to ensure a stable debouncing.
C_VLS_UP_AFS_MAX _PLAUS_LSL_UP	Upper limit of upstream sensor signal window to detect the sensor non-activity; See one row above, take the highest observed VLS_UP_DIAG value in case of open circuit on Vg or Vip, consider open circuit present before engine start and open circuit created after start and after operative readiness of upstream WRAF Sensor was already finished.
C_CTR _RAW_ACT_SYM _LSL_UP	Counter threshold to set the raw symptom of sensor non-activity; Start with 5000 and check how often the counter starts to increment i.e. at low load and speed condition in the no failure case. If it is very often that the conditions for a not active sensor are met in the no failure case (i.e. low dynamic sensor in IS – worst case), then increase the limit or decrease the increment (see ID_CTR_INC_RAW_ACT_LSL_UP)
ID_CTR_INC_RAW_ACT_LSL _UP	Counter in- and decrement to detect raw symptom of upstream sensor non-activity; In principle, the counter can be increased faster for higher load as the probability for a good sensor to stay within the narrow lambda boundaries is lower for high load.
C_CTR _RAW_ACT_END _LSL_UP	Counter threshold to set end flag of first part of diagnosis in case of faultless sensor. In case of a faulty sensor, the end bit should not be set before the failure is detected. Therefore, chose threshold such that it represents the longest duration to detect a faulty sensor.
C_CTR _RAW_ACT_RST _LSL_UP	Intermittent failures shall not cause an immediate reset of the raw symptom. To reset the raw symptom, the counter has to fall below this threshold.
C_FAC_DYN_INT_ACT_LSL _UP	Relative sensor signal damping admitted to monitor the sensor activity;

	The Open Circuit diagnosis must work until the MIL would be turned on for the dynamic diagnosis. But if fuel cut off is frequently done in this project, the open circuit could also be detected via the plausibility diagnosis in PUC. In this case, the activity check could be switched off for a certain slow lambda sensor. In this case, it must be ensured that the Open Circuit diagnosis still works in the emission test.
C_N_MIN_ACT_LSL_UP	Lower engine speed to activate the sensor activity; To be able to deactivate the activity check below an engine speed where even a new sensor shows a very low activity. I.e. 600 rpm
C_T_SUM_AFL_AFR_ACT_LSL_UP	Lower forced stimulation period admitted to monitor the sensor activity; To be able to deactivate the activity check below a forced stimulation period time where even a new sensor shows a very low activity. I.e. shortest period time in the engine speed / load area which occurs during emission test.
C_LAMB_SP_DE_PLS_ACT_LSL_UP	Lower forced stimulation amplitude admitted to monitor the sensor activity; See C_T_SUM_AFL_AFR_ACT_LSL_UP.
C_MAF_KGH_MIN_ACT_LSL_UP	Lower mass airflow in Kg/h admitted to monitor the sensor activity; See C_N_MIN_ACT_LSL_UP; I.e. 20 kg/h to exclude Idle Speed for warm engine.
C_CRLC_ACT_LSL_UP	Correlation factor for the moving mean value; It must be chosen very small, to have an almost frozen mean value in case of a good lambda sensor signal. The smaller the value, the bigger the activity integral for a good sensor.
C_CTR_LAMB_DE_INT_ACT_LSL_UP	Number of forced stimulation periods to calculate the total cumulated lambda deviation; The smaller the difference is between the slow dynamic sensor and the sensor with open circuit on Vg or Vip, the longer the integration should be to get a better safety margin between good and malfunction system. I.e. 5.
C_CTR_SYM_MAX_ACT_LSL_UP	Counter threshold to set the sensor non-activity symptom flag; I.e. 3.
C_CTR_SYM_INC_ACT_LSL_UP	Counter increment to set the sensor non-activity symptom flag. For detection of intermittent errors this counter increment should be 2.
C_LAMB_DE_TOT_ACT_LSL_UP	Threshold of the total cumulated lambda deviation to debounce the sensor non-activity symptom; Install the limit slow dynamic sensor and measure the value of the activity integral at the lowest engine speed and load area where the plausibility diagnosis is still active. The constant should be chosen smaller than the result of this measurement. Open the WRAF Sensor lines Vg or Vip and observe the value for the activity integral. The constant must be bigger than the result of this measurement.
C_CTR_SYM_DEC_ACT_LSL_UP	Counter decrement to set the sensor non-activity symptom flag. For detection of intermitted errors this counter decrement should be 1.

ID_LAMB_GAIN_VLS_DOWN	Gain factor to emphasize no activity of the sensor if downstream sensor is far away from stoichiometric value. In the region around the downstream sensor set point the gain should be 1. If the downstream signal is far away from the set point, we have strong indication of no activity and the gain can be decreased below 1 to accelerate the failure detection.
ID_LAMB_GAIN_LS_UP_DYN	Gain factor to consider an aged linear lambda sensor; In case that the slow dynamic lambda sensor would result in an open circuit detection, this map can help to increase the activity integral. Take two different aging stages of the lambda sensor where the dynamic diagnosis already has a significant diagnosis value above 0. Calibrate this map to get the same activity integral (LAMB_DE_INT_ACT_LSL_UP) than for a new sensor.

16.83 Linear Oxygen Sensor dynamic diagnosis

16.83.1 Calibration interfering functions

16.83.1.1 Before start of the calibration of the dynamic diagnosis, the following other functions must be calibrated:

- Basic Engine Tuning (Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control

16.83.1.2 Before calibration of the dynamic diagnosis, the following modifications on the calibration data should be done:

For the calibration of the minimum and maximum amplitude, all functions which would give additional stimulation should be switched off:

Lambda Adaptation

Trim Control

Canister Purge

Currently, only the synchron operation of catalyst diagnosis and dynamic diagnosis is used by the projects. The main reason is the available time during emission test.

For this mode, two ways of calibration are possible:

Make the catalyst diagnosis countinously running or copy the forced stimulation parameters from catalyst diagnosis to the separate maps for dynamic diagnosis.

The adaptation of the sensor time constant is not recommended. The PVE test would not be possible without modification of calibration data as a normal sensor is suddenly exchanged to a maximum aged sensor. So the recommendation is to take care that with the maximum aged lambda sensor, the lambda control is not too nervous so that the driveability is still ok and that the catalyst diagnosis can still be performed. If it is decided to not use the sensor time constant adaptation, it is not required to read the text below.

For the calibration of the T1_LAMB_AGI map, it is required to set the gain factors of the lambda control to 0 (just in the I-part of lambda control, 1 increment above 0 is required to keep the lambda control centered around 0).

With the adaptation of the sensor time constant, the limit sensor choice is not necessarily due to emission reasons, but can also be due to driveability impact or because the sensor reaction is “unreasonable” slow.

As during the calibration of the limit sensor amplitude, the adaptation of the sensor time constant is not yet done, the lambda control parameters must also be set to 0 (like for the calibration of the T1_LAMB_AGI map) to keep the result of lambda amplitude free from lambda control feedback.

16.83.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

1. C_CRLC_LPF_LAMB_DIAG_DYN_LSL_UP

2. New Sensors amplitude

3. Limit Sensors amplitude

4. Calibration of remaining items
- ✓ correlation constant
- ✓ counters
- ✓ adaptation
- ✓ failure limit

16.83.3 Calibration method

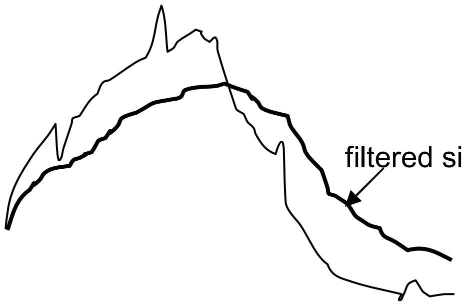
Dynamic Diagnosis

The calibration requires a chassis dyno roller.
Required parts: 1 standard new Sensor and 1 maximum aged Sensor or a Sensor with small wholes in the protection tube.
The calibration must be checked in emission test.

Hint for calibration of C_CRLC_LPF_LAMB_DIAG_DYN_LSL_UP:

good

too slow – loss of amplitude



too fast – no filter effect

LC_DIAG_DYN_LSL_UP_CAT_SYN	Boolean switch to synchronise the dynamic diagnosis with the catalyst efficiency diagnosis; I.e. 1 for synchronized processing of catalyst and dynamic diagnosis.
LC_T1_AD_DIAG_DYN_LSL_UP	Boolean switch to allow the adaptation of the sensor time constant model T1_LSL_UP[i]; I.e. 0 to forbid the adaptation.
C_CRLC_LPF_LAMB_DIAG_DYN_LSL_UP	Correlation factor for low pass filtered lambda value. Purpose is to filter out high frequent disturbances. The filtered lambda signal amplitude should not be significantly smaller than amplitude of the unfiltered lambda sensor signal. I.e. 0,3.
C_LAMB_MIN_DIAG_DYN_LSL_UP	Lowest allowed sensor signal min value; This value shall detect a shift of lambda setpoint in rich direction. Carefully handle this constant, as a too big value can lead to a significant reduction of diagnosis cycles. As during catalyst diagnosis no lambda setpoint shift is allowed, the value can be choosen similarly to C_LAMB_AMPL_MAX_DYN_LSL_UP: i.e. richest lambda during catalyst diagnosis in steady state condition (without disturbance) – 0,04.
C_LAMB_MAX_DIAG_DYN_LSL_UP	Highest allowed sensor signal max value; See C_LAMB_AMPL_MAX_DYN_LSL_UP: i.e. leanest lambda during catalyst diagnosis in steady state condition (without disturbance) + 0,04.
C_LAMB_AMPL_MIN_DYN_LSL_UP	Calibration data for adjust the expected amplitude: low range; This check can prevent a detection of a slow dynamic of upstream WRAF Sensor in case of Open Circuit on Pin Vg or Vip. As it is however not possible to run the catalyst diagnosis with open circuit conditions (lambda mean value conditions and O2 loading range not fulfilled), it can be set to maximum. With that calibration, the minimum condition will never be inhibit the diagnosis cycle.
C_LAMB_AMPL_MAX_DYN_LSL_UP	Calibration data for adjust the expected amplitude: high range; This constant is thought to exclude events with an exaggerate amplitude due to any event which disturbed the lambda control signal. But on the other hand side, it can significantly reduce the number of performed cycles. Therefore it should not be choosen too close to the standard new amplitude. The value depends on the signal noise on lambda which is very project / sensor specific. The biggest possible amplitude for a new sensor + tolerance must be choosen.
IP_LAMB_AMPL_MAX_DYN_LSL_UP	Nominal sensor expected amplitude during the Dynamic Diagnosis; Set C_CTR_MIN_DIAG_DYN_LSL_UP to 10. Adjust the relevant operation point from the map (constant on Chassis Dyno). Check LAMB_AMPL_MV_DIAG_DYN_LSL_UP[i] which is the amplitude. Enter this amplitude into the map. It is recommended to subtract a small value from the measured one to get really diagnosis result 0 for a new sensor (i.e. 0,005).

IP_LAMB_AMPL_MIN_DYN_LSL_UP	Limit sensor expected amplitude during the Dynamic Diagnosis; Fill the lambda control gain parameters with 0. Set C_CTR_MIN_DIAG_DYN_LSL_UP to 10. Adjust the relevant operation point from the map (constant on Chassis Dyno). Check LAMB_AMPL_MV_DIAG_DYN_LSL_UP[i] which is the amplitude. Enter this amplitude into the map.
C_CTR_MIN_DIAG_DYN_LSL_UP	Number of forced stimulation periods needed to calculate the short term mean value; As the engine load and speed correction is performed only once after C_CTR_MIN_DIAG_DYN_LSL_UP cycles, it should be set to 1.
C_CTR_MIN_DIAG_EOL_DYN_LSL_UP	Number of forced stimulation periods needed to calculate the short term mean value (EOL test). See C_CTR_MIN_DIAG_DYN_LSL_UP.
C_CYCNR_MIN_DIAG_DYN_LSL_UP	Minimum number of short term mean values to calculate the long term mean value; In synchronous mode: i.e. C_CTR_MIN_DIAG_DYN_LSL_UP * C_CYCNR_MIN_DIAG_DYN_LSL_UP should be 1/2 of the required catalyst diagnosis cycles.
C_CYCNR_EOL_DIAG_DYN_LSL_UP	Number of long term mean values to deliver the sensor dynamic diagnostic (EOL test); Number of possible dynamic diagnosis cycles for the end of line test. Customer specific.
C_CYCNR_END_DIAG_DYN_LSL_UP	Number of long term mean values to deliver the sensor dynamic diagnostic; End of dynamic diagnosis in synchronous mode triggered either by end of catalyst diagnosis or by number of cycles bigger than this treshold. I.e. 20.
C_FAC_AD_THD_DIAG_DYN_LSL_UP	Diagnosis value threshold for begin adaptation of sensor time constant model. As for the time beeing, the lambda control will force the amplitude of the sensor to the sensor model, an adaptation cycle would start as soon as the sensor model was adapted one time (i.e. by a measured amplitude which is slightly smaller than the max value). This is especially true for a fast (new) sensor which reacts fast to the lambda control. Therefore this threshold should be set to a significant value like i.e. 0,5.
C_FAC_AD_RST_DIAG_DYN_LSL_UP	Diagnosis value threshold to reset adaptation of sensor time constant model; This value must be smaller than C_FAC_AD_THD_DIAG_DYN_LSL_UP to realize a hysteresis. I.e. 0,1.
C_CRLC_LPF_FAC_AD_DYN_LSL_UP	Correlation factor for low pass filtered (sensor time constant) adaptation factor; I.e. 0,3.

C_FAC_MV_THD_DIAG_DYN_LSL_UP	Limited diagnosis value for the error diagnosis. This treshold should be determined with the slow dynamic sensor which causes either a driveability impact or an exceeding of emission threshold in emission test. Due to the adapted sensor time constant, it can be, that just the availability of a even slower sensor is not given (i.e. just a 0,2 mm whole in the protection tube can be still ok for emissions and driveability). In that case, the choice can be done just with the reason that the sensor is “unreasonable” slow
C_CTR_WAIT_DIAG_DYN_LSL_UP	Number of forced stimulation periods during the diagnosis status transition “wait” to “acquisition”; For the unsynchronous mode only. I.e. 2.
C_N_MIN_DIAG_DYN_LSL_UP	Minimum engine speed to activate the diagnosis; Only for unsynchronous mode. Choose values in relation to minimum load while steady state operation in emission test.
C_N_MAX_DIAG_DYN_LSL_UP	Maximum engine speed to activate the diagnosis; Only for unsynchronous mode. Choose values in relation to maximum load while steady state operation in emission test.
C_MAF_MAX_DIAG_DYN_LSL_UP	Maximum mass airflow rate to activate the diagnosis function; Only for unsynchronous mode. Choose values in relation to maximum load while steady state operation in emission test.
C_MAF_MIN_DIAG_DYN_LSL_UP	Minimum mass airflow rate to activate the diagnosis function; Only for unsynchronous mode. Choose values in relation to minimum load while steady state operation in emission test.
IP_T_DYN_DIAG	Time in one lean/rich cycle during which the pointer for maximum and minimum amplitude is updated; This map shall include the time for a new sensor to reach the maximum amplitude + 10% of the complete cycle time. The target is to make the diagnosis distance between new and aged sensor bigger in the low engine speed / load operation area where even the maximum slow sensor reaches the maximum amplitude. Measure LAMB_AMPL_MV_DIAG_DYN_LSL_UP (with C_CTR_MIN_DIAG_DYN_LSL_UP = 10 and C_CYCNR_MIN_DIAG_DYN_LSL_UP = 1) for every relevant operating point with IP_T_DYN_DIAG = IP_T_PER_LAMB_DE_CAT_DIAG (for synchronous operation) * 1, * 0,6, * 0,5, *0,45, * 0,4, * 0,35, * 0,3, * 0,25; Do that measurement for a new sensor and for an old sensor. Compare the result for LAMB_AMPL_MV_DIAG_DYN_LSL_UP for both sensors and every relevant operation point. Choose the value for IP_T_DYN_DIAG according to the factor on IP_T_PER_LAMB_DE_CAT_DIAG which gave almost no decrease of amplitude for the new sensor but already a significant reduction of amplitude for the limit aged sensor.

16.84 Linear Oxygen Sensor on Air diagnosis

16.84.1 Calibration interfering functions

16.84.1.1 Before start of the calibration of the Sensor on Air diagnosis, following other functions must be calibrated:

- Intake Manifold Model (MAP System)
- Temperature Model upstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of upstream lambda sensor

16.84.1.2 Before calibration of the Sensor on Air diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.84.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.84.3 Calibration method

Sensor on Air Diagnosis

The calibration can be done on street.
A sensor which is not mounted must be connected to the ECU (i.e. with breakout box or directly on the connector).

C_VLS_UP_DIAG_MAX_AIR_LSL_UP	Upstream sensor signal max. threshold during engine operation; Minimum voltage for the sensor on air out of the sensor specification (similar to the “low” threshold in the function lambda sensor plausibility diagnosis during fuel cut off - C_VLS_UP_DIAG_MIN_PUC_LSL_UP).
C_T_SYM_DIAG_AIR_LSL_UP	Time filter to detect a symptom; I.e. 25 sec.
C_T_END_DIAG_AIR_LSL_UP	Time to have a diagnostic available; I.e. 100 sec.

16.85 Linear Oxygen Sensor plausibility diagnosis during fuel cut off

16.85.1 Calibration interfering functions

16.85.1.1 Before start of the calibration of the WRAF Sensor plausibility diagnosis during fuel cut off, following other functions must be calibrated:

- Temperature Model upstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of upstream lambda sensor

16.85.1.2 Before calibration of the WRAF Sensor plausibility diagnosis during fuel cut off, the following modifications on the calibration data should be done:

Nothing.

16.85.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.85.3 Calibration method

WRAF Sensor plausibility diagnosis during fuel cut off

The calibration can be done on street.
But it is more simple on Chassis Dyno Roller.
The calibration must be checked in emission test.

C_T_DIAG_SYM_PUC_LSL_UP	Time filter to detect a symptom; Accumulated time in a driving cycle where the too high or low signal must be present to enter an error. This is very dependent from the possible fuel cut off time during the emission test.
C_T_DIAG_SYM_EOL_PUC_LSL_UP	Time filter to detect a symptom (EOL test); The debounce time can be choosen smaller to make the test possible at the end of line.
C_T_DLY_DIAG_PUC_LSL_UP	Waiting time after beginning of PUC to test sensor signal; Choose a low engine speed and make fuel cut off. Measure the time delay which allows the sensor to show the lean signal without further increasing. Check this also with a dynamically slow sensor.
C_T_DLY_DIAG_EOL_PUC_LSL_UP	Waiting time after beginning of PUC to test sensor signal (EOL test); See C_T_DLY_DIAG_PUC_LSL_UP.
C_VLS_UP_DIAG_AFS_PUC_LSL_UP	Upstream sensor output voltage in PUC corresponding to Open Circuit on WRAF Sensor; Corresponding to maximum possible VLS_UP_DIAG threshold in case of open circuit on Vg or Vip. Take this VLS_UP_DIAG and add 50 mV.

C_VLS_UP_DIAG_MIN_PUC_LSL_UP	Minimum admissible upstream sensor output voltage in PUC; Corresponding to a sensor specific voltage which must be calculated according to the sensor specification, including the tolerance chain from the Engine Control Unit. – e.g. 3,1 V.
C_VLS_UP_DIAG_MAX_PUC_LSL_UP	Upstream sensor output voltage in PUC corresponding to Open Circuit on WRAF Sensor; Corresponding to a sensor specific voltage which must be calculated according to the sensor specification, including the tolerance chain from the Engine Control Unit. – e.g. 4,9 V.
C_TEG_MIN_DIAG_PUC_LSL_UP	Minimum admissible exhaust gas temperature in PUC. To ensure no impact from a cooled down sensor. I.e. 300 °C.
C_T_DIAG_END_PUC_LSL_UP	Time to have a diagnosis available; Choose a time which is shorter than the available fuel cut off time in the emission test cycle.
C_T_DIAG_END_EOL_PUC_LSL_UP	Time to have a diagnosis available (EOL test); Choose a time which is shorter than the available fuel cut off time during the end of line test.

16.86 Linear Oxygen Sensor Heater Coupling Diagnosis

16.86.1 Calibration interfering functions

16.86.1.1 Before start of the calibration of the heater coupling diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control
- Catalyst Purge

16.86.1.2 Before calibration of the heater coupling diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.86.2 Calibration flowchart

The sequence is described by the order of constants and maps in the chapter “Calibration method” below.

16.86.3 Calibration method

The calibration shall be done on chassis dynamometer.
A WRAF Sensor break out box and a Resistor Decade is required.
The calibration must be checked in emission test.

Determination of min. possible heater coupling resistance:

1. Connect the break out box between sensor and ECU plugs. The heater coupling failure can be simulated installing a variable resistor between the UN and the negative potential of Uheater – lines.
2. Adjust C_LAMB_DELTA_LPF_THD, C_CTR_SYM_DIAG_LSH_LSL_UP and C_CYCNR_MAX_DIAG_LSH_LSL_UP to their maximum values.
3. Carry out emission tests with different resistance values (i.e. 1 Mohm, 700Kohm, 300K, 200K and 100K) in order to determine, in which case the emissions are near the threshold defined by the legislation.

C_LAMB_SP_DE_DIAG_LSH_LSL_UP	Maximum value of the forced excitation amplitude to activate the diagnosis; I.e. maximum value.
C_TEG_MIN_DIAG_LSH_LSL_UP	Minimum value of the exhaust temperature to activate the function. The colder the lambda sensor environment is, the bigger can the heater coupling be. To see the impact, check heater coupling diagnosis result right after operative readiness after coldstart and see it with warmed up engine. I.e. 350 °C.
C_MAF_INT_DIAG_LSH_LSL_UP	Threshold for the activation of the MAF-Integral; 1. Adjust C_MAF_INT_DIAG_LSH_LSL_UP equal “0” to activate the function. 2. Measure some changes from PUC to PL. Evaluate the results of DELTA_LAMB_SP_FALL/RISE; i.e. at the transition from PUC <-> PL evaluate if the diagnosis value is greater than zero. Vary C_MAF_INT_DIAG_LSH_LSL_UP until no influence of PUC phase can be found. 3. Calibrate C_MAF_INT_DIAG_LSH_LSL_UP with the maximum measured value. I.e. 25 g.
C_T_AFL_AFR_DIAG_LSH_LSL_UP	Maximum forced stimulation cycle time to activate the heater-coupling diagnosis; I.e. maximum.
C_CRLC_LPF_FALL_DIAG_LSH_LSL_UP	Filter constant for Fall; I.e. 0,5.
C_CRLC_LPF_RISE_DIAG_LSH_LSL_UP	Filter constant for Rise; I.e. 0,5.
C_LSHPWM_MIN_DIAG_LSH_LSL_UP	minimum heater PWM value allowed to carry out the heater coupling diagnosis; The calibration depends on the delay time, calibrated in IP_T_DLY_TRIG_LSH_UP. If the counterflank of the currently active flank comes before the delay time is elapsed, the VLS_UP_RISE / FALL cannot be taken correctly. I.e. if the delay time is 6 ms, the minimum off respectively on time for the PWM is 6 + 2 (for polling) ms. For a heater PWM frequency of 10 Hz., 8 ms would correspond to 8 %. I.e. 10 %.
C_LSHPWM_MAX_DIAG_LSH_LSL_UP	maximum heater PWM value allowed to carry out the heater coupling diagnosis; See comment for minimum threshold above. I.e. 90 %.
IP_T_DLY_TRIG_LSH_UP	Time delay to trigger oxygen sensor signal and lambda model; Simulate the heater coupling with a resistor of ~ 500 kohm. Vary the delay time to obtain the highest value of CTR_SYM_DIAG_LSH_LSL_UP[i]. Repeat this procedure by different heater PWM values. I.e. 0,006 sec.

C_LAMB_DELTA_LPF_THD	Threshold for the maximum transition of the sensor signal; 1. Use the chassis dyno, adjust the variable resistor to the limit value to be detected. 2. Vary the load/engine speed according usual conditions during emission test cycle. At each condition proceed as described below. 3. Set C_CYCNR_MAX_DIAG_LSH_LSL_UP to a reasonable value, for example 50. 4. Observe if LAMB_DELTA_RISE/FALL_LPF[i] are relatively stable, otherwise increase C_CYCNR_MAX_DIAG_LSH_LSL_UP 5. Set C_LAMB_DELTA_LPF_THD to the value of LAMB_DELTA_RISE/FALL_LPF[i]. Evaluate the dispersion during each measurement. If the values are too low, check the calibration of map IP_T_DLY_ACQ_VLS_UP. 6. Observe the value of CTR_SYM_DIAG_LSH_LSL_UP[i]. 7. Set C_LAMB_DELTA_LPF_THD to the lowest value obtained over all load/engine conditions. I.e. 0,02.
C_CYCNR_MAX_DIAG_LSH_LSL_UP	Quantity of valid diagnosis values in one function cycle; See C_LAMB_DELTA_LPF_THD. I.e. 100.
C_CTR_SYM_DIAG_LSH_LSL_UP	Limit value of the diagnosis results to diagnose the heater coupling; See C_LAMB_DELTA_LPF_THD. I.e. 50.

16.87 Oxygen Sensor Downstream Diagnosis

16.87.1 Calibration interfering functions

16.87.1.1 Before start of the calibration of the OBD2 downstream oxygen sensor diagnosis, following other functions must be calibrated:

- Basic Engine Tuning (i.e. Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control
- Catalyst Purge

16.87.1.2 Before calibration of the OBD2 downstream oxygen sensor diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.87.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.87.3 Calibration method

The calibration can be done on the road.
The calibration must be checked in emission test.
The diagnosis for switching time of the downstream sensor is responsible to ensure a fast enough switching to detect a possible catalyst damage.
It is very recommended to activate it.
If the vehicle has no or not sufficient fuel cut off phases, a possible deterioration of sensor switching must be detected with the fuel trim diagnosis which will not always be possible.
Conclusion is, that a fuel cut off phase is required for a proper diagnosis of the monitor sensors.

Application Conditions

C_TCO_MIN_DIAG_MPL_LS_DOWN	Minimum coolant temperature for diagnosis of the monitor sensors; The operative readiness for the downstream sensor is activated in an early stage. If after the operative readiness a fuel cut off follows, the sensor temperature could still be low and the dynamic low. Therefore its recommended to set the temperature according to a slightly warmed up engine. I.e. 50 °C.

C_VS_MIN_DIAG_MPL_LS_DOWN	Minimum vehicle speed for diagnosis of the monitor sensor;s; There is no special reason to exclude low vehicle speed. I.e. 0 km/h.
C_VS_MAX_DIAG_MPL_LS_DOWN	Maximum vehicle speed for diagnosis of the monitor sensors. There is no special reason to exclude high vehicle speed. It must be ensured that the temperature of the downstream sensor is still in the specified range for high speed / high load operation. Check the diagnosis behaviour for very high load and speed. I.e. 255 km/h (max.).
C_TEMP_CAT_MIN_DIAG_MPL_LS_DOWN	Catalyst temperature threshold for diagnosis of the monitor sensors; See explanation for C_TCO_MIN_DIAG_MPL_LS_DOWN. I.e. 350 °C.

Monitoring the rich-lean switching times in the trailing throttle fuel cut-off

C_MAF_PUC_MIN_DIAG_SWT_LS_DOWN	Mass air flow threshold for diagnosis of the switching times; Measure the behaviour of the switching time for the lowest MAF_KGH during PUC (low engine rpm). If that is still acceptable, adjust the constant to a value slightly smaller than the smallest MAF_KGH during PUC in emission test. In case that there is a bad behaviour of the switching time, check if there are fuel cut off phases during emission test with higher MAF_KGH and select the value slightly below this higher MAF_KGH.
C_MAF_PUC_MAX_DIAG_SWT_LS_DOWN	Mass air flow threshold for diagnosis of the switching times; To inhibit the switching time diagnosis for fuel cut off phases with high engine speed. Check the behaviour of the downstream diagnosis at entry to fuel cut off at high engine speed. If there is no problem, choose a MAF_KGH which corresponds to an engine speed of i.e. 5000 rpm.
C_VLS_PUC_MIN_DIAG_SWT_LS_DOWN	Voltage threshold for monitor sensor diagnosis; Minimum VLS_DOWN to start the diagnosis at start of fuel cut off phase. Subtract approximately 50 mV from the lowest fuel trim setpoint which occurs during emission test.
C_FAC_VLS_MAX_DIAG_SWT_LS_DOWN	Reduction factor for start of switching time determination; This factor should be small to avoid an unintended start of the diagnosis, i.e. by wallfilm effects due to release of the accelerator pedal. I.e. 0,6.
C_FAC_VLS_MIN_DIAG_SWT_LS_DOWN	Reduction factor for end of switching time determination; I.e. 0,1.
C_VLS_HYS_DIAG_SWT_LS_DOWN	Monitor sensor voltage hysteresis; Measure the downstream lambda sensor voltage at entry into fuel cut off in 10 ms recurrence at low load. Check the maximum peaks which occure due to cylinder to cylinder richness deviation. Take this as hysteresis, so that the diagnosis can run even with this (small peaks).
C_CTR_SWT_DIAG_LS_DOWN	Condition for the start of the lambda sensor switching time check; Measure the number of possible diagnosis cycles during emission test and chose the constant a little smaller. The minimum number of cycles should however not fall short of 3.
C_CTR_SWT_LS_DOWN	Diagnostic threshold for CTR_CYCNR_SWT_LS_DOWN[NC_CBK_EX_NR]; The map IP_FAC_CYCNR_MAX_LS_DOWN_ACT can be calculated in a way, that the failure threshold can be set to 1.

IP_FAC_CYCNR_MAX_LS_DOWN_ACT	Weighting factor for CTR_SWT_ACT_LS_DOWN[NC_CBK_EX_NR] Measure the standard switching time for a new sensor for different MAF_KGH. Take oxygen sensors with small wholes in the protection tube and equipp the vehicle with a limit catalyst which must be detected as malfunctioning. The oxygen sensor which is too slow for a good catalyst diagnosis result can be chosen as limit sensor. Measure the switching time for this sensor for different MAF_KGH. Adjust the map that the limit sensor results in a diagnosis result of 1.

Monitoring the sensor voltage after leaving trailing throttle fuel cut-off

C_MAF_INT_PUC_DIAG_PUE_LS_DOWN	Threshold for activation of the diagnosis; The duration of the fuel cut off phase must be long enough to ensure the fuel cut off voltage level of 0,00 V. Otherwise the increase of VLS_DOWN after end of PUC would not be detected and a failure is entered. Check this with a new catalyst.
C_VLS_DIF_MIN_DIAG_PUE_LS_DOWN	Threshold for VLS_DIF_DIAG_PUE_LS_DOWN[NC_CBK_EX_NR]; Measure the standard voltage right after PUC (after the first movement of the downstream sensor which comes immediately after reactivation of injection). Chose a value in the middle between this voltage and 0 V.
C_MAF_INT_DIAG_PUE_LS_DOWN	Threshold for start of the diagnosis; Take a new catalyst system (not green but with maximum O2 load capacity). Measure the MAF integral which is required for the limit slow Oxygen Sensor (see switching time diagnosis) to reach the first voltage plateau right after reactivation of injection. Multiply this with a safety factor of i.e. 2 or more (the smaller the MAF integral, the higher the safety factor must be). If the switching time diagnosis is activated as well an the fuel trim diagnosis is calibrated well, the MAF integral can be chosen much higher. In this case, the PUE diagnosis covers only the detection of a stuck sensor (this symptome would also be detected by fuel trim diagnosis later on depending on driving style).
C_CTR_SYM_INC_DIAG_PUE_LS_DOWN	Counter increment for PUE_VLS_DOWN diagnosis; Statistical evaluation, i.e. 1.
C_CTR_SYM_MAX_DIAG_PUE_LS_DOWN	Maximum value of counter for PUE_VLS_DOWN diagnosis; Statistical evaluation, i.e. 2. That means that in case of 2 malfunction events out of 3 diagnosis cycles, an error is entered.
C_CTR_END_DIAG_PUE_LS_DOWN	Counter threshold for CTR_END_DIAG_PUE_LS_DOWN_[NC_CBK_EX_NR]; Measure the number of possible diagnosis cycles during emission test and chose the constant a little smaller. The minimum number of cycles should however not fall short of 3.

16.88 O2 sensor (lin, up) dynamic diagnosis after NOx cat regeneration

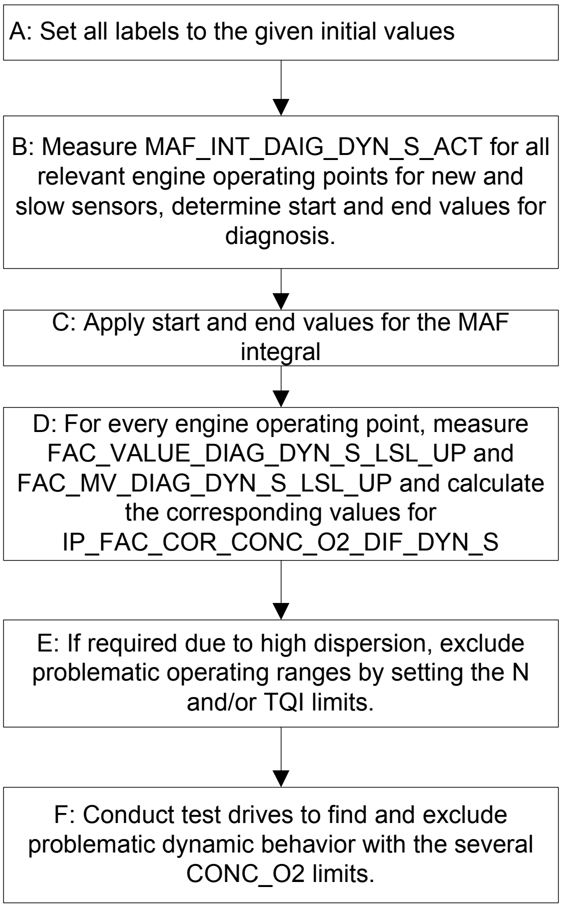
16.88.1 Calibration interfering functions

The following functions must be working before the operability detection can be calibrated:

- Intake manifold model
- lambda setpoint determination, including sensor model, coordination of lambda setpoint requests and lambda calculation for stratified combustion
- Engine operation functions, including combustion management
- NOx trap regeneration strategy
- Lambda sensor must be working and signal acquisition and correction must be fully calibrated.

16.88.2 Calibration flowchart

The following steps should be executed in the order shown:



16.88.3 Calibration method

16.88.3.1 Resources

Slow dynamics sensors are required, both a "good" limit sample and a "bad" sample. For calibration of MAF integral limits and correction maps, an engine or chassis dyno is required. Calibration of constraints should be done on the road with dynamic driving patterns.

16.88.3.2 Data overview (Step A)

The following table gives an overview of the data values. Initial data should be applied before calibration is started, they make sure that the diagnosis is not disabled by any means and that the required data can be recorded. The data will be changed during the calibration process.

Label	Initial value	Expected range
C_CONC_O2_CLC_DEC_MAX_DYN_S	1	<0.02
C_CONC_O2_CLC_HOM_MAX_DYN_S	1	<0.05
C_CONC_O2_CLC_MIN_DIAG_DYN_S	0	>0.05
C_CONC_O2_DIF_MAX_DIAG_DYN_S	1	<0.06
C_CONC_O2_DIF_ST_MAX_DIAG_DYN_S	1	<0.05
C_CRLC_CONC_O2_CLC_LPF_DYN_S	0.1	0.01...0.2
C_CTR_DIAG_DYN_S_LSL_UP	5	1...10
C_FAC_CONC_O2_COR_DIAG_DYN_S	1	0.9...1.1
C_FAC_DIAG_DYN_S_LSL_UP_MAX	127.996	Depends on other values and dynamic limit sensors
C_MAF_INT_ST_DIAG_DYN_S	0g	0...20g
C_MAF_INT_END_DIAG_DYN_S	1000g	20...100g
C_N_MIN_STOP_DIAG_DYN_S	0 rpm	0...1500
C_N_MAX_STOP_DIAG_DYN_S	8160 rpm	- in stratified combustion range -
C_TQI_MIN_DIAG_DYN_S	0 Nm	>0
C_TQI_MAX_DIAG_DYN_S	1000 Nm	- in stratified combustion range -
LC_DIAG_DYN_S_LSL_UP_MOD	1	Tbd
IP_FAC_COR_CONC_O2_DIF_DYN_S	0.03	0.01...0.3, depending on the MAF integral thresholds

16.88.3.3 Calibration of MAF integral thresholds (Step B/C)

Measure MAF_INT_DIAG_DYN_S_ACT[i], CONC_O2_CLC_DIAG_DYN_S[i] and CONC_O2_MES_DIAG_DYN_S[i] for the several engine operating points for both slow and fast sensors. After a regeneration phase, the CONC_O2 values will rise more or less slowly from around 0 to the steady state for stratified combustion.

C_MAF_INT_ST_DIAG_DYN_S	**Set to a MAF_INT_DIAG_DYN_S_ACT value where the CONC_O2_MES_DIAG_DYN_S value for a new sensor has (almost) reached its steady state for all relevant operating points. Setting this too low will increase dispersion for good sensors.**

C_MAF_INT_END_DIAG_DYN_S	**Set a bit lower than the lowest MAF_INT_DIAG_DYN_S_ACT value for which the CONC_O2_MES_DIAG_DYN_S value for a bad sensor has reached its steady state value for any operating point. Setting this too high will increase the influence of slight gain errors in the lambda sensor or in the realization of the fuel mass set point.**

16.88.3.4 Calibration of the weighting map and diagnostic limit (Step D/E)

LC_DIAG_DYN_S_LSL_UP_MOD is used to select one of two methods to calculate the diagnostic result. If set to 1, the diagnostic value more or less resembles the T1 constant of the PT1 behavior of the sensor, but the dispersion may be high for slow sensors. If set to 0, the value is more stable. If the flag is altered, all subsequent steps must be repeated.

For every operating point and with the bad sensor, clear the error memory and let the engine run until LV_DIAG_DYN_S_LSL_UP_END = 1 is reached. Record CONC_O2_DIF_INT_DIAG_DYN_S, FAC_VALUE_DIAG_DYN_S_LSL_UP and FAC_MV_DIAG_DYN_S_LSL_UP. If CONC_O2_DIF_INT_DIAG_DYN_S hits its limit, lower the initial values in the weighting map and start over.
If FAC_VALUE_DIAG_DYN_S_LSL_UP shows high dispersion already on the engine or chassis dyno, the corresponding operating points should be excluded via C_N_MIN/MAX_STOP_DIAG_DYN_S and C_TQI_MIN/MAX_DIAG_DYN_S. The diagnosis should also be blocked in the homogenous stratified combustion range, because the axes for the weighting map are N_32 and MAF_CYL and they uniquely describe an operating point only in one combustion mode.

After collecting the data, calculate the correct factors for the weighting map: Select a target diagnostic value X for the bad sensor and calculate the values from the current IP_FAC_COR_CONCO2_DIF_DYN_S$_{\mathrm{old}}$ values as

$$\mathrm{IP\_FAC\_COR\_CONC\_O2\_DIF\_DYN\_S}_{\mathrm{new}} = \frac{X \cdot \mathrm{IP\_FAC\_COR\_CONC\_O2\_DIF\_DYN\_S}_{\mathrm{old}}}{\mathrm{FAC\_MV\_DIAG\_DYN\_S\_LSL\_UP}_{\mathrm{old}}}$$

$$\mathrm{IP\_FAC\_COR\_CONC\_O2\_DIF\_DYN\_S}_{\mathrm{old}} \cdot \frac{\mathrm{CONC\_O2\_DIF\_INT\_DIAG\_DYN\_S}_{\mathrm{lim}}}{\mathrm{CONC\_O2\_DIF\_INT\_DIAG\_DYN\_S}_{\mathrm{old}}}$$

but make sure that the factor is not higher than
with CONC_O2_DIF_INT_DIAG_DYN_S$_{\mathrm{lim}}$ being the physical limit of the variable and CONC_O2_DIF_INT_DIAG_DYN_S$_{\mathrm{old}}$ the highest value found for the current operating point with the old IP value. If this limit is violated, the integrals may saturate to their physical limits for a bad sensor, giving too low diagnostic results. Select a lower target value X in this case. If there is room for a higher value, the value should be increased, as this can only improve accuracy.

The diagnostic limit C_FAC_DIAG_DYN_S_LSL_UP_MAX should be a bit lower than the target X to make sure that bad sensors are detected reliably.

16.88.3.5 Calibration of engine dynamics constraints (Step F)

The integrals in the diagnosis may take a few seconds for low engine loads. If the load changes rapidly while the integral runs, the result may be wrong. The following labels are available to block or abort the diagnosis in such conditions:

C_CONC_O2_CLC_DEC_MAX_DYN_S	Detects too high gradients in engine load, which in stratified mode usually lead to a rapid decrease in O_2 concentration and thus violate this limit.
C_CONC_O2_CLC_HOM_MAX_DYN_S	Maximum modeled O_2 concentration in homogenous mode, useful to exclude very short homogenous phases.
C_CONC_O2_CLC_MIN_DIAG_DYN_S	Minimum for the modeled and low pass filtered O_2 concentration in stratified mode, may be used to exclude too high engine load.
C_CRLC_CONC_O2_CLC_LPF_DYN_S	Used to do low pass filtering on modeled O2 concentration for the above limit. Decrease the value to increase the filtering effect.
C_CONC_O2_DIF_MAX_DIAG_DYN_S	Maximum difference between measured and modeled O_2 concentration, may be used to exclude instationary conditions.
C_CONC_O2_DIF_ST_MAX_DIAG_DYN_S	Same as above, but for the moment of homogenous-to-stratified transition, useful to exclude homogenous phases that are too short for slow sensors.
C_CTR_DIAG_DYN_S_LSL_UP	Minimum number of samples in average. Must reliably fit into the test driving cycle, but must be high enough to sufficiently reduce dispersion.
C_FAC_CONC_O2_COR_DIAG_DYN_S	May be set >1 to reduce the diagnostic value for good sensors and improve differentiation between good and bad sensors

16.89 O_2 sensor heater management

16.89.1 Upstream oxygen sensor heater management

16.89.1.1 Calibration interfering functions

16.89.1.1.1 Before start of the calibration of the upstream oxygen sensor heater management, following other functions must be calibrated:

- Basic engine tuning (ignition, basic injection, torque model, variable valve timing)
- Intake manifold model (MAP/MAF system)
- Exhaust gas temperature model and dew point recognition upstream catalyst
- Internal resistance determination (oxygen sensor temperature for linear lambda sensors)
- Signal acquisition of linear lambda sensor (controller, for linear lambda sensors only)
- Readiness detection of upstream lambda sensor
- Basic Lambda Setpoint

16.89.1.1.2 Before calibration of the upstream oxygen sensor heater management, the following modifications on the calibration data should be done:

Nothing.

16.89.1.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below. Parameters which are relevant for cold start may be calibrated independently on the remaining parameters for heater control and sensor protection.

Remark: If the same N_32 axis points are used for the interpolation maps IP_V_EFC_CTL_LSH_UP / IP_V_EFC_CTL_LSH_DOWN the calibration of the precontrol maps upstream and downstream can be done at the same time.

16.89.1.3 Calibration method

Calibration under cold start and hot restart conditions

The calibration shall be done in a climate chamber using a lambda sensor with tip-temperature measurement capability (TTS).

IP_V_EFC_INI_LSH_UP	Initial effective heater voltage. This map is dependent on the inital sensor temperature TEMP_INI_LS_UP[i] (differentiation between cold start and hot restart) and has main influence on the maximum temperature rise rates during POW_RISE. For calibration the following aspects are important: 1) The sensor specification for maximum intial voltage must be fulfilled.

2) Calibration with too large map entries may lead large temperature rise rates which violate the sensor specification. This has to be avoided.
3) In combination with too large map entries of IP_T_TEMP_THD_LSH_UP the maximum allowable tip temperature – if available – may exceed the specified limit before dew point recognition. This has to be avoided.
4) The data should be calibrated to achieve the lowest possible light-off time under consideration of 1-3.

The calibration should at best be done in a climate chamber in combination with TEMP_INI_LS_UP[i], IP_T_TEMP_THD_LSH_UP and C_V_EFC_INC_ LSH_UP using aTTS with strong limit heater (critical for temperature rise rates). On the other hand the lowest temperature during dew-point recognition should exceed the recommendation in the specification – if available – for weak limit heater.

IP_T_TEMP_THD_LSH_UP	Duration until critical water splash sensor temperature (typ. < 350°C, see sensor specification) reached under any conditions. Check must be done with TTS. Check on chassis dyno is not necessary. Calibration has to be done in accordance with IP_TEMP_INI_LS_UP
C_T_MAX_POW_RISE_LSH_UP	Maximum allowed time for state POW_RISE. Calibration has to be done with TTS. Under all conditions tip temperature has to reach a minimum temperature and should not exceed the maximum operating temperature (see sensor specification for operating range of temperature). Cirtical edge is of course warm start with long heating for maximum allowed POW_RISE time. E. g. 14s.
C_V_EFC_INC_LSH_UP	Effective heater voltage increment to raise temperature. Calibration shall be done under consideration of the maximum specification value. In general a larger value may shorten light-off time but may also increase the temperature rise rate above the specified limit (thermal stress). Too large values may also lead to a violation of the maximum specified temperature threshold unitl dew-point detection. The increment of heating voltage must be determined with a TTS sensor. In general smaller values are recommended. E.g. 0.4V/s.
C_V_EFC_DEC_LSH_UP	Effective heater voltage decrement to lower temperature. Calibration shall be done under consideration of the maximum value in the sensor specification. If no value is specified the decrement can be choosen same as increment. Because of risk for high thermal stress smaller values are recommended. E.g. 0.4V/s.
C_V_EFC_RED_LSH_UP	Reduced effective heater voltage during danger of water splash damage. Calibration should be done such that the temperature is kept below the specified value (<300°C for most sensors, with safety margin). For calibration a TTS with strong limit heater is recommended. E.g. 4V. Remark: According to sensor specification it may be required that until dew point recognition the effective heater voltage does not exceed a certain level instead of a certain temperature (see LC_TEMP_DEW_LSH_UP).
C_V_EFC_STEP_LSH_UP	Additional effective heater voltage step to IP_V_EFC_ INI_LSH_UP on transition from LSH_POW_RED to LSH_POW_RISE. The calibration has to be done with

	TTS if the data is not specified in the sensor specification anyway. Calibration of this data has to take into account the maximum permitted temperature gradient, if it is mentioned within sensor specification. E.g. 1V.
LC_TEMP_DEW_LSH_UP	Calibration of this data equal to 1 allows to skip the initial transition of the heater state machine from LSH_OFF to LSH_POW_RISE before entering LSH_POW_RED if dew point has not been recognized yet. Setting this logical calibration data is required to fulfill component specifications where a maximum effective heater voltage before dew point recognition is demanded. In other cases in which a maximum temperature (e.g. 350°C) until dew point determination is recommended this data should be calibrated equal to 0, i.e. the state machine enters LSH_POW_RISE after engine start in any case.

Calibration of lambda sensor heater control

The calibration shall be done on a chassis dyno. For binary lambda sensors the tip-temperature should be measured using a sensor with temperature measurement capability (TTS) or by evaluating the results of the internal resistance determination. For linear lambda sensors, the most accurate tip temperature is the one measured from the system; therefore it is best to rely on this temperature. After calibration the results should be checked under real conditions on road because of possible heat accumulation on chassis dyno.

IP_V_EFC_CTL_LSH_UP	Open loop control effective heater voltage. The map entries can be determined best on chassis dyno, as it is very sensible to geometry of the exhaust gas system. For each load as characterized by exhaust gas temperature and engine speed the necessary heating voltage to reach the setpoint temperature has to be determined. Cooling of the fan should be adjusted to medium level. If the system has two exhaust gas banks which differ in geometry just focus on bank 1 for calibration. For bank 2 see IP_FAC_V_EFC_TEG_ LSH_UP. For linear lambda sensor set the setpoint and observe the additive part of the lambda sensor heater power (V_EFC_CTL_ADD_LSH_UP[i]). Adjust IP_V_EFC_ CTL_LSH_UP according to an additive part of 0 V. The TTS Sensor measures up to 80 °C lower temperature than the measurement through the ECU. It is mainly useful for preheating. For binary sensors the setpoint temperature can be controlled by two ways: either by using a TTS or by evaluation of the determined internal resistance values and the corresponding conversion to element temperature (see engineering specification). For set-point temperature please refer to engineering specification. E.g. 650°C.
IP_FAC_V_EFC_TEG_LSH_UP	Factor for the heat transfer rate, bank 2 only. This interpolation map reflects the difference in geometry between the exhaust gas banks due to, e.g., different cooling by airstream. Tests are done best on road (highway etc.)

C_V_EFC_AS_LSH_UP	Effective heater voltage calibration system additive constant. This data shall only be used for application purposes and provides the opportunity for global change of heater voltage. Default value: 0V.
C_FAC_V_EFC_AS_LSH_UP	Multiplicative correction factor to effective heater voltage. Calibration data only for application system purposes, e.g. check system reaction on heater deactivation without leaving state LSH_POW_CTL. Default value: 1.

The following calibration is relevant only for a system with linear sensor upstream and binary sensor downstream.

LC_LSH_CTL_CLL_INH_LSH _UP[NC_CBK_EX_NR]	Boolean constant to permit suspension of closed loop heater control. It should be set = 1 for binary sensors (no closed loop control recommended). For system configurations with linear oxygen sensor upstream LC_LSH_CTL_CLL_INH_LSH_UP[i] = 0
C_TTIP_SP_LS_UP[NC_CBK_EX _NR]	Oxygen sensor set temperature for closed loop control. For calibration see data of sensor specification (best working point).
C_TTIP_DIF_MIN_CTL_P_LS_UP	Minimum required temperature difference in order to calculate P term of controller. If the closed cloop heater control is required to act also on small deviations between measured and set-point temperature this data shall be set to small values, e.g. 0°C.
C_FAC_CTL_P_LSH_UP	Multiplicative scaling factor for closed loop P-term. For common approach this data shall be set close to 1 and the calculation of the P share be achieved by calibration of the corresponding maps IP_FAC_POS_CTL_P LSH_UP and IP_FAC_NEG_CTL_P_LSH_UP. E.g. 1.
C_FAC_CTL_I_LSH_UP	Multiplicative scaling factor for closed loop I-term. For common approach this data shall be set close to 1 and the calculation of the I share be achieved by calibration of the corresponding maps IP_FAC_POS_CTL_I_ LSH_UP and IP_FAC_NEG_CTL_I_LSH_UP. E.g. 1.
IP_FAC_NEG_CTL_P_LSH_UP	Closed loop controller P-term factor for temperature too high; decrease heater voltage. The map values shall be calibrated such that the conroller may react sufficiently on steps of load and revolution number, i.e. to keep temperature fluctuations smaller than 15-20°C without tendency to temperature oscillations. As the dependence on revolution number and exhaust gas temperature is small the same values may be used for all map entries. A pragmatic way to calibrate the p-share would be first to find a certain p-value for a given load point where the temperature oscillates with constant amplitude while I controller is deactivated via corresponding map. This p-share value shall then multiplied by 0.45 and used as final calibration value (Ziegler-Nichols-method). E.g. 0.12V/K.
IP_FAC_POS_CTL_P_LSH_UP	Closed loop controller P-term factor for temperature too low; increase heater voltage. See IP_FAC_NEG_CTL_P_LSH_UP.

IP_FAC_NEG_CTL_I_LSH_UP	Closed loop controller I-term factor for temperature too high; decrease heater voltage. Calibration shall be done after IP_FAC_NEG_CTL_P_LSH_UP has been calibrated properly. An empirical way would be to start with high I-shares with the system in oscillating condition. As next step the I-share shall reduced sufficiently until the oscillations disappear. E.g. 0.002 V/K.
IP_FAC_POS_CTL_I_LSH_UP	Closed loop controller I-term factor for temperature too low; increase heater voltage. See IP_FAC_NEG_CTL_I_LSH_UP.
ID_TTIP_SP_DIF_LSH_UP	Time dependent reduction factor for TTIP threshold of transition conditions LSH_POW_RISE to LSH_POW_CTL. This calibration data facilitates the transition from state LSH_POW_RISE to LSH_POW_CTL step-wize when subtracted from C_TTIP_SP_LS_UP. The aim is to provide the activation condition for start of the OBDII heater diagnosis before forced operative readiness is set. Calibration should be done such that the TTIP setpoint difference C_TTIP_SP_LS_UP - C_TTIP_MIN_LS_UP _READY amounts to 0°C short before the time when T_TOUT_LS_UP_READY[i] for setting of forced readiness has expired (e.g. 118s). This means, e.g. for C_TTIP_SP_LS_UP = 780°C and C_TTIP_MIN_LS_UP = 610°C, the maximum map entry at 118s should be chosen as 170°C. The lowest map entry for 0s may be chosen same as C_TTIP_SP_LS_UP. The map values between lowest and largest time may be evenly spread over the whole range. This also holds for the time axis.

Calibration data referring to sensor protection

The calibration shall be done in a climate chamber using a lambda sensor with tip-temperature measurement capability (TTS).

C_V_EFC_MAX_LSH_UP	Maximum effective voltage the heater is allowed to run. For calibration see data of sensor specification (long run). Additionally the voltage drop of electrical wiring which has to be determined for each system individually shall be considered. E.g. 13.6V.
C_V_EFC_MAX_ST_LSH_UP	Maximum effective voltage at which the heater is allowed to run in the first start phase. For calibration see data of sensor specification (start phase), e.g. 10V. The variable belongs to C_T_MAX_V_EFC_MAX_ST_LSH_UP.
C_T_MAX_V_EFC_MAX_ST_LSH_UP	Primary corresponding timer threshold to C_V_EFC_MAX_ST_LSH_UP, e.g. 10s. For calibration see sensor specification (start phase).
C_T_AST_MAX_LSH_UP	Secondary corresponding timer threshold to C_V_EFC_MAX_ST_LSH_UP. Intention is a back up, if heater state POW_CTL is reached very early e.g. due to warm sensor. For calibration see sensor specification (start phase) and usual time to reach state POW_CTL including safety margin. e.g. 60s
C_V_EFC_TOL_LSH_UP	Effective heater voltage threshold above which the voltage may be limited if the threshold is exceeded persistently. For calibration see sensor specification, e.g. 13.4V.

C_T_MAX_V_EFC_TOL_LSH_UP	Maximum permitted duration where excessive heater voltage is tolerated for short-term, e.g. 10s. For calibration see sensor specification. This data refers to the voltage threshold C_V_EFC_TOL_LSH_UP.
C_V_EFC_LIM_LSH_UP	Voltage to which the effective heater voltage is limited if the heater voltage exceeds the threshold C_V_EFC_TOL_LSH_UP for longer than C_T_MAX_V_EFC_TOL_LSH_UP. For calibration see sensor specification, e.g. 12.8V. (Remark: may in some cases be choosen same as C_V_EFC_TOL_LSH_UP)
C_T_MAX_V_EFC_LIM_LSH_UP	Maximum duration while heater voltage limited to C_V_EFC_LIM_LSH_UP, e.g. 20s. For calibration see sensor specification.
C_TEG_DYN_MAX_LSH_UP	Maximum permitted exhaust gas temperature above which LSH is switched off. If exhaust gas temperature exceeds this threshold overheating may occur, therefore heating shall no more be allowed; see data of sensor specification for maximum exhaust gas temperature. For very high exhaust gas temperatures the ceramic temperature determination may run out of the sensible range. Therefore a check with TTS is recommended. E.g. 950°C
C_VB_MAX_PROT_LSH_UP	Maximum voltage at which the heater is allowed to run. This data refers to battery voltage VB and not to effective heater voltage. For calibration see data of sensor specification, e.g. 16.5V
C_V_EFC_PROT_VB_LSH_UP	Effective voltage at which the heater is allowed to run even with VB exceeding C_VB_MAX_PROT_LSH_UP. This means that the actual battery voltage is applied to the heater with the frequency of the heater control. For calibration see data of sensor specification, as safety calibration this data should be chosen as 0V.

Activation and calibration of forced lambda sensor heating before engine start

The following calibration data section is relevant only for cases in which the lambda sensor heater shall be switched on before engine start for application purpose in order to get a valid lambda signal (for linear sensor) or lambda sensor voltage (binary sensor) at engine start. If possible the calibration should be done once using a TTS (see above).

It shall be emphasized that during this procedure the dew point recognition as lambda sensor safety mechanism is disabled. Therefore a high risk for lambda sensor damage due to water splash is present (see also meaning of C_V_EFC_RED_LSH_UP). This feature is for application purpose only !

LC_LSH_UP_MAN_ACT[NC_CBK_EX_NR]	Setting this calibration data activates the initiation of lambda sensor forced heating before engine start without awaiting dew point recognition. Its activation is triggered by the transition of LC_LSH_UP_MAN_ACT[i] = 0 => 1 and can thus not be activated w/o application system for safety reasons. The activated forced heating is indicated by LV_LSH_UP_ MAN_ACT[i] which can be used as interface for other functions. HIGH RISK FOR SENSOR DAMAGE !!!
C_V_EFC_INI_LSH_UP_MAN_ACT	Initial effective heater voltage when forced lambda

	sensor heating before engine start is required. This data should be calibrated such that the temperature rising rate does not exceed the specified limits in order to prevent additional risk for sensor damage, e.g. 6V.
C_V_EFC_MAX_LSH_UP_MAN_ ACT	Absolute maximum permitted effective heater voltage during forced heating before engine start. Calibration should be done such that during the initial voltage rising phase the effective heater voltage does not take excessive values which may lead to overheating (additional risk for sensor damage should be avoided). E.g.: 12V
C_FAC_V_EFC_LSH_UP_MAN_ ACT	Factor which allows to reduce the effective heater voltage of the open loop value during POW_CTL as derived from IP_V_EFC_CTL_LSH_UP. Background is that during forced heating before engine start no lambda sensor cooling due to forced convection by cold exhaust gas is present. Therefore the heater voltage shall be reduced to prevent the sensor from overheating in order to avoid additional risk for sensor damage; e.g. 0.8.
C_T_MAX_CDN_LSH_UP_ MAN_ACT	Time threshold for transition from state POW_RISE to POW_CTL with activated forced heating before engine start. This calibration should be done such that the lambda sensor has sufficient time to reach nominal operating temperature before switching to open loop control in POW_CTL, e.g. 20s. When this time has passed and after an additional time span of a couple of seconds (e.g. 10s, in order to await stable temperature conditions) the lambda sensor may be considered as ready for signal acquisition at engine start or 2-4 sec after engine start for binary / linear lambda sensors, respectively.

16.89.2 Downstream oxygen sensor heater management

16.89.2.1 Calibration interfering functions

16.89.2.1.1 Before start of the calibration of the downstream oxygen sensor heater management, following other functions must be calibrated:

- Basic engine tuning (ignition, basic injection, torque model, variable valve timing)
- Intake manifold model (MAP/MAF system)
- Internal resistance determination
- Exhaust gas temperature model and dew point recognition downstream catalyst
- Readiness detection of downstream lambda sensor

16.89.2.1.2 Before calibration of the downostream oxygen sensor heater management, the following modifications on the calibration data should be done:

Nothing.

16.89.2.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below. Parameters which are relevant for cold start may be calibrated independently on the remaining parameters for heater control and sensor protection.

Remark: If the same N_32 axis points are used for the interpolation maps IP_V_EFC_CTL_LSH_UP / IP_V_EFC_CTL_LSH_DOWN the calibration of the precontrol maps upstream and downstream can be done at the same time.

16.89.2.3 Calibration method

Calibration under cold start and hot restart conditions

The calibration shall be done in a climate chamber using a lambda sensor with tip-temperature measurement capability (TTS).

IP_V_EFC_INI_LSH_DOWN	Initial effective heater voltage. This map is dependent on the inital sensor temperature TEMP_INI_LS_DOWN[i] (differentiation between cold start and hot restart) and has main influence on the maximum temperature rise rates during POW_RISE. For calibration the following aspects are important: 1) The sensor specification for maximum intial voltage must be fulfilled. 2) Calibration with too large map entries may lead large temperature rise rates which violate the sensor specification. This has to be avoided. 3) In combination with too large map entries of IP_T_TEMP_THD_LSH_DOWN the maximum allowable tip temperature may exceed the specified limit – if available – before dew point recognition.

This has to be avoided.

4) The data should be calibrated to achieve the lowest possible light-off time under consideration of 1-3.

The calibration should at best be done in a climate chamber in combination with TEMP_INI_LS_DOWN[i], IP_T_TEMP_THD_LSH_DOWN and C_V_EFC_INC_LSH_DOWN using aTTS with strong limit heater (critical for temperature rise rates). On the other hand the lowest temperature during dew-point recognition should exceed the recommended value in the specification – if available – for weak limit heater.

IP_T_TEMP_THD_LSH_DOWN	Duration until critical water splash sensor temperature (typ. < 300°C, see sensor specification) reached under any conditions. Check must be done with TTS. Check on chassis dyno is not necessary. Calibration has to be done in accordance with IP_TEMP_INI_LS_DOWN.
C_T_MAX_POW_RISE_LSH_DOWN	Maximum allowed time for state POW_RISE. Calibration has to be done with TTS. Under all conditions tip temperature has to reach a minimum temperature and should not exceed the maximum operating temperature (see sensor specification for operating range of temperature). Cirtical edge is of course warm start with long heating for maximum allowed POW_RISE time. E. g. 14s.
C_V_EFC_INC_LSH_DOWN	Effective heater voltage increment to raise temperature. Calibration shall be done under consideration of the maximum specification value. In general a larger value may shorten light-off time but may also increase the temperature rise rate above the specified limit (thermal stress). Too large values may also lead to a violation of the maximum specified temperature threshold unitl dew-point detection. The increment of heating voltage should be determined with a TTS sensor. In general smaller values are recommended. E.g. 0.4V/s.
C_V_EFC_DEC_LSH_DOWN	Effective heater voltage decrement to lower temperature. Calibration shall be done under consideration of the maximum value in the sensor specification. If no value is specified the decrement can be choosen same as increment. Because of risk for high thermal stress smaller values are recommended. E.g. 0.4V/s.
C_V_EFC_RED_LSH_DOWN	Reduced effective heater voltage during danger of water splash damage. Calibration should be done such that the temperature is kept below the specified value (<300°C for most sensors, with safety margin) or that the heater voltage does not exceed a specified limit. For calibration a TTS with strong limit heater is recommended. E.g. 4V.
C_V_EFC_STEP_LSH_DOWN	Additional effective heater voltage step to IP_V_EFC_INI_LSH_DOWN on transition from LSH_POW_RED to LSH_POW_RISE. The calibration has to be done with TTS if the data is not specified in the sensor specification anyway. Calibration of this data has to take into account the maximum permitted temperature gradient, if it is mentioned within sensor specification. E.g. 1V.

Calibration of lambda sensor heater control

The calibration shall be done on a chassis dyno. The tip-temperature should be measured using a sensor with temperature measurement capability (TTS) or by evaluating the results of the internal resistance determination. After calibration the results should be checked under real conditions on road because of possible heat accumulation on chassis dyno.

IP_V_EFC_CTL_LSH_DOWN	Open loop control effective heater voltage. The map entries can be determined best on chassis dyno, as it is very sensible to geometry of the exhaust gas system. For each load as characterized by exhaust gas temperature and engine speed the necessary heating voltage to reach the setpoint temperature has to be determined. The setpoint temperature can be controlled by two ways: either by using a TTS or by evaluation of the determined internal resistance values and the corresponding conversion to element temperature (see engineering specification). Cooling of the fan should be adjusted to medium level. If the system has two exhaust gas banks which differ in geometry just focus on bank 1 for calibration. For bank 2 see IP_FAC_V_EFC_TEG_ LSH_DOWN. For set-point temperature please refer to engineering specification. E.g. 650°C.
IP_FAC_V_EFC_TEG_LSH_DOWN	Factor for the heat transfer rate, bank 2 only. This interpolation map reflects the difference in geometry between the exhaust gas banks due to, e.g., different cooling by airstream. Tests are done best on road (highway etc.)
C_V_EFC_AS_LSH_DOWN	Effective heater voltage calibration system additive constant. This data shall only be used for application purposes and provides the opportunity for global change of heater voltage. Default value: 0V.
C_FAC_V_EFC_AS_LSH_DOWN	Multiplicative correction factor to effective heater voltage. Calibration data only for application system purposes, e.g. check system reaction on heater deactivation without leaving state LSH_POW_CTL. Default value: 1.

Calibration data referring to sensor protection

The calibration shall be done in a climate chamber using a lambda sensor with tip-temperature measurement capability (TTS).

C_V_EFC_MAX_LSH_DOWN	Maximum effective voltage the heater is allowed to run. For calibration see data of sensor specification (long run). Additionally the voltage drop of electrical wiring which has to be determined for each system individually shall be considered. E.g. 13.6V.
C_V_EFC_MAX_ST_LSH_DOWN	Maximum effective voltage at which the heater is allowed to run in the first start phase. For calibration see data of sensor specification (start phase), e.g. 10V. The variable belongs to C_T_MAX_V_EFC_MAX_ST_LSH_DOWN.
C_T_MAX_V_EFC_MAX_ST_LSH_DOWN	Primary corresponding timer threshold to C_V_EFC_MAX_ST_LSH_DOWN, e.g. 10s. For calibration see sensor specification (start phase).
C_T_AST_MAX_LSH_DOWN	Secondary corresponding timer threshold to C_V_EFC_MAX_ST_LSH_DOWN. Intention is a back up, if heater state POW_CTL is reached very early e.g. due to warm sensor. For calibration see sensor

	specification (start phase) and usual time to reach state POW_CTL including safety margin. e.g. 60s
C_V_EFC_TOL_LSH_DOWN	Effective heater voltage threshold above which the voltage may be limited if the threshold is exceeded persistently. For calibration see sensor specification, e.g. 13.4V.
C_T_MAX_V_EFC_TOL_LSH_DOWN	Maximum permitted duration where excessive heater voltage is tolerated for short-term, e.g. 10s. For calibration see sensor specification. This data refers to the voltage threshold C_V_EFC_TOL_LSH_DOWN.
C_V_EFC_LIM_LSH_DOWN	Voltage to which the effective heater voltage is limited if the heater voltage exceeds the threshold C_V_EFC_TOL_LSH_DOWN for longer than C_T_MAX_V_EFC_TOL_LSH_DOWN. For calibration see sensor specification, e.g. 12.8V. (Remark: may in some cases be choosen same as C_V_EFC_TOL_LSH_DOWN)
C_T_MAX_V_EFC_LIM_LSH_DOWN	Maximum duration while heater voltage limited to C_V_EFC_LIM_LSH_DOWN, e.g. 20s. For calibration see sensor specification.
C_TEG_DYN_MAX_LSH_DOWN	Maximum permitted exhaust gas temperature above which LSH is switched off. If exhaust gas temperature exceeds this threshold overheating may occur, therefore heating shall no more be allowed; see data of sensor specification for maximum exhaust gas temperature. For very high exhaust gas temperatures the ceramic temperature determination may run out of the sensible range. Therefore a check with TTS is recommended. E.g. 950°C
C_VB_MAX_PROT_LSH_DOWN	Maximum voltage at which the heater is allowed to run. This data refers to battery voltage VB and not to effective heater voltage. For calibration see data of sensor specification, e.g. 16.5V
C_V_EFC_PROT_VB_LSH_DOWN	Effective voltage at which the heater is allowed to run even with VB exceeding C_VB_MAX_PROT_LSH_DOWN. This means that the actual battery voltage is applied to the heater with the frequency of the heater control. For calibration see data of sensor specification, as safety calibration this data should be chosen as 0V.

16.90 Upstream oxygen sensor heater OBDI diagnosis

16.90.1 General Informations

This calibration hint refers to the following specification: A01M

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements. The error detection is effected via the ECU hardware and is able to detect short circuit to battery voltage, short circuit to ground and open circuit.

16.90.1.1 Requirements

- The calibration shall be carried out with a common oxygen sensor.
- Additionally a break-out box is necessary to simulate the three possible electrical circuit faults
- A standard application system performing online variable recording with a minimum sample rate of 100 ms is required.

16.90.2 General calibration hint

16.90.2.1 Calibration interfering functions

- functionalities which have to be calibrated and running well in advance:
  - ❖ exhaust gas temperature model

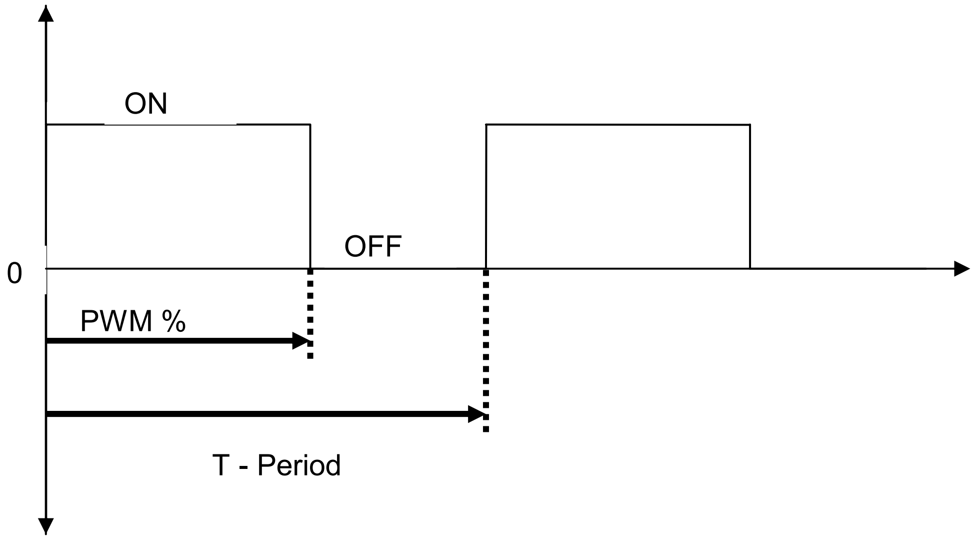
16.90.3 Calibration method

16.90.3.1 Calculation of LSHPWM limits

The upper and lower limits for the PWM thresholds (C_LSHPWM_MAX_DIAG_LSH_UP and C_LSHPWM_MIN_DIAG_LSH_UP) are dependent on the filter time of the heater driver and the PWM frequency used. For calibration the heater driver PWM frequency needs to be known.

Typically the filter time of the heater driver for the recognition

- of a short circuit to battery (SCB) is 0,05 ms (min. ON).
- of a short circuit to ground (SCG) is 0,25 ms (min. OFF).
- of open circuit (OC) is 0,40 ms (min. ON).



As an example a PWM frequency of 10 Hz is used which leads to a period of 100 ms.

C_LSHPWM_MIN_DIAG_LSH_UP	is the minimum permitted heater effective voltage PWM for upstream LSH OBD1 diagnosis. In order for an OC to be recognised, the heater driver must remain on for at least 0,4 ms. Hence this represents (100% * 0,40 ms / 100 ms) PWM = 0.4 %. As the PWM resolution is 0.3891 %, this value is chosen for the calibration constant. Additionally the calibration data C_LSHPWM_MIN_DIAG_LSH_UP must be lower or equal to NC_LSHPWM_BOL_LSH_UP.
C_LSHPWM_MAX_DIAG_LSH_UP	is the maximum permitted heater effective voltage PWM for upstream LSH OBD1 diagnosis. In order for a SCG to be recognised, the heater driver must remain off for at least 0,25 ms. Hence this represents (100% * (1- (0,25 ms / 100 ms))) PWM = 99.75 %. As the PWM resolution is 0.3891 %, 100.00 – 0.39 = 99.61 % value is chosen for the calibration constant. Additionally the calibration constant C_LSHPWM_MAX_DIAG_LSH_UP must be higer or equal to NC_LSHPWM_TOL_LSH_UP.

16.90.3.2 Calculation of exhaust gas temperature limit

C_TEG_DYN_MIN_DIAG_LSH_UP	is the minimum exhaust gas temperature threshold to permit SCB fault to be set during LSH preheating state. This constant shall be calibrated such that the exhaust gas temperature is sufficiently warm to heat the sensor to a temperature where no heater inrush current exceeding the driver over-current threshold (typ. 8 A) occurs. The inrush current transient will only occur in the initial few seconds of heating (1 to 5 seconds) and is dependent on the sensor type and environmental conditions.

16.90.3.3 Calibration data for error debouncing

C_ABC_INC_DIAG_LSH_UP	is the anti-bounce counter increment for upstream O2-sensor heater diagnosis. This constant shall be calibrated according to project philosophy. As a first hint the increment may be set to 1.

C_ABC_MAX_DIAG_LSH_UP	is the maximum value of the anti-bounce counter for upstream O2-sensor heater diagnosis. After having reached this number the error flag is being set. The constant shall be calibrated according to project philosophy. As a first hint C_ABC_MAX_DIAG_LSH_UP may be set to 50 which means that using a recurrence of 0,1 s the diagnosis will be finished after 5 s after the activation conditions have been met and the fault being present. Additionally this number should not be chosen too large since several OBD II functions are intented to start after the electrical diagnosis has finished and LV_END_DIAG_LSH_UP is set, e.g. the heater OBD II diagnosis.

16.90.4 Validation

The validation is done using a break-out box to simulate the possible electrical faults. Attention shall be paid to the SCG test connecting the heater cabling to ground since in case of a short in the battery – lambda sensor connection a fuse will blow and in case of a lambda sensor - µ-controller short cut the lambda sensor may overheat without the safety precautions being able to disrupt.

16.91 Downstream oxygen sensor heater OBDI diagnosis

16.91.1 General Informations

This calibration hint refers to the following specifications: A01N

The purpose of the diagnosis shall be to detect electrical faults within the oxygen sensor heater circuit as defined by OBD I requirements. The error detection is effected via the ECU hardware and is able to detect short circuit to battery voltage, short circuit to ground and open circuit.

16.91.1.1 Requirements

- The calibration shall be carried out with a common oxygen sensor.
- Additionally a break-out box is necessary to simulate the three possible electrical circuit faults
- A standard application system performing online variable recording with a minimum sample rate of 100 ms is required.

16.91.2 General calibration hint

16.91.2.1 Calibration interfering functions

- functionalities which have to be calibrated and running well in advance:
    - ❖ exhaust gas temperature model

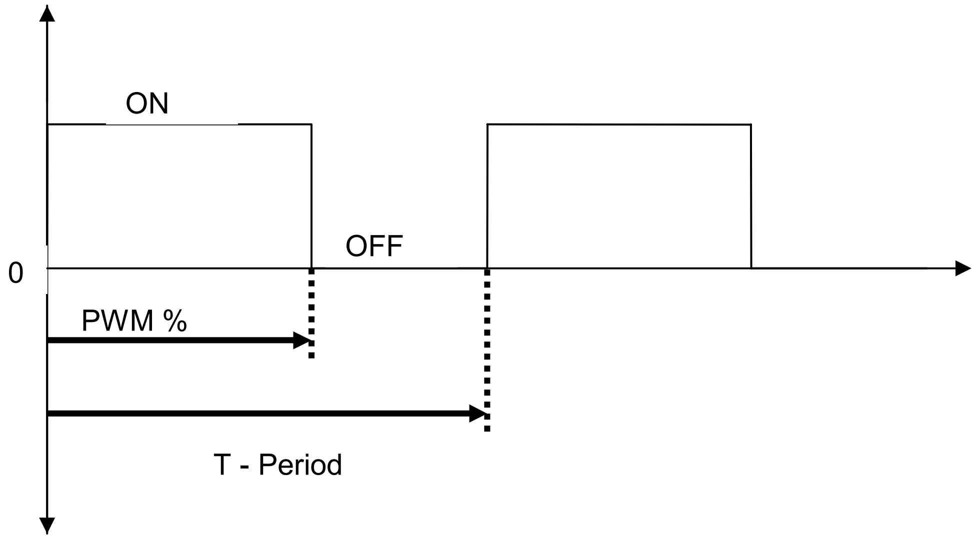
16.91.3 Calibration method

16.91.3.1 Calculation of LSHPWM limits

The upper and lower limits for the PWM thresholds (C_LSHPWM_MAX_DIAG_LSH_DOWN and C_LSHPWM_MIN_DIAG_LSH_DOWN) are dependent on the filter time of the heater driver and the PWM frequency used. For calibration the heater driver PWM frequency needs to be known.

Typically the filter time of the heater driver for the recognition

- of a short circuit to battery (SCB) is 0,05 ms (min. ON).
- of a short circuit to ground (SCG) is 0,25 ms (min. OFF).
- of open circuit (OC) is 0,40 ms (min. ON).



As an example a PWM frequency of 10 Hz is used which leads to a period of 100 ms.

C_LSHPWM_MIN_DIAG_LSH_DOWN	is the minimum permitted heater effective voltage PWM for upstream LSH OBD1 diagnosis. In order for an OC to be recognised, the heater driver must remain on for at least 0,4 ms. Hence this represents (100% * 0,40 ms / 100 ms) PWM = 0.4 %. As the PWM resolution is 0.3891 %, this value is chosen for the calibration constant. Additionally the calibration data C_LSHPWM_MIN_DIAG_LSH_DOWN must be lower or equal to NC_LSHPWM_BOL_LSH_DOWN.
C_LSHPWM_MAX_DIAG_LSH_DOWN	is the maximum permitted heater effective voltage PWM for upstream LSH OBD1 diagnosis. In order for a SCG to be recognised, the heater driver must remain off for at least 0,25 ms. Hence this represents (100% * (1- (0,25 ms / 100 ms))) PWM = 99.75 %. As the PWM resolution is 0.3891 %, 100.00 – 0.39 = 99.61 % value is chosen for the calibration constant. Additionally the calibration constant C_LSHPWM_MAX_DIAG_LSH_DOWN must be higer or equal to NC_LSHPWM_TOL_LSH_DOWN.

16.91.3.2 Calculation of exhaust gas temperature limit

C_TEG_DYN_MIN_DIAG_LSH_DOWN	is the minimum exhaust gas temperature threshold to permit SCB fault to be set during LSH preheating state. This constant shall be calibrated such that the exhaust gas temperature is sufficiently warm to heat the sensor to a temperature where no heater inrush current exceeding the driver over-current threshold (typ. 8 A) occurs. The inrush current transient will only occur in the initial few seconds of heating (1 to 5 seconds) and is dependent on the sensor type and environmental conditions.

16.91.3.3 Calibration data for error debouncing

C_ABC_INC_DIAG_LSH_DOWN	is the anti-bounce counter increment for upstream O2-sensor heater diagnosis. This constant shall be calibrated according to project philosophy. As a first hint the increment may be set to 1.
C_ABC_MAX_DIAG_LSH_DOWN	is the maximum value of the anti-bounce counter for upstream O2-sensor heater diagnosis. After having reached this number the error flag is being set. The constant shall be calibrated according to project philosophy. As a first hint C_ABC_MAX_DIAG_LSH_UP may be set to 50 which means that using a recurrence of 0,1 s the diagnosis will be finished after 5 s after the activation conditions have been met and the fault being present. Additionally this number should not be chosen too large since several OBD II functions are intented to start after the electrical diagnosis has finished and LV_END_DIAG_LSH_DOWN is set, e.g. the heater OBD II diagnosis.

16.91.4 Validation

The validation is done using a break-out box to simulate the possible electrical faults. Attention shall be paid to the SCG test connecting the heater cabling to ground since in case of a short cut in the battery – lambda sensor connection a fuse will blow and in case of a lambda sensor - µ-controller short cut the lambda sensor may overheat without the safety precautions being able to disrupt.

16.92 Downstream Fuel Trim diagnosis

16.92.1 Calibration interfering functions

16.92.1.1 Before start of the calibration of the downstream fuel trim, the following other functions must be calibrated:

- Basic Engine Tuning (i.e. Ignition, Basic Injection, Torque Model, Variable Valve Timing)
- Intake Manifold Model (MAP System)
- Wallfilm Compensation Model
- Evaporative Emission Control
- Temperature Model up- and downstream catalyst
- Signal Acquisition of linear lambda sensor (controller and heater calibration)
- Readiness detection of up- and downstream lambda sensor
- Lambda Control Parameter fixed
- Forced Stimulation
- Basic Lambda Setpoint
- Trim Control
- Catalyst Purge

16.92.1.2 Before calibration of the downstream fuel trim diagnosis, the following modifications on the calibration data should be done:

Nothing.

16.92.2 Calibration flowchart

The sequence is described by the order of constants and maps in the table of the “Calibration method” section below.

16.92.3 Calibration method

Monitoring of Trim Controller I-share

The calibration can be done on the road.
The calibration should be checked in emission test.
The failure can be caused i.e. by adding + / - 4 % on IP_LAMB_LS_UP[NC_CBK_EX_NR].

C_LAMB_DELTA_I_MAX_DIAG	Maximum limit of LAMB_DELTA_I; This value should be slightly lower than the maximum possible trim control limit. If 5 % for trim control limit is used, take I.e. 4 % for the diagnosis limit.
C_LAMB_DELTA_I_MIN_DIAG	Minimum limit of LAMB_DELTA_I; See explanation for C_LAMB_DELTA_I_MAX_DIAG. I.e. – 4 %.
C_T_SUM_MAX_MAX_DELTA_I	Total duration of trim control on the maximum limit;

_LAM	It must be shorter than the reset time, i.e. 30 % of it and shorter than the maximum available fuel trim activation time in the emission test. If the trim control I-share is calibrated quite slowly, the time can be even very short, i.e. 10 sec., as the I-share itself can be treated as a kind of debouncing. The time should be longer if it is known, that the trim control I-share is calibrated quite fast and / or the A/F precontrol is not precise.
C_T_SUM_MIN_MAX_DELTA_I_LAM	Total duration of trim control on the minimum limit; See at C_T_SUM_MAX_DIAG_LAM_ADJ. I.e. 10 sec.
C_T_SUM_RST_MAX_DELTA_I_LAM	Time counter to reset min and max counter; See also C_T_SUM_MAX_MAX_DELTA_I_LAM for further explanation.
C_T_SUM_MAX_ERR_DELTA_I_LAM	The value gives a kind of characteristic number for reliability. If a failure symptom during C_T_SUM_READY_DELTA_I_LAM was available for not longer than C_T_SUM_MAX_ERR_DELTA_I_LAM, than the end flag is set. If the symptom was available for a longer time, then it is decided to wait for one complete "reset cycle", which means it will take at least C_T_SUM_RST_MAX_DELTA_I_LAM seconds until the end flag will be set, except a failure is detected before.
C_T_SUM_READY_DELTA_I_LAM	Timer for fast end of trim diagnosis. The purpose is to set the end flag in a completely symptomless driving cycle earlier. If a failure symptom during C_T_SUM_READY_DELTA_I_LAM was available for not longer than C_T_SUM_MAX_ERR_DELTA_I_LAM, than the end flag is set. In general, to fulfill its purpose, it shall be shorter than C_T_SUM_RST_MAX_DELTA_I_LAM, i.e. half as long.

Monitoring of Trim Controller Deviation

The calibration can be done on the road.
The calibration should be checked in emission test.
A catalyst with maximum oxygen storage capacity and with no storage capacity shall be used for the final check of the calibration.
If the failure is simulated via adjustment of IP_LAMB_LS_UP +/- 10%, it depends on the calibration of the MAF integrals and the VLS_DOWN_DIF thresholds if this failure will be met at first in a driving cycle like the FTP75. Because of the dynamic driving, the VLS_DOWN_DIF thresholds might not be met during a long time, and then at first the trim control I-share diagnosis would be entered into the failure memory. Anyway, the calibration must be adjusted to be able to produce the failure in the FTP75 emission test. The demonstration with an external tool in the FTP75 test cycle might be possible, if a fix downstream sensor signal is applied only for the phase of constant driving and not for fuel cut off phases. Otherwise, other diagnosis functions would find an error. The failure MAF integral must be calibrated so that it is exceeded at the end of this constant driving phase. But be careful to check if the trim control P-share would be able to bring the VLS_DOWN signal away from the diagnosis threshold under all circumstances for a good sensor.
Another possibility to demonstrate it is to make the VLS_DOWN thresholds very aggressive (close to values which can occure with good sensor), but this is not recommended due to the risk of wrong failure entry.

For the PVE test it seems to be more simple. A stuck VLS_DOWN must be simulated (external tool) which would lead to exceeded thresholds. And then, a driving cycle must be performed, which does not include any fuel cut off.

The failure MAF integral should not be smaller than 2/3 of the reset MAF integral to prevent a failure entry due to a damaged catalyst (oscillating VLS_DOWN).

C_VLS_DIF_MAX_DIAG	Maximum threshold for VLS_DIF_DLY deviation; Lowest setpoint of trim controller – significant lean voltage (i.e. 0,05 V) which would not occure during normal operation with trim control P-share on (be careful if P-share has only small effect). I.e. 0,65 (setpoint) – 0,05 V (lean voltage) = 0,60 V for C_VLS_DIF_MAX_DIAG.
C_VLS_DIF_MIN_DIAG	Minimum threshold for VLS_DIF_DLY deviation; The problem with this value is, that it must be choosen so high, so that the lambda sensor supplier would never guarantee this voltage for an aged sensor. So this diagnosis is reliable only for a part of the downstream lambda sensor lifetime. C_VLS_DIF_MIN_DIAG must be choosen to a value, that the lowest setpoint of trim controller + C_VLS_DIF_MIN_DIAG is higher than the VLS_DOWN voltage which occurs under normal conditions (i.e. after full load or catalyst purge or catalyst overheat protection) at the time when the p-share of fuel trim is activated (take into account also the VLS_DOWN after warmstart when the sensor is still a little cold).
C_MAF_INT_VLS_DIF_DLY_MIN	Maxmium MAF integral of VLS_DIF_DLY deviation (rich_side); It must be less than the reset integral, but not too less to prevent a failure entry in case of a damaged catalyst (oscillating VLS_DOWN) i.e. 70 % and less than the maximum available fuel trim activation integral in the emission test. I.e. 500 g.
C_MAF_INT_VLS_DIF_DLY_MAX	Maximum MAF integral of VLS_DIF_DLY deviation (lean_side); See C_MAF_INT_VLS_DIF_DLY_MIN. I.e. 500 g.
C_MAF_INT_RST_VLS_DOWN_DIF_DIAG	Threshold for integral to start a new diagnostic cycle and to set the end flag; It must be possible to reach this maf integral during the emission test as also the end flag is set after exceeding first time this reset integral in the no failure case. I.e. 750 g.
C_CAT_DIAG_MAX_DELTA_I_LAM	Deactivation threshold for the diagnosis to prevent a wrong failure entry due to oscillating VLS_DOWN after the catalyst was damaged.

Limited dynamic for the function “Monitoring the Trim Controller Deviation”

A catalyst with maximum oxygen storage capacity shall be used for the calibration.
A chassis dyno roller is recommended.
Check the behaviour of VLS_DOWN while slowly changing the parameters N / MAF / LAM_MV. Check the impact on VLS_DOWN_DIF.
Find out the acceptable change quickness and calibrate the correlation constants accordingly. If even a very slow change of the parameter makes trouble, keep the correlation constant small.
If there is no trouble due to fast changes until a certain absolute difference between the mean value and the current value, then find out the maximum acceptable absolute difference for a fast change and calibrate the window accordingly.

C_N_LDC_VLS_DIF_DLY	If only a small change quickness is acceptable, the correlation constant and the acceptable window of the parameter must be choosen small. The bigger the acceptable change quickness is, the higher the correlation constant can be choosen.
C_MAF_LDC_VLS_DIF_DLY	See C_N_LDC_VLS_DIF_DLY;
C_LAM_MV_LDC_VLS_DIF_DLY	See C_N_LDC_VLS_DIF_DLY;
C_N_CRLC_LDC_VLS_DIF_DLY	See C_N_LDC_VLS_DIF_DLY;
C_MAF_CRLC_LDC_VLS_DIF_DLY	See C_N_LDC_VLS_DIF_DLY;
C_LAM_MV_CRLC_LDC_VLS_DIF_DLY	See C_N_LDC_VLS_DIF_DLY;
C_MAF_INT_MIN_VLS_DIF_DLY_LDC	See C_N_LDC_VLS_DIF_DLY;

17.1 Actuator control - Requirements for infrastructure (SF mode)

Input data:

Export actions:

ACTION_INFR_GetVAcr(OUT <V_acr_bas>**)**
This action provides the standard signal voltages of the actuator measurement system.
ACTION_INFR_SetPwmDucyAcr(IN <Pwm_acr>**)**
This action adjusts the duty-cycle and the current direction of the actuator power stage output.
ACTION_INFR_SetPwmFrqAcr(IN <Frq_pwm_acr>**)**
This action adjusts the frequency of the PWM signal from the PWM signal generator
ACTION_INFR_GetElDiagAcrDr(OUT <Lv_state_acr_dr>**)**
This action reads the status flag information of the actuator power stage!
ACTION_INFR_DisableAcrDr( )
This action is able to switch-off the actuator power stage.
ACTION_INFR_EnableAcrDr( )
This action is able to switch-on the actuator power stage.

Description for actions:

ACTION_INFR_GetVAcr(V_acr_bas**)**					
This action reads the signal voltages of the position sensor delivered from the infrastructure. The AD conversion is performed autonomously every millisecond by the infrastructure. When the action is called the gathered information will be provided to the application software level.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
V_acr_bas	OUT	0...3FFH	0...4.9951	4.9e-3	V
Signal voltage of actuator position sensor					

ACTION_INFR_SetPwmDucyAcr(Pwm_acr**)**					
This action writes the PWM duty-cycle value for the actuator power stage in the infrastructure. The PWM update and the current direction of the actuator power stage are performed autonomously by the infrastructure. When the action is called old requests will be replaced by the new request.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Pwm_acr	IN	8000...7FFFH	-100...99.997	3.05e-3	%
Output of the actuator position controller included PWM duty-cycle and current direction					

ACTION_INFR_SetPwmFrqAcr(Frq_pwm_acr**)**					
This action writes the PWM frequency, which is tuneable, for the actuator PWM signal generator into the infrastructure.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Frq_pwm_acr	OUT	0...FFFFH	0...6553.5	0.1	1/s
PWM generator frequency					

ACTION_INFR_GetElDiagAcrDr(<Lv_state_acr_dr>**)**					
This action reads the status flag information of the actuator power stage. The readout of the SF is performed autonomously and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Lv_state_acr_dr	OUT	0...1H	0...1	1	-
Status flag information from the actuator power stage provided for the diagnosis					

ACTION_INFR_DisableAcrDr( )
The action is used for the deactivation of the actuator power stage via enable/disable line.

ACTION_INFR_EnableAcrDr( )
The action is used for the activation of the actuator power stage via enable/disable line.

FUNCTION DESCRIPTION:

17.1.1 Closed-loop actuator position control

General information:

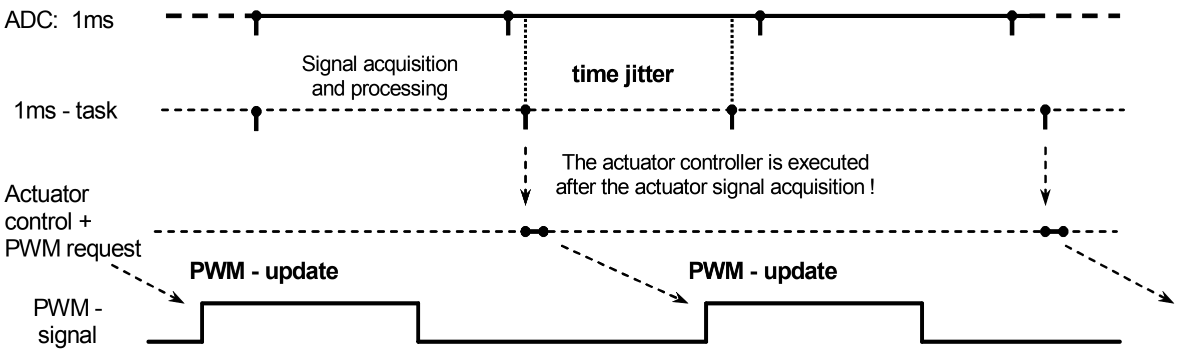
This chapter describes the time behaviour between actuator valve position signal acquisition, digital position controller calculation and the PWM output generation for the actuator power stage. The aim is to synchronise all functions for smallest time delay. The actuator valve position signal acquisition and the digital position controller are calculated in the 1 ms ASW task asynchronously to the AD queue converted every millisecond and the PWM generation (update is only possible after a complete duty-cycle). The maximum time delay between the AD conversion and PWM generation depend on time jitter between:

- AD conversion and actuator signal determination ($0 \leq T_1 \leq 1$ ms)
- Position controller calculation and PWM update ($0 \leq T_2 \leq 1$ / Frq_pwm_acr)

The maximum time delay T_{delay} is the summation of T_1 and T_2 !

($0 \leq T_{delay} \leq 3$ ms for a frequency of 500 Hz, $0 \leq T_{delay} \leq 2$ ms for a frequency of 1000 Hz)

Signal flow diagram



17.1.2 Actuator position sensor signal acquisition

General information:

The following actions are used for the acquisition of the signal voltage of the actuator valve position measurement system. The actions deliver the actuator valve position to the application software level from the standard AD queue converted every millisecond.

- The AD conversion is performed autonomously by the infrastructure every 1 ms.

Requirements for ACTION_INFR_GetVAcr:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
V_acr_bas	Not relevant	< 1% of reference supply voltage for sensor	10bit	-	-

Diagnosis: no electrical diagnosis done here

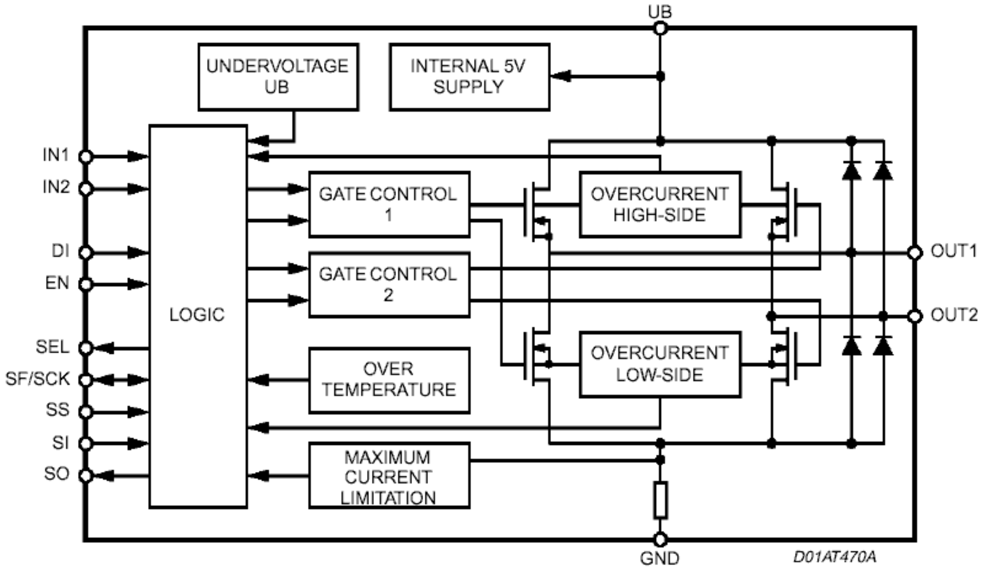
Coincidence requirements: The AD conversion is performed autonomously by the infrastructure every 1 ms.

17.1.3 Power stage for actuator position control

General information:

The used power stage is an full H-Bridge, designed for the control of DC motors in safety critical applications and under extreme environmental conditions. The power stage is protected against over temperature and short circuits and has an under voltage lockout for all the supply voltages (main DC power supply). All malfunctions cause the output stages to go tristate.

The following picture shows the internal structure of the used power stage:



Infineon TLE 7209R

IN1 / IN2 - Input pins for output power control
OUT1 / OUT2 - Output pins connected with the actuator
EN / DI - Enable and disable pin of the power stage

17.1.3.1 Control of the actuator power stage

General information:

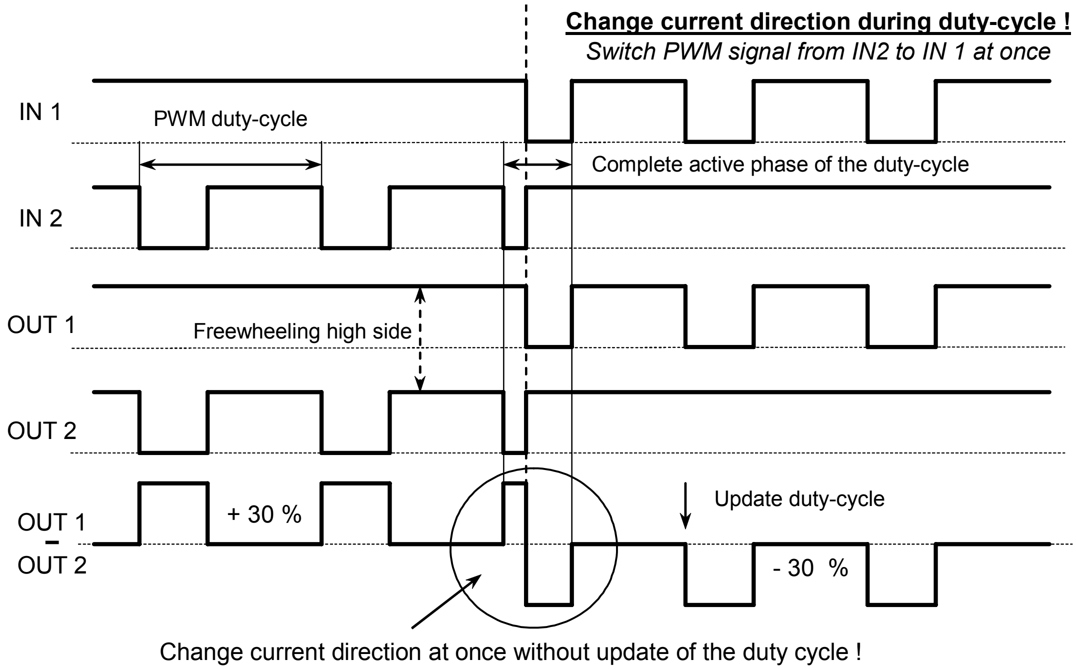
The power stage delivers the energy for the closed-loop electronic actuator valve position control. The power of the output stages (OUT1 and OUT2) should be managed by **only one** PWM signal from the ECU06 main controller (TriCore). The control strategy uses a special feature of the TriCore processor for the change of the current direction within the motor electrical circuit. The TriCore is able to switch the internal PWM source between the input pins IN1 and IN2 of the power stage, therefore only one PWM channel is necessary.

- The output stages of an active power stage change between the states "electric-power supply" and "electric freewheeling" permanently. It is absolutely necessary to manage the power stages with "**freewheeling high side**" to fulfill the high EMC requirements.

- The duty-cycle of the PWM signal starts always with an active phase "electric-power supply" and then the passive phase "electric freewheeling high side" follows.
- The current direction of the motor electrical circuit is determined autonomously by infrastructure means of the PWM request delivered from the actuator position controller. A positive PWM duty-cycle request means forward direction and a negative PWM duty-cycle request means backwards direction. The described behaviour can also be changed by configuration.
- The current direction is adjusted by the PWM source assignment asynchronously to the PWM duty-cycle, that means the current direction can be changed within the duty cycle, see signal flow diagram below.

The physical range of the duty cycle is 0 to 100% and the resolution 100% / 2^15 = 3.05e-3. After ignition on or reset the duty cycle is set to 0 %.

Signal flow diagram



Requirements for ACTION_INFR_SetPwmDucyAcr :

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Pwm_acr	-	-	3.05e - 3 %	-	After IGKON or RST the duty – cycle must be set to **0 %** !

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The time duration between set and update of the duty cycle has to be less than 1/Frq_pwm_acr. The PWM frequency is set by calling ACTION_INFR_SetPwmFrqAcr() in the application software.

Requirements for ACTION_INFR_SetPwmFrqAcr:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Frq_pwm_acr	-	-	0.1 Hz	-	Value is fixed once at RST or IGKON. **The value must not be changed while active PWM signal generator!**

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The value can be changed in accordance to hardware requirements. Default is 1000 Hz.

17.1.3.2 Actuator power stage diagnosis based on SF

General information:

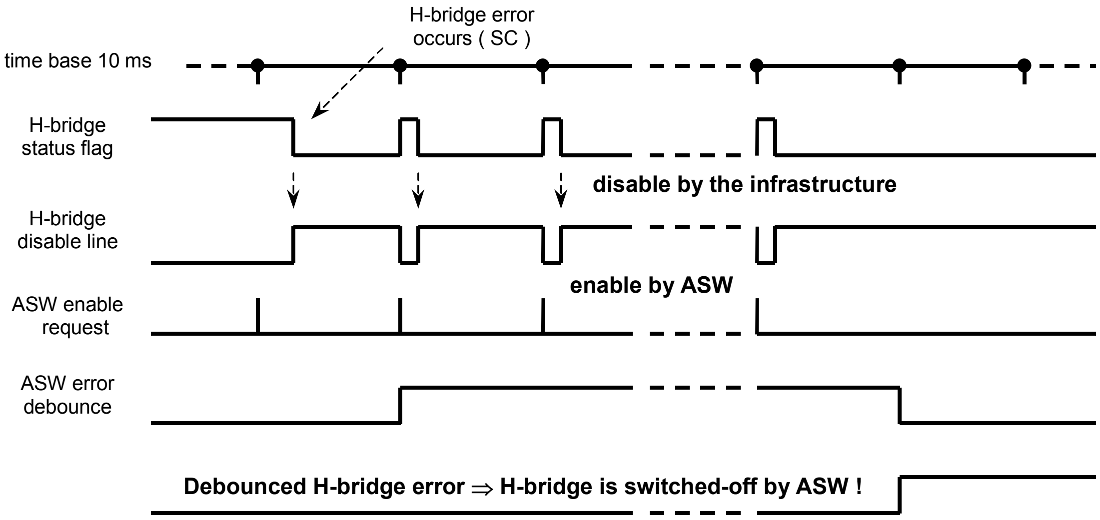
The used actuator power stage is an intelligent full H-Bridge with integrated diagnostic and must be configured in status flag mode. This action returns the result of the internal electrical diagnosis delivered by the status flag line of the actuator power stage. The following errors are detected by the internal H-bridge diagnosis:

- Overcurrent
- Overtemperature
- Undervoltage

In the status flag mode it is not possible to distinguish the errors by the software, that means only the information “error is present” will be indicated ! With detected error the power stage is switched-off automatically. The re-activation is only possible with a signal change on the enable/disable line of the power stage.

- The device readout is performed autonomously by the infrastructure.
- If the infrastructure detects an error on the power stage via status flag line, then the infrastructure must disable the H-bridge by enable/disable line autonomously.
- The error information are gathered in the infrastructure until the application reads out the information by calling ACTION_INFR_GetElDiagAcrDr().
- After having read out the information by calling ACTION_INFR_GetElDiagAcrDr(), the data inside the infrastructure are reset.

Signal flow diagram



Requirements for ACTION_INFR_GetElDiagAcrDr:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Lv_state_acr_dr	-	-	<bit coded>	-	The logical variable is set, if the error delivered by status flag of the actuator power stage has been detected.

Diagnosis:

ACTION_INFR_GetElDiagAcrDr returns the electric diagnosis of the actuator power stage.

Coincidence requirements:

The re-activation process of the actuator power stage during the error detection is a co-operation between application software and infrastructure, that means with error detection the infrastructure must disable the H-bridge (power stage) and the application software must be able to activate the power stage again, see signal flow diagram.

17.1.3.3 Actuator power stage activation/deactivation request

General information:

The actuator power stage is equipped with two separate digital IO-lines for the enable and disable of the output transistors. Both lines must be set to enable for the activation, otherwise the power stage is set to high-resistance.

One enable line is connected to the main controller and the other one is not used due to no safety relevance of actuator valve (i.e. it is connected to supply voltage via resistance).

These actions describe the access to the enable/disable line from the main controller to the actuator power stage.

Requirements for ACTION_INFR_DisableAcrDr:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
-	-	-	-	-	After the ECU reset the actuator power stage must be deactivated !

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The actuator power stage deactivation request has to be performed at once. The infrastructure must be able to deactivate the power stage via enable/disable line itself during the diagnosis.

Requirements for ACTION_INFR_EnableAcrDr:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
-	-	-	-	-	After the IGKON or RST the actuator power stage must be deactivated !

Diagnosis: no electrical diagnosis done here

Coincidence requirements: The actuator power stage activation request has to be performed at once. The power stage activation request may only be performed by the application software level !

17.2 Aggregate adaptation module, ACRC

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
AV_OPEN_EGR	V/O	0...FFH	0...99.60937	0.390625	[%]
Actual opening value of the EGR valve after adaptation

Stuck valve or potentiometer failure					
STK_AV_EGR	V/O	0...FFH	0...99.60937	0.390625	[%]
Actual value of the stroke of EGR valve					
LV_EGR_ACT	V/O	0...1H	0...1	1	[-]
Logical value for EGR-control active					
LV_ER_FDOUT	O	0...1H	0...1	1	[-]
LV_ER_FDOUT					

Input data:

OPG_ACR	LV_PWM_ACR_OFF_REQ	STATE_ACR_CTL	

FUNCTION DESCRIPTION:

This function is used for the adaptation of the actuator control modules to the remaining software system. The Module has to be executed after the ACRC functionality has been calculated.

Application conditions:

Initialization:	at RST set all to zero and LV_ER_FDOUT = 0
Recurrences:	10 ms
Activation:	at all engine operating states
Deactivation:	no deactivation

Formula section:

AV_OPEN_EGR = OPG_ACR

STK_AV_EGR = OPG_ACR

LV_EGR_ACT = **(**STATE_ACR_CTL == PWM_CTL**)**

LV_ERR_EGR_2 = LV_PWM_ACR_OFF_REQ

17.3 ACRC position determination

Output data:

Name	**Mode**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
OPG_ACR	O/V	0...FFFH	0...99.9756	0.02441	%
Measured opening of the actuator valve					
V_ACR	O/V	0...3FFH	0...4.995117	0.00488	V
Voltage value for actuator position control delivered from the measuring system					
V_ACR_MV	V	0...7FFH	0...4.997559	0.002441	V
Voltage value for actuator position control delivered from the measuring system with higher resolution					
V_ACR_BAS	V	0...3FFH	0...4.995117	0.00488	V
Raw value of the measuring system for actuator position control					

Input data:

FAC_ACR_SLOP	V_ACR_AD_BOL	LV_OPG_ACR_INI_REQ	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_OPG_ACR_INI	1	0...FFFH	0...99.9756	0.02441	%
Replacement value for sensor signal acquisition					

Import actions:

ACTION_INFR_GetVAcr(OUT <V_acr_bas>**)**
This action provides the standard signal voltages of the ACR measurement system.

17.3.1 General information

The electrical actuator is equipped with a linear position sensor system. The propose of this module is to determine the actual valve position for the closed-loop digital position control.

Application Condition

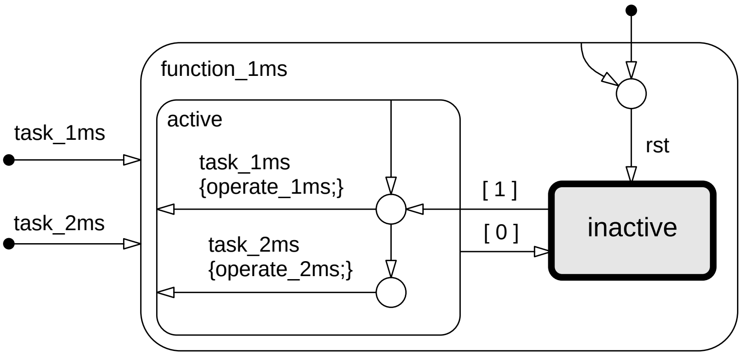

Figure 1 ACRC_position_determination/ APP_CDN/ APP_CDN

Function Description

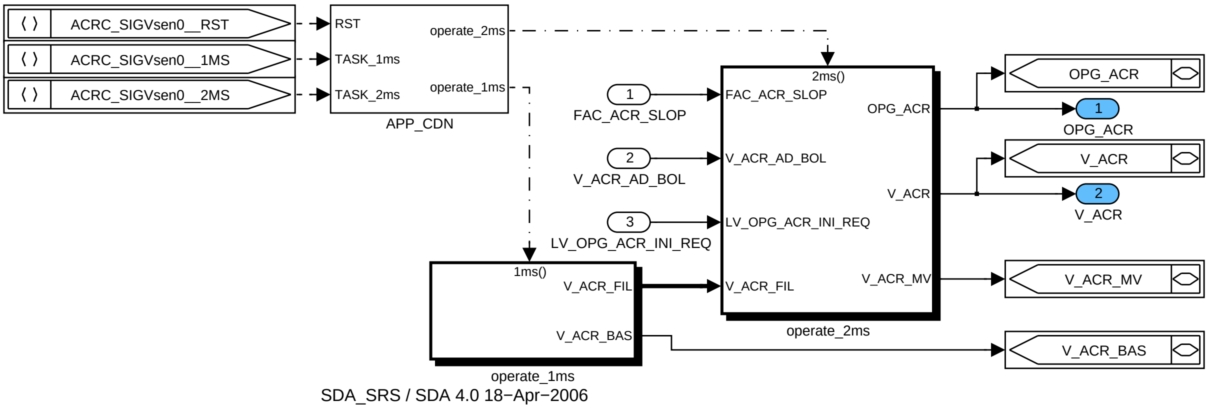

Figure 2 ACRC_POSITION_DETERMINATION

17.3.1.1 Signal pre processing

The described filter function is a part of signal processing. The AD value of the measuring system has a resolution of 10 bit (1024 increments) according to the AD converter. The smallest signification bit (one increment) is the fault of the AD conversion process and this bit can alternate from conversion to conversion. To compensate this behaviour the described bit filter is used, see below.

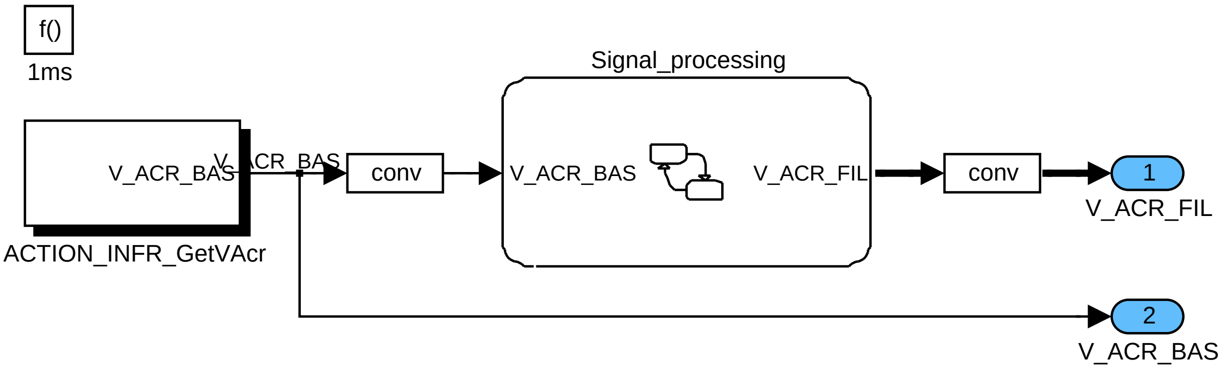

Figure 3 ACRC_POSITION_DETERMINATION/ OPERATE_1MS

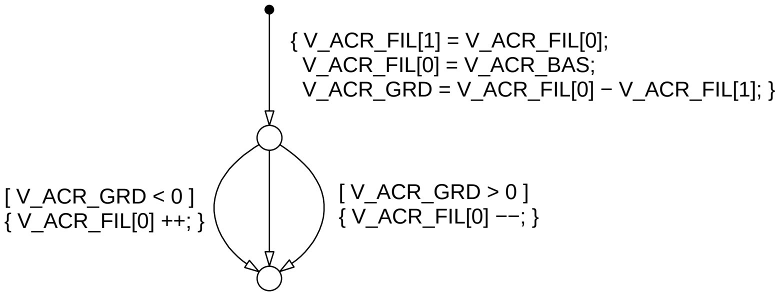

Figure 4 ACRC_position_determination/ operate_1ms/ Signal_processing

17.3.1.2 Signal standardization

The aim of this chapter is to provide the valve position for the digital position controller. The signal voltage of the measuring system is determined by over-sampling and averaging after the signal pre-processing. Afterwards the position signal is standardised by the electrical valve adaptation value and the standard slop of the measuring system and is limited in the range between 0 % and 100 %.

The output of the signal acquisition is set to C_OPG_ACR_INI if the replacement value for the sensor signal acquisition has been requested.

17.4 System variables in the exhaust pipe

17.4.1 Calculation of the exhaust manifold pressure PRS_EX

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PRS_EX	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Pressure in the exhaust system					
PRS_EX_INC	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Increase of exhaust pressure in comparison to ambient pressure					
MAF_FLOW_EX	V/O	0000...FFFFH	0...2047.96875	0.03125	kg/h
air mass flow out of the exhaust manifold					
PRS_EX_EGR	O/V	0000...FFFFH	0...5434	0.083	hPa
Pressure in the exhaust system (for MAF_EGR-Calculation)					
PRS_EX_EGR_INC	O/V	0....FFFFH	0....5434	0.0829	hPa
increase of exhaust pressure in comparison to ambient pressure (for MAF_EGR-Calculation)					

Input data:

MAF_CYL	AMP	LV_RLY_MAIN	NC_CBK_EX_NR
N_32	MFF_SP[NC_CBK_EX_NR]	NC_MAF_FAC_CYL	NC_CYL_NR
LV_IGK			

FUNCTION DESCRIPTION:

There is an increase of the pressure in the exhaust pipe in comparison to the ambient pressure. The increase of the pressure is higher with increasing mass flow in the exhaust pipe. The cylinder mass air flow is direct proportional to the exhaust mass flow. Therefore the pressure increase in the exhaust pipe is a function of the cylinder mass flow.

The exhaust pressure PRS_EX is a function of the ambient pressure and the increase of the pressure in the exhaust pipe. which is a function of the mass flow in the exhaust pipe.

Application conditions:

Initialisation: all = 0 at reset

Recurrence: 1000ms

Activation: LV_IGK = 0 -> 1

Deactivation: LV_RLY_MAIN = 1 -> 0 (also calculated in PWL phase)

Formula section:

PRS_EX_INC = IP_PRS_EX_INC (MAF_CYL)

PRS_EX = PRS_EX_INC + AMP

MAF_FLOW_EX = MAF_CYL / NC_CBK_EX_NR +
(MFF_SP[NC_CBK_EX_NR = 2] *
NC_CYL_NR/NC_CBK_EX_NR * N / NC_MAF_FAC_CYL) –
MAF_EGR

PRS_EX_EGR_INC = IP_PRS_EX_EGR INC (MAF_FLOW_EX)

PRS_EX_EGR = PRS_EX_EGR_INC + AMP

Calibration data:

additive basic ignition angle correction due to EGR influence in stratified mode					
EGR_RATIO_COR_2	V	0...FFFFH	0...99.99847	1.5259e-3	[%]
corrected EGR_RATIO for LDP of IP_IGA_BAS_EGR					

Input data:

MAF	N_32	LV_EGR_ACT	TCO
MFF_SP_S	LV_SP_RATE_CYL_EGR_SWI	EGR_RATIO_SP	LAMB_SP

FUNCTION DESCRIPTION:

General information:

Homogeneous mode:

In homogeneous mode, if EGR function is active, the basic ignition angle IGA_BAS_IVVT is improved by the additive EGR correction value IGA_BAS_EGR_COR. This value depends from N_32, MAF, TCO, EGR_RATIO_SP and LAMB_SP.

Stratified mode:

In stratified mode, if EGR function is active, the basic ignition angle IGA_BAS_S is improved by the additive EGR correction value IGA_BAS_EGR_COR. IGA_BAS_EGR_COR is calculated from ~~IP_IGA_EGR_S corrected by~~ the coolant temperature TCO (IP_IGA_EGR_S).

Application conditions:

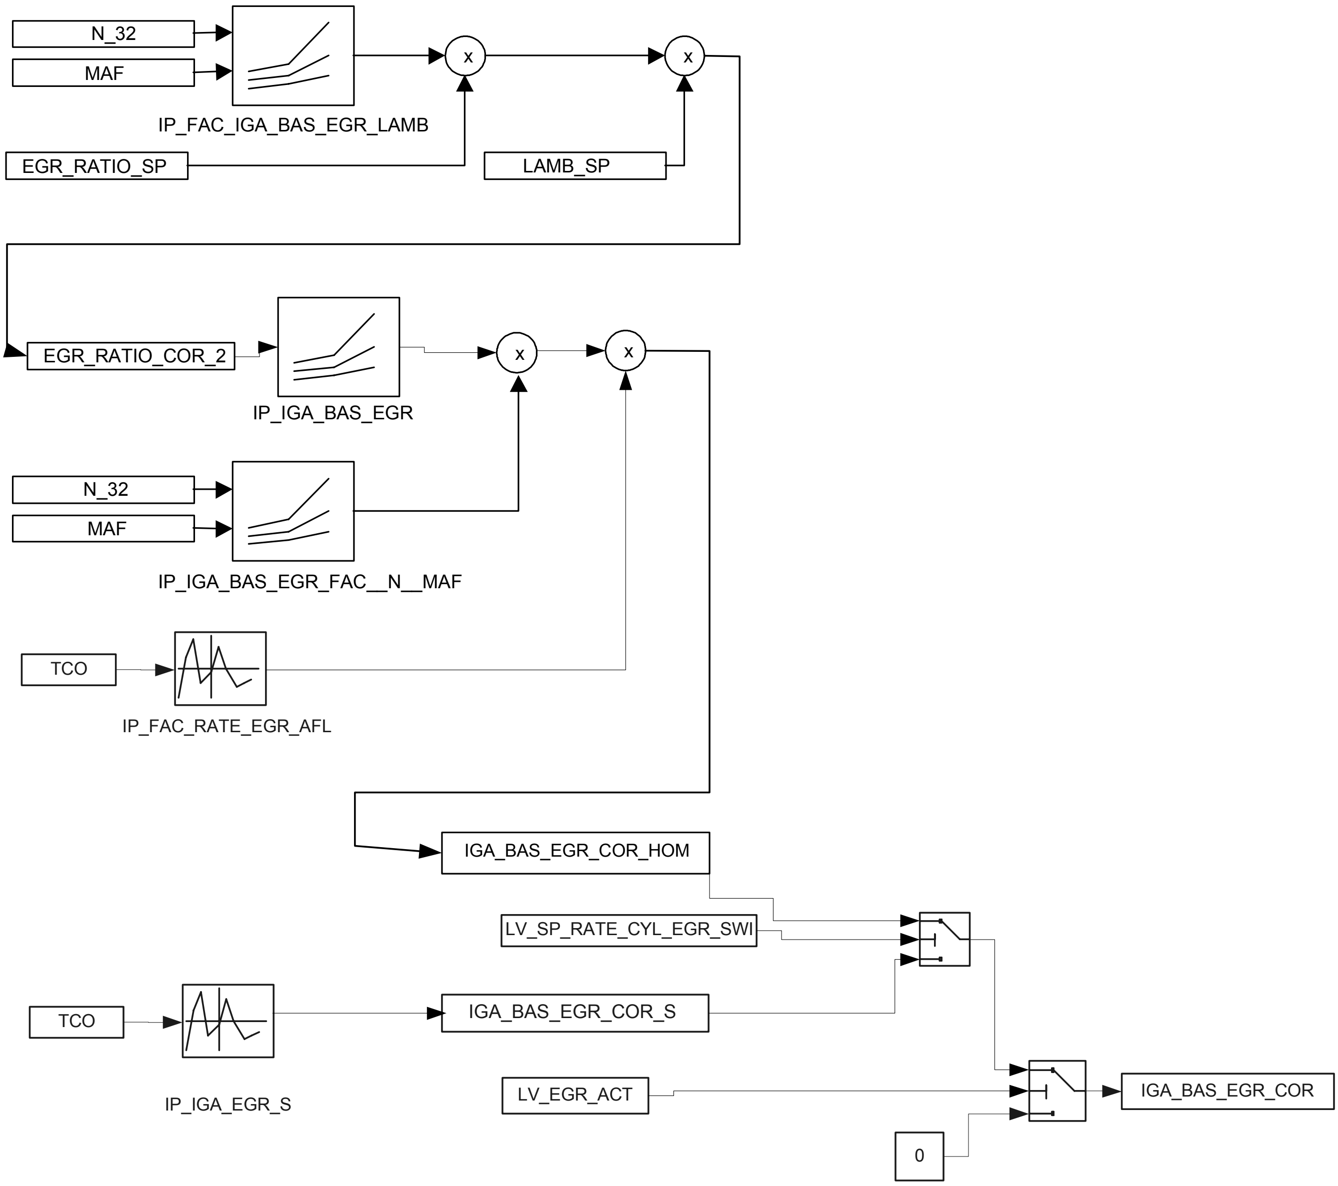
Activation: LV_EGR_ACT = 1

Deactivation: LV_EGR_ACT = 0

Update Rate: 10 ms

Initialization: IGA_BAS_EGR_COR = 0

Signal flow diagram:



Formula section:

EGR_RATIO_COR_2 = EGR_RATIO_SP * IP_FAC_IGA_BAS_EGR_LAMB * LAMB_SP

IGA_BAS_EGR_COR_HOM = IP_IGA_BAS_EGR *
IP_IGA_BAS_EGR_FAC__N__MAF *

Lower limitation threshold of the actuator position setpoint					

17.6.1 General information

This module describes the generation of the actuator valve position setpoint for closed – loop digital position control. All setpoint requests delivered from the remaining software system are gathered, coordinated and filially limited in the physical limits of the actuator valve. At the end of the module the position setpoint is provided for the digital position controller directly.

Application Condition

17.7.1 General information

The following module shall provide all remaining actuator valve position setpoint requests for all engine operating states. At the end of the function the power stage activation condition according to position setpoint request is calculated.

Application Condition

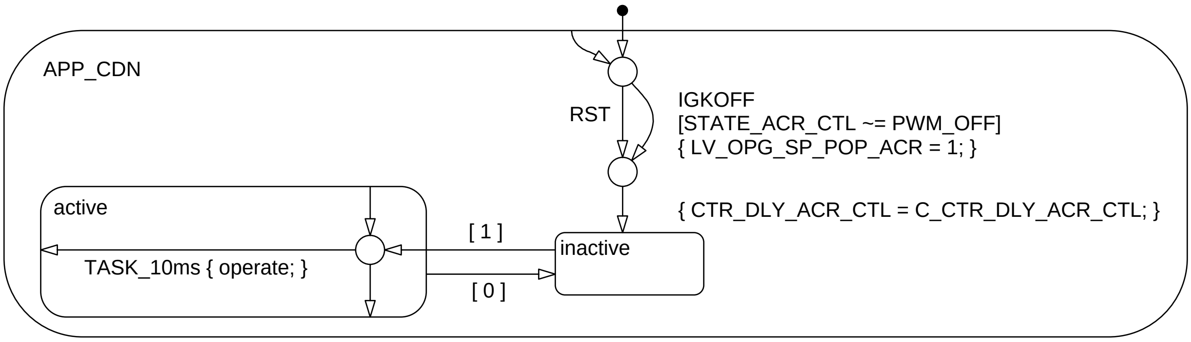

Figure 12 ACRC_setpoint_selection_ai/ APP_CDN/ APP_CDN

Function Description

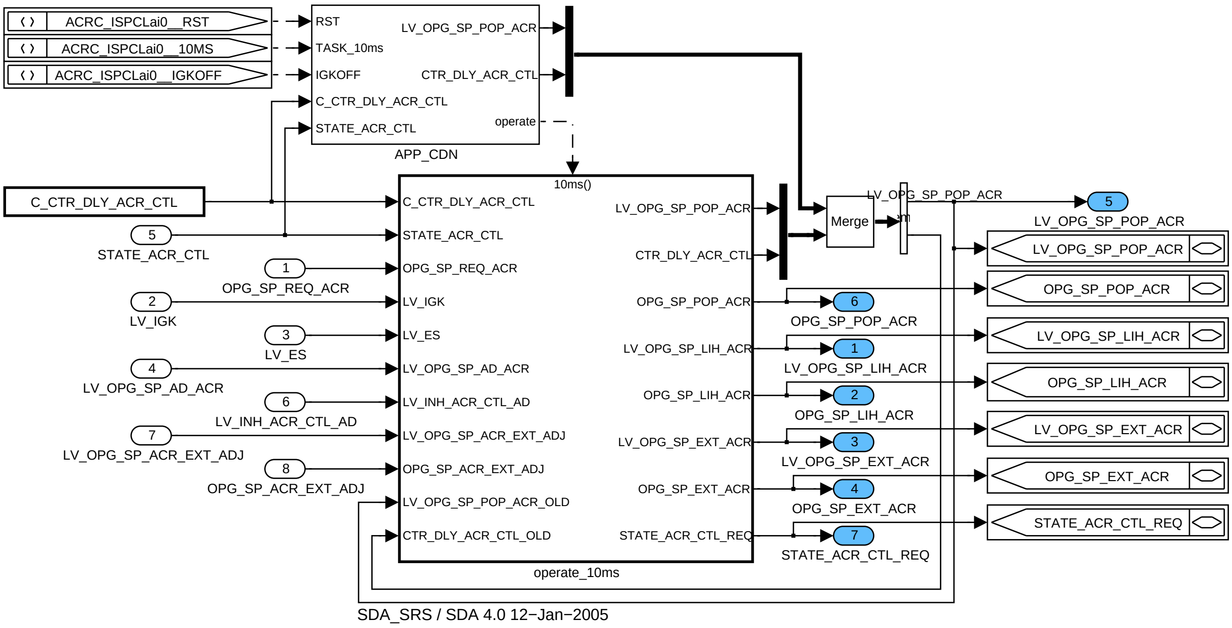

Figure 13 ACRC_setpoint_selection_ai

17.7.1.1 Setpoint generation

The module defines the following setpoint requests: Limp - home position setpoint request active with deactivated power stage, external position setpoint request made with the calibration system and the setpoint request setpoint during post - operating phase after ignition off. During the post - operating phase the setpoint is set to C_OPG_SP_POP_ACR and will be removed first after a defined calibration time.

At the end of the function the power stage activation request is performed. In normal operating the transition between active and passive closed - loop control is calculated here. Closed - loop control will be finished after a defined delay time and position setpoint requests lower than C_OPG_SP_EXT_ACR. With passive closed - loop control it is possible to deactivate the power stage via disable line or to close the actuator valve with output of a constant PWM duty - cycle. The decision will be done with the logical configuration constant LC_PWM_ACR_OFF_ENA !

This action adjusts the frequency of the PWM signal from the PWM signal generator

17.8.1 General information

This module describes the digital position controller used for the closed-loop control of an electrical actuator. The position controller is carried out as a digital robust position controller. Calibration data are determined according to SiemensVDO internal position controller design algorithms. The controller algorithm is split in a 2 ms functionality for closed-loop position control and a 10 ms functionality for static preload, battery voltage correction and position setpoint rate limitation.

Application Condition

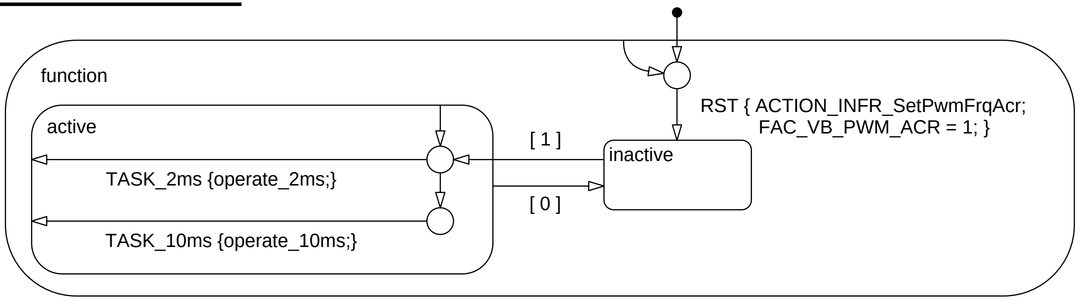

Figure 19 ACRC_position_controller/ APP_CDN/ APP_CDN

Function Description

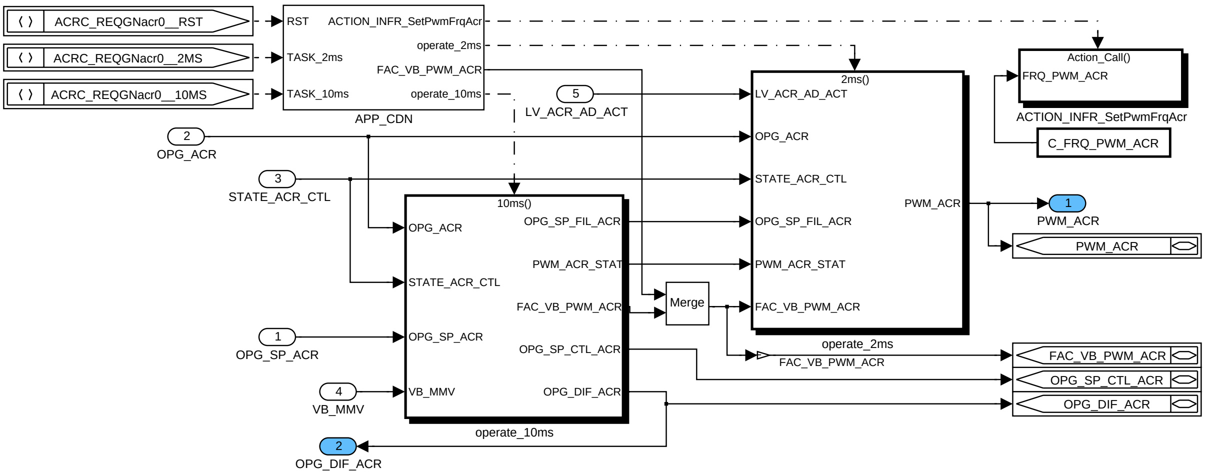

Figure 20 ACRC_position_controller

17.8.1.1 Functional part of 10ms

The 10 ms functionality of the position controller is only calculated if the closed-loop position control has been requested. Closed-loop position control will be indicated by the state PWM_CTL (= 2) of the state variable STATE_ACR_CTL.

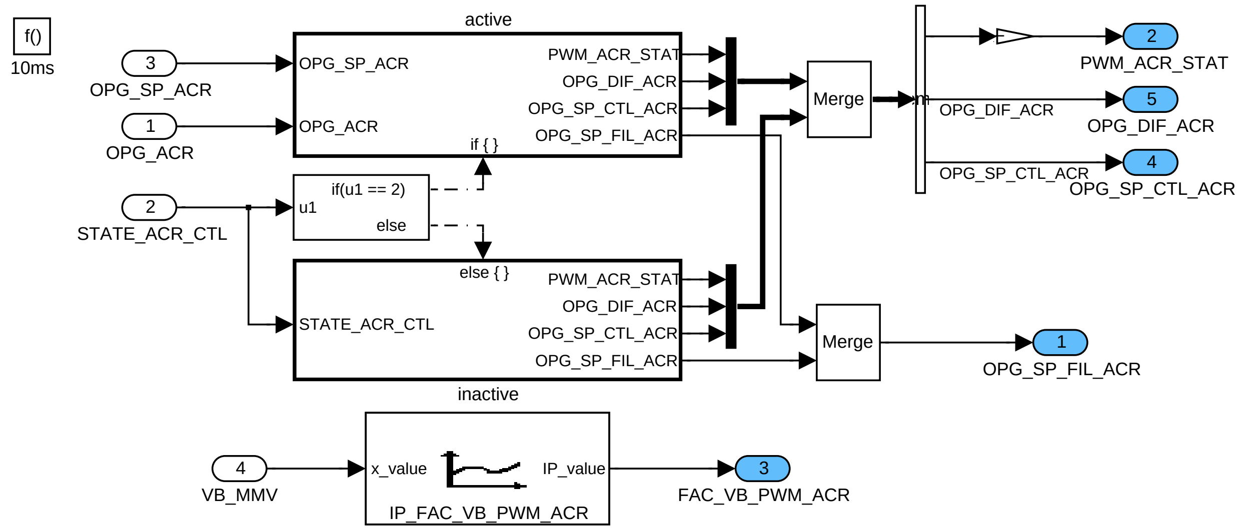

Figure 21 ACRC_position_controller/ operate_10ms

ACR position controller

This function part contains the calculation of the battery correction factor, the static pre - load of the position controller output and a final position setpoint filter function as a part of the closed - loop position control. In the inactive state of the position control algorithm the battery voltage correction factor is set to 1, the static preload is set to C_PWM_ACR_CLOSE and all other values are set to zero.

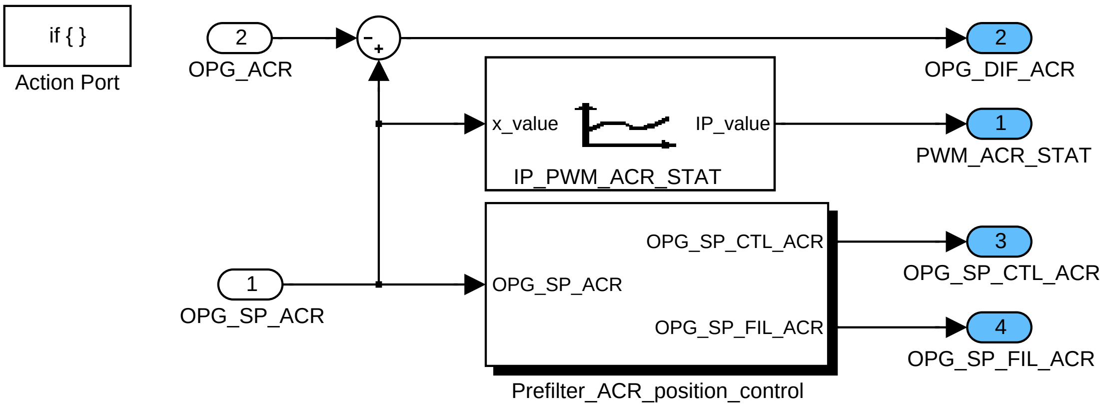

Figure 22 ACRC_position_controller/ operate_10ms/ active

Pre–filter functionality

The position setpoint filter function consists of a rate limitation functionality and a weighting between the described setpoint rate limitation and the direct setpoint request. The weighting can be chosen by the calibration constant C_FAC_OPG_SP_ACR. Finally the setpoint request for the digital position controller is corrected by the static transfer amplification factor C_FAC_K_FIL_ACR_CTL of the position controller filter function.

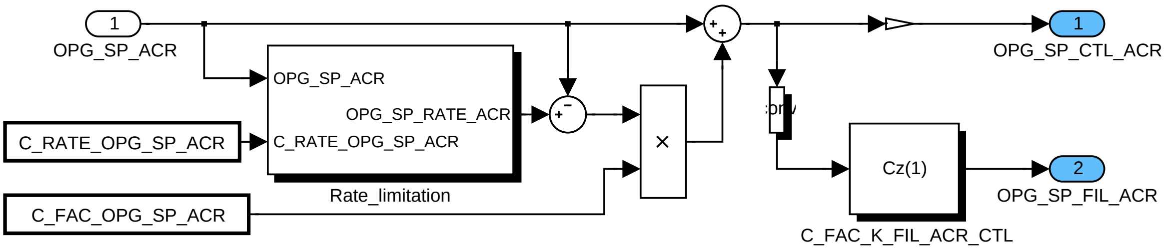

Figure 23 ACRC_position_controller/ operate_10ms/ active/ Prefilter_ACR_position_control

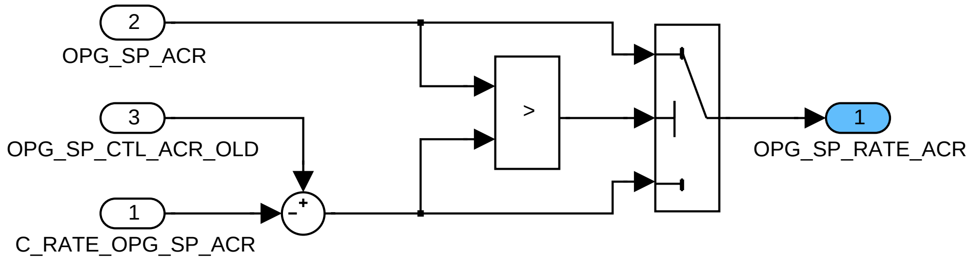

Figure 26 ACRC_position_controller/ operate_10ms/ active/ Prefilter_ACR_position_control/ Rate_limitation/ Close_direction

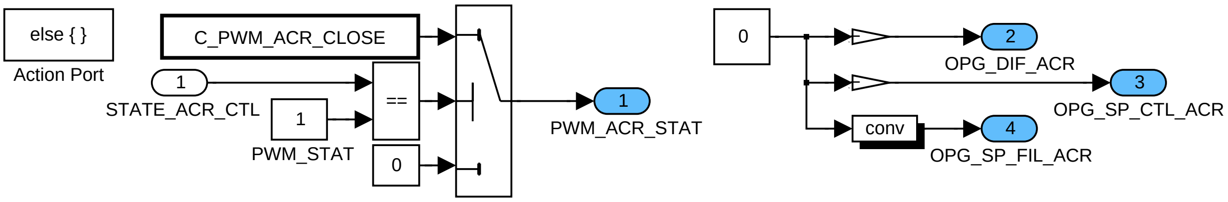

Note: The state variable OPG_SP_RATE_ACR_OLD from the active part is also set to zero !

Figure 27 ACRC_position_controller/ operate_10ms/ inactive

17.8.1.2 Functional part of 2ms

The 2 ms functionality of the position controller is only calculated if the closed-loop position control has been requested. Closed-loop position control will be indicated by the state PWM_CTL (= 2)of the state variable STATE_ACR_CTL.

After the calculation of the position controller the static preload and the battery voltage correction are considered. Finally the PWM duty-cycle of the position controller output will be limited between -100 % and 100 %.

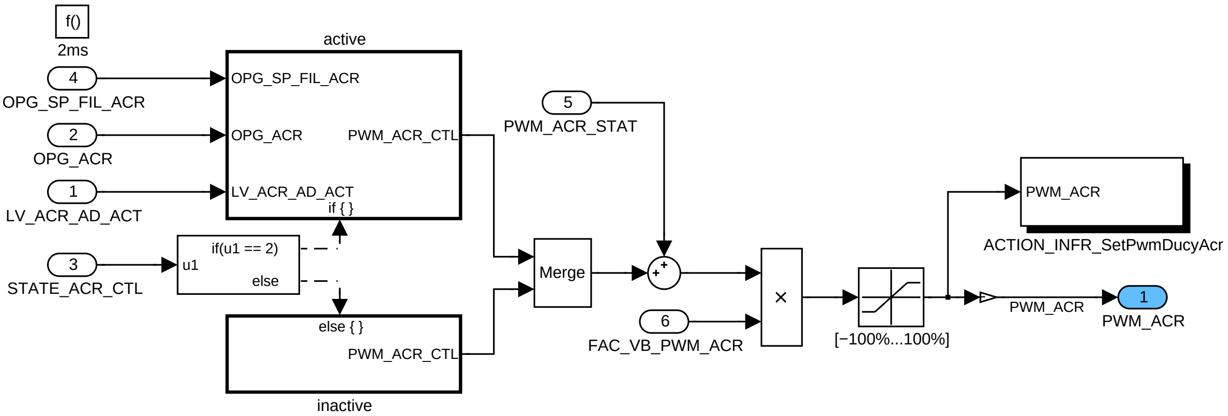

Figure 28 ACRC_position_controller/ operate_2ms

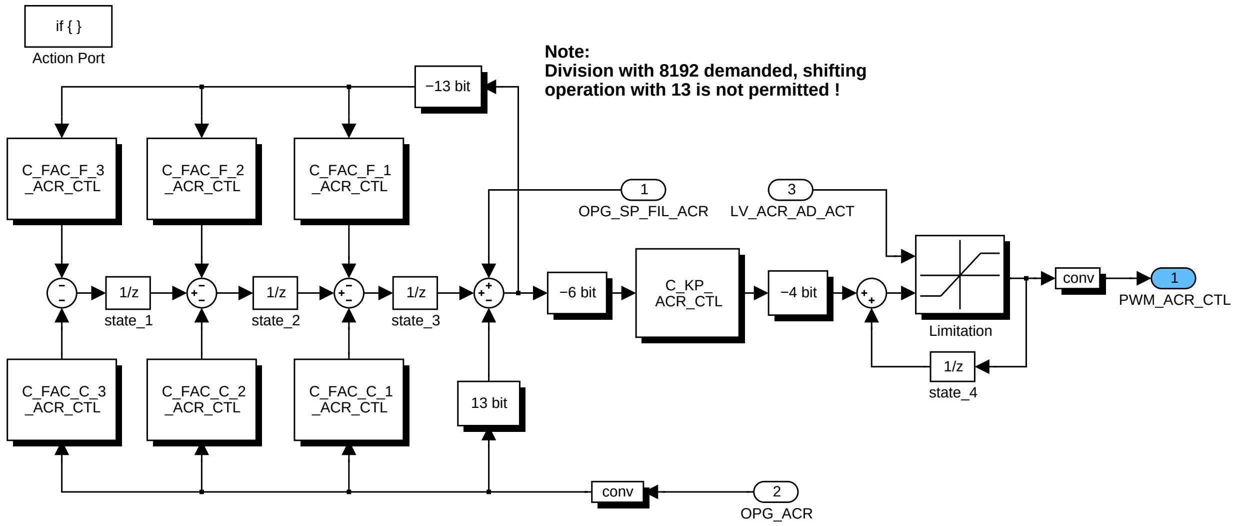
ACR position controller

The position control algorithm is a robust digital position controller and based on the pole placement design. The position controller consists of a filter function third order in backwards direction and a amplification factor with integrated integrator in forward direction. The output of the integrator is limited between a lower and upper limitation threshold. In the inactive state of the controller algorithm all state variables (state_x, x = 1...4) and the controller output are set to zero.

Calibration data are determined according to SiemensVDO internal position controller design algorithms.



Note:
Division with 8192 demanded, shifting operation with 13 is not permitted !

PWM_ACR = KP * z / (z − 1) * [C(1) / F(1) * OPG_SP_ACR − C(z) / F(z) * OPG_ACR]

C_FAC_x_y_ACR_CTL : HEX = 8000...7FFFH, DEC = −4...4, RES = 2^−13 = 1.2207e−4

C_KP_ACR_CTL : HEX = 0...400H, DEC = 0...64, RES = 2^−4 = 0.0625

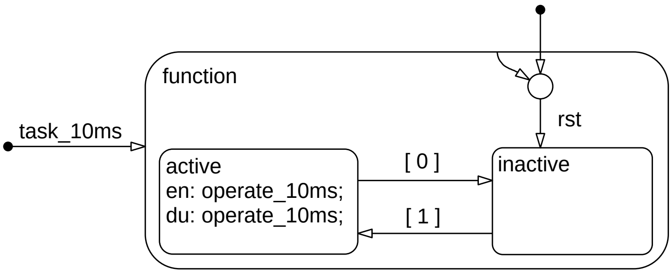
Import actions:

ACTION_INFR_DisableAcrDr( )
This action is able to switch-off the ACR power stage.
ACTION_INFR_EnableAcrDr( )
This action is able to switch-on the ACR power stage.

17.9.1 General information

The propose of this module is to coordinate all states of closed – loop position control. The state variable STATE_ACR_CTL indicates the current state of the actuator systems. The operating can be divided in the power stage is deactivated via disable line, the actuator is controlled means of static PWM duty-cycle for active valve closing and the closed – loop position control.

Application Condition



ACRC_position_controller_ai/APP_CDN/APP_CDN

Function Description

LV_ERR_ACR_AD	LV_ERR_ACR_CTL	LV_ERR_ACR_DR	LV_ERR_MAP_TPS_PLAUS

General information:

The EGR-Control is activated (LV_ACR_CTL_ENA = 1), if the coolant temperature TCO is higher than a threshold value C_TCO_MIN_EGR and the engine is running at part load or idle speed (LV_FL=0). If idle speed is detected the EGR-function is activated after the time T_AST> C_T_AST_EGR.

Application conditions:

Initialisation: at RST set LV_ACR_CTL_ENA to zero !

Recurrence: 20ms

Activation: at all engine operating states

Deactivation: no deactivation

Formula section:

```
if      TCO > C_TCO_MIN_EGR                          and

17.11.1 General information

The actuator valve position is determined by a measuring system. In order to reduce measurement inaccuracy, the sensor signal voltage is referenced to its sensor supply voltage. The electrical value of the lower and upper mechanical stop depends on the actuator characteristic, the actuator temperature and the valve coking therefore the electrical valve characteristic has to be learnt. After the actuator adaptation the adaptation values of the lower, the upper mechanical stop and the sensor slope are stored at the end of the driving cycle as "non-volatile".

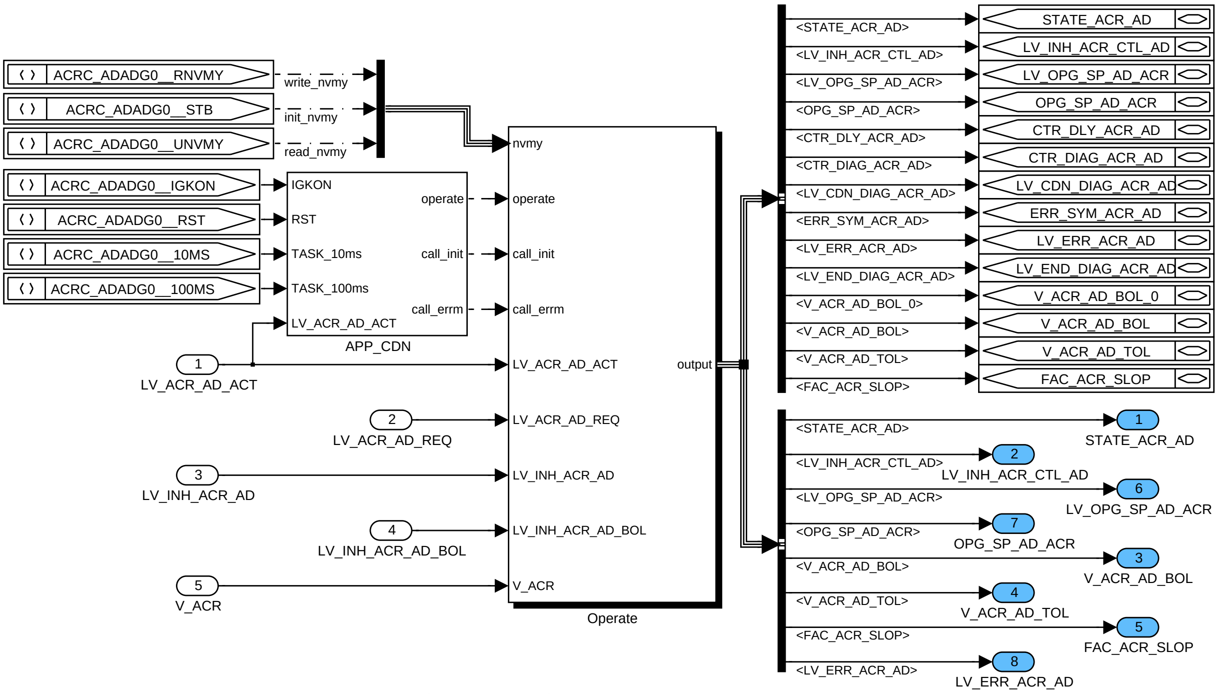
Function Description



SDA_SRS / SDA 4.0 19−Jul−2005

Figure 35 ACRC_adaptation_and_diagnosis

17.11.1.1 Adaptation functionalities

The adaptation functionality consists of a complete adaptation of the actuator valve and a continuously adaptation only for the lower mechanical valve stop. The adaptation algorithms are controlled by the variable LV_ACR_AD_ACT and the related inhibition conditions. The variables are provided in corresponding application incidence module.
After the reset of the functionality a complete adaptation of the actuator valve is started if the variable LV_ACR_AD_ACT has been set otherwise the continuously adaptation of the lower mechanical stop will be performed.

The adaptation module contain own diagnostic functions for the check of the adaptation values and the correct function of the actuator valve.

Error symptoms for the actuator adaptation are defined as follows :

SYM_0 – Adaptation conditions not fulfilled
SYM_1 – Lower adaptation value outside range
SYM_2 – Adaptation position not reached
SYM_3 – Upper adaptation value outside range

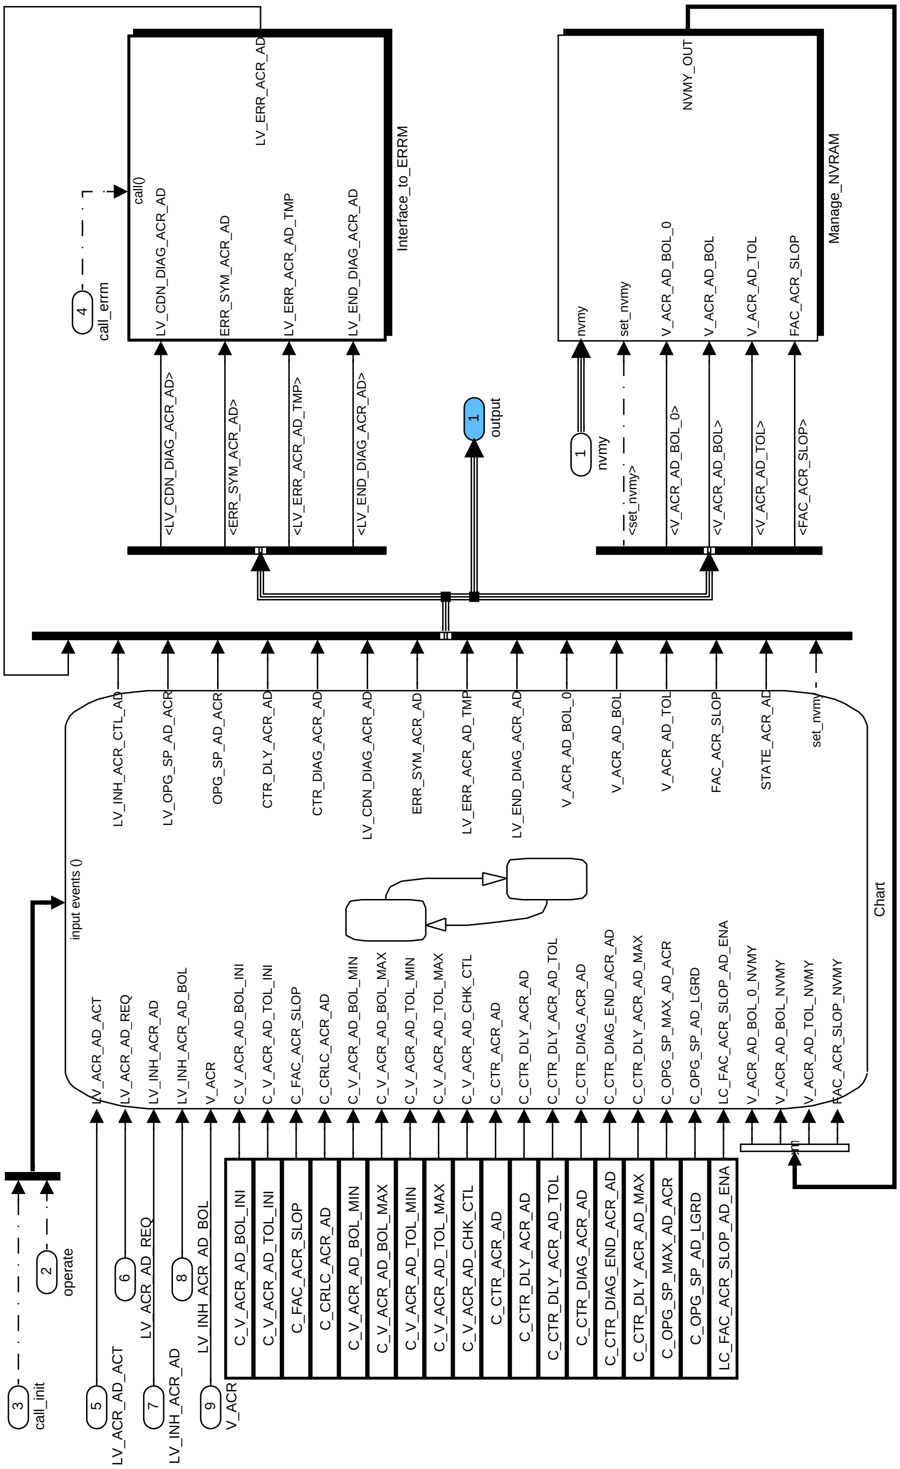


Figure 36 ACRC_adaptation_and_diagnosis/ Operate

State machine of the actuator adaptation

The state flow diagram of the actuator adaptation functionality contains the complete and the continuously adaptation functionality. The state machine is reset with a new reset event generated by the application conditions that means the functionality will be restarted on the default transition dependent on LV_ACR_AD_ACT.

The inhibition variable LV_INH_ACR_AD of the adaptation function is only check after the initialisation state has been finished. If the inhibition variable is set during the check then an error entry will be performed.

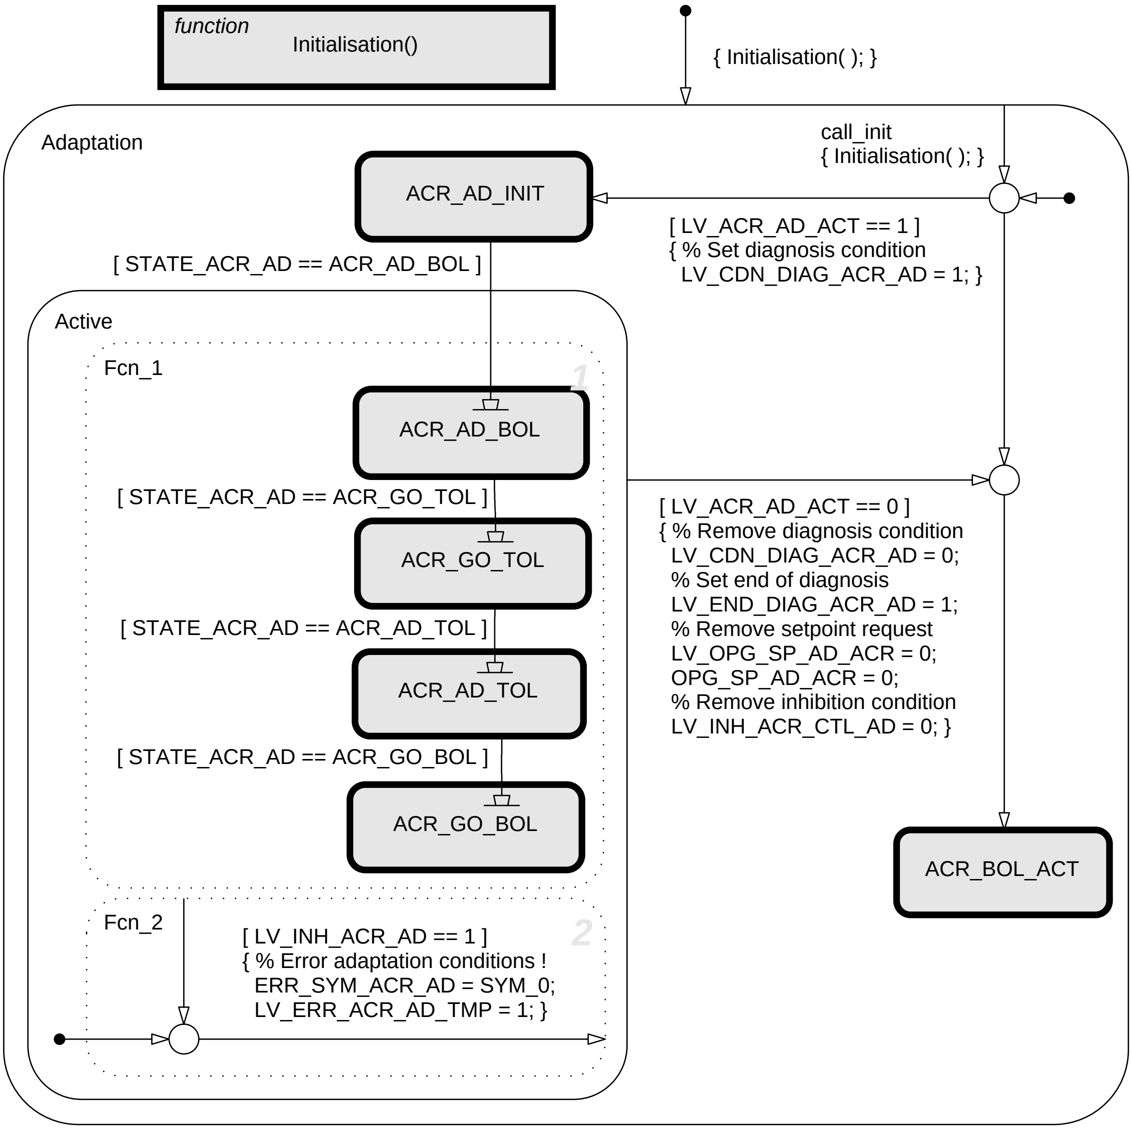

Figure 37 ACRC_adaptation_and_diagnosis/ Operate/ Chart

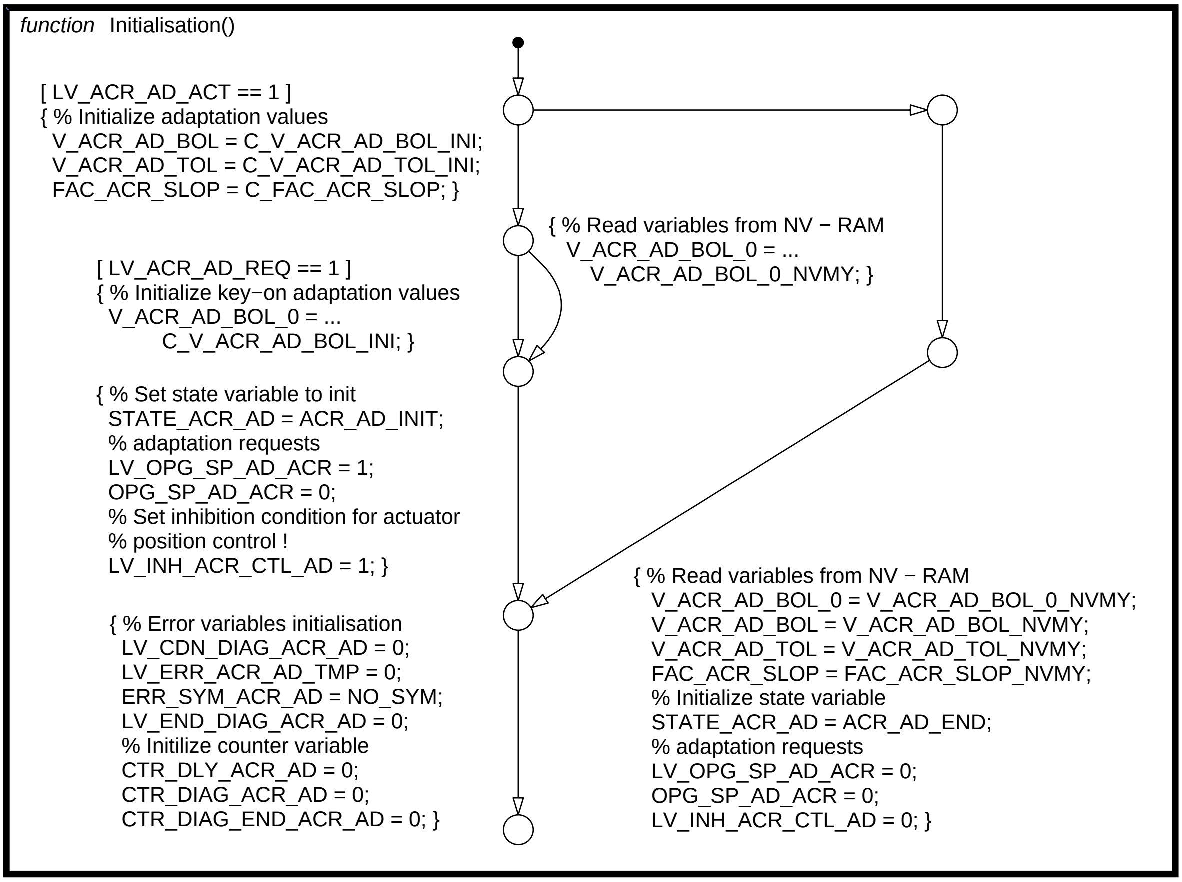
Initialisation function

The following function is used for the initialisation of the actuator adaptation. The function is called from the application condition module and shall initialise the adaptation values, the used error and auxiliary values.



```
function  Initialisation()

[ LV_ACR_AD_ACT == 1 ]
{ % Initialize adaptation values
  V_ACR_AD_BOL = C_V_ACR_AD_BOL_INI;
  V_ACR_AD_TOL = C_V_ACR_AD_TOL_INI;
  FAC_ACR_SLOP = C_FAC_ACR_SLOP; }

{ % Read variables from NV − RAM
  V_ACR_AD_BOL_0 = ...
    V_ACR_AD_BOL_0_NVMY; }

[ LV_ACR_AD_REQ == 1 ]
{ % Initialize key−on adaptation values
  V_ACR_AD_BOL_0 = ...
       C_V_ACR_AD_BOL_INI; }

{ % Set state variable to init
  STATE_ACR_AD = ACR_AD_INIT;
  % adaptation requests
  LV_OPG_SP_AD_ACR = 1;
  OPG_SP_AD_ACR = 0;
  % Set inhibition condition for actuator
  % position control !
  LV_INH_ACR_CTL_AD = 1; }

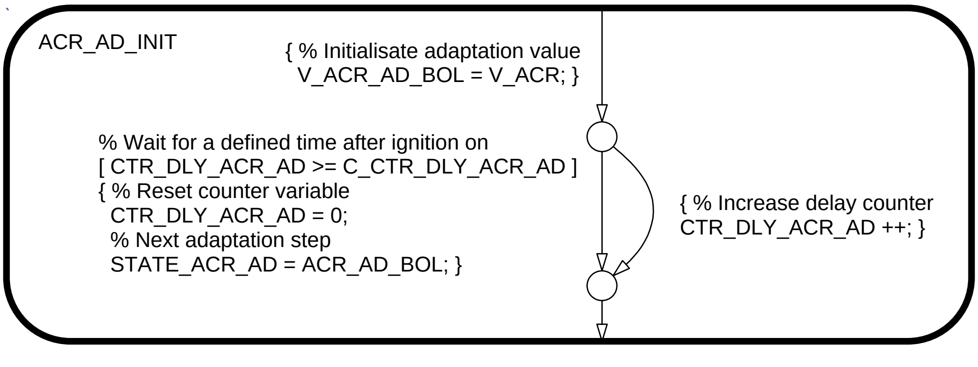
{ % Read variables from NV − RAM
  V_ACR_AD_BOL_0 = V_ACR_AD_BOL_0_NVMY;
  V_ACR_AD_BOL = V_ACR_AD_BOL_NVMY;
  V_ACR_AD_TOL = V_ACR_AD_TOL_NVMY;
  FAC_ACR_SLOP = FAC_ACR_SLOP_NVMY;
  % Initialize state variable
  STATE_ACR_AD = ACR_AD_END;
  % adaptation requests
  LV_OPG_SP_AD_ACR = 0;
  OPG_SP_AD_ACR = 0;
  LV_INH_ACR_CTL_AD = 0; }

{ % Error variables initialisation
  LV_CDN_DIAG_ACR_AD = 0;
  LV_ERR_ACR_AD_TMP = 0;
  ERR_SYM_ACR_AD = NO_SYM;
  LV_END_DIAG_ACR_AD = 0;
  % Initilize counter variable
  CTR_DLY_ACR_AD = 0;
  CTR_DIAG_ACR_AD = 0;
  CTR_DIAG_END_ACR_AD = 0; }
```

Figure 38 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Initialisation

Initialisation state of the actuator adaptation

At the start of the actuator adaptation the following initialisation function is necessary. During the initialisation state the adaptation waits a defined time for valid adaptation conditions.



```
ACR_AD_INIT

{ % Initialisate adaptation value
  V_ACR_AD_BOL = V_ACR; }

% Wait for a defined time after ignition on
[ CTR_DLY_ACR_AD >= C_CTR_DLY_ACR_AD ]
{ % Reset counter variable
  CTR_DLY_ACR_AD = 0;
  % Next adaptation step
  STATE_ACR_AD = ACR_AD_BOL; }

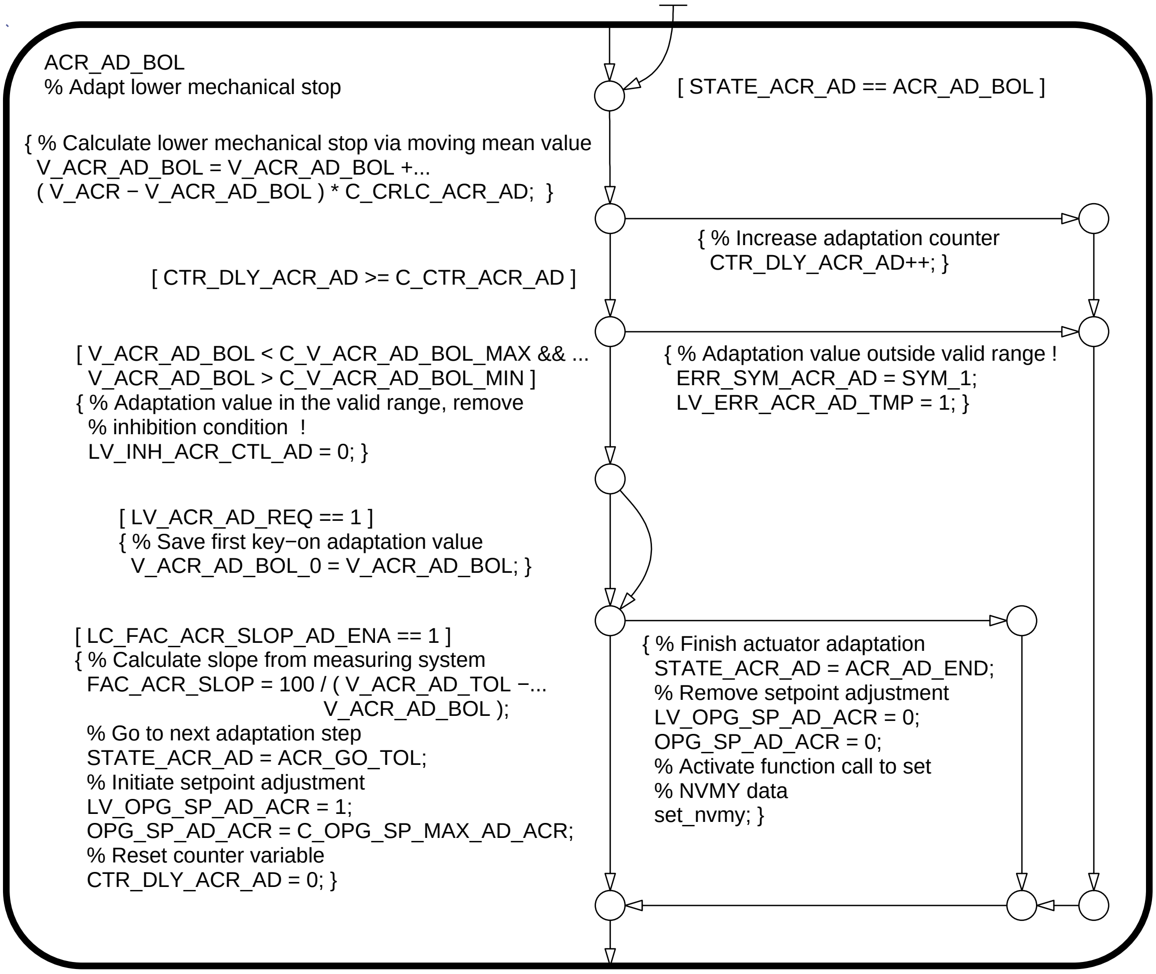
{ % Increase delay counter
CTR_DLY_ACR_AD ++; }
```

Figure 39 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ ACR_AD_INIT

Adaptation of the lower mechanical stop

In the following state the lower mechanical stop of the actuator valve is learnt. The adaptation value is determined as moving mean value of the sensor signal voltage. The corresponding correlation constant C_CRLC_ARC_AD defines the calculation of the adaptation value. The adaptation is performed only for a defined adaptation time to get a valid adaptation value. At the end of the algorithm the adaptation value is check of validity. If the adaptation value is outside of the valid range than an error entry will be performed.

Additionally the further adaptation functionality, the adaptation of the upper mechanical stop, can be chosen via configuration data LC_FAC_ACR_SLOP_AD_ENA. If the constant is set then the upper mechanical stop and the sensor slope will be learnt, otherwise the adaptation will be finished and the initialisation values will be used !



```
ACR_AD_BOL
% Adapt lower mechanical stop

[ STATE_ACR_AD == ACR_AD_BOL ]

{ % Calculate lower mechanical stop via moving mean value
  V_ACR_AD_BOL = V_ACR_AD_BOL +...
  ( V_ACR − V_ACR_AD_BOL ) * C_CRLC_ACR_AD;  }

{ % Increase adaptation counter
  CTR_DLY_ACR_AD++; }

[ CTR_DLY_ACR_AD >= C_CTR_ACR_AD ]

[ V_ACR_AD_BOL < C_V_ACR_AD_BOL_MAX && ...
  V_ACR_AD_BOL > C_V_ACR_AD_BOL_MIN ]
{ % Adaptation value in the valid range, remove
  % inhibition condition  !
  LV_INH_ACR_CTL_AD = 0; }

{ % Adaptation value outside valid range !
  ERR_SYM_ACR_AD = SYM_1;
  LV_ERR_ACR_AD_TMP = 1; }

[ LV_ACR_AD_REQ == 1 ]
{ % Save first key−on adaptation value
  V_ACR_AD_BOL_0 = V_ACR_AD_BOL; }

[ LC_FAC_ACR_SLOP_AD_ENA == 1 ]
{ % Calculate slope from measuring system
  FAC_ACR_SLOP = 100 / ( V_ACR_AD_TOL −...
                         V_ACR_AD_BOL );
  % Go to next adaptation step
  STATE_ACR_AD = ACR_GO_TOL;
  % Initiate setpoint adjustment
  LV_OPG_SP_AD_ACR = 1;
  OPG_SP_AD_ACR = C_OPG_SP_MAX_AD_ACR;
  % Reset counter variable
  CTR_DLY_ACR_AD = 0; }

{ % Finish actuator adaptation
  STATE_ACR_AD = ACR_AD_END;
  % Remove setpoint adjustment
  LV_OPG_SP_AD_ACR = 0;
  OPG_SP_AD_ACR = 0;
  % Activate function call to set
  % NVMY data
  set_nvmy; }
```

Figure 40 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ Active/ ACR_AD_BOL

Drive actuator in the upper mechanical stop

The following state drives the actuator valve in the upper mechanical stop via setpoint adjustment. At first the setpoint for closed-loop position control is set to a defined start value and the power stage is switched on. Afterwards the setpoint is increased via change limitation to 100 %.

Additionally the state checks the correct function of the closed-loop position control system. If the setpoint is set to 100 % then the actuator valve must exceed a diagnostic threshold otherwise an adaptation error is indicated and the adaptation is stopped.

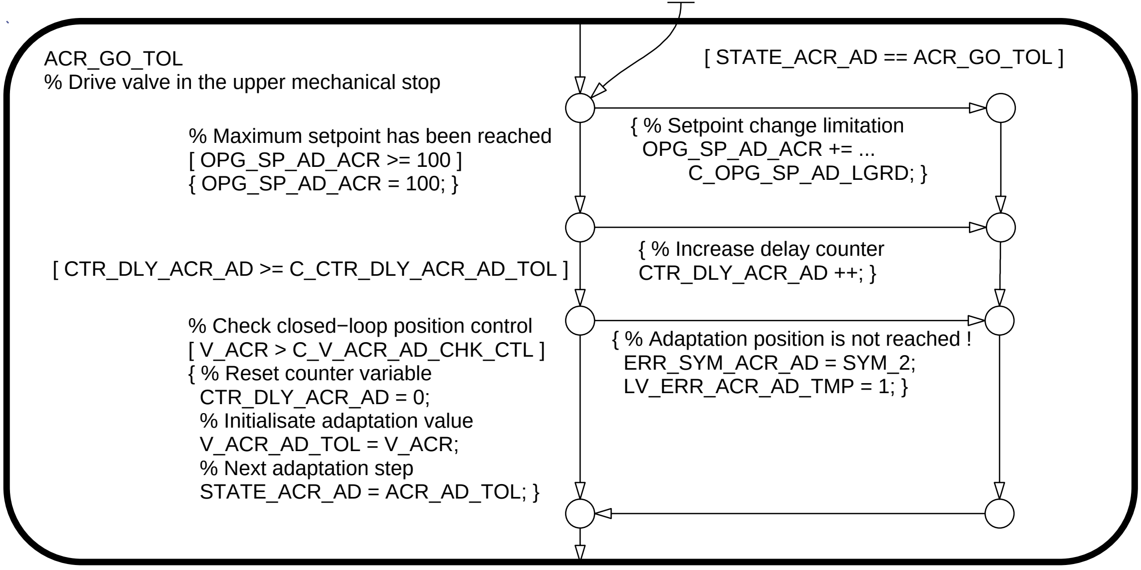


Figure 41 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ Active/ ACR_GO_TOL

Adaptation of the upper mechanical stop

In the next adaptation state the upper mechanical stop of the actuator valve is learnt. The adaptation value of the upper mechanical stop is determined as moving mean value of the sensor signal voltage. The corresponding correlation constant C_CRLC_ARC_AD defines the calculation of the adaptation value. The adaptation is performed only for a defined adaptation time to get a valid adaptation value. At the end of the algorithm the adaptation value of the upper mechanical stop is check of validity. If the adaptation value is outside of the valid range than an error entry will be performed.

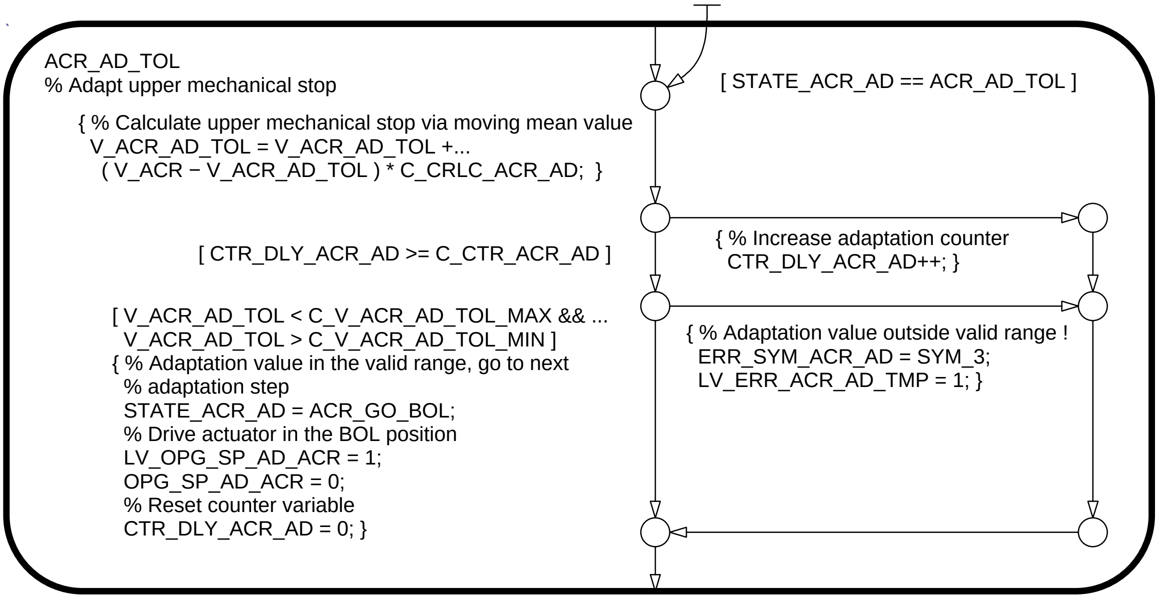

Figure 42 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ Active/ ACR_AD_TOL

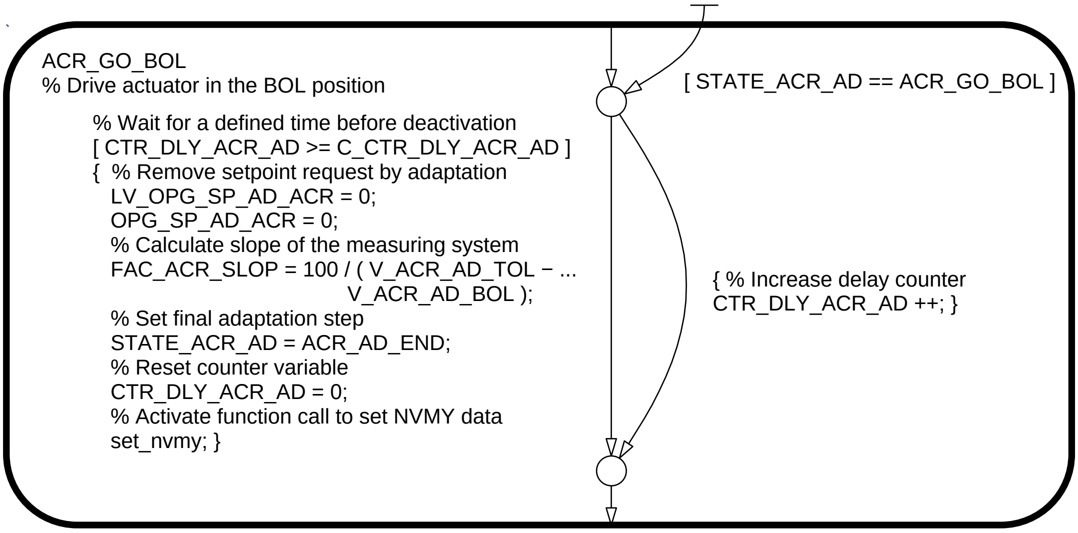
Finish actuator adaptation

The last state of the adaptation shall drive the actuator valve in the lower mechanical stop and calculate the sensor signal slop of the measuring system. The adaptation state will be left if a defined waiting time is elapsed.



```
ACR_GO_BOL
% Drive actuator in the BOL position
```

```
[ STATE_ACR_AD == ACR_GO_BOL ]
```

```
% Wait for a defined time before deactivation
[ CTR_DLY_ACR_AD >= C_CTR_DLY_ACR_AD ]
{  % Remove setpoint request by adaptation
   LV_OPG_SP_AD_ACR = 0;
   OPG_SP_AD_ACR = 0;
   % Calculate slope of the measuring system
   FAC_ACR_SLOP = 100 / ( V_ACR_AD_TOL − ...
                              V_ACR_AD_BOL );
   % Set final adaptation step
   STATE_ACR_AD = ACR_AD_END;
   % Reset counter variable
   CTR_DLY_ACR_AD = 0;
   % Activate function call to set NVMY data
   set_nvmy; }
```

```
{ % Increase delay counter
CTR_DLY_ACR_AD ++; }
```

Figure 43 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ Active/ ACR_GO_BOL

Continuously adaptation of the lower mechanical stop

If the actuator valve is in closing position, then the adaptation of the lower mechanical stop will be started after a defined delay time. A closed actuator valve is indicated by the state variable STATE_ACR_CTL of the position control software. The adaptation value is determined as moving mean value of the sensor signal voltage. The corresponding correlation constant C_CRLC_ARC_AD defines the calculation of the adaptation value.

At the end of the algorithm the adaptation value is check of validity. If the adaptation value is outside of the valid range than an error entry will be performed.

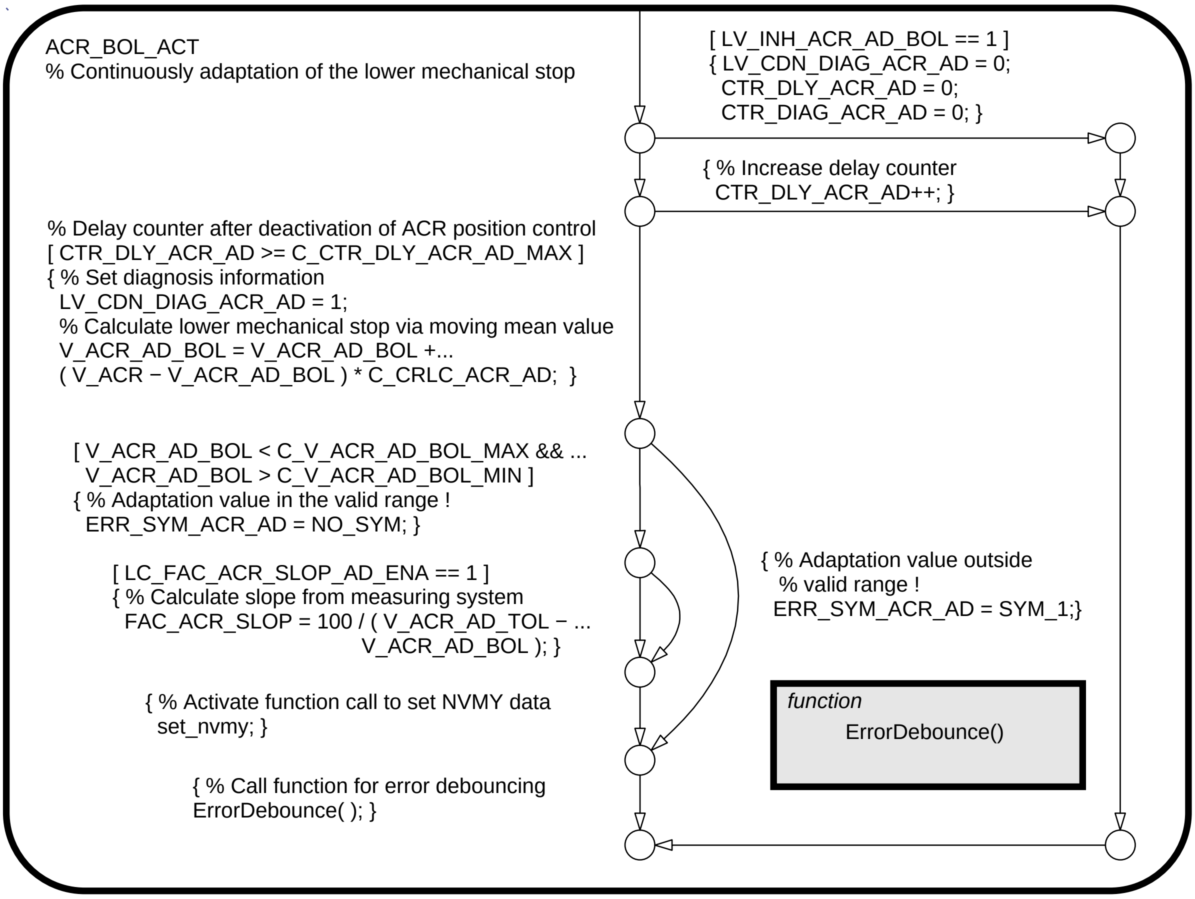


Figure 44 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ ACR_BOL_ACT

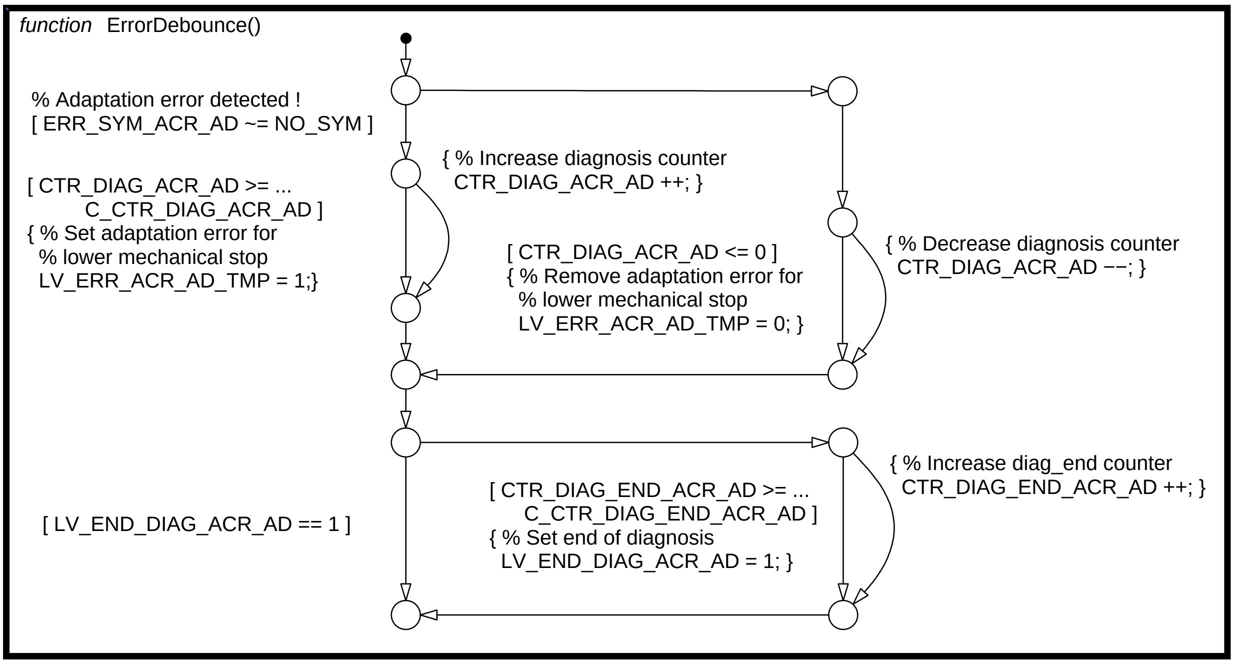

Figure 45 ACRC_adaptation_and_diagnosis/ Operate/ Chart/ Adaptation/ ACR_BOL_ACT/ ErrorDebounce

Interface to the error management

The following algorithm set the detected error and the end of diagnosis information according the diagnostic result and delivers the result to Error Management.

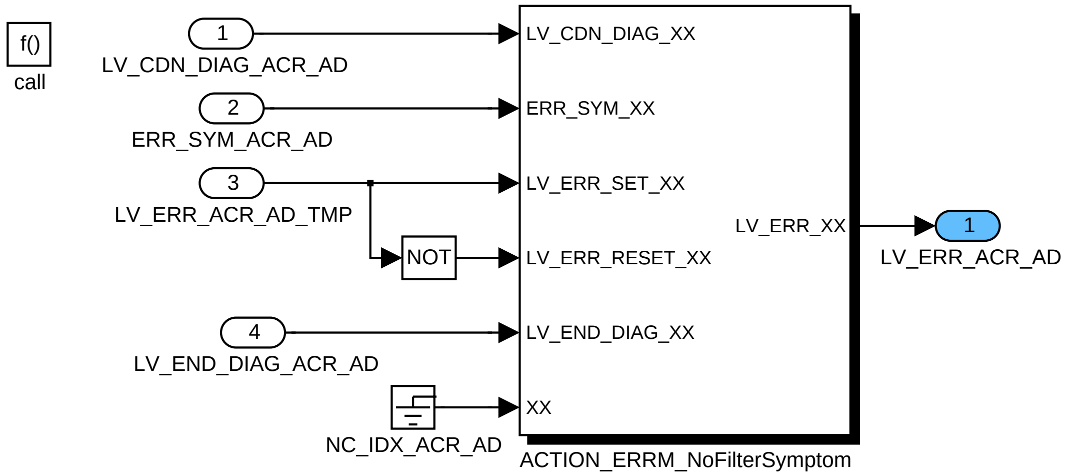

Figure 46 ACRC_adaptation_and_diagnosis/ Operate/ Interface_to_ERRM

Manage non-volatile variables

The last section describes the data handling of variables defined in the non-volatile memory. Three function calls are available for the initialisation, the readout and the update of the non-volatile memory. A special feature has been implemented for the data update. New adaptation values are only stored for an error free system and a successful adaptation end. Otherwise the last valid adaptation values will be used again for the NVRAM update!

17.12.1 General information

This module describes the coordination of the actuator adaptation with corresponding diagnosis functions. The actuator adaptation can be split in a standard adaptation during IGKON and post operation phase and a continuously adaptation only for the adaptation of the lower mechanical stop. Separate inhibition conditions for the described adaptations are available.

Application Condition

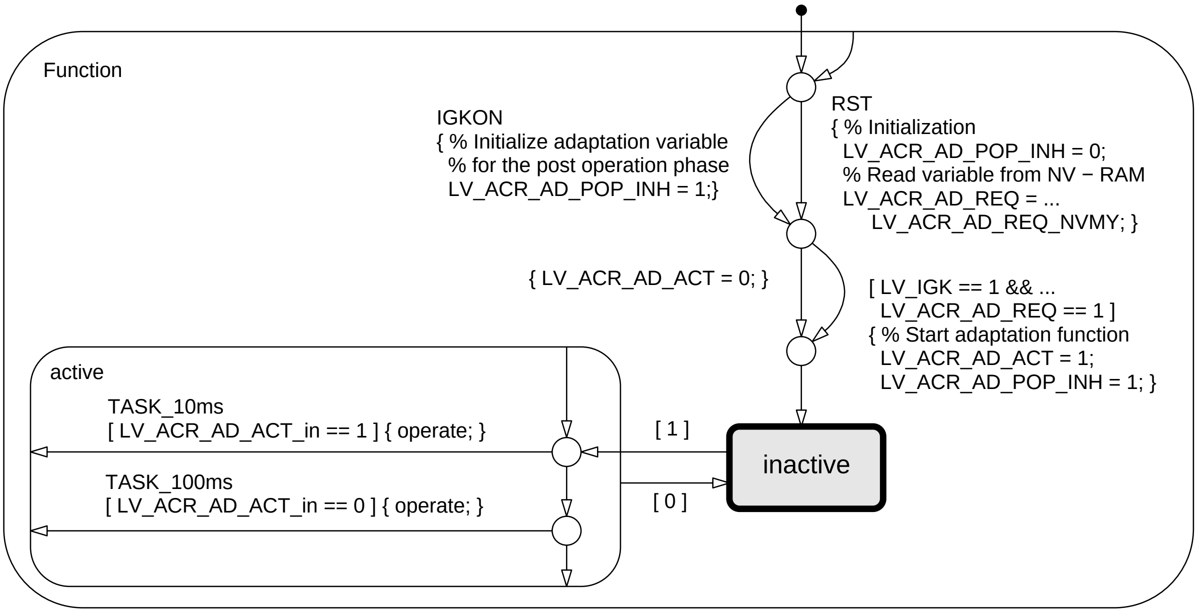

Figure 52 ACRC_adaptation_and_diagnosis_ai/ APP_CDN/ APP_CDN

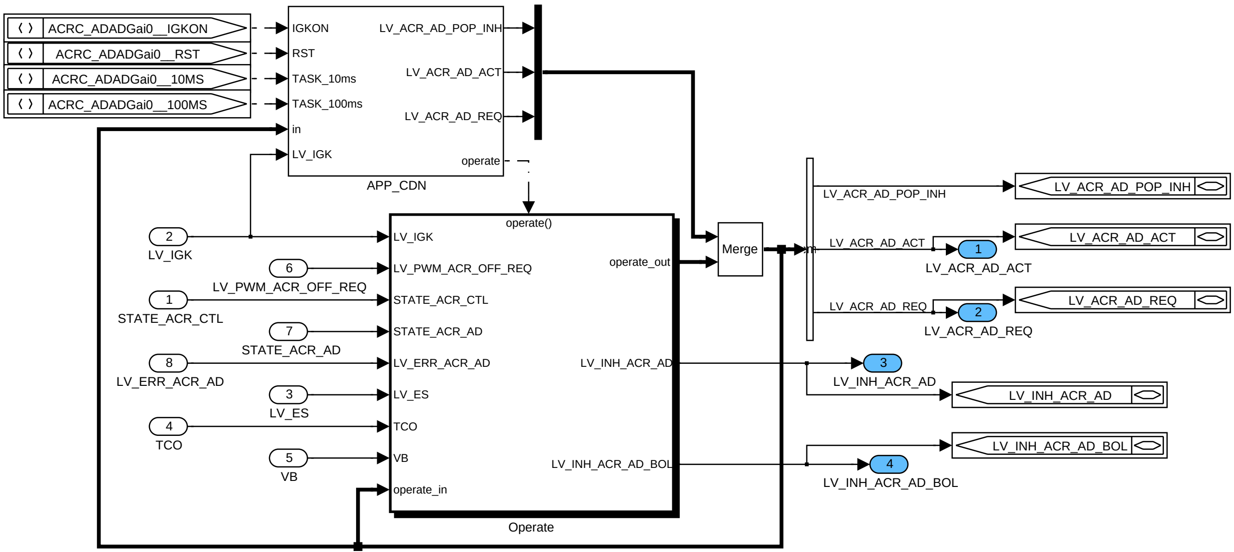
Function Description



SDA_SRS / SDA 4.0 02−Mar−2005

Figure 53 ACRC_adaptation_and_diagnosis_ai

17.12.1.1 Coordination of the adaptation functionality

The adaptation request LV_ACR_AD_REQ is checked every time the control unit is switched on. If an adaptation is requested then a "first key on" adaptation will be performed with LV_ACR_AD_ACT = 1. The actuator adaptation is necessary in the following cases:

- In initial start (first engine run or control unit exchange), that means no adaptation values are stored in the non volatile memory
- Check sum error (NVMY – error) is current
- Adaptation request bit LV_ACR_AD_REQ is set

Each of these points ends with a new adaptation request. After the activation of the "key on" actuator adaptation the corresponding inhibition condition will be checked continuously.

A second part of the adaptation functionality is the actuator adaptation in the post operating phase. After ignition off and engine stop the corresponding inhibition variable is once checked. If all activation conditions are fulfilled then the actuator adaptation will be started, the inhibition variable is **not** checked during the adaptation to avoid possible error entries.

17.15.1 General information

The used power stage is an intelligent full H-Bridge, designed for the control of DC and stepper motors in safety critical applications and under extreme environmental conditions. The H-Bridge is protected against over-temperature, short circuits and has an under voltage lockout for all supply voltages (main DC power supply). All malfunctions cause the output stages to go tristate.

In this application the power stage is implemented in the status flag mode, that means indicated errors can not be distinguished by the software. The following errors can be detected only by the power stage:

Undervoltage / Overcurrent / Overtemperature / hardware disabled manually

Error-symptoms are defined to this diagnosis function as following:

- SYM_0 - ACR power stage error

This action computes the elementary treatment case no filtering is used

17.17.1 General information

The task of this diagnosis is to detect an actuator valve error or a jammed actuator. The diagnostic observes the control deviation of the closed-loop position control system dependent on the gradient of the actuator valve position setpoint.

Additionally the position controller output is monitored by this diagnostic function. If the moving mean value of PWM_ACR exceeds a defined threshold than an error will be indicated. The calculation of the moving mean value is done by an low pass filter first order.

Application Condition

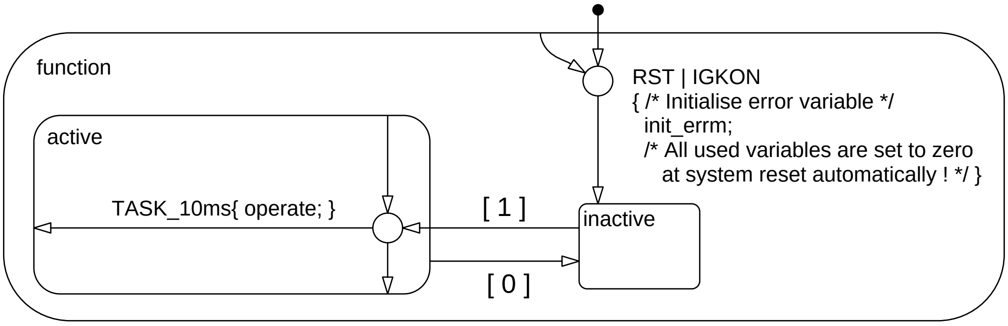

Figure 61 ACRC_actuator_diagnosis/ APP_CDN/ APP_CDN

Function Description

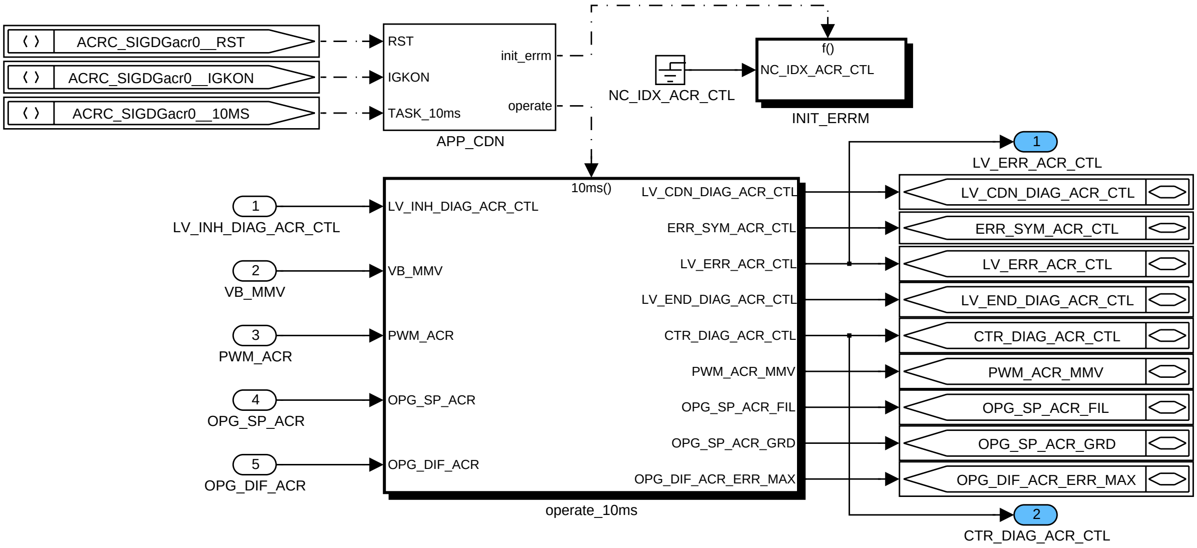

Figure 62 ACRC_actuator_diagnosis

17.17.1.1 Monitoring of the actuator valve function

The anti-bounce of the error detection is done at the end of the module without generic debounce algorithm. The increment and decrement value of the implemented algorithm can be calibrated.

The following error symptoms can be distinguished:

- PWM error of the closed loop position control system

- System deviation outside the admissible range

Error symptoms are defined to this diagnosis function as following:

SYM_0 – System deviation outside range

SYM_1 – PWM_ACR outside range

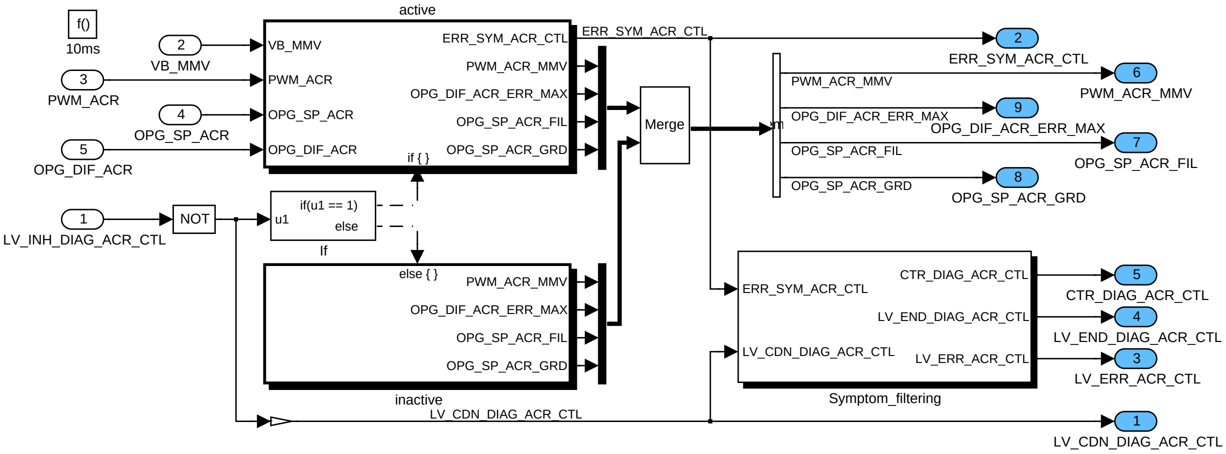

Figure 63 ACRC_actuator_diagnosis/ operate_10ms

Actuator failure detection

This chapter calculates the admissible error of the control deviation and the moving mean value of the position controller output, after than the error symptom determination will be performed !

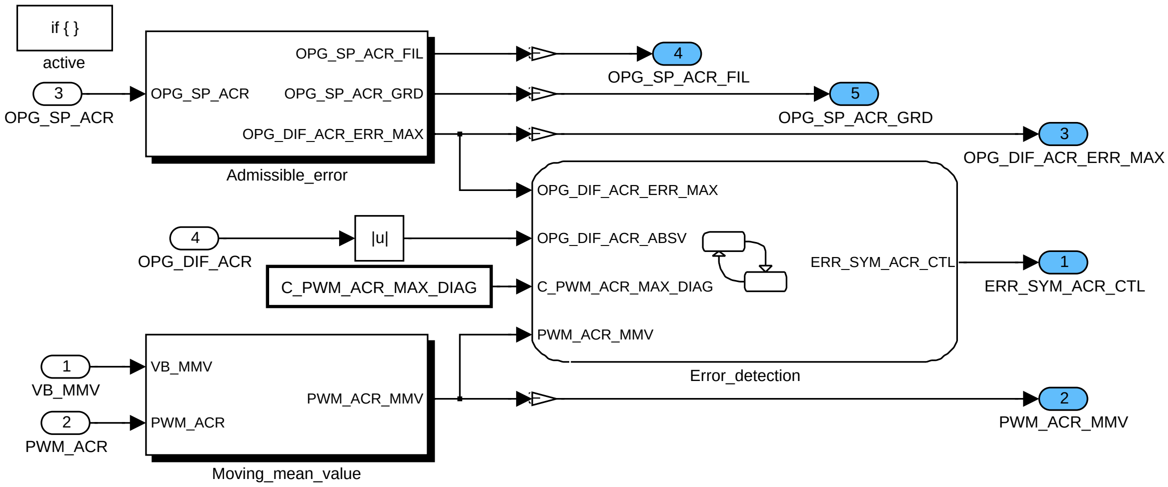

Figure 64 ACRC_actuator_diagnosis/ operate_10ms/ active

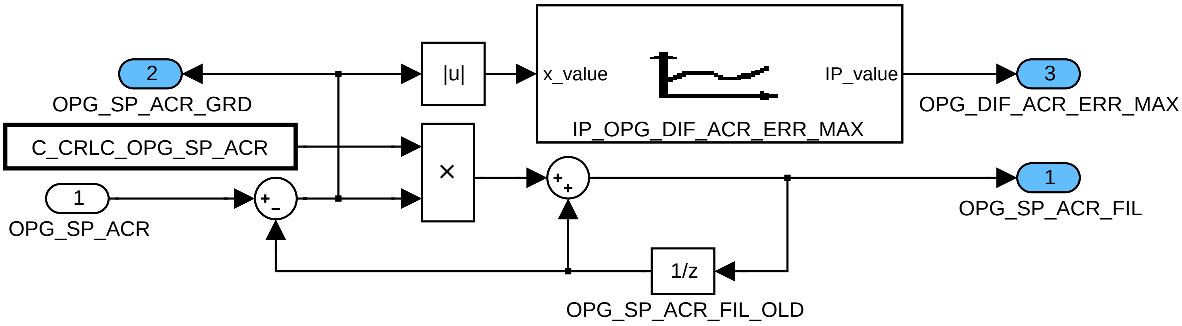

Figure 65 ACRC_actuator_diagnosis/ operate_10ms/ active/ Admissible_error

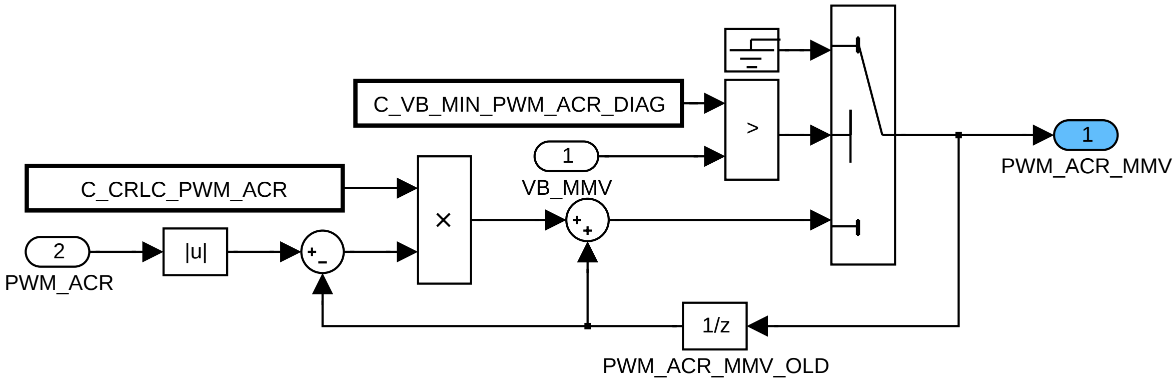

Figure 66 ACRC_actuator_diagnosis/ operate_10ms/ active/ Moving_mean_value

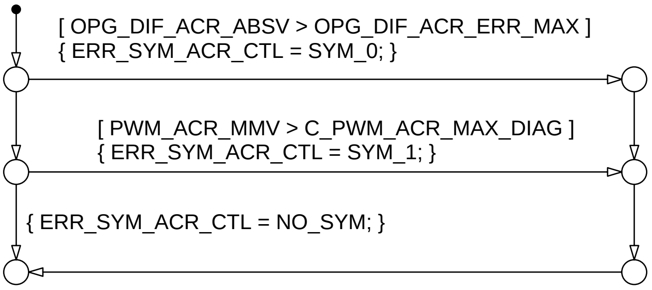

Figure 67 ACRC_actuator_diagnosis/ operate_10ms/ active/ Error_detection

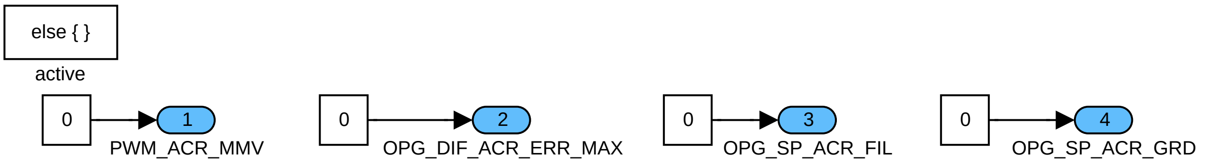

The state variables PWM_ACR_MMV_OLD and OPG_SP_ACR_FIL_OLD from the active state are also set to zero

Figure 68 ACRC_actuator_diagnosis/ operate_10ms/ inactive

Error symptom filtering

Finally the anti-bounce algorithm for the determined error symptoms and the end of diagnosis information are calculated. In case of errors the debounced error variable can be set for the driving cycle with the corresponding inhibition condition.

17.19 ACRC limp home management

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_PWM_ACR_OFF_REQ	O/V	0...1H	0...1	1	-
ACR position control deactivation requested from monitoring level 1					
LV_OPG_ACR_INI_REQ	O/V	0...1H	0...1	1	-
Logical variable requests the replacement value for actuator signal acquisition					

Input data:

LV_ERR_VCC_ACR	LV_ERR_SENS_ACR	LV_ERR_ACR_DR	LV_ERR_ACR_CTL
LV_ERR_ACR_AD			

17.19.1 General information

The limp home management monitors the diagnostic functions of the closed-loop actuator control system. In case of monitoring level 1 errors the limp home function requests the deactivation of the power stage and actuator position control. The following diagnostic functions for ACRC position control are available:

- ACRC position sensor diagnosis
- ACRC power stage diagnosis
- ACRC actuator diagnosis
- ACRC adaptation diagnosis

Application Condition

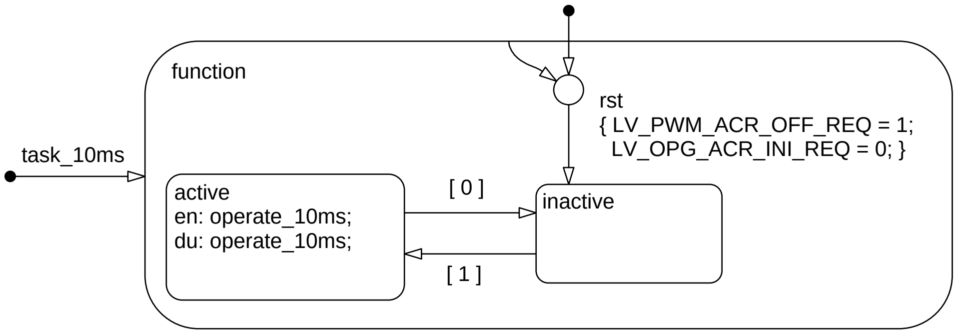

Figure 76 ACRC_limp_home_management/ APP_CDN/ APP_CDN

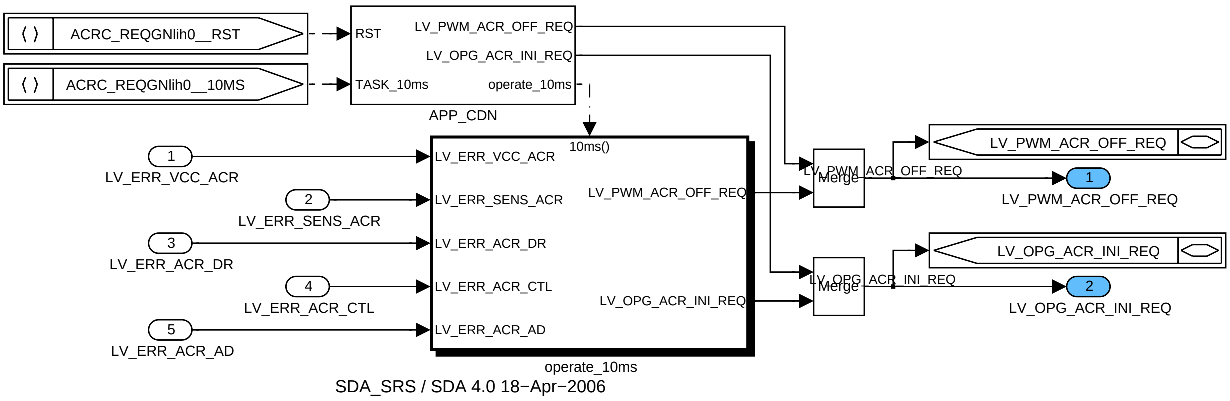

Figure 77 ACRC_LIMP_HOME_MANAGEMENT

17.19.2 Calculate switch-off request for ACR power stage

The following section calculates the power stage deactivation request with monitoring level 1 errors. Additionally the request for the replacement value of the sensor signal acquisition is determined.

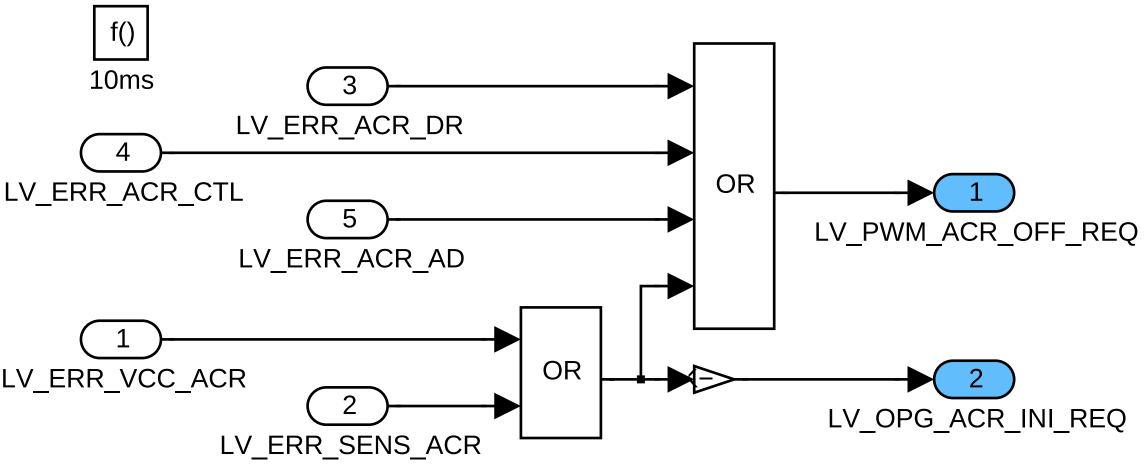

Figure 78 ACRC_LIMP_HOME_MANAGEMENT/ OPERATE_10MS

17.20 Calibration hints for actuator position control

17.20.1 Calibration interfering functions

No special requirements for the calibration with interfering functions are known.

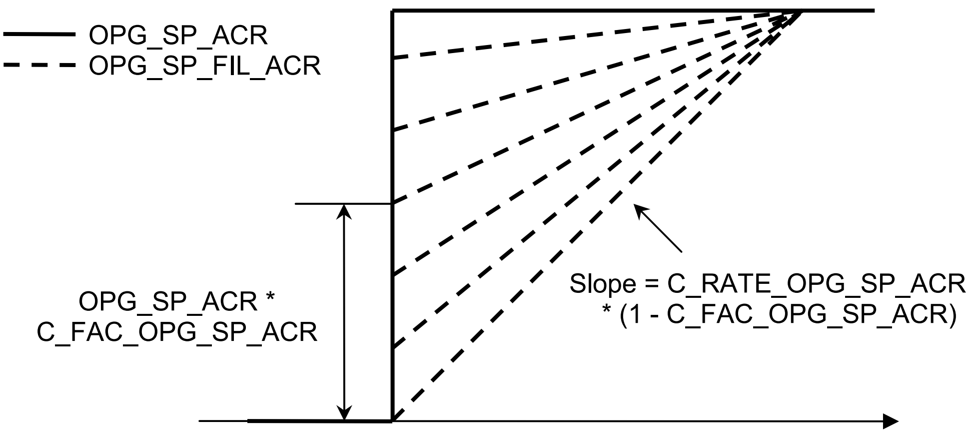
17.20.2 Calibration flowchart

The sequence is described by the order in calibrated methods.

17.20.3 Calibration method

Actuator position controller

C_FRQ_PWM_ACR	The calibration constant defines the frequency of the PWM output signal delivered from the position controller. The value is determined by the technical actuator specification and the ECU requirements (power loss and EMC of the actuator power stage). A recommend value is 1000 Hz!
C_RATE_OPG_SP_ACR C_FAC_OPG_SP_ACR	The setpoint filter function consists of a gradient limitation and a weighting between the setpoint gradient limitation and the direct setpoint request. The weighting can be chosen by the calibration constant C_FAC_OPG_SP_ACR see below



C_FAC_C_1_ACR_CTL C_FAC_C_2_ACR_CTL C_FAC_C_3_ACR_CTL C_FAC_F_1_ACR_CTL C_FAC_F_2_ACR_CTL C_FAC_F_3_ACR_CTL	The filter coefficients of the digital position controller are defined according to the internal SiemensVDO position controller design algorithm.
C_FAC_K_FIL_ACR_CTL	The static correction factor is calculated as follow:

$$\text{C\_FAC\_K\_FIL\_ACR\_CTL} = 1 + \sum_{i=1}^{3} \text{C\_FAC\_C\_i\_ACR\_CTL}$$

The correction factor can be fine-tuned with the external setpoint adjustment after successful operating of the position control system. A large setpoint of the control system shows the finally control deviation OPG_DIF. Increase or decrease the calibration value to correct the control deviation, finally OPG_DIF should be set to 0 % (a maximum difference of one AD converter increment is permitted).

C_KP_ACR_CTL	Usually the amplification factor of the digital position controller is determined also according to the internal SiemensVDO position controller design algorithm. But the position controller is a very robust controller algorithm that means the calibration value can be adapted to the requirements of the control system.
C_PWM_MIN_ACR_CTL C_PWM_MAX_ACR_CTL	Both variables limit the output of the digital position controller. Usually the operating range of the position controller is defined from -100 % to 100 % PWM duty-cycle.
C_PWM_MAX_ACR_AD	Limitation threshold during actuator valve adaptation. The value shall protect the actuator against destroyment. The limitation value has to be calibrated with respect of the battery voltage correction and the technical specifications made for the actuator.
IP_FAC_VB_PWM_ACR	The battery voltage correction is determined by a characteristic line. To avoid too high amplification values the data points are used to limit the correction value. With nominal value of the battery voltage the correction factor should be 1. Theoretical correction formula : $\mathrm{FAC\_VB\_PWM\_ACR} = \frac{\mathrm{VB\_MMV}_{\mathrm{nominal}}}{\mathrm{VB\_MMV}}$
IP_PWM_ACR_STAT	The characteristic line can be used for the calibration of the static preload of the actuator valve. Usually the characteristic line should be calibrated to zero, that means the position controller has to be able to compensate the static preload completely!
C_PWM_ACR_CLOSE	The calibration constant defines the static PWM duty-cycle to close the actuator valve with power after deactivation of the digital position controller. The value must be chosen lower than zero, a recommend value is -10 %.

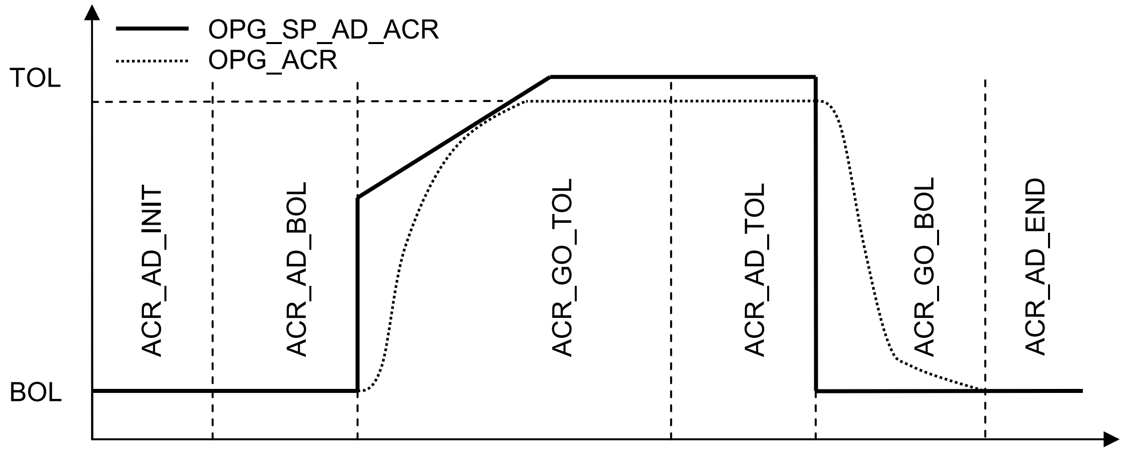
Actuator setpoint selection

C_OPG_SP_LIH_ACR	The limp-home position setpoint defines usually the setpoint request with deactivated control system. Normally the value is calibrated to 0 %.
C_OPG_SP_EXT_ACR	The calibration value is used for the setpoint adjustment requested from calibration system. The default calibration should be 0 %. **Note:** With active external setpoint request the position control system is not deactivated at small setpoint requests that means the position controller output can reach large PWM duty-cycles and can destroy the electrical actuator (monitor PWM_ACR_MMV).
C_OPG_SP_POP_ACR	The setpoint defines the setpoint request during the post operating phase of the electronic control unit (LV_IGK == 0). The setpoint request is used for the correct deactivation of the position control system. Calibrate the value with 0 %.
C_CTR_OPG_SP_POP_ACR	The counter variable describes the remaining activation of the closed-loop position control system with transition in the post-operating phase (LV_IGK == 0). Calibrate the value lower than 100 (that corresponded with 1 s).
C_OPG_SP_MIN_ACR_CTL	The described threshold is used to deactivate the position control system at small position setpoint requests. The position controller will be deactivated if the setpoint request

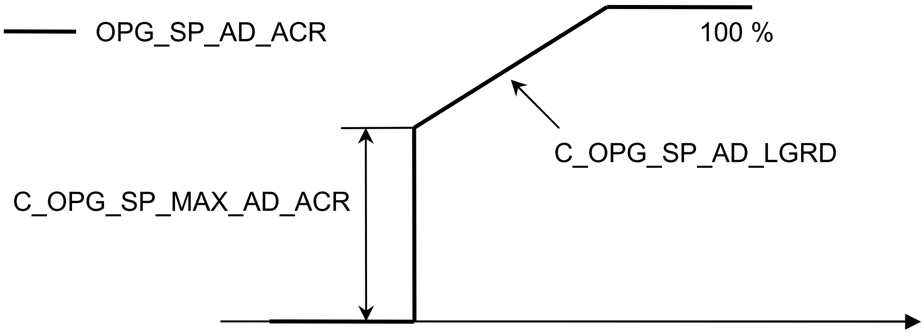
	falls below the threshold, recommend value is 0.3 %.
C_CTR_DLY_ACR_CTL	When the setpoint request falls below the above described threshold C_OPG_SP_MIN_ACR_CTL then a delay counter will be started and if the delay counter is elapsed then the digital position controller will be deactivated. The delay time has to be chosen with respect to actuator dynamic. That means the actuator valve must be able to reach the requested setpoint before deactivation. e.g. C_CTR_DLY_ACR_CTL = 25 that are 250 ms
C_OPG_SP_MIN_ACR	The lower setpoint limitation is used to limit the setpoint request in lower direction. The setpoint and the actual value of the control system have been implemented in unsigned integer. To get a negative control deviation OPG_DIF in each case the limitation value has to be calibrated larger than zero. Usually a recommend value is 0.2 %!
C_OPG_SP_MAX_ACR	The upper setpoint limitation is used to limit the setpoint request in upper direction. The aim is to protect the upper mechanical stop of the actuator and to get an additional sensor distance for the sensor range check diagnosis. The value should be chosen with respect to the tolerances of the ECU and the actuator measuring system.
LC_PWM_ACR_OFF_ENA	The configuration constant defines the state of the actuator power stage in normal operating with deactivated position controller. The algorithm can be distinguished two function modes. • LC_PWM_ACR_OFF_ENA = 0 The power stage is in the active state after deactivation of the digital position controller and the calibration constant C_PWM_ACR_CLOSE set the PWM duty-cycle for active valve closing. • LC_PWM_ACR_OFF_ENA = 1 The power stage will be deactivated via enable/disable line with deactivation of the digital position controller.

Actuator adaptation and diagnosis

LC_ACR_AD_REQ	The "first key on" actuator adaptation can be requested by a manual adaptation request via calibration system. Set the logical constant and an actuator adaptation will be performed with each reset.
LC_ACR_AD_POP_ENA	Logical constant to perform the actuator adaptation during post operation phase (LV_IGK = 1 ⇒ 0) ! The constant has to be set for an adaptation request.
C_ACR_AD_VB_MIN	Lowest admissible battery voltage to enable actuator valve adaptation. The calibration constant must be calibrated with respect to the position controller limitation threshold. Usually the value is set to 10 V according to battery voltage correction FAC_VB_PWM_ACR !
C_ACR_AD_TCO_MIN	Minimum engine temperature to enable actuator valve adaptation. The threshold shall inhibit the valve adaptation with iced actuator. Calibrate larger than 0 °C !



C_V_ACR_AD_BOL_INI	The calibration value should contain the smallest possible sensor voltage of the measuring system for the lower mechanical stop. The value is defined in the data sheet of the actuator, e.g. 0.2 V!
C_V_ACR_AD_TOL_INI	The position controller must reach the upper mechanical stop therefore the value must contain the largest possible sensor signal voltage for the upper mechanical stop, e.g. 4.9V and larger!
C_FAC_ACR_SLOP	The nominal value of the sensor slope is defined in the data sheet of the actuator valve. Usually the recommend value is 27.8 %/V!
C_CTR_ACR_AD	Counter variable for the adaptation of the lower and upper mechanical stop to get valid adaptation values. The adaptation interval must be calibrated with respect to the correlation constant C_CRLC_ACR_AD, see below. A value of 10 corresponds with 100 ms adaptation time.
C_CTR_DLY_ACR_AD	Delay counter for the activation of the lower and upper mechanical stop adaptation. A recommend value is 10.
C_CTR_DLY_ACR_AD_TOL	Delay counter for the adaptation of the upper mechanical stop. A recommend value is 10.
C_CTR_DLY_ACR_AD_MAX	Delay counter for the continuously adaptation of the lower mechanical stop. The value is used to get a valid sensor signal for the lower mechanical stop. Calibrate the value with 20 that corresponds with 2.0 s delay time.
C_CTR_DIAG_ACR_AD	Diagnostic counter for the check of the adaptation value during continuously BOL adaptation. Usually the value is set to 10 (correspond with 1 s error debounce time).
C_CTR_DIAG_END_ACR_AD	End of diagnosis counter during continuously adaptation of the lower mechanical stop. A recommend value is 20.
C_OPG_SP_MAX_AD_ACR C_OPG_SP_AD_LGRD	The position controller must drive the actuator valve in the upper mechanical stop before the adaptation can be started. C_OPG_SP_MAX_AD_ACR is used to reach the upper stop into a short time and C_OPG_SP_AD_LGRD is used to protect the actuator valve, that means the valve reach the upper mechanical stop with speed limitation. • C_OPG_SP_MAX_AD_ACR = 80 % • C_OPG_SP_AD_LGRD = 0.5 %



C_CRLC_ACR_AD	The correlation constant is used for the calculation of the moving mean values used for determination of the sensor adaptation values. The filter rate of the filter algorithm is increased with falling correlation constant. The constant must be calibrated with consideration of the adaptation interval C_CTR_ACR_AD, e.g. C_CRLC_ACR_AD = 0.02!
C_V_ACR_AD_CHK_CTL	The calibration threshold is used for the check of the actuator function. If the actuator valve is adjusted in the upper mechanical stop then the described calibration threshold must be exceed otherwise an adaptation error occurs. The value must lie outside the diagnostic windows of the lower and upper mechanical stop, • C_V_ACR_AD_CHK_CTL = 2.5 V.
C_V_ACR_AD_BOL_MIN C_V_ACR_AD_BOL_MAX	The diagnostic thresholds for the lower mechanical stop are defined by the data sheet of the actuator and tolerance calculation made for the ECU and the measuring system, possible range: 0.4 V – 0.7 V!
C_V_ACR_AD_TOL_MIN C_V_ACR_AD_TOL_MAX	The diagnostic thresholds for the upper mechanical stop are defined by the data sheet of the actuator and tolerance calculation made for the ECU and the measuring system, possible range: 4.4 V - 4.7 V!
LC_FAC_ACR_SLOP_AD_ENA	The logical constant allows to activate the adaptation of upper mechanical stop and the corresponding sensor signal slope during the "first key on" and the continuously adaptation. The value must be calibrate to one !

17.21 Calibration hints for actuator diagnosis

17.21.1 Calibration interfering functions

No special requirements for the calibration with interfering functions are known.

17.21.2 Calibration flowchart

The sequence is described by the order in calibrated methods.

17.21.3 Calibration method

Actuator position sensor diagnosis

C_V_MIN_SENS_ACR C_V_MAX_SENS_ACR	The electrical diagnostic thresholds define the admissible range of the actuator valve sensor signal. Both values are the result of the worst-case tolerance calculation made for the measuring system and the correct choice of the upper position setpoint limitation C_OPG_SP_MAX_ACR. Usually the admissible range should be defined from 0.15 V to 4.85 V. When the admissible diagnostic range for the upper signal range check is to small then a reduction of C_OPG_SP_MAX_ACR can solve the problem.
C_ABC_INC_SENS_ACR C_ABC_MAX_SENS_ACR	Calibrate the debounce counter increment with 2 and the maximum value with 40 for the electrical diagnosis, in this case the corresponding debounce time is 200 ms.

Actuator power stage diagnosis based on SF mode

C_VB_MIN_ACR_DR_DIAG	The power stage diagnosis is inhibited below the battery voltage threshold to get only valid diagnostic information from the power stage status flag.
C_ABC_INC_ACR_DR C_ABC_MAX_ACR_DR	Calibrate the debounce counter increment with 2 and the maximum value with 40 for the power stage diagnosis, in this case the corresponding debounce time is 200 ms.

Actuator diagnosis

C_ABC_INC_ACR_CTL C_ABC_DEC_ACR_CTL C_ABC_MAX_ACR_CTL	Calibrate the anti-bounce counter decrement larger than the increment value. In case of actuator malfunctions the diagnostic function has to indicate errors with a maximum admissible debounce time of 500 ms. The anti-bounce counter maximum value can be calculate as follow : C_ABC_MAX_ACR_CTL = 500 ms / 10 ms *... C_ABC_INC_ACR_CTL Recommend values are: • C_ABC_INC_ACR_CTL = 1 • C_ABC_DEC_ACR_CTL = 5 • C_ABC_MAX_ACR_CTL = 50

C_CRLC_OPG_SP_ACR	The calculation of the actuator position setpoint gradient is performed by a low pass filter of first order. The described correlation constant defines the corresponding filter time constant. The constant can be calculated by the definition of the continuously time constant: $\mathrm{C\_CRLC\_OPG\_SP\_ACR} = 1 - e^{-\frac{0.01\mathrm{s}}{T_{\mathrm{request}}}}$ A time constant smaller than 100 ms should be defined, e.g. C_CRLC_OPG_SP_ACR = 0.181 (50ms) !
IP_OPG_DIF_ACR_ERR_MAX	The characteristic map defines the admissible control deviation error dependent on the actuator position setpoint gradient. The admissible error has to be increase with rising actuator setpoint gradient.
C_PWM_ACR_MAX_DIAG	If the moving-mean value of the position controller output duty-cycle exceeds the defined threshold than an error will be indicated. The diagnosis threshold can be set to 95% with respect to correlation constant of the corresponding low pass filter, see the next label.
C_CRLC_PWM_ACR	The calculation of the moving mean value is done by a first order low pass filter. The correlation factor describes the time constant of the low pass filter and can be calculated as follows: $\mathrm{C\_CRLC\_PWM\_ETC} = 1 - e^{-\frac{0.01\mathrm{s}}{T_{\mathrm{request}}}}$ With a chosen time constant of 1 s the correlation constant can be calculated with 0.01, that means after a PWM step from zero to 100% PWM duty-cycle the above mentioned diagnostic threshold of 95% will be reached after 3*T_{request} (3 s) according to the low pass filter characteristic.
C_VB_MIN_PWM_ACR_DIAG	If the battery voltage falls below the described threshold than the component protection is deactivated. A value of approximately 10V is recommended.

17.22 Customer adaptation module, ACRC

17.22.1 BMW software to ACRC adaptation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
OPG_SP_REQ_ACR	V/O	0...FFFH	0...99.97558	0.0244141	[%]
Actuator valve position setpoint request in normal operation

18.2.1.1 SUBFUNCTION: operate

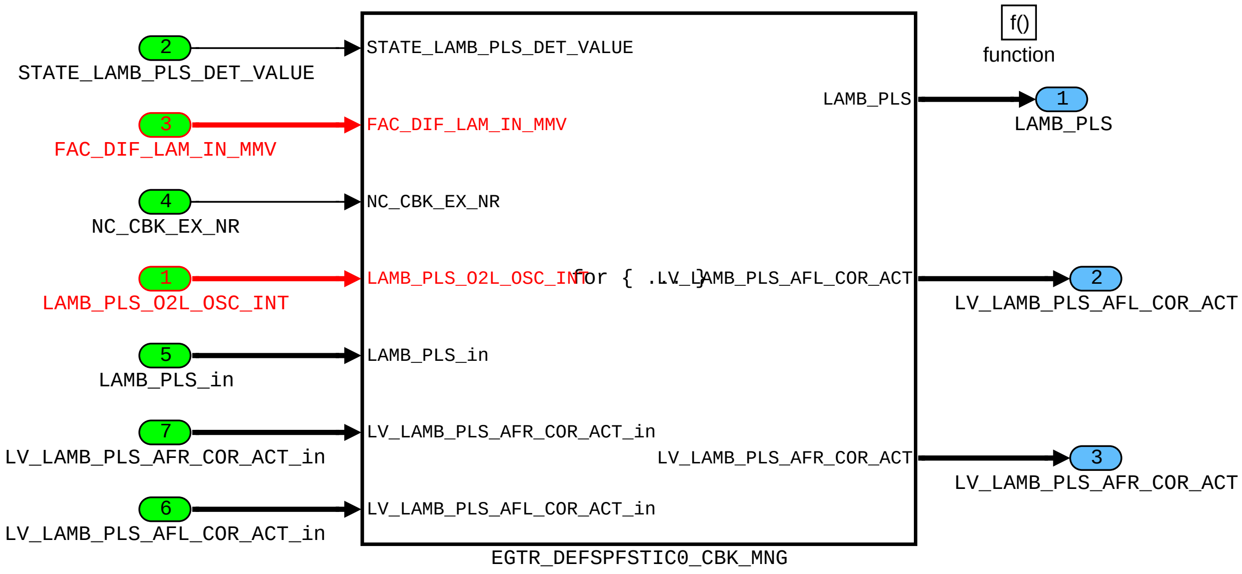

Figure 3 EGTR_DEFSPFSTIC0/ operate

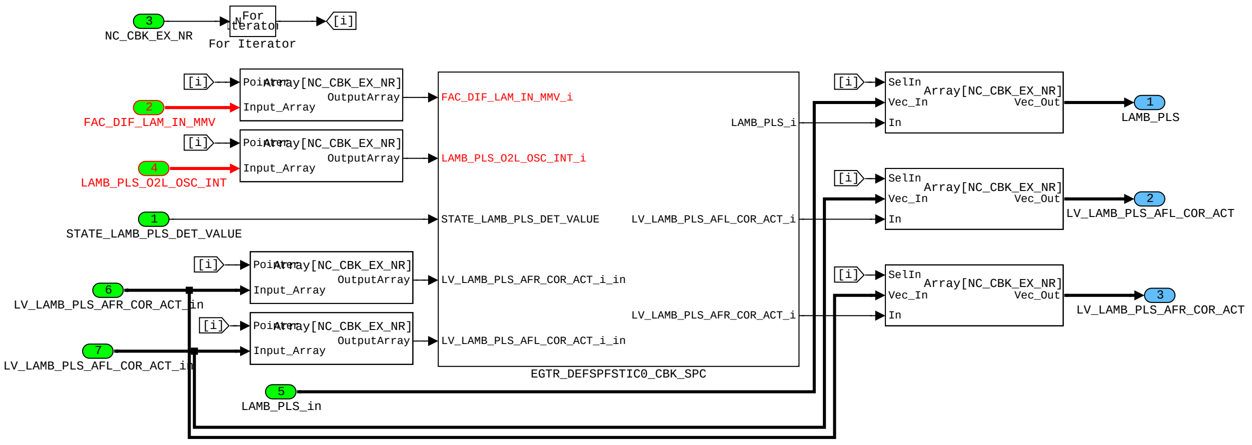

Figure 4 EGTR_DEFSPFSTIC0/ operate/ EGTR_DEFSPFSTIC0_CBK_MNG

Corrective action depending on lambda cotnroller difference

Depending on the lambda control difference FAC_LAM_DIF_IN[i] a corrective intervention on the lambda pulse can be applied. In case of too lean mixture the lean deviation can be suppressed and in case of too rich mixture the rich deviation can be suppressed. Activation and deactivation of the corrective intervention is realised with different thresholds in order to apply a hysteresis.

With LC_LAMB_PLS_COR_ACT_IS this corective action can also be applied in idle speed.

General Information

The forced lambda stimulation generates an output signal that causes lean and rich deviations of the air fuel ratio from the lambda controller set point. By means of the stimulation parameters (set point deviation, period time and gradient) a well defined O2 load for the catalyst can be calibrated. So the catalyst efficiency can be increased.

Furthermore the forced lambda stimulation is used by diagnosis functions for the up stream lambda sensor and by the catalyst efficiency diagnosis.
The recurrence time is defined by T_SAMPLE in 20 ms.
NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

18.3.1.1 Vectorization level for for-loop:

Here the vectors are split for the for-loop-calculation.

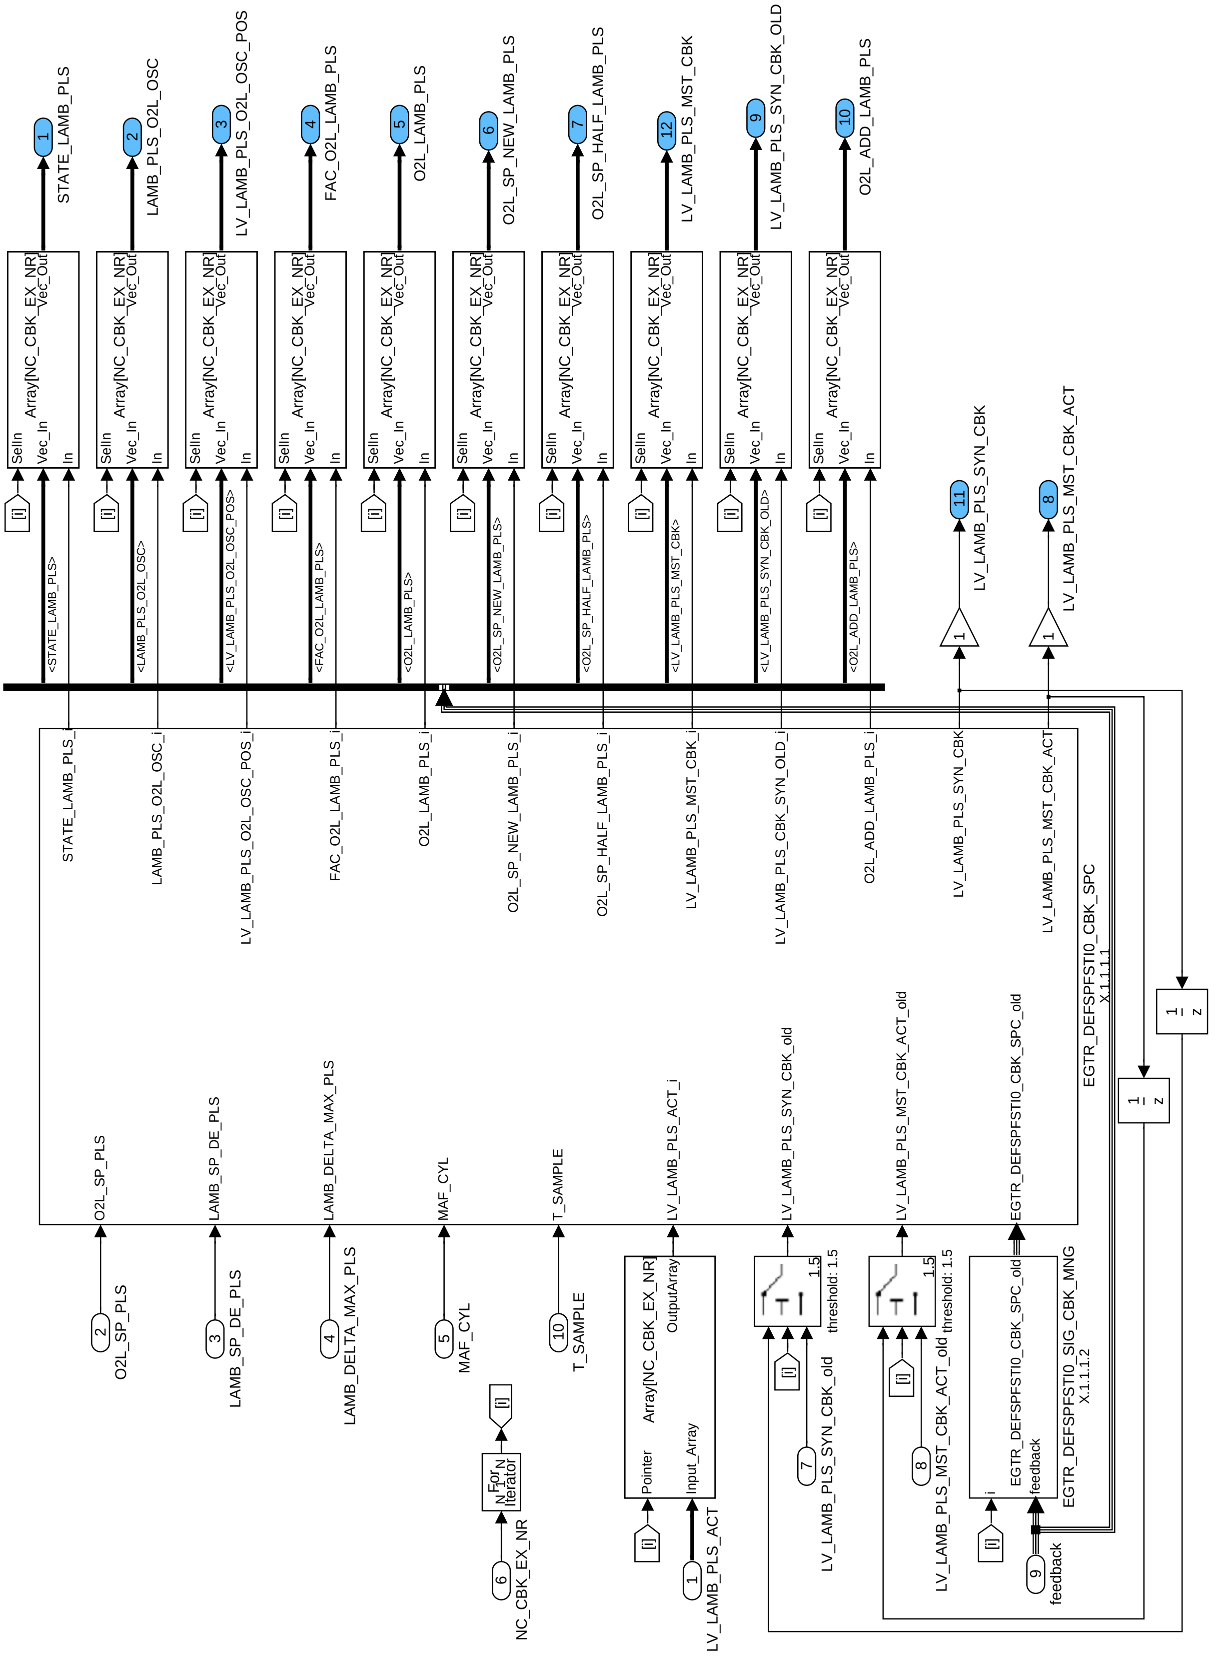

Figure 11:
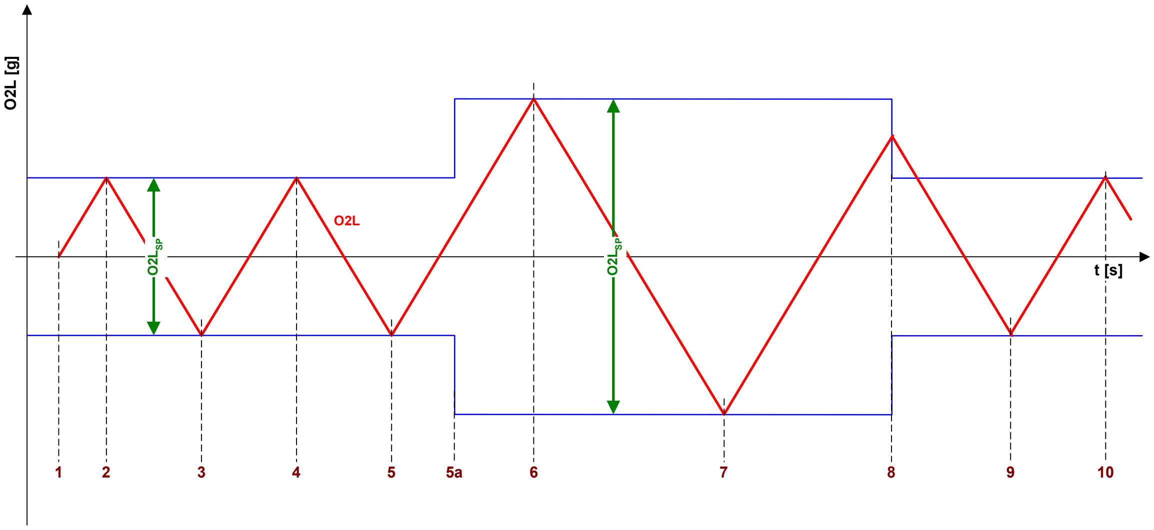
Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG

18.3.1.1.1 Execution of state machine:

In state OFF the output of the forced lambda stimulation is 0. This state is active if LV_LAMB_PLS_ACT[i] is not set.
In case of LV_LAMB_PLS_ACT[i] = 1 either state AFL or state AFR is active. In state AFL the set point deviation is increased stepwise to the calibrated set point deviation. In state AFR the set point deviation is decreased. The transition between both states depend on the O2 loading calculated in both states (CLC_O2L_LAMB_PLS). When the current O2 loading reaches the current set point (O2L_SP_NEW_LAMB_PLS[i]) then the transition to the opposite state takes place. The O2 loading is calculated with the formula:

$$m_{O_2} = 23\% \cdot \int \left(1 - \tfrac{1}{1+\Delta\lambda_{SP}}\right) \cdot \dot{m}_{air} dt$$

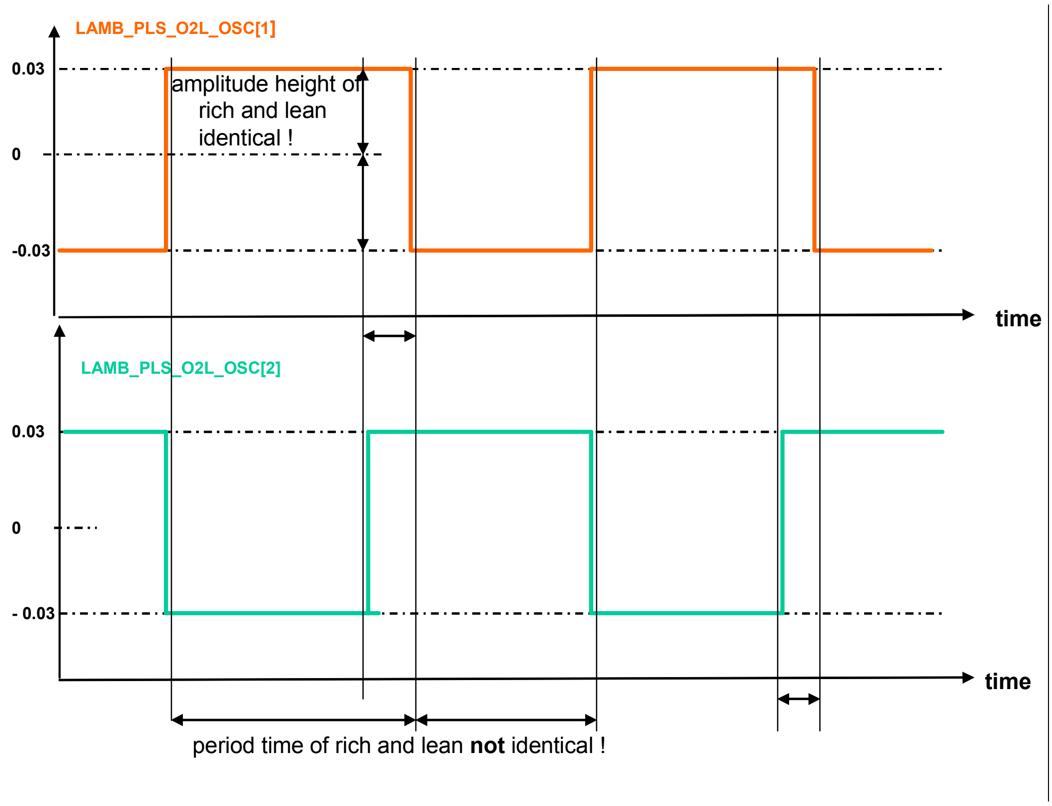
In order to realise synchronisation of both banks two flags are defined.
LV_LAMB_PLS_MST_CBK_ACT is a common flag that defines whether forced stimulation is already active for one bank. Master bank is the bank that has set the flag LV_LAMB_PLS_MST_CBK_ACT; this is also indicated by the bank selective flag LV_LAMB_PLS_MST_CBK[i] which must be set to 1 for the master bank and to 0 for the slave bank.
The second flag to synchronise both banks is LV_LAMB_PLS_SYN_CBK. This flag is set by the master when the transition from state AFR to AFL occurs in order to inform the slave to execute the desired transition.



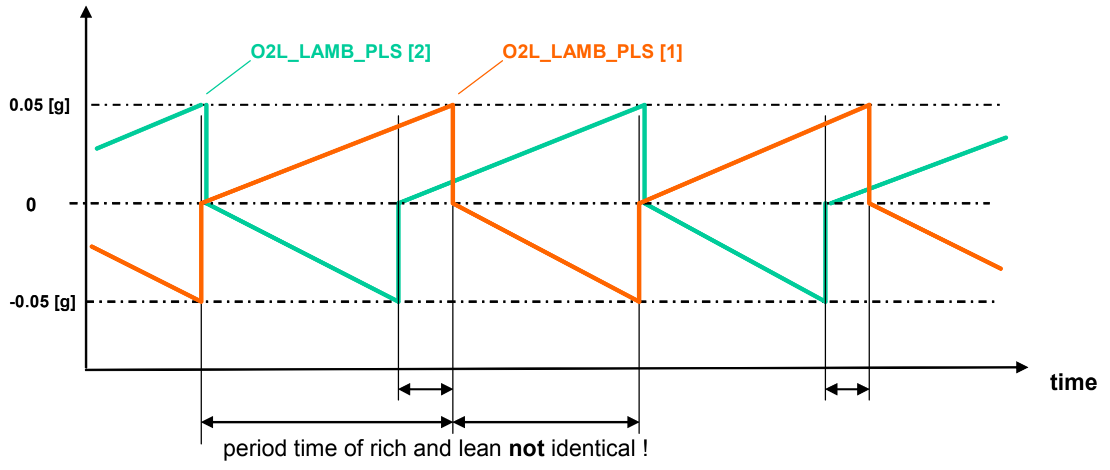
If the set point from Determination of forced lambda stimuation parameters (O2L_SP_PLS) changes the O2 loading set point that is adjusted switches for the next half wave to an intermedieate value and the next but one half wave will be the target value.
Asynchronous or synchronous operation:
The master bank changes from lean to rich or from rich to lean, if the O2 threshold O2L_SP_NEW_PLS is reached. The synchronization pulse LV_LAMB_PLS_SYN_CBK is set at the end of the rich phase.
In case of asynchronous forced stimulation (LC_O2L_PLS_CBK_SYN=0) the slave changes from lean to rich at synchronization pulse and from rich to lean, if the O2 threshold is reached.
In case of synchronous forced stimulation (LC_O2L_PLS_CBK_SYN=1) the slave changes from rich to lean at synchronization pulse and from lean to rich, if the O2 threshold is reached.
Timesynchronous operation:

general specification

Due to the formula for O2 load calculation the time duration of the lean part of the forced stimulation period is slightly longer than the rich part.
During the bankwise asynchronous operation mode (LC_O2L_PLS_CBK_SYN=0), this fact leads to small overlapping phases, where both banks are in the same STATE_LAMB_PLS = RICH or LEAN.

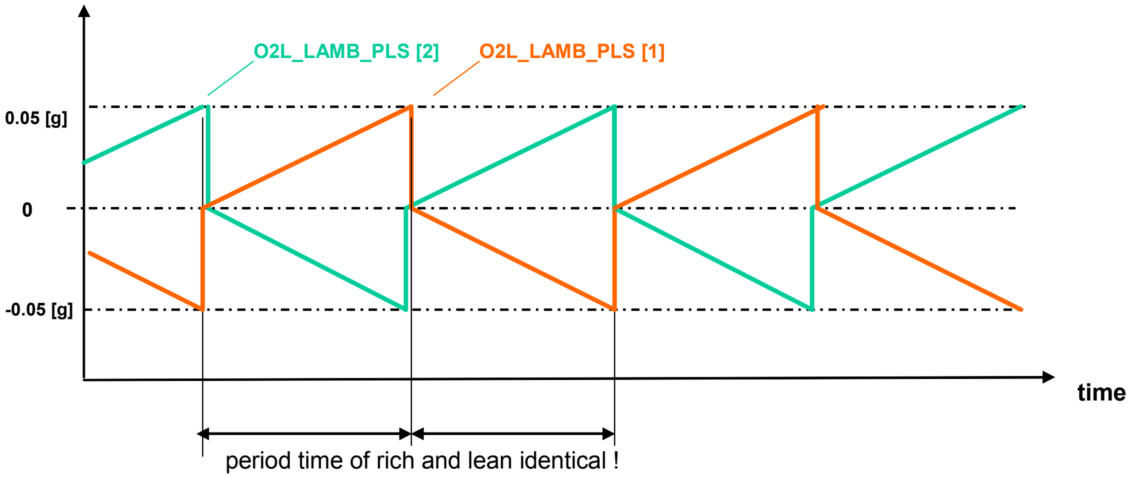


O2 load calculation



To prevent this behaviour and achieve a duration of the rich and lean phase of exact the same length, the amplitude of the forced stimulation LAMB_PLS_O2L_OSC can be corrected during the lean or during the rich phase (STATE_LAMB_PLS = AFL or AFR).

O2 load calculation



COR_AFL:
To switch on the timesynchronous operation with correction of the amplitude in STATE_LAMB_PLS=AFL set C_STATE_LAMB_PLS_O2L_OSC_COR = 1 (COR_AFL) .
As a consequence the amplitude LAMB_PLS_O2L_OSC is no more symmetric on the lean and rich side.
LAMB_PLS_O2L_OSC is limited to the calibrated value on the rich side and will be corrected to a slightly higher value on the lean side.
The correction factor on the lean side is calculated as follows:

$$m_{O_2}\_lean = -m_{O_2}\_rich$$

$$\frac{LAMB\_PLS\_O2L\_OSC(lean)}{1+LAMB\_PLS\_O2L\_OSC(lean)} = -\frac{LAMB\_PLS\_O2L\_OSC(rich)}{1+LAMB\_PLS\_O2L\_OSC(rich)}$$

$$LAMB\_PLS\_O2L\_OSC(lean) = -\frac{LAMB\_PLS\_O2L\_OSC(rich)}{1+2*LAMB\_PLS\_O2L\_OSC(rich)}$$

COR_AFR :
To switch on the timesynchronous operation with correction of the amplitude in STATE_LAMB_PLS=AFR set C_STATE_LAMB_PLS_O2L_OSC_COR = 2 (COR_AFR).
LAMB_PLS_O2L_OSC is then limited to the calibrated value on the lean side and will be corrected to a slighly lower value on the rich side.
The correction factor is on the rich side calculated as follows:

$$LAMB\_PLS\_O2L\_OSC(rich) = -\frac{LAMB\_PLS\_O2L\_OSC(lean)}{1+2*LAMB\_PLS\_O2L\_OSC(lean)}$$

COR_OFF:
If timesynchronous operation is not requested, it is possible to enable normal operation mode with symmetric amplitude hight by setting C_STATE_LAMB_PLS_O2L_OSC_COR = 0 (COR_OFF).

Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC

18.3.1.1.1.1 No title given

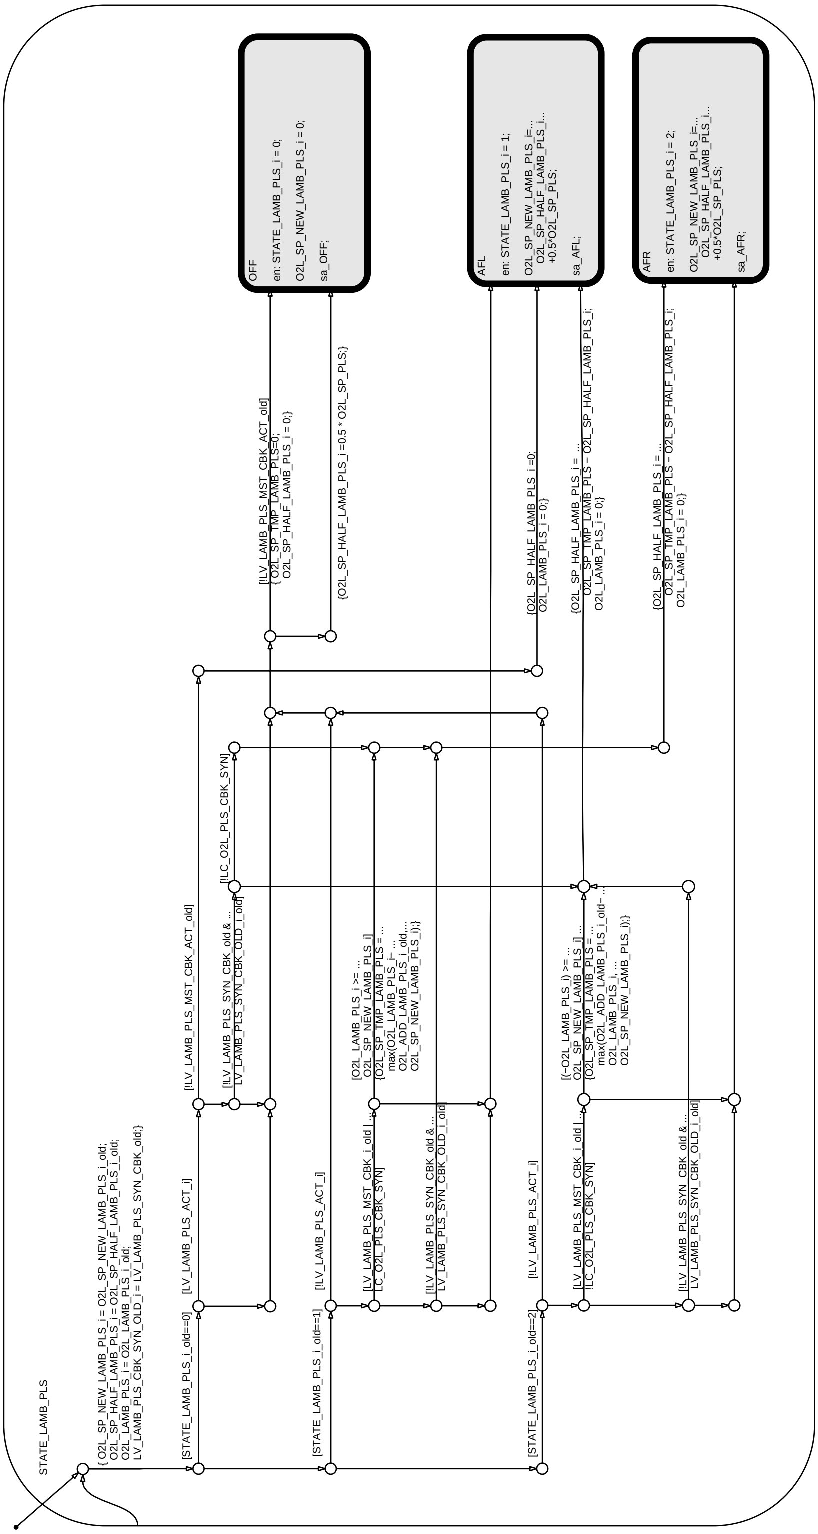

Figure 13:
Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC/STATE_LAMB_PLS

18.3.1.1.1.2 Calculation of O2 loading:

The O2 loading is calulated with the already mentioned formula. If the O2 loading that is to added each sample step is smaller than its resolution then the O2 loading is increased or decreased (depending on the sign) by the resolution value.

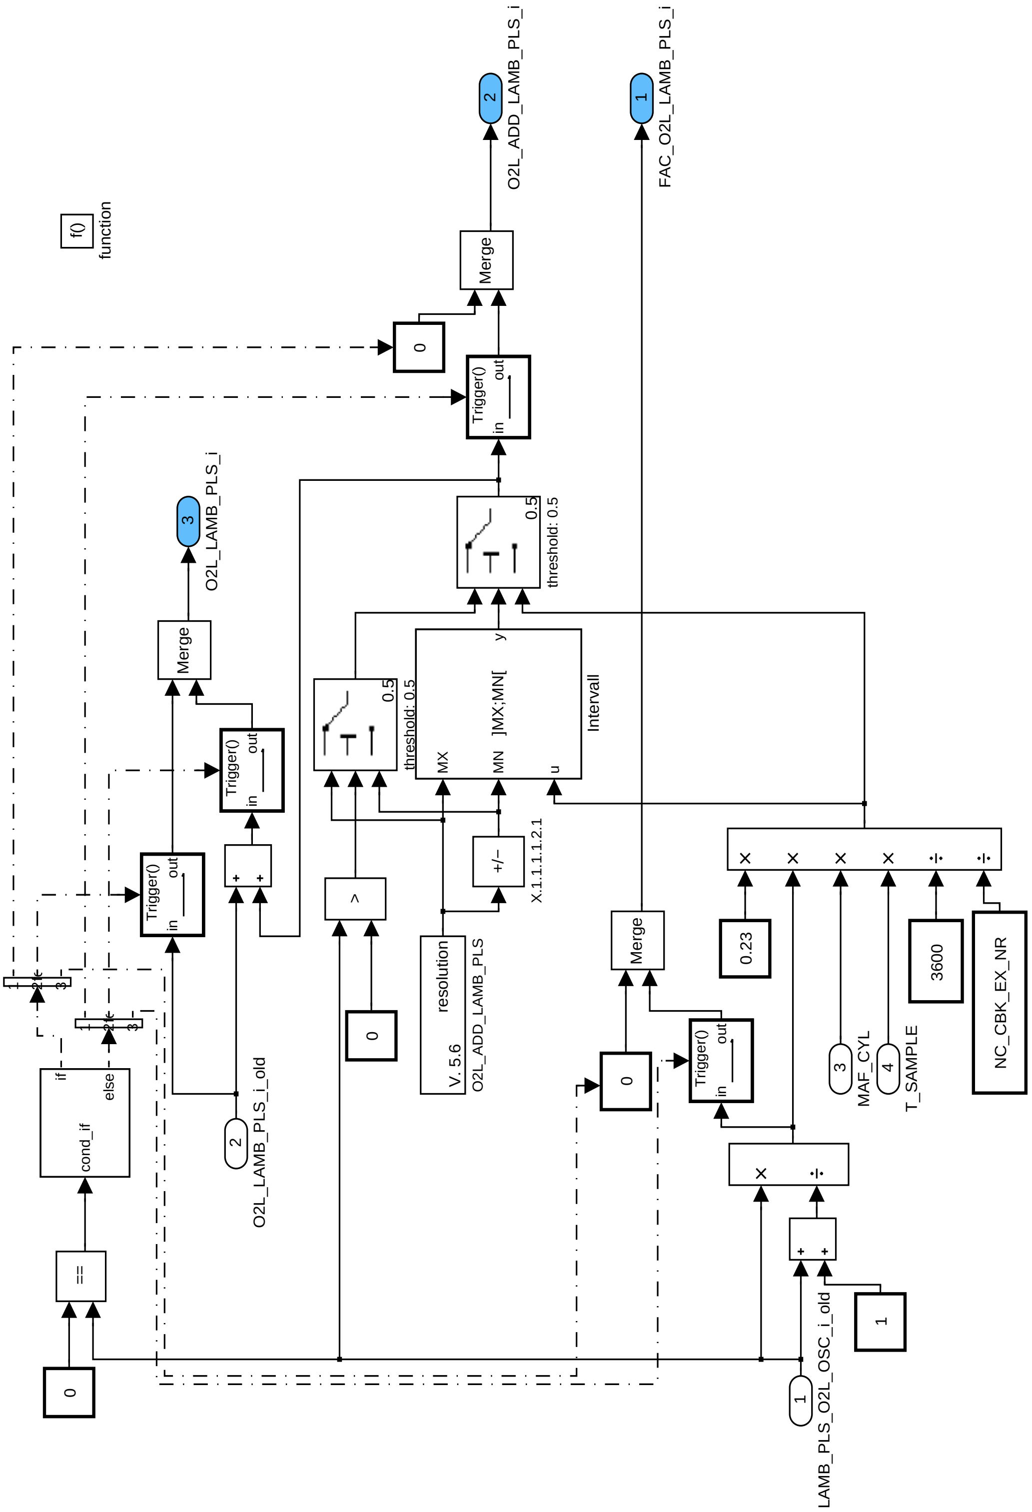

Figure 14:
Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC/CLC_O2L_LAMB_PLS

18.3.1.1.1.3 STATE "AFL":

In that state the lambda set point deviation LAMB_PLS_O2L_OSC[i] is increased step wise by LAMB_DELTA_MAX_PLS and limited to LAMB_SP_DE_PLS.
If timesynchronous operation mode is activated with C_STATE_LAMB_PLS_O2L_OSC_COR = 1, the lambda set point deviation is not symmetric. The rich half wave is limited to LAMB_SP_DE_PLS, but the lean half wave is corrected to a slightly higher value.
If the LAMB_PLS_O2L_OSC[i] becomes positive (indicated by rising edge of LV_LAMB_PLS_O2L_POS[i]) the sign of the current O2 loading changes in order adjust the right O2 loading (given by the set point).

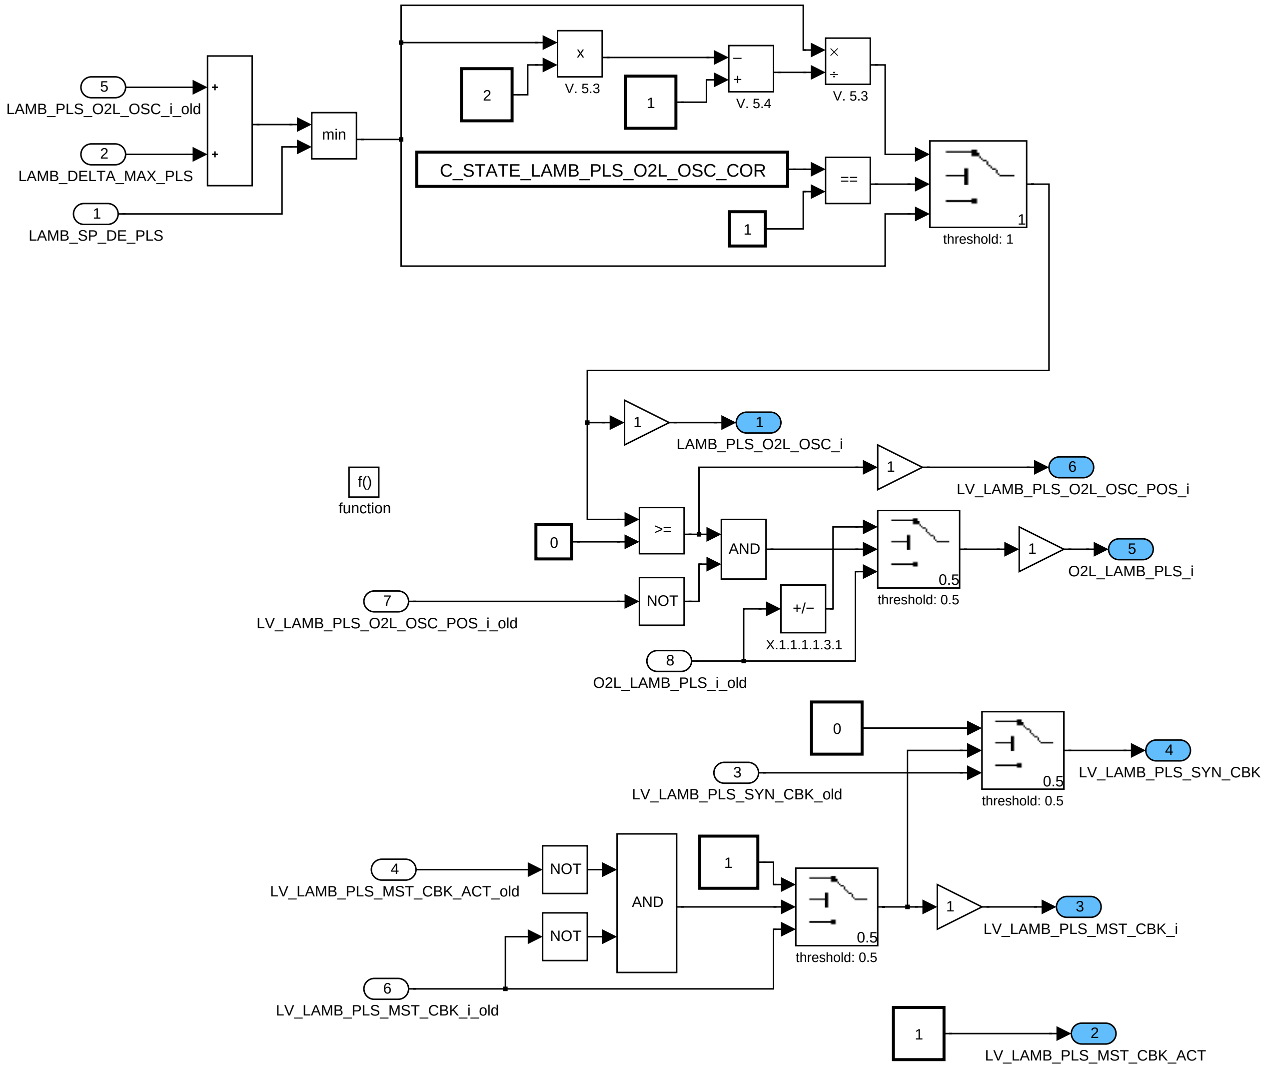

Figure 15:
Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC/STATE_LAMB_PLS__AFL

18.3.1.1.1.4 STATE "AFR":

In that state the lambda set point deviation LAMB_PLS_O2L_OSC[i] is decreased step wise by LAMB_DELTA_MAX_PLS and limited to minus LAMB_SP_DE_PLS.
If timesynchronous operation mode is activated with C_STATE_LAMB_PLS_O2L_OSC_COR = 2, the lambda set point deviation is not symmetric. The lean half wave is limited to LAMB_SP_DE_PLS, but the rich half wave is corrected to a slightly lower value.
If the LAMB_PLS_O2L_OSC[i] becomes negative (indicated by falling edge of LV_LAMB_PLS_O2L_POS[i]) the sign of the current O2 loading changes as in state AFL .
When the O2 loading set point is reached the master bank sets the synchronization flag.

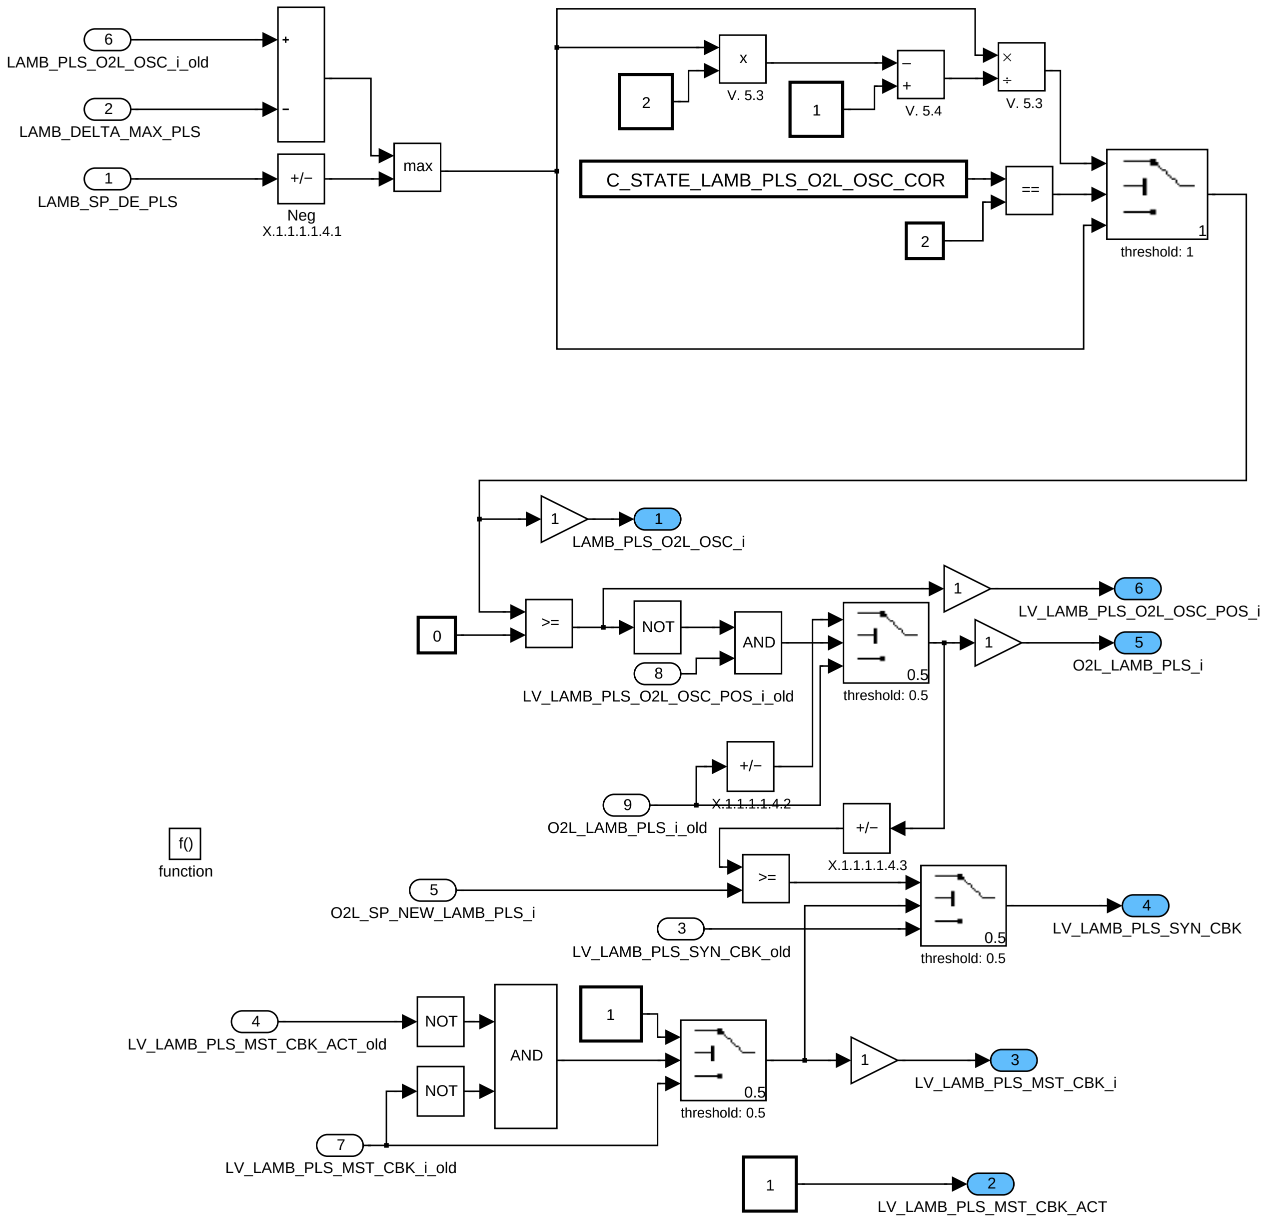

Figure 16:
Path: EGTR_DEFSPFSTI0/operate/EGTR_DEFSPFSTI0_CBK_MNG/EGTR_DEFSPFSTI0_CBK_SPC/STATE_LAMB_PLS__AFR

18.3.1.1.1.5 STATE "OFF":

In that state all flags and the current O2 loading are set to 0.

18.5.1 EGTR_DEFSPCENRD0

This function determines the oxygen loading for different catalyst enrichment (purge) cases that is to be relased during pre cat purge. The oxygen loading to be released during main cat purge is defined in the main function based on the oxygen loading for the pre catayst. Furthermore a priorization of the different cases is included.

The different enrichment cases after lean air fuel mixture condition, that are described within this function, are catalyst purge

- after trailing throttle fuel cut-off phase (PUC),
- after secondary air injection (SA),
- after hot start (HST) and
- after catalyst heating (CH) with lean air fuel mixture condition.
- after cylinder cut-off at gear shifting (GS_SCC).

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Application Condition

18.5.1.1 SUBFUNCTION: operate

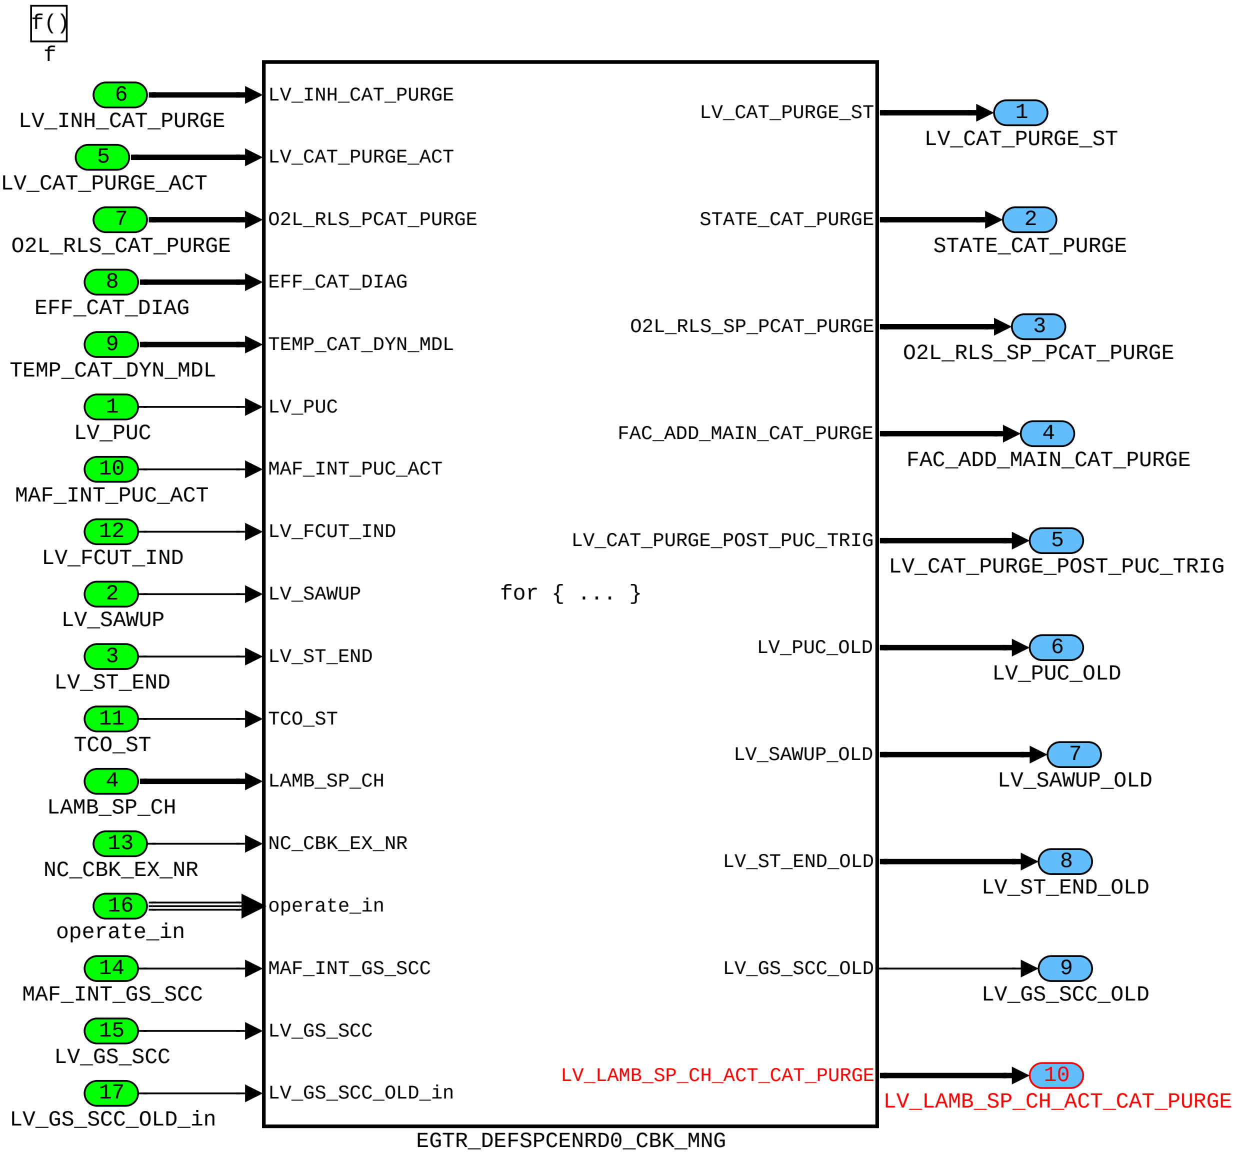

Figure 26 EGTR_DEFSPCENRD0/ operate

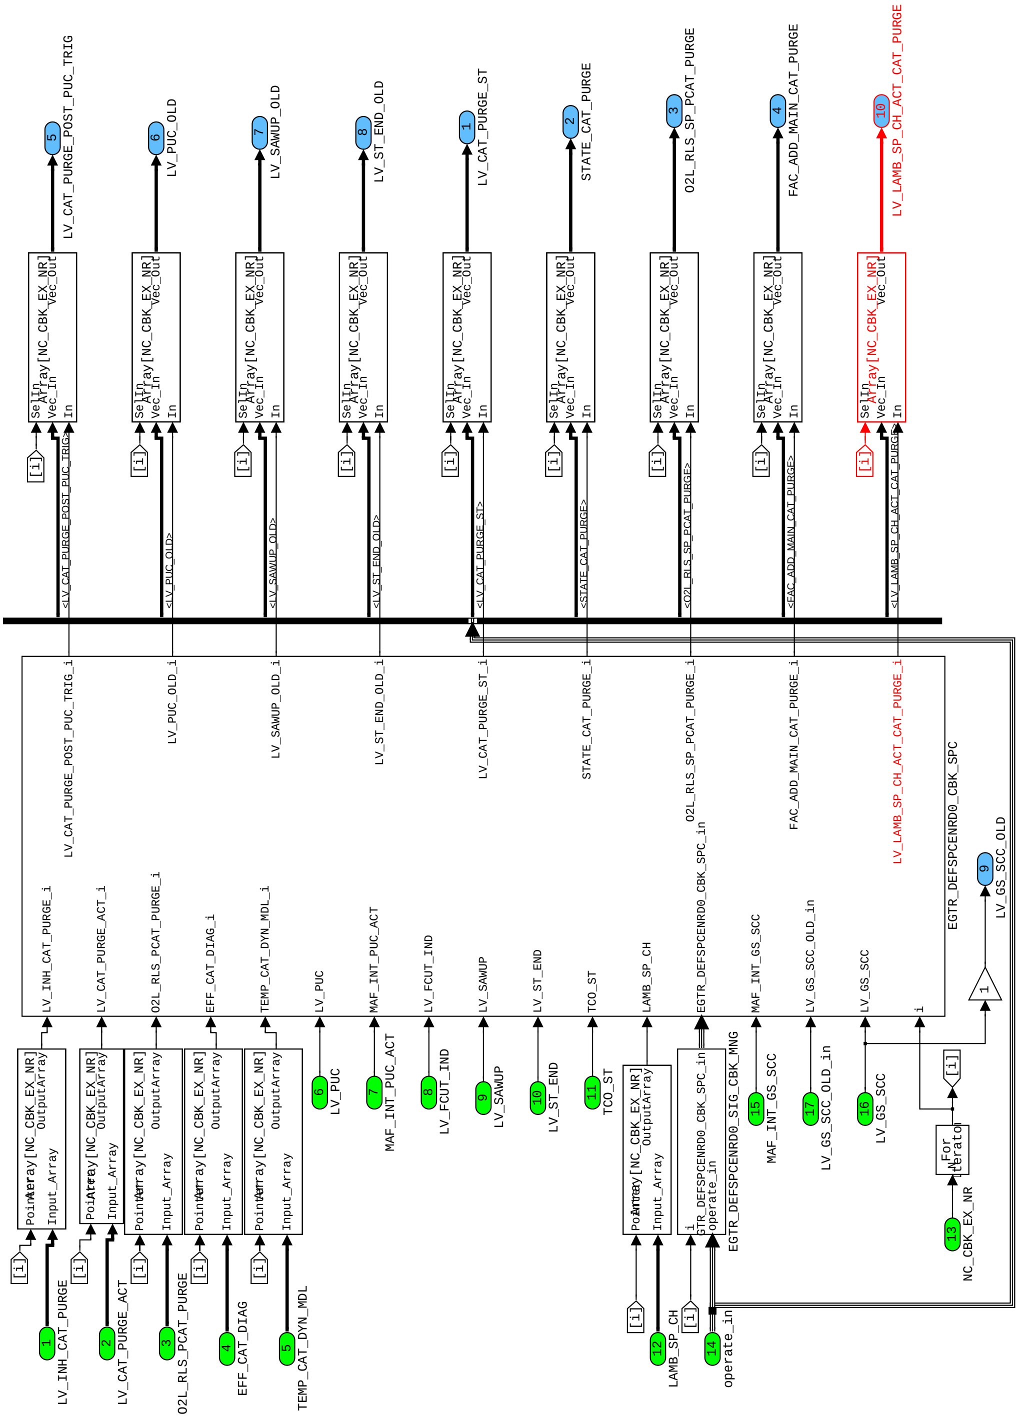

Figure 27 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG

Different catalyst purge cases

If LV_CAT_PURGE_ACT[i] is or gets 0 and STATE_CAT_PURGE[i] is not changing (compared to one sample step before) then the state is set to “CAT_PURGE_OFF”.

When one of the different cat purge cases gets active the flag LV_CAT_PURGE_ST[i] is set for one sample step to inform the main function.

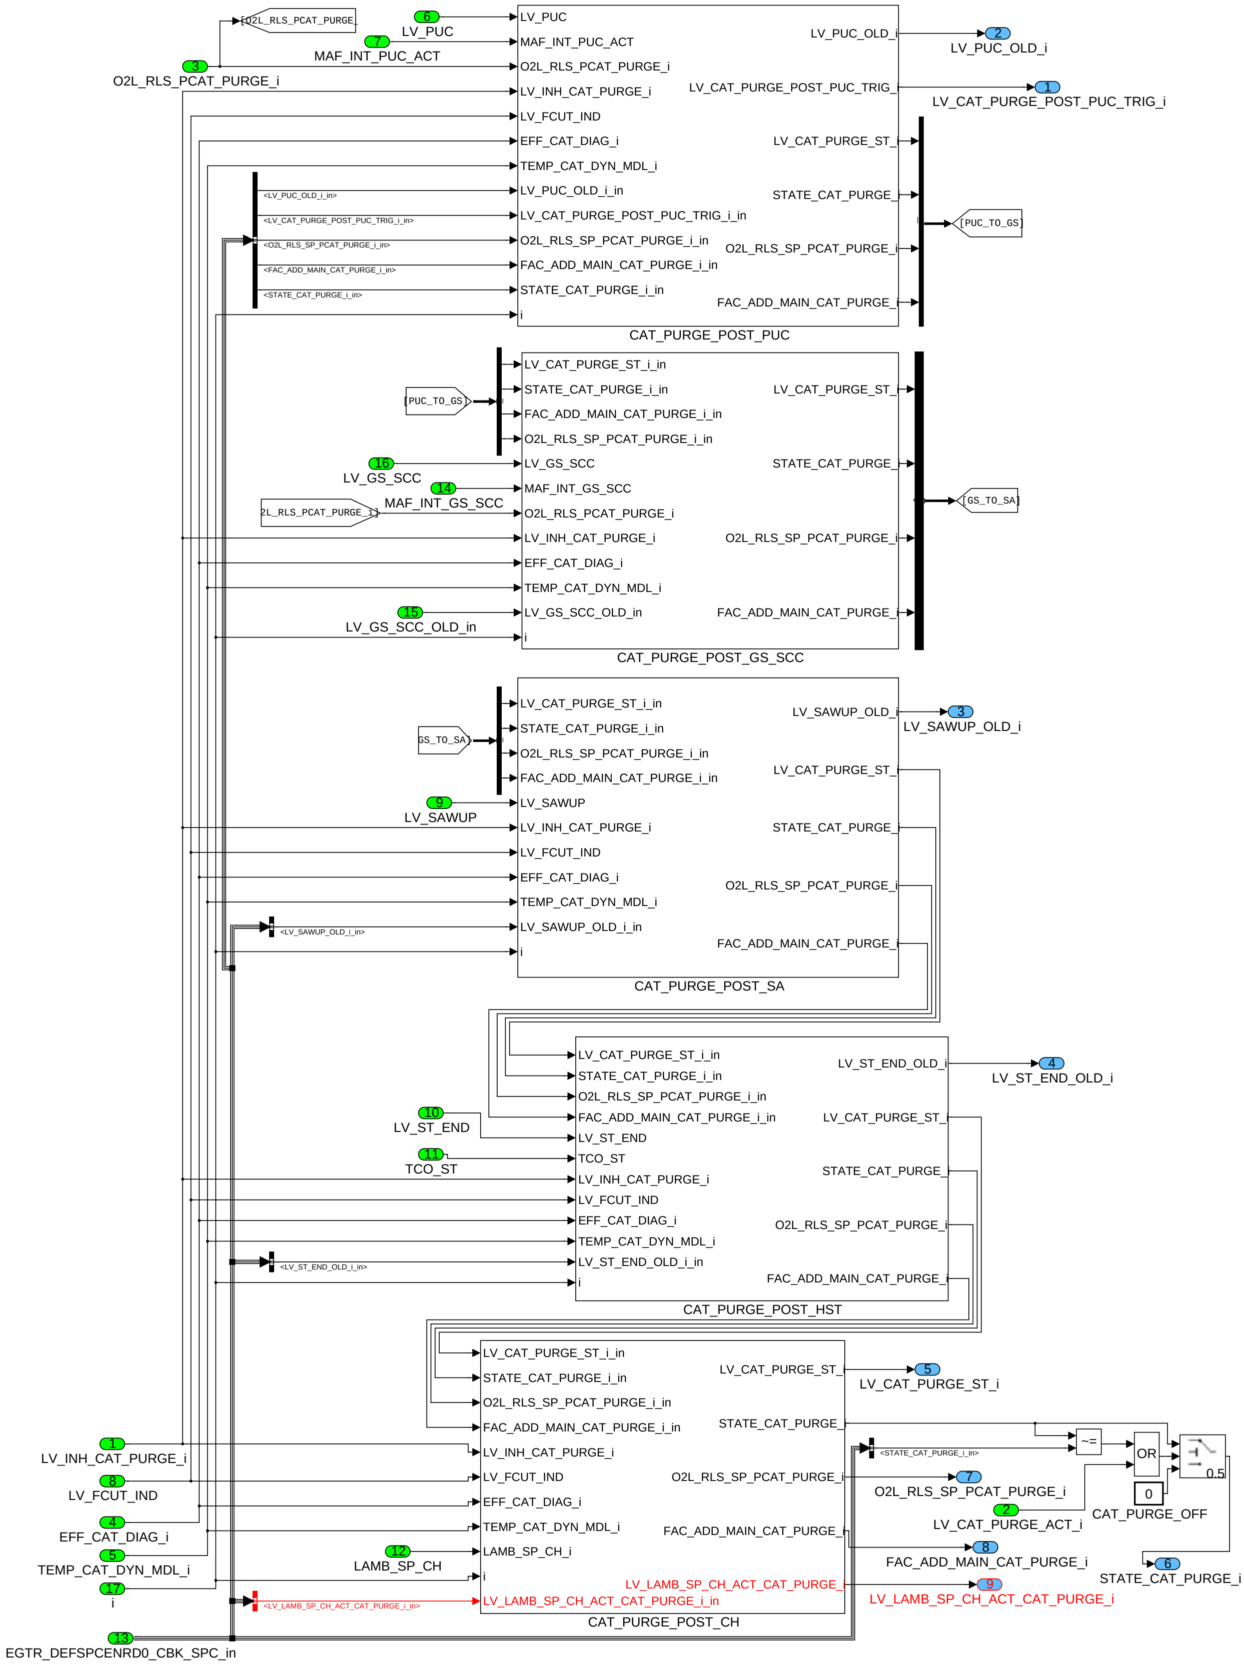

Figure 28 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC

Catalyst purge after catalyst heating with lean air fuel mixture condition

Cat purge after catayst heating is activated at falling edge of LV_LAMB_CH. Cat purge after trailing throttle fuel cut-off phase must not be active, no cylinder must be shut off and the inhibition flag must not be set.

The cat purge state is set to “CAT_PURGE_CH”.

The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_CH multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_CH.

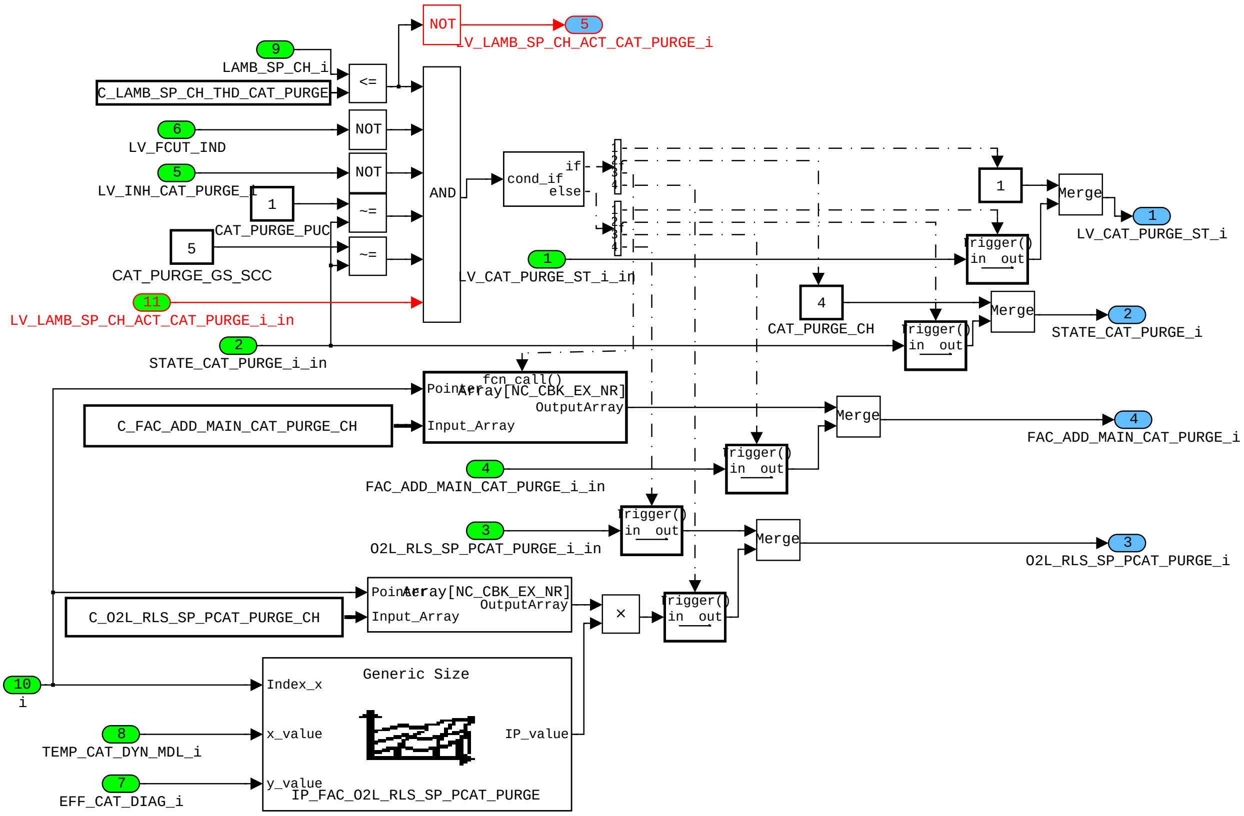

Figure 29 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC/ CAT_PURGE_POST_CH

Catalyst purge after cylinder cut-off at gear shifting

Cat purge after cylinder cut-off at gear shifting is activated by a falling edge of LV_GS_SCC. It is similar to purge after PUC and has the same priority.

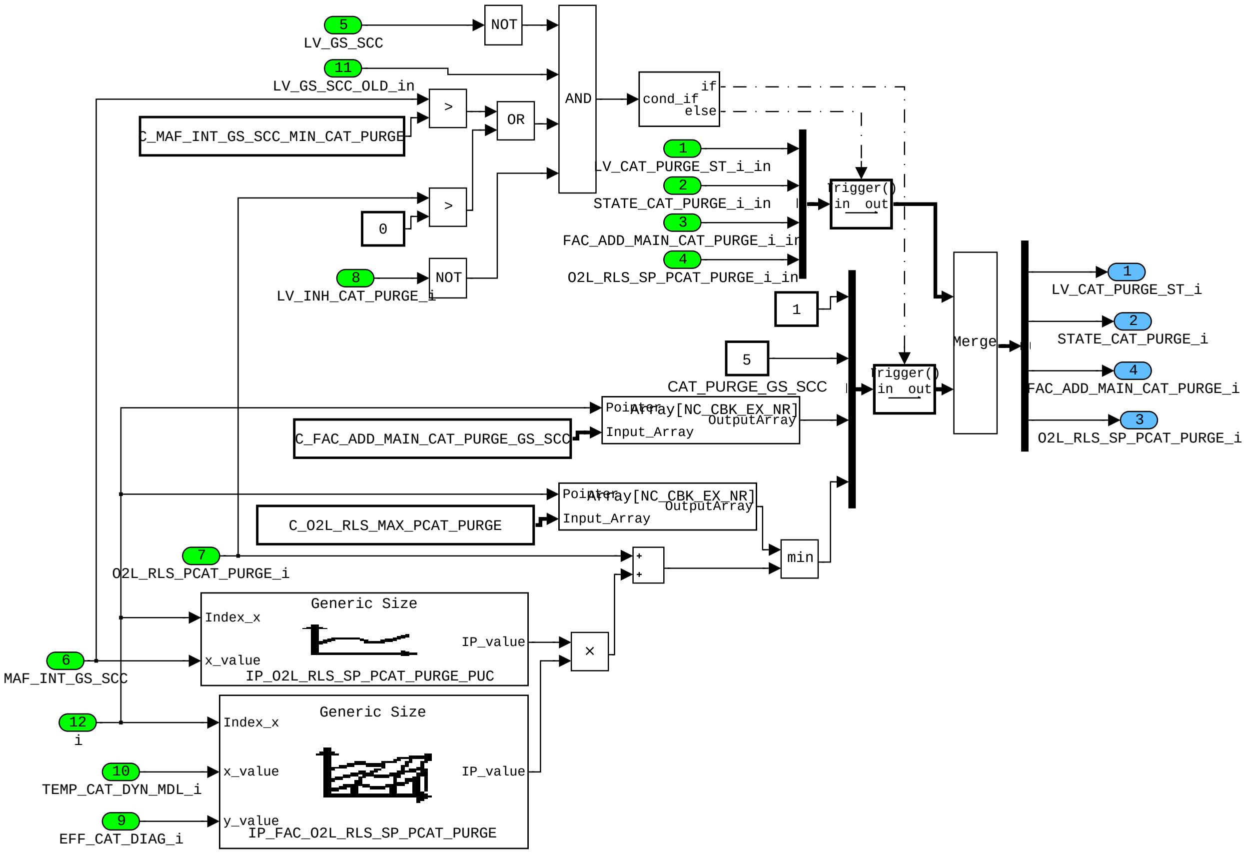

Figure 30 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC/ CAT_PURGE_POST_GS_SCC

Catalyst purge after hot start

Cat purge after hot start is activated at rising edge of LV_ST_END when the cooling temperature at start (TCO_ST) is above a calibration threshold. No other cat purge case must be active, no cylinder must be shut off and the inhibition flag must not be set.

The cat purge state is set to “CAT_PURGE_HST”.

The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_HST multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_HST.

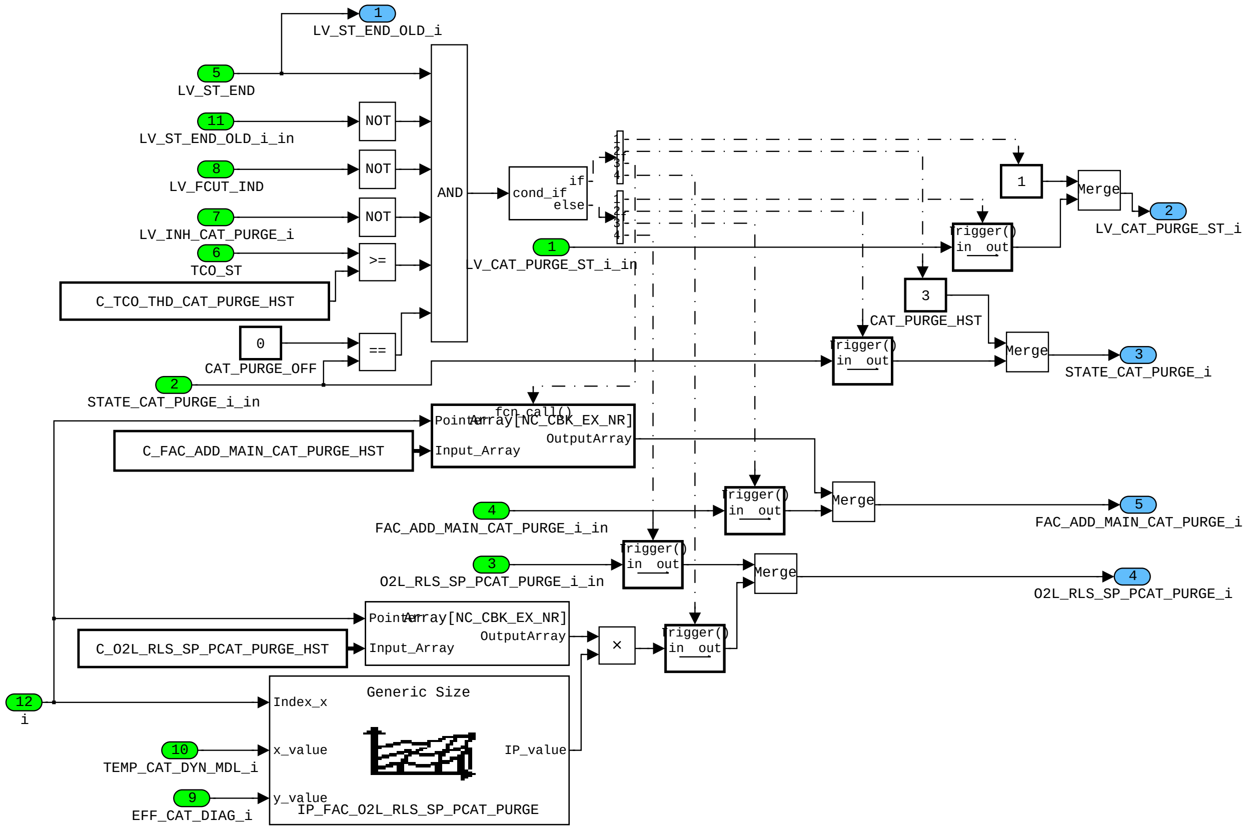

Figure 31 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC/ CAT_PURGE_POST_HST

Catalyst purge after trailing throttle fuel cut-off phase

Cat purge after trailing throttle fuel cut-off (PUC) is activated at falling edge of LV_PUC. The inhibition flag must not be set and the air mass that was integrated during PUC must be above a minimum threshold or during last cat purge the pre cat purge was not finished (O2L_RLS_PCAT_PURGE[i] > 0).

If at least one cylinder is shut off (LV_FCUT_IND = 1) when the conditions above are fulfilled then the start of cat purge is delayed till no cylinder is shut off any more. This is realized by means of the auxiliary flag LV_CAT_PURGE_POST_PUC_TRIG[i].

The cat purge state is set to “CAT_PURGE_PUC”.

The oxygen loading to be relased during pre catalyst purge is defined by IP_O2L_RLS_SP_PCAT_PURGE_PUC multiplied by a catayst temperature and efficiency depending factor. The result is limited to the maximum oxygen loading of the pre catalyst defined by C_O2L_RLS_MAX_PCAT_PURGE. The additional factor to calculate the main catayst loading is set to 1.

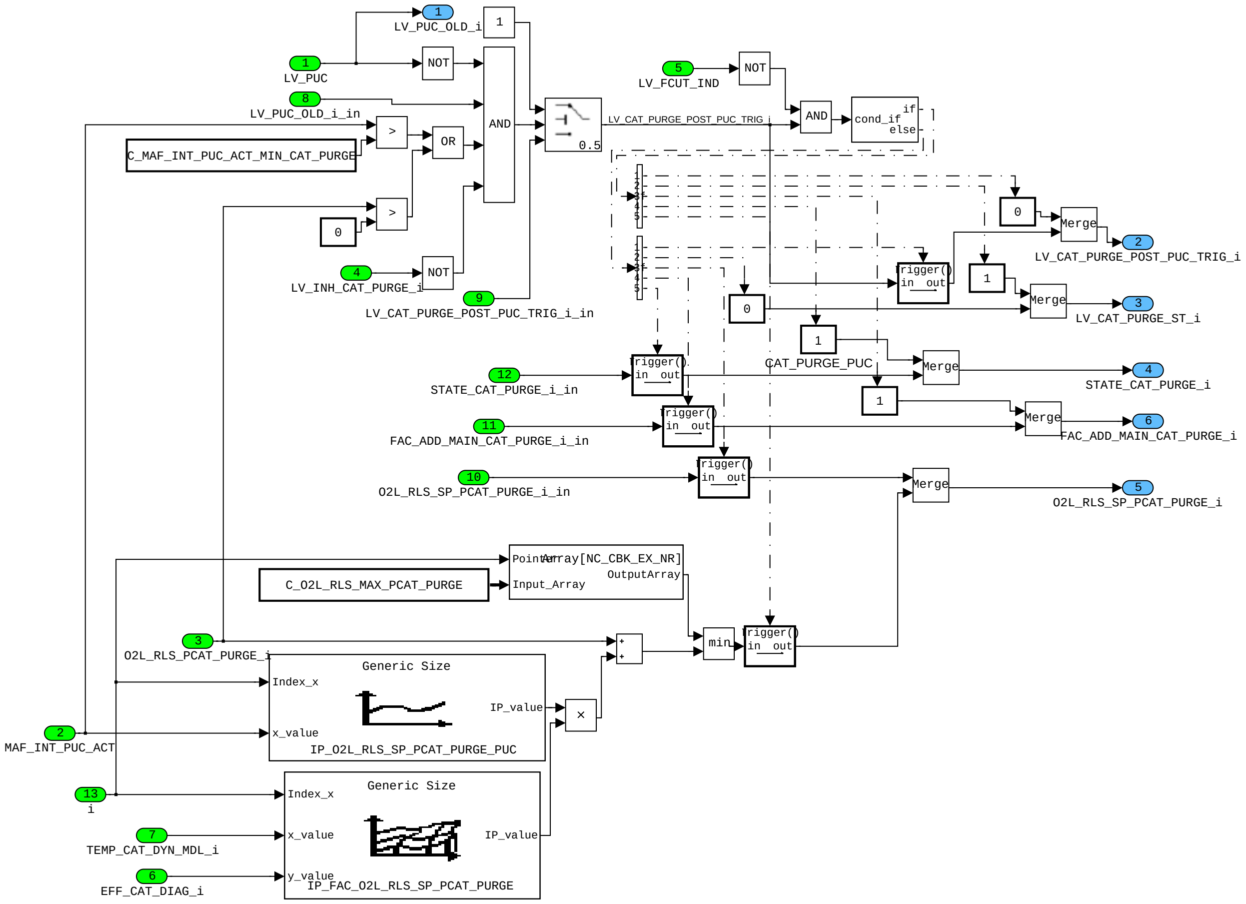

Figure 32 EGTR_DEFSPCENRD0/ operate/ EGTR_DEFSPCENRD0_CBK_MNG/ EGTR_DEFSPCENRD0_CBK_SPC/ CAT_PURGE_POST_PUC

Catalyst purge after secondary air injection

Cat purge after secondary air is activated at falling edge of LV_SAWUP. Cat purge after trailing throttle fuel cut-off phase must not be active, no cylinder must be shut off and the inhibition flag must not be set.

The cat purge state is set to “CAT_PURGE_SA”.

The oxygen loading to be relased during pre catalyst purge is defined by C_O2L_RLS_SP_PCAT_PURGE_SA multiplied by a catayst temperature and efficiency depending factor. An additional factor to calculate the main catayst loading is set by C_FAC_ADD_MAIN_CAT_PURGE_SA.

lambda set point shift of catalyst purge function					

18.6.1 EGTR_DEFSPCENR0

The catalyst purge function realizes fast adjustment of optimized conditions for a high catalyst efficiency after a transition from trailing throttle fuel cut-off phase or other lean air fuel mixture conditions to stoichiometric conditions. That requires a fuel enrichment in order to reduce the oxygen content inside the catalyst. The degree of the fuel enrichment depends on the oxygen and the NOx content in the catalyst.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Application Condition

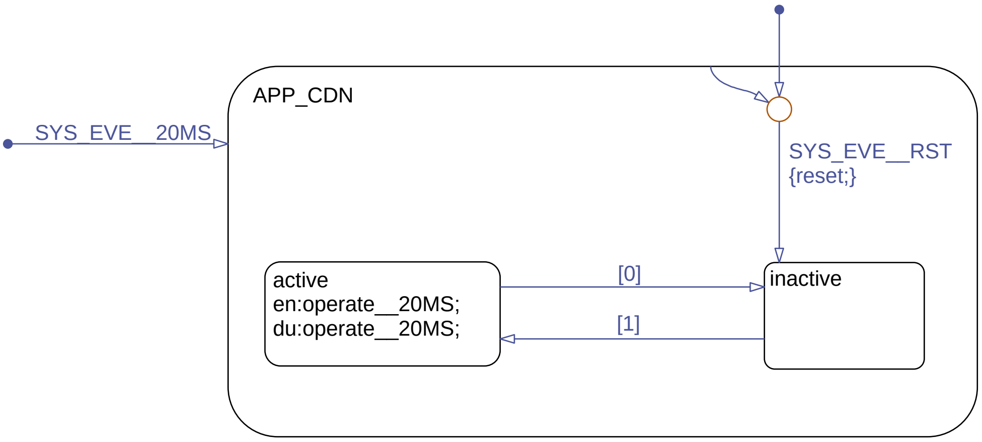

Figure 39 EGTR_DEFSPCENR0/ APP_CDN/ Chart

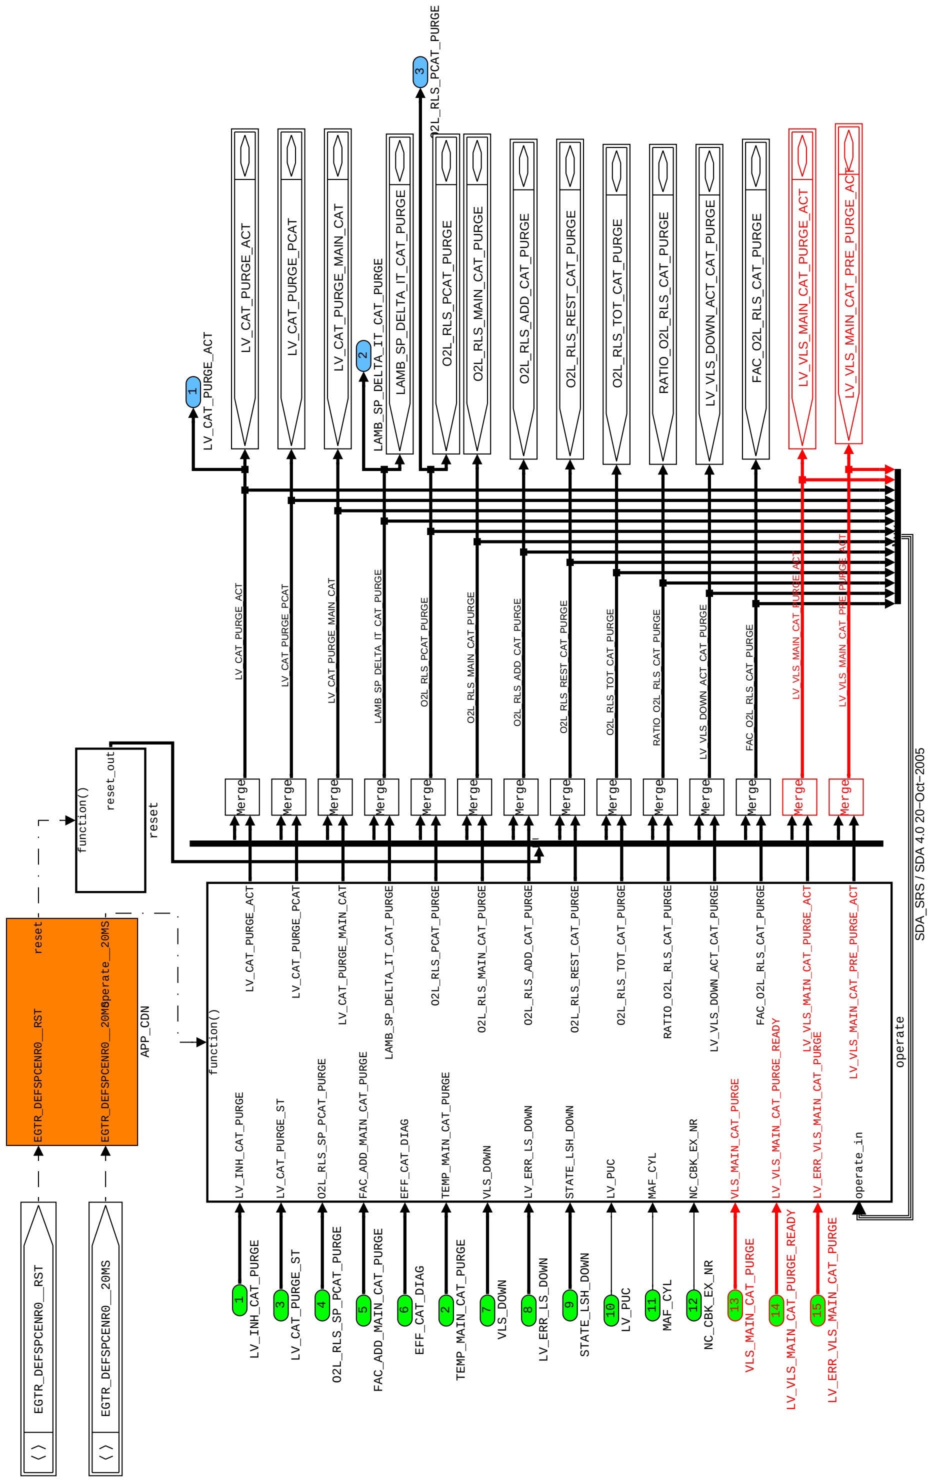

Figure 40 EGTR_DEFSPCENR0

18.6.1.1 SUBFUNCTION: operate

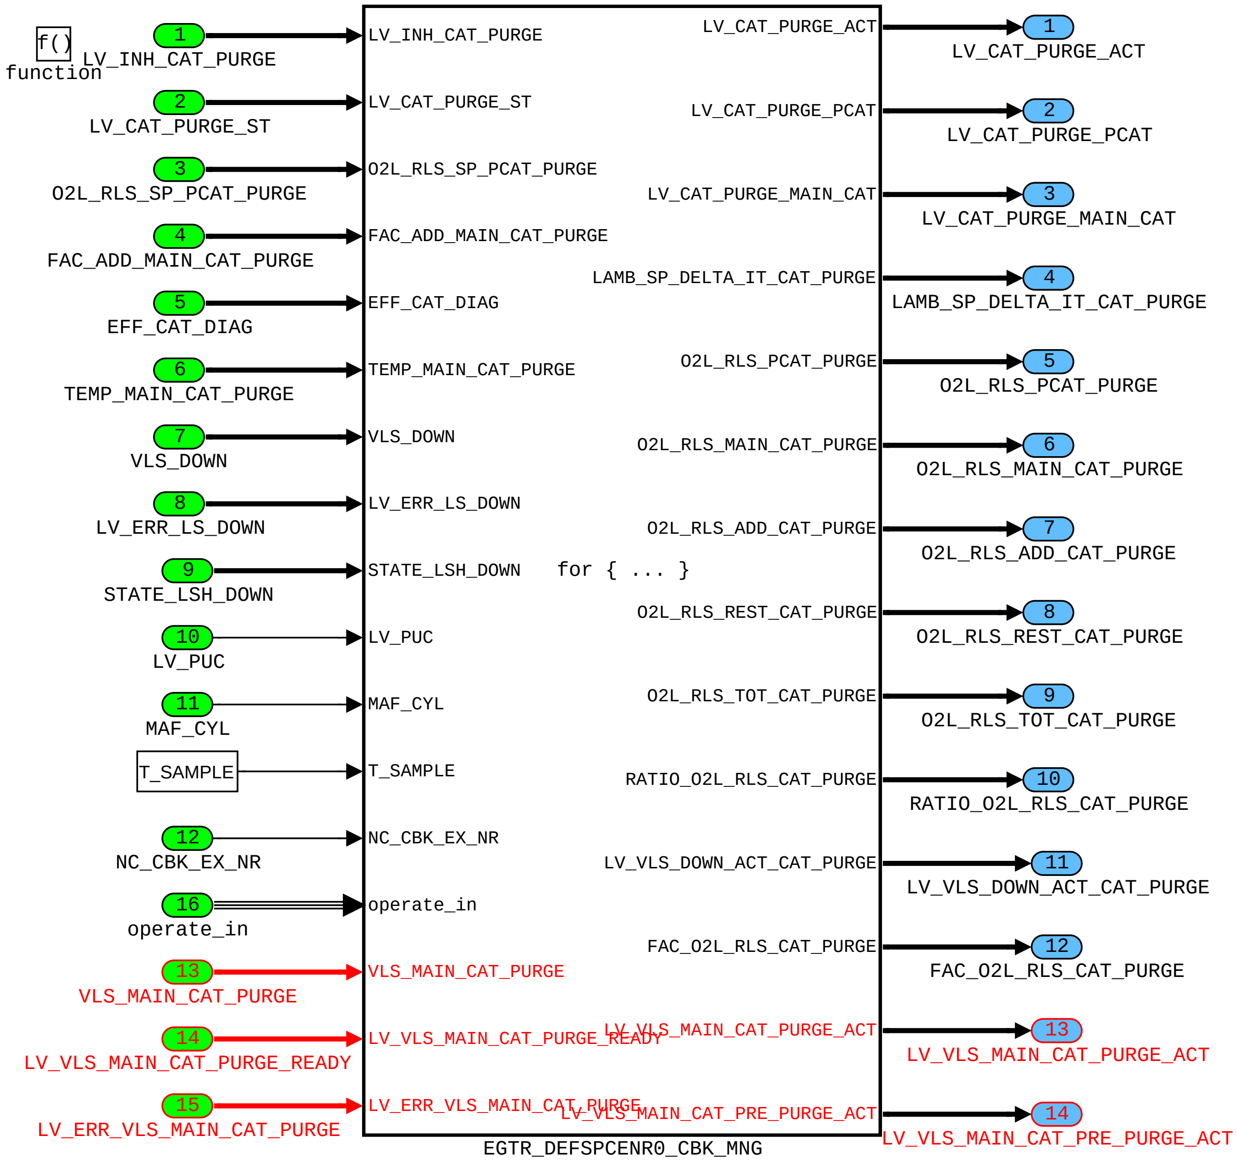

Figure 41 EGTR_DEFSPCENR0/ operate

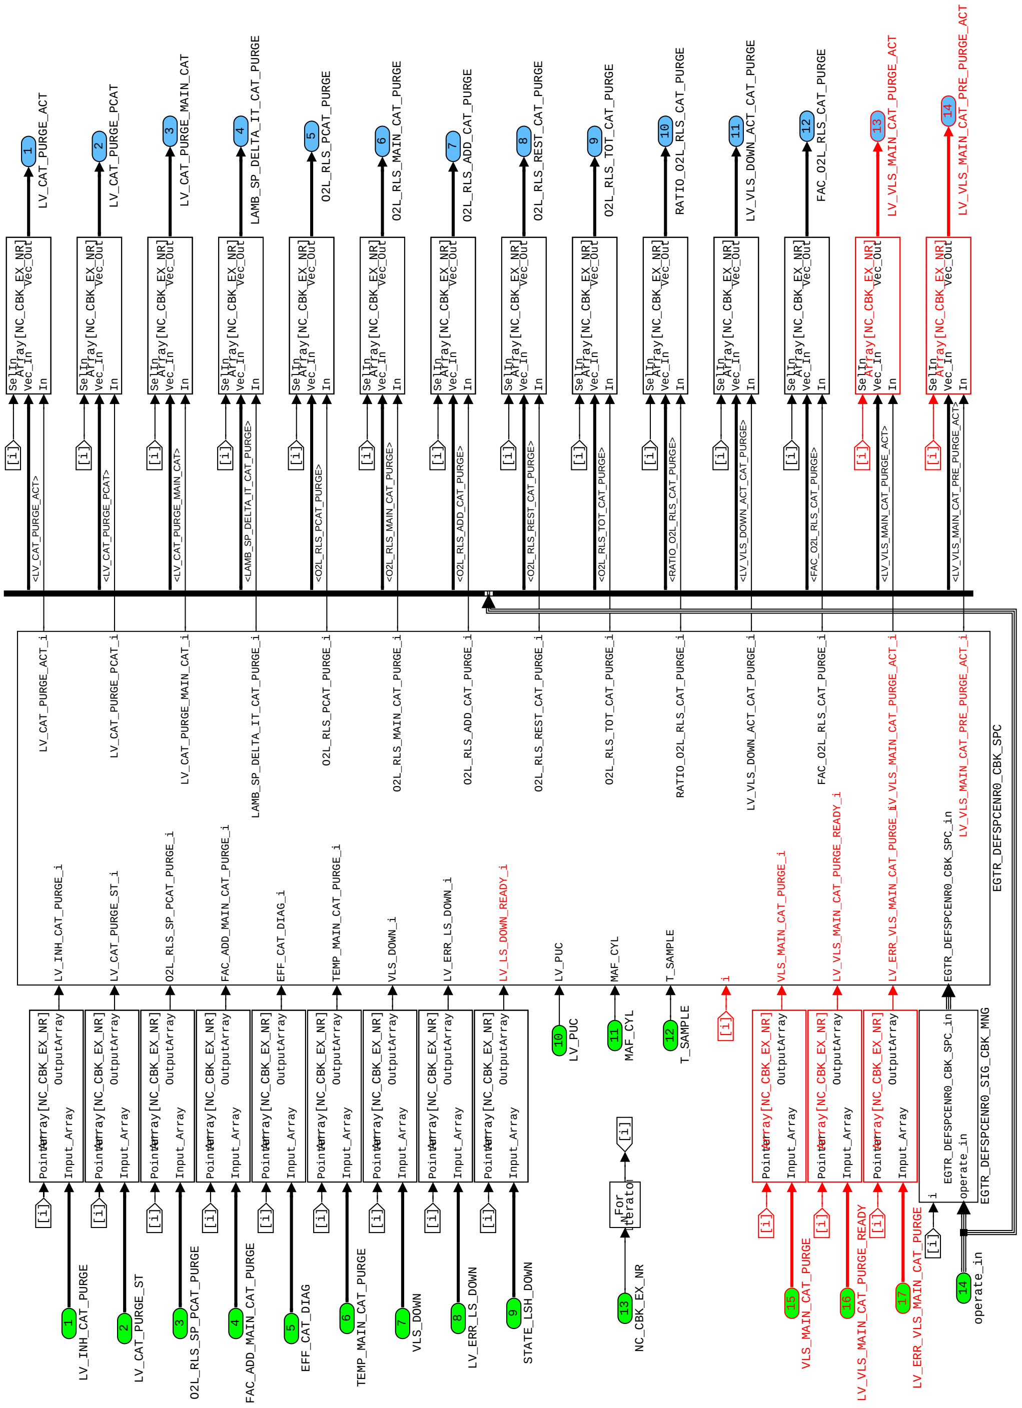

Figure 42 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG

<u>Management of catalyst purge initialization and pre and main catayst purge</u>

If LV_CAT_PRUGE_ST[i] is set by the function “Oxygen loading determination for catalyst enrichment function” the initialization sub-system (”INI_CAT_PURGE”) is called. The flag is set only for one sample step.

Depending on LV_CAT_PURGE_PCAT[i] and LV_CAT_PURGE_MAIN_CAT[i] one of the sub-systems “PRE_CAT_PURGE” or “MAIN_CAT_PURGE” is called.

If LV_PUC or the inhibition flag is set no cat purge is executed or an active cat purge is interrupted (sub-system “NOT_CAT_PURGE is called).

The cat purge activity flag LV_CAT_PURGE[i] is set to 1 if pre or main cat purge is active.

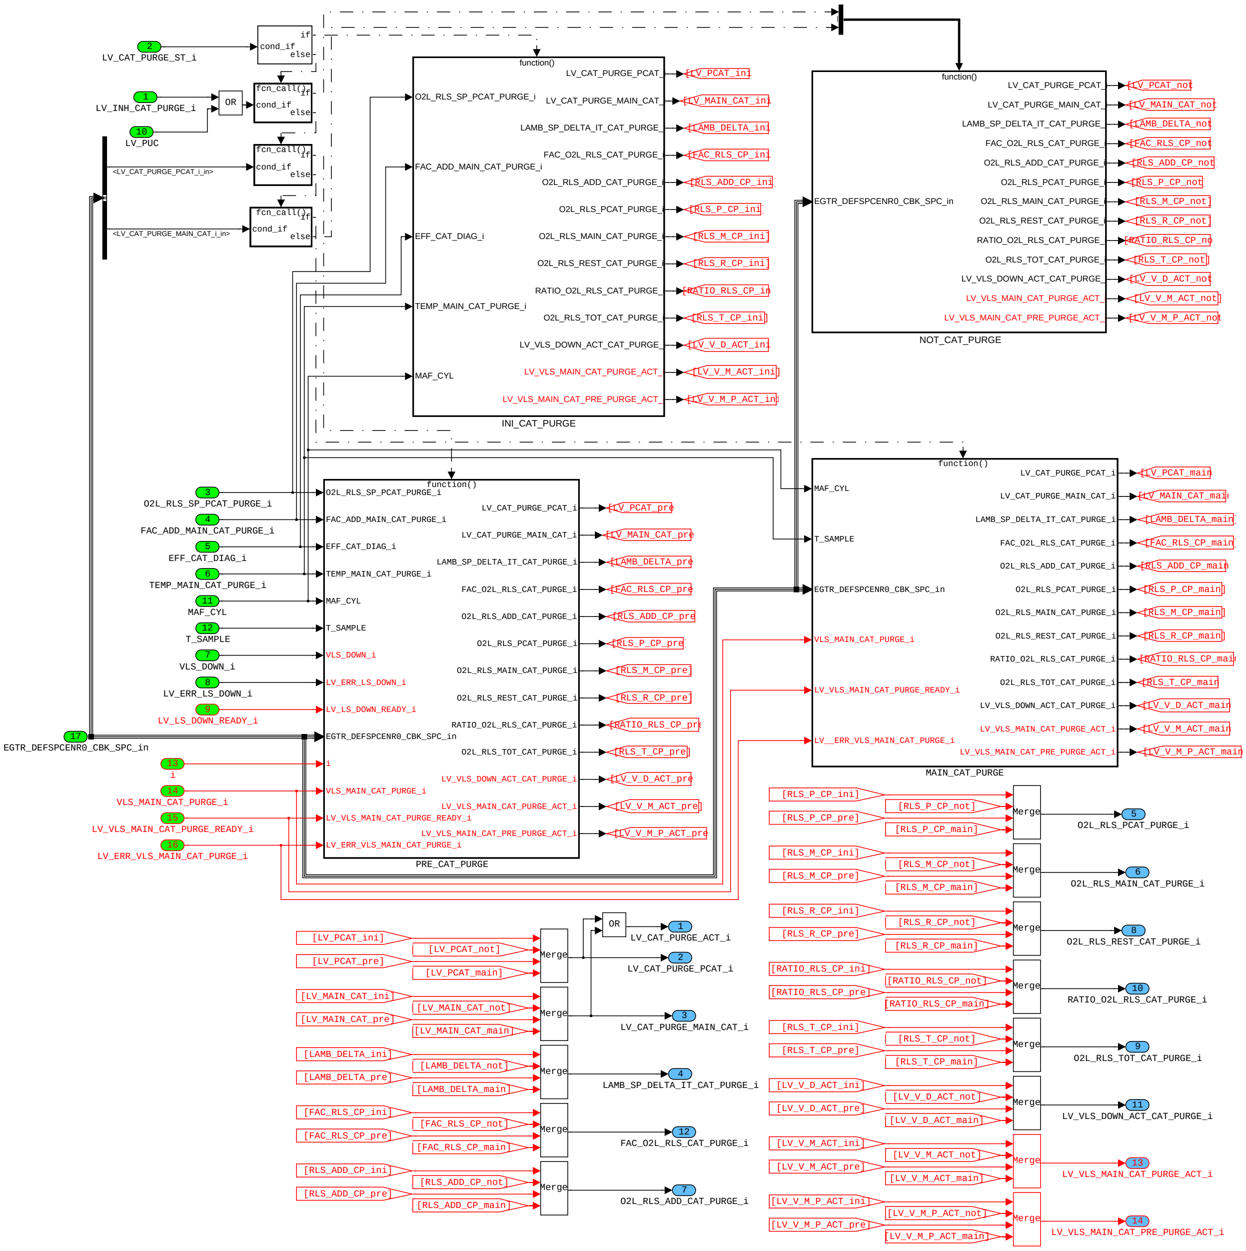

Figure 43 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC

Initialization of catalyst purge

Pre cat purge is activated by setting the respective flag. Main cat purge is deactivated.

The oxygen loading release integral for pre cat purge O2L_RLS_PCAT_PURGE[i] is initialised by O2L_RLS_SP_PCAT_PURGE[i]. The oxygen loading release integral for main cat purge is calulated by multiplying the one for pre cat purge with a factor map and with the additional factor defined in the function “Oxygen loading determination for catalyst enrichment function”. The rest oxygen loading release and the total oxygen loading release is the sum of the one for pre cat purge and main cat purge.

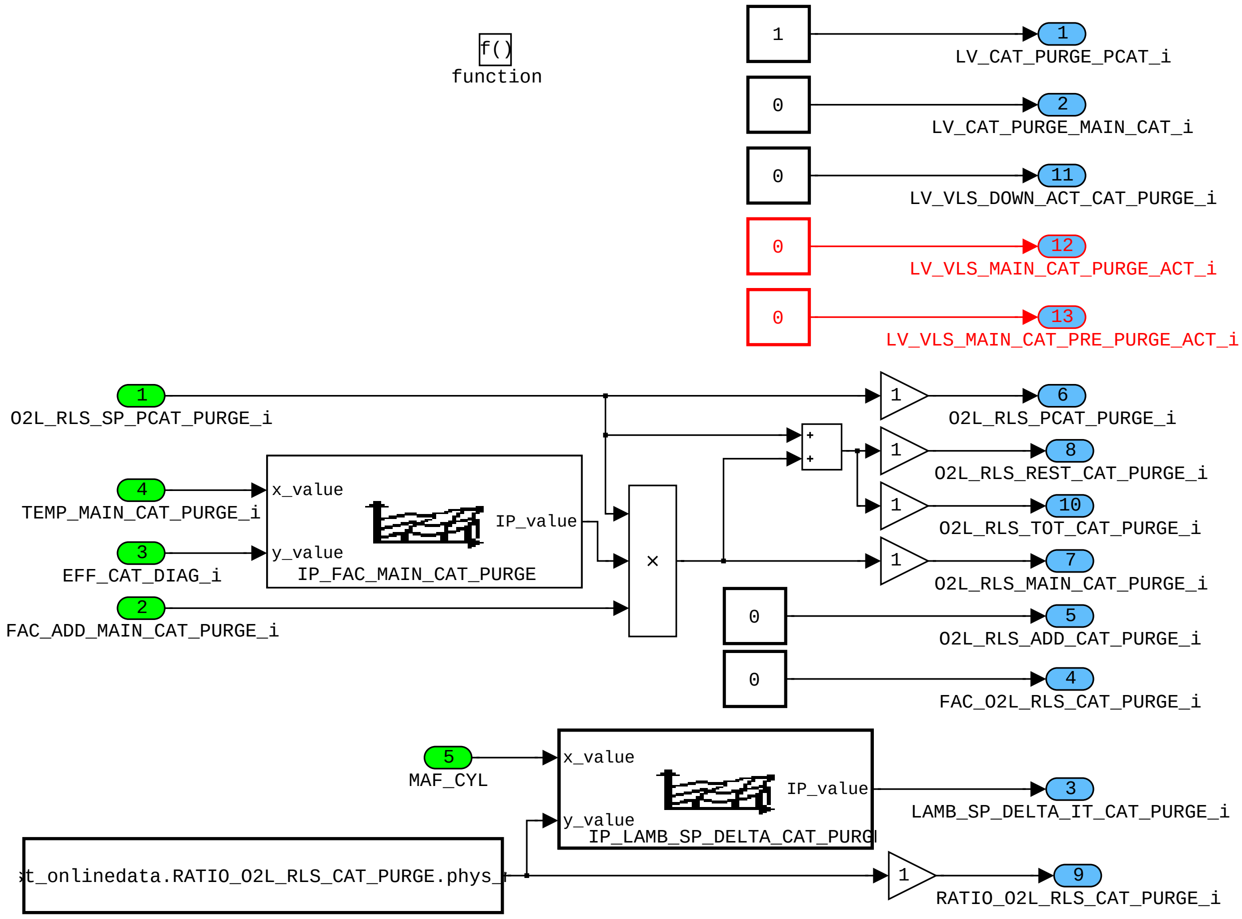

Figure 44 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ INI_CAT_PURGE

Main catalyst purge

If the oxygen loading for the main catalyst is released (O2L_RLS_MAIN_CAT_PURGE[i] <= 0) the end of main cat purge is detected and the respective sub-system “MAIN_CAT_PURGE_END” is triggered. Otherwise the sub-system ”MAIN_CAT_PURGE_CLC” is called.

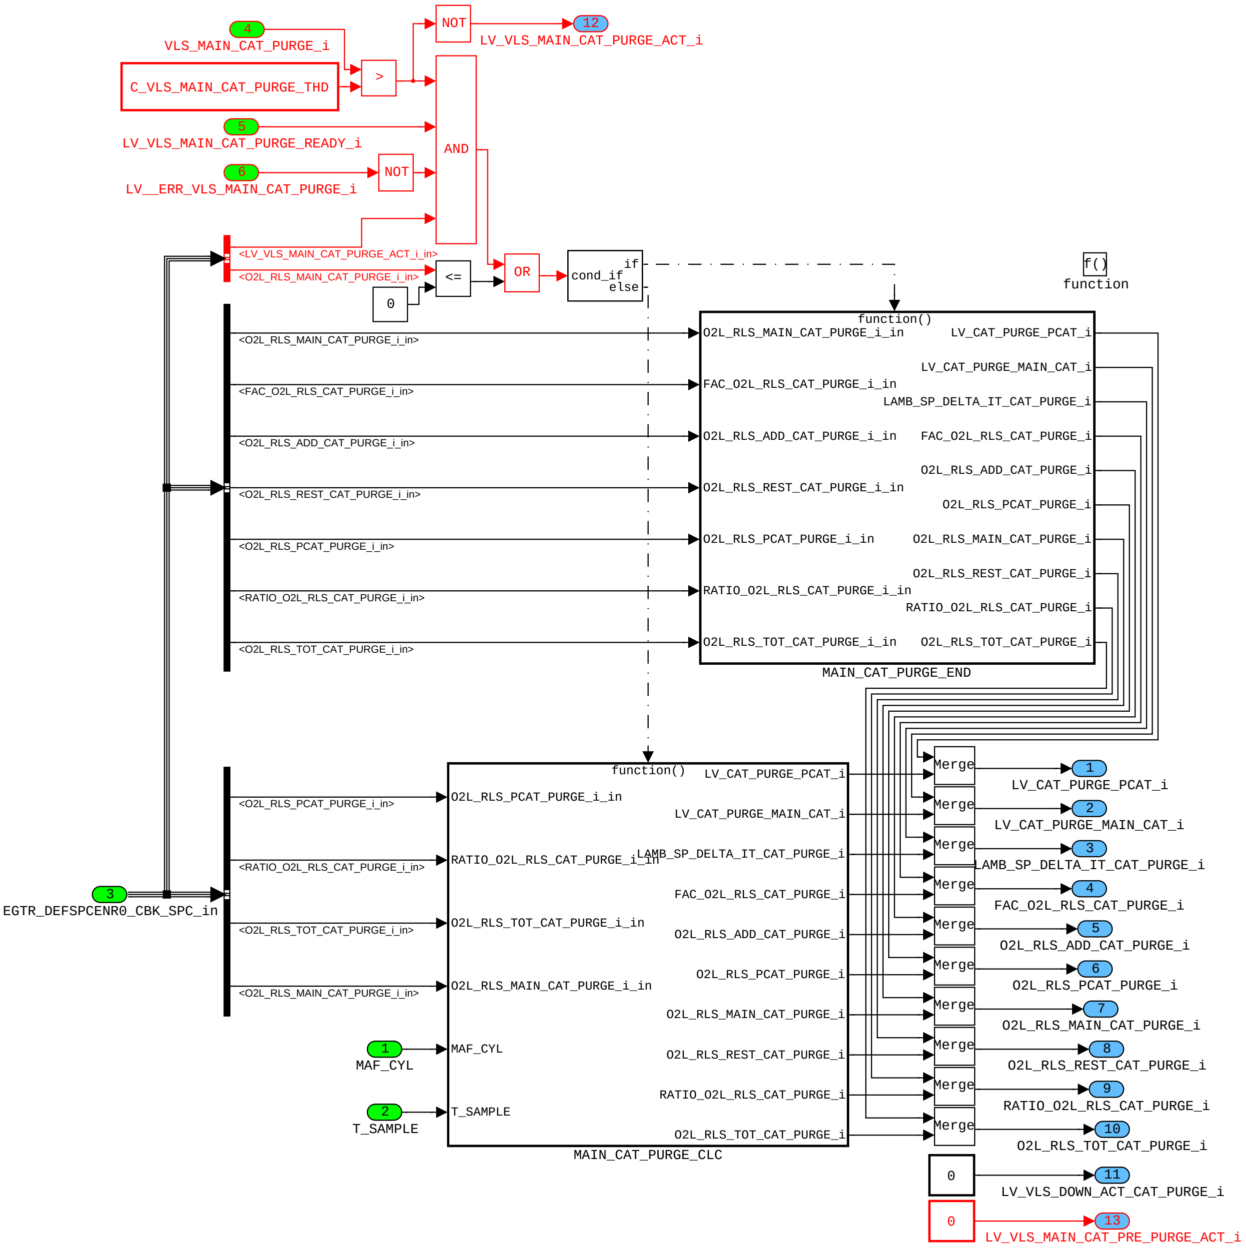

Figure 45 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ MAIN_CAT_PURGE

Calculation of main catalyst purge oxygen loading release

See textual description for “Calculation of pre catalyst purge oxygen loading release”.

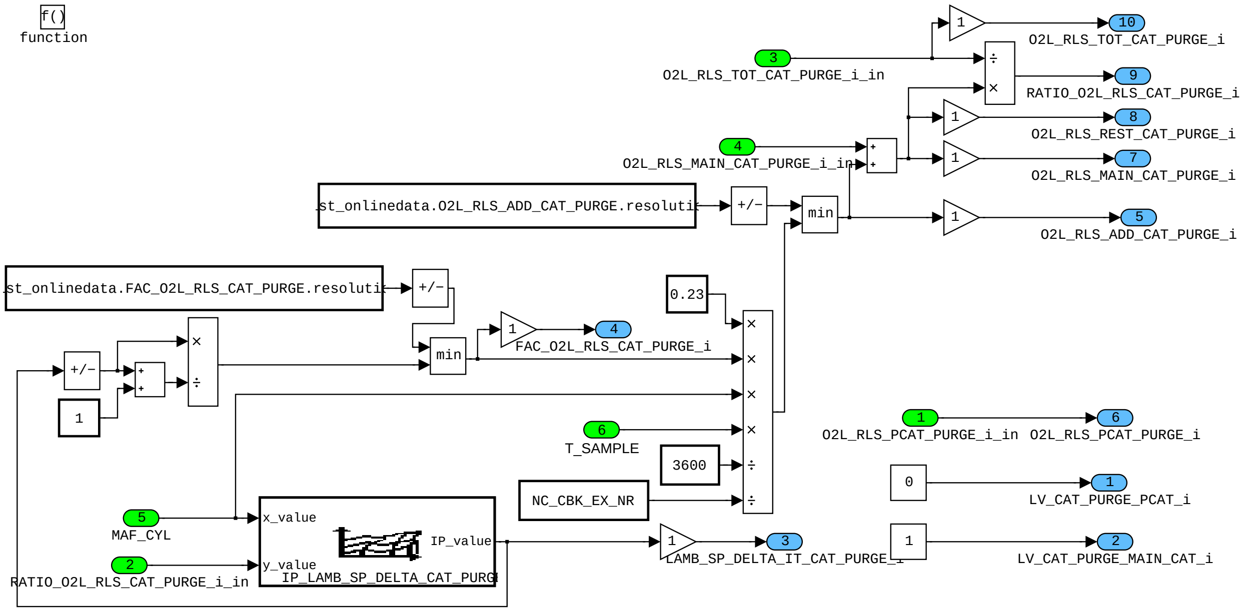

Figure 46 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ MAIN_CAT_PURGE/ MAIN_CAT_PURGE_CLC

End of main catalyst purge

Pre cat purge and main cat pruge is deactivated by setting the respective flags. The rich shift of the lambda set point is set to 0

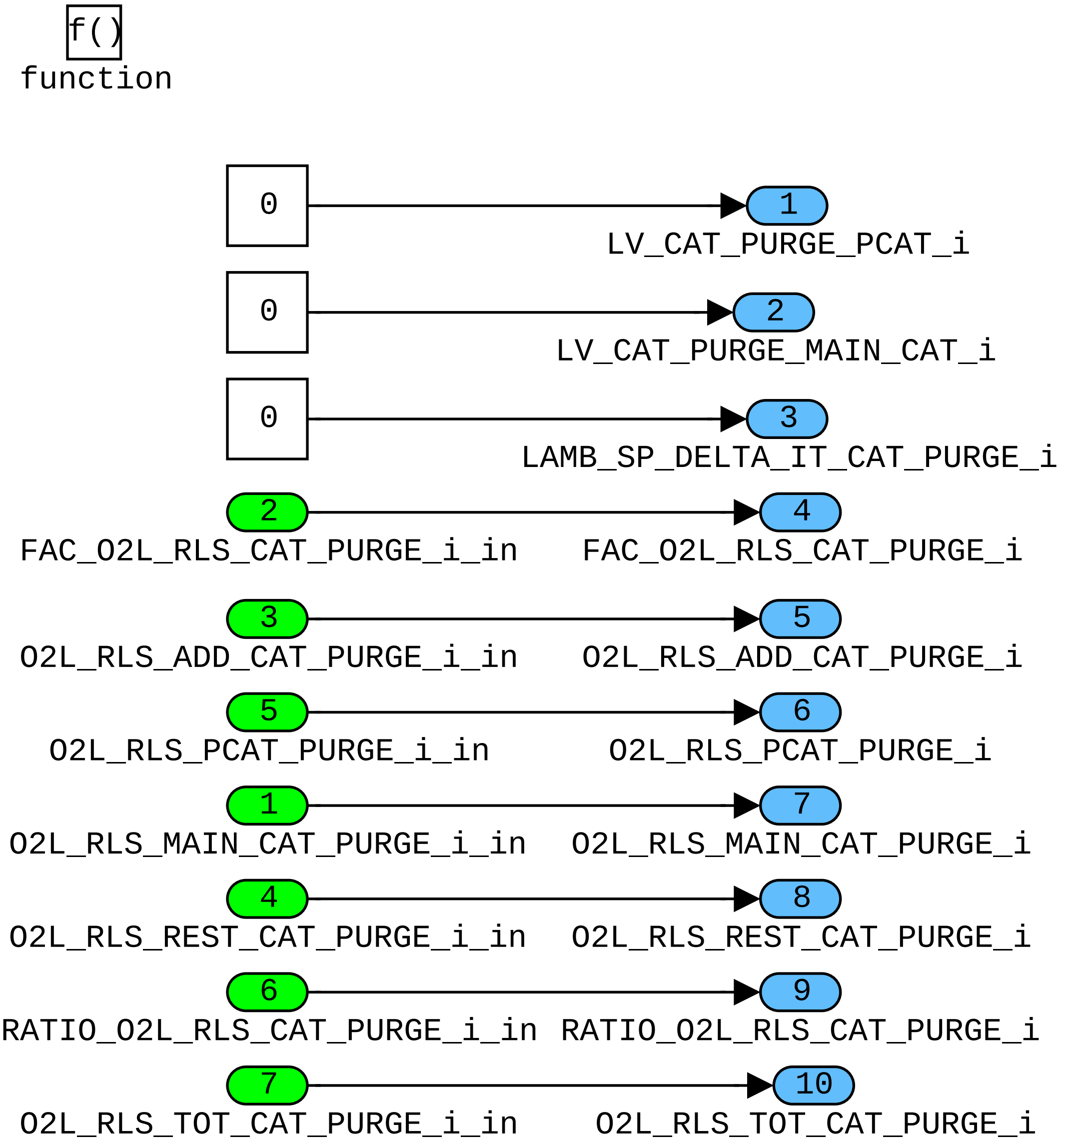

Figure 47 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ MAIN_CAT_PURGE/ MAIN_CAT_PURGE_END

Catalyst purge not active

Pre cat purge and main cat purge is deactivated by setting the respective flags to 0. The rich shift of the lambda set point is also set to 0.

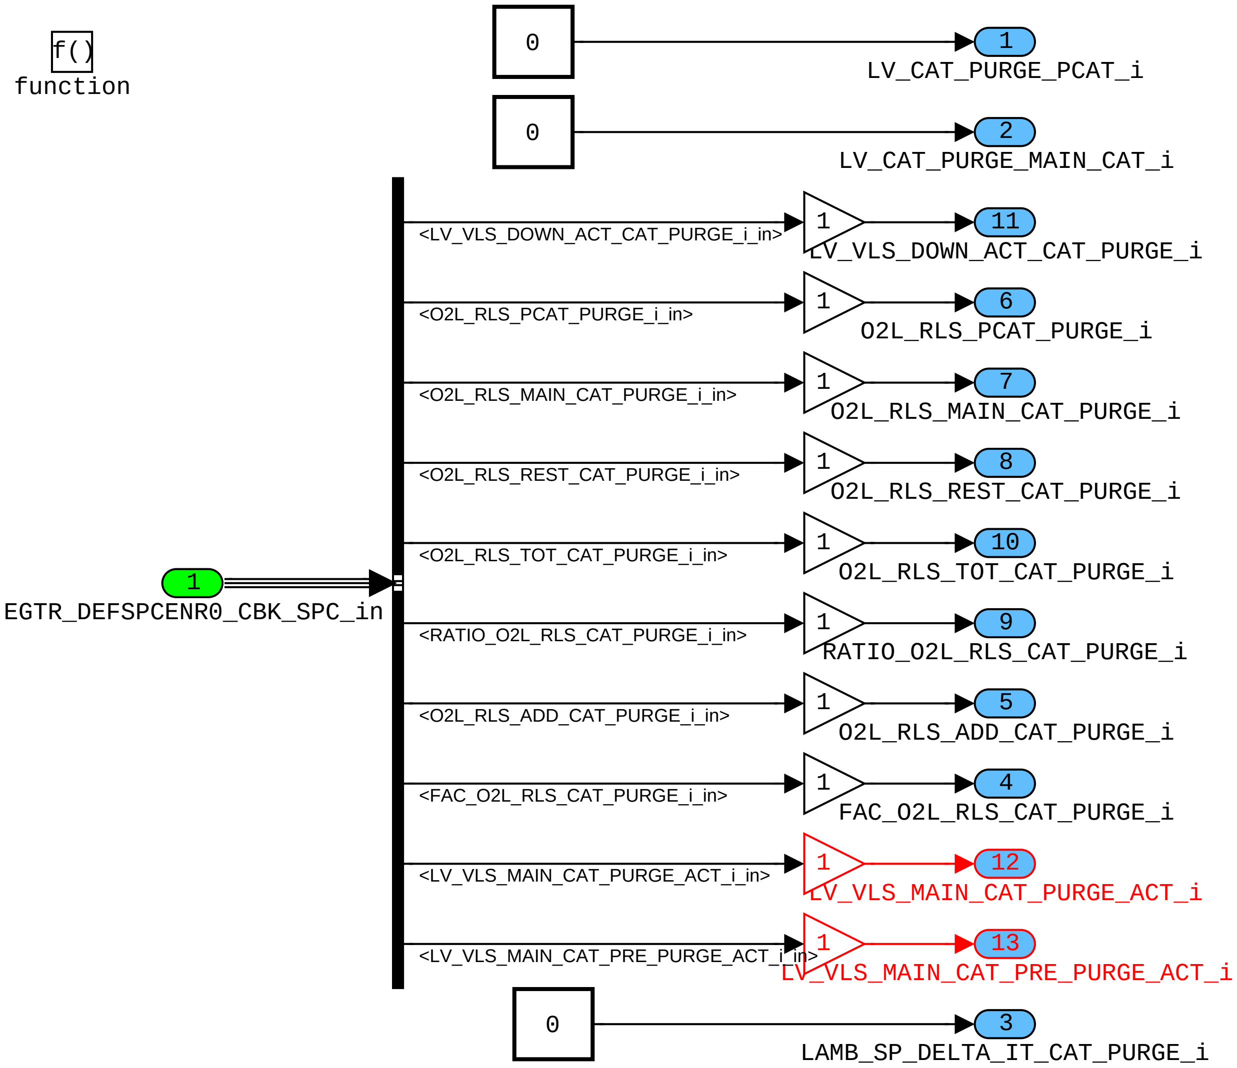

Figure 48 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ NOT_CAT_PURGE

Pre catalyst purge

If the oxygen loading for the pre catalyst is released (O2L_RLS_PCAT_PURGE[i] <= 0) or the downstream sensor signal exceeds a calibration threshold the end of pre cat purge is detected and the respective sub-system is triggered. The downstream signal is only evaluated if no error at the downstream sensor is present and the heater state is in “LSH_POW_CTL”. Furthermore the downstream signal must have been below the calibration threshold.

If the above mentioned conditions are not fulfilled the sub-system “PRE_CAT_PRUGE_CLC” is called.

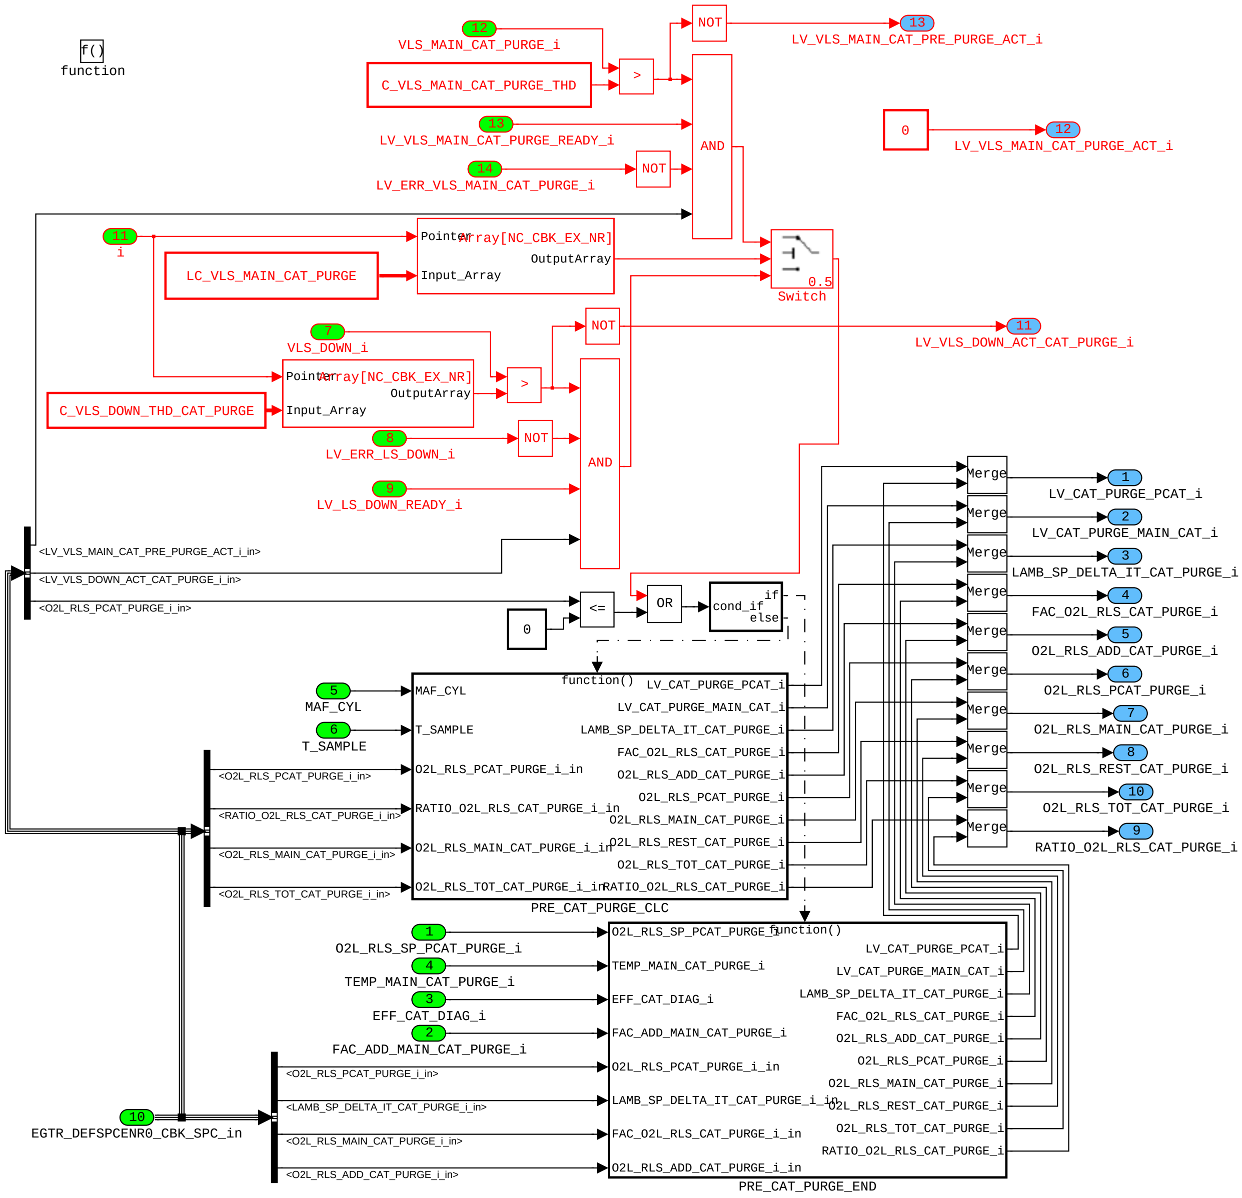

Figure 49 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ PRE_CAT_PURGE

Calculation of pre catalyst purge oxygen loading release

The rich shift of the lambda set point is taken from the respective map. The oxygen loading release is calulated by the following formula:

$$m_{O_2} = 0.23 \cdot \int \frac{-\Delta\lambda_{SP}}{1-\Delta\lambda_{SP}} \cdot \dot{m}_{air} dt$$

The remaining oxygen loading release (O2L_RLS_REST_CAT_PURGE[i]) is renewed and the quotient (RATIO_O2L_RLS_CAT_PURGE[i]): rest / total oxygen loading release is calculated.

For the calculation of the oxygen loading the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

The fraction of the formula above is minimized to the resolution of its variable (FAC_O2L_RLS_CAT_PURGE[i]). The oxygen loading that is added each sample step is also minimized to the resolution of its variable (O2L_RLS_ADD_CAT_PURGE[i]).

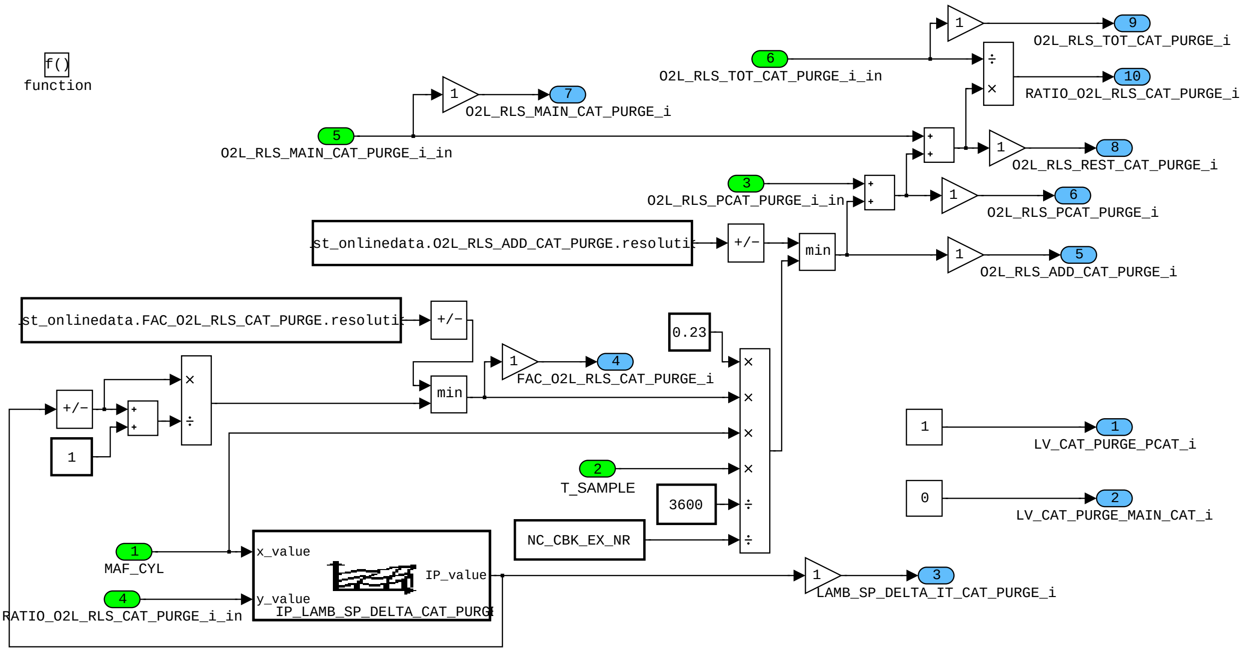

Figure 50 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ PRE_CAT_PURGE/ PRE_CAT_PURGE_CLC

End of pre catalyst purge

Main cat purge is activated by setting the respective flag. Pre cat purge is deactivated.

By newly evaluating the map IP_FAC_MAIN_CAT_PURGE the oxygen loading to be released during main cat purge is updated. The rest and total oxygen loading release is renewed and the quotient: rest / total oxygen loading release is also updated.

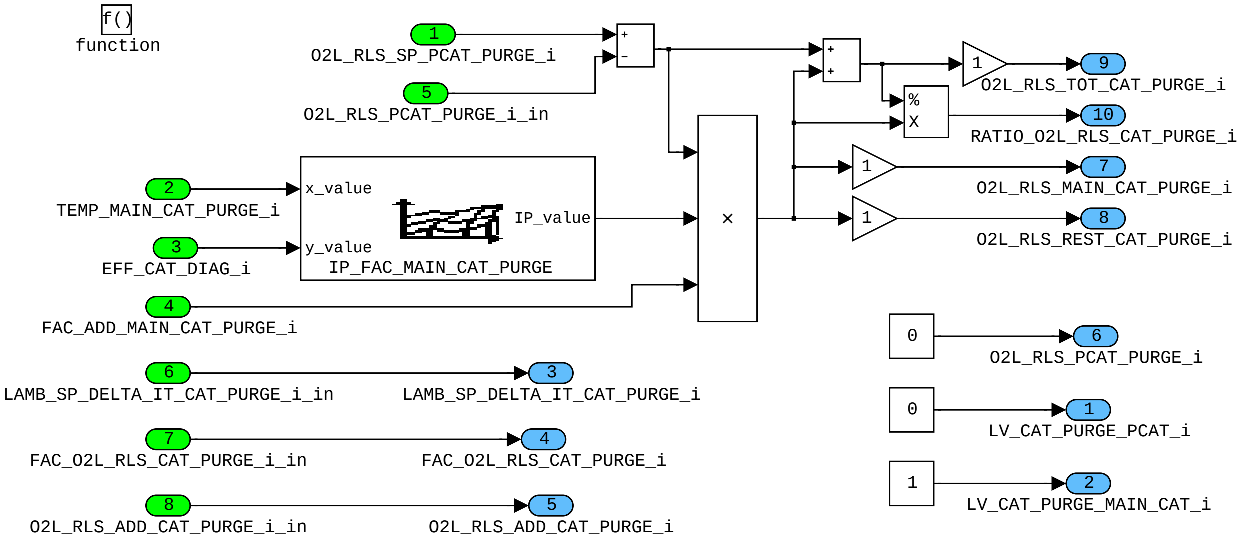

Figure 51 EGTR_DEFSPCENR0/ operate/ EGTR_DEFSPCENR0_CBK_MNG/ EGTR_DEFSPCENR0_CBK_SPC/ PRE_CAT_PURGE/ PRE_CAT_PURGE_END

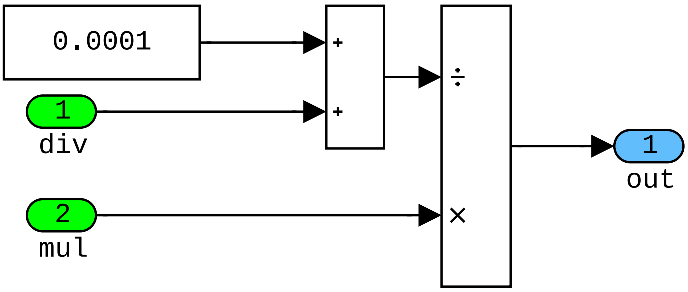

Normal division delivers two warning ’division by zero’ during initialization, although subsystem is never triggered.

General Information

This function defines the general inhibition of catalyst purge and the temperature of the main catalyst by means of a temperature gradient.
NC_CBK_EX_NR defines the number of exhaust banks.

Additionally, MAFintegrals from INSY (MAF_INT_PUC_ACT and MAF_INT_PUC_NOT_ACT) and an MAFintegral for gear shifting with cylinder cutoff (MAF_INT_GS_SCC) are included.
An additionally interface to NOXM for cat purge after lean operation is included.

Application Conditions

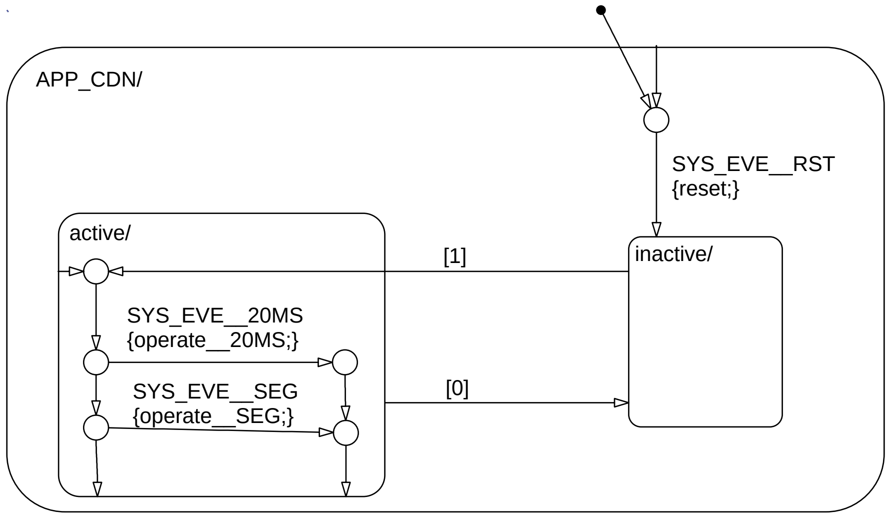

Figure 60:

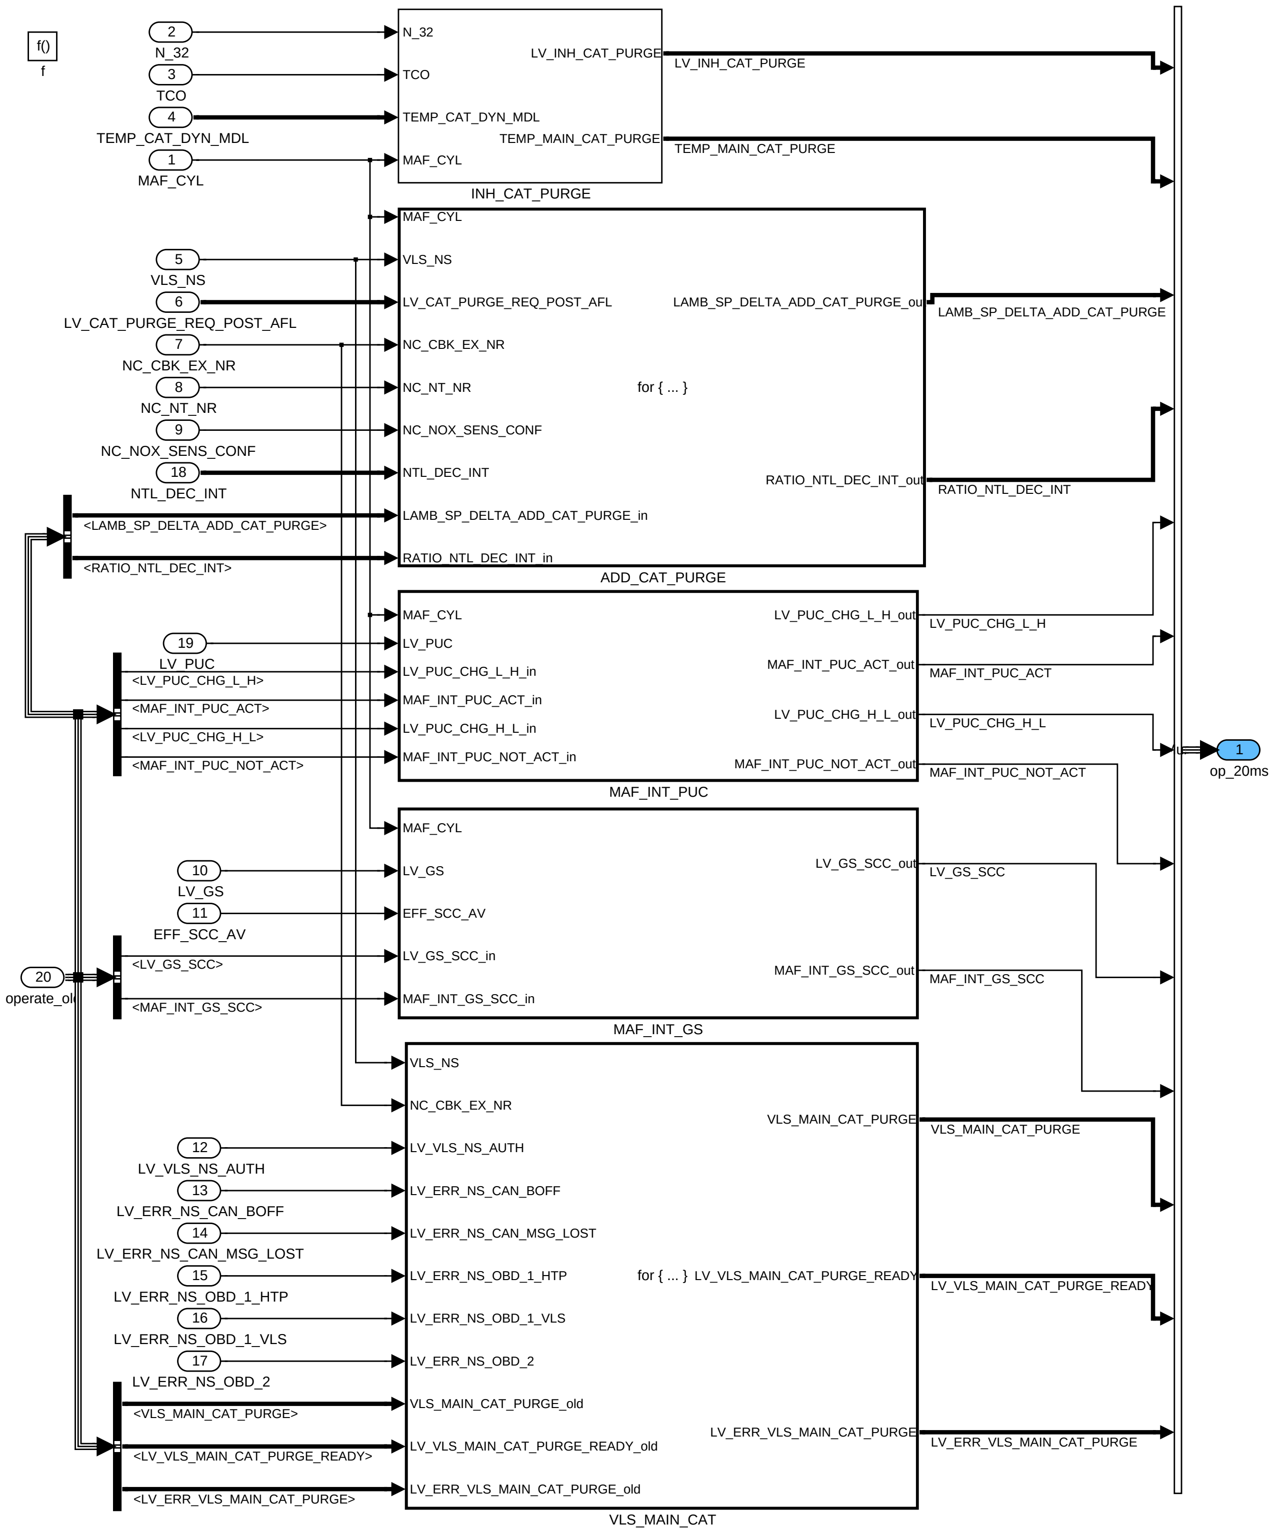

Figure 62:
Path: EGTR_DEFSPCENRI0/operate_20MS

18.8.1.1 LV_INH_CAT_PURGE and TEMP_MAIN_CAT_PURGE

LC_CAT_PURGE_INH[i] can inhibit each exhaust bank separately, while the threshold conditions of MAF_CYL, N_32 and TCO is valid for both banks in the same way. A vector operation must be applied.

The temperatur gradient calculation for the main catalyst is a vector operation too.

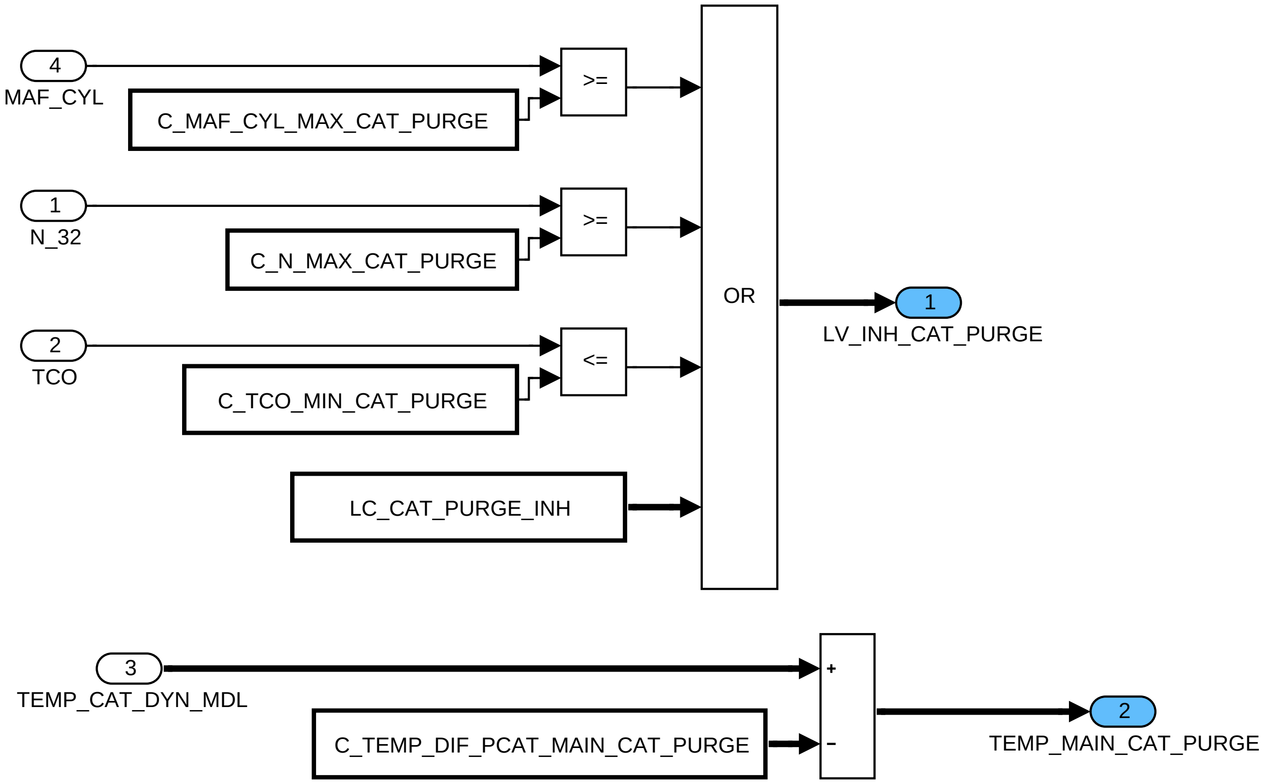

Figure 63:
Path: EGTR_DEFSPCENRI0/operate_20MS/INH_CAT_PURGE

18.8.1.2 LAMB_SP_DELTA_ADD_CAT_PURGE

This cat purge interface to NOXM is used after lean operation.
Vector size of input signals depend from NC_NT_NR and NC_NOX_SENS_CONF. Vector size of output signal depends from NC_CBK_EX_NR. Therefore the input signals have to be used dependend on different exhaust gas configurations. Especially, if NC_CBK_EX_NR is greater than the number of NOx sensors or NOx traps only the signal of the first bank have to be used for calculation of both banks.

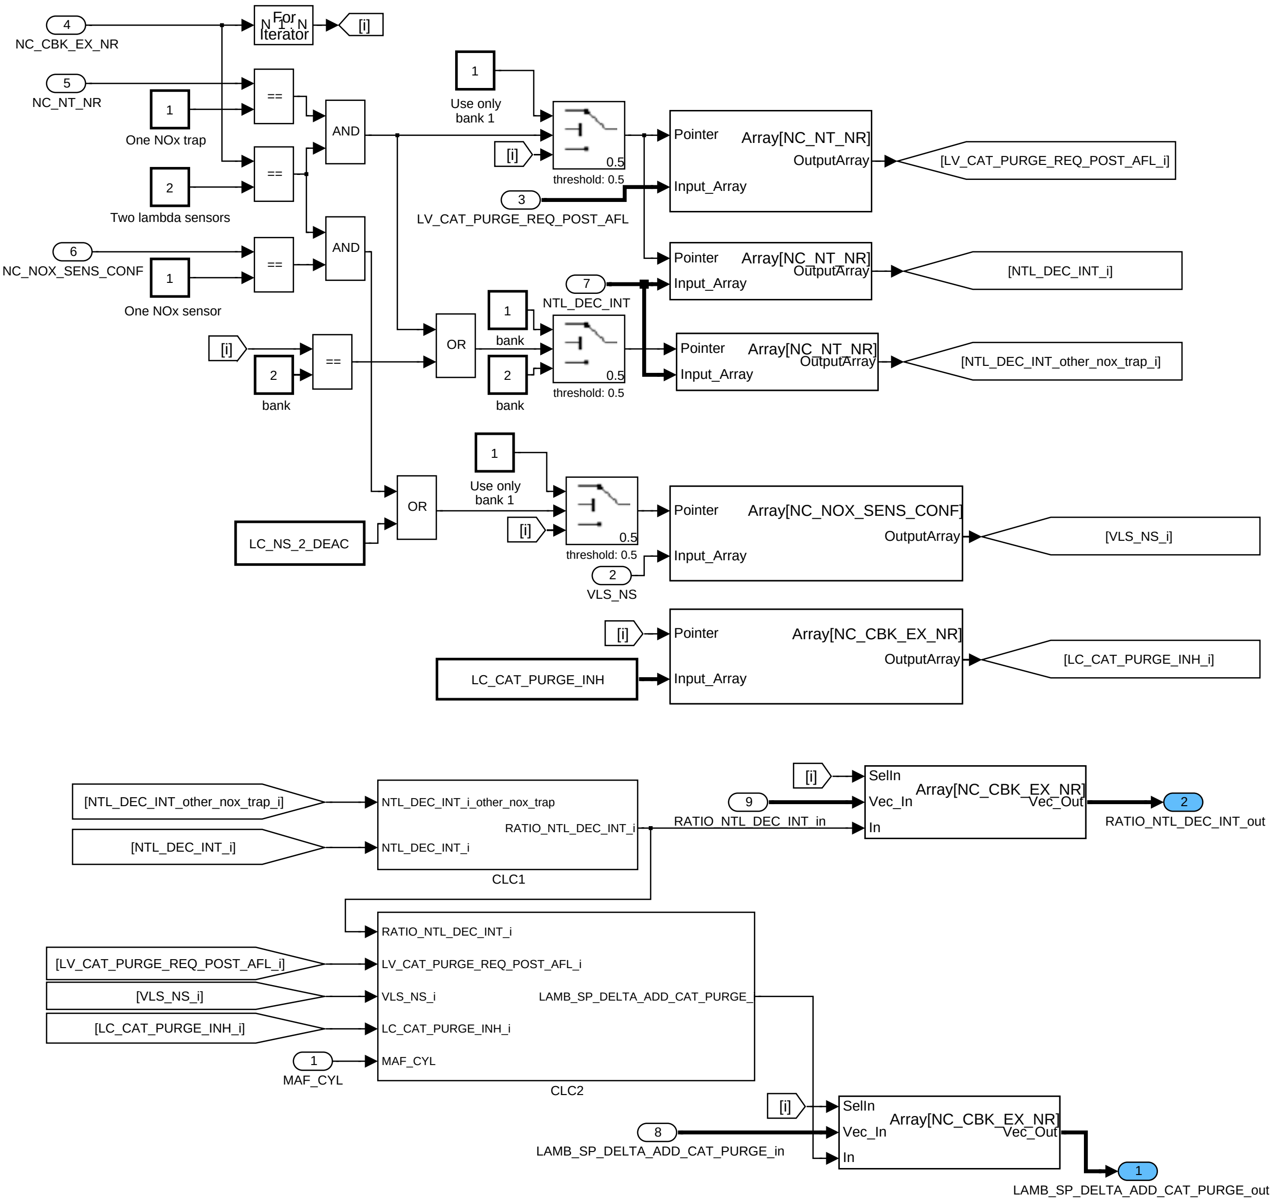

Figure 64:

18.8.1.3 MAF_INT_PUC_ACT and MAF_INT_PUC_NOT_ACT

Calculation of MAF integrals is done depending on LV_PUC, the reset of the integrals is done depending on edges of LV_PUC.

These edges will be detected in the synchronous segment loop and stored in LV_PUC_CHG_L_H or _H_L, to avoid loosing edges at high speed. After reset of an integral the edge memory flag will be cleared.

18.9.1 EGTR_DEFSPFSTIA0

The reccurence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Function Description

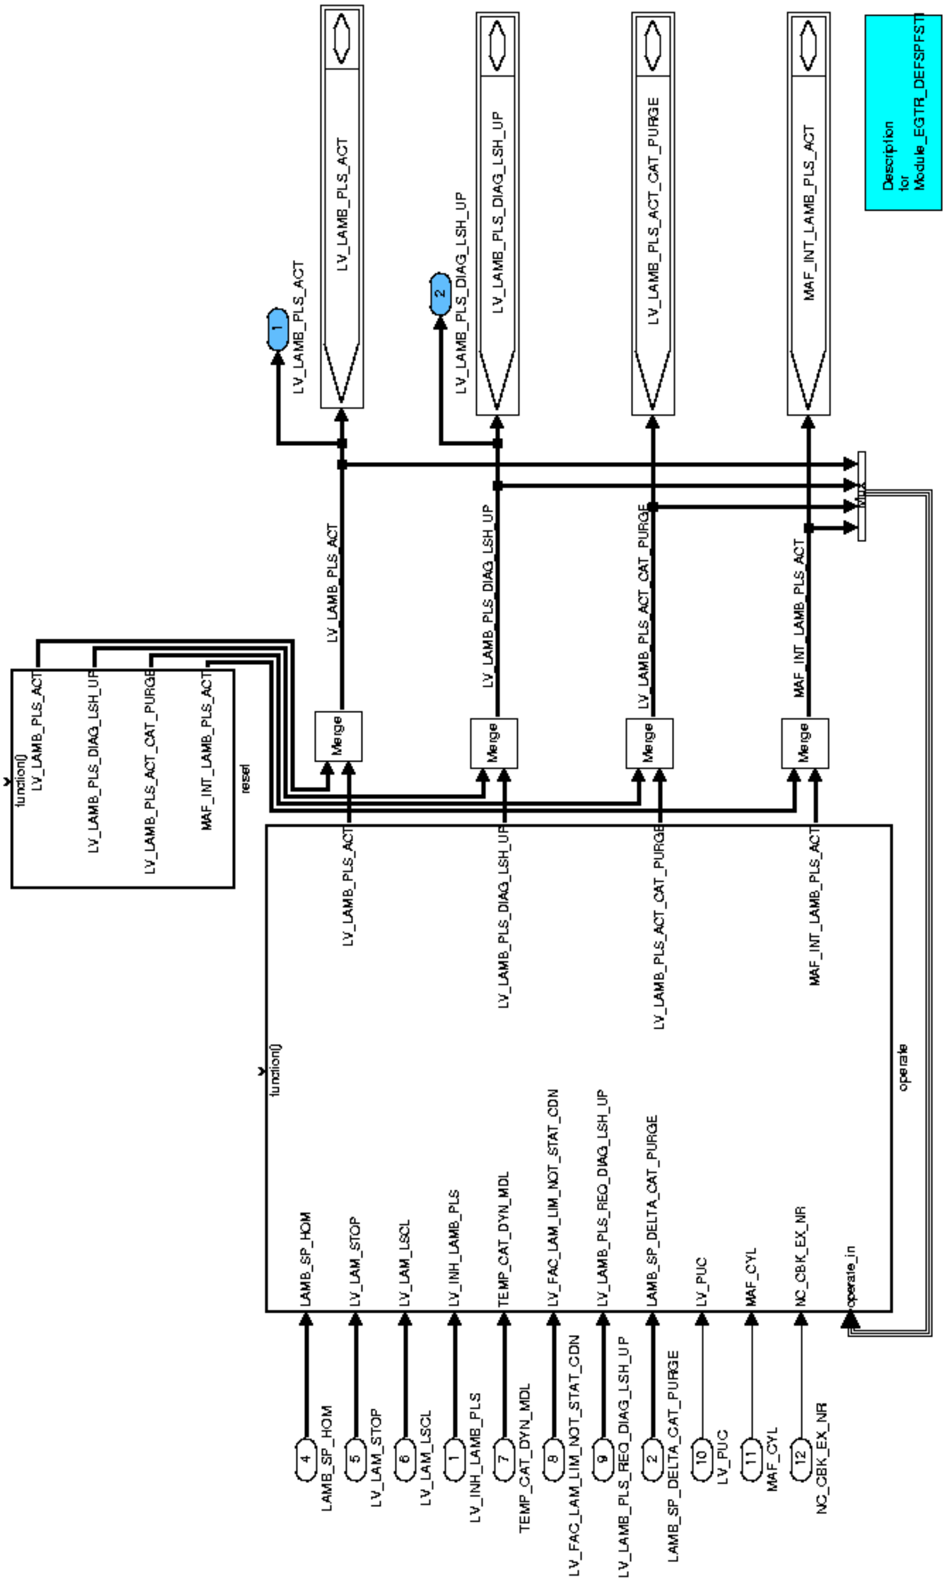

Figure 75 EGTR_DEFSPFSTIA0

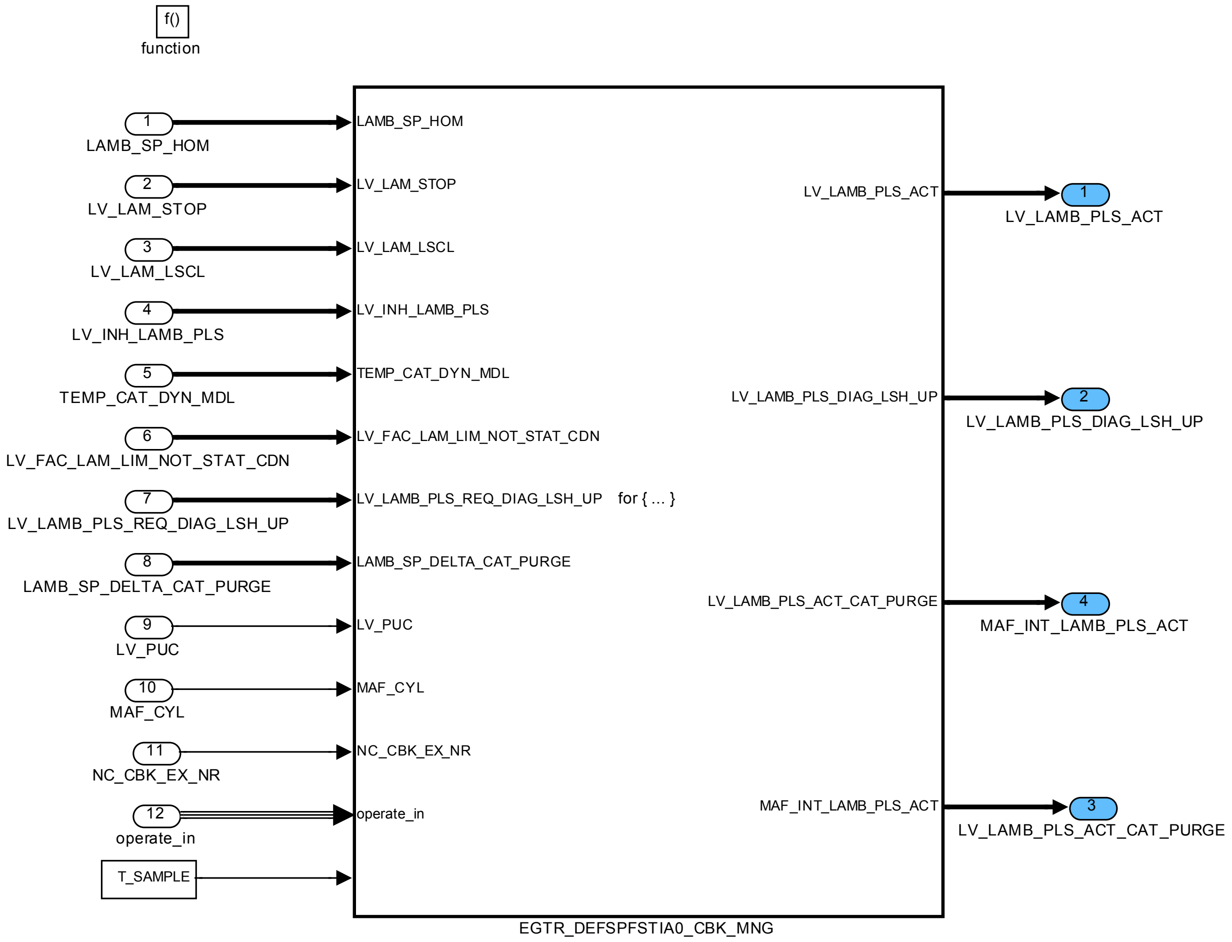

Figure 76 EGTR_DEFSPFSTIA0/ operate

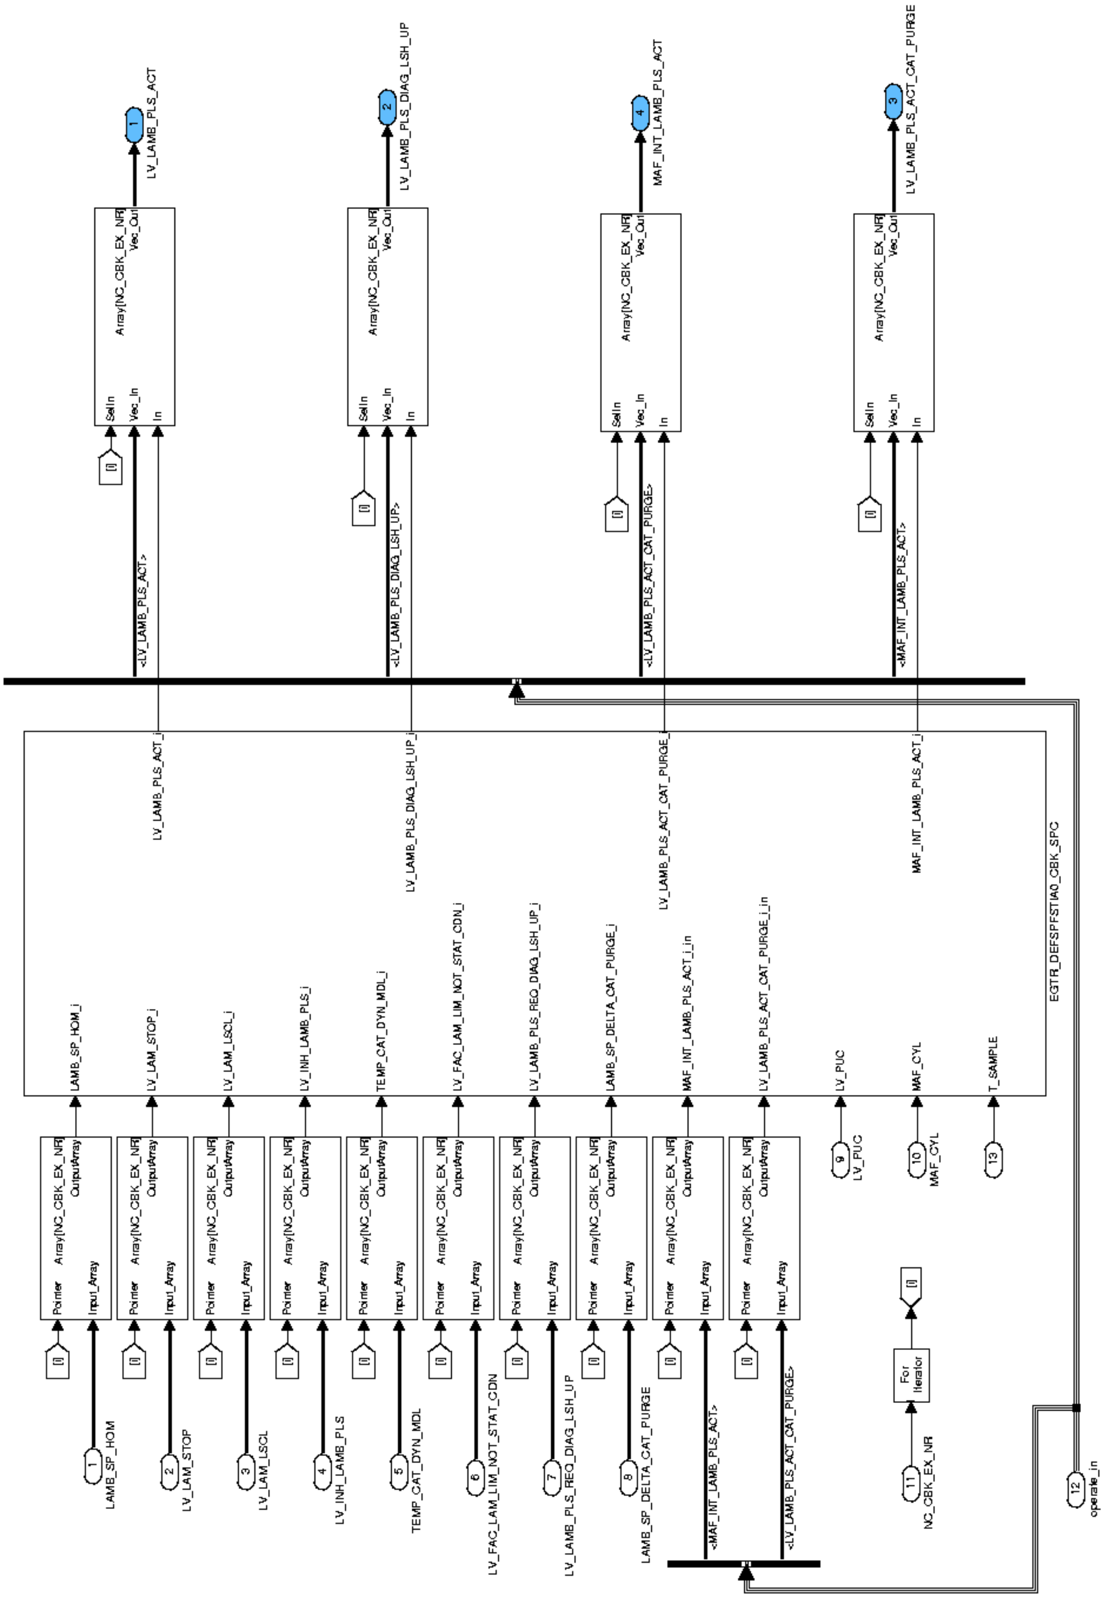

Figure 77 EGTR_DEFSPFSTIA0/ operate/ EGTR_DEFSPFSTIA0_CBK_MNG

Activation / deactivation

The forced stimulation is activated in requested mode if the following conditions are fulfilled:

- engine state pull fuel cut off is inactive

- no inhibition from application incidences
- the request has been recognised (LV_LAMB_PLS_REQ_DIAG_LSH_UP[i] = 1)

The activation in the requested mode has higher priority than the common mode.

The common mode is only activated if the activation condition for the requested mode are not fulfilled. For the activation in the common mode the following conditions must be fulfilled:

- engine state pull fuel cut off is inactive
- no inhibition from application incidences
- lambda controller is activated and not in stop mode
- no lambda controller limitation under non stationary operating conditions
- lambda set point deviation from catalyst purge is below calibration limit including hysteresis consideration (LV_LAMB_PLS_ACT_CAT_PURGE[i]); this flag is evaluated each time when the activation conditions are checked
- the lambda set point is in a valid range
- the catalyst temperature value exceeds a calibration threshold

If these conditions above are all fulfilled a mass air flow integral is calculated. The forced stimulation in the common mode will be finally activated when the integral exceeds a calibration limit.

For the calculation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

The forced lambda stimulation distinguishes between 5 different parameters which are listed hereafter with its priority:

a) Priority 1: forced stimulation parameters for requested mode
b) Priority 2: forced stimulation parameters for catalyst efficiency diagnosis
c) Priority 3: forced stimulation parameters for WRAF sensor dynamic diagnosis
d) Priority 4: forced stimulation parameters for idle speed
f) Priority 5: forced stimulation parameters for normal operation

18.11.1 EGTR_FCTDGCEFLD0

The limited dynamic conditions LV_CAT_LDC[i] for catalyst efficiency diagnosis is set if the limited dynamic conditions for engine speed, mass air flow and lambda controller output exist and a calibration threshold for the integral of the air flow is exceeded.

Moreover the summation of the throttle position gradient LOAD_GRD_SUM_CAT_LDC[i] must not exceed a calibration threshold.

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Figure 95 EGTR_FCTDGCEFLD0/ operate

Cylinder bank independent calculation

Calculation of LOAD_CAT_LDC gradient:

The LOAD_CAT_LDC gradient is calculated with the reccurence T_SAMPLE in [ms].

To this effect, the LOAD_CAT_LDC values are written into the ring buffer. Thus, the last two LOAD_CAT_LDC values are available in addition to the current LOAD_CAT_LDC value. The LOAD_CAT_LDC gradient is based on a LOAD_CAT_LDC difference of twice T_SAMPLE in [ms].

The LOAD_GRD_CAT_LDC reflects the gradient of the actual driver's demand prior to the corrections. If C_LOAD_GRD_SUM_MIN is larger than C_LOAD_GRD_SUM_MAX the LOAD_CAT_LDC gradient summation LOAD_GRD_SUM_CAT_LDC will be no condition to determine the limited dynamic bit LV_CAT_LDC[i].

Limited engine speed (N) dynamics:

The floating mean value N_MMV_CAT_LDC is computed using the filtering constant C_N_CRLC_CAT_LDC. The limited dynamics condition only exist while the engine speed N lies within the dynamics window around N_MMV_CAT_LDC.

If the above limited dynamics condition is violated, the floating mean value N_MMV_CAT_LDC is set to the current engine speed in order to reach the limited dynamics condition faster.

Limited mass air flow (MAF) dynamics:

The floating mean value MAF_MMV_CAT_LDC is computed using the averaging constant C_MAF_CRLC_CAT. The limited dynamics condition only exist while the air mass MAF stays within the dynamics window around MAF_MMV_CAT_LDC.

If the above limited dynamics condition is violated, the floating mean value MAF_MMV_CAT_LDC is set to the current air-mass value in order to reach the limited dynamics condition faster.

Limited mean oxygen value (FAC_LAM_MV[i]) dynamics

The floating mean value FAC_LAM_MV_MMV_CAT_LDC[i] is computed inside the AGGR LACO.

The limited dynamics condition continues to exist while the mean oxygen value FAC_LAM_MV[i] stays within the dynamics window around FAC_LAM_MV_DELTA_CAT_LDC[i].

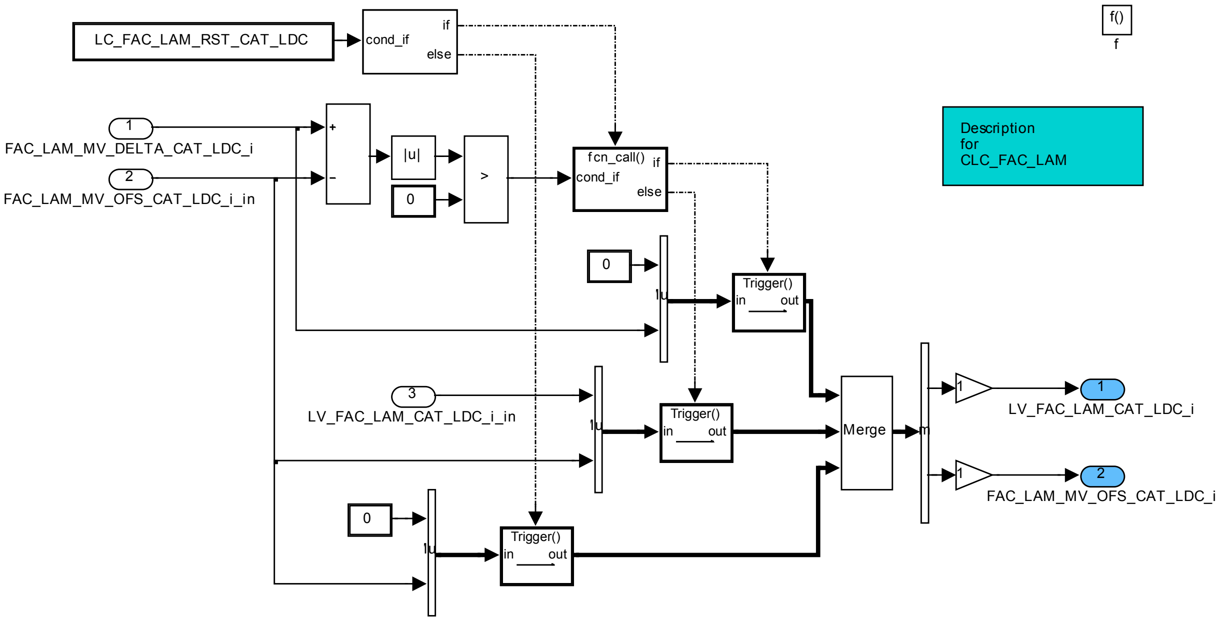

Figure 100 EGTR_FCTDGCEFLD0/ operate/ EGTR_FCTDGCEFLD0_CBK_MNG/ EGTR_FCTDGCEFLD0_CBK_SPC/ CLC_FAC_LAM

Setting of LV_CAT_LDC[i]

When the air mass flow integral exceeds a calibration limit the flag LV_CAT_LDC[i] is set to 1 indicating that the limited dynamics are fulfilled.

The reccurence time is defined by T_SAMPLE in [ms].

For the calculation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

18.12.1 EGTR_FCTDGCEFAC0

This function determines the activation flag LV_CAT_DIAG_CDN_ACT[i] for catalyst efficiency diagnosis (OSC method). This flag can be also be set manually by LC_CAT_DIAG_CDN_ACT_MAN.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements, the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

For the calculation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

lambda linearization from downstream LS signal					

General Information

That catalyst diagnosis function is suitable for single branch (only one exhaust bank) and twin branch exhaust lines (two exhaust banks).

For a twin branch exhaust line the function has the same structure for both exhaust lines. The conversion properties of the two catalysts are monitored separately.

NC_CBK_EX_NR labels the number of exhaust banks.

For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

The signals from the control sensor upstream and the associated monitoring sensor downstream from the catalyst are used for catalyst diagnosis.

If a catalyst has good conversion properties, the oscillating lambda signal upstream from the catalyst generated by the lambda controller (which shall ensure defined O2-load of catalyst) downstream is smoothed by the Oxygen Storage Capacity of the catalyst.

If the conversion provided by the catalyst is low due to aging, poisoning by leaded fuel or misfire, then the oscillating lambda signal upstream of the catalyst also exists downstream of the catalyst.

The lambda oscillation downstream of the catalyst is detected by an oxygen sensor (monitoring sensor).

Every monitored catalyst or combination of catalysts shall be indicated when the HC emission exceeds the applicable emission test threshold.

Description:

The diagnosis algorithm is realized with a state machine in order to improve specification understanding and coherence between specification and SW.

Monitoring cycle:(STATE_CAT_DIAG[i]: CYC_LEAN and CYC_RICH)

The first monitoring cycle is started following the rich-lean change (LV_AVL 0->1). A monitoring cycle lasts one complete lambda controller period (2 subsequent lambda richness changes).

Several monitoring cycles are needed to finish the diagnosis.

At activation of Catalyst diagnosis the Forced stimulation is switched to higher Cat diag forced stimulation (soft switch in NC_NOM_CAT_DIAG_STEP cycles) and Trim control is switched to Cat diag parameters (P-share and I-share with own calibration, additionally shift of VLS setpoint depends from EFF_CAT_DIAG_HOM value). VLS_DOWN signal from monitoring Lambda sensor is converted with inverse sensor characteristic LAMB_CAT_DOWN_i.

In the wait state before the first cycle after every reactivation (rich-lean change LV_AFL) only LAMB_CAT_DOWN_MV_i is calculated. LAMB_CAT_DOWN_SUM_i is obtained by the summation of the LAMB_CAT_DOWN_i over a complete monitoring cycle. If LAMB_CAT_DOWN_MV_i agree with VLS_DOWN setpoint, catalyst diagnosis could start. WAIT state turns to RAMP_UP state and the O2load (realized by forced stimulation) ramps up from nominal value to catalyst diagnosis value. After ramp up of O2load finished, forced stimulation informs the catalyst diagnosis by forced stimulation state, really evaluated catalyst diagnosis cycles could start (CYC_LEAN/RICH).

LAMB_CAT_DOWN_MV_i is the mean value of the LAMB_CAT_DOWN_i - O2_load downstream the Catalyst calculated as inverse characteristic of binary lambda sensor from VLS_DOWN_i signal for one monitoring cycle. The calculation of MASS_O2_CAT_DIF_CYC_i is based on LAMB_CAT_DOWN_MV_i of the previous monitoring cycle. MASS_O2_CAT_DIF_CYC_i is the integrated difference between actual LAMB_CAT_DOWN_i signal and LAMB_CAT_DOWN_MV_i of the previous monitoring cycle.

Illustration monitoring cycle

Validity check: (STATE_CAT_DIAG_i: Transition CYC_RICH -> CYC_LEAN)
The obtained MASS_O2_CAT_DIF_CYC[i] of a monitoring cycle is only used for the calculation of the diagnosis value if the validity check was passed (STATE_VLD_CAT_DIAG_i reach the minimum value for validity)
To pass the validity check it is necessary that:
LAMB_CAT_DOWN[i] must cross at least once LAMB_CAT_DOWN_MV[i] of the previous monitoring: 0.bit of STATE_VLD_CAT_DIAG_i is set (bit '1CROSS').
OR
The deviation between LAMB_CAT_DOWN[i] and LAMB_CAT_DOWN_MV[i] of the last monitoring cycle is smaller than C_LAMB_CAT_MV_DELTA_MAX: 1.bit of STATE_VLD_CAT_DIAG_i is set (bit 'MVDEL').
OR
LAMB_CAT_DOWN[i] cross two times LAMB_CAT_DOWN_MV[i] of the previous monitoring (periodically braking down of VLS_DOWN occurs): 2.bit of STATE_VLD_CAT_DIAG_i is set (bit '2CROSS').
AND
Difference between actual and the LAMB_CAT_DOWN_MV[i] of the last monitoring cycle is not too high (if LAMB_CAT_DOWN[i] cross two times LAMB_CAT_DOWN_MV[i], higher difference allowed): 3.bit of STATE_VLD_CAT_DIAG_i is set (bit 'DIVMV').
AND
LAMB_CAT_DOWN_MV[i] is in the right range 4.bit of STATE_VLD_CAT_DIAG_i is set (bit 'RANGE').
AND
Catalyst temperature dynamic is limited: 5.bit of STATE_VLD_CAT_DIAG_i is set (bit 'TEMP').
Illustration validity check

Calculation of diagnosis value: (STATE_CAT_DIAG[i]: Transition CYC_RICH -> CYC_LEAN)
Monitoring cycle counter CTR_CAT_DIAG[i] is incremented for each valid monitoring cycle.
MASS_O2_CAT_DIF_CYC[i] is weighted by engine speed and load (IP_FAC_MASS_O2_CAT_DIAG_XX). From that calculation MASS_O2_CAT_DIF_RATIO[i] results. MASS_O2_CAT_DIF_RATIO[i] is summed up for all monitoring cycles. That summation give MASS_O2_CAT_DIF_RATIO_SUM[i]. Finally, the average of MASS_O2_CAT_DIF_RATIO_SUM[i] over all valid monitoring cycles give the diagnosis value EFF_CAT_DIAG_HOM[i]
End of diagnosis: (STATE_CAT_DIAG[i]: Transition CYC_LEAN -> END)
If the necessary number of valid monitoring cycles CTR_CAT_DIAG[i] reaches C_CTR_MIN_CAT_DIAG the diagnosis is ended for that driving cycle and the catalyst diagnosis value EFF_CAT_DIAG_HOM[i] is calculated and stored in the EEPROM.
The monitoring counter CTR_CAT_DIAG[i] is used to set the readiness code. For this reason C_CTR_MIN_CAT_DIAG must be reached in the emission test cycle.
State diagram: STATE_CAT_DIAG[i]

Note: The priorities of the conditions to change between states are defined by order described in the STATEFLOW diagram below. The condition 8 as transition to PASSIVE is twice available and contain the same conditions each.
The recurence time is defined by T_SAMPLE in [ms].
Application Assistance
For OBD II O2 sensor diagnosis: C_CTR_MIN_CAT_DIAG has to be applied higher then the thresholds C_SUM_CYC_MIN_DIAG and C_SUM_CYCNR_MIN_DIAG (LV_LS_FRQ_DIAG_READY -> 1 and LV_LS_SWT_DIAG_READY -> 1).
They have to be reached before STATE_CAT_DIAG[i] is set to END.
Hint:
An active catalyst diagnosis can disable the module Downstream Fuel Trim Regulation also a additional lambda offset can be imposed on the basic lambda setpoint in the module Basic Lambda setpoint . When the catalyst diagnosis is completed the above functions return to their normal operation.
Overview: Chronological order of diagnosis algorithm:
Triggering of catalyst diagnosis calculation by LV_AFL[i] 0->1...
%setpoint of the O2-load with CAT DIAG for the lambda controller (output, not used here)
1) LAMB_CAT_DOWN[i] = IP_LAMB_CAT(VLS_DOWN[i]) %every recurrence
2) LAMB_CAT_DOWN_SUM[i] n+1 = LAMB_CAT_DOWN_SUM[i] n+ LAMB_CAT_DOWN[i] %every recurrence
3) LAMB_CAT_DOWN_MV[i] = LAMB_CAT_DOWN_SUM[i] / CTR_LAMB_CAT_DOWN_SUM[i]
(after end of current diagnosis period)
4) FLOW_O2_CAT_DIF[i] = 0.23 * (1/3600)[g/ms] * I1/LAMB_CAT_DOWN_MV[i] - 1/LAMB_CAT_DOWN[i] I * MAF_CYL[kg/h]
5) MASS_O2_CAT_DIF_CYC[i]n+1 = MASS_O2_CAT_DIF_CYC[i] n + FLOW_O2_CAT_DIF[i]*T_SAMPLE[ms] %every recurrence
6) RATIO_MASS_O2_CAT_DIF [i] = MASS_O2_CAT_DIF_CYC[i] * IP_FAC_TEMP_CAT_DIF_STAT / (C_O2L_CAT_AFL * IP_FAC_MASS_O2_CAT_DIAG_XX) (with XX for AT or MT (after end of current diagnosis period)
7) RATIO_MASS_O2_CAT_DIF_SUM[i] n+1 = RATIO_MASS_O2_CAT_DIF_SUM[i] n + MASS_O2_CAT_DIF_RATIO[i]
(after end of current diagnosis period and passed validity check)
8) EFF_CAT_DIAG_HOM[i] = MASS_O2_CAT_DIF_RATIO_SUM[i] / CTR_CAT_DIAG[i]
(Catalyst diagnosis value after diagnosis finished)
Scheduling of formulas:
1+2: states WAIT, RAMP_UP, CYC_LEAN, CYC_RICH
3: state WAIT, transitions RAMP_UP or CYC_RICH to CYC_LEAN
4+5: states CYC_LEAN, CYC_RICH
6+7: transition CYC_RICH to CYC_LEAN
8: transition CYC_LEAN to END
Several system events will trigger a function response:
EGTR_FCTDGCEF0__RST (reset): reset
EGTR_FCTDGCEF0__20MS (regular trigger every 20 msec): operate
EGTR_FCTDGCEF0__CLFMY (clear failure memory): reset
EGTR_FCTDGCEF0__STB (standby; ECU programming or fault): reset, init_nvmy
EGTR_FCTDGCEF0__UNVMY (update non volatile memory): save_nvmy

EGTR_FCTDGCEF0__RNVMY (read non volatile memory): read_nvmy

Application Conditions

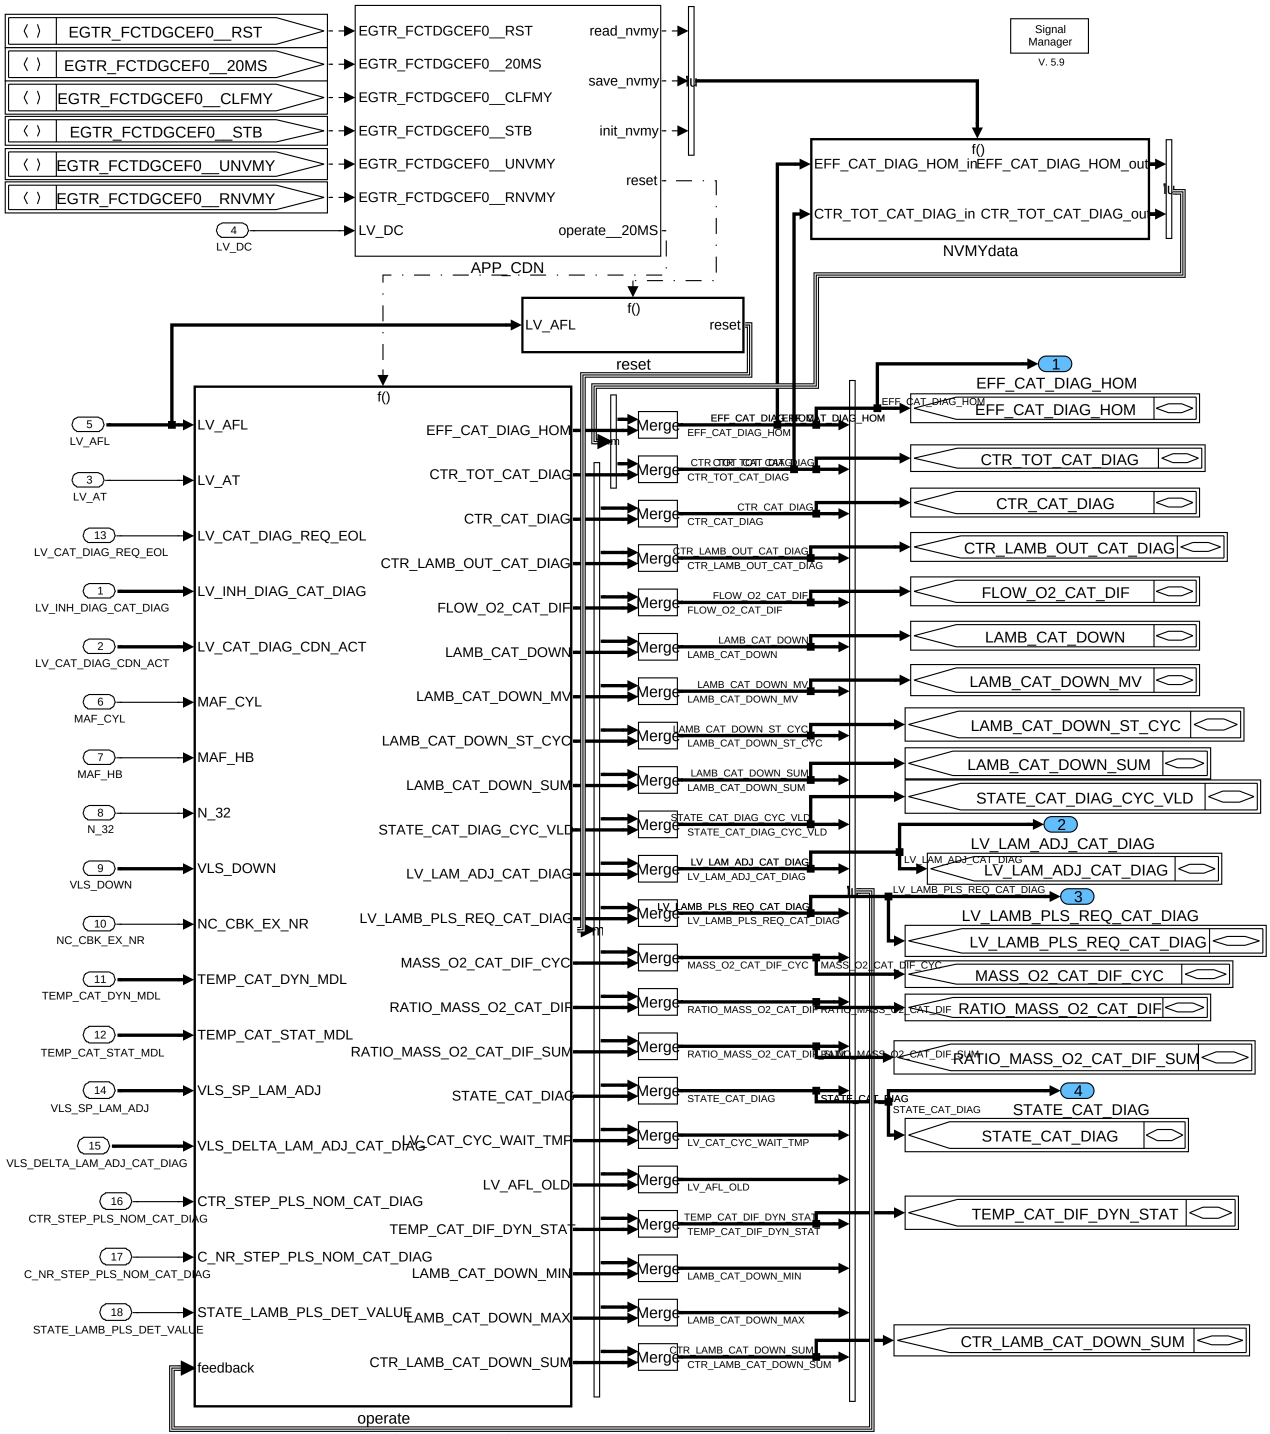
Function description



SDA_SRS / SDA V 5.0 Pre Release 07−Oct−2005

Figure 119: Path: EGTR_FCTDGCEF0

18.13.1 SUBFUNCTION: operate

18.13.1.1 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG

18.13.1.1.1 Checking state:

Checking the transition conditions with aid of the state machine. Then, in case of changing the actual state, performing the respective transition actions and state actions for the new state.

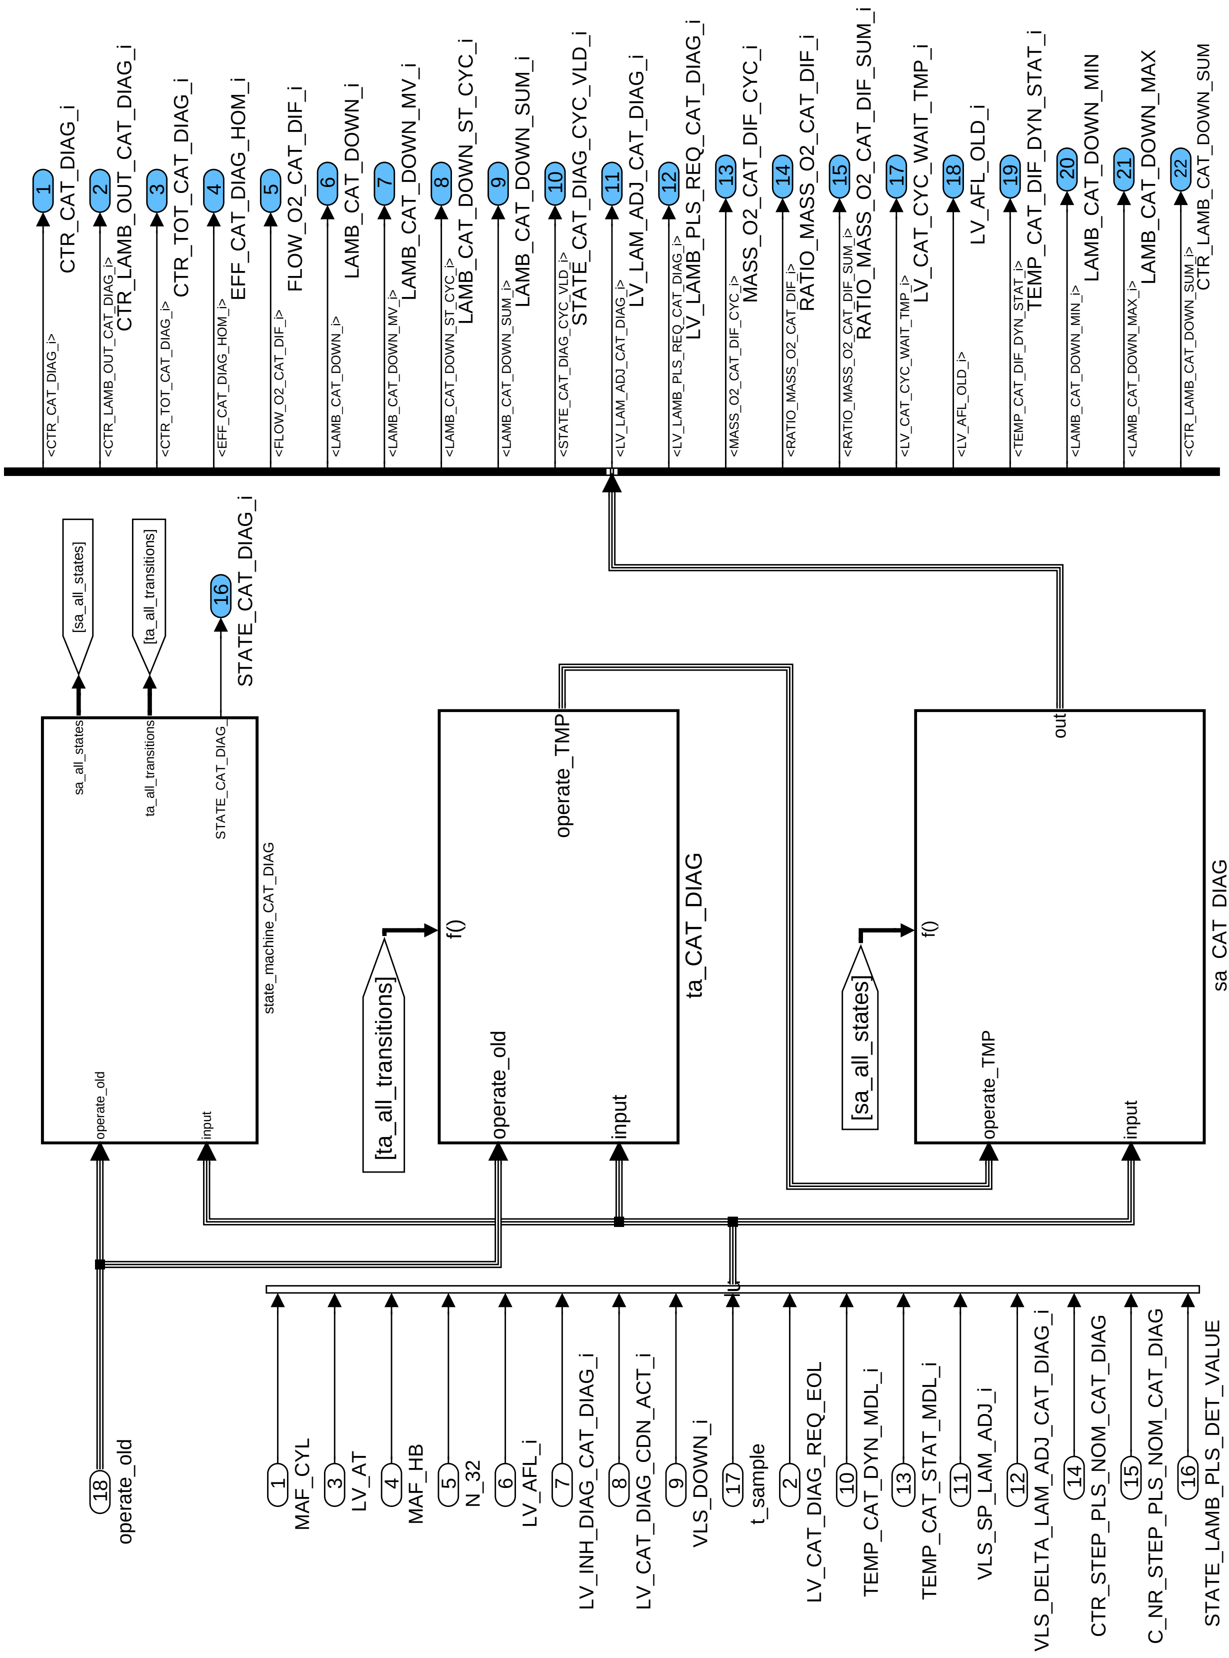


Figure 120: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC

18.13.1.1.1.1 State machine:

Checking the respective transition conditiones in dependence on current state and evaluation of the new state in compliance with exclusion thresholds, i.e. with the engine speed, the counter for the minimum required monitoring cycles to complete the catalyst diagnosis and the counter numerating subsequently following invalid monitoring cycles.
Afterwards issue of the trigger vectors for transition actions and state actions.

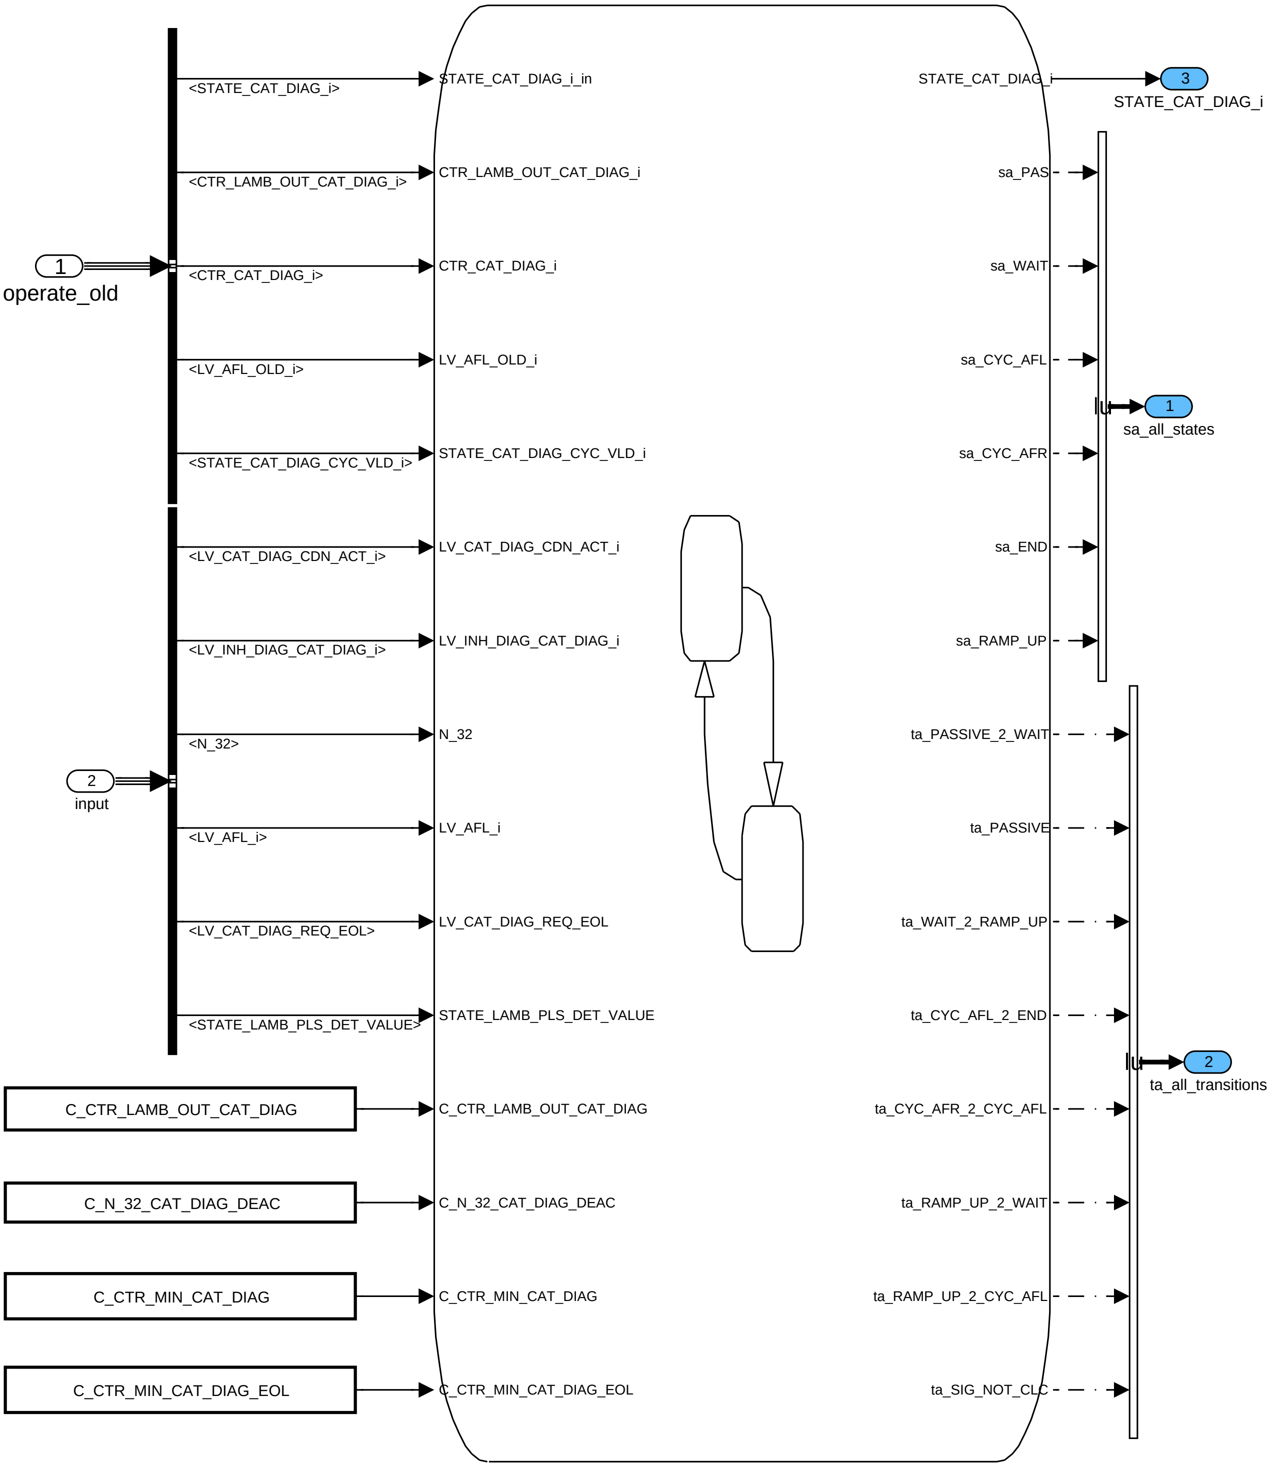

Figure 121: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/state_machine_CAT_DIAG

18.13.1.1.1.1.1 No title given

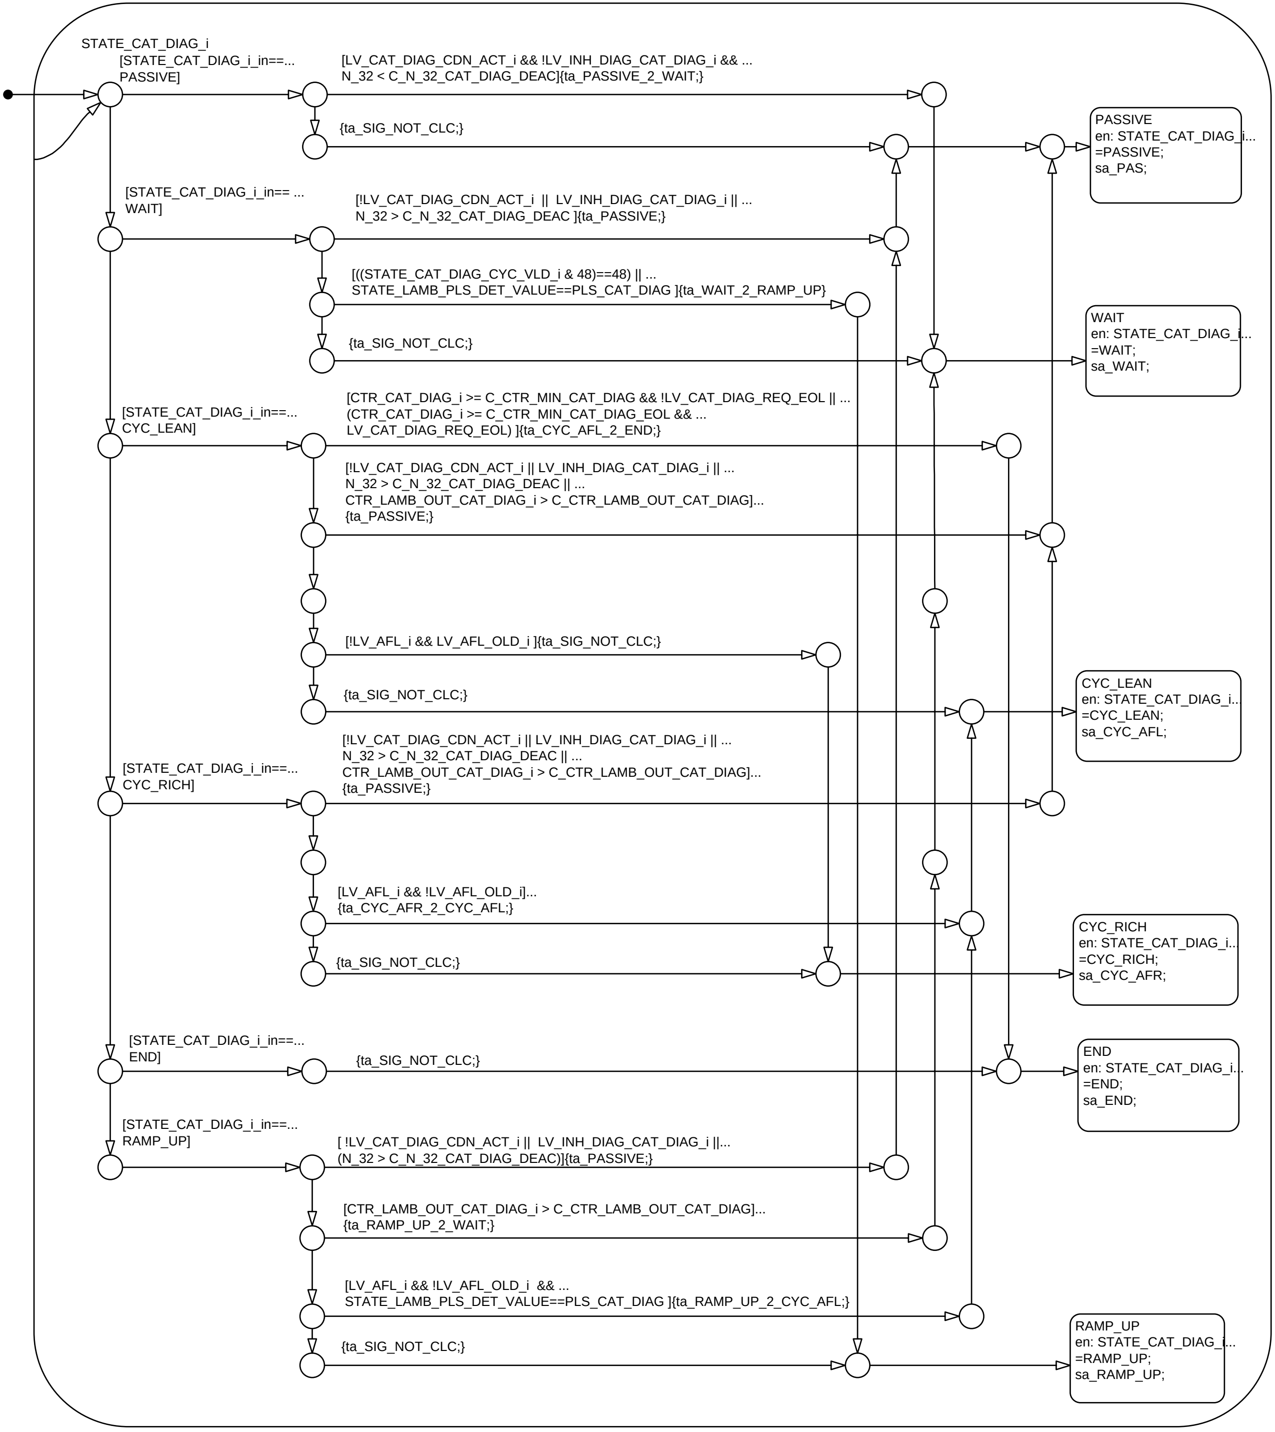

Figure 122: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/state_machine_CAT_DIAG/Chart

18.13.1.1.1.2 Transition actions:

Performing the concerned transition action induced by the issued trigger vector.

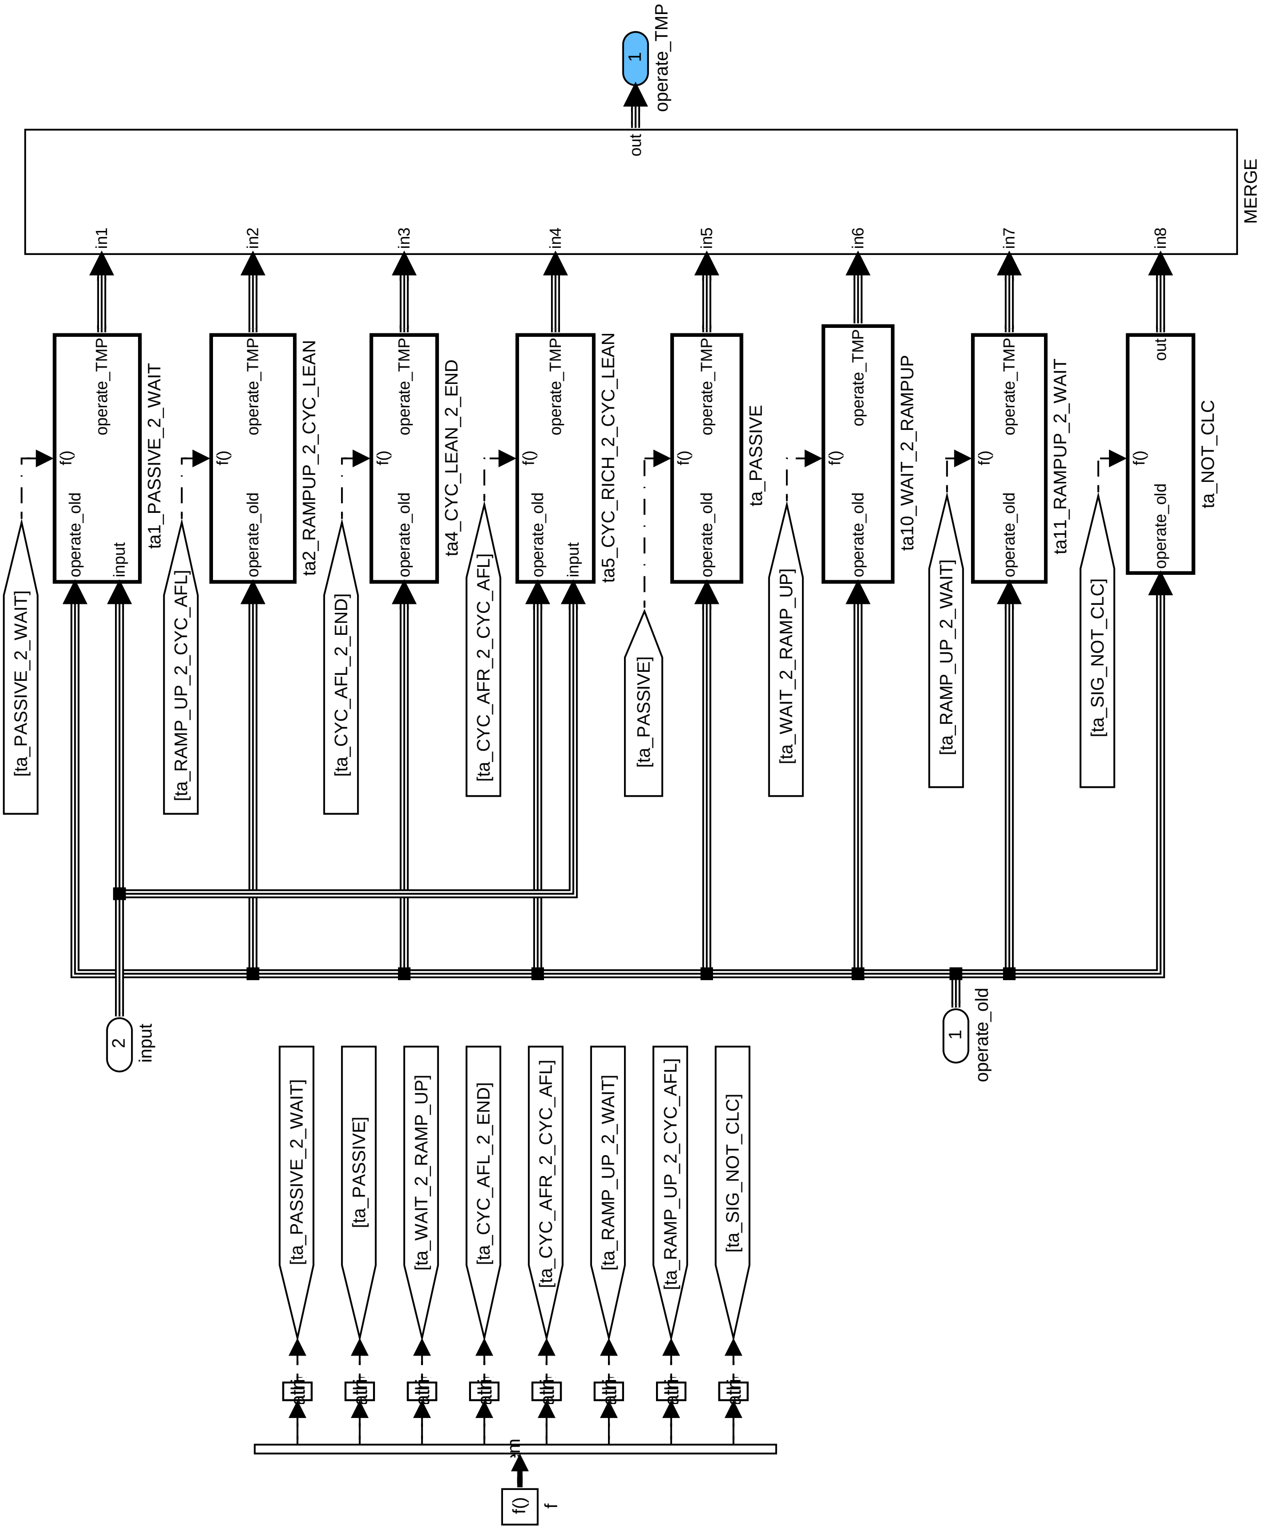

Figure 123: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG

18.13.1.1.1.2.1 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA1_PASSIVE_2_WAIT

18.13.1.1.1.2.1.1 Transition action PASSIVE to WAIT:

Setting the temporary WAIT state flag to zero to indicate the downstream lambda sum of this monitoring cycle not to be complete (no valid mean value for the next cycle).
Initializing the downstream lambda sum and its counter to zero.
Storing the old value of LV_AFL for edge detection.

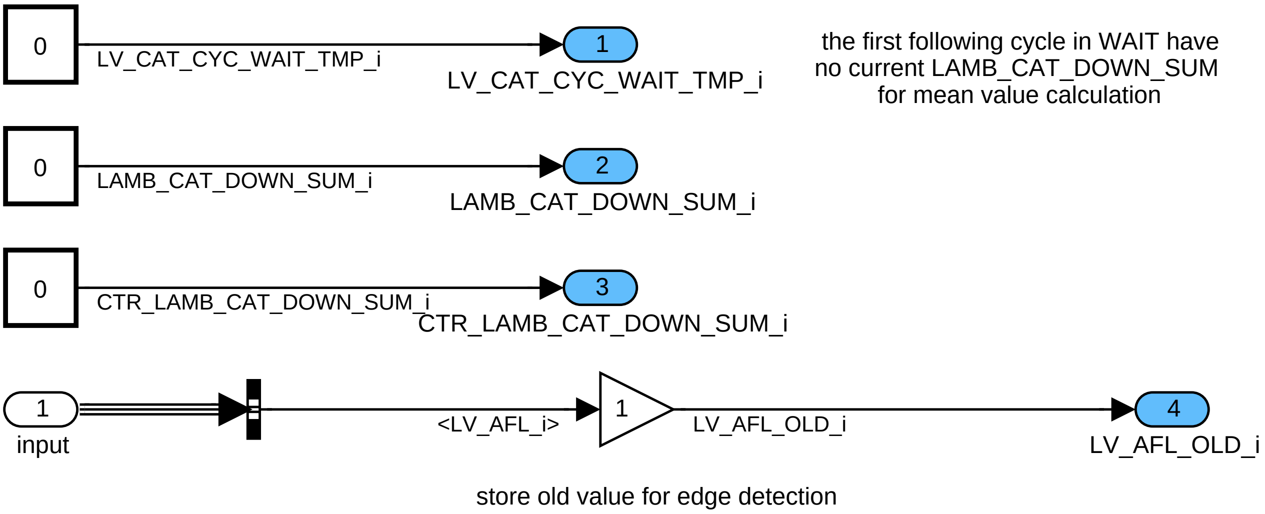

Figure 124: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta1_PASSIVE_2_WAIT/CLC

18.13.1.1.1.2.2 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA2_RAMPUP_2_CYC_LEAN

18.13.1.1.1.2.2.1 Transition action RAMP_UP to CYC_LEAN:

Calculation of the downstream lambda mean value of last cycle. Initializing the downstream lambda sum, its counter and the related oxygen mass to zero.
Storing the downstream lambda signal at start of the monitoring cycle and initializing the concerning min/max values to the same value.
Resetting the validity bits with regard to crossing events, setting the validity bit with regard to the permitted difference between the actual downstream lambda signal and the mean value of last cycle.

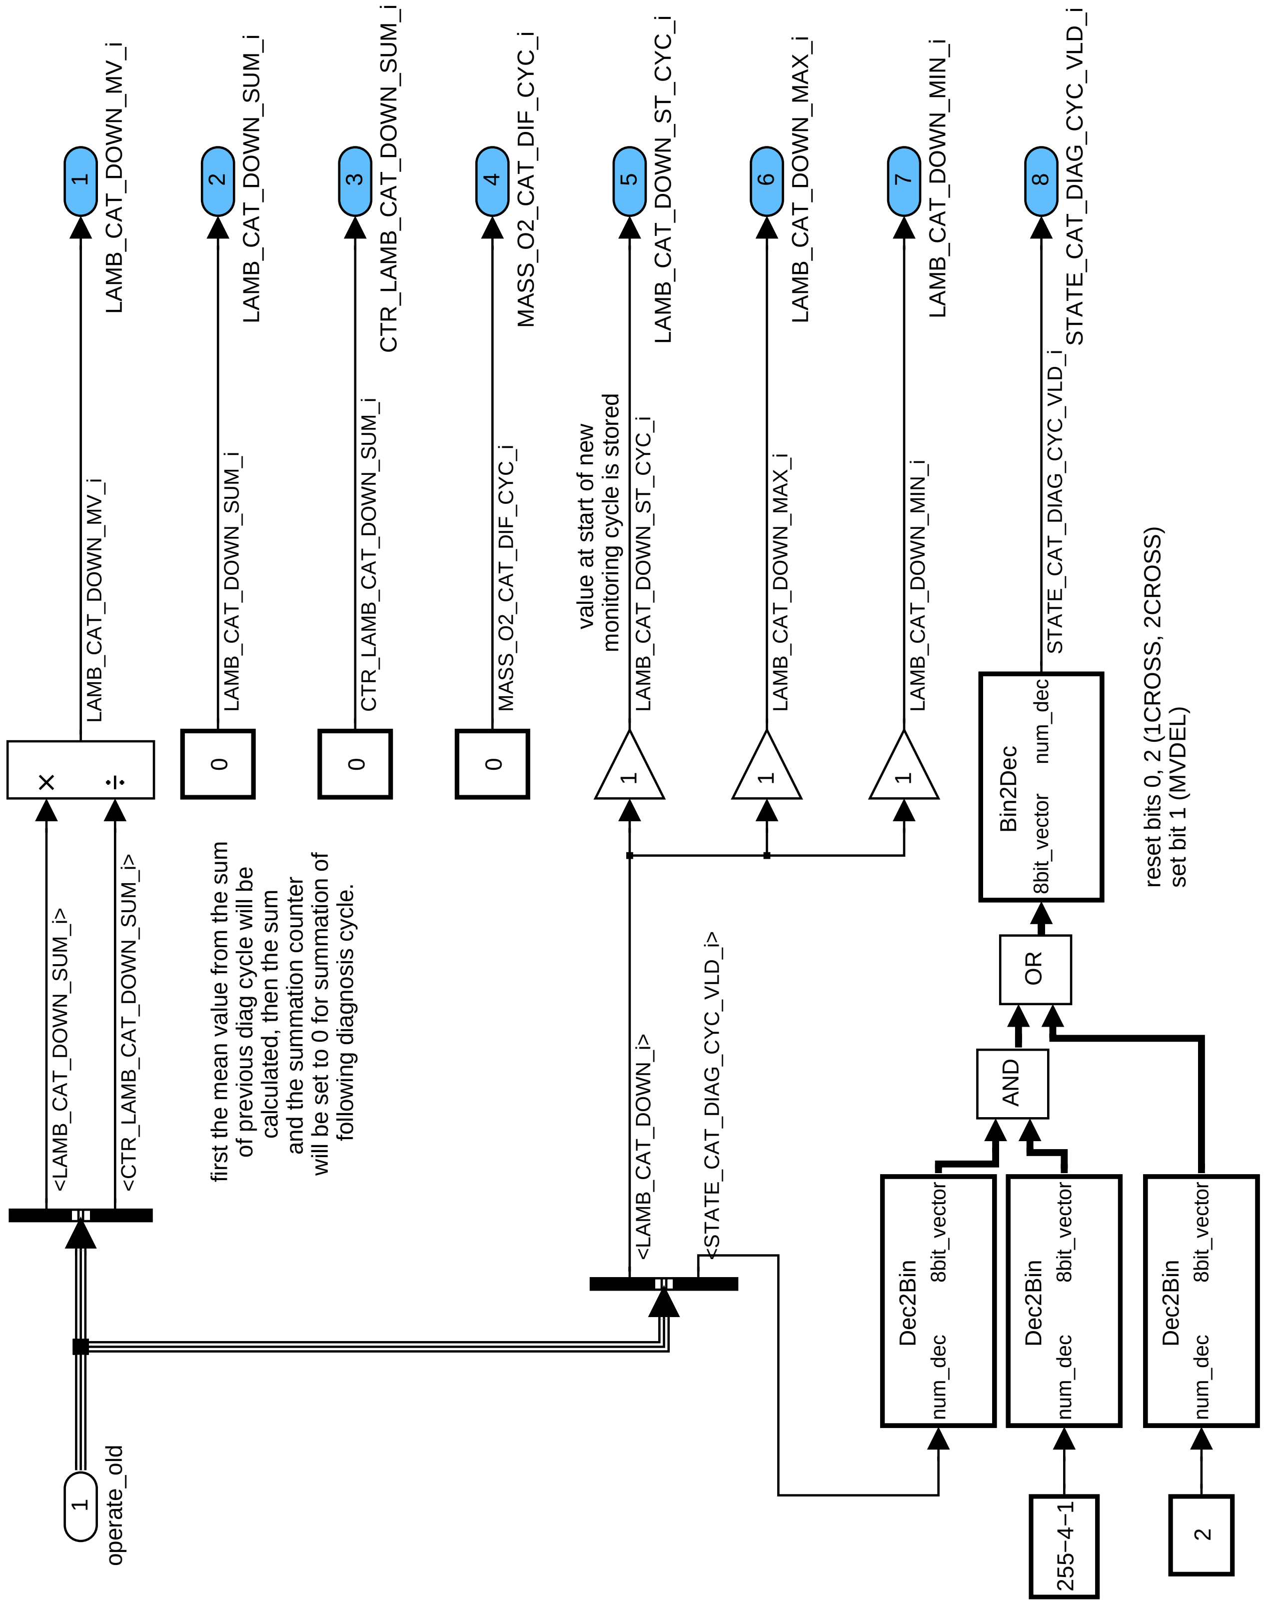

Figure 125: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta2_RAMPUP_2_CYC_LEAN/CLC

18.13.1.1.1.2.3 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA4_CYC_LEAN_2_END

18.13.1.1.1.2.3.1 Transition action CYC_LEAN to END:

Calculation of the new diagnosis value and incrementing the total number of completed diagnosis cycles since ECU programming by one.
Resetting forced stimulation and trim control parameters to nominal values and all validity bits to zero.

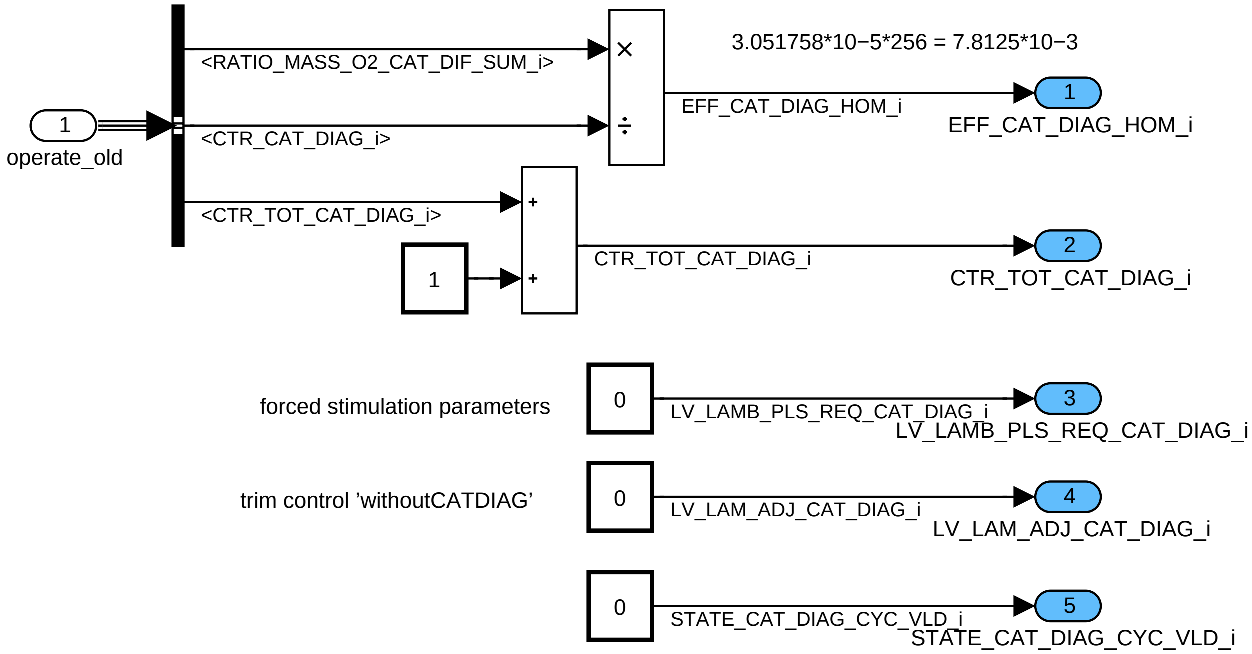

Figure 126: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta4_CYC_LEAN_2_END/CLC

18.13.1.1.1.2.4 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA5_CYC_RICH_2_CYC_LEAN

18.13.1.1.1.2.4.1 Transition action CYC_RICH to CYC_LEAN:

Start of a new monitoring cycle.
Calculation of the downstream lambda mean value of last cycle.
Evaluation of the diagnosis value merely related to last monitoring cycle. Computation of the actual temperature difference between dynamic and stationary catalyst temperature.
Incrementing/resetting the number of cycles showing lambda to be out of range and setting the validity bits. In case of validity sum up the diagnosis value and increment the counter of valid cycles by one.
Initializing the single cycle bound sums and counters for next cycle.

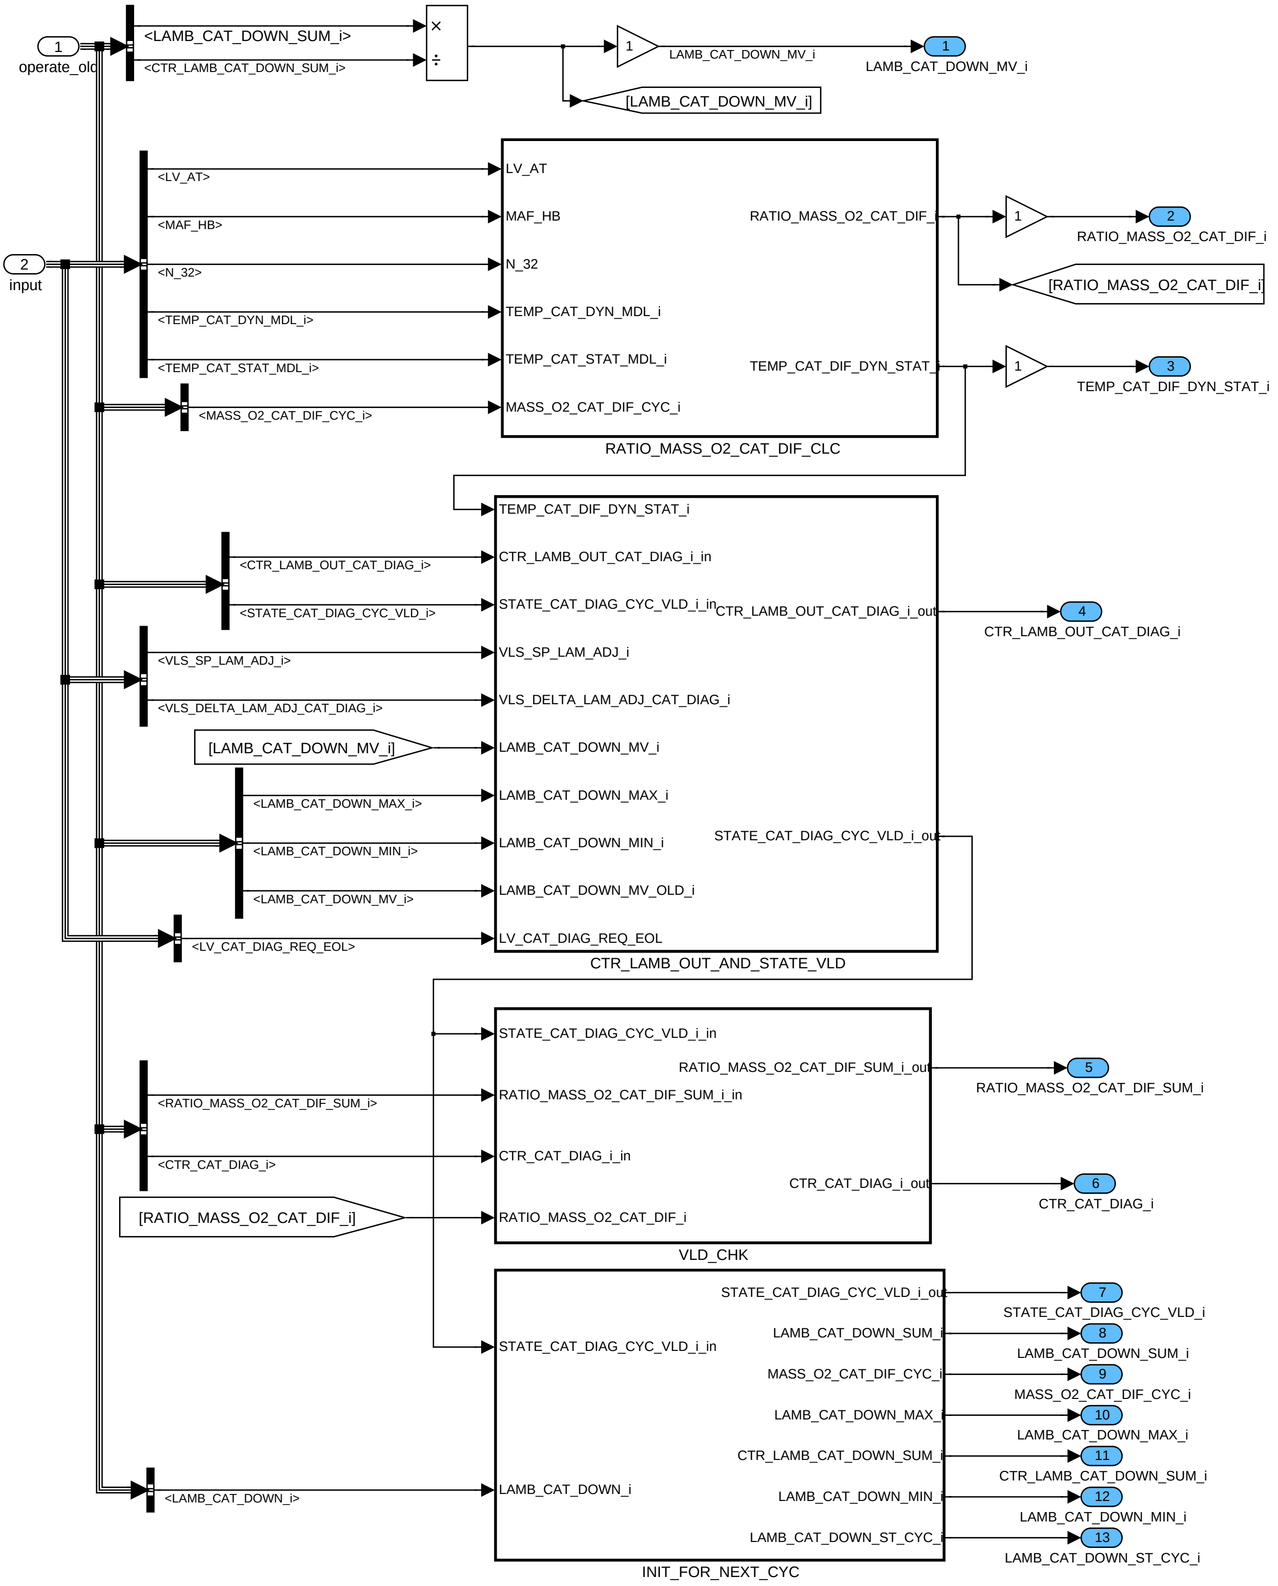

Figure 127: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta5_CYC_RICH_2_CYC_LEAN/CLC

18.13.1.1.1.2.4.1.1 Weighting the diagnosis value:

Weighting the diagnosis value related to last monitoring cycle, taking into account the concerning working point and temperature dynamics.

18.13.1.1.1.2.4.1.2 Monitoring cycle validity:

Computing the absolute difference between downstream lambda mean value and the corrected lambda setpoint and comparing it to the stored maximally admissible difference. Setting the RANGE bit in dependence on the result. Incrementing/resetting the counter of monitoring cycles showing lambda to be out of range.
Comparing the stat/dyn temperature difference to the stored maximally allowed value and setting the TEMPERATURE bit accordingly.
Computing the difference between downstream lambda min/max and dividing by eight. Adding this to the stored maximum allowed if the temperature range is o.k. Comparing the result to the absolute difference between actual and old mean value and setting the cycle validity bit in correspondence with.

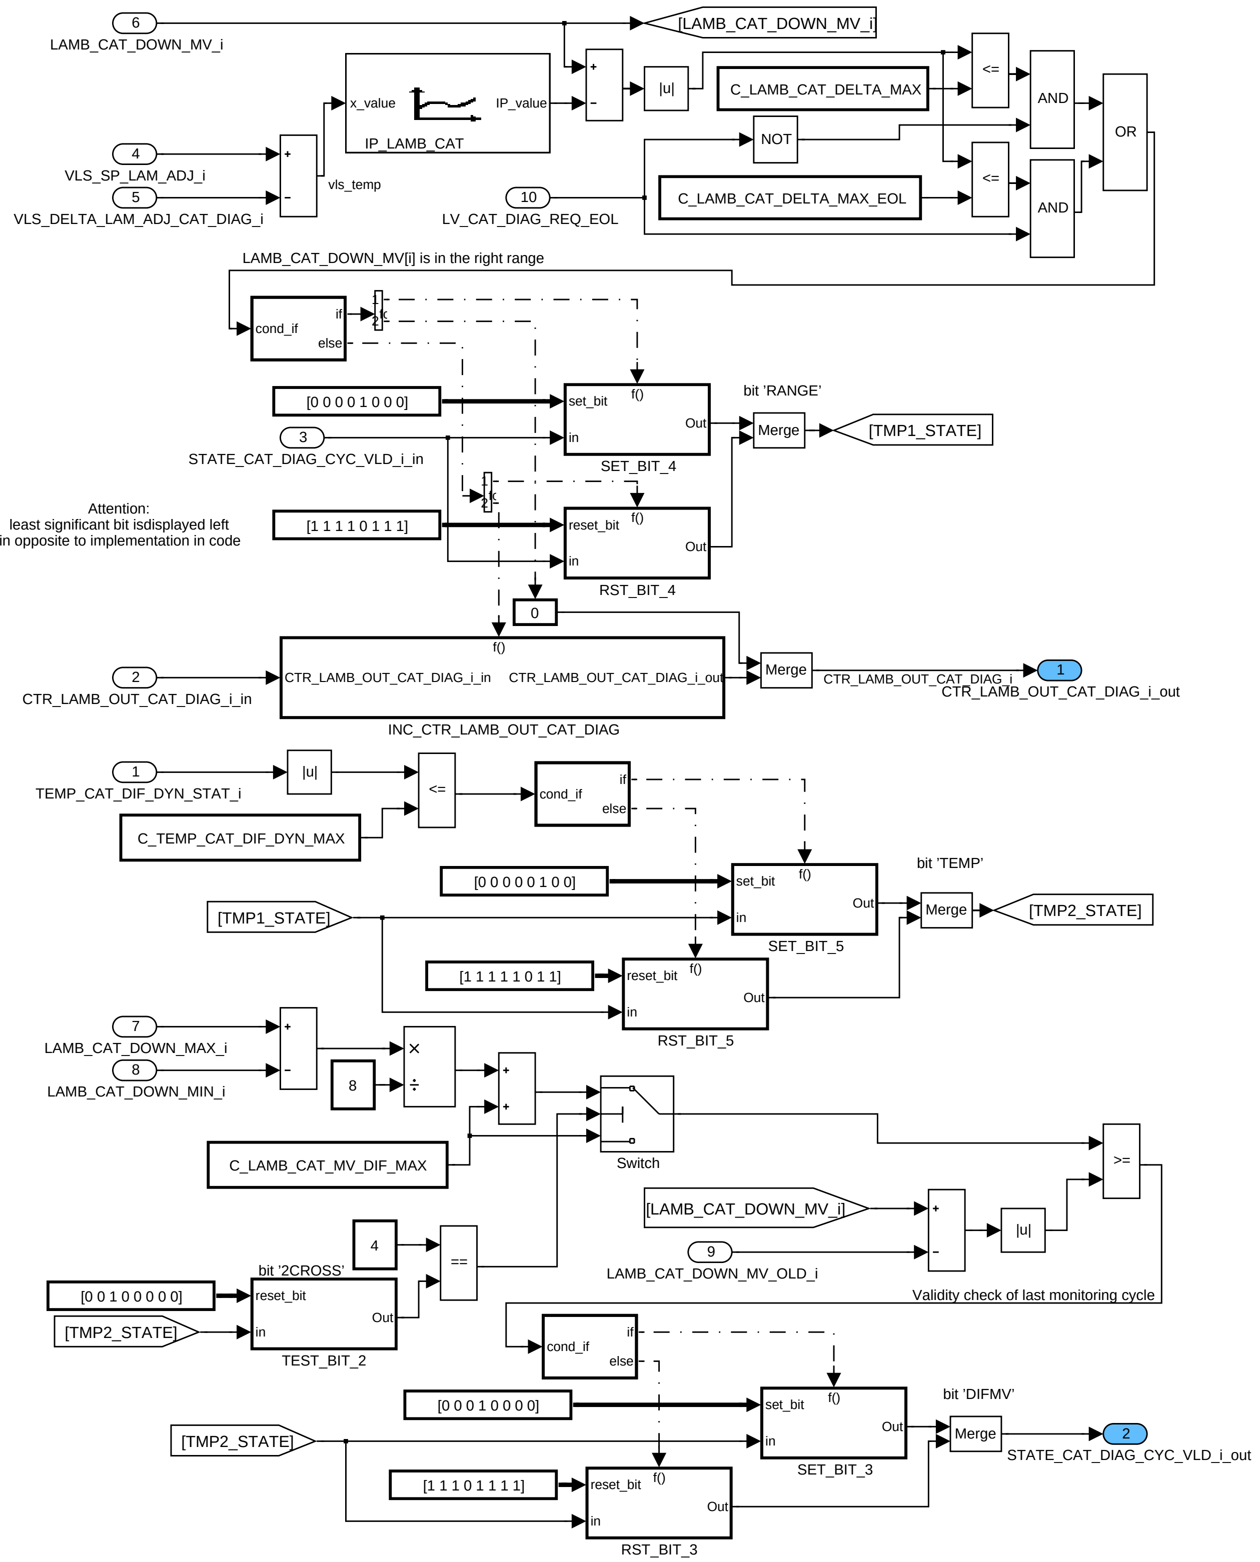

Figure 129: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta5_CYC_RICH_2_CYC_LEAN/CLC/CTR_LAMB_OUT_AND_STATE_VLD

18.13.1.1.1.2.4.1.2.1 Incrementing/resetting counter:

Incrementing/resetting the number of cycles showing lambda to be out of range.

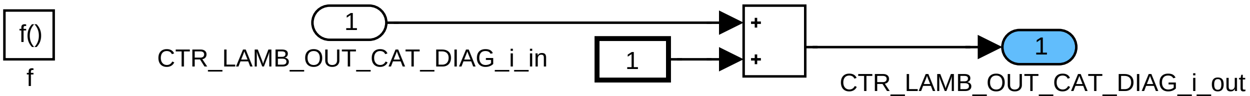

Figure 130: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta5_CYC_RICH_2_CYC_LEAN/CLC/CTR_LAMB_OUT_AND_STATE_VLD/INC_CTR_LAMB_OUT_CAT_DIAG

18.13.1.1.1.2.4.1.3 Validity Check:

Checking last cycle for validity. If the last cycle is valid summing up the diagnosis value and adding one to the number of valid monitoring cycles.

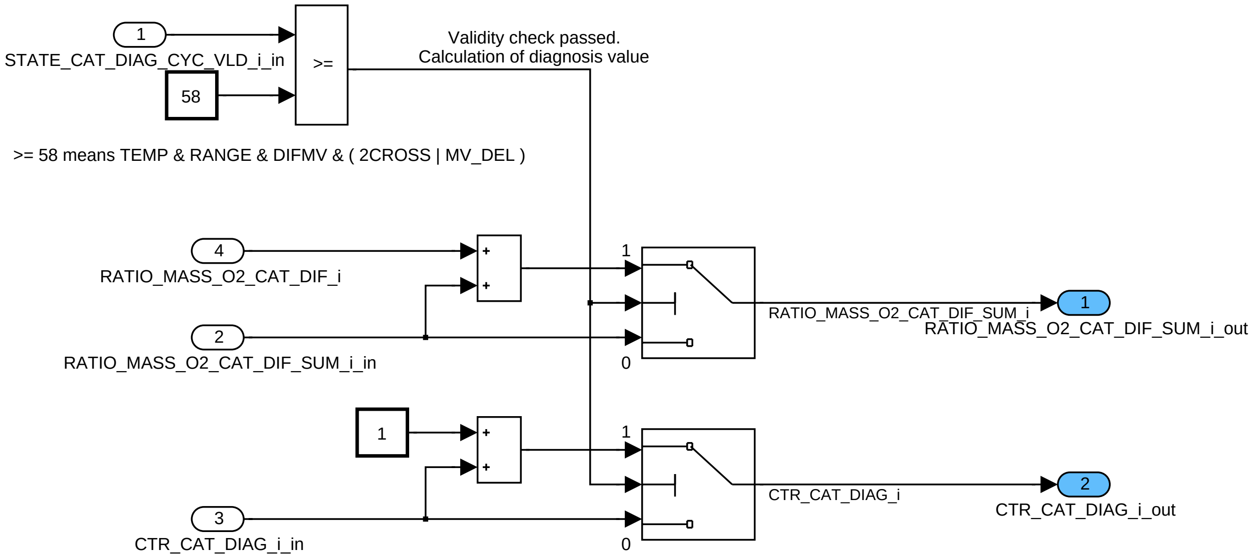

Figure 131: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta5_CYC_RICH_2_CYC_LEAN/CLC/VLD_CHK

18.13.1.1.1.2.4.1.4 Initialization for next cycle:

Resetting the validity bits with regard to crossing events, setting the validity bit with regard to the permitted difference between the actual downstream lambda signal and the mean value of last cycle.
Initializing the downstream lambda sum, its counter and the related oxygen mass to zero.
Storing the downstream lambda value at start of the monitoring cycle and initializing the concerning min/max values to the same value to detect crossing events.

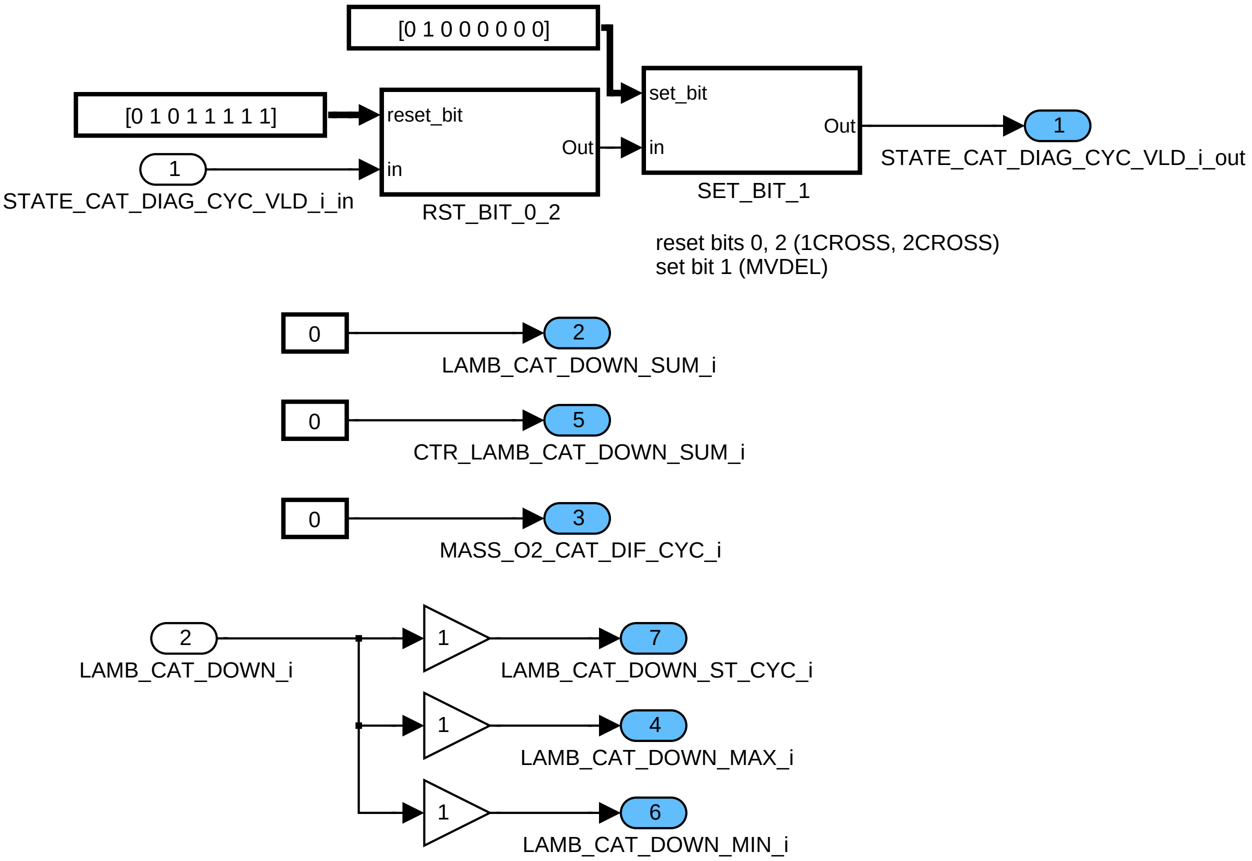

Figure 132: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta5_CYC_RICH_2_CYC_LEAN/CLC/INIT_FOR_NEXT_CYC

18.13.1.1.1.2.5 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA_PASSIVE

18.13.1.1.1.2.5.1 Transition action X to PASSIVE:

Resetting forced stimulation and trim control to nominal mode and all validity bits to zero.

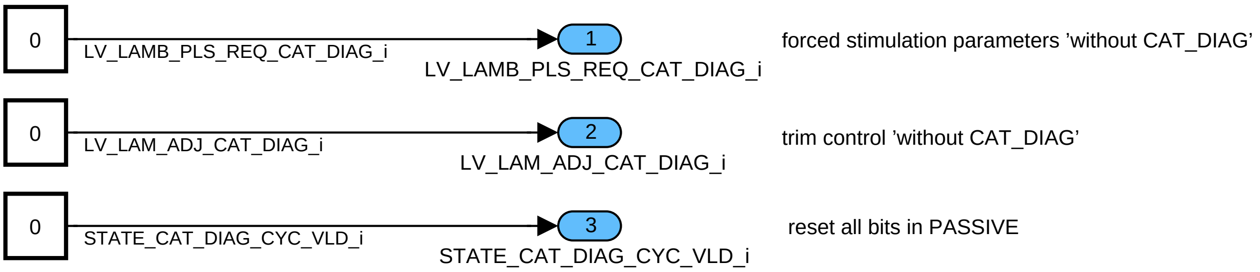

Figure 133: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta_PASSIVE/CLC

18.13.1.1.1.2.6.1 Transition action WAIT to RAMP_UP:

Setting forced stimulation and trim control to catalyst diagnosis mode and the number of cycles showing lambda to be out of range to zero.

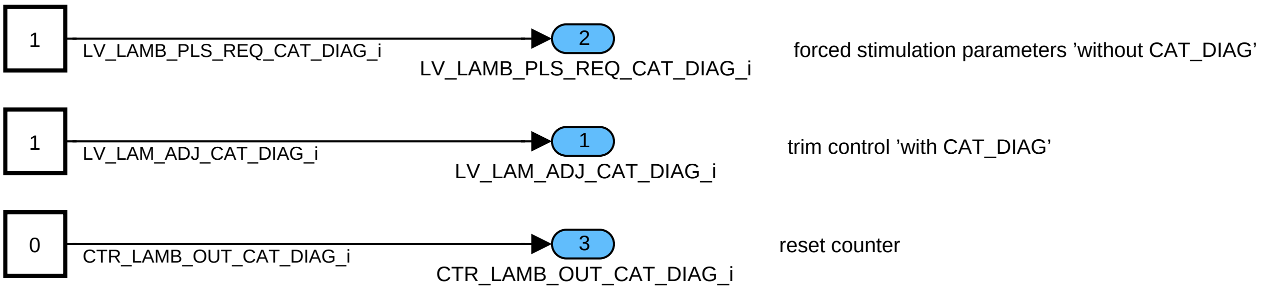

Figure 134: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta10_WAIT_2_RAMPUP/CLC

18.13.1.1.1.2.7 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/TA_CAT_DIAG/TA11_RAMPUP_2_WAIT

18.13.1.1.1.2.7.1 Transition action RAMP_UP to WAIT:

Resetting forced stimulation and trim control to nominal mode because of lambda being out of range. Resetting all validity bits to zero.

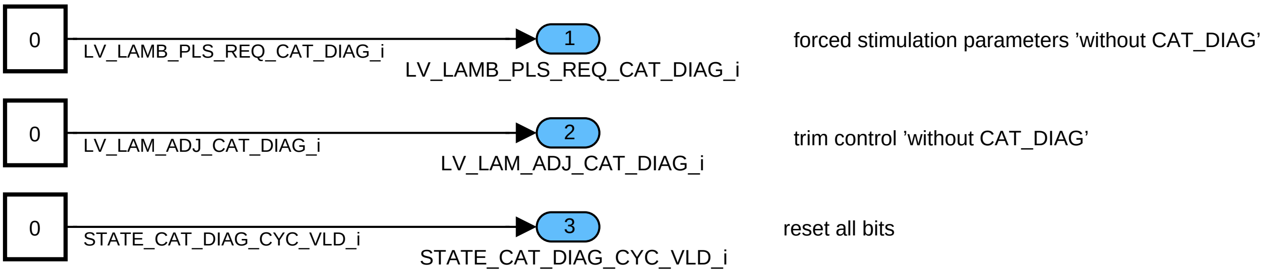

Figure 135: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ta_CAT_DIAG/ta11_RAMPUP_2_WAIT/CLC

18.13.1.1.1.3 State actions:

Performing the concerned state action induced by the issued trigger vector.

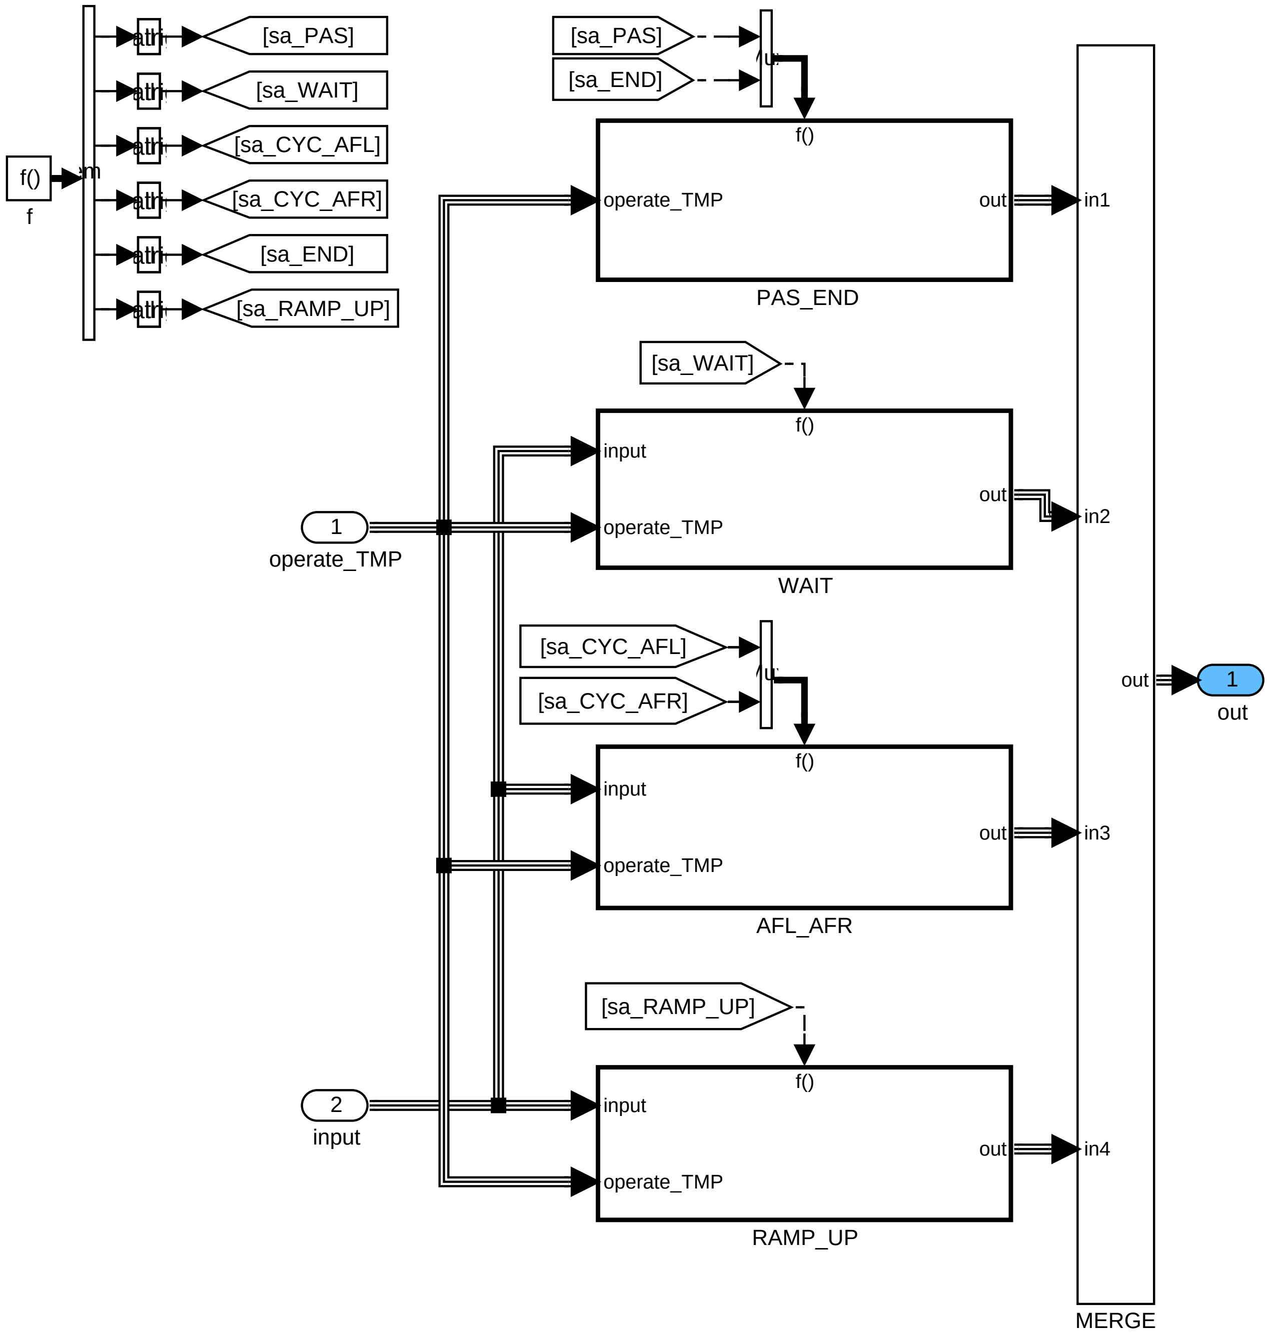

Figure 136: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG

18.13.1.1.1.3.1 State action PASSIVE/END:

No performance of any action in states PASSIVE and END.

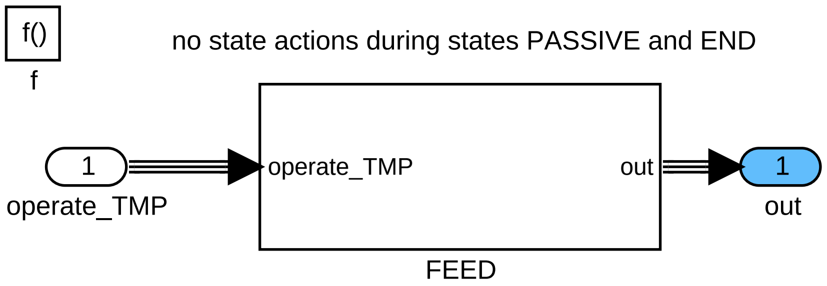

Figure 137: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/PAS_END

18.13.1.1.1.3.2 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/SA_CAT_DIAG/WAIT

18.13.1.1.1.3.2.1 State action WAIT:

Converting the downstream sensor voltage to the related downstream lambda value.
Checking the flag for lean state and comparing with the allied old value. This action is checking for the start of a new monitoring cycle.
In case of a transition zero to one and validity of the cycle calculation of the downstream lambda mean value and resetting the downstream lambda sum and its counter afterwards. Calculating the new trim control setpoint the new trim control setpoint, the stat/dyn temperature difference and setting the validity bits.
In case of a transition zero to one and non validity of the cycle resetting the downstream lambda sum and its counter and marking the cycle as non valid.
Summing up downstream lambda and incrementing the counter in all other cases.

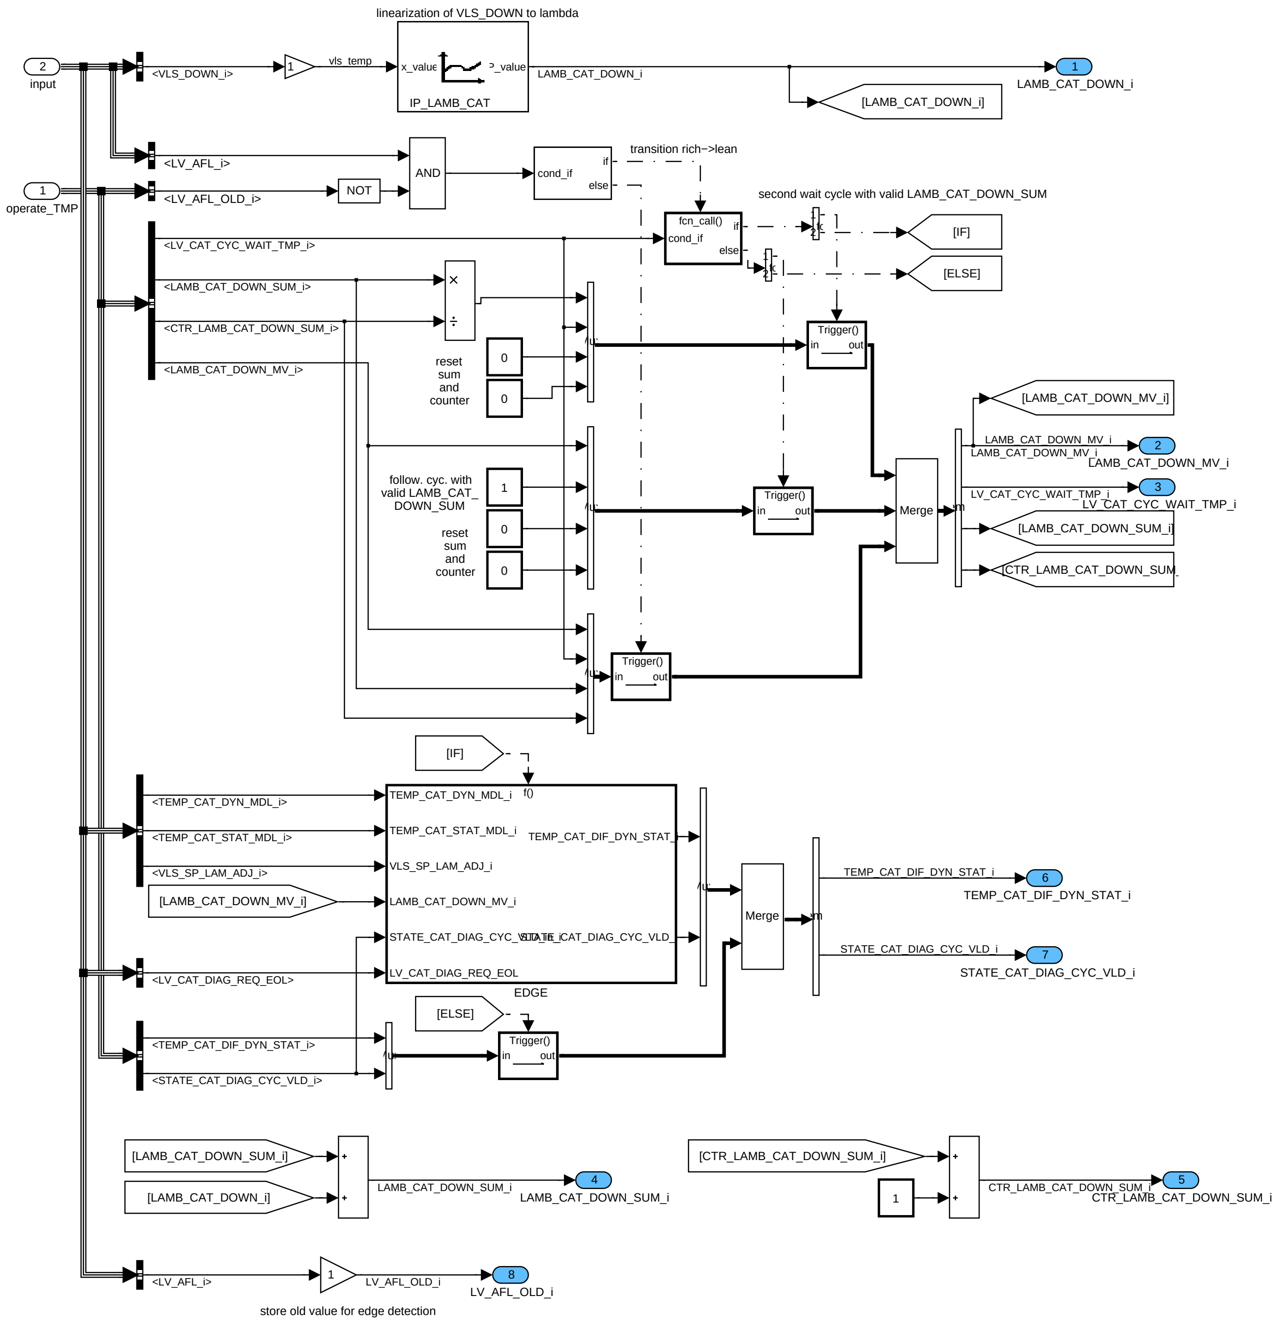

Figure 138: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/WAIT/CLC

18.13.1.1.1.3.2.1.1 State action WAIT/edge action:

Computing the absolute difference between downstream lambda mean value and lambda setpoint and comparing it to the stored maximally admissible difference. Setting the RANGE bit in dependence on the result.
Comparing the stat/dyn temperature difference to the stored maximally allowed value and setting the TEMPERATURE bit accordingly.

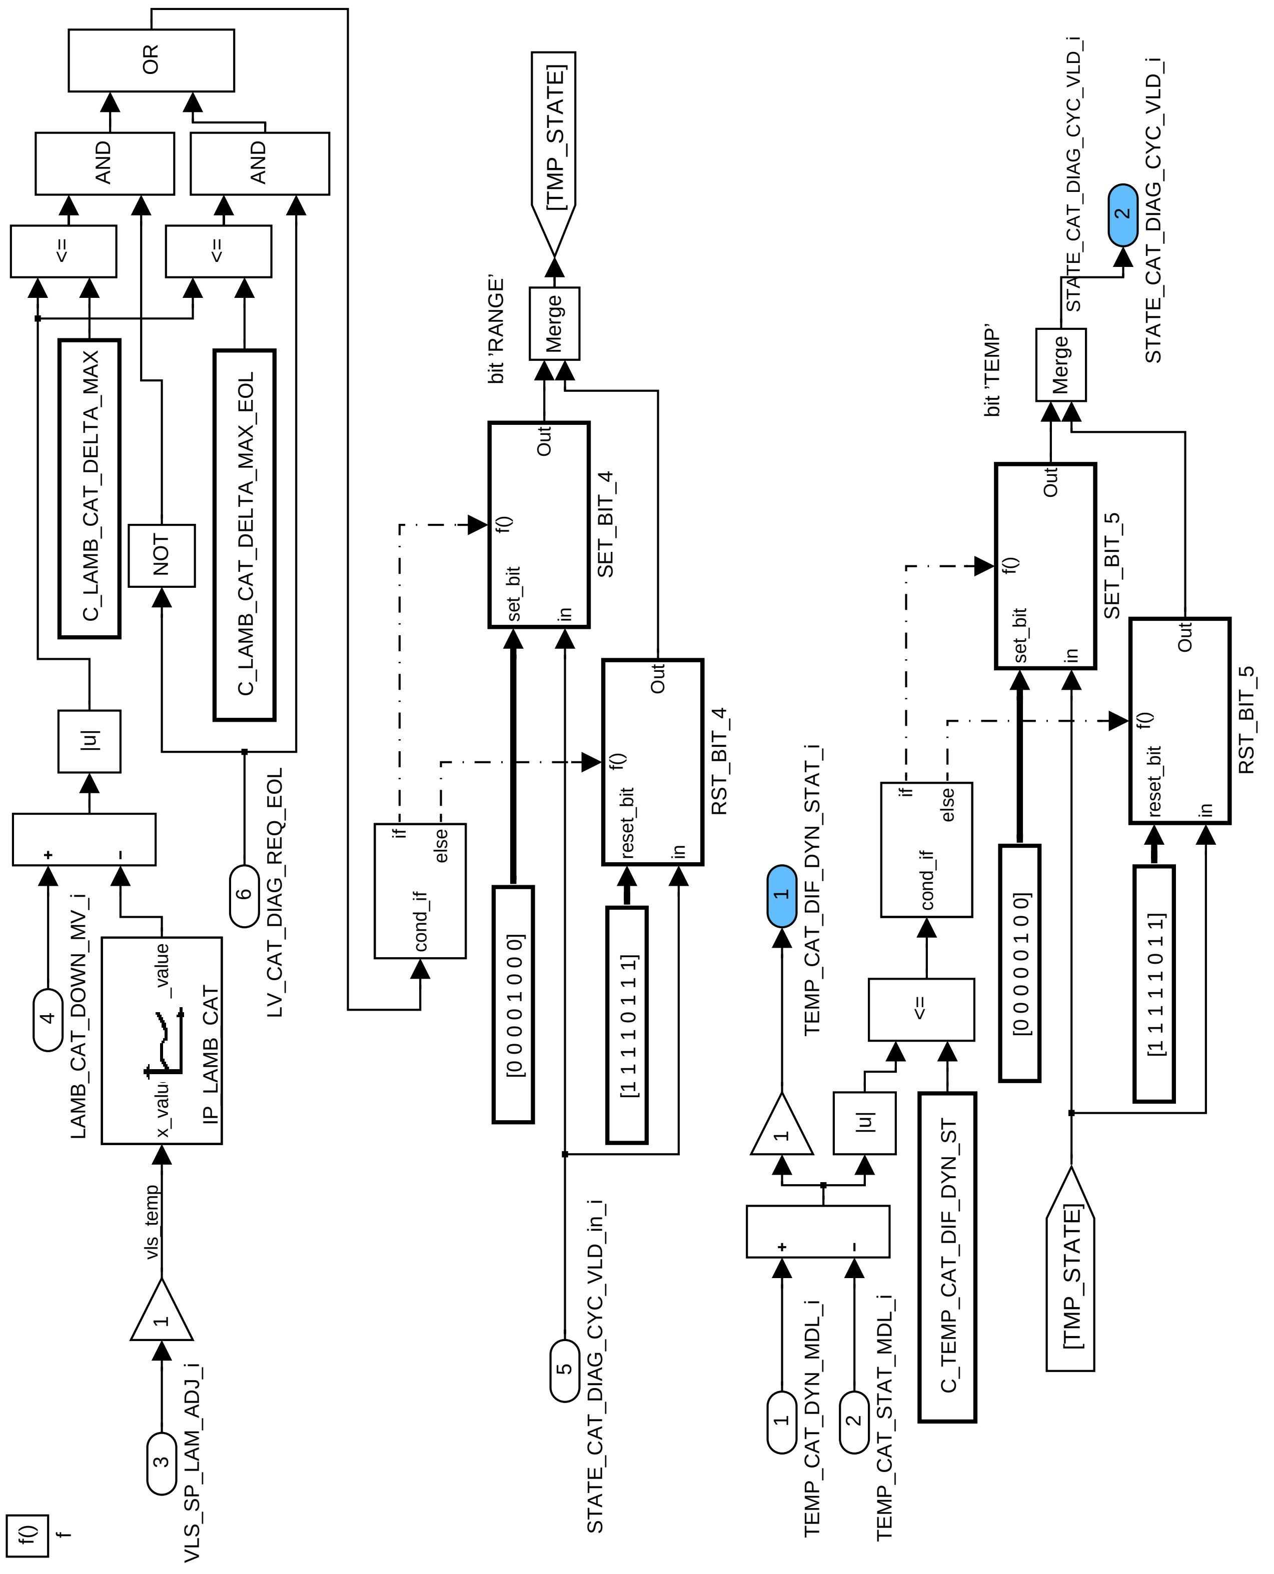

Figure 139: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/WAIT/CLC/EDGE

18.13.1.1.1.3.3 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/SA_CAT_DIAG/AFL_AFR

18.13.1.1.1.3.3.1 State action AFL/AFR:

Converting the downstream sensor voltage to the related downstream lambda value.
Comparing the actual downstream lambda value with stored min/max values and overwriting in case of exceeding.
Summing up the actual downstream lambda value and incrementing the counter.
Calculation of the actual downstream oxygen mass flow and integrating the passed part of the cycle.
Setting of the summary validity bits.
Storing the old lean state flag for edge detection.

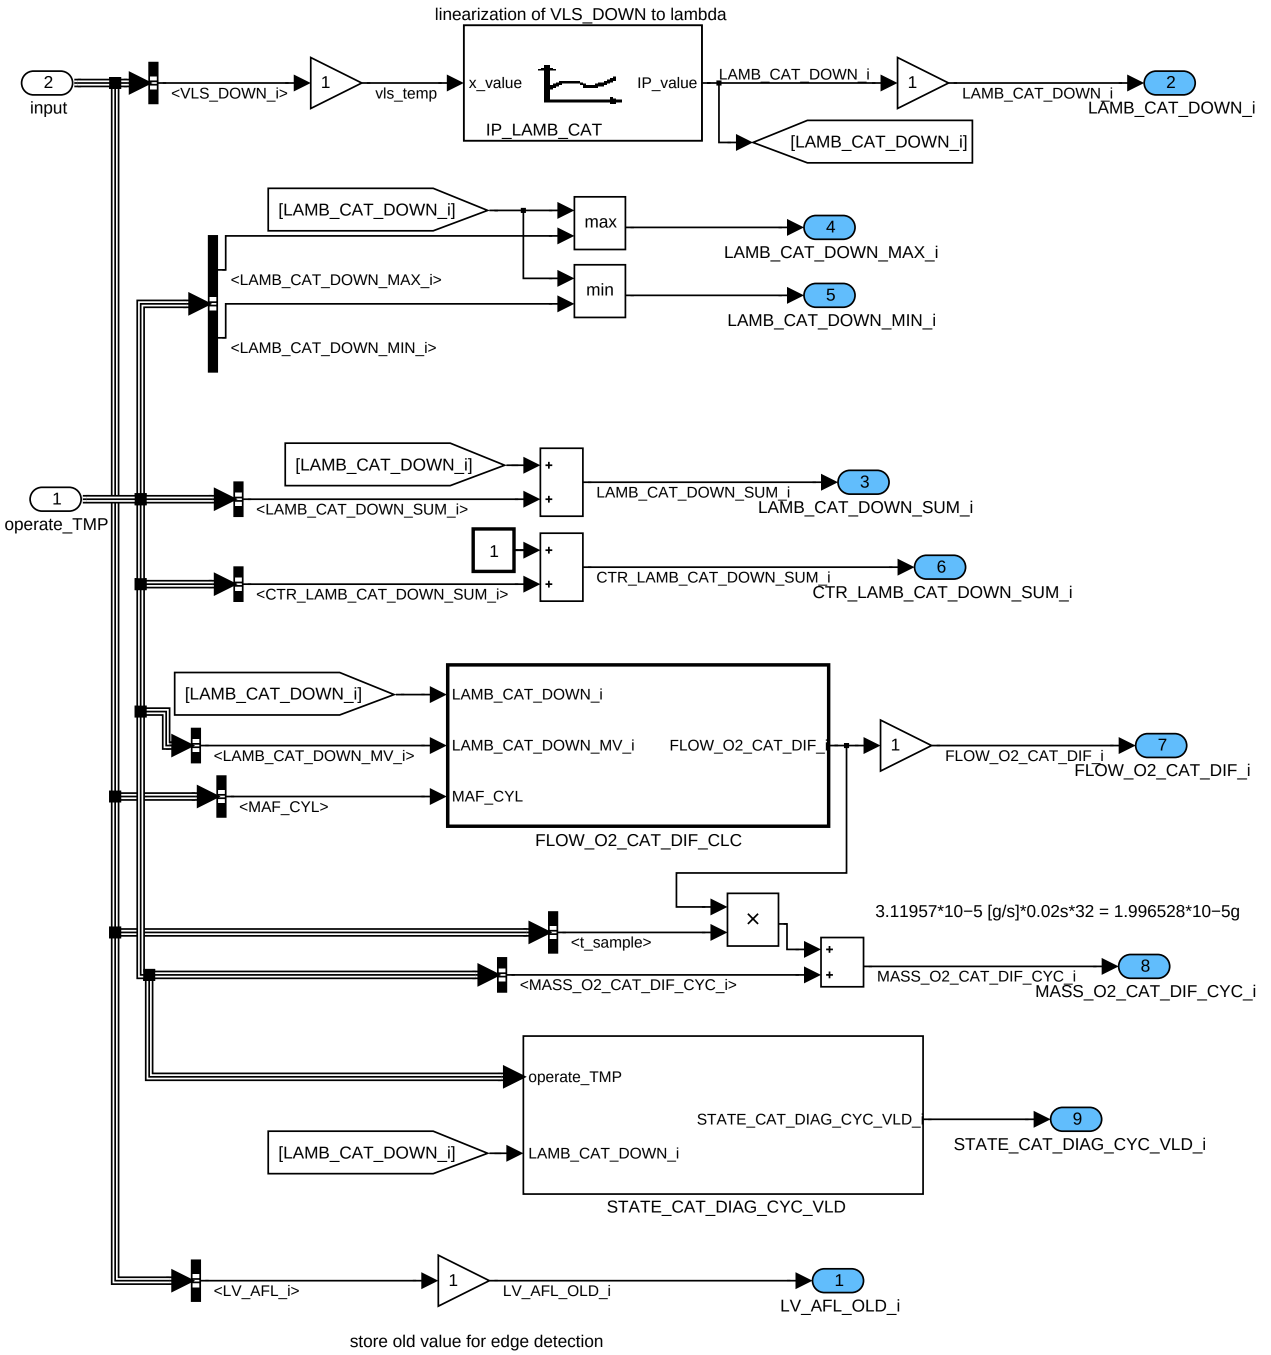

Figure 140: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/AFL_AFR/CLC

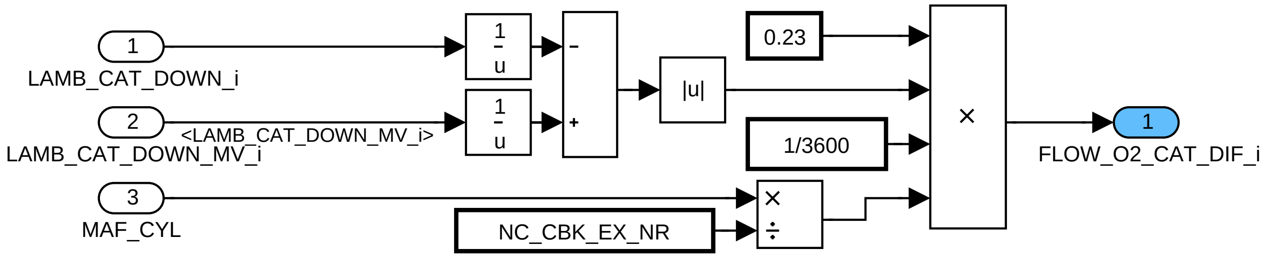
18.13.1.1.1.3.3.1.1 Downstream oxygen mass flow:

Calculation of the actual downstream oxygen mass flow.



calculation 0.23*2/65536*0.03125*1000/3600*512=3.11957*10−5 [g/s]

Figure 141: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/AFL_AFR/CLC/FLOW_O2_CAT_DIF_CLC

18.13.1.1.1.3.3.1.2 Check for cycle validity:

Resetting the 1CROSS bit. Checking for 1CROSS AND 2CROSS. Comparing the absolute difference between downstream lambda and lambda mean value to the related stored maximum and setting the MVDEL bit accordingly.

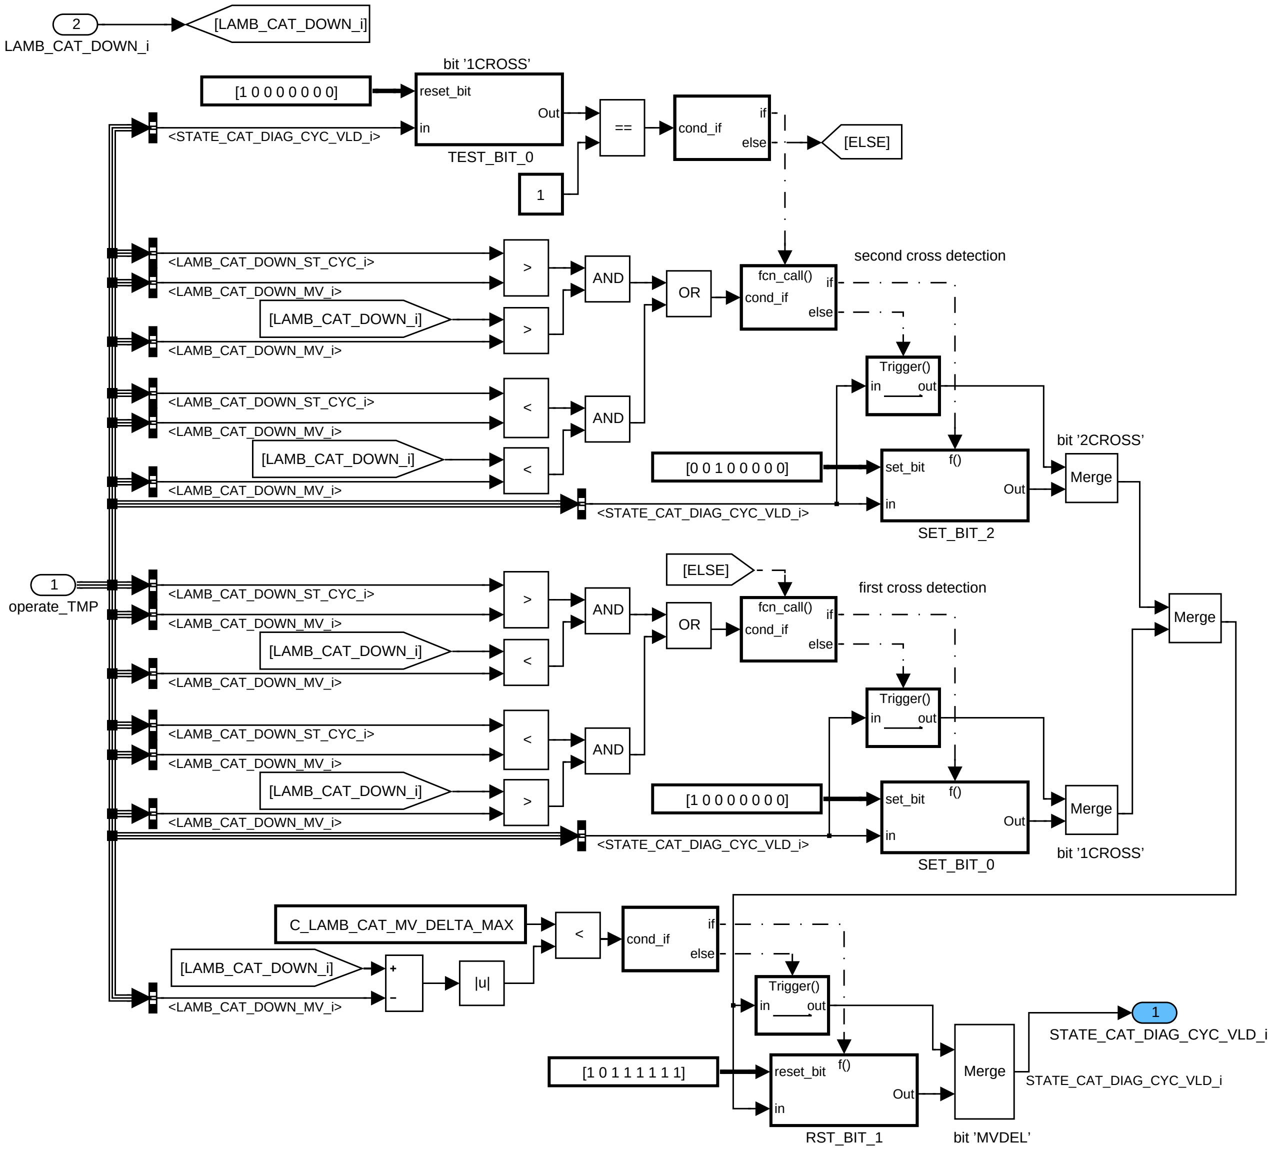


Figure 142: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/AFL_AFR/CLC/STATE_CAT_DIAG_CYC_VLD

18.13.1.1.1.3.4 EGTR_FCTDGCEF0/OPERATE/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/SA_CAT_DIAG/RAMP_UP

18.13.1.1.1.3.4.1 State action RAMP_UP:

Converting the downstream sensor voltage to the related downstream lambda value.
Checking the flag for lean state and comparing with the allied old value (checking for the start of a new monitoring cycle).
In case of a transition zero to one calculation of the downstream lambda mean value, incrementing the counter of monitoring cycles showing lambda out of range, setting of the summary validity bits and summing up downstream lambda and its counter.

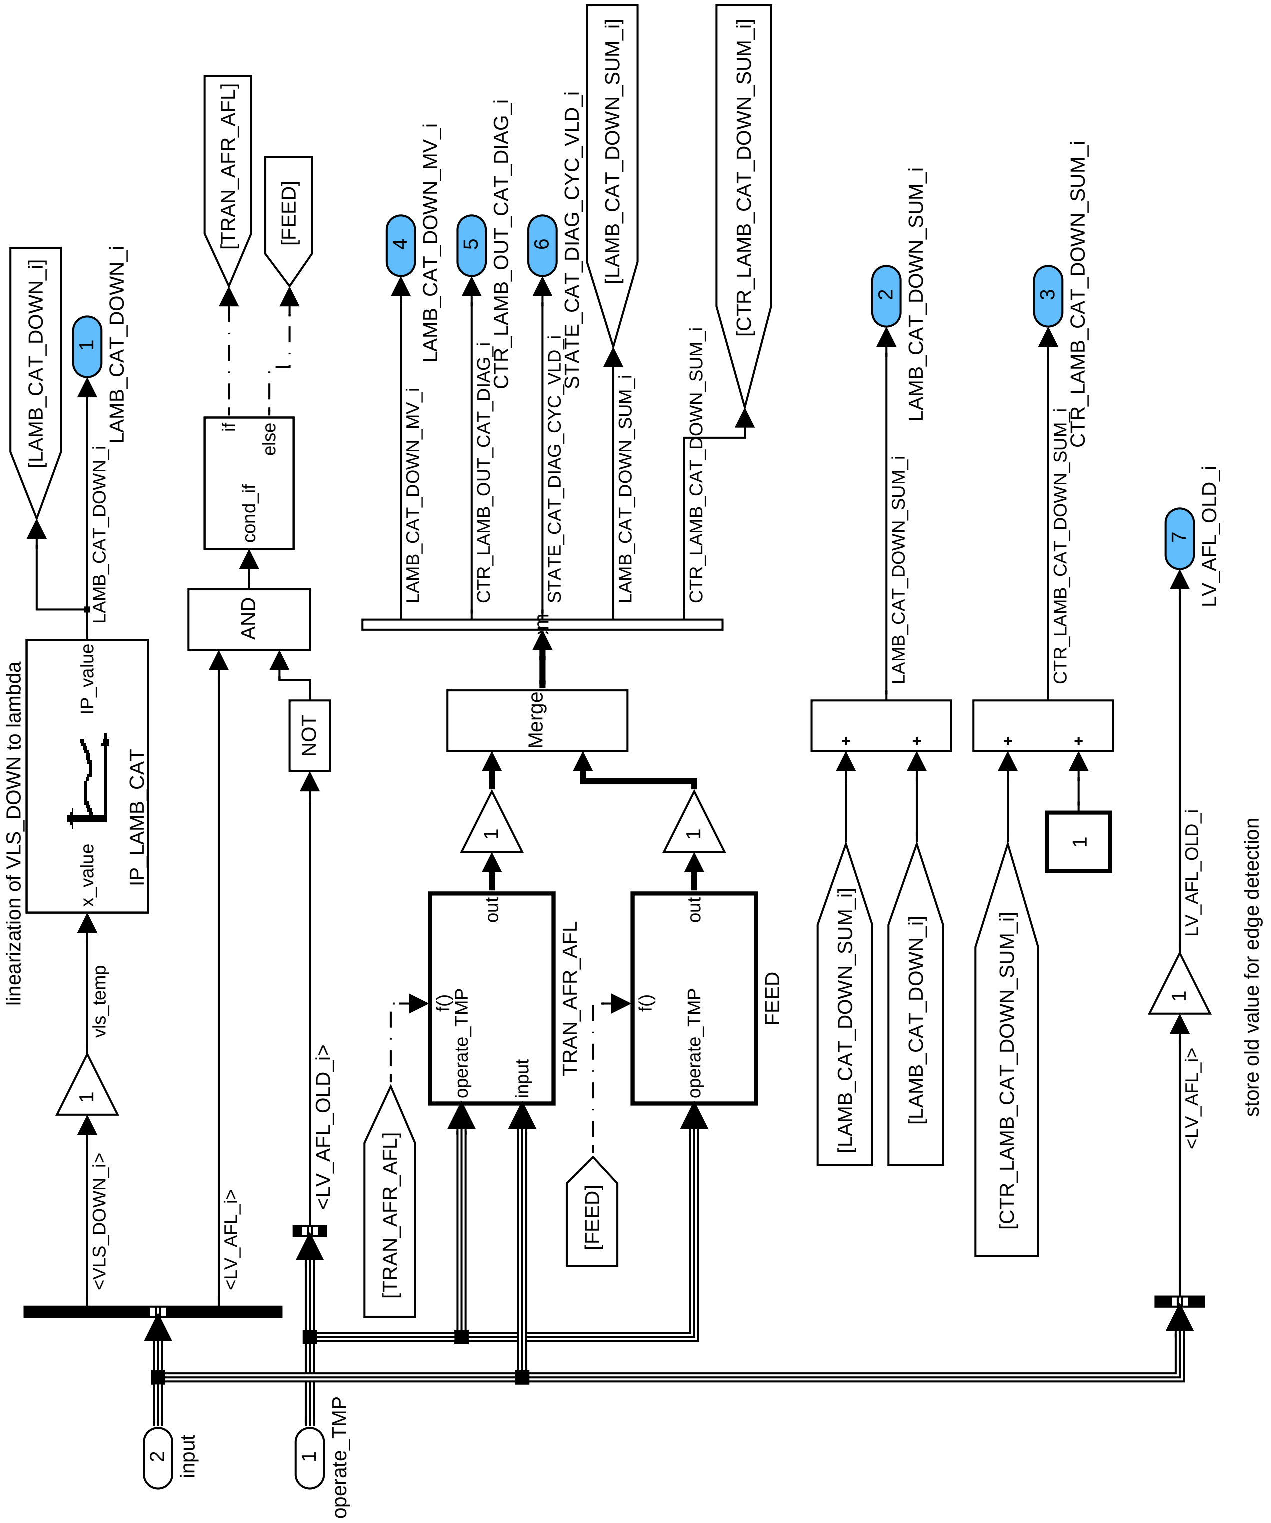

Figure 143: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/RAMP_UP/CLC

18.13.1.1.1.3.4.1.1 TRAN_AFR_AFL:

Calculation of the downstream lambda mean value of last cycle and correcting the influence of asymmetric sensor characteristic.
Checking the actual sensor signal to be in the allowed range and setting the respective validity bit in accordance with as well as the counter of non valid monitoring cycles and the summary validity bits.
Resetting the downstream lambda sum and its counter to zero.

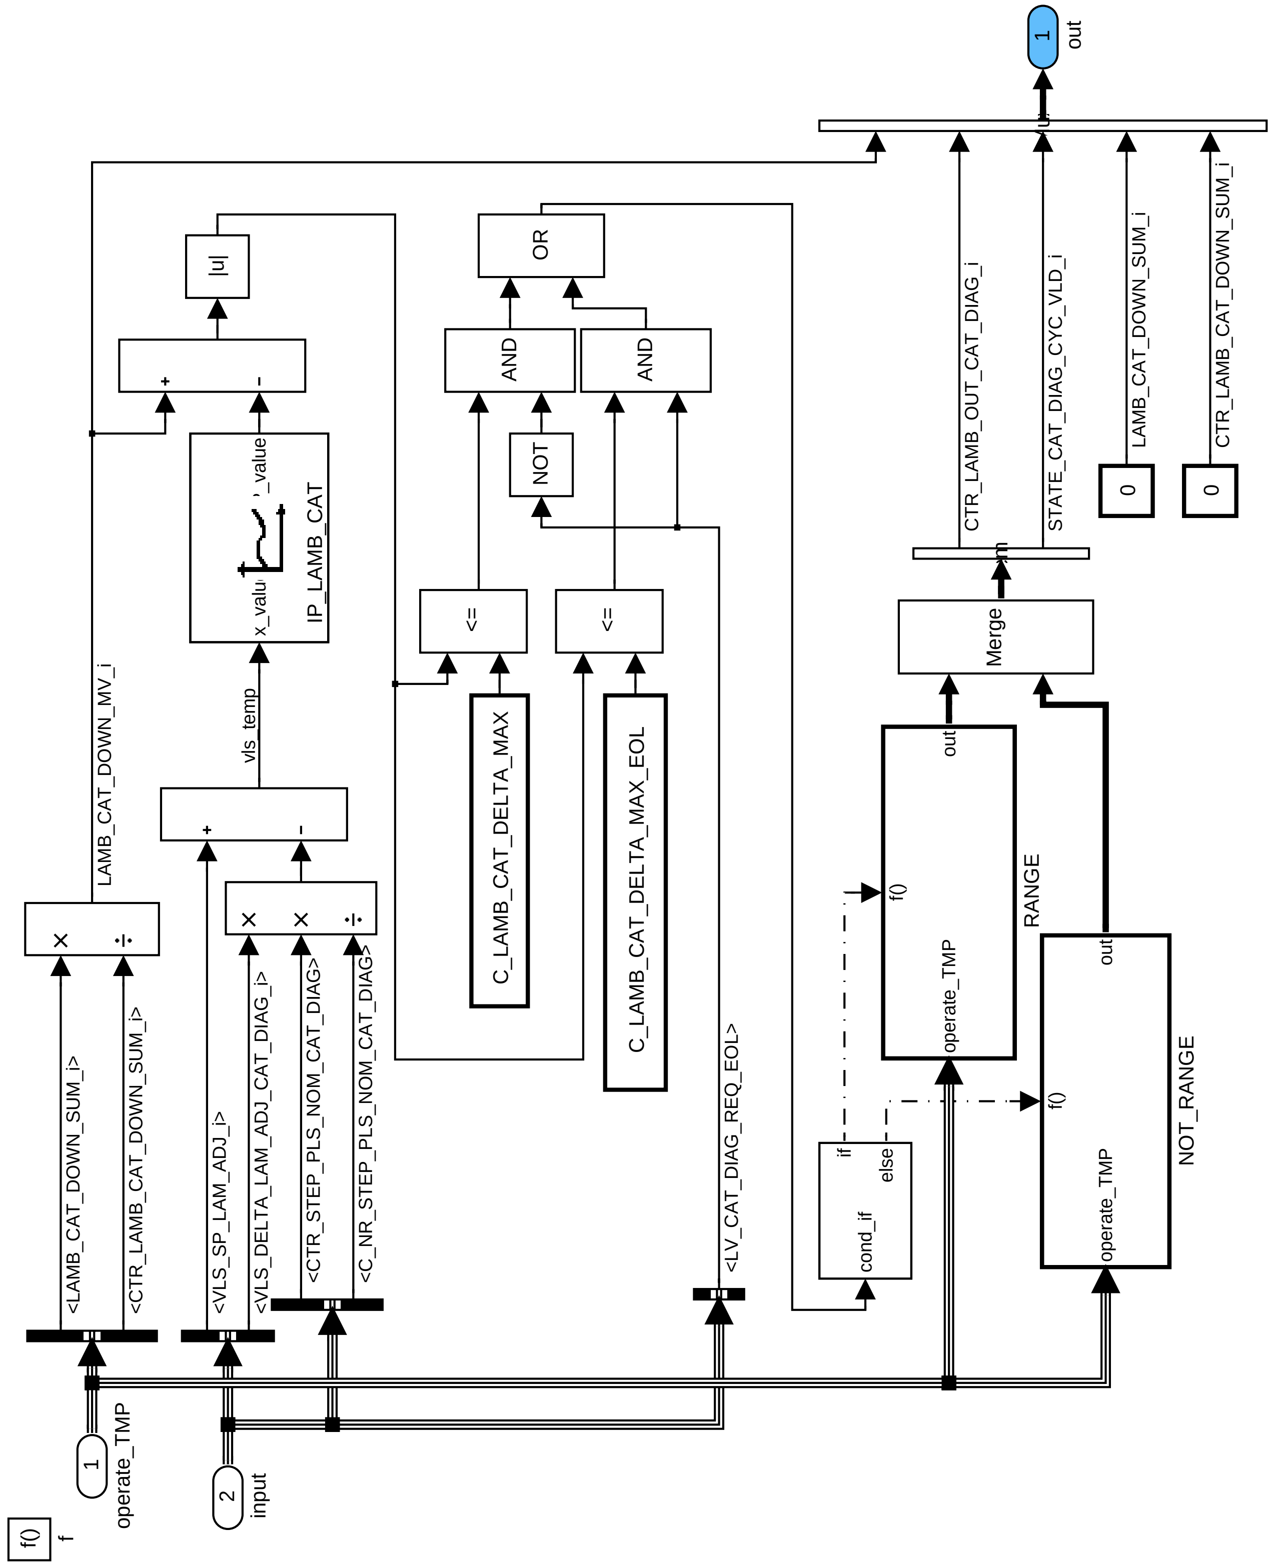

Figure 144: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/sa_CAT_DIAG/RAMP_UP/CLC/TRAN_AFR_AFL

18.13.1.1.1.3.4.1.1.1 TRAN_AFR_AFL/RANGE

Setting the counter of monitoring cycles showing lambda to be out of range to zero and the bit indicating that the diagnosis mean value is in the right range to one.

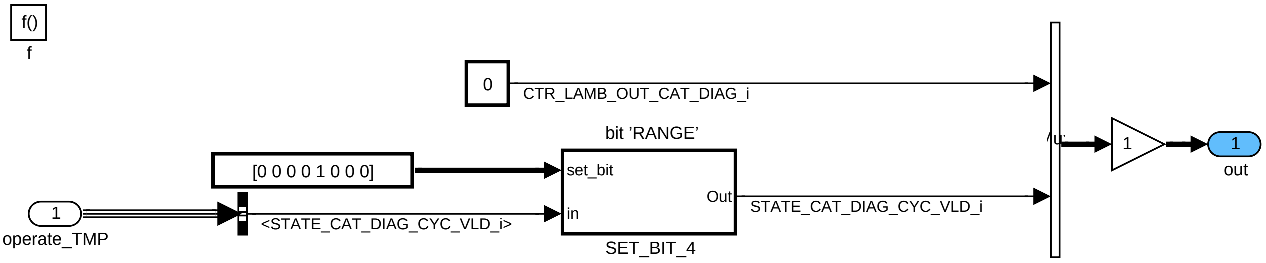

Figure 145: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ sa_CAT_DIAG/RAMP_UP/CLC/TRAN_AFR_AFL/RANGE

18.13.1.1.1.3.4.1.1.2 TRAN_AFR_AFL/NOT_RANGE

Adding one to the number of monitoring cycles showing lambda to be out of range and resetting the validity bit indicating that the diagnosis mean value is in the right range.

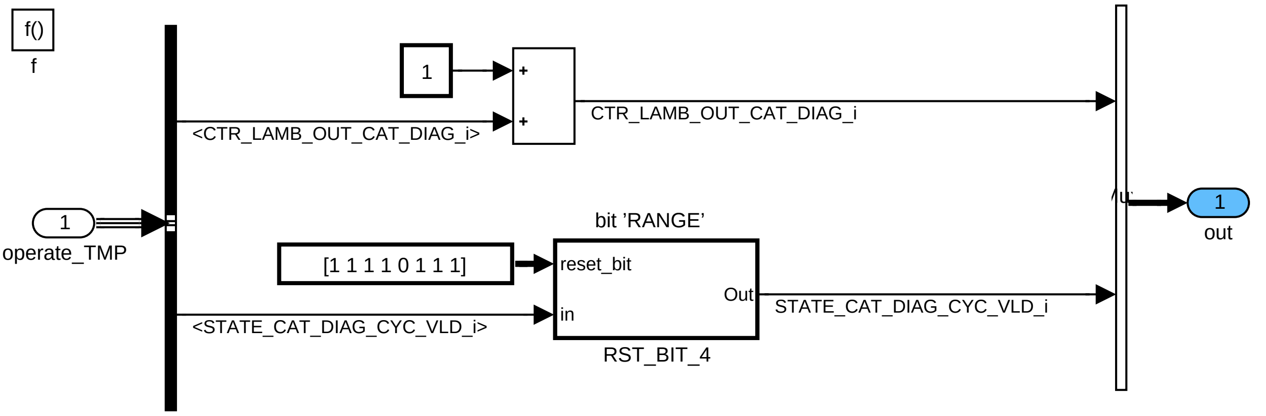

Figure 146: Path: EGTR_FCTDGCEF0/operate/EGTR_FCTDGCEF0_CBK_MNG/EGTR_FCTDGCEF0_CBK_SPC/ sa_CAT_DIAG/RAMP_UP/CLC/TRAN_AFR_AFL/NOT_RANGE

18.13.2 Handling data at non volatile memory:

Triggering of one of the following actions:
RNVMY (read non volatile memory): Reading the diagnosis value of last completed diagnosis cycle and the number of totally completed diagnosis cycles since ECU programming from non volatile memory.
UNVMY (update non volatile memory): Saving the diagnosis value of last completed diagnosis cycle and the number of totally completed diagnosis cycles since ECU programming to non volatile memory.
STB (standby): Initializing the diagnosis value and the number of totally completed diagnosis cycles since ECU programming to zero and saving to non volatile memory.

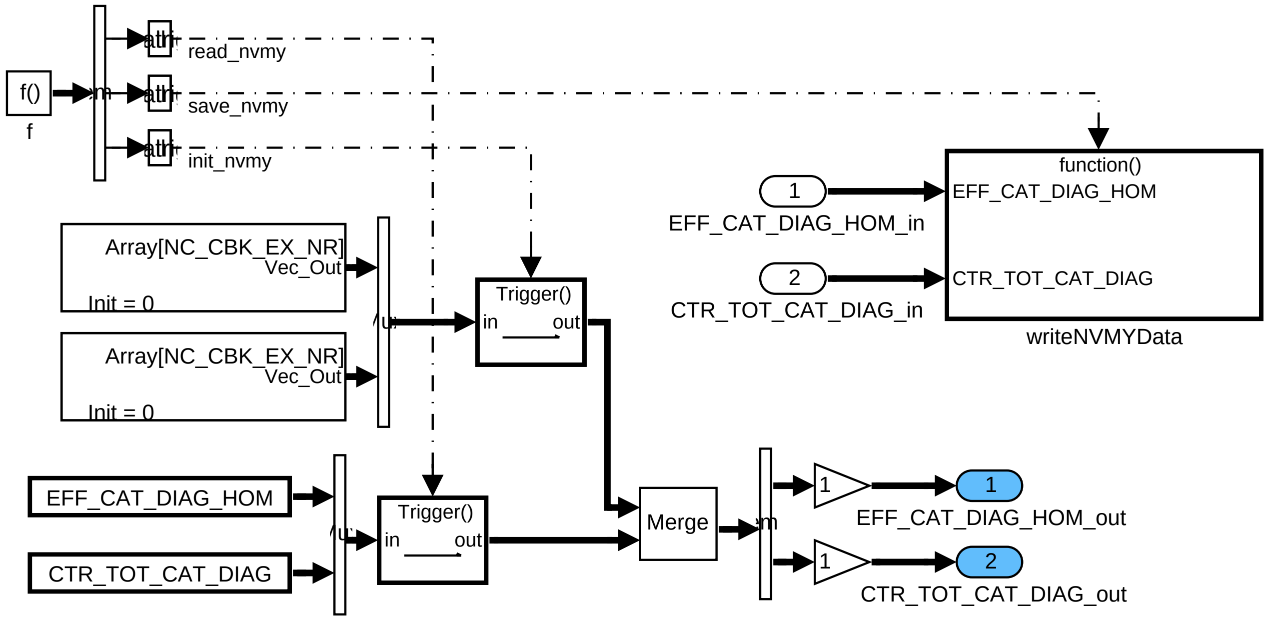

Figure 147: Path: EGTR_FCTDGCEF0/NVMYdata

18.13.2.1 Writing to non volatile memory (UNVMY):

Storing the final diagnosis value to non volatile memory and incrementing there the total number of completed diagnosis cycles since ECU programming by one.

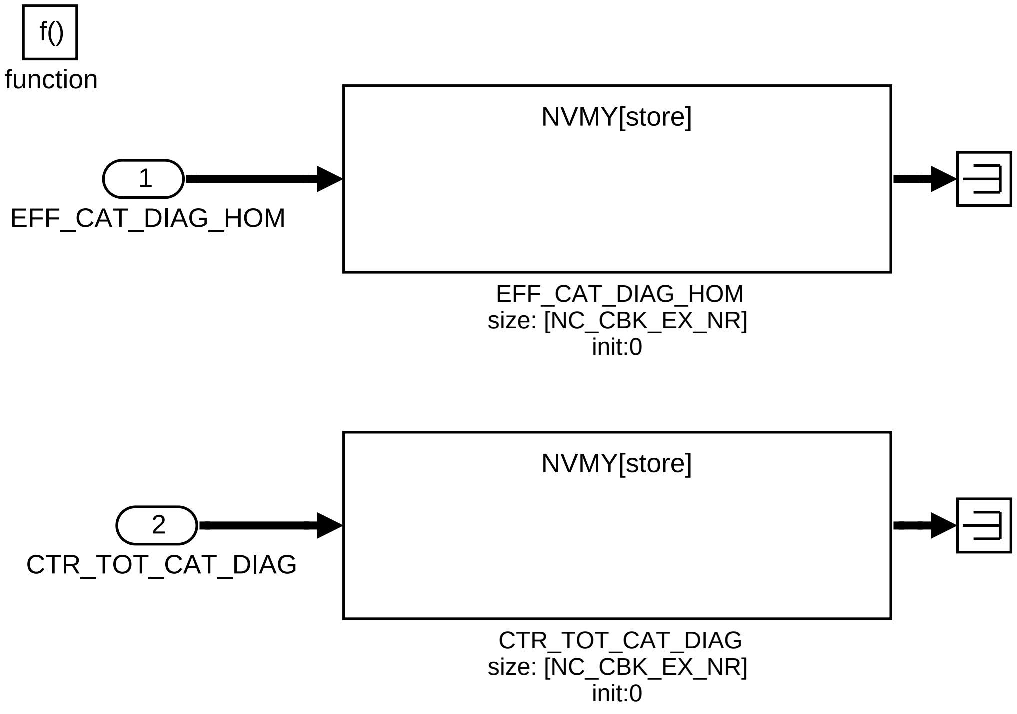

Figure 148: Path: EGTR_FCTDGCEF0/NVMYdata/writeNVMYData

18.13.3 RESET:

Initializing all listed variables to zero.

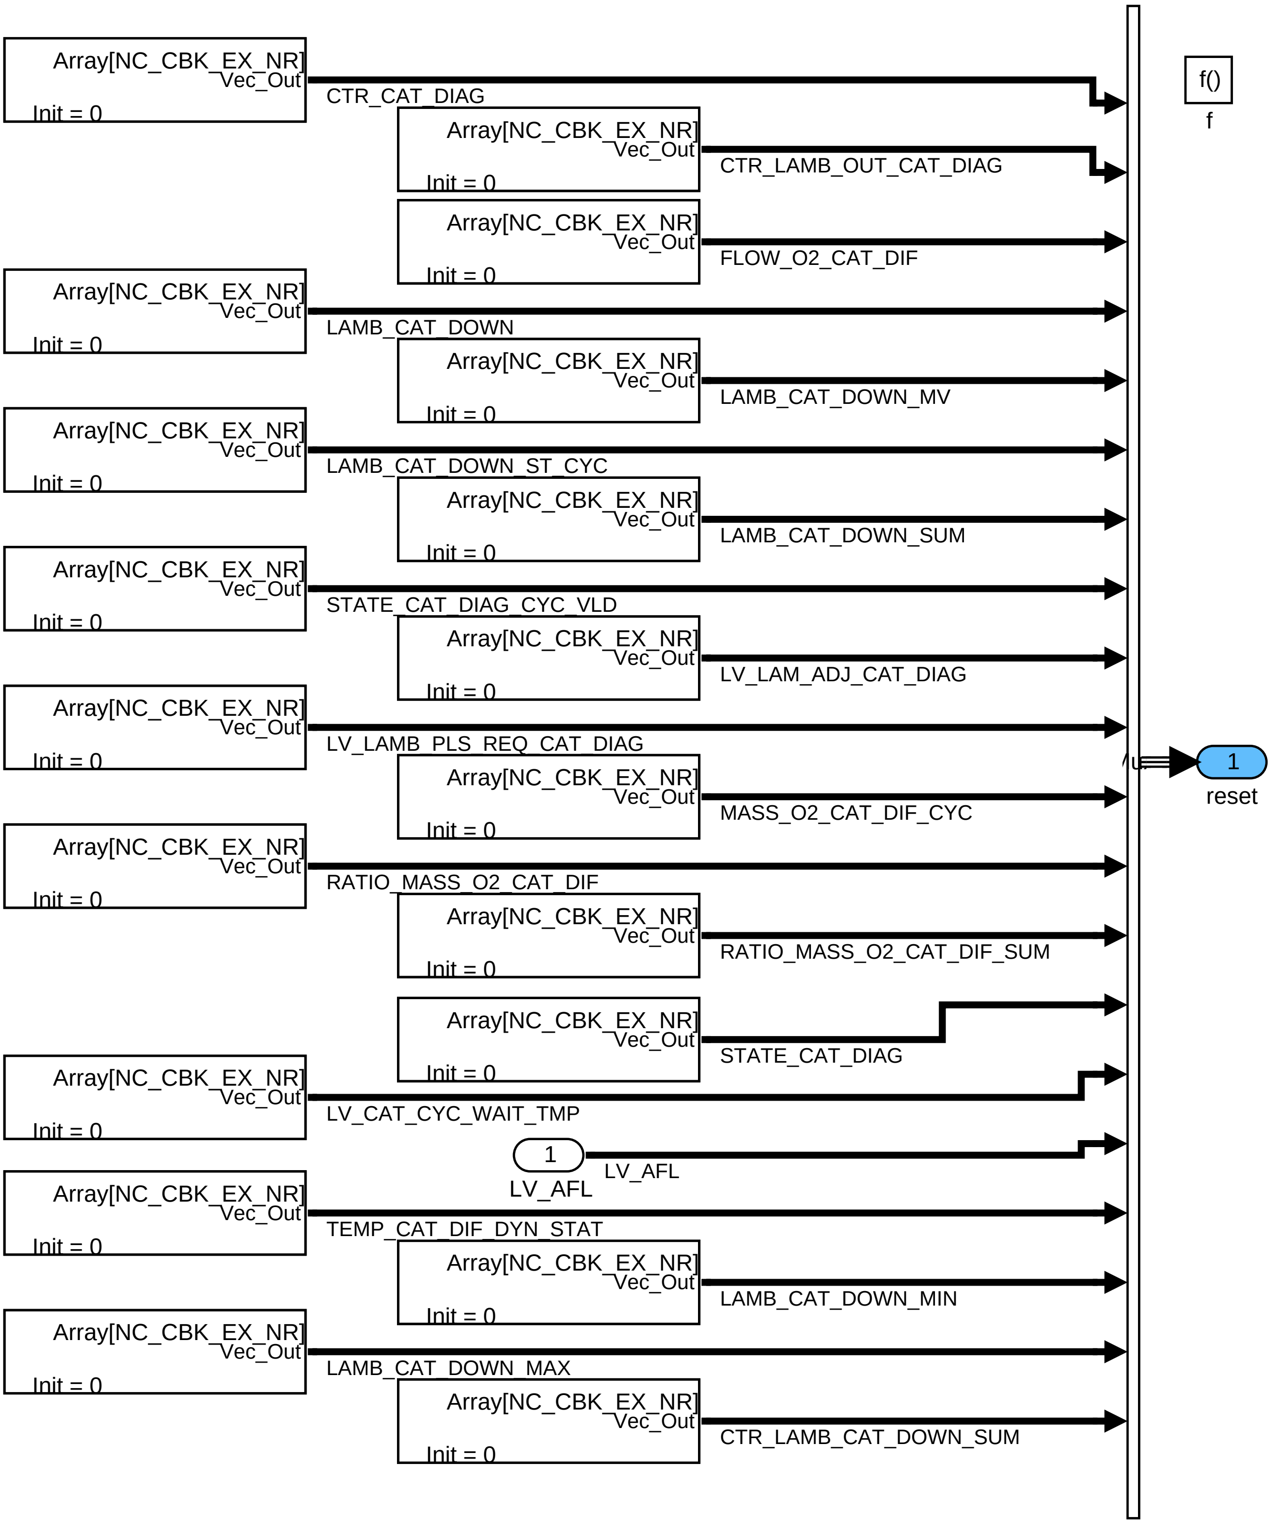

Figure 149: Path: EGTR_FCTDGCEF0/reset

General Information

This modul coordinates the results of both catalyst diagnosis methods
- lambda=1 catalyst diagnosis (HOM): EFF_CAT_DIAG_HOM[NC_CBK_EX_NR]
- lean catalyst diagnosis (AFL): O2L_CAT_DIAG_AFL[NC_CBK_EX_NR]

The common result is EFF_CAT_DIAG[NC_CBK_EX_NR]

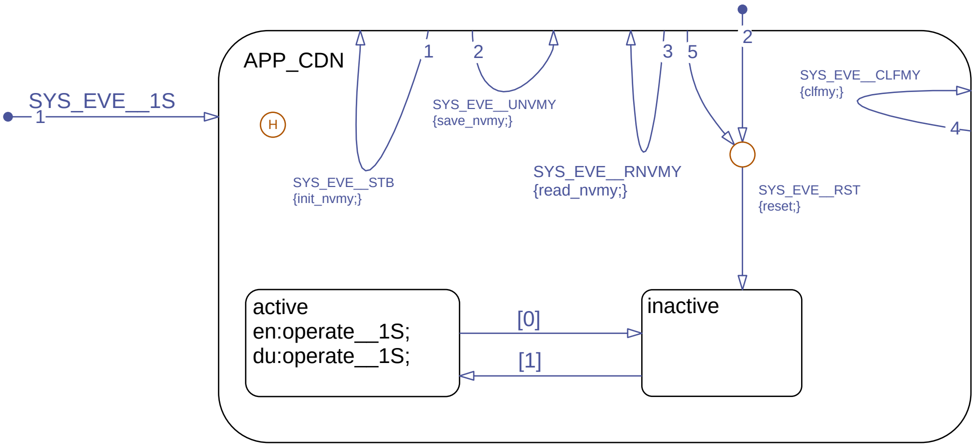

Figure 150:
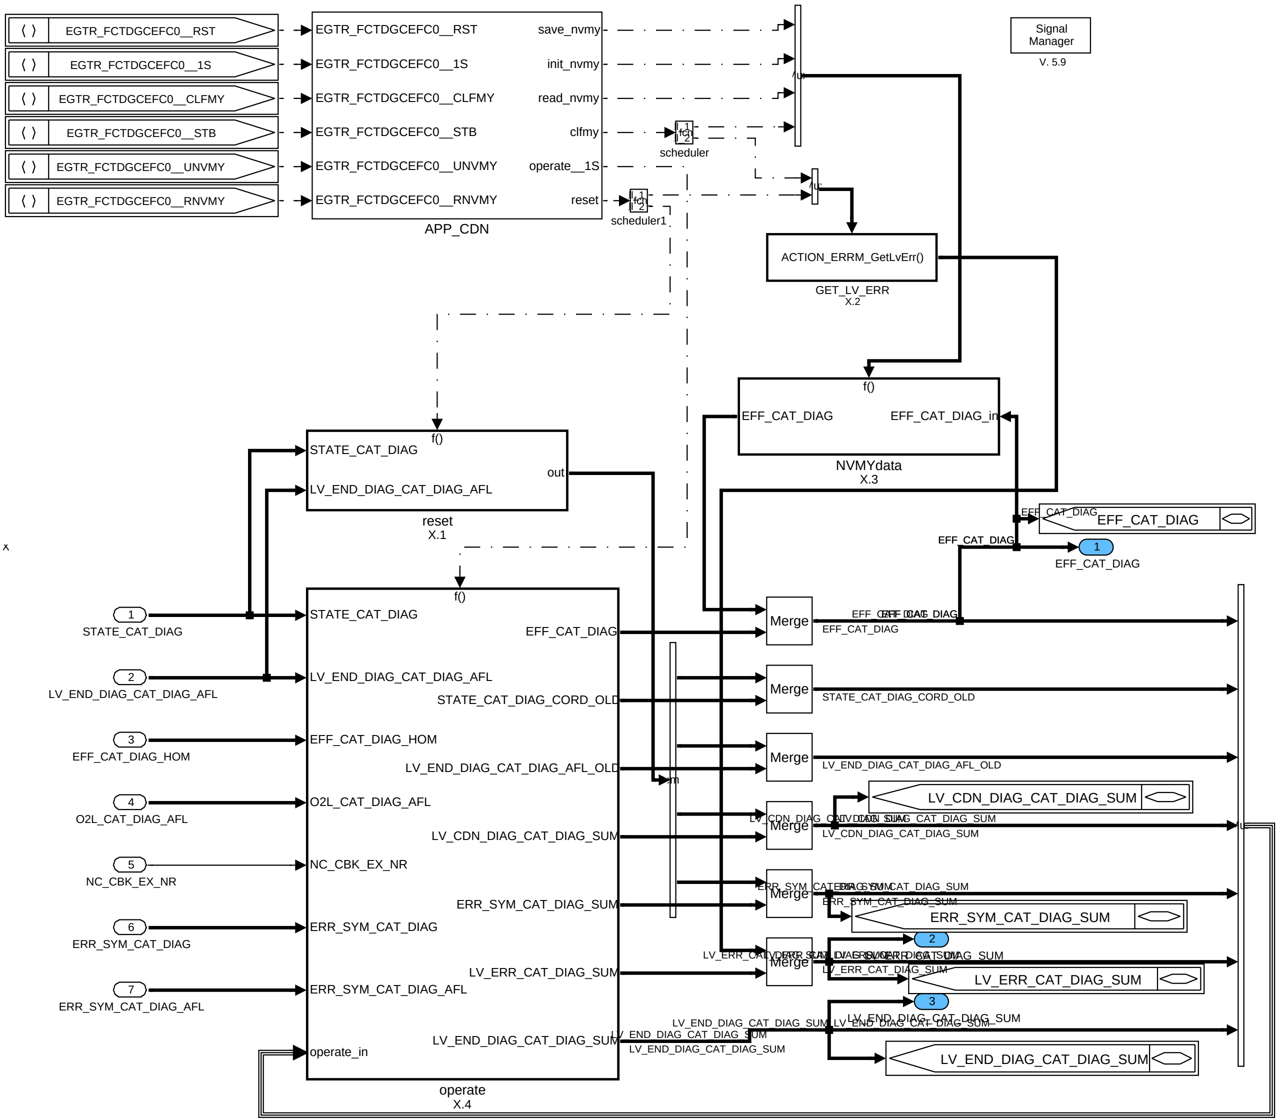
Path: EGTR_FCTDGCEFC0/APP_CDN/Chart



SDA_SRS / SDA V 5.1 06−Apr−2006

Figure 151:
Path: EGTR_FCTDGCEFC0

18.14.1 Reset

The old values will be initialized with the regarding inputs, due to avoid an edge detection after reset.

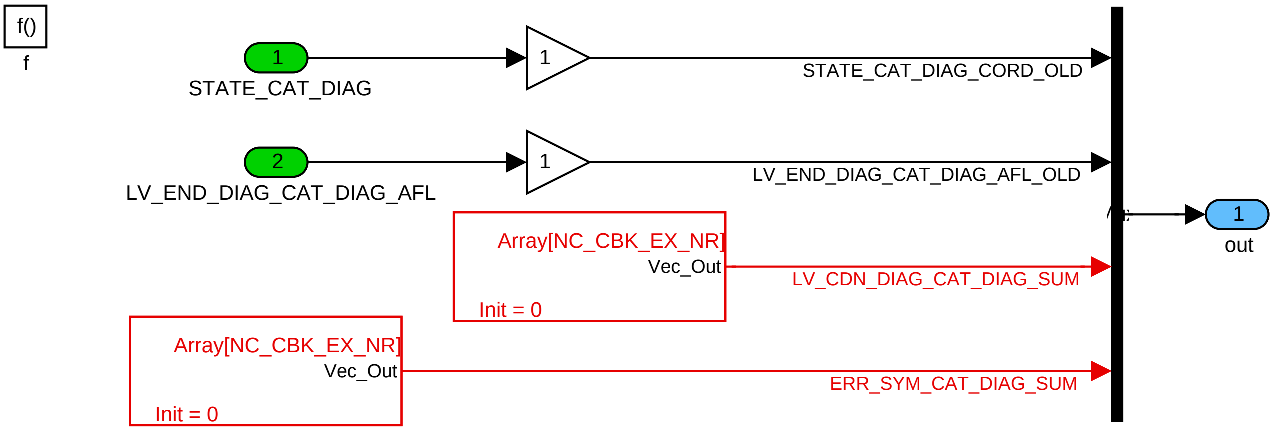


Figure 152:
Path: EGTR_FCTDGCEFC0/reset

18.14.2 Synchronization of the LV_ERR_CAT_DIAG_SUM

Synchronisation between LV_ERR_CAT_DIAG_SUM and its result from ERRM is done using action ACTION_ERRM_GetLvErr() at reset and clrfmy.

18.14.3 EFF_CAT_DIAG[NC_CBK_EX_NR] will be stored in the non-volatile memory

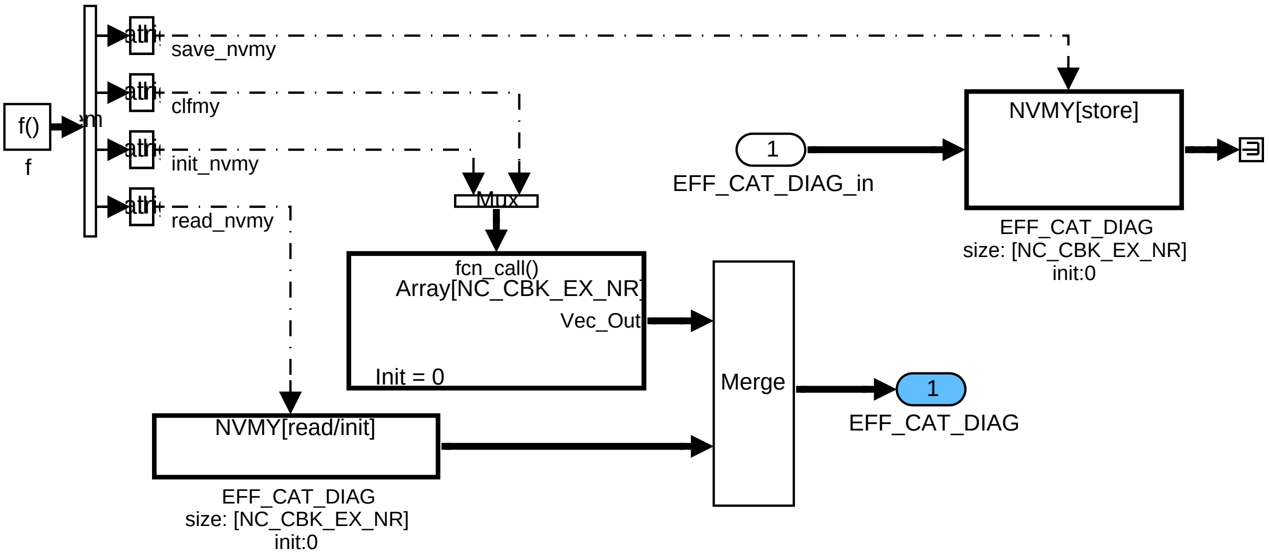

Figure 153:
Path: EGTR_FCTDGCEFC0/NVMYdata

18.14.4 FORMULA SECTION

18.14.4.1 Calculation of the summary diagnosis results

18.14.4.1.1 Calculation of the summary diagnosis "end" and "error symptom" outputs

The summary diagnosis is a combination of the TWC diagnosis of homogeneous and lean combustion modes. Last finished diagnosis saves the summary diagnosis result. When the ABC counter is calibrated to e.g. 2, then both diagnoses can influence the diagnosis result depending on which one is executed.

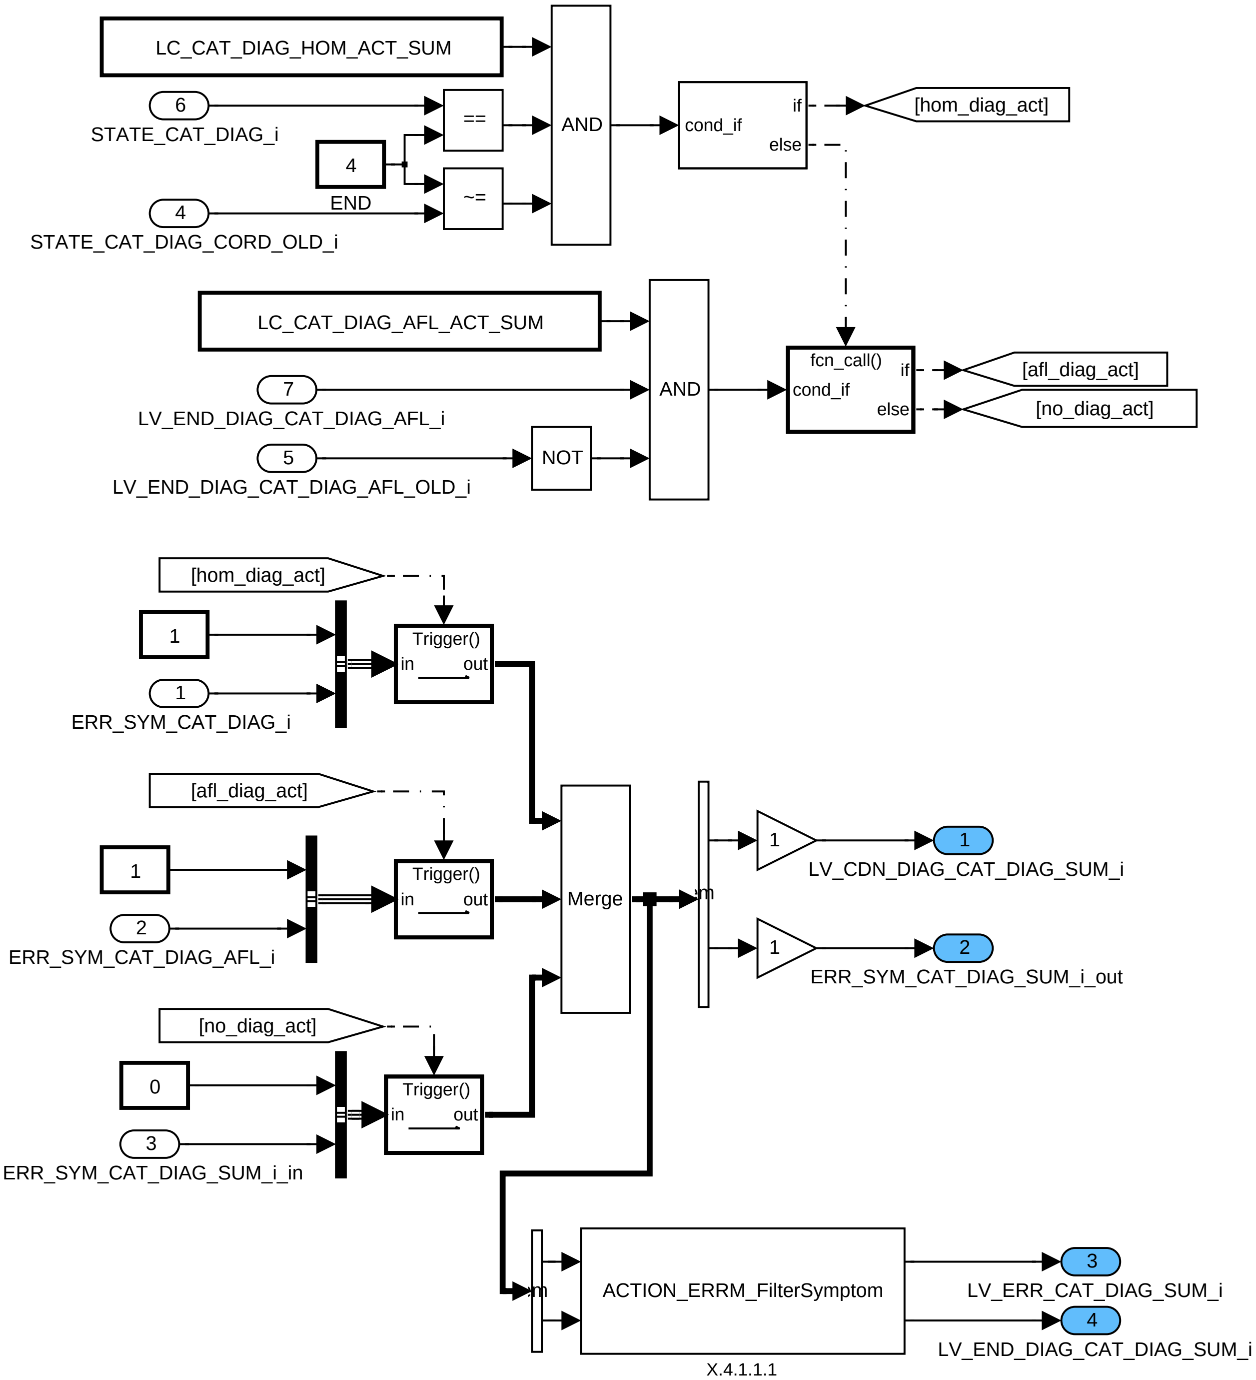

Figure 154:
Path: EGTR_FCTDGCEFC0/operate/CBK_MNG/CLC0

18.14.4.1.1.1 Call of the ERRM

Import actions:

ACTION_ERRM_FilterSymptom(IN<XX>, IN<lv_cdn_diag_XX>, IN<err_sym_XX >, IN<C_ABC_INC_XX >, IN<C_ABC_DEC_XX >, IN<C_ABC_MAX_XX >, OUT<LV_ERR_XX>)
The action computes the elementary anti-bounce filter for one failure treatment and returns filter results

Configuration for diagnostic symptoms:

Diagnostic CAT_DIAG_SUM[i]	Symptom description	Symptom	Filter type
Catalyst sum diagnosis	´CAT_EFFIC_LOW´	SYM_0	STD
	´CAT_DAMAGED’	SYM_1	
	Not used	SYM_2	
	Not used	SYM_3	

18.14.4.1.2 Calculation of the TWC efficiency

NC_CBK_EX_NR = 1 (one-bank system): calculation for index i = 1
NC_CBK_EX_NR = 2 (two-bank system): calculation for index i = 1 and 2

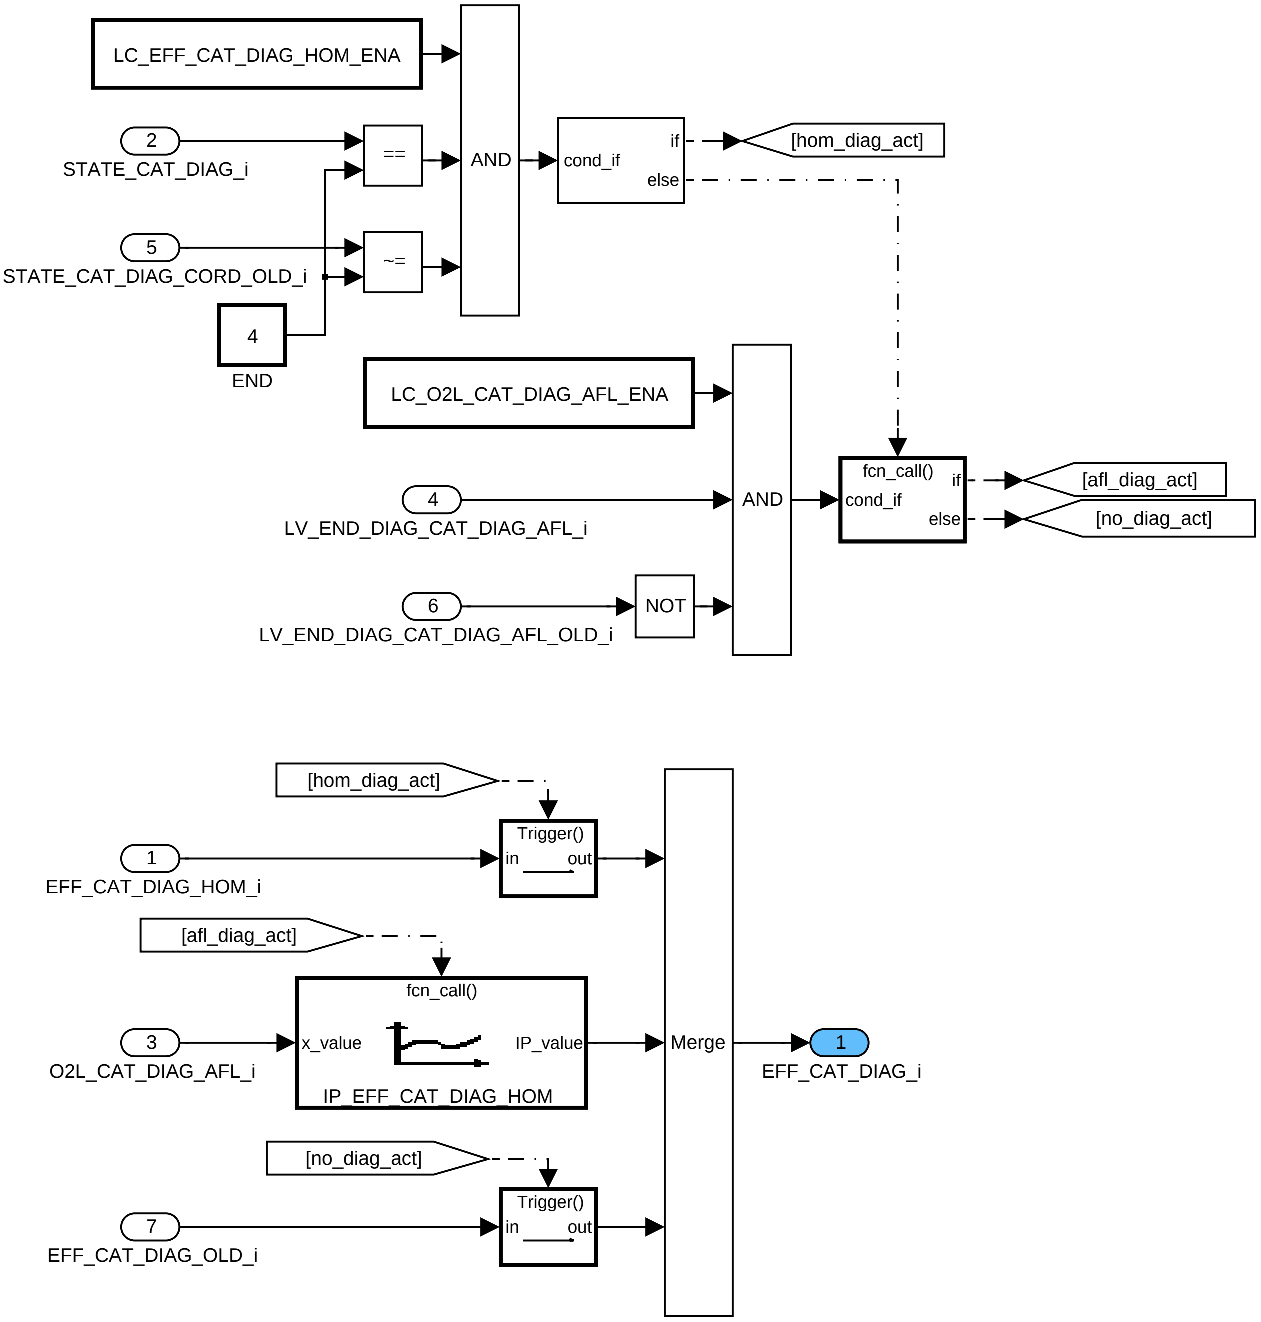

Figure 155:
Path: EGTR_FCTDGCEFC0/operate/CBK_MNG/CLC1

18.14.4.1.3 Calculation of the old values

The old values of the input signals will be stored for each bank.

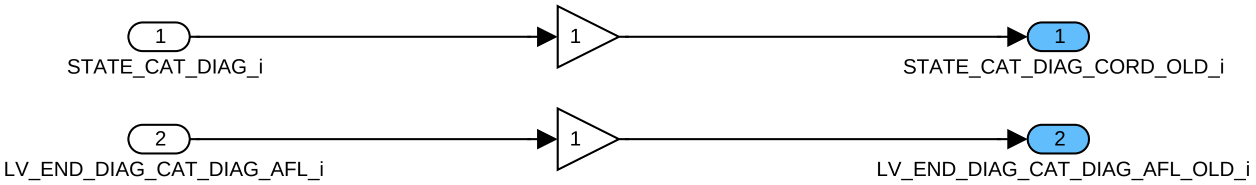

Figure 156:
Path: EGTR_FCTDGCEFC0/operate/CBK_MNG/CLC2

18.15.1 Inhibition of diagnosis

FUNCTION DESCRIPTION:

General information:

The inhibition of the catalyst diagnosis can be deactivated by :

LC_INH_CAT_DIAG_MAN_DEAC = 1.

For LC_INH_CAT_DIAG_MAN_DEAC = 1 the catalyst diagosis function is not inhibited by a component failure.

Description:

If one of the following components fail the catalyst efficiency diagnosis function is stopped by LV_INH_DIAG_RBM_CAT_DIAG[i] = 1. The inhibition is calculated bank-wise.

Application conditions:

Initialization:	at reset all Variables shall be set to 0
Recurrence:	0.02 sec
Activation:	LV_DC transition 0 -> 1 (start driving cycle)
Deactivation:	LV_DC transition 1 -> 0 (driving cycle terminated)

Formula section:

Inhibition due to OBDI error

```
If        LV_ERR_MAF = 1
    or    LV_ERR_AMP = 1
    or    LV_ERR_AMP_PLAUS = 1
    or    LV_ERR_TPS = 1
    or    LV_ERR_LOAD_TPS_PLAUS = 1
    or    LV_ERR_IVVT = 1
    or    LV_ERR_LS_UP[i] = 1              // Global error flag for upstream sensor
    or    LV_ERR_LS_DOWN[i] = 1            // Global error flag for downstream sensor
    or    LV_ERR_DELTA_I_LAM[i] = 1
    or    LV_ERR_VLS_DOWN_DIF[i] = 1
    or    LV_ERR_CPS = 1
    or    LV_ERR_CRK = 1
    or    LV_ERR_TCO = 1
    or    LV_ERR_FSD[i] = 1
    or    LV_MIS_STATE_A = 1
    or    LV_MIS_STATE_B = 1
    or    LV_ERR_DIAGCPS = 1
```

```
    or      LV_ERR_FSD_LAM_LIM_x = 1
    or      LV_ERR_FUP = 1
    or      LV_ERR_FUP_MFP_PLAUS = 1
    or      LV_ERR_H_PRS_SYS = 1
    or      LV_ERR_VCV = 1
    or      LV_ERR_FUP_ORNG = 1
    or      LV_ERR_FUP_ST = 1
    or      LV_ERR_TTIP_MES_LSH_UP_x = 1
    or      LV_ERR_CAM_CUS = 1
    or      LV_ERR_SLV_IVVT_IN = 1
    or      LV_ERR_MAP_TPS_PLAUS = 1

Then        LV_INH_DIAG_RBM_CAT_DIAG[i] = 1
                    (Catalyst efficiency diagnosis inhibited due to OBD error )
Else        LV_INH_DIAG_RBM_CAT_DIAG[i] = 0
                    (Catalyst efficiency diagnosis not inhibited)
Endif
```

<u>Inhibition due to environmental condition / calibration:</u>

```
If          [ LV_MTC_CUR_OFF = 1
    Or      LV_INH_DIAG_RBM_CAT_DIAG[i] = 1]
    and     LC_INH_CAT_DIAG_MAN_DEAC = 0
Then        LV_INH_DIAG_CAT_DIAG[i] = 1
                    (Catalyst efficiency diagnosis inhibited)
Else        LV_INH_DIAG_CAT_DIAG[i] = 0
                    (Catalyst efficiency diagnosis not inhibited)
Endif
```

<u>Catalyst diagnosis specific load for limited dynamics calculation</u>

LOAD_CAT_LDC = FAC_TQ_REQ

The definition of both variables are different, therefore a linear interpolation between the physical limits (min and max) of FAC_TQ_REQ shall be applied, i.e LOAD_CAT_LDC = 0% if FAC_TQ_REQ = 0; LOAD_CAT_LDC = 99,9023438% if FAC_TQ_REQ = 1.999969.

Calibration data:

LC_INH_CAT_DIAG_MAN_DEAC	1	0...1H	0...1	1	[-]
Manual deactivation of CAT diagnosis inhibition conditions					

18.15.2 Interface for Rate – Based - Monitoring

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CAT_DIAG_i monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_CAT[i] data.

Within STATE_RBM_CAT[i], three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for catalyst diagnosis)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_CAT[i] = 0

on failure memory reset :

bit 1 of STATE_RBM_CAT[i] = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_FSD[i]	LV_ERR_AMP	LV_ERR_DIAGCPS	
LV_ERR_MAF			LV_ERR_AMP_PLAUS

LC_CAT_DIAG_RESU	1	0... 1H	0... 1	1	[-]
Switch over the failure memory setting: separate for each catalyst or common for OBD emiss. limit					

General Information

For 2 exhaust gas bank system 1 bank (catalyst) could be aged over OBD limit, but if other catalyst is O.K, emissions of whole vehicle need not be over OBD limit, so MIL needn t go on. A separate diagnosis of every cylinder bank(catalyst), or common diagnosis is switchable. A common EFF_CAT_DIAG_SUM is calculated from separate EFF_CAT_DIAG[i] values of separate banks and error memory entered if common value is over the threshold. For 50% catalyst conversion a higher threshold will be observed.

Configuration for diagnostic symptoms:

Diagnostic CAT_DIAG[i]	Symptom description	Symptom	Filter type
Catalyst diagnosis	´CAT_EFFIC_LOW´	SYM_0	NO
	´CAT_DAMAGED’	SYM_1	NO

NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements, the variable extension _i is used in the model instead of [i] as found in the textual description.

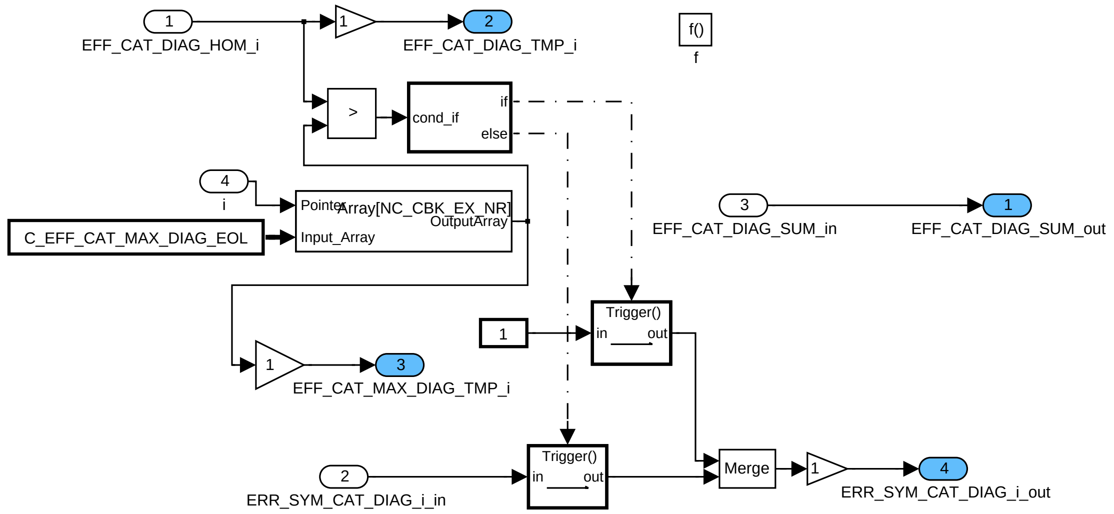

Figure 163:

18.16.2.1.1.1.1.2 Switch by LC_CAT_DIAG_RESU

This function is switchable with LC_CAT_DIAG_RESU: separate comparison of EFF_CAT_DIAG[i] with threshold and separate failure for every cylinder bank is stored, or from separate EFF_CAT_DIAG[i] is a common EFF_CAT_DIAG_SUM calculated and failure is stored only if common treshold C_EFF_CAT_MAX_DIAG_SUM is exceeded, or separate EFF_CAT_DIAG[i] exceeds a threshold C_EFF_CAT_MAX_50_DIAG. (Catalyst efficiency lower, then 50%). This modul is to call immediatelly after modul Catalyst efficiency diagnosis (OSC Method) is finished. For crossways question of symptoms i = the actually calculated bank and y = the other bank as actually calculated.

18.16.2.1.1.1.1.3 Set LV_END_DIAG_CAT_DIAG[i]

When LV_END_DIAG_CAT_DIAG[i] is set to 1 the current failure status must be stored in the Error Management (by means of a service of ERRM).

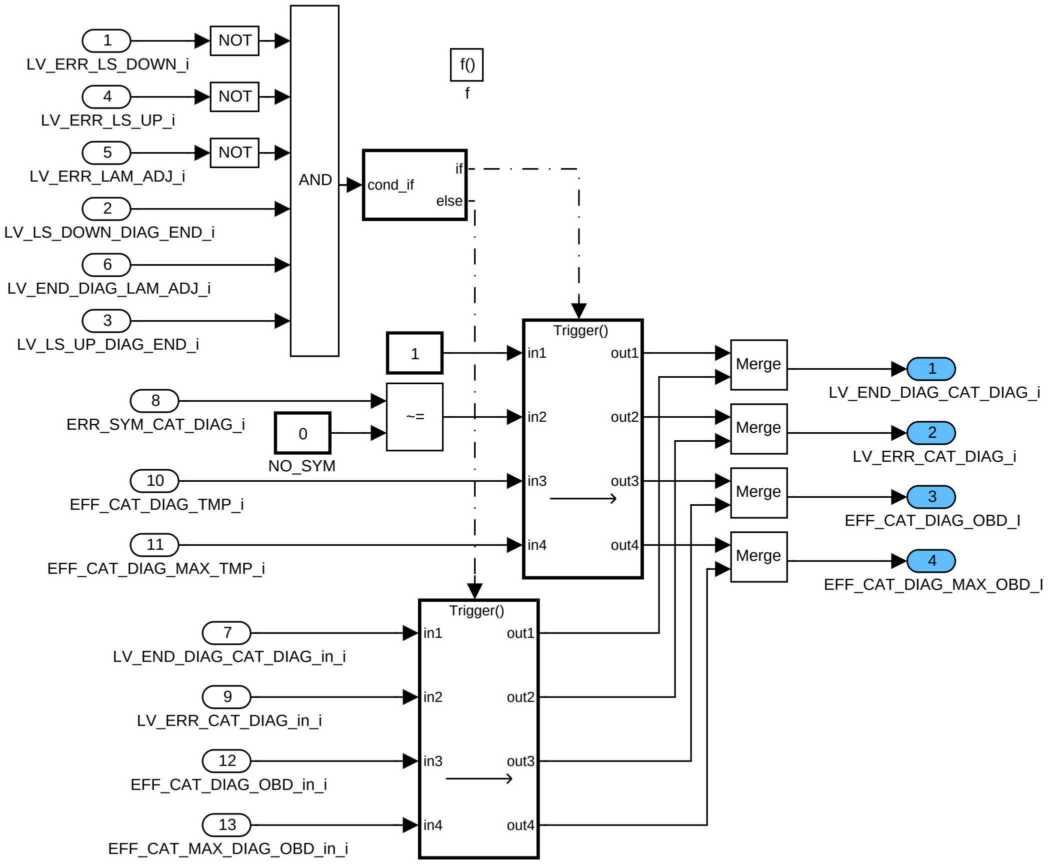

Figure 172:

18.16.2.1.1.2 Set readiness flag for the catalyst diagnosis through diagnosis from lean conditions

In case of lean combustion condition, a lean catalyst diagnosis is executed, but the homogeneuse diagnosis is not executed. In this case, readiness flag will be set by lean catalst diagnosis.

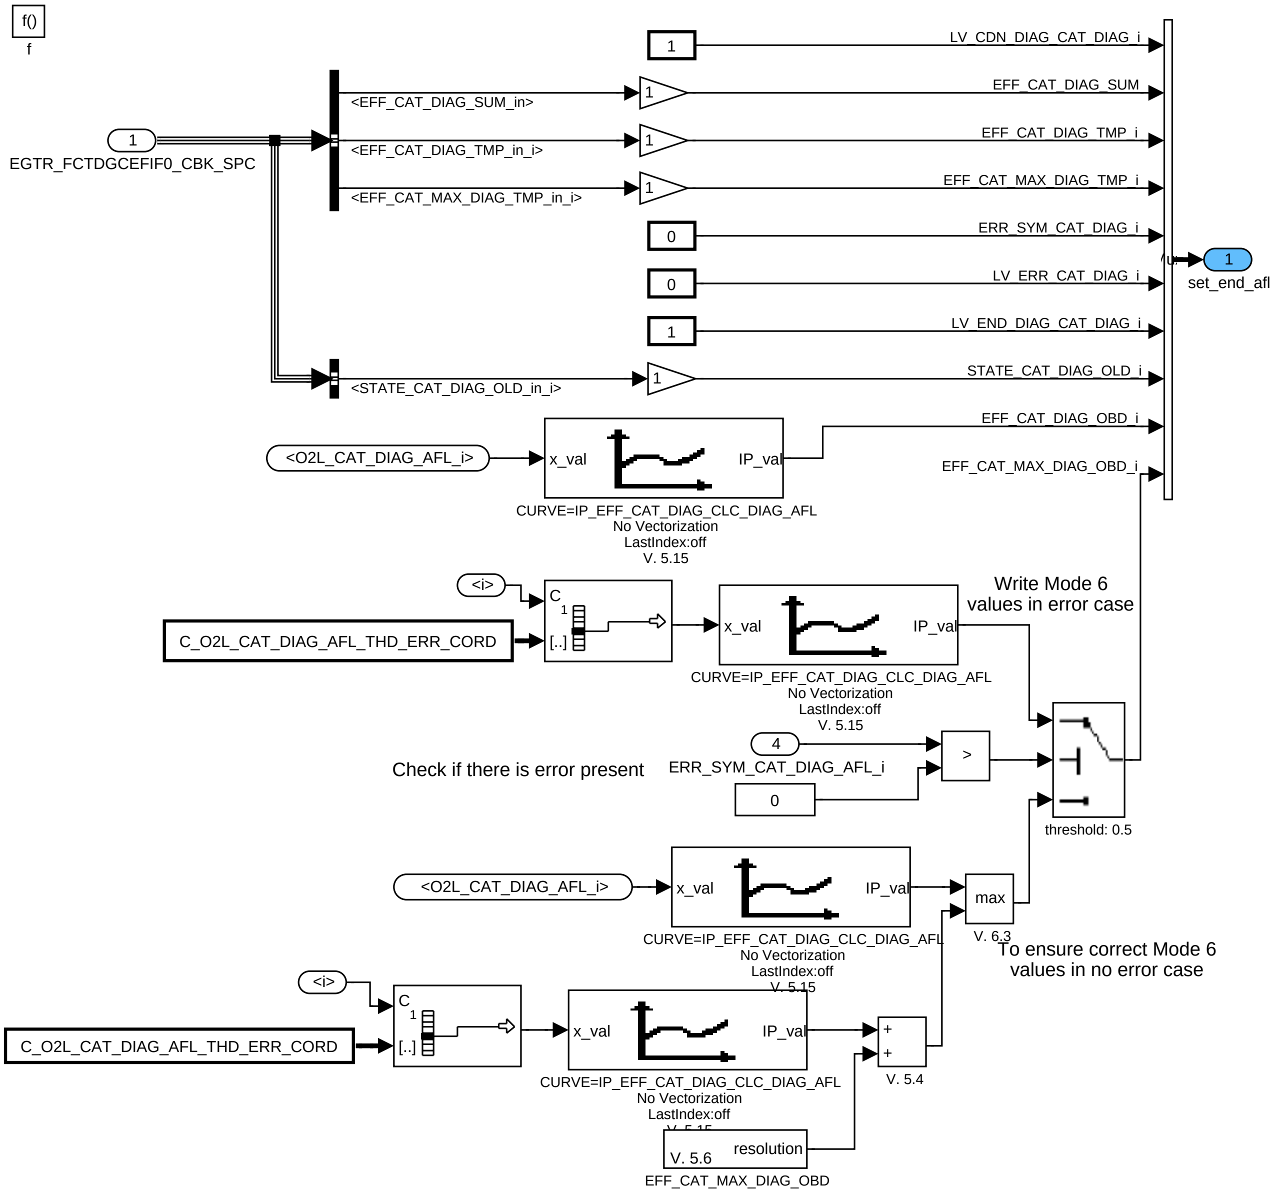

Figure 173:

18.16.3 Initialization at RESET

SDA needs initialisation of LV_END_DIAG_CAT_DIAG to run simulation. That is why LV_END_DIAG_CAT_DIAG is initialised to zero at Reset block. In the software this variable should be initialized by Error Management system.

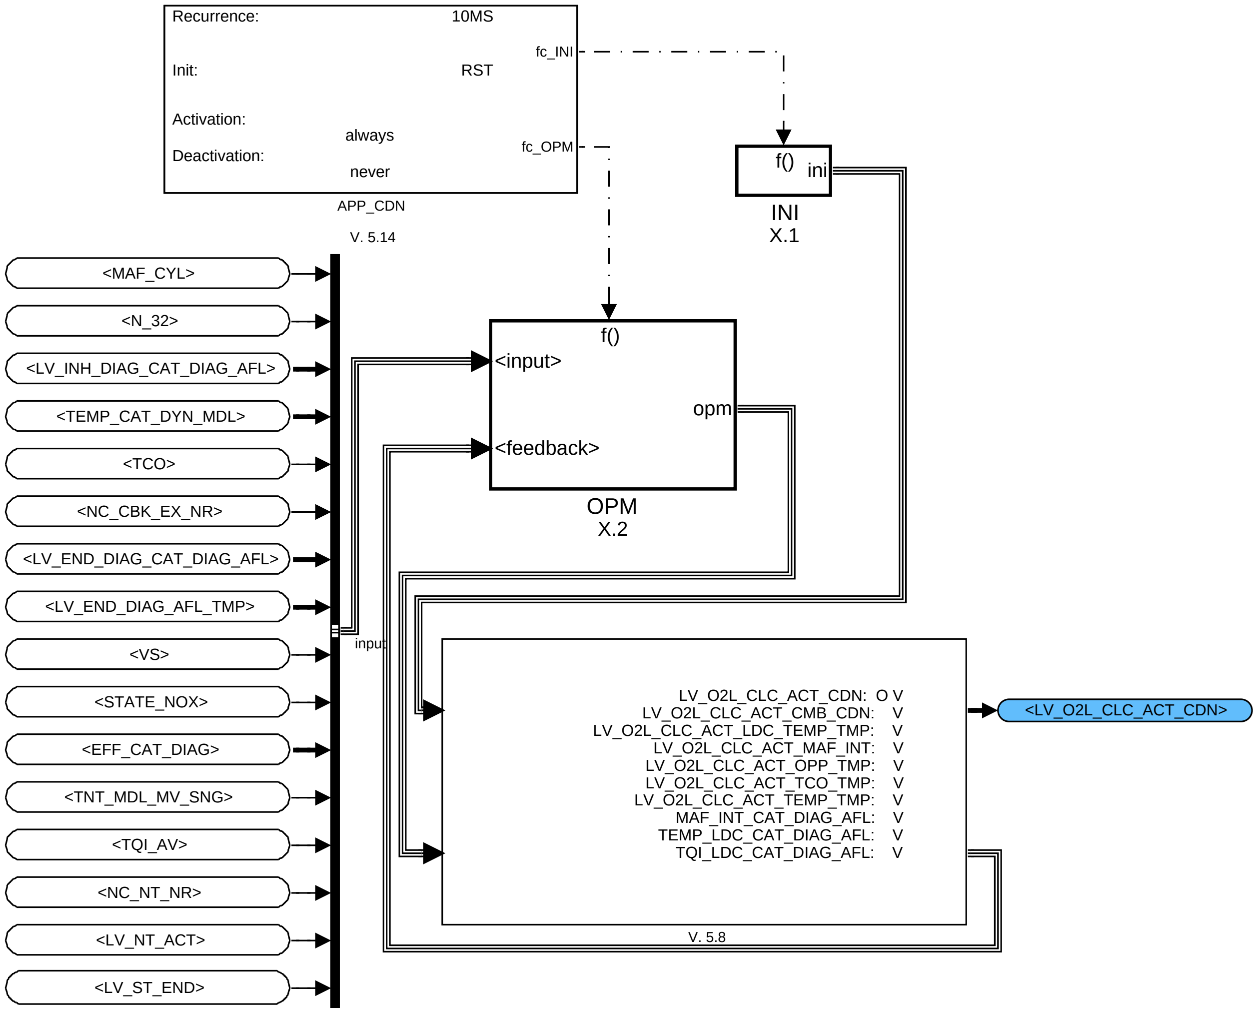
General Information

Activation condition for calculation of OSC values in module "TWC diagnosis at lean operation - OSC calculation".
If two separate exhaust bank systems are concerned, then:
  i = 1, for cylinder bank 1
  i = 2, for cylinder bank 2
Otherwise:
  i = 1

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: always
Deactivation: never

Function description



SDA_SRS / SDA V 5.1 06−Apr−2006

Figure 175: Overview level

18.17.1 INITIALIZATION

All variables are initialized with "0"

18.17.2 FORMULA SECTION

The bank specific and bank not specific calculations are done separate

18.17.2.1 Function active - bank not specific calculations

In this case are checked:
Operating point
Coolant temperature
Combustion conditions

18.17.2.1.1 Check of the operating point

Deactivation of the diagnosis, when the mass air flow and rotational speed exceed defined range. Additional, dynamic of the torque request are checken

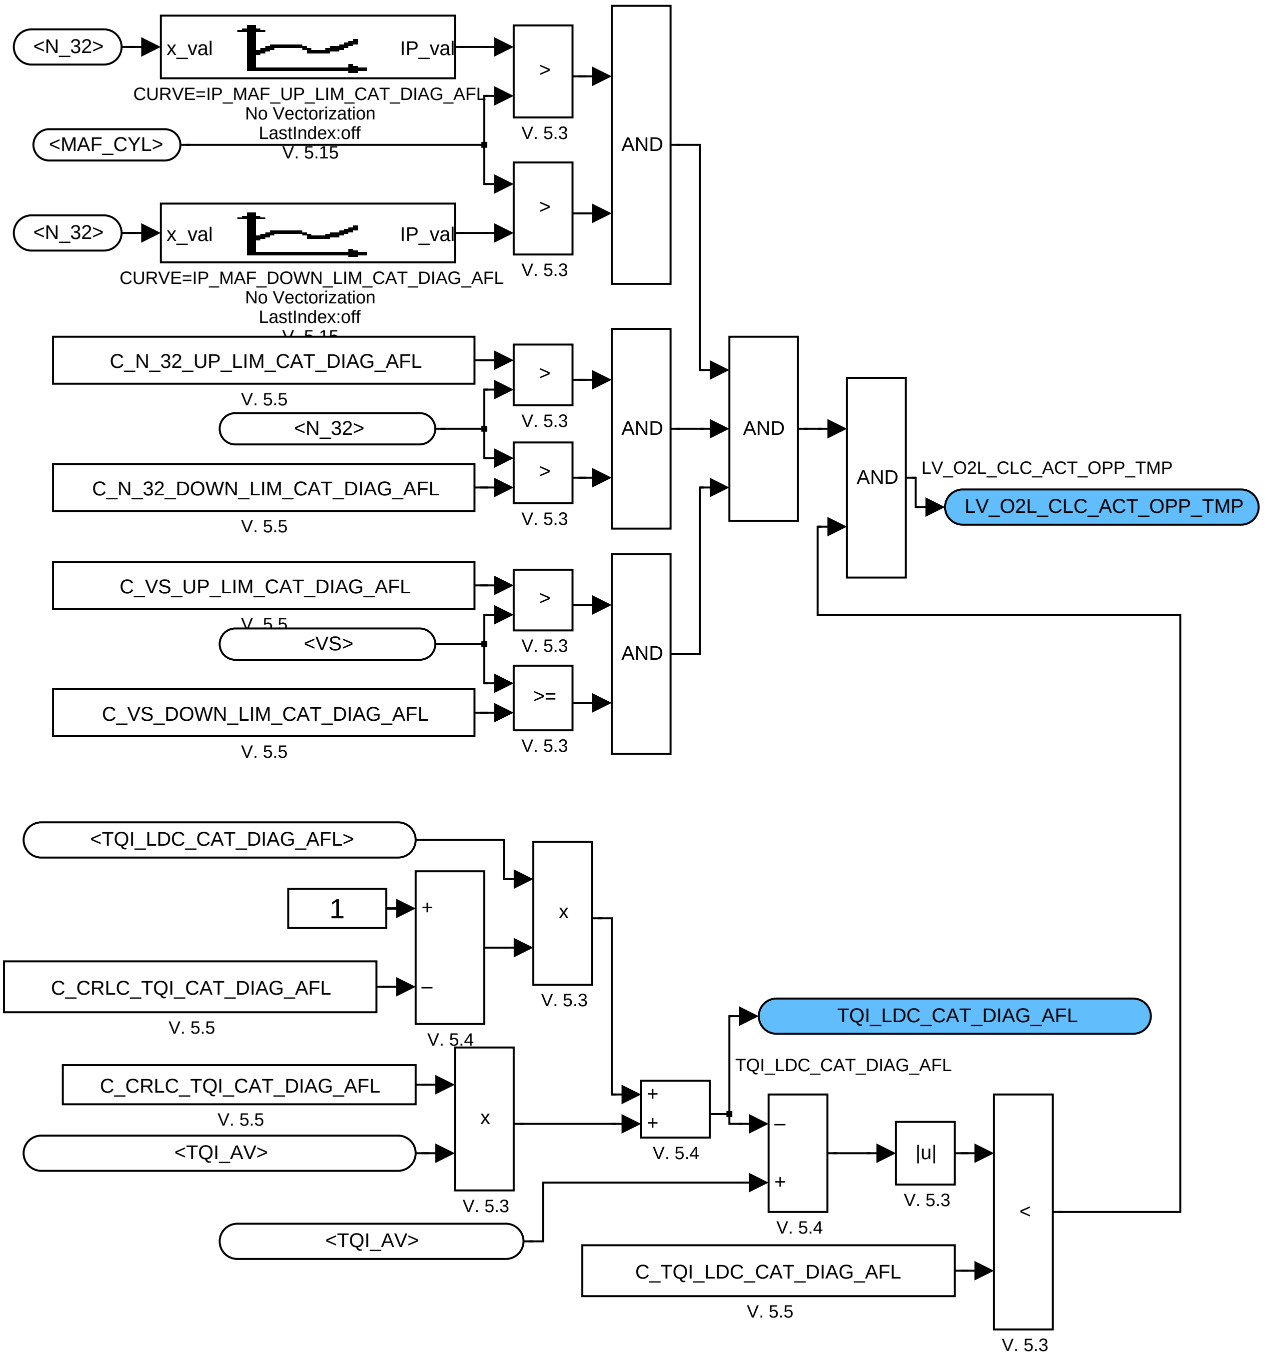


Figure 176:

18.17.2.1.2 Check of coolant temperature

Deactivation of the diagnosis, when the coolant temperature exceeds defined range

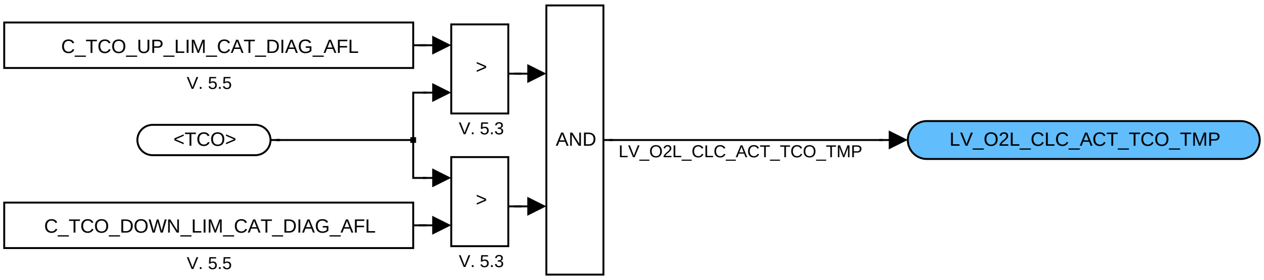

Figure 177:

18.17.2.1.3 Check of the combustion conditions

Deactivation when the NOx after treatment equipment is not active

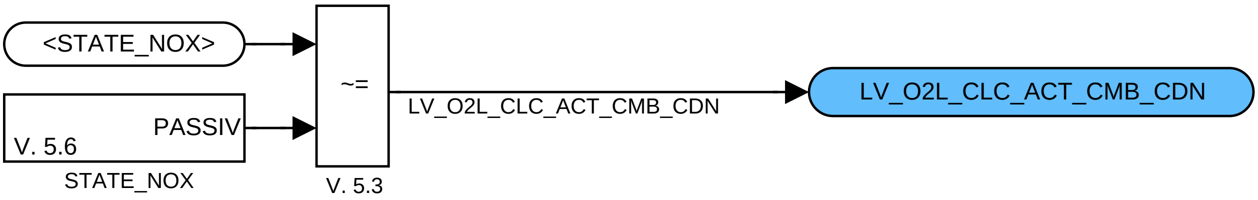

Figure 178:

18.17.2.2 Function active - bank specific calculations

18.17.2.2.1 Check of bank specific activation conditions

In this case:
The static temperature of TWC monolith is checked
The limited dynamic of TWC monolith temperature is checked
The MAF integral is calculated after high load phase
The final activation condition flag is calculated

18.17.2.2.1.1 Check of the TWC and NT monolith temperatures

Deactivation of the diagnosis, when the monolith temperatures of TWC and NT (NOx Trap) exceed defined range. For the NT, a mean value of the both monolith is used. In case of down limit of the TWC temperature, it can be different for catalysts with different aging state

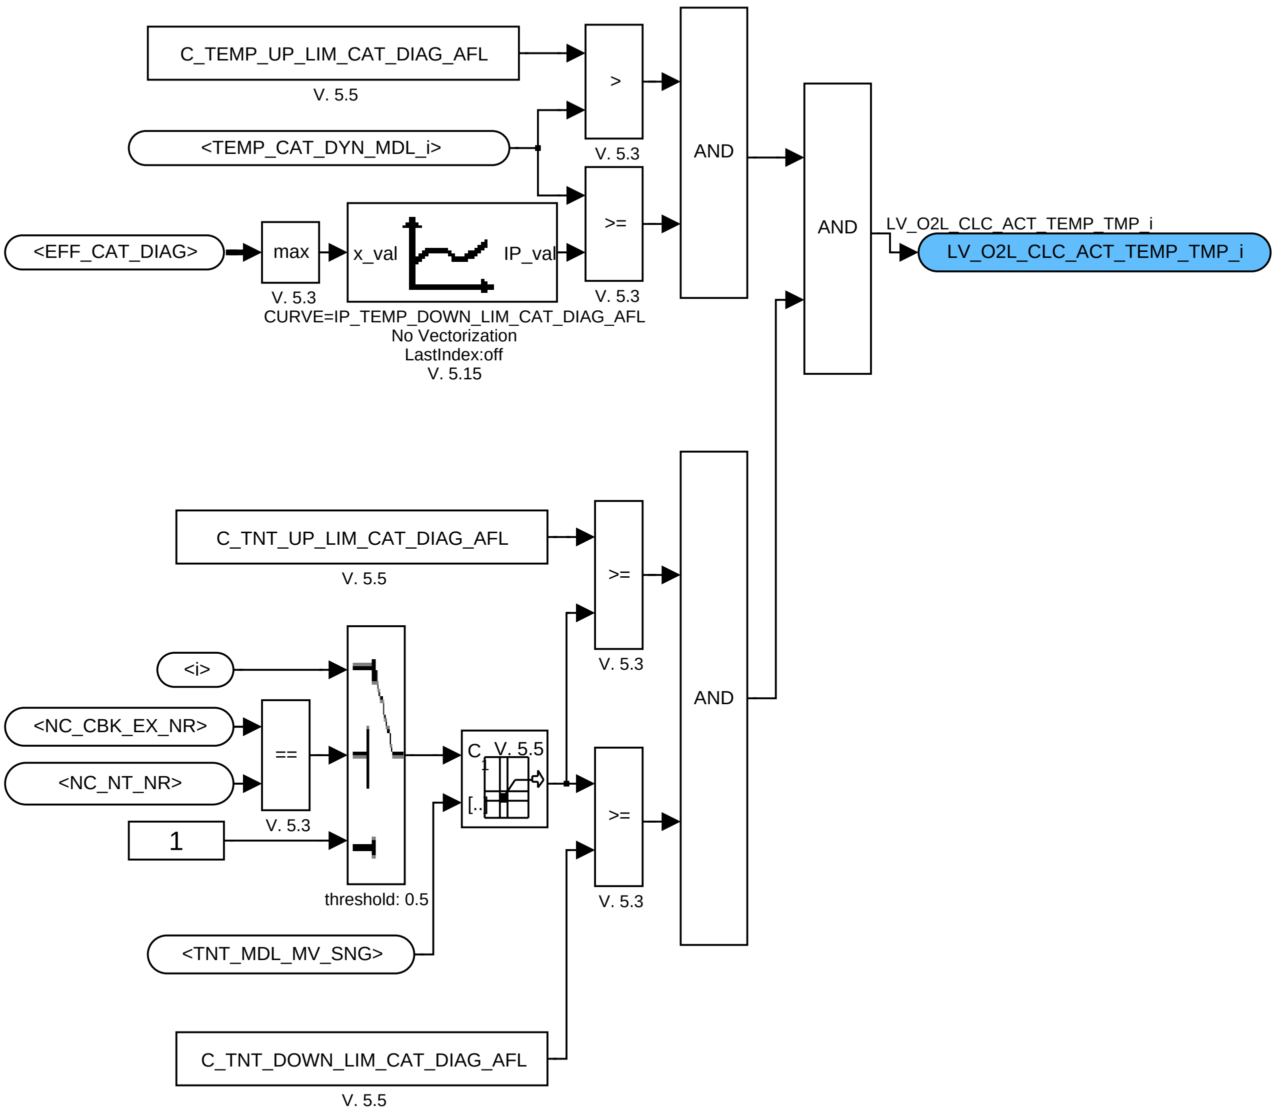

Figure 179:

18.17.2.2.1.2 Check of the limited dynamic of the TWC monolith temperature

The difference between filtered and not filtered TWC monolith temperature is shall not exceed defined threshold

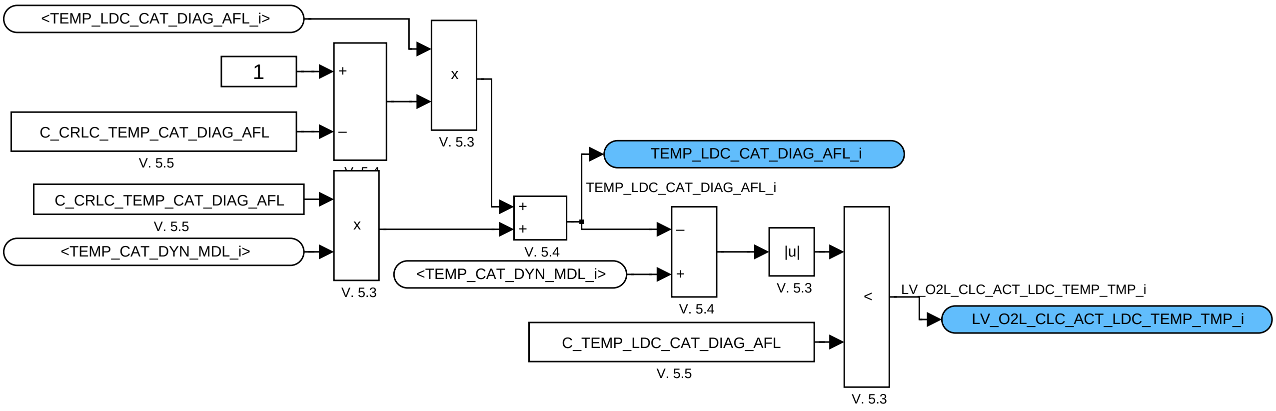

Figure 180:

18.17.2.2.1.3 Check of the MAF integral

Deactivation of the diagnosis after high load phase till defined MAF integral is not released

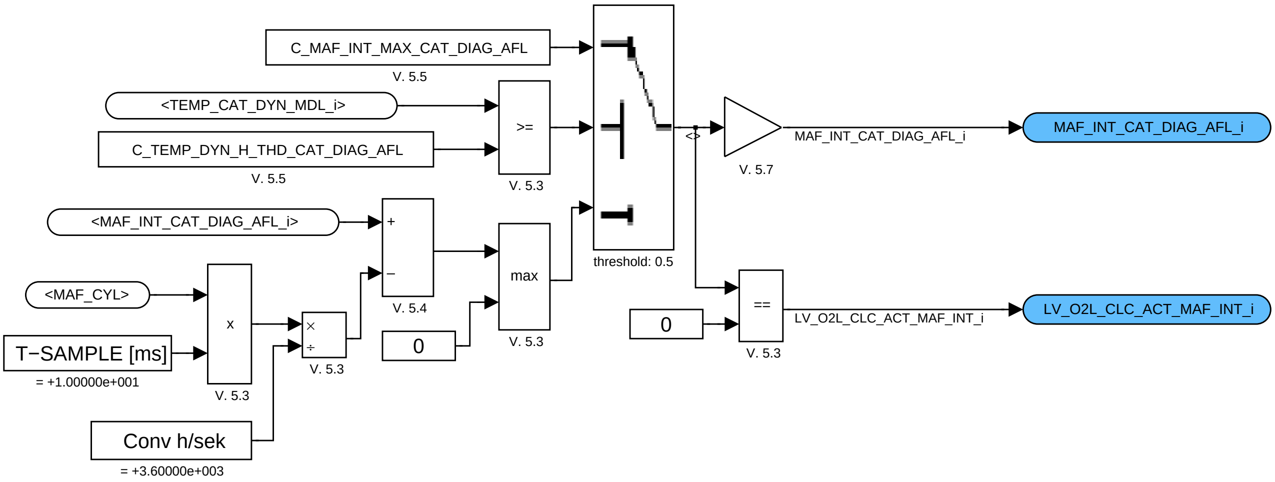

Figure 181:

18.17.2.2.1.4 Calculation of the final activation flag

The end activation flag results from the condition checked in this module, the inhibition condition and the diagnosis end condition. The diagnosis is deactivated when the calculation of it results is finished

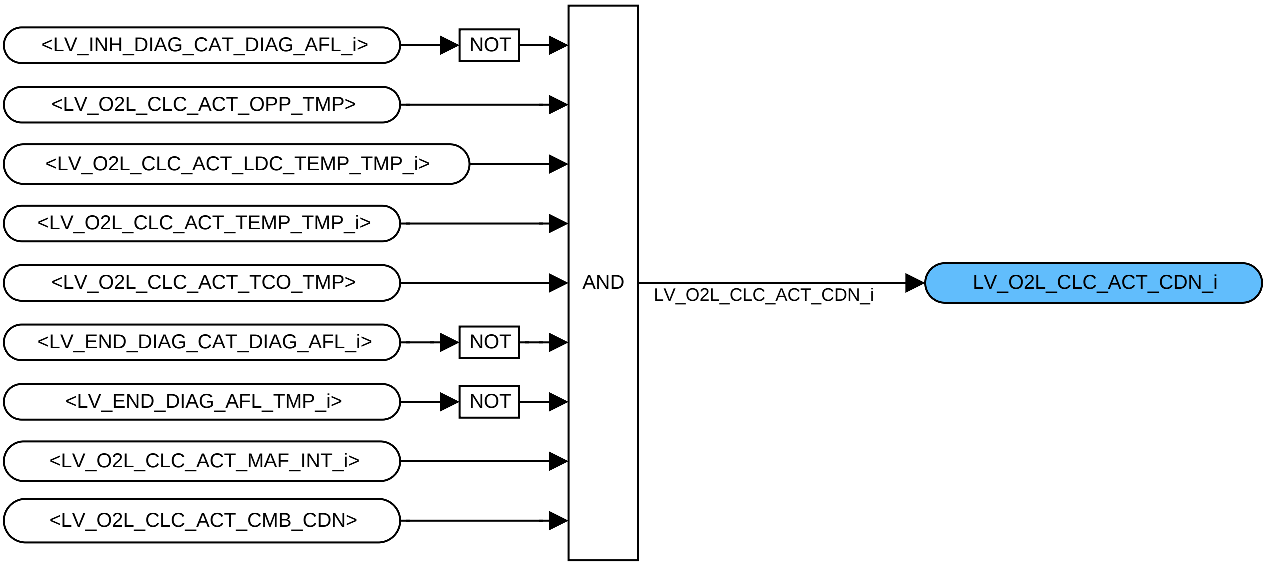

Figure 182:

18.17.2.3 Check activation conditions

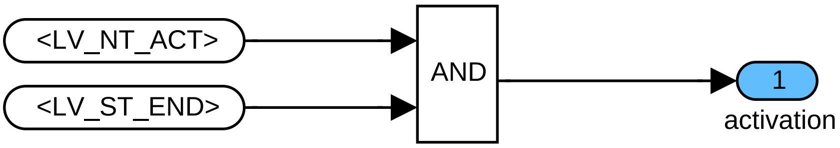

Figure 183:

18.17.2.4 Function not active

All variables are set to "0"

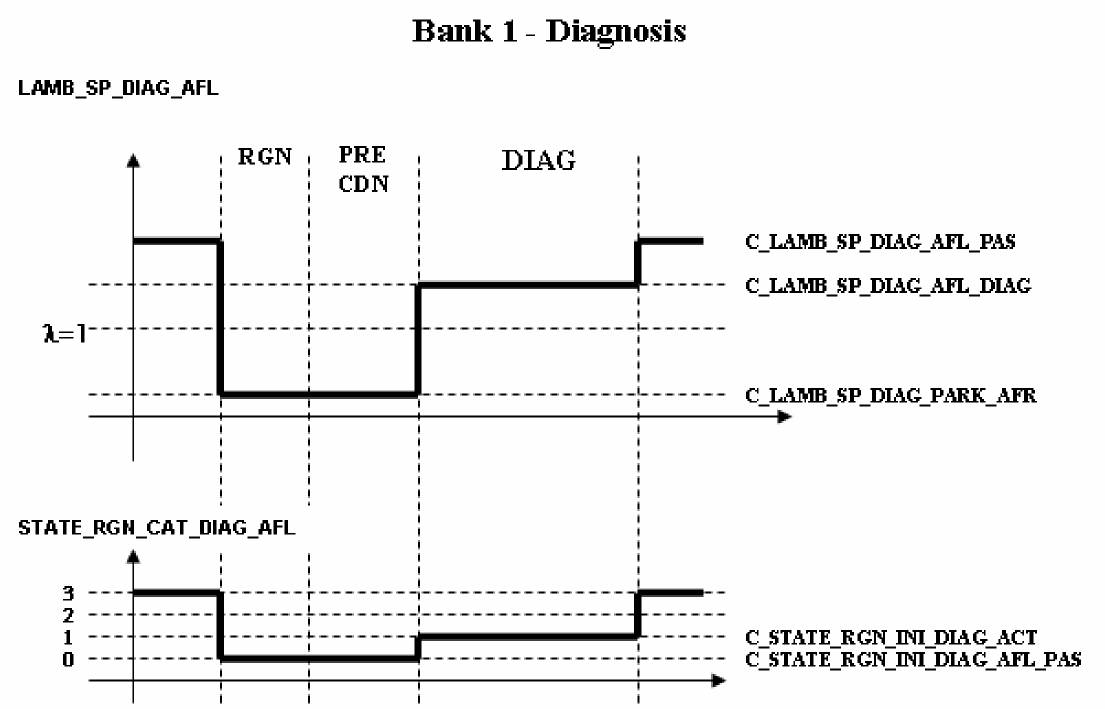
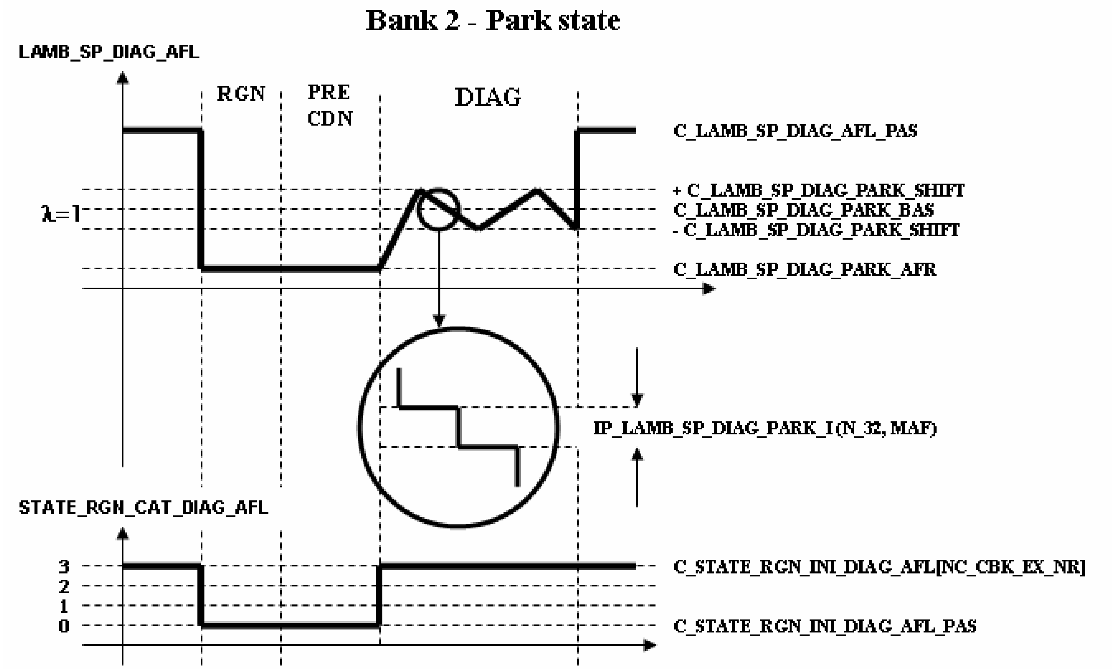
General Information

For the configuration without binary sensor after one bank, phases with rich and lean lambda value are required. When this conditions are not given by NOx Catalyst Regeneration, then a separately lambda setpoint directly after regeneration is generated. Directly before switching to the diagnosis, rich precondition of the catalysts is possible. Moreover, for each bank is used different lambda setpoint strategy. While at first bank (Picture 1, diagnosis) are the O2L values of the precatalyst and of the whole exhaust line (precatalyst + NOx Trap) calculated, the second bank (Picture 2, park state) is parked to minimize it influence to the diagnosed bank. The strategy is successively switched between both banks.

Picture 1: Lambda setpoint strategy for the diagnosed bank:



Picture 2: Lambda setpoint strategy for the parked bank:



Bank 2 - Park state

Application Conditions

Initialization: RST

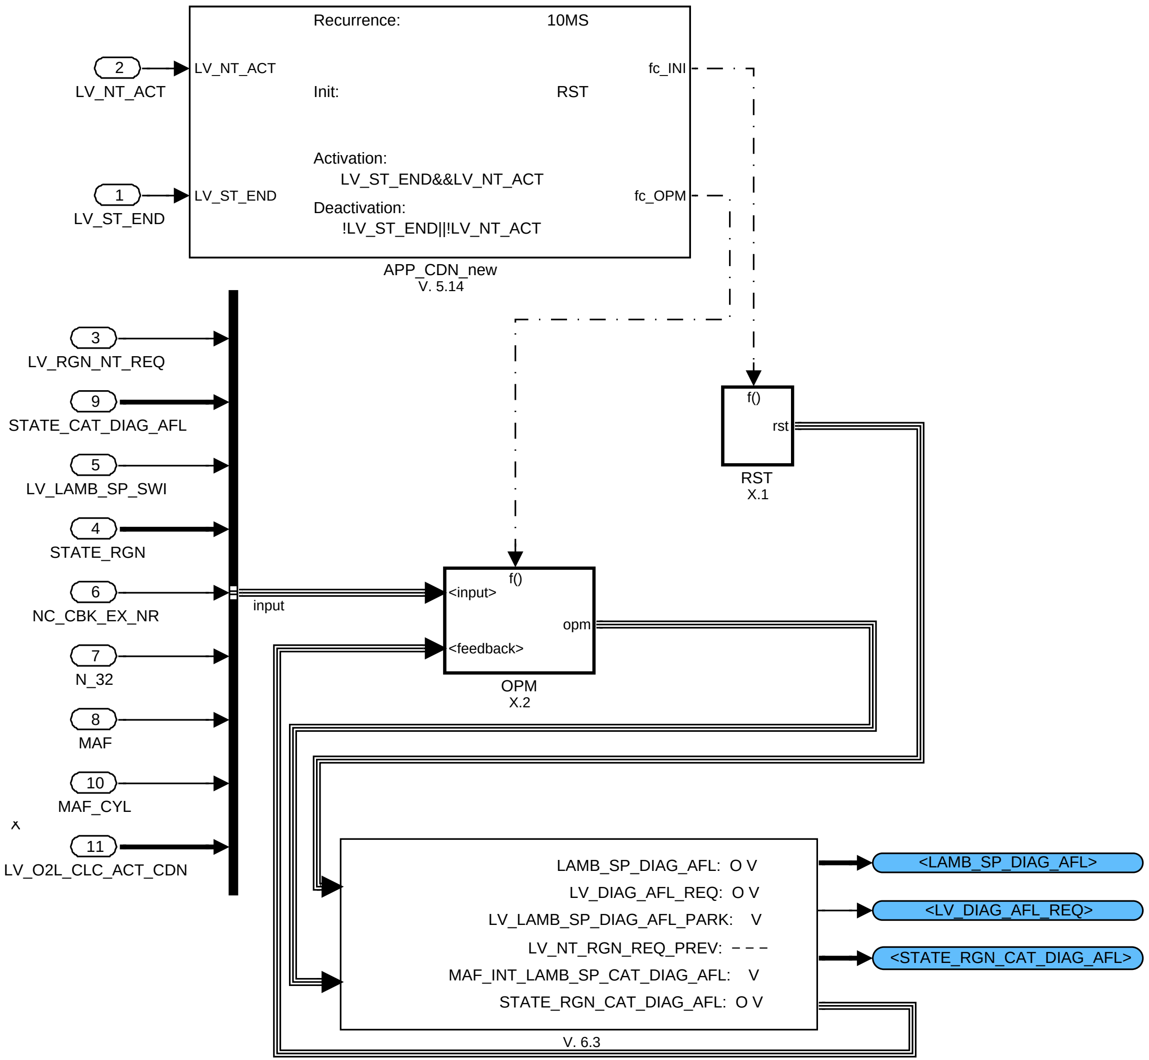
Activation: LV_ST_END && LV_NT_ACT
Deactivation: !LV_ST_END || !LV_NT_ACT

Function description



SDA_SRS / SDA V 5.2.3 22−Jan−2007

Figure 184:

18.18.1 INITIALIZATION AT RESET

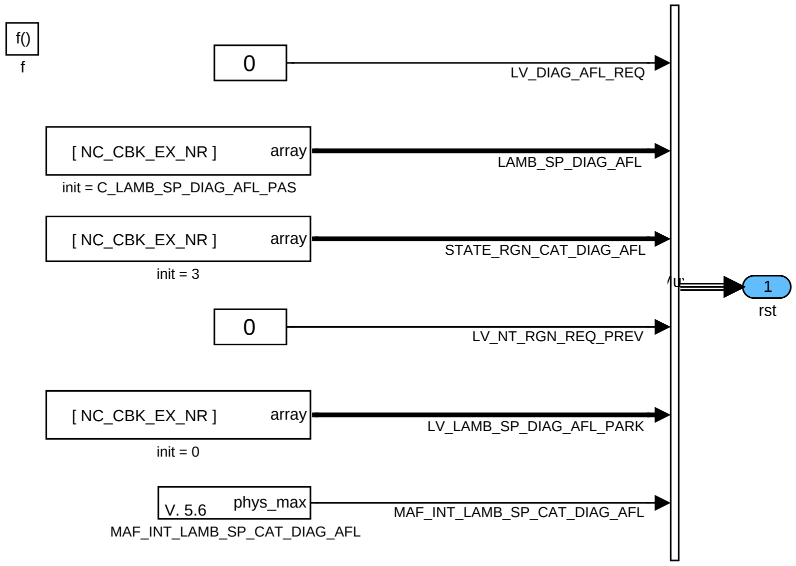


Figure 185:

18.18.2 FORMULA SECTION

The calculation of the STATE_RGN_CAT_DIAG is only active when the lambda behaviour during regeneration doesn't suit the requirements for the diagnosis. Otherwise the STATE_RGN is taken for the other modules of this diagnosis.
Then the activation flag for calculation of O2L values is checked. If any bank is not active, all variables are initialized.
The function contains of two main sections:
1.2.1: Calculation of the lambda setpoint and the regeneration state for the diagnosis (LAMB_SP_CLC)
1.2.2: Passive state (LAMB_SP_NOT_CLC)
1.2.3: Initialization when the activation conditions are not fulfilled

18.18.2.1 Initialization when the activation flag for O2L calculation at any bank is false

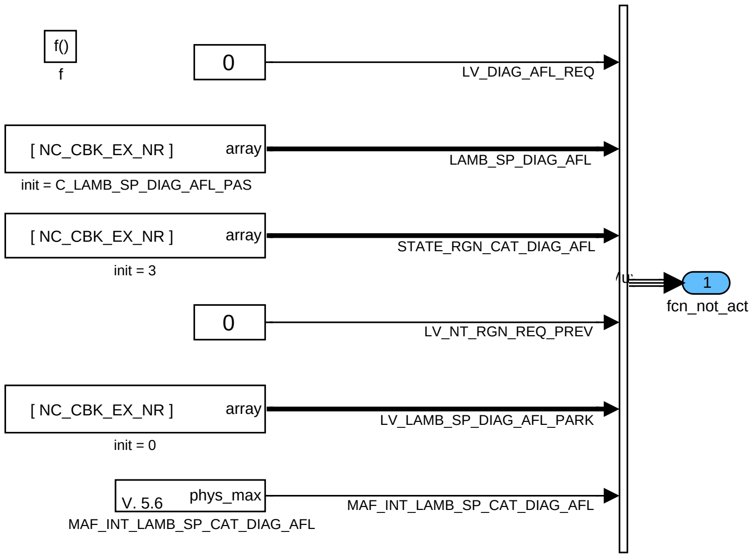

Figure 186:

18.18.2.2 CALCULATION OF THE LAMBDA SETPOINT AND THE REGENERATION STATE FOR THE DIAGNOSIS (LAMB_SP_CLC)

The calculation is split up into following sections:
- Request for the diagnosis
- Calculation of the regeneration state for the diagnosis
- Calculation of the lambda setpoint
- Calculation of the old variables

18.18.2.2.1 Request for the diagnosis

As long as the request LV_DIAG_AFL_REQ is set, the lambda set point for the system is defined by this function. This request is reset, when either all, or just any bank (depending on initialization STATE_RGN_CAT_DIAG_AFL of that bank, which will not be diagnosed in current cycle) switches to STATE_CAT_DIAG_AFL=PASSIVE

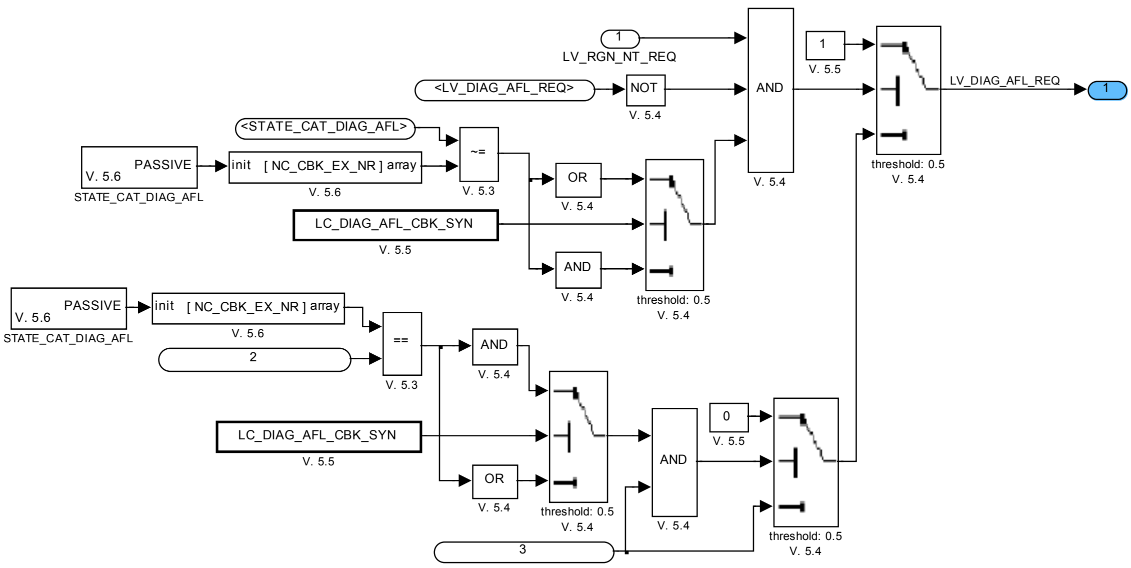

Figure 187:

18.18.2.2.2 Calculation of the regeneration state for the diagnosis

The own regeneration state for the diagnosis is initialized at the beginning of the NOx Trap regeneration. When the Nox Trap regeneration is finished, then depending on calibration a precondition phase is started. When the precondition is finished, then the own regeneration state is initialized accordingly for activation of the diagnosis at relevant bank and neutral park of the other

18.18.2.2.2.1 Check conditions

Check of the NOx Trap regeneration state, precondition state and bank alternate bit. The calculations follow in next picture

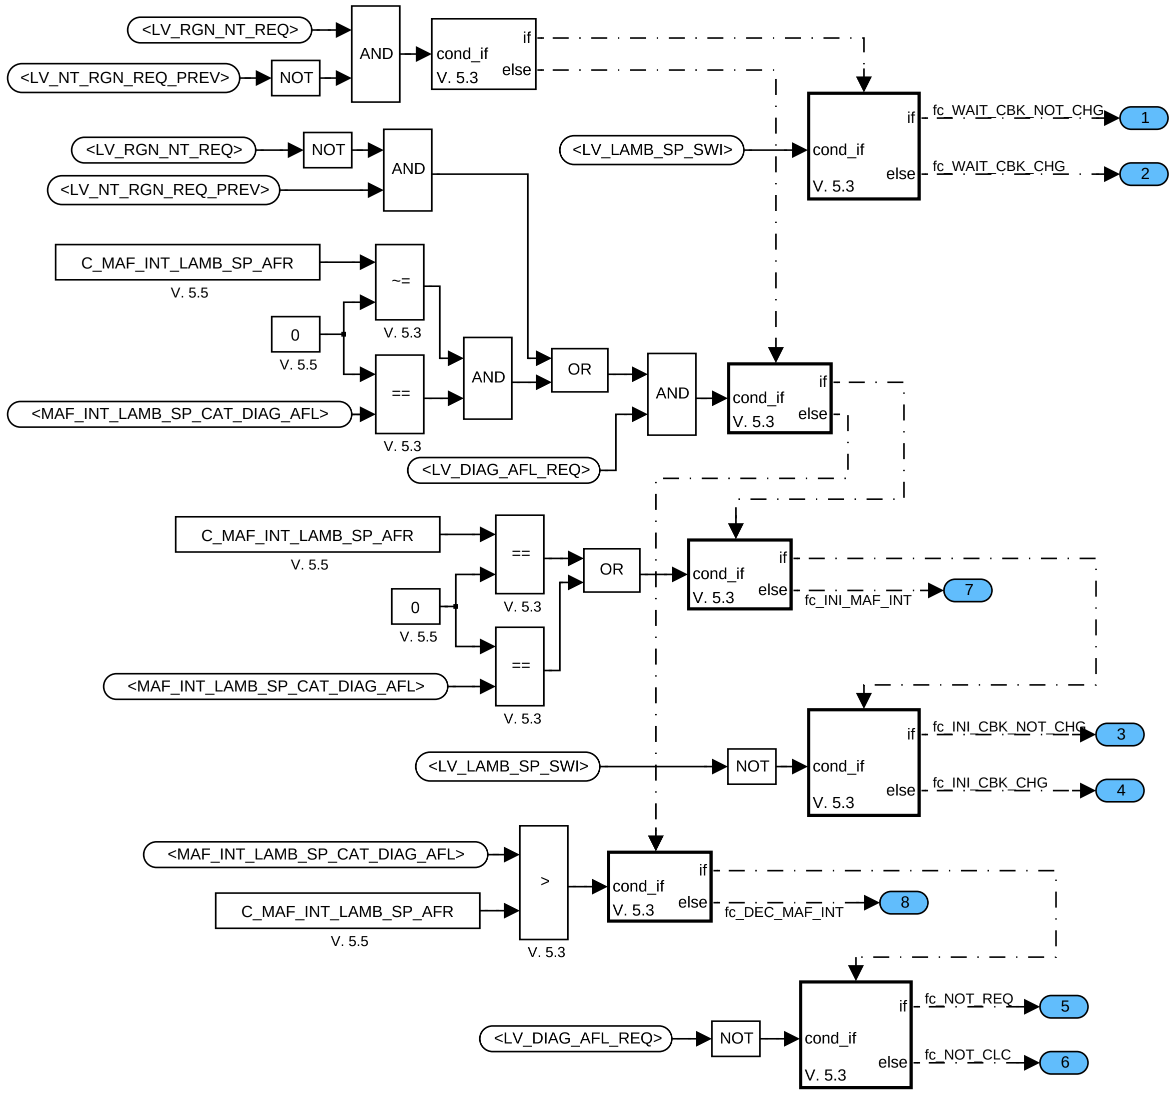

Figure 188:

18.18.2.2.2.2 Calculations

Calculation of the own regeneration state, lambda set point and MAF integral is done in following cases:

a) Waiting for the end of the Nox Trap regeneration and precondition, banks not interchanging
b) Waiting for the end of the Nox Trap regeneration and precondition, banks interchanging accordingly to C_STATE_RGN_INI_DIAG_AFL_PAS
c) Initialization for diagnosis state without interchanging of the banks
d) Initialization for diagnosis state with interchanging of the banks accordingly to C_STATE_RGN_INI_DIAG_AFL
e) Request for the diagnosis d sn't exist
f) Request for the diagnosis exists, but initializations don't take place
g) Initialization of the MAF integral for precondition phase
h) Decrementing of the MAF integral during precondition phase

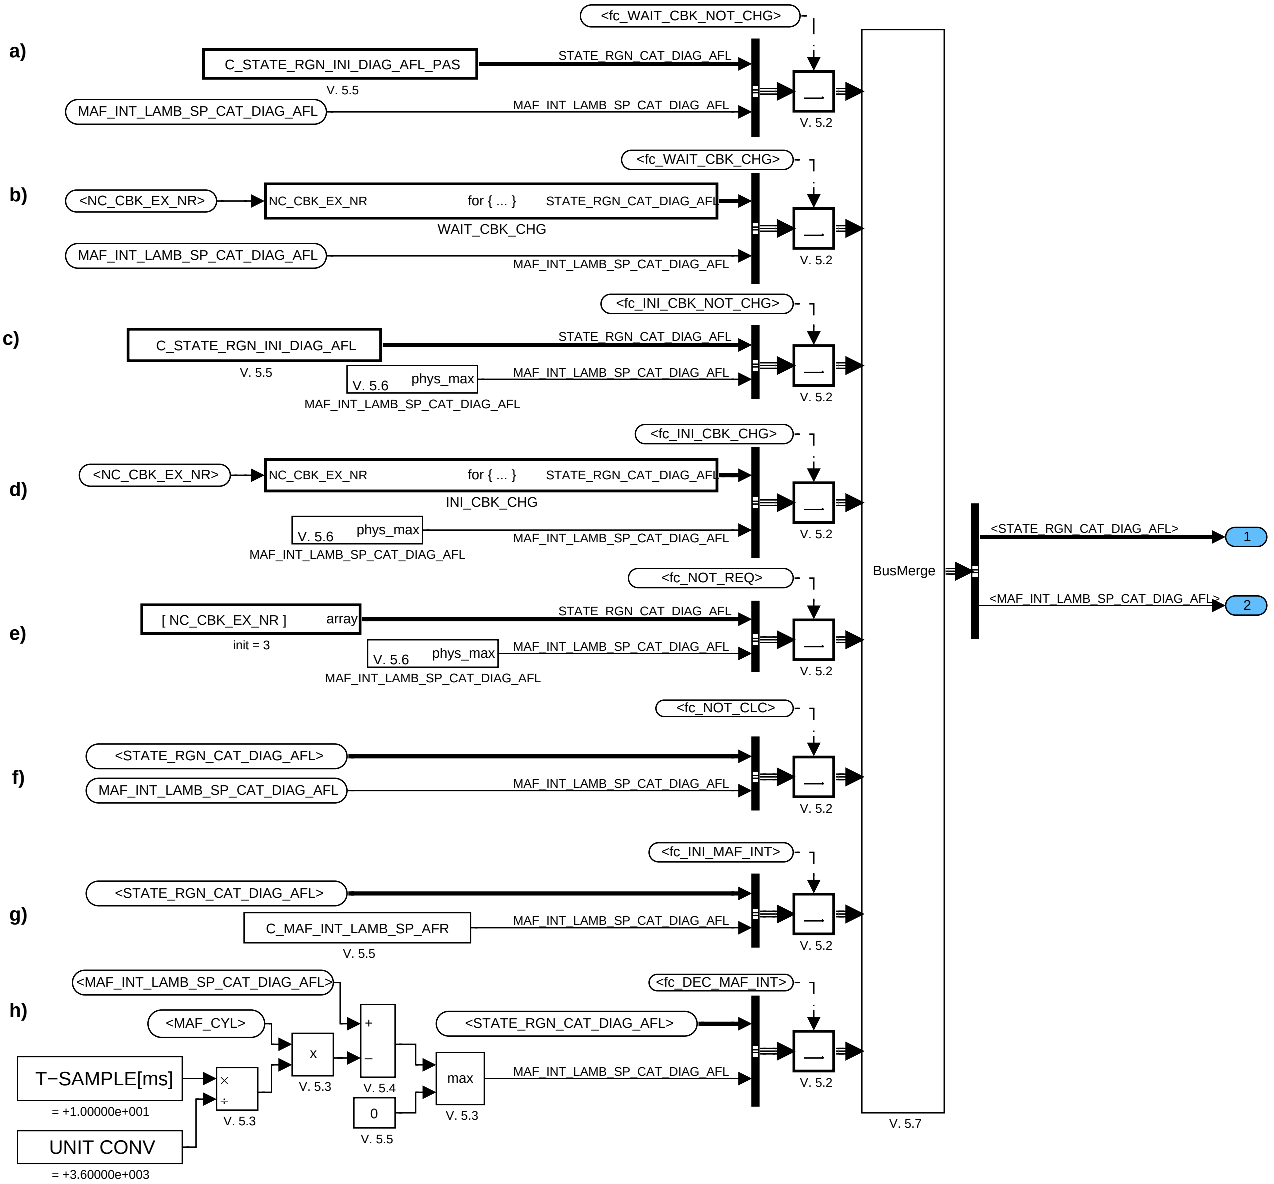

Figure 189:

18.18.2.2.3 Multiple bank system

18.18.2.2.3.1 Bank specific calculations - Lambda set point

The lambda set point for the precondition phase is active directly after Nox Trap regeneration. During this regeneration "WAIT" is active. After precondition the lambda set point for the diagnosed bank is calculated ("DIAG"), for the parked bank ("PARK") the calculations are done inside CLC_LAMB_PARK. When the request for the diagnosis isn't active, PASSIVE is called

18.18.2.2.3.1.1 Check of the regeneration and diagnosis requests

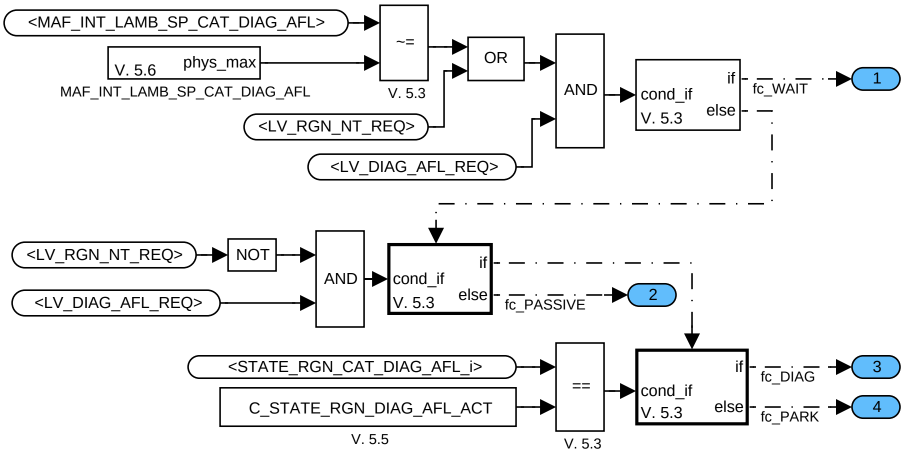

Figure 190:

18.18.2.2.3.1.2 Calculation of the lambda set point

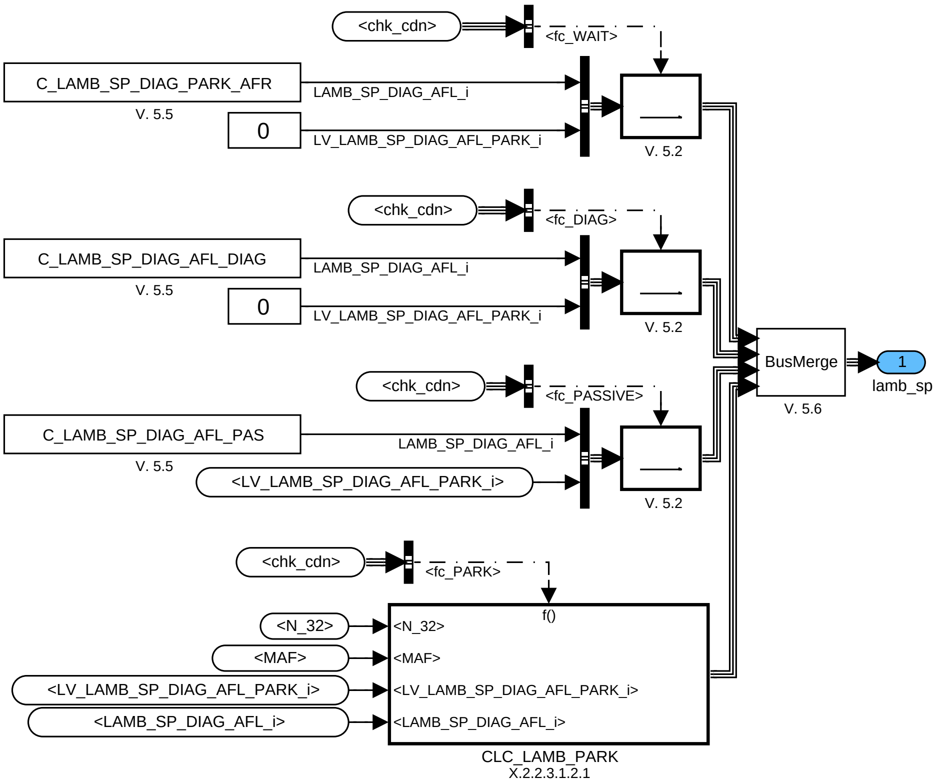

Figure 191:

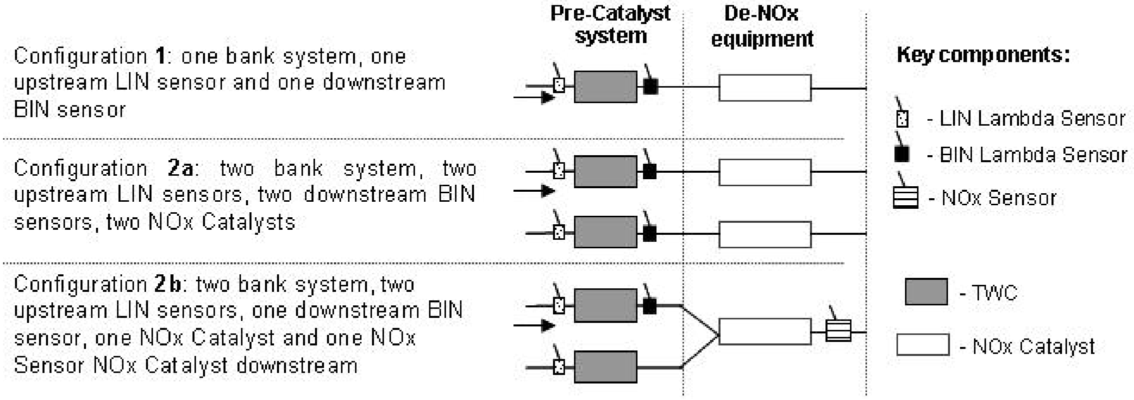
General Information

For calculation of O2L the fresh gas per cylinder, linear lambda signal (TWC upstream), binary lambda signal (TWC downstream or NOx-Trap downstream) are used. The O2L removal is calculated when the linear lambda signal upstream shows the rich mixture (less then 1) and the binary lambda signal downstream shows the lean mixture (less then 500 [mV]). The O2L addition is calculated when the linear lambda signal upstream shows lean mixture (greater then 1) and the binary lambda signal downstream shows the rich mixture (greater then 500 [mV])

If two separate exhaust bank system are concerned, the diagnosis is relevant for two exhaust gas configurations switched with C_STATE_EX_CONF:
CONF_1: Exhaust gas configuration equipped with DeNOx technology, with two LIN-Sensors upstream TWC, two BIN-Sensors downstream TWC, two NOx Traps (NT) and one NOx-Sensor downstream NT (Picture 1, configuration 2a)
CONF_2: Exhaust gas configuration equipped with DeNOx technology, with two LIN-Sensors upstream TWC, one BIN-Sensor downstream TWC, one NOx Traps (NT) and one NOx-Sensor downstream NT (Picture 1, configuration 2b)

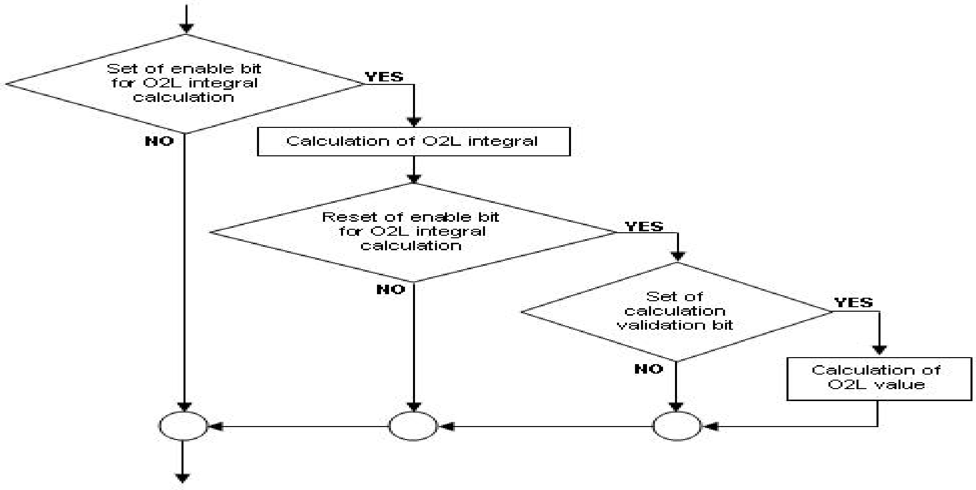
Picture 1: Exhaust gas configurations



The O2L-values are calculated in four cases:
Case 1: Regeneration with high amplitude
Case 2: Regeneration with low amplitude
Case 3: Park phase (for CONF_1 calculated O2L concerns TWC, for CONF_2 calculated O2L concerns sum of TWC and NT)
Case 4: Load phase

For each case for the calculation of O2L is one validation bit in STATE_O2L_CLC_VLD[NC_CBK_EX_NR] defined:
Bit 0 (STATE_O2L_CLC_VLD_B0): Case 1
Bit 1 (STATE_O2L_CLC_VLD_B1): Case 2
Bit 2 (STATE_O2L_CLC_VLD_B2): Case 3
Bit 3 (STATE_O2L_CLC_VLD_B3): Case 4

Picture 2: Signal flow for calculation of O2L values:



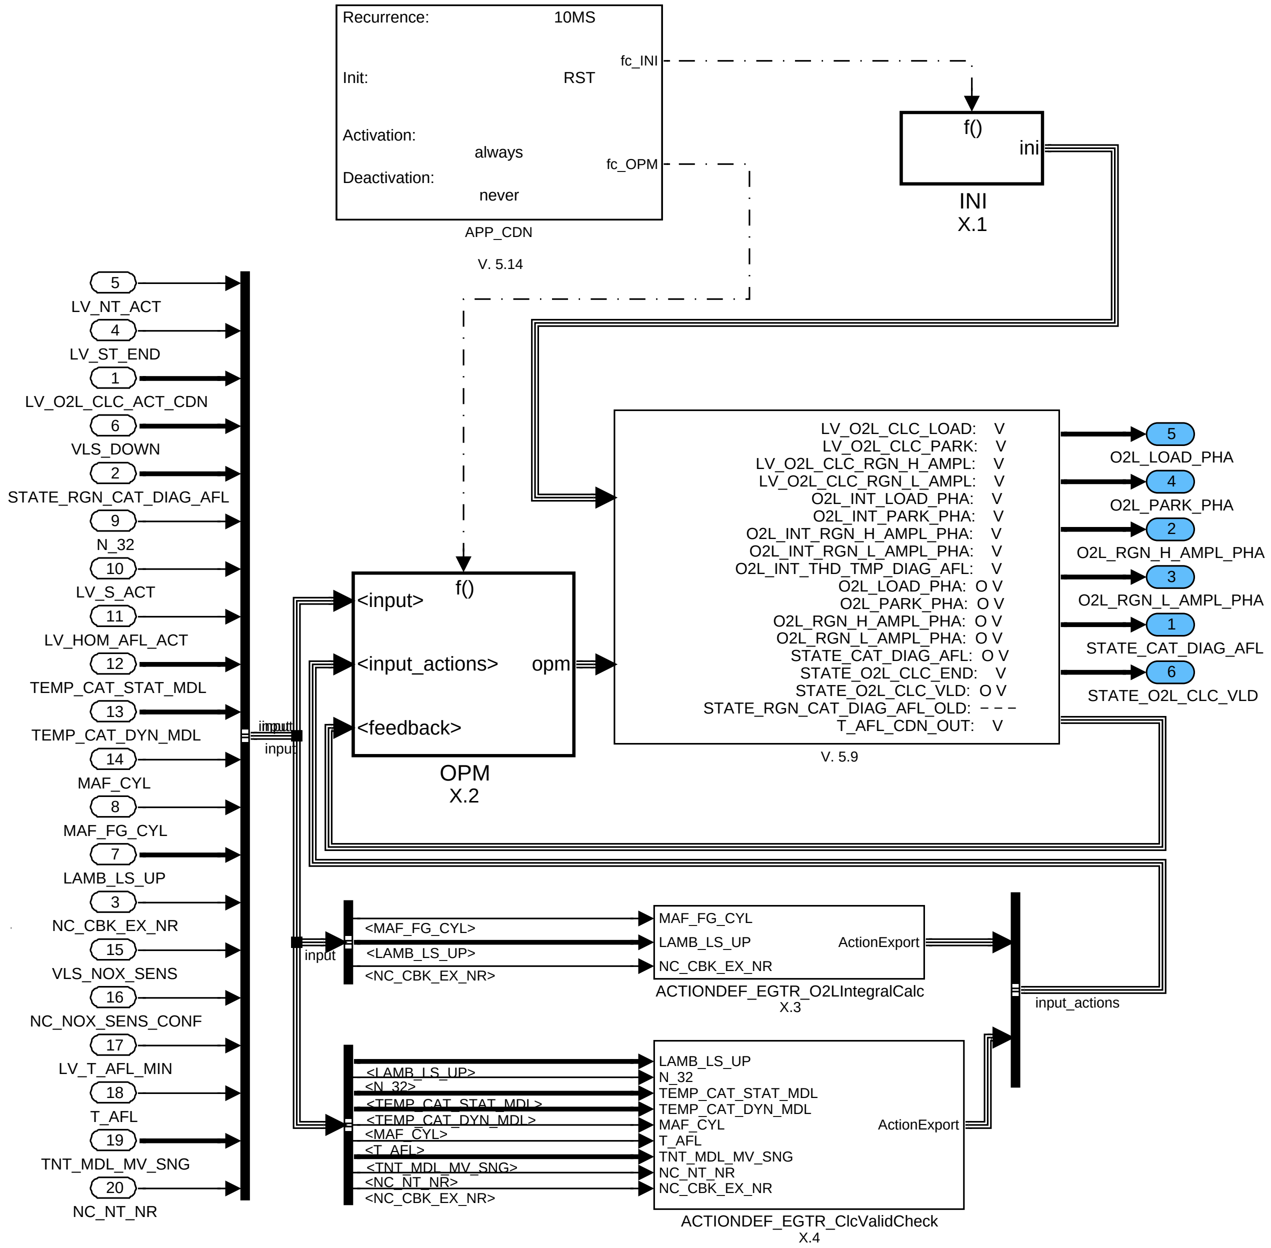
If two separate exhaust bank systems are concerned, then:
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2
Otherwise:
i = 1

NC_NOX_SENS_CONF is the number of NOx-Sensors. Therefore
NC_NOX_SENS_CONF = 0, for no NOx-Sensor
NC_NOX_SENS_CONF = 1 (n = 1), for one NOx-Sensor
NC_NOX_SENS_CONF = 2 (n = i), for two NOx-Sensors

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: always
Deactivation: never

Function description



SDA_SRS / SDA V 5.2.5 26−Feb−2007

Figure 199:

18.19.1 Initialization

O2L_INT_THD_TMP_DIAG_AFL=C_O2L_INT_THD_TMP_DIAG_AFL
All other variables are initialized with "0"

18.19.2 Formula section

All calculations are bank specific
Additional information:
"i" is an indicator for current bank within of for loop depending on NC_CBK_EX_NR.
"n" is an indicator for signals of NOx-Sensor. Therefore:
Case 1: If NC_CBK_EX_NR=1 then n=1 (in system the number of NOx-Sensors can not be greater then number of exhaust bank).
Case 2a: If NC_CBK_EX_NR=2 and NC_NOX_SENS_CONF=1 then n=1

Case 2b: If NC_CBK_EX_NR=2 and NC_NOX_SENS_CONF=2 then n=i

18.19.2.1 Check of the activation condition

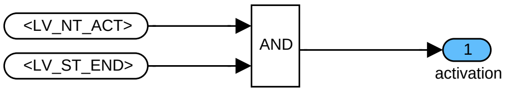


Figure 200:

18.19.2.2 Activation condition fulfilled

18.19.2.2.1 Overview of the function structure

At first, checking of transition condition and generation of function call for the active state of state machine "STATE_CAT_DIAG_AFL" are done. When the transition conditions are not fulfilled, the same state as in previous cycle is executed. In one calculation cycle only one state can be executed. The old value of STATE_RGN (for each bank separate) is also calculated after calculating of STATE_CAT_DIAG_AFL

18.19.2.2.1.1 STATE FLOW

Calculation of STATE_CAT_DIAG_AFL and generation of the function call for execution of one of it states

18.19.2.2.1.1.1 STATE_CAT_DIAG_AFL

18.19.2.2.1.2.1.1 Calculations

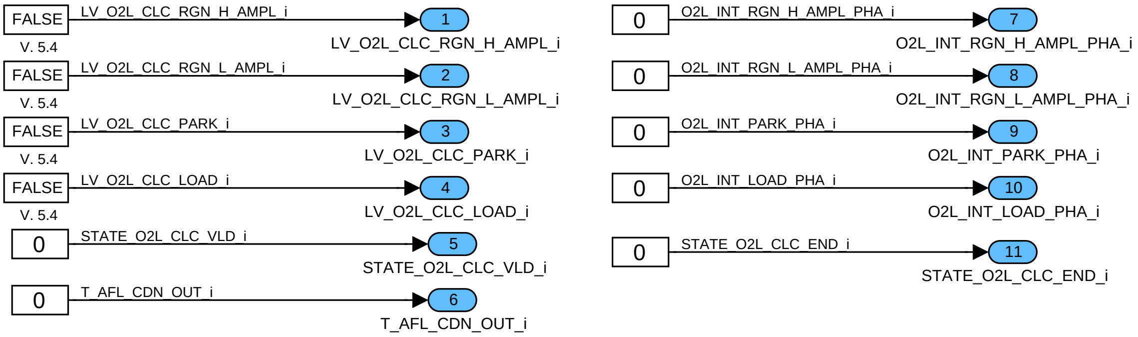

Figure 202:

18.19.2.2.1.2.2 STATE ACTION: STATE_CAT_DIAG_AFL="RICH_CDN"

In this states the O2L is calculated in one of two cases: either during high regeneration phase or during low regeneration phase.
For every of these phases are calculated separately:
a) Activation flag
b) O2L removal

For both phases:
a) Validation bits of O2L is calculated (BIT 0 for high amplitude phase and BIT 1 for low amplitude phase, BIT 2 and 3 are not calculated)
b) Counter for exit from LEAN-CDN is not changed
c) Outputs of not active state are calculated (LEAN_CDN)

18.19.2.2.1.2.2.1 OSC calculation in high amplitude regeneration - activation flag

Switching between exhaust gas configurations for calculation of the activation flag is done using C_STATE_EX_CONF

18.19.2.2.1.2.3 STATE ACTION: STATE_CAT_DIAG_AFL="LEAN_CDN"

In this states the O2L is calculated in one of two cases: either during park phase or during load phase.
For every of these phases are calculated separately:
a) Activation flag
b) O2L addition

For both phases:
a) Validation bits of O2L (BIT 2 for park phase and BIT 3 for load phase, BIT 0 and BIT 1 are not calculated)
b) Counter for exit from LEAN-CDN phase
c) Outputs of not active state (RICH_CDN)

18.19.2.2.1.2.3.1 OSC calculation in park phase - activation flag

Switching between exhaust gas configurations for calculating of activation flag

18.19.2.2.1.2.3.1.1 STATE_EX_CONF_1

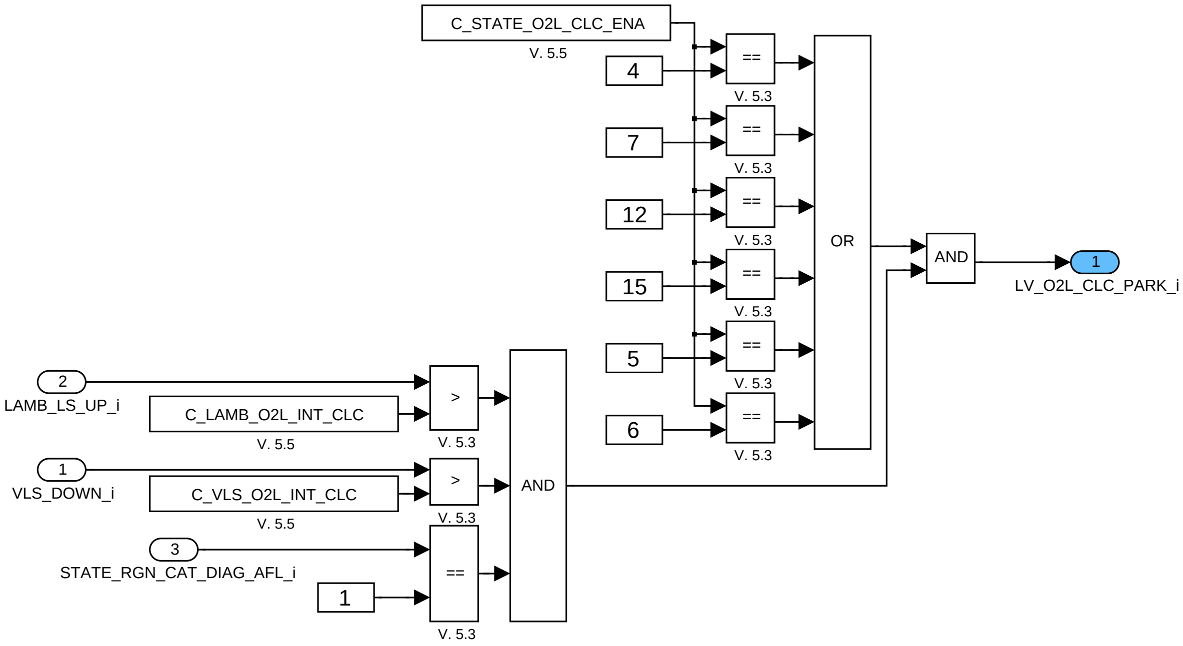

Figure 216:

18.19.2.2.1.2.3.1.2 STATE_EX_CONF_2

Apart from common conditions for calculation of the O2L integral in PARK phase, the bit 2 (saying that the calculation is finished), is checked. It shall forbid a recalculation of the O2L integral in PARK phase. Additional, to optimize the diagnosis duration, the calculation can be stopped when the O2L integral reaches defined threshold

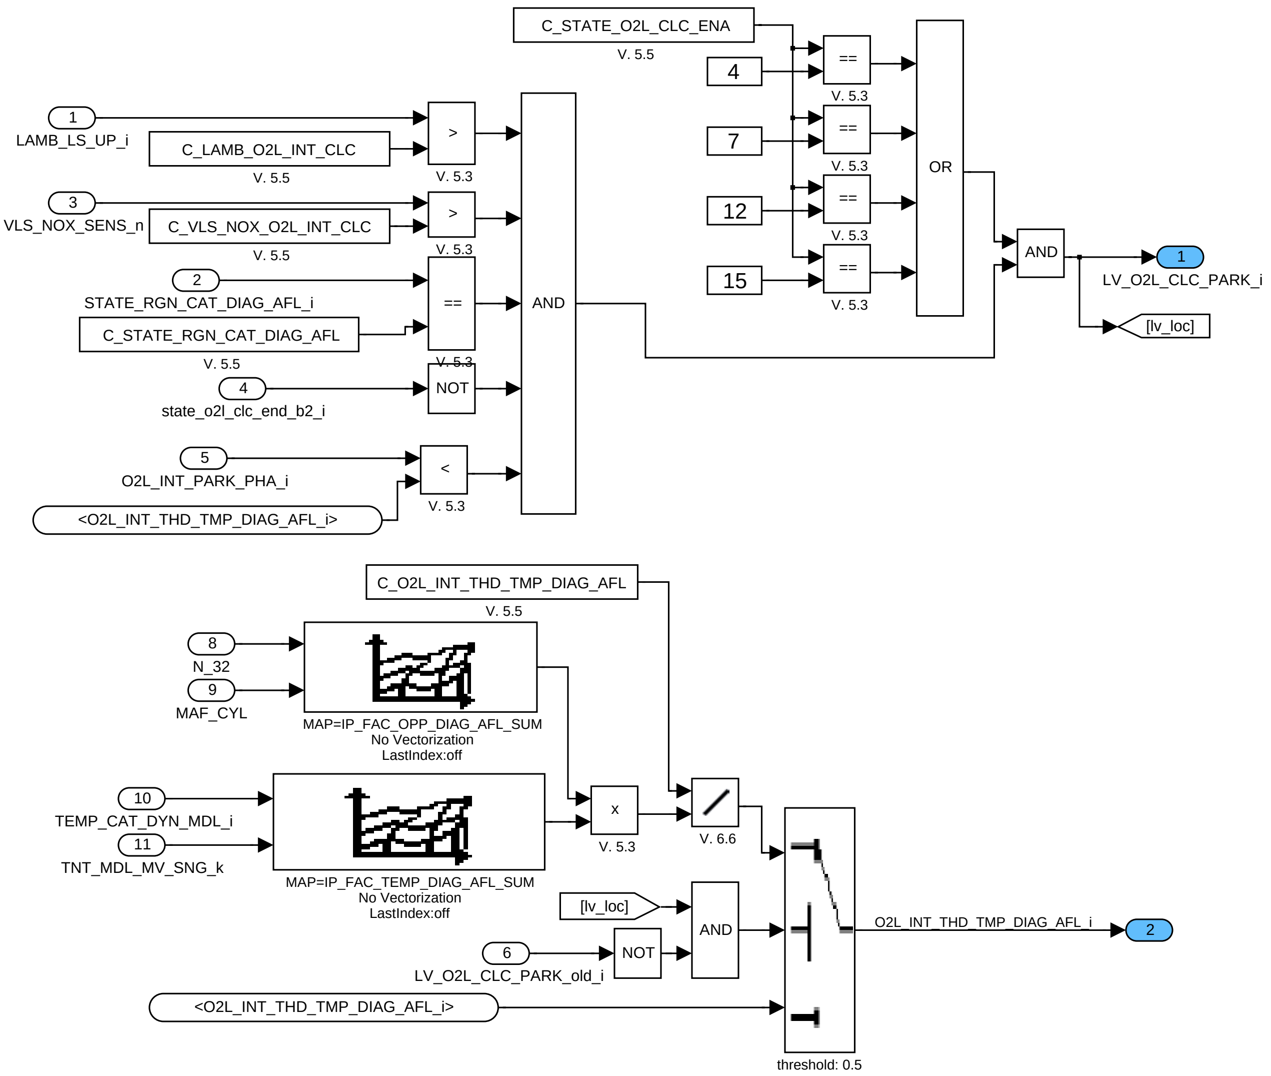

Figure 217:

18.19.2.2.1.2.3.2 OSC calculation - park phase

The calculation of O2L is done in two steps:
Step 1: Calculation of O2L integral
Step 2: Calculation of O2L after calculating of O2L integral

18.19.2.2.1.2.3.2.1 Calculation of O2L-integral at park phase

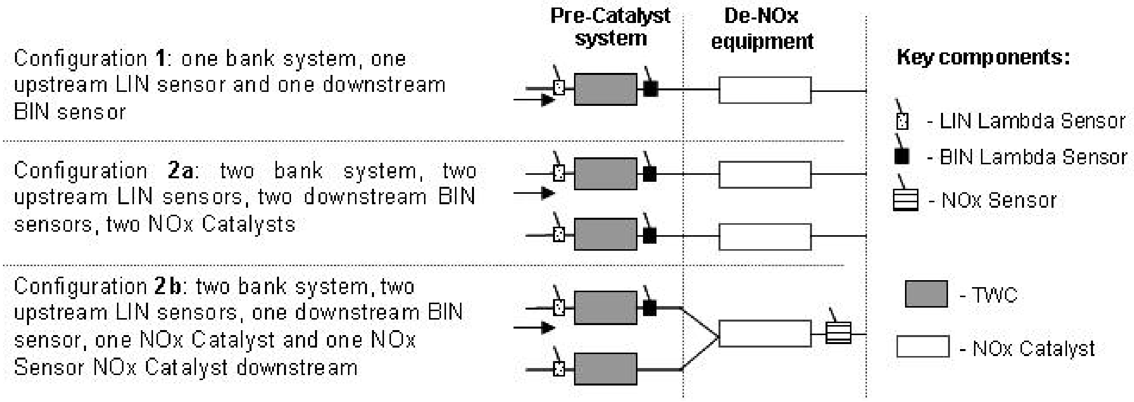
General Information

In this module the diagnosis values are calculated and the link to the error management is implemented.
The calculation of diagnosis value is possible in several ways. Only one method is taken for calculation of finally diagnosis value. Choice of method is partly depending on exhaust gas configuration and number of regeneration cycles during diagnosis cycle. The finally bank specific diagnosis value is after that taken for calculation of diagonally diagnosis value. At the end the error indicator and the error symptom are calculated using bank specific and bank diagonally diagnosis value and the error management is called with condition "true".
Short description of all methods, numbering is equal to value in C_STATE_O2L_ERR_CLC and bit in STATE_O2L_MV_CLC_VLD:
Method 0: Mean value of O2L calculated during regeneration with high amplitude phase (excepted configuration 2b)
Method 1: Mean value of O2L calculated during regeneration with low amplitude phase (excepted configuration 2b)
Method 2: Mean value of O2L calculated during park phase (excepted configuration 2b)
Method 3: Mean value of O2L calculated during load phase (excepted configuration 2b)
Method 4: Mean value of O2L mean values calculated in all occurred phases (excepted configuration 2b)
Method 5: Corrected O2L value with empirical method to compensate of lambda sensor dynamic using phases with high and low regeneration amplitude (except configuration 2b)
Method 6: Corrected O2L value with mathematical method to compensate of lambda sensor dynamic using phases with high and low regeneration amplitude (except configuration 2b)
Method 7: O2L calculated using TWC- and NOx-Catalyst oxygen storage capacity for calculating of O2L value for bank without downstream Lambda Sensor (only configuration 2b)

Picture 1: The diagnosis is able for following exhaust gas configurations:

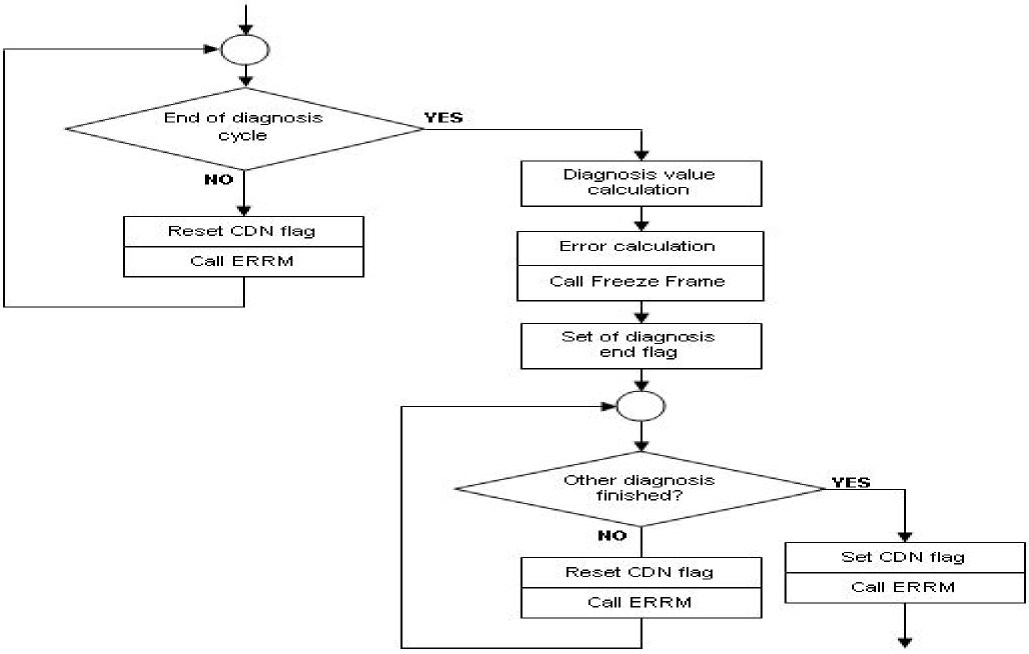


Configuration **1**: one bank system, one upstream LIN sensor and one downstream BIN sensor

Configuration **2a**: two bank system, two upstream LIN sensors, two downstream BIN sensors, two NOx Catalysts

Configuration **2b**: two bank system, two upstream LIN sensors, one downstream BIN sensor, one NOx Catalyst and one NOx Sensor NOx Catalyst downstream

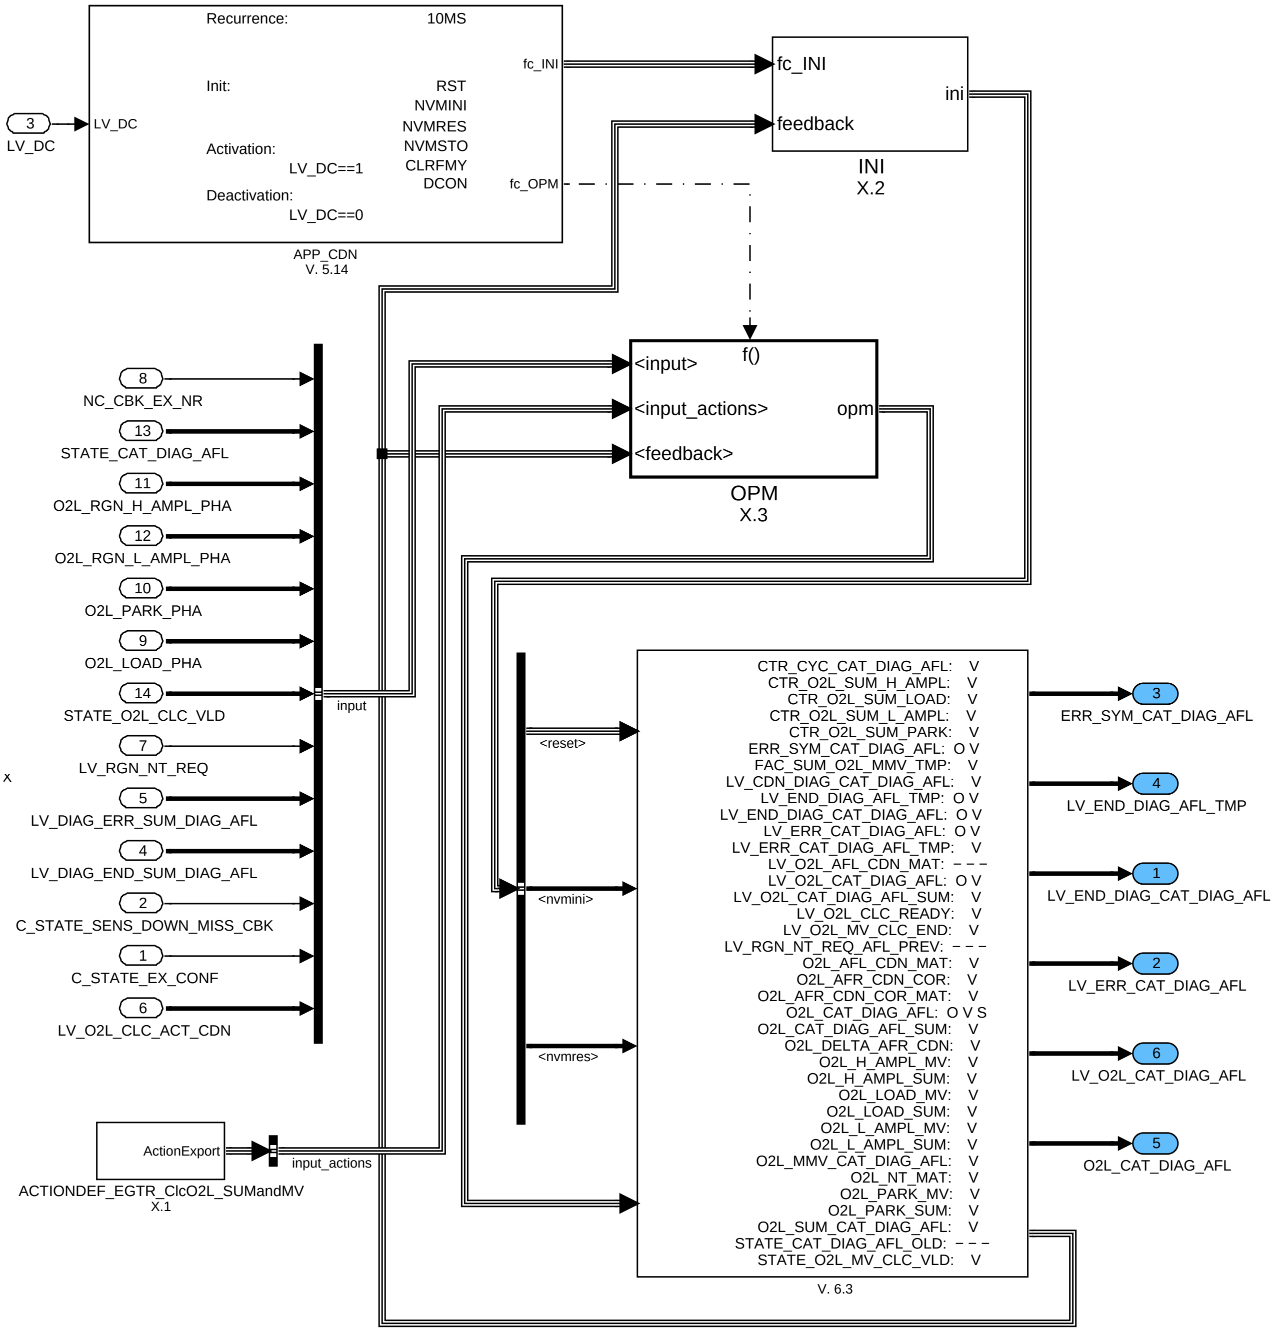
Picture 2: Signal flow for calculation of Error Indicator



If two separate exhaust bank systems are concerned, then:
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2
Otherwise:
i = 1

Application Conditions

Initialization: RST, NVMINI, NVMRES, NVMSTO, CLRFMY
Recurrence: 10MS
Activation: LV_DC==1
Deactivation: LV_DC==0



SDA_SRS / SDA V 5.2.3 07−Feb−2007

Figure 238:

18.20.1 INITIALIZATION

18.20.1.1 Initialization of NVMY data

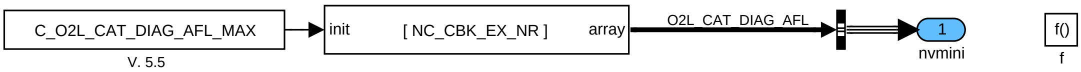


Figure 239:

18.20.1.2 Initialization at reset and function activation (start driving cycle)

At reset and function activation (DCON) all variables except NVMY data and diagnostic result are initialized with "0".
The diagnostic result is initialized according the filtering configuration.

18.20.2 FORMULA SECTION

The formula section consists of two main sections:
Regeneration cycles counter, bank diagonally calculations inclusive calculation of method 7 and the final diagnosis result
Methods 1 to 6 and ERRM interface

18.20.2.1 Regeneration cycles counter, bank diagonally calculations inclusive method 7 and final diagnosis value

18.20.2.1.1 Counting of the regeneration cycles

18.20.2.1.1.1 Bank specific calculation of the regeneration cycles counter

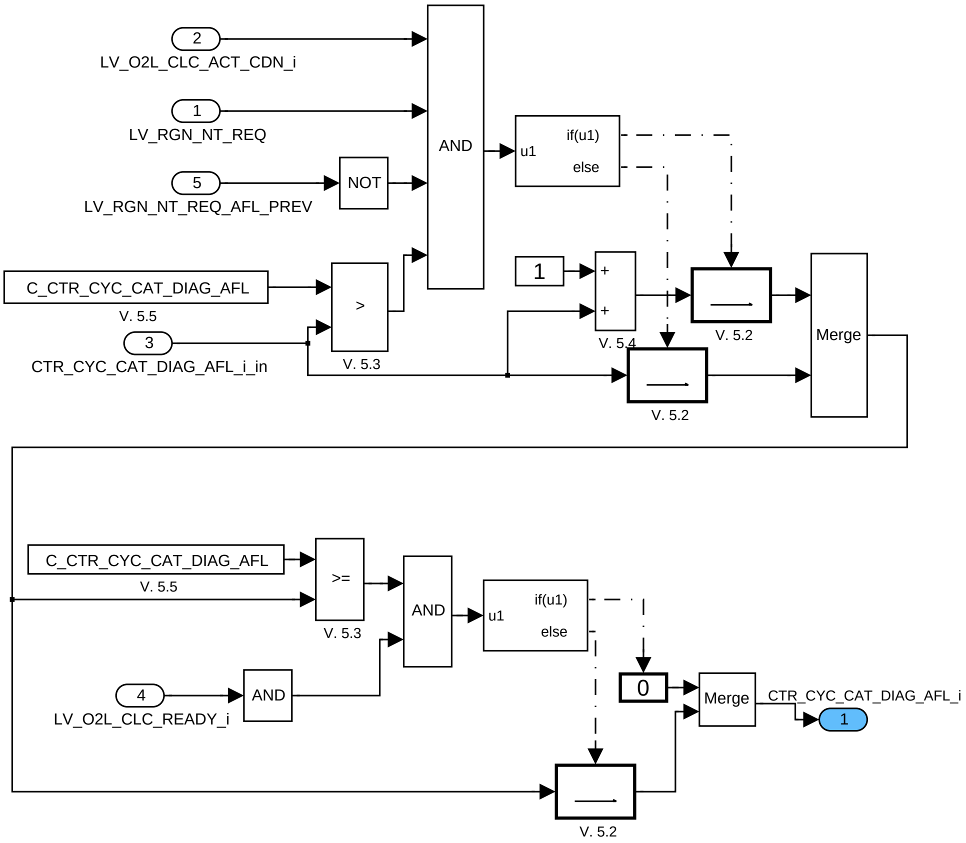

Figure 240:

18.20.2.1.2 Bank diagonally calculations inclusive method 7 and final diagnosis value

This section consists of:
Calculation of flag indicating, that diagnosis on any bank is finished
Calculation of O2L value of NOx-Catalyst in case of configuration 2b
Calculation of temporary O2L value for bank without binary downstream sensor in case of exhaust gas configuration 2b
Calculation of finally O2L value for both banks and validation bit in case of exhaust gas configuration 2b
Choice of method for calculation of finally diagnosis value
Calculation of sum diagnosis value over all banks

18.20.2.1.2.1 Calculation of flag indicating, that diagnosis on any bank is finished

The calculation of all banks is synchronized. This flag says that the calculation of all banks is finished. Then first the diagonal calculation and after that the calculation of diagnosis results is done.
This flag is active only for one cycle.

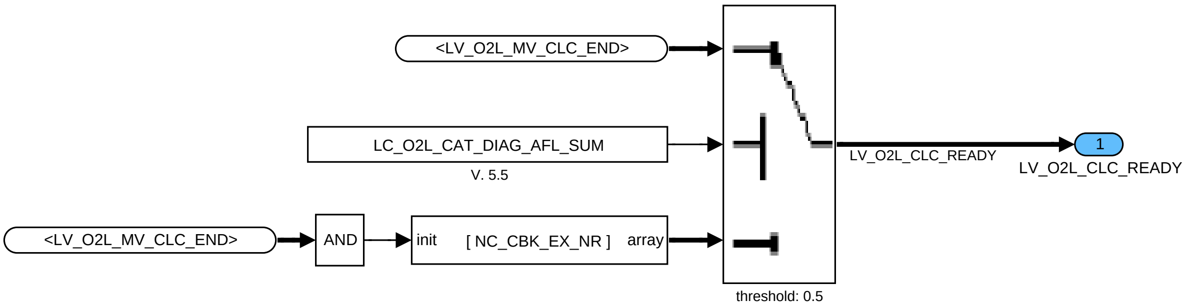

Figure 241:

18.20.2.1.2.2 Calculation of O2L value of NOx-Catalyst in case of configuration 2

The O2L value of NOx catalyst is a difference between O2L value of the whole line and O2L value of precatalyst calculated at bank with downstream binary sensor. The O2L value calculated at bank with downstream binary sensor is corrected according to the dynamic of this sensor. This is given using the IP_FAC_O2L_AFR_CDN_COR (see also Method 5)

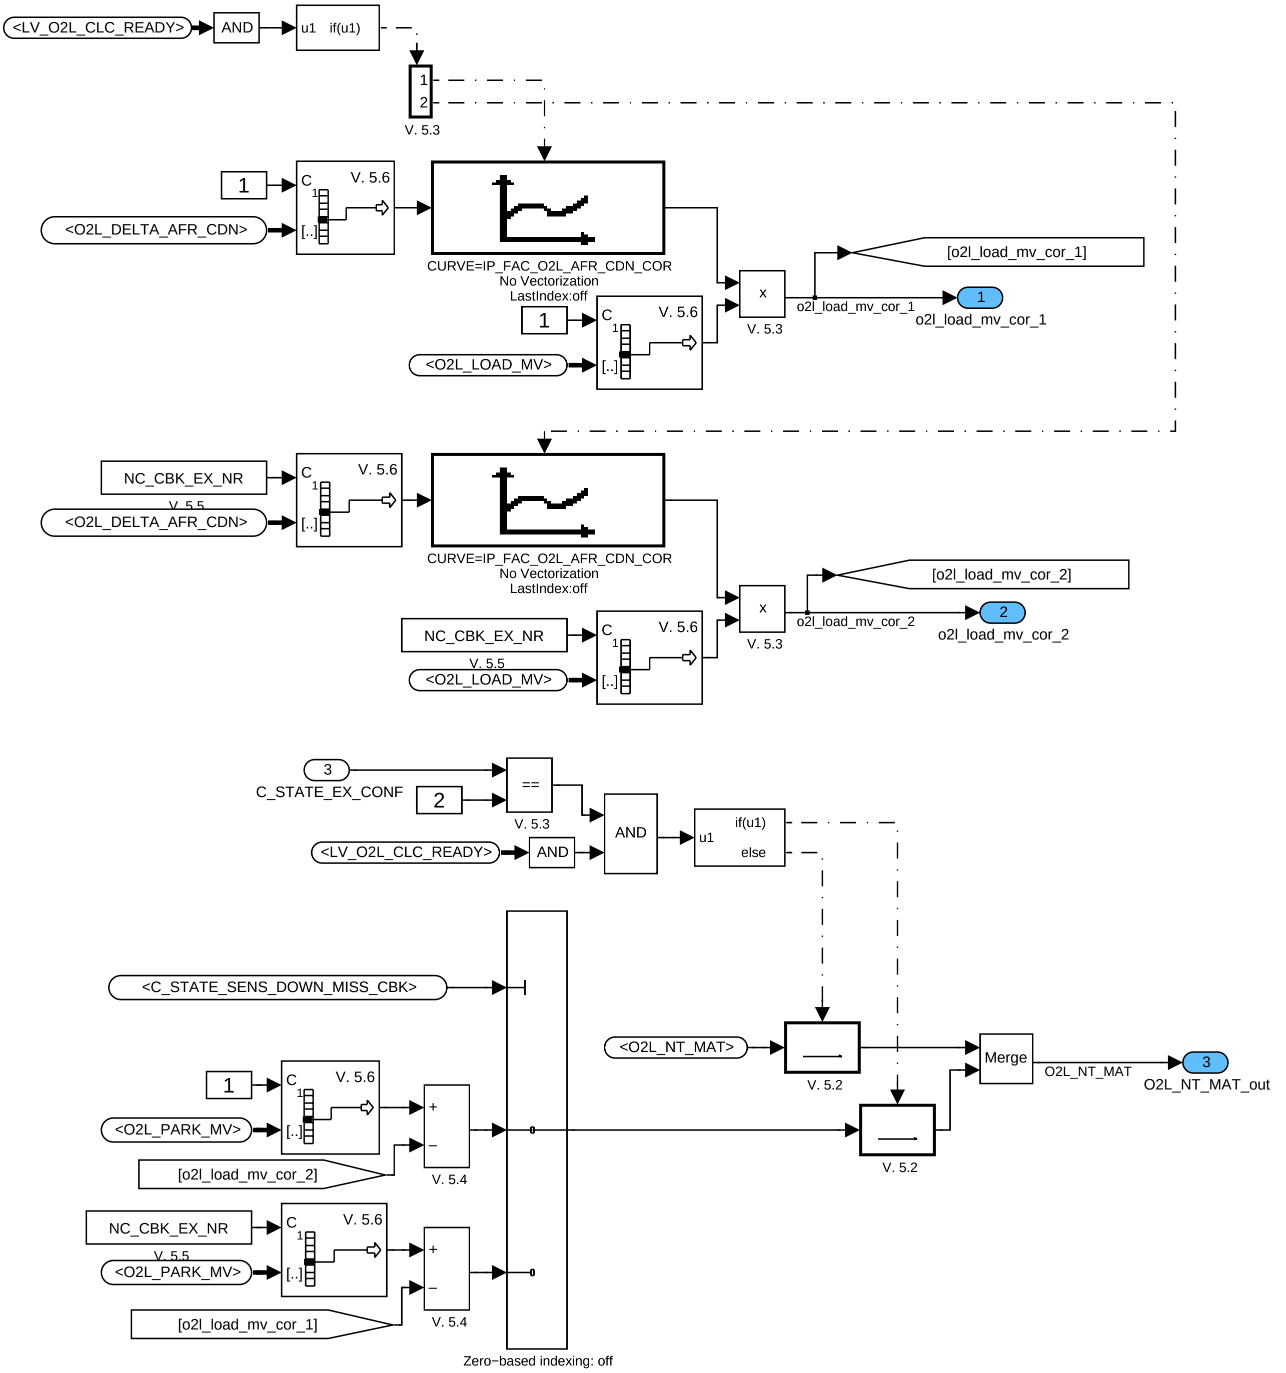

Figure 242:

18.20.2.1.2.3 Calculation of temporary O2L value for bank without binary downstream sensor in case of exhaust gas configuration 2

The O2L value of precatalyst is a difference between O2L value of the whole line and O2L value of NOx catalyst calculated at bank without downstream binary sensor

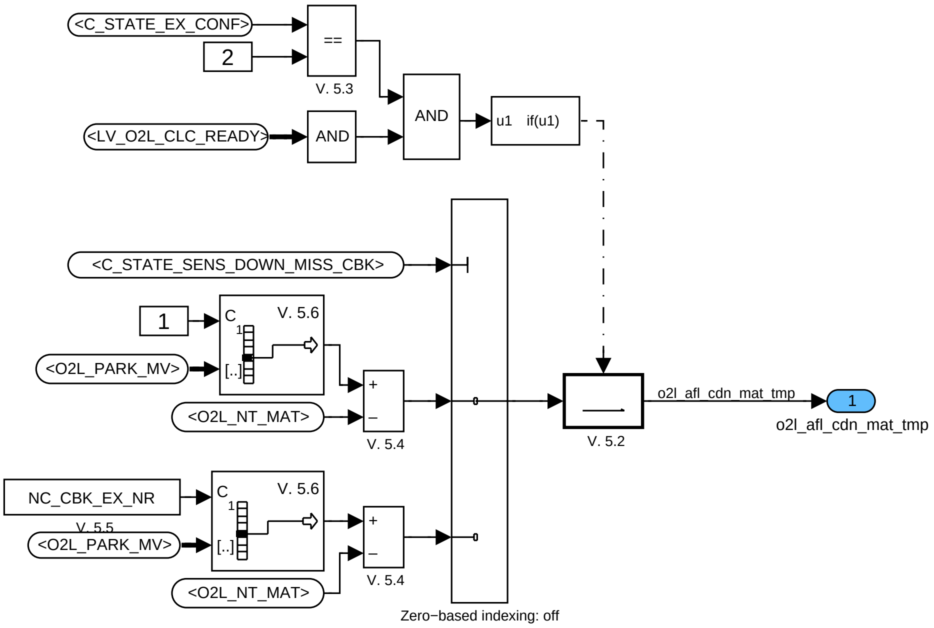

Figure 243:

18.20.2.1.2.4 Calculation of finally O2L value for both banks and validation bit in case of exhaust gas configuration 2 (Method 7)

After all diagonal calculations the result is checked, the diagnosis value of Method 7 is assigned and the valid flag is set for one recurrence.

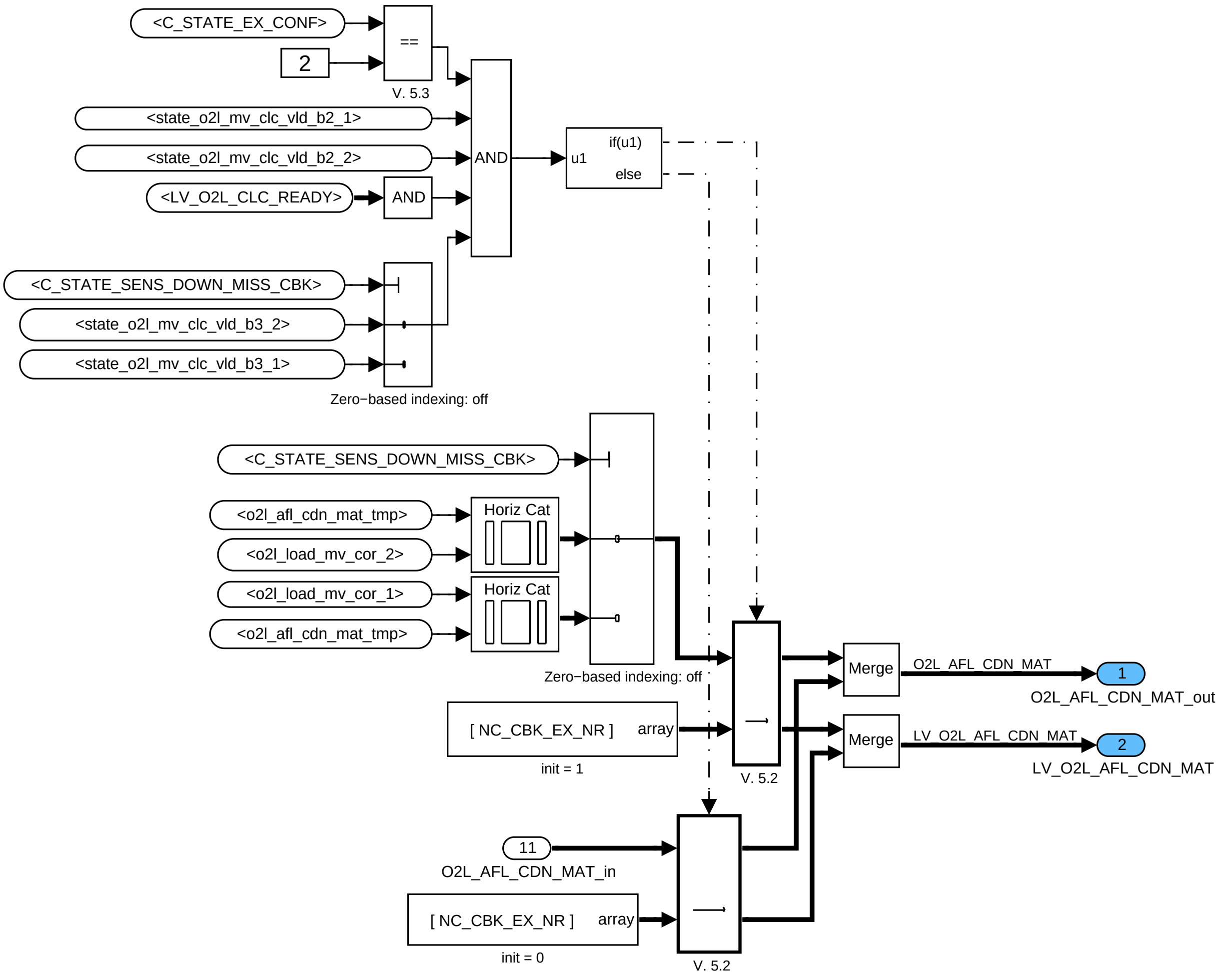

Figure 244:

18.20.2.1.2.5 Choice of method for calculation of finally diagnosis value

The O2L_CAT_DIAG_AFL used for calculation of diagnosis results is represented by O2L_xxx calculated by chosen method. The LV says that the calculation was plausible. This flag is stored in STATE_O2L_MV_CLC_VLD (when this diagnosis was finished before others) and the STATE is reset when the diagnosis condition was true.

18.20.2.1.2.5.1 Choice of the method and calculation temporary diagnosis value

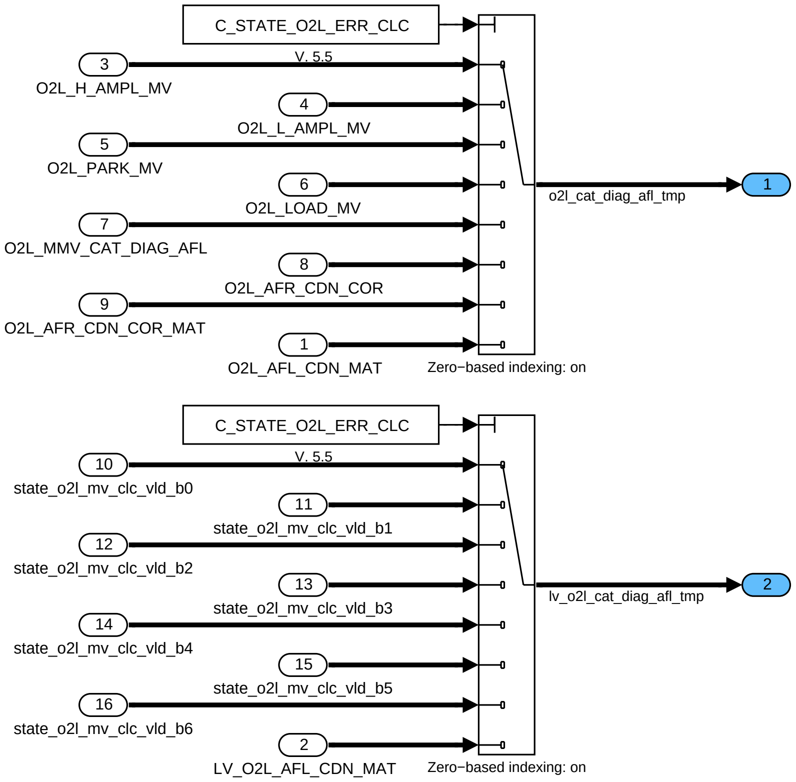

Figure 245:

18.20.2.1.2.5.2 Final diagnosis value and plausibility indicator

18.20.2.1.2.5.2.1 Calculation

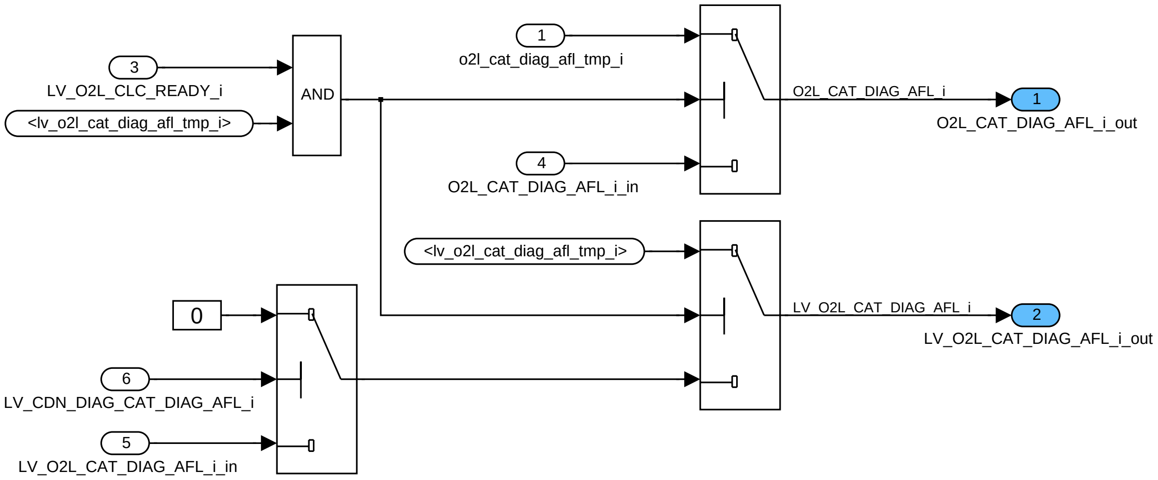

Figure 246:

18.20.2.1.2.6 Calculation of sum diagnosis value over all banks

Indexes "1" and "2" are used regarding cylinder bank 1 and 2. Sum diagnosis value considers all banks

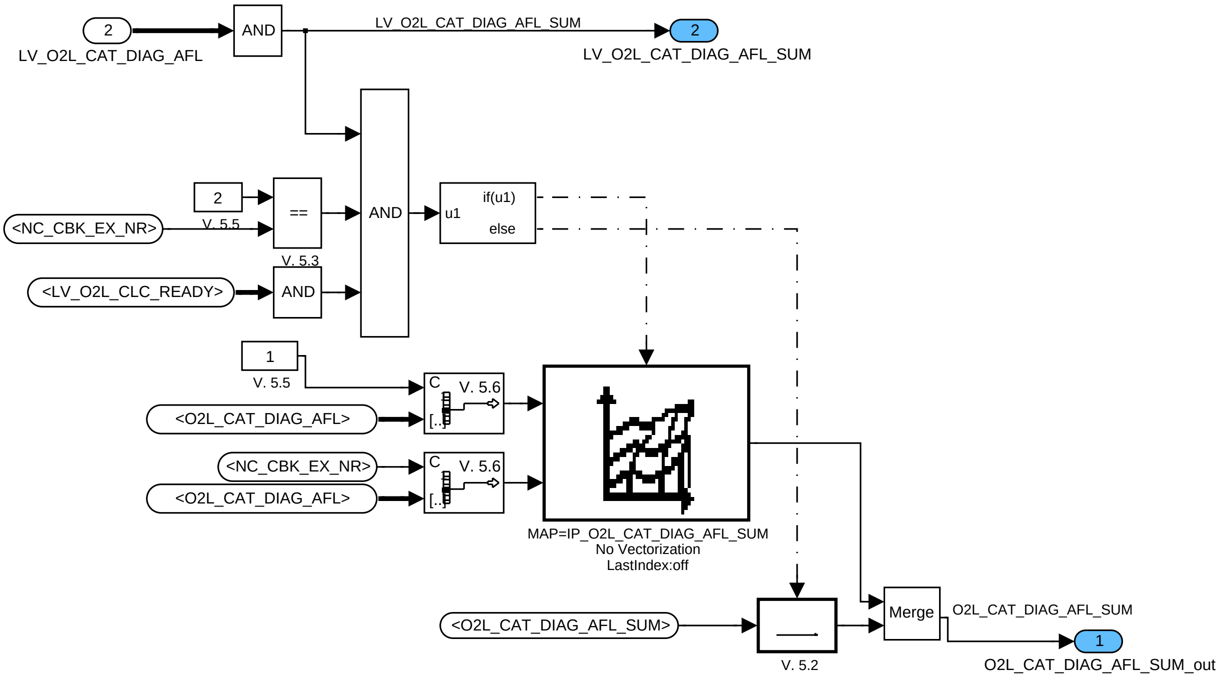

Figure 247:

18.20.2.2 Multiple bank system calculation

18.20.2.2.1 Methods 1 to 6 and ERRM interface

This section consists of three further sections:
Calculation of O2L sum and mean values
Calculation of corrected O2L values and set up of state including plausibility bits
Calculation of error symptom, condition flag and ERRM interface

18.20.2.2.1.1 Calculation of O2L sum and mean values

This section consists of:
Calculation of flag triggering calculation of mean values
Calculation of phase specific sum and mean values
Calculation of mean value of phase specific mean values (Method 4)

18.20.2.2.1.1.1 Calculation of flag triggering calculation of mean values

At the end of defined diagnosis cycles the flag triggering calculation of mean values (only one recurrence) is set for every bank separate (LV_O2L_MV_CLC_ACT_TMP). The flag LV_O2L_MV_CLC_END saves the LV_O2L_MV_CLC_ACT_TMP and is used in next cycle for calculation of summary flag of all banks (LV_O2L_CLC_READY). After that the diagonal values and diagnosis results are calculated.
The flag triggering calculation of the mean values can be set by checking counter of regeneration cycles (independent of plausibility) or counter of valid O2L calculation cycles

18.20.2.2.1.1.1.1 Check of regeneration cycles counter

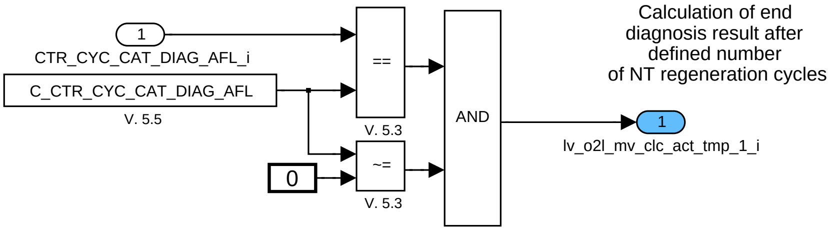

Figure 248:

18.20.2.2.1.1.1.2 Check of counter of valid O2L calculation cycles

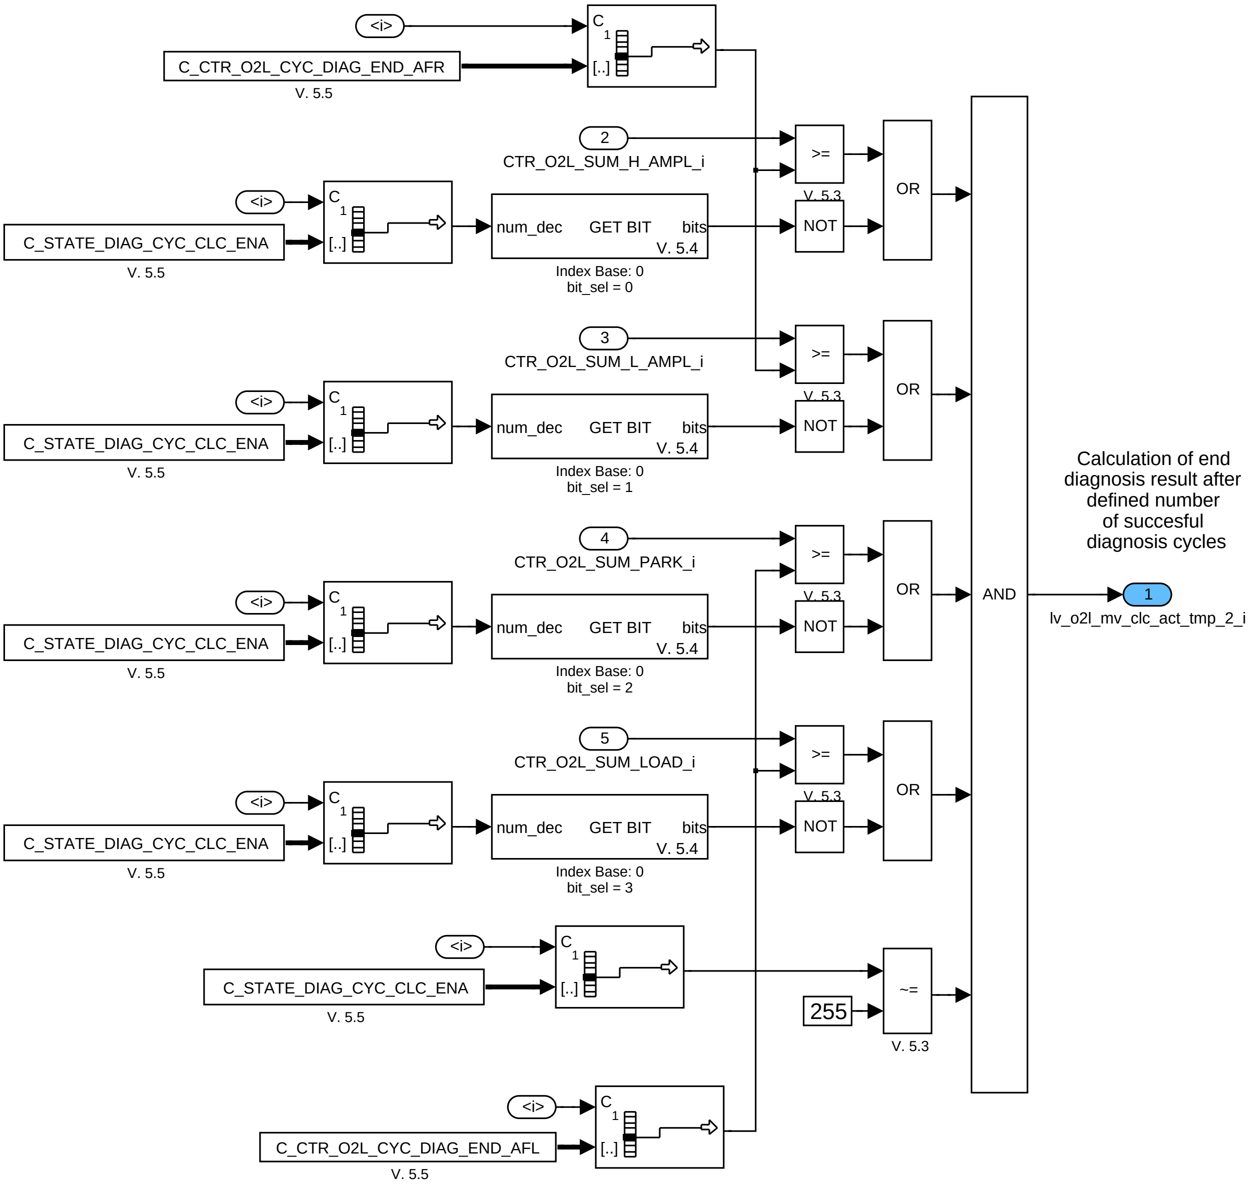

Figure 249:

18.20.2.2.1.1.1.3 Check of storage capacity of TWC for calculation of pre-end diagnosis result (no error present)

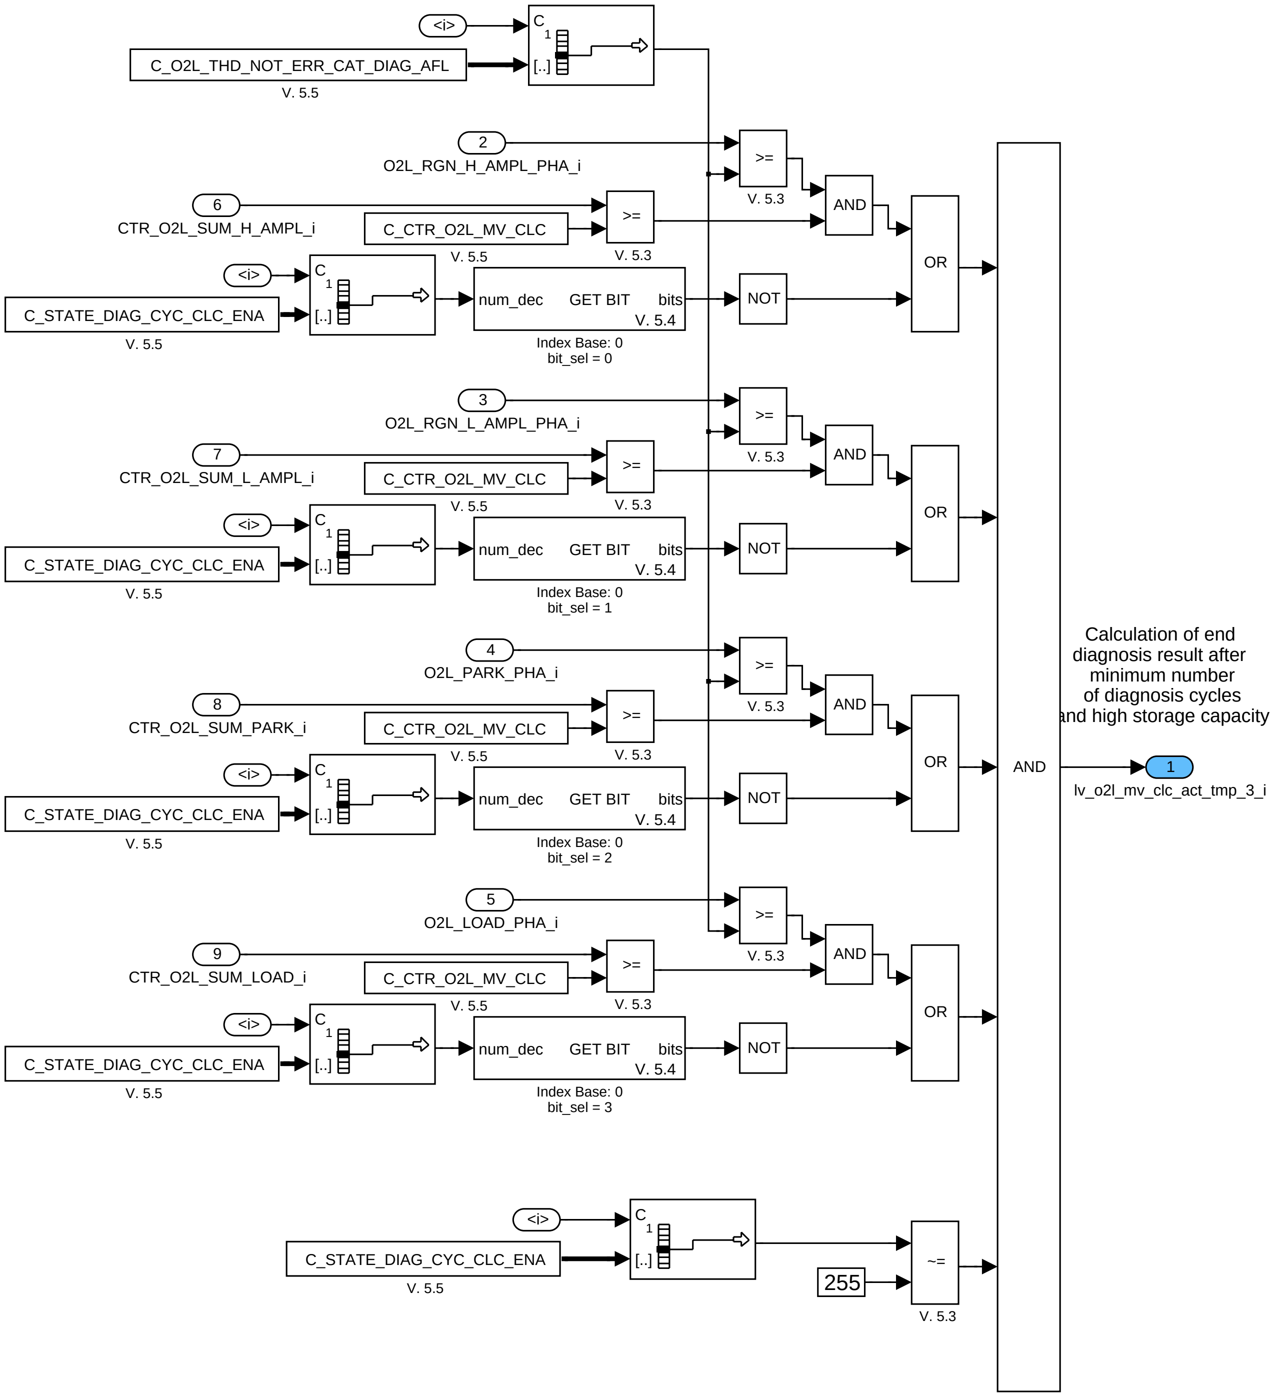

Figure 250:

18.20.2.2.1.1.1.4 Set final triggering flag for calculation of mean values

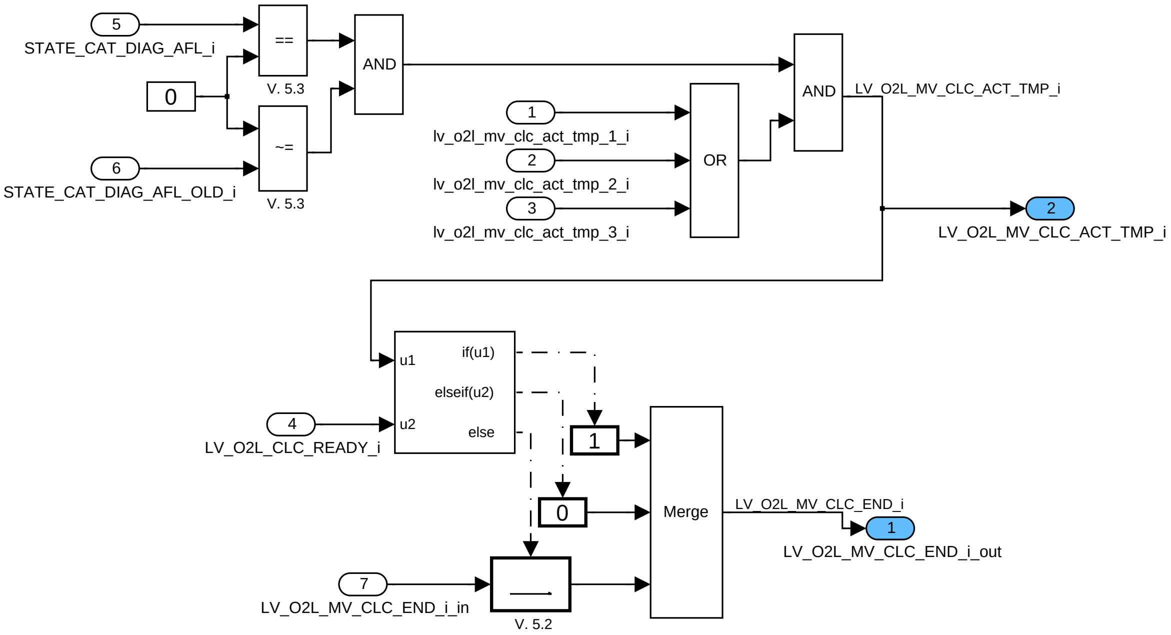

Figure 251:

18.20.2.2.1.1.2 Calculation of phase specific sum and mean values

The sum and mean values are calculated using local ACTION ClcO2L_SUMandMV

Figure 252:

18.20.2.2.1.1.3 Mean value of phase specific mean values (Method 4)

This is calculation of the mean value of O2L values calculated in different phases (e.g. H_AMPL and L_AMPL). The phase, which is taken into the calculation, is chosen through C_STATE_O2L_MMV_CLC_ENA

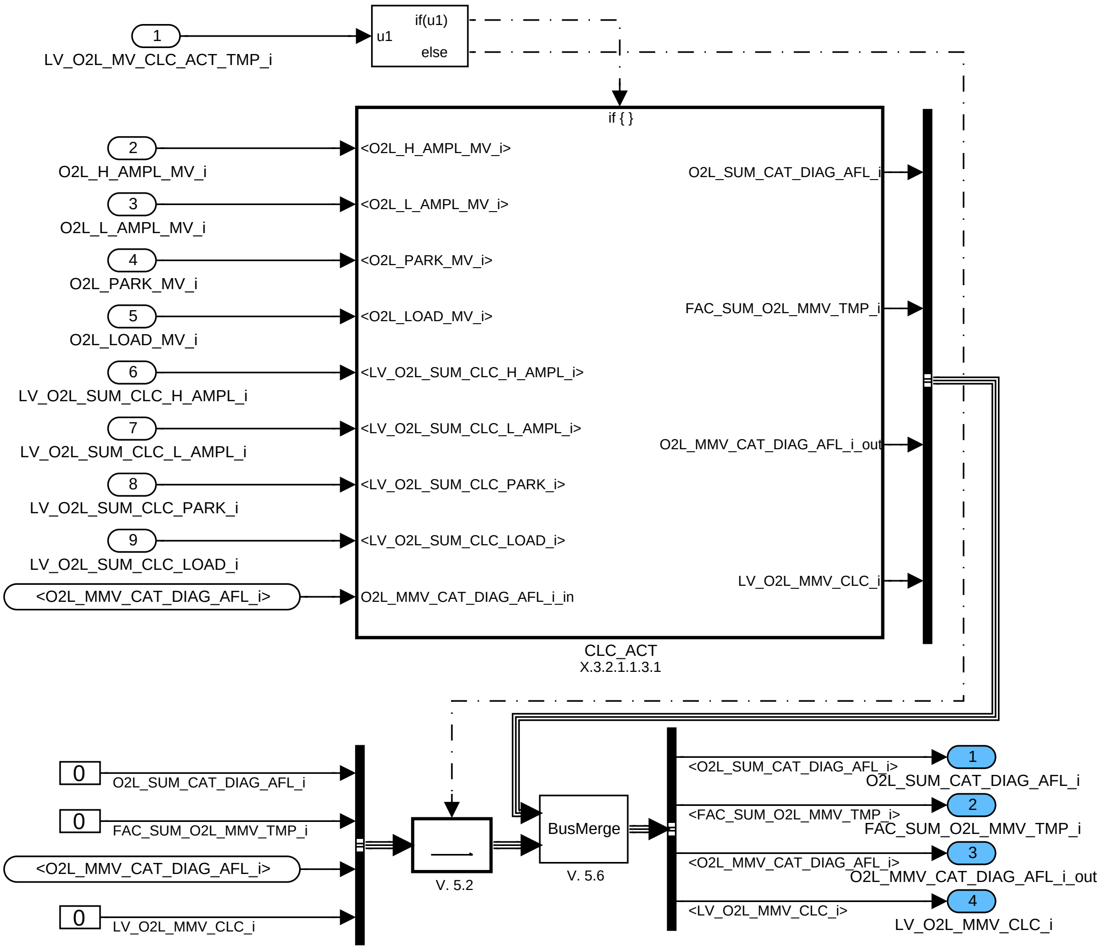

Figure 253:

18.20.2.2.1.1.3.1 Calculations

18.20.2.2.1.1.3.1.1 Calculation of sum

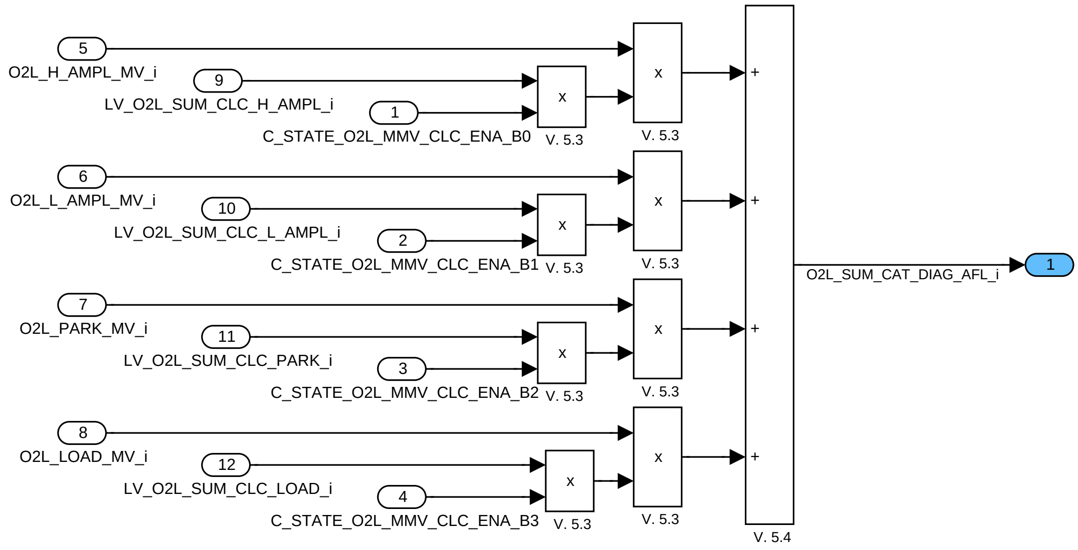

Figure 254:

18.20.2.2.1.1.3.1.2 Calculation of denominator

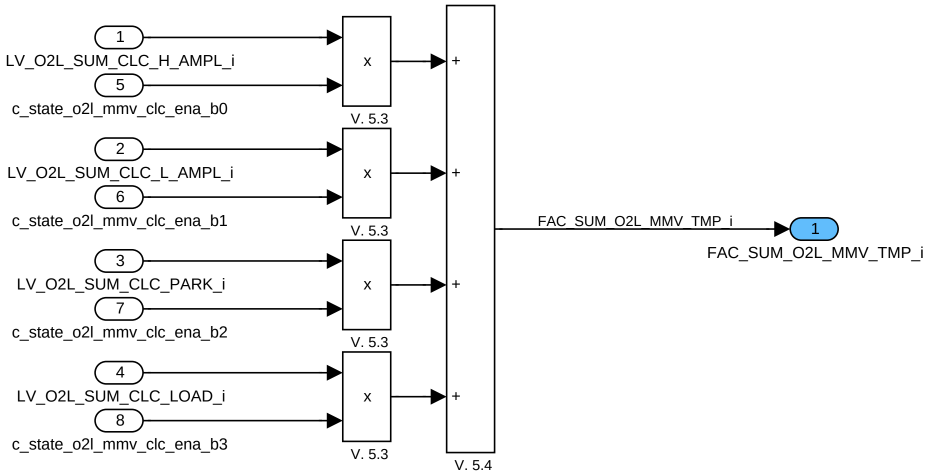

Figure 255:

18.20.2.2.1.1.3.1.3 Check denominator for calculation of MMV

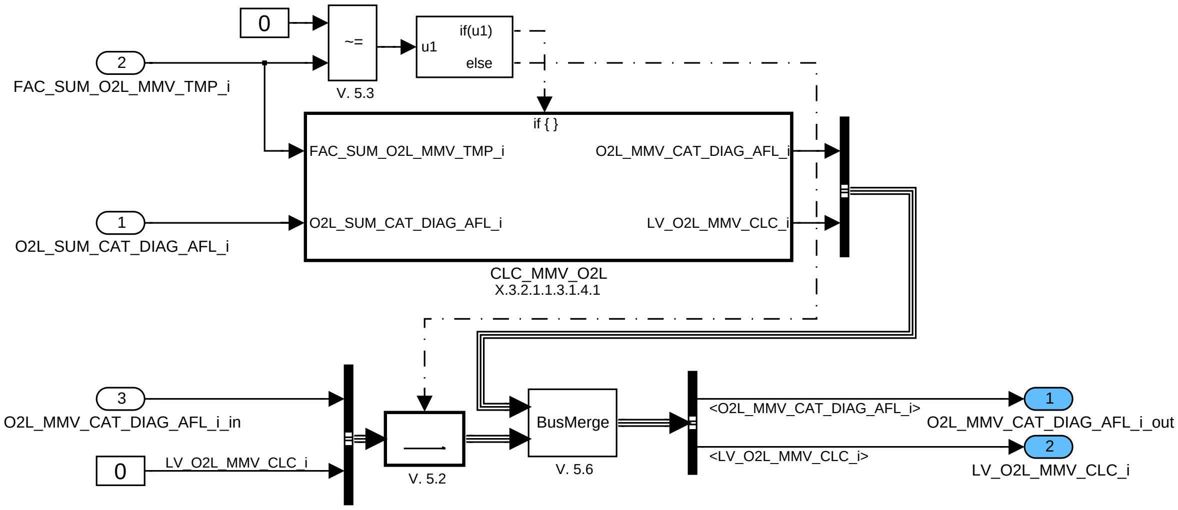

Figure 256:

18.20.2.2.1.1.3.1.3.1 Calculation of MMV

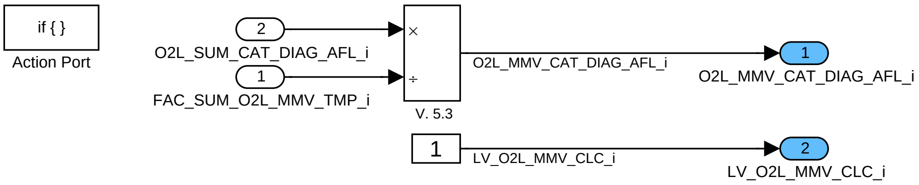

Figure 257:

18.20.2.2.1.2 Calculation of corrected O2L values and set up of state including plausibility bits

This section consists of:
Calculation of corrected O2L values
Set up of state including plausibility bits

18.20.2.2.1.2.1 Calculation of corrected O2L values (Methods 5, 6)

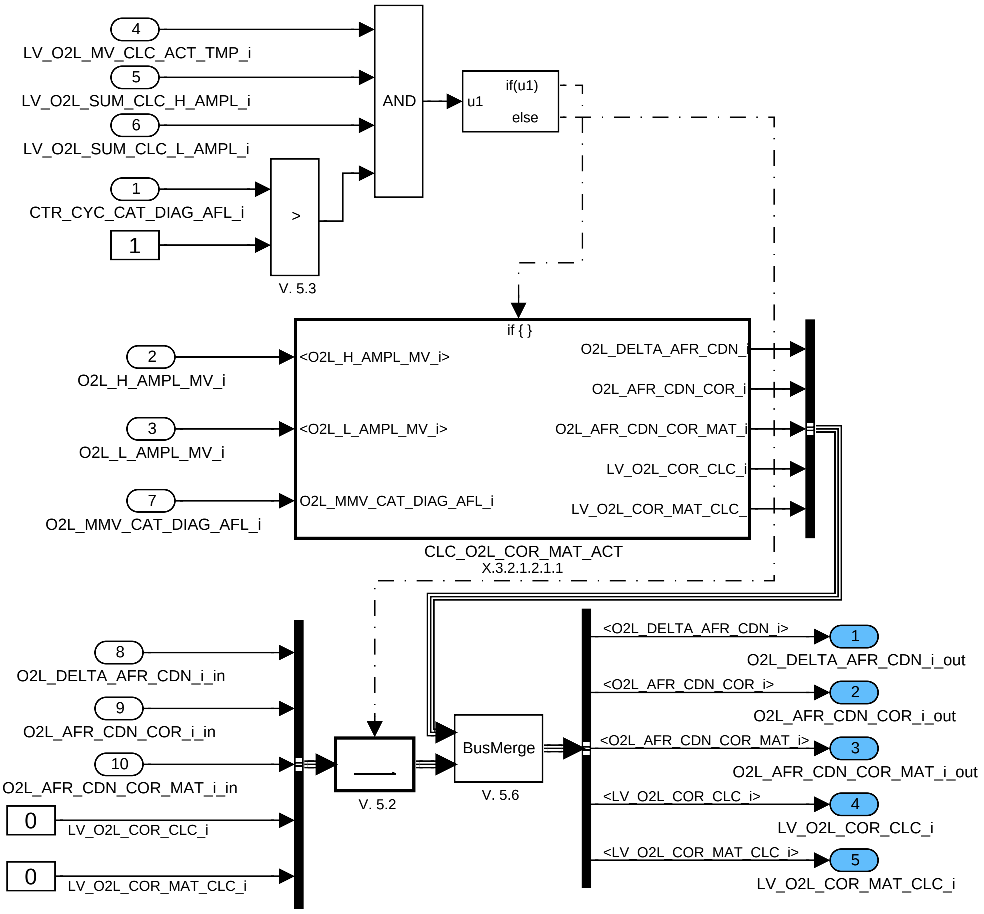

Figure 258:

18.20.2.2.1.2.1.1 Calculations

18.20.2.2.1.2.1.1.1 Calculation of delta O2L between H_AMPL and L_AMPL

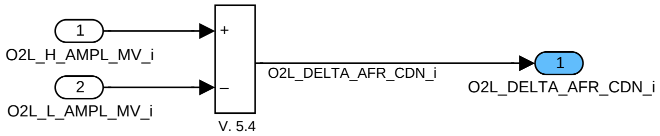

Figure 259:

18.20.2.2.1.2.1.1.2 Calculation of corrected O2L value with method 5

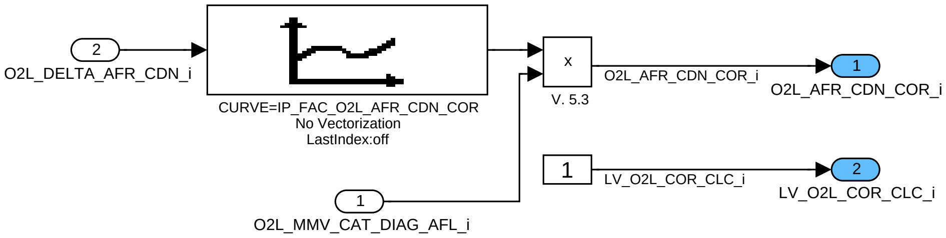

Figure 260:

18.20.2.2.1.2.1.1.3 Calculation of corrected O2L value with method 6

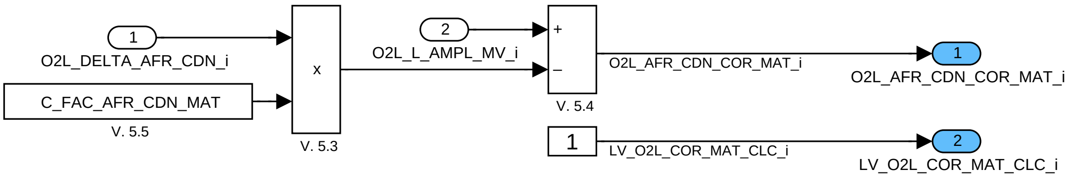

Figure 261:

18.20.2.2.1.2.2 Collecting of validation bit of all O2L calculation methods into a state

For each method for calculation of final diagnosis value exists one validation bit:
Bit 0: Using of O2L mean value from H_AMPL phase
Bit 1: Using of O2L mean value from L_AMPL phase
Bit 2: Using of O2L mean value from PARK phase
Bit 3: Using of O2L mean value from LOAD phase
Bit 4: Using of O2L mean value mean values of all phases
Bit 5: Using of O2L value corrected with empirical method
Bit 6: Using of O2L value corrected with mathematical method
Bit 7: Using of O2L calculated in lean condition in case of configuration 2b

18.20.2.2.1.2.2.1 Set up of the state

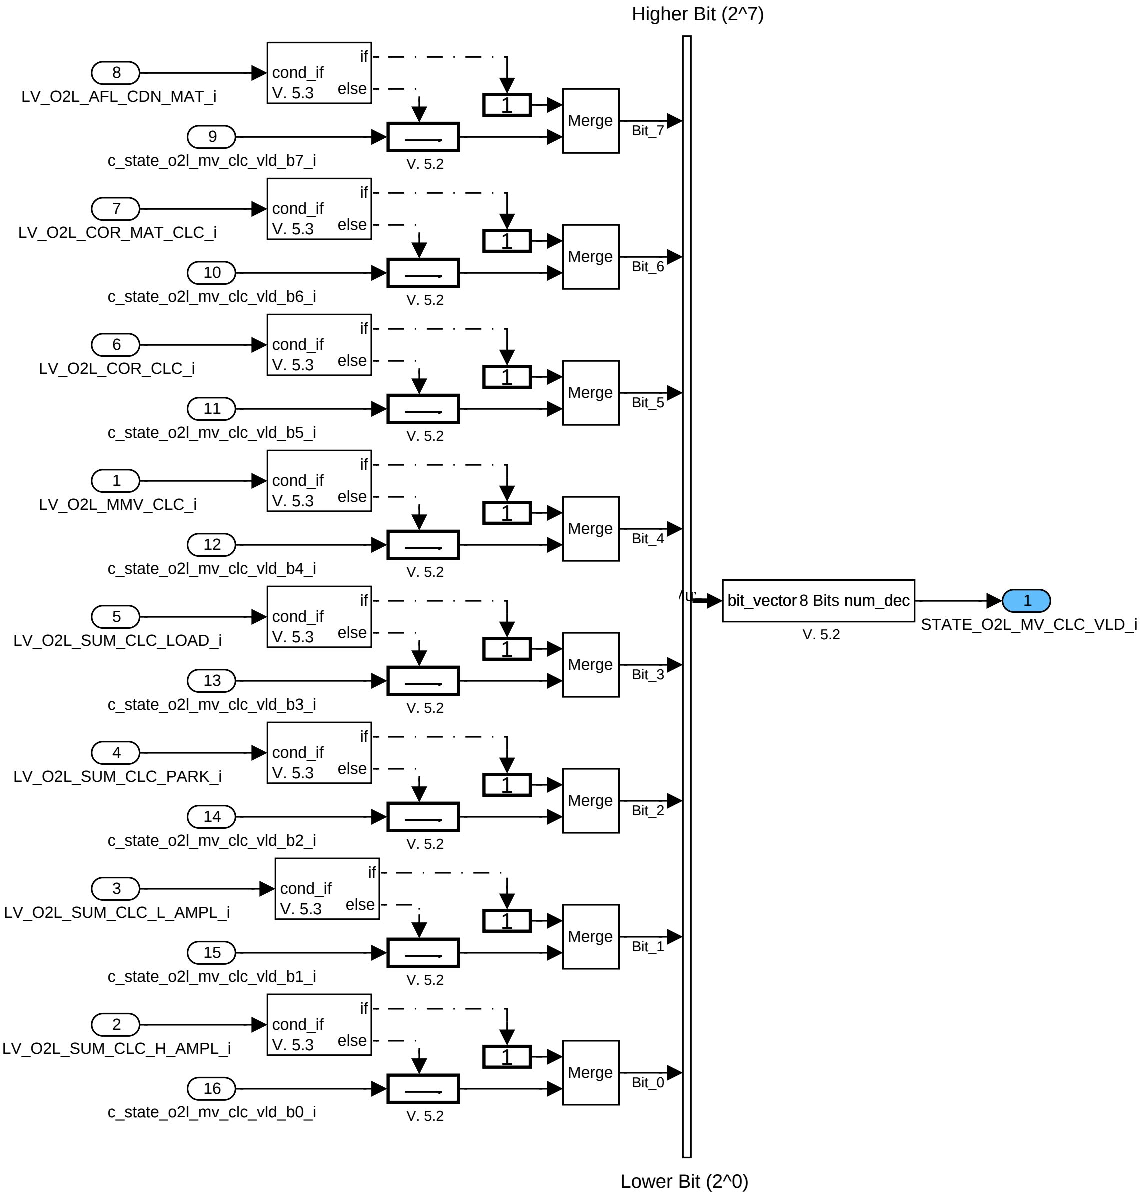

Figure 262:

18.20.2.2.1.2.2.2 Reset of the state

The STATE_O2L_MV_CLC_VLD is reset when the diagnosis condition bit was true in previous cycle

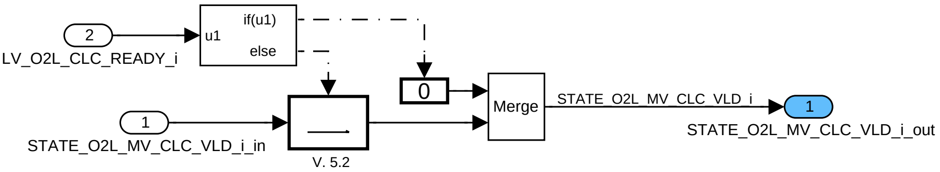

Figure 263:

18.20.2.2.1.3 Calculation of error symptom, condition flag and ERRM interface

This section consists of:
Calculation of temporary diagnosis error after finishing of diagnosis cycle

Calculation of temporary diagnosis end bit
Calculation of condition bit for calculation of error symptom using temporary error indicator after finishing of this and other relevant diagnosis
Interface to ERRM
