FUNCTION DESCRIPTION:

General information:

This flag deactivates the NOx catalyst aging adaptation when errors occure which must not stop the lean operation and the NOx catalyst management, but can cause an inaccuracy in the model, which must not be adapted.

With the calibration data LC_INH_NT_AGI_MAN it is possible to deactivate the NOx trap aging adaptation manually.
With the calibration data LC_INH_NT_AGI_OFF it is possible to make the adaptation allways working. These bits are useful for the calibration phase.

Number of NOx catalyst:	NC_NT_NR	i = 1...NC_NT_NR
Number of NOx sensors:	NC_NOX_SENS_CONF	k = 1...NC_NOX_SENS_CONF
Number of lambda sensors:	NC_CBK_EX_NR	m = 1...NC_CBK_EX_NR

Typical configurations:
[NC_CBK_EX_NR:NC_NT_NR:NC_NOX_SENS_CONF] =[1:1:1], [2:2:2], [2:2:1], [2:1:1]

Application conditions:

Recurrence: 10 ms
Activation: --
Deactivation: --
Initialisation: --

Formula section:

```
if(0)      STATE_NOX = STOP --> !STOP
then(0)    LV_INH_NT_AGI_THD = 0

53.14.1 NOx catalyst sulphur model (NOXM modul 704G)

General information:

The NOx catalyst sulphur model can handle single branched and twin branched exhaust gas lines with the configuration data NC_NT_NR defined in the NOx catalyst management module.

If NC_NT_NR=1, just one exhaust line is taken into account, if NC_NT_NR=2, the software calculates the twin branch version.

i belongs to NC_NT_NR.

Description:

The NOx catalyst sulphur model calculates the NOx catalyst sulphur loading.

The sulphur loading is increased only in lean burn phase (-> STATE_NOX = LOAD). The sulphur loading increment is calculated out of the fuel sulphur concentration and converted to a NOx mass loading equivalent (sulphur load in NO2 mass loading equivalent is loss of NOx storage capacity).

When the desulfation is active, the sulphur which is chemically stored in the NOx-trap is released depending on the NOx-trap monolith temperature, lambda, the modeled sulphur load NT_SUL on the corresponding layer and the value of NT_AGI_THERMO.

During the desulfation the NOx-trap sulphur load is decremented until it reaches 0.

C_CRLC_SU_NOX includes

- the factor for transformation of MFF_SP * N_32 {mg/stk * 1/min} to a fuel mass flow
  {mg / TA} =0,1s / 2 / 60s = 1 / 1200)
- and the factor for number of cylinders and number of NOx traps
  = NC_CYL_NR / NC_NT_NR
- and the factor for transformation of C_SU_CONC_FUEL {ppm} to mass part sulphur
  in fuel {mg S/mg fuel} = 1E-6
- and the factor for transformation of sulphur load {mg S} to sulphur load NO2 equivalent
  {mg NO2} = 2 * 46 / 32 = 2,875.

Example values:

- four cylinder and one NOx trap: 9,5833 E-9
- six cylinder and two NOx traps: 7,1875 E-9

Calculation inside this function is done by high resolution variable NT_SUL_32. Valid output to other functions is low resolution variable NT_SUL.

Unsymmetrical EGR branch

If the exhaust gas recirculation is unsymmetrical (exaust gas is taken from one bank and added to the intake air for both banks) then the different sulfur loading of the NOx traps will be considered by setting C_STATE_EGR_CBK to the bank with the EGR branch. In a symmetrical or a one-bank-system C_STATE_EGR_CBK have to be set to 0.

The splitting of the sulfur to both NOx traps is shown in the following picture. The sulphur is proportional to the fuel flow and the fuel split is controlled by the air flow, which depends from the EGR ratio.

53.14.1.3 OPERATE

Calculation before MAIN

Before the MAIN part, which is calculated for each bank, the difference of the fuel due to the unsymmetrical EGR will be calculated. It will be added or subtracted inside MAIN to both banks.

(If MFF_SP_2 is not existing caused by NC_CBK_EX_NR = 1, but access demanded by other variables depending on other indices of bigger size, then MFF_SP_1 is used.)

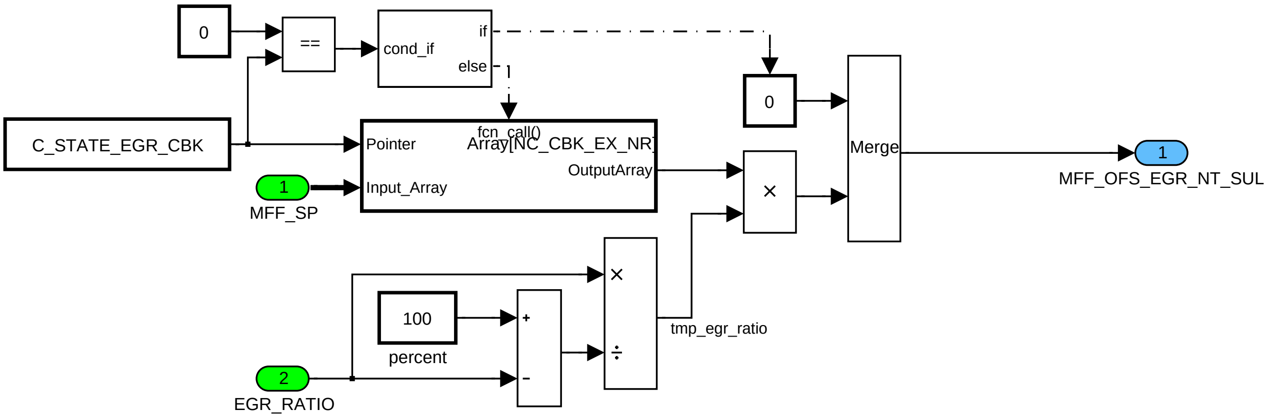

Figure 148 NOXM_MODUL704G/ operate/ BEFORE_MAIN

MAIN (for each NOx trap)

The function consists of the following parts

- manual initialization
- sulphur load update (from NOx catalyst aging)
- sulphur loading during LOAD phase
- sulphur release during desulfation

  (splitted in two parts: before and after T_SO2P_DLY)

The for loop of the MAIN part is controlled by the number of NOx traps

NC_NT_NR = 1 means one NOx trap (calculation for i = 1)

NC_NT_NR = 2 means two NOx traps (calculation for i = 1 and 2)

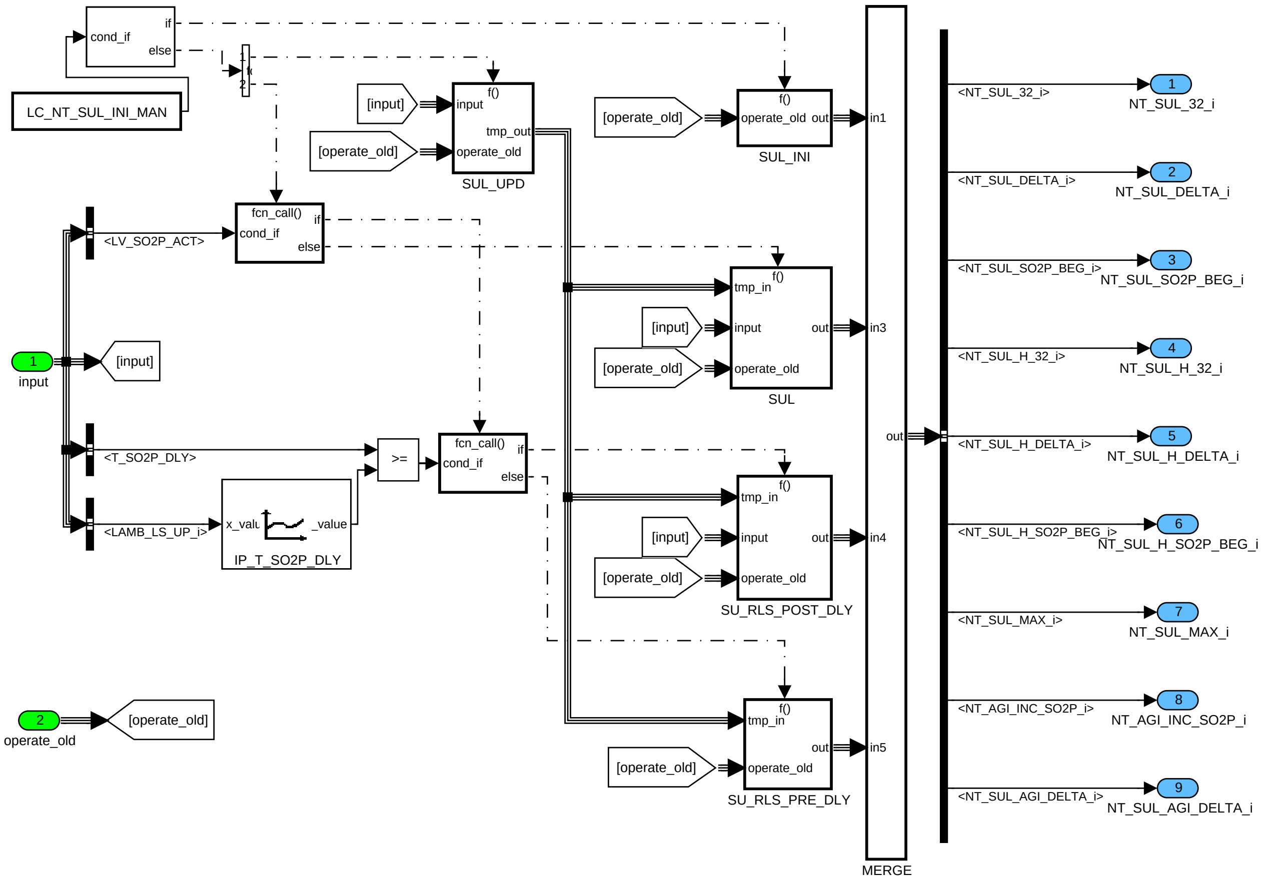

Figure 149 NOXM_MODUL704G/ operate/ CBK_MNG/ MAIN

Manual initialization

If LC_NT_SUL_INI_MAN ist set, then the sulfur load of the NOx traps will be initialized with C_NT_SUL_INI.

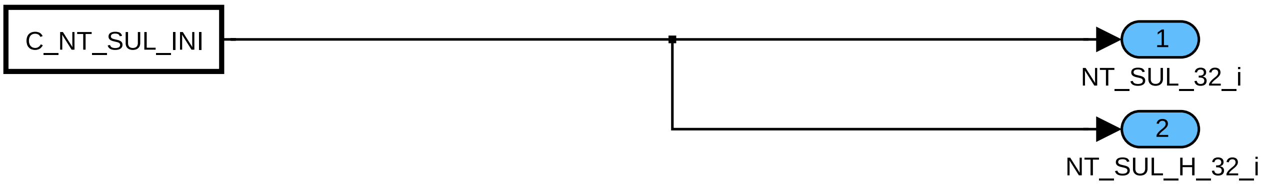

Figure 150 NOXM_MODUL704G/ operate/ CBK_MNG/ MAIN/ SUL_INI/ CLC

Sulphur load update

The update value NT_SUL_UPD comes from the aging modul. The update takes place if the value is new and not zero.

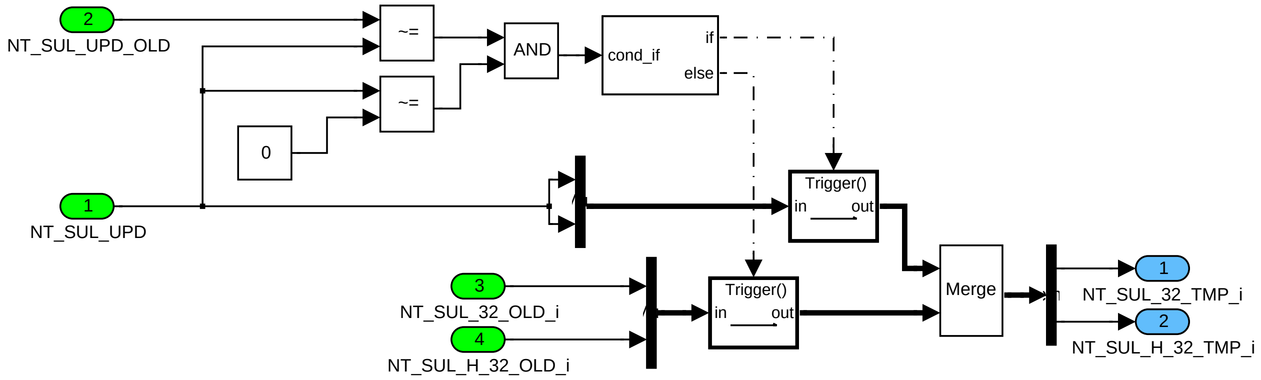

Figure 151 NOXM_MODUL704G/ operate/ CBK_MNG/ MAIN/ SUL_UPD/ CLC

Calculation of sulphur loading increment

The offset of the EGR depending fuel will be added to the bank without EGR branch and subtracted to the bank with EGR. C_STATE_EGR_CBK selects the bank with EGR branch. From these corrected fuel values the sulphur increment for the NOx traps will be calculated.

The temporary variable mff_sp_tmp_i has the same resolution and limits as MFF_SP.

(If MFF_SP_2 is not existing caused by NC_CBK_EX_NR = 1, but access demanded by other variables depending on other indices of bigger size, then MFF_SP_1 is used.)

General Information

Gasoline contains sulphur, which is chemically stored in the NOx catalyst. Due to this sulphur compounds, the NOx trap storage capacity and the NOx trap efficiency will decrease. The sulphates can be decomposed under high temperature with rich mixture. This catalyst state (high temperature, rich exhaust gas composition) is called NOx catalyst desulfation.
If a desulfation request is set, the function is able to request catalyst heating. When an enough high monolith-temperature is reached the desulfation is started by switching to a suitable lambda value. This desulfation lambda depends on the actual minimum monolith temperature and on the desulfation mode.
Two desulfation modes are implemented: a fast way with a single, rich lambda value or a way with a lambda alternating around lambda=1 and thereby with two main lambda values, a lower rich value and an upper lean value. This way permits low H2S emissions.
The decision, which desulfation process is chosen, is made dependent on the vehicle speed or a manual application.
It can't be guaranteed the setting of a lambda request is followed immediately by a change of lambda. For this reason, this function contents a detection of a desulfating atmosphere (that means a high temperature level and a rich exhaust gas composition.

Application Conditions

53.15.1 FORMULA SECTION

The bank specific and bank not specific calculations are done separately.
First the bank specific calculations are done (SO2P_ACT_MNG). This section contains detection of the desulfation atmosphere.
Bank not specific and bank diagonal calculations are included in subsystem REQ_CLC. In this section the request for desulfation is calculated.

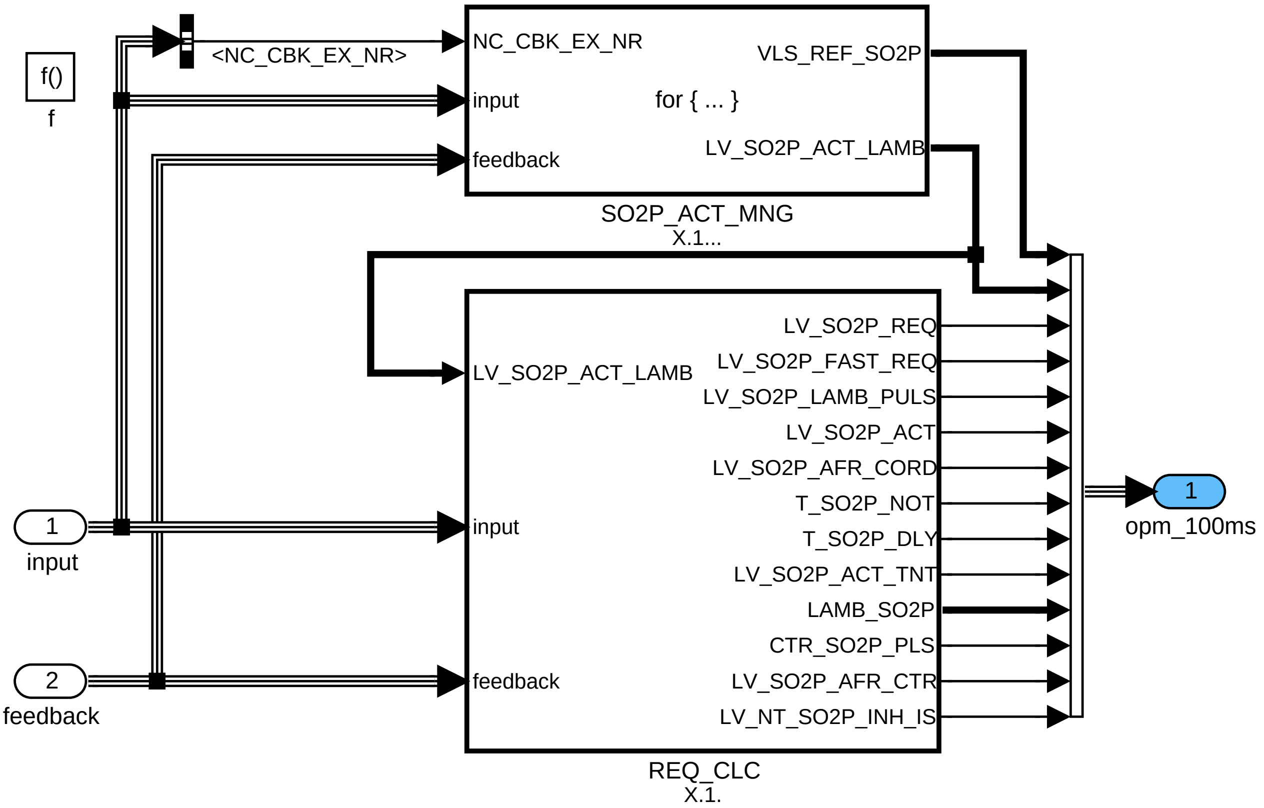

Figure 163:

53.15.1.1 BANK SPECIFIC CALCULATIONS

53.15.1.1.1 Management of different exhaust gas configurations

Index "k" corresponds to number of NOx Sensors in the system. Supported is only configuration where number of NOx Sensors is less or equal to number of exhaust banks. If one NOx Sensor and two banks exist then for both banks shall be taken the same NOx Sensor voltage signal

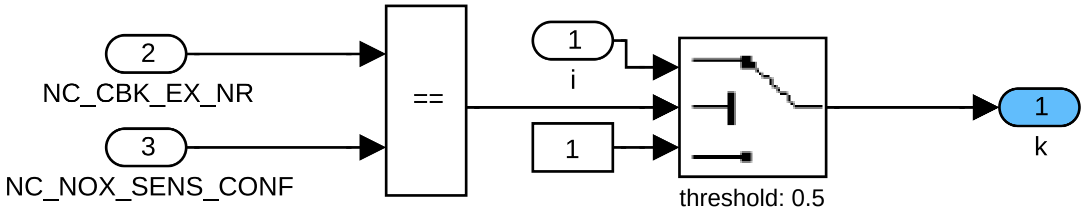

Figure 164:
Path: NOXM_REQGNNTD0/OPM_100MS/SO2P_ACT_MNG/CLC_k

53.15.1.1.2 Detection of a desulfating or non-desulfating atmosphere

For the detection of the exhaust gas composition one of available signals is chosen and converted to binary voltage value of lambda if needed. After that the desulfation atmosphere can be detected using Lambda value.

```
LV_CH_SO2P_WOUT_LIM = 0                % fuel consumption limited for CH
```

Application conditions:

This module controls the desulfation that is forced by an external request.

Initialization : reset all values from output table except LV_CH_SO2P_WOUT_LIM to zero

Recurrence : **100** ms

Formula section:

Catalyst heating without limitations due to fuel consumptions

```
If      LV_SO2P_REQ_2 = 0              % desulfation successful finished
Then    LV_CH_SO2P_WOUT_LIM = 0        % fuel consumption limited for CH
End If
```

State machine for desulfation by scan tool

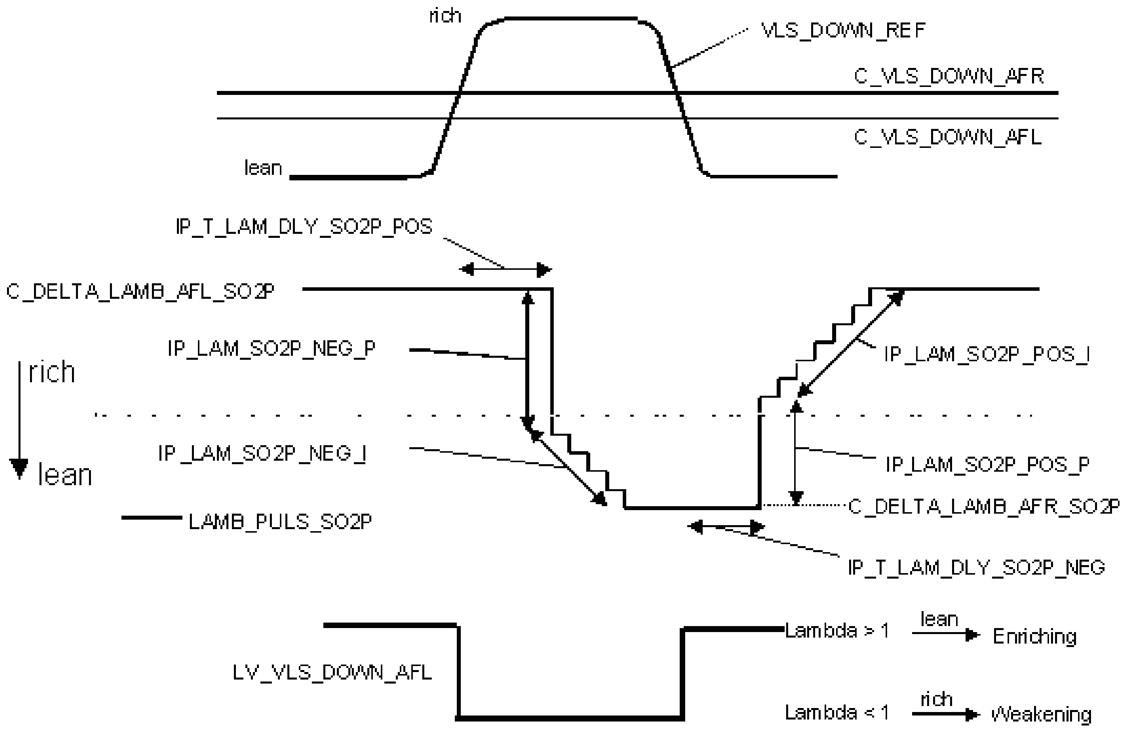
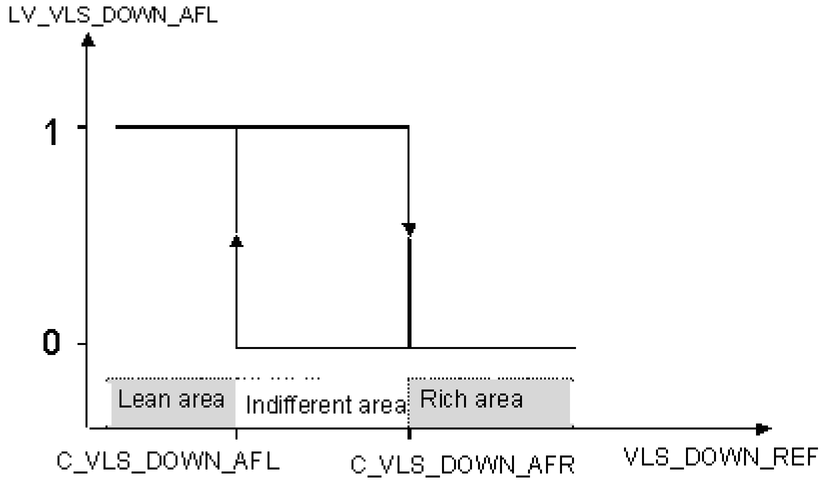
53.17.1 General information

The sub function *“Desulfation controlled lambda alternation”* allows a desulfation with an alternating lambda value controlled by the output voltage of the downstream sensor. The deviation of the basic lambda setpoint will only be carried out, if the lambda setpoint is in the range of 1. Alternation is defined by the maximum rich rsp. lean lambda shift, the p-jump and the delay time at rich or lean side befor p-jump. Gradients are defined according to engine conditions.

Definition of lambda deviation for lambda controller:



State and hysteresis of LV_VLS_DOWN_AFL as function of VLS_DOWN:



Physical relationship between values, Air-Fuel cycle evaluation at LS downstream:

53.17.1.2 FORMULA SECTION

The function contains of two main Sections:

SECTION 1: Detection of lean/rich mixture

SECTION 2: Realization of lambda controller deviation

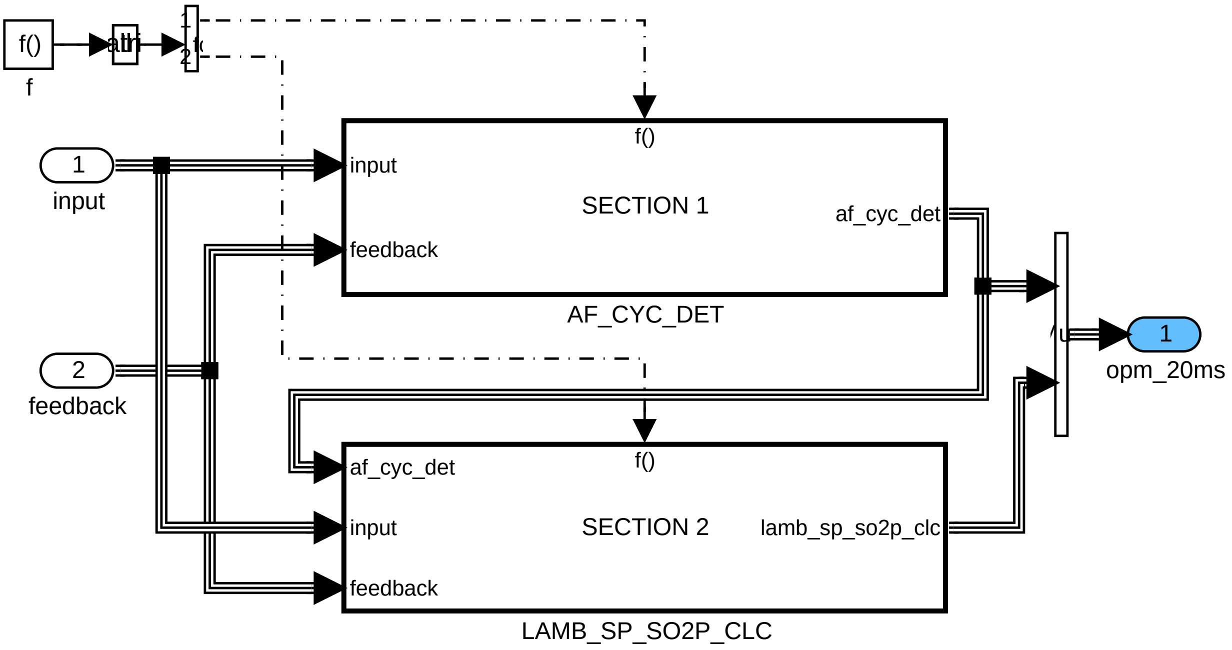

Figure 190 NOXM_DEFSPNTDLS0/ OPM_20MS

SECTION 1: Detection of lean/rich mixture

The function shall provide an indication of the current Air-Fuel mixture ratio at LS downstream position, i.e. mixture lean or rich, and determine the lean and rich cycle time separately for further evaluation by other functions. This shall be carried out as follows:

AF transition detection:

There are several possibilities as reference for oxygen signal depending on existing sensors and their provided signals: NOx-sensor or binary oxygen sensor. The choosen output signal is scaled if necessary to the reference signal VLS_DOWN_REF.

The function shall detect a change in AF mixture from lean to rich or vice versa ignoring possible jitter in the sensor signal. This shall be facilitated by the following method: If the timer T_AFL_DOWN_LOCK falls below the threshold IP_T_AFL_DOWN_LOCK_xxx, the timer shall be incremented and the transition flag LV_VLS_DOWN_TRA shall be reset. Should, during following recurrence cycles, the timer equal or exceed the threshold and if the AF mixture flag is currently indicating lean, the function shall observe the VLS_DOWN_i signal for a change to rich as indicated by VLS_DOWN_i exceeding the threshold C_VLS_DOWN_AFR. Once this has occurred, the LV_VLS_DOWN_AFL flag shall be changed to indicate a rich mixture (LV_VLS_DOWN_AFL = 0), the counter CTR_VLS_DOWN_AFL_CYC shall be incremented to indicate the number of complete AF cycles since the last activation of the lambda controller, the timer T_AFL_DOWN_LOCK shall be reset and LV_VLS_DOWN_TRA is set to indicate the AF mixture transition. The same procedure, except increment of counter CTR_VLS_DOWN_AFL_CYC, applies for a currently rich mixture. A transition to a lean mixture shall be detected by VLS_DOWN falling below threshold C_VLS_DOWN_AFL.

Remark: The timer T_AFL_DOWN_LOCK and associated engine operating point dependent threshold IP_T_AFL_DOWN_LOCK_xxx reduce the effect of rapid oxygen sensor signal changes, noise generated by cylinder to cylinder AF mixture deviations, that would cause the lambda controller to execute a P-jump. The mapped lock-out time represents the delay between injection of the AF mixture and the burnt AF mixture reaching and being detected by the downstream oxygen sensor. The lock-out time shall not exceed the exhaust gas delay for any particular engine operating point otherwise the lambda controller frequency will be affected. Downstream oxygen sensor signal changes occurring within this delay time may not be considered to be due to the change in controlled lambda but from noise and shall be ignored.

Timer / counter incrementation:

The function shall increment the respective timer dependent on the current state of the AF mixture, as determined by LV_VLS_DOWN_AFL (lean mixture; increment T_VLS_DOWN_CYC_AFL. rich mixture; increment T_VLS_DOWN_CYC_AFR). Should at any time the desulfation control be deactivated, the function shall reset the counter CTR_VLS_DOWN_AFL_CYC.

As calibrateable back up solution a switch of LV_VLS_DOWN_AFL can also be forced by exceeding the time counter threshold for the corresponding cycle time (C_T_VLS_DOWN_CYC_AFL/AFR_MAX)

Increment T_VLS_DOWN_CYC_AFL / Increment T_VLS_DOWN_CYC_AFR

The timers T_VLS_DOWN_CYC_AFL and T_VLS_DOWN_CYC_AFR shall be incremented according to their specified conditions until they reach a maximum value of FFFFH at which point they shall no longer be incremented.

Increment CTR_VLS_DOWN_AFL_CYC

The Air-Fuel cycle counter CTR_VLS_DOWN_AFL_CYC shall be incremented for every lean to rich AF mixture transition, to indicate that a complete AF cycle has passed. The counter shall be incremented in such manner until it reaches a maximum value of FFFFH at which point it shall no longer be incremented.

Increment T_AFL_DOWN_LOCK

The timer T_AFL_DOWN_LOCK shall be incremented according to the specified conditions until it reaches a maximum value of FFFFH at which point it shall no longer be incremented.

SECTION 2: Realization of lambda controller deviation

The lambda control correction adjusts the fuel-air mixture to richness 1 in average. The lambda controller uses a PI strategy. It is adjusted to produce a leaner or a richer mixture according to the oxygen sensor information.

If LAMB_PULS_SO2P exceeds the limitations C_DELTA_LAMB_AFL/AFR_SO2P then LAMB_PULS_SO2P is limited to those values.

The calibration constants C_T_LAM_DLY_SO2P_POS and C_T_LAM_DLY_SO2P_NEG are provided for the pre-control of the P-jump delay. The IP_LAM_XX_YY maps have common data points.

The last calculated LAMB_PULS_SO2P value before the corresponding Lambda transition from lean to rich and from rich to lean remains constant until the delay time T_LAM_DLY_SO2P has come to an end, i.e. I component is frozen. LAMB_PULS_SO2P can not be changed or reset during this time.

To provide best performance (drivability, interface to other functions as e.g. desulfation) all banks reaching lean status wait with P-jump to rich side until last bank also has reached lean status (common P-jump to rich side).

High resolution variable LAMB_PULS_SO2P_H_RES_i shall be used for internal calculation. LAMB_PULS_SO2P_i with low resolution shall be the relevant output for other functions.

Remark: The transition flag LV_VLS_DOWN_TRA is just set during one recurrence of the corresponding specification. It has to be ensured that this spike is noticed by this part.

This SECTION contains of two main chapters:

SECTION 2.1: Calculation of activation condition and check of all banks (not for loop)

SECTION 2.2: Lambda deviation calculation (for loop)

SECTION 2.1: Calculation of activation condition and check of all banks (not for loop)

Activation condition for desulfation

53.18 Application Incidence for NOx catalyst desulfation - λ stimulation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_LAMB_PULS_SO2P	V/O	0...1H	0...1	1	[-]
flag inhibiting the NOx catalyst desulfation - lambda stimulation					

Input data:

LV_ERR_LS_DOWN[NC_CBK_EX_NR]			

Description:

This flag deactivates the NOx catalyst desulfation with lambda stimulation.

With the calibration data LC_INH_LAMB_PULS_SO2P_MAN it is possible to deactivate the NOx trap desulfation with lambda stimulation.
With the calibration data LC_INH_ LAMB_PULS_SO2P_OFF it is possible to make the NOx trap desulfation with lambda stimulation allways working.

Application conditions:

Initialisation: 0 at reset

Recurrence: 100ms

Activation: at every engine state

```
If      LC_INH_LAMB_PULS_SO2P_OFF = 1
then    LV_INH_LAMB_PULS_SO2P = 0    % no further calculation necessary
endif
```

Formula section:

```
If      LV_ERR_LS_DOWN[i] = 1            // at least one
    or  LC_INH_LAMB_PULS_SO2P_MAN = 1
then    LV_INH_LAMB_PULS_SO2P = 1
else    LV_INH_LAMB_PULS_SO2P = 0
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_INH_LAMB_PULS_SO2P_MAN	1	0...1H	0...1	1	[-]
Codeword for the manual setting of the inhibiting bit NOx trap desulfation by lambda stimulation					
LC_INH_LAMB_PULS_SO2P_OFF	1	0...1H	0...1	1	[-]
Codeword for the deactivation of inhibiting the NOx trap desulfation by lambda stimulation

LV_NT_AD_CMPL=        0
MAF_INT_PUC_O2_STC = 0
```

53.19.3 STATE_NOX_PRJ = O2_STC

General information:

The state O2_STC is active during PUC, if an O2_STC measurement is requested.

Recurrence: 100 ms

Formula section:

```
LV_INH_RGN_AD = 1
LV_NT_O2_STC_ACT = 1

if MAF_INT_PUC_ACT <> 0 then MAF_INT_PUC_O2_STC = MAF_INT_PUC_ACT
if LV_INH_NT_O2_STC = 1 then LV_NT_AD_VLD = 0
```

53.19.4 STATE_NOX_PRJ = FULL_RGN

General information:

The state FULL_RGN enables a full regeneration of the NOx catalyst.

After the full saturation of the NOx storage catalyst a full regeneration is requested. During the full regeneration the integral of the reducing agent (NOx catalyst management) and the Lambda-Sensor switch time is detected. Depending on the results the actual available storage capacity can be determined and the calculated amount of stored sulphur in the NOx catalyst is confirmed or has to be corrected.

The full regeneration should be carried out with a constant rich mixture, this is managed by the flag LV_NT_RGN_REQ_AD. This flag prevents that the lambda setpoint during the regeneration is pulled to a leaner value (handled in the chapter “Lambda Setpoint for Catalyst Regeneration”).

Recurrence: **10** ms

Formula section:

   endif
endif
```

53.19.5 STATE_NOX_PRJ = COMMUNICATION

General information:

The state COMMUNICATION handles the communication with the requesting modules after successfull completion of adaptation cycle.

Recurrence: 100 ms

Formula section:

```
T_NT_AD_COM          = T_NT_AD_COM + TA
LV_NT_AD_CMPL         =
    (T_NT_AD_COM <= C_T_NT_AD_COM)
```

53.19.6 Additional reducing agent mass for complete regeneration after elongated stratified phase

Description:

To compensate deep storage of NOx during extended stratified mode a additional reducing agent mass for completion of regeneration is calculated. Regeneration phase is elongated accordig to duration of lean phase.

Application conditions:

Recurrence: 20ms

Activation:

```
If      LC_RGN_REQ_AD_VLD_ACT = 1
then    "function active"
        at every engine state; independend from STATE_NOX_PRJ
else    "function not active"

Input data:

DIST_NT	LV_NT_AD_CMPL	LV_NT_O2_STC_ACT	NTL_DEC_INT_AD
NT_O2_STC_BAS	LV_NT_AD_VLD		

FUNCTION DESCRIPTION:

General information:

The oxygen storage capacity adaptation allowes an adaptation of the NOx catalyst oxygen storage capacity which will decrease within time due to thermal aging effects.

The adaptation can be taken into consideration as factor or as offset value; this module offers both possibilities.

The main adaptation value is the factor, the offset is calculated using the factor.

Description:

Application conditions:

Initialisation:

```
If      there are no stored values or checksum error has occured or scantool reset
then    NT_O2_STC_AD = 1; LV_NT_O2_STC_LIM = 1, set all other default values (=0)
else    use previously stored values
endif
```

Recurrence: 1000 ms

Sulphur model threshold for missing desulfation error					

Import actions:

ACTION_ERRM_FilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <ABC_INC>, IN <ABC_DEC>, IN <ABC_MAX>, OUT <LV_ERR>)
This action computes the elementary anti-bounce filter
ACTION_ERRM_GetLvEndDiag(IN <IDX_DIAG>, OUT <LV_END_DIAG>)
Action that returns the diagnosis end information
ACTION_ERRM_GetLvErr(IN <IDX_DIAG>, OUT <LV_ERR>)
Action that returns the status of the debounced failure

53.24.1 General information

If the stratified combustion mode is irreversible forbidden due to NOx catalyst aging, a failure mode entry is done.

If the NOx trap is aged reversible by sulfur, a failure mode entry is done.

Application Condition

Thermische Nox-Kat-Alterung					

Input data:

NT_AGI_THERMO_GRD	FAC_NT_AGI_LIM	NT_AGI_THERMO	ECU_STATE

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the outputs are different from the specified values due to the input data attributes.

Application conditions:

Initialisation at reset or at exit powerlatch:

F_grad_katalt = NT_AGI_THERMO_GRD
F_katalt = FAC_NT_AGI_LIM
F_katalt_tabg = NT_AGI_ THERMO

Recurrence : 200ms

Activation: every engine state

Formula section:

Remark: all formulas are valid in a **physical** meaning

```
If      ECU_STATE = not("PWL")
  Then
        F_grad_katalt       = NT_AGI_THERMO_GRD
        F_katalt        = FAC_NT_AGI_LIM
        F_katalt_tabg  = NT_AGI_ THERMO
end
```

FUNCTION DESCRIPTION:

General information:

This module is for configuration of the On-Board-Diagnosis Communication functionality.

54.1.1 Configuration of OBD services: NC_STATE_OBD_SRV

0 : the SERVICE is not supported
1 : the SERVICE is supported

NC_STATE_OBD_SRV	Supported EOBD SERVICEs from 01h – 09h	
BIT	**Function**	**Supported**
0	SERVICE 01h : Request current powertrain diagnostic data	**1**
1	SERVICE 02h : Request powertrain freeze frame data	**1**
2	SERVICE 03h : Request emission-related diagnostic trouble codes	**1**
3	SERVICE 04h : Clear/reset emission-related diagnostic information	**1**
4	SERVICE 05h : Request oxygen sensor monitoring test results	0
5	SERVICE 06h : Request on-board monitoring test results for specific monitored systems	**1**
6	SERVICE 07h : Request emission-related diagnostic trouble codes detected during current or last completed driving cycle	**1**
7	SERVICE 08h : Request control of on-board system, test or component	0
8	SERVICE 09h : Request vehicle information	**1**
9	RESERVED	0
10	RESERVED	0
11	RESERVED	0
12	RESERVED	0
13	RESERVED	0
14	RESERVED	0
15	RESERVED	0

54.1.2 Autolearning and Microcontroller configuration: NC_STATE_OBD_CONF

NC_STATE_OBD_CONF		Supported EOBD/ARB Configuration
BIT	**Function**	**Configured**
0	Internal format of the microcontroller	0
1	Sensor configuration	**1**
2	Autolearning	**1**
3	RESERVED	0
4	RESERVED	0
5	RESERVED	0
6	RESERVED	0
7	RESERVED	0

Internal format of the microcontroller	
Value	**Description**
0	The internal format of the microcontroller is INTEL
1	The internal format of the microcontroller is MOTOROLA

Sensor configuration	
Value	**Description**
0	BINARY Sensor configuration
1	LINEAR Sensor configuration

Autolearning – for O2 sensors configuration	
Value	**Description**
0	Without autolearning
1	With autolearning

54.1.3 Project specific calibration data: NLC_STATE_PRJ_SPC_CAL

Project specific calibration data - NLC_STATE_PRJ_SPC_CAL	
Value	**Description**
0	EOBD is configured by generic configuration data
1	EOBD is configured by project specific calibration data

Formula section:

NLC_STATE_PRJ_SPC_CAL = 1

54.1.4 Configuration of oxygen sensors (2 Banks 4 Sensors): NC_STATE_PID_13_PSN_LS

NC_STATE_PID_13_PSN_LS		
BIT	**Function**	**Value**
0	Bank 1 Sensor 1 (upstream 1)	**1**
1	Bank 1 Sensor 2 (downstream 1)	**1**
2	Bank 1 Sensor 3	0
3	Bank 1 Sensor 4	0
4	Bank 2 Sensor 1 (upstream 2)	**1**
5	Bank 2 Sensor 2 (downstream 2)	**1**
6	Bank 2 Sensor 3	0
7	Bank 2 Sensor 4	0

Each bit indicates the presence or absence of the oxygen sensors for each cylinder bank, the first sensor being the nearest of the engine.

0 : sensor not present

1 : sensor present

54.1.5 Position of oxygen sensors for OBD (2 Banks 4 Sensors): STATE_PSN_LS_SAE

Formula section:

```
IF      (NC_STATE_OBD_CONF & 0x04)
THEN    With autolearning
        STATE_PSN_LS_SAE = PSN_LS          //set to the value defined by the project
ELSE    STATE_PSN_LS_SAE = NC_STATE_PID_13_PSN_LS
ENDIF
```

54.1.6 Configuration of oxygen sensors (4 Banks 2 Sensors): NC_STATE_PID_1D_PSN_LS

NC_STATE_PID_1D_PSN_LS		
BIT	**Function**	**Value**
0	Bank 1 Sensor 1 (upstream 1)	0
1	Bank 1 Sensor 2 (downstream 1)	0
2	Bank 2 Sensor 1 (upstream 2)	0
3	Bank 2 Sensor 2 (downstream 2)	0
4	Bank 3 Sensor 1	0
5	Bank 3 Sensor 2	0
6	Bank 4 Sensor 1	0
7	Bank 4 Sensor 2	0

Each bit indicates the presence or absence of the oxygen sensors for each cylinder bank, the first sensor being the nearest of the engine.

0 : sensor not present

1 : sensor present

54.1.7 Position of oxygen sensors for OBD (4 Banks 2 Sensors): STATE_PSN_LS_1_SAE

Formula section:

STATE_PSN_LS_1_SAE = NC_STATE_PID_1D_PSN_LS

54.1.8 Configuration of secondary air pump: NLC_STATE_VAR_SAP

Configuration of secondary air pump – NLC_STATE_VAR_SAP	
Value	**Description**
0	Secondary air pump **NOT** supported
1	Secondary air pump supported

Formula section:

NLC_STATE_VAR_SAP = 1

54.1.9 Position of Secondary Air Pump for OBD: STATE_VAR_SAP_SAE

Formula section:

```
IF      (NC_STATE_OBD_CONF & 04h)
THEN    With autolearning
        STATE_VAR_SAP_SAE (bit 0) = LV_VAR_SAP
ELSE    STATE_VAR_SAP_SAE is set to NLC_STATE_VAR_SAP
ENDIF
```

54.1.10 Configuration of EVAP Monitor: NLC_STATE_EVAP

Configuration of EVAP Monitor – NLC_STATE_EVAP	
Value	**Description**
0	EVAP Monitor **NOT** supported
1	EVAP Monitor supported

Formula section:

NLC_STATE_EVAP = 1

54.1.11 Value for EVAP Monitor for OBD: STATE_EVAP_SAE

Formula section:

```
IF      (NC_STATE_OBD_CONF & 04h)
THEN    With autolearning
        STATE_EVAP_SAE (bit 0) = LV_CONF_DMTL
ELSE    STATE_EVAP_SAE = NLC_STATE_EVAP
ENDIF
```

54.2 AGGR Adaptation for OBDC

54.2.1 Initialization of secondary-air variables

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SUM_AFL_VLS_DIAG_SA_1_SAE	V/O	0...FFFFH	0...65535	1	[-]
Counter of lean events within the secondary air diagnosis					
SUM_AFL_VLS_DIAG_SA_2_SAE	V/O	0...FFFFH	0...65535	1	[-]
Counter of lean events within the secondary air diagnosis					
SAF_DIAG_MIN_SAE	O/S	0...FF00H	0...255	3.9063e-3	[kg/h]
Mean diagnosis value of minimum secondary air flow for SAE					
SAF_DIAG_MAX_SAE	O/S	0...FF00H	0...255	3.9063e-3	[kg/h]
Mean diagnosis value of maximum secondary air flow for SAE					

FUNCTION DESCRIPTION:

General information:

Secondary air system diagnosis is not supported in MSD projects, thus all needed variables must be stubbed.

Application conditions:

Initialisation: at reset all variables = 0

Recurrence: -

Activation: -

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_SA_SWI_ACQ	1	0...1H	0...1	1	[-]
Logical constant for the decision SAF_KGH through model value (=0) or SAFM is used (=1)					
C_SUM_AFL_VLS_MIN_DIAG_SA_1	1	0...FFFFH	0...65535	1	[-]
Threshold of lean events within the secondary air diagnosis					

54.2.2 Calculation of non-implemented variables

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VLS_COR_LSL[NC_CBK_EX_NR]	V/O	0...3FFH	0...4.99511	4.8828e-3	[V]
Corrected output signal of lambda sensor					

Input data:

VLS_UP_COR[NC_CBK_EX_NR]			

FUNCTION DESCRIPTION:

General information:

VLS_COR_LSL[i] is not supported in MSD projects, thus all needed variables must be calculated.

Application conditions:

Initialisation: at reset = 0

Recurrence: 10ms

Activation: every engine operating state

Formula section:

VLS_COR_LSL[i] = VLS_UP_COR[i] *//calculation is done in physical way*

54.3 Mode 01h - Request current powertrain diagnostic data

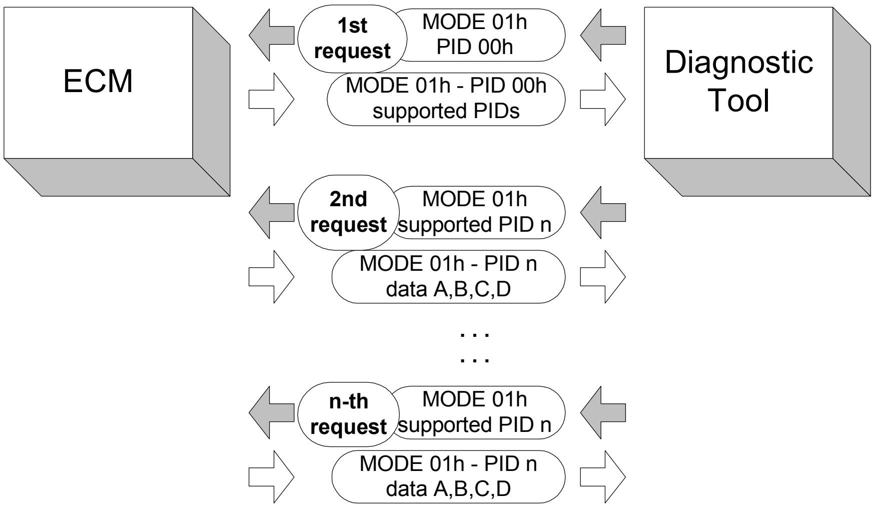
54.3.1 Functional description for ISO 14230-4

The purpose of this mode is to allow access to current emission-related data values including analog inputs and outputs, digital inputs and outputs, system status information, and calculated parameter values.

Each request contains a Parameter IDendification (PID) which indicates to the ECM the specific information to be transmitted. The information transmitted by the ECM must be the latest ones, all acquisitions shall correspond to actual measurements and not to values selected by the ECM for the limp home mode.

Not all PIDs are applicable or supported by all systems. Then, all ECUs must at least answer to PID 00h by sending back the list of the PIDs used.

You can find the exhaustive list of generic PIDs definition in chapter “PID description for mode 01h”. The specific list of supported PIDs can be found in chapter “Emission-related software and system configuration”.



Request message definition (read supported PIDs)

Bytes	Parameter name	Hex value
#01	**Request current powertrain diagnostic data**	01
#02	PID	00-20-40-60-80-A0-C0-E0

Positive reponse message definition (read supported PIDs)

#06	Data D (optional)	C	XX

C =Conditional - Data B -D depend on selected PID value
M = Mandatory

Negative response message

Bytes	Parameter name	Hex value
#1	**Negative response**	7F
#2	**Request current powertrain diagnostic data**	01
#3	Error code = Service not supported Sub function not supported - Invalid format	11 12

Error code

Error code	Cause
Service not supported	The requested mode is not supported (vehicle is not an EOBD or OBD2 system)
Sub function not supported - Invalid format	The requested PID is not supported or the length of the request is incorrect

54.4 Mode 02h - Request powertrain freeze frame data

Import:

ACTION_ERRM_ReadFrfByDtc	**(** **IN <TypeOfFF>** **IN <FFidentifier>** **IN <DtcIdentifier>** **IN <LevelOfDTC>** **INOUT <Frf>** **OUT <ResultFrf>** **)**
This API returns a Freeze Frame related to the DTC given in parameter.	

54.4.1 Functional description for ISO 14230-4

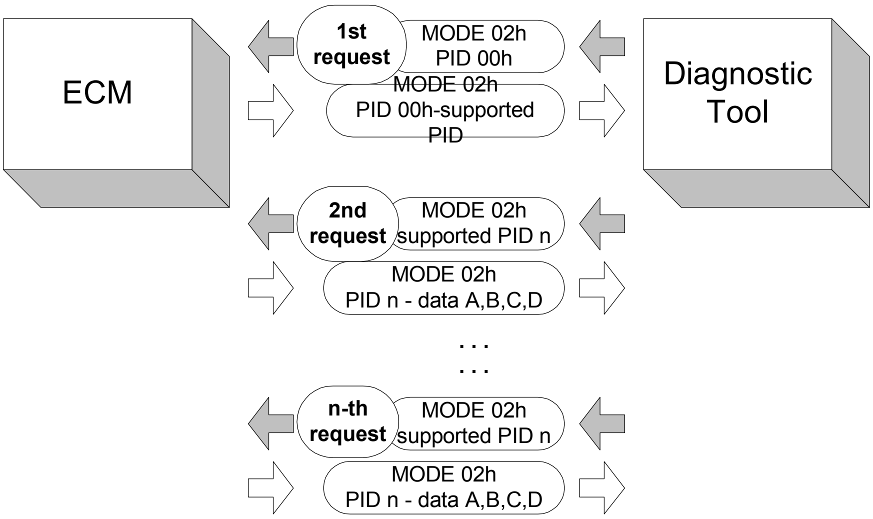
The purpose of this mode is to allow access to emission-related data values which were stored during the freeze frame required by OBD-II regulations.

Each request contains a Parameter IDendification (PID) which indicates to the ECM the specific information to be transmitted.
The information to be transmitted is the freeze frame data which has been stored by the ECM at the failure occurrence. Like mode 01h, no limp home value shall be transmitted. The definition of the failure context is given by the frame number - in this case, we only select one failure context which is defined by the frame number 00h.

Not all PIDs are applicable or supported by all systems. Then, all ECUs must at least answer to PID 00h by sending back the list of the PIDs used.

PID 02h is the DTC that caused the freeze frame data to be stored. If freeze frame data is not stored in the ECM, the system should report 00 00h as the DTC. Any data reported when the stored DTC is 00 00h may not be valid.

You can find the exhaustive list of generic PIDs definition, scaling information, and display formats for the required freeze frame in chapter “PID description for mode 02h”.
The specific list of supported PIDs for current project can be found in chapter “Emission-related software and system configuration”.



54.4.2 Message data bytes

```

54.5 Service 03h - Request emission-related powertrain diagnostic trouble codes

Import action:

ACTION_ERRM_ReadDtcByTypeOfDtc	**(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <ListOfDtc>** **OUT <ResultDtc>** **)**
This API returns a list of DTC.	

54.5.1 Functional description for ISO 14 230-4

The purpose of this mode is to enable the off-board test device to obtain stored emission-related powertrain diagnostic trouble codes (DTCs).

This operation should be divided in two phases (not necessary) :
1st phase : the diagnostic tool requests the number of emission-related troubles codes (mode = 01h, PID = 01h).
If ECM does not have stored codes, then that module shall respond with a message indicating zero codes are stored.
2nd phase : the diagnostic tool requests the diagnostic troubles codes stored (mode = 03h).

If additional trouble codes are set between the time that the number of codes are reported by an ECM, and the stored codes are reported by an ECM, then the number of codes reported could exceed the number expected by the diagnostic tool. In this case the diagnostic tool should repeat this cycle until the number of codes reported equals the number expected based on the Mode 01 response.

If there is no emission-related diagnostic trouble code to report, no response is required, but for ISO 14230-4 interfaces, the module will respond with a report containing no codes. (all Codes = 00 for the response)

Request message

Bytes	Parameter name	CVT	Hex value
#01	**Request emission-related powertrain diagnostic trouble codes**	M	03

Formula section

```
ACTION_ERRM_ReadDtcByTypeOfDtc
        (
        IN <OBD & CONFIRMED>
        IN <LAW>
        INOUT <DTC#1 to DTC#m>
        OUT <ResultDtc>
        )

IF      ResultDtc != BUFFER_FULL
        Positive response
ELSE
        Negative response general reject
ENDIF
```

First positive response message

Bytes	Parameter name	Hex value
#01	**Request emission-related powertrain diagnostic trouble codes positive response**	43
#02	Code #1 (msb)	XX or 00
#03	Code #1 (lsb)	XX or 00
#04	Code #2 (msb)	XX or 00
#05	Code #2 (lsb)	XX or 00
#06	Code #3 (msb)	XX or 00
#07	Code #3 (lsb)	XX or 00

Next positive response if more than 3 DTC

Bytes	Parameter name	Hex value
#01	**Request emission-related powertrain diagnostic trouble codes positive response**	43
#02	Code #4 (msb)	XX or 00
#03	Code #4 (lsb)	XX or 00
#04	Code #5 (msb)	XX or 00
#05	Code #5 (lsb)	XX or 00
#06	Code #6 (msb)	XX or 00
#07	Code #6 (lsb)	XX or 00

The standard does not request the order in which the diagnostic trouble codes shall be transmitted.

In the case of less than 3 codes for a response have been stored, the answer shall be completed by 0000h in order to guarantee a fixed length.

Negative response message

Bytes	Parameter name		Hex value
#1	**Negative response**		7F
#2	**Request emission-related powertrain diagnostic trouble codes**		03
#3	Error code =	Service not supported	11
		Sub function not supported - Invalid format	12
		general reject	10

Error code

Error code	Cause
Service not supported	The requested mode is not supported (vehicle is not an EOBD or OBD2 system)
Sub function not supported - Invalid format	The length of the request is incorrect

54.6 Service 04h - Clear/reset emission-related diagnostic information

Import action:

```
ACTION_ERRM_ClrInfoByTypeOfDtc
                              (
                              IN <TypeOfDTC>
                              OUT <ResultClrInfo>
                              )
```

This API clears all failure in dynamic memory

54.6.1 Functional description

The purpose of this service is to provide a means for the diagnostic tool to command on-board ECM to clear the whole failure memory (all emission-related and non emission-related diagnostic information) (See Error Management specification).

Request message

Bytes	Parameter name	Hex value
#01	**Request to clear/reset emission-related diagnostic information**	**04**

The ECM shall respond to this service request with ignition ON and the engine not running and ECM not locked by immobylizer. ECUs that cannot perform this operation under other conditions, such as with the engine running, shall respond negatively with condition not correct.

Formula section

```
ACTION_ERRM_ClrInfoByTypeOfDtc
                              (
                              IN <ALL>
                              OUT <ResultClrInfo>
                              )

IF      ResultClrInfo = INFO_CLEARED THEN
        Positive response
ELSE
        Negative response with "Condition not correct"
ENDIF
```

Refer to Error Management module

Example :
- Clear number of emission-related diagnostic trouble codes stored (Mode 01h, PID 01h)
- Clear emission-related diagnostic trouble codes (Mode 03h)
- Clear emission-related diagnostic trouble code for the freeze frame data (Mode 01h, PID 02h)
- Clear freeze frame data of the failure (Mode 02h)
- Reset status of system monitoring tests (Mode 01h, PID 01h - Readiness code)
- Clear on board monitoring test results for continuously monitored systems (Mode 07h)
- Clear distance travelled while MIL is activated (Mode 01h, PID 21h)
- Clear on-board monitoring test results for non-continuously monitored systems (Mode 06h)
  - Clear the LV_READY_XXX (inhibition of the result)

Positive response message

Bytes	Parameter name	Hex value
#01	**Request to clear/reset emission-related diagnostic information positive response**	**44**

Negative response message

Bytes	Parameter name		Hex value
#1	**Negative response**		**7F**
#2	**Request to clear/reset emission-related diagnostic information**		**04**
#3	Error code =	Service not supported	11
		Sub function not supported - Invalid format	12
		Condition not correct	22

Error code

Error code	Cause
Condition not correct	Engine running ECU locked by immobilizer
Service not supported	The requested mode is not supported (vehicle is not an EOBD or OBD2 system)
Sub function not supported - Invalid format	The length of the request is incorrect

54.7 Service 05h - Request oxygen sensor monitoring test results

Input data:

LV_READY_XXX			

54.7.1 Functional description

The purpose of this service is to allow access to the on-board oxygen sensor monitoring test results. The same information may be obtained by the use of service $06.
The request message for test results includes a Test ID value that indicates the information requested.

Many methods may be used to calculate test results for this service by different manufacturers. If data values are to be reported using these messages that are different from those specified, ranges of test values have been assigned that can be used which have standard units of measure. The external test equipment can convert these values and display them in the standard units.

The ECU will respond to this message by transmitting the requested test data last determined by the system. The latest test results are to be retained, even over multiple ignition OFF cycles, until replaced by more recent test results. Test results are requested by Test ID.

Not all test values are applicable or supported by all vehicles. An optional feature of this service is for the ECU to indicate which Test IDs are supported. Test ID $00 is a bit-encoded value that indicates support for Test IDs from $01 to $20. Test ID $20 indicates support for Test IDs $21 through $40, etc. This is the same concept as used for PID support in services $01 and $02 as specified

If Test ID $00 is not supported, then the ECU does not use this feature to indicate Test ID support.

54.7.2 Message data bytes

54.7.2.1 Request oxygen sensor monitoring test results request message definition (read supported TIDs)

— Request oxygen sensor monitoring test results request message (read supported TIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic

54.7.3.2 Oxygen sensor location definition

The Oxygen sensor location value used in the request message shall indicate the Oxygen Sensor location as defined by PID $13 or $1D as specified in mode 1.

Oxygen sensor location description

Oxygen sensor location (one, and only one bit can be set to a 1)		
Bit	**Sensor location[1)]**	**Alternative sensor location[2)]**
0	Bank 1 - Sensor 1	Bank 1 - Sensor 1
1	Bank 1 - Sensor 2	Bank 1 - Sensor 2
2	Bank 1 - Sensor 3	Bank 2 - Sensor 1
3	Bank 1 - Sensor 4	Bank 2 - Sensor 2
4	Bank 2 - Sensor 1	Bank 3 - Sensor 1
5	Bank 2 - Sensor 2	Bank 3 - Sensor 2
6	Bank 2 - Sensor 3	Bank 4 - Sensor 1
7	Bank 2 - Sensor 4	Bank 4 - Sensor 2
[1)] If Service $01 PID $13 supported. [2)] If Service $01 PID $1D supported.		

54.7.3.3 Test result description

The following table defines the test result.

Test Result description

Hex	# of bytes	Description
00 - FF	1	The Test Result parameter includes either a constant or a calculated value depending on the Test ID.

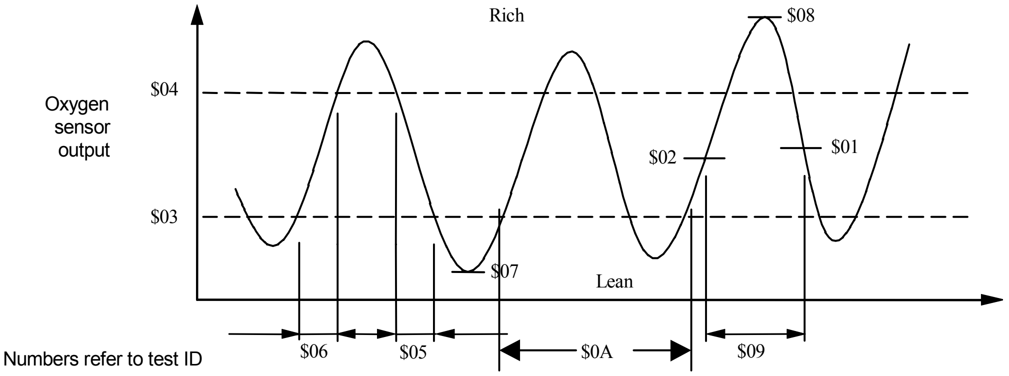
54.7.3.4 Minimum and Maximum Test Limit description

The following table defines Minimum and Maximum Test Limit.

Minimum and Maximum Test Limit description

Test Limit	# of bytes	Description
Minimum	1	The minimum test limit (only for calculated test result) is the minimum value to which the test result is compared. The Test Limit value is either a minimum or a maximum value to which the test results are compared. The Test Limit unsigned numeric value
Maximum	1	The maximum test limit (only for calculated test result) is the maximum value to which the test result is compared.

Results of latest mandated on-board oxygen sensor monitoring test, see figure below.



Test ID value example

54.8 Service 06h - Request on-board monitoring test result for non-continuously monitored system

Input data:

LV_READY_XXX			

54.8.1 Functional description

The purpose of this service is to allow access to the results (test value and test limit) for an on-board diagnostic monitoring tests of specific components/system that are not continuously monitored.
The latest test results are to be retained, even over multiple ignition 'off' cycles, until replaced by more recent test results.

Not all TIDs are applicable or supported by all systems. Then, all ECUs must at least answer to TID 00h by sending back the list of the PIDs used.

This service can be used as an alternative to service 05h to report oxygen sensor test results.

You can find the exhaustive list of generic TIDs definition in chapter “TID description for mode 06h”.
The specific list of supported TIDs for current project can be found in chapter “Emission-related software and system configuration”.

Request message (read supported PIDs)

Bytes	Parameter name	Cvt	Hex value
#01	**Request on-board monitoring test results for non-continuously monitored systems**	**M**	**06**
#02	On-board diagnostic monitor ID	M	00-20-40-60-80-A0-C0-E0

Positive response (read supported PIDs)

Bytes	Parameter name	Cvt	Hex value
#01	**Request on-board monitoring test results for non-continuously monitored systems positive response**	**M**	**46**
#02	Test ID	M	00-20-40-60-80-A0-C0-E0
#03	Test limit type and component ID	M	FF
#04	Data A	M	XX
#05	Data B	M	XX
#06	Data C	M	XX
#07	Data D	M	XX

Request message (read test result)

Bytes	Parameter name	CVT	Hex value
#01	**Request on-board monitoring test results for non-continuously monitored systems**	**M**	**06**
#02	On-board diagnostic monitor ID	M	XX

Response message (report test status)

Bytes	Parameter name		Hex value
#01	**Request on-board monitoring test results for non-continuously monitored systems positive response**	**M**	**46**
#02	Test ID	M	XX
#03	Test limit type and component ID	M	XX
#04	Test value (msb)	M	XX
#05	Test value (lsb)	M	XX
#06	Test limit (msb)	M	XX
#07	Test limit (lsb)	M	XX

Formula section:

```
IF LV_READY_XXX = ON THEN
        Negative response (No result since last reset/clear)
ELSE
        Positive response with test result
END
```

Test limit type and component ID definition

Byte #3	Value	Description
bit 0 to bit 6		Component ID - Manufacturer defined - necessary when multiple components or systems are present on the vehicle and have the same definition of test ID.
bit 7		Most significant bit indicates type of test limit, where:
	0	Test limit is maximum value - test fails if test value is greater than this value
	1	Test limit is minimum value - test fails if test value is less than this value
		If the test result should be within a range of values, two messages will be returned, one with the minimum limit value and one with the maximum limit value.

Negative response message

Bytes	Parameter name		Hex value
#1	**Negative response**		7F
#2	**Request on-board monitoring test results for non-continuously monitored systems**		06
#3	Error code =	Service not supported Sub function not supported - Invalid format Condition not correct	11 12 22

54.8.1.1 Error code

Error code	Cause
Service not supported	The requested mode is not supported (vehicle is not an EOBD or OBD2 system)
Sub function not supported - Invalid format	The requested TID is not supported or the length of the request is incorrect
Condition not correct	No result since last reset/clear or Test in progress

54.9 Service 07 - Request on_board monitoring test results for continuously monitored system

Import action:

```
ACTION_ERRM_ReadDtcByTypeOfDtc
                          (
                          IN <TypeOfDtc>
                          IN <LevelOfDtc>
                          INOUT <ListOfDtc>
                          OUT <ResultDtc>
                          )
```

This API returns a list of non confirmed DTC.

54.9.1 Functional description

The purpose of this service is to enable the off-board test device to obtain test results for emission-related powertrain components/systems that are continuously monitored during normal driving conditions.
The intented use of this data is to assist the service technician after a vehicle repair, and after clearing diagnostic information, by reporting test results after a single driving cycle. If the test failed during the driving cycle, the DTC associated with that test will be reported. Test results reported by this service do not necessarily indicate a faulty component/system. If test results indicate a failure after additional driving, then the MIL will be illuminated and a DTC will be set and reported with Mode 03, indicating a faulty component/system. Once Service $03 indicates a faulty component/system, Service $07 may or may not continue to report it as a one-trip failure also.
If an ECU does not have stored DTCs then it shall respond with a message indicating no codes are stored by setting the parameter "Number of DTC" to 00h.

Request message

Bytes	Parameter name	CVT	Hex value
#01	**Request on-board monitoring test results for continuously monitored system**	M	07

Formula section:

```
ACTION_ERRM_ReadDtcByTypeOfDtc
                          (
                          IN <OBD&TEMPORARY>
                          IN <LAW>
                          INOUT <DTC#1 to DTC#m>
                          OUT <ResultDtc>
                          )

IF      ResultDtc != NO_BUFFER_FULL
        Positive response
ELSE
        Negative response general reject
ENDIF
```

First positive response message

Bytes	Parameter name	Hex value
#01	**Request on-board monitoring test results for continuously monitored system positive response**	47
#02	Code #1 (msb)	XX or 00
#03	Code #1 (lsb)	XX or 00
#04	Code #2 (msb)	XX or 00
#05	Code #2 (lsb)	XX or 00
#06	Code #3 (msb)	XX or 00
#07	Code #3 (lsb)	XX or 00

Next positive response message

Bytes	Parameter name	Hex value
#01	**Request on-board monitoring test results for continuously monitored system positive response**	47
#02	Code #4 (msb)	XX or 00
#03	Code #4 (lsb)	XX or 00
#04	Code #5 (msb)	XX or 00
#05	Code #5 (lsb)	XX or 00
#06	Code #6 (msb)	XX or 00
#07	Code #6 (lsb)	XX or 00

If different failures have the same stored DTC number, only one DTC number shall be reported.

The standard does not request the order in which the diagnostic trouble codes shall be transmitted.

In the case of less than 3 codes have been stored, the answer shall be completed by 0000h in order to guarantee a fixed length.

Negative response message

Bytes	Parameter name		Hex value

0	PID 20h : PIDs supported ($21 - $40)	MOD_1_PID_4_DIAG
1	PID 1Fh : Time Since Engine Start	
2	PID 1Eh : Auxiliary Input Status	
3	PID 1Dh : Location of oxygen sensors	
4	PID 1Ch : OBD requirements	
5	PID 1Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2	
6	PID 1Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1	
7	PID 19h : Bank 2 Sensor 2 or Bank 3 Sensor 2	

54.10.2 Description of PID 01h - Monitor status since DTCs cleared

PID $01 definition

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
01	Monitor status since DTCs cleared			
	The bits in this PID shall report two pieces of information for each monitor: a) Monitor status since DTCs were last cleared, saved in NVRAM or KAM. b) Monitors supported on this vehicle.			
	Number of emission-related DTCs and MIL status	A (bit)	byte 1 of 4	DTC and MIL status:
	# of DTCs stored in this ECU	0-6	hex to decimal	DTC_CNT: xxxd
	Malfunction Indicator Light (MIL) Status	7	0 = MIL OFF; 1 = MIL ON	MIL: OFF or ON
	The MIL status shall indicate "OFF" during the key on, engine off bulb check unless the MIL has also been commanded "ON" for a detected malfunction.			
	Supported tests which are continuous	B (bit)	byte 2 of 4 (Low Nibble)	Support status of continuous monitors:
	Misfire monitoring	0	0 = monitor not supported (NO) 1 = monitor supported (YES)	MIS_SUP: NO or YES
	Misfire monitoring shall be supported on both, spark ignition and compression vehicles if the vehicle utilises a misfire monitor.			
	Fuel system monitoring	1	0 = monitor not supported (NO) 1 = monitor supported (YES)	FUEL_SUP: NO or YES
	Fuel system monitoring shall be supported on vehicles that utilise oxygen sensors for closed loop fuel feedback control, and utilise a fuel system monitor, typically spark ignition engines.			
	Comprehensive component monitoring	2	0 = monitor not supported (NO) 1 = monitor supported (YES)	CCM_SUP: NO or YES
	Comprehensive component monitoring shall be supported on spark ignition and compression ignition vehicles that utilise comprehensive component monitoring.			
	reserved (bit shall be reported as ‘0’)	3		---

PID $01 definition (continued)

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
	Status of continuous monitoring tests since DTC cleared:	B (bit)	byte 2 of 4 (High Nibble)	Completion status of continuous monitors since DTC cleared:
	Misfire monitoring	4	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	MIS_RDY: YES or NO
	Misfire monitoring shall always indicate complete for spark ignition engines. Misfire monitoring shall indicate complete for compression ignition engines after the misfire evaluation is complete.			
	Fuel system monitoring	5	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	FUEL_RDY: YES or NO
	Fuel system monitoring shall always indicate complete for both spark ignition and compression ignition engines.			
	Comprehensive component monitoring	6	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	CCM_RDY: YES or NO
	Comprehensive component monitoring shall always indicate complete on both spark ignition and compression ignition engines. NOTE It can be assumed that by the time any non-continuous monitors are complete, continuous comprehensive component monitoring will also be complete. Bit 6 is allowed to always indicate "complete" on spark ignition vehicles that support other non-continuous monitors.			
	reserved (bit shall be reported as ‘0’)	7		---
	Supported tests run at least once per trip	C (bit)	byte 3 of 4	Support status of non-continuous monitors:
	Catalyst monitoring	0	0 = monitor not supported (NO) 1 = monitor supported (YES)	CAT_SUP: NO or YES
	Heated catalyst monitoring	1		HCAT_SUP: NO or YES
	Evaporative system monitoring	2		EVAP_SUP: NO or YES
	Secondary air system monitoring	3		AIR_SUP: NO or YES
	A/C system refrigerant monitoring	4		ACRF_SUP: NO or YES
	Oxygen sensor monitoring	5		O2S_SUP: NO or YES
	Oxygen sensor heater monitoring	6		HTR_SUP: NO or YES
	EGR system monitoring	7		EGR_SUP: NO or YES
	Status of tests run at least once per trip	D (bit)	byte 4 of 4	Completion status of non-continuous monitors since DTCs cleared:
	Catalyst monitoring	0	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	CAT_RDY: YES or NO
	Heated catalyst monitoring	1		HCAT_RDY: YES or NO
	Evaporative system monitoring	2		EVAP_RDY: YES or NO
	Secondary air system monitoring	3		AIR_RDY: YES or NO
	A/C system refrigerant monitoring	4		ACRF_RDY: YES or NO
	Oxygen sensor monitoring	5		O2S_RDY: YES or NO
	Oxygen sensor heater monitoring	6		HTR_RDY: YES or NO
	EGR system monitoring	7		EGR_RDY: YES or NO

Data Byte	Application data to use		Formating conversion used
data A	(bit 0 to 6) :	NR_DTC	-
	(bit 7) :	STATE_MIL	
data B	STATE_READY_OBD_1 *		
data C	C_STATE_READY_OBD_2		
data D	STATE_READY_OBD_2		

*) The bit 0 up to 3 of this byte is calibration value C_STATE_READY_OBD_1.
The bit 4 up to 6 of this byte indicate if the tests has been performed continuously since the reinitialization of the memorized information.

Formula section:

```
ACTION_ERRM_ReadQuantityOfDtc
                                        (

54.10.3 Description of PID 03h - Status of fuel system

PID $03 definition

PID (hex)	Description	Data Byte	Scaling/bit	External test equipment SI (Metric) / English display
03	Fuel system 1 status:	A (bit)	byte 1 of 2	FUELSYS1:
	(unused bits shall be reported as ‘0’; no	0	1 = Open loop - has not yet satisfied conditions to go closed loop	OL
	more than one bit at a time can be set to a ‘1’	1	1 = Closed loop - using oxygen sensor(s) as feedback for fuel control	CL
	of that bank)	2	1 = Open loop due to driving conditions (e.g. power enrichment, deceleration enleanment)	OL-Drive
		3	1 = Open loop - due to detected system fault	OL-Fault
		4	1 = Closed loop, but fault with at least one oxygen sensor - may be using single oxygen sensor for fuel control	CL-Fault
		5-7	reserved (bits shall be reported as ‘0’)	---
	NOTE Fuel systems do not refer to injector banks. Fuel systems are intended to represent completely different fuel systems that can independently enter and exit closed loop fuel. Banks of injectors on a V-engine are generally not independent and share the same closed-loop enablement criteria.			
	Fuel system 2 status:	B (bit)	byte 2 of 2	FUELSYS2:
	(unused bits shall be reported as ‘0’; no	0	1 = Open loop - has not yet satisfied conditions to go closed loop	OL
	more than one bit at a time can be set to a ‘1’	1	1 = Closed loop - using oxygen sensor(s) as feedback for fuel control	CL
	of that bank)	2	1 = Open loop due to driving conditions (e.g. power enrichment, deceleration enleanment)	OL-Drive
		3	1 = Open loop - due to detected system fault	OL-Fault
		4	1 = Closed loop, but fault with at least one oxygen sensor - may be using single oxygen sensor for fuel control	CL-Fault
		5-7	reserved (bits shall be reported as ‘0’)	---

54.10.4 Description of PID 04h - Calculated load value

PID $04 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
04	Calculated LOAD Value!	A	0 %	100 %	100/255 %	LOAD_PCT: xxx.x %
	The OBD regulations previously defined CLV as: (current airflow / peak airflow @ sea level) * (BARO @ sea level / BARO) * 100% Various manufacturers have implemented this calculation in a variety of ways. The following definition, although a little more restrictive, will standardise and improve the accuracy the calculation. LOAD_PCT = [current airflow] / [(peak airflow at WOT@STP as a function of rpm) * (BARO/29.92) * SQRT(298/(AAT+273))] — Where: STP = Standard Temperature and Pressure = 25 ^{o}C, 29.92 in Hg BARO, SQRT = square root, — WOT = wide open throttle, AAT=Ambient Air Temperature and is in ^{o}C Characteristics of LOAD_PCT are: — Reaches 1.0 at WOT at any altitude, temperature or rpm for both naturally aspirated and boosted engines. — Indicates percent of peak available torque. — Linearly correlated with engine vacuum — Often used to schedule power enrichment. — Compression ignition engines (diesels) shall support this PID using fuel flow in place of airflow for the above calculations. NOTE Both spark ignition and compression ignition engines shall support PID $04. See PID $43 for an additional definition of engine LOAD.					

Data Byte	Application data to use	Formating conversion used
data A	LOAD_CLC	no

54.10.5 Description of PID 05h - Engine coolant temperature

PID $05 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
05	Engine Coolant Temperature	A	-40 °C	+215 °C	1 °C with -40 °C offset	ECT: xxx °C (xxx °F)
	ECT shall display engine coolant temperature derived from an engine coolant temperature sensor or a cylinder head temperature sensor. Many diesels do not use either sensor and may substitute Engine Oil Temperature instead.					

Data Byte	Application data to use	Formating conversion used
data A	TCO_MES	Shift to different range

54.10.6 Description of PID 06h - Short term fuel trim - Bank 1 and Bank 3

PID $06 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
06	Short Term Fuel Trim - Bank 1 (use if only 1 fuel trim value) Short Term Fuel Trim - Bank 3	A B	-100 % (lean)	+99.22 % (rich)	100/128 % (0 % at 128)	SHRTFT1: xxx.x % SHRTFT3: xxx.x %
	Short Term Fuel Trim Bank 1/3 shall indicate the correction being utilised by the closed loop fuel algorithm. If the fuel system is in open loop, SHRTFT1/3 shall report 0% correction. NOTE Data B shall only be included in the response message of a PID $06 if supported by the vehicle. If PID $1D Oxygen Sensor Location of Bank 1, 2, 3, 4 is supported then the external test equipment shall determine based on the data content (Bank 3 supported) of PID $1D if Data B of PID $06 is supported or not.

54.10.7 Description of PID 07h - Long term fuel trim - Bank 1 and Bank 3

PID $07 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
07	Long Term Fuel Trim - Bank 1 (use if only 1 fuel trim value) Long Term Fuel Trim - Bank 3	A B	-100 % (lean)	+99.22 % (rich)	100/128 % (0 % at 128)	LONGFT1: xxx.x % LONGFT3: xxx.x %
	Fuel trim correction for Bank 1/3 stored in Non-volatile RAM or Keep-alive RAM. LONGFT shall indicate the correction being utilised by the fuel control algorithm at the time the data is requested, in both open loop and closed loop fuel control. If no correction is utilised in open loop fuel, LONGFT shall report 0% correction. If long-term fuel trim is not utilised at all by the fuel control algorithm, the PID shall not be supported. NOTE Data B shall only be included in the response message of a PID $07 if supported by the vehicle. If PID $1D Oxygen Sensor Location of Bank 1, 2, 3, 4 is supported then the external test equipment shall determine based on the data content (Bank 3 supported) of PID $1D if Data B of PID $07 is supported or not.

54.10.10 Description of PID 0Ah - Fuel pressure (gauge)

PID $0A definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0A	Fuel Rail Pressure (gauge)	A	0 kPa (gauge)	765 kPa (gauge)	3 kPa per bit (gauge)	FRP: xxx kPa (xx.x psi)
	FRP shall display fuel rail pressure at the engine when the reading is referenced to atmosphere (gauge pressure).					

Data Byte	Application data to use	Formating conversion used
data A	FUP	Shift to different range

54.10.11 Description of PID 0Bh - Intake manifold absolute pressure

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0B	Intake Manifold Absolute Pressure	A	0 kPa (absolute)	255 kPa (absolute)	1 kPa per bit (absolute)	MAP: xxx kPa (xx.x inHg)
	MAP shall display manifold pressure derived from a Manifold Absolute Pressure sensor, if a sensor is utilised. If a vehicle uses both a MAP and MAF sensor, both the MAP and MAF PIDs shall be supported.					

Data Byte	Application data to use	Formating conversion used
data A	MAP_SAE	None

54.10.12 Description of PID 0Ch - Engine speed

PID $0C definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0C	Engine RPM	A , B	0 min^{-1}	16383.75 min^{-1}	¼ rpm per bit	RPM: xxxxx min^{-1}

Data Byte	Application data to use	Formating conversion used
data A	MSB (N)	Shift to different range
data B	LSB (N)	Shift to different range

54.10.13 Description of PID 0Dh - Vehicle speed

PID $0D definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0D	Vehicle Speed Sensor	A	0 km/h	255 km/h	1 km/h per bit	VSS: xxx km/h (xxx mph)
	VSS shall display vehicle road speed, if utilised by the control module strategy. Vehicle speed may be derived from a vehicle speed sensor, calculated by the PCM using other speed sensors, or obtained from the vehicle serial data communication bus.					

Data Byte	Application data to use	Formating conversion used
data A	VS	no

54.10.14 Description of PID 0Eh - Ignition timing advance

PID $0E definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0E	Ignition Timing Advance for #1 Cylinder	A	-64 °	63.5 °	½ ° with 0 ° at 128	SPARKADV: xx °
	Ignition timing spark advance for #1 cylinder (not including mechanical advance)					

Data Byte	Application data to use	Formating conversion used
data A	IGA_IGC[0]	Shift to different range

54.10.15 Description of PID 0Fh - Intake air temperature

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0F	Intake Air Temperature	A	-40 °C	+215 °C	1 °C with -40 °C offset	IAT: xxx °C (xxx °F)
	IAT shall display intake manifold air temperature, if utilised by the control module strategy. IAT may be obtained directly from a sensor, or may be inferred by the control strategy using other sensor inputs.					

Data Byte	Application data to use	Formating conversion used
data A	TIA_MES	Shift to different range

54.10.16 Description of PID 10h - Air flow rate from MAF

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
10	Air Flow Rate from Mass Air Flow Sensor	A , B	0 g/s	655.35 g/s	0.01 g/s	MAF: xxx.xx g/s (xxxx.x lb/min)
	MAF shall display the airflow rate as measured by the MAF sensor, if a sensor is utilised.					

Data Byte	Application data to use	Formating conversion used
data A	MSB (MAF_KGH_MES)	Kg/h into g/s
data B	LSB (MAF_KGH_MES)	Kg/h into g/s

54.10.17 Description of PID 11h - Absolute throttle position sensor

PID $0A - $11 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
11	Absolute Throttle Position	A	0 %	100 %	100/255 %	TP: xxx.x %
	Absolute throttle position (not “relative” or “learned” throttle position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP shall display (1.0 / 5.0) = 20% at closed throttle and 50% at 2.5 volts. Throttle position at idle will usually indicate greater than 0%, and throttle position at wide open throttle will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage. NOTE See PID $45 for a definition of Relative Throttle Position.					

Data Byte	Application data to use	Formating conversion used
data A	OBD_TPS_1	no

54.10.18 Description of PID 12h - Commanded secondary air status

With autolearning the value for the LV_VAR_SAP is defined to the value defined by the project

IF PID $12 supported and LV_VAR_SAP <> 0

THEN

PID $12 definition

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
12	Commanded Secondary Air Status	A (bit)	byte 1 of 1	AIR_STAT:
	(if supported, one, and only	0	1 = upstream of first catalytic converter	AIR_STAT: UPS
	one bit at a time can be set	1	1 = downstream of first catalytic converter inlet	AIR_STAT: DNS
	to a 1)	2	1 = atmosphere / off	AIR_STAT: OFF
		3-7	reserved (bits shall be reported as ‘0’)	---

Data Byte	Calibration data to use	Formating conversion used
data A	STATE_OBD_SA	-

ENDIF

54.10.19 Description of PID 13h - Location of oxygen sensors

PID $13 definition

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
13	Location of Oxygen Sensors	A (bit)	byte 1 of 4	O2SLOC:
	(where sensor 1 is closest to the engine. Each bit indicates the presence or absence of an oxygen sensor at the following location)	0	1 = Bank 1 - Sensor 1 present at that location	O2S11
		1	1 = Bank 1 - Sensor 2 present at that location	O2S12
		2	1 = Bank 1 - Sensor 3 present at that location	O2S13
		3	1 = Bank 1 - Sensor 4 present at that location	O2S14
		4	1 = Bank 2 - Sensor 1 present at that location	O2S21
		5	1 = Bank 2 - Sensor 2 present at that location	O2S22
		6	1 = Bank 2 - Sensor 3 present at that location	O2S23
		7	1 = Bank 2 - Sensor 4 present at that location	O2S24

With autolearning the value for the PSN_LS is defined like this:

```
IF      PID 13h is supported
THEN    PSN_LS is defined to the value defined by the project
ELSE    PSN_LS is defined to 0
ENDIF
```

Data Byte	Calibration data to use	Formating conversion used
data A	PSN_LS	no

54.10.20 Description of PID 14h - Bank 1 Sensor 1 (not supported)

54.10.21 Description of PID 15h - Bank 1 Sensor 2

PID $15 definition if PID $13 is supported!

PID (hex)	Description Use if PID $13 or PID $1D are supported!	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
15	Oxygen Sensor Output Voltage Bank 1 – Sensor 2	A	0 V	1.275 V	0.005 V	O2Sxy: x.xxx V
	Short Term Fuel Trim (B1-S2) (associated with this sensor $FF if this sensor is not used in the calculation)	B	-100.00 % (lean)	99.22 % (rich)	100/128 % (0 % at 128)	SHRTFTxy: xxx.x %
	These PIDs shall be used for a conventional, 0 to 1 Volt oxygen sensor. Any sensor with a different full scale value shall be normalised to provide nominal full scale at $C8 (200 decimal). Wide-range/linear oxygen sensors shall use PID $25 or PID $35.

54.10.44 Description of PID 2C - Commanded EGR

IF NC_INF_CONF <> 0 *(only supported for MSD)*

THEN

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
2C	Commanded EGR	A	0% (no flow)	100% (max. flow)	100/255 %	EGR_PCT: xxx.x%
	Commanded EGR displayed as a percent. EGR_PCT shall be normalised to the maximum EGR commanded output control parameter. EGR systems use a variety of methods to control the amount of EGR delivered to the engine. 1) If an on/off solenoid is used – EGR_PCT shall display 0% when the EGR is commanded off, 100% when the EGR system is commanded on. 2) If a vacuum solenoid is duty cycled, the EGR duty cycle from 0 to 100% shall be displayed. 3) If a linear or stepper motor valve is used, the fully closed position shall be displayed as 0%, the fully open position shall be displayed as 100%. Intermediate positions shall be displayed as a percent of the full-open position. For example, a stepper-motor EGR valve that moves from 0 to 128 counts shall display 0% at 0 counts, 100% at 128 counts and 50% at 64 counts. 4) Any other actuation method shall be normalised to display 0% when no EGR is commanded and 100% at the maximum commanded EGR position.					

Data Byte	Application data to use	Formating conversion used
data A	OPG_SP_ACR	-

ENDIF

54.10.45 Description of PID 2D definition - EGR Error

IF NC_INF_CONF <> 0 *(only supported for MSD)*

THEN

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
2D	EGR Error = (EGR actual – EGR commanded) / EGR commanded * 100%	A	-100 % (less than commanded)	+99.22 % (more than commanded)	100/128 % (0 % at 128)	EGR_ERR: xxx.x%

EGR error, as a percent of commanded EGR. Often, EGR valve control outputs are not in the same engineering units as the EGR feedback input sensors. For example, an EGR valve can be controlled using a duty-cycled vacuum solenoid, however, the feedback input sensor is a position sensor. This makes it impossible to display "actual" versus "commanded" in the same engineering units. EGR error solved this problem by displaying a normalised (non-dimensional) EGR system feedback parameter. EGR error is defined to be:

(actual EGR – commanded EGR) / commanded EGR.

For example if 10% EGR is commanded and 5% is delivered to the engine, the EGR_ERR is (5% - 10%) / 10 = -50% error.

EGR_ERR may be computed using various control parameters such as position, steps, counts, etc. All EGR systems must react to quickly changing conditions in the engine; therefore, EGR_ERR will generally show errors during transient conditions. Under steady condition, the error will be minimized (no necessarily zero, however) if the EGR system is under control.

If the control system does not use closed loop control, EGR_ERR shall not be supported.

54.10.50 Description of PID 32h - Evap System Vapor Pressure (not supported)

54.10.51 Description of PID 33h - Barometric Pressure

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
33	Barometric Pressure	A	0 kPa (absolute)	255 kPa (absolute)	1 kPa per bit (absolute)	BARO: xxx kPa (xx.x inHg)
	Barometric pressure utilised by the control module. BARO is normally obtained from a dedicated BARO sensor, from a MAP sensor at key-on and during certain modes of driving, or inferred from a MAF sensor and other inputs during certain modes of driving. The control module shall report BARO from whatever source it is derived from. NOTE Some weather services report local BARO values adjusted to sea level. In these cases, the reported value may not match the displayed value on the external test equipment. NOTE If BARO is inferred while driving and stored in non-volatile RAM or Keep-alive RAM, BARO may not be accurate after a battery disconnect or total memory clear.

54.10.65 Description of PID 41 - Monitor status this driving cycle

PID $41 definition

PID (hex)	Description	Data Byte	Scaling/bit	External test equipment SI (Metric) / English display
41	Monitor status this driving cycle			
	The bit in this PID shall report two pieces of information for each monitor: 1) Monitor enable status for the current driving cycle. This bit shall indicate when a monitor is disabled in a manner such that there is no way for the driver to operate the vehicle for the remainder of the driving cycle and make the monitor run. Typical examples are: Engine-off soak not long enough (e.g., cold start temperature conditions not satisfied) Monitor maximum time limit or number of attempts/aborts exceeded Ambient air temperature too low or too high BARO too low (high altitude) The monitor shall not indicate "disabled" for operator-controlled conditions such as rpm, load, throttle position, minimum time limit not exceeded, ECT, TP, etc. 2) Monitor completion status for the current driving/monitoring cycle. Status shall be reset to "not complete" upon starting a new monitoring cycle. Note that some monitoring cycles can include various engine-operating conditions; other monitoring cycles begin after the ignition key is turned off. Some status bits on a given vehicle can utilise engine-running monitoring cycles while others can utilise engine-off monitoring cycles. Resetting the bits to "not complete" upon starting the engine will accommodate most engine-running and engine-off monitoring cycles, however, manufacturers are free to define their own monitoring cycles. NOTE PID $41 bits shall be utilised for all non-continuous monitors which are supported, and change completion status in PID $01. If a non-continuous monitor is not supported or always shows "complete", the corresponding PID $41 bits shall indicate disabled and complete. PID $41 bits may be utilised at the vehicle manufacturer's discretion for all continuous monitors which are supported with the exception of bit 03 which shall always showed CCM as enabled for spark ignition and compression ignition engines.			

PID $41 definition (continued)

PID (hex)	Description	Data Byte	Scaling/bit	External test equipment SI (Metric) / English display
41	Monitor status this driving cycle			
		A (bit)	**byte 1 of 4**	
	Reserved - shall be reported as $00	0-7		---
	Enable status of continuous monitors this monitoring cycle:	**B (bit)**	byte 2 of 4 (Low Nibble)	Enable status of continuous monitors this monitoring cycle: NO means disabled for rest of this monitoring cycle or not supported in PID $01, YES means enabled for this monitoring cycle.
	Misfire monitoring	0	0 = monitor disabled for rest of this monitoring cycle or not supported (NO) 1 = monitor enabled for this monitoring cycle (YES)	MIS_ENA: NO or YES
	Fuel system monitoring	1		FUEL_ENA: NO or YES
	Comprehensive component monitoring	2		CCM_ENA: YES
	reserved (bit shall be reported as ‘0’)	3

54.10.66 Description of PID 42 - Control module voltage

PID $42 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
42	Control module voltage	A , B	0 V	65.535 V	0.001 V per bit	VPWR: xx.xxx V
	VPWR – power input to the control module. VPWR is normally battery voltage, less any voltage drop in the circuit between the battery and the control module. NOTE 42-volt vehicles may utilise multiple voltages for different systems on the vehicle. VPWR represents the voltage at the control module; it may be significantly different than battery voltage.					

Data Byte	Application data to use	Formating conversion used
data A	MSB (VB)	Shift to different range
data B	LSB (VB)	

54.10.67 Description of PID 43 - Absolute Load Value

PID $43 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
43	Absolute Load Value	A , B	0 %	25700%	100/255 %	LOAD_ABS: xxx.x%
	The absolute load value has some different characteristics than the LOAD_PCT defined in PID 04 This definition, although restrictive, will standardise the calculation. LOAD_ABS is the normalised value of air mass per intake stroke displayed as a percent. LOAD_ABS = [air mass (g/intake stroke)] / [1.184 (g/intake stroke) * cylinder displacement in litres] Derivation: air mass (g / intake stroke) = [total engine air mass (g/sec)] / [rpm (revs/min)* (1 min / 60 sec) * (1/2 # of cylinders (strokes /rev)] LOAD_ABS = [air mass (g)/intake stroke] / [maximum air mass (g)/intake stroke at WOT@STP at 100% volumetric efficiency] * 100% Where: STP = Standard Temperature and Pressure = 25 ^{o}C, 29.92 in Hg (1013 hPa) BARO, WOT = wide open throttle The quantity (maximum air mass (g)/intake stoke at WOT@STP at 100% volumetric efficiency) is a constant for a given cylinder swept volume. The constant is 1.184 (g/litre 3) * cylinder displacement (litre 3/intake stroke) based on air density at STP Characteristics of LOAD_ABS are: Ranges from 0 to approximately 0.95 for naturally aspirated engines, 0 – 4 for boosted engines Linearly correlated with engine indicated and brake torque Often used to schedule spark and EGR rates Peak value of LOAD_ABS correlates with volumetric efficiency at WOT. Indicates the pumping efficiency of the engine for diagnostic purposes. Spark ignition engine are required to support PID $43. Compression ignition (diesel) engines are not required to support this PID. NOTE See PID $04 for an additional definition of engine LOAD..					

Data Byte	Application data to use	Formating conversion used
data A	MSB (LOAD_ABSV)	no
data B	LSB (LOAD_ABSV)	no

54.10.68 Description of PID 44 - Commanded Equivalence Ratio

Table .1 — PID $44 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
44	Commanded Equivalence Ratio	A , B	0	1.999	0.0000305	EQ_RAT: x.xxx
	Fuel systems that utilise conventional oxygen sensor shall display the commanded open loop equivalence ratio while the fuel control system is in open loop. EQ_RAT shall indicate 1.0 while in closed loop fuel. Fuel systems that utilise wide-range/linear oxygen sensors shall display the commanded equivalence ratio in both open loop and closed loop operation. To obtain the actual A/F ratio being commanded, multiply the stoichiometric A/F ratio by the equivalence ratio. For example, for gasoline, stoichiometric is 14.64:1 ratio. If the fuel control system was commanding an 0.95 EQ_RAT, the commanded A/F ratio to the engine would be 14.64 * 0.95 = 13.9 A/F					

Data Byte	Application data to use	Formating conversion used
data A	MSB(LAMB_SP_HOM[1])	Shift to different resolution =
data B	LSB(LAMB_SP_HOM[1])	

54.10.69 Description of PID 45 - Relative Throttle Position

PID $45 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
45	Relative Throttle Position	A	0 %	100 %	100/255 %	TP_R: xxx.x %
	Relative or "learned" throttle position shall be displayed as a normalised value, scaled from 0 to 100%. TP_R should display a value of 0% at the "learned closed-throttle position. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP shall display (1.0 – 1.0 / 5.0) = 0% at closed throttle and 30% at 2.5 volts. Because of the closed-throttle offset, wide open throttle will usually indicate substantially less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage. See PID $11 for a definition of Absolute Throttle Position.

data A	OBD_TPS_REL	-

54.10.70 Description of PID 46 - Ambient air temperature

PID $46 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
46	Ambient air temperature (same scaling as IAT - $0F)	A	-40 °C	+215 °C	1 °C with -40 °C offset	AAT: xxx °C / xxx °F
	AAT shall display ambient air temperature, if utilised by the control module strategy for OBD monitoring. AAT may be obtained directly from a sensor, may be obtained indirectly via the vehicle serial data communication bus, or may be inferred by the control strategy using other sensor inputs.					

Data Byte	Application data to use	Formating conversion used

54.10.71 Description of PID 47 - Absolute Throttle Position B

PID $47 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
47	Absolute Throttle Position B	A	0 %	100 %	100/255 %	TP_B: xxx.x %
	Absolute throttle position B, if utilised by the control module, (not “relative” or “learned” throttle position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP_B shall display (1.0 / 5.0) = 20% at closed throttle and 50% at 2.5 volts. Throttle position at idle will usually indicate greater than 0%, and throttle position at wide open throttle will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage.

54.10.72 Description of PID 48 - Absolute Throttle Position C (not supported)

54.10.73 Description of PID 49 - Accelerator Pedal Position D

PID $49 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
49	Accelerator Pedal Position D	A	0 %	100 %	100/255 %	APP_D: xxx.x %
	Accelerator Pedal Position D, if utilised by the control module, (not “relative” or “learned” pedal position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed pedal is 1.0 volt, APP_D shall display (1.0 / 5.0) = 20% at closed pedal and 50% at 2.5 volts. Pedal position at idle will usually indicate greater than 0%, and pedal position at wide open pedal will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage.

54.10.74 Description of PID 4A - Accelerator Pedal Position E

PID $4A definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
4A	Accelerator Pedal Position E	A	0 %	100 %	100/255 %	APP_E: xxx.x %
	Accelerator Pedal Position E, if utilised by the control module, (not “relative” or “learned” pedal position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed pedal is 1.0 volt, APP_E shall display (1.0 / 5.0) = 20% at closed pedal and 50% at 2.5 volts. Pedal position at idle will usually indicate greater than 0%, and pedal position at wide open pedal will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage.

54.10.75 Description of PID 4B - Accelerator Pedal Position F (not supported)

54.10.76 Description of PID 4C - Commanded Throttle Actuator Control

PID $4C definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
4C	Commanded Throttle Actuator Control	A	0% (closed throttle)	100% (wide open throttle)	100/255 %	TAC_PCT: xxx.x%
	Commanded TAC displayed as a percent. TAC_PCT shall be normalised to the maximum TAC commanded output control parameter. TAC systems use a variety of methods to control the amount of throttle opening. 1) If a linear or stepper motor is used, the fully closed throttle position shall be displayed as 0%, the fully open throttle position shall be displayed as 100%. Intermediate positions shall be displayed as a percent of the full-open throttle position. For example, a stepper-motor TAC that moves the throttle from 0 to 128 counts shall display 0% at 0 counts, 100% at 128 counts and 50% at 64 counts. 2) Any other actuation method shall be normalised to display 0% when the throttle is commanded closed and 100% when the throttle is commanded open.

54.10.78 Description of PID 4E - Time since diagnostic trouble codes cleared

PID $4E definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
4E	Time since diagnostic trouble codes cleared	A, B	0 min	65535 min 1092.25 hours	1 min per count	CLR_TIME: xxxx hrs, xx min
	Time accumulated since DTCs were cleared (via an external test equipment or possibly, a battery disconnect). This PID is not associated with any particular DTC. It is simply an indication for I/M (Inspection/Maintenance), of the last time an external test equipment was used to clear DTCs. If greater than 65,535 min have occurred, CLR_TIME shall remain at 65,535 min and not wrap to zero.					

Data Byte	Application data to use	Formating conversion used
data A	MSB (T_DTC_CLR)	-
data B	LSB (T_DTC_CLR)	

54.10.79 Description of PID 4F up to FFh - Reserved

FUNCTION DESCRIPTION:

General information:

Read on-board oxygen sensor monitoring test results by an external tester. The use of this mode is optional, depending on the method used by the vehicle manufacturer to comply with the requirement for oxygen sensor monitoring.
Mode05 is only supported if lambda sensors are mounted (PSN_LS = 11H or 33H, see below).

PSN_LS:

BIT	Function	Status
0	Bank 1 Sensor 1	1= available, 0 = not available
1	Bank 1 Sensor 2	1= available, 0 = not available
2	Bank 1 Sensor 3	1= available, 0 = not available
3	Bank 1 Sensor 4	1= available, 0 = not available
4	Bank 2 Sensor 1	1= available, 0 = not available
5	Bank 2 Sensor 2	1= available, 0 = not available
6	Bank 2 Sensor 3	1= available, 0 = not available
7	Bank 2 Sensor 4	1= available, 0 = not available

Formula section:

```
If      PSN_LS = 33h            //means, that
              Bank1 / Sensor 1 and
              Bank2 / Sensor 1 and
              Bank1 / Sensor 2 and
              Bank2 / Sensor 2            are available.
Then    all defined TID are supported
ElseIf  PSN_LS = 11h //means, that Bank1 / Sensor1 and Bank2 Sensor1 are available.
Then    only TID $81, $82, $83, $83 are supported
Else    Mode 5 is not supported
Endif
```

54.13.1 Overview of all implemented TID's

FUNCTION DESCRIPTION:

General information:

The CID is calculatated depending if the Threshold is working as a "Maximum" or "Minimum" threshold. The "Minimum" CID is always the "Maximum" CID + **80h**.

For example:

TID 03h / CID 05/85h : Secondary Air Monitor 1 – LinLam Min flow bank 1/2
=> CID 05h is a "Maximum" Threshold
=> CID 85h is a "Minimum" Threshold (85h = 05h + **80h**)

List of all TIDs
Catalyst monitor
TID 01h / CID 01h : Catalyst monitor Bank1
TID 01h / CID 02h : Catalyst monitor Bank2
Oxygen sensor monitor
TID 02h / CID 15h : Oxygen sensor monitor Bank1 – Sensor1 – Dynamic
TID 02h / CID 30h : Oxygen sensor monitor Bank1 – Sensor2 – Switchtime
TID 02h / CID 18 : Oxygen sensor monitor Bank2 – Sensor1 – Dynamic
TID 02h / CID 32h : Oxygen sensor monitor Bank2 – Sensor2 – Switchtime
Secondary air monitor
TID 03h / CID 20h : Secondary Air Monitor 2 – SA – meter Min flow, Step 1
TID 03h / CID 21h : Secondary Air Monitor 2 – SA – meter Min flow, Step 2
TID 03h / CID 05h(85h) : Secondary Air Monitor 1 – LinLam Min flow bank 1/2
Evaporative monitor
TID 05h / CID 07h(87h) : EVAP monitor – CPS check – Step 1
TID 05h / CID 08h : EVAP monitor – CPS check – Step 2
TID 05h / CID 09h : EVAP monitor – CPS check – Step 3
TID 05h / CID 13h : EVAP monitor – Module error – Max error
TID 05h / CID 14h : EVAP monitor – Module error – Plausibility error
TID 05h / CID 17h : EVAP monitor – Module error – Signal error
TID 05h / CID 12h(92h) : EVAP monitor – Module error – Min error
TID 05h / CID 15h(95h) : EVAP monitor – DMTL – Rough leak – Short cycle
TID 05h / CID 16h(96h) : EVAP monitor – DMTL – Small leak
TID 05h / CID 18h(98h) : EVAP monitor – DMTL – Rough leak – Long cycle
Oxygen heater monitor
TID 06h / CID 03h : Oxygen Sensor Heater Monitor Bank 1 – Sensor 2 - R
TID 06h / CID 04h : Oxygen Sensor Heater Monitor Bank 2 – Sensor 2 - R
TID 06h / CID 05h/85h:Oxygen Sensor Heater Monitor Bank 1–Sensor 1 - TTIP
TID 06h / CID 06h/86h:Oxygen Sensor Heater Monitor Bank 2–Sensor 1 - TTIP

54.13.2 Supported TIDs 01h – C0h

54.13.2.1 Description of TID 00h - Supported TIDs 01h - 20h

54.13.3 Description of TID 01 - Catalyst monitoring

General information:

TID 01 is only supported if the vehicle is equipped with lambda sensors UP and DOWN

Formula section:

```
If      PSN_LS = 33H
Then    TID 01 is supported
Else    TID 01 is not supported
Endif
```

54.13.3.1 CID 01h - Bank 1

OSC method (linear system)	
Std/Manufacturer defined **CID**	01h
Unit and scaling	NONE
Test value	CAT_DIAG_MOD_6[1]
Min test limit	NONE
Max test limit	CAT_MAX_DIAG_MOD_6[1]

Formula section:

```
IF      LV_READY_CAT_DIAG[1] = 0          OR
        LV_ERR_MEM_CAT_DIAG[1] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.3.2 CID 02h - Bank 2

OSC method (linear system)	
Std/Manufacturer defined **CID**	02h
Unit and scaling	NONE
Test value	CAT_DIAG_MOD_6[2]
Min test limit	NONE
Max test limit	CAT_MAX_DIAG_MOD_6[2]

Formula section:

```
IF      LV_READY_CAT_DIAG[2] = 0          OR
        LV_ERR_MEM_CAT_DIAG[2] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.4 Description of TID 02h - Lambda sensor diagnosis

General information:

TID 02 is only supported if the vehicle is equipped with lambda sensors UP and DOWN or UP.

Formula section:

```
If      PSN_LS = 33H or 11H
Then    TID 02 is supported
    If      PSN_LS = 11H
    Then    CID 30h / 32h are not supported
            //no Downstream sensors
    Endif
Else    TID 02 is not supported
Endif
```

54.13.4.1 CID 15h – Dynamic diagnosis (linear), Bank 1

Sensor dynamic diagnosis	
Std/Manufacturer defined **CID**	15h (MAX)
Unit and scaling	NONE
Test value	FAC_DYN_LSL_DIAG_SAE[1]
Min test limit	0
Max test limit	FAC_DYN_LSL_DIAG_TOL_SAE[1]

Formula section:

```
IF      LV_READY_DYN_VLD_LS_UP[1] = 0      OR
        LV_ERR_MEM_DYN_VLD_LS_UP[1] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.4.2 CID 18h - Dynamic diagnosis (linear), Bank 2

Sensor dynamic diagnosis	
Std/Manufacturer defined **CID**	18h (MAX)
Unit and scaling	NONE
Test value	FAC_DYN_LSL_DIAG_SAE[2]
Min test limit	0
Max test limit	FAC_DYN_LSL_DIAG_TOL_SAE[2]

Formula section:

```
IF      LV_READY_DYN_VLD_LS_UP[2] = 0        OR
        LV_ERR_MEM_DYN_VLD_LS_UP[2] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.4.3 CID 30h - Switchtime diagnosis (downstream binary), Bank 1

Switchtime diagnosis	
Std/Manufacturer defined **CID**	30h
Unit and scaling	NONE
Test value	CTR_SAVE_SWT_LS_DOWN[1]
Min test limit	NONE
Max test limit	C_CTR_SWT_LS_DOWN

Formula section:

```
IF      LV_READY_SWT_LS_DOWN[1] = 0        OR
        LV_ERR_MEM_SWT_LS_DOWN[1] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.4.4 CID 32h - Switchtime diagnosis (downstream binary), Bank 2

Switchtime diagnosis	
Std/Manufacturer defined CID	32h
Unit and scaling	NONE
Test value	CTR_SAVE_SWT_LS_DOWN[2]
Min test limit	NONE
Max test limit	C_CTR_SWT_LS_DOWN

Formula section:

```
IF      LV_READY_SWT_LS_DOWN[2] = 0        OR
        LV_ERR_MEM_SWT_LS_DOWN[2] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.5 Description of TID 03h - Secondary air monitoring

General information:

TID 03h is only supported if SA pump is learnt. Depending of hardware configuration in the car only one type of SA monitioring is active (via lambda-sensor **or** flow meter).

Formula section:

```
If      LV_VAR_SAP = 1
Then    TID 03 is supported
    If      LC_SA_SWI_ACQ = 1
    Then    CID 05h(=85h) are not supported        //no diagnosis via lambda sensor
    Else    CID 20h and 21h are not supported      //no diagnosis via SAF meter
    Endif
Else    TID 03 is not supported
Endif
```

54.13.5.1 CID 20h/21h - Secondary air monitor with flow meter (SAFM)

Monitoring of minimum flow rate	
Std/Manufacturer defined **CID**	20h
Unit and scaling	NONE
Test value	SAF_DIAG_MIN_SAE
Min test limit	NONE
Max test limit	C_SAF_DIAG_MIN
Monitoring of minimum flow rate	
Std/Manufacturer defined **CID**	21h
Unit and scaling	NONE
Test value	SAF_DIAG_MAX_SAE
Min test limit	NONE
Max test limit	C_SAF_DIAG_MAX

Formula section:

```
IF      LV_READY_SA_SYS = 0          OR
        LV_ERR_MEM_SA_SYS = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
Endif
```

54.13.5.2 CID 85h - Secondary air monitor with lambda sensor (LISL)

Monitoring of minimum flow rate, Bank 1 / Bank 2	
Std/Manufacturer defined **CID**	85h (identifier 05h + 80h)
Unit and scaling	NONE
Test value	**MIN [** SUM_AFL_VLS_DIAG_SA_1_SAE; SUM_AFL_VLS_DIAG_SA_2_SAE **]**
Min test limit	C_SUM_AFL_VLS_MIN_DIAG_SA_1
Max test limit	NONE

Formula section:

```
IF      LV_READY_SA_SAP = 0        OR
        LV_ERR_MEM_SA_SAP = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.6 Description of TID 05h - Evaporative Monitor

General information:

All DMTL related CID's are only supported if the CAR is equipped with the DMTL module.

Formula section:

If LV_CONF_DMTL = 0

Then CID's 13h/14h/17h/ 12h(=92h)/15h(=95h)/16h(=96h)/18h(=98h)

... are not supported

Else all CID's of TID 05h are supported

Endif

54.13.6.1 CID 09h/87h/88h - Purge Flow monitor (TEV check)

Functional check TEV – Step 1	
Std/Manufacturer defined **CID**	87h (identifier 07h + 80h)
Unit and scaling	NONE
Test value	CL_MMV_SAE
Min test limit	C_CL_MMV_DIAGCPS
Max test limit	NONE
Functional check TEV – Step 2	
Std/Manufacturer defined **CID**	08h
Unit and scaling	NONE
Test value	SUM_DIAG_DIAGCPS_SAE
Min test limit	NONE
Max test limit	C_SUM_DIAGCPS_MAX
Functional check TEV – Step 3	
Std/Manufacturer defined **CID**	09h
Unit and scaling	NONE
Test value	MAF_DIAGCPS_SAE
Min test limit	NONE
Max test limit	MAF_DIAGCPS_THD_SAE

Formula section:

IF LV_READY_DIAGCPS = 0 **OR**

LV_ERR_MEM_DIAGCPS = 1

THEN Positive response with test result

ELSE Positive response with all data equal to 0000h

ENDIF

54.13.6.2 CID 13h/14h/17h/92h - DMTL module diagnosis

DMTL module – MAX error	
Std/Manufacturer defined **CID**	13h
Unit and scaling	NONE
Test value	M6_CUR_DMTL_COR_FIL_CID19
Min test limit	NONE
Max test limit	C_CUR_DMTL_REF_LEAK_MAX
DMTL module – Plausibility error	
Std/Manufacturer defined **CID**	14h
Unit and scaling	NONE
Test value	M6_CUR_DMTL_DMTLS_TEST
Min test limit	NONE
Max test limit	M6_CUR_DMTL_THD_DMTLS_TEST
DMTL module - Signal error	
Std/Manufacturer defined **CID**	17h
Unit and scaling	NONE
Test value	M6_CTR_CNL_SMALL_LEAK_MES
Min test limit	NONE
Max test limit	C_SUM_CNL_SMALL_LEAK_MES_MAX
DMTL module – MIN error	
Std/Manufacturer defined **CID**	92h (identifier 12h + 80h)
Unit and scaling	NONE
Test value	M6_CUR_DMTL_COR_FIL_CID18
Min test limit	C_CUR_DMTL_REF_LEAK_MIN
Max test limit	NONE

Formula section:

```
IF      LV_READY_DMTLM = 0        OR
        LV_ERR_MEM_DMTLM = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.6.3 CID 95h/98h - Rough-leak diagnosis

Leak detection DMTL – Long cycle	
Std/Manufacturer defined **CID**	98h (identifier 18h + 80h)
Unit and scaling	NONE
Test value	M6_CUR_DMTL_ROUGH_LEAK_LEN_END
Min test limit	M6_CUR_DMTL_THD_ROUGH_LEAK_LEN
Max test limit	NONE
Leak detection DMTL – Short cycle	
Std/Manufacturer defined **CID**	95h (identifier 15h + 80h)

Unit and scaling	NONE
Test value	M6_CUR_DMTL_ROUGH_LEAK_END
Min test limit	M6_CUR_DMTL_THD_ROUGH_LEAK
Max test limit	NONE

Formula section:

```
IF      LV_READY_ROUGH_LEAK = 0        OR
        LV_ERR_MEM_ROUGH_LEAK = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.6.4 CID 96h - Small-leak diagnosis

Leak detection DMTL – Short cycle	
Std/Manufacturer defined **CID**	96h (identifier 16h + 80h)
Unit and scaling	NONE
Test value	M6_CUR_DMTL_SMALL_LEAK_END
Min test limit	M6_CUR_DMTL_REF_LEAK
Max test limit	NONE

Formula section:

```
IF      LV_READY_SMALL_LEAK = 0        OR
        LV_ERR_MEM_SMALL_LEAK = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.7 Description of TID 06h - Oxygen sensor heater monitoring

General information:

TID 06 is only supported if the vehicle is equipped with lambda sensors UP and DOWN or UP.

Formula section:

```
If      PSN_LS = 33H or 11H
Then    TID 06 is supported
    If      PSN_LS = 11H
    Then    CID 03h / 04h are not supported    //no Downstream sensors
    Endif
Else    TID 06 is not supported
Endif
```

54.13.7.1 CID 05h / 85h - Oxygen sensor heater monitor, Bank 1 Sensor 1 (linear)

Sensor temperature	
Std/Manufacturer defined **CID**	05h (MAX) 85h (MIN)
Unit and scaling	NONE
Test value	TTIP_MES_LS_UP_OBD_LSH_UP[1]
Min test limit	C_TTIP_MIN_OBD_LSH_UP
Max test limit	C_TTIP_MAX_OBD_LSH_UP

Formula section:

```
IF      LV_READY_OBD_VLD_LSH_UP[1] = 0        OR
        LV_ERR_MEM_OBD_VLD_LSH_UP[1] = 1
THEN    Positive response with test result
ELSE    Positive response with all data equal to 0000h
ENDIF
```

54.13.7.2 CID 03h - Oxygen sensor heater monitor, Bank 1 Sensor 2 (binary)

Sensor resistance	
Std/Manufacturer defined **CID**	03h
Unit and scaling	NONE
Test value	R_IT_OBD_LSH_DOWN[1]
Min test limit	NONE
Max test limit	R_IT_THD_OBD_LSH_DOWN[1]

Formula section:

```
IF      LV_READY_OBD_LSH_DOWN[1] = 0        OR
```

```
          LV_ERR_MEM_OBD_LSH_DOWN[1] = 1
THEN      Positive response with test result
ELSE      Positive response with all data equal to 0000h
ENDIF
```

54.13.7.3 CID 06h / 86h - Oxygen sensor heater monitor, Bank 2 Sensor 1 (linear)

Sensor temperature	
Std/Manufacturer defined **CID**	06h (MAX) 86h (MIN)
Unit and scaling	NONE
Test value	TTIP_MES_LS_UP_OBD_LSH_UP[2]
Min test limit	C_TTIP_MIN_OBD_LSH_UP
Max test limit	C_TTIP_MAX_OBD_LSH_UP

Formula section:

```
IF        LV_READY_OBD_VLD_LSH_UP[2] = 0          OR
          LV_ERR_MEM_OBD_VLD_LSH_UP[2] = 1
THEN      Positive response with test result
ELSE      Positive response with all data equal to 0000h
ENDIF
```

54.13.7.4 CID 04h - Oxygen sensor heater monitor, Bank 2 Sensor 2 (binary)

Sensor resistance	
Std/Manufacturer defined **CID**	04h
Unit and scaling	NONE
Test value	R_IT_OBD_LSH_DOWN[2]
Min test limit	NONE
Max test limit	R_IT_THD_OBD_LSH_DOWN[2]

Formula section:

```
IF        LV_READY_OBD_LSH_DOWN[2] = 0            OR
          LV_ERR_MEM_OBD_LSH_DOWN[2] = 1
THEN      Positive response with test result
ELSE      Positive response with all data equal to 0000h
ENDIF
```

54.14 VIT description for mode 09h

Input data:

MOD_9_VIT_1_DIAG	MOD_9_VIT_2_DIAG	MOD_9_VIT_3_DIAG	MOD_9_VIT_4_DIAG

Import action:

ACTION_ERRM_SelectRbmData (**INOUT < ListRbmData >,** **OUT < ResultRbmData >** **)**
This API calculates and returns the Rate-Based Monitoring data to be transmitted to the Scan-Tool, when requested by the Mode 09$ (InfoType $08).

54.14.2 Description of Mode 09h, VIT 01h – Messagecount VIN

54.14.3 Request vehicle information request message

Message direction:	External test equipment → All ECUs		
Message Type:	Request		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information request SID	09	SIDRQ
#2	InfoType: MessageCount VIN	01	INFTYP

Positive responses (read InfoType value)

Request vehicle information response message

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: MessageCount VIN	01	INFTYP
#3	MessageCount VIN = 5 response messages	05	MC_CALID

54.14.4 Description of Mode 09h, VIT 02h - VIN

Request vehicle information request message

Message direction:	External test equipment → All ECUs		
Message Type:	Request		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information request SID	09	SIDRQ
#2	InfoType: VIN	02	INFTYP

54.14.5 Response positive report VIN

First positive response

— Request vehicle information response message (1)

Message direction:	ECU#1 → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: VIN	02	INFTYP
#3	MessageCount VIN = 1st response message	01	MC_CALID
#4	Data A: Pad-byte	00	byte always 0
#5	Data B: Pad-byte	00	byte always 0
#6	Data C: Pad-byte	00	byte always 0
#7	Data D:	XX*	VIN char 0

* 30h, if there is no VIN.

Second positive response

Request vehicle information response message (2)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: VIN	02	INFTYP
#3	MessageCount VIN = 2nd response message	02	MC_CALID
#4	Data A:	XX*	VIN char 1
#5	Data B:	XX*	VIN char 2
#6	Data C:	XX*	VIN char 3
#7	Data D:	XX*	VIN char 4

* 30h, if there is no VIN.

thirth positive response

— Request vehicle information response message (3)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: VIN	02	INFTYP
#3	MessageCount VIN = 3rd response message	03	MC_CALID
#4	Data A:	XX*	VIN char 5
#5	Data B:	XX*	VIN char 6
#6	Data C:	XX*	VIN char 7
#7	Data D:	XX*	VIN char 8

* 30h, if there is no VIN

forth positive response

Request vehicle information response message (4)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: VIN	02	INFTYP
#3	MessageCount VIN = 4nd response message	04	MC_CALID
#4	Data A:	XX*	VIN char 9
#5	Data B:	XX*	VIN char 10
#6	Data C:	XX*	VIN char 11
#7	Data D:	XX*	VIN char 12

* 30h, if there is no VIN

fifth positive response

Request vehicle information response message (5)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: VIN	02	INFTYP
#3	MessageCount VIN = 5nd response message	05	MC_CALID
#4	Data A:	XX*	VIN char 13
#5	Data B:	XX*	VIN char 14
#6	Data C:	XX*	VIN char 15
#7	Data D:	XX*	VIN char 16

* 30h, if there is no VIN

54.14.6 Description of Mode 09h, VIT 03h – Messagecount Calibration IDs

54.14.7 Request vehicle information request message

Message direction:	External test equipment → All ECUs		
Message Type:	Request		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information request SID	09	SIDRQ
#2	InfoType: MessageCount Calibration Id	03	INFTYP

Positive responses (read InfoType value)

Request vehicle information response message

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: MessageCount Calibration Id	03	INFTYP
#3	MessageCount Calibration Id = 8 response messages	08	MC_CALID

54.14.8 Description of Mode 09h, VIT 04h - Calibration IDs

Request vehicle information request message

Message direction:	External test equipment → All ECUs		
Message Type:	Request		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information request SID	09	SIDRQ
#2	InfoType: Calibration Id	04	INFTYP

54.14.9 Response positive report Calibration ID

First positive response

— Request vehicle information response message (1)

Message direction:	ECU#1 → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 1st response message	01	MC_CALID
#4	Data A: SW version number char 1	NC_BMW_HW_NR_3 *or 30	second digit in BCD
#5	Data B: SW version number char 2	NC_BMW_HW_NR_4 *or 30	first digit in BCD
#6	Data C: SW version number char 3	NC_BMW_HW_NR_4 *or 30	second digit in BCD
#7	Data D: SW version number char 4	NC_BMW_HW_NR_5 *or 30	first digit in BCD

* 30h, if there is no HW_NR.

Second positive response

Request vehicle information response message (2)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 2nd response message	02	MC_CALID
#4	Data A: SW version number char 5	NC_BMW_HW_NR_5 *or 30	second digit in BCD
#5	Data B: SW version number char 6	NC_BMW_HW_NR_6 *or 30	first digit in BCD
#6	Data C: SW version number char 7	NC_BMW_HW_NR_6 *or 30	second digit in BCD
#7	Data D: Pad-Byte	00	byte always 0

* 30h, if there is no HW_NR.

thirth positive response

— Request vehicle information response message (3)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 3rd response message	03	MC_CALID
#4	Data A: Pad-Byte	00	byte always 0
#5	Data B: Pad-Byte	00	byte always 0
#6	Data C: Pad-Byte	00	byte always 0
#7	Data D: Pad-Byte	00	byte always 0

forth positive response

Request vehicle information response message (4)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 4th response message	04	MC_CALID
#4	Data A: Pad-Byte	00	byte always 0
#5	Data B: Pad-Byte	00	byte always 0
#6	Data C: Pad-Byte	00	byte always 0
#7	Data D: Pad-Byte	00	byte always 0

fifth positive response

Request vehicle information response message (5)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 5nd response message	05	MC_CALID
#4	Data A: Calibration version number char 1	CAL_NR_3 or 30*	second digit in BCD
#5	Data B: Calibration version number char 2	CAL_NR_4 or 30 *	first digit in BCD
#6	Data C: Calibration version number char 3	CAL_NR_4 or 30 *	second digit in BCD
#7	Data D: Calibration version number char 4	CAL_NR_5 or 30 *	first digit in BCD

* if no CAL_NR in software;

sixth positive response

Request vehicle information response message (6)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 6nd response message	06	MC_CALID
#4	Data A: Calibration version number char 5	CAL_NR_5 or 30 *	second digit in BCD
#5	Data B: Calibration version number char 6	CAL_NR_6 or 30 *	first digits in BCD
#6	Data C: Calibration version number char 7	CAL_NR_6 or 30 *	second digit in BCD
#7	Data D: Pad-Byte	00	byte always 0

* if no CAL_NR in software;

seventh positive response

Request vehicle information response message (7)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 7nd response message	07	MC_CALID
#4	Data A: Pad-Byte	00	byte always 0
#5	Data B: Pad-Byte	00	byte always 0
#6	Data C: Pad-Byte	00	byte always 0
#7	Data D: Pad-Byte	00	byte always 0

eight positive response

Request vehicle information response message (8)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Id	04	INFTYP
#3	MessageCount Calibration Id = 8nd response message	08	MC_CALID
#4	Data A: Pad-Byte	00	byte always 0
#5	Data B: Pad-Byte	00	byte always 0
#6	Data C: Pad-Byte	00	byte always 0
#7	Data D: Pad-Byte	00	byte always 0

54.14.10 Description of Mode 09h, VIT 05h – Messagecount Calibration verification numbers

Request vehicle information request message

Message direction:	External test equipment → All ECUs		
Message Type:	Request		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information request SID	09	SIDRQ
#2	InfoType: MessageCount Calibration Verification Number	05	INFTYP

Positive responses (read InfoType value)

Request vehicle information response message

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: MessageCount Calibration Verification Number	05	INFTYP
#3	MessageCount Calibration Verification Number = 2 response messages	02	MC_CVN

54.14.11 Description of Mode 09h, VIT 06h - Calibration verification numbers

The on-board software will calculate the CVN (CRC) based on memory content in a cyclic way. The result will be stored non volatile. That means the previous value will be available till a new one is calculated.
At first initialisation of ECU no CVN is available till first one is calculated (app. 1min).

Request vehicle information request message (read InfoType values)

Data Byte	Parameter Name	Hex Value	Mnemonic
#1	**Request vehicle information request SID**	**09**	**SIDRQ**
#2	InfoType (read InfoType values)	06	INFTYP

54.14.11.1 Response positive report calibration verification number

<u>First positive response</u>

Request vehicle information response message (1)

Message direction:	ECU → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Verification Number	06	INFTYP

Configuration byte which defines the VITs supported by the mode 09 (19h - 20h)) for ISO 15765-4					

54.15.1 Activation of OBD communication on CAN / K-line

FUNCTION DESCRIPTION:

General information:

Depending on calibration or coding, a different OBD communication can be applied.

Application conditions:

Activation: only once after ECU power-on reset

Formula section:

```
If      LC_VAR_OBDC_CAN = 1
Then    OBD communication on CAN is active (ISO 15765 – 4)
Else    If      LV_VAR_OBDC_CAN = 1
        Then    OBD communication on CAN is active (ISO 15765 – 4)
        Else    OBD communication on K-line is active (ISO 9141-2, ISO 14230-4)
        Endif
Endif
```

54.15.2 Configuration and calibration of OBD communication on K-line (ISO 9141-2, ISO 14230-4)

Description:

MOD_i_PID / TID / VIT_j_DIAG variable definition

MOD_i_PID / _TID / _VIT_j_DIAG defines supported PIDs list for mode i. This definition depends on software **configuration** (ie if it is implemented in the software) and depends on system. Indeed, for a same software, we can have different system corresponding.

To define the software configuration, we use constants (NC_MOD_i_XXX_j_DIAG)

To define system, we use functions (F_MOD_i_XXX_j_DIAG) depends on different **calibrations**.

System configuration (calibration):

The definition of F_MOD_i_XXX_j_DIAG is: C_MOD_i_XXX_j_DIAG.

Software configuration:

The definition of all NC_MOD_x_PID_y_DIAG are inside the concerning table:

e.g. in the table below NC_MOD_x_PID_y_DIAG = **11100101 = E5h**

NC_MOD_x_PID_y_DIAG		C_MOD_x_PID_y_DIAG
BIT	Function	Supported
0	PID 10h : Function H	**Yes**
1	PID 0Fh : Function G	No
2	PID 0Eh : Function F	**Yes**
3	PID 0Dh : Function E	No
4	PID 0Ch : Function D	No
5	PID 0Bh : Function C	**Yes**
6	PID 0Ah : Function B	**Yes**
7	PID 09h : Function A	**Yes**

Formula section:

MOD_i_XXX_j_DIAG = NC_MOD_i_XXX_j__DIAG && F_MOD_i_XXX_j_DIAG(calibration) with && = bit per bit and.

54.15.2.1 Supported PIDs for Mode 01h

Description:

No: the PID is not supported
Yes: the PID is supported

NC_MOD_1_PID_1_DIAG		C_MOD_1_PID_1_DIAG
BIT	Function	Supported
0	PID 08h : Short term fuel trim - Bank 2	**Yes**
1	PID 07h : Long term fuel trim - Bank 1	**Yes**
2	PID 06h : Short term fuel trim - Bank 1	**Yes**
3	PID 05h : Engine coolant temperature	**Yes**
4	PID 04h : Calculated load value	**Yes**
5	PID 03h : Fuel system status	**Yes**
6	PID 02h : Trouble code that caused required freeze frame	No
7	PID 01h : DTCs and supported tests	**Yes**

NC_MOD_1_PID_2_DIAG		C_MOD_1_PID_2_DIAG
BIT	Function	Supported
0	PID 10h : Air flow rate from MAF sensor	**Yes**
1	PID 0Fh : Intake air temperature	**Yes**
2	PID 0Eh : Ignition time advance	**Yes**
3	PID 0Dh : Vehicle speed	**Yes**
4	PID 0Ch : Engine RPM	**Yes**
5	PID 0Bh : Intake manifold absolute pressure	**Yes**
6	PID 0Ah : Fuel pressure (gauge)	**Yes**
7	PID 09h : Long term fuel trim - Bank 2	**Yes**

NC_MOD_1_PID_3_DIAG		C_MOD_1_PID_3_DIAG
BIT	Function	Supported
0	PID 18h : Bank 2 Sensor 1(binary)	No
1	PID 17h : Bank 2 Sensor 2	No
2	PID 16h : Bank 2 Sensor 1	No
3	PID 15h : Bank 1 Sensor 2	**Yes**
4	PID 14h : Bank 1 Sensor 1(binary)	No
5	PID 13h : Location of oxygen sensors	**Yes**
6	PID 12h : Secondary air status	**Yes**
7	PID 11h : Absolute throttle position sensor	**Yes**

NC_MOD_1_PID_4_DIAG		C_MOD_1_PID_4_DIAG
BIT	Function	Supported
0	PID 20h : PIDs supported ($21 - $40)	**Yes**
1	PID 1Fh : Time since engine start	**Yes**
2	PID 1Eh : Reserved	No
3	PID 1Dh : Reserved	No
4	PID 1Ch : OBD requirements	**Yes**
5	PID 1Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2	No
6	PID 1Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1	No
7	PID 19h : Bank 2 Sensor 2 or Bank 3 Sensor 2	**Yes**

NC_MOD_1_PID_5_DIAG		C_MOD_1_PID_5_DIAG
BIT	Function	Supported
0	PID 28h : Bank 2 Sensor 1 (Wide range O2S)	**Yes**
1	PID 27h : Bank 2 Sensor 2 (Wide range O2S)	No
2	PID 26h : Bank 2 Sensor 1 (Wide range O2S)	No
3	PID 25h : Bank 1 Sensor 2 (Wide range O2S)	No
4	PID 24h : Bank 1 Sensor 1 (Wide range O2S)	**Yes**
5	PID 23h : Fuel pressure high range (gauge)	**Yes**
6	PID 22h : Relative fuel pressure	No
7	PID 21h : Distance travelled while MIL is activated	**Yes**

NC_MOD_1_PID_6_DIAG		C_MOD_1_PID_6_DIAG
BIT	Function	Supported
0	PID 30h : Number of warm-ups since diagnostic trouble codes cleared	**Yes**
1	PID 2Fh : Fuel Level Input	**Yes**
2	PID 2Eh : Command Evaporative Purge	**Yes**
3	PID 2Dh : EGR Error	**Yes**
4	PID 2Ch : Command EGR	**Yes**
5	PID 2Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2 (Wide range O2S)	No
6	PID 2Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1 (Wide range O2S)	No
7	PID 29h : Bank 2 Sensor 2 or Bank 3 Sensor 2 (Wide range O2S)	No

NC_MOD_1_PID_7_DIAG		C_MOD_1_PID_7_DIAG
BIT	Function	Supported
0	PID 38h : Bank 2 Sensor 1 or Bank 3 Sensor 1 (Wide range O2S)	**Yes**
1	PID 37h : Bank 1 Sensor 4 or Bank 2 Sensor 2 (Wide range O2S)	No
2	PID 36h : Bank 1 Sensor 3 or Bank 2 Sensor 1 (Wide range O2S)	No
3	PID 35h : Bank 1 Sensor 2 (Wide range O2S)	No
4	PID 34h : Bank 1 Sensor 1 (Wide range O2S)	**Yes**
5	PID 33h : Barometric Pressure	**Yes**
6	PID 32h : Evap System Vapor Pressure	No
7	PID 31h : Distance since diagnostic trouble codes cleared	**Yes**

NC_MOD_1_PID_8_DIAG		C_MOD_1_PID_8_DIAG
BIT	Function	Supported
0	PID 40h : PIDs supported ($41 - $60)	**Yes**
1	PID 3Fh : Catalyst Temperature Bank 2, Sensor 2	**Yes**
2	PID 3Eh : Catalyst Temperature Bank 1, Sensor 2	**Yes**
3	PID 3Dh : Catalyst Temperature Bank 2, Sensor 1	**Yes**
4	PID 3Ch : Catalyst Temperature Bank 1, Sensor 1	**Yes**
5	PID 3Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2 (Wide range O2S)	No
6	PID 3Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1 (Wide range O2S)	No
7	PID 39h : Bank 2 Sensor 2 or Bank 3 Sensor 2 (Wide range O2S)	No

NC_MOD_1_PID_9_DIAG		C_MOD_1_PID_9_DIAG
BIT	Function	Supported
0	PID 48h : Absolute Throttle Position C	No
1	PID 47h : Absolute Throttle Position B	**Yes**
2	PID 46h : Ambient air temperature	**Yes**
3	PID 45h : Relative Throttle Position	**Yes**
4	PID 44h : Commanded Equivalence Ratio	**Yes**
5	PID 43h : Absolute Load Value	**Yes**
6	PID 42h : Control module voltage	**Yes**
7	PID 41h : Monitor status this driving cycle	**Yes**

NC_MOD_1_PID_A_DIAG		C_MOD_1_PID_A_DIAG
BIT	Function	Supported
0	PID 50h : Reserved	No
1	PID 4Fh : Reserved	No
2	PID 4Eh : Time since diagnostic trouble codes cleared	**Yes**
3	PID 4Dh : Minutes run by the engine while MIL activated	**Yes**
4	PID 4Ch : Commanded Throttle Actuator Control	**Yes**
5	PID 4Bh : Accelerator Pedal Position F	No
6	PID 4Ah : Accelerator Pedal Position E	**Yes**
7	PID 49h : Accelerator Pedal Position D	**Yes**

54.15.2.2 Supported PIDs for Mode 02h

Description:

No: the PID is not supported
Yes: the PID is supported

NC_MOD_2_PID_1_DIAG	C_MOD_2_PID_1_DIAG	
BIT	Function	Supported
0	PID 08h : Short term fuel trim - Bank 2 and Bank 4	**Yes**
1	PID 07h : Long term fuel trim - Bank 1 and Bank 3	**Yes**
2	PID 06h : Short term fuel trim - Bank 1 and Bank 3	**Yes**
3	PID 05h : Engine coolant temperature	**Yes**
4	PID 04h : Calculated load value	**Yes**
5	PID 03h : Fuel system status	**Yes**
6	PID 02h : Trouble code that caused required freeze frame	**Yes**
7	PID 01h : DTCs and supported tests	No

NC_MOD_2_PID_2_DIAG	C_MOD_2_PID_2_DIAG	
BIT	Function	Supported
0	PID 10h : Air flow rate from MAF sensor	**Yes**
1	PID 0Fh : Intake air temperature	**Yes**
2	PID 0Eh : Ignition time advance	**Yes**
3	PID 0Dh : Vehicle speed	**Yes**
4	PID 0Ch : Engine RPM	**Yes**
5	PID 0Bh : Intake manifold absolute pressure	**Yes**
6	PID 0Ah : Fuel pressure (gauge)	**Yes**
7	PID 09h : Long term fuel trim - Bank 2 and Bank 4	**Yes**

NC_MOD_2_PID_3_DIAG		C_MOD_2_PID_3_DIAG
BIT	Function	Supported
0	PID 18h : Not required	No
1	PID 17h : Not required	No
2	PID 16h : Not required	No
3	PID 15h : Not required	No
4	PID 14h : Not required	No
5	PID 13h : Not required	No

54.16 Service 01h - Request current powertrain diagnostic data

54.16.1 Functional description

The purpose of this service is to allow access to current emission-related data values, including analogue inputs and outputs, digital inputs and outputs, and system status information. The request for information includes a parameter identification (PID) value that indicates to the on-board system the specific information requested. PID specifications, scaling information, and display formats are included in Annex B of ISO 15031-5.4.

The ECU(s) will respond to this message by transmitting the requested data value last determined by the system. All data values returned for sensor readings will be actual readings, not default or substitute values used by the system because of a fault with that sensor.

Not all PIDs are applicable or supported by all systems. PID 00h is a bit-encoded value that indicates for each ECU which PIDs are supported. PID 00h indicates support for PIDs from 01h to 20h. PID 20h indicates support for PIDs 21h through 40h, etc. PID 00h is required for those ECUs that respond to a corresponding service 01h request message as specified in Annex A of ISO 15031-5.4.

IMPORTANT — All emissions-related OBD ECUs shall support service 01h and PID 00h. Service 01h with PID 00h is defined as the universal "initialization/keep alive/ping" message for all emissions-related OBD ECUs.

The request message may contain up to six (6) PIDs. An external test equipment is not allowed to request a combination of PIDs supported and PIDs, which report data values. The ECU shall support requests for up to six (6) PIDs. The request message may contain the same PID multiple times. The ECU shall treat each PID as a separate parameter and respond with data for each PID (data returned may be different for the same PID) as often as requested.

The order of the PIDs in the response message is not required to match the order in the request message.

54.16.2 Message data bytes

54.16.2.1 Read supported PIDs

Request current powertrain diagnostic data request message (read supported PIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request current powertrain diagnostic data request SID**	**M**	**01**	**SIDRQ**
#2	PID#1 (PIDs supported: see Annex A of ISO 15031-5.4)	M	xx	PID
#3	PID#2 (PIDs supported: see Annex A of ISO 15031-5.4)	U	xx	PID
#4	PID#3 (PIDs supported: see Annex A of ISO 15031-5.4)	U	xx	PID
#5	PID#4 (PIDs supported: see Annex A of ISO 15031-5.4)	U	xx	PID
#6	PID#5 (PIDs supported: see Annex A of ISO 15031-5.4)	U	xx	PID
#7	PID#6 (PIDs supported: see Annex A of ISO 15031-5.4)	U	xx	PID
U = User Optional — PID may be included to avoid multiple PID supported request messages				

NOTE To request PIDs supported range from C1h - FFh another request message with PID#1 = C0h and PID#2 = E0h shall be sent to the vehicle.

54.16.2.2 Report supported PIDs

ECU(s) must respond to all supported ranges if requested. A range is defined as a block of 32 PIDs (e.g. range #1: PID 01h-20h). The ECU shall not respond to unsupported PID ranges unless subsequent ranges have a supported PID(s).

Request current powertrain diagnostic data response message (report supported PIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request current powertrain diagnostic data response SID**	**M**	**41**	**SIDPR**
	data record of supported PIDs = [			PIDREC_
#2	1st supported PID	M	xx	PID
#3	Data A: supported PIDs,	M	xx	DATA_A
#4	Data B: supported PIDs,	M	xx	DATA_B
#5	Data C: supported PIDs,	M	xx	DATA_C
#6	Data D: supported PIDs]	M	xx	DATA_D
:	:	:	:	:
	data record of supported PIDs = [			PIDREC_
#n-4	mth supported PID	C1	xx	PID
#n-3	Data A: supported PIDs,	C2	xx	DATA_A
#n-2	Data B: supported PIDs,	C2	xx	DATA_B
#n-1	Data C: supported PIDs,	C2	xx	DATA_C
#n	Data D: supported PIDs]	C2	xx	DATA_D
C1 = Conditional — PID value shall be the same value as included in the request message if supported by the ECU C2 = Conditional — value indicates PIDs supported; range of supported PIDs depends on selected PID value (see C1)				

NOTE The response message shall only include the PID(s) and Data A - D which are supported by the ECU. If the request message includes (a) PID value(s) which are not supported by the ECU those shall not be included in the response message.

54.16.2.3 Read PID values

Request current powertrain diagnostic data request message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request current powertrain diagnostic data request SID**	**M**	**01**	**SIDRQ**
#2	PID#1 (see Annex B of ISO 15031-5.4)	M	xx	PID
#3	PID#2 (see Annex B of ISO 15031-5.4)	U	xx	PID
#4	PID#3 (see Annex B of ISO 15031-5.4)	U	xx	PID
#5	PID#4 (see Annex B of ISO 15031-5.4)	U	xx	PID
#6	PID#5 (see Annex B of ISO 15031-5.4)	U	xx	PID
#7	PID#6 (see Annex B of ISO 15031-5.4)	U	xx	PID
U = User Optional — the parameter may be present or not				

54.16.2.4 Report PID values

Request current powertrain diagnostic data response message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request current powertrain diagnostic data response SID**	**M**	**41**	**SIDPR**
 #2 #3 #4 #5 #6	data record of 1st supported PID = [PID#1 data A, data B, data C, data D]	 M M C1 C1 C1	 xx xx xx xx xx	PIDREC_ PID DATA_A DATA_B DATA_C DATA_D
:	:	:	:	:
 #n-4 #n-3 #n-2 #n-1 #n	data record of mth supported PID = [PID#m data A, data B, data C, data D]	 C2 C2 C3 C3 C3	 xx xx xx xx xx	PIDREC_ PID DATA_A DATA_B DATA_C DATA_D
C1 = Conditional — "data B - D" depend on selected PID value C2 = Conditional — parameter is only present if supported by the ECU C3 = Conditional — parameters and values for "data B - D" depend on selected PID number and are only included if PID is supported by the ECU				

NOTE Not all PIDs, which are included in the request message may be supported by all emission-related ECUs, which shall comply with this specification. Therefore, each vehicle ECU, which supports at least one (1) PID, shall send a response message including the PID(s) with data.

54.16.2.5 Parameter definition

54.16.2.5.1 PIDs supported

"Annex A of ISO 15031-5.4" specifies the interpretation of the data record of supported PIDs.

54.16.2.5.2 PID and data byte descriptions

"Annex B of ISO 15031-5.4" specifies standardised emission-related parameters.

54.17 Service 01h - Request current powertrain diagnostic data (Application Incident)

Import action:

ACTION_ERRM_ReadReadinessCode **(** **INOUT <ReadinessCode>** **OUT <ResultReadinessCode>** **)**
This API allows to read the readiness code information
ACTION_ERRM_ReadQuantityOfDtc **(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <Quantity>** **OUT <ResultQuantity>** **)**
This API returns the quantity of DTC with a certain type, which are stored in memory

Input data:

T_ACT_MIL	STATE_PSN_LS_SAE	OBD_TPS_REL	STATE_OBD_SA
C_CLC_READY_OBD_1	LOAD_ABSV	STATE_LS[NC_CBK_EX_NR]	LOAD_CLC

OBD_EGR_DIF	FUP_RNG_H_MES	NC_INJ_CONF	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
ID_STATE_SRV_1_PID	12	0...FFH	0...255	1	[-]
LDPM_STATE_PID_SRV_1_2_OBDC	12	0...BH	0...11	1	[-]
Table of bytes which defines the PID's supported by the service 01h (01h - 60h)					

General information:

Depending on calibration of ID_STATE_SRV_1_PID the PID's are supported or not.

Each LDPM[0...11] of the table represents an 8 PIDs configuration:

0 => the PID is not supported
1 => the PID is supported

54.17.1 Description of PID 00h - Defines Supported PIDs 01h - 20h

DATA A - Supported PIDs 01h to 08h

PID 00h – DATA A - Supported PID 01h to 08h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_1_PID[0]
0	PID 08h : Short term fuel trim - Bank 2	1
1	PID 07h : Long term fuel trim - Bank 1	1
2	PID 06h : Short term fuel trim - Bank 1	1
3	PID 05h : Engine coolant temperature	1
4	PID 04h : Calculated load value	1
5	PID 03h : Fuel system status	1
6	PID 02h : Trouble code that caused required freeze frame	1
7	PID 01h : DTCs and supported tests	1

DATA B - Supported PIDs 09h to 10h

PID 00h – DATA B - Supported PID 09h to 10h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_1_PID[1]
0	PID 10h : Air flow rate from MAF sensor	1
1	PID 0Fh : Intake air temperature	1
2	PID 0Eh : Ignition time advance	1
3	PID 0Dh : Vehicle speed	1
4	PID 0Ch : Engine RPM	1
5	PID 0Bh : Intake manifold absolute pressure	1
6	PID 0Ah : Fuel pressure (gauge)	1
7	PID 09h : Long term fuel trim - Bank 2	1

DATA C - Supported PIDs 11h to 18h

PID 00h – DATA C - Supported PID 11h to 18h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_1_PID[2]
0	PID 18h : Bank 2 Sensor 1 or Bank 3 Sensor 1	0
1	PID 17h : Bank 1 Sensor 4 or Bank 2 Sensor 2	0
2	PID 16h : Bank 1 Sensor 3 or Bank 2 Sensor 1	0
3	PID 15h : Bank 1 Sensor 2	1
4	PID 14h : Bank 1 Sensor 1	0
5	PID 13h : Location of oxygen sensors	1
6	PID 12h : Secondary air status	1
7	PID 11h : Absolute throttle position sensor	1

DATA D - Supported PIDs 19h to 20h

PID 00h - DATA D - Supported PID 19h to 20h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_1_PID[3]
0	PID 20h : PIDs supported ($21 - $40)	1
1	PID 1Fh : Time Since Engine Start	1
2	PID 1Eh : Auxiliary Input Status	0
3	PID 1Dh : Location of oxygen sensors	0
4	PID 1Ch : OBD requirements	1
5	PID 1Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2	0
6	PID 1Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1	0
7	PID 19h : Bank 2 Sensor 2 or Bank 3 Sensor 2	1

54.17.2 Description of PID 01h - Monitor status since DTCs cleared

PID $01 definition

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
01	Monitor status since DTCs cleared			
	The bits in this PID shall report two pieces of information for each monitor: (a) Monitor status since DTCs were last cleared, saved in NVRAM or KAM. (b) Monitors supported on this vehicle.			
	Number of emission-related DTCs and MIL status	A (bit)	byte 1 of 4	DTC and MIL status:
	# of DTCs stored in this ECU	0-6	hex to decimal	DTC_CNT: xxxd
	Malfunction Indicator Light (MIL) Status	7	0 = MIL OFF; 1 = MIL ON	MIL: OFF or ON
	The MIL status shall indicate "OFF" during the key on, engine off bulb check unless the MIL has also been commanded "ON" for a detected malfunction.			
	Supported tests which are continuous	B (bit)	byte 2 of 4 (Low Nibble)	Support status of continuous monitors:
	Misfire monitoring	0	0 = monitor not supported (NO) 1 = monitor supported (YES)	MIS_SUP: NO or YES
	Misfire monitoring shall be supported on both, spark ignition and compression vehicles if the vehicle utilises a misfire monitor.			
	Fuel system monitoring	1	0 = monitor not supported (NO) 1 = monitor supported (YES)	FUEL_SUP: NO or YES
	Fuel system monitoring shall be supported on vehicles that utilise oxygen sensors for closed loop fuel feedback control, and utilise a fuel system monitor, typically spark ignition engines.			
	Comprehensive component monitoring	2	0 = monitor not supported (NO) 1 = monitor supported (YES)	CCM_SUP: NO or YES
	Comprehensive component monitoring shall be supported on spark ignition and compression ignition vehicles that utilise comprehensive component monitoring.			
	reserved (bit shall be reported as ‘0’)	3		---

PID $01 definition (continued)

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
	Status of continuous monitoring tests since DTC cleared:	B (bit)	byte 2 of 4 (High Nibble)	Completion status of continuous monitors since DTC cleared:
	Misfire monitoring	4	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	MIS_RDY: YES or NO
	Misfire monitoring shall always indicate complete for spark ignition engines. Misfire monitoring shall indicate complete for compression ignition engines after the misfire evaluation is complete.			
	Fuel system monitoring	5	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	FUEL_RDY: YES or NO
	Fuel system monitoring shall always indicate complete for both spark ignition and compression ignition engines.			
	Comprehensive component monitoring	6	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	CCM_RDY: YES or NO
	Comprehensive component monitoring shall always indicate complete on both spark ignition and compression ignition engines. NOTE It can be assumed that by the time any non-continuous monitors are complete, continuous comprehensive component monitoring will also be complete. Bit 6 is allowed to always indicate "complete" on spark ignition vehicles that support other non-continuous monitors.			
	reserved (bit shall be reported as ‘0’)	7		---
	Supported tests run at least once per trip	C (bit)	byte 3 of 4	Support status of non-continuous monitors:
	Catalyst monitoring	0	0 = monitor not supported (NO) 1 = monitor supported (YES)	CAT_SUP: NO or YES
	Heated catalyst monitoring	1		HCAT_SUP: NO or YES
	Evaporative system monitoring	2		EVAP_SUP: NO or YES
	Secondary air system monitoring	3		AIR_SUP: NO or YES
	A/C system refrigerant monitoring	4		ACRF_SUP: NO or YES
	Oxygen sensor monitoring	5		O2S_SUP: NO or YES
	Oxygen sensor heater monitoring	6		HTR_SUP: NO or YES
	EGR system monitoring	7		EGR_SUP: NO or YES
	Status of tests run at least once per trip	D (bit)	byte 4 of 4	Completion status of non-continuous monitors since DTCs cleared:
	Catalyst monitoring	0	0 = monitor complete, or not applicable (YES) 1 = monitor not complete (NO)	CAT_RDY: YES or NO
	Heated catalyst monitoring	1		HCAT_RDY: YES or NO
	Evaporative system monitoring	2		EVAP_RDY: YES or NO
	Secondary air system monitoring	3		AIR_RDY: YES or NO
	A/C system refrigerant monitoring	4		ACRF_RDY: YES or NO
	Oxygen sensor monitoring	5		O2S_RDY: YES or NO
	Oxygen sensor heater monitoring	6		HTR_RDY: YES or NO
	EGR system monitoring	7		EGR_RDY: YES or NO

Data Byte	Application data to use		Formating conversion used
data A	(bit 0 to 6) :	NR_DTC	-
	(bit 7) :	STATE_MIL	
data B	STATE_READY_OBD_1 *		
data C	C_STATE_READY_OBD_2		
data D	STATE_READY_OBD_2		

*) The bit 0 up to 3 of this byte is calibration value C_STATE_READY_OBD_1.
The bit 4 up to 6 of this byte indicate if the tests has been performed continuously since the reinitialization of the memorized information.

Formula section:

```
ACTION_ERRM_ReadQuantityOfDtc
                            (
                            IN <OBD & CONFIRMED>
                            IN <LAW>
                            INOUT <NR_DTC>
                            OUT <ResultQuantity>
                            )

ACTION_ERRM_ReadReadinessCode
                            (
                            INOUT < C_STATE_READY_OBD_2,

                                     STATE_READY_OBD_2>
                            OUT <ResultReadinessCode>
                            )

IF      (ResultQuantity = DTC_PRESENT          OR
        ResultQuantity = NO_DTC_PRESENT)       AND
        ResultReadinessCode = POSITIVE_RESPONSE
THEN
        Positive response

ELSE
        No answer
ENDIF
```

These actions should be sent at each time we use the mode 01h PID01.
Refer to “Error management” module.

54.17.3 Description of PID 03h - Status of fuel system

```
IF          (ID_STATE_SRV_1_PID[2] & 20h)        // PID 13h is supported
THEN
   IF       (STATE_PSN_LS_SAE & 11h)
   THEN
```

PID $03 definition

PID (hex)	Description	Data Byte	Scaling/bit	External test equipment SI (Metric) / English display
03	Fuel system 1 status:	A (bit)	byte 1 of 2	FUELSYS1:
	(unused bits shall be reported as ‘0’; no	0	1 = Open loop - has not yet satisfied conditions to go closed loop	OL
	more than one bit at a time can be set to a ‘1’	1	1 = Closed loop - using oxygen sensor(s) as feedback for fuel control	CL
	of that bank)	2	1 = Open loop due to driving conditions (e.g. power enrichment, deceleration enleanment)	OL-Drive
		3	1 = Open loop - due to detected system fault	OL-Fault
		4	1 = Closed loop, but fault with at least one oxygen sensor - may be using single oxygen sensor for fuel control	CL-Fault
		5-7	reserved (bits shall be reported as ‘0’)	---
	NOTE Fuel systems do not refer to injector banks. Fuel systems are intended to represent completely different fuel systems that can independently enter and exit closed loop fuel. Banks of injectors on a V-engine are generally not independent and share the same closed-loop enablement criteria.			
	Fuel system 2 status:	B (bit)	byte 2 of 2	FUELSYS2:
	(unused bits shall be reported as ‘0’; no	0	1 = Open loop - has not yet satisfied conditions to go closed loop	OL
	more than one bit at a time can be set to a ‘1’	1	1 = Closed loop - using oxygen sensor(s) as feedback for fuel control	CL
	of that bank)	2	1 = Open loop due to driving conditions (e.g. power enrichment, deceleration enleanment)	OL-Drive
		3	1 = Open loop - due to detected system fault	OL-Fault
		4	1 = Closed loop, but fault with at least one oxygen sensor - may be using single oxygen sensor for fuel control	CL-Fault
		5-7	reserved (bits shall be reported as ‘0’)	---

data A	STATE_LS[1]	no
data B	STATE_LS[2]	no

ENDIF

54.17.4 Description of PID 04h - Calculated load value

PID $04 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
04	Calculated LOAD Value!	A	0 %	100 %	100/255 %	LOAD_PCT: xxx.x %
	The OBD regulations previously defined CLV as: (current airflow / peak airflow @ sea level) * (BARO @ sea level / BARO) * 100% Various manufacturers have implemented this calculation in a variety of ways. The following definition, although a little more restrictive, will standardise and improve the accuracy the calculation. LOAD_PCT = [current airflow] / [(peak airflow at WOT@STP as a function of rpm) * (BARO/29.92) * SQRT(298/(AAT+273))] — Where: STP = Standard Temperature and Pressure = 25 °C, 29.92 in Hg BARO, SQRT = square root, — WOT = wide open throttle, AAT=Ambient Air Temperature and is in °C Characteristics of LOAD_PCT are: — Reaches 1.0 at WOT at any altitude, temperature or rpm for both naturally aspirated and boosted engines. — Indicates percent of peak available torque. — Linearly correlated with engine vacuum — Often used to schedule power enrichment. — Compression ignition engines (diesels) shall support this PID using fuel flow in place of airflow for the above calculations. NOTE Both spark ignition and compression ignition engines shall support PID $04. See PID $43 for an additional definition of engine LOAD.					

Data Byte	Application data to use	Formating conversion used
data A	LOAD_CLC	no

54.17.5 Description of PID 05h - Engine coolant temperature

PID $05 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
05	Engine Coolant Temperature	A	-40 °C	+215 °C	1 °C with -40 °C offset	ECT: xxx °C (xxx °F)
	ECT shall display engine coolant temperature derived from an engine coolant temperature sensor or a cylinder head temperature sensor. Many diesels do not use either sensor and may substitute Engine Oil Temperature instead.					

Data Byte	Application data to use	Formating conversion used
data A	TCO_MES	Shift to different range

54.17.6 Description of PID 06h - Short term fuel trim - Bank 1 and Bank 3

PID $06 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
06	Short Term Fuel Trim - Bank 1 (use if only 1 fuel trim value)	A	-100 % (lean)	+99.22 % (rich)	100/128 % (0 % at 128)	SHRTFT1: xxx.x %
	Short Term Fuel Trim - Bank 3	B				SHRTFT3: xxx.x %
	Short Term Fuel Trim Bank 1/3 shall indicate the correction being utilised by the closed loop fuel algorithm. If the fuel system is in open loop, SHRTFT1/3 shall report 0% correction. NOTE Data B shall only be included in the response message of a PID $06 if supported by the vehicle. If PID $1D Oxygen Sensor Location of Bank 1, 2, 3, 4 is supported then the external test equipment shall determine based on the data content (Bank 3 supported) of PID $1D if Data B of PID $06 is supported or not.					

```

54.17.7 Description of PID 07h - Long term fuel trim - Bank 1 and Bank 3

PID $07 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
07	Long Term Fuel Trim - Bank 1 (use if only 1 fuel trim value)	A	-100 % (lean)	+99.22 % (rich)	100/128 % (0 % at 128)	LONGFT1: xxx.x %
	Long Term Fuel Trim - Bank 3	B				LONGFT3: xxx.x %
	Fuel trim correction for Bank 1/3 stored in Non-volatile RAM or Keep-alive RAM. LONGFT shall indicate the correction being utilised by the fuel control algorithm at the time the data is requested, in both open loop and closed loop fuel control. If no correction is utilised in open loop fuel, LONGFT shall report 0% correction. If long-term fuel trim is not utilised at all by the fuel control algorithm, the PID shall not be supported. NOTE Data B shall only be included in the response message of a PID $07 if supported by the vehicle. If PID $1D Oxygen Sensor Location of Bank 1, 2, 3, 4 is supported then the external test equipment shall determine based on the data content (Bank 3 supported) of PID $1D if Data B of PID $07 is supported or not.					

```
IF   (ID_STATE_SRV_1_PID[2] & 20h)          // PID 13h is supported

54.17.10 Description of PID 0Ah - Fuel pressure (gauge)

PID $0A definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0A	Fuel Rail Pressure (gauge)	A	0 kPa (gauge)	765 kPa (gauge)	3 kPa per bit (gauge)	FRP: xxx kPa (xx.x psi)
	FRP shall display fuel rail pressure at the engine when the reading is referenced to atmosphere (gauge pressure).					

Data Byte	Application data to use	Formating conversion used
data A	FUP	Shift to different range

54.17.11 Description of PID 0Bh - Intake manifold absolute pressure

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0B	Intake Manifold Absolute Pressure	A	0 kPa (absolute)	255 kPa (absolute)	1 kPa per bit (absolute)	MAP: xxx kPa (xx.x inHg)
	MAP shall display manifold pressure derived from a Manifold Absolute Pressure sensor, if a sensor is utilised. If a vehicle uses both a MAP and MAF sensor, both the MAP and MAF PIDs shall be supported.					

Data Byte	Application data to use	Formating conversion used
data A	MAP_SAE	None

54.17.12 Description of PID 0Ch - Engine speed

PID $0C definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0C	Engine RPM	A , B	0 min^{-1}	16383.75 min^{-1}	¼ rpm per bit	RPM: xxxxx min^{-1}

Data Byte	Application data to use	Formating conversion used
data A	MSB (N)	Shift to different range
data B	LSB (N)	Shift to different range

54.17.13 Description of PID 0Dh - Vehicle speed

PID $0D definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0D	Vehicle Speed Sensor	A	0 km/h	255 km/h	1 km/h per bit	VSS: xxx km/h (xxx mph)
	VSS shall display vehicle road speed, if utilised by the control module strategy. Vehicle speed may be derived from a vehicle speed sensor, calculated by the PCM using other speed sensors, or obtained from the vehicle serial data communication bus.					

Data Byte	Application data to use	Formating conversion used
data A	VS	no

54.17.14 Description of PID 0Eh - Ignition timing advance

PID $0E definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0E	Ignition Timing Advance for #1 Cylinder	A	-64 °	63.5 °	½ ° with 0 ° at 128	SPARKADV: xx °
	Ignition timing spark advance for #1 cylinder (not including mechanical advance)					

Data Byte	Application data to use	Formating conversion used
data A	IGA_IGC[0]	Shift to different range

54.17.15 Description of PID 0Fh - Intake air temperature

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
0F	Intake Air Temperature	A	-40 °C	+215 °C	1 °C with -40 °C offset	IAT: xxx °C (xxx °F)
	IAT shall display intake manifold air temperature, if utilised by the control module strategy. IAT may be obtained directly from a sensor, or may be inferred by the control strategy using other sensor inputs.					

Data Byte	Application data to use	Formating conversion used
data A	TIA_MES	Shift to different range

54.17.16 Description of PID 10h - Air flow rate from MAF

PID $0B definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
10	Air Flow Rate from Mass Air Flow Sensor	A , B	0 g/s	655.35 g/s	0.01 g/s	MAF: xxx.xx g/s (xxxx.x lb/min)
	MAF shall display the airflow rate as measured by the MAF sensor, if a sensor is utilised.					

Data Byte	Application data to use	Formating conversion used
data A	MSB (MAF_KGH_MES)	Kg/h into g/s
data B	LSB (MAF_KGH_MES)	Kg/h into g/s

54.17.17 Description of PID 11h - Absolute throttle position sensor

PID $0A - $11 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
11	Absolute Throttle Position	A	0 %	100 %	100/255 %	TP: xxx.x %
	Absolute throttle position (not “relative” or “learned” throttle position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP shall display (1.0 / 5.0) = 20% at closed throttle and 50% at 2.5 volts. Throttle position at idle will usually indicate greater than 0%, and throttle position at wide open throttle will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage. NOTE See PID $45 for a definition of Relative Throttle Position.					

Data Byte	Application data to use	Formating conversion used
data A	OBD_TPS_1	no

54.17.18 Description of PID 12h - Commanded secondary air status

With autolearning the value for the STATE_VAR_SAP_SAE is defined to the value defined by the project.

IF (ID_STATE_SRV_1_PID[2] & 40h) **AND** (STATE_VAR_SAP_SAE <> 0)

THEN

PID $12 definition

PID (hex)	Description	Data byte	Scaling/bit	External test equipment SI (Metric) / English display
12	Commanded Secondary Air Status	A (bit)	byte 1 of 1	AIR_STAT:
	(if supported, one, and only	0	1 = upstream of first catalytic converter	AIR_STAT: UPS
	one bit at a time can be set	1	1 = downstream of first catalytic converter inlet	AIR_STAT: DNS
	to a 1)	2	1 = atmosphere / off	AIR_STAT: OFF

54.17.44 Description of PID 2C - Commanded EGR

IF NC_INJ_CONF <> 0 *(only supported for MSD)*

THEN

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
2C	Commanded EGR	A	0% (no flow)	100% (max. flow)	100/255 %	EGR_PCT: xxx.x%
	Commanded EGR displayed as a percent. EGR_PCT shall be normalised to the maximum EGR commanded output control parameter. EGR systems use a variety of methods to control the amount of EGR delivered to the engine. 1) If an on/off solenoid is used – EGR_PCT shall display 0% when the EGR is commanded off, 100% when the EGR system is commanded on. 2) If a vacuum solenoid is duty cycled, the EGR duty cycle from 0 to 100% shall be displayed. 3) If a linear or stepper motor valve is used, the fully closed position shall be displayed as 0%, the fully open position shall be displayed as 100%. Intermediate positions shall be displayed as a percent of the full-open position. For example, a stepper-motor EGR valve that moves from 0 to 128 counts shall display 0% at 0 counts, 100% at 128 counts and 50% at 64 counts. 4) Any other actuation method shall be normalised to display 0% when no EGR is commanded and 100% at the maximum commanded EGR position.

54.17.45 Description of PID 2D definition - EGR Error

IF NC_INJ_CONF <> 0 *(only supported for MSD)*

THEN

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
2D	EGR Error = (EGR actual – EGR commanded) / EGR commanded * 100%	A	-100 % (less than commanded)	+99.22 % (more than commanded)	100/128 % (0 % at 128)	EGR_ERR: xxx.x%
	EGR error, as a percent of commanded EGR. Often, EGR valve control outputs are not in the same engineering units as the EGR feedback input sensors. For example, an EGR valve can be controlled using a duty-cycled vacuum solenoid, however, the feedback input sensor is a position sensor. This makes it impossible to display "actual" versus "commanded" in the same engineering units. EGR error solved this problem by displaying a normalised (non-dimensional) EGR system feedback parameter. EGR error is defined to be: (actual EGR – commanded EGR) / commanded EGR. For example if 10% EGR is commanded and 5% is delivered to the engine, the EGR_ERR is (5% - 10%) / 10 = -50% error. EGR_ERR may be computed using various control parameters such as position, steps, counts, etc. All EGR systems must react to quickly changing conditions in the engine; therefore, EGR_ERR will generally show errors during transient conditions. Under steady condition, the error will be minimized (no necessarily zero, however) if the EGR system is under control. If the control system does not use closed loop control, EGR_ERR shall not be supported.

54.17.48 Description of PID 30h - Number of warm-ups since diagnostic trouble codes cleared

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
30	Number of warm-ups since diagnostic trouble codes cleared	A	0	255	1 warm-up per count	WARM_UPS: xxx
	Number of OBD warm-up cycles since all DTCs were cleared (via an external test eqiupment or possibly, a battery disconnect). A warm-up is defined in the OBD regulations to be sufficient vehicle operation such that coolant temperature rises by at least 22 °C (40 °F) from engine starting and reaches a minimum temperature of 70 °C (160 deg °F) (60 °C (140 °F) for diesels). This PID is not associated with any particular DTC. It is simply an indication for I/M, of the last time an external test equipment was used to clear DTCs. If greater than 255 warm ups have occurred, WARM_UPS shall remain at 255 and not wrap to zero.

54.17.50 Description of PID 32h - Evap System Vapor Pressure (not supported)

54.17.51 Description of PID 33h - Barometric Pressure

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
33	Barometric Pressure	A	0 kPa (absolute)	255 kPa (absolute)	1 kPa per bit (absolute)	BARO: xxx kPa (xx.x inHg)
	Barometric pressure utilised by the control module. BARO is normally obtained from a dedicated BARO sensor, from a MAP sensor at key-on and during certain modes of driving, or inferred from a MAF sensor and other inputs during certain modes of driving. The control module shall report BARO from whatever source it is derived from. NOTE Some weather services report local BARO values adjusted to sea level. In these cases, the reported value may not match the displayed value on the external test equipment. NOTE If BARO is inferred while driving and stored in non-volatile RAM or Keep-alive RAM, BARO may not be accurate after a battery disconnect or total memory clear.

54.17.65 Description of PID 41 - Monitor status this driving cycle

PID $41 definition

PID (hex)	Description	Data Byte	Scaling/bit	External test equipment SI (Metric) / English display
41	Monitor status this driving cycle			
	The bit in this PID shall report two pieces of information for each monitor: 1) Monitor enable status for the current driving cycle. This bit shall indicate when a monitor is disabled in a manner such that there is no way for the driver to operate the vehicle for the remainder of the driving cycle and make the monitor run. Typical examples are: Engine-off soak not long enough (e.g., cold start temperature conditions not satisfied) Monitor maximum time limit or number of attempts/aborts exceeded Ambient air temperature too low or too high BARO too low (high altitude) The monitor shall not indicate "disabled" for operator-controlled conditions such as rpm, load, throttle position, minimum time limit not exceeded, ECT, TP, etc. 2) Monitor completion status for the current driving/monitoring cycle. Status shall be reset to "not complete" upon starting a new monitoring cycle. Note that some monitoring cycles can include various engine-operating conditions; other monitoring cycles begin after the ignition key is turned off. Some status bits on a given vehicle can utilise engine-running monitoring cycles while others can utilise engine-off monitoring cycles. Resetting the bits to "not complete" upon starting the engine will accommodate most engine-running and engine-off monitoring cycles, however, manufacturers are free to define their own monitoring cycles. NOTE PID $41 bits shall be utilised for all non-continuous monitors which are supported, and change completion status in PID $01. If a non-continuous monitor is not supported or always shows "complete", the corresponding PID $41 bits shall indicate disabled and complete. PID $41 bits may be utilised at the vehicle manufacturer's discretion for all continuous monitors which are supported with the exception of bit 03 which shall always showed CCM as enabled for spark ignition and compression ignition engines.

54.17.66 Description of PID 42 - Control module voltage

PID $42 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
42	Control module voltage	A , B	0 V	65.535 V	0.001 V per bit	VPWR: xx.xxx V
	VPWR – power input to the control module. VPWR is normally battery voltage, less any voltage drop in the circuit between the battery and the control module. NOTE 42-volt vehicles may utilise multiple voltages for different systems on the vehicle. VPWR represents the voltage at the control module; it may be significantly different than battery voltage.					

Data Byte	Application data to use	Formating conversion used
data A	MSB (VB)	Shift to different range
data B	LSB (VB)	

54.17.67 Description of PID 43 - Absolute Load Value

PID $43 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
43	Absolute Load Value	A , B	0 %	25700%	100/255 %	LOAD_ABS: xxx.x%
	The absolute load value has some different characteristics than the LOAD_PCT defined in PID 04 This definition, although restrictive, will standardise the calculation. LOAD_ABS is the normalised value of air mass per intake stroke displayed as a percent. LOAD_ABS = [air mass (g/intake stroke)] / [1.184 (g/intake stroke) * cylinder displacement in litres] Derivation: air mass (g / intake stroke) = [total engine air mass (g/sec)] / [rpm (revs/min)* (1 min / 60 sec) * (1/2 # of cylinders (strokes /rev)] LOAD_ABS = [air mass (g)/intake stroke] / [maximum air mass (g)/intake stroke at WOT@STP at 100% volumetric efficiency] * 100% Where: STP = Standard Temperature and Pressure = 25 °C, 29.92 in Hg (1013 hPa) BARO, WOT = wide open throttle The quantity (maximum air mass (g)/intake stoke at WOT@STP at 100% volumetric efficiency) is a constant for a given cylinder swept volume. The constant is 1.184 (g/litre 3) * cylinder displacement (litre 3/intake stroke) based on air density at STP Characteristics of LOAD_ABS are: Ranges from 0 to approximately 0.95 for naturally aspirated engines, 0 – 4 for boosted engines Linearly correlated with engine indicated and brake torque Often used to schedule spark and EGR rates Peak value of LOAD_ABS correlates with volumetric efficiency at WOT. Indicates the pumping efficiency of the engine for diagnostic purposes. Spark ignition engine are required to support PID $43. Compression ignition (diesel) engines are not required to support this PID. NOTE See PID $04 for an additional definition of engine LOAD..

data A	MSB (LOAD_ABSV)	no
data B	LSB (LOAD_ABSV)	no

54.17.68 Description of PID 44 - Commanded Equivalence Ratio

Table .2 — PID $44 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
44	Commanded Equivalence Ratio	A , B	0	1.999	0.0000305	EQ_RAT: x.xxx
	Fuel systems that utilise conventional oxygen sensor shall display the commanded open loop equivalence ratio while the fuel control system is in open loop. EQ_RAT shall indicate 1.0 while in closed loop fuel. Fuel systems that utilise wide-range/linear oxygen sensors shall display the commanded equivalence ratio in both open loop and closed loop operation. To obtain the actual A/F ratio being commanded, multiply the stoichiometric A/F ratio by the equivalence ratio. For example, for gasoline, stoichiometric is 14.64:1 ratio. If the fuel control system was commanding an 0.95 EQ_RAT, the commanded A/F ratio to the engine would be 14.64 * 0.95 = 13.9 A/F

54.17.69 Description of PID 45 - Relative Throttle Position

PID $45 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
45	Relative Throttle Position	A	0 %	100 %	100/255 %	TP_R: xxx.x %
	Relative or "learned" throttle position shall be displayed as a normalised value, scaled from 0 to 100%. TP_R should display a value of 0% at the "learned closed-throttle position. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP shall display (1.0 – 1.0 / 5.0) = 0% at closed throttle and 30% at 2.5 volts. Because of the closed-throttle offset, wide open throttle will usually indicate substantially less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage. See PID $11 for a definition of Absolute Throttle Position.

54.17.70 Description of PID 46 - Ambient air temperature

PID $46 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
46	Ambient air temperature (same scaling as IAT - $0F)	A	-40 °C	+215 °C	1 °C with -40 °C offset	AAT: xxx °C / xxx °F
	AAT shall display ambient air temperature, if utilised by the control module strategy for OBD monitoring. AAT may be obtained directly from a sensor, may be obtained indirectly via the vehicle serial data communication bus, or may be inferred by the control strategy using other sensor inputs.

54.17.71 Description of PID 47 - Absolute Throttle Position B

PID $47 definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
47	Absolute Throttle Position B	A	0 %	100 %	100/255 %	TP_B: xxx.x %
	Absolute throttle position B, if utilised by the control module, (not “relative” or “learned” throttle position) shall be displayed as a normalised value, scaled from 0 to 100%. For example, if a 0 to 5.0 volt sensor is used (uses a 5.0 volt reference voltage), and the closed throttle position is a 1.0 volts, TP_B shall display (1.0 / 5.0) = 20% at closed throttle and 50% at 2.5 volts. Throttle position at idle will usually indicate greater than 0%, and throttle position at wide open throttle will usually indicate less than 100%. For systems where the output is proportional to the input voltage, this value is the percent of maximum input reference voltage. For systems where the output is inversely proportional to the input voltage, this value is 100% minus the percent of maximum input reference voltage.

54.17.76 Description of PID 4C - Commanded Throttle Actuator Control

PID $4C definition

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling/bit	External test equipment SI (Metric) / English display
4C	Commanded Throttle Actuator Control	A	0% (closed throttle)	100% (wide open throttle)	100/255 %	TAC_PCT: xxx.x%
	Commanded TAC displayed as a percent. TAC_PCT shall be normalised to the maximum TAC commanded output control parameter. TAC systems use a variety of methods to control the amount of throttle opening. 1) If a linear or stepper motor is used, the fully closed throttle position shall be displayed as 0%, the fully open throttle position shall be displayed as 100%. Intermediate positions shall be displayed as a percent of the full-open throttle position. For example, a stepper-motor TAC that moves the throttle from 0 to 128 counts shall display 0% at 0 counts, 100% at 128 counts and 50% at 64 counts. 2) Any other actuation method shall be normalised to display 0% when the throttle is commanded closed and 100% when the throttle is commanded open.

54.17.89 Description of PID 59 to FF - ISO/SAE reserved

54.18 Service 02h - Request powertrain freeze frame data

Import actions:

ACTION_ERRM_ReadFrfByDtc	**(** **IN <TypeOfFF>** **IN <FFidentifier>** **IN <DtcIdentifier>** **IN <LevelOfDTC>** **INOUT <Frf>** **OUT <ResultFrf>** **)**
This API returns a Freeze Frame related to the DTC given in parameter.	

54.18.1 Functional description

The purpose of this service is to allow access to emission-related data values in a freeze frame. This allows expansion to meet manufacturer specific requirements not necessarily related to the required freeze frame, and not necessarily containing the same data values as the required freeze frame. The request message includes a parameter identification (PID) value that indicates to the on-board system the specific information requested. PID specifications, scaling information, and display formats for the freeze frame are included in Annex B of ISO 15031-5.4.

The ECU(s) will respond to this message by transmitting the requested data value stored by the system. All data values returned for sensor readings will be actual stored readings, not default or substitute values used by the system because of a fault with that sensor.

Service 02h PID 02h indicates the DTC that caused the freeze frame data to be stored. If freeze frame data is not stored in the ECU, the system shall report 00 00h as the DTC.

The frame number byte will indicate 00h for the freeze frame data. Manufacturers may optionally save additional freeze frames and use this service to obtain that data by specifying the freeze frame number in the request message. If a manufacturer uses these additional freeze frames, they will be stored under conditions specified by the manufacturer, and contain data specified by the manufacturer.

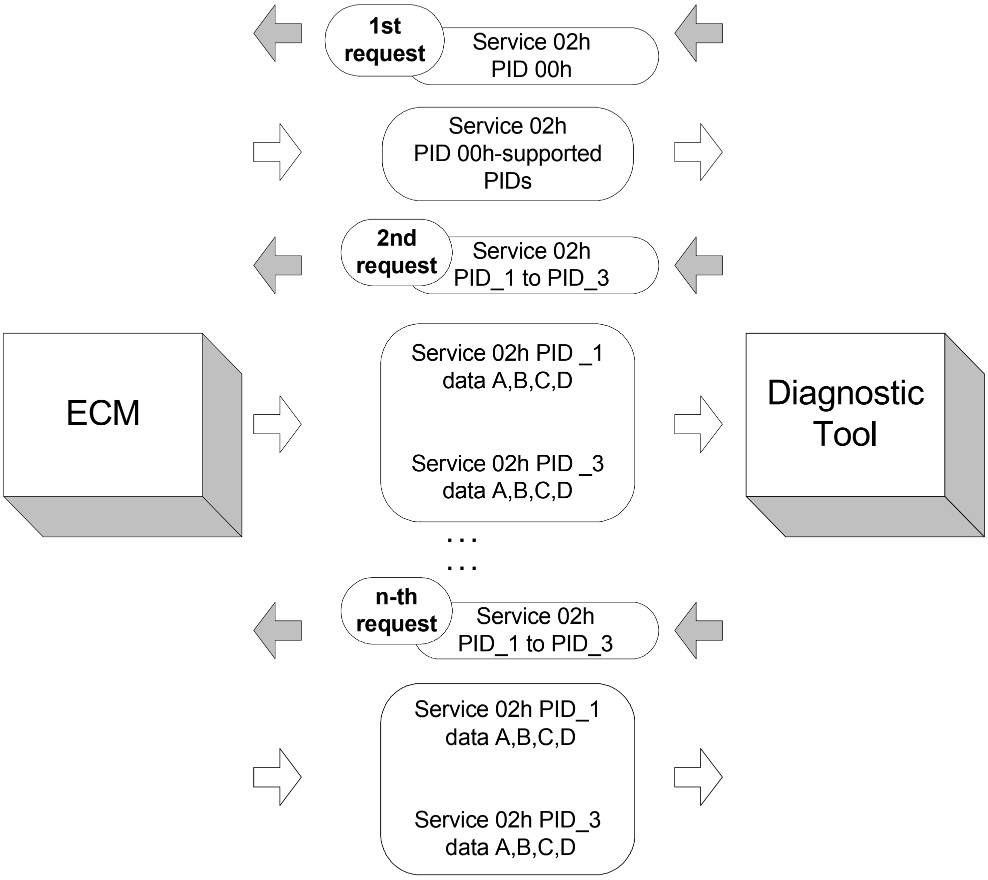
Not all PIDs are applicable or supported by all systems. PID 00h is a bit-encoded value that indicates for each ECU which PIDs are supported. PID 00h indicates support for PIDs from 01h to 20h. PID 20h indicates support for PIDs 21h through 40h, etc. PID 00h is required for those ECUs that respond to a corresponding service 02h request message as specified in Annex A of ISO 15031-5.4.

The order of the PIDs in the response message is not required to match the order in the request message.

The request message may contain up to three (3) PIDs. An external test equipment is not allowed to request a combination of PIDs supported and PIDs, which report data values. The ECU shall support requests for up to three (3) PIDs. The request message may contain the same PID multiple times. The ECU shall treat each PID as a separate parameter and respond with data for each PID as often as requested.

Proper response from server/ECU for ISO 15765-4 protocol:

Service 02h not supported	The ECU shall not respond
Service 02h supported PID requested, no Freeze Frame stored	PID 02h indicates 0000h, but if PIDs are requested, ECU must not respond except if supported PIDs (00h, 20h, …) have been requested, then the ECU shall send a response with the supported PID and data bytes
Service 02h unsupported PID requested, no Freeze Frame stored	PID 02h indicates 0000h, but if PIDs are requested, ECU must not respond except for support PIDs 00h, 20h, etc.
Service 02h supported PID requested, Freeze Frame stored	Respond within P2 timing
Service 02h unsupported PID requested, Freeze Frame stored	The ECU shall not respond



54.18.2 Message data bytes

54.18.2.1 Read supported PIDs

Request powertrain freeze frame data request message (read supported PIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request powertrain freeze frame data request SID**	**M**	**02**	**SIDRQ**
#2	PID#1 (PIDs supported: Annex A of ISO 15031-5.4)	M	xx	PID
#3	frame #	M	xx	FRNO_
#4	PID#2 (PIDs supported: Annex A of ISO 15031-5.4)	U	xx	PID
#5	frame #	U/C	xx	FRNO_
#6	PID#3 (PIDs supported: Annex A of ISO 15031-5.4)	U	xx	PID
#7	frame #	U/C	xx	FRNO_

U = User Optional — PID may be included to reduce multiple PID supported request messages
C = Conditional — parameter is only included if preceding PID# is included

NOTE To request PIDs supported range from 61h - FFh, multiple request messages with PIDs = 60h, 80h, A0h, C0h and E0h shall be sent to the vehicle.

54.18.2.2 Report supported PIDs

ECU(s) must respond to all supported ranges if requested. A range is defined as a block of 32 PIDs (e.g. range #1: PID 01h-20h). The ECU shall not respond to unsupported PID ranges unless subsequent ranges have a supported PID(s).

Request powertrain freeze frame data response message (report supported PIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request powertrain freeze frame data response SID**	**M**	**42**	**SIDPR**
#2	1st supported PID	M	00	PID
#3	frame #	M	xx	FRNO_
	data record of supported PIDs = [			DATAREC
#4	Data A: supported PIDs,	M	xx	DATA_A
#5	Data B: supported PIDs,	M	xx	DATA_B
#6	Data C: supported PIDs,	M	xx	DATA_C
#7	Data D: supported PIDs]	M	xx	DATA_D
:	:	:	:	:
#n-5	mth supported PID	C1	xx	PID
#n-4	frame #	C1	xx	FRNO_
	data record of supported PIDs = [			DATAREC
#n-3	Data A: supported PIDs,	C2	xx	DATA_A
#n-2	Data B: supported PIDs,	C2	xx	DATA_B
#n-1	Data C: supported PIDs,	C2	xx	DATA_C
#n	Data D: supported PIDs]	C2	xx	DATA_D

C1 = Conditional — PID value shall be the same value as included in the request message if supported by the ECU
C2 = Conditional — value indicates PIDs supported; range of supported PIDs depends on selected PID value (see C1)

NOTE The response message shall only include the PID(s) and Data A - D which are supported by the ECU. If the request message includes (a) PID value(s) which are not supported by the ECU those shall not be included in the response message.

54.18.2.3 Read freeze frame PID values

Request powertrain freeze frame data request message (read freeze frame PID values)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request powertrain freeze frame data request SID**	**M**	**02**	**SIDRQ**
#2	PID#1 (see Annex B of ISO 15031-5.4)	M	xx	PID
#3	frame #	M	xx	FRNO
#4	PID#2 (see Annex B of ISO 15031-5.4)	U	xx	PID
#5	frame #	C1	xx	FRNO
#6	PID#3 (see Annex B of ISO 15031-5.4)	U	xx	PID
#7	frame #	C1	xx	FRNO

U = User Optional — the parameter may be present or not
C1 = Conditional — parameter is only present if preceding PID# is present

54.18.2.4 Report freeze frame PID values

Request powertrain freeze frame data response message (report freeze frame PID values)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request powertrain freeze frame data response SID**	**M**	**42**	**SIDPR**
#2	1st supported PID	M	xx	PID_
#3	frame #	M	xx	FRNO_
#4 #5 #6 #7	data record of 1st supported PID = [data A, data B, data C, data D]	M C1 C1 C1	xx xx xx xx	DATA_A DATA_B DATA_C DATA_D
:	:	:	:	:
#2	mth supported PID	C2	xx	PID_
#3	frame #	C2	xx	FRNO_
#4 #5 #6 #7	data record of mth supported PID = [data A, data B, data C, data D]	C3 C4 C4 C4	xx xx xx xx	DATA_A DATA_B DATA_C DATA_D

C1 = Conditional — “data B - D” depend on selected PID
C2 = Conditional — parameter shall be the same value as included in the request message and only present if supported
C3 = Conditional — data A shall be included if preceding PID is supported
C4 = Conditional — parameters and values for “data B - D” depend on selected PID number

54.18.2.5 Parameter definition

54.18.2.5.1 PIDs supported

“Annex A of ISO 15031-5.4” specifies the interpretation of the data record of supported PIDs.

54.18.2.5.2 PID and data byte descriptions

“Annex B of ISO 15031-5.4” specifies standardised emission-related parameters.

54.18.2.5.3 Frame # description

The frame number identifies the freeze frame, which includes emission-related data values in case an emission-related DTC is detected by the ECU.

54.18.2.6 Formula section

ACTION_ERRM_ReadFrfByDtc

```
(
IN <LAW>
IN <FIRST>
IN <NO_DTC>
IN <LAW>
INOUT <Frf>
OUT <ResultFrf>
)
```

```
IF (PID = X0h)  where PID X0h means PID 00h, 20h, 40h, 60h, 80h, A0h, C0h, E0h

```

54.19 Service 02h - Request powertrain freeze frame data (Application Incident)

Import action:

```
ACTION_ERRM_ReadFrfByDtc(
                         IN <TypeOfFF>,
                         IN <FFIdentifier>,
                         IN <DtcIdentifier>,
                         IN < LevelOfDtc>,
                         INOUT <Frf>,
                         OUT <ResultFrf>
                        )
```

This API returns a freeze frame or a part of freeze frame.

Input data:

STATE_PSN_LS_SAE	STATE_VAR_SAP_SAE	NC_INJ_CONF	

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
ID_STATE_SRV_2_PID	12	0...FFH	0...255	1	[-]
LDPM_STATE_PID_SRV_1_2_OBDC	12	0...BH	0...11	1	[-]
Table of bytes which defines the PID's supported by the service 01h (01h - 60h)					

FUNCTION DESCRIPTION:

General information:

Depending on calibration of ID_STATE_SRV_2_PID the PID's are supported or not.

Each LDPM[0...11] of the table represents an 8 PIDs configuration:

0 => the PID is not supported
1 => the PID is supported

" IDX" is used instead of the array definition [NC_NR_ERR_DYN].

At STATE_PSN_LS_SAE you can see the configuration of the oxygen-sensors:

BIT	Function	Status
0	Bank 1 Sensor 1	1= available, 0 = not available

6	Bank 2 Sensor 3	1= available, 0 = not available
7	Bank 2 Sensor 4	1= available, 0 = not available

54.19.1 Description of PID 00h - Supported PIDs 01h - 20h

DATA A - Supported PIDs 01h to 08h

PID 00h - DATA A - Supported PID 01h to 08h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_2_PID[0]
0	PID 08h : Short term fuel trim - Bank 2 and Bank 4	1
1	PID 07h : Long term fuel trim - Bank 1 and Bank 3	1
2	PID 06h : Short term fuel trim - Bank 1 and Bank 3	1
3	PID 05h : Engine coolant temperature	1
4	PID 04h : Calculated load value	1
5	PID 03h : Fuel system status	1
6	PID 02h : Trouble code that caused required freeze frame	1
7	PID 01h : Monitor status since DTCs cleared	0

DATA B - Supported PIDs 09h to 10h

PID 00h - DATA B - Supported PID 09h to 10h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_2_PID[1]
0	PID 10h : Air flow rate from MAF sensor	1
1	PID 0Fh : Intake air temperature	1
2	PID 0Eh : Ignition time advance	1
3	PID 0Dh : Vehicle speed	1
4	PID 0Ch : Engine RPM	1
5	PID 0Bh : Intake manifold absolute pressure	1
6	PID 0Ah : Fuel pressure (gauge)	1
7	PID 09h : Long term fuel trim - Bank 2	1

DATA C - Supported PIDs 11h to 18h

PID 00h - DATA C - Supported PID 11h to 18h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_2_PID[2]
0	PID 18h : Bank 2 Sensor 1 or Bank 3 Sensor 1	0
1	PID 17h : Bank 1 Sensor 4 or Bank 2 Sensor 2	0
2	PID 16h : Bank 1 Sensor 3 or Bank 2 Sensor 1	0
3	PID 15h : Bank 1 Sensor 2	0
4	PID 14h : Bank 1 Sensor 1	0
5	PID 13h : Location of Oxygen Sensors	1
6	PID 12h : Secondary air status	1
7	PID 11h : Absolute throttle position sensor	1

DATA D - Supported PIDs 19h to 20h

PID 00h - DATA D - Supported PID 19h to 20h		
BIT	**Function**	**Bitmask:** ID_STATE_SRV_2_PID[3]
0	PID 20h : PIDs supported ($21 - $40)	1
1	PID 1Fh : Time Since Engine Start	1
2	PID 1Eh : Auxiliary Input Status	0
3	PID 1Dh : Location of oxygen sensors	0
4	PID 1Ch : OBD requirements to which vehicle is designed	0
5	PID 1Bh : Bank 2 Sensor 4 or Bank 4 Sensor 2	0
6	PID 1Ah : Bank 2 Sensor 3 or Bank 4 Sensor 1	0
7	PID 19h : Bank 2 Sensor 2 or Bank 3 Sensor 2	0

54.19.1.1 Description of PID 02h - Diagnostic trouble codes

PID (hex)	Description	Data byte	Min. value	Max. value	Scaling	External test equipment SI (Metric) / English display
02	DTC that caused required freeze frame data storage ($0000 indicates no freeze frame data)	A, B	00 00	FF FF	Hexadecimal e.g. P01AB (DTCs defined in ISO 15031-6)	DTCFRZF: Pxxxx, Cxxxx, Bxxxx, Uxxxx

54.19.3.9 Description of PID 4C – Commanded throttle actuator control

DATA_A = ENVD_OBD_38_IDX *// FRF of OBD_TPS_SP*

54.20 Service 03h - Request emission-related powertrain diagnostic trouble codes – OBD on CAN

Import actions:

ACTION_ERRM_ReadDtcByTypeOfDtc **(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <ListOfDtc>** **OUT <ResultDtc>** **)**
This API returns a list of DTC.
ACTION_ERRM_ReadQuantityOfDtc **(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <Quantity>** **OUT <ResultQuantity>** **)**
This API returns the quantity of DTC with a certain type, which are stored in memory

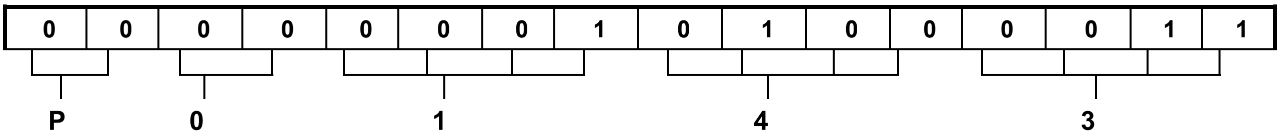
54.20.1 Functional description

The purpose of this service is to enable the external test equipment to obtain “confirmed” emission-related DTCs (diagnostic trouble codes).

Send a Service $03 request for all emission-related DTCs. Each ECU that has DTCs will respond with one (1) message containing all emission-related DTCs. If an ECU does not have emission-related DTCs then it shall respond with a message indicating no DTCs are stored by setting the parameter # of DTC to 00h

.

DTCs are transmitted in two (2) bytes of information for each DTC. The first two (2) bits (high order) of the first (1) byte for each DTC indicate whether the DTC is a Powertrain, Chassis, Body, or Network DTC (refer to ISO 15031-6 for additional interpretation of this structure). The second two (2) bits will indicate the first digit of the DTC (0 through 3). The second (2) nibble of the first (1) byte and the entire second (2) byte are the next three (3) hexadecimal characters of the actual DTC reported as hexadecimal. A Powertrain DTC transmitted as 0143h shall be displayed as P0143.



Diagnostic trouble code encoding example DTC P0143

54.20.2 Message data bytes

54.20.2.1 Request message definition

Request emission-related DTC request message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request emission-related DTC request SID**	**M**	**03**	**SIDRQ**

54.20.2.2 Response message definition

Request emission-related DTC response message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request emission-related DTC response SID**	**M**	**43**	**SIDPR**
#2	# of DTC = [no emission-related DTCs stored emission-related DTCs stored]	M	xx = [00, 01 - FF	#OFDTC
#3 #4	DTC#1 (High Byte) DTC#1 (Low Byte)	C C	xx xx	DTC1HI DTC1LO
:	:	:	xx	
#n-1 #n	DTC#m (High Byte) DTC#m (Low Byte)	C C	xx xx	DTCmHI DTCmLO
C = Conditional — DTC#1 - DTC#m are only included if # of DTC parameter value ≠ $00				

54.20.2.3 Parameter definition

54.20.2.3.1 # of DTC parameter description

The # of DTC parameter reports the emission-related DTC(s) currently (at the time of the request message processing) stored in the ECU(s).

54.20.2.4 Formula section

```

```

54.21 Service 04h - Clear/reset emission-related diagnostic information

Export actions:

ACTION_OBDC_Srv04Cnd (OUT < PRM_STATE_SRV_4_RESP >)
This function permit to clear all failures in dynamic memory, or not

Import actions:

ACTION_ERRM_ClrInfoByTypeOfDtc(IN <TypeOfDTC> OUT <ResultClrInfo>)
This API clears all failure in dynamic memory
ACTION_OBDC_Srv04SpActions ()
This function permit to project to add their own manufacturer specific "clearing/resetting" actions
ACTION_OBDC_Srv04CndSp (OUT <>)
This action permit to clear all failures in dynamic memory, or not - contains project specific conditions This action is included only if it is defined in appl. inc. xxI06E01.xxx

Input data:

NLC_ERR_CLR_ENG_RUN_SAE	LV_IGK	LV_ES	

54.21.1 Functional description

The purpose of this service is to provide a means for the external test equipment to command ECUs to clear the whole failure memory (all emission-related and non emission-related diagnostic information) (refer to Error Management module)

This includes:

— MIL and number of diagnostic trouble codes	(can be read with Service 01h, PID 01h)
— Clear the I/M (Inspection/Maintenance) readiness bits	(Service 01h, PID 01h and 41h)
— Confirmed diagnostic trouble codes	(can be read with Service 03h)
— Pending diagnostic trouble codes	(can be read with Service 07h)
— Diagnostic trouble code for freeze frame data	(can be read with Service 02h, PID 02h)
— Freeze frame data	(can be read with Service 02h)
— Status of system monitoring tests	(can be read with Service 01h, PID 01h)
— On-board monitoring test results	(can be read with Service 06h)
— Distance travelled while MIL is activated	(can be read with Service 01h, PID 21h)
— Number of warm-ups since DTCs cleared	(can be read with Service 01h, PID 30h)
— Distance travelled since DTCs cleared	(can be read with Service 01h, PID 31h)
— Time run by the engine while MIL is activated	(can be read with Service 01h, PID 4Dh)
— Time since diagnostic trouble codes cleared	(can be read with Service 01h, PID 4Eh)
— Reset misfire counts of standardized Test ID 0Bh to zero	(can be read with Service 06h)

Description of parameter OUT used by function ACTION_OBDC_Srv04Cnd ():

PRM_STATE_SRV_4_RESP: Result to say if the function is done or not.

Authorised values for PRM_STATE_SRV_4_RESP are:
(1) The call of the function is successful
(0) The call of the function is not successful

Description for actions:

ACTION_OBDC_Srv04Cnd (OUT < PRM_STATE_SRV_4_RESP >)					
This function permit to clear all failures in dynamic memory, or not. In this function the project should define their own conditions in order to permit or not the clearing performed with Service 04h					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_SRV_4_RESP	OUT	00H..FFH	0..255	1	-
Result to say if the function is done or not					

The purpose of this function is to define the conditions in order to permit to clear all failures in dynamic memory, or not.
All ECUs shall respond to this request message with ignition ON, with the engine not running.

Formula section:

```
IF NLC_ERR_CLR_ENG_RUN_SAE THEN
        IF LV_IGK
        THEN
                PRM_STATE_SRV_4_RESP = 1
        ELSE
                PRM_STATE_SRV_4_RESP = 0
        ENDIF
ELSE
        IF LV_IGK AND LV_ES
        THEN
                PRM_STATE_SRV_4_RESP = 1
        ELSE
                PRM_STATE_SRV_4_RESP = 0
        ENDIF
ENDIF
```

54.21.2 Message data bytes

54.21.2.1 Request message

Bytes	Parameter name	Hex value
#01	**Request to clear/reset emission-related diagnostic information**	04

For safety and/or technical design reasons, ECUs that can not perform this operation under other conditions, such as with the engine running shall send a negative response message with response code 22h - conditionsNotCorrect.

54.21.2.1.1 Formula section

If there are used the generic conditions in order to check if the clearing of all failures in dynamic memory, can be performed or not, this is the sequence to be respected:

```
IF ACTION_OBDC_Srv04Cnd()
THEN
        ACTION_ERRM_ClrInfoByTypeOfDtc
                                        (
                                        IN <ALL>
                                        OUT <ResultClrInfo>
                                        )
        CALL ACTION_OBDC_Srv04SpActions()
        Positive response;
ELSE
        Negative response with "Condition not correct";
ENDIF
```

If there are used the project specific conditions in order to check if the clearing of all failures in dynamic memory, can be performed or not, this is the sequence to be respected:

```
IF ACTION_OBDC_Srv04CndSp()
THEN
        ACTION_ERRM_ClrInfoByTypeOfDtc
                                        (
                                        IN <ALL>
                                        OUT <ResultClrInfo>
                                        )
        CALL ACTION_OBDC_Srv04SpActions()
        Positive response;
ELSE
        Negative response with "Condition not correct";
ENDIF
```

54.21.2.2 Positive response message

Bytes	Parameter name	Hex value
#01	**Request to clear/reset emission-related diagnostic information positive response**	44

54.21.2.3 Negative response message

Bytes	Parameter name	Hex value
#1	**Negative response**	7F
#2	**Request to clear/reset emission-related diagnostic information**	04
#3	Error code = Condition not correct	22

54.21.2.4 Error code

Error code	Cause
Condition not correct	In case of ECU can not perform the clearing

54.22 Service 04h - Clear/reset emission-related diagnostic information (Application Incident)

Input data:

N_32	LV_LOCK_IMOB	VS	

Export actions:

ACTION_OBDC_Srv04CndSp (OUT < PRM_STATE_SRV_4_SP_RESP >)
This function permit to clear all failures in dynamic memory, or not
ACTION_OBDC_Srv04SpActions ()
This function permit to project to add their own manufacturer specific "clearing/resetting" actions

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NLC_ERR_CLR_ENG_RUN_SAE	1	0...1H	0...1	1	[-]
Byte which indicates if the erase will be done when engine is running or not					

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_32_MAX_CLR_FMY_SRV_4	1	0...FFH	0...8160	32	[rpm]
Maximum engine speed threshold to erease error memory in service 04					

FUNCTION DESCRIPTION:

General information:

The purpose of this function is to define the conditions in order to permit to clear all failures in dynamic memory, or not.

54.22.1 Definition of NLC_ERR_CLR_ENG_RUN_SAE

Description:

Erase with or without engine running - NLC_ERR_CLR_ENG_RUN_SAE	
Value	**Description**
0	The clearing of failures is performed when engine is NOT running
1	The clearing of failures is performed when engine is running

Formula section:

NLC_ERR_CLR_ENG_RUN_SAE = 1

54.22.2 Description of parameter OUT used by function ACTION_OBDC_Srv04CndSp():

Description:

PRM_STATE_SRV_4_SP_RESP: Result to say if the function is done or not.

Authorised values for PRM_STATE_SRV_4_SP_RESP are:
(1) The call of the function is successful
(0) The call of the function is not successful

Description for actions:

ACTION_OBDC_Srv04CndSp (OUT < PRM_STATE_SRV_4_SP_RESP >)					
This function permit to clear all failures in dynamic memory, or not. In this function the project should define their own conditions in order to permit or not the clearing performed with Service $04					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_SRV_4_SP_RESP	OUT	00H...FFH	0...255	1	[-]
Result to say if the function is done or not					

Formula section:

```
IF   LV_LOCK_IMOB = 0          AND
     VS = 0                    AND
     N_32 < C_N_32_MAX_CLR_FMY_SRV_4
THEN
     PRM_STATE_SRV_4_SP_RESP = 1
ELSE
     PRM_STATE_SRV_4_SP_RESP = 0
ENDIF
```

54.22.3 Description of parameter OUT used by function ACTION_OBDC_Srv04SpActions():

Description:

Other manufacturer specific "clearing/resetting" actions may also occur in response to the Service $04 request.

ACTION_OBDC_Srv04SpActions ( )					
This function permit to project to add their own manufacturer specific "clearing/resetting" actions performed at a Service $04 request (e.g. writing in NVMY information related to the number ok Km when the clearing was performed, the type of the tool which performed the clearing, etc)					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
see description at beginning of specification

ACTION not used yet

54.23 Service 06h - Request on-board monitoring test result for non-continuously monitored system – OBD on CAN

54.23.1 Functional description

The purpose of this service is to allow access to the results for on-board diagnostic monitoring tests of specific components / systems that are continuously monitored (e.g. mis-fire monitoring) and non-continuously monitored (e.g. catalyst system).

The request message for test values includes an On-Board Diagnostic Monitor ID (see Annex D of ISO 15031-5.4) that indicates the information requested. Unit and Scaling information is included in Annex E of ISO 15031-5.4.

The vehicle manufacturer is responsible for assigning "Manufacturer Defined Test IDs" for different tests of a monitored system. The latest valid test values (results) are to be retained, even over multiple ignition OFF cycles, until replaced by more recent test values (results). Test values (results) are requested by On-Board Diagnostic Monitor ID. Test values (results) are always reported with the Minimum and Maximum Test Limits. The Unit and Scaling ID included in the response message defines the scaling and unit to be used by the external test equipment to display the test values (results), Minimum Test Limit, and Maximum Test Limit information.

If an On-Board Diagnostic Monitor has not been completed at least once since Clear/reset emission-related diagnostic information or battery disconnect, then the parameters Test Value (Results), Minimum Test Limit, and Maximum Test Limit shall be set to zero (0000h) values.

Not all On-Board Diagnostic Monitor IDs are applicable or supported by all systems. On-Board Diagnostic Monitor ID 00h is a bit-encoded value that indicates for each ECU which On-Board Diagnostic Monitor IDs are supported. On-Board Diagnostic Monitor ID 00h indicates support for On-Board Diagnostic Monitor IDs from 01h to 20h. On-Board Diagnostic Monitor ID 20h indicates support for On-Board Diagnostic Monitor IDs 21h through 40h, etc. This is the same concept for PIDs/TIDs/InfoTypes support in services 01h, 02h, 06h, 08h, and 09h. On-Board Diagnostic Monitor ID 00h is required for those ECUs that respond to a corresponding service 06h request message as specified in Annex A of ISO 15031-5.4.

The request message including supported On-Board Diagnostic Monitor IDs may contain up to six (6) OBDMIDs. A request message including an On-Board Diagnostic Monitor ID, which reports test values shall only contain one (1) OBDMID. An external test equipment is not allowed to request a combination of OBDMIDs supported and a single OBDMID, which report test values. The ECU shall support requests for up to six (6) supported OBDMIDs and only one (1) OBDMID which reports test values.

A unique method must be utilized for displaying data for monitors that have multiple tests. Many OBD monitors have multiple tests that that are done in either a serial or parallel manner. If a monitor uses multiple OBD Monitor ID/Test ID combinations that may not all complete at the same time, the following method shall be used to update the stored test results at the time of monitor completion:

After the monitor completes, update all Monitor ID/Test ID combinations (or “test results”) that were utilized by the monitor with appropriate passing or failing results. If a test result (or “Monitor ID/Test ID”) was not utilized during this monitoring event, set the Test Values and Minimum and Maximum Test Limits to their initial values (0000h, test not completed). Test results from the previously completed monitoring events shall not be mixed with test results from the current completed monitoring event.

In some cases, test results (or “Monitor ID/Test ID combinations”) will be displayed as being incomplete even though the monitor (as indicated by PID 41h) was successfully completed and either passed or failed. In other cases, some Test IDs will show passing results while others will show failing results after the monitor (as indicated by PID 41h) was successfully completed and failed. Note that OBD-II regulations prohibit a passing monitor from showing any failing test results. If an initial, serial test indicates a failure and a subsequent re-test of the system indicates a passing result, the test that was utilized to make the passing determination should be displayed, while the failing test that was utilized to make the initial determination should be reset to it's initial values (0000h, test not completed).

As an example of a serial monitor, an evaporative system monitor can fail for a large evaporative system leak and never continue to test for small leaks or very small leaks. In this case, the Test ID for the large leak would show a failing result, while the small leak test and the very small leak test would show incomplete. As an example of the parallel monitor, a purge valve flow monitor can pass by having a large rich lambda shift, a large lean lambda shift or a large engine rpm increase. If the purge valve is activated and a large rich lambda shift occurs, the Test ID for the rich lambda shift would show a passing result while the other two Test IDs would show incomplete. Since some Test IDs for a completed monitor will show incomplete, PID 41h must be used to determine monitor completion status.

54.23.2 Message data bytes

54.23.2.1 Read supported OBDMIDs

Request on-board monitoring test results for specific monitored systems request message (read supported OBDMIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request on-board monitoring test results for specific monitored systems request SID**	**M**	**06**	**SIDRQ**
#2	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	M	xx	OBDMID
#3	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	U	xx	OBDMID
#4	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	U	xx	OBDMID
#5	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	U	xx	OBDMID
#6	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	U	xx	OBDMID
#7	On-Board Diagnostic Monitor ID (OBDMIDs supported: Annex A of ISO 15031-5.4)	U	xx	OBDMID
U = User Optional — OBDMID may be included to avoid multiple OBDMID supported request messages				

NOTE To request OBDMIDs supported range from C1h - FFh another request message with OBDMID#1 = C0h and OBDMID#2 = E0h shall be sent to the vehicle

54.23.2.2 Report supported OBDMIDs

ECU(s) must respond to all supported ranges if requested. A range is defined as a block of 32 OBDMIDs (e.g. range #1: OBDMID 01h-20h). The ECU shall not respond to unsupported OBDMID ranges unless subsequent ranges have a supported OBDMID(s).

Request on-board monitoring test results for specific monitored systems response message (report supported OBDMIDs)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request on-board monitoring test results for specific monitored systems response SID**	**M**	**46**	**SIDPR**
	data record of supported OBDMID = [			OBDMIDREC
#2	1st supported OBDMID	M	xx	OBDMID
#3	Data A: supported OBDMIDs,	M	xx	DATA_A
#4	Data B: supported OBDMIDs,	M	xx	DATA_B
#5	Data C: supported OBDMIDs,	M	xx	DATA_C
#6	Data D: supported OBDMIDs]	M	xx	DATA_D
:	:	:	:	:
	data record of supported OBDMID = [			OBDMIDREC
#n-4	m^{th} supported OBDMID	C1	xx	OBDMID
#n-3	Data A: supported OBDMIDs,	C2	xx	DATA_A
#n-2	Data B: supported OBDMIDs,	C2	xx	DATA_B
#n-1	Data C: supported OBDMIDs,	C2	xx	DATA_C
#n	Data D: supported OBDMIDs]	C2	xx	DATA_D
C1 =	Conditional — OBDMID value shall be the same value as included in the request message if supported by the ECU			
C2 =	Conditional — value indicates OBDMIDs supported; range of supported OBDMIDs depends on selected OBDMID value (see C1)			

NOTE The response message shall only include the OBDMID(s) and Data A - D which are supported by the ECU. If the request message includes (a) OBDMID value(s) which are not supported by the ECU those shall not be included in the response message.

54.23.2.3 Read OBDMID test values

Request on-board monitoring test results for specific monitored systems request message (read OBDMID test values)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request on-board monitoring test results for specific monitored systems request SID**	**M**	**06**	**SIDRQ**
#2	On-Board Diagnostic Monitor ID	M	xx	OBDMID

54.23.2.4 Report OBDMID test values

Request on-board monitoring test results for specific monitored systems response message (report OBDMID test values)

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request on-board monitoring test results for specific monitored systems response SID**	**M**	**46**	**SIDPR**
	data record of supported OBDMID = [			OBDMIDREC

#n	Max. Test Limit (Low Byte)#m]	C2	xx	MAXTLLO

C1 = Conditional — parameter is only present if more than one (1) Manufacturer Defined TID is supported by the ECU for the requested Monitor ID.

C2 = Conditional — parameter and value depends on selected Manufacturer Defined TID number and are only included if the Manufacturer Defined TID is supported by the ECU. The value shall be zero (00h) in case the On-Board Diagnostic Monitor has not been completed at least once since Clear/reset emission-related diagnostic information or battery disconnect.

54.23.2.5 Response code

Note : The response is given following the condition made by the project.
Here is an example :

Formula section:

```
IF      Conditions from the specification XXI06Q01.XXX are fullfield
        THEN
                Positive response with test result
        ELSE
                Positive response with all data equal to 0000h
ENDIF
```

54.23.3 Parameter definition

54.23.3.1 On-Board Diagnostic Monitor IDs supported

The On-Board Diagnostic Monitor IDs supported is the same concept as used for PID support in services 01h and 02h as specified in Annex A of ISO 15031-5.4.

54.23.3.2 On-Board Diagnostic Monitor ID description

The On-Board Diagnostic Monitor ID is a one (1) byte parameter and is defined in Annex D of ISO 15031-5.4. An On-Board Diagnostic Monitor may have more than one (1) monitor test (Test ID).

54.23.3.3 Standardised and Manufacturer Defined Test ID description

The Standardised and Manufacturer Defined Test ID is a one (1) byte parameter. For example, the On-Board Diagnostic Monitor " Oxygen Sensor Monitor Bank 1 - Sensor 1" may have the following Standardised Test ID:
The table below specifies the range of identifiers.

Standardised Test ID description

Range (Hex)	Description
00	ISO/SAE reserved
01	Rich to lean sensor threshold voltage (constant)
02	Lean to rich sensor threshold voltage (constant)
03	Low sensor voltage for switch time calculation (constant)
04	High sensor voltage for switch time calculation (constant)
05	Rich to lean sensor switch time (calculated)
06	Lean to rich sensor switch time (calculated)
07	Minimum sensor voltage for test cycle (calculated)
08	Maximum sensor voltage for test cycle (calculated)
09	Time between sensor transitions (calculated)
0A	Sensor period (calculated)
0B	EWMA (Exponential Weighted Moving Average) misfire counts for last ten (10) driving cycles (calculated, rounded to an integer value) General EWMA calculation: 0.1 * (current misfire counts) + 0.9 * (previous misfire counts average) Initial value for (previous misfire counts average) = 0 Note: Internal ECU calculation registers with precision higher than one count must be used and retained to calculate the contents of registers 0Bh and 0Ch to prevent rounding errors. If this is not done, these registers will never count back down to zero after misfire stops. The calculations must be done using the high precision registers, then rounded to the nearest integer value to be output as register 0Bh and 0Ch **High_Precision_EWMA_Misfire_Counts** $_{\text{current}}$ **= Rounded [(0.1) * High_Precision_Misfire_Counts** $_{\text{current}}$ **+ (0.9) * High_Precision_EWMA_Misfire_Counts** $_{\text{previous}}$**]** Where: Rounded means rounded to the nearest integer. The high precision values are never reported, they are only used for internal calculations. This TEST ID shall be reported with OBD Monitor IDs A2h – ADh and the Scaling ID 24h.
0C	Misfire counts for last/current driving cycles (calculated, rounded to an integer value)
0D - 7F	Reserved for future standardisation

Manufacturer Defined Test ID description

Range (Hex)	Description
80 - FE	Manufacturer Defined Test ID range - this parameter is an identifier for the test performed within the On-Board Diagnostic Monitor.
FF	Reserved by document

Results of latest mandated on-board oxygen sensor monitoring tests, see figure below.

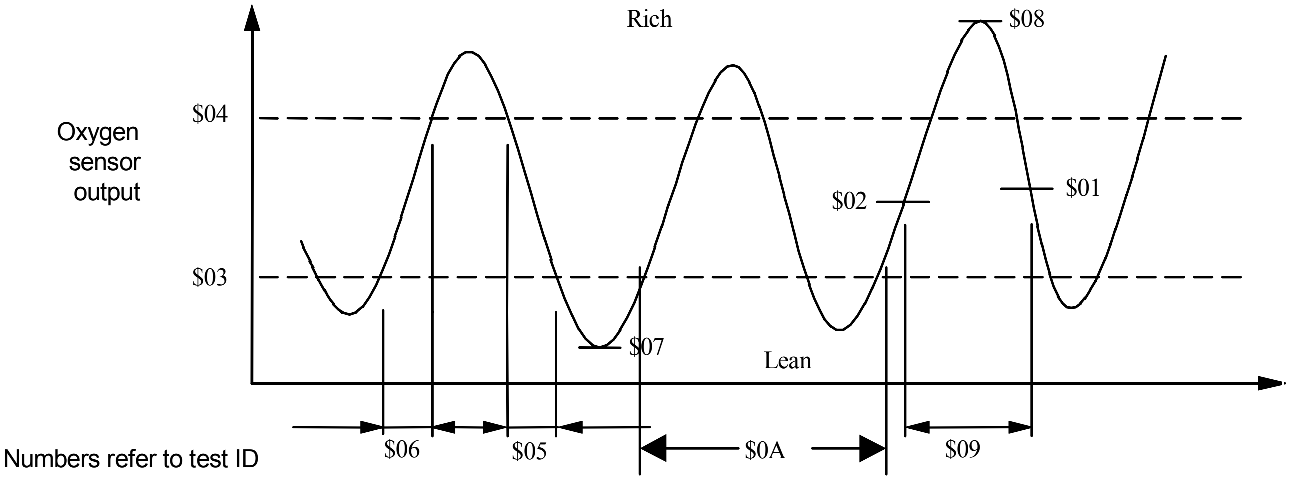

Figure 1 — Standardised Test ID value example

54.23.3.4 Unit and Scaling ID definition

The Unit and Scaling ID is a one (1) byte identifier to reference the scaling and unit to be used by the external test equipment to calculate and display the test values (results), Minimum Test Limit, and the Maximum Test Limit for the Standardised and Manufacturer Defined Test ID requested. All standardised Unit And Scaling IDs are specified in Annex E of ISO 15031-5.4.

54.23.3.5 Test Value (result) description

The Test Value represents the test result and is defined in the table below.

Test Value description

Parameter name	# of bytes	Description
Test Value	2 (High and Low Byte)	Test Value (Result) - this value shall be calculated and displayed by the external test equipment based on the Unit and Scaling ID included in the response message. The Test Value shall be within the Minimum and Maximum Test Limit to indicate a "Pass" result.

54.23.3.6 Minimum Test Limit description

The Minimum Test Limit parameter is defined in the table below.

Minimum Test Limit description

Parameter name	# of bytes	Description
Minimum Test Limit	2 (High and Low Byte)	The Minimum Test Limit shall be calculated and displayed by the external test equipment based on the Unit and Scaling ID included in the response message. The Unit and Scaling IDs are specified in Annex E of ISO 15031-5.4. The Minimum Test Limit shall be the minimum value for the monitor identified by the On-Board Diagnostic Monitor ID. For the Standardised Test IDs which are constant values the Minimum Test Limit shall be the same value as reported for the Test Value. It is the vehicle manufacturer's responsibility to provide information whether a Test Value which equals the Minimum Test Value results in a "Pass" or "Fail" condition.

54.23.3.7 Maximum Test Limit description

The Maximum Test Limit parameter is defined in the table below.

Maximum Test Limit description

Parameter name	# of bytes	Description
Maximum Test Limit	2 (High and Low Byte)	The Maximum Test Limit shall be calculated and displayed by the external test equipment based on the Unit and Scaling ID included in the response message. The Unit and Scaling IDs are specified in Annex E of ISO 15031-5.4. The Maximum Test Limit shall be the maximum value for the monitor identified by the On-Board Diagnostic Monitor ID. For the Standardised Test IDs which are constant values the Maximum Test Limit shall be the same value as reported for the Test Value. It is the vehicle manufacturer's responsibility to provide information whether a Test Value which equals the Maximum Test Value results in a "Pass" or "Fail" condition.

E1 - FF	**Vehicle manufacturer defined OBDMIDs**	0

54.24.2 Configuration of calibratable TID's

Description:

The table ID_STATE_SRV_6_TID will be filled with calibrated TID values. Each position in the table will have an associated TID and OBDMID.

- If the calibration of the TID = xy => TID is sended with xy
- If the calibration of the TID = 0 => TID is not supported
- If the calibration of all TID's of the OBDMID = 0 => OBDMID is not supported

Example:

If for instance in a project will be supported the following TIDs:
TIDs 01h, 02h, 03h, 04h, 05h, 81h, 82h, 90h, 98h, C1h

=> configure NC_NR_TID = 10
(LDP_STATE_TID_ID_STATE_SRV_6 automatically is set to 10)
=> ID_STATE_SRV_6_TID will have the dimension 10.

Configuration of the table ID_STATE_SRV_6_TID:

pos val	x[0]	x[1]	x[2]	x[3]	x[4]	x[5]	x[6]	x[7]	x[8]	x[9]
	01h	**02h**	**03h**	**02h**	**05h**	**81h**	**82h**	**81h**	**98h**	**C1h**
	OBDMID yy			**OBDMID zz**				**OBDMID vv**		

Each position in table will have an associated OBDMID:
Postion 0: TID 01h=> for OBDMID yy
Postion 1: TID 02h=> for OBDMID yy

Postion 2: TID 03h=> for OBDMID yy

Postion 3: TID 02h=> for OBDMID zz
Postion 4: TID 05h=> for OBDMID zz
Postion 5: TID 81h=> for OBDMID zz
Postion 6: TID 82h=> for OBDMID zz
Postion 7: TID 81h=> for OBDMID vv
Postion 8: TID 98h => for OBDMID vv
Postion 9: TID C1h => for OBDMID vv

Each OBDMID can be disabled separately:
e.g. if at position x[0], x[1], x[2] configure value 00h => OBDMID yy is **not supported**.

Formula section:

```
IF      ALL configured TIDs for the same OBDMID have value 00h
THEN    OBDMID IS NOT SUPPORTED
ELSE    OBDMID IS SUPPORTED
ENDIF
```

54.24.3 Configuration of table-size

Description:

The table-size of ID_STATE_SRV_6_TID depends on number of defined TID's (= NC_NR_TID), see Tables 1.4 ff.

Formula section:

TID's are defined from position 0...42

=> NC_NR_TID = **43**

54.24.4 Description of OBDMID 01h - 06h (Lambda sensor diagnosis)

General information:

Additional to the calibration the support of the OBDMID's can be learnt. Depending on the learning result (see STATE_PSN_LS_SAE and STATE_PSN_LS_1_SAE) the OBDMID 01h – 06h are supported or not.

54.24.4.1 Description of OBDMID 01h - Oxygen Sensor Monitor Bank 1 - Sensor 1

Formula section:

```
IF (STATE_PSN_LS_SAE & 01h) OR (STATE_PSN_LS_1_SAE & 01h)
THEN OBDMID 01h IS SUPPORTED
ELSE OBDMID 01h IS NOT SUPPORTED
ENDIF
```

Dynamic diagnosis – TID 83	
Position in table	[0]
Unit and scaling	83h (Raw value 8000...7FFFh / -327.68...327.67)
Test value	FAC_DYN_LSL_DIAG_SAE[1]
Min test limit	0 = 0000h
Max test limit	FAC_DYN_LSL_DIAG_TOL_SAE[1] (e.g. 0.9)

Formula section:

```
IF      ID_STATE_SRV_6_TID[0] <> 0
THEN    TID is supported
    IF      LV_READY_DYN_VLD_LS_UP[1] = 0      OR

    ELSE    Positive response with all data equal to 0000h
    ENDIF
ELSE    TID is not supported
ENDIF
```

54.24.5 Description of OBDMID 21 - 22h (Catalyst diagnosis)

General information:

Additional to the calibration the support of the OBDMID's can be learnt. Depending on the learning result (see STATE_PSN_LS_SAE and STATE_PSN_LS_1_SAE) the OBDMID 21h – 22h are supported or not.

54.24.5.1 Description of OBDMID 21h - Catalyst Monitor Bank 1

Formula section:

```
IF (STATE_PSN_LS_SAE & 03h) OR (STATE_PSN_LS_1_SAE & 03h)
THEN OBDMID 21h IS SUPPORTED
ELSE OBDMID 21h IS NOT SUPPORTED
ENDIF
```

OSC method (linear system) – TID 81	
Position in table	[12]
Unit and scaling	05h (Raw value 0...FFFFh / 0...2)
Test value	CAT_DIAG_MOD_6[1]
Min test limit	0 = 0000h
Max test limit	CAT_MAX_DIAG_MOD_6[1] (e.g. 0.8)

Formula section:

```
IF        ID_STATE_SRV_6_TID[12] <> 0
THEN      TID is supported
    IF        LV_READY_CAT_DIAG[1] = 0          OR
              LV_ERR_MEM_CAT_DIAG[1] = 1
    THEN      Positive response with test result
    ELSE      Positive response with all data equal to 0000h
    ENDIF
ELSE      TID is not supported
ENDIF
```

54.24.5.2 Description of OBDMID 22h - Catalyst Monitor Bank 2

Formula section:

```
IF (STATE_PSN_LS_SAE & 30h) OR (STATE_PSN_LS_1_SAE & 0Ch)
THEN OBDMID 22h IS SUPPORTED
ELSE OBDMID 22h IS NOT SUPPORTED
ENDIF
```

OSC method (linear system) – TID 81	
Position in table	[13]
Unit and scaling	05h (Raw value 0...FFFFh / 0...2)
Test value	CAT_DIAG_MOD_6[2]
Min test limit	0 = 0000h
Max test limit	CAT_MAX_DIAG_MOD_6[2] (e.g. 0.8)

Formula section:

```
IF        ID_STATE_SRV_6_TID[13] <> 0
THEN      TID is supported
    IF        LV_READY_CAT_DIAG[2] = 0          OR
              LV_ERR_MEM_CAT_DIAG[2] = 1

    ELSE      Positive response with all data equal to 0000h
    ENDIF
ELSE      TID is not supported
ENDIF
```

54.24.6 Description of OBDMID 3Bh – 3Dh (EVAP diagnosis)

General information:

Additional to the calibration the support of the OBDMID's can be learnt. OBDMID 3Bh – 3Ch are only supported if the vehicle is equipped with DMTL module.

Formula section:

```
IF      STATE_EVAP_SAE <> 0
THEN    OBDMID 3Bh – 3Ch are supported
ELSE    OBDMID 3Bh – 3Ch are not supported
ENDIF
```

54.24.6.1 Description of OBDMID 3B - EVAP Monitor Large (0.040" / 1.0mm)

Leak detection DMTL – Long cycle – TID 81	
Position in table	[14]
Unit and scaling	0Dh (Current 0...FFFFh / 0...256 mA)
Test value	M6_CUR_DMTL_ROUGH_LEAK_LEN_END
Min test limit	M6_CUR_DMTL_THD_ROUGH_LEAK_LEN
Max test limit	FFFFh (256 mA)
Leak detection DMTL – Short cycle – TID 82	
Position in table	[15]
Unit and scaling	0Dh (Current)
Test value	M6_CUR_DMTL_ROUGH_LEAK_END
Min test limit	M6_CUR_DMTL_THD_ROUGH_LEAK
Max test limit	FFFFh (256 mA)

Formula section:

```
IF      ID_STATE_SRV_6_TID[14] / [15] <> 0          //each seperate
THEN    TID's are supported
        IF      LV_READY_ROUGH_LEAK = 0             OR

    ENDIF
ELSE        TID is not supported
ENDIF
```

54.24.6.3 Description of OBDMID 3D - EVAP Purge Flow monitor

Functional check TEV – Step 1 – TID 81

Position in table	[20]
Unit and scaling	05h (Raw value 0...FFFFh / 0...2)
Test value	CL_MMV_SAE
Min test limit	C_CL_MMV_DIAGCPS
Max test limit	FFFFh (2)
Functional check TEV – Step 2 – TID 82	
Position in table	[21]
Unit and scaling	03h (Raw value 0....FFFFh / 0...655,35)
Test value	SUM_DIAG_DIAGCPS_SAE
Min test limit	0h(0)
Max test limit	C_SUM_DIAGCPS_MAX
Functional check TEV – Step 3 – TID 83	
Position in table	[22]
Unit and scaling	2Dh (Weight per stroke 0...FFFFh / 0...655,35 mg/stk)
Test value	MAF_DIAGCPS_SAE
Min test limit	0h (0 mg/stk)
Max test limit	MAF_DIAGCPS_THD_SAE

Formula section:

```
IF          ID_STATE_SRV_6_TID[20] / [21] / [22] <> 0          //each seperate
THEN        TID's are supported
     IF             LV_READY_DIAGCPS = 0           OR
                    LV_ERR_MEM_DIAGCPS = 1
     THEN           Positive response with test result
     ELSE           Positive response with all data equal to 0000h
     ENDIF
ELSE        TID's are not supported
ENDIF
```

54.24.7 Description of OBDMID 41h – 46h (Oxygen sensor heater diagnosis)

General information:

Additional to the calibration the support of the OBDMID's can be learnt. Depending on the learning result (see STATE_PSN_LS_SAE and STATE_PSN_LS_1_SAE) the OBDMID 41h – 46h are supported or not.

54.24.7.1 Description of OBDMID 41h Oxygen Sensor Heater Monitor Bank 1 Sensor 1

Formula section:

```
IF (STATE_PSN_LS_SAE & 01h) OR (STATE_PSN_LS_1_SAE & 01h)
THEN OBDMID 41h IS SUPPORTED
ELSE OBDMID 41h IS NOT SUPPORTED
ENDIF
```

Sensor temperature – TID 85	
Position in table	[23]
Unit and scaling	96h (Temperature FE6F...4E20 / -3276,8...3276,7°C)

Test value	TTIP_MES_LS_UP_OBD_LSH_UP[1]
Min test limit	C_TTIP_MIN_OBD_LSH_UP
Max test limit	C_TTIP_MAX_OBD_LSH_UP

Formula section:

```
IF          ID_STATE_SRV_6_TID[23] <> 0
THEN        TID is supported
    IF          LV_READY_OBD_VLD_LSH_UP[1] = 0          OR

        ENDIF
    ELSE        TID is not supported
    ENDIF
```

54.24.8 Description of OBDMID 71h – 72h (Secondary air diagnosis)

General information:

Additional to the calibration the support of the OBDMID's can be learnt. OBDMID 71h – 72h are only supported if the vehicle is equipped with SA pump. Depending on Hardware configuration only one monitor is active (via lambda-sensor **or** flow meter).

Formula section:

```
IF      STATE_VAR_SAP_SAE <> 0
THEN    OBDMID 71h – 72h are supported
    IF      LC_SA_SWI_ACQ = 1
    THEN    OBDMID 71h is not supported          //SA flow meter equipped
    ELSE    OBDMID 72h is not supported          //SA flow meter not equipped
    ENDIF
ELSE    OBDMID 71h – 72h are not supported
ENDIF
```

54.24.8.1 Description of OBDMID 71h – Secondary air monitor with lambda sensor

Monitoring of minimum flow rate – TID 81	
Position in table	[27]
Unit and scaling	01h (Raw value 0...FFFFh / 0...65535)
Test value	MIN [SUM_AFL_VLS_DIAG_SA_1_SAE, SUM_AFL_VLS_DIAG_SA_2_SAE]
Min test limit	C_SUM_AFL_VLS_MIN_DIAG_SA_1
Max test limit	FFFFh (65535)

Formula section:

```
IF      ID_STATE_SRV_6_TID[27] <> 0
THEN    TID is supported
    IF      LV_READY_SA_SAP = 0          OR
            LV_ERR_MEM_SA_SAP = 1
    THEN    Positive response with test result
    ELSE    Positive response with all data equal to 0000h
    ENDIF
ELSE    TID is not supported
ENDIF
```

54.24.8.2 Description of OBDMID 72h – Secondary air monitor with SA flow meter

Monitoring of minimum flow rate – TID 82	
Position in table	[28]
Unit and scaling	27h (Weight per time 0...FFFFh / 0...655,35 g/s)
Test value	SAF_DIAG_MIN_SAE
Min test limit	0h

Max test limit	C_SAF_DIAG_MIN
Monitoring of minimum flow rate – TID 83	
Position in table	[29]
Unit and scaling	27h (Weight per time 0...FFFFh / 0...655,35 g/s)
Test value	SAF_DIAG_MAX_SAE
Min test limit	0h
Max test limit	C_SAF_DIAG_MAX

Formula section:

```
IF      ID_STATE_SRV_6_TID[28] / [29] <> 0          //each seperate
THEN    TID are supported
    IF          LV_READY_SA_SYS = 0          OR
                LV_ERR_MEM_SA_SYS = 1

54.25 Service 07h - Request emission-related diagnostic trouble codes detected during current or last completed driving cycle – OBD on CAN

Import actions:

ACTION_ERRM_ReadDtcByTypeOfDtc	**(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <ListOfDtc>** **OUT <ResultDtc>** **)**
This API returns a list of non confirmed DTC.	
ACTION_ERRM_ReadQuantityOfDtc	**(** **IN <TypeOfDtc>** **IN <LevelOfDtc>** **INOUT <Quantity>** **OUT <ResultQuantity>** **)**
This API returns the quantity of DTC with a certain type, which are stored in memory	

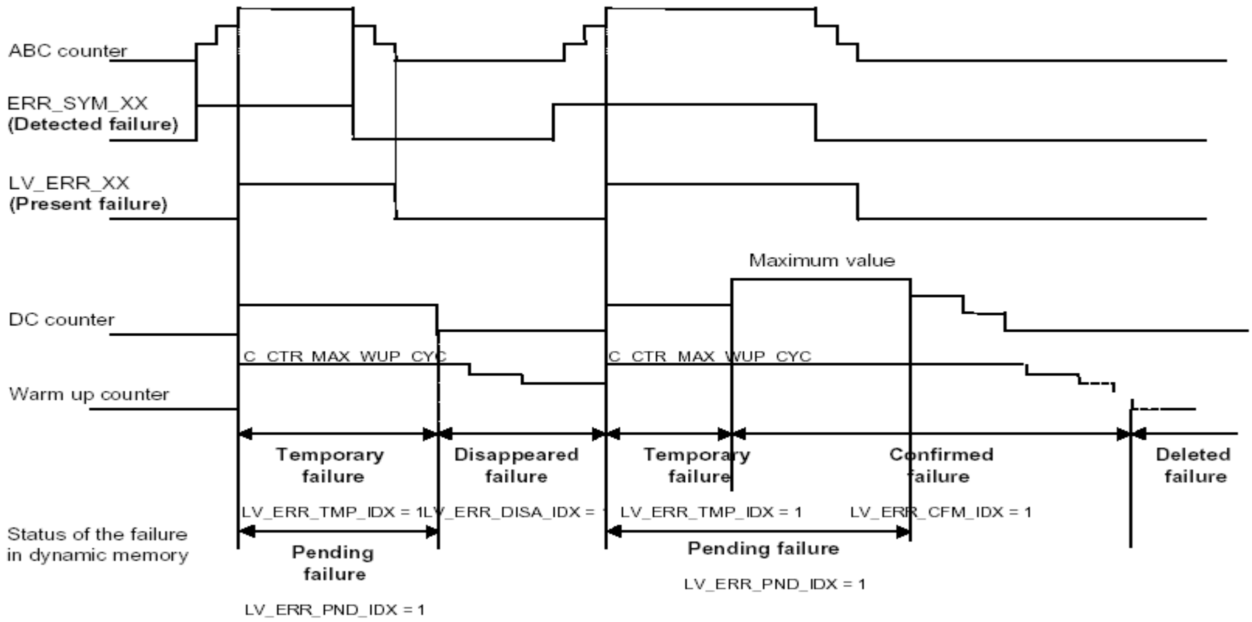
54.25.1 Functional description for ISO 15765-4

The purpose of this service is to enable the external test equipment to obtain “pending” diagnostic trouble codes detected during current or last completed driving cycle for emission-related components / systems that are tested or continuously monitored during normal driving conditions. Service 07h is required for all DTCs and is independent of Service 03h.

The intended use of this data is to assist the service technician after a vehicle repair, and after clearing diagnostic information, by reporting test results after a single driving cycle. If the test failed during the driving cycle, the DTC associated with that test will be reported. Test results reported by this service do not necessarily indicate a faulty component / system. If test results indicate a failure after additional driving, then the MIL will be illuminated and a DTC will be set and reported with service 03h, indicating a faulty component / system. This service can always be used to request the results of the latest test, independent of the setting of a DTC.

Test results for these components / systems are reported in the same format as the DTCs in Service $03 - refer to the functional description for service $03.

If an ECU does not have stored DTCs then it shall respond with a message indicating no codes are stored by setting the parameter "Number of DTC" to 00h.



54.25.2 Message data bytes

54.25.2.1 Request message definition

Request emission-related diagnostic trouble codes detected during current or last completed driving cycle request message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request emission-related diagnostic trouble codes detected during current or last completed driving cycle request SID**	**M**	**07**	**SIDRQ**

54.25.2.2 Response message definition

Request emission-related diagnostic trouble codes detected during current or last completed driving cycle response message

Data Byte	Parameter Name	Cvt	Hex Value	Mnemonic
#1	**Request emission-related diagnostic trouble codes detected during current or last completed driving cycle response SID**	**M**	**47**	**SIDPR**
#2	# of DTC = [no emission-related DTCs # of emission-related DTCs]	M	 00 01 - FF	#OFDTC
#3 #4	DTC#1 (High Byte) DTC#1 (Low Byte)	C C	xx xx	DTC1HI DTC1LO
:	:	:	xx	
#n-1 #n	DTC#m (High Byte) DTC#m (Low Byte)	C C	xx xx	DTCmHI DTCmLO
C = Conditional — DTC#1 - DTC#m are only included if # of DTC parameter value ≠ $00				

54.25.2.3 Formula section

```
ACTION_ERRM_ReadQuantityOfDtc
                                        (
                                        IN <OBD&PENDING>
                                        IN <LAW>

This action fill the ECU CALID with the correct values from the project
ACTION_OBDC_*GetCALIDCalib* (OUT <>)
This action fill the CALIB CALID with the correct values from the project
ACTION_OBDC_*GetCALIDSelSeg* (OUT <>)
This action fill the several or all segments of memory CALID with the correct values from the project
ACTION_OBDC_*GetECUNAME*(OUT <>)
This action fills the emission related ECU Name
ACTION_ERRM_SelectRbmData (INOUT <>, OUT <>)
This API calculates and returns the Rate-Based Monitoring data to be transmitted to the Scan-Tool, when requested by the Service 09$ (InfoType $08).
cks_service (IN <component>, IN<command>, OUT<status>)
This action performs CRC check control

Input data:

NC_STATE_CKS_CONF_CAN	NC_STATE_COMP_TYP_CAN	NC_STATE_SRV_9_CAN_VIT	

54.26.1 Functional description

The purpose of this service is to enable the off-board test device to request vehicle specific information such as Vehicle Identification Number (VIN) and calibration IDs.

54.26.1.1 Read supported Info Type

54.26.1.1.1 Request message

Bytes	Parameter name	CVT	Hex value

#1	**Request vehicle information**	M	09
#2	Info Type#1 (VITs supported : 01h - 20h)	M	00
#3	Info Type#2 (VITs supported : 21h - 40h)	U	20
#4	Info Type#3 (VITs supported : 41h - 60h)	U	40
#5	Info Type#4 (VITs supported : 61h - 80h)	U	60
#6	Info Type#5 (VITs supported : 81h - A0h)	U	80
#7	Info Type#6 (VITs supported : A1h - C0h)	U	A0

U = User optional	Info Type may be included to avoid multiple Info Type supported request messages

To request Info Types supported range from C1h to FFh another request message with Info Type#1 = C0h and Info Type#2 = E0h shall be sent to the vehicle.

54.26.1.1.2 Positive response message

Bytes	Parameter name	CVT	Hex value
#1	**Request vehicle information**	M	49
#2	Info Type = 1st supported Info Type	M	00
#4	Supported Info Type 01h - 08h	M	XX
#5	Supported Info Type 09h - 10h	M	XX
#6	Supported Info Type 11h - 18h	M	XX
#7	Supported Info Type 19h - 20h	M	XX
#n-4	Info Type = mth supported Info Type	C1	XX
#n-3	Supported Info Type m1h - m8h	C2	XX
#n-2	Supported Info Type m9h - (m+1)0h	C2	XX
#n-1	Supported Info Type (m+1)1h - (m+1)8h	C2	XX
#n	Supported Info Type (m+1)9h - (m+2)0h	C2	XX

C1 = Conditional	Info Type value shall be the same value as included in the request message if supported by the ECU
C2 = Conditional	Value indicates Info Type supported, the range of supported Info Type depends on selected Info Type value

The response message shall only include the Info Types and Data A - D which are supported by the ECU. If the request message includes (a) Info Type value(s) which are not supported by the ECU, those shall not be included in the response message.

54.26.1.2 Read Info Type values

54.26.1.2.1 Request message

Bytes	Parameter name	CVT	Hex value
#1	**Request vehicle information**	M	09
#2	Info Type (Read Info Type values)	M	02, 04, 06, 08, 0A

54.26.1.2.2 Positive response message

Bytes	Parameter name	CVT	Hex value
#1	**Request vehicle information**	M	49
#2	Info Type (Report Info Type values)	M/C1	02, 04, 06, 08, 0A
#3	Number of data items	M/C1	XX
#4	Data #1	M/C2	XX
#5	Data #2	C2	XX
#n	Data #m	C2	XX

C1 = Conditional	Info Type value shall be the same value as included in the request message
C2 = Conditional	Data #2 to Data #m depend on selected Info Type value

54.26.1.3 Negative response message

Bytes	Parameter name	CVT	Hex value
#1	**Negative response**	M	7F
#2	**Request emission-related powertrain diagnostic trouble codes**	M	09
#3	Error code = Request correctly received response pending	M	78

54.26.1.3.1 Error code

Error code	Cause
Request correctly received response pending	The on-board processor requires significant time to calculate the CRCs

54.26.4 Description of Service 09h, INFOTYPE 04h - Calibration IDs

A Calibration ID will be reported for the ECM, depending on the software architecture. Calibration ID can include a maximum of 16 ASCII characters. Calibration ID can contain only printable ASCII characters, and will be reported as ASCII values.
Calibration ID should uniquely identify the software installed in the ECM.
The amount of Calibration Id is included in the "Number of data items" parameter.
About Calibration coherence identifier definition sees the file: ECU reprogramming, coherence system (Chapter 0)

Request vehicle information request message

#18	Data_O : Calibration ID for XXX: char 15	XXX	CALID
#19	Data_P : Calibration ID for XXX: char 16	XXX	CALID
----	------	-----	-----
#n	Data_A: Calibration ID for YYY: char 1	YYY	CALID
#n+1	Data_B: Calibration ID for YYY: char 2	YYY	CALID
# n+2	Data_C: Calibration ID for YYY: char 3	YYY	CALID
# n+3	Data_D: Calibration ID for YYY: char 4	YYY	CALID
# n+4	Data_E: Calibration ID for YYY: char 5	YYY	CALID
# n+5	Data_F: Calibration ID for YYY: char 6	YYY	CALID
# n+6	Data_G: Calibration ID for YYY: char 7	YYY	CALID
# n+7	Data_H: Calibration ID for YYY: char 8	YYY	CALID
# n+8	Data_I: Calibration ID for YYY: char 9	YYY	CALID
# n+9	Data_J: Calibration ID for YYY: char 10	YYY	CALID
# n+10	Data_K: Calibration ID for YYY: char 11	YYY	CALID
# n+11	Data_L : Calibration ID for YYY: char 12	YYY	CALID
# n+12	Data_M : Calibration ID for YYY: char 13	YYY	CALID
# n+13	Data_N : Calibration ID for YYY: char 14	YYY	CALID
# n+14	Data_O : Calibration ID for YYY: char 15	YYY	CALID
# n+15	Data_P : Calibration ID for YYY: char 16	YYY	CALID

Note:

- The sequence of the 16 bytes (Data_A – Data_P) from #n to #n+15 is depending of the components number. This is depending of how many components are configured in the configuration byte NC_STATE_COMP_TYP_CAN.
    - o e.g. (if it is configured to 1 component we have only one sequence of 16 bytes, if it is configured to 2 components we have two sequences of 16 bytes, and so on).
    - o e.g. if it is configured to 1 component than the positive response will be constructed using only one data set for CALID and the length of response is 19 bytes.

  - e.g. if it is configured to 2 components than the positive response will be constructed using two data sets for CALID XXX, and YYY and the length of response is 35 bytes.
- the order of the CALID in the response is the same like in the NC_STATE_COMP_TYP_CAN:

Positive response

SID	InfoType	1st group of 16 bytes	2nd group of 16 bytes	3rd group of 16 bytes	4th group of 16 bytes	5th group of 16 bytes
49	04	CALID for one area or a combination of several or all section areas of the ECU	ECU CALID	CALIB CALID	SBOOT CALID	CBOOT CALID

54.26.5 Description of Service 09h, INFOTYPE 06h - Calibration verification numbers

The on-board software will calculate the CVN (CRC) based on memory content
If the calculation does not use all four bytes, the CVN shall be right justified and filled with 00h.
The amount of CVNs is included in the "Number of data items" parameter.

Request vehicle information request message (read InfoType values)

Data Byte	Parameter Name	Hex Value	Mnemonic
#1	**Request vehicle information request SID**	**09**	**SIDRQ**
#2	InfoType (read InfoType values)	06	INFTYP

54.26.5.1 Response positive report calibration verification number

Request vehicle information response message

Message direction:	ECU#1 → External test equipment		
Message Type:	Response		
Data Byte	**Description (all values are in hexadecimal)**	**Byte Value (Hex)**	**Mnemonic**
#1	Request vehicle information response SID	49	SIDPR
#2	InfoType: Calibration Verification Number	06	INFTYP
#3	Number of data items:	XX	NODI
#4	Data_A : 1st byte of CRC for XXX calculation value	XXX	DATA_A
#5	Data_B : 2nd byte of CRC for XXX calculation value	XXX	DATA_B
#6	Data_C : 3rd byte of CRC for XXX calculation value	XXX	DATA_C
#7	Data_D : 4th byte of CRC for XXX calculation value	XXX	DATA_D
----	-----	-----	-----
#n	Data_A : 1st byte of CRC for YYY calculation value	YYY	DATA_A
#n+1	Data_B : 2nd byte of CRC for YYY calculation value	YYY	DATA_B
#n+2	Data_C : 3rd byte of CRC for YYY calculation value	YYY	DATA_C
#n+3	Data_D : 4th byte of CRC for YYY calculation value	YYY	DATA_D

Note:

- The sequence of the 4 bytes (Data_A – Data_D) from #n to #n+3 is depending of the components number. This is depending of how many components are configured in the configuration byte NC_STATE_COMP_TYP_CAN.
  - e.g. (if it is configured to 1 component we have only one sequence of 4 bytes, if it is configured to 2 components we have two sequences of 4 bytes, and so on).
- the order of the CVNs in the response is the same like in the NC_STATE_COMP_TYP_CAN:

Positive response

SID	**InfoType**	**1st group of 4 bytes**	**2nd group of 4 bytes**	**3rd group of 4 bytes**	**4th group of 4 bytes**	**5th group of 4 bytes**
49	06	CRC for one area or a combination of several or all section areas of the ECU	ECU CRC	CALIB CRC	SBOOT CRC	CBOOT CRC

Application conditions:

Initialisation: At NVMINI system event:

STATE_CKS_BOOT_1_SAE = 0
STATE_CKS_BOOT_2_SAE = 0
STATE_CKS_ECU_SAE = 0
STATE_CKS_CAL_SAE = 0
STATE_CKS_SEL_SEG_SAE = 0

Recurrence: -

Activation: -

Formula section:

```
IF NC_STATE_CKS_CONF_CAN is 1
THEN
AT RESET:
          Restore values for STATE_CKS_SEL_SEG_SAE, STATE_CKS_BOOT_1_SAE,
          STATE_CKS_BOOT_2_SAE, STATE_CKS_ECU_SAE, STATE_CKS_CAL_SAE from
          NVMY
ENDIF
```

At reception of the request the correct flow is:

```
IF NC_STATE_CKS_CONF_CAN is 1
THEN (1)
      IF for the first time after a reprogramming event of the ECU(s), the
checksum computation is not ready
      THEN (2)
            A negative response message with response code 78h –
      RequestCorrectlyReceived-ResponsePending must be sent by the ECU(s) until
      the checksum computation is done and positive response message is
      available
      ELSE (2)
            Check if checksum is done
            IF checksum for all COMPONENTs, depending of the configuration of
      the project is done
            if (cks_service(component, NC_CMD_CRC_SRV_CHK_READY) == component)
            THEN (3)
                Intitialize STATE_CKS_SEL_SEG_SAE, STATE_CKS_BOOT_1_SAE,
                STATE_CKS_BOOT_2_SAE, STATE_CKS_ECU_SAE,
                STATE_CKS_CAL_SAE, with CKS values:
                IF (NC_STATE_COMP_TYP_CAN & 10h)   //Several sections
                  THEN STATE_CKS_SEL_SEG_SAE = cks_service_cift(component for
                  several sections, NC_CMD_CRC_SRV_GET_CKS)

Table of bytes which defines the INFOTYPEs supported by the service 09h (01h – 20h) – ISO 15765-4					

54.27.1 NC_STATE_CKS_CONF_CAN

NC_STATE_CKS_CONF_CAN	
Value	**Description**
1	Method #1: The CVN(s) must not be computed on demand, but instead shall be computed at least once per trip. A trip shall be of reasonable length (e.g. 5 - 10 minutes). The computed CVN(s) shall be stored in NVM (Non Volatile Memory) for immediate access by the external test equipment. Once the computation is completed for the very first time after a reprogramming event of the ECU(s) or a battery disconnect, the results shall be made available to the external test equipment even if the engine is running. If the CVN(s) are requested before they have been computed a negative response message with response code $78 - RequestCorrectlyReceived-ResponsePending shall be sent by the ECU(s) until the positive response message is available for the ISO 14230-4 and ISO 15765-4 protocols.
2	Method #2: If method #1 does not apply the ECU(s)' on-board software shall compute the CVN(s) on an external test equipment request message. If the ECU(s) are not able to send an immediate positive response message a negative response message with response code $78 - RequestCorrectlyReceived-ResponsePending shall be sent by the ECU(s) until the positive response message is available for the ISO 14230-4 and ISO 15765-4 protocols.

Formula section:

NC_STATE_CKS_CONF_CAN = 1

54.27.2 NC_STATE_COMP_TYP_CAN

NC_STATE_COMP_TYP_CAN		
BIT	**Function**	**Supported**
0	Use CBOOT area	0
1	Use SBOOT area	0
2	Use CALIB area	**1**
3	Use ECU area	**1**
4	One area or a combination of several or all section areas of the ECU	0
5	Dummy value, always 0	0
6	Dummy value, always 0	0
7	Dummy value, always 0	0

Formula section:

see Table

54.27.3 NC_STATE_SEL_SEG_CAN

NC_STATE_SEL_SEG_CAN	
Value	**Description**
XX	The value of the define represent the area of one component or a a combination of several or all section areas of the ECU

Formula section:

NC_STATE_SEL_SEG_CAN = 0 (not used)

54.27.4 Supported INFOTYPEs for Service 09h – ISO 15765-4

Description:

In the table **ID_STATE_SRV_9_CAN_VIT** each byte represents an 8 INFOTYPEs configuration

54.27.6 Description of Service 09h, INFOTYPE 04h - Calibration IDs

Description:

A Calibration ID will be reported for the ECM, depending on the software architecture. Calibration ID can include a maximum of 16 ASCII characters. Calibration ID can contain only printable ASCII characters, and will be reported as ASCII values.
Calibration ID should uniquely identify the software installed in the ECM.
The amount of Calibration Id is included in the "Number of data items" parameter.
About Calibration coherence identifier definition see the file : ECU reprogramming, coherence system (Chapter 0)

54.27.6.1 ACTION_OBDC_*GetCALIDCBoot* (OUT < PRM_STATE_BOOT_1 >)

Description for actions:

ACTION_OBDC_*GetCALIDCBoot* (OUT < PRM_STATE_BOOT_1 >)					
This action fill the CBOOT CALID with the correct values from the project

Software structure of 16 ASCI elements filled up with CALIB CALID(Calibration Identifications only for Calibration area). This structure has to be filled byte by byte.

Remark:
bmw_cal_nr[0..6] has to be defined inside the project as interface, because the actual CALIB CALID must be evaluated from the BMW_UIF (reprog-history) table first.

PRM_STATE_CAL[0] = bmw_cal_nr[0] *//CALIB CALID Character 1*
PRM_STATE_CAL[1] = bmw_cal_nr[1] *//CALIB CALID Character 2*
PRM_STATE_CAL[2] = bmw_cal_nr[2] *//CALIB CALID Character 3*

54.27.6.6 Description of Service 09h, INFOTYPE 0Ah - ECUNAME

Description for actions:

ACTION_OBDC_*GetECUNAME*(OUT <PRM_STATE_ECU_NAME>)					
This action fills the emission related ECU Name					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_STATE_ECU_NAME[0...19]	IN	0...FFH	0...255	1	[-]
See description bellow					

FUNCTION DESCRIPTION:

Description of parameter OUT used by action ACTION_OBDC_GetECUNAME():

PRM_STATE_ECU_NAME:

Software structure of 20 ASCII characters filled up with ECU Name of an emission related ECU. This structure has to be field byte by byte.

Defined field assignment:

- Data bytes 1-4, “XXXX”, contains ECU acronym, and
- Data byte 5, “-“, contains delimiter, and
- Data bytes 6-20, “YYYYYYYYYYYYYYY”, contains text name

ECU acronyms:

The first 4 bytes from the response of InfoType 0Ah have to be one of the acronyms described in the table bellow.

The emissions-related ECUs (control modules) have to report the external test equipment acronym and name as listed below. This table is not complete and emissions-related ECUs not listed in the table must be reported to ISO/SAE for definition.		
External test equipment reported acronym (max 1 – 4 chars	**Full name of Control Module/emissions-related ECU**	**External test equipment reported name (max 15 chars.)**
ABS	Anti-Lock Brake System (ABS) Control Module	**AntiLock Brake**
AFCM	Alternative Fuel Control Module	**Alt. Fuel Crtl**
AHCM	Auxiliary Heater Control Module	**Aux. Heat Crtl**
BECM	Battery Energy Control Module	**B+ Energy Crtl**
BSCM	Brake System Control Module	**Brake System**
CCM	Cruise Control Module	**Cruise Control**
CTCM	Coolant Temperature Control Module	**Cool Temp Crtl**

55.1 CPU Load Measurement

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CPU_LOAD	O/V	0...400H	0..100	0.0977	%
Type: U16. CPU load above measurement level.					
CPU_LOAD_MAX	O/V/S	0...400H	0..100	0.0977	%
Type: U16. Maximum detected CPU load above measurement level.					
CPU_LOAD_FIL	O/V	0...400H	0..100	0.0977	%
Type: U16. Filtered CPU load above measurement level.					
CPU_LOAD_FIL_MAX	O/V/S	0...400H	0..100	0.0977	%
Type: U16. Maximum detected filtered CPU load above measurement level.					
CPU_LOAD_TSK_PER_MIN	O/V	0...FFFFFFFFH	0..4294967295	1	Ticks
Type: U32. Minimum time between 2 Instances of TASK_BG_MES.					
CPU_LOAD_TSK_PER_CTR	O/V	0...FFFFFFFFH	0..4294967295	1	-
Type: U32. Numbers of calls of TASK_BG_MES.					
CPU_LOAD_SES_CTR	O/V	8000...7FFFH	-32768..32767	1	-
Type: S16. Session counter of CPU load measurement.					

FUNCTION DESCRIPTION:

General information:

In a priority-based system, working with a background task (task configured at the lowest priority level and systematically running when no higher priority treatments are triggered), the real processor load is always 100%. Nevertheless, the CPU time spent for the background task can be considered as potential free CPU time (if a higher priority treatment is triggered, the background task will be interrupted).

As a consequence, the CPU load (CPU_LOAD) is then defined as the processor activity above the background level (priority level 0).

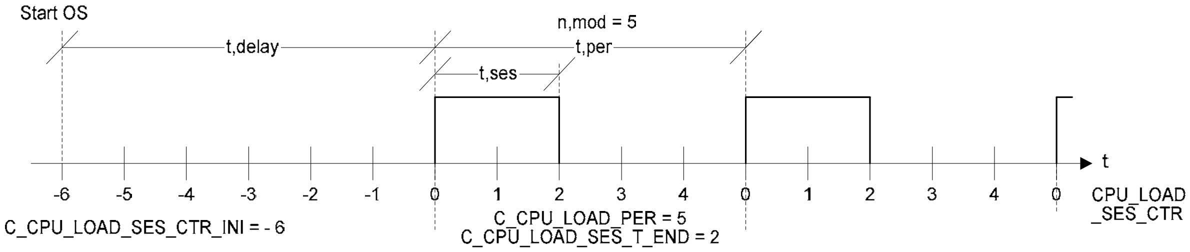
The computation of the CPU load consumed above the background level (priority 0) is based on the usage of a measurement background task (TASK_BG_MES) of fixed and known net duration $t_{\mathrm{TASK\_BG\_MES,net}}$ (automatically characterized by the minimum time between two tasks occurrences: CPU_LOAD_TSK_PER_MIN) at the priority level 1 and a time function in a task (priority > 1) with fixed recurrence (e.g. 100ms). The duration of TASK_BG_MES can be tuned with the temporization value C_CPU_LOAD_TSK_MES_DLY. The temporization is necessary to increase the measurement background task time having enough measurement resolution.

The detected minimum duration time (depending on the chosen temporization) is shown in value CPU_LOAD_TSK_PER_MIN and shall be put to C_CPU_LOAD_TSK_PER_MIN.

After having fixed C_CPU_LOAD_TSK_MES_DLY and C_CPU_LOAD_TSK_PER_MIN, these two calibrations, plus C_CPU_LOAD_PER and C_CPU_LOAD_SES_T_END (see description below) shall be set none tunable in DDS in order to make sure that no miscalibration is possible.

During a measurement session t_{ses} of period t_{per} occurring every fixed modulo counter n_{mod} (C_CPU_LOAD_PER), TASK_BG_MES is triggered once from the application and then continuously re-activates itself.

This measurement session t_{ses} starts at the beginning of the period t_{per} and can be tuned up to 100% of the period t_{per} (boundary case, where C_CPU_LOAD_SES_T_END is set equal C_CPU_LOAD_PER). The measurement session t_{ses} shall be less than or equal to 1 second. A start delay of measurement can be defined by setting the session counter CPU_LOAD_SES_CTR to a negative value at initialization (calibration C_CPU_LOAD_SES_CTR_INI).



The potential free CPU factor $\mathrm{CPU}_{\mathrm{free}}$ is obtained by multiplying the counted occurrences n (CPU_LOAD_TSK_PER_CTR) of measurement background task (TASK_BG_MES) over the measurement session with the duration of the measurement background task.

$$\mathrm{CPU}_{\mathrm{free}} = \frac{n \cdot t_{\mathrm{TASK\_BG\_MES,net}}}{t_{ses}}$$

The CPU load value (CPU_LOAD) is then deduced from the potential $\mathrm{CPU}_{\mathrm{free}}$ value.

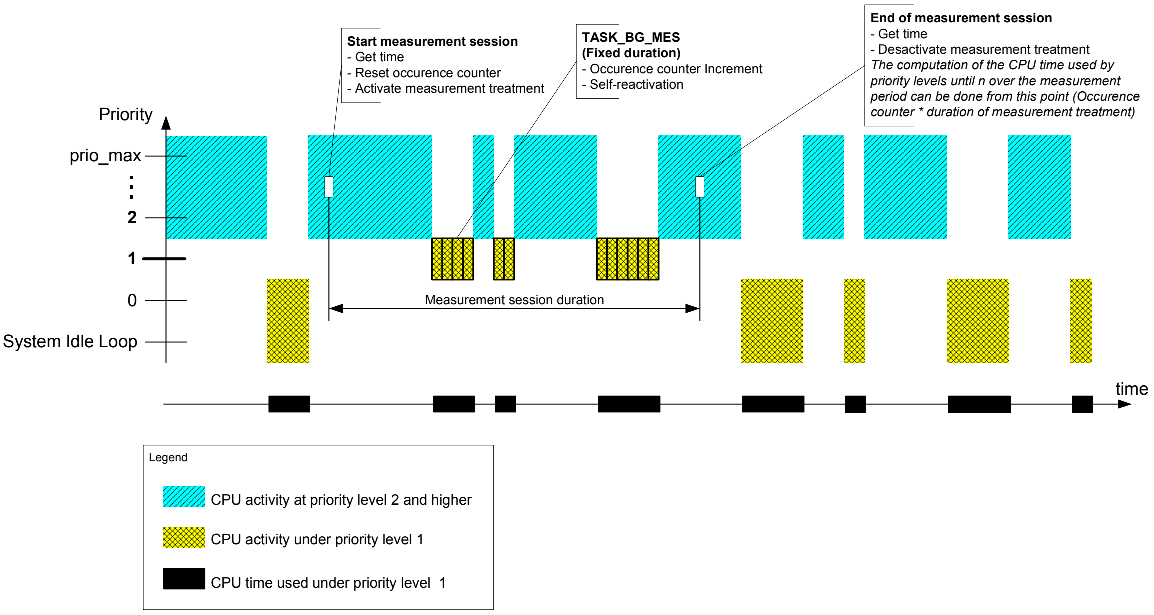
$$\mathrm{CPU}_{\mathrm{load}} = 1 - \mathrm{CPU}_{\mathrm{free}} = 1 - \frac{n \cdot t_{\mathrm{TASK\_BG\_MES,net}}}{t_{ses}}$$

Due to a continuous activity at priority level 1 during the measurement period, it must be noticed that the background treatments running at priority 0 will not occur during the measurement session.

CPU_LOAD_FIL is the PT_1 filtered value of CPU_LOAD with P=1 and T_1 set by C_CPU_LOAD_FTC (see description of calibration).

The variable CPU_LOAD_MAX represents the maximum detected CPU load value. The variable CPU_LOAD_FIL_MAX represents the maximum of the filtered CPU load value.

The following diagram summarizes the principle of the measurement method:



Start measurement session
- Get time
- Reset occurence counter
- Activate measurement treatment

TASK_BG_MES
(Fixed duration)
- Occurence counter Increment
- Self-reactivation

End of measurement session
- Get time
- Desactivate measurement treatment

*The computation of the CPU time used by priority levels until n over the measurement period can be done from this point (Occurence counter * duration of measurement treatment)*

Figure 1: The principle of the measurement method

Three APIs are available in order to have a flexible measurement method:

Measurement enable API:

This API shall be called at least at initialization if the measurement has to be done. After measurement disable API was called measurement enable API shall be used to enable measurement again.

Measurement disable API:

Shall be used to disable measurement method.

Clear Maximum API:

Shall be used to clear CPU_LOAD_MAX and CPU_LOAD_FIL_MAX.

Calibration data:

Name	Dim	Hex. Limits	Phys. limits	Resol.	Unit
C_CPU_LOAD_TSK_PER_MIN	1	0...FFFFH	0..65535	1	Ticks
Type: U16. Learned minimum time between 2 Instances of TASK_BG_MES.					
C_CPU_LOAD_TSK_MES_DLY	1	0...FFFFH	0..65535	1	-
Type: U16. Temporization for background task duration.					
C_CPU_LOAD_PER	1	1..7FFFH	1..32767	1	-
Type: S16. Time factor between 2 measurement sessions depending on the task recurrence.					
C_CPU_LOAD_SES_T_END	1	1..1F4H	1..500	1	-
Type: S16. End of meas. session. In a 2ms task the max. allowed session time of 1s is set by using factor 500.					
C_CPU_LOAD_SES_CTR_INI	1	8000..0H	-32768..0	1	-
Type: S16. Start delay of measurement session.					
C_CPU_LOAD_FTC	1	0..FFFFH	0..0.9999	1/65536	-
Type: U16. Filter time constant for CPU_LOAD_FIL.					

C_CPU_LOAD_TSK_PER_MIN and C_CPU_LOAD_TSK_MES_DLY:

The calibration C_CPU_LOAD_TSK_PER_MIN must be set equal to the value CPU_LOAD_TSK_PER_MIN after it is computed depending on the temporization value C_CPU_LOAD_TSK_MES_DLY.

C_CPU_LOAD_PER and C_CPU_LOAD_SES_T_END:

The measurement window is to be set with C_CPU_LOAD_PER (modulo counter of measurement session, measurement window always starts if counter is zero and if start is allowed) and C_CPU_LOAD_SES_T_END (measurement window stops at this counter value). If C_CPU_LOAD_PER is equal to C_CPU_LOAD_SES_T_END the duty cycle of the measurement is 100%.

C_CPU_LOAD_SES_CTR_INI:

With C_CPU_LOAD_SES_CTR_INI an easy start delay of measurement session can be set. The content of the value is calculated with

$$\mathrm{C\_CPU\_LOAD\_SES\_CTR\_INI} = -\frac{\text{requested start delay}}{\text{time triggered function recurrence}}$$

Example: The requested start delay after OS initialization is 500ms. The time triggered function is called every 100ms.

$$\mathrm{C\_CPU\_LOAD\_SES\_CTR\_INI} = -\frac{500\mathrm{ms}}{100\mathrm{ms}} = -5$$

C_CPU_LOAD_FTC:

Filter time constant for filtered CPU load (CPU_LOAD_FIL).

$\mathrm{C\_CPU\_LOAD\_FTC} = \frac{T \cdot n_{mod}}{T \cdot n_{mod} + T_1}$, with T = recurrence of time triggered function, n_{mod} is the modulo counter C_CPU_LOAD_PER and T1 is the needed filter time.

Example: The time triggered function is called every 100ms. n_{mod} is set to 6. The filter time shall be 2s.

$$\mathrm{C\_CPU\_LOAD\_FTC} = \frac{100\mathrm{ms} \cdot 6}{100\mathrm{ms} \cdot 6 + 2\mathrm{s}} = \frac{600\mathrm{ms}}{600\mathrm{ms} + 2000\mathrm{ms}} = 0.2308 \text{ phys.} \rightarrow 15124\text{d (3B14H)}$$

56.1 Acquisition of after relay battery voltage

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VB_MES	O	0...3FFH	0...28.7055	2.81E-02	[V]
Computed battery voltage					

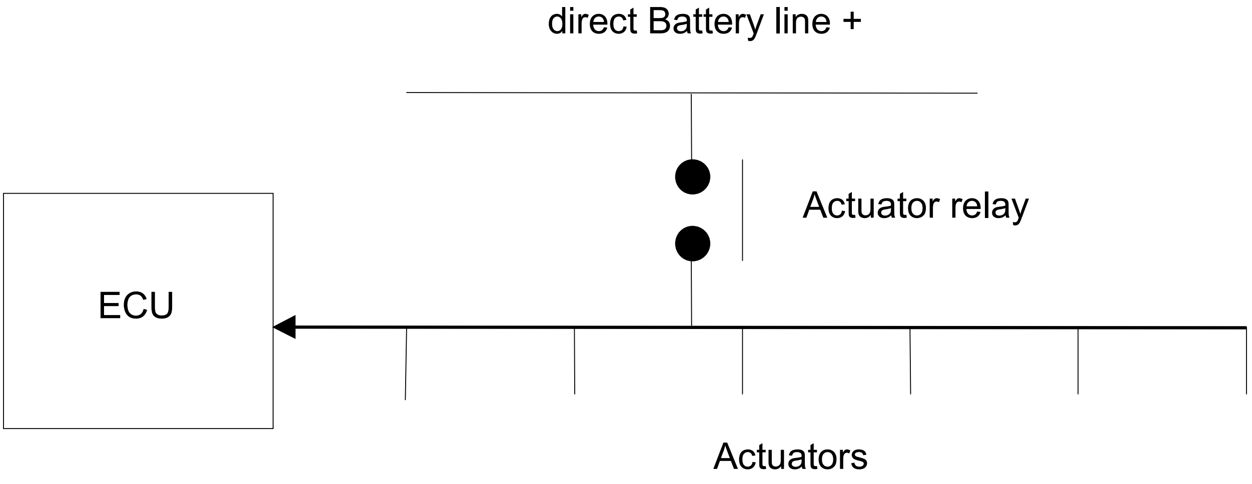
Input data:

VB_BAS			

FUNCTION DESCRIPTION:

General information:

The acquisition of the raw values is performed every 1 ms with the resolution of 10 bits.



Application conditions:

Activation: at reset

Initialization: VB_MES = 0.

Recurrence : NC_VB_SAMPLE_NR ms

System Description:

The range of VB_BAS and VB_MES depends to the voltage divider (means 0 - 5V at ADC) at the input of the µC. The input is the ADC-value of the VB-Pin.

Formula section:

$$VB\_MES = (1/NC\_VB\_SAMPLE\_NR) * \sum_{n=1}^{NC\_VB\_SAMPLE\_NR} VB\_BAS_n$$

NC_VB_SAMPLE_NR = 2^n ; 1 =< n =< 6 (NC_VB_SAMPLE_NR is initialized with 4 or 8)

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_VB_SAMPLE_NR	1	0...FFH	0...255	1	[-]
Number of acquisition for filtering					
NC_VB_MAX	1	B4...140H	18...32	0.1	[V]
Maximum battery voltage linked to the voltage dividor					

56.2 Acquisition of raw after key battery voltage

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_IGK_MES	V/O	0...3FFH	0...28.7055	2.81E-02	[V]
Computed ignition key voltage					

Input data:

V_IGK_BAS			

FUNCTION DESCRIPTION:

General information:

The acquisition of the raw values is performed every 1 ms with the resolution of 10 bits. V_IGK_BAS is the same ADC-value which is used in Key on/Key off detection.

Application conditions:

Activation: at reset

Initialization: V_IGK_MES = 0

Recurrence : NC_V_IGK_SAMPLE_NR ms

Formula section:

$$V\_IGK\_MES = (1/NC\_V\_IGK\_SAMPLE\_NR) * \sum_{n=1}^{NC\_V\_IGK\_SAMPLE\_NR} V\_IGK\_BAS_n$$

$NC\_V\_IGK\_SAMPLE\_NR = 2^{n}$; 1 =< n =< 6 (NC_V_IGK_SAMPLE_NR is initialized with 4 or 8)

Configuration data:

Name	DIM	Hex. limits	Phys. limits	Resol.	Unit
NC_V_IGK_MAX	1	B4...140H	18...32	0.1	[V]
Maximum battery voltage linked to the voltage divisor of the key voltage					
NC_V_IGK_SAMPLE_NR	1	0...FFH	0...255	1	[-]
Number of acquisition for filtering					

56.3 Input system event : Key off recognition

Output data:

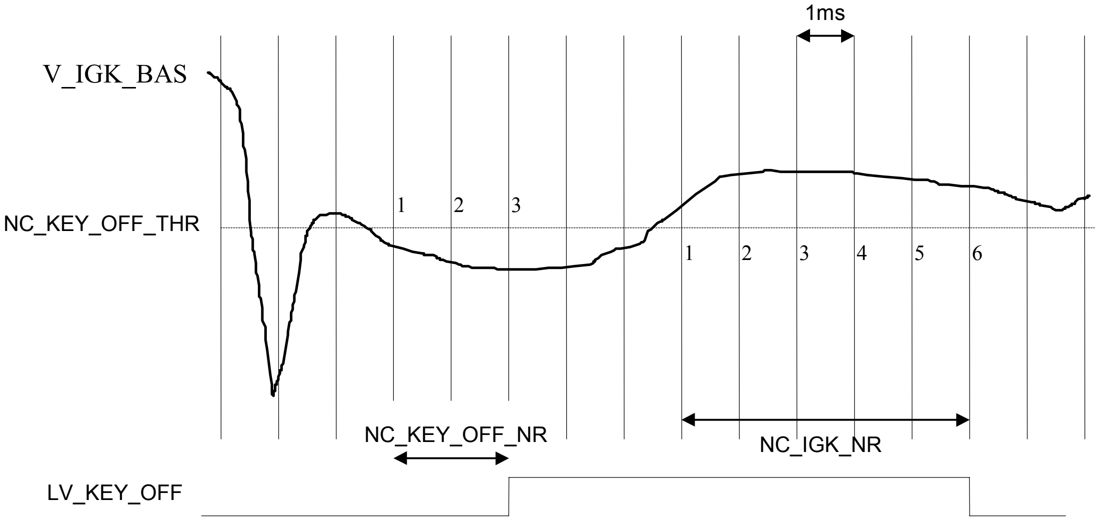
Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_KEY_OFF_THR	1	0...3FFH	0...28.7055	0.0280601	[V]
Threshold for key off detection (typical value : 142 = 4 Volts)					
NC_KEY_OFF_NR	1	0...FFH	0...255	1	[-]
Samples filter for key off detection (typical value : 3)					
NC_IGK_NR	1	0...FFH	0...255	1	[-]
Samples filter for key on detection (typical value : 6)					

FUNCTION DESCRIPTION:

General information:

According to the battery voltage raw value (V_IGK_BAS) after ignition key, the ignition key ON / OFF recognition is performed.



See on Analogic Acquisition Sampling chapter the recurrence of V_IGK_BAS acquisition.

Application conditions:

Activation: at reset

Initialization:

```
if      first value V_IGK_BAS > NC_KEY_OFF_THR
  then        LV_KEY_OFF  =  0
  else        LV_KEY_OFF  =  1
endif
```

Recurrency: 1ms

Formula section:

Ignition key ON recognised :

```
If      V_IGK_BAS > NC_KEY_OFF_THR
        for at least NC_IGK_NR number of successive samples ( * 1 msec. )
then    LV_KEY_OFF = 0 (ON)
```

Ignition key OFF recognised :

```
If      V_IGK_BAS ≤ NC_KEY_OFF_THR
        for at least NC_KEY_OFF_NR number of successive samples ( * 1 msec. )
then    LV_KEY_OFF = 1 (OFF)
```

56.4 Ignition : Key on recognition

FUNCTION DESCRIPTION:

Application conditions:

Activation: at reset

Initialization: LV_IGK = 0
LV_WAKE_UP = 0
T_IGK_LIH = C_T_IGK_LIH
LV_IGK_PREL = 1
T_DLY_IGK_OFF_PREL = C_T_DLY_IGK_OFF_PREL
T_TEMP_IGK_OFF_PREL = C_T_TEMP_IGK_OFF_PREL

Recurrency: 10ms

Formula section:

56.4.1 Vehicle without BN2000 (LV_VAR_BN = 0)

```
If    LV_KEY_OFF = 1   and   T_DLY_IGK_OFF_PREL > 0
  then      LV_IGK_PREL  =  0

56.5 PWSL - Requirements to infrastructure interface

Export actions:

ACTION_INFR_GetElDiagRlyMain(OUT<cdn_diag_rly_main>, **OUT**<err_rly_main>**)**
Return of the electric diagnosis for the main relay
ACTION_INFR_GetVDcdcSopc(OUT<PRM_VDCDC>)
Return the output voltage of the DCDC converter
ACTION_INFR_SetIGK_OFF(IN <LV_IGK_OFF_ACK >)
This action sets the output pin for acknowledge IGK off / the starter relay for start stop automatic (STST)
ACTION_INFR_GetElDiagIGK_OFF(OUT<CDN_DIAG_ACK_IGK_OFF>, OUT <ERR_DIAG_ACK_IGK_OFF>)
This action returns diagnosis status of acknowledge IGK off line / start relay STST driver stage (conditions and symptoms).

Description for actions:

ACTION_INFR_GetElDiagRlyMain(OUT<cdn_diag_rly_main**>, OUT<**err_rly_main**>)**					
This action reads the value of cdn_diag_rly_main respectively err_rly_main. In case of bit 1, the diagnosis condition is fulfilled otherwise the diagnosis condition isn´t fulfilled if the bit is equal 0. In case of error err_rly_main is set to 1 or 0 if no error occurs					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
cdn_diag_rly_main	OUT	0...7H	0...7	1	-
Diagnosis condition for symptoms of lv_cdn_diag_RLY_MAIN: bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled					
err_rly_main	OUT	0...7H	0...7	1	-
Raw value of error symptom: bit 0: Set, if raw value of error symptom SCP (SYM_0) is set bit 1: Set, if raw value of error symptom SCG (SYM_1) is set bit 2: Set, if raw value of error symptom OC (SYM_2) is set					
Raw value of error symptom. The relevant bit is set, if the error has been detected.					
ACTION_INFR_SetIGK_OFF(IN < LV_IGK_OFF_ACK >)					
This action sets the output pin for acknowledge IGK off / the starter relay STST					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
LV_IGK_OFF_ACK	IN	0H 1H	output pin high output pin low	1	-
Acknowledge IGK off / Starter relay STST control bit					
ACTION_INFR_GetElDiagIGK_OFF(OUT <CDN_DIAG_ACK_IGK_OFF>, **OUT** <ERR_DIAG_ACK_IGK_OFF>**)**					
This action returns diagnosis status of acknowledge IGK off line / start relay STST driver stage (conditions and symptoms).					
Parameter	**Type**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
CDN_DIAG_ACK_IGK_OFF	OUT	0...7H	0...7	1	[-]

FUNCTION DESCRIPTION:

General information:

Description for actions:

ACTION_INFR_GetVDcdcSopc(OUT<PRM_VDCDC>)					
Return the output voltage of the DCDC converter					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_VDCDC	OUT	0 ... 7FFF H	0 ... 639.98046875	640/32768	V
Returns the output voltage of the DC/DC converter					

Requirements for ACTION_INFR_GetElDiagRlyMain:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
cdn_diag_rly_main	-	-	<bit coded>	err_diag_rly_main	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2)
err_rly_main	-	-	<bit coded>	cdn_diag_rly_main	Bitcoded result of each symptom **bit 0:** raw value of error symptom SCP (SYM_0) **bit 1:** raw value of error symptom SCG (SYM_1) . **bit 2:** raw value of error symptom OC (SYM_2)

Diagnosis: ACTION_INFR_GetElDiagRlyMain returns the electric diagnosis for the Main Relay.

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_GetVDcdcSopc:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
PRM_VDCDC	640/32768 V	-	640/32768 V		This OUT parameter returns the output voltage of the DC/DC converter

Requirements for ACTION_INFR_SetIGK_OFF

The acknowledge IGK off / starter relay STST is controlled by the ECU output pin 1-13 (N43: MSA, N53: RES_OUT_7 , N54: SAP).

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

lv_igk_off_ack	-	-	<bit coded>		0H = output pin shall be switched to high off, 1H = output pin shall be switched to low

Diagnosis: no electrical diagnosis done here

Coincidence requirements: -

Requirements for ACTION_INFR_GetElDiagIGK_OFF

This action returns the result of the electric diagnosis of acknowledge IGK off / starter relay power stage for start stop automatic (STST).

- The device readout is performed autonomous by the Infrastructure each 10 ms.
- The error informations are gathered in the Infrastructure (or-ed symptom) until the Application reads out the information by calling ACTION_INFR_GetElDiagIGK_OFF.
- After having read out the information by calling ACTION_INFR_GetElDiagIGK_OFF, the data inside the Infrastructure are reset. Resetting of cdn_diag... avoids unambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagIGK_OFF: Reset cdn_diag... indicates, that the gathering of the information is not completely finished.

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
cdn_diag_ack_igk_off	-	-	1	err_diag_ack_igk_off	Diagnosis condition for each symptom - Bit 0 : Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled - Bit 1 : Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled - Bit 2 : Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled

Diagnosis: ACTION_INFR_GetElDiagIGK_OFF returns electric diagnosis of acknowledge IGK off / start relay control STST signal

Coincidence requirements: No coincidence requirements with other events

56.6 AGGR PWSL adaptation

56.6.1 Outputs for SV aggregates, SV internally

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_VB_CDN_OBD_1	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for OBD-I diagnosis					
LV_VB_CDN_OBD_2	V/O	0...1H	0...1	1	-
Boolean for battery voltage condition fulfilled for OBD-II diagnosis					

Input data:

LV_CDN_VB_OBD1	LV_CDN_VB_OBD2	

FUNCTION DESCRIPTION:

Adaptation to aggregate environment.

Application conditions:

Initialisation: 0

Recurrence : same recurrence as corresponding input data

Activation: every engine operating state

Formula section:

LV_VB_CDN_OBD_1 = LV_CDN_VB_OBD1

LV_VB_CDN_OBD_2 = LV_CDN_VB_OBD2

56.7 Battery voltage VB

56.7.1 Computation of VB

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VB	V/O	0...FFH	0...25.89843	0.1015625	[V]
Relay - battery voltage					
V_IGK	V/O	0...FFH	0...25.89843	0.1015625	[V]
Key - battery voltage					

Input data:

VB_MES	V_IGK_MES		

FUNCTION DESCRIPTION:

General information:

The battery voltage (V_IGK_MES and VB_MES (10 bit)) is measured up to 30V, 28V or 26V (means 0-5V at ADC), depending on the project-specific solution, but the range of VB (8 bit) remains 0-26 V. For the computation of VB in hex the correction factor NC_FAC_VB_RATIO is necessary; its value depends on the project-specific battery voltage range. NC_FAC_VB_RATIO is definded in the “List of Configuration Datas”. The following table shows how NC_FAC_VB_RATIO is formed.

Measured battery voltage range (for example)	NC_FAC_VB_RATIO
0 ..... 26 V	26V / 26V
0 .. 28,8 V	28,8V / 26V
0 ..... 30 V	30V / 26V

Application conditions:

Activation: at reset

Initialisation: VB = 0

V_IGK = 0

Recurrence: 10 ms

Formula section:

HEX calculation:

VB = (VB_MES / 4) * NC_FAC_VB_RATIO

V_IGK = (V_IGK_MES / 4) * NC_FAC_VB_RATIO

VB relay:

```
If      VB_MES <= 26 Volt
Then    VB = (VB_MES / 4 ) * NC_FAC_VB_RATIO
Else    VB = 26 Volt        (FF hex)
Endif
```

VB key:

```
If      V_IGK_MES <= 26 Volt
Then    V_IGK = (V_IGK_MES / 4 ) * NC_FAC_VB_RATIO
Else    V_IGK = 26 Volt        (FF hex)
Endif
```

56.7.2 Secured battery voltage computation

Output data:

Name	V/S	Hex. limits	Phys. limits	Resol.	Unit
VB_SECU	V	0...FFH	0...25.89843	0.1015625	[V]
Battery Voltage secured for dwell computation					

Input data:

VB			

Description:

A secured battery voltage value is a mix of VB and V_IGK values which provides a safer battery voltage for functions especially in case of VB - relay wire to the ECU disconnection.

The securate battery voltage value can be used for exemple for dwell computation in order to protect ignition coil and ECU ignition output stage against too long dwell time.

VB_SECU = MAX(VB, V_IGK - NC_VB_SECU)

with VB_SECU - NC_VB_SECU satured to zero

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_VB_SECU	1	0...FFH	0...25.89843	0.1015625	[V]
Battery voltage offset (typical value = 1,02V)					
NC_FAC_VB_RATIO	1	0...FFH	0...1.99218	0.0078125	[-]
Factor to adapt the HEX-range to the range of 0 to 26 V					

56.7.3 Battery voltage conditions for diagnosis / jump start detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_VB_JUMP	V/O	0...1H	0...1	1	[-]
Logical value for detected overvoltage (jump start)					
LV_CDN_VB_OBD1	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for OBD diagnosis (=10V)					
LV_CDN_VB_OBD2	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for OBD-II diagnosis (=11V)					
LV_CDN_VB_MIN_DIAG	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for remaining diagnosis					
LV_CDN_VB_CAN_DIAG	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for CAN diagnosis					
LV_CDN_VB_BN_DIAG	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for BN2000 diagnosis					
LV_CDN_VB_CAN_TQ_DIAG	V/O	0...1H	0...1	1	[-]
Boolean for battery voltage condition fulfilled for TQ_CAN-interfaces					

Input data:

VB	LV_IGK		

FUNCTION DESCRIPTION:

General information:

Depending on VB there is a detection:

- Jump start
- Valid range for OBD1 diagnosis
- Valid range for OBD2 diagnosis
- Valid range for CAN diagnosis
- Valid range for BN2000 diagnosis
- Valid range for TQ-CAN interface diagnosis
- Valid range for remaining customer diagnosis

Application conditions:

Initialisation: all 0

Recurrence: 10ms

Activation: at reset

56.7.3.1 Detection of overvoltage (Jump start)

Description:

The bit LV_VB_JUMP is used by functions which must not run when overvoltage is detected for example secondary air injection to prevent damages to the components.

Formula section:

Jump start detection:

```
If      VB  > C_VB_MIN_JUMP
Then    LV_VB_JUMP = 1
Else    LV_VB_JUMP = 0
Endif
```

56.7.3.2 Battery voltage valid for OBD diagnosis

Description:

Depending of OBD1/OBD2 there is a different flag for the valid VB range

Formula section:

Valid range for OBD1 diagnosis:

```
If      VB > C_VB_MIN_OBD1 and VB < C_VB_MAX_OBD1
Then    LV_CDN_VB_OBD1 = 1
Else    LV_CDN_VB_OBD1 = 0
Endif
```

Valid range for OBD2 diagnosis:

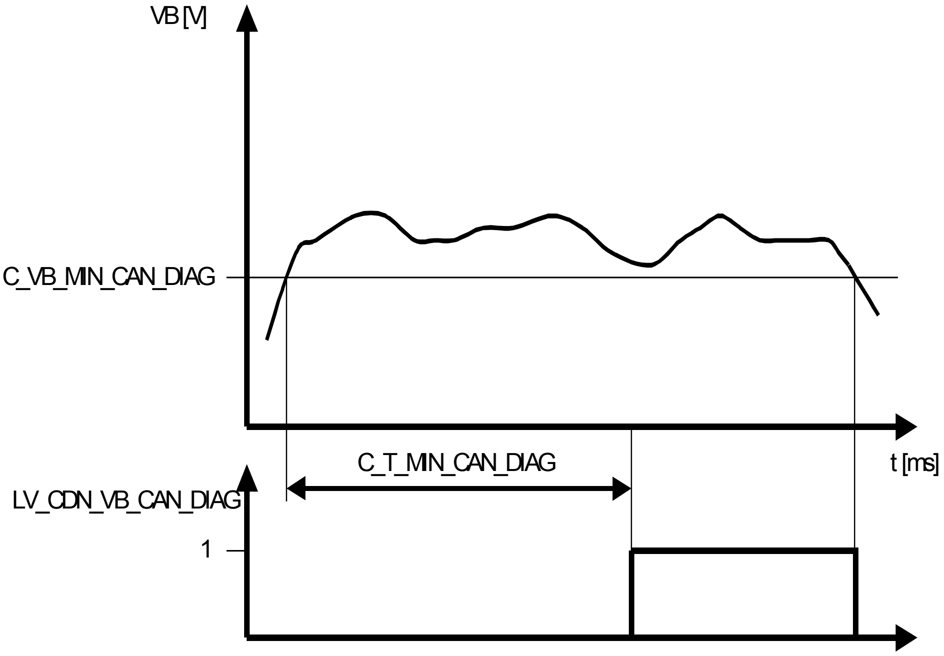
```
If      VB > C_VB_MIN_OBD2  and VB < C_VB_MAX_OBD2
Then    LV_CDN_VB_OBD2 = 1
Else    LV_CDN_VB_OBD2 = 0
Endif
```

56.7.3.3 Minimum battery voltage detection for CAN diagnosis

Description:

Due to low battery voltage CAN messages can be mutilated. So CAN timeout diagnosis is only done if battery voltage is valid for a minimum duration time.

Signal flow diagram:



Formula section:

Valid range for CAN diagnosis:

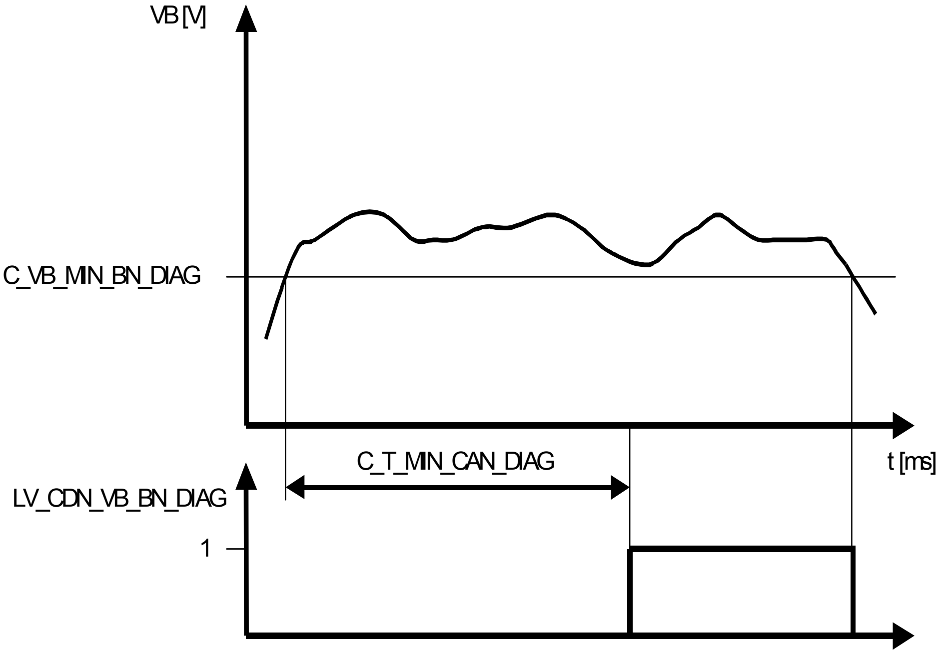
```
If      LV_IGK = 1                      and
        VB  >  C_VB_MIN_CAN_DIAG        for
        time > C_T_MIN_CAN_DIAG
         (timer always started at every transition VB  >  C_VB_CAN_DIAG
        and at transition LV_IGK 0 -> 1)
Then    LV_CDN_VB_CAN_DIAG = 1
Else    LV_CDN_VB_CAN_DIAG = 0
Endif
```

56.7.3.4 Minimum battery voltage detection for BN2000 diagnosis

Description:

Due to low battery voltage BN2000 messages can be mutilated. So BN2000 timeout diagnosis is only done if battery voltage is valid for a minimum duration time.

Signal flow diagram:



Formula section:

Valid range for BN2000 diagnosis:

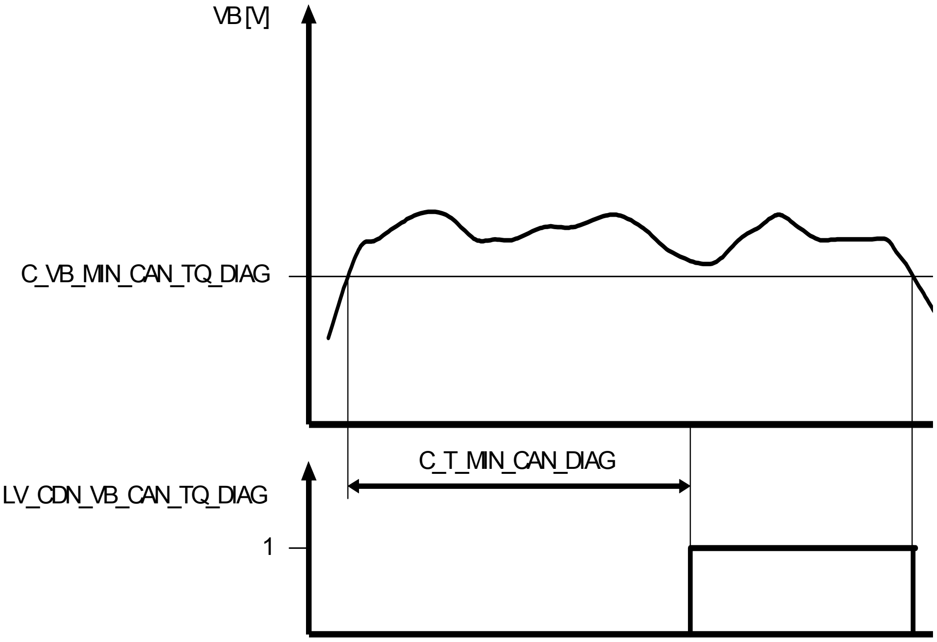
```
If      LV_IGK = 1                     and
        VB  >  C_VB_MIN_BN_DIAG        for
        time > C_T_MIN_CAN_DIAG
         (timer always started at every transition VB  >  C_VB_BN_DIAG
        and at transition LV_IGK 0 -> 1)
Then    LV_CDN_VB_BN_DIAG = 1
Else    LV_CDN_VB_BN_DIAG = 0
Endif
```

56.7.3.5 Minimum battery voltage detection for TQ_CAN-interfaces

Description:

Due to low battery voltage CAN messages can be mutilated. So the TQ_CAN-interfaces should only be enabled if battery voltage is valid for a minimum duration time.

Signal flow diagram:



Formula section:

Valid range for BN2000 diagnosis:

```
If      LV_IGK = 1                      and
        VB  >  C_VB_MIN_CAN_TQ_DIAG for
        time > C_T_MIN_CAN_DIAG
        (timer always started at every transition VB > C_VB_MIN_CAN_TQ_DIAG
        and at transition LV_IGK 0 -> 1)
Then    LV_CDN_VB_CAN_TQ_DIAG = 1
Else    LV_CDN_VB_CAN_TQ_DIAG = 0
Endif
```

56.7.3.6 Minimum Battery Voltage Detection for non OBD Diagnosis

Description:

The remaining diagnosis functions which are not covered by the above mentioned conditions are disabled below a separate threshold, which should be lower as OBD1/2 and CAN.

Formula section:

Valid range for non OBD diagnosis:

```
If      VB < C_VB_MIN_DIAG   or
        LV_IGK = 0
Then    LV_CDN_VB_MIN_DIAG = 0
Else    LV_CDN_VB_MIN_DIAG = 1
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VB_MIN_JUMP	1	0...FFH	0...25.89843	0.1015625	[V]
VB -threshold for maximum permissible battery voltage					
C_VB_MIN_OBD1	1	0...FFH	0...25.89843	0.1015625	[V]
VB –threshold for minimum permissible battery voltage for OBD diagnosis					
C_VB_MAX_OBD1	1	0...FFH	0...25.89843	0.1015625	[V]
VB -threshold for maximum permissible battery voltage for OBD diagnosis					
C_VB_MIN_OBD2	1	0...FFH	0...25.89843	0.1015625	[V]
VB -threshold for minimum permissible battery voltage for OBD2 diagnosis					
C_VB_MAX_OBD2	1	0...FFH	0...25.89843	0.1015625	[V]
VB -threshold for maximum permissible battery voltage for OBD2 diagnosis					
C_VB_MIN_DIAG	1	0...FFH	0...25.89843	0.1015625	[V]
Battery voltage threshold for low voltage detection for remaining diagnosis					
C_VB_MIN_CAN_DIAG	1	0...FFH	0...25.89843	0.1015625	[V]
Battery voltage threshold for CAN diagnosis					
C_T_MIN_CAN_DIAG	1	0...FFH	0...2550	10	[ms]
VB-Time-condition for CAN diagnosis					
C_VB_MIN_BN_DIAG	1	0...FFH	0...25.89843	0.1015625	[V]
Battery voltage threshold for BN2000 diagnosis					
C_VB_MIN_CAN_TQ_DIAG	1	0...FFH	0...25.89843	0.1015625	[V]
Battery voltage threshold for CAN-TQ interface diagnosis					

56.7.4 Moving average value for battery voltage

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VB_MMV	V/O	0...FFH	0...25.89843	0.1015625	[V]
Moving mean value of battery voltage VB					

Input data:

VB			

A moving average value VB_MMV is used in the chapter “Engine speed setpoint calculation” to define a minimum N_SP_IS in dependance of the battery voltage:

Application conditions:

Activation: *at reset*

Initialization: VB_MMV = 14 V

Recurrence: 10 ms

Formula section:

$VB\_MMV_k = VB\_MMV_{k-1} + (VB_k - VB\_MMV_{k-1}) \cdot C\_CRLC\_VB.$

Calibration data:

Name	**Dim**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
C_CRLC_VB	1	0...FFH	0...0.99609	3.91E-03	[-]
Low pass filter correlation constant for VB_MMV					

56.8 Main relay control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_RLY_MAIN	V/O	0...1H	0...1	1	[-]

C_T_IGK_OFF_ACK_DIAG_PLS	1	0...FFH	0...2.55	0.01	[s]
Timer constant for diagnosis pulse, in which acknowledge IGK off pin level is set to Low					

Import actions:

ACTION_INFR_SetIGK_OFF(IN <lv_igk_off_ack>**)**
This action sets the output pin level for acknowledge IGK off / starter relay control for engine start stop automatic (STST)

56.8.1 Main relay control

FUNCTION DESCRIPTION:

General information:

Purpose of this module is to get an entry point to switch on or off the main relay and get a status of the control command through LV_RLY_MAIN.

Upon ignition key transition from OFF to ON, the ECU voltage regulator is set to ON and the core microprocessor is reset. Then, so as to power up the system (system = ECU + actuators + sensors), the main relay has to be switched ON (most of actuators are supplied by the main relay).

Upon ignition key transition from ON to OFF, the ECU enters in the post-operating phase. At its end, the system shutdown is obtained by disabling the power supply on sensors and actuators. For that it is necessary to switch off the main relay. Then, the ECU can be switched off too.

To summarize, the main relay is switched on as soon as the ignition key is turned in the ON position and it remains ON until the ECU voltage regulator is switched off.

The system depending switching state is stored in the flag LV_RLY_MAIN_SYS. This request can be overruled by the request of the calibration system or tester (serial communication). To prevent destruction of components (actuators which are supplied via main relay), switching is only allowed when engine stopped (LV_ES =1). While engine is running, always the system depending switching state is used.

Table with z-axis for STATE_TBL_ALTER and STATE_TBL_ALTER_DC					

FUNCTION DESCRIPTION:

This function delivers a alternator use profile over alternator load, alterantor chip temperatur and alterantor speed.

During a driving cycle (LV_ES = 0 and LV_ST_END = 1) the absolute temporary use profile STATE_TBL_ALTER_DC is calculated. It is a accumulated time of the related alternator operating points. Additional an timer is incremented (T_STATE_TBL_ALTER_DC) during calculation of STATE_TBL_ALTER_DC.

After a driving cycle (LV_ES 0->1) the relative use profile STATE_TBL_ALTER is calculated out of STATE_TBL_ALTER_DC, the old profile STATE_TBL_ALTER and the timer T_STATE_TBL_ALTER / _DC. This profile is saved in non volatile memory. The timer is calculated out of it's old value and the new timer T_STATE_TBL_ALTER_DC and is saved in non volatile memory. The timer T_STATE_TBL_ALTER and the profile STATE_TBL_ALTER show the behaviour of the alternator during the lifetime of the vehicle.

T_STATE_TBL_ALTER and STATE_TBL_ALTER are saved in NVMY during power latch phase.

Application conditions:

Initialisation: STATE_TBL_ALTER and T_STATE_TBL_ALTER from NVMY, all other = 0 at reset,

at LC_AD_CLR 0->1 **or** LC_AD_CLR_ALTER 0->1, T_STATE_TBL_ALTER = 0 and STATE_TBL_ALTER = 0

Recurrence: 1s

Activation: at every engine state

Formula section:

```
// Calculation of alternator profile during driving cycle:
If    LV_ES = 0  and  LV_ST_END = 1  and  LV_STATE_TBL_ALTER_INH = 0
Then        // calculation of STATE_TBL_ALTER_DC with x = ID_STATE_TEMP_ALTER,
            // y = ID_STATE_LOAD_ALTER, z = ID_STATE_N_ALTER:

diagnosis condition					
LV_END_DIAG_PLAUS_IGK_BN	V/O	0...1H	0...1	1	[-]
end of diagnosis					

Input data:

STATE_PLAUS_IGK_BN	VB	LV_VAR_BN	

FUNCTION DESCRIPTION:

Description:

For BN2000-vehicles there are two possibilities of getting the LV_IGK-signal:

1) via CAN (from the control unit CAS)

2) via HW-signal (“Weckleitung”)

In order to detect a CAS error or a HW-error (e.g. shortcut to ground) a plausibility check has to be done between CAN-signal and HW-signal.

Error symptoms are defined to this diagnosis function as follows:

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> -   short cut to battery        (= SYM_0)
 │  │  └────> -   short cut to ground         (= SYM_1)
 │  └───────> -   CAS error                   (= SYM_2)
 └──────────> -   CAS-plausibility error      (= SYM_3)
```

Application conditions:

Initialisation: all 0 at reset

Recurrence: 10ms

Activation:

```
if      LV_VAR_BN = 1
Then    if      (VB > = C_VB_MIN_IGK_DIAG)
        then    LV_CDN_DIAG_PLAUS_IGK_BN = 1
        endif
Else    LV_CDN_DIAG_PLAUS_IGK_BN = 0
Endif
```

Deactivation:

```
if      (VB < C_VB_MIN_IGK_DIAG)        or
        at      State bus sleep
then    LV_CDN_DIAG_PLAUS_IGK_BN = 0
endif
```

Formula section:

```
IF      STATE_PLAUS_IGK_BN = 0H
THEN    ERR_SYM_PLAUS_IGK_BN = NO_SYM
        LV_ERR_PLAUS_IGK_BN = 0     after rebounce
ELSEIF  STATE_PLAUS_IGK_BN = 1H
THEN    ERR_SYM_PLAUS_IGK_BN = SYM_0            //SCB, Master CAN
        LV_ERR_PLAUS_IGK_BN = 1     after debounce
ELSEIF  STATE_PLAUS_IGK_BN = 2H
THEN    ERR_SYM_PLAUS_IGK_BN = SYM_1            //SCG, Master CAN
        LV_ERR_PLAUS_IGK_BN = 1     after debounce
ELSEIF  STATE_PLAUS_IGK_BN = 4H
THEN    ERR_SYM_PLAUS_IGK_BN = SYM_2            //CAS error, Master HW
        LV_ERR_PLAUS_IGK_BN = 1     after debounce
ELSEIF  STATE_PLAUS_IGK_BN = 8H
        LV_ERR_PLAUS_IGK_BN = 1     after debounce
THEN    ERR_SYM_PLAUS_IGK_BN = SYM_3            // CAN-signal not plausible
ENDIF
```

For calculation of condition-diagnosis-bit and end of diagnosis-bit LV_END_DIAG_PLAUS_IGK_BN see “Anti-bounce – algorithmus, calculation of the end of diagnosis”

FUNCTION DESCRIPTION:

General information:

The Main Relay Diagnosis is performed to detect if the Main Relay has switched and remains on after Key-On and if it has switched off after the Power Latch Phase.

56.11.1 Main relay “switch on” / "switched off" diagnosis

Description:

The diagnosis is delayed for C_T_DLY_RLY_MAIN_DIAG to allow the relay to switch on/off. After this the actual VB is compared with a diagnostic threshold. If the error conditions are fulfilled the error is debounced.

If an error is detected after the Power Latch Phase the ECU is switched off after T_RLY_MAIN_DIAG has elapsed.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Main relays has not switched off     (= SYM_0)
 │ │ └───> Main relays has not switched on      (= SYM_1)
 │ └─────> -                                    (= SYM_2)
 └───────> -                                    (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 or reset or at clearing error memory but

T_RLY_MAIN_DIAG is calculated as described below

Recurrence:

The application recurrence for the Diagnosis is **10 ms**;
The „Main Relay Off“-Detection is performed only once after power latch.

Activation: see Formula section

Formula section:

Detection if Main Relay is on during Key-On

Call I/O Power-Stage-Diagnosis (Short to Ubatt) and ignore return value in order to restart the Power- Stage after shut off due to short circuit to battery

//this is done to try to wake up the power stage after instable battery voltage

ACTION_INFR_GetElDiagRlyMain (**OUT**<cdn_diag_rly_main>, **OUT**<err_rly_main>)

```
If(1)     LV_RLY_MAIN = 1                          and

            Else(2)     C_T_DLY_RLY_MAIN_DIAG               //is still running
            Endif(2)
    Else(1) LV_CDN_DIAG_RLY_MAIN = 0                        //no Diagnosis
    Endif(1)
    set lock condition once to extend power latch phase (PWL_LOCK_CDN)
```

Calculation end of diagnosis

LV_END_DIAG_RLY_MAIN is calculated by error management after diagnosis is active

Detection if Main Relay is off after Power Latch Phase:

```
If(1)       LV_RLY_MAIN = 0
Then(1)         LV_END_DIAG_RLY_MAIN = 0
                LV_ERR_RLY_MAIN = 0     //reset of error to be able to set it with new symptom
                start time:   C_T_DLY_RLY_MAIN_DIAG
                //time to allow the relay to switch
            If(2)       PWL_LOCK_CDN is set and
                        C_T_DLY_RLY_MAIN_DIAG has run out
            Then(2)     start  T_RLY_MAIN_DIAG  for  C_T_RLY_MAIN_DIAG
                        (start the time window during  the diagnosis is performed)
                If(3)       T_RLY_MAIN_DIAG  is still running
                Then(3)     LV_CDN_DIAG_RLY_MAIN = 1
                    If(4)       VB  >  C_VB_RLY_MAIN_DIAG
                                //connection to battery via main relay
                    Then(4)     ERR_SYM_RLY_MAIN = SYM_0
                                LV_ERR_RLY_MAIN = 1             //after debounce
                    Else(4)     ERR_SYM_RLY_MAIN = NO_SYM
                                LV_ERR_RLY_MAIN = 0             //after rebounce
                    Endif(4)
                Else(3)     LV_CDN_DIAG_RLY_MAIN = 0
                            erase lock condition for power latch phase (PWL_LOCK_CDN)
            Else(2)     T_RLY_MAIN_DIAG = 0                 //reset
                        LV_CDN_DIAG_RLY_MAIN = 0            //no switched off Diagnosis
            Endif(2)
    Else(1) LV_CDN_DIAG_RLY_MAIN = 0                        //no Diagnosis
    Endif(1)
```

56.11.2 Main relay “switched on too slow” diagnosis for pre-drive check

Description:

The main relay diagnosis is performed at reset to detect if the main relay has been switched on within the correct timing. This diagnostic is comparable to main relay switch on, but is separated for having faster reaction time.

Additionally, it is checked if the output voltage of the DCDC-converter has reached a minimum level. This minimum level is a necessary condition to perform the SOPC (switch off path check).

Once no failure has been found, diagnosis is then disabled.

The diagnosis starts after LV_IGK 0->1. After this the actual VB is compared with a diagnostic threshold. If the error conditions are fulfilled the error is debounced.

Error-symptoms are defined to this diagnosis function as following :

```
 ┌─┬─┬─┬─┐
 └─┴─┴─┴─┘
  │ │ │ └─> Main relay hasn't switched before predrive check    (= SYM_0)
  │ │ └───> -                                                   (= SYM_1)
  │ └─────> -                                                   (= SYM_2)
  └───────> DCDC converter voltage not high enough              (= SYM_3)
```

Application conditions:

Initialisation: ERRM data according filter type: **NO**

At reset : LV_CDN_DIAG_RLY_MAIN_DLY = 0
LV_ERR_RLY_MAIN_DLY = 0
ERR_SYM_RLY_MAIN_DLY = NO_SYM
CTR_END_DIAG_RLY_MAIN_DLY = 0
CTR_DIAG_RLY_MAIN_DLY = 0
LV_DIAG_END_RLY_MAIN_DLY = 0
LV_RLY_MAIN_DLY_ERR = 0
CTR_END_DIAG_VDCDC_SOPC = 0
CTR_DIAG_VDCDC_SOPC = 0

At clearing FMY: only reset of FMY variables according ERRM

Recurrence: 10 ms

Activation: LV_IGK = 1

Deactivation: LV_DIAG_END_RLY_MAIN_DLY = 1 **and** LV_RLY_MAIN_DLY_ERR = 0
set LV_CDN_DIAG_RLY_MAIN_DLY = 0

Formula section:

Number of recurrences with diagnosis deactivation after diagnosis activation conditions are met (= 2)					

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)
ACTION_INFR_GetElDiagIGK_OFF(OUT< Cdn_diag_ack_igk_off>, OUT< Err_diag_ack_igk_off >)

Note :

ACTION_INFR_GetElDiagIGK_OFF(), ACTION_INFR_SetElDiagIGK_OFF() are defined in the IRS (Infrastructure requirement specification)

FUNCTION DESCRIPTION:

General information:

The HW line acknowledge IGK off / starter relay for start stop automatic (STST) is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.
The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_ACK_IGK_OFF executions, to avoid the usage of wrong infrastructure information.

Error-symptoms and conditions: are defined to this diagnosis function as following

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	**Name**	**Description**	**Nr**		
HW line acknowledge IGK_OFF / starter relay for start stop automatic (STST)	ACK_IGK_OFF	Sym 0 Short circuit to battery (SCP)	0	MPL_STD_INI	CC
		Sym 1 Short circuit to ground (SCG)	1		
		Sym 2 Open circuit (OC)	2		
		Sym 3 -	3		

Application conditions:

Initialisation: at transition LV_IGK 0 --> 1:
Set delay counter for NC_PSD_DLY_ACK_IGK_OFF

at reset:
Set delay counter for NC_PSD_DLY_ACK_IGK_OFF

Recurrence:
```
If      LV_IGK_OFF_ACK = 0
then    100 ms
else    20ms
endif
```

Activation: LC_IGK_OFF_ACK = 1 **and** LV_IGK_OFF_ACK_ENA = 1

Deactivation: LC_IGK_OFF_ACK = 0 **or** LV_IGK_OFF_ACK_ENA = 0

Formula section:

```
If      LV_IGK = 1            and
        LV_CDN_VB_OBD1 = 1
Then
```

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_ACK_IGK_OFF and basic diagnosis conditions CDN_DIAG_ACK_IGK_OFF) received from the infrastructure:

ACTION_INFR_GetElDiagIGK_OFF (OUT<Cdn_diag_ack_igk_off>, OUT<Err_diag_ack_igk_off>)

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_ACK_IGK_OFF
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_ACK_IGK_OFF

```
        If Activation conditions are met for the NC_PSD_DLY_ACK_IGK_OFF
           recurrence of the diagnosis
        Then  [CDN_DIAG_ACK_IGK_OFF valid from Infrastructure]
        Else  CDN_DIAG_ACK_IGK_OFF = 0
        Endif

Else
        CDN_DIAG_ACK_IGK_OFF = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_ACK_IGK_OFF and ERR_DIAG_ACK_IGK_OFF.

ACTION_ERRM_FilterMulticondition (IN<ACK_IGK_OFF>, IN<CDN_DIAG_ACK_IGK_OFF>, IN<ERR_DIAG_ACK_IGK_OFF>, IN<C_ABC_INC_ACK_IGK_OFF>, IN<C_ABC_MAX_ACK_IGK_OFF>, OUT<LV_ERR_ACK_IGK_OFF>)
This algorithm determines:

ERR_DIAG_ACK_IGK_OFF	(detected error symptom for ACK_IGK_OFF diagnosis)
LV_ERR_ACK_IGK_OFF	(Error flag for debounced error of ACK_IGK_OFF)
LV_CDN_DIAG_ACK_IGK_OFF	(Diagnosis condition information)
LV_END_DIAG_ACK_IGK_OFF	(End of diagnosis information)

56.13 Functional diagnosis for generator switch off after start

Output data:

End of Diagnosis EGY_MIN for transportation mode					

Input data:

STATE_EGY_MIN_KWP	LV_IGK		

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect an activated energy spare mode. There are different energy spare modes. In this chapter the transportation mode is treated.

Error treatment:

Diagnostic Instance		Symptoms		ABC type	CARB class
Description	Name (XX)	Description	Nr		
Energy spare mode for transportation mode (EGY_MIN_2 - Energiesparmodus) error flag	EGY_MIN_2		0	NO	CC
		Transportmodus	1		
			2		
			3		

Possible configuration for ABC type and CARB class (see also “Table of Failure”)

ABC Type: STD_INI, STD, MEM, MEM_INI, DEC_CAL, STC, NO, MPL_STD_INI

CARB Class: MIS, FSD, CC, CAT, HC, EVAP, SA, AC, LS, LSH, EGR, OTHER, NO

Application conditions:

```
Initialisation:  all 0 at LV_IGK 0 -> 1 or reset
                 LV_END_DIAG_EGY_MIN_2 is initialized by ERRM
Recurrence:      1s
Activation:      If      LV_IGK = 1 and LC_EGY_MIN_DIAG_2 = 1
                 Then    LV_CDN_DIAG_EGY_MIN_2 = 1
                 Endif
Deactivation:    If      LV_IGK = 0 or LC_EGY_MIN_DIAG_2 = 0
                 Then    LV_CDN_DIAG_EGY_MIN_2 = 0
                 Endif
```

Formula section:

```
If      STATE_EGY_MIN_KWP = 2
Then    LV_ERR_EGY_MIN_2 = 1

56.15.1 Outputs for BMW functions which are not defined as PWSL exported data

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the output are different from the specified values due to the input data attributes.

General information:

In case of vehicle variant E60 the DME takes over certain functionalities of the former “Powermodul”-ECU. If no IBS is implemented in the car these functionalities are calculated by the ultra-low-cost-powermanagement (an add-on to the actual powermanagement).

Application conditions:

Initialisation: all 0 after reset

except:

ALTER_COD_0 = 7 H // initalisation to max value

ALTER_COD_1 = 1F H // initalisation to max value

```
If LV_VAR_BN = 0  then                // for  CAN 11
        B_kl15_ep = 1
        B_kl15_vorab = 1
endif
```

Ub = Batt_coort = W_ub = 1st valid ADC-value

U_fgen x = 1st calculated value

Gen_manufak = Gen_typkenn = 255

B_rd_gentyp = 1

B_dev0..7detec = LF_BSD_CPT_AVL

Recurrence : all BSD driver timing

except:

```

Tlrfgen = T_LOAD_RESP_ALTER (according the table~~s~~ below)

for writing into register 1 (three bit's for information reserved)

ID_KFTLRGEN2_INV	n=0	n=1	n=2	n=3	n=4	n=5	n=6	n=7	output data: T_lrfgen
tn [sec]	0	0,2	0,4	3	6	9	12	15	input data: T_LOAD_RESP_ALTER

Depending on ALTER_COD_0 and ALTER_COD_1 the load response should be read/writen out/into register 1 (see fkt-LR-write). tn [sec] can't be send by BSD directly because the number of protocoll bits are limited. This bit combination has to be translated according the tables. Translation from bit combination to tn [sec] and vice versa. If the input data is between two break points, then the minimum break point must be used.

Table of Contents

Index

57.1 AGGR SAIR adaptation: Secondary Air

57.1.1 Outputs for BMW functions which are not defined as SAIR exported data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
B_fasls	O/V	0...1H	0...1	1	-
1: activation of secondary air pump is possible					
B_genslp	O/V	0...1H	0...1	1	-
1: secondary air pump is active (condition for voltage request SAP)					
B_sls	O/V	0...1H	0...1	1	-
1: secondary air pump is active					
Md_na_sls	O/V	8000...7FFFH	-3276.8 ...3276.7	0.1	Nm
torque losses secondary air pump					
Ms_sl	O/V	0...FFFFH	0...2047.96875	0.03125	kg/h
Massenstrom Sekundärluft					

Input data:

SAF_KGH			

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Application conditions:

Initialisation: all variables are initialisied with 0

Recurrence: **200 ms:** Ms_sl

Activation: every engine state

In the power latch phase:

0: Ms_sl

Formula section:

B_fasls = 0

B_genslp =0

B_sls = 0

Md_na_sls = 0 Nm

Ms_sl = SAF_KGH

Engine torque reserve active front steering					
Mdi_res_sl	V/O	8000...7FFFH	-3276.8...3276.7	0.1	[Nm]
Engine torque reserve for power steering					

Input data:

TQ_ADD_PSTE_2	TQ_ADD_PSTE	TQ_LOSS_PSTE	

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the outputs are different from the specified values due to the input data attributes.

Application conditions:

Initialisation: 0 Nm

Recurrence : 10 ms

Activation: every engine state

Formula section:

Remark: all formulas are valid in a **physical** meaning

Md_na_sl = TQ_LOSS_PSTE

Mdi_res_afs = TQ_ADD_PSTE_2

Mdi_res_sl = TQ_ADD_PSTE

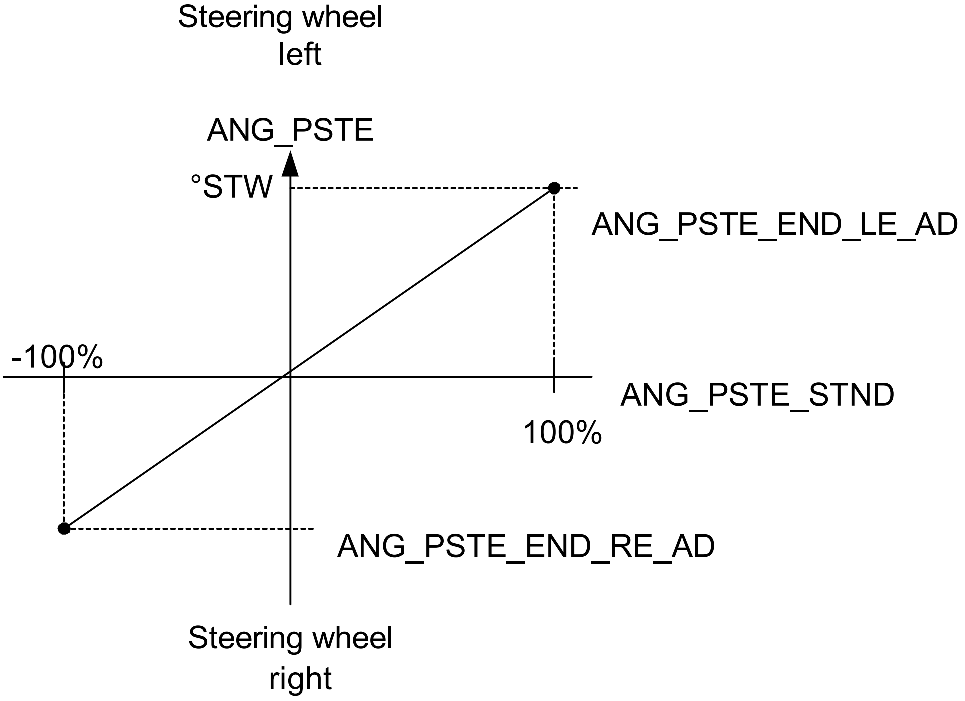
58.2.2.1 Adaptation of steering wheel lock

General information:
This module contains the calculation of the relative steering wheel sensor (ANG_PSTE_STND) and relating adaptations (ANG_PSTE_END_RI_AD, ANG_PSTE_END_LE_AD) depending on the steering wheel angle ANG_PSTE received via CAN.

general specification

To enable a new adaptation of the steering wheel angles after every reset, the values ANG_PSTE_END_LE/_RI_AD should be initialised as follows:
the adaptation values restored out of the non-volatile memory minus a calibratable constant.
Signal flow diagram:



Application hint:

to ensure a proper adaptation of ANG_PSTE_END_LE/RI please note that the range of the adaptation incrementation should be calibrated within the following range
C_ANG_PSTE_AD_LGRD = 0.1 °STW ... 1.5 °STW

58.2.2.2 Filtering of steering wheel angle velocity

General information:
This module contains the filtering of the steering-wheel angle velocity as well as the detection of the steering direction change and the state of the steering wheel (steering wheel: released or held tight). It is used as an input for the torque loss for power-steering-calculation: if the steering-wheel is held tight the providing of a torque loss for power-steering is necessary; whereas if the steering-wheel is released only the torque (Schleppmoment) of the power-steering pump itself is sufficient.

General Information

58.3.1 Summary of power steering losses

FUNCTION DESCRIPTION:

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: LV_IGK && (LV_VAR_PSTE_2 || LV_VAR_PSTE || LV_VAR_PSTE_3)
Deactivation: never

Function description

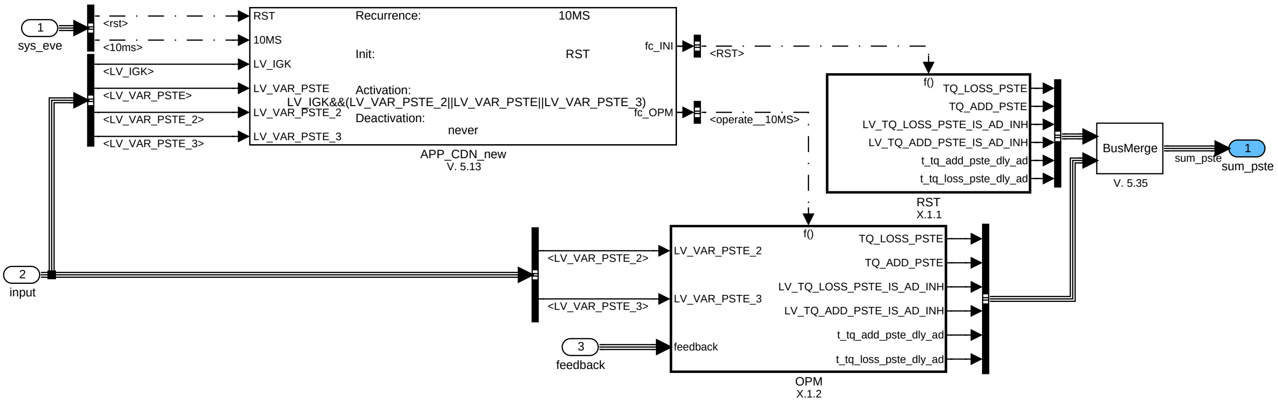

Figure 23:
Path: STSY_MD013/SUM_PSTE

58.3.1.1 Reset of variables is done here.

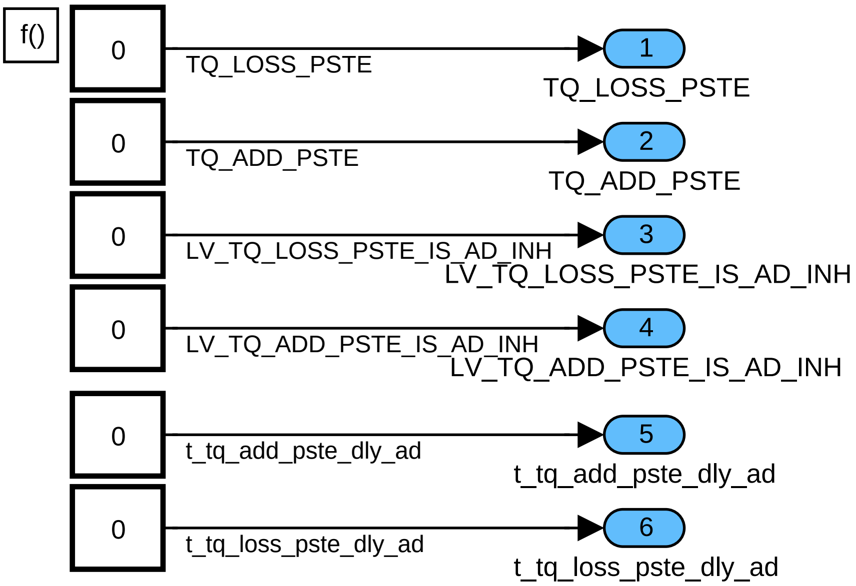

Figure 24:
Path: STSY_MD013/SUM_PSTE/RST

58.3.1.2 Formula section:

"TQ_LOSS_PSTE_1, TQ_LOSS_PSTE_2 and TQ_LOSS_PSTE_3 have to be calculate before TQ_LOSS_PSTE (using current values)."

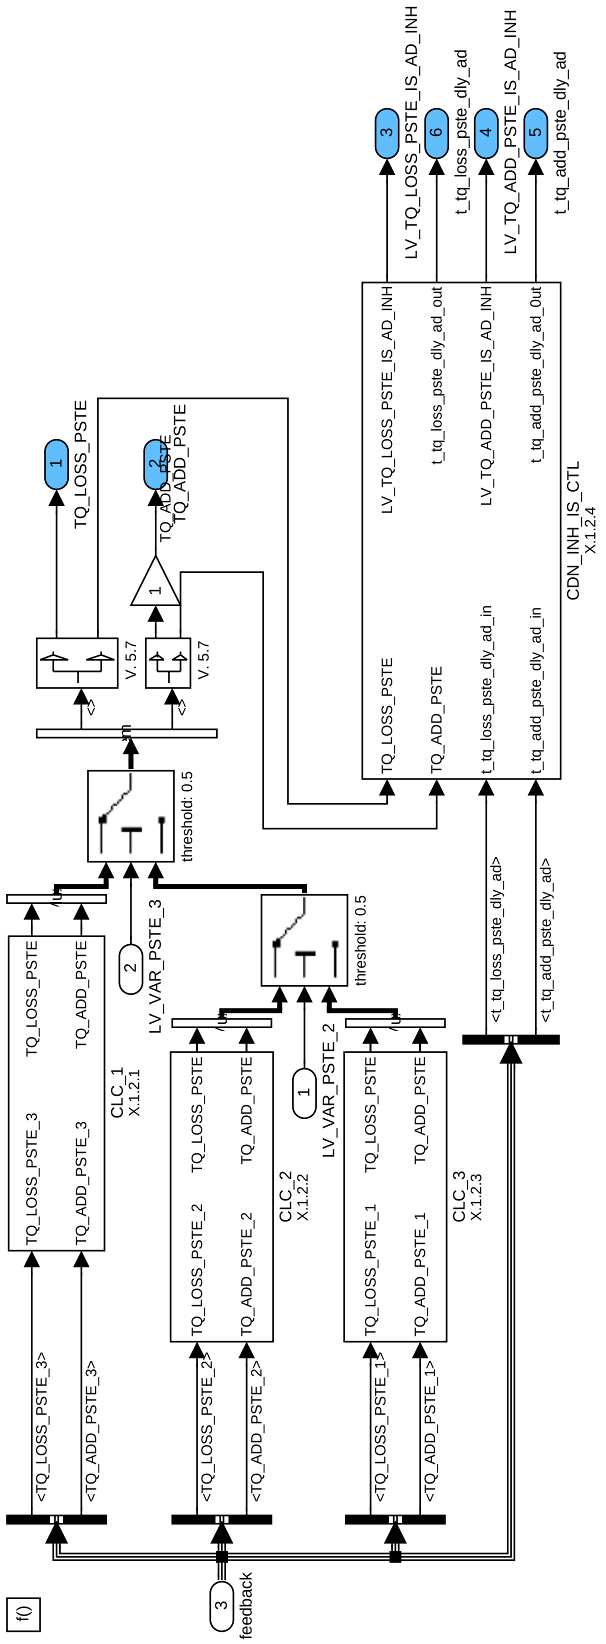

Figure 25:

58.3.2 Torque losses power steering assistance

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: LV_IGK && LV_VAR_PSTE
Deactivation: never

Function description

58.3.2.1 Reset of variables

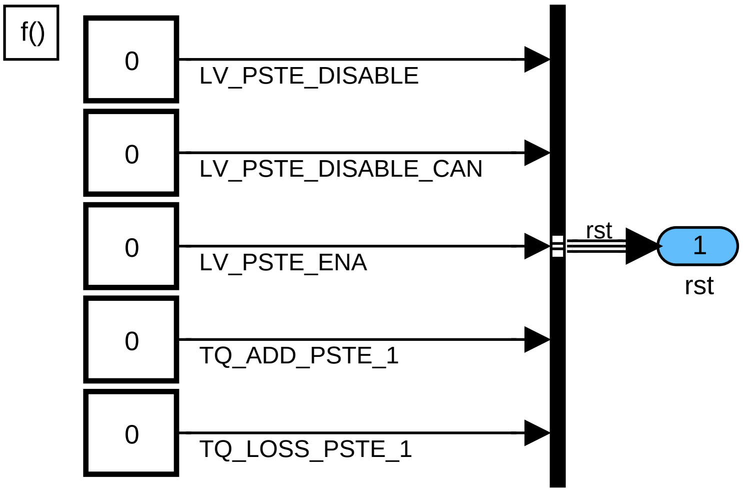

Figure 31:
Path: STSY_MD013/TQLO_PSTEA/RST

58.3.2.2 Function description.

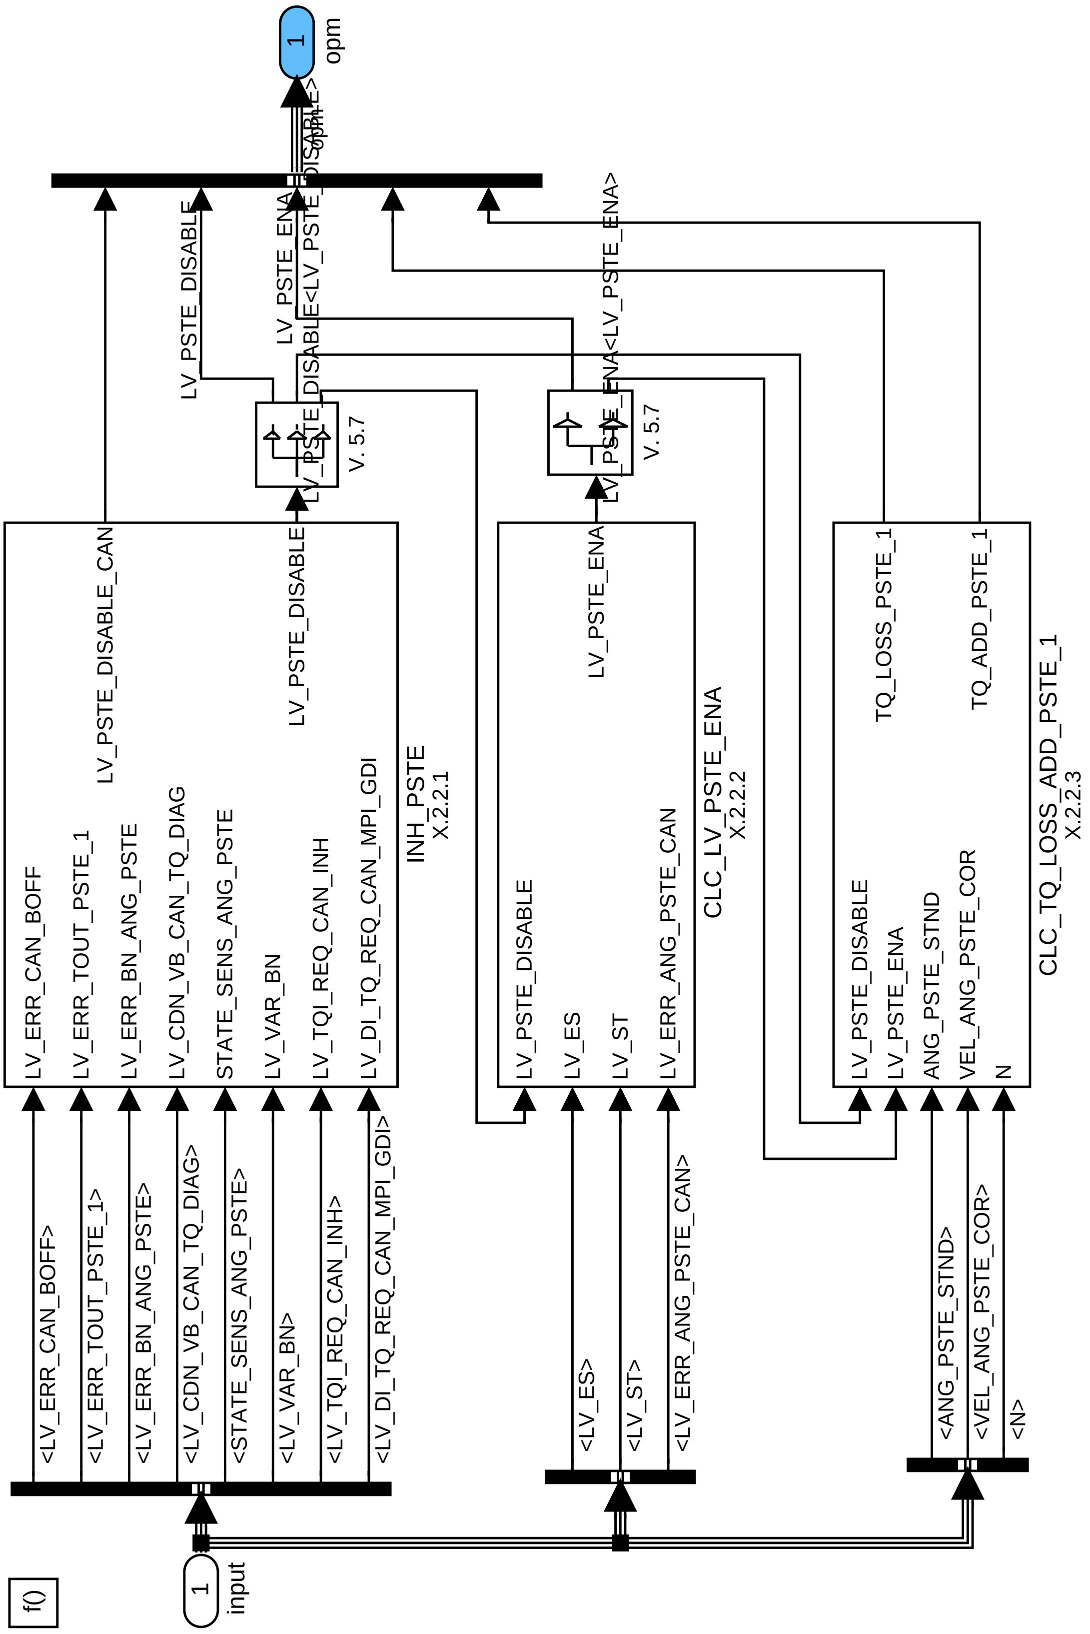

Figure 32:
Path: STSY_MD013/TQLO_PSTEA/OPM

58.3.2.2.1 Inhibition of power steering

General information:
TQ_LOSS_PSTE_1 describes the needed torque during activation of power steering. ANG_PSTE is the angle of power steering and VEL_ANG_PSTE the velocity of ANG_PSTE.

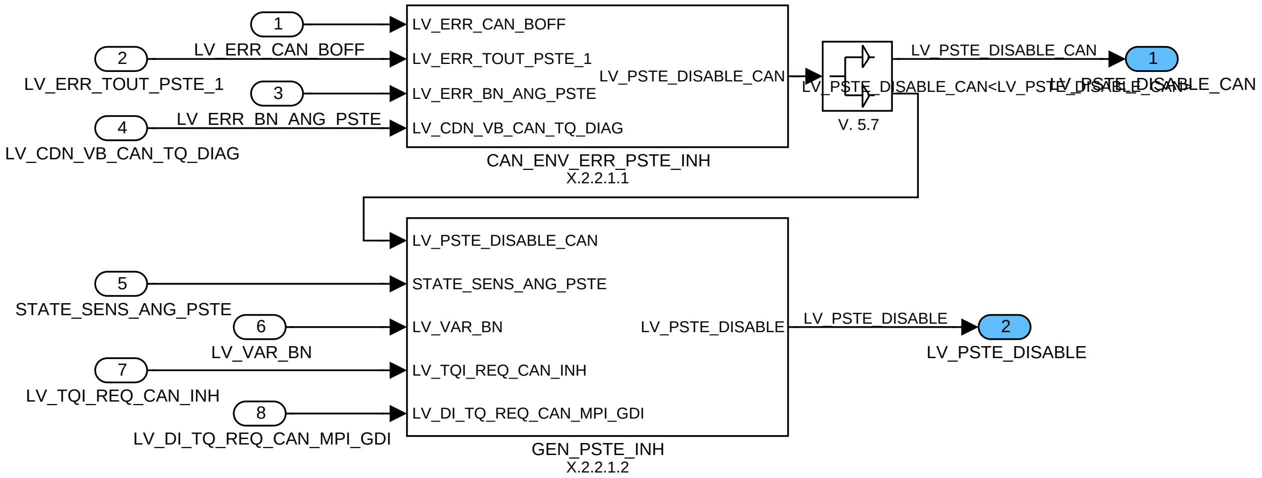

Figure 33:
Path: STSY_MD013/TQLO_PSTEA/OPM/INH_PSTE

58.3.3 Torque Loss for active power steering (BN 2000)

General information:

general specification

TQ_LOSS_PSTE_2 describes the torque demand and losses of active power steering. There are two informations the predicted and the Active Torque losses.

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: LV_IGK && LV_VAR_BN && LV_VAR_PSTE_2
Deactivation: never

Function description

58.3.3.1 Reset of variables.

58.3.4 Torque Loss for active power steering via EHB3 Control Unit (BN 2000)

General information:

general specification

TQ_LOSS_PSTE_3 describes the torque demand and losses of active power steering. Torque loss and reserve are calculated via torque request from EHB3-CPU.

Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: LV_IGK && LV_VAR_PSTE_3
Deactivation: never

Function description

58.3.4.1 Reset of variables.

59.1 SUSY - Requirements to Infrastructure

Input data:

LV_SWI_AEB			

Export actions:

ACTION_INFR_SetAEB(IN <lv_swi_aeb>**)**
This action sets the AEB driver **ACTION_INFR_GetElDiagAEB(**OUT <Cdn_diag_aeb>, OUT <Err_diag_aeb>**)** This action reads the failure and condition information for a symptom of the AEB actuator power stage.

Description for actions:

ACTION_INFR_SetAEB (IN <lv_swi_aeb> **)**					
This action sets the AEB driver					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_swi_aeb	IN	0…1H	0…1	1	-
AEB driver pin level					

ACTION_INFR_GetElDiagAEB(OUT <Cdn_diag_aeb>, OUT <Err_diag_aeb>)					
This action reads the failure and condition information for a symptom of AEB power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cdn_diag_aeb	OUT	0 ... 7H	0 ... 7	1	-
Diagnosis condition for symptom: Bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled Bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled Bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled (all combinations are possible)					
Err_diag_aeb	OUT	0 ... 7H	0 ... 7	1	-
Raw value of error symptom: Bit 0: Set, if raw value of error symptom SCP (SYM_0) is set Bit 1: Set, if raw value of error symptom SCG (SYM_1) is set Bit 2: Set, if raw value of error symptom OC (SYM_2) is set (all combinations are possible)					
Raw value of error symptom. The relevant bit is set, if the error has been detected.					

FUNCTION DESCRIPTION:

Requirements for ACTION_INFR_SetAEB:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

lv_swi_aeb	Not relevant	Not relevant	1	Not relevant	-

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

General information:

ACTION_INFR_GetElDiagAEB() returns the result of the electrical diagnosis of AEB actuator power stage.

_ The device readout is performed autonomous by the Infrastructure each 10ms.
_ The error informations of every symptom is gathered in the Infrastructure (or-ed symptom) until the Application reads out the information by calling ACTION_INFR_GetElDiagAEB().
_ After having read out the information by calling ACTION_INFR_GetElDiagAEB(), the data inside the Infrastructure is reset. Resetting of Cdn_diag_aeb avoids ambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagAEB(): Reset Cdn_diag_aeb indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_INFR_GetElDiagAEB:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag_aeb	-	-	<bit coded>	Err_diag_aeb	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag_aeb	-	-	<bit coded>	Cdn_diag_aeb	Bitcoded result of each symptom **bit 0:** raw value of error symptom SCP (SYM_0) **bit 1:** raw value of error symptom SCG (SYM_1) **bit 2:** raw value of error symptom OC (SYM_2) The relevant bit is set, if the raw error has been detected.

Diagnosis: ACTION_INFR_GetElDiagAEB returns the electric diagnosis for AEB power stage

Coincidence requirements: no coincidence requirements to other events

59.2.1 MISC_M905G

The functionality “active engine bracket” supports the controllable engine suspension. To improve the driveability of the vehicle and to decrease the transmission of engine vibrations, it is possible to switch the engine bracket from the state “stiff” to the state “soft”.

To compensate the more rough combustion in stratified mode the engine brackets are switched into a soft characteristic.

Application Condition

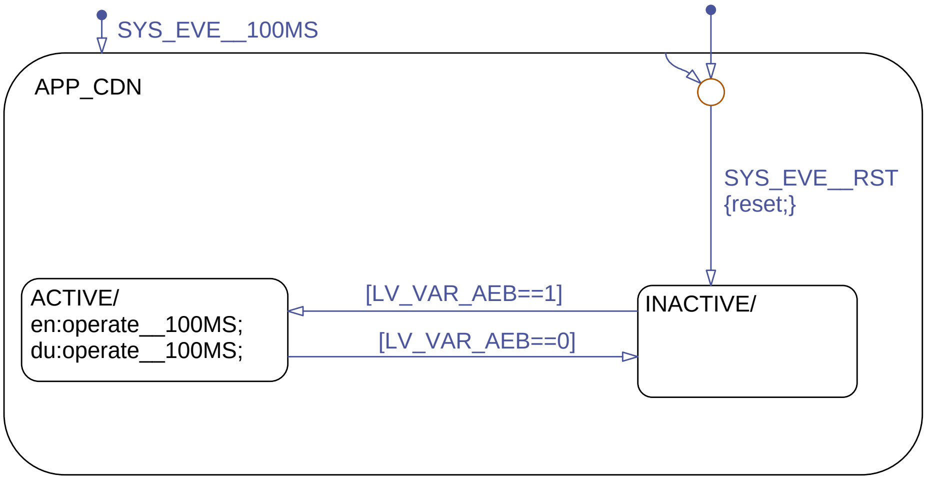

Figure 1 MISC_M905G/ APP_CDN/ Chart1

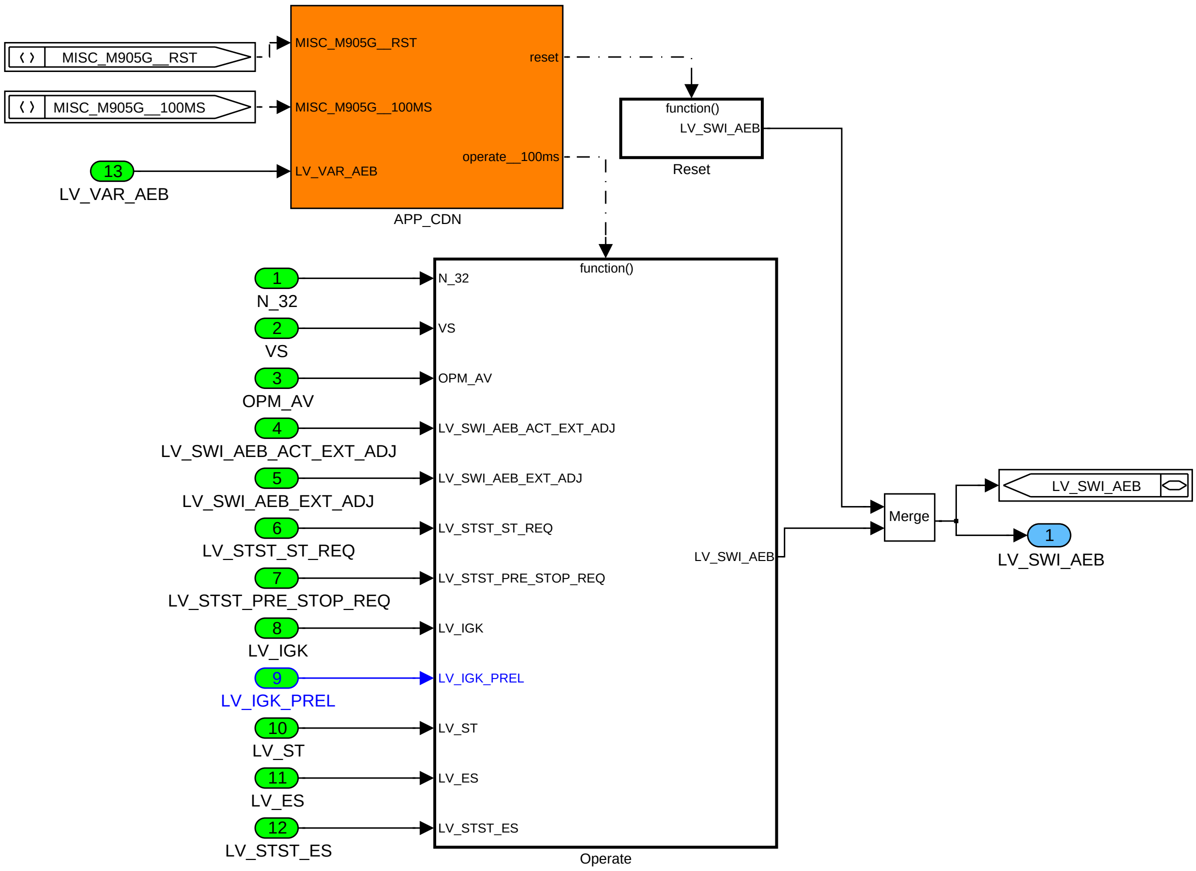
Function Description



SDA_SRS / SDA 4.0 30−May−2006

Figure 2 MISC_M905G

59.2.1.1 MISC_M905G/OPERATE

Dependent on engine speed and vehicle speed in each combustion mode, the logical variable LV_SWI_AEB is set to 1 and the corresponding ECU-Pin is set under current. In this case the engine bracket is switched to the state “soft”. Otherwise the "stiff" mode of the engine brackets is active. There is a hysteresis for engine speed and vehicle speed (common for all combustion modes) to avoid toggling of LV_SWI_AEB. The logical constant LC_SWI_AEB_TYP is introduced to take the different engine bracket types into account, which are provided from different suppliers.

Raw value of error symptom for AEB (only parameter)					

Input data:

LV_IGK	LV_VB_CDN_OBD_1	LV_ERR_SPI_MPS	LV_VAR_AEB

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN<CDN_DIAG_XX >, IN<ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT< LV_ERR_XX>)
ACTION_INFR_GetElDiagAEB (OUT< CDN_DIAG_XX>, OUT< ERR_DIAG_XX >)

FUNCTION DESCRIPTION:

General information:

The AEB is driven by the ECU via an output driver. The failure detection is done by ECU Hardware. The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements. The AEB can be switched on or off (no PWM-signal).

Description:

The purpose is to perform the electrical diagnosis of the AEB actuator. 3 symptoms are distinguished:

Error-symptoms and conditions: are defined to this diagnosis function as following

```
□□□□
 | | | └─> Short circuit to battery (SCP)     (= SYM_0)
 | | └───> Short circuit to ground (SCG)      (= SYM_1)
 | └─────> Open circuit (OC)                  (= SYM_2)
 └───────> Not used                           (= SYM_3)
```

Application conditions:

Initialisation: ERRM variables are initialized according Filter-type.
At Reset: CDN_DIAG_AEB = 0

Recurrence: 100ms

Activation: LV_IGK = 1 **and** LV_VAR_AEB = 1

Deactivation: LV_IGK = 0 **or** LV_VAR_AEB = 0

Formula section:

```
If    LV_ERR_SPI_MPS = 0
      and   LV_CDN_VB_OBD_1 = 1
      and   LV_IGK = 1

Then

      Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_AEB and
      diagnosis conditions CDN_DIAG_AEB) received from the infrastructure:

      ACTION_INFR_GetElDiagAEB (OUT<CDN_DIAG_AEB>, OUT<ERR_DIAG_AEB>)

      Basic diagnosis conditions are set according infrastructure information:
      CDN_DIAG_AEB
      Failure symptoms (raw value) are set according infrastructure information:
      ERR_DIAG_AEB

      If    Activation conditions are met for the NC_PSD_DLY_AEB recurrence
      Then
            { No additional diagnosis conditions are necessary }
      Else
            CDN_DIAG_AEB = 0
      Endif
Else
            CDN_DIAG_AEB = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_AEB and ERR_DIAG_AEB.

ACTION_ERRM_FilterMulticondition (IN<*AEB*>, IN<CDN_DIAG_AEB>,
IN<ERR_DIAG_AEB>, IN<C_ABC_INC_AEB>, IN<C_ABC_MAX_AEB>,
OUT< LV_ERR_AEB>)

This algorithm determines:

ERR_SYM_AEB	(detected error symptom for AEB diagnosis)
LV_ERR_AEB	(Error flag for debounced error of AEB)
LV_CDN_DIAG_AEB	(Diagnosis condition information)
LV_END_DIAG_AEB	(End of diagnosis information)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_AEB	1	0...FFH	0...255	1	[-]
Debounce counter increment AEB[i] power stage diagnosis					
C_ABC_MAX_AEB	1	1...FFH	1...255	1	[-]
Debounce counter maximum value AEB[i] power stage diagnosis					

Configuration for diagnostic symptoms :

Diagnostic AEB	Symptom description	Symptom	Filter type
Active engine bracket Diagnostic	*SCP*	*SYM_0*	*MPL_STD_INI*

T_DLY_TQ_MAX_ARS	V/O	0...FFFFH	0...655.35	0.01	[s]
Delay time for activation of LV_TQ_MAX_ARS					

Input data:

N_32	LV_IGK	VS_FIL	LV_VAR_BN
TQ_LOSS_ARS_AV_CAN	TQ_LOSS_ARS_SP_CAN	AC_VEH_TRV_TCS	

FUNCTION DESCRIPTION:

If either:

- the target torque loss via CAN is bigger than the minimum selection of maximum target torque loss (depending on VS_FIL, AC_VEH_TRV_TCS) and 100 Nm

or:

- the actual value of torque loss via CAN is bigger than the minimum selection of the actual value (maximum) of torque loss (depending on VS_FIL, AC_VEH_TRV_TCS) and 100 Nm

then after a time delay (C_T_DLY_TQ_MAX_ARS) LV_MAX_ARS is set to 1.

LV_MAX_ARS is indicating whether maximum torque request is present or not. The logical variable is used for validating the status of ARS.

Application conditions:

Initialisation: LV_TQ_MAX_ARS = 0
TQ_LOSS_ ARS_SP_MAX = 0 Nm
TQ_LOSS_ARS_SP_MAX_1 = 0 Nm

60.2 Variant coding

60.2.1 General

Certain functionalities in the engine management system can be changed over or shut off via variant code or data record identifier. The variant code can be set by means of calibratable constants via application system. After the data record identifier has been changed, the control unit must be reset as the data record identification is only updated during system initialization. A further method to descern one variant from another is the automatical learning by means of diagnosis or by utilization of variant specific input signals.

60.2.2 Automatically learnt variants

Input data:

LV_ACIN	LV_ACCIN	STATE_PSTE_3_SRC	STATE_ETCU_SPT_SWI

FUNCTION DESCRIPTION:

Two states have been defined for automatic learning of the vehicle equipment:

1) Vehicle without equipment xx LV_VAR_xx = 0
2) Vehicle with equipment xx LV_VAR_xx = 1

The state which is valid in each case is saved in the non-volatile memory after the ECU self-holding phase. The state is initialised with 1) in the case of a new control unit (EEPROM has been erased) and when the variants are reset via serial protocol.
In state 1) re-learning to state 2) is possible within 3 seconds after ECU- reset and within a calibratable time after ignition key on. Learning is done by receiving the equipment related CAN- message.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_DET_VAR_CAN	1	0...FFH	0...255	1	[s]
time for learning variants via CAN after ignition key on					
LC_VAR_NOX	1	0...1H	0...1	1	[-]
Switch for learning of NOx sensor					

Transmission type

1) Variant is „Manually shifted transmission “ or transmission variant is to be learnt:

LV_AT = 0

LV_VAR_AMT = 0

LV_VAR_TCT = 0

This state is active as long as there is no non-volatile memory entry during an ECU initialisation. After this, the CAN communication will be observed to learn variants. After a timeout for the EGS message and SSG-message, LV_AT and LV_VAR_AMT will stay inactive. This is interpreted as variant „Manually shifted transmission.“

2) Variant is „Automatically shifted transmission with BN2000“:

LV_AT = 1

LV_VAR_AMT = 0

LV_VAR_TCT = 0

Re-learning conditions:

receiving CAN message “DREHMOMENT_ANF_EGS” (BN2000)

3) Variant is „Twin clutch transmission with BN2000“:

LV_VAR_TCT = 1

LV_VAR_AMT = 0

LV_AT = 0

Re-learning conditions:

receiving CAN message “DREHMOMENT_ANF_DKG” (BN2000)

4) Variant is “Automated manual transmission (SSG) with BN2000”:

LV_AT = 0

LV_VAR_AMT = 1

LV_VAR_TCT = 0

Re-learning conditions:

receiving CAN message “DREHMOMENT_ANF_SSG” (BN2000)

additional 1) Variant is “BN 2000 transmission (SSG, DKG or EGS)”:

LV_VAR_ETCU =1

Re-learning conditions:

receiving CAN message “GETRIEBEDATEN” (BN2000)

additional 2) Variant is “BN 2000 sportgear box" (DKG or EGS)”:

LV_VAR_ETCU_SPT =1

Re-learning conditions:

receiving STATE_ETCU_SPT_SWI = 1 of CAN message “GETRIEBEDATEN_2” (BN2000)

Air conditioner

1) Vehicle without air conditioner	LV_VAR_ACIN = 0
2) Vehicle with air conditioner	LV_VAR_ACIN = 1

Re-learning conditions:

receiving the LV_ACCIN bit (STATE_ACIN_CAN > 0H) of CAN message WAERMESTROM_KLIMA (IHKA, BN2000).

Dashboard with CAN interface

All vehicles are equipped with dashboard therefore

LV_VAR_ICL = 1 //default value

Vehicle with ASR device

1) Vehicle without ASR	LV_VAR_ASR = 0
2) Vehicle with ASR	LV_VAR_ASR = 1

Re-learning conditions:

receiving CAN message “DREHMOMENT_ANF_DSC” (BN2000)

LV_VAR_ASR_3 = 0

LV_VAR_ASR_4 = 0

LV_VAR_MSW = 0

BN-Vehicle with Multifunctional steering wheel (CRU interface) - (BN2000 only)

1) Vehicle without multifunctional steering wheel	LV_VAR_BN_MSW = 0
2) Vehicle with multifunctional steering wheel	LV_VAR_BN_MSW = 1

Re-learning conditions: receiving CAN-message “BEDIENUNG_TEMPOMAT” (SZ-Lenksäule)

Vehicle with PSTE (Power steering) device

1) Vehicle without PSTE	LV_VAR_PSTE = 0
2) Vehicle with PSTE	LV_VAR_PSTE = 1

Re-learning conditions:

receiving CAN message “LENKRADWINKEL” (SZ-Lenksäule, BN2000)

Distance Cruise Control (BN2000 only)

1) Vehicle without DCC	LV_VAR_DCC = 0
2) Vehicle with DCC	LV_VAR_DCC = 1

Re-learning conditions:

receiving the CAN message DREHMOMENT_ANF_ACC (ACC, BN2000)

Anti-roll-stabilisation (BN2000 only)

1) Vehicle without ARS	LV_VAR_ARS = 0
2) Vehicle with ARS	LV_VAR_ARS = 1

Re-learning conditions: receiving the CAN message STAT_ARS (ARS, BN2000)

Active Front Steering (BN2000 only)

1) Vehicle without AFS	LV_VAR_PSTE_2 = 0
2) Vehicle with AFS	LV_VAR_PSTE_2 = 1

Re-learning conditions:

receiving the CAN message DREHMOMENT_ANF_AFS (AFS, BN2000)

Electrical Fuel Pump (BN2000 only)

1) Vehicle without EFP-control-unit	LV_VAR_BN_EFP = 0
2) Vehicle with EFP-control-unit	LV_VAR_BN_EFP = 1

Re-learning conditions: receiving the CAN message STAT_EKP (EKP, BN2000)

Reverse Gear via CAN (E60 - MT only)

1) MT-Vehicle without GEAR_REV	LV_VAR_BN_GEAR_REV = 0
2) MT-Vehicle with GEAR_REV	LV_VAR_BN_GEAR_REV = 1

Re-learning conditions:

receiving the CAN message STAT_GANG_RUECKWAERTS (LM, BN2000)

Dipped Beam via CAN (BN2000 only)

1) Vehicle without LTG_HDLP_L	LV_VAR_BN_LTG_HDLP_L = 0
2) Vehicle with LTG_HDLP_L	LV_VAR_BN_LTG_HDLP_L = 1

Re-learning conditions: receiving the CAN message LAMPENZUSTAND (LM, BN2000)

Längsdynamikmodul (Longitudinal dynamics module) - LDM (E9x only)

1) Vehicle without LDM	LV_VAR_BN_LDM = 0
2) Vehicle with LDM	LV_VAR_BN_LDM = 1

Re-learning conditions:

receiving the CAN message "Anforderung Radmoment Antriebsstrang" (LDM, BN2000)

Status Anhänger (State Trailer) - TRL (BN2000 only)

1) Vehicle without TRL	LV_VAR_BN_TRL = 0
2) Vehicle with TRL	LV_VAR_BN_TRL = 1

Re-learning conditions:

receiving the CAN message STAT_ANHAENGER (K-CAN/AHM, BN2000)

Steuerung Crashabschaltung EKP (BN2000 only)

1) Vehicle without EKP_CRASH on CAN	LV_VAR_EFP_CRASH = 0
2) Vehicle with EKP_CRASH on CAN	LV_VAR_EFP_CRASH = 1

Re-learning conditions:

receiving the CAN message CTR_CRASH_SWO_EKP (MRSZ, BN2000)

EHB3 - Steering (BN2000 only)

1) Vehicle without EHB3	LV_VAR_PSTE_3 = 0
2) Vehicle with EHB3	LV_VAR_PSTE_3 = 1

Re-learning conditions:

receiving the CAN message DREHMOMENT_ANF_STE (EHB3, BN2000)

NOx – sensor

```
IF    LC_VAR_NOX = 1
THEN
      LV_VAR_NOX = 1
ELSE
      Learning of NOx - sensor
      1) Vehicle without NOx – sensor          LV_VAR_NOX = 0
      2) Vehicle with NOx – sensor             LV_VAR_NOX = 1
      Re-learning conditions:
      receiving the CAN message ID = 130h or ID = 135h on LoCAN
ENDIF
```

PBR – park brake (EMF) (BN2000 only)

1) vehicle without PBR: LV_VAR_PBR = 0
2) vehicle with PBR: LV_VAR_PBR = 1

Re-learning conditions:

Receiving the CAN message STATUS_EMF (EMF, BN2000)

TQ_PBR – park brake torque information (EMF) (BN2000 only)

1) vehicle without TQ_PBR:	LV_VAR_TQ_PBR = 0
2) vehicle with TQ_PBR:	LV_VAR_TQ_PBR = 1

Re-learning conditions:

Receiving the CAN message ST_RQ_EMF (EMF, BN2000)

Getriebedaten 3 – some transmission control units (BN2000 only)

1) Vehicle without ETCU_3 LV_VAR_ETCU_3 = 0

2) Vehicle with ETCU_3 LV_VAR_ETCU_3 = 1

Re-learning conditions:

receiving the CAN message GETRIEBEDATEN_3 (EGS_EL, BN2000)

Sollmomentanforderung – DXC message (BN2000 only)

1) Vehicle without DXC LV_VAR_4WD = 0

2) Vehicle with DXC LV_VAR_4WD = 1

Re-learning conditions:

receiving the CAN message SOLL_MOM_ANF (DXC, BN2000)

60.2.2.1 Sport-Switch / Sound-Flap

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CONF_SOF_SWI	V/O/S	0H 1H 2H	NO_SOF_SWI SOF_SWI SOF_SWI_AMT	1	[-]
Configuration of sport-switch					

Input data:

LV_SOF_SWI	LV_SOF_SWI_AMT		

Sport-Mode-Switch:

Two states have been defined for automatic learning of the Sport-Switch interface:
1) Vehicle without Sport-Switch
2) Vehicle with Sport-Switch (normal sport switch / AMT sport switch)

The state which is valid in each case is saved in the non-volatile memory after the ECU holding phase. The state is initialized with 1) in the case of a new control unit and when the variant is reseted .

Re-learning from the 1 variant to 2 variant is possible at each engine operating state. Learning is based on the evaluation of LV_SOF_SWI or LV_SOF_SWI_AMT (Switch pressed).

At each engine operating state the learning is effected.

```
If   CONF_SOF_SWI = 0
     Then If     LV_SOF_SWI = 1
            Then CONF_SOF_SWI = 1
            Else If     LV_SOF_SWI_AMT = 1
                 Then   CONF_SOF_SWI = 2
                 Else   CONF_SOF_SWI = 0
                 Endif
```

```
        Endif
    Else    CONF_SOF_SWI = CONF_SOF_SWI
Endif
```

Application conditions:

Initialisation: in case of new control unit: CONF_SOF_SWI =0

Recurrence: 100ms

Activation: at every engine operating state

Meaning of CONF_SOF_SWI:
0: no Sport-switch
1: Sport-switch
2: Sport-switch AMT^

60.2.2.2 Automatically learnt variants by power stage diagnosis

Output data:

LV_VAR_AEB	O/V/S	0...1H	0...1	1	[-]
Active engine bracket configured [stored]					

Input data:

LV_CDN_VB_MIN_DIAG	LC_AD_CLR_VAR		

FUNCTION DESCRIPTION:

Description:

The components which are automatically learnt by powerstage diagnosis are:
--> see table in formula section.

The learning of the lambda sensors (here: via diagnosis of the lambda sensor heater) is a special case, because only specific combinations of the possibilities are valid.

Two states have been defined:
1) Vehicle without component EF, etc.
2) Vehicle with component EF, etc.

The state which is valid in each case is saved in the non-volatile memory after the ECU holding phase. The state is initialized with 1) in the case of a new control unit and when the variant is reset.

The re-learning from state 1) to state 2) is done only once after each ECU-initialisation (if the activation conditions are fulfilled). If a variant has been learnt and is afterwards reset to zero (via LC_AD_CLR_VAR), relearning is only possible after reset.

Learning of the components is based on the evaluation of the powerstage diagnosis of the related components. Therefore the components have to be activated for the learning cycle in order to get a proper power stage diagnosis. In state 1) the diagnosis is effected, however, an entry into the failure memory is suppressed.

The diagnosis result of the first 100ms-(or 200ms-)cycle must be rejected (due to initialisation). From the second cycle on the diagnosis is effected 10 times (1 check per recurrence). If at least 7 checks are error-free (symptom “open load” is zero) and valid (in case of LV_VAR_xxx = 0), the variant EF, ECRAS_UP, EBOX_CFA, AEB etc. has been learnt and LV_VAR_xxx = 1. With this state, the related powerstage diagnosis is cleared completely, i.e. the error entry is enabled.
If the variant LV_VAR_ECRAS_UP has been learnt, the detection of the ECRAS_DOWN variant (the lower ECRAS flap) is enabled (LV_VAR_ECRAS_DOWN). The algorithm and setting of LV_VAR_ECRAS_DOWN is done in ECRAS diagnosis module, not in the variant coding module.
The variant LV_VAR_EBOX_CFA is only learnt if LC_VAR_EBOX_CFA = 0. If LC_VAR_EBOX_CFA = 1, then LV_VAR_EBOX_CFA is also set 1 without learning.

Application conditions:

Initialisation: if ‘new control unit’ or
‘failure of nonvolatile memory recognized’ or
LC_AD_CLR_VAR 0→1 then LV_VAR_xxx = 0
LC_AD_CLR_SOF 0→1 then LV_VAR_SOF = 0

Recurrence:	200 ms	LSH_UP/_DOWN	(due to low PWM frequency)
	100 ms	all other components	

Activation: after every reset (once):

if LV_CDN_VB_MIN_DIAG = 1 **and**

LV_VAR_xxx = 0

Formula section:

Table for automatically learnt variants by power stage diagnosis - LV_VAR_xxx:

Component	Variant Keyword xxx	LV_VAR_xxx = 0	LV_VAR_xxx = 1

STATE_VAR_DET_CUS_2	V/O	0...FFFFFFFFH	0...4294967295	1	[-]
carrier double-word 2 of all learned variants for customer environment					

FUNCTION DESCRIPTION:

General information:

All learned variants LV_VAR_xx must be merged in two variables for customer use. This variables (carrier double-words) are calculated once per driving cycle after the automatically learning of variants has been finished or if LV_VAR_MAF changes from 0 -> 1. The LV_VAR- bits for each variant has to be mirrored in the bits of the carrier double-words. The places of the variants in the words are described in the table in the formula section.

Application conditions:

Initialisation: all 0

Recurrence: 1000 ms

Activation: at reset

Deactivation: -

Formula section:

The table contains the LV_VAR_xx- flags, how they have to be mirrored in the carrier double-words STATE_VAR_DET_CUS_1 and STATE_VAR_DET_CUS_2. Position 0x0 is the LSB, position 0x80000000 is the MSB of the carrier double-word (like shown in the picture below).

Input data:

NC_HW_REV	NC_FLS_DFT		

Export actions:

ACTION_INFR_GetLd(OUT <V_VAR_LD>)
This action returns the LOT detection for ECU variant coding
ACTION_INFR_GetAmpDt(OUT <V_VAR_AMP**>)**
This action returns the AMP detection for ECU variant coding

Description for actions:

ACTION_INFR_GetLd(OUT <V_VAR_LD>)

This action returns the LOT detection for ECU variant coding

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
V_VAR_LD	OUT	0 ... 7FFFH	0 ... 5	1.5259e-4	V
Voltage for LOT detection					

ACTION_INFR_GetAmpDt(OUT <V_VAR_AMP**>)**

This action returns the AMP detection for ECU variant coding

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
V_VAR_AMP	OUT	0 ... 7FFFH	0 ... 5	1.5259e-4	V
Voltage for AMP detection					

General information:

The detection of ECU variants is realised by a learning function. The state for a successful ECU variant detection is checked at every ECU initialisation. The according information has to be detected in a previous ECU initialisation by the learning function and has to be stored in the non-volatile memory. If the check, which ECU variant is identified, gets to a valid result, the learning function for ECU detection won't be started again. Otherwise it will start up like in the description below:

Combination table:

Muster	**Lot-Detection v_var_ld**	**AMP-Detection v_var_amp**
C1.1 Lot1	0V - 0,4V 47k Rpd	0V - 0,4V 47K Rpd
C1.1 Lot2	3,1V - 3,3V 47k Rpu	0V - 0,4V 47K Rpd
C1.2 Lot3	1,45V - 1,85V 47k / 47k - Teiler	0V - 0,4V 47K Rpd **lock engine**
C1.1 Lot4	0,83V - 1,23V 22k / 10k - Teiler	0V - 0,4V 47K Rpd
C1.1 Lot5	0,83V - 1,23V 22k / 10k - Teiler	0V - 0,4V 47K Rpd
C2 Lot1	0,93V - 1,13V 22k / 10k - Teiler	3,1V - 3,3V 47K Rpu
C2 Lot2	1,88V - 2,08V 22k / 33k - Teiler	3,1V - 3,3V 47K Rpu
C2 Lot3	2,39V - 2,59V 22k / 68k - Teiler	3,1V - 3,3V 47K Rpu
C2 serial	3,10V - 3,3V 10k Rpu	3,1V - 3,3V 47K Rpu

Comment: C1.2 Lot3 is locked for delivery due to SW not using KNK control

C1.1 Lot5 is learnt as C1.1 Lot4 because there is no difference regarding Lot-Detection

For Initialization ONLY:

```
SWITCH (NC_HW_REV)
case   STATE_LRN_ECU_C1_LOT1
               STATE_LRN_ECU = C1_LOT1  /* C1_LOT1 ecu learned */

case   STATE_LRN_ECU_C1_LOT2
               STATE_LRN_ECU = C1_LOT2 /* C1_LOT2 ecu learned */

case   STATE_LRN_ECU_C1_LOT3
               STATE_LRN_ECU = C1_LOT3 /* C1_LOT3 ecu learned */
               ECU_LOCK_REQ  = 1

case   STATE_LRN_ECU_C1_LOT4
               STATE_LRN_ECU = C1_LOT4 /* C1_LOT4 ecu learned */

case   STATE_LRN_ECU_C2_LOT1
               STATE_LRN_ECU = C2_LOT1 /* C2_LOT1 ecu learned */

case   STATE_LRN_ECU_C2_LOT2
               STATE_LRN_ECU = C2_LOT2       /* C2_LOT_2 ecu learned */

case   STATE_LRN_ECU_C2_LOT3
               STATE_LRN_ECU = C2_LOT3       /* C2_LOT_3 ecu learned */

case   STATE_LRN_ECU_C2_SERIAL:
               STATE_LRN_ECU = SERIAL_ECU            /* Serial ecu learned */

60.4 Logic inputs

60.4.1 Standard management of logic inputs

FUNCTION DESCRIPTION:

General information:

Logic inputs are inputs whose state is acquired by a µP port read.
Logic inputs which are connected to a pull-up inside the ECU are valid only when VBR is present. Without VBR these inputs are read as a low level.

Initialization:

See general Initialization chapter.

Logic state:

The input is “ON” when the voltage level is high at the ECU connector and is “OFF” when the voltage level is low at the ECU connector.

Recurrence:

Logical inputs are read every 10 ms with a jitter of 1 ms maximum.

Filtering of the interferences:

When the state of the logical input is changed, the acquistion is checked by another acquisition after 40 µs delay. If the new acquisition is not the same the change is ignored.
This filtering is proposed as a base in order to provide a more reliable information. In case of bigger interferences or bounces, a complementary application filtering should be added.

Diagnostic:

No diagnostic is done on logic inputs into basic software.

60.5 Logic inputs

Output data:

Name	**Mode**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
LV_IM_CS_PN	O/V	0...1H	0...1	1	-
clutch switch

LV_IM_BLS_MON	O	0...1H	0...1	1	-
brake light switch for Monitoring					

List of logic Inputs

.

Name	Port - Channel	Logic state
LV_PIN_CS_PN	E_S_KUP	Positive Logic
LV_PIN_BTS	E_S_BLTS	Positive Logic
LV_PIN_BLS	E_S_BLS	Positive Logic

60.5.1 List of logic outputs

Input data:

LV_RLY_MAIN	LV_CONF_DMTL	LV_HDMTL_ON	LV_VAR_RLY_ST
LV_EBOX_CFA	LV_ACCOUT_RLY	LV_DMTL_PUMP	LV_DMTLS
LV_RLY_ST	LV_SOF	LV_EF	LV_SWI_AEB
LV_RLY_CRCV_HEAT	LV_VAR_RLY_ACCOUT		

Description:

Name	ECU Pin Name	Definition
Switched internal	A_S_HR	main relay
Switched internal	Internal	power latch
LV_EBOX_CFA	A_S_EBOXL	E-box cooling fan
LV_ACCOUT_RLY	A_S_KOREL	air conditioning compressor relay
LV_RLY_ST	A_S_START	starter relay
LV_EF	A_S_AKL	exhaust flap, only if CONF_EF_B_KL61 = 0
LV_SWI_AEB	A_S_MLA	Automatic engine brackets
LV_SOF	A_S_ESK	sound flap
LV_RLY_CRCV_HEAT	A_T_PTC	crankcase ventilation heater relay
LV_RLY_MAIN	A_S_HR	main relay

Additional for LV_CONF_DMTL = 1

Name	ECU Pin Name	Definition
LV_DMTL_PUMP	A_S_DMTLP	tank leakage detection motor
LV_DMTLS	A_S_DMTLV	tank leakage detection vent
LV_HDMTL_ON	A_S_DMTLH	tank leakage detection heater

General information:

As there are no free logical output stages left for the activation/deactivation of the crankcase ventilation heater relay and the sound flap, PWM output stages are used for this purpose. To keep changes/efforts as lean as possible the pins which were supposed to be used for a PWM-controlled PTC-heater/sound flap are now used for the crankcase ventilation heater relay/sound flap control, thus resulting in an "incorrect" naming of the pins themself (A_T_PTC/A_T_ESK).

60.5.2 Definition of logic outputs

60.5.2.1 LV_LS_UP/DOWN_0/1

The logic outputs for the lambda sensor input resistors are set corresponding to switch SW1 described in chapter ‘System Variables, Upstream/Downstream oxygen sensor internal resistance determination’.

60.5.2.2 Logic outputs controlled by learning algorithm

ACC-Relay:

If LV_VAR_RLY_ACCOUT = 0

then	the related PIN is controlled by the learning algorithm (see chapter “General: Variant Coding/Automaticallly learnt variants via powerstage-dignosis”)
else	the PIN is controlled by LV_ACCOUT_RLY

Starter-Relay:

If	LV_VAR_RLY_ST = 0
then	the related PIN is controlled by the learning algorithm (see chapter “General: Variant Coding/Automaticallly learnt variants via powerstage-dignosis”)
else	the PIN is controlled by LV_RLY_ST

Crankcase ventilation heater relay:

As there is a 100% installation in all variants of NG6 engines the Pin is always controlled by LV_RLY_CRCV_HEAT.

60.5.3 Engine speed signal ESS

The engine speed signal ESS (ECU Pin A_F_TD) is a tooth-fixed event. The ESS signal is set at the teeth 5, 25, 45, 65, 85, 105 and reset at the teeth 15, 35, 55, 75, 95, 115. The artificially generated teeth are used in the CAM limp home. Since the cylinder group assignment for the output of the ESS signal is not decisive, the CRK limp home has no influence on the output of the ESS signal.

60.6 Variant Coding diagnosis

60.6.1 Diagnosis of successful BMW coding of variants via KWP

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_ERR_VAR_COD	V/O/S	0...1H	0...1	1	[-]
Configuration variant coding error					
ERR_SYM_VAR_COD	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
symptoms of variant coding error					
LV_CDN_DIAG_VAR_COD	V/O	0...1H	0...1	1	[-]
condition for diagnosis of variant coding					
LV_END_DIAG_VAR_COD	V/O	0...1H	0...1	1	[-]
diagnosis of variant coding ended					

Input data:

LV_IGK	VIN_SHO[7]		

FUNCTION DESCRIPTION:

General information:

If not disabled by C_IDX_COD_CONV, this function checks the successful BMW coding of variants via KWP. Therefore the CAL-ID (identifier of the calibration- dataset) which is actual programmed in Flash memory is compared with the CAL-ID in the E2PROM. The CAL-ID is written to E2PROM memory only by receiving the tester command $3B_90 - Kurze Fahrgestellnummer schreiben. The receiving of this command is interpreted as successful coding.
If the two Call-IDs are not equal, a error is written into error memory. This error can only be erased by clearing the error memory.

Description:

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘

61.1 THRO - Requirements for infrastructure (ETC)

Input data:

LV_RLY_MTC_HEAT			

Export actions:

ACTION_INFR_SetMTCHEAT(IN <lv_rly_mtc_heat>**)**
This action sets the output pin for the “MTC_HEAT Switch” **ACTION_INFR_GetElDiagMTCHEAT(**OUT <Cdn_diag_mtcheat>, OUT <Err_diag_mtcheat>**)** This action reads the failure and condition information for a symptom of the MTCHEAT actuator power stage.

Description for actions:

ACTION_INFR_SetMTCHEAT (IN <lv_rly_mtc_heat> **)**					
This action sets the MTCHEAT driver					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
lv_rly_mtc_heat	IN	0…1H	0…1	1	-
MTCHEAT driver pin level					

ACTION_INFR_GetElDiagMTCHEAT(OUT <Cdn_diag_mtcheat>, OUT <Err_diag_mtcheat>)					
This action reads the failure and condition information for a symptom of MTCHEAT power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cdn_diag_mtcheat	OUT	0 ... 7H	0 ... 7	1	-
Diagnosis condition for symptom: Bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled Bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled Bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled (all combinations are possible)					
Err_diag_mtcheat	OUT	0 ... 7H	0 ... 7	1	-
Raw value of error symptom: Bit 0: Set, if raw value of error symptom SCP (SYM_0) is set Bit 1: Set, if raw value of error symptom SCG (SYM_1) is set Bit 2: Set, if raw value of error symptom OC (SYM_2) is set (all combinations are possible)					
Raw value of error symptom. The relevant bit is set, if the error has been detected.					

FUNCTION DESCRIPTION:

Requirements for ACTION_INFR_SetMTCHEAT:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**

lv_rly_mtc_heat	Not relevant	Not relevant	1	Not relevant	-

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

General information:

ACTION_INFR_GetElDiagMTCHEAT() returns the result of the electrical diagnosis of MTCHEAT actuator power stage.

_ The device readout is performed autonomous by the Infrastructure each 10ms.
_ The error informations of every symptom is gathered in the Infrastructure (or-ed symptom) until the Application reads out the information by calling ACTION_INFR_GetElDiagMTCHEAT().
_ After having read out the information by calling ACTION_INFR_GetElDiagMTCHEAT(), the data inside the Infrastructure is reset. Resetting of Cdn_diag_mtcheat avoids ambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagMTCHEAT(): Reset Cdn_diag_mtcheat indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_INFR_GetElDiagMTCHEAT:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag_mtcheat	-	-	<bit coded>	Err_diag_mtcheat	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag_mtcheat	-	-	<bit coded>	Cdn_diag_mtcheat	Bitcoded result of each symptom **bit 0:** raw value of error symptom SCP (SYM_0) **bit 1:** raw value of error symptom SCG (SYM_1) **bit 2:** raw value of error symptom OC (SYM_2) The relevant bit is set, if the raw error has been detected.

Diagnosis: ACTION_INFR_GetElDiagMTCHEAT returns the electric diagnosis for MTCHEAT power stage

Coincidence requirements: no coincidence requirements to other events

61.2 AGGR THRO adaptation

Output data:

61.3.1 Standardization of the TPS-Voltage

FUNCTION DESCRIPTION:

General information:

With the help of the determined adaptation values, the TPS-Position is standardized using the standard slope of the throttle position sensors C_TPS_SLOP.
For a better control of smaller opening angles the amplified poti 1 is used (TPS_AV_GAIN_1).
To calculate the controller difference at the lower stop a control opening angle of the throttle value with positive/negative physical limits is needed (TPS_AV_CTL).

Application conditions:

Initialisation: TPS_LIH = TPS_LIH_INI

Recurrence: 5ms

Activation: at every operating state

Formula section:

actual value 1&2:

TPS_AV_1 = (V_TPS_1_FIL – V_TPS_AD_EL_BOL_1) * C_TPS_SLOP

TPS_AV_2 = (V_TPS_AD_EL_BOL_2 – V_TPS_2_FIL) * C_TPS_SLOP

actual contol value 1&2:

TPS_AV_CTL_1 = (V_TPS_1_FIL – V_TPS_AD_EL_BOL_1) * C_TPS_SLOP

TPS_AV_CTL_2 = (V_TPS_AD_EL_BOL_2 – V_TPS_2_FIL) * C_TPS_SLOP

actual value: amplified poti 1:

TPS_AV_GAIN_1 =

$$\left(\frac{V\_TPS\_GAIN\_1\_FIL - V\_TPS\_AD\_OFS\_GAIN\_1}{TPS\_AD\_SLOP\_GAIN\_1} - V\_TPS\_AD\_EL\_BOL\_1\right) * C\_TPS\_SLOP$$

actual control value: amplified poti 1:

TPS_AV_CTL_GAIN_1 =

$$\left(\frac{V\_TPS\_GAIN\_1\_FIL - V\_TPS\_AD\_OFS\_GAIN\_1}{TPS\_AD\_SLOP\_GAIN\_1} - V\_TPS\_AD\_EL\_BOL\_1\right) * C\_TPS\_SLOP$$

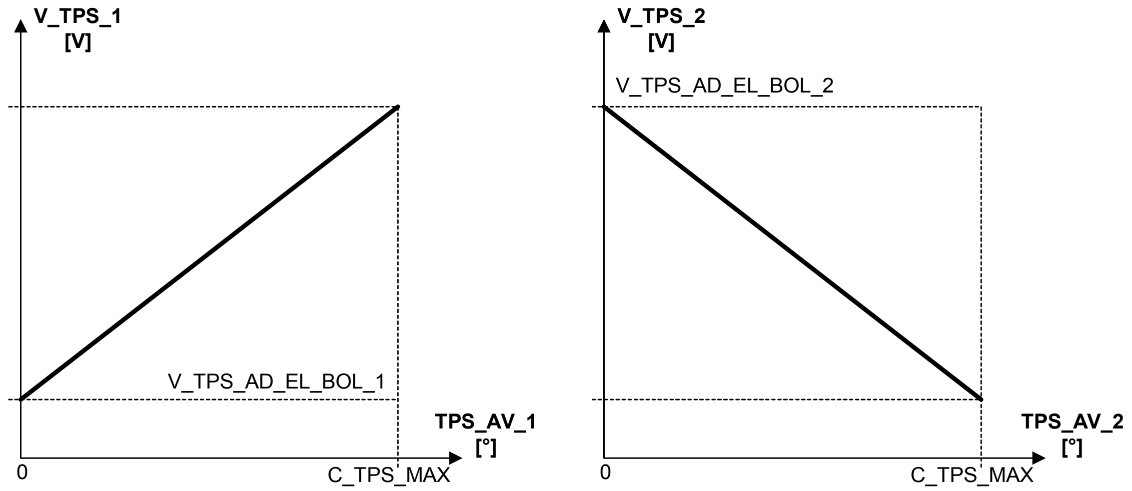

Fig. 1: **Standardization of the TPS-Voltage**

61.3.2 Selection of actual value TPS_AV / TPS_AV_CTL

Description:

The selection of actual value TPS_AV / TPS_AV_CTL depends on the hysteresis for amplifed/non-amplified poti 1 and the status of TPS/ETC diagnosis.

Formula section:

Calculation hysteresis band:

V_TPS_GAIN_TOL_ENA_1 = 5V / TPS_AD_SLOP_GAIN_1 – C_V_TPS_SWI_GAIN_1

V_TPS_GAIN_BOL_ENA_1 = V_TPS_GAIN_TOL_ENA_1 – C_V_TPS_HYS_GAIN_1

Hysteresis for amplifed/non-amplified poti 1:

Hysteresis for use of amplified / non-amplified TPS 1:

```
if      V_TPS_1 < V_TPS_GAIN_BOL_ENA_1          and
        LV_TPS_GAIN_ACT_1 = 0
then    LV_TPS_GAIN_ACT_1 = 1
    elseif    V_TPS_1 > V_TPS_GAIN_TOL_ENA_1    and
              LV_TPS_GAIN_ACT_1 = 1
    then      LV_TPS_GAIN_ACT_1 = 0
    endif
endif
```

Selection in errorfree case:

```
TPS1 &TPS2 errorfree, no TPS plausibility error:
if        STATE_TPS_DIAG = TPS_NO_ERROR
then
          if     LV_TPS_GAIN_ACT_1 = 1
          inside operation range of amplified TPS1:
          then   TPS_AV      = TPS_AV_GAIN_1
                 TPS_AV_CTL = TPS_AV_CTL_GAIN_1
                 TPS_LIH     = TPS_LIH_1
          outside operation range of amplified TPS1:
          else   TPS_AV      = TPS_AV_1
                 TPS_AV_CTL = TPS_AV_CTL_1
                 TPS_LIH     = TPS_LIH_1
          endif
endif
```

Selection in error-cases:

```
TPS1 & TPS2 erroneous or MTC without power:
if        STATE_TPS_DIAG = TPS_DBL_ERROR          or
          STATE_ETC_LIH = ETC_LIH_1               or
          STATE_ETC_LIH = ETC_LIH_2_REV           or
          STATE_ETC_LIH = ETC_LIH_2
then      TPS_AV     = C_TPS_MAX
          TPS_LIH    = TPS_LIH_INI

TPS2 erroneous:
elseif    STATE_TPS_DIAG = TPS_LIH_1
then
          if     LV_TPS_GAIN_ACT_1 = 1
          inside operation range of amplified TPS1:
          then   TPS_AV      = TPS_AV_GAIN_1
                 TPS_AV_CTL = TPS_AV_CTL_GAIN_1
                 TPS_LIH     = TPS_LIH_1
          outside operation range of amplified TPS1:
          else   TPS_AV      = TPS_AV_1
                 TPS_AV_CTL = TPS_AV_CTL_1
                 TPS_LIH     = TPS_LIH_1
          endif
```

TPS1 erroneous:

```
elseif      STATE_TPS_DIAG = TPS_LIH_2
then        TPS_AV      = TPS_AV_2
            TPS_AV_CTL  = TPS_AV_CTL_2
            TPS_LIH     = TPS_LIH_2
```

TPS plausibility error:

```
elseif      STATE_TPS_DIAG = TPS_LIH_MAX
then        TPS_AV      = MAX(TPS_AV_1; TPS_AV_2)
            TPS_AV_CTL  = MAX(TPS_AV_CTL_1; TPS_AV_CTL_2)
            TPS_LIH     = TPS_LIH_INI
Endif
```

61.3.3 TPS gradient limitation

Description:

To eliminate eventually malfunctions the potentiometer values are verified by a gradient limitation. Is the difference between the old and new potentiometer voltage value exceeding the gradient threshold then keeps the old poti value. If by the next measuring the gradient limitation exceeded again, then the new poti value will adopt.

Formula section:

```
IF          $|V\_TPS\_X_n - V\_TPS\_X_{n-1}| \le C\_V\_TPS\_GRD\_MAX$
Then                $V\_TPS\_X\_FIL = V\_TPS\_X_n$

Elseif      $|V\_TPS\_X_n - V\_TPS\_X_{n-1}| > C\_V\_TPS\_GRD\_MAX$          and
            $|V\_TPS\_X_{n-1} - V\_TPS\_X_{n-2}| > C\_V\_TPS\_GRD\_MAX$

    Then            $V\_TPS\_X\_FIL = V\_TPS\_X_n$
    Else            $V\_TPS\_X\_FIL = V\_TPS\_X\_FIL_{n-1}$
Endif
```

```
IF $|V\_TPS\_GAIN\_1_n - V\_TPS\_GAIN\_1_{n-1}| \leq C\_V\_TPS\_GAIN\_GRD\_MAX$
  Then     $V\_TPS\_GAIN\_1\_FIL_n = V\_TPS\_GAIN\_1_n$
  Elseif   $|V\_TPS\_GAIN\_1_n - V\_TPS\_GAIN\_1_{n-1}| > C\_V\_TPS\_GAIN\_GRD\_MAX$ and
           $|V\_TPS\_GAIN\_1_{n-1} - V\_TPS\_GAIN\_1_{n-2}| > C\_V\_TPS\_GAIN\_GRD\_MAX$
     Then  $V\_TPS\_GAIN\_1\_FIL_n = V\_TPS\_GAIN\_1_n$
     Else  $V\_TPS\_GAIN\_1\_FIL_n = V\_TPS\_GAIN\_1\_FIL_{n-1}$
  Endif
```

61.3.3.1 Calculation of throttle position gradient: (TPS_GRD)

Description:

The gradient is calculated as (absolute value of) difference from the actual throttle value and the throttle value i-4 (that is the throttle value which was actual 40ms before). Therefore the converted throttle values are written into a ring-buffer with 4 values.

Application conditions:

Recurrence: 10ms

Formula section:

$TPS\_GRD = | (TPS\_AV_i - TPS\_AV_{i-4}) * 25 |$

The throttle gradient direction is calculated as follows

```
If     $(TPS\_AV_i - TPS\_AV_{i-4}) < 0$
then   $LV\_TPS\_GRD\_UP = 0$     (negative throttle gradient)
else   $LV\_TPS\_GRD\_UP = 1$     (positive throttle gradient)
endif
```

61.3.4 Segment synchronous throttle valve position: (TPS_SEG)

Description:

The segment synchronous TPS is needed as input for the intake manifold model. The calculation is carried out segment synchronously.With the help of the adaptation values the TPS-position is standardized to a range between 0° and C_TPS_MAX degree.

Formula section:

$TPS\_SEG\_1 = (V\_TPS\_1 - V\_TPS\_AD\_EL\_BOL\_1) * C\_TPS\_SLOP$

$TPS\_SEG\_2 = (V\_TPS\_AD\_EL\_BOL\_2 - V\_TPS\_2) * C\_TPS\_SLOP$

$TPS\_SEG\_GAIN\_1 =$

$$\left(\frac{\mathrm{V\_TPS\_GAIN\_1 - TPS\_AD\_OFS\_GAIN\_1}}{\mathrm{TPS\_AD\_SLOP\_GAIN\_1}} - \mathrm{V\_TPS\_AD\_EL\_BOL\_1}\right) * \mathrm{C\_TPS\_SLOP}$$

0° ≤ TPS_SEG_x ≤ C_TPS_MAX.

Selection in errorfree case:

TPS1 &TPS2 errorfree, no TPS plausibility error:

```
if          STATE_TPS_DIAG = TPS_NO_ERROR
then
            if      LV_TPS_GAIN_ACT_1 = 1
            inside operation range of amplified TPS1:
            then    TPS_SEG     = TPS_SEG_GAIN_1
            outside operation range of amplified TPS1:
            else    TPS_SEG     = TPS_SEG_1
            endif
endif
```

Selection in error-cases:

TPS1 & TPS2 erroneous:

```
if          STATE_TPS_DIAG = TPS_DBL_ERROR
            STATE_ETC_LIH = ETC_LIH_1                    or
            STATE_ETC_LIH = ETC_LIH_2_REV                or
            STATE_ETC_LIH = ETC_LIH_2
then        TPS_SEG = TPS_LIH_INI
```

TPS2 erroneous:

```
elseif      STATE_TPS_DIAG = TPS_LIH_1
then
            if      LV_TPS_GAIN_ACT_1 = 1
            inside operation range of amplified TPS1:
            then    TPS_SEG     = TPS_SEG_GAIN_1
            outside operation range of amplified TPS1:
            else    TPS_SEG     = TPS_SEG_1
      endif
```

TPS1 erroneous:

```
elseif      STATE_TPS_DIAG = TPS_LIH_2
then     TPS_SEG  = TPS_SEG_2
```

TPS plausibility error:

```
else     TPS_SEG  = MAX( TPS_SEG_1; TPS_SEG_2 )
endif
```

Calibration data:

```

Application conditions:

Initialisation: according filtertype **STD_INI** *(all 0 at LV_IGK 0->1 or reset)*
Recurrence: 5ms
Activation:

```
If      LV_IGK = 1                     and
        LV_ERR_TPS_1/2 = 0             and
        LV_ERR_TPS_MAF_1/2 = 0         //calculation for channel 1 and 2 seperate
Then    LV_CDN_DIAG_TPS_1/2 = 1
Else    LV_CDN_DIAG_TPS_1/2 = 0
Endif
```

Formula section:

Calculation End of Diagnosis:

For calculation of LV_END_DIAG_TPS_1/2 see "Anti-bounce algorithm, calculation of the end of diagnosis".

Error detection TPS_1 short circuit to ground:

```
If      V_TPS_1  <  C_V_TPS_MIN_DIAG_1
Then    ERR_SYM_TPS_1 = SYM_1
        LV_ERR_TPS_1 = 1        //after debounce, remains active until next initialization
```

Error detection TPS_1 short circuit to Vbatt or open load:

```
Elself  V_TPS_1  >  C_V_TPS_MAX_DIAG_1
Then    ERR_SYM_TPS_1 = SYM_0
        LV_ERR_TPS_1 = 1        //after debounce, remains active until next initialization
Else    ERR_SYM_TPS_1 = NO_SYM
Endif
```

Error detection TPS_2 short circuit to ground or open load:

```
If      V_TPS_2  <  C_V_TPS_MIN_DIAG_2
Then    ERR_SYM_TPS_2 = SYM_1
        LV_ERR_TPS_2 = 1        //after debounce, remains active until next initialization
```

Error detection TPS_2 short circuit to VBatt:

```
Elself  V_TPS_2  >  C_V_TPS_MAX_DIAG_2
Then    ERR_SYM_TPS_2 = SYM_0
        LV_ERR_TPS_2 = 1        //after debounce, remains active until next initialization
Else    ERR_SYM_TPS_2 = NO_SYM
Endif
```

Calibration data:

End of diagnosis TPS_RATIO diagnosis					
LV_DET_ERR_TPS_RATIO	O/V	0...1H	0...1	1	[-]
Logic variable set if TPS_RATIO error is detected					

Input data:

LV_ST_END			

FUNCTION DESCRIPTION:

General information:

In the case of an error-free system, the Poti-voltages V_TPS_1 and V_TPS_2 must not differ by more than C_V_TPS_RATIO_HYS. The voltage V_TPS_2 is “inverted” in order to carry out the channel comparison.

Description:

If the threshold C_V_TPS_RATIO_HYS is exceeded, the TPS_RATIO error will be debounced.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
 │  │  │  └─> -                        (= SYM_0)
 │  │  └────> -                        (= SYM_1)
 │  └───────> -                        (= SYM_2)
 └──────────> TPS – Ratio exeeded      (= SYM_3)
```

Application conditions:

Initialisation: according filter type **STD_INI**

Recurrence: 5ms

Activation:

```
If          LV_IGK = 1
      and   LV_ST_END = 1
      and   LV_ERR_TPS_1/2 = 0          both channels must be errorfree
      and   LV_ERR_TPS_MAF_1/2 = 0
Then        LV_CDN_DIAG_TPS_RATIO = 1
Else        LV_CDN_DIAG_TPS_RATIO = 0
            LV_DET_ERR_TPS_RATIO = 0
Endif
```

Formula section:

```
If      | V_TPS_1 - (5[V] - V_TPS_2) |  >  C_V_TPS_RATIO_HYS
Then    ERR_SYM_TPS_RATIO = SYM_3          //anti bounce increment
        LV_DET_ERR_TPS_RATIO = 1
Else    ERR_SYM_TPS_RATIO = NO_SYM         //anti bounce decrement
        LV_DET_ERR_TPS_RATIO = 0
Endif
```

LV_ERR_TPS_RATIO , LV_END_DIAG_TPS_RATIO is calculated by error management

Calibration data:

Input data:

STATE_TPS_DIAG	LV_TPS_SUB_DIAG_ERR	LV_TPS_SUB_DIAG_NOT_VLD	LV_HOM_ACT

TPS_AV_1	TPS_AV_2	TPS_SUB_DIAG	

FUNCTION DESCRIPTION:

General information:

This function is only performed if calibrated LC_USE_MAF_TPS_DIAG = 1.

If RATIO error is detected the algorithm is used to decide if channel one or two or both are not plausible. It is based on the modelled TPS value TPS_SUB_DIAG.

X = channel 1 and 2

Description:

Detection of TPS fist error:

The integration is done for C_T_TPS_DIF_INT if diagnosis conditions are active.

TPS_DIF_DIAG_X is the difference between the mesured value TPS_AV_X and the modelled TPS value TPS_SUB_DIAG.

TPS_DIF_DIAG_COR_X is the corrected value based on N, MAF_SP_TQI, PQ.

TPS_SUM_DIF_DIAG_COR_X is the integrated value of TPS_DIF_DIAG_COR_X.

Depending on TPS_SUM_DIF_DIAG_COR_X channel one or two or both are set as not plausible and the diagnosis is switched off.

The plausibility check cannot be performed if TPS_SUB_DIAG cannot be calculated in the right way because an active lambda-sensor fault or a load-sensor fault.
In this case, the two channels are declared as faulty when LV_DET_ERR_TPS_RATIO is set for C_T_TPS_DIF_INT.

Continuous TPS / TPS_SUB_DIAG monitoring for single channel

In the case of one channel is diagnosed as faulty, a plausibility check for the remaining channel to the other one is no longer possible. In this case, the substitute value TPS_DIF_DIAG_COR_X is used for the plausibility check while the engine is running. The difference between the measured TPS_AV value and the substitute value TPS is normalized and the mean value is established with a correlation constant.
The plausibility check cannot be performed when a mass air flow signal is missing; in this case, the channel is declared as faulty.
Error symptom definition see TPS-FIRST-ERROR diagnosis.

Check of the combustion mode with active TPS error

In order to perform the first / second error diagnosis the combustion-mode must be homogeneous, thus there's a delay timer which runs after a present Ratio / Single TPS error.

If the timer is elapsed without active HOM mode, a TPS double fault is set and the throttle is switched off.

Error symptoms are defined for this diagnosis function as:

ERR_SYM_TPS_MAF_1:

☐☐☐☐

```

LV_IGK	LV_ES	LV_ST	LV_MTC_CUR_OFF
BIOS_HBR_FAULT_STATUS_MTC			

FUNCTION DESCRIPTION:

General information:

Error detection is effected via the ECU hardware (MTC H-Bridge IC).

Description:

The following errors symptoms (Error state BIOS_HBR_FAULT_STATUS_MTC is delievered from the basic software) can be distinguished:

- Undervoltage
- Overcurrent
- Overtemperature

Error-symptoms are defined to this diagnosis function as following:

```
☐☐☐☐
 │ │ │ └─> -                                    (= SYM_0)
 │ │ └───> -                                    (= SYM_1)
 │ └─────> ETC – driver is faulty               (= SYM_2)
 └───────> -                                    (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** reset

Recurrence: 5ms

Activation:

```
    If      LV_IGK = 1                      and
            LV_ES = 0                       and
            LV_ST = 0                       and
            LV_MTC_CUR_OFF = 0              //Position controller has power
    Then    LV_CDN_DIAG_MTC_DR = 1
    Else    LV_CDN_DIAG_MTC_DR = 0
    Endif
```

Formula section:

```
If      BIOS_HBR_FAULT_STATUS_MTC = 1
Then    ERR_SYM_MTC_DR = SYM_2
        LV_ERR_MTC_DR = 1       //after debounce
Else    ERR_SYM_MTC_DR = NO_SYM
        LV_ERR_MTC_DR = 0       //after rebounce
Endif
```

Calculation end of diagnosis:

LV_END_DIAG_MTC_DR is calculated by error management

Calibration data:

Debounce timer for MTCPWM error					

Input data:

MTCPWM	LV_TPS_AD_ACT	TPS_DIF	LV_IGK
LV_ES	LV_ST	LV_MTC_CUR_OFF	STATE_ETC_LIH
LV_TPS_SP_EXT_ADJ	LV_TPS_SP_JAM		

FUNCTION DESCRIPTION:

General information:

This diagnosis is to detect a throttle valve error or a jammed actuator.

The following diagnosis are performed:

- Pulse width modulation check
- Control difference check

Description:

Pulse width modulation check:
If the given pulse width modulation signal MTCPWM exceeds the position controller permissible maximum value C_MTCPWM_PI_MAX_DIAG for longer than C_T_MTCPWM_PI_DIAG then the error is detected and a reversible limp home is applied.

If the pulse width modulation signal lies below the threshold C_MTCPWM_PI_MAX_DIAG as long as T < C_T_MTCPWM_PI_DIAG_CUR_OFF then the jammed throttle valve could break free (LV_ERR_MTC_CTL_1 is reset to 0) and the reversible limp home is passive.

If the pulse width modulation signal lies below the threshold C_MTCPWM_PI_MAX_DIAG for longer then C_T_MTCPWM_PI_DIAG_CUR_OFF then a irreversible limp home is applied (Throttle is switched off).

Error symptoms are defined to this diagnosis as:

MTC_CTL_1

```
☐☐☐☐
 │ │ │ └─> MTC; pulse width modulation <1s exceeded    (= SYM_0)
 │ │ └───> -                                           (= SYM_1)
 │ └─────> -                                           (= SYM_2)
 └───────> -                                           (= SYM_3)
```

MTC_CTL_2

```
☐☐☐☐
 │ │ │ └─> MTC; pulse width modulation >1s exceeded    (= SYM_0)
 │ │ └───> -                                           (= SYM_1)
 │ └─────> -                                           (= SYM_2)
 └───────> -                                           (= SYM_3)
```

Checking the control difference
If the throttle valve control difference TPS_DIF exceeds the permissible maximum value C_TPS_DIF_MAX_DIAG for longer than C_T_TPS_DIF_DIAG then a error is detected and a irreversible limp home is applied (Throttle is switched off).

Error symptoms are defined to this diagnosis as:

MTC_CTL_3

```
☐☐☐☐
 │ │ │ └─> MTC; control difference check    (= SYM_0)
 │ │ └───> -                                (= SYM_1)
 │ └─────> -                                (= SYM_2)
```

```
└──────> -                                  (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** reset

Recurrence: 10ms

```
Activation:     If          LV_IGK = 1
                    and     LV_ST = 0
                    and     (LV_ES = 0   or  LV_TPS_SP_EXT_ADJ = 1)
                    and     LV_TPS_AD_ACT = 0
                    and     LV_MTC_CUR_OFF = 0
                    and     STATE_ETC_LIH <> 10H
                    and     LV_TPS_SP_JAM = 0
                Then        LV_CDN_DIAG_MTC_CTL_n = 1    (n = 1,2,3)
                Else        Deactivation:
                            LV_CDN_DIAG_MTC_CTL_n = 0
                Endif
```

Interface of TPS monitor with the Rate-Based Monitoring statistics					

Input data:

LV_END_DIAG_TPS_AD	LV_END_DIAG_TPS_AD	LV_END_DIAG_TPS_AD_BOL	LV_END_DIAG_MTC_CTL_3

FUNCTION DESCRIPTION:

General information:

With this module the interface between the TPS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_TPS data.

Within STATE_RBM_TPS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
- Monitor disabled because of system malfunction (bit 1, not valid for TPS)
- Monitor indiv. RBM conditions encountered within this DC (bit 2 not valid for TPS)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_TPS = 0

on failure memory reset :

bit 1 of STATE_RBM_TPS = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

```
If    bit 0 of STATE_RBM_TPS = 0
Then        If      LV_END_DIAG_MTC_CTL_3 = 1    and
                    LV_END_DIAG_TPS_AD_BOL = 1            and
                    LV_END_DIAG_TPS_AD = 1
            Then    bit 0 of STATE_RBM_TPS = 1
            Endif
Endif
bit 2 of STATE_RBM_TPS = 1     (no individual RBM conditions)
```

FUNCTION DESCRIPTION:

General information:

The throttle position is determined by a two-channeled sensor system (contact potentiometer). Both channels deliver inverse dispersing voltage signals. In order to reduce the measurement inaccuracy, the two signal voltages will be referenced to their supply voltage. After the initial engine start and component change the characteristic Potentiometer value is learnt within an adaptation routine. The value for the lower stop is stored at the end of the driving cycle in the non-volatile memory.

A plausibilization unit monitors both sensor signals, as well as the belonging supply voltage and from them establishes the system state of the THR-position acquisition (undisturbed, disturbed, THR-position not recognizable). From the voltages of both TPS-channels, the THR-position for each channel is determined, taking into consideration the adaptation values for the lower stop. Based on the determined state of the system, the resulting THR-position is determined by the individual values. In case of a disturbance of the position acquisition (LV_ERR_TPS_x ≠ 0, see chapter TPS diagnosis), the selection of the position is conducted from one of the two TPS-channels - respectively, in case of a complete collapse, the THR-control is switched off (limp home).

Application conditions:

Initialisation: all error memory outputs are initialized with 0
(LV_ERR_..., LV_CDN_DIAG_..., ERR_SYM_..., LV_END_DIAG_...)
LV_TPS_ST_BOL_END = 0 at transition LV_IGK 0 → 1
remaining outputs see chapters

Recurrence: 5ms

Activation: see Chapters

Signal flow diagram:

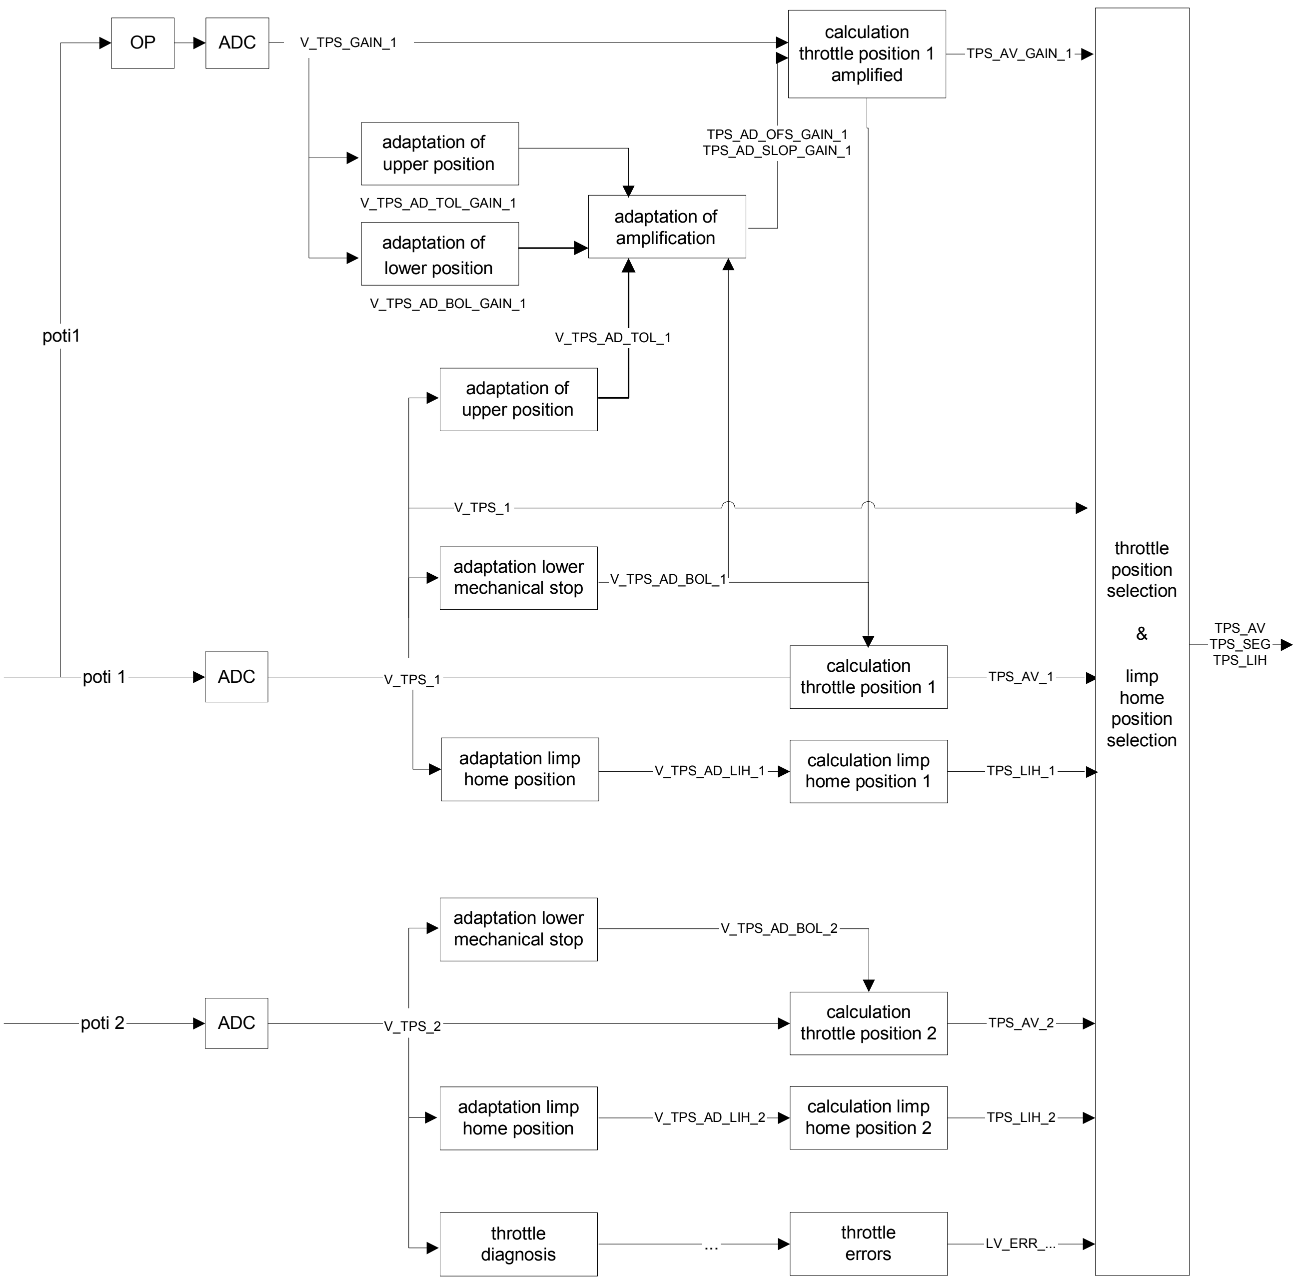

Fig. 1: Overview of the functions of the TPS-position acquisition

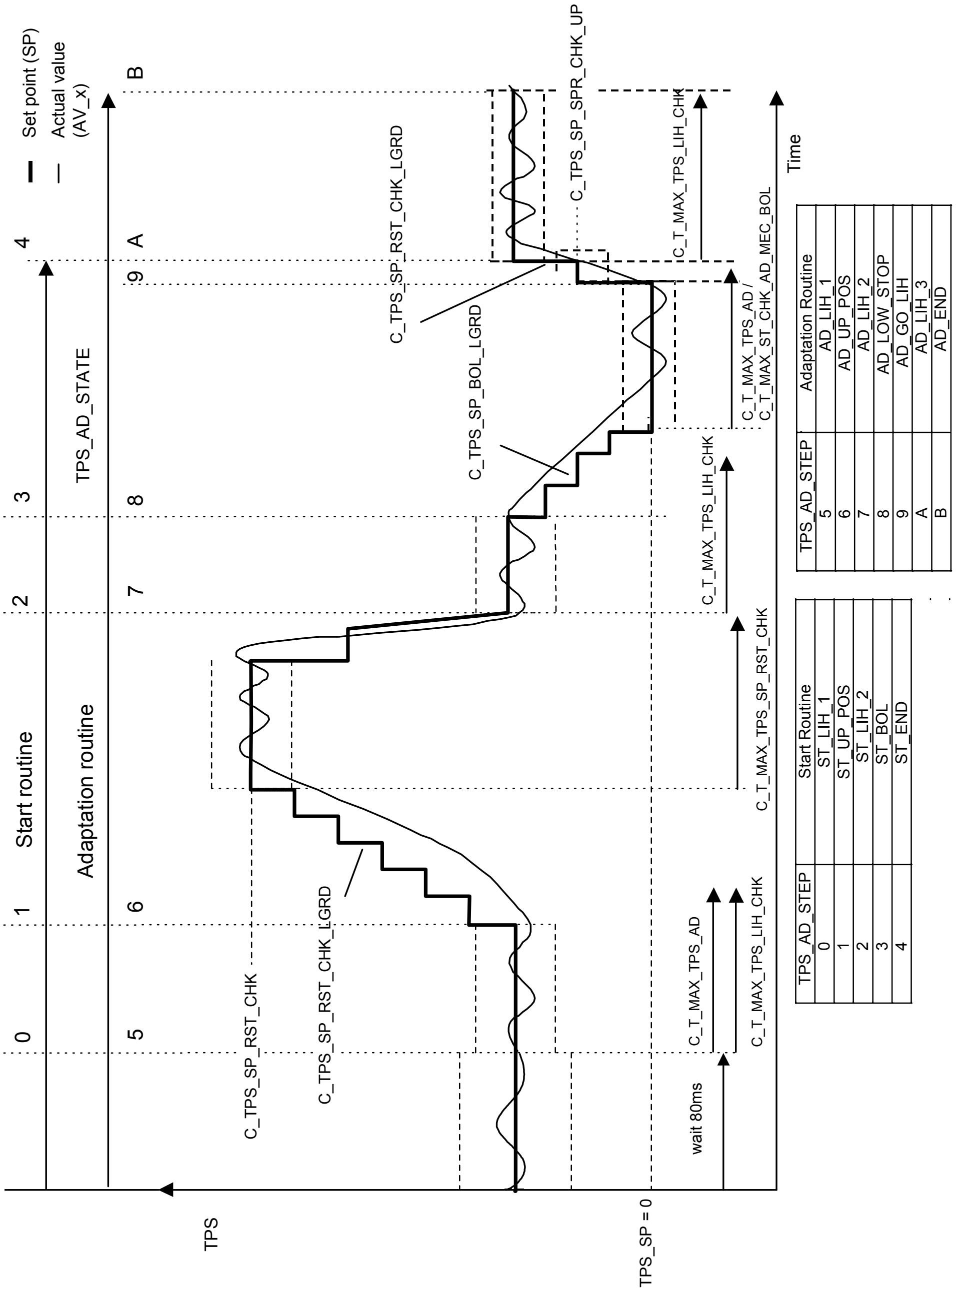
61.9.1 Algorithm of adaptation and start-check

Description:

The acquisition of the throttle position includes two sections: the start-check routine and adaptation routine. The start-check routine is a kind of slightly reduced adaptation routine with own thresholds and the possibility to be aborted after a first LIH-check by engine start. It is carried out at every switch on the engine control unit. In the case engine is started before start routine is finished, old adaption values for the lower mechanical stop are used. The adaptation routine starts only if the adaptation is requested.



TPS_AD_STEP	Start Routine
0	ST_LIH_1
1	ST_UP_POS
2	ST_LIH_2
3	ST_BOL
4	ST_END

TPS_AD_STEP	Adaptation Routine
5	AD_LIH_1
6	AD_UP_POS
7	AD_LIH_2
8	AD_LOW_STOP
9	AD_GO_LIH
A	AD_LIH_3
B	AD_END

Fig. 2 Time conditions of start-check / adaption routine

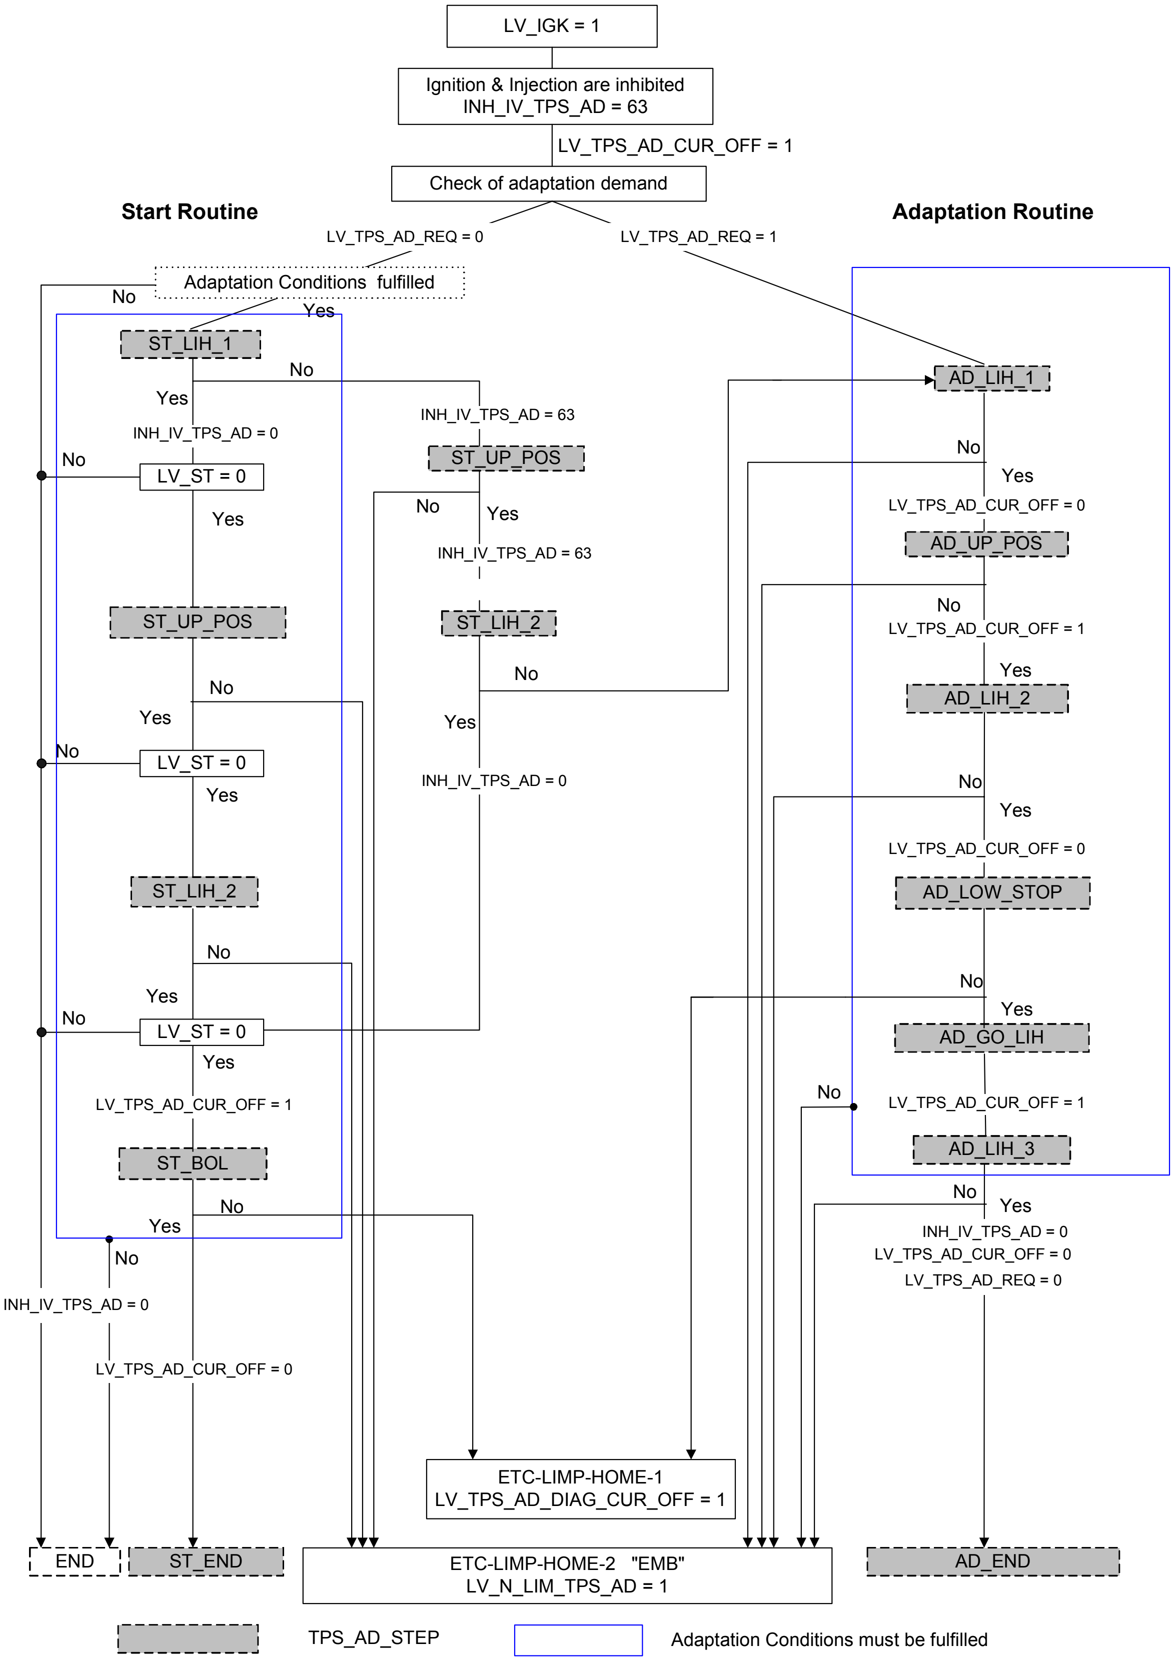


Fig. 3 Algorithm of Adaptation and Start-check

The Algorithm shows the reactions in passed and not passed conditions of both routines.

61.9.2 Initialization

General information:

The delivered voltage from the TPS-poti is a measurement for the throttle position. Because of the electrical and the mechanical tolerances, the characteristic potentiometer values must be adapted. The adaptation and diagnosis of the Poti-voltages for the lower mechanical stops and Limp Home (LIH) occurs within a set routine. By learning and checking of the Limp Home position it delivers information whether there has been an exchange in the throttle actuator. The adapted lower mechanical stop and the upper check position are used as a reference point for the calculation of the throttle valve position. The upper mechanical stop is not learned. During the adaptation phase no limitations of the THR-setpoint are active. The learned value for the lower stop and the upper position is stored at the end of the driving cycle as „non-volatile".

Formula section:

At the beginning of the adaptation (either 1st adaptation at end of line or adaptation requested by failed start check) the values are described with the following EEPROM- and Default-values:

Default (only if adaptation requested LV_TPS_AD_REQ = 1):

V_TPS_AD_LIH_1 = C_V_TPS_SP_LIH_1
V_TPS_AD_LIH_2 = C_V_TPS_SP_LIH_2
V_TPS_AD_EL_BOL_1 = C_V_TPS_AD_BOL_INI_1
V_TPS_AD_EL_BOL_2 = C_V_TPS_AD_BOL_INI_2
TPS_AD_SLOP_GAIN_1 = C_TPS_AD_SLOP_GAIN_INI_1
V_TPS_AD_OFS_GAIN_1 = C_V_TPS_AD_OFS_GAIN_INI_1
TPS_LIH_1 = TPS_LIH_2= TPS_SP_AD = TPS_LIH_INI

Always:

TPS_LIH_INI = C_TPS_SLOP / 2 *
(C_V_TPS_SP_LIH_1– C_V_TPS_AD_BOL_INI_1-
C_V_TPS_SP_LIH_2+ C_V_TPS_AD_BOL_INI_2)

TPS_SP_AD = TPS_LIH_1

61.9.3 Calculation of ERRM output variables

61.9.3.1 Diagnosis condition definition

Description:

The diagnosis condition for LV_ERR_TPS_AD is true as long as the adaptation routine is active.

The diagnosis condition for LV_ERR_TPS_ST_CHK_1 is true if TPS_AD_STEP = ST_LIH_2.

The diagnosis condition for LV_ERR_TPS_ST_CHK_2 is true if TPS_AD_STEP = ST_UP_POS **or** ST_LIH_2.

The diagnosis condition for LV_ERR_TPS_AD_BOL is true if TPS_AD_STEP = ST_BOL.

Formula section:

If TPS_AD_STEP = 5H **or** 6H **or** 7H **or** 8H **or** 9H **or** AH

Then LV_CDN_DIAG_TPS_AD = 1

```
Else    LV_CDN_DIAG_TPS_AD = 0
Endif
If      TPS_AD_STEP = 1H or 2H
Then    LV_CDN_DIAG_TPS_ST_CHK_2 = 1
Else    LV_CDN_DIAG_TPS_ST_CHK_2 = 0
Endif
If      TPS_AD_STEP = 2H
Then    LV_CDN_DIAG_TPS_ST_CHK_1 = 1
Else    LV_CDN_DIAG_TPS_ST_CHK_1 = 0
Endif
If      TPS_AD_STEP = 3H
Then    LV_CDN_DIAG_TPS_AD_BOL = 1
Else    LV_CDN_DIAG_TPS_AD_BOL = 0

Endif
```

61.9.3.2 Error symptom definition

Description:

Error symtoms are defined for this diagnosis as:

Adaptation routine

TPS_AD

```
┌─┬─┬─┬─┐

 └───────> -                                   (= SYM_3)
```

61.9.3.3 Calculation end of diagnosis

Description:

The end of diagnosis in errorfree case is set on the end of Start-check/Adaptation or latest if a error is set.

Formula section:

```
Calculation end of diagnosis in error case
If      LV_ERR_TPS_XY = 1   (XY = AD or ST_CHK_1 or ST_CHK_2 or AD_BOL)
Then    LV_END_DIAG_TPS_XY = 1
Calculation end of diagnosis in errorfree case
Else    If      TPS_AD_STEP = ST_END
        Then    LV_END_DIAG_TPS_ST_CHK_1 = 1
                LV_END_DIAG_TPS_ST_CHK_2 = 1
                LV_END_DIAG_TPS_AD_BOL = 1
        Endif
        If      TPS_AD_STEP = AD_END          or
                LV_TPS_AD_REQ = 0
        Then    LV_END_DIAG_TPS_AD = 1
        Endif
Endif
```

61.9.4 Requests to activate the adaptation-routine or start-check

Description

After the control unit is switched on the activation bit for start-check or adaptation is set (LV_TPS_AD_ACT=1).

If the adaptation request LV_TPS_AD_REQ is set then the adaptation-routine will start otherwise the start-routine is activated.

Conditions for setting LV_TPS_AD_REQ:

- In initial start (first engine run or control unit exchange), that means no adaptation values are stored in the non volatile memory
- After a component exchange , if the poti values are lie outside the tolerance window
- Check sum error is current
- Initiated by the tester
- Adaptation demand requested by diagnosis e.g. if adaptation or start-check was failled

Formula section:

```
If      Adaptation request is active
Then    LV_TPS_AD_REQ = 1
Endif

If      LV_IGK 0->1
Then    LV_TPS_AD_ACT = 1           //activation bit for adaptation or start-check
        LV_TPS_AD_CUR_OFF = 1       //request to switch off ETC
        INH_IV_TPS_AD = 63          //inhibition of injection
    If      LV_TPS_AD_REQ = 0
    Then    Start routine
            TPS_AD_STEP = ST_LIH_1
    Else    Start of adaptation routine
            TPS_AD_STEP = AD_LIH_1
    Endif
Endif
```

61.9.4.1 Monitoring of adaptation or start-check conditions

Description:

To get a plausible battery voltage the check of conditions for adaptation or start-check is delayed 80 ms after control unit is switched on.

If the conditions are exceeded the routine (adaptation or start-check) is stopped, injection will be released.

If the conditions are exceeded during the adaptation routine then:

- Error “Adaptations conditions exceeded” is set
- ETC limp home 2 “EMB” is activated
- New adaptation in the next driving cycle is requested

If the conditions are exceeded during the start check routine, it will be ignored without error entry.

Formula section:

```
If(1)   LV_TPS_AD_ACT = 1        and          //Adaptation or Start-check is active
        time delay of 80ms after LV_IGK = 1 is ellapsed
Then(1)
    If(2)   LV_IGK = 0                                  or
            VB  <  C_VB_MIN_TPS_AD                      or
            N  >  C_N_MAX_TPS_AD                        or
            VS  >  2km/h (NC_VS_MAX_TPS_AD)             or

                Endif(3)
    Else(2)     continue adaptation or start-check
    Endif(2)
Endif(1)
```

61.9.5 Start check routine

General information:

The Start-check routine includes:

- First limp home check and Adaptation of the Limp Home Position
- Limp home spring test
- Second limp home check
- Adaption of lower mechanical stop

61.9.5.1 First Check of Limp Home position at Start routine (ST_LIH_1)

Description:

When checking the Limp Home position the throttle valve is staying without current hold by spring power in the Limp Home position. The actual sensor-signals are compared with their adaptations in the non-volatile memory.

If the actual voltage values during the time interval are outside the hysteresis (Fig. 4) then no agreement is recognised and a new adaptation is necessary or an engine start must be cancelled (Fig. 3).

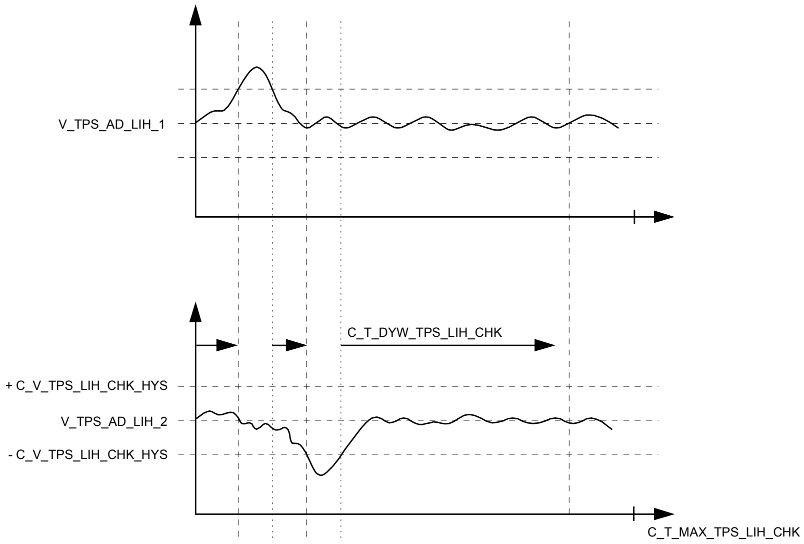

Fig. 4 Checking the Limp Home position (CHK_LIH)

Formula section:

TPS_AD_STEP = ST_LIH_1

LIH Check:

IF(1) LV_TPS_AD_ACT = 1 **and**
LV_MTC_CUR_OFF = 1 **and**
LV_TPS_AD_REQ = 0

Then(1) Start Time: C_T_MAX_TPS_LIH_CHK

```
        If(2)           T< C_T_MAX_TPS_LIH_CHK
        Then (2)        Start Time: C_T_DYW_TPS_LIH_CHK
            IF(3) $|V\_TPS\_X - V\_TPS\_AD\_LIH\_x| \le C\_V\_TPS\_LIH\_CHK\_HYS$ ( X = Poti 1, 2 )
                        and     within the interval: C_T_DYW_TPS_LIH_CHK
            Then(3)     "Check Limp home ok"
                        CTR_ST_CHK_CHK_LIH_1_READY is incremented once
                        TPS_AD_STEP = ST_UP_POS
                        LV_TPS_AD_CUR_OFF = 0
                        INH_IV_TPS_AD = 0
            Else(3)  start "Then (2)" again
        Else(2)         CTR_ST_CHK_CHK_LIH_1_ERR is incremented once
                        TPS_AD_STEP = ST_UP_POS
                        Ignition and injection remains deactivated
                        LV_TPS_AD_CUR_OFF = 0
    Else(1)     INH_IV_TPS_AD = 0
    Endif
```

Limp Home position:
Calculation of limp home positions right after CHK_LIH_1. A synchronized TPS_LIH is necessary for the Throttle catch function:

$TPS\_LIH\_1 = (V\_TPS\_AD\_LIH\_1 – V\_TPS\_AD\_EL\_BOL\_1) * C\_TPS\_SLOP$
$TPS\_LIH\_2 = (V\_TPS\_AD\_EL\_BOL\_2 – V\_TPS\_AD\_LIH\_2) * C\_TPS\_SLOP$
$0° \le TPS\_LIH\_x \le C\_TPS\_MAX$

Continuously LIH AD:

The Continuously limp home adaptation is calculated parallel to the first Limp home check. If the first Limp home Check is passed then the engine start is not locked any more and the start routine is going on with or without successfully adaptation.

```
IF(1)       LV_TPS_AD_ACT = 1                       and
            LV_MTC_CUR_OFF = 1                      and
            LV_TPS_AD_REQ = 0                       and
            "LIH CHECK 1 active":
            INH_IV_TPS_AD = 63                      and
            TPS_AD_STEP = ST_LIH_1
Then(1) Start Time: C_T_TPS_AD_HYS

    Then(2) IF(3) $\left| \frac{V\_TPS\_x_1 + V\_TPS\_x_{END}}{2} - C\_V\_TPS\_SP\_LIH\_x \right|$
```

```
                    ≤ C_V_TPS_AD_WIN_LIH
        Then(3)     $V\_TPS\_AD\_LIH\_x = \frac{V\_TPS\_x_1 + V\_TPS\_x_{END}}{2}$
        Else (3) IF(4) $\frac{V\_TPS\_x_1 + V\_TPS\_x_{END}}{2} > C\_V\_TPS\_AD\_WIN\_LIH +$
                                            $C\_V\_TPS\_SP\_LIH\_x$
            Then (4) V_TPS_AD_LIH_x = C_V_TPS_AD_WIN_LIH +
                                        C_V_TPS_SP_LIH_x
            Else (4) V_TPS_AD_LIH_x =C_V_TPS_SP_LIH_x -
                                        C_V_TPS_AD_WIN_LIH
      Else(2)  start "Then (1)" again
  Else(1)      continue with the old adaptation values
  Endif
```

61.9.5.2 Spring Test at the Start routine (ST_UP_POS)

Description:

Out of the Limp home position the throttle position setpoint is increased using the changing limitation until the setpoint for testing the retracting spring is reached. Now a timer is started. The actual value of the throttle position has to reach the setpoint within the hysteresis within a limit maximum of time.

Regarding certain cases with closed throttle at the limp home position it is necessary to switch on the position controller near the lower mechanical stop to prevent that the throttle is going into the lower mechanical stop with high acceleration.

Signal flow diagram:

Endif(1)
```

61.9.5.4 Adaption of lower mechanical stop and limp home spring test opening at Start routine (ST_BOL)

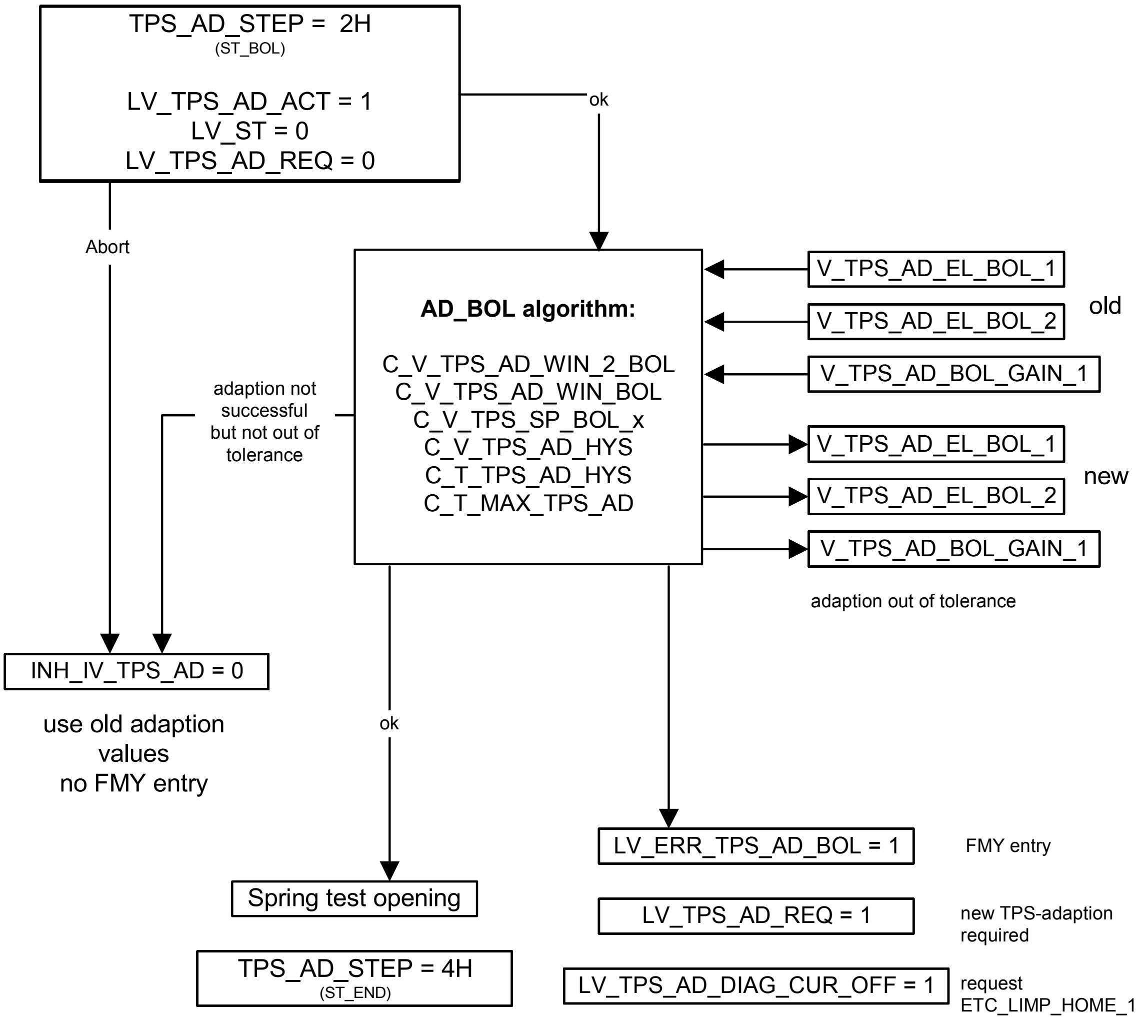
Description:

During a complete start check (not aborted by a quick start), the lower mechanical stop is learnt. After successful adaptation, the adaptation values V_TPS_AD_EL_BOL_1/2 are saved in the non-volatile memory. If the adaptation is not completed successfully (e.g. abnormal termination due to violation of the activation conditions), the adaptation value learnt last remains valid.

During adaptation, all voltage values must be within the adaptation window V_TPS_AD_EL_BOL_X ± C_V_TPS_AD_WIN_2_BOL; otherwise LV_ERR_TPS_AD_BOL is set.

A hysteresis band C_V_TPS_AD_HYS is placed around the first detected value (pots 1 and 2). If all values are within this hysteresis band during the adjustable time C_T_TPS_AD_HYS, the adaptation values are determined from the first and last value each (Fig. 6). If the value of a pot is outside of the hysteresis band, the operation is re-started for the two pots. The learning algorithm is limited by the maximum time C_T_MAX_ST_CHK_AD_MEC_BOL.

Signal flow diagram:



Formula section:

```

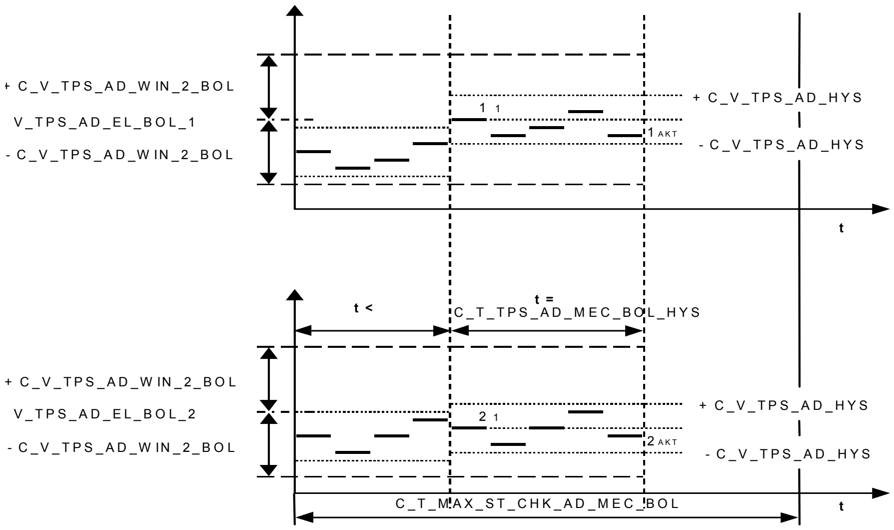

Fig. 5 Determination of the adaptation values in case of MEC_BOL adaptation during start routine

61.9.6 Adaptation routine

General information:

The Adaption routine includes:

- Limp home check and Adaptation of Limp Home Position
- Limp home spring test closing and adaptation of upper position
- Limp home check
- Limp home spring test opening and Adaptation of lower mechanical stop
- Limp home check

61.9.6.1 Adaption of Limp Home position at Adaption routine (AD_LIH_1)

Description:

The first step is the adaptation of the Limp Home position. The actuator is without current and is forced by the spring power in the limp home position.

The learning of the adaptation value depict the algorithm in Fig. 6. During the adaptation all the voltage values must be in the adaptation windows. A hysteresis band is set up around each of the first recorded values (poti 1 and 2). If all the values lie in this hysteresis band during an adjustable time then the adaptation values are determined from each first and last value. If the Poti-value lies outside the hysteresis band then the process is newly started for both Poti's. The learning algorithm is limited by the maximum time. This procedure is the same for the Limp home position and the lower mechanical stop. Just the calibration values are different.

An error memory entry occurs only at the adaptation after ECU-first initialisation not at the continuous LIH-adaptation. An error is detected if the adaptation could not be carried out during the max. time C_T_MAX_TPS_AD.

Formula section:

```
TPS_AD_STEP = AD_LIH_1
Start time: C_T_MAX_TPS_AD
    If (1)   |V_TPS _x - C_V_TPS_SP_LIH_x)| ≤ C_V_TPS_AD_WIN_LIH)

61.9.6.2 Spring test at the adaptation routine (AD_UP_POS)

Description:

After passing the check of limp home position the adaptation routine goes on with the spring test. Out of the Limp home position the throttle position set point is increased using the changing limitation until the set point for testing the retracting spring is reached. Now a timer is started. The actual value of the throttle position has to reach the set point within the hysteresis and a limit of time. Then the upper position will be adapted and the throttle is returning currentless.

Formula section:

```
TPS_AD_STEP = AD_UP_POS
begin       TPS_SP_AD + C_TPS_SP_RST_CHK_LGRD
until       TPS_SP_AD ≥ C_TPS_SP_RST_CHK
Start Time : C_T_MAX_TPS_SP_RST_CHK
If(1) |TPS_AV - C_TPS_SP_RST_CHK |≤ C_TPS_SP_RST_CHK_HYS)     and
      T <  C_T_MAX_TPS_SP_RST_CHK
Then(1)     Start time C_T_MAX_TPS_AD
```

```
        IF(2)   T <  C_T_MAX_TPS_AD
      Then(2)
          If(3)  Within the interval:     C_T_TPS_AD_HYS                        and
                 $| V\_TPS\_1_{1+n} - V\_TPS\_1_{1} | \leq C\_V\_TPS\_AD\_HYS$        (n=1,2;3;…)
          Then(3)
                 New calculation of upper value of amplified poti 1

                INH_IV_TPS_AD = 0               (Activate ignition and injection)
    Endi
```

61.9.6.3 Second Check of Limp Home position at Adaptation routine (AD_LIH_2)

Description:

After the return spring test the adaptation routine repeats the ckeck of limp home position.

Formula section:

```
TPS_AD_STEP = AD_LIH_2
Start time: C_T_MAX_TPS_LIH_CHK
If(1)      T < C_T_MAX_TPS_LIH_CHK
Then(1)
   If(2)   within the interval: C_T_DYW_TPS_LIH_CHK                and
           |V_TPS_x - V_TPS_AD_LIH_x| ≤  C_V_TPS_LIH_CHK_HYS  ( X = Poti 1, 2 )
   Then(2) LV_TPS_AD_CUT_OFF = 0
           TPS_AD_STEP = AD_LOW_STOP
   Else(2) goto If (1)
Else(1)    ERR_SYM_TPS_AD = SYM_2       “Spring test and CHK_LIH not passed”
           LV_ERR_TPS_AD = 1
           LV_TPS_AD_ACT = 0            (Stopping the TPS adaptation)
           LV_N_LIM_TPS_AD = 1          (ETC-LIMP-HOME-2, )
           LV_TPS_AD_REQ = 1            (New TPS adaptation nesecarry)
           INH_IV_TPS_AD = 0            (Activate ignition and injection)
Endif
```

61.9.6.4 Adaptation of lower mechanical stop during adaption routine (AD_LOW_STOP)

Description:

As soon as the mechanical stop is reached, the described adaptation algorithm in Fig. 7, is triggered. The scanned data is used for both, calculation of the lower mechanical / electrical stop and for the amplification characteristic. After the adaptation of the lower stop and calculated amplification the throttle at the electrical stop opens a small angle in relation to the mechanical stop. This is necessary to prevent a chock.

Formula section:

```
TPS_AD_STEP = AD_LOW_STOP
Begin          TPS_SP_AD - C_TPS_SP_BOL_LGRD
Until          TPS_SP_AD = 0
Start Time: C_T_MAX_TPS_AD
If (1)     |V_TPS _x  - C_V_TPS_SP_BOL _x| ≤ C_V_TPS_AD_WIN_BOL)
```

```
Then(1)
  If(2)     $T < C\_T\_MAX\_TPS\_AD$
  Then(2)
    IF(3)      Within the interval: C_T_TPS_AD_HYS                         and
               $|V\_TPS\_x_{1+n} - V\_TPS\_x_1| \leq C\_V\_TPS\_AD\_HYS$
               (n=1,2;3;…)
    Then(3)
       $V\_TPS\_AD\_EL\_BOL\_x = \frac{V\_TPS\_x_1 + V\_TPS\_x_{END}}{2}$
       $V\_TPS\_AD\_BOL\_GAIN\_1 = \frac{V\_TP1\_GAIN\_1_1 + V\_TPS\_GAIN\_1_{END}}{2}$
     slope of amplifaction of amplified poti 1:
           $TPS\_AD\_SLOP\_GAIN\_1 = \frac{V\_TPS\_AD\_TOL\_GAIN\_1 - V\_TPS\_AD\_BOL\_GAIN\_1}{V\_TPS\_AD\_TOL\_1 - V\_TPS\_AD\_EL\_BOL\_1}$
     offset of amplifaction of amplified poti 1:
     $V\_TPS\_AD\_OFS\_GAIN\_1 = V\_TPS\_AD\_BOL\_GAIN\_1 - V\_TPS AD\_EL\_BOL\_1 * TPS\_AD\_SLOP\_GAIN \_1$
         TPS_AD_STEP = AD_GO_LIH
    Else(3) go to If(2)
  Else(2)  go to else(1)
Else (1)        ERR_SYM_TPS_AD = SYM_3
                "Adaptation value - lower mechanical stop – outside range"

                LV_ERR_TPS_AD = 1

                LV_TPS_AD_ACT = 0                   (Stopping the TPS adaptation)
                LV_TPS_AD_DIAG_CUR_OFF = 1          (ETC-LIMP-HOME-1 demand)
                LV_TPS_AD_REQ = 1                   (New TPS adaptation necessary)
                INH_IV_TPS_AD = 0                   (Activate ignition and injection)
Endif
```

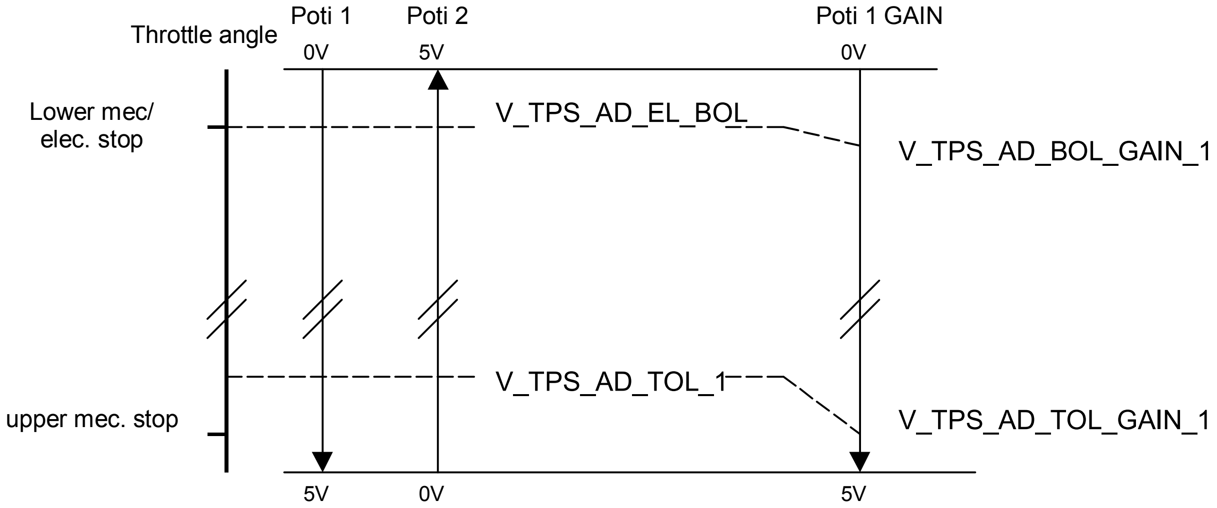

Fig 7. Definition of the adaptation positions

61.9.6.5 Limp home spring Test opening (AD_GO_LIH)

Description:

After finish the lower adaptation the MTC opens the throttle using the change limitation until the nominal values for current cut off is reached. As from that position the spring returns the throttle currentless to the Limp Home position and carries through the Limp Home Check again, because it is possible that the throttle itself clamps at the mechanical stop.

Formula section:

```
TPS_AD_STEP = AD_GO_LIH
begin
            TPS_SP_AD + C_TPS_SP_RST_CHK_LGRD
until       $TPS\_SP\_AD \geq C\_TPS\_SP\_SPR\_CHK\_UP$
LV_TPS_AD_CUR_OFF = 1
TPS_SP_AD = TPS_LIH_INI
TPS_AD_STEP = AD_LIH_3
Third Limp Home Check
```

61.9.6.6 Third Check of Limp Home position at Adaptation routine (AD_LIH_3)

Description:

After the spring test at the lower stop follows the check of limp home position again. Now the adaptation routine is finished. Depending on the passed test the adaptation request is cancelled.

Formula section:

```
TPS_AD_STEP = AD_LIH_3
Start time: C_T_MAX_TPS_LIH_CHK
If(1)         T <  C_T_MAX_TPS_LIH_CHK
Then(1)       Start Time: C_T_DYW_TPS_LIH_CHK
    If(2)     within the interval: C_T_DYW_TPS_LIH_CHK                and
              |V_TPS_X -V_TPS_AD_LIH_x|  ≤ C_V_TPS_LIH_CHK_HYS       ( X = Poti 1, 2 )
    Then(2)       LV_TPS_AD_CUR_OFF = 0
                  INH_IV_TPS_AD =0
                  TPS_AD_STEP = AD_END
    Else (2)      go to If (1)
Else (1)          ERR_SYM_TPS_AD = SYM_2        "Spring test and CHK_LIH not passed"
                  LV_ERR_TPS_AD = 1
                  LV_TPS_AD_ACT = 0          (Stopping the TPS adaptation)
                  LV_TPS_AD_REQ = 1          (New TPS adaptation necessary)
                  LV_N_LIM_TPS_AD = 1        (ETC-LIMP-HOME-2)
                  INH_IV_TPS_AD = 0          (Activate ignition and injection)
Endif
```

Limp Home position:

TPS_LIH_1 = (V_TPS_AD_LIH_1 – V_TPS_AD_EL_BOL_1) * C_TPS_SLOP

TPS_LIH_2 = (V_TPS_AD_EL_BOL_2 – V_TPS_AD_LIH_2) * C_TPS_SLOP

0° ≤ TPS_LIH_x ≤ C_TPS_MAX

FUNCTION DESCRIPTION:

General information:

The following TPS/ETC-Limp Home system reactions are defined:

- **TPS-EMERGENCY-MAX**	*(STATE_TPS_DIAG = TPS_LIH_MAX)*
- **TPS-EMERGENCY-X**	*(STATE_TPS_DIAG = TPS_LIH_X)*
- **ETC-LIMP-HOME-1**	*(STATE_ETC_LIH = ETC_LIH_1)*
- **ETC-LIMP-HOME-2-REV**	*(STATE_ETC_LIH = ETC_LIH_2_REV)*
- **ETC-LIMP-HOME-2 (SAS)**	*(STATE_ETC_LIH = ETC_LIH_2)*
- **ETC-LIMP-HOME-3**	*(STATE_ETC_LIH = ETC_LIH_3)*

All **ETC-LIMP-HOME-..** have a higher priority then all **TPS-EMERGENCY-..**

Application conditions:

Initialization: all outputs = 0 at LV_IGK 0->1 or reset or at clearing error memory
LV_ERR_TPS according ABC type **STD_INI**

Recurrence: 5ms

Activation: LV_IGK = 1
Deactivation: LV_IGK = 0 (set LV_CDN_DIAG_TPS = 0)

Signal flow diagram:

61.10.1 TPS-EMERGENCY-MAX

(STATE_TPS_DIAG = TPS_LIH_MAX)

Description:

If TPS-Emergency MAX is activ, there is a maximum selection between the two channels (see “Determination of the Throttle Position”).

Formula section:

```
If      LV_DET_ERR_TPS_RATIO = 1
Then    STATE_TPS_DIAG = TPS_LIH_MAX
Endif
```

61.10.2 TPS-EMERGENCY-X

(STATE_TPS_DIAG = TPS_LIH_X)

Description:

If one TPS channel (=Y) is detected as faulty then TPS-EMERGENCY-X is active.
If TPS-EMERGENCY-X is active, the throttle position acqusition is done with a leading Poti-X
(see “Acqusition of the throttle position”).

Formula section:

```
If      LV_ERR_TPS_Y = 1                or
        LV_ERR_TPS_MAF_Y = 1
Then    STATE_TPS_DIAG = TPS_LIH_X
Endif
```

Idle speed demand:

```
If      STATE_TPS_DIAG = TPS_LIH_X            and
        LV_CT = 1
Then    LV_TPS_MTC_N_LIM = 1    (see “Engine speed limit coordination)
Endif
```

61.10.3 ETC-LIMP-HOME-1 / ETC-LIMP-HOME-2-REV

(STATE_ETC_LIH = ETC_LIH_1) / (STATE_ETC_LIH = ETC_LIH_2_REV)

Description:

ETC-LIMP-HOME-1 is demanded by the ETC diagnosis (see “Engine throttle diagnosis and adaptation”) and the ETC driver diagnosis.

During ETC-LIMP-HOME-1 the following limp home measures are defined:

- Throttle valve without power (hold by spring power in the Limp-Home position)
- Engine speed limitation in limp home mode (with considering the drivers request)

ETC-LIMP-HOME-2-REV is initiated reversible until the ETC-Limp Home throttle position (for calibration data and additional information see: “Check of the Limp-Home position” in chapter “Engine throttle diagnosis and adaptation”) has been safely reached.
If the Limp-Home Position is reached ETC-LIMP-HOME-1 is set, if not ETC-LIMP-HOME-2 is set.

During ETC-LIMP-HOME-2_REV the following limp home measures are defined:

- Throttle valve without power (hold by spring power in the Limp-Home position)
- Engine speed limitation in limp home mode (without considering the drivers request)

Formula section:

Activation condition of ETC-LIMP-HOME-1:

If(1) [STATE_ETC_LIH = ETC_NO_LIH **and**
LV_ERR_MTC_DR = 1 **or**
LV_ERR_MTC_CTL_3 = 1 **or**
LV_TPS_AD_DIAG_CUR_OFF = 1]

Or

[STATE_ETC_LIH = ETC_LIH_3 **and**
LV_ERR_MTC_CTL_2 = 1

Then(1)

Activation of ETC-LIMP-HOME-2-REV:

STATE_ETC_LIH = ETC_LIH_2_REV
LV_MTC_CUR_OFF_REQ = 1 (ETC without power request)
LV_N_LIM_ETC_LIH = 1
LV_TPS_MTC_N_LIM = 1 (see “Engine speed limit coordination)

Check of Limp Home position:

Start Time: C_T_MAX_TPS_LIH_CHK

IF(2) T < C_T_MAX_TPS_LIH_CHK **and**
I V_TPS_X – V_TPS_AD_LIH_X I < C_V_TPS_LIH_CHK_HYS
Within the interval: C_T_DYW_TPS_LIH_CHK

Activation of ETC-LIMP-HOME-1/Deactivation of ETC-LIMP-HOME-2-REV:

```
          Then(2)    "Check limp home ok"
                     STATE_ETC_LIH = ETC_LIH_1
                     LV_MTC_LIH_CUR_OFF = 1
                     LV_N_LIM_ETC_LIH = 0
                     LV_TPS_MTC_N_LIM = 0
```

Activation of ETC-LIMP-HOME-2:

```
          Else(2)    STATE_ETC_LIH = ETC_LIH_2
          Endif(2)
Else(1)   STATE_ETC_LIH = ETC_NO_LIH
Endif(1)
```

61.10.4 ETC-LIMP-HOME-2 (SAS)

(STATE_ETC_LIH = ETC_LIH_2)

Description:

ETC-LIMP-HOME-2 (German abbreviation: SAS = Sicherheitsschubabschalten) is demanded by the ETC diagnosis (see "Engine throttle diagnosis and adaptation") and/or the TPS diagnosis (if both TPS channels are faulty). ETC-LIMP-HOME-2 is set unreversible for the engine run.
During ETC-LIMP-HOME-2 the following limp home measures are defined:

- Throttle valve without power (hold by spring power in the Limp-Home position)
- Engine speed limitation in limp home mode (without considering the drivers request)

Formula section:

Activation of ETC-LIMP-HOME-2:

```
If        STATE_ETC_LIH = ETC_NO_LIH          or
          STATE_ETC_LIH = ETC_LIH_1           or
          STATE_ETC_LIH = ETC_LIH_2_REV       or
          STATE_ETC_LIH = ETC_LIH_3
    and
          LV_N_LIM_TPS_AD               or
          [LV_ERR_TPS_1 = 1             and
          LV_ERR_TPS_2 = 1]             or
          [LV_ERR_TPS_MAF_1 = 1         and
          LV_ERR_TPS_MAF_2 = 1]         or
          [LV_ERR_TPS_X = 1             and
          LV_ERR_TPS_MAF_Y = 1]
```

```
Then    STATE_ETC_LIH = ETC_LIH_2
        LV_N_LIM_ETC_LIH = 1
        LV_MTC_CUR_OFF_REQ = 1      (ETC without power request)
        LV_TPS_MTC_N_LIM = 1        (see “Engine speed limit coordination)
Endif
```

61.10.5 ETC-LIMP-HOME-3

(STATE_ETC_LIH = ETC_LIH_3)

Description:

ETC-LIMP-HOME-3 is demanded by the ETC position controller diagnosis (see “Engine throttle diagnosis and adaptation”). ETC-LIMP-HOME-3 is set reversible for the engine run. During ETC-LIMP-HOME-3 the following limp home measures are defined:

- Engine speed limitation in limp home mode (without considering the drivers request)

Formula section:

Activation of ETC-LIMP-HOME-3:

```
If      STATE_ETC_LIH = ETC_NO_LIH            and
        LV_ERR_MTC_CTL_1 = 1
Then    STATE_ETC_LIH = ETC_LIH_3
        LV_N_LIM_ETC_LIH_REV = 1
        LV_TPS_MTC_N_LIM = 1        (see “Engine speed limit coordination)
Else    STATE_ETC_LIH = ETC_NO_LIH
Endif
```

61.10.6 Calculation of LV_ERR_TPS

Description:

LV_ERR_TPS is used for MIL activation and inhibition of functions. The error is set depending the present status of ETC limp-home (combination of operation-mode and present TPS errors).

Formula section:

```
LV_CDN_DIAG_TPS = 1
If      STATE_ETC_LIH = ETC_LIH_1                 or
        STATE_ETC_LIH = ETC_LIH_2_REV             or
        STATE_ETC_LIH = ETC_LIH_2
Then    ERR_SYM_TPS = SYM_2
Else    ERR_SYM_TPS = NO_SYM
Endif
```

LV_ERR_TPS, LV_END_DIAG_TPS is calculated by error management.

Input data:

LV_IGK	LV_CDN_VB_MIN_DIAG	LV_ERR_SPI_MPS	

Import actions:

ACTION_ERRM_FilterMulticondition(IN< RLY_MTC_HEAT >, IN< CDN_DIAG_RLY_MTC_HEAT >, IN< ERR_DIAG_RLY_MTC_HEAT >, IN<C_ABC_INC_RLY_MTC_HEAT>, IN<C_ABC_MAX_RLY_MTC_HEAT>, OUT<LV_ERR_RLY_MTC_HEAT>)
ACTION_INFR_GetElDiagMTCHEAT(OUT< Cdn_diag_rly_mtc_heat>, OUT< Err_diag_rly_mtc_heat>)

Note : ACTION_INFR_GetElDiagMTCHEAT() is defined in the IRS (Infrastructure requirement specification AGGR THRO)

FUNCTION DESCRIPTION:

General information:

The signal from the driver which controls the throttle housing heater relay is diagnosed. The relay is driven by the ECU via an output driver. The failure detection is done by ECU Hardware and given to ASW. The purpose of the diagnosis is based on the detection of electrical faults as defined by OBD I requirements.

Description:

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_RLY_MTC_HEAT executions, to avoid the usage of wrong infrastructure information. The error detection algorithm operates the electrical diagnosis of powerstage outputs of ATIC39.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Vbatt(SCP)          (= SYM_0)
 │ │ └───> Short circuit to GND(SCG)            (= SYM_1)
 │ └─────> Open load(OC)                        (=SYM_2)
 └───────> -                                    (=SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

Set delay counter for NC_PSD_DLY_RLY_MTC_HEAT

Recurrence: 100 ms

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_RLY_MTC_HEAT = 0) the diagnosis conditions are set according infrastructure information: CDN_DIAG_RLY_MTC_HEAT.
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_RLY_MTC_HEAT.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_RLY_MTC_HEAT and ERR_DIAG_RLY_MTC_HEAT.

ACTION_ERRM_FilterMulticondition (IN<RLY_MTC_HEAT>, IN<CDN_DIAG_RLY_MTC_HEAT>, IN<ERR_DIAG_RLY_MTC_HEAT>, IN<C_ABC_INC_RLY_MTC_HEAT>, IN<C_ABC_MAX_RLY_MTC_HEAT>, OUT<LV_ERR_RLY_MTC_HEAT>)

This algorithm determines:

ERR_SYM_RLY_MTC_HEAT	(Detected error symptom)
LV_ERR_RLY_MTC_HEAT	(Error flag for debounced error)
LV_CDN_DIAG_RLY_MTC_HEAT	(Diagnosis condition information)
LV_END_DIAG_RLY_MTC_HEAT	(End of diagnosis information)

Diagnosis inhibition:

```
If      LV_IGK = 1                    and
        LV_CDN_VB_MIN_DIAG = 1        and
        LV_ERR_SPI_MPS = 0
Then    LV_INH_DIAG_RLY_MTC_HEAT = 0
Else    LV_INH_DIAG_RLY_MTC_HEAT = 1
Endif
```

```
If      LV_INH_DIAG_RLY_MTC_HEAT = 0

Then
```

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_RLY_MTC_HEAT and basic diagnosis conditions CDN_DIAG_RLY_MTC_HEAT) received from the infrastructure:

ACTION_INFR_GetElDiagMTCHEAT (OUT<Cdn_diag_rly_mtc_heat>, OUT<Err_diag_rly_mtc_heat>)

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_RLY_MTC_HEAT
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_RLY_MTC_HEAT

```
        If Activation conditions are met for the NC_PSD_DLY_RLY_MTC_HEAT
           recurrence of the diagnosis
        Then  [CDN_DIAG_RLY_MTC_HEAT valid from Infrastructure]
        Else  CDN_DIAG_RLY_MTC_HEAT = 0
        Endif
Else
        CDN_DIAG_RLY_MTC_HEAT = 0
Endif
```

61.12.1 Throttle housing heater relay control

General information:

Under very cold conditions it is possible that the throttle valve ices due to the humidity in the blow by gas. Additionally after engine stop a accumulation of water is possible between flap and housing. When the dew point drops the water freezes and the detection of the ETC bottom limit is disturbed. The described module is used for the removing of ice between throttle flap and body.

To ensure the function of the ETC the housing is heated before engine start. The ECU controls a relay through the Pin A_S_BBH. This is done immediately after unlocking the vehicle and the wake up of the ECU. If the ECU is locked after powerlatch no control is done.

The heater relay is deactivated.

In order to take care of the battery capacity the heater is only activated in defined time intervals. An often re-activation shall be avoid.

Hint: The output of the air temperature sensor VP_TIA and cooling water sensor VP_TCO are calculated by using the action infrastructure ACTION_INFR_GetVpTia (VP_TIA) and ACTION_INFR_GetVpTco (VP_TCO). To ensure the availability of TIA and TCO in ECU_STATE ***WAKE_UP*** the action calls are active after ECU reset.

Application conditions:

Initialization:	at reset, all variables are initialized with 0,
	but LV_MTC_HEAT_READY = 1
	set delay counter for C_DLY_RLY_MTC_HEAT
Recurrence:	100 ms
Activation:	after reset, every engine operating state
	Activation conditions are met for the

C_DLY_RLY_MTC_HEAT recurrence

61.12.2 ETC ice breaking

FUNCTION DESCRIPTION:

General information:

In case of very low temperatures it is possible that the throttle actuator is jammed by ice. The described module is used for the detection and the removing of ice between throttle flap and body. The functionality is able to detect the location of the throttle flap disturbance. We can distinguish ice in closing and opening throttle flap direction.
The ice shall be removed with a variation of the setpoint for the digital position controller. CTR_TPS_JAM_DET_ACT is used to count these events. It needs to be saved reset resistant AND in NVMY !

Signal flow diagram:

% Ice breaking was not successful !
[ CTR_TPS_JAM_PLS >= C_CTR_TPS_JAM_PLS_MAX ]
```

61.12.3 Diagnosis conditions and error symptom definition

Description:

The diagnostic conditions of the ETC jam detection are true as long as the general disable condition isn't set. The error symptoms are defined for this diagnosis as:

ERR_SYM_TPS_JAM_DET

```
  |_|_|_|_|
   |  |  |  └─> TPS jammed in closing direction          (= SYM_0)
   |  |  └────> TPS jammed in opening direction          (= SYM_1)
   |  └───────> -                                        (= SYM_2)
   └──────────> -                                        (= SYM_3)
```

Application conditions:

Initialisation: at IGKON or RST set all error variables ...TPS_JAM_DET to zero (done by the error – management function)

Recurrence: 20 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn’t fulfilled !

Formula section:

```
if    LV_TPS_JAM_DET_DI == 0
then  { Set condition and end of diagnosis information }
      LV_CDN_DIAG_TPS_JAM_DET      = 1
      lv_end_diag_tps_jam_det      = 1
      ERR_SYM_TPS_JAM_DET( k )     = ERR_SYM_TPS_JAM_DET( k-1 )
else  { remove condition diagnosis information }
      LV_CDN_DIAG_TPS_JAM_DET      = 0
endif
```

61.12.4 Control condition for ETC jam detection

Description:

The following section describes the deactivation condition and the continuously part of the ETC jam detection. The aim is to control the state machine and the ice-breaking function.

Application conditions:

Initialisation: at IGKON or RST set all to zero

Recurrence: 20 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn't fulfilled !

Formula section:

```
{ Calculate blocking time for active ice-breaking }
if      CTR_TPS_JAM_INH > 0
```

```
then    CTR_TPS_JAM_INH – = 1H        { counter is decremented }
endif

{ Calculate deactivation condition for ETC jam detection }
if      LV_TPS_JAM_OPEN_DIR == 1
then    { Deactivation in opening direction }
        LV_TPS_JAM_DET_DEAC = ( ...
                                TPS_SP_MDL  < TPS_JAM_ACT – C_TPS_JAM_HYS     or
                                TPS_AV      > TPS_JAM_ACT + C_TPS_JAM_HYS     )
else    { Deactivation in closing direction }
        LV_TPS_JAM_DET_DEAC = ( ...
                                TPS_SP_MDL  > TPS_JAM_ACT + C_TPS_JAM_HYS     or
                                TPS_AV      < TPS_JAM_ACT – C_TPS_JAM_HYS )
endif
```

61.12.5 State machine for ETC jam detection

Description:

This section describes the state machine of the ETC jam detection functionality. The state machine is used for the coordination of the different requirements during the detection of jammed ETC throttle actuator. Additionally the function manages all kind of requests to the remaining software system, that are engine speed limitation, throttle position setpoint adjustment and the inhibition of selected functions. The state machine distinguishes the following states:

STATE_TPS_JAM_DET	Note
INIT	The initialisation state initialises all important variables and checks the transition conditions to the other states.
ICE_BREAK	The ice-breaking state is used for an active breaking of ice in the throttle actuator. For this case the throttle position setpoint is varied by a rectangle function. If the ice-breaking is not successful after a defined number of rectangle pulses the function changes into the state throttle position setpoint limitation. During the active ice-breaking engine speed limitation is requested !
BREAK_END	The ice-breaking was not successful or the inhibition counter for ice-breaking isn't yet expired.

Application conditions:

Initialisation: at IGKON or RST set all to zero with exception of CTR_TPS_JAM_DET_ACT and STATE_TPS_JAM_DET = INIT

~~at first power up/on saved RAM lost (or reprogramming): CTR_TPS_JAM_ACT = 0~~

~~at reset: CTR_TPS_JAM_ACT = restored from NVMY~~

Recurrence: 20 ms

Activation: LV_IGK == 1

Deactivation: When the activation condition isn't fulfilled !

Formula section:

```
{ Reset of the activation counter in service }
if    LC_CTR_TPS_JAM_DET_ACT_CLR == 1 or
LV_CTR_TPS_JAM_DET_ACT_EXT_ADJ == 1
Then        { The throttle has been changed in service ! The activation counter is reset ! }
            CTR_TPS_JAM_DET_ACT = 0
EndIf

switch( STATE_TPS_JAM_DET )          { State machine of ETC jam detection ! }
   case   INIT:                      { ETC jam detection is in the initialisation state }

FUNCTION DESCRIPTION:

General information:

The following module described the application incidence of the ETC jam detection and should be used for the control of the ice-breaking algorithm.

61.13.1 Engine Speed Monitoring for TPS Jam Function being active

General information:

The following functionality is used for the detection of abnormal engine operating state, in this case the ETC jam detection functionality will be locked and the ETC actuator diagnosis must indicate an ETC actuator error.

Application conditions:

Initialisation: at RST set all to zero

Recurrence: 20 ms

Activation: All engine operating states

Deactivation: No deactivation

Formula section:

```
if      LV_IGK == 1
then    if    LV_IS == 1     and
          VS < C_VS_MAX_TPS_JAM     and
          ( N > C_N_MAX_NEUT_TPS_JAM      and     GEAR == 0     or
            N > C_N_MAX_GEAR_TPS_JAM      and     GEAR ~= 0     )
        then         CTR_DLY_TPS_JAM += 1H
        else         CTR_DLY_TPS_JAM = 0
```

```
        endif
        if      GEAR == 0
        then    if      CTR_DLY_TPS_JAM ≥ C_CTR_MAX_NEUT_TPS_JAM
                then    LV_TPS_SP_JAM_OFF = 1       { set for the driving cycle }
                endif
        else    if      CTR_DLY_TPS_JAM ≥ C_CTR_MAX_GEAR_TPS_JAM
                then    LV_TPS_SP_JAM_OFF = 1       { set for the driving cycle }
                endif
        endif
else    { Re-initialize function variables }
        LV_TPS_SP_JAM_OFF = 0; CTR_DLY_TPS_JAM = 0
endif
```

61.13.2 Control condition for ETC jam detection

Description:

The following section describes the control conditions of the ETC jam detection. The aim is to gather all activation and inhibition conditions for an efficient control of the algorithm.

Application conditions:

Initialisation: at RST set all to zero

Recurrence: 20 ms

Activation: All engine operating states

Deactivation: No deactivation

Formula section:

```
{ Calculate activation condition for ETC jam detection }
LV_TPS_JAM_DET_ACT = (  ...
                TIA_THR                 < IP_TIA_MAX_TPS_JAM      and
                | MTCPWM |              > C_PWM_ETC_TPS_JAM       and
                T_MTCPWM_PI_DIAG        > C_T_MIN_DIAG_TPS_JAM    and
                CTR_TPS_JAM_DET_ACT< C_CTR_TPS_JAM_DET_ACT_MAX)

{ Calculate disable condition for ETC jam detection }
LV_TPS_JAM_DET_DI = (  LV_IGK                 == 0      or
                       LV_ERR_TIA_THR         == 1      or
                       LV_ERR_MAF             == 1      or
                       LV_ERR_MAP             == 1      or
                       LV_TPS_SP_JAM_OFF      == 1      or
                       LV_MTC_CUR_OFF         == 1      )
```

TPS_SP_EXT	TPS_SP_MDL	TPS_SP_PWL	LV_ES
LV_TPS_SP_LIH	LV_TPS_PWL	LV_TPS_AD_ACT	LV_TPS_AD_REQ
LV_TPS_SP_EXT	LV_TPS_SP_JAM	TPS_SP_JAM	

FUNCTION DESCRIPTION:

General information:

This module is describing the generation of the throttle position setpoint TPS_SP which is used as an input variable in the module ETC Position Controller.

The module consists of two blocks (see figure 1): In a first step the setpoint is selected depending on the engine state, in a second step the selected value is limited. This limitation acts as protection so that the throttle blade does not hit the mechanical stops with too high energy. Otherwise the throttle could be damaged.

The setpoint before limitation TPS_SP_SEL is selected from the following variables:

- Basic throttle position setpoint: TPS_SP_MDL (output of BMW OBJ EISY)
- Throttle position setpoint for engine stopped: TPS_SP_ES
- Throttle position setpoint for jam detection: TPS_SP_JAM
- Throttle position setpoint during adaptation: TPS_SP_AD
- Throttle position setpoint in case of external activation: TPS_SP_EXT
- Throttle position setpoint during the post operating phase: TPS_SP_PWL
- Throttle position setpoint when the position controller is switched off: TPS_LIH

From TPS_SP_SEL the final setpoint TPS_SP is generated by means of a limitation function which is including a limitation by absolute values and by gradients.

The setpoint is determined every 10 ms, except during adaptation (5ms).

Signal flow diagram:

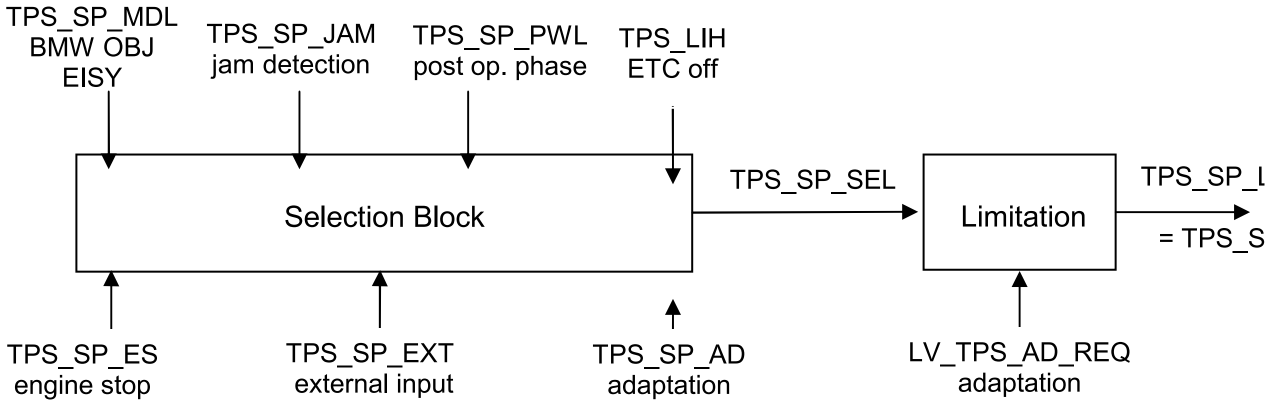

Figure 1: Throttle position setpoint selection and limitation.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialisation: -

Update rate: 10 ms (5ms during adaptation)

61.14.1 Throttle position setpoint selection

For the selection logic see figure 2.

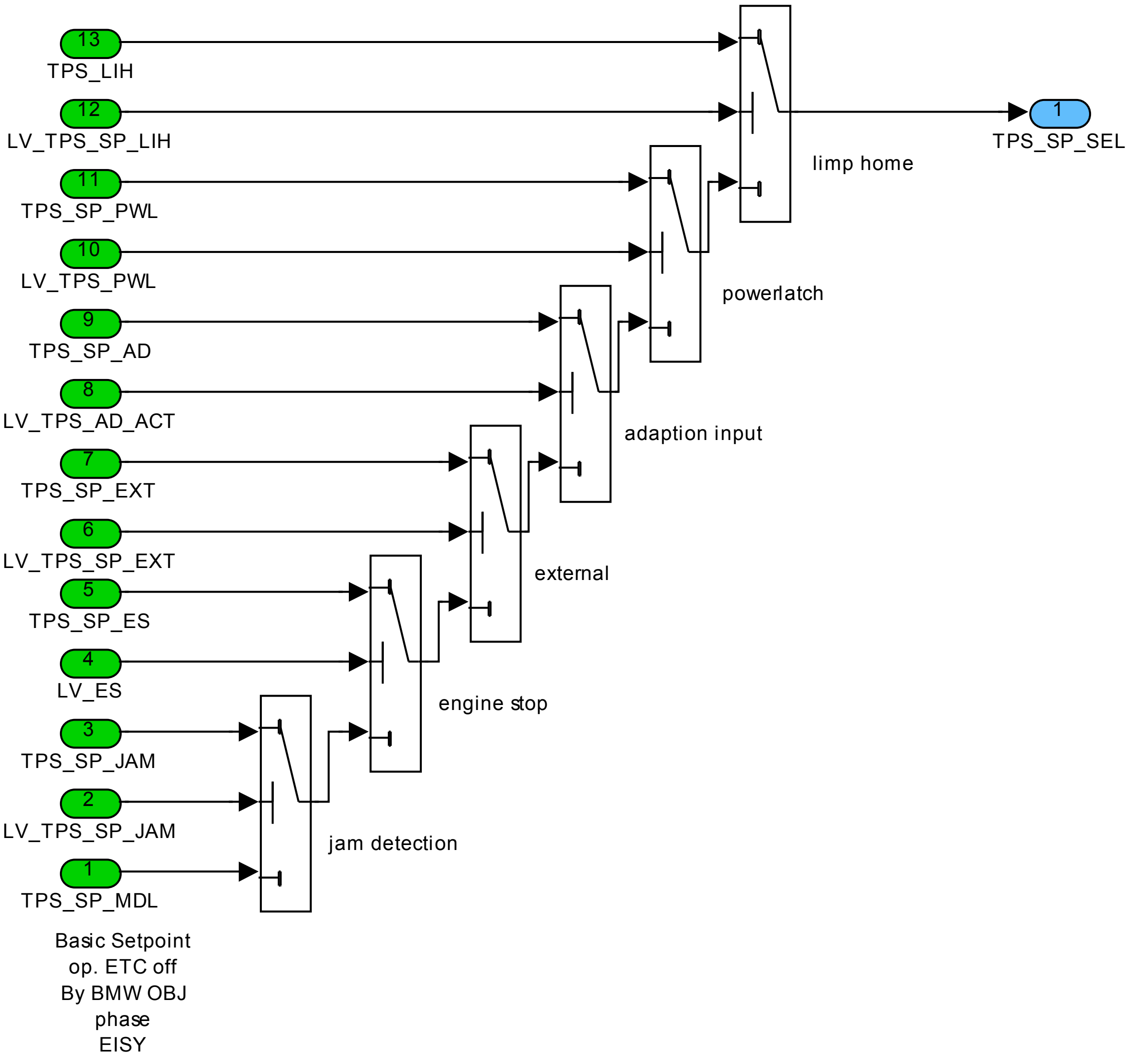

Figure 2: Throttle position setpoint selection block.

61.14.1.1 Throttle position setpoint for jam detection

During jam detection the throttle position setpoint is set from the jam detection module.

Formula section:

```
if      (LV_TPS_SP_JAM = 1          and
        LV_ES = 0                   and
        LV_TPS_SP_EXT = 0           and
        LV_TPS_AD_ACT= 0                    and
        LV_TPS_PWL = 0              and
        LV_TPS_SP_LIH = 0 )

then    TPS_SP_SEL = TPS_SP_JAM

else    TPS_SP_SEL = TPS_SP_MDL

endif
```

61.14.1.2 Throttle position setpoint for engine stopped

During the engine state “Engine stopped” (LV_ES = 1) the throttle position setpoint is determined by the special variable TPS_SP_ES.

Formula section:

```
if      (LV_ES = 1                  and
        LV_TPS_SP_EXT = 0           and
        LV_TPS_AD_ACT= 0                    and
        LV_TPS_PWL = 0              and
        LV_TPS_SP_LIH = 0 )

then    TPS_SP_SEL = TPS_SP_ES

endif
```

61.14.1.3 Throttle position setpoint by external device

In case of request by an external device the throttle position setpoint is set by the value TPS_SP_EXT.

Formula section:

```
if      ( LV_TPS_SP_EXT = 1         and
        LV_TPS_AD_ACT= 0                    and
        LV_TPS_PWL = 0              and
        LV_TPS_SP_LIH = 0)

then    TPS_SP_SEL = TPS_SP_EXT

endif
```

61.14.1.4 Throttle position setpoint during adaptation

During TPS adaptation the throttle position setpoint is set from the adaptation module.

Formula section:

```
if      (LV_TPS_AD_ACT= 1          and
        LV_TPS_PWL = 0             and
        LV_TPS_SP_LIH = 0 )

then    TPS_SP_SEL = TPS_SP_AD

endif
```

61.14.1.5 Throttle position setpoint during post operating phase

To avoid that for ‘Pin 15 Off’ the throttle blade is currentless and set to limp home position, a throttle position setpoint during the post operating phase is available.

Formula section:

```
if      ( LV_TPS_PWL = 1           and
        LV_TPS_SP_LIH = 0 )

then    TPS_SP_SEL =  TPS_SP_PWL

endif
```

61.14.1.6 Throttle position setpoint for ETC controller switched off

In case of the ETC controller switched off the TPS setpoint is set to the limp home position TPS_LIH.

<u>**Formula section:**</u>

```
if      LV_TPS_SP_LIH = 1

then    TPS_SP_SEL = TPS_LIH

endif
```

61.14.2 Throttle position setpoint limitation

The task of this function is a protection mechanism for the throttle blade. Therefore, it must be evaluated <u>after</u> the TPS setpoint selection.

For adjusting the setpoint to the physics of the throttle the variable TPS_SP_SEL is limited by

a) absolute values, for the non adapted throttle (LV_TPS_AD_REQ =1 remains set after adaptation) the values indicated by "(_TPS_AD_REQ)" are used,
b) a gradient valid for the whole operating range,
c) a gradient valid for the range of upper and lower stop.

The intermediate results of the limitation actions mentioned above are stored in the following way: a) b) c)
TPS_SP_SEL --> TPS_SP_LIM_1 --> TPS_SP_LIM_2 --> TPS_SP_LIM = TPS_SP

For illustration see figure 3.

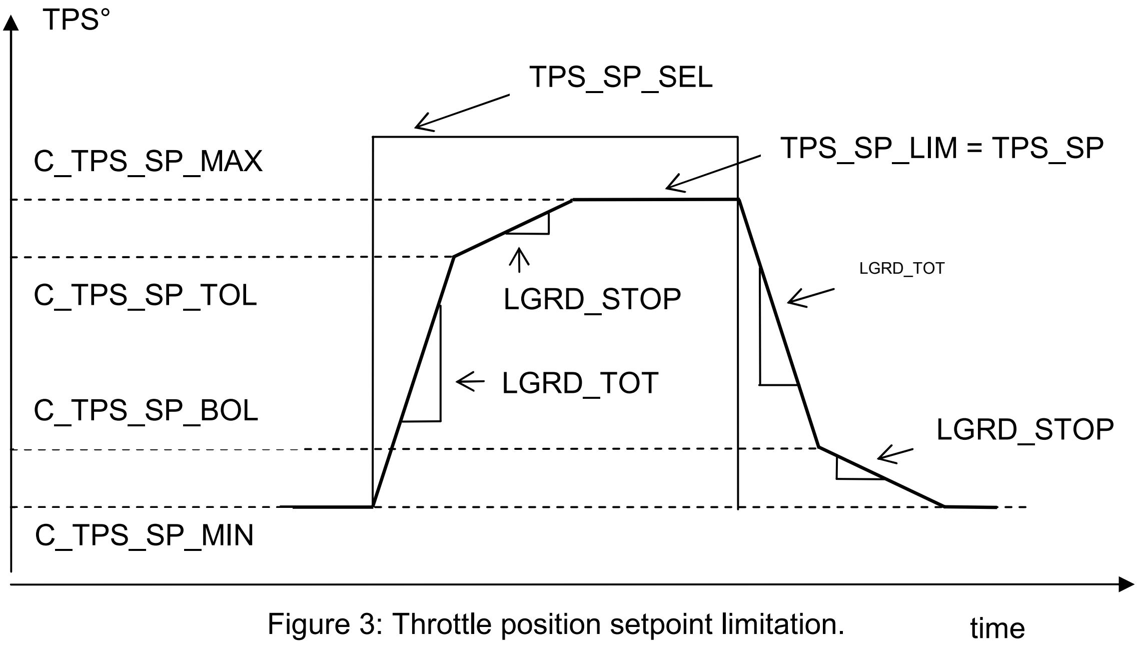

Figure 3: Throttle position setpoint limitation.

61.14.2.1 Limitation using absolute values

The throttle position setpoint may not fall below the value C_TPS_SP_MIN(_TPS_AD_REQ) or exceed C_TPS_SP_MAX(_TPS_AD_REQ).

Formula section:

```
if      ( TPS_SP_SEL  >  C_TPS_SP_MAX(_TPS_AD_REQ) )
then    TPS_SP_LIM_1 =  C_TPS_SP_MAX(_TPS_AD_REQ)
else    if      TPS_SP_SEL <  C_TPS_SP_MIN(_TPS_AD_REQ)
        then    TPS_SP_LIM_1 =  C_TPS_SP_MIN(_TPS_AD_REQ)
        else    TPS_SP_LIM_1 =  TPS_SP_SEL
        endif
endif
```

61.14.2.2 Gradient limitation over whole operating range

The gradient of the throttle position setpoint is limited throughout the whole operating range. A maximum change of C_TPS_SP_LGRD_TOT is permitted.

Formula section:

```
if      TPS_SP_LIM_1 > TPS_SP_LIM$_{i-1}$
then    TPS_SP_LIM_2 =
                MIN(TPS_SP_LIM_1, TPS_SP_LIM$_{i-1}$ + C_TPS_SP_LGRD_TOT)
else    TPS_SP_LIM_2 =
                MAX(TPS_SP_LIM_1, TPS_SP_LIM$_{i-1}$ - C_TPS_SP_LGRD_TOT)
endif
```

61.14.2.3 Gradient limitation near upper and lower position

The throttle position gradient is additionally limited as soon as the throttle position is near the upper or lower stop position: If TPS_SP_LIM_2 is close to the stop positions, for one step the setpoint TPS_SP_LIM is set to the value C_TPS_SP_TOL(_TPS_AD_REQ) or C_TPS_SP_BOL(_TPS_AD_REQ), respectively. When TPS_SP_LIM_2 is further moving towards the stops a gradient C_TPS_SP_LGRD_STOP < C_TPS_SP_LGRD_TOT is permitted. Thus a mechanical collision of blade and stops should be avoided (at least when TPS_AV is close toTPS_SP).

An additional protection mechanism near the mechanical stops is taking into account also the actual position TPS_AV of the throttle blade. If the difference between the desired TPS_SP and the actual TPS_AV is too high, the ETC controller will react aggressively. This reaction could lead to banging the throttle against the mechanical stops. To avoid such a behaviour the following algorithm is implemented: If TPS_AV is too far away from TPS_SP_LIM_2 (near the lower stop: TPS_AV > C_TPS_AV_BOL > C_TPS_SP_BOL whereas TPS_SP_LIM_2 ≈ C_TPS_SP_BOL; near the upper stop: TPS_AV < C_TPS_AV_TOL < C_TPS_SP_TOL whereas TPS_SP_LIM_2 ≈ C_TPS_SP_TOL), then TPS_SP_LIM is kept on the value C_TPS_SP_BOL (or C_TPS_SP_TOL, respectively) until TPS_AV is arriving below C_TPS_AV_BOL (or above C_TPS_AV_TOL) such that the difference between desired and actual position is small enough to have no strong ETC controller reactions. For illustration of the algorithm see figure 4.

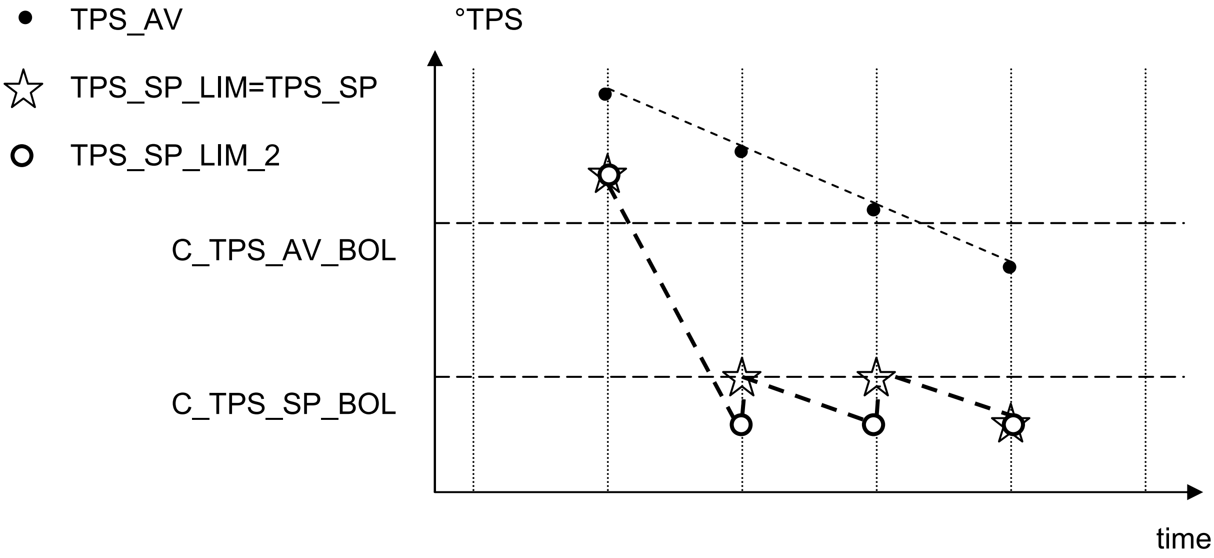

Figure 4: TPS_SP limitation mechanism at lower mechanical stop depending on TPS_AV.

Formula section:

```
if      TPS_SP_LIM_2  >  C_TPS_SP_TOL(_TPS_AD_REQ)          {above top limit}

then    if      ( TPS_SP_LIM$_{i-1}$  < C_TPS_SP_TOL(_TPS_AD_REQ)          or
                  TPS_AV  <  C_TPS_AV_TOL )

        then    TPS_SP_LIM = C_TPS_SP_TOL(_TPS_AD_REQ)

        else    TPS_SP_LIM = MIN(TPS_SP_LIM_2,
                                  TPS_SP_LIM$_{i-1}$+C_TPS_SP_LGRD_STOP)
        endif

else    if      TPS_SP_LIM_2 < C_TPS_SP_BOL(_TPS_AD_REQ)  {below bottom limit}

        then    if      ( TPS_SP_LIM$_{i-1}$ >C_TPS_SP_BOL(_TPS_AD_REQ) or
                        TPS_AV  >  C_TPS_AV_BOL )

                then    TPS_SP_LIM = C_TPS_SP_BOL(_TPS_AD_REQ)

                else    TPS_SP_LIM = MAX(TPS_SP_LIM_2,
                                          TPS_SP_LIM$_{i-1}$ -C_TPS_SP_LGRD_STOP)
                endif
```

```
        else    TPS_SP_LIM = TPS_SP_LIM_2

        endif

    endif
```

Remark: For correct working of the algorithm the following settings **must** be chosen:

- C_TPS_SP_BOL(_TPS_AD_REQ) < C_TPS_AV_BOL < TPS_LIH
- C_TPS_SP_TOL(_TPS_AD_REQ) > C_TPS_AV_TOL

61.14.2.4 Output of limited setpoint

Formula section:

TPS_SP = TPS_SP_LIM

61.15 Throttle Position Setpoint Selection (Appl. Inc.)

61.15.1 Throttle position setpoint for engine stopped

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TPS_SP_ES	V/O	0...3FFFH	0...119.5	7.29E-03	[°TPS]
Throttle position setpoint for engine stopped					

Input data:

LV_ES	TCO		

FUNCTION DESCRIPTION:

General information:

For engine stopped TPS_SP_ES is generated from a TCO dependent map. The TPS_SP_ES value must be chosen with respect to the expected TPS_SP_ST. A sensible choice diminishes the transient time when the TPS_AV is approaching TPS_SP_ST.

Application conditions:

Initialisation: -

Recurrence: 10 ms

Activation: in every engine state

Formula section:

```
If    LV_ES = 1

      then    TPS_SP_ES  =  IP_TPS_SP_ES

endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

TPS_SP_EXT	V/O	0...3FFFH	0...119.5	7.29E-03	[°TPS]
Throttle position setpoint of external device					
LV_TPS_SP_EXT	V/O	0...1H	0...1	1	[-]
Bit active for external input of throttle position setpoint					

Input data:

LV_ES	LV_IGK	PV_AV	TPS_SP_EXT_ADJ
LV_TPS_SP_EXT_ADJ	C_TPS_SP_MAX		

Description:

For different tasks during calibration phase and for service procedures at the workshops, it is necessary to implement an external adjustment at throttle position.

Throttle position can be influenced via serial tester (KWP) or manual in the following way:

C_TPS_SP_EXT_ADJ_ENA = 0 : no manual adjustment

C_TPS_SP_EXT_ADJ_ENA = 1 : manual setpoint via application system

C_TPS_SP_EXT_ADJ_ENA = 2 : manual setpoint via PV_AV

C_TPS_SP_EXT_ADJ_ENA = 3 : manual setpoint via PV_AV and application system

Application conditions:

Initialisation: 0

Recurrence: 10ms

Activation: LV_IGK = 1

Formula section:

```
If(1)     LV_TPS_SP_EXT_ADJ = 1
Then(1)   LV_TPS_SP_EXT = 1
          TPS_SP_EXT = (TPS_SP_EXT_ADJ / 100%) * C_TPS_SP_MAX
                                              //to convert from % into °TPS
Else(1)   If(2)   C_TPS_SP_EXT_ADJ_ENA = 1     and
                  LV_ES = 1
          Then(2)     TPS_SP_EXT = C_TPS_SP_AS_MAN
                      LV_TPS_SP_EXT = 1
          Else(2)     If(3)   C_TPS_SP_EXT_ADJ_ENA = 2          and
                              PV_AV > C_PV_AV_EXT_ADJ_MIN       and
                              LV_ES = 1
```

```
                then(3) TPS_SP_EXT = IP_TPS_SP_EXT_ADJ
                        LV_TPS_SP_EXT = 1
                else(3)      If(4)  C_TPS_SP_EXT_ADJ_ENA = 3     and
                             PV_AV > C_PV_AV_EXT_ADJ_MIN
                        then(4) TPS_SP_EXT = C_TPS_SP_AS_MAN +
                                                      IP_TPS_SP_EXT_ADJ
                                LV_TPS_SP_EXT = 1
                        else(4) LV_TPS_SP_EXT = 0
                                TPS_SP_EXT = 0
                        endif(4)
                endif(3)
        endif(2)

Bit for throttle position setpoint in post operating phase active					
CTR_T_TPS_PWL	O	0...FFH	0...255	1	[s]
Timer after engine stop					

Input data:

LV_ES	LV_IGK	N_32	LV_MTC_CUR_OFF

General information:

To avoid that for ‚Power Down‘ the currentless throttle is set to the limp home position, for a tuneable time period a throttle position setpoint during the post operating phase is available.

A time counter is started on detection of ignition key OFF and N < 32 rpm (engine stopped). If the counter reaches its maximum C_T_MTC_ISA_OFF, the throttle is actuated to the setpoint C_TPS_SP_PWL_UP by the current TPS_SP and then de-energized. Thus, it is ensured that the throttle are closed until a defined time after ignition key OFF and engine stopped.

If the throttle is already deenergized when ignition key OFF is detected, it is not re-energized.

Formula section:

```
If (1)      LV_IGK = 0                                   and
            LV_MTC_CUR_OFF = 0; at LV_IGK = 1 to 0
Then(1)     LV_TPS_PWL =1
    If(2)       LV_ES = 0
    Then(2)         TPS_SP_PWL = IP_TPS_SP_PWL
    Else (2)    Timer started          (LV_ES = 1 to 0)
                if (3)      (CTR_T_TPS_PWL < C_T_MTC_ISA_OFF)
                Then(3)         TPS_SP_PWL = IP_TPS_SP_PWL
                Else (3)

Input data:

TPS_AV	TPS_AV_CTL	TPS_LIH	TPS_SP
LV_MTC_CUR_OFF	VB	C_TPS_SP_LGRD_STOP	LV_IGK

FUNCTION DESCRIPTION:

General information:

The position controller is an adaptive PID-controller with a feed forward control.

Application conditions:

Initialisation: at deactiavtion **or** LV_IGK 0->1 **or** ECU reset

Recurrence: 5 ms

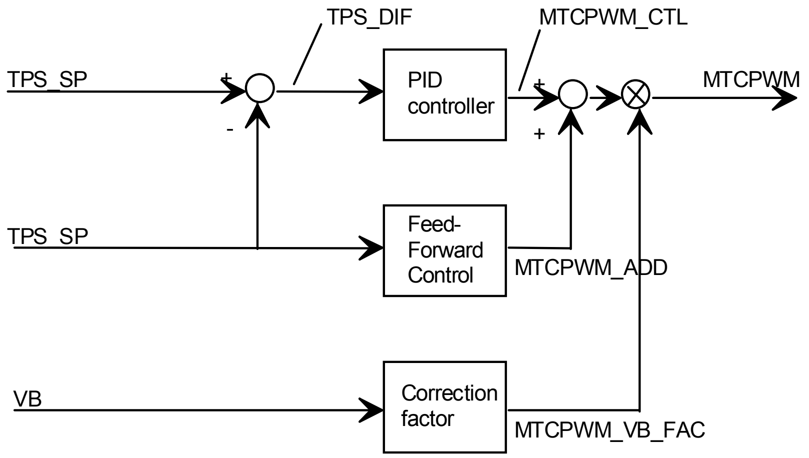
Activation: **If** LV_MTC_CUR_OFF = 0

Deactivation: **If** LV_MTC_CUR_OFF = 1

Then Initialization of variables:

[MTCPWM, MTCPWM_P, MTCPWM_I, MTCPWM_I_ADD
MTCPWM_D, MTCPWM_ADD, MTCPWM_CTL] with 0
TPS_SP_CTL = (S16) C_TPS_SP_STOP_HYS
T_MTCPWM_CLOSE_ACT = 0
LV_MTCPWM_CLOSE_ACT = 0
TPS_DIF = 0x3FFF
TPS_DIF_GRD = 0x3FFF

Signal flow diagram:



61.16.1 PID-Controller

Description:

The PID-controller is nonlinear. It consists of three parts: P-part, I-part and D-part P- and I-part depend on deviation. The D-part depends on deviation gradient.

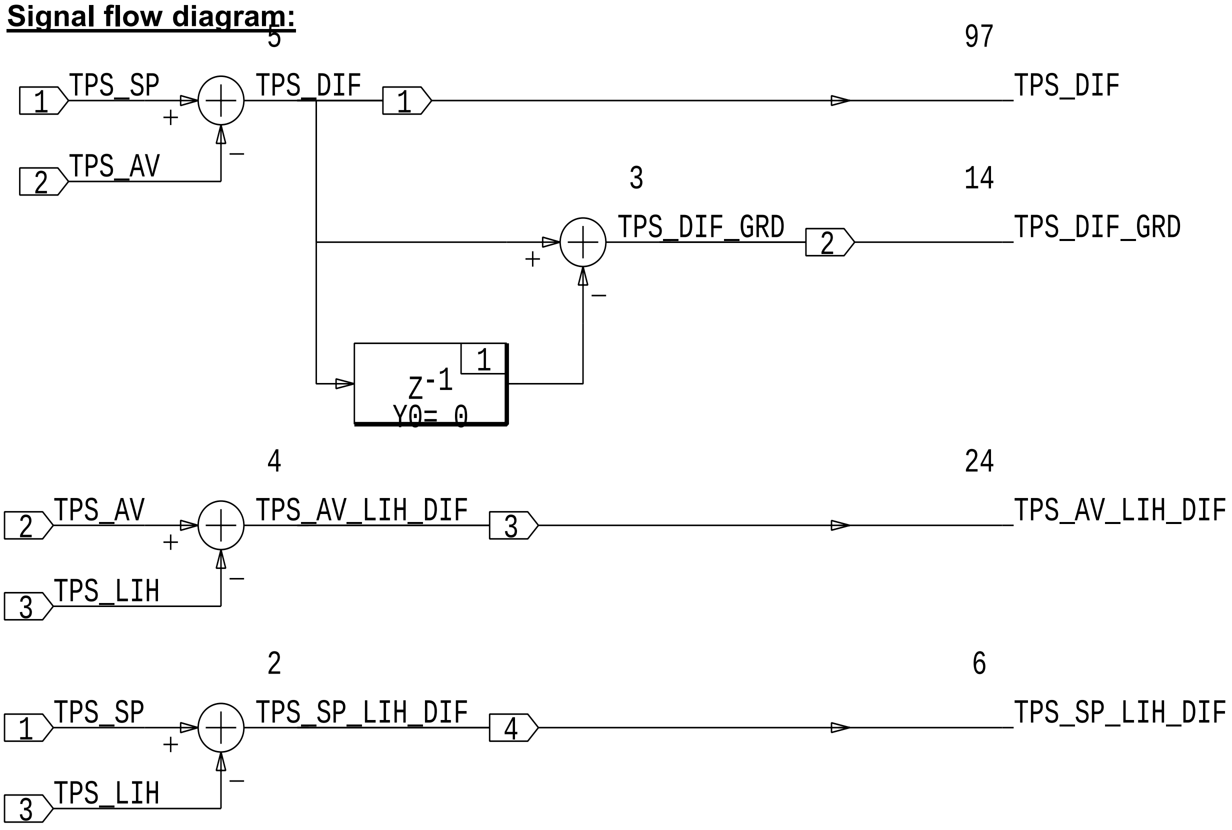
Near the mechanical bottom limit the controller deviation is calculated with an offset on the actual throttle position that is equal to the setpoint gradient limitation, even if setpoint value is at its lower limit. So the throttle is moving to the stop with a defined velocity. To calculate the controller deviation a value of the throttle position that can also be negativ is formed. The time where duty cycle is above the closing value is measured. If meanwhile the setpoint leaves the lower bottom limit, the time counter is set back to zero.

16-NOV-98

Discrete Procedure SuperBlock Deviation | Procedure Class Standard | Inputs 3 | Outputs 4

61.16.1.1 Calculation of Deviation

Signal flow diagram:



Formula section:

controller deviation:

```
If      TPS_SP > C_TPS_SP_STOP_HYS
then    TPS_DIF   =   TPS_SP - TPS_AV
        TPS_SP_CTL = C_TPS_SP_STOP_HYS
else    TPS_SP_CTL = TPS_SP_CTL - C_TPS_SP_LGRD_STOP
        TPS_DIF   =   MAX(TPS_SP_CTL;C_TPS_SP_CTL_MAX) - TPS_AV_CTL
endif
```

Remark: C_TPS_SP_STOP_HYS should be calibrated nearly to 0.

gradient of the controller deviation:

$$TPS\_DIF\_GRD = TPS\_DIF_n - TPS\_DIF_{n-1}$$

difference between the actual value and the limp home position:

TPS_AV_LIH_DIF = TPS_AV - TPS_LIH

TPS_SP_LIH_DIF = TPS_SP - TPS_LIH

61.16.1.2 Duty Cycle Supervision / Set Timer

Description:

Below the threshold C_TPS_SP_STOP_MAX is supervised if the throttle is at bottom mechanical limit, i.e. if he duty cycle has exceeded the threshold C_MTCPWM_CLOSE * MTCPWM_VB_FAC. In that case a time counter is started.

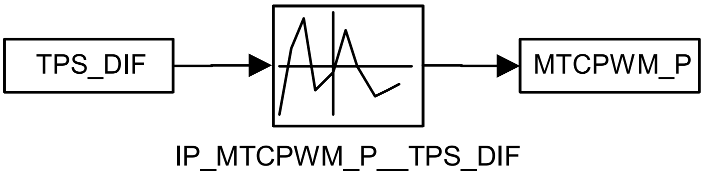
Formula section:

```
If (1)          TPS_SP ≤ C_TPS_SP_STOP_MAX
then (1)
    if (2)          MTCPWM <= C_MTCPWM_CLOSE * MTCPWM_VB_FAC +
                                        C_MTCPWM_HYS
    then (2)        T_MTCPWM_CLOSE_ACT = T_MTCPWM_CLOSE_ACT + 5ms
    else (2)        T_MTCPWM_CLOSE_ACT = 0
    endif (2)
else (1)        T_MTCPWM_CLOSE_ACT = 0
endif (1)
```

Remark: It´s not allowed to calibrate C_TPS_SP_STOP_MAX smaller than C_TPS_SP_STOP_HYS!

61.16.1.3 P-share:

Signal flow diagram:



Formula section:

MTCPWM_P = IP_MTCPWM_P__TPS_DIF

61.16.1.4 I- share:

Formula section:

detection of the TPS_SP direction :

```
if (1)          $TPS\_SP\_LIH\_DIF < - C\_TPS\_SP\_LIH\_DIF\_HYS$
then (1)        $LV\_TPS\_SP\_POS = 0$
else (1)
    if (2)      $TPS\_SP\_LIH\_DIF > C\_TPS\_SP\_LIH\_DIF\_HYS$
    then (2)    $LV\_TPS\_SP\_POS = 1$
    endif (2)
endif (1)

if (1)          $LV\_TPS\_SP\_POS_n \neq LV\_TPS\_SP\_POS_{n-1}$
then (1)        $LV\_TPS\_CHG\_POS = 1$
        if (2)      $LV\_TPS\_SP\_POS_n < LV\_TPS\_SP\_POS_{n-1}$
            and     $MTCPWM\_I \geq -C\_MTCPWM\_I\_ADD$
        then (2)    $MTCPWM\_I\_ADD = -C\_MTCPWM\_I\_ADD$
        else (2)
            if (3)      $LV\_TPS\_SP\_POS_n > LV\_TPS\_SP\_POS_{n-1}$
                and     $MTCPWM\_I \leq C\_MTCPWM\_I\_ADD$

            endif (3)
        endif (2)
else (1)        $MTCPWM\_I\_ADD_n = MTCPWM\_I_{n-1}$
                $LV\_TPS\_CHG\_POS = 0$
endif (1)
MTCPWM_I   =    $MTCPWM\_I\_ADD + IP\_MTCPWM\_I\_\_TPS\_DIF$
                $* IP\_MTCPWM\_I\_FAC\_\_TPS\_AV\_LIH\_DIF$
```

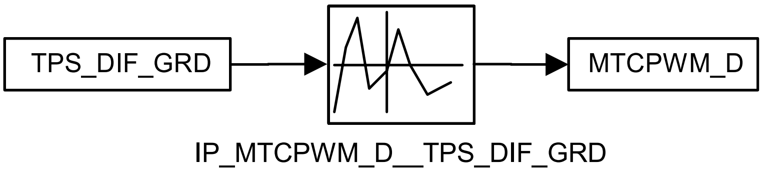
Limitation of I-share:

I-share is limited to a range C_MTCPWM_I_MAX_NEG, C_MTCPWM_I_MAX_POS.

```
if (1)          MTCPWM_I > C_MTCPWM_I_MAX_POS
then (1)        MTCPWM_I = C_MTCPWM_I_MAX_POS
else (1)
    if (2)      MTCPWM_I < C_MTCPWM_I_MAX_NEG
    then (2)    MTCPWM_I = C_MTCPWM_I_MAX_NEG
    else (2)    MTCPWM_I = MTCPWM_I
    endif (2)
endif (1)
```

61.16.1.5 D-share:

Signal flow diagram:



Formula section:

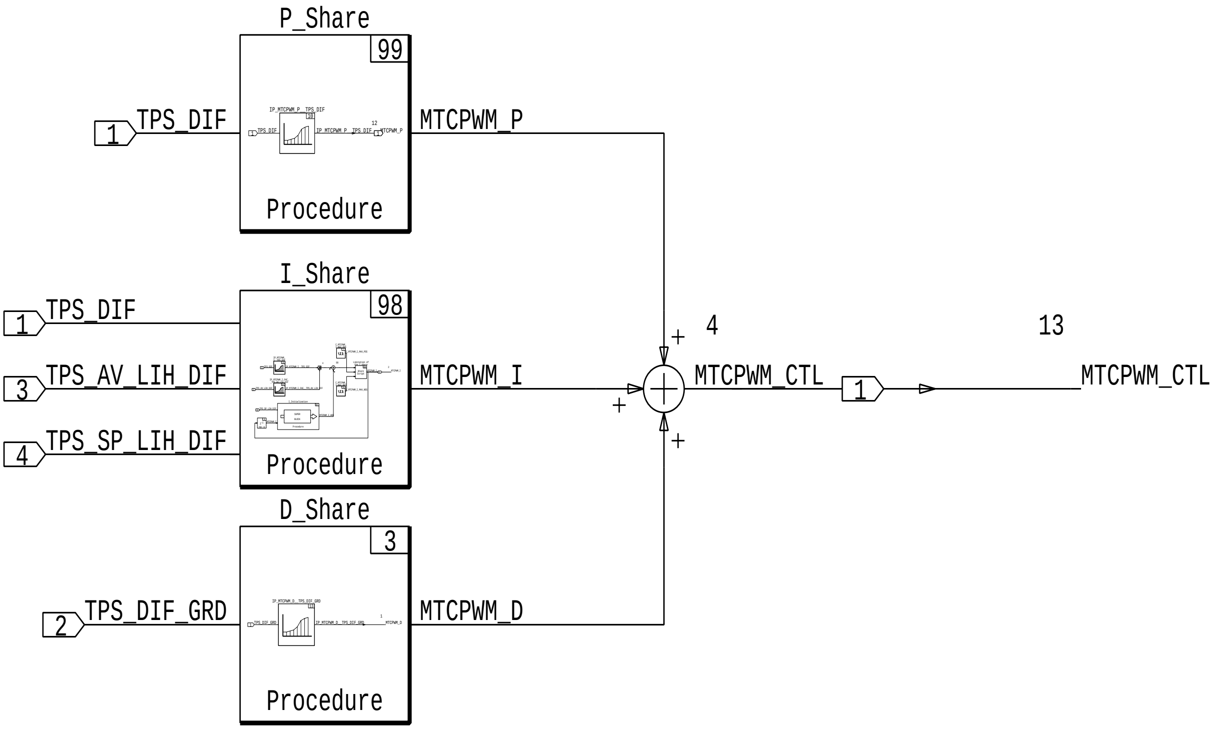
MTCPWM_D = IP_MTCPWM_D__TPS_DIF_GRD

61.16.1.6 Calculation of Controller Value:

Discrete Procedure SuperBlock	Procedure Class	Inputs	Outputs
PID_controller	Standard	4	1

16-NOV-98

Signal flow diagram:



Formula section:

MTCPWM_CTL = MTCPWM_P + MTCPWM_I + MTCPWM_D

61.16.1.7 Initialization of Position Controller after “mechanical limitation stop” respectively closing mode

If the throttle is opening beginning at bottom mechanical limit and exceeds the calibratable threshold C_TPS_SP_STOP_HYS the I-share is initialized with C_MTCPWM_I_INI, TPS_DIF_GRD is set to actual TPS_DIF and T_MTCPWM_CLOSE_ACT is set to zero.

```
if          TPS_SP > C_TPS_SP_STOP_HYS
      and   T_MTCPWM_CLOSE_ACT > 0
then        MTCPWM_I = C_MTCPWM_I_INI
            TPS_DIF_GRD = TPS_DIF
            T_MTCPWM_CLOSE_ACT = 0
endif
```

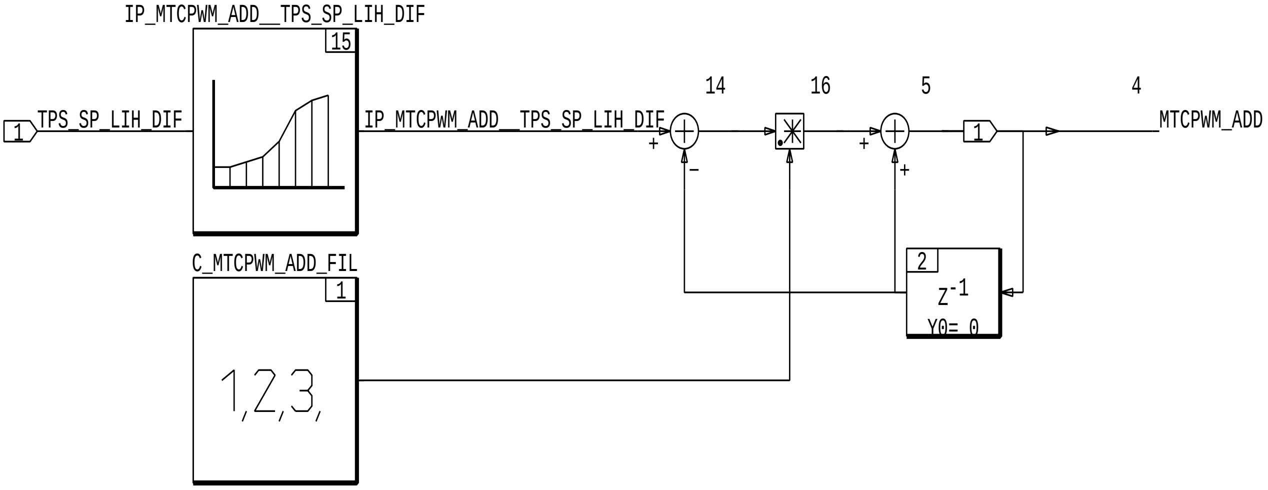
61.16.2 Feed - Forward Control of the MTC

Description:

The friction torque of the bearing and of the spring set a very strong non-linearization of the control course. To compensate this and to avoid instability a feed-forward-control is used dependent on the throttle setpoint deviation to LIH-position (TPS_SP_LIH_DIF). For to take into consideration the dynamic behavior a PT1-filter with the time constant C_MTCPWM_ADD_FIL is used.

Signal flow diagram:



Formula section:

$$\text{MTCPWM\_ADD}_n = \text{MTCPWM\_ADD}_{n-1} + (\text{IP\_MTCPWM\_ADD\_\_TPS\_SP\_LIH\_DIF}_n - \text{MTCPWM\_ADD}_{n-1}) * \text{C\_MTCPWM\_ADD\_FIL}$$

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

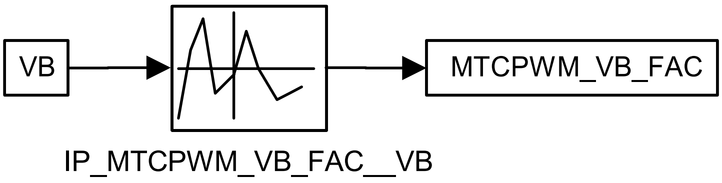
PT1-filtering constant					

61.16.3 Battery Voltage Correction

Description:

The control duty cycle will be corrected through the battery voltage VB.

Signal flow diagram:



Formula section:

MTCPWM_VB_FAC = IP_MTCPWM_VB_FAC__VB

Applikationsdaten:

Name	Dim	Hex. Limit	Phys. Limit	Auflös.	Einh.
IP_MTCPWM_VB_FAC__VB	8	0...FFH	0...1.99218	0.0078125	[-]
LDP_VB__MTCPWM_VB_FAC	8	0...FFH	0...25.89843	0.1015625	[V]
battery voltage correction					

61.16.4 Calculation of MTCPWM

Description:

The duty cycle that controls the main throttle is the sum of a feed-forward-controller value and the PID-controller value. This sum is corrected by a factor depending on battery voltage. Is the throttle position for sure at the lower mechanical stop, the duty cycle is limited to the allowed value. A rise of the duty cycle over the maximum value marks that the throttle position has reached the mechanical stop. The maximum duty cycle is allowed only for a defined time. Then the duty cycle is switched back to the closing level.

Formula section:

```
MTCPWM   =   (MTCPWM_CTL+ MTCPWM_ADD) * MTCPWM_VB_FAC
LV_MTCPWM_CLOSE_ACT = 0
    if (1)          T_MTCPWM_CLOSE_ACT > 0
    then (1)        MTCPWM =   MAX{(C_MTCPWM_CLOSE_MAX * MTCPWM_VB_FAC);
                                   MTCPWM}
            if (2)  T_MTCPWM_CLOSE_ACT > C_ T_MTCPWM_CLOSE_ACT_MAX
            then (2)        MTCPWM = C_MTCPWM_CLOSE * MTCPWM_VB_FAC
                            LV_MTCPWM_CLOSE_ACT = 1
            endif (2)
    endif (1)
```

62.2.1 Ignition angle efficiency

The ignition efficiency values EFF_IGA_AV (actual efficiency), EFF_IGA_BAS_COR (basic efficiency), EFF_IGA_BAS_COR_KNK_FIL (efficiency with mean knock correction) and EFF_IGA_MIN (minimum efficiency due to IGA_MIN) provide the link from an ignition angle to a torque efficiency. They are used in different torque modules to calculate the actual indicated engine torque, basic indicated engine torque values or the minimum indicated engine torque.

The efficiency calculation follows always the same strategy:

- calculation of all specific delta ignition angle IGA_DIF...
- calculation of efficiencies using engine mode depending function "EFF_IGA(IGA_DIF...)".

Input data:

EFF_IGA_BAS_COR_CBK[NC_CBK_EX_NR]	EFF_LAMB_AV_CBK[NC_CBK_EX_NR]	EFF_SCC_AV	FAC_EFF_IGA
IGA_REF_COR_CBK[NC_CBK_EX_NR]	LV_ACT_AJ	LV_HOM_RUN	LV_REQ_ISC
LV_TQ_IGA_ENA	TQI_REF	TQI_SP_CAN	TQI_SP_CBK[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

General information:

For homogeneous (*LV_HOM_RUN = 1*) the module ignition angle setpoint delivers IGA_DIF_SP_H_RNG as an output which depends on the torque setpoint TQI_SP_CBK[NC_CBK_EX_NR]. For the calculation of the setpoint of ignition efficiency EFF_IGA_SP the actual cylinder fuel cut-off efficiency EFF_SCC_AV, the Exhaust Gas Recirculation efficiency and the actual lambda efficiency EFF_LAMB_AV are considered which are multiplied with the reference torque value TQI_REF.

By evaluation of the standardised ignition characteristic the spark retard value IGA_DIF_SP_H_RNG is calculated (*a negative value*) and will be applied on the reference ignition angle to define the ignition angle setpoint for torque interventions. In a system with variable valve lift the standardised ignition characteristic depends on the actual engine mode. Two modes are distinguished: load control via inlet valve lift and load control via the main throttle. To pay this different load controls attention the basic standardised ignition characteristic given by IP_IGA_DIF_SP_H_RNG is corrected with engine mode depending factor FAC_IGA_DIF.

Hereafter, it is determined if a fast torque intervention request implies a spark retard for its application through the logical flag LV_TQ_IGA_REQ.
If EFF_IGA_SP >= EFF_IGA_BAS_COR then no torque intervention is necessary and LV_TQ_IGA_ACT is set to 0 since there is no spark retard requested by torque. In this case IGA_DIF_SP_H_RNG is set to the passive value which is the maximum value for difference ignition angle *(=0 °CRK*). Then IGA_DIF_SP_H_RNG is not a limitation for the basic ignition angle in any case.

If EFF_IGA_SP < (EFF_IGA_BAS_COR – Threshold) then a significant spark retard resulting from a torque request has to be applied. For this LV_TQ_IGA_REQ is set to 1.
The value of the Threshold used here depends on both if an anti-jerk intervention is activated and if the engine is in idle speed phase. In normal condition (*no anti-jerk nor idle speed*) the threshold is Threshold = C_EFF_IGA_THD_1. In case of Anti-Jerk intervention a specific threshold will be used (*Threshold_1 = C_EFF_IGA_THD_AJ*) ; in idle speed also another specific threshold (*Threshold_2 = C_EFF_IGA_THD_IS*) instead of the normal one. Finally, the minimal threshold between both preceding is retained to be *applied (Threshold = Min(Threshold_1,Threshold_2)*).
IGA_DIF_SP_H_RNG is deduced from EFF_IGA_SP and is added (*negative value*) to the reference ignition angle to get the ignition angle setpoint for torque intervention.

The main reason for the existence of these two cases is to reduce ignition angle jitters if torque values are jittering (TQI_SP_CBK[NC_CBK_EX_NR] *and TQI_REF*). If no significant torque intervention is recognised then IGA_DIF_SP_H_RNG is set to the passive value 0°CRK. In this case the torque controlled ignition angle setpoint has definitely no impact any more to the applied ignition angle which is then only determined from the basic ignition angle and knock control.

This functionality allows choosing what parameter (*Ignition, Injection, ETC, etc…*) will be impacted first by a fast torque intervention and how this torque reduction request will be handled.

IGA_SP_CAN_H_RNG is calculated like IGA_SP_H_RNG only with calculations depending on TQI_SP_CAN.

Application conditions:

Activation: LV_HOM_RUN = 1

Deactivation: LV_HOM_RUN = 0

Initialisation: IGA_SP_CBK_H_RNG[NC_CBK_EX_NR] = IGA_SP_H_RNG = 60°CRK **and**

IGA_SP_CBK_CAN_H_RNG[NC_CBK_EX_NR] = IGA_SP_CAN_H_RNG = 60°CRK **and**
LV_TQ_IGA_ACT = 0 at reset

Update Rate: 10 ms

Formula section:

```
IF      EFF_SCC_AV > 0
then    EFF_IGA_SP_CBK_1[NC_CBK_EX_NR] = TQI_SP_CBK[NC_CBK_EX_NR] / (TQI_REF * EFF_SCC_AV * EFF_LAMB_AV_CBK[NC_CBK_EX_NR] )
else    EFF_IGA_SP_CBK_1[NC_CBK_EX_NR]
    =TQI_SP_CBK[NC_CBK_EX_NR]/(TQI_REF* EFF_LAMB_AV_CBK[NC_CBK_EX_NR] )
endif
EFF_IGA_SP_CBK_1_CAN[NC_CBK_EX_NR] = TQI_SP_CAN / (TQI_REF * EFF_SCC_AV * EFF_LAMB_AV_CBK[NC_CBK_EX_NR] )
```

<u>note</u>: if division by 0 then set EFF_IGA_SP_CBK_1 to maximum Hexa value.

EFF_IGA_SP_CBK[NC_CBK_EX_NR]=Min(EFF_IGA_SP_CBK_1[NC_CBK_EX_NR] , 1.0)

EFF_IGA_SP_CBK_CAN[NC_CBK_EX_NR]=Min(EFF_IGA_SP_CBK_1_CAN[NC_CBK_EX_NR] , 1.0)

Those preliminary calculations have to be done all the time whatever should be the value of LV_TQ_IGA_ACT.

Fast torque intervention request determination

Preliminary calculations for threshold:

```
If      LV_ACT_AJ = 1
Then            Threshold_1 = C_EFF_IGA_THD_AJ
Else            Threshold_1 = C_EFF_IGA_THD_1
Endif
If      LV_REQ_ISC = 1
Then            Threshold_2 = C_EFF_IGA_THD_IS
Else            Threshold_2 = C_EFF_IGA_THD_1
Endif
And             Threshold = Min(Threshold_1,Threshold_2)
```

Threshold, Threshold_1, Threshold_2 here are only an intermediate variable to clarify those choices on the Torque intervention.

Fast Torque Intervention request determination upon Threshold
(Reduction to a global variable instead of cylinder bank selective approach):

```
If      (EFF_IGA_SP_CBK[CBK_1]<(EFF_IGA_BAS_COR_CBK[CBK_1] - Threshold)
        Or
        (EFF_IGA_SP_CBK[CBK_2]<(EFF_IGA_BAS_COR_CBK[CBK_2] - Threshold))
Then            LV_TQ_IGA_REQ = 1
Elseif  EFF_IGA_SP_CBK[CBK_1] >= EFF_IGA_BAS_COR_CBK[CBK_1]
        Or
        EFF_IGA_SP_CBK[CBK_2] >= EFF_IGA_BAS_COR_CBK[CBK_2]
        then            LV_TQ_IGA_REQ = 0
        else            LV_TQ_IGA_REQ $_{n}$ = LV_TQ_IGA_ACT $_{n-1}$
Endif
```

//LV_TQ_IGA_ACT determination:

```
If      C_TQ_IGA_INH = 0
```

```
Then    LV_TQ_IGA_ACT = LV_TQ_IGA_ENA
Else    If      C_TQ_IGA_INH = 1
        Then    LV_TQ_IGA_ACT = 0
        Else    If      LV_TQ_IGA_ENA = 1  and  LV_TQ_IGA_REQ = 1
                Then    LV_TQ_IGA_ACT = 1
                Else    LV_TQ_IGA_ACT = 0
                Endif
        Endif
Endif
```

Setpoint spark retard calculation (for visual purposes, [C] =[NC_EX_CBK_NR] in the following concerning _CBK_ variables):

```
If          LV_TQ_IGA_ACT = 1
Then    EFF_IGA_INV_COR_CBK[C] = (100 – EFF_IGA_SP_CBK[C]*100) / FAC_EFF_IGA
        EFF_IGA_INV_COR_CBK_CAN[C] = (100 - EFF_IGA_SP_CBK_CAN[C]*100) / FAC_EFF_IGA

        IGA_DIF_SP_CBK_H_RNG[C] = IP_IGA_DIF_SP_H_RNG(EFF_IGA_INV_COR_CBK[C])
        IGA_DIF_SP_CBK_CAN_H_RNG[C] = IP_IGA_DIF_SP_H_RNG (EFF_IGA_INV_COR_CBK_CAN[C])

        IGA_SP_CBK_H_RNG[C] = IGA_REF_COR_CBK[C] + IGA_DIF_SP_CBK_H_RNG[C]
        IGA_SP_CBK_CAN_H_RNG[C] = IGA_REF_COR_CBK[C] + IGA_DIF_SP_CBK_CAN_H_RNG[C]
Else    IGA_SP_CBK_H_RNG[C] = IGA_SP_CBK_CAN_H_RNG[C]   = 60°CRK
Endif
```

Calculation of Arithmetic Mean Values:

IGA_SP_H_RNG = mean(IGA_SP_CBK_H_RNG*[C]*)
IGA_DIF_SP_H_RNG = mean(IGA_DIF_SP_CBK_H_RNG*[C]*)
IGA_SP_CAN_H_RNG = mean(IGA_SP_CBK_CAN_H_RNG*[C]*)
IGA_DIF_SP_CAN_H_RNG = mean(IGA_DIF_SP_CBK_CAN_H_RNG*[C]*)

FUNCTION DESCRIPTION:

General information:

The objective of this module is to generate a torque intervention by fuel cut-off pattern.
This torque intervention could be caused by several conditions which are summarized in the label LV_AUTH_TQ_PAT (see chapter 1.1.1 "Authorization for single cylinder cut-off"). The label LV_FCUT_FAST can be used for project specific fast fuel cut-off conditions (see module "Torque based pattern calculation (Appl. Inc.)").
Based on the TQI_REQ_FAST and the TQI_REF corrected with the basic a/f ratio efficiency and the ignition angle efficiency an efficiency setpoint for the single cylinder cut-off EFF_SCC_SP is calculated, which leads to the pattern index NR_PAT_SCC (see chapter 1.1.3 "Setpoint efficiency fuel cut-off").
In general, a torque reduction could be realized by spark retarding or single cylinder cut-off. With the scaling factor FAC_IGA_MIN_TEG_IGA_BAS a scaling between earliest cylinder cut-off (no spark retarding) and latest cylinder cut-off (full spark retarding up to IGA_MIN) can be realized (see chapter 1.1.2 "Determination of scaling factor").

Application conditions:

Activation:	at every engine state
Deactivation:	-
Initialization:	EFF_SCC_SP = 1 at reset EFF_SCC_SP_HYS = 1 at reset NR_PAT_SCC = 0 at reset
Update rate:	10 ms

62.5.1.1 Authorization for single cylinder cut-off

General information:

The authorization flag is set depending on:

- a manual enabling => LV_TQ_SCC_ENA_MAN
- a request from traction control (ASR) => LV_ASR_ACT
- a request from gear shift intervention (GS), if gear shift intervention is not explicitly inhibited because gear shift intervention should only work via spark retarding => LV_GS_ACT and LV_TQ_GS_IGA (see module "Torque request for gear shift intervention")
- a request from engine speed limitation (N_MAX) => LV_N_MAX
- other project specific requests for fast fuel cut-off => LV_FCUT_FAST (see module "Torque based pattern calculation (Appl. Inc.)")
- a request from torque management => LV_TQ_SCC_REQ and LV_TQ_SCC_INH
- a request from safety concept => LV_TQ_LIM_INTV (see module "Torque request for safety")

Due to logical calibration constants nearly all of these request can be inhibited, except of the requests from torque management and safety concept.

Formula section:

```
IF      LC_TQ_SCC_ENA_MAN == 1
        OR   LV_TQ_LIM_INTV == 1
        OR   (LV_TQ_SCC_INH == 0
                  AND   LC_TQ_SCC_INH_MAN == 0
                  AND   LV_TQ_SCC_REQ == 1)
        OR   (LV_ASR_ACT == 1 AND LC_INH_FCUT_ASR == 0)
        OR   (LV_N_MAX == 1 AND LC_INH_FCUT_N_MAX == 0)
        OR   [LV_AMT_ACT == 1
              AND (LV_INH_FCUT_AMT = 0 OR LC_INH_FCUT_AMT == 0)]
        OR   [LV_VAR_TCT == 1                                AND
             LV_GS = 1                                       AND
             (LV_INH_FCUT_GS = 0 OR LC_INH_FCUT_TCT == 0)]
        OR   (LV_DCC_INC_ACT == 1and LV_DCC_PUC_INH = 0
                                     AND LC_INH_FCUT_DCC == 0)
        OR   (LV_LDM_ACT == 1and LV_LDM_PUC_INH = 0
                                     AND LC_INH_FCUT_LDM == 0)
        OR   (LV_FCUT_FAST == 1 AND LC_INH_FCUT_FAST == 0)
        OR   (LV_GS_ACT == 1 AND LV_VAR_TCT == 0
             AND LC_INH_FCUT_GS == 0
             AND NOT(LV_TQ_GS_IGA == 1 AND LC_INH_FCUT_GS_IGA == 0))
THEN    LV_AUTH_TQ_PAT = 1
ELSE    LV_AUTH_TQ_PAT = 0
ENDIF
```

62.5.1.2 Determination of scaling factor

General information:

The factor FAC_IGA_MIN_TEG_IGA_BAS is used to scale between the efficiencies EFF_IGA_MIN_TEG (corrected basic minimum ignition angle including spark retard limitation due to exhaust gas temperature) and EFF_IGA_BAS_COR (corrected basic minimum ignition angle without spark retard limitation due to exhaust gas temperature). For a torque intervention due to gear shift, traction control, engine speed limitation and fast fuel cut-off the possibility of deactivating this scaling factor must be realized. So the scaling factor can be set equal to "1", if one of that interventions is active and if this method will be allowed (LC_ENA_FCUT_TOT_... = 1). It is also set equal to "1", if the basic efficiency for fuel cut-off is smaller than "1".

Formula section:

```
IF        EFF_SCC_BAS < 1.0
          OR    (LV_GS_ACT == 1
                AND LC_ENA_FCUT_TOT_GS == 1
                AND LV_TQ_GS_SCC == 1)
          OR    (LV_ASR_ACT == 1 AND LC_ENA_FCUT_TOT_ASR == 1)
          OR    (LV_N_MAX == 1 AND LC_ENA_FCUT_TOT_N_MAX == 1)
          OR    (LV_AMT_ACT== 1 AND LC_ENA_FCUT_TOT_AMT == 1)
          OR    (LV_DCC_INC_ACT== 1 and LV_DCC_PUC_INH ==0
                                        AND LC_ENA_FCUT_TOT_DCC == 1)
          OR    (LV_LDM_ACT== 1 and LV_LDM_PUC_INH ==0
                                        AND LC_ENA_FCUT_TOT_LDM == 1)
          OR    (LV_FCUT_FAST == 1 AND LC_ENA_FCUT_TOT_FAST == 1)
THEN      FAC_IGA_MIN_TEG_IGA_BAS = 1
ELSE      FAC_IGA_MIN_TEG_IGA_BAS = C_FAC_IGA_MIN_TEG_IGA_BAS
ENDIF
```

62.5.1.3 Setpoint efficiency fuel cut-off

62.5.1.3.1 Overview

Description:

Depending on the authorization flag LV_AUTH_TQ_PAT the efficiency EFF_SCC_SP is set to the calculated value EFF_SCC_SP_1 or is set equal to "1". Additionally, two application labels allow to manipulate the efficiency setpoint (LC_EFF_SCC_SP_MAN and C_EFF_SCC_SP_MAN). Depending on the efficiency setpoint a pattern is calculated. To avoid uncomfortable jumps of pattern, if the setpoint EFF_SCC_SP jitters, the calculation of the pattern index NR_PAT_SCC is done by applying a hysteresis C_EFF_SCC_SP_HYS on EFF_SCC_SP (see figure 1).

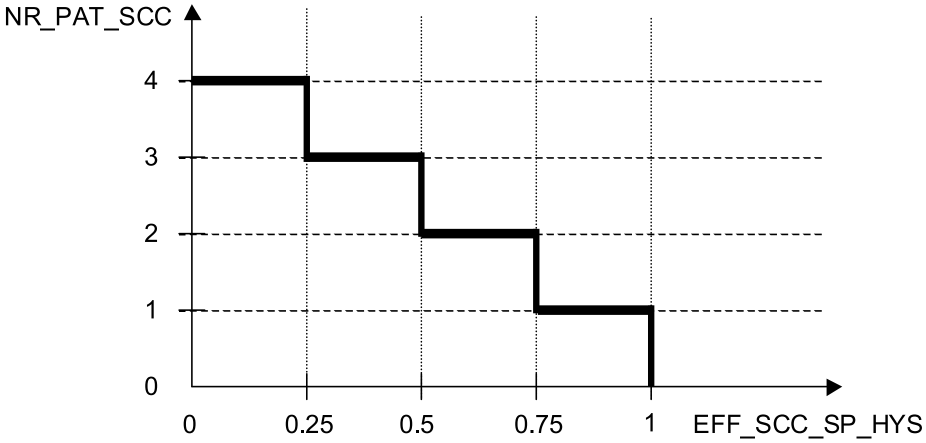

Figure 1: Example for a four cylinder engine

Formula section:

```
IF        LV_AUTH_TQ_PAT == 1
THEN      EFF_SCC_SP_2 = EFF_SCC_SP_1
ELSE      EFF_SCC_SP_2 = 1.0
ENDIF

IF        LC_EFF_SCC_SP_MAN == 1
THEN      EFF_SCC_SP = C_EFF_SCC_SP_MAN
ELSE      EFF_SCC_SP = EFF_SCC_SP_2
ENDIF

IF        (EFF_SCC_SP - EFF_SCC_SP_HYS  >  C_ EFF_SCC_SP_HYS)
          OR    (EFF_SCC_SP  ≥  1 - C_ EFF_SCC_SP_HYS)
          OR    (EFF_SCC_SP  <  EFF_SCC_SP_HYS)
THEN      EFF_SCC_SP_HYS  =  EFF_SCC_SP
```

```
ELSE     EFF_SCC_SP_HYS  =  EFF_SCC_SP_HYS
ENDIF

NR_PAT_SCC  =  ID_NR_PAT_SCC(EFF_SCC_SP_HYS)
```

62.5.1.3.2 Calculation of efficiency for single cylinder cut-off

Description:

The efficiency for single cylinder cut-off depends on the ratio between TQI_REQ_FAST and TQI_REF corrected with the basic efficiencies for a/f ratio and ignition angle. Generally, a scaling between EFF_IGA_MIN_TEG and EFF_IGA_BAS_COR is possible. The philosophy of this function is to give the customer the possibility to work with minimum ignition angle before fuel cut-off or to work with the basic ignition angle.

Formula section:

```
IF       LV_HOM_ACT = 1
THEN     EFF_SCC_SP_1 =  TQI_REQ_FAST /
                          (TQI_REF
                          * EFF_LAMB_BAS_COR
                          * (FAC_IGA_MIN_TEG_IGA_BAS
                          * EFF_IGA_BAS_COR
                          + (1.0 - FAC_IGA_MIN_TEG_IGA_BAS)
                          * EFF_IGA_MIN_TEG_LGRD))
ELSE     EFF_SCC_SP_1 =  TQI_REQ_FAST /
                          TQI_MIN_S
ENDIF

IF       EFF_SCC_SP_1 > 1.0
THEN     EFF_SCC_SP_1 = 1.0
ELSEIF   EFF_SCC_SP_1 < 0.0
THEN     EFF_SCC_SP_1 = 0.0
ENDIF
```

62.5.1.3.3 Rate limitations for negative gradients

Description:

Changes of the efficiency EFF_IGA_MIN_TEG has to be limited in falling direction to avoid high frequent jumps between pattern and spark retarding. Therefore a calibratable rate limit function is added. The principle application parameters for these rate limitations are C_MIN_DEC_EFF_IG_MIN_TEG_1, C_MIN_DEC_EFF_IG_MIN_TEG_2 and C_LGRD_EFF_IGA_MIN_TEG. The background is illustrated in figure 2.

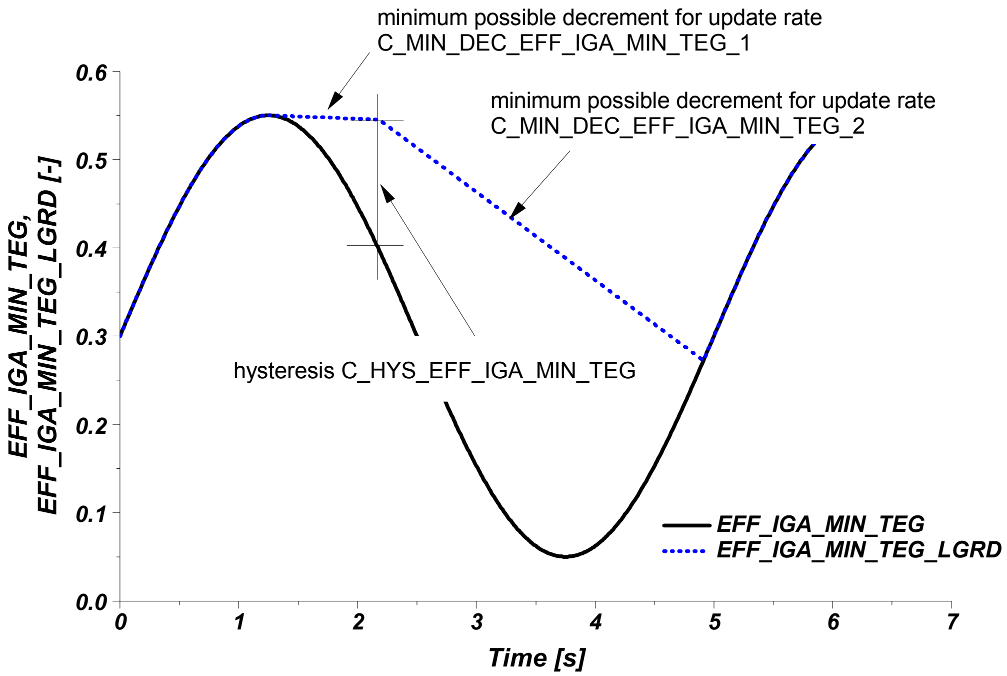

Figure 2: Rate limitations for EFF_IGA_MIN_TEG

Formula section:

```
IF      ($EFF\_IGA\_MIN\_TEG\_LGRD\_1_{k-1} > EFF\_IGA\_MIN\_TEG_k$)
THEN    IF      (($EFF\_IGA\_MIN\_TEG\_LGRD\_1_{k-1} - EFF\_IGA\_MIN\_TEG_k$)
                > $C\_MIN\_DEC\_EFF\_IGA\_MIN\_TEG\_1$)
        THEN    $EFF\_IGA\_MIN\_TEG\_LGRD\_1_k = EFF\_IGA\_MIN\_TEG\_LGRD\_1_{k-1}$
                                        $- C\_MIN\_DEC\_EFF\_IGA\_MIN\_TEG\_1$
        ELSE    $EFF\_IGA\_MIN\_TEG\_LGRD\_1_k = EFF\_IGA\_MIN\_TEG_k$
        ENDIF
ELSE    $EFF\_IGA\_MIN\_TEG\_LGRD\_1_k = EFF\_IGA\_MIN\_TEG_k$
ENDIF
```

```

Sum of cylinders which are shut off due to malfunctions					

Input data:

INH_IV_MIS	INH_IV_DIAG_ERR	INH_IV_IGC	

General information:

EFF_SCC_BAS is the basic efficiency for single cylinder fuel cut-off. It is calculated by count of opened injectors divided by the number of cylinders (NC_CYL_NR), whereas only injectors which are shut off due to failures (e.g. failure on injector / ignition output stage) are considered.

Activation: at every engine state

Deactivation: -

Initialization: EFF_SCC_BAS = 1.0 at reset and LV_IGK = 0 -> 1

Update rate: 10 ms

Formula section:

SUM_INH_IV_BAS = bitwise summation (Bits 0 to (NC_CYL_NR-1)) of:

INH_IV_MIS **or** INH_IV_DIAG_ERR **or** INH_IV_IGC

Maximal possible value: NC_CYL_NR

```
If      LC_EFF_SCC_BAS_SWI_CLC = 1
Then    If      LC_ENA_EFF_SCC_BAS_MAN = 1
        Then    EFF_SCC_BAS = C_EFF_SCC_BAS_MAN
        Else    EFF_SCC_BAS = 1.0
        Endif
Else    EFF_SCC_BAS = 1- (SUM_INH_IV_BAS / NC_CYL_NR)
Endif
```

62.5.3 Actual efficiency fuel cut-off

Output data:

Name	V/S	Hex. limits	Phys. limits	Resol.	Unit
EFF_SCC_AV	V/O	0...FFFFH	0...1.99996	0.0305e-3	[-]
Actual efficiency fuel cut-off					
EFF_SCC_AV_CAN	V/O	0...FFFFH	0...1.99996	0.0305e-3	[-]
Actual efficiency fuel cut-off					
SUM_INH_IV_TOT	V	0...8H	0...8	1	[-]
Sum of cylinders which are shut off either by means of static or dynamic fuel cut-off pattern					
INH_IV_TOT	V	0...FFFFH	0...65535	1	[-]
Overall shut off pattern (static and dynamic)					

Input data:

LV_LDM_ACT	LV_GS_ACT	LV_AMT_ACT	LV_DCC_INC_ACT
LV_DCC_PUC_INH	LV_ASR_ACT	NC_CYL_NR	LV_LDM_PUC_INH
INH_IV	INH_SWI_IV		

FUNCTION DESCRIPTION:

General information:

EFF_SCC_AV is the actual efficiency from fuel cut-off interventions. The value is calculated by count of opened injectors divided by the number of cylinders (NC_CYL_NR). The input value INH_IV defines the status of each injector during the next injection cycle due to static fuel cut-off. The input value INH_SWI_IV defines the status of all injectors during the next injection cycle due to dynamic fuel cut-off.

Further information see in chapter “Basic SW inputs and Outputs” in subchapter “Injection information”.

Every static fuel cut-off request intervention deriving from pattern (engine speed limitation, ASR and GS), trailing throttle fuel cut-off, misfire, engine stop, etc. is considered by means of INH_IV.

Every dynamic fuel cut-off request intervention deriving from "torque based pattern"- and/or "sequential fuel cut off and restart fuel feed"-interventions is considered by means of INH_SWI_IV.

The pattern INH_IV_TOT is the bitwise OR of all pattern (static and dynamic) and SUM_INH_IV_TOT is the corresponding sum of cylinders which are shut off.

The EFF_SCC_AV_CAN is calculated like EFF_SCC_AV only at external intervention the efficiency is not regarded.

Activation:	at every engine state except engine stopped	
Deactivation:	at engine stopped	
Initialization:	LV_EFF_SCC_AV_AUTH = 0	at reset or at engine stop
Update rate:	10 ms	

Formula section:

```
If      INH_IV = 1              (bitwise)       or
        INH_SWI_IV = 1          (bitwise)
Then    INH_IV_TOT = 1          (bitwise)
Else    INH_IV_TOT = 0          (bitwise)
Endif
```

SUM_INH_IV_TOT = bitwise summation of INH_IV_TOT (Bits 0 to (NC_CYL_NR-1))

Maximal possible value: NC_CYL_NR

EFF_SCC_AV_CLC = 1- (SUM_INH_IV_TOT / NC_CYL_NR)

```
If      EFF_SCC_AV_CLC < 1              and
        LV_EFF_SCC_AV_AUTH = 0
Then    EFF_SCC_AV = 1
Else    EFF_SCC_AV = EFF_SCC_AV_CLC
        LV_EFF_SCC_AV_AUTH = 1
Endif
```

Calculation of EFF_SCC_AV_CAN for CAN Torque:

```
If      LV_GS_ACT = 1           or
        LV_AMT_ACT = 1          or
        LV_ASR_ACT = 1          or
        (LV_DCC_INC_ACT = 1     and
        LV_DCC_PUC_INH = 0)     or
        (LV_LDM_ACT = 1         and
        LV_LDM_PUC_INH = 0)
Then    EFF_SCC_AV_CAN = 1
Else    EFF_SCC_AV _CAN = EFF_SCC_AV
Endif
```

Determination of fast fuel cut-off conditions
General information:

The objective of this module is to define the condition for fast fuel cut-off. This function shall prevent engine speed overshooting during gear shift with manual transmission vehicles. If fast fuel cut-off is enabled, cylinder deactivation will be managed by the torque management.

Description:

The fast fuel cut-off will be enabled for the following situation:
the coolant temperature must exceed a calibratable threshold (see activation condidtions) and the load must decrease
the accelerator pedal must be released and the clutch has to be opened; these conditions have to be happen within a maximum time frame
if the clutch pedal has been pushed during this observation time and if it is still pushed the fast fuel cut-off is possible
the variant turbo regards the flag LV_GS_ACT_FL in order to set fast fuel cut-off

LV_S_RUN	LV_GS_DEC_ACT	LV_AMT_DEC_ACT	LV_AMT_INC_ACT

FUNCTION DESCRIPTION:

General information:

The initialization module is a temporary software module which is gradually reduced in that amount how functionallity of the MS45CP software is growing.
It generates output data (torque values, state bits and other values) as substitute input values for existing SW modules. The source modules will be realized in future.

Application conditions:

Recurrence:
Activation: at every engine operating state
Initialisation: at reset

ACP = ACP_MMV = 0 bar

TQI_AV_S	EFF_SCC_AV	LV_HOM_RUN	
TQ_LOSS	EFF_LAMB_AV	TQI_AV	TQI_AV_HOM

FUNCTION DESCRIPTION:

General information:

TQI_AV is the actual indicated engine torque produces either in homogeneous or stratified combustion mode. The combustion mode is indicated by the logical variable LV_S_ACT (1 ... stratified combustion; 0 ... homogeneous combustion). TQ_AV is the actual static effective torque at clutch. TQE is the actual effective torque at clutch inclusive inertia.

These values are used for external units (e.g. traction control and gear box) as a feedback signal.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization at reset

TQ_AV = TQE = TQE_DIF = 0 Nm

Update rate: 10 ms

Formula section:

EFF_TOT_AV = EFF_IGA_AV * EFF_SCC_AV * EFF_LAMB_AV

TQ_AV = TQI_AV + TQ_LOSS

TQE_DIF = C_FAC_TQE * N_GRD

TQE = TQ_AV - TQE_DIF

The dynamic torque is derived as follows:

TQE_DIF = J (kg*m^2) * $d\omega/dt$ (1/s^2)

TQE_DIF = J (kg*m^2) * $\pi/30 *$ N_GRD (1/min/s)

TQE_DIF = C_FAC_TQE (kg*m^2*min) * N_GRD (1/min/s)

C_FAC_TQE = J (kg*m^2) * $\pi/30$

63.1 Idle Speed Adaptation

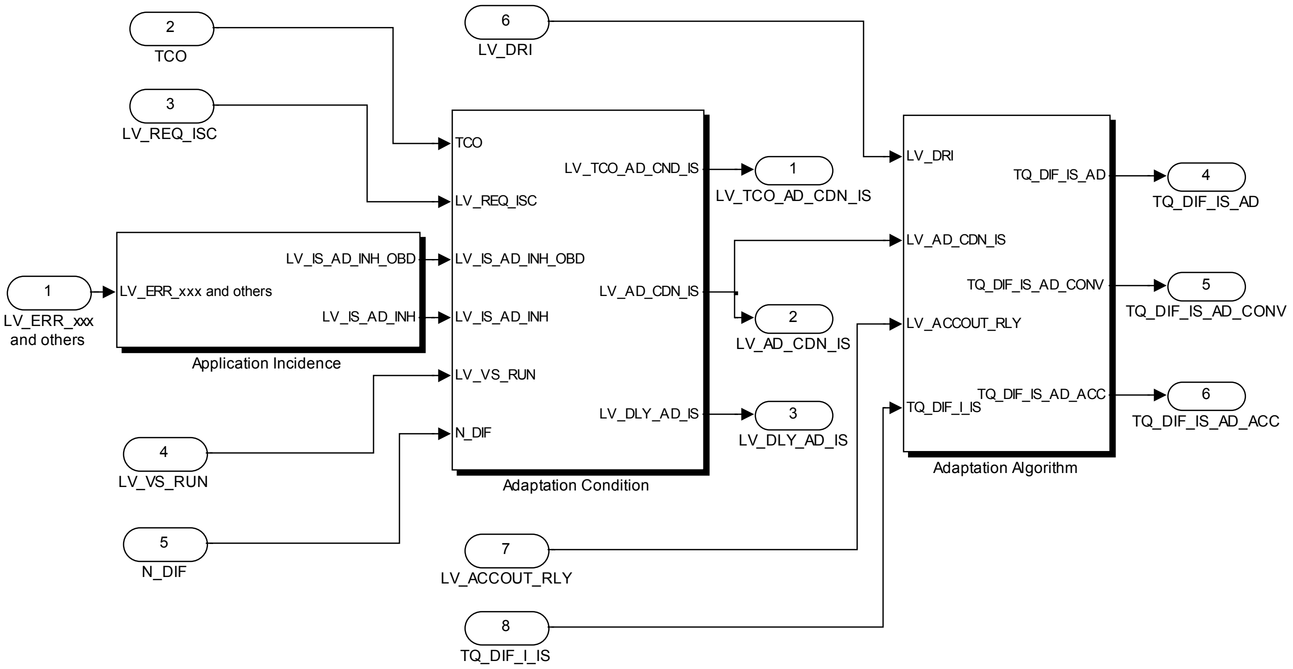

Figure 1: Idle Speed Adaptation, Overview

Functional Description:

The present adaptation is introduced to compensate spread and series variation of engine, air conditioning compressor and hydraulic converter torque losses. It is calculated during idle speed, using the integral part of the idle speed controller for the adaptation of three different parameters:

- TQ_DIF_IS_AD is the adaptation of the basic engine torque losses, without taking the drivetrain into account (disengaged gear),
- TQ_DIF_IS_AD_CONV is an adaptation of the hydraulic converter torque request at idle speed (for automatic transmission only),
- TQ_DIF_IS_AD_ACC is an adaptation value which consideres two adaptation cases depending on the actual situation:
  - air conditioning compressor and converter active at the same time
  - only air conditioning compressor active

The function consists of the following blocks:

- Application Incidence: Checks whether a relevant error has occurred.
- Adaptation Condition: Checks whether the adaptation conditions are fulfilled.
- Adaptation Algorithm: Calculation of the specific adaptation parameters.

These parameters are integrated directly in the specific functions, i.e. the adaptation of the converter torque TQ_DIF_IS_AD_CONV is used in the function "Converter torque" ...

Adaptation parameters for new torque consuming components should be integrated in the same way into the adaptation algorithm module.

63.2 Application Incidences for Idle speed adaptation

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit.
LV_IS_AD_INH_OBD	V/O	0...1H	0...1	1	[-]
Application incidence value					
LV_IS_AD_INH	V/O	0...1H	0...1	1	[-]
Application incidence value (additional adaptation inhibitation conditions, project specific)					

Input data:

LV_ERR_MAF	LV_ERR_PVS_DOUBLE	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_BN_VS_TCS
LV_ERR_TCO	LV_ERR_AMP	LV_ERR_IGC	LV_ERR_AMP_PLAUS

			LV_ST_END
TCO			LV_ERR_MAP_TPS_PLAUS

FUNCTION DESCRIPTION:

General information:

The idle speed adaptation is inhibited if on of the errors described in the formula section occur. Additionally it is possible to inihibit the idle speed adaptation for a certain time after start dependent on the start temperature.

Application conditions:

Initialization:	all 0 at LV_IGK 0 > 1 and reset
Recurrence:	100 ms
Activation:	at every engine state

Description:

If one of these error bits is set, LV_IS_AD_INH_OBD = 1 and LV_IS_AD_INH = 1.
Adaptation is not allowed see application conditions.

Formula section:

```
If      LV_ST_END = 0->1

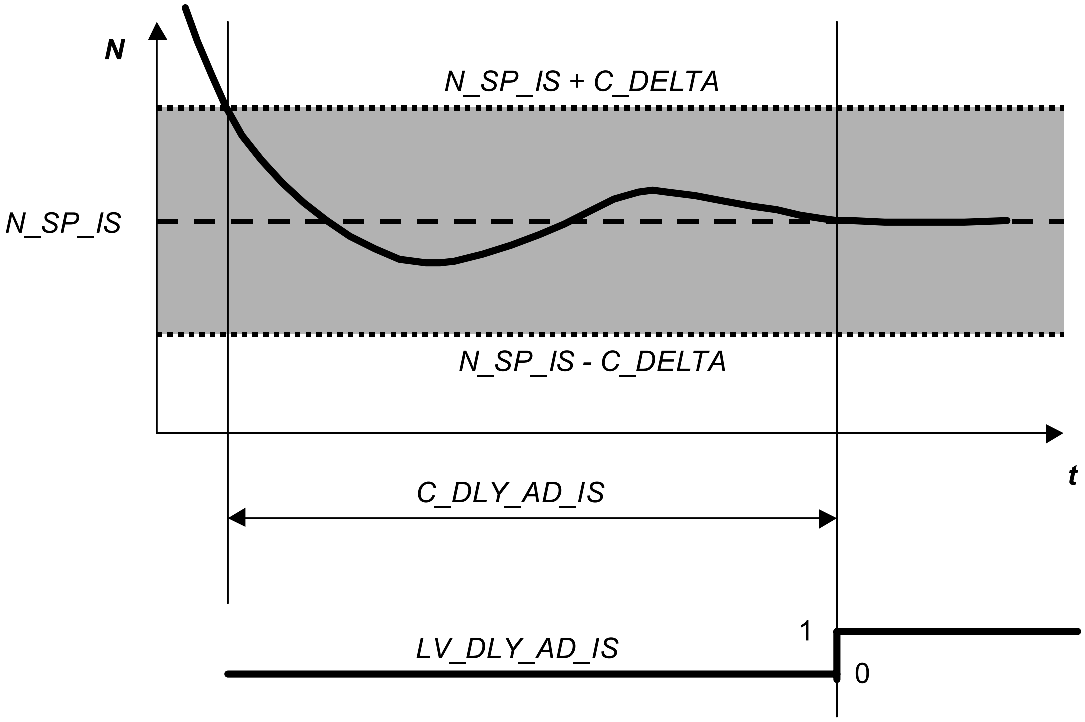
temperature bottom limit for ISC adaptation					

63.3.1 Activation conditions for the Idle Speed Adaptation

The adaptation process is released when all of the following conditions are fulfilled (LV_AD_CDN_IS = 1):

- ♦ engine running in idle state (LV_REQ_ISC = 1)
- ♦ idle speed has settled for a given time delay (T_DLY_AD_IS is the timer value):



Delay timer for idle speed adaptation activation

- vehicle stopped (LV_VS_RUN = 0)
- coolant temperature in operating range:

LV_IS_AD_INH_OBD = 0 (see module "Application Incidence")

- LV_IS_AD_INH = 0 (see module "Application Incidence")

63.4.1 General Information

Application conditions:

Initialization:

E2PROM Variables

At first initialization, after a checksum failure or at service tester request LV_TQ_LOSS_AD_CLR_EXT_ADJ or LC_AD_CLR 0 ->1 , all parameters are set to zero:

TQ_DIF_IS_AD = 0 Nm,

TQ_DIF_IS_AD_CONV_NEUT = 0 Nm,

TQ_DIF_IS_AD_CONV = 0 Nm,

TQ_DIF_IS_AD_CONV_1 = 0 Nm,

TQ_DIF_IS_AD_ACC_NEUT = 0 Nm,

TQ_DIF_IS_AD_ACC_CONV = 0 Nm,

TQ_DIF_IS_AD_ACC = 0 Nm,

TQ_DIF_IS_AD_ACC_1 = 0 Nm,

TQ_DIF_IS_AD_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_OPM_2 = 0 Nm,

TQ_DIF_IS_AD_ACC_1_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_ACC_1_OPM_2 = 0 Nm,

TQ_DIF_IS_AD_ACC_CONV_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_ACC_CONV_OPM_2 = 0 Nm,

TQ_DIF_IS_AD_CONV_1_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_CONV_1_OPM_2 = 0 Nm,

TQ_DIF_IS_AD_ACC_NEUT_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_ACC_NEUT_OPM_2 = 0 Nm,

TQ_DIF_IS_AD_CONV_NEUT_OPM_1 = 0 Nm,

TQ_DIF_IS_AD_CONV_NEUT_OPM_2 = 0 Nm

Variables initialized after reset and after the E2PROM has been read

TQ_DIF_IS_AD_ACC_1_INTER = TQ_DIF_IS_AD_ACC_1,

TQ_DIF_IS_AD_ACC_NEUT_INTER = TQ_DIF_IS_AD_ACC_NEUT,

TQ_DIF_IS_AD_ACC_CONV_INTER = TQ_DIF_IS_AD_ACC_CONV,

TQ_DIF_IS_AD_CONV_NEUT_INTER = TQ_DIF_IS_AD_CONV_NEUT,

TQ_DIF_IS_AD_CONV_1_INTER = TQ_DIF_IS_AD_CONV_1,

LV_AT_NEUT_CTL = 0 [-]

Activation:

Deactivation:

-

Update rate:

100 ms

FUNCTION DESCRIPTION:

The complete function is calculated every 100ms independent of the status of the adaptation condition. If the adaptation conditions are fulfilled (LV_AD_CDN_IS = 1), the corresponding adaptation value is fed by the I-gain of the idle speed controller value TQ_DIF_I_IS :

- The adaptation of ACC and CONV (TQ_DIF_IS_AD_ACC_CONV) is calculated if the gear is engaged (LV_DRI = 1) and the air conditioning compressor is switched on (LV_ACCOUT_RLY = 1).
- The adaptation of ACC and CONV with neutral control active (TQ_DIF_IS_AD_ACC_NEUT) is calculated if the gear is engaged (LV_DRI = 1), neutral control active (LV_AT_NEUT_CTL = 1) and the air conditioning compressor is switched on (LV_ACCOUT_RLY = 1).
- If LV_ACCOUT_RLY = 1 and LV_DRI = 0, the adaptation of the air conditioning compressor is calculated (TQ_DIF_IS_AD_ACC_1).
- The Hydraulic converter torque adaptation with neutral control passive (TQ_DIF_IS_AD_CONV_1) is calculated if LV_DRI = 1, LV_AT_NEUT_CTL = 0 and LV_ACCOUT_RLY =0.
- The Hydraulic converter torque adaptation with neutral control active (TQ_DIF_IS_AD_CONV_NEUT) is calculated if LV_DRI = 1, LV_AT_NEUT_CTL = 1 and LV_ACCOUT_RLY =0.
- The basic adaptation of the idle speed controller (TQ_DIF_IS_AD) is calculated if the gear is disengaged (LV_DRI = 0) and the air conditioning compressor is switched off (LV_ACCOUT_RLY = 0).

Therefore, a fraction of the integral part of the idle speed controller (FAC_TQ_DIF_IS_AD * TQ_DIF_I_IS) is added at each cycle to the concerned adaptation parameter, whose value is limited through a min/max limiter. The adaptation parameters are stored, even after deactivation of the function. These values are used as start values after re-entering into the same adaptation path.

The outputs of the different adaptation paths are always covered with values of the last adaptation, even if the adaptation conditions are not fulfilled or the engine is not in idle. But these values will only be adapted (changed) if the certain adaptation path is activated and they are certainly only considered in the single modules (“Torque Loss and Lead for ACC”, “Converter Torque”) in conformance with the actual situation (ACC on, drivetrain engaged). Only the basic torque losses (TQ_DIF_IS_AD) are always considered in the module “Torque Losses”.

TQ_DIF_IS_AD_CONV is considered in the converter torque calculation module, TQ_DIF_IS_AD_ACC in the calculation of the air conditioning compressor losses. TQ_DIF_IS_AD is added in the torque losses.

The integration is done with high resolution values (long signed word).

At the end of the integration the conversion from high resolution (signed long word) to “normal” resolution (signed word) is done. Only the high word is taken from the signed long word value.

63.4.1.3 Functional overview of the adaptation algorithm

Depending of the status of several logical variables (LV_DRI, LV_ACCOUT_RLY, LV_AT_NEUT_CTL) and the automatic gearbox clutch information STATE_MOD_GB the different adaptation paths are chosen. With the help of the logical field STATE_MOD_GB the logical variable LV_AT_NEUT_CTL is created.

A filter first order is used to smooth the adaptation value changes in case of engaging/disengaging the drive w/o neutral control active and/or switching on/off the AC.

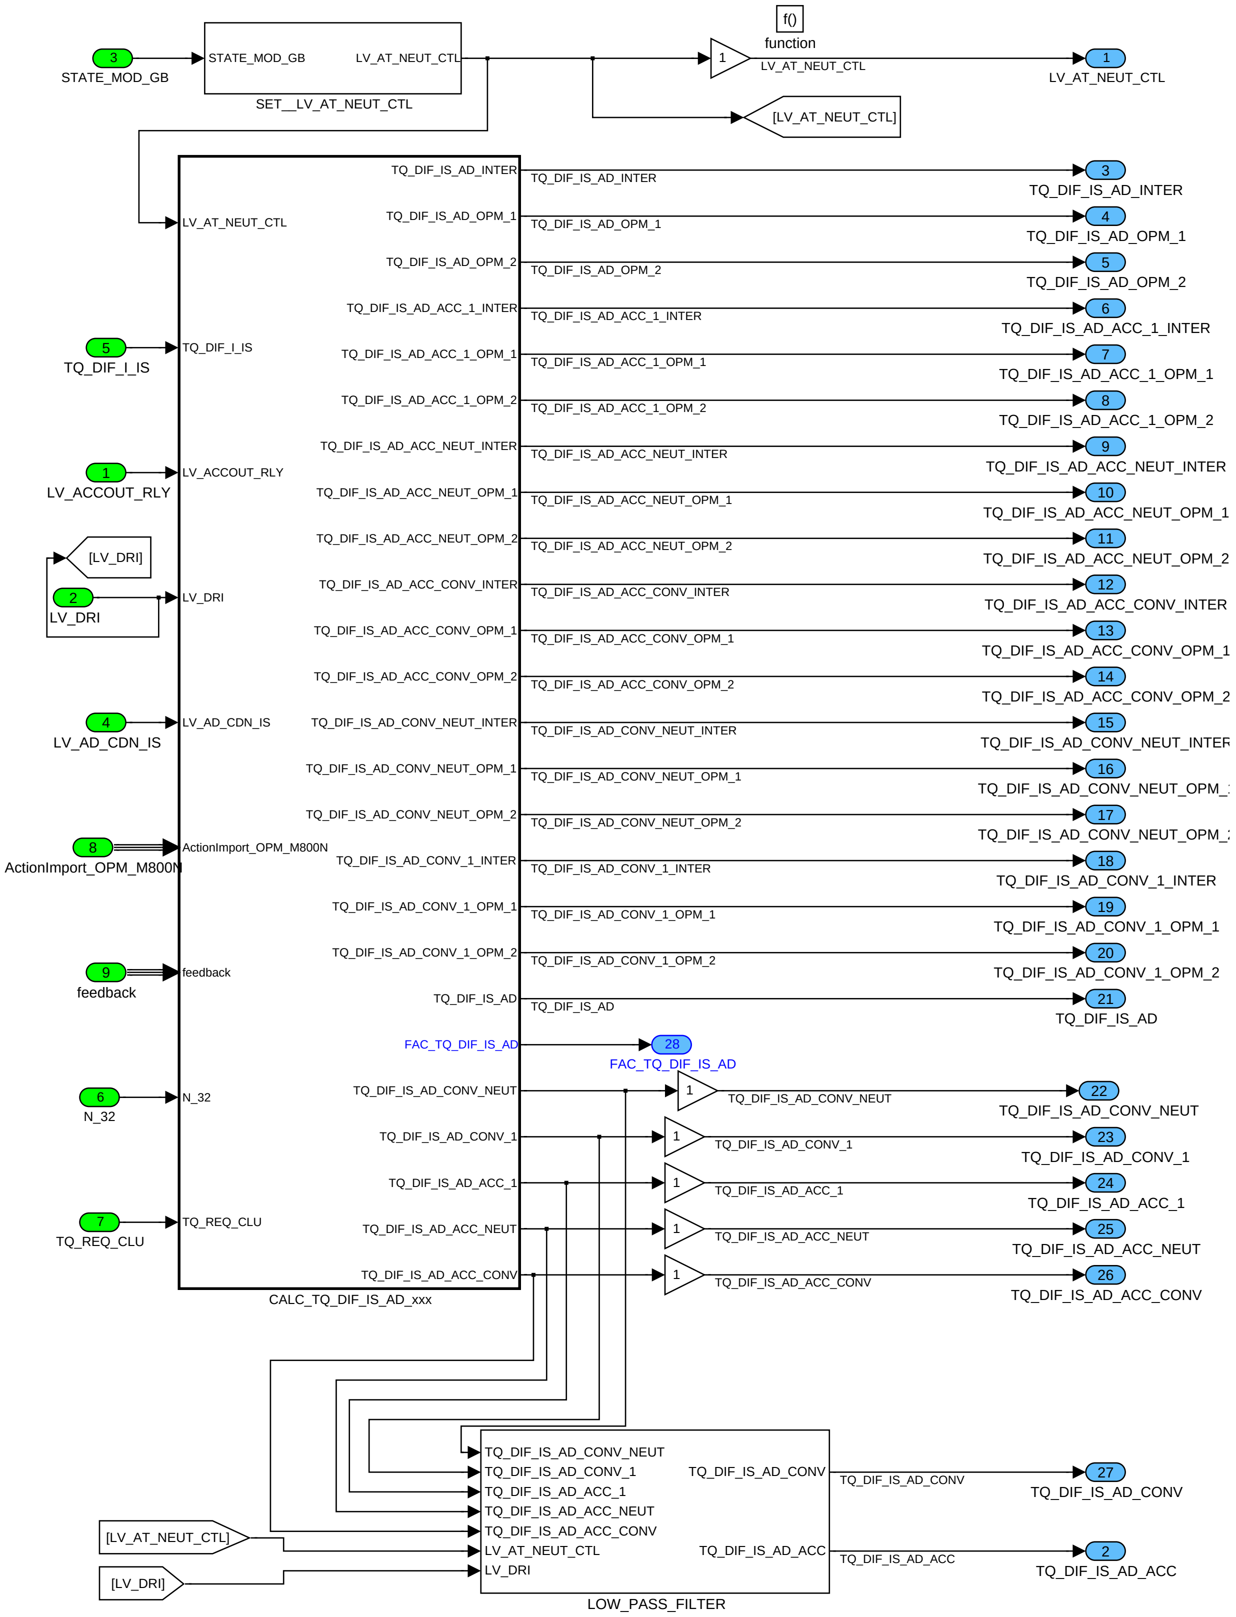

Figure 17 TQLO_M800N/ Operate

Setting of LV_AT_NEUT_CTL

With the help of the logical field STATE_MOD_GB the logical variable LV_AT_NEUT_CTL is created.

Depending on that information a separate set of adaptation values is chosen.

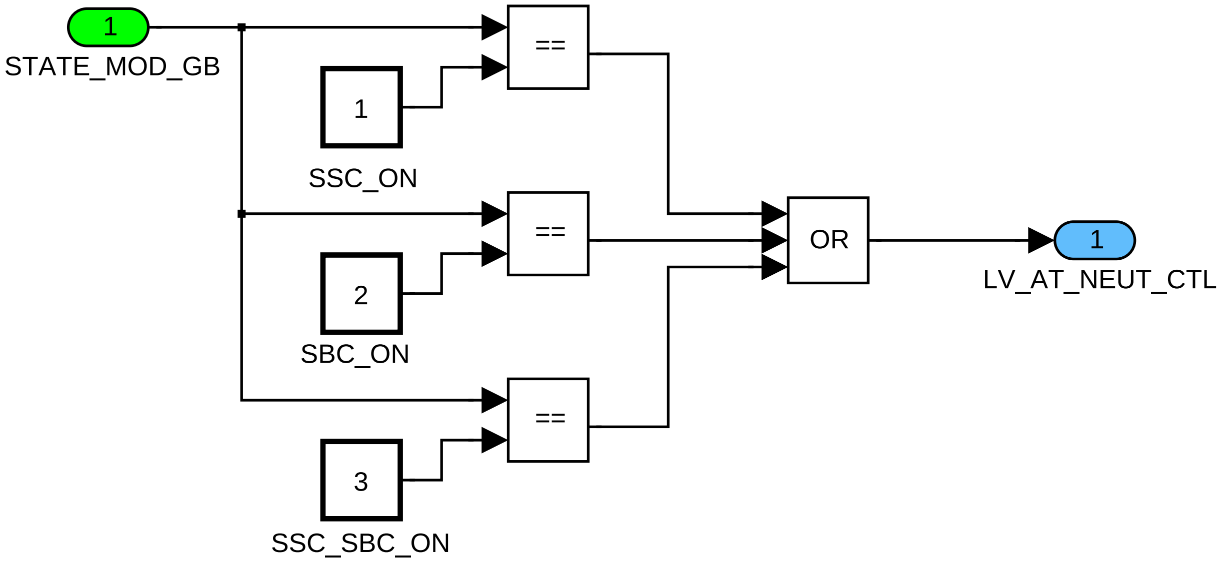

Figure 18 TQLO_M800N/ Operate/ SET__LV_AT_NEUT_CTL

Calculation of the different adaptation values TQ_DIF_IS_AD_XXX

Depending of the status of several logical variables (LV_DRI, LV_ACCOUT_RLY, LV_AT_NEUT_CTL) the different adaptation paths are chosen.

To ensure that the adaptation values don't change during the transition from OPM_1 to OPM_2 and vice versa the flags LV_OPM_SEL_TQ_IS_AD_1/_2 are taken into account. Only if LV_OPM_SEL_TQ_IS_AD_1 is set or LV_OPM_SEL_TQ_IS_AD_2 is set the corresponding integrator out value is routed through.

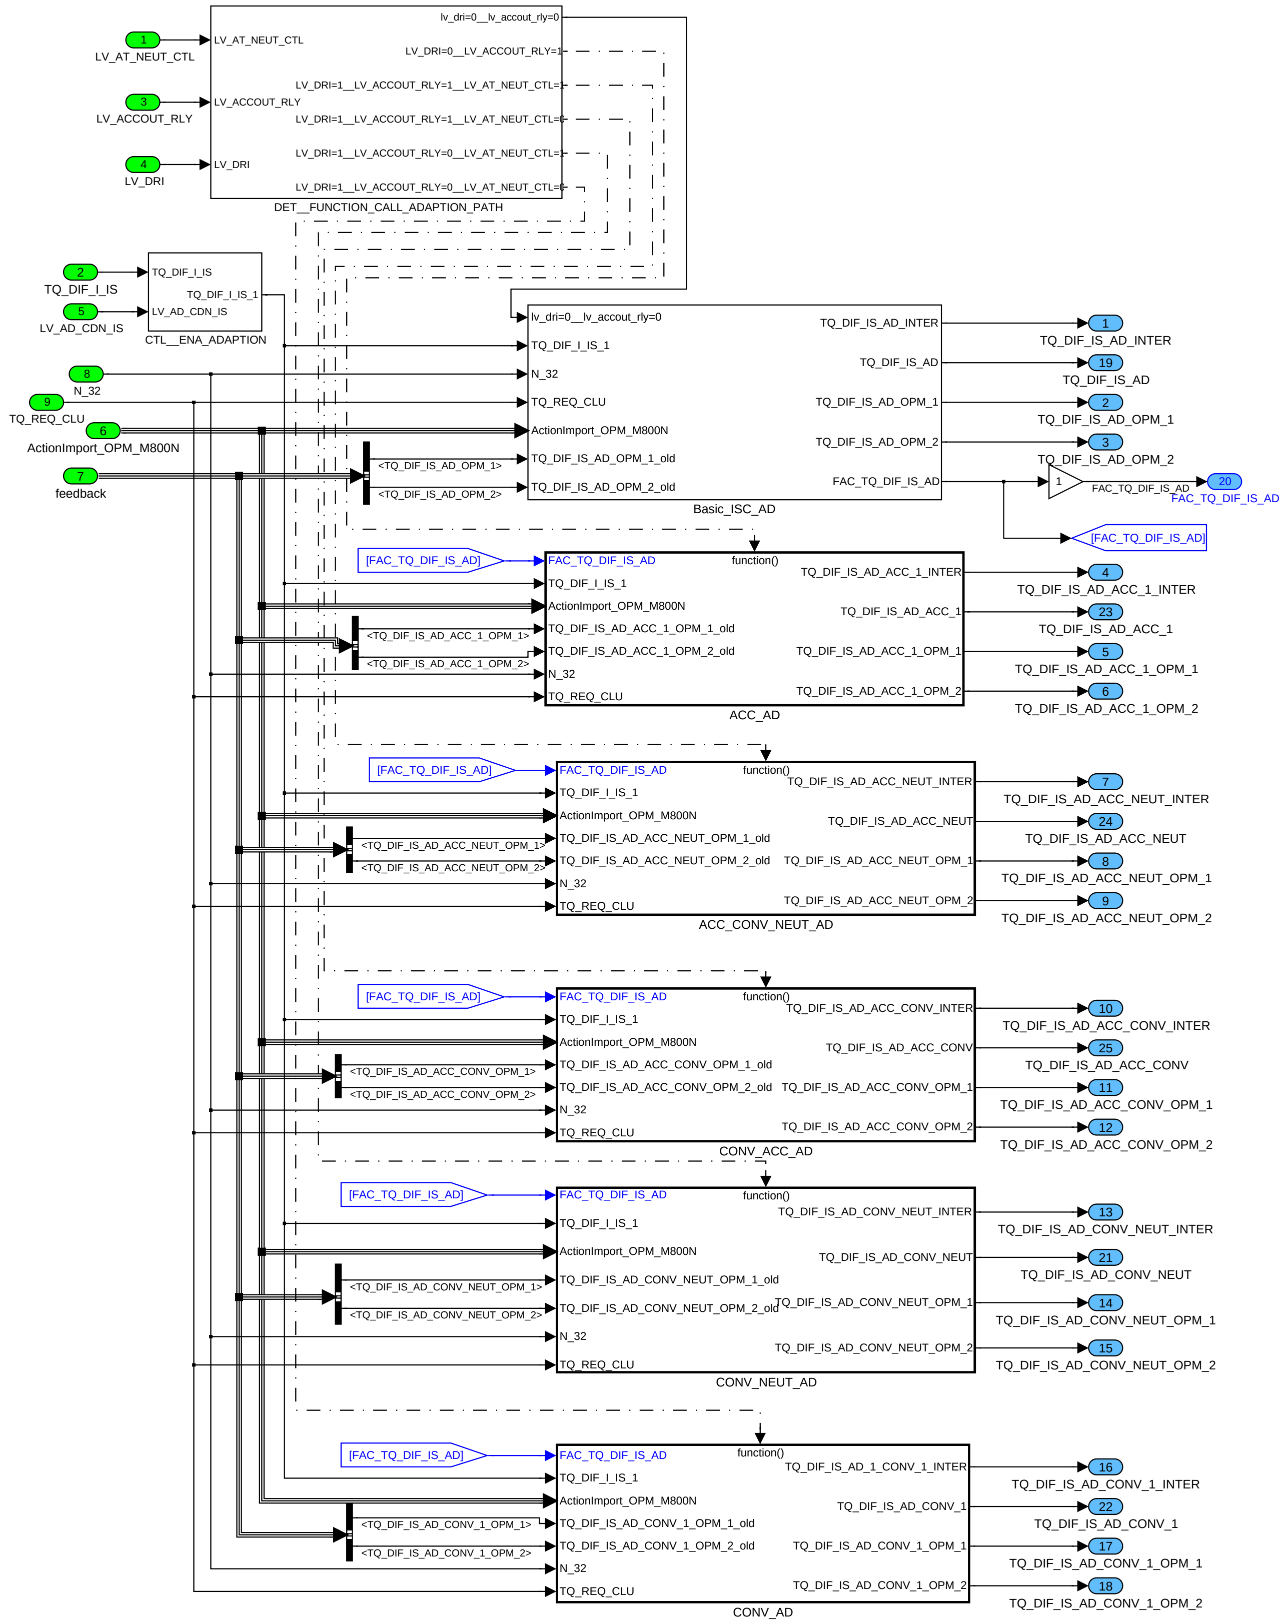

Figure 19 TQLO_M800N/ Operate/ CALC_TQ_DIF_IS_AD_xxx

Creation of the function calls for the several adaptation values

Depending on the logical status of the flags LV_DRI, LV_AT_NEUT_CTL and LV_ACCOUT_RLY the corresponding subsystem is triggered. So in total 6 different combinations are possible.

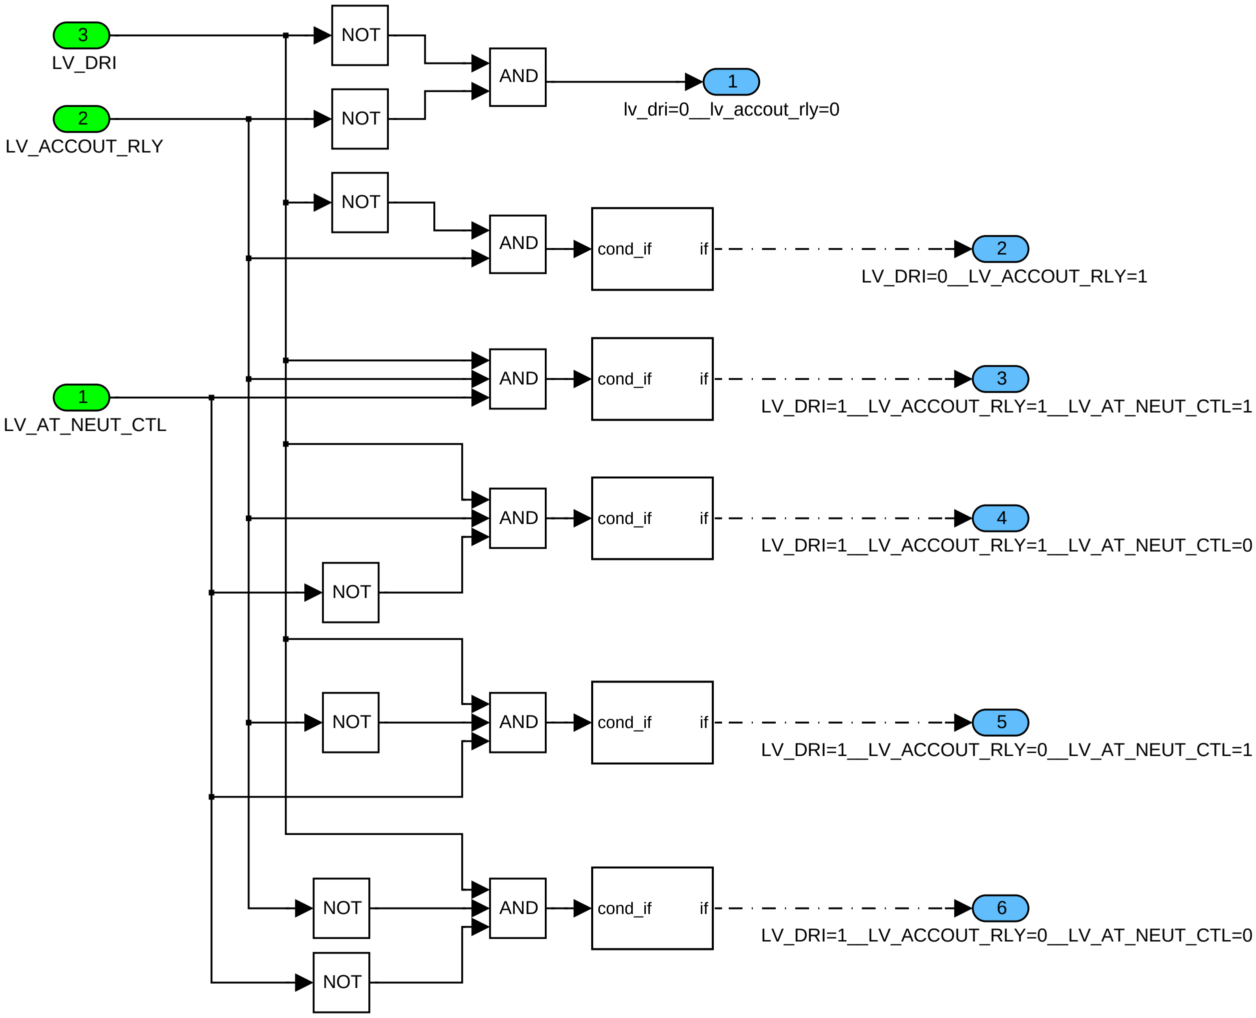

Figure 20 TQLO_M800N/ Operate/ CALC_TQ_DIF_IS_AD_xxx/ DET__FUNCTION_CALL_ADAPTION_PATH

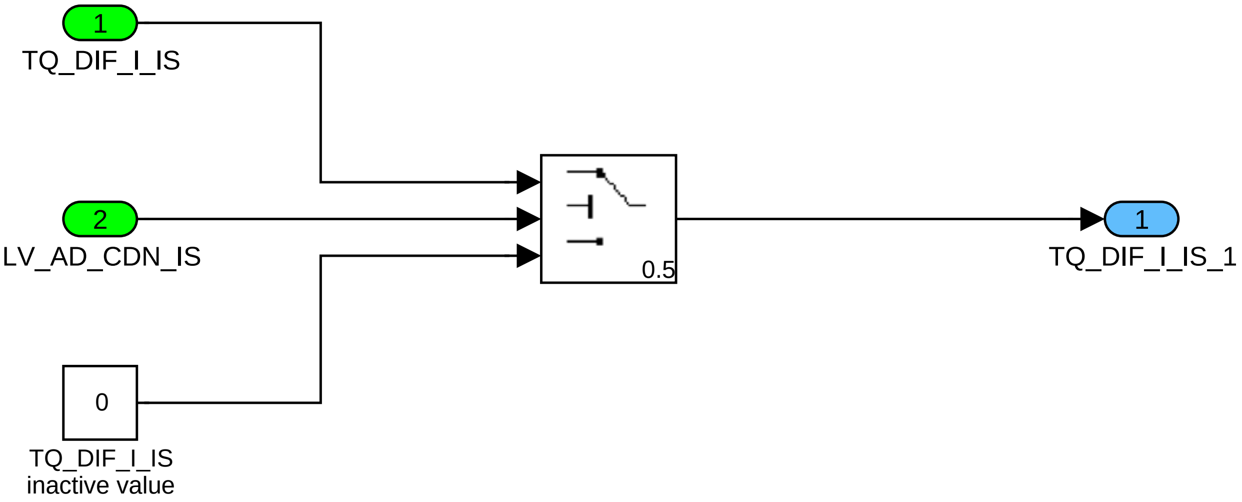
Input for adaptation algorithm TQ_DIF_I_IS

The adaptation algorithm is fed by the I-gain of the idle speed controller. Due to the fact that the whole function is calculated continuously the input into the adaptation algorithm is controlled via the enable flag LV_AD_CDN_IS. If the adaptation condition is not fulfilled the passive value 0 Nm is routed into the adaptation algorithm. Thus no adaptation value change takes place.



This functions controls the input signal into the adatation algorithm
− if the adaptation conditions are not fullfilled the adaptation is fed by 0Nm
− if the adaptation gets active the adaptation is fed by the idle speed controller TQ_DIF_I_IS

Figure 21 TQLO_M800N/ Operate/ CALC_TQ_DIF_IS_AD_xxx/ CTL__ENA_ADAPTION

Basic adaptation value (TQ_DIF_IS_AD)

This adaptation value is applied for a MT or AT vehicle with drive not engaged.

The speed of the adaptation process is defined through the calibration parameter The speed of the adaptation process is defined through the parameter FAC_TQ_DIF_IS_AD and the function's update rate. This factor is calculated in the map IP_FAC_TQ_DIF_IS_AD, which is depend on the absolut value of TQ_DIF_I_IS. This provides a fast or a slow adaptation.

The sign of the input in the integrator function will be inverted because the output of the Subsystem is coordinated into TQ_LOSS [neg....0] Nm .

The sign of the input in the integrator function will not be changed because the output of the Subsystem is coordinated into TQ_CONV [0...pos.] Nm .

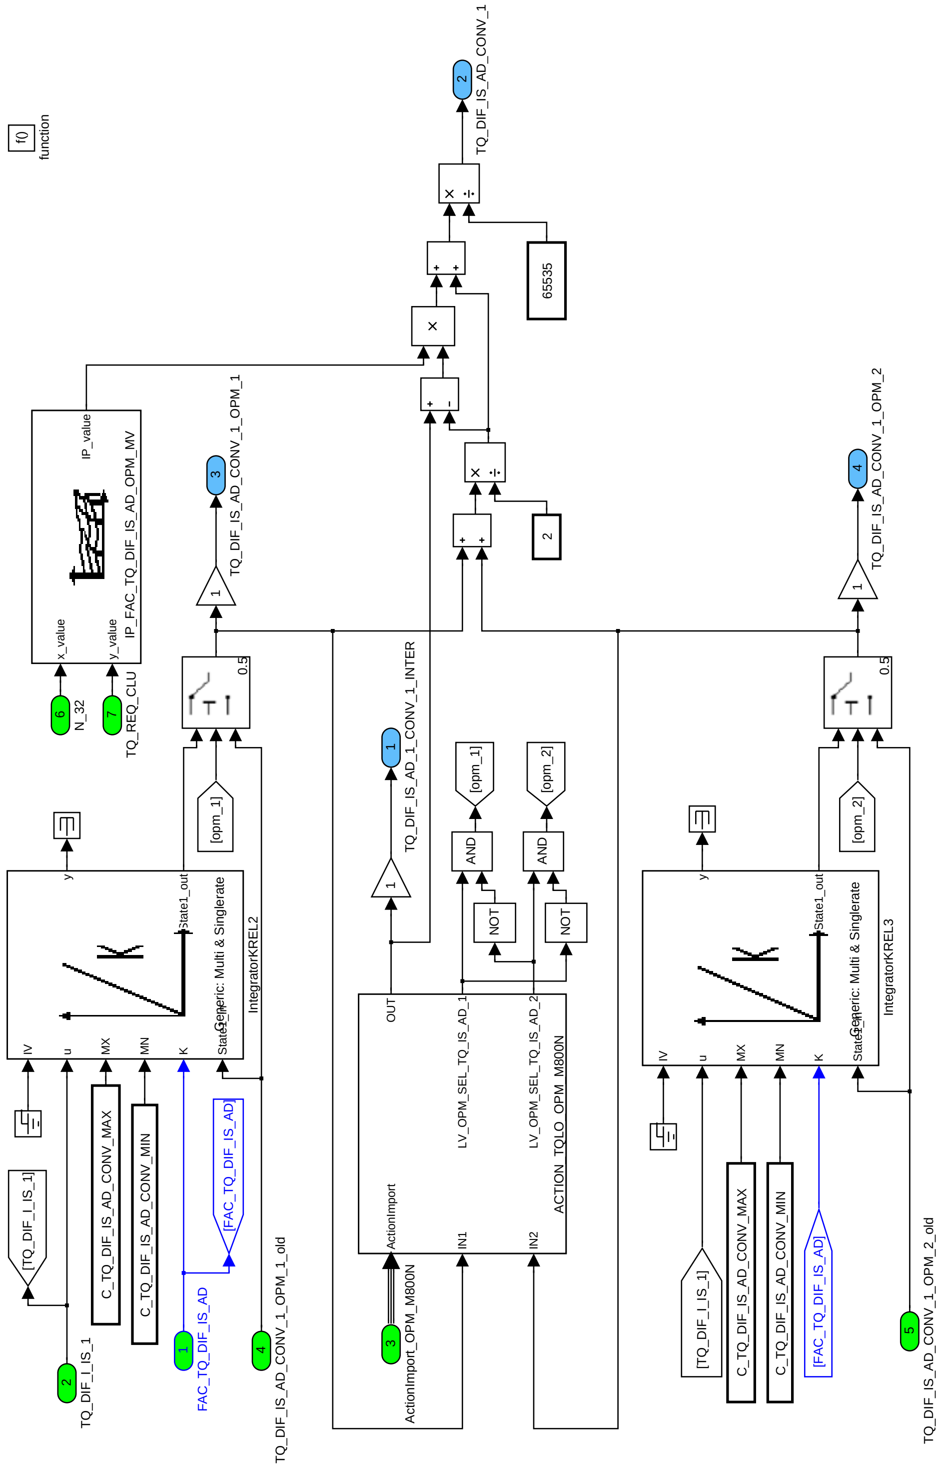

Figure 27 TQLO_M800N/ Operate/ CALC_TQ_DIF_IS_AD_xxx/ CONV_AD

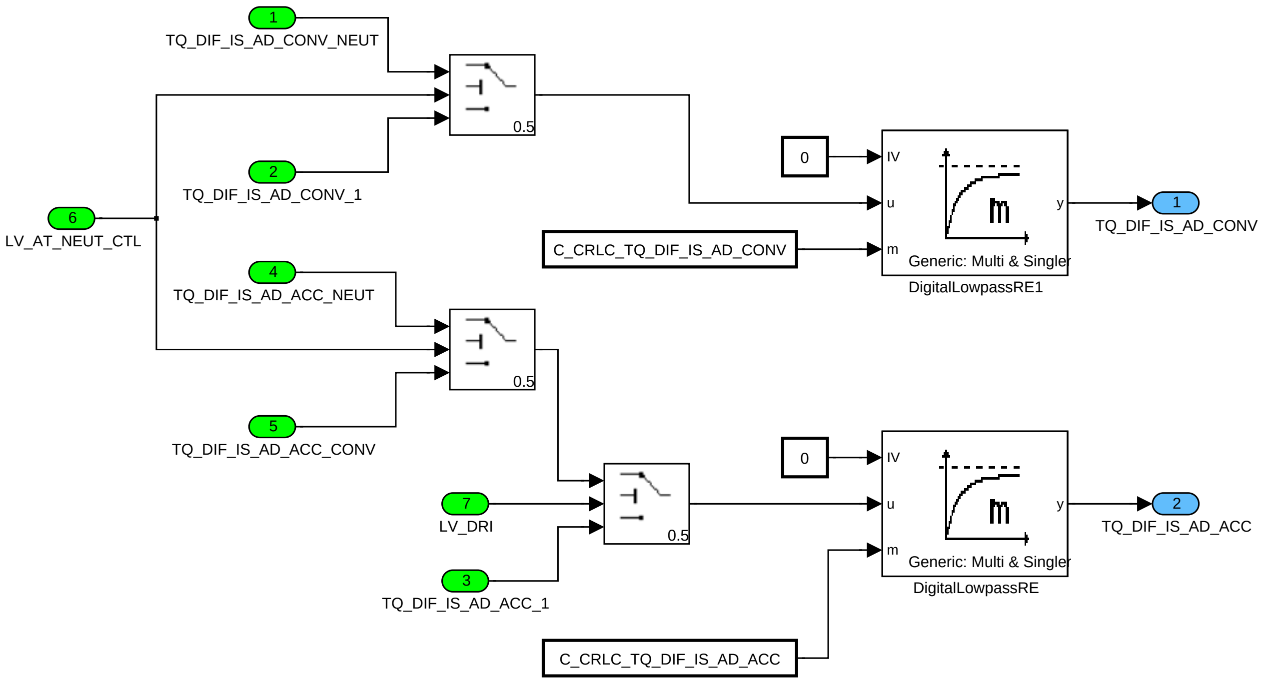
Filtering of the adaptation values

In order to be able to use one input for the ACC torque losses module and one adaptation value for the converter torque calculation module, switches are introduced to change between TQ_DIF_IS_AD_ACC_1, TQ_DIF_IS_AD_ACC_CONV and TQ_DIF_IS_AD_ACC_NEUT in dependency of the status of the logical inputs. To prevent abrupt changes in TQ_DIF_IS_AD_ACC (in case of switching between TQ_DIF_AD_IS_ACC_CONV to TQ_DIF_AD_IS_ACC_NEUT or the TQ_DIF_IS_AD_ACC_1), the output value of the final switch is smoothed by a low pass filter. The same strategy is applied in case of a change of the status of the neutral control. The change between TQ_DIF_IS_AD_CONV_NEUT and TQ_DIF_IS_AD_CONV_1 is also routed via a low pass filter.

During the first ACC adaptations, TQ_DIF_IS_AD_ACC may be erroneous and should therefore be limited to small values.



N.B.: This Module has to be calculated even if LV_AD_CDN_IS == 0;
if the adapation is disabled but drive is engaged/disengaged //AC
switched on/off the calculation of the corresponding torque adaptation
value has to be performed!

Table of Contents

Index

64.1 Detection of Driver or Cruise control passive (No TQ demand).

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CT	V/O	0...1H	0...1	1	[-]
Logical variable for detecting driver request passive					

Input data:

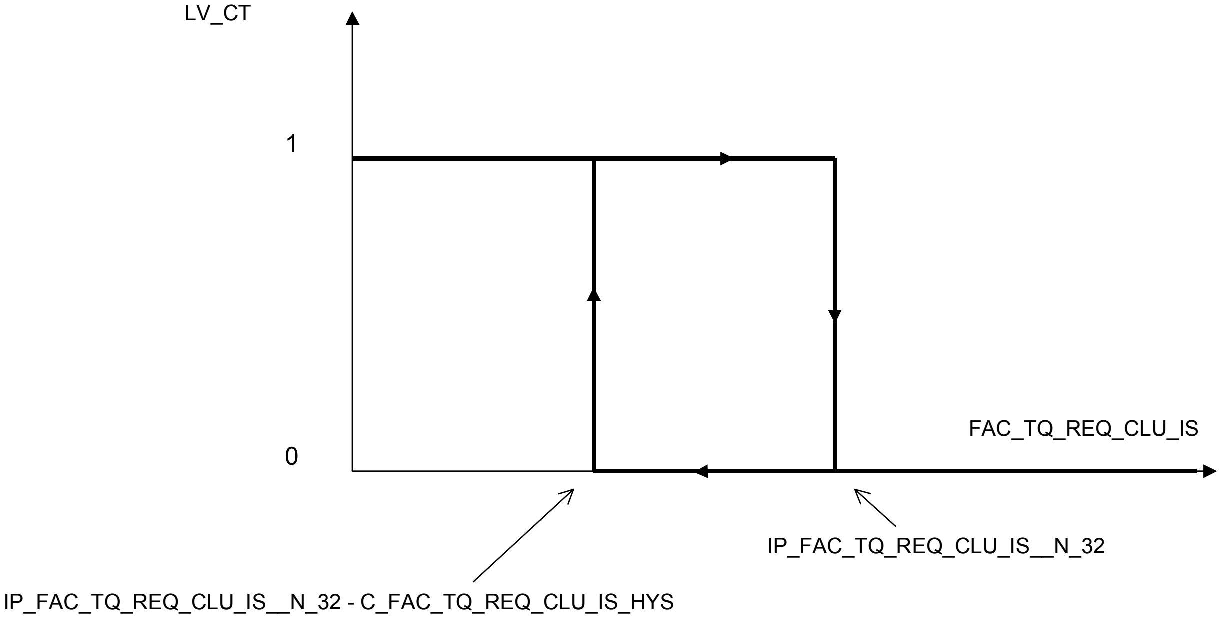
LV_MTC_CUR_OFF	FAC_TQ_REQ_CLU_LDM	N_32	

General information:

The detection of LV_CT = 0 (no torque request from driver or cruise control or LDM) is done by evaluating the torque scaling factor FAC_TQ_REQ_CLU_LDM (driver / cruise / LDM).
In case of LV_MTC_CUR_OFF = 1 (no more throttle control), the throttle will remain in the fixed limp home position, which is around 8° (depending on the used throttle); this is a part load position (LV_CT=0). All torque requests can only be realized by spark advance interaction or single cylinder cut off coordination. For this purpose the driver passive detection is deactivated (LV_CT=0).

Formula section:

```
If      LV_MTC_CUR_OFF = 1
Then    LV_CT = 0
Else    if     LV_CT = 1
        Then   if     FAC_TQ_REQ_CLU_LDM ≥ IP_FAC_TQ_REQ_CLU_IS__N_32
               Then   LV_CT = 0
               Endif
        Else   if     (FAC_TQ_REQ_CLU_LDM ≤ IP_FAC_TQ_REQ_CLU_IS__N_32
                                          - C_FAC_TQ_REQ_CLU_IS_HYS )
               Then   LV_CT = 1
               Endif
        Endif
Endif
```



Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_FAC_TQ_REQ_CLU_IS__N_32	0	0...FFFFH	0...1.99996	0.0305e-3	[-]

Threshold on FAC_TQ_REQ_CLU for IS detection					
C_FAC_TQ_REQ_CLU_IS_HYS	1	0...FFFFH	0...1.99996	0.0305e-3	[-]
Hysteresis on threshold on FAC_TQ_REQ_CLU for IS detection					

64.2 Basic functions: FL, INF & REACX

64.2.1 Full Load: (LV_FL)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_FL	O/V	0...1H	0...1	1	-
Basic function FL					
LV_FL_RAW	O/V	0...1H	0...1	1	-
LV condition “pedal value” is fullfilled					

Input data:

FAC_TQ_REQ_DRIV	N_32	TCO	VS
N	LV_AT	T_AST	CL_MMV
LOAD_THD_FL	LV_CT	STATE_ETC_LIH	STATE_TPS_DIAG
LV_TI_LIM_ACT	LV_TQ_LIM_INTV		

FUNCTION DESCRIPTION:

General information:

Main parameter for full load is an engine speed dependent load threshold. Additional parameters to disable full load are several failure conditions, coolant temperature, engine speed and vehicle speed. After fullfillment of all other conditions, the state LV_FL can be suppressed for a certain time.

Application conditions:

Activation :	at every engine operating state
Deactivation :	-
Initialization :	LV_FL and LV_FL_RAW = 0 LV_FL_1 and LV_FL_2 and LV_FL_3 = 0
Update rate :	10 ms

Formula section:

Intermediary values:

check pedal value for full load request, including hysteresis:

check requested torque setpoint for full load request, including hysteresis:

```
if  LOAD_THD_FL  ≥  IP_LOAD_THD_FL
  then   LV_FL_2  =  1
  else
    if  LOAD_THD_FL  <  IP_LOAD_THD_FL - C_LOAD_THD_FL_HYS
      then   LV_FL_2  =  0
      else   LV_FL_2  remains unchanged
    endif
endif
```

check conditions that prevent full load:

```
if  LV_CT = 1                                                     or
    STATE_ETC_LIH ≠ ETC_NO_LIH  and  STATE_ETC_LIH ≠ ETC_LIH_1  or
    STATE_TPS_DIAG = TPS_LIH_MAX                                  or
    LV_TI_LIM_ACT = 1
    or
    LV_TQ_LIM_INTV = 1
  then   LV_FL_3  =  0
  else   LV_FL_3  =  1
endif
```

```
if       LV_FL_1 = 1   and   LV_FL_2 = 1   and   LV_FL_3 = 1 and
         TCO  ≥  C_TCO_MIN_FL
  then   LV_FL_RAW  =  1
  else   LV_FL_RAW  =  0
endif
```

Full load recognition:

```
if  LV_FL_RAW  =  1
 then
        check engine/ vehicle conditions for full load:
        if  ( CL_MMV ≤      C_CL_MMV_THD_FL  and
              N_32    ≥  C_N_MIN_FL              and
              VS      ≥  C_VS_MIN_FL )   at least one time since reset        or

            ( CL_MMV >      C_CL_MMV_THD_FL  and
              N_32    ≥  C_N_MIN_CP_FL           and
              VS      ≥  C_VS_MIN_FL )   at least one time since reset

        then  start timer T_TI_DLY_FL if not yet started
              check full load time delay:
              if  C_N_MIN_FL_DLY ≤    N_32    <  C_N_MAX_FL_DLY  and
                  C_T_MIN_FL_DLY ≤    T_AST   <  C_T_MAX_FL_DLY
              then

                    if      T_TI_DLY_FL  > C_T_TI_DLY_FL(_AT)_2     (LV_AT = 0/1)
                    then  LV_FL  =  1
                    endif
              else

                    if      T_TI_DLY_FL  > C_T_TI_DLY_FL(_AT)_1     (LV_AT = 0/1)
                    then  LV_FL  =  1
                    endif
              endif

              increment timer T_TI_DLY_FL

        else  reset timer T_TI_DLY_FL
              LV_FL  =  0
        endif

 else         LV_FL  =  0

endif
```

64.2.2 Intercept function : (LV_INF)

Output data:

Name	**Mode**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
LV_INF	O/V	0...1H	0...1	1	-
Basic function " Intercept "					

Input data:

LV_CT	N_32	N_GRD	N_SP_IS
T_MIN_D_ISA	LV_PUC	LV_PU	LV_IS

FUNCTION DESCRIPTION:

General information:

In the engine operating states trailing throttle (LV_PU) or trailing throttle fuel cut off (LV_PUC), the **intercept function (LV_INF)** can be enabled below an engine speed threshold IP_N_MAX_INF.

For this purpose, the engine speed gradient N_GRD is monitored.

If the negative engine speed gradient exceeds the adjustable constant C_N_GRD_MIN during trailing throttle fuel cut off the injection will be reactivated to counteract the high negative engine speed gradient.

Application conditions:

Activation : at every engine operating state

Initialization : LV_INF = 0

Update rate : every segment

Formula section:

```
If      LV_CT      =  1              and
        N_32       <  IP_N_MAX_INF   and
        N_GRD      <  C_N_GRD_MIN
then    LV_INF     =  1
else    LV_INF     =  0
```

Calibration data:

Name	**Dim**	**Hex. limits**	**Phys. limits**	**Resol.**	**Unit**
C_N_GRD_MIN	1	80...00H	-4096...0	32	min-1/s

Maximum engine speed for intercept function					

64.3 Torque Request for Safety Diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
CTR_ABC_TQI_REQ_LIM	V / O	0...FFFF H	0 ... 65535	1	-
counter for torque request for safety is active					
LV_ERR_TQI_LIM	V/O	0...1H	0...1	1	-
Error flag torque request for safety is active					

Input data:

LV_TQ_LIM_INTV	LV_MTC_CUR_OFF	LV_ES	LV_IGK

FUNCTION DESCRIPTION:

General information:

The objective of this function is to determine the number of intervention actions concerning the torque request for safety and to set the failure table entry depending on LV_ERR_TQI_LIM if the counter exceeds a calibratable threshold.

The monitoring level generates a desired indicated torque TQI_SP_MON. If the actual torque TQI_REF_IGA_LAMB exceeds this value for more than a calibratable threshold a torque demand for the slow and the fast path is generated. The flag LV_TQ_LIM_INTV shows whether this torque intervention is active or not (see chapter D – "Torque request for safety").

LV_ERR_TQI_LIM.

Description:

The counter is initialized with zero for ECU reset, ignition key off, engine starts and engine stops. Otherwize it is incremented, if LV_TQ_LIM_INTV is active.

Application conditions:

Activation: *LV_IGK = 1* ***and*** *LV_ES = 0* ***and*** *LV_MTC_CUR_OFF = 0*

Deactivation: LV_MTC_CUR_OFF == 1

Initialization: 0

by: ECU reset

OR LV_IGK == 0

OR LV_ES == 1

Recurrence: 100 ms

Formula section:

```
IF      LV_TQ_LIM_INTV == 1
THEN    LV_ERR_TQI_LIM = 1 after debounce
ELSE    the debounce counter (CTR_ABC_TQI_LIM) is set to 0.
ENDIF
```

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 |  |  |  └─> -                                    (= SYM_0)
 |  |  └────> -                                    (= SYM_1)
 |  └───────> -                                    (= SYM_2)
 └──────────> -    Engine Torque implausible       (= SYM_3)
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_MAX_TQI_LIM	1	0 ... FFFF H	0 ... 65535	1	-
maximum counter for torque request for safety					
C_ABC_INC_TQI_LIM	1	0 ... FF H	0 ... 255	1	-
increment counter for torque request for safety					

64.4 Torque Coordination General

General information:

The torque structure introduces the engine torque as a fundamental quantity . Either torque at clutch or indicated engine torque is used depending on the needs for the coordination structure.

Every external or internal torque requests are coordinated in the torque coordination modules where several criteria such as emissions, fuel consumption, engine protection and driveabillity are considered. Then torque request is distributed to the different regulated quantities load, ignition, mixture and fuel cut-off.

In this way the complexity can be reduced by the modular approach of the torque structure.

Every subfunction is linked by a torque interface to the torque structure (e.g. idle speed control, anti jerk function, engine speed limitation or catalyst heating, etc.). So the mutual interference of the subfunctions disapear because there is no direct link anymore to the different regulated quantities which decrease the tuning effort.

For the following overview of the torque structure only the most important modules and interface variables are mentionend to show the main track through the structure.

Pedal value interpretation

The Driver requests his driving wish by manipulation of the drivng pedal. As a result a certain pedal value PV_AV is observed which is transformed by different functions into a scaling factor FAC_TQ_REQ_DRIV (0...1).

Coordination of scaling factors for requested torque

This module coordinates different "driver" whises comming from the manual driver, cruise control or variable vehicle speed limitation.

The result is a coordinated scaling factor FAC_TQ_REQ.

Torque request at clutch general

The structure "Torque request at clutch general" consits of the modules "Maximum torque at clutch" and "Minimum torque at clutch". By the scaling factor FAC_TQ_REQ the requested torque at clutch TQ_REQ_CLU is calculated.

Torque Transient

The driver torque request TQ_REQ_CLU is filtered to protect the powertrain from jerking. The step response of the torque transient function are linear ramps. The slope of the ramps are a function of gear ratio, engine speed, torque range and torque increase and decrease state.

The outputs are TQ_REQ_CLU_TRA and TQI_REQ_TRA (TQ_REQ_CLU_TRA – TQ_LOSS) which is the indicated torque representation.

Parallel a torque reserve can be activated by "Torque reserve for torque transient" withe the output variable TQ_ADD_TRA. This torque reserve minimizes the difference between torque setpoint TQI_REQ_TRA and the actual engine torque TQI_AV which leads to a better response behavior of the engine at positive torque jump requests.

Torque reserve coordination

The torque reserve builds up an additionbal load which can be used when a fast torque increase is necessary (e.g. idle speed control) or if the ignition efficiency has to be reduced like for catalyst heating. The torque reserve quantities TQ_ADD_XXX are added to the requested torque value inside the slow torque path. Automatically parallel to the load increase a spark retard is done which will compensate the torque. To build up a torque reserve is a torque neutral process.

Minimum / Maximum torque request selection

This module collects all torque requests to generate the torque setpoint for the slow path TQI_REQ_SLOW and TQI_REQ_FAST for the fast path.

External torque requests:	
- driver torque request	TQI_REQ_TRA , TQI_ADD_ACT
- traction control (torque reduction/ increase)	TQI_ASR/MSR_FAST/SLOW
- automatic transmission (gear support)	TQI_GS_FAST/SLOW_INC/DEC

Internal torque requests:	
- engine speed limitation	TQI_N_MAX
- vehicle speed limitation	TQI_VS_MAX
- cruise control (optional)	
- engine power limitation	TQI_P_MAX
- catalyst protection	TQI_CAT_PROT
- torque plausibility check in level 1	TQI_REQ_LIM_SLOW/FAST

Minimum indicated engine torque at trailing throttle

This module will provide a minimum indicated engine torque TQI_MIN_PU to limit the throttle opening to a minimum value to ensure a safe combustion and to limit the intake manifold pressure.

For the engine operation states the status bit LV_TQI_BOL_SET is delivered to prepare the trailing throttle fuel cut-off. It indicates that the torque setpoint TQI_SP is below the minimum torque TQI_BOL at minimum ignition efficiency.

Torque coordination

The coordinated torque values TQI_REQ_SLOW and TQI_REQ_FAST are entered into the slow and fast torque path where they are confronted with

- torque limitations TQI_MIN_PU, TQI_BAS
- idle speed control TQ_DIF_P_D_SLOW_IS, TQ_DIF_P_D_FAST_IS
- standardization to efficiency 1.00 by EFF_TOT_BAS_SLOW (for the air path torque TQI_REQ_SLOW)
- anti jerk correction TQ_DIF_AJ

The output from the slow path is MAF_SP_TQI which is an input into the inverse air path to determine the throttle opening.

TQI_SP the final target torque is the output from the fast torque path to be obtained in homogeneous mode. It serves as an input for the fast torque path like ignition angle, lambda adjustment (where it is necessary) and fuel cut-off pattern calculations.

64.5.1 TQSP_MD00S

General information:

The engine start torque TQ_ST influences the torque at clutch during start phase as a result it determines the engine speed transient response. It is calculated from a one dimensional map versus engine speed difference N_DIF.

TQ_ST is imported into module “Minimum Torque at Clutch” in order to increase engine speed during start phase. To bring the engine speed to its setpoint at idle the engine speed overshoot can be limitted supported by the tuning data IP_TQ_ST_MT(AT)_XY which depend on engine operation mode OPM_AV_SEL_TQ_ST.

Application conditions:

Activation:	LV_TQ_MIN_CLU = 0
Deactivation:	LV_TQ_MIN_CLU = 1
Initialization:	TQ_ST = 0 Nm at transition LV_ST = 0 to 1
Update rate:	10 ms

FAC_TQ_REQ_CRU	FAC_TQ_REQ_DRIV	LV_MAF_BLS_DIAG	LV_LDM_ENA
FAC_TQ_REQ_DCC			

64.7.1 TQSP_MD00L

General information:

The module "Torque Request at Clutch General" supplies the BMW torque structure with the torque scaling factor FAC_TQ_REQ_CLU from the driver or a cruise control.

FAC_TQ_REQ is exported and can be used from a transmission control unit for calculation of gear shifting points.

If a MAF error is detected and brake is active then the torque request is set to zero.

Application conditions:

Initialisation:	*all = 0 at reset*
Recurrence:	*10 ms*
Activation:	*at every engine state*
Deactivation:	-

FUNCTION DESCRIPTION:

General information:

LV_TQI_REQ_CAN_INH collects all states or flags within engine management which shall lead to ignoring external torque requests.

Application conditions:

Initialisation: LV_TQI_REQ_CAN_INH = 0 for LV_IGK 0 --> 1 or at reset

Recurrence: 10ms

Activation: at every engine state

Deactivation: otherwise

Formula section:

```
If      SF_TQD = 3                or          // --> see remark *
        LV_ERR_MTC_CTL_1 = 1

then    LV_TQI_REQ_CAN_INH = 1

else    LV_TQI_REQ_CAN_INH = 0

Endif
```

Remark:

Input data:

TQI_SP_MON	TQI_AV	N_32	LV_MTC_CUR_OFF
LV_IGK	LV_TQ_LIM_EXT_ADJ	LV_ES	LC_AD_CLR_TQ

FUNCTION DESCRIPTION:

General information:

The ETC safety concept monitors the torque generation of the engine by comparing the actual indicated engine torque TQI_AV to the desired indicated engine torque TQI_SP_MON. In order to avoid a false diagnosis decision caused by tolerances and disturbances this torque intervention function is introduced.

The module '*Torque Request for Safety*' delivers two torque request values TQI_REQ_LIM_FAST for the fast torque path (ignition and fuel cut-off) and TQI_REQ_LIM_SLOW for the slow torque path (air path) which leads to a torque intervention if the actual reference torque TQI_AV exceeds the setpoint TQI_SP_MON by more than a specified threshold.

This state is indicated by the bit LV_TQ_LIM_INTV_1. It is set if TQI_AV is bigger than the setpoint TQI_SP_MON plus the offset TQI_DIF_LIM.

The bit LV_TQ_LIM_INTV is set to 1 if LV_TQ_LIM_INTV_2 = 1 and set to 0 C_T_TQ_LIM_INTV seconds after an transition of LV_TQ_LIM_INTV_2 to 0 to prevent LV_TQ_LIM_INTV from to fast jittering if the torque limitation goes on off on ... and is used for diagnosis. LV_TQ_LIM_INTV_2 is used to activate ignition or fuel cut of intervention.

TQI_AV is calculated from the reference torque value TQI_REF which includes the actual engine speed N_32 and MAF and actual efficencies of lambda ignition and cylinder shut off.

TQI_DIF_LIM is the safety offset which is the sum of TQI_SP_MON and IP_TQI_DIF_LIM which depends on N_32 and TQI_SP_MON itself.

If the actual torque TQI_AV is inside the permitted range (LV_TQ_LIM_INTV_1 = 0) then TQI_REQ_LIM_2 is set to the calibratible value C_TQI_REQ_LIM_PAS (e.g. max. engine torque + 10%).

The torque increase of TQI_REQ_LIM_3 is realized by a change limitation (C_TQ_LIM_INC) to avoid positive torque jumps if the limitation condition disappears.

TQI_REQ_LIM_SLOW is also limited by a rate limiter to avoid negative jumps of the throttle.

By the tuneable logical constants LC_TQ_LIM_INH_FAST and LC_TQ_LIM_INH_SLOW either the fast torque output or the slow torque output or both can be inhibited (set to passive values) for further investigations.

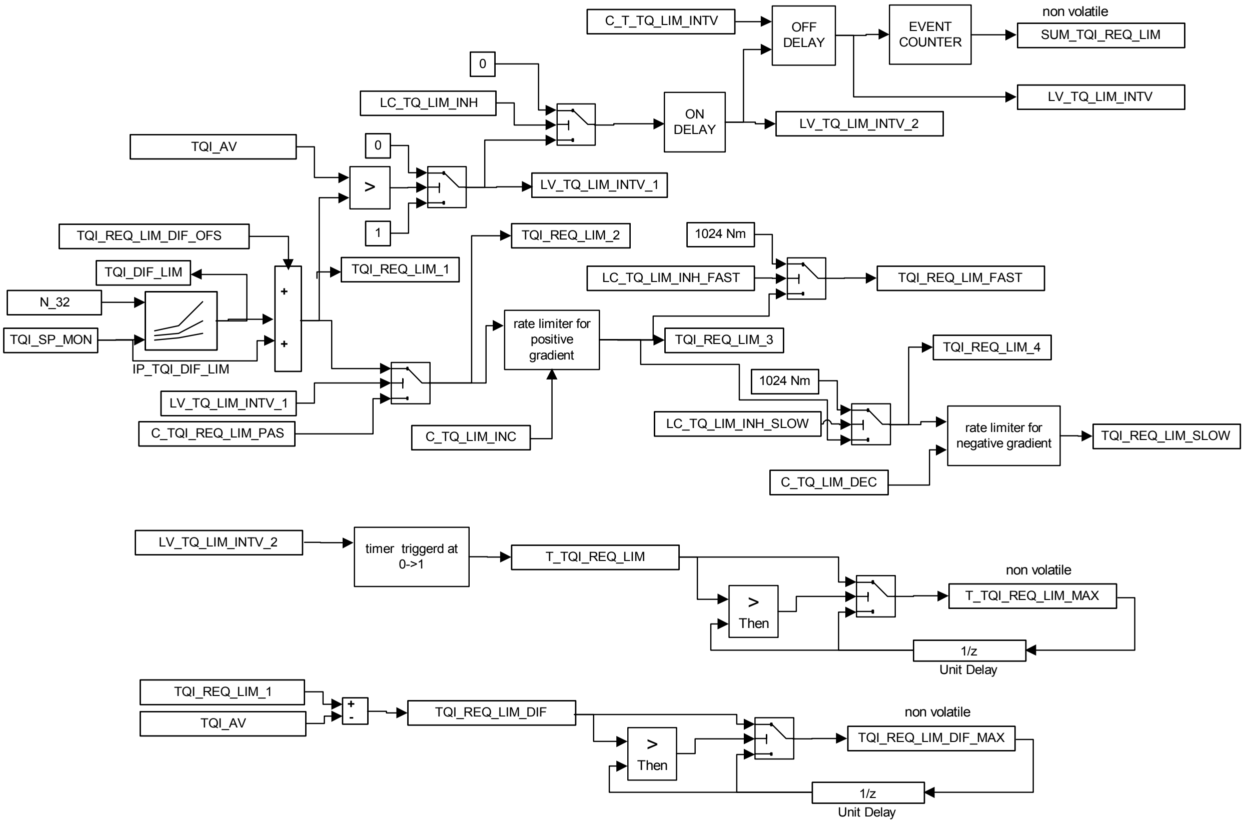
ON-Delay:

The ON-Delay is necessary because of this module is not synchronized to the module ‘Desired indicated engine torque’ of level 2. This could cause inaccurate torque limitation in case of a high positive torque gradient in level 1 while TQI_SP_MON is not updated yet.

Drag Pointer functions:

Within the tuning phase is reliable a statistical evaluation of interventions. Therefore some drag pointers information are available.

Signal flow diagram:



Application conditions:

Activation: LV_IGK = 1 **and** LV_ES = 0 **and** LV_MTC_CUR_OFF = 0

Deactivation: otherwise

Initialization: at reset **or** LV_IGK = 0 **or**

LV_ES = 1 **or** LV_MTC_CUR_OFF = 1

then LV_TQ_LIM_INTV = 0

LV_TQ_LIM_INTV_1 = 0

LV_TQ_LIM_INTV_2 = 0

TQI_REQ_LIM_FAST = C_TQI_REQ_LIM_PAS

TQI_REQ_LIM_SLOW = C_TQI_REQ_LIM_PAS

        ENDIF
ENDIF
```

ON-Delay:

```
IF      [(LV_TQ_LIM_INTV_1$_{k-2}$ == 1) AND (LV_TQ_LIM_INTV_1$_{k-1}$ == 1) AND
        (LV_TQ_LIM_INTV_1$_k$ == 1)]
        {delay by 2 recurrencies of the module}
THEN    LV_TQ_LIM_INTV_2$_k$ = 1
ELSE    LV_TQ_LIM_INTV_2$_k$ = 0
ENDIF
```

Off-Delay:

```
IF      LV_TQ_LIM_INTV_2$_k$ == 1
THEN    (LV_TQ_LIM_INTV = 1
        T_TQ_LIM_INTV = C_T_TQ_LIM_INTV)
ELSE    (T_TQ_LIM_INTV = T_TQ_LIM_INTV – [update rate]            {limited to 0}
        IF      T_TQ_LIM_INTV == 0
        THEN    LV_TQ_LIM_INTV = 0
        ENDIF)
ENDIF
```

Request-Calculation (II):

```
IF      LV_TQ_LIM_INTV_2$_k$ == 1
THEN    TQI_REQ_LIM_2 = TQI_REQ_LIM_1
ELSE    TQI_REQ_LIM_2 = C_TQI_REQ_LIM_PAS
ENDIF
```

Rate limiter for positive gradient:

```
IF      (TQI_REQ_LIM_2 > (TQI_REQ_LIM_3$_{k-1}$ + C_TQ_LIM_INC))
THEN    TQI_REQ_LIM_3$_k$ = TQI_REQ_LIM_3$_{k-1}$ + C_TQ_LIM_INC
ELSE    TQI_REQ_LIM_3$_k$ = TQI_REQ_LIM_2
ENDIF
```

TQI_REQ_LIM_FAST calculation:

```
IF      LC_TQ_LIM_INH_FAST == 1             {fast torque request path disabled}
THEN    TQI_REQ_LIM_FAST = 1023.97          {upper limit}
ELSE    TQI_REQ_LIM_FAST = TQI_REQ_LIM_3$_k$
ENDIF
```

TQI_REQ_LIM_4 calculation:

```
IF      LC_TQ_LIM_INH_SLOW == 1             {slow torque request path disabled}
THEN    TQI_REQ_LIM_4 = 1023.97             {upper limit}
ELSE    TQI_REQ_LIM_4 = TQI_REQ_LIM_3$_k$
ENDIF
```

Rate limiter for negative gradient:

```
IF      (TQI_REQ_LIM_4 < (TQI_REQ_LIM_ SLOW$_{k-1}$ – C_TQ_LIM_DEC))
THEN    TQI_REQ_LIM_SLOW$_k$ = TQI_REQ_LIM_SLOW$_{k-1}$ - C_TQ_LIM_DEC
ELSE    TQI_REQ_LIM_SLOW$_k$ = TQI_REQ_LIM_4
ENDIF
```

Event counter active torque limitation: SUM_TQI_REQ_LIM

```
At transition LV_TQ_LIM_INTV =  0 -> 1
THEN    increment SUM_TQI_REQ_LIM by 1
ELSE    SUM_TQI_REQ_LIM unchanged
ENDIF
```

The counter SUM_TQI_REQ_LIM is stored in non volatile memory till error memory is erased or is reseted at external adjustment or LC_AD_CLR_TQ

Drag pointer of torque intervention:

```
IF LV_TQ_LIM_INTV_2 = 1 and TQI_REQ_LIM_DIF < TQI_REQ_LIM_DIF_MAX
Then    TQI_REQ_LIM_DIF_MAX = TQI_REQ_LIM_DIF
else    TQI_REQ_LIM_DIF_MAX unchanged
endif
```

```
IF(1) LV_TQ_LIM_INTV_2$_{n}$ = 1 and LV_TQ_LIM_INTV_2$_{n-1}$ = 0
Then(1)   T_TQI_REQ_LIM = 0s        ("reset at activation")
Else(1) IF(2)         LV_TQ_LIM_INTV_2$_{n}$ = 1
    Then (2) T_TQI_REQ_LIM = T_TQI_REQ_LIM + Update rate
            IF(3) T_TQI_REQ_LIM > T_TQI_REQ_LIM_MAX
            Then(3) T_TQI_REQ_LIM_MAX = T_TQI_REQ_LIM
            Else(3)       T_TQI_REQ_LIM_MAX unchanged
    Else(2)       T_TQI_REQ_LIM unchanged
Endif
```

The drag pointers TQI_REQ_LIM_DIF_MAX and T_TQI_REQ_LIM_MAX are stored in non volatile memory till error memory is erased or a reset is done at external adjustment or LC_AD_CLR_TQ .

FUNCTION DESCRIPTION:

General information:

Gear ratio calculation is depending on transmission type (manual or automatic). When manual transmission is detected and (LV_AT == 0 && LV_VAR_TCT == 0), gear ratio is detected by using engine speed / vehicle speed ratio. In case of automatic transmission, gear ratio is detected by using the CAN-information of EGS. If LV_VAR_TCT = 1 then gear ratio is calculated versus CAN informations coming from DKG.

Application conditions:

Activation: at all engine operating states except LV_ES and LV_ST .

Deactivation: at engine operating states LV_ES and LV_ST .

Recurrence: 10 ms **except** subchapter 65.2.1.1: 100 ms

65.2.1 Manual transmission (LV_AT = 0 and LV_VAR_TCT = 0)

Application conditions:

Initialisation: GR_MT = 0 **at** [LV_ES = 1 **or** LV_ST = 1 **or** LV_CS = 1]

Formula section:

Executed only if LV_AT = 0 and LV_VAR_TCT = 0

```
if(1) LV_CS = 0
then(1)  if(2)     [ LV_ERR_VS = 1  and  LV_ERR_CAN_BOFF = 1 ]    or

C_MIN_VS_RATIO	1	0...FFH	0...255	1	[km/h]
Minimum engine speed for engine speed / vehicle speed ratio calculation					

65.2.1.1 Adaptation of different rear axle transmission ratios (only manual transmission)

Different rear axle ratios are used for the versions for different countries within the various vehicle series. The function aims at learning the rear axle ratio and to use it for correction for gear detection.
The gear detection is applied with the standard rear axle. Moreover, the standard reduction ratio is applied as fixed value. Moreover, the n/vs ratio used by the vehicle for driving in 2nd gear and trailing throttle fuel cut-off is applied.

Learning the new rear axle ratio
The adaptation of the rear axle ratio is only effected in 2nd gear and at trailing throttle fuel cut-off PUC. The quotient of the actual value and the setpoint of the n/vs ratio is used for calculation of the new rear axle ratio and the factor between the actual and setpoint reduction ratio.
The rear axle ratio is adapted via an adaptive correlation constant C_CRLC_FAC_GR.
Moreover, FAC_GR is biased with FAC_GR_MMV_AV.

Application conditions:

Initialisation: FAC_GR_MMV_AV = 1.0
when ECU is new or
when adaptation is reset by LC_AD_CLR_VAR or
when values of group VAR could not be read out from the non volatile memory;
else: FAC_GR_MMV_AV is read back from non volatile memory

N_VS_RATIO = 255 rpm/(km/h)

Formula section:

Executed only if (LV_AT = 0 and LV_VAR_TCT = 0)

if GEAR = 2 **and**
LV_PUC = 1 **and**
LV_CS = 0 **and**
LV_ERR_CS = 0 **and**
LV_IM_BLS = 0 **and**
LV_ERR_BLS_PLAUS = 0 **and**
$|\text{N\_VS\_RATIO}_{n-1} - \text{N\_VS\_RATIO}_{n}| < \text{C\_N\_VS\_CRU\_GRD\_FAC\_GR\_MAX}$

then *Calculation of the rear axle ratio "ACTUAL to SETPOINT values - rear axle"*

$$\text{FAC\_GR} = \frac{\text{N\_VS\_RATIO}}{\text{C\_N\_VS\_CRU\_GEAR2\_PUC\_SP}}$$

Adaptation of the rear axle ratio:

$$\text{FAC\_GR\_MMV\_AV}_{n} = \text{FAC\_GR\_MMV\_AV}_{n-1} + \text{C\_CRLC\_FAC\_GR} * (\text{FAC\_GR} - \text{FAC\_GR\_MMV\_AV}_{n-1})$$

Reduction ratio of the currently installed rear axle:

$$\text{GR\_RAX\_AV} = \text{C\_GR\_RAX\_SP} * \text{FAC\_GR\_MMV\_AV}$$

The calculated N_VS_RATIO ratio is continually divided by the current value of FAC_GR_MMV_AV and the current multiplication result is used to obtain the correct gear from the value applied map ID_GR_MT__N_VS_RATIO.

The adaptation value FAC_GR_MMV_AV can be reset to 1 via the KWP command "delete variant".

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_GR_RAX_SP	1	0...FFFFH	0...255.99609	3.91E-03	[-]

Gradient of N/VS ratio below which FAC_GR is adapted					

65.2.2 Twin Clutch Transmission (LV_VAR_TCT = 1)

Gear ratio and LV_DRI are calculated versus CAN informations coming from DKG.

Application conditions:

Initialisation: GR_MT, LV_DRI = 0 **at** [LV_ES = 1 **or** LV_ST = 1]

Formula section:

Executed only if LV_VAR_TCT = 1

GR_MT, LV_DRI = f(GEAR_INFO), see list below:

GEAR_INFO	Corresponding gear	GR_MT	LV_DRI
0H	neutral or park	0	0
1H	1st gear	1	1
2H	2nd gear	2	1
3H	3rd gear	3	1
4H	4th gear	4	1
5H	5th gear	5	1
6H	6th gear	6	1
7H	7th gear	7	1
AH	reverse gear	0	1

65.2.3 Automatic transmission (LV_AT = 1)

Gear ratio and LV_DRI are calculated versus CAN informations coming from EGS.

Application conditions:

Initialisation: GR_AT, LV_DRI = 0 **at** [LV_ES = 1 **or** LV_ST = 1]

Formula section:

Executed only if LV_AT = 1

GR_AT, LV_DRI = f(GEAR_INFO), see list below:

GEAR_INFO	Corresponding gear	GR_AT	LV_DRI
0H	neutral or park	0	0
1H	1st gear	1	1
2H	2nd gear	2	1
3H	3rd gear	3	1
4H	4th gear	4	1
5H	5th gear	5	1
6H	6th gear	6	1
7H	7th gear	7	1
AH	reverse gear	0	1

65.2.4 Information if the reverse gear (AT or TCT) is activ/inactiv :

Formula section:

```
If      (LV_AT = 1 or LV_VAR_TCT = 1)
        and   GEAR_INFO = AH
then    STATE_GEAR_REV_AT_AMT = 1
else    STATE_GEAR_REV_AT_AMT = 0
endif
```

65.2.5 Low range detection (LV_RNG_L, LV_RNG_L_AT)

Depending on LC_RNG_L, the sport-switch and the LV_RNG_L_AT-request from EGS, the bit LV_RNG_L will be activated.

Meaning of C_STATE_ETCU_PROG_INFO:

Bit	LV_RNG_L_AT will be set at condition:
0	*AT / TCT in "S" / "DS" ("comfort transmission"; LV_VAR_ETCU_SPT=0)*
1	*AT / TCT in manual mode "M1 ... 6" ("comfort transmission"; LV_VAR_ETCU_SPT=0)*
2	*AT- / TCT-sport-switch in "S" / "DS" ("sport transmission"; LV_VAR_ETCU_SPT=1)*
3	*AT- / TCT-sport-switch in manual mode "M1 ... 6" ("sport transmission"; LV_VAR_ETCU_SPT=1)*
4	*Gearbox-sportswitch active and AT / TCT ("comfort transmission"; LV_VAR_ETCU_SPT=0)*
5	*Gearbox-sportswitch active and AT / TCT ("sport transmission"; LV_VAR_ETCU_SPT=1)*
6	*always with MT*
7	*not used*

Formula section:

If

AT / TCT "comfort" in "S-mode"

[STATE_ETCU_PROG_INFO = 1H **and**

LV_VAR_ETCU_SPT = 0 **and**

Bit 0 of C_STATE_ETCU_PROG_INFO is set**]** **or**

AT / TCT "comfort" in "M-mode"

[STATE_ETCU_PROG_INFO = 2H **and**

LV_VAR_ETCU_SPT = 0 **and**

65.2.6 Common Gear Ratio Independent from AT or MT (GEAR)

Description:

At not stopped or starting engine, GEAR displays the actual gear ratio independent from transmission type.

Application conditions:

Initialisation: GEAR = 0

Formula section:

```
If (1)          LV_ES = 0
    and         LV_ST = 0
  then (1)
    if (2)      LV_AT = 1
      then (2)  GEAR = GR_AT
      else (2)  GEAR = GR_MT
    endif (2)
  else (1)      GEAR = 0
endif (1)
```

65.2.7 Gear Ratio for exhaust flap functionality

Description:

For the exhaust flap function the detected gear shall not change during gear shift. For this purpose the variable GEAR_EF is generated from GEAR.

Application conditions:

Initialisation: GEAR_EF = 0

Formula section:

If LV_CS = 0

```
    then    GEAR_EF  =  GEAR        no gear shift because clutch is closed
    else    GEAR_EF  =  GEAR_EF     gear shift possible because open clutch, GEAR_EF remains
                                    unchanged
  endif
```

C_VS_MIN_DT	1	0... FFH	0... 255	1	[km/h]
Threshold for vehicle running and drive-train closed detection					
LC_MOD_DT_TCT	1	0... 1H	0... 1	1	[-]
Mode selection of drive train engaged detection for variant twin clutch transmission (0 = like MT; 1 = like AT)					

General Information

General information:
Drive train engaged active (LV_DT=1) means drive train is closed, engine torque is transmitted to the wheels and the vehicle is running (VS >= C_VS_MIN_DT).
The depedabillity to the vehicle-speed has different reason for AT and MT/AMT vehicle.
AT:
With engaged gear it´s normally not necessary to have an agressive idle-speed control. The only exception is a sudden breaking at slowly moving vehicle with engaged gear. In this case it´s necessary to switch to the strong P_D - parameter map of the idle-speed control to avoid idle-speed break-down.
MT:
At start of the vehicle without pushing the accelerator pedal it´s necessary to switch as fast as possible to the smooth P_D idle-speed control map to avoid vehicle jerking. Depending on slip of the clutch it may last too long until a gear-position determination is possible. Therefore in this case the switching from agressive to the smooth P_D map can happen even at slow vehicle speed.
Nevertheless the actualisation of LV_DT is strongly depending on the update-rate of the input signal VS .

Application Conditions

65.4 Clutch Switch detection

Output data:

Name	V/S	Hex. limits	Phys. limits	Resol.	Unit
LV_CS_CUS	O/V	0...1H	0...1	1	[-]
Boolean for clutch switch detection					

Input data:

LV_IM_CS_PN	LV_AT		
STATE_ETCU_CLU	LV_VAR_TCT		

General information:

Clutch switch detection is required for function management at transient conditions. It´s only necessary for cars with manual transmission.
At determination of the ´real´ clutch-switch closing (LV_IM_CS_PN=1) LV_CS_CUS resets at change of LV_IM_CS_PN from 1 → 0 or STATE_ETCU_CLU 03H/4H/5H.

Application conditions:

Activation: LV_AT = 0

Deactivation : LV_AT = 1

Initialisation: **if** LV_AT=0 and LV_VAR_TCT = 0
then LV_CS_CUS = LV_IM_CS_PN

time recurrency : 10ms

Formula section:

```
if    LV_VAR_TCT = 0
  then      LV_CS_CUS  =  LV_IM_CS_PN
  elseif    STATE_ETCU_CLU = 3H or 4H or 5H
        then      LV_CS_CUS  =  0
        else      LV_CS_CUS  =  1
      endif
endif
```

FUNCTION DESCRIPTION:

General information:

The diagnosis is performed for AT or TCT vehicles in order to manage the OBD requirement which is defined by law (MIL activation and Freeze – frame storage).
Depending of CAN 12H / 11H and TCT/ AT and LC_ETCU_FRF the diagnosis is performed in a different way.

Description:

- Request of Gearbox to ECU: STATE_ETCU_OBD
- Response from ECU to Gearbox: STATE_DIAG_GS

Calculation of STATE_DIAG_GS (only first 3 bits, only valid for LC_ETCU_FRF = 1):

	Case 1	**Case 2**	**Case 3**	**Case 4**
Init	No FRF **000**	FRF not from GS **001**	FRF from GS **010**	FRF from GS **010**
Event	GS error	GS error	OBD error	OBD error with higher prior (FSD / MSF)
Result	FRF from GS **010**	FRF not from GS **001**	FRF from GS **010**	FRF from OBD error **001** (next DC)

Application conditions:

```
Initialisation:   according ABC configuration "STD_INI" + NLC_ABC_CAL_DEC_GS = 1
                  STATE_DIAG_GS = 0 at LV_IGK 0->1 or reset or at clearing error memory

Recurrence:       10ms

Activation:       If      (LV_AT = 1 or LV_VAR_TCT = 1) and
                          LV_CDN_VB_OBD1 = 1

LV_ERR_VS	LV_ST	LV_ES	LV_VAR_TCT

FUNCTION DESCRIPTION:

General information:

This module performs the diagnosis of the clutch switch. This is valid only in case of manual transmission.

The diagnosis is based on the verification of the presence of the expected clutch action to shift the gears necessary to bring the vehicle to a certain speed. It is highly improbable that the vehicle is accelerated several consecutive times to a certain speed with the clutch always depressed or never depressed.

Description:

If there’s a a change in LV_IM_CS_PN, the CS is diagnosed as error-free and the diagnosis is switched off if end of diagnosis is reached.

If there’s no change in LV_IM_CS_PN then each time the vehicle is stopped, the diagnosis is enabled. Until the vehicle gets to a certain speed, LV_IM_CS_PN is monitored for value change (clutch pedal actuation). If, for several times (Anti bounce is inrementing by one inrement per diagnosis cycle) the vehicle gets to speed and the clutch switch state has never changed (always 0 or 1) then a failure is recognized.

Depending of status LV_IM_CS_PN 0/1 at beginning of monitoring period there is the symtom OL/SCB or SCG.

Application conditions:

Initialisation: according filter type: ***"STD-INI",*** all other outputs 0 at LV_IGK 0->1 **or** reset **or** at clearing error memory

Recurrence: 1s (10 ms for LV_IM_CS_PN detection)

Activation:

```
If      LV_IGK = 0                   or
        LV_ES = 1                    or

Interface of CS monitor with the Rate-Based Monitoring statisticsBit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1)Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1)Bit 2: individual RBM condition					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_CS	LV_ERR_VS
LV_AT		LV_VAR_TCT	

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the CS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_CS data.

Within STATE_RBM_CS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)

  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)

  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

  (not valid for CS diagnosis)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_CS = 0

on failure memory reset :

bit 1 of STATE_RBM_CS = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_VS			

```
If(1)      { CPU optimization at LV_DC 0 → 1 transition }
           CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
           While bit 1 of STATE_RBM_CS = 0 do
                 with each XX failure of the above list :
                 ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                 SYNCHRONIZATION<CALL>)
                 If(2)        XX has a pending status
                 Then(2)
                              bit 1 of STATE_RBM_CS = 1
                 Endif(2)
           Endwhile
Else(1)
           { the dynamic failure memory is empty }
           No action
Endif(1)
```

Every 1 s :

```
If    bit 0 of STATE_RBM_CS = 0
Then       If    LV_END_DIAG_CS = 1     or
                 LV_AT = 1              or
                 LV_VAR_TCT = 1
           Then  bit 0 of STATE_RBM_CS = 1
           Endif
Endif
If    bit 1 of STATE_RBM_CS = 0
Then
           If    LV_ERR_VS = 1
           Then  bit 1 of STATE_RBM_CS = 1
           Endif
Endif
bit 2 of STATE_RBM_CS = 1
```

LV_TCT_LIH_CAN			

FUNCTION DESCRIPTION:

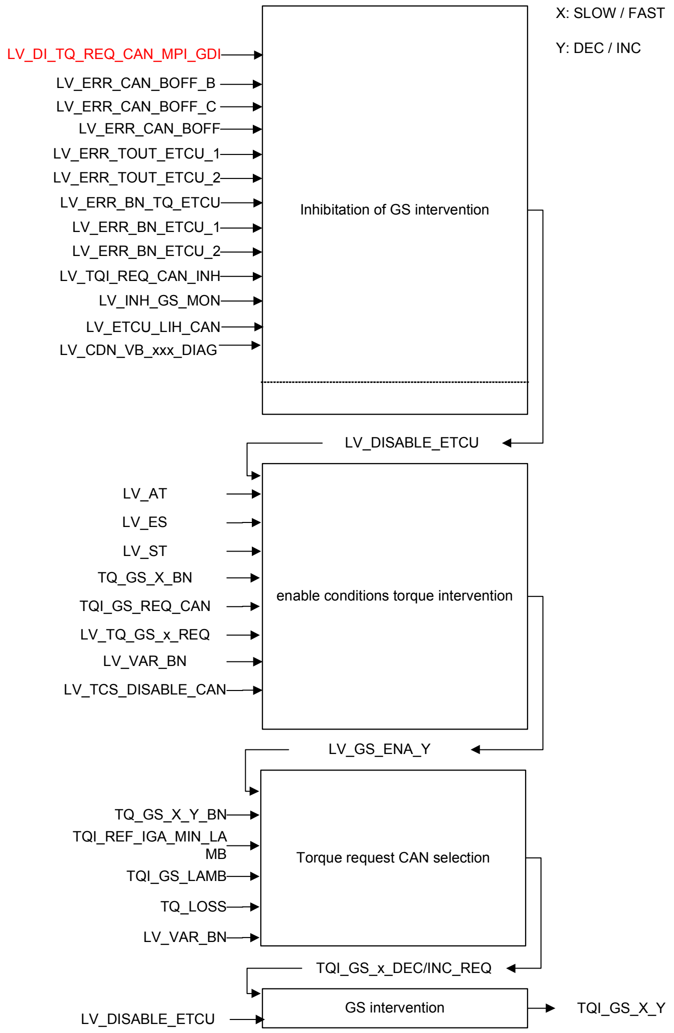
General information:

There are two different gearbox control units: the common electronic transmissiom control unit (LV_AT) and the twin clutch transmission control unit (LV_VAR_TCT). Depending which variant is active the torque request for gear shift is requested by AT or TCT.

During a gear shift operation of the automatic transmission a low engine torque helps the transmission to perform a smooth gear shift and avoids sudden changes of wheel slip that could cause problems on certain road surfaces, i.e. wet or icy roads. A transmission control unit (ETCU) torque reduction or increase demand via CAN is realized by spark retard (fast path) or charge intervention by ETC (slow path). A decision can be done which path is realized. Normally the intervention is done only by spark retard. By configuration of BN 2000 the Slow and fast path are own signals of CAN messages.

Some plausibilities are done for validation and limitation of torque requests.

Signal flow diagram:



65.8.1 Enable conditions

65.8.1.1 Inhibitation GS intervention

FUNCTION DESCRIPTION:

If the EMS detects a safety relevant error at throttle, no automatic transmission vehicle or pedal value sensor the logical variable LV_ETCU_DISABLE is set to 1 in order to indicate a static EMS error.

Gear shift intervention function is enabled if engine state is not “engine stopped”, “start” or “idle speed”, if LV_ETCU_DISABLE is not set, no CAN error is present and automatic transmission is detected. Additional a time condition during torque intervention is check which limits the duration of torque intervention.

Application conditions:

Initialisation: LV_ETCU_DISABLE /CAN = 0; **at reset**

Recurrence: 10 ms

Activation: (LV_AT = 1 **or** LV_VAR_TCT = 1) **and** LV_IGK = 1

Deactivation: -

Formula section:

65.8.2 Torque request CAN selection

FUNCTION DESCRIPTION:

If one of the GS interventions enabled (LV_GS_ENA_DEC/INC = 1), the torque request is received from CAN and copied into TQI_GS_FAST_DEC/INC. At CAN 11H the requested torque is adjusted by ignition retardation. Only if ignition retardation is not sufficient for the requested torque reduction, TQI_GS_SLOW_DEC is set to TQI_GS_REQ. So the throttle is used too. At BN the slow and fast path are different messages.

After LV_GS_ACT_DEC/INC changes back to 0, both TQI_GS_FAST_DEC/INC and TQI_GS_SLOW_DEC/INC become their maximum/minimum value again.

Application conditions:

Initialisation: **at reset** TQI_GS_FAST_DEC_REQ = 1023,97Nm
TQI_GS_SLOW_DEC_REQ = 1023,97Nm
TQI_GS_FAST_INC_REQ = 0 Nm
TQI_GS_SLOW_INC_REQ = 0 Nm

Recurrence: 10 ms
Activation: (LV_AT = 1 **or** LV_VAR_TCT = 1) **and** at LV_IGK = 1
Deactivation: -

Formula section:

```
if      LV_VAR_BN = 1
then    TQI_GS_SLOW_DEC_REQ_1 = TQ_GS_SLOW_DEC_BN - TQ_LOSS

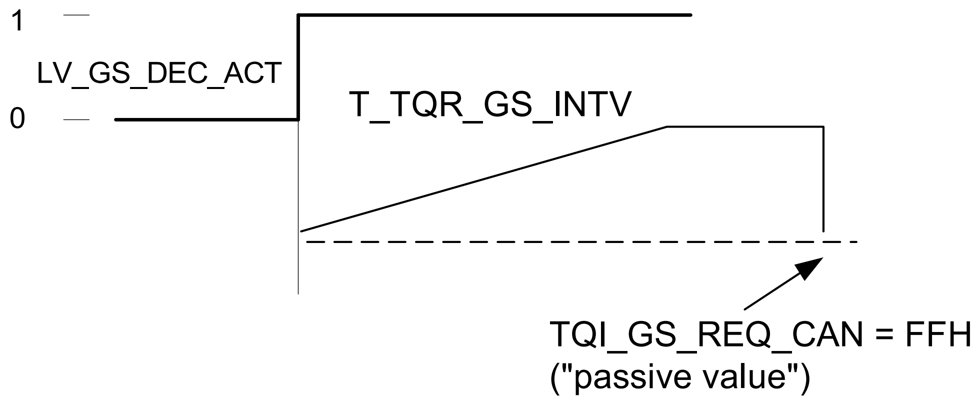
        TQI_GS_FAST_INC_REQ = 0 Nm
endif
```

65.8.3 Determination of gear shift torque intervention duration (CAN11H only)

FUNCTION DESCRIPTION:

The duration of decreased gear shift torque intervention T_TQR_GS_INTV is measured beginning at transition of LV_GS_DEC_ACT from 0 to 1. T_TQR_GS_INTV is needed for limitation of gear shift intervention duration during enable conditions. T_TQR_GS_INTV is reseted to 0 if TQI_GS_SLOW_REQ_CAN or TQI_GS_FAST_REQ_CAN = FFH .

Signal flow diagram:



Application conditions:

Initialisation:	T_TQR_GS_INTV = 0 at reset **or** at transition LV_IGK 0 --> 1
Recurrence:	10 ms
Activation:	at LV_IGK = 1 and LV_VAR_BN = 0
Deactivation:	-

65.8.4 GS intervention

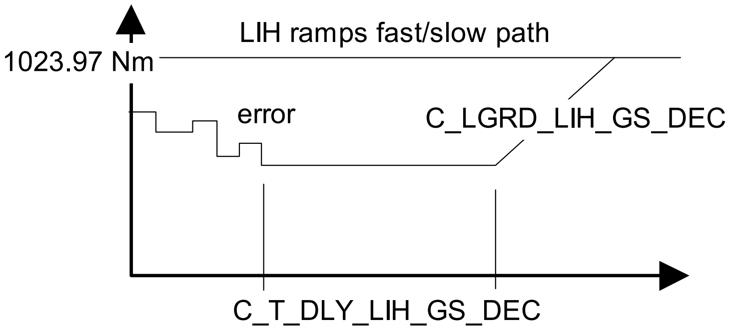
65.8.4.1 GS decreased intervention and emergency operation

FUNCTION DESCRIPTION:

If during an active GS intervention an GS error or an EMS error occurs, the current torque reduction is continued for the time C_T_DLY_LIH_GS_DEC and then subsequently increased to TQI_GS_FAST_DEC = TQI_GS_SLOW_DEC = 1023,97 Nm using C_LGRD_LIH_GS_DEC.

At transition from Limp home condition active to passive after torque inrease to TQI_GS_FAST_DEC = TQI_GS_SLOW_DEC = 1023,97 Nm at limp home operation the counter T_GS_LIH_CTR is stopped and set to 0.

Signal flow diagram:



Application conditions:

Initialisation: at reset **or** at transition LV_IGK 0 --> 1
LV_GS_DEC_LIH = 0

65.8.4.2 GS increased intervention and emergency operation

FUNCTION DESCRIPTION:

If during an active GS intervention an GS error or an EMS error occurs, the current torque offset is continued for the time C_T_DLY_LIH_GS_INC and then subsequently decreased to TQI_GS_FAST_INC = TQI_GS_SLOW_INC = 0 Nm using C_LGRD_LIH_GS_INC.

At transition from Limp home condition active to passive after torque decrease to TQI_GS_FAST_INC = TQI_GS_SLOW_INC = 0 Nm at limp home operation the counter T_GS_LIH_CTR is stopped and set to 0.

65.8.4.3 Inhibiting fuel cut off during TCT-intervention

FUNCTION DESCRIPTION:

In order to avoid an increasing emission for very low emission vehicles the fuel cut off is inhibited. As result during TCT-intervention the SCC is suppressed in order to meet ULEV2 limits. In that case the reduction of the moment should only be done via spark retard.

Application conditions:

Initialisation: at reset **or** at transition LV_IGK 0 --> 1

LV_INH_FCUT_GS = 0

Recurrence: 10 ms

Activation: LV_IGK = 1 **and** LV_VAR_TCT = 1

Deactivation: -

VS	GR_AT		TQ_CONV_CAN
LV_ERR_CAN_BOFF	LV_ERR_TOUT_ETCU_1	TQ_DIF_IS_AD_CONV	
LV_ERR_BN_TQ_ETCU	LV_VAR_TCT	STATE_TCT_INTV	TQ_TCT_CAN

FUNCTION DESCRIPTION:

General information:

TQ_CONV describes the hydraulic torque losses inside the converter of an automatic gearbox due to speed difference between converter turbine and pump. There are two kinds of transmission types with and w/o a relevant torque loss at P/N. So the calculation of TQ_CONV_STN at LV_DRI = 0 (= P/N) can be inhibited by LC_TQ_CONV_DRI_INH = 1. Additional to the calculated converter torque TQ_CONV_STN a converter torque transmitted via CAN TQ_CONV_CAN can be used by setting LC_TQ_CONV_CAN_INH to zero. In case of TQ_CONV_CAN is enabled (LC_TQ_CONV_CAN_INH = 0) and a timeout CAN-message ETCU1- or CAN bus off error is recogniced TQ_CONV = TQ_CONV_STN as calculated in ECU.

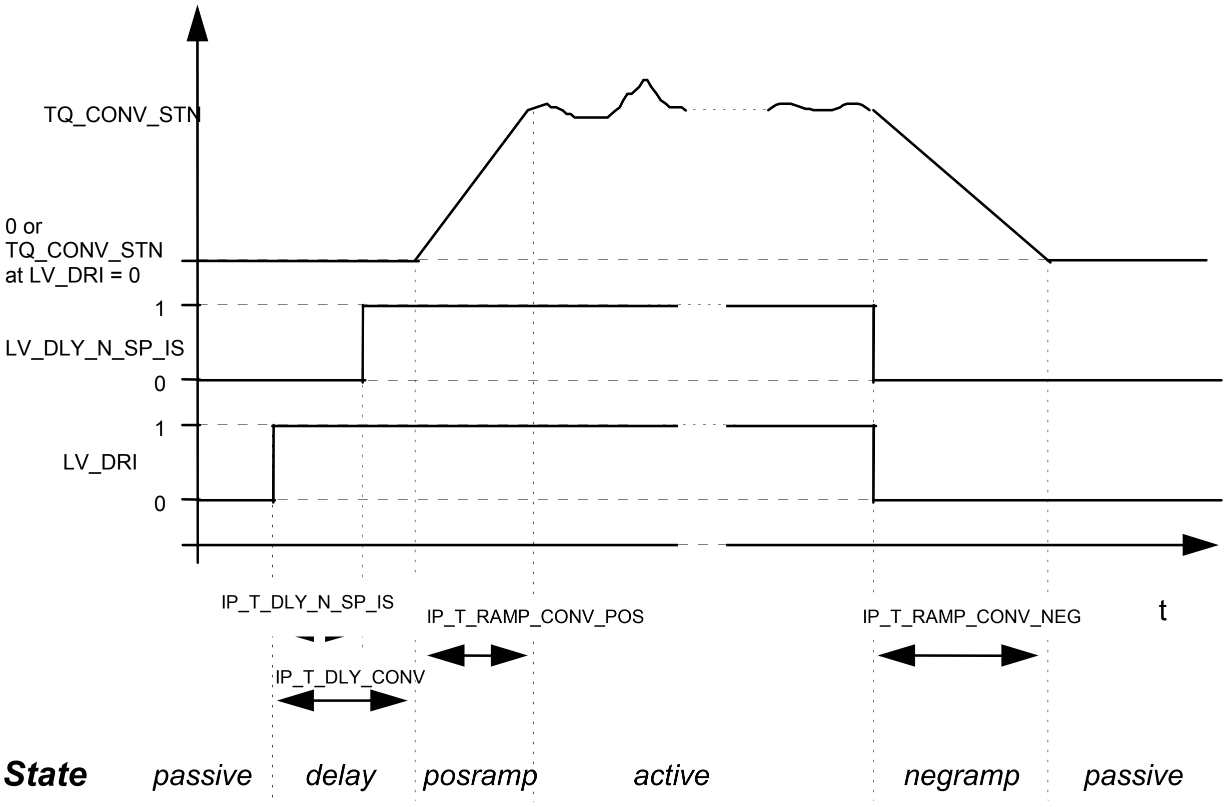
In order to assist the idle speed controller, TQ_CONV_STN is calculated for a reference condition with an engine speed set to N_SP_IS. As a result, TQ_CONV_STN is bigger than the real converter torque for N < N_SP_IS and smaller for N > N_SP_IS.

The converter torque adaptation TQ_DIF_IS_AD_CONV is calculated in the idle speed adaptation module.

After a delay of IP_T_DLY_CONV, TQ_CONV is reached following a ramp with the length IP_T_RAMP_CONV_POS (The calibration parameter IP_T_RAMP_CONV_POS is used to calculate the ramp gradient, which is kept constant for this ramp, even if TQ_CONV_STN changes during this time. Therefore, the observed ramp length may differ from IP_T_RAMP_CONV_POS). After disengaging the gear it is suppressed without any time delay, following a ramp with the length IP_T_RAMP_CONV_NEG. In case of LC_TQ_CONV_CAN_INH = 0 no ramps are calculated!

The change of the idle speed setpoint N_SP_IS during gearshift is synchronised with the converter torque request by application of a time delay T_DLY_N_SP_IS after engaging the gear.

The present model is valid for open converter clutch only. However, the latter normally can be closed or slips only in an operating range N >> N_SP_IS, in which TQ_CONV_STN -> 0 (or TQ_CONV_STN in case of LC_TQ_CONV_DRI_INH = 0).



Application conditions:

Activation: at every engine state (LV_AT = 1 or LV_VAR_TCT = 1)

65.10.2 Determination of Torque reserve for TCT

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_TCT	O/V	8000...7FFFH	-1024... 1023.96875	0.03125	[Nm]
Torque reserve for TCT					
LV_TOUT_TCT	V	0...1H	0...1	1	[-]
Logical variable to start deactivation of torque reserve and condition for switch off TCT calculation					
T_TCT	V	0...1FEH	0...5.1	0.01	[s]
Timer for duration of transient TQ_ADD_TCT correction					

Input data:

	N_32	LV_ST	
LV_VAR_TCT	STATE_ETCU_CLU		

FUNCTION DESCRIPTION:

General information:

To guarantee idle quality during gear shift a positive torque reserve can be requested.

Application conditions:

Initialisation: at reset

TQ_ADD_TCT = 0 Nm

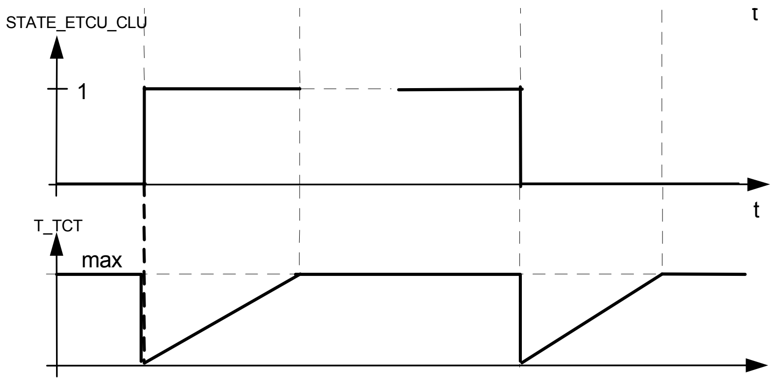
LV_TOUT_TCT = 0

T_TCT = 0 s

Recurrence: 10 ms

Activation: {**[**STATE_ETCU_CLU = 1 **and** LV_ST = 0**]**

and LV_VAR_TCT = 1}



Formula section:

```
IF T_TCT < 1FEH
Then    LV_TOUT_TCT = 0
Else    LV_TOUT_TCT = 1
endif

if      LV_TOUT_TCT = 0
then    TQ_ADD_TCT = max [ IP_TQ_ADD_TCT; 0 Nm ]
else    $TQ\_ADD\_TCT_{N}$ = max [ ( $TQ\_ADD\_TCT_{N-1}$ - C_TQ_ADD_TCT_LGRD );
                                        0 Nm ]
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_TQ_ADD_TCT	6	0...FFFFH	-1024... 1023.96875	0.03125	[Nm]

Torque reserve for TCT					
C_TQ_ADD_TCT_LGRD	1	0...7FFFH	0...1023.97	0.03125	[Nm]
Limitation gradient for TQ_ADD_TCT decrease after deactivation					

65.10.3 Determination of Torque reserve for GS Transmission

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TQ_ADD_TRANS	O/V	8000...7FFFH	-1024... 1023.96875	0.03125	[Nm]
Torque reserve for Transmission					

Input data:

LV_AT			TQ_ADD_CONV
TQ_ADD_CONV_2	LV_VAR_TCT	TQ_ADD_TCT	

To serve the torque reserve interface it is switch between TCT and AT transmissions.

Initialisation: at reset

TQ_ADD_TRANS = 0 Nm

Recurrence: 10 ms

Activation: LV_AT = 1 or LV_VAR_TCT = 1

Formula section:

```
IF LV_VAR_TCT = 1
Then    TQ_ADD_TRANS = TQ_ADD_TCT
Else IF LV_AT = 1
    Then    TQ_ADD_TRANS = TQ_ADD_CONV + TQ_ADD_CONV_2
    Else    TQ_ADD_TRANS = 0Nm
endif
```

66 Vehicle motion determination

Table of Contents

Index

66.1 Acquisition of vehicle speed

Output data:

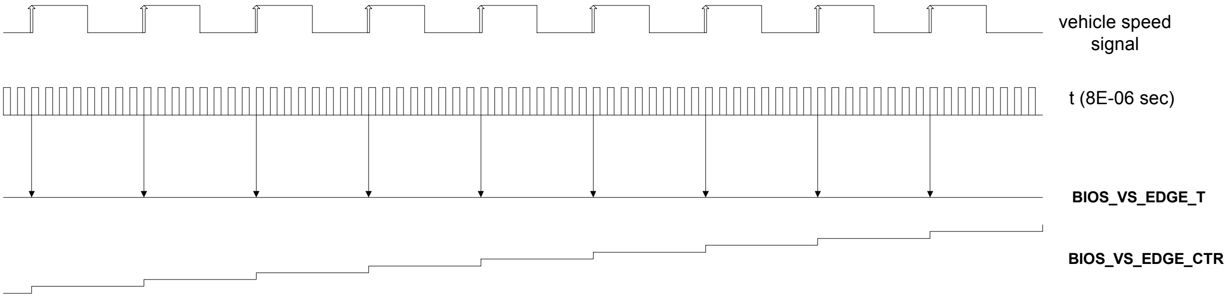
Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
BIOS_VS_EDGE_CTR	O	0 ... FFFFH	0 ... 65565	1	-
Vehicle speed sensor tooth counter (free running counter)					
BIOS_VS_EDGE_T	O	0 ... FFFFH	0 … 524280	8	µs
timestamp of last tooth (free running timer)					

FUNCTION DESCRIPTION:

General information:

The wheel sensor signal (high and low) is recorded by incrementation of the free running edge counter BIOS_VS_EDGE_CTR with one digit at every change from low to high. The value is stored as BIOS_VS_EDGE_CTR in a free running counter too.

Signal flow diagram:



66.2 VHMD - Requirements to infrastructure interface

Export actions:

ACTION_INFR_GetVsPulsStamp(OUT< vs_edge_ctr_av >, <vs_edge_t_av>, <vs_edge_t_av_max)
Reading of information about "vehicle speed"
ACTION_INFR_GetVsRrPulsStamp(OUT< vs_rr_edge_ctr_av >, <vs_rr_edge_t_av>, <vs_rr_edge_t_av_max)
Reading of information about vehicle speed on rough road

Description for actions:

ACTION_INFR_GetVsPulsStamp(OUT <vs_edge_ctr_av>, OUT<vs_edge_t_av>, OUT <vs_edge_t_av_max>)					
This action reads the actual value of vehicle speed tooth counter (free running counter) and the actual timestamp of last tooth (free running timer)					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
vs_edge_ctr_av	OUT	0 ... FFFFh	0 ... 65565	1	-
actual value of vehicle speed tooth counter (free running counter)					
vs_edge_t_av	OUT	0... FFFFFFFFh	0...34359738,37	0,008	ms
actual timestamp of last tooth (free running timer)					
vs_edge_t_av_max	OUT	0... FFFFFFFFh	0...34359738,37	0,008	ms
actual maximal timestamp of last tooth (free running timer)					

ACTION_INFR_GetVsRrPulsStamp(OUT< vs_rr_edge_ctr_av >, <vs_rr_edge_t_av>, <vs_rr_edge_t_av_max)					
This action reads the actual value of vehicle speed tooth counter (free running counter) on "rough road" and the actual timestamp of last tooth (free running timer)					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
vs_rr_edge_ctr_av	OUT	0 ... FFFFh	0 ... 65565	1	-
actual value of vehicle speed tooth counter (free running counter)					
vs_rr_edge_t_av	OUT	0... FFFFFFFFh	0...34359738,37	0,008	ms
actual timestamp of last tooth (free running timer)					
vs_rr_edge_t_av_max	OUT	0... FFFFFFFFh	0...34359738,37	0,008	ms

FUNCTION DESCRIPTION:

General information:

ACTION_INFR_GetVsPulsStamp()
This Action reads the actual value of vehicle speed tooth counter (free running counter) and the actual timestamp of last tooth (free running timer)

ACTION_INFR_GetVsRrPulsStamp()
This Action reads the actual value of vehicle speed tooth counter (free running counter) on rough road and the actual timestamp of last tooth (free running timer)

Requirements for ACTION_INFR_GetVsPulsStamp():

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
vs_edge_ctr_av	-	-	<bit coded>

VS_EDGE_T_AV_DIF	V	0...FFFFFFFFH	0...34359738.36	0.008	[ms]
actual timestamp difference					

Input data:

LV_ERR_VS_PLAUS	VS_FIL		

Import Actions:

ACTION_INFR_GetVsPulsStamp(**OUT**<vs_edge_ctr_av>, **OUT**<vs_edge_t_av>, **OUT**<vs_edge_t_av_max)
Reading of information about "vehicle speed"

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_MIN_RUN	1	0...FFH	0...255	1	[km/h]
vehicle speed threshold for running vehicle detection					
C_T_VST	1	1...14H	10...200	10	[ms]
Time delay for detection of vehicle stop					
C_VS_EDGE_SUM_MIN	1	1...FFH	1...255	1	[-]
minimum number of wheel segments for evaluation of vehicle speed					
C_VS_FAC	1	0...1000000H	0...0.29127	0.0174e-6	[m]
Vehicle distance per segment					

FUNCTION DESCRIPTION:

General information:

Running vehicle is detected if vehicle speed VS ≥ C_VS_MIN_RUN.

Application conditions:

Initialisation: VS = 0 ; VS_H = 0 ; LV_VS_RUN = 0

Recurrence: 10ms

Activation: at every engine operating state

Formula section:

```
If      LV_ERR_VS_PLAUS = 0          // no sensor-error
Then    VS = VS_SENS        VS_H = VS_SENS
Else    VS = VS_FIL         VS_H = VS_FIL
Endif
If      $VS \geq C\_VS\_MIN\_RUN$
Then    LV_VS_RUN = 1
Else    LV_VS_RUN = 0
Endif
```

66.4.1 Internal vehicle speed signal

FUNCTION DESCRIPTION:

General information:

A new edge is detected, if $VS\_EDGE\_CTR\_AV_{n} >= VS\_EDGE\_CTR\_AV_{n-10ms}$. If ($VS\_EDGE\_CTR\_AV_{n}$ - $VS\_EDGE\_CTR\_AV_{n-x}$) > C_VS_EDGE_SUM_MIN a new vehicle speed calculation is started. If during the time C_T_VST no changed edge is detected, the logical variable for stopped vehicle LV_VST is set to 1 and VS_SENS as well as VS_SENS_GRD are set to 0.

With the constant C_VS_FAC the adaption of the rolling circumference and the number of teeth per rotation is done.

Application conditions:

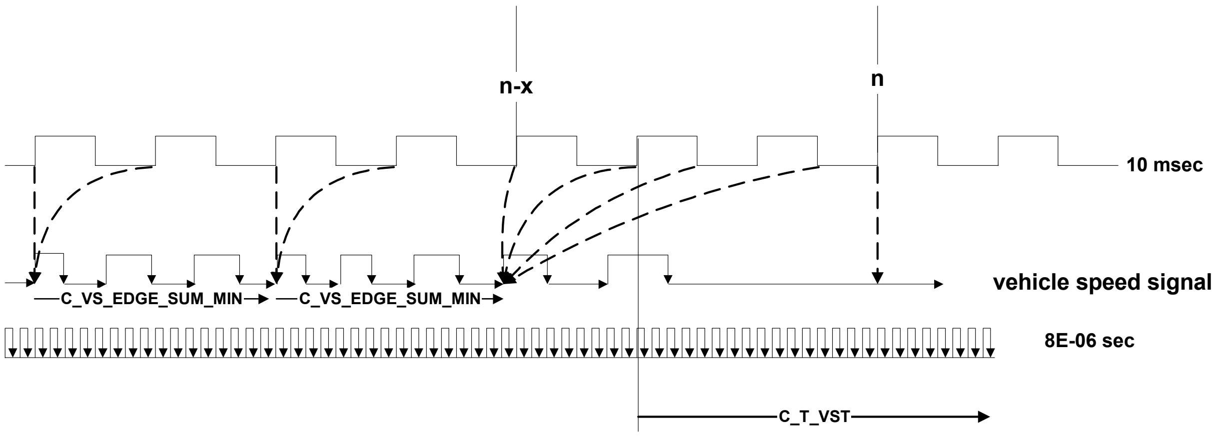
Initialization : VS_SENS = 0
VS_SENS_GRD = 0
LV_VST = 1

Activation : at every engine operating state

Deactivation : -

Update rate : 10ms

Signal flow diagram:



Formula section:

ACTION_INFR_GetVsPulsStamp(VS_EDGE_CTR_AV, VS_EDGE_T_AV, VS_EDGE_T_AV_MAX)

$VS\_EDGE\_T\_AV\_DIF = VS\_EDGE\_T\_AV_{n} - VS\_EDGE\_T\_AV_{n-x}$

```
IF    VS_EDGE_T_AV_DIF < 0   //   (Overflow)
THEN      VS_EDGE_T_AV_DIF = VS_EDGE_T_AV_DIF + VS_EDGE_T_AV_MAX
ELSE      VS_EDGE_T_AV_DIF = (VS_EDGE_T_AV_n - VS_EDGE_T_AV_n-x)
ENDIF
```

C_VS_FAC = (dynamic wheel circumference [m]) / (number of teeth [-])

$VS\_SENS = C\_VS\_FAC * (VS\_EDGE\_CTR\_AV_{n} - VS\_EDGE\_CTR\_AV_{n-x}) / VS\_EDGE\_T\_AV\_DIF$

$VS\_SENS\_GRD = (VS\_SENS_{n} - VS\_SENS_{n-x}) / VS\_EDGE\_T\_AV\_DIF$

66.5 Mileage counter

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
DIST	S/O/V	00000000H... FFFFFFFFH	0... 429496729500	100	m
Distance accumulation [100m]					
DIST_KWP	S/O	0...FFFFH	0...524280	8	Km
Distance accumulation [8km]					

Input data:

CTR_KM_CAN	VS_EDGE_CTR_AV	C_VS_FAC	LV_ES

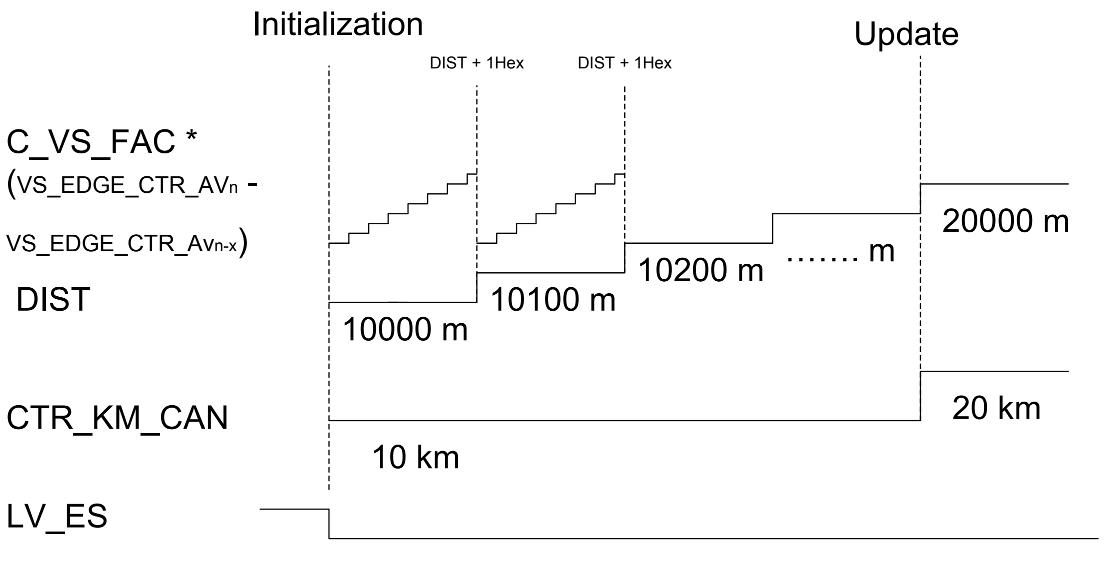
FUNCTION DESCRIPTION:

General information:

This function is to accumulate the covered distance since the first vehicle start in resolution of 100m for EOBD propose. The information for updating of the calculation (CTR_KM_CAN, VS_EDGE_CTR_AV) is sent by CAN.

Signal flow diagram:

DIST calculation



Application conditions:

Initialisation: restored out of NVMY, first value = 0

Recurrence: 200ms

Activation: LV_ES = 0

Description:

After activation DIST is restored out of NVMY and the calculation starts with (C_VS_FAC * $VS\_EDGE\_CTR\_AV_n$ - $VS\_EDGE\_CTR\_AV_{n-x}$) until DIST is incremented with 1Hex (100m).
This calculations is done until the next update of CTR_KM_CAN, then DIST is set to CTR_KM_CAN and the calculation starts from beginning.
If there is no update of CTR_KM_CAN (e.g. Timeout error), then the calculation remains active for this Driving cycle.

DIST_KWP is calculated from DIST but different resolution for BMW diagnosis tool.

Formula section:

DIST: See signal flow diagramm

DIST_KWP = DIST

66.6.1 Plausibility check of electrical VS signal (PIN)

General information:

An vehicle speed signal error is detected if at calibratable engine speed-, mass air flow- and time thresholds the vehicle speed signal VS = 0. Depending if the vehicle is MT / AT different calibration data a applied (If LV_AT = 1 then _AT are used, else _MT are used).

Description:

If vehicle speed VS = 0 **and** engine speed N >= C_N_VS_MIN_DIAG_AT / _MT **and** (mass air flow MAF >= C_MAF_VS_MIN_DIAG_AT / _MT [for MSVx] **or** TQ_AV >= C_TQ_AV_VS_MIN_DIAG_AT / _MT [for MSDx]) the time counter T_VS_DIAG is started. The vehicle speed signal error bit LV_ERR_VS_PLAUS is set to 1 **if** T_VS_DIAG >= C_T_VS_MIN_DIAG.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                              (= SYM_0)
 │ │ └───> -                              (= SYM_1)
 │ └─────> -                              (= SYM_2)
 └───────> Vehicle speed not plausible    (= SYM_3)
```

Application conditions:

Initialization: The configuration is **STD_INI**

*(=> all 0 at LV_IGK 0->1 **or** reset **or** clearing error memory)*

Recurrence: 100 ms

Activation:

```
If    LV_IGK = 1                      and
      LV_ERR_MAF = 0                  and
      LV_ERR_LOAD_TPS_PLAUS = 0       and
      LV_ERR_MAP_TPS_PLAUS = 0        and
      LV_TCHA_DIAG_REQ = 0            and
      LV_ERR_VS_PLAUS = 0
Then  LV_CDN_DIAG_VS_PLAUS = 1
Else  LV_CDN_DIAG_VS_PLAUS = 0
Endif
```

Formula section:

Timer start:

```
If(1)     VS       =    0                                   and
          N        >=   C_N_VS_MIN_DIAG_AT / _MT            and
          (MAF     >=   C_MAF_VS_MIN_DIAG_AT / _MT          or   [for MSVx]
          TQ_AV    >=   C_TQ_AV_VS_MIN_DIAG_AT / _MT)            [for MSDx]
Then(1)   T_VS_DIAG starts to count
          ERR_SYM_VS_PLAUS = SYM_3
Else(1)   T_VS_DIAG is set to 0
          ERR_SYM_VS_PLAUS = NO_SYM
Endif(1)
```

Error recognition:

```
If(1)      T_VS_DIAG   >=      C_T_VS_MIN_DIAG
Then(1)    LV_ERR_VS_PLAUS= 1      (set directly)
Endif(1)

If(1)      VS > 0
Then(1)    LV_ERR_VS_PLAUS= 0      (set directly)
Endif(1)
```

End of Diagnosis:

```
If (1)     N           >=      C_N_VS_MIN_DIAG_AT / _MT              and
           (MAF        >=      C_MAF_VS_MIN_DIAG_AT / _MT            or    [for MSVx]
           TQ_AV       >=      C_TQ_AV_VS_MIN_DIAG_AT / _MT)               [for MSDx]
Then(1)    T_VS_END_DIAG             starts to count
           If(2)       T_VS_END_DIAG     >=      C_T_VS_MIN_DIAG
           Then(2)     LV_END_DIAG_VS_PLAUS = 1
           Endif(2)
Endif(1)
```

66.6.2 Emission relevant VS double error (No PIN signal / No CAN signal)

General information:

LV_ERR_VS is set if neither a VS signal is available from ECU-PIN (LV_ERR_VS_PLAUS) nor a signal is received from CAN (11H / 12H).

Description:

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                              (= SYM_0)
 │ │ └───> -                              (= SYM_1)
 │ └─────> no vehicle speed signal        (= SYM_2)
 └───────> -                              (= SYM_3)
```

Application conditions:

Initialization: The configuration is **STD_INI**

(=> all 0 at LV_IGK 0->1 ***or*** *reset* ***or*** *clearing error memory)*

Recurrence: 100 ms (called just after VS_PLAUS diagnosis)

Activation:

```
If      LV_IGK = 1
        LV_END_DIAG_VS_PLAUS = 1
Then    LV_CDN_DIAG_VS = 1
Else    LV_CDN_DIAG_VS = 0
```

```
                Endif
```

Formula section:

```
If      LV_ERR_VS_PLAUS = 1
Then    If      LV_VAR_BN = 1
        Then    If      LV_ERR_BN_VS_TCS = 1
                Or      LV_ERR_CAN_BOFF = 1
                Then    ERR_SYM_VS = SYM_2          // ABC increments
                Else    ERR_SYM_VS = NO_SYM         // ABC decrements
                Endif
        Else    If      LV_ERR_TOUT_ASR_1 = 1
                Or      LV_ERR_CAN_BOFF = 1
                Then    ERR_SYM_VS = SYM_2          // ABC increments
                Else    ERR_SYM_VS = NO_SYM         // ABC decrements
                Endif
Else    ERR_SYM_VS = NO_SYM                         // ABC decrements
Endif
```

LV_ERR_VS and LV_END_DIAG_VS is calculated from error management.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

ABC Increment value for VS diagnosis					
C_ABC_MAX_VS	1	1...FFH	1...255	1	[-]
ABC Maximum value for VS diagnosis					

Hint:

All conditions for setting LV_ERR_VS are already filtered, thus the debounce of this diagnosis should be very fast e.g. inc/max = 1/1.

66.7 Vehicle speed sensor diagnosis (Applic. Inc.)

66.7.1 Interface for Rate – Based – Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_VS_PLAUS	V/O	0...7H	0...7	1	[-]
Interface of VS_PLAUS monitor with the Rate-Based Monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					

Input data:

LV_DC	LV_END_DIAG_VS_PLAUS		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the VS_PLAUS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_VS_PLAUS data.

Within STATE_RBM_VS_PLAUS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)

  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)

  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

  (not valid for VS_PLAUS diagnosis)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_VS_PLAUS = 0

on failure memory reset :

bit 1 of STATE_RBM_VS_PLAUS = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

Bit 0:

```
If    bit 0 of STATE_RBM_VS_PLAUS = 0
then
      if      LV_END_DIAG_VS_PLAUS = 1
      then    bit 0 of STATE_RBM_VS_PLAUS = 1
      endif
endif
```

Bit 1:

bit 1 of STATE_RBM_VS_PLAUS = 0

Bit 2:

bit 2 of STATE_RBM_VS_PLAUS = 1

Validation Bit for Status off MSW					

General information:

The multifunction steering wheel (MSW) with buttons the position of which is transferred digitally through a serial data line serves as interface between the driver and the CRU system. According to extension stage, a distinction is made between low and high version with 8-bit and 16-bit transmission protocol. Only the 8-bit data frame is relevant for the engine control. For plausibility check whether the MSW is still active, a toggle bit is appended to the 7-bit information. This bit changes its level cyclically.

Application conditions:

Recurrence: 10ms

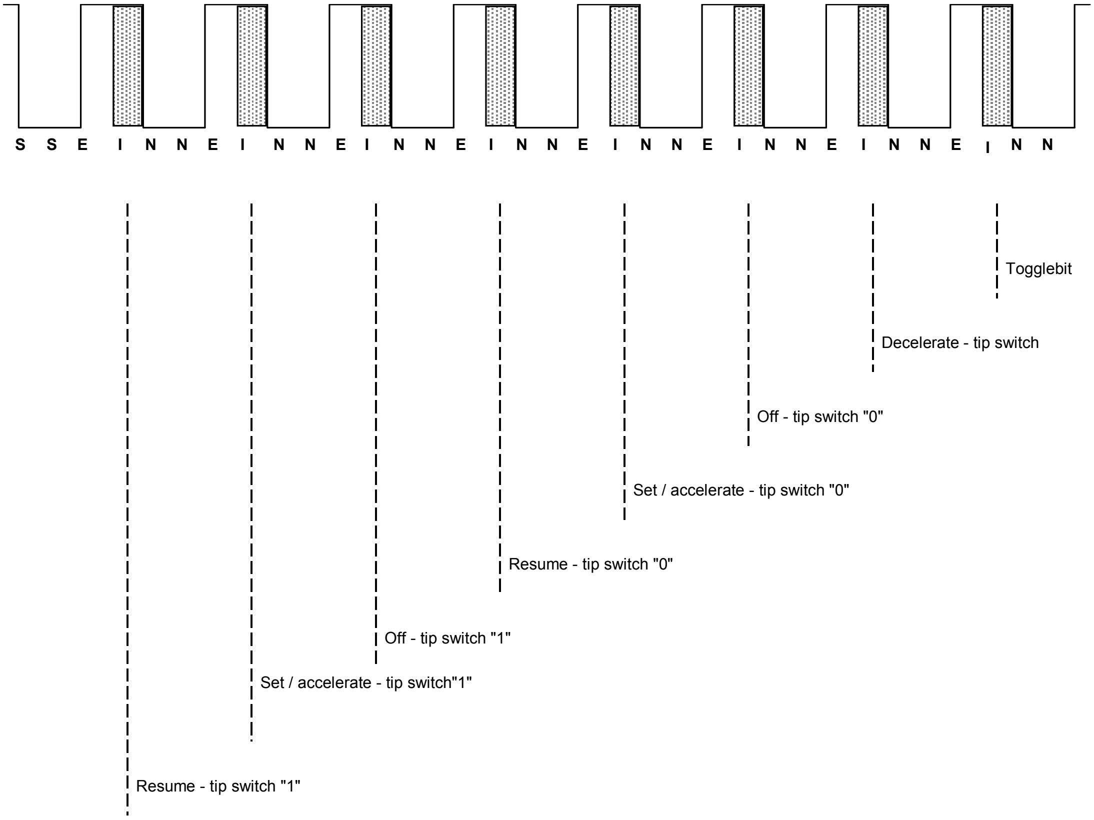
67.1.1 Serial data line from the MSW

General information:

The buttons of the multifunction steering wheel are not interlocked mechanically against one another, which means that a priority must be introduced for the switch position. The S/A and DEC functions are an exception. Here the buttons are formed as rocker in the MSW and thus cannot be actuated simultaneously. The position of the buttons is encoded digitally the MSW control unit and transferred through a serial data line. In the 8-bit data frame, which is transmitted by the MSW, the buttons are encoded as follows:

8-bit data frame of the transmission module

S = Start bit
N = Zero bit
E = One bit
I = Info bit



Resume, setting/acceleration as well as off buttons are encoded redundantly and numbered for differentiating the information (0;1). The encoding of the buttons is high active, i.e. for a pressed button a 1 is transmitted as useful information. Furthermore a toggle bit is transmitted in the bit position 0 of the 8-bit data frame, a special bit information which changes its level cyclical. The toggle bit can thus also be used for error detection, like the switch positions, which are encoded redundantly.

The following distinctions are made in the transmitted functions of the MSW:

1. Rest: SET/ACC and DEC and RES and OFF not pressed.
2. SET/ACC: SET/ACC and no DEC pressed
3. DEC: DEC and no SET/ACC pressed
4. RES: RES pressed.
5. OFF: OFF pressed.

67.2 Distance cruise control diagnosis (LV_ERR_DCC)

Output data:

LV_ERR_BN_TQ_DCC	ERR_SYM_BN_TQ_DCC	LV_DCC_OFF_ACK	STATE_DCC_INTV
LV_BRAKE_DET	LV_DI_TQ_REQ_CAN_MPI_GDI	LV_ERR_CRK	LV_TQI_REQ_CAN_INH
LV_ERR_PVS			

FUNCTION DESCRIPTION:

General information:

At implausible DCC messages, e.g. timeout errors, or ECU internal errors a reversible or irreversible error is detected and reflect to the DCC Unit. This should be confirmed by the DCC switch-off flag LV_DCC_OFF_ACK. Only if the switch-off is confirmed by DCC the reversible DCC error is reset. This is necessary for a safety communication between ECU and DCC.

Description:

The following symptoms can be detected:

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 │  │  │  └─> DCC irreverible off        (= SYM_0)
 │  │  └────> DCC reversible off         (= SYM_1)

Input data:

LV_IGK	LV_VAR_MSW	C_T_READY_CRU	BIOS_CRU_TOG
LV_VAR_BN_MSW	BIOS_CRU_DATA	BIOS_LV_CRU_ERR	

FUNCTION DESCRIPTION:

General information:

In this function the diagnosis of the relevant signals from the MSW for the cruise control is made. The following error can be distinguished:

- Redundant coding of the signal
- Toggle switch test
- Toggle bit monitoring

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 or reset

Recurrence: see diagnosis

Activation:

```
If      V_IGK  >  C_VB_MIN_MSW_DIAG
    and Time since  V_IGK > C_VB_MIN_MSW_DIAG  greater than  C_T_READY_CRU
    and LV_VAR_MSW = 1
    and LV_VAR_BN_MSW = 0
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VB_MIN_MSW_DIAG	1	0...FFH	0...25.89843	0.1015625	[V]
Min. battery voltage for MSW diagnosis					

67.3.1 Determination of STATE_MSW_DATA / LV_MSW_MSG_VLD

Description:

The datas are used for function cruise control.

Formula section:

Calculation of LV_MSW_MSG_VLD:

```
If      a single message is valid (no ERR_SYM_... is active, BIOS_LV_CRU_ERR = 0)
Then    LV_MSW_MSG_VLD = 1
Else    LV_MSW_MSG_VLD = 0
Endif
```

Calculation of STATE_MSW_DATA:

STATE_MSW_DATA = (range converted) BIOS_CRU_DATA

67.3.2 Redundant coding check of the signal (LV_ERR_MSW_2)

Application conditions:

Recurrence: 80ms
= every four equal messages plus delay time due to different recurrency
[4 x (15ms + Delay)]

Description:

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                              (= SYM_0)
 │ │ └───> -                              (= SYM_1)
 │ └─────> -                              (= SYM_2)
 └───────> Signal implausible             (= SYM_3)
```

Formula section:

Calculation of diagnosis condition:

```
If      at least one of the bits for WA, S/B or OFF is active in BIOS_CRU_DATA
Then    LV_CDN_DIAG_MSW_2 = 1
        Error detection and plausibility:
        If      Redundant coding is infringed (see "Supplementary functions" chapter, CRU )
        Then    ERR_SYM_MSW_2 = SYM_3
                // LV_ERR_MSW_2 = 1    after debounce by error management
        Else    ERR_SYM_MSW_2 = NO_SYM
                // LV_ERR_MSW_2 = 0    after rebounce by error management
        Endif
Else    LV_CDN_DIAG_MSW_2 = 0
Endif
```

Calculation end of diagnosis:

LV_END_DIAG_MSW_2 is calculated by error management if diagnosis condition is true.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_MSW_2	1	0...FFH	0...255	1	[-]
Debounce counter increment - MSW diagnosis					
C_ABC_MAX_MSW_2	1	1...FFH	1...255	1	[-]
Debounce counter maximum value - MSW diagnosis					

67.3.3 Toggle switch test (LV_ERR_MSW_3)

Application conditions:

Recurrence: 80ms
= every four equal messages plus delay time due to different recurrency
[4 x (15ms + Delay)]

Description:

The toggle switch condition is checked for each new message (BIOS_CRU_DATA) in which S/B or VE are active. If this is infringed, the preceding message remains valid.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                               (= SYM_0)
 │ │ └───> -                               (= SYM_1)
 │ └─────> -                               (= SYM_2)
 └───────> Rocker switch defect            (= SYM_3)
```

Formula section:

Calculation of diagnosis condition:

```
If      S/B or VE is active in BIOS_CRU_DATA
Then    LV_CDN_DIAG_MSW_3 = 1
        Error detection and plausibility:
        If      S/B and VE are simultaneously active
        Then    ERR_SYM_MSW_3 = SYM_3
                // LV_ERR_MSW_3 = 1    after debounce by error management
        Else    ERR_SYM_MSW_3 = NO_SYM
                // LV_ERR_MSW_3 = 0    after rebounce by error management
        Endif
Else    LV_CDN_DIAG_MSW_3 = 0
Endif
```

Calculation end of diagnosis:

LV_END_DIAG_MSW_3 is calculated by error management if diagnosis condition is true.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_MSW_3	1	0...FFH	0...255	1	[-]
Debounce counter increment - MSW diagnosis					
C_ABC_MAX_MSW_3	1	1...FFH	1...255	1	[-]
Debounce counter maximum value - MSW diagnosis					

67.3.4 Toggle bit monitoring (LV_ERR_MSW_TOG)

Application conditions:

Recurrence: each change of toggle bit (error free: *about 0.5s*)

Description:

The diagnosis condition is set latest if C_T_MAX_MSW_BIT_DIAG is reached, after this the diagnosis condition is on and T_TOG (time between two state changes of the toggle bit BIOS_CRU_TOG) is checked for MIN and MAX time at each new message.

If C_T_MAX_MSW_BIT_DIAG is reached without toggle bit change the error LV_ERR_MSW_TOG is set directly without debounce.

If toggle bit change is faster C_T_MIN_MSW_BIT_DIAG then the error symptom ERR_SYM_MSW_TOG is set and the anti-bounce is inrementing.

Error-symptoms are defined to this diagnosis function as following :

```
└─┴─┴─┴─┘
 │ │ │ └─> -                                   (= SYM_0)

```

Formula section:

Error detection and plausibility:

T_TOG is incrementing (10ms steps) and reseted at every toggle bit change

```
If          a full toggle bit cycle is received
Then        LV_CDN_DIAG_MSW_TOG = 1
    If          T_TOG ≤ C_T_MIN_MSW_BIT_DIAG
    Then        ERR_SYM_MSW_TOG = SYM_3
                // LV_ERR_MSW_TOG =  1 after debounce by error management
    Else        ERR_SYM_MSW_TOG = NO_SYM
                // LV_ERR_MSW_TOG =  0 after rebounce by error management
    Endif
ElseIf          T_TOG > C_T_MAX_MSW_BIT_DIAG
    Then        LV_CDN_DIAG_MSW_TOG = 1
                ERR_SYM_MSW_TOG = SYM_3
                LV_ERR_MSW_TOG = 1
                //set directly without debounce, Anti-bounce counter is set to max value
    Else        no change
    Endif
Endif
```

Calculation end of diagnosis:

LV_END_DIAG_MSW_TOG is calculated by error management if diagnosis condition is true.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

endif
```

67.4.2 Torque request CAN selection

FUNCTION DESCRIPTION:

If the DCC interventions enabled (LV_DCC_ENA_INC = 1), the torque request is received from CAN and copied into TQI_DCC_FAST/SLOW_INC. The slow and fast path are different messages.
After LV_DCC_INC_ACT changes back to 0, both TQI_DCC_FAST_INC and TQI_DCC_SLOW_INC becomes their minimum values again.

Application conditions:

Initialisation: at reset and at transition LV_IGK off --> on

TQI_DCC_FAST_INC_REQ /_1 = 0 Nm
TQI_DCC_SLOW_INC_REQ /_1 = 0 Nm

Recurrence: 10 ms
Activation: at LV_IGK = 1 and LV_VAR_DCC = 1
Deactivation: -

Formula section:

```
TQI_DCC_SLOW_INC_REQ_1 = TQ_DCC_SLOW_INC_BN - TQ_LOSS
TQI_DCC_FAST_INC_REQ_1 = TQ_DCC_FAST_INC_BN - TQ_LOSS
IF        LV_DCC_ENA_INC = 1
Then      TQI_DCC_SLOW_INC_REQ = TQI_DCC_SLOW_INC_REQ_1
          TQI_DCC_FAST_INC_REQ = TQI_DCC_FAST_INC_REQ_1
Else      TQI_DCC_SLOW_INC_REQ = 0 Nm
          TQI_DCC_FAST_INC_REQ = 0 Nm
```

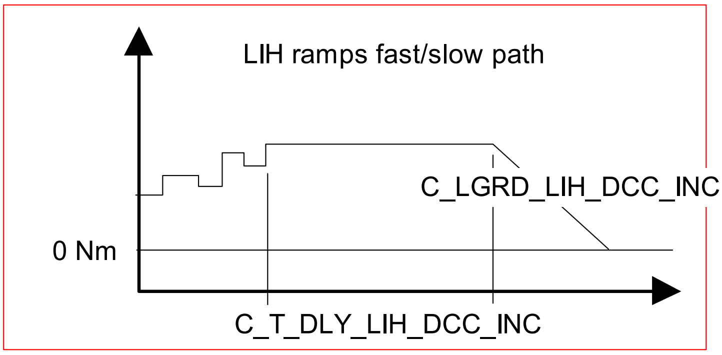
Endif

67.4.2.1 DCC increased intervention and emergency operation

FUNCTION DESCRIPTION:

If during an active DCC intervention an DCC or an EMS error occurs, the current torque offset is continued for the time C_T_DLY_LIH_DCC_INC and then subsequently decreased to TQI_DCC_FAST_INC = TQI_DCC_SLOW_INC = 0 Nm using C_LGRD_LIH_DCC_INC. The DCC unit itself controls the torque leading during active LV_TQ_DCC_INC_REQ. therefore you will haven't a plausible Torque request without LV_DCC_ENA_INC.

Signal flow diagram:



Application conditions:

Initialisation: at reset and at transition LV_IGK off --> on

LV_DCC_INC_LIH = 0

LV_DCC_INC_ACT = 0

TQI_DCC_FAST_INC = TQI_DCC_SLOW_INC = 0Nm

T_DCC_LIH_CTR = 0

Recurrence: 10 ms

Activation: LV_IGK = 1 **and** LV_VAR_DCC = 1

Formula section:

DCC_INC intervention and detection of DCC_INC limp home operation :

```
If(1)     TQI_DCC_FAST_INC_REQ_1 ≠ 0 Nm     and
          TQI_DCC_SLOW_INC_REQ_1 ≠ 0 Nm     and

67.5 Torque Request for Cruise Control

67.5.1 Torque request of DME internal Cruise control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_TQ_REQ_CRU	V/O	0...FFFFH	0...1.99996	3.05E-05	[-]
Scaling factor for requested torque at clutch from cruise control					

Input data:

FAC_TQ_CRU	LV_CRU_ACT	VS_FIL	VS_SP_DRIV_CRU
FAC_TQ_REQ_DRIV	FAC_TQ_CRU_INI	LV_VAR_DCC	LV_VAR_BN_LDM

General information:

Depending on the cruise controller manipulated variable FAC_TQ_CRU the interpretation of torque request is calculated. Regarding the different resolutions the output of cruise control is converted to resolutions at the torque structure interface.

Application conditions:

Activation: every engine state and LV_VAR_DCC = 0 and LV_VAR_BN_LDM = 0

Recurrence: 100 ms

Initialization: FAC_TQ_REQ_CRU = 0 at reset

Formula section:

General calculation after initialisation:

$$FAC\_TQ\_REQ\_CRU = \frac{FAC\_TQ\_CRU}{99{,}6\%}$$

At initialisation of Cruise control:

To get a smoothing transition into cruise controlled drive the initialisation ramp is depends on vehicle speed in relation the vehicle speed demand by driver:

```
This query once :
IF (1)       LV_CRU_ACT = 0 to 1
             FAC_TQ_CRU / 99,6% > FAC_TQ_REQ_DRIV
Then (1.1)   at the first time FAC_TQ_REQ_CRU = FAC_TQ_REQ_DRIV
    This query until the end condition (until (1)) is fulfilled:
    IF (2) VS_FIL ≤ VS_SP_DRIV_CRU
    Then (2)
        FAC_TQ_REQ_CRU = FAC_TQ_REQ_CRU + C_LGRD_TQ_CRU_INC_1
    Else (2)
        FAC_TQ_REQ_CRU = FAC_TQ_REQ_CRU + C_LGRD_TQ_CRU_INC_2
  Until (1.1) FAC_TQ_REQ_CRU ≥ FAC_TQ_CRU / 99,6%
Else (1)
             $FAC\_TQ\_REQ\_CRU = \frac{FAC\_TQ\_CRU}{99,6\%}$
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_LGRD_TQ_CRU_INC_1	1	0...FFFFH	0...1.99996	3.05E-05	[-]
Change limitation for cruise control requesrt out of lower vehicle speed					
C_LGRD_TQ_CRU_INC_2	1	0...FFFFH	0...1.99996	3.05E-05	[-]
Change limitation for cruise control requesrt out of higher vehicle speed

67.6.1 Summary

General information:

The cruise control (CRU) controls the vehicle speed by a P/I controller to the required target speed. The CRU button in the multifunction steering wheel activates the control functions, if no cut-off conditions or switch-on prohibitions are present. The WHEEL signal of the ASC 1 massage is evaluated as controlled variable. Corresponding to the existing control deviation, the value PV_CRU is calculated for controlling the charge intervention.

Using the system, the driver can activate a control for maintaining the desired speed set by him. The desired speed can be approached comfortably in positive and negative direction by setting the instantaneous speed or by additional functions. Controlled approach to a stored desired speed is also possible. The driver then can store or change his desired speed using the following functions:

- Setting/acceleration	(SET/ACC)
- Deceleration	(DEC)
- Resume	(RES)

- Tip-up	(TP_UP)
- Tip-down	(TP_DOWN)
- OFF	(OFF)

67.6.1.1 Constant drive

General information:

After reaching the desired speed, the vehicle speed is kept constant independent of driving resistance changes which act on the vehicle, e.g. rising and falling gradient or headwind, if there are no abnormal termination conditions and the engine power or the braking effect is sufficient.

67.6.1.2 Setting/acceleration (SET/ACC)

General information:

By activating the SET/ACC function, the driver can store the instantaneous speed as desired speed and thus switch on the CRU system. Also the speed can be changed with a defined acceleration from the controlled constant drive. After reaching the desired speed, the constant drive function of the control is active.

67.6.1.3 Deceleration (DEC)

General information:

If the controlled constant drive function is active, the speed reduction takes place in the DEC function by the driver. In this case the desired speed is reduced. If the driver ends the function, the achieved instantaneous speed is stored as new desired speed and the controlled constant drive function is adopted. It is not possible to switch the system on through the recognised DEC function.

67.6.1.4 Resume (RES)

General information:

When the driver activates the RES function, the vehicle is accelerated from the instantaneous speed with a defined acceleration to the stored desired speed. This applies both for larger and for smaller desired speeds compared with the instantaneous speed.

67.6.1.5 Tip-up

General information:

Proceeding from controlled constant drive, the driver can increase his desired speed in steps of 1 k.p.h. by activating the TP_UP function. This function can be selected several times consecutively, thus the vehicle can be brought to a new higher desired speed with a defined acceleration using the TP_UP function.

67.6.1.6 Tip-down

General information:

Proceeding from controlled constant drive, the driver can reduce his desired speed in steps of 1 k.p.h. by activating the TP_DOWN function. This function can be selected several times consecutively, thus the vehicle can be brought to a new lower desired speed with a defined deceleration using the TP_DOWN function.

67.6.1.7 Off

General information:

To switch the system off, the driver can select the OFF function of the multifunction steering wheel. In this way the cruise control system is switched off softly, whereby the achieved desired speed remains stored for later activation by RES. If the engine running is stopped (LV_IGK = 0, ES), then the readiness of CRU and the speed-setpoint are reduced to their initial values.

67.6.2 Ready state and display

General information:

A prerequisite for activating the CRU functions is the CRU ready state. After ECU initialization, the CRU state is initially passive. C_T_READY_CRU after ignition key on LV_IGK = 1 can be transformed into the ready state by pressing the OFF button once. To indicate CRU readiness to the driver, the CAN signal LV_CRU_MAIN_SWI is set from 0 to 1. In this way the CRU ready lamp is activated in the CAN combination device.

The transition into the passive state occurs by pressing the OFF button once from the CRU ready state without controlled drive. The CRU ready lamp goes out.

For this functionality, the OFF button must be recognized for the minimum time of C_T_CRUS_ON on actuation; the OFF button must not be actuated for at least C_T_CRUS between switch on ready and switch off ready.
The ready state is then also ended (-> passive) if the MSW diagnosis is momentarily not possible or a MSW error is momentarily present, see "Diagnosis and limp home" chapter.
Depending on the vehicle configuration LC_CRU_REQ_SWI is switched between Multifunction steering wheel and Switch pack. The reason is, in a variant with switch pack is the main switch of cruise control on with LV_IGK = 1.

Application conditions:

Initialisation: LV_CRU_MAIN_SWI =0

Recurrence: 10ms

Formula section:

```
If (1)  LV_IGK = 1 and T> C_T_READY_CRU  and

67.6.3 Evaluation serial data line from the MSW

General information:

The buttons position of multifunction steering wheel (MSW) which is transferred digitally through a serial data line serves as interface between the driver and the CRU system (look at "Basic SW Inputs /Outputs"). The system interfaces are evaluated with a 10 ms time pattern.
A additional condition to the reception of a transfer pulse (see MSW interface in the Basic SW chapter) for reading the Output of the MSW-IC memory is further the MSW Diagnosis conditions.

Description:

The debounced and recognised function of the driver interface is evaluated only after the conditions for the CRU mode have been fulfilled. If no CRU mode is possible in the current driving cycle or at the moment, then "Hard cut-off" (FAC_TQ_CRU = 0) must be triggered.

According to the current status of the CRU and the recognised function of the driver interface, the functions OFF ("Soft cut-off"), resume, setting/acceleration, Tip-Up, Tip-Down, deceleration and the transition into the controlled constant drive can be triggered.

The function setting/acceleration (SET/ACC) is triggered if the CRU is ready, is in constant drive or another active function.

The deceleration function (DEC) is triggered accordingly, but requires that the CRU is in controlled drive, i.e. there is no setting mode in this case.

The tip functions Tip Up and Tip Down are triggered if the controlled constant drive or one of the two tip functions is active. Furthermore, a Tip-Up in CRU ready or with running resume triggers the setting function.

The Tip-Down function in active resume mode triggers only the abnormal termination of the running function and sets VS_SP_DRIV_CRU to the actual speed VS_FIL, but allows no setting in the above sense.

Precondition for a renewed activation of CRU-functions after cut-off or abnormal terminations are generally that the CRU mode is possible in principle and at least 'Rest' (None) was recognised once. As soon as 'None' or still no new function has be recognised after 'Setting/acceleration' or 'Deceleration', 'Transition into constant drive' is triggered. This applies especially for the resume function (RES) which is interlocked until rest is recognised again.

Resume is triggered only at CRU ready without controlled drive.

The following applies in an overtaking process: The triggering for hard and soft cut-off comes through. The same applies for functions which increase the value FAC_TQ_CRU, such as acceleration and TIP UP, in order to is able to "overdrive" in this way PV_AV with the CRU. For all other functions, especially for "Deceleration" and "TIP DOWN", which reduce the FAC_TQ_CRU, the trigger is prevented, since the instantaneous driver wish via pedal is viewed as higher priority. With recognised RES position, triggering would make no sense.
For a possibly multiple actuation of buttons and superimposed CRU functions, priority must be given to the function recognition according to the following significance:

Significance	Button/function
1	Brake light switch
1	Clutch switch
1	Transmission switch runup lock
2	OFF
3	Deceleration
4	Setting/acceleration
5	Resume

Significance 1 has highest priority

The function selection is made according to priority (see above). The tip functions are executed immediately after recognition. In this way the vehicle response should be improved for the driver, if he requests the SET/ACC or DEC function. In a pure tip request, rest (None) must be recognised between the individual tips.

Application conditions:

Initialization: *STATE_MSW_CAN = "None"* *at reset and deactivation*

REQ_MSW / = "Hard_off"

Recurrence: 10ms

Activation: LV_IGK = 1 and V_IGK > C_VB_MIN_MSW_DIAG

Time (since V_IGK > C_VB_MIN_MSW_DIAG) > C_T_READY_CRU

(Diagnosis conditions)

(LV_VAR_MSW = 1 **or** (LV_VAR_BN_MSW = 1**and** LV_VAR_DCC = 0 **and** LV_VAR_BN_LDM = 0))

Deactivation: otherwise

Formula section:

The evaluation of MSW is only done by CAN 11H variants. In BN 2000 the MSW requests are done by instument message.

IF LV_VAR_BN_MSW = 0

Then

The Signal of STATE_MSW_DATA has to be received multiple (LV_MSW_MSG_VLD = 1) before it is considered in the REQ_MSW evaluation. The following distinctions are made because of the evaluation of STATE_MSW_DATA and an additional time condition:

REQ_MSW	STATE_MSW_DATA
0. HARD OFF:	MSW not allowed, ready or available
1. SOFT OFF:	OFF pressed.
2. TP_UP:	SET/ACC and no DEC pressed for < C_T_MIN_MSW.
3. TP_DOWN:	DEC and no SET/ACC pressed for < C_T_MIN_MSW.
4. SET/ACC:	SET/ACC and no DEC pressed for ≥ C_T_MIN_MSW.
5. RES:	RES pressed.
6. DEC:	DEC and no SET/ACC pressed for ≥ C_T_MIN_MSW .
7. NONE:	SET/ACC and DEC and RES and OFF not pressed.

STATE_MSW_CAN	STATE_MSW_DATA
0. None:	
1. SET/ACC /TP_UP:	SET/ACC pressed.
2. DEC /TP_DOWN:	DEC pressed.
3. RES:	RES pressed.
4. OFF:	OFF pressed
5.	not used
6.	not used .
7. Error:	LV_ERR_MSW_2 = 1; LV_ERR_MSW_3 = 1 LV_ERR_MSW_TOG = 1

else

REQ_MSW	STATE_BN_MSW		
0. HARD OFF:	MSW message not valid (7FH or LV_ERR_BN_MSW ==1 or LV_ERR_CAN_BOFF == 1)		
1. SOFT OFF:	TIP UP or DOWN	"OFF pressed"	
2. TIP_UP:	TIP_PRE	pressed for (	≥ C_T_MIN_TIP_MSW. and < C_T_MIN_MSW.)
3. TIP_DOWN:	TIP_POST	pressed for (	≥ C_T_MIN_TIP_MSW. and < C_T_MIN_MSW.)
4. SET/ACC:	TIP_PRE	pressed for	≥ C_T_MIN_MSW.
5. RES:	TIP_AXIAL.		
6. DEC:	TIP_POST	pressed for	≥ C_T_MIN_MSW.
7. NONE:	NONE		
8. MARK_UP	PRESS_PRE		
9. MARK_DOWN	PRESS_POST		

The state REQ_MSW = TIP_UP/TIP_DOWN is held for minimum C_T_MIN_TIP_MSW.

endif

General information:

The stage cruise control is an add-on function of the cruise control. If is available then it's possible to program steps of vehicle speed witch are shown in the speedometer. The driver can used this function for jumps between fixed Steps during cruise control. The requirement is a steering lever with additional options MARK_UP and MARK_DOWN or the I drive functionality.
Basically there are two different ways of programming during drive or at standing vehicle.

The following assumptions of message from the CCC_MASK are done:

- receiving only at different data's
- the message to the instrument will sent after a complete receive of CCC_MASK message
- depending on the calibration of C_MAX_STEP the quantity of evaluated NR_VS_CRU_IF is limited

Application conditions:

Initialisation: NR_STEP_ON = 0; COUNT_VS_STEP out of NVMY

VS_SP_DRIV_CRU_CAN = VS_MIN_CRU

LV_PROG_STEP_1 = 0

Evaluation of key and stage information for programming:

Vevicle speed steps:

VS_STEP_m: $m = \sum_{14}^{0}$

m: Step number (0...14)

	NR_VS_CRU				
	0	1	2	3	4
VS_STEP_CAN_1 =	VS_STEP_0	VS_STEP_3	VS_STEP_6	VS_STEP_9	VS_STEP_12
VS_STEP_CAN_2 =	VS_STEP_1	VS_STEP_4	VS_STEP_7	VS_STEP_10	VS_STEP_13
VS_STEP_CAN_3 =	VS_STEP_2	VS_STEP_5	VS_STEP_8	VS_STEP_11	VS_STEP_14

VS_STEP_m; m 0-14

VS_STEP_CAN_i (i = 1,2,3) = VS_STEP_m

Programed vehicle speed steps:

VS_STEP_k: $k = \sum VS\_STEP\_m$; for VS_STEP > 0 km. p. h.

"0 = kmph means there is no programed VS_CRU at this n_m step"

COUNT_VS_STEP = number of VS_STEP_k

NR_VS_CRU : If a VS_STEP_m is changed the NR_VS_CRU is updated to the respective column number. In other cases and at first activation of Steps the Numbers is cycling updated. Additional the instrument unit itselfs saves the steps internal.

NR_STEP_ON : current step number of sorted Vehicle speed steps.

Concerning some programming rules of the steps, it is necessary to vary some variables in dependancy on the equipped ICL. The difference is, whether the vehicle speed is announced in miles or kilometers.

FUNCTION DESCRIPTION:

The State of cruise control is the evaluation of the request and the cruise conditions.
If one of the following conditions is detected, no controller can be activated or an activated controller function is switched off. In this case a distinction is made between hard (FAC_TQ_CRU = 0) and soft cut-off (FAC_TQ_CRU through ramp function to zero).

Application conditions:

Application conditions:

Initialisation: *STATE_CRU_OFF_IRR, STATE_CRU_OFF_REV out of NVMY*

LV_CRU_ACT_VLD = 0 at LV_IGK 0->1 ***or*** *at reset*

all other outputs = 0

Recurrence: 10 ms

Activation: LV_VAR_DCC = 0 and LV_VAR_BN_LDM = 0

Deactivation: LV_VAR_DCC = 1 or LV_VAR_BN_LDM = 1 then

Initialisation: STATE_CRU_OFF_IRR, STATE_CRU_OFF_REV =00H

Formula section:

STATE_CRU_CAN	STATE_CRU
0. None:	PASSIVE
1. CONST	CONST_DRIVE or TIP
2. not used	
3. RES:	RES
4. not used	
5. SET/ACC	SET/ACC
6. not used	
7. DEC	DEC

If FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU and STATE_CRU not "passive"
Then STATE_CRU_CAN = "None"
Endif

67.6.5.2.1 Conditions for hard cut-off

The control functions of the cruise control can be activated only if:

- CRU ready state present LV_CRU_MAIN_SWI = 1

<u>Irreversible cut-off due to diagnosis failures</u>

With the following diagnosis errors the CRU is irreversible hard cut off for this engine run. The CRU-readiness and the CRU readiness light are reseted. The CRU function can be activated by LV_IGK=0/1 change, as long as no running diagnosis errors are present. A distinction is done between the irreversible failures because of an error output for CAN message.

Formula section:

```
If      STATE_VS_ICL_DISP = 1          "km/h; mph"
Then    VS_MIN_CRU = C_VS_MIN_CRU_M
Else    VS_MIN_CRU = C_VS_MIN_CRU_K
Endif
```

// Recognition if cruise control is really configuration of car (in Case of E90 LV_VAR_BN = 1 instead of no build in cruise control)

```

Then    REQ_CRU = Hard off
Endif
```

67.6.5.2.2 Conditions for soft cut-off:

General information:

If one of the following conditions is detected, the controller function is switched off. In this FAC_TQ_CRU is set through ramp function to zero.

Formula section:

```
If
[9]     REQ_MSW = SOFT_OFF                                  or    /* MSW-request */
[10]    [LV_CRU_OVER_ACT = 0 and
        (VS_DIF_CRU > C_VS_SP_DIF_MAX_CRU or
        VS_DIF_CRU < C_VS_SP_DIF_MIN_CRU)]
                                                            or    /* control deviation too large */
[11]    [LV_CRU_OVER_ACT = 1 and
        ((T_DLY_CRU ≥ C_T_DLY_MAX_CRU) or
        (VS_SP_DRIV_CRU - VS_CRU ≥ C_VS_DIF_DLY_CRU_POS) or
        (VS_SP_DRIV_CRU - VS_CRU < C_VS_DIF_DLY_CRU_NEG))]
                                                            or
[12]    (VS_CRU ≥ VS_SP_CRU_MAX for longer than C_T_DLY_VS_SP_CRU_MAX)
        Remark: if this condition is interupted than time-counter is reset to 0
                                                            or
[13]    ASR- or ESP-control for minimum time active
        (LV_CRU_OFF_BY_ASR_ESP_CTL = 1)

Then     REQ_CRU = Soft off
Endif
```

67.6.5.2.3 Overtaking function

Description:

If the throttle wish FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU and ≥ IP_FAC_TQ_REQ_CLU_IS__N_32 , then the controlled detectes overtaking and the value VS_DIF_I_CRU remains stored as threshold value. The time for the overtaking function T_DLY_CRU is started. The adjustable time C_T_DLY_MAX_CRU states whether starting controlled constant drive is possible after ending the overtaking function.
During the overtaking function, 'Overdriving' FAC_TQ_REQ_DRIV by the acceleration (ACC) and Tip-up functions is possible.
If the time C_T_DLY_MAX_CRU or the max. Deviation from the stored target speed is exceeded, no automatic start of controlled constant drive is possible any more. The CRU mode is ended. The functions of the cruise control can be activated again exclusively by the multifunction steering wheel. At resume the after overtaking function is finished the resume function is activated with the initilisation calculation of VS_DIF_I_CRU.
During the overtaking function the calculation of FAC_TQ_CRU is calculated normal with freezed I - share and calculated P-Share.

Application conditions:

Initialisation: LV_CRU_OVER_ACT = 0

Formula section:

```
If    LV_CRU_OVER_ACT = 0
Then        If      (STATE_CRU = constant drive or tip)            and
                    REQ_MSW != TIP_UP                              and

        Then    REQ_CRU = NONE
        Else    REQ_CRU = REQ_MSW
        Endif
Endif
```

67.6.5.2.4 Condition for cruise control intervention

Description:

The cruise control intervention is active if the vehicle is in operation depending of FAC_TQ_CRU. The Status is needed in the Cruise control monitoring of ETC Safety Unit.
If an MSW request is active but LV_CRU_ACT stays 0 due to environmental conditions (VS_CRU < VS_MIN_CRU, "Soft off", "Hard off" etc.) LV_CRU_ACT_INH is set.

Formula section:

```
If   LV_CRU_ACT = 0                                              and
     (LV_MSW_IDLE = 1            or
     (LV_CRU_MAIN_SWI = 0 → 1        and
     LV_VAR_BN = 1))                                             and
     VS_CRU >= VS_MIN_CRU                                        and
     ((REQ_MSW = TIP_UP  or  SET/ACC)        or
     (LV_VAR_BN = 1                and
     (REQ_MSW = TIP_DOWN or DECE or MARK_UP or MARK_DOWN)) or
      (REQ_MSW = RES     and
       Triggering the RES function for plausible VS_SP_DRIV_CRU
     (VS_MIN_CRU <= VS_SP_DRIV_CRU <= VS_SP_CRU_MAX)))
```

```
Then     LV_CRU_ACT = 1
Endif
```

LV_CRU_ACT is reseted to 0 if an off condition is present.

```
If       LV_CRU_ACT = 1   and   REQ_CRU =  "Soft off" or "Hard off"
Then     LV_CRU_ACT = 0
Endif

If       LV_CRU_ACT = 0  and  REQ_MSW > 1H  and  REQ_MSW != 7H
         and LV_CRU_OFF_IRR = 0
Then     LV_CRU_ACT_INH = 1
Else     LV_CRU_ACT_INH = 0
Endif
```

67.6.6.1 General calculation of cruise control and constant drive

Application conditions:

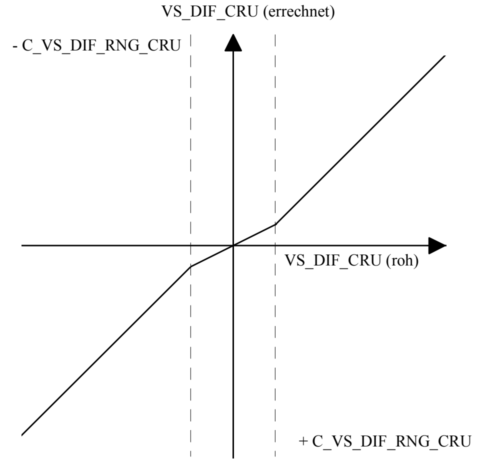
Recurrence: 100 ms

Initialisation: FAC_TQ_CRU = FAC_TQ_CRU_INI based on setting conditions

FUNCTION DESCRIPTION:

Description:

On setting in PU/PUC or with very small FAC_TQ_REQ_DRIV (driver gets off the pedal bevor setting Cruise Control), a very small I component setpoint (or 0) would be the results and it follows an undershooting below the required target speed. To prevent this, the I share set value is calculated depending on AC_CRU so that a minimum FAC_TQ_CRU results.



Formula section:

Basically calculation for all cruise states:

Total formula:

FAC_TQ_CRU = (VS_DIF_CRU + VS_DIF_I_CRU) * IP_FAC_PROP_CRU

Conditions for change limitations of FAC_TQ_CRU:

$|FAC\_TQ\_CRU_{n-1} - FAC\_TQ\_CRU_{n}| \leq C\_ FAC\_TQ\_CRU\_LGRD$

At driving by cruise control it should not be possible to request the maximum torque as well outside cruise control.

FAC_TQ_CRU <= C_ FAC_TQ_CRU_MAX

The non-linearized value of the control deviation from the reference input variable VS_SP_CRU and the control variable VS_CRU is calculated as

VS_DIF_CRU (rough)= VS_SP_CRU - VS_CRU

To achieve a quiet control in the range of the target variable, the internal control deviation VS_DIF_CRU can be reduced in the adjustable bandwidth | C_VS_DIF_RNG_CRU | by an applicable factor C_FAC_VS_DIF_RNG_CRU.

```
IF(1)            |VS_SP_CRU - VS_CRU | ≤ C_VS_DIF_RNG_CRU
Then(1)   VS_DIF_CRU = (VS_SP_CRU - VS_CRU ) * C_FAC_VS_DIF_RNG_CRU
Else(1) If(2)    (VS_SP_CRU - VS_CRU) > C_VS_DIF_RNG_CRU
    Then(2)  VS_DIF_CRU = (VS_SP_CRU - VS_CRU ) - C_VS_DIF_RNG_CRU
                        + C_VS_DIF_RNG_CRU * C_FAC_VS_DIF_RNG_CRU.
    Else(2)  VS_DIF_CRU = (VS_SP_CRU - VS_CRU )
                        + C_VS_DIF_RNG_CRU * C_FAC_VS_DIF_RNG_CRU.
    Endif (2)
Endif(1)
```

I share calculation:

Basically there are 3 states of STATE_I_CRU: NORM, LIM and FREEZE (for detailed information see formula section below)

If the FAC_TQ_CRU is on limitation (max, min value or freeze at PUC) then the I share is freezed **STATE_I_CRU = LIM** until a normal calculation of FAC_TQ_CRU is possible again. At constant driving or LV_CRU_OVER_ACT = 1 the I share is freezed **STATE_I_CRU = LIM** but in the calculation of FAC_TQ_CRU there is no interupt.

Calculation in case of controller active:

```
If      REQ_CRU = SOFT_OFF
Then    STATE_I_CRU = LIM
Else    If      [ STATE_CRU = DEC          AND
                (VS_DIF_I_CRU + C_VS_DIF_DELTA_I – IVS_DIF_CRUI >= 0)] OR
                [STATE_CRU = CONST_DRIVE     AND
                LV_CRU_OVER_ACT = 0     AND
                FAC_TQ_CRU > (IP_FAC_TQ_REQ_CLU_IS__N_32 –
                              C_FAC_TQ_REQ_CLU_IS_HYS) * 99,998%)
                              + C_FAC_TQ_CRU_OFS     AND
                 FAC_TQ_CRU < C_FAC_TQ_CRU_MAX]
        Then    // General calculation

                STATE_I_CRU = NORM
                VS_DIF_I_CRU $_{N}$ = VS_DIF_I_CRU $_{N-1}$ + VS_DIF_CRU *
                                                      IP_FAC_VS_DIF_I_CRU
                VS_SP_CRU$_{START}$ = VS_SP_CRU
                VS_DIF_I_CRU$_{START}$ = VS_DIF_I_CRU
        Else    If      STATE_CRU = SET_ACC    OR
                        STATE_CRU = RESUME
                Then    // Calculation during freeze of I share at SET/ACC, RES

                        STATE_I_CRU = FREEZE
                        VS_SP_CRU_STAT = VS_SP_CRU$_{n}$ - VS_SP_CRU$_{START}$
                        VS_DIF_I_CRU = VS_DIF_I_CRU$_{START}$ +
                                IP_FAC_VS_SP_DIF_I_CRU * VS_SP_CRU_STAT
                Else    // Calculation during limitation of I share

                        STATE_I_CRU = LIM
                        VS_SP_CRU$_{START}$ = VS_SP_CRU
                        VS_DIF_I_CRU$_{START}$ = VS_DIF_I_CRU
                Endif
        Endif
Endif
```

Calculation in case of controller passive:

Initialisation value calculated once on transition passive to active:

```
IF LV_AT = 0
Then    FAC_TQ_CRU_INI =    FAC_TQ_REQ_DRIV_MMV * 99,998 % +
        IP_FAC_TQ_CRU_INI_ADD_MT * AC_CRU
Else    FAC_TQ_CRU_INI =    FAC_TQ_REQ_DRIV_MMV * 99,998 % +

67.6.6.1.1 Controlled constant drive (CONST_DRIVE)

For controlled constant drive, the reference input variable VS_SP_CRU corresponds to the last target speed value reached, i.e. VS_SP_DRIV_CRU. No control of the reference input variable is performed in this range.

With the basic function of control, the vehicle speed is controlled corresponding to the required reference input variable VS_SP_CRU. This occurs until a cut-off condition arises or a condition for cruise control is infringed. The resume function is locked in the controlled constant drive. On recognition of other CRU functions, the reference input variable is controlled. To be able to trigger trailing throttle cut-off expediently, the value FAC_TQ_CRU is initially limited downwards to the value ((IP_FAC_TQ_REQ_CLU_IS__N_32 - C_FAC_TQ_REQ_CLU_IS_HYS)*99,998%). Thus there can be no IS output. Only if the control deviation VS_DIF_CRU drops below the applicable value C_VS_DIF_MIN_IS_CRU is FAC_TQ_CRU set equal to zero. However, this zero setting takes place at the earliest C_T_MIN_PUC_CRU seconds after entry into controlled constant drive. The trailing throttle cut-off is retained until the control deviation exceeds the applicable value C_VS_DIF_MAX_IS_CRU.

Formula section:

FAC_TQ_CRU conditions:

```

67.6.6.1.2 Cut-off of the CRU function

General information:

Soft cut-off

In the soft cut-off of the cruise control, the cruise control wish FAC_TQ_REQ_CRU is reduced to the driver wish FAC_TQ_REQ_DRIV with the adjustable decrement IP_FAC_TQ_CRU_DEC __N_32 for FAC_TQ_REQ_DRIV < FAC_TQ_REQ_CRU until the pedal driver demand is reached. FAC_TQ_CRU is then set to zero.

Hard cut-off

In the hard cut-off mode of the cruise control, the charge wish FAC_TQ_CRU is set equal to zero. There is no limitation gradient. The CRU State is readiness.

Application conditions:

Activation: see Capter:Cut -off Conditions and switch- on prohibitions

Formula section:

Soft cut-off

For FAC_TQ_REQ_DRIV < FAC_TQ_REQ_CRU there results:

FAC_TQ_CRU = FAC_TQ_CRU $_{n-1}$ - IP_FAC_TQ_CRU_DEC __N_32 until

FAC_TQ_REQ_DRIV = FAC_TQ_REQ_CRU

Hard cut-off

FAC_TQ_CRU = 0

Then, the CRU ready status is reached. Only now can the CRU mode be activated again.

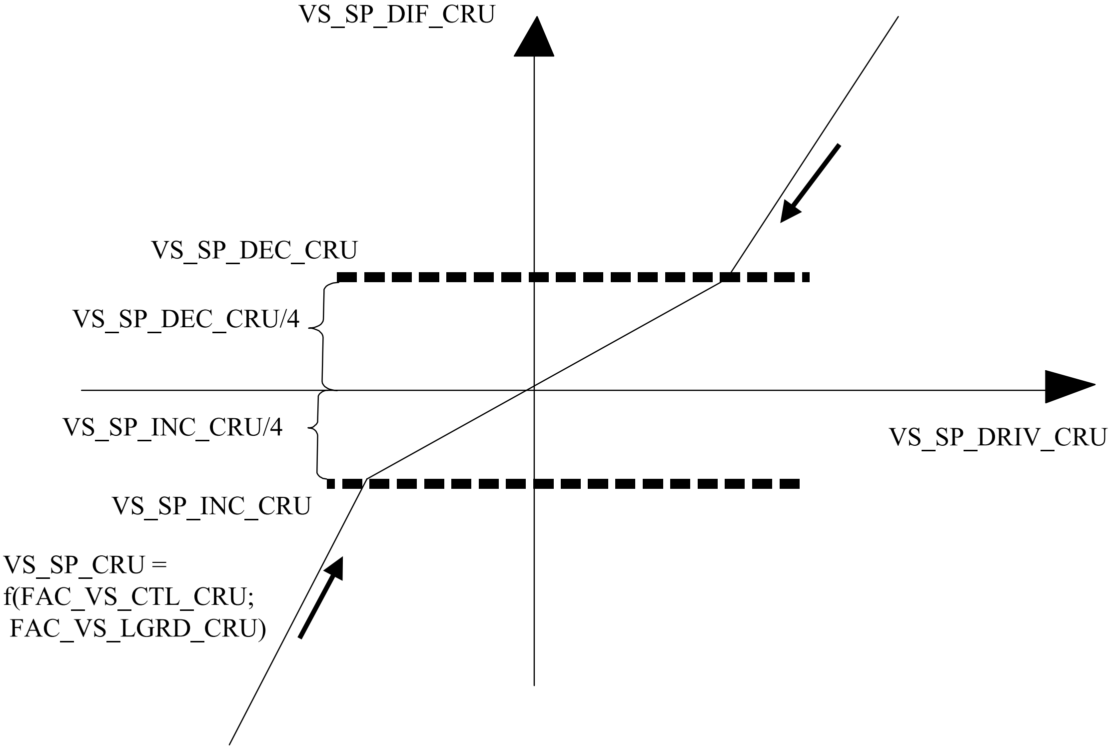
67.6.6.2 Controlled acceleration

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: VS_SP_CRU = VS_CRU

Description:



The reference input variable VS_SP_CRU is set equal to the instantaneous speed of the vehicle VS_CRU at the start of the function.

The controlled acceleration of the vehicle is performed by controlled in/decrementation of the reference input variable of the cruise control. On start of the function, the time T_CTL_CRU is started and incremented in each computing cycle.
Is VS_SP_CRU is brought close to VS_SP_DRIV_CRU with fixed increment (VS_SP_DEC_CRU/4 or VS_SP_INC_CRU/4).
A distinction is made between positive and negative acceleration.
FAC_VS_CTL_CRU and FAC_VS_LGRD_CRU are set by the momentarily active function of the cruise control, see following subchapter.

Formula section:

T_CTL_CRUn = T_CTL_CRUn-1 + 100 ms

VS_SP_DIF_CRU = VS_SP_CRU - VS_SP_DRIV_CRU

IF(1) 0 < VS_SP_DIF_CRU ≤ VS_SP_DEC_CRU

Then(1) $VS\_SP\_CRU_{n}$ = $VS\_SP\_CRU_{n-1}$- VS_SP_DEC_CRU/4

Else(1)

IF(2) VS_SP_DIF_CRU > VS_SP_DEC_CRU > 0

```
Then(2)    VS_SP_CRU$_n$ =  VS_SP_CRU$_{n-1}$
               - VS_SP_DEC_CRU            :Decrement
               * FAC_VS_CTL_CRU           :Factor for controlling
               * FAC_VS_LGRD_CRU          :Factor for intercepting
Else(2)
If(3) (-1 * VS_SP_INC_CRU) $\leq$ VS_SP_DIF_CRU < 0
Then(3)    VS_SP_CRU$_n$ =  VS_SP_CRU$_{n-1}$+ VS_SP_INC_CRU/4
Else(3)
If(4)      VS_SP_DIF_CRU < (-1 * VS_SP_INC_CRU)
Then(4) VS_SP_CRU$_n$ =  VS_SP_CRU$_{n-1}$
               + VS_SP_INC_CRU            :Increment
               * FAC_VS_CTL_CRU           :Factor for controlling
               * FAC_VS_LGRD_CRU          :Factor for intercepting
Endif
Set of VS_SP_CRU in case of driver intervention:
If         (STATE_CRU = Set_acc or Retard)                        and
           LV_VAR_BN = 1                                          and
           FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU                       and
           FAC_TQ_REQ_DRIV > IP_FAC_TQ_REQ_CLU_IS__N_32           and
           VS_CRU > VS_SP_CRU
Then       VS_SP_CRU = Min(VS_CRU, VS_SP_CRU_MAX)
Endif
```

Dec / Incrementation is interrupted if

VS_DIF_CRU > C_VS_DIF_MAX_AC_CRU **or**

VS_DIF_CRU < C_VS_DIF_MIN_AC_CRU

Dec / Incrementation is continued if

VS_DIF_CRU $\leq$ C_VS_DIF_MAX_AC_CRU **or**

67.6.6.3 Actuating the reference input variable

General information:

The multiplicative correction factor FAC_VS_CTL_CRU for in/decrementation the reference input variable in the controlled acceleration is calculated in each case for the individual functions of the cruise control. Also for automatic transmission, a distinction is made partially whether the converter clutch is just open or closed. The correction factor depends upon the time T_CTL_CRU. While the actuation of this function is active, the calculation of the I component is interrupted. The sum of the I component thus remains constant.

Formula section:

FAC_VS_CTL_CRU = IP_FAC_XX_CRU_yy__T_CTL_CRU

A distinction is made between the following CRU functions:

Resume:	IP_FAC_CRU_REST__T_CTL_CRU
Setting/acceleration:	**IF** LV_AT = 0 **or** (LV_AT = 1 **and** STATE_CC != open)
Manual gear or automatic with closed converter clutch	**Then** IP_FAC_CRU_AC__T_CTL_CRU
Automatic with open converter	**Else** IP_FAC_CC_CRU_AC__T_CTL_CRU
Clutch	**Endif**
Deceleration:	**IF** LV_AT = 0 **or** (LV_AT = 1 **and** STATE_CC != open)
Manual gear or automatic with closed converter clutch	**Then** IP_FAC_CRU_DECE__T_CTL_CRU
Automatic with open converter	**Else** IP_FAC_CC_CRU_DECE__T_CTL_CRU
Clutch	**Endif**

67.6.6.4 Intercepting the reference input variable target acceleration

General information:

To take account of the vehicle dynamics, the positive accelerations for high speeds as from approx. 80 k.p.h. must be reduced in the setting/acceleration and resume functions. For this purpose, the accelerations must be valued with a factor FAC_VS_LGRD_CRU for in/decrementing the reference input variable. The acceleration is valued with 1 below the threshold C_VS_AC_MIN_CRU. If VS_SP_CRU exceeds this threshold, then the factor FAC_VS_LGRD_CRU is reduced linearly by a ramp function up to the upper threshold C_VS_AC_MAX_CRU. The maximum reduction can be set through the value C_FAC_AC_POS_CRU.

To achieve comfortable interception of the reference input variable, the multiplicative correction factor, which is limited dependent on speed, must be calculated when in/decrementing the reference input variable in each case for the individual functions of the cruise control. While the interception of the reference input variable function is active, the calculation of the I component is interrupted. The sum of the I component remains constant. The correction factor depends upon the difference between reference input variable and target variable.

Formula section:

```
IF        VS_SP_CRU < C_VS_AC_MIN_CRU
Then          FAC_VS_LGRD_CRU = 1
Else If       VS_SP_CRU > C_VS_AC_MAX_CRU
    Then      IF LV_RNG_L_REQ = 1
              Then   FAC_VS_LGRD_CRU = C_FAC_AC_POS_CRU_RNG_L
              Else   FAC_VS_LGRD_CRU = C_FAC_AC_POS_CRU
Else          FAC_VS_LGRD_CRU =     FAC_VS_LGRD_CRU$_{vehicle-speed-dependent}$
                     * IP_FAC_LGRD_CRU_xx__VS_SP_DIF
```

During the acceleration IP_FAC_LGRD_CRU_xx__VS_SP_DIF = 1

(FAC_VS_LGRD_CRU = FAC_VS_LGRD_CRU$_{\text{vehicle-speed-dependent}}$)

- Resume (RES): IP_FAC_LGRD_CRU_REST__VS_SP_DIF

67.6.6.5 Interventions

Application conditions:

Initialisation: VS_SP_DRIV_CRU = VS_MIN_CRU at LV_IGK 0 to1

Formula section:

```
IF    STATE_VS_ICL_DISP = 1            "km/h; mph"
Then      VS_SP_CRU_MAX = C_VS_SP_CRU_MAX_M
Else      VS_SP_CRU_MAX = C_VS_SP_CRU_MAX_K
Endif
```

67.6.6.5.1 Resume (RES)

Description:

When the resume function is activated, the vehicle is brought to the last target speed with the adjustable positive or negative acceleration. In this case the control basic function is activated and the reference input variable is controlled. When controlling the reference input variable VS_SP_CRU, a distinction is made between a resume to high speeds and a resume to the low speeds.
In a resume to a target speed, the reference input variable is in / decremented per computing cycle (100 ms).

To achieve a comfortable transition from the CRU status of ready to CRU mode on start of the restart function, the I component of the P/I controller is preallocated depending upon the recognised acceleration of the vehicle. To achieve comfortable acceleration on activating the resume function and on reaching the stored target speed, the control and interception of the reference input variable functions are series connected with the controlled acceleration function. In these functions a multiplicative correction factor is calculated in each case for in/decrementing the reference input variable.
At resume the after overtaking function is finished the resume function is activated with the initilisation calculation of FAC_TQ_CRU.
The alghorithm for Step request is like the State resume. Only VS_SP_DRIV_CRU is set to the current select mark VS_SP_DRIV_STEP. Inside the controller a step request triggers the resume Function.

Formula section:

```
VS_SP_CRU = VS_CRU

IF      VS_CRU  <  VS_SP_DRIV_CRU

Then IF LV_RNG_L_REQ = 1
        Then  VS_SP_INC_CRU  =  3.6  *  ID_AC_POS_CRU_RESU_RNG_L  *  100 ms
        Else  VS_SP_INC_CRU  =  3.6  *  ID_AC_POS_CRU_RESU  *  100 ms
  VS_SP_CRU  = capter "calculation of controlled acceleration"
Else
If        VS_CRU  >  VS_SP_DRIV_CRU
Then   VS_SP_DEC_CRU  =  3.6  * IP_AC_NEG_CRU_RESU *  100 ms
     VS_SP_CRU  = capter "calculation of controlled acceleration"
Endif
```

        $VS\_SP\_CRU_{(n)} \geq VS\_SP\_CRU_{(n-1)}$    and
        FAC_TQ_REQ_DRIV > FAC_TQ_REQ_CRU                and
        FAC_TQ_REQ_DRIV > IP_FAC_TQ_REQ_CLU_IS__N_32    and
        VS_CRU > VS_SP_CRU
Then    VS_SP_CRU = VS_CRU
Endif
```

67.6.6.5.3 Setting/acceleration (SET/ACC)

Description:

On activating the setting/acceleration function from the CRU State of ready, the transition to ‘controlled constant drive’ takes place. Reference input variable VS_SP_CRU and target variable VS_SP_DRIV_CRU are set to the current speed VS_CRU.

On activating the setting/acceleration function from readiness, a timer T_CTL_CRU is started. As long as SET/ACC recognizes that this timer reaches the value C_T_MIN_CRU_CON, the CRU state changes from ‘controlled constant drive’ to ‘controlled acceleration’. The vehicle is brought to the required target speed with the adjustable positive ID_AC_POS_CRU_AC/_RNG_L or negative acceleration IP_AC_NEG_CRU_AC__N__FAC_TQ_CRU. In this case the control basic function is activated and the reference input variable VS_SP_CRU is controlled.

<u>As long as the setting/acceleration function is detected, the incrementation of the reference input variable takes place per computing cycle (100 ms) with the controlled acceleration function.</u>

On ending the setting/acceleration function, the target speed VS_SP_DRIV_CRU is set equal to the achieved vehicle speed VS_CRU. If the target speed VS_SP_DRIV_CRU stored in this way is greater than the instantaneous reference input variable VS_SP_CRU, then the value VS_SP_CRU is incremented further by the value VS_SP_INC_CRU through the controlled acceleration function. If the instantaneous reference input variable VS_SP_CRU is larger than the stored target speed VS_SP_DRIV_CRU, then the reference input variable is decremented with the controlled acceleration function.

<u>Formula section:</u>

```
REQ_MSW = ACC active:
IF        LV_RNG_L_REQ = 1
Then      VS_SP_INC_CRU  =  3.6  *  ID_AC_POS_CRU_AC_RNG_L  *  100 ms
Else      VS_SP_INC_CRU  =  3.6  *  ID_AC_POS_CRU_AC  *  100 ms
Endif
VS_SP_CRU$_{n}$  =   VS_SP_CRU$_{n-1}$

67.6.6.5.4 Tip-up

Description:

On activating the TIP_UP function, the vehicle is brought to the last target speed reached, i.e. VS_SP_DRIV_CRU plus C_VS_DIF_TIP_M/K [km/h] with the adjustable positive acceleration C_AC_POS_CRU_TIP. In this case the control basic function is activated and the reference input variable VS_SP_CRU is controlled. By each detection of the TIP_UP function, the target speed VS_SP_DRIV_CRU is increased by C_VS_DIF_TIP_M/K [km/h].
If the absolute amount of the difference VS_DIF_CRU is greater than or equal to C_VS_DIF_MAX_CRU, the reference input variable VS_SP_CRU is incremented per computing cycle (100 ms) with the controlled acceleration function by the value:

Formula section:

```
IF        LV_CRU_OVER_ACT = 1    and    REQ_CRU = "TIP_UP"
Then      VS_SP_CRU = VS_SP_DRIV_CRU = MIN(VS_CRU, VS_SP_CRU_MAX)
          LV_CRU_OVER_ACT_ACK = 1
else      LV_CRU_OVER_ACT_ACK = 0
endif

IF        VS_SP_DRIV_CRU ≥ VS_SP_CRU_MAX
Then      VS_SP_DRIV_CRU = VS_SP_CRU_MAX
Else if   STATE_VS_ICL_DISP = 1
    Then  VS_SP_DRIV_CRU = VS_SP_DRIV_CRU + C_VS_DIF_TIP_M [km/h]
    Else  VS_SP_DRIV_CRU = VS_SP_DRIV_CRU + C_VS_DIF_TIP_K [km/h]
    Endif
Endif
```

```
IF          $VS\_DIF\_CRU \geq C\_VS\_DIF\_MAX\_CRU$
Then        VS_SP_INC_CRU = 3.6 * C_AC_POS_CRU_TIP * 100 ms
            $VS\_SP\_CRU_{n}$ = $VS\_SP\_CRU_{n-1}$
               + VS_SP_INC_CRU             :Increment
                * FAC_VS_CTL_CRU           :Factor for controlling
                * FAC_VS_LGRD_CRU          :Factor for intercepting

Else if     STATE_VS_ICL_DISP = 1
    Then    VS_SP_CRU = VS_SP_CRU + C_VS_DIF_TIP_M [km/h]
    Else    VS_SP_CRU = VS_SP_CRU + C_VS_DIF_TIP_K [km/h]
    Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

67.6.6.5.5 Tip-down

Description:

On activating the TIP_DOWN function, the vehicle is brought to the last target speed reached, i.e. VS_SP_DRIV_CRU minus C_VS_DIF_TIP_M/K [km/h] by the adjustable negative acceleration C_AC_NEG_CRU_TIP. In this case the control basic function is activated and the reference input variable VS_SP_CRU is controlled. At each detection of the TIP_DOWN function, the target speed VS_SP_DRIV_CRU is reduced by C_VS_DIF_TIP_M/K [km/h].
VS_SP_CRU and VS_SP_DRIV_CRU cannot be less than VS_MIN_CRU.
If the absolute amount of the difference VS_DIF_CRU is greater than or equal to C_VS_DIF_MAX_CRU, the reference input variable VS_SP_CRU is decrements per computing cycle (100 ms) with the controlled acceleration function. The charge wish FAC_TQ_CRUis limited to the value (IP_FAC_TQ_REQ_CLU_IS__N_32*99,998%). so that no trailing throttle cut-off is triggered (except for: PUC was already active before TIP_DOWN).

Formula section:

```
IF          LV_CRU_OVER_ACT = 1    and    REQ_CRU = "TIP_DOWN"
Then        VS_SP_CRU = VS_SP_DRIV_CRU = MIN(VS_CRU; VS_SP_CRU_MAX)
            LV_CRU_OVER_ACT_ACK = 1
else        LV_CRU_OVER_ACT_ACK = 0
endif

IF          VS_SP_DRIV_CRU < VS_MIN_CRU
Then        VS_SP_DRIV_CRU = C_VS_SP_CRU_MIN
Else if     STATE_VS_ICL_DISP = 1
    Then    VS_SP_DRIV_CRU = VS_SP_DRIV_CRU - C_VS_DIF_TIP_M [km/h]
    Else    VS_SP_DRIV_CRU = VS_SP_DRIV_CRU - C_VS_DIF_TIP_K [km/h]
    Endif
Endif

IF          |VS_DIF_CRU| ≥ C_VS_DIF_MAX_CRU
Then        VS_SP_DEC_CRU  =  3.6  *  C_AC_NEG_CRU_TIP  *  100 ms
    $VS\_SP\_CRU_{n} = VS\_SP\_CRU_{n-1}$
                              -  VS_SP_DEC_CRU              :Decrement
                              *  FAC_VS_CTL_CRU             :Factor for controlling
                                   *  FAC_VS_LGRD_CRU            :Factor for intercepting
Else if     STATE_VS_ICL_DISP = 1
    Then    VS_SP_CRU = VS_SP_CRU - C_VS_DIF_TIP_M [km/h]
    Else    VS_SP_CRU = VS_SP_CRU - C_VS_DIF_TIP_K [km/h]
    Endif
Endif
```

$FAC\_TQ\_CRU \geq ((IP\_FAC\_TQ\_REQ\_CLU\_IS\_\_N\_32 - C\_FAC\_TQ\_REQ\_CLU\_IS\_HYS) * 99{,}998\%)$

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_AC_NEG_CRU_TIP	1	0...5C28H	0...511.9789	2.17E-02	[m/s²]

Control difference threshold for incrementing VS_SP_CRU					

67.6.6.5.6 Deceleration

Description:

On activating the deceleration function, the vehicle is brought to the required target speed with the adjustable negative C_AC_NEG_CRU_DEACC or positive acceleration C_AC_POS_CRU_DEACC (for the steady state). In this case the control basic function is activated and the reference input variable VS_SP_CRU is controlled.
As long as the deceleration function is detected, the decrementation of the reference input variable takes place per computing cycle (100 ms) with the controlled acceleration function

On ending the deceleration function, the target speed VS_SP_DRIV_CRU is set equal with the reached vehicle speed VS_CRU. If the target speed VS_SP_DRIV_CRU thus stored is smaller than the instantaneous reference input variable VS_SP_CRU, then the value VS_SP_CRU is decremented by the value VS_SP_DEC_CRU further via the controlled acceleration function. VS_SP_CRU and VS_SP_DRIV_CRU cannot be smaller than VS_MIN_CRU. If the instantaneous reference input variable VS_SP_CRU is smaller than the stored target speed VS_SP_DRIV_CRU, then the reference input variable is incremented with the controlled acceleration function.

Formula section:

REQ_MSW = DEC active:

VS_SP_DEC_CRU = 3.6 * C_AC_NEG_CRU_DEACC * 100 ms

$\mathrm{VS\_SP\_CRU}_n = \mathrm{VS\_SP\_CRU}_{n-1}$

- VS_SP_DEC_CRU : Decrement

* FAC_VS_CTL_CRU : Factor for controlling

* FAC_VS_LGRD_CRU : Factor for intercepting

REQ_MSW = DEC passive:

VS_SP_DRIV_CRU = Min(VS_CRU, VS_SP_CRU_MAX)

```
IF    VS_SP_DRIV_CRU <  VS_SP_CRU
Then      VS_SP_DEC_CRU  =  3.6  *  C_AC_NEG_CRU_DEACC  * 100 ms
          VS_SP_CRU  = capter "calculation of controlled acceleration"
Else      VS_SP_INC_CRU  =  3.6  *  C_AC_POS_CRU_DEACC  * 100 ms
          VS_SP_CRU  = capter "calculation of controlled acceleration"
Endif
```

As long as decrementing the reference input variable VS_SP_CRU is active, the calculation of the I component is released.

Calculation of VS_DIF_I_CRU until

$\mathrm{VS\_DIF\_I\_CRU} + \mathrm{C\_VS\_DIF\_DELTA\_I} < |\mathrm{VS\_DIF\_CRU}|$

67.6.7.1 Runup lock

Application conditions:

Initialisation: 0 at reset

Activation: LV_AT = 0 **and** LV_VAR_AMT = 0 **and** LV_VAR_TCT = 0

Deactivation: LV_AT = 1 **or** LV_VAR_AMT = 1 **or** LV_VAR_TCT = 1

Recurrence: 100 ms

Description:

In vehicles with manual transmission, the ratio between engine speed and vehicle speed is monitored on activating a function of the cruise control. At the start of a function, the ratio N_VS_CRU = N / VS_FIL is stored.

The instantaneous ratio between engine speed and vehicle speed is formed in each cycle

$N\_VS\_CRU_n = N_n / VS\_FIL_n$

Remark:

If the percentage ratio exceeds the threshold value C_N_VS_MAX_CRU, hard cut-off has to ocurrs.

67.6.7.2 Filter of vehicle speed

Application conditions:

Initialization: 0 at reset

Activation: LV_VAR_ASR = 1

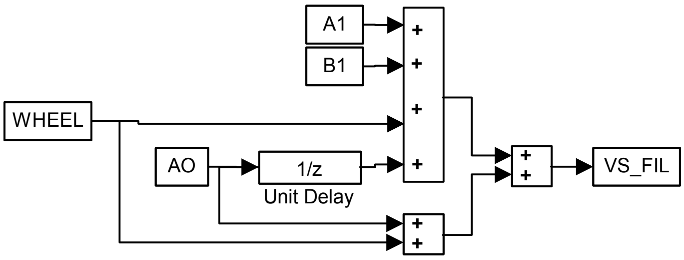
Recurrence: 10ms

General information:

For the CAN signal WHEEL, a 1st order IIR filter is used for evaluating the vehicle speed for the CRU and the speed limitation. The jitter error of the input signal WHEEL is smaller than 1%. A jitters error smaller than 0.2% must be achieved for the control variable VS_FIL with the filter. The frequency limit of the filter is approx. fg = 0.80 (Hz). Filtration of the speed signal is performed independently of the CRU mode with a 10ms time pattern.

Signal flow diagram:

The structure of the filter is represented as follows:



z^{-1} means a delay by one sampling time. The sampling time is T_{ab} = 10(ms) and thus f_{ab} = 100 (Hz). At a quality Q = 1, the filter factors are calculated as:

Formula section:

$$A1 = A0 = \frac{1}{1+W}; \qquad B1 = -\frac{1-W}{1+W}; \qquad \text{with } W = \frac{1}{\mathrm{Tan}\frac{\pi}{\Omega}}; \qquad W = C\_FAC\_VS\_FIL$$

```
If      LV_ERR_VS = 1                 // VS-double-error (PIN & CAN-signal)
Then    VS_FIL = 0
Else    If      LV_ERR_CAN_BOFF = 1          or
                LV_ERR_BN_VS_TCS = 1         or
                LV_ERR_TOUT_ASR_1 = 1
        Then    VS_FIL = VS_SENS (converted)
        ElseIf  LV_ERR_VS_CAN = 1
           Then     T_ERR_VS_CAN decrements (Start value C_T_ERR_VS_CAN )
                If      T_ERR_VS_CAN = 0
                Then    VS_FIL = 0
                Else    VS_FIL n = VS_FIL n-1
                Endif
```

```
            Else    VS_FIL is calculated
                    T_ERR_VS_CAN = 0
            Endif
        Endif
Endif
```

67.6.7.3 Filter of Vehicle Speed for Cruise control

Application conditions:

Initialisation: 0 at reset

Activation: LV_VAR_ASR = 1

Recurrence: 100ms

General information:

With integration of stage cruise control the vehicle speed of instrument message is used. There is a deviation of DSC vehicle speed to the vehicle Speed of ICL therefore the visible signal has to be used to supress a shown deviation to the driver.

Formula section:

```
If      LV_VAR_BN_MSW = 1       and
        LC_VS_CRU_FIL =1        and
        LV_ERR_CAN_BOFF = 0     and
        LV_ERR_BN_VS_TCS = 0    and
        LV_ERR_BN_ICL = 0
Then    $VS\_DIF\_ICL\_TCS = VS\_DIF\_ICL\_TCS_{n-1} - C\_CRLC\_VS\_CRU\_MMV$     *
        $(VS\_DIF\_ICL\_TCS_{(n-1)} - VS\_ICL\_DISP + VS\_FIL)$
        VS_CRU = VS_FIL + VS_DIF_ICL_TCS
        (a physical conversion VS_ICL_DISP has be done)
Else    VS_CRU = VS_FIL
Endif
```

67.6.8 Checking the conditions of the CRU mode

67.6.8.1 Acceleration monitoring

Application conditions:

Initialisation: 0 m/s² at reset

Recurrence: 10 ms

Description:

To monitor the vehicle dynamics in cruise control mode, the instantaneous acceleration of the vehicle is calculated in each computing cycle. The acceleration calculation is performed independently of the CRU mode with a 10 ms time pattern.

Formula section:

$$AC\_CRU = AC\_CRU + (VS\_FIL_{n} - VS\_FIL_{n-1}) / 10ms * C\_FAC\_AC\_CRU\_MMV$$

Remark:
If the instantaneous acceleration exceeds the adjustable value C_AC_MAX_CRU, hard cut-off is performed, see chapter hard off conditions.

67.6.8.2 Plausibility check of the speed signal VS_FIL

General information:

The vehicle speed is acquired through the CAN signal WHEEL. To detect possible errors - if WHEEL is currently received and identified as correct by the ASR control unit a plausibility check is performed.

The filtered external vehicle speed VS_CRU is compared with the vehicle speed sensor signal. If a maximum allowed absolute deviation C_VS_MAX_DIAG is exceeded, there is an error entry.

Application conditions:

Initialisation: 0 at reset or LV_IGK = 0 → 1

Recurrence: Checking every 100 ms:

Activation: LV_VAR_ASR = 1

Formula section:

```
IF   LV_ERR_VS              = 1         or
     LV_ERR_CAN_BOFF        = 1         or
     LV_ERR_BN_VS_TCS       = 1         or
     LV_ERR_BN_ICL          = 1         or
     LV_ERR_VS_CAN          = 1
THEN      LV_VS_DIAG_NOT_PLAUS = 0
          T_VS_DIAG_NOT_PLAUS = 0
ELSE      IF   |VS_CRU - VS|  ≥  C_VS_MAX_DIAG
```

```
        THEN T_VS_DIAG_NOT_PLAUS ++

67.6.8.3 Recognition ASR/ESP-control and valid minimum time

Application conditions:

Initialisation: 0 at reset

Recurrence: 100 ms

Description:

Recognition ASR/ESP-control and valid minimum time :

LV_CRU_OFF_BY_ASR_ESP_CTL = active:

Recognition due to the combination of the signals LV_PLAUS_ASR_CTL, LV_ASR_REQ and LV_PLAUS_ESP_CTL of the CAN-message ASC3

LV_PLAUS_ASR_CTL	LV_TQ_ASR_REQ	LV_PLAUS_ESP_CTL	function	minimum time before cut-off CRU
1	1	0	ASR-control	C_T_CRU_ASR_OFF
1	1	1	ESP-control	C_T_CRU_ESP_OFF
1	0	1	ESP-control only brake	C_T_CRU_ESP_BRAKE_OFF

67.6.8.4 Mean moving value calculation of Driver demand:

FUNCTION DESCRIPTION:

For initialisation of I share of the cruise control function it is nessessary to calulate a very slow driver demand

Application conditions:

Initialisation: 0 at reset

Recurrence: 10 ms

Formula section:

$$\mathrm{FAC\_TQ\_REQ\_DRIV\_MMV} = \mathrm{FAC\_TQ\_REQ\_DRIV\_MMV}_{n-1} + (\mathrm{FAC\_TQ\_REQ\_DRIV} - \mathrm{FAC\_TQ\_REQ\_DRIV\_MMV}_{n-1}) * \mathrm{C\_FAC\_TQ\_REQ\_DRIV\_MMV}$$

68 Vehicle speed limitation

Table of Contents

Index

68.1 VHSL General

General information:

The Aggregate VHSL replaces previous function which was engine speed based. Aim of function is to provide better control of vehicle speed, particularly in the avoidance of overshoot of the setpoint, and stability after gear changes (esp. in CVT vehicles).

The aggregate consits of the following main functions:

Vehicle speed limitation manager
Interface not used for the fix limitation ->VHSL_1.0.0. The state variable STATE_VSL is used only as aggregate internal interface in case of a variable vehicle speed limitation.

Vehicle speed limitation controller
This modules aims to limit the vehicle speed to C_VS_MAX_VSL. A PI controller is used to define the engine torque limitation. In order to minimise speed overshoot, a predicted vehicle speed is calculated and the I controller is initilised with a calculated torque reduction.

Vehicle speed limitation output
This functionality limits the engine torque output by TQI_VS_MAX. The value of TQI_VS_MAX is initialised with the current engine output torque requirement. This will be calculated as the maximum of TQI_AV and minimum of TQI_BAS_MIN, TQI_REQ_TRA. This starting value of TQI_VS_MAX is then stored.

Vehicle speed limit calculation
A filtered vehicle acceleration, AC_VEH_MMV is used to predict a future vehicle speed VS_PRED. The vehicle speed limit, VS_MAX is also determinated at this point. For the fix limitation this limit will be given by the constant C_VS_MAX_VSL.
Another part is the calculation of the vehicle speed deviation which is an essential variable for the vehicle speed controller.

Vehicle speed limitation manager (Appl. Inc.)
This module deals with the activation of the fix vehicle speed limitation functionality. The function is switched on, LV_VS_MAX_VSL is set, when the vehicle speed, VS_HIGH_RES exceeds the set point minus an offset, C_VS_MAX_VSL - C_VS_MAX_HYS_ON. On the other hand the function is reset, and turned off, when the vehicle speed, VS_HIGH_RES drops below the set point minus a hysterisis

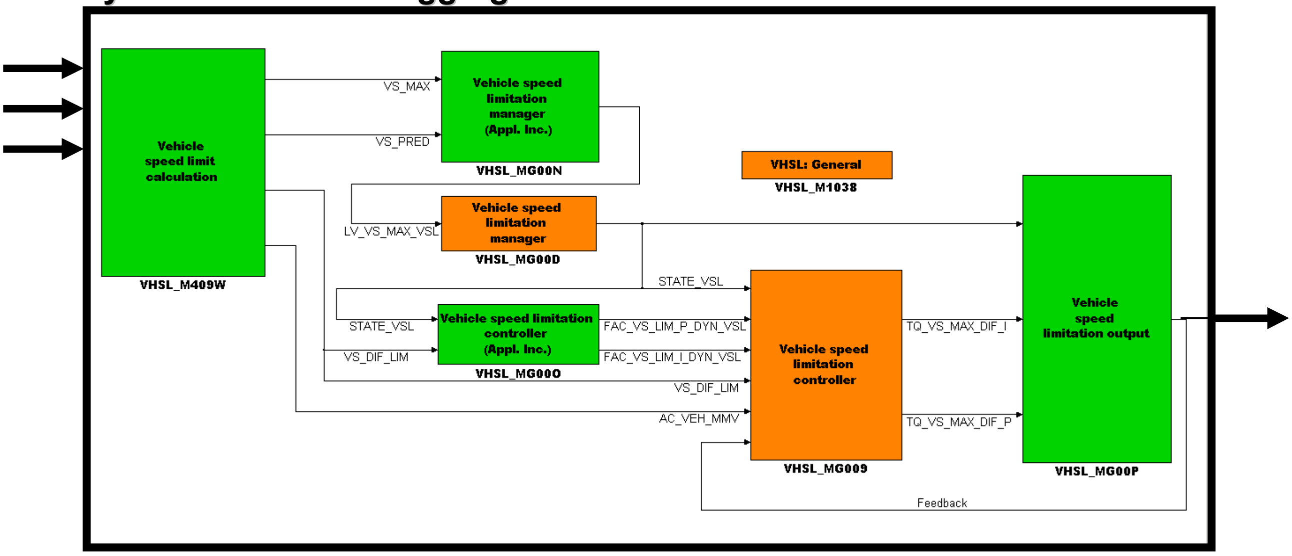
Vehicle speed limitation controller (Appl. Inc.)
The control dynamic is determined by LV_FAC_CTL_DYN_CHG_VSL. The I and PD control parameters are calculated based on the dynamic behaviour of the controller.

The aggregate is available in 2 variants:
- Variant 1 : Fix Vehicle Speed Limitation
- Variant 2 : Variable Vehicle Speed Limitation

Architecture Overview:

Variant 1:

System Arhitecture Aggregate VHSL Version 1



68.2 Vehicle speed limit calculation

68.4.1 General Information

This module deals with the activation of the fix vehicle speed limitation functionality. The function is switched on, LV_VS_MAX is set, when the predicted vehicle speed, VS_PRED exceeds the set point minus an offset, VS_MAX – C_VS_MAX_HYS_ON. On the other hand the function is reset, and turned off, when the predicted vehicle speed, VS_PRED drops below the set point minus a hysterisis VS_MAX – C_VS_MAX_HYS_OFF. An additional activation condition is that engine speed should be below of a threshold, C_N_MIN_VS_MAX. This threshold must be set to a low value away from the VS_MAX engine speed area. 68.8 Calibration hints for function Vehicle Speed Limitation (gen)

Calibration interfering functions

- torque model must be calibrated first
- of big importance is the calibration of *Torque Transient* function
- calibration of C_VS_FIL for the filtered vehicle speed of the function *Vehicle Motion Determination*
- Vehicle Motion Determination (VHMD), Gear Detection (TRSM) and Torque Transient (DRVB) should be calculated first

Calibration flowchart

The sequence of calibration is described by the order in *Calibrated methods*.

Calibration method

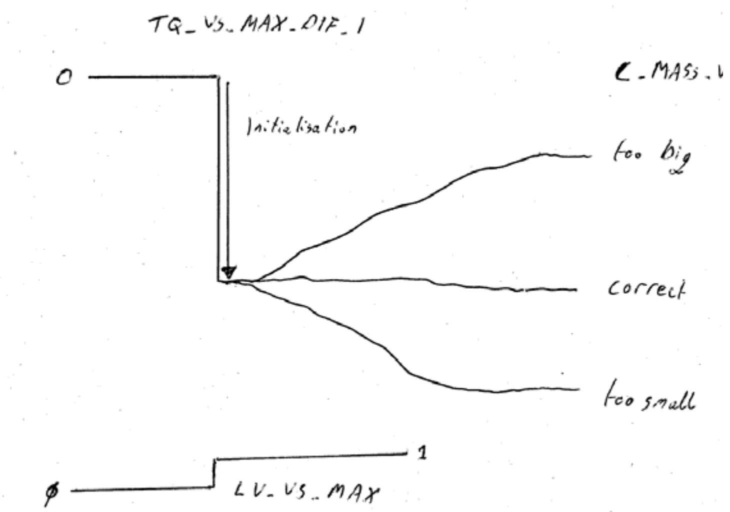
Vehicle speed limitation controller

C_LGRD_TQ_VS_MAX_I
C_MASS_VEH

68.8.1.1 Initialisation of I term

Initialisation of the I term is calculated from the vehicle acceleration, vehicle equivalent mass and gear ratio. The objective is to directly remove most of the vehicle acceleration force when the function is activated (LV_VS_MAX 0 -> 1).
Calibration procedure:

a) Set C_LGRD_TQ_VS_MAX_I to 0 (no limiting)
b) Accelerate to VS_MAX in various gears with constant pedal
c) Compare initialisation of I term with steady state value



When

steady state = initial value then vehicle mass is correct
steady state < initial value then vehicle mass is too small
steady state > initial value then vehicle mass is too high

If problems arise, check that AC_VEH_MMV =~ AC_VEH when function is initialised, if value is lagging then increase C_CRLC_AC_VEH_VS_MAX. Try to perform the test on a flat piece of road so that the road load is not changing. Start the acceleration well before VS_MAX, so that a quasi-steady state has been obtained.

Remember that C_MASS_VEH may be more than the actual vehicle mass due to the inertia of the engine and drivetrain. It may however be advantageous to have the initialisation value slightly small, so that a smooth entry to C_VS_MAX is obtained, i.e. acceleration is not completely stopped before C_VS_MAX is reached.

Reset C_LGRD_TQ_VS_MAX_I to 40 Nm, to avoid hard load changes when entering VS_MAX control.

Suggested initial data:
C_MASS_VEH = 1600 kg (use actual vehicle mass)
C_LGRD_TQ_VS_MAX_I = 40 Nm (/100ms)

68.8.1.2 Troubleshooting

1) Unstable at VS_MAX
    a. P / I terms too high (IP_FAC_VS_MAX_I / _P)
    b. ID_T_VS_MAX_PRED too large
    c. AC_VEH_MMV not filtered enough (C_CRLC_AC_VEH_VS_MAX too low)
2) Overshoot of VS_MAX
    a. P / I terms too small
    b. C_VS_MAX_HYS_ON too small
    c. Vehicle mass calibration (C_MASS_VEH) too low
    d. Prediction time (ID_T_VS_MAX_PRED) too small / short
    e. Difference limiter for I term too slow (increase C_LGRD_TQ_VS_MAX_I)
3) Toggling of LV_VS_MAX
    a. Hysterisis too small (increase C_VS_MAX_HYS_OFF)
4) Hard load change when function activated
    a. Difference limiter for I term too fast (decrease C_LGRD_TQ_VS_MAX_I)
    b. Vehicle mass calibration too high (C_MASS_VEH)
    c. ID_T_VS_MAX_PRED too large
    d. C_VS_MAX_HYS_ON too small

68.9 Calibration hints for function Vehicle Speed Limitation (cus)

Calibration interfering functions

- torque model must be calibrated first
- of big importance is the calibration of *Torque Transient* function
- calibration of C_VS_FIL for the filtered vehicle speed of the function *Vehicle Motion Determination*
- Vehicle Motion Determination (VHMD), Gear Detection (TRSM) and Torque Transient (DRVB) should be calculated first

Calibration flowchart

The sequence of calibration is described by the order in *Calibrated methods*.

Calibration method

Vehicle speed limitation controller

C_VS_MAX_VSL	C_VS_MAX_VSL is the control setpoint. Suggested initial data: C_VS_MAX_VSL = 205 km/h for USA vehicles Note: The whole function can be deactivated by setting the setpoint (C_VS_MAX_VSL) to 327.67 km/h (0x7FFFh).
C_VS_MAX_HYS_ON C_VS_MAX_HYS_OFF	Set ON value to ensure function is active sufficiently early to avoid an overshoot. Set the OFF value sufficiently lower to avoid "chatter" – rapid on / off switching of the function.  Suggested initial data: C_VS_MAX_HYS_ON = 2 km/h (i.e. function on when VS_HIGH_PRED > 203 km/h) C_VS_MAX_HYS_OFF = 5 km/h (i.e function off when VS_HIGH_PRED < 200 km/h)
C_N_MIN_VS_MAX	Set C_N_MIN_VS_MAX to a low value away from the VS_MAX engine speed area. Suggested initial data: C_N_MIN_VS_MAX = 1500 rpm
C_CRLC_AC_VEH_VS_MAX	*Filtered Vehicle Speed Acceleration* AC_VEH ->1st order Filter -> AC_VEH_MMV Set the filter constant (C_CRLC_AC_VEH_VS_MAX) to give a smooth, but still fast reacting AC_VEH_MMV in the area of VS_MAX. Check with hard load changes (0 to 100% pedal etc). Suggested initial data: C_CRLC_AC_VEH_VS_MAX = 0.2

ID_T_VS_MAX_PRED	*Vehicle Speed Prediction* VS_PRED = (AC_VEH_MMV * T_VS_MAX_PRED) + VS_HIGH_RES Calibrate ID_T_VS_MAX_PRED to give sufficient time for vehicle speed to be stabilised after function turned on, without having an overshoot. Suggested initial data: LDP_N_VS_VS_MAX = [16 20 26 32 40 55 105 220]; ID_T_VS_MAX_PRED = 1 second (perhaps more for lower gears)
IP_FAC_VS_LIM_P_L_DYN_VSL IP_FAC_VS_LIM_P_H_DYN_VSL IP_FAC_VS_LIM_I_L_DYN_VSL IP_FAC_VS_LIM_I_H_DYN_VSL	*Calibration of P and I control factor* Calibrate IP_FAC_VS_LIM_P_L(H)_DYN_VSL and IP_FAC_VS_LIM_I_L(H)_DYN_VSL to give good stable control of the vehicle speed. Check correct control is obtained in the following situations: entry to VS_MAX (also in downhill conditions etc.) gear changes at VS_MAX load changes (via pedal) at VS_MAX road load changes at VS_MAX (e.g. hills) It may be worth applying a empirical tuning method (e.g. Ziegler-Nichols), or at the least, checking the stability limits of the system (by further increasing P & I term), before finalising these values. Suggested initial data: IP_FAC_VS_LIM_I_L(H)_DYN_VSL = 4 Nm (/ (km/h).100ms) IP_FAC_VS_LIM_P_L(H)_DYN_VSL = 40 Nm (/ (km/h))
LC_VSL_ACT_MAN	Logical calibratible for long time activation/deactivation of the vehicle speed limitation function.
LC_VS_MAX_VSL_MAN	Logical calibratible for long time activation/deactivation of the vehicle speed limitation function in case LC_VSL_ACT_MAN ==1. LC_VS_MAX_VSL_MAN =1 then limitation always active LC_VS_MAX_VSL_MAN =1 then limitation inhibited
C_VS_THD_H_VSL	
C_VS_THD_L_VSL	
C_FAC_RAMP_VS_DEC_VSL	
C_FAC_RAMP_VS_INC_VSL

FUNCTION DESCRIPTION:

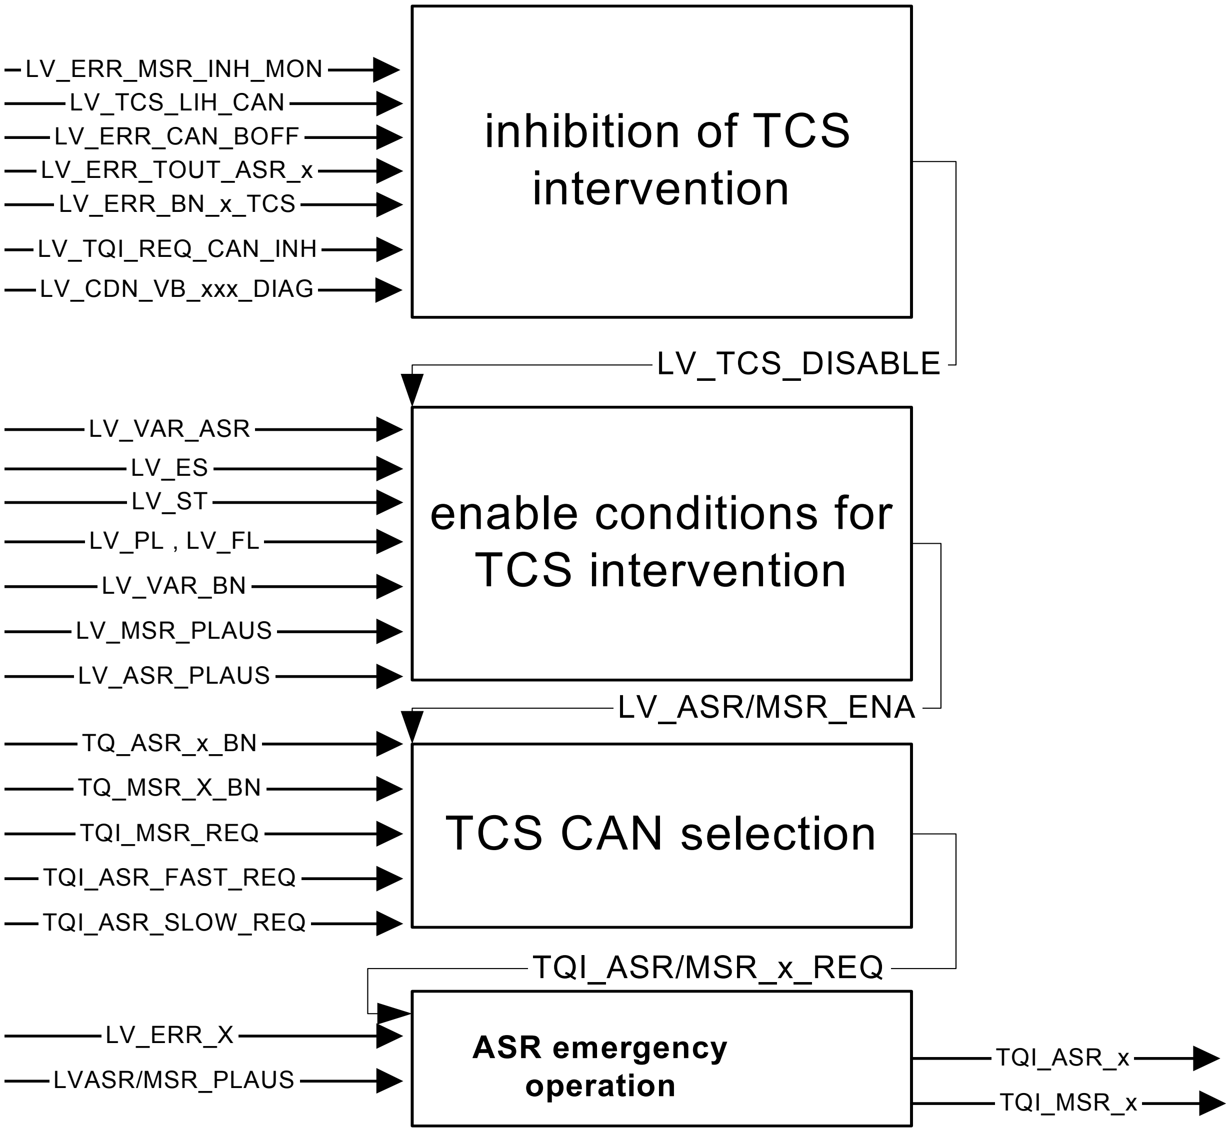
Traction control function avoids wheel spinning on e.g. icy surfaces by reducing the engine torque in addition to brake the wheel. The ECU permanently checks, if a probable traction control torque intervention request can be executed, by checking, if an error at one or several of the relevant components for torque intervention occurred (LV_TCS_DISABLE). If no error is recognized and an actual traction control request is received, a check is done, if at actual engine operating condition a torque intervention allowed (LV_ASR_ENA or LV_MSR_ENA). Both torque request values, for fast and slow torque intervention are handed over to relevant torque coordination functions to adjust the engine torque.

MSR function avoids the vehicle from skidding on e.g. icy surfaces by reducing the drag torque of the engine at trailing throttle and trailing throttle fuel cut off. For to reach a higher lateral stability of the wheels the indicated engine torque is increased to reduce wheel slip.

Signal flow diagram:



69.2.1 inhibition TCS intervention

FUNCTION DESCRIPTION:

If the EMS detects a safety relevant error at throttle the logical variable LV_TCS_DISABLE is set to 1 in order to indicate a static EMS error.

Application conditions:

Initialisation:	LV_TCS_DISABLE = 0 ; LV_TCS_DISABLE_CAN = 0 at reset
Recurrence:	10 ms
Activation:	every engine operating state
Deactivation:	-

Formula section:

```

```

69.2.2 Enable conditions for TCS torque intervention

FUNCTION DESCRIPTION:

General information:

Depending on the configuration and plausible torque interfaces an inc (MSR). or decreaced (ASR) torque intervention is possible.

The State STATE_TQ_TCS_PLAUS indicates the interrupted condition witch is responsible for enable Bit = 0. The [x] Value shows the HEX adress inside the Bitwise coded State.

Application conditions:

Initialisation:	LV_ASR/TCS/MSR_ENA = 0; *STATE_TQ_TCS_PLAUS = 0* at reset
Recurrence:	10 ms
Activation:	every engine operating state

Formula section:

```

69.2.3 Torque request CAN selection

FUNCTION DESCRIPTION:

If one of the TCS interventions enabled (LV_ASR/MSR_ENA = 1), the torque request is received from CAN and copied into TQI_ASR/MSR_FAST. The slow and fast path are different messages.
After LV_ASR/MSR_ACT changes back to 0, both TQI_ASR/MSR_FAST and TQI_ASR/MSR_SLOW become their maximum/minimum value again.

Application conditions:

Initialisation: **at reset** TQI_ASR_FAST_REQ = 1023.97 Nm
TQI_ASR_SLOW_REQ = 1023.97 Nm
TQI_MSR_FAST_REQ = 0 Nm
TQI_MSR_SLOW_REQ = 0 Nm

Recurrence: 10 ms
Activation: at LV_IGK = 1
Deactivation: -

Formula section:

```

endif
```

69.2.4 TCS intervention

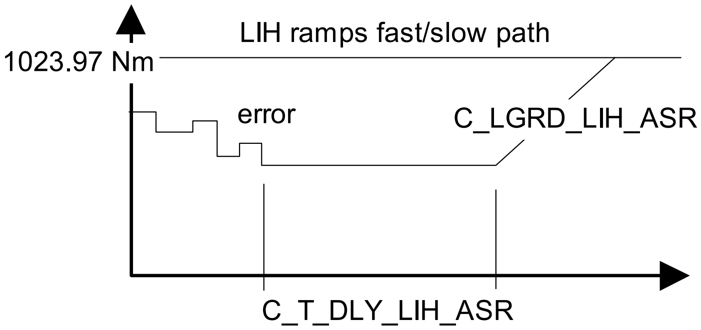
69.2.4.1 ASR intervention and emergency operation

FUNCTION DESCRIPTION:

If during an active TCS intervention an TCS error or an EMS error occurs, the current torque reduction is continued for the time C_T_DLY_LIH_ASR and then subsequently increased to TQI_ASR_FAST = TQI_ASR_SLOW = 1023,97 Nm using C_LGRD_LIH_ASR.

At transition from limp home condition active to passive after torque increase to TQI_ASR_FAST = TQI_ASR_SLOW = 1023,97 Nm at limp home operation the counter T_TCS_LIH_CTR is stopped and set to 0.

Signal flow diagram:



Application conditions:

Initialisation: at reset **or** at transition LV_IGK 0 --> 1
LV_ASR_LIH = 0
LV_ASR_ACT= 0
TQI_ASR_FAST = TQI_ASR_SLOW = 1023.97 Nm
T_ASR_LIH_CTR = 0

Recurrence: 10 ms

Activation: LV_IGK = 1

Formula section:

General information:

This function is used to control an open loop, 2- or 3-stage variable intake manifold. The output VIM_AV is generated to be used for the volumetric efficiency of the engine which is influenced by the VIM position. For a 2-stage variable intake manifold VIM_AV should be set to 0% / 100% in order to facilitate the application of the volumetric efficiency.
For test purpose at assembling line or workshop the VIM can be switched by a serial communication tool, if available (external adjustment).

Signal flow diagram:

Determination of the used range

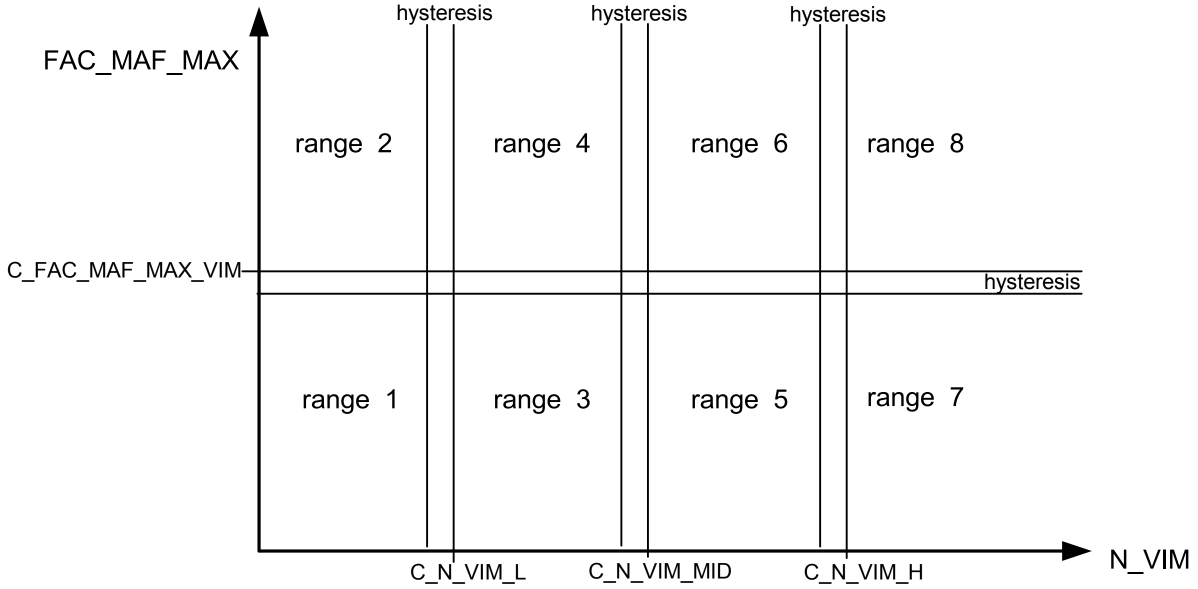

Diagram is valid if external adjustment is inactive.

Application conditions:

Initialisation: VIMPWM_1 = C_VIMPWM_PAS — at ECU initialisation
VIMPWM_2 = C_VIMPWM_PAS — and at function deactivation

VIM_AV = C_VIM_AV_1

T_OPEN_VIM_DEAC = C_T_OPEN_VIM_DEAC

all others: physical 0

at LV_IGK 0->1 or at reset : LV_VIM_RLS_TMP = 0

Recurrence: 10 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

Condition for release of VIM function

```
If      LV_ST_END = 1                                and
        C_VB_MIN_VIM  ≤  VB  ≤  C_VB_MAX_VIM             and
        ID_STATE_RLS_VIM = 1                         and
        LV_ERR_VIM_1 = 0                             and
        LV_ERR_VIM_2 = 0
then    LV_VIM_RLS  =  1
else    LV_VIM_RLS  =  0
endif
```

Corrected engine speed for VIM function:

```
If    LV_VIM_RLS  =  1
then          N_VIM  =  N * IP_FAC_N_VIM * IP_FAC_TIA_N_VIM
endif
```

Hysteresis for switching thresholds:

Valid for all 4 thresholds, C_N_VIM_L, C_N_VIM_MID, C_N_VIM_H and C_FAC_MAF_MAX_VIM: when increasing the input value (N_VIM / FAC_MAF_MAX) then switch at
input value > threshold ,
when decreasing the input value then switch back at
input value < threshold - hysteresis .

threshold	C_N_VIM_L / -_MID / -_H	C_FAC_MAF_MAX_VIM
hysteresis	C_N_VIM_HYS	C_FAC_MAF_MAX_VIM_HYS

Determination of desired flap position

i = 1...2

```
if(1)   LC_PWM_VIM_MAN = 1

70.2.1 Summary of all VIM diagnosis

FUNCTION DESCRIPTION:

This function shall summarize all VIM failures in one flag only for each VIM.

Description:

Application conditions:

Initialisation: reset **or** FMY reset **or** LV_IGK = 0 -> 1

LV_ERR_VIM_1 = 0

LV_ERR_VIM_2 = 0

Recurrence: 100ms

Activation: every ECU state

Formula section:

```
If LV_ERR_VIM_1_EL = 1 or LV_ERR_VIMPWM_1_FB = 1
Then LV_ERR_VIM_1 = 1
Else  LV_ERR_VIM_1 = 0
Endif

If LV_ERR_VIM_2_EL = 1 or LV_ERR_VIMPWM_2_FB = 1
Then LV_ERR_VIM_2 = 1
Else  LV_ERR_VIM_2 = 0
Endif
```

70.2.2 Diagnostic information from infrastructure

FUNCTION DESCRIPTION:

Description:

The DISA control unit is controlled by a PWM signal line driven by the ATIC 39. The driver can distinguish between three symptoms: ‘Short circuit to Vbatt’, ‘Short circuit to GND’ and ‘Open Load’.
This function reads the failure information (ERR_DIAG_VIM_1/2) from the infrastructure.

Application conditions:

Initialisation: reset **or** reset of failure memory **or** LV_IGK = 0 -> 1

CDN_DIAG_VIM_1_BAS = 0
CDN_DIAG_VIM_2_BAS = 0
ERR_DIAG_VIM_1 = 0
ERR_DIAG_VIM_2 = 0

Recurrence: 100ms

Activation: every ECU state

Formula section:

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_VIM_1/2 and diagnosis conditions CDN_DIAG_VIM_1_BAS/ 2_BAS received from the infrastructure:

Diagnosis conditions are set according infrastructure info.: CDN_DIAG_VIM_1_BAS/ 2_BAS
Failure symptoms are set according infrastructure info.: ERR_DIAG_VIM_1/2

70.2.3 Failure feedback recognition of VIM

FUNCTION DESCRIPTION:

If a failure is detected from the DISA control unit, a failure feedback is send to the ECU by pulling the signal line (interface ECU to the DISA control unit) to ground in a defined pattern. The time t_{low} is an identification for the failure.

Description:

For the recognition of the failure feedback the information, if a failure “short circuit to ground” is detected on the signal line between ECU and DISA control unit is used.

Application conditions:

Initialisation: at reset **or** FMY reset **or** LV_IGK = 0 -> 1

ERR_VIMPWM_1_FB = FFH
ERR_VIMPWM_2_FB = FFH

T_VIMPWM_1_FB = 0
T_VIMPWM_2_FB = 0

LV_VIMPWM_1_FB_VLD = 0
LV_VIMPWM_2_FB_VLD = 0

Recurrence: 100ms

*FB-Diagnosis has to be calculated **after** VIM-Powerstage-Diagnosis*

Activation:
LV_IGK = 1 **and**
LV_CDN_VB_MIN_DIAG = 1 **and**
N_32 ≤ C_N_MAX_ERR_VIM_FB **and**
LV_ERR_SPI_MPS = 0

Deactivation: not activation
at deactivation function is initialized one time

Formula section:

```
LV_VIMPWM_1_FB_VLD = 0

If      ERR_DIAG_VIM_1 = 2                  (SCG detected by Powerstage-diagnosis)
Then    T_VIMPWM_1_FB  =  T_VIMPWM_1_FB + 100ms
        ERR_VIMPWM_1_FB  =  FFH             (failure feedback possible)
    If  T_VIMPWM_1_FB > C_T_VIMPWM_1_FB_MAX
                                            (T_VIMPWM_1_FB out of range for FB)
    Then    ERR_VIMPWM_1_FB  =  00H
    Endif
Else
    If  C_T_VIMPWM_1_FB_MIN ≤ T_VIMPWM_1_FB ≤ C_T_VIMPWM_1_FB_MAX
    Then    failure feedback detected
            ERR_VIMPWM_1_FB  =  01H
            LV_VIMPWM_1_FB_VLD  =  1
    Else    no failure feedback possible
            ERR_VIMPWM_1_FB  =  00H
    Endif
    T_VIMPWM_1_FB  =  0
Endif
```

The same calculation is done for all ...VIMPWM_2...-outputs.

Calibration data:

70.2.4 Electrical diagnosis of VIM (LV_ERR_VIM_1 / 2_EL)

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result

FUNCTION DESCRIPTION:

General information:

The purpose is to diagnose the electrical signal from the two drivers which controls the VIM.

Description:

The driver can distinguish between three symptoms: ‘Short circuit to Vbatt’, ‘Short circuit to GND’ and ‘Open Load’.
The error detection algorithm in this function for “short circuit to GND” is respecting the status of the failure feedback recognition (ERR_VIMPWM_1_FB and ERR_VIMPWM_2_FB). The failure, detected by the HW, is delivered from the infrastructure ERR_DIAG_VIM_1 and ERR_DIAG_VIM_2.

Error-symptoms: are defined to this diagnosis function as following :

```
☐☐☐☐
 | | | └-> Short circuit to Vbatt          (= SYM_0)
 | | └---> Short circuit to GND            (= SYM_1)
 | └-----> Open load                        (=SYM_2)
 └-------> -                                (=SYM_3)
```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK 0 -> 1 or ECU reset)

LV_ERR_VIM_1_EL = 0

LV_ERR_VIM_2_EL = 0

CDN_DIAG_VIM_1_EL = 0

CDN_DIAG_VIM_2_EL = 0

ERR_SYM_VIM_1_EL = 0

ERR_SYM_VIM_2_EL = 0

LV_INH_DIAG_VIM_1_EL = 0

LV_INH_DIAG_VIM_2_EL = 0

Recurrence: 100ms

Activation: at every engine operating state

Formula section:

Diagnosis inhibition:

```
If      LV_IGK = 1                  and
        LV_CDN_VB_OBD1 = 1          and
        LV_ERR_SPI_MPS = 0
Then    LV_INH_DIAG_VIM_1_EL = 0
Else    LV_INH_DIAG_VIM_1_EL = 1
Endif

If      LV_INH_DIAG_VIM_1_EL = 0
Then
    Note: The failure symptoms ERR_SYM_VIM_1_EL and the diagnosis conditions
    CDN_DIAG_VIM_1_EL (raw values) shall be set according infrastructure information
    ERR_DIAG_VIM_1 and CDN_DIAG_VIM_1_BAS.

    If      Activation conditions are met for the NC_PSD_DLY_VIM_EL recurrence
    And     ERR_VIMPWM_1_FB = 00h
    Then

        { Additional diagnosis conditions }

        If  VIMPWM_1 < C_VIM_PWM_DIAG_MIN_SCP
                { condition that disables the SYM_0 detection }
        Then
              bit 0 of CDN_DIAG_VIM_1_EL  = 0     { Diagnosis of SCP is not possible }
        Endif
        If  VIMPWM_1 > C_VIM_PWM_DIAG_MAX_SCG
                { condition that disables the SYM_1 detection }
        Then
              bit 1 of CDN_DIAG_VIM_1_EL = 0      { Diagnosis of SCG is not possible }
        Endif
        If  VIMPWM_1 < C_VIM_PWM_DIAG_MIN_OC
            or VIMPWM_1 > C_VIM_PWM_DIAG_MAX_SCG
                { conditions that disable the SYM_2 detection }
        Then
              bit 2 of CDN_DIAG_VIM_1_EL  = 0     { Diagnosis of OC is not possible }
        Endif
    Else
        CDN_DIAG_VIM_1_EL = 0
    Endif
Else
        CDN_DIAG_VIM_1_EL = 0
```

Endif

The same calculation is done for all ...VIMPWM_2...-outputs.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_VIM_1/2_EL and ERR_DIAG_VIM_1/2.

```
ACTION_ERRM_FilterMulticondition    (IN<VIMPWM_1/2_EL>,
                                     IN<CDN_DIAG_VIM_1/2_EL>,
                                     IN<ERR_DIAG_VIM_1/2>,
                                     IN<C_ABC_INC_VIM_1/2_EL>,
                                     IN<C_ABC_MAX_VIM_1/2_EL>,
                                     OUT< LV_ERR_VIM_1/2_EL>,
                                     SYNCRONIZATION<CALL>)
```

This algorithm determines:

ERR_SYM_VIM_1/2_EL	(detected error symptom)
LV_ERR_VIM_1/2_EL	(Error flag for debounced error)
LV_CDN_DIAG_VIM_1/2_EL	(Diagnosis condition information)

70.2.5 Feedback diagnosis of VIM

FUNCTION DESCRIPTION:

General information:

If a failure is detected by the DISA control unit, a failure feedback is send to the ECU.

Description:

According the possible failure feedback from the DISA control unit (defined by ERR_VIMPWM_1/2_FB and LV_VIMPWM_1/2_FB_VLD), the diagnosis is managing the following failure: LV_ERR_VIMPWM_1/2_FB.

Error-symptoms of failure LV_ERR_VIMPWM_1/2_FB:

```
□□□□
│ │ │ └─> not used                              (= SYM_0)
│ │ └───> not used                              (= SYM_1)
│ └─────> not used                              (= SYM_2)
└───────> problem on DISA control unit detected (= SYM_3)
```

Application conditions:

Initialization: at reset **or** FMY reset **or** LV_IGK = 0 -> 1
at NVRAM error CTR_VIMPWM_1_EDGE and CTR_VIMPWM_2_EDGE are set to 0

Remark:

CTR_VIMPWM_1_EDGE and CTR_VIMPWM_2_EDGE are lifetime counter, the are not initialized at SW version change!
