18.20.2.2.1.3.1 Calculation of temporary diagnosis error after finishing of diagnosis cycle

The temporary diagnosis error is calculated at the end of diagnosis cycle. At this time, pre-store of environment data is executed

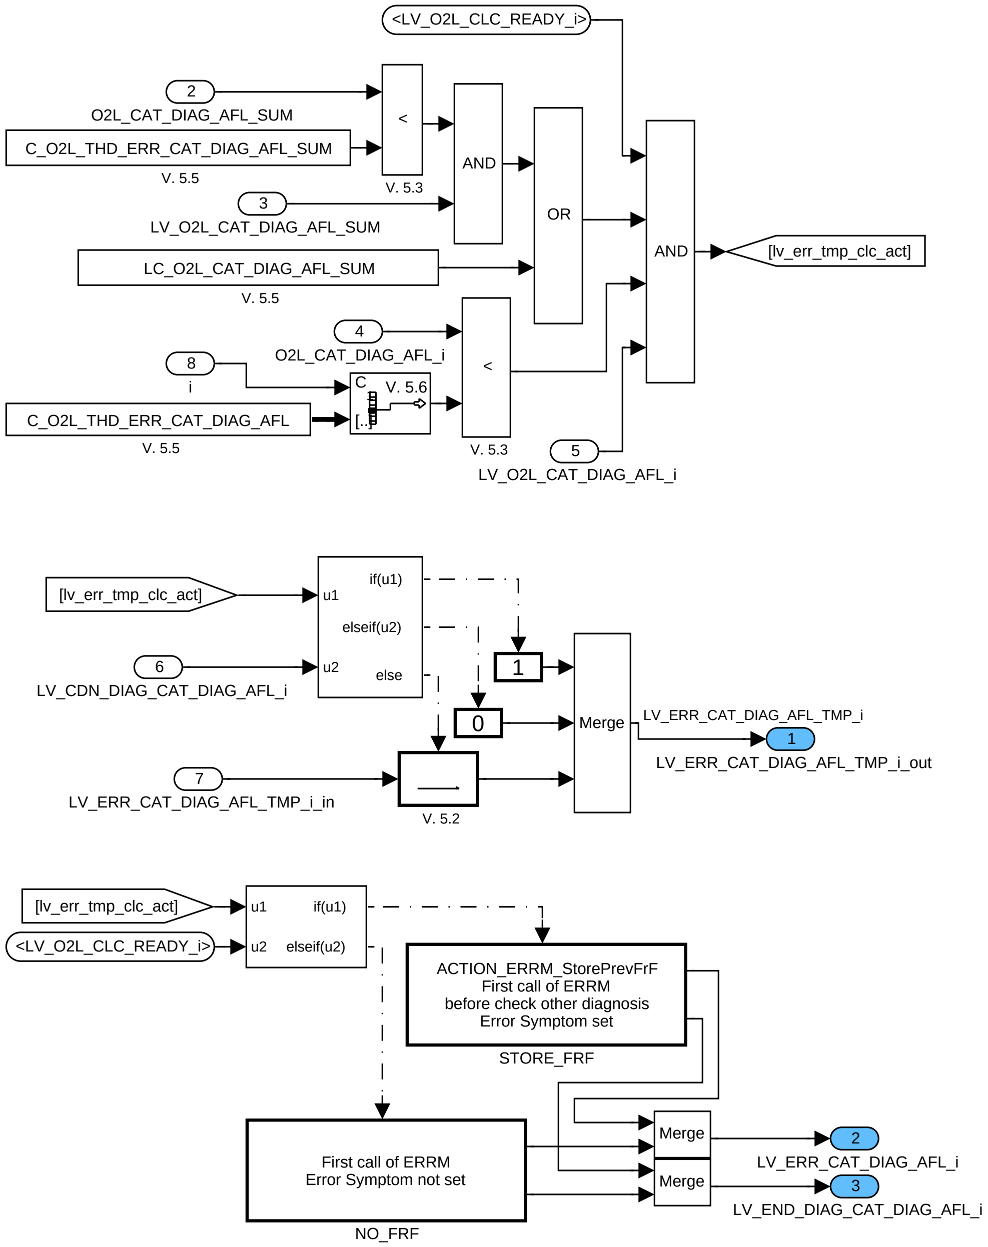

Figure 264:

18.20.2.2.1.3.2 Calculation of temporary diagnosis end bit

The temporary "end" bit is set when diagnosis cycle is finished and calculated O2L value is plausible.

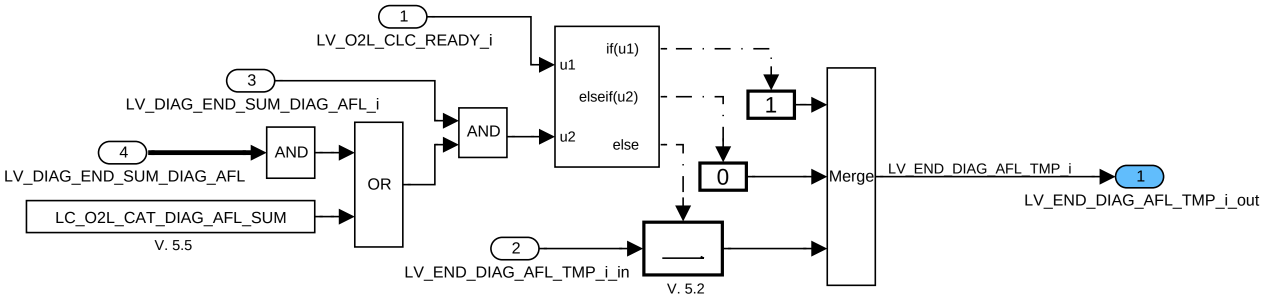

Figure 265:

18.20.2.2.1.3.3 Calculation of diagnosis condition bit and diagnosis error symptom

The diagnosis condition bit can be set when all other relevant diagnosis are finished and the result of this diagnosis is plausible. The calculation of error symptom is done after set of condition bit. The diagnosis condition bit is set only for one recurrence.

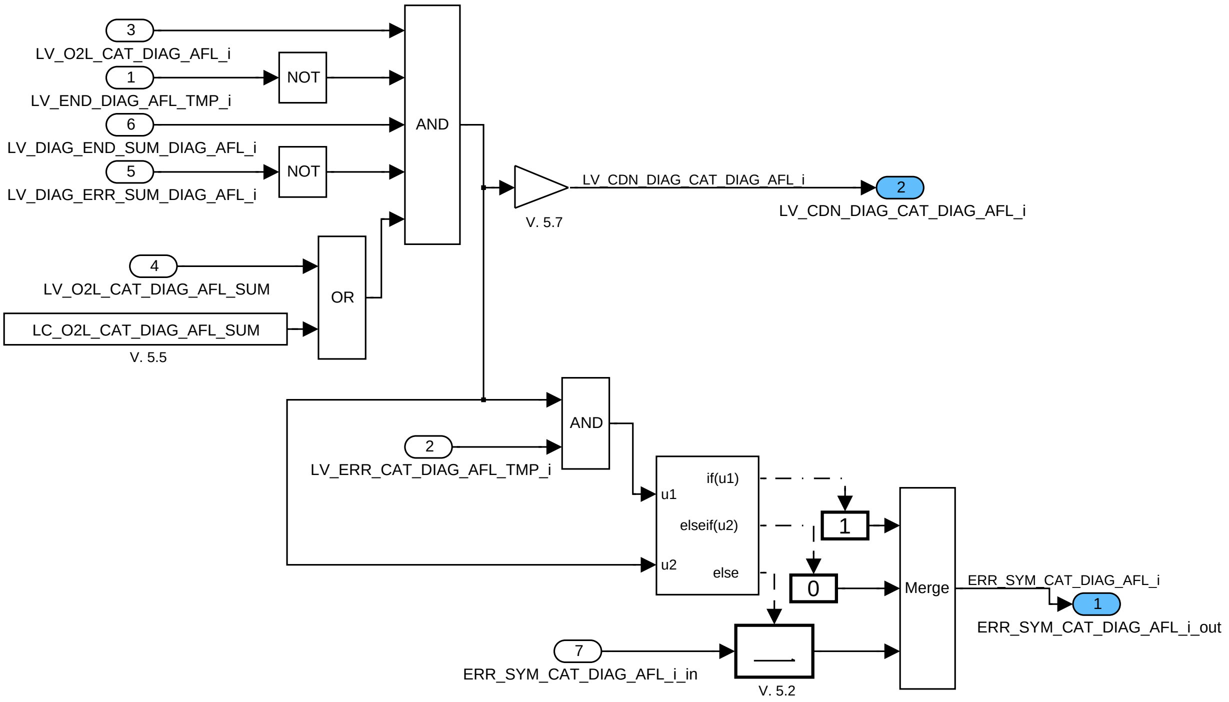

Figure 266:

18.20.2.2.1.3.4 Interface to error management

The diagnosis values are valid when the diagnosis condition flag is true. In this case the error management will take the diagnosis values into account.

Manually set of end and error sum flags of other relevant diagnosis to passed					

18.21.1 General information

The flag LV_INH_DIAG_CAT_DIAG_AFL permit to deactivate the corresponding diagnosis.

If two separate exhaust bank systems are concerned, then:

i = 1, for cylinder bank 1

i = 2, for cylinder bank 2

Otherwise:

i = 1

Oil pressure sensor linearisation table for relative sensor					

FUNCTION DESCRIPTION:

General information:

In case of oil pressure is below a minimum threshold the oil pressure switch switches from ground to open circuit (warning lamp on).

To avoid malfunction at high longitudinal or transversal accelerations the delay timer T_POIL_SWI is added.

The oil pressure switch (LV_POIL_SWI) has to be monitored also during power-latch-phase (due to oil pressure switch diagnosis).

Application conditions:

Initialisation: *at reset* *LV_POIL_SWI = 0*
T_POIL_SWI = C_T_POIL_SWI_BAS

Recurrence: 100 ms

Activation: at LV_IGK = 1

Deactivation: -

Formula section:

```
If      LC_POIL_CTL_ENA = 0
then    ACTION_INFR_GetPoilSwi(OUT <LV_BIOS_POIL_SWI>)

Endif
```

19.1.2 Acquisition of oil pressure sensor

FUNCTION DESCRIPTION:

General information:

The sensor voltage signal V_POIL is converted via a linearisation table into the oil pressure POIL. In case of an oil sensor error a subsitude value can be used.

Application conditions:

Initialisation: at transition LV_IGK 0 –> 1 **or** reset

```
If      V_POIL < C_V_POIL_MIN_DIAG    or
        V_POIL > C_V_POIL_MAX_DIAG
then    POIL = C_POIL_ERR_SUB
else    POIL = IP_POIL_V_POIL_REL
endif
```

Recurrence: 10 ms

Activation: ECU_STATE <> PWL **and** LC_POIL_CTL_ENA = 1

Deactivation:

```
if      ECU_STATE = PWL   or   LC_POIL_CTL_ENA = 0
then    POIL = POIL(n-1)
endif
```

Formula section:

```
If      LV_ERR_SENS_POIL = 0
then    POIL = IP_POIL_V_POIL_REL
else    POIL = C_POIL_ERR_SUB
endif
```

19.2 ENLU - Requirements to Infrastructure interface

Export actions:

ACTION_INFR_GetVPoilSens(OUT <v_poil>**)**
This action gets the Oil pressure sensor voltage
ACTION_INFR_GetPoilSwi(OUT <lv_bios_poil_swi>**)**
This action reads the input pin of the "POIL Switch"
ACTION_INFR_GetElDiagPoil_dr(OUT <Cdn_diag_Poil_dr>, OUT <Err_diag_Poil_dr>**)**
This action reads the failure and condition information for a symptom of the oil pressure actuator power stage.
ACTION_INFR_SetFrqPwmPoilDr(IN <frq_poil_pwm**>)**
This action sets the frequency of the oil pressure actuator PWM
ACTION_INFR_SetPwmPoilDr(IN <poil_pwm**>)**
This action sets the duty cycle of the oil pressure actuator PWM

Description for actions:

ACTION_INFR_GetVPoilSens(OUT <v_poil>**)**					
This action gets the Oil pressure sensor voltage					
Name	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
v_poil	OUT	0...3FFH	0...4.9951118757	0.0048828125	V
Oil pressure sensor raw acquisition					

ACTION_INFR_GetPoilSwi(OUT <lv_bios_poil_swi>**)**					
This action reads the input pin of the "POIL Switch"					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
lv_bios_poil_swi	OUT	0...1H	0…1	1	-
Input pin of the "POIL Switch" (0= oil pressure failed; 1= oil pressure ok)					

ACTION_INFR_GetElDiagPoil_dr(OUT <Cdn_diag_Poil_dr>, OUT <Err_diag_Poil_dr>)					
This action reads the failure and condition information for a symptom of oil pressure actuator power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this action the information inside the infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cdn_diag_poil_dr	OUT	0...7H	0...7	1	-
Diagnosis condition for symptoms of POIL_DR: bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled (all combinations are possible)					
Err_diag_poil_dr	OUT	0...7H	0...7	1	-
Raw value of error symptom: bit 0: Set, if raw value of error symptom SCP (SYM_0) is set bit 1: Set, if raw value of error symptom SCG (SYM_1) is set bit 2: Set, if raw value of error symptom OC (SYM_2) is set (all combinations are possible)					
Raw value of error symptom. The relevant bit is set, if the error has been detected.					

ACTION_INFR_SetFrqPwmPoilDr(IN <frq_poil_pwm**>)**					
This action sets the frequency of the oil pressure actuator PWM					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

<table>

</table>

FUNCTION DESCRIPTION:

General information:

ACTION_INFR_GetVPoilSens()

Oil pressure sensor raw acquisition.

ACTION_INFR_GetPoilSwi()

This action reads the input pin of the "POIL Switch". Logical variable oil pressure switch (1= oil pressure o.k.).

ACTION_INFR_GetElDiagPoil_dr()

Returns the result of the electrical diagnosis of the oil pressure actuator power stage.

The device readout is performed autonomous by the Infrastructure each 10ms.
The error informations of every symptom is gathered in the infrastructure (or-ed symptom) until the application reads out the information by calling ACTION_INFR_GetElDiagPoil_dr().
After having read out the information by calling ACTION_INFR_GetElDiagPoil_dr(), the data inside the infrastructure is reset. Resetting of Cdn_diag_poil_dr avoids ambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagPoil_dr(): Reset Cdn_diag_poil_dr indicates that the gathering of the information is not completely finished.

ACTION_INFR_SetFrqPwmPoilDr()
The oil pressure actuator is controlled by a pulse width modulation control signal. To counter a rough-running actuator in case of fouling, the frequency of the PWM can be changed by the action SetFrqPwmPoilDr. The frequency information is transmitted to the BSW by the variable *frq_poil_pwm*.

ACTION_INFR_SetPwmPoilDr()
The oil pressure actuator is controlled by a PWM control signal. The extent of control is done by the duty cycle via the variable *poil_pwm*.

19.3 Oil overtemperature detection

19.3.1 Oil overtemperature detection – Detection algorithm

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_TOIL_THD_WARN_1	O/V	0...1H	0...1	1	-
TOIL > warning threshold 1					
LV_TOIL_THD_WARN_2	O/V	0...1H	0...1	1	-
TOIL > warning threshold 2					

Input data:

TOIL	LV_IGK		

FUNCTION DESCRIPTION:

General information:

There are two thresholds for detecting a TOIL overtemperature. In case TOIL exceeds the first threshold a statusflag is set and a checkcontrol-message is sent, indicating that the TOIL is within the “yellow area”. If TOIL exceeds the second threshold a statusflag is set and a checkcontrol-message is set, indicating that the TOIL is within the “red area”.
The statusflags are reset if TOIL < threshold.

Application conditions:

Initialisation:	LV_TOIL_THD_WARN_i	= 0	at reset
Recurrence:	1000ms		
Activation:	LV_IGK = 1		

Formula section:

Determination of LV_TOIL_THD_WARN_1:

```
IF      (TOIL                  >    C_TOIL_CHK_CTL_1)
THEN    LV_TOIL_THD_WARN_1     =    1
ELSE    LV_TOIL_THD_WARN_1     =    0
ENDIF
```

Determination of LV_TOIL_THD_WARN_2:

```
IF      (TOIL                  >    C_TOIL_CHK_CTL_2)
THEN    LV_TOIL_THD_WARN_2     =    1
ELSE    LV_TOIL_THD_WARN_2     =    0
ENDIF
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TOIL_CHK_CTL_1	1	0..FFH	-40...215	1	°C
warning threshold 1 for TOIL overtemperature (appl. suggestion: 155°C)					
C_TOIL_CHK_CTL_2	1	0...FFH	-40...215	1	°C
warning threshold 2 for TOIL overtemperature (appl. suggestion: 158°C)					

19.3.2 Oil overtemperature detection - Environmental data

Output data:

Anti - bounce counter increment					
C_ABC_MAX_POIL	1	1...FFH	1...255	1	[-]
Maximum value of the anti - bounce counter					

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect electrical faults as defined by OBD I requirements.
The signal of the oil pressure sensor on the A/D-input of the microcontroller is checked.

Description:

Error-symtoms are defined to this diagnosis function as following :

```
|_|_|_|_|
 | | | └─> Signal line short to battery voltage or 5 V power supply  (= SYM_0)
 | | └───> Signal line short to ground or open load                 (= SYM_1)
 | └─────> -                                                         (= SYM_2)
 └───────> -                                                         (= SYM_3)
```

Application conditions:

Initialization: all 0 at LV_IGK 0 -->1 **or** reset

Recurrence: 100ms

```
Activation:     If      LV_IGK = 1   and   LC_POIL_CTL_ENA = 1
                Then    LV_CDN_DIAG_SENS_POIL = 1
                Else    LV_CDN_DIAG_SENS_POIL = 0
                Endif
Deactivation:   LV_IGK = 0   or   LC_POIL_CTL_ENA = 0
```

Formula section:

Short circuit to VBatt or 5 V power supply:

```
If      V_POIL  >  C_V_POIL_MAX_DIAG
Then    ERR_SYM_SENS_POIL = SYM_0
```

Short circuit to ground or open load:

```
Else    If      V_POIL  <  C_V_POIL_MIN_DIAG
        Then    ERR_SYM_SENS_POIL = SYM_1
        Else    ERR_SYM_SENS_POIL = NO_SYM
        Endif
Endif
```

Calculation of present error and end of diagnosis:

LV_ERR_SENS_POIL and LV_END_DIAG_SENS_POIL is calculated by the error management.

19.5 Electrical diagnosis of oil pressure actuator

Output data:

Note :

- The data ERR_SYM_POIL_DR, LV_END_DIAG_POIL_DR and LV_CDN_DIAG_POIL_DR are not present in the output data table, because they are not used by other functions. Despite they are provided by the error management and are always visible.

Input data:

ECU_STATE	LC_POIL_CTL_ENA	LC_POIL_CTL_ENA	LV_CDN_VB_OBD1
LV_ERR_SPI_MPS	LV_IGK	LV_IGK	LV_POIL_SWI
POIL_PWM	TOIL		

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)
ACTION_INFR_GetElDiagPoil_dr(OUT< Cdn_diag_Poil_dr>, OUT< Err_diag_Poil_dr >)

Note :

ACTION_INFR_GetElDia*g*Poil_dr() is defined in the IRS (Infrastructure requirement specification)

FUNCTION DESCRIPTION:

General information:

The oil pressure actuator is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.
The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_POIL_DR executions, to avoid the usage of wrong infrastructure information.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to battery (SCP)        (= SYM_0)
 │ │ └───> Short circuit to ground (SCG)         (= SYM_1)
 │ └─────> Open circuit (OC)                     (= SYM_2)
 └───────> -                                     (= SYM_3)
```

Application conditions:

Initialisation: at transition LV_IGK 0 --> 1:

LV_ERR_POIL_DR,

ERR_SYM_POIL_DR,

LV_END_DIAG_POIL_DR

(according filter-type)

Set delay counter for NC_PSD_DLY_POIL_DR at reset:

CDN_DIAG_POIL_DR = 0,

LV_ERR_POIL_DR = 0 and

ERR_SYM_POIL_DR = 0,

LV_CDN_DIAG_POIL_DR = 0,

LV_END_DIAG_POIL_DR = 0,

(according filter-type)

Set delay counter for NC_PSD_DLY_POIL_DR

Recurrence: 100 ms

Activation: LV_IGK = 1 **and** LC_POIL_CTL_ENA = 1 **and** LV_ERR_SPI_MPS = 0

Deactivation: LV_IGK = 0 **or** LC_POIL_CTL_ENA = 0 **or** LV_ERR_SPI_MPS = 1

Formula section:

```
If      LV_IGK = 1                  and
        LV_CDN_VB_OBD1 = 1
Then
```

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_POIL_DR and basic diagnosis conditions CDN_DIAG_POIL_DR) received from the infrastructure:

ACTION_INFR_GetElDiagPoil_dr (OUT<Cdn_diag_poil_dr>, OUT<Err_diag_poil_dr>)

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_POIL_DR
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_POIL_DR

```
        If   Activation conditions are met for the NC_PSD_DLY_POIL_DR recurrence of
             the diagnosis
        Then { Additional diagnosis conditions }
             If    C_PWM_POIL_DR_MIN_DIAG_SCP > POIL_PWM
             then  bit 0 of CDN_DIAG_POIL_DR = 0 {Diagnosis of SCP not possible }
             Endif
             If    POIL_PWM > C_PWM_POIL_DR_MAX_DIAG_SCG
             then  bit 1 of CDN_DIAG_POIL_DR  = 0 {Diagnosis of SCG not possible }
             Endif
             If    POIL_PWM < C_PWM_POIL_DR_MIN_DIAG_OC
             Or    POIL_PWM > C_PWM_POIL_DR_MAX_DIAG_SCG
             then  bit 2 of CDN_DIAG_POIL_DR  = 0 {Diagnosis of OC not possible }
             Endif
        Else CDN_DIAG_POIL_DR = 0
        Endif
Else
        CDN_DIAG_POIL_DR = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_POIL_DR and ERR_DIAG_POIL_DR.

ACTION_ERRM_FilterMulticondition (IN<POIL_DR>, IN<CDN_DIAG_POIL_DR>, IN<ERR_DIAG_POIL_DR>, IN<C_ABC_INC_POIL_DR>, IN<C_ABC_MAX_POIL_DR>, OUT<LV_ERR_POIL_DR>)
This algorithm determines:

ERR_DIAG_POIL_DR	(detected error symptom for POIL_DR diagnosis)
LV_ERR_POIL_DR	(Error flag for debounced error of POIL_DR)
LV_CDN_DIAG_POIL_DR	(Diagnosis condition information)
LV_END_DIAG_POIL_DR	(End of diagnosis information)

Configuration for diagnostic symptoms :

Diagnostic **POIL_DR**	**Symptom description**	**Symptom**	**Filter type**
Driver diagnosis of oil pressure actuator	SCP	*SYM_0*	*MPL_STD_INI*
	SCG	*SYM_1*	
	OC	*SYM_2*	

19.6 Electrical diagnosis of oil pressure actuator for shortcut to ground (SCG)

Import actions:

ACTION_ERRM_GetLvErr(IN<IDX_DIAG>, OUT<LV_ERR>)
Action that returns the status of the debounced failure
ACTION_ERRM_FilterSymptom(IN<IDX_DIAG>, IN<LV_CDN_DIAG>, IN<ERR_SYM>, IN<ABC_INC>, IN<ABC_DEC>, IN<ABC_MAX>, OUT<LV_ERR>)
This action computes the elementary anti-bounce filter

FUNCTION DESCRIPTION:

General information:

In case of an electrical failure caused by a shortcut to ground (SCG) a special failure - reaction and a different warning - lamp (EML) - handling is necessary (caused by low oil - pressure the engine speed will be limited at 3000 rpm). Due to the need of a separate C_ERR_CLAS for this symptom of LV_ERR_POIL_DR it will be copied on LV_ERR_POIL_DR_SCG.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
|_|_|_|_|
 | | | └─> -                                        (= SYM_0)
 | | └───> Short circuit to ground (SCG)          (= SYM_1)
 | └─────> -                                        (= SYM_2)
 └───────> -                                        (= SYM_3)
```

Application conditions:

Initialisation: all output data according ABC configuration "**MEM**"

// LV_IGK 0->1 ***or*** *reset* ***or*** *at clearing error memory*

This action initialized the diagnostic result according the filtering configuration :

ACTION_ERRM_GetLvErr(IN<NC_IDX_DIAG_ POIL_DR_SCG >, OUT<LV_ERR_POIL_DR_SCG>)

Recurrence: 100 ms

Activation: LV_IGK = 1 **and** LC_POIL_CTL_ENA = 1 **and** LV_ERR_SPI_MPS = 0

Deactivation: LV_IGK = 0 **or** LC_POIL_CTL_ENA = 0 **or** LV_ERR_SPI_MPS = 1

Formula section:

LV_CDN_DIAG_POIL_DR_SCG = LV_CDN_DIAG_POIL_DR

```
If      ERR_SYM_POIL_DR = SYM_1
Then    ERR_SYM_POIL_DR_SCG = SYM_1
Else    ERR_SYM_POIL_DR_SCG = NO_SYM
Endif
```

For failure and error management treatment the anti-bounce mechanism is called with the parameters LV_CDN_DIAG_POIL_DR_SCG and ERR_SYM_POIL_DR_SCG.

ACTION_ERRM_FilterSymptom (IN< POIL_DR_SCG >, IN< LV_CDN_DIAG_POIL_DR_SCG >,
IN< ERR_SYM_POIL_DR_SCG >, IN< C_ABC_INC_POIL_DR_SCG >, IN< C_ABC_MAX_POIL_DR_SCG >,
IN< 1 >, OUT< LV_ERR_POIL_DR_SCG >)

This algorithm determines LV_ERR_POIL_DR_SCG and LV_END_DIAG_POIL_DR_SCG and delivers the result to Error Management.

Configuration for diagnostic symptoms :

Diagnostic POIL_DR_SCG	Symptom description	Symptom	Filter type
Driver diagnosis of oil pressure actuator only for shortcut to plus	-	SYM_0	MEM
	SCG	SYM_1	
	-	SYM_2	
	-	SYM_3	

19.7 Oil pressure switch diagnosis

FUNCTION DESCRIPTION:

General information:

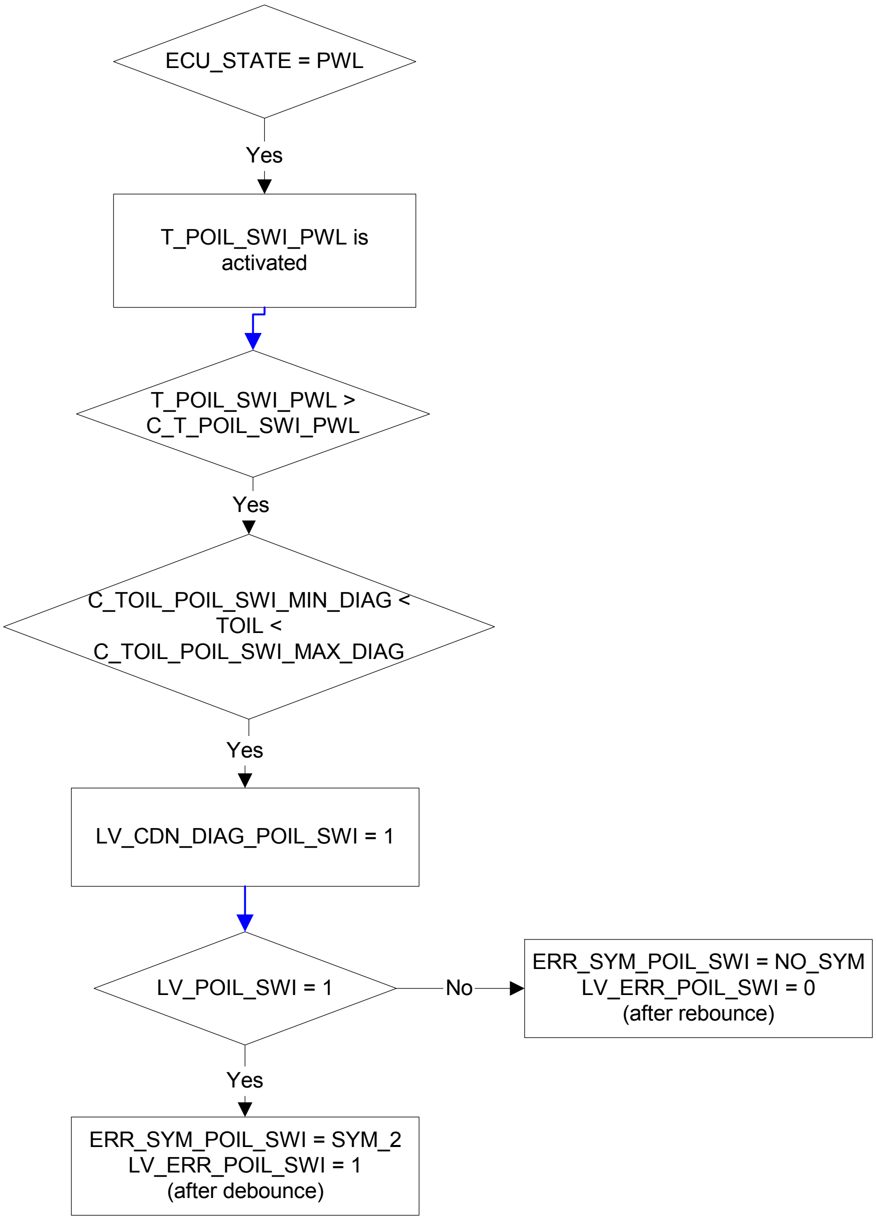
Due to the ECU recognizing the oil pressure as “ok” during “switch open”, a diagnosis of the oil pressure switch is required in order to detect a fallen off plug (open load).

Description:

Error symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─>                                  (= SYM_0)
 │ │ └───>                                  (= SYM_1)
 │ └─────> Open Load                        (= SYM_2)
 └───────> -                                (= SYM_3)
```

Signal flow diagram:



Application conditions:

Initialisation: according ERRM Type "**STD**" *(restored out from NVMY)*

at LV_IGK 0 → 1 **or** at reset: T_POIL_SWI_PWL = 0

Recurrence: 100 ms

Activation: LV_END_DIAG_POIL_SWI = 0 **and** ECU_STATE = PWL **and** LC_POIL_CTL_ENA = 0

Deactivation: LV_END_DIAG_POIL_SWI = 1 **or**
end of power-latch phase **or** LC_POIL_CTL_ENA = 1

Formula section:

The diagnosis shall be performed during the power-latch-phase until LV_END_DIAG_POIL_SWI = 1 or the end of power latch phase is reached.

```
IF (1)       ECU_STATE = PWL
THEN (1)     Timer T_POIL_SWI_PWL starts
             IF (2)       T_POIL_SWI_PWL > C_T_POIL_SWI_PWL
             THEN (2)     IF (3)       C_TOIL_POIL_SWI_MIN_DIAG <
                                              TOIL < C_TOIL_POIL_SWI_MAX_DIAG
                          THEN (3)     LV_CDN_DIAG_POIL_SWI = 1
                                       IF (4)       LV_POIL_SWI = 1
                                       THEN (4)     ERR_SYM_POIL_SWI = SYM_2
                                                    LV_ERR_POIL_SWI = 1 (after debounce)
                                       ELSE (4)     ERR_SYM_POIL_SWI = NO_SYM
                                                    LV_ERR_POIL_SWI = 0 (after rebounce)
                                       ENDIF (4)
                          ENDIF (3)
             ENDIF (2)
ENDIF (1)
```

19.8.2.1 Oil Temperature at Engine Stopping TOIL_STOP

TOIL_STOP is determined at each transition to ES. TOIL_STOP will be stored in the non-volatile memory during the ECU's self holding phase.
By occuring of EEPROM error TOIL_STOP should be initialized with –40 °C (0x0h).

Initialisation: with stored value

Formula section:

TOIL_STOP = TOIL

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

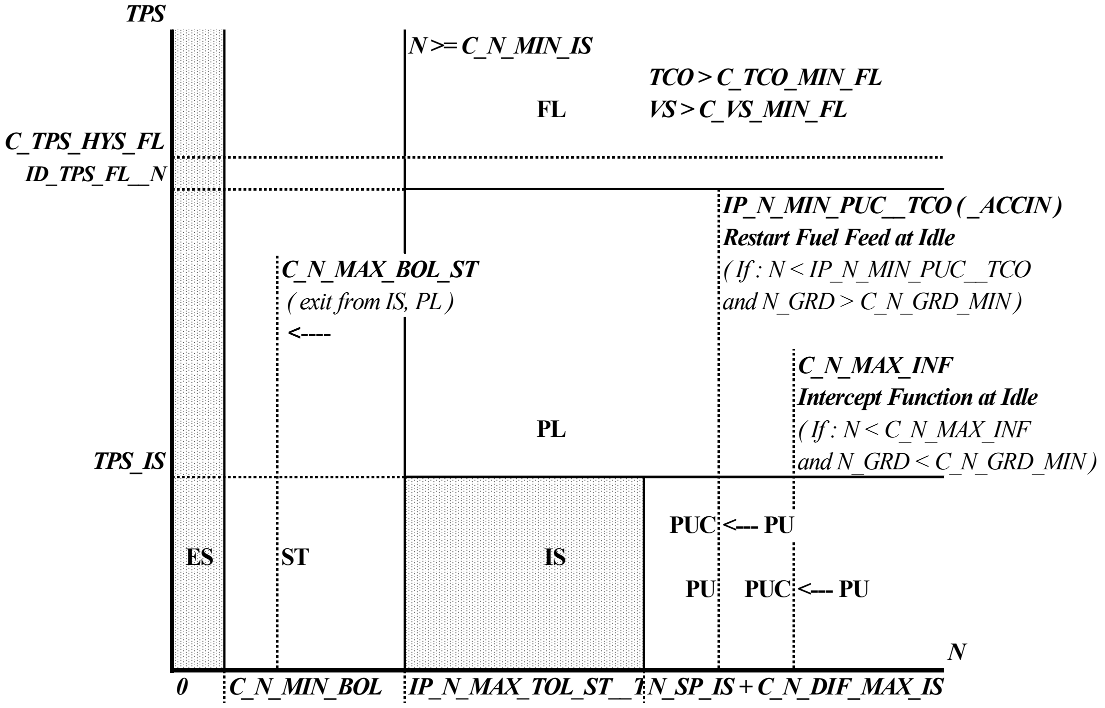
20.1 General Drawing



LV_ES : Engine Stopped

LV_ST : Start

LV_IS : Idle Speed

LV_PL : Part Load

LV_PU : Trailing Throttle

LV_PUC : Trailing Throttle Fuel Cut Off

20.2 Basic Operating States : LV_ES, LV_ST, LV_IS, LV_PL, LV_PU & LV_PUC

Output Data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
CYCNR_HYS_PUC_ST	-	0... FFFFH	0... 65535	1	[-]
Cycle counter for increased engine speed hysteresis for detection of LV_PUC after engine start

General Information

From the 6 different basic operating states only 1 can be active at the same time. So this function can be realised as a state machine. This specification describes the transition conditions.

Application Conditions

Initialization: RST, ERU2ES, ES2ERU
Activation: 10MS: always
SEG: always
Deactivation: never

20.2.1 Engine operating state "engine stopped"

Initialisation of Variables at Reset,ES2ERU and ERU2ES
LV_ES is the operating state which is set during ECU initialisation.
The engine operating state Engine Stopped (LV_ES) is characterized by N_32 < NC_N_MIN. In this engine operating state, the functions are assigned to initialisation values.
The entire scope of diagnosis and actuator control is accessible.

20.2.1.1 Initilisation of Variables at Reset

LV_ES is the operating state which is set during ECU initialisation

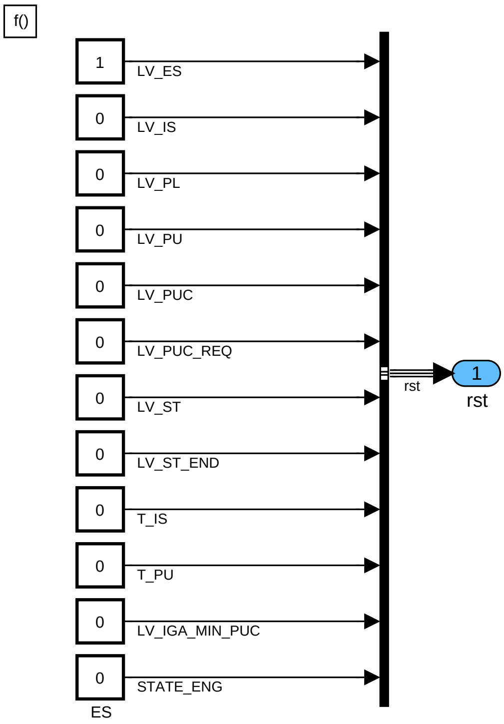

Figure 2:

20.2.1.2 Initilisation of Variables at ERU2ES Event

The initialization of variables are done at ERU2ES event

This condition represents END AFTER START

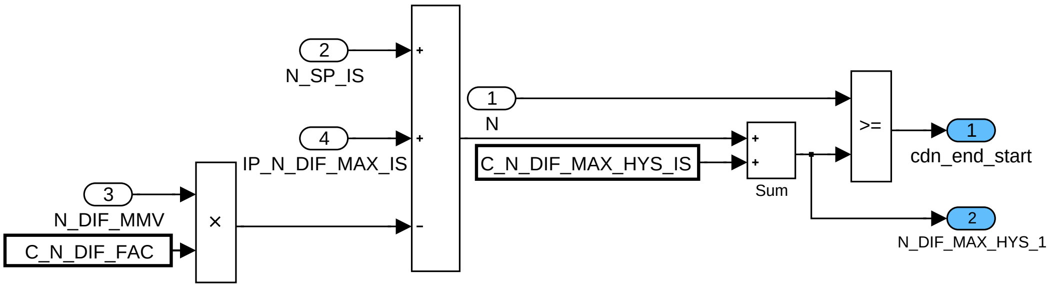

Figure 19:

20.2.2.3.1.1.1.1.2 Engine operating state : "Part Load" (LV_PL)

To facilitate this documentation, N_SP_IS is described in the chapter System Variables . The following states are calculated in this subchapter Exit to LV_IS : Idle Speed, Exit to LV_PU : Trailing Throttle.

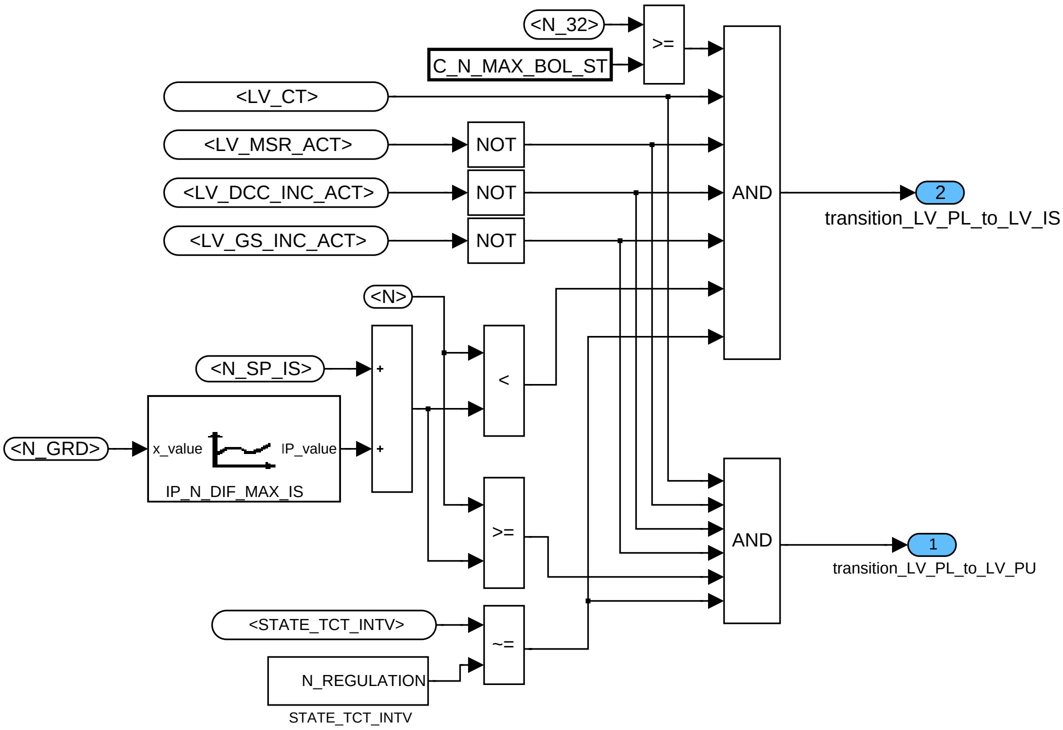

Figure 20:

20.2.2.3.1.1.1.1.3 Engine operating state : "Trailing Throttle" (LV_PU)

To facilitate this documentation, N_GRD and N_SP_IS are described in the chapter System Variables . The following state transitions are calculated Exit to LV_PL : Part Load, Exit to LV_IS : Idle Speed

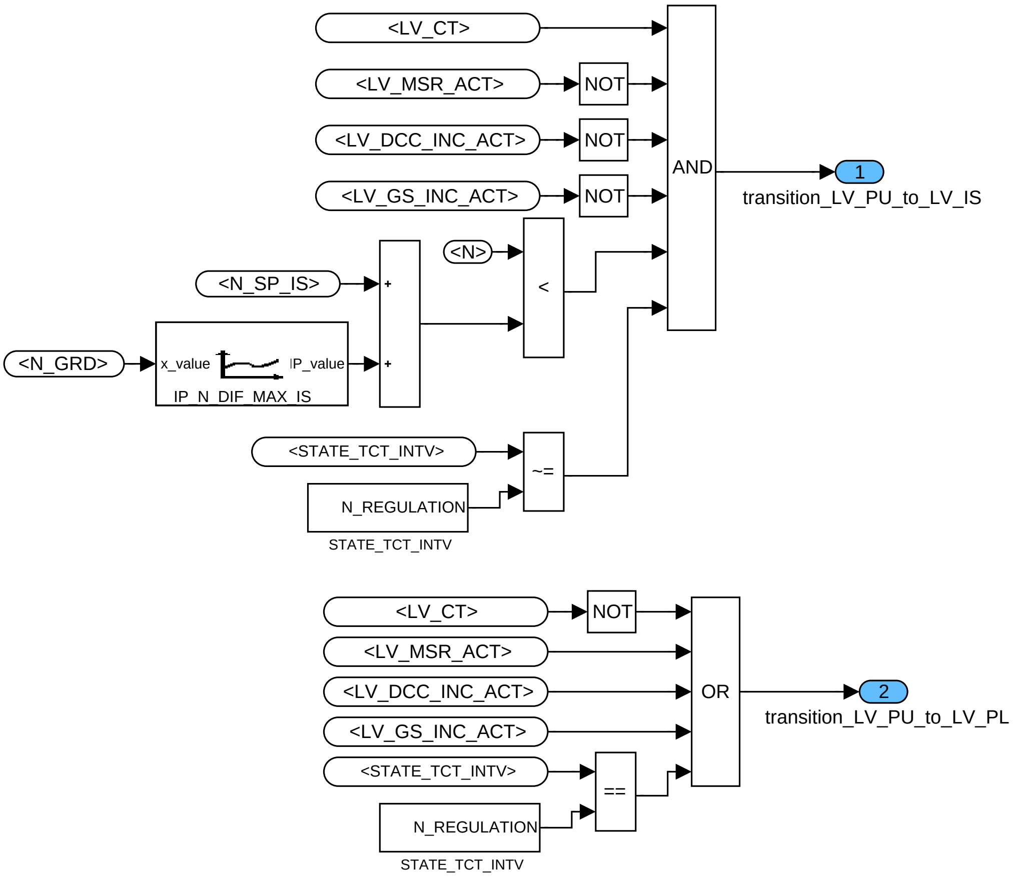

Figure 21:

20.2.2.3.1.1.1.1.4 Exit to LV_PUC : Trailing Throttle Fuel Cut Off

After active MSR function a delay time for entrance into PUC is started to suppress a jittering of MSR function.
T_PU_MSR started at LV_MSR_ACT 1 to 0

In order to avoid a sudden entry in PUC especially for TCT variant the flag LV_CS_PUC in dependence of STATE_ETCU_CLU is defined. The driveability in stop and go conditions is improved by using a delayed clutch switch for entry in PUC.

The flag is set if and only if N_32 < IP_N_MAX_INF

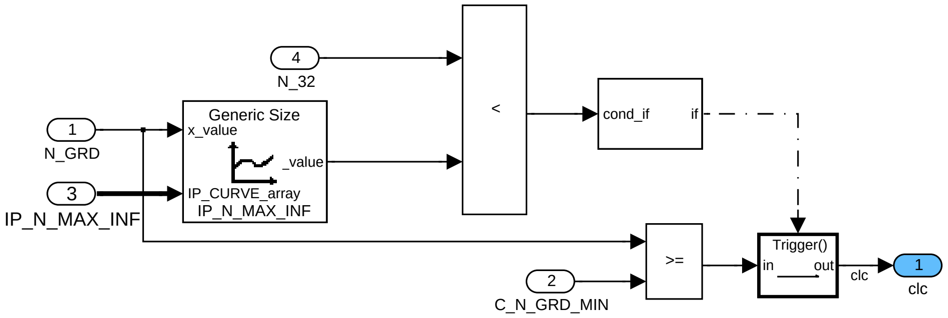

Figure 33:

20.2.2.3.1.3 Calculation of N_HYS variables

To facilitate this documentation, N_SP_IS is described in the chapter System Variables .

To facilitate this documentation, N_SP_IS is described in the chapter System Variables .

The engine speed threshold for termination of PUC (reactivation of injection at decreasing engine speed) is the reactivation engine speed N_MIN_PUC. It is dependant from TCO, gear ratio, vehicle type (transmission) and TQ_LOSS_ADD (additional torque losses). ARS and PSTE torque request maps remain preserved to keep the opportunity of separate treatment.

Function 'LV_PUC Hysteresis':
To avoid toggling PUC <> PU or PUC <> IS there is a hysteresis for the engine speed threshold which determines this transition. Transition from PUC when N < threshold (N_MIN_PUC); transition to PUC when N > threshold + hysteresis (N_MIN_PUC + N_HYS_ACT_PUC).
When entering Trailing Throttle Fuel Cut Off (LV_PUC), the engine speed hysteresis is set to a larger value, ID_N_HYS_MAX_PUC__GR_xx (xx = MT, AT), and a cycle counter is loaded with an adjustable number, C_CYCNR_HYS_PUC. The cycle counter is decremented once per program cycle in any engine operating state except 'Trailing Throttle Fuel Cut Off' (LV_PUC).
When the counter has reached its lower limit 0, the engine speed hysteresis is reset to the value ID_N_HYS_MIN_PUC__GR_xx. This value depends on gear GR_xx and vehicle speed VS and is the minimum engine speed hysteresis for LV_PUC. The hysteresis is reset to this minimum value also, if during counter decrementation the engine operating state changes to partload and this reset is enabled by calibration switch LC_N_HYS_CYL_CUT_OFF_xx_CONF.
If the coolant temperature is below the threshold C_TCO_MIN_PUC_ST when the engine is started, then the engine speed hysteresis for the detection of LV_PUC is increased to an adjustable value ID_N_HYS_PUC_ST__GR_xx, for an adjustable number of cycles C_CYCNR_HYS_PUC_ST. This results in faster catalyst heatup during trailing throttle operation.
For the customer request LV_INH_PUC_CUS = 1, the engine operating state LV_PUC is inhibited.
Description:

Constant for operation mode request from tester (end of line test)					

20.3.1 FUNCTION DESCRIPTION:

General Information:

Via tester an operation mode (e.g. homogenous) can be requested. This is necessary e.g. for end of line tests. This information is used in this module, to switch between several calibratable operation modes. The generated information word OPM_EXT_REQ is send to the customer- software via layer.

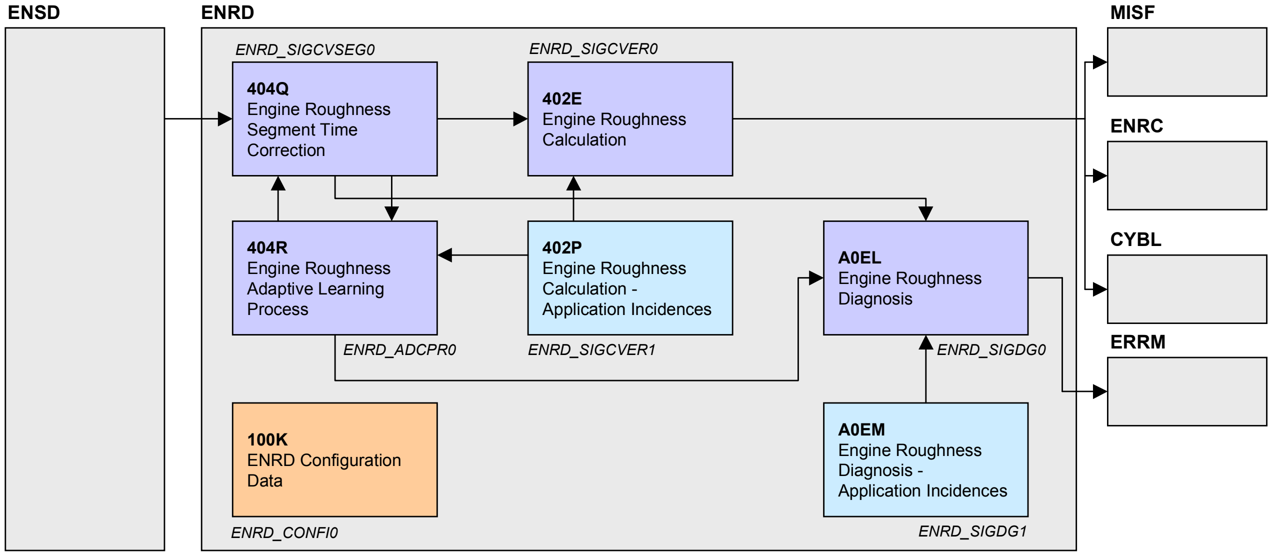
21.1 ENRD General

21.1.1 General description

The goal of the ENRD is to provide an engine roughness information to functions linked to combustion process like misfire monitoring, engine roughness control and cylinder balancing.

21.1.2 Architecture Overview



21.1.3 Description of the containing functions

21.1.3.1.1 404Q Engine roughness segment time correction

Segment times coming from ENSD are managed and corrected according adaptive learning values obtained in 404R module.

21.1.3.1.2 402P Engine roughness calculation - Application Incidences

Application specific requirements, fade-out requests are handled to act on the generic function core. (Template module, modified by the project according its integration environment)

21.1.3.1.3 402E Engine roughness calculation

Engine roughness indexes calculation is grounded on corrected segment time samples provided by 404Q module.

21.1.3.1.4 404R Engine roughness adaptive learning process

Engine roughness adaptive learning process provides adaptive values to 404Q module, to minimise noises produced by flywheel mechanical tolerances.

This module also consumes fade-out requests coming from 402P module.

21.1.3.1.5 A0EM Engine roughness diagnosis - Application Incidences

Application specific requirements, fade-out requests are handled to act on the generic engine roughness diagnosis function. (Template module, modified by the project according its integration environment)

21.1.3.1.6 A0EL Engine roughness diagnosis

This modules provides two diagnosis :

A diagnosis for the ER segment acquisition (thin synchronisation default criterion).

A check range diagnosis for the ER adaptive values obtained by the 404R module.

21.1.3.1.7 100K ENRD Configuration data

This module defines ENRD configuration data used during software integration & compilation. These configuration options defines mainly data and buffer size according the number of cylinders. This module is not attached to a software task.

21.2 ENRD Configuration Data

Input data:

NC_CYL_NR	NC_SEG_DLY_ER_MES	NLC_CONF_GAIN_ADD_ER	NC_SIZE_SEG_T_COR_BUF

General information :

The following describes the general rules for determination of the configuration data

21.2.1 Local configuration data

Here are listed the configuration data, which are used only in the ENRD aggregate.

Data	**Value**
NC_ENRD_VERS	**1**
NC_SIZE_SEG_T_COR_BUF	**7**
NC_SEG_DLY_ER_MES	**1**
NLC_CONF_GAIN_ADD_ER	**1**

Default configurations:

NC_CYL_NR	NC_SIZE_SEG_T_COR_BUF
3	7
4	9
5	11
6	7
8	9

Configuration data:

Name	**Dim**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
NC_ENRD_VERS	1	0...FFH	0...255	1	[-]
ENRD aggregate version					

21.3 Engine roughness segment time correction

21.3.1 Phasing reference for the acquisition of engine roughness segment time

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_MES	V/O	0...7H	0...7	1	[-]
Phasing reference of ER segment acquisition					

Input data:

SEG_NR	NC_CYL_NR	LV_SYN_ENG	

FUNCTION DESCRIPTION:

The ER segments provided by the aggregate ENSD, are used to observe in-cylinder combustion effects on crankshaft. The cylinder x combustion is located between cylinder X tdc and cylinder X+1 tdc. Consequently, at X+1 tdc, the T_SEG_ER obtained is relative to cylinder X combustion, a delay of 1 tdc between SEG_NR value at cylinder observed *(NC_SEG_DLY_ER_MES=1)*.

Exceptionally, if the segment is located after ER segment, this delay must be cancelled *(NC_SEG_DLY_ER_MES=0)*, because in such case the phasing reference SEG_NR is updated after T_SEG_ER acquisition.

SEG_NR_MES, the ER segments phasing reference, will be used to identify which cylinder is observed with the current engine roughness segment, it's particularly useful for ER segment adaptive values identification.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

SEG_NR_MES = 0

Recurrence: Segment

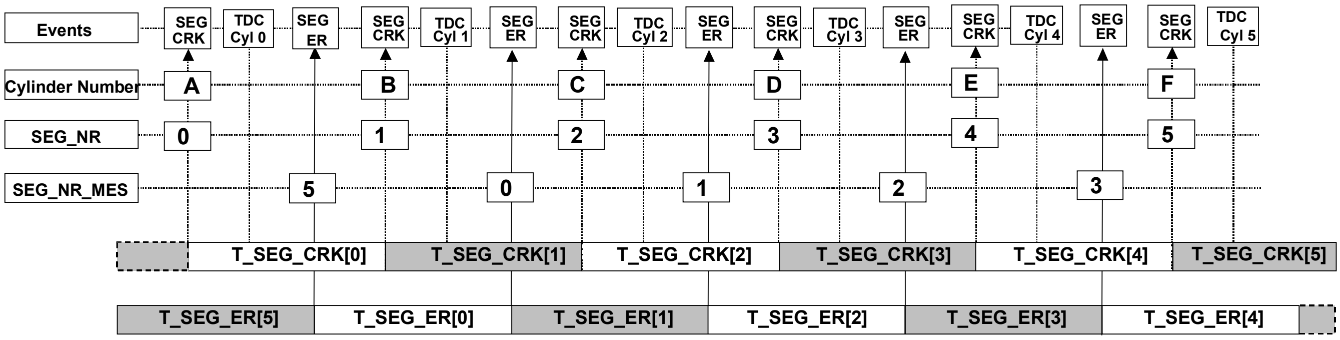
Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

SEG_NR_MES = (SEG_NR – NC_SEG_DLY_ER_MES) % NC_CYL_NR

Implant scheme:



6 Cylinder Engine Example : ***NC_SEG_DLY_ER_MES = 1***

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_SEG_DLY_ER_MES	-	0...2H	0...2	1	[-]
Delay between ER segment and Cylinder measured segment					

21.3.2 Engine roughness segment time acquisition and control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_T_MES	V	0...FFFFH	0...65535	1	[µs]
Engine roughness raw segment time relative to former TDC					
SEG_T_MES_CYL[NC_CYL_NR]	V/O	0...FFFFH	0...65535	1	[µs]
Buffer of cylinder engine roughness raw segment times					
LV_ENA_SEG_T_MES	V/O	0...1H	0...1	1	[-]
Engine roughness segment time validity flag					

Input data:

T_SEG_ER	LV_SYN_ENG	SEG_NR_MES	LV_INH_MIS_CRK
NC_CYL_NR	LV_ERR_CRK	LV_LIH_ERR_CRK	

General information:

Here's described the segment time buffers management & control

ER current raw segment time:

T_SEG_ER *(input from ENSD)*

Coming directly from the ENSD aggregate and update at each ER segment task according ER segment counter *(SEG_NR_MES)*.

Actual ER segment time sample is considered **unvalid** if :

- Engine synchronisation is disable (LV_SYN_ENG = 0)
- When on one crankshaft revolution at least one tooth less or more has been detected (LV_INH_MIS_CRK = 1 before antibounce counter),
- When the crahshaft error or limp home is activated (LV_ERR_CRK = 1 or LV_LIH_ERR_CRK = 1)
- SEG_T_MES obtained exceeds a defined valid range (C_SEG_T_MES_MIN & C_SEG_T_MES_MAX)

Cylinder ER raw segment times:

SEG_T_MES & SEG_T_MES_CYL[NC_CYL_NR] *(outputs)*

This is a buffer where T_SEG_ER values *(after data casting)* are stored according SEG_NR_MES counter. It allows having a memory of raw ER segments on a complete engine cycle. These values will be used by the ER adaptive learning process.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

```
SEG_T_MES = FFFFH
For x = 0 ... NC_CYL_NR-1
        SEG_T_MES_CYL[x] = FFFFH
EndFor
LV_ENA_SEG_T_MES = 0
```

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

```
SEG_T_MES = T_SEG_ER                    // physical equivalence conversion
If    LV_SYN_ENG = 0
      Or  SEG_T_MES > C_SEG_T_MES_MAX
      Or  SEG_T_MES < C_SEG_T_MES_MIN
      Or  LV_INH_MIS_CRK = 1
      Or  LV_ERR_CRK = 1
      Or  LV_LIH_ERR_CRK = 1
Then      LV_ENA_SEG_T_MES = 0
          SEG_T_MES = FFFFH
Else      LV_ENA_SEG_T_MES = 1
EndIf
SEG_T_MES_CYL[SEG_NR_MES] = SEG_T_MES
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_SEG_T_MES_MAX	1	0...FFFFH	0...65535	1	[µs]
ER maximum valid segment time					
C_SEG_T_MES_MIN	1	0...FFFFH	0...65535	1	[µs]
ER minimum valid segment time					

21.3.2.1 Correction of the engine roughness segment adaptive values

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_AD_COR_ER	V	8000H...7FFFH	-7.8125...7.81226	0.2384e-3	[°/oo]
ER segment adaptive values correction versus engine speed (for each segment)					

Input data:

SEG_NR_MES	N_32	NC_CYL_NR	LV_ENA_SEG_T_MES
LV_AT			

FUNCTION DESCRIPTION:

General information:

Due to crankshaft flexion appearance at high engine speed that decreases the misfire detection efficiency, an open-loop adaptive correction value depending on engine speed for each cylinder can be introduced per type of transmission.

A correction can be applied only for each singular segment of the flywheel.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

SEG_AD_COR_ER = 0

Recurrence: Segment

Activation: LV_ENA_SEG_T_MES = 1

Deactivation: LV_ENA_SEG_T_MES = 0

Formula section:

SEG_AD_COR_ER is updated according the following table *(function of NC_CYL_NR and the current value of SEG_NR_MES)*

SEG_NR_MES	NC_CYL_NR = 3	NC_CYL_NR = 4	NC_CYL_NR = 5	NC_CYL_NR = 6	NC_CYL_NR = 8
0	SEG_AD_COR_ER = 0				
1	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_1(N_32)				
2	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)	SEG_AD_COR_ER = 0	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)
3		SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_1(N_32)	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_3(N_32)	SEG_AD_COR_ER = 0	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_3(N_32)
4			SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_4(N_32)	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_1(N_32)	SEG_AD_COR_ER = 0
5				SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)	SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_1(N_32)
6					SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_2(N_32)
7					SEG_AD_COR_ER = IP_SEG_AD_COR_ER_xT_3(N_32)

_xT stands for _AT if LV_AT = 1 else stands for _MT

21.3.3 Engine roughness segment time correction

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	O	0...FFFFH	0...65535	1	[µs]
ER corrected segment times buffer (after adaptation)					
SEG_T_COR	V/O	0...FFFFH	0...65535	1	[µs]
Current ER corrected segment time					

Input data:

SEG_T_MES	SEG_AD_COR_ER	SEG_NR_MES	SEG_AD_MMV_ER[NC_CYL_NR]
LV_ENA_SEG_T_MES	LV_SYN_ENG		

FUNCTION DESCRIPTION:

General information:

The prerequisite for a reliable engine roughness evaluation is an accurate ER segment time measurement.

As the crankshaft flywheel teeth are subject to manufacturing tolerances, geometrical run-out and off-center installation which result in angles modulation, consequently the measured raw segment periods aren't similar and have systematic inaccuracies regarding other segments.

As these inaccuracies are systematic, they can be "learned" by an adaptive process during fuel cut-off periods and used for ER segment time correction. This adaptive process is described in the module : Engine roughness adaptive learning process.

ER segment adaptive values: SEG_AD_MMV_ER[NC_CYL_NR] *(inputs)*

ER adaptive values are stored according SEG_NR_MES counter. These adaptive values are obtained and updated by the ER segment adaptive values learning process. There's one ER segment adaptive value per engine cylinder.

Remark: The SEG_AD_MMV_ER_x are stored in ECU non-volatile memory.

ER current corrected segment time: SEG_T_COR *(output)*

This value is the current result of the ER segment correction process obtained with T_SEG_ER as input.

ER corrected segment times buffer: SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF] *(outputs)*

This is a buffer where are stored SEG_T_COR values (ER corrected segment time current value) who are needed for ER calculation.

SEG_T_COR is stored according a FIFO management (first in, first out).

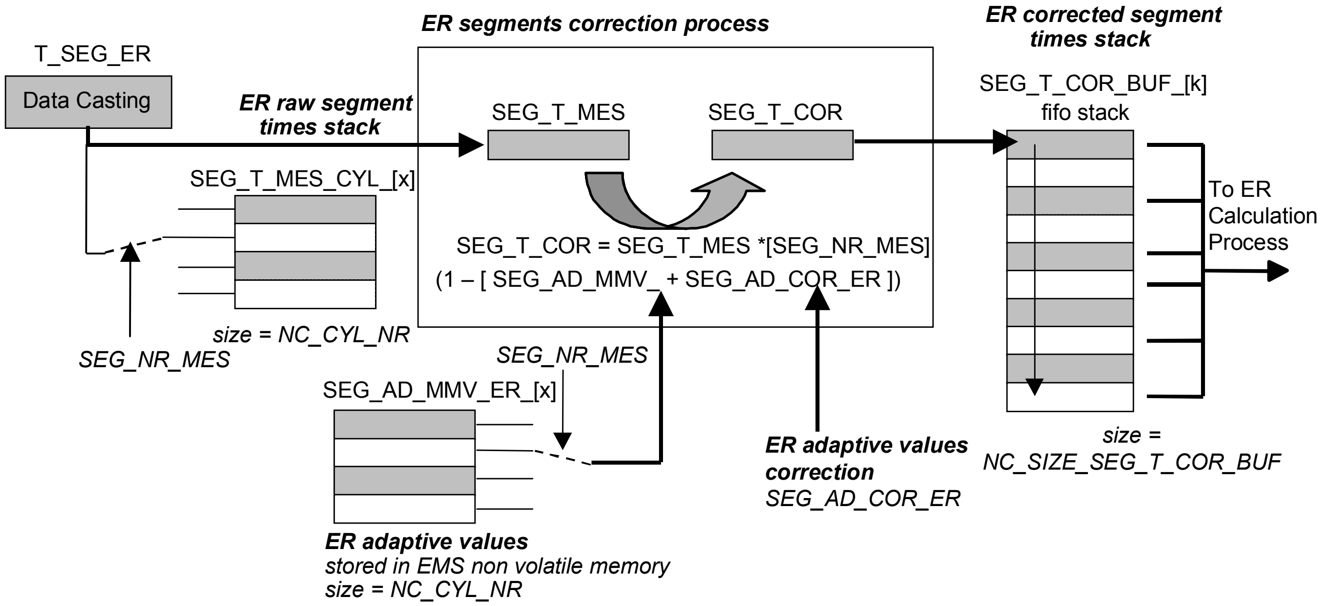
SEG_T_COR_BUF buffer size depends on engine type:

NC_SIZE_SEG_T_COR_BUF = *11 segment time samples for a 5 cylinder engine*

NC_SIZE_SEG_T_COR_BUF = *9 segment time samples for 4 & 8 cylinder engine*

NC_SIZE_SEG_T_COR_BUF = *7 segment time samples for 3 & 6 cylinder engine*

This size NC_SIZE_SEG_T_COR_BUF *is determined by the ER sample number required by ER calculation according engine type.*



Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation event*

```
SEG_T_COR = FFFFH
For k = 0 to NC_SIZE_SEG_T_COR_BUF-1
    SEG_T_COR_BUF[k] = FFFFH
EndFor
```

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

```
If(1) LV_ENA_SEG_T_MES = 0
Then(1) SEG_T_COR = FFFFH
    For(2) k = 0 to NC_SIZE_SEG_T_COR_BUF-1
        SEG_T_COR_BUF[k] = FFFFH
    EndFor(2)
Else(1) SEG_T_COR =
        SEG_T_MES * (1 – [SEG_AD_MMV_ER[SEG_NR_MES] + SEG_AD_COR_ER] )
    For(2) k : 1 to NC_SIZE_SEG_T_COR_BUF-1
        SEG_T_COR_BUF[k] is managed as a FIFO stack (SEG_T_COR_BUF last value is lost)
```

```
        EndFor(2)
        SEG_T_COR_BUF[0] = SEG_T_COR
EndIf(1)
```

Where:

SEG_T_MES : *Current uncorrected ER segment time after data casting*

SEG_T_COR : *Current ER corrected segment time*

SEG_AD_MMV_ER[SEG_NR_MES] : *ER segment adaptive value corresponding to current T_SEG_ER phasing*

SEG_AD_COR_ER : *Adaptive value correction versus engine speed corresponding to current T_SEG_ER phasing*

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_SIZE_SEG_T_COR_BUF	-	0...FFH	0...255	1	[-]
Size of the array of engine roughness corrected segment times					

21.3.4 Engine roughness calculation

21.3.5 General information

The engine roughness index (ER) is a system variable relative to crankshaft segments behaviour. This index is mainly used by the misfire monitoring & algorithms dedicated to combustion process control.

Integration version for 3,4,5,6 & 8 cylinder engines.

The engine roughness system variable is calculated each ER window end occurrence, every time the engine is running & synchronised.

21.3.6 Engine roughness segment reference

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_ER	V/O	0...7H	0...7	1	[-]
ER segment counter for segment identification (0 ... NC_CYL_NR - 1)					

Input data:

SEG_NR	NC_CYL_NR	LV_SYN_ENG	

Due to engine roughness definition, there is a delay of C_SEG_DLY_ER segments between ER actual value and the segment that was observed by this ER value.

SEG_NR_ER will be used to identify which cylinder is observed with the engine roughness system variable, it's particularly useful for misfire cylinder identification.

The segment counter SEG_NR_ER with the limit 0...(NC_CYL_NR - 1) is incremented in the same way as the common segment counter SEG_NR.

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation condition event*

SEG_NR_ER = 0

Recurrence: Segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

SEG_NR_ER = (SEG_NR + 2 * NC_CYL_NR – C_SEG_DLY_ER) % NC_CYL_NR

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_SEG_DLY_ER	1	0...CH	0...12	1	[-]
Delay of ER segment reference					

21.3.7 Engine roughness segments control process

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ENA_ER	V/O	0...1H	0...1	1	[-]
Engine roughness valid calculation control flag					

Input data:

SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	LV_ENA_SEG_T_MES	N	

Description:

All ER components calculations are based on corrected segment time acquisitions buffer values SEG_T_COR_BUF.

As soon as an invalid segment has been detected during acquisition process (LV_ENA_SEG_T_MES = 0) or segment adaptive calculation, ER calculation & misfire detection have to be disabled (LV_ENA_ER = 0).

Application conditions:

Initialisation: *at ECU reset, Engine Stop* ***Or*** *Deactivation condition event*

LV_ENA_ER = 0

Recurrence: Segment

Activation:

Engine roughness calculation is executed only if:

NC_SIZE_SEG_T_COR_BUF consecutive valid ER segment times have been acquired & stored in SEG_T_COR_BUF buffer.

"**Valid**" stands for:

LV_ENA_SEG_T_MES = 1 on NC_SIZE_SEG_T_COR_BUF consecutive ER segments

And no ER components calculation overflow on current segment *(DRV0, DRV1, DRV2 and ER components)*

And N <= C_N_MAX_ER

And N >= C_N_MIN_ER

In this case:

ER components are calculated as described below.

LV_ENA_ER = 1 *(if no overflow occurs during ER components calculation)*

Deactivation:

Engine roughness calculation is stopped & initialised when at least one of the NC_SIZE_SEG_T_COR_BUF consecutive segment times have been acquired & stored in SEG_T_COR_BUF buffer have been detected unvalid.

"**Unvalid**" stands for:

LV_ENA_SEG_T_MES = 0 at least one time on NC_SIZE_SEG_T_COR_BUF consecutive ER segments

Or at least one calculation overflow occurs one of ER components *(DRV0, DRV1, DRV2 or ER component)* on current segment.

Or N > C_N_MAX_ER

Or N < C_N_MIN_ER

In that case :

LV_ENA_ER = 0

ER components are initialised to 0

Calibration data:

ER additive correction components					

Input data:

LV_AT	LOAD_MIS	N_32	NC_CYL_NR
LV_ENA_ER	LV_VAR_TCT		

FUNCTION DESCRIPTION:

General information:

The misfire detection based on ER index can be complicated by the torsional/flexion vibrations especially with multiple cylinder engines with a long crankshaft. This affects on misfire detection efficiency, especially at high engine speed.

To balance this phenomenon, after segment timing correction with ER adaptive values *(see ER segment correction process)*, an irregular operation is determined from the measured cylinder segment times, cylinder specific additive and multiplicative corrections are applied on the raw engine roughness value *(ER_RAW)*.

FAC_ADD_ER[NC_CYL_NR] and FAC_GAIN_ER[NC_CYL_NR] correction coefficients are based on calibration tables specific to each cylinder and to transmission type (MT/AT).

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

```
For x = 0 to NC_CYL_NR-1
    FAC_GAIN_ER[x] = 1
    FAC_ADD_ER[x] = 0
EndFor
```

Input data:

N_32	LV_AT	LOAD_MIS	CTR_T_ZDLY_MIS
TCO	LV_IS	LV_VAR_TCT	

FUNCTION DESCRIPTION:

This function allows to determinate the coefficients relative to DRV2 components of the engine roughness, according different configurations:

If used *(see project/customer legal requirements concerning misfire monitoring after engine start)*, during zero delay misfire monitoring activation period, specific gain & filter coefficient can be apply to DRV2 component to be able to detect misfire just after engine start *(dynamic correction modified).*

Else, FAC_DRV2_ER & CRLC_DRV2_ER are defined according transmission type *(AT/MT)*.

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

Engine roughness without curvature component

Input data:

SEG_T_COR	SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	NC_CYL_NR	

General information:

The engine roughness calculation needs three individual components: a static component (DRV0_ER), a dynamic component (DRV1_ER) and a curvature component (DRV2_ER). These component definitions are specific to the engine cylinder number (see following related subchapters).

DRV2_MMV_ER is the filtered curvature component correction (DRV2_ER) who allows adding an artificial positive offset on ER value in case of dynamic curvature effects. This feature had a safety effect against wrong detection in case of segment oscillations.

ER_RAW is the engine roughness value without curvature component (DRV2_MMV_ER), used by cylinder balancing and engine warm up monitoring modules.

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

DRV0_ER = 0

DRV1_ER = 0

DRV2_ER = 0

DRV2_MMV_ER = 0

ER_RAW = 0

Recurrence: Segment

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Formula section:

Engine roughness static component:

DRV0_ER(n) = NC_CYL_NR * [SEG_T_COR(n) - SEG_T_COR(n+1)]

Engine roughness dynamic and curvature components:

DRV1_ER and DRV2_ER components are engine type specific.

3 Cylinder Engine

```
#If   NC_CYL_NR = 3
      DRV1_ER(n) = SEG_T_COR(n-2) - SEG_T_COR(n+1)
      DRV2_ER(n) =  FAC_DRV2_ER *
             max(0,[SEG_T_COR(n-3) - SEG_T_COR(n)] - [SEG_T_COR(n) - SEG_T_COR(n+3)])
#EndIf
```

4 or 8 Cylinder Engine

```
#If   NC_CYL_NR = 4 or 8
      DRV1_ER (n) = SEG_T_COR(n-2) - SEG_T_COR(n+2)
      DRV2_ER (n) =  FAC_DRV2_ER *
              max(0,[SEG_T_COR(n-4)- SEG_T_COR(n)] - [SEG_T_COR(n) -SEG_T_COR(n+4)])
#EndIf
```

5 Cylinder Engine

```
#If   NC_CYL_NR = 5
      DRV1_ER (n) = SEG_T_COR(n-2) - SEG_T_COR(n+3)
      DRV2_ER (n) =  FAC_DRV2_ER *
               max(0,[SEG_T_COR(n-5)- SEG_T_COR(n)] - [SEG_T_COR(n)-SEG_T_COR(n+5)])
#EndIf
```

6 Cylinder Engine

```
#If   NC_CYL_NR = 6
      DRV1_ER (n) = SEG_T_COR(n-3) - SEG_T_COR(n+3)
      DRV2_ER (n) =  FAC_DRV2_ER *
             max(0,[SEG_T_COR(n-3)- SEG_T_COR(n)] - [SEG_T_COR(n)-SEG_T_COR(n+3)])
#EndIf
```

Normalised engine roughness					
ER_STND_CYL[NC_CYL_NR]	V	8000...7FFFH	-32768...32767	1	[-]
Cylinder normalised engine roughness values					

Input data:

THD_AD_ER	SEG_T_COR_BUF[NC_SIZE_SEG_T_COR_BUF]	N	C_SEG_DLY_ER

Description:

ER is the complete engine roughness value including all ER components (DRV0_ER, DRV1_ER & DRV2_MMV_ER), specified & used by misfire detection module.

ER_STND is the normalised engine roughness value versus engine speed that could be amplified by a gain C_FAC_SCA_ER_STND. This is the nominal engine roughness value divided by the corresponding cubic corrected ER segment time (SEG_T_COR_BUF[C_SEG_DLY_ER])^3 . The cubic segment time is calculated by using a mantisse and an exponent.

ER & ER_STND calculation formula are generic to all engine type.

A positive offset (THD_AD_ER) is added to ER components as long as the ER adaptive learning process hasn't been executed. This, in a way to avoid wrong misfire detection in engine operation areas where crankshaft decelerations due to a misfire are very close to ER noise due to the flywheel mechanical tolerances.

This offset decreases as the ER adaptive learning progress. At the end of the learning process, this offset is null *(see next chapter ER adaptive values learning process for more informations)*.

Once the ER fast adaptive learning stage has been executed, these flywheel mechanical tolerances are sufficiently reduced to able to detect misfire in full legal range without adding a positive offset.

ER_CYL_x and ER_STND_CYL_x are the engine roughness values obtained for corresponding cylinder x, these values are switched according SEG_NR_ER segment reference.

Application conditions:

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *on Deactivation condition event*

```
  ER = 0
  ER_STND = 0
  For x = 0 to NC_CYL_NR-1
     ER_CYL[x] = 0
     ER_STND_CYL[x] = 0
  EndFor
```

Recurrence: Segment

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Formula section:

Engine roughness:

```
  ER = ER_RAW + DRV2_MMV_ER + THD_AD_ER
  ER_CYL[SEG_NR_ER] = ER
```

Normalised Engine roughness versus engine speed:

```
If      N < C_N_MAX_ER_STND
Then
      $ER\_STND = ER / (SEG\_T\_COR\_BUF_{[C\_SEG\_DLY\_ER]})^3 * 2^{(16+C\_FAC\_SCA\_ER\_STND)}$
      ER_STND_CYL[SEG_NR_ER] = ER_STND
Else
      ER_STND = 0
      ER_STND_CYL[SEG_NR_ER] = 0
EndIf
```

Note: if C_SEG_DLY_ER ≥ NC_SIZE_SEG_T_COR_BUF, SEG_T_COR_BUF[C_SEG_DLY_ER] data is limited to the last cell of the buffer.

ER filtered adaptive values used for reload (for each segment) if segment adaptive process not valid					

Input data:

LV_ENA_SEG_T_MES	LV_AT	GR_MT	GR_AT

FUNCTION DESCRIPTION:

Engine roughness segments adaptive process is inhibited when one of the following system conditions occurs. See application specific accessories that could have an impact on the transmission behaviour (CVT, Automatic gear shifting, specific gear ratios...).

Application conditions:

Initialisation: at ECU reset and engine Stop:

LV_INH_APP_ER_AD = 0

at ECU reset:

LV_REQ_SEG_AD_MMV_ER_APP = 0

SEG_AD_MMV_ER_APP[NC_CYL_NR] = 0

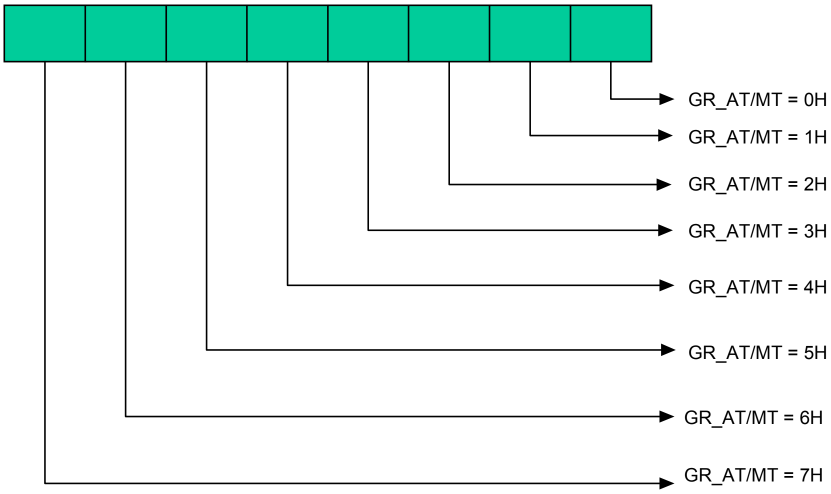
Update rate: Engine roughness segment

Activation: LV_ENA_SEG_T_MES = 1

Deactivation: LV_ENA_SEG_T_MES = 0

Diagram:

Bit-position within C_GR_INH_ER_AD_MT/AT



Example: Inhibition should be in 1st gear and 2st gear: => C_GR_INH_ER_AD_MT/AT = 6H

Formula section:

```
If      (LV_AT = 1 And C_GR_INH_ER_AD_AT[GR_AT] = 1)
   Or   ( LV_AT = 0 And C_GR_INH_ER_AD_MT[GR_MT] = 1)
Then    LV_INH_APP_ER_AD = 1
Else    LV_INH_APP_ER_AD = 0
EndIf
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_GR_INH_ER_AD_AT	1	0...FFH	0...255	1	[-]
Bitfield used to inhibit engine roughness adaptive according current AT gear ratio (Gear corresponding bit = 1, ER_AD inhibited)					
C_GR_INH_ER_AD_MT	1	0...FFH	0...255	1	[-]
Bitfield used to inhabit engine roughness adaptive according current MT gear ratio (Gear corresponding bit = 1, ER_AD inhibited)					

21.4.2 ER segment adaptive process inhibition related to OBDI diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_OBD_ER_AD	V/O	0...1H	0...1	1	[-]
ER segment adaptive process inhibition flag.					

Input data:

LV_ERR_CRK	LV_ERR_CPS	LV_ERR_DIAGCPS	STATE_ERR_IV
LV_SYN_ENG			

General information:

ER segment adaptive process is inhibited when one of the mentioned OBD I errors occurs.

Application conditions:

Initialization: 0 at reset

Update rate: Engine roughness segment

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

```
If      STATE_ERR_IV <> 0        or
        LV_ERR_CPS = 1           or
        LV_ERR_DIAGCPS = 1       or
        LV_ERR_CRK = 1

Then    LV_INH_OBD_ER_AD = 1
Else    LV_INH_OBD_ER_AD = 0
EndIf
```

21.4.3 End of line & After sale service request to reset ER segment adaptive values

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SEG_AD_RST_ER_EOL	V/O	0...1H	0...1	1	[-]
EOL specific request to reset ER segment adaptive values					

Input data:

LV_EOL_OBD	LV_ENA_SEG_T_MES	LV_REQ_SEG_AD_RST_EOL	

General information:

During end of line plant and/or for After sale services, a request is generated via communication protocol, to reset ER segment adaptive values & learning process *(see project communication protocol).*

Application conditions:

Initialization: 0 at reset

Update rate: Engine roughness segment

Activation: LV_ENA_SEG_T_MES = 1

Deactivation: LV_ENA_SEG_T_MES = 0

Formula section:

```
If    LV_EOL_OBD = 1                        // OBD end of line process request
      And   LC_SEG_AD_RST_ENA_EOL = 1
      And   LV_REQ_SEG_AD_RST_EOL = 1
            // EOL request to reset segment adaptive values
Then        LV_SEG_AD_RST_ER_EOL = 1
Else        LV_SEG_AD_RST_ER_EOL = 0
EndIf
```

Calibration data:

LC_SEG_AD_RST_ENA_EOL	1	0...1H	0...1	1	[-]
Specific EOL request enable flag to reset ER segment adaptive values & learning process					

21.4.4 Normalised engine roughness quotient for calibration

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ER_AV_QUO	V	0...FFH	0...2.55	0.01	[-]
Quotient of ER/THD_ER (to simplify calibration and testing)					

Input data:

ER	THD_ER	LV_REQ_INH_MIS	LV_ENA_ER
LV_ES	LV_ST		

FUNCTION DESCRIPTION:

General information:

To simplify the calibration, testing and controlling of the misfire function the variable ER_AV_QUO is defined.

Application conditions:

Initialisation: ER_AV_QUO = 0 at reset

Recurrence: updated every segment

Activation: LV_ENA_ER = 1

Deactivation: LV_ENA_ER = 0

Formula section:

```
If      LV_ES           =  1   or
        LV_ST           =  1   or
        LV_REQ_INH_MIS  =  1   or
        ER > 0
Then    ER_AV_QUO       =  0
Else    ER_AV_QUO       =  ER / THD_ER
Endif
```

21.5 Engine roughness adaptive learning process

General information:

To reduce systematic noises generated by target wheel mechanical tolerances, an adaptive learning process is required to improve the signal noise ratio on engine roughness variable and to avoid wrong misfire detection at high engine speed / low load.

ER segment adaptive values learning process is based on ER segments timing observation according a geometrical reference (ER segment time 0, SEG_NR_MES = 0).

During an engine deceleration in fuel cut-off mode on all cylinders (LV_INJ_CUT, no engine combustion influences), due to crankshaft inertia, engine speed can be considered in a short horizon as constant, thus on one engine cycle (720°Crk) timing dissimilarities between segment reference and others will be observed. For longer horizon observation, a deceleration is applied according current segment position in the engine cycle.

When all adaptation conditions fulfilled (smooth deceleration in fuel cut-off conditions), an adaptive values learning process is performed every **720° crank angle**, starting with **segment 0** *(adaptive process reference).*

If there is no cylinder specific mechanical damage or crankshaft torsion/flexion, the adaptation values for cylinders with the same mechanical segment will be approximately identical:

3 cylinder engine	4 cylinder engine	5 cylinder engine	6 cylinder engine	8 cylinder engine
SEG_AD_ER_0 *(geometrically singular)*	SEG_AD_ER_0 ≅ SEG_AD_ER_2	SEG_AD_ER_0 *(geometrically singular)*	SEG_AD_ER_0 ≅ SEG_AD_ER_3	SEG_AD_ER_0 ≅ SEG_AD_ER_4

TPS_GRD	TPS_AV	LV_STATE_RR	LOAD_GRD_MIS
MAF_DIF	LV_SEG_AD_DIF_MAX_ER	LV_SEG_AD_LIM_ER	LV_INH_OBD_ER_AD
LV_INH_APP_ER_AD			

FUNCTION DESCRIPTION:

Description:

LV_SEG_AD_FDOUT_ER combines all system conditions to generate a fade out condition as input for the generic segment adaptation process.

Update rate: segment occurrence for conditions & data process

10ms for free running decounters

Application conditions:

Activation: *LV_ENA_SEG_T_MES = 1*

Deactivation: *LV_ENA_SEG_T_MES = 0*

Action on deactivation event ***Or*** *ECU reset:*

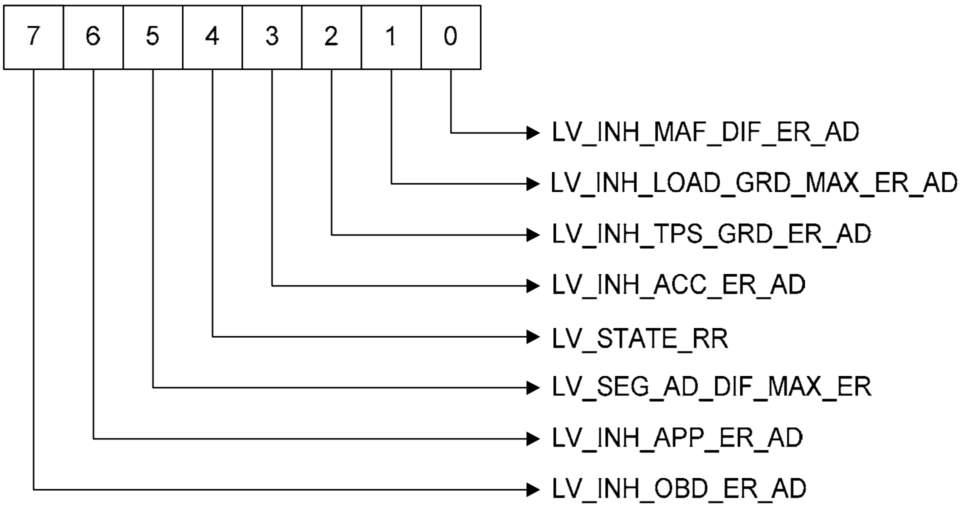
LV_SEG_AD_FDOUT_ER = 1

SEG_AD_FDOUT_ER_CDN = 0xFF

SEG_AD_FDOUT_ER_CDN_NR = 8

Definition of segment adaptation fade out conditions carrier:

SEG_AD_FDOUT_ER_CDN : *Carrier used for fade-out conditions merge*



21.5.1.1 Configurable Fade-out Management

Application conditions:

The Fade out management of the segment adaptive process can be configured with a bitfield mask calibration that allow to take in account or not some conditions set in the carrier.

If the corresponding bit in the SEG_AD_FDOUT_ER_CDN carrier structure is set to 0 in C_MASK_SEG_AD_FDOUT_ER calibration, then the corresponding condition will not fade-out the segment adaptive process via LV_SEG_AD_FDOUT_ER.

The number of fade-out conditions not masked by this calibration is set in SEG_AD_FDOUT_ER_CDN_NR.

Formula section:

SEG_AD_FDOUT_ER_CDN_NR =

sum (SEG_AD_FDOUT_ER_CDN **&** C_MASK_SEG_AD_FDOUT_ER)

! (bitfield operation) !

```
If    SEG_AD_FDOUT_ER_CDN_NR ≠ 0
Then      LV_SEG_AD_FDOUT_ER = 1
Else      LV_SEG_AD_FDOUT_ER = 0
EndIf
```

21.5.1.2 Maximum air-mass gradient

Due to trailing throttle / acceleration transition problems it is necessary to disable ER segment learning process for a short period when the air-mass gradient per segment exceeds a calibration value.

Application conditions:

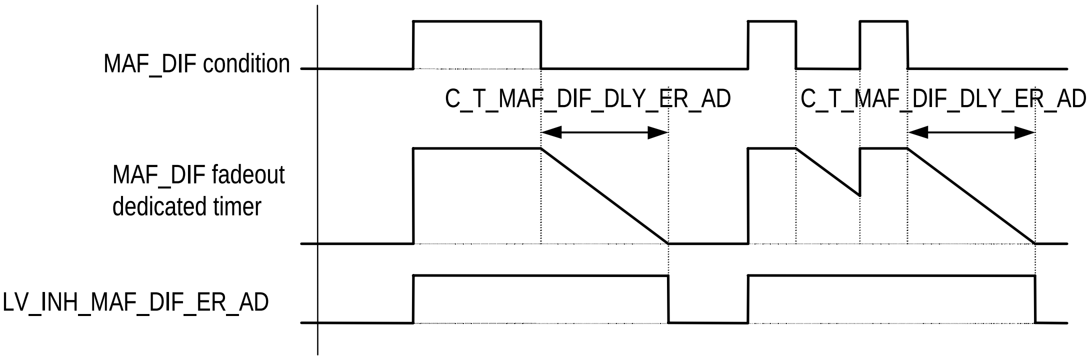
ER segment adaptation is disabled while the absolute of the air-mass gradient exceeds the value mentioned below:

After the last triggering of this segment adaptation is suppressed for a period of C_T_MAF_DIF_DLY_ER_AD.

Formula section:

```
If    | MAF_DIF | > IP_MAF_DIF_MAX_ER_AD(MAF)
Then
    After condition rising edge triggering, LV_INH_MAF_DIF_ER_AD flag is set to 1 as long as condition is true.
    After condition falling edge triggering, LV_INH_MAF_DIF_ER_AD flag is hold to 1 for a period of C_T_MAF_DIF_DLY_ER_AD.
EndIf
```

Fade out behaviour summary:



21.5.1.3 Maximum actual load gradient

Due to general intervention of the torque model it's necessary to disable ER segment adaptation for a short period when the actual torque gradient exceeds a calibration value.

Application conditions:

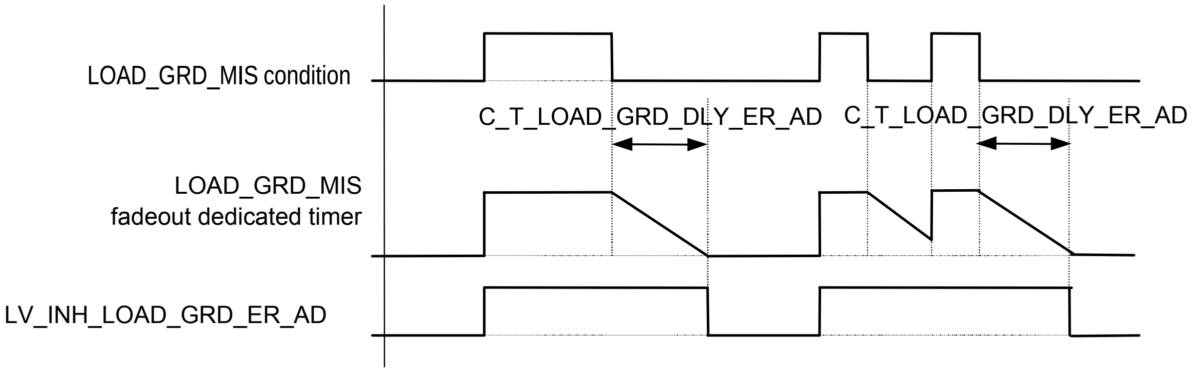
ER segment adaptation is disabled while the absolute of the torque gradient – here LOAD_GRD_MIS the reference for Misfire detection process – exceeds the value mentioned below.

After the last triggering of this segment adaptation is suppressed for a period of C_T_LOAD_GRD_DLY_ER_AD.

Formula section:

```
If    LOAD_GRD_MIS > IP_LOAD_GRD_ER_AD(LOAD_MIS)
Then
    After condition rising edge triggering, LV_INH_LOAD_GRD_MAX_ER_AD flag is set to 1 as long as condition is true.
    After condition falling edge triggering, LV_INH_LOAD_GRD_MAX_ER_AD flag is hold to 1 for a period of C_T_LOAD_GRD_DLY_ER_AD.
EndIf
```

Fade out behaviour summary:



21.5.1.4 Maximum throttle gradient

Due to trailing throttle / acceleration transient problems at low load it is necessary to disable ER segment adaptation for a short period when the throttle gradient exceeds a calibration value.

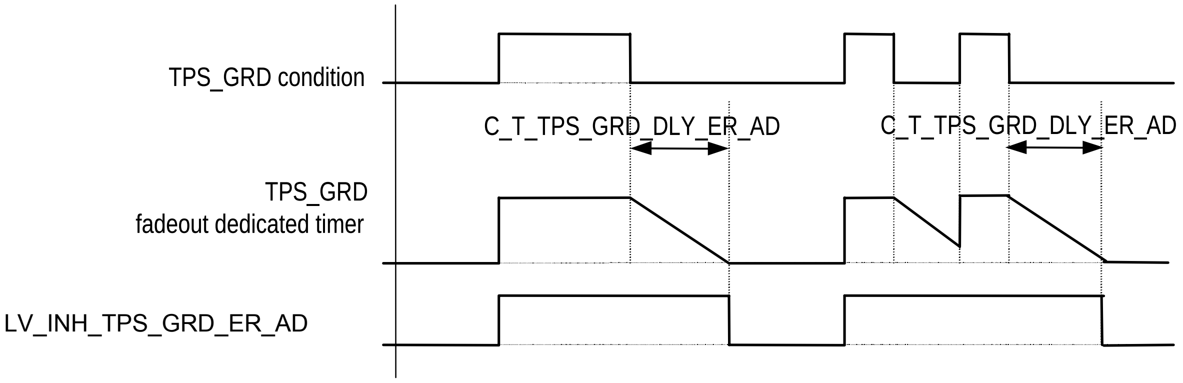
Application conditions:

ER segment adaptation is disabled while the throttle position gradient exceeds the value mentioned below.

After the last triggering of this segment adaptation is suppressed for a period of C_T_TPS_GRD_DLY_ER_AD.

Formula section:

```
If   TPS_GRD > IP_TPS_GRD_MAX_ER_AD(TP_AV)
Then
     After condition rising edge triggering, LV_INH_TPS_GRD_ER_AD flag is set to 1 as long as condition is true.
     After condition falling edge triggering, LV_INH_TPS_GRD_ER_AD flag is hold to 1 for a period of C_T_TPS_GRD_DLY_ER_AD.
EndIf
```



21.5.1.5 Air - conditioning compressor activation

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine.

This load jump can cause an ER segment period jump and crankshaft vibration.

Application conditions:

Engine roughness segment adaptation can be suppressed for the applicable constant period C_T_ACCOUT_DLY_ER_AD, starting if the air - conditioning compressor is switched on or off (LV_ACCOUT_RLY changes from 0 to 1 or from 1 to 0), during this period LV_INH_ACC_ER_AD is set to 1.

Formula section:

```
If    LV_ACCOUT_RLY = 0 → 1
      Or     LV_ACCOUT_RLY = 1 → 0
Then         LV_INH_ACC_ER_AD is set to 1 during C_T_ACCOUT_DLY_ER_AD
EndIf
```

21.5.1.6 Rough road condition active

Due to possible feedback from the driven wheels to the crankshaft it is necessary to fade out. ER segment adaptation when rough road condition is active (LV_STATE_RR = 1).

21.5.1.7 Engine roughness adaptive values on the same physical segment out of range

Due to possible feedback from Dual Mass Flywheel oscillations *(see transmission/crankshaft design)* in adaptive process engine speed range, fluctuations on ER adaptive values of identical physical segments can induce dissimilarity in ER segment correction. LV_SEG_AD_DIF_MAX_ER indicates that the engine roughness adaptive values difference on the same physical segment is out of range.

This flag is produced in the following chapter called: Engine roughness adaptive values difference on the same physical segment out of range.

21.5.1.8 Application specific inhibition request for engine roughness adaptive process

Due to possible accessories triggering specific to the application (CVT shifts...), an inhibition of the engine roughness adaptive process can be applied.

The inhibition is applied when LV_INH_APP_ER_AD = 1.

21.5.1.9 Inhibition request for engine roughness adaptive process linked to OBD errors

Due to possible troubles induced by OBD I sensors errors (CAM, CRK...), the engine roughness adaptive process can be inhibited by the flag LV_INH_OBD_ER_AD.

The inhibition is applied when LV_INH_OBD_ER_AD = 1.

Calibration data:

LV_INJ_CUT	LV_ENA_SEG_T_MES	LV_SEG_AD_FDOUT_ER_EOL	LV_SEG_AD_RST_ER_EOL
SEG_NR_MES	NC_CYL_NR	SEG_T_COR	LV_ENA_ER
LV_AT	LV_VAR_TCT		

Description:

The adaptive process is managed in two phases:

- A fast adaptive process for end of line procedures (EOL), who allow a fast convergence to ER flywheel adaptive values.
- At the end of the fast adaptive process, a slow adaptive process who will monitor ER adaptive values during the engine lifetime.

An end of line specific filtering mode, to be used on EOL or special service request.

At the beginning of the segment adaptation learning process, it is necessary to upper the engine roughness value with an additional offset (THD_AD_ER), depending on the target wheel tolerances to be excepted.

For instance, a flywheel with a ± 0.3°Crk mechanical tolerance on the ER segment corresponds to following segment drift:

Engine Type	ER Segment length	Induced Drift with ± 0.3°Crk tolerance on ER segment
3 cyl engine	240°Crk	2.5‰
4 cyl engine	180°Crk	3.33‰
5 cyl engine	144°Crk	4.17‰
6 cyl engine	120°Crk	5‰
8 cyl engine	90°Crk	6.68‰

The value by which the ER is increased at the beginning is gradually reduced to zero in a linear way until the 95% correction is obtained.

This number of steps is controlled by an internal adaptation counter CTR_SEG_AD_ER.

21.5.3.1 Engine roughness adaptive learning process

First time initialisation :

The ER segment adaptive values learning process is initialised when :

- ECU is initialised for the first time *(flash memory formatting)*
- A loss of adaptation values has been detected *(flash memory corrupted)*.
- A specific external tool request occurs *(use of **LV_SEG_AD_RST_ER_EOL**)*

// ER segment adaptive process control variables reseted

```
CTR_SEG_AD_ER = 0
DELTA_CRK_DIF_MAX_ER = NC_CYL_NR * 4 * C_CRK_DIF_MAX_ER
LV_SEG_AD_AVL_ER = 0
```

Update rate: ER segment task, every engine cycle when SEG_NR_MES = 0 ; SEG_T_MES_0 segment acquired.

Application conditions:

Activation/Deactivation: (based on LV_SEG_AD_RAW_ER evaluation)

// Raw adaptive value monitoring activation

```
If    LV_INJ_CUT = 1        // All cylinders shut-off
      And   N_32 < C_N_SEG_T_AD_RAW_MAX_ER
      And   N_32 > C_N_SEG_T_AD_RAW_MIN_ER
      And   LV_ENA_SEG_T_MES = 1
Then        LV_SEG_AD_RAW_ER = 1
Else        LV_SEG_AD_RAW_ER = 0
            LV_SEG_AD_ER = 0
EndIf
```

Formula section:

// Adaptive value learning process activation

```

LV_SEG_AD_ER	LV_SEG_AD_RAW_ER	SEG_T_MES_CYL[NC_CYL_NR]	SEG_NR_MES
LV_REQ_SEG_AD_MMV_ER_APP	SEG_AD_MMV_ER_APP[NC_CYL_NR]	LV_SEG_AD_ER	CTR_SEG_AD_ER

FUNCTION DESCRIPTION:

This function allows to determinate the coefficients for ER segment adaptive values filters used in the learning process. Three different stages can be differentiate :

- Nominal ER segment adaptive values filtering mode, used to monitor adaptive values during engine lifetime.
- Fast ER segment adaptive values filtering mode, used to quickly obtain valid adaptive values when the EMS is new.
- EOL specific filtering mode, to be used on EOL or special service request.

LV_SEG_AD_LIM_ER is set if at least one SEG_AD_MMV_ER_x value exceeds C_SEG_AD_MAX_ER.

First time initialisation :

The ER segment adaptive values learning process is initialised when :

- ECU is initialised for the first time *(flash memory formatting)*
- A loss of adaptation values has been detected *(flash memory corrupted)*.
- A specific external tool request occurs *(use of LV_SEG_AD_RST_ER_EOL defined in Application Incidences file)*

// ER segment adaptive values reseted

```
For x = 0 ... [NC_CYL_NR-1]
    SEG_AD_MMV_ER[x] = 0
EndFor
LV_SEG_AD_LIM_ER = 0
```

Initialisation at ECU reset:

```
For x = 0...(NC_CYL_NR - 1)
```

```
        SEG_AD_RAW_MMV_ER[x] = SEG_AD_MMV_ER[x]
    EndFor
```

Update rate: ER segment occurrence

Application conditions:

This process is executed every engine cycle when SEG_T_MES_0 (reference segment) is acquired and when the monitoring of the adaptive learning process is active

Activation: LV_SEG_AD_RAW_ER = 1

Process on activation transient:

```
    If      LC_SEG_AD_LIM_REAC_ER = 1    // reactivation of the adaptive values range check
    Then    LV_SEG_AD_LIM_ER = 0
    Else    No Operation
    EndIf
```

#ENDIF					

Input data:

SEG_AD_RAW_MMV_ER[NC_CYL_NR]	NC_CYL_NR	SEG_NR_MES	LV_SEG_AD_RAW_ER

General information:

Due to possible feedback from Dual Mass Flywheel oscillations *(see transmission/crankshaft design)* in adaptive process engine speed range, fluctuations on ER adaptive values of identical physical segments can induce dissimilarity in ER segment correction.

If difference between identical physical segments ER fast filtered adaptive values exceeds a calibratable gap, a fade out is applied.

ER identical physical segments adaptive value differences are evaluated each 720°Crk, for that this process is executed every engine cycle when SEG_T_MES_0 (*SEG_NR_MES = 0)* is acquired and when the adaptive monitoring process is active.

ER reference value for ER diagnosis					

21.8.1 FUNCTION DESCRIPTION:

Conclusions on the combustion quality of a cylinder can be drawn by monitoring the crankshaft acceleration. This can be used in the workshop for diagnostic purposes.

The cylinder individual engine roughness values ER_CYL[NC_CYL_NR], which are determined for misfire diagnosis, are taken, related to a TCO- and operating point-dependent threshold and then smoothed by moving mean value calculation.

The 6 diagnostic values are transferred to the workshop tester via K-line. If an ER diagnostic value exceeds a determined threshold, it can be assumed that the corresponding cylinder has a malfunction.

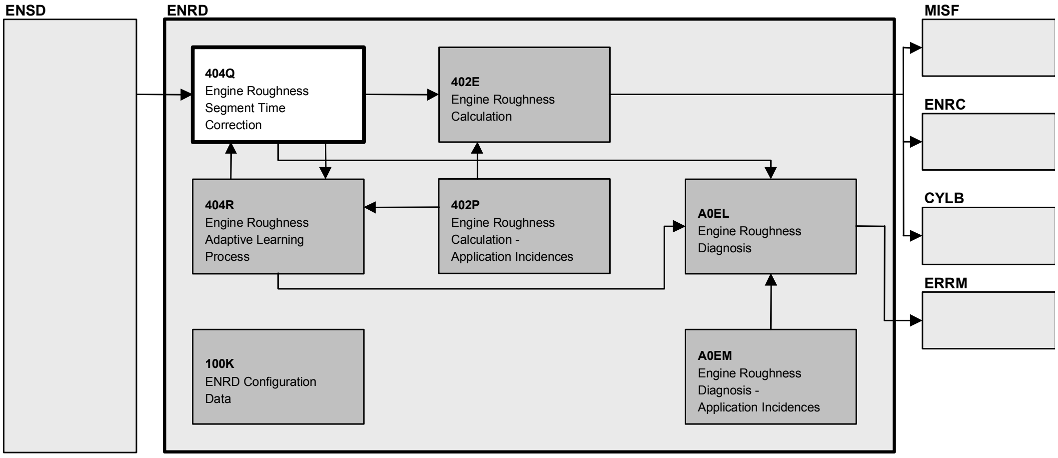
21.9 Engine roughness calculation & adaptation (gen)

21.9.1 Requirements

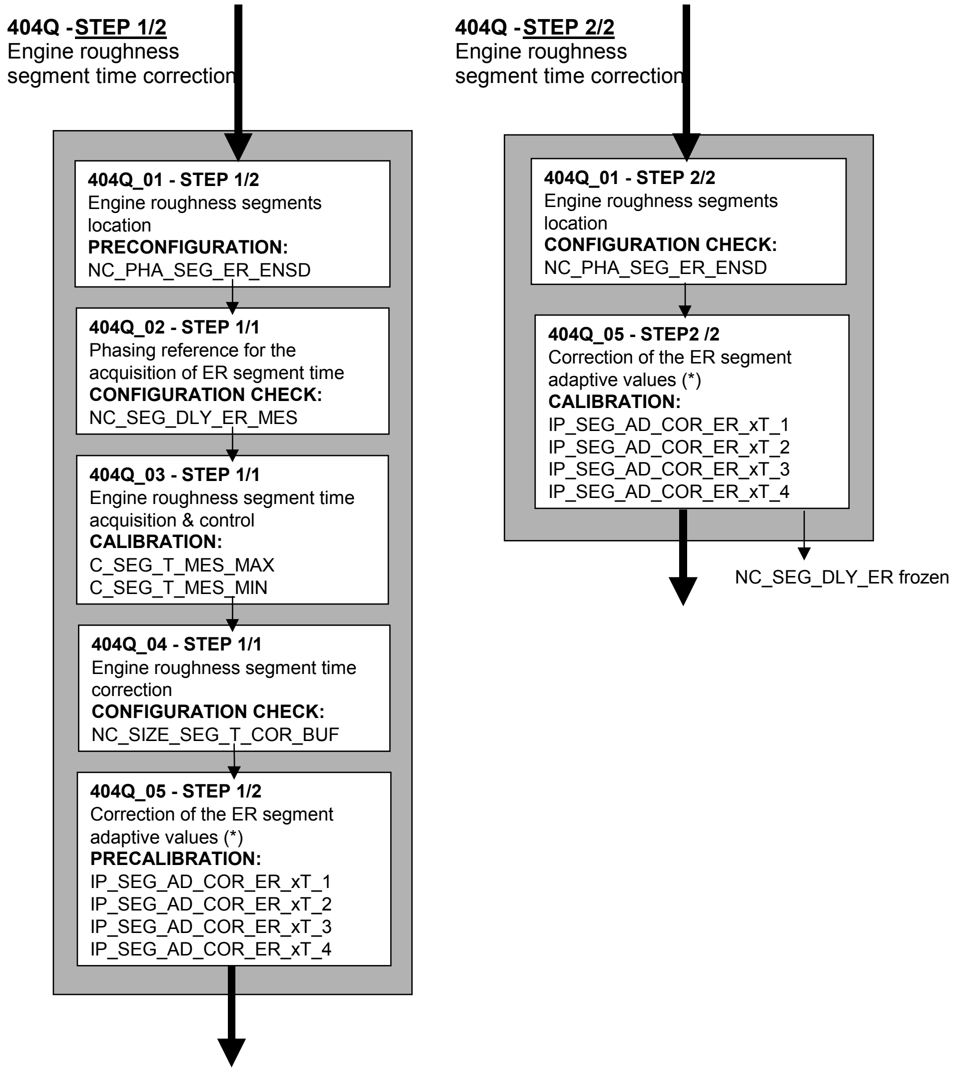
ENSD aggregate active and calibrated, no synchronisation errors/troubles

IGRE, IGSP & INJR precalibrated

21.9.2 Tuning hints for Engine roughness segment time correction (Module 404Q)



21.9.2.1 Module calibration flowchart



21.9.2.2 404Q_01: Engine roughness segments location

21.9.2.2.1 General information

To determinate the engine roughness indexes, crankshaft segment time samples are required. These segment time samples are acquired each (720 / NC_CYL_NR) °crankshaft angle. The ENSD aggregate (engine position and speed determination) provides one T_SEG_ER sample acquisition at each crankshaft segment task.

This segment location is different to T_SEG_CRK *(commonly used in the ECU by other functions)*, as the ER focuses on engine combustion behaviour, and is located regarding to the TDC's, and not to the long tooth position like for T_SEG_CRK.

The engine roughness segment starts NC_PHA_SEG_ER_ENSD°Crk after the TDC. Beginning and end of ER segments are successive and located at the same angle.

This value must be a multiple of flywheel tooth length (e.g. 6°Crk for 60-2 teeth flywheel or 10°Crk for 36-1 teeth flywheel).

Even if the ER segment phasing is defined in crankshaft angle, the ER segment acquisition task has to be imperatively located on the nearest tooth event corresponding to NC_PHA_SEG_ER _ENSD phasing angle.

21.9.2.2.2 Calibration Step 404Q_01 - Step 1/2

Task type: preconfiguration

This calibration step is a configuration choice according the number of cylinder of your application (NC_CYL_NR). These default values have been observed on most of the SV applications.

Please contact basic software person in charge of ENSD implementation on your project to see if there's no incompatibility between the ENSD configuration and these precalibrations.

Important Note

This calibration step is linked to ENSD, the configuration data NC_PHA_SEG_ER_ENSD must be defined in the ENSD configuration data module of the application (module 100D)

Example of configuration: *(default values)*

Engine type NC_CYL_NR	*ER segment length*	*NC_PHA_SEG_ER_ENSD typical value*
3 cylinder	240°Crk	42°Crk
4 cylinder	180°Crk	42°Crk
5 cylinder	144°Crk	36°Crk
6 cylinder	120°Crk	42°Crk
8 cylinder	90°Crk	42°Crk

21.9.2.2.3 Calibration Step 404Q_01 – Step 2 / 2

Task type: configuration check

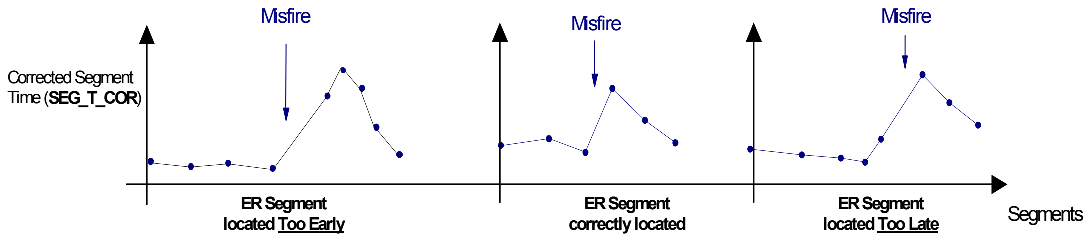
As this calibration/validation step uses the corrected segment time SEG_T_COR, previously all precalibrations/calibrations linked to the modules 404Q & 402E have to be already set.

Validation of Engine Roughness phasing (NC_PHA_SEG_ER_ENSD)

A check of the angular window used to measure the ER segment time should be performed to be sure that the whole engine speed drop due to a misfire is located on the segment chosen.

Remark: pre-defined values fit generally for most application.

Record at several engine speeds and loads (3000 rpm - 50% of full load) with single misfiring.



The acquisition of the segment time is performed every 720/NC_CYL_NR°Crk. We must be sure during the calibration of NC_PHA_SEG_ER_ENSD that the misfiring slope is taken into account between two contiguous acquisitions. This enables to localise the misfiring (number of cylinder for instance).

If the validation shows that the value of NC_PHA_SEG_ER_ENSD is not correct (window too early or too late), a change of NC_PHA_SEG_ER_ENSD is required or the switch to another phasing

Note: If the better NC_PHA_SEG_ER_ENSD phasing you've found exceeds more than 2 teeth of the default value, please inform the domain to check with an external tool (ex: B&S) the basic software results according the teeth number chosen.

21.9.2.2.4 404Q_02: Phasing reference for the acquisition of engine roughness segment time

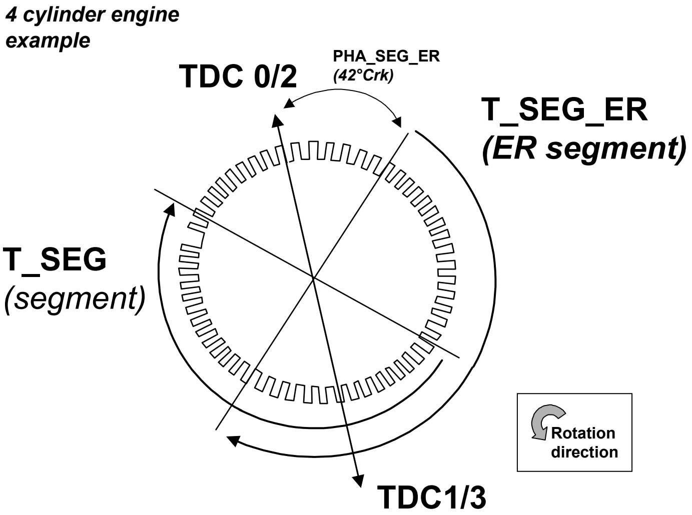
21.9.2.2.4.1 General Information

The ER segments are used to observe in-cylinder combustion effects on crankshaft. The cylinder x combustion is located between cylinder x tdc and cylinder x+1 tdc. Consequently, at x+1 tdc, the T_SEG_ER segment obtained is relative to cylinder X combustion, a delay of 1 tdc between SEG_NR value at cylinder observed (NC_SEG_DLY_ER_MES=1).

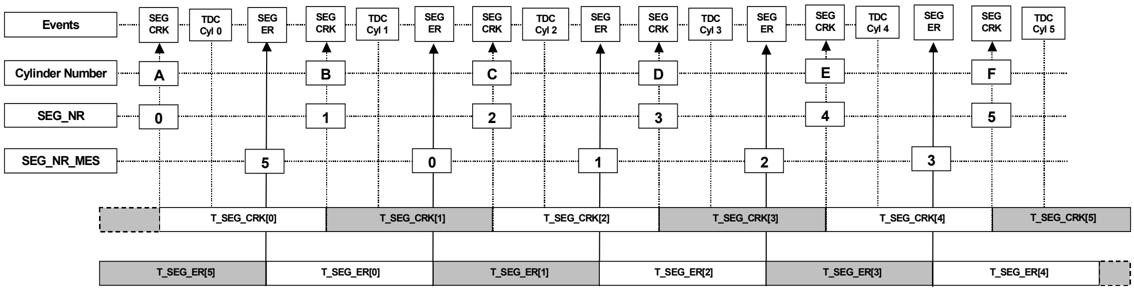
Identification of the segment is evaluated regarding SEG_NR value

Exceptionally, if the segment is located after ER segment, this delay must be cancelled (NC_SEG_DLY_ER_MES=0), because in such case the phasing reference SEG_NR is updated after T_SEG_ER acquisition.

SEG_NR_MES, the ER segments phasing reference, will be used to identify which cylinder is observed with the current engine roughness segment, it's particularly useful for ER segment adaptive values identification.



Implant scheme:



6 Cylinder Engine Example : *NC_SEG_DLY_ER_MES = 1*

21.9.2.2.4.2 Calibration Step 404Q_02 – Step 1 / 1

Task type: Configuration check

Please check, with your project ENSD configuration, the position of the SEG_NR toggle event versus the ER segment location.

21.9.2.2.5 404Q_03: Engine roughness segment time acquisition and control

21.9.2.2.5.1 General information

The rule of this module is to provide to ENRD:

- SEG_T_MES, the ER raw current segment time with correct resolution and format according ENRD calculation core (16 bits / 1µs for ENRD 2.0.0, 32 bits and identical to T_SEG_ER in the future).
- SEG_T_MES_CYL[NC_CYL_NR], the SEG_T_MES buffer, order by cylinder according SEG_NR_MES phasing. This array is used for ER segment adaptive learning process (Module 404R).
- LV_ENA_SEG_T_MES, validity information to share with all ENRD modules.

21.9.2.2.5.2 Calibration Step 404Q_03 – Step 1 / 1

Task type: calibration

This calibration step focuses on validity flag LV_ENA_SEG_T_MES definition.

This flag can be reset to 0, when a fine synchronisation trouble occurs (dedicated information LV_INH_MIS_CRK coming from ENSD), no calibration linked.

This flag can also be set if SEG_T_MES obtained via ENSD exceeds a defined valid range (C_SEG_T_MES_MIN & C_SEG_T_MES_MAX)

To define C_SEG_T_MES_MAX, see NC_N_MIN defined in ENSD (global NC_ data), typical NC_N_MIN = 30 rpm.

To defined C_SEG_T_MES_MIN, see NC_N_MAX defined in ENSD (global NC_ data), typical NC_N_MAX = 8160 rpm

21.9.2.2.6 404Q_04 Engine roughness segment time correction

21.9.2.2.6.1 General information

The prerequisite for a reliable engine roughness evaluation is an accurate ER segment time measurement.

As the crankshaft flywheel teeth are subject to manufacturing tolerances, geometrical run-out and off-centre installation which result in angles modulation, consequently the measured raw segment periods aren't similar and have systematic inaccuracies regarding other segments.

As these inaccuracies are systematic, they can be *"learned"* by an adaptive process during fuel cut-off periods and used for ER segment time correction. This adaptive process is described in the module: Engine roughness adaptive learning process.

The ER segment adaptive values SEG_AD_MMV_ER[NC_CYL_NR] are used to correct the ER raw segment time (obtained via ENSD) and provide to other ENRD modules the ER current corrected segment time: SEG_T_COR

21.9.2.2.6.2 Calibration Step 404Q_04 – Step 1 / 1

Task type: configuration check

SEG_T_COR is stored according a FIFO management (first in, first out). Just check the SEG_T_COR_BUF buffer size regarding engine type:

NC_SIZE_SEG_T_COR_BUF = 11 segment time samples for a 5 cylinder engine

NC_SIZE_SEG_T_COR_BUF = 9 segment time samples for 4 & 8 cylinder engine

NC_SIZE_SEG_T_COR_BUF = 7 segment time samples for 3 & 6 cylinder engine

This size NC_SIZE_SEG_T_COR_BUF is determined by the ER sample number required by ER calculation according engine type.

21.9.2.2.7 404Q_05: Correction of the engine roughness segment adaptive values

21.9.2.2.7.1 General information

On some applications, due to crankshaft flexion/torsion effects, the adaptive values are unsteady versus the engine speed, especially at high engine speed. As a result, these drifts produce additional noise on crankshaft segment times, who will decrease the signal / noise ratio for misfire detection.

Very often we can observe a general trend of these drifts versus the engine speed. To correct these effects, we apply an open loop correction on these adaptive values versus the engine speed in a way to cancel these drifts. A correction can be applied only for each singular segment of the flywheel.

As these corrections are in open loop, they can minimise the additional noises on segments <u>only</u> if the crankshaft segment drifts have identical trend on the overall car type population.

21.9.2.2.7.2 Calibration Step 404Q_05 – Step 1 / 2

<u>Task type: configuration check:</u>

Check that the number of calibration data appears as described in calibration data section (see above) according NC_CYL_NR

<u>Precalibration:</u>

<u>As the</u> Engine roughness adaptive learning process is not already calibrated, and adaptive values drifts (if exists) are not evaluated. Calibrations are initialised to 0.

IP_SEG_AD_COR_ER_xT_1=IP_SEG_AD_COR_ER_xT_2 = 0

IP_SEG_AD_COR_ER_xT_3 = IP_SEG_AD_COR_ER_xT_4 = 0

Note: _xT stands for _MT and _AT

21.9.2.2.7.3 Calibration Step 404Q_05 – Step 2 / 2

<u>Task type: calibration</u>

<u>Preliminary checks before calibration:</u>

To determinate the segment adaptive corrections IP_SEG_AD_COR_ER_xT_y needed for a car family, tests must be executed on all different transmission type, sensor, flywheel and crankshaft designs.

The amplitude of these corrections is the main aim of calibration definition, but as these corrections are open loop corrections, please take care to define average calibrations that can be suitable for the all cars population, respect to the transmission type:

- If we apply too important corrections, engines with small segment drifts will have reduced misfire detection efficiency than without correction.
- If we apply weak corrections, engines with important segment drifts will not reach expected misfire detection efficiency to fulfill OBDII/EOBD legal requirement at high engine speed.

We have to find the calibration data set that allows balancing in the best way between these two objectives to compensate the most important part of production vehicle population.

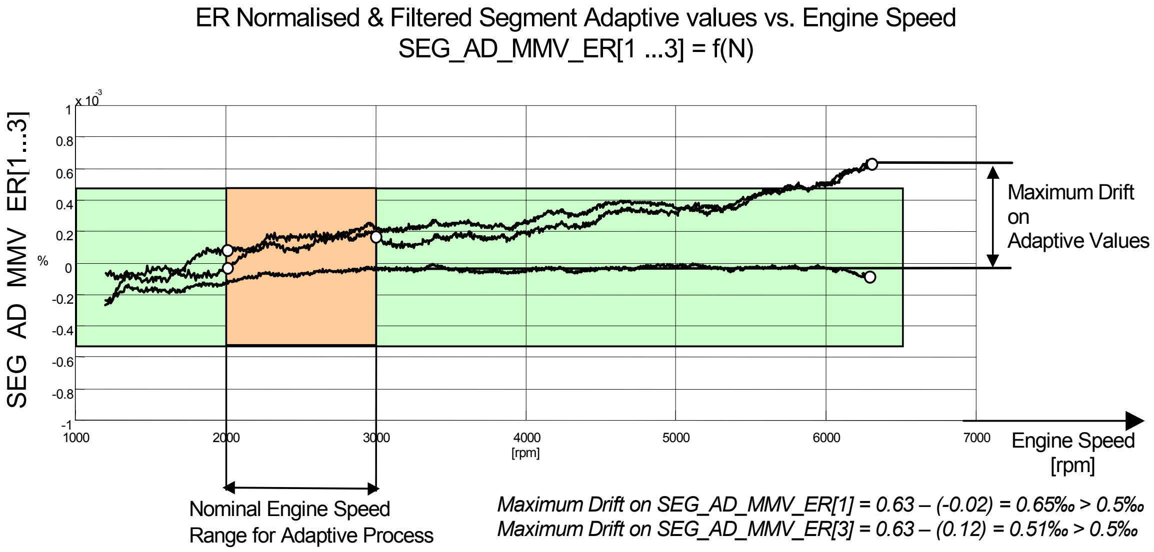
Before to start the calibration of segment adaptive correction, please check calibration data set relative to module 404R_03 (Engine roughness adaptive learning process management), especially C_N_MIN_SEG_AD_ER & C_CRLC_SEG_AD_ER.

Because the drift of segment adaptive values can be amplified (or created) by:

- A too light filtering (lot of noise on the SEG_AD_MMV_ER[NC_CYL_NR] values during the adaptive process) -> a noise capture at the end of the adaptive process could produce a drift.
- An engine speed range for learning where adaptive values are unsteady. Please, focus on the minimum engine speed, because very often the adaptive values are frozen when we go out of the adaptive conditions, and the main condition to exit of the learning process is the minimum engine speed C_N_MIN_SEG_AD_ER. So the last adaptive values learned (close to the minimum engine speed) are next apply to the segment time correction at each engine operating points

Worst operating case: highest engine speed with the adaptive value learned at the minimum engine speed

<u>Example</u> of a 4-cylinder engine with important segment drift at high engine speed.



ER Normalised & Filtered Segment Adaptive values vs. Engine Speed
SEG_AD_MMV_ER[1 ...3] = f(N)

Nominal Engine Speed
Range for Adaptive Process

Maximum Drift on SEG_AD_MMV_ER[1] = 0.63 – (-0.02) = 0.65‰ > 0.5‰
Maximum Drift on SEG_AD_MMV_ER[3] = 0.63 – (0.12) = 0.51‰ > 0.5‰

<u>Calibration Process:</u>

For each car available, execute coast down on chassis rolls in road mode, at least 4 times per car to check the repeatability of the crankshaft behaviour *(recommended: 1 coast down per acquisition file, easiest to process and post-process, add LV_PUC in acquisition file for cut-off information).*

Define calibrations to activate the ER adaptive process on engine speed range 1500 rpm to Engine Redline, extended fuel cut-off activation to this range, with no adaptive process fade-out and light filtering to be able to observe crankshaft behaviour (drift trends).

<u>For example:</u>

C_N_MAX_SEG_AD_ER = C_N_SEG_T_AD_RAW_MAX_ER = 6500 rpm

C_N_MIN_SEG_AD_ER = C_N_SEG_T_AD_RAW_MIN_ER = 1500 rpm

C_CRK_DIF_MAX_ER = C_DRV1_MAX_SEG_AD_ER = max values

C_NR_SEG_AD_ACT_MIN_ER = C_NR_SEG_DRV1_MIN_ER = 0

C_CRLC_SEG_AD_ER = C_CRLC_FAST_SEG_AD_ER = 0.1

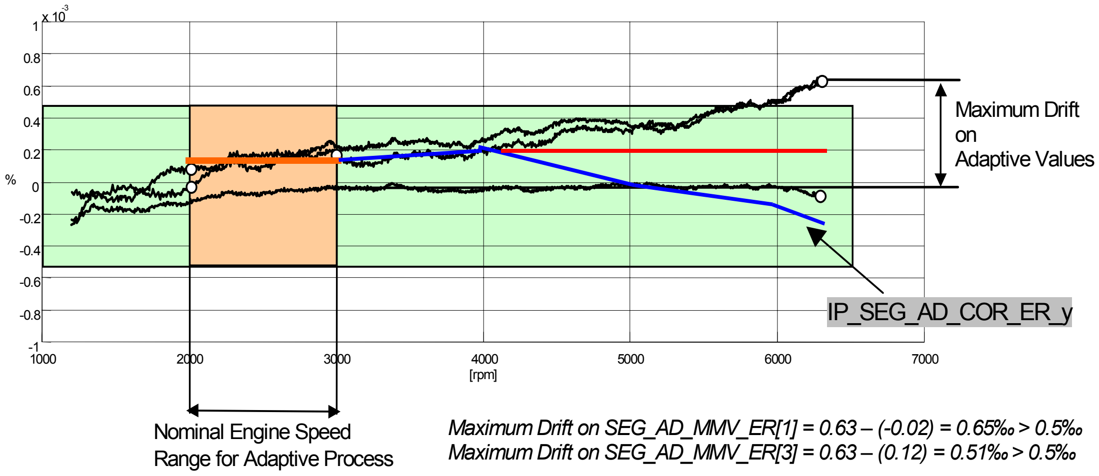
Check calibrations of 404R_01 module to obtain LV_SEG_AD_FDOUT_ER = 0 in the required engine speed range.

For each acquisition file obtained, observe the drift (trend and amplitude) for each segment between

1. Mean value of segment adaptive values on nominal engine speed range for adaptive process. In this example mean(SEG_AD_MMV_ER[1] & SEG_AD_MMV_ER[3]) = 0.17‰
2. Segment adaptive values at highest engine speed. In this example @ 6350 rpm SEG_AD_MMV_ER[1] = SEG_AD_MMV_ER[3] = 0.63‰

Compose the relative trend of segment adaptive trend as successive line sections to be able to approximate with 1D interpolation table. As IP_SEG_AD_COR_ER_xT_y corrections use multiple engine speed breakpoints LDPM_N_32_1_ENRD, set same origin for each line sections. To compensate the drifts, trend must be applied with opposite sign than the adaptive values observed.

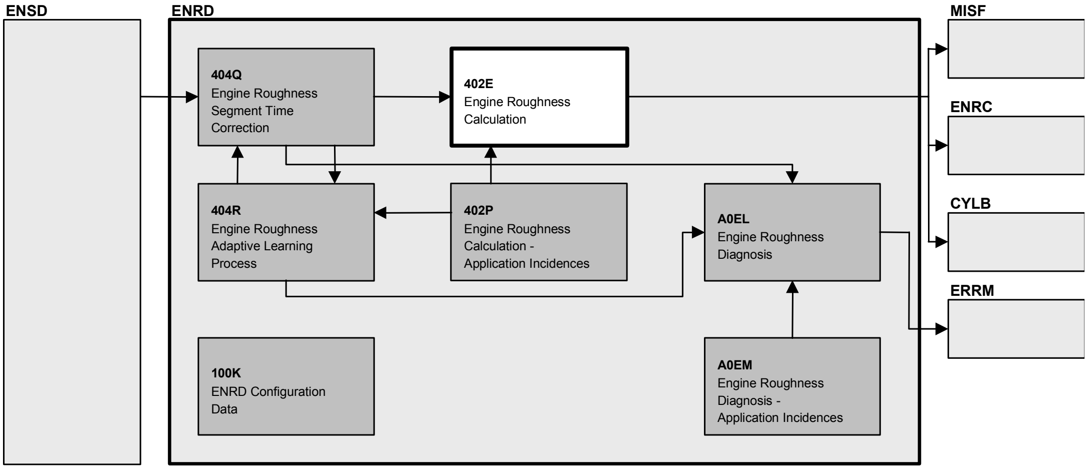
ER Segment Adaptive values vs. Engine Speed & Segment drift trends
SEG_AD_MMV_ER[1 ...3] = f(N)



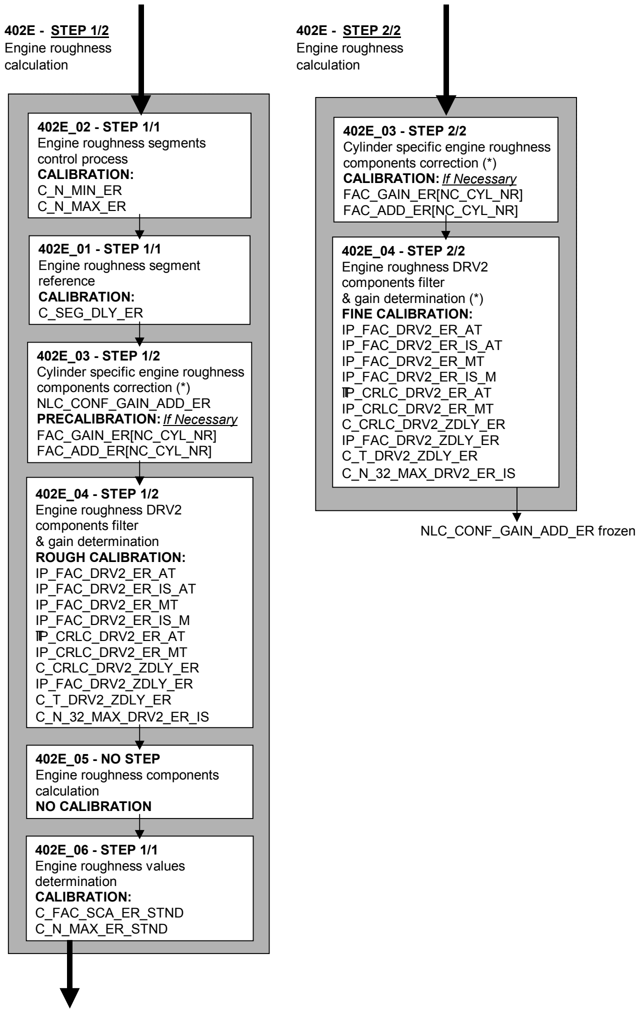
Maximum Drift on SEG_AD_MMV_ER[1] = 0.63 – (-0.02) = 0.65‰ > 0.5‰
Maximum Drift on SEG_AD_MMV_ER[3] = 0.63 – (0.12) = 0.51‰ > 0.5‰

Once all cars available are tested and evaluated, define the mean value per segment and per transmission type that could correct in the best way the most important sample of your car population.

21.9.3 Tuning hints for Engine roughness calculation (Module 402E)



21.9.3.1 Module calibration flowchart



21.9.3.2 Module calibration prerequisites

If NLC_CONF_GAIN_ADD_ER = 1, LOAD_MIS must be already calibrated for breakpoints calibration, see associated MISF calibration process.

21.9.3.3 402E_01: Engine roughness segment reference

21.9.3.3.1 General Information

Due to engine roughness definition, there is a delay of C_SEG_DLY_ER segments between ER actual value and the segment that was observed by this ER value.

SEG_NR_ER will be used to identify which cylinder is observed with the engine roughness system variable, it's particularly useful for misfire cylinder identification.

The segment counter SEG_NR_ER with the limit 0...(NC_CYL_NR - 1) is incremented in the same way than the common EMS segment counter SEG_NR.

21.9.3.3.2 Calibration Step 402E_01 – Step 1 / 1

Task type: calibration

To check correct cylinder identification via SEG_NR_ER segment counter, you must observe ER_RAW or ER regarding to SEG_NR_ER values.

Make an acquisition of ER_RAW, SEG_NR & SEG_NR_ER values, create a cylinder misfire sequence with C_TI_AS[0...NC_CYL_NR] = 1 then 0 then 1.

For a proper identification, in your acquisition file when you've produced C_TI_AS_0 = 0, the ER values must decrease as a misfire each NC_CYL_NR and on these TDC's, SEG_NR_ER must be equal to 0.

For C_TI_AS_1 = 0, the ER values must decrease as a misfire each NC_CYL_NR TDC's and on these TDC's, SEG_NR_ER must be equal to 1. Check in the same way all the other cylinders.

If C_TI_AS_[NC_CYL_NR] are not integrated on your project, unplug the correct cylinder with breaking box. Beware of equivalence between software and physical cylinder numbers.

If the segment counter SEG_NR_ER identify another cylinder, then correct the C_SEG_DLY_ER calibration data according the SEG_NR value you observe when you create a misfire.

Default calibration

NC_CYL_NR	C_SEG_DLY_ER
3	4
4	5
5	6
6	4
8	5

21.9.3.4 402E_02: Engine roughness segments control process

21.9.3.4.1 General Information

All ER components calculations are based on corrected segment time acquisitions buffer values SEG_T_COR_BUF.

As soon as an invalid segment has been detected during acquisition process (LV_ENA_SEG_T_MES = 0) or segment adaptive calculation, ER calculation & misfire detection have to be disabled (LV_ENA_ER = 0).

Engine roughness validity is also set according a valid engine speed range defined between C_N_MIN_ER & C_N_MAX_ER

21.9.3.4.2 Calibration Step 402E_02 – Step 1 / 1

The minimum engine speed for engine roughness calibration has to be lower than the requested minimum engine speed for misfire monitoring (N_IS_SP – 150 rpm for US applications). The Idle speed setpoint for hot engine minus 200 rpm is recommended (e.g. idle speed = 700 rpm; set C_N_MIN_ER = 500 rpm).

The maximum engine speed for engine roughness calibration has to be higher than the requested maximum engine speed for misfire monitoring (Fuel cut-off engine speed for US application, 4500 rpm for Europe). E.g. for C_N_MAX_ER = 4600 rpm for an EC application.

21.9.3.5 402E_04: Engine roughness DRV2 components filter & gain determination

21.9.3.5.1 General Information

This function allows to determinate the calibration coefficients relative to DRV2 components of the engine roughness, according different configurations:

If used *(see project/customer legal requirements concerning misfire monitoring after engine start)*, during zero delay misfire monitoring activation period, specific gain & filter coefficients can be apply to DRV2 component to be able to detect misfire just after engine start *(dynamic correction modified). This specific correction can be applied during a calibration time* C_T_ZDLY_MIS - C_T_DRV2_ZDLY_ER.

Else, FAC_DRV2_ER & CRLC_DRV2_ER are defined according transmission type *(AT/MT)*.

The misfire detection criteria ER must oscillate around 0 when there is no misfiring and have a negative value, representing the negative torque applied on the crankshaft, when there is misfiring.

21.9.3.5.2 Calibration Step 402E_04 – Step 1 / 2 – Rough Calibration

Example of calibration:

FAC_DRV2_ER = IP_FAC_DRV2_ER_xT = IP_FAC_DRV2_ER_IS_xT = 1.2 on the complete maps

IP_CRLC_DRV2_ER_xT = 0.4 on the complete map

C_CRLC_DRV2_ZDLY_ER = 0.95

IP_FAC_DRV2_ZDLY_ER = 0.4 on the complete map

C_T_DRV2_ZDLY_ER = 3.5s (with C_T_ZDLY_MIS= 5s, DRV2_ZDLY is 1.5s effective after engine start)

C_N_32_MAX_DRV2_ER_IS = 1700 rpm

Note: _xT stands for MT if LV_AT = 0 and stands for AT if LV_AT = 1

Calibration of FAC_DRV2_ER and CRLC_DRV2_ER in part load & idle speed mode

Target of the calibration:

Optimise IP_FAC_DRV2_ER_xT, IP_FAC_DRV2_ER_IS_xT, IP_FAC_DRV2_ZDLY_ER and IP_CRLC_DRV2_ER_xT in order that the oscillations generated after a misfiring or naturally by the engine are minimized or cancelled.

For that, it is aimed to oppose DRV2_MMV_ER to ER_RAW (DRV0_ER - DRV1_ER) when this later is negative to get finally ER near to 0.

The values IP_FAC_DRV2_ER_xT, IP_FAC_DRV2_ER_IS_xT are mainly responsible for the amplitude correction and it is nearly proportional to the amplitude of the crankshaft speed fluctuation. The biggest the value of FAC_DRV2_ER is, the biggest the correction value will be.

CRLC_DRV2_ER is mainly responsible for the correction fitting to the frequency of the speed fluctuation. The biggest the value is, the fastest but also the shortest the correction!

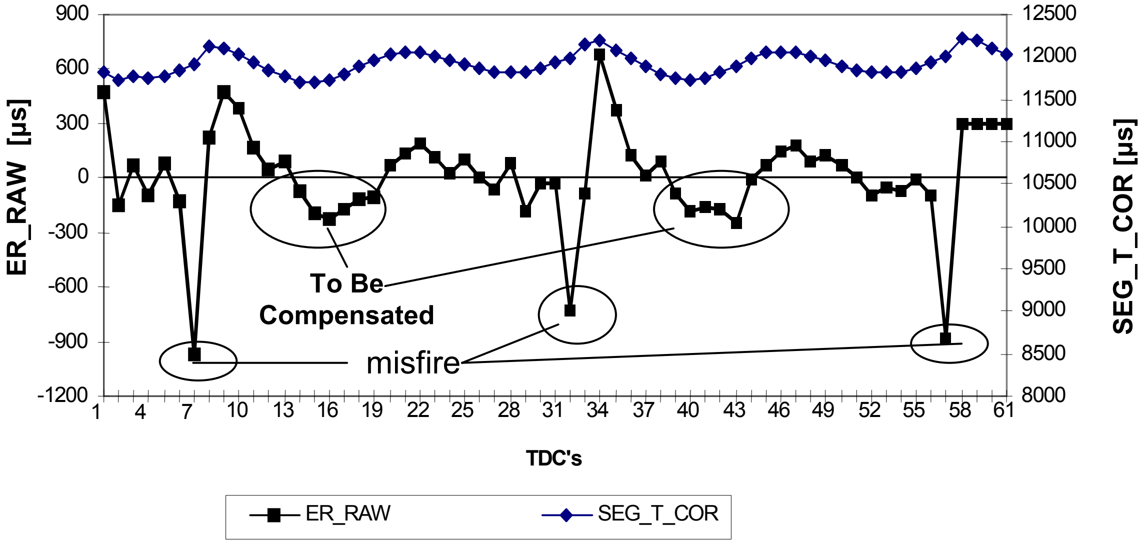
The term DRV2_ER enables the correction of ER_RAW; but the correction is generally performed too early. That explains the presence of the filtering value (CRLC_DRV2_ER) in order to adjust the correction position to fit with the real need. But the action of the filtering value reduces also the amplitude of the correction that is why the factor (FAC_DRV2_ER) is used. Therefore, the factor is generally greater than 1.

Adjust the filtering values IP_CRLC_DRV2_ER_xT in order that DRV2_MMV_ER is symmetrical to ER_RAW during oscillations after single misfiring by making the filter to “trail“ more or less. For that IP_FAC_DRV2_ER_xT & IP_FAC_DRV2_ER_IS_xT must be set to 1 or 1, 2.

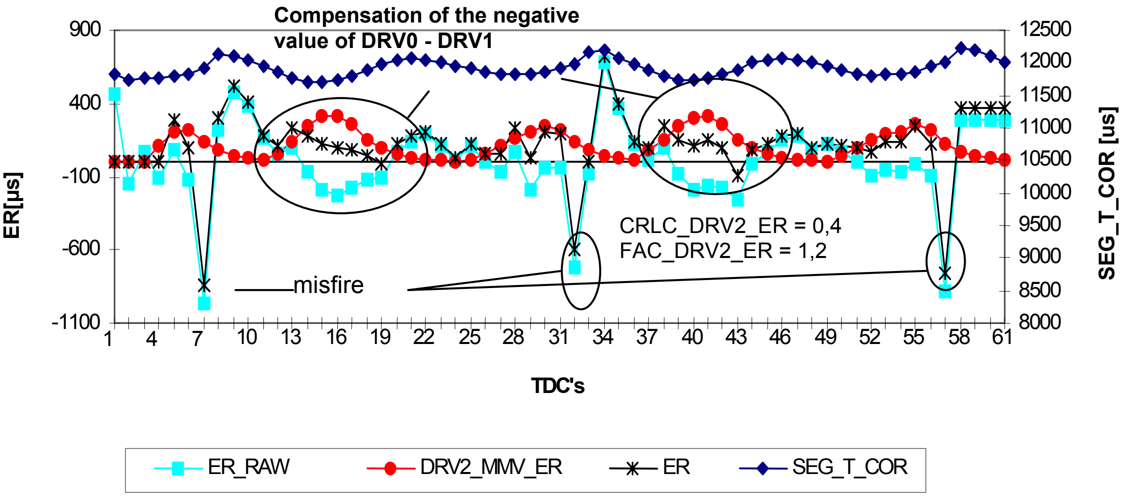
Adjust then the factor FAC_DRV2_ER in order that ER is always positive or null during oscillations. But take care to not reduce too much the value of ER at misfiring event by a too big value of DRV2_MMV_ER at this moment.

The following pictures show some examples of different calibration values (single misfire events with crankshaft oscillations afterwards).

When ER_RAW is observed during oscillations after one misfire event, we can see that ER_RAW had negative values. These negative values (due to oscillations) have to be compensated by the term DRV2.



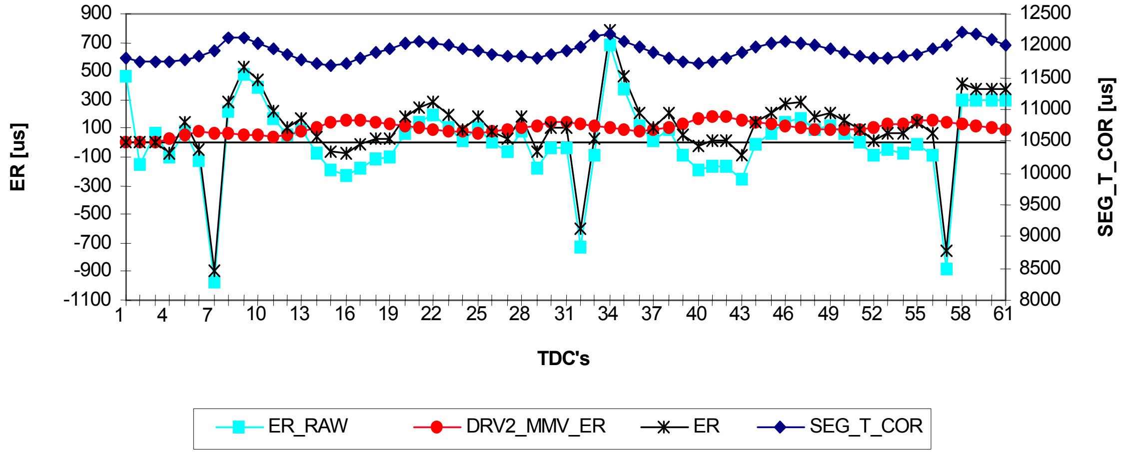
When CRLC_DRV2_ER and FAC_DRV2_ER are correctly calibrated, ER_RAW *(DRV0_ER - DRV1_ER)* should be compensated by DRV2_MMV_ER and ER remains positive or near 0:



Influence of CRLC_DRV2_ER, FAC_DRV2_ER is set at 1,2.

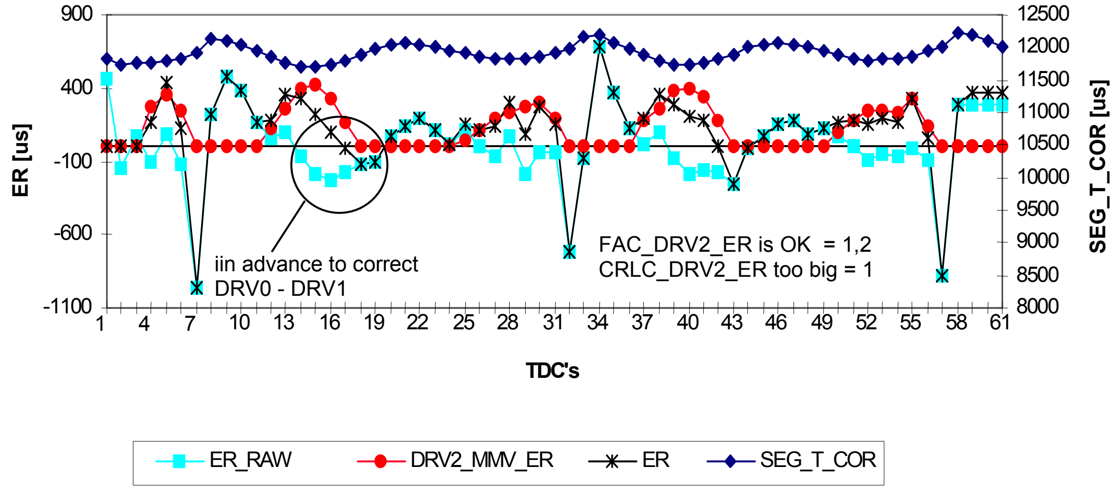
When CRLC_DRV2_ER is too small, DRV2_MMV_ER is delayed regarding ER_RAW and it compensates ER badly or decreases the final value of ER at time where misfire occurs:

⇒ Too slow response time



When CRLC_DRV2_ER is too big, DRV2_MMV_ER is in advance regarding ER_RAW and it compensates badly ER values:

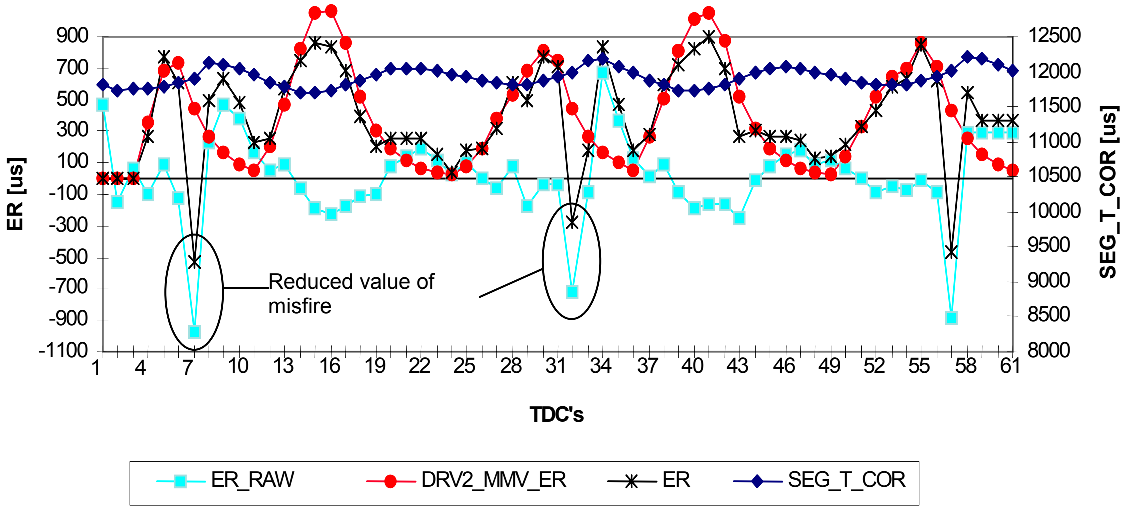
⇒Too fast response time



Influence of FAC_DRV2_ER, CRLC_DRV2_ER is set to 0,4.

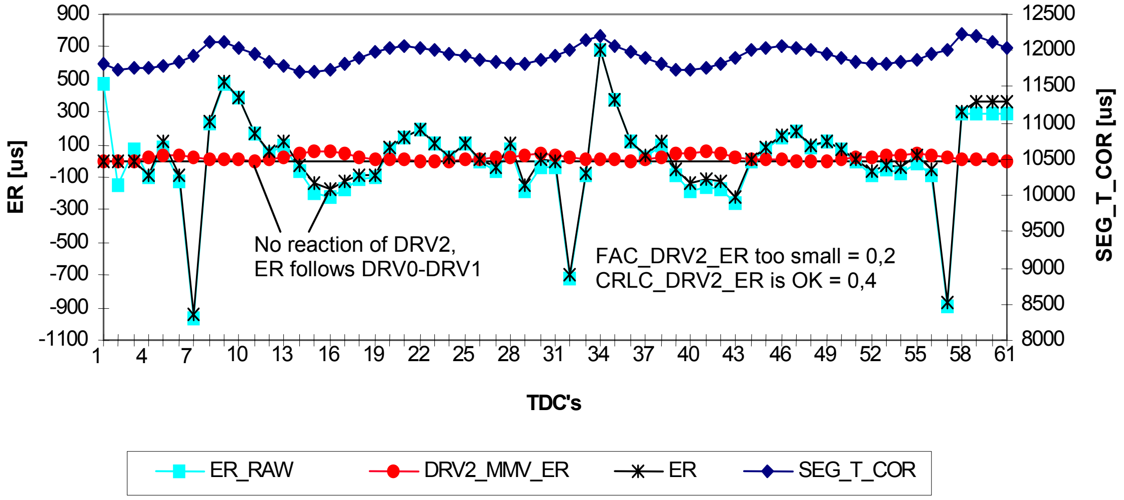
When FAC_DRV2_ER is too big, ER goes further from 0 and the value of ER is reduced at the time where a misfire event occurs, that can cause misdetection.

⇒ Too big correction ⇒ no misfire detection possible



When FAC_DRV2_ER is too small, ER can become negative during an oscillation and induce over-detection:

⇒ Too small correction ⇒ over-detection of misfire possible



The basic calibration should be performed on the chassis-dyno, and then a check on the street (several types of streets) is necessary. Make recordings at several gear ratios, several engine loads, several engine speeds and several misfiring rates

Record the values of SEG_T_COR, DRV0_ER, DRV1_ER, DRV2_MMV_ER, ER_RAW & ER.

N = breakpoints of the table

Load: limit of the positive torque and step of 100 mg/stk. to full load.

Gear ratios: 1st, 3rd, and 5th

Misfiring rate: 50%, 25%, 3% (for NC_CYL_NR = 4)

Then look for the best compromise between FAC_DRV2_ER and CRLC_DRV2_ER for each engine speed, engine load and transmission type.

If a specific DRV2_MMV_ER behaviour is necessary to compensate important oscillations due to idle speed controller at low engine speed, IP_FAC_DRV2_ER_IS_xT calibration maps are dedicated to such corrections.

C_N_32_MAX_DRV2_ZDLY_ER is the maximum authorised engine speed to apply these idle calibrations, to be set according the highest idle engine speed you require for this area.

21.9.3.6 Calibration Step 402E_04 – Step 2 / 2 – Fine Calibration

This calibration step occurs during (or after) a first misfire detection calibration phase (phase dedicated to misfire detection thresholds determination).

Calibration of FAC_DRV2_ER and CRLC_DRV2_ER in nominal mode

Check that no wrong misfire detections or non-misfire detections are induced due to inappropriate nominal DRV2 calibrations. For that, check ER index behaviour during misfire thresholds determination phase, check the difference between ER_RAW and ER in case of misfire, if too important, it means that you decrease too much the signal noise ratio in such case.

Calibration of FAC_DRV2_ER, CRLC_DRV2_ER & C_T_DRV2_ZDLY_ER in engine start mode (ZDLY)

For US applications it’s now mandatory to monitor misfire one engine cycle after engine start (ZDLY period) (legal definition of engine start = when engine speed reaches hot idle speed setpoint – 150 rpm). If we apply the nominal DRV2 components at engine start, this monitoring will be impossible due to a strong correction of the ER values during the engine cranking (high possible ER values).

Calibration target of DRV2 components in ZDLY:

The Goal of this calibration step is to centre ER values around at engine start and be able to detect misfire during this period.

For this, light coefficients are required for DRV2_ZDLY amount & filtering, see precalibrations.

Execute several engine crankings with and without misfire generation *(misfiring rate: 50%, 25%, 3% for NC_CYL_NR = 4)* and observe ER trend during first TDC's. Adjust FAC_DRV2_ER amount with IP_FAC_DRV2_ZDLY_ER calibration to have ER values centred on 0.

If a too important positive overshoot appears on ER (DRV2 correction too important), the misfire detection will not be possible.

If a too important negative overshoot appears on ER (DRV2 correction too little), there's a risk of wrong misfire detection during engine cranking.

Observe the mean time for engine stabilisation after cranking to switch to nominal engine running condition, this mean time will determinate the time to switch from ZDLY to nominal DRV2 calibrations.

Perform different engine crankings with different engine coolant temperatures (TCO) to be able to compensate the ER rise-up in any case during the zero delay phases, especially with engine cold start.

Precalibrations:

C_T_DRV2_ZDLY_ER = 3s, specific DRV2 correction applied only on first 2 seconds

C_CRLC_DRV2_ZDLY_ER = 0.94

IP_FAC_DRV2_ZDLY_ER = 0.4 *all map cells*

21.9.3.7 402E_03: Cylinder specific engine roughness components correction

21.9.3.7.1 General information:

The misfire detection based on ER index can be complicated by the torsion/flexion vibrations especially with multiple cylinder engines with a long crankshaft. This affects on misfire detection efficiency, especially at high engine speed.

To balance this phenomenon, after segment timing correction with ER adaptive values *(see ER segment correction process)*, an irregular operation is determined from the measured cylinder segment times, cylinder specific additive and multiplicative corrections are applied on the raw engine roughness value *(ER_RAW)*.

FAC_ADD_ER[NC_CYL_NR] and FAC_GAIN_ER[NC_CYL_NR] correction coefficients are based on calibration tables specific to each cylinder and to transmission type (MT/AT).

The measurement effect obtained by evaluating the crankshaft speed for the misfire detection is especially low in high engine speeds. In addition interferences can occur in this area such as mechanical tolerances of the target wheel and torsion vibrations of the crankshaft. This can eventually lead to, that in higher engine speeds; the conventional proceedings of the detection security can no longer be guaranteed for all cylinders.

After a correction of the mechanical tooth error an irregular operation is determined from the measured cylinder segment times. The interference caused by torsion vibrations is suppressed by adding a cylinder selective interference value, which is dependent on the load and engine speed areas of the operating point. The added interference variables are then determined on the engine test bench and put into cylinder individual maps.

The torsion depends on the drive train concept especially crankshaft and flywheel. If a change should occur (i.e. changed to a dual mass flywheel) then the calibration must be checked and if necessary, carried out again.

Function available only if NLC_CONF_GAIN_ADD_ER = 1 in your ENRD configuration date file.

21.9.3.7.2 Calibration Step 402E_03 – Step 1 / 2 – Precalibration

All values in the maps IP_FAC_ADD_ER_xT[NC_CYL_NR] are filled with zeros, all values for IP_FAC_GAIN_ER_xT[NC_CYL_NR] are filled with ones. Therefore no torsion correction is effective. This adjustment is valid during the whole measurement recording of the IP_FAC_ADD_ER_xT & IP_FAC_GAIN_ER_xT calibration.

Note: IP_FAC_ADD_ER_xT stands for IP_FAC_ADD_ER_AT for automatic transmissions & for IP_FAC_ADD_ER_MT for manual transmissions

21.9.3.7.3 Calibration Step 402E_03 – Step 2 / 2 – Calibration

Principle:

Measurement of the cylinder engine roughness values with the stationary operating points, engine speed and load over at least 500 working cycles.

No appearance of misfire.

Calculation of the ER-mean value for every cylinder.

Position of the engine speed: 3 operating points at low, middle and high loads (i.e. 33%, 55%, 85%) with a fine resolution in engine speeds (from 5000 rpm in 100 rpm intervals) beginning at 3000 rpm.

For the maps IP_FAC_GAIN_ER_xT [NC_CYL_NR] and IP_FAC_ADD_ER_xT [NC_CYL_NR], each cylinder can adjust its associated LDP table to fix the most judicious engine speeds.

Example:

To make explanations the clearest possible, LDP tables are the same for all the cylinders. However, once your LDP table frozen for one cylinder, you can completely change the position of the engine speed for another cylinder.

N [rpm]	2900	3008	3488	4000	4704	5696	6016	6240

Values in breakpoints: The value 0 is entered for masking all maps IP_FAC_ADD_ER_xT[NC_CYL_NR], for all loads in the lowest engine speed breakpoint and for the remaining breakpoints, measurements under stationary conditions and calculations of the cylinder individual ER-mean values.

Example:

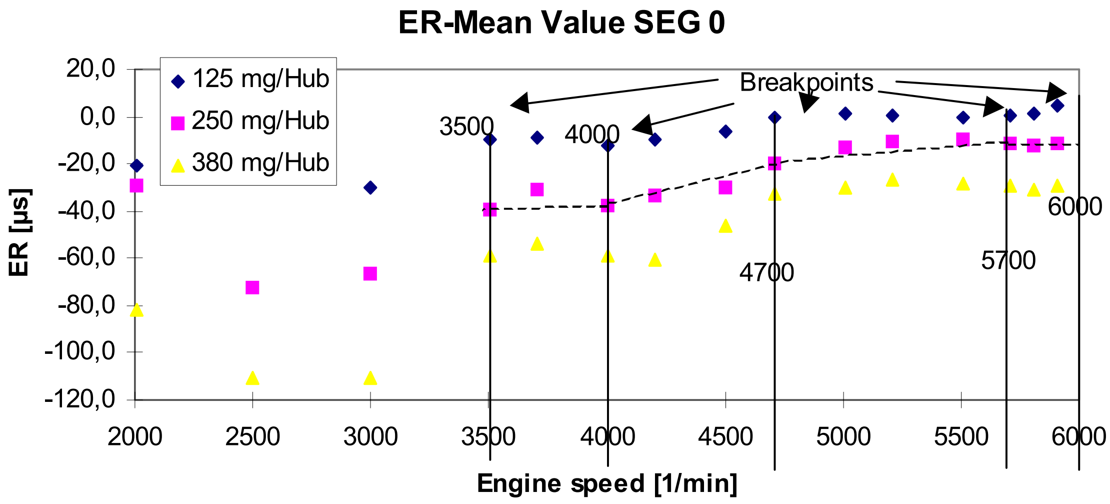
Measurements from over 500 firing cycles resulted in the following ER-mean values in µs for the single cylinder at 6000 rpm and 200 mg/stk:

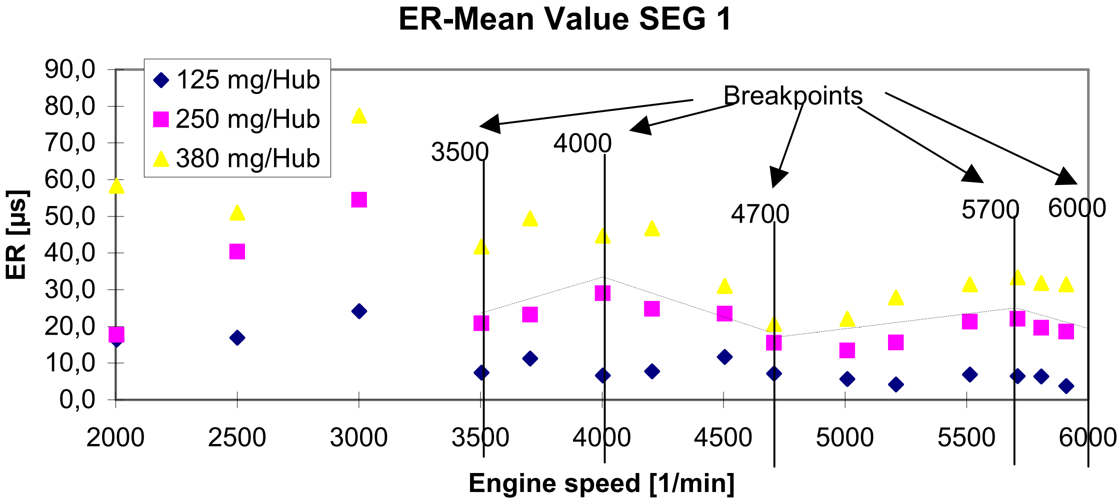
Cylinder 0: -1.3 Cylinder 1: -16.1 Cylinder 2: -8.6

Cylinder 3: 6.3 Cylinder 4: 2.6 Cylinder 5: 17.2.

The following values were entered on the 6000 rpm and 200 mg/stk breakpoints in the IP_FAC_ADD_ER_xT[NC_CYL_NR] maps:

IP_FAC_ADD_ER_xT[0] : -1.3 IP_FAC_ADD_ER_xT[1] : -16.1
IP_FAC_ADD_ER_xT[2] : -8.6 IP_FAC_ADD_ER_xT[3] : 6.3
IP_FAC_ADD_ER_xT[4] : 2.6 IP_FAC_ADD_ER_xT[5] : 17.2.





Graph: Position of the breakpoints with engine speed at [3500, 4000, 4700, 5700, 6000]. (Only two segments observed)

Calibration of the gain factor for torsion correction IP_FAC_GAIN_ER_xT[NC_CYL_NR]

In case of misfire, the factors in the cylinder individual maps IP_FAC_GAIN_ER_xT[0] ... IP_FAC_GAIN_ER_xT[5] should level out the collapse of the ER-values for the various cylinders. The relevant map is selected by means of segment number for the ER-value calculation SEG of the corresponding cylinders just as with the IP_FAC_ADD_ER_xT[NC_CYL_NR] maps. All IP_FAC_GAIN_ER_xT[NC_CYL_NR] maps have common engine speed breakpoints.

Dead application by filling with ones.
The factor value range should lie between 1 and approx. 1.8.

Precalibration
Maps IP_FAC_ADD_ER_xT[NC_CYL_NR] are completely calibrated, all values IP_FAC_GAIN_ER_xT[NC_CYL_NR] are filled with one.
This adjustment is valid during the whole measurement recording of the IP_FAC_GAIN_ER_xT[NC_CYL_NR] calibration.

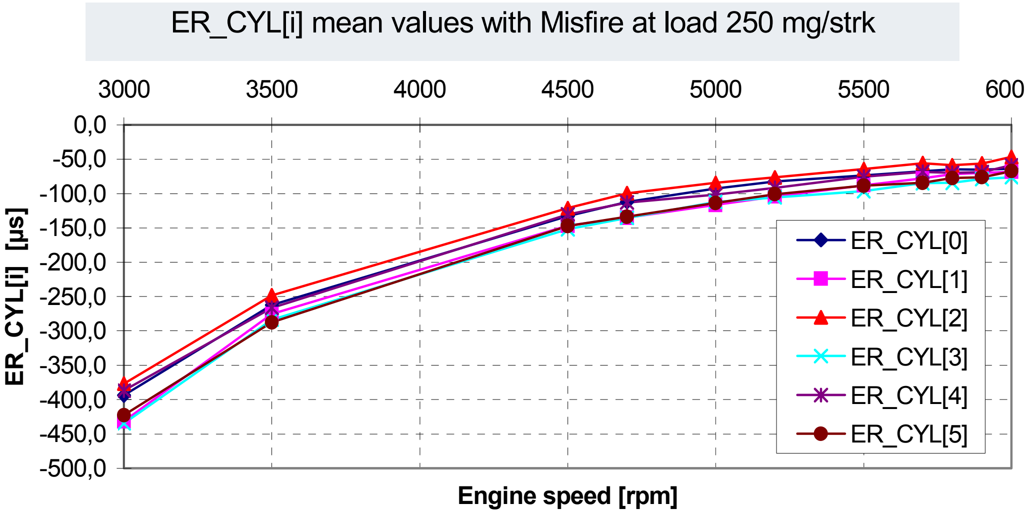
Calibration process
Principle: Measuring of the ER cylinder individual with steady operating points engine speed and load with generation of continuous misfire of cylinders. Various cylinders show different undershoots. Verification of individual misfiring of the same cylinder of which through sufficient intervals (e.g. every 4 firing cycles) influence each other.

1. Execute measurement file like describe above with at least 500 firing cycles for every misfiring cylinder *(NC_CYL_NR measurement files per operating point)*. Engine speed starting at 3000 rpm with a 500 rpm interval, starting at 5000 rpm with a 100 rpm interval *(focus on high engine speed)*.
2. Compute the ER mean values, ER_CYL[0] ... ER_CYL[5] only based on tdc's with cylinders in misfire for each operating point. *If Software misfire generator used, you can observe easily the misfire generated with flag LV_MIS_GEN.*
3. Choose the cylinder x with the highest absolute ER_CYL[x] value for overall operating points (here for example: cyl 3). Develop the ER_CYL[3] / ER_CYL[x] ratio for x=0...5 on every operating point. They are in accordance to the factors for the IP_FAC_GAIN_ER_xT[NC_CYL_NR] maps.
4. Check if the ratio ER_CYL[3] / ER_CYL[x] differs from the various load points. Set the engine speed breakpoints so that the linear regression produces a good approximation. Use of lowest breakpoint (suggestion: 3000 rpm) with one for masking.
5. Assignment of the cylinder x to the corresponding IP_FAC_GAIN_ER_xT[x] map

Example: (6cyl engine)

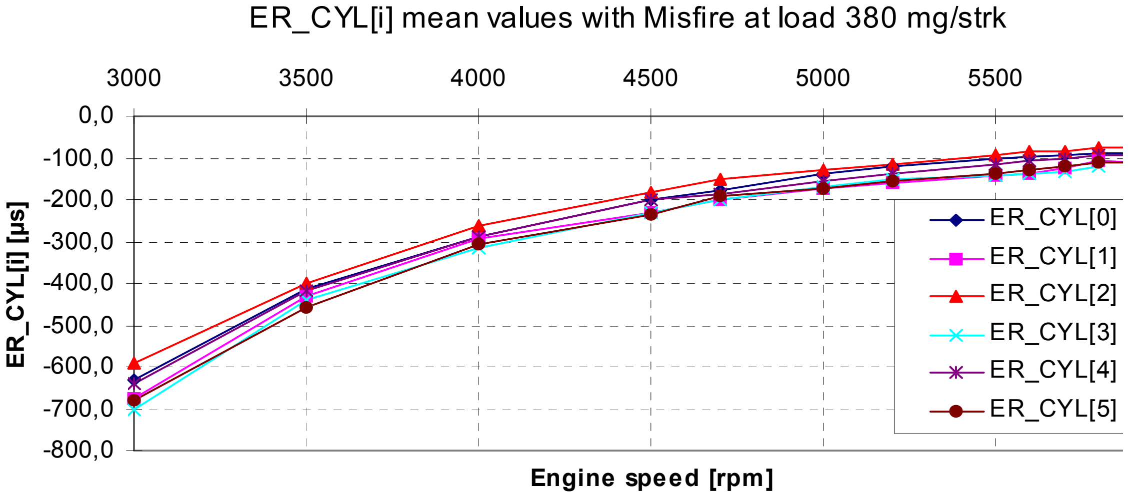
1. The measurements at 250 mg/stk produced the following mean values ER_CYL[x]

	ER_CYL[0]	**ER_CYL[1]**	**ER_CYL[2]**	**ER_CYL[3]**	**ER_CYL[4]**	**ER_CYL[5]**
3000	*-393.8*	*-431.3*	*-377.1*	*-434.7*	*-386.9*	*-422.8*
3500	*-262.4*	*-275.6*	*-248.1*	*-283.8*	*-266.3*	*-287.5*
4500	*-133.2*	*-146.7*	*-121.4*	*-152.2*	*-130.6*	*-147.1*
4700	*-112.2*	*-135.2*	*-99.8*	*-135.6*	*-113.1*	*-133.9*
5000	*-92.6*	*-116.6*	*-84.4*	*-112.0*	*-101.7*	*-114.1*
5200	*-82.2*	*-104.5*	*-76.8*	*-105.8*	*-91.8*	*-101.0*
5500	*-73.7*	*-88.1*	*-64.7*	*-96.8*	*-75.4*	*-88.9*
5700	*-67.8*	*-77.9*	*-55.9*	*-84.8*	*-68.3*	*-84.4*
5800	*-64.9*	*-72.0*	*-58.8*	*-84.5*	*-69.9*	*-77.4*
5900	*-65.2*	*-70.4*	*-56.1*	*-79.0*	*-68.7*	*-76.5*
6000	*-64.0*	*-68.6*	*-46.8*	*-76.0*	*-59.1*	*-67.4*



2. The measurement at 380 mg/stk produced the following mean values ER_CYL[x]

	ER_CYL[0]	ER_CYL[1]	ER_CYL[2]	ER_CYL[3]	ER_CYL[4]	ER_CYL[5]
3000	*-629.6*	*-677.6*	*-592.7*	*-700.1*	*-638.0*	*-680.4*
3500	*-413.1*	*-431.6*	*-398.6*	*-442.0*	*-417.4*	*-457.9*
4000	*-290.9*	*-293.5*	*-264.4*	*-313.6*	*-286.9*	*-305.9*
4500	*-198.2*	*-230.2*	*-180.7*	*-231.2*	*-200.5*	*-234.2*
4700	*-176.2*	*-200.7*	*-152.8*	*-198.5*	*-185.9*	*-191.7*
5000	*-140.0*	*-175.4*	*-130.9*	*-168.7*	*-154.0*	*-172.0*
5200	*-119.7*	*-162.2*	*-114.6*	*-152.5*	*-138.0*	*-155.2*
5500	*-103.1*	*-140.8*	*-92.5*	*-140.7*	*-115.0*	*-137.7*
5600	*-96.8*	*-137.9*	*-84.9*	*-137.0*	*-105.5*	*-129.3*
5700	*-94.9*	*-125.1*	*-83.4*	*-132.0*	*-103.0*	*-121.5*
5800	*-89.5*	*-108.6*	*-76.0*	*-120.1*	*-94.1*	*-112.6*
5900	*-88.3*	*-110.6*	*-77.4*	*-116.5*	*-94.4*	*-109.6*
6000	*-90.3*	*-99.8*	*-73.8*	*-115.6*	*-96.5*	*-106.4*



3. Cylinder 3 shows the absolute largest undershoot in ER above all observed measurement points

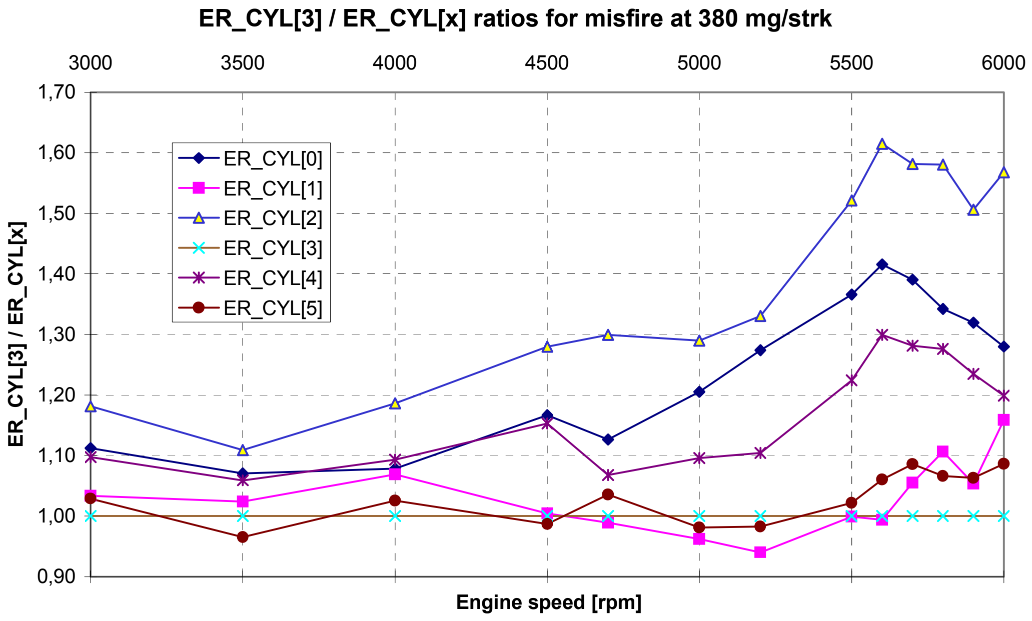
4. Normalisation ER_CYL[3] / ER_CYL[x] for operating point 5500 rpm. 380 mg/stk results

Cylinder 0 : 140.7 / 103.1 = 1.365   Cylinder 1 : 140.7 / 140.8 = 1

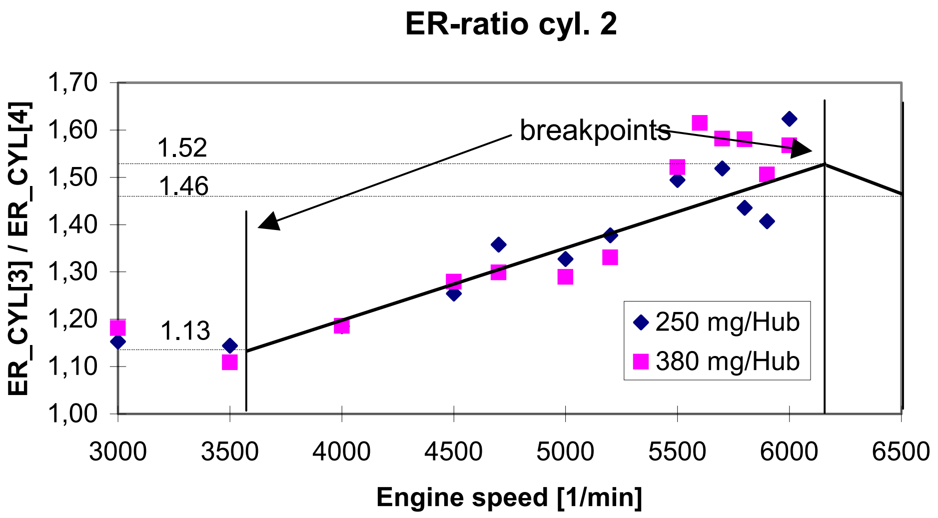
Cylinder 2 : 140.7 / 92.5 = 1.13   Cylinder 3 : 140.7 / 140.7 = 1

Cylinder 4 : 140.7 / 115 = 1.22   Cylinder 5 : 140.7 / 137.7 = 1.02

5. The total results for measurement series at 380 mg/stk :



6. Here only cylinder 2 is observed:



7. Cylinder 2 *(software order, see configuration file for equivalence between software & physical number)* corresponds to the table IP_FAC_GAIN_ER_xT[2]

N [rpm]	3000	3500	5700	6000
IP_FAC_GAIN_ER_*xT*[2]	1	1.13	1.52	1.46

8. Validation comment :

    Calibration on one vehicle per transmission type.

    Validation on at least two cars per transmission type, check that corrections obtained is valid for other cars with the same transmission type.

    Revalidation must be executed if any last minute crankshaft/DMF/transmission redesign occurs.

21.9.3.8 402E_05: Engine roughness components calculation

21.9.3.8.1 General information:

The engine roughness calculation needs three individual components: a static component (DRV0_ER), a dynamic component (DRV1_ER) and a curvature component (DRV2_ER). These component definitions are specific to the engine cylinder number (see following related subchapters).

DRV2_MMV_ER is the filtered curvature component correction (DRV2_ER) who allows adding an artificial positive offset on ER value in case of dynamic curvature effects. This feature had a safety effect against wrong detection in case of segment oscillations.

ER_RAW is the engine roughness value without curvature component (DRV2_MMV_ER) used by cylinder balancing and engine warm up monitoring modules.

21.9.3.8.2 Calibration Step 402E_05 – Step 0 – No Calibration

ER components calculation is only managed regarding NC_CYL_NR configuration data, no calibration data involved.

21.9.3.9 402E_06: Engine roughness values determination

21.9.3.9.1 General information:

ER is the complete engine roughness value including all ER components (DRV0_ER, DRV1_ER & DRV2_MMV_ER). Specified & used by misfire detection module.

ER_STND is the normalised engine roughness value versus engine speed that could be amplified by a gain C_FAC_SCA_ER_STND. This is the nominal engine roughness value divided by the corresponding cubic corrected ER segment time $(SEG\_T\_COR\_BUF[NC\_SEG\_DLY\_ER])^3$. The cubic segment time is calculated by using a mantisse and an exponent.

ER index is used by MISF aggregate only if NLC_USE_ER_STND_MIS = 0. In other case MISF uses the ER_STND index like for ENRC and CYLB aggregates.

21.9.3.9.2 Calibration Step 402E_06 – Step 1/1 –Calibration

Maximum engine speed to activate ER_STND calculation: C_N_MAX_ER_STND

This maximum engine speed is determined in function of the aggregates that uses this data.

If NLC_USE_ER_STND_MISF = 0, ENRC & CYLB not integrated. No modules will use ER_STND. As ER_STND use triple multiplication and huge data formatting for normalisation who consume CPU resources at TDC update rate. It could be interesting to stop this calculation process especially at high engine speed. In such case recommended calibration C_N_MAX_ER_STND = 0 rpm -> calculation cut-off.

For other configurations, it depends of the maximum engine speed needed for Aggregates using ER_STND data. *See table below for configuration sum-up.*

No ENRC & No CYLB integrated	ENRC & No CYLB integrated	CYLB & No ENRC integrated	CYLB & ENRC integrated
C_N_MAX_ER_STND = 0 rpm	C_N_MAX_ER_STND = Max(Eng Speed of ENRC)	C_N_MAX_ER_STND = Max(Eng Speed of CYLB)	C_N_MAX_ER_STND = Max(Max Eng Speed of CYLB, Max Eng Speed of ENRC)
C_N_MAX_ER_STND = 4500 + 100 rpm	C_N_MAX_ER_STND = Max(4500 + 100 rpm, Max Eng. Speed of ENRC)	C_N_MAX_ER_STND = Max(4500 + 100 rpm, Max Eng. Speed of CYLB)	C_N_MAX_ER_STND = Max(4500 + 100 rpm, Max Eng. Speed of CYLB, Max Eng. Speed of ENRC)
C_N_MAX_ER_STND = redline + 100 rpm	C_N_MAX_ER_STND = redline + 100 rpm	C_N_MAX_ER_STND = redline + 100 rpm	C_N_MAX_ER_STND = redline + 100 rpm

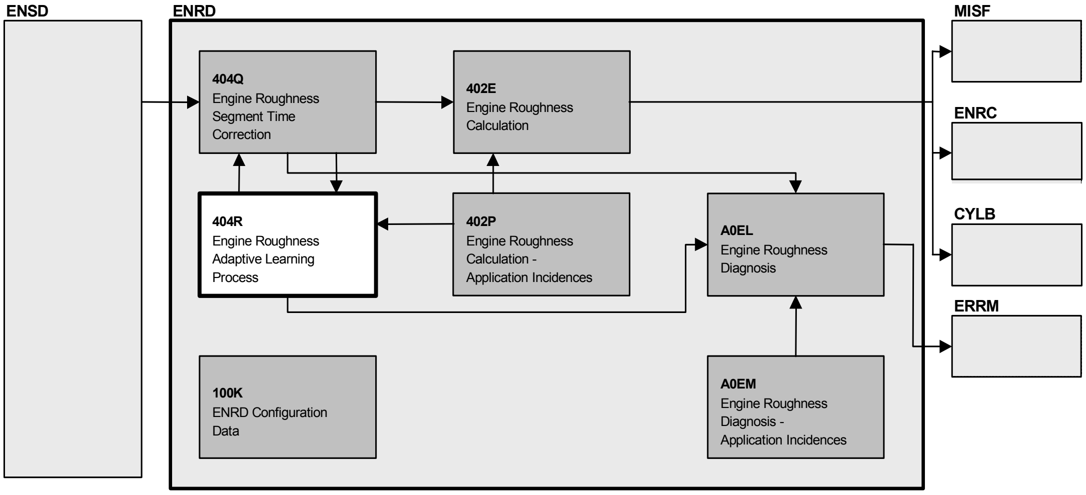
Scaling factor for normalised engine roughness index ER_STND:
C_FAC_SCA_ER_STND

This scaling factor have sense only when NLC_USE_ER_STND_MIS = 1 or ENRC integrated or CYLB integrated.

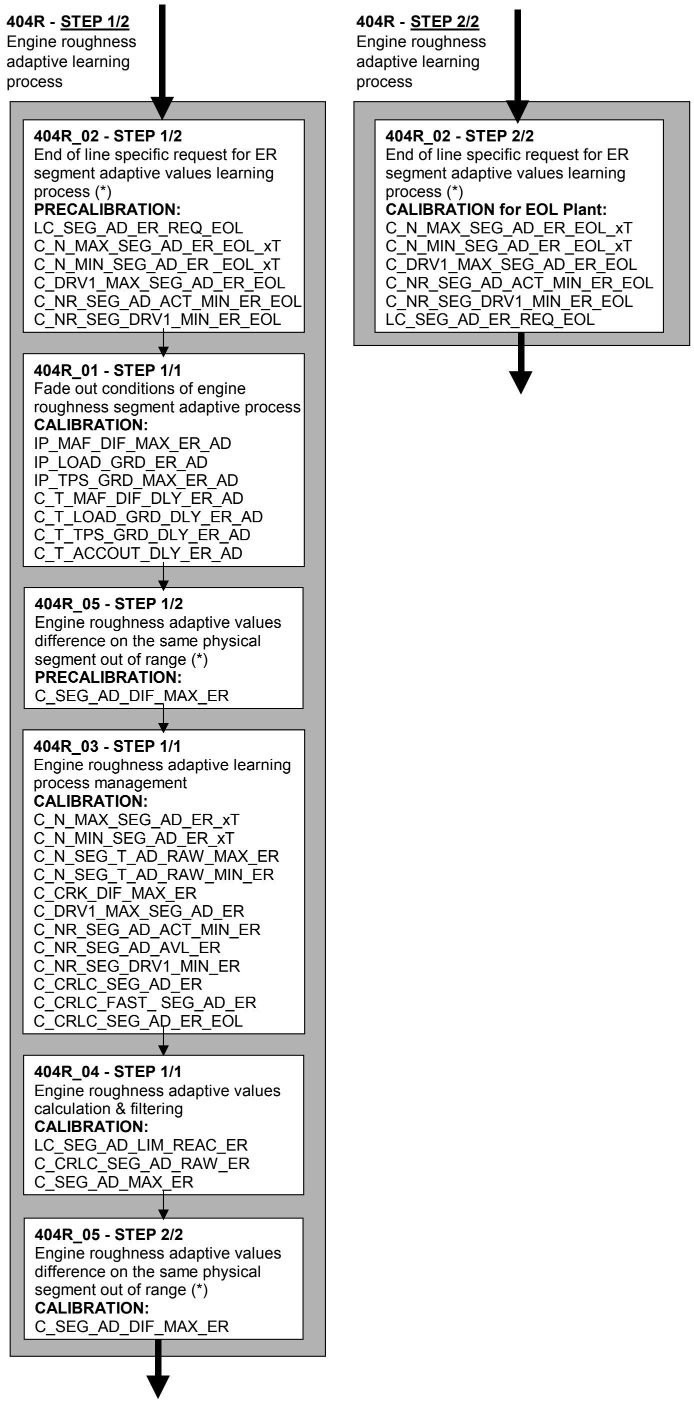
To determinate the best gain on ER_STND, please check that:

- No overflow occurs on ER_STND at low engine speed / high engine load with misfires (biggest engine speed drops possible).
- ER_STND quantum *(least resolution value)* must be smaller than at least the tenth of the smallest misfire drop at highest engine speed of legal target (4500rpm for EC or Redline for US) and lowest legal engine load for monitoring (see zero load line definition in MISF aggregate methodology).

21.9.4 Module 404R: Engine roughness adaptive learning process



21.9.4.1 Module calibration flowchart



21.9.4.2 404R_03: Engine roughness adaptive learning process management

21.9.4.2.1 General Information

The ER adaptive learning process is composed with two adaptive processes:

- A Fast adaptive process used for crankshaft/flywheel behaviour monitoring SEG_AD_RAW_MMV_ER[NC_CYL_NR]: The 'raw' adaptive values learned are not saved, there are only used to stop the slow adaptive process in case of important difference between SEG_AD_RAW_MMV_ER[NC_CYL_NR] values (fade-out condition).
- A Slow adaptive process used for flywheel mechanical noise learning SEG_AD_MMV_ER[NC_CYL_NR]. The adaptive values learned are used to correct basic segment time samples (SEG_T_MES).

The slow adaptive process is managed in two phases:

- A fast adaptive process for end of line procedures (EOL) who allow a fast convergence to ER flywheel adaptive values.
- At the end of the fast adaptive process, a slow adaptive process who will monitor ER adaptive values during the engine lifetime.

At the beginning of the fast segment adaptation learning process, it is necessary to upper the engine roughness value with an additional offset (THD_AD_ER), depending on the worst target wheel tolerances excepted to avoid wrong misfire detections due to flywheel mechanical tolerances. For instance, a flywheel with a ± 0.3°Crk mechanical tolerance on the ER segment corresponds to following segment drift:

Engine Type	ER Segment length	Induced Drift with ± 0.3°Crk tolerance on ER segment
3 cyl engine	240°Crk	2.5‰
4 cyl engine	180°Crk	3.33‰
5 cyl engine	144°Crk	4.17‰
6 cyl engine	120°Crk	5‰
8 cyl engine	90°Crk	6.68‰

The offset value (THD_AD_ER) by which the ER is increased at the beginning is gradually reduced to zero in a linear way until the 95% correction is obtained.

An internal adaptation counter CTR_SEG_AD_ER controls this number of engine cycle steps.

21.9.4.2.2 Calibration Step 404R_03 – Step 1/1 – Calibration

The calibration should be performed at the chassis-dyno with a max. tolerance target wheel but it is quite difficult to have one at its disposal, therefore any target wheel type can be used.

Example of calibration:

C_N_MAX_SEG_AD_ER_xT= 3500 rpm

C_N_MIN_SEG_AD_ER_xT = 2000 rpm

C_N_SEG_T_AD_RAW_MAX_ER = 3700 rpm

C_N_SEG_T_AD_RAW_MIN_ER = 1800 rpm

C_DRV1_MAX_SEG_AD_ER = 200

C_NR_SEG_DRV1_MIN_ER = 1 or 2 times NC_CYL_NR

C_NR_SEG_AD_ACT_MIN_ER = 1 or 2 times NC_CYL_NR

C_CRLC_SEG_AD_ER = 0.05

C_CRLC_FAST_SEG_AD_ER = 0.1

C_CRLC_SEG_AD_ER_EOL = 0.75

C_CRK_DIF_MAX_ER = *Check with Maximum Flywheel Tolerances provided by manufacturer for serial production, not for prototypes.*

C_NR_SEG_AD_AVL_ER = when SEG_AD_MMV_ER[NC_CYL_NR] reaches 95% of their final values = -ln(0.05) / C_CRLC_SEG_AD_ER_EOL = 3 / C_CRLC_SEG_AD_ER_EOL

Calibration of C_N_SEG_T_AD_RAW_MAX_ER, C_N_MAX_SEG_AD_ER_xT, C_N_SEG_T_AD_RAW_MIN_ER & C_N_MIN_SEG_AD_ER_xT:

Crankshaft oscillations (due to DMF, CVT ...) in some speed areas may disturb the adaptive process and may cause misdetections of misfire afterwards. To check this, the engine must be run at different speeds.

Remark: Check this item very carefully for engines with twin mass flywheels (DMF).

Set C_CRLC_SEG_AD_ER at 0.2 and the engine speed max and min thresholds to: C_N_SEG_T_AD_RAW_MIN_ER = C_N_MIN_SEG_AD_ER_xT = 900 rpm and C_N_SEG_T_AD_RAW_MAX_ER = C_N_MAX_SEG_AD_ER_xT = 6000 rpm (or redline) to enable the fast and slow target wheel learning processes in the complete engine speed range.

Run the complete engine speed range from 6000 to 1000 rpm very slowly in fuel cut off at several gear ratio and several temperatures. Control that values of SEG_AD_MMV_ER[NC_CYL_NR] do not vary more than 0.5‰ (stability of the adaptation value) for the calibration of the engine speed threshold.

Find the engine speed range where SEG_AD_MMV_ER[NC_CYL_NR] adaptive values are the more steady.

If some problems are observed *(curves, resonance)*, the adaptation has to be forbidden on such an area. Very often below 2000 rpm, due to drive train oscillations, the adaptive values start to diverge and above 3500 rpm adaptive values start to drift on some applications, to be checked.

Another point is to be sure that the adaptive processes are correctly executed and achieved during the End of Line process on chassis rolls in a way to have a full legal compliant car after EOL process. This point is a critical one, especially with AT and CVT transmission vehicles.

An adaptive range from 2000 rpm to 3500 rpm is often obtained and preferable. Control that the fuel cut-off phase is active inside the selected engine speed range.

Calibration of C_CRLC_SEG_AD_ER:

These calibrations impact the stability of the slow adaptation values SEG_AD_MMV_ER[NC_CYL_NR]

Select afterwards an engine speed between both previous engine speed thresholds (ex: 2500 rpm) at fuel cut off.

Make the filtering value C_CRLC_SEG_AD_ER vary for ex from 0.1 / 0.075 / 0.05 / 0.025 to 0.01.

Choose the value for which the adaptive value SEG_AD_MMV_ER[NC_CYL_NR] is nearly constant (variation lower than 0.5‰).

Robustness against disturbances

Check on the street, in fuel cut-off mode (PUC engine state), with several gear ratios by increasing and decreasing of the engine speed that the value of C_CRLC_SEG_AD_ER enables stable values of SEG_AD_MMV_ER[NC_CYL_NR]. Try several values of C_CRLC_SEG_AD_ER.

Remark: The segment stability should be checked during hot trip with warm engine. Hot conditions weaken drive train stiffness.

Result

The chosen value of C_CRLC_SEG_AD_ER should be the best compromise between adaptation stability at steady state conditions, fast learning and robustness against disturbances.

A value of 0.05 has shown in several cases to be the best compromise between adaptation stability, fast learning and robustness against disturbances. Notice that a value below this one could slow down too much the target wheel learning process.

Calibration of C_CRLC_SEG_AD_ER_EOL & C_NR_SEG_AD_AVL_ER

C_CRLC_SEG_AD_ER_EOL has to be chosen according two targets:

- Number of TDC in fuel cut-off mode during the EOL process *(normally not a critical point. often at least 100 tdc's in fuel cut-off)*
- Avoid learning too noisy adaptive values due to a too light filtering, even if corrected by slow adaptive process during engine lifetime.

C_NR_SEG_AD_AVL_ER is the needed number of engine cycles in EOL adaptive process to reach 95% of the final SEG_AD_MMV_ER[NC_CYL_NR] adaptive values obtained with C_CRLC_SEG_AD_ER_EOL *(1^{st} order filter)*

C_NR_SEG_AD_AVL_ER = -ln(0.05) / C_CRLC_SEG_AD_ER_EOL

≈ 3 / C_CRLC_SEG_AD_ER_EOL

Calibration of C_DRV1_MAX_SEG_AD_ER, C_NR_SEG_DRV1_MIN_ER & C_NR_SEG_AD_ACT_MIN_ER:

DRV1_ER is representative of the deceleration or acceleration of the engine in fuel cut-off.

Therefore for the robustness of the adaptation against disturbances, check on the street in deceleration phases and some brake events, with C_DRV1_MAX_SEG_AD_ER=200, if the adaptive values *(SEG_AD_MMV_ER[NC_CYL_NR])* are disturbed in a great extent *(It should stay nearly constant at the end of the adaptive phase)*. If the adaptive values are disturbed then measured the value of DRV1_ER in parallel to the adaptive value and reduces the value of C_DRV1_MAX_SEG_AD_ER if necessary.

C_NR_SEG_DVR1_MIN_ER = 2 times NC_CYL_NR is recommended.

C_NR_SEG_AD_ACT_MIN_ER is the delay in number of segment needed before starting the adaptive process after a fuel cut-off.

C_NR_SEG_AD_ACT_MIN_ER = 2 times NC_CYL_NR is recommended to avoid any phenomenon like extra combustions due to wallfilm or crankshaft oscillations after fuel cut-off.

21.9.4.3 404R_02: EOL specific request for ER segment adaptive learning process

21.9.4.3.1 General Information

During EOL process (LV_EOL_OBD = 1), it's possible to bypass nominal conditions for slow adaptive learning process with specific EOL calibrations. These calibrations must be adapted to customer EOL plant.

21.9.4.3.2 Calibration Step 404R_02 – Step 1/2 – Precalibration

In this calibration phase, check that LV_EOL_OBD isn't not active to not bypass nominal adaptive process conditions or else set LC_SEG_AD_ER_REQ_EOL = 1 (if LV_EOL_OBD is set to 0, LV_SEG_AD_FDOUT_ER_EOL will be forced to 1).

21.9.4.3.3 Calibration Step 404R_02 – Step 2/2 – Calibration

Example of calibration : *(identical to nominal adaptive conditions)*

C_N_MAX_SEG_AD_ER_EOL_xT = 3500 rpm

C_N_MIN_SEG_AD_ER _EOL_xT = 2000 rpm

C_N_MIN_SEG_AD_ER _EOL_MT = 2000 rpm

C_DRV1_MAX_SEG_AD_ER_EOL = 200 µs

C_NR_SEG_AD_ACT_MIN_ER_EOL = 1 or 2 times NC_CYL_NR

C_NR_SEG_DRV1_MIN_ER_EOL = 1 or 2 times NC_CYL_NR

LC_SEG_AD_ER_REQ_EOL = 1

Calibration

Adapt to the customer EOL plan:

- The engine speed range for adaptive process activation with C_N_MAX_SEG_AD_ER_EOL & C_N_MIN_SEG_AD_ER_EOL calibrations.
- The Maximum DRV1 value C_DRV1_MAX_SEG_AD_ER_EOL & associated delay C_NR_SEG_DRV1_MIN_ER_EOL to disable process activation if DRV1 exceeds.
- The delay C_NR_SEG_AD_ACT_MIN_ER_EOL to disable the adaptive process after beginning of the adaptive process.

Note : if LC_SEG_AD_ER_REQ_EOL is set to 0, EOL bypass for adaptive process will be always disable

21.9.4.4 404R_01: Fade out conditions of engine roughness segment adaptive process

21.9.4.4.1 General Information

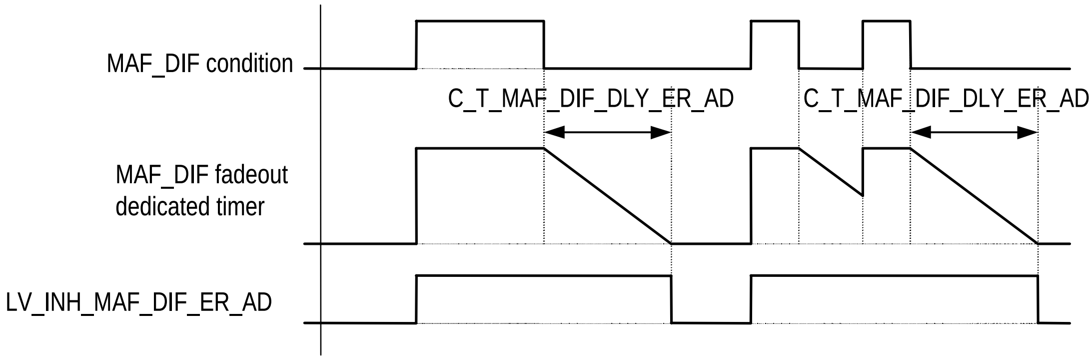
LV_SEG_AD_FDOUT_ER combines all system conditions to generate a fade out condition as input for the generic segment slow adaptation process, who provide SEG_AD_MMV_ER[NC_CYL_NR] values.

21.9.4.4.2 Calibration Step 404R_01 – Step 1/1 – Calibration

Calibration of IP_MAF_DIF_MAX_ER_AD & C_T_MAF_DIF_DLY_ER_AD ***: maximum air-mass gradient for adaptive process***

Due to trailing throttle / acceleration transition problems it is necessary to disable ER segment learning process for a short period when the air-mass gradient per segment exceeds a calibratable value *IP_MAF_DIF_MAX_ER_AD(MAF)*

Fade out behaviour summary:



Especially for engines with dual mass flywheels (DMF), critical behaviours at change from positive to negative torque on the power train could produce oscillations on crankshaft that could disturb slow adaptive process.

Check at the transitions from fuel cut off to part load and vice versa as well as all transition from low load to high load, if some speed fluctuations are critical to adaptive process.

Measure in parallel the load and look at which load difference the speed fluctuation is forced.

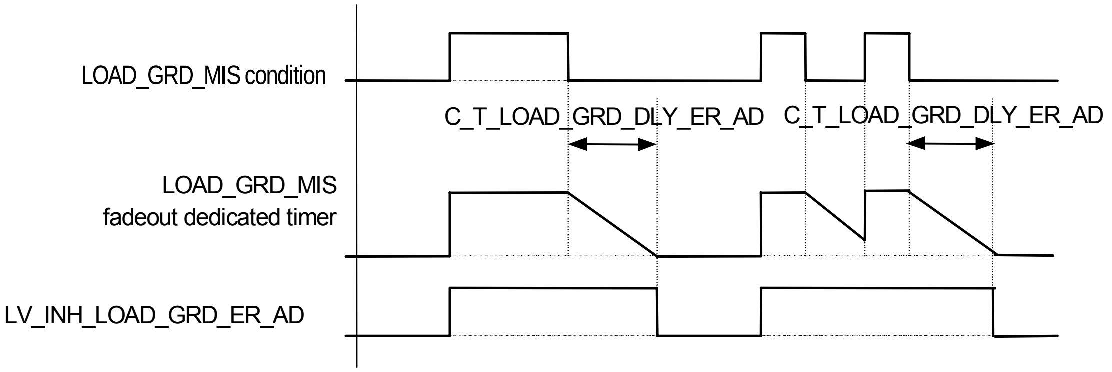
- Example: *IP_MAF_DIF_MAX_ER_AD(MAF). C_T_MAF_DIF_DLY_ER_AD* = 0.6s

MAF	IP_MAF_DIF_MAX_ER
87	2.2
103	5.0
169	20.0
218	40.0
261	65.4
272	201.5

Calibration of IP_LOAD_GRD_ER_AD & C_T_LOAD_GRD_DLY_ER_AD *: maximum engine load gradient for adaptive process*

Due to general intervention of the torque model it's necessary to disable ER segment adaptation for a short period when the actual torque gradient exceeds a calibratable value, *IP_LOAD_GRD_ER_AD(LOAD_MIS)*

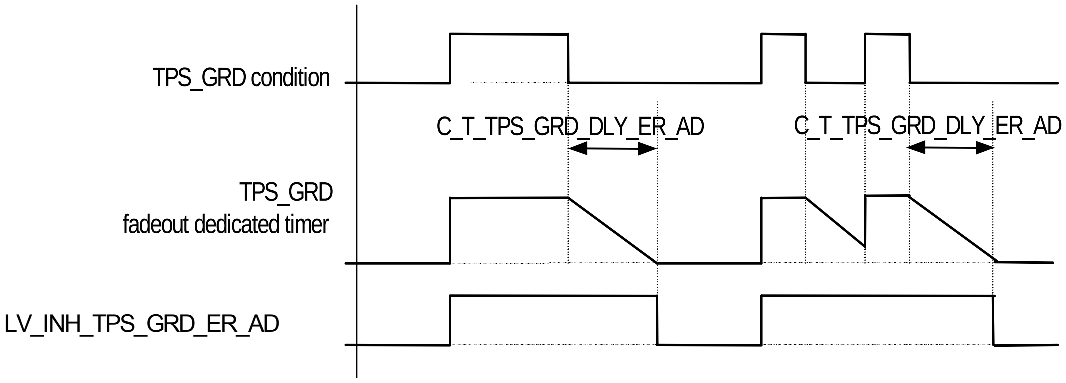
Fade out behaviour summary:



Calibration of IP_TPS_GRD_MAX_ER_AD & C_T_TPS_GRD_DLY_ER_AD*: maximum throttle gradient for adaptive process*

Due to trailing throttle / acceleration transient problems at low engine load it is necessary to disable ER segment adaptation for a short period when the throttle gradient exceeds a calibratable value, *IP_TPS_GRD_MAX_ER_AD*

Fade out behaviour summary:



The fade out through throttle gradient normally works at the transition from part load to fuel-cut-off. The air mass gradient is in this case too slow.

Example: IP_TPS_GRD_MAX_ER_AD. *C_T_TPS_GRD_DLY_ER_AD* = 0.8s

TPS_GRD	IP_TPS_GRD_MAX_ER_AD
2.8	23.4
12.2	70.3
20.2	140.6
23.4	187.5
27.2	398.4
50.1	996.0

Calibration of C_T_ACCOUT_DLY_ER_*AD Air - conditioning compressor activation*

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine.

This load jump could cause an ER segment period jump and crankshaft vibration.

To define C_T_ACCOUT_DLY_ER_AD, observe on SEG_AD_MMV_ER[NC_CYL_ER] the duration of the disturbance that could occurs on the crankshaft when ACC is active.

Example : C_T_ACCOUT_DLY_ER_AD = 0.75s

21.9.4.5 404R_04: Engine roughness adaptive values calculation & filtering

21.9.4.5.1 General Information

This function allows to determinate the coefficients for ER segment adaptive values filters used in the learning process. Three different stages can be differentiated:

- Nominal ER segment adaptive values filtering mode, used to monitor adaptive values during engine lifetime.
- Fast ER segment adaptive values filtering mode, used to quickly obtain valid adaptive values when the EMS is new.
- EOL specific filtering mode, to be used on EOL or special service request.

LV_SEG_AD_LIM_ER is set if at least one SEG_AD_MMV_ER[NC_CYL_NR] value exceeds C_SEG_AD_MAX_ER.

21.9.4.5.2 Calibration Step 404R_04 – Step 1/1 – Calibration

Calibration of C_CRLC_RAW_SEG_AD_ER

The aim of the fast adaptive process that provides SEG_AD_RAW_MMV_ER is to monitor the behaviours of the crankshaft that could produced wrong learning's on slow adaptive process, like oscillations produced by Dual Mass Flywheel (DMF) on a defined engine speed range.

Filtering induced by C_CRLC_FAST_SEG_AD_ER coefficient has to be enough light to observe such phenomenon, but not too much to avoid over fade-out due to noises on the slow adaptive learning process. Must be lighter than C_CRLC_SEG_AD_ER.

Example: C_CRLC_SEG_AD_ER = 0.05 ; C_CRLC_FAST_SEG_AD_ER = 0.1

LC_SEG_AD_LIM_REAC_ER allows to reactivate or not the absolute SEG_AD_MMV_ER[NC_CYL_NR] diagnosis. This absolute diagnosis is set as soon as at least one of the segment adaptive values exceeds the C_SEG_AD_MAX_ER calibration.

LC_SEG_AD_LIM_REAC_ER = 1, the diagnosis result is reinitialised each new activation of the segment adaptive process.

Generally C_SEG_AD_MAX_ER is set close to C_CRK_DIF_MAX_ER, the m*aximum Flywheel Tolerances provided by manufacturer for serial production, not for prototypes.*

21.9.4.6 404R_05: Engine roughness adaptive values difference on the same physical segment out of range

21.9.4.6.1 General information

Due to possible feedback from Dual Mass Flywheel oscillations *(see transmission/crankshaft design)* in adaptive process engine speed range, fluctuations on ER adaptive values of identical physical segments can induce dissimilarity in ER segment correction.

If difference between identical physical segments ER fast filtered adaptive values exceeds a calibratable gap *C_SEG_AD_DIF_MAX_ER,* a fade out of segment adaptive process is applied.

21.9.4.6.2 Calibration Step 404R_05 – Step 1/2 – Precalibration

In a first step, to avoid fade-out of segment adaptive process due to LV_SEG_AD_DIF_MAX_ER = 1, set C_SEG_AD_DIF_MAX_ER equals to C_CRK_DIF_MAX_ER

21.9.4.6.3 Calibration Step 404R_05 – Step 2/2 – Calibration

If on your application, crankshaft oscillations phenomenon occurs during fuel cut-off due for instance to DMF or CVT shifting, observe on SEG_AD_RAW_MMV_ER[NC_CYL_NR] values which amount of ER adaptive values difference on same physical segment could induce on SEG_AD_MMV_ER[NC_CYL_NR] drifts exceeding 0.5‰.

SEG_AD_RAW_MMV_ER[NC_CYL_NR] must change enough quickly *(see calibration of filter coefficient C_CRLC_SEG_AD_RAW_ER)* to allow to detect this drift amount before having too much impact on slow filtered adaptive values SEG_AD_MMV_ER[NC_CYL_NR].

The slow adaptive process will be retriggered only when all SEG_AD_DIF_ER_x differences will be less than C_SEG_AD_DIF_MAX_ER.

Check than the drifts of SEG_AD_RAW_MMV_ER[NC_CYL_NR] values don't come from a too wide engine speed range for fast adaptive process (drifts can occurs at low and high engine speed), *see C_N_SEG_T_AD_RAW_MAX_ER & C_N_SEG_T_AD_RAW_MIN_ER calibrations values.*

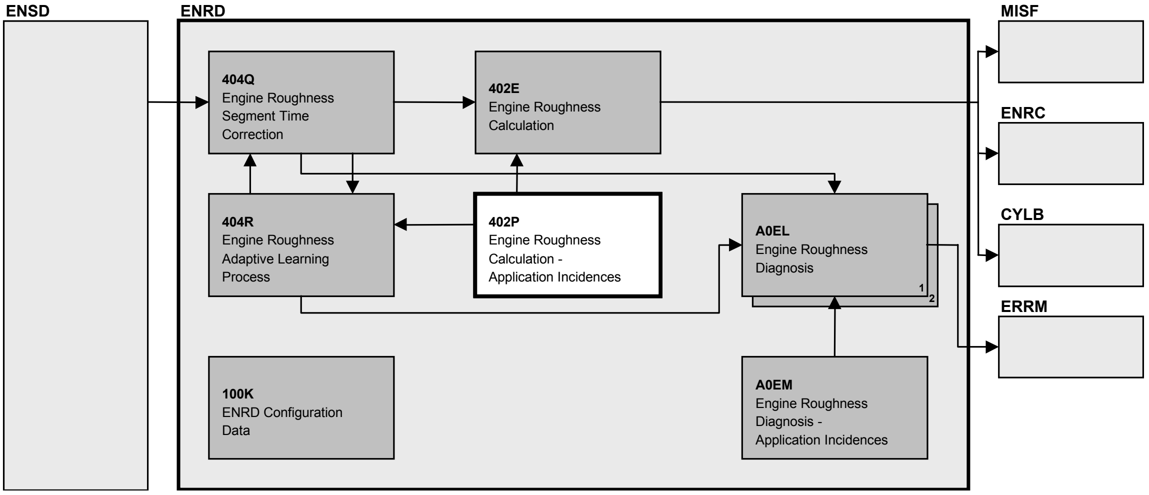
21.10 Engine roughness calculation & adaptation (cus)

21.10.1 Requirements

ENSD aggregate active and calibrated, no synchronisation errors/troubles

IGRE, IGSP & INJR precalibrated

21.10.2 Tuning hints for Engine roughness calculation - Application Incidences (Module 402P)



21.10.2.1 Inhibition of engine roughness adaptive process - Application specific

21.10.2.1.1 General Information

Engine roughness segments adaptive process can be inhibited when some system conditions that could disturb the adaptive process occur.

21.10.2.1.2 Calibration Steps

For this section, please see your application incidences file and associated calibration recommendations from your SV SI team.

LV_INH_APP_ER_AD must be set to 0, for nominal adaptive process conditions.

21.10.2.2 Engine roughness adaptive process inhibition related to OBDI diagnosis

21.10.2.2.1 General Information

Engine roughness segments adaptive process can be inhibited when some OBDI error that could disturb the adaptive process occurs (CRK, CAM, MAF, VVT ... sensors).

21.10.2.2.2 Calibration Steps

For this section, please see your application incidences file and associated calibration recommendations from your SV SI team (if using calibratable incidences matrix or QVM).

LV_INH_OBD_ER_AD must be set to 0, for nominal adaptive process conditions.

21.10.2.3 End of line & After sale service request to reset ER segment adaptive values

21.10.2.3.1 General Information

During end of line plant and/or for After sale services, a request is generated via communication protocol, to reset engine roughness segment adaptive values & learning process *(see project communication protocol).*

21.10.2.3.2 Calibration Steps

For this section, please see your application incidences file and associated calibration recommendations from your SV SI team (if using calibratable incidences matrix or QVM).

LV_SEG_AD_RST_ER_EOL must be set to 0, for nominal adaptive process conditions.

21.11 Engine roughness OBDII (gen)

21.11.1 Requirements

ENSD aggregate active and calibrated, no synchronisation errors/troubles

21.11.2.2 Module calibration prerequisites

ENSD robustness calibration executed

ECU C sample & crankshaft, sensor, flywheel design frozen

No diagnosis inhibition coming from Module A0EM: Engine roughness diagnosis - Application Incidences *(see project specific document based on D7 template 30Q01R01.00A).* The project specific tuning hint dedicated to this module is called: ER OBDII (cus).

21.11.2.3 A0EL_01: Engine roughness segment time acquisition error

Configuration data

Diagnosis	Symptom	Nr	P-Code/ Failure	P-Code/ Symptom	Failure class A/B
ER segment time acquisition	*Missing/Adding 1 tooth or more on engine roughness segment acquisition*	1	P0339 *(example)*	P0339 *(example)*	MIL_KEY / CARB_M
		2			
		3			
T_SEG_ER					

21.11.2.3.1 General Information

The purpose of this error is to diagnose synchronisation errors on engine roughness segments measurement.

An error symptom “*Missing/Adding 1 tooth or more on engine roughness segment acquisition*” is detected when a crankshaft synchronisation error caused by 1 or 2 missing/additional tooth occurs on one crankshaft revolution.

Note: In ENSD, most of the cases, the criterion to set LV_INH_MIS_CRK is smaller in term of missing/adding teeth number than the criterion to declare an engine desynchronisation. In consequence, LV_INH_MIS_CRK can be set without engine desynchronisation.

21.11.2.3.2 Calibration Step A0EL_01 – Step 1/1

Evaluate in mission, with a large C_ABC_MAX_T_SEG_ER maximum value and C_ABC_INC_T_SEG_ER = 1, the frequency of LV_INH_MIS_CRK occurrences.

A too important number of occurrences on one trip could bring to light troubles in ENSD robustness tuning, sensor and flywheel troubles.

There’s a handshake between LV_INH_MIS_CRK (low-level validity information) and ENRD application validity informations (LV_ENA_SEG_T_MES & LV_ENA_ER). As a final effect, it will fade-out monitoring in MISF & control in ENRC & CYLB.

If occurrences of LV_INH_MIS_CRK are too important, finally it could reduce the misfire monitoring coverage on cycle (act as a fade-out in the function).

Finally, to define C_ABC_MAX_T_SEG_ER value, you need to evaluate a compromise between error over detection and impact on monitoring ratio.

Note: there's no direct risk between misfire wrong detections and the bit LV_INH_MIS_CRK, as this bit will automatically shut-off the ER index calculation and inhibit the misfire monitoring as well. This diagnosis is mainly used to inform a too important occurrence of this error, which could have an impact on the diagnosis ratio for misfire monitoring. Most of the case, an ENSD error will be set before LV_ERR_T_SEG_ER, except if each time LV_INH_MIS_CRK is set without ENSD desynchronisation.

For associated Pcode, see if customer specific code already defined.

Subclass A	
Name	**Description**
MIL_KEY	Failure with impact on MIL / key cycle ***(Recommended)***

21.11.2.4 A0EL_02: Engine roughness segment adaptive values out of range error

Configuration data

Diagnosis	Symptom	Nr	P-Code/ Failure	P-Code/ Symptom	Failure class A/B
Er segment adaptation values at the limit	*Er segment adaptation values at the limit*	1	P0336 *(example)*	P0336 *(example)*	MIL_KEY / CARB_M
		2			
		3			
SEG_AD_ER					

21.11.2.4.1 General Information

The purpose is to diagnose the absolute range of ER segment adaptive values.

If during **or** at the end of the segment adaptive values learning process *(LV_SEG_AD_ER = 1 or LV_SEG_AD_ER = 1 -> 0),* at least one of the engine roughness segment adaptation values is at the limit (LV_SEG_AD_LIM_ER = 1), the error symptom SEG_AD_ER “engine roughness segment adaptation values at the limit” is detected.

21.11.2.4.2 Calibration Step A0EL_02 – Step 1/1

If LC_CDN_DIAG_SEG_AD_ER = 0, the adaptive values out of range information (LV_SEG_AD_LIM_ER) will be taken in account only at the end of the adaptive process. For this solution, an important maximum ABC counter calibration isn’t required (for instance C_ABC_MAX_SEG_AD_ER = 10).

Otherwise, if LC_CDN_DIAG_SEG_AD_ER = 1, the diagnosis will be executed continuously. In this case the maximum ABC counter calibration must be important if you would to be able to set the error based on more than only one adaptive process.

For associated Pcode, see if customer specific code already defined.

Subclass B	
Name	**Description**
CARB_M	CARB failure Middle priority *(Recommended)*

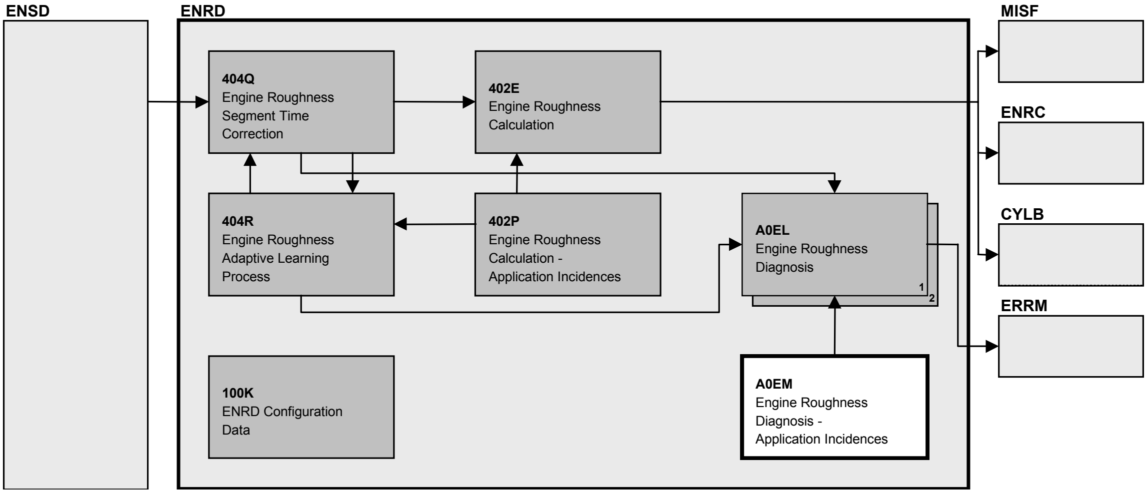
21.12 Engine roughness OBDII (cus)

21.12.1 Tuning requirements

ENSD aggregate active and calibrated, no synchronisation errors/troubles

IGRE, IGSP & INJR precalibrated

21.12.2 Tuning hints for Engine roughness diagnosis - Application Incidences



21.12.2.1 General information

For integration test and calibration, please contact your SI team for recommendations according what has been integrated for project specific inhibition of LV_ERR_T_SEG_ER & LV_ERR_SEG_AD_ER diagnosis *(application incidences file)*.

For a proper calibration of generic diagnosis, LV_INH_DIAG_T_SEG_ER & LV_INH_DIAG_SEG_AD_ER must be set to 0.

21.13 Customer adaptation module: AGGR ENRD

21.13.1 Outputs for BMW functions which are defined as ENRD exported data

Output data:

Torque for driving off assistance, basic value in operation mode 2					

22.1.1 FUNCTION DESCRIPTION:

The function “Driving off assistance” shall prevent the engine from stalling at driving off. Therefore an extra torque reserve is put at disposal if the necessity is given. This is shown by LV_N_SP_IS_CS = 1.defined in Engine speed setpoint calculation

In addition, an extra torque request is calculated under individual conditions. While this extra torque is effective, the idle speed controller can be suppressed or not via LC_TQ_DROF_ISC_OFF.

Application Condition

22.2.3 Formula section.

22.2.3.1 Idle speed setpoint N_SP_IS

FUNCTION DESCRIPTION:
General information:
The input value LV_DLY_N_SP_IS (output from module Converter Torque) is derived from LV_DRI including a tuneable delay time. If drive is engaged the converter torque is build up after a short delay time (about 400 ms). If the change in engine speed setpoint for drive engaged also is delayed the new setpoint can be adjusted more stable.
In general the transition from one idle speed setpoint to another is performed with adjustable change limitations. The only exception is: no change limitation before engine start has finished (LV_ST_END = 0). This is to ensure the desired engine speed setpoint immediately after start.

22.2.3.1.1 Nominal idle speed with tester offset(Calculation of N_SP_IS_2)

The nominal idle speed setpoint calculation takes into consideration air conditioning compressor ACC on/off, drivetrain engaged (LV_DLY_N_SP_IS) and offset by tester via KWP.
Table of nominal idle speed N_SP_IS_1, dependant from ACC and drivetrain engaged:

LV_ACIN	LV_DLY_N_SP_IS	N_SP_IS_1
0	0	IP_N_SP_IS
0	1	IP_DRI_N_SP_IS
1	0	IP_ACIN_N_SP_IS
1	1	IP_DRI_ACIN_N_SP_IS

The tester offset is multiplied by a factor IP_FAC_N_SP_OFS_KWP which is TCO dependant and limited by upper and lower thresholds.
N_SP_IS_2 is calculated here depending upon logical variable LV_ACIN and LV_DLY_N_SP_IS. Using these two variables the control input is generated using the lookup table. If both variable are zero then input from port 1 of multiport switch is passed, similarly the inputs at other ports are passed depending upon these two logical variable.

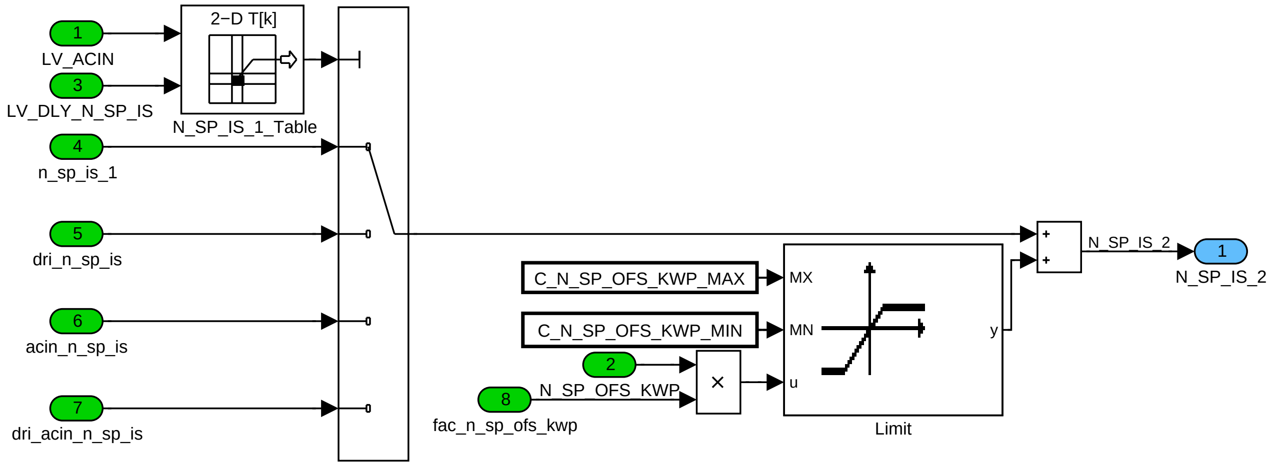

Figure 15:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_2

22.2.3.1.2 Pre calculation and calculation of N_SP_IS

22.2.3.1.2.1 Extraordinary engine speed setpoints(Calculation of first part of pre calculation.)

22.2.3.1.2.1.1 Idle speed setpoint due to Power Management

The engine speed setpoint N_SP_IS_POW_1 from Power Management is used if LV_N_SP_IS_POW_ACT = 1 and if it is the greatest of the speed setpoints entering the MAXselection

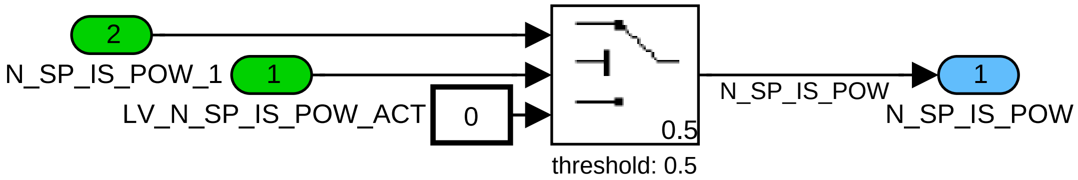

Figure 16:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DUE_TO_POW_MNG

22.2.3.1.2.1.2 Idle Speed setpoint required from heating control unit

The A/Cunit sets a requirement switch LV_REQ_HEAT to raise the idle speed in order to increase the heating power. If the vehicle is not equipped with A/C, LV_REQ_HEAT is made up with ambient temperature TAM. The idle speed setpoint C_N_SP_HEAT_MT/AT will be executed if LV_REQ_HEAT = 1 and if it is the greatest of the speed setpoints entering the MAXselection

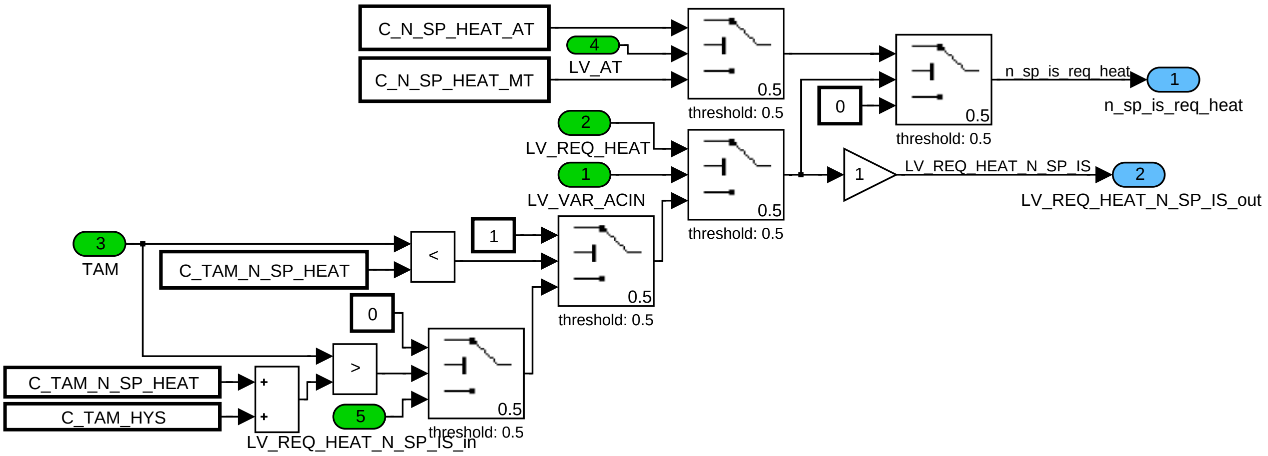

Figure 17:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DUE_TO_HEATING

22.2.3.1.2.1.3 Idle speed setpoint due to variant of power steering 2

The engine speed setpoint N_SP_IS_VAR_PSTE_2 depends on learnt variant LV_VAR_PSTE_2.

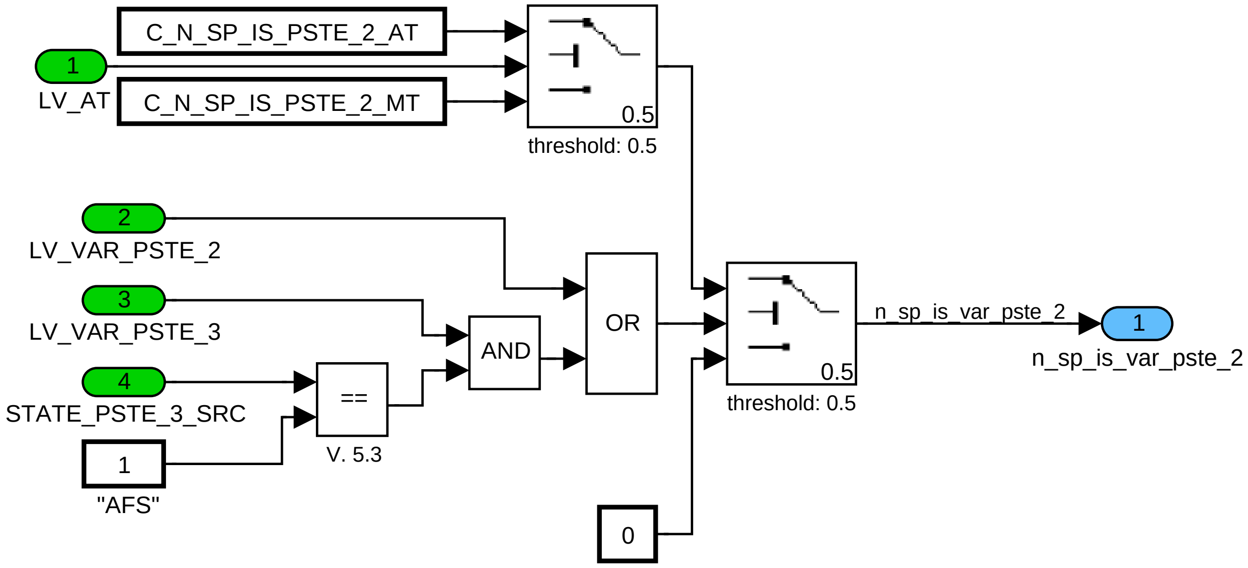

Figure 18:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DUE_TO_VAR_PSTE2

22.2.3.1.2.1.4 Idle speed setpoint due to variant of ARS

The engine speed setpoint N_SP_IS_ARS depends on learnt variant LV_VAR_ARS and vehicle speed.

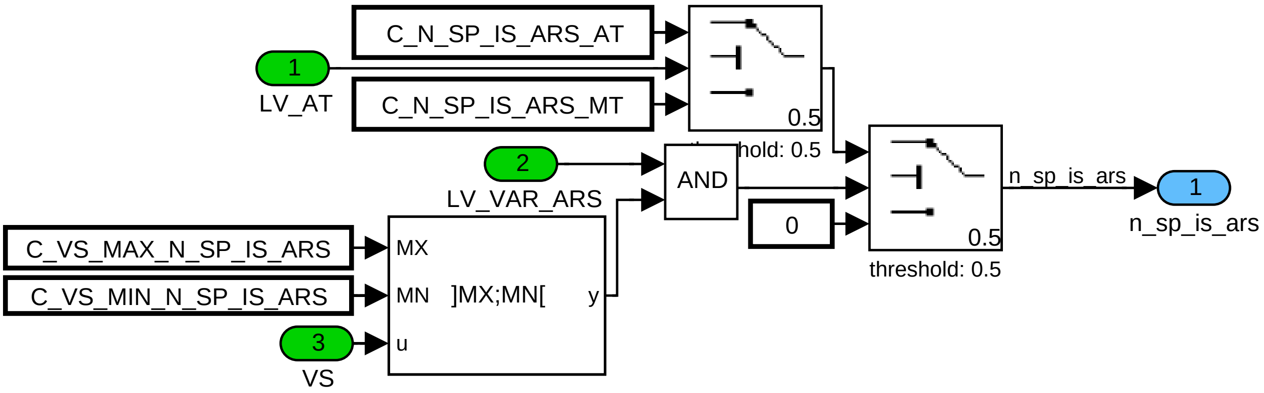

Figure 19:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DUE_TO_VAR_ARS

22.2.3.1.2.1.5 Idle Speed setpoint TOIL dependant

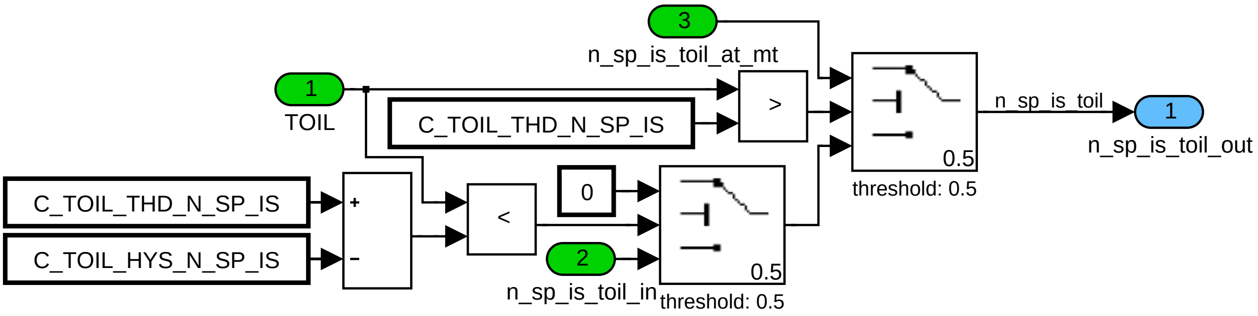

Figure 20:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_TOIL

22.2.3.1.2.1.6 Idle Speed setpoint depending on average spark retard due to knocking

N_SP_IS takes care of the ignition spark retard due to knocking. Exceeding a calibrateable threshold an increased setpoint is active.

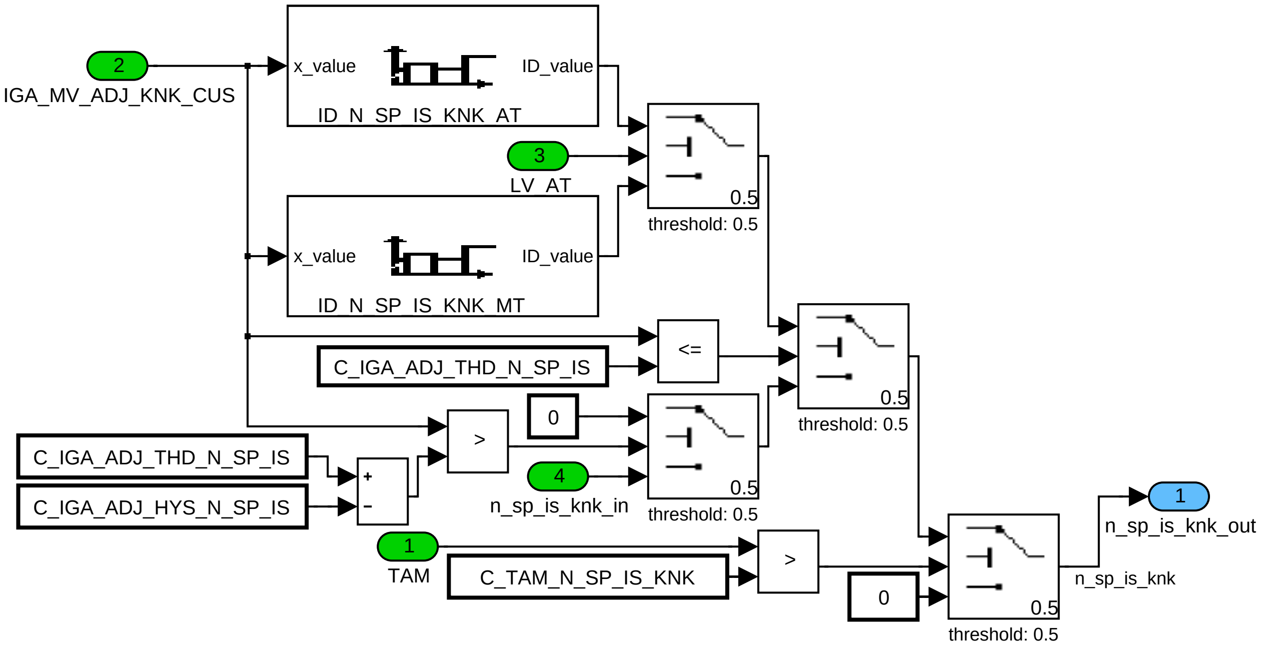

Figure 21:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_AVG_SPARK_KNCK

22.2.3.1.2.1.7 Idle Speed setpoint at driveoffsupport

Absolute engine speed setpoint dependant from TOIL and transmission variant, used under certain conditions where vehicle driveoff is expected and if it is the greatest of the speed setpoints entering the MAXselection, see below. Individual gradient limitation C_N_SP_INC/DEC_CS.

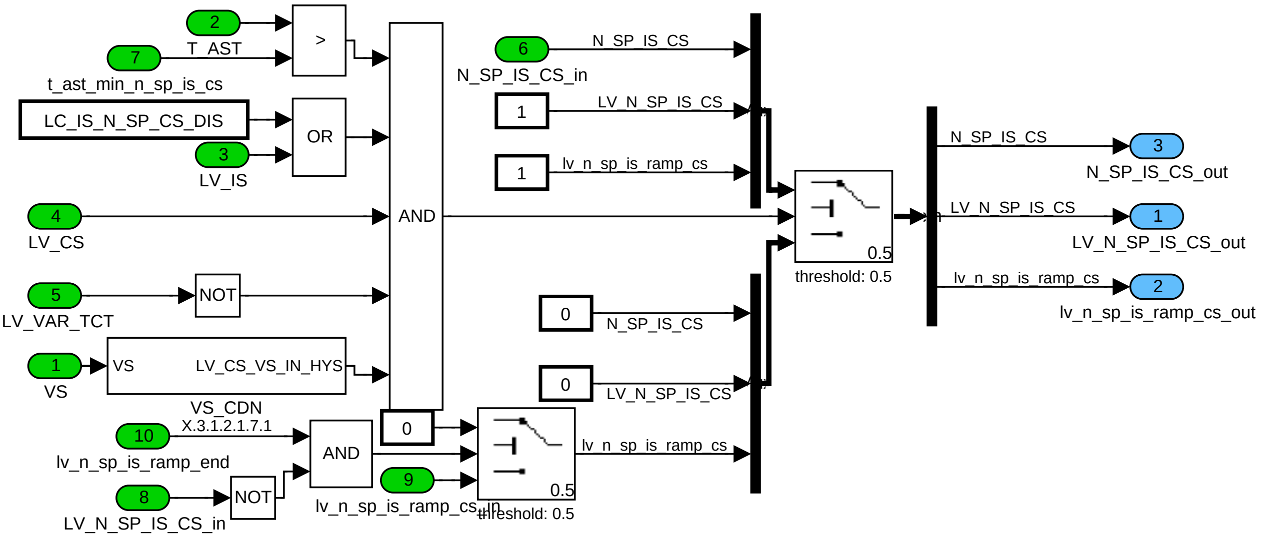

Figure 22:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DRIVE_SUPPORT

22.2.3.1.2.1.7.1 Calculation of logical variable

If VS is less than difference of maximum vehicle speed for drive of support (C_VS_MAX_N_SP_CS) and Vehicle speed hysteresis for VS threshold driveoffsupport

(C_VS_HYS_N_SP_CS) then generated LV_CS_VS_In_HYS_tmp is equal to 1 else if VS is greater than C_VS_MAX_N_SP_CS then . LV_CS_VS_In_HYS_tmp is set to 1 else it remains at old value.

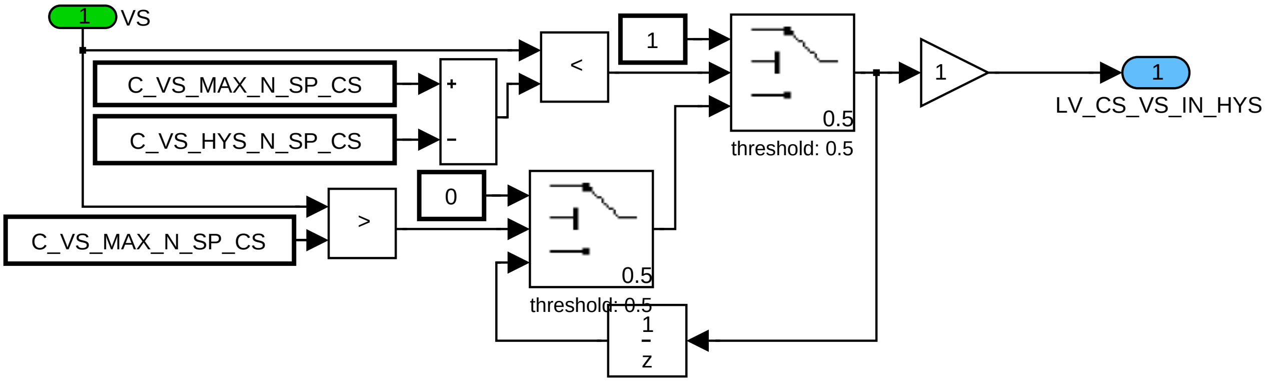

Figure 23:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_1/ISSP_DRIVE_SUPPORT/VS_CDN

22.2.3.1.2.2 Extraordinary engine speed setpoints(Calculation of second part of pre calculation.)

22.2.3.1.2.2.1 Idle Speed setpoint for power steering (EPS / PSTE / PSTE_2)

Absolute engine speed setpoint dependant from steering angle and steering angle velocity, used under certain conditions. If it is the greatest of the speed setpoints entering the MAXselection, see below.
For power steering variant EPS and AFS (ident: PSTE).

22.2.3.1.2.2.1.1 Idle speed setpoint for powersteering 1

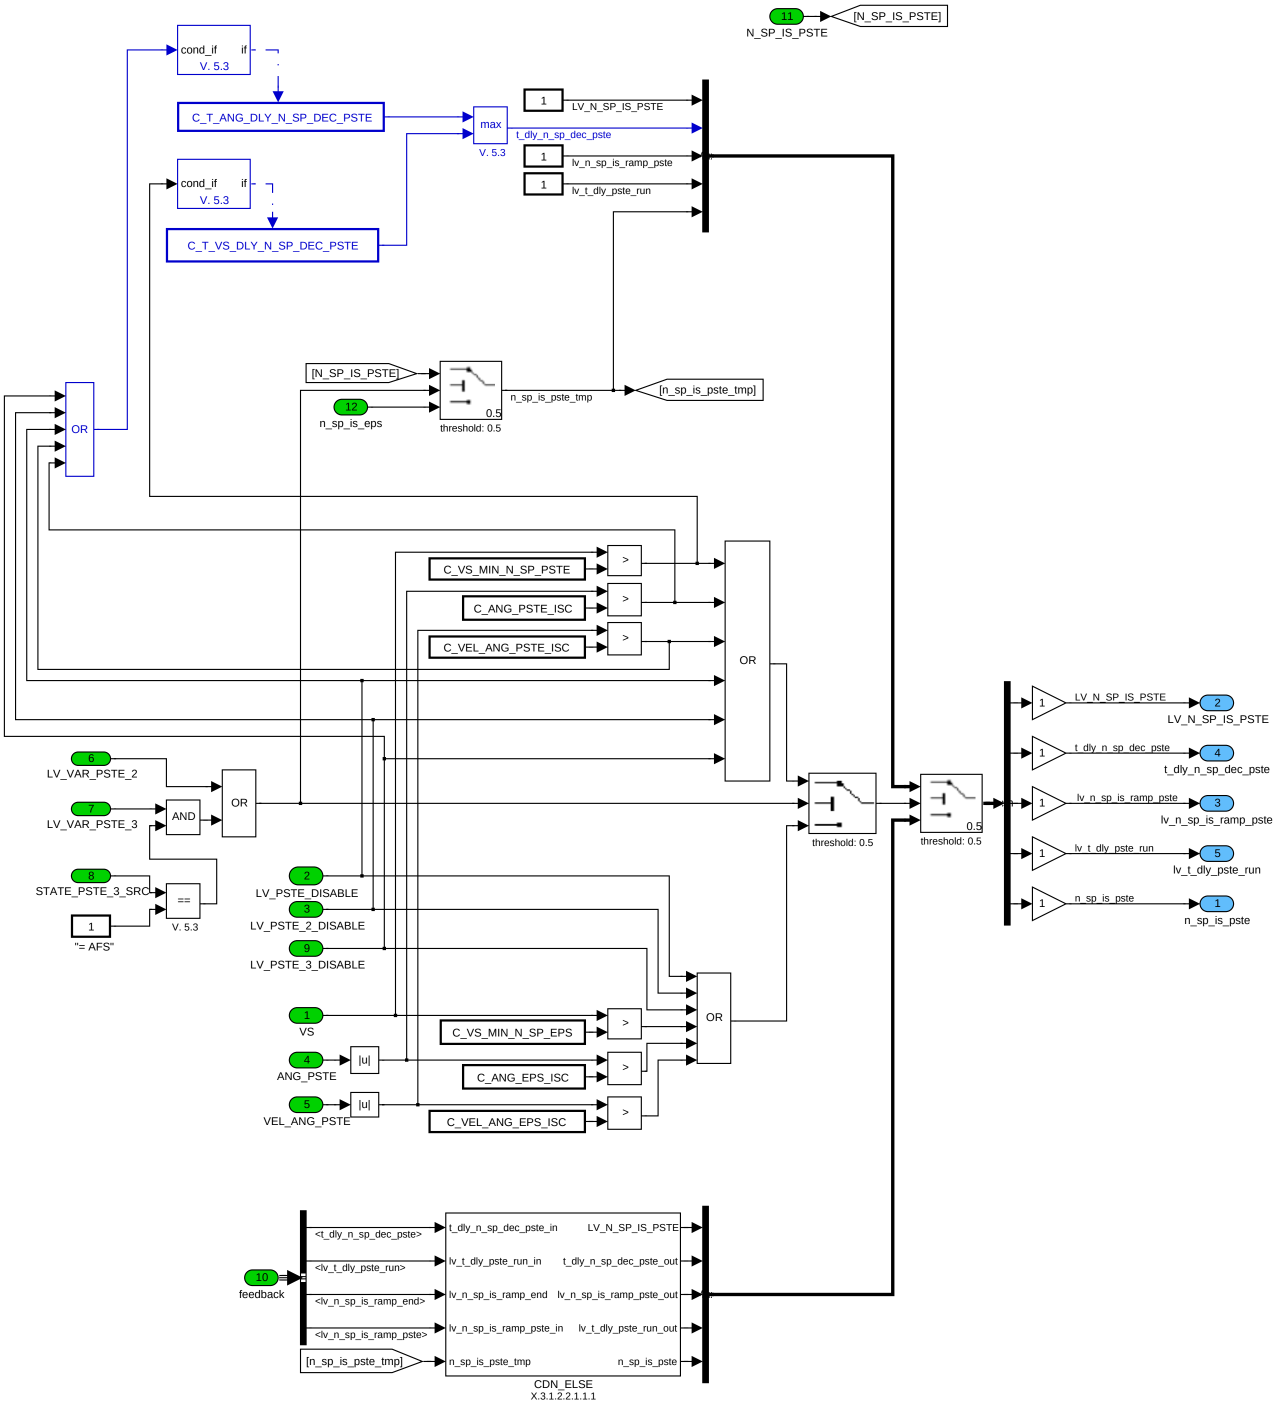

Figure 24:

22.2.3.1.2.2.2 Idle Speed setpoint at part load (PL)

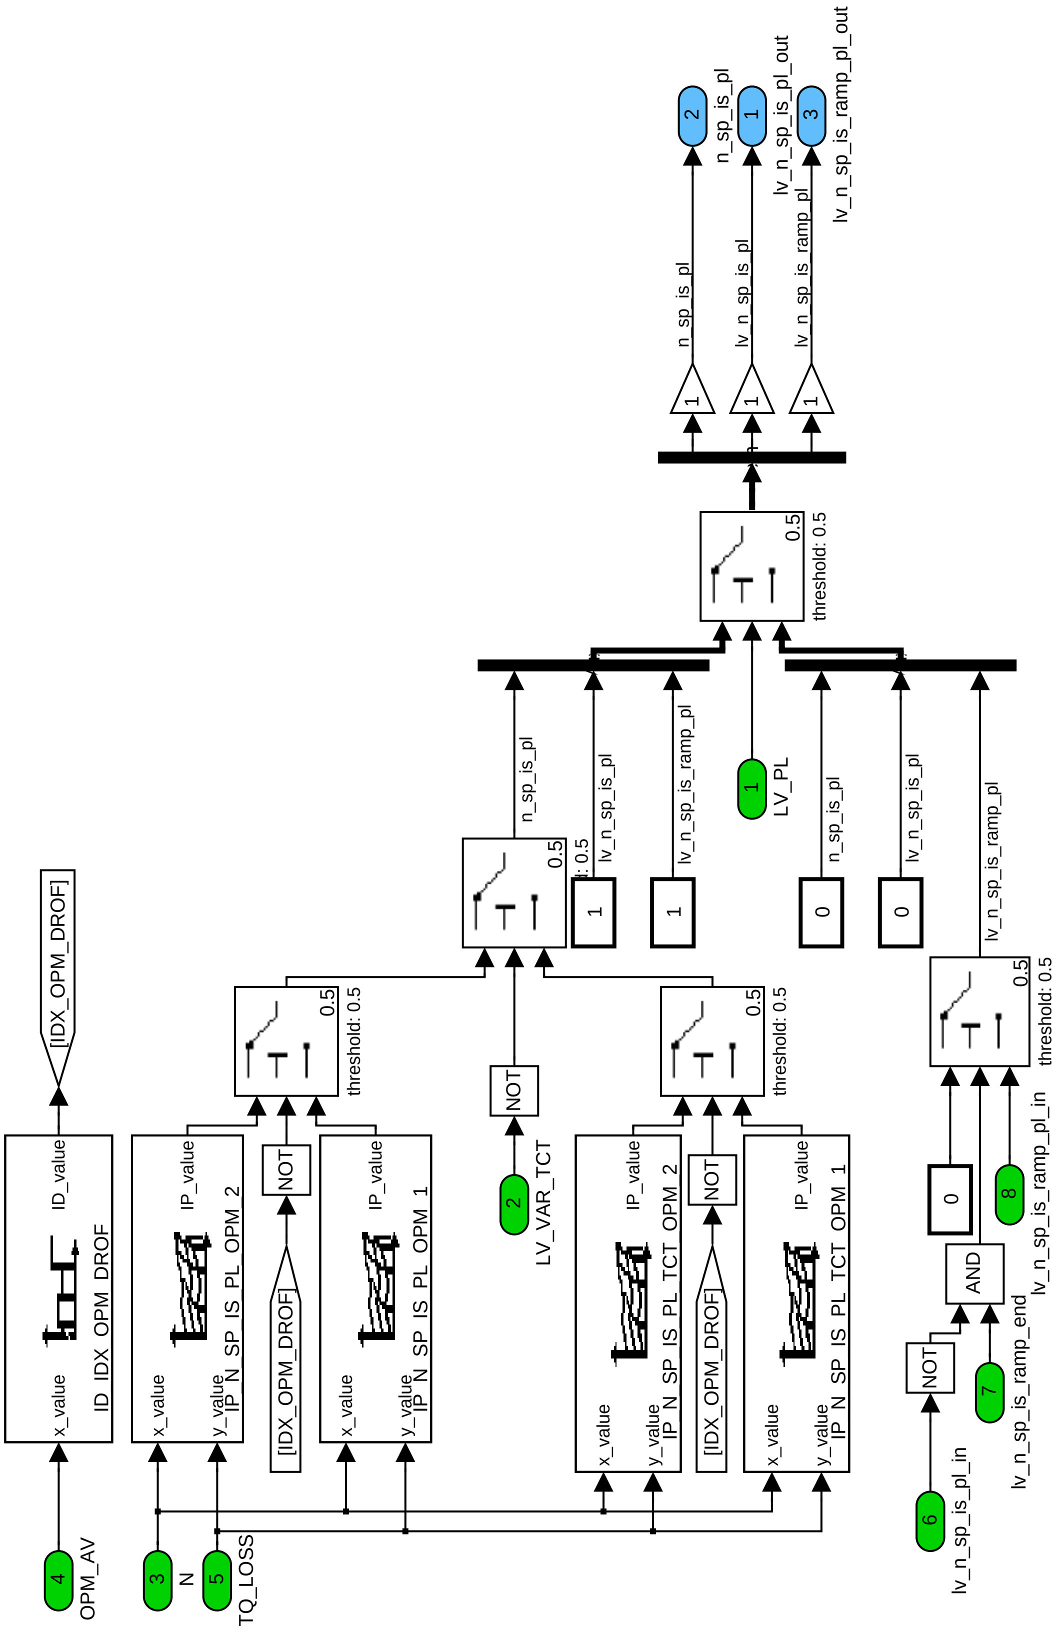

Figure 28:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_2/ISSP_AT_PL

22.2.3.1.2.2.3 Idle Speed setpoint due to power management request for power supply stability

The engine speed setpoint N_SP_IS_PWR_STAB can be activated by the power supply stability request from the power management. The height of this setpoint depends on whether the driving position is engaged or not.

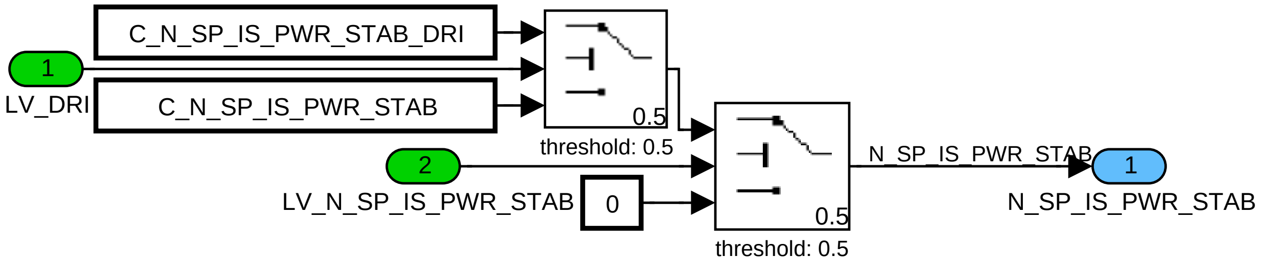

Figure 29:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_2/ISSP_PM_POW_SUPPLY

22.2.3.1.2.2.4 Idle speed set point due to TCT(twin clutch transmission)

The engine speed setpoint N_SP_IS_TCT_CAN from TCT is transmitted via CAN and used as N_SP_IS_TCT if LV_VAR_TCT = 1 and if it is the greatest of the speed setpoints entering the MAXselection.

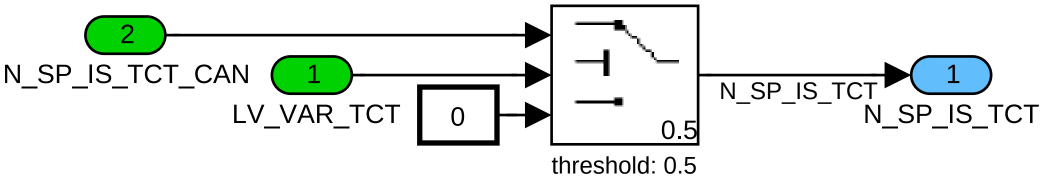

Figure 30:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_2/ISSP_DUE_TO_TCT

22.2.3.1.2.3 Exceptional engine speed setpoint

There are 4 other cases which are not mentioned in above formula section. First is a function which allows to bypass the MAXselection if a correspondingly command (LV_ACT_N_SP_IS_BAS_EXT_ADJ) was received via Kline. In this case, N_SP_IS_3 is set to the basis idle speed setpoint N_SP_IS_2.
Second is a function which allows to bypass the MAXselection if another correspondingly command (LV_ACT_N_SP_IS_EXT_ADJ) was received via Kline. In this case, N_SP_IS_3 is set to the requested idle speed setpoint N_SP_IS_EXT_ADJ.
Third is an extra idle speed setpoint C_N_SP_IS_SA_EOL during the secondary air function end of line test . It is valid during LV_ACT_SA_EOL = 1.
Fourth, a switch for activation of desulfatisation, LV_NT_SO2P_EXT_ADJ_ACT was introduced to increase N_SP_IS to 3000...4000 rpm.
4th case is limp home (highest priority). If PVS error and PVS limp home is requested (LV_N_SP_IS_LIH_ACT = 1) a different idle speed setpoint can be calibrated. So a higher vehicle dynamic as at nominal idle speed is possible.

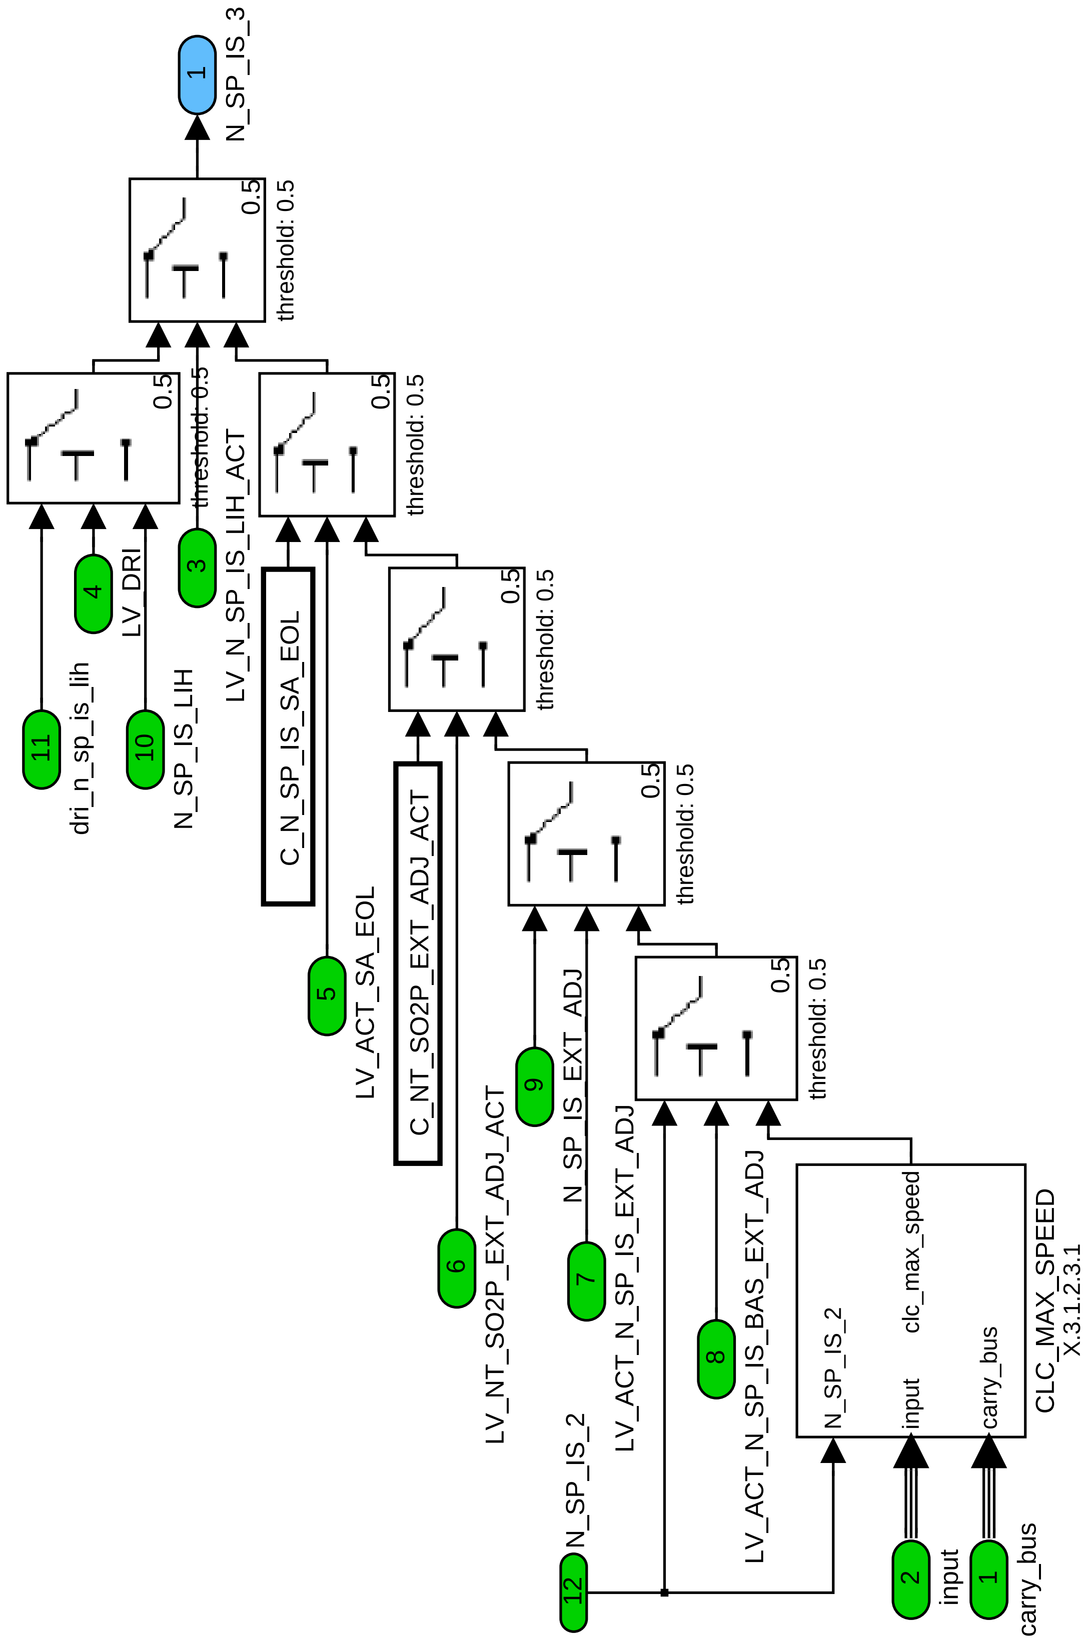

Figure 31:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_3

22.2.3.1.2.3.1 Calculation of maximum speed from set of idle speed. calculated in pre calculation subsystem.

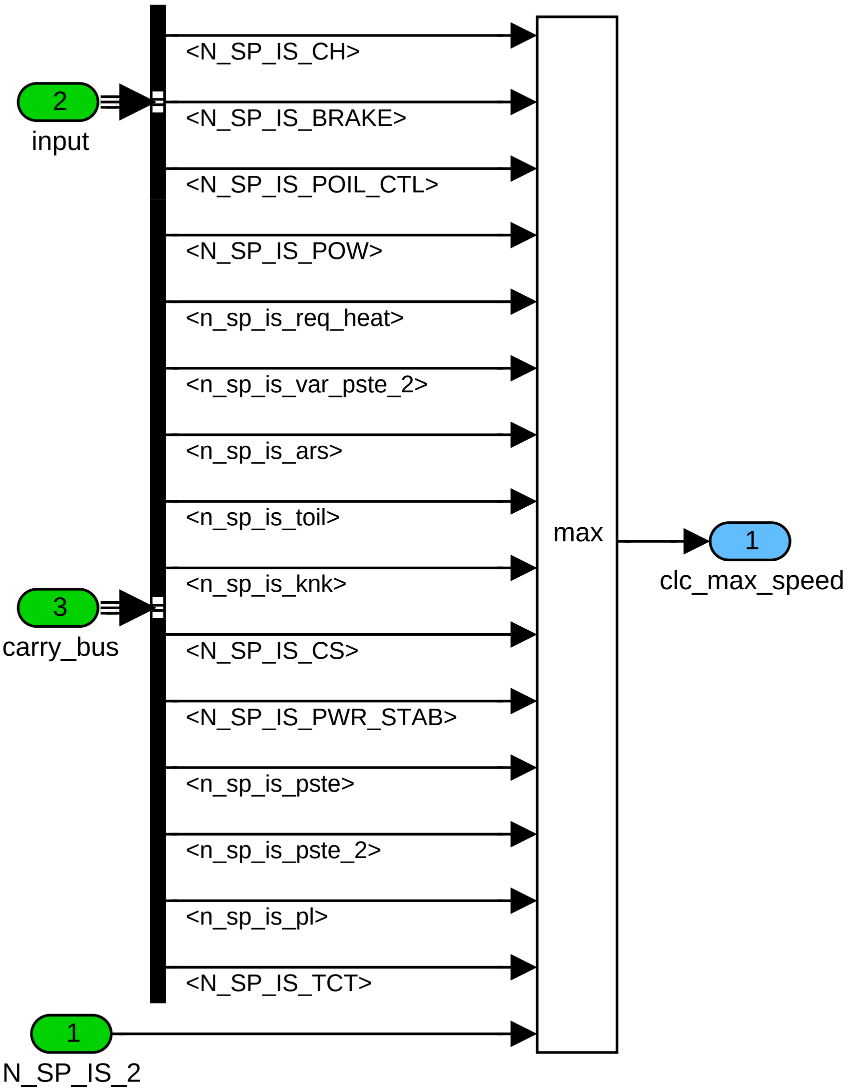

Figure 32:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_3/CLC_OUT_3/CLC_MAX_SPEED

22.2.3.1.3 Gradient limitation

The gradient limitation for N_SP_IS by C_N_SP_LGRD_IS, C_N_SP_DEC_IS_CH_DRI, C_N_SP_DEC/INC_CS or C_N_SP_DEC/INC_PSTE is finished as soon as the goal N_SP_IS_3 is reached (N_SP_IS = N_SP_IS_3)
During active limp home a special gradient limitation C_N_SP_LGRD_IS_LIH is used.

An increase of engine speed setpoint is not allowed in case of automatic transmission vehicle with drive engaged, vehicle standing or very low speed and engine operating state idle active. This is to prevent runaway of the car.

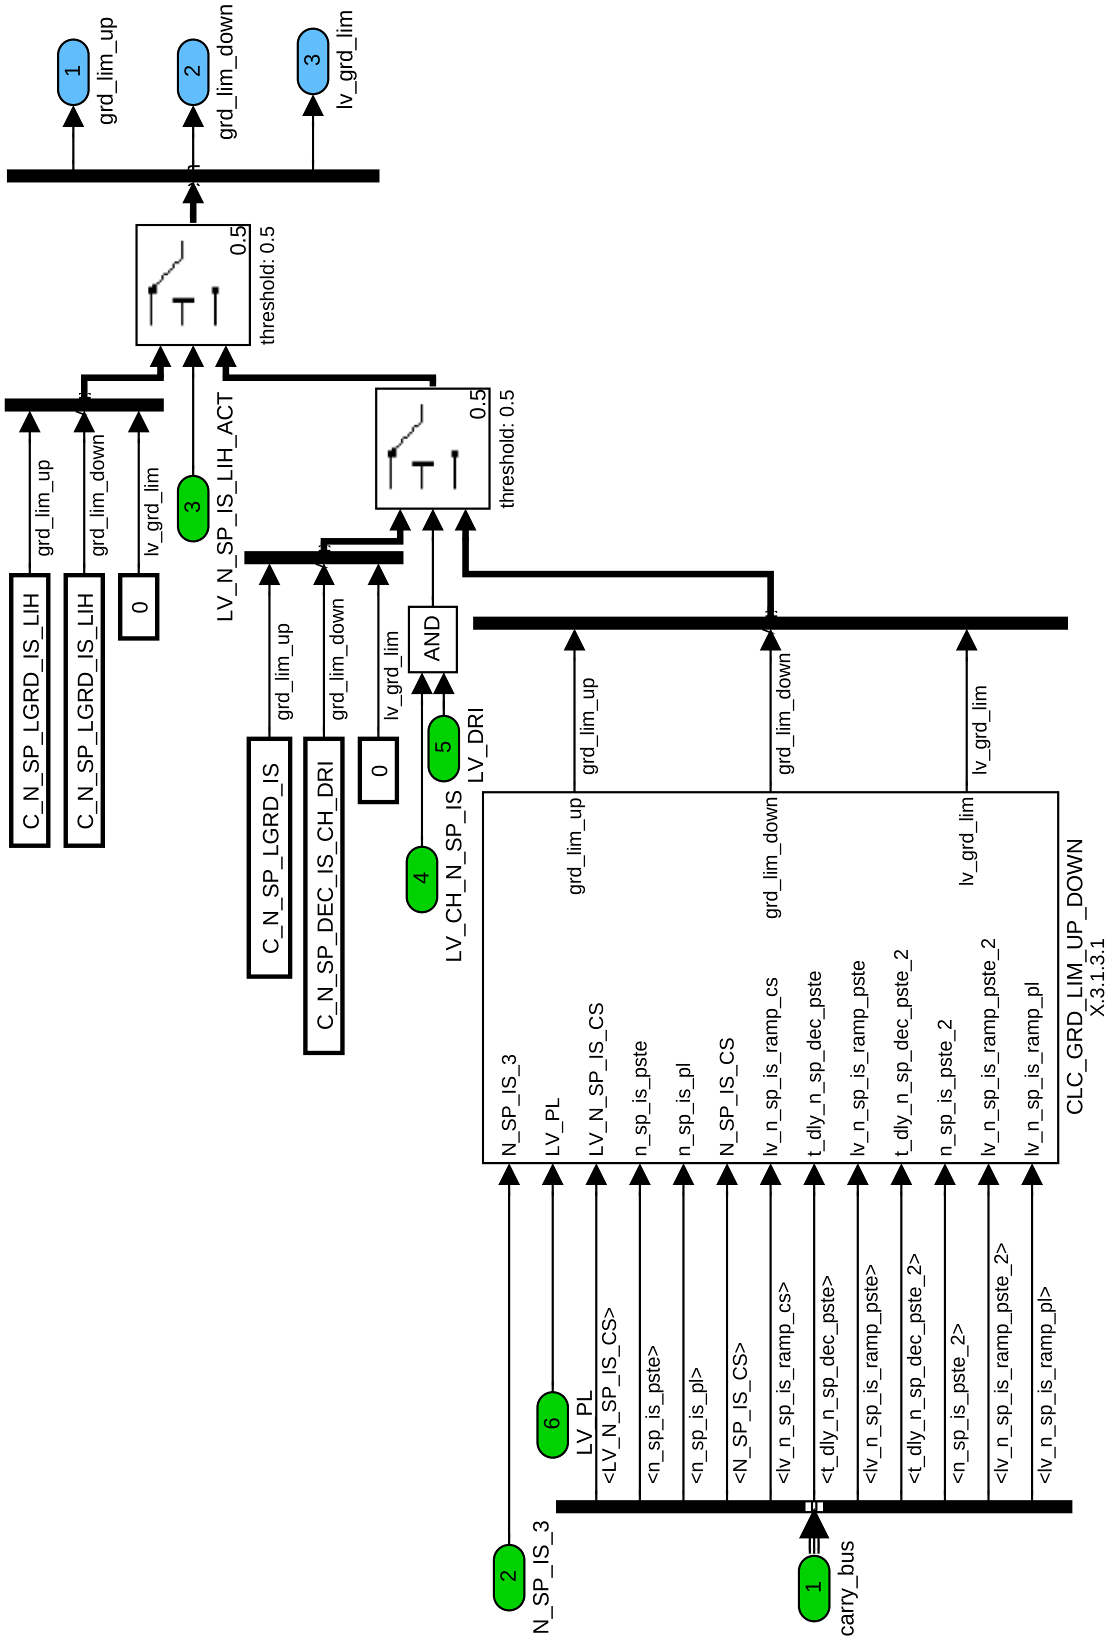

Figure 33:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_GRD_LIM

22.2.3.1.3.1 Calculation of Gradient limitation continued...

If LV_N_SP_IS_LIH_ACT is 0 and LV_DRI and LV_SH_N_SP_IS are 1 then this part is calculated.

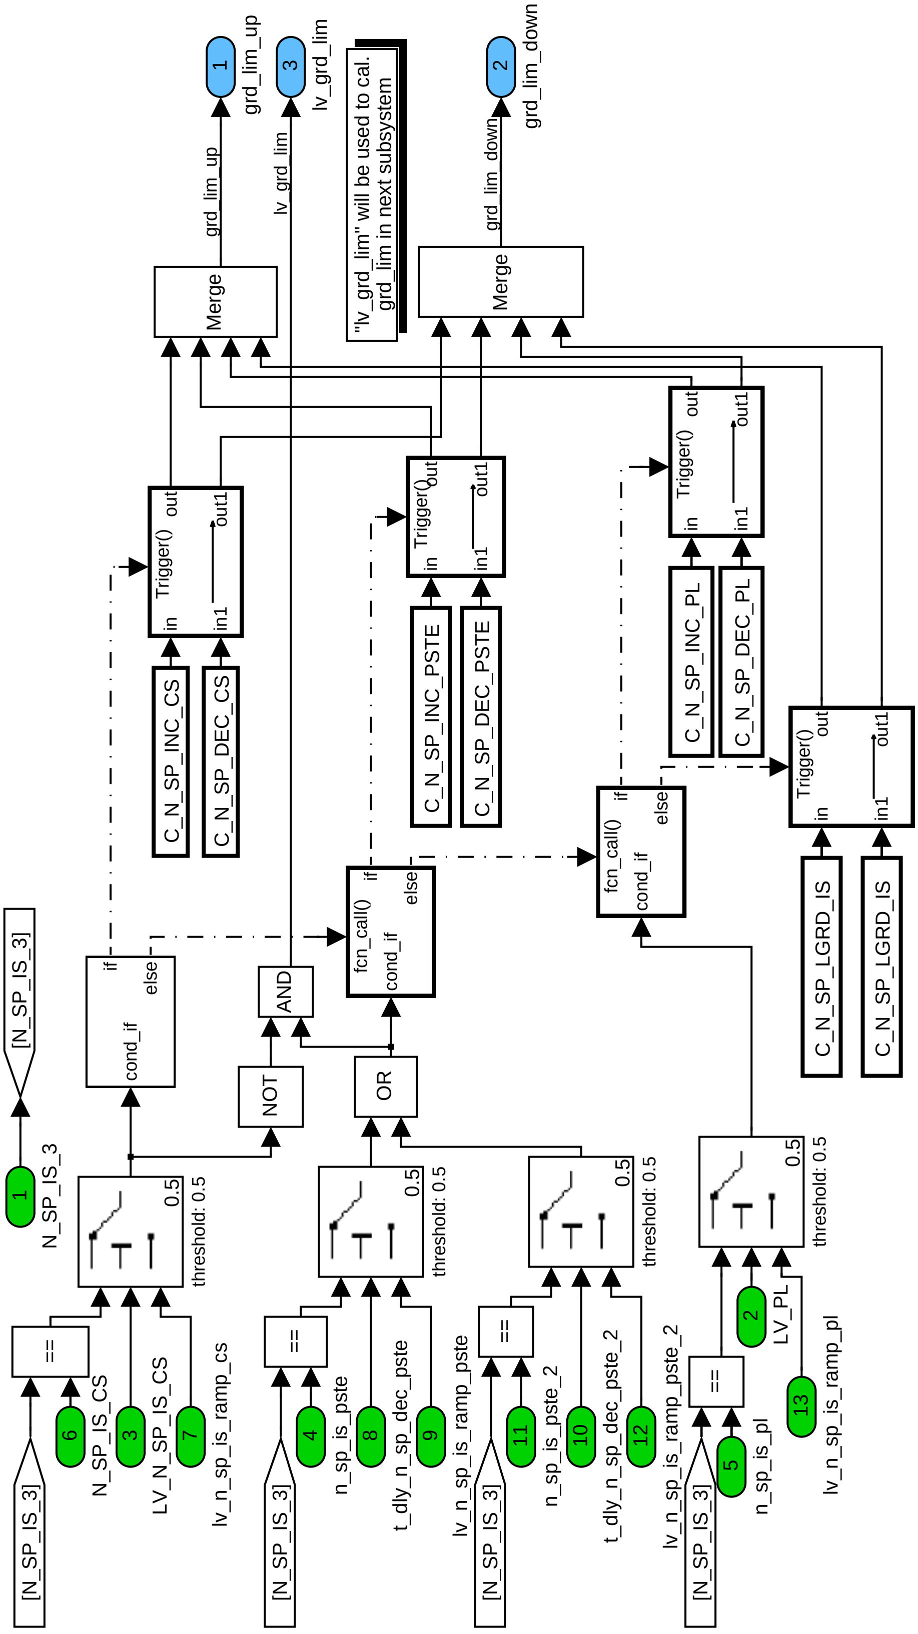

Figure 34:
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_GRD_LIM/CLC_GRD_LIM_UP_DOWN

22.2.3.1.4 Determination of N_SP_IS

During start and after end of start gradient limitation of N_SP_IS can be disabled by delay time C_T_DLY_GRD_LIM.

22.2.3.1.5 Calculated engine speed setpoint ratio

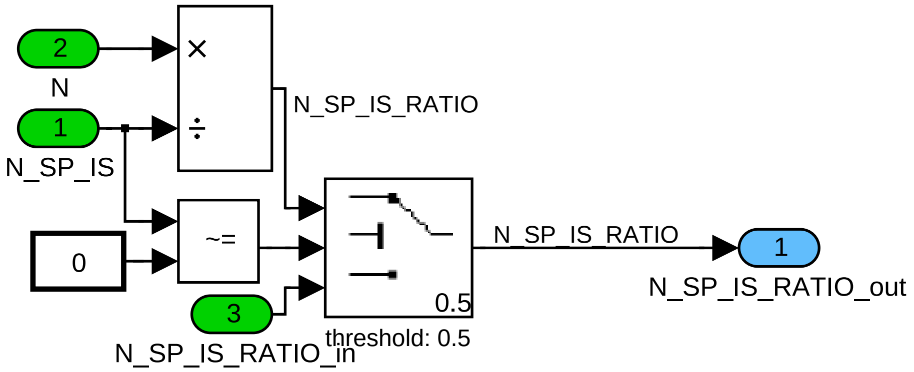

Figure 37:
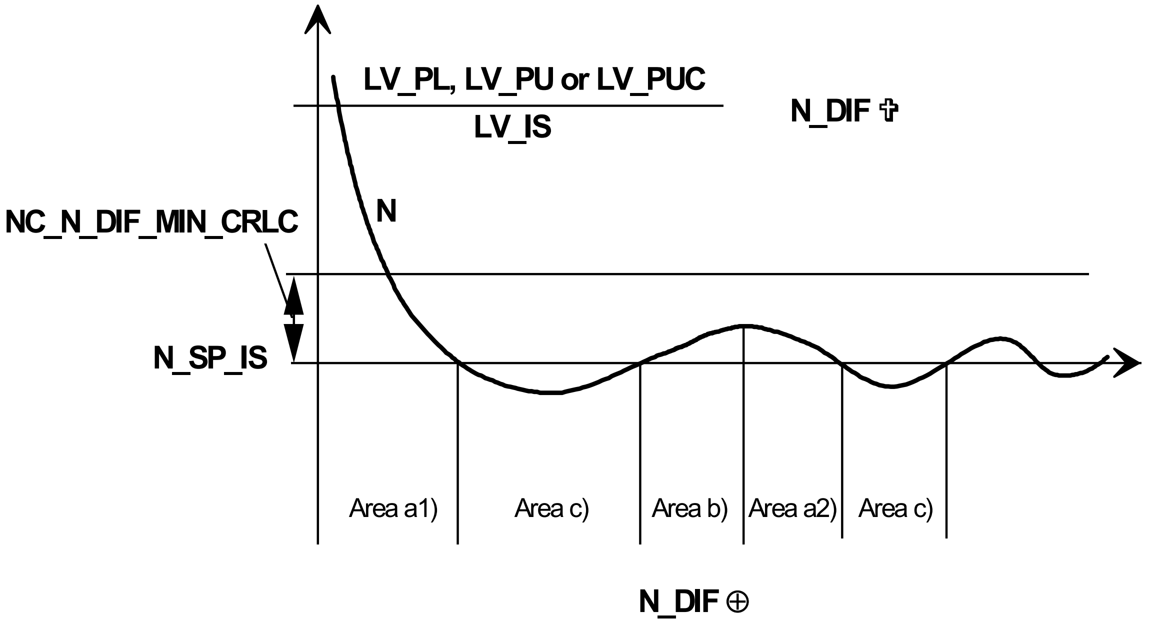
Path: ENSC_M400M/OPM_10MS/CLC_N_SP_IS/CLC_N_SP_IS_RATIO

22.2.3.2 Calculation of N_DIF and N_DIF_ST

22.2.3.2.1 Engine speed deviations N_DIF, N_DIF_MMV, N_DIF_COR



N_DIF_MMV calculation:
After entry in Idle (LV_IS=1), N_DIF_MMV is set to N_DIF taking into account the limits defined below. Then the moving mean value is determined:

N_DIF_MMV (n) = N_DIF_MMV (n-1) + (N_DIF - N_DIF_MMV(n-1)) * N_DIF_CRLC

The correlation constant C_N_DIF_CRLC may assume 3 discrete values:

a1) Decreasing engine speed above nominal idle speed after entry in Idle (LV_IS=1) and conditions b.) and c.) not previously met (or N_DIF < NC_N_DIF_MIN_CRLC):

(N_DIF (n-3) < N_DIF (n) and N_DIF (n) < 0)

N_DIF_CRLC = C_N_DIF_CRLC (per adjustment)

a2) Decreasing engine speed above nominal idle speed

and N_DIF > NC_N_DIF_MIN_CRLC

and condition b.) previously fulfilled

N_DIF_CRLC = 1

b) Increasing engine speed above nominal idle speed

((N_DIF (n-3) >= N_DIF (n) and N_DIF (n) < 0)

N_DIF_CRLC = 1

c) Engine speed below nominal idle speed after entry at idle and is still below idle speed

(N_DIF (n) >= 0)

N_DIF_CRLC = 0

Limits of N_DIF_MMV:

C_N_DIF_MIN_MMV (N_DIF_MMV (0
N_DIF_COR calculation:

N_DIF_COR is relevant for the idle controller (idle-charge actuator and ignition timing):

N_DIF_COR = N_DIF - N_DIF_MMV * C_N_DIF_FAC

Local actions:

ACTION_ENSC_OPERATION_MANAGER(IN <IN1>, IN <IN2>, OUT <OUT>, OUT <TQ_DIF_OPM_1>, OUT <TQ_DIF_OPM_2>)
Operation manager

22.4.1 Overview

The controller consists of three parts:

PD-part

PD-part separation into slow and fast path

I-part

An operation mode manager splits up each controller part (applied for 2 different operation modes) in accordance with the received interpolation factor FAC_TQ_ADD_IS_OPM_SEL.

The operation manager for idle speed control operates with the operation mode parameters used in the module *Idle speed torque reserve*.

Application Condition

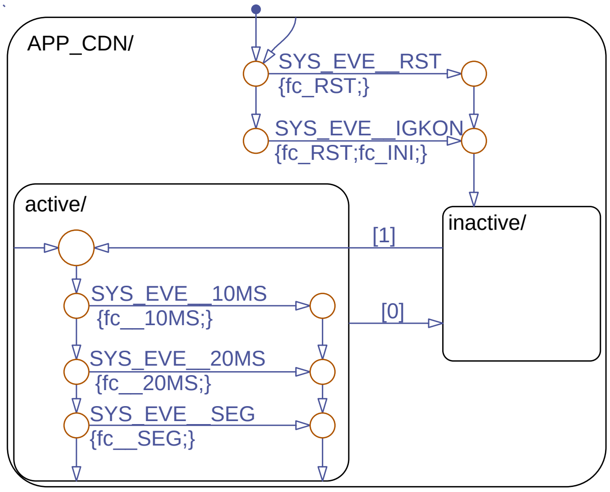

Figure 42 ENSC_M8006/ APP_CDN/ APPCND

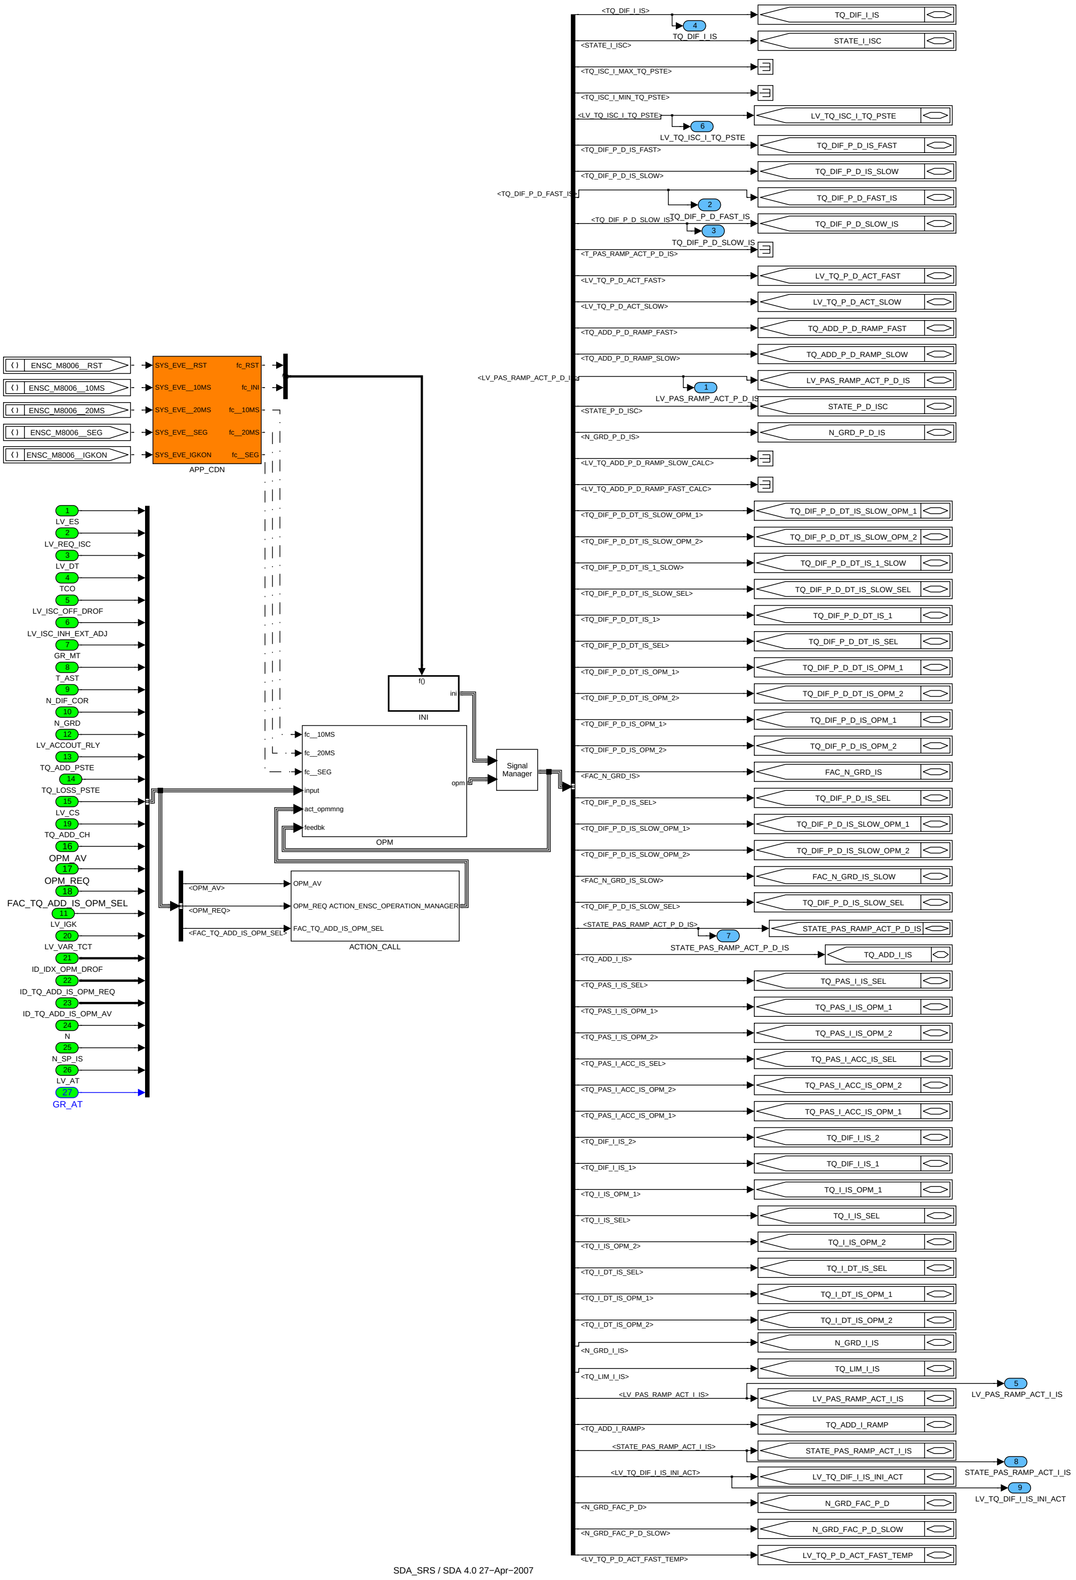

SDA_SRS / SDA 4.0 27−Apr−2007

Figure 43 ENSC_M8006

22.4.1.1 Operation mode manager

There are two input values IN_1, IN_2. Each input value belongs to a special operation mode OPM_1, OPM_2. Moreover the value OPM_SEL_AV indicates the active and OPM_SEL_REQ indicates the requested operation mode. The aim of the operation manager is to create an output value depending on the active operation mode. If there is a switch from one mode to another a smooth changeover from one input value to the other is possible by using the interpolation factor FAC_OPM_SEL.

A special logic takes care that the needed part is calculated only. That means if OPM_1 is active and there is no switch requested then the output value of the operation manager = IN_1 and some part of the algorithm for IN_2 are not calculated anymore. In this case the bit LV_OPM_SEL_1=1 indicates that only the calculation of the IN_1-path is done.

The information of the actual and the requested operation mode can be changed by interpretations maps ID_...OPM_SEL. The effect of this is, that by calibration the operation mode 1 can be wired to the input 2. That means the belonging for a operation mode to an input value is flexible.

The following tables defines the local variables described above:

Common variables:

OPM_AV (from Layer)	OPM_AV	Input	Actual operation mode
OPM_REQ (from Layer)	OPM_REQ	Input	Requested operation mode
-	OPM_SEL_AV	Internal value	Actual active operation mode after interpretation
-	OPM_SEL_REQ	Internal value	Requested operation mode after interpretation
FAC_TQ_ADD_IS_OPM_SEL (from Layer)	FAC_OPM_SEL	Input	Interpolation factor
LV_TQ_DIF_IS_OPM_SEL_1	LV_OPM_SEL_1	Output	Operation mode 1 active
LV_TQ_DIF_IS_OPM_SEL_2	LV_OPM_SEL_2	Output	Operation mode 2 active
LV_TQ_DIF_IS_OPM_RLS	LV_OPM_RLS	Output	Operation mode within valid range
ID_TQ_ADD_IS_OPM_AV	ID_OPM_AV	cal	Mapping of active operation mode
ID_TQ_ADD_IS_OPM_REQ	ID_OPM_REQ	cal	Mapping of requested operation mode

Controller parameter:

P_D_SLOW:

TQ_DIF_P_D_IS_SLOW_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_DIF_P_D_IS_SLOW_OPM_2	IN_2	Input	Input value for operation mode 2
TQ_DIF_P_D_IS_SLOW_SEL	OUT	Output	Result of interpolation

P_D_FAST:

TQ_DIF_P_D_IS_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_DIF_P_D_IS_OPM_2	IN_2	Input	Input value for operation mode 2
TQ_DIF_P_D_IS_SEL	OUT	Output	Result of interpolation

P_D_DT_SLOW:

TQ_DIF_P_D_DT_IS_SLOW_OPM_1	IN_1	Input	Input value for operation mode 1

<u>Filtering of N_GRD</u>

General information:

In order to be able to smooth the gradient for the idle speed control, there are 2 options for filtering the raw engine speed gradient N_GRD:

1) with ring buffer with 1 ... 6 buffers (calibrateable)

2) with 1st order low-pass filter.

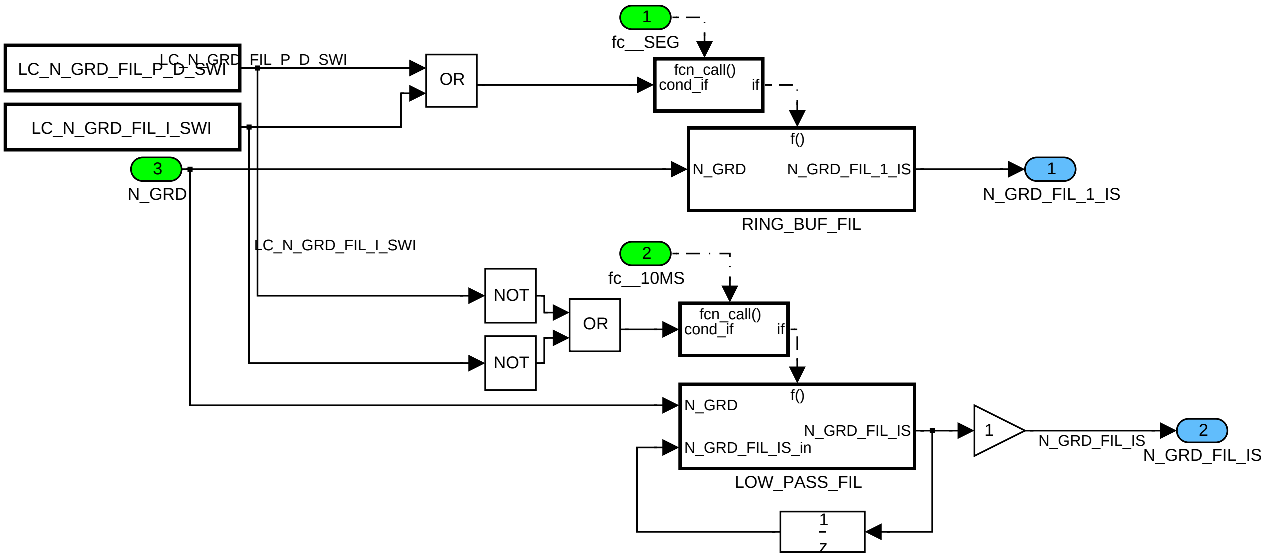

Figure 56 ENSC_M8006/ OPM/ FIL_OF_N_GRD

I-Controller

General information:

Signal flow diagram:

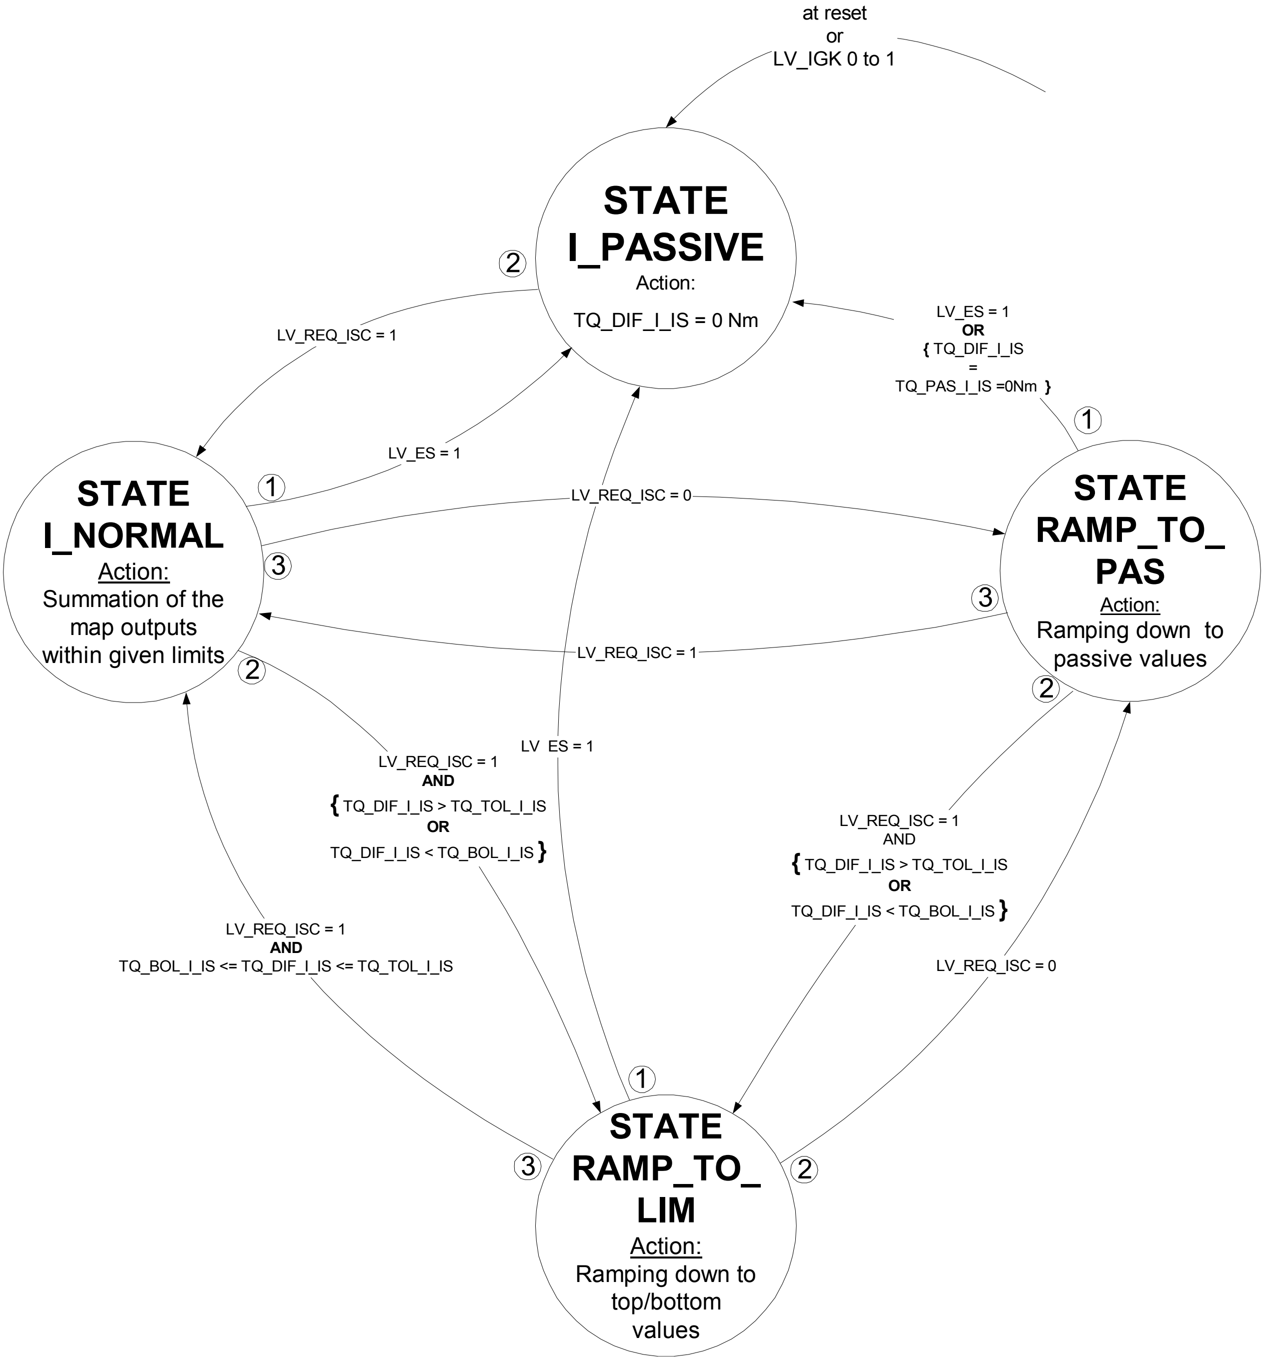

Figure 5: *State diagram of the integral part*

The integral part is devided into four states:

STATE_I_ISC = I_PASSIVE:

Initialization (at reset or when LV_IGK = 0 → 1; from all other states in case of LV_ES = 1)

STATE_I_ISC = I_NORMAL:

In this state the evaluation of the controller maps and the "normal" integration takes place.

STATE_I_ISC = RAMP_TO_LIM:

Ramp to limits; in this state the integral part is ramped down to the calibratible top/bottom limit values.

STATE_I_ISC = RAMP_TO_PAS:

Ramp to passive value 0 Nm; in this state the integral part is ramped down to zero in case LV_REQ_ISC = 0.

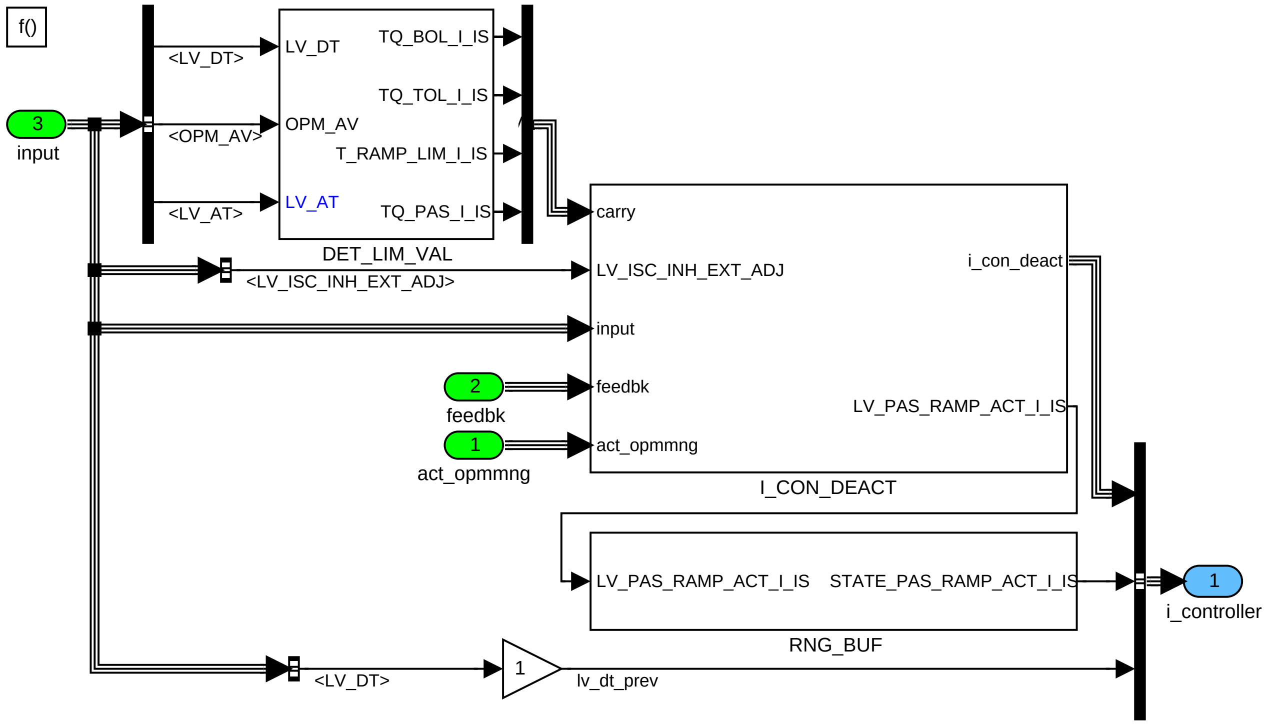

Figure 59 ENSC_M8006/ OPM/ I_CONTROLLER

Determination of the top/bottom limit values:

The passive value **(target value)** of the ramp operation is 0 Nm.

TQ_PAS_I_IS = 0Nm

Calculation when there is no transition from passive or "ramp to pas" to normal state.

Condition check on LV_DT and determination of TQ_ADD_I_IS

In STATE I_NORMAL, see figure 5, the "normal" integration takes place. A torque difference TQ_ADD_I_IS is determined in dependence of the speed deviation N_DIF_COR and the speed gradient N_GRD_I_IS (for LV_DT = 0) and only in dependance of the speed deviation N_DIF_COR for LV_DT = 1 and in addition depending on time after start T_AST, figure 6.

Considering the operation mode manager there are included separated paths in the functionality for the calculation of the idle speed controller I-share. This enables a proper engine running in throttled and unthrottled mode. Also in after start an additional factor is used for each mode.

To reach two important targets, TQ_ADD_I_IS should be calibrated as follows:

compensation of a speed offset

automatic precalibration of the integral part: if there is a load active after the driver released the gas pedal (ACC, power steering, etc), then speed falls with a higher gradient into idle range than in comparision to the situation without load. This means, that the integral part should carry higher (positive) values to intercept speed. That means, that with the help of the gradient dependancy in the integral part an automatic precalibration of the TQ_ADD_I_IS (so TQ_DIF_I_IS) can be reached, which is load dependant. It must be said, that this interception function must be synchronized with the PD-part calibration. With the correct calibration, the passive values are not needed any more.

The integration takes place within calibratible boundaries, figure 7.

STATE_RAMP_TO_PAS

At deactivation of ISC the integrator output is controlled to a passive-value by ramp limit activation. The determination of the ramp takes place in the same way as described before for the top/bottom limit ramps.

Actions:

The ramp limit operation starts at deactivation of the ISC. The necessary increment (**TQ_ADD_I_RAMP**) to reach the required ramp-slope **is only calculated once while transitioning into this state**. This value is valid until deactivation of the ramp limit operation.

While transition into this state, so while the ramp is active, there could be a change in TQ_PAS_I_IS. If in this case TQ_ADD_I_RAMP is negative for example and the passive value is higher than the actual value, then the new requested passive value can never be reached, because TQ_ADD_I_RAMP is only calculated once. Therefore TQ_PAS_I_IS is fixed while transition into this state to prevent a wrong comparison in the following condition:

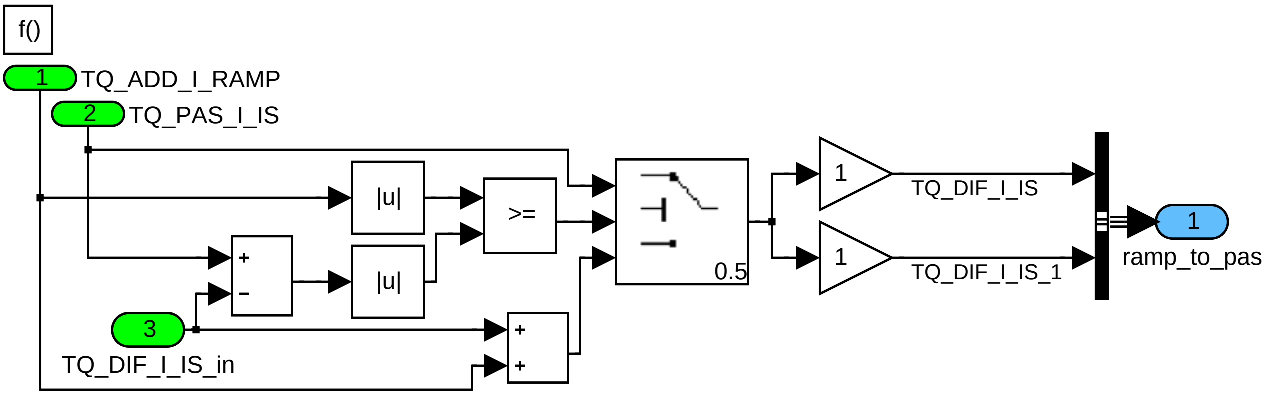

Figure 88 ENSC_M8006/ OPM/ I_CONTROLLER/ I_CON_DEACT/ I_CONT_ST_AUTOMATE/ RAMP_TO_PAS

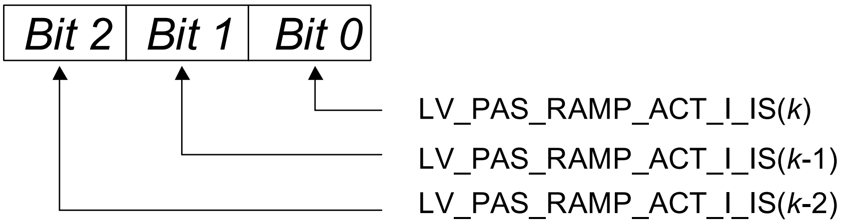
Circular buffer for LV_PAS_RAMP_ACT_I_IS

In the following circular buffer STATE_PAS_RAMP_ACT_I_IS, the last three values of LV_PAS_RAMP_ACT_I_IS are stored:



This information is needed for the monitoring of the idle speed controller. It is updated every 20ms; the values are shifted from Bit j to Bit j+1, j=0,1.

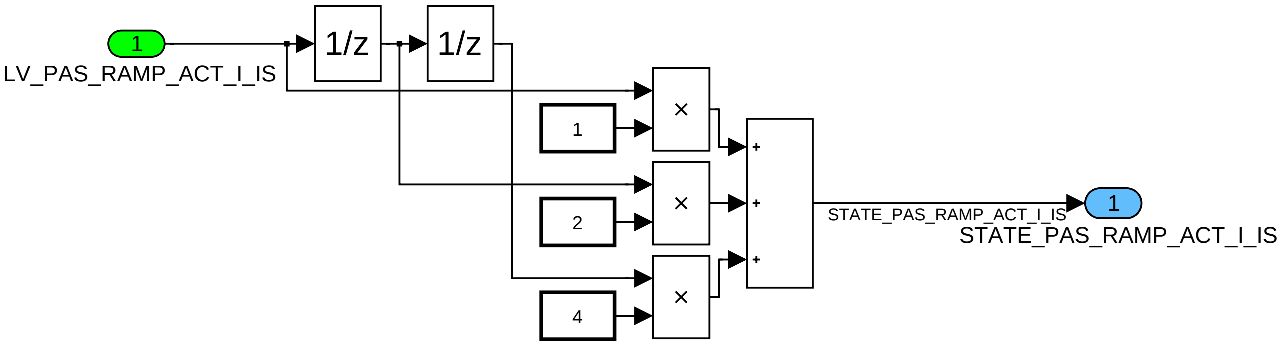


Figure 89 ENSC_M8006/ OPM/ I_CONTROLLER/ RNG_BUF

PD- Controller

General information:

State Machine

FUNCTION DESCRIPTION:

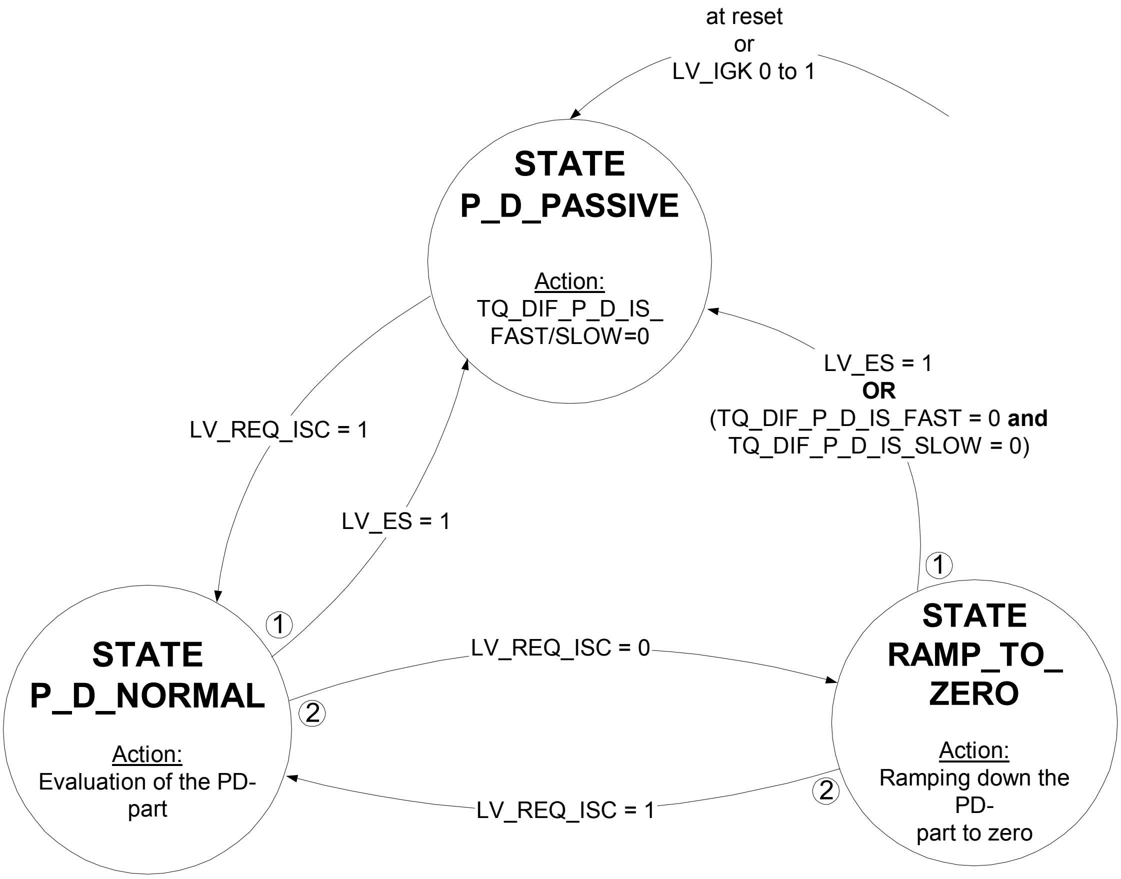

Figure 2: *State of the PD-part*

The PD-part is devided into three states:

STATE_P_D_ISC = P_D_PASSIVE:

Initialization (at reset or from LV_IGK = 0 → 1; from all other states in case of LV_ES = 1)

STATE_P_D_ISC = P_D_NORMAL:

In this state the evaluation of the controller maps takes place.

STATE_P_D_ISC = RAMP_TO_ZERO:

Ramp to passive value, which is always zero for the PD-part; in this state the PD-part is ramped down to zero in case of deactivation of the PD-part

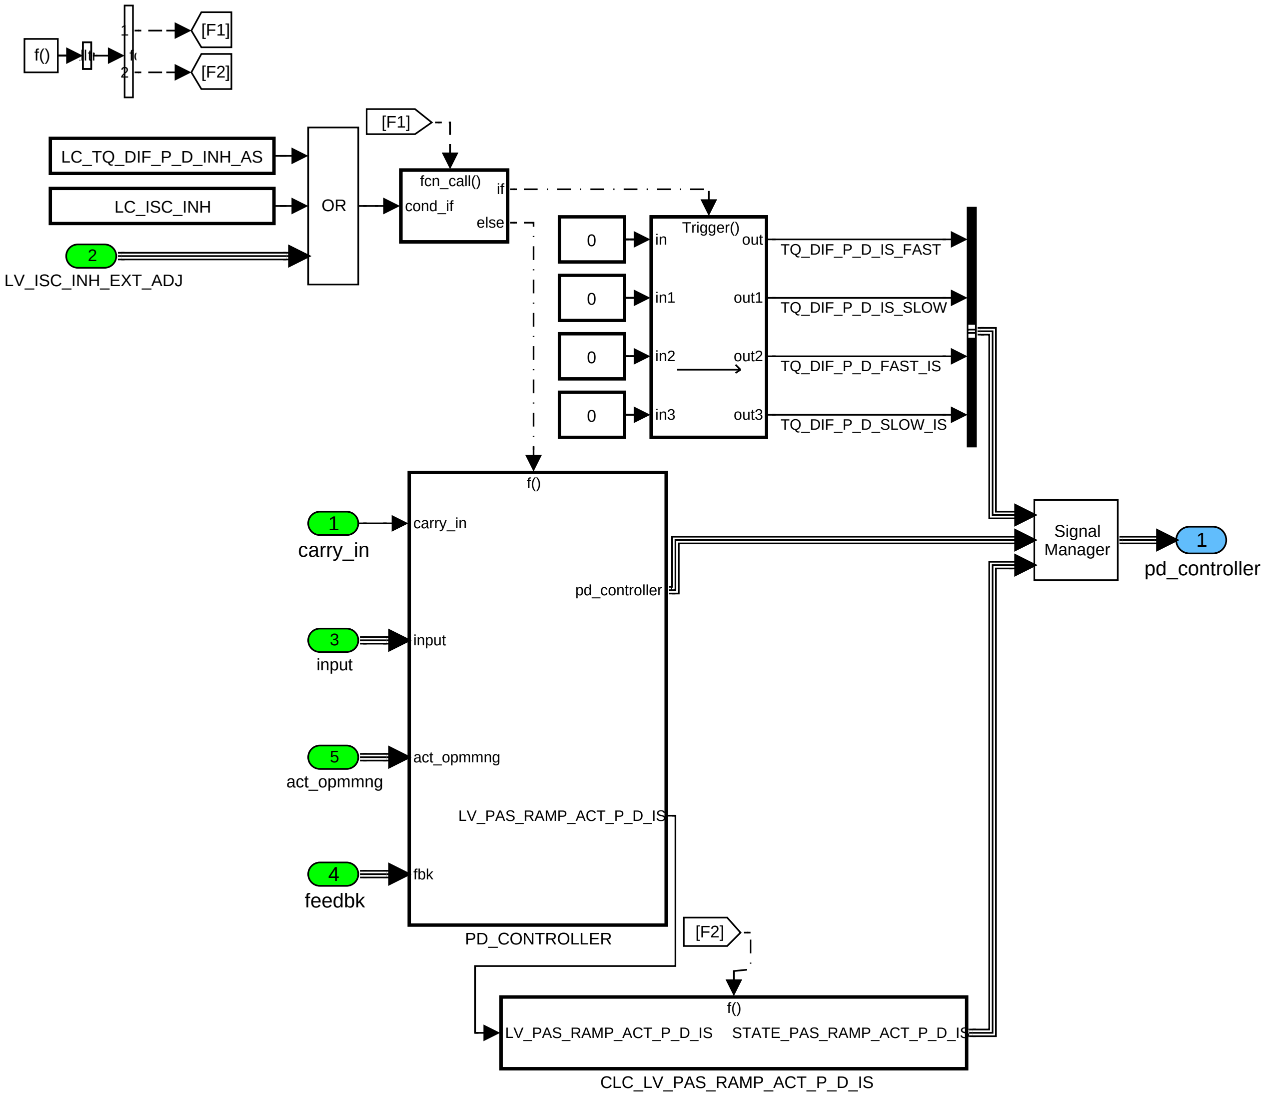

Figure 90 ENSC_M8006/ OPM/ PD_CONTROLLER

At deactivation: T_CTR_PU_ISC_ACT = C_T_DLY_ISC_ACT_PU

22.5.1 General

The activation of the idle speed controller depends on different driving situations. Five states are distinguished. The actual status of the idle speed activation is stored in STATE_REQ_ISC.

State 0: Idle speed controller is passive **(STATE_REQ_ISC = ISC_PASSIVE)**.

State 1: Activation of the ISC after start **(STATE_REQ_ISC = AFTER_START)**.

State 2: "Normal activation": Activiation of the ISC in case of LV_IS = 1
(STATE_REQ_ISC = NORMAL)

State 3: Activation of the ISC if speed remains stationary at a certain value in trailing throttle state **(STATE_REQ_ISC = TRAILING_THR)**.

State 4: Activation of the ISC in part load, in case of underspeed.
(STATE_REQ_ISC = PART_LOAD).

Formula section:

Action:

FlipFlop condition (LV_FF):

```
IF  N > (N_SP_IS + C_N_DIF_ISC_ACT_PL_UP)  THEN  LV_FF = 0
ELSE  IF  N < (N_SP_IS – C_N_DIF_ISC_ACT_PL_DOWN)  THEN  LV_FF = 1
```

```
IF      { LV_PL == 1 }  AND

        { LV_FF == 1 }  AND

        N_SP_IS < C_N_SP_IS_MAX_PL_ACT  AND

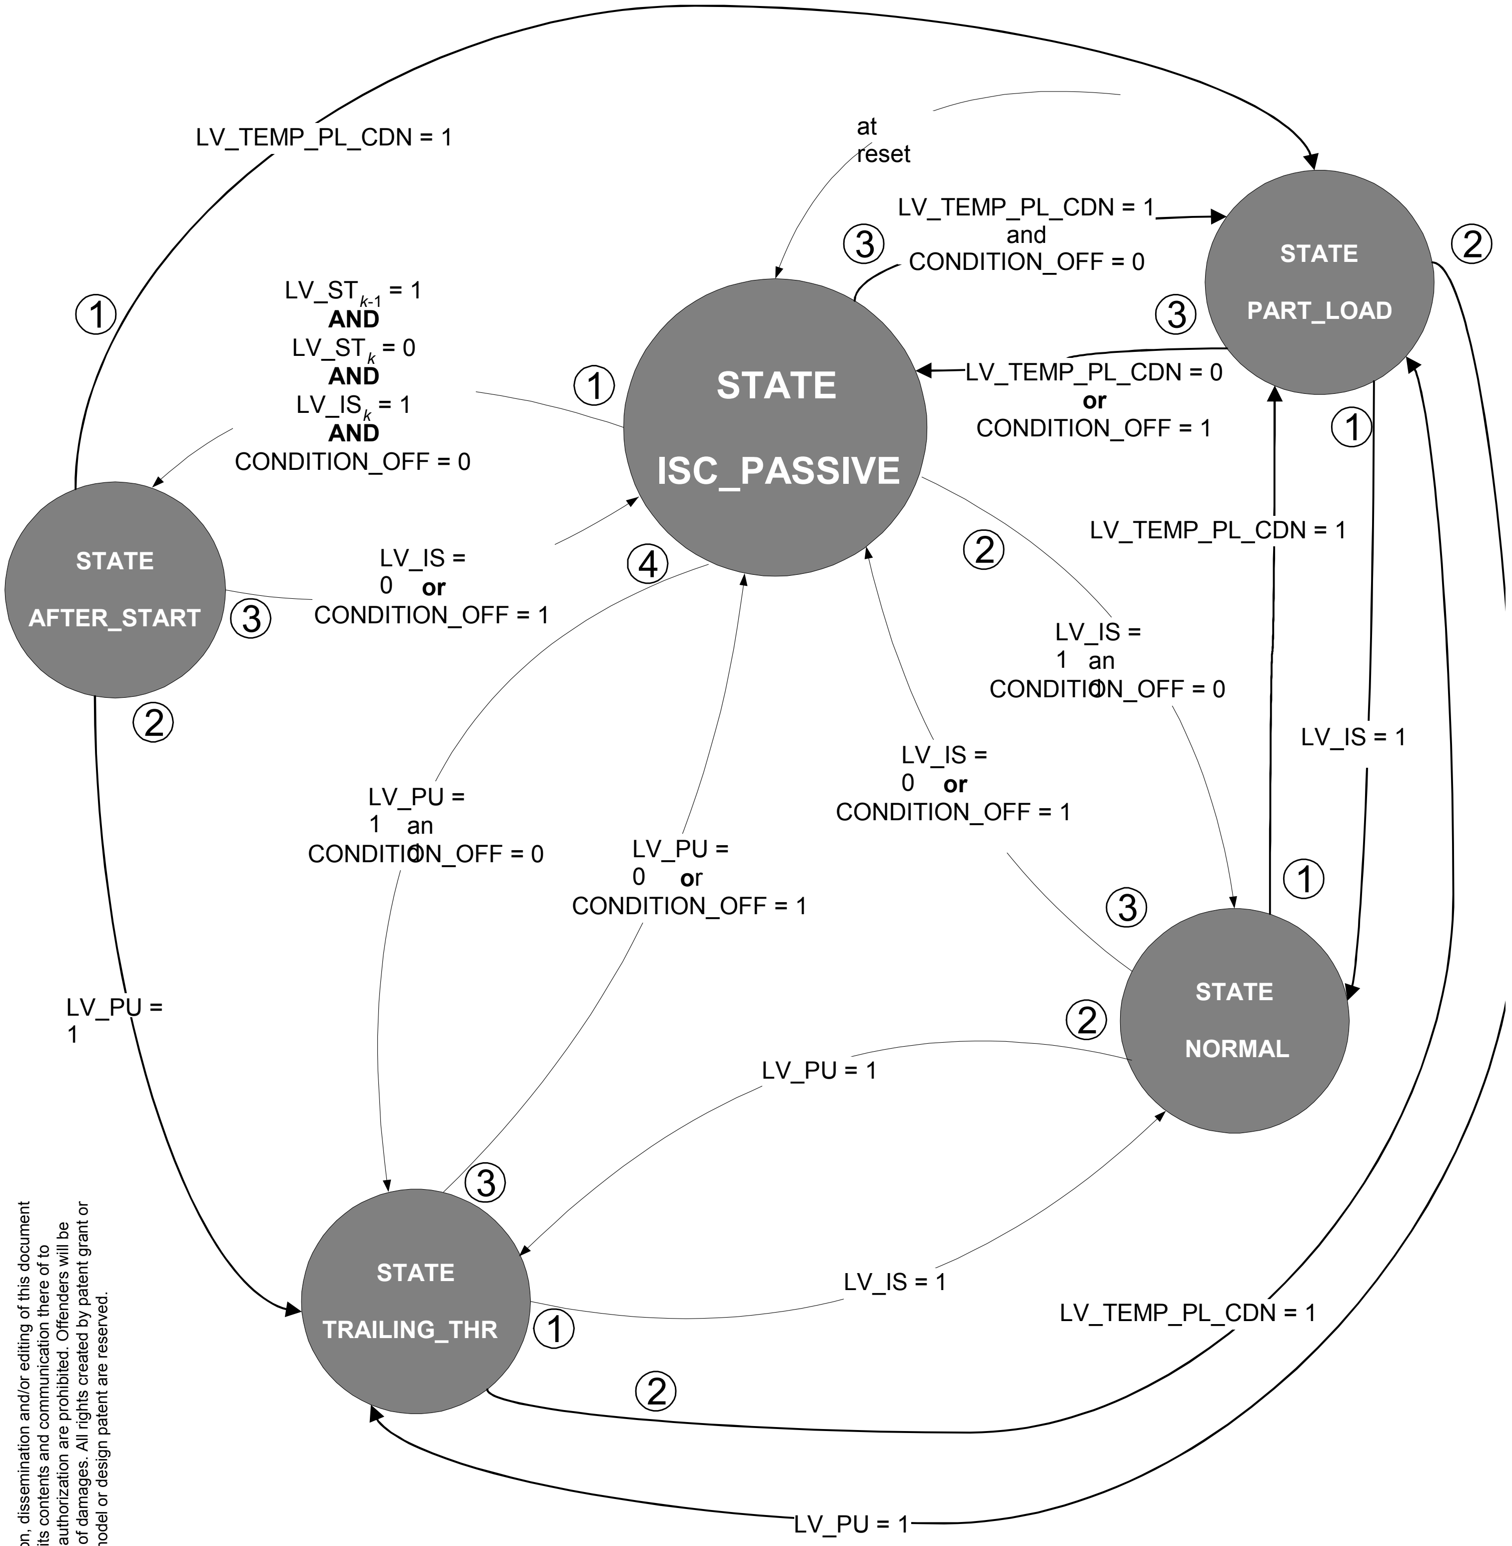
        { LC_ISC_PL_ACT_INH == 0 }

        OR

        { LV_N_SP_IS_CS  AND  { NOT LV_IS }   AND  { NOT LV_ST } }
THEN
        LV_TEMP_PL_CDN = 1

ELSE
        LV_TEMP_PL_CDN = 0
```

The following state diagram illustrates the connection between these five cases, figure 1.



Formula section:

Figure 1: *State diagram of the ISC activation.*
The numbers at different transitions of one state to another represent the priority
in which the transitions have to be checked.

22.5.2 ISC Passive (STATE ISC_PASSIVE)

FUNCTION DESCRIPTION:

This state is the idle speed controller passive state. The controller is deactivated if there is a transition to this state.

Formula section:

Action: LV_REQ_ISC = 0

Transition: see figure 1

Action during transition to AFTER_START: LV_NEG_N_GRD_FIL_MEM = 0
N_GRD_FIL_ISC_ACT_AST = 0

22.5.3 Checking ISC activation conditions after start (Entry into IS after ST, STATE AFTER_START)

FUNCTION DESCRIPTION:

After transition from engine state ST to IS, the activation of the ISC is requested if speed reaches a calibratible offset from N_SP_IS with a negative gradient N_GRD, figure 2. If speed does not reach this offset after decreasing and increasing again, the controller is also activated.

Transition: see figure 1

Action:

```
IF    LC_ISC_ACT_AST_CDN_SWI == 1
THEN
    LV_REQ_ISC = 1
ELSE
{
    % Calculation of a filtered gradient for after start activation

    $N\_GRD\_FIL\_ISC\_ACT\_AST_k = N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1} +$
    $+ C\_CRLC\_N\_GRD\_FIL\_ISC\_ACT\_AST \cdot \{ N\_GRD_k - N\_GRD\_FIL\_ISC\_ACT\_AST_{k-1} \}$

    % If N reaches the calibratible offset N_SP_IS + C_N_DIF_ISC_ACT_AST
    % with a negative gradient, then the controller is activated. If
    % speed increases again before reaching N_SP_IS + C_N_DIF_ISC_ACT_AST,
    % then the controller is activated, too. The falling gradient
    % is layed up in LV_NEG_N_GRD_FIL_MEM.

    IF      N_GRD_FIL_ISC_ACT_AST < 0
    THEN
            LV_NEG_N_GRD_FIL_MEM = 1

            IF      { N  <  N_SP_IS + C_N_DIF_ISC_ACT_AST }
            THEN
                    LV_REQ_ISC =1
            ENDIF

    ELSEIF  { N_GRD_FIL_ISC_ACT_AST >= 0 }  AND
            { LV_NEG_N_GRD_FIL_MEM == 1}

    THEN
            LV_REQ_ISC =1

    ENDIF
}
```

After setting LV_NEG_N_GRD_FIL_MEM, its value will not be changed until the after start is left to STATE 0.

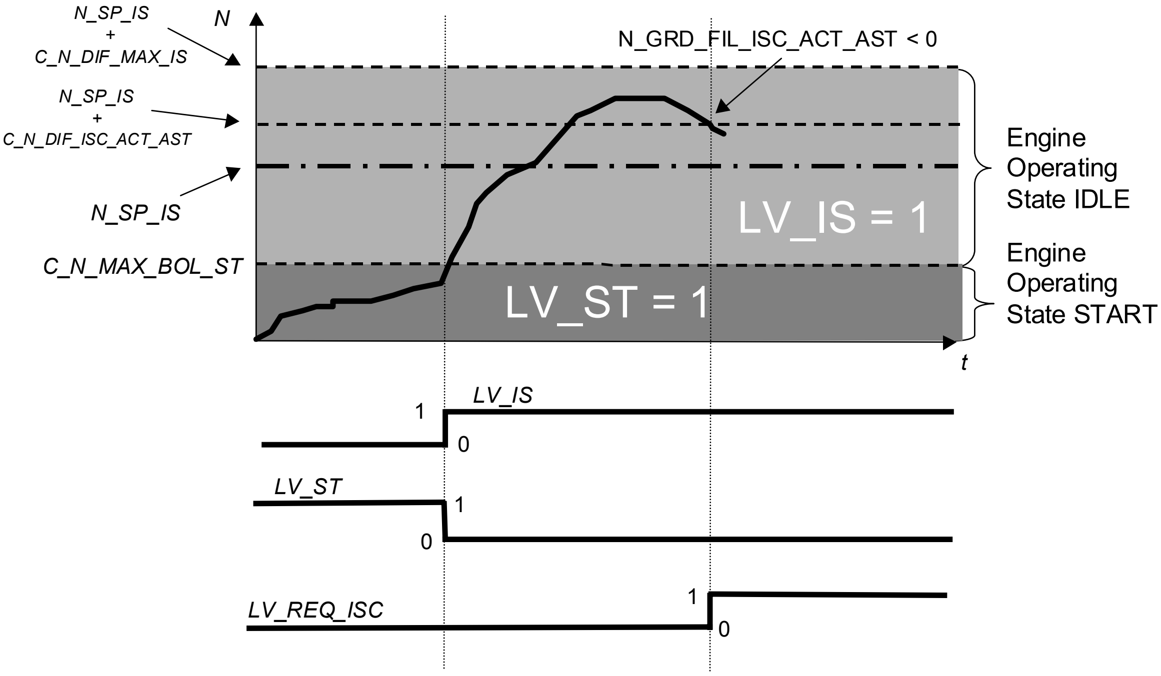


Figure 2: *ISC activation after start*

22.5.4 Checking ISC activation conditions for "normal activation", STATE NORMAL)

The idle speed controller is activated on principle in case of LV_IS = 1 (except STATE 1 is active).

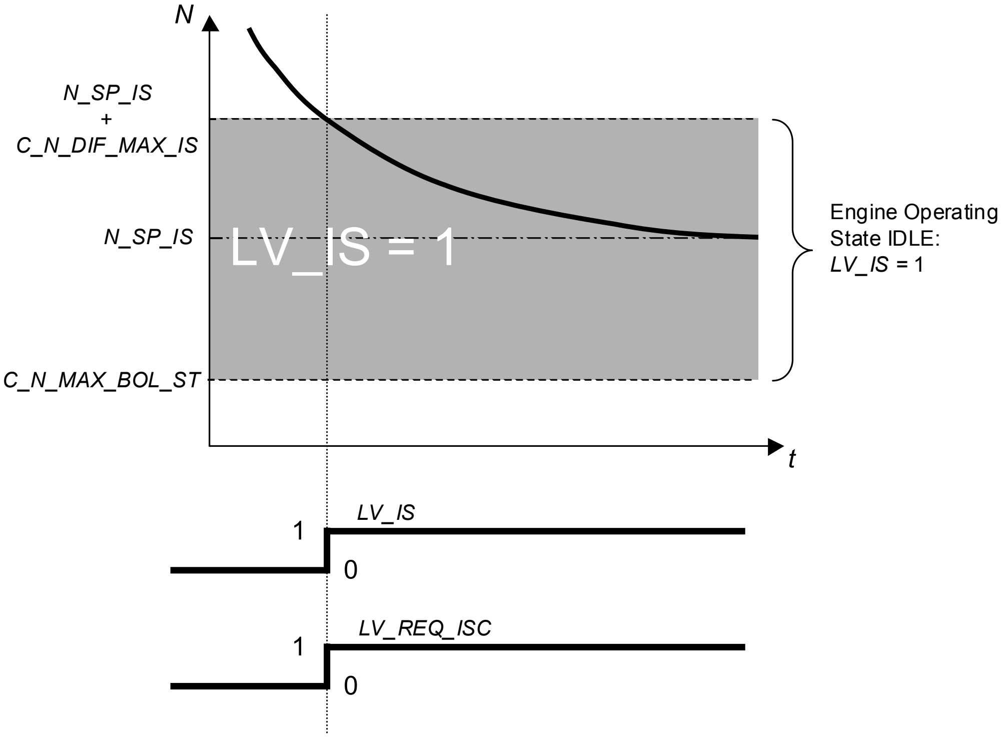

Figure 3: *Activation of the ISC in case of LV_IS = 1*

Formular section:

Transition: see figure 1

Action:

```
IF(LV_AT = 1)
THEN IF (LV_DT = 0)
        THEN LV_REQ_ISC = 1
        ELSE IF (N_GB < N - C_N_GB_DIF_N OR N_GRD < IP_N_GRD_N_SP_IS_RATIO OR N_DIF_COR >0 )
            THEN LV_REQ_ISC = 1
```

ELSE LV_REQ_ISC = 1;

22.5.5 ISC activation in case of low engine speed decrease in trailing throttle state (LV_PU = 1, STATE TRAILING_THR)

If speed decrease in trailing throttle state is very low or speed does not decrease, the idle speed controller is activated after a calibratible time *C_T_DLY_ISC_ACT_PU*. The condition for that is a standing vehicle (VS=0). The counter is started when entering PU ($LV\_PU_{k-1} = 0 \rightarrow LV\_PU_k = 1$). The counter is reinitialized with C_T_DLY_ISC_ACT_PU when leaving PU. See figure 4.

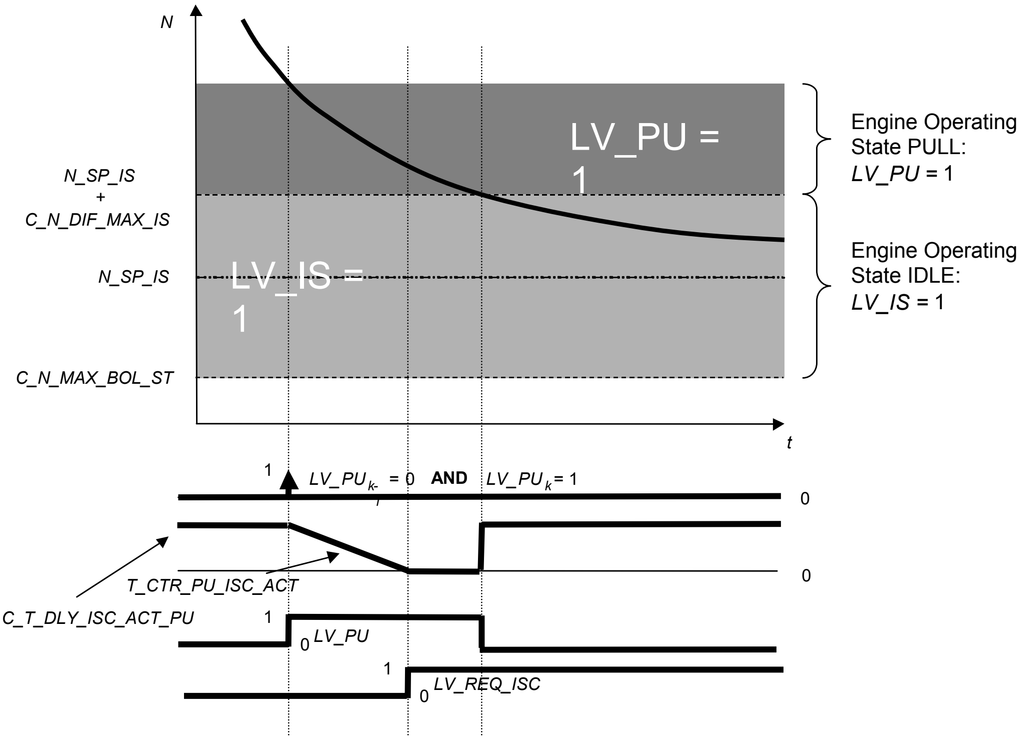

Figure 4: *Activation of the ISC in PU in case the speed decrease is too low and* ***the vehicle does not move (VS = 0)****. The counter starts from a tunable value C_T_DLY_ISC_ACT_PU and stops at zero.*

Formular section:

Transition: see figure 1

Action: start to ramp down *T_CTR_PU_ISC_ACT* when entering PU (the initialization of *T_CTR_PU_ISC_ACT* was already done before)

```
IF      { VS == 0  OR  LV_DT == 0 }   AND   { T_CTR_PU_ISC_ACT == 0 }
THEN
        LV_REQ_ISC = 1
ELSE
        LV_REQ_ISC = 0
ENDIF
```

Reinitialize *T_CTR_PU_ISC_ACT* with C_T_DLY_ISC_ACT_PU when leaving state TRAILING_THR

22.5.6 Conditions for ISC part load activation (STATE PART_LOAD)

In part load, the driver or cruise control torque request can be so small, that the idle speed setpoint N_SP_IS cannot be held and speed is decreasing. In this case, the idle speed controller is used to guaranty N ≥ N_SP_IS. The conditions for activating the ISC in this case depend on the speed and a calibratible hysteresis, figure 5.

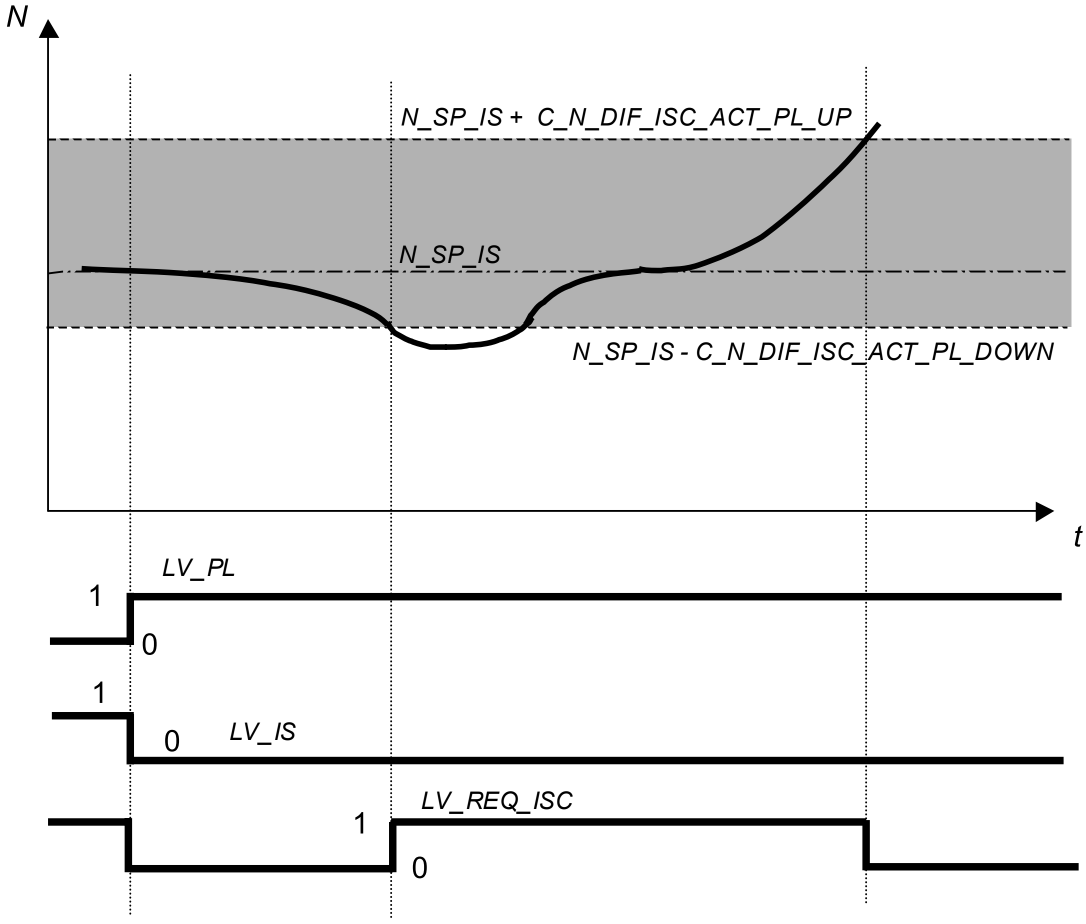

Figure 5: *Activating the ISC in part load*

Formula section:

Transition: see figure 1

Action: LV_REQ_ISC = 1

22.5.7 Checking ISC inhibit interfaces

During AMT shift intervention Phase 1 (LV_AMT_CRAWL_ON = 1) an additional Converter torque is calculated; during this time the ISC is looked State "PASSIVE".

All inhibit interfaces lead to CONDITION_OFF which is used in the state diagram (figure 1).

```
IF    LV_AMT_CRAWL_ON = 1
THEN        CONDITION_OFF  =  1
  ELSE      CONDITION_OFF  =  0
ENDIF
```

Additive torque reserve at idle at VVT-mode (mode1)					

22.6.1 Function description

General Information:

The module „Idle Speed Torque Reserve“ consists of two parts:

1. Idle speed torque reserve due to low engine speed
2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves

1. Idle speed torque reserve due to low engine speed

Depending on the predicted engine speed difference N_DIF_PRED a torque reserve by increasing the load is calculated. If actual engine speed falls it is possible to increase load before the actual engine speed is below the engine speed setpoint for idle speed. At the same time a spark retard compensates the supposed torque increase. So a quick torque incraease by spark advance can be realized to stabilize engine speed at its setpoint.

For negative gradients of TQ_ADD_IS_BOL_SEL a PT1-filter for TQ_ADD_IS_BOL calculation is applied to avoid torque jumps caused by fast changes of ignition angle. For positive gradients of the input TQ_ADD_IS_BOL_SEL the output value TQ_ADD_IS_BOL is identical to the input.

2. Idle speed torque reserve limitiation for stabilizing the ISC at high torque reserves

At high torque reserve requests (ex.: catalyst heating) the ignition angle can be retarded down to the minimum ignition angle IGA_MIN. This may cause problems with idle speed stability. In order to prevent speed from oscillating in case the actual ignition angle is in the near of IGA_MIN caused by high torque reserves, the maximum availible torque reserve must be limited. In order to reach this, a tunable calibration constant C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is introduced. C_TQ_DIF_ADD_IS_TOL_OPM_1/2 has the same influence than TQ_ADD_IS_BOL: while the last defines a minimum torque reserve, C_TQ_DIF_ADD_IS_TOL_OPM_1/2 takes influence on the maximum torque reserve in idle. The availible torque reserve range is shown in figure 1.

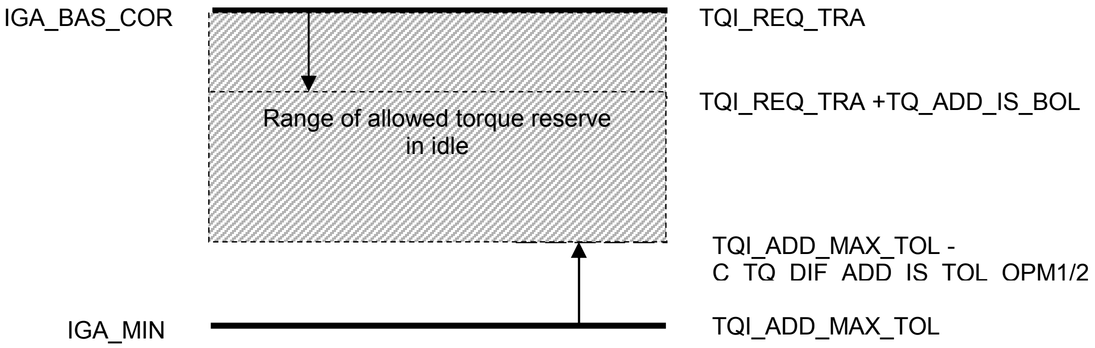

Figure 1: Availible torque reserve range after limiting:

TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL_OPM_1/2 defines the max. idle torque reserve

Since C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is a calibratable constant, this may cause a conflict situation as shown in figure 2.

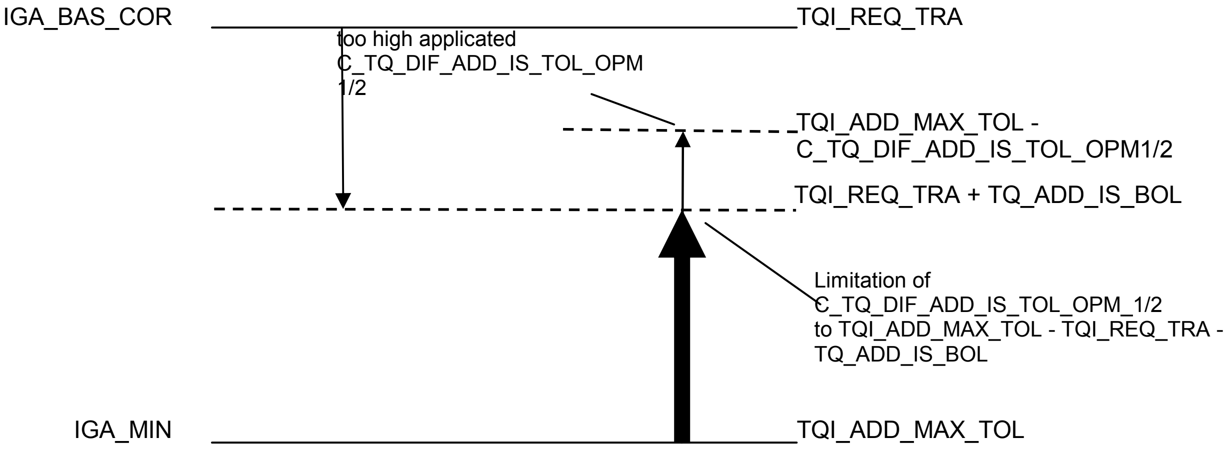

Figure 2: Limiting C_TQ_DIF_ADD_IS_TOL_OPM_1/2 in case of a conflict

In this case TQ_ADD_IS_BOL has a higher priority than C_TQ_DIF_ADD_IS_TOL_OPM_1/2, since the possibility of moving the ignition angle in direction spark advance by building up a torque reserve is more essential than keeping it at a certain point from IGA_MIN, which „only“ causes irregular running. The condition for a non-critical situation, figure 1, is

TQI_REQ_TRA+TQ_ADD_IS_BOL<= TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL_OPM_1/2 (1)

Solving this relation leads to

C_TQ_DIF_ADD_IS_TOL_OPM_1/2<=TQI_ADD_MAX_TOL - TQI_REQ_TRA - TQ_ADD_IS_BOL (2)

If relation (2) is not fulfilled, C_TQ_DIF_ADD_IS_TOL_OPM_1/2 is limited, figure 3.

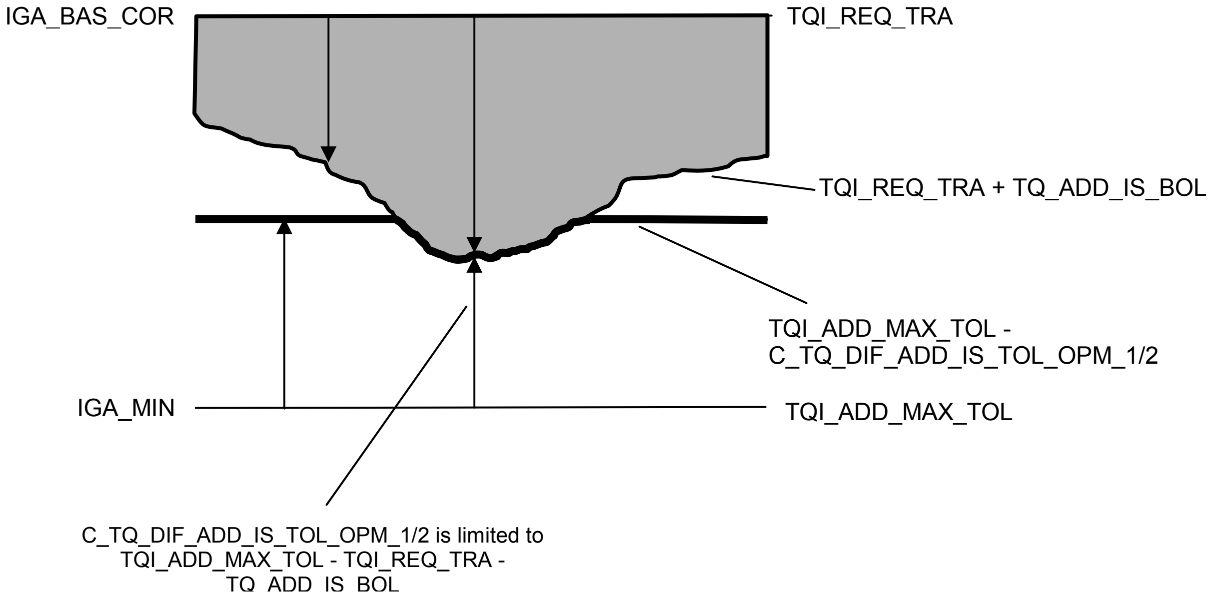

Figure 3: Limiting C_TQ_DIF_ADD_IS_TOL_OPM_1/2 in case TQI_REQ_TRA + TQ_ADD_IS_BOL is greater than TQI_ADD_MAX_TOL - C_TQ_DIF_ADD_IS_TOL_OPM_1/2

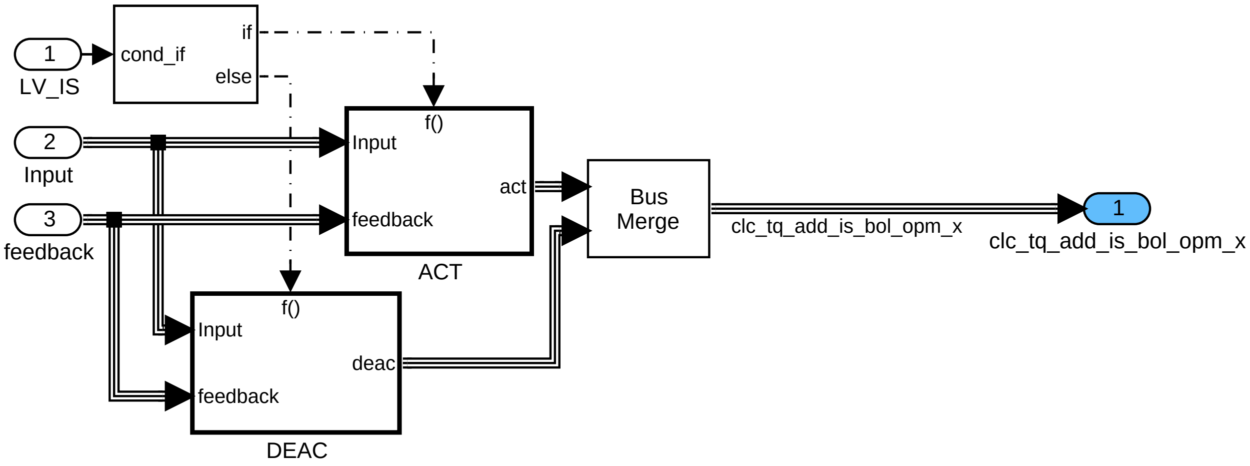

Figure 121 ENSC_M800I/ OPM/ CLC_TQ_ADD_IS_BOL_OPM_x

Activation

Operation mode manager

There are two input values IN_1, IN_2. Each input value belongs to a special operation mode OPM_1, OPM_2. Moreover the value OPM_SEL_AV indicates the active and OPM_SEL_REQ indicates the requested operation mode. The aim of the operation manager is to create an output value depending on the active operation mode. If there is a switch from one mode to another a smooth changeover from one input value to the other is possible by using the interpolation factor FAC_OPM_SEL.

A special logic takes care that the needed part is calculated only. That means if OPM_1 is active and there is no switch requested then the output value of the operation manager = IN_1 and some part of the algorithm for IN_2 are not calculated anymore. In this case the bit LV_OPM_SEL_1=1 indicates that only the calculation of the IN_1-path is done.

The information of the actual and the requested operation mode can be changed by interpretations maps ID_...OPM_SEL. The effect of this is, that by calibration the operation mode 1 can be wired to the input 2. That means the belonging for a operation mode to an input value is flexible.

general specification

The following table defines the local variable described above:

TQ_ADD_IS_BOL_OPM_1	IN_1	Input	Input value for operation mode 1
TQ_ADD_IS_BOL_OPM_2	IN_2	Input	Input value for operation mode 2
OPM_AV (from Layer)	OPM_AV	Input	Actual operation mode
OPM_REQ (from Layer)	OPM_REQ	Input	Requested operation mode
-	OPM_SEL_AV	Internal value	Actual active operation mode after interpretation
-	OPM_SEL_REQ	Internal value	Requested operation mode after interpretation
FAC_TQ_ADD_IS_OPM_SEL (from Layer)	FAC_OPM_SEL	Input	Interpolation factor
LV_TQ_ADD_IS_OPM_SEL_1	LV_OPM_SEL_1	Output	Operation mode 1 active
LV_TQ_ADD_IS_OPM_SEL_2	LV_OPM_SEL_2	Output	Operation mode 2 active
TQ_ADD_IS_BOL_SEL_1	OUT	Output	Result of interpolation
LV_TQ_ADD_IS_OPM_RLS	LV_OPM_RLS	Output	Operation mode within valid range
ID_TQ_ADD_IS_OPM_AV	ID_OPM_AV	cal	Mapping of active operation mode
ID_TQ_ADD_IS_OPM_REQ	ID_OPM_REQ	cal	Mapping of requested operation mode

PT1 Filter to limit negative gradient

For negative gradients of TQ_ADD_IS_BOL_SEL a PT1-filter for TQ_ADD_IS_BOL calculation is applied to avoid torque jumps caused by fast changes of ignition angle. For positive gradients of the input TQ_ADD_IS_BOL_SEL the output value TQ_ADD_IS_BOL is identical to the input.

22.7.1.3 Plausibility check

FUNCTION DESCRIPTION:

General information:

Engine speed deviation from the nominal engine speed is monitored either the vehicle is stopped and the throttle is settled after closing or after engine start. Due to different engine operating characteristics the coldstart-monitoring is performed by using limits depending on the temperature of cooling water and time after start.

If the difference to the nominal idle speed keeps too high or too low in spite of an activated idle speed controller, an idle speed control plausibility error is detected.

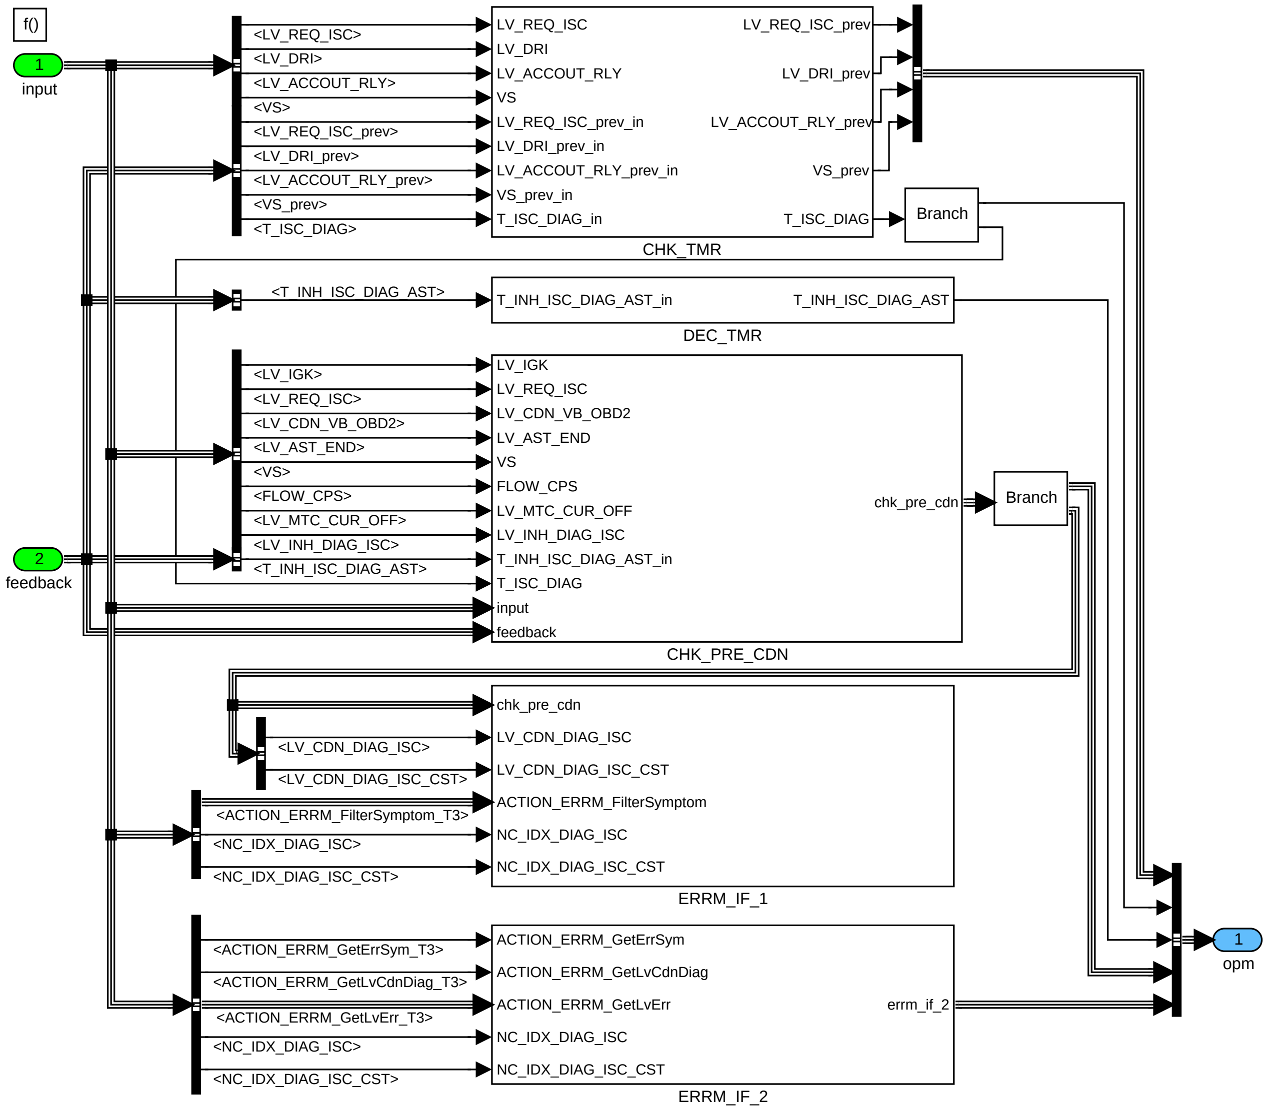

Figure 141 ENSC_MA09C/ OPM

Calculation of timer T_ISC_DIAG

The following timer is used for delaying the activation of the diagnosis algorithm when the idle speed controller is activated or speed is possibly excited due to strong disturbances such as ACC or drive train engaging (in order to prevent a diagnosis at high, normal speed deviations):

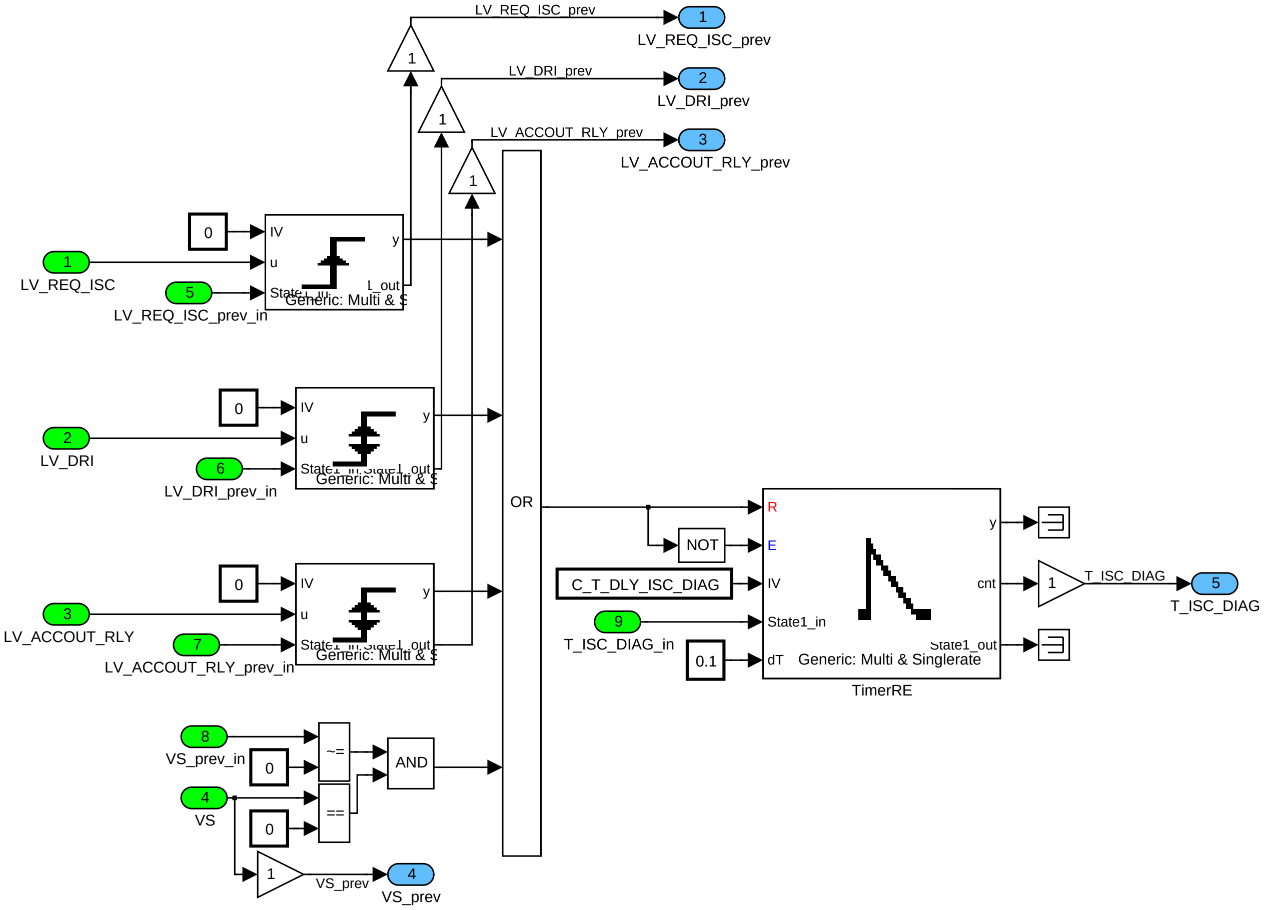

Figure 142 ENSC_MA09C/ OPM/ CHK_TMR

Calculation of timer T_INH_ISC_DIAG_AST

Timer is already initialised at system event EXITST. Here the timer starts decrementing.

22.8.3 Interface for Rate – Based Monitoring

General Information:

With this module the interface between the ISC / ISC_CST monitor and the rate based monitoring statistics is defined with STATE_RBM_ISC / STATE_RBM_ISC_CST data. Within STATE_RBM_ISC / ISC_CST, three different information are defined:

Conditions for monitoring are met long enough to detect manipulation (bit 0) (no intrusive operation, no short trip)

Monitor disabled because of system malfunction (bit 1) (depending on failure status: pending)

Monitor individual RBM conditions encountered within this DC(bit 2) (not valid for ISC daignosis)

Application Condition

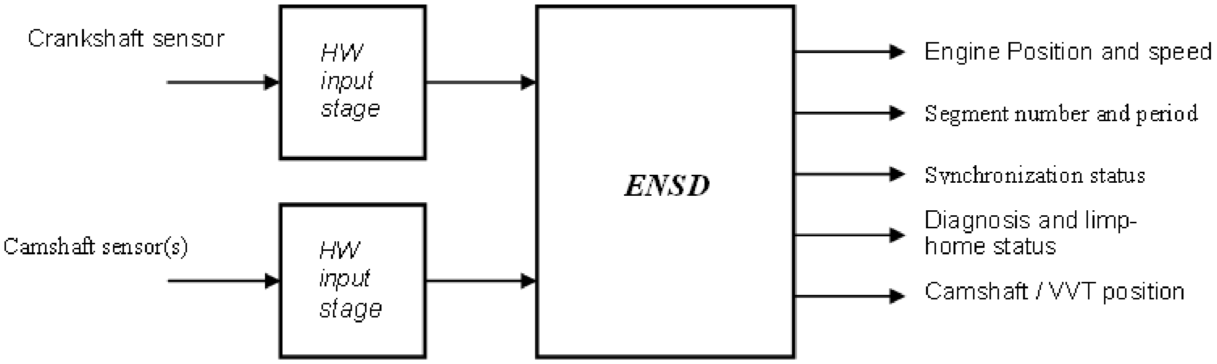
23.1 ENSD General

23.1.1 General Description



Up to 4 camshaft sensors are supported.

The ENSD aggregate calculates all output data which depend on crankshaft and camshaft sensor information. This includes:

- engine position
- engine speed
- engine speed gradient
- segment number and period
- synchronization status
- diagnosis and limp-home flags
- camshaft / VVT position feedback
- min./max. engine position for pre-injection

At engine start, three synchronization modes are activated:

1) Crankshaft (self-)synchronization:

   The purpose of this synchronization mode is to identify the crankshaft position (0...360° CRK). The crankshaft position is clearly identified at the reference gap of the crankshaft target wheel.

2) Camshaft (self-)synchronization:

   The purpose of this synchronization mode is to identify the camshaft position (0..720° CRK). The camshaft position is clearly identified as soon as an unambigous camshaft edge pattern is found.

3) Camshaft/crankshaft synchronization:

   The purpose of this synchronization mode is to identify the engine position (0..720° CRK). The engine position is clearly identified as soon as an unambigous crankshaft to camshaft position is found.

Injection / Ignition can be enabled as soon as

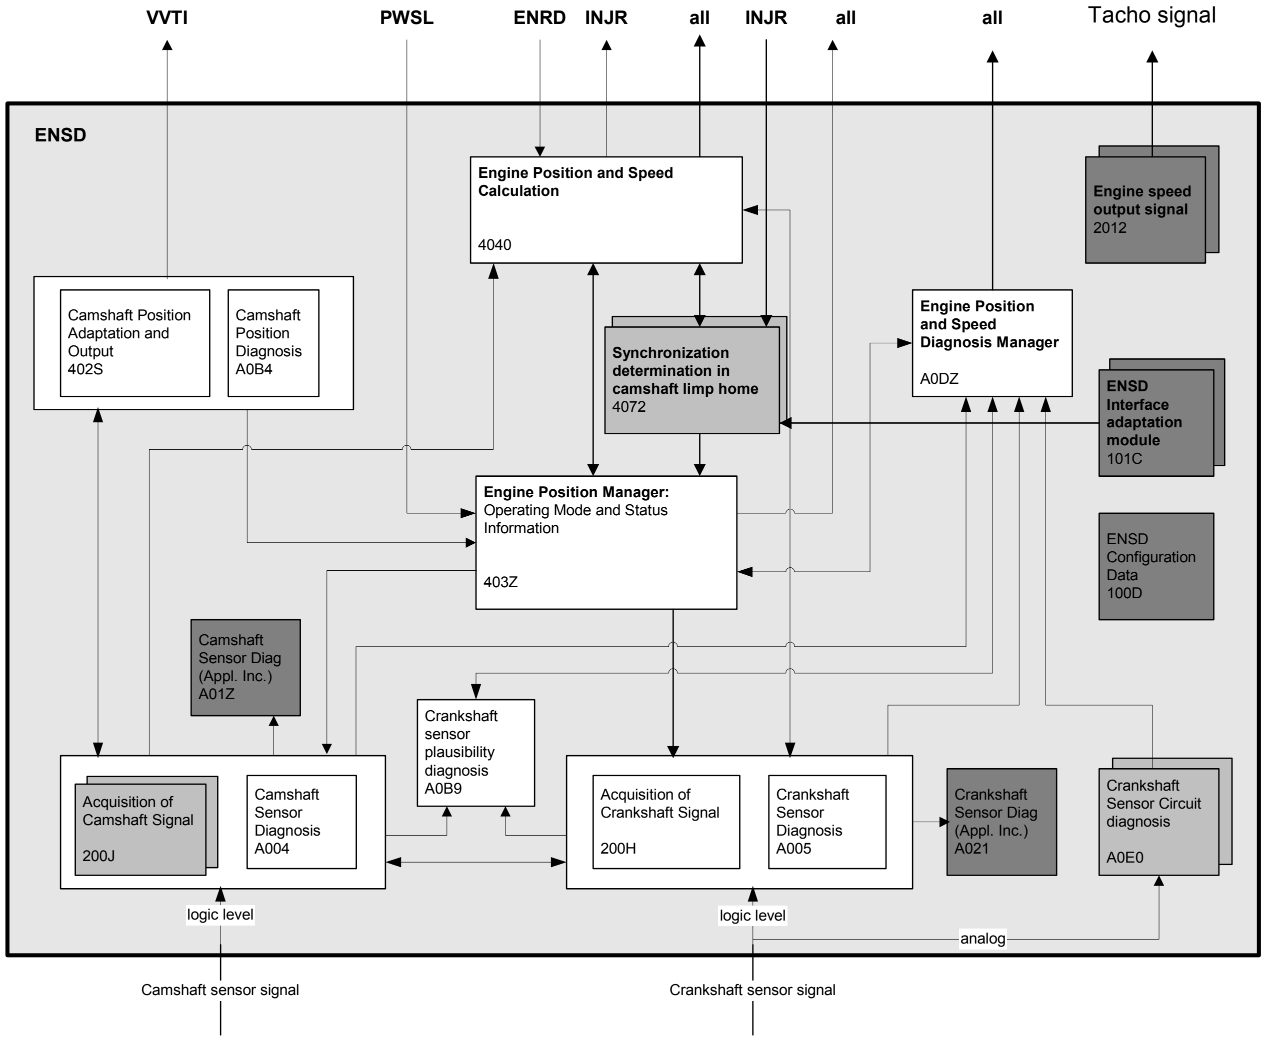
- engine position is identified (MPI engines)

- engine position is validated (DI / DS engines)

A corresponding status information (LV_SYN_ENG / LV_SYN_VLD) is produced and sent to the other aggregates.

23.1.2 Overview

The following figure shows the functional breakdown of the ENSD aggregate:



The light shaded blocs represent modules which are choosen in function of the actual system configuration (Hook modules).

The dark shaded blocs represent modules which have to be modified by the project („templates“ – Hook modules)

23.1.3 Short description of the containing functions

200H: Acquisition of crankshaft signal

Crankshaft synchronization, reference gap detection and crankshaft tooth validation. Measurements of tooth periods and segment periods

200J: Acquisition of camshaft signal

cam/crk synchronization (engine position offset determination), camshaft self-synchronization and engine position determination before engine synchronization (for pre-injection).

403Z: Engine position manager

Selection of operating modes (normal mode, camshaft or crankshaft limp-home mode) and generation of synchronization status information.

4040: Engine position and speed calculation

Calculation of engine position, speed, speed gradient, fast engine speed, segment period and number.

4072: Synchronization determination in camshaft limp-home

Engine synchronization determination in camshaft camshaft limp-home by specific injection pattern management

402S: Camshaft adaptation and position output

Camshaft edge position adaptation and camshaft position feedback for VVT-controller.

A0DZ: Engine position and speed diagnosis manager

Generation of diagnosis information and diagnosis inhibition flags.

A004: Camshaft sensor diagnosis

Camshaft segment period diagnosis and camshaft ratio check.

A0B4: Camshaft position diagnosis

Diagnosis of camshaft to crankshaft reference position.

A005: Crankshaft sensor diagnosis

Crankshaft tooth number and tooth period diagnosis.

A0B9: Crankshaft sensor plausibility diagnosis

Failure detection if crankshaft synchronization cannot be achieved, if camshaft signal is missing and if camshaft signal not valid for engine synchronization.

A021: Crankshaft sensor circuit diagnosis

Detection of open circuit and short circuit for magnetic crankshaft position sensor.

23.2 ENSD Configuration Data

Input data:

NC_CYL_NR	NC_NR_EDGE_CAM_IN	NC_NR_EDGE_CAM_EX	NC_N_MAX

NC_N_CRK_WIN_ENA			

General information :

The following describes the general rules for determination of the configuration data

23.2.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	Value
NC_CYL_NR	6
NC_N_MIN	22
NC_N_MAX	8160
NLC_CAM_IN	1: intake camshaft sensor(s) present in system
NLC_CAM_EX	1: exhaust camshaft sensor(s) present in system
NC_NR_CAM_CBK	1: camshaft sensor present on cylinder bank 1
NC_NR_EDGE_CAM_IN	6
NC_NR_EDGE_CAM_EX	6

23.2.2 Local configuration data

Here are listed the configuration data, which are used only in the ENSD aggregate.

Data	Value
NLC_LIH_CAM_IN	1: intake camshaft sensor available for crankshaft limp-home
NLC_LIH_CAM_EX	1: exhaust camshaft sensor available for crankshaft limp-home
NC_PRI_LIH_CAM_IN	Camshaft selection priority for crankshaft limp-home: 1: intake camshaft sensor(s)

Data	Value
NC_PRI_LIH_CAM_CBK	Camshaft selection priority for crankshaft limp-home: 1: sensor(s) on cylinder bank 1
NC_PRI_SYN_CAM_IN	Camshaft selection priority for engine synchronization: 1: intake camshaft sensor(s)
NC_PRI_SYN_CAM_CBK	Camshaft selection priority for engine synchronization: 1: sensor(s) on cylinder bank 1
NC_T_SEG_MIN_CAM_IN	Intake camshaft sensor minimum signal duration: 0,000694
NC_T_SEG_MIN_CAM_EX	Exhaust camshaft sensor minimum signal duration: 0,000694
NC_T_SEG_MAX_CAM_IN	Intake camshaft sensor maximum signal duration: 1,409090
NC_T_SEG_MAX_CAM_EX	Exhaust camshaft sensor maximum signal duration: 1,409090
NC_CRK_SENS_TYP	Crankshaft sensor type: 0: ACPS
NC_CAM_SENS_TYP	Camshaft sensor type: 2: ACAM TPO
NC_CAM_WHEEL_TYP	Camshaft target wheel type: 1: multi-teeth, 1 gap on crk
NC_NR_CONF_CAM	Number of camshaft target wheel configurations: 1: only 1 configuration
NC_ACT_CRK_EDGE	Active edge of crankshaft signal: 0: falling edges
NC_ACT_CAM_EDGE_SYN	Active edge of camshaft signal for cam/crk synchronization: 3: falling and rising edges
NC_ACT_CAM_EDGE_LIH	Active edge of camshaft signal for crankshaft limp-home: 3: falling and rising edges
NC_NR_TOOTH	60
NC_NR_GAP	1
NC_NR_TOOTH_GAP	2
NC_NR_TOOTH_TOL_ADD	2
NC_NR_TOOTH_TOL_MISS	2
NC_NR_TOOTH_STALL	3
NC_NR_VLD_TOOTH	6
NC_OFS_TDC0_REF_CRK	60°
NC_PSN_SEG_TDC_REF	54°

Data	Value
NC_PHA_SEG_ER_ENSD	42°
NC_CRK_WIN_SEG_LEN	30°
NLC_ESS	1: engine speed (tacho) output controlled by basic SW
NC_CAM_LIH_SWI	0: No specific method for synchronization determination in camshaft limp home
NC_N_SEG_HALF_END	22
NC_NR_TOOTH_FIRST_GAP_MIN	2: minimum number of teeth to be simulated to detect the first reference gap
NC_N_CRK_WIN_ENA	0: minimum engine speed for enabling acceptance windows for crankshaft acquisition

Application conditions:

Recurrence: once, at ignition key on (ECU reset)

Formula Section:

Edge index z	1	2	3	4	5	6
NC_PSN_EDGE_z_CAM_IN_1	80	210	390	430	570	30
NC_PSN_EDGE_z_CAM_EX_1	80	210	390	430	570	30

Note:

- Per definition edge #1 is the first electrical **FALLING** edge after TDC0
- Camshaft edge positions are given in °CRK relative to TDC0
- Camshaft edge positions are given for VVT passive and are only valid for BMW NG6 engines with a 3 teeth camshaft wheel

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CRK_SENS_TYP	1	0H 1H	ACPS MCPS	1	[-]

23.3 ENSD interface adaptation module

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TCO_CMN	V/O	0...FFH	-50...205	1	[°C]
Coolant temperature (ENSD internal)					
VB_CMN	V/O	0...FFH	0...28.8	1.13E-01	[V]
Battery voltage (ENSD internal)					

Input data:

TCO	VB	NC_CAM_LIH_SWI	

FUNCTION DESCRIPTION:

General information:

The aim is to get a common definition for coolant temperature and battery voltage inside ENSD aggregate whatever their definition is in the rest of software.

Description:

TCO_CMN and VB_CMN are stubbed

Application conditions:

Initialisation: none

Recurrence: at reset

Activation: *NC_CAM_LIH_SWI ≠ "INJ"*

Deactivation: NC_CAM_LIH_SWI = "INJ"

Formula section:

TCO_CMN = 0
VB_CMN = 0

Remark: As this module is only a stub, TCO and VB are not used.

23.4 Acquisition of Crankshaft Signal

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ST_CRK_SYN	-	0...7H	0...7	1	[-]
Crankshaft synchronisation state

At least one missing tooth has been simulated					

Input data:

N_32	LV_ACT_CRK	NC_CYL_NR	NC_NR_GAP

FUNCTION DESCRIPTION:

23.4.1 Crankshaft Synchronization

General information:

The crankshaft signal is generated by the crankshaft sensor in conjunction with the crankshaft target wheel. The target wheel has a theoretical number of NC_NR_TOOTH (typically 60) teeth, and NC_NR_TOOTH_GAP missing teeth (typically 2) forming the reference gap (“60-2”). The crankshaft sensor converts the mechanical shape into an electrical signal.

Magnetic Crankshaft Position Sensors (MCPS) deliver an AC signal with amplitude depending primarily on crankshaft speed, and sensor air gap. The signal is shaped into a rectangular signal by the ECU input circuitry. Each edge of that signal represents a tooth or a gap of the target wheel. Only signal edges generated from teeth will be processed by software (active signal edge definition). These may be falling or rising edges, depending on sensor polarity.

Active Crankshaft Position Sensors (ACPS) switch an open collector output on and off with every tooth or gap passing. Connecting the sensor output to a pull-up resistor inside the ECU generates a signal with rectangular shape. Each edge of that signal represents a tooth or a gap of the target wheel. Only falling signal edges will be processed by software (active signal edge definition), because they are faster. Design and installation of the sensor must ensure that falling signal edges are generated from teeth.

The corresponding configuration data is NC_ACT_CRK_EDGE.

The choice is taken in a way not to use the unprecise signal edge generated in the crankshaft reference gap.

It may be 0 (falling) or 1 (rising) with MCPS, depending on sensor polarity.

With ACPS it should always be 0, because the falling edge is faster due to the sensor’s open collector interface. The unprecise signal edge in the reference gap is avoided by choosing the correct installation of the sensor relativ to the target wheel motion direction.

Application conditions:

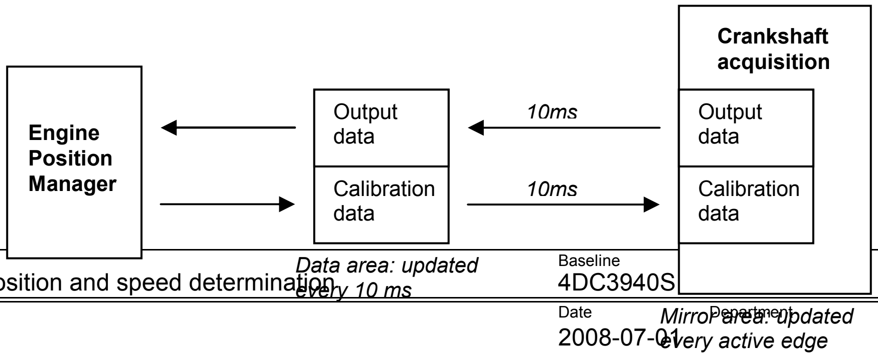
Recurrence:

For set of the RAM as flags, a mirror area is defined which contains a copy of the output and calibration data in the basic software area (see figure below).

The mirror area of the output data is updated by the lower layer at every active signal edge.

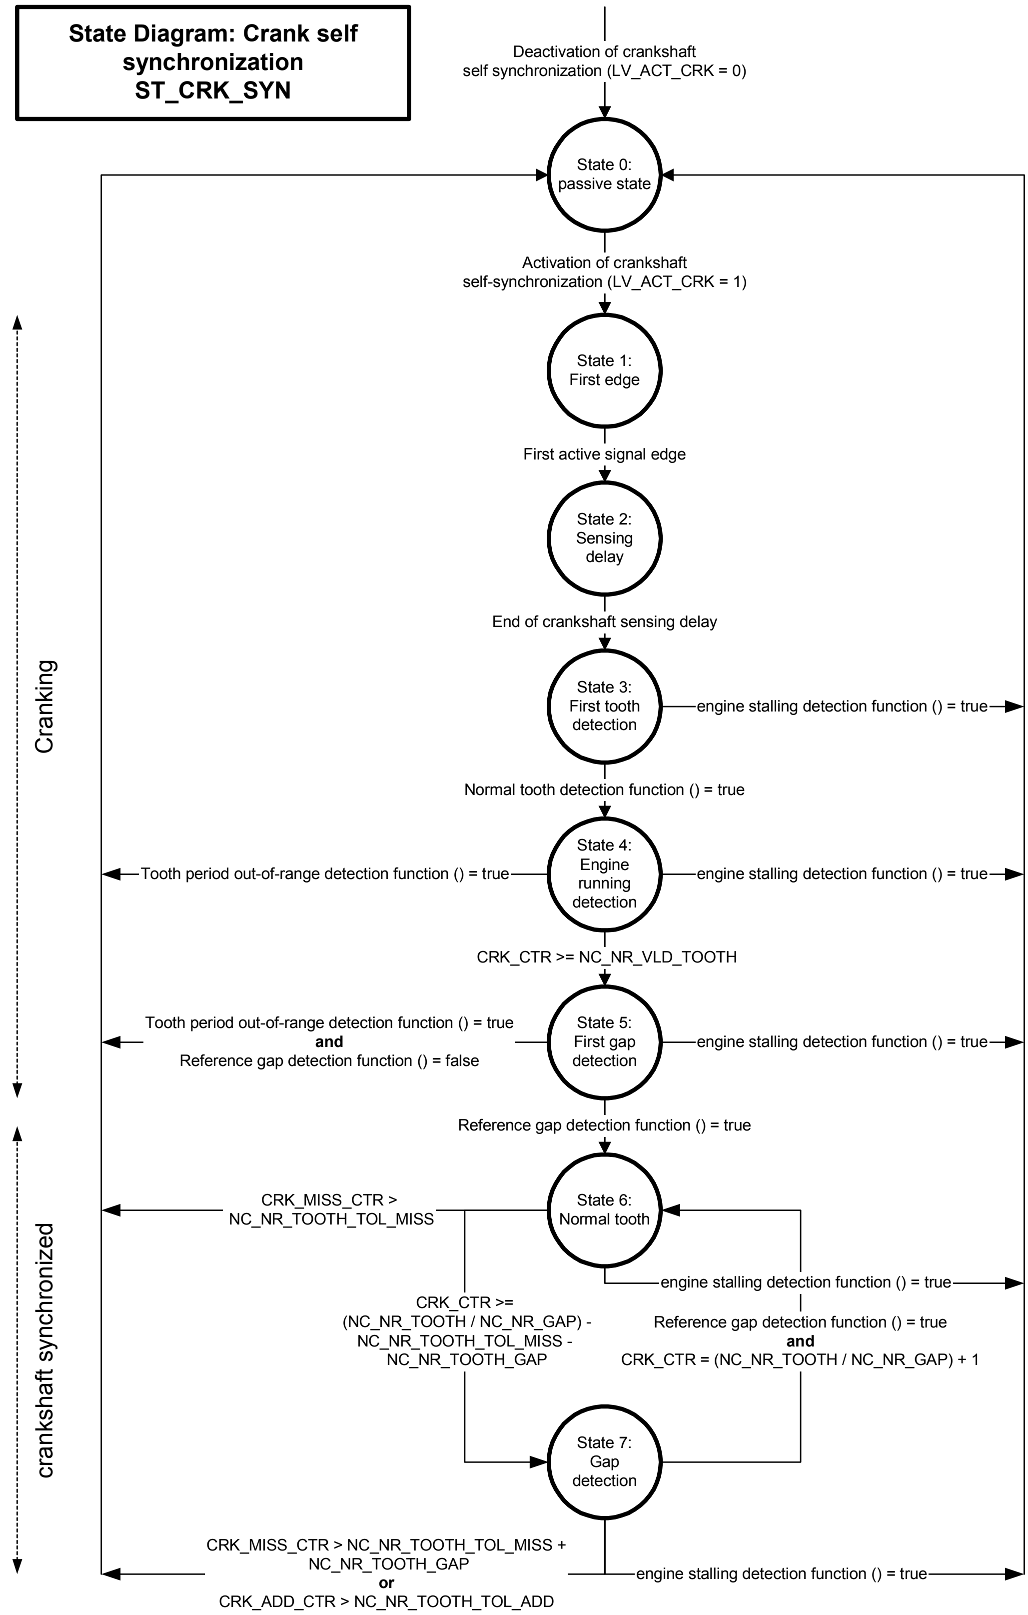
The mirror area of the calibration data is updated by the upper layer each 10ms.

The output data is copied from the mirror area every 10 ms

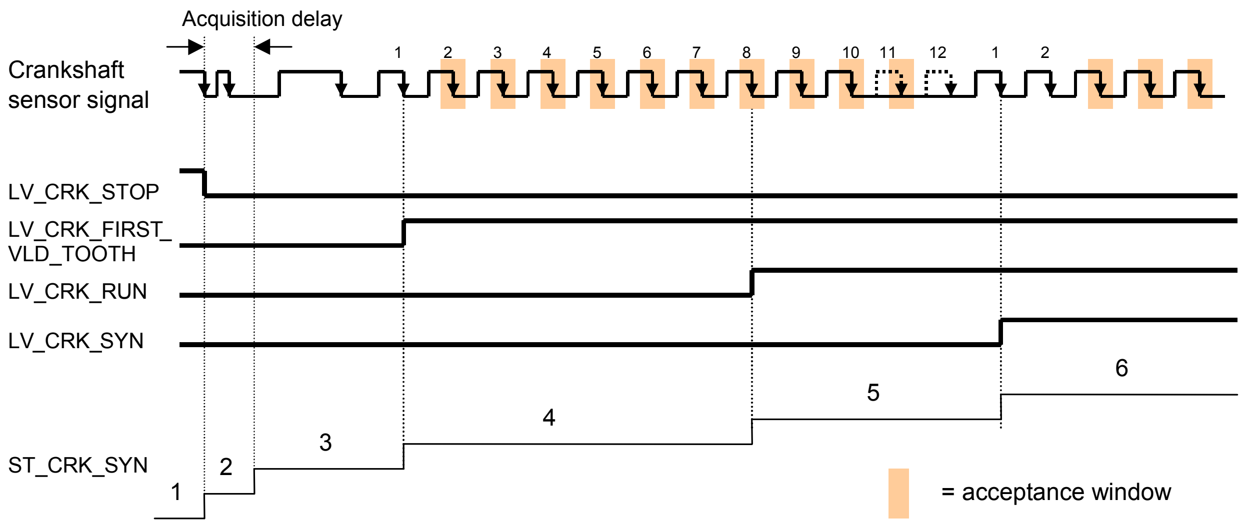


State Flow Diagram:

State Diagram: Crank self synchronization ST_CRK_SYN



Timing Diagram (example):



Formula section:

State 0: Crankshaft passive state

Input condition:

From state 4, 5:	Tooth period out-of-range detection function () = true
From state 6:	CRK_MISS_CTR > NC_NR_TOOTH_TOL_MISS
From state 7:	CRK_ADD_CTR > NC_NR_TOOTH_TOL_ADD Or CRK_MISS_CTR > NC_NR_TOOTH_TOL_MISS + NC_NR_TOOTH_GAP
From state 3,4,5,6,7:	Engine stalling detection function () = true
From EPM:	LV_ACT_CRK = 0

Output condition:

```

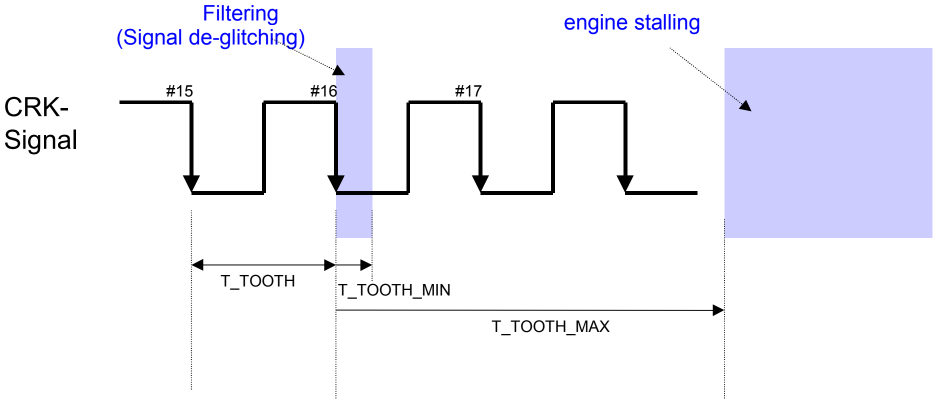
23.4.2 Definition of the sub function task

23.4.2.1 Normal tooth detection function ()

General information:

The purpose of this function is to validate the tooth period of a normal tooth when no acceptance window can be applied (first valid tooth, first tooth after a reference gap ...). The function returns false when the tooth period is too small (Signal edges detected before a delay time of T_TOOTH_MIN are not valid).



Formula section:

$$T\_TOOTH\_MIN = \frac{60}{NC\_NR\_TOOTH * NC\_N\_MAX}$$

```
If      T_TOOTH => T_TOOTH_MIN
Then    return (true)
Else    return (false)
Endif
```

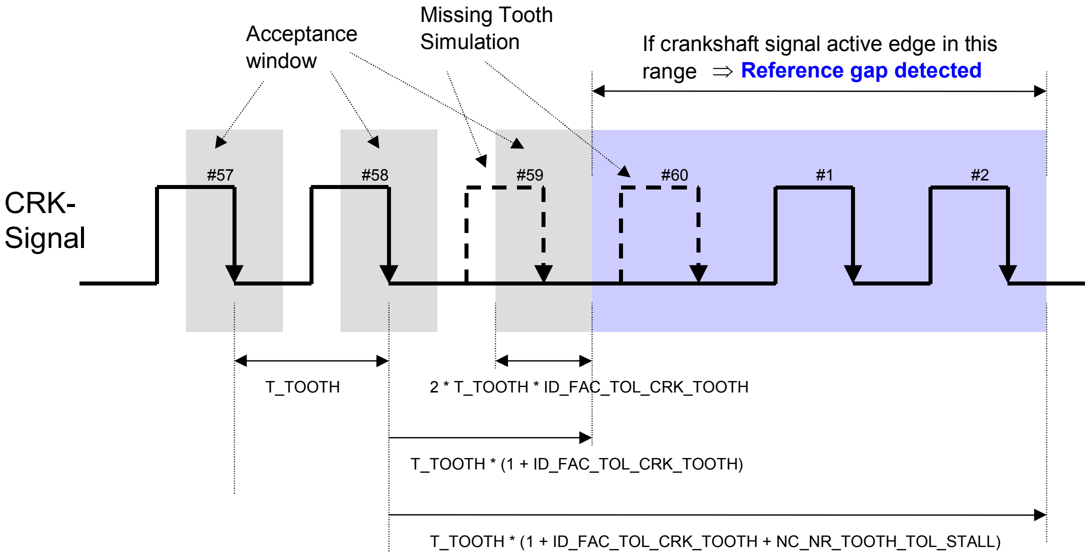
23.4.2.2 Reference gap detection function ()

General information:

The purpose of this function is to detect a reference gap.

A reference gap is detected if no signal edge was detected inside the crankshaft acceptance window and at least 1 (after synchronization) or NC_NR_TOOTH_FIRST_GAP_MIN (first gap detection) teeth have been completely simulated.

The follow figure shows the reference gap detection after synchronization:



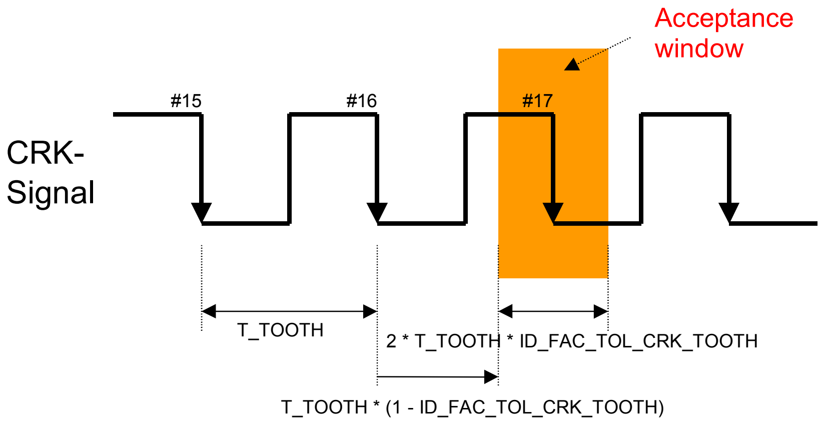
Formula section:

```
If      LV_CRK_SYN = 1
Then    If      Number of simulated missing teeth in gap position >=1
        Then    If      (NC_NR_TOOTH / NC_NR_GAP) – CRK_MISS_CTR <=
                            CRK_CTR <=
                            (NC_NR_TOOTH / NC_NR_GAP) + CRK_ADD_CTR
                Then    (correct tooth counter)
                        CRK_CTR = CRK_CTR + CRK_MISS_CTR – CRK_ADD_CTR
                        return (true)
                Else    return (false)
        Endif
Else    If      Number of simulated missing teeth in gap position >=
                        NC_NR_TOOTH_FIRST_GAP_MIN
        Then    return (true)
        Endif
Endif
```

23.4.2.3 Tooth period out-of-range detection function ()

General information:

The purpose of this function is to check if the tooth period is within a defined window area. The function returns true if the tooth period is outside the acceptance window.



Formula section:

Before first reference gap:

If T_TOOTH n-1 * (1 – ID_FAC_TOL_CRK_TOOTH) ≤ T_TOOTH n ≤ T_TOOTH n-1 * (1 + ID_FAC_TOL_CRK_TOOTH)

Then return (false)

Else return (true)

After first reference gap:

If T_TOOTH n-1 * (1 – ID_FAC_TOL_CRK_TOOTH) ≤ T_TOOTH n

Then return (false)

Else return (true)

Remark: If T_TOOTH > T_TOOTH n-1 * (1 + ID_FAC_TOL_CRK_TOOTH) after first reference gap, then a tooth is simulated (see below “Missing Tooth Simulation Function”).

The acceptance window is disabled

- on the first and second crankshaft signal edge after a reference gap detection
- on the first and second crankshaft signal edge after simulation of a missing tooth
- after engine synchronizarion, it could also be disabled below an engine speed, for example for engines having strong accelerations/decelerations at start:

  If N < NC_N_CRK_WIN_ENA

  And CRK_CTR > NC_NR_TOOTH_TOL_ADD

  And CRK_CTR < (NC_NR_TOOTH / NC_NR_GAP) - NC_NR_TOOTH_GAP - NC_NR_TOOTH_TOL_MIS – 2 (for latency time)

  This effectively means that the acceptance window is only applied for GAP detection below the configured engine speed threshold.

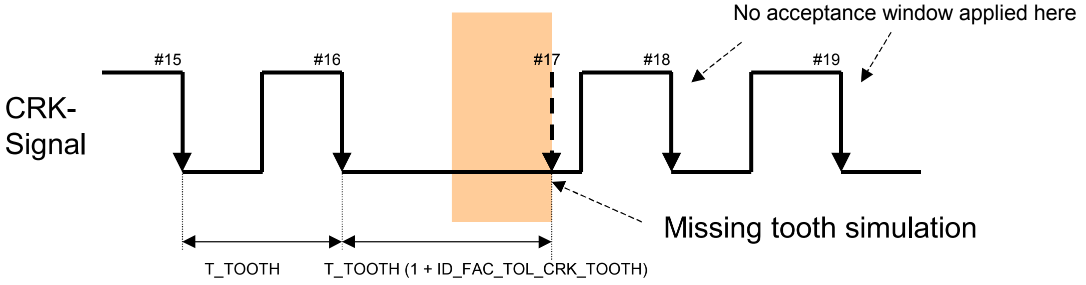
23.4.2.4 Missing Tooth Simulation Function ()

General information:

Simulate a tooth with tooth period T_TOOTH n-1 (last measured tooth period).

All measurements shall be based on the simulated tooth not on real edges.

Simulation starts at the last (real or simulated) signal edge if no signal edge is detected inside the acceptance window defined by ID_FAC_TOL_CRK_TOOTH.



Formula section:

Increment CRK_CTR.

Increment CRK_MISS_CTR.

LV_CRK_MISS_TOOTH = 1

23.4.2.5 Missing Tooth Simulation in Gap Position Function ()

General information:

Simulate a tooth with tooth period T_TOOTH n-1 (last measured tooth period).

Simulation starts at the last (real or simulated) signal edge if no signal edge is detected inside the acceptance window defined by ID_FAC_TOL_CRK_TOOTH.

Simulation stops when a edge is detected after the first simulated missing tooth.

All measurements shall be based on the simulated tooth not on real edges.

Formula section:

Increment CRK_CTR.

If number of simulated teeth < NC_NR_TOOTH_GAP

And

Missing tooth simulation stopped

Then Increment CRK_MISS_CTR

High acceleration during reference gap: only one tooth could be simulated

Endif

```
If      number of simulated teeth > NC_NR_TOOTH_GAP
Then    Increment CRK_ADD_CTR
        High deceleration during reference gap: more than NC_NR_TOOTH_GAP teeth
        simulated
Endif
```

23.4.2.6 Engine stalling detection function ()

General information:

Engine stalling is detected when the number of consecutive simulated teeth exceeds NC_NR_TOOTH_STALL or when the tooth period is greater than T_TOOTH_MAX.

Formula section:

$$\text{T\_TOOTH\_MAX} = \frac{60}{NC\_NR\_TOOTH * NC\_N\_MIN}$$

```
If      more than NC_NR_TOOTH_ STALL consecutive teeth are simulated
        Or
        T_TOOTH (1 + ID_FAC_TOL_CRK_TOOTH) >= T_TOOTH_MAX
Then    return (true)
Else    return (false)
Endif
```

23.4.3 Requirements to infrastructure

23.4.3.1 Crankshaft Tooth Time Measurement (T_TOOTH)

General information:

System request accuracy <= 4 us

The crankshaft tooth period T_TOOTH is the measured time between two consecutive valid active crankshaft signal edges (falling or rising according to configuration).

If a missing tooth is simulated, T_TOOTH represents the time period between the last two real valid signal edges. T_TOOTH keeps the latest value until a new measured value is available.

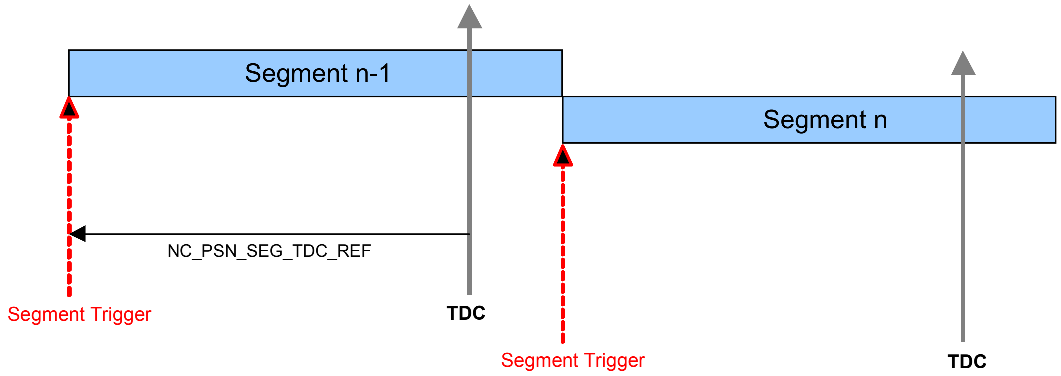
23.4.3.2 Segment Period Measurement (T_SEG_ENSD) and Trigger Generation

General information:

System request accuracy <= 1 us

At Segment event, a trigger is defined and a control signal is generated to trigger execution of segment synchronous tasks.

The corresponding time intervals T_SEG_ENSD are measured between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC.



Application conditions:

Initialisation:	T_SEG_ENSD is set to the maximum value
Recurrence :	before synchronization: once (when LV_CRK_RUN is set) after synchronization: NC_PSN_SEG_TDC_REF degrees before each TDC (segment trigger)
Activation :	LV_CRK_RUN = 1
Deactivation :	LV_CRK_STOP = 1

Formula section:

Before synchronization, one segment time is output at the moment when crankshaft rotation is validated. The first segment period is calculated from the most recent tooth period:

T_SEG_ENSD = (2 * T_TOOTH * NC_NR_TOOTH) / NC_CYL_NR

The same calculation applies to the first segment after synchronization.

After synchronization:

T_SEG_ENSD = time interval between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC

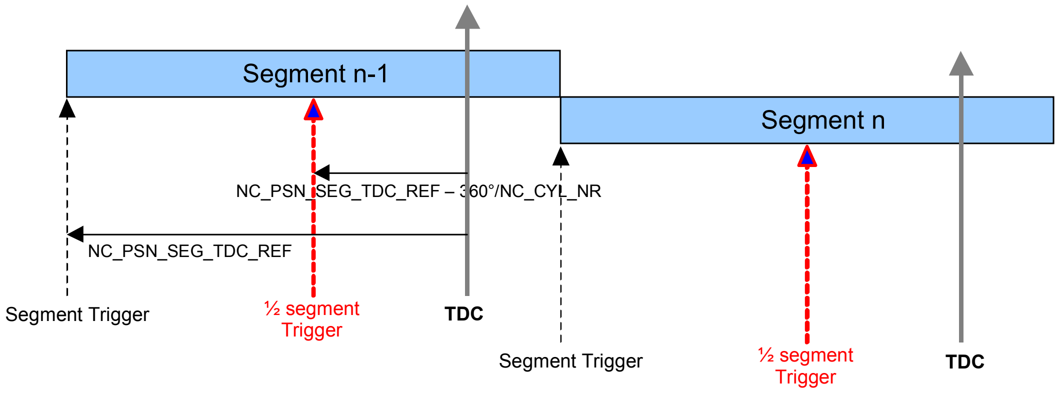
23.4.3.3 Half-Segment Period Measurement (T_SEG_HALF_ENSD) and Trigger Generation

General information:

System request accuracy <= 1 us

At the half of a segment (in the middle of two segment events) a half-segment event is generated and an half-segment trigger is defined and send to the ASW if the engine speed is lower than a threshold defined by NC_N_SEG_HALF_END.

This function provides a output value for the half-segment period. This measured time is send to the ASW.



Application conditions:

Initialisation:	T_SEG_HALF_ENSD is set to the maximum value
Recurrence:	before synchronization: once (when LV_CRK_RUN is set) after synchronization: NC_PSN_SEG_TDC_REF degrees before each TDC (segment trigger) **and** NC_PSN_SEG_TDC_REF – 360° CRK / NC_CYL_NR degrees before each TDC (half-segment trigger) **if** T_SEG_HALF_ENSD >= 60 / (NC_CYL_NR * NC_N_SEG_HALF_END)
Activation:	LV_CRK_RUN = 1
Deactivation:	LV_CRK_STOP = 1

Formula section:

The first half segment period is calculated from the most recent tooth period:

T_SEG_HALF_ENSD = (T_TOOTH * NC_NR_TOOTH) / NC_CYL_NR

After synchronization:

T_SEG_HALF_ENSD = time elapsed between

- a segment event and a half-segment event or
- a half-segment event and a segment event

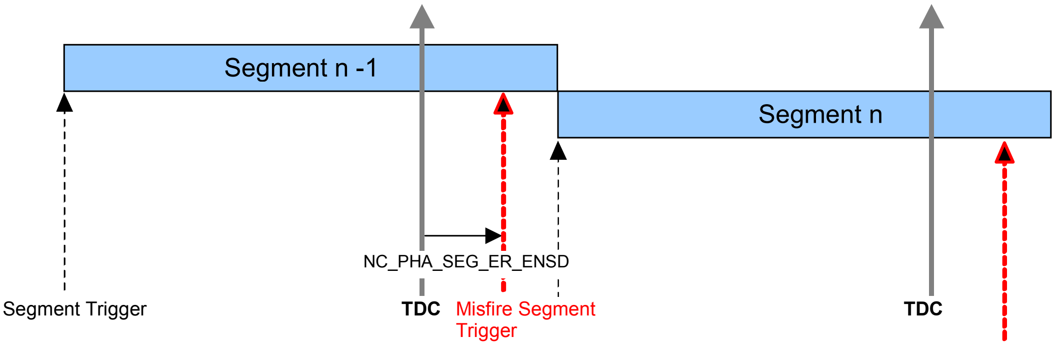
23.4.3.4 Misfire Segment Period Measurement (T_SEG_ER)

General information:

System request accuracy <= 1 us

The function provides output values for the misfire segment period.

The misfire segment period T_SEG_ER corresponds to the TDC period, measured at the tooth events, which are closest to NC_PHA_SEG_ER_ENSD after each TDC.



Application conditions:

Initialisation: T_SEG_ER is set to the maximum value

Recurrence: every misfire segment

Formula section:

T_SEG_ER = time interval between misfire segment tooth events.

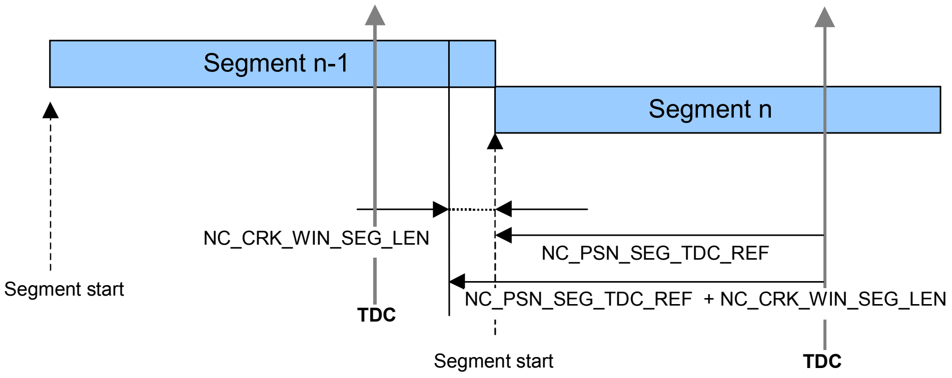
23.4.3.5 Crankshaft tooth window measurement (T_CRK_WIN_ENSD)

General information:

System request accuracy <= 1 us

The time interval elapsed between tooth events located between NC_CRK_WIN_SEG_LEN degrees before the end of each segment and the segment trigger is measured and send to the ASW segment synchronous

It provides and measures the time of the last NC_CRK_WIN_SEG_LEN teeth period before segment event.



Application conditions:

Initialisation: T_CRK_WIN_ENSD is set to the maximum value

Recurrence: every segment

Activation: LV_CRK_SYN = 1

Deactivation: LV_CRK_STOP = 1

Formula section:

```
If      LV_CRK_SYN is set to 1 between NC_CRK_WIN_SEG_LEN degrees before the
        end of the segment and the segment trigger event
Then    /* Recalculation from last available tooth period */
        T_CRK_WIN = (T_TOOTH * NC_NR_TOOTH) / (360°CRK /
        NC_CRK_WIN_SEG_LEN)
Else    /* Normal calculation */
        T_CRK_WIN_ENSD = time interval between tooth events located between
                NC_CRK_WIN_SEG_LEN degrees before the end of each segment and the
                segment triger
Endif
```

23.4.3.6 ID_FAC_TOL_CRK_TOOTH calculation

General information:

ID_FAC_TOL_CRK_TOOTH[0rpm] is used until crankshaft synchronization (i.e. until first gap is detected, LV_CRK_SYN is set).

Then after crankshaft synchronization, ID_FAC_TOL_CRK_TOOTH is calculated depending on engine speed value (N_32).

Calibration data:

23.4.4 System requirements to sensor signal

23.4.4.1 General

With both sensor technologies, there is an angular offset between the mechanical reference (usually the trailing edge of a tooth) and the timing reference of the sensor (zero crossing of the MCPS signal, output switching of the ACPS) for an active edge. This offset will further on be referred to as phase angle. The phase angle depends strongly on sensor tolerances, installation tolerances (air gap), and operating conditions (speed, temperature).

The tolerances given in the following paragraphs refer to the angular position of the crankshaft target wheel when an active signal edge is recognized by the input port of the µP, or to the rotation angle between such events, respectively.

23.4.4.2 Relative phase angle tolerances

The usual synchronization algorithms can accept ±3% tolerance of the target wheel rotation angle between consecutive active signal edges.

e.g. for a “60-2” target wheel, this is 6° (18°) ±0.2°

The sensor/target wheel combination has to fulfill this requirement at all operating conditions.

The permissible accumulation of tooth angle tolerances over a TDC segment is ±0.25% of the angle for one TDC segment (720°/ NC_CYL_NR) at segment reference conditions.

e.g. for four-cylinder engines	180°	±0.45°
e.g. for six-cylinder engines	120°	±0.3°

Segment reference conditions are: 2000rpm, 80°C.

Please note that for engines with more than 8 cylinders, this requirement is more stringent than the requirement for consecutive signal edges.

23.4.4.3 Relative phase angle stability

The angle for one TDC period measured under segment reference conditions must not have a drift > 0.045° versus speed variation from 2000 rpm...7000 rpm and temperature variation within the complete range. This requirement has to be fulfilled for all tolerances and all possible displacements of the target wheel relative to the sensor (air gap, radial run-out, crankshaft flexion, bearing clearance...).

In case of MCPS sensors, phase angle stability must be measured with the ECU hardware stage.

23.4.4.4 Repeatability

Two different definitions of repeatability are functionally equal. The choice depends on the sensor test bench and measurement equipment.

1. Phase angle repeatability

(mechanical edge to signal edge for the same tooth) ±0.025°

2. Interval repeatability

(signal edge to signal edge for the same pair of teeth) ±0.05°

In both cases the repeatability is determined from the maximum and minimum value out of a large number of measurements under constant conditions.

23.4.5 Hardware and HAL requirements

23.4.5.1 EMI

Any signal disturbance must be suppressed as far as possible. Supplemental trigger events must not be generated due to such disturbance, particularly not at the slow zero crossing in the reference gap.

23.4.5.2 Phase shift repeatability

At constant operating conditions, the phase shift introduced by the input circuitry must be constant within ±0.1 µs

General information:

This specification is dedicated to acquisition of the signal from sensors and target wheels on up to 4 camshafts (intake and exhaust, cylinder bank 1 and 2).

The operating mode of the signal acquisition is controled for each camshaft separately.

A diagnostic output is delivered to allow detection of camshaft signal failure.

The signal is used for:

1. Self synchronization of all camshafts: timing validation of the camshaft signal edges in correspondance with its theoretical position (used for VVT controler, for detection of crankshaft signal failure, and for limp-home in case of crankshaft signal failure).
2. Camshaft / crankshaft synchronization of the selected camshaft: determination of the offset for the engine position calculation.
3. Engine position interface for pre-injection (with the selected camshaft used for cam/crank synchronization)

These three functions are described with three states diagrams.

Application conditions:

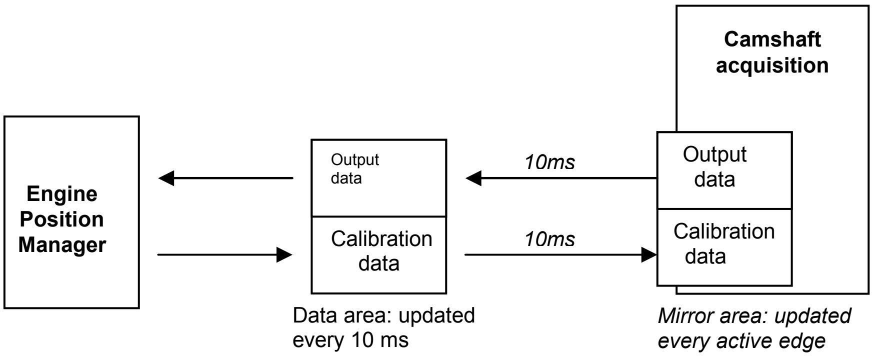
Recurrence:

For set of the RAM as flags, a mirror area is defined which contains a copy of the output and calibration data in the basic software area (see figure below).

The mirror area of the output data is updated by the lower layer at every signal edge.

The mirror area of the calibration data is updated by the upper layer each 10ms.

The output data is copied from the mirror area every 10 ms

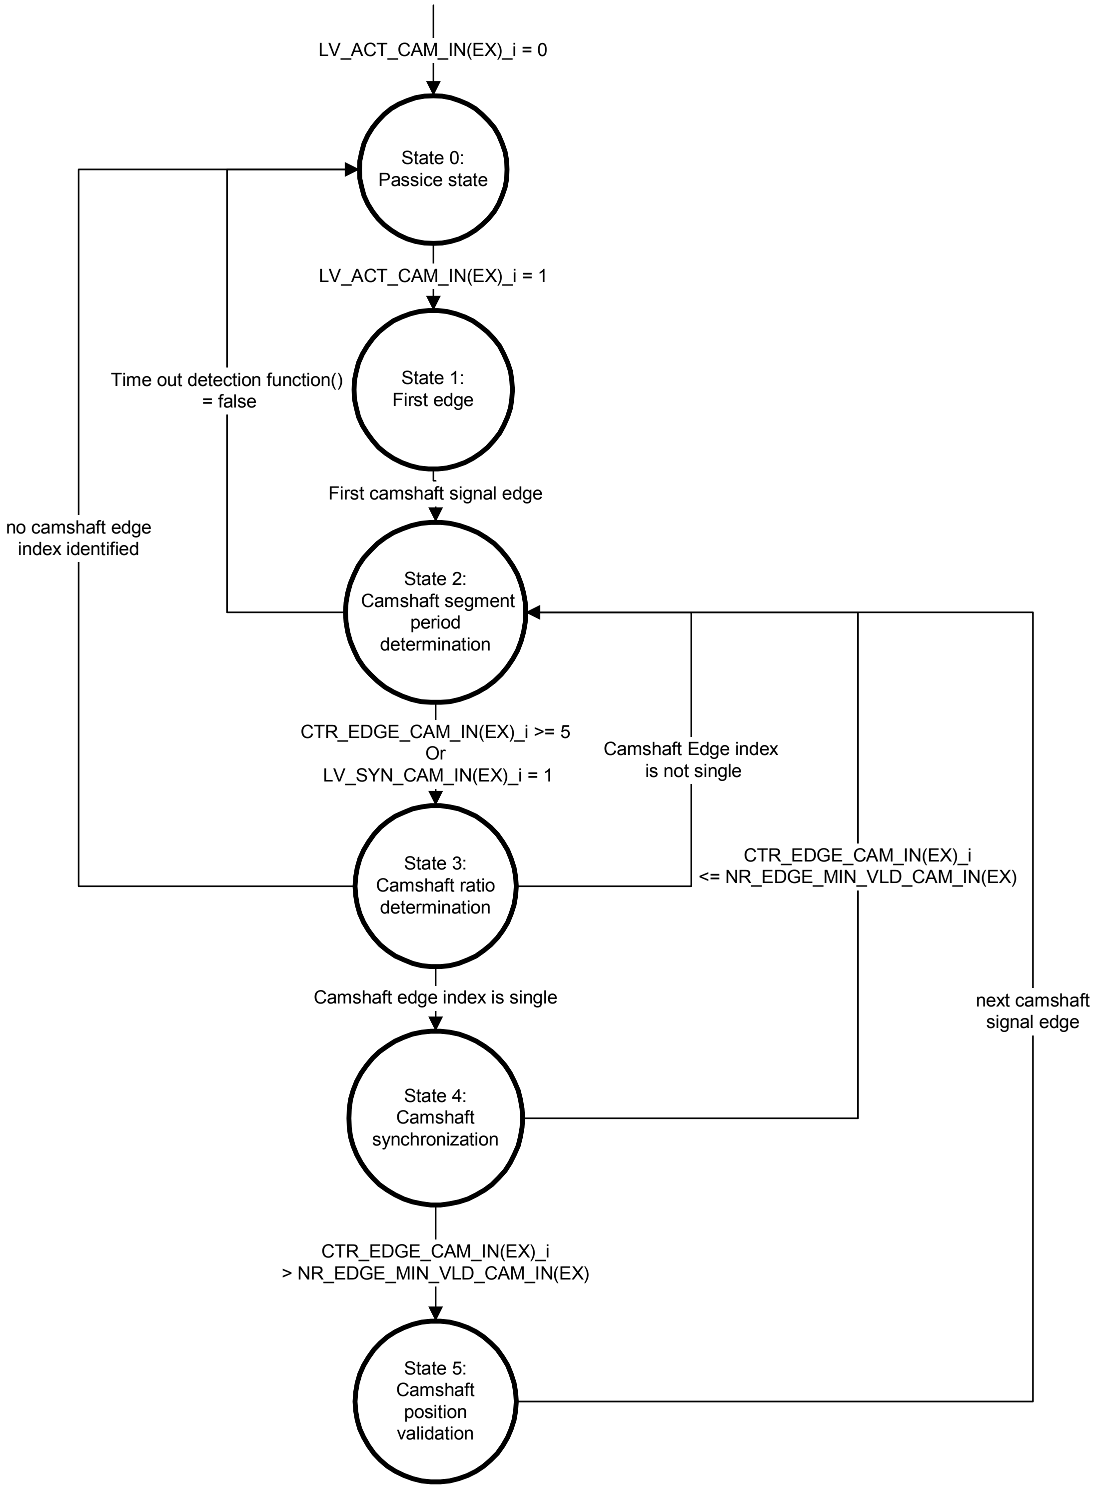


23.5.1 Camshaft Self-Synchronization

Application conditions:

Recurrence: every camshaft signal edge (falling and rising)

Signal flow diagram (ST_CAM_SS):



Formula section:

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN(EX)

State 0: Passive State

Input condition :

From EPM : LV_ACT_CAM_IN(EX)[i] = 0
From state 2 : Time out detection function () = false
From state 3 : No cam edge index identified

State 4: Camshaft synchronization

Input condition :

From state 3:	Cam Edge index is single

Output condition :

To state 2:	CTR_EDGE_CAM_IN(EX)[i] <= C_NR_EDGE_MIN_VLD_CAM_IN(EX)
To state 5:	CTR_EDGE_CAM_IN(EX)[i] > C_NR_EDGE_MIN_VLD_CAM_IN(EX)

Action in the state:	IDX_EDGE_CAM_IN(EX)[i] = camshaft edge index Wait next camshaft signal edge.

Action in transient:

To state 5:	LV_VLD_PSN_CAM_IN(EX)[i] = 1

State 5: Validation of camshaft position

Input condition:

From state 4: CTR_EDGE_CAM_IN(EX)[i] > C_NR_EDGE_MIN_VLD_CAM_IN(EX)

Output condition:

To state 2: Next camshaft signal edge

Action in the state: Wait next camshaft signal edge.

Action in transient:

None

23.5.2 Camshaft/Crankshaft Synchronization

General information:

Cam/crk synchronization is set as soon as the engine position is identified:

- Reference gap detected and
- Engine position offset determined

The engine position offset (PSN_ENG_CRK_OFF) can be

- 360° or 720° for NC_NR_GAP = 1
- 180°, 360°, 540°, 720° for NC_NR_GAP = 2

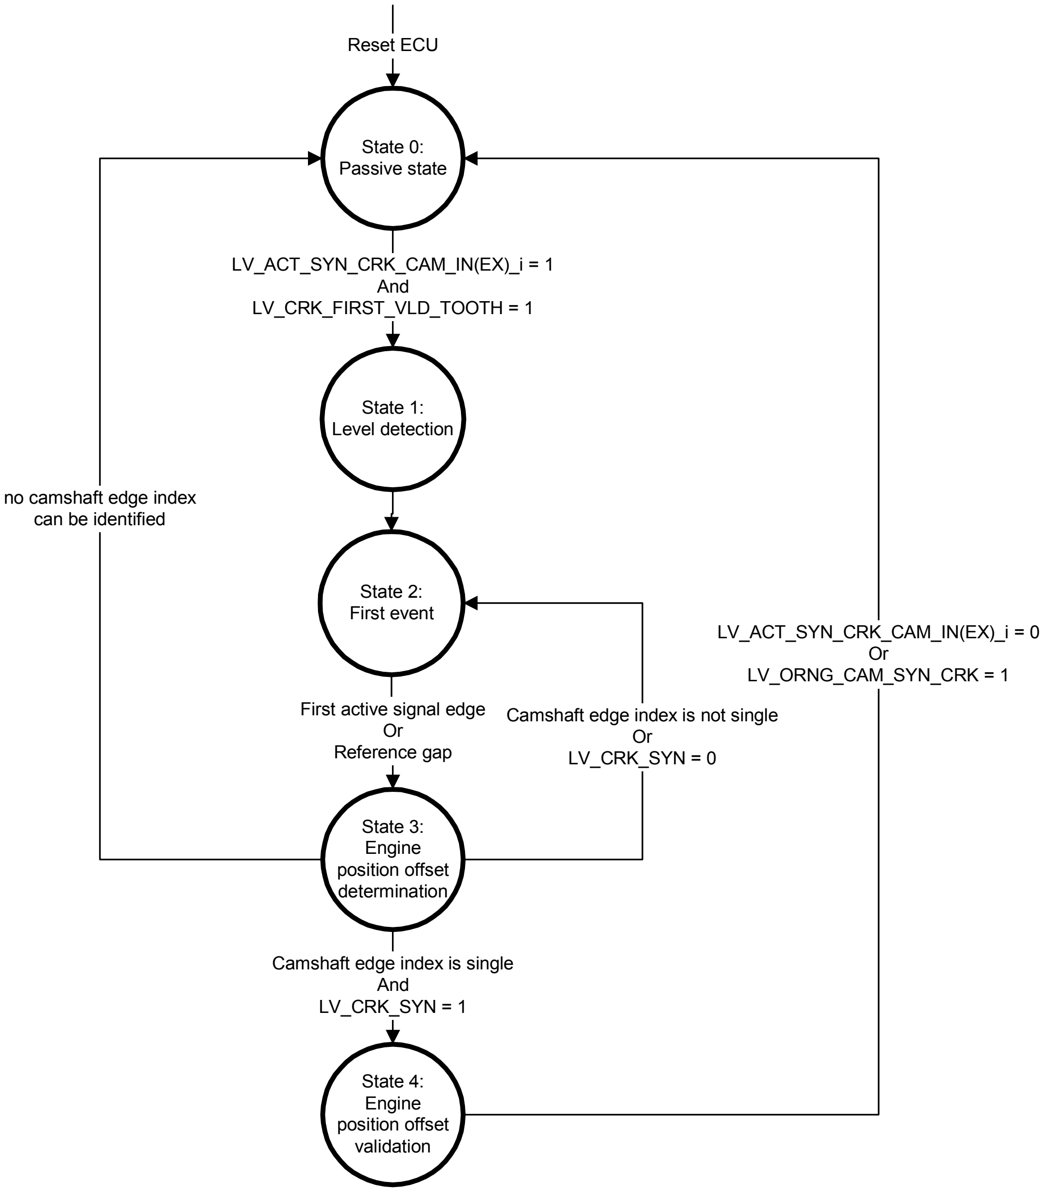
Application conditions:

Recurrence: every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1

every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2

every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Signal flow diagram ST_CAM_CRK_S:



Formula section:

State 0: Passive State

Then    LV_ORNG_CAM_SYN_CRK = 1
Endif
```

Action in transient :

None

23.5.3 Engine Position Interface for Pre-Injection

General information:

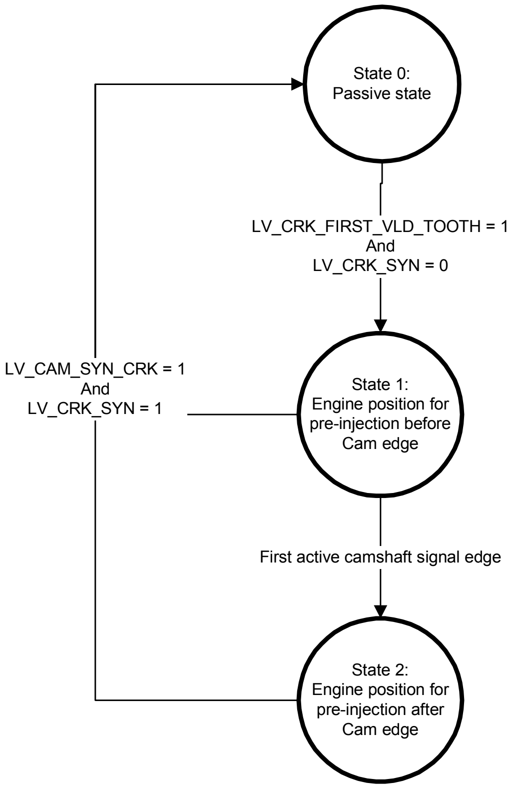
For rapid start of port-injection engines it is useful to start injection before synchronization on crankshaft signal is achieved. An approximative information about engine position is necessary for phasing the injection in a way to avoid emissions increase.

For this purpose, a minimum and the maximum engine position is determined according to the actual possible camshaft signal edge indexes found by camshaft signal acquisition for crankshaft synchronization. The minimum and the maximum position will converge gradually during the synchronization process.

Application conditions:

Recurrence:	every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1
	every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2
	every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Signal flow diagram (ST_CAM_PRE_INJ_S):



Formula section:

State 0: Passive State

23.5.4 Definition of the sub function tasks

23.5.4.1 Time-out detection function ()

General information:

Time-out is detected when the segment period exceeds NC_T_SEG_MAX_CAM_IN(EX). Time out detection is used for engine stalling detection during crankshaft limp-home.

Formula section:

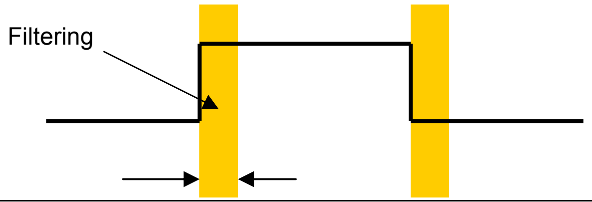
```
If      T_SEG_CAM_IN(EX)[i] <= NC_T_SEG_MAX_CAM_IN(EX)
Then    return (true)
Else    return(false)
Endif
```

23.5.4.2 Invalid segment period detection function ()

i = 1...NC_NR_CAM_CBK

General information:

Any signal edge detected before a delay time NC_T_SEG_MIN_CAM_IN(EX) following the previous signal edge will not produce any output.



Formula section:

```
If      T_SEG_CAM_IN(EX)[i] < NC_T_SEG_MIN_CAM_IN(EX)
Then    Invalid segment period
        return (true)
Else    return (false)
Endif
```

23.5.4.3 Camshaft segment ratio calculation function ()

General information:

The purpose of this function is to calculate a camshaft edge ratio from measured segment periods (measured ratio) and from designed edge positions (theoretical ratio).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN(EX)

Application conditions:

Recurrence : every camshaft edge.

Formula section:

Measured ratio :

RATIO_PER_CAM_IN(EX)[i] =

$(T\_SEG\_CAM\_IN(EX)[i]_{n} + T\_SEG\_CAM\_IN(EX)[i]_{n-3})$ /

$(T\_SEG\_CAM\_IN(EX)[i]_{n-1} + T\_SEG\_CAM\_IN(EX)[i]_{n-2})$

Theoretical ratio :

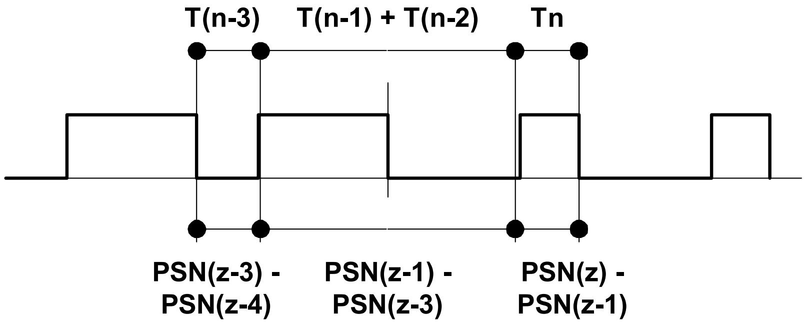
For all remaining indexes z:

RATIO_PSN_EDGE_CAM_IN(EX)[z][i] =

(NC_PSN_EDGE_CAM_IN(EX)[z][i] - NC_PSN_EDGE_CAM_IN(EX)[z-1][i]

+ NC_PSN_EDGE_CAM_IN(EX)[z-3][i] - NC_PSN_EDGE_CAM_IN(EX)[z-4][i]) /

(NC_PSN_EDGE_CAM_IN(EX)[z-1][i] - NC_PSN_EDGE_CAM_IN(EX)[z-3][i])



23.5.4.4 Camshaft edge recognition ()

General information:

The purpose of this function is to compare the measured camshaft edge ratio to the theoretical camshaft edge ratio. The camshaft edge is removed from the camshaft index index table if both ratios (theoretical and measured) are different more than ID_FAC_CAM_IN(EX).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN(EX)

Application conditions:

Recurrence: every camshaft edge.

Formula section:

For all remaining indexes z:

```
If      RATIO_PSN_EDGE_CAM_IN(EX)[z][i] * ID_FAC_CAM_IN(EX) >
        RATIO_PER_CAM_IN(EX)[i] > RATIO_PSN_EDGE_CAM_IN(EX)[z][i] /
        ID_FAC_CAM_IN(EX)
Then    keep index z in the table
Else    eliminate index z from the table
Endif
```

23.5.4.5 Camshaft edge index determination function ()

General information:

This function determines the possible camshaft signal indexes and returns the engine position offset when the index is identified.

This function is used for

- determination of position offset for engine synchronization
- determination of min/max engine position for pre-injection

The actions and tests of this function shall be performed for all remaining indexes of the list of possible camshaft signal indexes.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN(EX)

Application conditions:

Recurrence: every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1

every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2

every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Formula section:

```
If      active camshaft signal edge
Then    If      NC_ACT_CAM_EDGE_SYN = 3
        Then    Increment indexes in the list of possible camshaft signal index by 1
                modulo NC_NR_EDGE_CAM_IN(EX)
        Else    Increment by 2 indexes in the list of possible camshaft signal index by 2
                modulo NC_NR_EDGE_CAM_IN(EX)
Endif
```

Calculate theoretical angular distance between crankshaft tooth #1 and camshaft edge #z:

PSN_TOOTH1_CAM = NC_OFS_TDC0_REF_CRK +
NC_PSN_EDGE_CAM_IN(EX)[z][i]

Calculate theoretical angular distance between two successive active camshaft edges:

PSN_CAM_CAM is the distance between the current camshaft edge and the previous one, whereas PSN_CAM_CAM_1 is the distance between the current camshaft edge and the next one. PSN_CAM_CAM_1 is used in Test 10 in case of [CAM – CRK-Angle].

```
If      NC_ACT_CAM_EDGE_SYN = 3
Then    Falling and rising camshaft edges
        PSN_CAM_CAM = NC_PSN_EDGE_CAM_IN(EX)[z][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z-1][i]
        PSN_CAM_CAM_1 = NC_PSN_EDGE_CAM_IN(EX)[z+1][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z][i]

Else    Only Falling or only rising camshaft edges
        PSN_CAM_CAM = NC_PSN_EDGE_CAM_IN(EX)[z][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z-2][i]
        PSN_CAM_CAM_1 = NC_PSN_EDGE_CAM_IN(EX)[z+2][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z][i]

Endif
```

The number of possible indexes z will be reduced by checking the conditions described below.

The following table shows the actions to perform in function of the current event (n), previous event (n-1) and last event (n-2).

The event is a detection of a active camshaft edge (**CAM**) for synchronization or a detection of reference gap (**GAP**). If no event took place before (**none**), the tests are executed with the measured angular distance between engine start and current event.

To reduce the possible engine position range for pre-injection, the event could also be a measured crankshaft angle (**CRK-Angle**) from the last CAM event. The event should occur when :

REL_ANG_CRK_CAM = C_CRK_ANG_DLY_LST_CAM.

Note that two calibration datas are defined :

- C_CRK_ANG_DLY is the one used in case of [CRK-Angle – CAM] in Test 9 ;
- C_CRK_ANG_DLY_LST_CAM is the one used in case of [CAM - CRK-Angle] in Test 10.

This pre-injection improvement can be disabled by setting these calibration datas to 0°CRK.

Event (n)	CAM	CAM	GAP	GAP	CAM	CAM	GAP	CRK-Angle
Event (n-1)	None	CAM	None	CAM	GAP	GAP	GAP	CAM
Event (n-2)	-	-	-	-	None	CAM	-	-
Test	Test 1 Test 9	Test 2 Test 11	Test 3 Test 12	Test 4 Test 12	Test 1 Test 5 (1)	Test 2 Test 5 (1)	(2)	Test 10 (3)

(1) The first test shall be executed with event **n** and **n-2**. The second test shall be executed with event **n** and **n-1**

(2) No Camshaft index can be identified (All remaining indexes shall be removed)

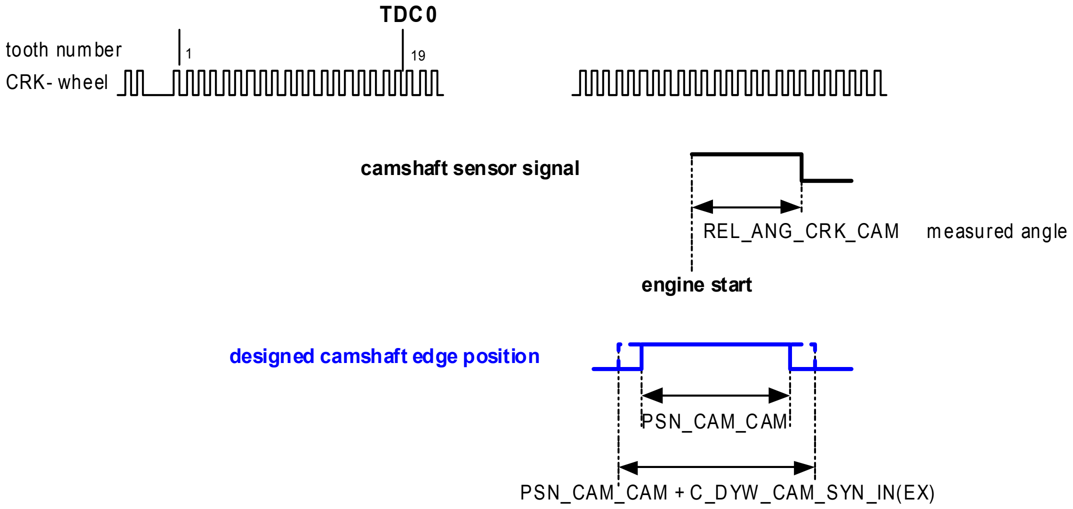
(3) CRK-Angle event will never be in position (n-1) as it will be replaced in the memory by the next event instead to be recorded in (n-1) position

NB1: The calculation of the CRK-Angle delay begins at each CAM edge, but is also reset in case of GAP event. No test should be performed in case of GAP –- CRK-Angle.

NB2: In all the following calculations, PSN_TOOTH1_CAM represents PSN_TOOTH1_CAM[z] (= PSN_TOOTH1_CAM for the camshaft edge z). If an other camshaft edge is used for computation, then PSN_TOOTH1_CAM[z] is mentioned.

Test 1:

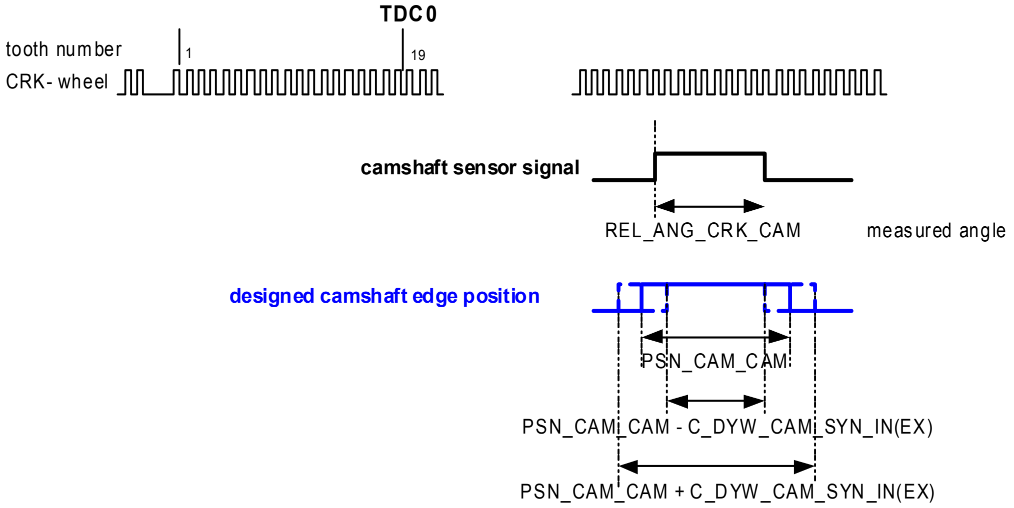
Active camshaft edge detected. No active camshaft edge occured before.



If	REL_ANG_CRK_CAM < PSN_CAM_CAM + CAM_DYW_SYN_IN(EX)
Then	(no operation)
Else	Remove index z from list of possible camshaft signal edge indexes
Endif	

Test 2:

Active camshaft edge detected. Last event was also an active camshaft edge.

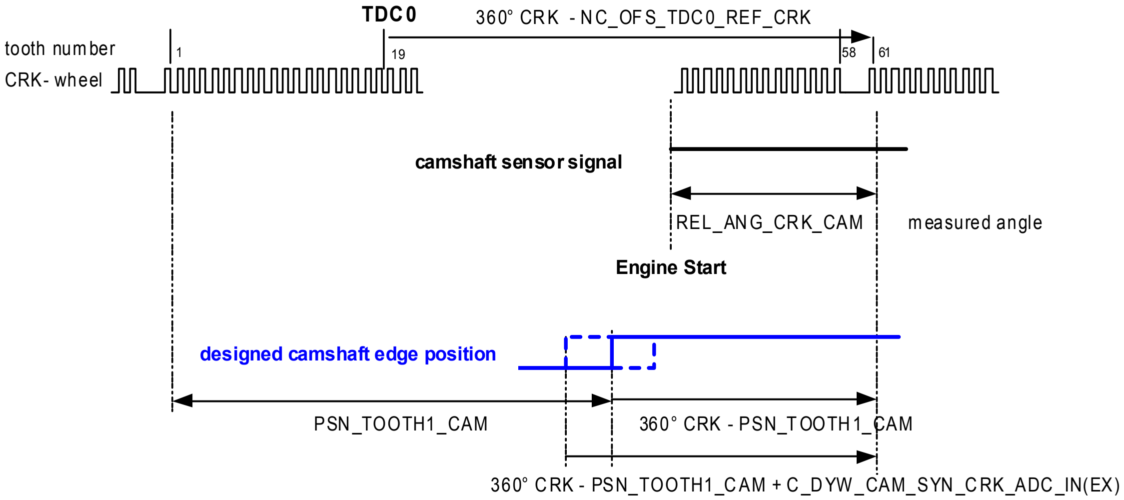


PSN_GAP = engine position offset for camshaft edge #z

```
If      PSN_CAM_CAM – CAM_DYW_SYN_IN(EX)
        < REL_ANG_CRK_CAM <
        PSN_CAM_CAM + CAM_DYW_SYN_IN(EX)
Then    PSN_ENG_CRK_OFS = PSN_GAP – 360° CRK
Else    Remove index z from list of possible camshaft signal edge indexes
Endif
```

Test 3:

First reference gap detected. No active camshaft edge occured before.



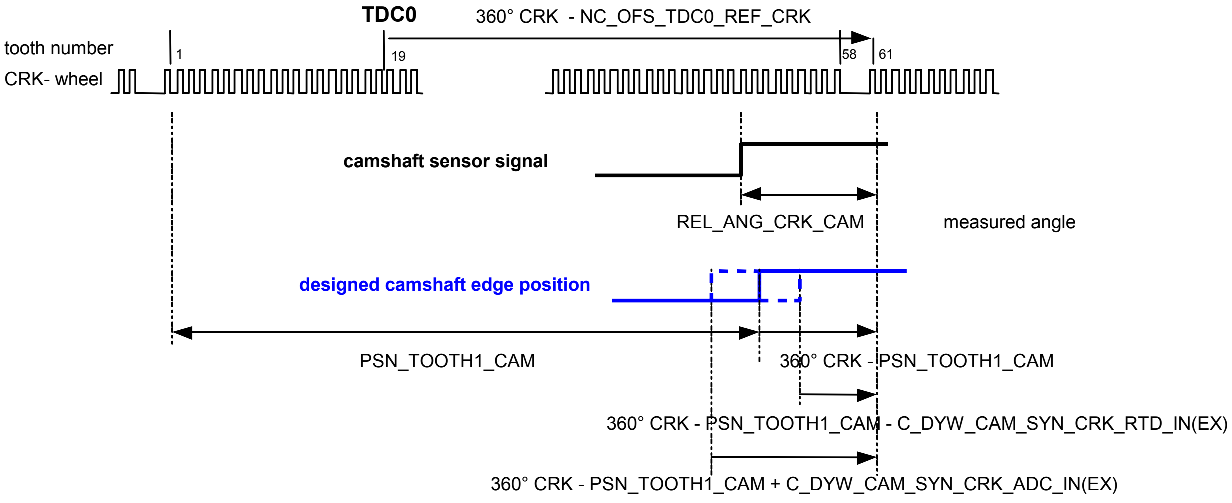
PSN_GAP = engine position offset for camshaft edge #z + 360° CRK / NC_NR_GAP

```
If      REL_ANG_CRK_CAM <
        PSN_GAP - PSN_TOOTH1_CAM +
        CAM_DYW_CRK_SYN_ADC_IN(EX)
        And
        REL_ANG_CRK_CAM < 360° CRK / NC_NR_GAP
Then      Engine position is PSN_GAP - NC_OFS_TDC0_REF_CRK
         PSN_ENG_CRK_OFS = PSN_GAP – 360° CRK
Else
        If      The camshaft edge can be found on both sides of
                the reference gap, it is not removed
                PSN_GAP - PSN_TOOTH1_CAM <
                CAM_DYW_CRK_SYN_RTD_IN(EX)
        Then
```

```
                Keep index z
            Else
                Remove index z from list of possible camshaft
                signal edge indexes
            Endif
    Endif
```

Test 4:

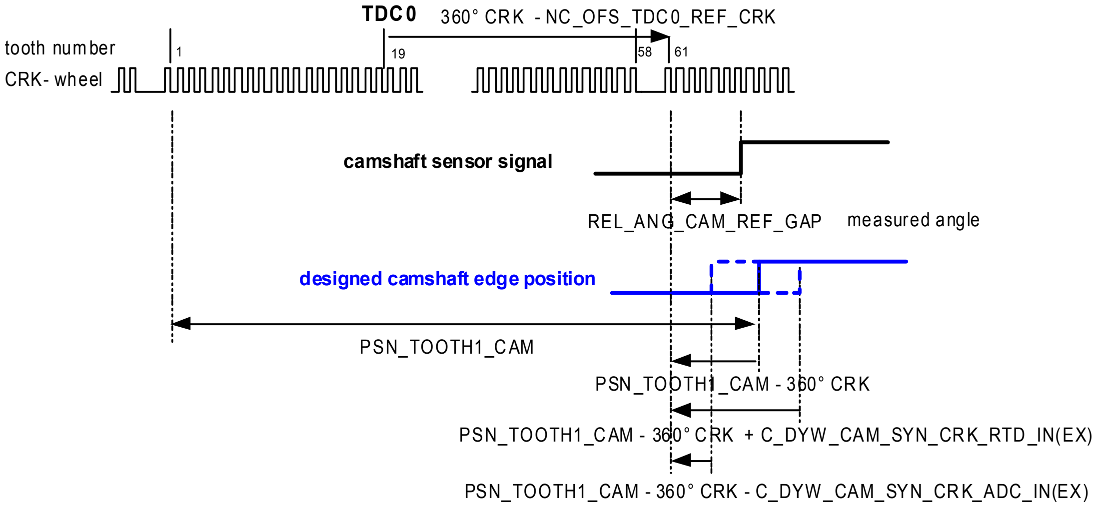
Reference gap detected. Last event was an active camshaft edge.



```
PSN_GAP = engine position offset for camshaft edge #z + 360° CRK / NC_NR_GAP
    If      PSN_GAP - PSN_TOOTH1_CAM –
            CAM_DYW_CRK_SYN_RTD_IN(EX)
            < REL_ANG_CRK_CAM <
            PSN_GAP - PSN_TOOTH1_CAM +
            CAM_DYW_CRK_SYN_ADC_IN(EX)
            And
            REL_ANG_CRK_CAM < 360° CRK / NC_NR_GAP
    Then
              Engine position is PSN_GAP - NC_OFS_TDC0_REF_CRK
             PSN_ENG_CRK_OFS = PSN_GAP – 360° CRK
    Else
            Remove index z from list of possible camshaft signal edge
            indexes
    Endif
```

Test 5:

Active camshaft edge detected. Last event was reference gap.



PSN_GAP = engine position offset for camshaft edge #z

If PSN_TOOTH1_CAM - PSN_GAP – CAM_DYW_CRK_SYN_ADC_IN(EX)
< REL_ANG_CAM_REF_GAP <
PSN_TOOTH1_CAM - PSN_GAP + CAM_DYW_CRK_SYN_RTD_IN(EX)

And

REL_ANG_CAM_REF_GAP < 360° CRK / NC_NR_GAP

Then *Engine position is PSN_GAP - NC_OFS_TDC0_REF_CRK*

PSN_ENG_CRK_OFS = PSN_GAP – 360° CRK

Else

Remove index z from list of possible camshaft signal edge indexes

Endif

Test 9:

Active camshaft edge detected. No active camshaft edge occured before.

This test is executed after test 1 only if no GAP occurred before CAM edge.

If an angular distance greater than the crank angle delay calibration has been measured without any new event, this test allows to eliminate the corresponding camshaft edges that should occur.

If NC_ACT_CAM_EDGE_SYN = 3 (both falling and rising edges used)

And C_CRK_ANG_DLY > 0

And REL_ANG_CRK_CAM >= C_CRK_ANG_DLY

```
                    And the cam edge z can not be seen on both sides of the reference gap
                    ((PSN_TOOTH1_CAM[z] - C_DYW_CAM_SYN_CRK_ADC_IN(EX)) modulo
                    (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z] +
                    C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo (360/NC_NR_GAP))
                    And the cam edge z-1 can not be seen on both sides of the reference gap
                    ((PSN_TOOTH1_CAM[z-1] - C_DYW_CAM_SYN_CRK_ADC_IN(EX))
                    modulo (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z-1] +
                    C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo (360/NC_NR_GAP))
        Then
                    If     REL_ANG_CRK_CAM <
                           PSN_TOOTH1_CAM modulo (360/NC_NR_GAP) +
                           CAM_DYW_CRK_SYN_RTD_IN(EX)
                    Then
                           Keep index z
                           Engine position range will be calculated in Pre-injection interface
                           computation after Cam edge function (Pre-inj action 2)
                    Else
                           Remove index z from list of possible camshaft signal edge indexes
                    Endif
        Else        (no operation)
        Endif
```

Test 10:

Crankshaft angle event detected. An active camshaft edge occurred before.

```
    If      C_CRK_ANG_DLY_LST_CAM > 0
    Then
        If          REL_ANG_CRK_CAM <
                    PSN_CAM_CAM_1 + CAM_DYW_SYN_IN(EX)

        Then        (No operation)
        Else        Remove index z from list of possible camshaft signal edge indexes
        Endif
```

On the remaining cam edges, after the first test has been performed on all edges:

PSN_GAP = engine position offset for camshaft edge #z

```
          If        The cam edge z can not be seen on both sides of the reference gap
                    ((PSN_TOOTH1_CAM[z] - C_DYW_CAM_SYN_CRK_ADC_IN(EX)) modulo
                    (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z] +
                    C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo (360/NC_NR_GAP))
          Then
                    If      REL_ANG_CRK_CAM <
                            (720 - PSN_TOOTH1_CAM) modulo (360/NC_NR_GAP) +
                            CAM_DYW_CRK_SYN_ADC_IN(EX)
                    Then    Keep index z
                            Engine position range will be calculated in Pre-injection interface
                            computation after Cam edge function (Pre-inj action 5)
                            Engine position is PSN_GAP - NC_OFS_TDC0_REF_CRK
                            PSN_ENG_CRK_OFS = PSN_GAP – 360° CRK
                    Else
                            Remove index z from list of possible camshaft signal edge indexes
                    Endif
          Else      No operation
          Endif
Else          No operation
Endif
```

Test 11:

Active camshaft edge detected. Last event was also an active camshaft edge.

This test is done after test 2. So we know that any Gap is between the two camshaft edge events. We can remove all indexes where a Gap is located between those and the previous cam edge.

On the remaining cam edges, after the first test has been performed on all edges:

```
          If        NC_ACT_CAM_EDGE_SYN = 3 (both falling and rising edges used)
                    And
                    The cam edge z can not be seen on both sides of the reference gap
                    ((PSN_TOOTH1_CAM[z] - C_DYW_CAM_SYN_CRK_ADC_IN(EX)) modulo
                    (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z] +
                    C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo (360/NC_NR_GAP))
                    And
                    The cam edge z-1 can not be seen on both sides of the reference gap
```

```
            ((PSN_TOOTH1_CAM[z-1] - C_DYW_CAM_SYN_CRK_ADC_IN(EX))
            modulo (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z-1] +
            C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo (360/NC_NR_GAP))
    Then
            If          PSN_TOOTH1_CAM[z-1] > PSN_TOOTH1_CAM[z]
                        Or
                        PSN_TOOTH1_CAM[z-1] < 360/NC_NR_GAP <
                        PSN_TOOTH1_CAM[z]
                        Or
                        PSN_TOOTH1_CAM[z-1] < 360 < PSN_TOOTH1_CAM[z]
                        Or
                        PSN_TOOTH1_CAM[z-1] < 360*(2-1/NC_NR_GAP) <
                        PSN_TOOTH1_CAM[z]
            Then
                        Remove index z
            Else
                        Keep index z
            Endif
    Endif
```

Test 12:

This test is executed on Gap after the test 3 or 4.

On the remaining cam edges, has been performed on all edges:

```
            If          NC_ACT_CAM_EDGE_SYN = 3 (both falling and rising edges
                        used)
                        And
                        The cam edge z can not be seen on both sides of the reference
                        gap
                        ((PSN_TOOTH1_CAM[z] -
                        C_DYW_CAM_SYN_CRK_ADC_IN(EX)) modulo
                        (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z] +
                        C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo
                        (360/NC_NR_GAP))
                        And
                        The cam edge z+1 can not be seen on both sides of the
                        reference gap
                        ((PSN_TOOTH1_CAM[z+1] -
                        C_DYW_CAM_SYN_CRK_ADC_IN(EX)) modulo
```

```
          (360/NC_NR_GAP)) < ((PSN_TOOTH1_CAM[z+1] +
          C_DYW_CAM_SYN_CRK_RTD_IN(EX)) modulo
          (360/NC_NR_GAP))
Then
          If        PSN_TOOTH1_CAM[z] >
                    PSN_TOOTH1_CAM[z+1]
                    Or
                    PSN_TOOTH1_CAM[z] < 360/NC_NR_GAP <
                    PSN_TOOTH1_CAM[z+1]
                    Or
                    PSN_TOOTH1_CAM[z] < 360 <
                    PSN_TOOTH1_CAM[z+1]
                    Or
                    PSN_TOOTH1_CAM[z] < 360*(2-
                    1/NC_NR_GAP) < PSN_TOOTH1_CAM[z+1]
          Then
                    Keep index z
          Else
                    Remove index z
          Endif
Endif
```

23.5.4.6 Cam/crk synchronization validation function ()

General information:

The purpose of this function is to check the angular distance between cam/crk events. The function returns false is the active camshaft signal edge z is outside the defined tolerance window.

i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN(EX)

Application conditions:

Recurrence:	every falling camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 1
	every rising camshaft signal edge and every reference gap if NC_ACT_CAM_EDGE_SYN = 2
	every camshaft signal edge (rising and falling) and every reference gap if NC_ACT_CAM_EDGE_SYN = 3

Formula section:

```
If      active camshaft signal edge
Then    If      NC_ACT_CAM_EDGE_SYN = 3
        Then    Increment indexes in the list of possible camshaft signal index by 1
                modulo NC_NR_EDGE_CAM_IN(EX)
        Else    Increment by 2 indexes in the list of possible camshaft signal index by 2
                modulo NC_NR_EDGE_CAM_IN(EX)
Endif
```

Calculate theoretical angular distance between crankshaft tooth #1 and camshaft edge #z:

```
    PSN_TOOTH1_CAM = NC_OFS_TDC0_REF_CRK +
            NC_PSN_EDGE_CAM_IN(EX)[z][i]
```

Calculate theoretical angular distance between two successive active camshaft edges:

```
If      NC_ACT_CAM_EDGE_SYN = 3
Then    Falling and rising camshaft edges
        PSN_CAM_CAM = NC_PSN_EDGE_CAM_IN(EX)[z][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z-1][i]
Else    Only Falling or only rising camshaft edges
        PSN_CAM_CAM = NC_PSN_EDGE_CAM_IN(EX)[z][i] –
                NC_PSN_EDGE_CAM_IN(EX)[z-2][i]
Endif
```

The following table shows the actions to perform in function of the current (n) and last event (n-1).

The event is a detection of a active camshaft signal edge for synchronization (CAM) or a detection of reference gap (GAP). Tests and edge elimination shall only be performed on active camshaft signal edges with current value of REL_ANG_CRK_CAM.

Event (n)	CAM	GAP	CAM	GAP
Event (n-1)	CAM	CAM	GAP	GAP
Test	Test 6	Test 7	Test 8	(*)

(*) No Camshaft index can be identified (All remaining indexes shall be removed)

Test 6:

Active camshaft edge detected. Last event was also a active camshaft edge.

```
If      PSN_CAM_CAM – CAM_DYW_SYN_IN(EX)
        < REL_ANG_CRK_CAM <
        PSN_CAM_CAM + CAM_DYW_SYN_IN(EX)
Then    camshaft signal edge is valid
        return (true)
Else    Invalid camshaft signal edge, synchronization validation failed
        return (false)
Endif
```

Test 7:

Reference gap detected. Last event was a active camshaft signal edge.

PSN_GAP = current engine position offset

```
If      PSN_GAP - PSN_TOOTH1_CAM – CAM_DYW_CRK_SYN_RTD_IN(EX)
        < REL_ANG_CRK_CAM <
        PSN_GAP - PSN_TOOTH1_CAM + CAM_DYW_CRK_SYN_ADC_IN(EX)
        And
        REL_ANG_CRK_CAM <= 360° CRK / NC_NR_GAP
        Then    camshaft signal edge is valid
                return (true)
        Else    Invalid camshaft signal edge
                return (false)
```

```
Endif
```

Test 8:

Active camshaft signal edge detected. Last event was a reference gap.

```
PSN_GAP = current engine position offset
If      PSN_TOOTH1_CAM - PSN_GAP – CAM_DYW_CRK_SYN_ADC_IN(EX)
        < REL_ANG_CAM_REF_GAP <
        PSN_TOOTH1_CAM - PSN_GAP + CAM_DYW_CRK_SYN_RTD_IN(EX)
        And
        REL_ANG_CAM_REF_GAP <= 360° CRK / NC_NR_GAP
        Then    camshaft signal edge is valid
                return (true)
        Else    Invalid camshaft signal edge
                return (false)
Endif
```

23.5.4.7 Pre-injection interface computation before Cam edge function ()

General information:

A truth table is used in order to define the possible engine position.

Application conditions:

Recurrence : every crankshaft edge (CRK) or every reference gap (GAP)

Formula section:

Event (n)	CRK	GAP
Pre-inj Action	1	2

Pre-inj Action 1

PSN_ENG_SYN_CAM_MIN n = **PSN_ENG_SYN_CAM_MIN** n-1 + 360°/NC_NR_TOOTH

PSN_ENG_SYN_CAM_MAX n = **PSN_ENG_SYN_CAM_MAX** n-1

Pre-inj Action 2

PSN_ENG_SYN_CAM_MIN n = **PSN_ENG_SYN_CAM_MIN** n-1 + (NC_NR_TOOTH_GAP+1)* 360°/NC_NR_TOOTH

PSN_ENG_SYN_CAM_MAX n = **PSN_ENG_SYN_CAM_MAX** n-1

23.5.4.8 Pre-injection interface computation after Cam edge function ()

General information:

A truth table is used in order to define the possible engine position.

Application conditions:

Recurrence:	every falling camshaft signal edge (CAM), every reference gap (GAP) or every active crankshaft edge (CRK) if NC_ACT_CAM_EDGE_SYN = 1
	every rising camshaft signal (CAM), every reference gap (GAP) or every active crankshaft edge(CRK) if NC_ACT_CAM_EDGE_SYN = 2
	every falling and rising camshaft signal edge (CAM), every reference gap (GAP) or every active crankshaft edge (CRK) if NC_ACT_CAM_EDGE_SYN = 3

Formula section:

Event (n)	CRK	CRK	CAM	GAP	GAP	CRK-Angle
Event (n-1)	CRK	CAM	CRK	CRK	CAM	CRK
Pre-inj Action	1	1	2	3	4	5

Pre-inj Action 1

PSN_ENG_SYN_CAM_MIN n = **PSN_ENG_SYN_CAM_MIN** n-1 + 360°/NC_NR_TOOTH

PSN_ENG_SYN_CAM_MAX n = **PSN_ENG_SYN_CAM_MAX** n-1 + 360°/NC_NR_TOOTH

Pre-inj Action 2

PSN_ENG_SYN_CAM_MIN = NC_PSN_EDGE_CAM_IN(EX)[z][i] – CAM_DYW_SYN_IN(EX)

for the lowest possible signal edge index z

PSN_ENG_SYN_CAM_MAX = NC_PSN_EDGE_CAM_IN(EX)[z][i] + CAM_DYW_SYN_IN(EX)

for the highest possible signal edge index z

Note: The possible signal edges z are determined by checking the conditions of “Camshaft Edge Index determination function()”. This function must be executed before action 2.

Pre-inj Action 3

PSN_ENG_SYN_CAM_MIN n = **PSN_ENG_SYN_CAM_MIN** n-1 + (NC_NR_TOOTH_GAP+1)* 360°/NC_NR_TOOTH

PSN_ENG_SYN_CAM_MAX n = **PSN_ENG_SYN_CAM_MAX** n-1 + (NC_NR_TOOTH_GAP+1)* 360°/NC_NR_TOOTH

Pre-inj Action 4

A camshaft edge has occured during the reference gap (when the camshaft edge is detected Pre-inj Action 2 is performed and when the first crankshaft edge after the reference is detected Pre-inj Action 4 is performed)

PSN_ENG_SYN_CAM_MIN n = **PSN_ENG_SYN_CAM_MIN** n-1 + **REL_ANG_CRK_CAM**

PSN_ENG_SYN_CAM_MAX n = **PSN_ENG_SYN_CAM_MAX** n-1 + **REL_ANG_CRK_CAM**

Pre-inj Action 5

A crank-angle event has occurred. A precise calculation of the engine position for pre-injection is possible.

PSN_ENG_SYN_CAM_MIN = NC_PSN_EDGE_CAM_IN(EX)[z][i] – CAM_DYW_SYN_IN(EX) + REL_ANG_CRK_CAM

for the lowest possible signal edge index z

PSN_ENG_SYN_CAM_MAX = NC_PSN_EDGE_CAM_IN(EX)[z][i] + CAM_DYW_SYN_IN(EX) + REL_ANG_CRK_CAM

for the highest possible signal edge index z

Note: The possible signal edge z is determined by checking the conditions of “Camshaft Edge Index determination function()”. This function must be executed before action 5.

23.5.4.9 VVT lock check function ()

General information:

The purpose of this function is to check the VVT lock position flag and to extend the cam/crk tolerance windows if the VVT is not in locked position at engine start.

Application conditions:

Recurrence: at transition of LV_STOP_ENG from 0 to 1

Or

Reset ECU

Formula section:

If LV_CAM_LOCK_IVVT_IN(EX)[i] = 0 for the camshaft sensor selected for cam/crk synchronization

And

```
        NLC_IVVT_IN(EX) = 1
Then    VVT not in locked position at engine start
        CAM_DYW_SYN_IN = C_DYW_CAM_SYN_IN + C_CAM_ADJ_VVT_SYN_IN
        CAM_DYW_SYN_EX = C_DYW_CAM_SYN_EX + C_CAM_ADJ_VVT_SYN_EX
        CAM_DYW_CRK_SYN_ADC_IN = C_DYW_CAM_CRK_SYN_ADC_IN + C_CAM_ADJ_VVT_SYN_CRK_ADC_IN
        CAM_DYW_CRK_SYN_ADC_EX = C_DYW_CAM_CRK_SYN_ADC_EX
        CAM_DYW_CRK_SYN_RTD_IN = C_DYW_CAM_CRK_SYN_RTD_IN
        CAM_DYW_CRK_SYN_RTD_EX = C_DYW_CAM_CRK_SYN_RTD_EX + C_CAM_ADJ_VVT_SYN_CRK_RTD_EX
Else
        VVT in locked position at engine start or no VVT at all
        CAM_DYW_SYN_IN = C_DYW_CAM_SYN_IN
        CAM_DYW_SYN_EX = C_DYW_CAM_SYN_EX
        CAM_DYW_CRK_SYN_ADC_IN = C_DYW_CAM_CRK_SYN_ADC_IN
        CAM_DYW_CRK_SYN_ADC_EX = C_DYW_CAM_CRK_SYN_ADC_EX
        CAM_DYW_CRK_SYN_RTD_IN = C_DYW_CAM_CRK_SYN_RTD_IN
        CAM_DYW_CRK_SYN_RTD_EX = C_DYW_CAM_CRK_SYN_RTD_EX
Endif
```

23.5.5 Requirements to Infrastructure

23.5.5.1 Camshaft segment period measurement

General information:

System request accuracy <= 4 us

The camshaft segment period T_SEG_CAM_IN(EX)[i] is the measured time between two consecutive valid camshaft signal edges.

23.5.5.2 Measurement of angular distance to active camshaft edge

General information:

The purpose of this function is to provide a measurement for

- the angular distance between the first valid crankshaft teeth and the first active camshaft edge
- the angular distance between two consecutive valid active camshaft signal edges

Only active camshaft signal edges shall be processed. The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Application conditions:

Recurrence: every active camshaft edge and every active crankshaft edge.

Formula section:

```
If      LV_CRK_FIRST_VLD_TOOTH = 0
Then    REL_ANG_CRK_CAM = 0
Else    If      active camshaft signal edge
        Then    REL_ANG_CRK_CAM = 0
        Else    If      active crankshaft signal edge or after missing tooth simulation
                Then    REL_ANG_CRK_CAM = REL_ANG_CRK_CAM +
                                  (360° CRK  / NC_NR_TOOTH)
                Else    REL_ANG_CRK_CAM is frozen
                Endif
        Endif
Endif
```

23.5.5.3 Measurement of angular distance from reference gap to active camshaft edge

General information:

The purpose of this function is to provide a measurement for

- the angular distance between a crankshaft reference gap and a active camshaft signal edge

Application conditions:

Recurrence: every active crankshaft signal edge

Formula section:

```
If      Reference Gap is detected
Then    REL_ANG_CAM_REF_GAP = 0
Else    If      crank active edge
        Then    REL_ANG_CAM_REF_GAP = REL_ANG_CAM_REF_GAP +
                                  (360° CRK / NC_NR_TOOTH)
        Else    REL_ANG_CAM_REF_GAP is frozen
        Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_NR_EDGE_MIN_VLD_CAM_IN	1	0...FFH	0...255	1	[-]
Number of intake camshaft signal edges for valid position output					
C_NR_EDGE_MIN_VLD_CAM_EX	1	0...FFH	0...255	1	[-]
Number of exhaust camshaft signal edges for valid position output

23.6 Engine speed signal output “TD”

FUNCTION DESCRIPTION:

The engine speed signal TD is a tooth-fixed event at the ECU Pin A_F_TD. The signal is set to ‘high’ at the teeth 1, 21, 41, 61, 81, 101 and reset to ‘low’ at the teeth 11, 31, 51, 71, 91, 111. This means: falling edge at every TDC, rising edge at every BDC (of any cylinder).
The artificially generated teeth are used in the CAM limp home. Since the cylinder group assignment is not decisive for the output of the TD signal, the CRK limp home has no influence on the output of the TD signal.

Initialisation :

The output signal is initialised with a low logic state (0).

23.7 Requirements to Infrastructure Interface for partial segment time acquisition

Export actions:

ACTION_INFR_EnableT5T()
This action activates segment time acquisition for 5 teeth- segments
ACTION_INFR_DisableT5T()
This action deactivates segment time acquisition for 5 teeth- segments
ACTION_INFR_GetT5T(IN <idx>, **OUT** <time>**)**
Acquisition of partial segment time over 5 teeth
ACTION_INFR_GetT5TDiag(OUT <diag**>)**
Diagnostic information for acquisition of 5-teeth- segments

Description for actions:

ACTION_INFR_EnableT5T()					
This action activates segment time acquisition for 5 teeth- segments					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

ACTION_INFR_DisableT5T()					
This action deactivates segment time acquisition for 5 teeth- segments					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit

ACTION_INFR_GetT5T(IN <idx>, **OUT** <time>**)**					
Signal acquisition for 5 teeth- segments					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
idx	IN	0…18H	0...23	1	[-]
Index of the array of measured partial segment time					
time	OUT	0…FFFFH	0...65,535	0,001	ms
Measured partial segment time over 5 teeth					

ACTION_INFR_GetT5T_Diag(diag**)**					
Diagnostic information for acquisition of 5-teeth- segments					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
diag	OUT	0…1H	0...1	1	[-]
Diagnostic for partial segment time acquisition, set to 1 when buffer content is valid					

General information:

The function shall sample a time stamp every 5 teeth and calculate the difference of the actual and the last time stamp. The result is stored in a buffer with 24 values. The return value of ACTION_INFR_GetT5T(idx,time) is the time from the indexed cell of the array.

Acquisition shall start at TDC cylinder 0. Values are written to the appropriate location of the array (e.g., the first partial segment time measured after TDC 0 is written to the first location of the array).
In case of overflow (below approx. 80rpm), the measured segment time is limited to the maximum value.
When enabling or disabling action is called, all buffer values are set to maximum value.
A diagnostic action delivers information about validity of the buffer contents. The return value is 0 after enabling as long as buffer content is not valid, and changes to one as soon as the buffer is ready to be read out. Buffer content is regarded as valid as soon as all 24 values in the buffer are filled.

Requirements for ACTION_INFR_EnableT5T:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

Diagnosis:

Coincidence requirements:

Requirements for ACTION_INFR_DisableT5T:

Diag	1		1		

Diagnosis: no diagnosis done here

Coincidence requirements: end of acquisition for the buffer (all 24 values filled)

23.8 AGGR ENSD adaptation: Engine Position and Speed Determination

23.8.1 Outputs for SV functions

23.8.1.1 Generation of N_TOOTH

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
N_TOOTH_CUS	O/V	0...1FE0H	0...8160	1	[rpm]
fast engine speed generated especially for engine start (independently of C_N_FAST_SWI)					

Input data:

LV_RUN_ENG	N_32	C_N_TOOTH_END	NC_NR_TOOTH
T_TOOTH			

FUNCTION DESCRIPTION:

Description:

As there is a strong request for a fast engine speed especially for engine start, and ENSD solely has the possibility to generate one out of four (N_FAST can either be similar to N_TOOTH or three differently calculated N_FASTs – see “engine position and speed calculation”), N_TOOTH has to be calculated additionally in this module.

Application conditions:

Initialisation: N_TOOTH_CUS = 0

Recurrence: 10ms

Activation: LV_RUN_ENG = 1 **and**

$N\_32 \le C\_N\_TOOTH\_END$

Deactivation: LV_RUN_ENG = 0 **or**

$N\_32 > C\_N\_TOOTH\_END$

Formula section:

N_TOOTH_CUS (phys) = 60 / (NC_NR_TOOTH * T_TOOTH)

23.8.1.2 Generation of LV_ERR_CAM_CUS

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_CAM_CUS	V/O	0...1H	0...1	1	[-]
Customer specific CAM error					

Input data:

LV_ERR_CAM_TOT			

Description:

LV_ERR_CAM_CUS is for customer specific adaptations on the ENSD interface LV_ERR_CAM_TOT.

Application conditions:

Initialisation: LV_ERR_CAM_CUS = 0 at reset, LV_IGK 0->1 and clearance of failurememory

Recurrence: every Camshaft signal edge (just after calculation of all CAM diagnosis)

Activation: every engine operating state

Formula section:

LV_ERR_CAM_CUS = LV_ERR_CAM_TOT

23.9 Segment time acquisition for partial segments

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_T_SEG_5_TOOTH_VLD	V/O	0...1H	0...1	1	[-]
Flag: acquisition of partial segment times valid					
LV_T_SEG_5_TOOTH_ACT	-	0...1H	0...1	1	[-]
Flag: acquisition of partial segment times active					

Input data:

N_32			

Import actions:

ACTION_INFR_EnableT5T()
This action activates segment time acquisition for 5 teeth- segments
ACTION_INFR_DisableT5T()
This action deactivates segment time acquisition for 5 teeth- segments
ACTION_INFR_GetT5TDiag(OUT <diag**>)**
Diagnostic information for acquisition of 5-teeth- segments

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_32_MAX_SEG_5_TOOTH	1	0...FFH	0...8160	32	[rpm]
Maximum engine speed for acquisition of partial segment time over 5 teet					

FUNCTION DESCRIPTION:

General information:

The function shall measure the period for segments of 5 teeth, and output the result as an array of 24 values for the whole engine cycle.

Acquisition shall start at regular segment event for cylinder 0 (SEG_NR = 0). Every 5 teeth a time stamp shall be sampled, the period calculated as the difference of the actual and the last time stamp, and written to the array of temporary values at the appropriate location (e.g., the first partial segment time measured after start of regular segment 0 is written to the first location of the array).

Application conditions:

Activation: at ENG_STOP to SYN_ENG_IGK_ON
or RUN_ENG to SYN_ENG_IGK_ON

Deactivation : at SYN_ENG_IGK_ON to RUN_ENG (if supported by ECOP)
or SYN_ENG_IGK_ON to ENG_STOP
or SYN_ENG_IGK_OFF to PWL :
ACTION_INFR_DisableT5T()
LV_T_SEG_5_TOOTH_VLD = 0

LV_T_SEG_5_TOOTH_ACT = 0

Initialization : at reset :

LV_T_SEG_5_TOOTH_VLD = 0

LV_T_SEG_5_TOOTH_ACT = 0

Recurrence:

segment

Formula section:

```
If(1)       N_32 <= C_N_32_MAX_SEG_5_TOOTH
Then(1)
            If(2)       ( LV_T_SEG_5_TOOTH_ACT =  0)
            Then(2)     ACTION_INFR_EnableT5T()
                        LV_T_SEG_5_TOOTH_ACT = 1
            Endif(2)
              get diagnostic information from infrastructure
            ACTION_INFR_GetT5TDiag(
                        OUT          LV_T_SEG_5_TOOTH_VLD)
Else (1)
            If(3) ( LV_T_SEG_5_TOOTH_ACT =  1)
            Then(3)    ACTION_INFR_DisableT5T()
                         LV_T_SEG_5_TOOTH_ACT = 0
                         LV_T_SEG_5_TOOTH_VLD = 0
            Endif(3)
Endif(1)
```

FUNCTION DESCRIPTION:

General information:

The Engine Position Manager provides a summary of camshaft and crankshaft synchronization status information to the system. It sets the operating modes of camshaft and crankshaft acquisition depending on synchronization status, availability, and detected failures. The signal source for engine position will be selected based on the activated operating mode.

Camshaft and crankshaft signal acquisition will be set passive for a calibrated delay after key-off has been detected at low engine speed, and for another calibrated delay after a loss of synchronization at low engine speed. This avoids wrong injection, ignition and diagnosis with backward rotation after rapid key-off/on or stalling.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Engine synchronized (LV_SYN_ENG)	Yes (LV_SYN_ENG = 1)	No (LV_SYN_ENG = 0)
Crankshaft sensor available (LV_ERR_CRK = 0) At least one camshaft sensor available (LV_ERR_CAM = 0)	Standard Mode: Engine position and speed calculation with crankshaft sensor signal	Standard Mode Engine synchronisation with camshaft and crankshaft sensor information

Activation of Camshaft self-synchronisation reactivation ()
Activation of engine stop detection ()

If      LV_RUN_ENG = 1
Then    Activation of engine speed calculation
Endif

On 0 to 1 transition of LV_CAM_SYN_CRK:
    If          LV_ERR_CAM_IN(EX)[i] = 0
                For all available camshaft sensors
    Then        Activation of fast synchronization ()
    Else        Activation of slow synchronization ()
    Endif
```

Transition action:

To state 4: LV_CRK_MISS_RUN_ENG = 0

Stop timer C_T_DLY_STOP_ENG

State 4 : Engine Position Standard Mode

Engine position and speed calculation with crankshaft sensor signal.

Input conditions:

From state 3: LV_SYN_ENG = 1

Output conditions:

To state 0: LV_STOP_ENG = 1

Action in the state:

```
Reactivation of Camshaft self-synchronisation ()
Activation of engine position calculation standard mode ()
Activation of segment period calculation ()
Activation of speed gradient calculation ()
Activation of crankshaft sensor phase angle correction ()
Activation of engine stop detection ()

If     LV_SYN_VLD = 1
Then   Activation of Camshaft adaptation and position output ()
Endif
Activation of Engine backwards rotation detection ()
```

Transition action:

To state 0:

```
If     C_T_DLY_STOP_ENG > 0
       And LV_IGK = 1
       And LV_CRK_MISS_RUN_ENG = 0
Then   LV_CRK_MISS_RUN_ENG = 1
              Start timer C_T_DLY_STOP_ENG
       Reset LV_CRK_MISS_RUN_ENG after timer has elapsed
Endif
```

State 5 : Synchronisation Crankshaft Limp-Home Mode

Engine synchronisation without crankshaft sensor signal.

Input conditions:

From state 2: LV_LIH_ERR_CRK = 1

And

LV_ERR_CRK = 1

Output conditions:

To state 0: LV_STOP_ENG = 1

Or

LV_IGK = 0

Or

LV_ERR_LIH_CRK_CAM = 1

To state 6: LV_SYN_ENG=1

Action in the state:

Activation of crankshaft limp-home synchronization() for the selected camshaft signal

Activation of calculation of PSN_ENG_CAM_LIH_CRK()

Activation of engine position calculation crankshaft limp-home mode

Reactivation of Camshaft self-synchronisation ()

Activation of engine stop detection ()

```
If    LV_RUN_ENG = 1
Then  Activation of engine speed calculation
      Endif
```

Transition action:

To state 6: LV_CRK_MISS_RUN_ENG = 0

Stop timer C_T_DLY_STOP_ENG

State 6 : Engine Position Crankshaft Limp-Home Mode

Engine position and speed calculation without crankshaft sensor signal.

Input conditions:

From state 5: LV_SYN_ENG = 1

Output conditions:

To state 0: LV_STOP_ENG = 1

Action in the state:

Activation of engine position calculation crankshaft limp-home mode

Activation of Camshaft self-synchronisation reactivation ()

Activation of segment period calculation

Activation of speed gradient calculation

Activation of engine stop detection ()

Transition action:

To state 0:

```
If      C_T_DLY_STOP_ENG > 0
        And LV_IGK = 1
        And LV_CRK_MISS_RUN_ENG = 0
Then    LV_CRK_MISS_RUN_ENG = 1
                Start timer C_T_DLY_STOP_ENG
        Reset LV_CRK_MISS_RUN_ENG after timer has elapsed
Endif
```

State 7 : Synchronisation Camshaft Limp-Home Mode

Engine synchronisation without camshaft sensor signal.

Input conditions:

From state 2: LV_LIH_ERR_CAM = 1

Output conditions:

To state 0: LV_STOP_ENG = 1
Or
LV_IGK = 0

To state 8: LV_SYN_ENG = 1

Action in the state:

Activation of camshaft limp-home synchronization()

LV_FIRST_VLD_TOOTH = LV_CRK_FIRST_VLD_TOOTH

LV_RUN_ENG = LV_CRK_RUN

Activation of calculation of PSN_ENG_CRK in camshaft limp-home mode()

Activation of engine position calculation standard mode

Activation of engine stop detection ()

If LV_RUN_ENG = 1

Then Activation of engine speed calculation

Endif

Transition action:

To state 8: LV_CRK_MISS_RUN_ENG = 0

Stop timer C_T_DLY_STOP_ENG

State 8 : Engine Position Camshaft Limp-Home Mode

Engine position and speed calculation without camshaft sensor signal.

Input conditions:

From state 7: LV_SYN_ENG = 1

Output conditions:

To state 0: LV_STOP_ENG = 1

Action in the state:

Activation of Synchronization determination in camshaft limp home()

Activation of Synchronization validation in camshaft limp home()

Reactivation of Camshaft self-synchronisation ()

Activation of PSN_ENG_CRK correction in camshaft limp home()

Activation of engine position calculation standard mode

Activation of segment period calculation

Activation of segment number correction in camshaft limp home()

Activation of speed gradient calculation

Activation of crankshaft sensor phase angle correction

Activation of engine stop detection ()

Activation of Engine backwards rotation detection ()

Transition action:

```
To state 0:    If     C_T_DLY_STOP_ENG > 0
                      And LV_IGK = 1
                      And LV_CRK_MISS_RUN_ENG = 0
               Then   LV_CRK_MISS_RUN_ENG = 1
                          Start timer C_T_DLY_STOP_ENG
                      Reset LV_CRK_MISS_RUN_ENG after timer has elapsed
               Endif
```

23.10.2 Definition of the sub-function tasks

23.10.2.1 Fast Engine synchronization

General information:

Fast engine synchronization is in charge to synchronize as soon as the crankshaft signal acquisition is synchronized and a camshaft signal information is available on the selected camshaft.

Application conditions:

Recurrence: on 0 to 1 transition of LV_CAM_SYN_CRK

Formula section:

```
If      LV_CAM_SYN_CRK = 1
Then    LV_SYN_ENG = 1
Endif
```

23.10.2.2 Slow Engine synchronization

General information:

Slow engine synchronization is activated when a failure was detected on at least one camshaft sensor. The engine is synchronized as soon as a number of calibratable camshaft edges has occured (engine synchronized when synchronization is validated). This avoids multiple injection and ignition events with wrong synchronization.

Application conditions:

Recurrence: at every active camshaft edge and on 0 to 1 transition of LV_CAM_SYN_CRK

The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Formula section:

The engine speed value used to calculate NR_VLD_CAM_SYN_CRK is the one determined at transition from 0 to 1 of LV_CAM_SYN_CRK (see § Synchronization validation)

```
If      LV_CAM_SYN_CRK = 1
```

```
Then    If      CTR_VLD_CAM_SYN_CRK > NR_VLD_CAM_SYN_CRK
        Then    LV_SYN_ENG = 1
        Endif
Endif
```

Remark: CTR_VLD_CAM_SYN_CRK is incremented in "synchronization validation ()" function

23.10.2.3 Crankshaft limp-home synchronization

General information:

Only the informations of the selected camshaft signal is used to perform the engine synchronization.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: at every camshaft edge

Formula section:

```
If      LV_SYN_CAM_IN(EX)[i] = 1 for the selected camshaft signal
Then    LV_FIRST_VLD_TOOTH = 1
        LV_RUN_ENG = 1
        LV_SYN_ENG = 1
Endif
```

23.10.2.4 Camshaft limp-home synchronization

General information:

No camshaft signals are available for the Crank/Cam synchronization so the engine synchronization is performed as soon as the crankshaft is synchronized (the engine revolution can not be identified so a default value is used).

Application conditions:

Recurrence: at every reference gap

Formula section:

```
If      LV_CRK_SYN = 1
Then    LV_SYN_ENG = 1
Endif
```

23.10.2.5 Synchronisation validation

General information:

Synchronisation is validated as soon as a number of calibratable camshaft edges has occured. During validation phase, the angular distance between cam/crk events is checked. Engine synchronisation is reset if one of the tests fails.
i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: *at every active camshaft edge and on 0 to 1 transition of LV_CAM_SYN_CRK as long as LV_SYN_VLD = 0*

The active camshaft edge for synchronization is defined by NC_ACT_CAM_EDGE_SYN.

Formula section:

At transition from 0 to 1 of LV_CAM_SYN_CRK, NR_VLD_CAM_SYN_CRK = ID_NR_VLD_CAM_SYN_CRK.

Increment CTR_VLD_CAM_SYN_CRK

```
If      LV_CAM_SYN_CRK = 1
Then    If      CTR_VLD_CAM_SYN_CRK > NR_VLD_CAM_SYN_CRK
        Then    LV_SYN_VLD = 1
                Deactivation of Camshaft/Crankshaft synchronisation for the camshaft
                signal selected for this synchronization:
                LV_ACT_SYN_CRK_CAM_IN(EX)[i] = 0
        Endif
Endif
```

23.10.2.6 Synchronisation validation in camshaft limp home

General information:

Synchronization validation information is set as soon as it is requested by “Synchronization determination in camshaft limp home” module which is then deactivated.

Application conditions:

Initialisation: none

Recurrence: each segment event

Formula section:

```
If      LV_SYN_VLD_CAM_LIH = 1
Then    LV_SYN_VLD = 1
        Deactivation of Synchronization determination in camshaft limp home()
End if
```

23.10.2.7 Camshaft Selection for synchronisation

General information:

Target wheels on intake and exhaust camshafts may be different, and all may be useable for synchronization. A camshaft signal can only be selected if no error is detected on the respective camshaft (LV_ERR_CAM_IN(EX)[i] = 0). For port-injection engines activation of synchronization mode on intake camshafts should be preferred. Pre-injection needs to be synchronized with intake timing, and the engine position for pre-injection is calculated from the synchronization signal.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Formula section:

The selection order is given by the following table:

	NC_PRI_SYN_CAM_CBK = 1	NC_PRI_SYN_CAM_CBK = 2
NC_PRI_SYN_CAM_IN = 0	CAM_EX_1 CAM_EX_2 CAM_IN_1 CAM_IN_2	CAM_EX_2 CAM_EX_1 CAM_IN_2 CAM_IN_1
NC_PRI_SYN_CAM_IN = 1	CAM_IN_1 CAM_IN_2 CAM_EX_1 CAM_EX_2	CAM_IN_2 CAM_IN_1 CAM_EX_2 CAM_EX_1

The first camshaft sensor in the above list which fulfills the following conditions is selected:

- physically present in the system (configuration data NLC_CAM_IN, NLC_CAM_EX and NC_NR_CAM_CBK)
- no failure reported on it (LV_ERR_CAM_IN(EX)[i] = 0)

The crankshaft synchronization mode is activated on one camshaft signal by setting LV_ACT_SYN_CRK_CAM_IN(EX)[i] for the selected camshaft.

LV_ERR_CAM is set if all available camshaft sensors report and error.

23.10.2.8 Camshaft Selection for limp-home

General information:

Target wheels on intake and exhaust camshafts may be different, and not all may be useable for limp-home. The availability of camshaft sensors for limp-home is given by NLC_LIH_CAM_IN(EX) and NC_NR_CAM_CBK. A camshaft signal can only be selected if no error is detected on the respective camshaft (LV_ERR_CAM_IN(EX)[i] = 0).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Formula section:

The selection order is given by the following table:

	NC_PRI_LIH_CAM_CBK = 1	NC_PRI_LIH_CAM_CBK = 2
NC_PRI_LIH_CAM_IN = 0	CAM_EX_1 CAM_EX_2 CAM_IN_1 CAM_IN_2	CAM_EX_2 CAM_EX_1 CAM_IN_2 CAM_IN_1
NC_PRI_LIH_CAM_IN = 1	CAM_IN_1 CAM_IN_2 CAM_EX_1 CAM_EX_2	CAM_IN_2 CAM_IN_1 CAM_EX_2 CAM_EX_1

The first camshaft sensor in the above list which fulfills the following conditions is selected:

- physically present in the system (configuration data NLC_CAM_IN, NLC_CAM_EX_IN and NC_NR_CAM_CBK)
- no failure reported on it (LV_ERR_CAM_IN(EX)[i] = 0)
- available for crankshaft limp-home (NLC_LIH_CAM_IN = 1 or NLC_LIH_CAM_EX = 1)

The crankshaft limp-home mode is activated on one camshaft signal by setting LV_ACT_LIH_CRK_CAM_IN(EX)[i] for the selected camshaft.

LV_ERR_LIH_CRK_CAM is set if no more camshaft sensors is available.

23.10.2.9 Engine stop detection

Application conditions:

Recurrence: 10ms

Formula section:

LV_STOP_ENG is set if one of the conditions in the table below are met:

In Standard mode (States 3 and 4)	In Camshaft limp-home mode (States 7 and 8)	In Crankshaft limp-home mode (States 5 and 6)	In Engine position Standard and Camshaft limp-home mode (States 4 and 8)
LV_CRK_STOP = 1	LV_CRK_STOP = 1	LV_CAM_STOP_IN(	LV_ENG_BACK_CF

		EX)[i] = 1 for the selected camshaft signal	M switches from 0 to 1
LV_ORNG_CAM_SYN_CRK = 1 (*)			
LV_ERR_CRK = 1 And LC_INH_LIH_CRK = 0			

(*) This information is available as long as LV_SYN_VLD = 0.

23.10.2.10 Camshaft self-synchronisation reactivation

General information:

When the self-synchronization of a camshaft signal goes to the fiasco state (LV_CAM_STOP_IN(EX)[i] = 1), the self-synchronization on this camshaft signal will be reactivated as soon as possible. If this camshaft is selected for the synchronization in crankshaft limp-home mode an engine stop is detected (by *engine stop detection()* sub-function task) and a new synchronization is restarted.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Recurrence: 10ms

Formula section:

For all available camshaft signal sensors:

```
If      LV_CAM_STOP_IN(EX)[i] = 1
AndLV_ACT_LIH_CRK_CAM_IN(EX)[i] = 0
Then    Activation of Camshaft self-synchronisation for this camshaft signal
Endif
```

23.10.2.11 *Calculation of PSN_ENG_CRK in standard mode()*

General information:

Formula section:

Before synchronization (LV_SYN_ENG = 0):

Truth table					
LV_CRK_SYN n	0	1			
LV_CRK_SYN n-1	0	0		1	
LV_CAM_SYN_CRK n	0	0	1	0	1
LV_CAM_SYN_CRK n-1	0	0	0	0	0

Engine position action	**1**	**2**	**3**	**4**	**5**

Action 1:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

Action 2:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

PSN_ENG_CRK_GAP = 360° - NC_OFS_TDC0_REF_CRK

Action 3:

PSN_ENG_CRK = 360° - NC_OFS_TDC0_REF_CRK + PSN_ENG_CRK_OFS

Action 4:

PSN_ENG_CRK = PSN_ENG_SYN_CAM_MIN

PSN_ENG_CRK_GAP n = PSN_ENG_CRK_GAP n-1 + (360°/NC_NR_TOOTH)

Action 5:

PSN_ENG_CRK = PSN_ENG_CRK_GAP + PSN_ENG_CRK_OFS

After the synchronization (LV_SYN_ENG = 1):

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 720°.

23.10.2.12 *Calculation of PSN_ENG_CRK in camshaft limp-home mode()*

General information:

Formula section:

Before synchronization (LV_SYN_ENG = 0):

Truth table		
LV_CRK_SYN n	0	1
LV_CRK_SYN n-1	0	0
Engine position action	**1**	**2**

Action 1:

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 360°

Action 2:

PSN_ENG_CRK = 720° - NC_OFS_TDC0_REF_CRK

After the synchronization (LV_SYN_ENG = 1):

PSN_ENG_CRK is incremented on the tooth signal and jitter from 0 to 720°

23.10.2.13 *PSN_ENG_CRK correction in camshaft limp-home()*

General information:

This function updates PSN_ENG_CRK depending on synchronization determination test result in camshaft limp home.

Application conditions:

Initialisation: none

Recurrence: none

Activation: LV_SEG_NR_UPD_REQ = 1

Deactivation: LV_SEG_NR_UPD_REQ = 0

Formula section:

PSN_ENG_CRK = PSN_ENG_CRK + (360°CRK / NC_NR_GAP)

23.10.2.14 *Calculation of PSN_ENG_CAM_LIH_CRK()*

General information:

The purpose of this function is to provide engine position during crankshaft limp-home. In crankshaft limp-home, the engine position is calculated from the camshaft sensor selected by LV_ACT_LIH_CRK_CAM_IN(EX)[i].

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Initialization: PSN_ENG_CAM_LIH_CRK = 0

Recurrence: every camshaft signal edge

Activation: LV_SYN_ENG = 1

Deactivation: LV_SYN_ENG = 0

Formula section:

For z = IDX_EDGE_CAM_IN(EX)[i] and the camshaft sensor selected for crankshaft limp home by LV_ACT_LIH_CRK_CAM_IN(EX)[i]:

```
If      z is a falling camshaft signal edge
Then    If      NC_ACT_CAM_EDGE_LIH = 1
                Or
                NC_ACT_CAM_EDGE_LIH = 3
        Then    PSN_ENG_CAM_LIH_CRK = NC_PSN_EDGE_CAM_IN(EX)[z][i] +
                    Average value of PSN_EDGE_AD_CAM_IN(EX)[z][i] for all falling
                    camshaft signal edges
        Else    no update of PSN_ENG_CAM_LIH_CRK
        Endif
Else    If      NC_ACT_CAM_EDGE_LIH = 2
                Or
                NC_ACT_CAM_EDGE_LIH = 3
        Then    PSN_ENG_CAM_LIH_CRK = NC_PSN_EDGE_CAM_IN(EX)[z][i] +
                    Average value of PSN_EDGE_AD_CAM_IN(EX)[z][i] for all rising
                    camshaft signal edges
        Else    no update of PSN_ENG_CAM_LIH_CRK
        Endif
End
```

23.10.2.15 Engine backwards rotation detection ()

General information:

The aim of this function is to detect a change in the direction of engine rotation which would lead to a false crankshaft teeth counter value and thus to a wrong timing for injection and/or ignition events. This could occur at low engine speed with hard compression phases.
This functionality gets a lower performance if camshaft target wheel is symmetrical as only the tests on crankshaft signal can be done (Action 1 and Test 2).
i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Initialisation: at reset or engine stalling (LV_STOP_ENG transition from 0 to 1)
LV_ENG_BACK_DET = 0
LV_ENG_BACK_CFM = 0

Recurrence: 10ms and every camshaft edge (for all camshaft sensors) and every reference gap and at engine stalling (LV_STOP_ENG transition from 0 to 1)

Activation: LC_ENG_BACK_INH = 0

Deactivation: when application conditions are not fulfilled

Formula section:

```
If      ( N_TOOTH < C_N_NOT_REST And  LV_CRK_MISS_TOOTH = 1 )
        or LV_ENG_BACK_DET = 1
Then    LV_ENG_BACK_DET = 1
        Activation of Engine backwards rotation confirmation ()
Else    LV_ENG_BACK_DET = 0
        LV_ENG_BACK_CFM = 0
End
```

LV_CRK_MISS_TOOTH is reset after reading.

Engine backwards rotation confirmation ():

The following table shows the test or action to perform in function of the current event.The event is a detection of a camshaft edge (CAM) or a detection of reference gap (GAP) or an engine stall (Engine stall).

Event	GAP	Engine stall	CAM
Test / Action	Action 1	Test 2	Test 3

Action 1:

This event means that the reference gap has been detected at the expected position (the number of teeth between 2 gaps is correct) and thus that engine backwards rotation is not confirmed.

LV_ENG_BACK_DET = 0

Test 2:

This event means that the number of teeth between 2 gaps is not correct due to engine backwards rotation which is thus confirmed.

```
If      LV_LOST_SYN_CRK = 1
Then    LV_ENG_BACK_CFM = 1
```

Test 3:

This test is only done on the camshaft signal that generated the event. It checks wether camshaft signal position is correct versus crankshaft signal or versus previous camshaft signal. If not, engine backwards rotation is confirmed.

```
If      LV_ERR_CAM_IN(EX)[i] = 0
Then    if      {
                ( LV_SYN_CAM_IN(EX)[i] = 1          'z value, which represents camshaft
                edge number, is know as camshaft is self-synchronized
```

```
                And
                ( PSN_ENG_ENSD ≤ NC_PSN_EDGE_CAM_IN(EX)[z][i]  -
                C_DYW_CAM_CRK_SYN_ADC_IN(EX)
                Or PSN_ENG_ENSD ≥ NC_PSN_EDGE_CAM_IN(EX)[z][i] +
                C_DYW_CAM_CRK_SYN_RTD_IN(EX) ) )
                Or
                LV_ORNG_RATIO_CAM_IN(EX)[i] = 1 }
        Then    LV_ENG_BACK_CFM = 1
        Else    if      LV_SYN_CAM_IN(EX)[i] = 1
                Then    LV_ENG_BACK_DET = 0
                End
        End
End
```

Input data:

LV_RUN_ENG	LV_CRK_SYN	NC_NR_TOOTH	PSN_ENG_CRK
PSN_ENG_SYN_CAM_MIN	PSN_ENG_SYN_CAM_MAX	PSN_ENG_CAM_LIH_CRK	T_TOOTH
T_SEG_HALF_ENSD	T_CRK_WIN_ENSD	LV_STOP_ENG	NC_NR_TOOTH
NC_PSN_SEG_TDC_REF	NC_CRK_WIN_SEG_LEN	T_SEG_ENSD	LV_SEG_NR_UPD_REQ

FUNCTION DESCRIPTION:

At engine stalling (LV_STOP_ENG 0 to 1), all output data are set to initialization value.

23.11.1 Engine Position Calculation Standard Mode

General information:

The function provides output values for engine position in standard operating mode.

Application conditions:

Initialisation: PSN_ENG = PSN_ENG_ENSD = 0

Recurrence: every update of the corresponding input values

Formula section:

PSN_ENG = PSN_ENG_ENSD (resolution conversion)

PSN_ENG_ENSD = PSN_ENG_CRK + ID_CRK_PHA_COR

PSN_ENG_SYN_MIN = PSN_ENG_SYN_CAM_MIN

PSN_ENG_SYN_MAX = PSN_ENG_SYN_CAM_MAX

The resolution of variables that are exported outside the aggregate is different from the resolution used internally!

23.11.2 Engine Position Calculation Crankshaft Limp-Home Mode

General information:

The function provides output values for engine position in crankshaft limp-home mode.

Application conditions:

Initialisation: PSN_ENG = PSN_ENG_ENSD = 0

Recurrence: every update of the corresponding input values

Formula section:

PSN_ENG = PSN_ENG_ENSD (resolution conversion)

PSN_ENG_ENSD = PSN_ENG_CAM_LIH_CRK

PSN_ENG_SYN_MIN = PSN_ENG_SYN_CAM_MIN

PSN_ENG_SYN_MAX = PSN_ENG_SYN_CAM_MAX

The resolution of variables that are exported outside the aggregate is different from the resolution used internally!

23.11.3 Segment Period Calculation

General information:

The function provides output values for the segment period.

The engine cycle is divided into a number of TDC periods corresponding to the number of cylinders NC_CYL_NR. The corresponding time intervals T_SEG_AV are measured between tooth events located NC_PSN_SEG_TDC_REF degrees before each TDC.

The segment number SEG_NR indicates the number of the cylinder that will be next in the firing order. A control signal is generated to trigger execution of segment synchronous tasks.

Application conditions:

Initialisation: T_SEG_AV is set to the maximum value

SEG_CTR = 0

SEG_NR = 0

Activation: LV_RUN_ENG = 1

Recurrence : when LV_RUN_ENG is set
And when LV_CRK_SYN is set
And every segment trigger

Formula section:

T_SEG_AV = T_SEG_ENSD saturated to maximum value at low speed.

At engine synchronization, SEG_NR is initialized with current segment number.

SEG_CTR is incremented at every segment.

23.11.4 Segment number correction in camshaft limp home

General information:

This function updates SEG_NR value in camshaft limp home mode depending on synchronization determination test result.

Application conditions:

Initialisation: none

Recurrence: none

Activation: LV_SEG_NR_UPD_REQ = 1

Deactivation: LV_SEG_NR_UPD_REQ = 0

Formula section:

SEG_NR = SEG_NR + NC_CYL_NR / (2 * NC_NR_GAP)

23.11.5 Engine speed N, N_32, N_MMV

General information:

The engine speed is determined in each segment from the segment period T_SEG_ENSD.

Application conditions:

Activation: LV_RUN_ENG = 1

Recurrence: when LV_RUN_ENG is set
And when LV_CRK_SYN is set
And every segment trigger

Formula section:

N = $\frac{2*60}{NC\_CYL\_NR*T\_SEG\_ENSD}$ for T_SEG_ENSD in s

N_32 = N in resolution 32 rpm

Before synchronization and at synchronization, one engine speed is output at the moment when crankshaft rotation is validated. The output value will be calculated from the most recent tooth period (see “Segment Period Calculation”)

N_MMV is the moving mean value calculated on the last 720° CRK:

N_MMV = $\frac{N_n + N_{n-1} + \ldots + N_{n-NC\_CYL\_NR}}{NC\_CYL\_NR}$

Before engine synchronisation N_MMV = N. After engine synchronisation and before the first engine cycle is completed, N_MMV is calculated as the mean value of the most recent segments of this cycle.

Set N_FAST to N if no fast engine speed calculation is required.

```
If      C_N_FAST_SWI = 0
Then    N_FAST = N
Endif
```

23.11.6 Fast Engine speed based on last tooth period

General information:

Provide engine speed calculated every 10ms on the last crankshaft tooth period during cranking, synchronisation and start phase. Calculation is done until speed threshold is reached.
If, during running, Engine speed becomes lower than this threshold, this calculation is started again
In the formula after, T_TOOTH in s is the time for the last crankshaft tooth period, acquired in BSW just before the 10ms trigger event used for update rate of N_TOOTH here.

Application conditions:

Initialisation: N_TOOTH = 0

Recurrence : 10ms

Activation: LV_RUN_ENG = 1

Deactivation: LV_RUN_ENG = 0

Formula section:

```
If      N_32 <= C_N_TOOTH_END
Then    N_TOOTH = 60 / (NC_NR_TOOTH * T_TOOTH)
```

```
Endif
If      C_N_FAST_SWI = 1
Then    N_FAST = N_TOOTH
Endif
```

23.11.7 Fast Engine Speed based on Half-Segment Period Calculation

General information:

This function provides fast engine speed based on half-segment period.

Application conditions:

Initialisation: T_SEG_HALF_AV is set to the maximum value

Recurrence: before synchronization: once at transition from LV_RUN_ENG from 0 to 1
after synchronization: every ½ segment trigger **and** segment trigger

Activation: LV_RUN_ENG = 1

Formula section:

```
If      C_N_FAST_SWI = 2
Then    N_FAST = $\frac{60}{NC\_CYL\_NR * T\_SEG\_HALF\_ENSD}$
Endif
```

T_SEG_HALF_AV = T_SEG_HALF_ENSD saturated to maximum value at low speed.

23.11.8 Fast Engine Speed based on Crankshaft Tooth Window

General information:

This function provides fast engine speed output based on a crankshaft window at the end of each segment. Updated every segment

Application conditions:

Initialisation: N_FAST = 0

Recurrence : every segment trigger

Activation: LV_RUN_ENG = 1

And

(C_N_FAST_SWI = 3 **Or** C_N_FAST_SWI = 4)

Deactivation: C_N_FAST_SWI <> 3 **And** C_N_FAST_SWI <> 4

Formula section:

$$N\_CRK\_WIN = \frac{60}{T\_CRK\_WIN\_ENSD} \quad \frac{NC\_CRK\_WIN\_SEG\_LEN}{360° \; CRK}$$

```
If      C_N_FAST_SWI = 3
Then    N_FAST = N + C_FAC_N_FAST * (N_CRK_WIN n – N_CRK_WIN n-1)
Endif
If      C_N_FAST_SWI = 4
Then    N_FAST = N + C_FAC_N_FAST * (N n – N_CRK_WIN n-1)
Endif
```

23.11.9 Engine speed gradient N_GRD, N_GRD_H_RES

General information:

The engine speed gradient is the acceleration of the crankshaft in rpm/s. For engins with an even number of cylinders (2...8), the gradient is calculated from the duration of the most recent engine revolution, and the duration of the previous engine revolution. With this calculation, the gradient is free from errors due to mechanical tolerances of the crankshaft target wheel.

For three-cylinder engins, the gradient is calculated from the most recent segment time, and the segment time before. Errors from mechanical tolerances of the crankshaft target wheel are not corrected, but are supposed to have a minor effect due to the greater angle of the segments.

Application recurrence: every segment trigger

Formula section:

For even cylinder numbers, the duration of the most recent engine revolution is the sum of the most recent NC_CYL_NR/2 segment times. For e.g. a four-cylinder engine, this is:

$$T\_REV\_AV = T\_SEG\_ENSD_{n} + T\_SEG\_ENSD_{n-1}$$

The duration of the previous engine revolution is for the example of a four-cylinder engine:

$$T\_REV\_PREV = T\_SEG\_ENSD_{n-2} + T\_SEG\_ENSD_{n-3}$$

N_GRD calculation:

N_GRD_H_RES =

$$\frac{60*(T\_REV\_PREV - T\_REV\_AV)}{T\_REV\_PREV * T\_REV\_AV * 0.5*(T\_REV\_PREV + T\_REV\_AV)}$$

for T_REV_AV and T_REV_PREV in s

N_GRD = N_GRD_H_RES in resolution 32 rpm/s.

The resolution of the segment time introduces an error into the calculation of the engine speed gradient, depending on engine speed.

For a timer resolution of 0.25µs, a difference of 1 timer tick between T_REV_AV and T_REV_PREV corresponds to:

0.015 rpm/s at 600 rpm

and 15 rpm/s at 6000 rpm

For three-cylinder engins, the gradient is calculated as follows:

N_GRD_H_RES =

$$\frac{2*60*(T\_SEG\_ENSD_{n-1} - T\_SEG\_ENSD_{n})}{3*T\_SEG\_ENSD_{n-1}*T\_SEG\_ENSD_{n}*0.5*(T\_SEG\_ENSD_{n-1}+T\_SEG\_ENSD_{n})}$$

N_GRD = N_GRD_H_RES in resolution 32 rpm/s.

The resolution of the segment time introduces an error into the calculation of the engine speed gradient, depending on engine speed.

A difference of 1 timer tick between $T\_SEG\_ENSD_{n}$ and $T\_SEG\_ENSD_{n-1}$ corresponds to:

0.51 rpm/s at 600 rpm

and 51 rpm/s at 6000 rpm

23.11.10 Crankshaft Sensor Phase Angle Correction

General information:

The sensor phase angle is defined as the rotation angle of the target wheel between the mechanical reference and the electrical reference for a tooth of the target wheel.

The mechanical reference in the target wheel drawing usually is the trailing edge of a tooth in the defined rotation direction. The mechanical reference position is reached when the center of the sensor is aligned to that angular reference.

The electrical reference may be on the falling or on the rising edge of the sensor output signal, see active edge definition in the acquisition of crankshaft signal. The reference position is reached when the sensor output signal switches (for active sensors) respectively has its zero crossing (for VR sensors).

A retard of the electrical reference relative to the mechanical edge is defined as a positive phase angle. With most sensors, the signal edge is generated at the center of each tooth at low speed. At high speed the signal edge may be retarded.

The typical phase angle ID_CRK_PHA_COR (at typical air gap and operating temperature) of the used sensor/target wheel combination is calibrated in a table versus engine speed. The value corresponding to the actual engine speed is added to the actual engine position delivered from crankshaft acquisition, in order to obtain a corrected engine position (see position calculation in the first chapter of this specification).

Application conditions:

Recurrence: every segment trigger

Activation: LV_CRK_SYN = 1

Deactivation: LV_CRK_SYN = 0

Calibration data:

NC_CAM_LIH_SWI			

FUNCTION DESCRIPTION:

General information:

This functions aims at initializing the variables used by ENSD or others aggregates in case no camshaft limp home method has been selected.

Description:

Application conditions:

Initialisation: none

Recurrence: at reset

Activation: NC_CAM_LIH_SWI = “None”

Deactivation: NC_CAM_LIH_SWI ≠ “None”

Formula section:

LV_SYN_VLD_CAM_LIH = 0
LV_CAM_LIH_EXT_ENA = 0
LV_SEG_NR_UPD_REQ = 0

Remark: as this module is only a stub, N, N_GRD, SEG_CTR, LV_VS_RUN, INH_INJ, TCO_CMN, VB_CMN and SEG_NR are not used.

23.13 Camshaft adaptation and position output

C_TOL_REF_CRK_CAM_EX			

FUNCTION DESCRIPTION:

General information:

The function provides a feedback about the actual camshaft position relative to the engine position measured with the crankshaft sensor. The signals of one, two or four camshaft sensors are treated (intake and/or exhaust camshaft on one or two cylinder banks).

The actual engine position is captured with every camshaft signal edge. The camshaft position is calculated as the difference between the captured engine position, and the engine position measured on the respective camshaft. The difference may be due to tolerances, or due to an intentional displacement by a camshaft phasing system (VVTI).

Two different adaptive learning algorithms eliminate the tolerances, in order to measure exactly the VVTI displacement.

The reference position adaptation is done for all signal edges. It is performed on all intake camshafts as long as LV_DI_AD_REF_CAM_IVVT_IN = 0. It is performed on all exhaust camshafts as long as LV_DI_AD_REF_CAM__IVVT_EX = 0. The camshafts are then situated in their respective VVTI passive positions. After the completion of the adaptation LV_AD_END_CAM_IN(EX)[i] is set and PSN_AD_CAM_IN(EX)[i] is calculated as the mean value of all adaptated signal edges. The reference edge has the index 1. It is the first electrical falling edge of the camshaft signal after TDC0.

The position of other signal edges is adapted continuously relative to the reference signal edge, in order to always deliver a coherent position information.

Both adaptation algorithms are performed only at a limited dynamic variation of the camshaft position measured at the reference edge.

The logical calibration bit LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] is set if the VVTI system is inhibited on the corresponding camshafts. The respective camshafts will be treated like being constantly in the VVTI passive position. If an engine has more camshaft sensors then VVTI actuators, then NLC_IVVT_IN(EX) = 0 indicates that VVTI is not existing on intake or on exhaust camshafts.

23.13.1 Engine Position Determination from Camshaft signal

General information:

As soon as camshaft is self-synchronized, the actual engine position is calculated at every camshaft signal edge from theorical position plus adaptation value for the actual signal edge index.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Recurrence : *every CAM active edge*

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]

PSN_ENG_CAM_IN(EX)[i] (n) = NC_PSN_EDGE_CAM_IN(EX)[z][i] +
PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) +
ID_CAM_PHA_COR

23.13.2 Camshaft Position Output

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN(EX)[i] = 1 **And** LV_SYN_VLD = 1

Recurrence: *every update of IDX_EDGE_CAM_IN(EX)[i]*

Initialization:

PSN_CAM_IN(EX)[i] = 0
PSN_EDGE_CAM_IN(EX)[z][i] = 0

Formula section:

for z = IDX_EDGE_CAM_IN(EX)[i]

PSN_EDGE_CAM_IN(EX)[z][i] = PSN_ENG_ENSD - PSN_ENG_CAM_IN(EX)[i]

In the following calculations, the resolution has to be converted:

PSN_CAM_IN(EX)[i] = PSN_EDGE_CAM_IN(EX)[z][i]

PSN_DIF_EDGE_CAM_IN(EX)[i] = PSN_ENG_ENSD (n) - PSN_ENG_ENSD (n-1)

T_DIF_EDGE_CAM_IN(EX)[i] = T_SEG_CAM_IN(EX)[i]

23.13.3 Camshaft Position Adaptation

23.13.3.1 Reference Position Adaptation

General information:

The reference position adaptation is done whenever it is not disabled by the corresponding flag from VVTI, or if there is no VVTI on that camshaft, and if the condition for limited dynamic variation of the camshaft position is true. A flag is set to signal successful adaptation.

The flag is reset when the adaptation inhibit conditions become false.

If LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1

Then LV_AD_END_CAM_IN(EX)[i] = 0

The camshaft position output value should be zero in VVTI passive position. At each ocurrence of the reference camshaft signal edge, a portion of the position deviation is added to the previous adaptation value, as long as adaptation conditions are true, this is done for all the camshaft signal edges.

If the conditions stay true for a number of revolutions, then the flag for successful end of adaptation is set (LV_AD_END_CAM_IN(EX)[i] = 1).

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN(EX)_I =1 **And** LV_SYN_VLD = 1

And

LV_DI_AD_REF_CAM_IVVT_IN(EX) = 0 **Or** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 1 **Or** NLC_IVVT_IN(EX) = 0

Recurrence: every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)

Initialization:

LV_AD_END_CAM_IN(EX)[i] = 0

CTR_REV_AD_REF_CAM_IN(EX)[i] = 0

PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] are initialized to 0)

PSN_AD_CAM_IN(EX)[i] = Sum **(** PSN_EDGE_AD_CAM_IN(EX)[z][i]

for z = 1…NC_NR_EDGE_CAM_IN(EX) **)** / NC_NR_EDGE_CAM_IN(EX)

(resolution conversion)

LV_CAM_AD_SAVE_IN(EX)[i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, LV_CAM_AD_SAVE_IN(EX)[i] is initialized to 0)

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

At reset: CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]

(All these adaptive values has to be reset in case of cam/crk mechanical change (Chain change, camshaft sensor change…))

Formula section:

```
If      |PSN_EDGE_CAM_IN(EX)[1][i] (n) – PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| < C_GRD_AD_REF_MAX_CAM_IN(EX)
Then    increment CTR_REV_AD_REF_CAM_IN(EX)[i]
        The adaptation values are calculated for all indexes (for z = 1…NC_NR_EDGE_CAM_IN(EX))
        PSN_EDGE_AD_CAM_IN(EX)[z][i] (n) = PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_REF_CAM_IN(EX) * PSN_EDGE_CAM_IN(EX)[z][i]
Else    CTR_REV_AD_REF_CAM_IN(EX)[i] = 0
Endif

If      CTR_REV_AD_REF_CAM_IN(EX)[i] >= C_NR_REV_AD_REF_CAM_IN(EX)
Then    CTR_REV_AD_REF_CAM_IN(EX)[i] = 0
        PSN_AD_CAM_IN(EX)[i] = Sum ( PSN_EDGE_AD_CAM_IN(EX)[z][i]
        for z = 1…NC_NR_EDGE_CAM_IN(EX) ) / NC_NR_EDGE_CAM_IN(EX)
        (resolution conversion)
        If      LV_CAM_AD_SAVE_IN(EX)[i] = 1
        Then    If   |CAM_PSN_LST_REF_AD_IN(EX)[i] - PSN_EDGE_AD_CAM_IN(EX)[1][i]| < C_TOL_TOOTH_OFF_CAM_IN(EX)
                Then CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]
                Else nothing
                Endif
                LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 1 (to allow the ONE_TOOTH_OFF diagnosis only if a reference adaptation has been done after the very first one)
        Else    If   C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0
                Then      CAM_PSN_LST_REF_AD_IN(EX)[i] = PSN_EDGE_AD_CAM_IN(EX)[1][i]
                          LV_CAM_AD_SAVE_IN(EX)[i] = 1 (set at the end of the very first reference adaptation)
```

```
                Else    nothing
                Endif
        Endif
        LV_AD_END_CAM_IN(EX)[i] = 1
Else
        LV_TOOTH_OFF_DET_ENA_IN(EX)[i] = 0
Endif

If      LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1
Then    CTR_REV_AD_REF_CAM_IN(EX)[i] = 0
Endif
```

23.13.3.2 Continuous Edge Position Adaptation

The continuous position adaptation is enabled at a limited dynamic variation of the camshaft position measured at the reference signal edge.

The difference of the actual camshaft position measured at the reference edge, and the actual camshaft position measured at any other signal edge, is calculated once per camshaft revolution. That difference is multiplied with a cofficient (<<1) and added to the previous adaptation value to form the new adaptation value, which is applied in the following camshaft revolution. This way the camshaft position output value calculated at any signal edges will approach the camshaft position output value calculated at the reference signal edge.

Application conditions:

Activation:

LV_VLD_PSN_CAM_IN[i] = 1 **And** LV_SYN_VLD = 1

And

LV_DI_AD_REF_CAM_IVVT_IN(EX) = 1 **And** LC_NOT_ADJ_CAM_IVVT_IN(EX)[i] = 0 **And** NLC_IVVT_IN(EX) = 1

Recurrence: *every reference camshaft signal edge (IDX_EDGE_CAM_IN(EX)[i] = 1)*

Initialization:

PSN_EDGE_AD_CAM_IN(EX)[z][i] from saved value in NVMY (if adaptation value has never been learned or if the stored value could not be read, PSN_EDGE_AD_CAM_IN(EX)[z][i] is initialized to 0)

PSN_EDGE_AD_CAM_IN(EX)[z][i] and LV_CAM_AD_SAVE_IN(EX)[i] shall be saved in NVMY only if: LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0 (otherwise the last stored values, which have been stored after last driving cycle without error, shall not be changed)

Formula section:

For the following equations, the index z of the camshaft signal edges equals IDX_EDGE_CAM_IN(EX)[i] (z=1 for reference edge). The adaptation values are calculated for all indexes from 2 to NC_NR_EDGE_CAM_IN(EX).

```
If      |PSN_EDGE_CAM_IN(EX)[1][i] (n) - PSN_EDGE_CAM_IN(EX)[1][i] (n-1)| <
        C_GRD_AD_MAX_CAM_IN(EX)
Then    PSN_EDGE_AD_CAM_IN(EX)[z][i] (n)        =
        PSN_EDGE_AD_CAM_IN(EX)[z][i] (n-1) + C_CRLC_AD_CAM_IN(EX) *
        (PSN_EDGE_CAM_IN(EX)[z][i] - PSN_EDGE_CAM_IN(EX)[1][i])
Endif
```

23.13.3.3 Reference adaptive values save authorization at Powerlatch

Before saving the adaptive values in NVMY during PWL, it is important to check if they are correct. Even if the REF_CRK_CAM error is not set, the calculated adaptive values can be wrong (for example, the error flag could have been reset on a quick key 0 to 1 transition).

Application conditions:

Activation:

ECU_STATE = PWL

Recurrence: *once during PWL, for all camshaft edges of all present camshaft sensors, before saving the NVMY adaptive values*

Initialization:

LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] =0

Formula section:

```
If      PSN_EDGE_AD_CAM_IN(EX)[z][i] < - C_TOL_REF_CRK_CAM_IN(EX)
        or      PSN_EDGE_AD_CAM_IN(EX)[z][i] > C_TOL_REF_CRK_CAM_IN(EX)
Then    LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1
Else
        If      LV_CAM_AD_SAVE_IN(EX)[i] = 1
                And
                CAM_PSN_LST_REF_AD_IN(EX)[i] <>
                PSN_EDGE_AD_CAM_IN(EX)[1][i]
                And
                C_TOL_TOOTH_OFF_CAM_IN(EX) <> 0
        Then    LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] = 1
        Else    nothing, (if LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] has been set to 1
                due to anyone of the camshaft edges, it must stay to 1 and  the adaptive
                will not be saved. Contrary, if all the camshaft edges are correct, adaptive
```

values can be saved, LV_CAM_AD_PWL_NOT_SAVE_IN(EX)[i] must stay at 0)

Endif

Endif

23.14.1 Calculation of Fail Safe Delay

General information:

Calculation of the time delay to inhibit cam/crk diagnosis when there is a risk of reverse engine rotation.

Application conditions:

Initialisation:	no initialization value.
Recurrence:	10ms **and** 1 to 0 transition of LV_IGK
Activation:	no condition
Deactivation:	no condition

Formula section:

```
If      LV_IGK = 0   And   LV_INH_DIAG_ENSD = 0
Then    check N_TOOTH every 10ms
        If      0 < N_TOOTH < C_N_NOT_REST
        Then    Inhibition of all diagnosis functions except sensor circuit diagnosis
                LV_INH_DIAG_ENSD = 1
                Wait for a time C_T_DLY_REST_IGK
                LV_INH_DIAG_ENSD = 0
        Endif
Endif
```

```
If      LV_STOP_ENG = 1   And LV_ENG_BACK_DET = 0
    /* to be checked before LV_ENG_BACK_DET reset on LV_STOP_ENG transition */
        And
        /* don't activate fail safe delay if cam/crk synchronization is out of range */
        LV_ORNG_CAM_SYN_CRK = 0
        And
        /* don't activate fail safe delay if tooth period is out of range */
        LV_ORNG_TOOTH_PER_CRK = 0
        And
        LV_INH_DIAG_ENSD = 0
Then    If      0 < N_TOOTH < C_N_NOT_REST
                        (N_TOOTH: most recently calculated engine speed)
        Then    Inhibition of all diagnosis functions except sensor circuit diagnosis
                LV_INH_DIAG_ENSD = 1
                Wait for a time C_T_DLY_REST_STALL
                Stop timer C_T_DLY_REST_STALL at 0 to 1 transition of LV_IGK
                LV_INH_DIAG_ENSD = 0
        Endif
Endif
```

23.14.2 Diagnosis general inhibition in case of engine backwards rotation detection

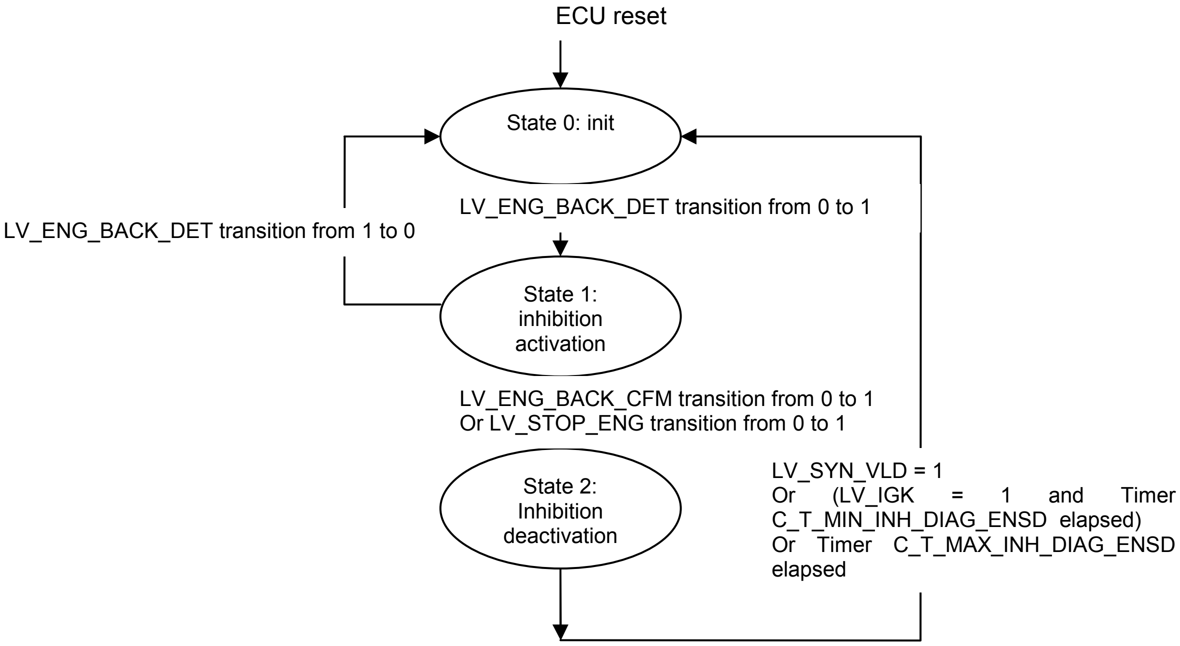
General information:

Inhibits cam/crk diagnosis when a reverse engine rotation has been detected until confirmation/nullification.

Application conditions:

Initialisation:	no initialization value.
Recurrence:	10ms **and** transition from 1 to 0 of LV_IGK **and** every update of LV_ENG_BACK_DET or LV_ENG_BACK_CFM **and** transition from 0 to 1 of LV_SYN_VLD **and** transition from 0 to 1 of LV_STOP_ENG
Activation:	LC_ENG_BACK_INH = 0
Deactivation:	when application conditions are not fulfilled

Formula section:



State 0: Initialisation

Input conditions:

External event: ECU reset

From state 1: LV_ENG_BACK_DET transition from 1 to 0

From state 2: LV_SYN_VLD = 1

Or (LV_IGK = 1 and timer C_T_MIN_INH_DIAG_ENSD elapsed)

Or timer C_T_MAX_INH_DIAG_ENSD elapsed

Output conditions:

To state 1: LV_ENG_BACK_DET transition from 0 to 1

And Timer C_T_DLY_REST_IGK stopped

Action in the state:

Set timer to C_T_MIN_INH_DIAG_ENSD

Set timer to C_T_MAX_INH_DIAG_ENSD

Transition action:

None

State 1: Inhibition activation

Input conditions:

From state 0: LV_ENG_BACK_DET transition from 0 to 1

Output conditions:

To state 0: ECU reset

Or LV_ENG_BACK_DET transition from 1 to 0

To state 2: LV_ENG_BACK_CFM transition from 0 to 1

Or LV_STOP_ENG transition from 0 to 1

Action in the state:

LV_INH_DIAG_ENSD = 1

LV_IGN_INJ_LOCK_REQ = 1

Stop timer C_T_MIN_INH_DIAG_ENSD if on-going

Stop timer C_T_MAX_INH_DIAG_ENSD if on-going

Transition action:

To state 0: LV_INH_DIAG_ENSD = 0

LV_IGN_INJ_LOCK_REQ = 0

To State 2: Start timer C_T_MAX_INH_DIAG_ENSD

Start timer C_T_MIN_INH_DIAG_ENSD if LV_IGK = 0

State 2: Inhibition deactivation

Input conditions:

From state 1: LV_ENG_BACK_CFM transition from 0 to 1

Or LV_STOP_ENG transition from 0 to 1

Output conditions:

To state 0: ECU reset

Or LV_SYN_VLD = 1

Or (LV_IGK = 1 and timer C_T_MIN_INH_DIAG_ENSD elapsed)

Or timer C_T_MAX_INH_DIAG_ENSD elapsed

Action in the state:

Start timer C_T_MIN_INH_DIAG_ENSD on transition of LV_IGK from 1 to 0

Transition action:

To state 0: LV_INH_DIAG_ENSD = 0

LV_IGN_INJ_LOCK_REQ = 0

Remark: if C_T_MIN_INH_DIAG_ENSD = 0, then timer is started at transition of LV_IGK from 1 to 0 and considered as elapsed immediately.

23.14.3 Diagnosis Manager

General information:

One purpose of the diagnosis manager is to provide a summary of diagnostic information, in order to facilitate taking the necessary actions in case of a failure, e.g. switch to limp-home mode. The corresponding outputs are crankshaft limp-home request a general camshaft error flag for IVVT, and a general camshaft error for synchronization.

The other purpose is to avoid getting multiple error codes and freeze frames for the same failure. The corresponding outputs are the inhibit flags for the various diagnosis functions.

i = 1...NC_NR_CAM_CBK

Application conditions:

Initialisation: no initialization value.

Recurrence: every change in the error flags of one of the diagnostic functions

Or

when error memory is cleared

Or

At key 0 to 1 transition

Activation:

Deactivation:

Formula section:

LV_ERR_CRK

LV_ERR_CRK = 1 **if** LV_ERR_CRK_SYN = 1 **or** LV_ERR_CRK_TOOTH_PER = 1 **or** LV_ERR_CRK_TOOTH = 1 **or** LV_ERR_CRK_PLAUS = 1 **or** LV_ERR_CRK_OC = 1

LV_ERR_CRK = 0 **if** LV_ERR_CRK_SYN = 0 **and** LV_ERR_CRK_TOOTH_PER = 0 **and** LV_ERR_CRK_TOOTH = 0 **and** LV_ERR_CRK_PLAUS = 0 **and** LV_ERR_CRK_OC = 0.

If LV_ERR_CRK = 1, all other diagnoses on the crankshaft signal will be inhibited via the interfaces LV_INH_DIAG_CRK_SYN, LV_INH_DIAG_CRK_TOOTH, LV_INH_DIAG_CRK_TOOTH_PER, LV_INH_DIAG_CRK_PLAUS and LV_INH_DIAG_CRK_OC, except the one that detected the failure.

LV_ERR_CAM_IN(EX)[i]

LV_ERR_CAM_IN(EX)[i] = 1 **if** LV_ERR_SYN_CAM_IN(EX)[i] = 1 **or** LV_ERR_PER_CAM_IN(EX)[i] = 1 **or** LV_ERR_PLAUS_CAM_IN(EX)[i] = 1 **or** LV_ERR_REF_CRK_CAM_IN(EX)[i] = 1 **or** LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 1 **or** LV_ERR_TOOTH_OFF_IN(EX)[i] = 1.

LV_ERR_CAM_IN(EX)[i] = 0 **if** LV_ERR_SYN_CAM_IN(EX)[i] = 0 **and** LV_ERR_PER_CAM_IN(EX)[i] = 0 **and** LV_ERR_PLAUS_CAM_IN(EX)[i] = 0 **and** LV_ERR_REF_CRK_CAM_IN(EX)[i] = 0 **and** LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 0 **and** LV_ERR_TOOTH_OFF_IN(EX)[i] = 0.

If LV_ERR_CAM_IN(EX)[i] = 1, other diagnoses on the same camshaft signal will be inhibited via the interfaces LV_INH_DIAG_SYN_CAM_IN(EX)[i], LV_INH_DIAG_PER_CAM_IN(EX)[i], LV_INH_DIAG_PLAUS_CAM_IN(EX)[i], LV_INH_DIAG_REF_CRK_CAM_IN(EX)[i] and LV_INH_DIAG_TOOTH_OFF_IN(EX)[i], except the one that detected the failure.

LV_ERR_CAM_TOT

VVT actuators existing in the system are given by a logical combination of the configuration data NLC_IVVT_IN(EX) and the calibration data LC_NOT_ADJ_CAM_IVVT_IN(EX)[i].

LV_ERR_CAM_TOT = 1 if LV_ERR_CAM_IN(EX)[i] = 1 for one of the sensors on camshafts with IVVT actuator.

LV_ERR_CAM_TOT = 0 if LV_ERR_CAM_IN(EX)[i] = 0 for all sensors on camshafts with IVVT actuator.

23.14.4 Inhibition of camshaft sensor diagnosis for crankshaft synchronization

General information:

Calculation of the inhibition flag of camshaft sensor diagnosis for crankshaft synchronization in case of possible reverse rotation.

I = 1...NC_NR_CAM_CBK

Application conditions:

Initialisation: LV_INH_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0 at ECU reset **and** 0 to 1 transition of LV_IGK

Recurrence: 10ms **and** transition from 0 to 1 of LV_STOP_ENG **and** transition from 0 to 1 of LV_SYN_VLD

Activation: -

Deactivation: -

Formula section:

```
If     LV_SYN_ENG = 0
       And    LC_ENG_BACK_INH = 0
       And    LV_INH_DIAG_ENSD = 0
       And    0 < N_TOOTH < C_N_NOT_REST
       And    LV_ORNG_TOOTH_PER_CRK = 1
Then   LV_INH_DIAG_SYN_CRK_CAM_IN(EX)[i] = 1
Endif

If     LV_SYN_VLD = 1
Then   LV_INH_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0
Endif
```

23.15.1.1 Camshaft Segment Period Diagnosis

FUNCTION DESCRIPTION:

General information:

Camshaft signal acquisition validates the segment period by minimum limits derived from the maximum engine speed. The diagnostic state indicates when a segment period was too short, e.g. due to supplementary signal transitions. The camshaft signal acquisition will filter out such signal transitions as far as possible. If there are too many additional pulses however, the camshaft signal acquisition may not be able to synchronize any more, or the accuracy of camshaft position measurement may be degraded.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Camshaft segment period too short "CAM_PER"    (= SYM_0)
 │ │ └───> (not used)                                     (= SYM_1)
 │ └─────> (not used)                                     (= SYM_2)
 └───────> (not used)                                     (= SYM_3)
```

Application conditions:

Initialisation:
LV_CDN_DIAG_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_ERR_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
ERR_SYM_PER_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*

Recurrence: every camshaft signal edge

Activation: LV_ACT_CAM_IN(EX)[i] = 1
And LV_INH_DIAG_PER_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_EXT_PER_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_ENSD = 0

When the activation conditions are fulfilled then LV_CDN_DIAG_PER_CAM_IN(EX)[i] = 1

Deactivation:

When the activation conditions are not fulfilled then *LV_CDN_DIAG_PER_CAM_IN(EX)[i] = 0*

Formula section:

Symptoms calculation:

```
If    LV_ORNG_PER_CAM_IN(EX)[i] = 1
Then    ERR_SYM_PER_CAM_IN(EX)[i] = "SYM_0" {detection of symptom CAM_PER]
Else    ERR_SYM_PER_CAM_IN(EX)[i] = NO_SYM
Endif
```

LV_ORNG_PER_CAM_IN(EX)[i] is reset after reading.

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

```
Apply filter on current symptoms
If filtering result available (after debounce)
Then
    LV_ERR_PER_CAM_IN(EX)[i] = filtering result
    LV_END_DIAG_PER_CAM_IN(EX)[i] = 1
    Deliver the result to Error Management
Endif
```

Configuration for diagnostic symptoms:

See Appl. Inc.

23.15.1.2 Camshaft Synchronization Diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect camshaft sensor failure. Each time the camshaft signal synchronization algorithm fails, it will set the diagnostic flag LV_ORNG_RATIO_CAM_IN(EX)[i] for the appropriate camshaft.

The camshaft signal acquisition will filter out supplementary signal transitions as far as possible. If there are too many additional pulses however, the camshaft signal acquisition will not be able to synchronize any more. Synchronization may also be impossible due to missing or inaccurate signal transitions of the sensor.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 |  |  |  └─> Camshaft synchronization failure "SYNC_LOSS"     (= SYM_0)
 |  |  └────> (not used)                                       (= SYM_1)
 |  └───────> (not used)                                       (= SYM_2)
 └──────────> (not used)                                       (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_SYN_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_SYN_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_ERR_SYN_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
ERR_SYM_SYN_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*

Recurrence: *every camshaft signal edge*

Activation: LV_ACT_CAM_IN(EX)[i] = 1
And LV_INH_DIAG_SYN_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_EXT_SYN_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_ENSD = 0

When activation conditions are fulfilled then LV_CDN_DIAG_SYN_CAM_IN(EX)[i] = 1.

Deactivation:

When activation conditions are not fulfilled then LV_CDN_DIAG_SYN_CAM_IN(EX)[i] = 0.

Formula section:

Symptoms calculation:

If LV_ORNG_RATIO_CAM_IN(EX)[i] = 1

Then ERR_SYM_SYN_CAM_IN(EX)[i] = "SYM_0" {Detection of symptom SYNC_LOSS}

Else ERR_SYM_SYN_CAM_IN(EX)[i] = NO_SYM

```
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

```
Apply filter on current symptoms
If filtering result available (after debounce)
Then
    LV_ERR_SYN_CAM_IN(EX)[i] = filtering result
    LV_END_DIAG_SYN_CAM_IN(EX)[i] = 1
    Deliver the result to Error Management
Endif
```

23.16.1 Camshaft Position diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect when the camshaft reference position is outside of the designed range relative to the engine position from crankshaft. This allows to detect engine misbuilds (wrong assembly of the valve train), camshaft drive defects, or sensor failures that are not detected by the normal signal diagnosis.

i = 1...NC_NR_CAM_CBK   z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Error-symptoms are defined for this diagnostic function as following:

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │  │  │  └─> Camshaft to crankshaft reference violated "REF_CRK_CAM"  (= SYM_0)
  │  │  └────> (not used)                                              (= SYM_1)
  │  └───────> (not used)                                              (= SYM_2)
  └──────────> (not used)                                              (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_REF_CRK_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_REF_CRK_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
LV_ERR_REF_CRK_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*
ERR_SYM_REF_CRK_CAM_IN(EX)[i] = *Refer to filtering configuration for the initialisation value*

Recurrence: *every update of the camshaft edge position adaptation values PSN_EDGE_AD_CAM_IN(EX)[z][i]*

Activation: LV_VLD_PSN_CAM_IN(EX)[i] = 1
And LV_INH_DIAG_REF_CRK_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_EXT_REF_CRK_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_ENSD = 0

When the activation conditions are fulfilled then LV_CDN_DIAG_REF_CRK_CAM_IN(EX)[i] = 1.

Deactivation:

When the activation conditions are not fulfilled then LV_CDN_DIAG_REF_CRK_CAM_IN(EX)[i] = 0

Formula Section

Symptoms calculation:

```
If      PSN_EDGE_AD_CAM_IN(EX)[z][i] < - C_TOL_REF_CRK_CAM_IN(EX)
        or
        PSN_EDGE_AD_CAM_IN(EX)[z][i] > C_TOL_REF_CRK_CAM_IN(EX)
Then    ERR_SYM_REF_CRK_CAM_IN(EX)[i] = “SYM_0” {Detection of symptom
        REF_CRK_CAM}
Else    ERR_SYM_REF_CRK_CAM_IN(EX)[i] = NO_SYM
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering :

```
apply filter on current symptoms
If filtering result available  (after debounce)
then
    LV_ERR_REF_CRK_CAM_IN(EX)[i] = filtering result
    LV_END_DIAG_REF_CRK_CAM_IN(EX)[i] = 1
    Deliver the result to Error Management
Endif
```

Configuration for diagnostic symptoms :

See Appl. Inc.

23.16.2 One-tooth-off diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect a sudden drift is the camshaft position.

i = 1...NC_NR_CAM_CBK z = 0...NC_NR_EDGE_CAM_IN/EX

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 |  |  |  └─> Sudden drift "ONE_TOOTH_OFF"        (= SYM_0)
 |  |  └────> (not used)                           (= SYM_1)

23.17.2 Interface of TOOTH_OFF_IN/EX error for Rate-based-monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_TOOTH_OFF_IN[NC_NR_CAM_CBK]	O/V	0...7H	0...7	1	[-]
Interface of TOOTH_OFF_IN monitor with the Rate-Based Monitoring statistics					
STATE_RBM_TOOTH_OFF_EX[NC_NR_CAM_CBK]	O/V	0...7H	0...7	1	[-]
Interface of TOOTH_OFF_EX monitor with the Rate-Based Monitoring statistics					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_TOOTH_OFF_IN[NC_NR_CAM_CBK]	LV_END_DIAG_TOOTH_OFF_EX[NC_NR_CAM_CBK]
LV_INH_DIAG_TOOTH_OFF_IN[NC_NR_CAM_CBK]	LV_INH_DIAG_TOOTH_OFF_EX[NC_NR_CAM_CBK]		

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TOOTH_OFF_IN/EX[i] monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TOOTH_OFF_IN/EX[i] data.

Within STATE_RBM_TOOTH_OFF_IN/EX[i] , three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for TOOTH_OFF_IN/EX[i] diagnosis)

***Remark**: Calculation must be made seperate for ..._EX[i] and ..._IN[i]*

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0 and bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 0

bit 2 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 1

on failure memory reset :

bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_SYN_CAM_IN/EX[i]
LV_ERR_PER_CAM_IN/EX[i]
LV_ERR_PLAUS_CAM_IN/EX[i]
LV_ERR_SYN_CRK_CAM_IN/EX[i]
LV_ERR_REF_CRK_CAM_IN/EX[i]

```
If(1)      { CPU optimization at LV_DC 0 → 1 transition }
           CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
           While  bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i]  = 0 do
                  with each XX failure of the above list :
```

```
                ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                SYNCHRONIZATION<CALL>)
                If(2)      XX has a pending status
                Then(2)    bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 1
                Endif(2)
            Endwhile
    Else(1) { the dynamic failure memory is empty }
            No action
    Endif(1)
```

Every 1 s :

```
If   bit 0 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 0
Then       If     LV_END_DIAG_TOOTH_OFF_IN/EX[i] = 1
           Then   bit 0 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 1
           Endif
Endif

If   bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 0
Then
           If     LV_INH_DIAG_TOOTH_OFF_IN/EX[i] = 1
           Then   bit 1 of STATE_RBM_TOOTH_OFF_IN/EX[i] = 1
           Endif
Endif
```

LV_INH_DIAG_EXT_CRK_TOOTH	LV_INH_DIAG_EXT_CRK_TOOTH_PER	LV_INH_DIAG_EXT_CRK_SYN	

General information:

The purpose of the function is to detect failures on the crankshaft signal while the system is synchronized.

The diagnosis is divided in three different parts: tooth number error, implausible tooth period, and loss of synchronization on crankshaft signal.

23.18.1.1 Crankshaft Sensor Diagnosis with Tooth Number Error

FUNCTION DESCRIPTION:

General information:

The number of teeth per crankshaft revolution is monitored by the crankshaft signal acquisition. The algorithm may tolerate a number of missing/additional teeth per revolution without loosing synchronization, depending on the used target wheel and on configuration data. The bit LV_ORNG_NR_TOOTH_CRK indicates wrong tooth number during the most recent crankshaft revolution.

If a tooth was missing or added during one revolution, then all variables based on teeth counting will be produced with an error. This concerns for example spark advance, segment time, misfire segments, camshaft position, etc. The purpose of the function is to provide information when the crankshaft signal is inaccurate, in order to take the necessary actions.

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 │ │ │ └─> Incorrect crankshaft tooth number "TOOTH_NUMBER"   (= SYM_0)
 │ │ └───> (not used)                                         (= SYM_1)
 │ └─────> (not used)                                         (= SYM_2)
 └───────> (not used)                                         (= SYM_3)
```

Application conditions

Initialisation:

LV_CDN_DIAG_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
LV_ERR_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*
ERR_SYM_CRK_TOOTH = *Refer to filtering configuration for the initialisation value*

Recurrence: *once per crankshaft revolution, after detection of the reference gap, except in the first revolution after synchronization*

Activation: LV_CRK_SYN = 1
And LV_INH_DIAG_CRK_TOOTH = 0
And LV_INH_DIAG_EXT_CRK_TOOTH = 0
And LV_INH_DIAG_ENSD = 0
And N_32 > C_N_32_MAX_DIAG_CRK_TOOTH

When the activation conditions are fulfilled then LV_CDN_DIAG_CRK_TOOTH = 1.

Deactivation:

When the activation conditions are not fulfilled then LV_CDN_DIAG_CRK_TOOTH = 0.

Formula Section

Symptoms calculation:

```
If   LV_ORNG_NR_TOOTH_CRK = 0
Then     ERR_SYM_CRK_TOOTH = NO_SYM
Else     ERR_SYM_CRK_TOOTH = "SYM_0" {Detection of symptom TOOTH_NUMBER}
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

```
Apply filter on current symptoms
If filtering result available (after debounce)
Then
    LV_ERR_CRK_TOOTH = filtering result
    LV_END_DIAG_CRK_TOOTH = 1
    Deliver the result to Error Management
Endif
```

Configuration for diagnostic symptoms :

See Appl. Inc.

Calculation of missing/added tooth information for misfire

Initialisation:

LV_INH_MIS_CRK = 0 at reset and at engine stalling (LV_STOP_ENG transition from 0 to 1).

Recurrence: *once per crankshaft revolution, after detection of the reference gap, except in the first revolution after synchronization*

Activation: LV_CRK_SYN = 1

Deactivation: *LV_CRK_SYN = 0*

Formula Section

Symptoms calculation:

```
If   LV_ORNG_NR_TOOTH_CRK = 0
Then     LV_INH_MIS_CRK = 0
Else     LV_INH_MIS_CRK = 1
Endif
```

LV_ORNG_NR_TOOTH_CRK is reset after reading at the reference gap

23.18.1.2 Crankshaft Sensor Diagnosis with implausible Tooth Period

FUNCTION DESCRIPTION:

General information:

Crankshaft signal acquisition validates the tooth period by limits derived from the current engine speed.

Before synchronization, LV_ORNG_TOOTH_PER_CRK indicates implausible gradient of the tooth period. This flag is also set if a reference gap occurs during valid teeth phase or when the first reference gap cannot be detected.

After synchronization, LV_ORNG_TOOTH_PER_CRK is set if spikes are detected outside the crankshaft window acceptance window.

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 |  |  |  └─> Implausible crankshaft tooth period "TOOTH_PERIOD"   (= SYM_0)
 |  |  └────> (not used)                                           (= SYM_1)
 |  └───────> (not used)                                           (= SYM_2)
 └──────────> (not used)                                           (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
LV_ERR_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*
ERR_SYM_CRK_TOOTH_PER = *Refer to filtering configuration for the initialisation value*

Recurrence: if LV_CRK_SYN = 1: every reference gap
If LV_CRK_SYN = 0: when LV_ORNG_TOOTH_PER_CRK is set

Activation: LV_RUN_ENG= 1
And LV_LIH_ERR_CRK = 0
And LV_INH_DIAG_CRK_TOOTH_PER = 0
And LV_INH_DIAG_EXT_CRK_TOOTH_PER = 0
And LV_INH_DIAG_ENSD = 0

When the activation conditions are fulfilled then LV_CDN_DIAG_CRK_TOOTH_PER = 1.

Deactivation:

When the activation conditions are not fulfilled then LV_CDN_DIAG_CRK_TOOTH_PER = 0.

Formula Section

Symptoms calculation:

Before crankshaft synchronization (LV_CRK_SYN = 0)

```
If      LV_ORNG_TOOTH_PER_CRK = 0
Then    ERR_SYM_CRK_TOOTH_PER = NO_SYM
Else    ERR_SYM_CRK_TOOTH_PER = “SYM_0" {Detection of symptom
        TOOTH_PERIOD}
Endif
```

After crankshaft synchronization (LV_CRK_SYN = 1)

```
If      LV_ORNG_TOOTH_PER_CRK = 1 set at a tooth event or end of tolerance window
Then    ERR_SYM_CRK_TOOTH_PER = “SYM_0" {Detection of symptom
        TOOTH_PERIOD}
Endif
LV_ORNG_TOOTH_PER_CRK is reset after reading
If      LV_ORNG_TOOTH_PER_CRK = 0 at the reference gap
Then    ERR_SYM_CRK_TOOTH_PER = NO_SYM
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

```
Apply filter on current symptoms
If filtering result available (after debounce)
Then
    LV_ERR_CRK_TOOTH_PER = filtering result
    LV_END_DIAG_CRK_TOOTH_PER = 1
    Deliver the result to Error Management
Endif
```

Configuration for diagnostic symptoms :

See Appl. Inc.

23.18.1.3 Crankshaft Sensor Diagnosis with Loss of Synchronization

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect crankshaft failure when the system looses synchronization on the crankshaft signal.

Synchronization will be lost if the reference gap is not detected at the correct position plus/minus a tolerance of missing/additional teeth, depending on the used target wheel and on configuration data.

If the signal fails completely (no more crankshaft signal edges are detected), then no error will be detected by this diagnosis, since the condition is similar to stopped engine. A failure then may be detected by the crankshaft sensor plausibility diagnosis (e.g. test against the camshaft signal).

Description:

Error-symptoms are defined for this diagnostic function as following:

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> Loss of synchronization "SYNC_LOSS"        (= SYM_0)
 │  │  └────> (not used)                                 (= SYM_1)
 │  └───────> (not used)                                 (= SYM_2)
 └──────────> (not used)                                 (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_CRK_SYN = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_CRK_SYN = *Refer to filtering configuration for the initialisation value*
LV_ERR_CRK_SYN = *Refer to filtering configuration for the initialisation value*
ERR_SYM_CRK_SYN = *Refer to filtering configuration for the initialisation value*

Recurrence: *once per crankshaft revolution, after the reference gap, except in the first revolution after synchronization, or when the bit LV_LOST_SYN_CRK is set.*

Activation: LV_CRK_SYN = 1
And LV_INH_DIAG_CRK_SYN = 0
And LV_INH_DIAG_EXT_CRK_SYN = 0
And LV_INH_DIAG_ENSD = 0

When activation conditions are fulfilled then LV_CDN_DIAG_CRK_SYN = 1.

Deactivation:

When activation conditions not are fulfilled then LV_CDN_DIAG_CRK_SYN = 0.

Formula Section

Symptoms calculation:

```
If    LV_LOST_SYN_CRK = 0
Then     ERR_SYM_CRK_SYN = NO_SYM
Else     ERR_SYM_CRK_SYN = “SYM_0" {Detection of symptom SYNC_LOSS}
Endif
```

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Filtering:

```
Apply filter on current symptoms
If filtering result available (after debounce)
Then
    LV_ERR_CRK_SYN = filtering result
    LV_END_DIAG_CRK_SYN = 1
    Deliver the result to Error Management
Endif
```

23.19.1.1 Diagnosis of crankshaft sensor

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect a failure if synchronization on crankshaft signal cannot be achieved.

One of the available camshaft signals is selected for crankshaft synchronization by setting one of the flags LV_ACT_SYN_CRK_CAM_IN[i] in the engine position control function. The signal edge counter of that camshaft is observed while the crankshaft is not synchronized. If the count reaches a calibrated number, and the system is still not synchronized with the crankshaft signal, then crankshaft sensor plausibility error is set without further debouncing. If valid crankshaft teeth have already been detected, the symptom will be “implausible signal”, otherwise it will be “missing signal”.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined to this diagnostic function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 |  |  |  └─> Signal missing          (= SYM_0)
 |  |  └────> Signal implausible      (= SYM_1)
 |  └───────> (not used)              (= SYM_2)
 └──────────> (not used)              (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_CRK_PLAUS = 0 at reset
LV_END_DIAG_CRK_PLAUS = 0 at reset
ERR_SYM_CRK_PLAUS = NO_SYM at reset
LV_ERR_CRK_PLAUS = 0 at reset

Recurrence:	every update of CTR_EDGE_CAM_IN(EX)[i] And 0 to 1 transition of LV_STOP_ENG
Activation:	LV_ACT_CRK = 1 And LV_INH_DIAG_CRK_PLAUS = 0 And LV_INH_DIAG_EXT_CRK_PLAUS = 0 And LV_INH_DIAG_ENSD = 0

When the activation condition is fulfilled then LV_CDN_DIAG_CRK_PLAUS = 1.

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_CRK_PLAUS = 0.

Formula Section

Symptoms calculation:

```
If      LV_STOP_ENG = 1
        And
        LV_CRK_MISS_RUN_ENG = 1
Then    ERR_SYM_CRK_PLAUS = "SYM_0"
        {Crankshaft signal missing but engine is still turning}
```

```
else
        If      LV_CRK_SYN = 0
        and     CTR_EDGE_CAM_IN(EX)[i] >
                C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX
        Then    If      LV_FIRST_VLD_TOOTH = 1
                Then    ERR_SYM_CRK_PLAUS = “SYM_1"
                        {Detection of symptom SIGNAL IMPLAUSIBLE}
                Else    ERR_SYM_CRK_PLAUS = “SYM_0"
                        {Detection of symptom SIGNAL MISSING}
                Endif
                LV_ERR_CRK_PLAUS = 1
                LV_END_DIAG_CRK_PLAUS = 1
        Endif
Endif
```

LV_ERR_CRK_PLAUS and ERR_SYM_CRK_PLAUS are reset to initialization value at 0 to 1 transition of LV_IGK.

```
If      LV_CRK_SYN = 1
Then    LV_END_DIAG_CRK_PLAUS = 1
        LV_ERR_CRK_PLAUS = 0
        ERR_SYM_CRK_PLAUS = NO_SYM
        Deliver the result to Error Management
Endif
```

Configuration for diagnostic symptoms :

Diagnostic Crankshaft sensor	**Symptom description**	**Symptom**	**Filter type**
Crankshaft sensor	*SIGNAL MISSING*	*SYM_0*	*NO*
	SIGNAL IMPLAUSIBLE	*SYM_1*	
		SYM_2	
		SYM_3	

NB: The filter type for this diagnosis can not be configured, it behaves as a MEM filter.

23.19.1.2 Camshaft sensor plausibility diagnosis

FUNCTION DESCRIPTION:

General information:

The functional camshaft diagnosis cannot detect a failure when a camshaft sensor delivers no signal at all. Missing signal will be detected if the camshaft edge counter is not incremented at least once per engine cycle.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined to this diagnostic function as following:

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> Signal missing        (= SYM_0)
 │  │  └────> (not used)            (= SYM_1)
 │  └───────> (not used)            (= SYM_2)
 └──────────> (not used)            (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_PLAUS_CAM_IN(EX)[i] = 0 at reset
LV_END_DIAG_PLAUS_CAM_IN(EX)[i] = 0 at reset
ERR_SYM_PLAUS_CAM_IN(EX)[i] = NO_SYM at reset
LV_ERR_PLAUS_CAM_IN(EX)[i] = 0 at reset

CTR_CYC_ENG_PLAUS_CAM_IN(EX)[i] = C_NR_CYC_ENG_PLAUS_CAM_MAX at reset

Recurrence: once per engine cycle (two crankshaft revolutions), at any phasing i.e. on crankshaft revolution which was on-going at engine synchronization

Activation:
LV_CRK_SYN = 1
And LV_INH_DIAG_PLAUS_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_EXT_PLAUS_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_ENSD = 0
And C_NR_CYC_ENG_PLAUS_CAM_MAX ≠ 0

When the activation condition is fulfilled then LV_CDN_DIAG_PLAUS_CAM_IN(EX)[i] =1.

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_PLAUS_CAM_IN(EX)[i] = 0.

Formula Section

Symptoms calculation:

Camshaft sensor plausability diagnosis for intake	*SIGNAL MISSING*	*SYM_0*	*NO*
		SYM_1	
		SYM_2	
		SYM_3	
Camshaft sensor plausability diagnosis for exhaust	*SIGNAL MISSING*	*SYM_0*	*NO*
		SYM_1	
		SYM_2	
		SYM_3	

NB: The filter type for this diagnosis can not be configured, but it behaves as a MEM if LC_CTR_DEC_PLAUS_CAM = 0, and as a STD_INI if LC_CTR_DEC_PLAUS_CAM = 1

23.19.1.3 Camshaft Sensor Diagnosis for Crankshaft Synchronization

FUNCTION DESCRIPTION:

General information:

The purpose of the function is to detect a failure of the camshaft information for crankshaft synchronization.

Up to four camshaft signals may be available in the system (intake and/or exhaust on one or two cylinder banks). The Engine Position Control selects one camshaft for synchronization by activating the corresponding operating mode. The camshaft signal acquisition will indicate “camshaft signal out of range for crankshaft synchronization” by setting LV_ORNG_CAM_SYN_CRK, which has to be reset by the diagnosis after treatment. A counter is incremented at every recurrence if LV_ORNG_CAM_SYN_CRK is set. The error is detected when the counter reaches a calibrated maximum.

i = 1...NC_NR_CAM_CBK

Description:

Error-symptoms are defined to this diagnostic function as following:

```
|_|_|_|_|
 | | | └-> Camshaft signal  not valid for crankshaft synchronization    (= SYM_0)
 | | └───> (not used)                                                  (= SYM_1)
 | └─────> (not used)                                                  (= SYM_2)
 └───────> (not used)                                                  (= SYM_3)
```

Application conditions:

Initialisation:

LV_CDN_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0 at reset
LV_END_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0 at reset
ERR_SYM_SYN_CRK_CAM_IN(EX)[i] = NO_SYM at reset

LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 0 at reset

Recurrence: every crankshaft reference gap and every camshaft edge

Activation:
LV_ACT_CRK = 1
And LV_INH_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_EXT_SYN_CRK_CAM_IN(EX)[i] = 0
And LV_INH_DIAG_ENSD = 0

When the activation condition is fulfilled then LV_CDN_DIAG_SYN_CRK_CAM_IN(EX)[i] = 1

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_SYN_CRK_CAM_IN(EX)[i] = 0.

Formula Section

Symptoms calculation:

For LV_ACT_SYN_CRK_CAM_IN(EX)[i] = 1 (camshaft sensor currently selected for synchronization):

```
if      LV_ORNG_CAM_SYN_CRK = 0
then    ERR_SYM_SYN_CRK_CAM_IN(EX)[i] = NO_SYM
else    ERR_SYM_SYN_CRK_CAM_IN(EX)[i] = “SYM_0" {SIGNAL INVALID}
        increment CTR_ORNG_CAM_SYN_CRK
endif

if      CTR_ORNG_CAM_SYN_CRK > C_CTR_ORNG_CAM_SYN_CRK_MAX
then    LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 1
        LV_END_DIAG_SYN_CRK_CAM_IN(EX)[i] = 1
        Deliver the result to Error Management
        reset CTR_ORNG_CAM_SYN_CRK
endif

if      LV_SYN_VLD = 1
then    LV_END_DIAG_SYN_CRK_CAM_IN(EX)[i] = 1
        ERR_SYM_SYN_CRK_CAM_IN(EX)[i] = NO_SYM
        LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 0
        Deliver the result to Error Management
        reset CTR_ORNG_CAM_SYN_CRK
endif
```

For LV_ACT_SYN_CRK_CAM_IN(EX)[i] = 0 (camshaft sensor currently **not** selected for cam/crk synchronization):

```
if      LV_SYN_CAM_IN(EX)[i] = 1
        And
        LV_AD_END_CAM_IN(EX)[i] = 1
then    ERR_SYM_SYN_CRK_CAM_IN(EX)[i] = NO_SYM
        If          LC_CAM_ERR_ENA_VVT = 1
        Then    LV_ERR_SYN_CRK_CAM_IN(EX)[i] = 0
                LV_END_DIAG_SYN_CRK_CAM_IN(EX)[i] = 1
                Deliver the result to Error Management
        Endif
endif
```

LV_ERR_SYN_CRK_CAM_IN(EX)[i], ERR_SYM_SYN_CRK_CAM_IN(EX)[i] and CTR_ORNG_CAM_SYN_CRK are reset to initialization value at 0 to 1 transition of LV_IGK.

Inhibition condition for the diagnosis of crankshaft sensor					

Input data:

LV_ERR_CRK_PLAUS			

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_EXT_CRK_PLAUS allows to deactivate the corresponding diagnostic.

Application conditions:

Initialisation:
At reset event : LV_INH_DIAG_EXT_CRK_PLAUS = 0

Recurrence:
Application incidence recurrence = once at reset

Activation:
-/-

Deactivation:
When the activation condition is not fulfilled

Formula section:

LV_INH_DIAG_EXT_CRK_PLAUS = 0

Diagnosis / Failure Flag	Symptom		DTC
Crankshaft sensor plausibility diagnosis LV_ERR_CRK_PLAUS	Bit 0	Signal Missing	P0374
	Bit 1	Signal Implausible	P0373
	Bit 2	unused	
	Bit 3	unused

Calibration interfering functions:

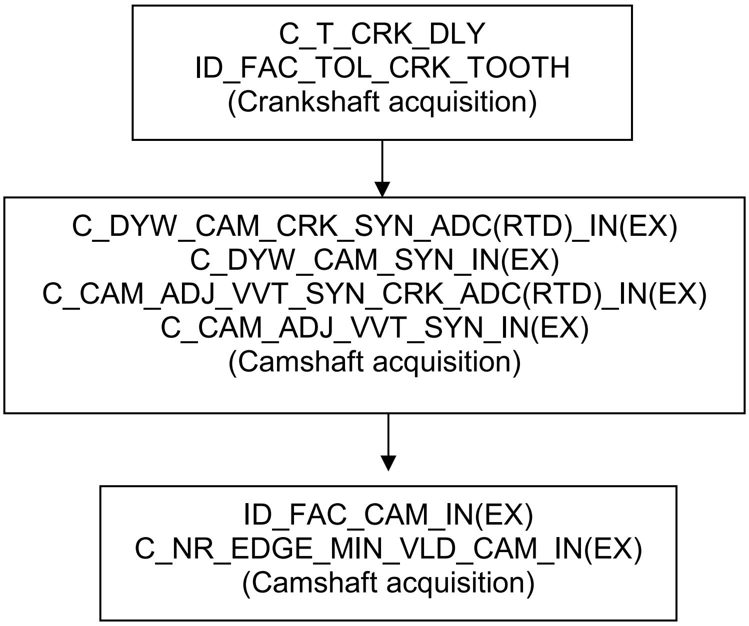
INJR, VVTI, IGSP and IGRE must be pre-calibrated

Calibration of C_DYW_CAM_SYN_IN(EX) and C_CAM_ADJ_VVT_SYN_IN(EX) influences pre-injection function (INJR-aggregate).

Calibration of C_NR_EDGE_MIN_VLD_CAM_IN(EX) influences VVT-function (VVTI-aggregate)

Note that engine will not start if one of the following calibration data is wrong (too low or too high).

Calibration flowchart:



Calibration process:

Calibration data ID_FAC_TOL_CRK_TOOTH

Calibration data ID_FAC_TOL_CRK_TOOTH defines the width of the crankshaft acceptance window for:

1) tooth validation
2) reference gap detection

ID_FAC_TOL_CRK_TOOTH [0rpm] is used for detection of the first reference gap and tooth validation before crankshaft synchronization.

Calibration of ID_FAC_TOL_CRK_TOOTH depends on engine accelerations / decelerations and crankshaft sensor/target wheel accuracy.

- ID_FAC_TOL_CRK_TOOTH [0rpm] should be calibrated taking into account engine accelerations before crankshaft synchronization (engine turning with starter):

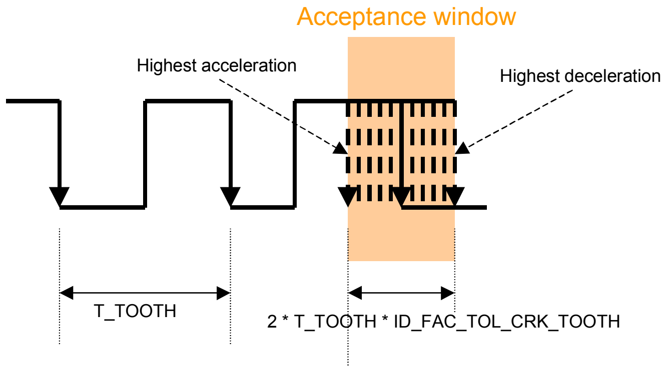
If NC_NR_TOOTH_FIRST_GAP_MIN = 2 (two teeth need to be simulated during first reference GAP):

- Low value should be preferred (between 0.2 and 0.3) in order to synchronize as soon as first reference gap occurs
- If calibration value is too high, engine synchronization will be late (after occurrence of first gap) or engine will not start at all.
- If value is too low (< 0.2), crankshaft tooth period error (LV_ERR_CRK_TOOTH_PER) could occur.

If strong accelerations are observed during reference GAP, it implies NC_NR_TOOTH_FIRST_GAP_MIN = 1 (only one tooth need to be simulated during first reference GAP) and then:

- medium value should be preferred (between 0.4 and 0.6) in order to distinguish correctly the GAP from the normal teeth and thus synchronize as soon as first reference gap occurs
- If calibration value is too high, engine synchronization will be late (after occurrence of first gap) or engine will not start at all.
- If value is too low, a normal tooth with strong deceleration could be considered as a GAP.

- ID_FAC_TOL_CRK_TOOTH [> 0rpm] should be calibrated taking into account engine accelerations/decelerations after engine synchronization (especially first combustion after synchronization):
  - Low value should be preferred (between 0.25 and 0.4) in order to detect invalid teeth and to avoid loss of synchronization after first combustion (especially if high acceleration occurs during reference gap, e.g. gap just after TDC).
  - Large window is not safer as margin of robustness for gap detection decreases.
- ID_FAC_TOL_CRK_TOOTH is also used for crankshaft tooth validation:



- If a active crankshaft edge occurs before the acceptance window defined by ID_FAC_TOL_CRK_TOOTH, the signal edge is invalid and the tooth counter is not incremented.
- If no active crankshaft edge occurs inside the acceptance window defined by ID_FAC_TOL_CRK_TOOTH, a crankshaft tooth is simulated and the tooth counter is incremented.

In both cases the, the tooth counter and, consequently, the engine position is corrected immediately. Otherwise, when the acceptance window is too large (high value of

ID_FAC_TOL_CRK_TOOTH), the engine position is corrected only at reference gap (no immediate correction possible) and timing events (injection/ignition) occur too late or too early. Therefore, for the speed range where engine acceleration is small, low values of ID_FAC_TOL_CRK_TOOTH should be prefered

- If less than NC_NR_GAP teeth are simulated during the reference gap (in case of high engine acceleration / speed variations), the crankshaft tooth counter is corrected and error symptom “ERR_SYM_CRK_TOOTH” is set. In order to avoid false crank error detection, ID_FAC_TOL_CRK_TOOTH should be small.

- Crankshaft acceptance window is deactivated for the defined speed range when ID_FAC_TOL_CRK_TOOTH is set to zero. Consequently, reference gap detection is also deactivated.

- After synchronization acceptance window could be disabled below NC_N_CRK_WIN_ENA, for example for engines having strong accelerations/decelerations at start: In this case the acceptance window is only applied for GAP detection and some teeth around the GAP below the configured engine speed threshold and should be adapted to accelerations/decelerations occuring on teeth where the GAP is searched.

Calibration data C_T_CRK_DLY

After the first active crankshaft edge, the crankshaft acquisition is deactivated during a sensing delay. The duration of the sensing delay is defined by the the calibration data C_T_CRK_DLY.

The purpose is to avoid acquisition of signal spikes:

- at very low engine speed (< 30rpm): In this case, the output signal level of a magnetic crankshaft position sensor (MCPS) is too low in order to produce plausible signal edges at the µC input pin.

- during start of the starter motor: a high current is drawn from the battery until the starter motor reaches its nominal speed. The current and voltage gradient can produce electromagnetic disturbances on the sensor lines and the ECU.

Calibration data C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX)

Engine synchronization in ENSD is based on camshaft level detection at engine start and evaluation of the angular distance between crankshaft and camshaft signal events.

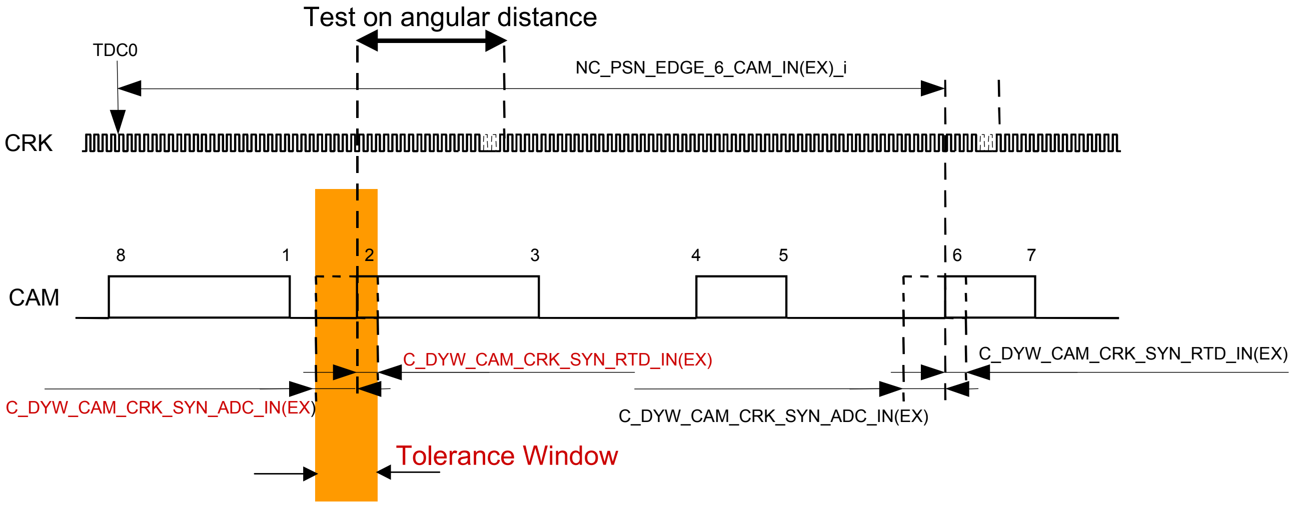
Possible camshaft to crankshaft signal events are:

1. start position to reference gap
2. camshaft signal edge to reference gap (see figure below)
3. reference gap to camshaft signal edge

If the measured angular distance between one of the above events is inside the designed distance including a tolerance window, engine synchronizes.

The advance range of the tolerance window is defined by calibration data C_DYW_CAM_CRK_SYN_ADC_IN(EX).

The retard range of the tolerance window is defined by calibration data C_DYW_CAM_CRK_SYN_RTD_IN(EX).



C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX) should be calibrated taking into account engine-to-engine variations of camshaft to crankshaft edge positions (including angular shift of camshaft to crankshaft):

- The maximum spread from designed camshaft edge position to advanced position should be included in C_DYW_CAM_CRK_SYN_ADC_IN(EX)

- The maximum spread from designed camshaft edge position to retarded position should be included in C_DYW_CAM_CRK_SYN_RTD_IN(EX)

Please note that TDC0 is the reference position for all camshaft and crankshaft positions.

All mechanical and electrical tolerances of the sensors, the target wheels and the mounting should be included:

- mounting tolerances of camshaft and crankshaft sensor
- mounting tolerances of camshaft and crankshaft target wheel
- camshaft and crankshaft sensor accuracy
- machining of camshaft and crankshaft target wheel
- angular shift of crankshaft to crankshaft target wheel position

Sum up all these tolerance values for the intake and exhaust camshaft and set calibration values C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX) accordingly.

Consider also that mechanical tolerances and angular shift of crank to cam can vary during engine lifetime (for example: increased belt/chain length). This variation occurs generally in retard direction.

If the camshaft sensor features a pre-calibration mode in order to adapt the air-gap between sensor and target wheel, sensor accuracy for pre-calibration mode shall be considered (low accuracy at cranking, auto-adaptation generally terminated several engine revolutions after engine synchronization).

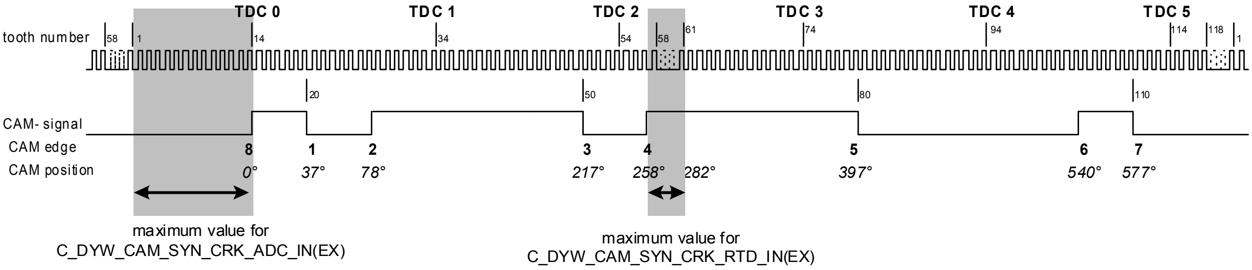
Comments:

1) The **maximum value for the tolerance window** is:

C_DYW_CAM_CRK_SYN_RTD_IN(EX) = minimal angular distance over one engine cycle between designed camshaft edge position and reference gap for all camshaft edges **before** reference gap

C_DYW_CAM_CRK_SYN_ADC_IN(EX) = minimal angular distance over one engine cycle between designed camshaft edge position and reference gap for all camshaft edges **after** reference gap

Example multi-teeth target wheel:



If a value higher than this maximum value is calibrated, engine position cannot be unambiguously identified at reference gap and the cam/crk synchronization out-of-range flag LV_ORNG_CAM_SYN_CRK is set.

Remember that the position of the reference gap is defined as the position in °CRK of the first active crankshaft edge after the gap.

2) Calibration data C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX) applies for **VVT actuator locked at engine start** (normal condition).

Calibration data C_CAM_ADJ_VVT_SYN_CRK_ADC(RTD)_IN(EX)

If the VVT actuator is not locked at engine start (flag LV_CAM_LOCK_IVVT_IN(EX)_i set to 0), the cam/crk synchronization tolerance windows defined by C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX) will be extended by calibration data C_CAM_ADJ_VVT_SYN_CRK_ADC(RTD)_IN(EX):

VVT on intake camshaft (adjustement in advance direction):

-> VVT actuator range in C_CAM_ADJ_VVT_SYN_CRK_ADC_IN

VVT on exhaust camshaft (adjustement in retard direction):

-> VVT actuator range included in C_CAM_ADJ_VVT_SYN_CRK_RTD_EX

C_CAM_ADJ_VVT_SYN_CRK_ADC(RTD)_IN(EX) should be lower than or equal to VVT actuator range. Actual value depends on time for VVT actuator to return to passive position and cam/crk configuration. Cam/crk synchronization should not be out-of-range (CTR_ORNG_CAM_SYN_CRK should remain zero).

Calibration data C_DYW_CAM_SYN_IN(EX)

Calibration data C_DYW_CAM_SYN_IN(EX) is used to test the angular distance between two camshaft edges (crankshaft events are not considered).

C_DYW_CAM_SYN_IN(EX) does not depend on absolute crankshaft or camshaft edge positions but is based exclusively on relative angular distances. The angular distance between camshaft edges is measured via the number of crankshaft signal edges which occurs between two camshaft events.

If the measured angular distance between two successive camshaft edges is inside the designed distance including a tolerance window, then

- the list of possible camshaft signal indexes is updated, and, consequently, the minimum and maximun engine position converges gradually (before engine synchronization: for pre-injection)
- the camshaft signal edge is valid for synchronization

C_DYW_CAM_SYN_IN(EX) should be calibrated taking into account engine-to-engine variations of camshaft edge positions:

- camshaft and crankshaft sensor accuracy
- machining of camshaft and crankshaft target wheel

Sum up all these tolerance values for the intake and exhaust camshaft and set calibration values C_DYW_CAM_SYN_IN(EX) accordingly.

If the camshaft sensor features a pre-calibration mode in order to adapt the air-gap between sensor and target wheel, sensor accuracy for pre-calibration mode shall be considered (as for C_DYW_CAM_SYN_CRK_ADC(RTD)_IN(EX)).

Comments:

1) C_DYW_CAM_SYN_IN(EX) must be lower than half the minimum angular distance between designed camshaft edge positions:

   C_DYW_CAM_SYN_IN(EX) < 0.5 * min(NC_PSN_EDGE_z_CAM_IN(EX)_i - NC_PSN_EDGE_z-1_CAM_IN(EX)_i)

2) Calibration data C_DYW_CAM_SYN_IN(EX) applies for **VVT actuator locked at engine start** (normal condition).

Calibration data C_CAM_ADJ_VVT_SYN_ IN(EX)

If the VVT actuator is not locked at engine start (flag LV_CAM_LOCK_IVVT_IN(EX)_i set to 0), the cam/crk tolerance windows defined by C_DYW_CAM_SYN_IN(EX) will be extended by calibration data C_CAM_ADJ_VVT_SYN_IN(EX):

VVT on intake camshaft (adjustement in advance direction):

-> VVT actuator range in C_CAM_ADJ_VVT_SYN_IN

VVT on exhaust camshaft (adjustement in retard direction):

-> VVT actuator range included in C_CAM_ADJ_VVT_SYN_EX

C_CAM_ADJ_VVT_SYN_IN(EX) should be lower than VVT actuator range. Actual value depends on time for VVT actuator to return to passive position and cam/crk configuration. Engine start could be longer (impact on pre-injection), but cam/crk synchronization should not be out-of-range (CTR_ORNG_CAM_SYN_CRK should remain zero).

Calibration data ID_FAC_CAM_IN(EX)

Calibration data ID_FAC_CAM_IN(EX) defines the tolerance factor for camshaft edge ratio calculation used for:

1) camshaft self-synchronization

2) camshaft sensor diagnosis ratio check

The camshaft edge ratio is defined as:

$$\frac{T\_SEG\_CAM\_IN(EX)\_i_n + T\_SEG\_CAM\_IN(EX)\_i_{n-3}}{T\_SEG\_CAM\_IN(EX)\_i_{n-1} + T\_SEG\_CAM\_IN(EX)\_i_{n-2}}$$

This measured ratio is compared to the designed (theoretical) ratio multiplied/divided by tolerance factor ID_FAC_CAM_IN(EX).

Calibration of ID_FAC_CAM_IN(EX) depends on engine accelerations/decelerations and engine-to-engine variations of camshaft edge positions.

If calibration data ID_FAC_CAM_IN(EX) is too low, camshaft out-of-range ratio flag (LV_ORNG_RATIO_CAM_IN(EX)_i) occurs and camshaft self-synchronization is reset.

The maximum value depends on the camshaft target wheel configuration: The upper limit is defined by theoretical ratio for falling and rising edges. If calibration data is higher than upper limit, the camshaft edge position cannot be identified and the camshaft will not self-synchronize.

If ID_FAC_CAM_IN(EX) is too low, camshaft self-synchronization is lost during high engine accelerations/decelerations resulting in de-activation of VVT.

Calibration data C_NR_EDGE_MIN_VLD_CAM_IN(EX)

Calibration data C_NR_EDGE_MIN_VLD_CAM_IN(EX) defines the number of camshaft edges to start camshaft reference position adaptation and to generate a camshaft position output for VVT control.

Generally, camshaft edges are less precise at engine start. Some camshaft sensors feature a pre-calibration mode in order to adapt the airgap between sensor and target wheel. In this case, camshaft edge positions are shifting during engine start until the nominal position (best accuracy) is reached. Camshaft reference position adaptation can only be started when camshaft edge position don’t shift anymore (otherwise wrong adaptation values are stored).

Camshaft sensor pre-calibration mode ends after a number of defined camshaft edges are detected. Calibration value C_NR_EDGE_MIN_VLD_CAM_IN(EX) should be greater or equal to this value specified in the sensor specification / data sheet.

If VVT actuator is not in passive position at engine start, calibration data C_NR_EDGE_MIN_VLD_CAM_IN(EX) should be greater than the number of camshaft edges necessary to bring the VVT actuator back to passive locked position (oscillations must be finished).

Calibration data LC_CAM_SWI_CONF

It is possible within ENSD to use the same SW for 2 different camshaft configurations (with same number of camshaft edges). When this feature is used, NC_NR_CONF_CAM shall be set to 2 and LC_CAM_SWI_CONF indicates which camshaft configuration will be used.

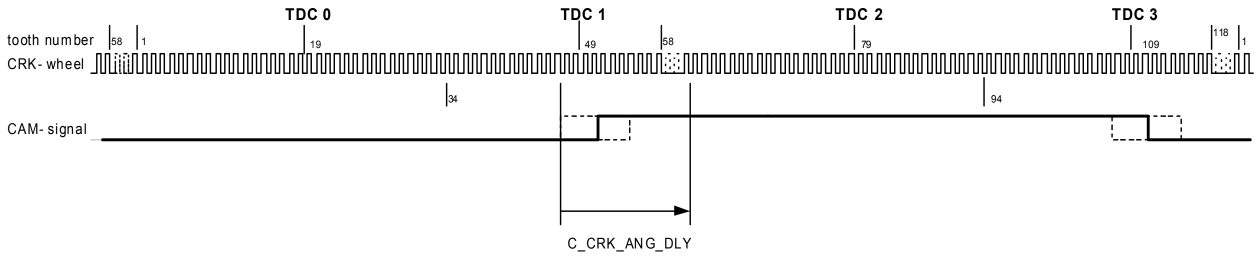
Calibration data C_CRK_ANG_DLY and C_CRK_ANG_DLY_LST_CAM

The maximum and minimum engine position are updated as soon as a crankshaft angle C_CRK_ANG_DLY has occured since first valid tooth and no camshaft signal edge was detected or as soon as a crankshaft angle C_CRK_ANG_DLY_LST_CAM has occured since last CAM and no camshaft signal edge was detected.

It has to be calibrated according to CAM/CRK configuration and timing.

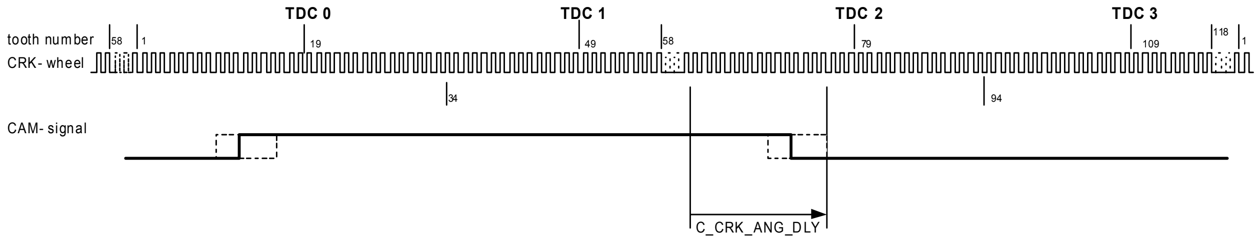
Two cases must be distinguished:

1) Camshaft edge before reference gap:



C_CRK_ANG_DLY = minimum angular distance between designed camshaft edge and reference gap + C_DYW_CAM_CRK_SYN_ADC_IN(EX)

2) Camshaft edge after reference gap:



C_CRK_ANG_DLY = minimum angular distance between designed camshaft edge and reference gap + C_DYW_CAM_CRK_SYN_RTD_IN(EX)

C_CRK_ANG_DLY_LST_CAM = min(angular distances CAM-CAM including tolerance value C_DYW_CAM_SYN_IN(EX), angular distances CAM-GAP including tolerance value C_DYW_CAM_CRK_SYN_ADC_IN(EX))

C_CRK_ANG_DLY = min(angular distances CAM-CAM including tolerance value C_DYW_CAM_SYN_IN(EX), angular distances GAP-CAM including tolerance value C_DYW_CAM_CRK_SYN_RTD_IN(EX))

C_CRK_ANG_DLY = 720°CRK and C_CRK_ANG_DLY_LST_CAM = 720°CRK disables this functionality.

23.21 Camshaft Position Determination

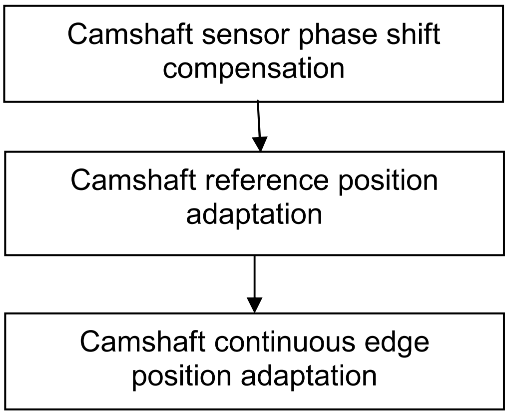
Calibration interfering functions:

INJR, VVTI, IGSP and IGRE pre-calibrated

Calibration data of this function are used for

- Camshaft position feedback for VVTI – function
- Crankshaft limp-home (Engine position and speed determination function)
- Camshaft position diagnosis (Engine position and speed determination function OBDI)

Calibration flowchart:



For system without VVT, only camshaft reference position adaptation has to be calibrated.

Calibration process:

Camshaft sensor phase shift compensation

The camshaft sensor phase shift vs. engine speed can be compensated by calibrating ID_CAM_PHA_COR.

Camshaft reference position adaptation

Camshaft reference adapation is performed when the VVT actuator is in passive position or when no VVT actuator is present in the system. The camshaft adaptation values represent the angular displacement of the camshaft signal edges relative to the designed position (NC_PSN_EDGE_z_CAM_IN(EX)_i). This angular displacement is caused by mechanical and sensor tolerances.

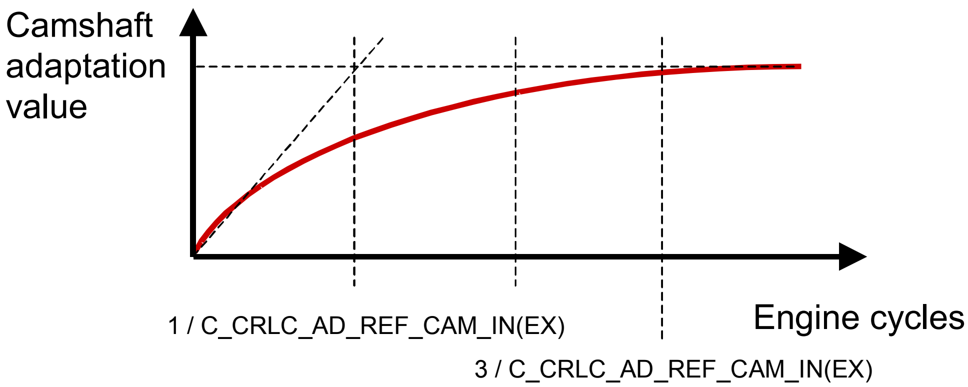
The camshaft reference position adaptation values are used for

- VVT position feedback
- Crankshaft limp-home

Calibration data C_NR_REV_AD_REF_CAM_IN(EX) defines the duration of the camshaft reference position adapation in number of engine cycles.

A filter with parameter C_CRLC_AD_REF_CAM_IN(EX) is applied to the camshaft edge adaptation values during the defined number of cycles.

Filter recurrency is the number of engine cycles. Steady state value is reached in 3/C_CRLC_AD_REF_CAM_IN(EX) engine cycles.



C_CRLC_AD_REF_CAM_IN(EX) = 1.0 (upper limit) means that steady state value is reached in 3 engine cycles (fastest value)

C_CRLC_AD_REF_CAM_IN(EX) = 0.0039 (lower limit) means that steady state value is reached in 3*256=768 engine cycles.

When the variation of camshaft edge positions during one camshaft revolution (VVT passive) is greater then the maximum gradient C_GRD_AD_REF_MAX_CAM_IN(EX), no reference position adaptation will be performed on the camshaft edge.

Note that adaptation values are applied immediately. If adaptation is calibrated very fast, the resulting jumps in the position output value that may be larger than C_GRD_AD_REF_MAX_CAM_IN(EX). In that case, adaptation is only performed every second engine cycle.

C_NR_REV_AD_REF_CAM_IN(EX) should be calibrated according to VVT function requirements. This calibration value determines the maximum dead time for VVT position feedback. In fact, continuous edge position adaptation cannot be started and, consequently, VVT position feedback is not available until the reference position adaptation is finished.

The filter on adaptation values has to converge before the end of reference adaptation.

Consequently, C_CRLC_AD_REF_CAM_IN(EX) should be calibrated as:

C_CRLC_AD_REF_CAM_IN(EX) > 3 / C_NR_REV_AD_REF_CAM_IN(EX

C_GRD_AD_REF_MAX_CAM_IN(EX) should be calibrated with respect to the max. allowed camshaft edge position variation with the VVT actuator in passive position. This value is generally very small.

Continuous edge position adaptation

Continuous edge position adapation is only performed when a VVT actuator is present in the system. It is activated when camshaft position is valid and reference position adaptation is not active.

Camshaft edges are adapted with reference to signal edge #1 (first falling edge after TDC0) on which only reference adaptation is done. Every angular displacement of edge #1 is considered as a camshaft displacement. The continous adaptation compensates the (unintentional) angular displacement of signal edges relative to the reference edge position due to temperature drift of the sensor etc.

A filter with time constant parameter C_CRLC_AD_CAM_IN(EX) is applied to the camshaft edge adaptation values during continuous edge position adaptation.

Filter recurrency is the number of engine cycles. Adaptation steady state value is reached in 3/C_CRLC_AD_CAM_IN(EX) engine cycles.

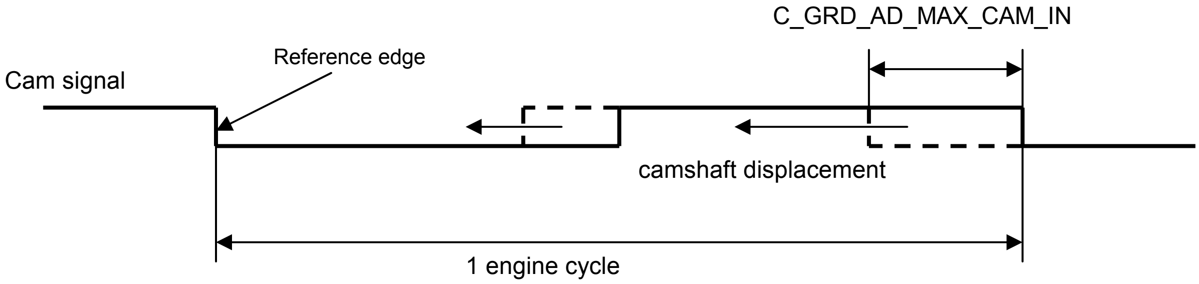
C_CRLC_AD_CAM_IN(EX) = 1.0 (upper limit) means that steady state value is reached in 3 engine cycles (fastest value)

C_CRLC_AD_CAM_IN(EX) = 0.0039 (lower limit) means that steady state value is reached in 3*256=768 engine cycles.

When the variation of camshaft edge positions between two consecutive camshaft reference edges (one engine cycle) is greater then the maximum gradient C_GRD_AD_MAX_CAM_IN(EX), no continuous edge position adaptation is performed.

The camshaft adaptation values should not be updated due to intentional VVT displacement during one engine cycle. Therefore C_GRD_AD_MAX_CAM_IN(EX) should be calibrated with respect to max. allowed camshaft edge variations with the VVT actuator in a fixed active position.

Example (half-moon target wheel, intake camshaft):

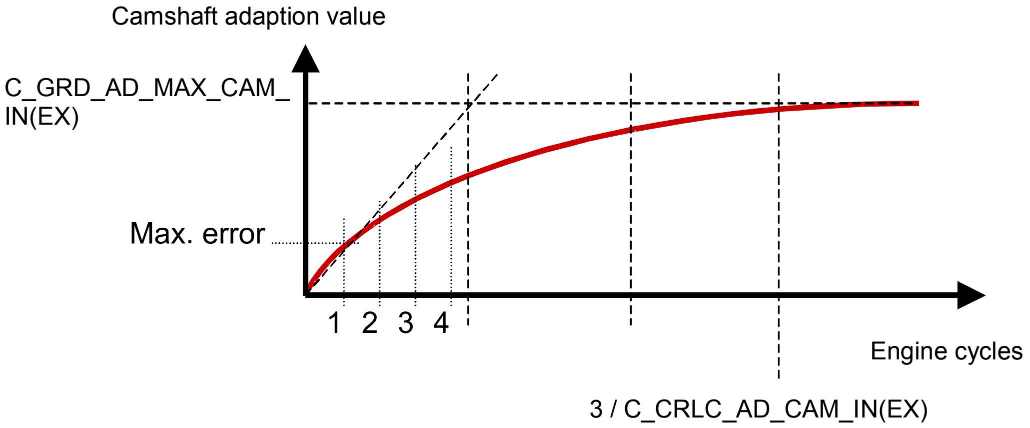


Calibration value C_CRLC_AD_CAM_IN(EX) should be calibrated according to the maximum tolerated error on VVT position during one engine cycle (VVT requirement):

C_CRLC_AD_CAM_IN(EX) = max. position error / C_GRD_AD_MAX_CAM_IN(EX)

(see figure below)

C_GRD_AD_MAX_CAM_IN(EX) is defined with respect to the maximum VVT actuator speed as above.

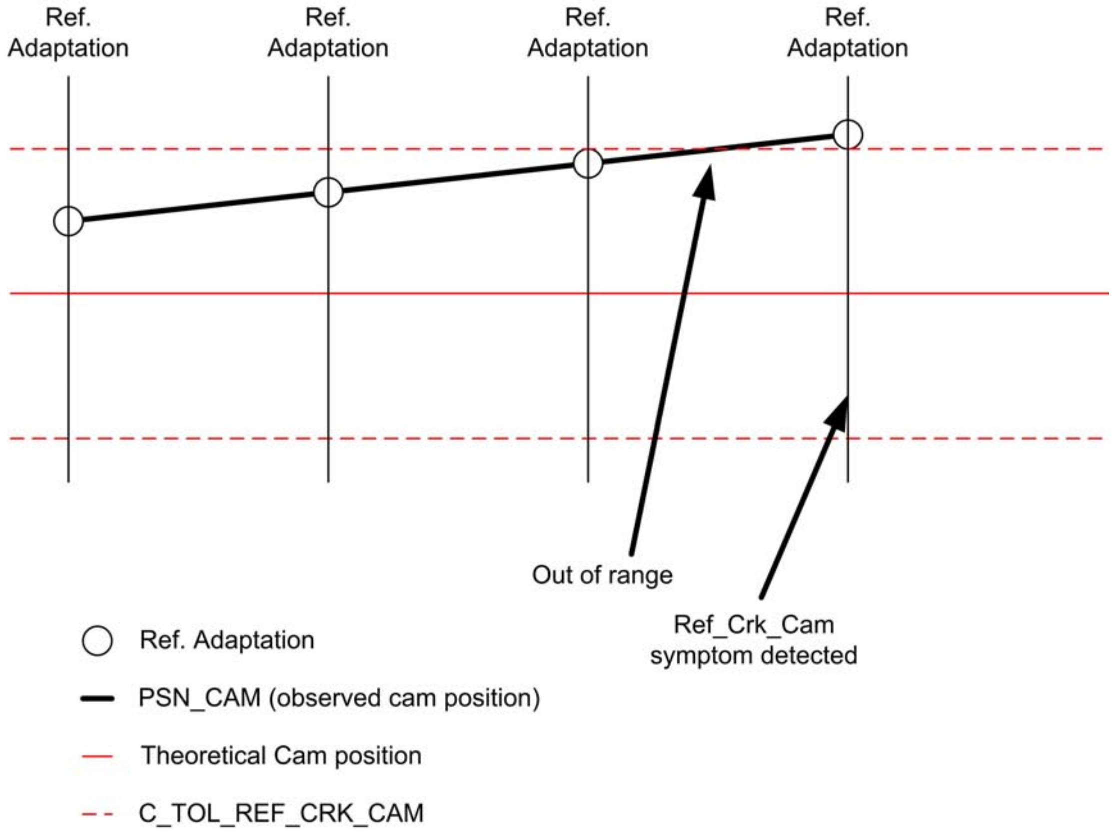


Generally, continuous position adapation should be much slower than reference position adaptation (C_CRLC_AD_CAM_IN(EX) << C_CRLC_AD_REF_CAM_IN(EX)).

Camshaft position diagnosis

REF_CRK_CAM symptom:

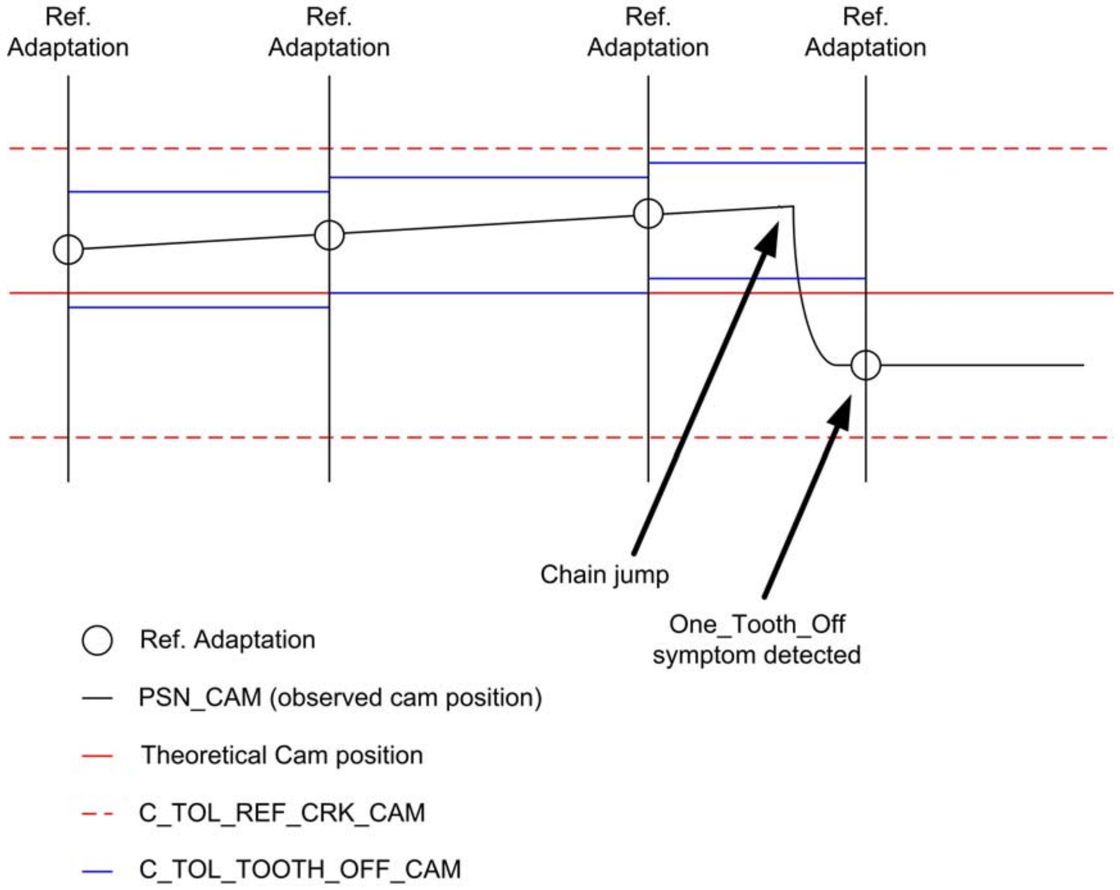
C_TOL_REF_CRK_CAM_IN and C_TOL_REF_CRK_CAM_EX represent the maximum tolerance between the adaptive camshaft edge position and the theoretical position. This difference can be due to mounting and electrical tolerances, and to slow deviation. If the observed camshaft position differs from the theory of more than C_TOL_REF_CRK_CAM_IN(EX), the symptom REF_CRK_CAM_IN(EX) is detected.



C_TOL_TOOTH_OFF_CAM_IN(EX) are not represented on this figure, because REF_CRK_CAM symptom is prioritary to ONE_TOOTH_OFF.

ONE_TOOTH_OFF symptom

C_TOL_TOOTH_OFF_CAM_IN and C_TOL_TOOTH_OFF_CAM_EX are used for ONE_TOOTH_OFF symptom detection. It represents the maximal sudden crk angle drift (between two consecutive adaptations) defined by OBDII to respect the emission standards. It can detect a quick jump of the camshaft edges positions which can be due to a chain jump for example.



To inhibit this diagnosis, C_TOL_TOOTH_OFF_CAM_IN(EX) have to be calibrated to 0.

23.22 Camshaft Sensor OBDI

Calibration interfering functions:

INJR, VVTI, IGSP and IGRE pre-calibrated

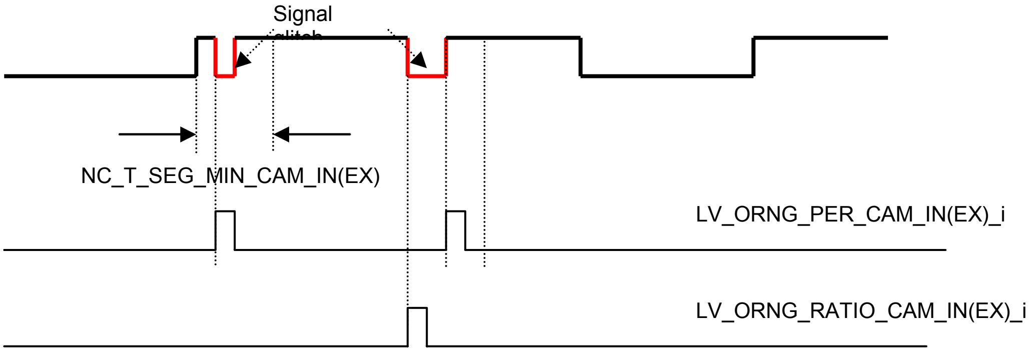
ACQ of CRK/CAM signal calibrated.

Calibration process:

The purpose of this diagnosis is to detect signal glitches on the camshaft sensor signal.

The camshaft sensor diagnosis is splitted in two parts:

- Camshaft segment period diagnosis based on segment time measurement
- Camshaft synchronization diagnosis based on camshaft ratio calculation



LV_ORNG_PER_CAM_IN(EX)_i is set if a spike occurs shortly after a valid camshaft signal edge.

LV_ORNG_RATIO_CAM_IN(EX)_i is set if a spike occurs between two valid camshaft signal edges. Note that the subsequent ratio calculations will also be wrong (ratio calculation done on last 2 (single tooth) or 4 (multi-teeth) camshaft segments).

The filter type can now be selected in Appl. Inc. file. In the case of a STD_INI (preferred solution), anti-bounce counter inc/max for camshaft segment period diagnosis should be set as:

C_ABC_INC_DIAG_PER_CAM_IN(EX) = NC_NR_EDGE_CAM_IN(EX)

C_ABC_MAX_DIAG_PER_CAM_IN(EX) = (NC_NR_EDGE_CAM_IN(EX) * max_symptom)

With this calibration, LV_ERR_PER_CAM_IN(EX)_i will be set

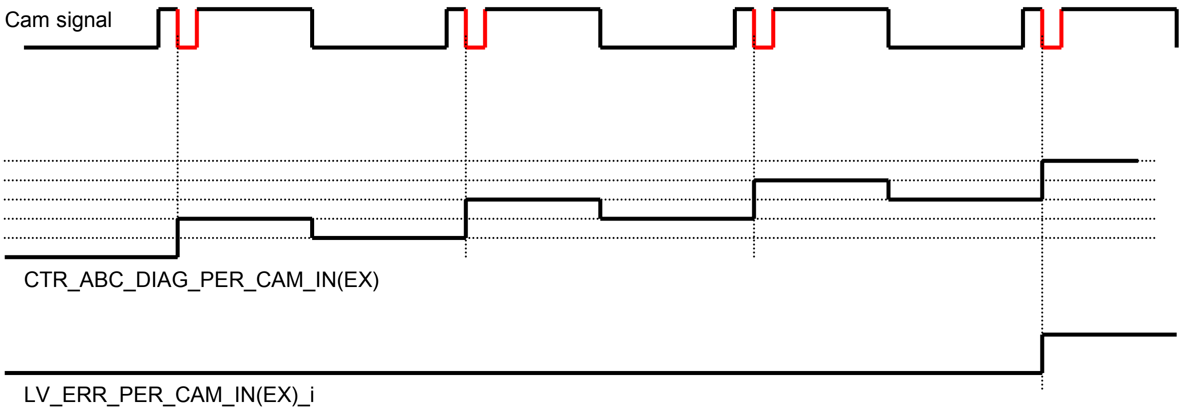
- as soon as a number of max_symptom succesive symptoms has occured on each camshaft edge
- as soon as a number of (C_ABC_MAX_DIAG_PER_CAM_IN(EX) – max_symptom) +1 succesive symptoms has occured during successive engine cycles on the same camshaft edge

For example:

half-moon camshaft target wheel

signal glitch on every rising signal edge max_symptom = 3

C_ABC_INC = 2, C_ABC_MAX = 6



If a camshaft ratio calculation is wrong, the camshaft self-synchronization is restarted. During the next 3 (single-tooth) or 5 (multi-teeth) camshaft edges no camshaft ratio will be calculated and the anti-bounce counter will be decremented by 3 or 5 (ENSD 4.0.0). Thus, the anti-bounce increment should be higher than 3 (single-tooth) or 5 (multi-teeth).

The filter type can now be selected in Appl. Inc. file. In the case of a STD_INI (preferred solution), anti-bounce counter inc/max for camshaft segment period diagnosis should be set as:

C_ABC_INC_DIAG_SYN_CAM_IN(EX) = NC_NR_EDGE_CAM_IN(EX) ... 2 * NC_NR_EDGE_CAM_IN(EX)

C_ABC_MAX_DIAG_SYN_CAM_IN(EX) = 2 * NC_NR_EDGE_CAM_IN(EX) ... 4 * NC_NR_EDGE_CAM_IN(EX)

Whatever the filter type is, the calibration should ensure that a periodic camshaft ratio out-of-range calculation produces a camshaft synchronization error.

The best way is to calibrate on car by generating electromagnetic disturbances on the signal lines (for example with a Schaffner on battery as used for EMI tests). No error should be set when generated disturbances are within the EMI levels which apply for the project.

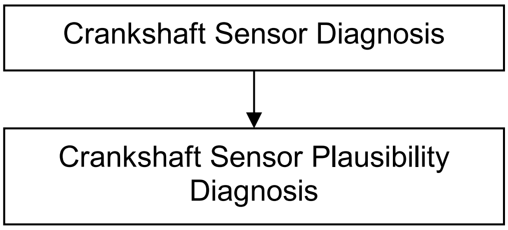
23.23 Crankshaft Sensor OBDI (ACPS)

Calibration interfering functions:

INJR, VVTI, IGSP and IGRE pre-calibrated.

ACQ of CRK/CAM signal calibrated.

Calibration flowchart:



Calibration process:

Crankshaft sensor diagnosis

The purpose of this diagnosis is to detect disturbances on the crankshaft signal and target wheel failures.

Open-circuits or short-circuit to battery or ground are detected with the crankshaft sensor circuit diagnosis.

Crankshaft sensor diagnosis depends on crankshaft synchronization status:

1) before synchronization:

A tooth period out-of-range flag is set (LV_ORNG_CRK_TOOTH_PER) and the corresponding anti-bounce counter incremented if an invalid crankshaft signal edge is detected (spike or missing tooth) after engine running detection. The signal edge is invalid when outside the crankshaft acceptance window defined by ID_FAC_TOL_CRK_TOOTH.

Tooth number diagnosis (LV_ERR_CRK_TOOTH) and loss of synchronization diagnosis (LV_ERR_CRK_SYN) are not activated.

2) after synchronization:

A tooth number out-of-range flag is set (LV_ORNG_CRK_TOOTH) and the corresponding anti-bounce counter incremented if one or more additional or missing teeth are detected during one engine revolution (information also to misfire-aggregate).

This diagnosis is inhibited below an engine speed threshold (engine start or rough engine stall) defined by C_N_32_MAX_DIAG_CRK_TOOTH.

However, even in this case, the information LV_INH_MIS_CRK is still sent to misfire-aggregate.

The value C_N_32_MAX_DIAG_CRK_TOOTH has to be calibrated lower than idle engine speed, but higher than starter speed.

If the number of tolerated additional or missing teeth is exceed during one engine cycle, a loss-of-synchronization flag is set (LV_LOST_SYN_CRK) and, for filter types with anti-bounce counters, the corresponding anti-bounce counter incremented.

If signal spikes are detected outside the crankshaft acceptance window defined by ID_FAC_TOL_CRK_TOOTH, a tooth period out-of-range flag is set and, for filter types with anti-bounce counters, the corresponding anti-bounce counter incremented at reference gap.

If the diagnoses filter types are set to MEM (preferred solution), or to filter types with anti-bounce counters:

Anti-bounce increment should be higher than 1 in order to detect sporadic crankshaft signal failures.

False detection of LV_ERR_CRK_TOOTH_PER may occur with interrupted start, or with vehicle abuse, e.g. high gear at very low speed. To suppress this, apply a very slow anti-bounce counter calibration. There is virtually no impact on ignition/injection timing, since signal disturbances will be corrected by the acquisition algorithm.

The number of re-synchronizations after loss of synchronization should be restricted to a very small number (max. 2 or 3) by calibrating C_ABC_MAX_DIAG_CRK_SYN to 1.5 to 3 times C_ABC_INC_DIAG_CRK_SYN. Engine could be damaged when timing error on injection/ignition is too high and, consequently, the engine should be definitely stopped (LV_ERR_CRK).

C_ABC_MAX_DIAG_CRK_TOOTH_PER should be calibrated higher than C_ABC_MAX_DIAG_CRK_TOOTH as the anti-bounce counter CTR_ABC_CRK_TOOTH_PER is incremented once at engine start when engine stopped close before reference gap (gap during valid teeth phase).

Crankshaft sensor plausibility diagnosis

The purpose of this diagnosis is to check if the crankshaft or camshaft signal is missing or implausible.

The anti-bounce counter CTR_ORNG_CAM_SYN_CRK is incremented by 1 if the camshaft signal edge is outside the tolerance window defined by C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX) or if no camshaft signal was detected during one engine revolution (multi-teeth target wheel) as long as synchronization is not yet validated.

If more than C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX camshaft edges have occurred and the engine is still not synchronized, LV_ERR_CRK_PLAUS is set.

The counter CTR_CYC_ENG_PLAUS_CAM_IN(EX)_i is incremented by 1 if no camshaft signal was detected during one engine cycle. It is decremented by 1 if at least one camshaft signal edge is detected during one engine cycle.

C_CTR_ORNG_CAM_SYN_CRK_MAX determines the time to detect camshaft error (for example missing signal) and to switch to camshaft limp-home mode or to another camshaft sensor. Consequently, it determines the starting time in case of camshaft sensor failure. Every time CTR_ORNG_CAM_SYN_CRK is incremented, the cam/crk synchronization is reset. The number of re-synchronizations should be limited to 1...5.

A camshaft error is set when CTR_ORNG_CAM_SYN_CRK exceeds C_CTR_ORNG_CAM_SYN_CRK_MAX. For single-tooth camshaft configurations, C_CTR_ORNG_CAM_SYN_CRK_MAX should be higher than 1 in order to avoid false cam error detection in case of early ignition key release during start.

C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX determines the time to detect crankshaft error (for example missing signal) and to switch to crankshaft limp-home mode. Consequently, it determines the engine starting time in case of crankshaft sensor failure. C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX must be higher than the number of camshaft edges per engine cycle.

C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX >= NC_NR_EDGE_CAM_IN(EX)

If crankshaft failure occurs, low value of C_NR_EDGE_CAM_IN(EX)_SYN_CRK_MAX prevents engine stalling.

C_NR_CYC_ENG_PLAUS_CAM_MAX determines time to detect camshaft error when engine is running (engine will remain synchronized). During this time, camshaft position feedback will be wrong and VVT cannot work properly. Once camshaft error is detected, the VVT actuator switches to limp-home.

A camshaft error is set when C_NR_CYC_ENG_PLAUS_CAM_MAX engine cycles have occured without camshaft signal.

The diagnosis is inhibited with C_NR_CYC_ENG_PLAUS_CAM_MAX = 0.

Calibration data LC_CAM_ERR_ENA_VVT

If a camshaft error is detected at engine start and failure disappears during driving cycle:
- LV_ERR_SYN_CRK_CAM will be debounced and cam/crk diagnosis information updated if LC_CAM_ERR_ENA_VVT = 1
- LV_ERR_SYN_CRK_CAM remains 1 until next ignition key on transition if LC_CAM_ERR_ENA_VVT = 0

If IVVT - actuator can be reactivated during driving cycle after camshaft error, LC_CAM_ERR_ENA_VVT should be set to 1. If no reactivation is possible, LC_CAM_ERR_ENA_VVT should be set to 0.

Calibration data LC_CTR_DEC_PLAUS_CAM

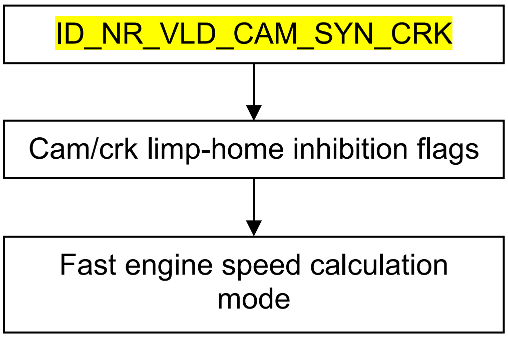
If a camshaft error is detected at engine start and failure disappears during driving cycle:
- LV_ERR_PLAUS_CAM_IN will be debounced and cam/crk diagnosis information updated if LC_CTR_DEC_PLAUS_CAM = 1 (STD_INI filter type behavior, preconized for IVVT-aggregate use)
- LV_ERR_PLAUS_CAM_IN remains 1 until next ignition key on transition if LC_CTR_DEC_PLAUS_CAM = 0 (MEM filter type behavior)

23.24 Engine Position and Speed Determination

Calibration interfering functions:

INJR, VVTI, IGSP and IGRE pre-calibrated

Calibration flowchart:



Calibration process:

Camshaft/Crankshaft Limp-Home

The following calibrations define if limp-home mode can be activated or not.

- LC_INH_LIH_CRK (crankshaft limp-home: crankshaft sensor failure, engine position determination with camshaft sensor)
- LC_INH_LIH_CAM (Camshaft limp-home: failure on all camshaft sensors, engine position determination with crankshaft sensor)

Calibration data ID_NR_VLD_CAM_SYN_CRK

Engine synchronization is validated as soon as a number of ID_NR_VLD_CAM_SYN_CRK valid camshaft signal edges has occurred after engine start .

During synchronization validation phase, the angular distance between cam/crk events are checked and engine synchronization is reset (LV_SYN_ENG) if one of the tests fails.

ID_NR_VLD_CAM_SYN_CRK should be set to the number of camshaft edges which should be checked. This value depends on camshaft/crankshaft configuration and project needs.

For DS- and DI-engines, injection is enabled as soon as LV_SYN_VLD is set to 1 (i.e. after a certain number of camshaft edges has been checked after engine start or loss of synchronization). The target is quick and safe engine start (no risk of wrong injection/ignition) at low engine speed but mainly safe engine resynchronization at high engine speed.

Generally, it is sufficient to check one camshaft edge (ID_NR_VLD_CAM_SYN_CRK = 1) at low engine speed but more than one at high engine speed (ID_NR_VLD_CAM_SYN_CRK = 4).

The risk of wrong injection/ignition is further reduced with ID_NR_VLD_CAM_SYN_CRK >1 but engine starting time increases.

- For engine start positions where no camshaft edge occurs before reference gap, engine position could be wrong when LV_SYN_ENG is set (e.g. camshaft sensor signal is missing). Engine position is validated as soon as LV_SYN_VLD is set.
- It is preferable to set ID_NR_VLD_CAM_SYN_CRK > 0 in order to reset engine synchronization (and disable injection/ignition) in case of wrong engine position at reference gap. Generally, for DS and DI engines, injection should be enabled on LV_SYN_VLD.

Fast Engine Speed Computation

A fast engine speed (N_FAST) can be calculated depending on the state of switch C_N_FAST_SWI:

C_N_FAST_SWI = 0:

Fast engine speed calculation de-activated. No additional CPU load.

C_N_FAST_SWI = 1:

Fast engine speed calculation based on last crankshaft tooth period T_TOOTH. Calculation is done until speed threshold C_N_TOOTH_END is reached. N_FAST based on last tooth period is used to calculate more precisely injection/ignition events during engine start (C_N_TOOTH_END = 1200 ... 1800rpm).

C_N_FAST_SWI = 2:

Fast engine speed calculation based on half-segment period calculation.

C_N_FAST_SWI = 3:

Fast engine speed calculation based on crankshaft tooth window. A filter with time constant C_FAC_N_FAST is applied:

N_FAST = N + C_FAC_N_FAST + (N_CRK_WIN n – N_CRK_WIN n-1)

C_N_FAST_SWI = 4 is used only for development purposes.

The output data N_TOOTH is calculated independently of calibration switch C_N_FAST_SWI until speed threshold C_N_TOOTH_END. This data is also used to determine the activation condition of the reverse engine rotation detection and the fail safe delay. A necessary condition to start the fail safe delay is that N_TOOTH is lower then C_N_NOT_REST. Therefore, N_TOOTH shall be calculated at least until C_N_NOT_REST:

C_N_TOOTH_END + 32rpm > C_N_NOT_REST

(+32 rpm for resolution conversion)

Calibration data ID_CRK_PHA_COR

Calibration data ID_CRK_PHA_COR represents the angular shift of the crankshaft active edges in function of engine speed. This angular shift is generally very small.

This functionality is not activated and, therefore, ID_CRK_PHA_COR should be calibrated to 0 (zero).

Calibration data ID_CAM_PHA_COR

Calibration data ID_CAM_PHA_COR represents the angular shift (in °CRK) of the camshaft signal edges in function of engine speed. For most camshaft sensors, this phase shift is small and ID_CAM_PHA_COR can be calibrated to zero.

Calibration of engine backwards rotation detection:

This functionality uses calibration already used for cam/crk synchronisation (C_DYW_CAM_CRK_SYN_ADC_IN(EX)_i and C_DYW_CAM_CRK_SYN_RTD_IN(EX)_i) and crankshaft acquisition (ID_FAC_TOL_CRK_TOOTH which sets LV_CRK_MISS_TOOTH). Check that detection and confirmation are correct with the values already calibrated.

Backward rotation detection is based on missing tooth simulation below an engine speed threshold. A change of rotation direction can only be detected if ID_FAC_TOL_CRK_TOOTH is not too high for engine speed breakpoints lower than C_N_NOT_REST.

Calibration data C_T_DLY_STOP_ENG:

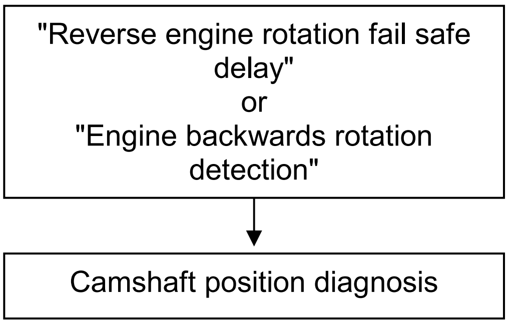
A crankshaft error plausibility symptom rises up ("signal missing") if LV_CRK_MISS_RUN_ENG is set after an engine stop request indicating that engine is still turning but engine speed is not available (f.ex. crk sensor failure). This information can be used for other functions/ECUs to prevent switching to passive state. LV_CRK_MISS_RUN_ENG is reset after a delay time C_T_DLY_STOP. C_T_DLY_STOP_ENG should be calibrated as the time interval between an engine stop request (crankshaft sensor failure) and engine resynchronization in crankshaft limp-home mode (or crankshaft failure setting when crankshaft limp-home is inhibited). This feature can be inhibited with C_T_DLY_STOP_ENG = 0 when not used.

Calibration interfering functions:

INJR, VVTI, IGSP and IGRE pre-calibrated

C_N_TOOTH_END has to be calibrated before calibration of reverse engine rotation fail safe delay.

Calibration flowchart:



Calibration process:

Reverse engine rotation fail safe delay

Crankshaft and camshaft diagnosis are inhibited during the reverse engine rotation fail safe delay.

The reverse engine fail safe delay is activated:

- on engine stop if the last calculated engine speed is lower than C_N_NOT_REST and no reverse engine rotation has been detected. Duration is C_T_DLY_REST_STALL
- If reverse engine detection is inhibited on ignition key off as soon as the engine speed drops below C_N_NOT_REST. Duration is C_T_DLY_REST_IGK

The purpose of the fail safe delay is to prevent false error detection in case of reverse engine rotation.

Set calibration data for reverse engine fail safe delay to a high value (for example: C_N_NOT_REST = 1000rpm, C_T_DLY_REST_IGK(STALL) = 5s).

Display all camshaft and crankshaft diagnosis symptoms with SAM2000 (lowest possible sampling, for example: 5ms), N_TOOTH and LV_STOP_ENG.

At least, two vehicle tests should be done:

a) low rpm clutch engagement (3^{rd} gear)

- stall the engine with 3^{rd} gear engaged, engine turning with idle speed
- start engine with 3^{rd} gear engaged, vehicle stopped

From SAM2000 measurement:

- determine engine speed (N_TOOTH) when engine stop is set (LV_STOP_ENG) or when synchronization is reset. This value should be calibrated for C_N_NOT_REST (repeat several times and apply a security margin)

- determine the time duration between engine stop and the instant when LV_FIRST_VLD_TOOTH is definitely zero. This value should be calibrated for C_T_DLY_REST_STALL (repeat several times and apply a security margin).

b) stop engine shortly after engine synchronization (rapid key on – key off).

As before: determine time duration between engine stop and the instant when LV_FIRST_VLD_TOOTH is definitely zero. Calibrate this value for C_T_DLY_REST_IGK.

Note that N_TOOTH is used to determine the activation condition of the reverse engine rotation fail safe delay. A necessary condition to start the fail safe delay is that N_TOOTH is lower then C_N_NOT_REST. Therefore, N_TOOTH shall be calculated at least until C_N_NOT_REST (C_N_TOOTH_END has to be calibrated accordingly).

Engine backwards rotation detection

Engine backwards rotation detection is activated if LC_ENG_BACK_INH is set to 0.

Crankshaft and camshaft diagnosis are inhibited when a reverse engine rotation has been detected until its confirmation or nullification.

Inhibition is stopped and cam/crk diagnosis reactivated as soon as:

- delay time C_T_MAX_INH_DIAG_ENSD has elapsed without ignition key transition **or**
- engine resynchronizes and synchronization is validated **or**
- delay time C_T_MIN_INH_DIAG_ENSD has elapsed after a key off transition **or**
- ignition key off and delay time C_T_MIN_INH_DIAG_ENSD elapsed after engine stop **or** backward rotation confirmation

Tests to be done for calibration of engine backwards rotation

a) low rpm clutch engagement (3rd gear)

- stall the engine with 3rd gear engaged, engine turning with idle speed
- start engine with 3rd gear engaged, vehicle stopped
- start engine with reverse gear engaged, vehicle running forward

b) stop engine shortly after engine synchronization (rapid key on – key off).

Determine engine speed when backwards rotation occurs: calibrate this value for C_N_NOT_REST with a margin.

C_T_MIN_INH_DIAG_ENSD should be set to the time necessary to stall engine (at low engine speed) after a key on to off transition. This calibration value is similar to C_T_DLY_REST_IGK.

C_T_MAX_INH_DIAG_ENSD is the maximum delay before reactivating diagnosis after engine backwards rotation confirmation. It should be set to the maximum duration of reverse rotation if diagnosis inhibition until LV_SYN_VLD is not acceptable, otherwise it should be set to its maximum value.

Camshaft position diagnosis

The purpose of this diagnosis is to detect a abnormal angular shift of the camshaft sensor signal edges relative to the crankshaft. A error symptom is set when one of the camshaft adaptation values is outside the defined tolerance range.

The tolerance window C_TOL_REF_CRK_CAM_IN(EX) shall include all mechanical and electrical tolerances of the sensors, the target wheels and the mounting:

- mounting tolerances of camshaft and crankshaft sensor
- mounting tolerances of camshaft and crankshaft target wheel
- camshaft and crankshaft sensor accuracy
- machining of camshaft and crankshaft target wheel
- angular shift of crankshaft to crankshaft target wheel position

Sum up all these tolerance values for the intake and exhaust camshaft and set calibration values C_TOL_REF_CRK_CAM_IN(EX) accordingly.

Consider also that mechanical tolerances and angular shift of crank to cam can vary during engine lifetime (for example: increased belt/chain length).

In contrast to tolerance window C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX), the following features shall **not** be considered for in C_TOL_REF_CRK_CAM_IN(EX):

- camshaft sensor pre-calibration mode (sensor self-adaptation)
- VVT actuator range

This is the reason why C_TOL_REF_CRK_CAM_IN(EX) is generally lower than C_DYW_CAM_CRK_SYN_ADC(RTD)_IN(EX).

Anti-bounce counter inc/max for camshaft position diagnosis should be set as

C_ABC_INC_DIAG_REF_CRK_CAM_IN(EX) = NC_NR_EDGE_CAM_IN(EX)

C_ABC_MAX_DIAG_REF_CRK_CAM_IN(EX) = (NC_NR_EDGE_CAM_IN(EX) * max_symptom)

With this calibration, LV_ERR_REF_CRK_CAM_IN(EX)_i will be set

- as soon as a number of max_symptom succesive symptoms has occured on each camshaft edge
- as soon as a number of (C_ABC_MAX_DIAG_REF_CRK_CAM_IN(EX) – max_symptom) +1 succesive symptoms has occured during successive engine cycles on the same camshaft edge

FUNCTION DESCRIPTION:

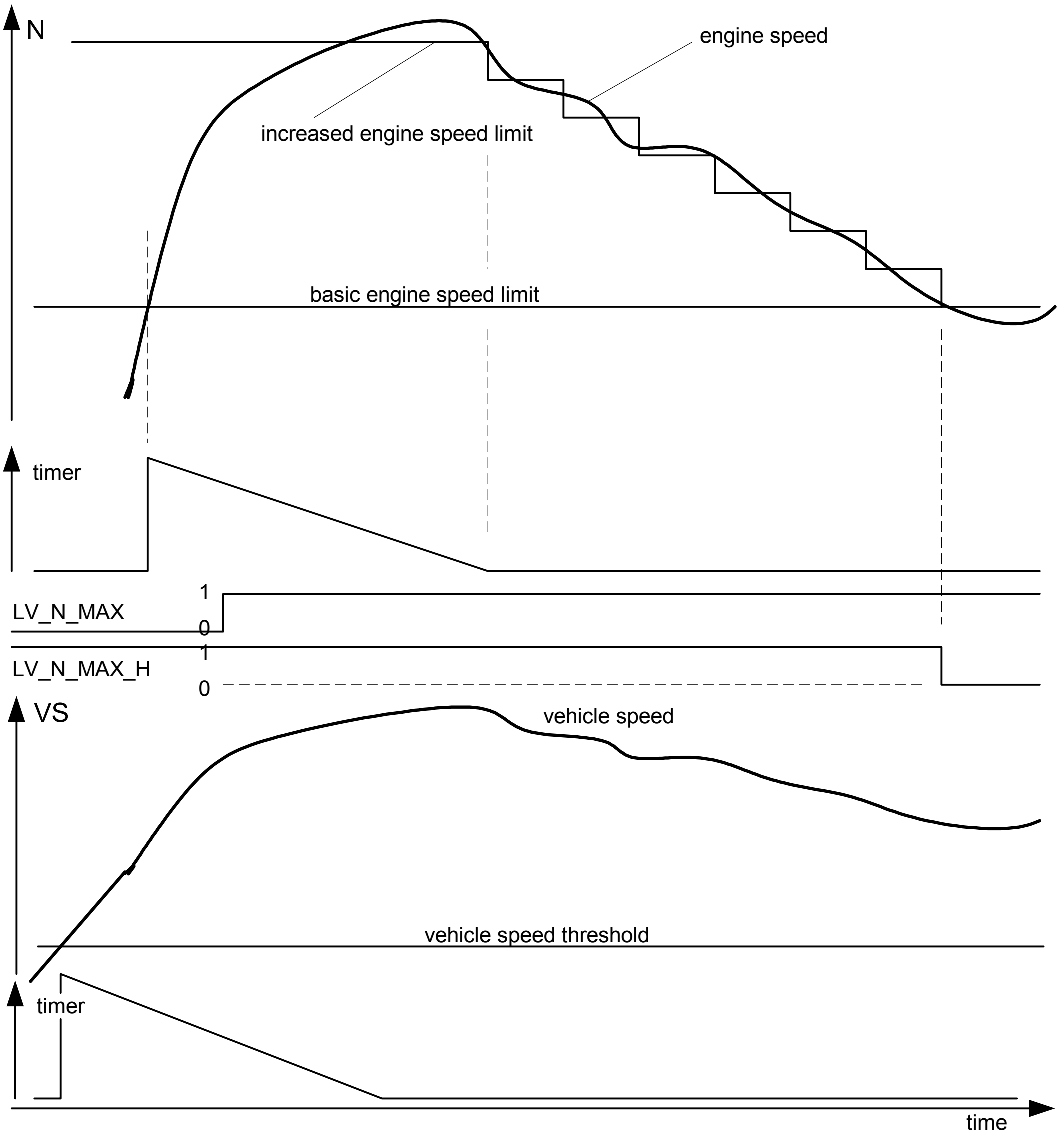
General information:

Several conditions can activate an engine speed limit. The actual engine speed limit is calculated as minimal selection of all requests.



Signal flow diagram

If the vehicle speed is below a threshold or exceeded this threshold not more than a calibrateable time before, an increased speed limit is valid for a short time (this is **not** true, if the transmission variant is AT and the reverse gear is engaged, i.e. if LV_AT and STATE_GEAR_REV_AT_AMT = 1). So if the engine speed exceeds the basic engine speed limit while the time after VS exceeded C_VS_THD_N_MAX_H_xx is at the most C_T_MAX_N_MAX_H_xx, the increased engine speed limit is valid for a calibrateable time.

After this time the valid limit is changed towards the basic engine speed limit via calibrateable steps. If C_T_MAX_N_MAX_H_xx is terminated without limitation being active (LV_N_MAX = 0), N_MAX_xx is set from increased speed limit to basic engine speed in one step.

A jump back to the increased engine speed limit is possible not before the engine speed limitation is finished (LV_N_MAX = 0). Furthermore the VS condition must be fulfilled (still or again). All the 4 parameters

- basic engine speed limit
- increased engine speed limit
- time for increased engine speed limit and
- stepwidth to basic engine speed limit

are seperately calibrateable for the 3 vehicle variants

- automatic or twin clutch transmission
- manual transmission
- automatic manual transmission

- automatic ot twin clutch transmission in manual mode 'M'

and dependant from the actual gear.

C_VS_THD_N_MAX_H_xx and C_T_MAX_N_MAX_H_xx are seperately calibrateable for the 3 vehicle variants (xx = MT/ AT).

Above a specific engine speed, the calculation of the stratified combustion mode is switched off. To enable a stratified limp home mode even when the stratified combustion mode calculation is switched off, the engine speed limitation N_MAX_LIH_STATE_CMB_S is introduced to reactivate stratified mode calculation.

Application conditions:

Initialisation:
N_MAX_THD = NC_N_REF_MAX (= 8160 rpm)
N_MAX_THD_1 = 0
N_MAX_THD_2 = 0
LV_VS_MAX = 0
N_MAX_THD_LIH = NC_N_REF_MAX (= 8160 rpm)
N_MAX_LIH_EGS = NC_N_REF_MAX (= 8160 rpm)
STATE_N_MAX_THD_LIH = 0

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

a1) Basic engine speed limit :

Manual transmission vehicle

```
If      (LV_AT = 0   and LV_VAR_TCT = 0)
  Then  N_MAX_MT   =  ID_N_MAX_MT
  Else  N_MAX_MT   =  NC_N_REF_MAX
Endif
```

Automatic transmission or twin clutch transmission vehicle

```
If      (LV_AT = 1 or LV_VAR_TCT = 1)
Then
        If      STATE_GEAR_REV_AT_AMT = 0
        then    if    [ (( STATE_ETCU_PROG_INFO=1 and LV_VAR_BN=0 ) or
                           ( STATE_ETCU_PROG_INFO=2 and LV_VAR_BN=1 )     )  and
                          LC_VAR_ETCU_SPT_SWI = 0 ]   or

                      [ LV_INH_GP_SUP = 1  and  LC_VAR_ETCU_SPT_SWI = 1 ]

                Then        N_MAX_AT   =   ID_N_MAX_AT_MAN

                else        N_MAX_AT   =   ID_N_MAX_AT

                endif

        Else    N_MAX_AT  =   C_N_MAX_DRI_RVL
        Endif
Else    N_MAX_AT           =   NC_N_REF_MAX
Endif
```

Remark: a change of the vehicle-(transmission-)type is done only during VS = 0 km/h.

a2) Parameters for increased engine speed limit :

Parameter	Vehicle type *)	Value
VS-threshold	1)	C_VS_THD_N_MAX_H_MT
	3)	C_VS_THD_N_MAX_H_AT
	4)	C_VS_THD_N_MAX_H_AT_MAN
increased engine speed limit	1)	ID_N_MAX_H_MT
	3)	ID_N_MAX_H_AT
	4)	ID_N_MAX_H_AT_MAN
time before decrementation begins	1)	ID_T_N_MAX_H_MT
	3)	ID_T_N_MAX_H_AT
	4)	ID_T_N_MAX_H_AT_MAN
decrease stepwidth	1)	ID_N_DEC_N_MAX_H_MT
	3)	ID_N_DEC_N_MAX_H_AT
	4)	ID_N_DEC_N_MAX_H_AT_MAN

*) Vehicle types :		
	1)	Manual transmission vehicle
	2)	Automatic manual transmission vehicle
	3)	Automatic/Twin clutch transmission vehicle
	4)	Automatic/Twin clutch transmission vehicle in 'M' (manual) mode

Functionality (N_MAX_MT/ AT = ...) : see signal flow diagram above.

Status bit for increased engine speed limit:

```
If   ID_N_MAX_MT < N_MAX_MT < NC_N_REF_MAX
     OR
     [ ID_N_MAX_AT < N_MAX_AT < NC_N_REF_MAX          and
```

```
      STATE_GEAR_REV_AT_AMT = 0                              and
      { (((STATE_ETCU_PROG_INFO != 1  and  LV_VAR_BN = 0) or
          (STATE_ETCU_PROG_INFO != 2  and  LV_VAR_BN = 1)  ) and
         LC_VAR_ETCU_SPT_SWI = 0 )     or
        ( LV_INH_GP_SUP = 0  and  LC_VAR_ETCU_SPT_SWI = 1 )  }  ]

    OR

    [ ID_N_MAX_AT_MAN < N_MAX_AT < NC_N_REF_MAX   and
      STATE_GEAR_REV_AT_AMT = 0                      and
      { (((STATE_ETCU_PROG_INFO = 1  and  LV_VAR_BN = 0) or
          (STATE_ETCU_PROG_INFO = 2  and  LV_VAR_BN = 1)   ) and
         LC_VAR_ETCU_SPT_SWI = 0 )     or
      ( LV_INH_GP_SUP = 1  and  LC_VAR_ETCU_SPT_SWI = 1 )  }  ]

  Then   LV_N_MAX_H  =  1

  Else   LV_N_MAX_H  =  0

Endif
```

a4) Engine speed limit if limp home mode required by throttle monitoring

In case of limp home request from main throttle controller a lower engine speed limit should be active.

```
If          LV_N_LIM_REQ_MON            ==1        or
            LV_TPS_MTC_N_LIM            ==1        or
            LV_MTC_LIH_ACT              ==1        or
            LV_N_LIM_REQ_RST_CHK        ==1        or
            LV_MAF_BLS_DIAG             ==1        or
            LV_ERR_ECU_CKS              ==1        or
            LV_ERR_ECU_RAM              ==1

  Then      N_MAX_LIH_ETC       =    C_N_MAX_MTC_LIH
  Else      N_MAX_LIH_ETC       =    NC_N_REF_MAX
Endif
```

a5) Engine speed limit if limp home mode only due to MTC error

```
If          LV_MTC_LIH_CUR_OFF   ==  1

Then        N_MAX_LIH_MTC          =   IP_N_MAX_MTC_CUR_OFF( PV_AV )

Else        N_MAX_LIH_MTC          =   NC_N_REF_MAX

Endif

If          N_MAX_LIH_MTC or N_MAX_LIH_ETC not  NC_N_REF_MAX

  Then      LV_N_MAX_ETC_LIH = 1

  Else      LV_N_MAX_ETC_LIH = 0

Endif
```

a6) Engine speed limit for vehicle speed limitation

In case of vehicle speed limitation the engine speed limitation will be activated.

```
If(1)                  LV_GP   =  0
  Then(1)
    If(2)              VS_MAX_SEL_EXT_REQ  =  1

                       T_GEAR_VS_MAX ≠ 0]              or
                       ((LV_AT = 1 or LV_VAR_TCT = 1)  and
                       STATE_CC ≠ "Closed")
              Then(7)  N_MAX_VS_MAX = N * VS_RATIO,
              Else(7)  N_MAX_VS_MAX remains
            Endif(7)
          Else(6)      N_MAX_VS_MAX = NC_N_REF_MAX
        Endif(6)
    Endif(2)
  Else(1)              {Engine speed limit for vehicle speed limitation deactivated
                       LV_VS_MAX        =  0
                       N_MAX_VS_MAX =  NC_N_REF_MAX }
Endif(1)
```

a7) Engine speed limit for energy spare mode (production, transportation or garage mode)

```
IF        STATE_EGY_MIN_KWP = 1
then      N_MAX_EGY = C_N_MAX_EGY_1
elseif    STATE_EGY_MIN_KWP = 2                AND
          CTR_KM_CAN <= C_CTR_KM_CAN_EGY_2_MAX
then      N_MAX_EGY = C_N_MAX_EGY_2
elseif    STATE_EGY_MIN_KWP = 3
then      N_MAX_EGY = C_N_MAX_EGY_3
else      N_MAX_EGY = 1FE0H
ENDIF
```

a8) Engine speed limit in order to avoid a maximum torque in powertrain due to jump start

```
IF        LV_CS = 1
then      N_MAX_DROF = IP_N_MAX_DROF( VS )
else      N_MAX_DROF = 1FE0H
```

ENDIF

a9) Engine speed limit in order to avoid overspeed in oil pressure limb home mode

N_MAX _LIH_PRS_OIL = N_LIH_PRS_OIL + C_N_MAX_PRS_OIL_ADD

a10) Engine speed limitation for automatic transmission in case of TCU - EGS limb home (CAN error)

```
IF        ( LV_ETCU_DISABLE_CAN == 1          AND
            LV_ST_END == 1                    AND
            T_AST > C_T_AST_ETCU_CAN_VLD )          OR
            STATE_ST_TQ_LIM_GS == 1
THEN        N_MAX_LIH_EGS = IP_N_MAX_LIH_EGS (VS)
ELSE        N_MAX_LIH_EGS = N_MAX_LIH_EGS + C_N_MAX_LIH_EGS_LGRD
endif
```

b) Selection of the currently active engine speed limit N_MAX_THD:

The lowest active engine speed limitation is selected as input for the controller:

```
N_MAX_THD      =      max(  C_N_MAX_THD_MIN,
                            min(  N_MAX_MT,
                                  N_MAX_AMT,
                                  N_MAX_AT,
                                  N_MAX_LIH_ETC,
                                  N_MAX_LIH_MTC,
                                  N_MAX_VS_MAX,
                                  N_MAX_LIH_STATE_CMB_S,
                                  N_MAX_EGY,
                                  N_MAX_DROF,
                                  N_MAX_LIH_PRS_OIL,
                                  N_MAX_LIH_EGS )     )
```

c1) Currently active engine speed limit (BN) depending on TCO N_MAX_THD_1(orange area):

N_MAX_THD_1 = IP_N_MAX_1_TCO

c2) Currently active engine speed limit (BN) depending on TCO N_MAX_THD_2 (red area):

N_MAX_THD_2 = IP_N_MAX_2_TCO

d) Selection of the currently active engine speed limit due to limp home N_MAX_THD_LIH :

The lowest active engine speed limitation caused by limp home is used for determination of the level of limitation (STATE_N_MAX_THD_LIH):

```
N_MAX_THD_LIH          = min( N_MAX_LIH_ETC,
                              N_MAX_LIH_MTC,
                              N_MAX_LIH_STATE_CMB_S,
                              N_MAX_EGY,
                              N_MAX_LIH_PRS_OIL)
```

```
If      N_MAX_THD_LIH < C_N_MAX_THD_LIH_L
Then    STATE_N_MAX_THD_LIH = 2              // major limitation of N due to LIH
Else    If      N_MAX_THD_LIH < C_N_MAX_THD_LIH_H
        Then    STATE_N_MAX_THD_LIH = 1      // minor limitation of N due to LIH
        Else    STATE_N_MAX_THD_LIH = 0      // no limitation of N due to LIH
        Endif
Endif
```

24.2.1 Function description

General information:

The objective of this function is to protect the engine against overspeed and therefore to control the engine speed. A PI controller is used to hold the engine speed at the engine speed limit setpoint, which derives from the module 'Engine speed limit coordination' from chapter 4. Engine overspeed mainly is controlled by reduction of engine torque. The output value of this module is TQI_N_MAX, which is an input in the torque coordination module. Different tasks are designed in this module:

prediction of engine speed to avoid great engine speed overshoots, especially in the first phase of controlling

activation of speed limit controller due to speed deviation between predicted engine speed and engine speed limit

PI controller

activation of fuel cut off for exceeding the engine speed limit for more than a calibratable difference

rate limiter for the output in increasing direction to avoid uncomfortable jumps in the torque demand

Application Condition

24.2.1.2 Formula section

Calculation of predicted engine speed

The engine speed prediction shall activate the engine speed limitation controller before the real engine speed reaches the threshold N_MAX_THD. Therefore the complete controller has a PID behaviour at activation, to prevent high engine speed overshoot.

The prediction is deactivated, if the controller has stopped the engine speed increase. During the following period the PI controller can guarantee the engine speed limitation up to N_MAX_THD without predicting the engine speed.

Due to a bad resolution of N_GRD, the prediction is only calculated, if a clear high engine speed gradient is detected. This is possible by comparing the gradient N_GRD with an engine speed depending threshold IP_N_GRD_THD__N_32.

The prediction is stopped latest, if the real engine speed is no longer increasing (N_GRD =< 0).

general specification

To prevent sudden changes for the engine speed limit controller input at activation or deactivation, it is necessary to have a PT1 filter for the engine speed controller input. So a negative feed back of the controller output to the real engine speed is prevented.

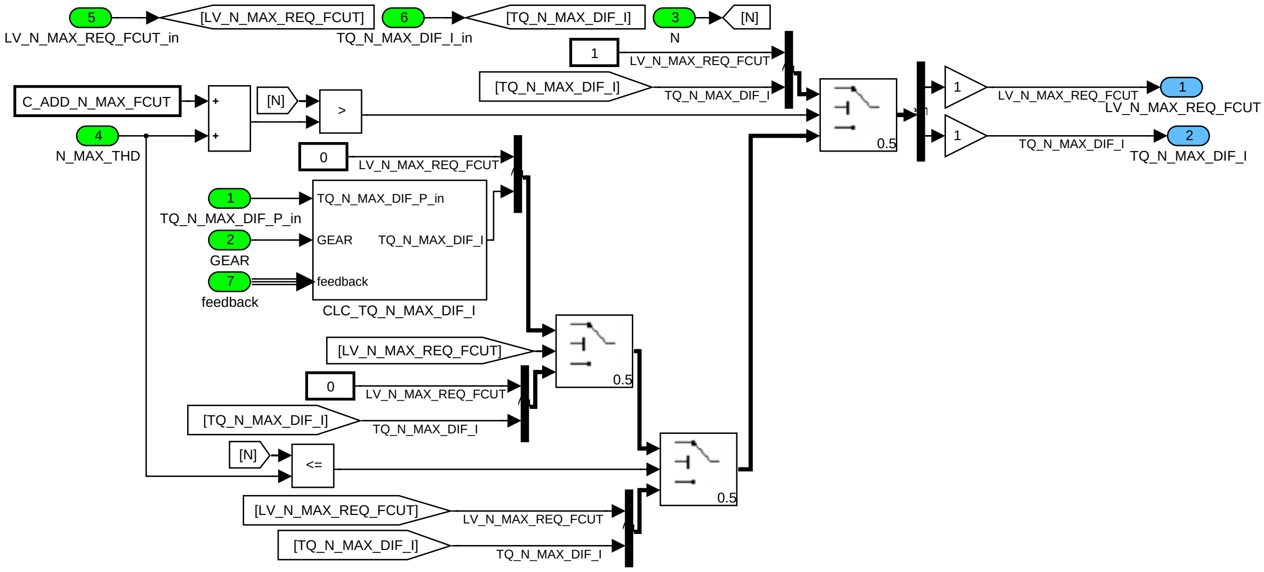

Figure 8 ENSL_M901E/ OPM/ CLC_LV_N_MAX/ ACT_FUEL_CUT_OFF

Initialisation of N MAX integrator.

Calculation of TQ_N_MAX_DIF_I

The integrator has to be initialized for the transition of LV_N_MAX from 0 to 1 and for the transition of LV_N_MAX_REQ_FCUT from 1 to 0. In the first case the integrator output is set to zero and in the second case the integrator output has to ensure that the TQI_N_MAX does not show a step (during LV_N_MAX_REQ_FCUT active the TQI_N_MAX is set to zero).

Determination of TQ_N_MAX_REF, TQ_N_MAX_DIF_P, TQ_N_MAX_DIF_I and TQ_N_MAX_INP_I

The integrator input has to be set to zero, when the TQ_N_MAX_1 is smaller than zero and the calculated input TQ_N_MAX_INP_~~I~~_1 is smaller than or equal to zero. This avoids a steadily decrease of the integrator output which could cause problems when re entering the controller.

TQ_N_MAX_REF, TQ_N_MAX_DIF_P, TQ_N_MAX_DIF_I and TQ_N_MAX_INP_I are calculated here.

Selected index of fuel cut off pattern at highest event					

Input data:

N	LV_N_MAX	TRT	LV_VS_MAX
CTR_KM_CAN	N_GRD	VS	PV_AV
GEAR_EF	LV_CS	NR_PAT_SCC	

General information:

This function is for detection of an overreving event and with non-volatile storage of environmental datas if triggered.

Description:

An overreving event starts at exceeding the engine speed C_N_LIM_MIN and active engine speed limitation (LV_N_MAX = 1).

At each overreving event, the event frequency counter CTR_N_MAX is incremented by 1. The timer T_SUM_N_MAX is always incremented at every active event and remains at the maximum value if reached. The timer T_N_TMP recorded the duration of each event and is used for the T_N_MAX calculation (= the duration with the highest event)

The remaining environmental data are stored at the first event but will be only overritten if the new event has a higher engine speed then the old one. At the end of a driving cylce the datas are stored in NVMY.

Application conditions:

Initialisation: all data restored out of NVMY

Recurrence: segment synchronous

Activation: **at** **[** LV_N_MAX = 1 **and** LV_VS_MAX = 0 **]**

Deactivation: **at** LV_N_MAX = 0

Formula section:

determination of event-frequency-counter :

```
if      N > C_N_LIM_MIN
then    CTR_N_MAX = CTR_N_MAX + 1        ( only once per trigger )
else    CTR_N_MAX = CTR_N_MAX
endif
```

determination of total time :

```
if      N > C_N_LIM_MIN
then    starts timer T_SUM_N_MAX (always incremented, remains at FFFFH if reached)
else    stop timer T_SUM_N_MAX
endif
```

determination of individual time per event :

```
if      N > C_N_LIM_MIN
then    T_N_TMP ++
        N_MAX_TMP = MAX [ N ]
elseif          N_MAX_TMP > N_MAX        //stored in NVMY or stored at last event
    then        T_N_MAX = T_N_TMP        //update
    else        T_N_MAX = T_N_MAX        //unchanged
    endif
    T_N_TMP = 0          //reset
    N_MAX_TMP = 0        //reset
endif
```

determination of environmental data at first event :

```
if      N > C_N_LIM_MIN
then    N_MAX           = N
        TRT_N_MAX       = TRT
        CTR_KM_N_MAX    = CTR_KM_CAN
        N_GRD_N_MAX     = N_GRD
        VS_N_MAX        = VS
        PV_AV_N_MAX     = PV_AV
```

```
            GEAR_EF_N_MAX           = GEAR_EF
            LV_CS_N_MAX             = LV_CS
            NR_PAT_SCC_N_MAX        = NR_PAT_SCC
endif
```

determination of environmental data at the next events:

```
if          N > C_N_LIM_MIN    and
            N > N_MAX                          (stored in NVMY or stored at last event)
then        update of all environmental data:
            N_MAX                   = N
            TRT_N_MAX               = TRT
            CTR_KM_N_MAX            = CTR_KM_CAN
            N_GRD_N_MAX             = N_GRD
            VS_N_MAX                = VS
            PV_AV_N_MAX             = PV_AV
            GEAR_EF_N_MAX           = GEAR_EF
            LV_CS_N_MAX             = LV_CS
            NR_PAT_SCC_N_MAX        = NR_PAT_SCC
else        old values remains unchanged:
            N_MAX                   = N_MAX
            TRT_N_MAX               = TRT_N_MAX
            CTR_KM_N_MAX            = CTR_KM_N_MAX
            N_GRD_N_MAX             = N_GRD_N_MAX
            VS_N_MAX                = VS_N_MAX
            PV_AV_N_MAX             = PV_AV_N_MAX
            GEAR_EF_N_MAX           = GEAR_EF_N_MAX
            LV_CS_N_MAX             = LV_CS_N_MAX
            NR_PAT_SCC_N_MAX        = NR_PAT_SCC_N_MAX
endif
```

T_REL_CAN_ST_2	V	0...FFFFFFFFH	0...4294967295	1	[s]
Time counter value at the end of engine off phase					

Input data:

T_REL_CAN	LV_ES	LV_IGK	LV_T_REL_CAN_REG
LV_VAR_BN	LV_ST_END	T_AST	TCO
TCO_STOP	T_REL_CAN_2		

FUNCTION DESCRIPTION:

The time T_ES describes the engine off duration time. For this the relative time counter of CAN Message INSTR2 is evaluated. This counter is incremented every minute by 1 Hex and started at zero again if FFFFH is reached. A destinction between CAN11h and BN2000 is necessarry because of different Hexlimits of T_REL_CAN_... .

At the transition into the Engine State LV_ES the last valid Value of T_REL_CAN is hand over to the non-volatile memory as T_REL_CAN_ES.

As soon as the condition LV_ES and LV_IGK = 1 is recognised the Value of T_REL_CAN is hand over to T_REL_CAN_ST and will be updated every minute until the State LV_ES is leaving.

As soon as T_REL_CAN_ST is present the Time T_ES is calculated and will be updated every minute until the State LV_ES is leaving too.

The time T_ES is compared with the difference of TCO_STOP and TCO. This is to check if time T_ES is possible at this temperature range.

The time T_ES_2 calculated in every second. This is needed for the calculation of restart factor of the mass fuel flow (fac_st_rest). Simular to T_ES, as soon as T_REL_CAN_ST_2 is present the Time T_ES_2 is calculated and will be updated every second until the State LV_ES is leaving too.

General information:

The engine off duration time will be used mainly in temperature critical functions like injection and dew point recognition

Application conditions:

Initialisation at reset: T_ES = 0
T_ES_2 = 0
T_REL_CAN_ES_2= 0 (out of NVMY)
T_REL_CAN_ST_2= 0
T_ES_AST = 0

          LV_ST_END_T_ES = 1
Endif (1)
```

Calculation of T_ES_2:

```
If(1)    LV_ST_END = 0
Then (1)
    If (2)    LV_VAR_BN = 1 and  LV_T_REL_CAN_REG = 1
    Then (2)        T_REL_CAN_ST_2 = T_REL_CAN_2
        If (3)      (T_REL_CAN_ST_2 ≥ T_REL_CAN_ES_2)
        Then (3)    T_ES_2 = T_REL_CAN_ST_2 - T_REL_CAN_ES_2
        Else (3)    T_ES_2= C_T_ES_SUB * 60
        Endif (3)
        If(4)LV_T_ES_NOT_PLAUS = 1
        Then(4)     T_ES_2 = C_T_ES_SUB * 60
        Endif (4)
      Else(2) T_ES_2 = T_ES *60
      Endif (2)
Else(1)             T_ES_2= 0
Endif (1)
```

Calculation of plausibility of T_ES for diagnosis:

```
If(1)    T_AST = C_T_AST_T_ES
Then (1)
    If (2a)   (LV_IGK = 1   or LV_VAR_BN = 1)  and
              LV_T_REL_CAN_REG = 1
    Then (2a)       T_REL_CAN_AST = T_REL_CAN
        If (3)      ( T_REL_CAN_AST ≥ T_REL_CAN_ES )    or
                    LV_VAR_BN = 1
        Then (3)    T_ES_AST =     T_REL_CAN_AST - T_REL_CAN_ES
        Else (3)    T_ES_AST =  (T_REL_CAN_AST - T_REL_CAN_ES)  +  FFFFH
        Endif (3)
        If (4)      (T_ES_AST < C_T_ES_TCO_PLAUS_MIN
                    and
                    TCO_STOP - TCO > C_TCO_STOP_T_ES_PLAUS_MIN)
                                                             or
                    (T_ES_AST > C_T_ES_TCO_PLAUS_MAX
                    and
                    C_TCO_STOP_T_ES_MIN < TCO_STOP                     and
```

```
                 TCO_STOP - TCO < C_TCO_STOP_T_ES_PLAUS_MAX)
        Then(4)  LV_T_ES_NOT_PLAUS_AST = 1
                 T_ES_AST = C_T_ES_SUB
        Else (4)
          If(5)  T_ES >= C_T_ES_TCO_PLAUS_MIN                     and
                 TCO < ( C_TCO_STOP_T_ES_MIN –
                                  C_TCO_STOP_T_ES_PLAUS_MAX)
          Then(5)      LV_T_ES_NOT_PLAUS_AST = 0
          Endif(5)
        Endif (4)
      Endif (2a)
  Endif (1)
```

Please note:

Please note the influence the definition of the 'engine off duration' has on the 'engine off duration diagnosis':

In chapter 'Engine off duration diagnosis' ERR_SYM_T_ES = SYM_2 (no signal from CAN) is not used any longer as it is already covered by the error-entries for CAN-Timeouts. Otherwise there would be a double-error-entry.

Therefore it is important that SYM_2 "no signal from CAN" will never occur. This is currently ensured by definition of LV_END_DIAG_T_ES_WIN, defined in chapter 'Engine off duration': LV_END_DIAG_T_ES_WIN is condition for the start of the diagnosis, but LV_END_DIAG_T_ES_WIN is only set if there is a signal from CAN.

As a consequence the definition of LV_END_DIAG_T_ES_WIN **must not** be changed. This solution should be kept this way in the running projects in series.

If the definition of LV_END_DIAG_T_ES_WIN will be changed then also ERR_SYM_T_ES = SYM_2 has to be removed from diagnosis.

25.2.1 Cycle counter CYC_CAST

FUNCTION DESCRIPTION:

General information:

- CYC_CAST shows the number of 120°crk cycles that have elapsed during the actual start phase (LV_ST=1). The start value is either zero or limited by the constant C_CYC_CAST_MAX_ST_ES (if start break off was detected).
- During actual after start phase (LV_AST from 0 to 1), the counter is reseted and restarts counting the number of cycles after start. When LV_AST is finished CYC_CAST remains at its last value.

Application conditions:

Activation: LV_ST = 1 or LV_AST = 1

Deactivation: LV_ST = 0 and LV_AST = 0

Initialization: CYC_CAST = 0 at ECU-reset

Recurrence: Every TDC

Formula section:

```
If      LV_AST  0 => 1
    then    CYC_CAST = 0
            else if     LV_ST or LV_AST is 1 and CYC_CAST < 65535
            then        $CYC\_CAST_n = CYC\_CAST_{n-1} + 1$
            else    $CYC\_CAST_n = CYC\_CAST_{n-1}$
    if      LV_ST_ES = 1
            then    if      CYC_CAST > C_CYC_CAST_MAX_ST_ES
            then            CYC_CAST = C_CYC_CAST_MAX_ST_ES
    endif
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CYC_CAST_MAX_ST_ES	1	0...FFFFH	0...65535	1	[-]
Max value of CYC_CAST for the beginning of incrementation if LV_ST_ES is set					

25.2.2 Start Break off LV_ST_ES

Description:

Activation:

For *engine stall during start phase*, i.e. transition from LV_ST to LV_ES before N_32 reaching IP_N_MAX_TOL_ST__TCO, the flag **LV_ST_ES** is set to 1, if LV_ST was active for a minimum number of cycles C_CYC_CAST_MIN_ST_ES. (Hint: At the same time the counter CYC_CAST will be frozen to its actual value).

Deactivation and application:

Case 1 (start after C_T_MIN_ECU_REST elapsed or powerlatch ended):

A timer T_ST_ES is started at the transition from LV_ST to LV_ES. If the timer elapses before a new start takes place (T_ST_ES ≥ C_T_MIN_ECU_REST), LV_ST_ES is reset and CYC_CAST is set to zero in the next start.

Application conditions:

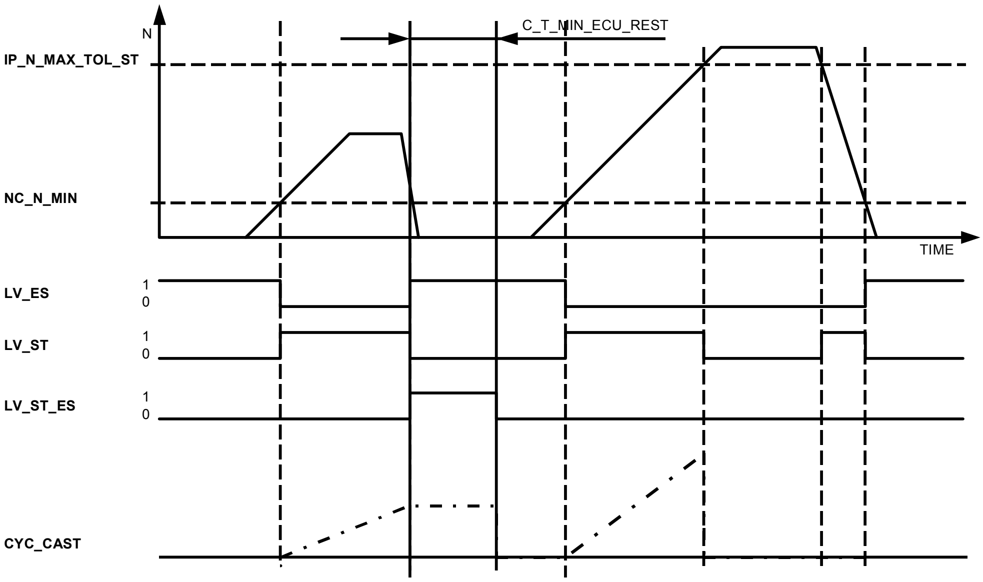
Initialisation: T_ST_ES = 0 at ECU reset

Recurrence: 100 ms

Formula section:

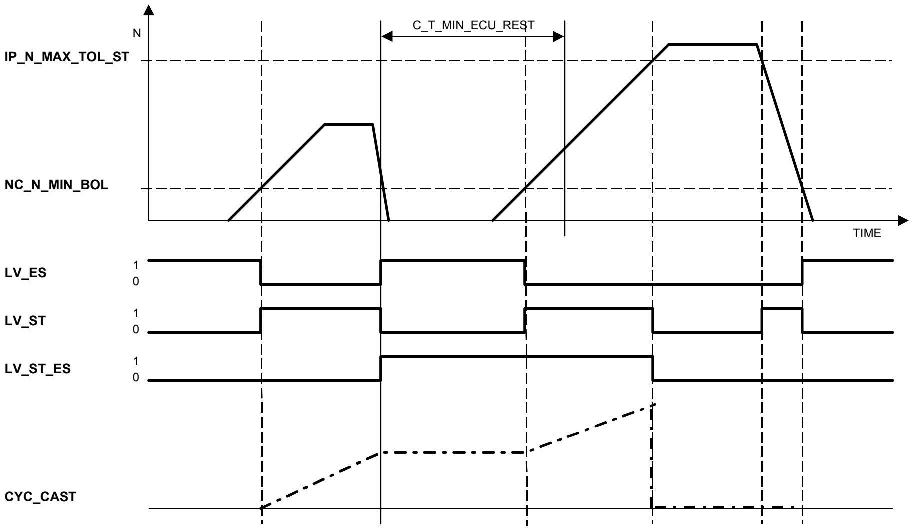
```
If      transition LV_ST → LV_ES
and     LV_ST_END = 0                       ; eng.op.state Start not left
and     CYC_CAST ≥ C_CYC_CAST_MIN_ST_ES
then    LV_ST_ES = 1
endif
If      LV_AST  0 => 1
and     LV_ST  1 => 0
or      T_ST_ES ≥ C_T_MIN_ECU_REST
then    LV_ST_ES = 0
endif

If      LV_ST_ES = 1        and     LV_ES=1
then    T_ST_ESn = T_ES_STn-1 + 1
    If      T_ST_ES >= C_T_MIN_ECU_REST
    then    LV_ST_ES = 0
            CYC_CAST = 0
            endif
else    T_ST_ES = 0
endif
```



Case 2 (start within C_T_MIN_ECU_REST):

If a new start takes place before the timer has elapsed (T_ST_ES < C_T_MIN_ECU_REST), LV_ST_ES remains set until the engine operation state start is exited to part load or idle, In this case the counter CYC_CAST starts with the previous frozen CYC_CAST-value *limited to a adjustable maximum value (see definition of CYC_CAST).*



Remark :

If C_T_MIN_ECU_REST > C_T_MAX_ECU (power latch time) and powerlatch-phase ended the value of CYC_CAST is reseted to zero for the next engine start after “start break off”-event.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_MIN_ECU_REST	1	1...FFFFH	0.1...6553.5	0.1	[s]
Time threshold to detect new start after start-break off.					
C_CYC_CAST_MIN_ST_ES	1	0...FFFFH	0...65535	1	[-]
Min value of CYC_CAST for the detection of LV_ST_ES					

25.2.3 Restart function detection (LV_REST)

FUNCTION DESCRIPTION:

General information:

The re-start function is requested as an injection time correction during start.

- If the CAN clock timing is available LV_T_REL_CAN_REG=1 the re-start factor is calculated by TCO_STOP, T_AST_REST and T_ES (see “Fuel mass setpoint and pre-injection time calculation”).
- If the CAN clock timing is not available LV_T_REL_CAN_REG=0 the re-start factor is calculated as a substitue from IP_TI_ST_REST.

Application conditions:

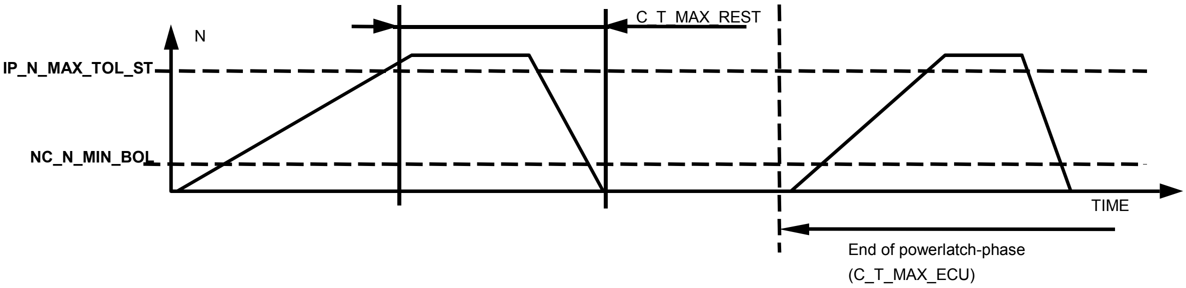
Activation:

After transition from engine start (LV_ST = 1) to engine stop (LV_ES = 1) LV_REST is checked to the end of the powerlatch-phase. As the engine was operated in part load or idle before engine stop, the next start is considered as a restart if following conditions are fullfilled:

If TCO_REST < FFH (no flash-error)
and TCO ≥ TCO_REST - C_TCO _DIF_MAX_REST

then LV_REST = 1
else LV_REST = 0

Therefore the restart-flag LV_REST is set to **1** before the next start, if the start happens before the end of the powerlatch-phase and the coolant temperature did not drop too much. The calculation of start injection time deactivation factor will start with CYC_CAST = 0.



Deactivation:

A counter T_AST is started at transition LV_ST → (LV_IS or LV_PL) .

If the engine operating state engine stopped (LV_ES) is detected before the counter has reached its maximum value C_T_MAX_REST, the related coolant temperature is stored :

(TCO → TCO_REST) in a non volatile memory.

Recurrence: segment

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_MAX_REST	1	1...FFH	1...255	1	[s]
Time delay after switching on from LV_ST to detect LV_REST					
C_TCO_DIF_MAX_REST	1	0...50H	0...60	0.75	[°C]
Coolant temperature threshold to detect LV_REST					

25.2.4 Engine stall detection LV_STALL

General information:

Engine stall detection is used for injection and CRK diagnosis.

If engine is stopped with ignition-key-on there are two different possibilities:

- Engine is stalling
- CRK error is active

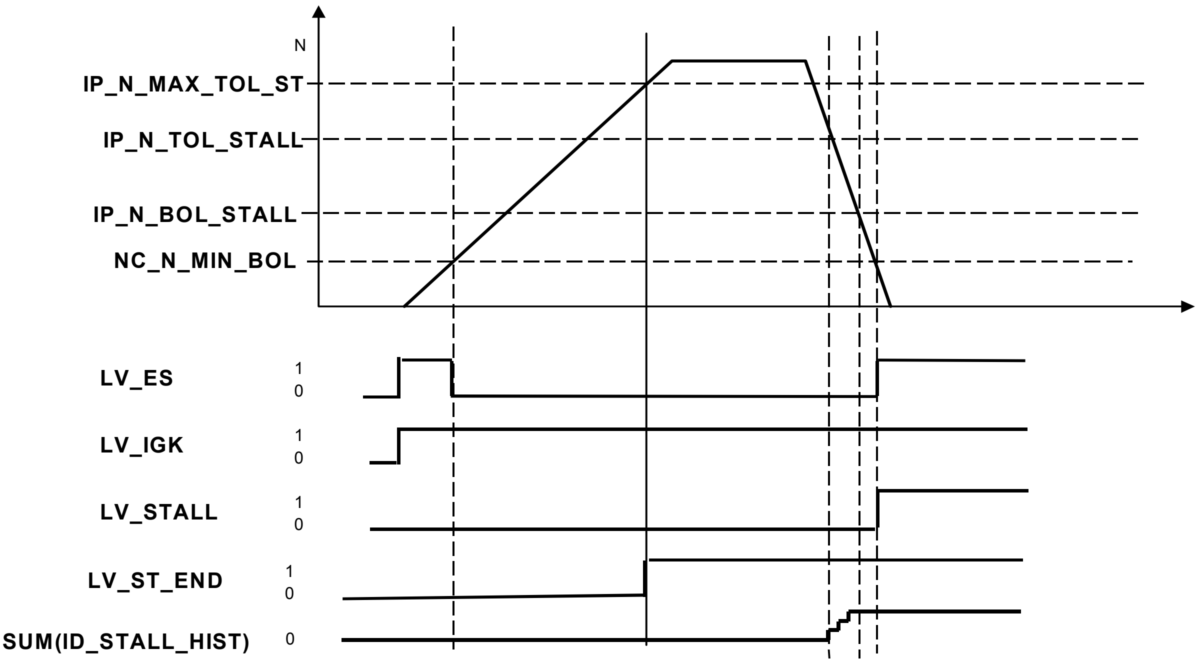
In order to detect a real engine stalling the engine speed value N_TOOTH_CUS is monitored. The reason for monitoring N_TOOTH_CUS instead of N is that N_TOOTH_CUS is calculated with a recurrency of 10ms, whereas N is calculated segment-syncronous. With engine-speed-values of < 1500 rpm the segment-time increases, the resulting update-rate of N is not precise enough for the different cases of engine-stall-detection.
If a CRK error occurs N_TOOTH_CUS is set to 0. If the engine is stalling N_TOOTH_CUS is passing a defined stalling-window.

Description:

ID_STALL_HIS is a buffer for the 32 last update rates (= 320ms History).

If N_TOOTH_CUS is between IP_N_TOL/BOL_STALL then the value in the buffer is set to 1 (=true-event).
After transition from engine running (LV_ST_END = 1) to engine stop (LV_ES = 1) with **turned on ignition** (LV_IGK = 1), it is checked if the sum of true-events in the buffer is bigger then a stalling - threshold.

Signal flow diagram:



Application conditions:

Initialisation: LV_STALL is restored out of NVMY

Recurrence: 10ms

Activation: N_TOOTH_CUS < C_N_MAX_CDN_STALL **and** LV_ST_END = 1

Formula section:

Reset of event-counter and ring-buffer after activation:

ID_STALL_HIS = 0

CTR_N_WIN_STALL = 0

Caclulation of LV_STALL:

```
if      IP_N_BOL_STALL < N_TOOTH_CUS < IP_N_TOL_STALL
then    ID_STALL_HIS = 1
        CTR_N_WIN_STALL ++          (stop ++ if FFH is reached)
else    ID_STALL_HIS = 0
        CTR_N_WIN_STALL = 0
```

```
endif

If      LV_ES  0 => 1
    and LV_ST_END = 1
    and LV_IGK = 1
    and SUM( ID_STALL_HIS ) > C_CTR_N_WIN_STALL
then    LV_STALL = 1
endif
```

Reset LV_STALL

```
if      LV_ST_END  0 => 1
then    LV_STALL = 0
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_MAX_CDN_STALL	1	0...1FE0H	0...8160	1	[rpm]
Engine-speed threshold for deactivation of stalling detection

LPDM_TCO__N_STALL	9	0...FEH	-48...142.5	0.75	[°C]
Maximum engine speed for engine stalling detection					

25.2.5 After-Start function : (LV_AST)

FUNCTION DESCRIPTION:

General information:

The after-start function serves to supply the extra injection quantity required after start by the cold walls of the combustion chamber.
The after-start function (**LV_AST**) is requested whenever the engine exits the operating state start (LV_ST) and is executed simultaneously with other engine operating states, except engine stopped (LV_ES) and start (LV_ST).
The value of T_AST when engine stopped (LV_ES=1) - after LV_ST_END = 1 has reached once - detected is transfered in T_AST_REST and safed in the non volatile memory at the end of the powerlatch - phase.

The variable T_AST indicates the time after leaving start-state. After reaching it's maximum value, T_AST is frozen. Reset occurs with every new start (Transition from LV_ST = 0 to 1).

T_AST_DIAG is calculated from T_AST to satisfy OBD requirements: recurrency must be 500ms for input signal aquisition/diagnosis.

Application conditions:

Activation:

The state **LV_AST** is activated as soon as the engine operating state start (LV_ST) is exited to go to the engine operating states idle speed (LV_IS) or part load (LV_PL).

Deactivation:

TI_CAST = 0 (refer to Chapter : ” Injection ”).

Recurrence:

Segment (LV_AST), 100ms (T_AST/T_AST_REST), 500ms (T_AST_DIAG)

Formula section:

```
If          LV_ES = 0  AND  LV_ST = 0
then
    if      T_AST < max. Value
    then    increment T_AST
    endif
endif
T_AST_DIAG = T_AST    (physical meaning)

If    LV_ES = 1 or LV_ST = 1 or LV_AST_END = 1
Then        LV_AST = 0
Else        LV_AST = 1
Endif

If    $LV\_ST\_END_{n} = 0$     and    $LV\_ST\_END_{n-1} = 1$          and
      $LV\_ES_{n} = 1$          and    $LV\_ES_{n-1} = 0$
Then        T_AST_REST = T_AST
Endif
```

25.2.6 State warm up

FUNCTION DESCRIPTION:

General information:

Calculation of state warm up. When end of warm up phase and catalyst heating is detected, LV_WUP_CAN is set to 1.

Application conditions:

Initialisation: 0

Recurrence: 100 ms

Formula section:

IF T_AST > IP_T_AST_SWI_WUP__CTR_KM_CAN **or**
TCO > C_TCO_SWI_WUP
THEN LV_WUP_CAN = 1 (catalyst heating ended indication, engine at operating temperature)
ELSE LV_WUP_CAN = 0

Calibration data:

Time condition for setting LV_WUP_CAN					

25.2.7 Cumulated time since engine start for OBD scan tool (PID1F)

FUNCTION DESCRIPTION:

General information:

Time after start is needed for OBD scan tool (PID1F)

Application conditions:

Initialisation: at reset or transition LV_DC = 1->0 set T_AST_SAE = 0 s

Recurrence: 1s

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

$T\_AST\_SAE_n = T\_AST\_SAE_{n-1} + 1s$

25.3 Starter Relay Control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_RLY_ST	O/V	0...1H	0...1	1	-
Starter relay output					

Input data:

LV_ACT_RLY_ST_EXT_ADJ	N_32	LV_RLY_ST_EXT_ADJ	TCO

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_N_MAX_TOL_STR	9	0...FFH	0...8.16E+3	32	rpm
LDPM_TCO_9	9	0...FEH	-48...142.5	0.75	°C
Top level end of starter relay control					

25.3.1 General information:

The function is defined to switch the starter relay output, dependent on the engine speed. An interface for external adjustment is offered. Through the action call is the ECU pin level "Starter Relay " set.

Diagnosis condition of engine off duration error					
LV_END_DIAG_T_ES	V/O	0...1H	0...1	1	[-]
End of diagnosis of engine off duration error					

Input data:

LV_IGK	LV_T_REL_CAN_REG	LV_T_ES_NOT_PLAUS	LV_CDN_VB_OBD2
LV_ERR_TCO	LV_END_DIAG_TCO_EL	LV_END_DIAG_TCO_GRD	LV_END_DIAG_TCO_STUCK
TCO	LV_ERR_ECU_NVMY	LV_T_ES_PLAUS_AST_END	LV_END_DIAG_T_ES_WIN

FUNCTION DESCRIPTION:

General information:

The engine off duration should be monitored concerning legislation requirements. Two different error symptoms are detectable.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                          (= SYM_0)
 │ │ └───> -                          (= SYM_1)
 │ └─────> no signal from CAN         (= SYM_2)
 └───────> T_ES not plausible to TCO  (= SYM_3)
```

Application conditions:

Initialisation: according ERRM initialization type "**STD_INI**"

Recurrence: 100 ms

Activation: LV_IGK = 1 **and** LV_END_DIAG_T_ES = 0

Formula section:

```
If      LV_ST_END = 1                       and
        LV_CDN_VB_OBD2 = 1                  and
        LV_ERR_TCO = 0                      and
        LV_END_DIAG_TCO_EL = 1              and
        LV_END_DIAG_TCO_GRD = 1             and
        (LV_END_DIAG_TCO_STUCK = 1 or
        TCO > C_TCO_STUCK_T_ES_DIAG)        and
        LV_T_ES_PLAUS_AST_END = 1           and
        LV_END_DIAG_T_ES_WIN = 1            and
        LV_ERR_ECU_NVMY = 0

Then    LV_CDN_DIAG_T_ES = 1
    If          LV_T_REL_CAN_REG = 0
    Then        ERR_SYM_T_ES = SYM_2                //no signal from CAN
    Else        If      LV_T_ES_NOT_PLAUS = 1
                Then    ERR_SYM_T_ES = SYM_3        //T_ES not plausible to TCO
                Else    ERR_SYM_T_ES = NO_SYM
                Endif
    Endif
Else    LV_CDN_DIAG_T_ES = 0
Endif
```

Remark: LV_END_DIAG_T_ES and LV_ERR_T_ES is calculated in anti bounce.

Please note:

Please note the influence the definition of the 'engine off duration' has on the 'engine off duration diagnosis':

In chapter 'Engine off duration diagnosis' ERR_SYM_T_ES = SYM_2 (no signal from CAN) is not used any longer as it is already covered by the error-entries for CAN-Timeouts. Otherwise there would be a double-error-entry.

Therefore it is important that SYM_2 "no signal from CAN" will never occur. This is currently ensured by definition of LV_END_DIAG_T_ES_WIN, defined in chapter 'Engine off duration': LV_END_DIAG_T_ES_WIN is condition for the start of the diagnosis, but LV_END_DIAG_T_ES_WIN is only set if there is a signal from CAN.

As a consequence the definition of LV_END_DIAG_T_ES_WIN **must not** be changed. This solution should be kept this way in the running projects in series.

If the definition of LV_END_DIAG_T_ES_WIN will be changed then also ERR_SYM_T_ES = SYM_2 has to be removed from diagnosis.

Input data:

LV_END_DIAG_T_ES	LV_END_DIAG_T_ES	T_ES_CUS	C_T_ES_TCO_PLAUS_MAX
C_T_ES_TCO_PLAUS_MIN	CTR_ERR_DYN_NR	LV_ERR_TCO	LV_ERR_ECU_NVMY
LV_ERR_TCO_STUCK_RNG			

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the T_ES monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_T_ES data.

Within STATE_RBM_T_ES, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor indiv. RBM conditions encountered within this DC (bit 2 not valid for T_ES)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_T_ES = 0

LV_CDN_RBM_DIAG_T_ES = 0

on failure memory reset :

bit 1 of STATE_RBM_T_ES = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_ERR_TCO_PLAUS
LV_ERR_ECU_NVMY	LV_ERR_TCO_STUCK_RNG		

```
If(1)      { CPU optimization at LV_DC 0 → 1 transition }
           CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
           While bit 1 of STATE_RBM_T_ES = 0 do
                 with each XX failure of the above list :
                 ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                 SYNCHRONIZATION<CALL>)
                 If(2)        XX has a pending status
                 Then(2)      bit 1 of STATE_RBM_T_ES = 1
                 Endif(2)
           Endwhile
Else(1)    { the dynamic failure memory is empty }
           No action
Endif(1)
```

Every 1 s :

```
If         T_ES_CUS > C_T_ES_TCO_PLAUS_MAX                  or
           T_ES_CUS < C_T_ES_TCO_PLAUS_MIN
Then       LV_CDN_RBM_DIAG_T_ES = 1
Endif
If    bit 0 of STATE_RBM_T_ES = 0
Then       If    LV_END_DIAG_T_ES = 1    and
                 LV_CDN_RBM_DIAG_T_ES = 1
           Then  bit 0 of STATE_RBM_T_ES = 1
           Endif
Endif
If    bit 1 of STATE_RBM_T_ES = 0
Then       If    LV_ERR_TCO = 1    or
                 LV_ERR_ECU_NVMY = 1
           Then  bit 1 of STATE_RBM_T_ES = 1
           Endif
Endif
```

bit 2 of STATE_RBM_T_ES = 1   (no individual RBM conditions)

26.1 ENTE Configuration data for MSD80 project

Input data:

NLC_TCO_2_CONF	NC_ECTPWM_MAX	NC_ECTPWM_MIN	NC_ECTPWM_SUB_DIAG

FUNCTION DESCRIPTION:

General information:

The logical constants NC(NLC)_xxx_CONF are necessary to adapt the Aggregate to a given system environment. The values describe either the variant of a used system component, or a vehicle component is available or not.

With use of the logical constant **NLC_ECT_CONF** the availability of an electronically controlled thermostat within the system is determined. In case of a vehicle configuration with an ECT, the component control and diagnosis is included within the aggregate version. (refer: ENTE A.I.D.)

With use of the logical constant **NLC_TCO_2_CONF** the availability of a coolant temperature sensor at radiator outlet is determined. In case of a vehicle configuration with a TCO_2 sensor, the sensor signal acquisition and diagnosis is included within the aggregate version. (refer: ENTE A.I.D.)

The configuration constant **NC_ECF_CONF** allows to determine the wanted fan control strategy. In principal it is possible to choose between a RLY- or a PWM-control architecture. A RLY/PWM fan control strategy in parallel is also existing. In this case the aggregate architecture allows switching either the control of RLY-fan(s) or the control of PWM–fan(s) during ECU runtime depending on the setting of a corresponding configuration bit. The control of both variants (RLY- and PWM-fan(s)) at the same time is not allowed and not supported within the aggregate.

Independent on the chosen fan control strategy (PWM/RLY), the configuration constant **NC_ECF_NR** describes the number of available cooling fans (hardware components) at the vehicle. In case of a PWM-fan configuration, the number of available PWM cooling fans at the vehicle is always equal to the number of PWM fan output stages provided by the ECU hardware.

Because one or more RLY-switch(es) may control only one cooling fan (hardware component) in case of a RLY-fan configuration, the number of RLY-switch(es) per cooling fan can be different. With use of the configuration constant **NC_ECF_RLY_NR**, the number of RLY output stages per cooling fan are determined.

With use of the constant **NC_ECTPWM_xxx** it is possible to adjust the PWM output range of the electronic controlled thermostat signal during normal operation conditions or when a thermostat error occurs. In case of a thermostat failure the PWM output signal is set to a defined value for safety issues.

The following describes the general rules for determination of the configuration data.

26.1.1 Local configuration data

Here are listed the configuration data, which are used only in the ENTE aggregate.

Data	**Value**
NLC_ECT_CONF	[1] Electronically controlled thermostat (ECT) is available
NLC_TCO_2_CONF	[1] Coolant temperature sensor at radiator outlet is available
NC_ECF_CONF	[1] Control of PWM-fan(s) requested (only PWM fan(s))
NC_ECF_NR	[1] Number of available cooling fans (hardware components) at the vehicle
NC_ECF_RLY_NR	[0] Number of RLY output stages per cooling fan (hardware components) (NC_ECF_RLY_NR=0 have to be adjusted in case of NC_ECF_CONF=1)
NC_ECTPWM_MAX	99,6 % Maximum limitation of ECTPWM signal
NC_ECTPWM_MIN	0,4 % Minimum limitation of ECTPWM signal
NC_ECTPWM_SUB_DIAG	[4,31%] – (B08**H**) Adjusted ECTPWM signal in case of failures
NC_NR_TCO_SENS	2

Configuration data:

Name	**Dim**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
NLC_ECT_CONF	1	0...1H	0...1	1	[-]
System configuration flag (compiler) if an electronic controlled thermostat is available (=1) or not (=0)					
NC_ECF_CONF	1	0...3H	0...3	1	[-]

26.2 Acquisition of electronically controlled thermostat signal

26.2.1 Pulse width modulated outputs

Input data:

ECTPWM			

FUNCTION DESCRIPTION:

General information:

Not all vehicles are equipped with an electronic controlled thermostat for the regulation of the coolant liquid circulation. Depending on the hardware configuration a pulse width modulated value (ECTPWM) for the electronic controlled thermostat is calculated or not. Only in case of a vehicle configuration with an electronic controlled thermostat a pulse width modulated signal is generated at the ECU output.

PWM output name	Frequency	Updating of duty cycle	Range of duty cycle
ECTPWM	hardware dependent	1000 ms	0 -100%

Application conditions:

Initialisation at reset: ECTPWM = 0%

Activation: at every engine operating state

Deactivation: -

26.3 Acquisition of electronically controlled cooling fan signal

Input data:

ECFPWM[NC_ECF_NR]	NC_ECF_NR		

FUNCTION DESCRIPTION:

General information:

Depending on the hardware configuration a pulse width modulated value is calculated (ECFPWM[NC_ECF_NR]) to control the requested cooling fan(s). In case of a vehicle configuration with a PWM controlled cooling fan(s), a signal at the ECU output is generated.

PWM output name	Frequency	Updating of duty cycle	Range of duty cycle
ECFPWM[NC_ECF_NR] (ECFPWM_ECF)	100 Hz (10 Hz during power latch)	200 ms	0 -100%

Application conditions:

Activation: at every engine operating state

Deactivation: -

(see: "ENTE scheduler")

26.4 ENTE – Requirements to infrastructure interface

Input data:

NC_NR_TCO_SENS			

Export actions:

ACTION_INFR_GetVpTco (OUT <>)
This action provides the digitized voltage value of the available coolant temperature sensors in an array.

Description for actions:

ACTION_INFR_GetVpTco (OUT <>)					
This action provides the digitized voltage value of the available coolant temperature sensors in an array delivered from the infrastructure. The AD conversion is performed autonomously by the infrastructure. When the action is called the gathered information will be provided to the application software level. The dimension of the parameter *Vp_tco_sens* is given by configuration input NC_NR_TCO_SENS. The index range is 0 … NC_NR_TCO_SENS-1.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Vp_tco_sens [NC_NR_TCO_SENS]	OUT	0...7FFFH	0...4.999847412	1.53E-04	V
Coolant temperature sensor voltage value					

FUNCTION DESCRIPTION:

General information:

The following action is used for the acquisition of the digitized voltage value of the adressed coolant temperature sensor in an array. The action delivers the coolant temperature sensor voltage value to the application software level from the standard AD converter queue.

- NC_NR_TCO_SENS is valid from 1...255.

  The voltage belonging to the first sensor is returned in Vp_tco_sens[0].

  The voltage belonging to the *n* sensor is returned in Vp_tco_sens[n-1].
- The AD conversion is performed autonomously by the infrastructure, the returned value is not older than 10 ms.
- The voltage value is gathered in the infrastructure until the application reads out the information by calling the action, old values are replaced by new values.

Requirements for ACTION_INFR_GetVpTco:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Vp_tco_sens [NC_NR_TCO_SENS]			10 Bit	The following coinicidence requirement has to be fulfilled in case of NC_NR_TCO_SENS > 1: Vp_tco_sens[k] is digitized at point in time t_k. For the returned array the maximum allowed time periode $\mid t_k - t_i \mid$ must less than 10ms.	No comment

Diagnosis: no electrical diagnosis done here

Coincidence requirements: When calling this action, all returned voltages must be within the last 100 ms.

26.5 Engine temperature management input/output

Input data:

LV_RAS_OUT			

Export actions:

ACTION_INFR_SetRas (IN <Lv_ras_out>)
This action gives the control of the RAS signal
ACTION_INFR_GetElDiagRas (OUT<Cdn_diag_ras_out_el>, OUT<Err_diag_ras_out_el>)
This action reads the primary failure and condition information for a symptom of the radiator shutter

Description for actions:

ACTION_INFR_SetRas(IN <Lv_ras_out>)					
This action gives the control of the RAS signal					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
lv_ras_out	IN	0...1H	0...1	1	-
lv_ras_out = 1 --> PKKS open. Magnet not feeded lv_ras_out = 0 --> PKKS closed. Magnet feeded					

ACTION_INFR_GetElDiagRas (OUT<Cdn_diag_ras_out_el>, OUT<Err_diag_ras_out_el>)					
This action reads the primary failure and condition information for a symptom of the RAS.					
Name	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cdn_diag_ras_out_el	OUT	0...7H	0...7	1	-
Primary diagnosis condition for each symptom of RAS Bit 0: diagnosis condition for symptom SYM_0 Bit 1: diagnosis condition for symptom SYM_1 Bit 2: diagnosis condition for symptom SYM_2					
Err_diag_ras_out_el	OUT	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	-
Raw value of error symptom for RAS (only parameter)					

FUNCTION DESCRIPTION:

1.1 Set bit signal for RAS control

General information:

This action is used to set the RAS signal.

Requirements for ACTION_INFR_SetRas:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Lv_ras_out	-	-	1 Bit		The Ras_Out signal is a single bit signal lv_ras_out = 1 PKKS open – Magnet not feeded lv_ras_out = 0 PKKS closed – Magnet feeded

Diagnosis: no electrical diagnosis done here

Coincidence requirements: An update of the signal passed to the Infrastructure has to be performed within the next five periods.

1.2 Get RAS electrical diagnosis result

General information:

This action returns the result of the electrical diagnosis of the RAS.

- The device readout is performed autonomous by the Infrastructure.
- The error information are gathered in the Infrastructure until the Application reads out the information by calling ACTION_INFR_GetElDiagRas.
- After having read out the information by calling ACTION_INFR_GetElDiagRas, the data inside the Infrastructure are reset.

Requirements for ACTION_INFR_GetElDiagRas:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag_ras_out_el	-	-	<bit coded>	Err_diag_ras_out_el	Diagnosis condition for each symptom of RAS **Bit 0:** diagnosis condition for symptom SYM_0 **Bit 1:** diagnosis condition for symptom SYM_1 **Bit 2:** diagnosis condition for symptom SYM_2 The relevant bit is set, if the condition for a valid diagnosis is fulfilled.
Err_diag_ras_out_el	-	-	<bit coded>	Cdn_diag_ras_out_el	Bit coded result of each symptom **0H** = NO_SYM **1H** = SYM_0 – SCP **2H** = SYM_1 – SCG **4H** = SYM_2 – OC **8H =** SYM_3 – not used The relevant bit is set, if the error has been detected.

Diagnosis: ACTION_INFR_GetElDiagRas returns the electric diagnosis of the RAS.

Coincidence requirements: no coincidence requirements to other events

26.6 AGGR ENTE adaptation: Engine temperature

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TCO_EX	V/O	0...FEH	-48...142.5	0.75	[°C]

Boolean for electronic controlled thermostat mechanical error					

Input data:

TCO_2	LV_ERR_TCO_2		TCO_2_MES
ECFPWM[NC_ECF_NR]	LV_ES		LV_ERR_TH

FUNCTION DESCRIPTION:

Adaptation of ENTE variables to MSD70 environment.

General information:

At the MSD70 platform only one electronic controlled cooling fan is available. The number of cooling fans is configured with “1” therefore. In this case the following condition is permitted:

ECFPWM[NC_ECF_NR] = ECFPWM[1]

Application conditions:

Initialisation: all 0 at reset
except:

LV_ERR_ECT_MEC = LV_ERR_TH

Recurrence: 1000 ms

Activation: every engine state

Formula section:

TCO_EX = TCO_2

TCO_EX_MES = TCO_2_MES

LV_ERR_TCO_EX = LV_ERR_TCO_2

ECFPWM_ECF = ECFPWM[1]

LV_ERR_ECT_MEC = LV_ERR_TH

Input data:

TCO_SUB	LV_ERR_TCO	LV_ERR_TCO_PREL	TIA_IM
LV_ERR_TIA_IM	LV_ES	NC_NR_TCO_SENS	VP_TCO_COPL[NC_NR_TCO_SENS]
LV_ECU_SLA			

Import actions:

ACTION_INFR_GetVpTco (OUT <>)

FUNCTION DESCRIPTION:

General information:

The coolant temperature raw sensor voltage is measured with use of an A/D converter by the ECU hardware. The software then is generating a modified sensor signal (VP_TCO[0]), which is requested by the application software for further execution.

The modified sensor signal (VP_TCO[0]) is converted into a measured temperature value (TCO_MES) with use of a one-dimension interpolation table (IP_TCO_MES).

Application conditions:

See separate chapters:

26.7.1 Coolant temperature gradient monitoring

FUNCTION DESCRIPTION:

General information:

The measured coolant temperature (TCO_MES) is monitored for not plausible gradients. It is checked if the temperature difference between the old and the new measured coolant temperature (TCO_MES) exceeds the permissible gradient C_TCO_MES_GRD_MAX. In this case the old measured value remains unchanged. If the temperature difference between the measured coolant temperature values is exceeding the permissible gradient again during the next measurement, the new measured value is transferred into the working memory. A measured value can be inhibited only if the gradient exceeded for one time (recurrence).

The monitoring of the coolant temperature gradient does not lead to failure entries. The only purpose is to extract implausible measured values (noise).

Application conditions:

Initialisation at Reset:

```
FOR k = 0 to NC_NR_TCO_SENS -1
    IF  LV_ECU_SLA =1
        THEN VP_TCO[k] = VP_TCO_COPL[k]
        ELSE
        ACTION_INFR_GetVpTco(VP_TCO[k])

    ENDIF
END FOR
// all sensor values are imported and provided as output
$TCO\_MES_{(n)} = TCO\_MES_{(n-1)} = IP\_TCO\_MES$
// acquisition of the main coolant temperature measurement signal
```

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

```
// all sensor values are imported and provided as output
FOR k = 0 to NC_NR_TCO_SENS - 1
    IF  LV_ECU_SLA =1
        THEN VP_TCO[k] = VP_TCO_COPL[k]
        ELSE
        ACTION_INFR_GetVpTco(VP_TCO[k])
    ENDIF
END FOR
// VP_TCO[0] is used as input signal for the interpolation table IP_TCO_MES
TCO_MES = IP_TCO_MES
// acquisition of the main coolant temperature measurement signal
If      $| TCO\_MES_{(n-1)} - TCO\_MES_{(n)} | > C\_TCO\_MES\_GRD\_MAX$
then    $TCO\_MES_{(n)} = TCO\_MES_{(n-1)}$          (only one time!)
```

```
else        TCO_MES(n) = TCO_MES(n)
endif
```

26.7.2 Coolant temperature acquisition

FUNCTION DESCRIPTION:

General information:

The actualisation of the coolant temperature value (TCO) is only executed, if no coolant temperature error / preliminary error is detected. In case of a detected error, the TCO value will be set to the calculated coolant temperature substitute value (TCO_SUB).

The initialisation of the coolant temperature value (TCO) is always performed as long as the engine operating state “Engine stop” is active.

Application conditions:

Initialisation:

at Reset TCO = TCO_MES
at Reset **or** Engine stop: LV_CDN_INI_TCO = 1

at Engine stop to Engine run (ES_to_ERU):
LV_CDN_INI_TCO = 0

Activation: at every engine operating state

Deactivation: -

26.7.2.1 Coolant temperature acquisition at engine stop

Application conditions:

Recurrence: 10 ms

Activation: LV_CDN_INI_TCO = 1

Deactivation: LV_CDN_INI_TCO = 0

Formula section:

```
if (1)          LV_ERR_TCO = 0          and
                LV_ERR_TCO_PREL = 0
then (1)        TCO = TCO_MES
else (1)
        if (2)      LV_ERR_TIA_IM = 0
        then (2)    TCO = IP_TCO_INI_TIA_IM
        else (2)    TCO = C_TCO_INI_TIA_IM
```

```
        endif (2)
endif (1)
```

26.7.2.2 Coolant temperature acquisition at engine run

Recurrence: 100 ms

Activation: LV_CDN_INI_TCO = 0

Deactivation: LV_CDN_INI_TCO = 1

Formula section:

```
if (1)          LV_ERR_TCO = 0
then (1)
        if (2)      LV_ERR_TCO_PREL = 0
        then (2)    TCO = TCO_MES
        else (2)    $TCO_{(n)} = TCO_{(n-1)}$
        endif (2)
else (1)        TCO = TCO_SUB
endif (1)
```

26.7.3 Coolant temperature at engine start

FUNCTION DESCRIPTION:

General information:

The coolant temperature at engine start (TCO_ST) is determined as long as the engine operating state “Engine stop” is detected. During this time, TCO_ST is set with the actual coolant temperature value TCO.

Application conditions:

Initialisation at Reset:

TCO_ST = TCO_MES

TCO_ST_DC = TCO_MES

Recurrence: 10 ms

Activation: LV_ES = 1

Deactivation: LV_ES = 0

Formula section:

TCO_ST = TCO
TCO_ST_DC = TCO

26.7.4 Coolant Temperature at engine stop

FUNCTION DESCRIPTION:

General information:

The coolant temperature at engine stop (TCO_STOP) is determined at each transition to the engine operating state "Engine stop". TCO_STOP will be stored in the non-volatile memory during the ECU's self-holding phase.

Application conditions:

Initialisation at Reset:

TCO_STOP = TCO_STOP

(stored in the non-volatile memory)

Initialization at Engine run to Engine stop (ERU_to_ES):

TCO_STOP = TCO

Activation: at every engine operating state

Deactivation: -

Calibration data:

      endif
endif
```

26.8.2 Coolant temperature (radiator outlet) acquisition

FUNCTION DESCRIPTION:

General information:

The actualisation of the coolant temperature value at radiator outlet (TCO_2) is only executed, if no coolant temperature (radiator outlet) error / preliminary error is detected. In case of a detected error, the TCO_2 value will be set to its substitute value, which is calculated by the coolant temperature (TCO) in combination with an offset value.

The initialisation of the coolant temperature value at radiator outlet (TCO_2) is only performed once per engine run as long as the engine operating state "Engine stop" is active. If the engine stalls and in this case the engine operating state is changing to "Engine stop" again, a new initialization of the coolant temperature at radiator outlet will not be done. Power latch must always be finished before a new initialization process is performed as long as no ECU reset occurs. An ECU reset is handled like the beginning of a new engine run and an initialization of the TCO_2 value is also done in this case for at least one recurrence.

Application conditions:

Initialisation at Reset

LV_CDN_INI_TCO_2 = 1

TCO_2 = TCO_2_MES

Initialisation at Engine stop to Engine run (ES_to_ERU):

LV_CDN_INI_TCO_2 = 0

Activation: at every engine operating state

Deactivation: -

26.8.2.1 Coolant temperature (radiator outlet) acquisition (at ES after RESET)

Application conditions:

Recurrence: 10 ms

Activation: LV_CDN_INI_TCO_2 = 1

Deactivation: LV_CDN_INI_TCO_2 = 0

Formula section:

if (1) LV_ERR_TCO_2 = 0 **and**
LV_ERR_TCO_2_PREL = 0
then (1) TCO_2 = TCO_2_MES
else (1) TCO_2 = TCO - C_TCO_2_DIF_TCO

```
endif (1)
```

26.8.2.2 Coolant temperature (radiator outlet) acquisition (at ERU / at ES after ERU_to_ES)

Application conditions:

Recurrence: 100 ms

Activation: LV_CDN_INI_TCO_2 = 0

Deactivation: LV_CDN_INI_TCO_2 = 1

Formula section:

```
if (1)          LV_ERR_TCO_2 = 0
then (1)
        if (2)      LV_ERR_TCO_2_PREL = 0
        then (2)    TCO_2 = TCO_2_MES
        else (2)    $TCO\_2_{(n)} = TCO\_2_{(n-1)}$
        endif (2)
else (1)        TCO_2 = TCO - C_TCO_2_DIF_TCO
endif (1)
```

26.8.3 Coolant temperature (radiator outlet) at engine start

FUNCTION DESCRIPTION:

General information:

The coolant temperature (radiator outlet) and the measured coolant temperature at engine start (TCO_2_ST, TCO_2_MES_ST) is determined as long as the engine operating state “Engine stop” is detected. During this time, TCO_2_ST is updated with the actual coolant temperature value at radiator outlet (TCO_2) and TCO_2_MES_ST is updated with the measured coolant temperature value at radiator outlet (TCO_2_MES).

Application conditions:

Initialisation at Reset:

TCO_2_ST = TCO_2_MES

TCO_2_MES_ST = TCO_2_MES

Recurrence: 10 ms

Activation: LV_ES = 1

Deactivation: LV_ES = 0

Formula section:

TCO_2_ST = TCO_2
TCO_2_MES_ST = TCO_2_MES

26.8.4 Temperature difference between the coolant temperature sensors

FUNCTION DESCRIPTION:

General information:

The main coolant temperature sensor (TCO) is located next to the engine, while the second coolant temperature sensor (TCO_2) is fixed at radiator outlet. The temperature difference between the coolant temperature values (TCO_1_2) is determined and used for further calibration issues. Only positive values for the coolant temperature difference are plausible at normal driving conditions.

Application conditions:

Initialisation at Reset:

TCO_1_2 = 95.25°C

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

TCO_1_2 = TCO – TCO_2

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

TAM	MAF_KGH	N_REL_CWP	T_AST
VS	OPM_AV		

FUNCTION DESCRIPTION:

General information:

The coolant temperature substitute model (TCO_SUB) is initialized with the coolant temperature at engine start (TCO_ST) as soon as the system event “Engine stop” to “Engine run” is detected. The substitute model increment values are dependent on the actual engine performance (equivalent to mass air flow MAF_KGH), ambient temperature and vehicle speed. To take the smaller incrementation values at higher coolant temperatures into consideration, the increment values are weighted.

During “Idle speed” and “Pull fuel cutoff” phases the calculation of the coolant temperature substitute value remains activated.

A delay time after engine start to activate the incrementation of the temperature substitute value is incremented, to simulate the warm up of the real coolant temperature very efficient.

In case of a coolant temperature acquisition failure (LV_ERR_TCO = 1), the coolant temperature substitute value is reinitialized with the latest valid coolant temperature value. In this case the model incrementation starts from the initialization value on.

Application conditions:

Initialisation at Engine stop to Engine run (ES_to_ERU):

T_DLY_TCO_SUB = 0

T_DLY_TCO_SUB_COR_STATE_COC = 0

$TCO\_SUB_{(n)} = TCO\_SUB_{(n-1)} = TCO\_ST$

FAC_TCO_SUB_COR_STATE_COC = 1

Initialisation at Exit start (EXIT_ST):

LV_CDN_ENA_TCO_SUB = 1

T_N_REL_CWP_GRD_H = C_T_N_REL_CWP_GRD_H

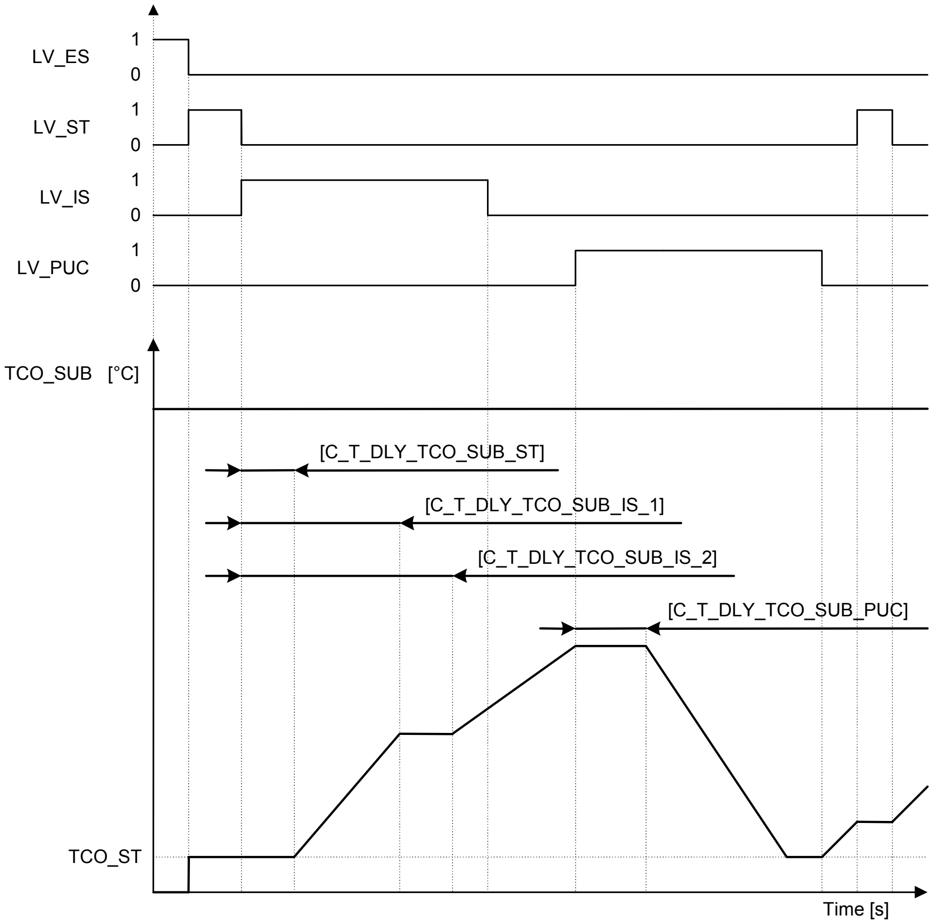
CTR_N_REL_CWP_H = C_CTR_N_REL_CWP_H

Initialisation at Engine run to Engine stop (ERU_to_ES):

LV_CDN_ENA_TCO_SUB = 0

Recurrence:	1000 ms
Activation:	LV_CDN_ENA_TCO_SUB = 1
Deactivation:	LV_CDN_ENA_TCO_SUB = 0

Signal flow diagram:



Formula section:

Calculation of the factor FAC_TCO_SUB_COR_STATE_COC for CWP functionality:

```
If          N_REL_CWP  <  C_N_REL_CWP_THD_COC
then        T_DLY_TCO_SUB_COR_STATE_COC  =  0
            T_DLY_THD_TCO_SUB_ST  =  C_T_DLY_TCO_SUB_ST_CWP_OFF
            FAC_TCO_SUB_COR_STATE_COC = 1
else        T_DLY_THD_TCO_SUB_ST  =  C_T_DLY_TCO_SUB_ST_CWP_ON
    if      T_DLY_TCO_SUB_COR_STATE_COC
                < C_T_DLY_TCO_SUB_COR_STATE_COC
    then    FAC_TCO_SUB_COR_STATE_COC  =
            C_FAC_TCO_SUB_COR_STATE_COC
    else    FAC_TCO_SUB_COR_STATE_COC  =  1
    endif
            T_DLY_TCO_SUB_COR_STATE_COC  =
            T_DLY_TCO_SUB_COR_STATE_COC + 1 s
endif
```

Calculation of factor FAC_TCO_SUB_COR_N_REL_CWP for CWP functionality:

```
            FAC_TCO_SUB_COR_N_REL_CWP  =
            IP_FAC_TCO_SUB_COR_N_REL_CWP
                * FAC_TCO_SUB_COR_STATE_COC
```

Calculation of the substitute model increment value during “Engine start”:

```
If          LV_ST = 1
then        TCO_SUB_INC  =  0
endif
```

Calculation of factor FAC_TCO_SUB_VS for vehicle speed functionality:

```
If  (TCO_SUB >= C_TCO_SUB_MIN_FAC_VS)
then
   FAC_TCO_SUB_VS = IP_FAC_TCO_SUB_VS
else
  FAC_TCO_SUB_VS = 1
endif
```

Calculation of the substitute model increment value during “Part load” or “Pull”:

```
If (1)          LV_PL = 1                                  or
```

```

26.10 Control of the electric fan

26.10.1 Control of ECFPWM[NC_ECF_NR] with ignition key on

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ECFPWM[NC_ECF_NR]	V/O	0...FFH	0...99.60937	0.390625	[%]
Pulse width modulated output signal for the electronic controlled cooling fan(s)					
T_N_PERC_ECF_ACT	V	0...FFH	0...51	0.2	[s]
Time condition for electric fan during self diagnostic					

Input data:

N_PERC_ECF	LV_IGK	LV_ECFPWM_ECF_EXT_ADJ	ECFPWM_ECF_EXT_ADJ
LV_ERR_ECF[NC_ECF_NR]	NC_ECF_NR		

FUNCTION DESCRIPTION:

General information:

The electric fan is controlled with a 100 Hz PWM signal to regulate its rotational speed. The calculated pulse width modulation depends on various components which are handled by the BMW “Wärmemanagementkoordinator”.

Application conditions:

Initialisation: all = 0 at reset

T_N_PERC_ECF_ACT = C_T_N_PERC_ECF_ACT

Recurrence: 200ms

Activation: LV_IGK = 1

(see: “*ENTE scheduler*”)

26.10.1.1 Calculation of PWM-signal for the electric cooling fan

Description:

All calculations which are necessary for the computation of the overall cooling fan speed are done by the BMW “Wärmemanagementkoordinator”. Via layer BMW hands over the final cooling fan speed N_PERC_ECF which is already standardized to percentage.

Self-diagnosis runs each time the electric fan is switched on. The electric fan should be operated with constant, low speed stage for this.

```
If      N_PERC_ECF  >  C_N_PERC_ACT_ECF  and
        T_N_PERC_ECF_ACT > 0 sec.
Then    T_N_PERC_ECF_ACT is decremented
        ECFPWM[0]  =  C_N_PERC_ACT_ECF
Else    ECFPWM[0]  =  N_PERC_ECF
Endif
```

Formula section:

```
If (1)      LV_ERR_ECF[0] = 1
then (1)    ECFPWM[0] = NC_ECFPWM_ECF_SUB_DIAG
else (1)
    if (2)      LV_ECFPWM_ECF_EXT_ADJ = 1

Pulse width modulated output signal for the electronic controlled thermostat					
T_ECTPWM_AST	-	0...FFH	0...255	1	[s]
time for ECTPWM-calculation after start					

Input data:

LV_ECTPWM_EXT_ADJ	ECTPWM_EXT_ADJ	LV_ERR_ECT_EL	ECTPWM_CLC
LV_ES	LV_ST_END	TCO	LV_ERR_ECT_EL_OC
LV_ERR_ECT_EL_SCP			

26.12.1 Adjustment of the pulse width modulated output signal (ECTPWM)

FUNCTION DESCRIPTION:

General information:

For calibration issues and service tool operations the calculated pulse width modulated signal (ECTPWM_CLC) has to be adjusted manually before it is sent to the power stage of the electronic controlled thermostat (ECTPWM). Two possibilities for the manual adjustment are existing. With the logical constant LC_ECTPWM_MAN it is possible to adjust the calibratable value C_ECTPWM_MAN to the PWM output with use of the calibration system. The service tool allows the adjustment of the PWM signal as well. In this case the logical variable LV_ECTPWM_EXT_ADJ is set from logical low (0) to logical high (1) and the adjustable value ECTPWM_EXT_ADJ is used as output signal (ECTPWM).

As soon as the thermostat failure algorithm detects a electrical thermostat failure, the PWM output signal is set to a calibratable value (NC_ECTPWM_SUB_DIAG) at once and the ECT control state “LIH” is activated.

Application conditions:

Initialisation: all 0 at reset,

Except: T_ECTPWM_AST :
at reset or at transition LV_ES 0 --> 1: T_ECTPWM_AST = 0

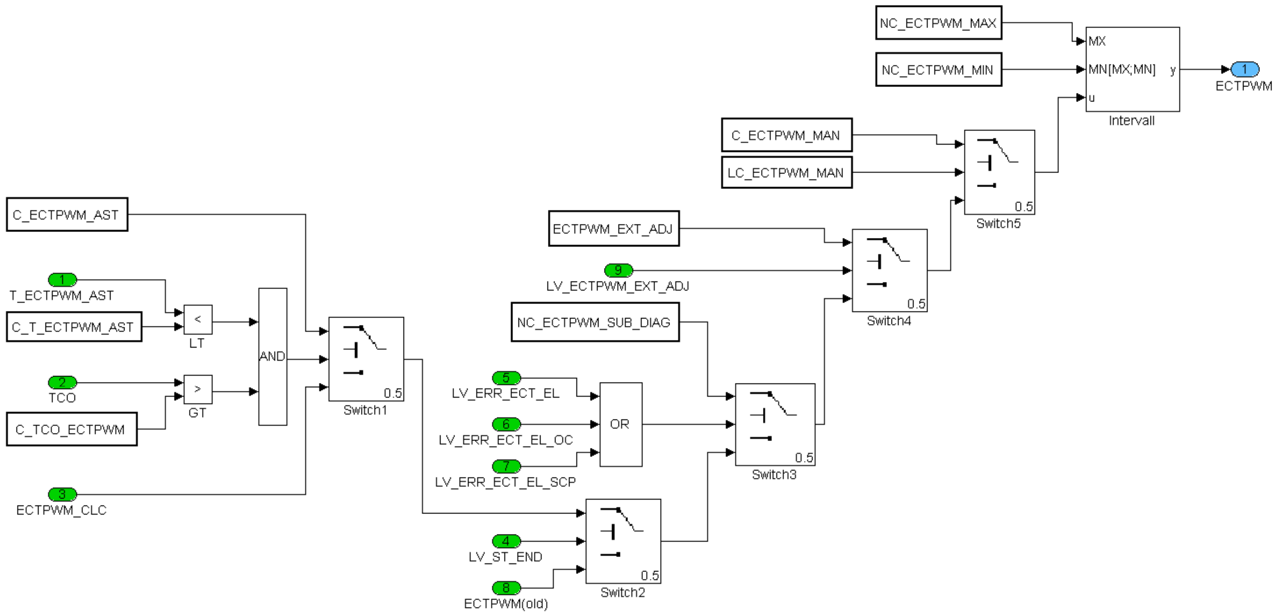
// the time condition C_T_ECTPWM_AST is reset each time
the engine state “engine stop” is reached or ecu is reset

Recurrence: 1000 ms

Activation: at every engine operating state

Deactivation: -

Signal flow diagram:



Formula section:

If LV_ST_END = 1 **and** T_ECTPWM_AST < C_T_ECTPWM_AST

Then T_ECTPWM_AST = ++

Endif

```
If (1)      LC_ECTPWM_MAN = 1
Then (1)    ECTPWM = C_ECTPWM_MAN

                                        and
                                        TCO < C_TCO_ECTPWM
                              Then(5)         ECTPWM = C_ECTPWM_AST
                                              // for   time C_T_ECTPWM_AST
                              Else (5)  ECTPWM = ECTPWM_CLC
                              Endif (5)
                        Endif(4)
                  Endif(3)
            Endif (2)
Endif (1)
```

26.12.2 Limitation of the pulse width modulated output signal (ECTPWM)

FUNCTION DESCRIPTION:

General information:

The limits of the pulse width modulated output signal for the electronic controlled thermostat are fixed to NC_ECTPWM_MIN for the lower and NC_ECTPWM_MAX for the upper value. The controller output signal must be limited as soon as the amount of the controller is reaching the limits.

The power stage output signal for the electronic controlled thermostat is limited to a minimum and a maximum value to guarantee a continuous working electrical diagnosis of the power stage.

Application conditions:

Initialisation: all 0 at reset

Recurrence: 1000 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

$NC\_ECTPWM\_MIN \leq ECTPWM \leq NC\_ECTPWM\_MAX$

Calibration data:

FUNCTION DESCRIPTION:

Description:

This modul consists of three parts.

- End of line Sytem test functionality
- Calculation of ECRASPWM
- Setting of STATE_ECRAS_SYS

EOL-System test: the system test is activated by LV_ACT_ECRAS_EOL_EXT_ADJ which is set by tester (see "Services for EOL tests" chapter). During this EOL test several ECRASPWM will be set for a certain time. This allows that every possible failure can be detected by the ECRAS feedback diagnosis.
Calculation of ECRASPWM: The ECRAS PWM signal will be claculated. ECRASPWM requests will be prioritised.
Setting of STATE_ECRAS_SYS: A State STATE_ECRAS_SYS is created which displays specific information about the whole ECRAS system (eg. diagnosis, EOL etc.).

Application conditions:

Initialisation: reset **or** LV_IGK = 0 -> 1 all 0, except ECRASPWM = C_ECRASPWM_DIAG

Recurrence: 100 ms

Activation: always

Deactivation: none

Formula section:

EOL System test

```

Boolean for ratio time after engine start enable condition					

Input data:

LV_IS	LV_PUC	MAF_KGH	VS
TAM			

FUNCTION DESCRIPTION:

General information:

The coolant temperature increase after engine start is most dependent on the ambient- and the engine operating conditions. To avoid monitoring failures within the diagnosis functions related to the coolant temperature behaviour, the influence of critical engine driving conditions must be taken into consideration. To allow a comparison to the time elapsed since engine start, the activation time of the critical driving conditions are calculated in percent of the elapsed time. The percentage values are used in several diagnosis functions to cancel monitoring in order to avoid failures.

Application conditions:

Initialisation at Exit start (EXIT_ST):

LV_CDN_ENA_RATIO_T_AST = 1

all other output data are set to “0” [phys]

Initialisation at Engine run to Engine stop (ERU_to_ES):

LV_CDN_ENA_RATIO_T_AST = 0

T_DIAG_AST = 0 s

Recurrence: 1000 ms

Activation: LV_CDN_ENA_RATIO_T_AST = 1

Deactivation: LV_CDN_ENA_RATIO_T_AST = 0

Formula section:

Calculation of the after start time for diagnosis functions:

```
If      $\text{T\_DIAG\_AST} < 65535\ \text{s}$
then    $\text{T\_DIAG\_AST}_{(n)} = \text{T\_DIAG\_AST}_{(n-1)} + 1\ \text{s}$
else    $\text{T\_DIAG\_AST}_{(n)} = \text{T\_DIAG\_AST}_{(n-1)}$
endif
```

Calculation of the "idle speed" period after start:

```
If      $\text{LV\_IS} = 1$
then    $\text{T\_IS\_AST}_{(n)} = \text{T\_IS\_AST}_{(n-1)} + 1\ \text{s}$
else    $\text{T\_IS\_AST}_{(n)} = \text{T\_IS\_AST}_{(n-1)}$
endif
$\text{RATIO\_T\_IS\_AST} = (\text{T\_IS\_AST} / \text{T\_DIAG\_AST}) * 100\ \%$
```

Calculation of the " trailing throttle fuel cut-off " period after start:

```
If      $\text{LV\_PUC} = 1$
then    $\text{T\_PUC\_AST}_{(n)} = \text{T\_PUC\_AST}_{(n-1)} + 1\ \text{s}$
else    $\text{T\_PUC\_AST}_{(n)} = \text{T\_PUC\_AST}_{(n-1)}$
endif
$\text{RATIO\_T\_PUC\_AST} = (\text{T\_PUC\_AST} / \text{T\_DIAG\_AST}) * 100\ \%$
```

Calculation of the "low load" period after start:

```
If      $\text{MAF\_KGH} <= \text{IP\_MAF\_KGH\_LOAD\_MIN\_AST}$
then    $\text{T\_LOAD\_MIN\_AST}_{(n)} = \text{T\_LOAD\_MIN\_AST}_{(n-1)} + 1\ \text{s}$
else    $\text{T\_LOAD\_MIN\_AST}_{(n)} = \text{T\_LOAD\_MIN\_AST}_{(n-1)}$
```

```
endif
RATIO_T_LOAD_MIN_AST = (T_LOAD_MIN_AST / T_DIAG_AST) * 100 %
```

Calculation of the "low vehicle speed" period after start:

```
If      VS <= C_VS_THD_VS_MIN_AST
then    $T\_VS\_MIN\_AST_{(n)} = T\_VS\_MIN\_AST_{(n-1)} + 1\ s$
else    $T\_VS\_MIN\_AST_{(n)} = T\_VS\_MIN\_AST_{(n-1)}$
endif
RATIO_T_VS_MIN_AST = (T_VS_MIN_AST / T_DIAG_AST) * 100 %
```

Calculation of the "high vehicle speed" period after start:

```
If      VS > C_VS_THD_VS_MAX_AST
then    $T\_VS\_MAX\_AST_{(n)} = T\_VS\_MAX\_AST_{(n-1)} + 1\ s$
else    $T\_VS\_MAX\_AST_{(n)} = T\_VS\_MAX\_AST_{(n-1)}$
endif
RATIO_T_VS_MAX_AST = (T_VS_MAX_AST / T_DIAG_AST) * 100 %
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_THD_VS_MIN_AST	1	0...FFH	0...255	1	km/h
Minimum vehicle speed threshold for “low vehicle speed” period calculation after start					
C_VS_THD_VS_MAX_AST	1	0...FFH	0...255	1	km/h
Maximum vehicle speed threshold for “high vehicle speed” period calculation after start					
IP_MAF_KGH_LOAD_MIN_AST	4	0...FFFFH	0...2047.96875	0.03125	kg/h
LDP_TAM_IP_MAF_KGH_LOAD_MIN_AST	4	0...FEH	-48...142.5	0.75	°C
Ambient temperature dependent minimum engine load threshold for “low load” period calculation after start					

26.16 Coolant temperature sensor diagnosis

VP_TCO[NC_NR_TCO_SENS]	NC_NR_TCO_SENS		

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis function is to detect electrical failures as defined by OBD I and OBD II requirements. The coolant temperature raw sensor voltage (VP_TCO[0]) is measured with use of an A/D converter by the ECU hardware. The modified sensor signal is converted then into a measured temperature value (TCO_MES). Each by the ECU hardware measured raw sensor value is checked as well as the converted temperature signal.

Application conditions:

See separate chapters:

26.16.1 Global coolant temperature failure

FUNCTION DESCRIPTION:

General information:

A global coolant temperature error is set without debounce as soon as an electrical-, or signal gradient-, or stuck signal-, or plausibility- error is detected. All separate diagnosis functions are performed all the time if the diagnosis conditions are fulfilled. The deactivation of diagnosis functions with use of configuration switches is not possible.

In addition a preliminary coolant temperature error is set as soon as debouncing of an electrical-, or signal gradient- symptom occurs. The preliminary coolant temperature error will be stored in the non-volatile memory during the ECU’s self-holding phase to be available at the beginning of the next driving cycle.

Application conditions:

Initialisation at Reset:

LV_ERR_TCO = 0
LV_CDN_ENA_TCO_PREL = 1
LV_ERR_TCO_PREL = LV_ERR_TCO_PREL_DET *(NVMY)*
LV_ERR_TCO_PREL_DET = LV_ERR_TCO_PREL_DET *(NVMY)*
(NVMY: stored in the non-volatile memory)

Initialisation at Engine stop to Engine run (ES_to_ERU):

LV_ERR_TCO_PREL_DET = 0
LV_CDN_ENA_TCO_PREL = 0

Initialisation at Engine stop

LV_CDN_ENA_TCO_PREL = 1

Initialisation at FMY clear:

LV_ERR_TCO = 0
LV_ERR_TCO_PREL = 0
LV_ERR_TCO_PREL_DET = 0

Recurrence: 100 ms
Activation: at every engine operating state

Formula section:

If LV_ERR_TCO_EL = 1 **or**
LV_ERR_TCO_GRD = 1 **or**
LV_ERR_TCO_STUCK = 1 **or**
LV_ERR_TCO_STUCK_RNG = 1 **or**
LV_ERR_TCO_PLAUS = 1 **or**
then LV_ERR_TCO = 1 (without debounce)

```
else        LV_ERR_TCO = 0
endif
```

26.16.1.1 Preliminary coolant temperature failure at engine stop

Application conditions:

Recurrence: 100 ms

Activation: LV_CDN_ENA_TCO_PREL = 1

Deactivation: LV_CDN_ENA_TCO_PREL = 0

Formula section:

```
If          CTR_ABC_TCO_EL > 0            or
            CTR_ABC_TCO_GRD > 0           or
            LV_ERR_TCO_PREL_DET = 1
then        LV_ERR_TCO_PREL = 1           (without debounce)

else        LV_ERR_TCO_PREL        = 0
endif
```

26.16.2 Coolant temperature signal range diagnosis (TCO_EL)

FUNCTION DESCRIPTION:

General information:

The purpose of the signal range- or electrical diagnosis is to detect electrical errors in the input circuit of the coolant temperature sensor. The analog sensor input signal is converted into a digital value with use of an A/D converter. All symptoms of the error code are handled by anti-bouncing. Only one symptom can be active at a time.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │ │ │ └─> Short circuit to  Vbatt or Open Circuit "SCP_OC"     (= SYM_0)
  │ │ └───> Short circuit to Ground "SCG"                        (= SYM_1)
  │ └─────> (not used)                                           (= SYM_2)
  └───────> (not used)                                           (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_EL = *Refer to filtering configuration for the initialisation*
LV_END_DIAG_TCO_EL = *Refer to filtering configuration for the initialisation*
LV_CDN_DIAG_TCO_EL = *Refer to filtering configuration for the initialisation*
ERR_SYM_TCO_EL = *Refer to filtering configuration for the initialisation*

Recurrence: 100 ms

Activation: LV_IGK = 1 **and**
LV_CDN_VB_MIN_DIAG = 1 **and**

        endif (2)
    endif (1)
```

End of diagnosis:

For the calculation of LV_END_DIAG_TCO_EL see "Anti-bounce Algorithm, calculation of the end of diagnosis".

26.16.3 Coolant temperature signal gradient diagnosis (TCO_GRD)

FUNCTION DESCRIPTION:

General information:

The purpose of the signal gradient diagnosis is to detect a not plausible gradient on the measured coolant temperature sensor signal. The monitoring is based on a comparison between the actual measured and the last measure coolant temperature value. The symptom of the error code is handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                                          (= SYM_0)
 │  │  └───> -                                          (= SYM_1)
 │  └─────> -                                          (= SYM_2)
 └───────> Coolant temperature signal gradient error         (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_GRD = *Refer to filtering configuration for the initialisation*

LV_END_DIAG_TCO_GRD = *Refer to filtering configuration for the initialisation*

LV_CDN_DIAG_TCO_GRD = *Refer to filtering configuration for the initialisation*

ERR_SYM_TCO_GRD = *Refer to filtering configuration for the initialisation*

Recurrence: 100 ms

Activation:

```
If      LV_IGK = 1                     and

26.17.4 Interface for Rate – Based - Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_TCO_STUCK	V/O	0...7H	0...7	1	[-]
Interface of TCO_STUCK monitor with the Rate-Based Monitoring statistics					

Input data:

LV_END_DIAG_TCO_STUCK	CTR_ERR_DYN_NR	LV_DC	LV_CDN_CST_RBM

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TCO_STUCK monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TCO_STUCK data.

Within STATE_RBM_TCO_STUCK, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_STUCK = 0

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_STUCK = 0

on failure memory reset :

bit 1 of STATE_RBM_TCO_STUCK = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_PLAUS	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK_RNG

```
    If(1)       { CPU optimization at LV_DC 0 → 1 transition }
                CTR_ERR_DYN_NR <> 0   { the dynamic failure memory isn't empty }
    Then(1)
                While  bit 1 of STATE_RBM_TCO_STUCK = 0 do
                       with each XX failure of the above list :
                       ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                       SYNCHRONIZATION<CALL>)
                       If(2)        XX has a pending status
                       Then(2)      bit 1 of STATE_RBM_TCO_STUCK = 1
                       Endif(2)
                Endwhile
    Else(1)
                { the dynamic failure memory is empty }

Input data:

VP_TCO [NC_NR_TCO_SENS]	TIA_THR	LV_CDN_VB_MIN_DIAG	LV_INH_DIAG_TCO_2_EL
LV_IGK	T_DIAG_AST	CTR_ABC_TCO_2_EL	LV_INH_DIAG_TCO_2_GRD
CTR_ABC_TCO_2_GRD	TCO_2_MES	NC_NR_TCO_SENS	LV_ERR_TCO_2_PLAUS

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis function is to detect electrical failures as defined by OBD I requirements. The coolant temperature (radiator outlet) raw sensor voltage (VP_TCO [1]) is measured with use of an A/D converter by the ECU hardware. The modified sensor signal is converted then into a measured temperature value at radiator outlet. Each by the ECU hardware measured raw sensor value is checked as well as the converted temperature signal.

A global coolant temperature (radiator outlet) error is set without debounce as soon as an electrical- or signal gradient- or coolant temperature (radiator outlet) plausibility error is detected. All separate diagnosis functions are performed all the time if the diagnosis conditions are fulfilled. The deactivation of diagnosis functions with use of configuration switches is not possible.

In addition a preliminary coolant temperature (radiator outlet) error is set as soon as debouncing of an electrical-, or signal gradient- symptom occurs. The preliminary coolant temperature (radiator outlet) error will be stored in the non-volatile memory during the ECU's self-holding phase to be available at the beginning of the next driving cycle.

Application conditions:

Initialisation at Reset:

LV_ERR_TCO_2 = 0
LV_CDN_ENA_TCO_2_PREL = 1
LV_ERR_TCO_2_PREL = LV_ERR_TCO_2_PREL_DET *(NVMY)*
LV_ERR_TCO_2_PREL_DET = LV_ERR_TCO_2_PREL_DET *(NVMY)*
(NVMY: stored in the non-volatile memory)

Initialisation at Engine stop to Engine run (ES_to_ERU):

LV_ERR_TCO_2_PREL_DET = 0
LV_CDN_ENA_TCO_2_PREL = 0

Initialisation at FMY clear:

LV_ERR_TCO_2 = 0
LV_ERR_TCO_2_PREL = 0
LV_ERR_TCO_2_PREL_DET = 0

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

```
If      LV_ERR_TCO_2_EL = 1        or
        LV_ERR_TCO_2_GRD = 1       or
        LV_ERR_TCO_2_PLAUS = 1
then    LV_ERR_TCO_2 = 1           (without debounce)
else    LV_ERR_TCO_2 = 0
endif
```

26.18.1.1 Preliminary coolant temperature (radiator outlet) failure (at ES after RESET)

Application conditions:

Recurrence: 100 ms

Activation: LV_CDN_ENA_TCO_2_PREL = 1

Deactivation: LV_CDN_ENA_TCO_2_PREL = 0

Formula section:

```
If      CTR_ABC_TCO_2_EL > 0          or
        CTR_ABC_TCO_2_GRD > 0         or
        LV_ERR_TCO_2_PREL_DET = 1
then    LV_ERR_TCO_2_PREL = 1         (without debounce)
else    LV_ERR_TCO_2_PREL = 0
endif
```

26.18.1.2 Preliminary coolant temperature failure (at ERU / at ES after ERU_to_ES)

Application conditions:

Recurrence: 100 ms

Activation: LV_CDN_ENA_TCO_2_PREL = 0

Deactivation: LV_CDN_ENA_TCO_2_PREL = 1

Formula section:

```
If      CTR_ABC_TCO_2_EL > C_CTR_ABC_THD_TCO_2_PREL     or
        CTR_ABC_TCO_2_GRD > C_CTR_ABC_THD_TCO_2_PREL    or
        LV_ERR_TCO_2_PLAUS = 1
then    LV_ERR_TCO_2_PREL_DET = 1     (irrevocable for current driving cycle)
endif

If      CTR_ABC_TCO_2_EL > 0          or
        CTR_ABC_TCO_2_GRD > 0         or
        LV_ERR_TCO_2_PLAUS = 1        or
then    LV_ERR_TCO_2_PREL = 1         (without debounce)
else    LV_ERR_TCO_2_PREL = 0
endif
```

26.18.2 Coolant temperature (radiator outlet) signal range diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the signal range- or electrical diagnosis is to detect electrical errors in the input circuit of the coolant temperature (radiator outlet) sensor. The analog sensor input signal is converted into a digital value with use of an A/D converter. All symptoms of the error code are handled by anti-bouncing. Only one symptom can be active at a time.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to  Vbatt or Open Circuit "SCP_OC"   (= SYM_0)
 │ │ └───> Short circuit to Ground "SCG"                      (= SYM_1)
 │ └─────> (not used)                                         (= SYM_2)
 └───────> (not used)                                         (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_2_EL = *Refer to filtering configuration for the initialisation*

LV_END_DIAG_TCO_2_EL = *Refer to filtering configuration for the initialisation*

LV_CDN_DIAG_TCO_2_EL = *Refer to filtering configuration for the initialisation*

    endif (2)
endif (1)
```

End of diagnosis:

For the calculation of LV_END_DIAG_TCO_2_EL see “Anti-bounce Algorithm, calculation of the end of diagnosis”.

26.18.3 Coolant temperature (radiator outlet) signal gradient diagnosis

FUNCTION DESCRIPTION:

General information:

The purpose of the signal gradient diagnosis is to detect a not plausible gradient on the measured coolant temperature (radiator outlet) sensor signal. The monitoring is based on a comparison between the actual measured and the last measured coolant temperature value at radiator outlet. The symptom of the error code is handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                                        (= SYM_0)
 │ │ └───> -                                        (= SYM_1)
 │ └─────> -                                        (= SYM_2)
 └───────> Coolant temperature signal gradient error       (= SYM_3)
```

Application conditions:

Initialisation:

LV_ERR_TCO_2_GRD = *Refer to filtering configuration for the initialisation*

LV_END_DIAG_TCO_2_GRD = *Refer to filtering configuration for the initialisation*

LV_CDN_DIAG_TCO_2_GRD = *Refer to filtering configuration for the initialisation*

ERR_SYM_TCO_2_GRD = *Refer to filtering configuration for the initialisation*

Recurrence: 100 ms

Activation:

```
If      LV_IGK = 1                          and

Input data:

LV_ERR_BSD	LV_INH_CWP_DIAG	LV_IGK	LV_CDN_VB_MIN_DIAG
LV_CWP_HW_LIH_IN_CHK			

FUNCTION DESCRIPTION:

General information:

This function detects an error in the hardware line for Limp Home Operation of the CWP.

A hardware signal is connected to the CWP to activate the limp home mode of the CWP in case of a BSD communication error. To detect the correct functionality of the hardware signal line, the CWP state is submitted to the ECU (EWM_ERR_3). The ECU compares the state of the LV_IGK or LV_CDN_VB_MIN_DIAG (dependend on a switch LC_SWI_CWP_INP) with the state of EWM_ERR3 register (LV_CWP_HW_LIH_IN_CHK). For no compliance a plausibility failure is set.

Description:

Error-symptoms are defined to this diagnosis function as following :

```
|_|_|_|_|
 | | | └─> -                                          (= SYM_0)
 | | └───> -                                          (= SYM_1)
 | └─────> -                                          (= SYM_2)
 └───────> Hardware input line not plausible          (= SYM_3)
```

Application conditions:

Initialisation: according ABC filter Type **STD_INI**; all other output data are set to 0 at LV_IGK 0→1 **or** reset **or** at clearing error memory

Recurrence: 100 ms

Activation: LV_ERR_BSD = 0 **and** LV_INH_CWP_DIAG = 0 **and** LV_IGK = 1

Deactivation: LV_ERR_BSD = 1 **or** LV_INH_CWP_DIAG = 1 **or** LV_IGK = 0

Formula section:

```

Time delay after the CDN Diag Flag can be set if no error is present --> End Diag Flag set by error Manag.					

Input data:

LV_INH_CWP_DIAG	LV_IGK	LV_ERR_BSD	

FUNCTION DESCRIPTION:

This function monitors the power reduction modes of the coolant water pump.

General information:

If the operating conditions of the electrical coolant water pump deviates from the normal conditions the output power of the pump will be reduced by the power management. Depending on the actual state a calibratible power setpoint is given. The state is determined separately by a state machine.

Description:

This diagnosis function is the inteface between BSD driver and waterpump controller.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
│ │ │ │ │
└─┴─┴─┴─┘
 |  |  |  └─> Pump is running dry                                (= SYM_0)

FUNCTION DESCRIPTION:

This state machine determines the operation mode of the coolant water pump. By distinguishing several operation modes a specific diagnosis of the CWP at different states is possible.

General information:

After initialization some transition conditions must be fulfilled to change from one state to the other.

Operating State of the CWP STATE CWP INT (controlled internally in the CWP electronics):

STATE_CWP_INT	Operating state of the CWP	Addition explanations concerning the operating State
0	initialization	Pump is initialized, not ready to operate
1	normal operation mode open loop control	No speed monitoring active (speed setpoint= actual speed) LV_N_MON_CWP_DEAC = 1
2	normal operation mode closed loop control	Speed Monitoring active, closed loop controlled operation LV_N_MON_CWP_DEAC = 0
3	power reduced mode	Power reduced operation due to low voltage supply Voltage suppy potetially not sufficient to achieve the required speed setpoint
4	power reduced mode	Power reduced operation due to high CWP electronics temperature (level 1) Pump is not able the achieve the required speed setpoint
5	power reduced mode	Power reduced operation due to high CWP electronics temperature (level 2) Pump is not able the achieve the required speed setpoint
6	pump running dry	Pump is running dry and limits threfore the max speed
7	temporary shut-off	High current consumption detected; automatic de-blocking disabled; max. 3 restarts are executed before permanent shut off
8	temporary shut-off	High current consumption detected; automatic de-blocking enabled; pump tries to de-block itself
9	permanent shut-off	Pump deactivates itself; possible reasons: - Voltage supply too high - Current consumption too high - CWP electronics temperature too high
10	unplausible operation	Actual pump speed deviates to desired pump speed; diagnosis active above opening temp. of the thermostat and voltage supply sufficient only

26.21 Electrical cooling fan diagnosis

26.21.1 Diagnostic information from infrastructure

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CDN_DIAG_ECFPWM_BAS[NC_ECF_NR]	V/O	0...7H	0...7	1	[-]
Primary diagnosis condition read from the infrastructure for each symptom of ECFPWM bit 0: diagnosis condition for symptom SYM_0 (SCP) bit 1: diagnosis condition for symptom SYM_1 (SCG) bit 2: diagnosis condition for symptom SYM_2 (OC)					
ERR_DIAG_ECFPWM[NC_ECF_NR]	V/O	0...7H	0...7	1	[-]
Raw value of error symptom for ECFPWM detected on interface ECU and ECF control unit bit 0: diagnosis condition for symptom SYM_0 (SCP) bit 1: diagnosis condition for symptom SYM_1 (SCG) bit 2: diagnosis condition for symptom SYM_2 (OC)					

Input data:

NC_ECF_NR	LV_IGK		

FUNCTION DESCRIPTION:

Description:

The ECF control unit is controlled by a PWM signal line driven by the ATIC 39. The driver can distinguish between three symptoms: ‘Short circuit to Vbatt’, ‘Short circuit to GND’ and ‘Open Load’.
This function reads the failure information (ERR_DIAG_ECFPWM[x]) from the infrastructure. The [x] is the placeholder for [NC_ECF_NR].

Application conditions:

Initialisation: reset or transition LV_IGK off --> on or reset of failure memory
CDN_DIAG_ECFPWM_BAS[x] = 0
ERR_DIAG_ECFPWM[x] = 0

Recurrence: 100ms
Activation: every ECU state

Formula section:

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_ECFPWM[x] and diagnosis conditions CDN_DIAG_ECFPWM_BAS[x]) received from the infrastructure:

Diagnosis conditions are set according infrastructure info.: CDN_DIAG_ECFPWM_BAS[x]
Failure symptoms are set according infrastructure info.: ERR_DIAG_ECFPWM[x]

26.21.2 ECF control unit: Failure feedback recognition

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

If LV_ECFPWM_FB_VLD[x] = 1 the failure number ERR_ECFPWM_FB[x] (01H) is valid					

Input data:

LV_ERR_SPI_MPS	ERR_DIAG_ECFPWM[NC_ECF_NR]	LV_CDN_VB_MIN_DIAG	LV_IGK

FUNCTION DESCRIPTION:

If a failure is detected from the ECF control unit, a failure feedback is send to the ECU by pulling the signal line (interface ECU to the ECF control unit) to ground in a definited pattern. The time t_{low} is a identification for the failure.

Description:

If a failure is detected from the ECF control unit, a failure feedback is send to the ECU by pulling the signal line (interface ECU to the ECF control unit) to ground in a definited pattern. The time t_{low} is a identification for the failure.

For the recognition of the failure feedback the information, if a failure “short circuit to ground” is detected on the signal line between ECU and ECF control unit is used.

Application conditions:

Initialisation: reset or transition LV_IGK off --> on or reset of failure memory

ERR_ECFPWM_FB[x] = FFH

T_ECFPWM_FB[x] = 0

LV_ECFPWM_FB_VLD[x] = 0

Recurrence: 100ms

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver, which controls the electrical cooling fan.

The input signal is a modulated control pulse (PWM).

Description:

The driver can distinguish between three symptoms: ‘Short circuit to Vbatt’, ‘Short circuit to GND’ and ‘Open Load’. The diagnosis of all these symptoms is possible at the same time in the duty cycle range C_ECFPWM_DIAG_MIN[[x] ... C_ECFPWM_DIAG_MAX[x].

The error detection algorithm in this function for “short circuit to GND” is respecting the status of the failure feedback recognition (ERR_ECFPWM_FB[x]). The failure, detected by the HW, is delivered from the infrastructure ERR_DIAG_ECFPWM[x].

Error-symptoms: are defined to this diagnosis function as following

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Vbatt          (= SYM_0)
 │ │ └───> Short circuit to GND            (= SYM_1)
 │ └─────> Open load                       (= SYM_2)
 └───────> -                               (= SYM_3)
```

Application conditions:

Initialization: according filter-type: MPL_STD_INI

Recurrence: 100ms

Activation: activation in all engine states

Formula section:

```
If      LV_CDN_VB_MIN_DIAG = 1
        and LV_ERR_SPI_MPS= 0
Then    If      Activation conditions are met for the NC_PSD_DLY_ECF_EL recurrence
        and     C_ECFPWM_DIAG_MIN[x] ≤ ECFPWM[NC_ECF_NR] ≤ C_ECFPWM_DIAG_MAX[x]
        and     ERR_ECFPWM_FB[x] = 00H (no failure feedback possible)
        Then    CDN_DIAG_ECF_EL[x] = CDN_DIAG_ECFPWM_BAS[x]
                ERR_DIAG_ECFPWM[x] is used for debounce mechanism
        Else    CDN_DIAG_ECF_EL[x] = 0 (diagnosis not possible)
        Endif
Else    CDN_DIAG_ECF_EL[x] = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_ECF_EL[x] and ERR_DIAG_ECFPWM[x].

```
ACTION_ERRM_FilterMulticondition    (IN<ECF_EL[x]>,
                                     IN<CDN_DIAG_ECF_EL[x] >,
                                     IN<ERR_DIAG_ECFPWM[x] >,
                                     IN<C_ABC_INC_ECF_EL[x] >,
                                     IN<C_ABC_INC_ECF_EL[x]>,
                                     OUT< LV_ERR_ECF_EL[X] >,
                                     SYNCRONIZATION<CALL>)
```

This algorithm determines:

ERR_SYM_ECF_EL[x]	(detected error symptom for ECF diagnosis)
LV_ERR_ECF_EL[x]	(Error flag for debounced error of ECF)
LV_CDN_DIAG_ECF_EL[x]	(Diagnosis condition information)
LV_END_DIAG_ECF_EL[x]	(End of diagnosis information)

LV_INH_DIAG_ECT_EL			

Import actions:

ACTION_ERRM_FilterSymptom(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX >, IN<C_ABC_MAX_XX>, OUT< LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result

FUNCTION DESCRIPTION:

General information:

A global electronically controlled thermostat error (LV_ERR_ECT) is set without debounce as soon as SCG (LV_ERR_ECT_EL) or a mechanical (LV_ERR_ECT_MEC) thermostat failure is detected. The activation of the mechanical thermostat diagnosis (ECT rationality check) is not configurable with a configuration switch. Both, the electrical- and mechanical thermostat diagnosis function are performed if the vehicle is equipped with an electrically controlled thermostat.

Application conditions:

Initialisation at Reset: LV_ERR_ECT = 0

Recurrence: 500 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

```
If      LV_ERR_ECT_EL = 1          or
        LV_ERR_ECT_MEC = 1
then    LV_ERR_ECT = 1             (without debounce)
else    LV_ERR_ECT = 0
endif
```

26.22.1 ECT diagnosis (Electrical diagnostic with PWM output -- Multicondition filter)

FUNCTION DESCRIPTION:

General information:

The ECT is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.

general specification

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

The purpose is to perform the electrical diagnosis of the ECT actuator. 3 symptoms are distinguished, each having its own error location:

Error-symptoms and conditions: are defined to this diagnosis function as following

```
☐☐☐☐
 │ │ │ └─> Short circuit to battery “SCP”                    (= SYM_0)

Then      ERR_SYM_ECT_EL_SCP = SYM_0
Else      ERR_SYM_ECT_EL_SCP = NO_SYM
Endif
If        bit 1 of ERR_DIAG_ECT_EL = 1      //SCG
```

```
Then    ERR_SYM_ECT_EL = SYM_1
Else    ERR_SYM_ECT_EL = NO_SYM
Endif
If      bit 2 of ERR_DIAG_ECT_EL = 1     //OC
Then    ERR_SYM_ECT_EL_OC = SYM_2
Else    ERR_SYM_ECT_EL_OC = NO_SYM
Endif
```

LV_ERR_ECT_EL(_XX) and LV_END_DIAG_ECT_EL(_XX) are calculated by error management.

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanisms are called with the parameters ERR_SYM_ECT_EL(_XX) and LV_CDN_DIAG_ECT_EL(_XX).

ACTION_ERRM_FilterSymptom (IN<ECT_EL_XX>, IN<LV_CDN_DIAG_ECT_EL(_XX)>, IN<LV_ERR_ECT_EL(_XX)>, IN<C_ABC_INC_ECT_EL(_XX)>, IN<C_ABC_MAX_ECT_EL(_XX)>, OUT< LV_ERR_ECT_EL(_XX)>, SYNCRONIZATION<CALL>)

This algorithm determines:

ERR_SYM_ECT_EL(_XX)	(detected error symptom for ECT diagnosis)
LV_ERR_ECT_EL(_XX)	(Error flag for debounced error of ECT)
LV_CDN_DIAG_ECT_EL(_XX)	(Diagnosis condition information)
LV_END_DIAG_ECT_EL(_XX)	(End of diagnosis information)

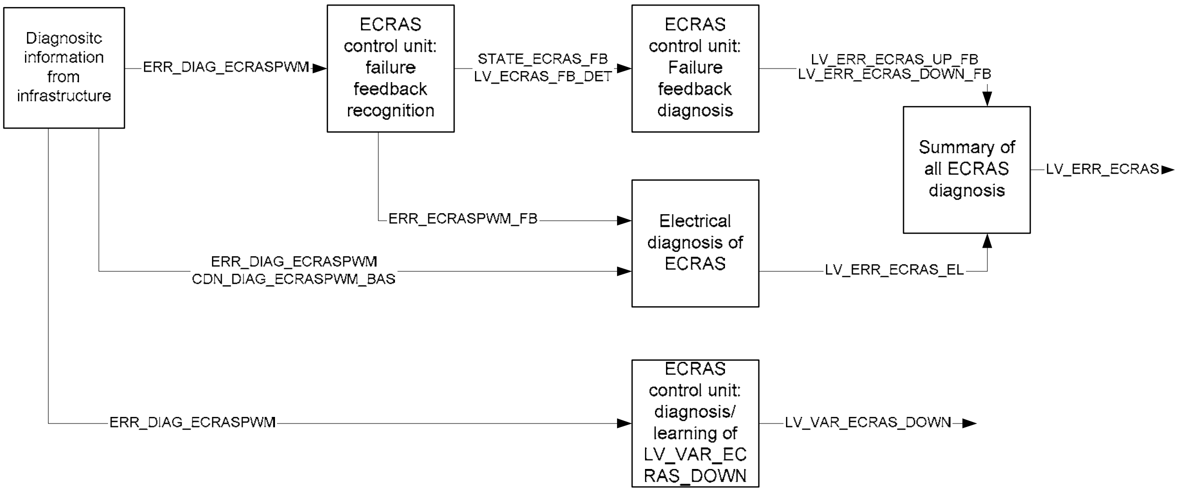
LV_ECRAS_UP_1	LV_ECRAS_DOWN_1		

General information:

This modul consists of 6 parts. The parts and their correlation is described in the figure below. The diagnostic information from the infrastructure is used for detection of feedback from the ECRAS control unit and for the electrical diagnosis. The information from the infrastructure is also used for the diagnosis / learning of the ECRAS variant with the second flap (LV_VAR_ECRAS_DOWN). The recognised feedbacks from the ECRAS control unit are processed by the failure feedback diagnosis.



26.24.1 Summary of all ECRAS diagnosis

FUNCTION DESCRIPTION:

Description:

This function shall summarize all ECRAS failures in one flag only.

Application conditions:

Initialisation: reset **or** reset of failure memory **or** LV_IGK = 0 -> 1

all = 0

Recurrence: 100ms

Activation: LV_VAR_ECRAS_UP = 1

Formula section:

If LV_ERR_ECRAS_EL = 1 **or**
LV_ERR_ECRAS_UP_FB = 1 **or**
LV_ERR_ECRAS_DOWN_FB = 1

Then LV_ERR_ECRAS = 1

Else LV_ERR_ECRAS = 0

Endif

26.24.2 Diagnostic information from infrastructure

FUNCTION DESCRIPTION:

Description:

The ECRAS control unit is controlled by a PWM signal line driven by the ATIC 39. This driver is able to distinguish between three symptoms: 'Short circuit to Vbatt', 'Short circuit to GND' and 'Open Load'.

This function shall reads the failure information (ERR_DIAG_ECRASPWM) delivered from the infrastructure (basic software).

Application conditions:

Initialisation: reset **or** reset of failure memory **or** LV_IGK = 0 -> 1

all = 0

Recurrence: 100ms

Activation: LV_VAR_ECRAS_UP = 1

Formula section:

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_ECRASPWM and diagnosis conditions CDN_DIAG_ECRASPWM_BAS) received from the infrastructure:

Diagnosis conditions are set according infrastructure info.: CDN_DIAG_ECRASPWM_BAS
Failure symptoms are set according infrastructure info.: ERR_DIAG_ECRASPWM

26.24.3 ECRAS control unit: Failure feedback recognition

FUNCTION DESCRIPTION:

Description:

If a failure is detected from the ECRAS control unit, a failure feedback is send to the ECU by pulling the signal line (interface ECU to the ECRAS control unit) to ground in a definited pattern. The time t_{low} is a identification for the failure. Depending on t_{low} a specific failure is identified and set in STATE_ECRAS_FB.

For the recognition of the failure feedback the information, if a failure "short circuit to ground" is detected on the signal line between ECU and ECRAS control unit is used.

Application conditions:

Initialisation: reset **or** reset of failure memory **or** LV_IGK = 0 -> 1

ERR_ECRASPWM_FB = FFH, all others = 0

Recurrence: 100ms

Activation: LV_CDN_VB_MIN_DIAG = 1 **and**
LV_ERR_SPI_MPS= 0 **and**
LV_VAR_ECRAS_UP = 1 **and**
LV_IGK = 1

Deactivation: at deactivation function is initialized one time

Formula section:

```
STATE_ECRAS_FB      = 0H
LV_ECRAS_FB_DET     = 0

If    bit 1 of ERR_DIAG_ECRASPWM  = 1 (SCG detected by HW)
Then        T_ECRASPWM_FB  = T_ECRASPWM_FB  + 100ms
            ERR_ECRASPWM_FB  = FFH       (ECRAS ECU failure possible)
            If      T_ECRASPWM_FB > C_T_ECRASPWM_FB_MAX

26.24.4 Electrical diagnosis of ECRAS

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver, which controls the electrical cooling fan.

The input signal is a modulated control pulse (PWM).

Description:

The driver can distinguish between three symptoms: ‘Short circuit to Vbatt’, ‘Short circuit to GND’ and ‘Open Load’.
The error detection algorithm in this function for “short circuit to GND” is respecting the status of the failure feedback recognition (ERR_ECRASPWM_FB). The failure, detected by the HW, is delivered from the infrastructure ERR_DIAG_ECRASPWM .

Error-symptoms: are defined to this diagnosis function as following

```
□□□□
 | | | └─> Short circuit to Vbatt        (= SYM_0)
 | | └───> Short circuit to GND          (= SYM_1)
 | └─────> Open load                     (= SYM_2)
 └───────> -                             (= SYM_3)
```

Application conditions:

Initialization: according filter-type: **MPL_STD_INI**

LV_INTR_DIAG_ECRAS_EL = 0 at LV_IGK 0->1 **or** reset **or** clear FMY

Recurrence: 100ms

Activation: LV_VAR_ECRAS_UP = 1

Deactivation: if LV_INTR_DIAG_ECRAS_EL = 1, set CDN_DIAG_ECRAS_EL = 0
if LV_VAR_ECRAS_UP = 0, set LV_END_DIAG_ECRAS_EL = 1

Formula section:

```
If      VS >= C_VS_MAX_ECRAS_DIAG
Then    LV_INTR_DIAG_ECRAS_EL = 1        //remains active until next initialization
Endif
```

```
If        LV_CDN_VB_MIN_DIAG = 1
    and   LV_ERR_SPI_MPS= 0
    and   LV_IGK = 1
Then
    Note: The failure symptoms ERR_SYM_ECRAS_EL and the diagnosis conditions
    CDN_DIAG_ECRAS_EL (raw values) shall be set according infrastructure information
    ERR_DIAG_ECRASPWM and CDN_DIAG_ECRASPWM_BAS.

    If    Activation conditions are met for the NC_PSD_DLY_ECRAS_EL recurrence
    And   ERR_ECRASPWM_FB = 00h
    Then

        { Additional diagnosis conditions }

        If  ECRASPWM < C_ECRASPWM_DIAG_MIN_SCP
                { condition that disables the SYM_0 detection }
        Then
            bit 0 of CDN_DIAG_ECRAS_EL  = 0   { Diagnosis of SCP is not possible }
        Endif
        If  ECRASPWM > C_ECRASPWM_DIAG_MAX_SCG
                { condition that disables the SYM_1 detection }
        Then
            bit 1 of CDN_DIAG_ECRAS_EL = 0    { Diagnosis of SCG is not possible }
        Endif
        If  ECRASPWM < C_ECRASPWM_DIAG_MIN_OC
            or ECRASPWM > C_ECRASPWM_DIAG_MAX_SCG
                { conditions that disable the SYM_2 detection }
        Then
            bit 2 of CDN_DIAG_ECRAS_EL  = 0   { Diagnosis of OC is not possible }
        Endif
    Else
        CDN_DIAG_ECRAS_EL = 0
    Endif
Else
        CDN_DIAG_ECRAS_EL = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_ECRAS_EL and ERR_DIAG_ECRASPWM .

```
ACTION_ERRM_FilterMulticondition     (IN<ECRAS_EL >,
                                      IN<CDN_DIAG_ECRAS_EL  >,
                                      IN<ERR_DIAG_ECRASPWM  >,
                                      IN<C_ABC_INC_ECRAS_EL  >,
                                      IN<C_ABC_MAX_ECRAS_EL >,
                                      OUT< LV_ERR_ECRAS_EL  >,
                                      SYNCRONIZATION<CALL>)
```

This algorithm determines:

ERR_SYM_ECRAS_EL	(detected error symptom for ECRAS diagnosis)

LV_ERR_ECRAS_EL	(Error flag for debounced error of ECRAS)
LV_CDN_DIAG_ECRAS_EL	(Diagnosis condition information)
LV_END_DIAG_ECRAS_EL	(End of diagnosis information)

26.24.5 ECRAS control unit: Failure feedback diagnosis

FUNCTION DESCRIPTION:

General information:

If a failure is detected by the ECRAS control unit (ECRAS_UP), a failure feedback is send to the ECU and recognized.

Description:

According the possible failure feedback from the ECRAS control unit (defined by ERR_ECRASPWM_FB and STATE_ECRAS_FB), the diagnosis is managing the following failure: LV_ERR_ECRAS_UP_FB, LV_ERR_ECRAS_DOWN_FB. Additional the diagnosis ability of the ECRAS control unit will be diagnosed (LV_DIAG_ECRAS / _END).

Error-symptoms of failure LV_ERR_ECRAS_UP_FB :

```
 │ │ │ └─> electrical failure                    (= SYM_0)
 │ │ └───> mechanical failure                    (= SYM_1)
 │ └─────> not used                              (= SYM_2)
 └───────> no answer of ECRAS                    (= SYM_3)
```

Error-symptoms of failure LV_ERR_ECRAS_DOWN_FB :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> electrical failure                    (= SYM_0)
 │ │ └───> not used                              (= SYM_1)
 │ └─────> not used                              (= SYM_2)
 └───────> not used                              (= SYM_3)
```

Application conditions:

26.24.6 ECRAS control unit: diagnosis/detecting of LV_VAR_ECRAS_DOWN

FUNCTION DESCRIPTION:

Description:

If an ECRAS control unit is detected (LV_VAR_ECRAS_UP) a learn algorithm / diagnosis for the variant LV_VAR_ECRAS_DOWN will be start once. LV_VAR_ECRAS_DOWN will be recognised by a pattern of short circiuit to ground and normal phases of the ECRASPWM signal set by the ECRAS control unit. For this mode the ECRAS control unit has to be driven by an ECRASPWM of 90% (learnig mode – see Calculation of ECRASPWM).

Application conditions:

Initialisation: all = 0 at reset **or** LV_IGK 0->1, except LV_ECRAS_DOWN_DET_SET and LV_VAR_ECRAS_DOWN from NVMY
LV_ECRAS_DOWN_DET_SET = 0 and LV_VAR_ECRAS_DOWN = 0 at LC_AD_CLR_VAR 0→1

Recurrence: 100 ms

Activation: LV_CDN_VB_MIN_DIAG = 1 and
LV_IGK = 1

Formula section:

```
IF   LV_VAR_ECRAS_UP = 1
     //setting and resetting of LV_ECRAS_DOWN_DET_SET
     if      T_ECRAS_DOWN_DET >= C_T_ECRAS_DOWN_DET

Raw value of error symptom for RAS (only parameter)					

Input data:

LV_IGK	LV_VB_CDN_OBD_1	LV_ERR_SPI_MPS	LV_RAS_OUT
LC_RAS_ACT			

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN<CDN_DIAG_XX >, IN<ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT< LV_ERR_XX>)
ACTION_INFR_GetElDiagRas (OUT< CDN_DIAG_XX>, OUT< ERR_DIAG_XX >)

FUNCTION DESCRIPTION:

General information:

The RAS is driven by the ECU via an output driver. The failure detection is done by ECU Hardware. The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements. The RAS can be switched on or off (no PWM-signal).

Description:

The purpose is to perform the electrical diagnosis of the RAS actuator. 3 symptoms are distinguished:

Error treatment

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	**Name (XX)**	**Description**	**Nr**		
Radiator shutter	RAS	Short circuit to Vbatt SCP	0	MPL_STD_INI	CC
		Short circuit to Ground SCG	1		
		Open Circuit OC	2		
		-	3		

Possible configuration for ABC type and CARB class (see also “Table of Failure”)

ABC Type: STD_INI, STD, MEM, MEM_INI, DEC_CAL, STC, NO, MPL_STD_INI

CARB Class: MIS, FSD, CC, CAT, HC, EVAP, SA, AC, LS, LSH, EGR, OTHER, NO

Application conditions:

Initialisation: ERRM variables are initialized according Filter-type.
At Reset: All 0
Set delay counter for NC_PSD_DLY_RAS

Recurrence: 100ms

Activation: LV_IGK = 1 **and** LC_RAS_ACT= 1

Deactivation: LV_IGK = 0 **or** LC_RAS_ACT= 0

Formula section:

```
If  LV_ERR_SPI_MPS = 0
    and  LV_VB_CDN_OBD_1 = 1
Then

    Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_RAS and
    diagnosis conditions CDN_DIAG_RAS) received from the infrastructure:
    ACTION_INFR_GetElDiagRas (OUT<CDN_DIAG_RAS>, OUT<ERR_DIAG_RAS>)

    Basic diagnosis conditions are set according to infrastructure information:
    CDN_DIAG_RAS
    Failure symptoms (raw value) are set according to infrastructure information:
    ERR_DIAG_ RAS

    If    Activation conditions are met for the NC_PSD_DLY_RAS recurrence
    Then
          { No additional diagnosis conditions are necessary }
    Else
          CDN_DIAG_RAS = 0
    Endif
Else
          CDN_DIAG_RAS = 0
```

Endif

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_RAS and ERR_DIAG_RAS.

ACTION_ERRM_FilterMulticondition (IN<RAS_OUT>, IN<CDN_DIAG_RAS>,
IN<ERR_DIAG_RAS>, IN<C_ABC_INC_RAS>, IN<C_ABC_MAX_RAS>,
OUT< LV_ERR_RAS>)

This algorithm determines:

ERR_SYM_RAS	(detected error symptom for RAS diagnosis)
LV_ERR_RAS	(Error flag for debounced error of RAS)
LV_CDN_DIAG_RAS	(Diagnosis condition information)
LV_END_DIAG_RAS	(End of diagnosis information)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

T_AST_MAX_DIAG_TCO_PLAUS	V	0...FFFFH	0...65535	1	[s]
Maximum time after start to reach closed-loop enable temperature for coolant temperature plausibility diagnosis					
TCO_DIF_DIAG_TCO_PLAUS	V	80...7FH	-96...95.25	0.75	[°C]
Difference between closed-loop enable- and coolant temperature at start for coolant plausibility diagnosis					

Input data:

LV_PUC	TCO	TCO_ST	TCO_SUB
LV_ST_END	TIA_THR_ST	T_DIAG_AST	RATIO_T_IS_AST
LV_CDN_VB_OBD_2	LV_INH_DIAG_TCO_PLAUS		

FUNCTION DESCRIPTION:

General information:

To monitor the activation of the lambda control after start above a coolant temperature threshold (OBD II requirement), a plausibilization between the coolant temperature increase (TCO) and the calculated coolant temperature increase (TCO_SUB) is made.

The coolant temperature plausibility diagnosis is performed once per engine run.

If the engine stalls and the coolant temperature plausibility diagnosis has not run out, then at the next engine start the timer will be initialized new and the diagnosis starts again. When the diagnosis is finished, the Boolean for end of coolant temperature plausibility diagnosis is set.

Remark: *At the time when the “TCO-plausibility diagnosis” is performed, it is not possible to distinguish between a “TCO-plausibility error” and a “Thermostat error” (which can only be detected later). Therefore a “TCO-plausibility error” is entered, even if the problem may be related to the Thermostat (in order to activate the limp home in case there is really a problem with the coolant temperature sensor).*
That means, if additionally to the “TCO- plausibility error” a “Thermostat diagnosis error” is detected, the “TCO-plausibility error” can be ignored.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                                        (= SYM_0)
 │  │  └────> -                                        (= SYM_1)
 │  └───────> -                                        (= SYM_2)
 └──────────> Coolant temperature plausibility error   (= SYM_3)
```

Application conditions:

Initialisation at EXIT_ST:

LV_ERR_TCO_PLAUS = 0

LV_CDN_DIAG_TCO_PLAUS = 0

LV_END_DIAG_RBM_TCO_PLAUS = 0

ERR_SYM_TCO_PLAUS = “NO_SYM”

FUNCTION DESCRIPTION:

General information:

The coolant temperature sensor plausibility diagnosis is performed at transition from the logical value for “Start” from “1” to “0”. If the engine stalls or one of the conditions for inhibiting the diagnosis is present, it will be stopped and starts again at the next engine start.

The diagnosis is finished as soon as the boolean for end of coolant temperature sensor plausibility diagnosis is set to “1”. In this case the boolean for coolant temperature plausibility error indicates either a not plausible (= 1) or a normal (= 0) coolant temperature sensor signal.

Depending on project specific requirements, the coolant temperature sensor plausibility diagnosis can be inhibited by setting of LV_INH_DIAG_TCO_PLAUS.

Application conditions:

Initialisation:

```
If      Reset or Transition: LV_IGK = 0 -> 1
then    LV_INH_DIAG_TCO_PLAUS= 0
endif
```

Recurrence: 1000 ms

Activation:

```
If          LV_CDN_DIAG_TCO_PLAUS = 1
then    (Calculation of the TCO plausi. diagnosis interface parameter enabled)
endif
```

Deactivation:

```
If      LV_CDN_DIAG_TCO_PLAUS = 0
then    (Calculation of the TCO plausi. diagnosis interface parameter disabled)
endif
```

Formula section:

```
If      LV_ERR_TCO_EL = 0                  and
        LV_ERR_TCO_GRD = 0                 and
        LV_ERR_TCO_STUCK = 0               and

Interface of TCO_PLAUS monitor with the Rate-Based Monitoring statistics					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_RBM_TCO_PLAUS	LV_CDN_CST_RBM

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TCO_PLAUS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TCO_PLAUS data.

Within STATE_RBM_TCO_PLAUS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_PLAUS = 0

on failure memory reset :

bit 1 of STATE_RBM_TCO_PLAUS = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_STUCK	LV_ERR_TCO_GRD	LV_ERR_TIA_EL
LV_ERR_TIA_PLAUS	LV_ERR_TCO_STUCK_RNG		

```
If(1)       { CPU optimization at LV_DC 0 → 1 transition }
            CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
            While  bit 1 of STATE_RBM_TCO_PLAUS = 0 do
                   with each XX failure of the above list :
                   ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                   SYNCHRONIZATION<CALL>)
                   If(2)          XX has a pending status
                   Then(2)
                                  bit 1 of STATE_RBM_TCO_PLAUS = 1
                   Endif(2)
            Endwhile
Else(1)
            { the dynamic failure memory is empty }
            No action
Endif(1)
```

Every 1 s :

```
If    bit 0 of STATE_RBM_TCO_PLAUS = 0
Then
            If     LV_END_DIAG_RBM_TCO_PLAUS = 1
            Then   bit 0 of STATE_RBM_TCO_PLAUS = 1
            Endif
Endif

If    bit 1 of STATE_RBM_TCO_PLAUS = 0
Then
            If     LV_INH_DIAG_RBM_TCO_PLAUS = 1
            Then   bit 1 of STATE_RBM_TCO_PLAUS = 1
            Endif
Endif

If    bit 2 of STATE_RBM_TCO_PLAUS = 0
Then
```

```
        If      LV_CDN_CST_RBM = 1
        Then    bit 2 of STATE_RBM_TCO_PLAUS = 1
        Endif
Endif
```

Input data:

TCO_MES	TCO_ST	TCO_SUB	LV_ST_END
LV_CDN_VB_MIN_DIAG	LV_INH_DIAG_TCO_STUCK		

FUNCTION DESCRIPTION:

General information:

The purpose of the signal stuck diagnosis is to detect a stuck measured coolant temperature sensor signal. The diagnosis function checks if after a variation of the calculated coolant temperature substitute value (TCO_SUB) also a variation of the measured coolant temperature value (TCO_MES) is detected.

The diagnosis is performed only once per engine run. The symptom of the error code is not handled by anti-bouncing.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
☐☐☐☐
 | | | └─> -                                          (= SYM_0)

26.30.2 Interface to rate-based monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_TCO_STUCK_RNG	V/O	0...FFH	0...255	1	[-]
Interface of TCO_STUCK_RNG monitor with the Rate-Based Monitoring statistics					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_TCO_STUCK_RNG	LV_CDN_CST_RBM

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TCO_STUCK_RNG monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TCO_STUCK_RNG data.

Within STATE_RBM_TCO_STUCK_RNG, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

Application conditions:

Initialisation:

at ECU reset:

bit 0, bit 1 and bit 2 of STATE_RBM_TCO_STUCK_RNG = 0

at LV_DC 0 → 1 transition:

bit 0, bit 1 and bit 1 of STATE_RBM_TCO_STUCK_RNG = 0

on failure memory reset:

bit 1 of STATE_RBM_TCO_STUCK_RNG = 0

Recurrence: 100ms

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once:

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_PLAUS	LV_ERR_TIA_PLAUS
LV_ERR_TCO_STUCK	LV_ERR_TIA_EL	LV_ERR_TAM_PLAUS	LV_ERR_TAM_CAN
LV_ERR_BN_T_ICL	LV_ERR_CAN_BOFF	LV_ERR_ECU_NVMY	LV_ERR_T_ES
LV_ERR_TOUT_ICL_3			

```
If(1)     { CPU optimization at LV_DC 0 → 1 transition }
          CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
          While  bit 1 of STATE_RBM_TCO_STUCK_RNG = 0 do
                 with each XX failure of the above list :
                 ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                 SYNCHRONIZATION<CALL>)
                 If(2)        XX has a pending status
                 Then(2)
                              bit 1 of STATE_RBM_TCO_STUCK_RNG = 1
                 Endif(2)
          Endwhile
Else(1)
          { the dynamic failure memory is empty }
          No action
Endif(1)
```

Every 100ms:

```
If    bit 0 of STATE_RBM_TCO_STUCK_RNG = 0
Then
          If      LV_END_DIAG_TCO_STUCK_RNG = 1
          Then    bit 0 of STATE_RBM_TCO_STUCK_RNG = 1
          Endif
Endif
If    bit 1 of STATE_RBM_TCO_STUCK_RNG = 0
Then
          If      LV_INH_DIAG_TCO_STUCK_RNG = 1
          Then    bit 1 of STATE_RBM_TCO_STUCK_RNG = 1
          Endif
Endif
If    bit 2 of STATE_RBM_TCO_STUCK_RNG = 0
```

```
Then
        If      LV_CDN_CST_RBM = 1
        Then    bit 2 of STATE_RBM_TCO_STUCK_RNG = 1
        Endif
Endif
```

TCO	TCO_ST	TCO_2_MES	TCO_2_MES_ST
N	LV_INH_DIAG_TCO_2_PLAUS	TIA_THR_ST	LV_PL
LV_ST_END	LV_TCO_2_PLAUS_ENA_EXT	LV_CDN_VB_OBD2	VS

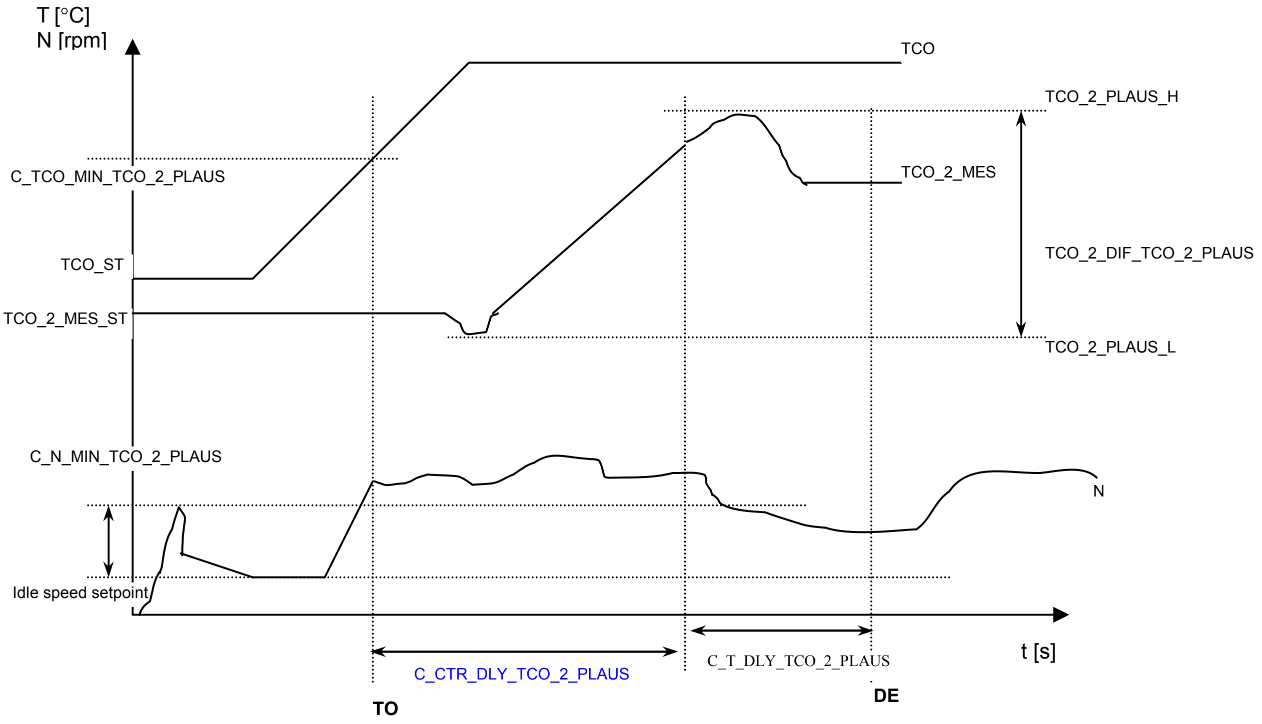
FUNCTION DESCRIPTION:

General information:

The diagnosis is based on monitoring the alteration of TCO_2_MES (positive and negative change) at:

- During warm – up phase (long term check, no error detection)
- After opening of thermostat (long term check with error detection)
- Just after start (short test with error detection)

26.31.1.1 Signal flow diagram:



Application conditions:

Initialisation at EXIT_ST:

LV_ERR_TCO_2_PLAUS = 0
LV_CDN_DIAG_TCO_2_PLAUS = 0
LV_END_DIAG_TCO_2_PLAUS = 0
ERR_SYM_TCO_2_PLAUS = “NO_SYM”
LV_END_DIAG_RBM_TCO_2_PLAUS = 0
LV_TCO_2_PLAUS_ENA = 0
TCO_2_DIF_TCO_2_PLAUS = 0 °C
TCO_2_PLAUS_H = -48°C
TCO_2_PLAUS_L = 142,5°C
CTR_DLY_TCO_2_PLAUS = C_CTR_DLY_TCO_2_PLAUS
T_DLY_TCO_2_PLAUS = C_T_DLY_TCO_2_PLAUS

Recurrence: 1000 ms

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Description:

- During warm – up phase (long term check, no error detection)

The TCO_2 rationality diagnostic function will only run if TCO_ST and TIA_THR_ST are within a tunable range after engine start. TCO_2_PLAUS_H and TCO_2_PLAUS_L are continuously updated from engine start, after first being initialized to TCO_2_ST at power up. The difference between these two values, TCO_2_DIF_TCO_2_PLAUS, is also calculated. When this value exceeds a minimum threshold C_TCO_2_DIF_MIN_TCO_2_PLAUS then the diagnosis is finished with a positive rationality check result.

- After opening of thermostat (long term check with error detection)

The error detection is based on a change of TCO_2_MES after the opening temperature of the thermostat is reached and following the vehicle/engine is driven under certain conditions (vehicle speed, part load, engine speed, opening of thermostat) for the delay time CTR_DLY_TCO_2_PLAUS. However, should one condition drop below the threshold or the engine exit part load state during this tunable period, then the timer is reinitialized/incremented.

Additional, at CTR_DLY_TCO_2_PLAUS = 0 a second delay timer is started (T_DLY_TCO_2_PLAUS) to wait for the change of TCO_2_MES. If the delay time is over and there’s still no change in TCO_2_MES then the error is set.

- Just after start (short test with error detection)

Apart from the long term checks, an extra rationality check is carried out at engine start; if TCO_ST is smaller than a threshold and TCO_2_MES_ST – TCO_ST is greater than a threshold then a fault is also detected.

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> TCO_2 to high after ST    (= SYM_0)
 │  │  └────> -                         (= SYM_1)

FUNCTION DESCRIPTION:

General information:

Task of the coolant thermostat is to effect a quick engine warm up after start. The thermostat is closed after engine start to limit the cooling-liquid circulation until the thermostat regulating temperature is reached. The thermostat opens at this temperature and the limitation of the cooling-liquid circulation is finished. If an opened stuck thermostat occurs, the cooling-liquid circulation will not be limited after start. That means an increase of the engine warm up time and can cause emission increase as well.

To take this behaviour into consideration, an opened stuck thermostat must be detected if either other diagnosis functions are inhibited or the coolant temperature does not reach its operating temperature within 20°F. The conditions for inhibiting the diagnosis are described in the chapter “Application incidences for coolant thermostat monitoring”. The coolant temperature model (TCO_SUB) must simulate the worst engine warm up temperature behaviour for a normal working thermostat (heating on. A/C on. etc.) after start until the thermostat opening temperature is reached.

Description:

The error detection is done by a comparison between the raw value of the coolant temperature sensor and the value of the coolant temperature substitute model.

Error-symptoms are defined to this diagnosis function as following:

☐☐☐☐

```
 │ │ │ └─> -                       (= SYM_0)
 │ │ └───> -                       (= SYM_1)

 └───────> TH open stuck           (= SYM_3)
```

26.33.1 Activation condition for thermostat monitoring

FUNCTION DESCRIPTION:

General information:

The initialization of the function is performed as soon as EXIT_ST is detected. In this case it is regardless if the actual thermostat diagnosis status is set to enabled or canceled.

Thermostat diagnosis is performed as soon as all conditions below are fulfilled at the same time. The function is enabled at once if LV_ST_END is set to “1”. A minimum and a maximum threshold for the coolant temperature at start are limiting the diagnosis activation range as well as a minimum threshold for the intake air temperature at start.

Thermostat monitoring is finished if either the logical value for “thermostat diagnosis finished” or the logical value for “thermostat diagnosis cancelled” equals to “1”. In this case the diagnosis activation bit is set to “0” (LV_ACT_DIAG_TH = 0).

Application conditions:

Initialisation at EXIT_ST:

LV_ERR_TH = 0

LV_CDN_DIAG_TH = 0

LV_END_DIAG_TH = 0

ERR_SYM_TH = “NO_SYM”

LV_END_DIAG_RBM_TH = 0

LV_END_DIAG_RBM_TH_TMP = 0

LV_ACT_DIAG_RBM_TH = 0

LV_CNL_DIAG_TH = 0

LV_ACT_DIAG_TH = 0

TCO_DIAG_TH = -48°C

LV_TCO_DE_MAX_DIAG_TH = 0

Recurrence: 1000 ms

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

Calculation of the functionality check (RBM) enable condition:

```
If        TCO_ST > C_TCO_ST_MIN_DIAG_TH        and
          TCO_ST < C_TCO_ST_MAX_DIAG_TH        and
          TIA_THR_ST > C_TIA_ST_MIN_DIAG_TH    and
          LV_CDN_VB_OBD2 = 1                   and
          LV_INH_DIAG_TH = 0                   and
          LV_CNL_DIAG_TH = 0
then      LV_ACT_DIAG_RBM_TH = 1
else      LV_ACT_DIAG_RBM_TH = 0
endif
```

Calculation of the functionality check enable condition:

```
If        LV_ACT_DIAG_RBM_TH = 1               and
          LV_END_DIAG_TH = 0
then      LV_ACT_DIAG_TH = 1
else      LV_ACT_DIAG_TH = 0
endif
```

Calculation of the intake air temperature deviation:

```
If (1)         TCO_SUB <= C_TCO_TH_OPEN_DIAG_TH     and
               LV_ACT_DIAG_RBM_TH = 1
then (1)
    if (2)     TIA_THR < TIA_MIN_DIAG_TH $_{(n-1)}$
    then (2)   TIA_MIN_DIAG_TH $_{(n)}$ = TIA_THR
    else (2)   TIA_MIN_DIAG_TH $_{(n)}$ = TIA_MIN_DIAG_TH $_{(n-1)}$
    endif (2)
else (1)       TIA_DE_DIAG_TH = TIA_MIN_DIAG_TH - TIA_THR_ST
endif (1)
```

Calculation of the coolant temperature deviation during high engine speed:

```
If (1)         TCO_SUB <= C_TCO_TH_OPEN_DIAG_TH     and
               LV_ACT_DIAG_RBM_TH = 1
then (1)
    if (2)     N >= C_N_MAX_DIAG_TH
               OR  N_REL_CWP > C_N_REL_CWP_MAX_DIAG_TH
    then (2)   (Trigger the coolant temperature deviation calculation)
```

```
                    1st. step: "Initialization" : No re-triggering until timer ends
                    TCO_DE_INI_DIAG_TH = TCO_MES
                    TCO_DE_DIAG_TH = TCO_MES - TCO_DE_INI_DIAG_TH
                    T_TCO_DE_DIAG_TH = C_T_TCO_DE_DIAG_TH
                    Timer T_TCO_DE_DIAG_TH starts

                    2nd. step: "Check for coolant temperature deviations"
                    TCO_DE_DIAG_TH = TCO_MES - TCO_DE_INI_DIAG_TH

          if (3)    TCO_DE_DIAG_TH < C_TCO_DE_MAX_DIAG_TH
          then  (3) LV_TCO_DE_MAX_DIAG_TH = 1
          endif (3)
     endif (2)
endif (1)
```

Calculation of the diagnosis result:

```
If (1)              LV_ACT_DIAG_TH = 1
then (1)            // Coolant thermostat functionality check enabled
                    // Calculation of chapter 1.2
endif (1)
```

Calculation of the diagnosis condition:

```
If (1)              LV_END_DIAG_TH = 1                    or
                    LV_INH_DIAG_TH = 1                    or
                    LV_CNL_DIAG_TH = 1
then (1)            LV_CDN_DIAG_TH = 0
    If(2)           Transition LV_END_DIAG_TH = 0 to LV_END_DIAG_TH = 1
    then(2)         TCO_DIAG_TH = TCO_MES
    endif (2)
endif (1)
```

Calculation of end of diagnosis for RBM:

```
If (1)              LV_ACT_DIAG_RBM_TH = 1                        and

```

26.33.2 Coolant thermostat functionality check

<u>FUNCTION DESCRIPTION:</u>

<u>General information:</u>

Task of the functionality check is to detect a stuck open thermostat. Correct functionality is not guaranteed if the coolant temperature does not reach a specified warmed up temperature.

The thermostat functionality check is enabled as long as the boolean for “coolant thermostat diagnosis activated” is set to "1". As soon as EXIT_ST is detected, all timers and initialization values are set to neutral values.

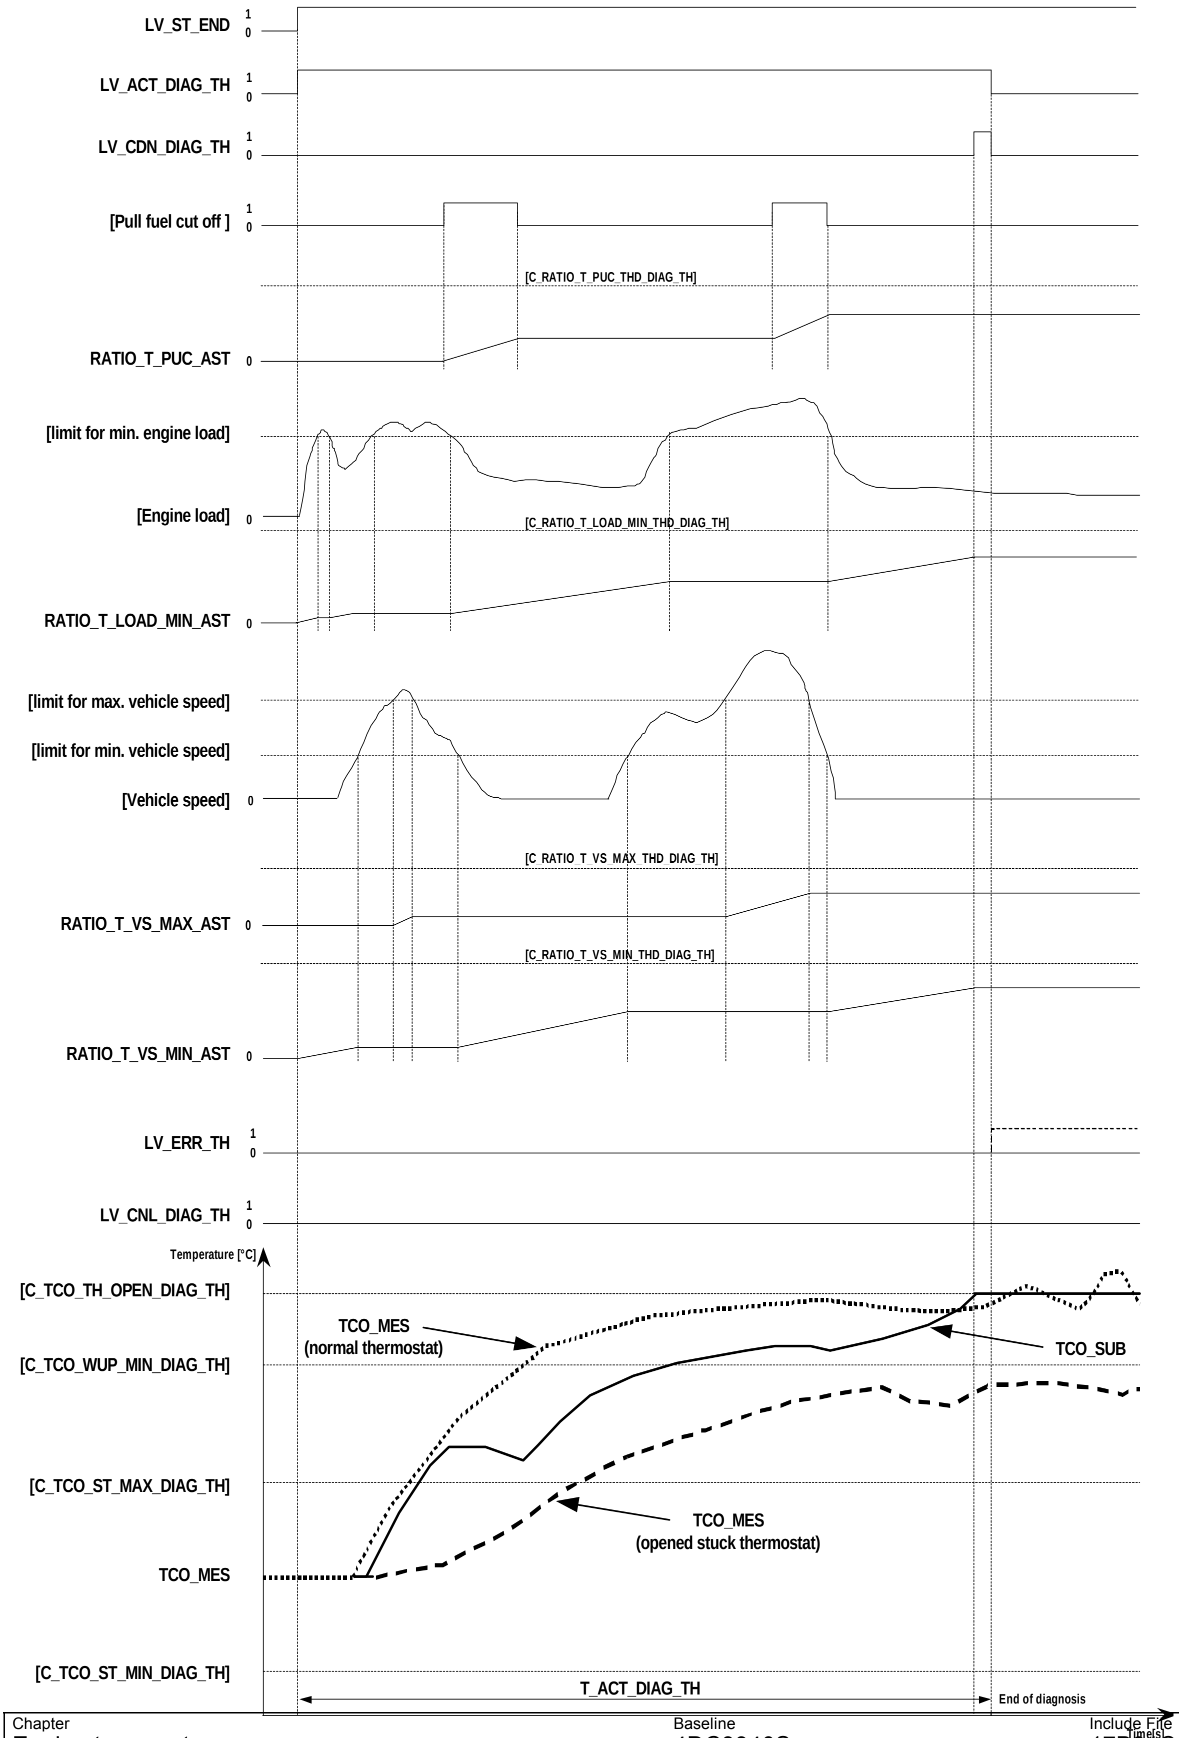
Application conditions:

Initialisation at EXIT_ST:

TIA_DE_DIAG_TH = 0°C
T_TCO_DE_DIAG_TH = 0s
TCO_DE_INI_DIAG_TH = 0°C
TCO_DE_DIAG_TH = 0°C
TIA_MIN_DIAG_TH = TIA_THR_ST

Recurrence:	1000 ms
Activation:	LV_ACT_DIAG_TH = 1 *(Coolant thermostat functionality check enabled)*
Deactivation:	LV_ACT_DIAG_TH = 0 *(Coolant thermostat functionality check disabled)*

Signal flow diagram:



Formula section:

Calculation of the diagnosis result:

FUNCTION DESCRIPTION:

General information:

The coolant thermostat diagnosis is performed at transition from the logical value for “engine stop” from “1” to “0”. If the engine stalls or one of the conditions for inhibiting the diagnosis is present, it will be stopped and starts again at the next engine start.

The diagnosis is finished as soon as the boolean for end of coolant thermostat diagnosis is set to “1”. In this case the boolean for coolant thermostat error indicates either an open stuck thermostat (= 1) or a normal working thermostat (= 0).

Depending on project specific requirements, the coolant thermostat diagnosis can be inhibited by setting of LV_INH_DIAG_TH.
Interface of thermostat monitoring with the RBM statistics:
Bit 0: cond. for monitoring are met long enough to detect malfunction (bit0=1)
Bit 1: inhib. of the monitor because of system failure(s) (bit1=1)
Bit 2: individual RBM cond. of the monitor were encountered within this DC (bit2=1)

Application conditions:

Initialisation: at RESET **or** EXIT_ST **or** LV_IGK = 0->1 **or** FMY clear:

LV_INH_DIAG_TH = 0
LV_INH_DIAG_RBM_TH = 0
LV_TIA_DE_INH_DIAG_TH = 0

LV_ECTPWM_INH_DIAG_TH = 0
LV_ECFPWM_INH_DIAG_TH = 0
T_ECTPWM_INH_DIAG_TH = C_T_ECTPWM_INH_DIAG_TH
T_ECFPWM_INH_DIAG_TH = C_T_ECFPWM_INH_DIAG_TH
T_N_REL_CWP_MAX_DIAG_TH = C_T_N_REL_CWP_MAX_DIAG_TH

at RESET or EXIT_ST:

MASS_VOL_CWP_DIAG_TH_TMP = 0l
MASS_VOL_CWP_DIAG_TH = 0l
TIA_DE_INH_DIAG_TH = 0°C
TIA_MIN_INH_DIAG_TH = TIA_THR_ST

Recurrence: 1000 ms

Activation: LV_ST_END = 1

(Coolant thermostat monitoring (Appl. Inc.)” function enabled)

Deactivation: LV_ST_END = 0

(Coolant thermostat monitoring (Appl. Inc.)” function disabled)

Formula section:

Calculation of Cooling water pump effected coolant mass volumetric flow:

```
MASS_VOL_CWP_DIAG_TH_TMP=(N_REL_CWP / 255)*C_MASS_VOL_CWP_MAX
//phs!
```

Calculation of the maximum CWP speed for TH monitoring:

```
If      N_REL_CWP > ID_N_REL_CWP_MAX_DIAG_TH
Then    If      T_N_REL_CWP_MAX_DIAG_TH > 0
        Then    T_N_REL_CWP_MAX_DIAG_TH - -              //count down
        Else    LV_N_REL_CWP_INH_DIAG_TH = 1             //set until next Ini
        Endif
Else    T_N_REL_CWP_MAX_DIAG_TH = C_T_N_REL_CWP_MAX_DIAG_TH
Endif
```

Calculation of the maximum intake air temperature deviation:

```
If      TIA_THR < TIA_MIN_INH_DIAG_TH $_{(n-1)}$
then    TIA_MIN_INH_DIAG_TH $_{(n)}$ = TIA_THR
else    TIA_MIN_INH_DIAG_TH $_{(n)}$ = TIA_MIN_INH_DIAG_TH $_{(n-1)}$
endif

TIA_DE_INH_DIAG_TH = TIA_MIN_INH_DIAG_TH - TIA_THR_ST

If      TIA_DE_INH_DIAG_TH < C_TIA_DE_MAX_INH_DIAG_TH
then    LV_TIA_DE_INH_DIAG_TH = 1                        //set until next Ini
endif
```

Calculation of the minimum CWP volume for TH monitoring:

```
If (1)      LV_N_REL_CWP_INH_DIAG_TH = 0                 and
            MASS_VOL_CWP_DIAG_TH(n) <=
                    C_MASS_VOL_CWP_MIN_DIAG_TH
then (1)
    If (2)          N_REL_CWP > C_N_REL_CWP_MIN_DIAG_TH
    then (2)        MASS_VOL_CWP_DIAG_TH$_{(n)}$ =       //Integration
                    MASS_VOL_CWP_DIAG_TH$_{(n-1)}$ + MASS_VOL_CWP_DIAG_TH_TMP$_{(n)}$
    else (2)        MASS_VOL_CWP_DIAG_TH$_{(n)}$ = 0
    endif (2)
else (1)            stop of integration, keep last value
```

```
endif (1)
```

Calculation of the ECTPWM condition for TH monitoring:

```
If      ECTPWM > C_ECTPWM_INH_DIAG_TH
then    if      T_ECTPWM_INH_DIAG_TH > 0
        then    T_ECTPWM_INH_DIAG_TH - -
        else    LV_ECTPWM_INH_DIAG_TH = 1
        endif
else    T_ECTPWM_INH_DIAG_TH = C_T_ECTPWM_INH_DIAG_TH
Endif
```

Calculation of the ECFPWM condition for TH monitoring:

```
If      ECFPWM > C_ECFPWM_INH_DIAG_TH
then    if      T_ECFPWM_INH_DIAG_TH > 0
        then    T_ECFPWM_INH_DIAG_TH - -
        else    LV_ECFPWM_INH_DIAG_TH = 1
        endif
else    T_ECFPWM_INH_DIAG_TH = C_T_ECFPWM_INH_DIAG_TH
endif
```

Calculation of diagnosis interface parameter:

```
If      LV_ERR_TCO = 1          or
        LV_ERR_MAF = 1          or
        LV_ERR_TIA = 1          or

26.34.2 Rate Base Monitoring interface for thermostat monitoring.

FUNCTION DESCRIPTION:

General information:

With this module the interface between the thermostat monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TH data.

Within STATE_RBM_TH, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for TH diagnosis)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_TH = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1of STATE_RBM_TH = 0

bit 2 of STATE_RBM_TH = 1

on failure memory reset :

bit 1 of STATE_RBM_TH = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TCO_EL	LV_ERR_TCO_GRD	LV_ERR_TCO_STUCK	LV_ERR_TCO_PLAUS
LV_ERR_TIA_EL	LV_ERR_TIA_PLAUS	LV_ERR_MAF	LV_ERR_VS
LV_ERR_TAM_CAN	LV_ERR_TAM_PLAUS	LV_ERR_ECT_EL	

```
If(1)    { CPU optimization at LV_DC 0 → 1 transition }
         CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
         While  bit 1 of STATE_RBM_TH = 0 do
                with each XX failure of the above list :
```

```
                    ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                    SYNCHRONIZATION<CALL>)
                    If(2)        XX has a pending status
                    Then(2)
                                 bit 1 of STATE_RBM_TH = 1
                    Endif(2)
            Endwhile
  Else(1)
            { the dynamic failure memory is empty }
            No action
  Endif(1)
Every 1 s :
If    bit 0 of STATE_RBM_TH = 0
Then
            If      LV_END_DIAG_RBM_TH = 1
            Then    bit 0 of STATE_RBM_TH = 1
            Endif
Endif
If    bit 1 of STATE_RBM_TH = 0
Then
            If      LV_INH_DIAG_RBM_TH = 1
            Then    bit 1 of STATE_RBM_TH = 1
            Endif
Endif
```

26.35 Torque Loss - Electric Cooling Fan

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_LOSS_ECF	V/O	8000...7FFFH	-1024...1023.97	0.03125	Nm
Torque loss of the electronic controlled cooling fan(s)					

Input data:

ECFPWM[NC_ECF_NR]	N	LV_IGK	LV_ES
STATE_ALTER	LV_POW_CORD_INH	NC_ECF_NR	

FUNCTION DESCRIPTION:

General information:

TQ_LOSS_ECF represents the engine torque loss due to power consumption by the electric cooling fan (ECF).

Application conditions:

Activation: LV_IGK = 1 and LV_ES = 0

Deactivation: -

Initialisation: TQ_LOSS_ECF = 0 Nm at reset

Recurrence: 100 ms

*(see: "*ENTE scheduler*")*

Formula section:

Annotation:

At the MSV70 project only one electronic controlled cooling fan is available. The number of cooling fans is configured with "1" therefore. In this case the following condition is permitted:

ECFPWM[NC_ECF_NR] = ECFPWM[1] = ECFPWM_1

Calculation of the torque loss:

```
If      ( LV_POW_CORD_INH = 0 and STATE_ALTER = 0 )     or

        N = 0

then    TQ_LOSS_ECF = 0 Nm

else    TQ_LOSS_ECF = ( IP_POW_LOSS_ ECF * 60 ) / ( 2 * 3.141828 * N )

endif
```

The change of TQ_LOSS_ECF is limited by limitation gradient C_LGRD_TQ_LOSS_ECF

Signal flow diagram:

27 Error management

Table of Contents

Index

27.1 ERRM General

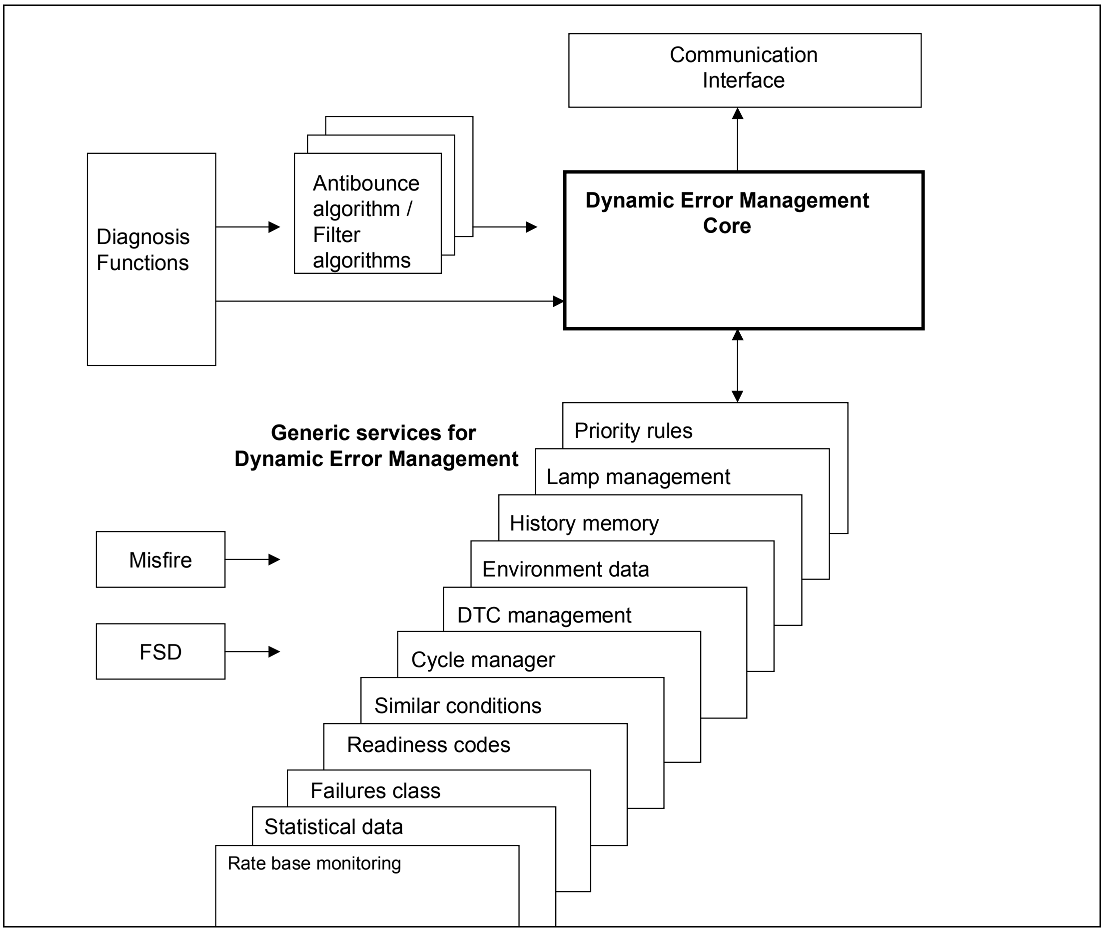
27.1.1 Target / Objectives of ERRM function

The purpose of the Error Management is :

- to collect, store and provide diagnostics information for repair and inspection programs
- to inform the driver via dashboard lamps from malfunctions which could affect emissions compliance with regulations (CARB for US market / EOBD for European market).

27.1.2 Architecture Overview

Principle of the dynamic error management is to receive diagnoses results (filtered or not by anti-bounce, muliti-condition, or statistical algorithms). These results are managed as diagnoses failures, according **CARB** and **EOBD** standards.



27.1.3 Description of the containing functions

- Dynamic Error Management core

The dynamic error management core manages different failures states thanks to the fault detection performed by the diagnoses : detected, present, temporary, pending, disappeared and confirmed. All failures are detected without any limitation on quantity. On the contrary, the number of present failures able to be stored into dynamic memory is limited. Management of this limitation is performed thanks to priority rules mecanism.

When a failure is stored into dynamic memory, the related environment data is stored, the lamp management may force lamp illumination (MIL, WAL,...), and DTCs management is done until failure is deleted. When deleted, failures are stored into history memory.

- History memory

History memory permits to trace historic of deleted failures. Some specific information are stored for each deleted failure. Only the more pertinent data linked to failure shall be stored.

- Debounce algorithm

The debounce algorithms is in charge of detected failures filtering according several available and predefined filters.

- Multi-conditions debounce algorithm

Debounce algorithm able to filter failures according a conditions per symptoms based algorithm.

- Cycle manager

Cycle manager computes driving cycle and warm-up cycle according to engine states and engine coolant temperature. Cycle manager permits to evaluate failure states.

- Failures class

Each failure can be configured to obtain a specific behaviour : emission relevant or not, can illuminate MIL or not ... This module contain to all the predefined behaviours each failure can be associated with. It permits to symplify greatly tuning of diagnosis by decreasing quantity of calibrations.

- DTC management

DTC management permits to catch some data when a failure becomes present and to generate a code identifier, called DTC. It permits to identify default of the function.

- Communication interface

This module allow to access failure memory data related to error management such as freeze frame, stored DTCs, readiness codes.

- Priority rules

This module manages dynamic memory size limitation. It defines criteria, called priority rules, to store or not a new failure into this dynamic memory.

- Environmental data

This module describes the structure of the freeze frame and its management : storage and delete.

- Similar conditions

Similar conditions are additional conditions based on engine and load status to erase a failure in memory (for Misfire and Fuel system failure only).

- Lamp management

Lamp management module can manage illumination of several warning lamps (MIL and other warning lamps) including pre-drive check.

- Readiness codes

Readiness codes allow to know if a diagnosis has been performed or not.

- Rate-based monitoring

Rate-base monitoring functionality : monitoring performances under real world conditions. Performs statistics calculation on diagnoses.

- Statistical data

Statistical data allows monitoring and storage of statistical data on error management data flow.

27.2 ERRM Configuration Data (MSD80 – 6 Cylinder)

Input data:

NC_ABC_CONF_FCT_DIAG_XX	NC_NR_DTC_FMT	NC_ERR_DTC_CONF
NC_NR_ENVD_CUS_SET_CMN	NC_MIL_CHK_TYP	NC_NR_ENVD_CUS_CMN
NC_NR_ENVD_PREV	NC_NR_ENVD_CUS_SET_SPC	NC_NR_ENVD_OBD
NC_NR_FRF_SET	NC_NR_ERR_DYN	NC_NR_ERR_HIS
NC_NR_WIN_SCDN	NC_NR_HIS	NC_NR_SYM_XX
NC_ENVD_CUS_CMN_UPD	NC_ERR_DTC_REQ_CUS	NC_ERR_DTC_REQ_OBD
NLC_ABC_INI_DC_END_DIAG	NC_NR_LAMP	NC_NR_DIAG_RBM
NC_ERR_PRI_H	NLC_INC_ERR_PRI	NLC_OLD_ERR_PRI
NLC_ERR_DET_UPD	NLC_ABC_INI_DC_END_DIAG	NLC_ENA_SCDN
NC_ERR_PRI_H	NLC_INC_ERR_PRI	NLC_OLD_ERR_PRI
NLC_OBD_FRF_PND	NLC_BENCH_MODE	NC_NR_ERR_INTM

General information:

The following chapters describe the general rules for configuration data determination.

27.2.1 Global configuration data

Data	Value	
	Typical values are listed below	
NLC_CAN_LAMP_ACT	**1**	Warning lamps interface type 0: warning lamps hardwired to ECU 1: warning lamps status sended to CAN inter-system
NLC_ERR_DET_UPD	**0**	Configuration for all diagnoses : 00h: no sporadic error detection 01h: sporadic error detection
NLC_ENA_SCDN	**1**	Similar conditions present or not : 0 : Similar conditions disable, acceptable for Europe applications. 1 : Similar conditions enable, for US applications
NLC_ENA_SCDN_NEW	**1**	Old or new Similar conditions functionality used : 0 : old SCDN functionality used 1 : new SCDN functionality used
NLC_OBD_RBM_ENA	**1**	Rate-based monitoring functionality present or not : 0 : Rate-based monitoring disabled 1 : Rate-based monitoring enabled

27.2.2 Local configuration data, project specific for MSD80

Here are listed the configuration data, which are specific for MSD80

Data	Value	
	Typical values are listed below	
NC_NR_DIAG_RBM	**52**	Number of diagnosis using the RBM statistics
NC_NR_WIN_SCDN	**10**	Quantity of diagnoses using similar conditions

27.2.3 Local configuration data

Here are listed the configuration data, which are used only in the ERRM aggregate.

Data	Value	
	Typical values are listed below	
NC_NR_ERR_DYN	**15**	Dynamic memory size (quantity of failures)
NLC_OLD_ERR_PRI	**0**	Failure chronological priority order **0: priority to new failures** 1: priority to old failures
NLC_INC_ERR_PRI	**0**	Set this bit to 1 to enable increased failure priority **Set this bit to 0 to disable increased failure priority**
NC_ERR_PRI_H	**6**	Failure priority level linked to NLC_INC_ERR_PRI
NC_NR_ENVD_OBD	**38**	Size of obd environmental data, Quantity of data byte
NC_NR_ENVD_CUS_CMN	**1**	Size of common environmental data, Quantity of data byte
NC_NR_ENVD_CUS_SET_CMN	**3**	Size of environmental data set, Quantity of data byte
NC_NR_ENVD_CUS_SET_SPC	**4**	Size of specific environmental data set Quantity of data byte
NC_NR_FRF_SET	**3**	Quantity of environmental data sets. Quantity of sets
NC_NR_ENVD_PREV	**1**	00h: Prestored freeze frame functionality is not used 01h...FFh: Quantity of XX failures instances using the prestored freeze frame
NC_ENVD_CUS_CMN_UPD	**1**	Way to update environmental data 0: no update at failure status change **1: update at failure change status (same as OBD)**
NC_NR_ERR_HIS	**10**	Size of history memory (quantity of failures)
NC_NR_HIS	**9**	Size of data stored for a single failure in history memory (quantity of data bytes)
NC_ERR_DTC_REQ_OBD	**0**	Type of OBD/CARB DTCs returned by API **0 : detailed for each symptom** 1 : limited to the global failure
NC_ERR_DTC_REQ_CUS	**1**	Type of customer DTCs returned by API 0 : detailed for each symptom **1 : limited to the global failure**
NC_ERR_DTC_CONF	**3**	Type of DTCs displayed through ERR_DTC_IDX 0 : J2012 DTC detailed for each symptom 1 : J2012 DTC limited to the global failure 2 : customer DTC detailed for each symptom **3 : customer DTC limited to the global failure**
NC_LDP_1_DTC_TABLE_SIZE	**1**	Table size definition for ID_ERR_DTC_XX. Must be set to NC_NR_DTC_FMT+1.
NC_LDP_2_DTC_TABLE_SIZE	**6**	Table size definition for ID_ERR_DTC_XX. Must be set to 6 - NC_NR_DTC_FMT.
NC_LDP_2_DTC_MIS_TABLE_SIZE	**8**	Table size definition for ID_ERR_DTC_MIS. Must be to NC_CYL_NR+2.
NC_NR_DTC_FMT	**0**	Defines 1 or 2 different DTC identifiers per symptom. Defintion with 1 DTC permits a DTC use in common for obd and customer. **0 : a single DTC per symptom (a single one for obd and cutomer)** 1 : 2 DTCs defined per symptom (one for obd, one for cutomer)

Data	Value	
	Typical values are listed below	
NC_MIL_CHK_TYP	**03h**	Pre-drive check strategy on stalling event : Bit0 = 0 : Disable pre-drive check after “stalling event/engine start” **Bit0 = 1 : Enable pre-drive check after “stalling event/engine start”** Display readiness status during pre-drive check (MIL blinking) : Bit1 = 0 : disable readiness status display during pre-drive check **Bit1 = 1 : enable readiness status display during pre-drive check**
NLC_OBD_FRF_PND	**0**	Defines the EOBD/CARB freeze frame strategy as follow : **0 : EOBD/CARB freeze frame data of mode 02h will be returned after confirmed failure detection** 1 : EOBD/CARB freeze frame data of mode 02h will be returned : - after a confirmed emission relevant failure, if confirmed in memory - after a pending emission relevant detection, if not confirmed in memory
NC_NR_LAMP	**0**	Number of warning lamps (not used because NLC_CAN_LAMP_ACT = CAN)

Data	Value	
	Typical values are listed below	
Filters		
NC_NR_SYM_XX See ATIC 39 diagnosis	**07h**	Configuration to define available symptom for each XX diagnosis : This constant is used in the multicondition filtering algorithm. 03h: SYM_0 & SYM_1 available **07h: SYM_0...SYM_2 available** *Please note that this configuration shall be mentioned in the “Table of failure” module, for each diagnosis*
NC_ABC_CONF_FCT_DIAG_XX	****)**	Configuration depends on each diagnosis XX behaviour : 00h: Standard configuration STD 03h: Standard configuration STD_INI with initialisation(only this config is available for multicondition) 0Bh: Memory configuration MEM 0Eh: Memory configuration MEM_INI 10h: Decrement calibration configuration DEC_CAL 13h: Statistical configuration STC *****) See initialization of each diagnosis***
NLC_ABC_INI_DC_END_DIAG	**01h**	Configuration for all diagnoses : 00h: Diagnosis inititialisation is managed at LV_IGK 0 → 1 transition **01h: End of diagnosis initialisation is managed at LV_DC 1 → 0 (only this configuration is available for multicondition filtering)**
NC_NR_ERR_INTM	**1**	Size of the sporadic error memory. When NLC_ERR_DET_UPD = 00h, then NC_NR_ERR_INTM must be set to 1.
NLC_BENCH_MODE	**1**	Bench – Mode is enabled

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NLC_CAN_LAMP_ACT	1	0...1H	0...1	1	[-]
Selection of the strategy to drive warning lamps (0: wire, 1: CAN)					
NLC_ERR_DET_UPD	1	0...1H	0...1	1	[-]
Activation of sporadic errors storage and visualisation					
NLC_ENA_SCDN	1	0...1H	0...1	1	[-]
Boolean to indicate if similar conditions functionality is present (1) or not (0)					
NLC_ENA_SCDN_NEW	1	0...1H	0...1	1	[-]
Activation of old/new similar conditions functionality (0:old strategy, 1:new strategy)					
NLC_OBD_RBM_ENA	1	0...1H	0...1	1	[-]
Activation of rate-based monitoring functionality (0: disabled, 1: enabled)					

27.3 AGGR ERRM adaptation (MSD80)

27.3.1 General interface description

Output data:

Export actions:

ACTION_ERRM_CLCed_report (IN <f_index>, IN <err_mask>, OUT <err_status>)
This action is called by customer OBJ File to inform SV error manager concerning actual failure situation in customer OBJs. Error Status is sent back to customer OBJs.
ACTION_ERRM_CLCrbm_report (IN <rbm_index>, IN <rbm_data>) This action is called by customer OBJ File to inform SV error manager concerning actual failure situation for RBM
ACTION_ERRM_CLCed_status (IN <f_index>, OUT <err_status>)
This action is called by customer in order to get informations concerning a specific failure index.

FUNCTION DESCRIPTION:

General information:

This three Action Calls are used to exchange failure memory informations through the interface module (Layer) between SV SW environment and Customer OBJs. The error handling is performed in the error mangement in the SV SW. Even the anti-bounce algorithm for Customer OBJ exported failures is handled by SV SW.

Description:

The transformation between the dynamicly created error index list (f_index) / (rbm_index) on the customer OBJ Files side and the as well dynamicly created errror index list on SV SW side is realized by the help of the following translation table.

-

Syntax : ACTION_ERRM_CLCed_report (IN <f_index>, IN <err_mask>, OUT <err_status>)

Parameter (in) :	f_index	Index of failure based on dynamic list of the customer OBJ
	err_mask	Includes ERR_SYM_XX and LV_CDN_DIAG_XX
Parameter (out) :	err_status	Includes several informations concerning the corresponding index of failure

Short description : *This action is called by customer OBJ File to inform SV error manager concerning actual error situation in customer OBJs. Error Status is sent back to customer OBJs.*

-

Syntax : ACTION_ERRM_CLCrbm_report (IN <rbm_index>, IN <rbm_data>)

Parameter (in) :	rbm_index	Index of RBM - failure based on list of the customer OBJ
	rbm_data	Includes LV_END_RBM_XX and LV_INH_RBM_XX and LV_CDN_RBM_XX
Parameter (out) :	- -	

Short description : *This action is called by customer OBJ File to inform SV error manager concerning actual error situation in customer OBJs for RBM statictics. There is no return value.*

-

Syntax : ACTION_ERRM_CLCed_status (IN <f_index>, OUT <err_status>)

Parameter (in) : f_index Index of failure based on dynamic list of the customer OBJ

Parameter (out) : err_status Includes several informations concerning the corresponding index of failure

Short description : *This action is called by customer in order to get informations concerning a specific failure index.*

Application conditions:

Initialisation: -

Recurrence: depending on the index of failure

Activation: at action request

Status if error is calibrated as OBD relevat

bit 15 of error_status **if** bit 4 of WAL_CONF_XX = 1 **or**
bit 4 of WAL_CONF_YY = 1
then bit 15 of error_status = 1
else bit 15 of error_status = 0

27.3.2 Output – data of diagnosis handled by customer OBJ File

FUNCTION DESCRIPTION:

General information:

All failures are fed by the customer diagnosis algorithm which detects malfunctions.

The relevant informations for the error management are transferred with the help of the action call.

To give a reflection of the actual status of the failure memory management - which might as well be used for QVM related affairs (if desired) and/or for the information of system developers – the relevant SV variables remain defined.

Since the debounce algorithm is part of the SV failure memory management, all corresponding calibration variables (C_ABC_...) remain on SV side.

All diagnosis are using the STD_INI debounce algorithm (not valid for LOAD_TPS_PLAUS diagnosis).

Description:

The following diagnosis LV_ERR_*(DIAG_INST)* are defined:

- ENWS (DIAG_INST = **MEC_IVVT_IN**)
- ANWS (DIAG_INST = **MEC_IVVT_EX**)

Application conditions:

Initialisation: according **STD_INI** configuration

(all 0 at LV_IGK 0->1 or reset)

only for DIAG_INST = LOAD_TPS_PLAUS

according **STD_INI** and **DEC_CAL** configuration

(all 0 at LV_IGK 0->1 or reset + cal. Decrement)

only for DIAG_INST = PUT_PLAUS

according **STD** configuration

all other Output data 0 at LV_IGK 0->1 or reset

Recurrence: see activation

Activation: at ACTION_ERRM_CLCed_report (IN <f_index>, IN <err_mask>, OUT <err_status>)

Formula section:

According the data delivered by the err_masks (includes ERR_SYM_*(DIAG_INST)* and LV_CDN_DIAG_*(DIAG_INST)* the anti-bounce algorithm is called:

If ERR_SYM_*(DIAG_INST)* is not NO_SYM

Then debounce of LV_ERR_*(DIAG_INST)* using general debounce algorithm

Else rebounce of LV_ERR_*(DIAG_INST)* using general debounce algorithm

Endif

End of diagnosis calculation LV_END_DIAG_*(DIAG_INST)* = 1*:*

--> see chapter "Anti-bounce Algorithm: Calculation of end of diagnosis"

27.3.3 Rate – base monitor Interface for OBJ-file diagnosis

FUNCTION DESCRIPTION:

General information:

With this module the interface between the Object-file diagnosis and the Rate-Based Monitoring statistics is defined with STATE_RBM_xx data.

Within STATE_RBM_xx, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0) (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1) (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

xx = applied for MEC_IVVT_IN / MEC_IVVT_EX / MAP_DIP_PLAUS / LOAD_TPS_PLAUS / TQ_CST

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_xx = 0

on failure memory reset :

bit 1 of STATE_RBM_xx = 0

Recurrence: see activation

Activation: at ACTION_ERRM_CLCrbm_report (IN <rbm_index>, IN <rbm_data>)

Deactivation: LV_DC = 0

Formula section:

Algorithm must be applied sperate for each defined xx diagnosis

```
If    bit 0 of STATE_RBM_xx = 0
Then
        If      LV_END_RBM_xx = 1
        Then    bit 0 of STATE_RBM_xx = 1
        Endif
Endif
If    bit 1 STATE_RBM_xx = 0
Then
        If      LV_INH_DIAG_RBM_xx = 1
        Then    bit 1 of STATE_RBM_xx = 1
```

```
        Endif
Endif
If      bit 2 STATE_RBM_xx = 0
Then    If      LV_CDN_RBM_xx = 1
        Then    bit 2 of STATE_RBM_xx = 1
        Endif
Endif
```

27.3.4 Outputs for SV aggregates, SV internally

FUNCTION DESCRIPTION:

General information:

Adaptation to aggregate-environment.

Application conditions:

Initialisation:	0 at reset
Recurrence:	same as corresponding input data
Activation:	every engine operating state

Formula section:

LV_EOL_OBD_DC = 0

Global error flag for IVVT system

```
If      LV_ERR_MEC_IVVT_IN     = 1
   Or   LV_ERR_MEC_IVVT_EX     = 1
   Or   LV_ERR_SLV_IVVT_IN     = 1
   Or   LV_ERR_SLV_IVVT_EX     = 1
Then    LV_ERR_IVVT            = 1
Else    LV_ERR_IVVT            = 0
Endif
```

Global error flag for OIL system

```
If      LV_ERR_TOIL_LEVEL      = 1
   Or   LV_ERR_QOIL_SENS       = 1
Then    LV_ERR_TOIL            = 1
Else    LV_ERR_TOIL            = 0
Endif
```

27.4 Emmision related variable definition

27.4.1 Calculation of minimum / maximum downstream lambda sensor voltage for service $06

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VLS_DOWN_MIN_DC[NC_CBK_EX_NR]	O/V	0...3FFH	0...4.99511	4.8828e-3	[V]
Min Voltage Value in a DC					
VLS_DOWN_MAX_DC[NC_CBK_EX_NR]	O/V	0...3FFH	0...4.99511	4.8828e-3	[V]
Max Voltage Value in a DC					

Input data:

VLS_DOWN[NC_CBK_EX_NR]	LV_DC	LV_END_DIAG_SCP_LS_DOWN[NC_CBK_EX_NR]	LV_END_DIAG_SCG_LS_DOWN[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

VLS_DOWN_MIN/MAX_DC[NC_CBK_EX_NR] are used for OBD communication (MODE 06h), indicating the maximum/minimum downstream voltage to check if sensors are not aged or damaged. Once the electical diagnosis (SCP and SCG) of the downstream lambda sensors has been completed in a driving cycle, VLS_DOWN_MIN/MAX_DC [NC_CBK_EX_NR] are updated respectively by VLS_DOWN[NC_CBK_EX_NR].

Application conditions:

Initialisation: VLS_DOWN_MIN_DC[NC_CBK_EX_NR = 0.425[V]
VLS_DOWN_MAX_DC[NC_CBK_EX_NR = 0.425[V]
at reset **or** clearing FMY **or** LV_DC 0->1

Recurrence: 100ms

Activation: LV_DC = 1

Formula section:

```
IF      LV_END_DIAG_SCG_LS_DOWN[NC_CBK_EX_NR] =1    AND
         VLS_DOWN[NC_CBK_EX_NR] < VLS_DOWN_MIN_DC[NC_CBK_EX_NR]
THEN    VLS_DOWN_MIN_DC[NC_CBK_EX_NR] = VLS_DOWN[NC_CBK_EX_NR]
ENDIF
IF      LV_END_DIAG_SCP_LS_DOWN[NC_CBK_EX_NR] =1 AND
         VLS_DOWN[NC_CBK_EX_NR]  > VLS_DOWN_MAX_DC[NC_CBK_EX_NR]
THEN    VLS_DOWN_MAX_DC[NC_CBK_EX_NR] = VLS_DOWN[NC_CBK_EX_NR]
ENDIF
```

27.5 Table of failures

FUNCTION DESCRIPTION:

General information:

This specification is automatic generated out from SW and Dataset and consits of two parts:

- **Part 1:** Configuration of Readiness class for each diagnosis instance.
- **Part 2:** Listing of all implemented diagnosis instances (LV_ERR_xx) including all calibration data (proposal) like error class (C_ERR_CLAS_xx), Environmental data (ID_ERR_ENVD_xx), Trouble codes (ID_ERR_DTC_xx).

  Remark:
  All diagnosis instances marked with grey colour do have a missing calibration !

27.5.1 Configuration part

Description:

For generation of the readiness-status of the OBD system in MODE 01h (only done if the diagnosis instance is calibrated as emission relevant / visible for SCAN – tool => LC_OBD_ERR = 1 / C_ERR_CLAS_xx , see “Failure classes”) all diagnosis must be clasified as:

- CARB_CC - Comprehensive component, continuous test
- CARB_MIS - Misfire monitoring, continuous test
- CARB_FSD - Fuel system monitoring, continuous test
- CARB_CAT - Catalyst monitoring, sequential test
- CARB_EVAP - Evaporative system monitoring, sequential test
- CARB_SA - Secondary air monitoring
- CARB_LS - Oxygen sensor monitoring
- CARB_LSH - Oxygen sensor heater monitoring
- CARB_EGR - EGR system monitoring, sequential test

Formula section:

All diagnosis instances are configured as **CARB_CC**,

27.6 Anti-bounce algorithms

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_SYM_PREV_XX	-	0...FH	0...15	1	[-]
Previous value of ERR_SYM_XX when the diagnosis conditions are fulfilled					
CTR_ABC_XX	V/O/S	0...FFH	0...255	1	[-]
anti bounce counter of diagnosis XX					
CTR_ABC_END_DIAG_XX	V	0...FFH	0...255	1	[-]
Counter for end of diagnosis XX generation					
LV_END_DIAG_XX	V	0...1H	0...1	1	[-]
Diagnostic done completely at least one time					
LV_CDN_DIAG_XX	V	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_XX	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	0	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					

Remark : The present failure and the anti-bounce counter may be saved or not (see 'Calculation of the Anti-bounce')

Input data:

LV_IGK	LV_DC	LV_ABC_INH	

Import actions:

#IF NLC_ERR_DET_UPD = 1
ACTION_ERRM_UpdErrDet (IN<XX>)
This action indicates each occurrence of the detected error
#ENDIF

Export actions:

Name
ACTION_ERRM_FilterSymptom(IN< XX >, IN< lv_cdn_diag_XX >, IN< err_sym_XX >, IN< C_ABC_INC_XX >, IN< C_ABC_DEC_XX >, IN< C_ABC_MAX_XX >, OUT< LV_ERR_XX >)
This action computes the elementary anti-bounce filter for one failure treatment and returns filter result
ACTION_ERRM_NoFilterSymptom(IN< XX >, IN< lv_cdn_diag_XX >, IN< err_sym_XX >, IN< lv_err_set_XX >, IN< lv_err_reset_XX >, IN< lv_end_diag_XX >, OUT< LV_ERR_XX >)
This action computes the elementary treatment case no filtering is used
ACTION_ERRM_AbcFilterSymptomEnd(IN< XX >, IN< C_ABC_MAX_XX>, OUT< LV_ERR_XX >)
This action erases diagnostic failure and sets the end of diagnostic in case of antibounce filter type
ACTION_ERRM_NoFilterSymptomEnd(IN< XX >, OUT< LV_ERR_XX >)
This action erases diagnostic failure and sets the end of diagnostic in case of no filter
ACTION_ERRM_AbcFilterReset(IN< XX >, OUT< LV_ERR_XX >)
This action resets data filter in case of antibounce filter type
ACTION_ERRM_NoFilterReset(IN< XX >, OUT< LV_ERR_XX >)
This action resets data filter in case of no filter
ACTION_ERRM_GetLvErr(IN< XX >, OUT< LV_ERR_XX >)
This action is used to get LV_ERR_XX value
ACTION_ERRM_GetLvEndDiag(IN< XX >, OUT< LV_END_DIAG_XX >)
This action is used to get LV_END_DIAG_XX value
ACTION_ERRM_GetLvCdnDiag(IN< XX >, OUT< LV_CDN_DIAG_XX >)
This action is used to get LV_CDN_DIAG_XX value
ACTION_ERRM_GetErrSym(IN< XX >, OUT< ERR_SYM_XX >)
This action is used to get ERR_SYM_XX value

ERR_SYM_XX is defined like output data for each diagnosis as following :

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
ERR_SYM_XX	O/V	0..0FH	All combination	1	-
		0H	NO_SYM		
		1H	SYM_0		
		2H	SYM_1		
		4H	SYM_2		
		8H	SYM_3		
		FH	BENCH_MODE		
Symptom : failure without filtering of diagnosis XX					

It is possible to combine several symptoms.

FUNCTION DESCRIPTION:

General information:

The filtering algorithm (anti-bounce or statistic) is used usually for the simple diagnosis (e.g. : usually OBD1 diagnosis). If there is another need, diagnosis manages itself the filtering and the end of diagnosis (e.g. : usually OBD2 diagnosis).

The filtering is used to filter the detected failure. The failure becomes present after filtering.

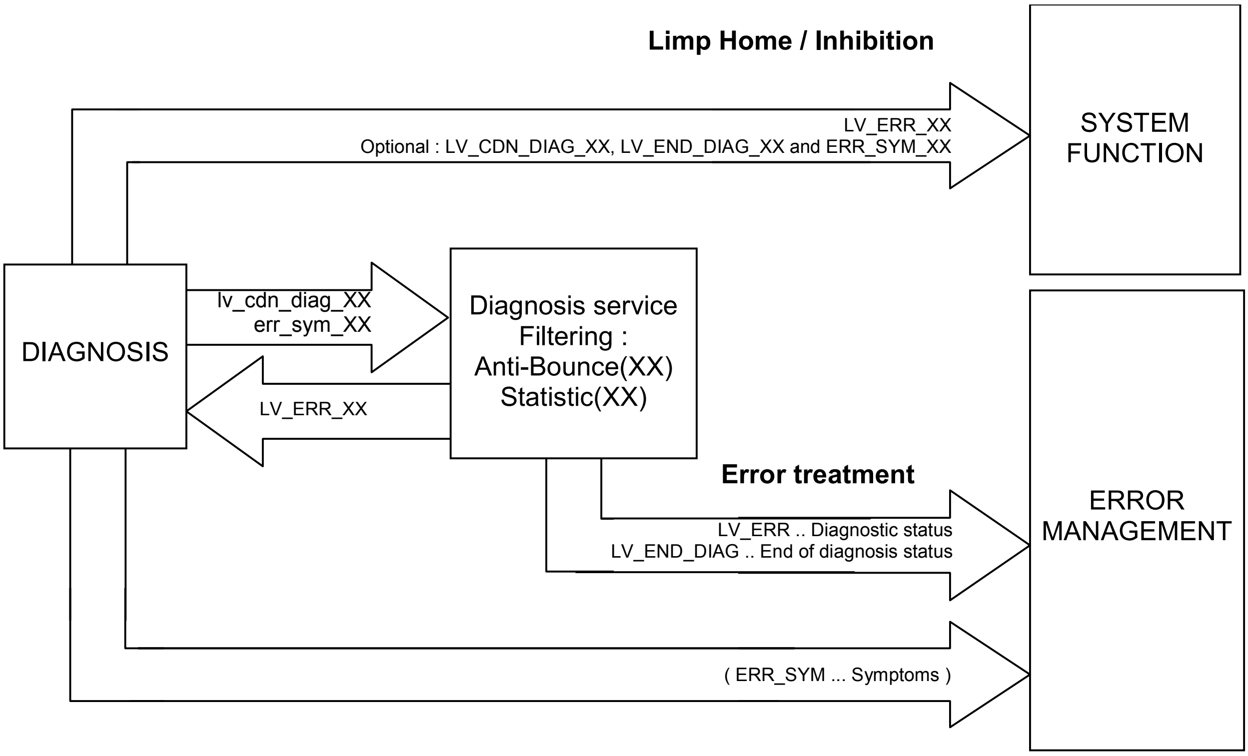
The end of diagnosis definition is realised after a time defined as the minimum time to detect a present failure.

The filtering algorithm (anti-bounce or statistic) uses one counter to check failure detection threshold and one counter to manage the end of diagnosis (Diagnostic result available).

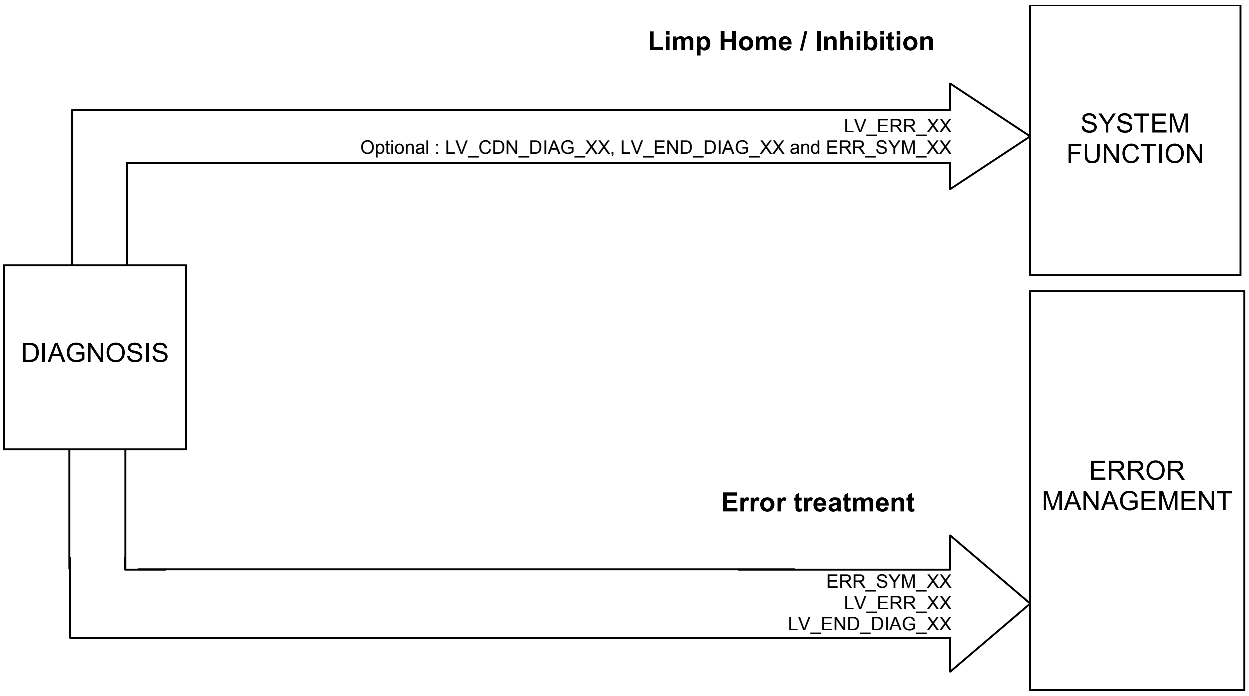
Filter choice selection : according to the diagnostic filtering configuration the filtering algorithm used is the anti-bounce filtering (NLC_ABC_STC_XX = 0) or the standard statistical filtering (NLC_ABC_STC_XX=1)

Signal flow diagram :

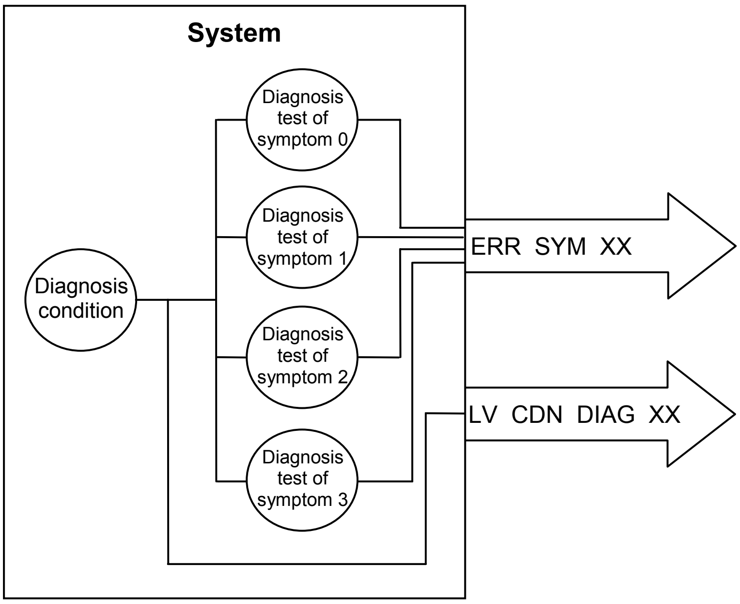
Diagnosis with an anti-bounce algorithm :



Diagnosis without anti-bounce algorithm :



The symptoms are evaluated when diagnosis conditions are fulfilled :



27.6.1 Initialisation of anti-bounce, statistical and multi-conditions filters

This paragraph is dedicated to the initialisation of main data, at the following events:

- ECU reset
- LV_IGK 0 → 1 transition before the end of the power-latch phase
- LV_DC 1 → 0 transition

27.6.1.1 At ECU reset

Management of NVMY

```
If          NVMY not corrupted and not first ECU power-up
Then
            CTR_ABC_ XX is restored from NVMY
            LV_ERR_XX is restored from NVMY
            ERR_SYM_XX is restored from NVMY
Else
            CTR_ABC_ XX = 0
            LV_ERR_XX = 0
            ERR_SYM_XX = 0
Endif

LV_CDN_DIAG_XX = 0
CTR_ABC_END_DIAG_XX = 0
LV_END_DIAG_XX = 0

If          NLC_ABC_NOT_SAVE_XX = 1
Then
            { case of STD_INI, MEM and STC configurations }
            CTR_ABC_XX = 0
            LV_ERR_XX = 0
            ERR_SYM_XX = 0
Endif
```

Configuration evaluation

```
If          NLC_ABC_INI_VALUE_XX = 1
Then
            { case of MEM_INI configuration }

            If      LV_ERR_XX = 1
            Then
                    CTR_ABC_XX = C_ABC_MAX_XX - C_ABC_INC_XX
            Else
                    CTR_ABC_XX = 0
            Endif
            LV_ERR_XX = 0
            ERR_SYM_XX = 0
Endif
```

27.6.1.2 At LV_IGK 0 → 1 transition, without ECU reset

```
If      NLC_ABC_NOT_SAVE_XX = 1 and NLC_ABC_INI_IGK_XX = 1
Then
        CTR_ABC_ XX = 0
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif

LV_CDN_DIAG_XX = 0

If      NLC_ABC_NOT_SAVE_XX = 0
        and NLC_ABC_INI_VALUE_XX = 1
        and NLC_ABC_INI_IGK_XX = 1
Then
        { case of MEM_INI configuration }
        If    LV_ERR_XX = 1
        Then
              CTR_ABC_XX = C_ABC_MAX_XX - C_ABC_INC_XX
        Else
              CTR_ABC_XX = 0
        Endif
        LV_ERR_XX = 0
        ERR_SYM_XX = 0
Endif

If      NLC_ABC_INI_DC_END_DIAG = 0
Then
        CTR_ABC_END_DIAG_XX = 0
        LV_END_DIAG_XX = 0
Endif
```

27.6.1.3 At LV_DC 1 → 0 transition

```
If      NLC_ABC_INI_DC_END_DIAG = 1
Then
        CTR_ABC_END_DIAG_XX = 0
        LV_END_DIAG_XX = 0
Endif

If      LV_ERR_XX = 0 and NLC_ABC_INI_VALUE_XX = 0
Then
        { all cases excepted MEM_INI configuration }
        CTR_ABC_XX = 0
        ERR_SYM_XX = 0
Endif
```

27.6.2 Recurrence

The recurrence is always managed by the diagnosis recurrence.

27.6.3 Filtering algorithm description

27.6.3.1 Description:

Syntax :	ACTION_ERRM_FilterSymptom(IN<XX>, IN<lv_cdn_diag_XX>, IN< err_sym_xx>, IN<C_ABC_INC_XX>, IN<C_ABC_DEC_XX>,IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)	
Parameter(in) :	XX	Type: index to identify the Diagnostic
	lv_cdn_diag_XX	Type: Diagnostic condition
	err_sym_XX	Status of failure
	C_ABC_INC_XX	Anti-bounce counter increment
	C_ABC_DEC_XX	Anti-bounce counter decrement
	C_ABC_MAX_XX	Maximum value of anti-bounce counter
Parameter(out) :	LV_ERR_XX	Type: Boolean (=1 when failure)
Short Description :	This action returns the filter result on symptoms detected at each diagnostic recurrence	

27.6.3.2 Antibounce algorithm filtering type

27.6.3.2.1 Calculation of the anti-bounce counter

Description:

Anti-bounce operation:

If the system failure is detected and the diagnosis conditions are fulfilled (LV_CDN_DIAG_XX = 1) then the failure is detected (ERR_SYM_XX ≠ 0) and the anti-bounce counter is incremented. In this case an action is called to manage some functionality (eg : to visualise the sporadic error of all diagnosis using this anti-bounce algorithm).

If the system failure isn't detected and the diagnosis conditions are fulfilled (LV_CDN_DIAG_XX = 1) then the failure isn't detected (ERR_SYM_XX = 0) and the anti-bounce counter is decremented.

If the diagnosis conditions aren't fulfilled (LV_CDN_DIAG_XX = 0) then the detected failure is unchanged ($ERR\_SYM\_XX_{(N)} = ERR\_SYM\_XX_{(N-1)}$) and the anti-bounce counter is unchanged.

The present failure is set when the anti-bounce counter has reached its MAX (unequal to zero).

The configuration allows:

- to save or not the present failure and the anti-bounce counter
- to initialise or not the present failure and the anti-bounce counter at transition LV_IGK 0 → 1
- to manage the decrement of the anti-bounce counter or not (the anti-bounce counter remains at the maximum value)
- to calibrate or not the decrement of the anti-bounce counter.

Anti-bounce bench mode:

To make easier the development phase, it may be interesting to force the LV_ERR_XX flag (present failure) and the associated symptoms in order to free the diagnosis and to test only the error management and/or the application incidence (limp home or inhibition) associated to the present failure. This mode is active only if the LC_ABC_BENCH and NLC_BENCH_MODE flags are set.

To set LV_ERR_XX to one and ERR_SYM_XX = FH (all detected error symptoms) :

Set the C_ABC_INC_XX calibration to the maximum value (FFH).

To set LV_ERR_XX to zero and ERR_SYM_XX = 0 (no detected error symptom) :

Set the C_ABC_INC_XX calibration to zero.

Note:

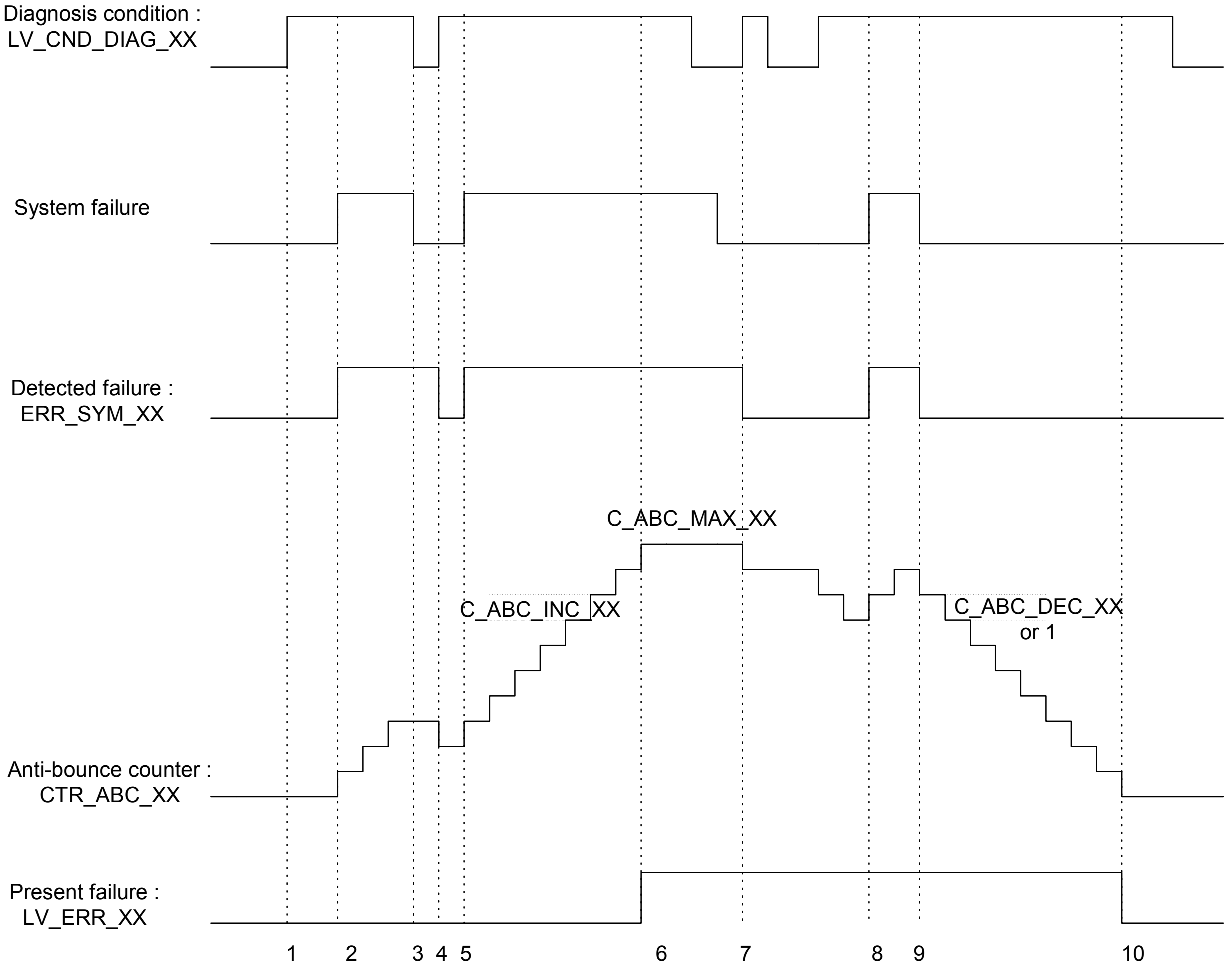
In this mode, the diagnosis condition (LV_CDN_DIAG_XX) and the end of diagnosis (LV_END_DIAG_XX) are set to 1 (LV_CDN_DIAG_XX = 1 means the ERR_SYM_XX is valid and LV_END_DIAG_XX = 1 means the LV_ERR_XX flag is valid).

Anti-bounce inhibition:

For specific needs, the anti-bounce filtering calculation (anti-bounce operation and anti-bounce bench mode) may be inhibited, with LV_ABC_INH inhibition flag.

Signal flow diagram:

1 -The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0):



1: The diagnosis conditions are fulfilled
but the failure isn't detected ➔ CTR_ABC_XX remains at the value 0.
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX = 0.

2: The diagnosis conditions are fulfilled
and the failure is detected. ➔ CTR_ABC_XX = 0 + C_ABC_INC_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

3: The diagnosis conditions aren’t fulfilled
and the failure remains detected. ➔ CTR_ABC_XX is frozen
LV_CDN_DIAG_XX = 0, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

.

4: The diagnosis conditions are fulfilled again
and the failure is no more detected. ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 0.

5: The diagnosis conditions are still fulfilled
and the failure is detected again ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 0.

6: The diagnosis conditions are still fulfilled,
the failure is still detected
and the failure becomes present. ➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

7: The diagnosis conditions are fulfilled,
the failure isn’t detected
and the failure remains present. ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 1.

8: The diagnosis conditions are still fulfilled,
the failure is detected again
and the failure remains present. ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 1.

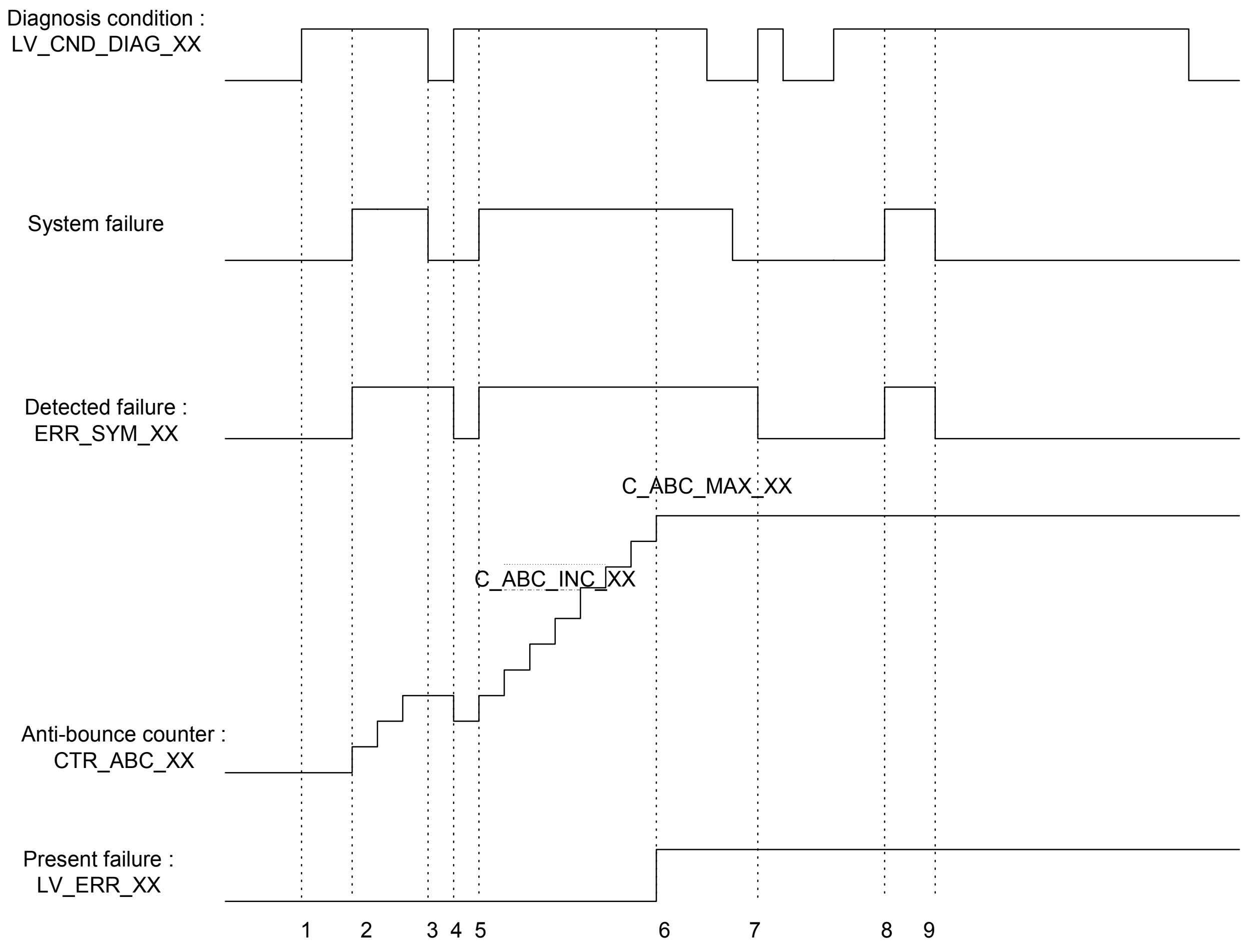
9: The diagnosis conditions are still fulfilled,
the failure isn't detected
and the failure remains present. ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 1.

10: The diagnosis conditions are still fulfilled,
the failure isn't detected
and the failure is no more present. ➔ CTR_ABC_XX = 0
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX = 0.

Remark

- Decrement value = 1 if NLC_ABC_CAL_DEC_XX bit = 0
- Decrement value = C_ABC_DEC_XX if NLC_ABC_CAL_DEC_XX bit = 1.

2-The anti-bounce counter isn’t decremented (NLC_ABC_NOT_DEC_XX = 1):



1: The diagnosis conditions are fulfilled
but the failure isn’t detected ➔ CTR_ABC_XX remains at the value 0.
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX = 0.

2: The diagnosis conditions are fulfilled
and the failure is detected. ➔ CTR_ABC_XX = 0 + C_ABC_INC_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

3: The diagnosis conditions aren’t fulfilled
and the failure remains detected. ➔ CTR_ABC_XX is frozen
LV_CDN_DIAG_XX = 0, LV_ERR_XX = 0.
ERR_SYM_XX <> 0.

4: The diagnosis conditions are fulfilled again
and the failure is no more detected. ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX – decrement
ERR_SYM_XX = 0. LV_ERR_XX = 0.

5: The diagnosis conditions are still fulfilled
and the failure is detected again ➔ CTR_ABC_XX =
LV_CDN_DIAG_XX = 1, CTR_ABC_XX + C_ABC_INC_XX
ERR_SYM_XX <> 0. LV_ERR_XX = 0.

6: The diagnosis conditions are still fulfilled,
the failure is still detected
and the failure becomes present. ➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

7: The diagnosis conditions are fulfilled,
the failure isn’t detected
and the failure remains present. ➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, (counter not decrement)
ERR_SYM_XX = 0. LV_ERR_XX = 1.

.

8: The diagnosis conditions are still fulfilled,
the failure is detected again
and the failure remains present. ➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1, LV_ERR_XX = 1.
ERR_SYM_XX <> 0.

.

.9: The diagnosis conditions are still fulfilled, the failure isn’t detected and the failure remains present.	➔ CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1,	(counter not decrement)
ERR_SYM_XX = 0.	LV_ERR_XX = 1.

Remark

- Decrement value = 1 if NLC_ABC_CAL_DEC_XX bit = 0
- Decrement value = C_ABC_DEC_XX if NLC_ABC_CAL_DEC_XX bit = 1.

Application conditions:

Initialization:	See "Initialisation of anti-bounce, statistical and multi-conditions filters" paragraph
Recurrence:	The recurrence is managed by the diagnosis.
Activation:	The activation is managed by the diagnosis for the anti-bounce operation or the anti-bounce bench mode.
Deactivation:	LV_ABC_INH = 1

Formula section:

Anti-bounce bench mode :

```
If(1)     (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1) and ((C_ABC_INC_XX = 0) or (C_ABC_INC_XX = FFH))
Then(1)
          If(2)     C_ABC_INC_XX = 0
          Then(2)
                    ERR_SYM_XX = 0
                    LV_ERR_XX = 0

      Endif(2)
  Endif(1b)
Endif(1a)
```

27.6.3.2.2 Calculation of the end of diagnosis

Description:

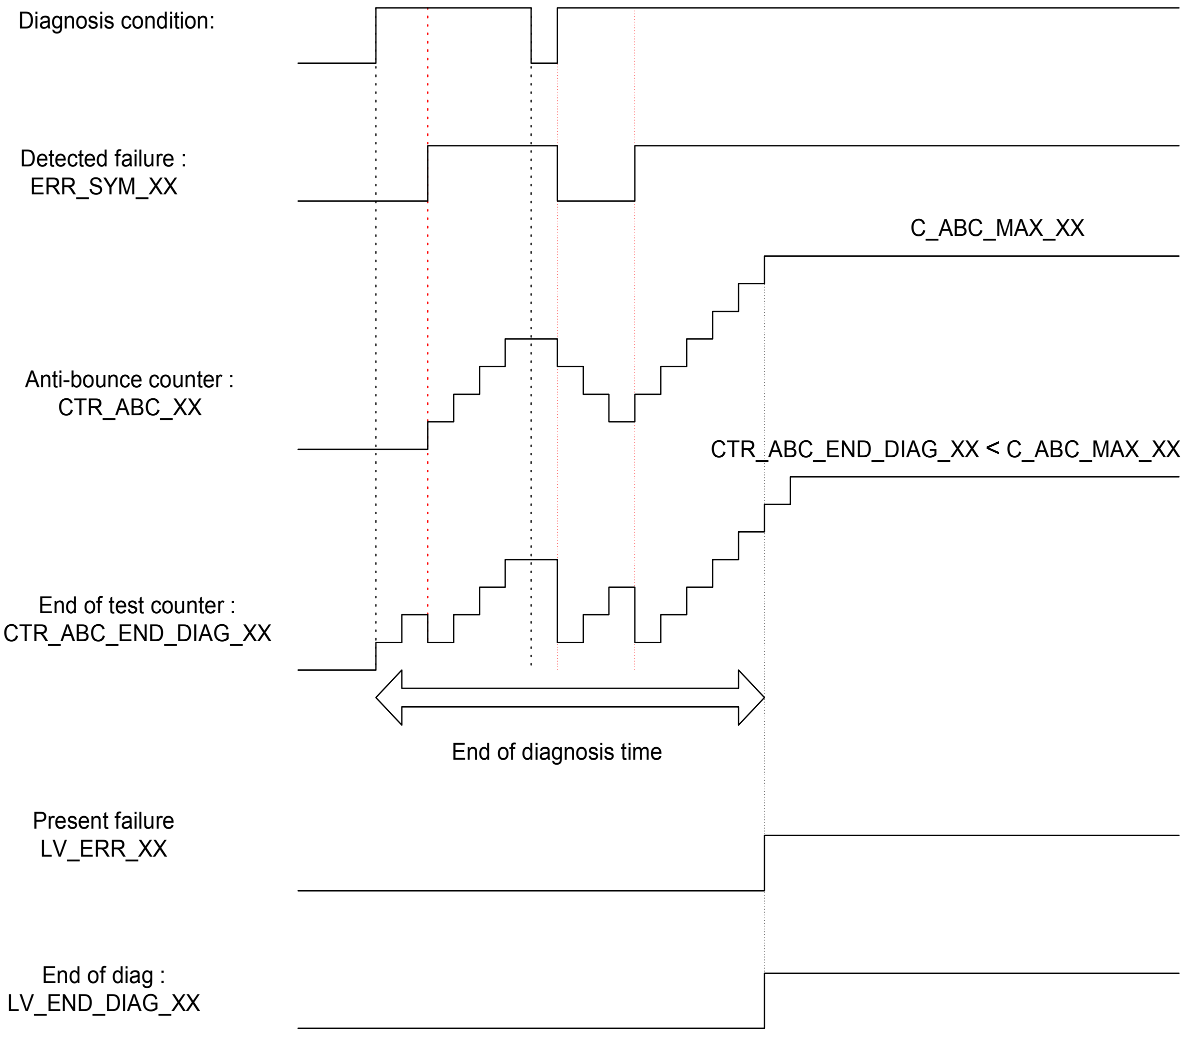
The end of diagnosis definition is set after a time defined like being the time necessary to evaluate the failure (present or not).

Signal flow diagram:

End of diagnosis algorithm illustration in standard case :

The end of diagnosis counter is reset at each transition of the detected failure.

When the failure becomes present : the end of diagnosis is set.

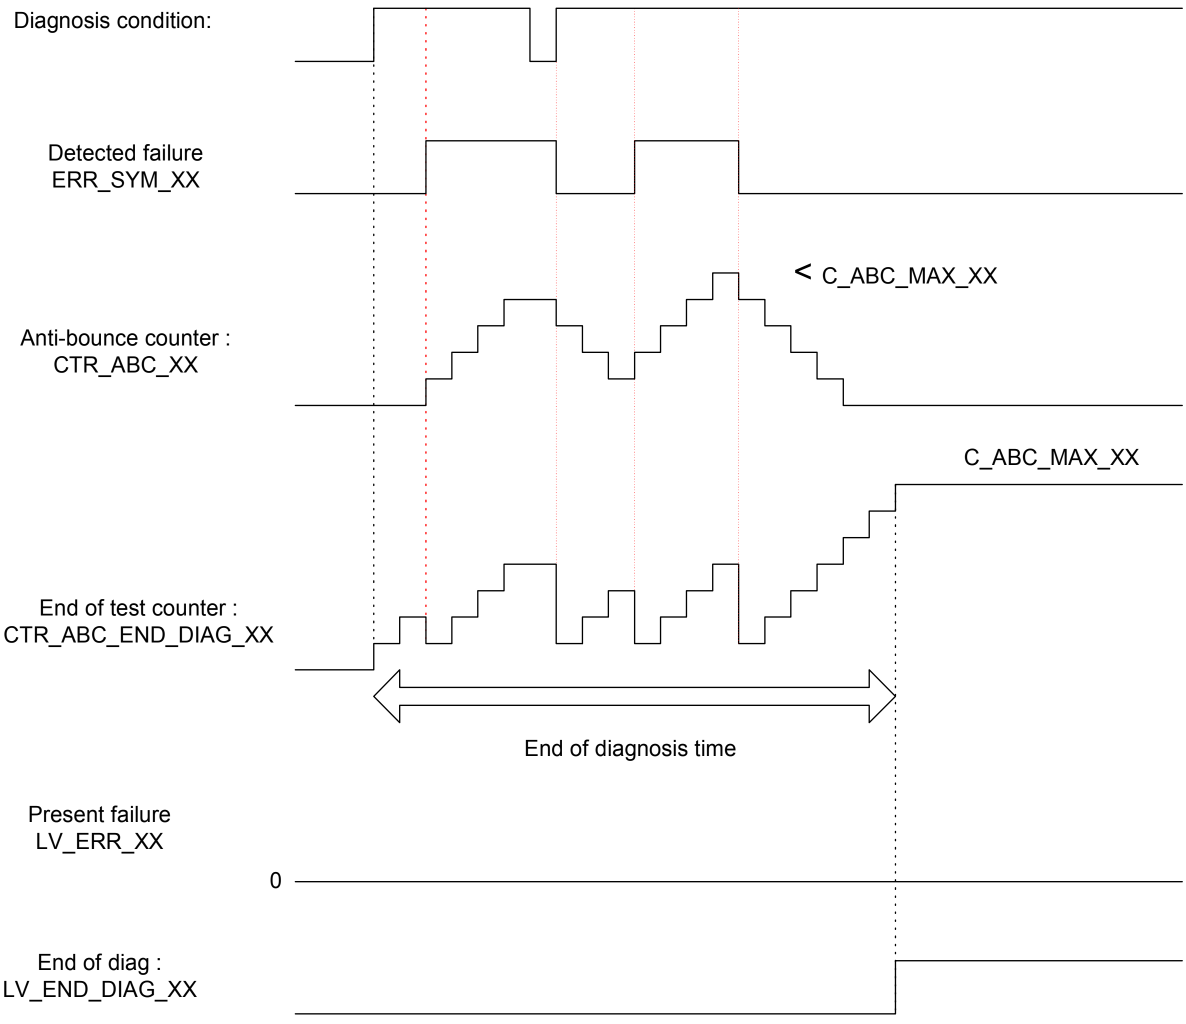


The detected failure will disappear and the anti-bounce counter won’t reach the maximum value then the failure won’t become present.

The end of diagnosis counter is reset at each transition of the detected failure.

When the detected failure is stable : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

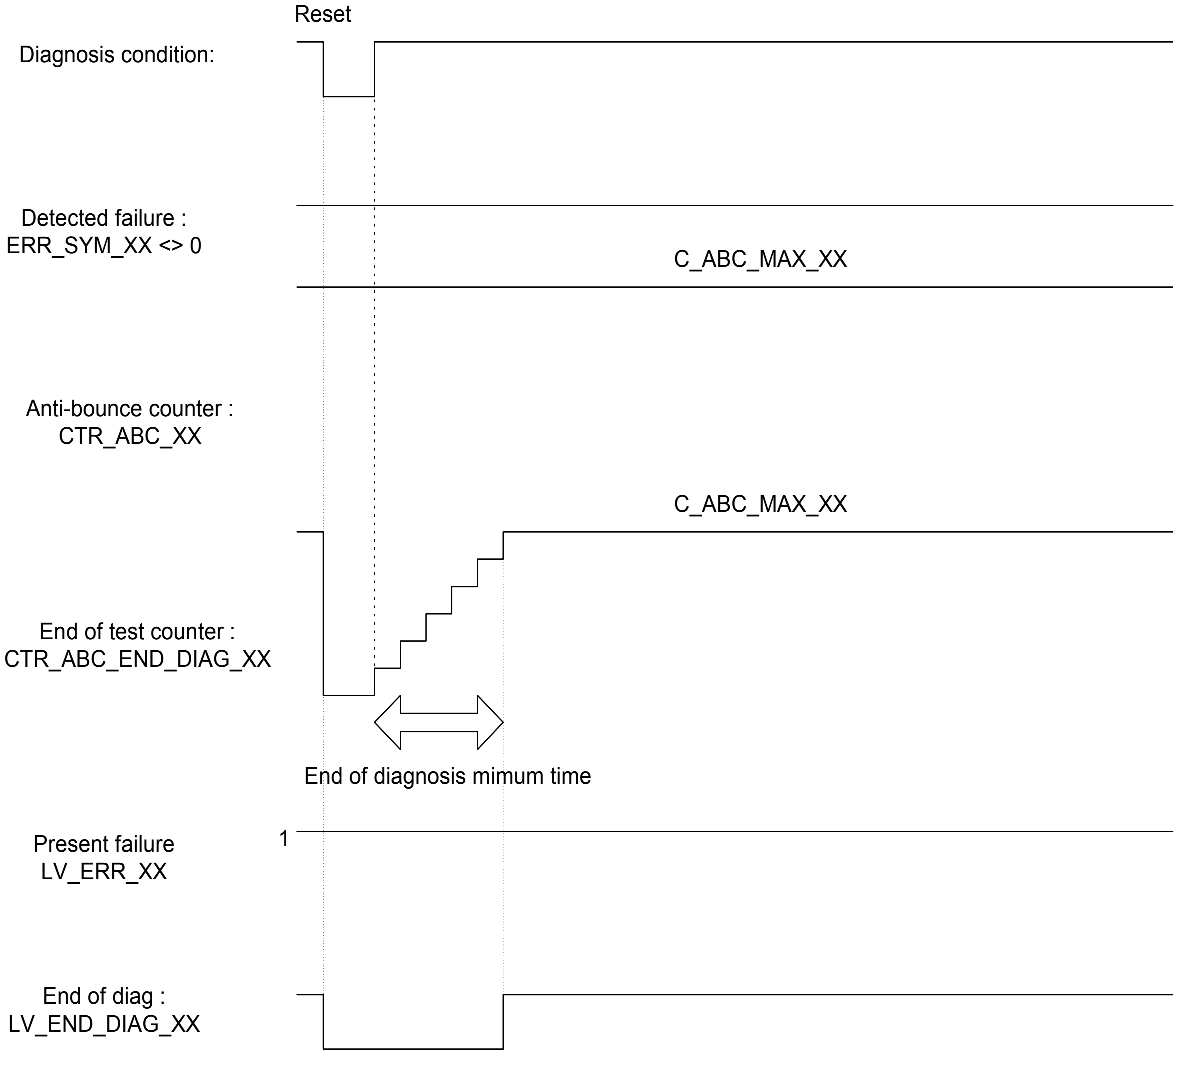


End of diagnosis algorithm illustration in case of reset event :

After the reset event, the detected failure remains present (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

The failure has been present and remains present after reset.



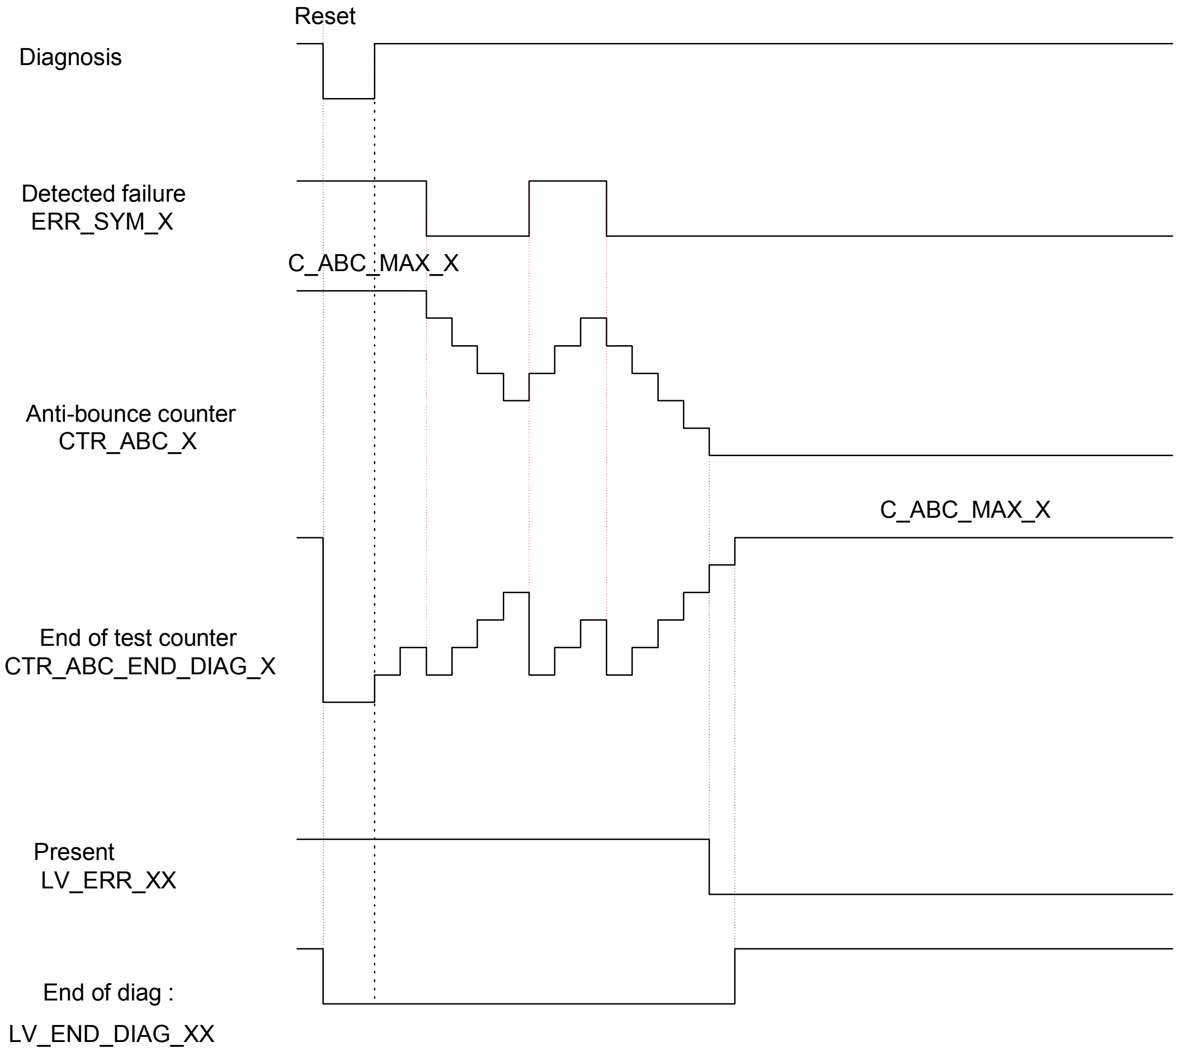
Before the reset, the failure was detected until the failure became present.

After the reset, the detected failure appears during a glitch so the end of diagnosis counter is reset at each transition of the detected failure,

When the detected failure disappears after all (stable) then

- the present failure disappears
- the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

  When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

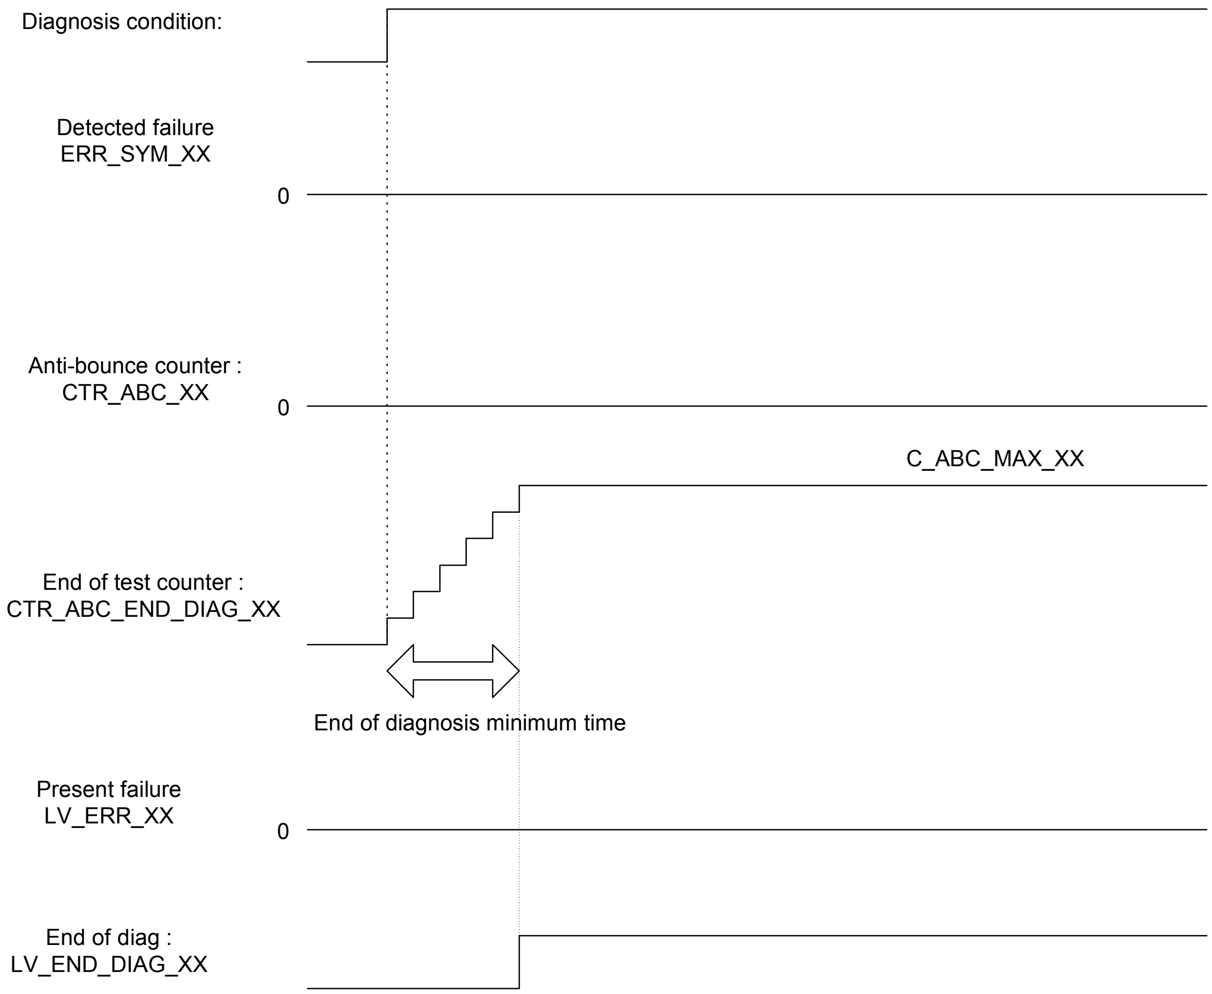


End of diagnosis algorithm illustration when the time to reach the end of diagnosis is minimum

The failure isn't detected (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the end of diagnosis counter has reached the maximum value : the end of diagnosis is set.

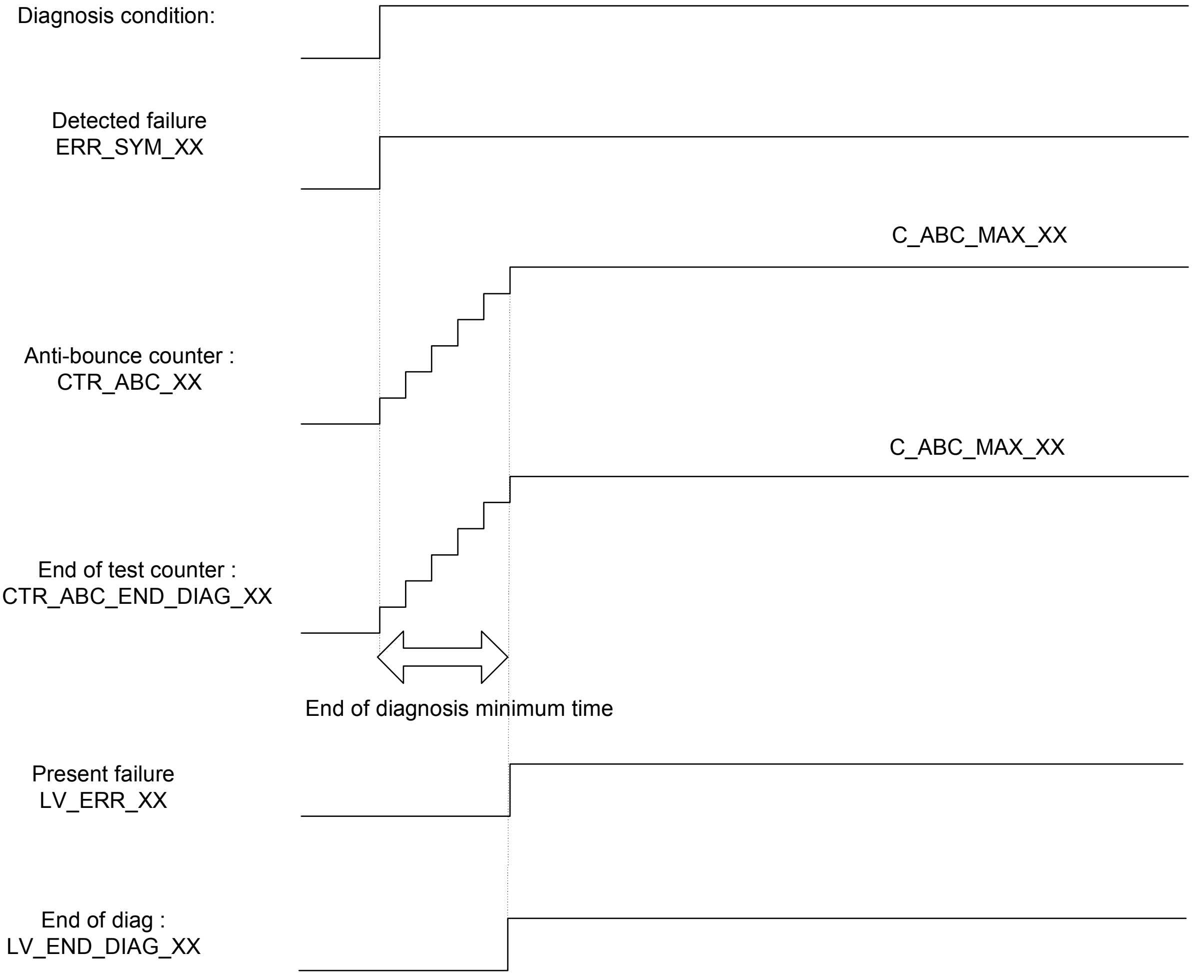
The end of diagnosis appears after the minimum time (the detected failure doesn't appear).



The failure is detected unchangingly (stable) : the end of diagnosis counter is incremented until the maximum value while the diagnosis conditions are fulfilled.

When the failure becomes present : the end of diagnosis is set.

The end of diagnosis and the failure appears after the minimum time (the detected failure is permanent).



Application conditions:

Initialization: See "Initialisation of anti-bounce, statistical and multi-conditions filters" paragraph

Recurrence: The recurrence is managed by the diagnosis.

Activation: The activation is managed by the diagnosis for the anti-bounce operation or the anti-bounce bench mode.

Deactivation: -

Formula section:

```
If(0) LV_ABC_INH = 0      {No inhibition of anti-bounce filtering}
Then(0)
    End of diagnosis in the bench mode:
    If(1)   (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1) and ((C_ABC_INC_XX = 0)
    or (C_ABC_INC_XX = FFH))
    Then(1)
            LV_CDN_DIAG_XX = 1
            LV_END_DIAG_XX = 1
            CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
    End of diagnosis in the normal mode:

      Then(1)
              {ERR_SYM_PREV_XX is updated at each diagnosis recurrence even
              during the inhibition, so that when the inhibition is removed
              ERR_SYM_PREV_XX is updated with the value calculated at the last
              diagnosis recurrence of the inhibition phase.}

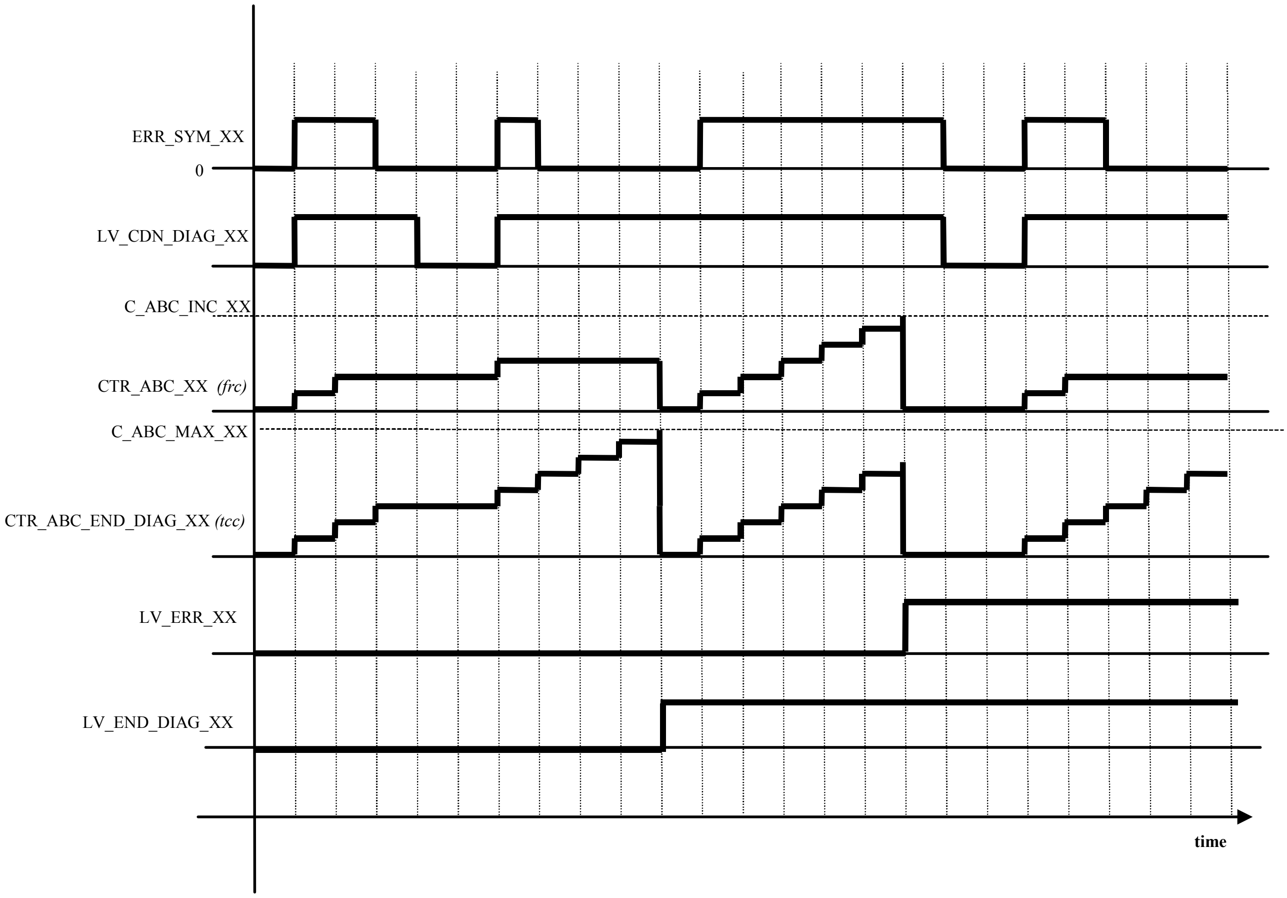
              ERR_SYM_PREV_XX = ERR_SYM_XX
        Endif(1)
Endif(0)
```

27.6.3.3 Standard statistical filtering type

General information:

The purpose is to make an error detection by statistical evaluation.

An error is only detected, if a symptom is active for C_ABC_INC_XX times within the test period C_ABC_MAX XX, with test symptom condition fulfilled (LV_CDN_DIAG_XX = 1).



In this chapter,

- the data CTR_ABC_XX represents the frequency counter
- the calibration C_ABC_INC_XX represents the maximum for frequency counter of the processed symptom
- the data CTR_ABC_END_DIAG_XX represents the period counter increment
- the calibration C_ABC_MAX_XX represents the maximum for test counter of the processed symptom

The calibration C_ABC_MAX_XX must be greater than C_ABC_INC_XX.

Formula section:

Anti-bounce in the bench mode :

```
If      (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1)
        and
        ((C_ABC_INC_XX = 0) or (C_ABC_INC_XX = FFH))
Then
        If      C_ABC_INC_XX = 0
        Then
                ERR_SYM_XX = 0
                LV_ERR_XX = 0
                CTR_ABC_XX = 0
        Else
                If      C_ABC_INC_XX = FFH
                Then
                        ERR_SYM_XX = 0FH
                        LV_ERR_XX = 1
                        CTR_ABC_XX = C_ABC_INC_XX
                Endif
        Endif
Endif
```

Frequency counter increment:

```
If          LV_CDN_DIAG_XX = 1
            and ERR_SYM_XX ≠ 0
            and C_ABC_INC_XX ≠ 0
Then
            If      NLC_ERR_DET_UPD = 1
                    and LC_ERR_DET_UPD = 1
            Then
                    ACTION_ERRM_UpdErrDet( IN<XX>, SYNCHRONIZATION<CALL> )
            Endif
            CTR_ABC_XX = CTR_ABC_XX + 1
Endif
```

Period counter increment:

```
If          LV_CDN_DIAG_XX = 1
Then
            CTR_ABC_END_DIAG_XX = CTR_ABC_END_DIAG_XX + 1
Endif
```

Detection of the error state for the current symptom:

```
If          CTR_ABC_XX >= C_ABC_INC_XX
Then
            LV_ERR_XX = 1
            { The current symptom is entered to failure memory }
Endif
```

Detection of the error free symptom:

```
If          CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
            and CTR_ABC_XX < C_ABC_INC_XX
Then
            LV_ERR_XX = 0
Endif
```

End of the diagnostic period for statistic symptom:

```
If          CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
            or CTR_ABC_XX = C_ABC_INC_XX
Then
            CTR_ABC_XX = 0
            CTR_ABC_END_DIAG_XX = 0
            { End of diagnostic period for statistic symptom is reached }
            LV_END_DIAG_XX=1
Endif
```

27.6.4 Description for ACTION_ERRM_NoFilterSymptom :

Syntax :	ACTION_ERRM_NoFilterSymptom(IN<XX>, IN<lv_cdn_diag_XX>, IN<err_sym_XX>, IN<lv_err_set_XX>, IN<lv_err_reset_XX>, IN<lv_end_diag_XX>, OUT<LV_ERR_XX>)	
Parameter(in) :	XX	Type: index to identify the Diagnostic
	lv_cdn_diag_XX	Type: Diagnostic condition
	err_sym_XX	Status of failure
	lv_err_set_XX	Type: Boolean to set the failure
	lv_err_reset_XX	Type: Boolean to reset the failure
	lv_end_diag_XX	Type: Boolean (=1 when result available)
Parameter(out) :	LV_ERR_XX	Type: Boolean (=1 when failure)
Short Description :	This action returns the result on symptoms detected at each diagnostic recurrence, when no filter is used.	

27.6.5 System Description:

This action is used in case of diagnostics which don’t need any filtering will use the “NO type” filter.

LV_ERR_XX is managed as a **STD** anti-bounce filtering type (saved in NVMY at end of power latch, ...).

LV_END_DIAG_XX is managed by error management (reset at DC transition, ...).
ERR_SYM_XX is updated at each diagnostic recurrence, to fulfil the diagnostic result.

Formula section :

```
If LV_ABC_INH = 0      {No inhibition of anti-bounce filtering}
Then
    If lv_end_diag_XX = 1
    Then
            LV_END_DIAG_XX = 1
    Endif

    If lv_err_set_XX = 1
    Then
            LV_ERR_XX = 1
    Endif

    If lv_err_reset_XX = 1
    Then
            LV_ERR_XX = 0
    Endif
```

```
        If lv_cdn_diag_XX =1
        Then
                LV_CDN_DIAG_XX = 1
                ERR_SYM_XX = err_sym_xx
        Else
                LV_CDN_DIAG_XX = 0
                { ERR_SYM_XX is unchanged }
        Endif
Endif
```

27.6.6 Description for ACTION_ERRM_AbcFilterSymptomEnd:

Syntax:	ACTION_ERRM_AbcFilterSymptomEnd(	IN<XX>, IN< C_ABC_MAX_XX>, OUT< LV_ERR_XX >)
Parameter(in):	XX	Type: index to identify the Diagnostic
	C_ABC_MAX_XX	Maximum value of anti-bounce counter
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action erases diagnostic failure and sets immediately the end of diagnostic information in case of anti-bounce filter (STD, STD_INI, STC, MEM and MEM_INI)	

Formula section :

```
If   LV_ABC_INH = 0          {No inhibition of anti-bounce filtering}
Then
        LV_CDN_DIAG_XX = 1
        ERR_SYM_XX = NO_SYM
        LV_ERR_XX = 0
        CTR_ABC_XX = 0
        LV_END_DIAG_XX = 1
        CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
Endif
```

27.6.7 Description for ACTION_ERRM_NoFilterSymptomEnd:

Syntax:	ACTION_ERRM_NoFilterSymptomEnd(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action erases diagnostic failure and sets immediately the end of diagnostic information in case of no filter (NO)	

Formula section :

```
If   LV_ABC_INH = 0          {No inhibition of anti-bounce filtering}
Then
        LV_CDN_DIAG_XX = 1
```

```
        ERR_SYM_XX = NO_SYM
        LV_ERR_XX = 0
        LV_END_DIAG_XX = 1
    Endif
```

27.6.8 Description for ACTION_ERRM_AbcFilterReset:

Syntax:	ACTION_ERRM_AbcFilterReset(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action resets data filter in case of ABC filter type	

Formula section :

```
If LV_ABC_INH = 0      {No inhibition of anti-bounce filtering}
Then
    LV_CDN_DIAG_XX = 0
    ERR_SYM_XX = NO_SYM
    LV_ERR_XX = 0
    CTR_ABC_XX = 0
    LV_END_DIAG_XX is unchanged
    CTR_ABC_END_DIAG_XX is unchanged
Endif
```

27.6.9 Description for ACTION_ERRM_NoFilterReset:

Syntax:	ACTION_ERRM_NoFilterReset(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action resets data filter in case of no filter usage	

Formula section :

```
If LV_ABC_INH = 0      {No inhibition of anti-bounce filtering}
Then
    LV_CDN_DIAG_XX = 0
    ERR_SYM_XX = NO_SYM
    LV_ERR_XX = 0
    LV_END_DIAG_XX is unchanged
Endif
```

27.6.10 Description for ACTION_ERRM_GetLvErr:

Syntax:	ACTION_ERRM_GetLvErr(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action returns the failure status for the diagnostic XX.	

Formula section :

LV_ERR_XX = failure status for the diagnostic XX

27.6.11 Description for ACTION_ERRM_GetLvEndDiag:

Syntax:	ACTION_ERRM_GetLvEndDiag(IN<XX>, OUT<LV_END_DIAG_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_END_DIAG_XX	Type: Boolean
Short Description:	This action returns the end of diagnostic flag for the diagnostic XX.	

Formula section :

LV_END_DIAG_XX = end of diagnostic flag for the diagnostic XX

27.6.12 Description for ACTION_ERRM_GetLvCdnDiag:

Syntax:	ACTION_ERRM_GetLvCdnDiag(IN<XX>, OUT<LV_CDN_DIAG_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_CDN_DIAG_XX	Type: Boolean
Short Description:	This action returns the condition status for the diagnostic XX.	

Formula section :

LV_CDN_DIAG_XX = condition status for the diagnostic XX

27.6.13 Description for ACTION_ERRM_GetErrSym:

Syntax:	ACTION_ERRM_GetErrSym(IN<XX>, OUT<ERR_SYM_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	ERR_SYM_XX	Status of failure
Short Description:	This action returns the symptoms for the diagnostic XX.	

Formula section :

ERR_SYM_XX = symptoms for the diagnostic XX

27.6.14 CPU load optimisation mechanisms

General information:

This section describes the mechanism of optimisation. The principle is to suspend the filter algorithm execution when it is not necessary.

Formula section:

```
If      NLC_BENCH_MODE = 0
Then
        { the bench mode isn't available whatever LC_ABC_BENCH value }
        the CPU load is reduced
Else
        { the bench mode is available if LC_ABC_BENCH = 1 }
        less CPU load reduction than with NLC_BENCH_MODE = 0
Endif
```

Case 1 : the diagnostic uses an anti-bounce filtering algorithm

```
If      LV_ERR_XX = 0
        and LV_END_DIAG_XX = 1
        and ERR_SYM_XX = 0
        and CTR_ABC_XX = 0
Then
        { it is not necessary to call the Error Management (including the filtering) }
        LV_END_DIAG_XX = 1    { unchanged }
        LV_ERR_XX = 0         { unchanged }
Endif
```

Case 2 : the diagnostic doesn't use an anti-bounce filtering algorithm

```
If      ( LV_ERR_XX = 0 and LV_END_DIAG_XX = 1 and ERR_SYM_XX = 0 )
Then
        { it is not necessary to call the Error Management }
        LV_END_DIAG_XX = 1    { unchanged }
        LV_ERR_XX = 0         { unchanged }
Endif
```

27.6.15 Synchronisation between Anti-bounce algorithm and Error Management

General information:

This section describes the mechanism of synchronisation of the failure filtering with the Error Management core. The principle is to call the Error Management upon events.

LV_END_DIAG_XX 0 → 1 transition

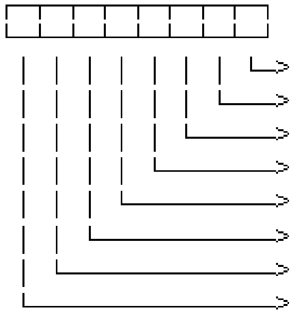
LV_ERR_XX 0 → 1 transition

LV_ERR_XX 1 → 0 transition

This mechanism is followed whatever the filter (type STD, STD_INI, DEC_CAL, MEM, MEM_INI, STC) but also for diagnoses which don't use any filter (type NO).

27.6.16 Configuration and calibration data

NC_ABC_CONF_FCT_DIAG_XX :



bit 0 : NLC_ABC_NOT_SAVE_XX
bit 1 : NLC_ABC_INI_IGK_XX
bit 2 : NLC_ABC_INI_VALUE_XX
bit 3 : NLC_ABC_NOT_DEC_XX
bit 4 : NLC_ABC_CAL_DEC_XX
bit 5 : NLC_ABC_STC_XX
bit 6 : Not used
bit 7 : Not used

Bits definition

- NLC_ABC_NOT_SAVE_XX : if this bit is set to 0 the anti-bounce context (CTR_ABC_XX and LV_ERR_XX) is saved at the end of power latch, only when the failure is in dynamic memory, and restored at the event Reset.
Limitation : the saved configuration is only available if the NVMY manager take into account the filter environment data (LV_ERR_XX, CTR_ABC_XX).

- NLC_ABC_INI_IGK_XX : LV_ERR_XX and CTR_ABC_XX are reset at the transition LV_IGK 0 -> 1 and at the event reset.

- NLC_ABC_INI_VALUE_XX : if this bit is set to 1 then the anti-bounce counter is initialised with C_ABC_MAX_XX – C_ABC_INC_XX if there was a failure between the last and this initialisation (NLC_ABC_NOT_SAVE_XX = 0 to test the failure before this initialisation) else the anti-bounce counter is initialised with 0 value.

- NLC_ABC_NOT_DEC_XX : if this bit is set to 0 then the anti-bounce counter can be decremented if the condition for decrement are fulfilled. If this bit is set to 1 then the anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains (the anti-bounce counter can be decremented anymore) until a transition LV_IGK 0 → 1 or reset following the NLC_ABC_INI_IGK_XX bit configuration (If the NLC_ABC_NOT_DEC_XX bit is set to 1 then NLC_ABC_NOT_SAVE_XX must be set to 1).

- NLC_ABC_CAL_DEC_XX : if this bit is set then the anti-bounce decrement is calibratable, the calibration is named C_ABC_DEC_XX else the anti-bounce decrement is equal to 1 and there isn't calibration.

- NLC_ABC_STC_XX : if this bit is set then the filter used is the statistical filter else the filter used is the anti-bounce filter (Standard configuration).

Predefined filter type :

	NLC_ABC_STC_XX	NLC_ABC_CAL_DEC_XX	NLC_ABC_NOT_DEC_XX	NLC_ABC_INI_VALUE_XX	NLC_ABC_INI_IGK_XX	NLC_ABC_NOT_SAVE_XX
STD_INI	0	0	0	0	1	1
STD	0	0	0	0	0	0
MEM	0	0	1	0	1	1
MEM_INI	0	0	1	1	1	0
DEC_CAL	0	1	0	0	0	0
STC	1	0	0	0	1	1
NO	0	0	0	0	0	0

The **standard configuration with initialisation (STD_INI)** is
NC_ABC_CONF_FCT_DIAG_XX = 3H (default configuration)

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0).
The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).
The filter used is the Anti-bounce (NLC_ABC_STC_XX = 0).

The **statistical configuration (STC)** is NC_ABC_CONF_FCT_DIAG_XX = 23H

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the frequency counter (CTR_ABC_XX) is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The filter used is the statistical (NLC_ABC_STC_XX = 1).

The **standard configuration (STD)** is NC_ABC_CONF_FCT_DIAG_XX = 0H

The data CTR_ABC_XX and LV_ERR_XX are saved (NLC_ABC_NOT_SAVE_XX = 0, NLC_ABC_INI_IGK_XX = 0, NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decrement (NLC_ABC_NOT_DEC_XX = 0).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **memory configuration (MEM)** is NC_ABC_CONF_FCT_DIAG_XX = BH

The data CTR_ABC_XX and LV_ERR_XX are reset at the transition LV_IGK 0 → 1 and reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains until a transition LV_IGK 0 → 1 or reset (NLC_ABC_NOT_DEC_XX = 1).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **memory configuration (MEM_INI)** is NC_ABC_CONF_FCT_DIAG_XX = EH

The data CTR_ABC_XX and LV_ERR_XX are initialised at the transition LV_IGK 0 → 1 and reset (NLC_ABC_INI_IGK_XX = 1). The anti-bounce counter is initialised to the C_ABC_MAX_XX – C_ABC_INC_XX value (NLC_ABC_INI_VALUE_XX = 1) only if there was a failure between the last and this initialisation (NLC_ABC_NOT_SAVE_XX = 0 to test the failure before this initialisation) else the anti-bounce counter is initialised with 0 value. The data LV_ERR_XX is initialised with 0 value.

The anti-bounce counter can be decremented if the condition for decrement are fulfilled until the anti-bounce counter hasn't reached the maximum value; when the anti-bounce counter has reached the maximum value then the anti-bounce counter and the failure remains until a transition LV_IGK 0 → 1 or reset (NLC_ABC_NOT_DEC_XX = 1).

The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).

The **decrement calibratable configuration (DEC_CAL)** is set with NC_ABC_CONF_FCT_DIAG_XX = 10H

The data CTR_ABC_XX and LV_ERR_XX are saved (NLC_ABC_NOT_SAVE_XX = 0, NLC_ABC_INI_IGK_XX = 0, NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decrement (NLC_ABC_NOT_DEC_XX = 0).

The decrement value is calibratable (NLC_ABC_CAL_DEC_XX = 1).

The standard configuration is NLC_ABC_INI_DC_END_DIAG = 0 and NLC_ERR_DET_UPD = 0 (default configuration).

Some functionalities (e.g. : to visualise the sporadic error of all diagnosis using this anti-bounce algorithm) aren't used when the failure is detected.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ABC_BENCH	1	0...1H	0...1	1	[-]
Logical constant to manage the anti-bounce bench mode					
LC_ERR_DET_UPD	1	0...1H	0...1	1	[-]
Logical constant to manage some functionality as the visualisation of the sporadic error					
C_ABC_DEC_XX	1	0...FFH	0...255	1	[-]
Anti-bounce counter decrement for XX diagnosis					
C_ABC_INC_XX	1	0...FFH	0...255	1	[-]
XX diagnosis anti-bounce counter increment (for anti-bounce filtering) or frequency counter maximum value (for statistical filtering)					
C_ABC_MAX_XX	1	1...FFH	1...255	1	[-]
XX diagnosis anti-bounce counter maximum value (for anti-bounce filtering) or threshold of period counter for failure detection (for statistical filtering)					

Remark :

The standard calibration is LC_ABC_BENCH = 0 **and** NLC_BENCH_MODE=0 (default calibration) then the bench mode isn't managed.

If the diagnosis doesn't manage calibratable decrement then the C_ABC_DEC_XX calibration isn't defined in calibration data (NLC_ABC_CAL_DEC_XX = 0).

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ABC_CONF_FCT_DIAG_XX	1	0...FFH	0...255	1	[-]
Anti-bounce algorithm configuration of each XX diagnosis					
NLC_ABC_INI_DC_END_DIAG	1	0...1H	0...1	1	[-]
Initialisation of LV_END_DIAG_XX at LV_DC transition or not					
NLC_BENCH_MODE	1	0...1H	0...1	1	[-]
Bench mode configuration (0: the bench mode is removed, max CPU optimisation is reached)					

Configuration detailed description:

NLC_ABC_INI_DC_END_DIAG

1 : Initialisation of LV_END_DIAG_XX at LV_DC 1→0 transition

0 : Initialisation of LV_END_DIAG_XX at LV_IGK 0→1 transition or ECU reset

27.7 Anti-bounce algorithm (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_INTM_DIAG_INST[NC_NR_ERR_INTM]	V/S	0...FFFFH	0...65535	1	[-]
Array of diagnosis instances with intermittent failure					
ERR_INTM_CTR_FRC[NC_NR_ERR_INTM]	V/S	0...FFH	0...255	1	[-]
Frequency of reappearence of failure stored in ERR_INTM_DIAG_INST					
CTR_ERR_INTM_NR	V	0...FFH	0...255	1	[-]
Number of failures stored in intermittent failure array					
LV_ABC_INH	V/O	0...1H	0...1	1	[-]
Anti-bounce filterings inhibition					

Export actions:

ACTION_ERRM_InhibitFiltering (IN<InhibitFilter>)
This action shall be used to inhibit anti-bounce filtering calculations

FUNCTION DESCRIPTION:

General information:

Intermittent failures are neither visualized nor stored with the following configuration :
NLC_ERR_DET_UPD = 00h

Application conditions:

Initialisation: ERR_INTM_DIAG_INST[0...NC_NR_ERR_INTM –1] = 0
ERR_INTM_CTR_FRC[0...NC_NR_ERR_INTM –1] = 0
CTR_ERR_INTM_NR = 0

Recurrence: -

Activation: at ECU reset

Formula section:

No action to be performed with this configuration.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_ERR_INTM	1	1...FFH	1...255	1	[-]
Maximum number of diagnosis instances to be listed in ERR_INTM_DIAG_INST					

27.7.1 Anti-bounce filtering inhibition

Description:

In addition, LV_ABC_INH flag must be securised to avoid any undesired inhibition.

To avoid failure recording during specific ECU phases (e.g. reprogramming,...), diagnoses are inhibited. To realize this inhibition, anti-bounce filtering calculations are frozen.

This inhibition is generally used during reprogramming phase.

Syntax:	ACTION_ERRM_InhibitFiltering (IN <InhibitFilter>)
Parameter(in):	InhibitFilter filter inhibition
Parameter(out:	No parameter
Short Description:	This API permits to activate or deactivate the anti-bounce calculation.

Application conditions:

Initialisation:	at ECU reset LV_ABC_INH = 0 (default value : Anti-bounce calculation is not inhibited)
Recurrence:	-
Activation:	at action request

Formula section:

LV_ABC_INH = 0

27.8 Multi-condition debounce algorithm

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
CTR_ABC_XX	V/O/S	0...FFH	0...255	1	[-]
anti bounce counter of diagnosis XX					
CTR_ABC_END_DIAG_XX	V/O	0...FFH	0...255	1	[-]
Counter for end of diagnosis XX generation					
CDN_DIAG_PREV_XX	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	0	[-]
Diagnostic condition of last failure symptom					

Input data:

LC_ABC_BENCH	NC_ABC_CONF_FCT_DIAG_XX	NLC_ABC_INI_DC_END_DIAG	NLC_ERR_DET_UPD
LC_ERR_DET_UPD	LV_IGK	LV_ABC_INH	NLC_BENCH_MODE

Import actions:

ACTION_ERRM_UpdErrDet (IN<XX>)
This action indicates each occurrence of the detected error

Export actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result
ACTION_ERRM_MultiFilterSymEnd(IN< XX >, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)
This action erases diagnostic failure and sets the end of diagnostic in case of multi-conditions filter type
ACTION_ERRM_MultiFilterReset(IN< XX >,OUT<LV_ERR_XX>)
This action resets data filter in case of multi-conditions filter type

General information:

Description:

According the diagnosis condition information CDN_DIAG_XX and the diagnosis symptom (raw value) information the symptom calculation ERR_SYM_XX is performed. Then the failure symptom is debounced to set the present failure LV_ERR_XX.

A special readiness calculation is done to set the end of diagnosis information. LV_END_DIAG_XX is set only if there was enough time to make a diagnosis of all symptoms or a failure gets present.

Note:

To set the LV_END_DIAG_XX is necessary to have the conditions for all symptoms at the same time for a given time.

Restrictions:

In case of multiple symptoms at the same time, only one symptom will be taken into account according the following priority rule: SYM_0 ==> SYM_3 ; Priority max ==> Priority Min

Only the last symptom present will be taken into account in this algorithm, so in case of symptom change, only the last symptom will be used to increment and decrement the counters.

Application conditions:

Initialization: At ECU reset and LV_IGK 0 → 1 transition

CDN_DIAG_PREV_XX = 0

Other data initialization

ERR_SYM_XX = *Refer to “Antibounce algorithms” chapter for initialization*
CTR_ABC_XX = *Refer to “Antibounce algorithms” chapter for initialization*
LV_ERR_XX = *Refer to “Antibounce algorithms” chapter for initialization*
CTR_ABC_END_DIAG_XX = *Refer to “Antibounce algorithms” chapter for initialization*

27.8.1 Multi-condition anti-bounce filter algorithm description

Description for ACTION_ERRM_FilterMulticondition:

Syntax : ACTION_ERRM_FilterMulticondition (IN<XX>, IN<CDN_DIAG_XX>, IN<ERR_DIAG_XX>, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)

Parameter(in):	XX	Type: index to identify the Diagnostic
	CDN_DIAG_XX	Type: Byte carrier (Each symptom condition)
	ERR_DIAG_XX	Type: Byte carrier (Raw value symptom)
	C_ABC_INC_XX	Type: Calibration byte for the increment value
	C_ABC_MAX_XX	Type: Calibration byte for the maximum value
Parameter(out):	LV_ERR_XX	Type: Boolean (=1 when failure)

Short Description: This action returns information necessary for the diagnostic and the error management.

Formula section:

Anti-bounce bench mode :

```
If(0) LV_ABC_INH = 0
Then
If(1) (LC_ABC_BENCH = 1 and NLC_BENCH_MODE=1) and ((C_ABC_INC_XX = 0) or (C_ABC_INC_XX = FFH))
Then(1)
        If(2)   C_ABC_INC_XX = 0
        Then(2)
                {Case force no failure}
                LV_ERR_XX = 0
                ERR_SYM_XX =  0
                CTR_ABC_XX = 0
                LV_END_DIAG_XX = 1
                CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
        Else(2)
                If(3)   C_ABC_INC_XX = FFH
                Then(3)
                        {Forced failure}
                        LV_ERR_XX = 1
                        ERR_SYM_XX = 0Fh
                        CTR_ABC_XX = C_ABC_MAX_XX
                        LV_END_DIAG_XX = 1
                        CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX
                Endif(3)
        Endif(2)
Endif(1)
```

Symptom calculation:

```
{Erase not available bit}

CDN_DIAG_XX = CDN_DIAG_XX and NC_NR_SYM_XX
ERR_DIAG_XX = ERR_DIAG_XX and NC_NR_SYM_XX

If(1)       CDN_DIAG_XX ≠ 0  {Diagnosis of at least one symptom is valid}
Symptom SYM_0 calculation:
Then(1)
            If(2)           bit 0 of CDN_DIAG_XX = 1
                            and
                            bit 0 of ERR_DIAG_XX = 1
            Then(2)
                            ERR_SYM_XX = 1H
                            {Memorization of last failure symptom number}
                            CDN_DIAG_PREV_XX = 1H

Symptom SYM_1 calculation:
            Else(2)
                  If(3)     bit 1 of CDN_DIAG_XX = 1

```

27.8.2 Description for ACTION_ERRM_MultiFilterSymEnd :

Syntax:	ACTION_ERRM_MultiFilterSymEnd(IN<XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX C_ABC_MAX_XX	Type: index to identify the Diagnostic Type: Calibration byte for the maximum value
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action erases diagnostic failure and sets immediately the end of diagnostic information in case of multi-conditions filter (MPL_STD_INI)	

Formula section :

LV_CDN_DIAG_XX = 1
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX = 1
CTR_ABC_END_DIAG_XX = C_ABC_MAX_XX

27.8.3 Description for ACTION_ERRM_MultiFilterReset:

Syntax:	ACTION_ERRM_MultiFilterReset(IN<XX>, OUT<LV_ERR_XX>)	
Parameter(in):	XX	Type: index to identify the Diagnostic
Parameter(out):	LV_ERR_XX	Type: Boolean
Short Description:	This action resets data filter in case of Multiconditions filter type	

Formula section :

LV_CDN_DIAG_XX = 0
ERR_SYM_XX = NO_SYM
LV_ERR_XX = 0
CTR_ABC_XX = 0
LV_END_DIAG_XX is unchanged
CTR_ABC_END_DIAG_XX is unchanged

27.8.4 Synchronization between multi-condition algorithm & Error Management

General information:

This section describes the mechanism of synchronisation of the failure filtering with the Error Management core. The principle is to call the Error Management upon events.

LV_END_DIAG_XX 0 → 1 transition
LV_ERR_XX 0 → 1 transition
LV_ERR_XX 1 → 0 transition

27.8.5 Mechanism for CPU load optimisation

General information:

This section describes the mechanism of optimisation. The principle is to suspend the filter algorithm execution when is not necessary. When the bench mode is used for a diagnostic XX the mechanism of CPU load optimisation is disabled for this instance.

Formula section:

```
If          LV_ERR_XX = 0
            and LV_END_DIAG_XX = 1
            and  ERR_SYM_XX = 0
            and CTR_ABC_XX = 0
Then
        It is not necessary to call error management (including filtering)
        LV_END_DIAG_XX = 1    {unchanged}
        LV_ERR_XX = 0         {unchanged}
Endif
```

27.8.6 Configuration data

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_SYM_XX	1	1...FH	1...15	1	[-]
Available symptom(s) for XX diagnostic					

Configuration data detailed description:

Symptoms 0 and 1 available:	03H
Symptoms 0, 1 and 2 available:	07H (typical value)
Symptoms 0, 1, 2 and 3 available:	0FH

Predefined filter type:

	NLC_ABC_STC_XX	NLC_ABC_CAL_DEC_XX	NLC_ABC_NOT_DEC_XX	NLC_ABC_INI_VALUE_XX	NLC_ABC_INI_IGK_XX	NLC_ABC_NOT_SAVE_XX
MPL_STD_INI	0	0	0	0	1	1

The **standard configuration with initialisation (MPL_STD_INI)** is NC_ABC_CONF_FCT_DIAG_XX = 3H (default configuration)

The data CTR_ABC_XX and LV_ERR_XX are Reset at the transition LV_IGK 0 → 1 and Reset (NLC_ABC_NOT_SAVE_XX = 1, NLC_ABC_INI_IGK_XX = 1) and the anti-bounce counter is initialised to 0 value (NLC_ABC_INI_VALUE_XX = 0).

The anti-bounce counter may be decremented (NLC_ABC_NOT_DEC_XX = 0).
The decrement value is equal to 1 (NLC_ABC_CAL_DEC_XX = 0).
The filter used is the Anti-bounce (NLC_ABC_STC_XX = 0).

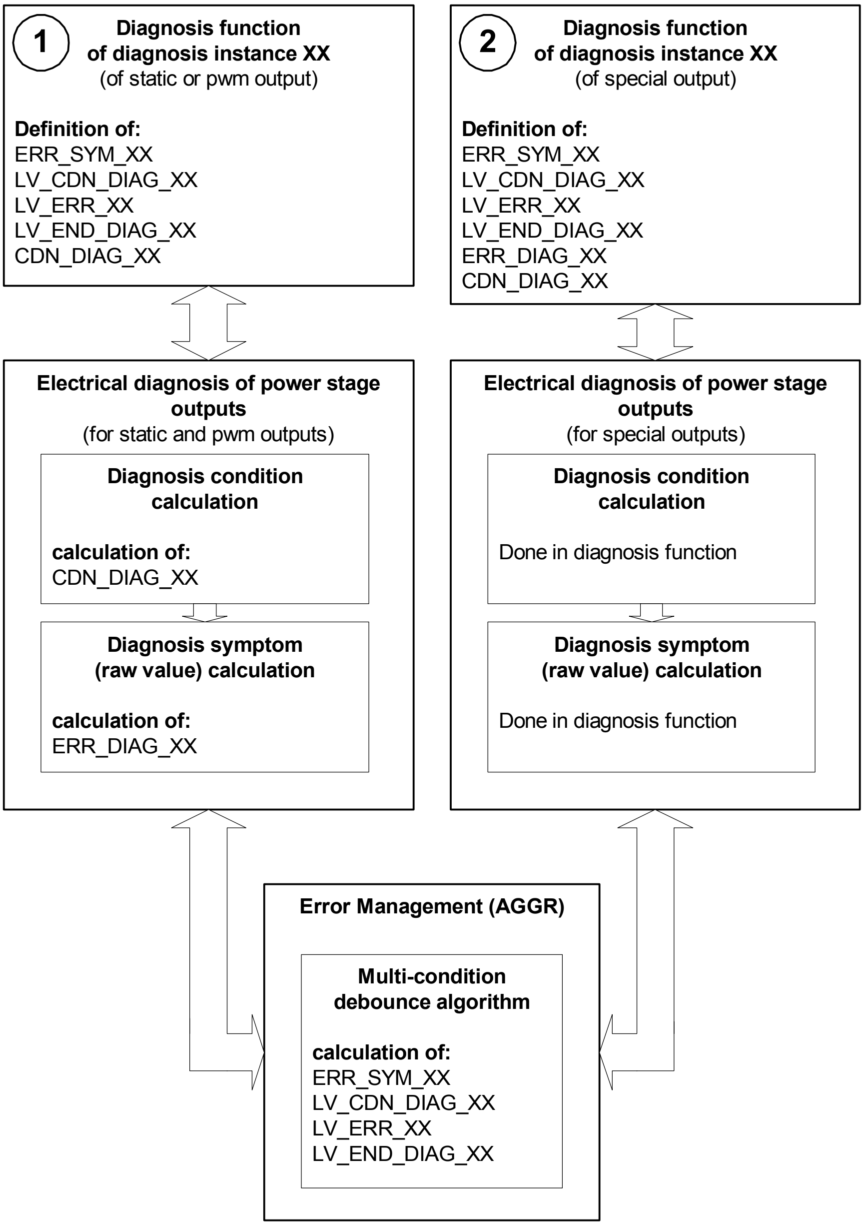
27.9 Electrical diagnosis of power stage outputs

FUNCTION DESCRIPTION:

General information:

In this function description the electrical diagnosis of power stage outputs is specified. Because of the possibility of different hardware configurations, the specification is splited into three parts plus one common part for the symptom debounce and error management treatment.

- Diagnosis of static outputs (e.g. relays)
- Diagnosis of pwm outputs (e.g. VVT actuator)
- Diagnosis of special outputs (other hardware configurations)



According these three different kind of driver outputs the management of the electrical diagnosis is different between static/pwm outputs and special outputs (see previous picture case 1 and 2).

For all types of these diagnoses three main calculations must be done:

- Diagnosis condition calculation
- Diagnosis symptom (raw value) calculation
- anti-bounce mechanism with error management treatments

In the following chapter these treatments are described.

27.9.1 Diagnosis of static outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	LV_INH_DIAG_XX		

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >, OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

General information:

The purpose is to diagnose electrical errors detected by the hardware for static outputs. The signal is controlled by the ATIC 39.

The driver can distinguish between three symptoms: ‘Short to battery’ SCB, ‘Short to ground’ SCG and ‘Open circuit’ OC.

Description:

By the diagnosis condition calculation the information given by the BSW (‘Diagnosis of symptom ... is valid’) that shows, that a diagnosis of a symptom was possible, since the last recurrence of the diagnosis function, is displayed for each symptom within the value CDN_DIAG_XX.

The information of the failure symptom is also delivered by the BSW (‘Failure symptom ... detected by HW’). According this information the diagnosis symptom (raw value) calculation is performed to set ERR_DIAG_XX.

The calculation of LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX and LV_END_DIAG_XX is done in the Multi-condition debounce algorithm (part of Error Management AGGR).

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation: CDN_DIAG_XX = 0

Formula section:

Diagnosis condition calculation:

CDN_DIAG_XX = 0

Diagnosis condition calculation for symptom 'Short to battery' SCB:

```
If      'Diagnosis of symptom SCB is valid'          (BSW information)
Then    bit 0 of CDN_DIAG_XX  = 1
Endif
```

Diagnosis condition calculation for symptom 'Short to ground' SCG:

```
If      'Diagnosis of symptom SCG is valid'          (BSW information)
Then    bit 1 of CDN_DIAG_XX  = 1
Endif
```

Diagnosis condition calculation for symptom 'Open circuit' OC:

```
If      'Diagnosis of symptom OC is valid'           (BSW information)
Then    bit 2 of CDN_DIAG_XX  = 1
Endif
```

Diagnosis symptom (raw value) calculation:

Symptom calculation for 'Short to battery' SCB:

```
If      'Failure symptom SCB detected by HW'      (BSW information)
Then    bit 0 of ERR_DIAG_XX = 1
Else    bit 0 of ERR_DIAG_XX = 0
Endif
```

Symptom calculation for 'Short to ground' SCG:

```
If      'Failure symptom SCG detected by HW'      (BSW information)
Then    bit 1 of ERR_DIAG_XX = 1
Else    bit 1 of ERR_DIAG_XX = 0
Endif
```

Symptom calculation for 'Open circuit' OC:

```
If      'Failure symptom OC detected by HW'       (BSW information)
Then    bit 2 of ERR_DIAG_XX = 1
Else    bit 2 of ERR_DIAG_XX = 0
Endif
```

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

27.9.2 Diagnosis of PWM outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	LV_INH_DIAG_XX	XXPWM	

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >,
OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose electrical errors detected by the hardware for PWM outputs. The signal is controlled by ATIC39.
The driver can distinguish between three symptoms: ‘Short to battery’ SCB, ‘Short to ground’ SCG and ‘Open circuit’ OC.

Because of the different filter times for SCB, SCG and OC detection, the diagnosis window, where a symptom can be detected, is defined for each symptom. A diagnosis window is defined by a minimum and a maximum duty cycle of the PWM signal controlled by the output of the driver.

SCB diagnosis window:

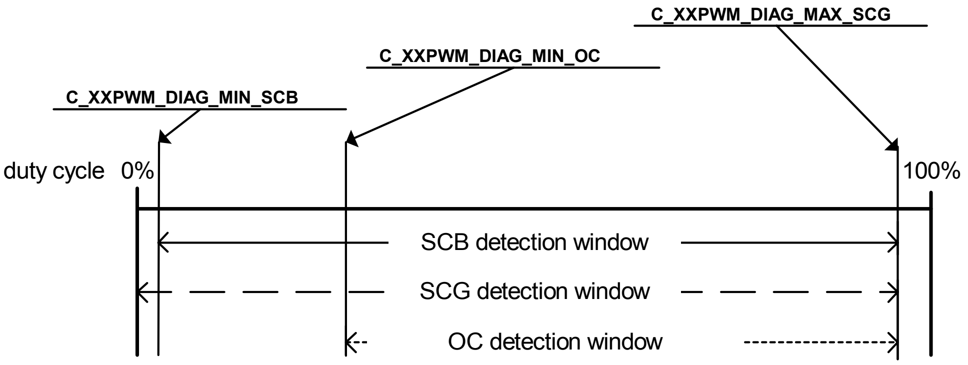
C_XXPWM_DIAG_MIN_SCB <-------> C_XXPWM_DIAG_MAX_SCG

SCG diagnosis window:

0 <-------> C_XXPWM_DIAG_MAX_SCG

OC diagnosis window:

C_XXPWM_DIAG_MIN_OC <-------> C_XXPWM_DIAG_MAX_SCG



For some diagnosis it's not necessary to define different diagnosis windows for each symptom. This is possible for all diagnosis, where a limitation of the duty cycle range is made within the function which controls the corresponding output. The limitation must be made in this way, that a diagnosis of all three symptoms can always (if LV_INH_DIAG_XX= 0) be made (CDN_DIAG_XX = 7H, LV_CDN_DIAG_XX = 1).

These two possibilities of a diagnosis condition calculation are described in the following chapter. It's distinguished between a "open range" (different diagnosis windows for each symptom necessary) and a "limited" duty cycle calculation.

27.9.2.1 Diagnosis condition calculation

27.9.2.1.1 "Open range" duty cycle

Description:

For an output with an "open range" duty cycle range, a diagnosis result of a symptom can be considered as valid, if the duty cycle of the PWM output was in the right window at least one time between two calculations of the diagnosis function and not only if diagnosis function is called. To have a better reflection of this behavior, the diagnosis condition is calculated independently of the diagnosis function.

If the recurrence of the 'diagnosis condition' calculation is the same like the 'symptom' calculation, the 'diagnosis condition' calculation must be treated after the 'symptom' calculation to have a new diagnosis condition CDN_DIAG_XX information of the following diagnosis window for the next symptom calculation.

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation CDN_DIAG_XX = 0

Formula section:

Diagnosis window calculation:

```
If      0 <= XXPWM < C_XXPWM_DIAG_MIN_SCB
Then    bit 1 of CDN_DIAG_XX = 1
        Diagnosis of SCG is valid

Else    If      XXPWM < C_XXPWM_DIAG_MIN_OC
        Then    bit 0 and bit 1 of CDN_DIAG_XX = 1
                Diagnosis of SCB, SCG  is valid

        Else    If      XXPWM <= C_XXPWM_DIAG_MAX_SCG
                Then    bit 0, bit 1 and bit 2 of CDN_DIAG_XX = 1
                        Diagnosis of SCB, SCG  and OC is valid
                Endif
        Endif
Endif
```

27.9.2.1.2 "Limited" duty cycle

Description:

For an output with a "limited" duty cycle range, the diagnosis result of a symptom can always be considered as valid, because of the current duty cycle. It only can be invalid because special conditions managed by the BSW.

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

at deactivation: CDN_DIAG_XX = 0

Formula section:

bit 0, bit 1 and bit 2 of CDN_DIAG_XX = 1

Diagnosis of SCB, SCG and OC is valid

27.9.2.2 Diagnosis symptom (raw value) calculation

FUNCTION DESCRIPTION:

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after LV_INH_DIAG_XX 1->0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: LV_INH_DIAG_XX = 1

Formula section:

Symptom calculation for 'Short to battery' SCB:

```
If      'Failure symptom SCB detected by HW'      (BSW information)
Then    bit 0 of ERR_DIAG_XX = 1
Else    bit 0 of ERR_DIAG_XX = 0
Endif
```

Symptom calculation for 'Short to ground' SCG:

```
If      'Failure symptom SCG detected by HW'      (BSW information)
Then    bit 1 of ERR_DIAG_XX = 1
Else    bit 1 of ERR_DIAG_XX = 0
Endif
```

Symptom calculation for 'Open circuit' OC:

```
If      'Failure symptom OC detected by HW'       (BSW information)
Then    bit 2 of ERR_DIAG_XX = 1
Else    bit 2 of ERR_DIAG_XX = 0
Endif
```

Diagnosis condition from BSW verification:

Diagnosis condition calculation for symptom 'Short to battery' SCB:

```
If      'Diagnosis of symptom SCB is not valid'   (BSW information)
Then    bit 0 of CDN_DIAG_XX  = 0
Endif
```

Diagnosis condition calculation for symptom 'Short to ground' SCG:

```
If      'Diagnosis of symptom SCG is not valid'      (BSW information)
Then    bit 0 of CDN_DIAG_XX  = 0
Endif
```

Diagnosis condition calculation for symptom 'Open circuit' OC:

```
If      'Diagnosis of symptom OC is not valid'       (BSW information)
Then    bit 0 of CDN_DIAG_XX  = 0
Endif
```

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

CDN_DIAG_XX = 0 (after failure debouncing and error management treatment)

27.9.3 Diagnosis of special outputs

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
ERR_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis symptom (raw value) for each symptom for XX					
CDN_DIAG_XX	-	0 ... 7H	0 ... 7	1	-
Diagnosis condition for each symptom for XX					

Input data:

LV_IGK	ERR_DIAG_XX	CDN_DIAG_XX	

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX>, IN< ERR_DIAG_XX >, OUT< LV_END_DIAG_XX >, OUT< LV_ERR_XX >, OUT< LV_CDN_DIAG_XX >, OUT< ERR_SYM_XX >)

General information:

The purpose is to diagnose electrical errors detected by the hardware for special outputs. Special outputs are outputs, which cannot be treated like "normal" static or pwm outputs, like described in the previous chapters.

Description:

The diagnosis condition calculation for the driver output is done in the diagnosis function of the diagnosis instance XX. It's displayed for each symptom within the value CDN_DIAG_XX.

Also the diagnosis symptom (raw value) calculation (ERR_DIAG_XX) is performed in the diagnosis function for special outputs.

The calculation of LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX and LV_END_DIAG_XX is done in the Multi-condition debounce algorithm (part of Error Management AGGR).

Application conditions:

Initialization: -

Recurrence: -

Activation: every ECU state

reactivation in the NC_PSD_DLY recurrence after CDN_DIAG_XX > 0 and LV_IGK 0->1 and reset and FMY reset

Deactivation: -

Formula section:

Diagnosis condition / Diagnosis symptom (raw value) calculation:

CDN_DIAG_XX and ERR_DIAG_XX are calculated in the diagnosis function.

ACTION_ERRM_FilterMulticondition (*XX*, CDN_DIAG_XX, ERR_DIAG_XX, LV_END_DIAG_XX, LV_ERR_XX, LV_CDN_DIAG_XX, ERR_SYM_XX)

Remark: For failure debouncing and error management treatment the algorithm Multi-condition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_XX and ERR_DIAG_XX.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_PSD_DLY	1	0 ... FFH	0 ... 255	1	-
The diagnosis is reactivated after (LV_INH_DIAG_XX 1->0 or CDN_DIAG_XX >0 (depending on case)) and LV_IGK 0->1 and reset and FMY reset after NC_PSD_DLY recurrences.					

27.10 Electrical diagnosis of powerstage outputs (Applic. Inc.)

General information:

This specification defines all output-data and calibration data for all ATIC39 powerstage diagnosis as well as specific functions like limp home which are not covered by the generic ATIC39 basic algorithm for static and PWM outputs

Remark:

For all static outputs a minimum switch-on time of 50ms for error symptom detection is necessary.

27.10.1 Diagnosis of static outputs

27.10.1.1 Crankcase ventilation heater relay diagnosis (LV_ERR_RLY_CRCV_HEAT)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_RLY_CRCV_HEAT	V/O	0...1H	0...1	1	[-]
Logical value for CRCV_HEAT error					
LV_CDN_DIAG_RLY_CRCV_HEAT	V/O	0...1H	0...1	1	[-]
Diagnosis condition CRCV_HEAT					
ERR_SYM_RLY_CRCV_HEAT	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected error symptom CRCV_HEAT					
LV_END_DIAG_RLY_CRCV_HEAT	V/O	0...1H	0...1	1	[-]
End of CRCV_HEAT diagnosis					
LV_INH_DIAG_RLY_CRCV_HEAT	V/O	0...1H	0...1	1	[-]
Diagnosis inhibition RLY_CRCV_HEAT diagnosis					
CDN_DIAG_RLY_CRCV_HEAT	V	0...7H	0...7	1	[-]
Diagnosis condition for each symptom of RLY_CRCV_HEAT bit 0: diagnosis condition for symptom SCP (SYM_0)bit 1: diagnosis condition for symptom SCG (SYM_1)bit 2: diagnosis condition for symptom OC (SYM_2)					
ERR_DIAG_RLY_CRCV_HEAT	-	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Raw value of error symptom for RLY_CRCV_HEAT (only parameter)					

Input data:

LV_IGK	LV_CDN_VB_MIN_DIAG	LV_ERR_SPI_MPS	

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the crankcase ventilation heater relay.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Vbatt        (= SYM_0)
 │ │ └───> Short circuit to GND          (= SYM_1)
 │ └─────> Open load                     (=SYM_2)
 └───────> -                             (=SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Recurrence: 1000ms

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_RLY_CRCV_HEAT = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_RLY_CRCV_HEAT. Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_RLY_CRCV_HEAT.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_RLY_CRCV_HEAT and ERR_DIAG_RLY_CRCV_HEAT.

This algorithm determines:

ERR_SYM_RLY_CRCV_HEAT	(Detected error symptom)
LV_ERR_RLY_CRCV_HEAT	(Error flag for debounced error)
LV_CDN_DIAG_RLY_CRCV_HEAT	(Diagnosis condition information)
LV_END_DIAG_RLY_CRCV_HEAT	(End of diagnosis information)

Diagnosis inhibition:

If LV_IGK = 1 **and**
LV_CDN_VB_MIN_DIAG = 1 **and**
LV_ERR_SPI_MPS = 0

Then LV_INH_DIAG_RLY_CRCV_HEAT = 0
Else LV_INH_DIAG_RLY_CRCV_HEAT = 1

Endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_RLY_CRCV_HEAT	1	0...FFH	0...255	1	[-]
Debounce counter increment CRCV_HEAT					
C_ABC_MAX_RLY_CRCV_HEAT	1	1...FFH	1...255	1	[-]
Debounce counter maximum value CRCV_HEAT					

27.10.1.2 Air condition compressor relay diagnosis (LV_ERR_RLY_ACCOUT)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_RLY_ACCOUT	V/O	0...1H	0...1	1	[-]
Boolean for error currently present on RLY_ACCOUT command signal.					
LV_CDN_DIAG_RLY_ACCOUT	V/O	0...1H	0...1	1	[-]
Diagnosis condition RLY_ACCOUT diagnosis					
ERR_SYM_RLY_ACCOUT	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Error symptom RLY_ACCOUT diagnosis					
LV_END_DIAG_RLY_ACCOUT	V/O	0...1H	0...1	1	[-]
End of diagnosis RLY_ACCOUT diagnosis					
LV_INH_DIAG_RLY_ACCOUT	V/O	0...1H	0...1	1	[-]
Diagnosis inhibition RLY_ACCOUT diagnosis					
CDN_DIAG_RLY_ACCOUT	V	0...7H	0...7	1	[-]
Diagnosis condition for each symptom of RLY_ACCOUT bit 0: diagnosis condition for symptom SCP (SYM_0) bit 1: diagnosis condition for symptom SCG (SYM_1) bit 2: diagnosis condition for symptom OC (SYM_2)					
ERR_DIAG_RLY_ACCOUT	-	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Raw value of error symptom for RLY_ACCOUT (only parameter)					

Input data:

LV_IGK	LV_CDN_VB_MIN_DIAG	LV_VAR_ACIN	LV_ERR_SPI_MPS
LV_VAR_RLY_ACCOUT			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the air condition relay signal.

The diagnosis is only active if “Vehicle with ACC” is learnt.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> Short circuit to Vbatt              (= SYM_0)
 │  │  └────> Short circuit to GND                (= SYM_1)
 │  └───────> Open load                           (=SYM_2)
 └──────────> -                                   (=SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Recurrence: 1s

Activation: LV_VAR_RLY_ACCOUT = 1 **AND**

LV_VAR_ACIN = 1

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_RLY_ACCOUT = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_RLY_ACCOUT .
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_RLY_ACCOUT.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG RLY_ACCOUT and ERR_DIAG_RLY_ACCOUT.

This algorithm determines:

ERR_SYM_RLY_ACCOUT	(Detected error symptom)
LV_ERR_RLY_ACCOUT	(Error flag for debounced error)
LV_CDN_DIAG_RLY_ACCOUT	(Diagnosis condition information)
LV_END_DIAG_RLY_ACCOUT	(End of diagnosis information)

Diagnosis inhibition:

```
IF      LV_IGK = 1                    AND
        LV_CDN_VB_MIN_DIAG = 1        AND
        LV_ERR_SPI_MPS = 0
THEN    LV_INH_DIAG_RLY_ACCOUT = 0
ELSE    LV_INH_DIAG_RLY_ACCOUT = 1
ENDIF
```

Calibration data:

Input data:

LV_IGK	LV_CDN_VB_MIN_DIAG	LV_VAR_EBOX_CFA	LV_ERR_SPI_MPS

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the signal from the driver which controls the EBOX cooling fan.

The input signal is modulated control pulse (PWM).

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Vbatt        (= SYM_0)
 │ │ └───> Short circuit to GND          (= SYM_1)
 │ └─────> Open load                     (=SYM_2)
 └───────> -                             (=SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Recurrence: 1s

Activation: LV_VAR_EBOX_CFA = 1

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_EBOX_CFA = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_EBOX_CFA.
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_EBOX_CFA.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_EBOX_CFA and ERR_DIAG_EBOX_CFA.

This algorithm determines:

ERR_SYM_EBOX_CFA	(detected error symptom)
LV_ERR_EBOX_CFA	(Error flag for debounced error)
LV_CDN_DIAG_EBOX_CFA	(Diagnosis condition information)
LV_END_DIAG_EBOX_CFA	(End of diagnosis information)

Diagnosis inhibition:

```
IF      LV_IGK = 1                  AND
        LV_CDN_VB_MIN_DIAG = 1      AND
        LV_ERR_SPI_MPS = 0
THEN    LV_INH_DIAG_EBOX_CFA = 0
ELSE    LV_INH_DIAG_EBOX_CFA = 1
ENDIF
```

Calibration data:

Input data:

LV_IGK	LV_CDN_VB_OBD1	LV_VAR_RLY_ST	LV_ST_END
LV_ERR_SPI_MPS			

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the starter signal from the driver which switches the output signal for the CAS - ECU. This diagnosis detects electrical faults as defined by OBD I requirements. The diagnosis is only performed if the variant “BN2000” is enabled.

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”

Error-symptoms are defined to this diagnosis function as following :

```
□□□□
 | | | └-> Short circuit to Vbatt        (= SYM_0)
 | | └---> Short circuit to GND          (= SYM_1)
 | └-----> Open load                     (= SYM_2)
 └-------> -                             (= SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Recurrence: 50ms in case of LV_ST_END = 0

1000ms in case of LV_ST_END = 1

Activation: LV_VAR_RLY_ST = 1

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_RLY_ST = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_RLY_ST.
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_RLY_ST.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_RLY_ST and ERR_DIAG_RLY_ST.

This algorithm determines:

ERR_SYM_RLY_ST	(detected error symptom)

Raw value of error symptom for SLV_IVVT_EX (only parameter)					

Input data:

LV_CDN_VB_OBD1	LV_IGK	IVVTPWM_0	IVVTPWM_1

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis is to detect electrical faults in the IVVT unit.

The input signal is a modulated control pulse (PWM).

Description:

For error detection algorithm see “Electrical diagnosis of powerstage outputs ATIC39”.
The diagnosis condition calculation is done according **“Open range”** duty cycle, thus a definition of the PWM diagnosis windows is neccessary (see calibration data).

Error-symptoms are defined to this diagnosis function as following :

```
☐☐☐☐
 | | | └─> Short circuit to VBatt          (= SYM_0)
 | | └───> Short circuit to GND            (= SYM_1)
 | └─────> Open load                       (= SYM_2)
 └───────> -                               (= SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**
(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Recurrence: 100ms

Activation: at every engine operating state

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_SLV_IVVT_IN/EX = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_SLV_IVVT_IN/EX.
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_SLV_IVVT_IN/EX .

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_SLV_IVVT_IN/EX and ERR_DIAG_SLV_IVVT_IN/EX.

This algorithm determines:

ERR_SYM_SLV_IVVT_IN/EX	(detected error symptom)
LV_ERR_SLV_IVVT_IN/EX	(Error flag for debounced error)
LV_CDN_DIAG_SLV_IVVT_IN/EX	(Diagnosis condition information)
LV_END_DIAG_SLV_IVVT_IN/EX	(End of diagnosis information)

Diagnosis inhibition:

IF LV_IGK = 1 **AND**

```
        LV_CDN_VB_OBD1 = 1          AND
        LV_ERR_SPI_MPS = 0

FUNCTION DESCRIPTION:

General information:

This module is the heart of the dynamic error management function. It defines statement of principles and mechanism of dynamic error management function.

Dynamic error management receives results from diagnosis function (may be filtered by antibounce algorithm). These results are, in this module, managed as diagnosis failure following **CARB** and **EOBD** standards.

In addition, this module uses generic services defined by others modules (priority rules for example).

27.11.1 Diagnosis failure description

27.11.1.1 Failures definition

Description:

Dynamic error management manages failures, which have different states.

Detected failure

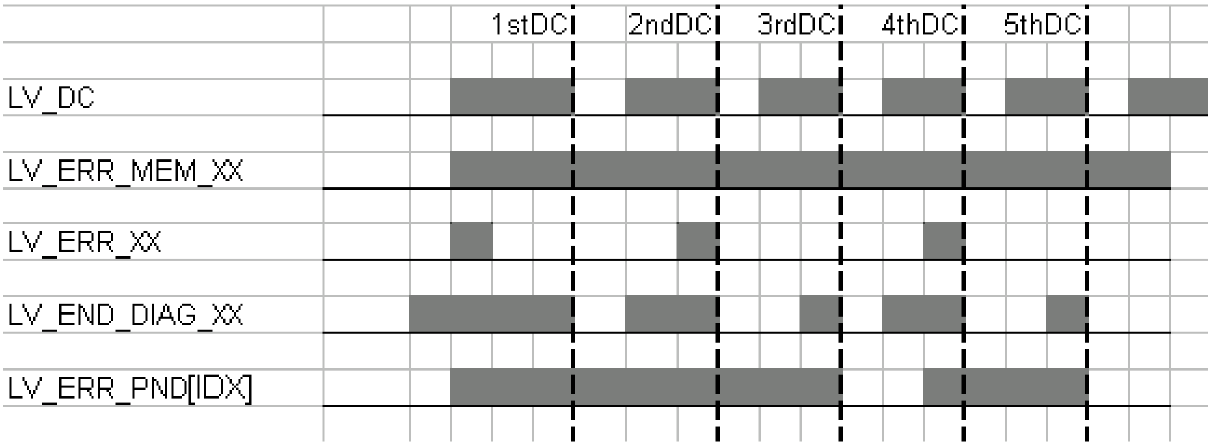
The detected failure is provided by a defective system (the error provided by this system is basic). It occurs when the diagnosis test and diagnosis condition of at least one symptom or more are true and disappears in other cases.

Present failure

The present failure is the detected failure after filtering. The real entry point of the error management is the present failure.

Pending failure

The pending failure is the detected failure after filtering. The failure shall stay pending until detection of a whole driving cycle without the failure present and the diagnosis done.



Temporary failure

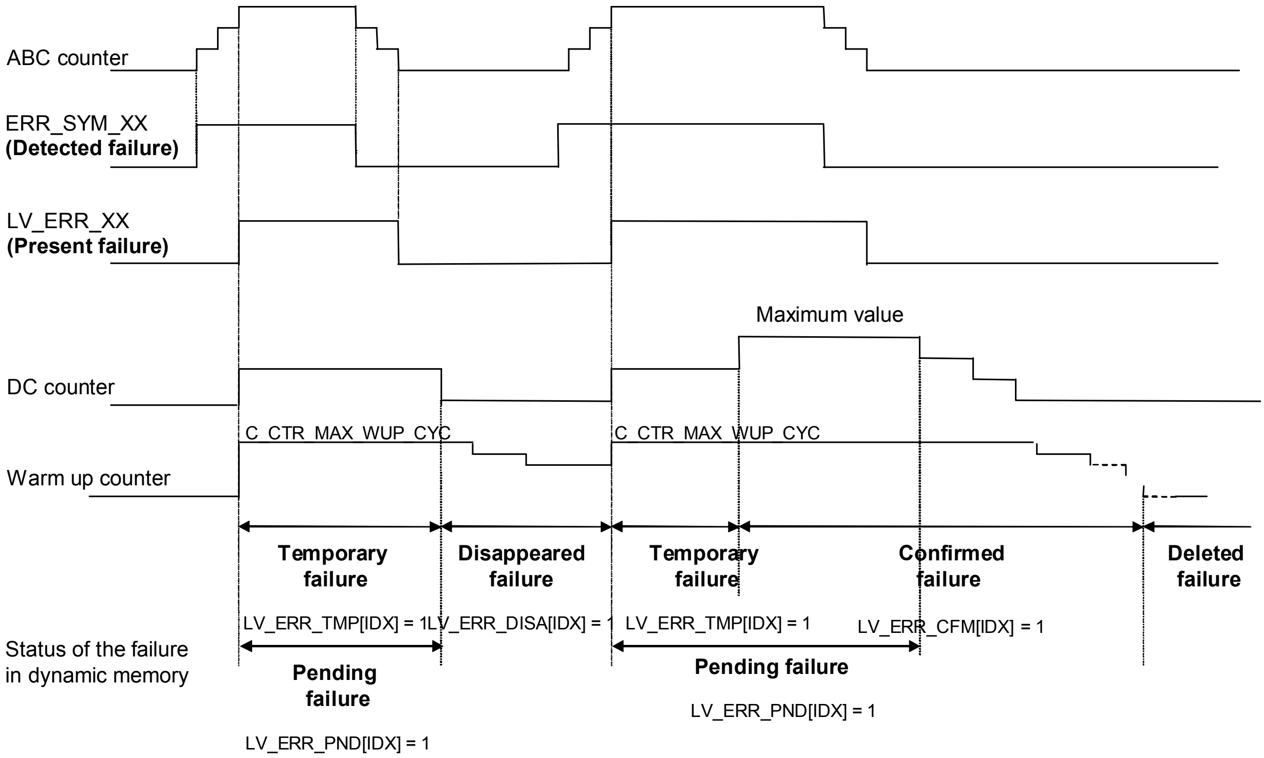
A failure is considered as temporary when this failure is present and leaves this state either when this failure is confirmed or disappeared (in this case, this failure isn't confirmed).

Disappeared failure

A failure is considered as disappeared, when no failure was detected during a complete driving cycle and the failure wasn't confirmed. It leaves this state either when the failure reoccurs or when the warm-up counter reaches 0.

Confirmed failure

A failure is considered as confirmed when the driving cycle counter reaches the maximum value and leaves this state when the warm-up counter reaches 0.



with XX = F(IDX)

27.11.1.2 Failures information

Description:

Each failure is constituted of informations, which are stored in the memory.

Some informations are allocated in the static memory. It means that these informations are available for each failure.

Static memory: XX represents any failure defined in the application (index of XX∈[1...65535])

- ABC counter	CTR_ABC_XX
- End of diagnosis counter	CTR_ABC_END_DIAG_XX
- End of diagnosis flag	LV_END_DIAG_XX
- Readiness flag	LV_READY_XX
- Diagnosis condition	LV_CDN_DIAG_XX
- Detected symptom	ERR_SYM_XX
- Present failure	LV_ERR_XX
- Failure is stored in dynamic memory	LV_ERR_MEM_XX

Some informations are allocated in the dynamic memory. It means that these informations are created in memory in case of a new dynamic failure entry (limited number of dynamic entries managed with priority rules).

Dynamic memory : IDX∈ [0...NC_NR_ERR_DYN-1]

- Frequency counter	CTR_FRC[IDX]
- Driving cycle counter	CTR_DC[IDX]
- Warm up counter	CTR_WUP_CYC[IDX]
- Memorized the first symptom (DTC)	ERR_SYM_MEM[IDX]
- Memorized the last symptom (DTC)	ERR_SYM_LST[IDX]
- Environmental data (Freeze frame)	ENVD_OBD[u][m] ENVD_CUS_CMN[v][m] ENVD_CUS_SET_CMN[W][x][m] ENVD_CUS_SET_SPC[y][z][m]
- Confirmed failure	LV_ERR_CFM[IDX]
- Disappeared failure	LV_ERR_DISA[IDX]
- Memorized MIL activation flag	LV_DC_MAX[IDX]
- Failure during DC	LV_ERR_DC[IDX]
- Temporary failure	LV_ERR_TMP[IDX]
- Pending failure	LV_ERR_PND[IDX]
- Marked failure	LV_ERR_MKD[IDX]

Remark :

To keep the link between the index of the failure in dynamic memory and the index of the failure in static memory, a transfer function is defined by : XX = F (IDX)

with m=IDX_FRF[IDX]

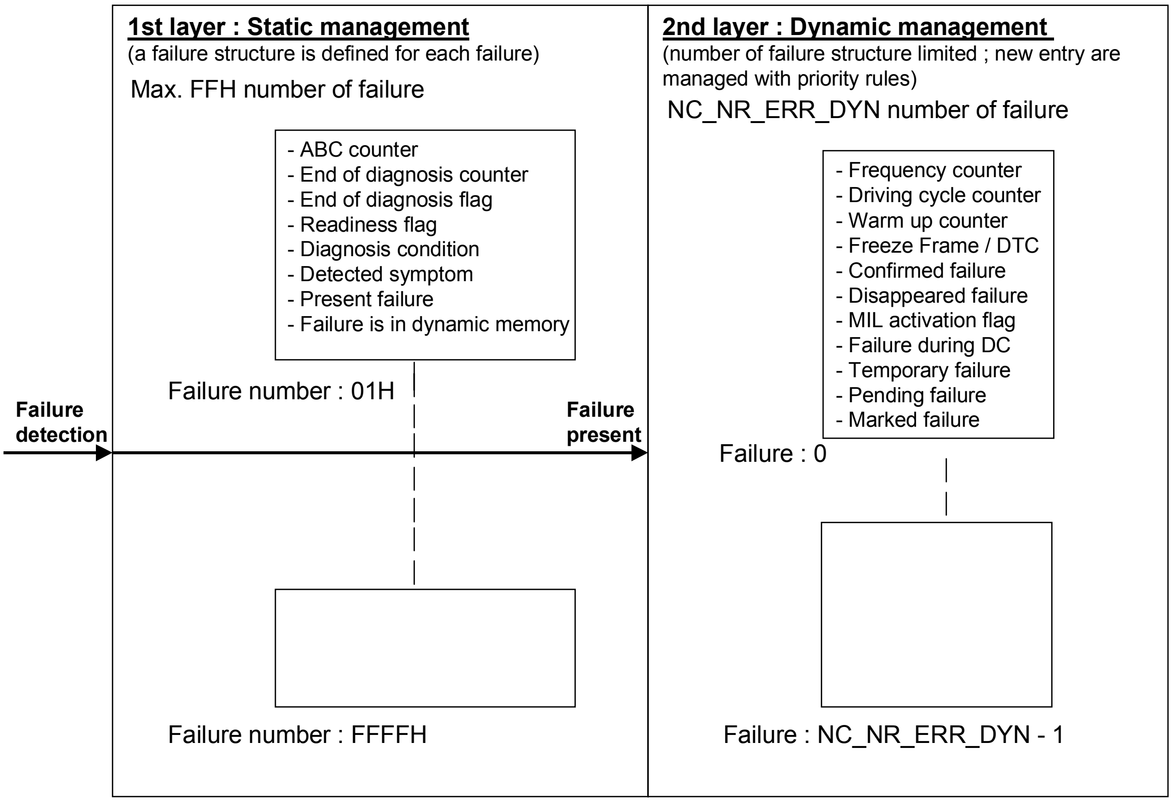
27.11.2 Memory management

Description:

As explained above, the memory is managed as two layers.

The first layer is managed as static memory. According to failure detection, ABC counter and end of diagnosis counter are incremented or decremented. Present failure information is the output of this layer. All failures are managed in the first layer.

When a present failure appears, it may provoke a dynamic entry in the second layer (dynamic) of the memory. In this second layer, only present failures are managed. The number of failure structure is limited to a maximum value defined by NC_NR_ERR_DYN.



27.11.2.1 Failures configuration

Description:

For every diagnosis two bytes exist to configure the failure. The following items can be influenced :

- control of dashboard lamp (MIL and/or Warning lamp 1 and/or Warning lamp 2)
- the emission relevance of a failure
- failure priority, used for failure storage

The definition of these bytes is done in Failure Class module.

27.11.2.2 Store / Erase a failure in 2nd layer memory

Description:

This module manages the “Entry” (storage) and “Exit” (deleting) of failures in the 2nd layer memory.

Storage :

Syntax : ACTION_ERRM_StoreErr (IN <XX>)

Parameter (in) : XX number of the failure to store in dynamic memory

Parameter (out) : -

Short description :

If other modules call the action to store the failure XX with ACTION_ERRM_StoreErr (IN<XX>) then the failure XX (with XX = F(IDX)) is taken into the 2nd layer memory and :

- frequency counter (number of occurrences of present failure) is updated ;
- the DTC is stored with ACTION_ERRM_StoreDtc (IN<IDX>) (if needed) ;
- the Freeze Frame is stored with ACTION_ERRM_StoreFrf (IN<IDX>) ;
- the index of diagnosis instance XX is stored in DIAG_INST[IDX] for visualisation

Deleting :

Syntax : ACTION_ERRM_EraseErr (IN <IDX>)

Parameter (in) : IDX index of failure in 2nd layer memory to erase

Parameter (out) : -

Short description :

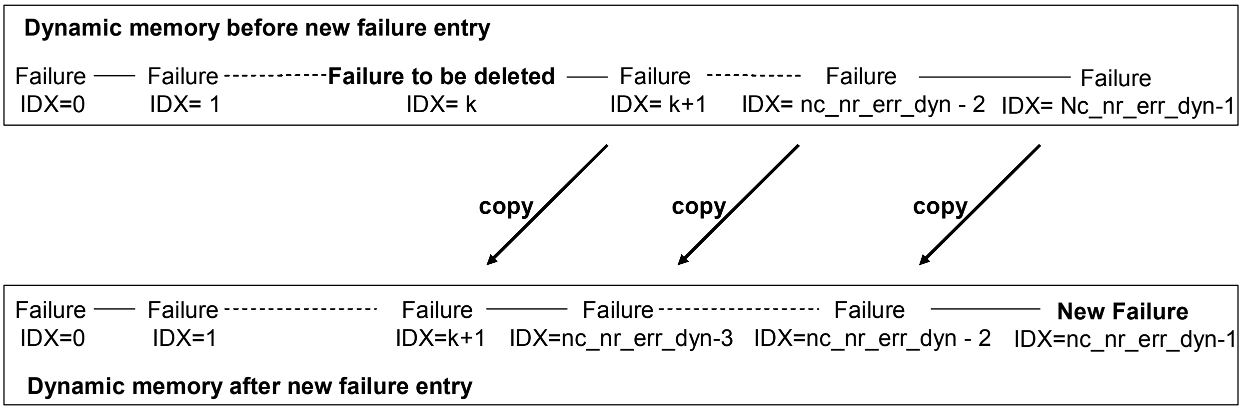
If other modules call the action to erase the failure XX with ACTION_ERRM_EraseErr (IN<IDX>) then the failure IDX is taken out of the 2nd layer memory and :

- the failure is stored in history memory with ACTION_ERRM_StoreHistory (IN<IDX>) ;
- the DTC of the failure is erased with ACTION_ERRM_EraseDtc (IN<IDX>) ;
- the Freeze Frame of the failure is erased with ACTION_ERRM_EraseFrf (IN<IDX>) ;
- similar conditions of the failure are erased with ACTION_ERRM_EraseScdn (IN<XX>) if existing

2nd layer memory description :

It is useful to sort the failures in the sequence in which they occurred ; first failure has index (IDX) number zero, second failure has index (IDX) number one, ... For example, when a new failure entry is accepted (memory is full), one failure is deleted, sorting algorithm is respected and the new failure entry is stored in last position.

In any case, sorting algorithm must be always respected.



Application conditions:

Initialization : On saved RAM lost

CTR_ERR_DYN_NR = 0 ; LV_ERR_MEM_XX = 0

CTR_FRC[IDX] = 0; LV_ERR_TMP[IDX] = 0; LV_ERR_MKD[IDX] = 0

DIAG_INST[IDX] = 0;

Recurrence: -

Activation: at Action request

Formula section:

Store the failure in 2nd layer memory :

```
ACTION_ERRM_StoreErr (IN <XX>) :
    If      LV_ERR_MEM_XX = 0
    Then    Failure XX is stored in 2nd layer memory in position IDX = CTR_ERR_DYN_NR
            LV_ERR_MEM_XX = 1
            LV_ERR_TMP[IDX] = 1
            DIAG_INST[IDX] = index of diagnosis instance XX (with XX=F(IDX))
            ACTION_ERRM_StoreDtc (IN<IDX>, SYNCHRONIZATION<CALL>)
            CTR_ERR_DYN_NR = CTR ERR_DYN_NR +1
            If      LV_MKD_MOD = 1
            Then    LV_ERR_MKD[IDX] = 1
            Endif
```

```
Else    ( IDX compliant with XX = F(IDX) )
Endif
CTR_FRC[IDX] = CTR_FRC[IDX] + 1
If      CTR_FRC[IDX]  > 255
Then    CTR_FRC[IDX] = 255
Endif
ACTION_ERRM_StoreFrf (IN<IDX>, SYNCHRONIZATION<CALL>)
(previous failure status (if disappeared) necessary for freeze frame calculation)
If      LV_ERR_DISA[IDX] = 1
Then    LV_ERR_DISA[IDX] = 0
        LV_ERR_TMP[IDX]  = 1
        ACTION_ERRM_StoreDtc (IN<IDX>, SYNCHRONIZATION<CALL>)
        (Store DTC corresponding of the first occurrence of the failure)
Endif
LV_ERR_PND[IDX] = 1
ACTION_ERRM_StoreDtcLst (IN<IDX>, SYNCHRONIZATION<CALL>)
(Store DTC corresponding of the last occurrence of the failure)
```

Clear the failure out of 2^{nd} layer memory

```
ACTION_ERRM_EraseErr (IN<IDX>) :
ACTION_ERRM_StoreHistory (IN<IDX>, SYNCHRONIZATION<CALL>)
ACTION_ERRM_EraseDtc (IN<IDX>, SYNCHRONIZATION<CALL>)
ACTION_ERRM_EraseFrf (IN<IDX>, SYNCHRONIZATION<CALL>)
If      failure is using similar conditions functionality (see Similar conditions Appli.Inc.)
        (LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)
Then    ACTION_ERRM_EraseScdn (IN<XX>, SYNCHRONIZATION<CALL>)
        (with XX=F(IDX))
Endif
Failure XX (with XX=F(IDX)) is cleared (all data in 2nd layer memory related to failure
IDX are filled with 0 ; all data in static memory related to failure XX are unchanged)
LV_ERR_MEM_XX = 0 (with XX = F(IDX))
CTR_ERR_DYN_NR = CTR_ERR_DYN_NR –1
```

Temporary flag management :

For each failure in 2nd layer memory

```
    If      LV_ERR_CFM[IDX] = 1
            or LV_ERR_DISA[IDX] = 1
    Then    LV_ERR_TMP[IDX] = 0
    Endif
```

27.11.2.3 Clear failure memory

Description:

For development conveniences, it is often useful to reinit all failure in the memory. This is possible by setting the calibration bit LC_ERR_FMY_CLR to 1.

Application conditions:

Initialisation:	-
Recurrence:	-
Activation:	0 → 1 transition of LC_ERR_FMY_CLR

Formula section:

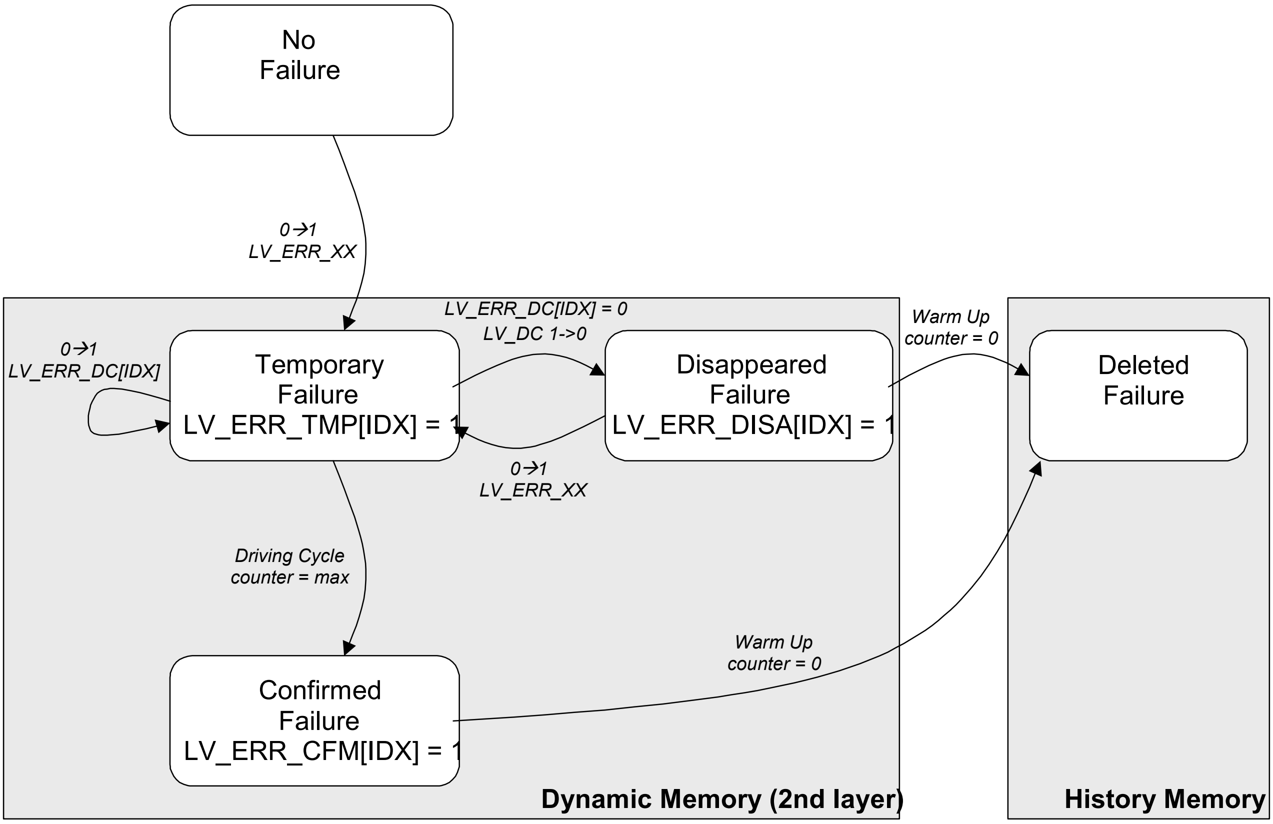
```
If      LC_ERR_FMY_CLR = 1
Then    Reset failure memory (all data in 2nd layer memory and all data in static memory)
        CTR_ERR_DYN_NR = 0
Endif
```

27.11.3 Failure management

27.11.3.1 State diagram

Description:

In the following diagram, the failure state progress is described.



There are also additional transitions possible due to :

- Overwriting/Erasement by priority rule or Tool Request :

Temporary Failure	→	Deleted Failure
Disappeared Failure	→	Deleted Failure
Confirmed Failure	→	Deleted Failure

	Driving Cycle counter value	Warm Up counter value
No Failure	0	0
Temporary Failure	[0, Max [without having reached Max	Max
Confirmed Failure	[0, Max] with having reached Max	] 0, Max]
Disappeared Failure	0	] 0, Max]
Deleted Failure	0	0

27.11.3.2 Present failure occurred

Description:

When a failure occurs (becomes present), this failure shall be stored in the 2nd layer memory (if possible). If the 2nd layer memory is full and marked mode is not set, a choice is made in the module "Priority rules" :

- RESP is set to OK by priority rules, if the failure can be stored in the 2nd layer memory ; in this case IDX gives the index of the failure to be replaced into dynamic memory;
- RESP is set to NOK by priority rules if the failure can't be stored in the 2nd layer memory.

To monitor the failure, ACTION_ERRM_TrigErrDyn shall be called when the failure occurs (the failure is evaluated or re-evaluated) or the failure is removed.

Application conditions:

Initialisation: -

Recurrence: -

Activation: at LV_END_DIAG_XX 0 → 1 transition

with (LV_ERR_XX = 1 **and** LV_ERR_MEM_XX = 1)

or

at LV_ERR_XX 1 → 0 transition

(due to the physical default disappears only: it means that a clear failure memory or diagnosis initialization aren't activation condition)

Formula section:

ACTION_ERRM_TrigErrDyn (IN<XX>, SYNCHRONIZATION<CALL>)
This action is called to indicate that a new failure has occurred, although failure is not stored.

Application conditions:

Initialisation: -

Recurrence: -

Activation: LV_ERR_XX 0 → 1 transition **with** LV_END_DIAG_XX = 1

or

LV_END_DIAG_XX 0 → 1 transition

with (LV_ERR_XX = 1 **and** LV_ERR_MEM_XX = 0)

Formula section:

If (1) CTR_ERR_DYN_NR < NC_NR_ERR_DYN

```
          or        LV_ERR_MEM_XX = 1
Then (1)  ACTION_ERRM_StoreErr (IN<XX>, SYNCHRONIZATION<CALL>)
Else (1)  If (2)    LV_MKD_MOD = 0
          Then (2)  ACTION_ERRM_PrioRule (OUT<RESP>, OUT<IDX>,
                    SYNCHRONIZATION<CALL>)
                    If (3)    RESP = OK
                    Then (3)  ACTION_ERRM_EraseErr (IN<IDX>,
                              SYNCHRONIZATION<CALL>)
                              ACTION_ERRM_StoreErr (IN<XX>,
                              SYNCHRONIZATION<CALL>)
                    Endif (3)
          Endif (2)
Endif (1)
```

ACTION_ERRM_TrigErrDyn (IN<XX>, SYNCHRONIZATION<CALL>)
This action is called to indicate that a new failure has occurred.

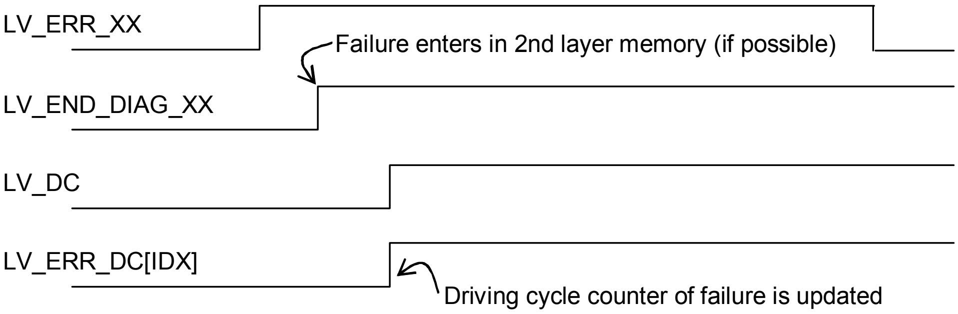
27.11.3.3 Error occurred during present driving cycle

Description:

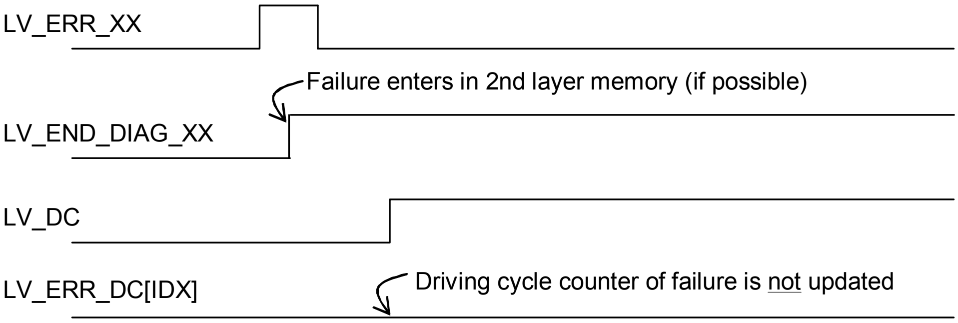
An active flag called LV_ERR_DC[IDX] indicates that an error XX (with XX = F(IDX)) has occurred during a driving cycle.

Even if the error disappears during the driving cycle, the flag remains active during the whole driving cycle.

Failure present, then driving cycle is recognized, then failure not present



Failure present, then failure not present, then driving cycle is recognized



Application conditions:

Initialisation: at ECU reset **or** transition LV_DC 1->0 after treatment done at this event

LV_ERR_DC[IDX] = 0

Recurrence: same as the diagnosis routine

all failures are updated at transition 0->1 of LV_DC

Activation: at every engine operating state

Formula section:

If LV_ERR_XX = 1 (failure is present)

and LV_END_DIAG_XX =1 (current diagnosis is available)

```
        and LV_DC = 1               (within driving cycle)
        and LV_ERR_MEM_XX =1        (failure is stored in dynamic memory)
    Then    LV_ERR_DC[IDX] = 1      (it remains 1 until the next initialization)
    Endif
```

27.11.3.4 Driving Cycle Counter management

Description:

The driving cycle counter CTR_DC[IDX] is associated to each failure which has a structure defined in second layer of memory.

This counter is incremented at each driving cycle in the following way:

- for all failures not using SCDN functionality (withLC_ENA_SCDN=0 or NLC_ENA_SCDN=0), when the associated failure gets present (LV_ERR_DC[IDX]).
- for failures using SCDN functionality (with LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)
  - when the failure gets present the first time (and stored)
  - when the failure gets present again in a following driving cycle
  - when the failure gets present again in another driving cycle (not previous) (driving cycle counter of this failure is != 0/max before new occurrence), if the similar conditions functionality decides, that the incrementation is possible

The driving cycle counter is decremented at the end of a driving cycle in the following cases:

- for all failures not using SCDN functionality (or LC_ENA_SCDN=0 or NLC_ENA_SCDN=0), when the associated failure was not present the complete DC (LV_ERR_DC[IDX] = 0).
- for failures using SCDN functionality (with LC_ENA_SCDN=1 and NLC_ENA_SCDN=1)
  - when similar conditions are encountered without failure (for failure with present MIL illumination)
  - when the similar conditions functionality decides that the decrementation is possible (for temporary failure or confirmed failure with no present MIL illumination)

The driving cycle counter is useful for MIL management and warm-up counter management (see specific chapter).

With the calibration LC_ENA_SCDN it's possible to enable/disable the similar conditions functionality. If LC_ENA_SCDN = 0 the failures using SCDN functionality (see similar conditions Appl.Inc) are treated like normal failures in the driving cycle counter management.

Application conditions:

Initialization: On saved RAM lost

LV_DC_MAX[IDX] = 0
CTR_DC[IDX] = 0
LV_ERR_DISA[IDX] = 0
LV_ERR_CFM[IDX] = 0

Recurrence: -

Activation: -

Formula section:

Treatment for all failures not using SCDN functionality (with LC_ENA_SCDN=0 or NLC_ENA_SCDN=0) stored in 2^{nd} layer memory :

Conditions to increment the driving cycle counter :

```
At LV_ERR_DC[IDX] 0 → 1 transition
LV_ERR_DISA[IDX] = 0
If      LV_DC_MAX[IDX] =1                       (for confirmed failure with MIL ON)
Then    CTR_DC[IDX] = DC_MAX_XX                        (counter is forced to max.)

Else    CTR_DC[IDX] = CTR_DC[IDX] + DC_INC_XX
        If      CTR_DC[IDX] ≥ DC_MAX_XX
        Then    CTR_DC[IDX] = DC_MAX_XX
                LV_DC_MAX[IDX] = 1                     (failure becomes confirmed)
                LV_ERR_CFM[IDX] = 1
        Endif
Endif
```

Conditions to decrement the driving cycle counter :

```
At transition LV_DC 1 -> 0:
If      LV_ERR_DC[IDX] = 0
        and     LV_END_DIAG_XX  = 1
Then    LV_ERR_PND[IDX] = 0                            (Pending fault is erased)
        If      LV_ERR_CFM[IDX] = 1                    (for confirmed failure)
        Then    If LV_DC_MAX[IDX] =1
                Then    CTR_DC[IDX] = CTR_DC[IDX] - DC_DEC_XX
                        If      CTR_DC[IDX] ≤ 0
                        Then    LV_DC_MAX[IDX] = 0
                                CTR_DC[IDX] = 0
                        Endif
                Else    CTR_DC[IDX] = 0
                Endif
        Else                                           (for temporary failure)
                CTR_DC[IDX] = 0
                LV_ERR_DISA[IDX] = 1                   (failure disappeared)
        Endif
```

Endif

Treatment for failures using SCDN functionality (LC_ENA_SCDN=1 and NLC_ENA_SCDN=1) (running within DC) stored in 2nd layer memory.

Conditions to increment the driving cycle counter :

Done upon ACTION_ERRM_IncrementDCctrSCDN call:

(see also similar conditions specification)

Description:

Syntax :	ACTION_ERRM_IncrementDCctrScdn (IN <XX>)	
Parameter (in) :	XX	failure in static memory with XX=F(IDX)
Parameter (out) :		

Short description:

With the ACTION_ERRM_IncrementDCctrScdn (IN <XX>) the driving cycle counter for the failure XX stored in 2nd layer memory at position IDX, which is using similar conditions functionality, is incremented. This action is called at the end of a diagnosis window in the following cases :

- failure occurred and similar conditions are recorded
- failure already stored in a previous driving cycle. Now failure gets present again and was also present in last driving cycle.
- failure already stored in a previous driving cycle. Now failure gets present again with SCDN recognition for detected failure.
- failure already stored in a previous driving cycle and LV_DC_MAX[IDX] = 1 (MIL is illuminated, if LC_MIL_ON =1).

For details see similar conditions specification.

Application conditions:

Initialization:	-
Recurrence:	-
Activation:	at action request

Formula section:

ACTION_ERRM_IncrementDCctrScdn (IN<XX>) :

```
If      LV_ERR_MEM_XX = 1              (failure XX is stored in 2nd layer memory)
Then    LV_ERR_DISA[IDX] = 0
        If    LV_DC_MAX[IDX] =1        (for confirmed failure with MIL on)
        Then  CTR_DC[IDX] = DC_MAX_XX        (counter is forced to max.)
        Else  ACTION_ERRM_ConfirmErrScdn (OUT<DCconf>, IN<XX>,
              SYNCHRONIZATION<CALL>)
              (allows direct failure confirmation; see similar conditions Appl.Inc.)
              If      DCconf = YES
```

```
                    Then   CTR_DC[IDX] = DC_MAX_XX        (counter is forced to max.)
                    Else   CTR_DC[IDX] = CTR_DC[IDX] + DC_INC_XX
                    Endif
                    If     CTR_DC[IDX] ≥ DC_MAX_XX
                    Then   CTR_DC[IDX] = DC_MAX_XX
                           LV_DC_MAX[IDX] = 1             (failure confirmed)
                           LV_ERR_CFM[IDX] = 1
                           LV_ERR_TMP[IDX] = 0
                    Endif
            Endif
Endif
```

Conditions to decrement the driving cycle counter :

At transition LV_DC 1 -> 0:

```
If          LV_ERR_DC[IDX] = 0
            and    LV_END_DIAG_XX  = 1
Then        ACTION_ERRM_DecrementDCctrSCDN (OUT<DCdec>, IN<XX>,
            SYNCHRONIZATION<CALL>)        (with XX=F(IDX))
            The similar conditions functionality decides, if it's possible to decrement the
            driving cycle counter.
            If     DCdec = YES                            (decrementing is possible)
            Then   LV_ERR_PND[IDX] = 0                    (Pending fault is erased)
                   If     LV_ERR_CFM[IDX] = 1             (for confirmed failure)
                   Then   If     LV_DC_MAX[IDX] = 1
                          Then   CTR_DC[IDX] = CTR_DC[IDX] - DC_DEC_XX
                                 If     CTR_DC[IDX] ≤ 0
                                 Then   LV_DC_MAX[IDX] = 0
                                        CTR_DC[IDX] = 0
                                 Endif
                          Else
                                 CTR_DC[IDX] = 0
                          Endif
                   Else                                   (for temporary failure)
                      CTR_DC[IDX] = 0
                      LV_ERR_DISA[IDX] = 1                (failure disappeared)
                   Endif
            Endif
```

```
Endif
```

27.11.3.5 Warm-Up counter management

Description:

As soon as the failure gets present and stored in the memory, the warm-up cycle counter is initialized.

With every valid warm-up cycle with no error occurrence, the warm-up cycle counter is decremented by 1. If the warm-up cycle counter reaches zero the error is deleted from the 2nd layer memory.

Application conditions:

Initialization: on saved ram lost
CTR_WUP_CYC[IDX]= 0
Recurrence: -
Activation: only at transition LV_DC 1 -> 0

Formula section:

Treatment for all failures not using SCDN functionality (or LC_ENA_SCDN = 0) stored in 2nd layer memory :

Condition to decrement the warm up counter :

The following treatment is done for all failure stored in 2nd layer memory **and only at transition LV_DC 1 -> 0** (**before** treatment of driving cycle counter decrementing at end of driving cycle):

```
If      ( LV_WUP_CYC = 1  and    C_CTR_MAX_WUP_CYC != 255 )
        the warm-up cycle is recognised and failure healing is possible
Then    If      ( CTR_DC[IDX] = 0   and    LV_ERR_DC[IDX] = 0 )
                the MIL is extinguished and no failure in this driving cycle
                or
                ( CTR_DC[IDX] != 0 and LV_DC_MAX[IDX] = 0
                case before the MIL may be illuminated
                and LV_ERR_DC[IDX] = 0 and LV_END_DIAG_XX = 1 )
                the failure is no more pending
        Then    CTR_WUP_CYC[IDX] = CTR_WUP_CYC[IDX] - 1
                If      CTR_WUP_CYC[IDX] = 0
                        Then   ACTION_ERRM_EraseErr (IN<IDX>,
                        SYNCHRONIZATION<CALL>)
                Endif
        Endif
Endif
```

Treatment for failures using SCDN functionality (and LC_ENA_SCDN = 1) (running within DC) stored in 2nd layer memory.

Condition to decrement the warm up counter :

The following treatment is done for all failure stored in 2nd layer memory **and only at transition LV_DC 1 -> 0** (**before** treatment of driving cycle counter decrementation at end of driving cycle):

```
If      ( LV_WUP_CYC = 1  and   C_CTR_MAX_WUP_CYC != 255 )
        the warm-up cycle is recognized and failure healing is possible
Then    If      ( CTR_DC[IDX] != 0 and LV_DC_MAX[IDX] = 0
                case before the MIL may be illuminated
                and LV_ERR_DC[IDX] = 0 and LV_END_DIAG_XX = 1 )
        then    ACTION_ERRM_DecrementDCctrSCDN (OUT<DCdec>, IN<XX>,
                SYNCHRONIZATION<CALL>) (with XX=F(IDX))
        The similar conditions functionality decides, if it's possible to decrement the
        driving cycle counter.
                If      DCdec = YES                (the failure is no more pending)
                Then    CTR_WUP_CYC[IDX] = CTR_WUP_CYC[IDX] - 1
                        If      CTR_WUP_CYC[IDX] = 0
                                Then  ACTION_ERRM_EraseErr (IN<IDX>,
                                SYNCHRONIZATION<CALL>)
                        Endif
                Endif
        Else    If      ( CTR_DC[IDX] = 0   and   LV_ERR_DC[IDX] = 0 )
                the MIL is extinguished and no failure in this driving cycle
                Then    CTR_WUP_CYC[IDX] = CTR_WUP_CYC[IDX] - 1
                        If      CTR_WUP_CYC[IDX] = 0
                                Then  ACTION_ERRM_EraseErr (IN<IDX>,
                                SYNCHRONIZATION<CALL>)
                        Endif
                Endif
        Endif
Endif
```

Condition to reload the warm up counter :

The following treatment is done for failure XX when it is stored in 2nd layer memory **when ACTION_ERRM_StoreErr (IN<XX>) is called :**

CTR_WUP_CYC[IDX] = C_CTR_MAX_WUP_CYC

27.11.4 Miscellaneous services to get information

27.11.4.1 API for determination of pending status of failures

General information:

This API shall be called to determine if any XX failure is pending or not.

Description:

Syntax:	ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT <PendingStatus>)	
Parameter(in):	XX	Diagnostic instance of the failure
Parameter(out):	PendingStatus	State of the failure : - TRUE : the XX failure is pending (or it's impossible to determine its status) - FALSE : the XX failure is not pending
Short Description:	This API shall be used to verify if a failure stored in the dynamic memory has the pending status or not. When it impossible to determine if the fault is pending or not (failure not store because the dynamic memory is full), this failure should be considered as pending anyway.	

Application conditions:

Initialisation: -

Recurrence: -

Activation: at action call

Deactivation: -

Formula section:

```
If (1)          { the XX failure analysed is present in the dynamic memory }
                LV_ERR_MEM_XX = 1  ( with XX = F(IDX) )
Then (1)
                If (2)          { IDX is the failure index, in the dynamic memory }
                                LV_ERR_PND[IDX] = 1
                Then (2)
                                PendingStatus = TRUE
                Else (2)
                                PendingStatus = FALSE
                Endif (2)
Else (1)
                { failure not stored in the dynamic memory }
```

```
        If (2)      LV_ERR_XX = 1
        Then (2)
                    { the failure is stored in the static memory but it's not present in the
                    dynamic memory : impossible to determine its status }
                    { then the failure shall be considered as pending }
                    PendingStatus = TRUE
        Else (2)
                    { the failure is neither stored in the static memory nor in the
                    dynamic memory }
                    PendingStatus = FALSE
        Endif (2)
    Endif (1)
```

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

TCO_ST_DSL_CMN	V/O	0...FEH	-48...142.5	0.75	[°C]
Coolant temperature at start (used only in ERRM for GS-DS diversity)					

Input data:

TCO	TCO_ST		

Export actions:

ACTION_ERRM_TrigErrDyn (IN <XX>)
This action is called by the error management function when a new failure occurs

27.12.1 Warm-up cycle inhibition

FUNCTION DESCRIPTION:

Description:

Wurm-up cycle is not inhibited

Application conditions:

Initialisation: at ECU reset

LV_INH_WUP_CYC = 0

TCO_DSL_CMN = TCO

TCO_ST_DSL_CMN = TCO_ST

Recurrence: 100 ms

Activation: LV_IGK = 1

Deactivation: -

Formula section:

LV_INH_WUP_CYC = 0

TCO_DSL_CMN = TCO

TCO_ST_DSL_CMN = TCO_ST

27.12.2 API for Trigger Event

General information:

This file defines the Action "ACTION_ERRM_TrigErrDyn" called by the error management function when a failure occurs or disappears.
The contain of this action should be provided by the project team

Description:

Syntax: ACTION_ERRM_TrigErrDyn (IN <XX>)

Parameter (in): XX diagnostic instance of failure ≡ index of failure in static memory

Parameter (out): -

Short description: This action allows to inform the communication tools in line as soon as a failure occurs

Application conditions:

Initialisation: -

Recurrence: -

Activation: at action request

Formula section:

ACTION_ERRM_TrigErrDyn (XX): **additional function not defined yet**

27.13 Cycle manager

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DC	V/O	0...1H	0...1	1	[-]
driving cycle status flag					
LV_WUP_CYC	V/O	0...1H	0...1	1	[-]
Warm-up cycle status flag					
LV_STATE_WUP	V/O	0...1H	0...1	1	[-]
tco state for exceeding the warm-up cycle tco threshold					

Input data:

LV_IGK	LV_ST_END	LV_ES	TCO_DSL_CMN
TCO_ST_DSL_CMN	LV_INH_WUP_CYC		

27.13.1 Driving cycle

FUNCTION DESCRIPTION:

General information:

Description:

A driving cycle consists of a vehicle operation phase from engine startup to engine shutoff and includes the power-lach phase after the engine running phase (In order manage all OBD failures set only in PWL phase).

After key is on, the flag LV_DC is set when the engine exits from “engine start” state.

The flag LV_DC is reset at the end of the power-latch phase before the NVMY management. In case of a LV_IGK 0→1 transition during the powerlatch phase or at ECU reset LV_DC is also reseted.

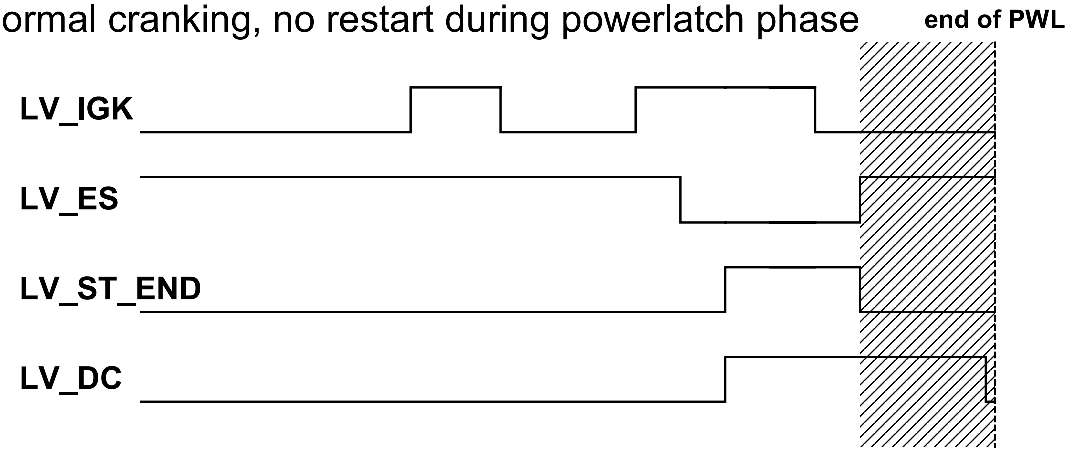
Remark :

For simplification and global coherence, the following rule is applied:

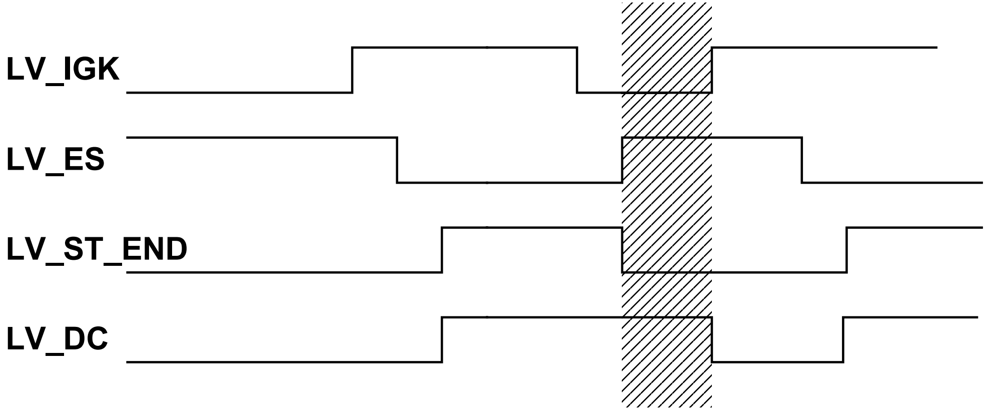
Engine stalling is ignored (if engine restarts after stalling, without key-off/key-on transition, the cycle is considered as the same driving cycle).

Signal flow diagram:

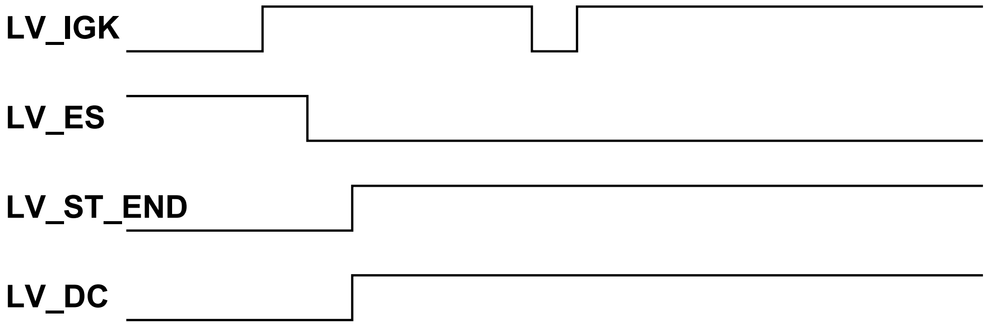
Normal cranking, no restart during powerlatch phase



Normal cranking, with restart during powerlatch phase



Short key off/on while engine is running



Application conditions:

Initialisation: At ECU reset

LV_DC = 0

Before storage of data of the error management within the NVMY the driving cycle is finished.

Recurrence: -

Activation: *see Formula section*

Formula section:

Activation:

```
If      LV_ST_END 0→1 transition
Then
        LV_DC = 1
Endif
```

Deactivation:

```
If      LV_IGK 0→1 transition
        and
        LV_ES =1
Then
        LV_DC = 0
Endif

If      End of power-latch phase is reached (before NVMY storing)
Then
        LV_DC = 0
Endif
```

27.13.2 Warm-Up Cycle and Warm-Up Status

FUNCTION DESCRIPTION:

General information:

The detection of the warm-up cycle is based on the coolant temperature. The warm-up cycle is detected as soon as the coolant temperature reaches C_TCO_WUP_THD and the change with regard to the starting temperature exceeds C_TCO_WUP_INC. These values are defined by law, so a change of these values is only for development validation commodity.

The application must guarantee warm-up cycle detection when a coolant temperature sensor error exists.

Therefore if a coolant temperature sensor error has been debounced, the threshold for warm-up cycle detection are referred to the backup coolant temperature value computed by the engine control (see chapter “Diagnosis and emergency operation“).

The warm-up status is needed for similar driving conditions test.

Application conditions:

Initialisation: *At ECU reset or LV_DC 1→0 transition (after warm-up cycle counter management)*

LV_WUP_CYC =0
LV_STATE_WUP = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

```
If    LV_INH_WUP_CYC = 0
Then
        If      TCO_DSL_CMN > C_TCO_WUP_THD
        Then
                LV_STATE_WUP = 1
                If      TCO_DSL_CMN > (TCO_ST_DSL_CMN + C_TCO_WUP_INC)
                Then
                        LV_WUP_CYC = 1
                Endif
        Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_TCO_WUP_THD	1	0...FEH	-48...142.5	0.75	[°C]
Minimum value for warm-up cycle detection					
C_TCO_WUP_INC	1	0...FEH	-48...142.5	0.75	[°C]
Minimum increase of the coolant temperature for warm-up cycle detection					

Calibration data detailed description:

C_TCO_WUP_THD =	at least 72 °C for gasoline engines	(OBD II requirement)
	at least 70 °C for gasoline engines	(EOBD requirement)
C_TCO_WUP_INC =	at least 23 °C for gasoline engines	(OBD II requirement)
	at least 22 °C for gasoline engines	(EOBD requirement)

In case of Diesel systems, recommended values are the same, except :

C_TCO_WUP_THD = at least 60 °C for gasoline engines (OBD II requirement)

27.14 Environmental data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ENVD_OBD[NC_NR_ENVD_OBD][NC_NR_ERR_DYN]	V/O/S	0...FFH	0...255	1	[-]

Pointer to make the link between the failure and the freeze frame					

Note:

The link between the failure stored in the dynamic error mangement at position *IDX* is made with IDX_FRF[*IDX*]. E. g. a failure stored at the position *IDX* = 2 belongs to freeze frame ENVD_..._[m] with m = IDX_FRF[2]

Input data:

ENVD_CONF_OBD[NC_NR_ENVD_OBD]	ENVD_CONF_CUS_CMN[NC_NR_ENVD_CUS_CMN]	ENVD_CONF_CUS_SET_CMN[NC_NR_ENVD_CUS_SET_CMN]
CTR_FRC[NC_NR_ERR_DYN]	NC_NR_ERR_DYN	LV_ERR_DISA[NC_NR_ERR_DYN]

Export actions:

ACTION_ERRM_StoreFrf (IN <IDX>)
This action stores the freeze frame of the failure IDX
ACTION_ERRM_EraseFrf (IN <IDX>)
This action erases the freeze frame of the failure IDX
ACTION_ERRM_StorePrevFrf (IN <XX>)
This action stores the prestored freeze frame for the diagnosis instance XX

FUNCTION DESCRIPTION:

General information:

This module describes the structure of the freeze frame and manages the storage and deleting of the freeze frame.

A freeze frame is a group of vehicle environment data catched when a failure occurs.

Freeze frame is filled up with variables, which are not limp home values : the variables are set up before going to the limp home.

A freeze frame is made of many parts :

- FRF_OBD: Environmental data, which are common to all failures and stored on time. It’s only updated, if the failure has disappeared before and occurs again.

  The content is defined by law. It’s called usually CARB Freeze Frame and the content is according to SAE J1979.

  Size of this part is defined by configuration data NC_NR_ENVD_OBD affected value is in the Environmental data (Appl. Inc.) module.

  Contents of this part is fixed and defined in Environmental data (Appl. Inc.) module.

- FRF_CUS_CMN : Environmental data, which are common to all failure.

  It’s stored one time, if NC_ ENVD_CUS_CMN_UPD = 0.

  With NC_ ENVD_CUS_CMN_UPD = 1, FRF_CUS_CMN is updated, if the failure was disappeared before and occurs again.

  The content is not required by law.

  Size of this part is defined by configuration data NC_NR_ENVD_CUS_CMN; affected value is in the Environmental data (Appl. Inc.) file.

  Contents of this part is fixed and defined in the Environmental data (Appl. Inc.) module.

- FRF_CUS_SET_CMN : Environmental data, which are common to all failure and stored many times. The content is not required by law. For each failure occurrence several catches (called sets) can be done.

  Size of this part is defined by configuration data, affected value is in the Environmental data (Appl. Inc.) module :

  NC_NR_FRF_SET for number of sets per freeze frame

  NC_NR_ENVD_CUS_SET_CMN for number of common data (in bytes) in each set

  Contents of this part is fixed and defined in the Environmental data (Appl. Inc.) module.

- FRF_CUS_SET_SPC : Environmental data, which are specific to each failure and stored many times. The content is not required by law. For each failure occurrence several catches (called sets) can be done.

  Size of this part is defined by configuration data, affected value is in Environmental data (Appl. Inc.) module :

  NC_NR_FRF_SET for number of sets per freeze frame

  NC_NR_ENVD_CUS_SET_SPC for number of specific data (in bytes) in each set

  Contents of this part is defined by calibration, process is described in the last chapter of this module.

Remark: This signal flow diagram doesn't include the prestored freeze frame functionality described in chapter 1.4.

27.14.1 Freeze frame storage

Description:

Syntax : ACTION_ERRM_StoreFrf (IN <IDX>).

Parameter (in) : IDX Index of failure in 2nd layer memory to store the freeze frame

Parameter (out) : -

Short description :

When the failure IDX gets present, the storage of a freeze frame is done in the 2nd layer memory by calling the action ACTION_ERRM_StoreFrf (IDX).

If several failures occur (TCO sensor, injector 1, injector 4), a freeze frame is stored for each failure. For ram memory limitation, the number of freeze frame is limited to NC_NR_ERR_DYN.

If same failure occurs several times (occurrence of the failure is defined by the frequency counter CTR_FRC[IDX]), the following rules are applied :

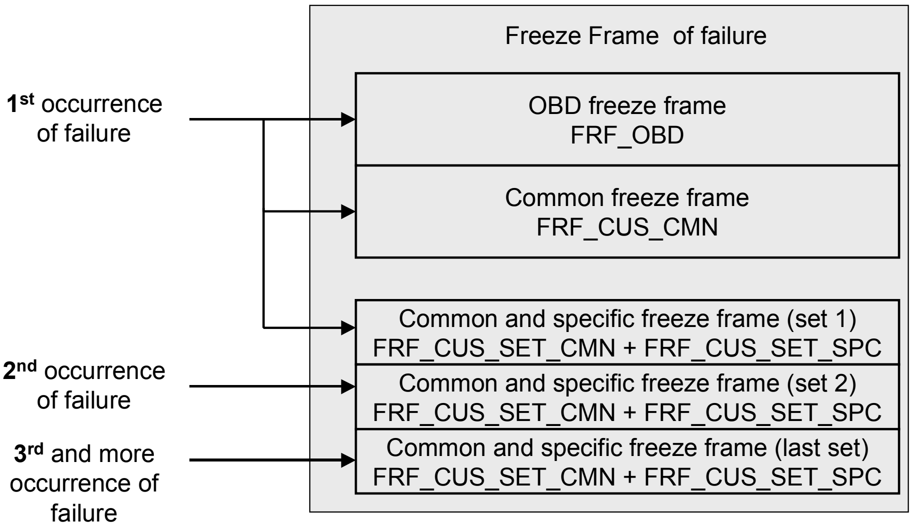
- 1st occurrence :

  ⇨ Store FRF_OBD +FRF_CUS_CMN +FRF_CUS_SET_CMN + FRF_CUS_SET_SPC
- occurrence ∈ [2 to NC_NR_FRF_SET]

  ⇨ Store FRF_CUS_SET_CMN + FRF_CUS_SET_SPC
- occurrence > NC_NR_FRF_SET

  ⇨ Replace last FRF_CUS_SET_CMN + FRF_CUS_SET_SPC

Example with NC_NR_FRF_SET set to 3



Freeze frame informations are available as long as the failure is not erased in 2nd layer memory.

Remark: Special behavior for FRF_OBD and FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed.

Application conditions:

Initialization: after system initialization the freeze frame is restored from non volatile memory or in case of a damaged non volatile memory the freeze frame is initialized with zero

Recurrence: -

Activation: at Action request

Formula section:

```
ACTION_ERRM_StoreFrf (IDX) :
If      CTR_FRC[IDX] = 1
Then    ( 1st occurrence : storage
          With  u = 1 ... NC_NR_ENVD_OBD
                v = 1 ... NC_NR_ENVD_CUS_CMN
                w = 1 ... NC_NR_ENVD_CUS_SET_CMN
                y = 1 ... NC_NR_ENVD_CUS_SET_SPC )
        If  (NC_NR_ENVD_PREV != 0        and
            XX = diagnosis instance XX using prestored freeze frame functionality (see
            Environmental data (Appl. Inc.) module) with XX = F(IDX))
        Then  ENVD_OBD[u][m] = ENVD_PREV_OBD[u][t]

                             FRF_CUS_CMN is updated
                     Endif
```

```
                **Endif**
                ENVD_CUS_SET_CMN[w][z][m] = ENVD_CONF_CUS_SET_CMN[w]
                ENVD_CUS_SET_SPC[y][z][m] = ID_ERR_ENVD_XX [ y ]
                (with XX = F(IDX))
            Endif
    Endif
```

27.14.2 Freeze frame deleting

Description:

Syntax : ACTION_ERRM_EraseFrf (IN <IDX>).

Parameter (in) : IDX Index of failure in 2^{nd} layer memory to store the freeze frame

Parameter (out) : -

Short description :

When the failure IDX is erased from 2^{nd} layer memory, the freeze frame of this failure is also erased by calling the action ACTION_ERRM_EraseFrf (IDX).

Application conditions:

Initialization: -

Recurrence: -

Activation: at Action request

Formula section:

```
ACTION_ERRM_EraseFrf (IDX) :
    ( Erase OBD freeze frame, common freeze frame and all specific freeze frame
            With    u = 1 ... NC_NR_ENVD_OBD
                    v = 1 ... NC_NR_ENVD_CUS_CMN
                    w = 1 ... NC_NR_ENVD_CUS_SET_CMN
                    y = 1 ... NC_NR_ENVD_CUS_SET_SPC
                    z = 1 ... NC_NR_FRF_SET )
    ENVD_OBD[u][m] = 0
    ENVD_CUS_CMN[v][m] = 0
    ENVD_CUS_SET_CMN[w][z][m] = 0
    ENVD_CUS_SET_SPC[y][z][m] = 0
```

27.14.3 Calibratable set of environmental data

Description:

The freeze frame part called FRF_CUS_SET_SPC contains environmental data, which are :

- specific to each failure, not required by law ;
- and calibratable.

This chapter describes “how to define by calibration the contents of FRF_CUS_SET_SPC”.

The calibratable system of environmental data is managed via tables defined as following:

ID_ENVD_FAC :	Configuration table, which describes all possible environmental data, which can be stored in a freeze frame (specific part) ; Affected value defined in Environmental data (Appl. Inc.) module.
ID_ERR_ENVD_XX :	Calibration table, which defines for each failure XX a maximum of NC_NR_ENVD_CUS_SET_SPC environmental data, which should be stored.

Example :

To store the environmental data	TIA and TCO_ST	in case of TCO failure ;
	MAP and AMP	in case of EGR failure ;

First, you should defined the possible environmental data in ID_ENVD_FAC table :

ID_ENVD_FAC[1] = &TIA

ID_ENVD_FAC[2] = &TCO_ST

ID_ENVD_FAC[3] = &MAP

ID_ENVD_FAC[4] = &AMP

Then, you should declare for each failure, the environmental data to stored :

ID_ERR_ENVD_TCO[1] = 1 ; ID_ERR_ENVD_TCO [2] = 2

ID_ERR_ENVD_EGR[1] = 3 ; ID_ERR_ENVD_EGR [2] = 4

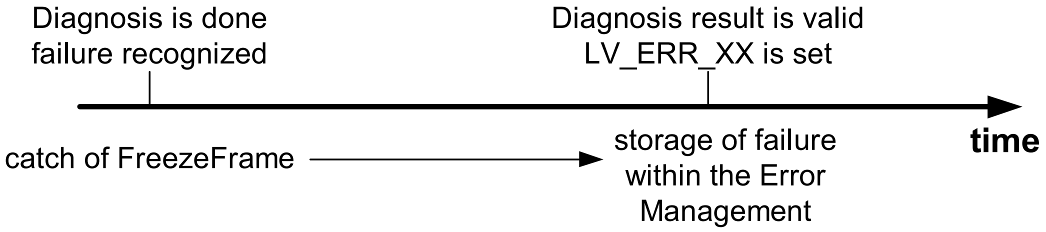
27.14.4 Prestored freeze frame

FUNCTION DESCRIPTION:

General information:

Usually the content for the freeze frame is catched, when the failure is stored within the failure memory. In special cases, when the entry of a failure within the failure memory is delayed, it’s necessary to catch the content for the freeze frame at the same time as the failure information is available.

Example:



Description:

Syntax : ACTION_ERRM_StorePrevFrf (IN <XX>).

Parameter (in) : XX diagnosis instance

Parameter (out) : -

Short description :

If ACTION_ERRM_StorePrevFrf (XX) is called by the diagnosis instance XX, a “prestored” freeze frame for diagnosis instance XX is stored. It’s used as content for the freeze frame, if the failure is entered in the failure memory later.

Application conditions:

Initialization: -

Recurrence: -

Activation: at Action request

Formula section:

ACTION_ERRM_StorePrevFrf (XX) :

with t related to failure XX, see Environmental data Appli.Inc.

ENVD_PREV_OBD[u][t] = ENVD_CONF_OBD[u]

ENVD_PREV_CUS_CMN[v][t] = ENVD_CONF_CUS_CMN[v]

ENVD_PREV_CUS_SET_CMN[w][t] = ENVD_CONF_CUS_SET_CMN[w]

ENVD_PREV_CUS_SET_SPC[y][t] = ID_ERR_ENVD_XX[y] (with XX = F(IDX))

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
ID_ERR_ENVD_XX	NC_NR_ENVD_CUS_SET_SPC	1...FFH	1...255	1	[-]
LDP_1_ID_ERR_ENVD_XX	NC_NR_ENVD_CUS_SET_SPC	0...FFH	0...255	1	[-]
Freeze frame FRF_CUS_SET_SPC : environmental data contents for failure XX					

Configuration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
NC_NR_ENVD_OBD	-	1...FFH	1...255	1	[-]
Number of different environment data (in bytes) which are fixed by the law (stored one time)					
NC_NR_ENVD_CUS_CMN	-	1...FFH	1...255	1	[-]
Number of different environment data (in bytes) which are common for all diagnosis instance (stored one time)					
NC_NR_ENVD_CUS_SET_CMN	-	0...FFH	0...255	1	[-]
Number of different environment data (in bytes) which are common for all diagnosis instance (stored many time)					
NC_NR_ENVD_CUS_SET_SPC	-	1...FFH	1...255	1	[-]
number of different environment data (in bytes) which are specific to each diagnosis instance (stored many time)typical value is 4					
NC_NR_FRF_SET	-	1...FFH	1...255	1	[-]
Number of different environment data groups (set) which can be store for one freeze frametypical value is 3 ; the value 0 is forbidden					
NC_ENVD_CUS_CMN_UPD	-	0...1H	0...1	1	[-]
Selection of FRF_CUS_CMN update method					
NC_NR_ENVD_PREV	-	1...FFH	1...255	1	[-]
Number of different failure instances XX using prestored freeze frameIf NC_NR_ENVD_PREV = 0 , then no prestored freeze frame functionality required					
NC_ID_ENVD_FAC	-	1...FFH	1...255	1	[-]
Size of ID_ENVD_FAC table					
ID_ENVD_FAC[255]	-	1...FFH	1...255	1	[-]
Possible stored environmental data in FRF_CUS_SET_SPC					

Configuration data detailed description:

NC_NR_ENVD_CUS_SET_SPC : Typical value is 4.

NC_NR_FRF_SET :	Typical value is 3. The value 0 is forbidden.
NC_ ENVD_CUS_CMN_UPD	0: FRF_CUS_CMN is not updated when failure status changes from "disappeared" to "temporary/confirmed". 1: FRF_CUS_CMN is updated when failure status changes from "disappeared" to "temporary/confirmed".
NC_NR_ENVD_PREV	0: No pre-stored freeze frame functionality required

Size of ID_ENVD_FAC is defined according number of data in the table ; maximum size is 255.

	Contents	Define by calibration ID_ERR_ENVD_XX (see Environmental data module) Possible stored environmental data : NC_ID_ENVD_FAC [1] = see DDLI list NC_ID_ENVD_FAC [2] = see DDLI list ... NC_ID_ENVD_FAC [255] = see DDLI list

27.15.2 Configuration of update of FRF_CUS_CMN

FUNCTION DESCRIPTION:

Description:

This file defines the update of the FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed. To follow specific customer requirements, this file is a template to be fulfilled by project team.

All data in gray should be completed by the project team.

Update of FRF_CUS_CMN in case of failure status change from disappeared to temporary/confirmed.	NC _ENVD_CUS_CMN_UPD = **1** 0: no update 1: update

27.15.3 Configuration for prestored freeze frame

FUNCTION DESCRIPTION:

Description:

This file defines the usage of the prestored freeze frame functionality. To follow specific customer requirements, this file is a template to be fulfilled by project team.

All data in gray should be completed by the project team.

Number of diagnosis instances XX using prestored freeze frame	NC_NR_ENVD_PREV = 1
Diagnosis instance XX	**prestored freeze frame number (t)**

ROUGH_LEAK	1

Remark: The usage of the prestored freeze frame functionality must be limited for special diagnosis functions, because of memory consumption.

27.15.4 Definition of OBD – Systemvariables for MODE 1 / 2

General information:

The variables are used for OBD powertrain diagnostic data (MODE1) and OBD Freeze-frame calculation (MODE 2).

Application conditions:

Initialisation: 0 at reset

Recurrence: 100ms

Activation: at every engine operating state

Formula section:

All calculation done in physical way

LOAD_CLC = IP_LOAD_CLC__N_32__MAF * IP_LOAD_CLC_AMP__AMP * 100%
LOAD_ABSV = (MAF / C_MAF_REF_OBD) * 100%
OBD_TPS_SP = (TPS_SP_MDL / C_TPS_SP_MAX) * 100%
OBD_TPS_1 = (V_TPS_1 / 5V) * 100%
OBD_TPS_2 = ((5V – V_TPS_2) / 5V) * 100%
OBD_TPS_REL = (TPS_AV / C_TPS_MAX) 100%
OBD_FTL = (FTL / C_FTL_REF_OBD) * 100%
OBD_PV_1 = (V_PVS_1 / 5V) * 100%
OBD_PV_2 = (V_PVS_2 / 2,5V) * 100%
OBD_EGR_DIF = I OPG_DIF_ACR / OPG_SP_ACR I * 100%

Monitor completion status for the current driving cycle					

Input data:

DIST	C_CTR_MAX_WUP_CYC	STATE_MIL	LV_DC
C_STATE_READY_OBD_1	C_STATE_READY_OBD_2	LV_END_DIAG_XX	WAL_CONF_XX
LV_WUP_CYC			

Import actions:

ACTION_ERRM_MonitorEnableStatus (INOUT < MonitorEnableStatus>)
This action allows to read the MonitorEnableStatus information

FUNCTION DESCRIPTION:

General information:

EOBD/CARB official requirements include a list of statistical data related to Error Management. These statistical data are counters and timers related to Error Management events. You can find below, in the following chapters, a description of all these requirements.

27.16.1 Time since diagnostic trouble codes cleared

Description:

Purpose of this strategy is to compute the time accumulated by the vehicle since diagnostic trouble codes cleared (referenced in ISO15031 as Modes 01h & 02h PID4Eh). It is simply an indication for I/M (Inspection/Maintenance), of the last time an external test equipment was used to clear DTCs.

Application conditions:

Initialization: on non-volatil memory reset or lost
or on failure erase service received
T_DTC_CLR = 0

Recurrence : 1 minute ±1 second, after event : on “failure erase” service received

Activation : -

Deactivation: -

Formula section :

```
{ T_DTC_CLR is updated at required recurrence }
{ T_DTC_CLR shall saturate to its maximal value 65535 }

If      T_DTC_CLR < 65535
Then
        T_DTC_CLR = T_DTC_CLR + 1
Endif
```

27.16.2 Distance counters since MIL activation and Minutes run by the engine with MIL activated

Description:

According to ISO/DIS 15031-5.8 (Road vehicles — Communication between vehicle and external equipment for emissions-related diagnostics — Part 5: Emissions-related diagnostic services), ECU must be able to indicate :

- the distance travelled while the MIL is activated
- the number of minutes run by the engine while MIL is activated

Distance Travelled While MIL is Activated

The purpose is to compute the covered distance while the MIL is illuminated (MIL blinking is considered as a MIL illumination). This mileage (DIST_ACT_MIL) is a global distance :

- which is not linked with any failure and is independent from the Pre-drive check
- which is dependent from the global inhibition MIL boolean
- which is dependent of the MIL request
- which is readable with Scan-Tool with kilometer as unit

Conditions for “Distance travelled” counter :

- reset to 0 when MIL state changes from deactivated to activated by this ECU
- accumulate counts in km if MIL is activated (ON)
- do not change value while MIL is not activated (OFF)
- reset to 0 if diagnostic information is cleared either by service 04h or 40 warm-up cycles without MIL activated
- do not wrap to 0 if value is FFFFh

Minutes run by the engine while MIL activated

The purpose is to compute the time accumulated while MIL is activated (Modes 01h & 02h PID4Dh). This duration shall be cleared when failure memory is erased and after 40 warm-up cycles.

Conditions for “Minutes run by the engine while MIL activated” counter :

- reset to 0 when MIL state changes from deactivated to activated by this ECU
- accumulate counts in minutes if MIL is activated (ON)
- do not change value while MIL is not activated (OFF)
- reset to 0 if diagnostic information is cleared either by service 04h or 40 warm-up cycles without MIL activated
- do not wrap to 0000h if value is FFFFh

Application conditions:

Initialization: On saved ram lost

or STATE_MIL transition OFF -> MIL_FLL or OFF -> ON

```
            or      failure erase service received
                    DIST_REL_ACT_MIL = DIST
                    DIST_ACT_MIL = 0
                    CTR_ACT_MIL = C_CTR_MAX_WUP_CYC
                    T_ACT_MIL = 0
                    T_ACT_MIL_60 = 0
```

Recurrence: upon LV_DC 1→0 transition and 1 s

Activation: all engine states

<u>Formula section:</u>

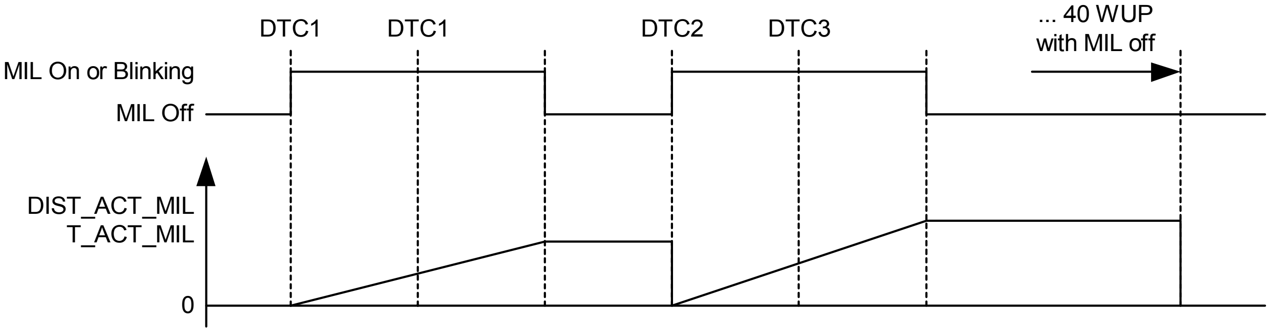
<u>Each 1s:</u>

```
If(1)   STATE_MIL = MIL_FLL
        or
        STATE_MIL = ON
Then(1)
        If(2)   ( DIST – DIST_REL_ACT_MIL ) < 65535
        Then(2)
                DIST_ACT_MIL = DIST – DIST_REL_ACT_MIL
        Else(2)
                DIST_ACT_MIL = 65535
        Endif(2)
        T_ACT_MIL_60 = T_ACT_MIL_60 + 1 s
        If(2)   (T_ACT_MIL_60 = 60)
        Then(2)
                T_ACT_MIL_60 = 0
                If(3)   T_ACT_MIL < 65535
                Then(3)
                        T_ACT_MIL = T_ACT_MIL + 1 min
                Else(3)
                        T_ACT_MIL = 65535
                Endif(3)
        Endif(2)
Endif(1)
```

<u>At LV_DC 1→0 transition :</u>

```
If(1)   LV_WUP_CYC = 1
```

```
        and
        STATE_MIL was OFF during all the warm-up cycle
        and
        CTR_ACT_MIL > 0
    Then(1)
        CTR_ACT_MIL = CTR_ACT_MIL –1
        If(2)   CTR_ACT_MIL = 0
        Then(2)
                DIST_REL_ACT_MIL = DIST
                DIST_ACT_MIL = 0
                T_ACT_MIL = 0
                T_ACT_MIL_60 = 0
        Endif(2)
    Endif(1)
```



27.16.3 Distance since diagnostic trouble codes cleared

Description :

Purpose of this strategy is to compute the distance accumulated by the vehicle since diagnostic trouble codes cleared (referenced in ISO15031 as mode01h&02hPID31h). It is simply an indication for Inspection/Maintenance, of the last time an external test equipment was used to clear DTCs.

Application conditions:

Initialization: on non-volatil memory reset or lost

or

on failure erase service received
DIST_DTC_CLR = 0
DIST_REL_DTC_CLR = DIST

Recurrence : 1 second

Activation : -

Deactivation: -

Formula section :

{ DIST_DTC_CLR is updated regularly regarding DIST }
{ DIST_DTC_CLR shall saturate to its maximal value 65535 km}

```
If      DIST - DIST_REL_DTC_CLR < 65535
Then
        DIST_DTC_CLR = DIST - DIST_REL_DTC_CLR
Else
        DIST_DTC_CLR = 65535
Endif
```

27.16.4 Number of warm-ups since diagnostic trouble codes cleared

Description:

Purpose of this strategy is to compute number of warm-ups since diagnostic trouble codes cleared (referenced in ISO15031 as Modes 01h & 02h PID30h). It’s just an indication for Inspection/Maintenance, to determine the last time an external test equipment was used to clear DTCs.

Application conditions:

Activation :	On LV_WUP_CYC 0 → 1 transition
Initialization:	On non-volatil memory reset or lost **or** on failure erase service received CTR_WUP_DTC_CLR=0
Recurrence :	none, executed single time on activation.

Formula section:

```
{ on detection of a warm-up cycle CTR_WUP_DTC_CLR is incremented }
{ CTR_WUP_DTC_CLR shall saturate to its maximal value 255 }

If      CTR_WUP_DTC_CLR < 255
Then
        CTR_WUP_DTC_CLR = CTR_WUP_DTC_CLR + 1
Endif
```

27.16.5 Monitor enable/completion status for the current driving cycle

General information:

Purpose of this strategy is to get the follwoing informations :
- if a diagnosis (a monitor) is disabled for rest of this monitoring cycle or not (referenced in ISO15031 as Modes 01h & 02h PID41h).
- if a diagnosis (a monitor) is completed for the current monitoring cycle or not (referenced in ISO15031 as Modes 01h & 02h PID41h).

Each concerned diagnosis is part of a generic list : Misfire, Fuel system, Comprehensive component, Catalyst, Heated catalyst, Evaporative system, Secondary air system, A/C system refrigerant, Oxygen sensor, Oxygen sensor heater, EGR system monitoring.

MonitorEnableStatus :
Each bit of STATE_ENA_OBD variable contains status for each predefined diagnosis as defined below :
Enable status of a diagnosis this monitoring cycle:
- NO (STATE_ENA_OBD[n]=0) means disabled for rest of this monitoring cycle or not supported in C_STATE_READY_OBD_1 & C_STATE_READY_OBD_2
- YES (STATE_ENA_OBD[n]=1) means enabled for this monitoring cycle.

MonitorCompletionStatus :
Each bit of STATE_CMPL_OBD variable contains status for each predefined diagnosis as defined below :
Completion status of a diagnosis this monitoring cycle:
- YES (STATE_CMPL_OBD[n]=0) means monitor complete this monitoring cycle, or not supported in C_STATE_READY_OBD_1 & C_STATE_READY_OBD_2
- NO (STATE_CMPL_OBD[n]=1) means monitor not complete this monitoring cycle.

Bit 0 to 7 of STATE_ENA_OBD[0..7] :

Misfire monitoring status bit :
    If      LV_END_DIAG_XX=1 for all diagnosis XX defined below
            Take into account all LV_END_DIAG_XX which fulfill the following condition:
                    this XX failure has the status CARB_MIS (see tables of failures) and
                    the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

    Then    Bit 0 of STATE_CMPL_OBD = 0
    Endif
```

Fuel system monitoring status bit :

```
If      LV_END_DIAG_XX=1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_FSD (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 1 of STATE_CMPL_OBD = 0
Endif
```

Comprehensive component monitoring status bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_CC (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 2 of STATE_CMPL_OBD = 0
Endif
```

Catalyst monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_CAT (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 8 of STATE_CMPL_OBD = 0
Endif
```

Heated catalyst bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_HC (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 9 of STATE_CMPL_OBD = 0
Endif
```

Evaporative system monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_EVAP(see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 10 of STATE_CMPL_OBD = 0
Endif
```

Secondary air system monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_SA (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 11 of STATE_CMPL_OBD = 0
Endif
```

A/C system refrigerant monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_AC (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 12 of STATE_CMPL_OBD = 0
Endif
```

Oxygen sensor monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_LS (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 13 of STATE_CMPL_OBD = 0
Endif
```

Oxygen sensor heater monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_LSH (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 14 of STATE_CMPL_OBD = 0
Endif
```

EGR system monitoring bit :

```
If      LV_END_DIAG_XX = 1 for all diagnosis XX defined below
        Take into account all LV_END_DIAG_XX which fulfill the following condition:
                this XX failure has the status CARB_EGR (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)

Then    Bit 15 of STATE_CMPL_OBD = 0
Endif
```

27.17 Statistical data (App. Inc.)

Output data:

```

Description :

Syntax:	ACTION_ERRM_MonitorEnableStatus (OUT < MonitorEnableStatus >)
Parameter (in):	No parameter
Parameter (out):	MonitorEnableStatus with the same format as MonitorEnableStatus
Short Description:	This API calculates and returns the monitor enable status result information in the software structure.

Application conditions:

Activation:	at ACTION request
Initialization:	all bits 0
Recurrence:	-

Formula section:

Misfire monitoring status bit :

```
if      AMP > C_AMP_MIN_MIS
then    Bit 0 of MonitorEnableStatus = 1
else    Bit 0 of MonitorEnableStatus = 0
endif
```

Fuel system monitoring status bit :

```
if      AMP > C_AMP_MIN_FSD                     and
```

```
          LV_INH_FSD_STOP_OIL = 0
then      Bit 1 of MonitorEnableStatus = 1
else      Bit 1 of MonitorEnableStatus = 0
endif
```

Comprehensive component monitoring status:

```
          Bit 2 of MonitorEnableStatus = 1
```

Catalyst monitoring bit :

```
if        AMP > C_AMP_MIN_CAT
then      Bit 8 of MonitorEnableStatus = 1
else      Bit 8 of MonitorEnableStatus = 0
endif
```

Heated catalyst monitoring status bit6 :

```
          Bit 9 of MonitorEnableStatus = 0
```

Evaporative system monitoring bit :

```
          Bit 10 of MonitorEnableStatus = 1
```

Secondary air system monitoring bit :

```
          Bit 11 of MonitorEnableStatus = 0
```

A/C system refrigerant monitoring bit :

```
          Bit 12 of MonitorEnableStatus = 0
```

Oxygen sensor monitoring bit :

```
          Bit 13 of MonitorEnableStatus = 1
```

Oxygen sensor heater monitoring bit :

```

```

EGR system monitoring bit :

```
          Bit 14 of MonitorEnableStatus = 0
```

```
MonitorEnableStatus [0..7] = MonitorEnableStatus [0..7] and C_STATE_READY_OBD_1
MonitorEnableStatus [8..15] = MonitorEnableStatus 8..15] and C_STATE_READY_OBD_2
```

27.17.2 Minutes run by the engine with MIL activated

Description:

According to ISO/DIS 15031-5.8 (Road vehicles — Communication between vehicle and external equipment for emissions-related diagnostics — Part 5: Emissions-related diagnostic services), ECU must be able to indicate :

- the number of minutes run by the engine while MIL is activated

Minutes run by the engine while MIL activated

The purpose is to compute the time accumulated while MIL is activated (Modes 01h & 02h PID4Dh). This duration shall be cleared when failure memory is erased and after 40 warm-up cycles.

Conditions for “Minutes run by the engine while MIL activated” counter :

- reset to 0 when MIL state changes from deactivated to activated by this ECU
- accumulate counts in minutes if MIL is activated (ON)
- do not change value while MIL is not activated (OFF)
- reset to 0 if diagnostic information is cleared either by service 04h or 40 warm-up cycles without MIL activated
- do not wrap to 0000h if value is FFFFh

Application conditions:

Initialization: On saved ram lost

or STATE_MIL transition OFF -> MIL_FLL or OFF -> ON

or failure erase service received

T_ACT_MIL_SAE = 0

T_ACT_MIL_SAE_60 = 0

Recurrence: upon LV_DC 1→0 transition and 1 s

Activation: LV_ES=0

Formula section:

Each 1s:

```
If(1)   STATE_MIL = MIL_FLL
        or
        STATE_MIL = ON
Then(1)
        T_ACT_MIL_SAE_60 = T_ACT_MIL_SAE_60 + 1 s
        If(2)   (T_ACT_MIL_SAE_60 = 60)
        Then(2)
                T_ACT_MIL_SAE_60 = 0
                If(3)   T_ACT_MIL_SAE < 65535
                Then(3)
                        T_ACT_MIL_SAE = T_ACT_MIL_SAE + 1 min
                Else(3)
                        T_ACT_MIL_SAE = 65535
                Endif(3)
        Endif(2)
Endif(1)
```

At LV_DC 1→0 transition : calculates after CTR_ACT_MIL calculation

```
If(2)   CTR_ACT_MIL = 0
Then(2)
    T_ACT_MIL_SAE = 0
    T_ACT_MIL_SAE_60 = 0
Endif(2)
```

27.18 Rate-Based Monitoring

Output data detailed description:

STATE_CTR_RBM[NC_NR_DIAG_RBM] : Information data for CTR_COMP_RBM[NC_NR_DIAG_RBM] and CTR_CDN_RBM[NC_NR_DIAG_RBM] calculations.

bit 0: incrementation of monitor individual numerator done in this DC
bit 1: incrementation of monitor individual denominator done in this DC

Input data:

LV_DC	T_AST	STATE_RBM[NC_NR_DIAG_RBM]	LV_INH_DC_RBM
NC_NR_DIAG_RBM	T_IS	TAM	AMP
LV_IS	LV_ES	VS	PV

FUNCTION DESCRIPTION:

General information:

To gain more information about the monitoring performance under real world conditions, CARB required to implement software algorithms to track and report in-use performance for the following monitors in a standardized format: Catalyst, Oxygen sensor, Evaporating system, EGR system, VVT system and Secondary air system.

For this kind of statistic different counters are necessary:

- Ignition cycle counter

  Counter that indicates the number of ignition cycles a vehicle has experienced
- General denominator

  Measures the number of times a vehicle is operated under standardized conditions
- Monitor individual numerator

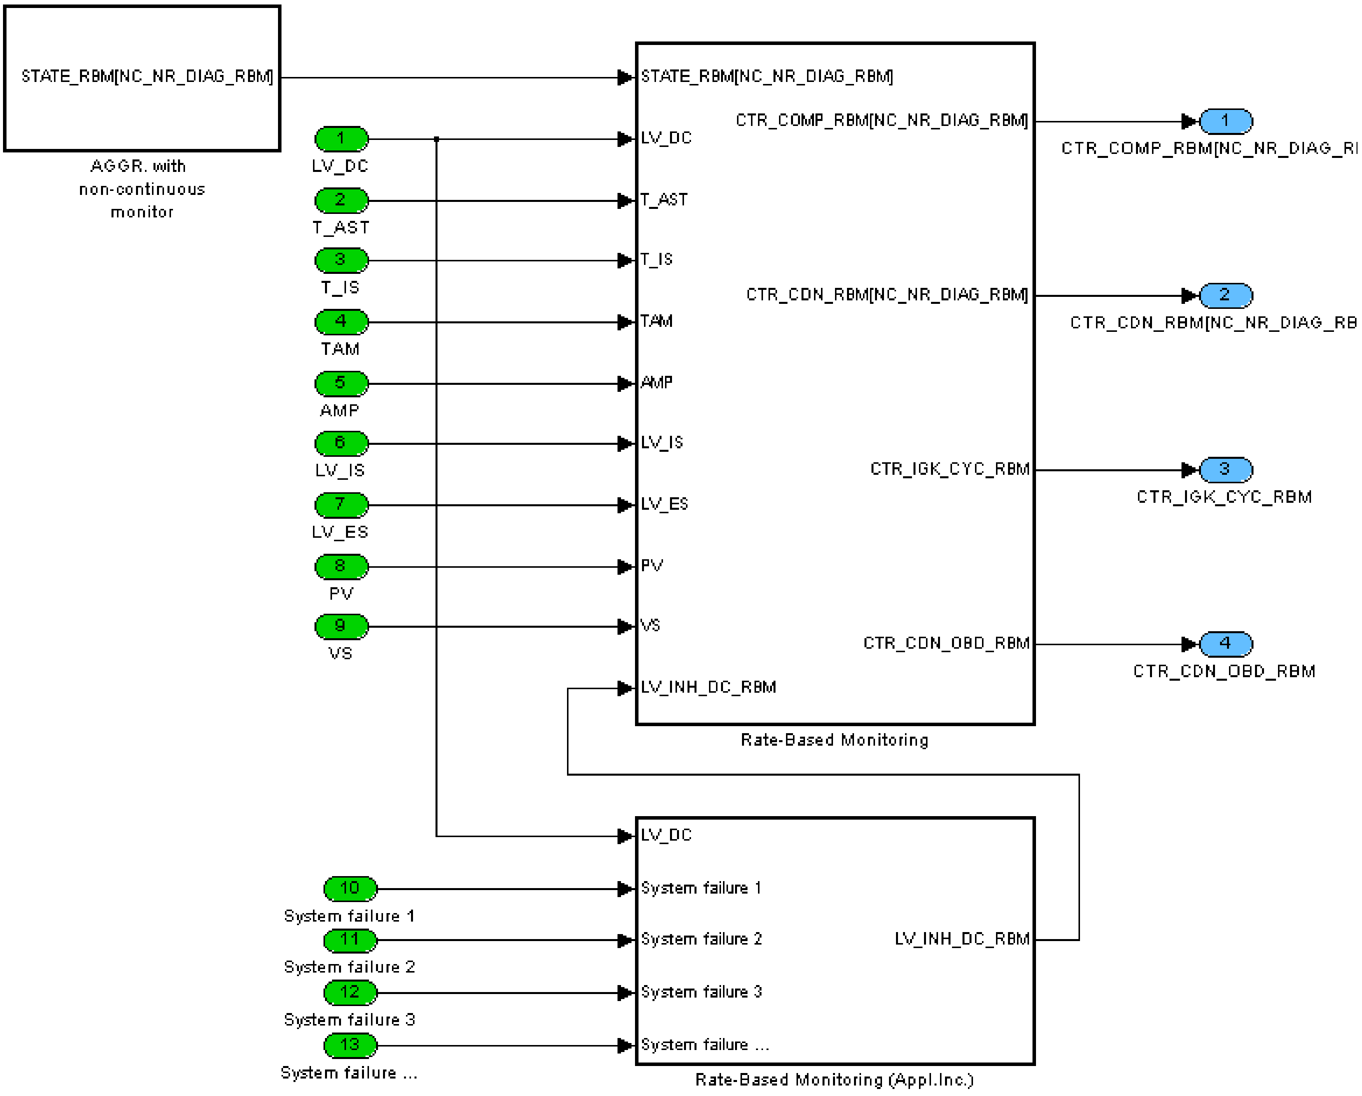
  Measures the number of driving cycles in which the monitor was done
- Monitor individual denominator

  Counter that indicates the number of times a vehicle is operated under monitor individual conditions.

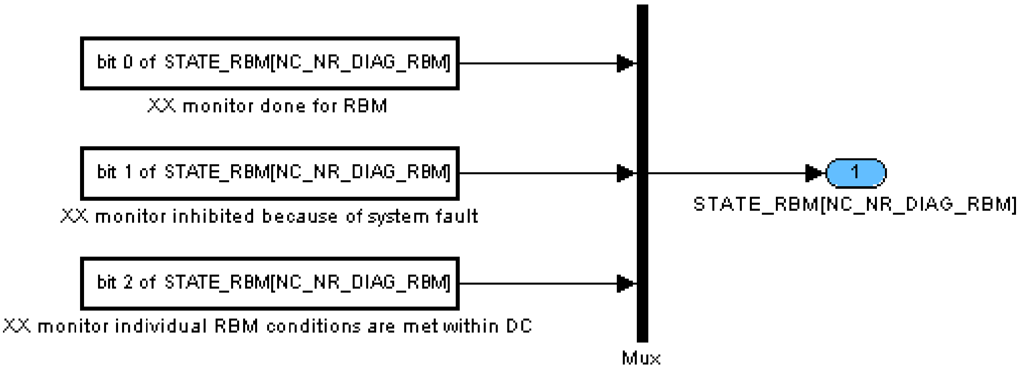
All these counters are set to zero only when a non-volatile memory reset occurs (e.g. reprogramming). They will not be initialized with zero on any other circumstances including when a scan-tool command to clear fault codes is received.

Signal flow diagram:

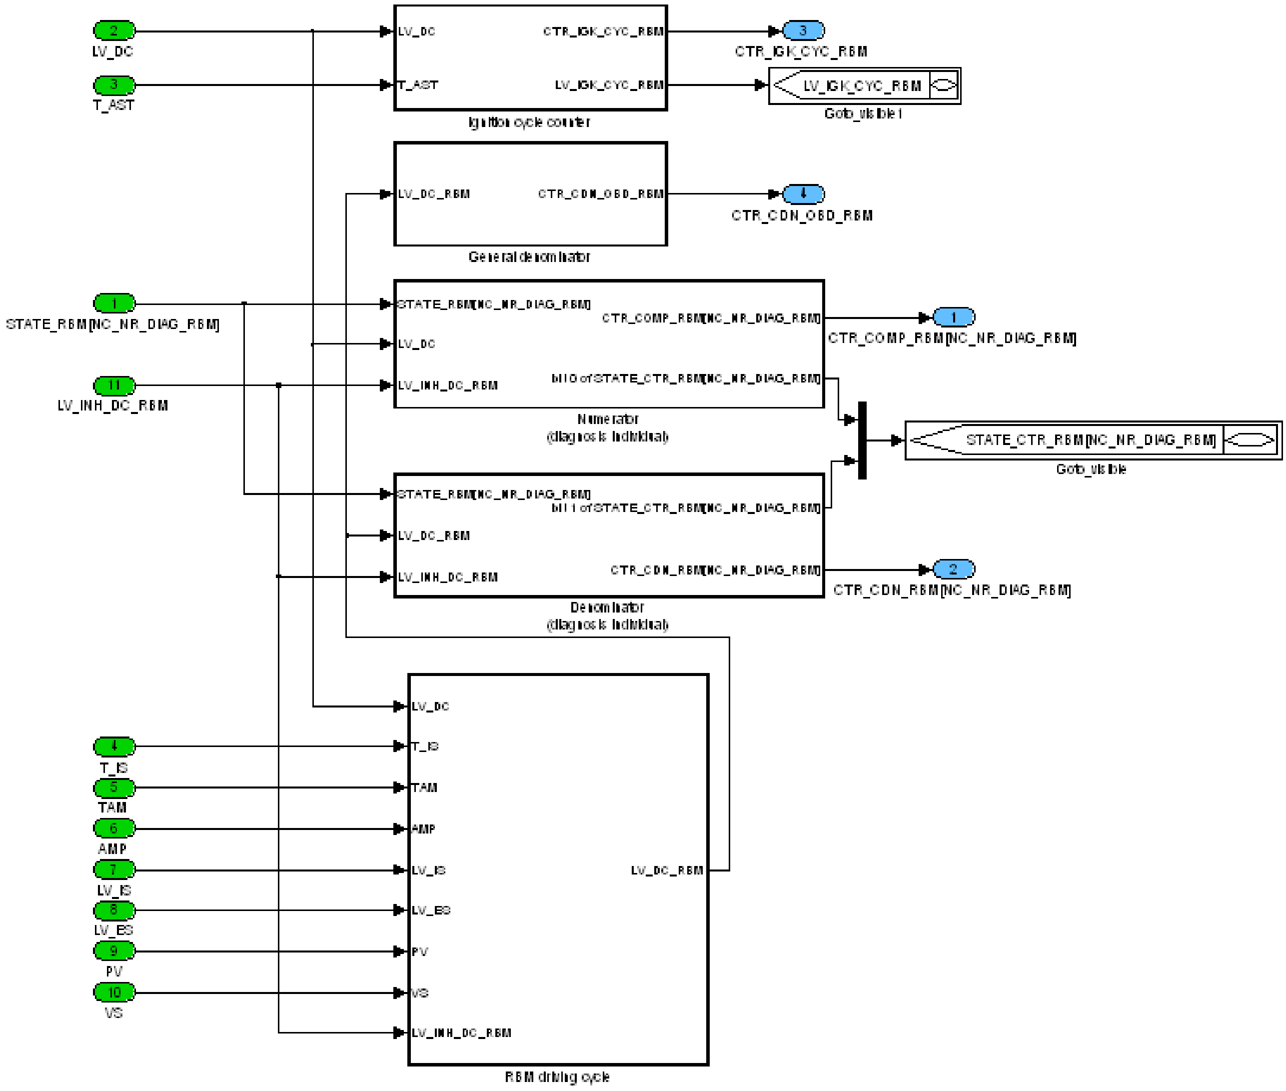
Overview :



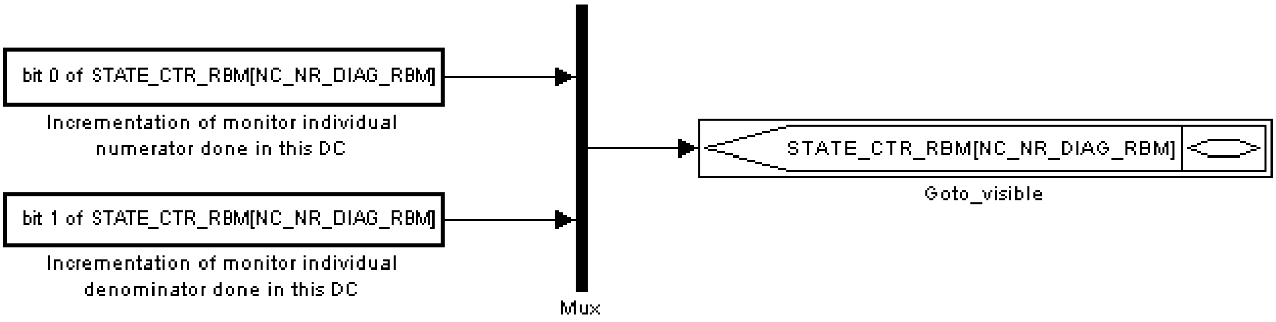
STATE_RBM[NC_NR_DIAG_RBM] definition :



Modules of Rate-Based Monitoring :



STATE_CTR_RBM[NC_NR_DIAG_RBM] definition:



27.18.1 Ignition cycle counter

Description:

The number of ignition cycles since the first ECU power up are counted within CTR_IGK_CYC_RBM. The counter is incremented each time a driving cycle with engine running for at least 2 seconds (±1s) (C_DLY_AST_RBM) is detected. This value is only initialized with 0 on saved RAM lost (or reprogramming). If CTR_IGK_CYC_RBM is incremented LV_IGK_CYC_RBM is set to 1 to indicate that counter is already incremented within this driving cycle.

If the counter reaches its maximum value, the value is set to 0 on the next calculation.

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_IGK_CYC_RBM = 0

at reset

CTR_IGK_CYC_RBM = restored from NVMY

at LV_DC 0 → 1 transition and ECU reset

LV_IGK_CYC_RBM = 0

Recurrence: 1 s

Activation: LV_DC = 1 **and** LV_IGK_CYC_RBM = 0

Formula section:

Quantity of driving cycles calculation:

```
If    T_AST >= C_DLY_AST_RBM        (time after start at least C_DLY_AST_RBM)
Then
        If     CTR_IGK_CYC_RBM = 65535 (maximum value of CTR_IGK_CYC_RBM)
        Then
               CTR_IGK_CYC_RBM = 0
        Else
               CTR_IGK_CYC_RBM = CTR_IGK_CYC_RBM + 1
        Endif
        LV_IGK_CYC_RBM = 1          (CTR_IGK_CYC_RBM incremented this DC)
Endif
```

27.18.2 General denominator calculation

Description:

The counter for the general denominator CTR_CDN_OBD_RBM is incremented each time a valid DC with standardized vehicle operation (LV_DC_RBM = 1) is recognized. The numbers of driving cycles are counted since the first ECU power up. This value is only initialized with 0 on saved RAM lost (or reprogramming).

If the counter reaches its maximum value, the value is set to 0 on the next calculation.

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_CDN_OBD_RBM = 0

at reset

CTR_CDN_OBD_RBM = restored from NVMY

Recurrence: -

Activation: LV_DC_RBM 0→1 transition

Formula section:

```
If      CTR_CDN_OBD_RBM = 65535 (maximum value of CTR_CDN_OBD_RBM)
Then
        CTR_CDN_OBD_RBM = 0
Else
        General denominator calculation:
        CTR_CDN_OBD_RBM     = CTR_CDN_OBD_RBM + 1
Endif
```

27.18.3 Monitor individual numerator calculation

Description:

For all monitors requiring Rate-Based Monitoring (m = 0 to (NC_NR_DIAG_RBM – 1)) a numerator must be calculated. This numerator CTR_COMP_RBM[m] is incremented, if the conditions for the monitor were present for a sufficient time (bit 0 of STATE_RBM[m] = 1), but only one time within the driving cycle. This value is only initialized with 0 on saved RAM lost (or reprogramming)

If the counter CTR_CDN_RBM[m] is halved, because of maximum value limitation, the value CTR_COMP_RBM[m] is also divided by 2 (positive rounded).

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_COMP_RBM[m] = 0

at reset

CTR_COMP_RBM[m] = restored from NVMY

at LV_DC 0 →1 transition or ECU reset

STATE_CTR_RBM[m] = 0

with m = 0 to (NC_NR_DIAG_RBM – 1)

Recurrence: 10 s **or** LV_DC 1 → 0 transition

Activation: LV_INH_DC_RBM = 0 **and** LV_DC = 1

Formula section:

```
For m = 0 to (NC_NR_DIAG_RBM – 1)
    all monitor requiring Rate-Based Monitoring
    { see specification “Rate-Based Monitoring (Appl. Inc.)” }
    If      bit 0 of STATE_CTR_RBM[m] = 0
            (Incrementation of CTR_COMP_RBM[m] not yet done in this DC)
    Then    If      bit 0 of STATE_RBM[m] = 1
                    (monitor is done for RBM)
            and     bit 1 of STATE_RBM[m] = 0
                    (monitor isn’t inhibited because of a system fault)
            Then    CTR_COMP_RBM[m] = CTR_COMP_RBM[m] + 1
                    bit 0 of STATE_CTR_RBM[m] = 1
                    (Incrementation of CTR_COMP_RBM[m] done in DC)
            Endif
    Endif
Endfor
```

27.18.4 Monitor individual denominator calculation

Description:

In comparison to the counter CTR_IGK_CYC_RBM, counting the numbers of driving cycles (longer C_DLY_AST_RBM) since the first ECU power-up, the monitor individual denominator is counting the number of DC in which special vehicle/driving and ambient conditions are met individually for each monitor.

The counter CTR_CDN_RBM[m] is managed individually for each monitor (m = 0 to (NC_NR_DIAG_RBM – 1)), for which the monitoring of the real in-use performance is made. To increment the monitor denominator, some common conditions must be fulfilled (LV_DC_RBM = 1) but also monitor individual conditions. These monitor individual conditions are managed within the monitor function (bit 2 of STATE_RBM[m]). The value is only initialized with 0 on saved RAM lost (or reprogramming).

If the counter CTR_COMP_RBM[m] is halved, because of maximum value limitation, the value CTR_CDN_RBM[m] is also divided by 2 (positive rounded).

Application conditions:

Initialisation: at first ECU power up / on saved RAM lost (or reprogramming)

CTR_CDN_RBM[m] = 0

at reset

CTR_CDN_RBM[m] = restored from NVMY

with m = 0 to (NC_NR_DIAG_RBM – 1)

Recurrence: 10 s **or** LV_DC 1 → 0 transition (before LV_DC_RBM initialisation performed at LV_DC 1 → 0)

Activation: LV_INH_DC_RBM = 0 **and** LV_DC_RBM = 1

Formula section:

```
For m = 0 to (NC_NR_DIAG_RBM – 1)
     all monitor requiring Rate-Based Monitoring
     { see specification “Rate-Based Monitoring (Appl. Inc.)” }
     If      bit 1 of STATE_CTR_RBM[m] = 0
             (incrementation is not done yet)

     Then    If      bit 1 of STATE_RBM[m] = 0
                     (monitor is not inhibit, because of a system fault)

             and     bit 2 of STATE_RBM[m] = 1
                     (monitor individual RBM conditions are met within this DC)

             Then    CTR_CDN_RBM[m] = CTR_CDN_RBM[m] +1

                             bit 1 of STATE_CTR_RBM[m] = 1
                     (incrementation is done within DC)

             Endif
     Endif
Endfor
```

27.18.5 Counter overflow treatment for monitor individual numerator and denominator

Description:

If either the numerator or denominator for a specific component reaches the maximum value (65535), both numbers shall be divided by two before either is incremented again to avoid overflow problems.

Application conditions:

Initialisation:	-
Recurrence:	-
Activation:	LV_DC 0 → 1 transition

Formula section:

```
For m = 0 to (NC_NR_DIAG_RBM – 1)
     all monitor requiring Rate-Based Monitoring
     { see specification “Rate-Based Monitoring (Appl. Inc.)” }
     If      CTR_CDN_RBM[m] = 65535 (maximum value of CTR_CDN_RBM[m])

             or

             CTR_COMP_RBM[m] = 65535 (maximum value of CTR_COMP_RBM[m])
     Then    CTR_CDN_RBM[m] = CTR_CDN_RBM[m] / 2

             CTR_COMP_RBM[m] = CTR_COMP_RBM[m] / 2

     Endif

Endfor
```

27.18.6 Standardized vehicle operation for Rate-Based Monitoring

FUNCTION DESCRIPTION:

General information:

For the calculation of the denominators for Rate-Based Monitoring, CARB standardized vehicle operations, which must be met to increment the denominator counter.

Description:

A special driving cycle (LV_DC_RBM) for Rate-Based Monitoring is defined, which is set, if the following standardized vehicle operations are fulfilled:

- Cumulated trip length (time since engine start) T_AST_RBM >= C_T_AST_RBM

  (CARB : 600 s)
- Cumulative vehicle operation >= C_VS_THD_RBM for minimum of C_T_VS_RBM

  (CARB : >= 40 km/h (25mph) for at least 300 s)
- Continuous vehicle operation in idle equal or longer than C_T_IS_RBM (accelerator pedal released and vehicle speed less or equal than 1 mph)

  (CARB : 30 s)

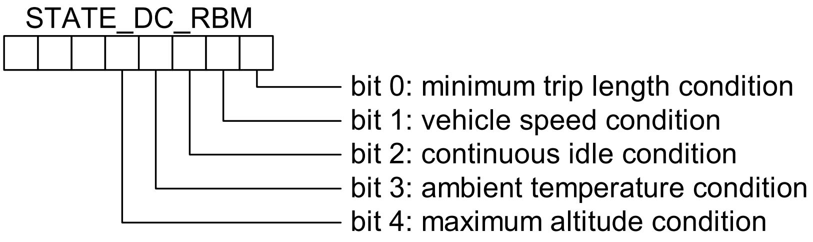
with

- altitude such as ambient pressure AMP > C_AMP_MIN_RBM

  (CARB : 8000 feet)
- ambient temperature (TAM) >= C_TAM_MIN_RBM

  (CARB : 20 °F)

Within STATE_DC_RBM the different conditions necessary to set LV_DC_RBM are visualized.



bit 0: minimum trip length condition
bit 1: vehicle speed condition
bit 2: continuous idle condition
bit 3: ambient temperature condition
bit 4: maximum altitude condition

bit value = 0: condition not met yet; bit value = 1: condition met

Application conditions:

Initialisation: at LV_DC 0 → 1 transition **or** reset

LV_DC_RBM = 0
STATE_DC_RBM = 0H
T_AST_RBM = 0 s
T_VS_RBM = 0 s
T_IS_RBM = 0 s

at LV_DC 1 → 0 transition

after individual numerator/denominator computations:

LV_DC_RBM = 0
STATE_DC_RBM = 0H

Recurrence: 100 ms

Activation: LV_DC = 1
and
LV_DC_RBM = 0
and
LV_INH_DC_RBM = 0

Formula section:

Ambient temperature

If (1)	TAM >= C_TAM_MIN_RBM		(ambient temperature condition)
Then (1)	bit 3 of STATE_DC_RBM	= 1	(ambient temperature condition reached)
Else (1)	bit 3 of STATE_DC_RBM	= 0	(ambient temperature condition not reached)
Endif (1)			

Maximum altitude

If (1)	AMP > C_AMP_MIN_RBM		(maximum altitude condition)

Import actions:

ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)

Description:

For development conveniences, it is often useful to reinit the rate base monitoring statistics. This is possible by setting the calibration bit LC_RBM_CLR to 1.

Application conditions:

Initialisation: -

Recurrence: -

Activation: 0 → 1 transition of LC_RBM_CLR

Formula section:

If LC_RBM_CLR = 1

Then ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)

Endif

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_RBM_CLR	1	0...1H	0...1	1	[-]
reinit the rate base monitoring statistics at LC_RBM_CLR 0->1					

27.19.3 Inhibition of standardized vehicle operation calculation

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_INH_DC_RBM	V/O	0...1H	0...1	1	[-]
Inhibition of standardized vehicle operation calculation, due to a system failure that influences the conditions necessary to set LV_DC_RBM					

Input data:

LV_ERR_AMP_PLAUS	LV_DC_RBM	LV_ERR_VS	CTR_ERR_DYN_NR
LV_ERR_VS	LV_ERR_TAM_CAN	LV_ERR_TAM_PLAUS	

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT <PendingStatus>)

FUNCTION DESCRIPTION:

General information:

The calculation of the standardized vehicle operation LV_DC_RBM, necessary for the calculation of the denominators for the Rate-Based Monitoring functionality, depends on different engine and ambient conditions.

Description:

With the value LV_INH_DC_RBM the inhibition of the standardized vehicle operation calculation is controlled. An inhibition is possible due to a system failure that influences the conditions necessary to set LV_DC_RBM.

Application conditions:

Initialisation: at ECU reset or LV_DC 0 → 1 transition : LV_INH_DC_RBM = 0

Recurrence: 1 s

Activation: LV_DC = 1

and LV_INH_DC_RBM = 0

Formula section:

At LV_DC 0 → 1 transition :

The pending status of the following failures has to be checked only once :

- LV_ERR_AMP
- LV_ERR_AMP_PLAUS
- LV_ERR_VS
- LV_ERR_TAM_PLAUS
- LV_ERR_TAM_CAN

```
If(1)       { CPU optimization at LV_DC 0 → 1 transition }
            CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
            While LV_INH_DC_RBM = 0 do
                  with each XX failure of the above list :
                  ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                  SYNCHRONIZATION<CALL>)
                  If(2)         XX has a pending status
                  Then(2)
                                LV_INH_DC_RBM = 1
                  Endif(2)
            Endwhile
Else(1)
            { the dynamic failure memory is empty }
            No action
Endif(1)
```

Every 1 s :

```
If          LV_ERR_AMP = 1
     or     LV_ERR_AMP_PLAUS = 1
     or     LV_ERR_VS = 1
     or     LV_ERR_TAM_PLAUS = 1
     or     LV_ERR_TAM_CAN = 1
Then        LV_INH_DC_RBM = 1
Endif
```

27.19.4 Calculation of cold start denominator

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CDN_CST_RBM	V/O	0...1H	0...1	1	[-]
Cold start conditions for individual denominator calculation					
T_AST_CST_RBM	V	0...FFFFH	0...65535	1	[s]
Comulative time (depending on ambient temperature) since engine start					

Input data:

TCO_ST	TAM	TAM_ST	

FUNCTION DESCRIPTION:

General information:

The individual monitor condition for evaporative system denominator calculation LV_CDN_CST_RBM (see §1968.2 - 4.3.2, section D) can be applied for other diagnosis (Bit 2 calculation of STATE_RBM_xx) that require extentend monitoring evaluation e.g. coolant or intake air rationality.

Application conditions:

Initialisation: at LV_DC 0 → 1 transition **or** reset

T_AST_CST_RBM = 0s

LV_CDN_CST_RBM = 0

Recurrence: 1s

Activation: LV_DC = 1

and

LV_CDN_CST_RBM = 0

and

LV_INH_DC_RBM = 0

Formula section:

Comulative time (depending on ambient temperature) since engine start:

```
If      C_TAM_MIN_CST_RBM ≤ TAM  ≤ C_TAM_MAX_CST_RBM
        (ambient temperature greater than or equal to 40 degrees Fahrenheit but
        less than or equal to 95 degrees Fahrenheit)
Then    If     T_AST_CST_RBM ≥ C_T_AST_CST_RBM

Maximum value of the driving cycle counter for failure XX					

FUNCTION DESCRIPTION:

General information:

Because the diagnosis system becomes more and more complex, to avoid multiplication of calibrations and to help the tuning team for simplifying the calibration process, each failure is defined via classes of failure.

Each class defines the type of this failure as emission relevant or not, as MIL handling or not, as using driving cycle for MIL illumination, and so on.

The configuration of a failure is defined by WAL_CONF_XX, PRI_CONF_XX, CTR_DC_INC_XX, CTR_DC_DEC_XX and CTR_DC_MAX_XX.

Format of WAL_CONF_XX		
Bit	Logical value	Description
0	LC_WAL_1_ON	Enable WAL_1 (0 : Off / 1 : On) See details in “Lamp management” module.
1	LC_WAL_2_ON	Enable WAL_2 (0 : Off / 1 : On) See details in “Lamp management” module.
2	LC_MIL_ON	Enable MIL (0 : Off / 1 : On) See details in “Lamp management” module.
3	LC_MIL_FLL	Enable flash mode for MIL (0 : Off / 1 : On) See details in “Lamp management” module.
4	LC_OBD_ERR	Defines failure as a “CARB/EOBD failure” (emission relevant). (failure visible via scantool) 0 : failure is <u>not</u> considered as a “CARB/EOBD failure” 1 : failure is considered as a “CARB/EOBD failure”

Format of PRI_CONF_XX		
Bit	**Logical value**	**Description**
0	LC_ERR_PRI_1	This option defines the priority of the XX diagnosis.
1	LC_ERR_PRI_2	It is used for storage of failure and freeze frame.
2	LC_ERR_PRI_3	000: lowest priority for errors which are not significant for emission 011: highest priority for errors, which are not significant for emission 100: lowest priority for errors, which are significant for emission 111: highest priority which are significant for emission See details in “Priority rules” module. For emission relevant (EOBD, CARB) failure : LC_ERR_PRI_3 = 1 For non emission relevant failure : LC_ERR_PRI_3 = 0

27.20.1 Failure assignation

For each failure XX, a failure class is allocated. The failure class number makes this affectation, which is a calibration named C_ERR_CLAS_XX.

This table is defined in the “General Diagnosis Information”.

Diagnosis instance	Failure Class number Class A / Class B
Failure XX	C_ERR_CLAS_XX
Failure YY	C_ERR_CLAS_YY
...	...

The failure class number is a byte divided in two subclasses named class B (defined by the most significant quartet) and class A (defined by the less significant quartet).

Failure class number for failure XX

C_ERR_CLAS_XX =

(	Class B		)	(	Class A		)

27.20.2 Failure class definition

A failure class defines for a failure, which belongs to this failure class :

Part sub-class A :

- if the failure have impact on MIL illumination or not ;
- if the failure have impact on MIL blinking or not ;
- if the failure have impact on Warning Lamp 1 or not ;
- if the failure have impact on Warning lamp 2 or not ;
- if the failure is considered as a CARB/EOBD failure (emission relevant)
  (failure visible with scantool, failure can set OBD freeze frame for mode 2h)

Part sub-class B :

- the increment value for driving cycle counter management ;
- the maximum value of driving cycle counter ;
- the decrement value for driving cycle counter management ;
- the priority of the failure.

Each subclass of a failure class is composed of 4 bits, so 16 different values are possible for each subclass. For each subclass, some values are predefined and some values are reserved for improvement/validation and are managed by calibration.

Sub Class A definition : ID_ERR_CLAS_A_FMT (1 byte x 16)

Subclass A Value (i) in hex / Name	**Description**	**ID_ERR_CLAS_A_FMT [i]**

Formula section:

For each failure XX allocated to the failure class number C_ERR_CLAS_XX :

CTR_DC_INC_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][0]

CTR_DC_MAX_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][1]

CTR_DC_DEC_XX = ID_ERR_CLAS_B_FMT[4 Most Significant Bit of C_ERR_CLAS_XX][2]

Bit 0,1,2 of PRI_CONF_XX = ID_ERR_CLAS_B_FMT [4 Most Significant Bit of C_ERR_CLAS_XX][3]

Remark: The increment of the DC counter (*) for the failures defined by the failure classes LAW_L, LAW_M and LAW_H depends on the required regulation (Carb/EOBD).

27.20.3 Example

To define the failure MIS_A (Misfiring A) as :

- a failure with high priority
- with only impact on MIL (On and Blinking)

Set the failure MIS_A in class number 64 (in hex) with C_ERR_CLAS_MIS_A = 64H.

That means :

- The value of sub class B is 6H => failure with high priority ;
- The value of sub class A is 4H => Failure with impact on MIL (On and blinking) ;

= > Failure is a “CARB/EOBD failure”

DC_INC_MIS_A = 3

DC_MAX_MIS_A = 6

DC_DEC_MIS_A = 2

WAL_CONF_MIS_A = %0001 1100 (in binary)

PRI_CONF_MIS_A = %0000 0110 (in binary)

FUNCTION DESCRIPTION:

General information:

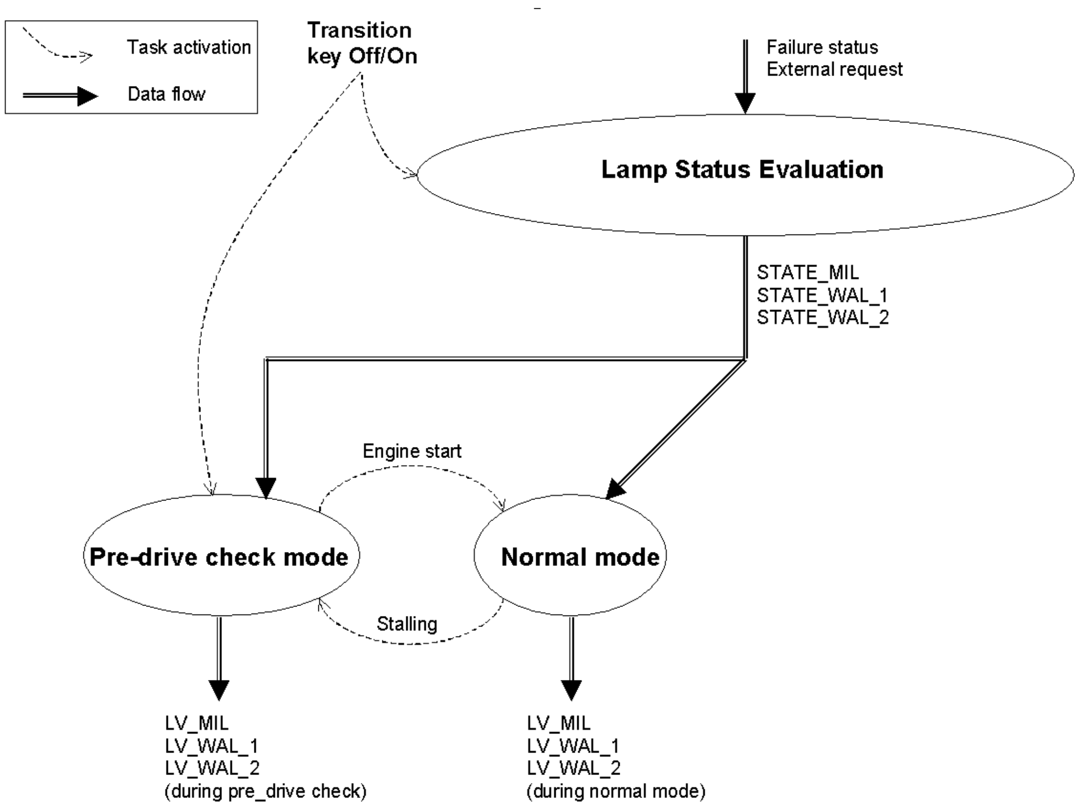
It is possible to manage up to three different lamps. They are called:

- MIL: Malfunction Indicator Lamp; this lamp is used to inform the vehicle driver in case of failures which can affect emissions.
- WAL_1: Warning Lamp 1 and WAL_2: Warning Lamp 2; these lamps are used to inform the vehicle driver in case of others failures.

For each lamp, a task evaluated the state of MIL, WAL_1 and WAL_2. These states STATE_MIL, STATE_WAL_1 and STATE_WAL_2 are respectively what error management commanded to the lamps regard to failure status.

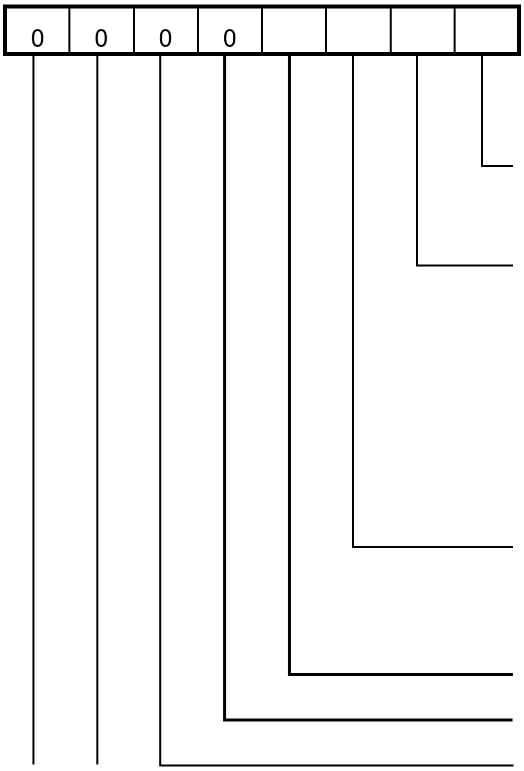
Then, the real physical state of each lamp (LV_MIL for MIL, LV_WAL_1 for WAL_1 and LV_WAL_2 for WAL_2) is build related to the mode in which they are. Lamps behavior is based on two modes:

- A predrive check mode between transition LV_IGK 0->1 and engine start; this mode is used to check the correct lamps working.
- A normal mode for the rest of the time.



A configuration byte is defined for each lamp: C_CONF_XXX (with XXX = MIL C_CONF_MIL, WAL_1 or WAL_2, C_CONF_WAL_1 C_CONF_WAL_2).

It is then possible to inhibit a lamp illumination, to allow or not external request for lamp illumination and to link lamp illumination each other's.



bit 0 of C_CONF_XXX : Global lamp XXX inhibition bit
0 : lamp XXX illumination is authorized
1 : lamp XXX is never illuminated except by an external request for lamp XXX

bit 1 of C_CONF_XXX : Lamp XXX request enable bit
0 : lamp XXX request input is never taken into account
1 : lamp XXX request input is taken into account

For MIL :
bit 2 of C_CONF_XXX: Special behavior for the Misfiring A failure in case of cylinder cut off.
0 : Without management of cylinder cut off
1 : With management of cylinder cut off
For WAL_1 and WAL_2 :
bit 2 of C_CONF_XXX : Illumination of MIL instead of lamp XXX
0 : no links between lamp XXX and MIL
1 : MIL is illuminated if illumination of lamp XXX is requested

bit 3 of C_CONF_XXX :
Inhibition of Predrive check for lamp XXX
0: Predrive check for lamp XXX enabled
1: Predrive check for lamp XXX disabled

Not used

Not used

Not used

Not used

Impact of each failure on lamp is defined in WAL_CONF_XX byte:

- bit 0 : if set, the present failure may caused a WAL_1 illumination ;
- bit 1 : if set, the present failure may caused a WAL_2 illumination ;
- bit 2 : if set, the failure may caused a MIL illumination when driving cycle counter reaches maximum ;
- bit 3: if set, the present failure may cause a MIL blinking.

27.21.1 Lamp Status Evaluation

Description:

Management of WAL_1 and WAL_2

Behavior of WAL_1 and WAL_2 are identical. WAL_1 and WAL_2 may be illuminated (state is ON) or not (state is OFF). When the global lamp inhibition bit is not set, the lamp is requested to illuminate:

- if at least one failure is present (LV_ERR_XX) with the corresponding bit of WAL_CONF_XX (bit 0 for WAL_1, bit 1 for WAL_2) in enable position and this failure is stored in 2nd layer memory ;
- or in case of allowed lamp request.

Management of MIL

MIL internal management is based on 3 states:

STATE_MIL = OFF	(MIL is requested continuously off)
STATE_MIL = ON	(MIL is requested continuously on)
STATE_MIL = MIL_FLL	(MIL is requested blinking at 1 Hz)

When the global MIL inhibition bit is not set, the MIL is requested to illuminate (ON):

- if at least one failure has reached its driving cycle maximum value and is unequal to zero (LV_DC_MAX[IDX]) with the corresponding bit of WAL_CONF_XX (bit 2) in enable position and this failure is stored in 2nd layer memory ;
- or in case of allowed lamp request ;
- or WAL_1 is requested to be illuminated and WAL_1 is link with MIL ;
- or WAL_2 is requested to be illuminated and WAL_2 is link with MIL ;

When the global MIL inhibition bit is not set, the MIL is requested to be blinking at 1hz (MIL_FLL):

- if at least one failure is present (LV_ERR_XX) with the corresponding bit of WAL_CONF_XX (bit 3) in enable position and this failure is stored in 2nd layer memory ;

A special calculation can be enabled for Misfire A failure with the management of cylinder shut off (bit 2 of C_CONF_MIL):

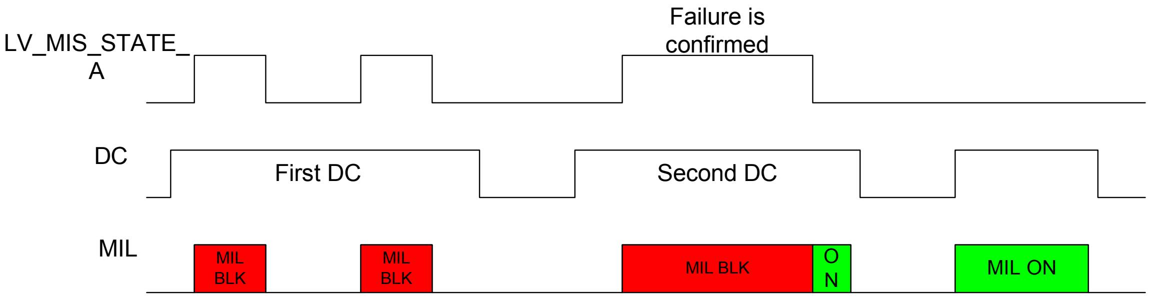
- bit 2 of C_CONF_MIL = 0: When a misfire A failure (LV_MIS_STATE_A) is present, the MIL is blinking.
- bit 2 of C_CONF_MIL = 1: If Misfire A failure (LV_MIS_STATE_A) is present with cylinder cut off, the MIL is blinking only for a calibratable time (C_DLY_INH_IV_MIS). After this time, the MIL is ON again.

Beware: The “blinking mode” is priority mode compared to “continuous on mode”.

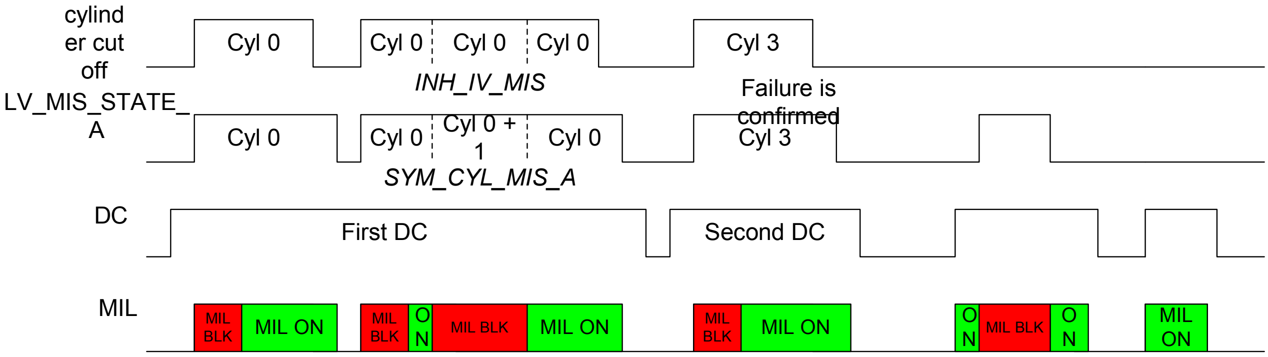
Signal flow diagram:

Special behavior for Misfire A failure with bit LC_MIL_INH_IV_MIS of C_CONF_MIL:

Behavior of Misfiring failure MIS_A without management of cylinder cut off (LC_MIL_INH_IV_MIS = 0)



Behavior of Misfiring A failure with management of cylinder cut off (LC_MIL_INH_IV_MIS = 1) :



Normal mode : MIL is ON (because the failure is confirmed)

Application conditions:

Initialization: -

Recurrence: 500 ms

Activation: -

Formula section:

```
If      bit 0 of C_CONF_WAL_1 = 1      (lamp WAL_1 illumination not authorized)
Then    STATE_WAL_1 = OFF      (lamp WAL_1 is off)
Else    If      at least one failure in 2nd layer memory has:

                                (MIL is requested continuously on)
                        Endif
                Endif
        Endif
Endif
If      at least one failure in 2nd layer memory has :
        (LV_ERR_XX and bit 3 of WAL_CONF_XX) = 1
        (at least one failure request to blink the MIL)
Then    STATE_MIL = MIL_FLL
        (MIL is requested blinking at 1Hz)
Endif
```

Endif

Remark:

For the misfiring A failure (treated as a particular case), the Bit 3 of WAL_CONF_XX mustn't be set to 1 by calibration (only bit 2 for continuous MIL illumination).

27.21.2 Lamp mode

27.21.2.1 Predrive Check mode

Description:

Predrive check mode is used to enable a visual check of the correct lamp working. Additionally it can be used to display readiness status as an option (MIL blinking).

Nevertheless a failure may also illuminate a lamp. Illumination of lamp during pre-drive check mode is performed only when :

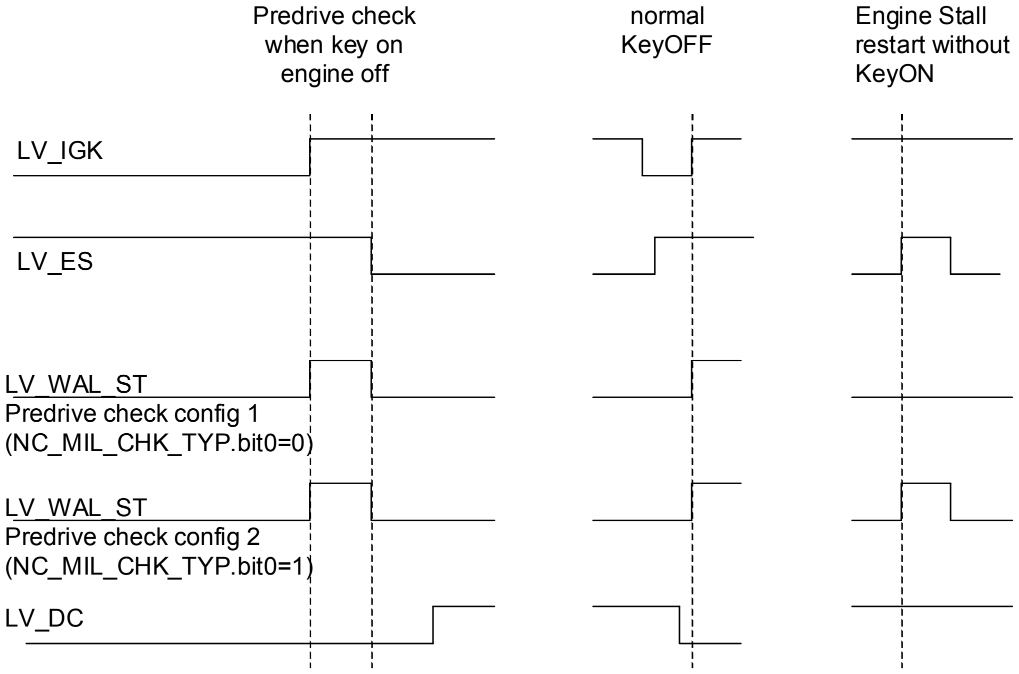
- the global lamp inhibition bit is not set (bit 0 of C_CONF_XXX = 1) and the lamp individual predrive check inhibition is not set (bit 3 of C_CONF_XXX = 1)
- or error management commands a lamp

A) Configuration of predrive check behaviour in case of stalling event:

with NC_MIL_CHK_TYP (bit 0)

Predrive check mode phase can be defined in 2 ways:
- between key on transition LV_IGK 0->1 and engine start (bit 0 of NC_MIL_CHK_TYP=0)

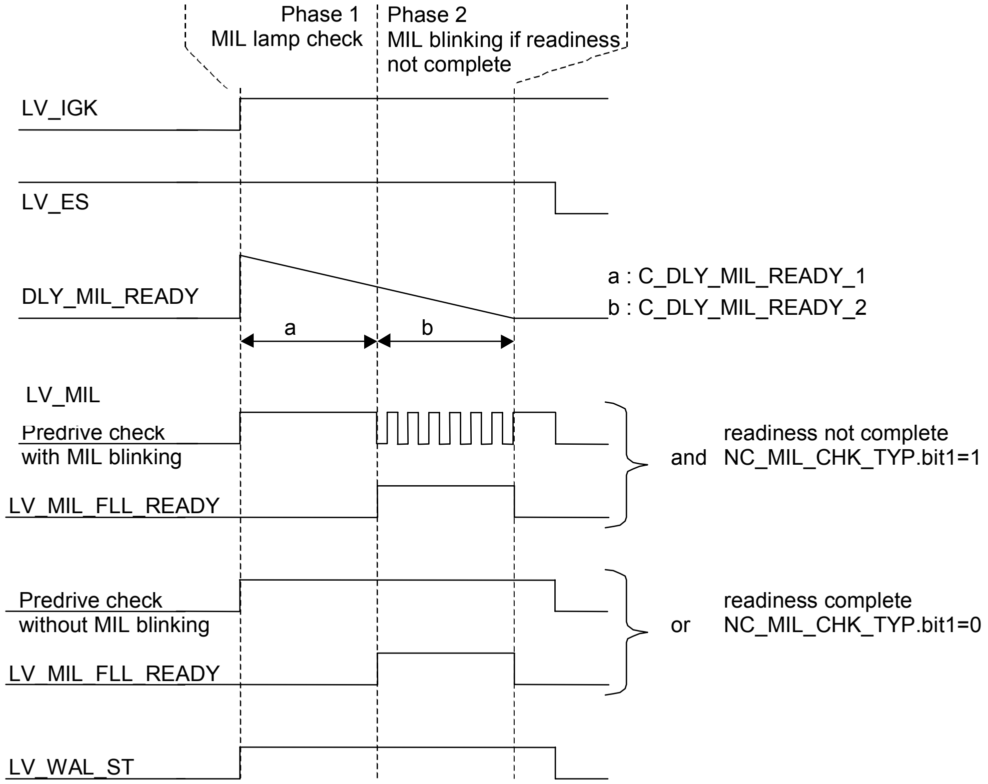
- or between key on transition LV_IGK 0->1 and engine start, plus between an engine stall event and engine start (bit 0 of NC_MIL_CHK_TYP=1)



B) Configuration of MIL blinking readiness status functionality:

with NC_MIL_CHK_TYP (bit 1)

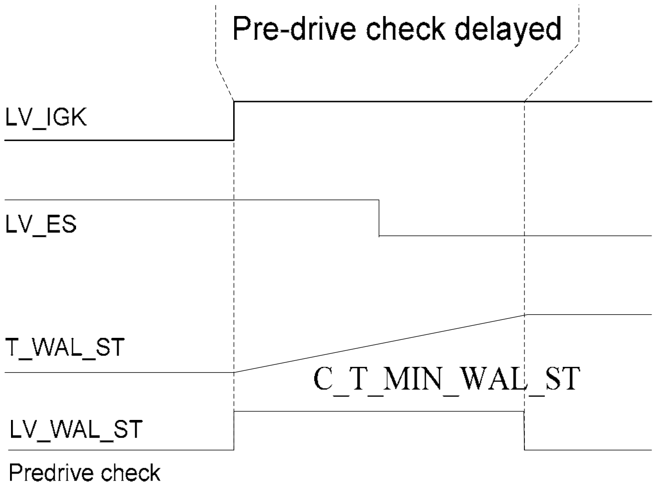
During predrive check mode, you can display the status of readiness codes through the MIL warning lamp : the MIL is blinking if readiness not complete.
This strategy is part of predrive check and does not affect the MIL status (STATE_MIL).



C) Management of minimum time of predrive check duration

-> only relevant after engine cranking (LV_ES 1->0)

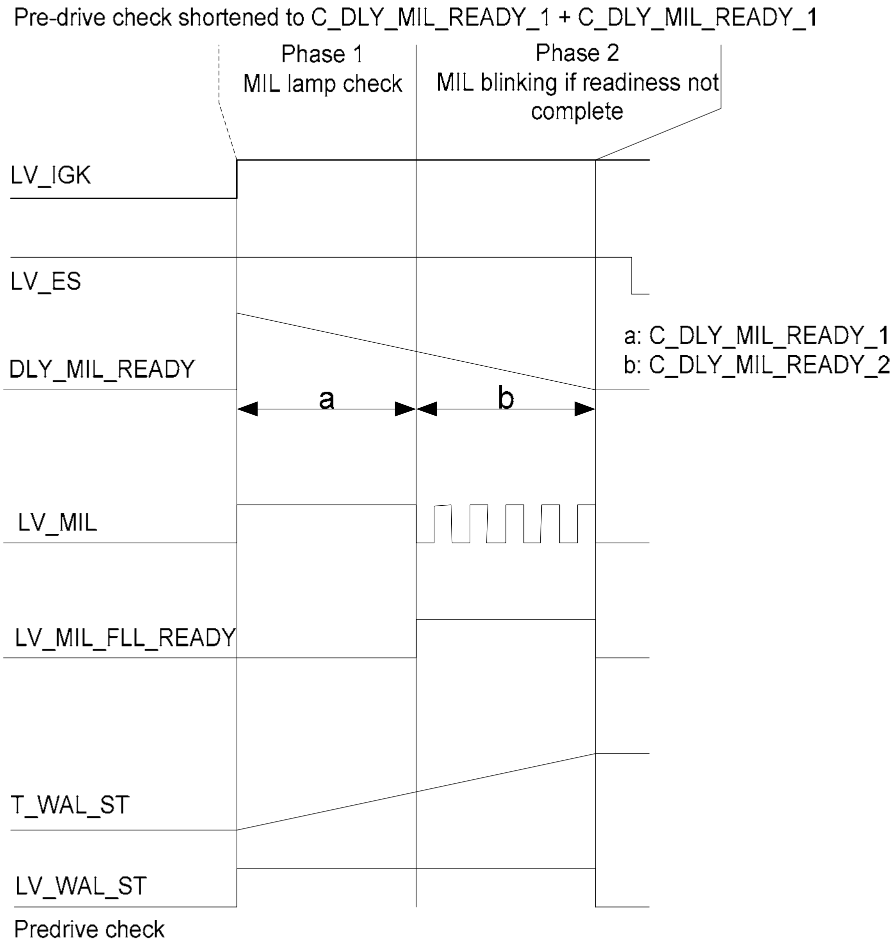
Wih the calibration C_T_MIN_WAL_ST it's possible to set a minimum time for the predrive check duration independant of engine cranking (LV_ES 1->0). This gives the possibility to illuminate the Mil for predrive check (e.g. in case of a quick start).



D) Management of maximum time of predrive check duration

-> only relevant before engine cranking (LV_ES = 0)

With the calibration LC_T_MAX_WAL_ST_ENA, it's possible to activated the maximum time of predrive check functionality. If this functionality is activated (LC_T_MAX_WAL_ST_ENA = 1) the maximum predrive check duration <u>before engine cranking</u> is C_DLY_MIL_READY_1 + C_DLY_MIL_READY_2. This gives the possibility to finish the predrive check before engine cranking e.g. in case of a long key on engine stop phase.



<u>Application conditions:</u>

Initialization: At LV_IGK transition 0 to 1
T_WAL_ST = 0 **and** LV_MIL_FLL_READY=0

At LV_ES transition 0 to 1
T_WAL_ST = 0

At LV_IGK transition 1 to 0 or if reset
LV_WAL_ST = 0 (Pre-drive check mode deactivated)

Recurrence: 500 ms and at LV_IGK 0 -> 1 transition

Activation: (pre-drive check enable between “stalling event/engine start”)

bit 0 of NC_MIL_CHK_TYP=1
and LV_IGK = 1 **and** LV_ES = 1

and (T_WAL_ST < C_DLY_READY_1 + C_DLY_READY_2

or LC_T_MAX_WAL_ST_ENA = 0)

27.23 Priority rules

Input data:

PRI_CONF_XX	WAL_CONF_XX	LV_ERR_DISA[NC_NR_ERR_DYN]	LV_DC_MAX[NC_NR_ERR_DYN]
LV_ERR_CFM[NC_NR_ERR_DYN]	NC_ERR_PRI_H		

Export actions:

ACTION_ERRM_PrioRule (OUT <RESP>, OUT <IDX>)
This action performs priority rules, when failure memory is full, to say if the new failure is accepted or not.

FUNCTION DESCRIPTION:

General information:

The dynamic error management module calls this module in case of present failure occurrence when the 2nd layer memory is full.

It defines criteria to store or not this failure in the 2nd layer memory (dynamic memory). Only one failure occurrence is stored.

Results of this module is either:

- "storage of new failure not possible"
- or ("storage of new failure possible" ; index of failure to delete in 2nd layer memory)

In case of new failure entry whereas the dynamic memory is full (number of stored failure = NC_NR_ERR_DYN), different criteria are applied to prioritize the failure:

- A new failure is more important than a disappeared failure
- Failure priority as defined in PRI_CONF_XX ;
    - Chronological failure order

      If NLC_OLD_ERR_PRI = 1: old failure has priority regards of new failure;

      (Failure i older than failure j means failure i has entered 2nd layer memory before failure j)

      If NLC_OLD_ERR_PRI = 0: new failure has priority regards of old failure;

      (Failure i newer than failure j means failure i has entered 2nd layer memory after failure j)

Additional features of this functionality:

- MIL can never be switched off
- Failure setting the OBD freeze frame (e.g. used for diagnostic communication with scantool / mode 2h) cannot be erased.
- The "increased priority" can be enabled with the configuration NLC_INC_ERR_PRI. This priority is a final rule, which is used, if it's not possible to enter a failure with any of the other possibilities. Then it's possible (only for failure with priority >= 4) to store the failure, if a confirmed failure not of the highest priority (priority < NC_ERR_PRI_H), which is not illumination the MIL anymore, can erased instead.

If the new failure entry is not accepted because of the priority, this failure will not be stored in the 2nd layer memory but limp home is activated, thus the freeze frame is not memorized and also no lamp management for this failure is possible.

Description:

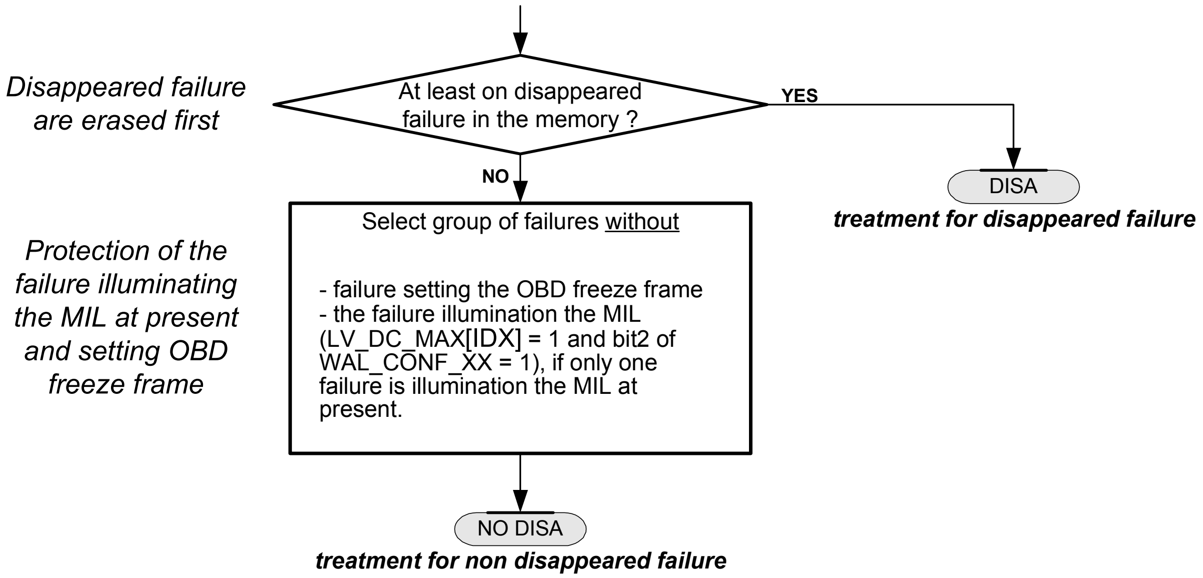
Syntax :	ACTION_ERRM_PrioRule (OUT <RESP>, OUT <IDX>)	
Parameter (in) :	-	
Parameter (out) :	RESP	OK if storage is possible; NOK if storage is not possible
	IDX	Index of failure in 2nd layer memory to delete
Short description :	This action performs priority rules, when failure memory is full, to say if the new failure is accepted or not.	

Application conditions:

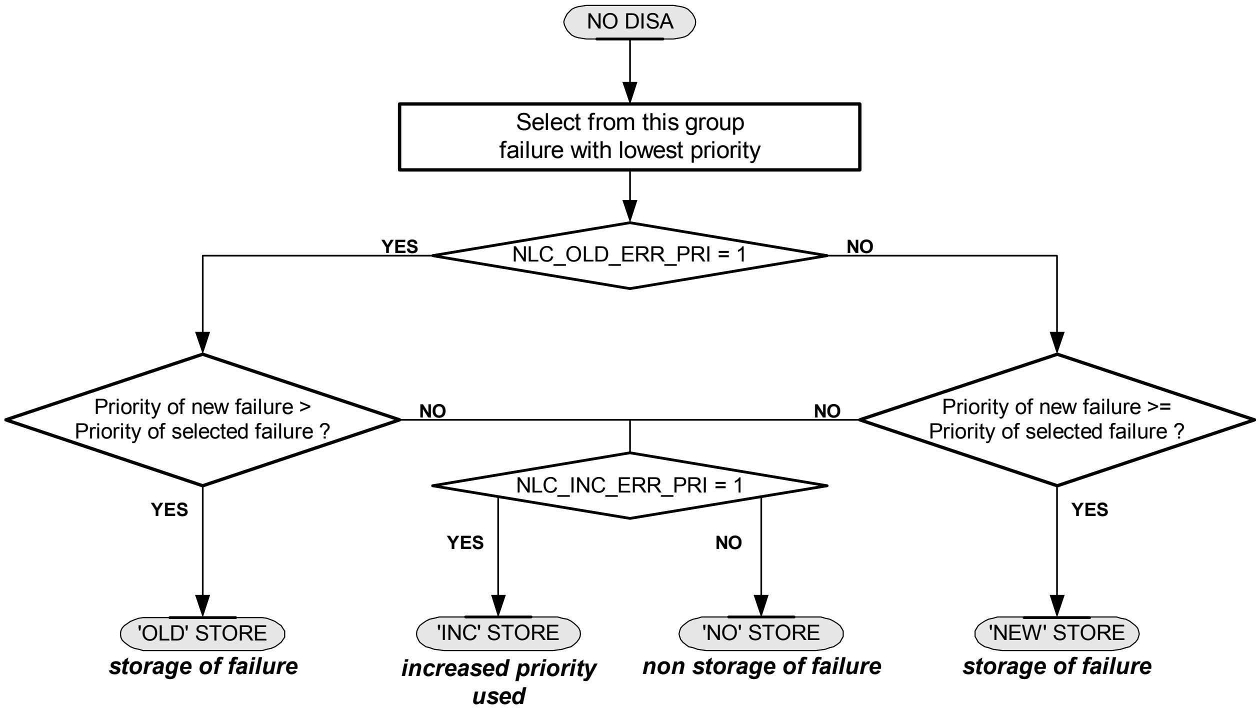
Activation:	-
Recurrence:	-
Deactivation:	at action request

Formula section:

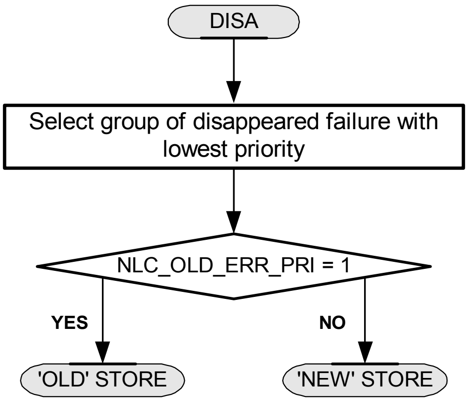
ACTION_ERRM_PrioRule (RESP, IDX) :



Treatment for non disappeared failure:



Treatment for disappeared failure:



Storage / non storage of failure:

Readiness flag related to diagnosis XX					

Input data:

LV_END_DIAG_XX	LV_ERR_DC[NC_NR_ERR_DYN]	LV_DC_MAX[NC_NR_ERR_DYN]	LV_DC
LV_ERR_MEM_XX	LV_EOL_OBD_DC	LV_ERR_XX	

Export actions:

ACTION_ERRM_InitReadiness ( )
This action initialise all the readiness flag

FUNCTION DESCRIPTION:

General information:

Readiness flag allows to know if a full diagnostic check (not in EOL phase) has been done or not (minimum number of checks necessary for MIL illumination if failure is present).

A readiness flag is defined for each diagnosis (LV_READY_XX). Based on these flags, readiness code status (2 bytes STATE_READY_OBD_1 and STATE_READY_OBD_2) are generated in the Communication Interface (API) file for Carb mode.

Readiness flags are mainly used by after market service and inspections maintenance. When after market achieves a repair, the system should be controlled before to give back the car to its owner.

Because some failure need a long time (and may be 2 DC) to be diagnosed, the repair operator need an as quick as possible information meaning the repairs is OK.

The readiness flag indicates when it is set to 0 that :

- the diagnosis related to failure XX is done since the last “clear DTC” service received.
- and if a failure XX is present, MIL would be illuminated.

For after market time optimisation, in case of no failure at all, the readiness flag is set to 0.

The readiness flag indicates when it is set to 1 that :

- the diagnosis related to failure XX is not done since the last “clear DTC” service received.
- or if a failure XX is present, MIL is not still illuminated (may takes many driving cycle).

After failure erase, all bits associated to supported functions are set to 1.

When the system has executed enough driving cycles for determining if MIL should be switch On or not, all the readiness flags are in 0 state. At this occurrence, failures which may have switch on the MIL could be considered as repaired if MIL is Off.

27.24.1 Readiness flag set to 0

Description:

The readiness flag LV_READY_XX is set to 0 when enough driving cycle has been done without failure XX.

Application conditions:

Initialization: On saved ram lost

LV_READY_XX = 1

Recurrence: at the recurrence of activation condition

Activation: at transition LV_DC 0->1
or at transition LV_END_DIAG_XX 0->1

Formula section:

```
If    LV_READY_XX = 1                          (diag XX not still ready)
      and LV_DC = 1                            (driving cycle valid)
            and LV_END_DIAG_XX = 1                       (diag done)
            and LV_EOL_OBD_DC = 0                        (not in EOL tests)
Then        If      LV_ERR_MEM_XX = 1          (failure in 2nd layer memory)
            Then    If      LV_ERR_DC[IDX] = 0 (no failure present this DC)
                    Then    LV_READY_XX = 0    (diag XX is ready)
                    Else    If      LV_DC_MAX[IDX] = 1
                            Then    LV_READY_XX = 0   (diag XX is ready)
                            Endif
                    Endif
            Else    If      LV_ERR_XX = 0
                    Then    LV_READY_XX = 0    (diag XX is ready)
                    Endif
            Endif
Endif
```

27.24.2 Readiness flag reinitialisation (set to 1)

Description:

Syntax : ACTION_ERRM_InitReadiness ( )

Parameter(in) : No parameter

Parameter(out) : No parameter

Short description :

The readiness flag LV_READY_XX is reinitialized (set to 1) upon communication tool request via the action ACTION_ERRM_InitReadiness ( ).

This reinitilisation is always done when all failure are erased from failure memory.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

For every failure : LV_READY_XX = 1

27.24.3 Readiness code information update

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Readiness code completion status 3					

Input data:

LV_DC			

Import actions:

ACTION_ERRM_ReadReadinessCode(INOUT<ReadinessCode>, OUT<ResultReadinessCode>)
ACTION_ERRM_ReadReadinessCodCus(INOUT<ReadinessCode>, OUT<ResultReadinessCode>)

Description:

Purpose of this paragraph is to update readiness code completion status. This update shall be done :

- at end of driving cycle, for readiness status display,
- on action call, for customer tool and Scan Tool coherency with STATE_READY_OBD_X.

Important remark: each time ACTION_ERRM_ReadReadinessCode is called Readiness codes completion status (STATE_READY_OBD_1 and STATE_READY_OBD_2) are calculated.

Application conditions:

Activation: at LV_DC 1→ 0 transition

Initialization: on non-volatil memory reset/lost **or** on failure erase service received

STATE_READY_OBD_1 = FFh,

STATE_READY_OBD_2 = FFh
{FFh value indicates that readiness code is not yet computed}

Recurrence: none, executed single time on activation.

Formula section:

{ Action call to update STATE_READY_OBD_1 and STATE_READY_OBD_2 }

Call ACTION_ERRM_ReadReadinessCode(INOUT<STATE_READY_OBD_1, STATE_READY_OBD_2>, OUT<ResultReadinessCode>)

Application conditions:

Activation : at LV_DC 1→ 0 transition

Initialization: on non-volatil memory reset/lost

or

on failure erase service received
STATE_READY_OBD_3 = FFh
{ *FFh value permits to indicate that readiness is not yet computed* }

Recurrence : none, executed single time on activation.

Formula section:

{ Action call to update STATE_READY_OBD_3 }

Call ACTION_ERRM_ReadReadinessCodCus(INOUT<STATE_READY_OBD_3>, OUT<ResultReadinessCode>)

27.25 Similar conditions

STATE_SCDN[k] : Similar conditions status for diagnostic instance k

bit 0:	0: SCDN will be recorded (updated) at next failure occurrence 1: SCDN are recorded
bit 1:	Recognition of similar conditions with failure detection this DC
bit 2:	Recognition of similar condition without failure/exceedance detection this DC It’s also set after C_CTR_SCDN_EQU_DC_MAX driving cycles without similar conditions without error
bit 3:	Failure XX was present last DC
bit 4:	Request to increment driving cycle counter of failure XX
bit 5:	" exceedance" of specific limit was reported for failure XX

Input data:

LV_DC	LV_STATE_WUP	N	LOAD_SCDN
LC_ENA_SCDN	NLC_ENA_SCDN	LV_ERR_DC[NC_NR_ERR_DYN]	CTR_DC[NC_NR_ERR_DYN]
LV_CDN_DIAG_XX			

Export actions:

ACTION_ERRM_DecrementDCctrScdn (OUT <DCdec>, IN <XX>)
This action calculates the possibility to decrement the driving cycle counter related to failure XX
ACTION_ERRM_EraseScdn(IN <XX>)
This action erase the similar conditions related to failure XX (if existing)
ACTION_ERRM_CdnDiagScdn (IN <XX>)
This action is used to calculate a ratio to recognize the similar condition without failure
ACTION_ERRM_EndWinScdn (IN <XX>, IN <EXC>)
This is used to store similar conditions and recognize similar condition with or without failure

Import actions:

ACTION_ERRM_IncrementDCctrScdn (IN <XX>)

FUNCTION DESCRIPTION:

General information:

The different states of a failure are managed regards their driving cycle and warm up cycle counters values (see Dynamic error management core for details).

For Misfire and Fuel system failures, some additional conditions should be fulfilled to increment and decrement their driving cycle counter. These additional conditions are related to engine conditions and are called similar conditions.

When similar conditions without failure are fulfilled for the failure XX already stored in the dynamic memory in a previous driving cycle, bit 2 of STATE_SCDN[k] is set to 1. That means, that the driving cycle counter of failure XX could be decremented at the end of the driving cycle if the failure XX will not get present till this treatment. If an exceedance is reported by the diagnostic function (bit 5 of STATE_SCDN[k] is set to 1), the driving cycle counter is not decremented at the end of the DC. Exception: Driving cycle counter decrementation linked with C_CTR_SCDN_EQU_DC_MAX DCs, see description below.

Also the incrementation of the driving cycle counter of a failure stored in dynamic memory is controlled by the similar conditions functionality. The incrementation done in the error management core is triggered by the ACTION_ERRM_IncrementDCctrScdn (XX) in the following cases:

- Similar conditions are recorded

  (bit 0 of STATE_SCDN[k] 0->1).
- A failure already stored in memory occurs again in the following driving cycle (bit 2 of STATE_SCDN[k] = 1).
- A temporary failure or a confirmed failure with MIL off (LV_DC_MAX[IDX] = 0) occurs again not in the following driving cycle but with similar conditions with failure (bit 1 of STATE_SCDN[k] = 1).
- A confirmed failure with MIL on (LV_DC_MAX[IDX] = 1) occurs again.

In all of these cases, the driving cycle counter is incremented (bit 4 of STATE_SCDN[k] 0→1).

For a temporary failure or confirmed failure with MIL off (LV_DC_MAX[IDX] = 0), even if similar conditions are not recognized during a C_CTR_CDN_EQU_DC_MAX number of driving cycles, the driving cycle counter of the failure can be decremented after C_CTR_CDN_EQU_DC_MAX driving cycles.

Similar conditions functionality is inhibited when LC_ENA_SCDN=0 or NLC_ENA_SCDN=0.

Remark:

To keep the link between the index of the failure using the similar condition and the index of the failure in static memory, a transfer function is defined: k = Scdn (XX). The link between the diagnosis instance and the similar conditions instance k is described in the application incidence of similar condition.

27.25.1 Ratio calculation to recognize the similar condition without failure

Description:

For the recognition of similar conditions the current engine speed / load conditions are compared with the recorded similar conditions window.

Based on two counters calculated with this algorithm the SCDN recognition at end of the diagnostic window is done. (see next chapter)

- CTR_SCDN_EQU[k]

  counting the number of times engine speed / load conditions are within the recorded similar conditions window (with LV_CDN_DIAG_XX = 1)

- CTR_SCDN_SUM[k]

  counting the number of times the diagnosis conditions are set (LV_CDN_DIAG_XX = 1)

The calculation of the counters is stopped, if an exceedance is reported from diagnostic function.

Syntax : ACTION_ERRM_CdnDiagScdn (IN <XX>)

Parameter (in) : XX failure XX using similar condition instance XX

Parameter (out) : -

Short description:

This action is called at each diagnosis condition. It is used to calculate a ratio to recognize the similar condition with or without failure.

Application conditions:

Initialization: at transition LV_DC 0 -> 1 or reset

bit 0, bit 3 of STATE_SCDN[k] = restored from NVMY
bit 1, bit 2, bit 4, bit 5 of STATE_SCDN[k] = 0

CTR_SCDN_EQU[k] = 0

```
CTR_SCDN_SUM[k]                              = 0
```

Recurrence:

Activation: At action request **and** LV_DC = 1

and LC_ENA_SCDN = 1 and NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

```
k = Scdn (XX)
If  bit 0 of STATE_SCDN[k]    = 1   (similar conditions are recorded for failure XX)
and bit 5 of STATE_SCDN[k]    = 0   (no exceedance reported from diagnostic function)
Then    If     LV_CDN_DIAG_XX = 1
        Then   CTR_SCDN_SUM[k] ++
               (check if current N, LOAD_SCDN point is within SCDN window)
               If     N <= N_SCDN_MAX_EQU[k]
               and    N >= N_SCDN_MIN_EQU[k]
               and    LOAD_SCDN <= LOAD_SCDN_MAX_EQU[k]
               and    LOAD_SCDN >= LOAD_SCDN_MIN_EQU[k]
               Then   CTR_SCDN_EQU[k] ++
               Endif
Endif
```

27.25.2 Record and recognition of similar conditions at end of diagnosis window

Description:

The similar conditions are stored for a failure XX (or updated) in the following cases:

- The similar conditions are frozen within the window N/LOAD_MAX/MIN_SCDN_EQU[k], if the corresponding failure is stored in the memory (failure gets present the first time)
- The similar conditions are stored again (updated) within the window N/LOAD_MAX/MIN_SCDN_EQU[k], if the corresponding failure occurs again and the driving cycle counter of this failure was 0 before.

In both cases bit 0 of STATE_SCDN[k] is 0 before the storage.

The recognition of similar conditions for detected failure is done by comparing, if the actual N/LOAD point is within the stored SCDN window. If also the same warmup status is reached at this time, similar conditions with failure are recognized. This calculation is done at the action call depending of the monitoring function, only in the following case:

- Similar conditions are stored in a previous driving cycle (bit 0 of STATE_SCDN[k] = 1)
- and the same failure XX was not present the last driving cycle. In case of same failure present last driving cycle, the driving cycle counter is incremented without asking for similar conditions.

- and failure is not illuminating the MIL. In case failure is illuminating the MIL at present the driving cycle counter is set to the maximum without asking for similar conditions.
- and driving cycle counter not already incremented in this driving cycle

If no error is present at the end of the diagnosis window, the ratio (CTR_SCDN_EQU[k] / CTR_SCDN_SUM[k]) is compared with the threshold C_CTR_SCDN_NOT_ERR_THD[k]. If the threshold and the same warmup status are reached at this time, similar conditions without failure are recognized.

This calculation is done at the end of a diagnosis window, only if no failure XX is present in the following cases:

- Similar conditions are already recorded for failure XX (bit 0 of STATE_SCDN[k] = 1) in a previous driving cycle
- Similar conditions were not already encountered within this driving cycle with no failure
- no exceedance reported from diagnostic function (bit 5 of STATE_SCDN[k] = 0)
- Driving cycle counter was not incremented this driving cycle yet.

Syntax :	ACTION_ERRM_EndWinScdn (IN <XX>, <EXC>)	
Parameter (in) :	XX	failure XX using similar condition instance XX
	EXC	Exceedance reported from Diagnostic function
Parameter (out) :	-	

Short description:

This action is called at each end of diagnosis windows if there's no failure or when the failure gets present or when an exceedance is recognized by the diagnostic function. This usage of this function depends on the diagnostic function. It is used for recognition of similar condition with or without failure

Application conditions:

Initialization: -

Recurrence: -

Activation: At action request **and** LV_DC = 1
and LC_ENA_SCDN = 1 **and** NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

```

Endif
```

27.25.3 SCDN storage and recognition for detected failure performed last DC

Description:

According regulation the information, if a failure XX (using SCDN functionality) was present the last driving cycle, must be respected to increment the DC counter. In case of a new failure occurrence, if the same failure was present the last driving cycle, the driving cycle counter must be incremented (if not already incremented this driving cycle) independently of similar conditions.

Application conditions:

Initialization: -

Recurrence:

Activation: At LV_DC transition 1 -> 0 **and**

LC_ENA_SCDN = 1 **and** NLC_ENA_SCDN = 1
(similar conditions enable)

Formula section:

```
For k = 0 to NC_NR_WIN_SCDN - 1
    k = Scdn(XX); XX = F(IDX)
        If    LV_ERR_DC[IDX]     = 1      (failure present in this DC)
        Then         bit 3 of STATE_SCDN[k] = 1
            (failure present the last driving cycle)
            CTR_SCDN_EQU_DC[k] = C_CTR_SCDN_EQU_DC_MAX
            (re-initialization of similar conditions counters)
        Else         bit 3 of STATE_SCDN[k] = 0
            (failure not present the last driving cycle)
        Endif
EndFor
```

27.25.4 SCDN usage to decrement driving cycle counter

Description:

Syntax :	ACTION_ERRM_DecrementDCctrScdn (OUT <DCdec>, IN <XX>)	
Parameter (in) :	XX	number of failure to store in dynamic memory
Parameter (out) :	DCdec	YES if decrementation of DC counter is possible NO if decrementation of DC counter is not possible

Short description:

At the end of a driving cycle (LV_DC 1->0) the driving cycle counter for the failure XX can be decremented if similar conditions without failure are recognized and no exceedance reported from diagnostic function (bit 5 of STATE_SCDN[k] = 0) (used for misfire monitoring). For temporary failure or confirmed failure with MIL off, even if similar conditions are not recognized during a C_CTR_CDN_EQU_DC_MAX number of driving cycle, the driving cycle counter of the failure can be decremented after C_CTR_CDN_EQU_DC_MAX driving cycles.

Application conditions:

Initialization: -

Recurrence: -

Activation: at action request

Formula section:

```
k = Scdn(XX)
DCdec = NO        (decrementation of DC counter is not possible)
If   bit 2 of STATE_SCDN[k] = 1          (similar conditions encountered
                                           with no failure)
and  bit 5 of STATE_SCDN[k] = 0          (no exceedance reported)
Then      DCdec = YES                    (decrementation of DC counter is possible)
Else      If    LV_DC_MAX[IDX] = 0       (failure is temporary or confirmed with
                                          MIL off)
          Then  CTR_SCDN_EQU_DC[k] = CTR_SCDN_EQU_DC[k] – 1
                If    CTR_SCDN_EQU_DC[k] = 0
                      bit 2 of STATE_SCDN[k] = 1
                      DCdec = YES        (decrementation of DC counter is possible)
                Endif
          Endif
Endif

If    DCdec = YES
and   (LV_DC_MAX[IDX] = 0             (failure is temporary or confirmed with MIL off and
                                       DC counter of failure will be 0 after decrementation)
      or  (LV_DC_MAX[IDX] = 1 and CTR_DC[IDX] <= DC_DEC_XX))
                                      (failure is confirmed with MIL on and
                                       MIL will be switched off after decrementation)
Then  bit 0 of STATE_SCDN[k] = 0      (The SCDN window of failure XX will be updated
                                       With new engine conditions (N / LOAD (min/max))
                                       at next failure occurrence)
Endif
```

27.25.5 Similar conditions erase

Description:

Syntax : ACTION_ERRM_EraseScdn (IN <XX>)

Parameter (in) : XX number of failure to store in dynamic memory

Parameter (out) : -

Short description:

The similar conditions are erased by calling the action ACTION_ERRM_EraseScdn :
- when saved ram lost (at initialization)
- when corresponding failure is erased (see dynamic error management core module)

Application conditions:

FUNCTION DESCRIPTION:

General information:

This file defines the usage of the similar conditions functionality.

27.26.1 Similar conditions window definition

27.26.1.1 Similar condition data definition

Description:

There is only some failure using the similar condition so this table allows to do the link between the index of the failure in static memory and the index of the failure using the similar condition:

Diagnosis instances XX using similar conditions functionality	NC_NR_WIN_SCDN = **10**

Diagnosis instance XX	**similar conditions instance (k)**
FSD_1	0
FSD_2	1
FSD_LAM_LIM_1	2
FSD_LAM_LIM_2	3
MIS_0	4
MIS_1	5
MIS_2	6
MIS_3	7
MIS_4	8
MIS_5	9
	(NC_NR_WIN_SCDN - 1)

One function is defined to do the link between the index of the failure in static memory and the index of the failure using the similar condition: k = Scdn(XX)

27.26.1.2 Load calculation for similar condition

Description:

The calculated load SAE1979 (LOAD_CLC) is used for similar condition.

Application conditions:

Initialisation:	At reset:	LOAD_SCDN = LOAD_CLC
Recurrence:	100 ms	
Activation:	-	

Formula section:

LOAD_SCDN = LOAD_CLC

27.26.1.3 Treatment activated by the fuel system diagnosis for the similar condition

Description:

This treatement allows to call the two generic ACTION_ERRM_CdnDiagScdn (IN <XX>), ACTION_ERRM_EndWinScdn (IN <XX>, IN <EXC>) actions using for the similar condition.

Application conditions:

Initialisation: -

Recurrence: fuel system diagnosis recurrency

Activation: -

Formula section:

```
For i = 0 to NC_CBK_EX_NR - 1
    Adaptation to calculate a ratio used to recognize the similar condition with or without failure:
    If LV_CDN_DIAG_FSD[i] = 1
    Then   ACTION_ERRM_CdnDiagScdn (FSD[i])
    Endif
    If LV_CDN_DIAG_FSD_LAM_LIM[i] = 1
    Then   ACTION_ERRM_CdnDiagScdn (FSD_LAM_LIM[i])
    Endif

    Adaptation for the record and recognition of similar conditions:

    If LV_END_DIAG_WIN_FSD[i] 0 ->1

    Then

            Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

            ACTION_ERRM_EndWinScdn (FSD[i], 0)

    Endif

    If LV_END_DIAG_WIN_FSD_LAM_LIM[i] 0 ->1

    Then

            Record and recognition of similar conditions at the end of diagnosis or when the failure is present:

            ACTION_ERRM_EndWinScdn (FSD_LAM_LIM[i], 0)

    Endif

EndFor
```

27.26.2 SCDN usage for direct failure confirmation

Export actions:

ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>)
This action calculates the possibility to confirm a failure XX directly

Description:

Syntax :	ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>)	
Parameter (in) :	XX	number of failure to store in dynamic memory
Parameter (out) :	DCconf	1 if failure must be confirmed directly
		0 if failure should not be confirmed directly

Short description:

With the ACTION_ERRM_ConfirmErrScdn (OUT <DCconf>, IN <XX>) the value DCconf is transmitted to the driving cycle counter management to give the possibility to confirm a failure directly by incrementing the driving cycle counter for the failure XX to the maximum. This treatment must be done in the following situation:

A temporary failure XX caused by misfire B is in the memory and a failure XX caused by misfire A occures (not stored before). Then the misfire B depending failure can be erased and the misfire A failure can be confirmed directly.

Application conditions:

Initialization:	-
Recurrence:	-
Activation:	at action request

Formula section:

DCconf = 0 (direct confirmation of failure XX is not possible)

27.27 Error management communication interface

Output data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_MKD_MOD	O	0...1H	0...1	1	[-]
Marked Mode

Export actions:

ACTION_ERRM_ReadDtcByTypeOfDtc (
IN <TypeOfDtc>,
IN <LevelOfDtc>,
INOUT <ListOfDtc>,
OUT <ResultDtc>)

This action returns a list of DTC. All the DTC returns have the same type defined by the parameter TypeOfDtc

```
ACTION_ERRM_ReadDtcByDtc (
                        IN <DtcIdentifier>,
                        IN <LevelOfDtc>,
                        OUT <ResultDtc>)
```

This action returns a result to learn if a DTC number of a certain level is stored in memory.

```
ACTION_ERRM_ReadInfoByTypeOfDtc (
                        IN <TypeOfDtc>,
                        IN <InfoIdentifier>,
                        INOUT <ListOfDtcInfo>,
                        OUT <ResultDtc> )
```

This action returns a structure of data of DTCs. All the data returned are related to DTC, which have the same type defined by the parameter TypeOfDtc and which are stored in dynamic memory.

```
ACTION_ERRM_ReadInfoByDtc (
                        IN <DtcIdentifier>,
                        IN <LevelOfDtc>,
                        IN <InfoIdentifier>,
                        INOUT <ListOfDtcInfo>,
                        OUT <ResultDtc> )
```

This action returns a structure of data of a DTC, which is stored in dynamic memory.

```
ACTION_ERRM_ReadDtcLevelByDtcLevel (
                        IN <DtcIdentifier>,
                        IN <LevelOfDtc>,
                        INOUT <ListofDtc>,
                        OUT <ResultDtc> )
```

This action returns a Customer DTCLevel of Law DTCLevel which is stored in dynamic memory or returns a Law DTCLevel of Customer DTCLevel which is stored in dynamic memory.

```
ACTION_ERRM_ReadQuantityOfDtc (
                        IN <TypeOfDtc>,
                        IN <LevelOfDtc>,
                        INOUT <Quantity>,
                        OUT <ResultQuantity>)
```

This action returns the quantity of DTCs with a certain type, which are stored in memory.

```
ACTION_ERRM_ReadFrfByDtc (
                        IN <TypeOfFF>,
                        IN <FFIdentifier>,
                        IN <DtcIdentifier>,
                        IN <LevelOfDtc>,
                        INOUT <Frf>,
                        OUT <ResultFrf>)
```

This action returns a Freeze_Frame (with a particular type) related to the DTC given in parameter.

```
ACTION_ERRM_ClrInfoByTypeOfDtc (
                        IN <TypeOfDtc>,
                        OUT <ResultClrInfo>)
```

This action clear all the failure in dynamic memory associated to DTC with a certain type.

```
ACTION_ERRM_ClrInfoByDtc (
                        IN <DtcIdentifier>,
                        IN <LevelOfDtc>,
                        OUT <ResultClrInfo>)
```

This action clear the failure in dynamic memory associated to a DTC number.

```
ACTION_ERRM_ControlDtcSettings (
                        IN <MarkedMode>)
```

This action allows to activate or deactivate the marked mode. In this mode all new failure which appears are marked and then erased when we leave this mode.

```
ACTION_ERRM_ActivateMarkedMode (
                         IN <MarkedMode> )
```

This API shall be used to activate/deactivate the marked mode.

```
ACTION_ERRM_ReadReadinessCode (
                        INOUT <ReadinessCode>,
                        OUT <ResultReadinessCode>)
```

This action allows to read the readiness code information

```
ACTION_ERRM_ReadReadinessCodCus (
                        INOUT <ReadinessCode>,
                        OUT <ResultReadinessCode>)
```

This action allows to read the customer specific readiness code information CARB_OTHER/NO_CARB

ACTION_ERRM_SelectRbmData (INOUT <ListRbmData>, OUT < ResultRbmData >)
This action is used to request the selection of data to be transmitted by the Communication Mode $09
ACTION_ERRM_SelectRbmByGroup (IN < GroupName >, INOUT < ListOfRbmDataByGroup >, OUT < ResultRbmDataSelection >)
This action determines within one single group, the data with lowest ratios.
ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)
This action clears all the Rate-Based Monitoring statistics

Import actions:

ACTION_ERRM_EraseErr (IN <IDX>)
ACTION_ERRM_InitReadiness ( )

FUNCTION DESCRIPTION:

General information:

This chapter provides an open interface for other module which have link with error management functionality (communication module for instance). This interface is described with API (Application Programming Interface) to provide access to dynamic data flow in contrast to static data flow accessed directly through variable names.

By calling API, you can access in failure memory data related to Error Management such freeze frame and DTC stored, readiness code state and so on.

An API can have some input parameters.

Results returns by the API are defined as output parameters.

To returns functional results, a software structure (buffer) is used that allows to returns some data with not fixed size (a list of data for instance).

This structure is defined by the parameter in INOUT.

In the output parameter, a flag indicate if the software buffer is full or not.

Way of reading the failure memory :

API has to read through the failure memory to access some data related to Error Management.

In this case the failure memory is read in the order following the first failure entry, that means the oldest one. Thus the software structure is fill in first with data related to first failure entry (if need), then with data related to second failure entry (if need) and so on.

Description of parameters IN, OUT, INOUT used by API:

The INPUT parameters used by API and their authorised value are defined below :

TypeOfDtc : Type of Dtc

Authorised values for TypeOfDtc are :

- ALL : all the DTC stored in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- ALL FIRST: all the DTC stored at the first time in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- ALL LAST: all the DTC stored at the last time in Dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
- PRESENT : all the DTC of present failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_XX = 1
- PENDING : all the DTC of pending failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_PND[IDX] = 1
- TEMPORARY : all the DTC of temporary failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_TMP[IDX] = 1
- CONFIRMED : all the DTC of confirmed failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_CFM[IDX] = 1
- DISAPPEARED : all the DTC of disappeared failure stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_DISA[IDX] = 1
- MARKED : all DTC of failure marked and stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_MKD[IDX] = 1
- NOT MARKED : all DTC of failure not marked and stored in dynamic memory.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and LV_ERR_MKD[IDX] = 0
- OBD : all DTC related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1
  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)

- OBD FIRST: all the DTC stored at the first time in Dynamic memory related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1

  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)
- OBD LAST: all the DTC stored at the last time in Dynamic memory.related to emission relevant failure.
  Failures concerned in error management : LV_ERR_MEM_XX = 1

  and a Carb/EOBD failure :
  (emission relevant)
  (definition see failure class specification)
- Logical AND combination between these values.
  For instance : PRESENT and CONFIRMED are failure in error management with flags : LV_ERR_MEM_XX = 1 and LV_ERR_XX = 1 and LV_ERR_CFM[IDX] = 1.

Calculation of ERR_SYM_DTC[IDX] and SYM_CYL_DTC_XX following the TypeOfDtc parameter:

For all failure except the misfiring failure treated by type :

```
case TypeOfDtc
        ALL : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] or ERR_SYM_MEM[IDX]
        ALL FIRST: ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]
        ALL LAST : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]
        PRESENT : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]
        PENDING : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]
        TEMPORARY : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]
        CONFIRMED : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]
        DISAPPEARED : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]
        MARKED :      ERR_SYM_DTC[IDX] =
                      ERR_SYM_LST[IDX] or ERR_SYM_MEM[IDX]
        NOT MARKED :        ERR_SYM_DTC[IDX] =
                            ERR_SYM_LST[IDX] or ERR_SYM_MEM[IDX]
        OBD : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] or ERR_SYM_MEM[IDX]
        OBD FIRST : ERR_SYM_DTC[IDX] = ERR_SYM_MEM[IDX]
        OBD LAST : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX]
End case
```

For the misfiring failure treated by type (XX = MIS_A, MIS_B1 or MIS_B4)

```
IF NLC_TREAT_DIAG_MIS = 0
case TypeOfDtc
        ALL : SYM_CYL_DTC_XX = SYM_CYL_LST_XX or SYM_CYL_MEM_XX
        ALL FIRST : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX
        ALL LAST: SYM_CYL_DTC_XX = SYM_CYL_LST_XX
        PRESENT: SYM_CYL_DTC_XX = SYM_CYL_LST_XX
        PENDING : SYM_CYL_DTC_XX = SYM_CYL_LST_XX
        TEMPORARY : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX
        CONFIRMED : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX
        DISAPPEARED : SYM_CYL_DTC_XX = SYM_CYL_MEM_XX
        MARKED : SYM_CYL_DTC_XX = SYM_CYL_LST_XX or SYM_CYL_MEM_XX
        NOT MARKED : SYM_CYL_DTC_XX =
                        SYM_CYL_LST_XX or SYM_CYL_MEM_XX
        OBD : SYM_CYL_DTC_XX = SYM_CYL_LST_XX or SYM_CYL_MEM_XX
        OBD FIRST: SYM_CYL_DTC_XX = SYM_CYL_MEM_XX
        OBD LAST: SYM_CYL_DTC_XX = SYM_CYL_LST_XX
End case
ENDIF        { NLC_TREAT_DIAG_MIS = 0 }
```

For the logical AND combination between the different TypeOfDtc values, the ERR_SYM_DTC[IDX] or SYM_CYL_DTC_XX will be calculated with a binary logical AND from the associated carrier symptom.

For instance : PRESENT and CONFIRMED are failure in error management with flags : LV_ERR_MEM_XX = 1 and LV_ERR_XX = 1 and LV_ERR_CFM[IDX] = 1.
It means : ERR_SYM_DTC[IDX] = ERR_SYM_LST[IDX] **&** ERR_SYM_MEM[IDX],
SYM_CYL_DTC_XX = SYM_CYL_LST_XX **&** SYM_CYL_MEM_XX.

Calculation of ERR_SYM_DTC[IDX] and SYM_CYL_DTC_XX in case the API doesn't use the TypeOfDtc parameter :

ERR_SYM_DTC[IDX] = ERR_SYM_LST **or** ERR_SYM_MEM[IDX]

SYM_CYL_DTC_XX = SYM_CYL_LST_XX **or** SYM_CYL_MEM_XX

DtcIdentifier : Number of the DTC (identifier)

Authorised value for DtcIdentifier are : NO_DTC, ...<integer>

TypeOfFF : Type of Freeze Frame

Authorised values for TypeOfFF are :

- LAW : part of the freeze frame defined by the law (Carb)

- CUS_CMN : part of the freeze frame defined for the customer and not in the set
- CUS_SET : part of the freeze frame defined for the customer and in the set
- All combination of these values.

LevelOfDtc : Allowing to access to OBD error codes or customer error codes.

Authorised values for LevelOfDtc are :

- LAW : the DTC corresponds to a OBD DTC (Carb)
- CUS : the DTC corresponds to a specific customer DTC

FFIdentifier : Number of FF (identifier)
Authorised values for FFIdentifier are :

- FIRST : first freeze frame is requested
- SECOND : second freeze frame is request
- ...

MarkedMode : State of the marked mode

Authorised values for MarkedMode are :

- ON : marked mode activation : all failure stored are marked.
- OFF : marked mode deactivation (normal mode)

InfoIdentifier : Identifier for the diagnosis related information which is returned by the API (only words are returned)

Authorised information for InfoIdentifier are (only one information is returned by the API):

- CTR_ABC_XX
- CTR_ABC_END_DIAG_XX
- LV_END_DIAG_XX
- LV_READY_XX
- LV_CDN_DIAG_XX
- ERR_SYM_XX
- LV_ERR_XX
- LV_ERR_MEM_XX

- ERR_SYM_LST[IDX]
- ERR_SYM_DTC[IDX]
- LV_ERR_CFM[IDX]
- LV_ERR_DISA[IDX]
- LV_ERR_TMP[IDX]

- LV_ERR_PND[IDX]
- LV_DC_MAX[IDX]
- LV_ERR_DC[IDX]
- LV_ERR_MKD[IDX]
- C_ERR_CLAS_XX
- WAL_CONF_XX
- PRI_CONF_XX
- DC_INC_XX
- DC_DEC_XX
- DC_MAX_XX
- ID_ERR_DTC_XX[0][0]
- ID_ERR_DTC_XX[0][1]
- ID_ERR_DTC_XX[0][2]
- ID_ERR_DTC_XX[0][3]
- ID_ERR_DTC_XX[0][4]

if NC_NR_DTC_FMT = 0

(Manage 6 DTC per failure)

- ID_ERR_DTC_XX[0][5]

else

(Manage 10 DTC per failure)

- ID_ERR_DTC_XX[1][0]
- ID_ERR_DTC_XX[1][1]
- ID_ERR_DTC_XX[1][2]
- ID_ERR_DTC_XX[1][3]
- ID_ERR_DTC_XX[1][4]

endif

Please note that some application incidences can provide additional project specific informations.

The OUTPUT parameters used by API and their authorised value are defined below :

ResultDtc : Result to say if there is some DTC in memory corresponding to the API request

Authorised values for ResultDtc are :

1st bit of ResultDtc :

- (0) NO_DTC_PRESENT : there is no DTC in memory corresponding to the API request
- (1) DTC_PRESENT : there is some DTC in memory corresponding to the API request

2nd bit of ResultDtc :

- (0) NO_BUFFER_FULL : The software buffer used to return data is not full
- (1) BUFFER_FULL : The software buffer used to return data is full

ResultFrf : Result to say if there is some Freeze Frame in memory corresponding to the API request

Authorised values for ResultFrf are :

1st bit of ResultFrf :

- (0) NO_FRF_PRESENT : there is no freeze frame in memory corresponding to the API request
- (1) FRF_PRESENT : there is some freeze frame in memory corresponding to the API request

2nd bit of ResultFrf :

- (0) NO_BUFFER_FULL : The software buffer used to return data is not full
- (1) BUFFER_FULL : The software buffer used to return data is full

ResultQuantity : Result to say if the result of the API is valid.

Authorised values for ResultQuantity are :

1st bit of ResultQuantity :

- (0) NO_DTC_PRESENT : there is no DTC in memory corresponding to the API request
- (1) DTC_PRESENT : there is some DTC in memory corresponding to the API request

ResultClrInfo : Result to say if the clear DTC made by the API is done or not.

Authorised values for ResultClrInfo are :

1st bit of ResultClrInfo :

- (0) INFO_CLEARED : DTC are cleared by the call of the API
- (1) INFO_NOT_CLEARED : no DTC is cleared by the call of the API

ResultReadinessCode : Result to say if the API is done or not.

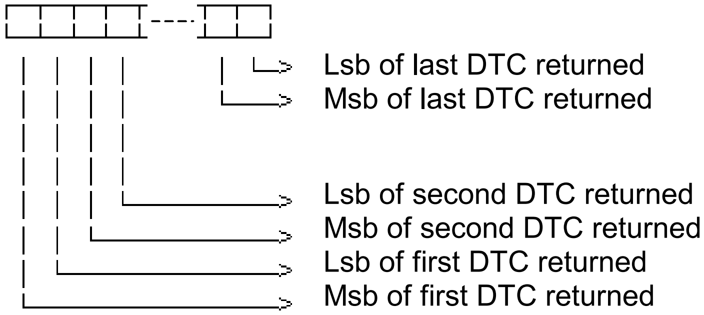
Authorised values for ResultReadinessCode are :

1st bit of ResultReadinessCode :

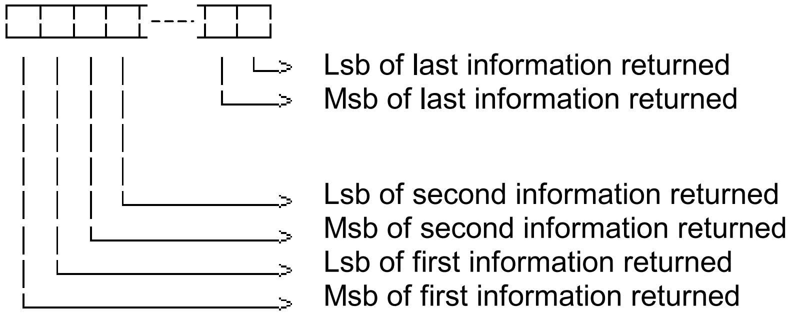
- (0) POSITIVE_RESPONSE : the call of the API is successful
- (1) NEGATIVE_RESPONSE : the call of the API is not successful

The INPUT/OUTPUT parameters used by API and their authorised value are defined below :

- ListOfDtc : Software structure filled up with a list of DTC

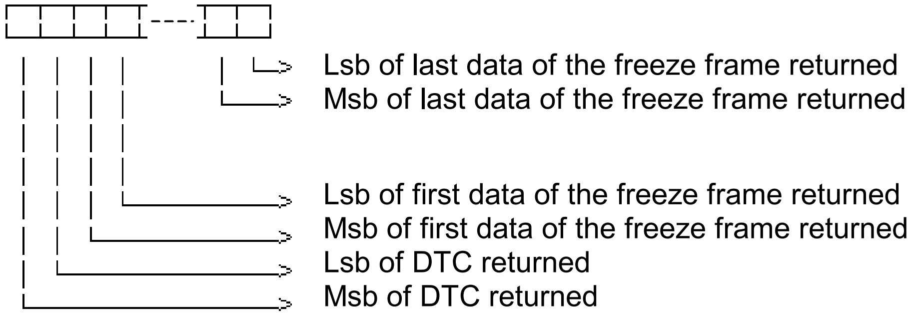


- ListOfDtcInfo : Software structure filled up with a list of DTCInfo



- Quantity : Software structure filled up with a quantity of DTC

- Frf : Software structure filled up with a freeze frame



- ReadinessCode : Software structure filled up with readiness code

27.27.1 API for reading Diagnostic Trouble Code (DTC)

27.27.1.1 Request a list of DTCs by type of DTC.

Description :

Syntax : ACTION_ERRM_ReadDtcByTypeOfDtc (
IN <TypeOfDtc>,
IN <LevelOfDtc>,
INOUT <ListOfDtc>,
OUT <ResultDtc>)

Parameter(in) :	TypeOfDtc	Type of DTC which is requested by the API.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if some DTC is in memory
Parameter(inout) :	ListOfDtc	Software structure fills up with a ListOfDtc

Short Description : This API returns a list of DTCs. All the DTC returns have the same type defined by the parameter TypeOfDtc and the same level defined in LevelOfDtc.

For each failure, if NC_NR_DTC_FMT = 0 then 6 DTC are defined : one DTC for each symptom (OBD or Customer), one OBD global DTC, one customer global DTC else 10 DTC are defined : one OBD DTC for each symptom, one OBD global DTC, one customer specific DTC number for each symptom and one customer global DTC.

When LevelOfDtc = LAW : OBD Dtc is request

If NC_ERR_DTC_REQ_OBD = SYMPTOM, the DTC is build up following the detected symptom. If more than one symptom is detected, a DTC per symptom detected is returned. There is a particular case for Misfiring failure. For this failure, the DTC number is built up following the cylinder where the misfiring is detected.

If NC_ERR_DTC_REQ_OBD = FAILURE, the OBD global DTC is returned.

When LevelOfDtc = CUS : Customer Dtc is request

If NC_ERR_DTC_REQ_CUS = SYMPTOM, the DTC is build up following the detected symptom. If more than one symptom is detected, a DTC per symptom detected is returned. There is a particular case for Misfiring failure. For this failure, the DTC number is built up following the cylinder where the misfiring is detected.

If NC_ERR_DTC_REQ_CUS = FAILURE, the customer global DTC is returned.

                    Endfor
            Endif
        Endif
    Endif
Endfor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

If there is duplicated DTC then only the oldest is returned

27.27.1.2 Request a DTC by DTC number

Description :

Syntax :	ACTION_ERRM_ReadDtcByDtc (IN <DtcIdentifier>, IN <LevelOfDtc>, OUT <ResultDtc>)	
Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Short Description :	This API returns a result to learn if a DTC number of a certain level is stored in memory.	

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultDtc = NO_DTC_PRESENT

2nd bit of ResultDTC = NO_BUFFER_FULL

```

27.27.2 API for reading the status of Diagnostic Trouble Code

27.27.2.1 Request a list of status of DTCs by type of DTC

Description :

Syntax :

```
ACTION_ERRM_ReadInfoByTypeOfDtc (
        IN <TypeOfDtc>,
        IN <InfoIdentifier>,
        INOUT <ListOfDtcInfo>,
        OUT < ResultDtc> )
```

Parameter(in) :	TypeOfDtc	Type of DTC which is requested by the API.
	InfoIdentifier	Information which is returned by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns a diagnosis information. All the information returned are related to DTC which have the same type defined by the parameter TypeOfDtc and which are stored in memory.

Diagnosis information returned is defined by InfoIdentifier parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
1st bit of ResultDtc = NO_DTC_PRESENT
2nd bit of ResultDtc = NO_BUFFER_FULL
For each failure stored in dynamic memory,
    If    the failure belongs to group defined by the parameters TypeOfDtc
    Then  1st bit of ResultDtc = DTC_PRESENT
          ListOfDtcInfo is fill up with data of this failure corresponding to InfoIdentifier.
    Endif
EndFor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

27.27.2.2 Request a status of a DTC by DTC number

Description :

Syntax : ACTION_ERRM_ReadInfoByDtc (
IN <DtcIdentifier>,
IN <LevelOfDtc>,
IN <InfoIdentifier>,
INOUT <ListOfDtcInfo>,
OUT <ResultDtc>)

Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
	InfoIdentifier	Information which is returned by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns a structure of diagnosis information related to a DTC which is stored in dynamic memory.

Diagnosis information returned is defined by InfoIdentifier parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultDtc = NO_DTC_PRESENT

2nd bit of ResultDtc = NO_BUFFER_FULL

                        If      SYM_CYL_DTC_XX [13]=1           (Multiple cylinder)
                        Then If         DtcIdentifier=ID_ERR_DTC_MIS [1] [NC_CYL_NR]
                             Then       1st bit of ResultDtc = DTC_PRESENT
                                        ListOfDtcInfo is fill up with data of this failure
                                        corresponding to InfoIdentifier.
                             Endif
                        Endif
                        If      SYM_CYL_DTC_XX [12]=1           (Random)
                        Then If         DtcIdentifier=ID_ERR_DTC_MIS[1][NC_CYL_NR+1]
                             Then       1st bit of ResultDtc = DTC_PRESENT
                                        ListOfDtcInfo is fill up with data of this failure
                                        corresponding to InfoIdentifier.
                             Endif
                        Endif
                        For each cylinder bit i which is set in SYM_CYL_DTC_XX
                             If DtcIdentifier = ID_ERR_DTC_MIS[1][i]
                             Then       1st bit of ResultDtc = DTC_PRESENT
                                        ListOfDtcInfo is fill up with data of this failure
                                        corresponding to InfoIdentifier.
                             Endif
                        Endfor
                Endif
        Endif
Endfor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the status of the first DTC found (oldest DTC) is returned.

27.27.2.3 Request a DTCLevel by an another DTCLevel

Description :

Syntax :

```
ACTION_ERRM_ReadDtcLevelByDtcLevel (
        IN <DtcIdentifier>,
        IN <LevelOfDtc>,
        INOUT <ListOfDtc>,
        OUT <ResultDtc> )
```

Parameter(in) :	DtcIdentifier	Number of the DTC (identifier) which is requested.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultDtc	Boolean to say if there is the DTC in memory
Parameter(inout) :	ListOfDtcInfo	Software structure fill up with ListOfDtcInfo

Short Description : This API returns the customer DTC from the Law DTC or the DTC Law from the DTC customer following the 'levelofDTC' parameter.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1^{st} bit of ResultDtc = NO_DTC_PRESENT

2^{nd} bit of ResultDtc = NO_BUFFER_FULL

```

    Endif
Endfor
```

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultDtc is set to BUFFER_FULL, software process is aborted.

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the status of the first DTC found (oldest DTC) is returned.

27.27.3 API for reading the number of Diagnostic Trouble Code

27.27.3.1 Request the quantity of DTC with a certain type stored in memory

Description :

```
Syntax :           ACTION_ERRM_ReadQuantityOfDtc (
                         IN <TypeOfDtc>,
                         IN <LevelOfDtc>,
                         INOUT <Quantity>,
                         OUT <ResultQuantity> )
```

Parameter(in) :	TypeOfDtc	Type of DTC which is requested by the API.
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultQuantity	Boolean to say if there is at least 1 DTC in memory
Parameter(inout) :	Quantity	Software structure fill up with quantity of Dtc

Short Description : This API returns the quantity of DTCs with a certain type, which are stored in memory. Quantity of DTCs is the number of failures in memory. If failures have same DTC values then they are counted once.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

Quantity = 0

ResultQuantity = NO_DTC_PRESENT

```
For each failure IDX stored in dynamic memory,
    If      the failure belongs to failures group defined by the parameter TypeOfDtc
    Then    ResultQuantity = DTC_PRESENT
            If  failure is not with status = CARB_MIS
            Then Condition for failure traitment is true

                                Quantity = Quantity +1
                         Endif
                  Else   (Customer DTC is request ; LevelOfDtc = CUS)
                         If     NC_REQ_CUS = SYMPTOM             (access by symptom)
                         Then   Quantity  = Quantity + j
                                with j = number of bit set in ERR_SYM_DTC_IDX
                         Else   (access by failure ; NC_REQ_OBD = FAILURE )
                                Quantity = Quantity +1
                         Endif
                  Endif

            Else  (particular case for misfiring failure)
                  XX = F (IDX) with XX = MIS_A, MIS_B1 or MIS_B4
                  If     LevelOfDtc = LAW                        (OBD DTC is request)
                  Then   If     SYM_CYL_DTC_XX [12]=1  (Random)
                         Then   Quantity = Quantity +1
                         Endif
                         If     SYM_CYL_DTC_XX [13]=1  (Multiple cylinder)
                         Then   Quantity = Quantity +1
                         Endif
                         If     (many cylinder bit is set in SYM_CYL_DTC_XX)
                                Quantity = Quantity + j
                                With j   = number of cylinder bit set in SYM_CYL_DTC_XX
                         Endif
```

```
                    Else   (Customer DTC is request ; LevelOfDtc = CUS)
                        If     SYM_CYL_DTC_XX [12]=1  (Random)
                        Then   Quantity = Quantity +1
                        Endif
                        If     SYM_CYL_DTC_XX [13]=1  (Multiple cylinder)
                        Then   Quantity = Quantity +1
                        Endif
                        If     (many cylinder bit is set in SYM_CYL_DTC_XX)
                               Quantity = Quantity + j
                               With j  = number of cylinder bit set in SYM_CYL_DTC_XX
                        Endif
                    Endif
                Endif
            Endif
        EndFor
```

For each duplicated DTC, the corresponding quantity will be subtracted. Duplicated DTC will be counted once.

27.27.4 API for reading the Freeze Frame

27.27.4.1 Request a freeze frame with a certain type by DTC

Description :

Syntax : ACTION_ERRM_ReadFrfByDtc(

```
ACTION_ERRM_ReadFrfByDtc(
        IN <TypeOfFF>,
        IN <FFIdentifier>,
        IN <DtcIdentifier>,
        IN < LevelOfDtc>
        INOUT <Frf>
        OUT <ResultFrf> )
```

Parameter(in) :	TypeOfFF	Type of freeze frame which are request by the API
	FFIdentifier	Identifier of freeze frame requested
	DtcIdentifier	Identifier of DTC of the freeze frame requested
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultFrf	Boolean to say if requested freeze frame is present
Parameter(inout) :	Frf	Software structure fill with Freeze frame

Short Description : This API returns a freeze frame or a part of freeze frame.

With the parameter TypeOfFF, some different part of a freeze frame (defined by the law or by the customer - including set or not) can be returned.

The parameter FFIdentifier is not used (reserved for future improvement).

The freeze frame can be requested :

- by DTC ; in this case the parameters DtcIdentifier and LevelOfDtc should be fulfilled.
- for the CARB/EOBD request (mode 02h) ; in this case, the parameter DtcIdentifier has to be set to NO_DTC, the parameter TypeOfFF has to be set to LAW, and the parameter FFIdentifier has to be set to FIRST.

  The freeze frame associated to the oldest Carb failure among highest priority Carb failure is returned.

See definitions of freeze frame in module “Environmental data” module in “Error management” aggregate.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

1st bit of ResultFrf = NO_FRF_PRESENT

2nd bit of ResultFrf = NO_BUFFER_FULL

```
If        (FFIdentifier = FIRST and TypeOfFF = LAW and DtcIdentifier = NO_DTC)

                                TypeOfFF
                                Exit
                        Endif
                Endif
                For each cylinder bit i which is set in SYM_CYL_DTC_XX

                        If DtcIdentifier = ID_ERR_DTC_MIS[1][i]

                        Then    1st bit of ResultFrf = FRF_PRESENT
                                Software structure is filled-up with DtcIdentifier  plus
                                freeze frame of failure according parameter
                                TypeOfFF
                                Exit
                        Endif
                Endfor
            Endif
        Endif
    Endfor
Endif
```

“Software structure is filled-up with freeze frame of failure according parameter TypeOfFF” means :

(for failure IDX)

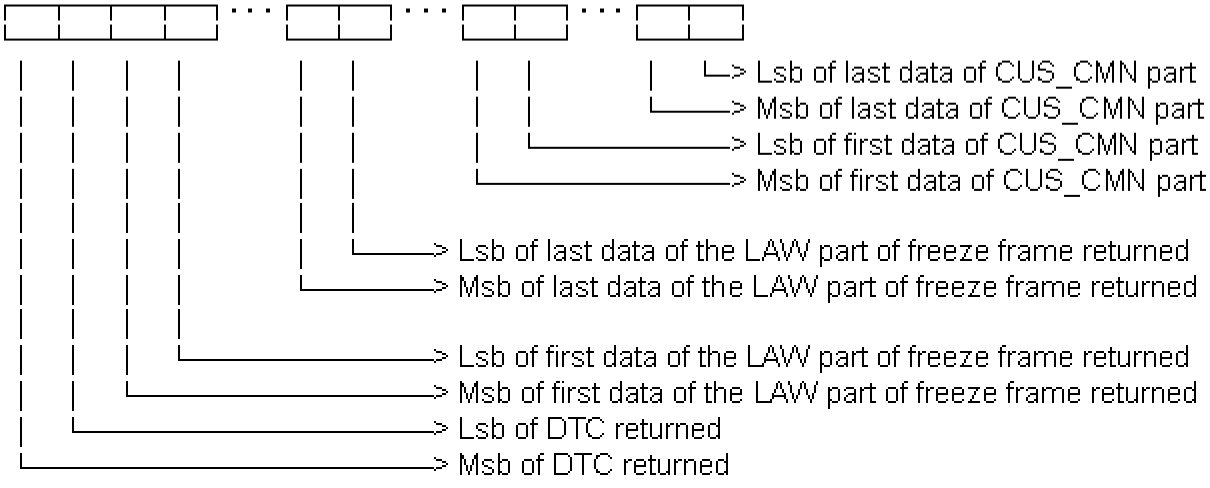
Software structure is filled-up with DTCIdentifier plus the softwate structure defined below :

```
If      TypeOfFF = LAW
Then    Software structure is fill up with ENVD_OBD[u][IDX]
Endif
If      TypeOfFF = CUS_CMN
Then    Software structure is fill up with ENVD_CUS_CMN[v][IDX]
Endif
If      TypeOfFF = CUS_SET
Then    Software structure is fill up with
                ENVD_CUS_SET_CMN[w][z][IDX] + ENVD_CUS_SET_SPC[y][z][IDX]
Endif
```

Combination of parameter Type OfFF is possible. For instance if TypeOfFF is equal to LAW and CUS_CMN, both part are returned. In case of multiple part of freeze frame to returned, , the following order is respected :

- Part LAW of the freeze frame is returned first ;
- Part CUS_CMN of the freeze frame is then returned ;
- Part CUS_SET of the freeze frame is then returned .

Example : In the case of a request with TypeOfFF = LAW and CUS_CMN then the following structure is returned :



When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is stopped. That means that only the freeze frame of the first DTC is found (oldest DTC) and returned by the API.

During all the software structure filling-in, if the software buffer is full then 2nd bit of ResultFrf is set to BUFFER_FULL, software process is aborted.

27.27.5 API for erasing Diagnostic information

27.27.5.1 Clear the failure associated to DTC with a certain type.

Description :

Syntax : ACTION_ERRM_ClrInfoByTypeOfDtc (
IN <TypeOfDtc>,
OUT < ResultClrInfo>)

Parameter(in) : TypeOfDtc Type of DTC which is requested by the API

Parameter(out) : ResultClrInfo Indicate if some DTC are cleared or not

Short Description : This API clear all the failure in dynamic memory associated to DTC with a certain type. It permits also to reinitialised all readiness code.

Remark :

For reason of design, and time resource, it’s recommended to activate this API when engine stop. (Ref. SAE Mode $04).

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
ResultClrInfo = INFO_NOT_CLEARED
For each failure stored in dynamic memory,
    If      the failure belongs to failures group defined by the parameter TypeOfDtc
    Then    ACTION_ERRM_EraseErr ( IN<IDX>, SYNCHRONIZATION<CALL> )
            All data in static memory related to failure XX (with XX = F(IDX)) is also cleared
            ResultClrInfo = INFO_CLEARED
    Endif
Endfor
```

In the case TypeOfDTC = All, then, the whole static memory shall be cleared (same behavior as clear failure memory using LC_ERR_FMY_CLR calibration bit)

{ All readiness bit are reinitialised }

ACTION_ERRM_InitReadiness (SYNCHRONIZATION<CALL>)

Retransmit “failure erase service received”

27.27.5.2 Clear the failure associated to a DTC

Description :

Syntax : ACTION_ERRM_ClrInfoByDtc (
IN <DtcIdentifier>,
IN <LevelOfDtc>,
OUT < ResultClrInfo>)

Parameter(in) :	DtcIdentifier	Number of DTC which is requested (identifier)
	LevelOfDtc	OBD or customer DTC is requested by the API
Parameter(out) :	ResultClrInfo	to say if some DTC are cleared or not

Short Description : This API clear all the failure in dynamic memory associated to a DTC. The erasing is also applicable when there are identical DTC identifiers in the memory.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
ResultClrInfo = INFO_NOT_CLEARED
{ All readiness bit are reinitialised }
ACTION_ERRM_InitReadiness ( SYNCHRONIZATION<CALL> )
For each failure stored in dynamic memory do
    If  failure is not with status = CARB_MIS
    Then Condition for failure traitment is true
    Endif
    If  NLC_TREAT_DIAG_MIS = 1
    Then Condition for failure traitment is true
    Endif
    If  Condition for failure traitment is true
    Then  If     LevelOfDtc = LAW                          (OBD DTC )

When a failure is found in dynamic memory with the right DtcIdentifier, the treatment is not stopped. That means that all failure with the right DTC are erased.

27.27.6 API to manage the entry or exit of “Marked Mode”

27.27.6.1 Activate/deactivate the marked mode with clear failure

Description :

Syntax : ACTION_ERRM_ControlDtcSettings (IN <MarkedMode>)

Parameter(in) : MarkedMode State of marked mode

Short Description : This API permits to activate or deactivate the marked mode. In this mode all new failure which appears are marked and then erased when we leave this mode (useful in End Of Line phase). For errm inhibition, please refer to ACTION_ERRM_ActivateMarkedMode ().

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
If    MarkedMode = ON
Then  LV_MKD_MOD = 1
Else  LV_MKD_MOD = 0
      For each failure (IDX) stored in dynamic memory,
         If    LV_ERR_MKD[IDX] = 1
         Then  ACTION_ERRM_EraseErr ( IN<IDX>, SYNCHRONIZATION<CALL> )
               All data in static memory related to failure XX (with XX = F(IDX)) is also cleared
         Endif
      EndFor
      Reset all diagnoses :
         - For all diagnoses using filterings (anti-bounce, statistical and multi-condition filtering) clear all counters (anti-bounce,statistical and multicondition counters, end of diagnosis counters), LV_ERR_XX, ERR_SYM_XX, and LV_END_DIAG_XX.
         - For diagnoses without any filtering, reset the diagnoses, LV_ERR_XX and LV_END_DIAG_XX.
Endif
```

27.27.6.2 Activate/deactivate the marked mode without clearing failures

Description :

Syntax : ACTION_ERRM_ActivateMarkedMode (IN <MarkedMode>)

Parameter(in) : MarkedMode State of marked mode ON or OFF

Short Description : This API shall be used to activate/deactivate the marked mode. In this mode, each new occuring failure is marked.
This is useful for ERRM inhibition. This inhibition may be used during a reprogramming phase.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

```
If    MarkedMode = ON
Then     LV_MKD_MOD = 1
Else     LV_MKD_MOD = 0
Endif
```

27.27.6.3 Deactivation of marked mode within driving cycle

FUNCTION DESCRIPTION:

General information:

Purpose of this module is to add a security mechanism regarding marked mode. Because marked mode permits to inhibit error management, a strategy shall be introduced to avoid wrong inhibition.

This strategy is to deactivate marked mode when a driving cycle is detected. After driving cycle ends, reactivation of marked mode is the not supported.

Description:

At a low recurrency, a pulling is made to check if driving cycle conditions are met. If met (LV_MKD_MOD=ON **and** LV_DC=1), market mode is deactivated. An explicit request to activate marked mode shall be done.

Signal flow diagram:

Application conditions:

Initialisation: none

Recurrence: 1 second

Activation: LV_MKD_MOD=ON **and** LV_DC=1

Deactivation: none

Formula section:

```
MarkedMode = OFF
ACTION_ERRM_ActivateMarkedMode (   IN <MarkedMode>,
                                     SYNCHRONIZATION<CALL> )
```

27.27.7 API for reading readiness code

27.27.7.1 Read the readiness code information

Description :

Syntax : ACTION_ERRM_ReadReadinessCode (
INOUT <ReadinessCode>,
OUT <ResultReadinessCode>)

Parameter(inout) :	ReadinessCode	Software structure fill with readiness code

Short Description : This API calculate and returns the readiness code information in the software structure.

Readiness code information are build from readiness flags.

Please see “Readiness Code” module of the “Error management” aggregate for more details.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

ResultReadinessCode = NEGATIVE_RESPONSE

(Calculation of STATE_READY_OBD_1)

STATE_READY_OBD_1 :

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit0 : Misfire monitoring supported

 |  |  |  |  |  └─────>  bit2 : Comprehensive component monitoring supported
 |  |  |  |  └───────>  bit3 : Reserved
 |  |  |  └─────────>  bit4 : Misfire monitoring status
 |  |  └───────────>  bit5 : Fuel system monitoring status
 |  └─────────────>  bit6 : Comprehensive component monitoring status
 └───────────────>  bit7 : Reserved
```

4 less significant bit of STATE_READY_OBD_1 = 4 less significant bit of C_STATE_READY_OBD_1
4 most significant bit of STATE_READY_OBD_1 = 4 less significant bit of C_STATE_READY_OBD_1

STATE_READY_OBD_2:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit 0 : Catalyst monitoring
 |  |  |  |  |  |  └───>  bit 1 : Heated catalyst
 |  |  |  |  |  └─────>  bit 2 : Evaporative system monitoring
 |  |  |  |  └───────>  bit 3 : Secondary air system monitoring
 |  |  |  └─────────>  bit 4 : A/C system refrigerant monitoring
 |  |  └───────────>  bit 5 : Oxygen sensor monitoring
 |  └─────────────>  bit 6 : Oxygen sensor heater monitoring
 └───────────────>  bit 7 : EGR system monitoring
```

STATE_READY_OBD_2 = C_STATE_READY_OBD_2

The readiness code calculation is performed in two steps:

1. setting of readiness of a specific group CARB_YY (e.g. CARB_SA, CARB_EVAP), depending on the dynamic Error Management. If at least one failure XX is confirmed with bit 4 of WAL_CONF_XX = 1 of the group CARB_YY, then the readiness of this group can be set to ready.
2. setting of readiness of a specific group CARB_YY, depending on the failure XX individual readiness information LV_READY_XX. E.g. in case of a failure free system only step 2 is used for the readiness code calculation.

Step 1:

```
If CTR_ERR_DYN_NR != 0        (at least one failure stored in Error Management)
Then  For IDX = 0 to CTR_ERR_DYN_NR – 1
          If      bit 4 of WAL_CONF_XX = 1 (failure is emission relevant)
                  with XX = DIAG_INST[IDX]
          and     LV_ERR_CFM[IDX] = 1              (failure is confirmed)
          Then    case CARB_YY for failure XX
                  CARB_MIS:   Bit 4 of STATE_READY_OBD_1 = 0
                  CARB_FSD:   Bit 5 of STATE_READY_OBD_1 = 0
                  CARB_CC:    Bit 6 of STATE_READY_OBD_1 = 0
                  CARB_CAT:   Bit 0 of STATE_READY_OBD_2 = 0
                  CARB_HC:    Bit 1 of STATE_READY_OBD_2 = 0
                  CARB_EVAP:  Bit 2  of STATE_READY_OBD_2 = 0
                  CARB_SA:    Bit 3 of STATE_READY_OBD_2 = 0
                  CARB_AC:    Bit 4 of STATE_READY_OBD_2 = 0
                  CARB_LS:    Bit 5 of STATE_READY_OBD_2 = 0
```

```
                CARB_LSH:   Bit 6 of STATE_READY_OBD_2 = 0
                CARB_EGR:   Bit 7 of STATE_READY_OBD_2 = 0
            Endif
        Endfor
    Endif
```

Step 2:

```
Misfire monitoring status bit4 :
    If      Bit 4 of C_STATE_READY_CMPL_OBD_1 = 0
    Then
        if  ∑ (LV_READY_XX) = 0

                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
        then    Bit 5 of STATE_READY_OBD_1 = 0
        endif
    Else
            Readiness for Fuel system monitoring status is set
            Bit 5 of STATE_READY_OBD_1 = 0
    EndIf

Comprehensive component monitoring status bit6 :
    If      Bit 6 of C_STATE_READY_CMPL_OBD_1 = 0
    Then
            if      ∑ (LV_READY_XX) = 0
                    Take into account all LV_READY_XX which fulfill the following condition:
                    this XX failure has the status CARB_CC (see tables of failures) AND
                    the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
            then    Bit 6 of STATE_READY_OBD_1 = 0
            endif
    Else
            Readiness for Comprehensive component status is set
            Bit 6 of STATE_READY_OBD_1 = 0
    EndIf
```

Bit 7 of STATE_READY_OBD_1 is unchanged

(Calculation of STATE_READY_OBD_2)

Catalyst monitoring bit 0 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_CAT (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 0 of STATE_READY_OBD_2 = 0
Endif
```

Heated catalyst bit 1 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_HC (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 1 of STATE_READY_OBD_2 = 0
Endif
```

Evaporative system monitoring bit2 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_EVAP(see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 2 of STATE_READY_OBD_2 = 0
Endif
```

Secondary air system monitoring bit3 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_SA (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 3 of STATE_READY_OBD_2 = 0
Endif
```

A/C system refrigerant monitoring bit4 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_AC (see tables of failures) and
                the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
Then    Bit 4 of STATE_READY_OBD_2 = 0
Endif
```

Oxygen sensor monitoring bit5 :

```
If      ∑ (LV_READY_XX) = 0
                Take into account all LV_READY_XX which fulfill the following condition:
                this XX failure has the status CARB_LS (see tables of failures) and
```

```
                    the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
    Then   Bit 5 of STATE_READY_OBD_2 = 0
    Endif
```

Oxygen sensor heater monitoring bit6 :

```
    If     LV_READY_XX = 0
                    Take into account all LV_READY_XX which fulfill the following condition:
                    this XX failure has the status CARB_LSH (see tables of failures) and
                    the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
    Then   Bit 6 of STATE_READY_OBD_2 = 0
    Endif
```

EGR system monitoring bit7 :

```
    If     LV_READY_XX = 0
                    Take into account all LV_READY_XX which fulfill the following condition:
                    this XX failure has the status CARB_EGR (see tables of failures) and
                    the bit 4 of WAL_CONF_XX = 1 (CARB/EOBD failure)
    Then   Bit 7 of STATE_READY_OBD_2 = 0
    Endif
```

ReadinessCode structure is filled up with : C_STATE_READY_OBD_2, STATE_READY_OBD_1 and STATE_READY_OBD_2.

ResultReadinessCode = POSITIVE_RESPONSE

Definition of Readiness Code:

In C_STATE_READY_OBD_1, a bit set to 1 means that corresponding test is supported according to the J1979 standard.

C_STATE_READY_OBD_1 :

bit0 : Misfire monitoring supported
bit1 : Fuel system monitoring supported
bit2 : Comprehensive component monitoring supported
bit3 = 0 (reserved)
bit4 = 0 (reserved)
bit5 = 0 (reserved)
bit6 = 0 (reserved)
bit7 = 0 (reserved)

With C_STATE_READY_OBD_CMPL_OBD_1, it’s possible to set directly Misfire, Fuel system, and comprehensive component readiness codes to "ready" status.

In C_STATE_READY_OBD_2, a bit set to 1 means that corresponding test is supported according to the J1979 standard.

C_STATE_READY_OBD_2:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit 0 : Catalyst monitoring
 |  |  |  |  |  |  └───>  bit 1 : Heated catalyst
 |  |  |  |  |  └─────>  bit 2 : Evaporative system monitoring
 |  |  |  |  └───────>  bit 3 : Secondary air system monitoring
 |  |  |  └─────────>  bit 4 : A/C system refrigerant monitoring
 |  |  └───────────>  bit 5 : Oxygen sensor monitoring
 |  └─────────────>  bit 6 : Oxygen sensor heater monitoring
 └───────────────>  bit 7 : EGR system monitoring
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_STATE_READY_OBD_1	1	0...FFH	0...255	1	[-]
Status configuration for readiness code (continuous tests)					
C_STATE_READY_OBD_2	1	0...FFH	0...255	1	[-]
Status configuration for readiness code (non continuous tests)					
C_STATE_READY_CMPL_OBD_1	1	0...FFH	0...255	1	[-]
Readiness MIS, FSD, CC directly set to ready					

Calibration data detailled description for C_STATE_READY_CMPL_OBD_1 :

Readiness code calculation for CARB_MIS, CARB_FSD, CARB_CC diagnosis :

0: readiness of conserned group is calculated based on the readiness of each comprehensive component diagnostic

1: readiness of conserned group always indicates "ready"

C_STATE_READY_CMPL_OBD_1:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit0 : 0
 |  |  |  |  |  |  └───>  bit1 : 0
 |  |  |  |  |  └─────>  bit2 : 0
 |  |  |  |  └───────>  bit3 : 0
 |  |  |  └─────────>  bit4 : set directly readiness for Misfire monitoring
 |  |  └───────────>  bit5 : set directly readiness Fuel system monitoring
 |  └─────────────>  bit6 : set directly readiness Comprehensive component monitoring
 └───────────────>  bit7 : 0
```

27.27.7.2 Read the readiness code information for customer specific purpose

Description :

Syntax : ACTION_ERRM_ReadReadinessCodCus(
INOUT <ReadinessCode>,
OUT <ResultReadinessCode>)

Parameter(inout):	ReadinessCode	Software structure filled-up with customer specific readiness code

Short Description : This API calculates and returns the readiness code information in the software structure.

Readiness code information are built thanks to readiness flags.

Please see “Readiness Code” module of the ERRM aggregate for more details.

Application conditions:

Deactivation : -

Initialization: -

Recurrence : -

Formula section :

ResultReadinessCode = NEGATIVE_RESPONSE

(Calculation of STATE_READY_OBD_3)

STATE_READY_OBD_3 :

```

27.27.8 Rate-Based Monitoring - Communication interface

FUNCTION DESCRIPTION:

Description:

The Rate-Based Monitoring statistics shall be reported to the Scan-Tool via the Mode $09.

The data to be transmitted are :

- Ignition cycle counter
- General denominator
- For each group of monitors, individual numerator and denominator of the monitor which has the lowest In-Use Performance ratios.

These statistics are required and transmitted within Mode $09 for the monitors of the following groups :

- Catalyst bank 1
- Catalyst bank 2
- Oxygen sensor upstream bank 1
- Oxygen sensor upstream bank 2
- EGR system and/or VVT system
- Secondary air system
- Evaporating system

The selection of data to be displayed on Scan-Tool shall respect some rules :

- For each group of monitors, the individual numerator and denominator of monitor which has the lowest numerical In-Use Performance ratio shall be reported.
- If two or more specific monitors of the same group have identical ratios, the corresponding numerator and denominator for the specific monitor that has the highest denominator shall be reported.
- Depending on system configurations, some components might not exist (e.g. O2 Sensor for bank 2 on vehicles with 1 bank engine). In this case the numerator and denominator shall be set to 0.

27.27.8.1 API to select Rate-Based Monitoring data to be transmitted via Mode $09

The following paragraph descibes the data selection algorithm to be executed only once (for CPU load saving reason), upon external tool request via Mode $09, by calling an API.

Syntax : ACTION_ERRM_SelectRbmData (INOUT < ListRbmData >,
OUT < ResultRbmData >)

Parameter (in) : No parameter

Parameter (out) : ResultRbmData

Parameter(inout) : ListRbmData

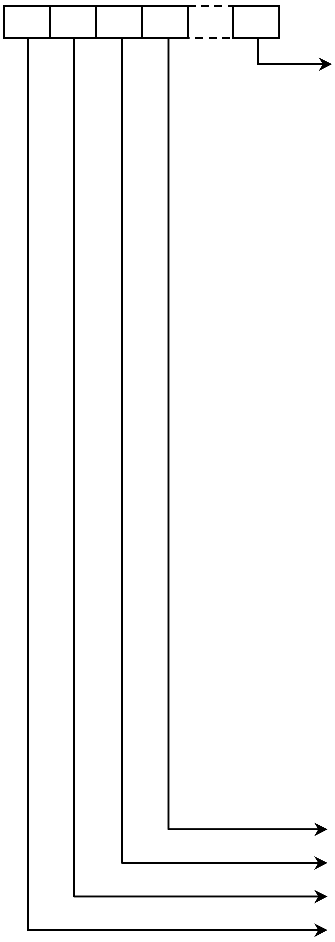
Short description : This API calculates and returns the Rate-Based Monitoring data to be transmitted to the Scan-Tool, when requested by the Mode 09$ (InfoType $08).

ResultRbmData : Indicates if the API has been executed or not.

Authorised values for ResultRbmDataSelection are :

- POSITIVE_RESPONSE : the call of the API is successful
- NEGATIVE_RESPONSE : the call of the API is unsuccessful

ListRbmData : Software structure filled-up with 16 counters of 2 bytes coming from Rate-Based Monitoring



EVAP Monitor Conditions Encountered Counts (denominator - LSB byte)
EVAP Monitor Conditions Encountered Counts (denominator - MSB byte)
EVAP Monitor Completion Condition Counts (numerator - LSB byte)
EVAP Monitor Completion Condition Counts (numerator - MSB byte)
AIR Monitor Conditions Encountered Counts (denominator - LSB byte)
AIR Monitor Conditions Encountered Counts (denominator - MSB byte)
AIR Monitor Completion Condition Counts (numerator - LSB byte)
AIR Monitor Completion Condition Counts (numerator - MSB byte)
EGR Monitor Conditions Encountered Counts (denominator - LSB byte)
EGR Monitor Conditions Encountered Counts (denominator – MSB byte)
EGR Monitor Completion Condition Counts (numerator - LSB byte)
EGR Monitor Completion Condition Counts (numerator - MSB byte)
O2 Sensor Monitor Conditions Encountered Counts Bank 2 (denominator – LSB byte)
O2 Sensor Monitor Conditions Encountered Counts Bank 2 (denominator - MSB byte)
O2 Sensor Monitor Completion Counts Bank 2 (numerator – LSB byte)
O2 Sensor Monitor Completion Counts Bank 2 (numerator - MSB byte)
O2 Sensor Monitor Conditions Encountered Counts Bank 1 (denominator - LSB byte)
O2 Sensor Monitor Conditions Encountered Counts Bank 1 (denominator - MSB byte)
O2 Sensor Monitor Completion Counts Bank 1 (numerator – LSB byte)
O2 Sensor Monitor Completion Counts Bank 1 (numerator – MSB byte)
Catalyst Monitor Conditions Encountered Counts Bank 2 (denominator - LSB byte)
Catalyst Monitor Conditions Encountered Counts Bank 2 (denominator - MSB byte)
Catalyst Monitor Completion Counts Bank 2 (numerator - LSB byte)
Catalyst Monitor Completion Counts Bank 2 (numerator - MSB byte)
Catalyst Monitor Conditions Encountered Counts Bank 1 (denominator - LSB byte)
Catalyst Monitor Conditions Encountered Counts Bank 1 (denominator - MSB byte)
Catalyst Monitor Completion Counts Bank 1 (numerator - LSB byte)
Catalyst Monitor Completion Counts Bank 1 (numerator - MSB byte)
Ignition Counter (LSB byte)
Ignition Counter (MSB byte)
OBD Monitoring Conditions Encountered Counts (general denominator - LSB byte)
OBD Monitoring Conditions Encountered Counts (general denominator - MSB byte)

Application conditions:

Initialization : Initialize the ListRbmData software structure with all counters set to 00h

ResultRbmData = NEGATIVE_RESPONSE

Recurrence : -

Activation : at Action call

Deactivation : -

Formula section:

ResultRbmData = POSITIVE_RESPONSE

27.27.8.2 API to select RBM statistic with lowest in-use performance ratio within one single group

General information:

This API shall be used to determine, within one single group (see specification “Rate-Based Monitoring (Appl. Inc.)”), the counters of the monitor which has the lowest in-use performance ratio.

Description:

Syntax : ACTION_ERRM_SelectRbmByGroup (
IN < GroupName >
INOUT < ListRbmDataByGroup >,
OUT < ResultRbmDataByGroup >)

Parameter (in) : GroupName

Parameter (out) : ResultRbmDataByGroup

Parameter(inout) : ListRbmDataByGroup

Short description : This API calculates and returns the Rate-Based Monitoring data with lowest ratios, within one single group.

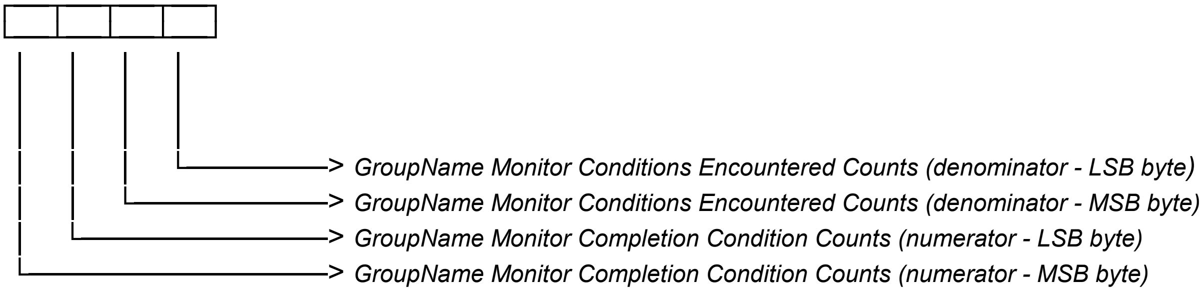
GroupName : Group name requested. See specification “Rate-Based Monitoring (Appl. Inc.)”

ResultRbmDataByGroup : Indicates if the API has been executed or not.

Authorised values for ResultRbmDataByGroup are :

- POSITIVE_RESPONSE : the call of the API is successful
- NEGATIVE_RESPONSE : the call of the API is unsuccessful

ListRbmDataByGroup : Software structure filled-up with the Rate-Based Monitoring counters of 2 bytes related to the requested group name.



Application conditions:

Initialization : -

Recurrence : -

Activation : at Action call

Deactivation : -

Formula section:

{ For CPU optimization reasons, this implementation assumes that Groups Names are ordered as indicated in the Rate-Based Monitoring (Appl. Inc.) file : Groups Names order must be respected and monitors belonging to a same group shall be joined }

{ If this requirement isn't respected, data sent to the Scan-Tool might be erroneous }

```
ResultRbmDataByGroup = NEGATIVE_RESPONSE
m = 0
While m ≤ ( NC_NR_DIAG_RBM – 1 ) do
    If(1) m monitor belongs to GroupName
    Then(1)

      If(2)  CTR_CDN_RBM[m] ≠ 0  { denominator is different from 0 }
      Then(2)

            m = m +1
            Fill-in ListRbmDataByGroup with numerator = 0 and denominator = 0
      Endif(1)
  Endwhile
  ResultRbmDataByGroup = POSITIVE_RESPONSE
```

27.27.8.3 API to clear all Rate-Based Monitoring statistics

General information:

Regulation text :
"Each number shall be reset to zero only when a non-volatile memory reset occurs (e.g., reprogramming event, etc.) or, if the numbers are stored in keep-alive memory (KAM), when KAM is lost due to an interruption in electrical power to the control module (e.g., battery disconnect, etc.). Numbers may not be reset to zero under any other circumstances including when a scan tool command to clear fault codes or reset KAM is received."

The service provided in this paragraph shall be used to clear all the Rate-Based Monitoring statistics after a reprogramming session of ECU software and/or calibration data.

This service shall not be called when a Scan Tool command to clear faults (Mode 04$) is received.

Description:

Syntax :	ACTION_ERRM_ClearRbmStatistics (OUT < ResultClrInfo>)
Parameter(in) :	No parameter.
Parameter(out) :	ResultClrInfo to inform if RBM statistics are cleared or not
Short Description :	This API clear all the Rate-Based Monitoring statistics

Remark : For design and CPU resource reasons, this API shall be called while engine is stopped.

Application conditions:

Initialization :	-
Recurrence :	-
Activation :	at Action call
Deactivation :	-

Formula section:

```
ResultClrInfo = STATISTICS_NOT_CLEARED
CTR_IGK_CYC_RBM = 0
CTR_CDN_OBD_RBM = 0
For m = 0 to ( NC_NR_DIAG_RBM –1 ) do
    CTR_CDN_RBM[m] = 0
    CTR_COMP_RBM[m] = 0
Endfor
ResultClrInfo = STATISTICS_CLEARED
```

Configuration data:

Name	Dim	Hex. Limits	Phys. Limits	Resol.	Unit
NC_ERR_DTC_REQ_OBD	-	0...1H	0...1	1	[-]
This bit shall be set to 0 (SYMPTOM) to read OBD DTC by symptomThis bit shall be set to 1 (FAILURE) to read OBD DTC by failure

Defines the EOBD/CARB freeze frame strategy the following ways :0 : EOBD/CARB freeze frame data of Mode 02h will be returned after detection of a confirmed failure .1 : EOBD/CARB freeze frame data of Mode 02h will be returned :after detection of a confir					

Configuration data detailed description:

NC_ERR_DTC_REQ_OBD : This bit shall be set to 0 (SYMPTOM) to read OBD DTC by symptom.
This bit shall be set to 1 (FAILURE) to read OBD DTC by failure.

NC_ERR_DTC_REQ_CUS : This bit shall be set to 0 (SYMPTOM) to read Customer DTC by symptom.
This bit shall be set to 1 (FAILURE) to read Customer DTC by failure.

NLC_OBD_FRF_PND : Definition the EOBD/CARB freeze frame strategy, as follow :
0 : EOBD/CARB freeze frame data of Mode 02h will be returned after detection of a confirmed failure.
1 : EOBD/CARB freeze frame data of Mode 02h will be returned :

- after detection of a confirmed emission relevant failure if confirmed in memory
- after pending emission relevant detection if not confirmed in memory

27.28 Communication Interface (Appl. Inc.)

27.28.1 Communication interface for BMW diagnosis tool

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_TYPE_BYTE[NC_NR_ERR_DYN]	O	0...FFH	0...255	1	[-]
Fault-type-byte					
ERR_TYPE_EXT_BYTE[NC_NR_ERR_DYN]	O	0...FFH	0...255	1	[-]
Fault-type-extension-byte					

Input data:

LV_END_DIAG_XX	LV_DC_MAX[NC_NR_ERR_DYN]	LV_ERR_XX	WAL_CONF_XX
LV_CDN_DIAG_XX	CTR_WUP_CYC[NC_NR_ERR_DYN]	ENVD_CUS_SET_CMN[NC_NR_ENVD_CUS_SET_CMN][NC_NR_FRF_SET][NC_NR_ERR_DYN]	LV_ERR_DC[NC_NR_ERR_DYN]

CTR_DC[NC_NR_ERR_DYN]			

FUNCTION DESCRIPTION:

General information:

This communication interface is to define the data contents needed for the BMW diagnosis information. The Information in the Fault-type-byte and Fault-type-extension-byte is bit-coded and requested via KWP communication.

Application conditions:

Initialisation: managed in the specific chapters

Recurrence: managed in the specific chapters

Activation: see chapter “KWP communication”

Formula section:

Definition of ERR_TYPE_BYTE[x]

Bit No:	Description	Input
0	Specifies the error symptom: 0001-Short circuit to VBATT or signal / value above threshold (Max)	**IF** ENVD_CUS_SET_CMN[1][x] = 1H
1	Specifies the error symptom: 0010-Short circuit to ground or signal / value below threshold (Min)	**IF** ENVD_CUS_SET_CMN[1][x] = 2H
2	Specifies the error symptom: 0100-Open circuit or no signal (Sig)	**IF** ENVD_CUS_SET_CMN[1][x] = 4H
3	Specifies the error symptom: 1000-Implausible signal / condition (Plaus)	**IF** ENVD_CUS_SET_CMN[1][x] = 8H
4	BMW Readiness flag. The bit is set to 0 if the test conditions are met and the diagnostic runs to completion at least once after the fault memory has been cleared, or after power failure	**IF** LV_READY_XX = 0
5	This bit is set when the fault has been saved to the fault memory as OBD debounced.	**IF** LV_DC_MAX[x] = 1
6	This bit is set when the fault is currently present	**IF** LV_ERR_XX = 1
7	MIL calibration status, specifies wheather the MIL is to be activated	**IF** MIL_ON bit of WAL_CONF_XX =1

Definition of ERR_TYPE_EXT_BYTE[x]

Bit No:	Description	Input
0	Only for Diagnostic diagnosis; This bit is set if the diagnosis is currently running	**For diagnostic diagnosis**** LV_END_DIAG_XX = 0 **AND** LV_CDN_DIAG_XX = 1
1	Only for Diagnostic diagnosis; This bit is set if the diagnosis is interrupted for this driving cycle	**For diagnostic diagnosis**** Not defined yet
2	Cycle flag. The bit is set if the diagnosis runs to completion in this driving cycle	**IF** LV_END_DIAG_XX = 1
3	This bit is to be set if the fault is stored as a result of an action by an tester	**IF** LV_ERR_MKD[x] = 1
4	This bit is to be set if the fault is currently requesting the MIL to be illuminated.	**IF** LV_DC_MAX[x] = 1 **AND** MIL_ON bit of WAL_CONF_XX =1
5	This bit is set if MIL debouncing has been achieved, the MIL is not currently being requested for this fault and output via the Scan Tool interface has not yet occured (HLC =0 & DLC >0). (former OBDII error)	**IF** LV_ERR_CFM[x] = 1 **AND** CTR_DC[x] = 0 **AND** MIL_ON bit of WAL_CONF_XX =1 **AND** CTR_WUP_CYC[x] > 0
6	Not yet defined	
7	Not yet defined	

**Diagnostic diagnosis are all sequential diagnosis (see “Table of failures – CARB status”)

27.29 Diagnosis Trouble Code Management (DTC)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Memorized the last cylinder of the misfire B4 failure (for the DTC building)					
#ENDIF					
ERR_DTC[NC_NR_ERR_DYN]	V/O/S	0...FFFFH	0...65535	1	[-]
DTC code stored in memory for failure IDX					

Input data:

ERR_SYM_XX	SYM_CYL_MIS_A	SYM_CYL_MIS_B1	SYM_CYL_MIS_B4
NC_CYL_NR	NLC_TREAT_DIAG_MIS		

Export actions :

ACTION_ERRM_StoreDtc (IN <IDX>)
This action stores the memorized symptom of the first occurrence of the failure IDX to build the DTC
ACTION_ERRM_StoreDtcLst (IN <IDX>)
This action stores the memorized symptom of the last occurrence of the failure IDX to build the DTC
ACTION_ERRM_EraseDtc (IN <IDX>)
This action erases the memorized symptom of the failure IDX

FUNCTION DESCRIPTION:

General information:

Purpose of this module is to catch some data (ERR_SYM_XX) when a failure occurs. Then, these data (ERR_SYM_MEM[IDX] and ERR_SYM_LST_[IDX]) are used to generate a code called DTC upon communication tool request (see Communication interface module). Additionally, for visualization (for communication tool, developpment purposes), a DTC code is stored in memory (ERR_DTC_[IDX]).

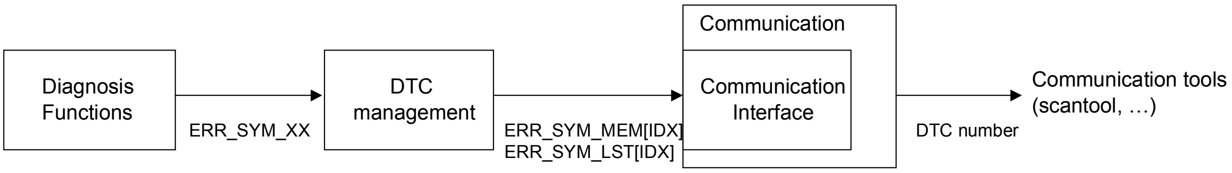
The DTC is a code used to identify the symptom of the failure or the failure (global failure). It is an interface between the diagnosis and the communication.

The customer and/or EOBD/CARB according to the standard J2012 define this DTC.

DTC encoding for regulation EOBD/CARB shall be done using J2012 definition (2 bytes interpreted [0000h to FFFFh] in hex, [P0000 to U3FFF] in J2012).

DTC encoding for customer is free. It can be in decimal, or applying J2012 definition, or any other encoding definition.

Signal flow diagram:



27.29.1 DTC Storage

27.29.1.1 DTC Storage / First occurence

Description:

When the failure IDX gets present (1st occurrence), the detected of the first symptom is stored in the 2nd layer memory by calling the action ACTION_ERRM_StoreDtc (IN<IDX>). Additionally, a DTC code is stored in dynamic memory for visualization :

- related to the symptom DTC if NC_ERR_DTC_CONF = 0
- related to the failure OBD DTC if NC_ERR_DTC_CONF = 1
- related to the customer specific symptom DTC if NC_ERR_DTC_CONF = 2
- related to the customer specific failure DTC if NC_ERR_DTC_CONF = 3

Syntax :	ACTION_ERRM_StoreDtc (IN <IDX>)	
Parameter (in) :	IDX	Index of failure in 2nd layer memory to store the DTC
Parameter (out) :	-	
Short description :	This action stores the memorised symptom of the first occurrence of the failure IDX to build the DTC	

Application conditions:

Initialization: ERR_SYM_MEM[IDX] is restored from the NVMY

SYM_CYL_MEM_MIS_A, SYM_CYL_MEM_MIS_B1 and

SYM_CYL_MEM_MIS_B4 are restored from NVMY

In case of damaged NVMY, ERR_SYM_MEM[IDX] = 0

SYM_CYL_MEM_MIS_A = 0,

SYM_CYL_MEM_MIS_B1 = 0,

SYM_CYL_MEM_MIS_B4 = 0,

ERR_DTC[IDX] = 0

Recurrence: -

Activation: at Action request

Formula section:

```
If      NLC_TREAT_DIAG_MIS = 0
        (Misfire are treated by type (LV_ERR_MIS_A, MIS_B1 and MIS_B4 is defined))
Then
        For a misfiring diagnosis:
        (XX stands for MIS_A, MIS_B1, and MIS_B4) (Misfire by type NLC_TREAT_DIAG_MIS=0)
                SYM_CYL_MEM_XX = SYM_CYL_XX

                If      NC_ERR_DTC_CONF = 0 or 1 or 4                   (J2012 DTC is stored)
                Then    If      SYM_CYL_MEM_XX [12] = 1         (Random)
                        Then    ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 0 ] [ NC_CYL_NR+1 ]

Endif
```

27.29.1.2 DTC Storage / Last occurence

Description:

For each occurence of the failure IDX (Last occurrence), the detected of the last symptom is stored in the 2^{nd} layer memory by calling the action ACTION_ERRM_StoreDtcLst (IN<IDX>).

Syntax : ACTION_ERRM_StoreDtcLst (IN<IDX>)

Parameter (in) : IDX Index of failure in 2^{nd} layer memory to store the DTC

Parameter (out) : -

Short description : This action stores the memorised symptom of the last occurrence of the failure IDX to build the DTC

Application conditions:

Initialization: ERR_SYM_LST[IDX] is restored from the NVMY

SYM_CYL_LST_MIS_A, SYM_CYL_LST_MIS_B1 and

SYM_CYL_LST_MIS_B4 are restored from NVMY

In case of damaged NVMY, ERR_SYM_LST[IDX] = 0

SYM_CYL_LST_MIS_A = 0,

SYM_CYL_LST_MIS_B1 = 0,

SYM_CYL_LST_MIS_B4 = 0,

Recurrence: -

Activation: at Action request

Formula section:

```
ERR_SYM_LST[IDX] = ERR_SYM_XX
If    NLC_TREAT_MIS_DIAG = 0
      (Misfire are treated by type)
then        For a misfiring diagnosis :
      (XX stands for MIS_A, MIS_B1 and MIS_B4)
      SYM_CYL_LST_XX = SYM_CYL_ XX
endif
```

```
If    NLC_TREAT_DIAG_MIS = 0
      (Misfire are treated by type (LV_ERR_MIS_A, MIS_B1 and MIS_B4 is defined))
Then        For a misfiring diagnosis:

            If    NC_ERR_DTC_CONF = 4                          (J2012 DTC is stored)
            Then  If    SYM_CYL_LST_XX [12] = 1 (Random)
                  Then  ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 0 ] [ NC_CYL_NR+1 ]
                  Else  If    SYM_CYL_LST_XX [13] = 1 (Multiple cylinder)
                              Or many cylinder bits are set in SYM_CYL_LST_XX
                        Then  ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 0 ] [ NC_CYL_NR ]
                        Else  (only one cylinder bit is set in SYM_CYL_LST_XX)
                                    i = bit number which is set in SYM_CYL_LST_XX
                                    ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 0 ] [ i ]
                        Endif
                  Endif
            Endif

            If    NC_ERR_DTC_CONF = 5                    (customer DTC is stored)
            Then  If    SYM_CYL_LST_XX [12] = 1 (Random)

                        Then  ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 1 ] [ NC_CYL_NR ]
                        Else  (only one cylinder bit is set in SYM_CYL_LST_XX)
                                    i = bit number which is set in SYM_CYL_LST_XX
                                    ERR_DTC[IDX] = ID_ERR_DTC_MIS [ 1 ] [ i ]
                        Endif
                  Endif
            Endif
```

For others diagnosis :

(also for misfire diagnosis if treated by cylinder (LV_ERR_MIS_x is defined))

```
If      NC_ERR_DTC_CONF = 4             (last symptom J2012 DTC is stored)
Then    If      only one bit is set in ERR_SYM_LST[IDX]
        Then    i = bit number which is set in ERR_SYM_LST[IDX]
                ERR_DTC[IDX] =  ID_ERR_DTC_XX [0] [ i ] with XX = F(IDX)
        Else    (many bit is set in ERR_SYM_LST[IDX])
                ERR_DTC[IDX] =  ID_ERR_DTC_XX [0] [4] with XX = F(IDX)
        Endif
Endif

If      NC_ERR_DTC_CONF = 5             (customer encoded DTC is stored)
Then    If      only one bit is set in ERR_SYM_LST[IDX]
        Then    i = bit number which is set in ERR_SYM_LST[IDX]
                ERR_DTC[IDX] =
                ID_ERR_DTC_XX [NC_NR_DTC_FMT] [ i ] with XX = F(IDX)
        Else    (many bit is set in ERR_SYM_LST[IDX])
                ERR_DTC[IDX] =
                ID_ERR_DTC_XX [NC_NR_DTC_FMT] [5 - NC_NR_DTC_FMT]
                with XX = F(IDX)
        Endif
Endif
```

27.29.2 DTC storage for the Misfiring (with NLC_TREAT_DIAG_MIS = 0, Misfire by type)

Description:

As describe above, the cylinder in default is memorised at the first occurrence. In this part each new cylinder in default will be memorised.

Application conditions:

Initialization:	treated above
Recurrence:	For Misfire A, B1 and B4: Misfire segment synchronous
Activation:	-

Formula section:

For a misfiring A diagnosis :

SYM_CYL_MEM_MIS_A is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_A

For a misfiring B1 diagnosis :

SYM_CYL_MEM_MIS_B1 is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_B1

For a misfiring B4 diagnosis :

SYM_CYL_MEM_MIS_B4 is updated with the new additional bits (cylinder, multiple and random) of SYM_CYL_MIS_B4.

27.29.3 DTC deleting

Description:

When the failure IDX is erased from 2nd layer memory, the memorised detected symptom is also erased by calling the action ACTION_ERRM_EraseDtc (IN <IDX>).

Syntax :	ACTION_ERRM_EraseDtc (IN <IDX>)	
Parameter (in) :	IDX	Index of failure in 2nd layer memory to store the DTC
Parameter (out) :	-	
Short description :	This action erases the memorised symptom of the failure IDX	

Application conditions:

Initialization:	-
Recurrence:	-
Activation:	at Action request

Formula section:

```
If    NLC_TREAT_DIAG_MIS = 0
      (Misfire are treated by type (LV_ERR_MIS_A, MIS_B1 and MIS_B4 is defined))
Then        For a misfiring A diagnosis :
            SYM_CYL_MEM_MIS_A = 0
            SYM_CYL_LST_MIS_A = 0
            ERR_DTC[IDX] = 0
            For a misfiring B1 diagnosis :
            SYM_CYL_MEM_MIS_B1 = 0
            SYM_CYL_LST_MIS_B1 = 0
            ERR_DTC[IDX] = 0
            For a misfiring B4 diagnosis :
            SYM_CYL_MEM_MIS_B4 = 0
            SYM_CYL_LST_MIS_B4 = 0
            ERR_DTC[IDX] = 0
Endif
```

For other diagnoses, including misfire diagnoses if treated by cylinder (LV_ERR_MIS_x is defined) :

```
            ERR_SYM_MEM[IDX] = 0
            ERR_SYM_LST[IDX] = 0
            ERR_DTC[IDX] = 0
```

27.29.4 Calibratable DTC number

Description:

The DTC numbers are defined by a calibration table called ID_ERR_DTC_XX.

This table defined for each failure XX :

a) with NC_NR_DTC_FMT = 0

- a DTC number for each symptom of the failure XX
- a global OBD DTC number for the failure XX
- a global customer specific DTC number

b) with NC_NR_DTC_FMT = 1

- a OBD DTC number for each symptom of the failure XX
- a global OBD DTC number for the failure XX
- a customer specific DTC number for each symptom of the failure XX
- a global customer specific DTC number

When a DTC is request by a diagnostic tool, the Communication Interface module build up the DTC number with information :

- ERR_SYM_MEM[IDX] and / or ERR_SYM_LST[IDX] stored in 2^{nd} layer memory ;
- Contents of table ID_ERR_DTC_XX .

There is a particular case for misfiring (MIS_A, MIS_B1, MIS_B4) diagnosis. The DTC numbers are defined by cylinder in a calibration table called ID_ERR_DTC_MIS.

(used if NLC_TREAT_DIAG_MIS = 0; Misfire by type)

- ID_ERR_DTC_MIS[0] [i] is the DTC for misfiring detection on the cylinder number i +1
- ID_ERR_DTC_MIS[0] [NC_CYL_NR] is the DTC for multiple misfiring
- ID_ERR_DTC_MIS[0] [NC_CYL_NR +1] is the DTC for random misfiring

- ID_ERR_DTC_MIS[1] [i] is the customer DTC for misfiring detection on the cylinder number i+1
- ID_ERR_DTC_MIS[1] [NC_CYL_NR] is the customer DTC for multiple misfiring
- ID_ERR_DTC_MIS[1] [NC_CYL_NR +1] is the customer DTC for random misfiring

Example 1:

The failure TCO (coolant temperature) is stored in the 2nd layer memory. The calibratable table of DTC has the following value :

a) with NC_NR_DTC_FMT = 0

DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure	Specific customer code
ID_ERR_DTC_ TCO [0] [0] = 0118h (P0118)	ID_ERR_DTC_ TCO [0] [1] = 0117h (P0117)	ID_ERR_DTC_ TCO [0] [2] = 0119h (P0119)	ID_ERR_DTC_ TCO [0] [3] = 0116h (P0116)	ID_ERR_DTC_ TCO [0] [4] = 0115h (P0115)	ID_ERR_DTC_ TCO [0] [5] = 30

b) with NC_NR_DTC_FMT = 1

	DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure
OBD DTC	ID_ERR_DTC_ TCO [0] [0] = 0118h (P0118)	ID_ERR_DTC_ TCO [0] [1] = 0117h (P0117)	ID_ERR_DTC_ TCO [0] [2] = 0119h (P0119)	ID_ERR_DTC_ TCO [0] [3] = 0116h (P0116)	ID_ERR_DTC_ TCO [0] [4] = 0115h (P0115)
Customer DTC	ID_ERR_DTC_ TCO [1] [0] = 31	ID_ERR_DTC_ TCO [1] [1] = 32	ID_ERR_DTC_ TCO [1] [2] = 33	ID_ERR_DTC_ TCO [1] [3] = 34	ID_ERR_DTC_ TCO [1] [4] = 30

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_TCO regards the symptom detected.

Example 2 :

One failure misfiring (LV_ERR_MIS_A, LV_ERR_MIS_B1 or LV_ERR_MIS_B4) is stored in the 2nd layer memory. The application is a NC_CYL_NR -cylinder engine. The calibratable table of DTC has the following value :

	Misfiring on 1st cylinder	Misfiring on 2nd cylinder	Misfiring on 3rd cylinder	Misfiring on 4th cylinder	...	Misfiring on NC_CYL_NR th cylinder	Multiple Misfiring	Random Misfiring
OBD DTC	ID_ERR_ DTC_MIS [0] [0] = 0301h (P0301)	ID_ERR_ DTC_MIS [0] [1] = 0302h (P0302)	ID_ERR_ DTC_MIS [0] [2] = 0303h (P0303)	ID_ERR_ DTC_MIS [0] [3] = 0304h (P0304)	...	ID_ERR_ DTC_MIS [0] [NC_CYL_NR - 1] = 03xxh (P03xx)	ID_ERR_ DTC_MIS [0] [NC_CYL_NR] = 0300h (P0300)	ID_ERR_ DTC_MIS [0] [NC_CYL_NR + 1] = 0300h (P0300)
Customer DTC	ID_ERR_ DTC_MIS [1] [0] = 11	ID_ERR_ DTC_MIS [1] [1] = 12	ID_ERR_ DTC_MIS [1] [2] = 13	ID_ERR_ DTC_MIS [1] [3] = 14	...	ID_ERR_ DTC_MIS [1] [NC_CYL_NR - 1] = 16	ID_ERR_ DTC_MIS [1] [NC_CYL_NR] = 10	ID_ERR_ DTC_MIS [1] [NC_CYL_NR + 1] = 10

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_MIS regards the symptom detected.

Calibration data:

Name	Dim	Hex. Limits	Phys. Limits	Resol.	Unit
ID_ERR_DTC_XX	NC_LDP_1_DTC_TABLE_SIZE * NC_LDP_2_DTC_TABLE_SIZE	0...FFFFH	0...65535	1	[-]
LDP_NR_1_ID_ERR_DTC_XX	NC_LDP_1_DTC_TABLE_SIZE	0...FFH	0...255	1	[-]
LDP_NR_2_ID_ERR_DTC_XX	NC_LDP_2_DTC_TABLE_SIZE	0...FFH	0...255	1	[-]
DTC table declaration for the diagnosis instance XX, J2012 shall be applied on OBD/CARB part					
ID_ERR_DTC_MIS	2* NC_LDP_2_DTC_MIS_TABLE_SIZE	0...FFFFH	0...65535	1	[-]
LDP_NR_1_ID_ERR_DTC_MIS	2	0...FFH	0...255	1	[-]
LDP_NR_2_ID_ERR_DTC_MIS	NC_LDP_2_DTC_MIS_TABLE_SIZE	0...FFH	0...255	1	[-]
DTC table declaration for misfiring diagnosis, J2012 shall be applied on OBD/CARB part					

With :

NC_LDP_1_DTC_TABLE_SIZE = NC_NR_DTC_FMT +1

NC_LDP_2_DTC_TABLE_SIZE = 6 - NC_NR_DTC_FMT

NC_LDP_2_DTC_MIS_TABLE_SIZE = NC_CYL_NR +2

Configuration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
NC_ERR_DTC_CONF	1	0...5H	0...5	1	[-]
Type of DTCs displayed through ERR_DTC[IDX]					
NC_NR_DTC_FMT	1	0...1H	0...1	1	[-]
Selection of 6 or 10 DTCs configurations					
NC_LDP_1_DTC_TABLE_SIZE	1	0...FH	0...15	1	[-]
Table size definition for ID_ERR_DTC_XX; set to NC_NR_DTC_FMT+1					
NC_LDP_2_DTC_TABLE_SIZE	1	0...FH	0...15	1	[-]
Table size definition for ID_ERR_DTC_XX; set to 6-NC_NR_DTC_FMT					
NC_LDP_2_DTC_MIS_TABLE_SIZE	1	0...FH	0...15	1	[-]
Table size definition for ID_ERR_DTC_MIS; set to NC_CYL_NR+2					

Configuration data detailed description:

NC_NR_DTC_FMT	= 0	6 DTCs configuration.
	= 1	10 DTCs configuration.

27.30 DTC Management (Appl. Inc.)

27.30.1 Definition of additional DTC information

FUNCTION DESCRIPTION:

General information:

For several diagnosis services it is necessary to transmit an additional information for each symptom.

Description:

These additional information can be calibrated for each symptom of a failure XX with the table ID_ERR_DTC_INFO_XX.

For this project it's used to define the DTCFailureTypeByte according to ISO 14229.

Example for diagnostic instance V_TCO_RNG:

additional Info for SYM_0	additional Info for SYM_1	additional Info for SYM_2	additional Info for SYM_3
ID_ERR_DTC_ INFO_V_TCO_RNG[0] = 05h	ID_ERR_DTC_ INFO_V_TCO_RNG[1] = 01h	ID_ERR_DTC_ INFO_V_TCO_RNG[2] = 00h	ID_ERR_DTC_ INFO_V_TCO_RNG[3] = 00h

Formula section:

27.31 History memory

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_ERR_HIS_NR	V/O/S	0...FFH	0...255	1	[-]
Number of failures stored in the history memory					
ERR_HIS_DTC[NC_NR_ERR_HIS]	V/O/S	0...FFFFH	0...65535	1	[-]
DTC of failure in history memory					
ERR_HIS[NC_NR_HIS][NC_NR_ERR_HIS]	V/O/S	0...FFH	0...255	1	[-]
Others data in history memory					

Output data detailed description:

ERR_HIS_DTC[NC_NR_ERR_HIS] array counts NC_NR_ERR_HIS elements (1… NC_NR_ERR_HIS).

ERR_HIS[NC_NR_HIS][NC_NR_ERR_HIS] array counts NC_NR_HIS x NC_NR_ERR_HIS elements (1… NC_NR_HIS, 1…NC_NR_ERR_HIS).

Input data:

ERR_HIS_CONF[NC_NR_HIS]	ERR_DTC[NC_NR_ERR_DYN]		

Export actions:

ACTION_ERRM_StoreHistory (IN <IDX>)
This action stores the failure IDX in the history memory

FUNCTION DESCRIPTION:

General information:

This module is called by the dynamic error management module just before erasing a failure in the 2nd layer memory (dynamic memory).

The principle is to copy some data related to this failure in a separate memory, called history memory. So the failure become historic failure.

The number of historic failure is limited to a maximum of NC_NR_ERR_HIS. When this maximum number is reach, new historic failure entry deletes the oldest historic failure in memory (“first in first out” principle).

History memory is defined by :

- ERR_HIS_DTC[y] with : y = index of failure in history memory

  A DTC number related to the failure.

- ERR_HIS[x][y] with : x = index of data stored for failure y in history memory

  y = index of failure in history memory

  Some others data.

Contents of history memory is the same for each failure and defined in History memory (Appl. Inc.) module.

The history memory can be read and erased separately by dedicated diagnosis tool service.

The history memory can be deleted by setting the calibration LC_ERR_FMY_HIS_CLR to 1.

27.31.1 Store a failure in history memory

Description:

Syntax : ACTION_ERRM_StoreHistory (IN <IDX>)

Parameter (in) : IDX Index of failure to store in history memory

Parameter(out) : -

Short description : This action stores a failure in history memory

Application conditions:

Initialization: after system initialization the history memory is restored from non-volatile memory or in case of a damaged non volatile memory the history memory is initialized with zero

Recurrence: -

Activation: at action request

Formula section:

```
If     CTR_ERR_HIS_NR < NC_NR_ERR_HIS
Then   CTR_ERR_HIS_NR = CTR_ERR_HIS_NR + 1
Else   ERR_HIS_DTC[y] = ERR_HIS_DTC[y+1]    (“first in first out” principle)
       ERR_HIS[x][y] = ERR_HIS[x][y+1]      (with x = 1..NC_NR_HIS, y = 1...CTR_ERR_HIS_NR–1)
Endif
ERR_HIS_DTC[y] = ERR_DTC[IDX]
ERR_HIS[x][y] = ERR_HIS_CONF[x]
( with x = 1.. NC_NR_HIS, y = CTR_ERR_HIS_NR )
```

27.31.2 Clear the History Memory

Description:

The history memory can be erased by setting the calibration bit LC_ERR_FMY_HIS_CLR at 1.

Application conditions:

Initialization:	after system initialization the history memory is restored from non-volatile memory or in case of a damaged non volatile memory the history memory is initialized with zero
Recurrence:	-
Activation:	at LC_ERR_FMY_HIS_CLR 0→1 transition

Formula section:

ERR_HIS_DTC[y] = 0
ERR_HIS[x][y] = 0
(with x = 1 ... NC_NR_HIS
y = 1 ... NC_NR_ERR_HIS)
CTR_ERR_HIS_NR = 0

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ERR_FMY_HIS_CLR	1	0...1H	0...1	1	[-]
Calibration to clear the history memory (when set to 1)					

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NR_ERR_HIS	1	0...FFH	0...255	1	[-]
Max number of failure in the historic memory					
NC_NR_HIS	1	0...FFH	0...255	1	[-]
Max number of data (in bytes) to stored for a failure in the historic memory					

27.32 History memory (Appl. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ERR_HIS_CONF[NC_NR_HIS]	O	0...FFH	0...255	1	[-]
Contents of history memory					

Input data:

NC_NR_ERR_HIS	NC_NR_HIS	ERR_TYPE_BYTE_IDX	CTR_FRC_IDX
ENVD_CUS_SET_CMN[NC_NR_ENVD_CUS_SET_CMN][NC_NR_FRF_SET][NC_NR_ERR_DYN]	C_ERR_CLAS_XX		

FUNCTION DESCRIPTION:

General information:

This file defines size and contents of the History memory.

History memory	Caracteristics	Value
	Max number of failure	NC_NR_ERR_HIS = 10
	Number of data to store for a failure (in bytes)	NC_NR_HIS = 9
	Contents	ERR_HIS_CONF[1] = ERR_TYPE_BYTE_IDX *BMW error type byte*
		ERR_HIS_CONF[2] = CTR_FRC_IDX *Frequency counter of error IDX*
		ERR_HIS_CONF[3] = ENVD_CUS_SET_CMN_2_1_IDX *Freeze frame data km-counter (high byte) 1st. occur.*
		ERR_HIS_CONF[4] = ENVD_CUS_SET_CMN_3_1_IDX *Freeze frame data km-counter (low byte) 1st. occur.*
		ERR_HIS_CONF[5] = ENVD_CUS_SET_CMN_2_2_IDX *Freeze frame data km-counter (high byte) 2st. occur.*
		ERR_HIS_CONF[6] = ENVD_CUS_SET_CMN_3_2_IDX *Freeze frame data km-counter (low byte) 2st. occur.*
		ERR_HIS_CONF[7] = ENVD_CUS_SET_CMN_2_3_IDX *Freeze frame data km-counter (high byte) last occur.*

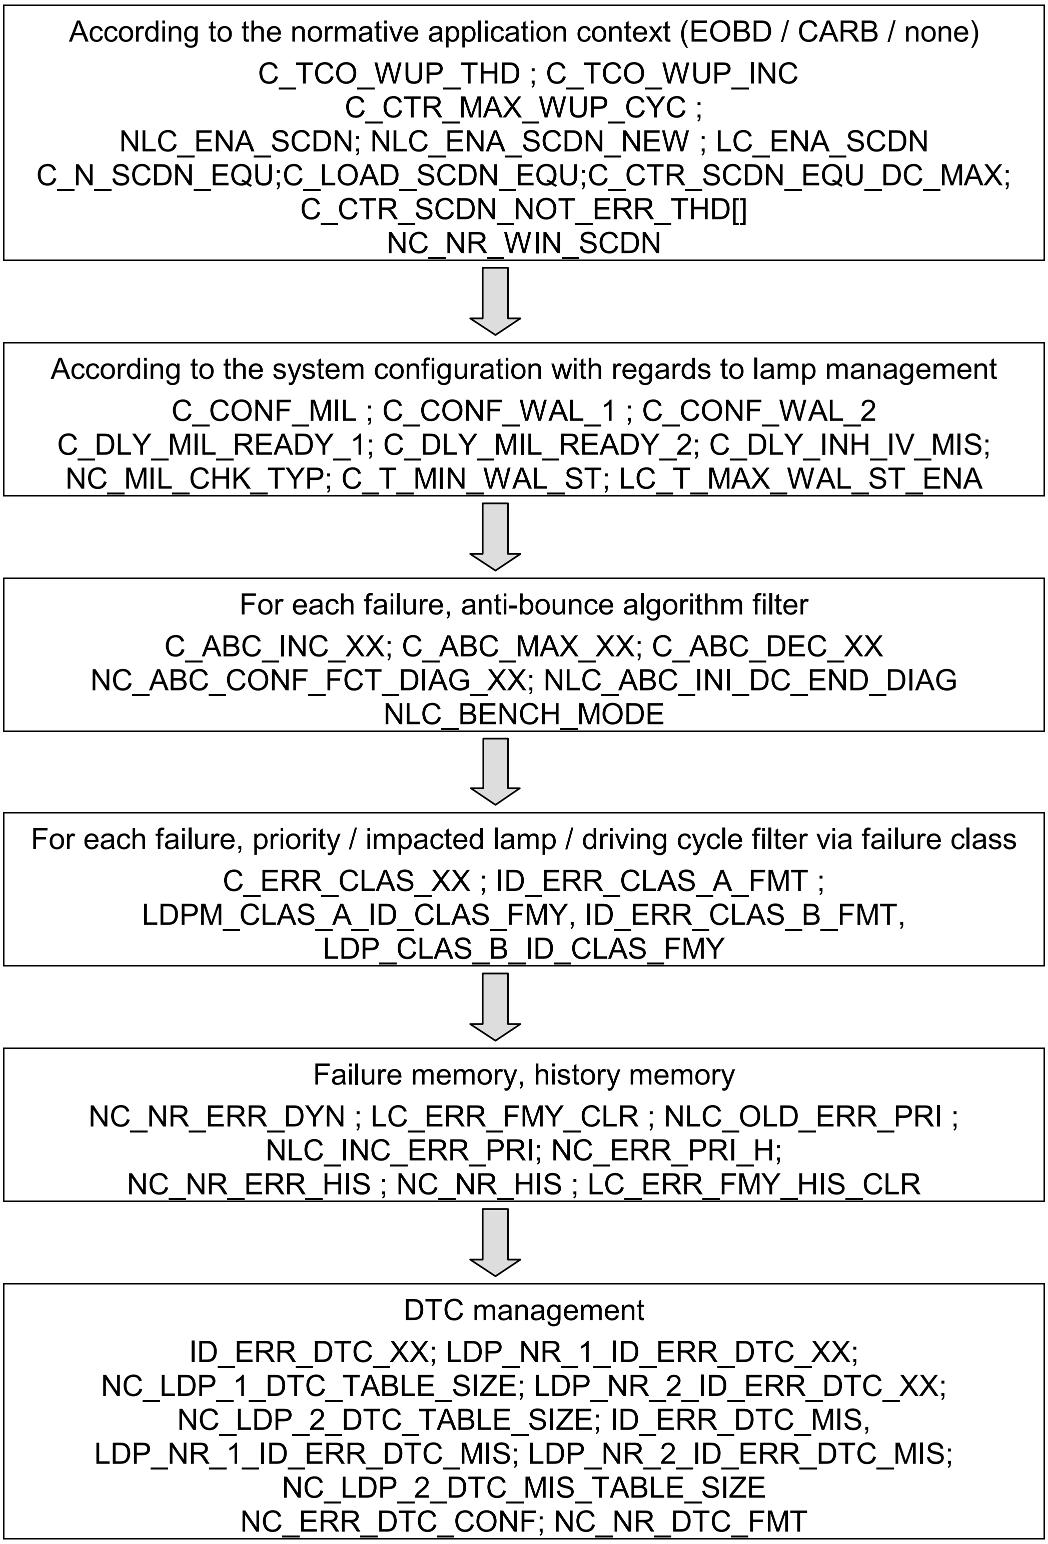
		ERR_HIS_CONF[8] = ENVD_CUS_SET_CMN_3_3_IDX *Freeze frame data km-counter (low byte) last occur.*
		ERR_HIS_CONF[9] = C_ERR_CLAS_XX *Error class*

27.33 Error management (gen)

27.33.1 Calibration interfering function

27.33.2 Calibration flowchart

Although, no strict sequence of calibration is needed for the Dynamic Error Management, a logical order is suggested below.



According to the normative application context (EOBD / CARB / none)
C_TCO_WUP_THD ; C_TCO_WUP_INC
C_CTR_MAX_WUP_CYC ;
NLC_ENA_SCDN; NLC_ENA_SCDN_NEW ; LC_ENA_SCDN
C_N_SCDN_EQU;C_LOAD_SCDN_EQU;C_CTR_SCDN_EQU_DC_MAX;
C_CTR_SCDN_NOT_ERR_THD[]
NC_NR_WIN_SCDN

According to the system configuration with regards to lamp management
C_CONF_MIL ; C_CONF_WAL_1 ; C_CONF_WAL_2
C_DLY_MIL_READY_1; C_DLY_MIL_READY_2; C_DLY_INH_IV_MIS;
NC_MIL_CHK_TYP; C_T_MIN_WAL_ST; LC_T_MAX_WAL_ST_ENA

For each failure, anti-bounce algorithm filter
C_ABC_INC_XX; C_ABC_MAX_XX; C_ABC_DEC_XX
NC_ABC_CONF_FCT_DIAG_XX; NLC_ABC_INI_DC_END_DIAG
NLC_BENCH_MODE

For each failure, priority / impacted lamp / driving cycle filter via failure class
C_ERR_CLAS_XX ; ID_ERR_CLAS_A_FMT ;
LDPM_CLAS_A_ID_CLAS_FMY, ID_ERR_CLAS_B_FMT,
LDP_CLAS_B_ID_CLAS_FMY

Failure memory, history memory
NC_NR_ERR_DYN ; LC_ERR_FMY_CLR ; NLC_OLD_ERR_PRI ;
NLC_INC_ERR_PRI; NC_ERR_PRI_H;
NC_NR_ERR_HIS ; NC_NR_HIS ; LC_ERR_FMY_HIS_CLR

DTC management
ID_ERR_DTC_XX; LDP_NR_1_ID_ERR_DTC_XX;
NC_LDP_1_DTC_TABLE_SIZE; LDP_NR_2_ID_ERR_DTC_XX;
NC_LDP_2_DTC_TABLE_SIZE; ID_ERR_DTC_MIS,
LDP_NR_1_ID_ERR_DTC_MIS; LDP_NR_2_ID_ERR_DTC_MIS;
NC_LDP_2_DTC_MIS_TABLE_SIZE
NC_ERR_DTC_CONF; NC_NR_DTC_FMT

Environmental data (freeze frame)

NC_NR_ENVD_OBD; NC_NR_ENVD_PREV ; NC_NR_ENVD_CUS_CMN;
NC_ENVD_CUS_CMN_UPD;
NC_NR_ENVD_CUS_SET_CMN ; NC_NR_ENVD_CUS_SET_SPC
NC_NR_FRF_SET ; ID_ENVD_FAC[255]; NC_ID_ENVD_FAC;
ID_ERR_ENVD_XX; LDP_1_ID_ERR_ENVD_XX

Communication interface (API)

C_STATE_READY_OBD_1; C_STATE_READY_OBD_2;
C_STATE_READY_OBD_3; C_STATE_READY_OBD_CMPL_OBD_1;
NC_ERR_DTC_REQ_OBD ; NC_ERR_DTC_REQ_CUS ;
NLC_OBD_FRF_PND; LC_STATE_READY_OBD_CARB_CC

Rate-based monitoring

NLC_OBD_RBM_ENA ; LC_RBM_CLR
NC_NR_DIAG_RBM ; C_AMP_MIN_RBM ; C_DLY_AST_RBM ;
C_T_AST_RBM ; C_T_IS_RBM ; C_T_VS_RBM ;
C_TAM_MIN_RBM ; C_VS_THD_RBM ; C_VS_THD_IS_CDN_RBM ;
C_PV_IS_RBM ;

27.33.3 Calibration process

27.33.3.1 Warm-up cycle definition

A warm-up cycle is detected as soon as the coolant temperature reaches a threshold value and the gap with starting temperature exceeds another value. Another calibration value defined the number of warm up cycle to wait, to erase the failure in memory. The decrementation of the warm up counter begins when the MIL is off and the failure is no more pending.

For Warm up cycle detection, light different value are given by the standards:

For gasoline engines (GS):

	EOBD	CARB
C_TCO_WUP_INC	22 Kelvin / 22°C	40 Fahrenheit / 22.22°C
C_TCO_WUP_THD	343 Kelvin / 69.85°C	160 Fahrenheit / 71,11°C
C_CTR_MAX_WUP	40	40

For diesel engines (DS):

	EOBD	CARB
C_TCO_WUP_INC	22 Kelvin / 22°C	40 Fahrenheit / 22.22°C

C_TCO_WUP_THD	343 Kelvin / 69.85°C	140 Fahrenheit / 60°C
C_CTR_MAX_WUP	40	40

27.33.3.2 Similar conditions

Similar conditions are additional conditions based on engine and load status to erase a failure in memory (for Misfire and Fuel system failure only).

⇨ For EOBD or non CARB application
Similar conditions are only required for CARB application, so it is possible to inhibit them for non-CARB application.
NLC_ENA_SCDN = 0
LC_ENA_SCDN = 0 or 1
Note : whatever the value of LC_ENA_SCDN, when NLC_ENA_SCDN = 0, it's impossible to enable similar conditions.

⇨ For CARB application
According CARB standard similar conditions are required with the following value:
NLC_ENA_SCDN = 1
LC_ENA_SCDN = 1
Note : if NLC_ENA_SCDN=1, it's possible to enable or disable similar conditions. But for CARB application it's mandatory to activate them with LC_ENA_SCDN = 1.
With the configuration NLC_ENA_SCDN_NEW the new SCDN functionality (SCDN window around the point, when failure is set in ERRM) could be used.

Exemple for a CARB application:

Calibration name	Physical value	Example of calibration value
LC_ENA_SCDN	1	1
C_N_SCDN_EQU	375 rpm	0B (Hex)
C_LOAD_SCDN_EQU	20 %	-
C_CTR_SCDN_EQU_DC_MAX	80	50 (Hex)

If new SCDN functionality is used additonal the calibration C_CTR_SCDN_NOT_ERR_THD[m] must be adapted to the system needs for each SCDN instance m.

The data NC_NR_WIN_SCDN is configured with the total number of instances used for similar condition calculation.

27.33.3.3 Lamp management

All warning lamp (MIL, WAL_1, WAL_2) configurations are managed with a dedicated calibration:
- C_CONF_MIL for MIL
- C_CONF_WAL_1 for WAL_1
- C_CONF_WAL_2 for WAL_2

It is possible to inhibit a lamp illumination, to inhibit a pre-drive check for a lamp, to allow or not external request for lamp illumination and to link MIL illumination with another lamp (WAL_1, WAL_2).

For vehicles which have a MIL blinking for readiness status displaying during pre-drive check, NC_MIL_CHK_TYP, C_DLY_MIL_READY_1 and C_DLY_MIL_READY_2 must be defined.

Bit 1 of NC_MIL_CHK_TYP = 1: The readiness status are displayed
C_DLY_MIL_READY_1: Delay to start MIL blinking for readiness display during pre-drive check (ARB: 15-20s)
C_DLY_MIL_READY_2: MIL blinking duration for readiness display during pre-drive check (ARB: 5-10s)

Example 1:

Calibration name	Physical value	Example of calibration value
C_CONF_MIL	-	2 (hex) / 0000 0010 (binary)
C_CONF_WAL_1	-	2 (hex) / 0000 0010 (binary)
C_CONF_WAL_2	-	0
C_DLY_MIL_READY_1	20 seconds	28 (Hex)
C_DLY_MIL_READY_2	10 seconds	14 (Hex)

In this example:

- The ECU manages three lamps
- MIL and WAL_1 support external request
- WAL_2 doesn’t support external request
- The pre-drive check is managed by the ECU

As regard Misfiring strategies, if cylinder shut-off is used in case of misfire A detection, C_CONF_MIL and C_DLY_INH_IV_MIS shall be adapted.

27.33.3.4 Anti-bounce Algorithms

27.33.3.4.1 Anti-bounce counter and statistic filters for diagnostics

The anti-bounce algorithm is used to filter a detected failure. The anti-bounce counter is managed with three calibrations:

- C_ABC_INC_XX, to increment the counter while an error is detected
- C_ABC_MAX_XX, to indicate the maximum value of the anti-bounce counter. If the maximum is reached the failure gets present.
- C_ABC_DEC_XX, to decrement the counter when an error is not detected.

Additionally the calibration LC_ABC_BENCH permits to switch on the bench mode for set / reset the failure manually (useful in development phase). The calibration LC_ERR_DET_UPD permits to manage the visualisation of the sporadic error. Both strategies must be included in software by configurations.

The bench mode is useful to set / reset failure manually for development purposes:
i) LC_ABC_BENCH = 1: bench mode is active.
ii) LC_ERR_DET_UPD = 1: sporadic visualisation mode is active.
iii) Then, when LC_ABC_BENCH = 1, use C_ABC_INC_XX to set / reset the failure.
C_ABC_INC_XX = 255: the failure is set
C_ABC_INC_XX = 0: the failure is reset

Important : It is NOT recommended to have the bench mode activated for the serial calibration.

With bench mode activated and C_ABC_INC_XX = 0:
ERR_SYM_XX = 0 LV_ERR_XX = 0 CTR_ABC_XX = 0
LV_CDN_DIAG_XX = 1 LV_END_DIAG_XX = 1

With bench mode activated and C_ABC_INC_XX = FFH:
ERR_SYM_XX = 0Fh LV_ERR_XX = 1 CTR_ABC_XX = C_ABC_MAX_XX
LV_CDN_DIAG_XX = 1 LV_END_DIAG_XX = 1

Without bench mode and C_ABC_INC_XX = 0:
ERR_SYM_XX = 0 LV_ERR_XX = 0 CTR_ABC_XX = 0
LV_END_DIAG_XX = 0 LV_CDN_DIAG_XX = 0 or 1

Each diagnosis has a specified filter type : STD_INI, STD, DEC_CAL, MEM, MEM_INI, NO.

Filter types

Meaning / Result	STD	STD_ INI	DEC_ CAL	MEM	MEM_ INI	STC	NO
LV_ERR_XX and CTR_ABC_XX are saved	**X**		**X**				**Not used**
LV_ERR_XX and CTR_ABC_XX aren't saved		**X**		**X**	**X**		**Not used**
LV_ERR_XX and CTR_ABC_XX are restored from NVMY at ECU reset	**X**		**X**				**Not used**
LV_ERR_XX and CTR_ABC_XX are initialized at LV_IGK 0 → 1 transition or reset		**X**		**X**	**X**	**X**	**Not used**
LV_ERR_XX and CTR_ABC_XX are initialized with the 0 value		**X**	**X**	**X**		**X**	**Not used**
LV_ERR_XX is initialized to 0 and CTR_ABC_XX is initialized with (C_ABC_MAX_XX - C_ABC_INC_XX)					**X**		**Not used**
The anti-bounce counter is decremented when the diagnosis condition are fulfilled without detected failure	**X**	**X**	**X**				**Not used**
The anti-bounce counter is decremented when the diagnosis condition are fulfilled without detected failure only if it hasn't reached the maximum value.				**X**	**X**		**Not used**
The anti-bounce decrement is equal to 1	**X**	**X**		**X**	**X**		**Not used**
The anti-bounce decrement is calibratable			**X**				**Not used**
Filter type is an anti-bounce mechanism	**X**	**X**	**X**	**X**	**X**		**Not used**
The anti-bounce decrement is calibratable						**X**	**Not used**

Important :
- For statistical filtering (STC), it's mandatory to respect the following criterion :
C_ABC_MAX_XX > C_ABC_INC_XX

27.33.3.4.2 Multicondition debounce algorithm

The multicondition debounce algorithm is used to filter a detected failure. This filter is used in case of the condition activation to do the test is not the same for each symptom. (e.g. output power diagnostic)

The anti-bounce counter is managed with two calibrations:
- C_ABC_INC_XX, to increment the counter while an error is detected
- C_ABC_MAX_XX, to indicate the maximum value of the anti-bounce counter. If the maximum is reached the failure gets present.

Bench mode and sporadic errors detection are also available with multicondition debounce algorithm (see §1.3.4.1)

For anti-bounce algorithm calibration (C_ABC_INC_XX, C_ABC_MAX_XX) depends on the sensor sensibility and the diagnosis recurrence.

Note : for each failure the only possible filtering configuration is MPL_STD_INI :

Meaning / Result	Filter type MPL_STD_INI
LV_ERR_XX and CTR_ABC_XX are saved	
LV_ERR_XX and CTR_ABC_XX aren't saved	X
LV_ERR_XX and CTR_ABC_XX are restored from NVMY at ECU reset	
LV_ERR_XX and CTR_ABC_XX are initialized at LV_IGK 0 → 1 transition or reset	X
LV_ERR_XX and CTR_ABC_XX are initialized with the 0 value	X
LV_ERR_XX is initialized to 0 and CTR_ABC_XX is initialized with (C_ABC_MAX_XX - C_ABC_INC_XX)	
The anti-bounce counter is decremented when the diagnosis condition are fulfilled without detected failure	X
The anti-bounce counter is decremented when the diagnosis condition are fulfilled without detected failure only if it hasn't reached the maximum value.	
The anti-bounce decrement is equal to 1	X
The anti-bounce decrement is calibratable	

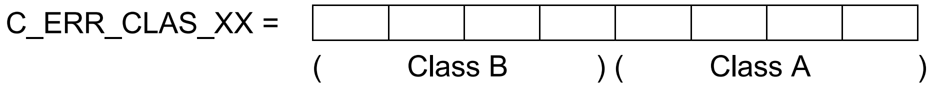
27.33.3.5 Failure Classes

The calibration of a failure, regarding failure treatment within the error management, is made via failure classes with a calibration named C_ERR_CLAS_XX. Each class defines the type of this failure as emission relevant or not, as MIL handling or not, as using driving cycle for MIL illumination, etc...

Definition of a failure class:

The failure class number is a byte divided in two subclasses named class B (defined by the most significant bits) and class A (defined by the less significant bits).

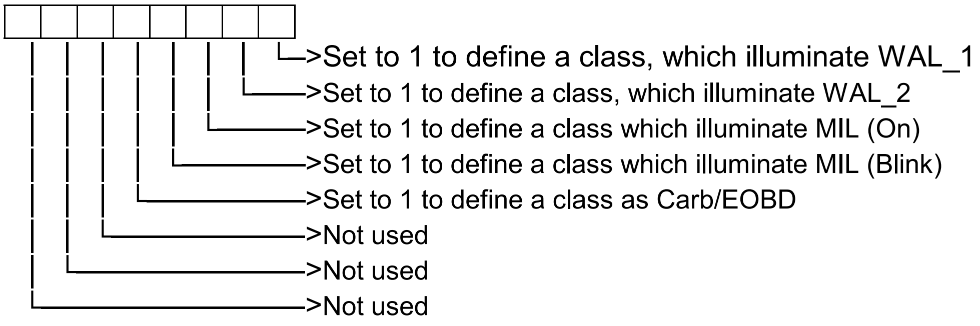
Failure class number for failure XX



Sub classes definitions are given with ID_ERR_CLAS_A_FMT and ID_ERR_CLAS_B_FMT:

Sub class A definition: (16 different subclasses A can be defined) Defines the impact of a failure on the different lamps (MIL, WAL_1 and WAL_2). To define subclass A number i, use ID_ERR_CLAS_A_FMT [i].

ID_ERR_CLAS_A_FMT [i]



WAL_1 (Warning Lamp 1), WAL_2 (Warning Lamp 2) and MIL (Malfunction Indicator Lamp) are lamps to indicate malfunction on the vehicle.

- When a failure occurs, WAL_1 can be immediately illuminated according the class of the failure. Idem for WAL_2 lamp.
- When a failure occurs, MIL can be illuminated when its driving cycle counter reach the maximum value according the class of the failure.
- When a failure occurs, MIL can blinked immediately according the class of the failure.

Sub class B definition: to be used to define priority and driving cycle counter (maximum, increment, decrement) of the failure.

To define sub class B number i use:

- ID_ERR_CLAS_B_FMT [i] [0] = increment value of the driving cycle counter
- ID_ERR_CLAS_B_FMT [i] [1] = maximum value of the driving cycle counter
- ID_ERR_CLAS_B_FMT [i] [2] = decrement value of the driving cycle counter
- ID_ERR_CLAS_B_FMT [i] [3] = priority of the failure

Definition of a class for a failure : to define the class of the failure XX, the calibration C_ERR_CLAS_XX must be used. This calibration contains two hexadecimal digits values :

- first digit represents the sub class B value of the failure XX (from 0H to FH)
- second digit represents the sub class A value of the failure XX (from 0H to FH)

Sub class A definition : to make easier the calibration, some pre-defined value are given (sub class 0 to 4), the others value is free for customer specific definitions (sub class 5 to FH) :

Sub Class A definition : ID_ERR_CLAS_A_FMT (1 byte x 16)

Subclass A Value (i) in hex / Name	**Description**	**ID_ERR_CLAS_A_FMT [i]**
0 / NO_LAMP	*- Predefined value –* Failure without impact on any lamp	%0000 0000 (in binary)
1 / WAL_1_ON	*- Predefined value -* Failure with impact on WAL1 lamp	%0000 0001 (in binary)
2 / WAL_2_ON	*- Predefined value –* Failure with impact on WAL2 lamp	%0000 0010 (in binary)
3 / MIL_ON	*- Predefined value -* Failure with impact on Mil (on)	%0001 0100 (in binary)
4 / MIL_ON_FLL	*- Predefined value –* Failure with impact on Mil (on & blinking)	%0001 1100 (in binary)
5 / LAMP_CUS_1	*Free for customer definition*	*Free for customer definition*
6 / LAMP_CUS_2	*Free for customer definition*	*Free for customer definition*
7 / LAMP_CUS_3	*Free for customer definition*	*Free for customer definition*
8 / LAMP_CUS_4	*Free for customer definition*	*Free for customer definition*
9 / LAMP_CUS_5	*Free for customer definition*	*Free for customer definition*
A / LAMP_CUS_6	*Free for customer definition*	*Free for customer definition*
B / LAMP_CUS_7	*Free for customer definition*	*Free for customer definition*
C / LAMP_CUS_8	*Free for customer definition*	*Free for customer definition*
D / LAMP_CUS_9	*Free for customer definition*	*Free for customer definition*
E / LAMP_CUS_10	*Free for customer definition*	*Free for customer definition*
F / LAMP_CUS_11	*Free for customer definition*	*Free for customer definition*

For failure without impact on emissions (non-CARB failure) : These failures have no impact on MIL ; according customer requirement, these failures might have impact on other lamp.

⇨ For non-CARB failures, use sub class A number 0 (NO_LAMP), 1 (WAL_1) or 2 (WAL_2) according customer requirement

For failure with impact on emissions (CARB failure) : These failures have impact on MIL. For CARB failure, use sub class A number 3 (MIL_ON)

Remark: A failure is considered as a CARB failure (emission relevant) when the bit 4 of ID_ERR_CLAS_A_FMT[i] = 1 (failure visible with scantools, failure can set OBD freeze frame for mode 2).

Sub class B definition : To make easier the calibration, some pre-defined value are given (sub class 0 to 7), the others value is free for customer definition (sub class 8 to FH) :

Sub Class B definition : ID_ERR_CLAS_B_FMT (4 bytes x 16)

		ID_ERR_CLAS_B_FMT			
Subclass B Value (i) in hex/ Name	**Description**	**[i] [0] DC inc**	**[i] [1] DC max**	**[i] [2] DC dec**	**[i] [3] Priority**
0 / NO_LAW_L	*- Predefined value –* Non Carb/EOBD failure with low priority	1	1	1	0
1 / NO_LAW_M	*- Predefined value -* Non Carb/EOBD failure with medium priority	1	1	1	1
2 / NO_LAW_H	*- Predefined value –* Non Carb/EOBD failure with high priority	1	1	1	2
3 / LAW_CC_L	*- Predefined value -* Carb/EOBD failure with low priority Comprehensive component	3	3	1	4
4 / LAW_L	*- Predefined value -* Carb/EOBD failure with low priority	3 / 2 *)	6	2	4
5 / LAW_M	*- Predefined value -* Carb/EOBD failure with medium priority	3 / 2 *)	6	2	5
6 / LAW_H	*- Predefined value -* Carb/EOBD failure with high priority	3 / 2 *)	6	2	6
7 / VALID	For validation	1	1	1	4
8 / NO_ERASE	*- Predefined value -* failure with high priority, not erasable by warm-up cycles.	3	3	0	6
9 / DC_CUS_1	*Free for customer definition*	-	-	-	-
A / DC_CUS_2	*Free for customer definition*	-	-	-	-
B / DC_CUS_3	*Free for customer definition*	-	-	-	-
C / DC_CUS_4	*Free for customer definition*	-	-	-	-
D / DC_CUS_5	*Free for customer definition*	-	-	-	-
E / DC_CUS_6	*Free for customer definition*	-	-	-	-
F / DC_CUS_7	*Free for customer definition*	-	-	-	-

Remark : The increment of the DC counter (*) for the failures defined by the failure classes LAW_L, LAW_M and LAW_H depends on the required regulation (Carb/EOBD).

For OBD1 failure without impact on emissions (non-CARB failure) :

For such kind of failure, the driving cycle counter algorithm filtering isn’t needed because anti-bounce algorithm already exists for these electrical failures. So, it is recommended to store immediately the failure after anti-bounce filtering. In addition, these failures have no impact on the MIL.
Therefore, for such failures : C_CTR_MAX_XX_DC = C_CTR_INC_XX_DC (≥ 1)

It is also recommended to start decrementing the warm-up counter immediately when the failure is no more present.

Therefore, for such failures : C_CTR_MAX_XX_DC = C_CTR_DEC_XX_DC (≥ 1)
Concerning priority, according standards, failure without impact on emission must have the lowest priority (for customer requirement, different level of lowest priority can be defined).

⇨ For non-CARB failure, use sub class B number 0 (NO_LAW_L), 1 (NO_LAW_M) or 2 (NO_LAW_H).

For OBD1 and OBD2 failure with impact on emissions (CARB failure) :
These failures have impact on the MIL. According to EOBD / CARB standards, the MIL must be deactivated after three subsequent sequential driving cycle without failure.
Therefore, for such failures : C_CTR_MAX_XX_DC = 3 * C_CTR_DEC_XX_DC
In addition for such failures : C_CTR_MAX_XX_DC = k * C_CTR_INC_XX_DC
(with k ≤ 2 ; CARB recommendation)

With k = 2 :for failure defined in CARB / EOBD standards (Ex : Fuel System, Misfiring,...) and for failure on comprehensive components without perceptible impact for the vehicle driver (Ex : TCO).

With k = 1 :for other failure on comprehensive components with perceptible impact for the vehicle driver (Ex : Injector valve).

Concerning priority, according standards, failure with impact on pollution must have the following priority :

- fuel system and misfiring failure :	highest priority
- all other failure with impact on pollution :	medium priority

⇨ For CARB failure defined in CARB /EOBD standards, use sub class B number 4 (LAW_L), 5 (LAW_M) or 6 (LAW_H)

⇨ For others comprehensive component CARB failure, use sub class B number 3 (LAW_CC_L)

Particular case for development phase:
In development phase, it might be useful to have immediately effect on the MIL when an error is present. In this particular case, the increment, maximum and decrement calibrations must be equal. The sub class B number 7 (VALID) have been defined for this behaviour.

Particular case for failure no erase:
Some cutomers want be able to keep the failure and so no erase after 40 warm-up cycle.

27.33.3.6 Failure memory / history memory definition

Failure and history memories sizes are defined by configurations.

For development conveniences, it is often useful to clear these memories :

- The failure memory can be erased with a single LC_ERR_FMY_CLR 0 → 1 transition

- The history memory can be erased with a single LC_ERR_FMY_HIS_CLR 0 → 1 transition.

Warning : after reset of failure memory, LC_ERR_FMY_CLR must be reset to 0, nominal value of this calibration.

27.33.3.7 Data Trouble Code (DTC)

27.33.3.7.1 DTC definition for diagnostic instance and misfiring

For each diagnosis XX, a DTC indentification number is defined in ID_ERR_DTC_XX calibration table. A DTC is an hex value identifier encoded as defined in J2012 normative document and according the customer specific definition.

A default value can be found in each diagnosis specification.

If a default value is not availble, please refer to the J2012 normative document. It contains an exhaustive list of normalised DTC codes.

The calibrated DTC, upon failure detection, will be displayed on scantool, customer specific tool and ERR_DTC_IDX system variable.

This calibration shall be filled up with non null values. If one or more symptoms are unused, corresponding DTCs shall be assigned to a non null value.

ID_ERR_DTC_XX[0], ID_ERR_DTC_XX[1], ID_ERR_DTC_XX[2], ID_ERR_DTC_XX[3]
shall be filled up with non null values (NC_NR_DTC_FMT = 0).

ID_ERR_DTC_XX[0][0], ID_ERR_DTC_XX[0][1], ID_ERR_DTC_XX[0][2], ID_ERR_DTC_XX[0][3]
ID_ERR_DTC_XX[1][0], ID_ERR_DTC_XX[1][1], ID_ERR_DTC_XX[1][2], ID_ERR_DTC_XX[1][3]
shall be filled up (NC_NR_DTC_FMT = 1).

The global J2012 encoded DTC shall also be filled up. This DTC is used in Scan Tool Mode $02, if more than one symptoms are active in ERR_SYM_MEM_IDX at the same time.

ID_ERR_DTC_XX[4], ID_ERR_DTC_XX[5]
shall be filled up with non null values (NC_NR_DTC_FMT = 0).

ID_ERR_DTC_XX[0][4], ID_ERR_DTC_XX[1][4]
shall be filled up with non null values (NC_NR_DTC_FMT = 1).

a) For the case NC_NR_DTC_FMT = 0 :

- ID_ERR_DTC_XX [0] : J2012 encoded DTC indentifier linked to the first symptom of failure XX ;
- ID_ERR_DTC_XX [1] : J2012 encoded DTC indentifier linked to the second symptom of failure XX;
- ID_ERR_DTC_XX [2] : J2012 encoded DTC indentifier linked to the third symptom of failure XX ;
- ID_ERR_DTC_XX [3] : J2012 encoded DTC indentifier linked to the fourth symptom of failure XX ;

- ID_ERR_DTC_XX [4] :global J2012 encoded DTC indentifier linked to the failure XX (does not depend on the detected symptom) ;
- ID_ERR_DTC_XX [5] : global customer encoded specific DTC indentifier.

There is a particular case for misfiring (MIS_A, MIS_B1, MIS_B4) diagnoses. The DTC is defined by cylinder within the ID_ERR_DTC_MIS calibration table.

- ID_ERR_DTC_MIS [0][i] is the J2012 encoded DTC for misfiring detection on the cylinder number i +1 ;
- ID_ERR_DTC_MIS [0][NC_CYL_NR] is the J2012 encoded DTC for global (multiple) misfiring ;
- ID_ERR_DTC_MIS [1][i] is the customer encoded DTC for misfiring detection on the cylinder number i+1 ;
- ID_ERR_DTC_MIS [1][NC_CYL_NR] is the customer encoded DTC for global (multiple) misfiring.

b) For the case NC_NR_DTC_FMT = 1 :

- ID_ERR_DTC_XX [0] [0] : J2012 encoded DTC indentifier linked to the first symptom of failure XX ;
- ID_ERR_DTC_XX [0] [1] : J2012 encoded DTC indentifier linked to the second symptom of failure XX;
- ID_ERR_DTC_XX [0] [2] : J2012 encoded DTC indentifier linked to the third symptom of failure XX ;
- ID_ERR_DTC_XX [0] [3] : J2012 encoded DTC indentifier linked to the fourth symptom of failure XX ;
- ID_ERR_DTC_XX [0] [4] :global J2012 encoded DTC indentifier linked to the failure XX (does not depend on the detected symptom) ;

- ID_ERR_DTC_XX [1] [0] : customer encoded specific DTC indentifier linked to the first symptom of failure XX ;
- ID_ERR_DTC_XX [1] [1] : customer encoded specific DTC indentifier linked to the second symptom of failure XX;
- ID_ERR_DTC_XX [1] [2] : customer encoded specific DTC indentifier linked to the third symptom of failure XX ;
- ID_ERR_DTC_XX [1] [3] : customer encoded specific DTC indentifier linked to the fourth symptom of failure XX ;
- ID_ERR_DTC_XX [1] [4] : global customer encoded specific DTC indentifier.

For the particular case of misfiring (MIS_A, MIS_B1, MIS_B4) diagnosis, DTC indentifiers are defined by cylinder in a calibration table called ID_ERR_DTC_MIS. (used if NLC_TREAT_DIAG_MIS = 0; Misfire by type)

- ID_ERR_DTC_MIS[0] [i] is the DTC for misfiring detection on the cylinder number i +1
- ID_ERR_DTC_MIS[0] [NC_CYL_NR] is the DTC for multiple misfiring
- ID_ERR_DTC_MIS[0] [NC_CYL_NR +1] is the DTC for random misfiring

- ID_ERR_DTC_MIS[1] [i] is the customer DTC for misfiring detection on the cylinder number i+1
- ID_ERR_DTC_MIS[1] [NC_CYL_NR] is the customer DTC for multiple misfiring
- ID_ERR_DTC_MIS[1] [NC_CYL_NR +1] is the customer DTC for random misfiring

Example 1:

The DTC calibration table for the TCO diagnosis (coolant temperature) is defined below :

DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure	Specific customer code
ID_ERR_DTC_ TCO [0] = 0118H, (P0118)	ID_ERR_DTC_ TCO [1] = 0117H (P0117)	ID_ERR_DTC_ TCO [2] = 0116H (P0116)	ID_ERR_DTC_ TCO [3] = 0115H (P0115)	ID_ERR_DTC_ TCO [4] = 0114H (P0114)	ID_ERR_DTC_ TCO [5] = 32H

In case this TCO failure is detected and stored into memory, DTC visualization with application system variable ERR_DTC_IDX will be :

- If NC_ERR_DTC_CONF = 0

  then the symptom DTC is visible on application system :

  ERR_DTC_IDX = 0118H, if failure is detected with 1st symptom

  ERR_DTC_IDX = 0117H, if failure is detected with 2nd symptom

  ERR_DTC_IDX = 0116H, if failure is detected with 3rd symptom

  ERR_DTC_IDX = 0115H, if failure is detected with 4th symptom

  ERR_DTC_IDX = 0114H, if failure is detected with multiple symptoms (more than one symptom active at the same time)

- If NC_ERR_DTC_CONF = 1

  then the global DTC is visible on application system : ERR_DTC_IDX = 0114H

- If NC_ERR_DTC_CONF = 2

  then the customer DTC is visible on application system : ERR_DTC_IDX = 0032H

If symptom 3 and 4 are not used, corresponding DTCs can be asigned to 0114H

Example 2:

One failure misfiring (MIS_A, MIS_B1 or MIS_B4) is stored in the 2nd layer memory. The application is a 6 cylinders system. The DTC calibratable tables is defined below :

ID_ERR_DTC_MIS :

	Misfiring on 1st cylinder	Misfiring on 2nd cylinder	Misfiring on 3rd cylinder	Misfiring on 4th cylinder	Misfiring on 5th cylinder	Misfiring on 6th cylinder	Global (multiple) Misfiring
OBD DTC	ID_ERR_DTC_ MIS [0][0] = 0301H (P0301)	ID_ERR_DTC_ MIS [0][1] = 0302H (P0302)	ID_ERR_DTC_ MIS [0][2] = 0303H (P0303)	ID_ERR_DTC_ MIS [0][3] = 0304H (P0304)	ID_ERR_DTC_ MIS [0][4] = 0305H (P0305)	ID_ERR_DTC_ MIS [0][5] = 0306H (P0306)	ID_ERR_DTC_ MIS [0][6] = 0300H (P0300)

Customer DTC	ID_ERR_DTC _MIS [1][0] = 11H	ID_ERR_DTC_ MIS [1][1] = 12H	ID_ERR_DTC_ MIS [1][2] = 13H	ID_ERR_DTC_ MIS [1][3] = 14H	ID_ERR_DTC_ MIS [1][4] = 15H	ID_ERR_DTC_ MIS [1][5] = 16H	ID_ERR_DTC_ MIS [1][6] = 10H

⇨ DTC visualization with application system with ERR_DTC_IDX (if failure is stored in the memory):

- If NC_ERR_DTC_CONF = 0

then the cylinder individual OBD DTC is visible on application system :

ERR_DTC_IDX = 0301H, if misfire is detected on cylinder 1
ERR_DTC_IDX = 0302H, if misfire is detected on cylinder 2
ERR_DTC_IDX = 0303H, if misfire is detected on cylinder 3
ERR_DTC_IDX = 0304H, if misfire is detected on cylinder 4
ERR_DTC_IDX = 0305H, if misfire is detected on cylinder 5
ERR_DTC_IDX = 0306H, if misfire is detected on cylinder 6

Only in case of multiple misfire:

ERR_DTC_IDX = 0300H

- If NC_ERR_DTC_CONF = 1

then the global (multiple) misfire OBD DTC is visible on application system :

ERR_DTC_IDX = P0300

- If NC_ERR_DTC_CONF = 2

then the cylinder individual customer DTC is visible on application system :

ERR_DTC_IDX = 11H, if misfire is detected on cylinder 1
ERR_DTC_IDX = 12H, if misfire is detected on cylinder 2
ERR_DTC_IDX = 13H, if misfire is detected on cylinder 3
ERR_DTC_IDX = 14H, if misfire is detected on cylinder 4
ERR_DTC_IDX = 15H, if misfire is detected on cylinder 5
ERR_DTC_IDX = 16H, if misfire is detected on cylinder 6

Only in case of multiple misfire:

ERR_DTC_IDX = 10H

Example 3:

The failure TCO (coolant temperature) is stored. The calibratable table of DTC has the following values:

a) with NC_NR_DTC_FMT = 0

DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure	Specific customer code
ID_ERR_TCO [0][0] = 0118H (P0118)	ID_ERR_TCO [0][1] = 0117H (P0117)	ID_ERR_TCO [0][2] = 0119H (P0119)	ID_ERR_TCO [0][3] = 0116H (P0116)	ID_ERR_TCO [0][4] = 0115H (P0115)	ID_ERR_TCO [0] [5] = 30

b) with NC_NR_DTC_FMT = 1

	DTC of the 1st symptom	DTC of the 2nd symptom	DTC of the 3rd symptom	DTC of the 4th symptom	Global DTC of the failure
OBD DTC	ID_ERR_TCO [0][0] = 0118H (P0118)	ID_ERR_TCO [0] [1] = 0117H (P0117)	ID_ERR_TCO [0][2] = 0119H (P0119)	ID_ERR_TCO [0][3] = 0116H (P0116)	ID_ERR_TCO [0][4] = 0115H (P0115)
Customer DTC	ID_ERR_TCO [1] [0] = 31H	ID_ERR_TCO [1] [1] = 32H	ID_ERR_TCO [1] [2] = 33H	ID_ERR_TCO [1] [3] = 34H	ID_ERR_TCO [1] [4] = 30H

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_TCO depending on symptom detected.

Example 4:

One failure misfiring (LV_ERR_MIS_A, LV_ERR_MIS_B1 or LV_ERR_MIS_B4) is stored in the 2nd layer memory. The application is a NC_CYL_NR -cylinder engine. The calibratable table of DTC has the following values :

	Misfiring on 1st cylinder	Misfiring on 2nd cylinder	Misfiring on 3rd cylinder	Misfiring On 4th Cylinder	...	Misfiring on NC_CYL_NR th cylinder	Multiple Misfiring	Random Misfiring
OBD DTC	ID_ERR_MIS [0][0] = 0301H (P0301)	ID_ERR_MIS [0][1] = 0302H (P0302)	ID_ERR_MIS [0][2] = 0303H (P0303)	ID_ERR_MIS [0][3] = 0304H (P0304)	...	ID_ERR_MIS [0] [NC_CYL_NR - 1] = 03xxH (P03xx)	ID_ERR_MIS [0] [NC_CYL_NR] = 0300H (P0300)	ID_ERR_MIS [0] [NC_CYL_NR + 1] = 0300H (P0300)
Customer DTC	ID_ERR_MIS [1][0] = 11H	ID_ERR_MIS [1][1] = 12H	ID_ERR_MIS [1][2] = 13H	ID_ERR_MIS [1][3] = 14H	...	ID_ERR_MIS [1] [NC_CYL_NR - 1] = 16H	ID_ERR_MIS [1] [NC_CYL_NR] = 10H	ID_ERR_MIS [1] [NC_CYL_NR + 1] = 10H

Upon request from the diagnosis tool, the DTC number sent to the tool will be one of the numbers defined in ID_ERR_DTC_MIS regards the symptom detected.

27.33.3.8 Environmental data (freeze frame size and contents)

The major part of freeze frame content has to be configured. Only the content of ENVD_CUS_SET_SPC (specific to each failure and stored many times) can be calibrated for each failure.

The content of this part is defined by using calibration ID_ERR_ENVD_XX and ID_ENVD_FAC configuration table.

ID_ERR_ENVD_XX:	Calibration table which defines for each failure XX the environmental data which should be stored in the set of freeze frame related to failure XX.

Example:

In order to store specific environmental data at each occurrence of a failure as follow:

- TIA and TCO_ST in case of TCO failure;
- MAP and AMP in case of EGR failure;

With :

ID_ENVD_FAC [1] = &TIA
ID_ENVD_FAC [2] = &TCO_ST
ID_ENVD_FAC [3] = &MAP (msb)
ID_ENVD_FAC [4] = &MAP (lsb)
ID_ENVD_FAC [5] = &AMP (msb)
ID_ENVD_FAC [6] = &AMP (lsb)

Then, for each failure, the environmental data to be stored is calibrated as follow :

ID_ERR_ENVD_TCO = [1,2,0,0]
ID_ERR_ENVD_EGR = [3,4,5,6]

27.33.3.9 Communication Interface

27.33.3.9.1 Readiness codes

Within the communication interface the behavior of functionalities in case of communication tool request must be defined:

- Readiness Code requested by law

Readiness code is requested by the CARB, with a scantool, to check if the diagnosis of each function has been performed.

C_STATE_READY_OBD_1:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit 0 : Misfire monitoring supported
 |  |  |  |  |  |  └───>  bit 1 : Fuel system monitoring supported
 |  |  |  |  |  └─────>  bit 2 : Comprehensive component monitoring supported
 |  |  |  |  └───────>  bit 3 : 0 (reserved)
 |  |  |  └─────────>  bit 4 : X (not used)
 |  |  └───────────>  bit 5 : X (not used)
 |  └─────────────>  bit 6 : X (not used)
 └───────────────>  bit 7 : X (not used)
```

C_STATE_READY_OBD_2:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit 0 : Catalyst monitoring supported
 |  |  |  |  |  |  └───>  bit 1 : Heated catalyst
 |  |  |  |  |  └─────>  bit 2 : Evaporative system monitoring supported
 |  |  |  |  └───────>  bit 3 : Secundary air system monitoring supported
 |  |  |  └─────────>  bit 4 : A/C system refrigerant monitoring
 |  |  └───────────>  bit 5 : Oxygen sensor monitoring supported
 |  └─────────────>  bit 6 : Oxygen sensor heater monitoring
 └───────────────>  bit 7 : EGR system monitoring supported
```

For comprehensive components (others components which may have impact indirectly on emission) the diagnosis has to be done a certain number of time to update readiness code.

An exception is made on comprehensive components, misfire and fuel system monitors. Legislation allows to set directly "ready" without computing theses 3 monitors.
This strategy can be activated with the calibration C_STATE_READY_OBD_CMPL_OBD_1 as defined below.

Readiness code calculation for CARB_MIS, CARB_FSD, CARB_CC diagnosis :
0: readiness of concerned group is calculated based on the readiness of each comprehensive component diagnostic
1: readiness of concerned group always indicates "ready"

C_STATE_READY_CMPL_OBD_1:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit0 : 0
 |  |  |  |  |  |  └───>  bit1 : 0
 |  |  |  |  |  └─────>  bit2 : 0
 |  |  |  |  └───────>  bit3 : 0
 |  |  |  └─────────>  bit4 : set directly ready Misfire monitoring status
 |  |  └───────────>  bit5 : set directly ready Fuel system monitoring status
 |  └─────────────>  bit6 : set directly ready Comprehensive component monitoring status
 └───────────────>  bit7 : 0
```

- Readiness Code requested by customer

There is also a possibility to manage customer specific readiness with C_STATE_READY_OBD_3 defined as below :

C_STATE_READY_OBD_3:

```
┌─┬─┬─┬─┬─┬─┬─┬─┐
└─┴─┴─┴─┴─┴─┴─┴─┘
 |  |  |  |  |  |  |  └─>  bit 0 : for diagnosis classified as CARB_OTHER
 |  |  |  |  |  |  └───>  bit 1 : for diagnosis classified as NO_CARB
 |  |  |  |  |  └─────>  bit 2 : 0
 |  |  |  |  └───────>  bit 3 : 0
 |  |  |  └─────────>  bit 4 : 0
 |  |  └───────────>  bit 5 : 0
 |  └─────────────>  bit 6 : 0
 └───────────────>  bit 7 : 0
```

Typical value for readiness code requested by law

Calibration name	Example of calibration
C_STATE_READY_OBD_1	07 (Hex) / 0000 0111 (Binary)
C_STATE_READY_OBD_2	25 (Hex) / 0010 0101 (Binary)

In this example : misfire, fuel system, comprehensive component, catalyst, evaporative system and oxygen sensor monitoring are supported.

27.33.3.10 Rate-Based Monitoring

For the for Rate-Based Monitoring statistics calculation, CARB has defined standardized vehicle operations (RBM Driving Cycle), which must be met to increment counters.

A special driving cycle (LV_DC_RBM) for Rate-Based Monitoring is defined, which is set, if the following standardized vehicle operations are fulfilled:

- Cumulated trip length (time since engine start) T_AST_RBM ≥ C_T_AST_RBM

  (CARB : 600 s)
- Cumulative vehicle operation ≥ C_VS_THD_RBM for minimum of C_T_VS_RBM

  (CARB : VS ≥ 40 km/h (25mph) for at least 300 s)
- Continuous vehicle operation in idle equal or longer than C_T_IS_RBM (accelerator pedal released and vehicle speed less or equal than 1 mph)

  (CARB : 30 s)

with

- altitude such as ambient pressure AMP > C_AMP_MIN_RBM

  (CARB : 8000 feet)
- ambient temperature (TAM) ≥ C_TAM_MIN_RBM

  (CARB : 20 °F)

CARB requested values are :

C_DLY_AST_RBM = **2 s**
C_T_AST_RBM = **600 s**
C_VS_THD_RBM = **40 km/h**

C_T_VS_RBM = **300 s**
C_T_IS_RBM = **30 s**

C_VS_THD_IS_CDN_RBM = **1,6 km/h**
C_PV_IS_RBM = 0 %
C_AMP_MIN_RBM equivalent to 8000 feet ~ **2400 m**
C_TAM_MIN_RBM = **20 °F** = **- 7° C**

Calibration proposed :

C_DLY_AST_RBM = 2 s
C_T_AST_RBM = 600 s
C_VS_THD_RBM = 40,00 km/h
C_T_VS_RBM = 300 s
C_T_IS_RBM = 30 s

C_VS_THD_IS_CDN_RBM = 2 km/h (VS resolution : 1 km/h)
C_PV_IS_RBM = 0,00 %
C_AMP_MIN_RBM = 749,993 hPa
C_TAM_MIN_RBM = - 7,5 °C

28 Evaporative system control

Table of Contents

Index

28.1 EVAC Configuration Data

Input data:

NC_NR_CP_LAM_AD	NC_NR_CP_BUF	NC_PSD_DLY_CPS	

General information:

The following document describes the general rules for definition of the configuation data for EVAC agregate.

28.1.1 Local configuration data

Data	Value
NC_NR_CP_LAM_AD	9
NC_NR_CP_BUF	80
NC_PSD_DLY_CPS	2

NC_NR_CP_LAM_AD: (default value = 9)

Number of fixed cp / Lambda adaptation slices after engine start. This value is used in the time control between purge and lambda adaptation (903P) to have maximum of flexibility.

NC_NR_CP_BUF: (default value = 20)

size of the fuel buffer fuel_flow_add_buf. The default value is 20 but some applications which have long engine displacement need a greater value to simulate the distance between canister purge valve and injectors (80 for example).

NC_PSD_DLY_CPS: (default value = 2)

Canister purge valve diagnosis: Number of recurrences with diagnosis deactivation after diagnosis activation conditions are met.

28.2 EVAC - Requirements for infrastructure

Input data:

Export actions:

ACTION_INFR_GetElDiagCPS(OUT<Cdn_diag_el_cps>, OUT<Err_diag_el_cps>)
This action reads the failure and the conditions information for each symptom from the infrastructure
ACTION_INFR_SetPWMDucyCPS(IN<Cppwm_cps>)
Sets the duty cycle of the PWM output signal
ACTION_INFR_SetPWMFrqCPS(IN<Frq_req_cp>)
Sets the frequency of the PWM output signal

Decription for actions:

ACTION_INFR_GetElDiagCPS(Cdn_diag_el_cps, Err_diag_el_cps)					
This action reads the diagnosis information and the failure symptoms (raw value) received from the infrastructure					
Name	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
Cdn_diag_el_cps	OUT	0...7H	0...7	1	[-]
Diagnosis condition for each symptom of CPS; bit 0: diagnosis condition for symptom SYM_0; bit 1: diagnosis condition for symptom SYM_1; bit 2: diagnosis condition for symptom SYM_2					
Err_diag_el_cps	OUT	0H 1H 2H 4H	NO_SYM SYM_0 SYM_1 SYM_2	0	[-]
Raw value of error symptom for CPS (only parameter)					

ACTION_INFR_SetPWMDucyCPS(Cppwm_cps)					
By calling this action the duty cycle of the PWM output signal is changed					
Name	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
Cppwm_cps	IN	0...FFH	0...99.60937	0.390625	[%]
Corrected PWM signal for CPS opening					

ACTION_INFR_SetPWMFrqCPS(Frq_req_cp)					
By calling this action the frequency of the PWM output signal is changed					
Name	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
Frq_req_cp	IN	0...FFH	0...255	1	[Hz]
CPS Output frequency					

FUNCTION DESCRIPTION:

General information:

This module describes the interfaces to the basic software (BSW) and the PWM output opening of the canister purge valve.

Requirements for ACTION_INFR_GetElDiagCPS:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag_el_cps	-	-	<bit coded>	Err_diag_el_cps	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag_el_cps	-	-	<bit coded>	Cdn_diag_el_cps	Bitcoded result of each symptom (SYM_0=SCP, SYM_1=SCG, SYM_2=OC) **0h** = NO_SYM **1h** = SYM_0 **2h** = SYM_1 **4h** = SYM_2 The relevant bit is set, if the error has been detected.

Diagnosis: ACTION_INFR_GetElDiagCPS() returns the electric diagnosis

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_SetPWMDucyCPS:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cppwm_cps	-	-	0.390625%	-	Output valve opening. Updating of duty cycle: 10ms

Diagnosis: no diagnosis

28.2.1 Coincidence requirements: -

Requirements for ACTION_INFR_SetPWMFrqCPS:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Frq_req_cp	-	-	1Hz	-	FRQ_REQ_CP is generally between 8 to 16 Hz.

Diagnosis: no diagnosis

28.2.2 Coincidence requirements: -

28.3 AGGR EVAC adaptation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CLOSE_ACT_CP	V/O	0...1H	0...1	1	[-]
Logical value for CPS valve closed					

Input data:

LV_CP_CLOSE_ACT			

FUNCTION DESCRIPTION:

Adaptation to aggregate environment.

Application conditions:

Initialisation: at reset:
LV_CLOSE_ACT_CP = LV_CP_CLOSE_ACT from NVMY

Recurrence: 20ms

Activation: at every engine state

Deactivation: -

Formula section:

LV_CLOSE_ACT_CP = LV_CP_CLOSE_ACT

28.4 Evaporative emission control variables

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_CDN_CP	V/O	0H 1H 2H 3H 4H 5H	NO_CDN CDN_NO_PURGE CDN_MIN_PURGE CDN_RAMP_OPEN CDN_RAMP_FAST CDN_NO_FAST	1	[-]
Activation conditions for evaporative emission control function					
LV_N_MAX_CP	V/O	0...1H	0...1	1	[-]
Maximum engine speed for canister purge calculations limit reached					
LV_CP_CLOSE_REQ	V/O	0...1H	0...1	1	[-]
Request to close the CPS valve					
LV_CP_WIN	V	0...1H	0...1	1	[-]
Engine operation within CP window (n & maf)					
LV_CP_DYW	V/O	0...1H	0...1	1	[-]
Dynamic window for canister purge					
LV_CP_PU	V	0...1H	0...1	1	[-]
Flag to interupt the purge in PU mode

28.4.1 Maximum engine speed flag management

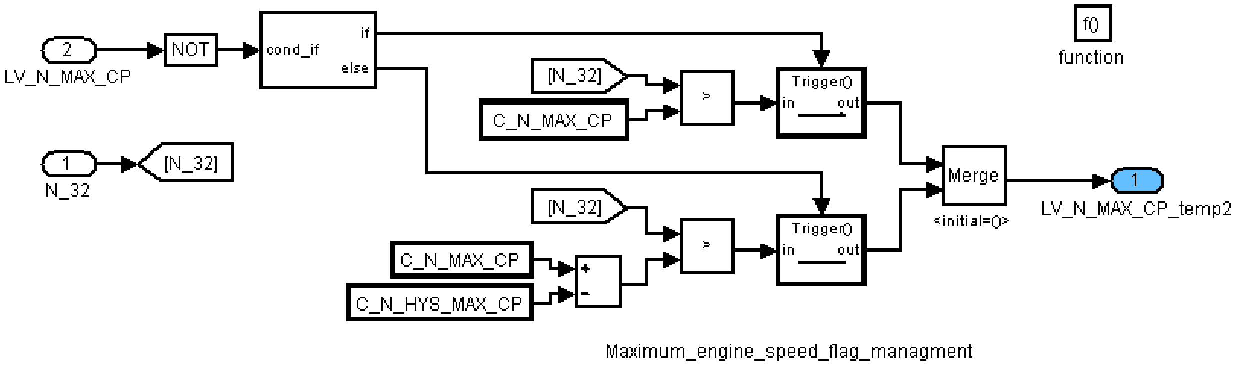
General information:

When the CPU load is critical it is possible to disable some of the canister purge calculations when the engine speed is above a threshold.

Application conditions:

Initialisation: at RST or IGKON
LV_N_MAX_CP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Signal flow diagram:



Formula section:

if LV_N_MAX_CP = 0
then LV_N_MAX_CP = [N_32 > C_N_MAX_CP]
else LV_N_MAX_CP = [N_32 > C_N_MAX_CP – C_N_HYS_MAX_CP]
endif
end

28.4.2 Dynamic engine conditions for canister purge

General information:

The limited dynamic condition for a variable exist if the current value stays inside a tolerance window.
If the values of n & maf (homogeneous) rsp. n, tqi_sp_s and lamb_sp_s (stratified) stay within a window around the moving mean value of this variable for a certain time, limited dynamic is detected.

C_FAC_LAM_CP_DYW should be always greater than C_FAC_LAM_DIF_MAX_CP.

Application conditions:

Initialisation: at RST or IGKON
N_DYW_CP = 0
MAF_DYW_CP = 0
TQI_DYW_CP = 0
LAMB_SP_S_DYW_CP = 0
FAC_LAM_CP_DYW = 0
T_DLY_DYW_CP = 0

Recurrence: called by superior bloc
Activation: called by superior block
Deactivation: --

Formula section:

```
if      LC_CP_DYW_CLC_ENA     = 1

            endif
    endif
    end
```

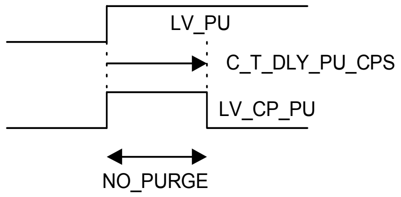
28.4.3 Trailling throttle information for canister purge

General information:

In case of trailling throttle condition LV_PU, the fuel coming from the purge could be important compared to the fuel injected. To prevent any malfunction we need to close immediatly the purge valve during a delay C_T_DLY_PU_CPS. During this time the flag LV_CP_PU is set to 1.



Application conditions:

Initialisation: at RST or IGKON
LV_CP_PU = 0
T_DLY_CP_PU_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if     LV_PU  0 → 1
then   T_DLY_CP_PU_TMP = C_T_DLY_PU_CPS
else   T_DLY_CP_PU_TMP = max (0, T_DLY_CP_PU_TMP – TA)
endif
LV_CP_PU = [T_DLY_CP_PU_TMP > 0 ]
end
```

28.4.4 Canister purge prohibition after "trailing fuel cut off"

After a fuel cut off phase (PUC) the engine needs a ceratain time to stabilize the air fuel ratio. During this phase the lambda controller has a deviation. To prevent that this deviation has an influence on the CL calculation, canister purge will be disabled after a PUC phase.

Application conditions:

Initialisation: at RST or IGKON
LV_CP_PUC = 0
T_DLY_CP_PUC_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if     LV_PUC  = 1
then   T_DLY_CP_PUC_TMP = C_T_DLY_PUC_CP
else   T_DLY_CP_PUC_TMP = max (0, T_DLY_CP_PUC_TMP – TA)
endif
LV_CP_PUC = [T_DLY_CP_PUC_TMP > 0 ]
end
```

28.4.5 Lambda control limitation reached

General information:

When the lambda control reaches a minimum or maximum value, the information LV_FAC_LAM_LIM_MIN rsp. LV_FAC_LAM_LIM_MAX is set. As soon as the lambda control value is again in its limits, the bit information is reset. In order to memorize this information and to wait for a lambda control value stabilized, an information is managed LV_LAM_LIM_CP.

This value is set to TRUE as long as any lambda control limit is exceeded and reset after a delay C_T_LAM_LIM_CP after the lambda control is within its limits again.

Application conditions:

Initialisation: at RST or IGKON
LV_LAM_LIM_CP = 0
T_DLY_LAM_LIM_CP_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if   LV_FAC_LAM_LIM_MIN [i]  = 1          at least one bench
or   LV_FAC_LAM_LIM_MAX [i]  = 1          at least one bench
then T_DLY_LAM_LIM_CP_TMP = C_T_LAM_LIM_CP
else T_DLY_LAM_LIM_CP_TMP = max (0, T_DLY_LAM_LIM_CP_TMP – TA)
endif
LV_LAM_LIM_CP = [T_DLY_LAM_LIM_CP_TMP > 0 ]
end
```

28.4.6 Lambda control within functional window

General information:

Parallel to the observation of lamba control limits using the flags LV_FAC_LAM_LIM_MIN and LV_FAC_LAM_LIM_MAX coming from the lambda controller, the canister purge strategy provides two independent limits C_FAC_LAM_CP_BOL & C_FAC_LAM_CP_TOL.
As long as at least one lambda controller is not running in a window defined by [C_FAC_LAM_CP_BOL, C_FAC_LAM_CP_TOL] an information is set to TRUE and reset after a delay C_T_DLY_LAM_CP after all lambda controllers are within [C_FAC_LAM_CP_BOL, C_FAC_LAM_CP_TOL] again.

Application conditions:

Initialisation: at RST or IGKON
LV_LAM_OUT_CP = 0
T_DLY_LAM_OUT_CP_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

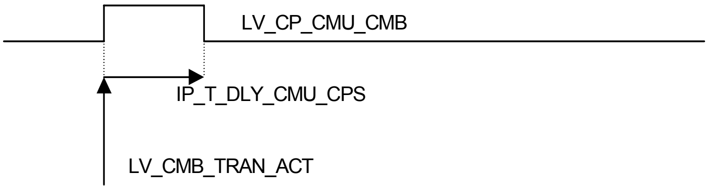
```
if   FAC_LAM_MV_MMV_CP [i] <= C_FAC_LAM_CP_BOL          at least one bench
or   FAC_LAM_MV_MMV_CP [i] >= C_FAC_LAM_CP_TOL          at least one bench
then T_DLY_LAM_OUT_CP_TMP = C_T_DLY_LAM_CP
else T_DLY_LAM_OUT_CP_TMP = max (0, T_DLY_LAM_OUT_CP_TMP – TA)
endif
```

```
LV_LAM_OUT_CP = [T_DLY_LAM_OUT_CP_TMP > 0 ]
end
```

28.4.7 Commutation interruption management

General information:

Before a combustion commutation, the CPS valve may be closed to purge the intake manifold. A delay will be added to wait for lambda stabilisation and manifold purge. During the commutation the evaporative emission control is in state NO_PURGE



Application conditions:

Initialisation: at RST or IGKON
LV_CP_CMU_CMB = 0
T_DLY_CMU_CP_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if    LV_CMB_TRAN_ACT
then  T_DLY_CMU_CP_TMP = IP_T_DLY_CMU_CPS (N_32)
else  T_DLY_CMU_CP_TMP = max (0, T_DLY_CMU_CP_TMP – TA)
endif
LV_CP_CMU_CMB = [T_DLY_CMU_CP_TMP > 0 ]
end
```

28.4.8 Catalyst purge interruption management

General information:

During NO_x regeneration of the catalyst and a time delay after that, the canister purge can be set configurable to off, open loop or closed loop.

Application conditions:

Initialisation: at RST or IGKON
LV_CP_CAT_PURGE = 0
T_DLY_CAT_PURGE_CP_TMP = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if    LV_HOM_ACT = 1
      and  [LV_NT_RGN_REQ
      or   (LV_CAT_PURGE_REQ_POST_AFL[i]          // at least one of these flags
           and LC_CP_CAT_PURGE_AFL_ACT)]
then  T_DLY_CAT_PURGE_CP_TMP = C_T_DLY_CAT_PURGE_CP
else  T_DLY_CAT_PURGE_CP_TMP =  max (0, T_DLY_CAT_PURGE_CP_TMP – TA)
endif
LV_CP_CAT_PURGE = [T_DLY_CAT_PURGE_CP_TMP > 0 ]
end

if    [LV_HOM_ACT = 1
      and  LV_CAT_PURGE_REQ_POST_AFL[i] transition 0 -> 1 // at least one of these
flags
then  T_DLY_CAT_PURGE_CP_AFL_TMP = C_T_DLY_CAT_PURGE_AFL_CP
else  T_DLY_CAT_PURGE_CP_AFL_TMP
                             = max (0, T_DLY_CAT_PURGE_CP_AFL_TMP – TA)
endif
LV_CP_CAT_PURGE_AFL = [T_DLY_CAT_PURGE_CP_AFL_TMP > 0 ]
end
```

28.4.9 Calculation of PRS_CPS

General information:

PRS_CPS is the pressure drop over the CP system, i.e. the difference between ambient air pressure and intake manifold pressure

Application conditions:

Initialisation: at RST or IGKON
PRS_CPS = 0
Recurrence: called by superior block
Activation: called by superior block
Deactivation: --

Formula section:

```
if    LC_PRS_CPS_EXT
then  PRS_CPS  = PRS_CPS_EXT
else  PRS_CPS  = AMP – MAP
```

end

28.4.10 Preselection of the canister purge state

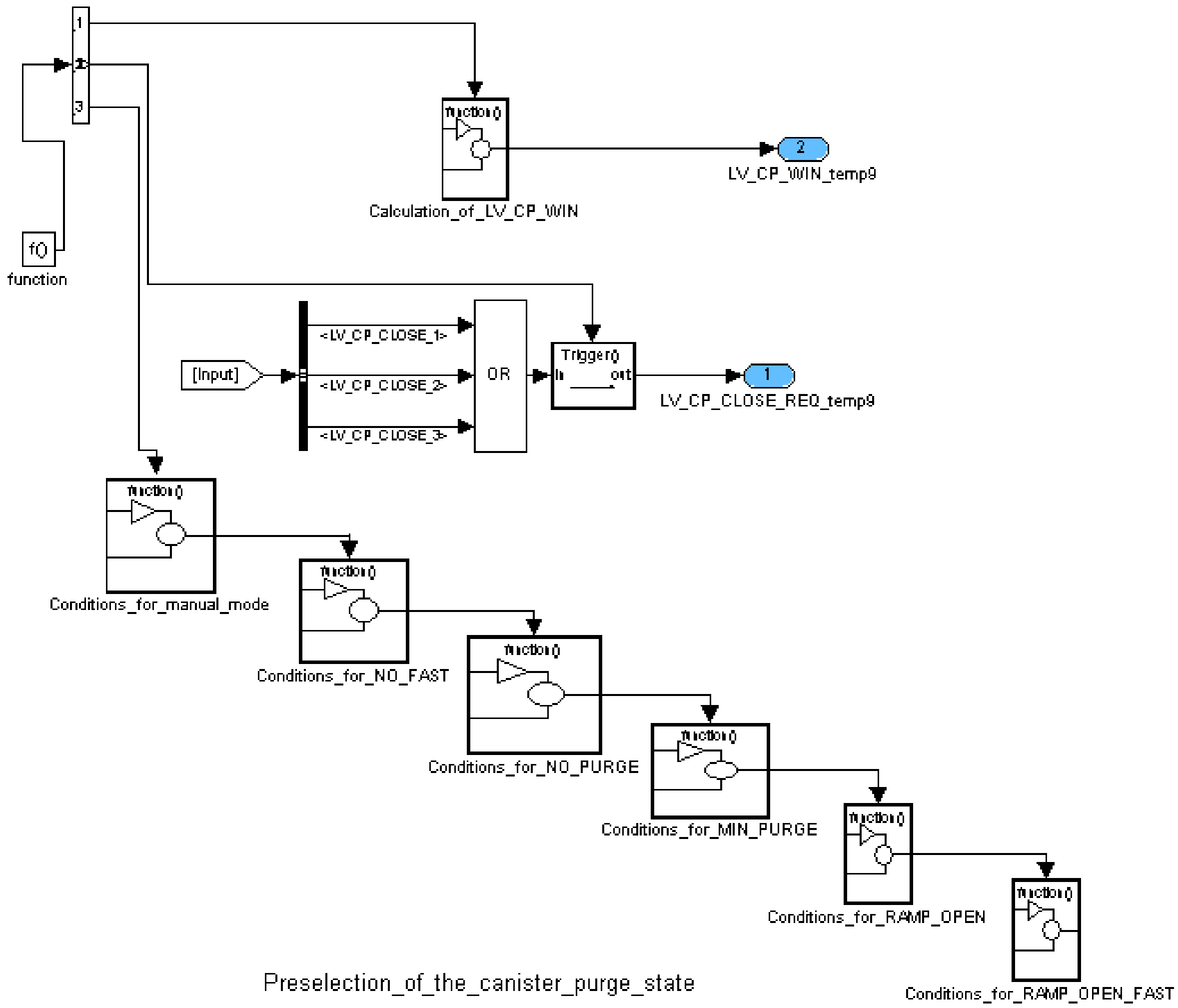
General information:

After activation of the function (LV_CP_ACT=1) there is a continuous check of the activation conditions.

Application conditions:

Initialisation:	at RST or IGKON all the values are set to zero.
Recurrence:	called by superior block
Activation:	called by superior block
Deactivation:	--

Signal flow diagram:



Formula section:

```
if      LV_HOM_ACT = 1
then  if LV_CP_WIN = 1
        then LV_CP_WIN =                          // Engine operation window for CP, hom.
               [      N_32        > C_N_CP_BOL
               and   N_32        < C_N_CP_TOL
               and   MAF         > [ IP_MAF_CP_BOL (N_32) - C_MAF_CP_BOL_HYS ]
               and   MAF         < IP_MAF_CP_TOL (N_32)]
        else LV_CP_WIN =                          // Engine operation window for CP, hom.
               [      N_32        > C_N_CP_BOL
               and   N_32        < C_N_CP_TOL
               and   MAF         > [ IP_MAF_CP_BOL (N_32) + C_MAF_CP_BOL_HYS ]
               and   MAF         < IP_MAF_CP_TOL (N_32)]
        endif

               and   TQI_SP_S > [ IP_TQI_CP_BOL (N_32) + C_TQI_CP_BOL_HYS ]
               and   TQI_SP_S < IP_TQI_CP_TOL (N_32)]
        endif
endif

LV_CP_CLOSE_REQ =
[       LV_CP_CLOSE_1                // request to close CPS with high speed
or      LV_CP_CLOSE_2                // request to close CPS with medium speed
or      LV_CP_CLOSE_3 ]              // request to close CPS with normal speed
```

Conditions for manual mode:

1. Test mode activated
   (LC_STATE_CDN_CP_MAN = 1)
   // in this case the conditions below are no more checked

➔ STATE_CDN_CP = C_STATE_CDN_CP_MAN

Conditions for immediate switch to NO_PURGE (without ramp):

1. Fuel cut off active
   (LV_FCUT_IND = 1) **or**
2. Trailing throttle operation started
   (LV_CP_PU = 1) **or**
3. Prohibition after PUC
   (LV_CP_PUC = 1) **or**
4. Deactivation due to high engine speed / CPU load
   (LV_N_MAX_CP = 1) **or**

5. Difference pressure intake manifold-environment below threshold
   (relevant for supercharger engine or high engine load)
   (PRS_CPS < C_PRS_MAX_CPS_2) **or**
6. Request for fast closing from appl.inc. module
   (LV_INH_CP_FAST = 1)

➔ STATE_CDN_CP = CDN_NO_FAST

Conditions for NO_PURGE:
(closing of the CPS required)

1. Conditions for NO_FAST are not fulfilled **and**
2. {canister purge manually forced to NO_PURGE
   (LC_CP_INH_MAN=1) **or**
3. Application incidences flag to inhibit canister purge and switch to NO_PURGE
   (LV_INH_CP=1) **or**
4. NO_PURGE locked for a certain time by EVAC control
   (STATE_LOCK_CP = NO_PURGE) **or**
5. Request to close CPS from OBD2 sequenceur
   (LV_CP_CLOSE_REQ=1) **or**
6. Difference pressure intake manifold-environment below threshold
   (relevant for supercharger engine)
   (PRS_CPS < C_PRS_MAX_CPS) **or**
7. Idle speed active and ambient air temperature below threshold
   (acoustic problems with the CPS at low ambient temperatures)
   [(LV_IS=1) **and** (TIA_THR < C_TIA_MIN_CP)] **or**
8. Combustion commutation and stabilization
   (LV_CP_CMU_CMB=1) **or**
9. Engine operation point outside CP window and NO_PURGE selected for this event
   [(LV_CP_WIN = 0) **and** (C_STATE_WIN_CP_NOT = NO_PURGE)] **or**
10. Lambda controller reached limits and no purge state is desired
    [(LV_LAM_LIM_CP = 1) **and** (C_STATE_LAM_LIM_CP = NO_PURGE)] **or**
11. Catalyst purge requests state NoPurge
    [(LV_CP_CAT_PURGE = 1
    and (LC_CP_CAT_PURGE_OFF = 1 or LV_CL_MDL_END_CAT_PURGE = 1)] **or**
    [LV_CP_CAT_PURGE_AFL = 1]

➔ STATE_CDN_CP = CDN_NO_PURGE

Conditions for MIN_PURGE:

1) "hard" conditions for MIN_PURGE:

The "hard" condtitions for MIN_PURGE force MIN_PURGE, i.e. no usage of the canister load model is possible.

LV_CP_CDN_MIN_PURGE_FAST =

1. {closed loop canister purge (“normal puge”) manually deactivated
   (LC_CP_CLL_INH_MAN=1) **or**
2. Application incidences flag to inhibit normal purge and switch to MIN_PURGE
   (LV_INH_CP_CLL=1)
   or
3. MIN_PURGE locked for a certain time by EVAC control

(STATE_LOCK_CP = MIN_PURGE) **or**

4. Trailing throttle
   (LV_PU = 1) **or**
5. Switch for not allowing NORMAL_PURGE in stratified set
   (LV_HOM_ACT=0 **and** LC_CP_CLL_S_INH=1) **or**
6. Engine operation point outside CP window and MIN_PURGE selected for this event
   [(LV_CP_WIN = 0) **and** (C_STATE_WIN_CP_NOT = MIN_PURGE)] } **or**
7. Catalyst purge requests open loop
   [(LV_CP_CAT_PURGE = 1) and (LC_CP_CAT_PURGE_OPL = 1)]

2) combination of all conditions for MIN_PURGE:

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. [Any of the "hard" conditions for MIN_PURGE is given
   (LV_CP_CDN_MIN_PURGE_FAST = 1) **or**
4. Lambda control in open-loop state in homogeneous mode
   (LV_HOM_ACT=1 **and** LV_LAM_LSCL[i] = 0)
   (at least one bank) **or**
5. Lambda control stopped in homogeneous mode
   (LV_HOM_ACT=1 **and** LV_LAM_STOP[i] = 1 **and** LV_LAM_STOP_SHO_PER[i] = 0)
   (at least one bank, both conditions has to be true for one bank) **or**
6. Lambda controller reached limits and min purge state is desired
   [(LV_LAM_LIM_CP=1) **and** (C_STATE_LAM_LIM_CP = MIN_PURGE)]

➔ STATE_CDN_CP = CDN_MIN_PURGE

Conditions for RAMP_OPEN:

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. Conditions for MIN_PURGE are not fulfilled **and**
4. Limited dynamics for canister purge fulfilled
   (LV_CP_DYW=1) **and**
5. [Lambda control in defined limits in homogeneous mode
   (LV_HOM_ACT=1 **and** LV_LAM_OUT_CP=0) **or**
6. Lambda setpoint within defined limits in stratified mode
   [LV_HOM_ACT=0 **and** (C_LAMB_SP_S_CP_BOL < LAMB_SP_S <C_LAMB_SP_S_CP_TOL)]]
   and
7. Engine operation within CP window (LV_CP_WIN = 1)

➔ STATE_CDN_CP = CDN_RAMP_OPEN

Conditions for RAMP_OPEN_FAST :

1. Conditions for NO_FAST are not fulfilled **and**
2. Conditions for NO_PURGE are not fulfilled **and**
3. Conditions for MIN_PURGE are not fulfilled **and**
4. Limited dynamics for canister purge fulfilled
   (LV_CP_DYW=1) **and**
5. [Lambda control in defined limits in homogeneous mode
   (LV_HOM_ACT=1 **and** LV_LAM_OUT_CP=0) **or**
6. Lambda setpoint within defined limits in stratified mode
   [LV_HOM_ACT=0 **and** (C_LAMB_SP_S_CP_BOL < LAMB_SP_S <C_LAMB_SP_S_CP_TOL)]]

➔ STATE_CDN_CP = CDN_RAMP_FAST

(the only difference between conditions for RAMP_OPEN and for RAMP_OPEN_FAST is the engine operation window.)

if none of the above conditions are fulfilled

➔ STATE_CDN_CP = NO_CDN

The calculation of STATE_CDN_CP is done in the following order:

```
if          Conditions for manual mode fulfilled
then        STATE_CDN_CP = C_STATE_CDN_CP_MAN
elseif          Conditions for NO_FAST fulfilled
then        STATE_CDN_CP = CDN_NO_FAST
elseif          Conditions for NO_PURGE fulfilled
then        STATE_CDN_CP = CDN_NO_PURGE
elseif          Conditions for MIN_PURGE fulfilled
then        STATE_CDN_CP = CDN_MIN_PURGE
elseif          Conditions for RAMP_OPEN fulfilled
then        STATE_CDN_CP = CDN_RAMP_OPEN
elseif          Conditions for RAMP_OPEN_FAST fulfilled
then        STATE_CDN_CP = CDN_RAMP_FAST
else        STATE_CDN_CP = NO_CDN
endif
end
```

28.5 Torque reserve for canister purge at idle

Output data:

Logical variable for inhibiting the torque reserve for canister purge in idle					

General Information:

The torque reserve for canister purge in idle should be active, when the canister purge function is in a controlled mode, so if STATE_CP = MAX_PURGE.

By increasing the engine load without increasing the torque output, a higher purge rate is possible.

Signal flow diagram:

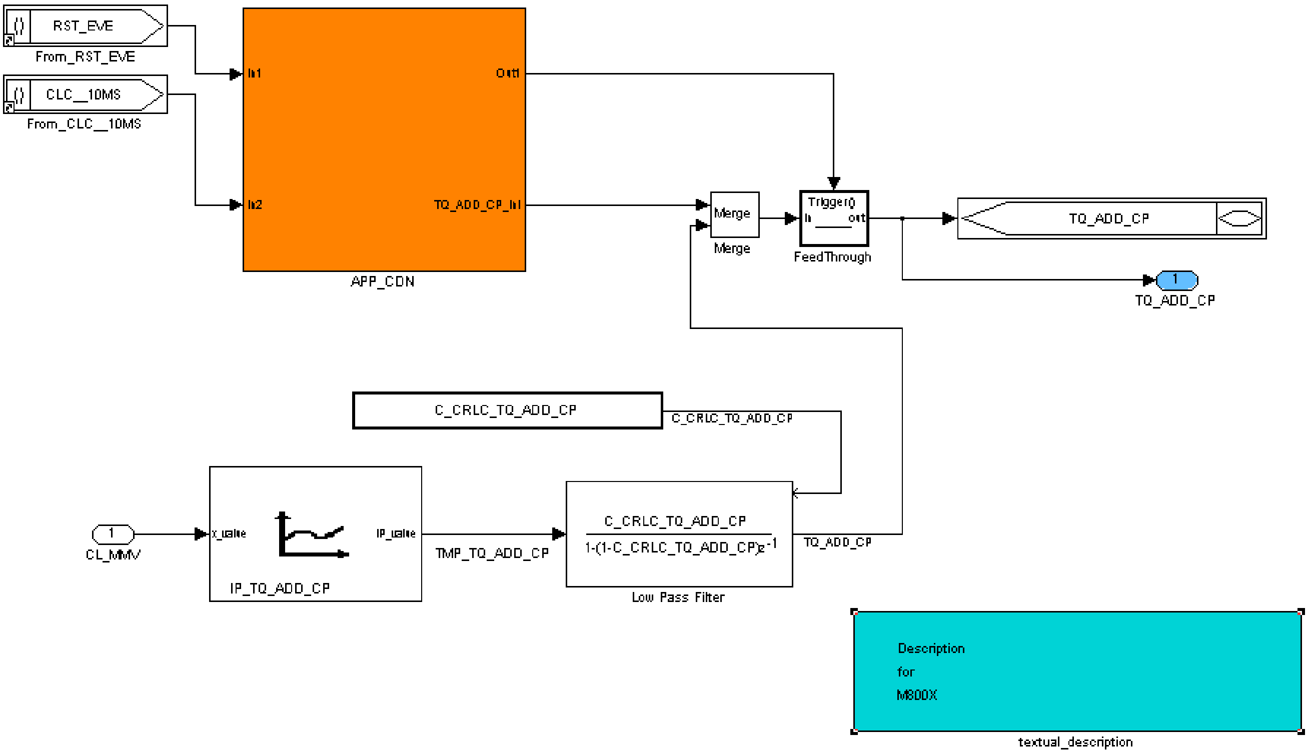

Figure 1: *Torque reserve for canister purge at idle*

FUNCTION DESCRIPTION:

General information:

Activation:

LV_IS = 1
and STATE_CP = MAX_PURGE
and LC_TQ_ADD_CP_INH = 0
and LV_HOM_RUN = 1

Deactivation:

LV_IS = 0
or STATE_CP ≠ MAX_PURGE
or LC_TQ_ADD_CP_INH = 1
or LV_HOM_RUN = 0

Initialization: at reset or deactivation
TQ_ADD_CP = 0

Recurreny: **20** ms

Formula section:

TMP_TQ_ADD_CP = IP_TQ_ADD_CP (CL_MMV)

$TQ\_ADD\_CP_n$= // filtered value of *TMP_TQ_ADD_CP*

$TQ\_ADD\_CP_{n-1} + C\_CRLC\_TQ\_ADD\_CP * (TMP\_TQ\_ADD\_CP - TQ\_ADD\_CP_{n-1})$

switch to activate / deactiate "intelligent MIN_PURGE"					

General information:

This module provides the flow setpoint for MIN_PURGE and the FUEL_FLOW setpoint for closed loop purge (“normal purge”).

Application conditions:

Initialisation: *on activation and on deactivation:*

FLOW_CPS_SP_MIN_PURGE = 0
RATIO_FUEL_SP_MAX_PURGE = 0
MFF_MAX_CP = 0
FLOW_MAX_CPS = 0
FLOW_MAX_PHY_CPS = 0

Recurrence: **100** ms
Activation: LV_CP_ACT = 1
Deactivation LV_CP_ACT = 0

Formula section:

```
// Flow setpoint for MIN_PURGE & fuel flow ratio for closed loop

case selection of STATE_OPM_ENG_CP

28.7.1 General information

General information:

The evaporative emissions of the fuel tank system are stored in an activated charcoal filter ACF to prevent an escape of the gas to the environment. The loading capacity of the filter is limited, so the filter must be purged temporarily. Therefore the canister purge solenoid CPS. that is positioned between the charcoal filter and the intake manifold is opened by the engine management system. To prevent driveability and emission problems, the opening of the CPS and so the purge flow MFF_CP must be controlled.

With the Evaporative Emission Control function, the opening of the CPS is controlled in dependence with the fuel mass stored in the canister. Therefore the canister load cl is calculated using the measured mass air flow MAF, the deviation of the lambda-control when the CPS is opened, the mass flow through the CPS and the stoichiometric constant of the fuel (14.7). The opening of the CPS is controlled in dependence with the canister load CL.

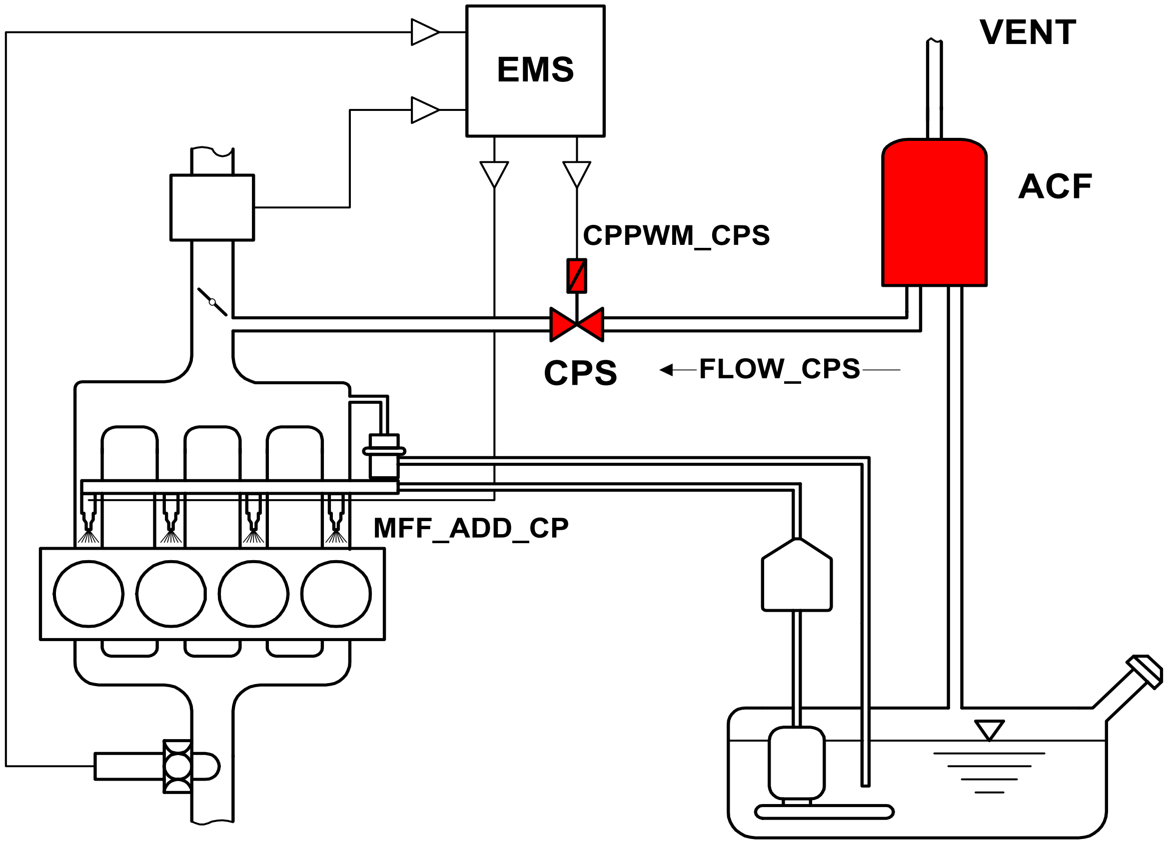

figure 1: evaporative emission control system

Application conditions:

Initialisation: at RST, IGKON or transition to CP_NOT_ACT:

PQ_CP_SP = 1
STATE_CP = CP_NOT_ACT
STATE_CLL_DEAC_CP = CP_NO_DEAC
STATE_LOCK_CP = UNLOCKED
all other values = 0

Recurrence: **20** ms
Activation: --
Deactivation: --

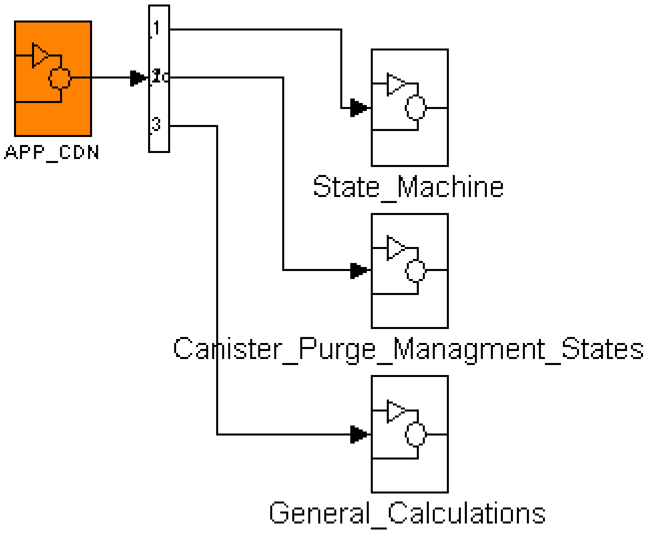

figure 2: structure of the evaporative emission control

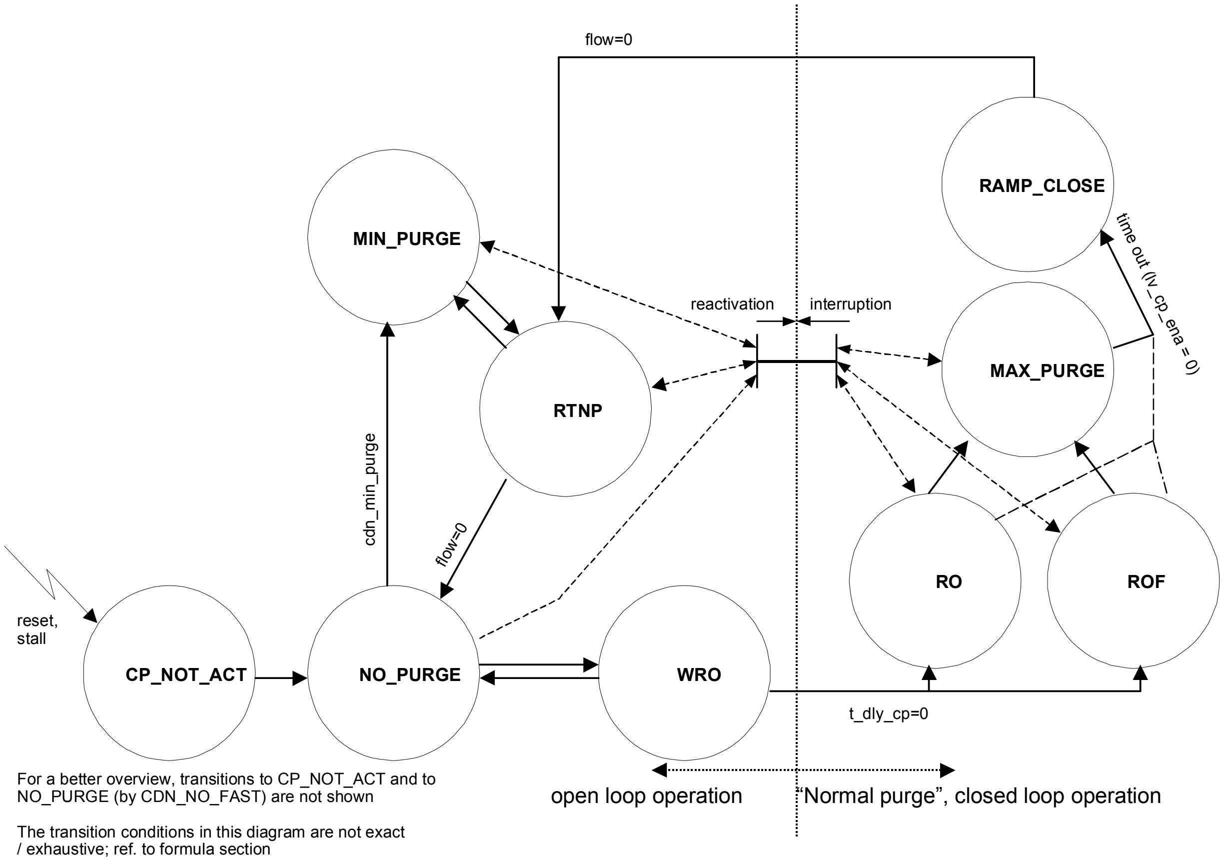
Formula section:

call “State machine”
call “Canister purge management states”
call “General calculations”
end

Temporary adaptation flags :

LV_RAMP_OPEN_ACT = LV_CP_RAMP_OPEN_ACT

28.7.2 State machine



For a better overview, transitions to CP_NOT_ACT and to NO_PURGE (by CDN_NO_FAST) are not shown

The transition conditions in this diagram are not exact / exhaustive; ref. to formula section

figure 3: State machine (simplified)

The canister purge control has the following states:

CP_NOT_ACT	function inactive, initial state
NO_PURGE	Valve closed, no purging.
RAMP_TO_NO_PURGE	Flow is currently ramped down from purging level to zero
MIN_PURGE	open loop purge with low flow
WAIT_RAMP_OPEN	waiting for lambda control stabilisation before leaning mode
RAMP_OPEN	Slow opening of the valve, learning mode
RAMP_OPEN_FAST	Faster opening of the valve; cl known from previous purge
MAX_PURGE	Controlled canister purge with high flow through the ACF
RAMP_CLOSE	Closing of the valve at the end of controlled operation

28.7.2.1 Brief description of the activation conditions of the different states

<u>General information:</u>

In the following, a brief description of the conditions of each state is given, this description is only for information and is <u>not precise</u>. In general, if the conditions below are met, the state described will be active.

The detailed conditions for transitions from each state to each other possible state and the actions to be done on the transitions are described in the next chapter “State Transitions”.

The “controlled states” are RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE & RAMP_CLOSE.

The “non-controlled states” are NO_PURGE, RAMP_TO_NO_PURGE, MIN_PURGE and WAIT_RAMP_OPEN.

NORMAL_PURGE Operation (closed loop operation)

If the conditions for NORMAL_PURGE are fulfilled, the NORMAL_PURGE operation is proceeded in the following sequences:

RAMP_OPEN → MAX_PURGE → RAMP_CLOSE

or RAMP_OPEN_FAST → MAX_PURGE → RAMP_CLOSE

These sequences can change, if one of the phases is disabled for a short time and the interrupt is not longer than an applicable time constant

- C_T_DI_RAMP_OPEN_CP_0/_1 (STATE_CLL_DEAC_CP = RAMP_OPEN_DEAC) **or**
- C_T_DI_MAX_CP_0/_1 (STATE_CLL_DEAC_CP = MAX_PURGE_DEAC) **or**
- C_T_DI_RAMP_FAST_CP_0/_1 (STATE_CLL_DEAC_CP = RAMP_FAST_DEAC)

If RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE operation was interrupted (any non-controlled state active) and the interruption time is lower than the adjustable times C_T_DI_RAMP_OPEN_CP_0/_1, C_T_DI_RAMP_FAST_CP_0/_1 rsp. C_T_DI_MAX_CP_0/_1, RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE operation starts immediately with the values which were stored when the operation was interrupted.

When the interruption times are longer than the corresponding constants, NORMAL_PURGE states are re-started with a new RAMP_OPEN / RAMP_OPEN_FAST phase. (FLOW_CTL_CPS starts with zero.)

CP_NOT_ACT

Function inactive, initial state

1. Engine stopped or stalled
2. coolant temperature threshold not once exceeded

NO_PURGE

Valve closed, no purging.

1. STATE_CDN_CP = CDN_NO_PURGE or CDN_NO_FAST **and**
2. [Fast shut-off necessary **or**
3. ramp from purge states to NO_PURGE finished]

RAMP_TO_NO_PURGE

Flow is currently ramped down from purging level to zero

If fast shut-off is necessary, the state machine will directly switch to NO_PURGE (immediate valve closing without ramp), otherwise, RAMP_TO_NO_PURGE will be active as long as the valve is closed by a ramp

1. STATE_CDN_CP = CDN_NO_PURGE **and**
2. Fast shut-off not necessary **and**
3. Ramp from purge states to NO_PURGE not finished **and**
4. [Previous state was MIN_PURGE or WAIT_RAMP_OPEN **and** time out from time scheduler LV_CP_ENA = 0]

An immediate switch to NO_PURGE without ramp is requested by STATE_CDN_CP = CDN_NO_FAST. In this case, FLOW_CTL_CPS is directly set to 0, no ramping down will occur.

MIN_PURGE

No controlled purge possible, open loop purge with low flow, thus low disturbance of lambda contro.

1. STATE_CDN_CP = CDN_MIN_PURGE **or**
2. Empty canister detected at the end of RAMP_OPEN

RAMP_OPEN

Slow opening of the valve, canister load not known, will be learned during RAMP_OPEN

1. STATE_CDN_CP = CDN_RAMP_OPEN **and**
2. Long time since the last MAX_PURGE (old cl value no more useable) **and**
3. The time delay for lambda control stabilization is elapsed or not necessary (due to MAX_PURGE or RAMP_OPEN disabling).

RAMP_OPEN_FAST

Faster opening of the valve than in RAMP_OPEN; cl known from previous normal purge operation

1. STATE_CDN_CP = CDN_RAMP_FAST **and**
2. Short time since the last MAX_PURGE (old cl value still useable) **and**
3. The time delay for lambda control stabilization is elapsed or not necessary (due to MAX_PURGE or RAMP_OPEN disabling)

MAX_PURGE

Controlled canister purge with high flow through the ACF

1. NO_PURGE / RAMP_TO_NO_PURGE / MIN_PURGE not requested **and**
2. RAMP_OPEN or RAMP_OPEN_FAST normally finished **and**
3. Can be directly reached from the non-controlled states, if MAX_PURGE was previously disabled and disabling time was lower than a threshold (STATE_CLL_DEAC_CP = MAX_PURGE_DEAC)
4. Can be entered at catalyst purge with canister load model running

RAMP_CLOSE

Closing of the valve at the end of controlled operation

1. NO_PURGE / RAMP_TO_NO_PURGE / MIN_PURGE not requested **and**
2. Canister purge time slice elablsed / Lambda adaption time active

endif
```

28.7.2.12 INITIALIZATIONS on transitions

The following submodules are called on transitions between the different states of canister purge control

28.7.2.12.1 Storage of Values for OBDII EVAP-System Monitoring (RO, ROF, MaxP)

This submodule is called, if RAMP_OPEN, RAMP_OPEN_FAST or MAX_PURGE is left due to purge time elapsed (LV_CP_ENA = 0).

In this case, the last calculated value of the canister load CL_MMV is stored as CL_MMV_CLC_END before RAMP_CLOSE operation starts. This value is used as input for the OBDII EVAP-System Monitoring.

In addition, this subroutine may be called if MAX_PURGE is left due to a valve closing request from OBD II function.

```
CL_MMV_CLC_END = CL_MMV
end
```

28.7.2.12.2 INITIALIZATION-VALUES on entering NO_PURGE

This submodule is called at every possible transition from any state to NO_PURGE except the transition CP_NOT_ACT → NO_PURGE.

On entering NO_PURGE, the initialisations listed below are done.

```
// Initialisation of the time counter for lambda controller stabilisation
FLOW_GRD_CPS          = 0
FLOW_TAR_CPS          = 0
FLOW_CTL_CPS          = 0
LV_CP_CLL             = 0
LV_STATE_MEM_CP_CLL   = 0
PQ_CP_SP              = 1           // In this mode no forced PQ is required
end
```

28.7.2.12.3 INITIALIZATION-VALUES on leaving NO_PURGE

If the NO_PURGE operation is left towards any other state, the following initialisations are done.

```
---
end
```

28.7.2.12.4 INITIALIZATION-VALUES on entering RAMP_TO_NO_PURGE

This submodule is called at every possible transition from any state to RAMP_TO_NO_PURGE.

On entering RAMP_TO_NO_PURGE, the initialisations listed below are done.

As cl is not updated during RAMP_TO_NO_PURGE, it’s sufficient to define the correction factor for closing speed FLOW_FAC_CP on transition from any state to RAMP_TO_NO_PURGE.

The start value of FLOW_CTL_CPS for the ramp has to be defined.

```
LV_CP_CLL          = 0
FLOW_TAR_CPS       = 0
FLOW_CTL_CPS       = min [FLOW_CTL_CPS, FLOW_MAX_CPS]
PQ_CP_SP           = 1                       // In this mode no forced PQ is required
if   STATE_CP      = MIN_PURGE
then FLOW_FAC_CP   = 1                       // ramp decrement cor. factor
else FLOW_FAC_CP   = IP_FLOW_FAC_CP (CL)
endif
end
```

28.7.2.12.5 INITIALIZATION-VALUES on leaving RAMP_TO_NO_PURGE

If the RAMP_TO_NO_PURGE operation is left towards any other state, the following initialisations are done.

```
---
end
```

28.7.2.12.6 INITIALIZATION-VALUES on entering MIN_PURGE

This submodule is called at every possible transition from any state to MIN_PURGE.
On entering MIN_PURGE, the initialisations listed below are done.
The start value of FLOW_CTL_CPS for the ramp has to be defined.

```
LV_CP_CLL          = 0
FLOW_CTL_CPS       = min [FLOW_CTL_CPS, FLOW_MAX_CPS]
PQ_CP_SP           = 1                  // In this mode no forced PQ is required
end
```

28.7.2.12.7 INITIALIZATION-VALUES on leaving MIN_PURGE

If the MIN_PURGE operation is left towards any other state, the following initialisations are done.

```
---
end
```

28.7.2.12.8 INITIALIZATION-VALUES on entering WAIT_RAMP_OPEN

This submodule is called at every possible transition from any state to WAIT_RAMP_OPEN.
On entering WAIT_RAMP_OPEN, the initialisations listed below are done.

```
T_DI_CP                  = 0          // reset of time counter for disabled normal purge
STATE_CLL_DEAC_CP        = CP_NO_DEAC
```

```
T_DLY_CP            = C_T_CP_PURGE_TUBE+
                IP_T_DLY_CP(MAF_KGH_FG_PRED_COR_CP) *
                C_FAC_T_DLY_PURGE_TUBE_CP
MAF_INT_CP          = 0
T_MAF_INT_CP        = 0
end
```

28.7.2.12.9 INITIALIZATION-VALUES on leaving WAIT_RAMP_OPEN

If the WAIT_RAMP_OPEN operation is left towards any other state, the following initialisations are done.

```
end
```

28.7.2.12.10 INITIALIZATION-VALUES on entering RAMP_OPEN

This submodule is called at every possible transition from any state to RAMP_OPEN.

If the RAMP_OPEN operation was disabled (Conditions for RAMP_OPEN were not fulfilled) for a time < C_T_DI_RAMP_OPEN_CP_0/_1 (T_DI_CP > 0, STATE_CLL_DEAC_CP = RAMP_OPEN_DEAC), initialisations for disabled RAMP_OPEN are done, otherwise the standard initialisations for RAMP_OPEN are done.

```
if      STATE_CLL_DEAC_CP       = RAMP_OPEN_DEAC
then                            // Initialisations for disabled RAMP_OPEN
        FLOW_CTL_CPS            = FLOW_CTL_CPS_DI
else                            // Standard-initialisations for RAMP_OPEN
        FLOW_CTL_CPS            = C_FLOW_INI_CPS
endif
LV_CP_CLL                       = 1
LV_CP_RAMP_OPEN_ACT             = 1
LV_DLY_GAS_CP                   = 0
LV_CP_AFL_IT                    = 1                     // lean
STATE_CLL_DEAC_CP               = CP_NO_DEAC
T_DI_CP                         = 0
if      STATE_OPM_ENG_CP = ENG_MODE_0
then    T_DLY_CP_OPEN                   =
        max[IP_T_DLY_CP (MAF_KGH_FG_PRED_COR_CP),1hex]
else    T_DLY_CP_OPEN                   =
        max[IP_T_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP),1hex]
endif
FLOW_CPS                        = FLOW_CTL_CPS

MAF_DLY_OLD_1_CP                = MAF_CP
```

```
MAF_DLY_OLD_2_CP              = MAF_CP
MAF_CPS_OLD_1                 = MAF_CPS
MAF_CPS_OLD_2                 = MAF_CPS
MAF_DLY_OLD_1_CPS             = MAF_CPS
MAF_DLY_OLD_2_CPS             = MAF_CPS
end
```

28.7.2.12.11 INITIALIZATION-VALUES on leaving RAMP_OPEN

If the RAMP_OPEN operation is left towards any other state, the following actual values for FLOW_CTL_CPS_DI are stored before the interruption of the operation:

```
LV_CP_RAMP_OPEN_ACT           = 0
LV_STATE_MEM_CP_CLL           = 1
FLOW_CTL_CPS_DI               = FLOW_CTL_CPS
if     (LV_CP_NEW_RAMP_OPEN = 0
       and  LV_CP_NEW_RAMP_OPEN_FAST = 0)
and    STATE_LOCK_CP          = UNLOCKED
then   STATE_CLL_DEAC_CP      = RAMP_OPEN_DEAC
       if    STATE_OPM_ENG_CP = ENG_MODE_0
       then  T_DI_CP          = C_T_DI_RAMP_OPEN_CP_0
       else  T_DI_CP          = C_T_DI_RAMP_OPEN_CP_1
       endif
else   if    STATE_LOCK_CP    ≠ UNLOCKED
       then  T_LOCK_CP_TMP    = C_T_LOCK_CP
       endif
endif
end
```

28.7.2.12.12 INITIALIZATION-VALUES on entering RAMP_OPEN_FAST

This submodule is called at every possible transition from any state to RAMP_OPEN_FAST.

If the RAMP_OPEN_FAST operation was disabled (Conditions for RAMP_OPEN were not fulfilled) for a time < C_T_DI_RAMP_FAST_CP_0/_1 (T_DI_CP > 0, STATE_CLL_DEAC_CP = RAMP_FAST_DEAC), initialisations for disabled RAMP_OPEN_FAST are done, otherwise the standard initialisations for RAMP_OPEN are done.

```
if     STATE_CLL_DEAC_CP      = RAMP_FAST_DEAC
then                          // Initialisations for disabled RAMP_OPEN_FAST
       FLOW_CTL_CPS           = FLOW_CTL_CPS_DI
else                          // Standard-initialisations for RAMP_OPEN_FAST
       FLOW_CTL_CPS           = C_FLOW_INI_CPS
endif
LV_CP_CLL                     = 1
LV_CP_RAMP_OPEN_ACT           = 1
LV_DLY_GAS_CP                 = 0
```

```
LV_CP_AFL_IT                 = 1                    // lean
STATE_CLL_DEAC_CP            = CP_NO_DEAC
T_DI_CP                      = 0
if     STATE_OPM_ENG_CP = ENG_MODE_0
then   T_DLY_CP_OPEN                  =
       max[IP_T_DLY_CP (MAF_KGH_FG_PRED_COR_CP),1hex]
else   T_DLY_CP_OPEN                  =
       max[IP_T_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP),1hex]
endif
FLOW_CPS                     = FLOW_CTL_CPS
FLOW_CPS_OLD_1               = FLOW_CTL_CPS
FLOW_CPS_OLD_2               = FLOW_CTL_CPS
FLOW_DLY_OLD_1_CP            = FLOW_CTL_CPS
FLOW_DLY_OLD_2_CP            = FLOW_CTL_CPS
MAF_CP_OLD_1                 = MAF_CP
MAF_CP_OLD_2                 = MAF_CP
MAF_DLY_OLD_1_CP             = MAF_CP
MAF_DLY_OLD_2_CP             = MAF_CP
MAF_CPS_OLD_1                = MAF_CPS
MAF_CPS_OLD_2                = MAF_CPS
MAF_DLY_OLD_1_CPS            = MAF_CPS
MAF_DLY_OLD_2_CPS            = MAF_CPS
end
```

28.7.2.12.13 INITIALIZATION-VALUES on leaving RAMP_OPEN_FAST

If the RAMP_OPEN_FAST operation is left towards any other state, the following initialisations are done.

```
LV_CP_RAMP_OPEN_ACT          = 0
LV_STATE_MEM_CP_CLL          = 1
FLOW_CTL_CPS_DI              = FLOW_CTL_CPS
if     (LV_CP_NEW_RAMP_OPEN = 0
       and   LV_CP_NEW_RAMP_OPEN_FAST = 0 )
then   STATE_CLL_DEAC_CP      = RAMP_FAST_DEAC
       if     STATE_OPM_ENG_CP = ENG_MODE_0
       then T_DI_CP                   = C_T_DI_RAMP_FAST_CP_0
       else T_DI_CP                   = C_T_DI_RAMP_FAST_CP_1
       endif
endif
end
```

28.7.2.12.14 INITIALIZATION-VALUES on entering MAX_PURGE

This submodule is called at every possible transition from any state to MAX_PURGE.

On entering MAX_PURGE, the initialisations listed below are done.

If the MAX_PURGE operation was disabled (Conditions for MAX_PURGE were not fulfilled) for a time t < C_T_DI_MAX_CP_0/_1 (T_DI_CP > 0, STATE_CLL_DEAC_CP = MAX_PURGE_DEAC), the initialisations for disabled MAX_PURGE are done additionally to the standard initialisations for MAX_PURGE.

```
if      STATE_CLL_DEAC_CP        = MAX_PURGE_DEAC
then    FLOW_CTL_CPS             = MIN (FLOW_CTL_CPS_DI;
                                   FLOW_MAX_CPS * C_FAC_FLOW_MAX_INI_CP;
                                   MFF_SP_MV * C_MFF_RATIO_FLOW_INI_CP
                                   * [N_32 * NC_CYL_NR * 3) / $10^5$ ] / CL_MMV)
                                   // [mg/stk] -> [kg/h]
else    ACTION_EVAM_Purge ()
endif
// standard initialisations
LV_CP_CLL                        = 1
STATE_CLL_DEAC_CP                = CP_NO_DEAC
T_DI_CP                          = 0
if          STATE_CP = RAMP_OPEN
then        T_DLY_REQ_CP_TMP         = C_T_DLY_REQ_CP
elseif          STATE_CP = NO_PURGE
            and LV_CP_CAT_PURGE = 1
            and LV_CL_MDL_ENA = 1
then        LV_CL_MDL_CAT_PURGE_ACT_CP = 1
            FLOW_CTL_CPS         = MIN (FLOW_MAX_CPS * C_FAC_FLOW_MAX_INI_CP;
                                   MFF_SP_MV * C_MFF_RATIO_FLOW_INI_CP
                                   * [N_32 * NC_CYL_NR * 3) / $10^5$ ] / CL_MMV)
                                   * C_FAC_FLOW_CAT_PURGE_INI_CP
                                   // [mg/stk] -> [kg/h]
endif

// Additionnal initialization in case of RAMP_OPEN_FAST to MAX_PURGE transition:
if      STATE_CP = RAMP_OPEN_FAST
then    FLOW_CPS_OLD_1           = FLOW_CPS
        FLOW_CPS_OLD_2           = FLOW_CPS
        FLOW_DLY_OLD_1_CP        = FLOW_CPS
        FLOW_DLY_OLD_2_CP        = FLOW_CPS
endif
end
```

28.7.2.12.15 INITIALIZATION-VALUES on leaving MAX_PURGE

If the MAX_PURGE operation is disabled or ends, the following actual values for FLOW_CTL_CPS_DI are stored before the interruption of the operation:

```
LV_STATE_MEM_CP_CLL              = 1
FLOW_CTL_CPS_DI                  = FLOW_CTL_CPS
T_DLY_REQ_CP_TMP                 = 0
if      (LV_CP_NEW_RAMP_OPEN     = 0
```

```
        and   LV_CP_NEW_RAMP_OPEN_FAST = 0
        and   LV_CL_MDL_CAT_PURGE_ACT_CP = 0)
  then  STATE_CLL_DEAC_CP            = MAX_PURGE_DEAC
        if    STATE_OPM_ENG_CP = MODE_0
        then  T_DI_CP                = C_T_DI_MAX_CP_0
        else  T_DI_CP                = C_T_DI_MAX_CP_1
        endif
  endif
  LV_CL_MDL_CAT_PURGE_ACT_CP         = 0
  end
```

28.7.2.12.16 INITIALIZATION-VALUES on entering RAMP_CLOSE

This submodule is called at every possible transition from any state to RAMP_CLOSE.

On entering RAMP_CLOSE, the initialisations listed below are done.

The Initialization value of FLOW_CTL_CPS for RAMP_CLOSE is the last calculated value of min (FLOW_CTL_CPS, FLOW_MAX_CPS) if the preceding operation was MAX_PURGE. If the RAMP_OPEN operation was preceding the Initialization value is the last calculated value of FLOW_CTL_CPS of the RAMP_OPEN operation.

```
STATE_CLL_DEAC_CP       = CP_NO_DEAC
T_DI_CP                 = 0
PQ_CP_SP                = 1              // In this mode no forced PQ is required
FLOW_TAR_CPS            = 0
if    STATE_CP          = MAX_PURGE
then  FLOW_CTL_CPS      = min [FLOW_CTL_CPS, FLOW_MAX_CPS]
endif
end
```

28.7.2.12.17 INITIALIZATION-VALUES on leaving RAMP_CLOSE

If the RAMP_CLOSE operation is left towards any other state, the following initialisations are done.

```
LV_STATE_MEM_CP_CLL = 1
end
```

28.7.3 Canister purge management states

28.7.3.1 NO_PURGE

General information:

In the NO_PURGE state of the Evaporative Emission Control no calculation of the CPS flow set point flow_ctl_cps, the fuel flow from the activated charcoal filter (ACF) MFF_CP, the Canister Load cl and the additive fuel flow for injection correction will be done.

Formula section:

```
call  "Time counter for disabled RAMP_OPEN or MAX_PURGE"
end
```

28.7.3.2 RAMP_TO_NO_PURGE

Formula section:

```
FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV) * FLOW_FAC_CP
if          LV_CP_CMU_CMB
then        FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_CMU_CP
elseif          LV_CP_CLOSE_1
then        FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_1_CP
elseif          LV_CP_CLOSE_2
then        FLOW_GRD_CPS = FLOW_GRD_CPS * C_FAC_DEC_COR_2_CP
endif
call  "FLOW_CTL_CPS ramping"
call  "Time counter for disabled RAMP_OPEN or MAX_PURGE"
end
```

28.7.3.3 MIN_PURGE

General information:

In the MIN_PURGE state, the CPS flow is calculated from calibration datas depending on combustion mode.

```
FLOW_TAR_CPS = FLOW_CPS_SP_MIN_PURGE * FAC_FLOW_TAR_COR_CP
if    FLOW_CTL_CPS$_{n-1}$ > FLOW_TAR_CPS                // actual value higher than SP
then  FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV)// decreasing flow
else  if LV_HOM_ACT = 1
      then FLOW_GRD_CPS = IP_FLOW_INC_CP (MFF_SP_MV)
                       * IP_FLOW_INC_COR_HOM_CP (MAF_CYL) // increasing flow
      else FLOW_GRD_CPS = IP_FLOW_INC_CP (MFF_SP_MV)   // increasing flow
      endif
      LV_STATE_MEM_CP_CLL = 0               // transition from normal purge finished
endif
call  "FLOW_CTL_CPS ramping"
call  "Time counter for disabled RAMP_OPEN or MAX_PURGE"
end
```

28.7.3.4 WAIT_RAMP_OPEN

General information:

The WAIT_RAMP_OPEN state is reached if the conditions for normal entry in RAMP_OPEN or RAMP_OPEN_FAST are given but the time counter for lambda controller stabilisation is not yet elapsed or CPS adaptation is active. It can only be reached by NO_PURGE.

To speed up the reaction of the lambda sensor in RAMP_OPEN or RAMP_OPEN_FAST, the purge tube may be purged itself for a short instance in WAIT_RAMP_OPEN. Using this functionality, the purge valve is opened rapidly and wide for a very short time to purge the diluted gas in the tubes and fill the purge tubes with "fresh" gas from the ACF.

For the calcuation of the air mass flow integral the unit conversion:
[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600
has to be considered.

Formula section:

```
if      LV_CPS_AD_ACT = 0
then
MAF_INT_CP = MAF_INT_CP + (MAF_CYL * TA / 3600)  // MAF Integral for Lambda
                                                       controller stabilisation
T_MAF_INT_CP = T_MAF_INT_CP + TA  // Total time of the MAF integration
                                              for min/max limitation
T_DLY_CP = max [$T\_DLY\_CP_{n-1}$ – TA, 0]         // Purge tube  time counter
// "purging the purge tube"
endif
 if     T_MAF_INT_CP          < C_T_CP_PURGE_TUBE
then
        FLOW_TAR_CPS        = C_FLOW_CPS_SP_PURGE_TUBE
        FLOW_GRD_CPS        = C_FLOW_CPS_GRD_PURGE_TUBE
else
        FLOW_TAR_CPS        = 0
        FLOW_GRD_CPS        = C_FLOW_CPS_GRD_PURGE_TUBE_CLOSE
endif
call   “FLOW_CTL_CPS ramping”
end
```

28.7.3.5 RAMP_OPEN

General information:

After a reset, an engine stall or if a certain time since the last MAX_PURGE operation has passed, the load cl of the canister is considered as not known. In this case the canister load value cl is initialized to a constant value c_cl_st_cp and the CPS is opened slowly, using a ramp function. So a high deviation of the lambda control shall be prevented.

The RAMP_OPEN operation is finished when the fuel flow MFF_CP is greater than a maximum value MFF_MAX_CP or when the CL_MMV value stay in a dynamic window. Then the MAX_PURGE operation starts, if the cl is above a threshold, otherwise the reaction of the system is configurable.

At the end of the RAMP_OPEN operation the remaining time of purge is reevaluated versus Canister Load cl is reevaluated.

Formula section:

```
call “calculation of PQ_CP_SP”                        (common)
call “calculation of the flow setpoint”               (common)
end
```

28.7.3.6 RAMP_OPEN_FAST Operation

General information:

After a short interruption of the MAX_PURGE operation the load cl of the ACF stay around the last value calculated. In this case the flow_ctl_cps is calculated as a function of the actual FLOW_CTL_CPS value and the objective value.

The RAMP_OPEN_FAST operation is finished. when one of the following conditions is set:

- FLOW_CTL_CPS is greater or equal to the value FLOW_TAR_CPS
- The fuel flow MFF_CP is greater than a maximum value MFF_MAX_CP

Then the MAX_PURGE operation starts. If the purge time is elapsed (LV_CP_ENA=0), the RAMP_OPEN_FAST operation ends. the RAMP_CLOSE operation starts immediately.

At the end of the RAMP_OPEN_FAST operation the purge time is reevaluated (see chapter “time scheduler”).

Formula section:

```
PQ_CP_SP =1            //  In this mode no forced PQ is required by canister purge
call “calculation of the flow setpoint”                     (common)
end
```

28.7.3.7 MAX_PURGE Operation

General information:

The MAX_PURGE operation is started when the RAMP_OPEN operation or the RAMP_OPEN_FAST operation is finished.

The MAX_PURGE operation ends when the purge time is elapsed. Then the RAMP_CLOSE operation starts.

During MAX_PURGE, the time counter T_DLY_MAX_CP is initialised to C_T_DLY_MAX_CP_0/_1. When the MAX_PURGE operation ends or when the MAX_PURGE is disabled, the time T_DLY_MAX_CP starts to count backwards down to 0.

Calculation of FLOW_CTL_CPS for MAX_PURGE

The value of FLOW_CTL_CPS during MAX_PURGE operation is calculated as a function of the filtered canister load CL_MMV and the maximum allowable fuel flow from the CPS MFF_MAX_CP (see flow setpoints module).

Formula section:

```
call “calculation of PQ_CP_SP”                               (common)
call “Calculation of LV_T_DLY_REQ_CP”
FLOW_TAR_CPS = min [MFF_MAX_CP / CL_MMV, FLOW_MAX_CPS] *
                                                  FAC_FLOW_TAR_COR_CP
if    $FLOW\_CTL\_CPS_{n-1}$ > FLOW_TAR_CPS                  // actual value higher than SP
then  FLOW_GRD_CPS = IP_FLOW_CPS_DEC (MFF_SP_MV)      // decreasing flow
else  if LV_HOM_ACT = 1
```

```
        then FLOW_GRD_CPS = IP_FLOW_CPS_INC (MFF_SP_MV)
                                * IP_FLOW_INC_COR_HOM_CP (MAF_CYL)// increasing flow
        else FLOW_GRD_CPS = IP_FLOW_CPS_INC (MFF_SP_MV)  // increasing flow
        endif
    endif
    (gradient limitation moved here from flow calculation chain)
    call   "FLOW_CTL_CPS ramping"
    end
```

28.7.3.7.1 Calculation of LV_T_DLY_REQ_CP

This management is usefull esssentially during an emision cycle. The aim is to stop the purge in case of request from the catalyst diagnosis (or an other OBD2 diagnosis), one time during the cycle.

LV_T_DLY_REQ_CP is set C_T_DLY_REQ_CP seconds after a Ramp_Open and stay to 1 until next trip or engine stalling.

The flag is set after having been for a time C_T_DLY_REQ_CP in an un-interrupted MAX_PURGE coming from RAMP_OPEN and stay to 1 until next trip or engine stalling .

When coming from any other state than RAMP_OPEN, the flag is not calculated.

Signal flow diagram:

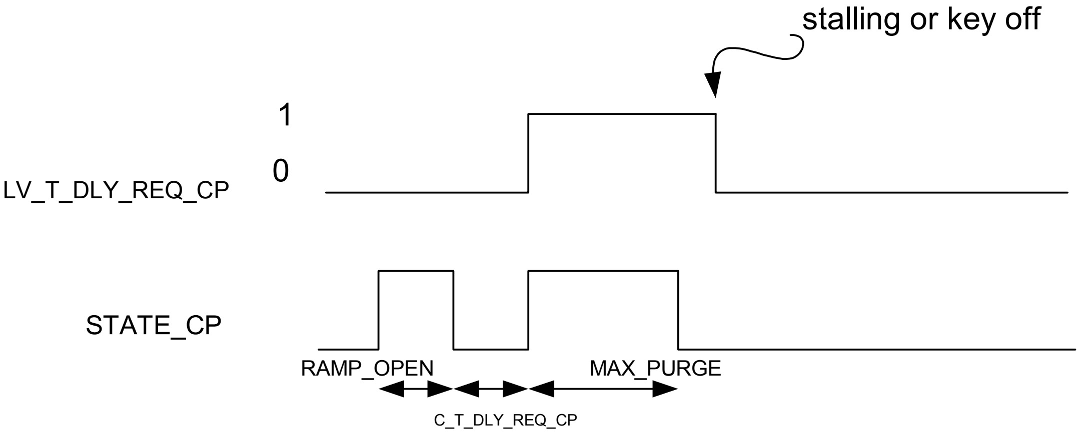

figure 4: LV_T_DLY_REQ_CP

Formula section:

```
if      T_DLY_REQ_CP_TMP > 1h
then    T_DLY_REQ_CP_TMP = max (1h, T_DLY_REQ_CP_TMP – TA)
endif
if      T_DLY_REQ_CP_TMP = 1h
then    LV_T_DLY_REQ_CP    = 1
endif
end
```

28.7.3.8 RAMP_CLOSE Operation

General information:

The RAMP_CLOSE operation starts if the purge time is elapsed.

The RAMP_CLOSE operation ends when the value of FLOW_CTL_CPS is equal to 0.

Calculation of FLOW_CTL_CPS for RAMP_CLOSE

When the RAMP_CLOSE operation is activated FLOW_CTL_CPS is decremented. The decrement value depends on the map values of IP_FLOW_DEC_CP. The closing speed of the CPS is so controlled by the mass fuel flow setpoint MFF_SP_MV.

Formula section:

```
FLOW_GRD_CPS = IP_FLOW_DEC_CP (MFF_SP_MV) * IP_FLOW_FAC_CP (CL)
call   “FLOW_CTL_CPS ramping”
end
```

28.7.4 Common submodules

The keywords in brackets at the end of the headline of each following submodule indicates, by which STATE_CP the corresponding submodule is called. If STATE_CP = CP_NOT_ACT, none of the following submodules is called. The following abbreviations are used:

NP	NO_PURGE
RTNP	RAMP_TO_NO_PURGE
MinP	MIN_PURGE
WRO	WAIT_RAMP_OPEN
RO	RAMP_OPEN
ROF	RAMP_OPEN_FAST
MaxP	MAX_PURGE
RC	RAMP_CLOSE

28.7.4.1 Time counter for disabled RAMP_OPEN or MAX_PURGE (NP, RTNP, MinP)

General information:

This calculation is called in NO_PURGE, RAMP_TO_NO_PURGE and MIN_PURGE.

If the RAMP_OPEN or the MAX_PURGE operation was interrupted (NO_PURGE, RAMP_TO_NO_PURGE or MIN_PURGE active) and the time counter T_DI_CP is greater than zeor which means that the interrupt-time is lower than the adjustable times C_T_DI_RAMP_OPEN_CP_0/_1 (RAMP_OPEN) or C_T_DI_MAX_CP_0/_1 (MAX_PURGE), a direct switch back to the previous state RAMP_OPEN or MAX_PURGE is possible, if the conditions for this previous state are once again given.

Otherwise (time counter T_DI_CP reached zero), NORMAL_PURGE has to restart with RAMP_OPEN.

TA = recurrence

Formula section:

```
If      (LV_CP_NEW_RAMP_OPEN = 0
        and LV_CP_NEW_RAMP_OPEN_FAST = 0
then    $T\_DI\_CP_n$                  = max [0, $T\_DI\_CP_{n-1}$ – TA]
else    T_DI_CP = 0
endif
$T\_LOCK\_CP_n$                  = max [0, $T\_LOCK\_CP_{n-1}$ – TA]
if      T_DI_CP                = 0
then    STATE_CLL_DEAC_CP = CP_NO_DEAC
endif
if      T_LOCK_CP = 0
then    STATE_LOCK_CP          = UNLOCKED
endif
end
```

28.7.4.2 Calculation of PQ_CP_SP (RO, MaxP)

General information:

This calculation is called only in Ramp_Open and MAX_PURGE, and available only in stratified and homogeneous lean burn modes.

In this mode a forced PQ is required by canister purge in order to increase PRS_CPS and to purge with more efficiency. IP_PQ_CP_SP is depending on engine speed and torque setpoint.

Formula section:

```

endif
```

28.7.4.3 Calculation of the flow setpoint (RO, ROF)

General information:

This calculation is called in RAMP_OPEN and RAMP_OPEN_FAST.

The opening of the CPS is controlled by the value of FLOW_CTL_CPS. This value describes the flow requested through the CPS. So a too high deviation of the lambda control at transient engine operation should be avoided. The opening sequence is as follows:

- When entering RAMP_OPEN or RAMP_OPEN_FAST, FLOW_CTL_CPS is initialised

- After start or re-start of RAMP_OPEN or RAMP_OPEN_FAST, the system waits for the gas transfer time between CPS valve and upstream lambda sensor (IP_T_DLY_CP).
- When this delay is elapsed or when using a binary lambda control and a transition rich to lean occurs, the next period of increment steps starts. The number of increment steps for this phase is defined from ID_FLOW_INC_NR_CP. This number is defined once at the beginning of the phase. For each increment the FLOW_CTL_CPS increase is fixed by IP_FLOW_INC_CP corrected by IP_FLOW_FAC_CP. The opening speed of the CPS is so controlled by the mass air flow MAF_CYL and the load CL of the activated charcoal canister ACF to avoid lambda regulation deviation.
- After the increment steps are carried out, the function waits again for gas transfer time or binary lambda sensor rich-lean transition.
- FLOW_CTL_CPS is limited to FLOW_TAR_CPS, the target flow setpoint.

The Pjump used depends of the bank selected (see canister load and lambda deviation module). The Pjump is related to gas enrichment.

The aim is to increase the FLOW_CTL_CPS with incremented values to prevent unexpected lambda deviation due to the lambda controller.

The increment number ID_FLOW_INC_NR_CP carried out is tuneable and depending on engine speed.

The time delay will allow to synchronize the flow variation, the gas transfer and the lambda control. As long as the maximum flow FLOW_TAR_CPS is not reached the sequence will start over.

Signal flow diagram:

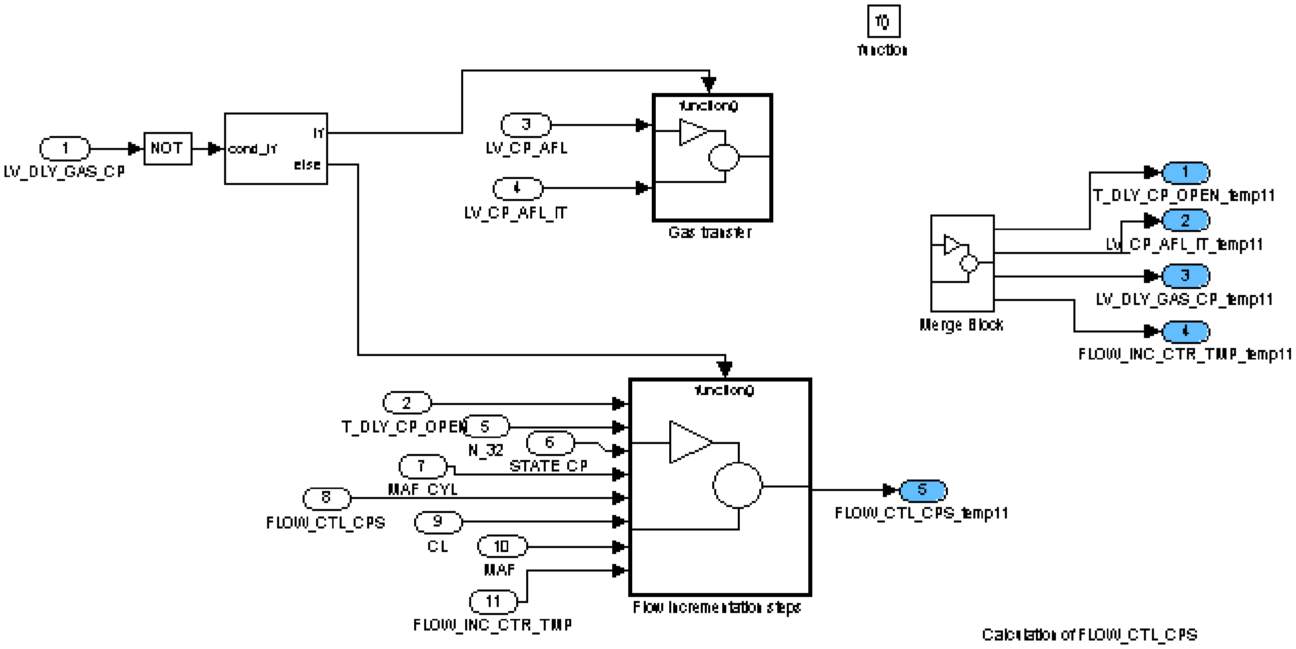

figure 6: calculation of FLOW_CTL_CPS for RAMP_OPEN_FAST

Formula section:

```
if      LV_DLY_GAS_CP = 0
then call   "Gas transfer"                    // waiting for gas transfer timer
```

```

if    STATE_CP = RAMP_OPEN_FAST
and   LC_CP_FLOW_LIM_OPEN_FAST = 0
then  FLOW_TAR_CPS       = min [MFF_MAX_CP / CL_MMV, FLOW_MAX_CPS]
else  [If STATE_OPM_ENG_CP = ENG_MODE_0
         then  FLOW_TAR_CPS       = IP_FLOW_MAX_OPEN_CPS (N_32, MAF)
                                           * FAC_FLOW_COR_CLL_CP
         else  FLOW_TAR_CPS       = IP_FLOW_MAX_OPEN_CPS_2 (N_32,
                                     MFF_SP_MV) * FAC_FLOW_COR_CLL_CP
      endif]
```

```
endif
FLOW_TAR_CPS = FLOW_TAR_CPS * FAC_FLOW_TAR_COR_CP
call   "FLOW_CTL_CPS ramping"
FLOW_INC_CTR_TMP              = max [ 0, FLOW_INC_CTR_TMP – 1]

if     FLOW_INC_CTR_TMP        = 0
then   // gas delay timer init
       LV_DLY_GAS_CP           = 0
       If STATE_OPM_ENG_CP = ENG_MODE_0
       then T_DLY_CP_OPEN            =
              max[IP_T_DLY_CP (MAF_KGH_FG_PRED_COR_CP),1hex]
       else T_DLY_CP_OPEN            =
              max[IP_T_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP),1hex]
       endif
       // T_DLY_CP_OPEN will be set to IP_T_DLY_CP / 10
       LV_CP_AFL_IT            = 1                          // lean
       FLOW_GRD_CPS       = 0
endif
end
```

28.7.4.4 FLOW_CTL_CPS ramping

The ramping up and down of the internal flow setpoint FLOW_CTL_CPS is defined by the target (final setpoint to be reached) FLOW_TAR_CPS and the flow gradient (increment rsp. decrement) FLOW_GRD_CPS.

This calculation is applied in all states with any flow ramps.

```
if     FLOW_CTL_CPS$_{n-1}$ > FLOW_TAR_CPS          // actual value higher than target
then   FLOW_CTL_CPS$_n$ =                           // decreasing flow
              max [FLOW_TAR_CPS, FLOW_CTL_CPS$_{n-1}$ - FLOW_GRD_CPS]
else   FLOW_CTL_CPS$_n$ =                           // increasing flow
              min [FLOW_TAR_CPS, FLOW_CTL_CPS$_{n-1}$ + FLOW_GRD_CPS]
endif
```

28.7.5 General calculations

General information:

This submodule is calculated in every state_cp except CP_NOT_ACT

When the maximum engine speed limitation is reached (LV_N_MAX_CP) some of the calculations for the injection correction must be stopped to decrease the CPU load. If LV_N_MAX_CP is active then the normal calculations of the following variables are not done and the values of these variables are set to 0.

Application conditions:

Initialisation: at RST or IGKON. values are set to zero.
Recurrence: called by superior block
Activation: --
Deactivation: --

Formula section:

```
call       "Time counter for time after MAX_PURGE operation"
if         LV_N_MAX_CP = 1
then  call "Default values for disabled calculations"
else  call "Commutation on diagnosis detection"
      call "OBD2 diagnosis activation"
      call "Calculation of FLOW_CPS and FLOW_COR_CPS"
endif
if         LC_CP_CLL_INH_MAN = 0
then  call "Padé-filter and PT1-Filter calculations"
endif
end
```

28.7.5.1 Time counter for time after MAX_PURGE operation

Depending on this time counter, RAMP_OPEN (counter=0) or RAMP_OPEN_FAST (>0) are activated for CL learning. As long as the counter has not reached zero, the CL used in the previous MAX_PURGE phase is considered as usable.

Formula section:

```
if         STATE_CP = MAX_PURGE
then       if    STATE_OPM_ENG_CP = ENG_MOD_0
           then  T_DLY_MAX_CP = C_T_DLY_MAX_CP_0           // counter init
           else  T_DLY_MAX_CP = C_T_DLY_MAX_CP_1
           T_DLY_CL_MDL = max [0, T_DLY_CL_MDL - TA]
elseif           LV_CP_CLL = 0
then       T_DLY_MAX_CP = max [0, T_DLY_MAX_CP - TA]
           T_DLY_CL_MDL = C_T_DLY_CL_MDL
else       $T\_DLY\_MAX\_CP_n = T\_DLY\_MAX\_CP_{n-1}$
           $T\_DLY\_CL\_MDL_n = T\_DLY\_CL\_MDL_{n-1}$
```

```
Endif

if      LV_CP_NEW_RAMP_OPEN = 1
then T_DLY_MAX_CP = 0
endif

if      T_DLY_MAX_CP        = 0
then LV_CL_CLC_VLD       = 0                    // switch off int. MIN_PURGE
endif
end
```

28.7.5.2 Default values for disabled calculations

When the maximum engine speed limitation is reached (LV_N_MAX_CP) some of the calculations for the injection correction must be stopped to decrease the CPU load. If LV_N_MAX_CP is active then the normal calculations of the following variables are not done and the values of these variables are set to 0.

Formula section:

```
FLOW_SP_CPS                   = 0
FLOW_COR_CPS             = 0
FLOW_CPS                 = 0
FLOW_TOT_CPS             = 0
MAF_CPS                  = 0
end
```

28.7.5.3 OBD2 diagnosis activation

General information:

In order to manage the priority between canister purge and catalyst diagnosis or between canister purge and O2 sensor diagnosis, the bit information LV_CP_ACT_REQ will be sent to the diagnosis OBD2 manager. Two cases are possible :

- first of all, when the conditions to purge are set in order to learn the canister load (RAMP_OPEN phase).
- when LV_T_DLY_REQ_CP=1 if the canister load (CL_MMV) is greater than a calibrated value C_CL_MMV_REQ.

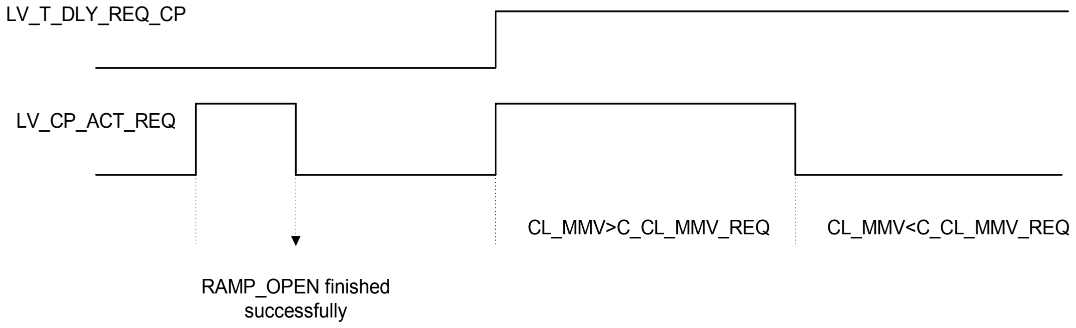

figure 7: LV_CP_ACT_REQ

Formula section:

```
LV_CP_ACT_REQ =
    [ LV_T_DLY_REQ_CP and (CL_MMV > C_CL_MMV_REQ) ]
or  STATE_CP = RAMP_OPEN
end
```

28.7.5.4 Calculation of FLOW_CPS and FLOW_COR_CPS

The setpoint of the mass flow through the CPS (FLOW_COR_CPS) is calculated using the actual calculated values of FLOW_CTL_CPS, a ramp gradient depending on MAF_CYL and the correction factors on ambient pressure and ambient temperature.

If the OBD II evaporative system monitoring (vaccum method) function is active (LV_DIAGCP_CPS_ACT=1), the opening of the CPS is controlled by the value of FLOW_SP_CPS_EVAP (see chapter OBDII functions).

The opening of the CPS can also be controlled by the application system using the switch LC_FLOW_CPS_AS and C_FLOW_CPS_AS.

The calculation of FLOW_SP_CPS is limited using a gradient value.

In RAMP_OPEN, RAMP_OPEN_FAST, NO_PURGE and RAMP_TOP_NO_PURGE, the gradient limitation is no more applied.

The flow request through the CPS is limited by the physical maximum flow at fully openend valve defined in FLOW_MAX_PHY_CPS (depending on pressure difference ambient air – intake manifold)

The value FLOW_TOT_CPS permits to measure the quantity of flow during an emission cycle.

Signal flow diagrams:

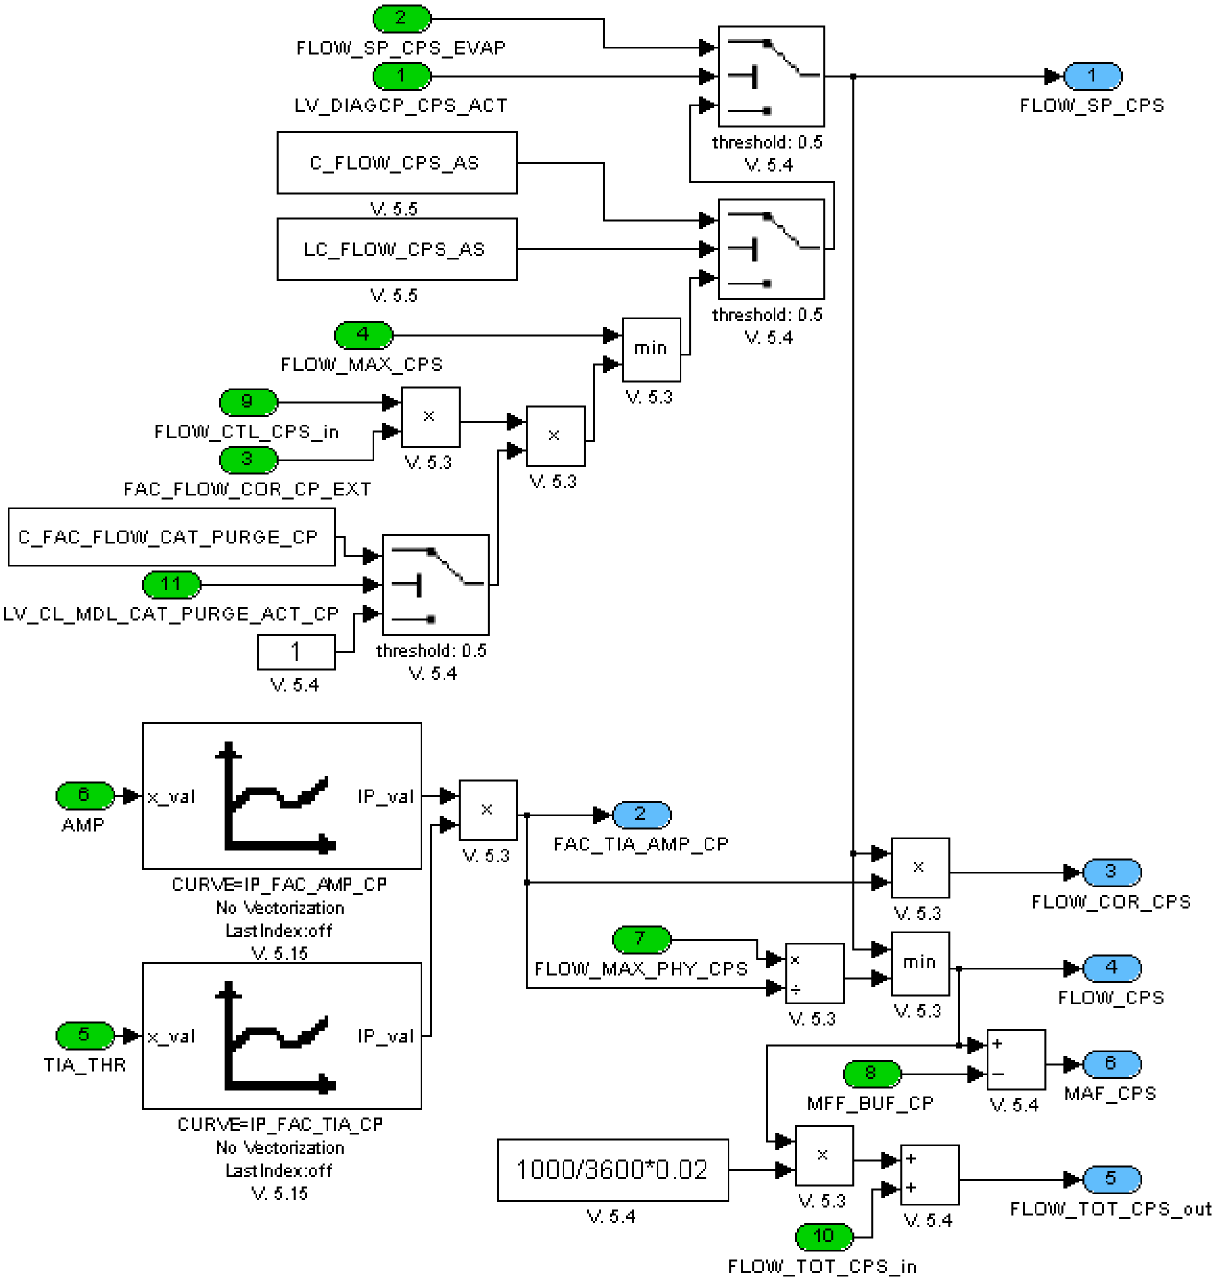

figure 8: Calculation of FLOW_CPS, FLOW_COR_CPS

Formula section:

```
if        LV_DIAGCP_CPS_ACT              // Interface with leak detection by vaccum
method
then      FLOW_SP_CPS        = FLOW_SP_CPS_EVAP
elseif         LC_FLOW_CPS_AS            // manual setting of flow_sp_cps
then      FLOW_SP_CPS = C_FLOW_CPS_AS
else      if LV_CL_MDL_CAT_PURGE_ACT_CP = 0
          then FLOW_SP_CPS = min
```

```
                    [FLOW_CTL_CPS * FAC_FLOW_COR_CP_EXT, FLOW_MAX_CPS]
          else FLOW_SP_CPS = min
                    [FLOW_CTL_CPS * FAC_FLOW_COR_CP_EXT *
                         C_FAC_FLOW_CAT_PURGE_CP, FLOW_MAX_CPS]
endif

// correction factor for ambient air temperature and ambient air pressure
FAC_TIA_AMP_CP =
          IP_FAC_AMP_CP     (AMP)
        * IP_FAC_TIA_CP     (TIA_THR)

FLOW_COR_CPS = FLOW_SP_CPS * FAC_TIA_AMP_CP
FLOW_CPS = min [
        FLOW_SP_CPS,
        FLOW_MAX_PHY_CPS / FAC_TIA_AMP_CP]

FLOW_TOT_CPS        = FLOW_TOT_CPS + FLOW_CPS / 360
MAF_CPS             = FLOW_CPS - MFF_BUF_CP
end
```

28.7.5.5 Padé- and Low pass filter calculations

(Calculation of FLOW_DLY_CP, FLOW_DLY_MMV_CP, MAF_CP, MAF_DLY_CP and MAF_DLY_MMV_CP)

Application conditions:

Initialisation: --
Recurrence: **100** ms
Activation: --
Deactivation: --

Signal flow diagram:

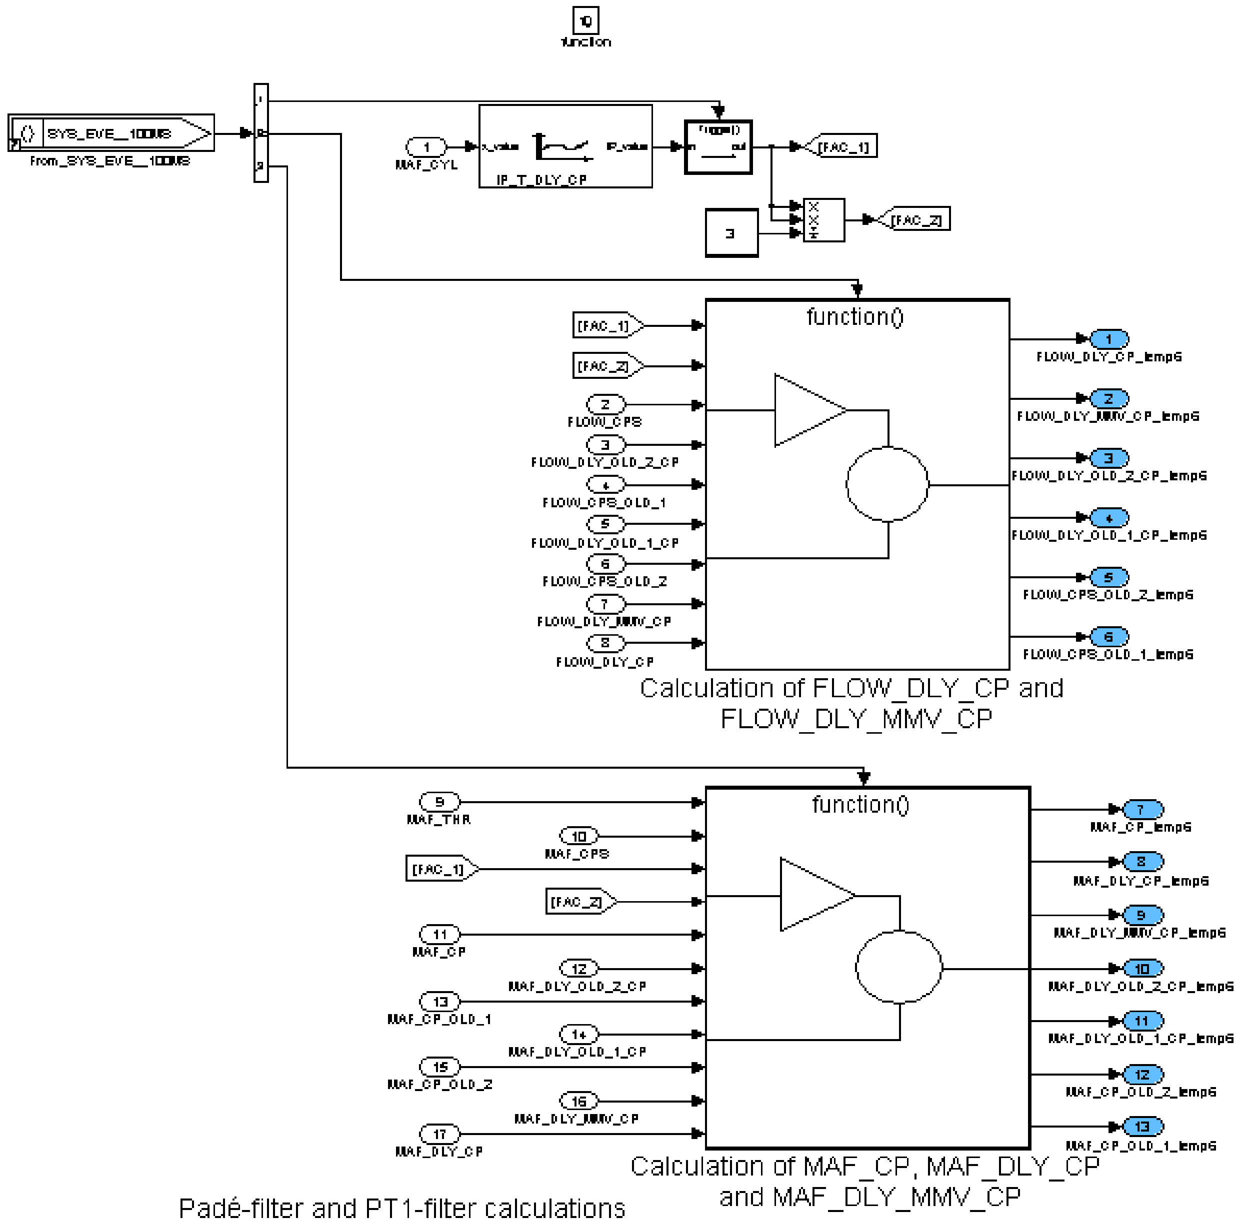

figure 9: Padé- and low pass filters

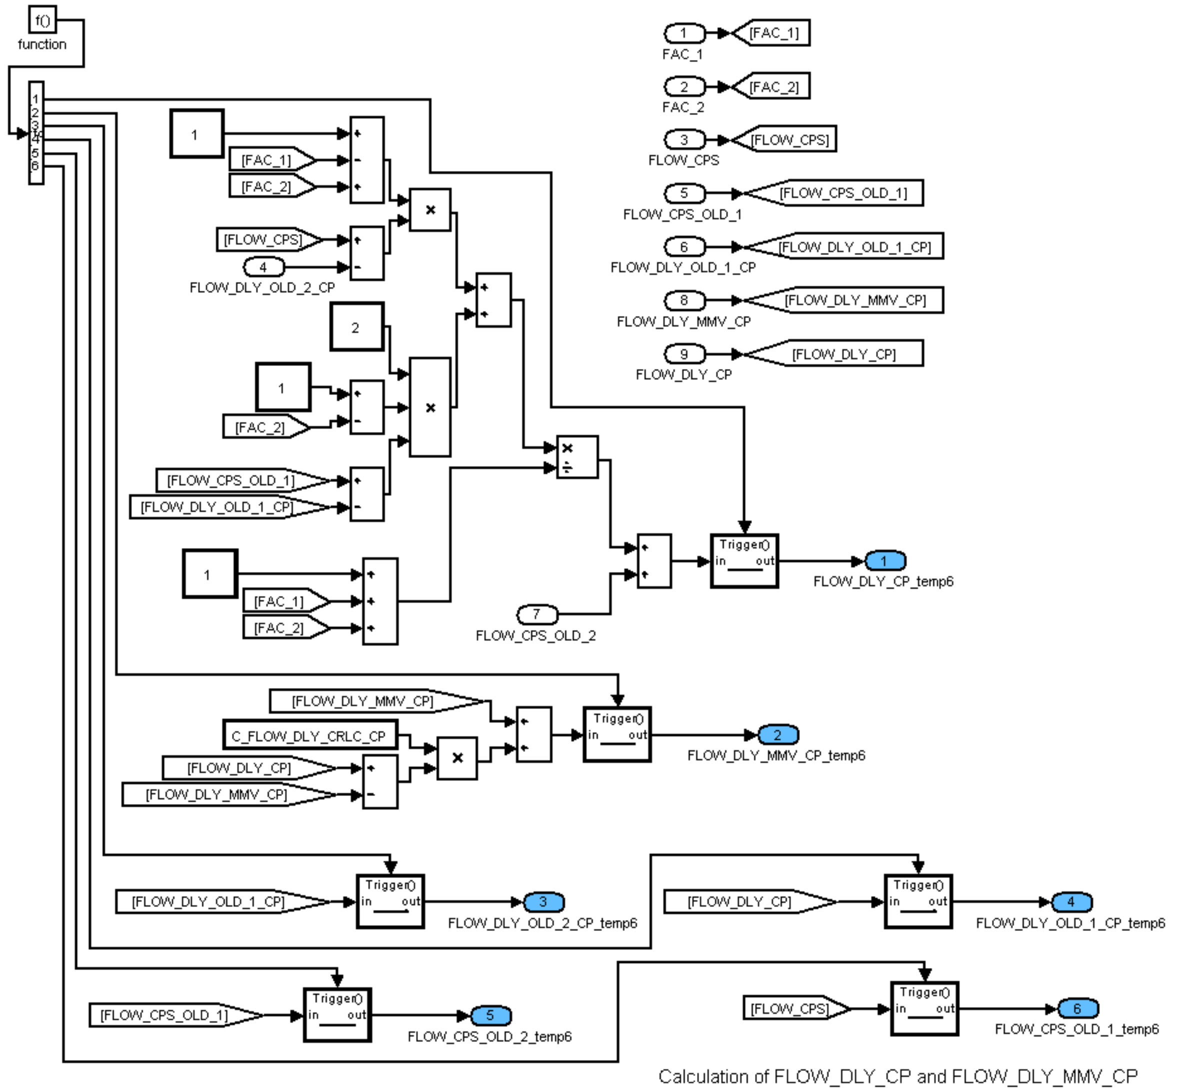

figure 10: calculation of FLOW_DLY_CP and FLOW_DLY_MMV_CP
the calc. of MAF_DLY_CP and MAF_DLY_MMV_CP is done following the same scheme

Formula section:

Padéfilter-parameters

if STATE_OPM_ENG_CP = ENG_MODE_0
then FAC_1 = IP_T_DLY_CP (MAF_KGH_FG_PRED_COR_CP)
else FAC_1 = IP_T_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP)
FAC_2 = FAC_1 * FAC_1 / 3

Calculation of FLOW_DLY_CP and FLOW_DLY_MMV_CP:

// Padé-filter
FLOW_DLY_CP=
1 / (1 + FAC_1 + FAC_2)
* [(1 - FAC_1 + FAC_2)
* (FLOW_CPS - FLOW_DLY_OLD_2_CP)
+ 2 * (1 - FAC_2) * (FLOW_CPS_OLD_1 - FLOW_DLY_OLD_1_CP)]
+ FLOW_CPS_OLD_2

```
// Low pass-filter
FLOW_DLY_MMV_CP$_n$= FLOW_DLY_MMV_CP$_{n-1}$ +
        (FLOW_DLY_CP$_n$ - FLOW_DLY_MMV_CP$_{n-1}$) * C_FLOW_DLY_CRLC_CP

// memorization for next recurrence
FLOW_DLY_OLD_2_CP      = FLOW_DLY_OLD_1_CP
FLOW_DLY_OLD_1_CP      = FLOW_DLY_CP
FLOW_CPS_OLD_2         = FLOW_CPS_OLD_1
FLOW_CPS_OLD_1         = FLOW_CPS
```

Calculation of MAF_CP, MAF_DLY_CP and MAF_DLY_MMV_CP:

```
MAF_CP = MAF_THR + MAF_CPS

// Padé-filter
MAF_DLY_CP(n)=
        1 / (1 + FAC_1 + FAC_2)
        * [ (1 - FAC_1 + FAC_2)
        * (MAF_CP$_n$ - MAF_DLY_OLD_2_CP)
        + 2 * (1 - FAC_2) * (MAF_CP_OLD_1 - MAF_DLY_OLD_1_CP) ]
        + MAF_CP_OLD_2

// Lowpass-filter
MAF_DLY_MMV_CP$_n$ = MAF_DLY_MMV_CP$_{n-1}$ +
        (MAF_DLY_CP$_n$ - MAF_DLY_MMV_CP$_{n-1}$) * C_MAF_DLY_CRLC_CP

// memorization for next recurrence
MAF_DLY_OLD_2_CP       = MAF_DLY_OLD_1_CP
MAF_DLY_OLD_1_CP       = MAF_DLY_CP
MAF_CP_OLD_2           = MAF_CP_OLD_1
MAF_CP_OLD_1           = MAF_CP
```

Calculation of MAF_DLY_CPS and MAF_DLY_MMV_CPS:

```
// Padé-filter
MAF_DLY_CPS(n)=
        1 / (1 + FAC_1 + FAC_2)
        * [ (1 - FAC_1 + FAC_2)
        * (MAF_CPS$_n$ - MAF_DLY_OLD_2_CPS)
        + 2 * (1 - FAC_2) * (MAF_CPS_OLD_1 - MAF_DLY_OLD_1_CPS) ]
        + MAF_CPS_OLD_2

// Lowpass-filter
MAF_DLY_MMV_CPS$_n$ = MAF_DLY_MMV_CPS$_{n-1}$ +
        (MAF_DLY_CPS$_n$ - MAF_DLY_MMV_CPS$_{n-1}$) * C_MAF_DLY_CRLC_CPS

// memorization for next recurrence
MAF_DLY_OLD_2_CPS      = MAF_DLY_OLD_1_CPS
MAF_DLY_OLD_1_CPS      = MAF_DLY_CPS
```

```
MAF_CPS_OLD_2          = MAF_CPS_OLD_1
MAF_CPS_OLD_1          = MAF_CPS
end
```

28.8.1 Project specific definition for "Time after start"

General information:

T_AST_CP has to be written in general with T_AST. Only special configurations, e.g. for stop-start functionality, T_AST_CP has to be written with other values (e.g. T_AST_DC).

Application conditions:

Initialisation: *T_AST_CP = 0 after reset*

Recurrence: 100ms

Activation: all engine states

Deactivation: --

Formula section:

T_AST_CP = T_AST

28.8.2 Activation of the Evaporative Emission Control Function

General information:

The Evaporative Emission Control function is activated (LV_CP_ACT=1), if the time after start exceeds IP_T_ST_AST_TCO_ST_CPS_MIN, which depends on coolant temperature after start. The function is active during all engine operating states except the following states:

- engine stopped (LV_ES=1)
- engine start (LV_ST=1)

For the MSA stop/start functionality it is necessary to calculate a seperat T_AST_CP, which represents the time after first start in an driving cycle.

Application conditions:

Initialisation: LV_CP_ACT = 0 after reset or stalling

Recurrence: 20ms
Activation:
Deactivation: --

Formula section:

LV_CP_ACT =
[T_AST_CP > IP_T_ST_AST_TCO_ST_CPS_MIN(TCO_ST)
and LV_ES = 0
and LV_ST = 0
and [LV_AST = 0 **or** LC_CP_AST_ACT = 0]
and LC_CP_ACT = 1]

28.8.3 Cross-locking table

General information:

This chapter describes the evaporative emission control inhibition.

Application conditions:

Initialisation: at reset:

Else    LV_INH_CP_CLL = 0
Endif
```

28.8.4 Project specific factor for MIN purge flow

General information:

With this function, the MIN_PURGE flow can be varied by a factor from 0 to 4 for vehicles without catalyst and lambda sensors or in case of using different engine operation modes (STATE_OPM_ENG_CP).

Application conditions:

Initialisation: FAC_FLOW_COR_CP_EXT = 1 *at reset*
FAC_FLOW_COR_CP_MIN_PURGE = 1 *at reset*

Recurrence: 100ms

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

```
If (1)  LV_VAR_LSH_UP = 1
```

```
Then (1)
        If (2) STATE_OPM_ENG_CP = 0
        Then (2) FAC_FLOW_COR_CP_MIN_PURGE = 1
        Else (2) FAC_FLOW_COR_CP_MIN_PURGE =
                    IP_FAC_REL_FLOW_CPS_WOUT_CAT
        Endif (2)
        FAC_FLOW_COR_CP_EXT  = 1
Else (1) FAC_FLOW_COR_CP_EXT  = IP_FAC_REL_FLOW_CPS_WOUT_CAT
        FAC_FLOW_COR_CP_MIN_PURGE = 1
Endif (1)
```

28.8.5 External calculations

General information:

With this function, it is possible to supply the “Evaporative emission control variables” function with a measured canister purge differential preasure. For further information on the use of this “external” differential preasure please refer to chapter “Evaporative emission control variables”.

Application conditions:

Initialisation: PRS_CPS_EXT = 0 at reset

Recurrence: 20ms

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

PRS_CPS_EXT = MAP_DIP_MES_BAS_2SEG

28.8.6 Management of LV_CP_CLOSE_CP_x with no OBD sequencer

General information:

This chapter describes the recommendations for evaporative emission control inhibition when no OBD sequencer is used. In this case the flags LV_CP_CLOSE_1, LV_CP_CLOSE_2, and LV_CP_CLOSE_3 must be managed within this module.

Examples that need to close purge are OBD diagnostics for leak detection and catalyst monitor.

Normally the flags LV_CP_CLOSE_CP_x are managed and defined by the OBD sequencer, if there is no sequencer it is recommended to set LC_TLDV_NOT_SEQ =1 and define and calculate these flags in the application inc. spec.

C_STATE_CONF_TLDV_CP and C_STATE_CONF_CAT_CP are used to configure the closing ramp of the CPS valve to inhibit purge during an OBD test.

Values of C_STATE_CONF_TLDV_CP and C_STATE_CONF_CAT_CP:

0: Canister purge remains active, no request to close the valve

1: Canister purge closed with highest speed closing ramp

2: Canister purge closed with medium speed closing ramp

3: Canister purge closed with normal speed closing ramp

Application conditions:

Initialisation: at reset or power loss:
LV_CP_CLOSE_1 = 0 (never changed after initialisation)
LV_CP_CLOSE_2 = 0 (never changed after initialisation)
LV_CP_CLOSE_3 = 0 (never changed after initialisation)

Recurrence: only initialisation

28.8.7 Selection of STATE_OPM_ENG_CP in case of engine operation mode change (OPM_AV)

General information:

This chapter describes the canister purge behaviour in case of changing engine operation mode (OPM_AV).

Application conditions:

Initialisation: at reset or power loss STATE_OPM_ENG_CP = 0

Recurrence: *100 ms*

Activation: every engine state

Formula Section:

STATE_OPM_ENG_CP = ID_STATE_OPM_ENG_CP

Setting of the flag LV_STATE_OPM_CHG_HOM_CP to detect the engine mode change from homogenious (ENG_MODE_0) to stratified (ENG_MODE_1/2) and vice versa and the flag LV_STATE_OPM_CHG_S_CP to detect the schange of the stratified engine mode (ENG_MODE_1 to ENG_MODE_2 and vice versa.

```
if    [(STATE_OPM_ENG_CP$_n$ = ENG_MODE_0
      and STATE_OPM_ENG_CP$_{n-1}$ != ENG_MODE_0)
      or  (STATE_OPM_ENG_CP$_n$ != ENG_MODE_0
      and STATE_OPM_ENG_CP$_{n-1}$ = ENG_MODE_0)]
then        LV_STATE_OPM_CHG_HOM_CP = 1
else        LV_STATE_OPM_CHG_HOM_CP = 0
endif

if     [(STATE_OPM_ENG_CP$_n$ = ENG_MODE_1
```

```
        and $\text{STATE\_OPM\_ENG\_CP}_{n-1}$ = ENG_MODE_2)
        or ($\text{STATE\_OPM\_ENG\_CP}_{n}$ = ENG_MODE_2
        and $\text{STATE\_OPM\_ENG\_CP}_{n-1}$ = ENG_MODE_1)]
    then    LV_STATE_OPM_CHG_S_CP = 1
    else    LV_STATE_OPM_CHG_S_CP = 0

    endif
```

28.8.8 end

28.8.9 Flow Reduction near engine operation mode switch

General information:

The two thresholds for an engine operating mode change is given by the two input values. Around this fuel mass point the flow through the CPS valve is reduced, to prevent disturbences at engine mode change by canister purge.

Application conditions:

Initialisation: *all values = 0 at reset*

Recurrence: *20 ms*

Activation: every engine state

Formula Section:

$\text{MFF\_GRD\_CP} = \mathbf{abs}(\text{MFF\_SP\_MV}_{n-1} - \text{MFF\_SP\_MV}_{n})$

$\text{MFF\_GRD\_MMV\_CPn} =$

$\text{MFF\_GRD\_MMV\_CP}_{n-1} + (\text{MFF\_GRD\_CP} - \text{MFF\_GRD\_MMV\_CP}_{n-1}) * \text{C\_CRLC\_MFF\_GRD\_CP}$

MFF_RED_OPM_THD_CP = IP_MFF_RED_OPM_CP(MFF_GRD_MMV_CP)

```
if      abs(MFF_SP_MV–MFF_MAX_S_CUS) < MFF_RED_OPM_THD_CP // HOMS<->S
then    LV_FLOW_TAR_COR_CP = 1
        FAC_FLOW_TAR_COR_CP =  max{ C_FAC_FLOW_TAR_COR_MIN_CP,
            abs(MFF_SP_MV–MFF_MAX_S_CUS)/ MFF_RED_OPM_THD_CP}
elseif  abs(MFF_SP_MV–MFF_MAX_HOMS_CUS) < MFF_RED_OPM_THD_CP
                                                        // HOMS<->HOM
then    LV_FLOW_TAR_COR_CP = 1
        FAC_FLOW_TAR_COR_CP = max{ C_FAC_FLOW_TAR_COR_MIN_CP,
            abs(MFF_SP_MV–MFF_MAX_HOMS_CUS)/ MFF_RED_OPM_THD_CP}
else    LV_FLOW_TAR_COR_CP = 0
```

```
            FAC_FLOW_TAR_COR_CP = 1
endif

end
```

28.8.10 Calculation of LV_C_FAC_LAM_0_CP_WIDE

General information:

At the start of each driving cycle the lambda deviation has to be monitored to detect the possibility of an error in the fuel system. If the possibility of an error is detected, the flag LV_C_FAC_LAM_0_CP_WIDE is set. This will open the limitations of FAC_LAM_0_CP.
TA = recurrence

Application conditions:

Initialisation:

```
at RST or LV_IGK=1
T_LAM_DEV_CHK_CP = C_T_LAM_DEV_CHK_MAX_CP
T_LAM_DEV_SYM_CP = 0
LV_C_FAC_LAM_0_CP_WIDE = 0
if     LC_LAM_CBK_CPS=0
then idx_cp = 0
else idx_cp = 1
endif
```

Recurrence: *20ms*
Activation: *every engine state*

Deactivation: --

Formula section:

```
if     LC_LAM_DEV_RESU_CP = 1
       and STATE_CP = MAX_PURGE
then   T_LAM_DEV_CHK_CP = C_T_LAM_DEV_CHK_MAX_CP
       T_LAM_DEV_SYM_CP = 0

28.8.11 External request for Time slice "Lambda adaption"

General information:

With the flag LV_STATE_T_SDL_CP_LAM_AD_EXT the time management for lambda adaptation and canister purge can be forced to change and stay in one of the lambda adaptaiton time slices.

Application conditions:

Initialisation: *LV_STATE_T_SDL_CP_LAM_AD_EXT = 0 after reset*

Recurrence: 20ms

Activation: all engine states

Deactivation: --

Formula section:

```
If   ( LV_LAM_LIM_LAM_AD [i] = 1     // shall be true, if at least one bench is true
     and  LC_LAM_LIM_AD_ENA = 1) // immediate lambda adaptation required
     or LV_CYL_BAL_LAM_AD_REQ_CUS = 1
then LV_STATE_T_SDL_CP_LAM_AD_EXT = 1
else LV_STATE_T_SDL_CP_LAM_AD_EXT = 0
```

NC_NR_CP_BUF	-	0...FFH	0...255	1	[-]
Size of the fuel buffer FUEL_FLOW_ADD_BUF					

General information:

When the Evaporative Emission Control is active, the fuel injection is corrected by an additive value MFF_ADD_LAM_CP to avoid emission and driveability problems caused by the fuel flow through the CPS. This correction is done all the time.

During RAMP_OPEN when the lambda control is shifted the buffer will be initialized to the last MFF_ADD_CP_KGH value.

The MFF_BUF_CP value is calculated to take into account the distance between the CPS VALVE and the injectors.

The value MFF_ADD_LAM_CP is added with a minus sign to the total formula of the injection calculation (see chapter INJECTION).

The value MFF_TOT_CP allow to measure the quantity of fuel during an emission cycle.

After the initialization phase the buffer must be calculated all the time, in order to have the buffer empty when the evaporative function is stopped.

Application conditions:

Initialisation: at reset and engine stop
MFF_TOT_CP = 0
at reset, engine stop and deactivation
MFF_ADD_BUF[all] = 0
MFF_BUF_CP = 0
MFF_ADD_LAM_CP = 0
MFF_CPS = 0
MFF_ADD_CYL_CP = 0
TQI_ADD_CP = 0
BUF_INP_CP = 0
BUF_OUT_CP = 0
IDX_CP = pointer at MFF_ADD_BUF[0]

Recurrence: **20** ms

Activation: [LV_CP_ACT = 1 **and** LC_CP_CLL_INH_MAN = 0]
Deactivation: [LV_CP_ACT = 0 **or** LC_CP_CLL_INH_MAN = 1]

Formula section:

```
if      LV_N_MAX_CP = 1
then    call  "Default values for disabled calculations"
else    call "handling of the ring buffer"
        if      LV_HOM_ACT = 1
        then    call "Injection correction calculation"
        else    call "Torque Correction calculation"
        endif
        MFF_TOT_CP = MFF_TOT_CP + MFF_BUF_CP / 360

endif
end
```

28.10.1 Default values for disabled calculations

When the maximum engine speed limitation is reached (LV_N_MAX_CP) some of the calculations for the injection correction must be stopped to decrease the CPU load. If LV_N_MAX_CP is active then the normal calculations of the following variables are not done and the values of these variables are set to 0.

Formula section:

```
MFF_ADD_BUF          = 0   (all values of the array)
MFF_BUF_CP           = 0
MFF_ADD_LAM_CP       = 0
TQI_ADD_CP           = 0
BUF_INP_CP           = 0
MFF_CPS              = 0
BUF_OUT_CP           = 0
MFF_ADD_CYL_CP       = 0
end
```

28.10.2 Handling of the ring buffer

The recurrence of this subchapter is configurable by LC_FLOW_CPS_CAL:

if LC_FLOW_CPS_CAL=0 then reccurency **20** ms
if LC_FLOW_CPS_CAL=1 then reccurency **40** ms
The buffer MFF_ADD_BUF has NC_NR_CP_BUF elements

IDX_CP, IDX_RD_CP and IDX_STEP_CP are pointers within the ring buffer; they have to be checked for exceeding the limits of the ring buffer.

IDX_CP is the current position within the ring buffer MFF_ADD_BUF. This position is incremented every 20 rsp. 40 ms, depending on LC_FLOW_CPS_CAL

Formula section:

Correction of MAF_KGH_FG_PRED (MAP and TIA)

```
If      STATE_OPM_ENG_CP = ENG_MODE_0
        Then MAF_KGH_FG_PRED_COR_CP = MAF_KGH_FG_PRED *
             IP_MAF_KGH_PRED_COR_MAP_TIA(MAP,TIA)
        Else MAF_KGH_FG_PRED_COR_CP = MAF_KGH_FG_PRED *
             IP_MAF_KGH_PRED_COR_MAP_TIA_2(MAP,TIA)

// The overflow handling of the buffer indices is not described here and has to be done software-internal

// reading
If LC_MAF_COR_ACT_CP = 0
then
        if   STATE_OPM_ENG_CP = ENG_MODE_0
        then IDX_RD_CP     = IDX_CP - IP_MFF_DLY_CP (MAF_CYL)
        else IDX_RD_CP     = IDX_CP - IP_MFF_DLY_CP_2 (MAF_CYL)
        endif
else
        if   STATE_OPM_ENG_CP = ENG_MODE_0
        then IDX_RD_CP     = IDX_CP -
             IP_MFF_DLY_CP (MAF_KGH_FG_PRED_COR_CP)
        else IDX_RD_CP     = IDX_CP -
             IP_MFF_DLY_CP_2 (MAF_KGH_FG_PRED_COR_CP)
        endif
endif

BUF_OUT_CP   = MFF_ADD_BUF[IDX_RD_CP] * MAF * N_32 * NC_CYL_NR * 3 /  $10^5$

// writing → IDX_STEP_CP elements are filled
if      MFF_ADD_CP_KGH = 0
then    BUF_INP_CP = 0
else    BUF_INP_CP     = MFF_ADD_CP_KGH /
             (max(MAF_THR,C_MAF_THR_MIN_BUF_CP) + MAF_CPS)
endif
if      LV_FAC_LAM_SHIFT_CP =1
        then MFF_ADD_BUF [all]    = BUF_INP_CP
             BUF_OUT_CP           = MFF_ADD_CP_KGH
             MFF_BUF_CP           = MFF_ADD_CP_KGH
        else if STATE_OPM_ENG_CP = ENG_MODE_0
             then IDX_STEP_CP    = IP_IDX_STEP_CP (MAF_KGH_FG_PRED_COR_CP)
             else  IDX_STEP_CP   =
                   IP_IDX_STEP_CP_2 (MAF_KGH_FG_PRED_COR_CP)
             endif
             for k = IDX_CP to IDX_CP + IDX_STEP_CP do
                   MFF_ADD_BUF[k] = BUF_INP_CP
             endfor
```

```
        endif
    // moving the position index
    IDX_CP = IDX_CP + IDX_STEP_CP + 1

    // final filtered buffer output
    $MFF\_BUF\_CP_n$ = [$MFF\_BUF\_CP_{n-1}$ + IP_CRLC_MFF_BUF_CP (MAF_CYL)
                              * (BUF_OUT_ CP – $MFF\_BUF\_CP_{n-1}$)]
    end
```

calibration hint:

If a modification of the recurrence of the ring buffer is done (modification on LC_FLOW_CPS_CAL), the delay times, which are calibrated as index, have to be updated according to the new recurrence.

28.10.3 Injection correction calculation

This correction is applied for homogeneous mode only. In stratified mode, correction is applied by torque (see next paragraph)

```
if    N_32 > 0
then  MFF_ADD_LAM_CP   = (MFF_BUF_CP * $10^5$) / (N_32 * NC_CYL_NR * 3)
else  MFF_ADD_LAM_CP   = 0
endif
MFF_ADD_CYL_CP = MFF_ADD_LAM_CP
TQI_ADD_CP           = 0
end
```

28.10.4 Torque Correction calculation

During stratified combustion, the impact of the premixed fuel flow coming from the CPS has to be compensated in an alternative way. It was demonstrated that the torque increase due to canister purge is dependent on the mass fuel flow from the CPS, the engine speed, and, additionally, on the mass flow of fuel that originates from the injector. The corrective torque will be calculated in the project spezific Torque coordination.

Formula section:

```
if    N_32 > 0
then  MFF_CPS          = MFF_BUF_CP * $10^5$ / (N_32 * NC_CYL_NR * 3)
else  MFF_CPS = 0
endif
MFF_ADD_CYL_CP = MFF_CPS
MFF_ADD_LAM_CP           = 0
TQI_ADD_CP           = 0
end
```

Enables the FAC_LAM_0_CP correction for stratified engine operation					

General information:

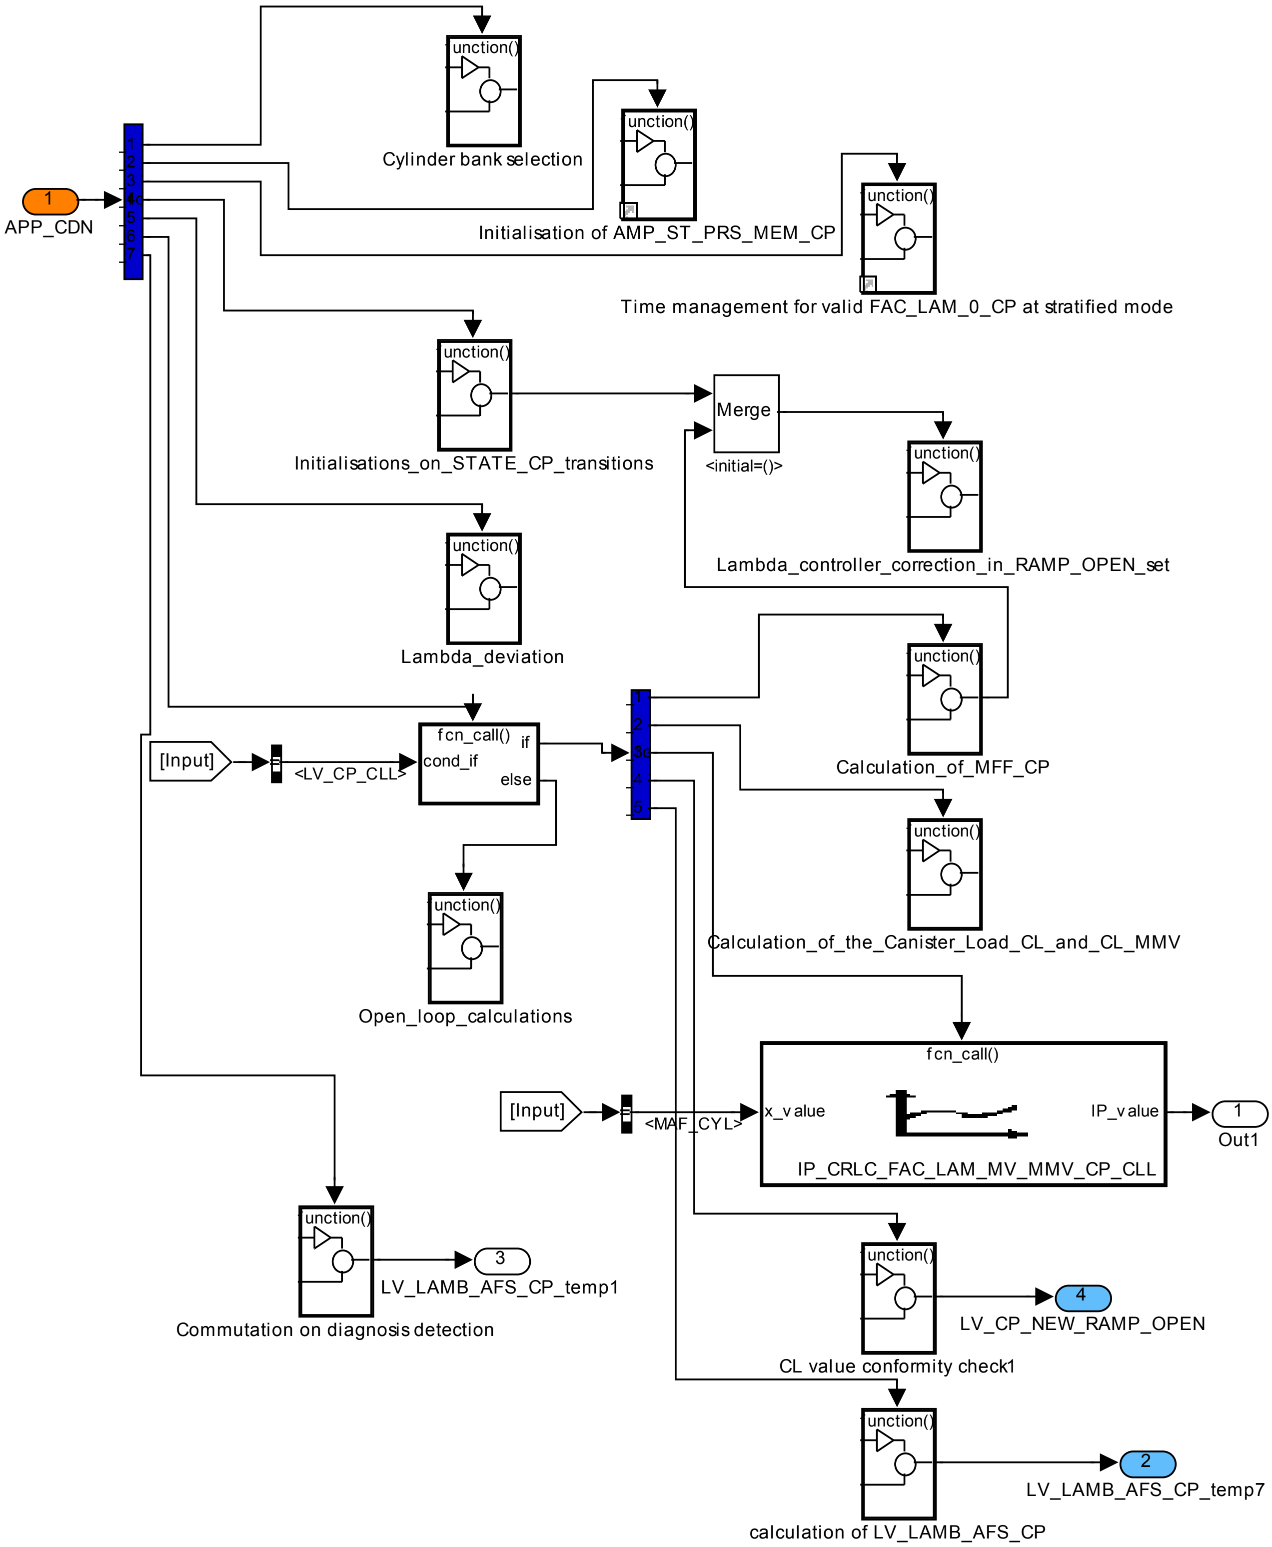
This module calculates the lambda deviation caused by the opening of the CPS valve and a canister load value using the lambda deviation value. The canister load is the concentration of fuel vapors within the mixture flow coming from the ACF.

The opening period cppwm of the CPS is controlled in dependence with the canister load CL.

Application conditions:

Initialisation: at RST, IGKON or deactivation
all values = 0
CL = C_CL_ST_CP
CL_MMV = C_CL_ST_CP
At first initialisation or NVMY error: LAMB_MMV_0_GRD_CP= 1
Recurrence: **20** ms
Activation: LV_CP_ACT = 1
Deactivation: LV_CP_ACT = 0

Signal flow diagram:



Formula section:

28.11.1 INITIALIZATION of AMP_ST_PRS_MEM_CP

Save the first valid ambient preasure AMP once after reset:

Application conditions:

Initialisation: AMP_ST_PRS_MEM_CP = 0 at RST
Recurrence: **100** ms
Activation: --
Deactivation: --

```
if    LV_ERR_AMP = 0 and LV_END_DIAG_AMP = 1 and AMP_ST_PRS_MEM_CP = 0
then  AMP_ST_PRS_MEM_CP = AMP
end
```

28.11.2 INITIALIZATIONS on STATE_CP transitions

The following submodules are to be calculated on transitions between the different states of canister purge control.

To follow a transition in CP control module, STATE_CP and STATE_CLL_DEAC_CP have to be memorised in this module.

At the case of STATE_OPM_ENG_CP != MODE_0 the intialization value for CL and CL_MMV is corrected in the direction of the last known CL_MMV. The correction can be weighted and limited.

Formula section:

```
if      STATE_CP ≠ STATE_CP_MEM              // transition detected
then    if      STATE_CP_MEM = RAMP_OPEN
        then    call ”INITIALIZATION-VALUES on leaving RAMP_OPEN”
                if      STATE_CP = MAX_PURGE

```

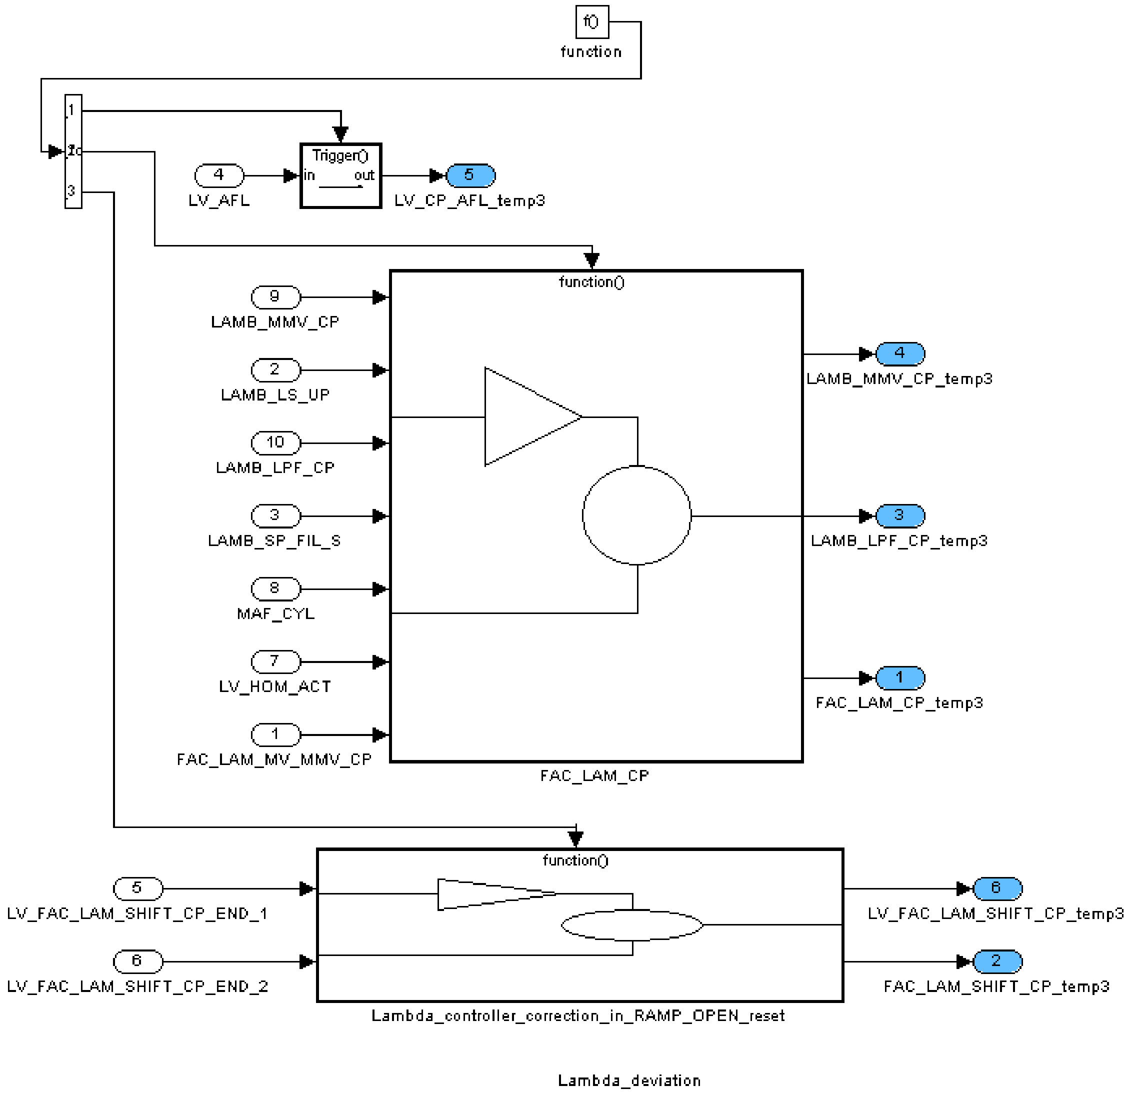
28.11.3 Lambda deviation

In case of two bank exhaust line configuration, the master-exhaust bank for evaporative emission control has to be defined using LC_LAM_CBK_CPS.

The additive constant C_FAC_LAM_DIF_CP_AS should be set to 0 in normal operation; it is only provided for validation purposes

The calculation of the filtered mean value of lambda controller output FAC_LAM_MV_MMV_CP is done inside LACO aggregate. Indeed, the filter constant for this calculation - CRLC_FAC_LAM_MV_MMV_CP - is provided by this module, depending on the STATE_CP.

In open loop, a strong filtering is desired to obtain a stable value for FAC_LAM_0_CP on entering the closed loop. Within the closed loop operation, the filtering should be less severe in order to enable a quick learning of CL and fast reactions on lambda deviations caused by canister purge.



Formula section:

```
// determination of the filter constant for FAC_LAM_MV_MMV_CP
// this value is passed to LACO
if      LV_CP_CLL = 1                                          // "Normal purge" active
then CRLC_FAC_LAM_MV_MMV_CP   = IP_CRLC_FAC_LAM_MV_MMV_CP_CLL (MAF_CYL)
else  CRLC_FAC_LAM_MV_MMV_CP   = IP_CRLC_FAC_LAM_MV_MMV_CP_OPL (MAF_CYL)
endif
LV_CP_AFL = LV_AFL [idx_cp]

// determination of the lambda deviation
// FAC_LAM_MV_MMV_CP is received from LACO where it is calculated using the filter constant defined above
call   "FAC_LAM_CP"
call   "lambda controller correction in RAMP_OPEN (reset)"  // check in every state_cp
end
```

  endif
  FAC_LAM_CP = FAC_LAM_CP + C_FAC_LAM_DIF_CP_AS
  end
```

28.11.3.2 Lambda controller correction in RAMP_OPEN (reset)

The flag requesting a shift of the lambda controller LV_FAC_LAM_SHIFT_CP is reset after all acknowledge flags from lambda controller are received.

Formula section:

```
if    LV_FAC_LAM_SHIFT_CP_END [i] = 1          // all benches have to be =1
then  LV_FAC_LAM_SHIFT_CP         = 0
      FAC_LAM_SHIFT_CP            = 0
endif
end
```

28.11.4 Calculation of MFF_CP

General information:

This calculation is calculated in RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE and RAMP_CLOSE.

The fuel flow from the ACF when the CPS is opened causes a deviation of the lambda control. This fuel flow can be calculated as a function of the difference of the lambda control values with closed / opened CPS, the mass air flow MAF_DLY_MMV_CP, the lambda value LAMB_LPF_CP and a constant taking into account the stoiciometric ratio C_RAF_CLC_CP.

The mass air flow MAF_DLY_MMV_CP is the filtered value of maf_cp using a Padé-filter and a moving mean value calculation to consider the delay time between the mass air flow maf_cp and the FAC_LAM_CP calculation. The fuel flow calculation MFF_LAM_CP is the result of the lambda control deviation.

The additive adaptive fuel mass flow MFF_ADD_CP_KGH caused by the canister purge is also regarded in the calculation.

When the deviation of the lambda control FAC_LAM_DIF_CP exceeds C_FAC_LAM_DIF_MAX_CP during RAMP_OPEN operation or when the RAMP_OPEN operation is finished successfully, the fuel injection time is corrected by an additive correction value and the lambda controller value FAC_LAM_CP is corrected by the value of FAC_LAM_DIF_CP. FAC_LAM_DIF_CP is then set to 0 because the lambda deviation is corrected.

During MAX_PURGE. RAMP_OPEN_FAST and RAMP_CLOSE operation there is a continuous additive adaptive correction of the fuel. The additive fuel flow MFF_ADD_CP_KGH is calculated from the calculated mass flow through the CPS FLOW_CPS and the filtered canister load CL_MMV.

During RAMP_OPEN, the MFF_ADD_CP_KGH is updated as soon as FAC_LAM_DIF_CP exceeds the threshold C_FAC_LAM_DIF_MAX_CP and a last time on the transition RAMP_OPEN to MAX_PURGE, so MFF_ADD_CP_KGH will change periodically during RAMP_OPEN. If RAMP_OPEN is disabled for a short time, the current value of MFF_ADD_CP_KGH is stored in MFF_ADD_CP_OLD on leaving RAMP_OPEN and restored on re-entering RAMP_OPEN (see initialisations).

Formula section:

```
if LV_HOM_ACT = 0
then call " Calculation of corrected FAC_LAM_0_CP in stratified"
endif
FAC_LAM_DIF_CP = FAC_LAM_0_CP - FAC_LAM_CP // calculation of FAC_LAM_DIF_CP
if    STATE_CP = RAMP_OPEN                      // lambda controller correction
then  if LV_HOM_ACT = 1
      then if    FAC_LAM_DIF_CP > C_FAC_LAM_DIF_MAX_CP
           then MFF_ADD_CP_KGH = CL_MMV * FLOW_CPS
                call "Lambda controller correction in RAMP_OPEN (set)"
           endif
      else MFF_ADD_CP_KGH = CL_MMV * FLOW_CPS
           if    FAC_LAM_DIF_CP > C_FAC_LAM_DIF_MAX_CP
           then LV_FAC_LAM_SHIFT_CP_AVL = 1
           endif
      endif
else  MFF_ADD_CP_KGH = CL_MMV * FLOW_CPS
endif
call  "MFF_LAM_CP"
MFF_CP = MFF_LAM_CP + MFF_ADD_CP_KGH
end
```

28.11.4.1 Lambda controller correction in RAMP_OPEN (set)

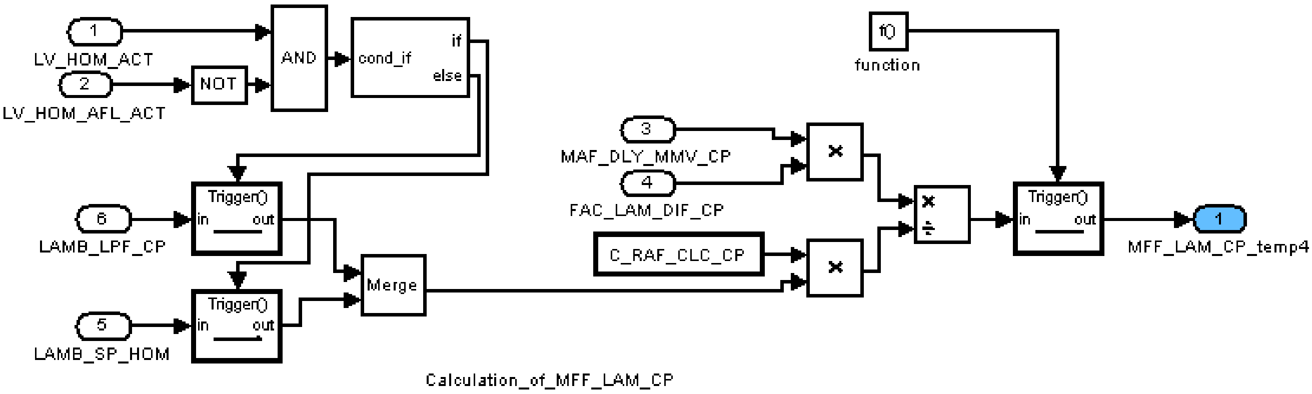
Called by:

- by RAMP_OPEN actions, when FAC_LAM_DIF_CP exceeds threshold
- On transition RAMP_OPEN to MAX_PURGE, if FAC_LAM_DIF_CP > 0

Formula section:

```
if      LV_FAC_LAM_SHIFT_CP     = 0
then    LV_FAC_LAM_SHIFT_CP     = 1
        FAC_LAM_SHIFT_CP        = FAC_LAM_DIF_CP
endif
FAC_LAM_DIF_CP                  = 0
LV_FAC_LAM_SHIFT_CP_AVL         = 1
end
```

28.11.4.2 MFF_LAM_CP



```
if      LV_HOM_ACT = 1 and LV_HOM_AFL_ACT= 0
then    MFF_LAM_CP =
          (MAF_DLY_MMV_CP * FAC_LAM_DIF_CP) / (C_RAF_CLC_CP * LAMB_SP_HOM)
else    MFF_LAM_CP =
          (MAF_DLY_MMV_CP * FAC_LAM_DIF_CP) / (C_RAF_CLC_CP * LAMB_LPF_CP)
endif
end
```

28.11.5 Calculation of the Canister Load CL, CL_MMV

General information:

This calculation is called in RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE and RAMP_CLOSE.

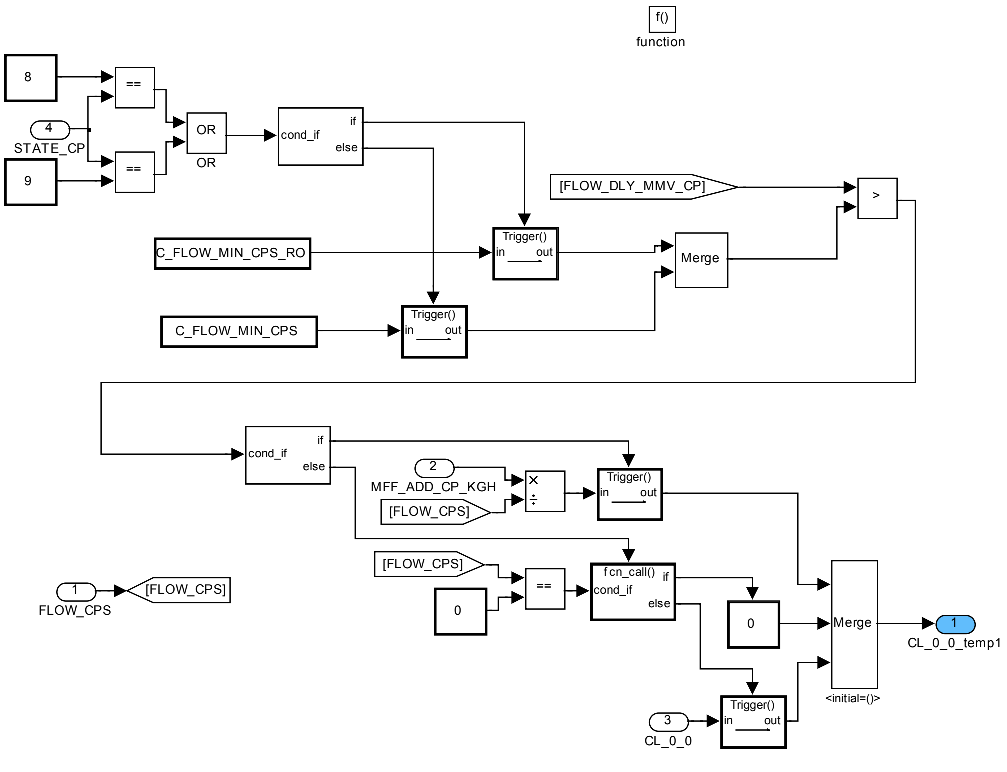
The load CL of the ACF is calculated as the ratio of the fuel flow MFF_LAM_CP and the flow FLOW_DLY_MMV_CP added to the ratio of the fuel flow MFF_ADD_CP_KGH and the flow FLOW_CPS.

The flow FLOW_DLY_MMV_CP is the filtered value of FLOW_CPS using a Padé-filter and a moving mean value calculation to consider the delay between the FLOW_CPS and the MFF_LAM_CP calculation. Those calculations are described in a separate chapter.

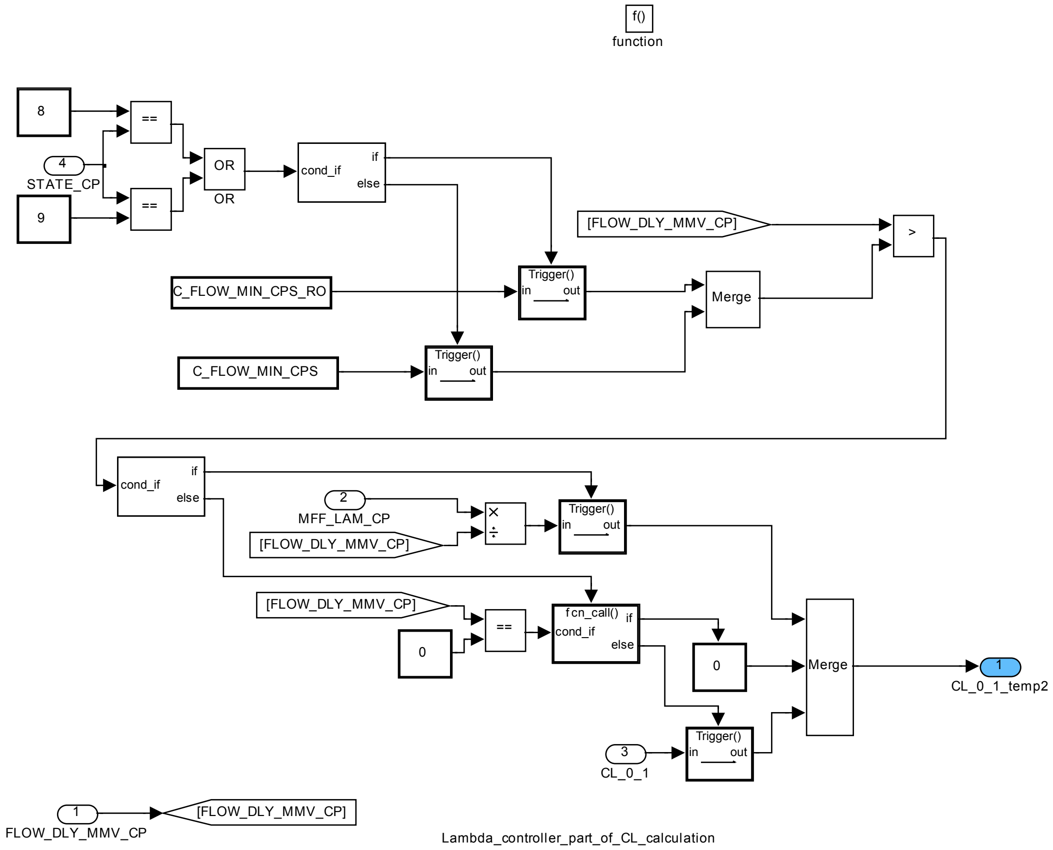
The minimum and maximum values of this ratio are limited by 0 and C_CL_MAX_CP. The value of CL is filtered using a moving mean value calculation. The value of CL is only calculated when the engine is operated at limited dynamics (LV_CP_DYW=1).

Application conditions:

Initialisation: all values = 0 at RST or IGKON
Recurrence: **100** ms
Activation: -- (called by superior block)
Deactivation: -- (called by superior block)



Injection_part_of_CL_calculation



Formula section:

```
if STATE_CP = RAMP_OPEN or RAMP_OPEN_FAST
then
        if      [ LV_CP_DYW            = 1                               //limited dynamics

Note: All values of IP_CL_CRLC_INI have to be bigger than the highest value of IP_CL_CRLC; otherwise, the filter constant CRLC_CL will be unstable.

28.11.5.3 CL value conformity check :

General information:

This calculation is called in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE.

When the calculation of the canister load create a high difference between the previous value CL_{n-1} and the new value CL_n a transition to MIN_PURGE is requested by setting of LV_CL_GRD_CHK_MAX.

Formula section:

```
LV_CL_GRD_CHK_MAX = [abs [$CL_{n-1}$ - $CL_n$] > C_CL_DYW_MAX_CP ]
end
```

28.11.6 CL_MMV evaluation for homogeneous engine operation mode request

Homogeneous lambda one combustion is requested by setting of the bit information LV_LAMB_AFS_CP (see chapter "Calculation of LV_LAMB_AFS_CP"). Two possibilities are given. If the canister load CL_MMV is greater then the threshold IP_CL_MMV_HOM_PRS_UP_CP. The threshold is taken from a map depending on the difference between the ambient preasure at reset and the actual ambient preasure. The bit information is reset if the canister load falls below the threshold IP_CL_MMV_HOM_PRS_DOWN_CP. The setting and reseting of the bit LV_LAMB_AFS_CP is debounced by the counters ABS_LAMB_AFS_CP.
The other possibility is given for lower CL_MMV values, if the vehicle drives not in the city. There is the increasement for purge flow much bigger then driving in the city. During driving in the city the fuel consumption increase is too high to request homogenious mode.

Application conditions:

Initialisation: all values = 0 at RST or IGKON
Recurrence: **100** ms
Activation: -- (called by superior block)
Deactivation: -- (called by superior block)

Formula section:

```
if LV_ERR_AMP = 0 and L_END_DIAG_AMP = 1
then AMP_DELTA_IT_CP = AMP - AMP_ST_PRS_MEM_CP
else AMP_DELTA_IT_CP = 0
endif

                        endif
                endif
        endif
endif
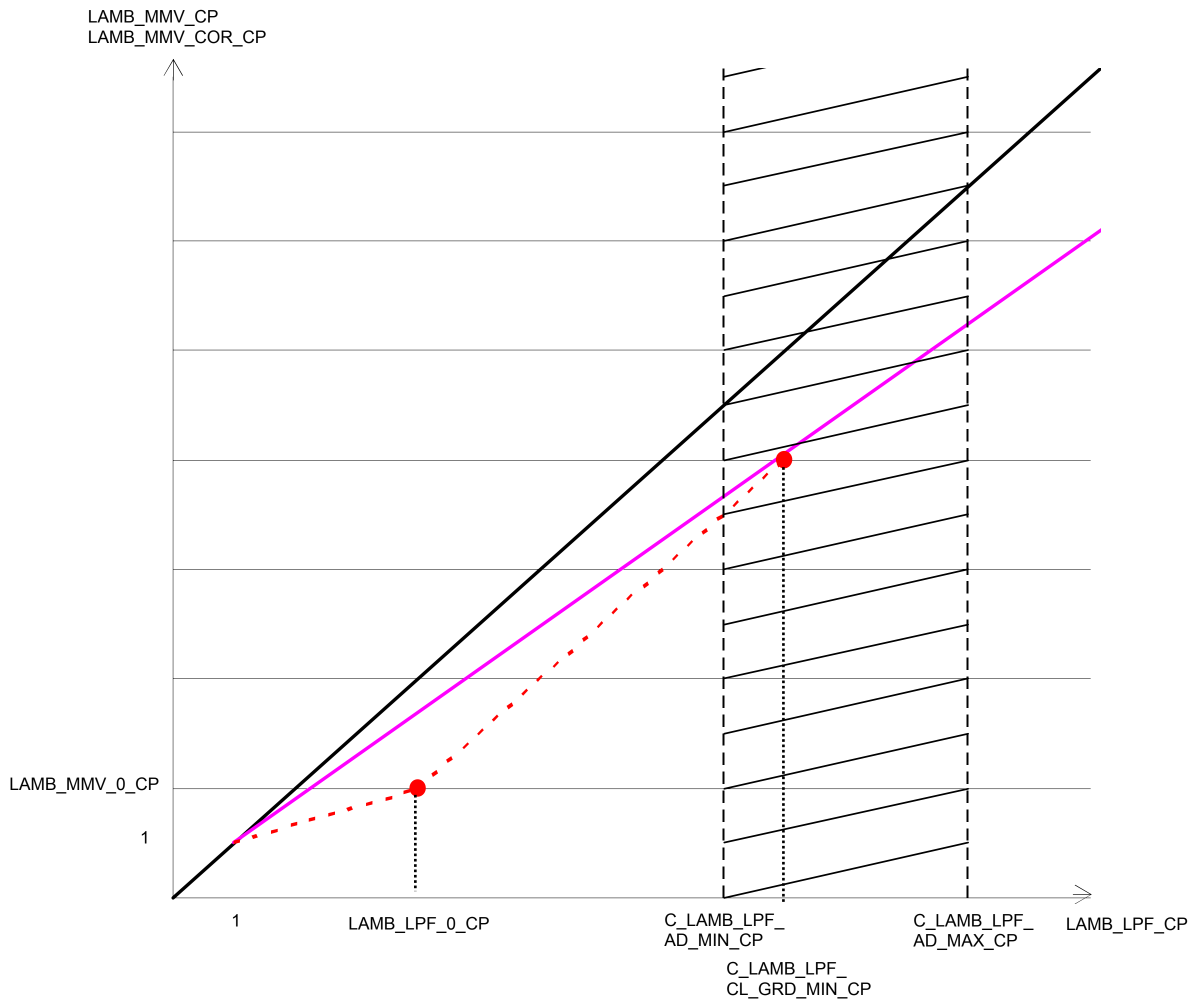
```

end

28.11.7 Adaptation of FAC_LAM_0_CP in stratified mode

In stratified mode it is necessary to adapt the start value of the lambda deviation concerning to the lambda setpoint during canister purge. The deviation between lambda setpoint and measured lambda value is component specific. Therefor a straigt line is approximated at everv start of RO or ROF. If the lambda setpount is in a defined window, the straight line will be adapted to the actual start value. Out of this straight line, a corrected lambda value LAMB_MMV_COR_CP will be calculated.



28.11.7.1 Initalisation at RO and ROF for FAC_LAM_0_CP correction at stratified mode

At initialization of RO or ROF the filtered lambda and lambda setpoint are stored.

LAMB_MMV_0_CP = LAMB_MMV_CP
LAMB_LPF_0_CP = LAMB_LPF_CP
T_CP_PER_RUN_CP = 0

28.11.7.2 Calculation of the straight line for LAMB_MMV_COR_CP

If LAMB_LPF_CP is in the window of C_LAMB_LPF_AD_MIN_CP and C_LAMB_LPF_AD_MAX_CP the straight line will be learned. The straight line is defined by the sampling point [LAMB_LPF_CP=1; LAMB_MMV_CP=1] and the gradient LAMB_MMV_0_GRD_CP.

```
if ((LAMB_LPF_CP > C_LAMB_LPF_AD_MIN_CP)
and  (LAMB_LPF_CP < C_LAMB_LPF_AD_MAX_CP))
then
    // new gradient calculated by the sampling points 1;1
    and LAMB_MMV_0_CP; LAMB_LPF_0_CP //
    LAMB_MMV_0_GRD_NEW_CP = (LAMB_MMV_CP-1)/(LAMB_LPF_CP-1)

    // Filter for the gradient of the straight line //
    LAMB_MMV_0_GRD_CP$_n$= LAMB_MMV_0_GRD_CP$_{n-1}$+
                    (LAMB_MMV_0_GRD_NEW_CP- LAMB_MMV_0_GRD_CP$_{n-1}$)
                    *C_CRLC_ LAMB_MMV_0_GRD_CP

    T_LAMB_MMV_COR_UPD_CP = 0
endif
```

28.11.7.3 Calculation of corrected FAC_LAM_0_CP in stratified

In stratified mode the value FAC_LAM_0_CP has to be corrected if the lambda setpoint changes. The calculation of the straight line depends on LAMB_LPF_CP and the start value LAMB_LPF_0_CP. If the start value is bigger then C_LAMB_LPF_AD_MIN_CP, the LAMB_MMV_COR_CP value will be on the solid line. If the start value is smaller then C_LAMB_LPF_AD_MIN_CP the value LAMB_MMV_COR_CP will be on the dotted line for LAMB_LPF_CP smaller then > C_LAMB_LPF_CLC_GRD_MIN_CP.

```
if    LC_FAC_LAM_0_COR_ACT_CP = 1
then
    if     (LAMB_LPF_0_CP  > C_LAMB_LPF_AD_MIN_CP or
            LAMB_LPF_CP > C_LAMB_LPF_CLC_GRD_MIN_CP)
    then          // LAMB_MMV_COR_CP is on the solid straight line //
        LAMB_MMV_COR_CP = 1 + [LAMB_MMV_0_GRD_CP *(LAMB_LPF_CP - 1)]
        // linear equation with the sampling points 1;1 and the gradient
        // LAMB_MMV_0_GRD_CP
    elseif LAMB_LPF_CP > LAMB_LPF_0_CP
    then LAMB_MMV_0_TMP_CP =
            1+ [LAMB_MMV_0_GRD_CP * (C_LAMB_LPF_CLC_GRD_MIN_CP - 1)]
        // y-value for the sampling point C_LAMB_LPF_CLC_GRD_MIN_CP,
        // needed for the calculation of the dotted straight line
        LAMB_MMV_COR_CP = LAMB_MMV_0_CP +
                [(LAMB_MMV_0_TMP_CP - LAMB_MMV_0_CP) *
                (LAM_LPF_CP - LAMB_LPF_0_CP)/
                (C_LAMB_LPF_CLC_GRD_MIN_CP - LAMB_LPF_0_CP)]
        // linear equation with the sampling points LAMB_LPF_0_CP;LAMB_MMV_0_CP
        // and C_LAMB_LPF_CLC_GRD_MIN_CP; LAMB_MMV_0_TMP_CP
        else  LAMB_MMV_COR_CP =
```

```
                    1 + [(LAMB_MMV_0_CP-1) * (LAMB_LPF_CL-1) / (LAMB_LPF_0_CP-1)]
                // linear equation with the sampling points 1;1 and
                // LAMB_LPF_0_CP;LAMB_MMV_0_CP
                endif
        endif
        FAC_LAM_0_CP = (LAMB_MMV_COR_CP – LAMB_LPF_CP) / LAMB_LPF_CP
else    FAC_LAM_0_CP = (LAMB_MMV_0_CP – LAMB_LPF_0_CP) / LAMB_LPF_0_CP
endif
```

28.11.7.4 Time management for valid FAC_LAM_0_CP at stratified mode

The run time of the current purge period is measured in T_CP_PER_RUN_CP. This time is compared with a thereshold caculated on the time since the last adaption of the straight line T_LAMB_MMV_COR_UPD_CP and the difference between the lambda setpoint at start of the purge period and the current setpoint. The threshold is weighted with a factor depending on the canister load.

```
T_CP_PER_RUN_CP = T_CP_PER_RUN_CP + 0.2
LAMB_LPF_DIF_IT_CP = ABS(LAMB_LPF_0_CP - LAMB_LPF_CP)
if      (LV_HOM_ACT = 0)
        & (T_CP_PER_RUN_CP >
        (IP_T_CP_PER_END_CP(LAMB_LPF_DIF_IT_CP,T_LAMB_MMV_COR_UPD_CP)
        *IP_T_CP_PER_END_COR_CP(CL_MMV)))
then    LV_CP_PER_END_REQ_S_CP = 1
else    LV_CP_PER_END_REQ_S_CP = 0
endif
```

28.11.8 Open loop calculations

Formula section:

```
if      LV_CL_MDL_ACT       = 1
then    CL_MMV$_n$            = CL_MDL
else    CL_MMV$_n$            = CL_MMV$_{n-1}$
endif
if      LV_STATE_MEM_CP_CLL
or      LV_CL_MDL_ACT       = 1
then    MFF_ADD_CP_KGH      = CL_MMV * FLOW_CPS
else    MFF_ADD_CP_KGH      = 0
endif
CL$_n$                        = CL$_{n-1}$            // no calculation
if      LV_CL_MDL_ACT       = 1
then    MFF_CP              = MFF_ADD_CP_KGH
else    MFF_CP              = 0
endif
(moved to lambda deviation)
LV_CL_GRD_CHK_MAX           = 0
FAC_LAM_DIF_CP              = 0
LV_CP_PER_END_REQ_S_CP = 0
end
```

28.11.9 Calculation of LV_LAMB_AFS_CP

General information:

A commutation to homogeneous lambda one combustion with the flag LV_LAMB_AFS_CP is requested if a short circuit to the ground of the CPS is detected, if the CL-MMV evaluation or the CPS adaptation request this mode. As CL_MMV is only evalutated in closed loop operation, there is the risk of getting stuck in homogeneous operation. Therefore timers limit the request for both criteria (T_AST and AMP) to an applicable time after which a homogeneous request is cancelled.

Application conditions:

Initialisation: all values = 0 at RST or IGKON
Recurrence: **20** ms
Activation: -- (called by superior block)
Deactivation: -- (called by superior block)

Formula section:

```
// Timer calculation
T_LAMB_AFS_T_AST               = max[T_LAMB_AFS_T_AST – TA, 0]
T_LAMB_AFS_AMP_VLD_CP          = max[T_LAMB_AFS_AMP_VLD_CP – TA, 0]
T_LAMB_AFS_T_AST_VLD_CP        = max[T_LAMB_AFS_T_AST_VLD_CP – TA, 0]

if      (LV_LAMB_AFS_T_AST_CP = 1 and VS > C_VS_MIN_LAMB_AFS)
then    T_LAMB_AFS_T_AST = C_T_LAMB_AFS_T_AST
endif

if      LV_CP_CLL = 1
then    T_LAMB_AFS_AMP_VLD_CP      = C_T_LAMB_AFS_AMP_VLD_CP
        T_LAMB_AFS_T_AST_VLD_CP    = C_T_LAMB_AFS_T_AST_VLD_CP
end

// sum of the conditions for LV_LAMB_AFS_CP
LV_LAMB_AFS_CP =
    [(ERR_SYM_EL_CPS = 2h and LC_LAMB_AFS_CP_CPS_SCG = 1)    or
    LV_CPS_AD_HOM_REQ = 1                                   or
    (LV_LAMB_AFS_AMP_CP = 1 and T_LAMB_AFS_AMP_VLD_CP > 0)  or
    (T_LAMB_AFS_T_AST > 0 and T_LAMB_AFS_T_AST_VLD_CP > 0)]

end
```

28.11.10 Engine operating point window

General information:

If the operating point (N,MFF) has a big distance to the operating point stored at entering RO or ROF at stratified engine mode, it is useful to start a new purge phase, due to imprecision in the lambda signal. If the engine operating point will exceed a small window (window_1), the CL-model will be activated, if the CL-model is not valid, a new RO or ROF will be requested. If the operating point will exceed a large window (window_2), a new RO or ROF will be requested.

Formula section:

```
if$_1$ LV_CP_CLL = 1
then$_1$ if$_2$ STATE_OPM_ENG_CP = ENG_MODE_2
    then$_2$ if$_3$ [(N_32_0_CP – N_32) >
        (IP_N_32_OPP_MIN(N_32_0_CP, MFF_SP_0_CP)* C_FAC_OPP_CP_1)
        or (N_32 - N_32_0_CP) >
        (IP_N_32_OPP_MAX(N_32_0_CP, MFF_SP_0_CP)* C_FAC_OPP_CP_1)
        or (MFF_SP_0_CP – MFF_SP_MV) >
        (IP_MFF_SP_OPP_MIN(N_32_0_CP, MFF_SP_0_CP) * C_FAC_OPP_CP_1)

28.11.11 Request for new RAMP OPEN and RAMP OPEN FAST :

General information:

When the "CL value conformity check" detects a non plausible CL value or when the "Time management for valid FAC_LAM_0_CP at stratified mode" requests an new RAMP Open or the enginge operating mode switches or the engine opeating point exceeds a window a transition to MIN_PURGE is requested by setting of LV_CP_NEW_RAMP_OPEN.

In this case no re-entering in the normal purge is possible, instead, WAIT_RAMP_OPEN is activated when the conditions are fullfilled and the transition to RAMP_OPEN or RAMP_OPEN_FASTis done after WAIT_RAMP_OPEN.

Formula section:

```
LV_CP_NEW_RAMP_OPEN = LV_CL_GRD_CHK_MAX

LV_CP_NEW_RAMP_OPEN_FAST =
      [LV_CP_PER_END_REQ_S_CP
      or    (LV_STATE_OPM_CHG_HOM_CP and LC_STATE_OPM_CHG_HOM_CP)
      or    (LV_STATE_OPM_CHG_S_CP and LC_STATE_OPM_CHG_S_CP)
      or    (LV_CL_MDL_ENA = 0 and LV_CP_OPP_WIN_1 = 1)
      or    LV_CP_OPP_WIN_2]
end
```

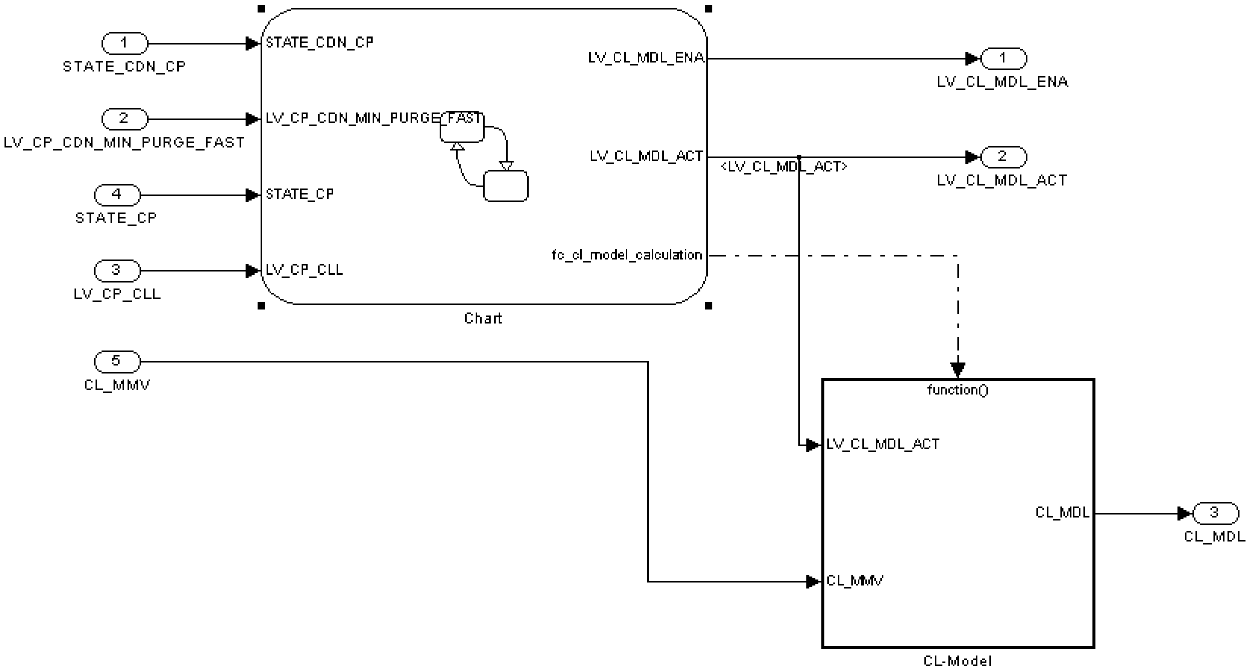
Minimum time in CP closed loop operation to enable CL model usage					

General information:

The evaporative emissions of the fuel tank system are stored in an activated charcoal filter ACF to prevent an escape of the gas to the environment. The loading capacity of the filter is limited, so the filter must be purged temporarily. Therefore the canister purge solenoid CPS. that is positioned between the charcoal filter and the intake manifold is opened by the engine management system. To prevent driveability and emission problems, the opening of the CPS and the purge flow MFF_CP must be controlled.

With the canister load modelling function (CL-Model), the continuity of the CL factor over time during phases of disturbed calculation is guarantied. Therefore the canister load CL will be substituted with the output of a SIMULINK model, which is a calculation result of a normalized exponential function.



Application conditions:

28.12.3 Canister Load modelling

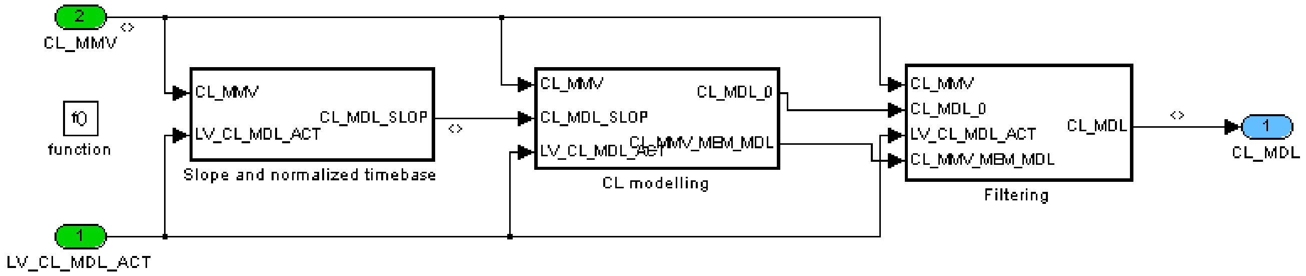

figure: structure of the canister load model

Formula section:

call “Slope and normalized timebase”
call “Modelling and output of CL_MDL”
call “Evaluation CL versus CL_MDL”
end

Calculation information:

The overview shows that the complete function is divided into three submodules, the used inputs are the recurrence time described in chapter Application conditions, the logical value LV_CL_MDL_VALUE_ACT indicating instationary driving conditions it is the result of the Data Type Conversion block with STATE_CDN_CL_MDL as input and the value of Canister Load.

The outgoing CL_MDL value is chosen via a switch block between either the Canister Load during stationary driving conditions at the one hand and the modelled Canister Load Load during instationary driving conditions at the other hand indicated by the variable LV_CL_MDL_VALUE_ACT.

28.12.3.1 Slope and normalized timebase

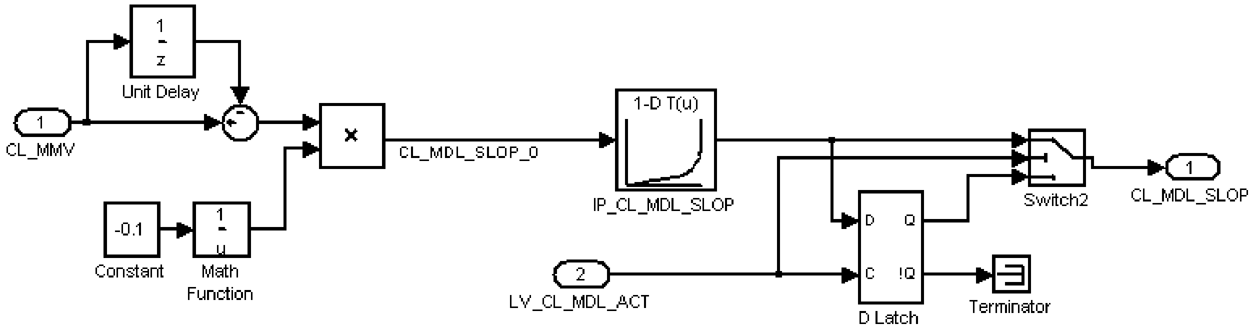

figure: slope and normalized timebase

This submodule calculates the (inverted) slope of CL_MMV by building the difference CL_MMV_n minus CL_MMV_{n-1}. The slope is used with the Map IP_CL_MDL_SLOP to read out the normalized time constant CL_MDL_SLOP which indicates the time position on a exponential function using the slope as an input. The outgoing CL_MDL_SLOP value is frozen when LV_CL_MDL_ACT=1.

Formula section:

```
if    LV_CL_MDL_ACT       = 0
then  CL_MDL_SLOP_0       = -(CL_MMV_MEM_CL_MDL-CL_MMV_MEM_CL_MDL_OLD)
      CL_MDL_SLOP         = IP_CL_MDL_SLOP (CL_MDL_SLOP_0)
else  $CL\_MDL\_SLOP_n$   = $CL\_MDL\_SLOP_{n-1}$
endif
end
```

28.12.3.2 Modelling and output of CL_MDL

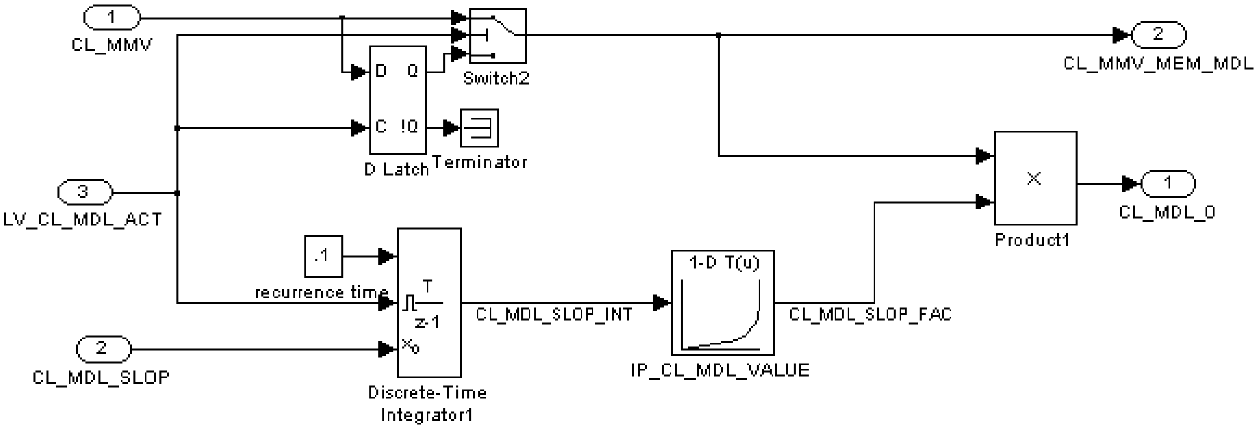

figure: modelling and output of CL_MDL

The output of IP_CL_MDL_VALUE is the normalized value of CL_MDL over $CL\_MDL\_SLOP_{integral}$. The input of IP_CL_MDL_VALUE is calculated with the Discrete-Time Integrator block. The starting point of integration is CL_MDL_SLOP.

Formula section:

```
if    LV_CL_MDL_ACT       = 0
then  CL_MDL_0            = CL_MMV_MEM_CL_MDL
      CL_MMV_MEM_MDL      = CL_MMV_MEM_CL_MDL
      CL_MDL_SLOP_INT     = 0
else  CL_MDL_SLOP_INT     = $CL\_MDL\_SLOP\_INT_{n-1}$ + CL_MDL_SLOP
      CL_MDL_SLOP_FAC     = IP_CL_MDL_VALUE (CL_MDL_SLOP_INT)
      CL_MDL_0            = CL_MMV_MEM_MDL * CL_MDL_SLOP_FAC
end
```

28.12.3.3 Evaluation CL_MMV versus CL_MDL

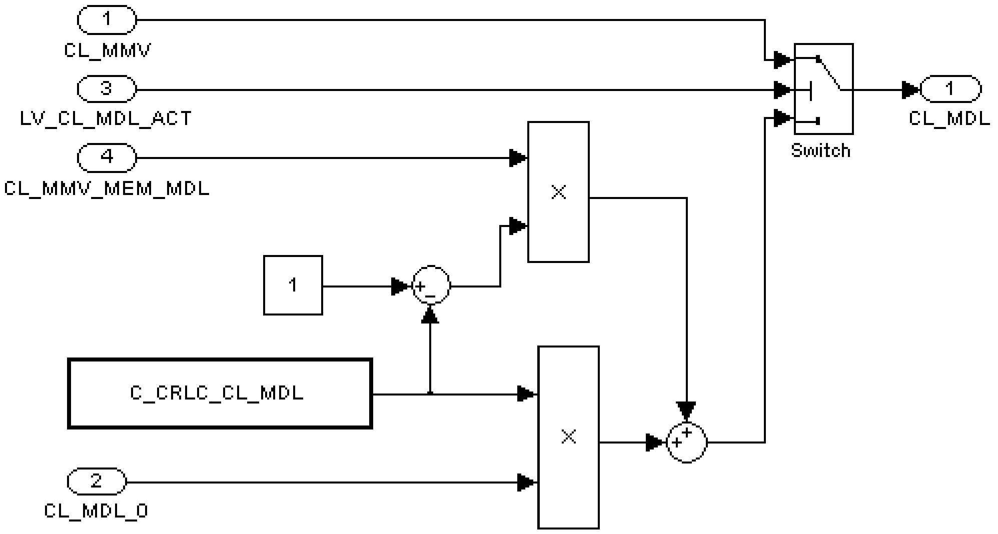

figure: evaluation CL versus CL_MDL

This submodul evaluates the CL_MMV_MEM_MDL value (frozen if LV_CL_MDL_ACT) versus the CL_MDL_0 value by using the filter constant C_CRLC_CL_MDL.

Formula section:

```
if    LV_CL_MDL_ACT      = 0
then  CL_MDL             = CL_MMV
else  CL_MDL             = CL_MDL_0 * C_CRLC_CL_MDL
                         + CL_MMV_MEM_MDL * (1-C_CRLC_CL_MDL)
end
```

General information:

Lambda adapation and canister purge both use a lambda deviation for their purposes. Indeed, as the canister purge itself causes a certain lambda deviation, both functions can not work simultaneous. As a consequence, a time management has to be installed partitioning the engine opertating time and enabling either canister purge or lambda adaptation while disabling the other function.

Signal flow diagram:

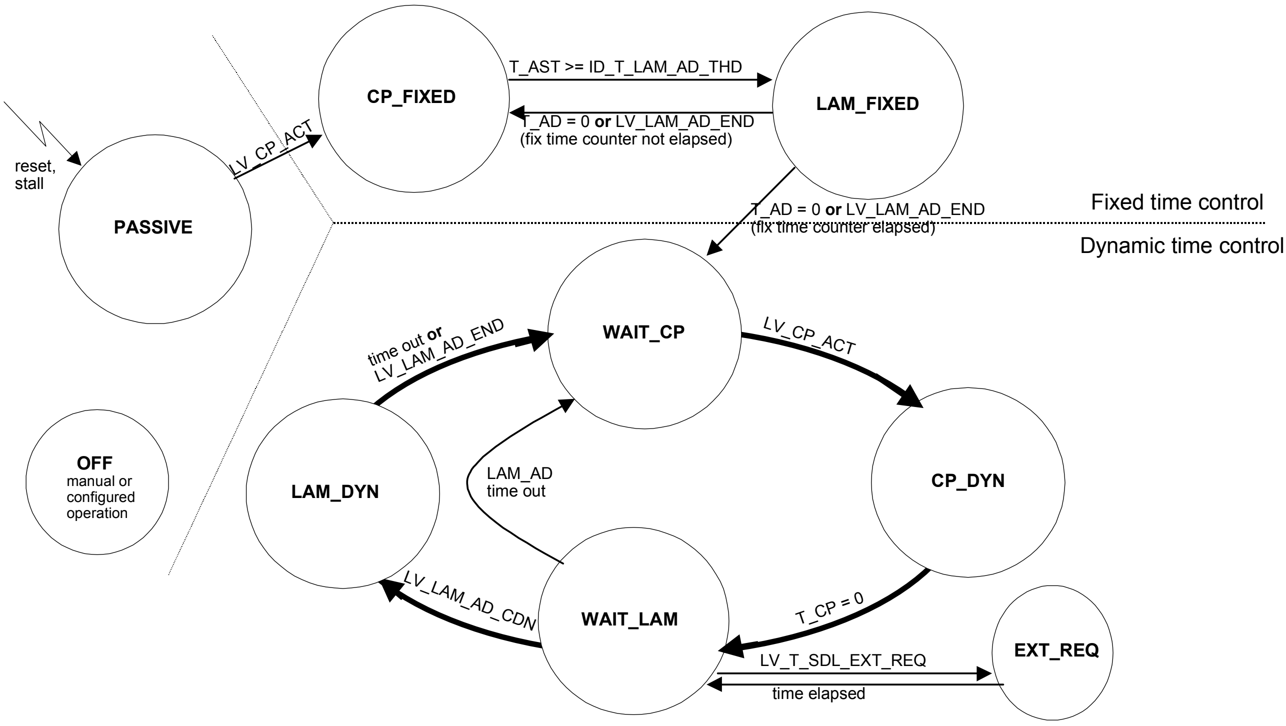

figure 1: time scheduler state diagram

The state diagram above only contains the recent transitions; all possible transitions are listed in the formula section below.

The following table indicates whether canister purge or lambda adapatation is enabled/ disabled depending on the state STATE_T_SDL_CP of the time scheduler.

STATE_T_SDL_CP	CP	LAM_AD
PASSIVE	✗	C
CP_FIXED	✓	✗
CP_DYN	✓	✗
WAIT_LAM	✓	✗
LAM_FIXED	✗	✓
LAM_DYN	✗	✓
WAIT_CP	✗	✓
EXT_REQ	✗	✗

configurable C

Lambda adaptation is enabled in the corresponding states after the CPS is closed

CP is enabled in WAIT_LAM for a calibratable time

figure 2: enabling of canister purge or lambda adaptation depending on state

In general the time control is splited into two main parts:

- At leaving start the time split between lambda adaption and canister purge is defined by a certain number of fixed time frames. The number of these fixed time frames is given by NC_NR_CP_LAM_AD -1 (last defines the start of dynamic time slices).
- After performing the fixed time frames, the time periods of canister purge and lambda adaption are depending on canister load and the necessity of lambda adaption, indicated by their corresponding functions, so dynamic time frames will be applied.
- For Hybrid and Stop/Start configurations the timers for the dynamic time slices are stopped during engine off time.

After the start phase has ended and canister purge is possible (LV_CP_ACT = 1), the manager starts with a time slice depending on TCO. For very cold condition, the dynamic time slices will be performed immediatily. For a mid range temperature, the fixed slices defined in ID_T_SET_T_AST_LAM_CP are done and for a high temperature at first one fixed canister purge time frame will perfaomed. After a defined time the manager will switch to the dynamic time slices.

During CP_FIXED period the canister purge is possible if the conditions for the function are fulfilled. If they're not fulfilled, neither canister purge nor lambda adaptation will be active.

During LAM_FIXED period the canister purge is disabled and the lambda adaptation is enabled. During this period and after the canister purge valve is closed, the lambda adaptation is possible if the conditions for the function are fulfilled. If they're not fulfilled, neither canister purge nor lambda adaptation will be active.

If the lambda adaptation sends its ready bit LV_LAM_AD_END, the lambda adaptation time will immediately end and the state switches to CP_FIXED.

This sequence (canister purge / lambda adapation) is repeated until ID_T_SET_T_AST_LAM_CP defines dynamic slices; for each period, the start time is defined by the corresponding value of the indexiation table ID_T_SET_T_AST_LAM_CP.

The dynamic time frames start with WAIT_CP after the fixed time frames are elapsed, see description of the different states below.

Description of the different time control states

PASSIVE

After each reset or engine stalling the time control starts with state PASSIVE and switches to CP_FIXED or WAIT_CP depending on TCO and when canister purge starts to be active, i.e. LV_CP_ACT = 1 is fulfilled. Lambda adaptation can be activated during this state (configurable)

CP_FIXED

Only canister purge is enabled. This state is active as long as no lambda adaptation is triggered by the corresponding time threshold. If a lambda adaptation is urgently requested, LAM_FIXED is selected.

LAM_FIXED

Only lambda adaption is enabled. This state is left, if the adaptation is finished or the next fixed or dynamic slice starts. If immediate lambda adpatation is requested via the flag LV_STATE_T_SDL_CP_LAM_AD_EXT, this state is not left until these flags have been reset. Afterwards, the fixed time slices are resumed.

CP_DYN

Canister purge is enabled. This state is left, if the timecounter T_CP elapses or an urgent lambda adaptation is requested.

LAM_DYN

Lambda adaption is enabled. To leave this state, a time counter initialised when detecting an empty canister has to have elapsed. The state is left, if the standard adaptation time counter has elapsed and no adaptation is currently ongoing or if the end of an adaptation cycle is signaled by lambda adaptation itself.

WAIT_LAM

Within WAIT_LAM, canister purge is enabled; this enabling may expire after a calibratable time. As soon as the conditions for a lambda adaptation are given, this state is left towards LAM_DYN and lambda adaptation starts. If the time counter for lambda adaptation C_T_MFF_AD_MAX is elapsed, WAIT_CP is selected and canister purge is enabled.

WAIT_CP

Within WAIT_CP, lambda adaptation is enabled. As soon as canister purge function is active (LV_CP_ACT = 1), this state is left towards CP_DYN and canister purge is enabled.

EXT_REQ

If functions other than canister purge and lambda adaptation request a certain time slice with both, lambda adaptation and canister purge deactivated, the time scheduler may switch to the state EXT_REQ for a calibratable time.

In all states with enabled lambda adaptation, the enabling starts when the canister purge valve is closed (LV_CP_CLOSE_ACT = 1).

At the “regular” entry of MAX_PURGE (i.e. not a re-entry after a short deactivation but an entry after finishing canister load learning phases RAMP_OPEN or RAMP_OPEN_FAST) the time slices for CP and lambda adaptation are re-evaluated; remaining time for canister purge is the minimum of IP_T_MAX_CP (depending on canister load) and the lambda adaption priorisation time T_PRI_TOT_LAM_AD. A small time T_PRI_TOT_LAM_AD from lambda adaptation is related to a high priority for lambda adaptation as the canister purge time will be decreased.

Three cases are handled:

High canister load

If the canister is detected full at the end of the learning phase the time control gives priority to the evaporative emission control by increasing the remaining purge time in order to decrease the canister load. The purge time IP_T_MAX_CP is used to purge the canister.

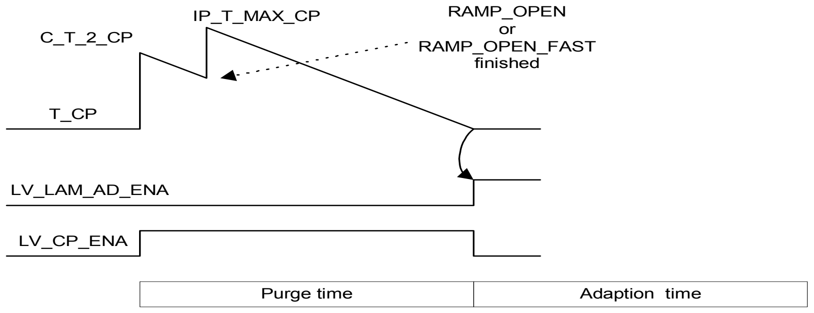

figure 3: canister purge time at high canister load

Medium canister load

If the canister is detected with a medium load, the purge time is calculated as the minimum value between the needs of the lambda adaption and canister purge using the lambda adaption priorisation time T_PRI_TOT_LAM_AD. A small time T_PRI_TOT_LAM_AD from lambda adaptation is related to a high priority for lambda adaptation as the canister purge time will be decreased.

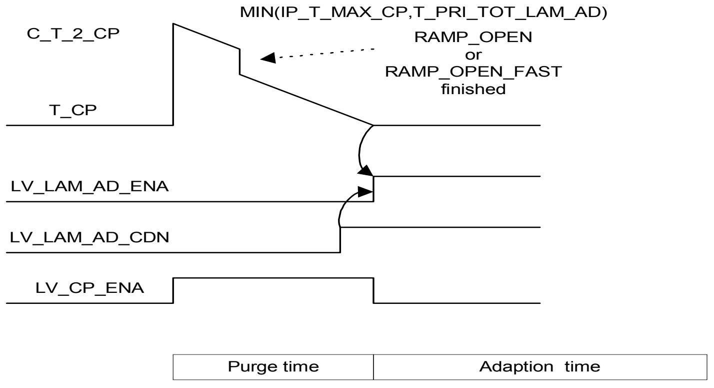

figure 4: canister purge time at medium canister load

Empty canister

If the canister is detected empty at the end of the learning phase, the canister purge is disabled for a time C_T_DI_CP and the lambda adaption is enabled.

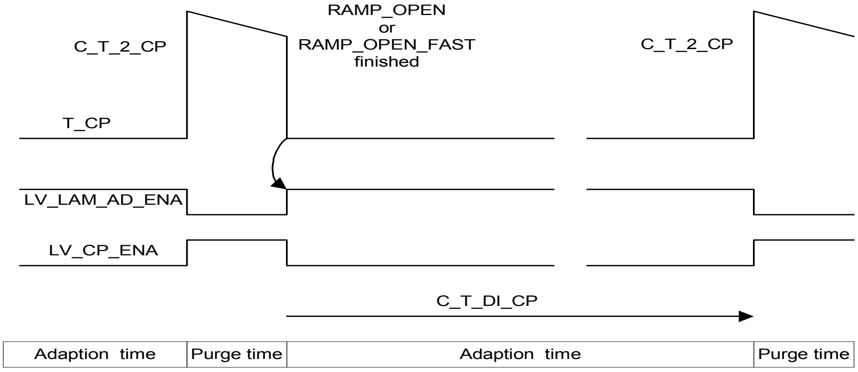

figure 5: canister purge time at low canister load

Application conditions:

Initialisation: at RST or IGKON:
STATE_T_SDL_CP = PASSIVE
all other values = 0
Recurrence: **100** ms
Activation: LV_IGK = 1

General information:

The PWM-setpoint to control the opening of the canister purge valve CPPWM is calculated from a map as a function of the flow setpoint and the pressure difference. This flow setpoint is deliverd from evapoarative emission control module.

The influence of the battery voltage VB on the opening of the CPS is corrected by the additive value IP_CPPWM_VB_1_ADD or IP_CPPWM_VB_2_ADD and multiplicative value IP_CPPWM_VB_FAC.

Two frequencies of the CPS are possible; the selection of the current frequency is dependent on engine speed and valve opening.

An additional PWM offset can be applied using C_CPPWM_AS (the offset) and LC_CPPWM_AS (the switch to turn the consideration of the offset on).

The term CPPWM_ADD_AD includes the valve adaptation value delivered from the canister purge valve characteristic adapation function (if included).

An external setpoint CPPWM_EXT_ADJ is applied, if LV_CPPWM_EXT_ADJ is true.

If a fault is detected on the canister purge valve (LV_ERR_EL_CPS=1), the opening of the CPS is controlled by the value of CPPWM_LIH (see chapter OBDI functions).

In case of high CPU load / high engine speed (LV_N_MAX_CP=1), the regular control of the valve is stopped to save CPU load.

The physical range for the frequency request FRQ_REQ_CP is 5 to 32 Hz.

Application conditions:

Initialisation:	LV_CP_CLOSE_ACT=1 and all other values =0	at reset or stalling
Recurrence:	**20** ms	
Activation:	*every engine state*	
Deactivation	--

Weighting factor for STO according to CPS characteristic					

28.15.1 General information

The purpose of the CPS_AD function is to find the STO(start-to-open-point) of the canister-purge-solenoid (CPS): The PWM-value (valid for the default frequency C_FRQ_MIN_CPS_AD) at which the CPS (canister-purge-solenoid-valve) has reached the end of it’s mechatronical delay time and starts to open (STO). Therefore the CPS is opened using a ramp, meanwhile monitoring the lambda-adaptation (FAC_LAMB) to detect a deviation caused by fuel purged through the CPS. Due to the fact that at a low canister-load (CL_MMV) the adaptation is getting less accurate or even impossible the purge-massflow during adaptation can be increased by rising the frequency (to have more opening-periods per second). The frequency is calculated according to CL_MMV. For PWM is a relative value (valid only for a special frequency) all PWM-values have to be corrected after computing the frequency.

The function CPS_AD (CPS-adaptation) is part of the EVAC-aggregate. To allow a fast purge of the ACF the PWM-ramp for opening the CPS has to start at the STO.

APP_CDN:

This chart is the function’s internal state-machine.

When the conditions (i.e. engine speed, canister load) are sufficient (checked by the function START_CDN_OK), the state active (substate adaptation) is entered.

For transparency the conditions are split into the flags: LV_CPS_AD_ST_CDN_OK, LV_CPS_AD_RUN_CDN_OK, LV_ENG_OK_CPS_ AD, LV_CPS_OK_CPS_AD, LV_T_OK_CPS_ AD, LV_CL_OK_CPS_ AD, LV_CTR_OK_CPS_AD. For details see APP_CDN-block.

The function LEARN_STO ist triggered during state active (by triggering the containing subsystem LEARN_STO). The output value STATE_CPS_AD_REQ is used to control the function’s internal state while STATE_CPS_AD is the reporting value from the function. After an interrupt or failed adaptation the flag LV_ERR_CPS_AD is set. After that in state closing the valve is closed and in state waiting there is time to compensate any lambda-deviation caused by the function.

The value LC_CPS_AD_CHK allws an override of the CPS_AD-conditions.

If maybe once a LEARN_SLOPE-function will be added, the state active will have to be divided into the substates LEARN_STO_active and LEARN_SLOPE_active.

At abortion (to avoid a lambda-step by suddenly closing the CPS) the function has to be shutdown by entering state CLOSE. This can be caused by changing conditions like N or by flags like LV_CPS_AD_INH. In this case the function goes into state CLOSING to prevent any further influence on the engine.

A decreasing CL_MMV value during adaptation is normal but – after a sufficient CL-value has been assured before function start – does not require a shutdown; the value LV_CPS_AD_RUN_CDN_OK is still 1.

If all conditions for CPS adaptation are met but the engine is not in homogeneous operation mode, this mode is requested via the flag LV_CPS_AD_HOM_REQ.

This request is hold up for the time C_T_CPS_AD_HOM_REQ or - if the engine mode changes - until the adaptation is finished or was interrupted. After a non-successful request or after the adaptation is finished / was interrupted, for the time C_T_DLY_CPS_AD_HOM_REQ no request for homogeneous operation mode is allowed.

After a non-successful request or after the adaptation is finished/ was interrupted, for the time C_T_DLY_CPS_AD_HOM_REQ no requests for homogeneous mode are allowed.

Per driving cycle only C_CTR_CPS_AD_HOM_REQ requests are allowed, afterwards CPS adaptation can only take place if the engine is in homogeneous operation mode due to other conditions.

Figure 9 EVAC_CPS_AD

28.15.1.1 SUBFUNCTION: LEARN_STO

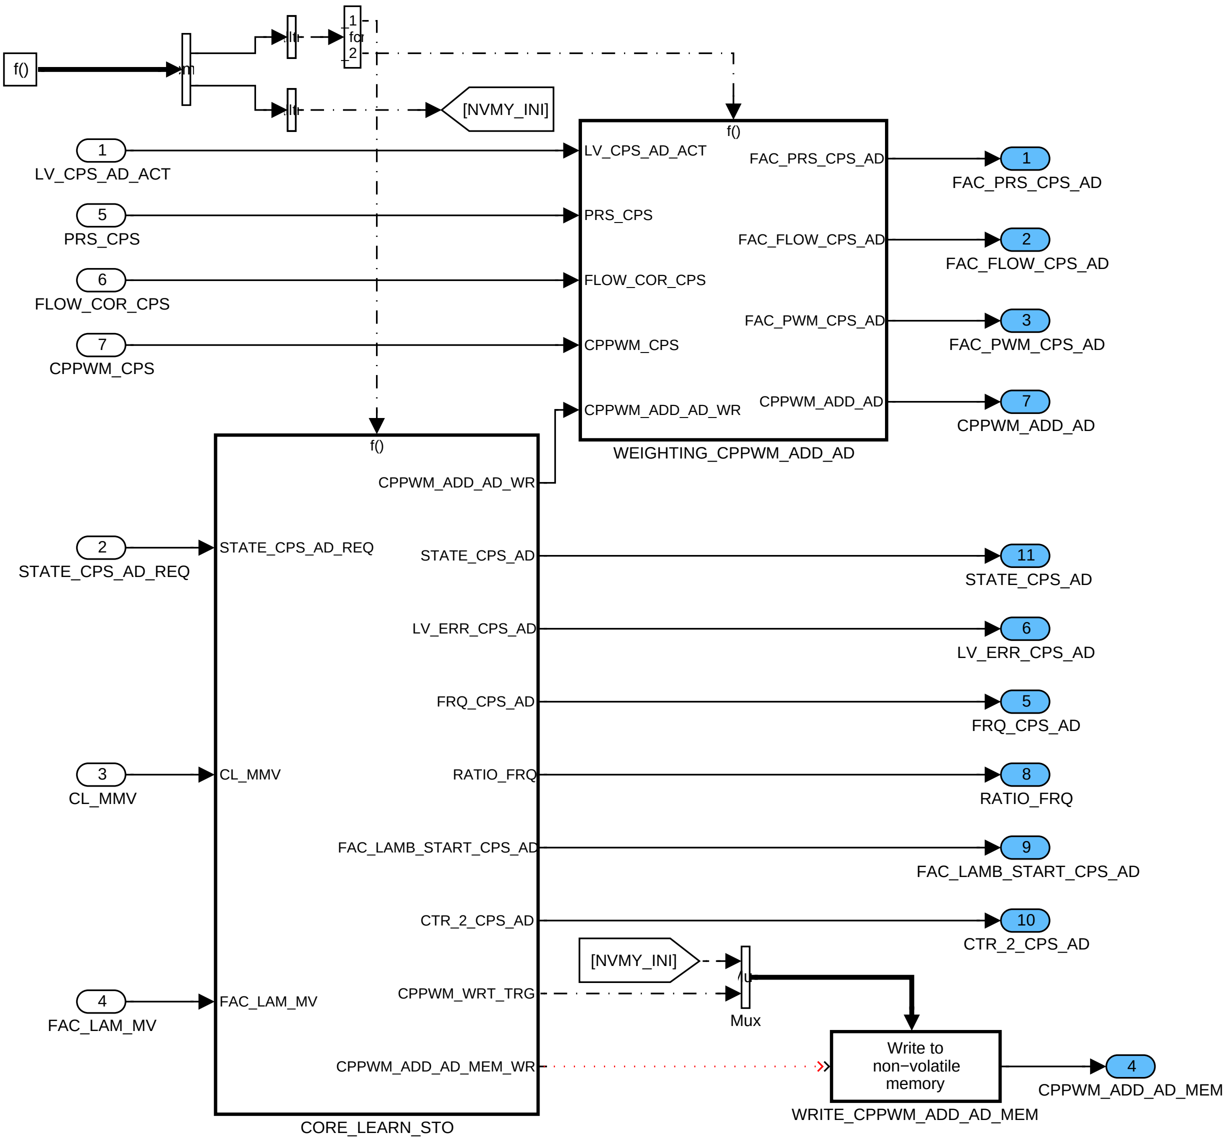

Figure 10 EVAC_CPS_AD/ LEARN_STO

<u>EVAC_CPS_AD/LEARN_STO/CORE_LEARN_STO</u>

This chart is the core of the CPS_AD-function. The states are:

Entry:

When entering the chart outputs are set to default values.

In case of a CPPWM_ADD_AD_MEM > maximum threshold (danger of engine disturbance) the memory value is set to minimum threshold.

CHECK_CONDITIONS:

This first substate is to prevent a new initialisation (state INIT) of the chart at the last trigger before it's state machine (APP_CDN) is leaving the state active. If PWM-adaptation is demanded by APP_CDN, the state CHECK_CONDITION will be left because of STATE_CPS_AD_REQ==2.

INIT_WAIT:

STATE_CPS_AD is set to 1 eporting that the function is in a wait-state (to allow manipulations during implementation using T_WAIT or provide some additional time for lambda recreation after any disturbance in the past).

CPPWM_ADD_AD_MEM_WR (output variable for CPPWM_ADD_AD_MEM in the non-volatile memory) is set to the last known value of CPPWM_ADD_AD_MEM.

calculations:

FAC_LAMB_START is the memory for the current FAC_LAMB-value to calculate a lambda-deviation caused by the function eliminating a constant lambda-offset.

To minimize the measuring error during STO-adaptation the adaptation has to be done at highest possible frequency to measure the highest possible fuel massflow. This is the frequency where the lambda-deviation caused by the opening-increment (CPPWM_INC_AD) is just small enough not to disturb the engine. CPPWM_INC_AD just as several other values are here adapted to the new frequency, using RATIO_FRQ which is calculated using the canister load CL_MMV.

Before entering INCREASE_PWM STATE_CPS is set to 7 reporting that PWM-adaptation is in process.

The two junctions are to avoid a calculated FRQ which is above C_FRQ_MAX_MEC_CPS.

IMPORTANT:

The code *{FRQ=abs(...* is paid to a stateflow-bug for *abs(* in stateflow is really *abs(fix(* and there aint't no *fix(* in stateflow. The correct mathematical expression here is *{FRQ=fix(...* to cut out the comma.

INCREASE_PWM:

Here the STO is detected. Frequent entering of the junction beside allows the monitoring of the lambda-deviation while opening the CPS. The time delay C_T_DLY_FAC_LAMB is to let the lambda-sensor detect the HC purged into the manifold.

If the function is interrupted (STATE_CPS_AD_REQ==4), the state ist left to go directly to CLOSE.

CLOSE:

The state CLOSE can be reached from INCREASE_PWM via regular ("success") or error-transition. Here the measured value is checked against calibration-thresholds. Each transition reports via STATE_CPS. The success-transition calculates the memorized STO (for FRQ_MIN_CPS_AD) and mixes it with the old one using C_CPPWM_AD_RATIO.

The CPS is closed using a ramp until STO is reached (assuming a massflow=0 at STO), then the CPS is completely closed.

WAIT_CLOSE:

This stat is to provide a time delay (time increment) for the closing ramp.

WAIT_LAMB_RGN:

The state gives the engine some time to „recover“ (C_T_WAIT_LAMB_RGN) from the lambda-deviation caused by the adaptation, i.e. to preserve a „calm“ idle-state for the next adaptation cycle.

WRITE_CPPWM_ADD_AD_MEM:

This block defines the write-to-non-volatile-memory of CPPWM_ADD_AD_MEM.

Due to change requirements the INTERNAL value CPPWM_ADD_AD has been deleted in this chart; there rests only the output CPPWM_ADD_AD_WR which is now replacing CPPWM_ADD_AD in the internal calculations.

At NVMY_INI, i.e. when the ECU is flashed with a new software, the adaptation value CPPWM_ADD_AD_MEM is initialized with the value C_CPPWM_ADD_AD_MEM_NVMY_INI and this value is written to the non-volatile memory. By this it can be assured that a reasonable start-to-open point is used for the purging cycles before the first CPS adaptation could be done.

For correct processing, the check of CPPWM_ADD_AD_MEM has been transferred from state CHECK_CONDITIONS to chart entry.

At NVMY_INI, i.e. when the ECU is flashed with a new software, the adaptation value CPPWM_ADD_AD_MEM is initialized with the value C_CPPWM_ADD_AD_MEM_NVMY_INI and this value is written to the non-volatile memory. By this it can be assured that a reasonable start-to-open point is used for the purging cycles before the first CPS adaptation could be done.

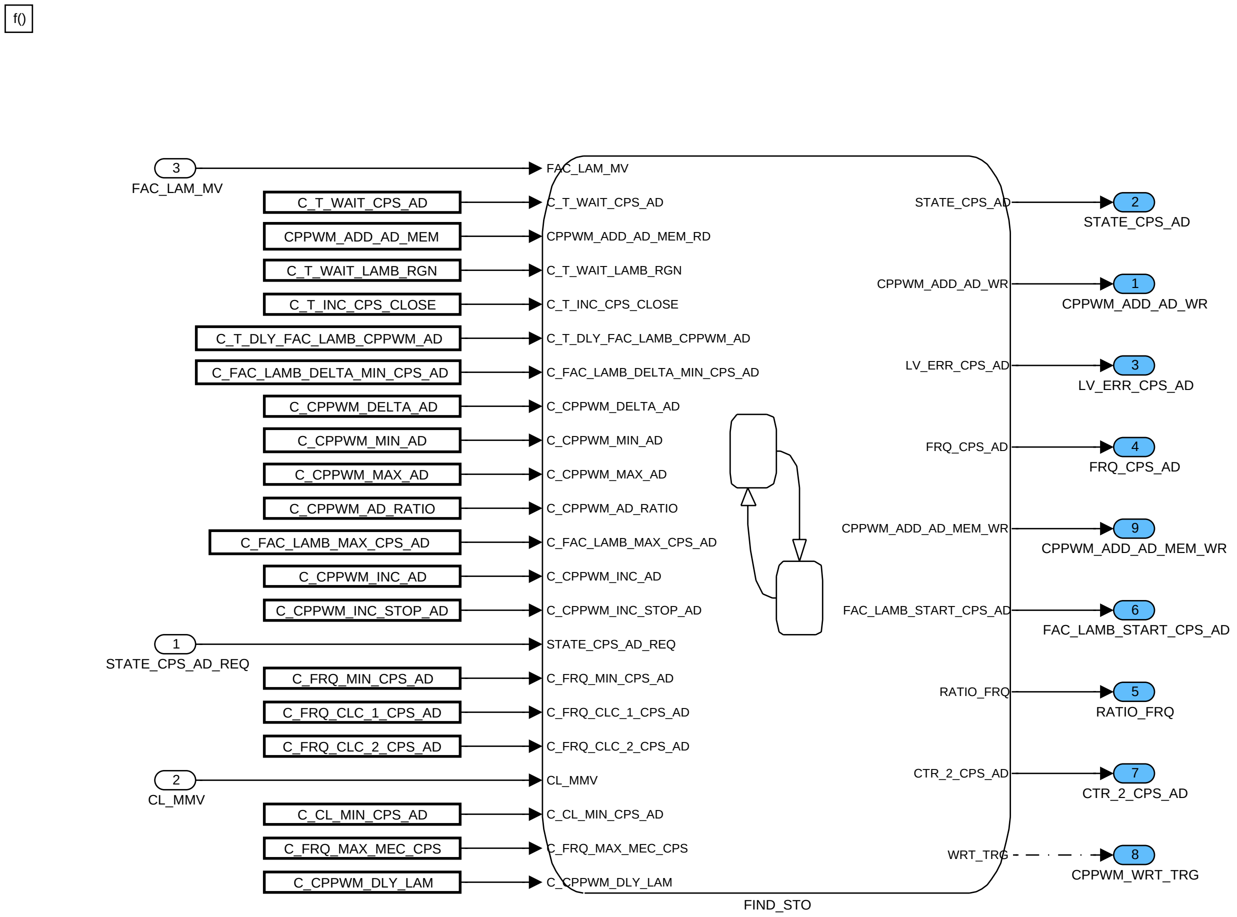

Figure 11 EVAC_CPS_AD/ LEARN_STO/ CORE_LEARN_STO

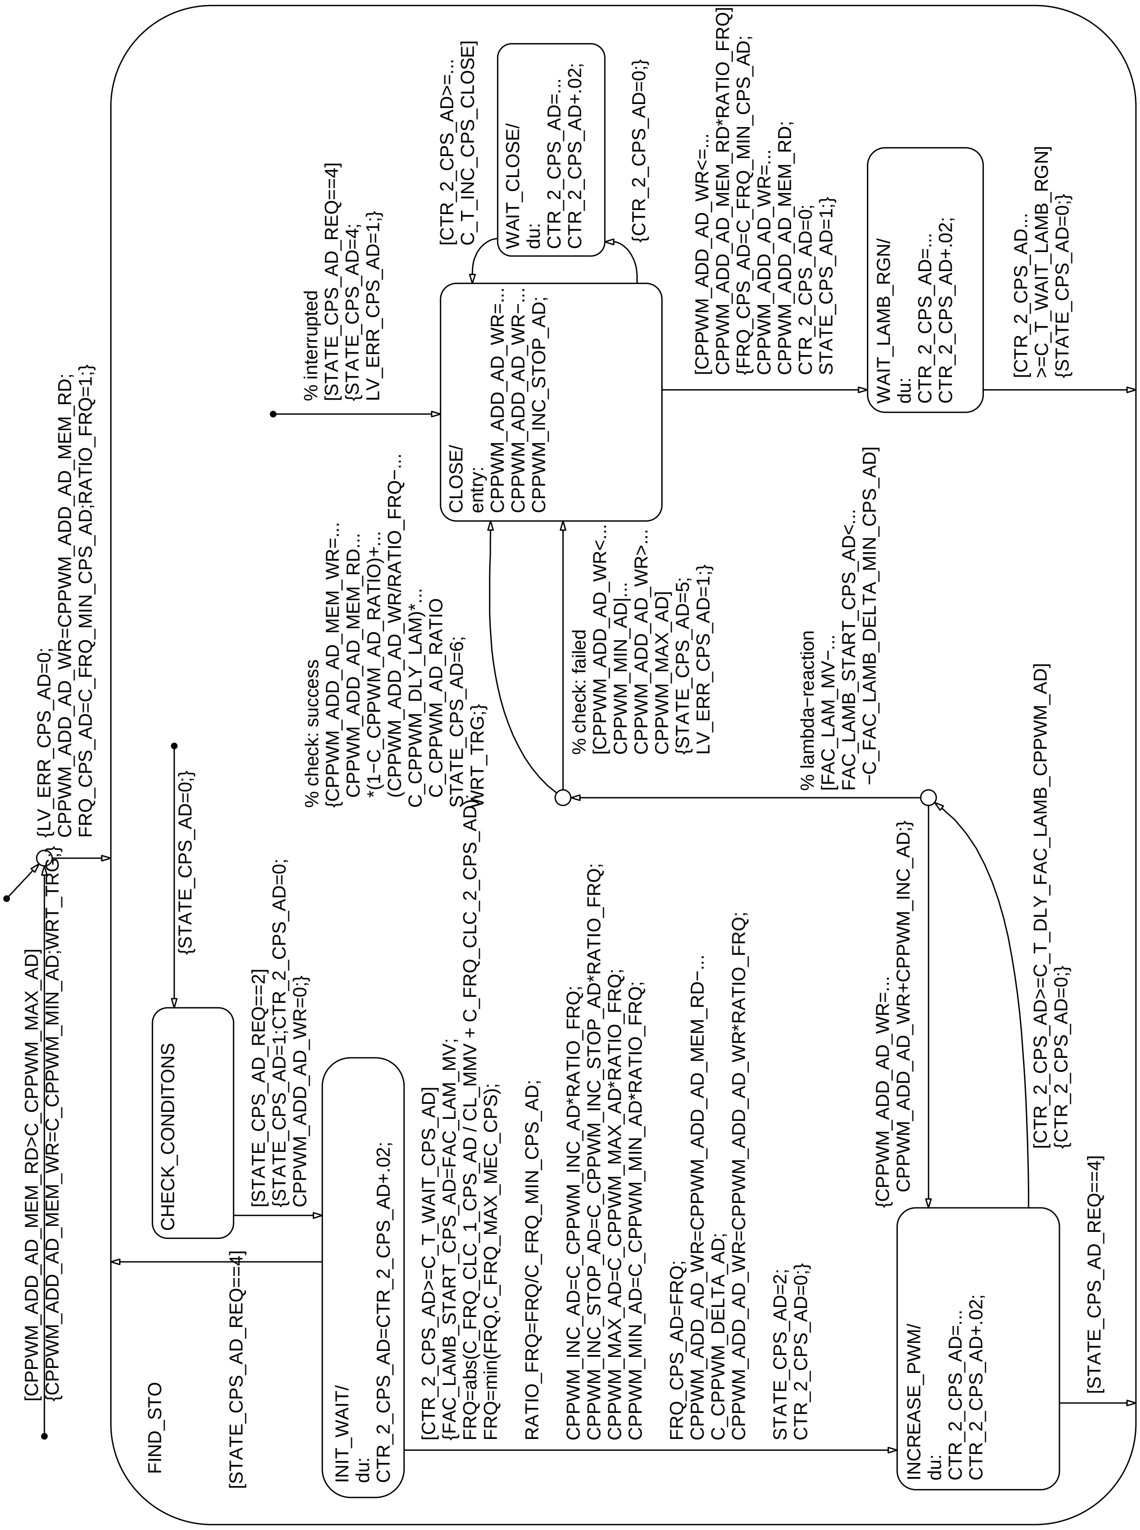

Figure 12 EVAC_CPS_AD/ LEARN_STO/ CORE_LEARN_STO/ FIND_STO

EVAC_CPS_AD/LEARN_STO/WEIGHTING_CPPWM_ADD_AD

This submodule does a weighting of the STO CPPWM_ADD_AD_WR to calculate the output CPPWM_ADD_AD. The PRS_CPS-weighting is to pay respect to a nonlinear behaviour of the CPS (to be defined by manufacturer, used for calibration of IP_CPPWM_OPEN_CPS). The FLOW- and PWM-weighting is to 'softly' eliminate the factor when reaching an operating state where STO is of almost no influence.

Then    LV_INH_DIAG_EL_CPS = 0
Else    LV_INH_DIAG_EL_CPS = 1
Endif
```

28.18 Calibration hints for EVAC control (gen)

28.18.1 Calibration interfering functions

Before to start the calibration work, it is absolute mandatory to have stable operating

- Lambda-Control and Injection Prec-Control
- Intake Manifold Model
- Idle Speed Control

Deficiencies in the calibration quality of the above mentioned may block the calibration/operation or demand a recalibration. Especially the Lambda Control and the Injection Pre-Control must be at a mature standard (Lambda Control output < 5% in stationary engine conditions).

28.18.2 Main operating situations

NO_PURGE

During this mode, CPS valve is closed

This mode is used

- when conditions to authorize evap control are not fulfilled (TCO, ...)
- while the lambda adaptation phase is ongoing
- in case of failures (CPS valve, ...)
- in case of OBD2 diagnosis request (catalyst check...)
- in case of evaporative system monitoring active

MIN_PURGE

The MIN_PURGE or open loop operation operation is used when the charcoal canister has to be purged even if its load cannot be learned.

The conditions are:

- Vehicle is not equipped with A/F control
- A/F regulation component failures (lambda sensor...)
- Transient driving conditions. In this case, the purge flow is adjusted to have a maximum of 5% A/F ratio deviation with a saturated canister.

NORMAL_PURGE / closed loop operation

The normal operation is used when the determination of the canister load is finished.

Purge flow is adjusted to have the maximum of A/F ratio deviation with a saturated canister.

The NORMAL_PURGE operation is proceeded in the following sequences:

RAMP_OPEN → MAX_PURGE → RAMP_CLOSE
RAMP_OPEN_FAST → MAX_PURGE → RAMP_CLOSE

RAMP_OPEN

At first start of the NORMAL_PURGE the canister load is unknown. So, the purge valve is opened slowly using a ramp (a high deviation of the lambda control shall be prevented). During this learning the fuel injection time is corrected to avoid emission and driveability problems. The Canister Load is determined by the fuel $_{purge}$ / flow $_{purge}$ ratio.

The RAMP_OPEN operation is finished when :

- CL is learned and stable or
- The canister fuel flow (MFF_CP) is greater than a threshold

RAMP_OPEN_FAST

When the canister load is considered as known, indicated by beeing within a certatin time interval since last MAX_PURGE, the closed loop operation may start with a faster learning phase / ramp. This RAMP_OPEN_FAST operation is finished when :

- The purge flow greater than a threshold
- The canister fuel flow (MFF_CP) is greater than a threshold.

MAX_PURGE

During MAX_PURGE operation the CPS valve is controlled by the canister load, thus a constant fuel ratio (fuel from cps / total fuel) is applied and the valve opening is controlled to keep this constant fuel ratio by adjusting the total purge flow.

The target is to reach high efficiency purging. When the CL is low the purge valve opening will be increased to find the maximum limit of canister fuel flow.

RAMP_CLOSE

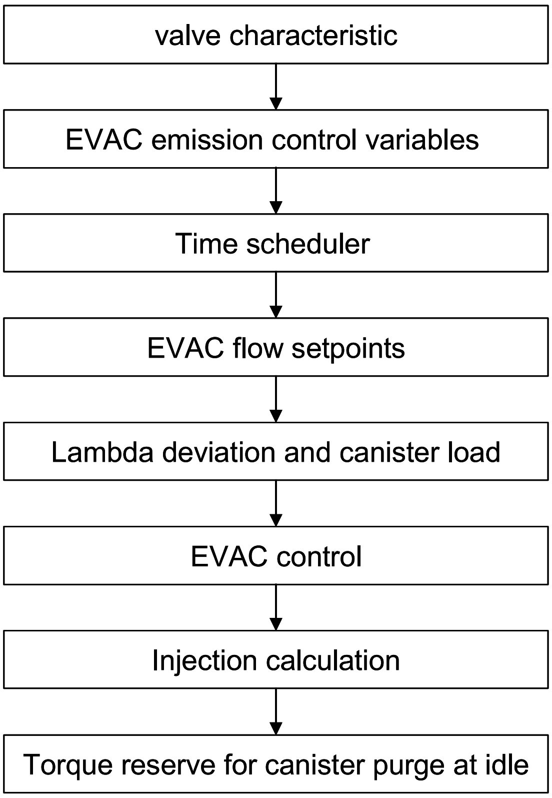
When the purge time is elapsed the purge flow is decreased via a ramp in RAMP_CLOSE operation.

28.18.3 Syntax

CalibrationDataName	description
	[defaultValue]

28.18.4 Calibration flowchart

The following flowchart shows the order to calibrate the EVAC functionalities. A continuous refining in this order is mandatory to achieve best results.



28.18.5 Valve characteristic

IP_CPPWM	CPS valve characteristic This table allows to define the valve opening (CPPWM) from two physical parameters such as the purge flow setpoint (FLOW_COR_SP_CPS) and the upstream/downstream differential pressure applied (PRS_CPS). The calibration values are gained from the flowbench measurements. An excel file IP_CPPWM.XLS allows to prepare easily the flowbench results (flow = f [pressure, valve opening]) to fill up IP_CPPWM (valve opening = f [flow, pressure]). Breakpoints recommended values for FLOW_COR_SP_CPS axe: • The breakpoint values allow to avoid to spent to much time at the beginning of Ramp Open mode (small opening). • The two first breakpoints have to following rule: • The first breakpoint will be zero (0 kg/h). The entire raw (valve opening) will be filled up with = 0 % whatever the differential pressure PRS_DIF_CPS The second breakpoint will be a small purge flow value like 0.05 kg/h. The raw (valve opening) will be filled out with the “start to open” beginning of flow depending on the differential pressure PRS_DIF_CPS. [-]
IP_CPPWM_VB_ADD_1	Additive VB correction for CPPWM at frq 1 [-]
IP_CPPWM_VB_ADD_2	Additive VB correction for CPPWM at frq 2 This additive battery correction is applied to adapt the valve opening due to battery voltage variation. The value is depending on the frequency selected.
IP_CPPWM_VB_FAC_1/2	Multiplicative VB correction for CPPWM at frequency 1 or 2. This factor correction is applied to adapt the valve opening due to battery voltage variation. The value is depending on the type of purge

	valve selected. [1]
IP_CPPWM_VB_FAC_PRS_CPS_1/2	Multiplicative VB correction for CPPWM at frequency 1 or 2. This factor corrects the "Additive VB correction for CPPWM at frq1" due to pressure CPS changes. [-]

28.18.5.1 Frequency management

C_N_FRQ_1_CPS	as required or specified
C_N_FRQ_2_CPS	
C_CPPWM_FRQ_1_CPS	
C_CPPWM_FRQ_2_CPS	

28.18.5.2 Thresholds on engine speed and CPPWM to shift CPS frequency.

C_N_FRQ_HYS_CPS **C_CPPWM_FRQ_HYS_CPS**	Hysteresis thresholds on engine speed and CPPWM to shift CPS frequency. These parameters allow to get stable frequency switching. The hysteresis value should be twice the engine speed and opening valve fluctuations. [-]
C_CPPWM_FRQ_1 **C_CPPWM_FRQ_2**	First CPS output frequency These calibrations will define the valve frequency value applied depending on engine speed and purge valve opening. The selection of the frequency allows to control the purge flow with a minimum of random variation. The intake manifold back pressure due to engine valves activities could disturb the pulsed purge flow. Then the purge fuel control becomes out of the target. [10]
IP_CPPWM_COR_FRQ	PWM correction following frequency value This factor correction is applied on the purge valve opening defined for the reference frequency control (FREQ1). From these measurements calculate the ratio between the purge valve opening at

the different frequencies and for the same conditions (purge flow, pressure). Calculate for each opening value the best ratio to satisfy most of cases.

[1]

28.18.6 EVAC emission control variables (403H)

28.18.6.1 Activation, engine speed limit

C_N_MAX_CP	Maximum engine speed value for canister purge calculations (CPU load reduction)
C_N_HYS_MAX_CP	Hysteresis value for canister purge calculations (CPU load reduction)
LC_CP_DYW_CLC_MAX_ENA	can be set to 0 if further CPU load reduction at high engine speed is needed

C_MAF_DYW_CP
C_N_DYW_CP
C_FAC_LAM_CP_DYW
C_DLY_N_MAF_DYW_CP
C_TQI_DYW_CP
C_N_2_DYW_CP
C_LAMB_SP_S_DYW_CP
C_LAMB_SP_S_DYW_CP
C_LAMB_SP_S_DYW_CP
C_LAMB_SP_S_DYW_CP
C_DLY_N_TQI_DYW_CP_1
C_DLY_N_TQI_DYW_CP_2

Dynamic window constants defining stable engine conditions for canister purge function during homogeneous combustion.

When stable engine conditions are reached, a timer is started for C_DLY_N_MAF_DYW_CP (hom.) rsp. C_DLY_N_TQI_DYW_CP (strat., hom.lean)

When the delay is elapsed the CL_MMV calculation is authorized.

The time delay allows the lambda controller to be centered again.

These calibrations have to be refined depending on the standard driving cycle used. The transient time duration will define the values.

Method:

- engine bench or Chassis Dyno
- stable engine conditions
- canister purge function not active
- Choose 6 engine load points, give preference to the stable phases of the emission cycle.
- For each engine load measure the deviation and variation(MIN and MAX) of the engine speed (N) and mass air flow value (MAF) (hom.) rsp. torque set

point value (TQI_SP_S) (lean).

- The dynamic window will be define using the formula [3 * (max-min) / 2]
- The division by 2 is the result of the specification description where the dynamic window is define as half window.

The time delay to set the stable condition information is tune on the emission cycle in order to filter the lambda deviations during transients. The condition engine stable must be active when lambda deviations (without purge) are elapsed.

C_CRLC_MAF_DYW_CP	Filter constant for limited dynamics calculation on MAF [0,1]
C_CRLC_N_DYW_CP	Filter constant for limited dynamics calculation on engine speed [0,1]
C_CRLC_LAM_DYW_CP	Filter constant for limited dynamics calculation on lambda controller controller in non-normal purge [0,1]
C_CRLC_LAMB_SP_S_DYW_CP	Filter constant for limited dynamics calculation on lambda setpoint in stratified [0,1]
C_CRLC_TQI_DYW_CP_1 **C_CRLC_TQI_DYW_CP_2**	Filter constant for limited dynamics calculation on tqi_sp in stratified, _2 for RAMP_OPEN_FAST and MAX_PURGE, _1 for all other states. [0,1]
C_CRLC_LSMB_SP_S_DYW_CP	Filter constant for limited dynamics calculation on lambda setpoint in stratified [0,1]
IP_TQI_CP_BOL	Minimum torque limit for activation of the RAMP_OPEN operation (stratified) [-]
IP_TQI_CP_TOL	Maximum torque limit for activation of the RAMP_OPEN operation (stratified [-]

C_T_DLY_CAT_PURGE_CP	Stabilisation time after catalyst regeneration

28.18.6.2 Preselection of the canister purge state

C_STATE_CDN_CP_MAN	manual selection of STATE_CDN_CP
C_PRS_MAX_CPS	[Barometric pressure – Manifold intake pressure] limit of the difference of the pressure applied for activation of the canister purge One condition of NO_PURGE is AMP – MAP < C_PRS_MAX_CPS. The value C_PRS_MAX_CPS = 0 enables the MAX_PURGE mode when MAP > AMP (case of supercharger engine) [0 mb]
C_PRS_MAX_CPS_2	To prevent backflow from intake manifold in the acf with charged engines, this threshold leads to a direct shut of the canister purge valve (no ramp) [AMP – MAP] < C_PRS_MAX_2_CPS

	disables close loop operation [10 mb]
C_STATE_WIN_CP_NOT	state to be forced if engine operation outside CP window; selection of "NONE" leads to an exiting of RAMP_OPEN, but not of RAMP_OPEN_FAST or MAX_PURGE
C_STATE_LAM_LIM_CP	state to be forced if lambda control limitation reached .
LC_STATE_CDN_CP_MAN	switch to activate test mode // manual setting of STATE_CDN_CP
C_TIA_MIN_CP	Minimum intake air temperature to enable canister purge function at idle. One of the condition of NO_PURGE is TIA < C_TIA_MIN_CP. Freezing conditions or acoustic problems can appear at idle. This value has to be checked during cold condition tests. The freezing conditions are depending on the location of the valve mounting. The acoustic problems are depending on the valve mounting support. [5° C]
C_LAMB_SP_S **C_LAMB_SP_S_CP_TOL** **C_LAMB_SP_S_CP_BOL**	Bottom and top limits on the LAMB_SP_S value [1,5] [2,5]
C_FAC_LAM_THD	Upper threshold for lamgda control output gradient If the lambda gradient exceeds the threshold conditions for CL_MDL or MinP are fulfilled. [-]
LC_FAC_LAM_GRD	Switch for enabling lambda control output gradient check [0]
LC_CP_INH_MAN	Switch for deactivation of canister purge and force NO_PURGE [0]
LC_PRS_CPS_EXT	switch to use externally calculated value for PRS_CPS [0]
LC_CP_CLL_INH_MAN	switch for deactivation of closed loop canister purge ("normal purge")

	[0]
C_CP_CLL_S_INH	Selection of MIN_PURGE during stratified mode (=1) [0]
LC_CP_CAT_PURGE_OPL **LC_CP_CAT_PURGE_OFF**	Defines the behaviour of the system during NOx regeneration of the catalyst and a time delay after that. The canister purge can be set configurable to off (LC_CP_CAT_PURGE_OFF = 1, OPL =0), open loop (LC_CP_CAT_PURGE_OPL = 1, OFF = 0) or closed loop (both = 0).

28.18.7 Time scheduler (903P)

C_STATE_MAN_SDL_CP	selection of manual scheduling mode [AUTOMATIC]
NC_NR_CP_LAM_AD **ID_T_SET_T_AST_LAM_CP** **LDP_T_AST_SET_ID_T_AST**	Set NC_NR_CP_LAM_AD equal to the total sum of fixed time slices (lambda adaptation and caniser purge) plus one for the dynamic time slices. Fill in LDP_T_AST_SET_ID_T_AST the start time of the fixed time slices and the last value for the dynamic time slices. The first value has to be zero. In the ID_T_SET_ID_T_AST the corresponding fixed (CP_FIXED or LAM_FIXED) states are filled in. Fill the last element with DYN_SDL to end the fixed time slices.
C_CL_MMV_T_BOL **C_CL_MMV_T_TOL** **C_T_DI_CP**	When an empty canister is detected at the end of the learning modes RAMP_OPEN or RAMP_OPEN_FAST (empty canister meaning CL_MMV < C_CL_MMV_T_BOL), (and C_STATE_MOD_SEL_CP="MAX_PURGE") the evaporative system control is stopped for the delay C_T_DI_CP. If the canister is detected full CL_MMV>C_CL_MMV_T_TOL the time control gives the priority to the CP time request. In case of middle load the time control check the request of lambda adaptation and canister purge. This value is checked during hot trip (worst case conditions: canister full and vapor generation) and canister purge cycle.

The goal is to optimize the lambda adaptation accuracy and the purge efficiency (no fuel vapor escape to the atmosphere).

C_T_MFF_AD_MAX

Initialisation time for dynamic lambda adaptation time slice. The timer counts as well while waiting for the lambda adaptation conditions to be met (in this period, canister purge may still be enabled). The lambda adaptation phase may be left if the feedback flag from lambda adaptation is set.

[240 s]

C_T_2_CP

Initialisation time for dynamic canister purge time slice, will be corrected at the end of RAMP_OPEN.

This value must be checked on emission cycle.

[240 s]

IP_T_MAX_CP

Dynamic canister purge time depending on canister load. At the end of RAMP_OPEN or RAMP_OPEN_FAST the purge time duration is modified to fit the canister load learnt.

IP_T_MAX_CP < C_T_2_CP.

This calibration is defined by measuring CL decrease on standard driving cycle (FTP, EURO 2000...) with worst case condition like ambient temperature... For different CL adjust the purging time duration to avoid canister purge breakthrough.

CL_MMV	[-]	0	0	0	0	1	1
IP_T_MAX_CP	[s]	60	90	200	230	260	280

C_CL_MMV_T_WAIT_LAM

CL threshold to switch off CP during WAIT_LAM if CL_MMV is below the threshold

[0,6]

C_TCO_COLD_DYN_T_CTL_CP

C_TCO_DYN_T_CTL

C_T_TCO_ST_STAT_SDL_CP

If the coolant temperature is below the first threshold at the start of a driving cycle, dynamic time slices are chosen. Between both thresholds, the fixed time slices are applied. Above the second threshold, one single fixed time slice for purging is chosen. The time for the fixed slice is given by C_T_TCO_ST_STAT_SDL_CP.

LC_CL_CP_DYN_END_ENA

Switch to enable end of CP phase when reaching low canister load (CP_DYN ->

	WAIT_LAM) [0]
LC_LAM_LIM_AD_ENA	Switch to enable forced lambda adaptation during canister purge [1]
LC_MFF_AD_ENA_PAS	Switch to enable lambda adaptation while cp passive [1]
LC_SDL_LAM_AD_CDN_OFF	Switch to ignore LV_LAM_AD_CDN (adapt. ongoing) for end of lambda adapt. time slice calculation; lambda adapt. will be interrupted if timer exceeds. [0]
LC_CYL_BAL_LAM_AD_INH_CP	Switch to deactivate the cylinder balancing manager influence on enabling lambda adaptation

28.18.8 EVAC flow setpoints (9076)

IP_FLOW_CPS_HOM

IP_FLOW_CPS_HOM_AFL

These values are the maximum canister purge flow in MIN_PURGE mode and homogeneous lambda 1 rsp. hom. lean combustion.

This ratio will limit the purge valve opening because no fuel compensation is done in this mode.

ΔLambda CP is the maximum lambda control deviation allowed to avoid driveability trouble (acceleration) when the lambda controller is not centered. This maximum deviation is obtained with charcoal canister full loaded. The recommended value of ΔLambda CP is about 5-6 % maximum.

From this maximum deviation the maximum purge flow can be evaluated for each engine load :

- Canister Load = (Fuel Mass CP) / Air Flow CP
- Air Flow CP = (Air Flow cylinder * ΔLambda_control CP) / $K_{stochiometric}$ * CLmax

We know the maximum Canister Load ≈ 2

and the usual $K_{stochiometric}$=14,57

- Air Flow CP= Air Flow cylinder * 0,00206

Nevertheless, we have to consider that for engine conditions like “High Load” and charcoal full loaded canister, the upstream/downstream differential pressure will be too low to generate sufficient purge flow then the lambda controller deviation will be also too low.

Method:

For each engine condition (N,MAF):

- Consider the maximum flow the purge valve can provide: IP_FLOW_CPS
- **if** IP_FLOW_CPS__PRS_CPS ≥ Air Flow cylinder * 0.00206

  then fill up IP_FLOW_CPS_HOM with Air $Flow_{cylinder}$ * 0.00206

  else fill up IP_FLOW_CPS_HOM with IP_FLOW_CPS

  endif

IP_FLOW_CPS_S

flow setpoint for MIN_PURGE / stratified operation

Method:

For stratified engine condition (N,MAF):

- Engine bench
- Bottle of gas (butane)
- Perform different opening of the valve with a canister full loaded and measure the impact on the torque.
- The calibration value will be the one in the limit of the driveability (ex 5Nm additional torque).
- The map is tuned using the canister purge valve flow FLOW_CPS

Only available in DI version

IP_RATIO_FUEL_MAX_CP_HOM

IP_RATIO_FUEL_MAX_CP_HOM_2

Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous stoiciometric operation

This map allows to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE modes.

These calibrations define the maximum purge fuel quantity regarding the fuel engine needs.

To avoid driveability troubles the current ratio limitation between purge fuel and total engine fuel is 25%.

- Fuel purge flow = In system air flow / K $_{\text{stochiometric}}$ * X% **{1}**
- Fuel purge = Total cylinder flow * FLOW_CPS * CL $_{\text{max}}$ **{2}**
- X% is the fuel purge/engine total fuel ratio (given by engine bench)
- FLOW_CPS is defined by IP_FLOW_MAX_CPS
- Cl_{max} = 0.7 (maximum value with butane)

Method:

- Calculate for each engine load defined by [MAF, N] the values **{1} and {2}**
- Final calibration value for each engine load defined by [MAF, N] = MIN [**{1}, {2}**]
- X%: start with 20% and following the hot trip or SHED results the percentage could be increase (less than 35%).

IP_RATIO_FUEL_MAX_CP_HOM_AFL

Only available in DI version

Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous lean operation

These calibrations allow to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE modes.

These calibrations define the maximum purge fuel quantity regarding the fuel engine needs.

To avoid driveability troubles the current ratio limitation between purge fuel and total engine fuel is 25%.

- Fuel purge flow = In system air flow / K $_{\text{stochiometric}}$ *lambda* X% **{1}**
- Fuel purge = Total cylinder flow * FLOW_CPS * CL $_{\text{max}}$ **{2}**

- X% is the fuel purge/engine total fuel ratio
- FLOW_CPS is defined by IP_ FLOW_MAX_CPS
- Cl$_{\text{max}}$ = 0.7 (maximum value with butane)

Method:

- Calculate for each engine load defined by [MAF, N] the values **{1} and {2}**
- Final calibration value for each engine load defined by [MAF, N] = MIN [**{1}, {2}**]
- X%: start with 10% and following the hot trip or SHED results the percentage could be increased.
- If the lean burn combustion is not used the map is tuned to 0.

IP_RATIO_FUEL_MAX_CP_S

Only available in DI version

Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous stratified operation

These calibrations allow to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used RAMP_OPEN, RAMP_OPEN_FAST

	and MAX_PURGE modes. These calibrations define the maximum purge fuel quantity regarding the fuel engine needs. To avoid driveability troubles the ratio is limited to take into account the torque. X%: start with 10% and following the hot trip or SHED results the percentage could be increase. If the stratified MAX_PURGE is not used the map is tuned to 0. [0,25]
IP_RATIO_FUEL_MAX_CP_COR	This table is corrective factor acting on MFF_KGH_MAX_CP calculation. The aim for tuning is to allow activation of the purge function at a lower TCO. In this case (that means at low TCO), IP_RATIO_FUEL_MAX_CP_COR allow to less open the CPS. This correction has been added in case of long warm up phase, to win purge efficiency by opening the CPS in advance.
C_CL_MAX_MIN_PURGE	on this worst case CL is based the base calibration of MIN_PURGE flow setpoint for intelligent MinPurge [1]
C_FAC_FLOW_SP_MIN_PURGE_MAX	maximum correction of MIN_PURGE flow setpoint for intelligent MinPurge [1]
IP_FAC_FLOW_SP_MIN_PURGE	Weighting factor for the CL deviation from the worstcase CL The flow setpoint can be corrected depending on the last learned CL_MMV value. [-]
IP_FLOW_CPS	FLOW_CPS for fully opened CPS (CPPWM=100%) Maximum flow at full opend depending on the preasure at the CPS. [-]
IP_FLOW_MAX_CPS	Flow setpoint for MAX_PURGE
IP_FLOW_MAX_CPS_2	These calibrations define the maximum purge flow regarding the air engine needs.

Calibrate together with IP_RATO_FUEL_MAX_CP_HOM

[-]

LC_FAC_FLOW_SP_MIN_PURGE

Switch to activate / deactiate "intelligent MIN_PURGE"

[0]

C_MFF_MIN_CP

Minimum injector fuel mass.

28.18.9 Lambda deviation and canister load (9077)

28.18.9.1 Filter constants

IP_CRLC_FAC_LAM_MV_MMV_CP_CLL

correlation constant for FAC_LAM_MV_MMV_CP calculation in case of Purge in closed loop

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_CRLC_FAC_LAM_MV_MMV_CP_CLL	[-]	0,500	0,500	0,500	0,500	0,500	0,500

IP_CRLC_FAC_LAM_MV_MMV_CP_OPL

correlation constant for FAC_LAM_MV_MMV_CP calculation in case of Purge in open loop

MAF_CYL	[kg/h]	12	45	70	140	250	50
IP_CRLC_FAC_LAM_MV_MMV_CP_OPL	[-]	0,250	0,250	0,250	0,250	0,250	0,2

IP_CRLC_LAMB_LPF_CP

Correlation constant for LAMB_MMV_CP calculation

IP_CRLC_MMV_CP

Correlation constant for LAMB_MMV_CP calculation

IP_CL_CRLC_RAMP_OPEN

CL_MMV filter coefficient during RAMP_OPEN_FAST

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_CL_CRLC_RAMP_OPEN	[-]	0,300	0,300	0,400	0,450	0,480	0,500

IP_CL_CRLC_OPEN_FAST

When the RAMP_OPEN_FAST is ongoing the Lambda controller has to be stable (no more than 5% of deviation)

This calibration result is also depending on ramp opening value during this mode.

IP_CL_CRLC_INI

Initialization value for correlation factor value

CL_MMV	[-]	0	0	0
IP_CL_CRLC_INI	[-]	0,150	0,150	0,150

IP_CL_CRLC

This calibration is the CL_MMV filter coefficient during MAX_PURGE mode. The values will define this filter coefficient will be limited by two borders. The high one is defined by the Canister load decrease in stable engine conditions, and the low one is defined by the normal acceleration/deceleration time duration

case A, canister load decreases in stable engine conditions

Method:

- IP_CL_CRLC has to be tuned to follow the canister load (CL) decrease.
- During MAX_PURGE, CL decreases and the canister weight loss follow the same law.
- A wrong IP_CL_CRLC value could result in a meaningful difference between the average CL value (CL_MMV is used for the calculation of injection compensation) and CL.

Test conditions:

- Different engine loads in stable conditions
- Charcoal canister full loaded (butane or fuel following legal procedure).
- C_T_1_CP, C_T_2_CP and IP_T_MAX_CP_CL_MMV set to a high value to keep MAX_PURGE mode until the canister becomes empty.
- IP_CL_CRLC pre-tuned to 0,005 (for the whole mapping).
- recording of CL
- if canister is loaded with butane: CL_MAX ≈ 0.63
- if canister is loaded with fuel: CL_MAX ≈ 0.7....2

case B, normal acceleration/deceleration time duration

During transient mode the Lambda controller varies. The time duration of the lambda controller is shorter than the one during the charcoal canister weight lost. This lambda controller variation has not to be taken such as a loss of canister load.

- Different engine load in stable conditions
- Purge deactivated
- start with normal acceleration/deceleration
- Measure the time spent (T2) by the lambda controller to reach a stable value {2}

Calculate the values (CL max * recurrence) / T2 s {2}

The final calibration value will be: {2} < IP_CL_CRLC < {1a, 1c}

Usual approach:

Part and full load

IF for MAF_CYL ≥ 90 kg/h the value calculated in {1a} > 0.005 then fill up the mapping table with 0,005

And for MAF_CYL < 90 kg/h fill up the mapping table with 0.005 * value calculated in {1b}

Idle speed

At idle the average value of the lambda controller (TI_LAM_MMV) varies. Then this variation generate another CL variation. For MAF_CYL breakpoint at idle and charcoal canister empty refine the coefficient filter to prevent these CL, CL_MMV oscillations.

IP_NR_STEP_CL

Number of step to change of correlation factor value

This is a filter-filter-constant map, it aims in filtering the transition from the IP_CL_CRLC_INI map to the standard-MAX_PURGE-map IP_CL_CRLC.

C_CL_FAC_LAM_DIF_MIN
C_CL_FAC_LAM_DIF_MAX

Lower and upper limits on FAC_LAM_DIF_CP variation

If these limits are exceeded in MAX_PURGE, the CL filter constant is taken from the faster map

	IP_CL_CRLC_INI, same principle as entering MAX_PURGE.
LC_CL_CLC_INH_FAC_LAM_DIF	Switch to freeze CL calculation in case of FAC_LAM_DIF_CP exceeding the above mentioned thresholds. The CL calculation is frozen until the CL filter constant reaches again its final value to prevent interdependencies between CL and CL_MMV calculation. This functionality should be used if oscillations occur (e.g. due to slow lambda controller) when using the faster CL filter constant.
C_PRS_MAX_2_CPS/_1	Pressure difference limit (environment-intake manifold) for CL_MMV calculation depending on STATE_OPM_ENG_CP [10 mb]
C_CRLC_FAC_LAM_GRD	Correlation constant for lambda gradient For calculation of the value FAC_LAM_GRD_MMV [-]
C_VS_MIN_LAMB_AFS	The value has to be set to a vehicle speed to detect highway driving.
C_T_LAMB_AFS_T_AST	Time between two highway driving phases to keep the homogeneous request.
C_T_LAMB_AFS_T_AST_VLD_CP	Maximum valid time for homogeneous combustion mode request in canister purge open loop calculation. The time has to be bigger then C_T_LAMB_AFS_T_AST.
C_T_LAMB_AFS_AMP_VLD_CP	Maximum valid time for homogenious combustion mode request in canister purge open loop calculation.

28.18.9.2 CL calculation

C_FLOW_MIN_CPS	Purge flow threshold to authorize CL_MMV calculation in RAMP_OPEN, RAMP_OPEN_FAST and MAX purge. if FLOW_CPS is lower than this calibration the last value of CL_MMV is kept. During the purge valve opening/closing, the flow FLOW_CPS takes small values. Small flow values can produce an incorrect purge flow and an incorrect canister load learning. This difference results in values of CL that do not correspond to a physical

reality.

Calculate the purge flow obtained by 1 bit of valve opening.

Method: Biggest purge flow (100% opening P). Divide this maximum flow by the format of the valve opening□and high (CPPWM) in case of byte the divisor will be 255. The calibration will be the value regarding 2 bits.

[0,04 kg/h]

C_CL_ST_CP

Initialization value for charcoal canister load at the beginning of RAM_OPEN mode.

CL_MMV and CL use the same initialization value

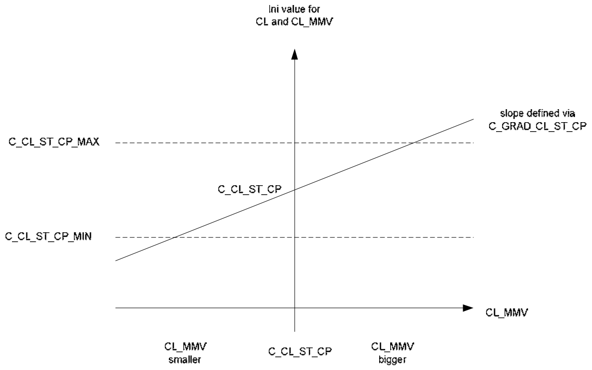
The calibrated value is about the half value of the maximum CL value encountered when the charcoal canister is loaded with butane. This value allows to reduce the work of the CL filter and to get too much deviation between CL and CL_MMV.

[0,3]

C_CL_ST_MIN_CP
C_CL_ST_MAX_CP
C_CL_ST_FAC_CP

At start of RO at stratified engine the initialization of CL and CL_MMV can be influenced with the last known CL_MMV in the limits of C_CL_ST_MIN_CP and C_CL_ST_MAX_CP. The influence of the last known canister load can be weighted with C_CL_ST_FAC_CP.

The values have to be calibrated in the way that at maximum deviation of real canister load to estimated canister load CL_MMV does not cause drivability influences.



C_CL_MAX_CP

The canister load is the fuel concentration of the A/F mixture that comes from the canister through the CPS valve.

	The mass of fuel (vapors) which is coming from the canister depends on: • the type of fuel used • the system design (pressure drop...) Charcoal canister loaded with butane • The measurements should lead to the theoretical value CL max = 0,7 Charcoal canister loaded with gasoline • The fuel from the canister is in the vapor state but the mass fuel flow is higher than the butane. This mass is depending on the type of fuel used and the in-use conditions. The C_CL_MAX_CP value equal to 2 could satisfied most of applications. Check this value during refueling in hot trip conditions (high vapor generation that can lead to a full and unstable canister load)
C_FAC_LAM_DIF_MAX_CP	Maximum Lambda controller deviation threshold during learning mode. This calibration is defined by the maximum lambda controller deviation to get no driveability trouble during accelerations while the RAMP_OPEN mode is ongoing. [5%]
C_FAC_LAM_DIF_CP_AS	Application system value to apply a lambda deviation
LC_LAM_CBK_CPS	Lambda controller selection (0 -> bank 0 , 1 -> bank1)
C_RAF_CLC_CP	Stochiometric ratio of usual fuel. This value has to be refined regarding the type of fuel defined by the application. [14,57]
LC_CL_FIL_INI_TRA_DEAC_CLL	Correlation factor calculation in case of NO_PURGE or MIN_PURGE → MAX_PURGE transition
C_CL_DYW_MAX_CP	This calibration aims to prevent wrong fuel correction when too fast variation of CL happens. This calibration is to get fuel correction robustness. In case where too high CL variation happen the MIN_MODE is forced. In RAMP_OPEN, RAMP_OPEN_FAST,

	MAX_PURGE modes [CL n-1 – CLn] is calculated. *if [CL n-1 – CLn] > C_CL_DYW_MAX_CP* *then MIN_MODE is forced*
C_CPPWM_MIN_CL	Minimum valve pwm signal to enable CL calcualation [-]
C_DEC_FAC_LAM_RAMP_OPEN	Decrement for FAC_LAM-ramp at end of RAMP_OPEN Fade out of the CRLC_FAC_LAM_CP for the FAC_LAM_CP calculation after RampOpen [-]
C_FAC_LAM_RAMP_OPEN	Weighting factor of FAC_LAM_LIM for CL calculation except at end of RAMP_OPEN
C_FAC_LAM_THD_CL_MEM	Threshold for FAC_LAM_GRD to save the last CL_MMV value
C_FLOW_MIN_CPS_RO	Limit on FLOW_CPS value for CL_MMV calculation (during RO and ROF) Avoid wrong CL calc. at low CPS flow. [-]
C_T_DLY_CP_INJ_LS_OFS	CL calculation will be enabled C_T_ ms before releasing the next lambda shift See description in the specification. [-]

IP_FAC_CRLC_CL	Reduction Factor at very low flow rates Correction for CRLC_CL. [-]
IP_FAC_LAM_CP_LS_COR	Correction factor for FAC_LAM_CP_LS calculation [-]
IP_FAC_LAM_GRD_MMV	Reduction Factor dependent on mean value of gradient of lamda control output [-]
IP_T_DLY_CP_INJ_LS	Time delay injector -> lambda sensor [-]

LC_CL_FIL_INI_TRA_DEAC_CLL	Correlation factor calculation in case of NO_PURGE or MIN_PURGE -> MAX_PURGE transition Initialisation of CRLC_CL at transiton allowed [0]
LC_CL_FIL_INTR	switch to continue with CRLC_CL_TMP_0 initialization on entering MAX_PURGE Initialisation of CRLC_CL at transiton [0]
LC_FAC_CRLC_CL_ENA_RAMP_OPEN	switch to enable the usage of correction factor FAC_CRLC_CL in RAMP_OPEN [1]
LC_FAC_LAM_CP_DEAC	switch to deactivate the "classical" lambda control influence during RAMP_OPEN [0]
LC_FAC_LAM_CP_LS_ENA	switch for permanent enabling of the lambda deviation part for CP system deviation calculation [0]
LC_INIT_CL_CRLC_RAMP_OPEN_FAST	Correlation factor calculation in case of RAMP_OPEN_FAST -> MAX_PURGE transition [0]
LC_LAMB_DE_ENA	Switch to enable the usage of the direct lambda deviation influence [0]
LC_VVL_THR_MOD_REQ_CP	switch to deactivate "Calculations for throttled VVL mode request" [0]
C_FAC_LAM_0_MIN/MAX	Minimum/ maximun threshold for FAC_LAM_0_CP in homogenious engine mode to avoid wrong CL calculation due to short term lambda deviations.
C_FAC_LAM_0_MIN_WIDE **C_FAC_LAM_0_MAX_WIDE**	Mininmum and maximum FAC_LAM_0_CP limits in case errors in the fuel system were detected

28.18.9.2.1 DI specials

C_CL_MMV_CHK	The canister purge force the homogeneous lambda 1 combustion to increase the capacity of purge, when the canister load is under the threshold C_CL_MMV_CHK

	the stratified combustion is active again. *Method:* On specific emission cycle (Ex : MAZDA), check if the cycle if finished During hot trip and fuel vapor generation, check the capacity of the function to prevent gas to the vent of the canister.
C_CL_MMV_HOM_CP	The canister purge force the homogeneous lambda 1 combustion to increase the capacity of purge, when the canister load is upper the threshold C_CL_MMV_HOM_CP the homogeneous lambda 1 combustion stay active. *Method:* On specific emission cycle (Ex : MAZDA), check if the cycle if finished During hot trip and fuel vapor generation, check the capacity of the function to prevent gas to the vent of the canister.
LC_LAMB_AFS_CP_CPS_SCG	switch to force hom1 operation if cps valve short circuit to ground error present
C_ABC_INC_LAMB_AFS_AMP_CP **C_ABC_DEC_LAMB_AFS_AMP_CP** **C_LAMB_AFS_AMP_MAX_CP**	Incrementation/ decrementation steps for anti bounce counter and max value for counter. Depending on the ambient prasure difference at start and current ambient preasure the counter is increased or decreased. By reaching the positive threshold a homogenious engine mode is requested, by reaching the negative threshold the request is reset. To avoid canister break through at big ambient prasure change.
IP_CL_MMV_HOM_PRS_UP/DOWN_CP	Threshold for ambient preassure for homogeinious request.
C_ABC_INC_LAMB_AFS_T_AST_CP **C_ABC_DEC_LAMB_AFS_T_AST_CP** **C_LAMB_AFS_T_AST_MAX_CP**	Incrementation/ decrementation steps for anti bounce counter and max value for counter. Depending on time after start the counter is increased or decreased. By reaching the positive threshold a homogenious engine mode is requested, by reaching the negative threshold the request is reset. To avoid canister break through at city driving.
IP_CL_MMV_HOM_T_AST_UP/DOWN_CP	Threshold for time after start for homogeinious request.
C_CRLC_LAMB_MMV_0_GRD_CP	Correlation constant for learning of the

	straight line for FAC_LAM_0_CP correction due to lambda setpoint changes.
C_LAMB_LPF_AD_MIN/MAX_CP	Lambda setpoint region where an adaption of the staight line for FAC_LAM_0_CP is possible.
C_LAMB_LPF_CLC_GRD_MIN_CP	Treshold for low pass flter Lambda for canister purge to activate adaption of the correction for FAC_LAM_0_CP
IP_N_32_OPP_MIN/MAX **IP_N_32_OPP_MIN/MAX_1** **IP_MFF_SP_OPP_MIN/MAX** **IP_MFF_SP_OPP_MIN/MAX_1**	Threshold depending on STATE_OPM_ENG_CP around the engine operating point (N and MFF_SP) at start of a purge cycle. At leaving of the frame a new RO is requested. To avoid CL calculation errors due to mismatch in lambda setpoint and measured signal.
C_FAC_OPP_CP_1	Percentage to define a smaller window to calculate CL via CL model.
LC_FAC_LAM_0_COR_ACT_CP	Activation of the correction of FAC_LAM_0_CP due to lambda setpoint changes. This can be deactivated if the operation point windows are very strict.
C_N_32_MIN_OPP_WIN_CP	N threshold below the usage of CL model for operation window is not used
C_MFF_SP_MIN_OPP_WIN_CP	MFF threshold below the usage of CL model for operation window is not used

28.18.9.3 Timer constants for limits exceeded tests

C_T_DLY_PU_CPS	CPS interrupt time during PU When the engine management goes in trailling throttle (LV_PU) the injection time becomes very small and near the minimum injection time. To prevent a big lambda deviation on transition PL to PU the CPS valve is closed immediately during a time C_T_DLY_PU_CPS. When this time is elapsed the function stay in MIN_PURGE during PU. The time must allow to close the valve during the gas transfer between the CPS valve and the oxygen sensor. This time is defined by the duration of the engine gas transfer. [0.1 s]
C_T_DLY_PUC_CP	CPS interruption time after PUC When the engine management goes in

	trailling throttle with fuel cut off (LV_PUC) the CPS valve is closed immediately. After this phase, the canister purge will stay in NO_PURGE for the time C_T_DLY_PUC_CP to prevent that the CL is influenced by lambda deviations that are due to transitional effects from the PUC phase. This time should be determined by forcing PUC phases with deactivated canister purge. C_T_DLY_PUC_CP should be at least the time that is needed for lambda controller stabilization after a PUC phase.
IP_T_DLY_CMU_CPS	Stabilization delay on lambda regulation after commutation When the engine have combustion commutations (e.g. homogeneous → stratified), all the parameters are unstable during a delay. To prevent driveability problems during the commutation the canister purge valve is closed during a time IP_T_DLY_CMU_CPS__N_32. The function is re activated as soon as the engine parameters are stable. Method: Perform different type of commutations and measure the time to have stable values
C_T_LAM_LIM_CP	Additional close loop deactivation duration due to LV_LAM_LIM activation. Set, when the lambda controller sets its flags indicating "lambda control limitation reached" [5 s]
C_FAC_LAM_CP_BOL	Lambda control functional window.
C_FAC_LAM_CP_TOL	This window is additional to the control of the limiation flags from the lambda controller, see above. To prevent wrong canister load learning, the lambda control value will be checked all the time in RAMP_OPEN. If C_FAC_LAM_CP_BOL < FAC_LAM_CP < C_FAC_LAM_CP_TOL, RAMP_OPEN is disabled or stopped temporarily and MIN_PURGE is applied. This calibration prevents the learning because the reference point FAC_LAM_0_CP is not centered at RAMP_OPEN start.

	The threshold is defined by the normal error due to the flows (air & fuel). The realistic error is estimated about 5%. The 5% standard lambda controller deviation during the learning mode is defined by C_FAC_LAM_DIF_MAX_CP. These calibrations are defined by: - standard error flow + C_FAC_LAM_DIF_MAX_CP [-10%]
C_T_DLY_LAM_CP	Time to inhibit learning modes RAMP_OPEN & RAMP_OPEN_FAST after lambda controller left functional window defined above. After the time delay C_T_DLY_LAM_CP the learning conditions will be checked once more. [20 s]
C_N_CP_BOL	Minimum speed limit for activation of the RAMP_OPEN operation (homogeneous) The low limit of close loop is used as value [620 1/min]
C_N_CP_TOL	Maximum speed limit for activation of the RAMP_OPEN operation (homogeneous) This parameter is defined using the measurement of the MAP = f [MAF,N] The difference of the pressure (AMP – MAP) has to be higher than 200mbar in the area defined by C_N_CP_TOL and IP_MAF_CP_TOL. [3500 1/min]
IP_MAF_CP_BOL	Minimum mass air flow limit for activation of the RAMP_OPEN operation (homogeneous) In low MAF, the purge flow is not big enough to make change the canister saturation degree. The low limit of close loop is used as value
IP_MAF_CP_TOL	Maximum mass air flow limit for activation of the RAMP_OPEN operation (homogeneous) This parameter is defined using the measurement of the MAP = f [MAF,N] The difference of the pressure (AMP –

MAP) has to be higher than 200mbar in the area defined by C_N_CP_TOL and IP_MAF_CP_TOL.

Hint: The values defined for the window have an impact on the calibration of the chapter 6.2.1

These four calibrations will allow to select the canister load learning area during homogeneous combustion

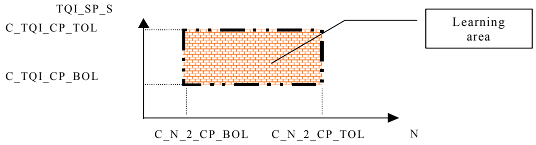
[50 mg/stroke] [400 mg/stroke]

28.18.9.4 Calculations for throttled VVL mode request

C_CL_MMV_VVL_REQ_BOL/ _TOL	Limit on CL_MMV for setting/ resetting LV_VVL_THR_MOD_REQ_CP Request for mode VVL mode with high CPS pressure to force a big purge flow at high canister load. [-]

28.18.9.5 Canister load learning window stratified

C_N_2_CP_BOL **C_N_2_CP_TOL** **C_TQI_CP_BOL** **C_TQI_CP_TOL**	Minimum / maximum engine speed / torque setpoint value limits for activation of the RAMP_OPEN operation (stratified) These four calibrations will allow to select the canister load learning area during stratified combustion



28.18.10 EVAC control (9008)

28.18.10.1 EVAC control – state machine

C_T_DLY_MAX_CP_0/1	Time between two MAX_PURGE operations for RAMP_OPEN_FAST activation for STATE_OPM_ENG_CP = ENG_MOD_0

	(_0) and STATE_OPM_ENG_CP != ENG_MOD_0 (_1). When leaving MAX_PURGE, a time counter T_DLY_MAX_CP starts to count backwards from this calibration value to 0. While the counter does not reach zero, a new learning mode via RAMP_OPEN_FAST is possible; if it reaches zero, the next learning mode has to be RAMP_OPEN [50 s]
C_T_DI_RAMP_OPEN_CP_0/1 **C_T_DI_RAMP_FAST_CP_0/1** **C_T_DI_MAX_CP_0/1**	Disable times of the states RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE for STATE_OPM_ENG_CP = ENG_MOD_0 (_0) and STATE_OPM_ENG_CP != ENG_MOD_0 (_1). If closed loop canister purge ("normal purge") is abandoned e.g. due to high engine dynamic, the time counter T_DI_CP starts to count backwards from the corresponding calibration values to 0. While it does not reach zero, a re-entering in the last closed loop state is possible as soon as the conditions for closed loop canister purge are given again. If the counter reaches 0, closed loop canister purge has to start with a new learning mode. This does not affect the exit of closed loop canister purge by LV_CP_NEW_RAMP_OPEN. A re-entry in RAMP_OPEN_FAST is only possible, if LC_CP_TRAN_DEAC_CLL is set to 1, otherwise (switch=0), no reversible interruption of RAMP_OPEN_FAST is enabled.
C_T_LOCK_CP	Locking time for locking MIN_PURGE or NO_PURGE after canister empty detection.

	[20 s]
C_STATE_MOD_SEL_CP	If the canister is detected empty at the end of RAMP_OPEN, closed loop canister purge can be inhibited for a time C_T_LOCK_CP by setting C_STATE_MOD_SEL_CP to "NO_PURGE" or "MIN_PURGE". Then the so selected state is the maximum possible CP state until the timer T_LOCK_CP reaches zero. [MIN_PURGE]
LC_CP_TRA_MAX_MIN_CDN_ENA	enable transition MAX_PURGE → MIN_PURGE with STATE_CDN_CP
LC_CP_TRA_MIN_PURGE_DFT_ENA	enable transition NO_PURGE → MIN_PURGE with STATE_CDN_CP = NO_CDN
LC_CP_TRA_MIN_RAMP_OPEN_DIS	enable trans. NO_PURGE → MIN_PURGE, if no RAMP_OPEN or RAMP_OPEN_FAST is possible although STATE_CDN_CP=RAMP_OPEN or RAMP_OPEN_FAST [1]
LC_CP_TRA_OPL_CDN_CLL_NOT	enable transition WAIT_RAMP_OPEN → NO_PURGE if LV_CP_CDN_RAMP_OPEN, _FAST no more given [0]
LC_CP_TRA_OPL_CDN_NOT	enable transition WAIT_RAMP_OPEN → NO_PURGE if STATE_CDN_CP = NO_CDN This switch is redundant to LC_CP_TRA_OPL_CDN_CLL_NOT [0]

28.18.10.2 EVAC control – states

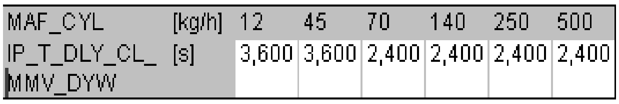
IP_PQ_CP_SP	[-]
C_CRLC_PQ_SP_CP	[0,25]
C_CL_MMV_PQ	[2]
	Setpoint value, filter constant and activation threshold on canister load for forced PQ (pressure quotient) during stratified mode for RAMP_OPEN and MAX_PURGE.

	A forced PQ is enabled in homogeneous lean burn mode if the switch LC_PQ_SP_CP_HOM_AFL is set to 1. The PQ setpoint can lead to further closing of the throttle thus leading to a higher pressure difference ambient ⇔ intake manifold thus enabling higher purge flows.
LC_PQ_SP_CP_HOM_AFL	Setpoint value, filter constant and activation threshold on canister load for forced PQ (pressure quotient) during stratified mode for RAMP_OPEN and MAX_PURGE. A forced PQ is enabled in homogeneous lean burn mode if the switch LC_PQ_SP_CP_HOM_AFL is set to 1. The PQ setpoint can lead to further closing of the throttle thus leading to a higher pressure difference ambient ⇔ intake manifold thus enabling higher purge flows. [0]
C_CL_CAT_DIAG	Canister load threshold to enable cat.diag. in MIN_PURGE (if cl < thd) If CL_MMV is below this threshold at the regular end of RAMP_OPEN, the flag LV_CL_CLC_AVL is set to 1 and passed to EGTR where it could enable a catalyst diagnosis in MIN_PURGE. [0,5]
C_CL_MMV_DYW	Dynamic window on CL_MMV value to stop leaning mode (RAMP_OPEN) and start MAX_PURGE. • The window is tuned to stop the RAMP_OPEN when the CL_MMV becomes stable inside the natural oscillation of FAC_LAM_MMV. • This tuning is done after IP_CL_CRLC_RAMP_OPEN • The tuning is done with empty canister (CL_MMV < 0,2) in idle (maximum effect by natural oscillation of lambda regulation). The window is defined as twice the value of CL_MMV oscillations. [0,024]
IP_T_DLY_CL_MMV_DYW	Minimum time duration of RAMP_OPEN when CL is inside the dynamic window

C_CL_MMV_DYW

Method:

- Charcoal canister empty
- Different stable engine load defined by MAF_CYL
- Start with RAMP_OPEN mode and measure the time spent to get CL_MMV stable and close to CL. Fill the IP_T_DLY_CL_MMV_DYW with the measured time.



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_T_DLY_CL_MMV_DYW	[s]	3,600	3,600	2,400	2,400	2,400	2,400

C_T_DLY_MAX_RAMP_OPEN

Initialisation time duration for RAMP_OPEN mode.

If no lambda shift occurs during RAMP_OPEN mode, no re-initialsisation of the timer T_RAMP_OPEN_STAB will occur and RAMP_OPEN will be left after C_T_DLY_MAX_RAMP_OPEN.

Method:

- Charcoal canister empty
- Idle speed mode

The final valve opening is defined by FLOW_MAX value. Measure the time spent to reach about 4/5 of FLOW_MAX at idle.

[20s]

LC_LAM_LIN_CPS

Type of O2 sensor (0 → binary sensor , 1 → linear sensor)

LC_DLY_MOD_CP

Switch the flow incrementation feedback.

0: Flow incremented if gastransfer timer elapsed (T-DLY_CP_OPEN = 0) or lambda sensor switch from rich to lean (LV_CP_AFL_IT 0 -> 1)

1: Flow incremented if gastranfer timer elapsed and lambda sensor is lean.

LC_FLOW_CTL_INI_DEAC_CP

Enable the re-initialisation of FLOW_CTL_CPS at re-entrance of MAX PURGE.

C_T_CP_PURGE_TUBE_CP

This defines the time starting at entering WAIT_RAMP_OPEN while the purge valve is opened. There a two way how this can be used:

	1. For evacuating the gas in the pipeline from the ACF to the purge valve whose HC-concentration may be not corresponding to the real canister load. Then C_T_CP_PURGE_TUBE should correspond to the worst-case time that is needed to evacuate the whole pipeline. 2. For making a short (but big) opening of the CPS valve to remove adhesive effects that could affect the start-to-open point of the purge valve. Then a very short time (e.g. 100ms) should be chosen, to avoid high lambda deviations due to this opening.
C_FAC_T_DLY_PURGE_TUBE_CP	Factor that is applied to the gas delay time at the beginning of WAIT_RAMP_OPEN. Should be set to a value >1 to ensure that all the gas from 'purging the tube' has vanished from the intake manifold to not disturb the RAMP_OPEN learning. If a small C_FLOW_CPS_GRD_PURGE_TUBE_CLOSE is applied, the time until the valve is completely closed has the be taken into account by this factor.
C_T_MAX_MAF_INT_CP_0/1	Maximum time to remain in WAIT_RAMP_OPEN even if the MAF integral has not reached the below mentioned threshold (e.g. at very low MAF operating points), _0 for homogeneous and _1 for stratified combustion modes.
C_T_MIN_MAF_INT_CP_0/1	Mininum time to remain in WAIT_RAMP_OPEN even if the MAF integral has already exceeded the below mentioned threshold (e.g. at high MAF operating points), _0 for homogeneous and _1 for stratified combustion modes.
C_MAF_INT_MAX_CP_0/1	MAF integral thresholds depending on STATE_OPM_ENG_CP. This value has to be chosen according to the lambda controller stabilization MAF integral value to ensure that the controller is in stationary conditions.

28.18.10.3 EVAC control – flow calculations

LC_FLOW_CPS_AS

as required

C_FLOW_CPS_AS

Manual value for FLOW_CPS and activation switch for that.

LC_CP_FLOW_LIM_OPEN_FAST

enable old calc. of FLOW_OPEN_CPS: fuel mass based

As soon as the limit flow FLOW_OPEN_CPS is reached, RAMP_OPEN_FAST is left towards MAX_PURGE. With the switch = 1, the limit flow FLOW_OPEN_CPS can be taken from a map IP_FLOW_MAX_OPEN_CPS, this is similar to the calculation in RAMP_OPEN.

With the switch = 0, the limit flow is calculated based on the maximum possible fuel for RAMP_OPEN_FAST; this is the solution of previous canister purge versions.

ID_FLOW_INC_NR_CP

Increment number for FLOW_CTL_CPS calculation during RAMP_OPEN and

RAMP_OPEN_FAST (steps à 20ms)

The ramping-up of the flow during RAMP_OPEN and RAMP_OPEN_FAST consists of two phases: flow incrementation and gas transfer delay.

Each flow incrementation phase consists of a ID_FLOW_INC_NR_CP incrementation steps with the amount of IP_FLOW_INC_CP rsp. IP_FLOW_INC_FAST_CP. After the incrementation phase, the system waits for gas delay or rich → lean switch of a binary lambda sensor.

N_32	[1/min]	0	2048	4096	5120
ID_FLOW_INC_NR_CP	[-]	11	12	15	19

IP_FLOW_INC_CP

During RAMP_OPEN, the valve is opening smoothly in order to control the lambda

This calibration defines the slope of FLOW_CPS by incrementing directly FLOW_CTL_CPS in homogeneous mode. The first step is defined by C_FLOW_INI_CPS.

The IP_FLOW_INC_CP values are defined by calculation. These increments will be checked during driving tests in hot conditions

(charcoal canister loaded)

(Lambda max = 5-6 %, CL max = 2)

Method:

- Driving tests in hot conditions
- Different engine load for stable engine conditions
- Charcoal canister full loaded
- Ramp open mode
- Calibrate the maximum canister purge time equal to 20 s
- Calibrate the lambda adaptative duration equal to 20 s
- For different engine loads (MAF_CYL) adjust IP_FLOW_INC_CP in order to get no more than 5-6% of lambda variation during RAMP_OPEN mode.

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_INC_CP	[kg/h]	0,002	0,003	0,005	0,006	0,009	0,013

IP_FLOW_INC_FAST_CP

During RAMP_OPEN_FAST the CL is known so the purge valve can be opened faster than the one used in RAMP_OPEN mode. In this case the slope of the purge valve opening will be a compromise between opening speed and lambda control. This map is used for homogeneous combustion.

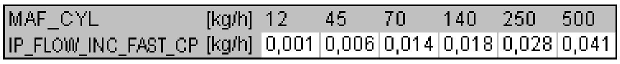
This calibration defines the slope of FLOW_CPS by incrementation of FLOW_CTL_CPS in Ramp Open fast.

Method

- Engine bench or Chassis Dyno
- Different engine loads for stable engine conditions
- Charcoal canister full loaded by butane or warmed fuel (50°C)
- Ramp open fast in Homogeneous mode
- For different engine loads (MAF_CYL) adjust IP_FLOW_INC_FAST_CP in

order to get ± 5-6 % maximum lambda variation during RAMP_OPEN mode. This calibration needs some repeated measurements. To get the repeatition fastly the time durations of some phases could be reduced (Lambda adaptation, Purge time duration)

These calibrations have to be refined during in-use tests in hot conditions (summer trip)



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_INC_FAST_CP	[kg/h]	0,001	0,006	0,014	0,018	0,028	0,041

IP_FLOW_DEC_CP

Purge opening decrement value for FLOW_CPS during RAMP_CLOSE mode. The slope of the closing prevents exhaust lambda variation.

This calibration defines the slope of FLOW_CPS.

Method:

- Charcoal canister full (legal procedure) and empty loads
- Canister Load learned in RAMP_OPEN and refined in MAX_PURGE.
- For different engine loads (MAF_CYL) adjust IP_FLOW_DEC_CP in order to get ± 5% maximum lambda variation at the end of RAMP_CLOSE mode. This calibration needs some repeated measurements. To get the repetition fastly the time durations of some phases could be reduced : Lambda adaptation, Purge time duration....

C_FAC_DEC_COR_CMU_CP

Purge opening decrement value for FLOW_CPS during combustion commutation.

This calibration defines the slope of FLOW_CPS.

Method:

- Charcoal canister full (legal procedure) and empty loads
- Canister Load learned in RAMP_OPEN and refined in MAX_PURGE
- Adjust C_FAC_DEC_COR_CMU_CP in

order to have no impact of the canister purge during the commutation. Compare with and without purge different types of commutation.

C_FAC_DEC_COR_1_CP	Other system functions could want to stop the canister purge function. The request of purge closing is controlled by the OBD2 controller. Depending on the type of request the closing speed is defined by C_FAC_DEC_COR_1_CP. The target of the calibration is to go in NO_PURGE mode fastly without taking care with pollution or lambda variation. Closing speed correction factor 1 is used for high speed closing *This calibration has to be done by the function transmitter of the close request* [1]
C_FAC_DEC_COR_2_CP	Other system functions could want to stop the canister purge function. The request of purge closing is controlled by the OBD2 controller. Depending on the type of request the closing speed is define by C_FAC_DEC_COR_2_CP. The target of the calibration is to go in NO_PURGE mode with a compromise between the closing speed and lambda variation. Closing speed correction factor 2 is used for medium speed closing *This calibration has to be done by the function transmitter of the close request* [1]
IP_FLOW_FAC_CP	Correction factor for FLOW_CPS applied in RAMP_OPEN, RAMP_OPEN_FAST or RAMP_CLOSE modes, for homogeneous and stratified modes. The correction value is depending of the CL value. The reference is based on canister full loaded (factor = 1). When the CL is lower the FLOW_CPS incrementation is increased. The values are defined by calculation. The values will be checked during driving tests with different charcoal canister loads. This factor must be calibrated by taken account that at each incrementation the

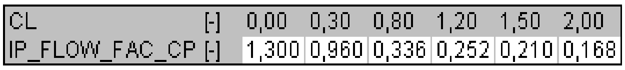
lambda variation must stay lower than 5-6%

Method:

- Driving tests, different charcoal canister loads
- Different engine load for stable engine conditions
- Ramp open mode

For different engine loads (MAF_CYL) adjust IP_FLOW_FAC_CP in order to control ± 5-6 % maximum lambda variation. This calibration needs some repeated measurements. To get the repeatition fastly the time durations of some phases could be reduced : Lambda adaptation, Purge time duration....

The calibration must be checked in Ramp open fast and ramp close mode for all the combustion modes.



CL	[-]	0,00	0,30	0,80	1,20	1,50	2,00
IP_FLOW_FAC_CP	[-]	1,300	0,960	0,336	0,252	0,210	0,168

LC_FLOW_CL_FAC_RAMP_OPEN_INH

As the accuracy of the CL value is much higher in RAMP_OPEN_FAST than in RAMP_OPEN, the weighting of the FLOW_GRD_CPS by IP_FLOW_FAC_CP should be turned off in RAMP_OPEN by setting the switch to 1, if the CL value has a high fluctuation during this state.

IP_FLOW_CPS_INC

(In MAX_PURGE, the closing of the valve must be the same as the one given by the ramp of FLOW_CTL_CPS during RAMP_CLOSE.)

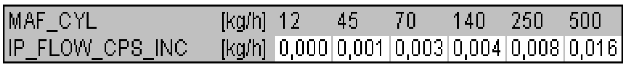
The purge valve opening/closing is done by FLOW_CTL_CPS variations.

In case where the evaporative system design is not good enough (fuel tank purged : the purge valve opening/closing has to be done slower. These calibrations allow to apply a 1st order on the purge flow needed. The purge flow integrated will define the purge valve opening.

Method:

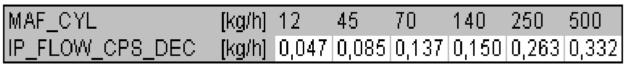
- Engine loads in stable conditions

- Charcoal canister full (legal procedure) and empty load
- CL learnt and MAX_PURGE mode acting.
- Change the purge target modifying IP_FUEL_FLOW_MAX_CP to get high variation in purge valve opening and purge flow needed.
- For different engine loads (MAF_CYL) adjust the INC and DEC in order to get ± 5% maximum lambda variation up to the valve opening setpoint is reached. This calibration needs some repeated measurements. To get the repeatition the time duration of Purge time duration could be lengthened.



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_CPS_INC	[kg/h]	0,000	0,001	0,003	0,004	0,008	0,016

IP_FLOW_CPS_DEC



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_CPS_DEC	[kg/h]	0,047	0,085	0,137	0,150	0,263	0,332

C_FLOW_INI_CPS

- This value is used to initialize FLOW_CTL_CPS at beginning of the RAMP_OPEN.
- This data is calculated to obtain most quickly the “start to open” valve opening point in idle. At the RAMP_OPEN start the purge valve opening has to be close to the “start to open” point defined in IP_CPPWM
- Method:
- Second breakpoint of purge flow axe in IP_CPPWM > C_FLOW_INI_CPS
- Check on engine bench for different engine loads that this value is enough to open correctly the valve and create e first deviation of lambda
- [0,01 kg/h]

IP_FLOW_MAX_OPEN_CPS

FLOW_CPS for fully opened CPS (CPPWM=100%)

This map defines the maximum purge flow value [kg/h] when the valve is fully opened; the values are from the flowbench measurements or from IP_CPPWM

The calibration needs the values

- MAF_CYL = f(MAF[mg/tdc], N_32[rpm]) and
- MAP = f(MAF[mg/tdc], N_32[rpm]) and

MAF_CYL ⇒ MAP ⇒ MAX FLOW CPS ⇒ IP_FLOW_MAX_CPS (MAX FLOW CPS)

An excel file FLOW_MAX.xls allows to calculate the calibration values to fill up automatically the FLOW_MAX_CP.

This map characterizes the maximum flow authorized during RAMP_OPEN or RAMP_OPEN_FAST mode. This map can be considered as flow setpoint for the learning modes.

At Idle IP_FLOW_MAX_OPEN_CPS should be limited. In order to keep sufficient idle actuator authority on purge the maximum purge flow will be limited at 10% of the maximum total air engine flow.

[-]

IP_FAC_AMP_CP

The canister purge flow ($Q_{\text{Purge Map}}$) values are defined at standard sea level barometric pressure ($P_{\text{Purge Map}}$) =1013 mb.

The factor correction by IP_FAC_AMP_CP allows to adapt the flow at the current barometric pressure.

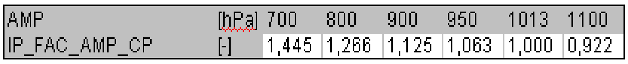
The variation of the canister purge flow is depending on the upstream pressure. This variation follows the law:

$Q_{\text{Purge}} = Q_{\text{Purge MAP}} * [P_{\text{baro current}} / P_{\text{Purge MAP}}]$

When the valve opening has to be

defined to get a needed canister purge flow the inverted law is used :

$Q_{\text{Purge MAP}} = Q_{\text{Purge}} * [P_{\text{Purge MAP}} / P_{\text{baro current}}]$



AMP	[hPa]	700	800	900	950	1013	1100
IP_FAC_AMP_CP	[-]	1,445	1,266	1,125	1,063	1,000	0,922

IP_FAC_TIA_CP

The canister purge flow ($Q_{\text{Purge Map}}$) values are defined at standard ambient temperature = 25°C

This factor correction allows to adapt the flow at the current ambient temperature

The variation of the canister purge flow follows the law:

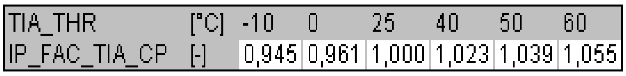
$Q_{Purge} = Q_{Purge\ MAP} * [T_{Purge\ MAP} / T_{current}]^{0,5}$

With T[°K]

When the valve opening has to be defined to get a needed canister purge flow the inverted law is used :

$Q_{Purge\ MAP} = Q_{Purge} * [T_{current} / T_{Purge\ MAP}]^{0,5}$

With T[°K]



TIA_THR	[°C]	-10	0	25	40	50	60
IP_FAC_TIA_CP	[-]	0,945	0,961	1,000	1,023	1,039	1,055

C_FLOW_CPS_SP_PURGE_TUBE

Flow setpoint for the first phase in WAIT_RAMP_OPEN. Depending on the intended usage (refer to C_T_CP_PURGE_TUBE), this flow setpoint has to be determined different.

1. Purging the tube: the flow setpoint must not be higher than the worst case MIN_PURGE flow setpoint for idle speed to not create too high lambda deviations.
2. Short, defined opening: if used to remove adhesive effects that could influence the SOP of the purge valve, a high flow setpoint (that ensures an opening of the valve, e.g. a CPPWM of about 20%) has to be chosen.

C_FLOW_CPS_GRD_PURGE_TUBE

Flow gradient for the first phase in WAIT_RAMP_OPEN. For purging the tube, smaller gradients can be chosen to avoid high lambda deviations. For a short, defined opening a big gradient should be applied to ensure that the valve is opened immediately to ensure that the target flow can be reached within the short time C_T_CP_PURGE_TUBE.

C_FLOW_CPS_GRD_PURGE_TUBE_CLOSE

Flow gradient for tube purging in WAIT_RAMP_OPEN (at closing cps). For purging the tube, smaller gradients can be chosen to avoid high lambda deviations. For a short, defined opening a big gradient should be applied to ensure that the valve is closed immediately to create only a short (but high) disturbance.

C_MAF_DLY_CRLC_CPS	Correlation constant for MAF_CPS_DLY-filter
C_T_DLY_CL_MDL	Time to activate CL-Model
IP_FLOW_MAX_OPEN_CPS_2	Max. limit for FLOW_CTL_CPS value for RAMP_OPEN & RAMP_OPEN_FAST with STATE_OPM_ENG_CP = 1
LC_CP_FLOW_LIM_OPEN_FAST	enable old calc. of FLOW_TAR_CPS during ROF: fuel mass based
LC_CP_TRA_MAX_MIN_CDN_ENA	enable transition MAX_PURGE (MIN_PURGE with STATE_CDN_CP = NO_CDN
LC_CP_TRA_MIN_PURGE_DFT_ENA	1: enable transition NO_PURGE (MIN_PURGE with STATE_CDN_CP = NO_CDN
LC_CP_TRA_MIN_RAMP_OPEN_DIS	enable trans. NO_PURGE (MIN_PURGE, if no RO or ROF is possible although STATE_CDN_CP=RO or ROF
LC_CP_TRAN_OPEN_MAX_ENA	enable transition RO (MaxP if flow target reached
C_MFF_RATIO_FLOW_INI	Maximal percentage of MFF at reentering MAX_PURGE.
C_FAC_FLOW_MAX_INI_CP	Factor to limit FLOW_CTL_CPS on re-entering MAX_PURGE in case of low canister load.

28.18.10.4 EVAC control – Padé- and Low pass filter calculations

IP_T_DLY_CP

This map allows to characterize the gas transfer duration between canister valve and oxygen sensor.

These value are used to calculate the Padé filter outputs for FLOW_CPS and MAF_CYL.

Method:

- Chassis Dyno and stable engine conditions
- Charcoal canister half loaded
- Canister purge strategy deactivated
- Opening/closing purge valve set by the application system calibration C_CPPWM_AS.

For different engine load (MAF_CYL) measurement of the time duration from the purge valve switching (open/close) to the beginning of the variations of :

- Lambda controller or
- O_2 sensor period or
- UEGO sensor

The value of IP_T_DLY_CP is calculated by dividing the measured time by the calculation recurrence of the PADÉ filter (100 ms).

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_T_DLY_CP	[0,1 s]	4,600	3,320	2,680	2,000	1,800	0,980

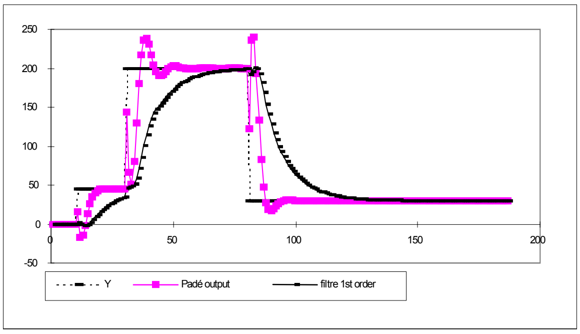
C_FLOW_DLY_CRLC_CP [0,3]

C_MAF_DLY_CRLC_CP Filter coefficient of FLOW_DLY_CP and MAF_TOT_CP_DLY_.

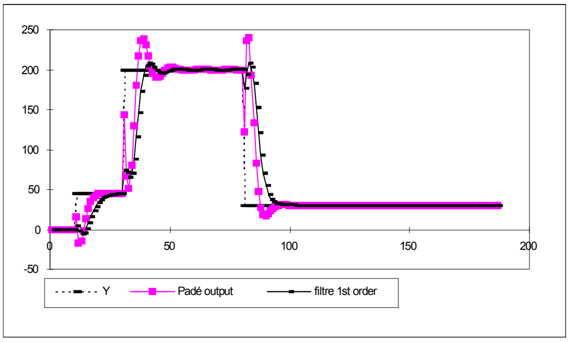
These coefficients cancel the PADE output oscillations.

The following example using two filter coefficient values show the effect on the output.

Filter coefficient = 0.1 ***Value too small because the ouput value is too much delayed***



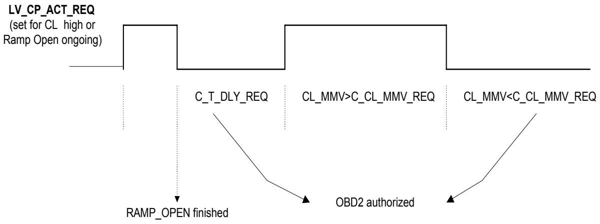
Filter coefficient : 0.3 ***Value adapted because the ouput value is close of PADE output without oscillations***



[0,3]

28.18.10.5 EVAC control – Common submodules

C_CL_MMV_REQ	When the canister load is bigger than the threshold C_CL_MMV_REQ the canister purge function does not be interrupted by another function (OBD2.....). The calibration value is defined by maximum canister load with butane. Take care this calibration value does not prevent the OBD2 and adaptive functions during SHED test or standard driving cycle when the charcoal canister is full loaded. [0,5]
C_T_DLY_REQ_CP	Time to set LV_T_DLY_REQ_CP The time C_T_DLY_REQ_CP authorizes ODB2 diagnosis activation even C_CL_MMV_REQ is set. When this time duration is elapsed the canister purge load takes highest priority. This time duration is refined in accordance with the standard driving cycle.



[120 s]

28.18.11 Injection calculation (903M)

28.18.11.1 Injection calculation – injection buffer

The injection correction model is characterized by a delay and a 1st order filter. The delay should represent the gas transfer time through the intake manifold, the appending filter should represent the flow dilution behaviour.

NC_NR_CP_BUF	Size of the fuel buffer MFF_ADD_BUF The buffer size has to be determined according to the expected delay times between CPS and injection valves.
LC_FLOW_CPS_CAL	Choice of recurence for injection buffer calculation. The injection buffer can be calculated with two different recurrencies: 20ms rsp. 40ms, LC_FLOW_CPS_CAL leading to a recurrency of 20ms. By selecting a slower update rate, higher gas delay times can be modelled with a given buffer size.
LC_DLY_GAS_CLC_VERS_CP	Determines whether the gas delay determination is done via the maps IP_MFF_DLY_CP and IP_IDX_STEP_CP (= 0) or calculated from the intake manifold volume with an temperature and pressure correction (=1). If a reliable determination of the IM volume is possible, this version should be preferred as the calibration effort for the first version is much higher.
IP_MFF_DLY_CP **IP_IDX_STEP_CP**	These calibrations allow to characterize the intake manifold gas transfer between the canister purge valve and the cylinders inlet. *Method:* • Engine bench or Chassis dyno in stable engine load conditions • Canister purge strategy deactivated • Change the injection time using the bench function (C_TI_AS) • Open and close the CPS valve via C_CPPWM_AS / LC_CPPWM_AS • For different MAF and MAP perform measurements of the gas transfer duration from the injector valve change to lambda deviation. • The time delay (valve to injector) is the difference between the map

IP_T_DLY_CP (time between the valve and the lambda sensor) and the previous measurement.

- The calibration values are the time measured divided by the calculation recurrence of MFF_BUF_CP.
- The recurrence is 20 or 40ms, depending on calibration.
- Set IP_MFF_DLY_CP all to maximum delay time!
- The buffer is filled with several elements calculated by IP_IDX_STEP_CP (high MAF -> many elements; low MAF -> less elements)

IP_MAF_KGH_PRED_COR_MAP_TIA

MAF correction as function of MAP and TIA to do a correciton in the gas delay time caused by differet intake manifold preassure

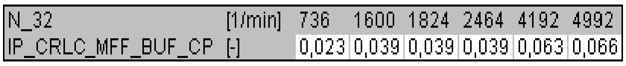
IP_CRLC_MFF_BUF_CP

The dilution behavior through the intake manifold is characterized by a 1st order filter. The filter coefficient is defined such as the exhaust lambda variations are the smallest from purging change.

Method:,

- IP_MFF_DLY_CP has to be tuned before.
- IP_CRLC_MFF_BUF_CP minimizes the lambda variation when canister fuel flow is controlled by the purge function.
- Engine bench or Chassis dyno in stable engine load conditions
- Charcoal canister half loaded
- Canister purge strategy activated in MAX_PURGE mode (CL known)
- Opening/closing purge valve set by changing the purge target (IP_FUEL_FLOW_MAX_CP)

For different engine load (N variation) measurement of the lambda variation (Linear sensor) due to purge target change. Adjust IP_CRLC_MFF_BUF_CP value before each change in order to have no exhaust lambda peak (lean or rich).



N_32	[1/min]	736	1600	1824	2464	4192	4992
IP_CRLC_MFF_BUF_CP	[-]	0,023	0,039	0,039	0,039	0,063	0,066

28.18.11.2 Injection calculation – torque correction in stratified

IP_MFF_MIN_CP_S	Canister purge margin on the fuel flow minimum value in stratified mode. This margin is used to prevent the minimum injection time in altitude or on deceleration. [5 mg/stk]
IP_FAC_TQI_CP	Factor used to convert a fuel mass in a torque. FAC_TQI_CP is a decimal factor which permit to convert a fuel mass in a torque. Because of the different resolutions of TQI_ADD_CP and MFF_CPS, the conversion (1389 mg/tdc / 1024 Nm) has to be taken into account by the calibration of FAC_TQI_CP. That means, if you want MFF_CPS = TQI_ADD_CP, then you have to calibrate FAC_TQI_CP to 0.73 (1024/1389) and not to 1. *Method:* • On engine dyno • On a reference point (N, TQI_SP_S, lambda) • Stratified mode • Open the valve with a full loaded canister (c_cppwm_as and lc_cppwm_as) • Decrease the fuel injected to go back to the reference point [0,67]

28.18.12 Torque reserve for canister purge at idle (800X)

LC_TQ_ADD_CP_INH	inhibit switch [1]
IP_TQ_ADD_CP	If not used set to [0 Nm]
C_CRLC_TQ_ADD_CP	Deactivation switch, filter constant and base map for canister purge torque reserve at idle. By increasing the engine load without increasing the torque output, a higher purge rate is possible due to the increase of engine's fuel demand (for a given purge fuel ratio). The torque reserve is only

applied in MAX_PURGE and idle speed depending on canister load CL_MMV.

Method :

- idle speed condition
- no additional load or torque reserve (cooling fan, air conditioning…)
- use the map ip_tq_n_add_is to change the torque reserve (ref chapter idle speed)
- Using the engine roughness criteria, measure the engine stability when you change torque reserve.

Make measurements for several torque reserve and record the injection time and the spark advance.
[0,5]

28.18.13 Canister Purge Valve Adaptation (902H)

Canister Purge Valve Adaptation Purpose of the canister purge solenoid (**CPS**) is to purge the tank venting charcoal filter by opening a pipe from the filter to the engine manifold; so the filter's CH-load is desorbed by fresh ambient air and sucked into the engine. For countinuous control of the purge airflow the CPS is opened pulse wide modulated (PWM).

Due to future legislation the CH-emissions of vehicles have to be cut down; one task is to accellerate purge. To keep the purge airflow as high as possible without disturbing the engine the CPS has to be controlled as accurately as possible. This means that the engine controller (which is also responsible for canister purge) has to „know" as much as possible about any car's individual CPS. The most important parameter is the start-to-open-point (**STO**); a dead time between switching on electric power and opening of the CPS; as visible in the figure beside. If the opening time (depending on PWM and frequency) is below this dead time the CPS will never open. The parameter STEP is presently assumed to be quiet low and therefore neglected while SLOPE is estimated to be almost constant as specified.

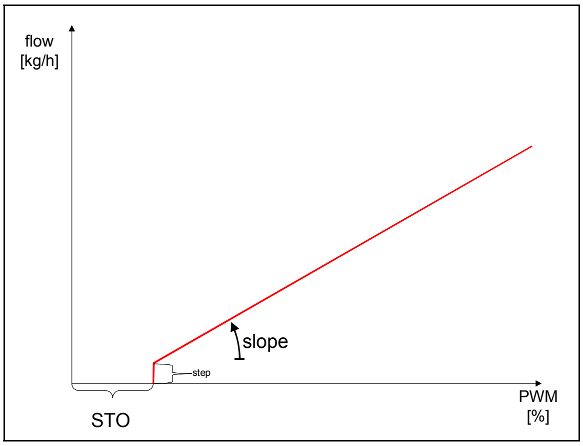


Figure: characteristic line of CPS

Up to now an average STO has been extimated, but expected future developments like high-flow-CPSs or the need for a better performance of canister purge induce an increasing demand for an exactly measured STO.

To measure the STO the CPS is ramp-opened until a decreasing lambda-value (caused by the purged HCs) is detected. For accurate measuring the HC flow has to be as high as possible without disturbing the engine. So the adaptation frequency is calculated depending on canister load (CL) and calibrated values. A too low CL interdicts adaptation.

Boundary conditions needed to start adaptation:

STATE_CP	3
LV_HOM_ACT	1
LV_CL_CLC_VLD	1
N	between C_N_MIN_CPS_AD and C_N_MAX_CPS_AD
T_AST	above C_T_ST_CPS_AD
LV_CPS_AD_INH	0
TQI_AV	between C_TQI_AV_MIN_CPS_AD and C_TQI_AV_MAX_CPS_AD
CL_MMV	above C_CL_MIN_CPS_AD
LV_CP_CLOSE_REQ	0
LC_CPS_AD_CHK	0 This flag (=1) is to start the function overriding **all** application conditions. If the function is started using this flag it will not stop until a sufficient lambda-deviation is detected (=STO learned). When function is going into wait-state after lerning, set flag back to 0. **Attention !** If no sufficient lambda-deviation is detected (i.e. if CL is too low) the CPS will be opened up to 100% PWM and stay there until the flag is reset.
FAC_LAM_CP	to take from engine model

Required for application work:
- Charcoal-filter with CL about 1,5 (75%)
- Min-flow-CPS
- Max-flow-CPS

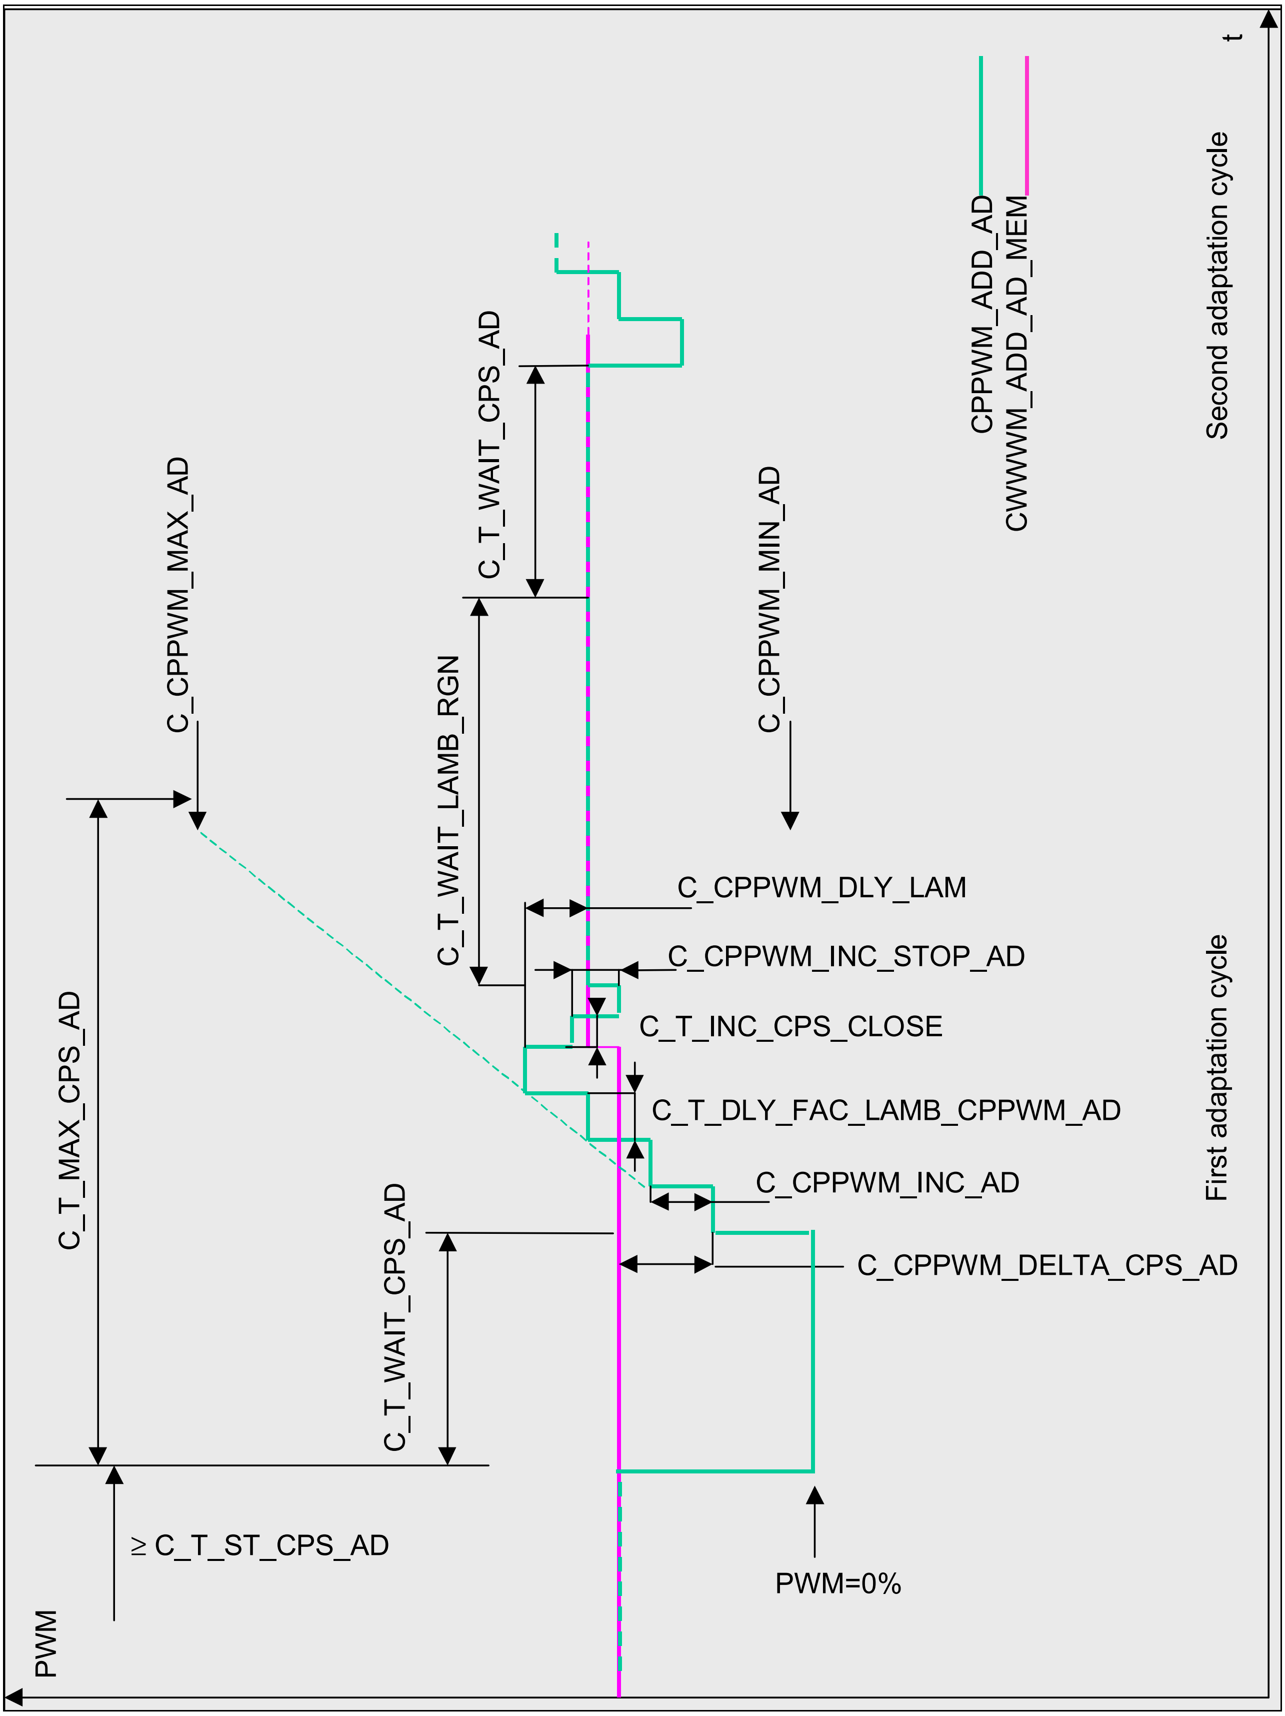

Figure: Adaptation cycle with calibraion values

Calibration method:

C_FRQ_MIN_CPS_AD	Minimum working frequency of CPS or default frequency of fixed-frequency-systems**; see CPS spec** or try 10 [Hz]
C_FRQ_MAX_MEC_CPS	Maximum allowed frequency of CPS**; see CPS spec** or try 30 [Hz].
C_FAC_LAMB_DELTA_MIN_CPS_AD	Minimum detectable lambda deviation caused by adaptation; **just above lambda-noise**. Watch FAC_LAMB at stable idle to estimate lambda noise or try 3 [%] as default.
C_FAC_LAMB_MAX_CPS_AD	Maximum allowed lambda deviation during adaptation without disturbing the engine; see engine or controller SPEC or: At low temperature (“cold morning”) open CPS stepwise, watch FAC_LAMB and see when engine is disturbed (sound/speed/vibrations).
C_CPPWM_AD_RATIO	Weighting factor of newly learned STO against old memorized value for calculation of new memorized value. 0.1 should be a useable default value. 1 can be used for monitoring during application work. This value acts like a “damper” against a badly learned STO.
C_CPPWM_DELTA_AD	Difference between PWM at start of adaptation and old memorized STO value to make sure adaptation starts below current STO. Should cover the measuring diffusion and a (smaller) possible drift of STO. This value also assures that after a “too high” learned STO the function will “climb back down”. Must be less than C_CPPWM_MIN_AD-C_CPPWM_DLY_LAM to avoid negative PWM value.Default: 5 [%]
C_CPPWM_DLY_LAM	Assuming the stepwise opening of CPS has continued between STO and lambda reaction (C_T_INC_AD < real physical time delay of C_T_DLY_FAC_LAMB_CPPWM_AD) this subtractive value compensates the PWM difference. Start application work with 0 [%]. Adapt using fully loaded canister at minimum frequency and watch FAC_LAMB. If learned STO (CPPWM_ADD_AD_MEM) is always higher than STO at beginning lambda deviation set the difference.
C_CPPWM_INC_AD	PWM increment for CPS opening during adaptation; depends on demanded function resolution and lambda regulation delay time. Has to be less than C_CPPWM_DELTA_AD. Default 1[%].
C_CPPWM_INC_STOP_AD	PWM icrement for CPS closing. Default 1[%].
C_CPPWM_MAX_AD	Maximum plausible STO-value at FRQ_MIN. See CPS spec or use 40[%] at 10Hz (= 40ms) as default.

C_CPPWM_MIN_AD	Minimum plausible STO-value at FRQ_MIN. Use 1[%] at 10Hz (= 1ms) or see CPS spec. Must be above (C_CPPWM_DELTA_AD to avoid negative PWM at next adaptation. Must be equal or higher than C_CPPWM_DLY_LAM+C_CPPWM_DELTA_AD
C_CYCNR_CPS_AD	Number of successful adaptations aimed during driving cycle. Default about 2 [-].
C_N_MAX_CPS_AD	Upper threshold of engine speed for adaptation. Default upper threshold of idle window; see engine spec or use 1200 [min^-1] as default.
C_N_MIN_CPS_AD	Lower threshold of engine speed for adaptation. Default lower threshold of idle window; see engine spec or use 600 [min^-1] as default-
C_T_DLY_FAC_LAMB_CPPWM_AD	Delay time between fuel purged into manifold and change of FAC_LAM value. Depends on engine speed and design. 1 [sec] may be a useable default value. After opening step of CPS this time passes until check for lambda deviation.
C_T_INC_CPS_CLOSE	Time increment for CPS closing, use 0,2 [sec] as default.
C_T_MAX_CPS_AD	Maximum allowed duration of one adaptation cycle. Try default 30 [sec]. As the figure shows, this time has to cover C_T_WAIT_CPS_AD and the ramp from C_CPPWM_MIN_AD-C_CPPWM_DELTA_AD to C_CPPWM_MAX_AD. So: C_T_MAX_CPS_AD≥ (C_CPPWM_MAX_AD- C_CPPWM_MIN_AD+ C_CPPWM_DELTA_AD)* C_T_INC_CPS_AD+ C_T_WAIT_CPS_AD
C_T_ST_CPS_AD	Minimum time between start engine and adaptation to ensure stable engine conditions. Default 60 [sec].
C_T_AST_DEAC_CPS_AD	Maximum time between start engine and end or abort of adaptation. If set to maximum value of T_AST this condition is disabled. Enter default 10000 [sec] to disable.
C_T_WAIT_CPS_AD	Delay time between function start and begin of CPS opening. Can be 0 [sec] if no delay demanded by application engineer.
C_T_WAIT_LAMB_RGN	Delay time after adaptation to regain stable conditions of lambda regulation. Try 10 [sec] and watch FAC_LAMB.
C_TQI_AV_MAX_CPS_AD	Upper threshold of engine torque for adaptation. Default upper threshold of idle window; see engine spec or use 40 [Nm]
C_TQI_AV_MIN_CPS_AD	Lower threshold of engine torque for adaptation.

	Default lower threshold of idle window; see engine spec or use 60 [Nm]

For first calibration or fixed frequency adaptation the frequency variation has to be terminated as follows:

C_FRQ_CLC_1_CPS_AD	=0
C_FRQ_CLC_2_CPS_AD	=C_FRQ_MIN_CPS_AD
C_CL_MIN_CPS_AD	Try as default: C_CL_MIN_CPS_AD=1 Use full canister and start purge to get current CL.Start adaptation with min-flow-CPS to get FAC_LAMB at STO. C_CL_MIN_CPS_AD=CL * C_FAC_LAMB_DELTA_MIN_CPS_AD/ FAC_LAMB

For frequency-variation:

The reliability of frequency calculation depends not only on it's own calibration but also on the precision of CL-detection which – vice versa – depends on CPS-adaptation. Therefore an iterative calibration is recommended:

1. Complete calibration as described below.
2. Wait for purge to detect CL again.
3. Recalibrate C_CL_MIN_CPS_AD, C_FRQ_MAX_CPS_AD, C_FRQ_SLOP_CPS_AD.
4. If a significant difference appears: Start again with step 2.

Use canister with CL about 1,5 (=75%).

Mount max-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate:

$$\mathrm{FRQ\_MAX\_CL\_MAX} = \frac{\mathrm{C\_FRQ\_MIN\_CPS\_AD} \times \mathrm{C\_FAC\_LAMB\_MAX\_CPS\_AD} \times 2}{\mathrm{FAC\_LAMB} \times \mathrm{CL}}$$

FRQ_MAX_CL_MAX has to be ≥ C_FRQ_MIN_CPS_AD !

Mount min-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate:

$$\mathrm{FRQ\_MIN\_CL\_MAX} = \frac{\mathrm{C\_FRQ\_MIN\_CPS\_AD} \times \mathrm{C\_FAC\_LAMB\_DELTA\_MIN\_CPS\_AD} \times 2}{\mathrm{FAC\_LAMB} \times \mathrm{CL}}$$

C_CL_MIN_CPS_AD	Crossing of FRQ_MIN-hyperbola and C_FRQ_MAX_MEC_CPS-line. Mount min-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate: C_CL_MIN_CPS_AD=CL * C_FRQ_MIN_CPS_AD /

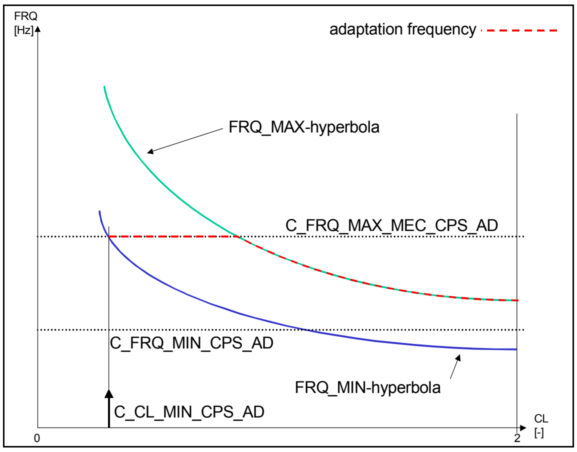
C_FRQ_MAX_MEC_CPS*
C_FAC_LAMB_DELTA_MIN_CPS_AD/
FAC_LAMB

Or try as default:
C_CL_MIN_CPS_AD=1

C_FRQ_CLC_1_CPS_AD,

C_FRQ_CLC_2_CPS_AD

The figure below shows two hyperbolas: The mimimum frequency required to generate a detectable FAC_LAMB and the maximum allowed frequency to not disturb the engine. The CL-range for adaptation is limited by the point where the minimum required frequency is getting higher than the maximum possible working frequency of the CPS.



Formula for hyperbola calculation:

$$FRQ = \frac{C\_FRQ\_CLC\_1\_CPS\_AD}{CL}$$

For precise measuring the working frequency will always be as high as possible (FRQ_MAX or C_FRQ_MAX_MEC_CPS). For individual tuning a second constant allows to move the hyperbola:

$$FRQ = \frac{C\_FRQ\_CLC\_1\_CPS\_AD}{CL} + C\_FRQ\_CLC\_2\_CPS\_AD$$

Use canister with CL about 1,5 (=75%).

Mount max-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL during RAMP_OPEN.
Calculate:

C_FRQ_CLC_1_CPS_AD=CL*C_FRQ_MIN_C

	PS_AD*C_FAC_LAMB_MAX_CPS_AD/ FAC_LAMB **Necessary condition, check:** C_FRQ_CLC_1_CPS_AD/2+ C_FRQ_CLC_2_CPS_AD ≥ C_FRQ_MIN_CPS_AD Fine tuning: Move frequency hyperbola by changing C_FRQ_CLS_2_CPS_AD or stretch/compress by changing C_FRQ_CLC_1_CPS_AD
C_FLOW_CLC_DIF_CPS_AD	Difference between C_FLOW_CLC_MAX_CPS_AD and begin of ramp
C_FLOW_CLC_MAX_CPS_AD	Maximum FLOW threshold for weighting-STO ramp
C_PRS_CPS_MAX_CPS_AD	Maximum PRS_CPS-threshold for CPS-adaptation
C_PWM_CLC_DIF_CPS_AD	Difference between CL_PWM_CLC_MAX_CPS_AD and begin of ramp
C_PWM_CLC_MAX_CPS_AD	Maximum CPPWM_CPS threshold for weighting-STO-ramp
IP_CPPWM_OPEN_CPS	Weighting factor for STO according to CPS characteristic
C_CPPWM_ADD_AD_MEM_NVMY_INI	Initialization value for CPPWM_ADD_AD_MEM value before first adaptation run. This value has to be subtrakted from the map IP_CPPWM taking the factors IP_CPPWM_OPEN_CPS, C_FLOW_CLC_MAX_CPS_AD, C_FLOW_CLC_DIF_CPS_AD, C_PWM_CLC_MAX_CPS_AD and C_PWM_CLC_DIF_CPS_AD.
C_T_CPS_AD_HOM_REQ	This constant should be calibrated long enough to ensure that a transition from stratified combustion mode to homogeneous combustion mode can take place and the other conditions for CPS adaptation (e.g. entering WRO state) can be fulfilled again.
C_T_DLY_CPS_AD_HOM_REQ	Minimum time between to homogeneous requests. Should be synchronized with fixed time slices / FTP cycle to ensure that homogenous combustion mode is not requested too frequently.
C_CTR_CPS_AD_HOM_REQ_MAX	Maximum number of homogenous requests per driving cycle. The maximum number of homogenous requests should also be chosen depending on the fixed time slices / FTP cycle to avoid too many homogenous requests that

	could affect emissions/ flow rate/ fuel consumption negatively.

28.18.14 Canister Load (CL) Model (907U)

C_CRLC_CL_MDL	Correlation constant for CL_MDL filtering [0,5]
C_FAC_T_CL_MDL_ACT	correction factor for re-init of CL mdl ena time counter after regaular leaving of active mode [1]
C_T_CL_MDL_ACT_MAX	Maximum time of CL model usage [40s]
C_T_CL_MDL_ACT_OFS	offset for re-init of CL mdl ena time counter after regaular leaving of active mode [30s]
IP_T_CL_MDL_CLL_ENA	Minimum time in CP closed loop operation to enable CL model usage [40s]
C_T_CL_MDL_CLL_ENA_INC	Increment for enable time counter if not in CP closed loop operation [0,1s]
IP_CL_MDL_SLOP	Timeshape over CL_MDL_SLOPE [-]
IP_CL_MDL_VALUE	Increment value on FLOW_SP_CPS [-]
LC_CL_MDL_ACT	Switch for activation of CL model calculation [0]
LC_CL_MDL_ENA	Switch for enabling CL model usage [0]

28.19 Calibration hints for EVAC control (cus)

28.19.1 Calibration interfering functions

Before to start the calibration work, it is absolute mandatory to have stable operating

- Lambda-Control and Injection Prec-Control
- Intake Manifold Model
- Idle Speed Control

Deficiencies in the calibration quality of the above mentioned may block the calibration/operation or demand a recalibration. Especially the Lambda Control and the Injection Pre-Control must be at a mature standard (Lambda Control output < 5% in stationary engine conditions).

28.20 Main operating situations

NO_PURGE

During this mode, CPS valve is closed

This mode is used

- when conditions to authorize evap control are not fulfilled (TCO, ...)
- while the lambda adaptation phase is ongoing
- in case of failures (CPS valve, ...)
- in case of OBD2 diagnosis request (catalyst check...)
- in case of evaporative system monitoring active

MIN_PURGE

The MIN_PURGE or open loop operation operation is used when the charcoal canister has to be purged even if its load cannot be learned.

The conditions are:

- Vehicle is not equipped with A/F control
- A/F regulation component failures (lambda sensor...)
- Transient driving conditions. In this case, the purge flow is adjusted to have a maximum of 5% A/F ratio deviation with a saturated canister.

NORMAL_PURGE / closed loop operation

The normal operation is used when the determination of the canister load is finished.

Purge flow is adjusted to have the maximum of A/F ratio deviation with a saturated canister.

The NORMAL_PURGE operation is proceeded in the following sequences:

RAMP_OPEN → MAX_PURGE → RAMP_CLOSE
RAMP_OPEN_FAST → MAX_PURGE → RAMP_CLOSE

RAMP_OPEN

At first start of the NORMAL_PURGE the canister load is unknown. So, the purge valve is opened slowly using a ramp (a high deviation of the lambda control shall be prevented). During this learning the fuel injection time is corrected to avoid emission and driveability problems. The Canister Load is determined by the fuel $_{purge}$ / flow $_{purge}$ ratio.

The RAMP_OPEN operation is finished when :

- CL is learned and stable or
- The canister fuel flow (MFF_CP) is greater than a threshold

RAMP_OPEN_FAST

When the canister load is considered as known, indicated by beeing within a certatin time interval since last MAX_PURGE, the closed loop operation may start with a faster learning phase / ramp. This RAMP_OPEN_FAST operation is finished when :

- The purge flow greater than a threshold
- The canister fuel flow (MFF_CP) is greater than a threshold.

MAX_PURGE

During MAX_PURGE operation the CPS valve is controlled by the canister load, thus a constant fuel ratio (fuel from cps / total fuel) is applied and the valve opening is controlled to keep this constant fuel ratio by adjusting the total purge flow.

The target is to reach high efficiency purging. When the CL is low the purge valve opening will be increased to find the maximum limit of canister fuel flow.

RAMP_CLOSE

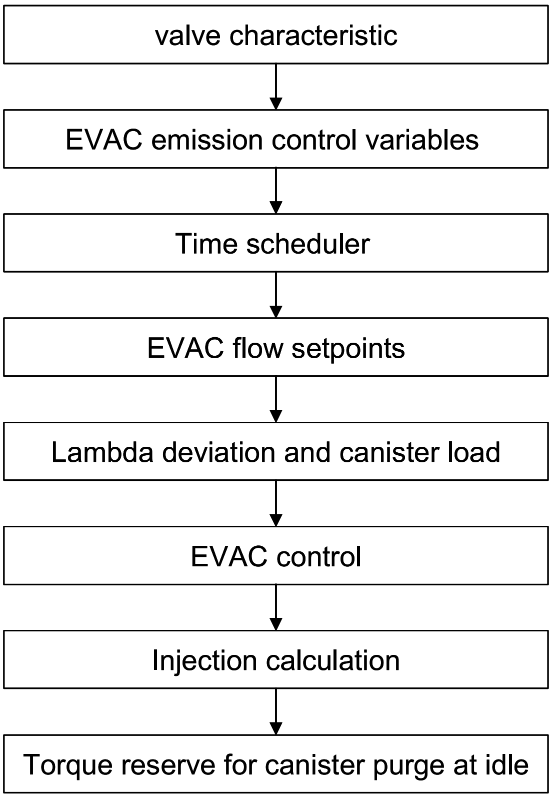
When the purge time is elapsed the purge flow is decreased via a ramp in RAMP_CLOSE operation.

28.21 Syntax

CalibrationDataName	description [defaultValue]

28.21.1 Calibration flowchart

The following flowchart shows the order to calibrate the EVAC functionalities. A continuous refining in this order is mandatory to achieve best results.



28.22 valve characteristic

IP_CPPWM

CPS valve characteristic

This table allows to define the valve opening (CPPWM) from two physical parameters such as the purge flow setpoint (FLOW_COR_SP_CPS) and the upstream/downstream differential pressure applied (PRS_CPS).

The calibration values are gained from the flowbench measurements.

An excel file IP_CPPWM.XLS allows to prepare easily the flowbench results (flow = f [pressure, valve opening]) to fill up IP_CPPWM (valve opening = f [flow, pressure]).

Breakpoints recommended values for FLOW_COR_SP_CPS axe:

- The breakpoint values allow to avoid to spent to much time at the beginning of Ramp Open mode (small opening).
- The two first breakpoints have to following rule:
- The first breakpoint will be zero (0 kg/h). The entire raw (valve opening) will be filled up with = 0 % whatever the differential pressure PRS_DIF_CPS

The second breakpoint will be a small purge flow value like 0.05 kg/h. The raw (valve opening) will be filled out with the “start to open” beginning of flow depending on the differential pressure PRS_DIF_CPS.

[-]

IP_CPPWM_VB_ADD_1

Additive VB correction for CPPWM at frq 1

[-]

IP_CPPWM_VB_ADD_2

Additive VB correction for CPPWM at frq 2

This additive battery correction is applied to adapt the valve opening due to battery voltage variation. The value is depending on the frequency selected.

IP_CPPWM_VB_FAC

Multiplicative VB correction for

CPPWM

This factor correction is applied to adapt the valve opening due to battery voltage variation. The value is depending on the type of purge valve selected.

[1]

28.22.1 Frequency management

C_N_FRQ_1_CPS **C_N_FRQ_2_CPS** **C_CPPWM_FRQ_1_CPS** **C_CPPWM_FRQ_2_CPS**	as required or specified

28.22.2 Thresholds on engine speed and CPPWM to shift CPS frequency.

C_N_FRQ_HYS_CPS
C_CPPWM_FRQ_HYS_CPS

Hysteresis thresholds on engine speed and CPPWM to shift CPS frequency.

These parameters allow to get stable frequency switching.

The hysteresis value should be twice the engine speed and opening valve fluctuations.

[-]

C_CPPWM_FRQ_1
C_CPPWM_FRQ_2

First CPS output frequency

These calibrations will define the valve frequency value applied depending on engine speed and purge valve opening. The selection of the frequency allows to control the purge flow with a minimum of random variation.

The intake manifold back pressure due to engine valves activities could disturb the pulsed purge flow. Then the purge fuel control becomes out of the target.

[10]

IP_CPPWM_COR_FRQ	PWM correction following frequency value This factor correction is applied on the purge valve opening defined for the reference frequency control (FREQ1). From these measurements calculate the ratio between the purge valve opening at the different frequencies and for the same conditions (purge flow, pressure). Calculate for each opening value the best ratio to satisfy most of cases.

[1]

28.23 EVAC emission control variables (403H)

28.23.1 Activation, engine speed limit

LC_CP_ACT	Switch for EVAC activation This switch enables / disables the canister purge LC_CP_ACT=0: canister purge deactivated
C_N_MAX_CP	Maximum engine speed value for canister purge calculations (CPU load reduction)
C_N_HYS_MAX_CP	Hysteresis value for canister purge calculations (CPU load reduction)
C_TCO_MIN_CP	Minimum temperature for EVAP-Control active The minimum threshold of the engine temperature for which the engine combustion has no instability while fuel is supplied by the canister purge system.

LC_CP_DYW_CLC_MAX_ENA	can be set to 0 if further CPU load reduction at high engine speed is needed
C_MAF_DYW_CP **C_N_DYW_CP** **C_FAC_LAM_CP_DYW** **C_DLY_N_MAF_DYW_CP** **C_TQI_DYW_CP** **C_N_2_DYW_CP** **C_LAMB_SP_S_DYW_CP** **C_LAMB_SP_S_DYW_CP** **C_LAMB_SP_S_DYW_CP** **C_LAMB_SP_S_DYW_CP** **C_DLY_N_TQI_DYW_CP**	Dynamic window constants defining stable engine conditions for canister purge function during homogeneous combustion. When stable engine conditions are reached, a timer is started for C_DLY_N_MAF_DYW_CP (hom.) rsp. C_DLY_N_TQI_DYW_CP (strat., hom.lean) When the delay is elapsed the CL_MMV calculation is authorized. The time delay allows the lambda controller to be centered again. These calibrations have to be refined depending on the standard driving cycle used. The transient time duration will define the values. *Method*: • engine bench or Chassis Dyno • stable engine conditions • canister purge function not active • Choose 6 engine load points, give preference to the stable phases of the emission cycle. • For each engine load measure the deviation and variation(MIN and MAX) of the engine speed (N) and mass air flow value (MAF) (hom.) rsp. torque set point value (TQI_SP_S) (lean). • The dynamic window will be define using the formula [3 * (max-min) / 2] • The division by 2 is the result of the specification description where the dynamic window is define as half window. • The time delay to set the stable condition information is tune on the emission cycle in order to filter the lambda deviations during transients. The condition engine stable must be active when lambda deviations (without purge) are elapsed.

C_CRLC_MAF_DYW_CP	Filter constant for limited dynamics calculation on MAF [0,1]
C_CRLC_N_DYW_CP	Filter constant for limited dynamics calculation on engine speed [0,1]
C_CRLC_LAM_DYW_CP	Filter constant for limited dynamics calculation on lambda controller controller in non-normal purge [0,1]
C_CRLC_LAMB_SP_S_DYW_CP	Filter constant for limited dynamics calculation on lambda setpoint in stratified [0,1]
C_CRLC_TQI_DYW_CP	Filter constant for limited dynamics calculation on tqi_sp in stratified [0,1]

28.23.2 Preselection of the canister purge state

C_STATE_CDN_CP_MAN	manual selection of STATE_CDN_CP
C_PRS_MAX_CPS	[Barometric pressure – Manifold intake pressure] limit of the difference of the pressure applied for activation of the canister purge One condition of NO_PURGE is AMP – MAP < C_PRS_MAX_CPS. The value C_PRS_MAX_CPS = 0 enables the MAX_PURGE mode when MAP > AMP (case of supercharger engine) [0 mb]
C_PRS_MAX_CPS_2	To prevent backflow from intake manifold in the acf with charged engines, this threshold leads to a direct shut of the canister purge valve (no ramp) [AMP – MAP] < C_PRS_MAX_2_CPS disables close loop operation [10 mb]
C_STATE_WIN_CP_NOT	state to be forced if engine operation outside CP window; selection of "NONE" leads to an exiting of RAMP_OPEN, but not of RAMP_OPEN_FAST or MAX_PURGE

C_STATE_LAM_LIM_CP	state to be forced if lambda control limitation reached .
LC_STATE_CDN_CP_MAN	switch to activate test mode // manual setting of STATE_CDN_CP
C_TIA_MIN_CP	Minimum intake air temperature to enable canister purge function at idle. One of the condition of NO_PURGE is TIA < C_TIA_MIN_CP. Freezing conditions or acoustic problems can appear at idle. This value has to be checked during cold condition tests. The freezing conditions are depending on the location of the valve mounting. The acoustic problems are depending on the valve mounting support. [5° C]
C_LAMB_SP_S **C_LAMB_SP_S_CP_TOL** **_CP_BOL**	Bottom and top limits on the LAMB_SP_S value [1,5] [2,5]

C_STATE_MAN_SDL_CP	selection of manual scheduling mode [AUTOMATIC]
NC_NR_CP_LAM_AD **ID_T_LAM_AD_THD** **ID_DUR_LAM_AD**	Number and arrays [NC_NR_CP_LAM_AD elements] for start time and duration of fixed lambda adaptation slices
C_CL_MMV_T_BOL **C_CL_MMV_T_TOL** **C_T_DI_CP**	When an empty canister is detected at the end of the learning modes RAMP_OPEN or RAMP_OPEN_FAST (empty canister meaning CL_MMV < C_CL_MMV_T_BOL), (and C_STATE_MOD_SEL_CP="MAX_PURGE") the evaporative system control is stopped for the delay C_T_DI_CP. If the canister is detected full CL_MMV>C_CL_MMV_T_TOL the time control gives the priority to the CP time request. In case of middle load the time control check the request of lambda adaptation and canister purge. This value is checked during hot trip (worst case conditions: canister full and vapor generation) and canister purge cycle. The goal is to optimize the lambda adaptation accuracy and the purge efficiency (no fuel vapor escape to the atmosphere).
C_T_MFF_AD_MAX	Initialisation time for dynamic lambda adaptation time slice. The timer counts as well while waiting for the lambda adaptation conditions to be met (in this period, canister purge may still be enabled). The lambda adaptation phase may be left if the feedback flag from lambda adaptation is set. [240 s]
C_T_2_CP	Initialisation time for dynamic canister purge time slice, will be corrected at the end of RAMP_OPEN. This value must be checked on emission cycle.

[240 s]

IP_T_MAX_CP

Dynamic canister purge time depending on canister load. At the end of RAMP_OPEN or RAMP_OPEN_FAST the purge time duration is modified to fit the canister load learnt.

IP_T_MAX_CP < C_T_2_CP.

This calibration is defined by measuring CL decrease on standard driving cycle (FTP, EURO 2000...) with worst case condition like ambient temperature... For different CL adjust the purging time duration to avoid canister purge breakthrough.

CL_MMV	[-]	0	0	0	0	1	1
IP_T_MAX_CP	[s]	60	90	200	230	260	280

28.25 EVAC flow setpoints (9076)

C_MFF_MIN_CP	Minimum limit on mass fuel flow The purge flow fuel setpoint is calculated to not lead to a remaining injector fuel mass setpoint falling below this limit. [5mg/tdc]
IP_FLOW_CPS_HOM **IP_FLOW_CPS_HOM_AFL**	These values are the maximum canister purge flow in MIN_PURGE mode and homogeneous lambda 1 rsp. hom. lean combustion.

This ratio will limit the purge valve opening because no fuel compensation is done in this mode.

ΔLambda CP is the maximum lambda control deviation allowed to avoid driveability trouble (acceleration) when the lambda controller is not centered. This maximum deviation is obtained with charcoal canister full loaded. The recommended value of ΔLambda CP is about 5-6 % maximum.

From this maximum deviation the maximum purge flow can be evaluated for each engine load :

- Canister Load = (Fuel Mass CP) / Air Flow CP
- Air Flow CP = (Air Flow cylinder * ΔLambda_control CP) / $K_{stochiometric}$ * CLmax

We know the maximum Canister Load ≈ 2 and the usual $K_{stochiometric}$=14,57

- Air Flow CP = Air Flow cylinder * 0,00206

Nevertheless, we have to consider that for engine conditions like “High Load” and charcoal full loaded canister, the upstream/downstream differential pressure will be too low to generate sufficient purge flow then the lambda controller deviation will be also too low.

Method:

For each engine condition (N,MAF):

- Consider the maximum flow the purge valve can provide: IP_FLOW_CPS
- **if** IP_FLOW_CPS__PRS_CPS ≥ Air Flow cylinder * 0.00206

  then fill up IP_FLOW_CPS_HOM with Air Flow$_{cylinder}$ * 0.00206

  else fill up IP_FLOW_CPS_HOM with IP_FLOW_CPS

  endif

IP_FLOW_CPS_S

flow setpoint for MIN_PURGE / stratified operation

Method:

For stratified engine condition (N,MAF):

- Engine bench
- Bottle of gas (butane)
- Perform different opening of the valve with a canister full loaded and measure the impact on the torque.
- The calibration value will be the one in the limit of the driveability (ex 5Nm additional torque).
- The map is tuned using the canister purge valve flow FLOW_CPS

Only available in DI version

IP_RATIO_FUEL_MAX_CP_HOM

Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous stoiciometric operation

This map allows to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE modes.

These calibrations define the maximum purge fuel quantity regarding the fuel engine needs.

To avoid driveability troubles the current ratio limitation between purge fuel and total engine fuel is 25%.

- Fuel purge flow = In system air flow / K $_{stochiometric}$ * X% **{1}**
- Fuel purge = Total cylinder flow * FLOW_CPS * CL $_{max}$ **{2}**

- X% is the fuel purge/engine total fuel ratio (given by engine bench)
- FLOW_CPS is defined by IP_FLOW_MAX_CPS
- Cl$_{max}$ = 0.7 (maximum value with butane)

Method:

- Calculate for each engine load defined by [MAF, N] the values **{1} and {2}**
- Final calibration value for each engine load defined by [MAF, N] = MIN [**{1}, {2}**]
- X%: start with 20% and following the hot trip or SHED results the percentage could be increase (less than 35%).

IP_RATIO_FUEL_MAX_CP_HOM_AFL

Only available in DI version

Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous lean operation

These calibrations allow to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used in RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE modes.

These calibrations define the maximum purge fuel quantity regarding the fuel engine needs.

To avoid driveability troubles the current ratio limitation between purge fuel and total engine fuel is 25%.

- Fuel purge flow = In system air flow / K $_{stochiometric}$ *lambda* X% **{1}**
- Fuel purge = Total cylinder flow * FLOW_CPS * CL $_{max}$

{2}

- X% is the fuel purge/engine total fuel ratio
- FLOW_CPS is defined by IP_ FLOW_MAX_CPS
- Cl_{max} = 0.7 (maximum value with butane)

Method:

- Calculate for each engine load defined by [MAF, N] the values **{1} and {2}**
- Final calibration value for each engine load defined by [MAF, N] = MIN [**{1}, {2}**]
- X%: start with 10% and following the hot trip or SHED results the percentage could be increased.
- If the lean burn combustion is not used the map is tuned to 0.

IP_RATIO_FUEL_MAX_CP_S	Only available in DI version Maximum fuel flow ratio (fuel flow through the CPS/ total fuel flow) for homogeneous stratified operation These calibrations allow to adapt the purge valve opening in order to purge with the maximum efficiency when the CL is not at the maximum value. These calibrations are used RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE modes. These calibrations define the maximum purge fuel quantity regarding the fuel engine needs. To avoid driveability troubles the ratio is limited to take into account the torque. X%: start with 10% and following the hot trip or SHED results the percentage could be increase. If the stratified MAX_PURGE is not used the map is tuned to 0. [0,25]
IP_RATIO_FUEL_MAX_CP_	This table is corrective factor acting on

COR	MFF_KGH_MAX_CP calculation. The aim for tuning is to allow activation of the purge function at a lower TCO. In this case (that means at low TCO), IP_RATIO_FUEL_MAX_CP_COR allow to less open the CPS. This correction has been added in case of long warm up phase, to win purge efficiency by opening the CPS in advance.

28.26 Lambda deviation and canister load (9077)

28.26.1 Filter constants

IP_CRLC_FAC_LAM_MV_MMV_CP_CLL

correlation constant for FAC_LAM_MV_MMV_CP calculation in case of Purge in closed loop

MAF_CYL	[kg/h]	12	45	70	140	250	5
IP_CRLC_FAC_LAM_MV_MMV_CP_CLL	[-]	0,500	0,500	0,500	0,500	0,500	0

IP_CRLC_FAC_LAM_MV_MMV_CP_OPL

correlation constant for FAC_LAM_MV_MMV_CP calculation in case of Purge in open loop

MAF_CYL	[kg/h]	12	45	70	140	25
IP_CRLC_FAC_LAM_MV_MMV_CP_OPL	[-]	0,250	0,250	0,250	0,250	0,2

IP_CRLC_LAMB_LPF_CP

Correlation constant for LAMB_MMV_CP calculation

IP_CRLC_MMV_CP

Correlation constant for LAMB_MMV_CP calculation

IP_CL_CRLC_RAMP_OPEN

CL_MMV filter coefficient during RAMP_OPEN_FAST

MAF_CYL	[kg/h]	12	45	70	140	250
IP_CL_CRLC_RAMP_OPEN	[-]	0,300	0,300	0,400	0,450	0,480

IP_CL_CRLC_OPEN_FAST

When the RAMP_OPEN_FAST is ongoing the Lambda controller has to be stable (no more than 5% of deviation)

This calibration result is also depending on ramp opening value during this mode.

IP_CL_CRLC_INI

Initialization value for correlation factor value

CL_MMV	[-]	0	0	0
IP_CL_CRLC_INI	[-]	0,150	0,150	0,150

IP_CL_CRLC

This calibration is the CL_MMV filter coefficient during MAX_PURGE mode. The values will define this filter coefficient will be limited by two borders. The high one is defined by the Canister load decrease in stable engine conditions, and the low one is defined by the normal acceleration/deceleration time duration

case A, canister load decreases in stable engine conditions

Method:

- IP_CL_CRLC has to be tuned to follow the canister load (CL) decrease.
- During MAX_PURGE, CL decreases and the canister weight loss follow the same law.
- A wrong IP_CL_CRLC value could result in a meaningful difference between the average CL value (CL_MMV is used for the calculation of injection compensation) and CL.

Test conditions:

- Different engine loads in stable conditions
- Charcoal canister full loaded (butane or fuel following legal procedure).
- C_T_1_CP, C_T_2_CP and IP_T_MAX_CP_CL_MMV set to a high value to keep MAX_PURGE mode until the canister becomes empty.
- IP_CL_CRLC pre-tuned to 0,005 (for the whole mapping).
- recording of CL
- if canister is loaded with butane: CL_MAX ≈ 0.63
- if canister is loaded with fuel: CL_MAX ≈ 0.7....2

case B, normal acceleration/deceleration time duration

During transient mode the Lambda controller varies. The time duration of the lambda controller is shorter than the one during the charcoal canister weight lost. This lambda controller variation has not to be taken such as a loss of canister load.

- Different engine load in stable conditions
- Purge deactivated
- start with normal acceleration/deceleration
- Measure the time spent (T2) by the lambda controller to reach a stable

value {2}

Calculate the values (CL max * recurrence) / T2 s {2}

The final calibration value will be: {2} < IP_CL_CRLC < {1a, 1c}

Usual approach:

<u>Part and full load</u>

IF for MAF_CYL ≥ 90 kg/h the value calculated in {1a} > 0.005 then fill up the mapping table with 0,005

And for MAF_CYL < 90 kg/h fill up the mapping table with 0.005 * value calculated in {1b}

<u>Idle speed</u>

At idle the average value of the lambda controller (TI_LAM_MMV) varies. Then this variation generate another CL variation. For MAF_CYL breakpoint at idle and charcoal canister empty refine the coefficient filter to prevent these CL, CL_MMV oscillations.

IP_NR_STEP_CL	Number of step to change of correlation factor value This is a filter-filter-constant map, it aims in filtering the transition from the IP_CL_CRLC_INI map to the standard-MAX_PURGE-map IP_CL_CRLC.
C_CL_FAC_LAM_DIF_MIN **C_CL_FAC_LAM_DIF_MAX**	Lower and upper limits on FAC_LAM_DIF_CP variation If these limits are exceeded in MAX_PURGE, the CL filter constant is taken from the faster map IP_CL_CRLC_INI, same principle as entering MAX_PURGE [-10/10%]
C_PRS_MAX_2_CPS	Pressure difference limit (environment-intake manifold) for CL_MMV calculation [10 mb]

C_FLOW_MIN_CPS

Purge flow threshold to authorize CL_MMV calculation in RAMP_OPEN, RAMP_OPEN_FAST and MAX purge.

if FLOW_CPS is lower than this calibration the last value of CL_MMV is kept.

During the purge valve opening/closing, the flow FLOW_CPS takes small values. Small flow values can produce an incorrect purge flow and an incorrect canister load learning. This difference results in values of CL that do not correspond to a physical reality.

Calculate the purge flow obtained by 1 bit of valve opening.

Method: Biggest purge flow (100% opening P). Divide this maximum flow by the format of the valve opening□and high (CPPWM) in case of byte the divisor will be 255. The calibration will be the value regarding 2 bits.

[0,04 kg/h]

C_CL_ST_CP

Initialization value for charcoal canister load at the beginning of RAM_OPEN mode.

CL_MMV and CL use the same initialization value

The calibrated value is about the half value of the maximum CL value encountered when the charcoal canister is loaded with butane. This value allows to reduce the work of the CL filter and to get too much deviation between CL and CL_MMV.

[0,3]

C_CL_MAX_CP

The canister load is the fuel concentration of the A/F mixture that comes from the canister through the CPS valve.

The mass of fuel (vapors) which is coming from the canister depends on:

- the type of fuel used
- the system design (pressure drop...)

Charcoal canister loaded with butane

- The measurements should lead to the theoretical value CL max = 0,7

Charcoal canister loaded with gasoline

- The fuel from the canister is in the

	vapor state but the mass fuel flow is higher than the butane. This mass is depending on the type of fuel used and the in-use conditions. The C_CL_MAX_CP value equal to 2 could satisfied most of applications. Check this value during refueling in hot trip conditions (high vapor generation that can lead to a full and unstable canister load)
C_FAC_LAM_DIF_MAX_CP	Maximum Lambda controller deviation threshold during learning mode. This calibration is defined by the maximum lambda controller deviation to get no driveability trouble during accelerations while the RAMP_OPEN mode is ongoing. [5%]
C_FAC_LAM_DIF_CP_AS	Application system value to apply a lambda deviation
LC_LAM_CBK_CPS	Lambda controller selection (0 -> bank 0 , 1 -> bank1)
C_RAF_CLC_CP	Stochiometric ratio of usual fuel. This value has to be refined regarding the type of fuel defined by the application. [14,57]
LC_CL_FIL_INI_TRA_DEAC_CLL	Correlation factor calculation in case of NO_PURGE or MIN_PURGE → MAX_PURGE transition
C_CL_DYW_MAX_CP	This calibration aims to prevent wrong fuel correction when too fast variation of CL happens. This calibration is to get fuel correction robustness. In case where too high CL variation happen the MIN_MODE is forced. In RAMP_OPEN, RAMP_OPEN_FAST, MAX_PURGE modes [CL n-1 - CLn] is calculated. *if [CL n-1 - CLn] > C_CL_DYW_MAX_CP* *then MIN_MODE is forced*

28.26.2.1 DI specials

C_CL_MMV_CHK	The canister purge force the homogeneous lambda 1 combustion to increase the capacity of purge, when the canister load is under the threshold C_CL_MMV_CHK the stratified combustion is active again. *Method:* On specific emission cycle (Ex : MAZDA), check if the cycle if finished During hot trip and fuel vapor generation, check the capacity of the function to prevent gas to the vent of the canister.
C_CL_MMV_HOM_CP	The canister purge force the homogeneous lambda 1 combustion to increase the capacity of purge, when the canister load is upper the threshold C_CL_MMV_HOM_CP the homogeneous lambda 1 combustion stay active. *Method:* On specific emission cycle (Ex : MAZDA), check if the cycle if finished During hot trip and fuel vapor generation, check the capacity of the function to prevent gas to the vent of the canister.
LC_LAMB_AFS_CP_CPS_SCG	switch to force hom1 operation if cps valve short circuit to ground error present

28.26.3 Timer constants for limits exceeded tests

C_T_DLY_PU_CPS	CPS interrupt time during PU When the engine management goes in trailling throttle (LV_PU) the injection time becomes very small and near the minimum injection time. To prevent a big lambda deviation on transition PL to PU the CPS valve is closed immediately during a time C_T_DLY_PU_CPS. When this time is elapsed the function stay in MIN_PURGE during PU. The time must allow to close the valve during the gas transfer between the CPS

	valve and the oxygen sensor. This time is defined by the duration of the engine gas transfer. [0.1 s]
IP_T_DLY_CMU_CPS	Stabilization delay on lambda regulation after commutation When the engine have combustion commutations (e.g. homogeneous → stratified), all the parameters are unstable during a delay. To prevent driveability problems during the commutation the canister purge valve is closed during a time IP_T_DLY_CMU_CPS__N_32. The function is re activated as soon as the engine parameters are stable. Method: Perform different type of commutations and measure the time to have stable values
C_T_LAM_LIM_CP	Additional close loop deactivation duration due to LV_LAM_LIM activation. Set, when the lambda controller sets its flags indicating "lambda control limitation reached" [5 s]
C_FAC_LAM_CP_BOL **C_FAC_LAM_CP_TOL**	Lambda control functional window. This window is additional to the control of the limiation flags from the lambda controller, see above. To prevent wrong canister load learning, the lambda control value will be checked all the time in RAMP_OPEN. If C_FAC_LAM_CP_BOL < FAC_LAM_CP < C_FAC_LAM_CP_TOL, RAMP_OPEN is disabled or stopped temporarily and MIN_PURGE is applied. This calibration prevents the learning because the reference point FAC_LAM_0_CP is not centered at RAMP_OPEN start. The threshold is defined by the normal error due to the flows (air & fuel). The realistic error is estimated about 5%. The 5% standard lambda controller deviation during the learning mode is defined by C_FAC_LAM_DIF_MAX_CP. These calibrations are defined by: • standard error flow +

	C_FAC_LAM_DIF_MAX_CP [-10%]
C_T_DLY_LAM_CP	Time to inhibit learning modes RAMP_OPEN & RAMP_OPEN_FAST after lambda controller left functional window defined above. After the time delay C_T_DLY_LAM_CP the learning conditions will be checked once more. [20 s]
C_N_CP_BOL	Minimum speed limit for activation of the RAMP_OPEN operation (homogeneous) The low limit of close loop is used as value [620 1/min]
C_N_CP_TOL	Maximum speed limit for activation of the RAMP_OPEN operation (homogeneous) This parameter is defined using the measurement of the MAP = f [MAF,N] The difference of the pressure (AMP – MAP) has to be higher than 200mbar in the area defined by C_N_CP_TOL and IP_MAF_CP_TOL. [3500 1/min]
IP_MAF_CP_BOL **IP_MAF_CP_TOL**	Minimum mass air flow limit for activation of the RAMP_OPEN operation (homogeneous) In low MAF, the purge flow is not big enough to make change the canister saturation degree. The low limit of close loop is used as value Maximum mass air flow limit for activation of the RAMP_OPEN operation (homogeneous) This parameter is defined using the measurement of the MAP = f [MAF,N] The difference of the pressure (AMP – MAP) has to be higher than 200mbar in the area defined by C_N_CP_TOL and IP_MAF_CP_TOL. ***Hint:*** The values defined for the window have an impact on the calibration of the chapter 6.2.1 These four calibrations will allow to select

the canister load learning area during homogeneous combustion

[50 mg/stroke] [400 mg/stroke]

28.26.4 Canister load learning window stratified

Minimum / maximum engine speed / torque setpoint value limits for activation of the RAMP_OPEN operation (stratified)

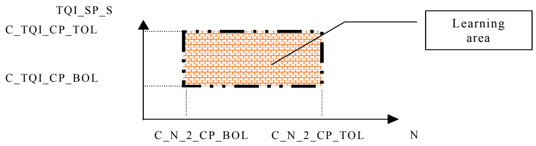
C_N_2_CP_BOL

C_N_2_CP_TOL

C_TQI_CP_BOL

C_TQI_CP_TOL

These four calibrations will allow to select the canister load learning area during stratified combustion



28.27 EVAC control (9008)

28.27.1 EVAC control - state machine

C_T_DLY_MAX_CP	Time between two MAX_PURGE operations for RAMP_OPEN_FAST activation. When leaving MAX_PURGE, a time counter T_DLY_MAX_CP starts to count backwards from this calibration value to 0. While the counter does not reach zero, a new learning mode via RAMP_OPEN_FAST is possible; if it reaches zero, the next learning mode has to be RAMP_OPEN [50 s]
C_T_DI_RAMP_OPEN_CP **C_T_DI_RAMP_FAST_CP** **C_T_DI_MAX_CP**	Disable times of the states RAMP_OPEN, RAMP_OPEN_FAST and MAX_PURGE If closed loop canister purge ("normal purge") is abandoned e.g. due to high engine dynamic, the time counter T_DI_CP starts to count backwards from the corresponding calibration values to 0. While it does not reach zero, a re-entering in the last closed loop state is possible as soon as the conditions for closed loop canister purge are given again. If the counter reaches 0, closed loop canister purge has to start with a new learning mode. This does not affect the exit of closed loop canister purge by LV_CP_NEW_RAMP_OPEN. A re-entry in RAMP_OPEN_FAST is only possible, if LC_CP_TRAN_DEAC_CLL is set to 1, otherwise (switch=0), no reversible interruption of RAMP_OPEN_FAST is enabled.
C_T_DLY_CP	Time delay to wait in WAIT_RAMP_OPEN (valve closed) before starting the learning modes. This time duration is defined by: • Duration for the engine gas

	transfer - Duration for lambda controller stabilization This value has to be checked in idle speed mode coming from MIN_PURGE mode and canister full loaded. The lambda deviation authorized in MIN_PURGE is 5% (see C_FLOW_MIN_CPS). [5 s]
C_T_LOCK_CP	Locking time for locking MIN_PURGE or NO_PURGE after canister empty detection. [20 s]
C_STATE_MOD_SEL_CP	If the canister is detected empty at the end of RAMP_OPEN, closed loop canister purge can be inhibited for a time C_T_LOCK_CP by setting C_STATE_MOD_SEL_CP to "NO_PURGE" or "MIN_PURGE". Then the so selected state is the maximum possible CP state until the timer T_LOCK_CP reaches zero. [MIN_PURGE]
LC_CP_TRA_MAX_MIN_CDN_ENA	enable transition MAX_PURGE → MIN_PURGE with STATE_CDN_CP
LC_CP_TRA_MIN_PURGE_DFT_ENA	enable transition NO_PURGE → MIN_PURGE with STATE_CDN_CP = NO_CDN
LC_CP_TRA_MIN_RAMP_OPEN_DIS	enable trans. NO_PURGE → MIN_PURGE, if no RAMP_OPEN or RAMP_OPEN_FAST is possible although STATE_CDN_CP=RAMP_OPEN or RAMP_OPEN_FAST [1]
LC_CP_TRA_OPL_CDN_CLL_NOT	enable transition WAIT_RAMP_OPEN → NO_PURGE if LV_CP_CDN_RAMP_OPEN, _FAST no more given [0]
LC_CP_TRA_OPL_CDN_NOT	enable transition WAIT_RAMP_OPEN → NO_PURGE

if STATE_CDN_CP = NO_CDN

This switch is redundant to LC_CP_TRA_OPL_CDN_CLL_NOT

[0]

28.27.2 EVAC control - states

IP_PQ_CP_SP	[-]
C_CRLC_PQ_SP_CP	[0,25]
C_CL_MMV_PQ	[2] Setpoint value, filter constant and activation threshold on canister load for forced PQ (pressure quotient) during stratified mode for RAMP_OPEN and MAX_PURGE. A forced PQ is enabled in homogeneous lean burn mode if the switch LC_PQ_SP_CP_HOM_AFL is set to 1. The PQ setpoint can lead to further closing of the throttle thus leading to a higher pressure difference ambient ⇔ intake manifold thus enabling higher purge flows.
LC_PQ_SP_CP_HOM_AFL	Setpoint value, filter constant and activation threshold on canister load for forced PQ (pressure quotient) during stratified mode for RAMP_OPEN and MAX_PURGE. A forced PQ is enabled in homogeneous lean burn mode if the switch LC_PQ_SP_CP_HOM_AFL is set to 1. The PQ setpoint can lead to further closing of the throttle thus leading to a higher pressure difference ambient ⇔ intake manifold thus enabling higher purge flows. [0]
C_CL_CAT_DIAG	Canister load threshold to enable cat.diag. in MIN_PURGE (if cl < thd) If CL_MMV is below this threshold at the regular end of RAMP_OPEN, the flag LV_CL_CLC_AVL is set to 1 and passed to EGTR where it could enable

a catalyst diagnosis in MIN_PURGE.

[0,5]

C_CL_MMV_DYW

Dynamic window on CL_MMV value to stop leaning mode (RAMP_OPEN) and start MAX_PURGE.

- The window is tuned to stop the RAMP_OPEN when the CL_MMV becomes stable inside the natural oscillation of FAC_LAM_MMV.
- This tuning is done after IP_CL_CRLC_RAMP_OPEN
- The tuning is done with empty canister (CL_MMV < 0,2) in idle (maximum effect by natural oscillation of lambda regulation).

The window is defined as twice the value of CL_MMV oscillations.

[0,024]

IP_T_DLY_CL_MMV_DYW

Minimum time duration of RAMP_OPEN when CL is inside the dynamic window C_CL_MMV_DYW

Method:

- Charcoal canister empty
- Different stable engine load defined by MAF_CYL
- Start with RAMP_OPEN mode and measure the time spent to get CL_MMV stable and close to CL. Fill the IP_T_DLY_CL_MMV_DYW with the measured time.

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_T_DLY_CL_MMV_DYW	[s]	3,600	3,600	2,400	2,400	2,400	2,400

C_T_DLY_MAX_RAMP_OPEN

Initialisation time duration for RAMP_OPEN mode.

If no lambda shift occurs during RAMP_OPEN mode, no re-initialsisation of the timer T_RAMP_OPEN_STAB will occur and RAMP_OPEN will be left after C_T_DLY_MAX_RAMP_OPEN.

Method:

- Charcoal canister empty

- Idle speed mode

The final valve opening is defined by FLOW_MAX value. Measure the time spent to reach about 4/5 of FLOW_MAX at idle.

[20s]

LC_LAM_LIN_CPS	Type of O2 sensor (0 → binary sensor , 1 → linear sensor)

28.27.3 EVAC control - flow calculations

LC_FLOW_CPS_AS	as required
C_FLOW_CPS_AS	Manual value for FLOW_CPS and activation switch for that.
LC_CP_FLOW_LIM_OPEN_FAST	enable old calc. of FLOW_OPEN_CPS: fuel mass based As soon as the limit flow FLOW_OPEN_CPS is reached, RAMP_OPEN_FAST is left towards MAX_PURGE. With the switch = 1, the limit flow FLOW_OPEN_CPS can be taken from a map IP_FLOW_MAX_OPEN_CPS, this is similar to the calculation in RAMP_OPEN. With the switch = 0, the limit flow is calculated based on the maximum possible fuel for RAMP_OPEN_FAST; this is the solution of previous canister purge versions.
ID_FLOW_INC_NR_CP	Increment number for FLOW_CTL_CPS calculation during RAMP_OPEN and RAMP_OPEN_FAST (steps à 20ms) The ramping-up of the flow during RAMP_OPEN and RAMP_OPEN_FAST consists of two phases: flow incrementation and gas transfer delay. Each flow incrementation phase consists of a ID_FLOW_INC_NR_CP incrementation steps with the amount of IP_FLOW_INC_CP rsp. IP_FLOW_INC_FAST_CP. After the incrementation phase, the system waits for gas delay or rich → lean

switch of a binary lambda sensor.

N_32	[1/min]	0	2048	4096	5120
ID_FLOW_INC_NR_CP	[-]	11	12	15	19

IP_FLOW_INC_CP

During RAMP_OPEN, the valve is opening smoothly in order to control the lambda

This calibration defines the slope of FLOW_CPS by incrementing directly FLOW_CTL_CPS in homogeneous mode. The first step is defined by C_FLOW_INI_CPS.

The IP_FLOW_INC_CP values are defined by calculation. These increments will be checked during driving tests in hot conditions (charcoal canister loaded)

(Lambda max = 5-6 %, CL max = 2)

Method:

- Driving tests in hot conditions
- Different engine load for stable engine conditions
- Charcoal canister full loaded
- Ramp open mode
- Calibrate the maximum canister purge time equal to 20 s
- Calibrate the lambda adaptative duration equal to 20 s
- For different engine loads (MAF_CYL) adjust IP_FLOW_INC_CP in order to get no more than 5-6% of lambda variation during RAMP_OPEN mode.

MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_INC_CP	[kg/h]	0,002	0,003	0,005	0,006	0,009	0,013

IP_FLOW_INC_FAST_CP

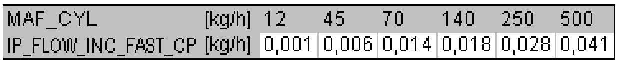
During RAMP_OPEN_FAST the CL is known so the purge valve can be opened faster than the one used in RAMP_OPEN mode. In this case the slope of the purge valve opening will be a compromise between opening speed and lambda control. This map is used for homogeneous combustion.

This calibration defines the slope of FLOW_CPS by incrementation of FLOW_CTL_CPS in Ramp Open fast.

Method

- Engine bench or Chassis Dyno
- Different engine loads for stable engine conditions
- Charcoal canister full loaded by butane or warmed fuel (50°C)
- Ramp open fast in Homogeneous mode
- For different engine loads (MAF_CYL) adjust IP_FLOW_INC_FAST_CP in order to get ± 5-6 % maximum lambda variation during RAMP_OPEN mode. This calibration needs some repeated measurements. To get the repeatition fastly the time durations of some phases could be reduced (Lambda adaptation, Purge time duration)

These calibrations have to be refined during in-use tests in hot conditions (summer trip)



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_INC_FAST_CP	[kg/h]	0,001	0,006	0,014	0,018	0,028	0,041

IP_FLOW_DEC_CP

Purge opening decrement value for FLOW_CPS during RAMP_CLOSE mode. The slope of the closing prevents exhaust lambda variation.

This calibration defines the slope of FLOW_CPS.

Method:

- Charcoal canister full (legal procedure) and empty loads
- Canister Load learned in RAMP_OPEN and refined in MAX_PURGE.
- For different engine loads (MAF_CYL) adjust IP_FLOW_DEC_CP in order to get

± 5% maximum lambda variation at the end of RAMP_CLOSE mode. This calibration needs some repeated measurements. To get the repetition fastly the time durations of some phases could be reduced : Lambda adaptation, Purge time duration....

C_FAC_DEC_COR_CMU_CP

Purge opening decrement value for FLOW_CPS during combustion commutation.

This calibration defines the slope of FLOW_CPS.

Method:

- Charcoal canister full (legal procedure) and empty loads
- Canister Load learned in RAMP_OPEN and refined in MAX_PURGE
- Adjust C_FAC_DEC_COR_CMU_CP in order to have no impact of the canister purge during the commutation. Compare with and without purge different types of commutation.

C_FAC_DEC_COR_1_CP

Other system functions could want to stop the canister purge function. The request of purge closing is controlled by the OBD2 controller. Depending on the type of request the closing speed is defined by C_FAC_DEC_COR_1_CP.

The target of the calibration is to go in NO_PURGE mode fastly without taking care with pollution or lambda variation.

Closing speed correction factor 1 is used for high speed closing

This calibration has to be done by the function transmitter of the close request

[1]

C_FAC_DEC_COR_2_CP

Other system functions could want to stop the canister purge function. The request of purge closing is controlled by the OBD2 controller. Depending on the type of request the closing speed is define by C_FAC_DEC_COR_2_CP.

The target of the calibration is to go in NO_PURGE mode with a compromise between the closing speed and lambda variation.

Closing speed correction factor 2 is used for medium speed closing

This calibration has to be done by the function transmitter of the close request

[1]

IP_FLOW_FAC_CP	Correction factor for FLOW_CPS applied in RAMP_OPEN, RAMP_OPEN_FAST or RAMP_CLOSE modes, for homogeneous and stratified modes. The correction value is depending of the CL value. The reference is based on canister full loaded (factor = 1). When the CL is lower the FLOW_CPS incrementation is increased.

The values are defined by calculation. The values will be checked during driving tests with different charcoal canister loads.

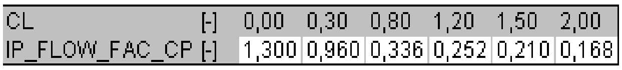
This factor must be calibrated by taken account that at each incrementation the lambda variation must stay lower than 5-6%

Method:

- Driving tests, different charcoal canister loads
- Different engine load for stable engine conditions
- Ramp open mode

For different engine loads (MAF_CYL) adjust IP_FLOW_FAC_CP in order to control ± 5-6 % maximum lambda variation. This calibration needs some repeated measurements. To get the repeatition fastly the time durations of some phases could be reduced : Lambda adaptation, Purge time duration....

The calibration must be checked in Ramp open fast and ramp close mode for all the combustion modes.



CL	[-]	0,00	0,30	0,80	1,20	1,50	2,00
IP_FLOW_FAC_CP	[-]	1,300	0,960	0,336	0,252	0,210	0,168

IP_FLOW_CPS_INC

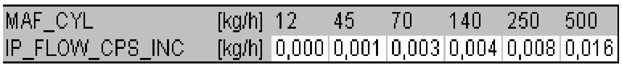
(In MAX_PURGE, the closing of the valve must be the same as the one given by the ramp of FLOW_CTL_CPS during RAMP_CLOSE.)

The purge valve opening/closing is done by FLOW_CTL_CPS variations.

In case where the evaporative system design is not good enough (fuel tank purged : the purge valve opening/closing has to be done slower. These calibrations allow to apply a 1st order on the purge flow needed. The purge flow integrated will define the purge valve opening.

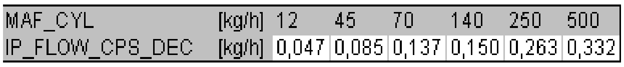
Method:

- Engine loads in stable conditions
- Charcoal canister full (legal procedure) and empty load
- CL learnt and MAX_PURGE mode acting.
- Change the purge target modifying IP_FUEL_FLOW_MAX_CP to get high variation in purge valve opening and purge flow needed.
- For different engine loads (MAF_CYL) adjust the INC and DEC in order to get ± 5% maximum lambda variation up to the valve opening setpoint is reached. This calibration needs some repeated measurements. To get the repeatition the time duration of Purge time duration could be lengthened.



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_CPS_INC	[kg/h]	0,000	0,001	0,003	0,004	0,008	0,016

IP_FLOW_CPS_DEC



MAF_CYL	[kg/h]	12	45	70	140	250	500
IP_FLOW_CPS_DEC	[kg/h]	0,047	0,085	0,137	0,150	0,263	0,332

C_FLOW_INI_CPS

- This value is used to initialize FLOW_CTL_CPS at beginning of the RAMP_OPEN.
- This data is calculated to obtain

most quickly the “start to open” valve opening point in idle. At the RAMP_OPEN start the purge valve opening has to be close to the “start to open” point defined in IP_CPPWM

- Method:
- Second breakpoint of purge flow axe in IP_CPPWM > C_FLOW_INI_CPS
- Check on engine bench for different engine loads that this value is enough to open correctly the valve and create e first deviation of lambda
- [0,01 kg/h]

IP_FLOW_MAX_OPEN_CPS

FLOW_CPS for fully opened CPS (CPPWM=100%)

This map defines the maximum purge flow value [kg/h] when the valve is fully opened; the values are from the flowbench measurements or from IP_CPPWM

The calibration needs the values

- MAF_CYL = f(MAF[mg/tdc], N_32[rpm]) and
- MAP = f(MAF[mg/tdc], N_32[rpm]) and

MAF_CYL ⇒ MAP ⇒ MAX FLOW CPS ⇒ IP_FLOW_MAX_CPS (MAX FLOW CPS)

An excel file FLOW_MAX.xls allows to calculate the calibration values to fill up automatically the FLOW_MAX_CP.

This map characterizes the maximum flow authorized during RAMP_OPEN or RAMP_OPEN_FAST mode. This map can be considered as flow setpoint for the learning modes.

At Idle IP_FLOW_MAX_OPEN_CPS should be limited. In order to keep sufficient idle actuator authority on purge the maximum purge flow will be limited at 10% of the maximum total air engine flow.

[-]

IP_FAC_AMP_CP

The canister purge flow ($Q_{Purge\ Map}$) values are defined at standard sea level barometric pressure ($P_{Purge\ Map}$) =1013 mb.

The factor correction by IP_FAC_AMP_CP allows to adapt the flow at the current barometric pressure.

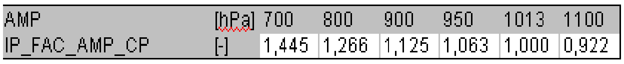
The variation of the canister purge flow is depending on the upstream pressure. This variation follows the law:

$$Q_{Purge} = Q_{Purge\ MAP} * [P_{baro\ current} / P_{Purge\ MAP}]$$

When the valve opening has to be

defined to get a needed canister purge flow the inverted law is used :

$$Q_{Purge\ MAP} = Q_{Purge} * [P_{Purge\ MAP} / P_{baro\ current}]$$



AMP	[hPa]	700	800	900	950	1013	1100
IP_FAC_AMP_CP	[-]	1,445	1,266	1,125	1,063	1,000	0,922

IP_FAC_TIA_CP

The canister purge flow ($Q_{Purge\ Map}$) values are defined at standard ambient temperature = 25°C

This factor correction allows to adapt the flow at the current ambient temperature

The variation of the canister purge flow follows the law:

$$Q_{Purge} = Q_{Purge\ MAP} * [T_{Purge\ MAP} / T_{current}]^{0,5}$$

With T[°K]

When the valve opening has to be defined to get a needed canister purge flow the inverted law is used :

$$Q_{Purge\ MAP} = Q_{Purge} * [T_{current} / T_{Purge\ MAP}]^{0,5}$$

With T[°K]
