28.28 Injection calculation (903M)

28.28.1 Injection calculation - injection buffer

The injection correction model is characterized by a delay and a 1st order filter. The delay should represent the gas transfer time through the intake manifold, the appending filter should represent the flow dilution behaviour.

NC_NR_CP_BUF	Size of the fuel buffer MFF_ADD_BUF The buffer size has to be determined according to the expected delay times between CPS and injection valves. [20]
LC_FLOW_CPS_CAL	Choice of recurence for injection buffer calculation. The injection buffer can be calculated with two different recurrencies: 20ms rsp. 40ms, LC_FLOW_CPS_CAL leading to a recurrency of 20ms. By selecting a slower update rate, higher gas delay times can be modelled with a given buffer size. [0]
IP_MFF_DLY_CP	These calibrations allow to characterize the intake manifold gas transfer between the canister purge valve and the cylinders inlet. *Method:* • Engine bench or Chassis dyno in stable engine load conditions • Canister purge strategy deactivated • Change the injection time using the bench function (C_TI_AS) • For different engine load (N variation) measurement of the gas transfer duration from the injector valve change to lambda deviation. • The time delay (valve to injector) is the difference between the map IP_T_DLY_CP (time between the valve and the lambda sensor) and the previous measurement. • The calibration values are the time measured divided by the calculation recurrence of MFF_BUF_CP. • The recurrence is 20 or 40ms,

<table>
<tr><td></td><td>depending on calibration.
<table><tr><td>N_32</td><td>[1/min]</td><td>736</td><td>1600</td><td>1824</td><td>2464</td><td>4192</td><td>4992</td></tr><tr><td>IP_MFF_DLY_CP</td><td>[-]</td><td>14</td><td>13</td><td>12</td><td>10</td><td>7</td><td>6</td></tr></table></td></tr>
<tr><td>**IP_CRLC_MFF_BUF_CP**</td><td>The dilution behavior through the intake manifold is characterized by a 1st order filter. The filter coefficient is defined such as the exhaust lambda variations are the smallest from purging change.
Method:,
• IP_MFF_DLY_CP has to be tuned before.
• IP_CRLC_MFF_BUF_CP minimizes the lambda variation when canister fuel flow is controlled by the purge function.
• Engine bench or Chassis dyno in stable engine load conditions
• Charcoal canister half loaded
• Canister purge strategy activated in MAX_PURGE mode (CL known)
• Opening/closing purge valve set by changing the purge target (IP_FUEL_FLOW_MAX_CP)
For different engine load (N variation) measurement of the lambda variation (Linear sensor) due to purge target change. Adjust IP_CRLC_MFF_BUF_CP value before each change in order to have no exhaust lambda peak (lean or rich).
<table><tr><td>N_32</td><td>[1/min]</td><td>736</td><td>1600</td><td>1824</td><td>2464</td><td>4192</td><td>4992</td></tr><tr><td>IP_CRLC_MFF_BUF_CP</td><td>[-]</td><td>0,023</td><td>0,039</td><td>0,039</td><td>0,039</td><td>0,063</td><td>0,066</td></tr></table></td></tr>
</table>

28.28.1.1.1 EVAC control - Common submodules

C_CL_MMV_REQ	When the canister load is bigger than the threshold C_CL_MMV_REQ the canister purge function does not be interrupted by another function (OBD2.....). The calibration value is defined by

	maximum canister load with butane. Take care this calibration value does not prevent the OBD2 and adaptive functions during SHED test or standard driving cycle when the charcoal canister is full loaded. [0,5]
C_T_DLY_REQ_CP	Time to set LV_T_DLY_REQ_CP The time C_T_DLY_REQ_CP authorizes ODB2 diagnosis activation even C_CL_MMV_REQ is set. When this time duration is elapsed the canister purge load takes highest priority. This time duration is refined in accordance with the standard driving cycle.  [120 s]

28.28.2 EVAC control - Application Incidences (902C)

C_STATE_CONF_CAT_CP	[0]
C_STATE_CONF_TLDV_CP	Configuration byte for closing speed of canister purge before catalyst diagnosis / leak detection diagnosis are started. With these constants, the closing speed in case of requests from catalyst diagnosis or leak detection can be configured. Four values are possible: 0-3. "0" means no reaction on the requests, i.e. no closing of the canister purge valve. 1-3 lead to a closing of the CPS, "1" with high speed depending on the speed correction factor [0]

28.28.3 Injection calculation - torque correction in stratified

IP_MFF_MIN_CP_S	Canister purge margin on the fuel flow minimum value in stratified mode. This margin is used to prevent the minimum injection time in altitude or on deceleration. [5 mg/stk]
IP_FAC_TQI_CP	Factor used to convert a fuel mass in a torque. FAC_TQI_CP is a decimal factor which permit to convert a fuel mass in a torque. Because of the different resolutions of TQI_ADD_CP and MFF_CPS, the conversion (1389 mg/tdc / 1024 Nm) has to be taken into account by the calibration of FAC_TQI_CP. That means, if you want MFF_CPS = TQI_ADD_CP, then you have to calibrate FAC_TQI_CP to 0.73 (1024/1389) and not to 1. *Method:* • On engine dyno • On a reference point (N, TQI_SP_S, lambda) • Stratified mode • Open the valve with a full loaded canister (c_cppwm_as and lc_cppwm_as) • Decrease the fuel injected to go back to the reference point [0,67]

28.29 Torque reserve for canister purge at idle

LC_TQ_ADD_CP_INH	inhibit switch [1]
IP_TQ_ADD_CP	If not used set to [0 Nm]
C_CRLC_TQ_ADD_CP	Deactivation switch, filter constant and base map for canister purge torque reserve at idle. By increasing the engine load without increasing the torque output, a higher purge rate is possible due to the increase of engine's fuel demand (for a given purge fuel ratio). The torque reserve is only applied in MAX_PURGE and idle speed depending on canister load CL_MMV. *Method* : • idle speed condition • no additional load or torque reserve (cooling fan, air conditioning…) • use the map ip_tq_n_add_is to change the torque reserve (ref chapter idle speed) • Using the engine roughness criteria, measure the engine stability when you change torque reserve. Make measurements for several torque reserve and record the injection time and the spark advance. [0,5]

28.30 Canister Purge Valve Adaptation

Canister Purge Valve Adaptation Purpose of the canister purge solenoid (**CPS**) is to purge the tank venting charcoal filter by opening a pipe from the filter to the engine manifold; so the filter's CH-load is desorbed by fresh ambient air and sucked into the engine. For countinuous control of the purge airflow the CPS is opened pulse wide modulated (PWM).

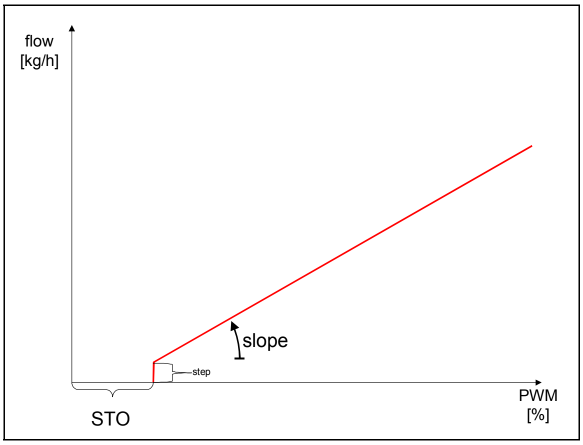

Figure: characteristic line of CPS

Due to future legislation the CH-emissions of vehicles have to be cut down; one task is to accellerate purge. To keep the purge airflow as high as possible without disturbing the engine the CPS has to be controlled as accurately as possible. This means that the engine controller (which is also responsible for canister purge) has to „know" as much as possible about any car's individual CPS. The most important parameter is the start-to-open-point (**STO**); a dead time between switching on electric power and opening of the CPS; as visible in the figure beside. If the opening time (depending on PWM and frequency) is below this dead time the CPS will never open. The parameter STEP is presently assumed to be quiet low and therefore neglected while SLOPE is estimated to be almost constant as specified.

Up to now an average STO has been extimated, but expected future developments like high-flow-CPSs or the need for a better performance of canister purge induce an increasing demand for an exactly measured STO.

To measure the STO the CPS is ramp-opened until a decreasing lambda-value (caused by the purged HCs) is detected. For accurate measuring the HC flow has to be as high as possible without disturbing the engine. So the adaptation frequency is calculated depending on canister load (CL) and calibrated values. A too low CL interdicts adaptation.

Boundary conditions needed to start adaptation:

STATE_CP	3
LV_HOM_ACT	1
LV_CL_CLC_VLD	1
N	between C_N_MIN_CPS_AD and C_N_MAX_CPS_AD
T_AST	above C_T_ST_CPS_AD
LV_CPS_AD_INH	0
TQI_AV	between C_TQI_AV_MIN_CPS_AD and C_TQI_AV_MAX_CPS_AD
CL_MMV	above C_CL_MIN_CPS_AD
LV_CP_CLOSE_REQ	0
LC_CPS_AD_CHK	0 This flag (=1) is to start the function overriding **all** application conditions. If the function is started using this flag it will not stop until a sufficient lambda-deviation is detected (=STO learned). When function is going into wait-state after lerning, set flag back to 0. **Attention !** If no sufficient lambda-deviation is detected (i.e. if CL is too low) the CPS will be opened up to 100% PWM and stay there until the flag is reset.
FAC_LAM_CP	to take from engine model

Required for application work:

- Charcoal-filter with CL about 1,5 (75%)
- Min-flow-CPS
- Max-flow-CPS

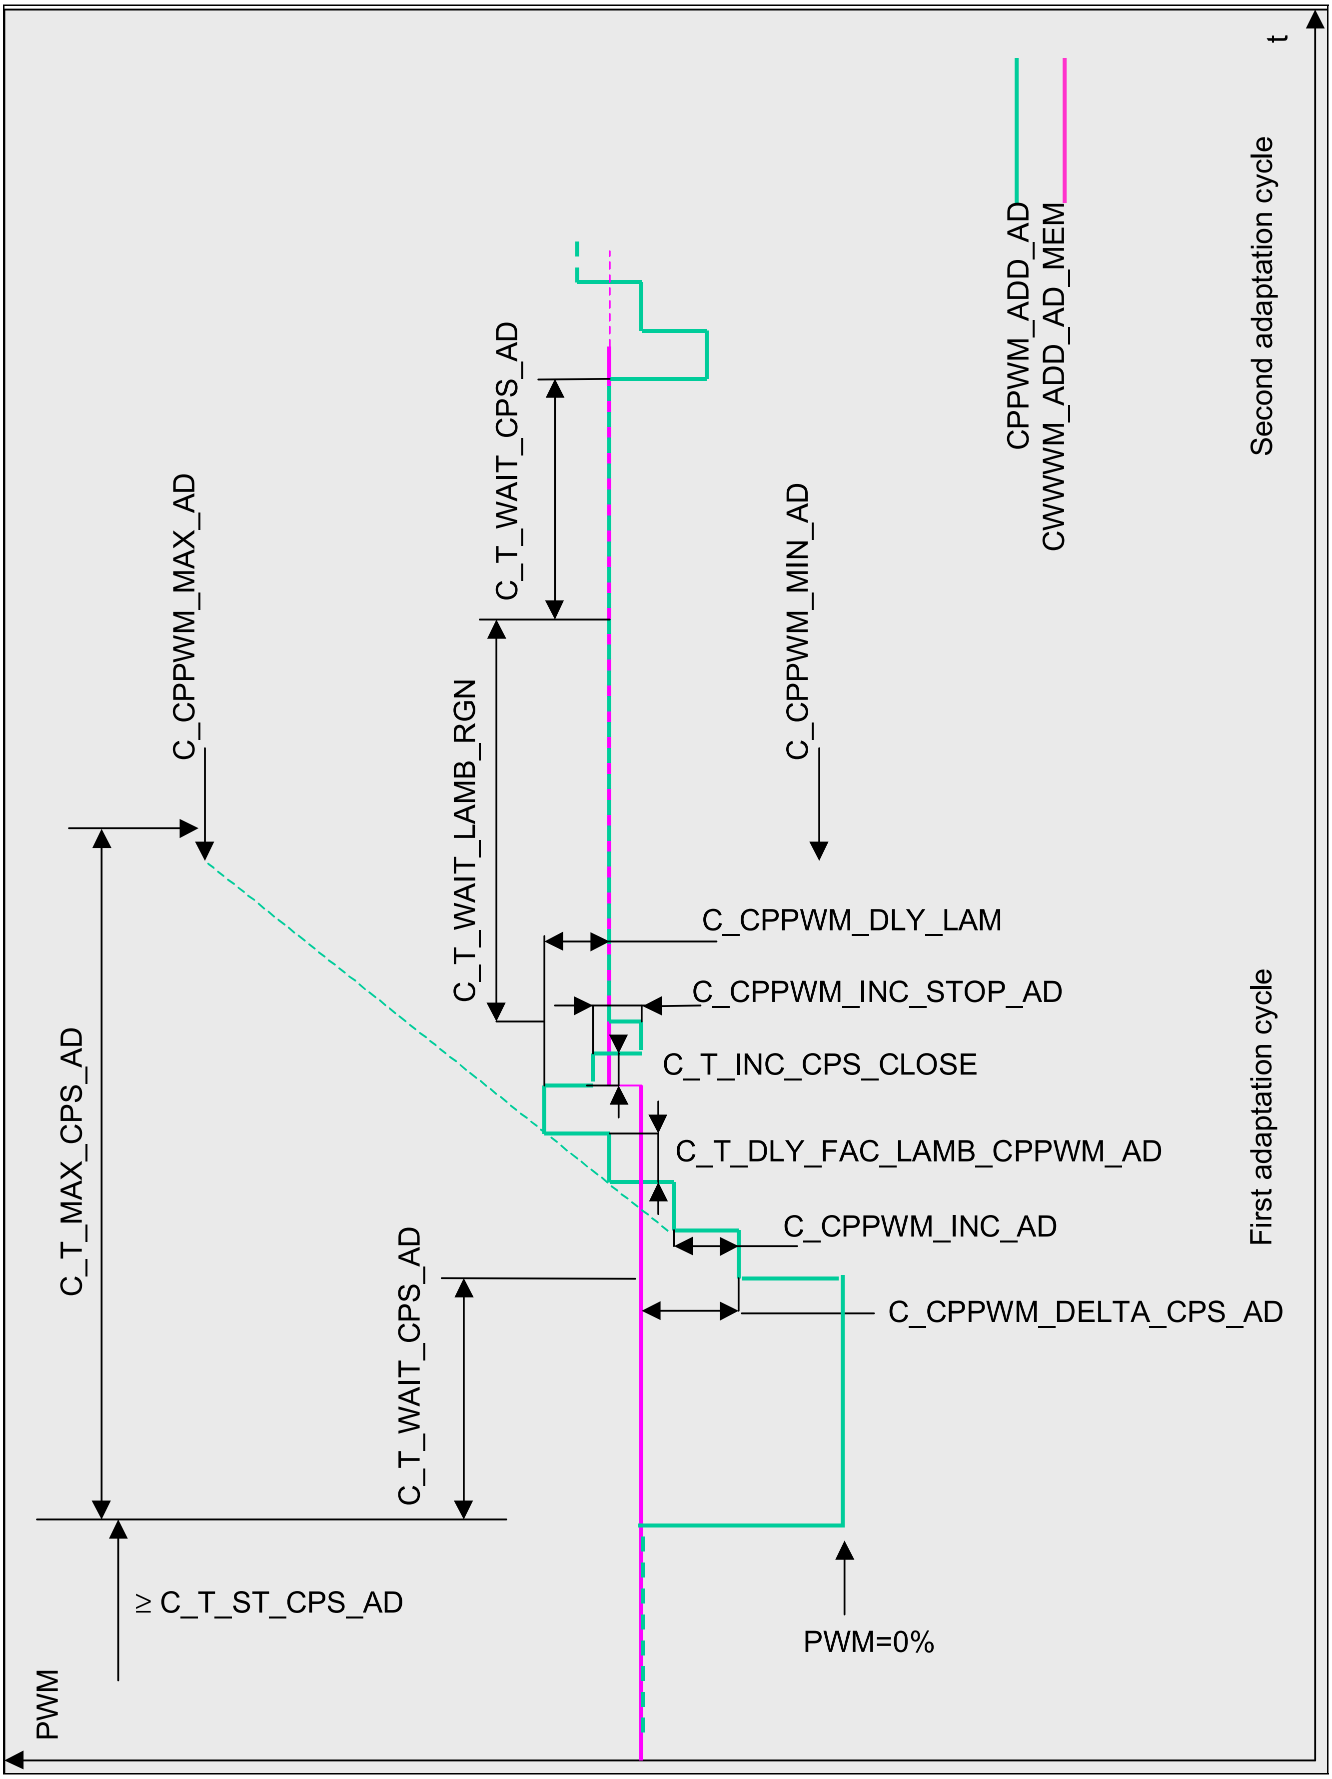

Figure: Adaptation cycle with calibraion values

Calibration method:

C_FRQ_MIN_CPS_AD	Minimum working frequency of CPS or default frequency of fixed-frequency-systems**; see CPS spec** or try 10 [Hz]
C_FRQ_MAX_MEC_CPS	Maximum allowed frequency of CPS**; see CPS spec** or try 30 [Hz].
C_FAC_LAMB_DELTA_MIN_CPS_AD	Minimum detectable lambda deviation caused by adaptation; **just above lambda-noise**. Watch FAC_LAMB at stable idle to estimate lambda noise or try 3 [%] as default.
C_FAC_LAMB_MAX_CPS_AD	Maximum allowed lambda deviation during adaptation without disturbing the engine; see engine or controller SPEC or: At low temperature (“cold morning”) open CPS stepwise, watch FAC_LAMB and see when engine is disturbed (sound/speed/vibrations).
C_CPPWM_AD_RATIO	Weighting factor of newly learned STO against old memorized value for calculation of new memorized value. 0.1 should be a useable default value. 1 can be used for monitoring during application work. This value acts like a “damper” against a badly learned STO.
C_CPPWM_DELTA_AD	Difference between PWM at start of adaptation and old memorized STO value to make sure adaptation starts below current STO. Should cover the measuring diffusion and a (smaller) possible drift of STO. This value also assures that after a “too high” learned STO the function will “climb back down”. Must be less than C_CPPWM_MIN_AD-C_CPPWM_DLY_LAM to avoid negative PWM value.Default: 5 [%]
C_CPPWM_DLY_LAM	Assuming the stepwise opening of CPS has continued between STO and lambda reaction (C_T_INC_AD < real physical time delay of C_T_DLY_FAC_LAMB_CPPWM_AD) this subtractive value compensates the PWM difference. Start application work with 0 [%]. Adapt using fully loaded canister at minimum frequency and watch FAC_LAMB. If learned STO (CPPWM_ADD_AD_MEM) is always higher than STO at beginning lambda deviation set the difference.
C_CPPWM_INC_AD	PWM increment for CPS opening during adaptation; depends on demanded function resolution and lambda regulation delay time. Has to be less than C_CPPWM_DELTA_AD. Default 1[%].
C_CPPWM_INC_STOP_AD	PWM icrement for CPS closing. Default 1[%].
C_CPPWM_MAX_AD	Maximum plausible STO-value at FRQ_MIN. See CPS spec or use 40[%] at 10Hz (= 40ms)

	as default.
C_CPPWM_MIN_AD	Minimum plausible STO-value at FRQ_MIN. Use 1[%] at 10Hz (= 1ms) or see CPS spec. Must be above (C_CPPWM_DELTA_AD to avoid negative PWM at next adaptation. Must be equal or higher than C_CPPWM_DLY_LAM+C_CPPWM_DELTA_AD
C_CYCNR_CPS_AD	Number of successful adaptations aimed during driving cycle. Default about 2 [-].
C_N_MAX_CPS_AD	Upper threshold of engine speed for adaptation. Default upper threshold of idle window; see engine spec or use 1200 [min^-1] as default.
C_N_MIN_CPS_AD	Lower threshold of engine speed for adaptation. Default lower threshold of idle window; see engine spec or use 600 [min^-1] as default-
C_T_DLY_FAC_LAMB_CPPWM_AD	Delay time between fuel purged into manifold and change of FAC_LAM value. Depends on engine speed and design. 1 [sec] may be a useable default value. After opening step of CPS this time passes until check for lambda deviation.
C_T_INC_CPS_CLOSE	Time increment for CPS closing, use 0,2 [sec] as default.
C_T_MAX_CPS_AD	Maximum allowed duration of one adaptation cycle. Try default 30 [sec]. As the figure shows, this time has to cover C_T_WAIT_CPS_AD and the ramp from C_CPPWM_MIN_AD-C_CPPWM_DELTA_AD to C_CPPWM_MAX_AD. So: C_T_MAX_CPS_AD≥ (C_CPPWM_MAX_AD- C_CPPWM_MIN_AD+ C_CPPWM_DELTA_AD)* C_T_INC_CPS_AD+ C_T_WAIT_CPS_AD
C_T_ST_CPS_AD	Minimum time between start engine and adaptation to ensure stable engine conditions. Default 60 [sec].
C_T_AST_DEAC_CPS_AD	Maximum time between start engine and end or abort of adaptation. If set to maximum value of T_AST this condition is disabled. Enter default 10000 [sec] to disable.
C_T_WAIT_CPS_AD	Delay time between function start and begin of CPS opening. Can be 0 [sec] if no delay demanded by application engineer.
C_T_WAIT_LAMB_RGN	Delay time after adaptation to regain stable conditions of lambda regulation. Try 10 [sec] and watch FAC_LAMB.
C_TQI_AV_MAX_CPS_AD	Upper threshold of engine torque for adaptation. Default upper threshold of idle window; see engine spec or use 40 [Nm]

C_TQI_AV_MIN_CPS_AD	Lower threshold of engine torque for adaptation. Default lower threshold of idle window; see engine spec or use 60 [Nm]

For first calibration or fixed frequency adaptation the frequency variation has to be terminated as follows:

C_FRQ_CLC_1_CPS_AD	=0
C_FRQ_CLC_2_CPS_AD	=C_FRQ_MIN_CPS_AD
C_CL_MIN_CPS_AD	Try as default: C_CL_MIN_CPS_AD=1 Use full canister and start purge to get current CL.Start adaptation with min-flow-CPS to get FAC_LAMB at STO. C_CL_MIN_CPS_AD=CL * C_FAC_LAMB_DELTA_MIN_CPS_AD/ FAC_LAMB

For frequency-variation:

The reliability of frequency calculation depends not only on it’s own calibration but also on the precision of CL-detection which - vice versa – depends on CPS-adaptation. Therefore an iterative calibration is recommended:

5. Complete calibration as described below.
6. Wait for purge to detect CL again.
7. Recalibrate C_CL_MIN_CPS_AD, C_FRQ_MAX_CPS_AD, C_FRQ_SLOP_CPS_AD.
8. If a significant difference appears: Start again with step 2.

Use canister with CL about 1,5 (=75%).

Mount max-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate:

$$\mathrm{FRQ\_MAX\_CL\_MAX} = \frac{\mathrm{C\_FRQ\_MIN\_CPS\_AD} \times \mathrm{C\_FAC\_LAMB\_MAX\_CPS\_AD} \times 2}{\mathrm{FAC\_LAMB} \times \mathrm{CL}}$$

FRQ_MAX_CL_MAX has to be ≥ C_FRQ_MIN_CPS_AD !

Mount min-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate:

$$\mathrm{FRQ\_MIN\_CL\_MAX} = \frac{\mathrm{C\_FRQ\_MIN\_CPS\_AD} \times \mathrm{C\_FAC\_LAMB\_DELTA\_MIN\_CPS\_AD} \times 2}{\mathrm{FAC\_LAMB} \times \mathrm{CL}}$$

C_CL_MIN_CPS_AD	Crossing of FRQ_MIN-hyperbola and C_FRQ_MAX_MEC_CPS-line. Mount min-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL. Calculate: C_CL_MIN_CPS_AD=CL * C_FRQ_MIN_CPS_AD / C_FRQ_MAX_MEC_CPS*

	C_FAC_LAMB_DELTA_MIN_CPS_AD/ FAC_LAMB Or try as default: C_CL_MIN_CPS_AD=1

C_FRQ_CLC_1_CPS_AD, C_FRQ_CLC_2_CPS_AD	The figure below shows two hyperbolas: The mimimum frequency required to generate a detectable FAC_LAMB and the maximum allowed frequency to not disturb the engine. The CL-range for adaptation is limited by the point where the minimum required frequency is getting higher than the maximum possible working frequency of the CPS.  Formula for hyperbola calculation: $FRQ = \frac{C\_FRQ\_CLC\_1\_CPS\_AD}{CL}$ For precise measuring the working frequency will always be as high as possible (FRQ_MAX or C_FRQ_MAX_MEC_CPS). For individual tuning a second constant allows to move the hyperbola: $FRQ = \frac{C\_FRQ\_CLC\_1\_CPS\_AD}{CL} + C\_FRQ\_CLC\_2\_CPS\_AD$ Use canister with CL about 1,5 (=75%). Mount max-flow-CPS and start adaptation. Get FAC_LAMB at STO. Start purge to get current CL during RAMP_OPEN. Calculate: C_FRQ_CLC_1_CPS_AD=CL*C_FRQ_MIN_CPS_AD*C_FAC_LAMB_MAX_CPS_AD / FAC_LAMB

	Necessary condition, check: C_FRQ_CLC_1_CPS_AD/2+ C_FRQ_CLC_2_CPS_AD ≥ C_FRQ_MIN_CPS_AD Fine tuning: Move frequency hyperbola by changing C_FRQ_CLS_2_CPS_AD or stretch/compress by changing C_FRQ_CLC_1_CPS_AD

AMP_MES			

General information:

The function “check filler cap during DC” is part of the tank leakage detection package.

The function controls the conditions, which are responsible , to enable a check of open filler cap. Is such a condition available, a request LV_ENA_CHK_FUC_ROUGH_LEAK_MES can be set and a rough leak measurement shall be enabled.

The trigger for the check of open filler cap can be either a valid refueling or a given rough leak suspicion. Are the conditions available, which enable a check, that means low acceleration and low oscillation of the fuel tank level, then a check will be done, if a minimum speed of the vehicle is reached.

A test request is still present for a calibratable number of driving cycles. In case of a detected open filler cap, a calibratable number of tests can be done, after a indication lamp in the instrument cluster was set.

29.2.1 Rough leak request due to check filler cap during DC

General information:

Conditions to set the test request LV_ENA_CHK_FUC_ROUGH_LEAK_MES:

- ☐ A valid refueling is given. Setting of the nv-bit LV_ENA_CHK_FUC_REFU. The resetting of this logical value is done, if a CFC-test has finished.
- ☐ Availability of a suspected rough leak from the tank leakage detection function. The request is stored until a CFC-test has finished.
- ☐ Setting of the test request, if the vehicle speed is greater or equal than a threshold.

Conditions to reset the test request LV_ENA_CHK_FUC_ROUGH_LEAK_MES:

- ☐ Vehicle speed is lower than a threshold
- ☐ Powerful acceleration of the vehicle
- ☐ high ambient pressure deviation

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: in case of reset or LV_IGK = 0 → 1:

AMP_CHK_FUC = AMP_MES, all other variables to 0

Restore out of the NV-memory:

LV_ENA_CHK_FUC_REFU, LV_ROUGH_LEAK_SUSP_CHK_FUC
LV_CTR_DC_CHK_FUC

In case of clear FMY:

All variables to 0

AMP_CHK_FUC = AMP_MES

Recurrence: 100 ms

Activation: LC_CONF_DMTL = 1, during all ECU states

Formula section:

```
If    LV_ROUGH_LEAK_SUSP = 1                  AND          // suspected rough leak

29.2.2 Decision of check filler cap open or closed

General information:

Conditions to set LV_CHK_FUC_END:

- ❑ Number of the maximum DC are reached. This condition is reached, if the engine stops C_CTR_DC_ENA_CHK_FUC_MAX times, indicated by T_AST. The number of the counted cycles is reseted, if the filler cap test has ended or in case of the error “open filler cap”.
- ❑ Cfc test successfully ended, to be recognized by the cycleflag of the rough leak test in common with no suspected rough leak
- ❑ End of the test with C_CTR_CHK_FUC_OPEN_MAX times open filler cap.

Conditions to reset LV_CHK_FUC_END:

- ❑ By initialisation of the ECU
- ❑ With recognition of a new valid refueling

Conditions to set LV_CHK_FUC_OPEN

- ❑ Cycle flag of the rough leak measurement

- ☐ Suspected rough leak

Condition to reset LV_CHK_FUC_OPEN

- ☐ End of check filler cap test

FUNCTION DESCRIPTION:

29.2.3 Control of the check filler cap lamp in the instrument cluster

General information:

Forming of the lamp control by LV_CHK_FUC_OPEN and the stored value LV_CHK_FUC_OPEN_ACT. If an opened filler cap is recognized and the vehicle speed is higher than a threshold for a calibratable time, the indication lamp will be set for a calibratable time. To prevent a setting of the lamp after the lamp has burned once, this information is stored in LV_CHK_FUC_OPEN_ACT. This bit shall be reseted after the end of the check filler cap test.

FUNCTION DESCRIPTION:

Application conditions:

FUNCTION DESCRIPTION:

General Information:

The diagnosis is used for the functional test of the CP solenoid. Therefore the CPS is diagnosed via its effects on the engine.

The functional check of the CPS consists of 3 steps:

- Step 1: based on the ACF load degree
- Step 2: based on
    - the engine speed change at IS,
    - the deviation of lambda-controller and
    - the measured MAP before and during CPS-opening
- Step 3: based on the difference between the measured air mass flow before and during a CPS opening

If the CPS has been detected to be OK within a step or as not OK after step 3 then the function is exited irreversibly until the next engine start.

The steps 1, 2 and 3 are processed successively, i.e. the next step may only be performed if the preceeding one has not been detected as OK. The only exception is step 1. Step 1 may also be performed parallel to step 2 and 3, which means:

After step 1 has been processed once and CPS has not been detected as OK then (if enable conditions are fulfilled) it is proceeded with step 2 and at the same time calculation of step 1 is started again. Calculation of step 1 is done until CPS is detected as OK within one of the steps (1, 2 or 3) or until CPS is dectected as definitely not OK by the end of step 3.

If the CPS is detected to be not OK after all 3 steps have been passed (end of step 3), then the error is set.

The complete diagnosis “functional check CPS” is performed only once per driving cycle.

Exception:

Activation of functional check CPS via EOL-test (LV_EOL_CPS 0 -->1):

Through the EOL-test the functional check CPS can be triggered several times per engine operation.

The diagnosis is addressed via the serial interface. Only STEP_2 will be performed.

For general enable conditions of the diagnosis see chapter "Appl. Inc. Functional Check CPS".

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                               (= SYM_0)
 │ │ └───> -                               (= SYM_1)
 │ └─────> CPS – EOL-error                 (= SYM_2)
 └───────> CPS – plausibility-error        (= SYM_3)
```

Application conditions:

Initialisation: 1) on transition LV_IGK OFF→ ON or reset:

All variables from output-data-section have to be initialized with zero:

except:
STATE_DIAGCPS_OLD = STEP_1
STATE_DIAGCPS = STEP_INIT
T_DIAGCPS_DLY = C_T_DIAGCPS_DLY
T_CL_MMV_DIAGCPS = C_T_CL_MMV_DIAGCPS
T_CL_MMV_DIAGCPS_2 = C_T_CL_MMV_DIAGCPS_2
CL_MMV_SAE = CL_MMV_SAE
SUM_DIAG_DIAGCPS_SAE =
SUM_DIAG_DIAGCPS_SAE
MAF_DIAGCPS_SAE = MAF_DIAGCPS_SAE
MAF_DIAGCPS_THD_SAE = MAF_DIAGCPS_THD_SAE

2) on clearing failure memory

All variables from output-data-section have to be initialized with zero:

except:
STATE_DIAGCPS_OLD = STEP_1
STATE_DIAGCPS = STEP_INIT
T_DIAGCPS_DLY = C_T_DIAGCPS_DLY
CL_MMV_SAE = FFFFH
SUM_DIAG_DIAGCPS_SAE = ~~FFH~~ 0H
MAF_DIAGCPS_SAE = 0
MAF_DIAGCPS_THD_SAE = FFFFH
T_CL_MMV_DIAGCPS = C_T_CL_MMV_DIAGCPS
T_CL_MMV_DIAGCPS_2 = C_T_CL_MMV_DIAGCPS_2

Recurrence: 100 ms

Activation: LV_DC = 1

Deactivation: LV_DC = 0

Conditions for End-of-line (EOL) - Test:

Description:

This is to secure that any time the functional check CPS is activated via EOL-Test :

- the functional check starts right from the beginning again
- only those steps of the functional check CPS are performed regarding the EOL-Test
- the diagnosis results of the functional check (issued via serial interface) are the results from the EOL-Test only

Formula section:

Detection of EOL-Request:

```
IF          (LV_EOL_CPS(k-1) = 0 AND LV_EOL_CPS(k) = 1)
THEN        LV_EOL_CPS_INI = 1
            STATE_DIAGCPS = STEP_INIT
ELSE        LV_EOL_CPS_INI = 0
ENDIF
```

Detection of OPM-Change:

```
IF     MAP_DIP_SP_MMV > C_MAP_DIP_SP_MMV_DIAGCPS
THEN   LV_OPM_AV_DIAGCPS_P_THR = 1       //GD, T-GD
ELSE   LV_OPM_AV_DIAGCPS_P_THR = 0       //UGD
ENDIF

IF     STATE_DIAGCPS = STEP_2       or
       STATE_DIAGCPS = STEP_3
THEN
   IF    (LV_OPM_AV_DIAGCPS_P_THR k ! =      // UGD <-> T- GD or GD
         LV_OPM_AV_DIAGCPS_P_THR k-1)
   THEN      LV_OPM_AV_CNG_DIAGCPS = 1
             STATE_DIAGCPS = STEP_INIT
   ELSE      LV_OPM_AV_CNG_DIAGCPS = 0
   ENDIF
ENDIF
```

The functionality in Step 1 which consists in counting the time during which the CL_MMV is above the threshold C_CL_MMV_DIAGCPS, needs to be reset in the following cases:

- transition between UGD/GD happens
- the system is in open loop (CL_MMV frozen)
- the canister load model is active (CL_MMV not reliable)

```
IF      (LV_OPM_AV_DIAGCPS_P_THR $_k$ ! =
         LV_OPM_AV_DIAGCPS_P_THR $_{k-1}$)        OR
        LV_CP_CLL = 0                            OR
        LV_CL_MDL_ACT = 1                        OR
        LV_CL_MMV_CAL_ACT = 0
        THEN  T_CL_MMV_DIAGCPS = C_T_CL_MMV_DIAGCPS
              T_CL_MMV_DIAGCPS_2 = C_T_CL_MMV_DIAGCPS_2
ENDIF
```

```

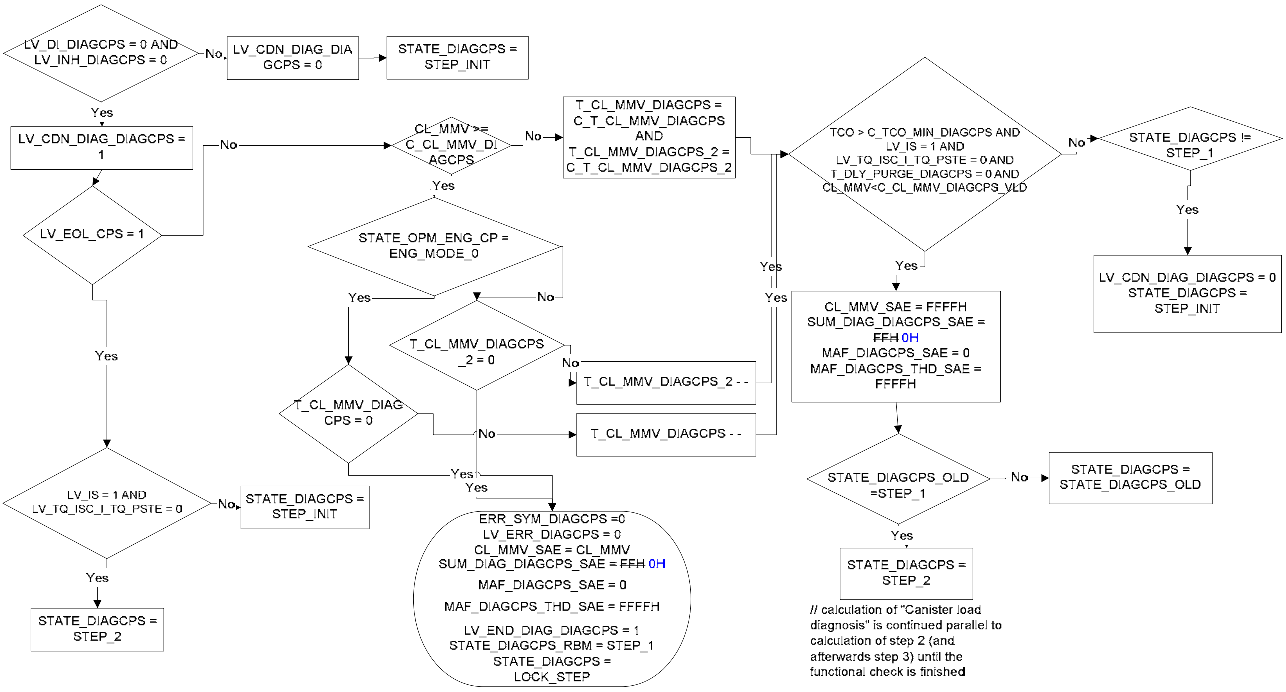
Canister load diagnosis

Description:

Functional check of the CPS based on the ACF- load degree. The “Canister Load diagnosis” is calculated permanently until the functional check CPS is finished (LV_END_DIAGCPS = 1).

Overview:



// calculation of "Canister load diagnosis" is continued parallel to calculation of step 2 (and afterwards step 3) until the functional check is finished

Formula section:

```
IF(1)       LV_DI_DIAGCPS = 0          AND
            LV_INH_DIAGCPS = 0
THEN(1)     LV_CDN_DIAG_DIAGCPS = 1

STEP 2: N-DIF-/LAM-/MAP-Diagnosis

Description:

In step 2, the CPS is evaluated based on the engine speed change (throttled mode), MAP change (unthrottled mode) and Lambda deviation at IS. To this effect, the CPS is opened for a short time and the engine speed monitored for a certain period.

After step 2 has been enabled for the first time, it is requested during each IS phase. This is repeated as long as a result has been reached in step 2. The function is not bound to one IS phase, but can be distributed to several IS phases.

STEP 3: MAF-DIF Diagnosis

Description:

If the functional check is not recognized as OK via step 1 and via step 2, but as not OK via both steps, then step 3 is requested.

In step 3 the CPS is considered on the basis of the measured mass air flow before and during a CPS opening phase.

FUNCTION DESCRIPTION:

General information:

The functional check is used for the functional test of the CP solenoid which means that the CPS is diagnosed via its effects on the engine.

There are many errors which make it necessary to stop the functional check CPS when they occure. Therefore a diagnosis has to be made whether the functional check can be enabled or not.

If LV_INH_DIAGCPS = 0 and LV_DI_DIAGCPS = 0 then the functional check is enabled.

If the bit LV_INH_DIAGCPS = 1 is set through one of the errors listed below, then the functional check is exited irreversibly until the next engine start.

If the bit LV_INH_DIAGCPS=0 and LV_DI_DIAGCPS=1 then the functional check is exited reversibly until LV_DI_DIAGCPS = 0 (recurrence 100 ms).

If one of the OBD errors ocurs as mentioned in the formula section the RBM of the functional check CPS diagnosis is inhibited by LV_INH_DIAG_RBM_DIAGCPS = 1.

Application conditions:

Initialisation: at every LV_IGK = 0→1 and reset all variables are initialized with 0

Recurrence: 100 ms

Activation: LV_DC = 1

Deactivation: LV_DC = 0

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_DIAGCPS	V/O	0...FFH	0...255	1	[-]
Interface of DIAGCPS monitor with the Rate-Based Monitoring statistics					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_RBM_DIAGCPS	

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the DIAGCPS monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_DIAGCPS data.

Within STATE_RBM_DIAGCPS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for DIAGCPS diagnosis)

Application conditions:

Initialisation : at LV_DC 0 → 1 transition :
bit 0, bit 1 and bit 2 of STATE_RBM_DIAGCPS = 0
on failure memory reset :
bit 1 of STATE_RBM_DIAGCPS = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_TPS_ST_CHK_2	LV_ERR_TPS_RATIO	LV_ERR_AMP	LV_ERR_EL_CPS
LV_ERR_TPS_1	LV_ERR_TPS_2	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_TPS_AD

LV_ERR_TPS_AD_BOL	LV_ERR_FUP_ORNG	LV_ERR_FUP_ST	LV_ERR_MAP_TPS_PLAUS

```
If(1)      { CPU optimization at LV_DC 0 → 1 transition }
           CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
           While  bit 1 of STATE_RBM_DIAGCPS = 0 do
                  with each XX failure of the above list :
                  ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                  SYNCHRONIZATION<CALL>)
                  If(2)        XX has a pending status
                  Then(2)      bit 1 of STATE_RBM_DIAGCPS = 1
                  Endif(2)
           Endwhile
Else(1)    { the dynamic failure memory is empty }
           No action
Endif(1)
```

Every 1 s :

```
If     bit 0 of STATE_RBM_DIAGCPS = 0
Then
           If      LV_END_RBM_DIAGCPS = 1          and
           Then    bit 0 of STATE_RBM_DIAGCPS = 1
           Endif
Endif
```

```
If     bit 1 of STATE_RBM_DIAGCPS = 0
```

```
Then
        If      LV_INH_DIAG_RBM_DIAGCPS = 1
        Then    bit 1 of STATE_RBM_DIAGCPS = 1
        Endif
Endif
bit 2 of STATE_RBM_DIAGCPS = 1
```

This action stores the prestored freeze frame for the diagnosis instance XX

General information:

In the scope of the legal requirements for On-Board Diagnosis (OBD II) it must be possible to detect a rough leak with a diameter of > 1.0 mm as well as a miniature leak with a diameter of > 0.5 mm within the tank system.

The leakage diagnostic unit DMTL is installed to the fresh air connector of the CP. To measure a leakage within the tank system, an excess pressure is built up in the tank system after closing the canister purge valve and changing over a valve in the diagnostic module. An excess pressure of approx. 25 hPa is built up by means of the electrical pump in the diagnostic module. The pump's power consumption is used as a measure for the tank tightness. The power consumption in a defined reference leakage serves as a reference for stating the size of a leakage.

29.5.1 Function description

The function is basically enabled via the variant bit LV_CONF_DMTL which is set to 1 via the data record if the DMTL module is installed.
The diagnostic sequence is controlled via the state machine of the central sequencing control system. It receives from the function enabling module the enable LV_ENA_SMALL_LEAK_MES for measuring the miniature leak, and the enable LV_ENA_ROUGH_LEAK_MES for measuring the rough leak. Subsequently, the state machine starts a reference leakage measurement. After the time C_T_REF_LEAK_MES_MAX has elapsed, a transition to the rough leak diagnosis is performed, except in case the current monitoring detects a module error or the diagnosis is interrupted due to a detected diagnosis.
The system detects a rough leak suspect if the pump current does not exceed the threshold CUR_DMTL_THD_ROUGH_LEAK within the time T_DMTL_ROUGH_LEAK and if the pump current does not reach the threshold CUR_DMTL_THD_ROUGH_LEAK_LEN after the extension time T_DMTL_ROUGH_LEAK. In case of a rough leak suspect a second reference measurement is performed on the basis of which the final decision on a rough leck suspect is made. Subsequently, a transition to the miniature leak diagnosis is performed. The tank system is detected to be “tight” if the pump current exceeds the reference current CUR_DMTL_REF_LEAK.
If the pump current is detected to have reached “steady state” twice after the time T_DMTL_SMALL_LEAK, a second reference measurement is performed. If a current increase is detected, a miniature leakage is diagnosed. In case of a current reduction, the tank system is detected to be “tight”.
At the end of the diagnosis, the pump motor is switched off and the change-over valve is reset to its regeneration position.
The errors are indicated with the logic variable LV_ERR_DMTLM for a DMTL module error, LV_ERR_ROUGH_LEAK in case a rough leak is present, or LV_ERR_SMALL_LEAK if a miniature leak has been detected.

A current diagnosis is indicated with the bit LV_DMTL_ACT; interruption of diagnosis is requested via the bit LV_DMTL_STOP. The diagnosis is interrupted if tank cover open has been detected, at the beginning of refueling, in case of an excessive battery voltage fluctuation during diagnosis, in case of decreasing pump current during the measuring phase or if a short-circuit of the pump output stage has been detected.
During the reference stage the function is finished without results if humidity has been detected.
The pump current CUR_DMTL is filtered after conversion to a standard voltage of 12 V in the function block of the pump current filtering. At the beginning of the reference measurement and at the beginning of the rough leak measurement, a smaller time constant is used to enable short transient period of the filter.
Moreover, the filtered battery voltage is sampled at the end of the reference measurement, and the change is monitored in the following rough/miniature leak measurement for the threshold C_VB_DMTL_DIF. The result LV_VB_DIF_MAX = 1 results in interruption of the diagnosis.
During the reference leakage measurement it is taken care of current fluctuations which can lead to an interruption of the diagnosis.

general specification

The function block "Fuel cap and refueling check" differentiates the corrected pump current and checks for exceeding a positive threshold C_THD_CUR_DMTL_DIF_REFU, i.e. for increasing pump current to detect "refueling", as the tank pressure and the pump current rise on refueling. When the tank cap is opened, the tank pressure collapses; thus the pump current is reduced. When the negative threshold C_THD_CUR_DMTL_DIF_FUC is no longer reached, the logic variable LV_DET_FUC_OPEN is set to indicate that the fuel cap is open.

A slow decrease of C_THD_CUR_DMTL_DIF_MES of the pump current leads to an interruption of the diagnosis.

The error and cycle flags are generated in the error block.

Enabling of the minimum leakage diagnosis is essentially initiated while the control unit is closed during off delay, below a certain level, while the vehicle does not run, if the CP is not excessively loaded, at ambient temperatures within a certain band width, the battery voltage within a certain band width and while the CPS is closed.

Moreover, the system checks whether a minimum time since engine start C_T_AST_DMTL_MIN has elapsed, a cold start was given and whether the engine is running.

When the bit LV_REQ_PWL_DMTL is set, the extension of the post-operating phase is enforced up to the end of diagnosis. The diagnosis is started with the delay C_T_DLY_ES_PWL after engine start.

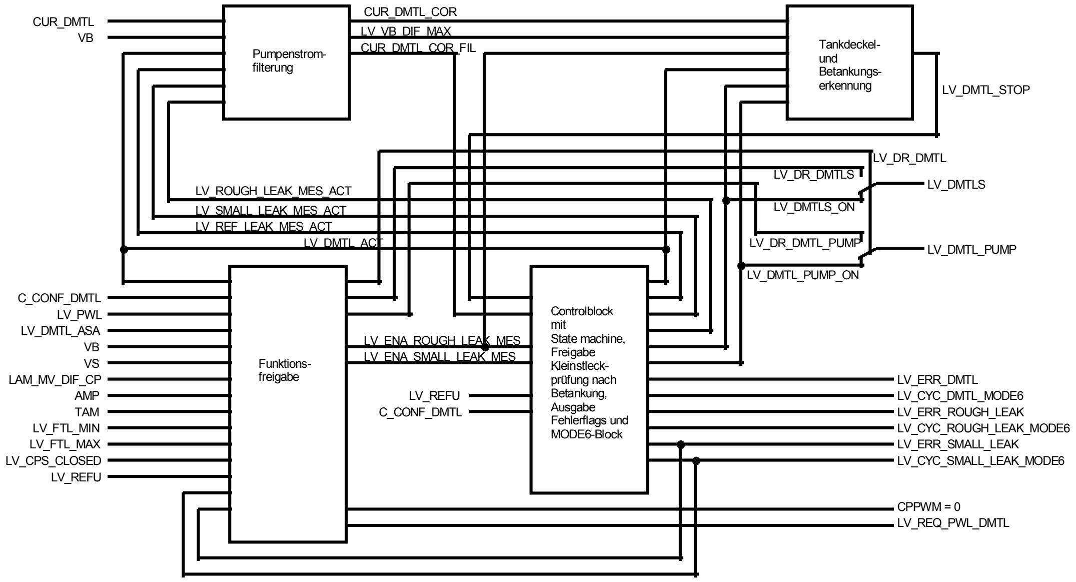
In the function block “Demand rough leak check due to Check Filler Cap” a rough leak check is activated after refuelling has been detected. With this check a tank cover check is performed. The error entry can be prevented while this check. If a rough leak has been detected a info in the instrument board will be activated in the combi instrument.

Application conditions:

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

Signal flow diagram:



Formula section:

```
If        LV_DR_DMTL = 1
    Then  LV_DMTLS = LV_DR_DMTLS
          LV_DMTL_PUMP = LV_DR_DMTL_PUMP
    Else  LV_DMTLS = LV_DMTLS_ON
          LV_DMTL_PUMP = LV_DMTL_PUMP_ON
Endif
```

29.5.2 Central sequencing control

General information:

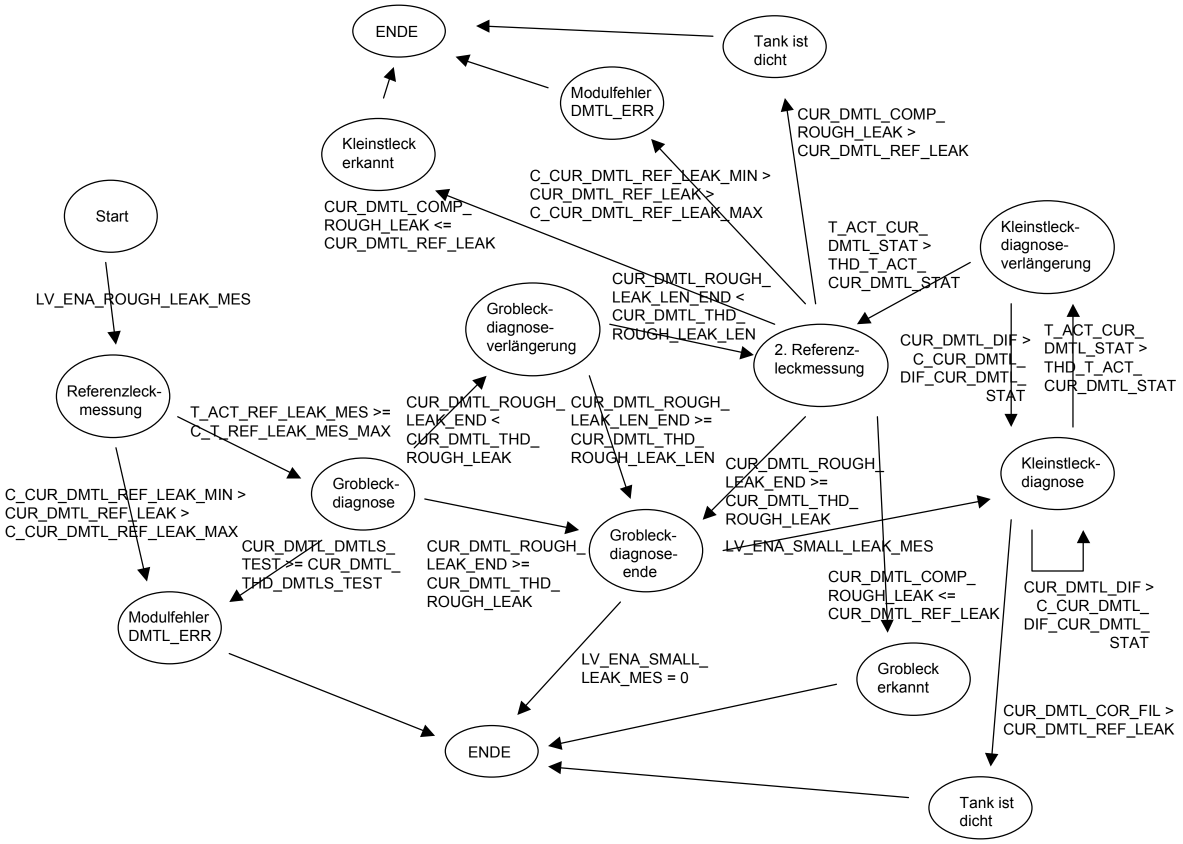
The sequence of measurements of the individual currents and coordination of the various output stages pertaining to the DMTL module is ensured by the central sequencing control.

Application conditions:

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

Signal flow diagram:



Formula section:

Diagnosis times for rough and small leak measurement:

```
If     LV_ERR_FTL = 0                              AND
       LV_ERR_FTL_PLAUS = 0

29.5.3 Pump current of DMTL module

General information:

The most important analog input of the "tank leakage diagnostic function" represents the pump current of the DMTL module. The current to be evaluated is recorded and calculated by voltage measurement at the corresponding shunts. Subsequently, the calculated current is corrected and filtered before it is included in calculation of the function as an input variable.

29.5.3.1 Pump current DMTL

General information:

The current of the pump motor by means of which an excess pressure is built up in the tank system serves as measure for the detection of a leakage in the tank system.
To detect the equivalent current from the measured voltage V_DMTL which is generated in the control unit using the measurement shunt, this requirement is taken into consideration via the calibratable constant C_R_DMTL.
The module is calculated with a time base of 10 ms.

Application conditions:

Initialisation: CUR_DMTL = 0

Recurrence: 10 ms

Activation: LV_CONF_DMTL = 1

Formula section:

CUR_DMTL = V_DMTL / C_R_DMTL

29.5.3.2 Filtering of pump current

General information:

The pump current is filtered after conversion to the referenced battery voltage. At the beginning and at the end of the reference measurement, a greater time constant is used to ensure a short filter settling time.
A correction factor for the pump current is taken as a function of the calculated value VB_DMTL_FIL via a characteristic IP_FAC_CUR_DMTL. Thus, the pump current CUR_DMTL is corrected depending on the battery voltage, and results in relation to CUR_DMTL_COR.

Application conditions:

Initialisation: CUR_DMTL_COR = 0
CUR_DMTL_COR_FIL = 0

Recurrence: 10 ms

Activation: LV_CONF_DMTL = 1

Formula section:

```
CUR_DMTL_COR = CUR_DMTL * IP_FAC_CUR_DMTL

If  STATE_DMTL = 0H → 1H   OR
    STATE_DMTL = 1H → 2H   OR
    STATE_DMTL = 3H → 7H   OR
    STATE_DMTL = 6H → 7H   OR
    STATE_DMTL = 7H → 4H
    Then  T_TIMER_DLY_DMTLS = C_T_DLY_DMTLS
Endif

If  T_TIMER_DLY_DMTLS > 0
    Then  $CUR\_DMTL\_COR\_FIL_{(n)} = CUR\_DMTL\_COR\_FIL_{(n-1)} + (CUR\_DMTL\_COR_{(n)} - CUR\_DMTL\_COR\_FIL_{(n-1)}) * C\_CRLC\_CUR\_DMTL\_FIL\_LIM$
          T_TIMER_DLY_DMTLS = T_TIMER_DLY_DMTLS – 10ms
    Else  $CUR\_DMTL\_COR\_FIL_{(n)} = CUR\_DMTL\_COR\_FIL_{(n-1)} + (CUR\_DMTL\_COR_{(n)} - CUR\_DMTL\_COR\_FIL_{(n-1)}) * C\_CRLC\_CUR\_DMTL\_FIL$
Endif

CUR_DMTL_COR_FIL_EOL = CUR_DMTL_COR_FIL          #only in case of tester diag
```

29.5.3.3 VB depending pump current correction

General information:

At the end of the reference measurement, the filtered battery voltage VB_DMTL_REF is measured and monitored for a higher deviation in the following rough or miniature leak measurement. If a high battery voltage deviation is detected, LV_VB_DIF_MAX is set and the diagnosis is aborted.

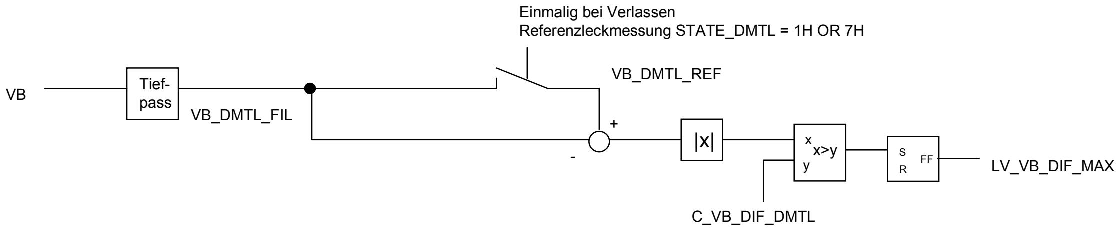
Application conditions:

Initialisation: LV_VB_DIF_MAX is restored from the NVMY
VB_DMTL_REF = VB_DMTL_FIL = 12V

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

Signal flow diagram:



Formula section:

```
If      LV_DMTL_ACT = 0 → 1
    Then    T_DLY_VB_DMTL_FIL = C_T_DLY_DMTLS
Endif
If      LV_DMTL_ACT = 1 AND T_DLY_VB_DMTL > 0
    Then    $VB\_DMTL\_FIL_{(n)} = VB\_DMTL\_FIL_{(n-1)} + (VB_{(n)} - VB\_DMTL\_FIL_{(n-1)}) * C\_CRLC\_VB\_DMTL\_FIL\_LIM$
            T_DLY_VB_DMTL = T_DLY_VB_DMTL – 100 ms
Endif
If      LV_DMTL_ACT = 1 AND T_DLY_VB_DMTL = 0
```

```
        Then  $VB\_DMTL\_FIL_{(n)}$ = $VB\_DMTL\_FIL_{(n-1)}$ +
                    $(VB_{(n)} - VB\_DMTL\_FIL_{(n-1)})$ * C_CRLC_VB_DMTL_FIL
    Endif

    If    STATE_DMTL = 1H → 2H    OR
          STATE_DMTL = 7H → 4H
        Then  VB_DMTL_REF = VB_DMTL_FIL
        Else  VB_DMTL_REF = VB_DMTL_REF
    Endif

    If    [STATE_DMTL = 2H               OR
          STATE_DMTL = 3H                OR
          STATE_DMTL = 5H                OR
          STATE_DMTL = 6H]               AND
          [If    LV_ENA_CHK_FUC_ROUGH_LEAK = 0
           Then  |VB_DMTL_REF - VB_DMTL_FIL| > C_VB_DMTL_DIF
           Else  |VB_DMTL_REF - VB_DMTL_FIL| > C_VB_DMTL_DIF_CHK_FUC
           Endif]
        Then  LV_VB_DIF_MAX = 1
        Else  LV_VB_DIF_MAX = 0
    Endif

    If    LV_DMTL_ACT = 0 → 1
        Then  LV_VB_DIF_MAX = 0
    Endif
```

29.5.4 Interruption of function due to current fluctuations

General information:

The function block monitors the filtered and corrected pump current for excessively high current fluctuations during the reference leakage measurement. If this case is detected, the tank leakage diagnosis is aborted. The interruption is cumulated in a counter.

Application conditions:

Initialisation: LV_CUR_DMTL_REF_DIF_MAX is restored out of NVMY
CTR_CUR_DMTL_REF_DIF_MAX is restored out of NVMY

Recurrence: 100 ms

Activation: LV_DMTL_ACT = 1

Formula section:

```
If        STATE_DMTL = 0H → 1H   OR
          STATE_DMTL = 3H → 7H   OR
          STATE_DMTL = 6H → 7H
    Then  T_DLY_CUR_DMTL_REF_DIF = C_T_DLY_DMTLS
Endif

If        [STATE_DMTL = 1H OR
          STATE_DMTL = 7H]       AND
          T_DLY_CUR_DMTL_REF_DIF > 0
    Then  CUR_DMTL_COR_FIL_MAX = CUR_DMTL_COR_FIL
          CUR_DMTL_COR_FIL_MIN = CUR_DMTL_COR_FIL
          T_DLY_CUR_DMTL_REF_DIF = T_DLY_CUR_DMTL_REF_DIF – 100 ms
Endif

If        [STATE_DMTL = 1H OR
          STATE_DMTL = 7H]       AND
          T_DLY_CUR_DMTL_REF_DIF = 0
    Then  CUR_DMTL_REF_DIF_MAX =
          MAX(CUR_DMTL_COR_FIL. CUR_DMTL_COR_FIL_MAX) -
          MIN(CUR_DMTL_COR_FIL. CUR_DMTL_COR_FIL_MIN)
Endif

If        CUR_DMTL_REF_DIF_MAX > C_CUR_DMTL_REF_DIF_MAX
    Then  LV_CUR_DMTL_REF_DIF_MAX = 1
    Else  LV_CUR_DMTL_REF_DIF_MAX = 0
Endif
```

```
If          LV_DMTL_ACT = 0 → 1
      Then  LV_CUR_DMTL_REF_DIF_MAX = 0
Endif

If          LV_CUR_DMTL_REF_DIF_MAX = 0 → 1           OR
            LV_CUR_DMTL_THD_DIF_MES = 0 → 1
      Then  CTR_CUR_DMTL_REF_DIF_MAX = CTR_CUR_DMTL_REF_DIF_MAX + 1
      Else  CTR_CUR_DMTL_REF_DIF_MAX = CTR_CUR_DMTL_REF_DIF_MAX
Endif
```

29.5.5 Function enabling

Application conditions:

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

General information:

The enabling of the tank leakage diagnostic function is to be represented here in terms of an overview. The individual bits comprised are explained subsequently in the following chapters. Some remarkable points are to be mentioned in this context.

Formula section:

```
If          ECU_STATE != PWL   →  ECU_STATE = PWL
      Then  T_DLY_ES_PWL = C_T_DLY_ES_PWL
Endif

If          ECU_STATE = PWL          AND
            T_DLY_ES_PWL > 0
      Then  T_DLY_ES_PWL = T_DLY_ES_PWL – 100 ms
            LV_T_DLY_DMTL_PWL = 0
      Else  LV_T_DLY_DMTL_PWL = 1
Endif

If          LV_REQ_PWL_ROUGH_LEAK = 1          OR
            LV_REQ_PWL_SMALL_LEAK = 1
      Then  LV_REQ_PWL_DMTL = 1
```

```
                T_DLY_REQ_PWL_DMTL = 0
    Endif

    If          LV_REQ_PWL_DMTL = 1                  AND

```

```
        T_AST >= C_T_AST_DMTL_MAX                 AND
        LV_ENA_MAIN_DMTL_FUC = 1
    Then LV_ENA_MAIN_DMTL = 1
    Else LV_ENA_MAIN_DMTL = 0
Endif
```

29.5.7 Tank level sensor

General information:

The function enabling of the tank leakage diagnostic function depends, amongst other things, on the tank being filled to between 15 % and 85 % of its capacity. The tank level information is transferred to the control unit via CAN in the INSTR2 message. If a level error is transmitted by CAN or if the CAN message is not issued, then the bit is set for a validated tank level LV_FTL_DMTL_VAL = 0.

Application conditions:

Initialisation: LV_FTL_DMTL_VAL = 0
LV_FTL_DMTL_MAX = 0
LV_FTL_DMTL_MIN = 0

Recurrence: 1 s

Activation: LV_IGK = 1

Formula section:

```
If      LV_IGK = 0 → 1
    Then T_DLY_IGK_FTL = C_T_DLY_IGK_FTL
         LV_FTL_DMTL_VAL = 0
Endif

If      LV_IGK  = 1                AND
        T_DLY_IGK_FTL >   0
    Then T_DLY_IGK_FTL = T_DLY_IGK_FTL – 1 s
Endif

If      LV_ERR_FTL = 0             AND
        T_DLY_IGK_FTL = 0
    Then LV_FTL_DMTL_VAL = 1
    Else LV_FTL_DMTL_VAL = 0
```

```
Endif

If      LV_ERR_FTL = 0
    Then LV_FTL_DMTL_MAX = LV_FTL_DMTL_MAX
         LV_FTL_DMTL_MIN = LV_FTL_DMTL_MIN
    Else LV_FTL_DMTL_MAX = 0
         LV_FTL_DMTL_MIN = 0
Endif

If      FTL > C_FTL_DMTL_MAX + C_HYS_FTL_DMTL
    Then LV_FTL_DMTL_MAX = 1
Endif

If      FTL < C_FTL_DMTL_MAX – C_HYS_FTL_DMTL
    Then LV_FTL_DMTL_MAX = 0
Endif

If      FTL < C_FTL_DMTL_MIN + C_HYS_FTL_DMTL
    Then LV_FTL_DMTL_MIN = 1
Endif

If      FTL > C_FTL_DMTL_MIN – C_HYS_FTL_DMTL
    Then LV_FTL_DMTL_MIN = 0
Endif
```

29.5.8 Tank level plausibility check

For the tank diagnostic function, it is necessary to detect a refueling process, to obtain certain tank level bits and to perform a plausibility check of the tank level signal.

29.5.8.1 Initialization of diagnostic quantities

Application conditions:

Initialisation: FCO_AV_DMTL is restored out of NVMY
FCO_DMTL_INI = 0 - FCO_AV_DMTL

Recurrence: 1 s

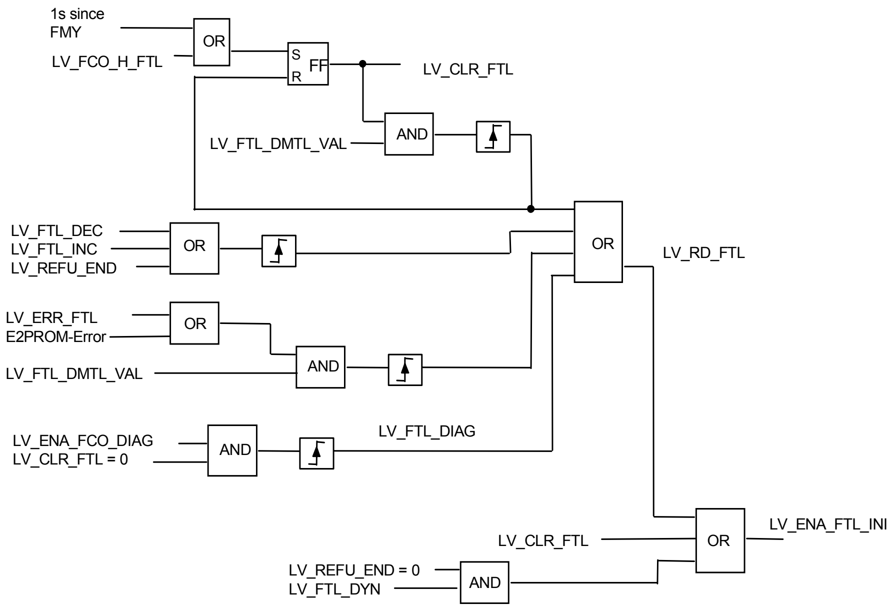
Activation: LV_IGK = 1

Deactivation: LV_IGK = 1 → 0

General information:

To perform a plausibility check of the level signal, a fuel consumption resulting from the difference between two fuel level values is compared with the fuel consumption resulting from the injection calculation.

Signal flow diagram:



In case of the initial initialization or an EEPROM error, FCO_AV_DMTL = FCO_DMTL_INI = FTL_INI = 0 is set.
In case the failure memory is deleted, FTL_INI = 0.

Formula section:

```
If      FCO_AV_DMTL > C_FTL_DIAG_MAX
  Then  LV_FCO_H_FTL = 1
Endif

If      FMY is cleared              OR
        LV_FCO_H_FTL = 1
  Then  LV_CLR_FTL = 1
Endif

If      LV_CLR_FTL = $1_{(n-1)}$    AND
        LV_FTL_DMTL_VAL = 1
  Then  LV_RD_FTL _1 = 1
        LV_CLR_FTL = $0_{(n)}$
Endif
If      LV_FTL_DEC = 1              OR
```

```
                LV_FTL_INC = 1              OR
                LV_REFU_END = 1
        Then    LV_RD_FTL _2 = 1
    Endif
    If          LV_ERR_FTL = 1              AND
                LV_FTL_DMTL_VAL = 1
        Then    LV_RD_FTL _3 = 1
    Endif
    If          LV_ENA_FCO_DIAG = 1         AND
                LV_CLR_FTL = 0
        Then    LV_RD_FTL _4 = 1
    Endif

    If          LV_RD_FTL_1 = 0 → 1                 OR
                LV_RD_FTL_2 = 0 → 1                 OR
                LV_RD_FTL_3 = 0 → 1                 OR
                LV_RD_FTL_4 = 0 → $1_{(n-1)}$       OR
                LV_CLR_FTL = 1                      OR
                [LV_REFU_END = 0            AND
                LV_FTL_DYN = 1]
        Then    LV_ENA_FTL_INI = 1
    Endif

    If          LV_ENA_FTL_INI = 1
        Then    FTL_INI = FTL
                FCO_AV_DMTL = 0
                FCO_DMTL_INI = FCO_DMTL
        Else    FTL_INI = FTL_INI
                FCO_AV_DMTL = FCO_DMTL - FCO_DMTL_INI
    Endif
```

29.5.8.2 Refueling detection case of ignition key ON and level reading

Application conditions:

Recurrence: 1 s

Activation: LV_IGK = 1

Initialization: DIF_FTL_VST = 0 in case of LV_IGK off to on

Formula section:

```
If      VS < C_VS_FTL_DIAG_MAX      UND      LV_FTL_DMTL_VAL = 1
        for a period longer than C_T_DLY_STOP_REFU
   Then LV_REFU_RLS_DIAG = 1
Endif

If      LV_FTL_DMTL_VAL = 0                        OR
        LV_ERR_VS = 1                              OR
        VS >= C_VS_FTL_DIAG_MAX
   Then LV_REFU_RLS_DIAG = 0
Endif

If      LV_REFU_RLS_DIAG = 0   AND   LV_FTL_DYN = 1
   Then LV_REFU_END = 1
   Else LV_REFU_END = 0
Endif

If      LV_ERR_VS = 1                              OR
        LV_ENA_FTL_DIAG = 0
   Then FTL_AV = FTL_VST_IN = DIF_FTL_VST = 0
Endif

If      LV_REFU_RLS_DIAG = 0 → 1
   Then FTL_VST_IN = FTL
        FCO_VST = FCO_DMTL
Endif

If      LV_REFU_RLS_DIAG = 1
   Then FTL_AV = FTL
        DIF_FTL_VST = FTL_AV - (FTL_VST_IN - (FCO_DMTL - FCO_VST))
Endif
```

Subsequently the following interrogations are processed:

```
If      LV_ERR_VS = 0                              AND
```

```
               LV_ENA_FTL_DIAG = 1                          AND
               DIF_FTL_VST > C_FTL_DIAG_MIN
         Then  LV_FTL_INC_IGK_ON = 1
         Else  LV_FTL_INC_IGK_ON = 0
Endif

If             LV_ERR_VS = 0                                AND
               LV_ENA_FTL_DIAG = 1                          AND
               DIF_FTL_VST < C_FTL_DEC_FTL_DIAG_MIN
         Then  LV_FTL_DEC_IGK_ON = 1
         Else  LV_FTL_DEC_IGK_ON = 0
Endif

If             LV_FTL_INC_IGK_ON = 1   OR        LV_FTL_DEC_IGK_ON = 1
         Then  LV_FTL_DYN = 1
         Else  LV_FTL_DYN = 0
Endif
```

In case of "delete failure memory", the following occurs:

LV_REFU_END = LV_FTL_DYN = FTL_VST_IN = FTL_AV = DIF_FTL_VST =

LV_FTL_DEC_IGK_ON = LV_FTL_INC_IGK_ON = LV_REFU_RLS_DIAG = 0

29.5.8.3 Refueling detection after restart

Application conditions:

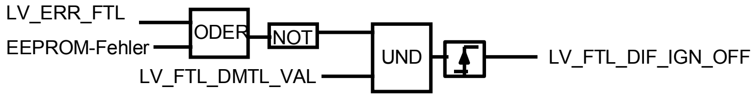
Recurrence: 1 s

Activation: LV_IGK = 1

Function description:

In the case of an EEPROM error or on initial initialization, this refueling detection must not be performed.

Signal flow diagram:



Formula section:

```
If        [LV_FTL_DMTL_VAL = 1 for minimum  one second      AND
           LV_ST_END = 1]                                       OR
          [LV_CLR_FTL = 1            AND
           LV_FTL_DIF_IGN_OFF = 1]
    Then  FTL_OLD = FTL
Endif

If        LV_FTL_DIF_IGN_OFF = 1
    Then  FTL_ST = FTL
          DIF_FTL_AST = FTL_ST - FTL_OLD
Endif

If        LV_FTL_DIF_IGN_OFF = 1
    then  If     LV_ENA_FTL_DIAG = 1                 AND
                 DIF_FTL_AST > C_FTL_DIAG_MIN
          Then   LV_FTL_INC = 1
          Else   LV_FTL_INC = 0
          Endif
          If     LV_ENA_FTL_DIAG = 1                 AND
                 DIF_FTL_AST < C_FTL_DEC_FTL_DIAG_MIN
          Then   LV_FTL_DEC = 1
          Else   LV_FTL_DEC = 0
          Endif
Endif

If        LV_REFU_RLS_DIAG = 0 → 1
Then      LV_FTL_DEC = 0
          LV_FTL_INC = 0
```

```
        DIF_FTL_AST = 0
Endif
```

In case of the initial initialization or an EEPROM error, FTL_OLD = 0 is initialized.

In case of "delete failure memory", the following occurs:

LV_FTL_IN = FTL_OLD = LV_FTL_DEC = LV_FTL_INC = FTL_ST = DIF_FTL_AST = 0

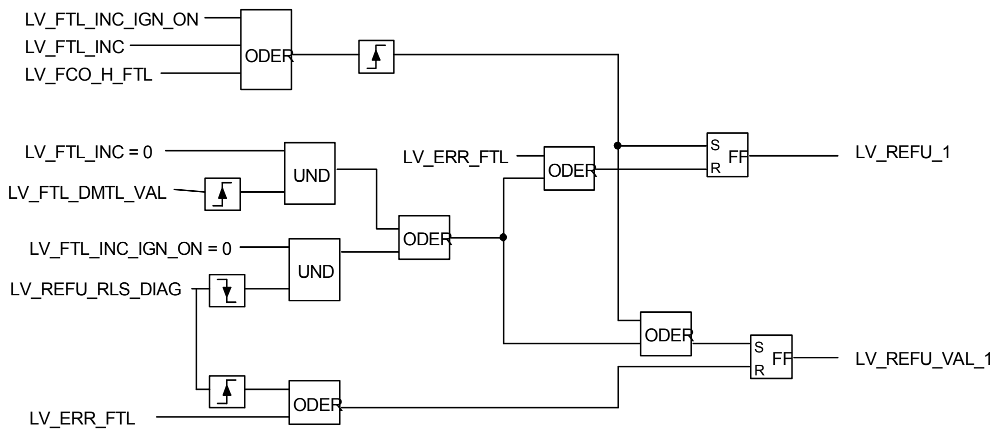
29.5.8.4 Refueling flag output

Application conditions:

Recurrence: 1 s

Activation: LV_IGK = 1

Signal flow diagram:



The output of the refueling bits LV_REFU and LV_REFU_VAL depends on the level diagnosis enable state.

The following logic is derived therefrom:

```
If          LV_ENA_FTL_DIAG = 1      AND   LV_REFU_1 = 1
    Then    LV_REFU = 1
    Else    LV_REFU = 0
Endif

If          LV_ENA_FTL_DIAG = 1      AND   LV_REFU_VAL_1 = 1
    Then    LV_REFU_VAL = 1
    Else    LV_REFU_VAL = 0
```

```
Endif
```

If no diagnosis has been enabled LV_ENA_FTL_DIAG = 0, then the refueling bits LV_REFU = 0 and LV_REFU_VAL = 0 are issued.

In case of "delete failure memory", the following occurs:
LV_REFU_1 = LV_REFU_VAL_1 = 0

29.5.8.5 Fuel level diagnosis

Application conditions:

Recurrence: 1 s

Activation: LV_IGK = 1

Formula section:

Consumption diagnosis enable:

```
If      LV_FTL_DMTL_VAL = 1                     AND
        [LV_FTL_DYN = 0          OR
        LV_REFU_END = 1]                        AND
        FCO_AV_DMTL > C_ENA_FCO_DIAG            AND
        LV_ENA_FTL_DIAG =1
    Then LV_ENA_FCO_DIAG = 1
    Else LV_ENA_FCO_DIAG = 0
Endif
```

Upper and lower threshold of the consumption diagnosis:

```
If      LV_FTL_DIAG = 1          AND    LV_ENA_FTL_DIAG = 1
    Then If     DIF_FCO_FTL = FCO_AV_DMTL - (FTL_INI - FTL) > C_FCO_DIAG_MAX
                Then   LV_FCO_DIAG_MAX = 1
                Else   LV_FCO_DIAG_MAX = 0
         Endif
         If     DIF_FCO_FTL = FCO_AV_DMTL - (FTL_INI - FTL) < C_FCO_DIAG_MIN
                Then   LV_FCO_DIAG_MIN = 1
                Else   LV_FCO_DIAG_MIN = 0
    Else LV_FCO_DIAG_MAX = 0     AND    LV_FCO_DIAG_MIN = 0
Endif
```

In case of "delete failure memory", the following occurs:

LV_FCO_DIAG_MAX = LV_FCO_DIAG_MIN = LV_ENA_FCO_DIAG = DIF_FCO_FTL = 0

29.5.8.6 Fuel level diagnosis enable

Application conditions:

Recurrence: 1 s

Activation: LV_IGK = 1

Formula section:

```
If          LV_CONF_DMTL = 1
    Then    LV_ENA_FTL_DIAG = 1
    Else    LV_ENA_FTL_DIAG = 0
Endif
```

29.5.8.7 Tank level error

Application conditions:

Initialisation: restored out of FMY

Recurrence: 1 s

Activation: LV_IGK = 1

Formula section:

```
If          LV_FTL_CAN_ERR = 1              OR
            LV_ERR_TOUT_ICL_2 = 1           OR
            LV_ERR_BN_KM_ICL = 1
    Then    LV_ERR_FTL = 1
    Else    LV_ERR_FTL = 0
Endif

If    LV_FTL_DIAG = 1
Then        If          [LV_FCO_DIAG_MAX = 1    OR
                        LV_FCO_DIAG_MIN = 1]            AND
                        LV_ERR_TOUT_ICL_2 = 0           AND
                        LV_ERR_BN_KM_ICL = 0
            Then    LV_ERR_FTL_PLAUS = 1
```

```
        Else    LV_ERR_FTL_PLAUS = 0
        Endif
    Endif
```

29.5.9 Enabling the rough leak check

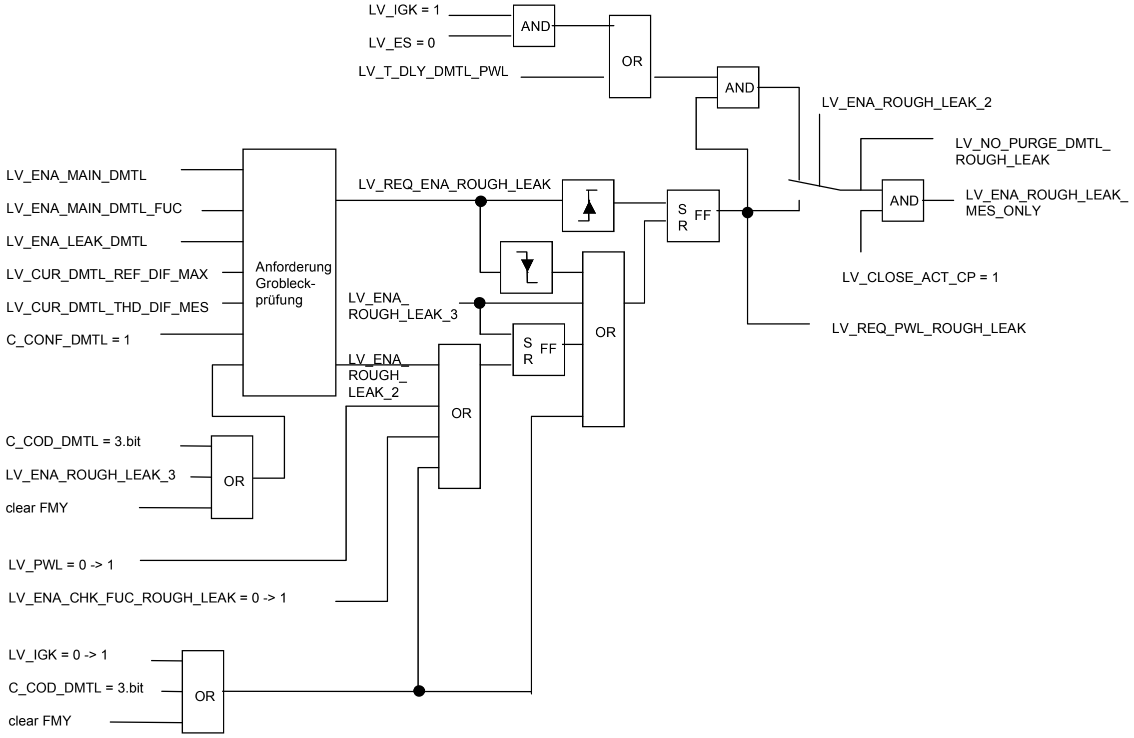
Application conditions:

Initialisation: LV_REQ_PWL_ROUGH_LEAK = 0
LV_INH_ROUGH_LEAK_MES = 0

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

Signal flow diagram:



Formula section:

```
If      LV_REQ_ENA_ROUGH_LEAK = 0 → 1
   Then LV_REQ_PWL_ROUGH_LEAK = 1
Endif

If      LV_REQ_ENA_ROUGH_LEAK = 1 → 0        OR
        LV_ENA_ROUGH_LEAK_3 = 1              OR

29.5.20 End of line test and factory test of DMTL function

Application conditions:

Recurrence: 100 ms

Activation: LV_CONF_DMTL = 1

Initialisation: LV_DMTL_ASA = 0

FUNCTION DESCRIPTION:

The end of line test and the factory test must permit execution of the tank leak diagnostic function via test unit.

The fundamental difference is the fact that at the end of line, the timeout monitoring of the test unit signal is deleted and that a change-over of "ignition key" into both directions does not interrupt the function. Another particularity of the end of line function is the fact that the function is started anew without any further test unit intervention if it has been aborted due to "engine speed detected, but START not exited", provided that all enable conditions are present.

On the other hand, activation in the factory is only admissible with the test unit connected and ignition key ON.

Formula section:

```
If            (STATE_EOL_KWP_DMTL  = 0 (Start Command from Tester received) )

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

FUNCTION DESCRIPTION:

General information:

With this module the interface between the tank leakage detection monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_DMTLM, STATE_RBM_ROUGH_LEAK and STATE_RBM_SMALL_LEAK data.

Within STATE_RBM_xxx, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)

  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)

  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)

  (not valid for DMTL function)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_DMTLM = 0
bit 0, bit 1 and bit 2 of STATE_RBM_ROUGH_LEAK = 0

30.1 AGGR EXTC adaptation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_CH_MOD_IVVT	V/O	0...FFH	0...255	1	[-]
Bit-coded mask, containing combustion-mode-request for catalyst heating and the desulfation strategy; 2. Prio					
STATE_CH_MOD_IVVT_REQ	V/O	0...FFH	0...255	1	[-]
Bit-coded mask, containing combustion-mode-request for catalyst heating and the desulfation strategy; 1. Prio					

Input data:

STATE_CH_MOD_REQ	STATE_CH	STATE_OPM_IVVT_CH	LV_SO2P_REQ

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

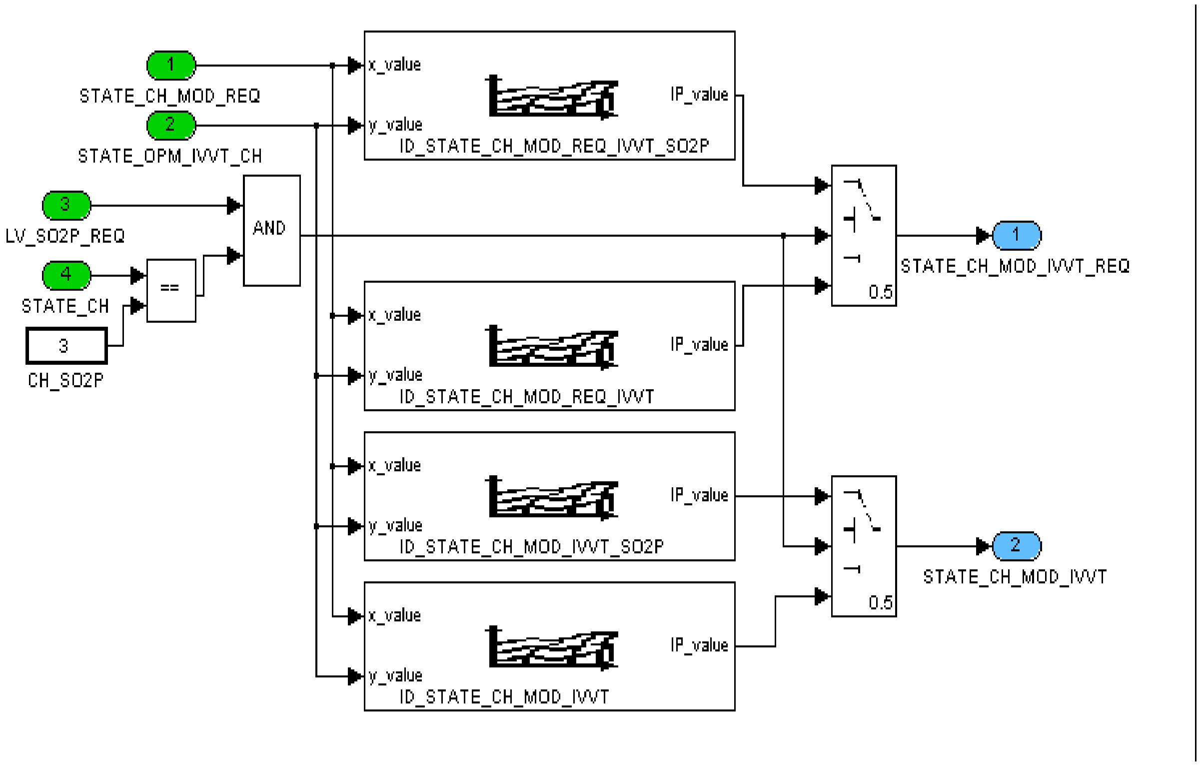
Application conditions:

Initialisation: *0 at reset except*

Recurrence : 10 ms

Activation: *every engine state*

Formula section:



Calibration data:

30.2 Catalyst heating functions and engine warm up

30.2.1 Catalyst Heating functions

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CH_N_SP_IS	V/O	0...1H	0...1	1	[-]
Catalyst Heating Function "increased idle speed setpoint"					
LV_TI_CH	V/O	0...1H	0...1	1	[-]
Catalyst Heating Function "lean injection"					

Input data:

STATE_CH			

General information:

Logical catalyst heating variables that have been used up to now are set depending on STATE_CH.

Application conditions:

Initialisation: all outputs = 0 at ECU initialization

Recurrence: 100 ms

Activation: at every engine operating state

Deactivation: -

Formula section:

```
If STATE_CH = 1
    Then
    LV_TI_CH = 1
    Else
    LV_TI_CH = 0
    Endif

IF STATE_CH = 1 OR 2
    Then
    LV_CH_N_SP_IS = 1
    Else
    LV_CH_N_SP_IS = 0
    endif
```

30.2.2 Warm-up function : (LV_WUP)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_WUP	V/O	0...1H	0...1	1	[-]
Warm up functions active					

Input data:

LV_ES	TI_WUP_1_ADD		

FUNCTION DESCRIPTION:

General information:

The injection is corrected with the warm-up enrichment.

The states warm-up (LV_WUP) and catalyst heating (LV_TI_CH) are used parallel.

Application conditions:

Initialisation :	LV_WUP = 1
Recurrence :	once per segment (720 °crk / NC_CYL_NR)
Activation :	at all engine operating states
Deactivation :	TI_WUP_1_ADD = 0 (refer to chapter : ” Injection ”). Is activated again at STATE_ENG = LV_ES

Formula section:

```
if    LV_ES = 1
  then      LV_WUP  =  1
endif

if    LV_WUP = 1
   then      if       TI_WUP_1_ADD > 0
                then          LV_WUP  unchanged  (stays at value 1)
                else          LV_WUP  =  0
             endif
   else      LV_WUP  unchanged  (stays at value 0)
endif
```

30.3 Catalyst heating coordination

Output Data:

Name	Mode	Hex. Limits	Phys. Limits	Resol.	Unit
LV_CH_AST_CDN	V	0... 1H	0... 1	1	[-]
Indicates if conditions for after start catalyst heating are fulfilled					
LV_CH_L_CDN	V	0... 1H	0... 1	1	[-]
Indicates if conditions for low load catalyst heating are fulfilled					
LV_CH_L_RGN	O/V	0... 1H	0... 1	1	[-]
Low load catalyst heating for NOx-trap - heating after regeneration is active					
LV_CH_SO2P_CDN	V	0... 1H	0... 1	1	[-]
Indicator for conditions of desulfation catalyst heating					
STATE_CH	O/V	0 1 2 3	CH_OFF CH_AST CH_L_LOAD CH_SO2P	-	[-]
State of catalyst heating					
TEMP_CAT_DIF_CH_L	O/V	8000... 7FFFH	-1024... 1023.96875	0.03125	[K]
Difference between actual catalyst temperature and deactivation threshold for low load CH					
TNT_DIF_CH_L	O/V	8000... 7FFFH	-1024... 1023.96875	0.03125	[K]

General Information

This module has to be calculated before any other catalyst heating module.
In this module the decision is made if catalyst heating after start, in low load or for desulfation is active. STATE_CH indicates the actual status and triggers other modules.

Application Conditions

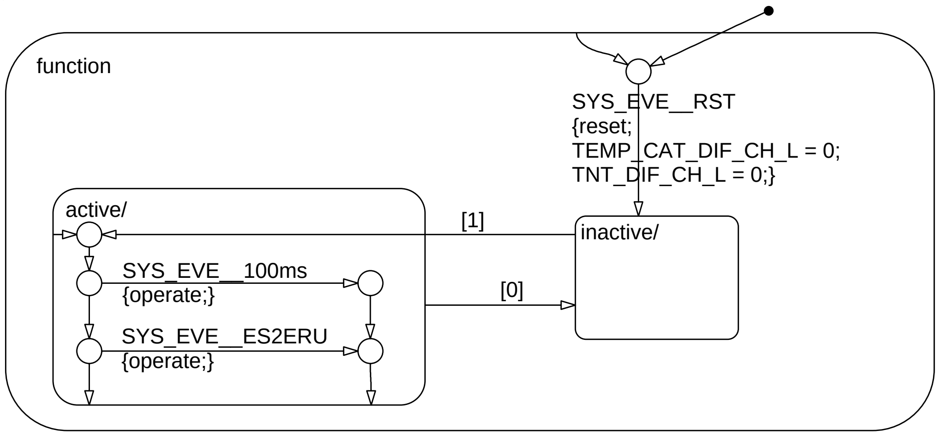

Figure 1:
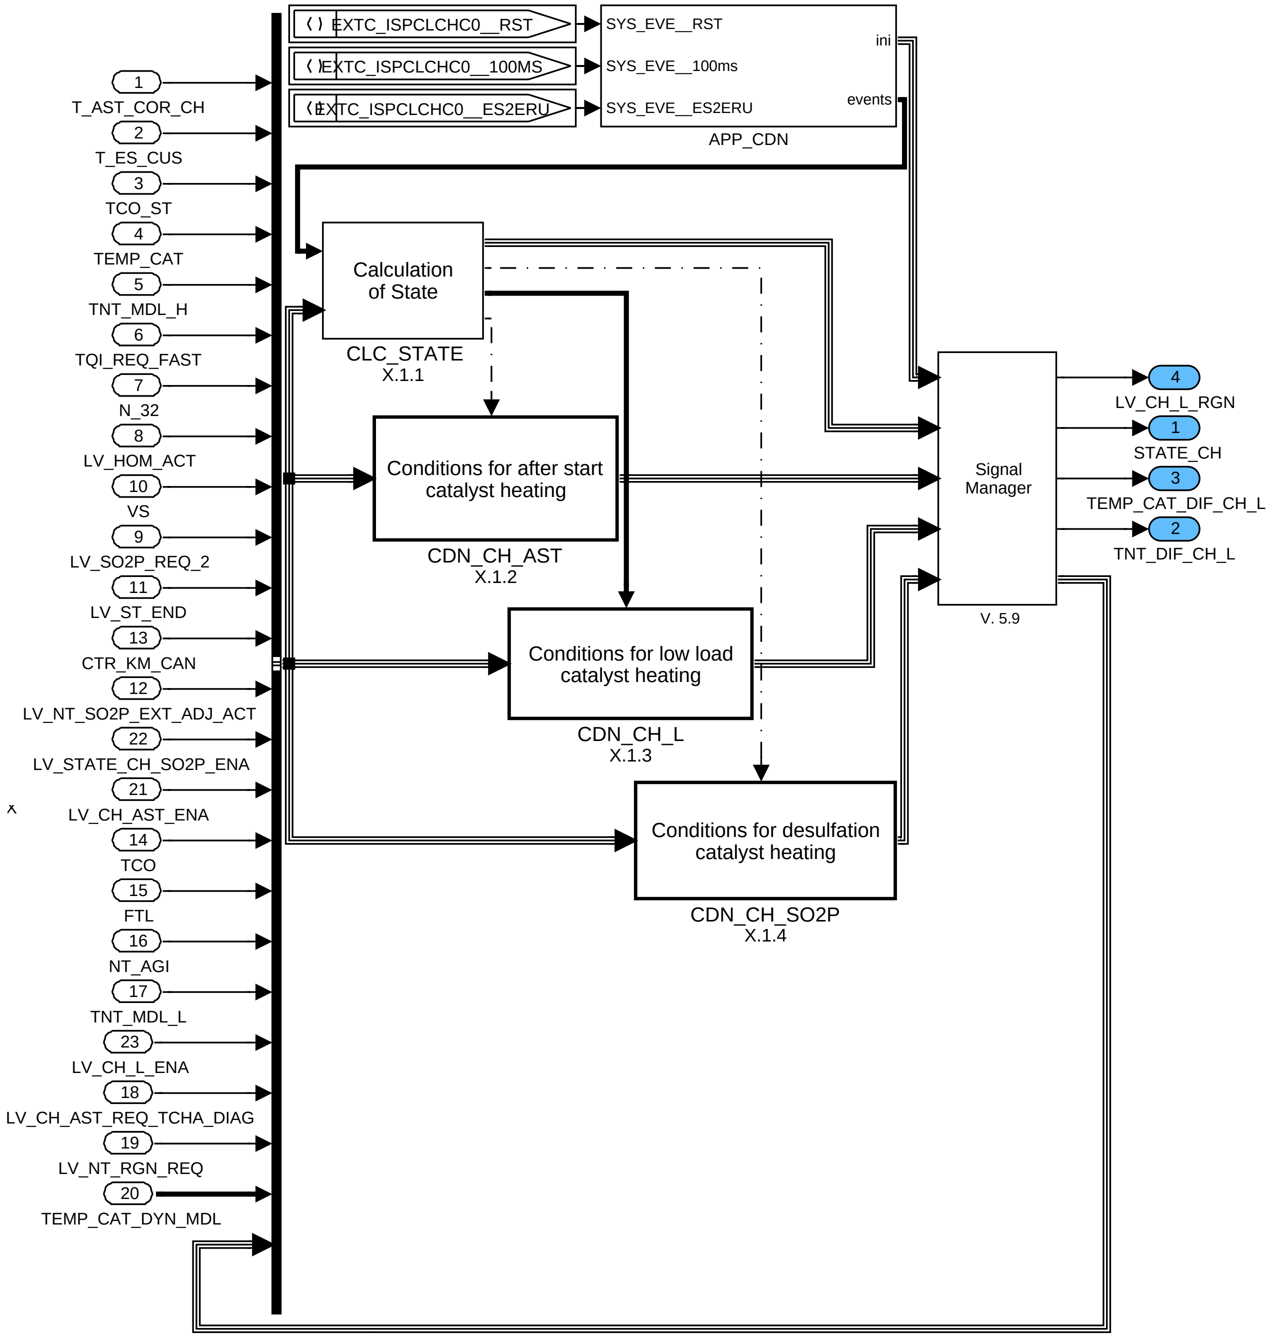
Path: EXTC_ISPCLCHC0/APP_CDN/Chart

Function description



SDA_SRS / SDA V 5.0.6 07−Dec−2006

Figure 2:
Path: EXTC_ISPCLCHC0

30.3.1 State machine

30.3.1.1 State machine - Subsystem

The conditions for activation of several catalyst heating measures are not calculated if another measure is active see stateflow chart.

With to LC_STATE_CH_MAN_ACT it is possible to switch STATE_CH manually.

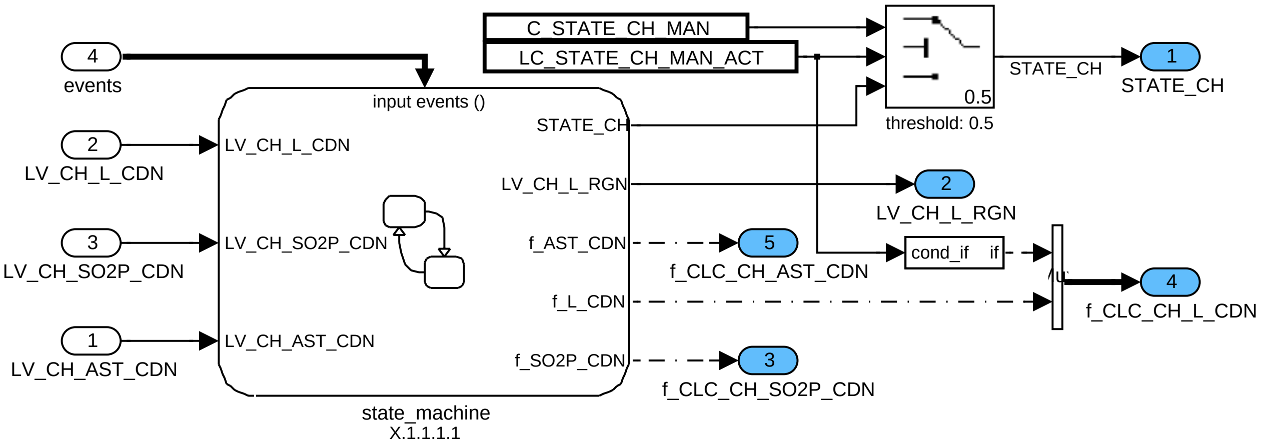


Figure 3:
Path: EXTC_ISPCLCHC0/CLC_STATE/SUB

30.3.1.1.1 state_machine

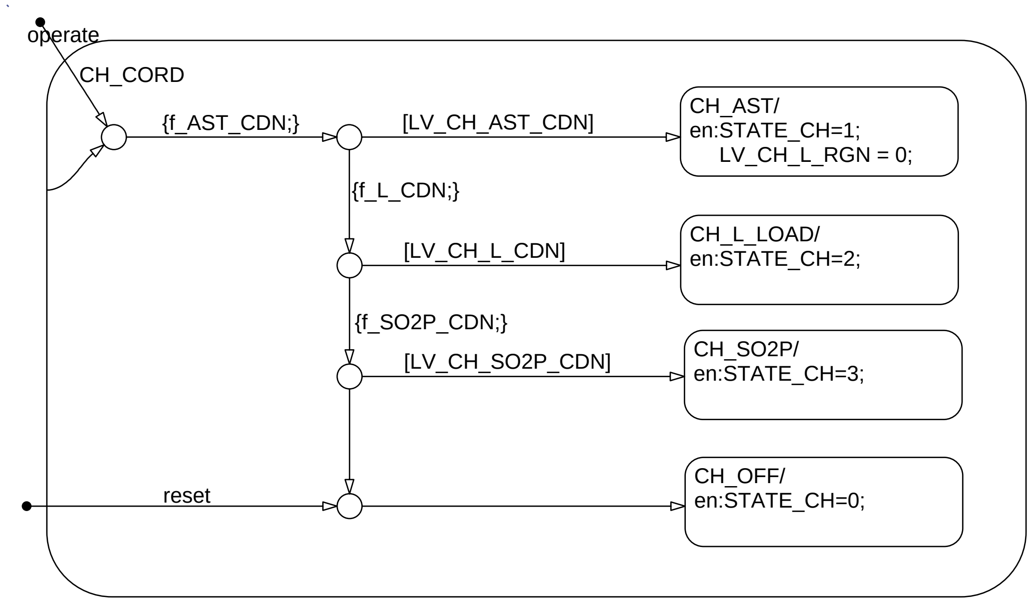

Figure 4:
Path: EXTC_ISPCLCHC0/CLC_STATE/SUB/state_machine

30.3.2 Conditions for after start heating

30.3.2.1 Conditions for after start heating - Subsystem

T_ES_CUS is the time with stopped engine. If one of the conditions stops catalyst heating, it only can be re-activated after next start.

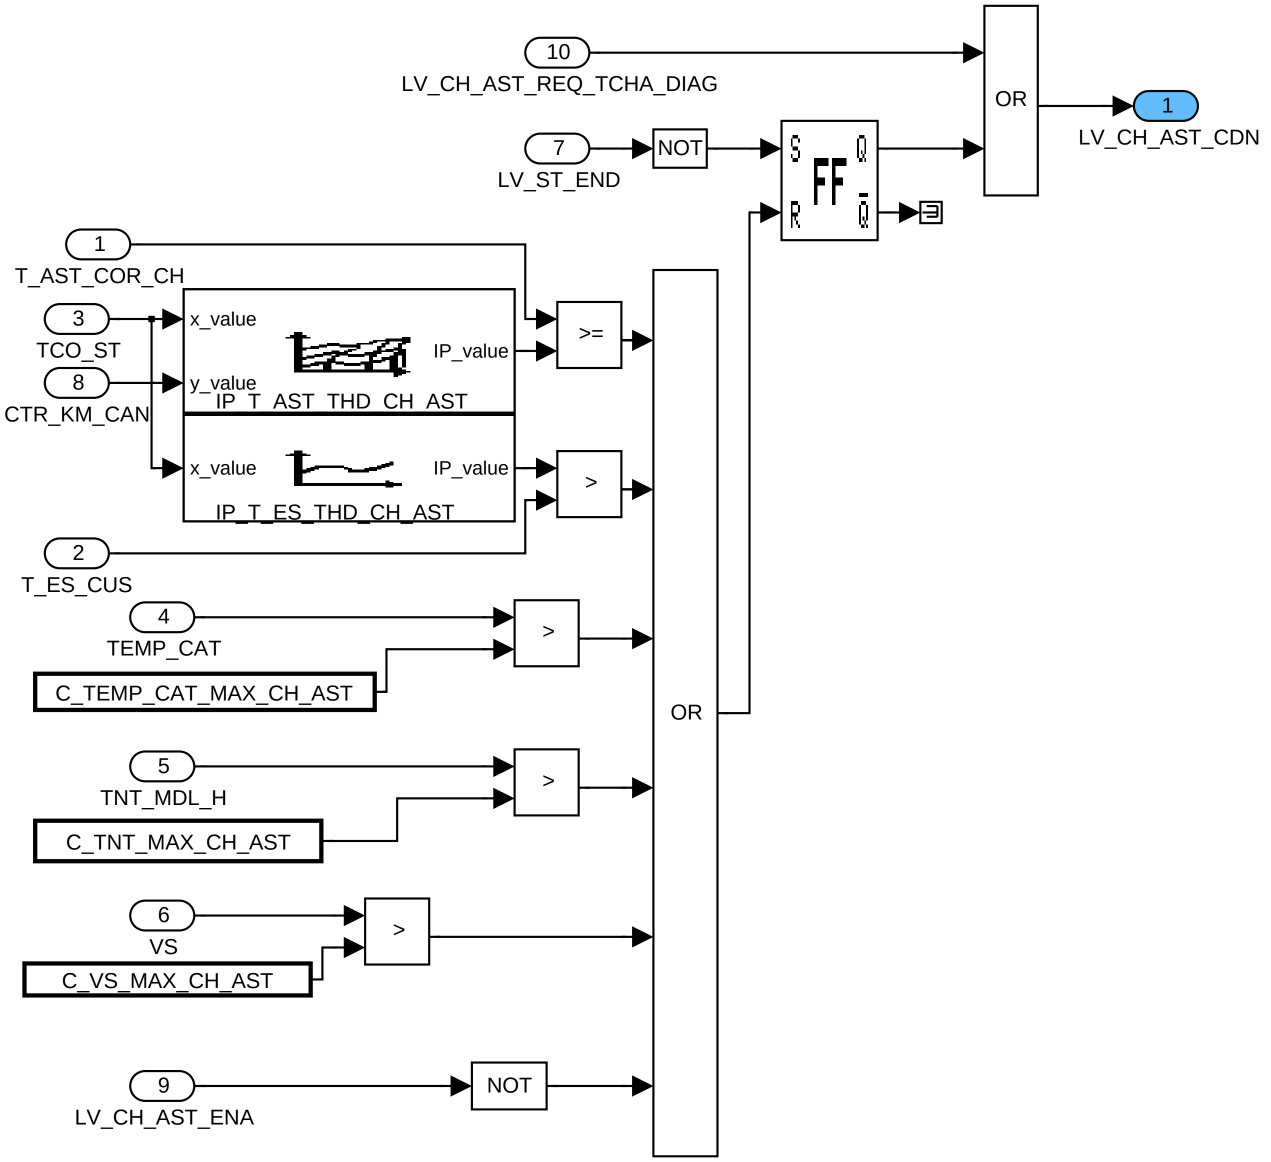

Figure 5:
Path: EXTC_ISPCLCHC0/CDN_CH_AST/SUB

30.3.3 Conditions for low load heating

30.3.3.1 Conditions for low load heating - Subsystem

TNT_MDL_L can be adjusted depending on NOx-trap aging.
Low load catalyst heating can be activated due to low temperatures in NOx-Trap or Pre-catalyst ('CH_L_CDN') or after regeneration of NOx-trap. In 2nd case the lambda-split function is activated (LV_CH_L_RGN = 1).
The differences between the actual temperatures and the thresholds TNT_DIF_CH_L and TEMP_CAT_DIF_CH_L are used as mapinputs in the setpoint calculation modules e.g. for torque reserve.

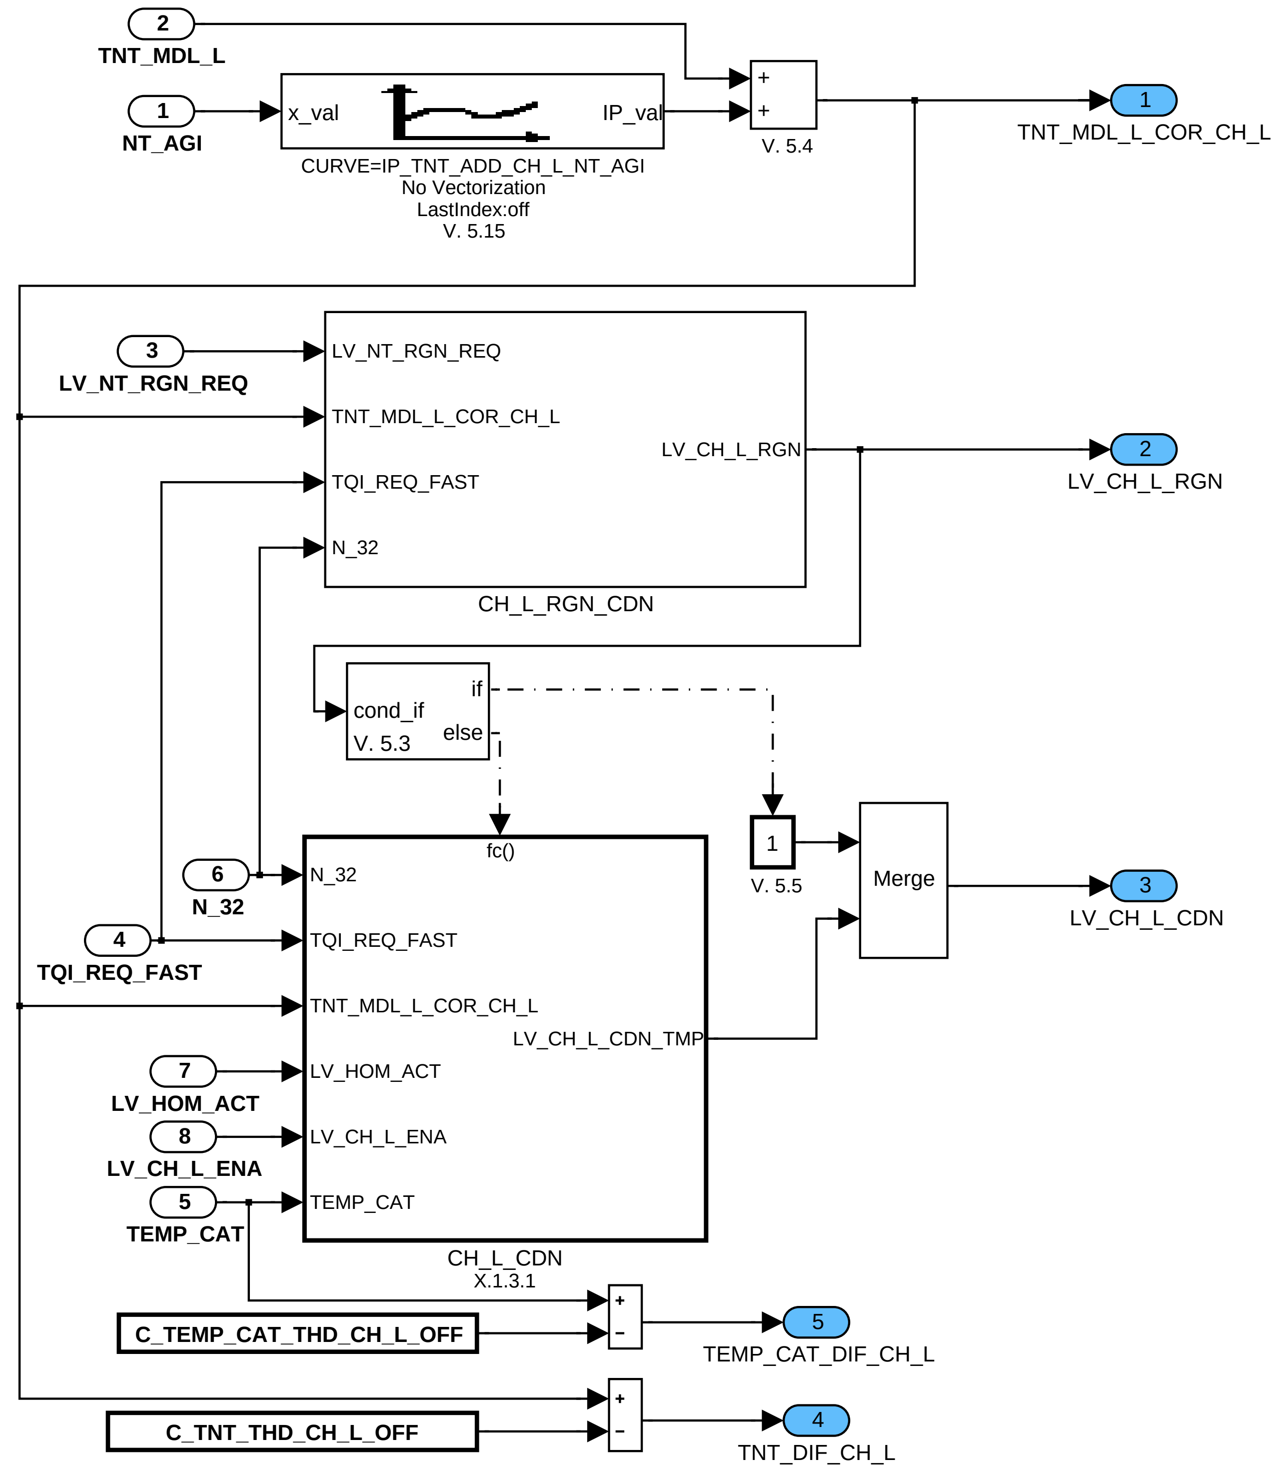

Figure 6:
Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB

30.3.3.1.1 Conditions for low load heating - Subsystem

For torque, engine speed and temperature there are each two thresholds for hysteresis application. For homogenous and stratified mode there are several activation thresholds for catalyst temperature. Attention: In low load catalyst heating one measure is to request homogeneous mode at too low temperatures! (See "Catalyst heating low load strategy"). These temperature thresholds have to be calibrated cohesive.

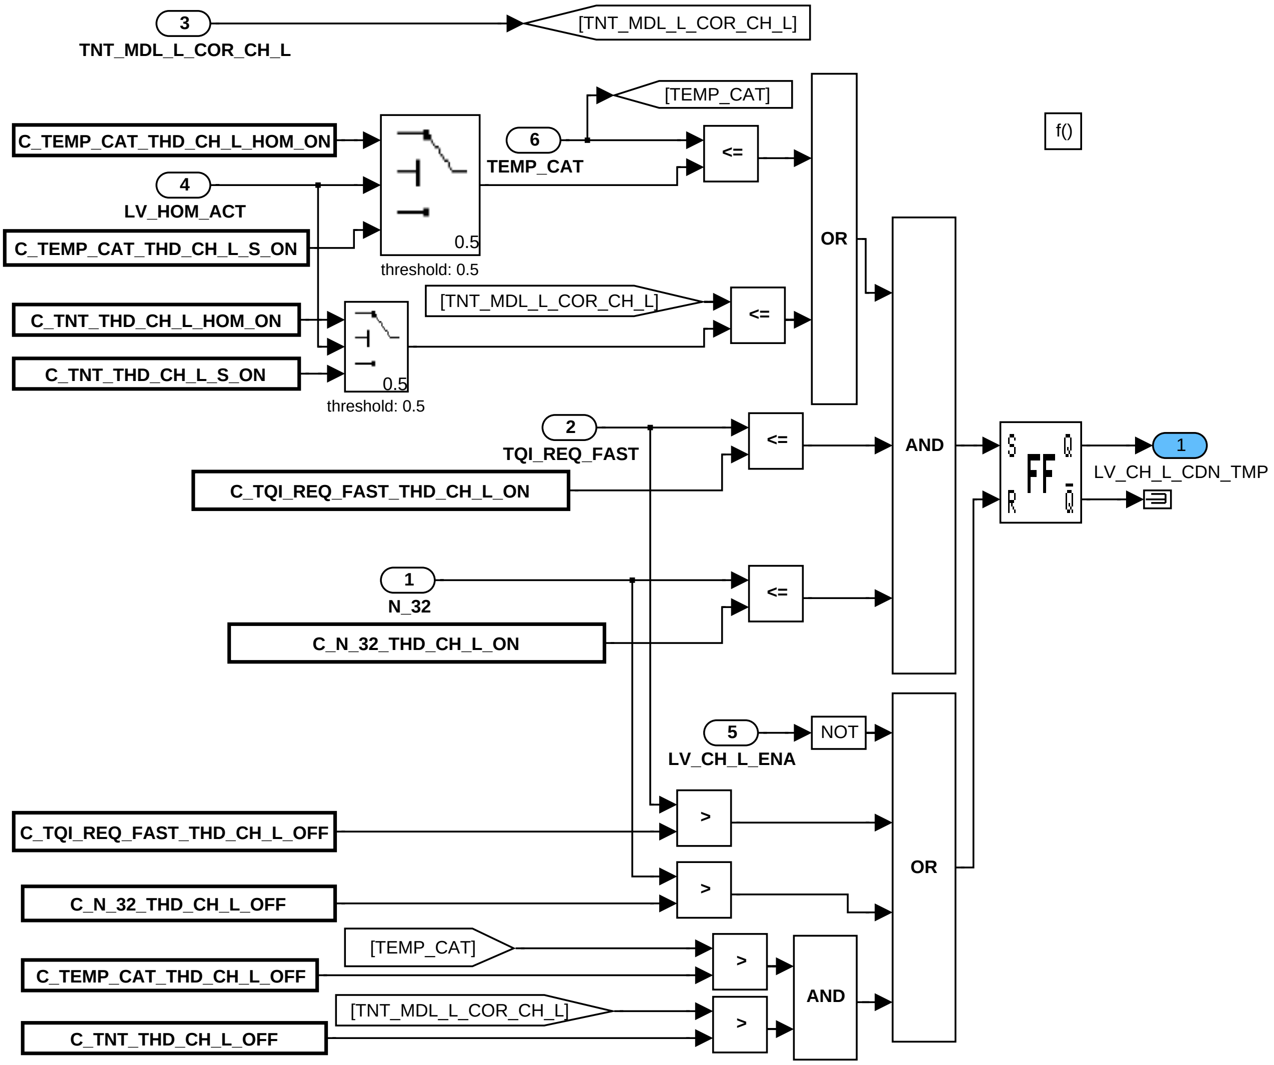

Figure 7:
Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB/CH_L_CDN

30.3.3.1.2 Conditions for low load heating after regeneratin (lambda split function)

LV_NT_RGN_REQ is 1 at active regeneration. The function can be deactivated depending on load-, temperature- or time threshold.

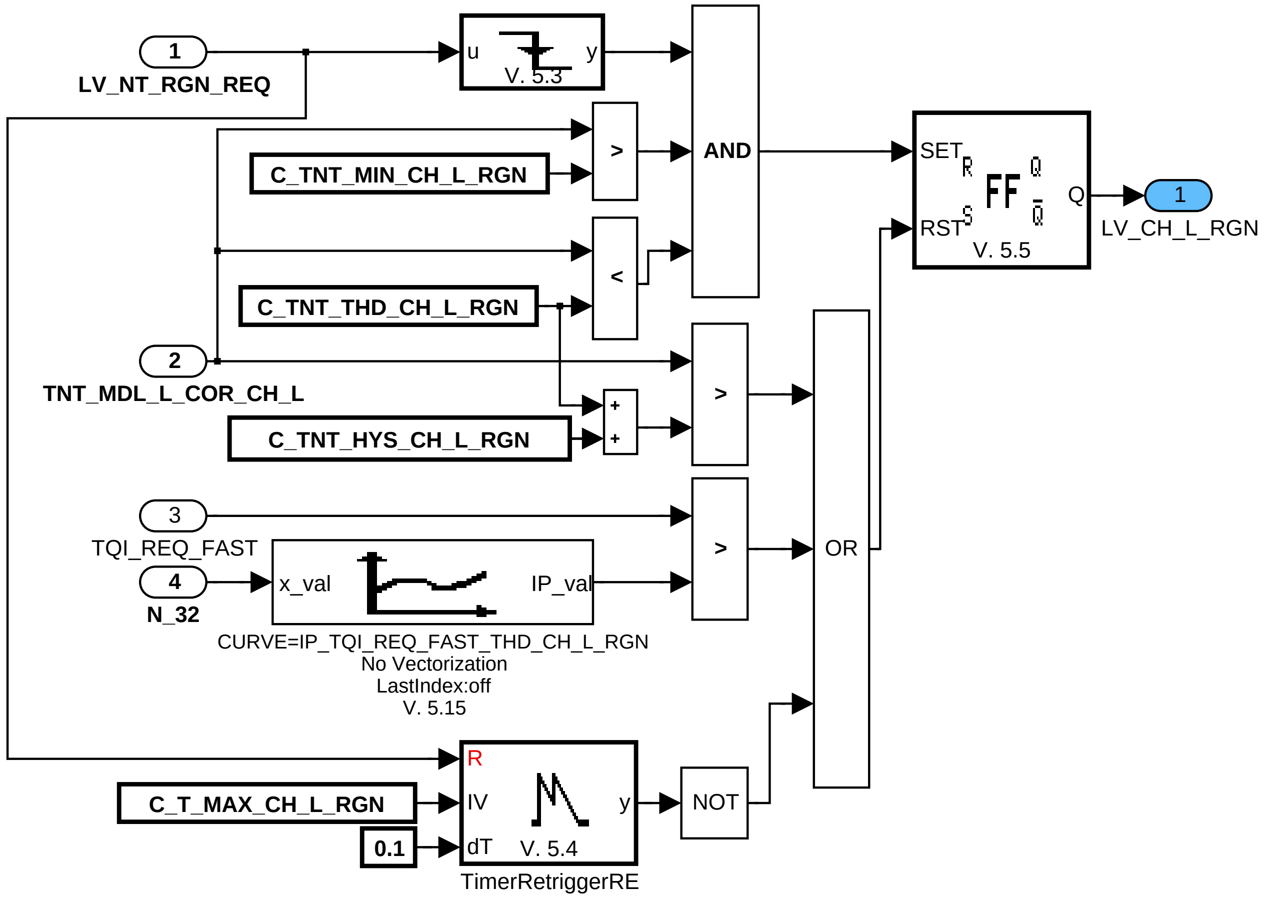

Figure 8:
Path: EXTC_ISPCLCHC0/CDN_CH_L/SUB/CH_L_RGN_CDN

30.3.4 Conditions for desulfation catalyst heating

30.3.4.1 Conditions for desulfation catalyst heating - 1st part

Vehicle speed and requested torque are filtered to avoid often on and off switching. TCO and FTL thresholds can only be re-set at engine off.

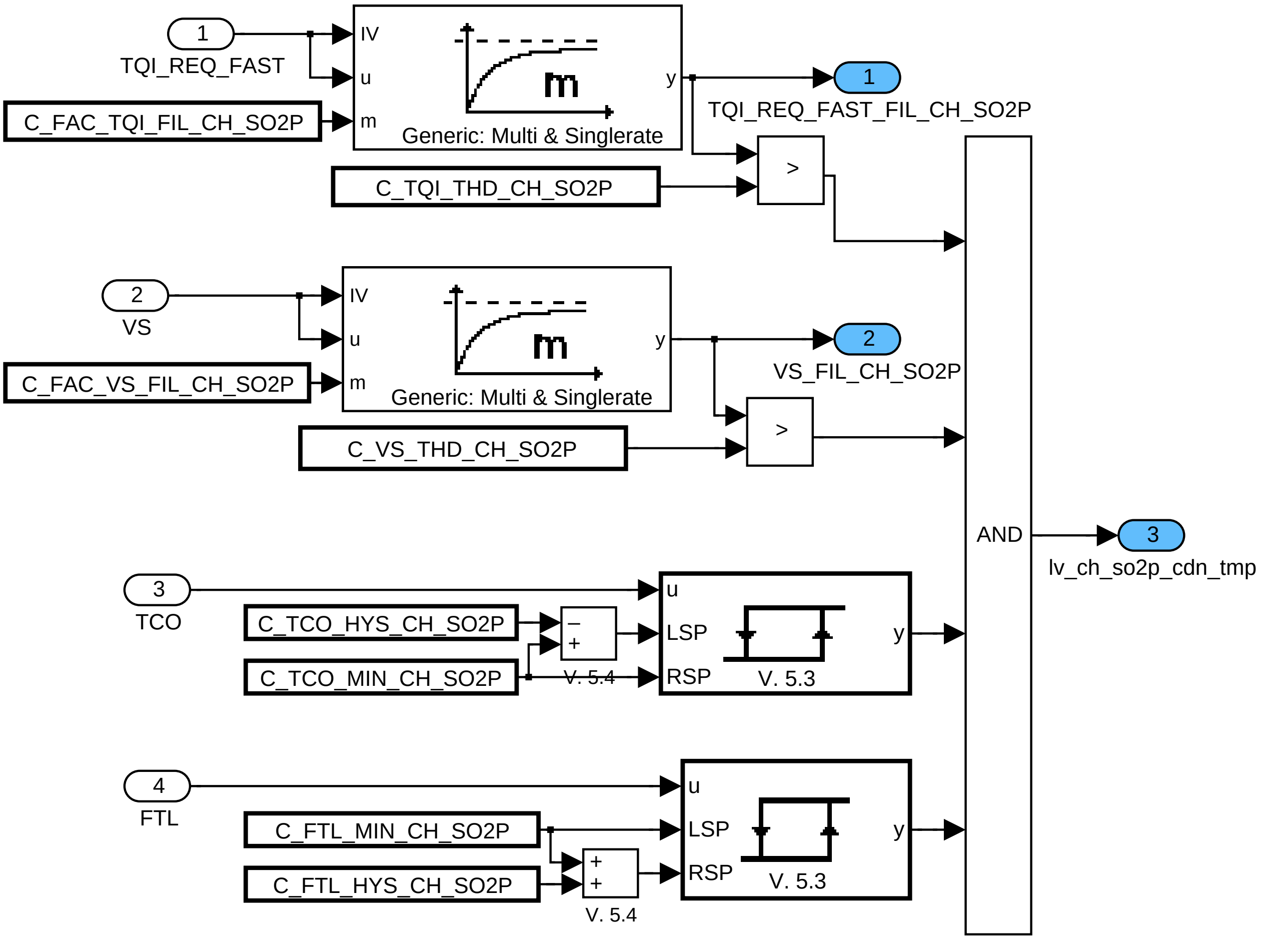

Figure 9:
Path: EXTC_ISPCLCHC0/CDN_CH_SO2P/SUB_1

30.3.4.2 Conditions for desulfation catalyst heating - 2nd part

LV_SO2P_REQ_2 indicates that catalyst heating is necessary due to imperatively desulfation.

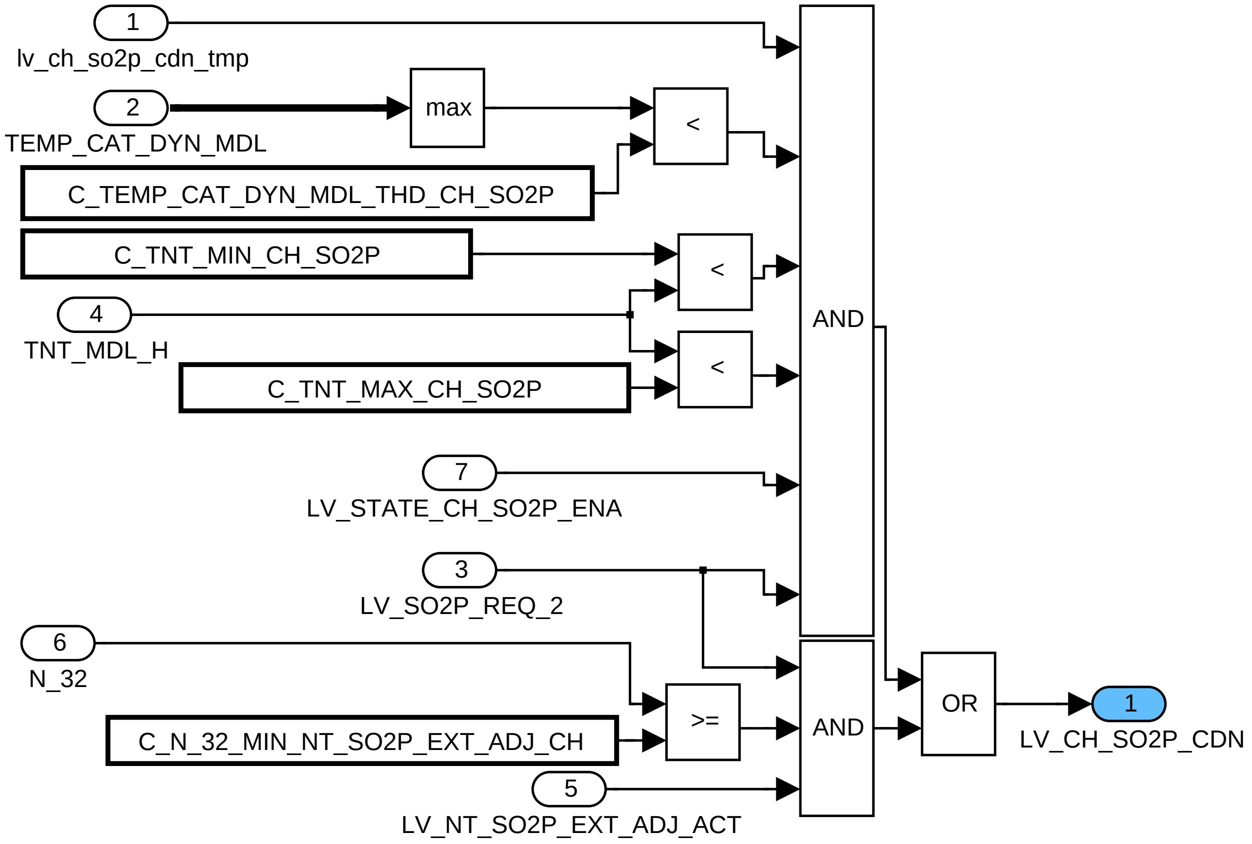

Figure 10:

LV_CTR_KM_CH_SO2P_INH_INI starts the kilometre counter DIST_CH_SO2P_INH.

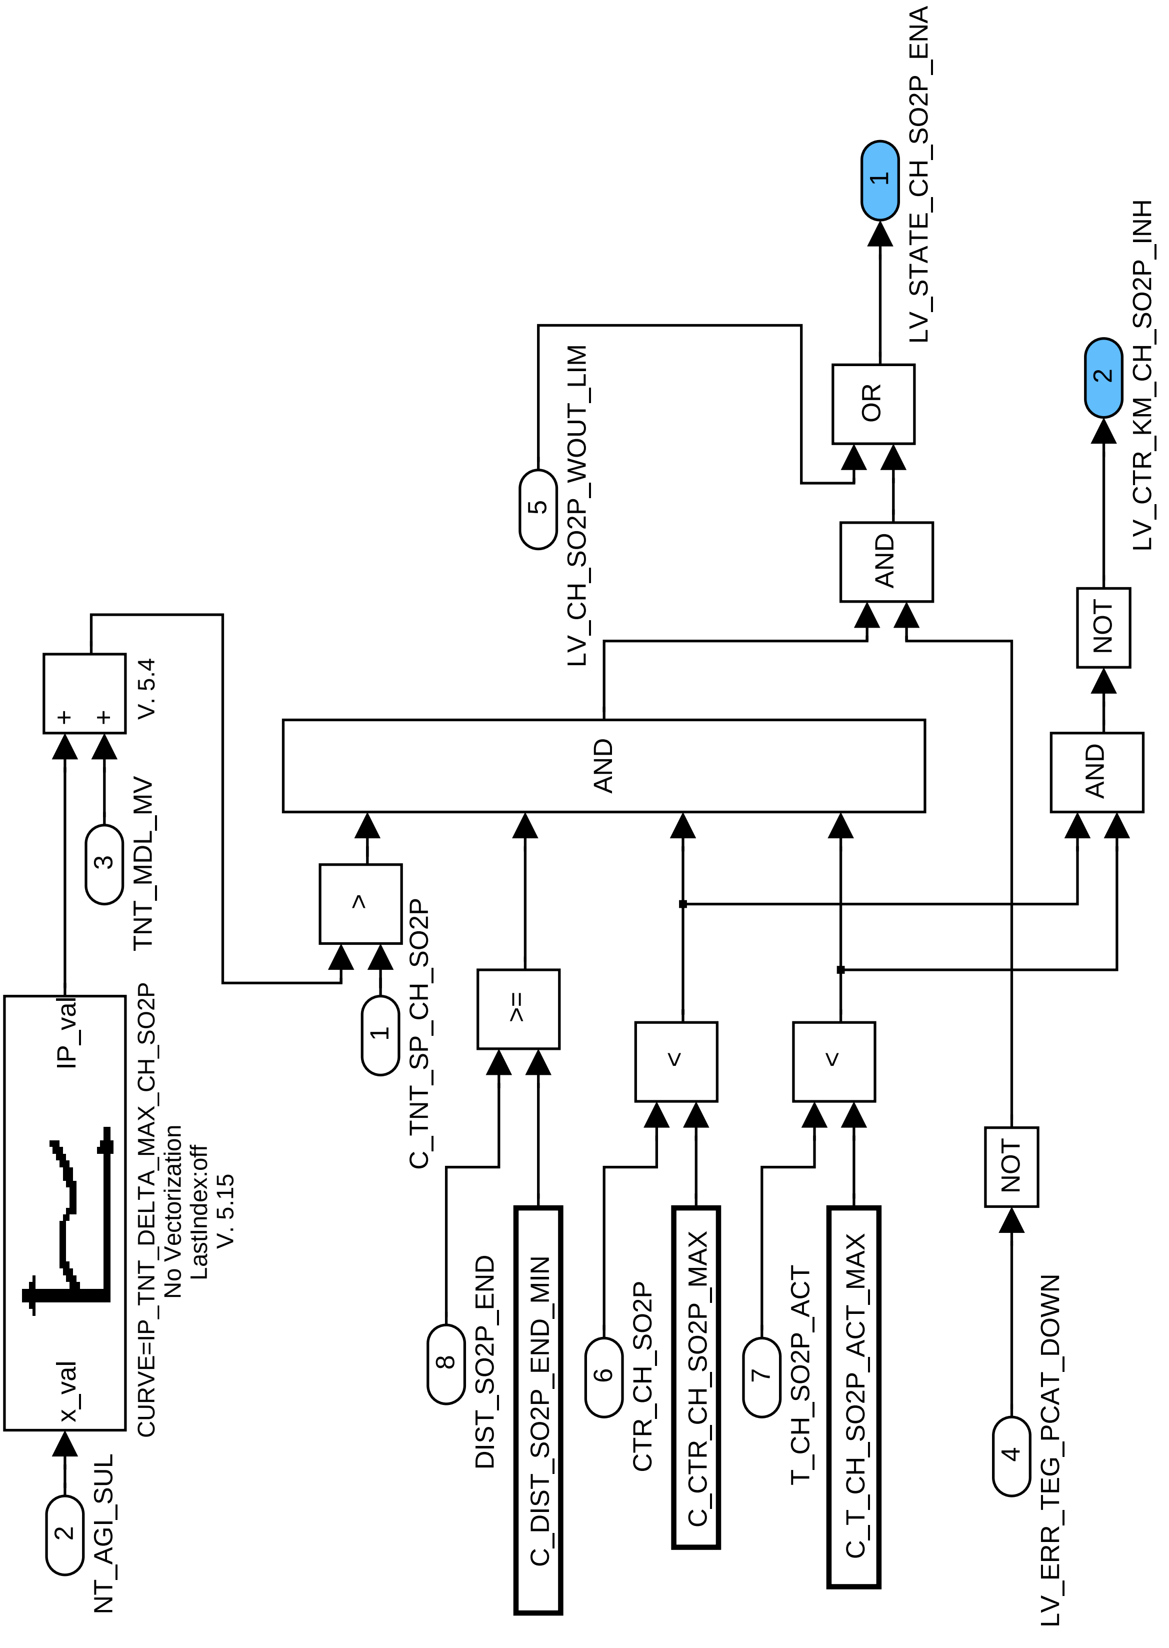

Figure 14:
Path: EXTC_ISPCLCHCAI0/operate/CLC_SO2P_CDN

30.4.2.2 Calculation of timer and counter - for desulfation catalyst heating

CTR_CH_SO2P counts the ineffective tryings to heat up the catalyst. T_CH_SO2P_ACT is the time, the catalyst is heated without started desulfation (temperature for desulfation not reached).DIST_SO2P_END are the kilometres that have been driven since the last successful desulfation. DIST_CH_SO2P_INH are the kilometres that have been driven since the time- or counter-threshold was reached. After C_DIST_CH_SO2P_INH_MAX is reached, the timer and the counter are initialized and the catalyst is heated again.

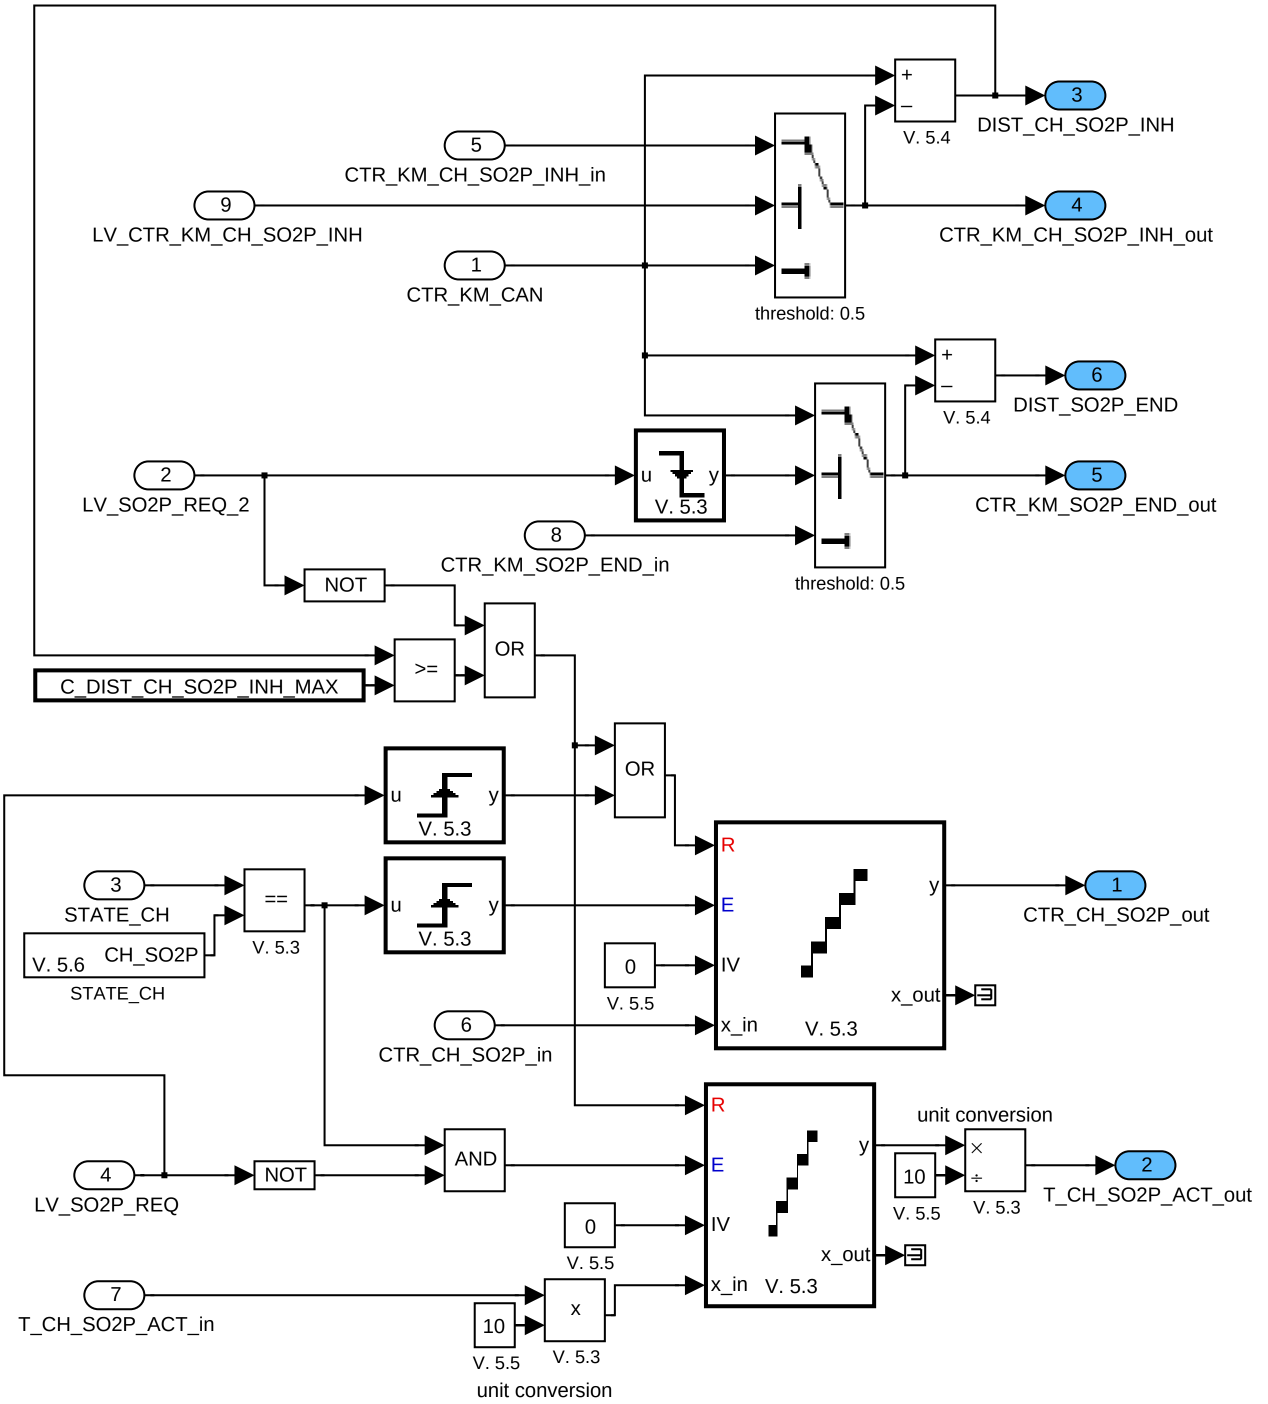

Figure 15:

General Information

The engine states during catalyst heating can be homogeneous (HOM), homogeneous with multiple injection (MPLH), stratified with post injection (MPLP) and homogeneous-stratified (HOMS). STATE_CH_MOD_AST, generated in this module, contains the information which catalyst heating strategy is active and is used for CH-setpoint calculation (for example fuel mass setpoint or lambda). Further the request which combustion mode is the most efficient for catalyst heating is generated in this module.

Application Conditions

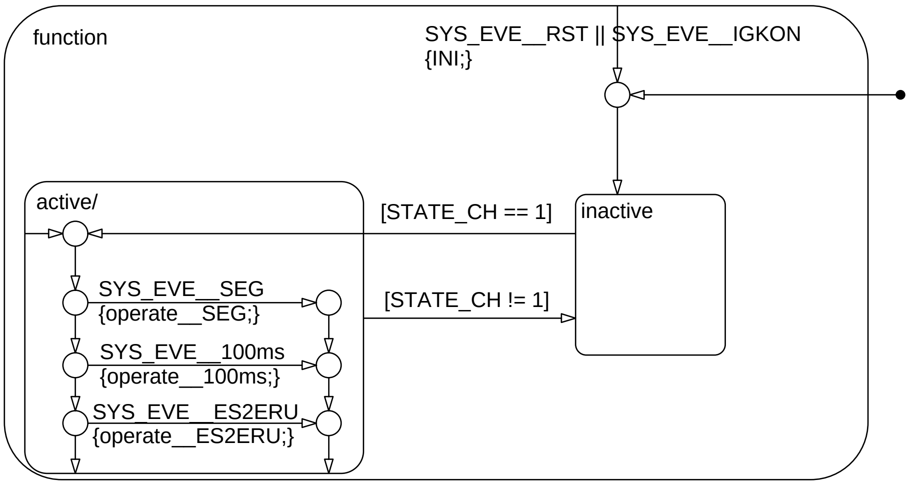

Figure 22:
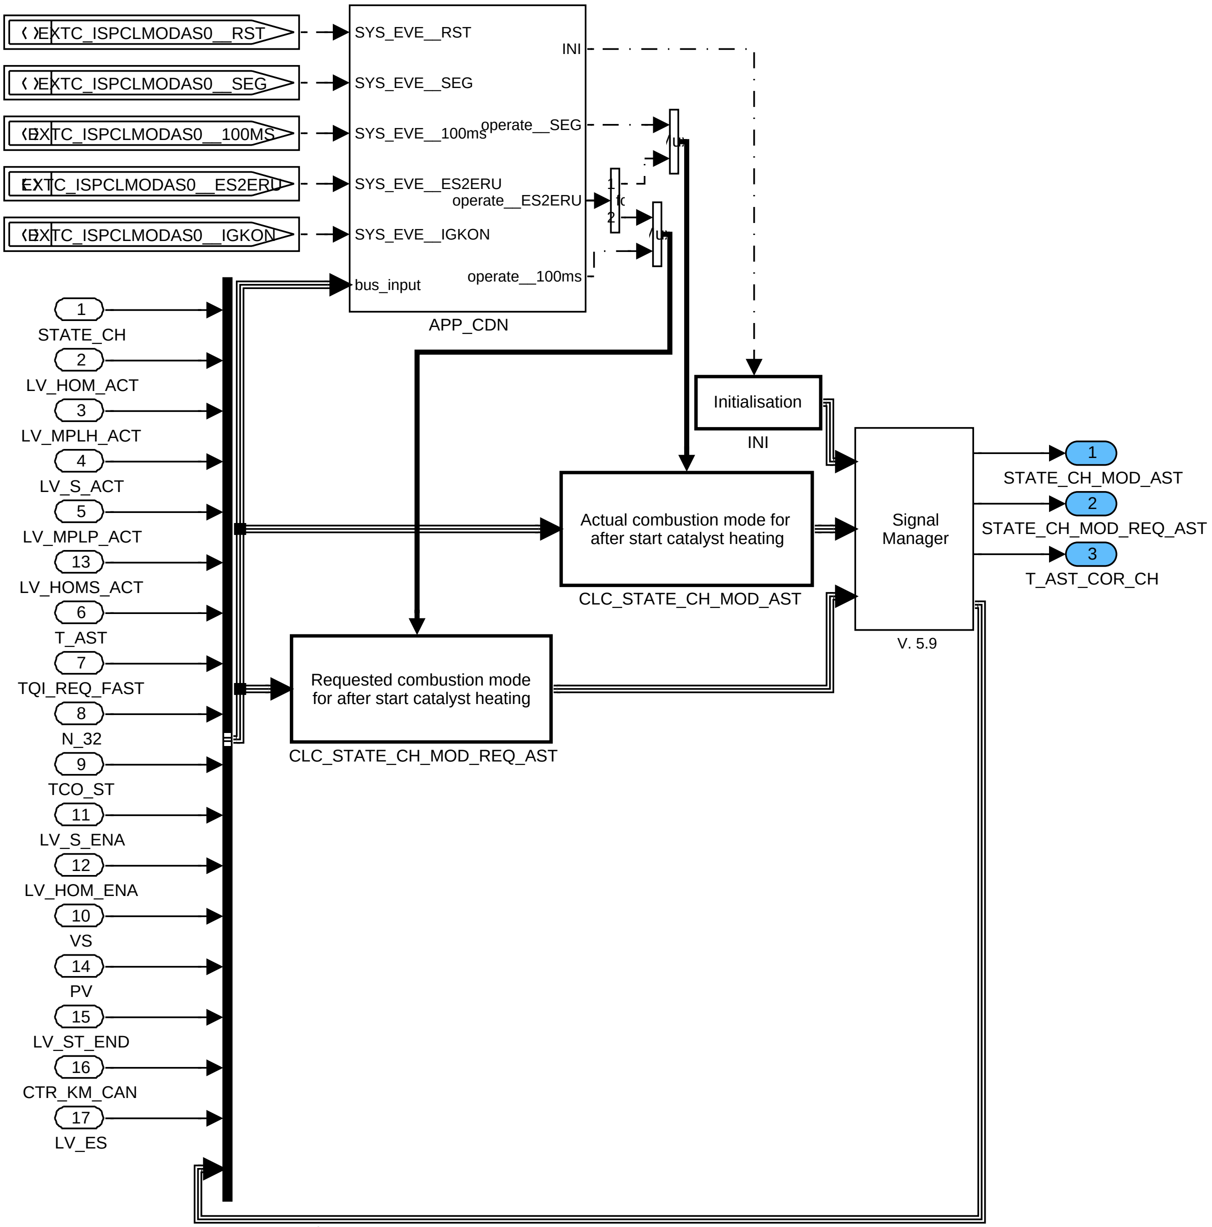
Path: EXTC_ISPCLMODAS0/APP_CDN/Chart

Function description



x

Figure 23:
Path: EXTC_ISPCLMODAS0

30.6.1 Initialisation

30.6.1.1 No title given

The outputs are initialised at reset and function deactivation.

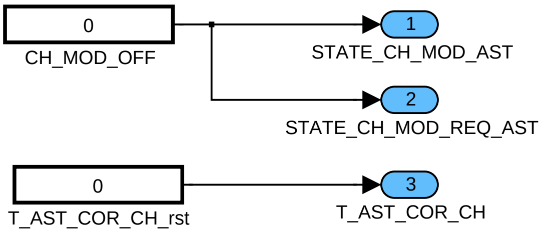


Figure 24:
Path: EXTC_ISPCLMODAS0/INI/SUB

30.6.2 Actual combustion mode for after start catalyst heating

30.6.2.1 No title given

STATE_CH_MOD_AST is set according to the bit-variables that show the actual mode (HOM, MPLH, HOMS or MPLP). If no mode is requested for catalyst heating (STATE_CH_MOD_REQ_AST = 0) also the actual mode is set to 0. It is also possible to set STATE_CH_MOD_AST manually.

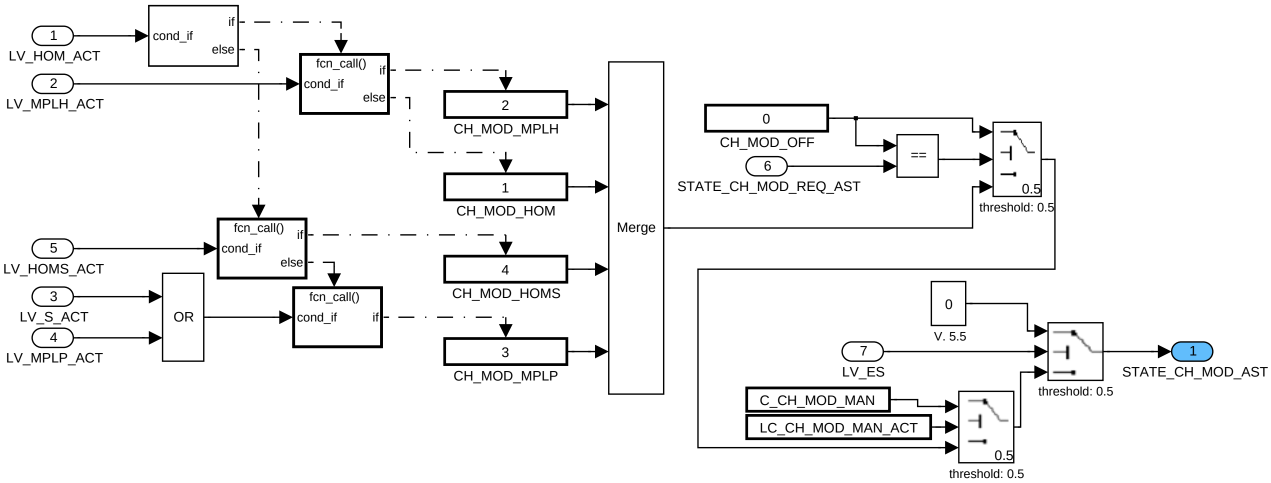

Figure 25:
Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_AST/SUB

30.6.3 Requested combustion mode for catalyst heating

30.6.3.1 No title given

ID_CH_MOD_BAS contains the strategy-order for catalyst heating.

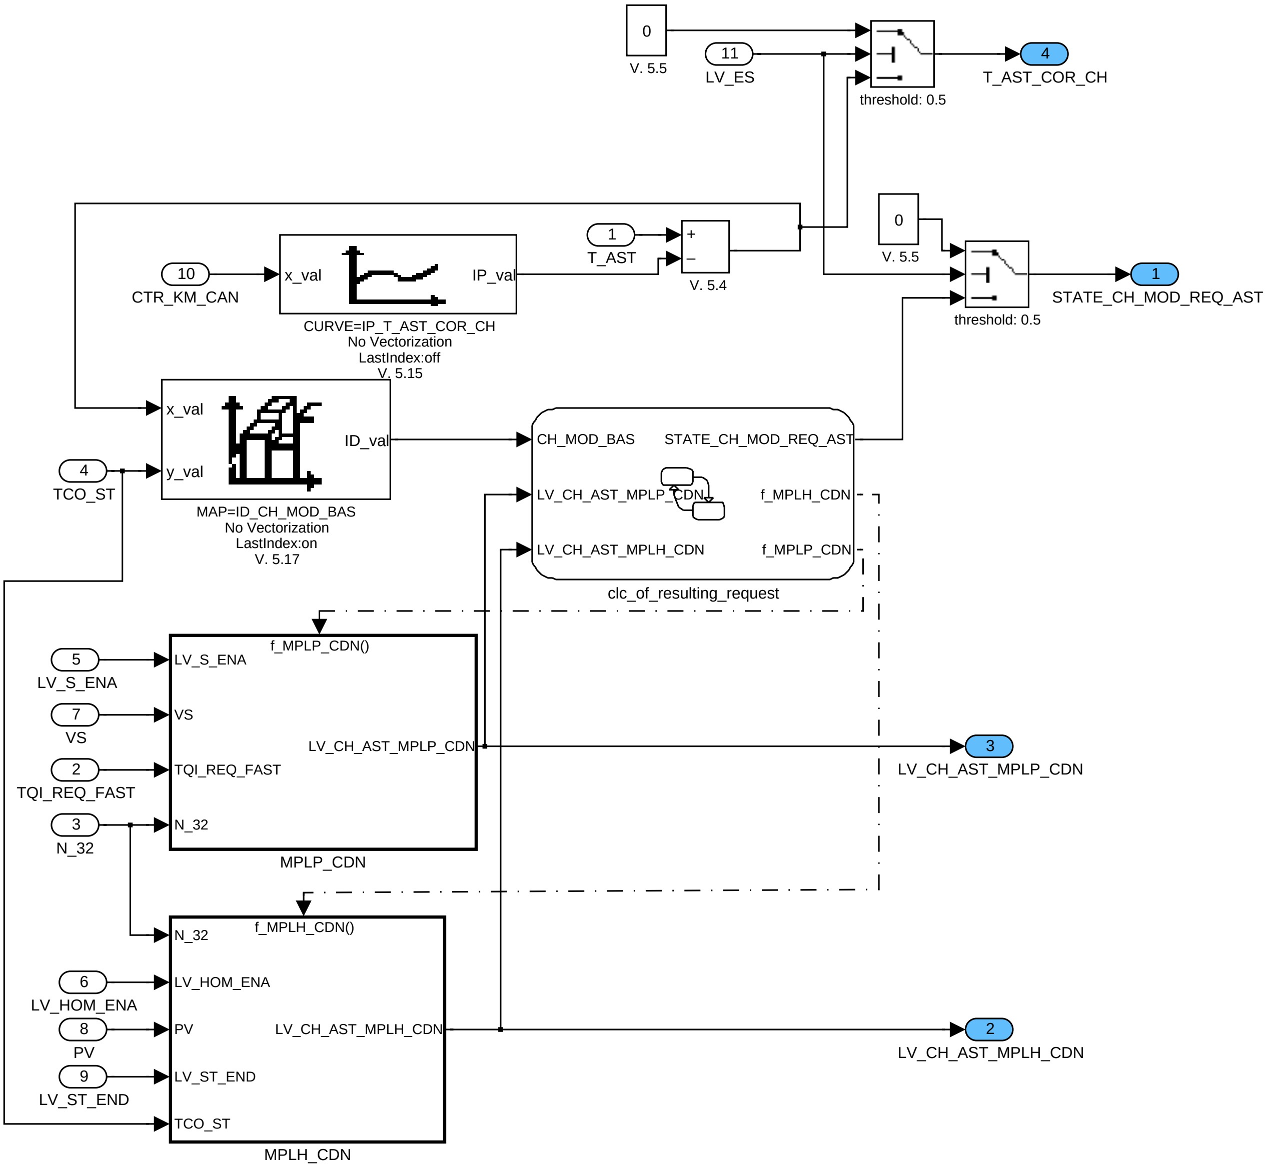

Figure 26:
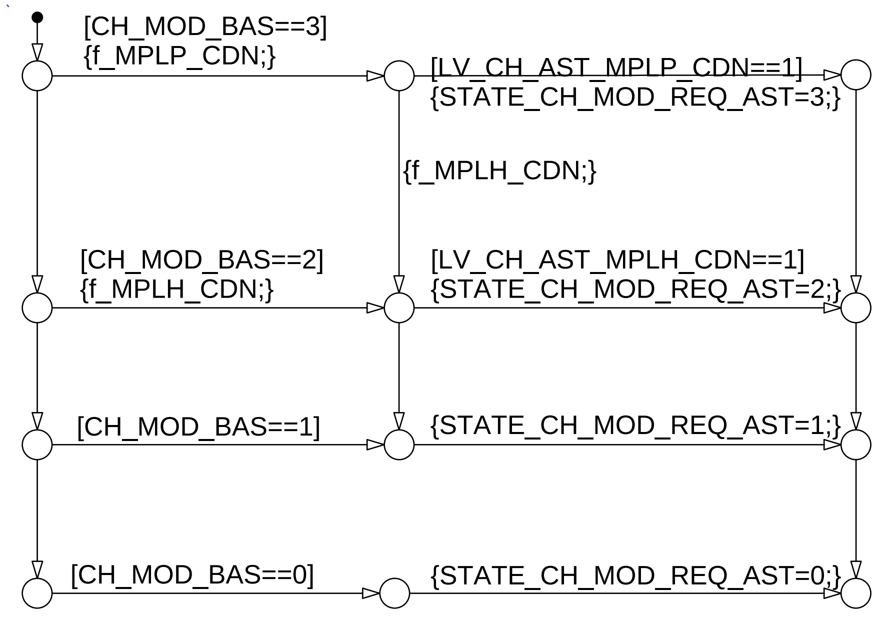
Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB

30.6.3.1.1 clc_of_resulting_request



Via function−call (e.g. f_MPLP_CDN) some conditions for the "optimal" combustion mode CH_MOD_BAS are checked. If this conditions (s. next subsystems) are not fulfilled, the next mode of the priority−order MPLP−MPLH−HOM is checked.

Figure 27:
Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/clc_of_resulting_request

30.6.3.1.2 Conditions for homogenous mode with multiple injection

LV_CH_AST_MPLH_CDN indicates if conditions for MPLH for catalyst heating are fulfilled. It is set to 0 if the engine speed is not in-between a calibratable range, LV_HOM_ENA is 0 or the pedal value exceeds C_PV_MAX_MPLH_CH for a certain time (C_T_MIN_PV_THD_MPLH_CH_DEAC). The bit LV_CH_AST_MPLH_CDN can only be set to 1 again after next engine start.

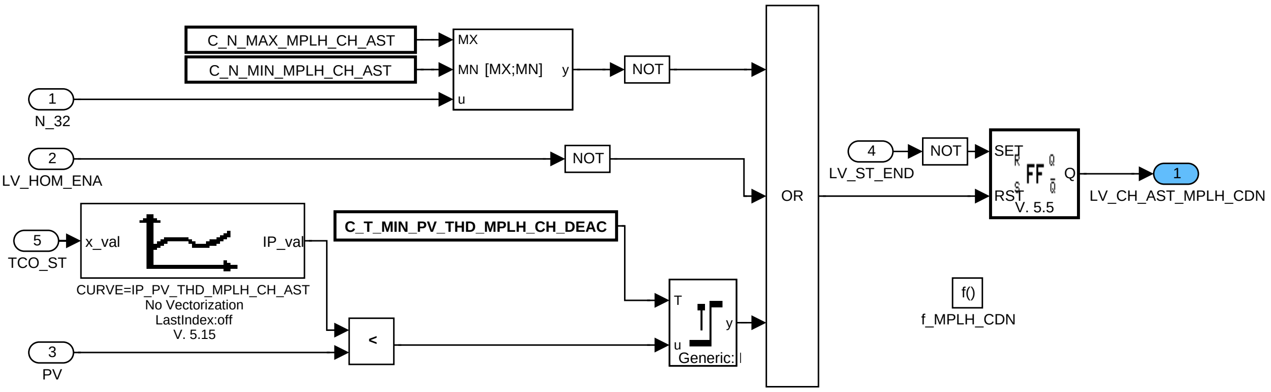


Figure 28:
Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/MPLH_CDN

30.6.3.1.3 Conditions for stratified mode

For stratified mode with post injection the torque request and the engine speed has to be in-between a calibratable range, the vehicle speed must be below a limit and LV_S_ENA must indicate that stratified mode is enabled.

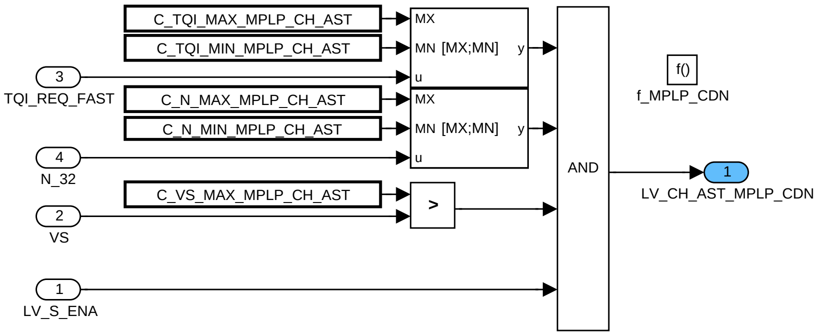

Figure 29:
Path: EXTC_ISPCLMODAS0/CLC_STATE_CH_MOD_REQ_AST/SUB/MPLP_CDN

30.7.1 General information

This module has to be calculated after “Catalyst heating coordination” and “Catalyst heating after start strategy” and before any other catalyst heating module.

The output STATE_CH_MOD_L will be merged in “Catalyst heating strategy” into STATE_CH_MOD. This value is used to trigger setpoint calculation modules. STATE_CH_MOD_REQ_L will be merged into STATE_CH_MOD_REQ.

Application Condition

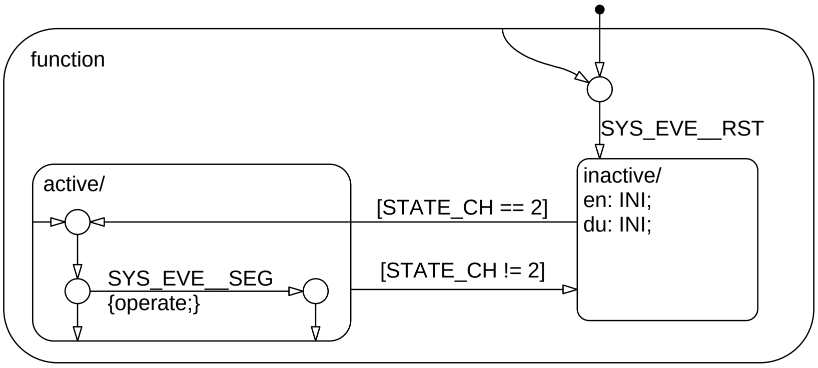

Figure 30 EXTC_ISPCLmodll0/ APP_CDN/ Chart

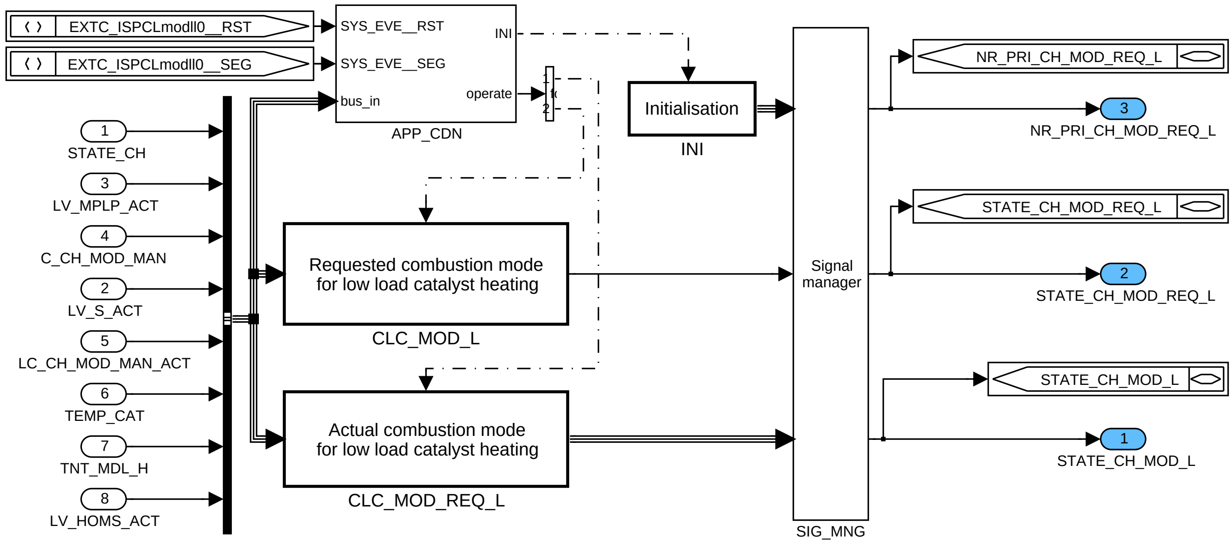
Function Description



SDA_SRS / SDA 4.0 22−Jun−2005

Figure 31 EXTC_ISPCLmodll0

30.7.1.1 Initialization

All outputs are set to 0 at reset and deactivated function.

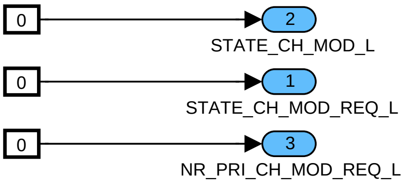


Figure 32 EXTC_ISPCLmodll0/ INI/ INI_SUB

30.7.1.2 Actual combustion mode for low load catalyst heating

Depending on the actual active combustion mode, STATE_CH_MOD_L is set to HOMS, MPLP or HOM. With (L)C_CH_MOD_MAN(_ACT) it is possible to set it manually.

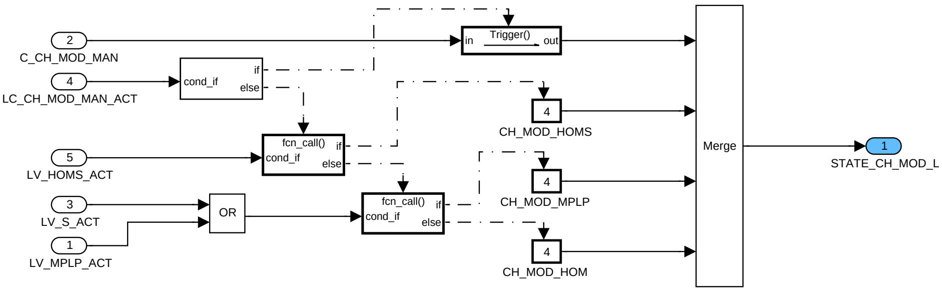

Figure 33 EXTC_ISPCLmodll0/ CLC_MOD_L/ CLC_MOD_L_SUB

30.7.1.3 Requested combustion mode for low load catalyst heating

If catalyst or NOx-Trap temperature falls below C_TEMP_CAT_MIN_SWI_HOMS_CH_L or C_TNT_MIN_SWI_HOMS_CH_L the HOMS – mode is requested to inhibit that the catalyst cools down under the working temperature. If one of the temperatures falls even below C_TEMP_CAT_MIN_SWI_HOM_CH_L or C_TNT_MIN_SWI_HOM_CH_L homogenous mode is requested. NR_PRI_CH_MOD_REQ_L is increased via C_NR_PRI_CH_MOD_REQ_L_ACT if the request shell be active.

General Information

general specification

This module has to be calculated after Catalyst heating coordination , Catalyst heating after start strategy , Catalyst heating low load strategy and before any other catalyst heating module.

The engine states during catalyst heating for desulfation can be homogeneous (HOM) and homogeneous with multiple injection (MPLH). STATE_CH_MOD_SO2P, generated in this module, contains the information which catalyst heating strategy is active and is used for CH-setpoint calculation (for example fuel mass setpoint or lambda). It will be merged in Catalyst heating strategy into STATE_CH_MOD. STATE_CH_MOD_REQ_SO2P will be merged into STATE_CH_MOD_REQ. Further a request is generated that contains the most efficient combustion mode for desulfation catalyst heating.

Application Conditions

Initialization: RST
Activation: 100MS: STATE_CH == 3
SEG: STATE_CH == 3
Deactivation: STATE_CH != 3 && STATE_CH_MOD_REQ_SO2P == 0

Function description

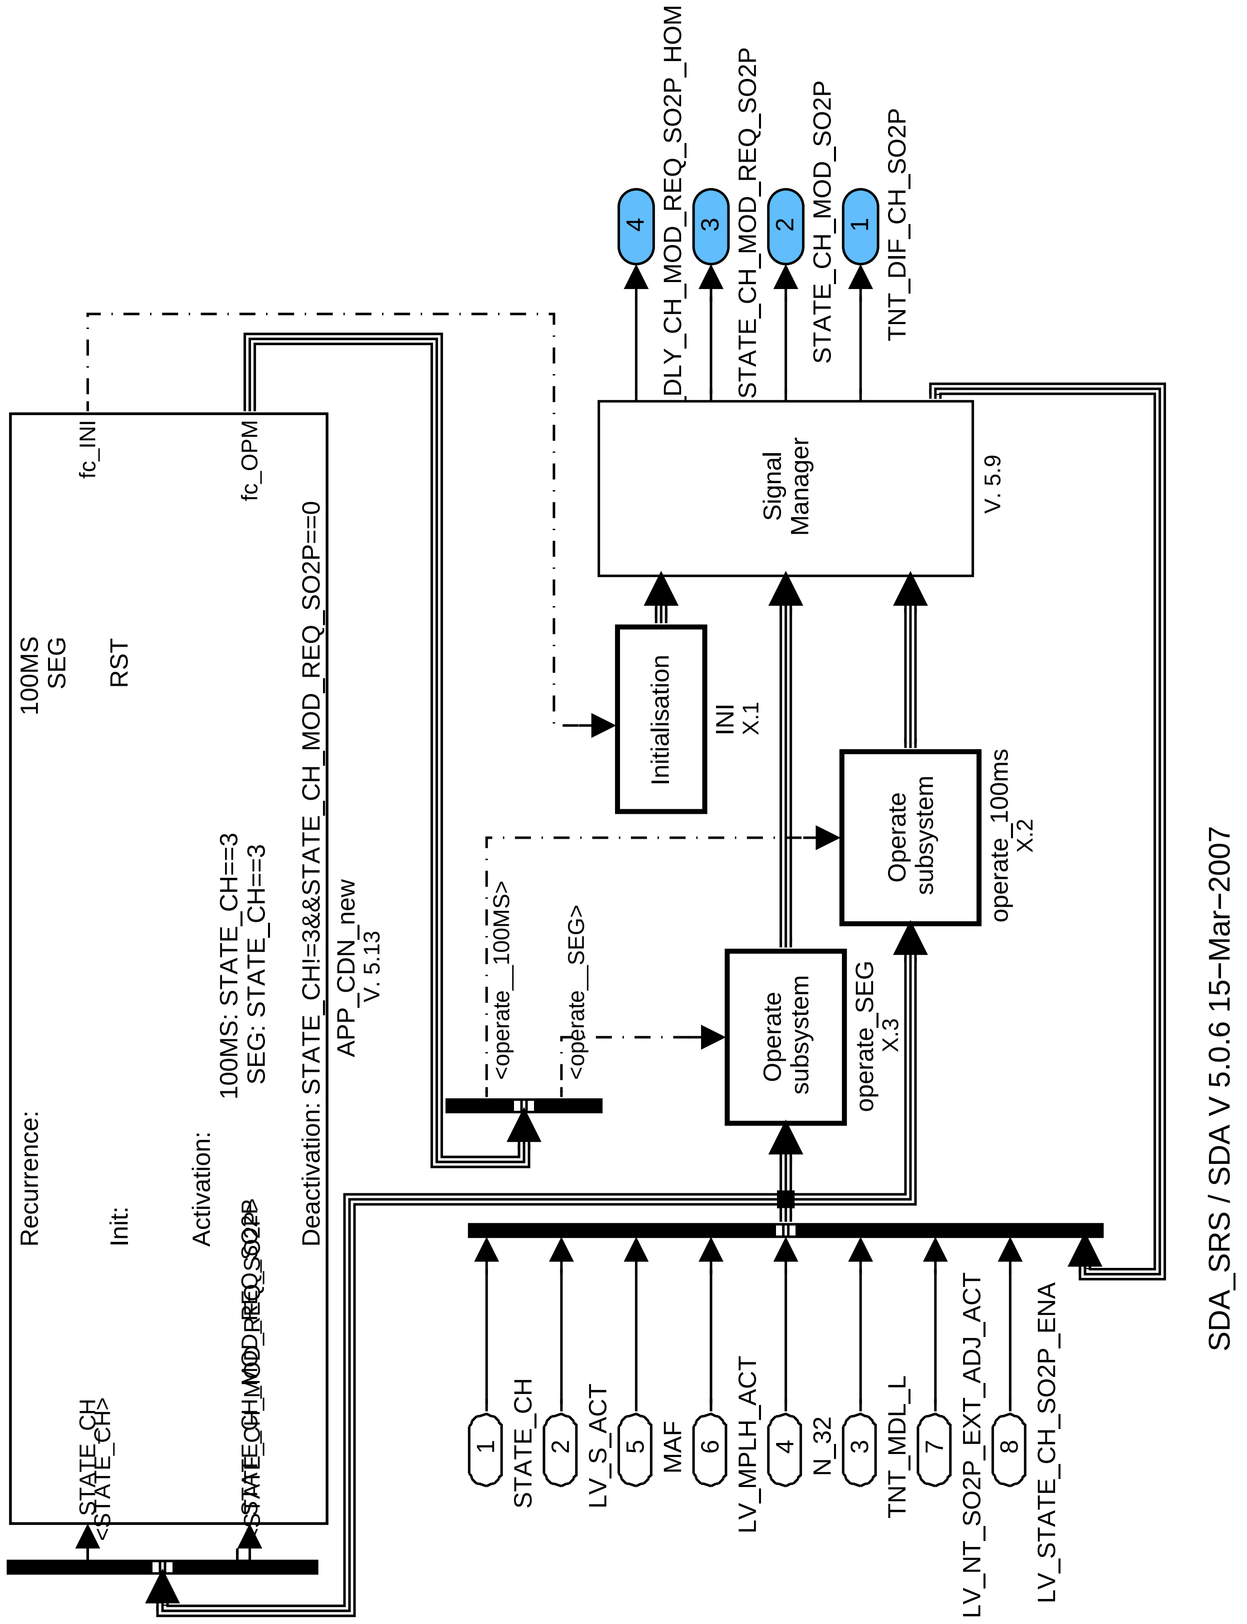

Figure 35:
Path: EXTC_ISPCLMODSO0

30.8.1 Initialisation

30.8.1.1 Initialisation - Subsystem

The outputs are initialised at reset and function deactivation.

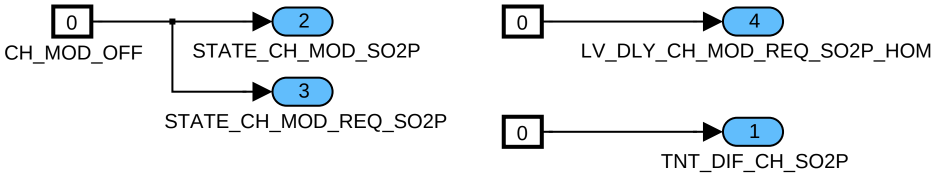

Figure 36:
Path: EXTC_ISPCLMODSO0/INI/SUB

30.8.2 100 ms - Task

30.8.2.1 100 ms - Task - Subsystem

At deactivation of desulfation catalyst heating due to torque or vehicle speed threshold (STATE_CH == 0 and LV_STATE_CH_SO2P_ENA=1) there is the possibility to request homogenous mode for a calibratable time.

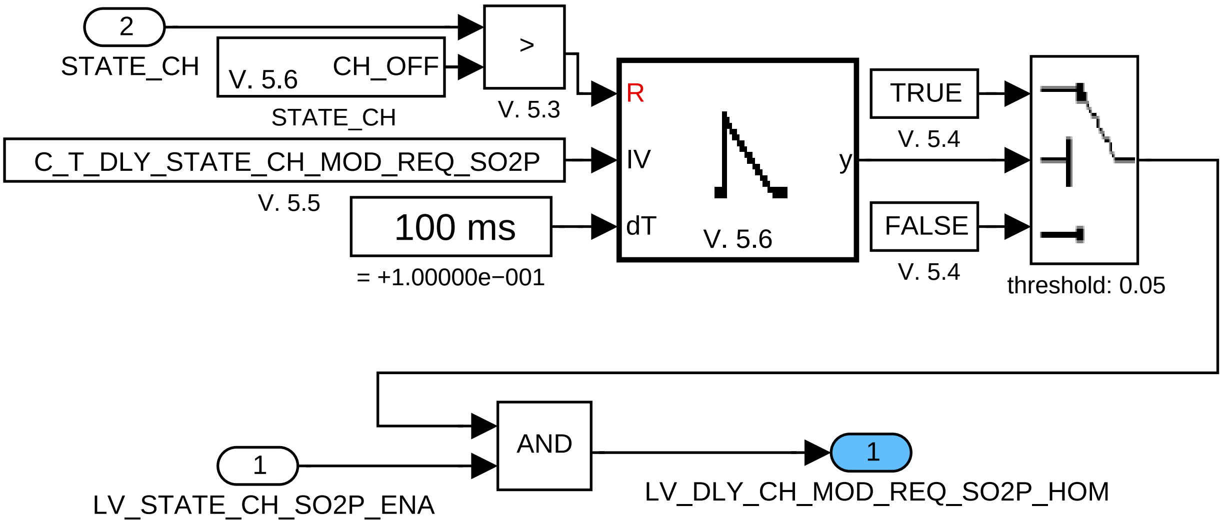

Figure 37:
Path: EXTC_ISPCLMODSO0/operate_100ms/SUB

30.8.3 Segment synchronous task

30.8.3.1 Segment synchronous task - Subsystem

TNT_DIF_CH_SO2P is the difference between the NOx-trap temperature setpoint and the actual value. It is negative if there is necessity to heat. The ID and the calibration data for manual setting have other physical meaning as the output of the spec because for catalyst heating for desulfation only HOM and MPLH can be used.

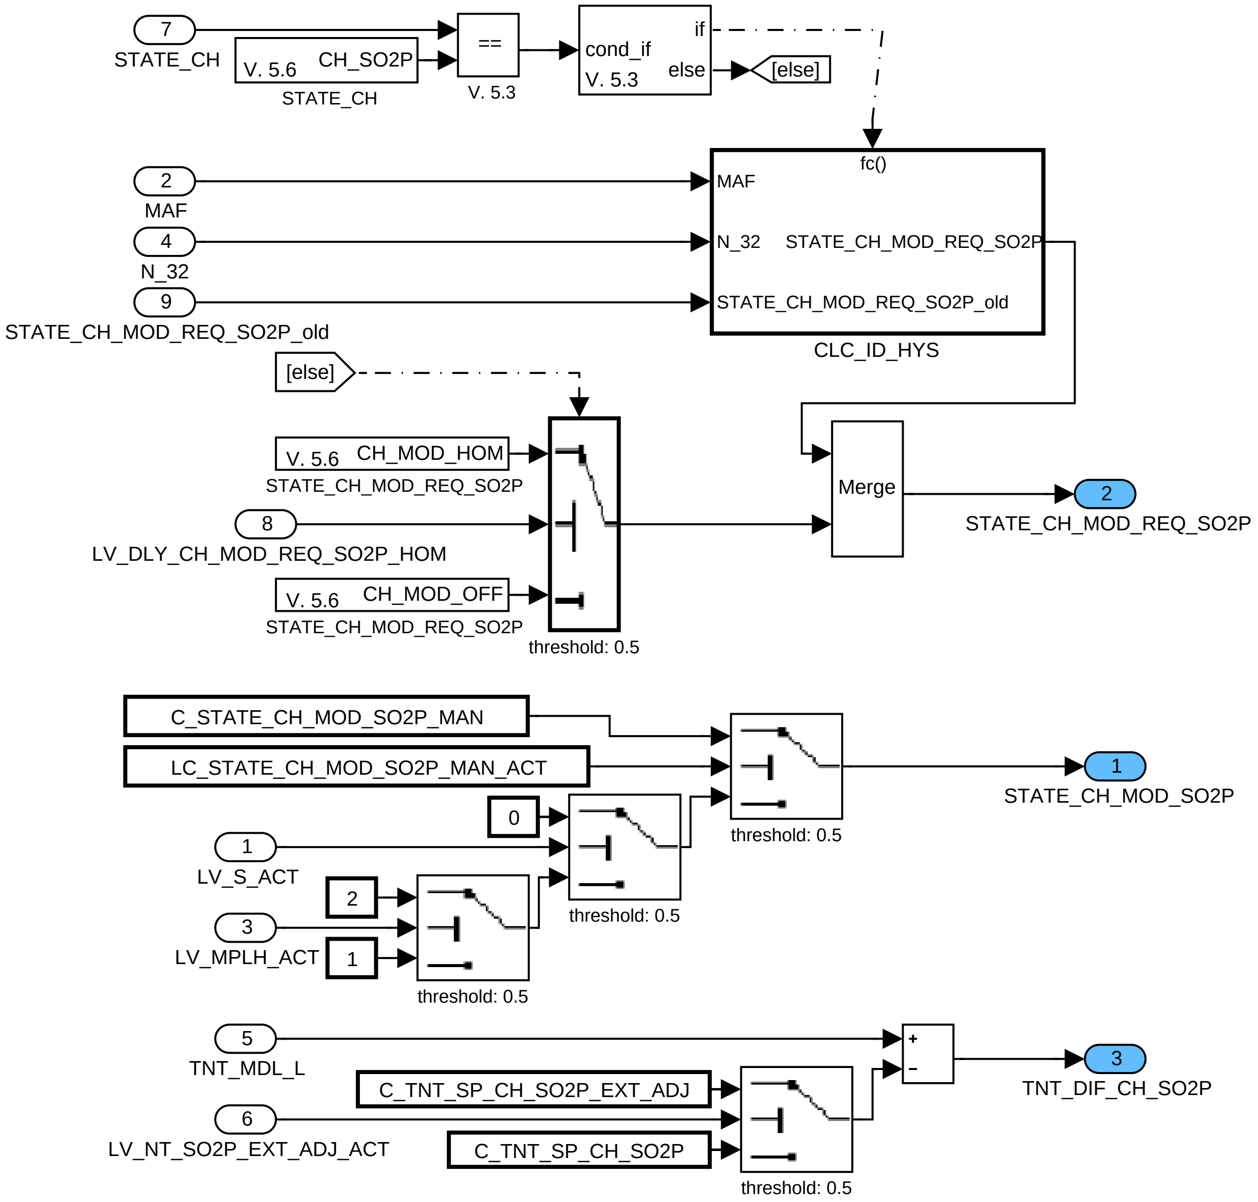

Figure 38:
Path: EXTC_ISPCLMODSO0/operate_SEG/SUB

30.8.3.1.1 EXTC_ISPCLMODSO0/OPERATE_SEG/SUB/CLC_ID_HYS

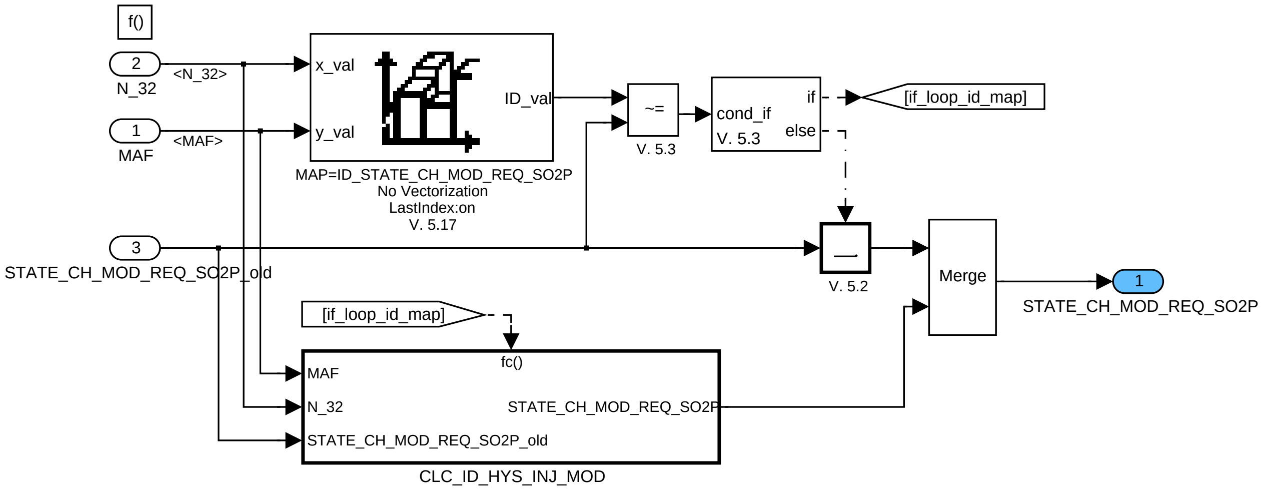

Figure 39:
Path: EXTC_ISPCLMODSO0/operate_SEG/SUB/CLC_ID_HYS

30.8.3.1.1.1 Change of injection mode

The basic for the changing of the injection mode is the hysteresis of N_32 and MAF to avoid the toggle between the injection modes. The actual values of N_32 and MAF are detected by the corresponding breakpoints. These indexes are going to the map ID_STATE_CH_MOD_REQ_SO2P. The hysteresis is calculated with the value of the corresponding breakpoint and the calibration constant. The changing of the injection mode is only possible after reaching the maximum threshold of the hysteresis. Example: Actual engine speed is 3000rpm. Corresponding breakpoint is 1632rpm. Calibration value is 200rpm. Result of the hysteresis is 1632rpm + 200rpm = 1832rpm. The calculation of MAF is the same.

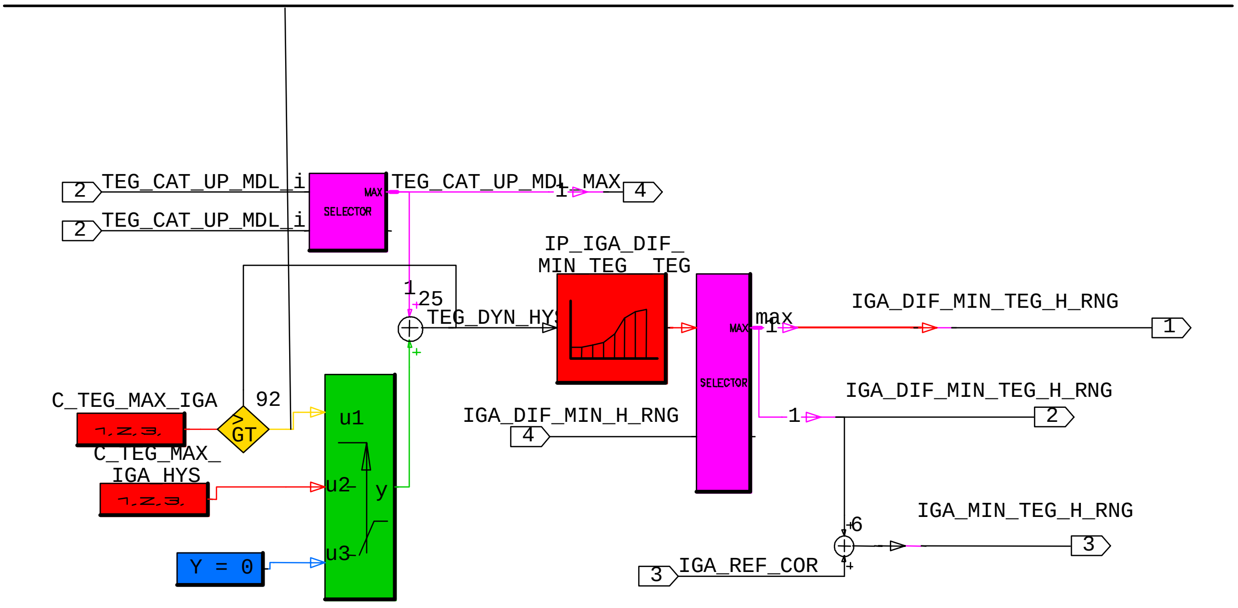
Temperature of exhaust gas with hysterisis for IGA_MIN limitation					
TEG_CAT_UP_MDL_MAX	V/O	0...7FF0H	0...2047	0.0625	[°C]
Maximal Temperature of exhaust gas between all cylinder bank					

Input data:

LV_HOM_RUN	LV_ST	LV_ES	TEG_CAT_UP_MDL[NC_CBK_EX_NR]
IGA_DIF_MIN_H_RNG	IGA_REF_COR		

FUNCTION DESCRIPTION:

Discrete SuperBlock	Sample Period	Sample Skew	Inputs	Outputs	Enable Signal
IGA_MIN_for_TEG	1.	0.	4	4	Parent



General information:

The minimum ignition angle IGA_MIN is the minimum allowable ignition angle that is possible to apply to the engine. Hencce, it only includes the combustion stability concern. It does not take into account any thermal effect. It should be used during the torque intervention phases in order to produce a fast reduction of the torque.
Applying IGA_MIN as actual ignition angle results in efficiency losses that should lead to an exhaust gas overheating and/or engine damages.

In order to avoid overheating of the components in the exhaust-system branch, minimum spark retard has to be limited in accordance with the actual exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR].

Moreover to determine the maximum possible torque reserve for catalyst heating, the torque reserve co-ordination module needs the minimum ignition angle efficiency and the minimum ignition angle with exhaust branch protection efficiency in order to limit and choose the different torque reserve requests.

Hence another minimum spark retard difference have to be calculated IGA_DIF_MIN_TEG_H_RNG which takes into account the exhaust gas system protection. It is the maximum between the one calculated versus the maximal exhaust gases temperature (TEG_CAT_UP_MDL_MAX) and the basic one IGA_DIF_MIN_H_RNG.
Classically IGA_DIF_MIN is calculated from a basic value of the minimum ignition angle corrected with a temperature dependent additive term. The basic minimum spark advance is here extracted from a calibration map.
To calculate the minimum spark retard limitation according to the exhaust gas temperature the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG is used. TEG_DYN_HYS is used as input for this map. This intermediate variable TEG_DYN_HYS represents the exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] increased by an hysterisis in order to anticipate the exhaust-system branch overheat.

The influence of the ignition angle on the exhaust gas temperature results from the ignition angle efficiency. Thus - in order to calibrate easily the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG - one should use the efficiencies resulting from IGA_DIF_MIN_H_RNG values with the map IP_EFF_IGA__IGA_DIF and limit these efficiencies according to the actual exhaust gas temperature to avoid exhaust-system branch overheat. Then, thanks to the reverse map IP_IGA_DIF__EFF or thanks to the torque model for ignition angle efficiency, it is possible to calculate the value of the map IP_IGA_DIF_MIN_TEG_H_RNG__TEG.

So, in all practical cases IGA_DIF_MIN_H_RNG is a negative value that is the maximum allowable spark retard for engine stable running and pollutant conditions. It includes the coolant temperature correction. The exhaust gas temperature limitation is then taken into account in IGA_DIF_MIN_TEG_H_RNG:

The actual exhaust gas temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] can be either measured by a sensor on the exhaust-system branch or calculated from an exhaust gas temperature model.

For engines with multiple cylinder bamks, this temperature TEG_CAT_UP_MDL[NC_CBK_EX_NR] of exhaust gas before catalyst is defined and dedicated for each cylinder banks individualy. Since here the limitation of IGA_MIN is just a protective function versus the catalyst overheating, only the maximal value from all those cylinder bank related TEG_CAT_UP_MDL[NC_CBK_EX_NR] temperature will be taken into account.

Note: Two different update rates are used in the following calculations: for everything related to TEG only 1000ms rate is used to update calculation in synchronisation with TEG updates; for calculations related to ignition angle a 10 time faster update rate of 100ms.
These calculations are only performed when engine is running (*not stalled*) in homogenous mode after the end of start phase.

Application conditions:

Activation: LV_HOM_RUN = 1 **and** LV_ST = 0 **and** LV_ES = 0
active only in homogenous mode after the end of start phase before engine stall

Deactivation: LV_HOM_RUN = 0 **or** LV_ST = 1 **or** LV_ES = 1

Initialisation:
IGA_MIN_TEG_H_RNG = -90 °CRK
IGA_DIF_MIN_TEG_H_RNG = -180 °CRK
IGA_DIF_MIN_TEG_1_H_RNG = -180 °CRK
TEG_DYN_HYS = 0 at reset

Update Rate:
TEG_DYN_HYS => 1000ms **and** synchronised with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates.
IGA_DIF_MIN_TEG_H_RNG => 100ms
IGA_MIN_TEG_H_RNG => 100ms
EFF_IGA_MIN_TEG => 100ms

Formula section:

Maximal cylinder bank exhaust gas temperature determination:

every 1000ms
in synchronisation with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates

$$TEG\_CAT\_UP\_MDL\_MAX = \underset{0}{\overset{NC\_CBK\_NR-1}{Max}} \left(TEG\_CAT\_UP\_MDL\_i\right)$$

Hysteris function on exhaust gas temperature for ignition effects anticipation:

every 1000ms
in synchronisation with TEG_CAT_UP_MDL[NC_CBK_EX_NR] updates

```
If      TEG_DYN_HYS_{n-1}  > C_TEG_MAX_IGA
Then    TEG_DYN_HYS_n      = TEG_CAT_UP_MDL_MAX_n + C_TEG_MAX_IGA_HYS
Else    TEG_DYN_HYS_n      = TEG_CAT_UP_MDL_MAX_n
Endif
```

IGA_DIF_MIN_TEG_1_H_RNG = IP_IGA_DIF_MIN_TEG_H_RNG__TEG (TEG_DYN_HYS)

IGA_DIF_MIN_TEG_1_H_RNG is just an intermediate variable for calculation to name the result of the interpolation

Limitation of Maximum possible spark retard according to exhaust temperature TEG_DYN_HYS:

every 100ms

IGA_DIF_MIN_TEG_H_RNG = Max (IGA_DIF_MIN_H_RNG . IGA_DIF_MIN_TEG_1_H_RNG)

Minimum ignition angle limited for exhaust temperature protection: every 100ms

IGA_MIN_TEG_H_RNG = IGA_REF_COR + IGA_DIF_MIN_TEG_H_RNG

Activation of manual setting of ignition angle difference for stratified catalyst heating with post injection					

General Information

For catalyst heating in stratified mode possibly with post injection there is an increase of exhaust gas temperature due to retarding the ignition angle. In this module a difference of the ignition angle is generated.

The function is divided into two parts: After start and low load catalyst heating.

30.10.1 Catalyst heating after start

Application Conditions

General Information

To heat up the catalyst a 2nd fuel mass pulse is injected in homogeneous mode short time before ignition. In this module the mass of this pulse is generated.
The ignition angle is being retarded to increase the exhaust temperature. The 2nd injection mass MFF_SP_2_MPLH_CH should be calculated depending on ignition angle. That is done through IGA_AV_MV_H_RNG.

30.14.2 Low load catalyst heating

Low load catalyst heating is activated after regeneration. With this function it is possilble to apply different lambda-setpoints for each bank. The function can only be used with Y exhaust-systems because the exhaust gases of the lean and the rich cylinder banks are mixed upstream the NOx-trap and cause exothermic reaction.

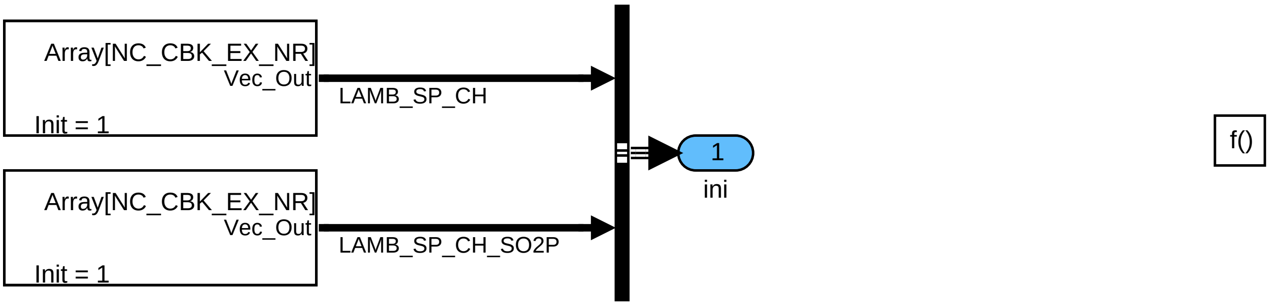

Figure 80:
Path: EXTC_REQGNCHL0/CH_SO2P/INI

30.14.3.2 Function: Desulfation catalyst heating

The basic lambda value for catalyst desulfation catalyst heating is applicatable for single or splitted injection. A temperature-depending factor weighs the difference between this basic-value and lambda=1. The resulting lambda setpoint is used for both cylinder banks. LAMB_SP_CH is used during catalyst heating phase, LAMB_SP_CH_SO2P is used during desulfation if there was catalyst heating active before. Due to C_LAMB_SP_CH_MAN it is possible to set the lambda setpoint cylinder individual.

General Information

For catalyst heating an additional fuel mass pulse is injected after the stratified injected main combustion has occurred. In this module the mass of this so called post injection is generated. The module has to be calculated before Injection phase of post injection for catalyst heating , MAF correction for catalyst heating in stratified mode and Ignition angle difference for catalyst heating with post injection .

General Information

For catalyst heating an additional fuel mass pulse is injected after the stratified injected main combustion has occurred. This will increase the temperature in the exhaust system, especially in the catalyst. In this module the injection phase of this so called post injection is generated.
The function is splitted into 3 parts: the phasing for after start catalyst heating, the phasing for low load heating and the calculation of further setpoints for the INJR aggregate.
SOI_MPLP_DIF_CH is an input for BMWfunctions where SOI_3_S_CUS is the (eventually changed) output. SOI_POST_INJ and EOI_POST_INJ are the actually phasings.

SOI_MPLP_DIF_CH means the difference crankshaft angle between the ignition angle and the start of the post injection.

30.16.1 Post injection for after start catalyst heating

Application Conditions

LV_ST_END	LV_AST	LV_PUC	
LV_SCC_i			

FUNCTION DESCRIPTION:

Application conditions:

Recurrence: every 1 s.

Initialisation: at reset LAMB_COP_CUS_i = C_LAMB_COP_PAS

Activation: If LV_ST_END = 1

Deactivation: -

General information:

If the temperature in the exhaust line exceeds a certain limit, the catalytic converter or even the exhaust line can be destroyed. To reduce the temperature the lambda is ramped down.

The exhaust line of a gasoline direct injection engine consists of a precatalyst and a NO_X-trap catalyst. The actual temperatures upstream (TEG_CAT_UP_MDL_i) and downstream of the precatalyst (TEG_CAT_DOWN_MDL_i or TEG_PCAT_DOWN_i, respectively) and the temperature in the NO_X-trap (TNT_MDL_H_i) are compaired to thresholds, separate for each temperature. The difference between an actual temperature and a threshold is input for an I-controller. Three different I-controllers are working in parallel.

Descriptions of LAMB_COP_i is the output LAMB_COP_CUS_i

In the following, **xx** serves as substitute for specification purposes. This is in detail:

xx = TEG_CAT_UP_MDL	for I-controller 1 (temperature upstream of the precatalyst)
xx = TEG_CAT_DOWN	for I-controller 2 (temperature downstream of the precat.)
xx = TNT_MDL_H	for I-controller 3 (temperature in the NO_X-trap catalyst)

Formula section:

30.17.1 Maximal selection between model or sensor based temperatur downstream the precatalyst

If a temperature sensor downstream the precatalyst is available the maximum value between the sensor based temperature TEG_PCAT_DOWN_i and the the model based temperature TEG_CAT_DOWN_MDL_i is choosen.

TEG_CAT_DOWN_i = MAX (TEG_PCAT_DOWN_i, TEG_CAT_DOWN_MDL_i)

Note:

If no temperature sensor downstream the precatalyst is available the variable has to be initialized as follows:

TEG_PCAT_DOWN_i = 0

30.17.2 Activation and Deactivation of the Controller

A single controller is activated (LV_xx_COP_i = 1) if the temperature xx_i exceeds its threshold C_xx_THD_COP. A singel controller is deactivated (LV_xx_COP_i = 0) if the temperature xx_i is below the threshold C_xx_THD_MIN_COP or if the temperature xx_i is below the threshold C_xx_THD_COP after the lambda was ramped up and has reached the the basic lambda setpoint LAMB_BAS_i.

All controllers are deactivated if one of the following logical variables is set to one:

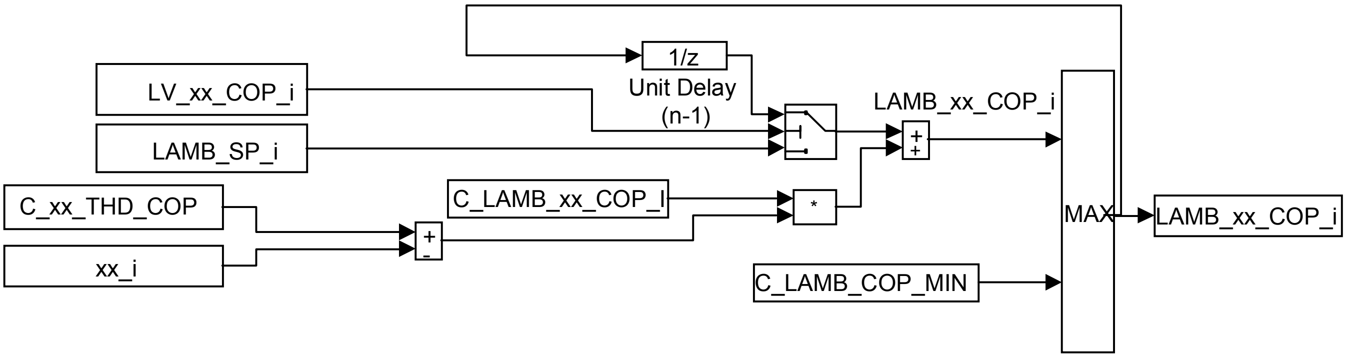
LV_AST, LV_PUC, LV_SCC_i.

For that case the lambda for catalyst overheat protection LAMB_COP_i is set to the passive value C_LAMB_COP_PAS.

```
(1) If      LV_AST = 1 or LV_PUC = 1or LV_SCC_i = 1
(1) then    LV_xx_COP_i = 0
(1) else
            (2) if      xx_i >= C_xx_THD_MIN_COP
            (2) then
                        (3) if      xx_i >= C_xx_THD_COP
                        (3) then    LV_xx_COP_i = 1
                        (3) else
                                    (4) if      LAMB_xx_COP_i > LAMB_BAS_i
                                    (4) then    LV_xx_COP_i = 0
                                    (4) endif
                        (3) endif
            (2) else  LV_xx_COP_i = 0
            (2) endif
(1) endif
```

At transition LV_xx_COP_i = 0 -> 1 the variable LAMB_xx_COP_i is initialized with LAMB_SP_i .

30.17.3 Controller Equations



```
If      LV_xx_COP_i = 1                                ...... (controller active)
then
LAMB_xx_COP_i (n) = LAMB_xx_COP_i (n-1) + C_LAMB_xx_COP_I *  (C_xx_THD_COP – xx_i)
else   LAMB_xx_COP_i = C_LAMB_COP_PAS            ...... (controller inactive)
endif
```

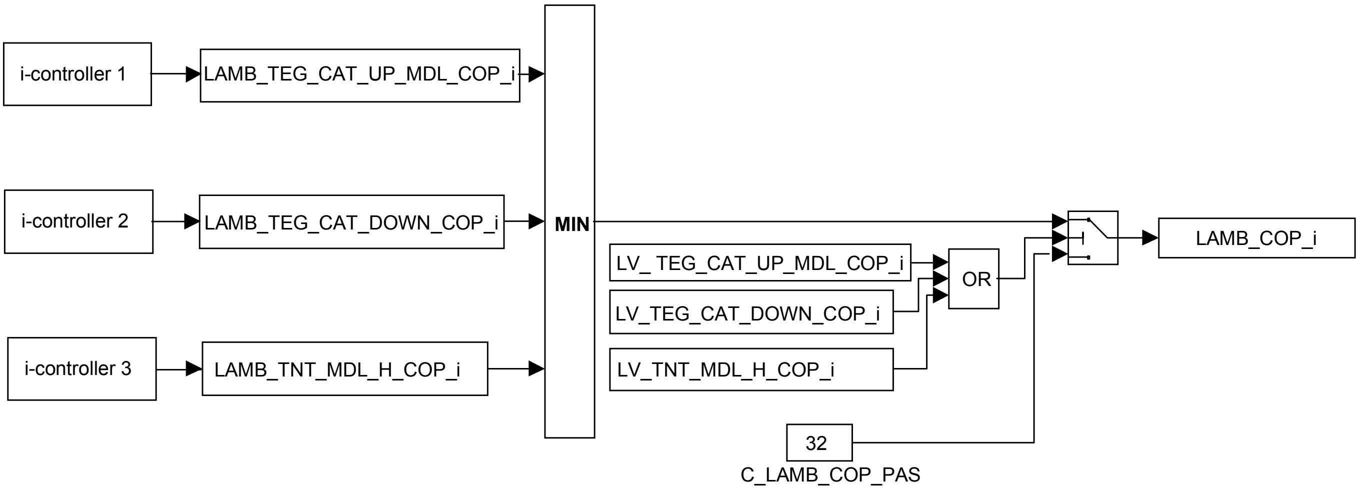
Application Hint: The passive value C_ LAMB_COP_PAS shoud be set to 32.

The value LAMB_xx_COP_i can not be smaller than the minimum allowed lambda value C_LAMB_COP_MIN:

LAMB_xx_COP_i = MAX (LAMB_xx_COP_i, C_LAMB_COP_MIN)

30.17.4 Calculation of LAMB_COP (Resulting lambda request)

System flow diagramm:



If at least one controller is active (LV_xx_COP_i = 1) the minimum controller output is selected for LAMB_COP_i:

```
if      LV_TEG_CAT_UP_MDL_COP_i = 1
        or
        LV_TEG_CAT_DOWN_COP_i = 1
        or
        LV_TNT_MDL_H_COP_i = 1
then    LAMB_COP_i = MIN (LAMB_xx_COP_i)
        LV_LAMB_COP_i = 1
else    LAMB_COP_i = C_LAMB_COP_PAS
        LV_LAMB_COP_i = 0
endif
```

If one of the temperatures **xx_i** exceeds the maximum threshold C_xx_THD_MAX_COP, the lambda enrichment is set to the minimum allowed lambda value C_LAMB_COP_MIN immediately.

```
If
TEG_CAT_UP_MDL_i >= C_TEG_CAT_UP_MDL_THD_MAX_COP
or
TEG_CAT_DOWN_MDL_i >= C_TEG_CAT_DOWN_THD_MAX_COP
or
```

```
TNT_MDL_H_i >= C_TNT_MDL_H_THD_MAX_COP

then LAMB_COP_i = C_LAMB_COP_MIN
endif
```

LC_DRI_ACT_MT	1	0... 1H	0... 1	1	[-]
Usage of gear-dependency of N_SP_IS_CH-maps for manual transmision					

General Information

For catalyst heating an increased idle speed is needed. In this modul there is a setpointcalculation for each strategy which is only calculated if actually needed.

N_SP_IS_CH is initialized with 0 because N_SP_IS is generated by a maximum-selection.

30.18.1 After start catalyst heating

There are several maps for engaged gear and not engaged. Via LC it is possible to use this dependency also for manual transmission.

Application Conditions

Function description

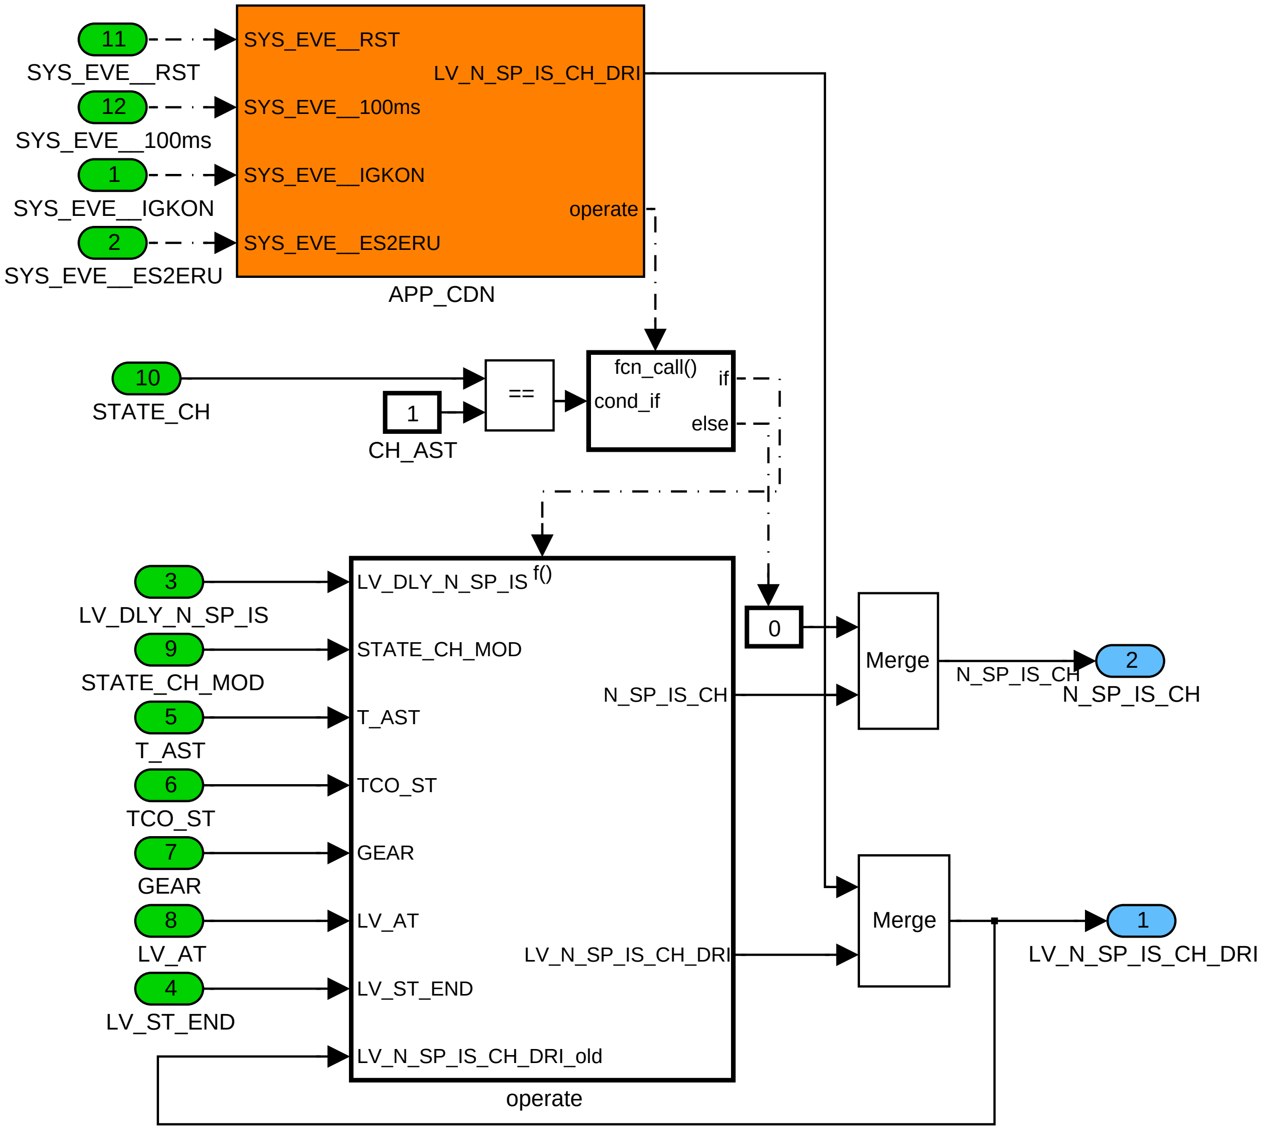

Figure 105:
Path: EXTC_REQGNIS0/clc_of_N_SP_IS_CH_AST

30.18.1.1 Operate subsystem: after start catalyst heating

For Gear > 0 there are several maps. With LC_DRI_ACT_MT it is possible to use the duplicated maps also for manual transmission. If these maps are used once they will be used until next engine start.

30.19.3.1.1 EXTC_REQGNCAM0/OPM_REQ/SUB/CH_AST

30.19.3.1.1.1 Operation Mode manager during after start catalyst heating

FAC_EFF_IGA_CH_SP = 0 means that emission-optimal settings are to be chosen. FAC_EFF_IGA_CH_SP = 1 means that engine-roughness-optimal settings of camshafts shell be chosen. This setpoint value shell result in FAC_EFF_IGA_CH which is used for interpolation betweet emission- and engine-roughness-optimal maps. STATE_OPM_IVVT_CH contains the same information in logical way. 2 means emission-optimum, 1 means engine-roughness-optimum, 0 means no request from catalyst heating side.

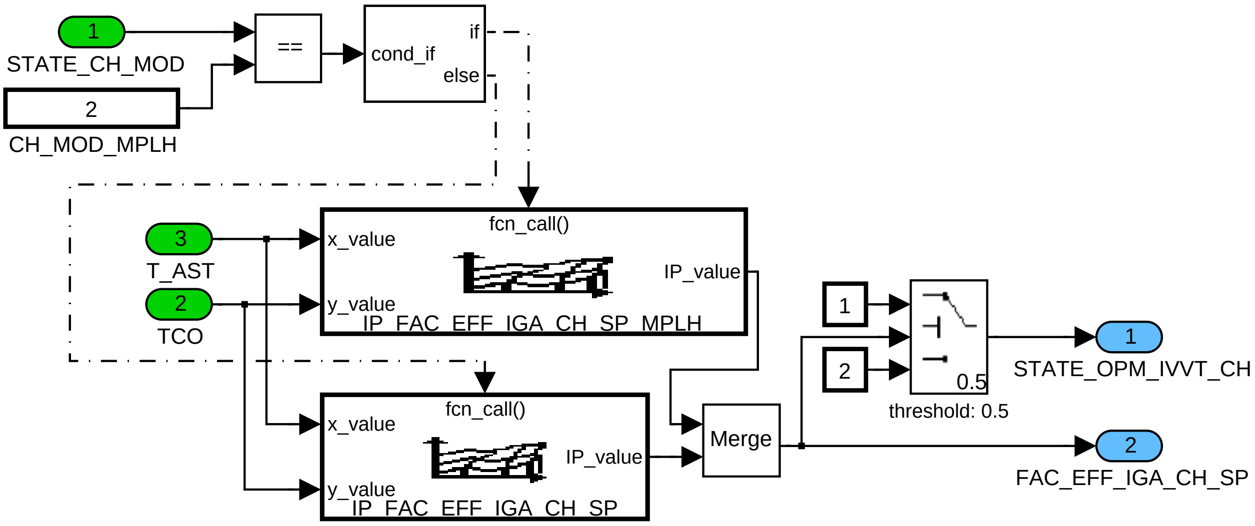

Figure 120:
Path: EXTC_REQGNcam0/OPM_REQ/SUB/CH_AST/SUB

30.19.3.1.2 EXTC_REQGNCAM0/OPM_REQ/SUB/CH_L

30.19.3.1.2.1 Operation Mode manager during low load catalyst heating

Only for homogeneous mode with single injection the setting of the operation mode request is calibratable. In all other cases '0' that means no alternation in camshaft setpoints is generated. FAC_EFF_IGA_CH_SP is set depending on the STATE so no values between 0 and 1 are possible.

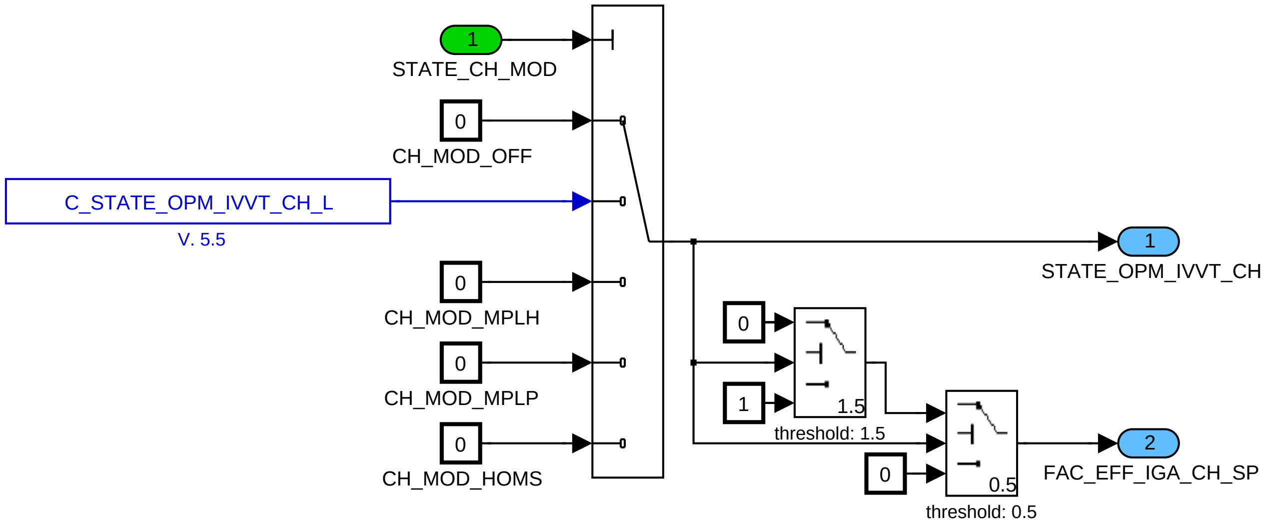

Figure 121:
Path: EXTC_REQGNcam0/OPM_REQ/SUB/CH_L/SUB

30.19.3.1.3 EXTC_REQGNCAM0/OPM_REQ/SUB/CH_SO2P

30.19.3.1.3.1 Operation Mode manager during catalyst heating for desulfation

For homogenous mode with single and with multiple injection the setting of the operation mode request is calibratable. In all other cases '0' that means no alternation in camshaft setpoints is generated. FAC_EFF_IGA_CH_SP is set depending on the STATE so no values between 0 and 1 are possible.

Basic difference of mass of air flow for low load stratified catalyst heating					
C_MAF_DIF_S_CH_MAN	1	0... FFFFH	0... 1389	0.0211948	[mg/stk]
Manual setting of MAF-difference for stratified catalyst heating					
LC_MAF_DIF_S_CH_MAN_ACT	1	0... 1H	0... 1	1	[-]
Activation of manual setting of MAF-difference for stratified catalyst heating					

General Information

During catalyst heating in stratified mode (possibly with post injection) it is necessary to reduce the mass of air flow and so the cooling effect. In this module the difference of MAF is generated.

Application Conditions

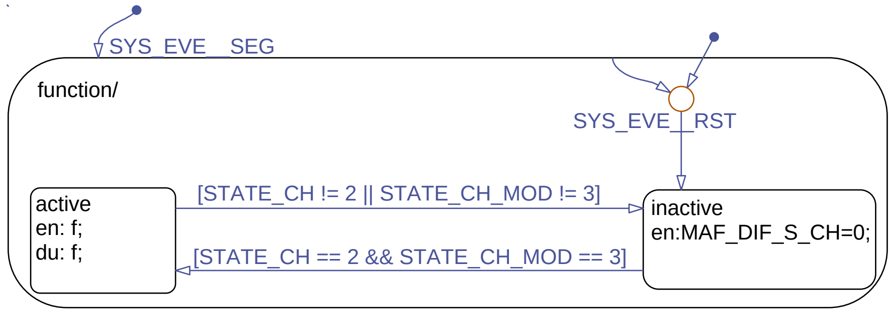

Figure 125:
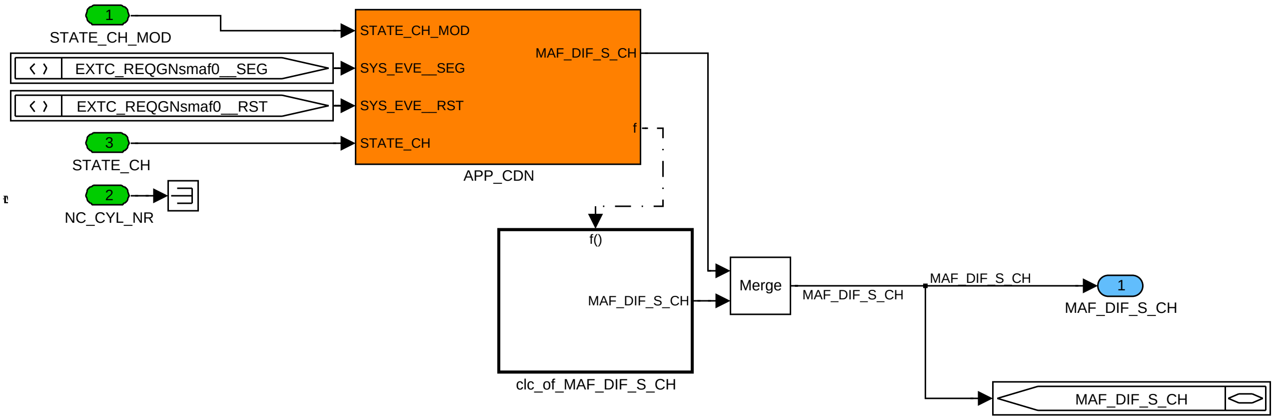
Path: EXTC_REQGNsmaf0/APP_CDN/Chart

Function description



SDA_SRS / SDA V 5.0.4 07−Nov−2006

Figure 126:
Path: EXTC_REQGNsmaf0

30.21.1 Calculation of MAF_DIF_S_CH in low load catalyst heating

There is a load/engine speed depending map, an external correction that is not used up to now and a 2nd correction depending on the actual mass of post injection. The read_vector block picks out one element (here the 1st) of the cylinder individuell MFF_POSTvector.

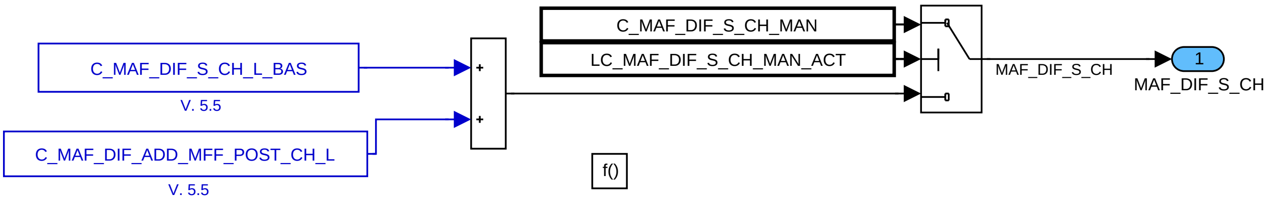


Figure 127:
Path: EXTC_REQGNsmaf0/clc_of_MAF_DIF_S_CH

General Information

This module concerns the calculation of a torque reserve which causes an ignition angle retardation and so exhaust gas temperature increase.

There are three functional parts: Cat. heating after (cold-) start, low load and for desulfation.

30.22.1 Catalyst heating after start

There are several setpoints for single and multiple injection. The output is ramped via a difference limiter.

Application Conditions

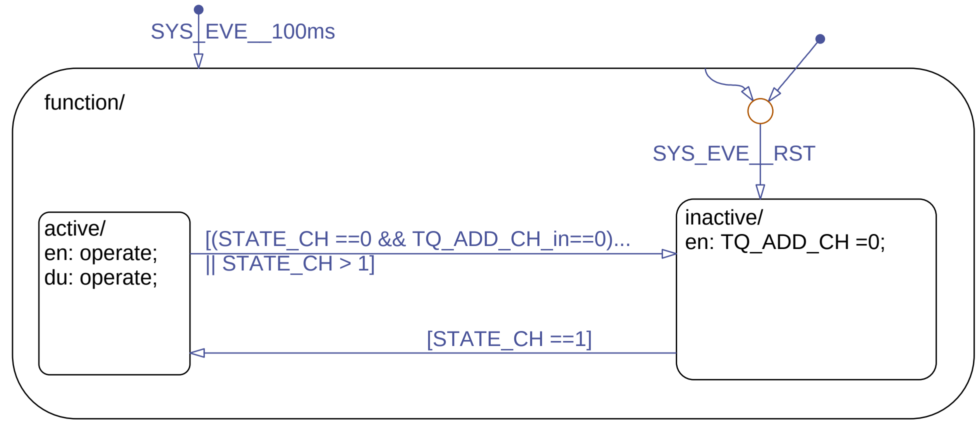

Figure 129:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_AST/APP_CDN/Chart

Function description

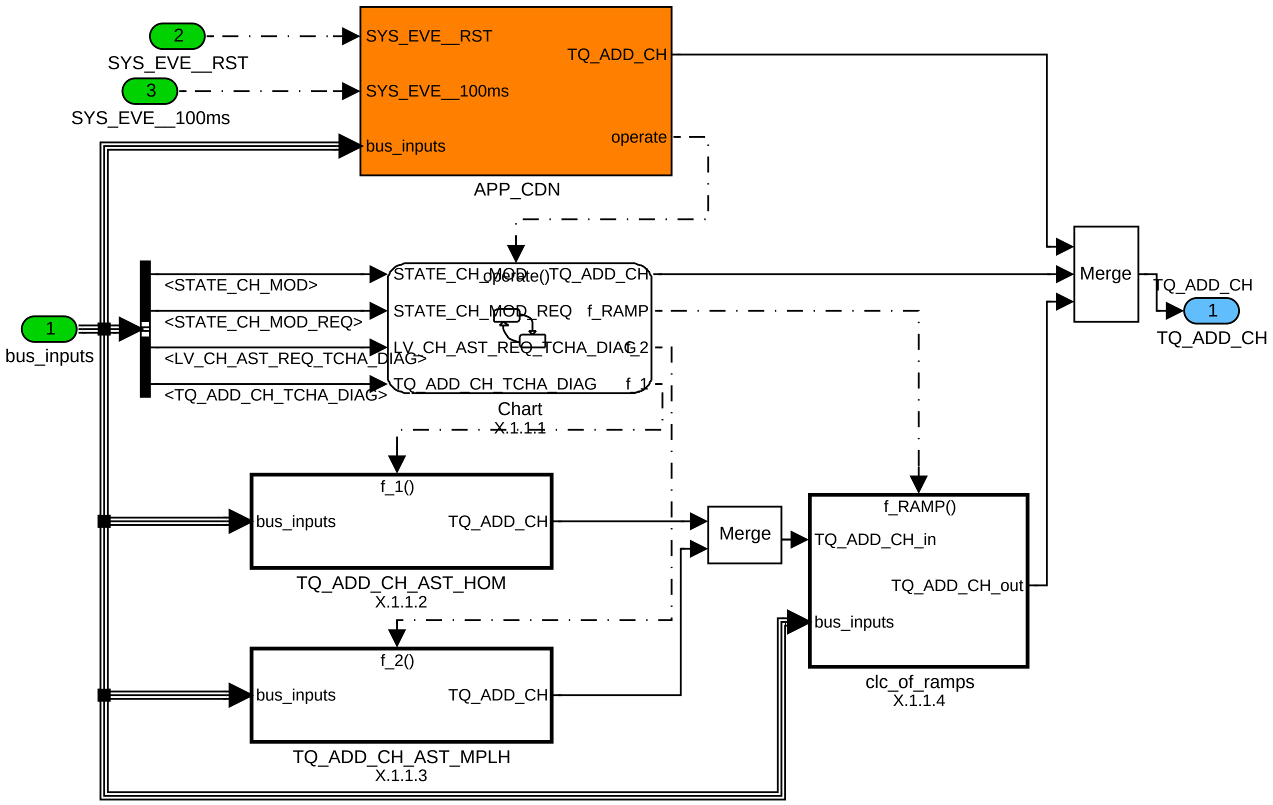

Figure 130:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_AST

30.22.1.3 Ramp-function

30.22.1.3.1 Ramp-function - Subsystem

With IP_FAC_TQ_ADD_CH_AMP the torque reserve can be reduced with decreasing ambient pressure and so increasing elevation. The resulting torque reserve is filtered by a difference limiter.

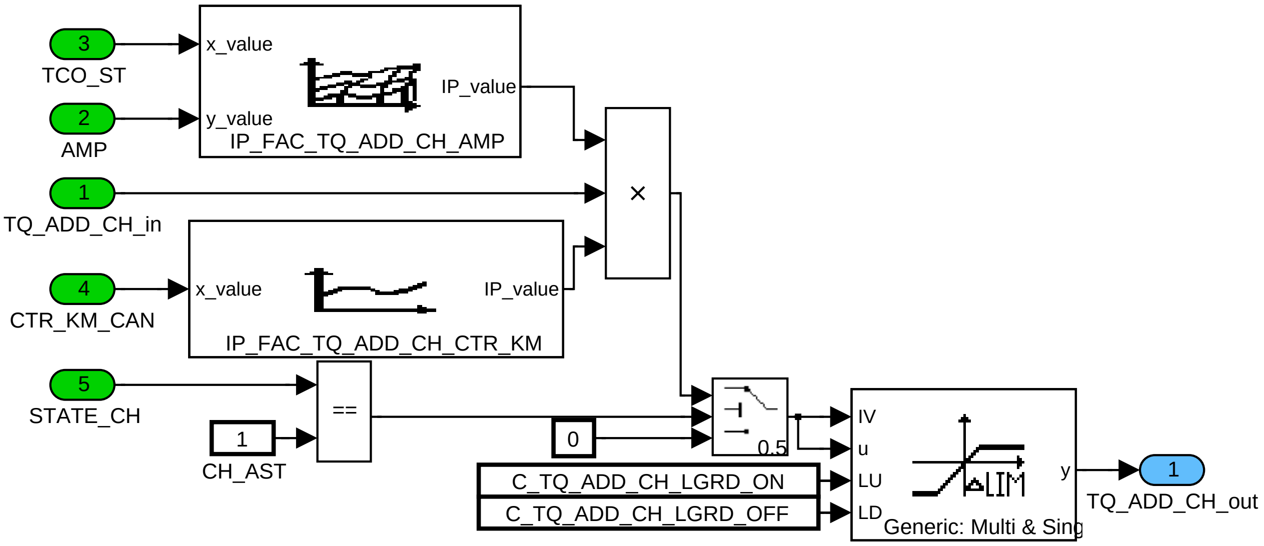

Figure 134:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_AST/clc_of_ramps/SUB

30.22.2 Catalyst heating in low load

In low load catalyst heating there is no homogeneous mode with split injection.

Application Conditions

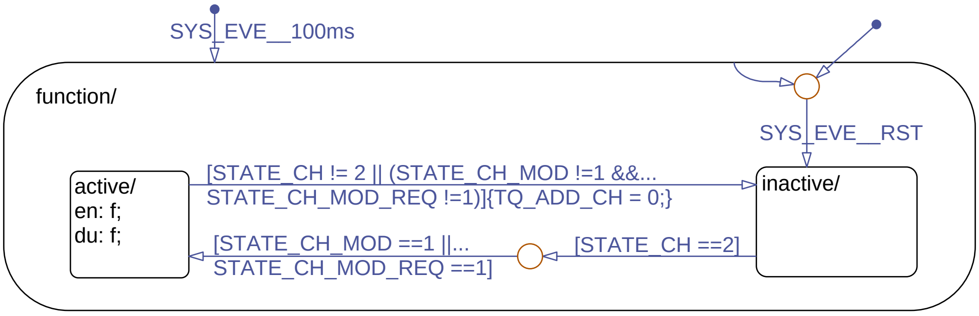

Figure 135:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_L/APP_CDN/Chart

Function description

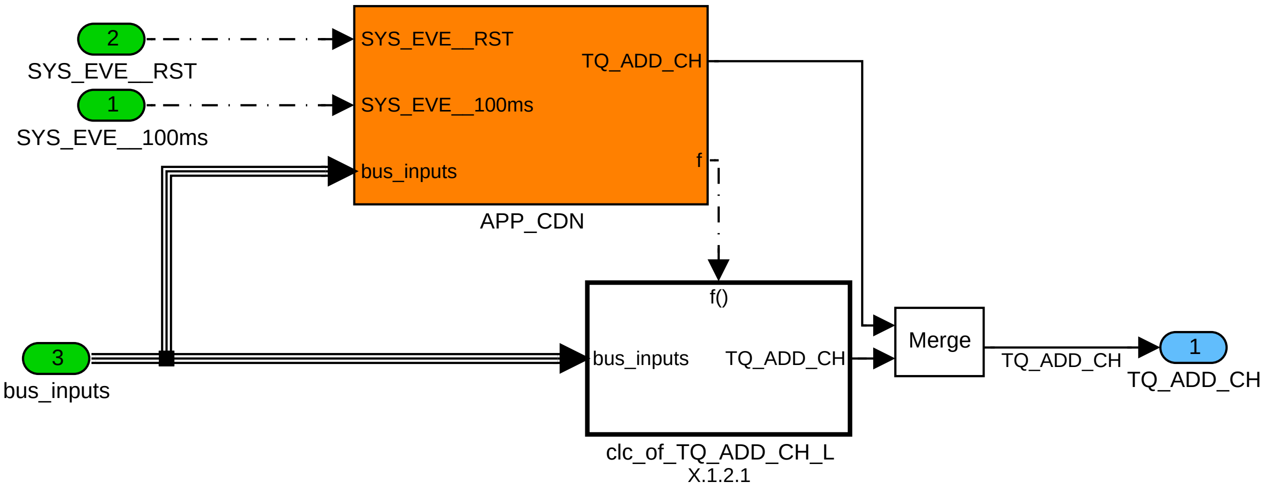

Figure 136:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_L

30.22.2.1.1 Torque reserve at low load catalyst heating - Subsystem

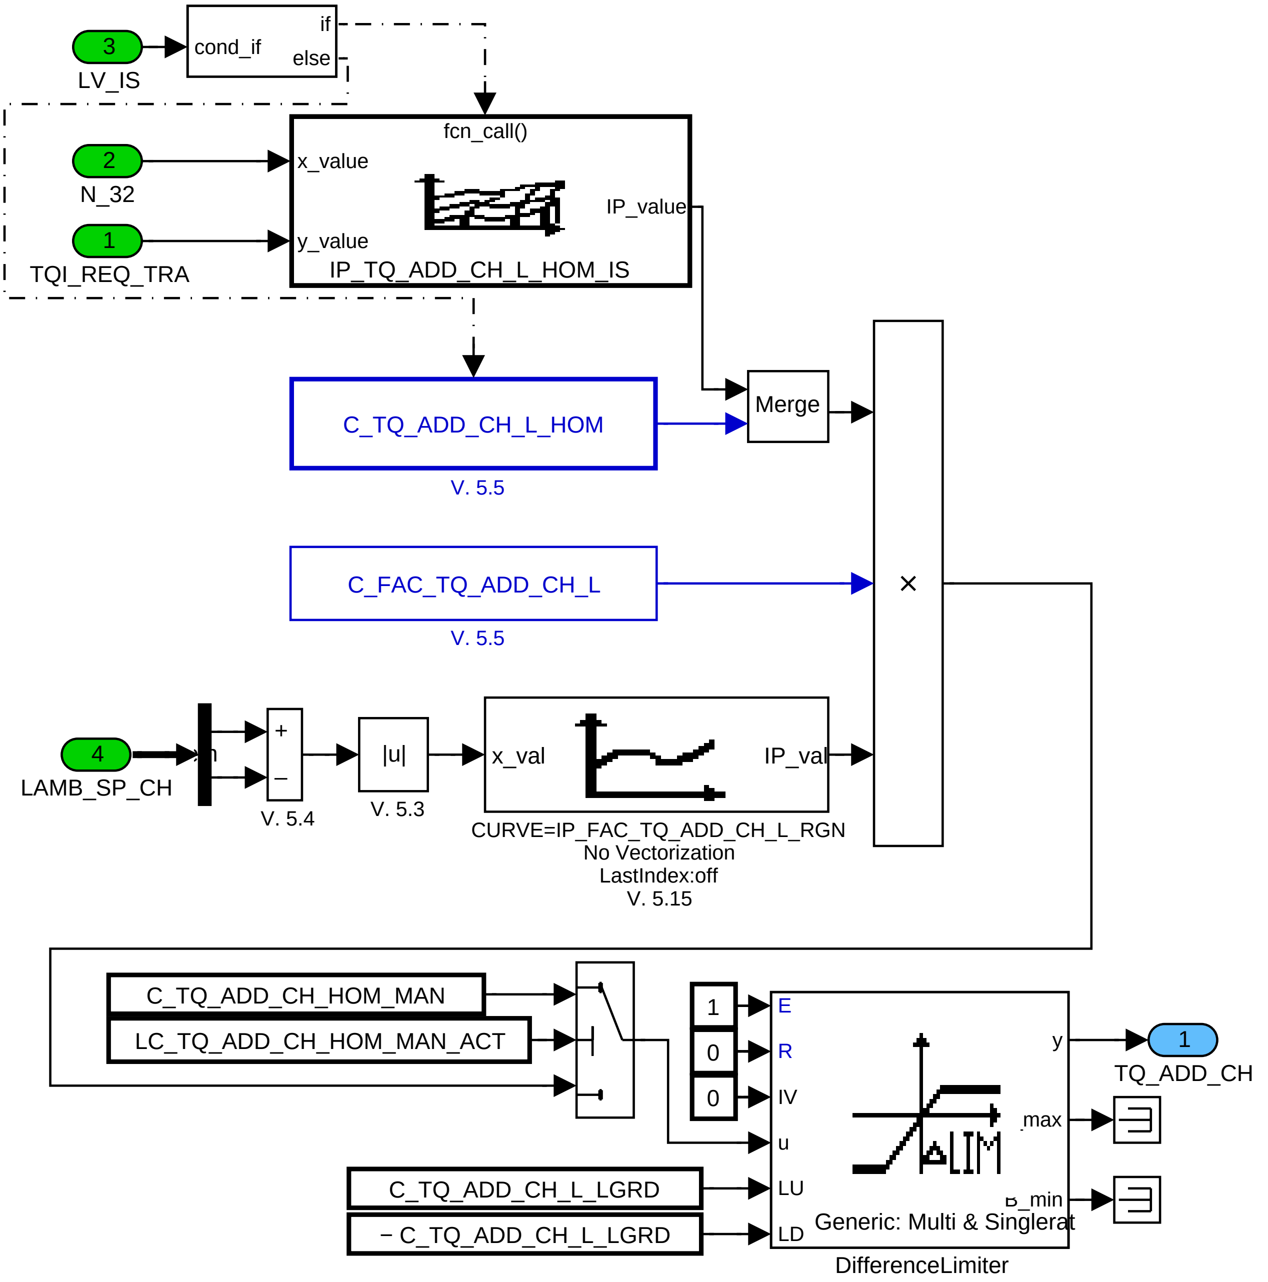

Figure 137:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_L/clc_of_TQ_ADD_CH_L/SUB

30.22.3 Catalyst heating for desulfation

TQ_ADD_CH is set by a controller, which controls the lowest NOx-trap temperature. Therefore TNT_DIF_CH_SO2P is the difference between the temperature setpoint for desulfation and the actual temperature (set in "Catalyst heating for desulfation strategy"). It is negative if temperature is too low.

Application Conditions

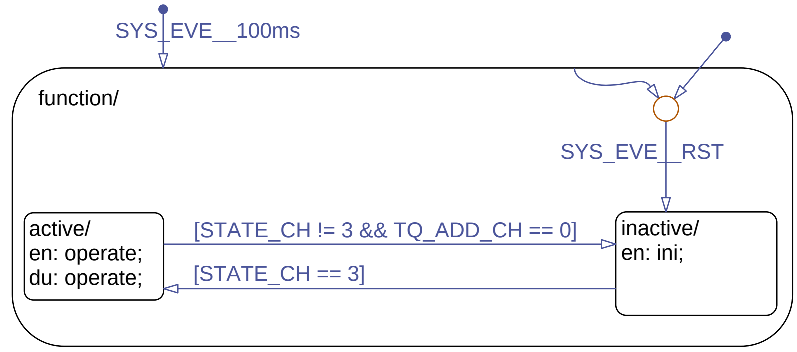

Figure 138:
Path: EXTC_REQGNCHT0/TQ_ADD_CH_SO2P/APP_CDN/Chart

Function description

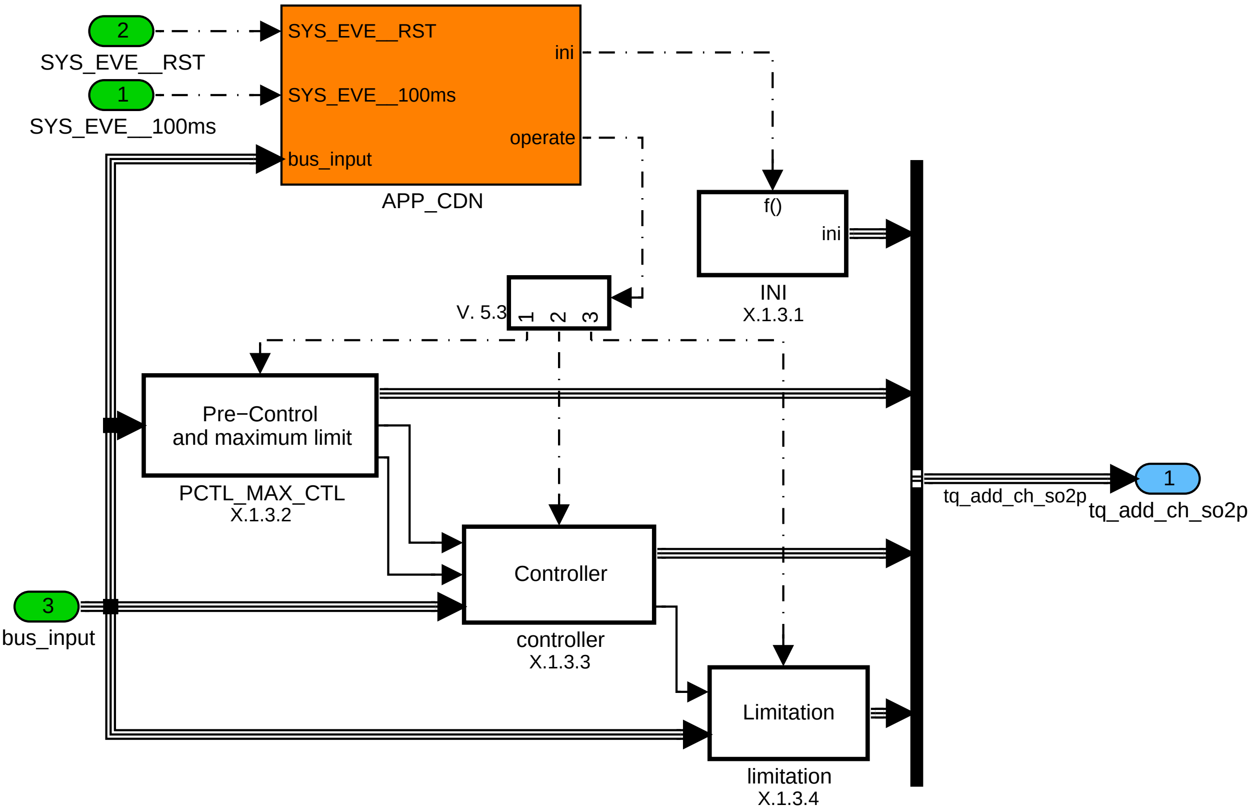

Figure 139:

30.22.3.3 Controller of NOx-trap temperature

30.22.3.3.1 Controller of NOx-trap temperature - Subsystem

The controller consists of an integral and a proportional part (PI-controller). The I-part is frozen if the overall controller output exceeds the maximum available torque reserve TQ_ADD_MAX or the map-value.
The pre-controlled value for TQ_ADD_SO2P is added to the PI-controller output.

31.1 EXTD – Requirements for infrastructure

Input data:

NC_NR_TEG_SENS			

Export actions:

ACTION_INFR_GetVpTeg (IN <CtrTegSens>, OUT <VpTegMes>,)
Action to read the sensor voltage of the different exhaust gas temperature sensors from the ADC

Description for actions:

ACTION_INFR_GetVpTeg (CtrTegSens, VpTegMes)					
The input parameter <CtrTegSens> gives the basic software the information which of the NC_NR_TEG_SENS exhaust gas temperature sensor voltages has to be provided to the application sofware. Every time the action is called the value of the corresponding AD channel is read out and delivered to the application sofware. Default SYNCHRONISATION is ASYNCHRONOUS					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
CtrTegSens	IN	0...5	1...6	1	-
Index of the exhaust gas temperature sensor					
VpTegMes	OUT	0...7FFFH	0...4.999847412109375	1.52587890625e-4	V
Exhaust gas temperature sensor voltage					

FUNCTION DESCRIPTION:

General information:

This chapter describes the acquistion of exhaust gas temperature sensor signals based on an analog sensor voltage.

Requirements for ACTION_INF_GetVpTeg:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
CtrTegSens	1			VpTegMes is the digitalizied voltage of the sensor with the index CtrTegSens	
VpTegMes	Not relevant	< 1% of reference supply voltage for sensor	ADC: 10bit Value: 15bit	The digitalisation of the value has to be carried out less than 10ms before the action calls the result.	

Diagnosis: no electrical diagnosis done

Coincidence requirements: The AD conversion is performed autonomously by the infrastructure. The recurrence has to be less than 10ms to guarantee that digitalisation value is not older than these 10ms.

Exhaust gas temperature downstream of pre-catalyst at engine start with wide range, unit: Kelvin					

Input data:

LV_ERR_PREL_TEG_PCAT_DOWN	LV_ERR_TEG_PCAT_DOWN	LV_IGK	MAF_KGH
TEG_CAT_DOWN_MDL[NC_CBK_EX_NR]			

General information:

The exhaust gas temperature sensor acquisition is suitable for single branch (only one exhaust bank) and twin branch exhaust lines (two exhaust banks).

For a twin branch exhaust line the exhaust gas temp. acquisition has the same structure for both exhaust lines. To differentiate variables and calibration data the **index i** is used:

i = 1 refers to temp. sensor in the first branch of a twin branch exhaust line or the temp. sensor in a single branch exhaust line

i = 2 refers to temp. sensor in the second branch of a twin branch exhaust line

This version is intended for an engine with a configuration that uses one temperature sensor. The exhaust gas temp. downstream of pre-cat.). TEG_PCAT_DOWN is used for the temperature modelling of the NOx catalyst monolith temperature (for GDI engine).

TEG_PCAT_DOWN_ST is the exhaust gas temperature at engine start used for dew point calculation of the NOx catalyst.

As the range of TEG_PCAT_DOWN and TEG_PCAT_DOWN_ST is limited to 0..1024°C, TEG_PCAT_DOWN_WIDE_RNG and TEG_PCAT_DOWN_WIDE_RNG_ST are calculated in a similar manner with a range of 0..2048K (equals -273..1775°C) to provide information about subzero and very high temperatures.

Sampling Rate: Ta = 0.1sec

Application conditions:

Activation: Ignition on LV_IGK = 1

Deactivation: Ignition off LV_IGK = 0

Initialisation:

At the transition LV_IGK 0 -> 1 (including reset) TEG_PCAT_DOWN_RAW is initialised with IP_TEG_WIDE_RNG__VP_TEG(VP_TEG_PCAT_DOWN). In that way the value TEG_PCAT_DOWN_RAW is available for the module “Exhaust gas temperature sensor diagnosis (TEG)” to make the “Plausibility check: Cold start”. That is necessary since the module “Exhaust gas temperature sensor diagnosis (TEG)” must have been performed since a valid LV_ERR_PREL_TEG_PCAT_DOWN is needed to determine TEG_PCAT_DOWN_ST and TEG_PCAT_DOWN_WIDE_RNG_ST.

At the first calculation of the module “Exhaust gas temperature” and at transition LV_ES 1 -> 0 TEG_PCAT_DOWN_ST and TEG_PCAT_DOWN_WIDE_RNG_ST are initialised:

```
If   LV_ERR_PREL_TEG_PCAT_DOWN = 0
     Then
          TEG_PCAT_DOWN_ST = IP_TEG__VP_TEG(VP_TEG_PCAT_DOWN)
          TEG_PCAT_DOWN_WIDE_RNG_ST =
                IP_TEG_WIDE_RNG__VP_TEG(VP_TEG_PCAT_DOWN)
     Else
          TEG_PCAT_DOWN_ST = C_TEG_PCAT_DOWN_ST_INI
          TEG_PCAT_DOWN_WIDE_RNG_ST = TEG_PCAT_DOWN_ST
End
```

FUNCTION DESCRIPTION:

The voltage VP_TEG_PCAT_DOWN is converted with a linear interpolation to an exhaust gas temperature downstream of the pre-catalyst TEG_PCAT_DOWN / TEG_PCAT_DOWN_WIDE_RNG.

The logical variable LV_ERR_PREL_TEG_PCAT_DOWN indicates a signal out of the specified range (short to ground or short to UB or line broken) or a not plausible temperature value. If active (LV_ERR_PREL_TEG_PCAT_DOWN = 1), the last valid temperature value is frozen until the error is debounced (LV_ERR_TEG_PCAT_DOWN = 1) or until a valid temp. value is obtained again.

With debounced error (LV_ERR_TEG_PCAT_DOWN = 1) a substitute value TEG_CAT_DOWN_MDL is assigned.

In normal operating mode (LV_ERR_PREL_PCAT_DOWN = 0 and LV_ERR_PCAT_DOWN = 0) the temperature depends on the temperature sensor voltage via map.

Formula section:

```
TEG_PCAT_DOWN_RAW$_N$ = IP_TEG_WIDE_RNG__VP_TEG(VP_TEG_PCAT_DOWN$_N$)
If   LV_ERR_TEG_PCAT_DOWN = 1
Then
     TEG_PCAT_DOWN_1 = TEG_CAT_DOWN_MDL - C_TEG_PCAT_DOWN_ADD_ERR
     TEG_PCAT_DOWN_2 = TEG_PCAT_DOWN_1
     TEG_PCAT_DOWN_WIDE_RNG = TEG_PCAT_DOWN_1
Else
     If  LV_ERR_PREL_TEG_PCAT_DOWN = 1
     Then
          TEG_PCAT_DOWN_1$_N$ = TEG_PCAT_DOWN_1$_{N-1}$
```

```
            $TEG\_PCAT\_DOWN\_2_{N} = TEG\_PCAT\_DOWN\_2_{N-1}$
            $TEG\_PCAT\_DOWN\_WIDE\_RNG_{N} = TEG\_PCAT\_DOWN\_WIDE\_RNG_{N-1}$
    else
            $TEG\_PCAT\_DOWN\_1_{N} = IP\_TEG\_\_VP\_TEG$
            $TEG\_PCAT\_DOWN\_2_{N} = TEG\_PCAT\_DOWN\_1_{N}$
            $TEG\_PCAT\_DOWN\_WIDE\_RNG_{N} = IP\_TEG\_WIDE\_RNG\_\_VP\_TEG$
    end
end
```

Ignition efficiency actual ignition angle bank selective for dew point					

Input data:

LV_PUC	LV_ST	LV_IGK	LV_ES
MAF_KGH	EFF_IGA_AV	TCO_ST	TIA
LV_HOM_ACT			

FUNCTION DESCRIPTION:

General information:

The exhaust gas temperature model has been removed from Siemens VDO side and is now modelled in the BMW objects. This module does satisfy the open interfaces of the dew point recognition between Siemens VDO and BMW.

Application conditions:

Initialisation: **IF** (there are no adaptation values stored **OR** the EEPROM does not work)
THEN CTR_COLD_ST = 0 (default value is set)
ELSE CTR_COLD_ST = CTR_COLD_ST stored in EEPROM (previously stored value is assigned)
END
At transition LV_ES = 1 -> 0
INT_TEG_MAF = 0 (Mass flow integral for dew point detection)
LV_TEG_MIN_THD = 0 (State: dew point not passed)
LV_TEG_CAT_DOWN_MIN_THD = 0 (State: dew point downstream of cat. not passed)

Recurrence: 1000ms

Activation: LV_ES and LV_ST = 0 (after leaving the engine state ST)

Deactivation: LV_ES = 1 (engine state ES is active)

Formula section:

Calculation of the number of cold starts:

After leaving the engine state ST the value of CTR_COLD_ST is incremented by the increment one.

The value CTR_COLD_ST is a measure of the number of cold-start tests and has to be stored in the flash-memory when the engine is switched off (LV_IGK = 0). After a new start of the engine CTR_COLD_ST is initialized with the stored value.

```
If        LV_HOM_ACT = 1
Then      EFF_IGA_AV_DEW = EFF_IGA_AV
Else      EFF_IGA_AV_DEW = 1
Endif;
```

```
IF   LV_PUC = 0  AND (LV_TEG_MIN_THD = 0 OR LV_TEG_CAT_DOWN_MIN_THD = 0)
     % For PUC active no increment of INT_TEG_MAF$_N$
THEN
     INT_TEG_MAF$_N$  = INT_TEG_MAF$_{N-1}$ + IP_INT_TEG(EFF_IGA_AV_DEW ,MAF_KGH) *
     MAF_KGH$_N$ * 1000ms
END
```

Dew point upstream of catalyst:

```
IF   INT_TEG_MAF$_N$ < IP_INT_TEG_THD(TCO_ST, TIA) *
       ID_CTR_COLD_ST(CTR_COLD_ST)
THEN
     LV_TEG_MIN_THD = 0                   % dew point not passed
ELSE
     LV_TEG_MIN_THD = 1                   % dew point passed
END
```

Dew point downstream of catalyst:

```
IF   INT_TEG_MAF$_N$ < IP_INT_TEG_CAT_DOWN_THD(TCO_ST, TIA) *
     ID_CTR_COLD_ST(CTR_COLD_ST)
THEN
     LV_TEG_CAT_DOWN_MIN_THD = 0          % dew point not passed
ELSE
     LV_TEG_CAT_DOWN_MIN_THD = 1          % dew point passed
END
```

Reset of cold start counter CTR_COLD_ST:

```
IF   LV_TEG_MIN_THD = 1 AND LV_TEG_CAT_DOWN_MIN_THD = 1
THEN
     CTR_COLD_ST = 0                      % reset of cold start counter
END
```

31.6.1 Dew point determination

Application conditions:

Activation: LV_ST = 0 and LV_ES = 0

Deactivation: LV_ES = 1

Recurrence: 100 ms

Initialisation:

Initialisation at engine start: transition LV_ES = 1 -> 0

```
LV_TNT_MIN_THD_2      =        0
LV_TNT_MIN_THD_READY_2   = 0
```

Initialisation at engine stop: transition LV_ES = 0 -> 1

```
 LV_TNT_MIN_THD_READY_2   = 0
LV_TNT_MIN_THD_2             = 0      % for a system with a NOx-sensor, the sensor
                                      % heating is activated by LV_TNT_MIN_THD_2.
                                      % Hence for a stopped engine the bit must be
                                      % initialized
                                      % Initialisation is done after calculation of
                                      EGY_DEW_NT_STOP
```

Function description:

On engine start, the calculated manifold wall temperature is compared to the reference value IP_TEG_WALL_TNT_DOWN_ST. If that temperature is higher than the reference value, it is assumed that no condensed water condenses from the exhaust gas. The status regarding reaching the dew point is represented by the bit LV_TNT_MIN_THD_2.
If the manifold wall temperature calculated is lower than the reference value (end of dew point not reached LV_TNT_MIN_THD_2 = 0), an additional amount of heat must be introduced into the exhaust-system branch. If the wall temperature exceeds the reference temperature or the amount of energy introduced into the exhaust system exceeds a certain threshold, end of dew point reached (LV_TNT_MIN_THD_2 = 1).
LV_TNT_MIN_THD_READY_2 is an internal flag to detect the first readyness after function start. To trigger the heater management function depending on low wall temperature (long PUC phase) the dew point detection is reseted below C_TEG_WALL_TNT_RED.
To set the dew point again, the hysteresis C_TEG_WALL_TNT_HYS must be passed.
To ensure, that values for TEG_WALL_NT_DOWN_MDL and TEG_WALL_NT_DOWN_MDL_ST are valid, the dew point detection is delayed by C_DLY_DEW_NT.

Formula section:

End of dew point after start:

```
If(1)       T_AST > C_DLY_DEW_NT
Then (1)
    If(2)        LV_TNT_MIN_THD_READY_2 == 0                    and
                 (TEG_WALL_NT_DOWN_MDL > IP_TEG_WALL_NT_DOWN_ST and
                 EGY_DEW_END_NT_INT ≥ EGY_DEW_END_NT) and
                 CAN_R_RATIO_NOX_SENS ≥ IP_R_RATIO_NOX_SENS_MIN_DEW
    then(2)      LV_TNT_MIN_THD_2  =  1
            if(3a)       TEG_WALL_NT_DOWN_MDL ≥ C_TEG_WALL_NT_RED
```

```
        then(3a)        LV_TNT_MIN_THD_READY_2 =  1
        endif(3a)
    else(2)         // Hysteresis of dew point during engine run
        if(3b)          LV_TNT_MIN_THD_READY_2 == 1
      then(3b)
        if(4)           TEG_WALL_NT_DOWN_MDL  < C_TEG_WALL_NT_RED
        then(4)         LV_TNT_MIN_THD_2   =  0
        else(4)
            if(5)           TEG_WALL_NT_DOWN_MDL >
                            C_TEG_WALL_NT_RED + C_TEG_WALL_NT_HYS
            then(5)         LV_TNT_MIN_THD_2      =  1
            endif(5)
        endif(4)
        else(3b)            LV_TNT_MIN_THD_2   =  0
        endif(4b)
    endif(2)
  endif (1)
```

31.6.2 Calculation of the NOx catalyst monolith temperature (sensor input)

Formula section:

TEG_PCAT_DOWN_COR[NC_CBK_EX_NR]

= TEG_PCAT_DOWN[NC_CBK_EX_NR] +TEG_PCAT_DOWN_ADD

31.6.2.1 Calculation of number of cold starts for Nox catalyst

After leaving the engine state ST the value of CTR_COLD_ST_NT is incremented by the increment one. At the same time dew point state detection is initialized LV_TNT_MIN_THD_2 = 0, i.e. the exhaust gas temperature is less than the temperature that characterizes the dew point.

The value CTR_COLD_ST_NT is a measure of the number of cold-start tests and has to be stored in the flash-memory when the engine is switched off (LV_IGK = 0). After a new start of the engine CTR_COLD_ST_NT is initialised with the stored value.

CTR_COLD_ST_NT is set to zero when the dew point of Temp_Model_2 is passed (LV_TNT_MIN_THD_2 = 1). The initialisation depends on Temp_Model_2 since it takes the longest for the second part of the Nox catalyst monolith to pass the dew-point.

In that way CTR_COLD_ST_NT is incremented for each engine start if the dew point of Temp_Model_2 was not passed before.

Application conditions:

Initialisation: from nonvolatile memory or = 0 if not possible

Recurrence: only once per engine run %CTR_COLD_ST_NT is only incremented per engine run

Activation: LV_ES =0

Formula section:

```
If      LV_TNT_MIN_THD_2 = 0     % at each transition from LV_ES = 1 -> 0
then    CTR_COLD_ST_NT ++        % CTR_COLD_ST_NT is incremented; if there is a
else    CTR_COLD_ST_NT = 0       % a transition of LV_TNT_MIN_THD =  0 -> 1 within the
endif                            % same DC, CTR_COLD_ST_NT has to be set to 0
```

31.6.3 Increasing the required energy

Function description:

On each restart, the amount of condensed water first increases and then decreases until the dew point is reached. To this effect, the energy introduced into the exhaust system EGY_DEW_END_NT_INT is calculated from the start and saved in the non-volatile memory at "engine stop" and after the latching phase has elapsed.
The amount of energy that has been brought into the exhaust system is weighted with FAC_EGY_DEW_NT_STOP, a factor dependent on the ambient temperature and the ratio of EGY_DEW_END_NT_INT and the threshold EGY_DEW_END_NT.
The result of this whole calculation is stored as EGY_DEW_NT_STOP in non volatile memory.
If the dewpoint is passed, EGY_DEW_NT_STOP is set to 0.

Application conditions:

Initialisation: at reset: from nonvolatile memory or = 0 if not possible

Recurrence: only once after transition from LV_ES 0 ->1

Activation: at transition from LV_ES 0->1

Formula section:

RATIO_EGY_DEW_NT = EGY_DEW_END_NT_INT / EGY_DEW_END_NT

FAC_EGY_DEW_NT_STOP = IP_FAC_EGY_DEW_END_NT_STOP

```
If        LV_TNT_MIN_THD_2    = 0
  then if FAC_EGY_DEW_NT_STOP >= 0
      then EGY_DEW_NT_STOP$_{(new)}$  =  EGY_DEW_NT_STOP$_{(last)}$
                         + IP_EGY_DEW_END_NT  * FAC_EGY_DEW_NT_STOP
      else EGY_DEW_NT_STOP$_{(new)}$  =  EGY_DEW_NT_STOP$_{(last)}$
                         + EGY_DEW_NT_STOP$_{(last)}$* FAC_EGY_DEW_NT_STOP
      endif
  else    EGY_DEW_NT_STOP $_{(new)}$  =  0
endif
```

31.6.4 Integration of energy brought into the exhaust system

Function description:

For dew point detection of the NOX-Trap, the energy, that is brought into the exhaust system, has to be integrated.

Application conditions:

Initialisation: EGY_DEW_END_NT_INT = 0 at transition LV_ES 1 -> 0

Recurrence: 200ms

Activation: LV_ST_END= 1 and LV_ES = 0

Deactivation: LV_ES =1

Formula section:

$$EGY\_DEW\_END\_NT\_INT = EGY\_DEW\_END\_NT\_INT_{(n-1)} + EGY\_DEW\_NT\_DOWN * 0,2s$$

31.6.5 Calculation of the total energy until end of dew point

Application conditions:

Activation: LV_CHECK_MDL_ST = 1

Deactivation: LV_ES = 1

Recurrence: 100ms

Initialisation:

Initialisation at engine start: transition LV_ES = 1 -> 0
EGY_DEW_END_NT = FFFFFFFFH
CTR_EGY_DEW_NT = 0

Function description:

To enable detection end of dew point, the necessary energy that has to be introduced into the exhaust system must be calculated first.

The value for the missing amount of energy is obtained from the map IP_EGY_DEW_END_NT. Input for this map is TEG_WALL_NT_DOWN_MDL_ST and TCO_ST.

ID_MAF_KGH_MIN_EGY_DEW_NT is a curve versus the wall temperature TEG_WALL_NT_DOWN_MDL which describes the minimum mass air flow, that has to exceeded to trigger the incrementing of CTR_EGY_DEW_NT.

MAF_KGH and of CTR_EGY_DEW_NT are inputs for IP_FAC_EGY_DEW_END_NT which will provide another factor for decreasing EGY_DEW_END_NT.

Formula section:

MAF_KGH_MIN_EGY_DEW_NT = ID_MAF_KGH_MIN_EGY_DEW_NT

```
If      MAF_KGH > MAF_KGH_MIN_EGY_DEW_NT
Then    CTR_EGY_DEW_NT ++                       % increment by 0.1
Else    CTR_EGY_DEW_NT = 0                      % reset counter
```

FAC_EGY_DEW_END_NT = IP_FAC_EGY_DEW_END_NT
FAC_EGY_DEW_END_NT_TAM_T_ES = IP_FAC_EGY_DEW_END_NT_TAM_T_ES

EGY_DEW_END_NT_TMP = **MIN**{ [(IP_EGY_DEW_END_NT * FAC_EGY_DEW_END_NT_TAM_T_ES + EGY_DEW_NT_STOP)*FAC_EGY_DEW_END_NT] **;** IP_EGY_DEW_NT_MAX * FAC_EGY_DEW_END_NT }

EGY_DEW_END_NT = **MIN**(EGY_DEW_END_NT_TMP **;** $\text{EGY\_DEW\_END\_NT}_{(n-1)}$)

31.7 NOx Catalyst Monolith Temperature Model (Appl. Inc.)

31.7.1 Additive correction of the input temperature TEG_PCAT_DOWN

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Input data:

VP_TEG_PCAT_DOWN	LV_IGK	T_AST_DIAG	VS
TQ_AV	TEG_CAT_DOWN_MDL	TAM	LV_VAR_TCHA
STATE_ENG			

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect electrical faults as defined by OBD I requirements.
VP_TEG_PCAT_DOWN is monitored for invalid gradients and values (see also “exhaust gas temperature ” in chapter “system variables”).

The diagnosis for "short circuit to Vbatt or open load" is only performed:

- either by reaching a certain voltage on the pin or after a calibrateable time after start or counter for activation of diagnosis reached calibrateable value
- and at the moment of diagnosis additional conditions are fullfilled

general specification

This functionality shell prevent a wrong failure detection due to too low sensor temperatures, i.e. at cold start.

Description:

Error-symptoms are defined to this diagnosis function as following:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └> Short circuit to Vbatt or Open load    (= SYM_0)
 │ │ └──> Short circuit to GND                    (= SYM_1)
 │ └────> -                                       (= SYM_2)
 └──────> -                                       (= SYM_3)
```

Application conditions

31.9.1 Output for BMW functions which are not defined as EXTD exported data

FUNCTION DESCRIPTION:

Remark: all formulas are valid in a **physical** meaning

Application conditions:

Initialisation at reset or at exit power latch phase for variables with BMW-naming convention:

0 °C:	Tkat_mod
0:	B_atm_tpnk1, B_atm_tpnk2, B_atm_tpvk1, B_atm_tpvk2
First valid value:	Tabg_sens1, Tabg_sens2, Tabg_sensturb1, Tabg_sensturb2

Recurrence: 200ms

Activation: at every engine state

Deactivation: ---

Formula section:

```
B_atm_tpvk1  =  LV_TEG_MIN_THD[1]
B_atm_tpvk2  =  LV_TEG_MIN_THD[2]
B_atm_tpnk1     =         LV_TEG_CAT_DOWN_MIN_THD[1]
B_atm_tpnk2     =         LV_TEG_CAT_DOWN_MIN_THD[2]

If ECU_STATE is not"PWL"
then
   Tkat_mod    = TEG_CAT_DOWN_MDL
   Tabg_sens1     =         TEG_PCAT_DOWN_COR[1]

Index

32.1 Total running time

Output data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
TRT	V/O/S	0...FFFFFFFFH	0...119304.64708	2.78E-05	[h]
Total running time					

Input data:

LV_IGK	LV_ES		

Function description:

The total running time is incremented by 100ms each if the conditions "ignition key ON" and "engine running" has been detected.

The total running time is saved in the non-volatile memory at the end of the driving cycle.

Formula section:

IF LV_IGK = 1 UND LV_ES = 0

THEN TRT = TRT + 2,7778e-5h

ELSE TRT = TRT

32.2 ECU power latch management - power down

Export actions:

ACTION_FCTM_SetPwlLockCdn (IN <Param1>)
Set related flag at pwl_lock_cdn
ACTION_FCTM_ClrPwlLockCdn (IN <Param1>)
Clear related flag at pwl_lock_cdn

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PWL_LOCK_CDN	V/O	0...FFFFH	0...65535	1	[-]
Power latch extension by project-specific configuration:see configuration-values in bitmask NC_PWL_LOCK_CDN_XXX					
T_PWL	V/O	0...FFFFH	0...6553.5	0.1	[s]
incrementing timer during PWL phase active					
LV_INH_PWL_TRAN_ES_EL	V/O	0...1H	0...1	1	[-]
flag active in shutdown-phase: IGK on is not accepted without reset					
LV_PWL_ACT	V/O	0...1H	0...1	1	[-]
power latch phase active (Do not use as Output)					

Input data:

NC_PWL_LOCK_CDN_XXX	STATE_LRN_ECU	LV_DIAG_END_RLY_MAIN_DLY	

FUNCTION DESCRIPTION:

Initialisations:

T_PWL = 0 at RST **or** EXIT_PWL

LV_PWL_ACT = 0

LV_PWL_ACT = 1 at TO_PWL

Recurrence: 100 ms

Activation: LV_PWL_ACT = 1

General information:

The relevant informations for setting PWL_LOCK_CDN are transferred with the help of the action call.

The ECU keeps active for a minimum time after entering the powerlatch-phase.
The minimum ECU power latch time (C_T_MIN_PWL) can only be extended by other functions locking a PWL-resource using the bitword PWL_LOCK_CDN (see project specifc list of PWL configuration data (definition of NC_PWL_LOCK_CDN_XXX)). If the maximum powerlatch time C_T_PWL_MAX is reached the ECU will be shut down and all not saved data will be lost.

Bit-position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PWL_LOCK_CDN																

Each other function is responsible itself to lock / unlock its own PWL-resource at entering / leaving the powerlatch-phase !

Formula section:

```
T_PWL = T_PWL + 100ms

If      (T_PWL > C_T_MIN_PWL                    and
        PWL_LOCK_CDN = 0)
Or      (T_PWL > C_T_MAX_PWL                    and
        at PWL_LOCK_CDN no NVMY Bit is set)
Or      LV_INH_PWL_TRAN_ES_EL = 1 (already in shut down)
Then    activate shut-down mechanism
Else    do nothing
Endif
```

Actions for shut-down mechanism:

reactivation by switching IGK on is forbidden

- LV_INH_PWL_TRAN_ES_EL = 1
- disable Monitoring-unit (MU)
- wait until MU-disable is confirmed **or** Communication with MU failed **or** LV_DIAG_END_RLY_MAIN_DLY = 0
- all function specific initializations with “end of power latch phase” are done.
- The power-supply-pin of the ECU is switched off.
- Call 5V reset detection.

Requirements for ACTION_FCTM_SetPwlLockCdn(<param>):

param: NC_PWL_LOCK_CDN_xxx (see Appl. INCI)

Set related flag at pwl_lock_cdn

pwl_lock_cdn |= 1 shifted left by <param>

Requirements for ACTION_FCTM_ClrPwlLockCdn (IN <Param1>)

param: NC_PWL_LOCK_CDN_xxx (see Appl. INCI)

Clear related flag at pwl_lock_cdn

pwl_lock_cdn &= not (1 shifted left by <param>)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_T_MIN_PWL	1	0...FFFFH	0...6553.5	0.1	[s]
minimum power-latch time for ECU switch off					
C_T_MAX_PWL	1	0...FFFFH	0...6553.5	0.1	[s]
maximum power-latch time for ECU switch off (if reached => not saved data will be lost)					

32.2.1 Configuration of PWL-resources

General information:

The bitmask PWL LOCK CDN shows all functions by a defined bit-position, which has locked a PWL resource for PWL extension.

Bit-position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PWL_LOCK_CDN																

It’s also possible, that more than one function has locked the PWL.
Here all functions must unlock its request before the ECU is switched off.

Bitmask-name	Bitposition	PWL-lock-configuration-Description
NC_PWL_LOCK_CDN_XXX	0...15	
Values for project		
NC_PWL_LOCK_CDN_NVMY	0	PWL for NVMY storage
NC_PWL_LOCK_CDN_RLY_MAIN	1	PWL for main relay diagnosis
NC_PWL_LOCK_CDN_EGR_AD	2	PWL for EGR adaptation
NC_PWL_LOCK_CDN_BN2000	3	PWL for BN2000
NC_PWL_LOCK_CDN_DMTL	4	PWL for DMTL diagnosis
NC_PWL_LOCK_CDN_ROM_CHK	5	PWL for ROM check
NC_PWL_LOCK_CDN_CUS	6	PWL for CUS functions required
NC_PWL_LOCK_CDN_HPDI	7	PWL for HDPI (shaker function)
project-specific configuration of PWL resources, which can be locked		

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_PWL_LOCK_CDN_NVMY	1	0...FFH	0...255	1	[-]

Start number of exhaust bank for calculations					
CTR_CBK_EX_NR_STOP_CLC	V/O	0 ... 1H	1 ... 2	1	-
Stop number of exhaust bank for calculations					

Input data:

NC_CYL_NR	LV_ST_END	N_32	SEG_NR
NC_IN_REF	NC_LAMB_REF		

FUNCTION DESCRIPTION:

General information:

This module is used for administration of runtime reduction and calculation optimization steps.

Pay Attention! This module has to be placed in the operating system immediately after the calculation of N_32 and SEG_NR, which are calculated by the ENSD aggregate. All aggregates, which are affected by calculation optimization, have to be calculated afterwards.

33.1.1 Runtime reduction

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset: STATE_CLC_RED = NC_STATE_CLC_RED_SEG_1

CTR_CYL_NR_ST_CLC = 0

CTR_CYL_NR_STOP_CLC = (NC_CYL_NR - 1)

CTR_CBK_IN_NR_ST_CLC = 1 (physical meaning)

CTR_CBK_IN_NR_STOP_CLC = NC_CBK_IN_NR

CTR_CBK_EX_NR_ST_CLC = 1 (physical meaning)

CTR_CBK_EX_NR_STOP_CLC = NC_CBK_EX_NR

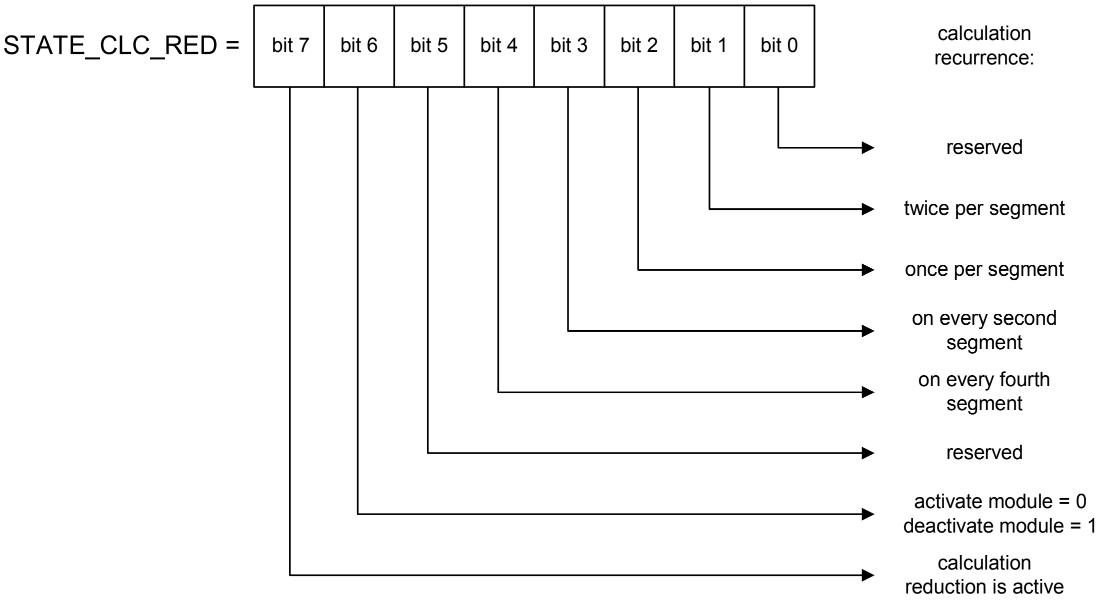
Recurrence : LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment synchronous

This chapter describes runtime reduction steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to the intake or exhaust bank, which is allocated to the related cylinder by NC_IN_REF and NC_LAMB_REF.

Formula Section :

33.1.1.1 Definition of STATE_CLC_RED



33.1.1.1.1 Definitions of the non calibrateable constants to generate STATE_CLC_RED

NC_STATE_CLC_RED_SEG_05 = 0x02H

NC_STATE_CLC_RED_SEG_1 = 0x04H

NC_STATE_CLC_RED_SEG_2 = 0x08H

        CTR_CBK_EX_NR_STOP_CLC = NC_CBK_EX_NR             (physical meaning)
    (3) ENDIF
```

Application hint

ID_CTR_CYL_NR_CLC describe the cylinder number, which will be calculated exclusive on the segment with the number SEG_NR, even if the runtime reduction is active. Therefor you have to specify the segment cylinder relation here proper to your engine type. For example (8 cyl. engine):

SEG_NR Segment number	ID_CTR_CYL_NR_CLC Exclusive calculated cylinder
0	3
1	4
2	5
3	6
4	7
5	0
6	1
7	2

Note that the related intake and exhaust banks will be calculated automatically by NC_IN_REF and NC_LAMB_REF.

Calibration data:

33.2 Run Time Optimization by Recurrency Switch

Output Data:

Name	Mode	Hex. Limit	Phys. Limit	Resol.	Unit
LV_CLC_2SEG_ENA	V/O	0...1H	0...1	1	-
activation flag for correction modes for non segment synchronuously calculation					
LV_CLC_2SEG	V/O	0...1H	0...1	1	-
Toggle-Bit for activation/deactivation of the segment synchronuously calculation					

Input Data:

N_32			

FUNCTION DESCRIPTION:

Application conditions:

Recurrence: every segment

Initialisation: LV_CLC_2SEG = 0; LV_CLC_2SEG_ENA = 0

Activation: every other engine state

Deactivation: engine stopped or engine start detected: LV_ES = 1 or LV_ST = 1

General Information:

At a high engine speed, run time problems may occur. Overstepping a certain engine speed threshold, the Toggle-Bit created in this module can evoke modules calculated segment synchronuously to switch to a recurrency of every second segment.

Formula section:

Activation of Toggle-Bit:

As soon as the engine speed exceeds a threshold C_N_SEG_2_ENA, the Toggle-Bit LV_CLC_2SEG gets activated and changes its value from zero to one the next segment and back to zero again the subsequent segment.

Activation of Correction-Bit:

At the same time, the bit LV_CLC_2SEG_ENA is set to one. This bit enables calculation corrections in files that use a segment counter or have to be corrected by any other influences caused by a calculation recurrence only every second segment.

Deactivation:

The deactivation of both bits is done as soon as the engine speed threshold is underspent again.

```
if    N_32  >    C_N_SEG_2_ENA
then        LV_CLC_2SEG_ENA      =    1
            LV_CLC_2SEG          =    0 → 1→ 0 → 1 → 0 → 1 → 0 → ...(toggling)
else        LV_CLC_2SEG_ENA = 0
            LV_CLC_2SEG  = 0
endif
```

Calibration Data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
C_N_SEG_2_ENA	1	0...FFH	0...8160	32	1/min
engine speed threshold for the activation of the calculation recurrence change to every second segment					

33.3 Restart function (FAC_ST_REST)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_ST_REST	O/V	0...FFH	0...1.9921875	0.0078125	-
Restart-factor for the correction of mass fuel flow at start					

Input data:

Considering coolant stop temperature and after start time for re-start calculation					

33.3.1 FMSP_M7003

FUNCTION DESCRIPTION:

General information:

In order to improve re-starts, a correction factor of mass fuel flow during pre-injection and start injection is calculated. This factor is multiplicative and decreases the mass fuel flow. In order to prevent, that no calculation of T_ES was done, the T_ES calculation task is called.

Application Condition

LDPM_TCO__MFF_DEAC_CST	10	0...FEH	-48...142.5	0.75	°C
Deactivation factor of post start enrichment at low fuel pressure					

33.4.1 FMSP_M7009

FUNCTION DESCRIPTION:

General information:

This enrichment takes place just after start in order to ensure the first combustions in cold conditions.

CYC_CAST is first the number of cycles (segments) at start. At the transition to after start, the counter is reset and represents then the number of after-start cycles during LV_AST=1.

Depending on fuel pressure FUP the functionality weighs up 2 cold post start injection times. Both injection times are calculated continuously and depending on a factor based on fuel pressure a interpolation between high and low pressure path estimates the executed after start injection TI_CAST.

Application conditions:

Initialisation: all outputs = 0 at ECU reset

Recurrence: segmentsynchronous

Activation: Post start auxiliary function (LV_AST) activated (exit from LV_ST to LV_IS or LV_PL) and (LV_CLC_2SEG = 1 or LV_CLC_2SEG_ENA = 0)

Deactivation: not Activation

Application Condition

TI_CAST_SWI

There are two input values TI_CAST_H_PRS and TI_CAST_LIH_L_PRS. Each input value belongs to the fuel pressure. Moreover FUP indicates which path is more weighted. It is ensured that a continuous cross-fading in the range TI_CAST_H_PRS and

general specification

TI_CAST_LIH_L_PRS is active in the after start time interval. The algorithms are calculated until LV_AST drops.

TI warm up correction at low fuel pressure					

33.5.1 FMSP_M700A

FUNCTION DESCRIPTION:

General information:

To cover the increased fuel requirement while the engine is cold, injection is corrected via the warm up enrichment.

The function splits up 2 warm-up enrichment parts -intermediate value- (applied for 2 different fuel pressure modes). In accordance with the received fuel pressure FUP the warm up injection represents the weighted enrichment parts.

Application conditions:

Activation : at every engine operating state, when (LV_CLC_2SEG = 1 **or** LV_CLC_2SEG_ENA = 0)

Deactivation : **not** Activation

Initialization : at ECU-Initialisation, LV_ES = 0 ->1, LV_ST = 0 -> 1:

TI_WUP, TI_TEMP and FAC_TI_WUP_FUP = 1,0

TI_WUP_1 = 1,000061, TI_WUP_1_ADD = 0,000061

Update rate : 1/segment

Application Condition

The input values TI_WUP_1_H_PRS and TI_WUP_1_LIH_L_PRS are calculated for the fuel high pressure and the fuel limp home low pressure mode. Each input value belongs to a fuel pressure mode. Depending on FUP a factor indicates which path is executed as a result of the interpolation.

FUNCTION DESCRIPTION:

General information:

MFF_SP_MV is set to MFF_SP_HOM or MFF_SP_S depending on LV_IGA_AND_INJ_SWI.

MFF_SP serves as input, e.g. for the function „Fuel Pressure Control“.

Application conditions:

Initialisation: at reset

Recurrence: If LV_ST_END = 0: 10 ms
If LV_ST_END = 1: every TDC

Activation: every engine state

Deactivation: -

Formula section:

Calculation of MFF_SP_MV and MFF_SP_FUP_CTL:

```
IF      LV_IGA_AND_INJ_SWI =  1         (homogeneous mode)
THEN    MFF_SP_MV           =  (MFF_SP_1_HOM[x] + MFF_SP_2_HOM[x] +
                               MFF_SP_3_HOM[x]) / NC_CYL_NR
        MFF_SP_FUP_CTL      =  MFF_SP_MV * (1-(SUM_INH_INJ / NC_CYL_NR))
ELSE    (stratified mode)
        MFF_SP_MV           =  (MFF_SP_1_S[x] + MFF_SP_2_S[x] + MFF_SP_3_S[x]) /
                               NC_CYL_NR
        MFF_SP_FUP_CTL      =  MFF_SP_MV * (1-(SUM_INH_INJ / NC_CYL_NR))
ENDIF
```

Calculation of MFF_SP[NC_CBK_EX_NR]:

```

General information:

The actual fuel consumption value (FCO_AV_1) is calculated from MFF_SP (incl. Lambdaadaptation) or MFF_SP_BAS (without Lam-ad) and several factors. During NOx regeneration additional FCO_AV_2 is calculated. This is not the real fuel mass, but it is used to avoid strong peaks in the FCO_AV signal. If NOx regeneration, desulfurization or the idle speed controller during stratifid mode is active, FCO_AV is additional filtered to avoid high gradients in the FCO signal. To ensure that the integrated fuel consumption (FCO) is still correct despite of the filtering and the use of FCO_AV_2 (-> FCO_FIL_DIF = 0), a balance controller (C_FCO_DIF_GAIN) is activated to balance FCO over a certain time.

Application conditions:

Initialisation: at reset **or** LV_IGK 0->1: all = 0, except FCO_DMTL = 0 only at reset and FCO_FIL_DIF =0 only at reset

Recurrence: every segment,

except calculation of T_RAMP_FCO_FIL and FCO_FIL_DIF_FB, 10ms recurrence

Activation: LV_ES = 0

Formula section:

```
// calculate FCO_AV_1
If      LC_FCO_MFF_ADD_CYL_CP = 1 // use Canister fuel flow for FCO calculation?
then    FCO_MFF_ADD_CYL_CP = MFF_ADD_CYL_CP

34.1 FUSL Configuration data

Output data:

FUNCTION DESCRIPTION:

34.1.1 Local configuration data ECU with current feedback of VCV via ATIC 39

Data	Value (physical)
NC_V_CUR_VCV_MES	2 [2**H**]

The following data is stored in the flash at end of ECU production and the values will never change during ECU live. The values are used to reduce the tolerances of the current feedback of the ATIC 39 for the VCV current control.

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_V_CUR_VCV_BOOT_H	1	8000...7FFFH	-5...4.99984	0.1526e-3	[V]
Measured voltage at high current					
C_V_CUR_VCV_BOOT_H_CMPL	1	8000...7FFFH	-5...4.99984	0.1526e-3	[V]
Measured voltage at high current complement					
C_V_CUR_VCV_BOOT_L	1	8000...7FFFH	-5...4.99984	0.1526e-3	[V]
Measured voltage at low current					
C_V_CUR_VCV_BOOT_L_CMPL	1	8000...7FFFH	-5...4.99984	0.1526e-3	[V]
Measured voltage at low current complement					

Configuration data:

Name	Dim	Hex. Limit	Phys. Limit	Resol.	Unit
NC_V_CUR_VCV_MES	1	0...2H	0...2	1	[-]
Value to select ECU with VCV shunt or not (0= not shunt, 1= shunt available, 2= feedback from ATIC)					

34.2 Acquisition of fuel pressure (V_FUP)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
V_FUP_SUM	V/O	0...FFFFFFFFH	0... 655359.99984	0.1526e-3	[V]
Accumulated mainfold air pressure measurements for segment number (2n-1), n=1,2,3,...					
V_FUP_SUM_1	V/O	0...FFFFFFFFH	0... 655359.99984	0.1526e-3	[V]
Accumulated mainfold air pressure measurements for segment number (2n), n=1,2,3,...					
CTR_V_FUP	V/O	0...FFFFH	0...65535	1	[-]
Number of samples in buffer V_FUP_SUM					
CTR_V_FUP_1	V/O	0...FFFFH	0...65535	1	[-]
Number of samples in buffer V_FUP_SUM_1					
LV_FUP_SEG_OLD	O	0...1H	0...1	1	[-]
Logical variable indicating the buffer to read the sensor voltage in BSW old value					
V_FUP	V	0...7FFFH	0...4.99984	0.1526e-3	[V]
LPG pressure in the fuel rail, voltage raw value (10 bits).					

Input data:

LV_ES	LV_FUP_SEG		

Import actions:

ACTION_INFR_GetVFupSens(OUT<V_Fup>)
This action gets the FUP sensor voltage

FUNCTION DESCRIPTION:

Signal flow diagram:

General information:

The raw value (voltage) for FUP is measured by continous conversion every 1 ms. The values (10 bit) are summed up in two alternating buffers, V_FUP_SUM or V_FUP_SUM_1. The numbers of values are counted in comparable buffers CTR_V_FUP or CTR_V_FUP_1. This mechanism is necessary to synchronize the measurement and the calculation of FUP_MES (build mean value with a standardized range)

Depending on the logical variable LV_FUP_SEG one of the two buffers — V_FUP_SUM or V_FUP_SUM_1 — and the respective counter — CTR_V_FUP or CTR_V_FUP_1 — are selected for writing, the contents of the other buffer (counter) is used for calculations and diagnosis (after this buffer and the corresponding counter have been read they are cleared).

After having read out one buffer — V_FUP_SUM or V_FUP_SUM_1 — the buffer has to be cleared as well as the corresponding counter — CTR_V_FUP or CTR_V_FUP_1.

A two-buffer-system is used to avoid incorrect FUP calculation.

The buffers will be filled when the segment is changing.

Application conditions:

Initialisation: **At** Reset

After HW reset, the buffers - V_FUP_SUM and V_FUP_SUM_1 - and the corresponding counters - CTR_V_FUP and CTR_V_FUP_1 - have to be cleared.

V_FUP_SUM = 0
V_FUP_SUM_1 = 0
CTR_V_FUP = 0
CTR_V_FUP_1 = 0
LV_FUP_SEG_OLD = 0

Recurrence: 1ms
Activation: -
Deactivation: -

Formula section:

```
If(1) ( LV_FUP_SEG = 0 and LV_FUP_SEG_OLD = 1 )
Then(1)
    V_FUP_SUM =
    CTR_V_FUP = 0
Else(1)
    If(2) ( LV_FUP_SEG =1 and LV_FUP_SEG_OLD = 0 )
    Then(2)
        V_FUP_SUM_1 =
        CTR_V_FUP_1 = 0
    Else(2)
        Do nothing
    Endif(2)
Endif(1)
```

$LV\_FUP\_SEG\_OLD_{(n)} = LV\_FUP\_SEG_{(n-1)}$

```
If(1) ( LV_FUP_SEG = 0 )
Then(1)
    $V\_FUP\_SUM = V\_FUP_{(n)} + V\_FUP_{(n+1)}$
    $CTR\_V\_FUP_{(n)} = CTR\_V\_FUP_{(n-1)} + 1$
Else(1)
    $V\_FUP\_SUM\_1 = V\_FUP_{(n)} + V\_FUP_{(n+1)}$
    $CTR\_V\_FUP\_1_{(n)} = CTR\_V\_FUP\_1_{(n-1)} + 1$
Endif(1)
```

34.3 FUSL - Requirements to Infrastructure (Multi piston pump with PWM controlled volume control valve (VCV))

Input data:

Export actions:

ACTION_INFR_GetElDiagVcv(OUT <Cdn_diag_vcv>, OUT <Err_diag_vcv>**)**
This action reads the failure and condition information for a symptom of the VCV actuator power stage.
ACTION_INFR_SetPwmVcv(IN <ducy>**)**
This action change the dutycycle of the VCV control PWM to increase or reduce fuel amount
ACTION_INFR_GetVFupSens(OUT <v_fup>**)**
This action gets the FUP sensor voltage of high pressure pipe system into the injection rail
ACTION_INFR_SetFrqPwmVcv(IN <frq>**)**
This action sets the frequency of the VCV control PWM
ACTION_INFR_GetVFupEfpSens(OUT <v_fup_efp>**)**
This action gets the FUP sensor voltage of low pressure pipe system to the high pressure pump
ACTION_INFR_GetVVcvCurMes(OUT <v_cur_vcv_mes>**)**
This action gets the shunt voltage from the maximum VCV current peak

Description for actions:

ACTION_INFR_GetElDiagVcv(OUT <Cdn_diag_vcv>, OUT <Err_diag_vcv>) This action reads the failure and condition information for a symptom of VCV power stage. The readout of the power stage is performed autonomous and the information is gathered. When calling this Action the information inside the Infrastructure is reset after returning the OUT parameters.					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cdn_diag_vcv	OUT	0 ... 7H	0 ... 7	1	-
Diagnosis condition for symptom: Bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled Bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled Bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled (all combinations are possible)					
Err_diag_vcv	OUT	0 ... 7H	0 ... 7	1	-
Raw value of error symptom: Bit 0: Set, if raw value of error symptom SCP (SYM_0) is set Bit 1: Set, if raw value of error symptom SCG (SYM_1) is set Bit 2: Set, if raw value of error symptom OC (SYM_2) is set (all combinations are possible)					
Raw value of error symptom. The relevant bit is set, if the error has been detected.

FUP high pressure sensor voltage					

ACTION_INFR_SetFrqPwmVcv(IN <frq>**)**					
This action sets the frequency of the VCV control PWM					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
frq	IN	A...3FFH	10...1023	1	Hz
VCV frequency					

ACTION_INFR_GetVFupEfpSens(OUT <v_fup_efp> **)**					
This action gets the FUP sensor voltage of low pressure pipe system to the high pressure pump					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
v_fup_efp	OUT	0...7FFFH	0..4.9998474	0.000152587890625	V
FUP EFP low pressure sensor voltage					

ACTION_INFR_GetVVcvCurMes(OUT <v_cur_vcv_mes>**)**					
This action gets the shunt voltage from the maximum VCV current peak					
Name	Type	Hex. Limits	Phys. Limits	Resol.	Unit
v_cur_vcv_mes	OUT	0...7FFFH	0...4.9998474	0.000152587890625	V
Shunt voltage from VCV					

FUNCTION DESCRIPTION:

General information:

ACTION_INFR_GetElDiagVcv() returns the result of the electrical diagnosis of VCV actuator power stage.

_ The device readout is performed autonomous by the Infrastructure each 10ms.
_ The error informations of every symptom is gathered in the Infrastructure (or-ed symptom) until the Application reads out the information by calling ACTION_INFR_GetElDiagVcv().
_ After having read out the information by calling ACTION_INFR_GetElDiagVcv(), the data inside the Infrastructure is reset. Resetting of Cdn_diag_vcv avoids ambigious results in case of too short calling reccurrence of ACTION_INFR_GetElDiagVcv(): Reset Cdn_diag_vcv indicates, that the gathering of the information is not completely finished.

Requirements for ACTION_INFR_GetElDiagVcv:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cdn_diag_vcv	-	-	<bit coded>	Err_diag_vcv	Diagnosis condition for each symptom **bit 0:** diagnosis condition for symptom SCP (SYM_0) **bit 1:** diagnosis condition for symptom SCG (SYM_1) **bit 2:** diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag_vcv	-	-	<bit coded>	Cdn_diag_vcv	Bitcoded result of each symptom **bit 0:** raw value of error symptom SCP (SYM_0) **bit 1:** raw value of error symptom SCG (SYM_1) **bit 2:** raw value of error symptom OC (SYM_2) The relevant bit is set, if the raw error has been detected.

Diagnosis: ACTION_INFR_GetElDiagVcv returns the electric diagnosis for VCV power stage

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_SetPwmVcv:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
ducy	Not relevant	Not relevant	0.0015259%	Not relevant	By the initialization the PWM value set to 0%.

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_GetVFupSens:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
v_fup	Not relevant	0,1 %	0.000152587890625 V	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_SetFrqPwmVcv:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
frq	Not relevant	Not relevant	1 Hz	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_GetVFupEfpSens:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
v_fup_efp	Not relevant	0,1 %	0.000152587890625 V	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

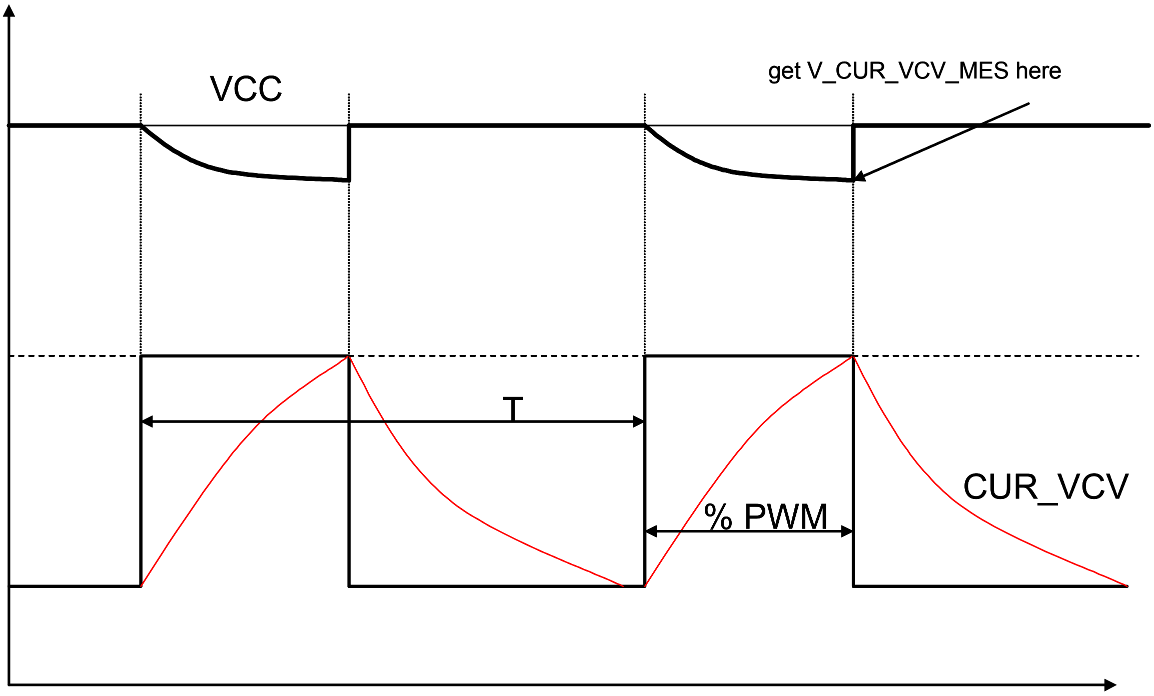
Requirements for ACTION_INFR_ GetVVcvCurMes(OUT <v_cur_vcv_mes>):

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
v_cur_vcv_mes	Not relevant	Not relevant	0.000152587890625 V	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements:

The current measurement have to capture the maximum current peak nearly from the switch OFF event from the output line driver. Therefore the IO driver have to handle the timing of the measure start event.



For projects with the curent feedback from shunt, the value v_cur_vcv_mes is provided every segment (if segments are available) or every 10ms (if no segments are available).

The PWM signal is updated every segment or ervery 10ms.

For projects with the curent feedback from ATIC 39, the feedback voltage has to be provided at the end of actual duty cycle. See picture below.

The value will be taken every segment (if segments are available) or every 10ms (if no segments are available).

For projects without curent feedback the value v_cur_vcv_mes has to set to 0V.

34.4 AGGR FUSL adaptation

34.4.1 Outputs for SV aggregates, SV internally

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
VFF_EFP	V/O	0...FFH	0...255	1	[l/h]
Required amount of fuel					
EFPPWM_CAN	V/O	0...FFH	0...99.60937	0.390625	[%]
Pump speed of the electrical fuel pump as 8 bit PWM signal					
FUP_AD	V/O	8000...7FFFH	-173890... 173884	5.3066911	[hPa]
Adaptation value for fuel pressure adaptation					

Input data:

VFF_EFP_REQ	EFPPWM	

FUNCTION DESCRIPTION:

Adaptation to aggregate environment.

Application conditions:

Initialisation at reset:

VFF_EFP = VFF_EFP_REQ
MIN (VFF_EFP, FEH)
EFPPWM_CAN = EFPPWM
MIN (EFPPWM_CAN, FEH)
FUP_AD = 0

Recurrence : If LV_ST_END == 1
then the recurrency is every segment
If LV_ST_END == 0
then the recurrency is every 10 ms

Activation: every engine operating state

Formula section:

VFF_EFP = VFF_EFP_REQ
MIN (VFF_EFP, FEH)
EFPPWM_CAN = EFPPWM
MIN (EFPPWM_CAN, FEH)
FUP_AD = 0

34.4.2 Miscellaneous

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ENG_OFF_N_CON	O	0...1H	0...1	1	[-]
Logical value engine stop mode active					
LV_PIN_ICH	O	0...1H	0...1	1	[-]
Independent car heater request for electrical fuel pump					
LV_ACR_EFPPWM_TEST_REQ	O	0...1H	0...1	1	[-]
Electrical fuel pump actuator test active					
LV_FUP_EFP_SP_EXT_REQ	O	0...1H	0...1	1	[-]
External request of fuel pressure setpoint (low pressure)					
LV_FUP_LIH_REQ	O	0...1H	0...1	1	[-]
Limp home mode for HPP requested					
NC_NR_N_FUP_SP	O	0...1FH	1...32	1	[-]
Number of engine speed datapoints for FUP_SP					
NC_NR_MFF_SP_FUP_SP	O	0...1FH	1...32	1	[-]
Number of mass fuel flow datapoints for FUP_SP					
FUP_RES_H_SP_CH	O	0...FFFFH	0...255.99609	3.9063e-3	[MPa]
Fuel pressure setpoint during catalyst heating

Temperature offset to TCO based on IGA_AV_MV and MFF_SP_MV					

34.5.1 FUSL_M400K

The temperature of the fuel has influence to the density and the volume of the fuel. This has consequences to several points of the function within the fuel supply aggregate and the injection timing. The influence is a lower efficiency of the pump and a influence on the injection valves due to higher temperature of different calculations of the fuel mass in the rail. Therefore two different temperature are modelled, TFU for the fuel pump control and TFU_IV for the injection valve temperature

Both fuel temperatures are expected to depend mainly on the coolant temperature. Beyond this there is an influence of the fuel volume flow, the engine temperature, the ambient temperature, the vehicle speed and time since the last engine stop and the air temperature.

Application condition:

Activation: LV_RUN_ENG = 1;

Deactivation: At power latch;

Initialisation: At reset: TFU_IV_SUB_RAW, TFU_IV_SUB, TFU_IV, TFU, TFU_RAW, TFU_LPF_TCO, TFU_IV_ST = TCO_ST;

At IGK off to on:

PT1 filter constant of TFU_RAW = 0

local variables of gradient limiters tfu_raw_step_clc and tfu_iv_sub_step_clc = 0

local counter for calculation delay of TFU values = 0

Recurrence: every 1S

Except the the following calculation:

TFU_LPF_CLC, TFU_IV_ST_CLC Activation: LV_T_REL_CAN_REG = 1 and LV_RUN_ENG = 0 Recurrence: 100 ms

TFU_INIT_NO_T_REL_CAN Activation: LV_T_REL_CAN_REG = 0 and LV_RUN_ENG = 0 Recurrence: 100 ms

TFU, which is calculated every C_T_TFU_CLC

TFU_IV_SUB_RAW, which is calculated every C_T_TFU_IV_SUB_RAW_CLC

TFU_IV_SUB, which is calculated every C_T_TFU_IV_SUB_CLC

Application Condition

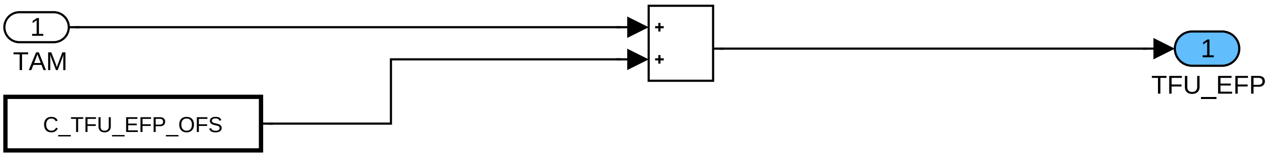

Figure 13 FUSL_M400K/ Operate/ Task_1S/ TFU_EFP_CLC

FUSL_M400K/OPERATE/TASK_1S/TFU_IV_CLC

For the calculation of the injection valve temperature, two functions are available, switchable by the logical constant LC_TEMP_CAPA_TFU_IV_SWI.

1. - For TFU_IV_SUB_MV a mixed temperature of the heating influence of the combustion chamber and the fuel temperature is calculated. The heating influence of the combustion chamber rests on TCO, MFF_SP_MV and ignition angle. The fuel temperature influence is

described by TEMP_CAPA_IV_MV (Temperature of the piezo stacks derived from their capacities).

With higher fuel flows through the injectors, the injector temperature is more influenced by the fuel temperature. The modeled injector temperature can be shifted by a fading factor based on the fuel flow to TEMP_CAPA_IV_MV.

The heat up phase of the injector tip during start is faster than the heating of the fuel temperature. During start phase and short after start, the fading function between TEMP_CAPA_IV_MV and TFU_IV_SUB_RAW can be blocked for a certain time by using C_T_AST_SWI_TFU_IV.

2. - The second function depends mainly on the coolant temperature, influenced by

engine speed, the mass flow through the engine, the ambient temperature and the rpm of the cooling water pump.

The output TFU_IV_SUB_RAW is filtered by a PT1 function. Because of the minimum resolution of the TFU values of 0,75°/digit, the input value of the PT1 is stored internal (not visible) and calculated with an finer resolution of 0,00036°/digit until it reaches the minimum digit.

By using C_T_TFU_IV_SUB_RAW_CLC or C_T_TFU_IV_SUB_CLC

the calculation recurrence of TFU_IV_SUB_RAW (PT1 funktion) or TFU_IV_SUB (GradientLimiter) can be reduced.

The gradient limiters for rising and falling edge, C_TFU_IV_SUB_LIM_DEC and C_

TFU_IV_SUB _LIM_INC have a finer resolution than TFU_IV_SUB. It takes several

calculation cycles until TFU_IV_SUB changes. During this calculation cycles of TFU_IV_SUB a internal variable (not visible) is incremented or decremented depending on rising or failing gradient until it reaches the minimum digit of TFU_IV_SUB (0.75°C).

If the CAN values are not valid (LV_T_REL_CAN_REG = 0), TFU_IV, TFU_IV_SUB and

TFU_IV_SUB_RAW = TCO.

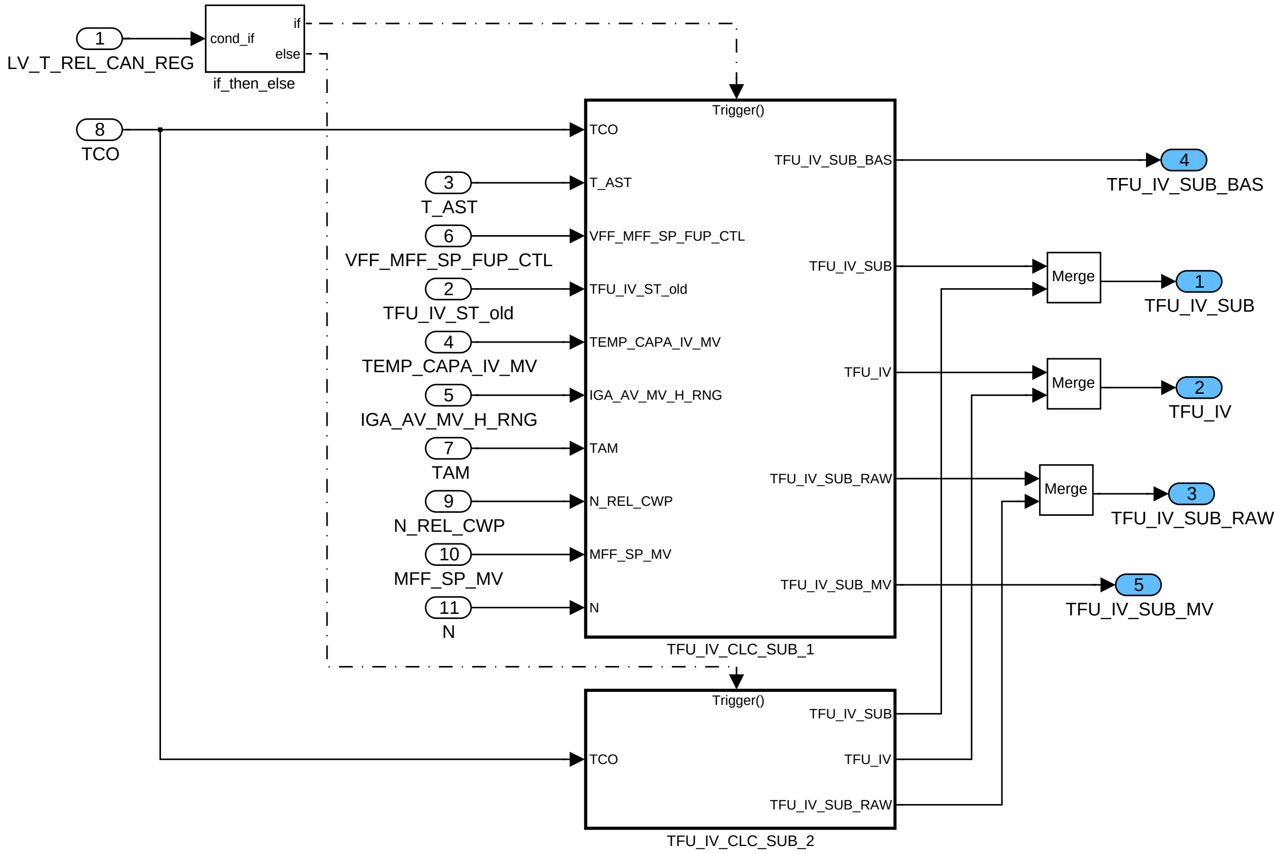

Figure 14 FUSL_M400K/ Operate/ Task_1S/ TFU_IV_CLC

FUSL_M400K/OPERATE/TASK_1S/TFU_OFS_AIR_CLC

Calculation of ambient air influence on fuel temperature due to vehicle speed and electrical cooling fan.

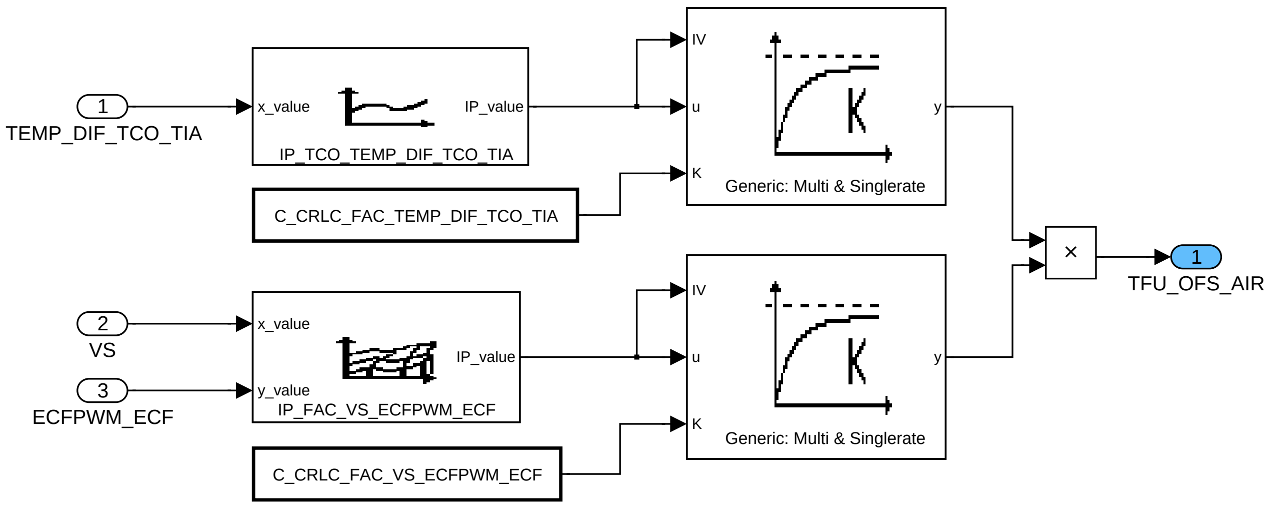

Figure 20 FUSL_M400K/ Operate/ Task_1S/ TFU_OFS_AIR_CLC

FUSL_M400K/OPERATE/TASK_1S/TFU_RAW_CLC

The temperature TFU_RAW is calculated from the fuel rail wall temperature reduced by the decrease of the temperature due to fuel flow through the fuel rail.

C_TFU_RAW_LIM_DEC and C_TFU_RAW_LIM_INC have a finer resolution than TFU_RAW. It takes several calculation cycles (GradientLimiter) until TFU_RAW changes. During this calculation cycles of TFU_RAW the local variable tfu_raw_step_clc is incremented or decremented depending on rising or failing gradient until it reaches the minimum digit of TFU_RAW (0.75°C). After a step of TFU_RAW the lasting value of tfu_raw_step_clc will be used for the next calculation.

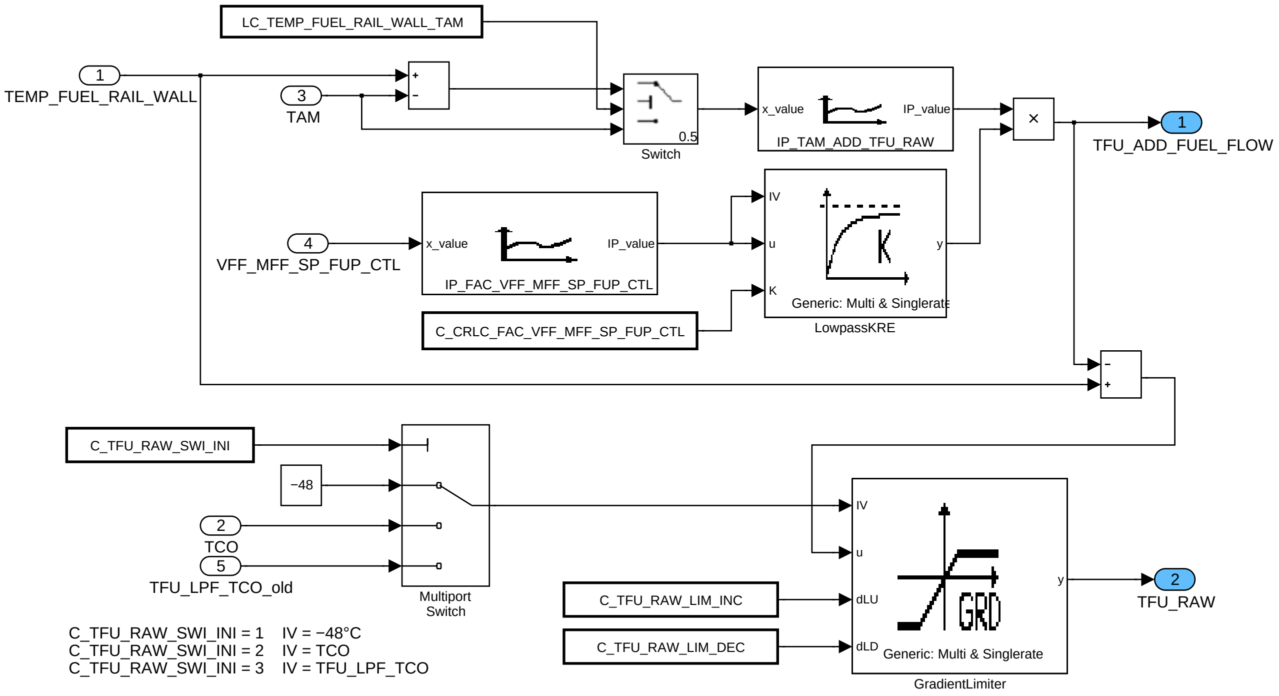

Figure 21 FUSL_M400K/ Operate/ Task_1S/ TFU_RAW_CLC

FUSL_M400K/OPERATE/TASK_TFU_IV_ES

At engine stop, a modelled injector temperature will be calculated based on TCO. Starting with the last modelled temperatures TFU_IV_SUB_RAW, TFU_IV_SUB and TFU_IV the values were incremented by the value C_CRLC_TFU_IV_ES until TCO is reached.

34.6.1 FUSL_M4018

The fuel pressure sensor is delivering a voltage signal corresponding to the fuel pressure in the rail. Out of this sensor voltage a fuel pressure value is calculated via liniarisation table. An additional filter can be applied.

Application Condition

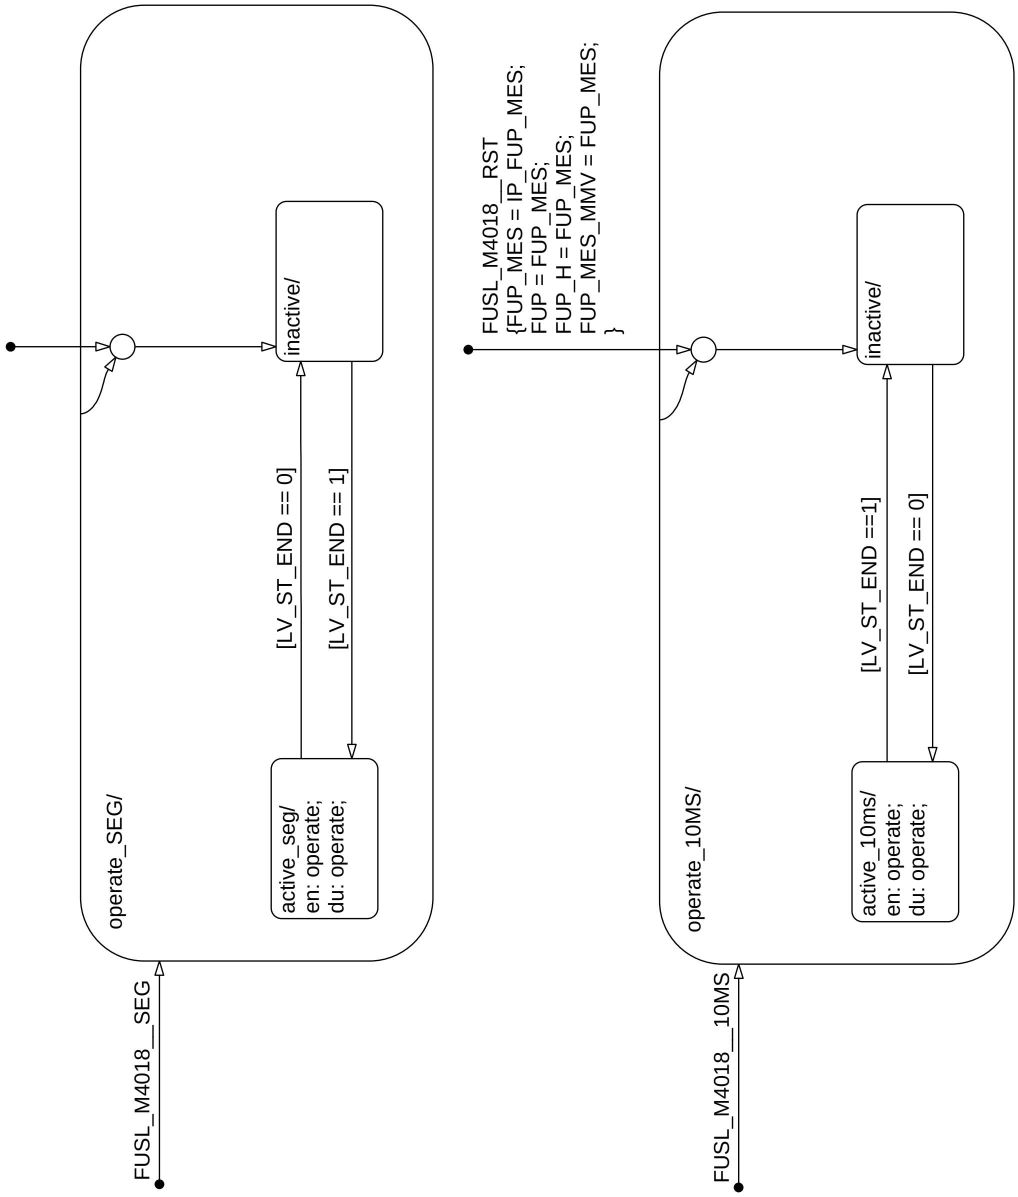

Figure 29 FUSL_M4018/ APP_CDN/ Chart

Function Description

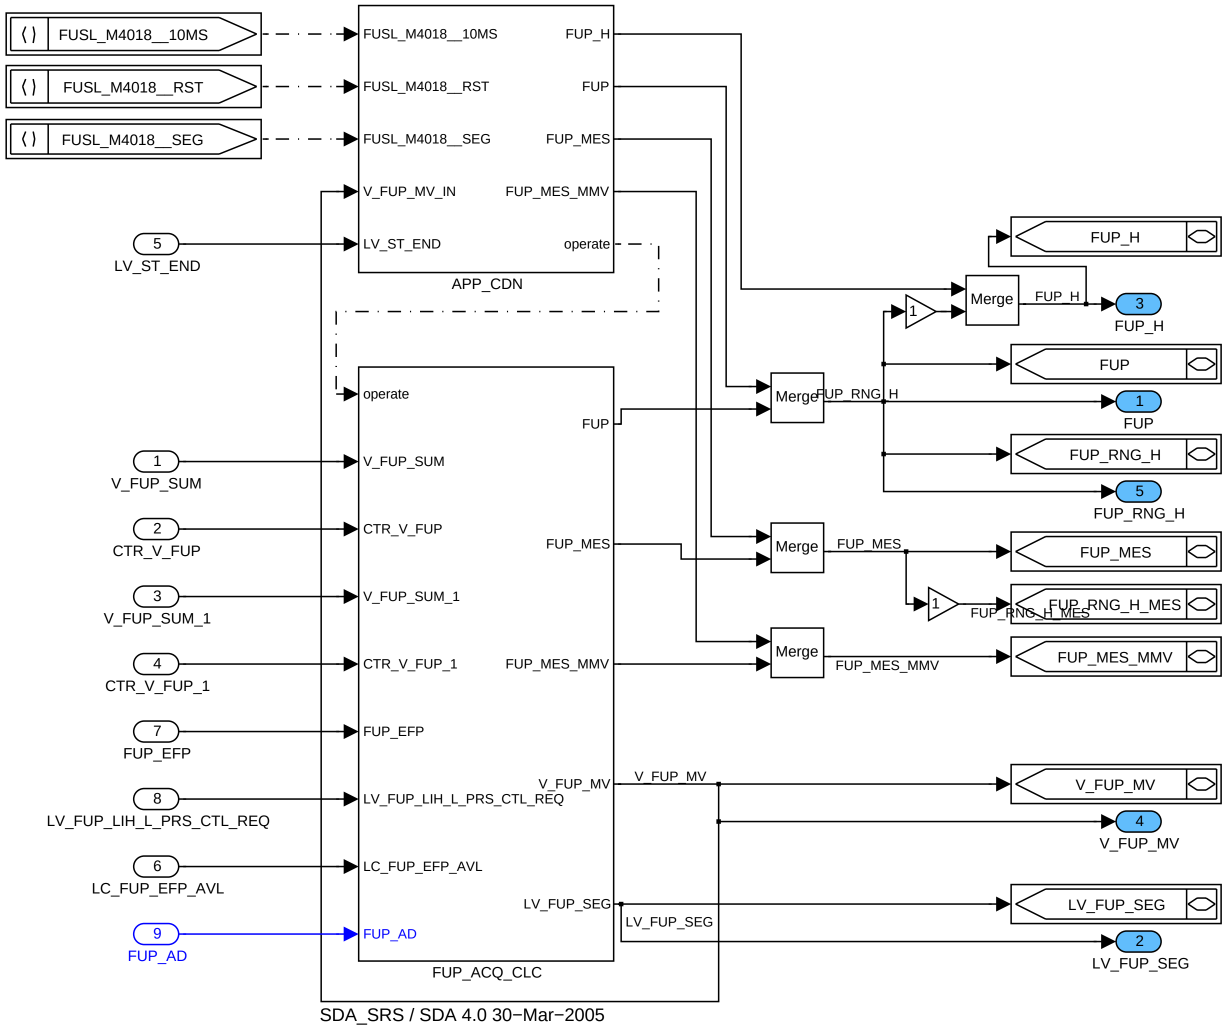

Figure 30 FUSL_M4018

34.6.1.1 FUSL_M4018/FUP_ACQ_CLC

The fuel pressure calculation is split into two parts.

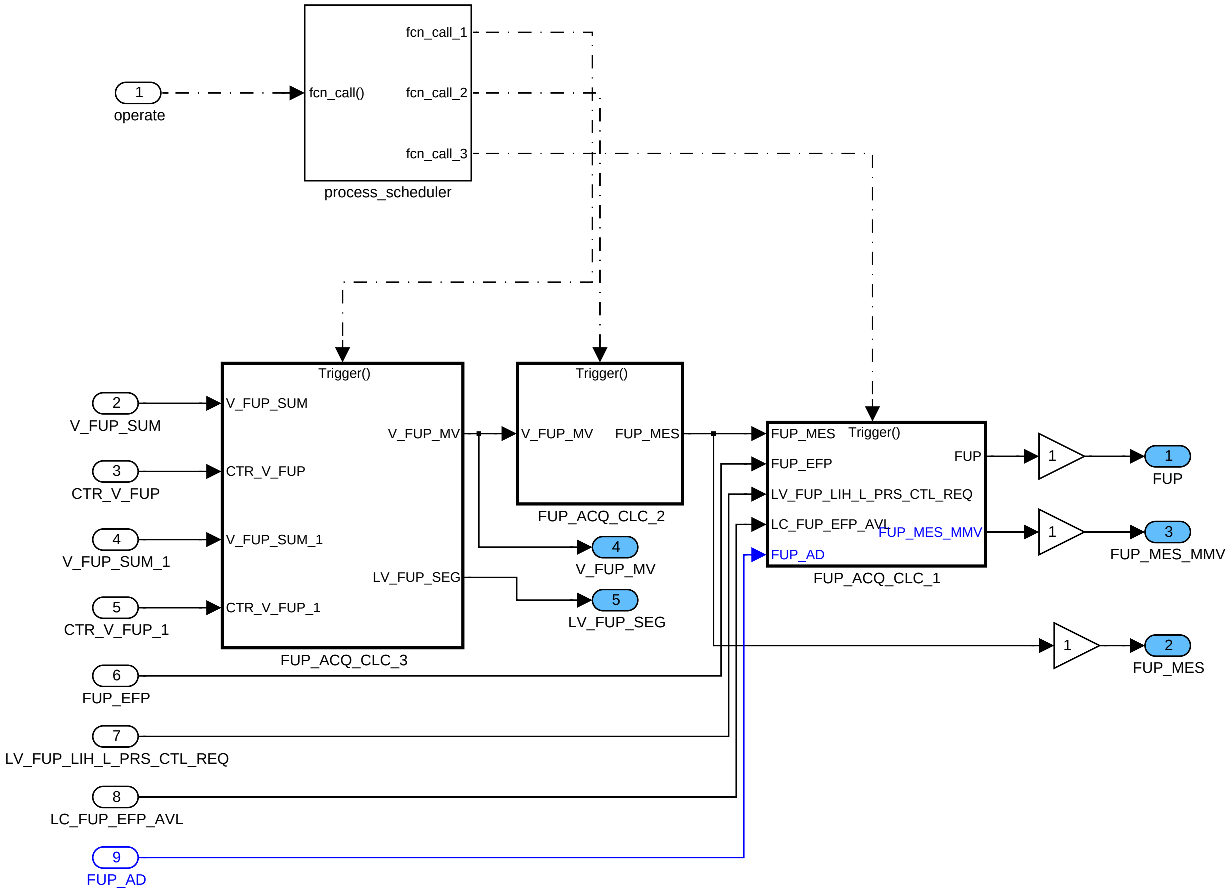

Figure 31 FUSL_M4018/ FUP_ACQ_CLC

FUSL_M4018/FUP_ACQ_CLC/FUP_ACQ_CLC_1

The liniarisation table gives the relationship between the sensor signal and the fuel pressure. This data has to be delivered by the sensor supplier.

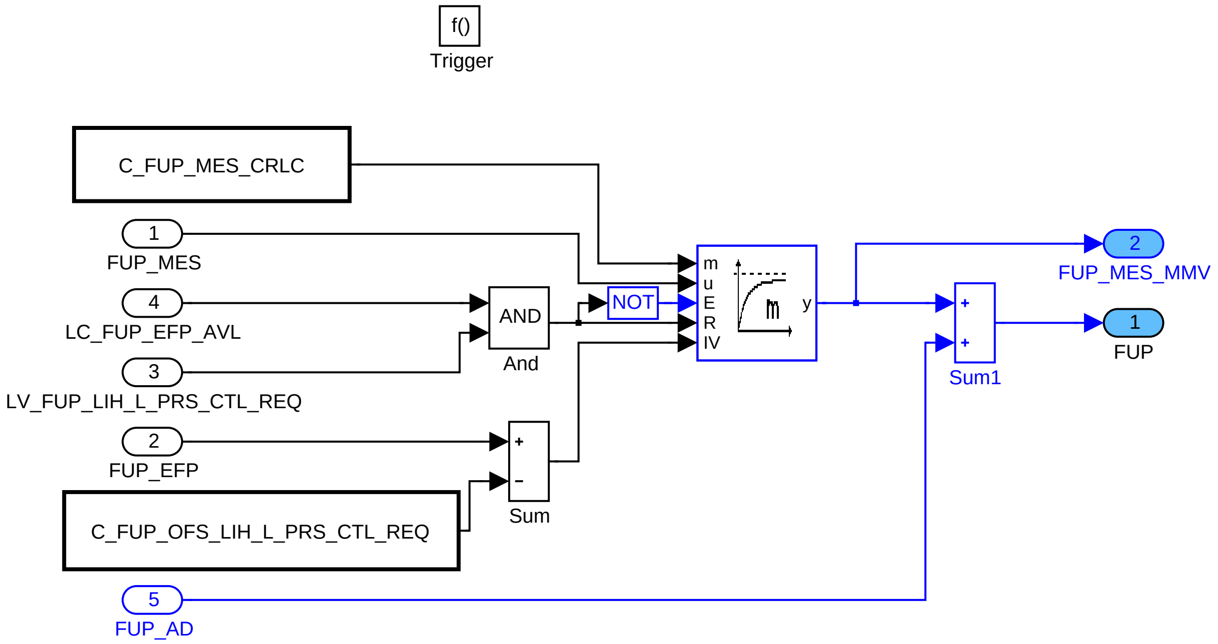

Figure 32 FUSL_M4018/ FUP_ACQ_CLC/ FUP_ACQ_CLC_1

FUSL_M4018/FUP_ACQ_CLC/FUP_ACQ_CLC_2

The correlation constant gives the filter constant for the fuel pressure. This filtering could be necessary to get a more stable signal for the fuel pressure.

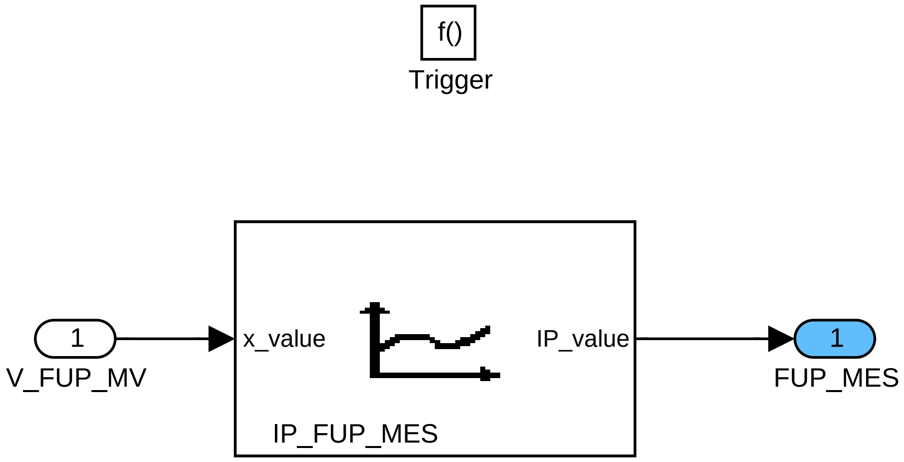

Figure 33 FUSL_M4018/ FUP_ACQ_CLC/ FUP_ACQ_CLC_2

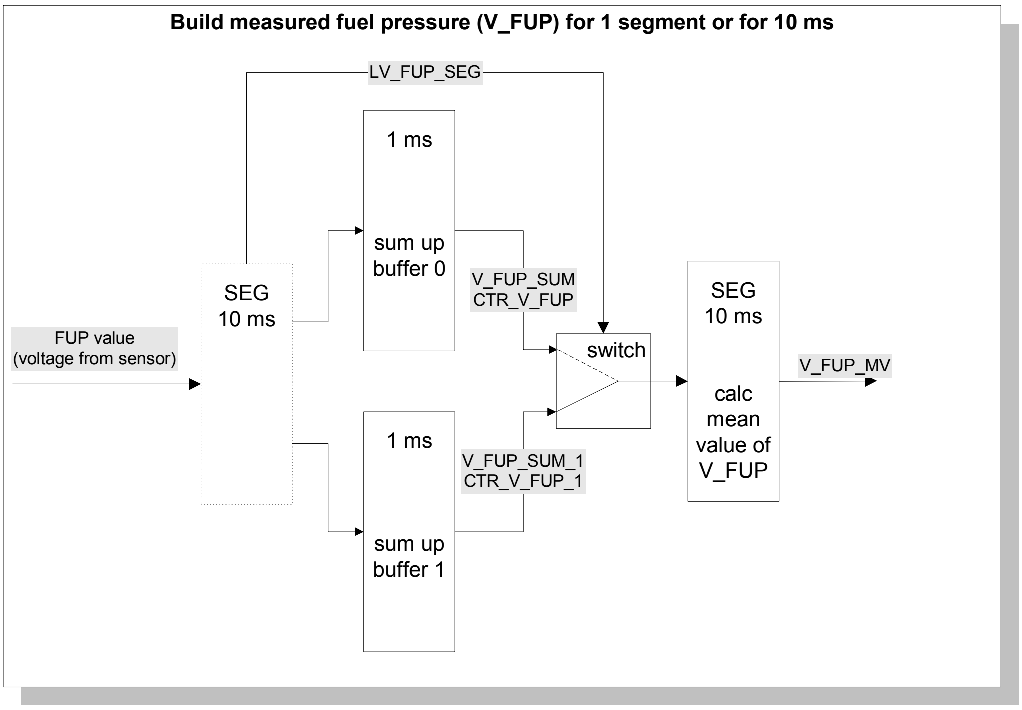
FUSL_M4018/FUP_ACQ_CLC/FUP_ACQ_CLC_3



The raw value (voltage) for FUP is measured by continous conversion every 1 ms. The values (10 bit) are summed up in two alternating buffers, SUM_V_FUP or SUM_V_FUP_1. The numbers of values are counted in comparable buffers CTR_FUP or CTR_FUP_1. This mechanism is necessary to synchronize the measurement and the calculation of FUP_MES (build mean value with a standardized range) and will be done within BSW.

Depending on the logical variable LV_FUP_SEG one of the two buffers — SUM_V_FUP or SUM_V_FUP_1 — and the respective counter — CTR_V_FUP or CTR_V_FUP_1 — are selected for writing, the contents of the other buffer (counter) is used for calculations and diagnosis (after this buffer and the corresponding counter have been read they are cleared).

After having read out one buffer — SUM_V_FUP or SUM_V_FUP_1 — the buffer has to be cleared as well as the corresponding counter — CTR_V_FUP or CTR_V_FUP_1.

A two-buffer-system is used to avoid incorrect FUP calculation.

34.7.1 Fuel pressure acquistion of low pressure signal

The raw value (voltage) for FUP_EFP is measured by continous conversion every 1 ms. The values (10 bit) are summed up in two alternating buffers, FUP_EFP_SUM or FUP_EFP_SUM_1. The numbers of values are counted in comparable buffers FUP_EFP_CTR or FUP_EFP_CTR_1. This mechanism is necessary to synchronize the measurement and the calculation of FUP_EFP_MES (build mean value with a standardized range)

Depending on the logical variable LV_FUP_EFP_SEG one of the two buffers — FUP_EFP_SUM or FUP_EFP_SUM_1 — and the respective counter — FUP_EFP_CTR or

FUP_EFP_CTR_1 — are selected for writing, the contents of the other buffer (counter) is used for calculations and diagnosis (after this buffer and the corresponding counter have been read they are cleared).

After having read out one buffer — FUP_EFP_SUM or FUP_EFP_SUM_1 — the buffer has to be cleared as well as the corresponding counter — FUP_EFP_CTR or FUP_EFP_CTR_1.

A two-buffer-system is used to avoid incorrect FUP_EFP calculation.

The fuel pressure of the feedline is calculated by means of the fuel pressure sensor for the feedline. Additionally in case of sensor error a substitude value will be taken.

Use **ACTION_INFR_GetVFupEfpSens(OUT** <v_fup_efp>**)**

34.8.1 Fuel pressure setpoint of low pressure pump

The module fuel pressure setpoint of electrical fuel pump delivers a fuel setpoint to the module fuel pressure control.

The fuel pressure setpoint of the low pressure pump is normally taken out of a map depending on engine speed and injected fuel mass. Exemptions are power latch phase of the electrical fuel pump and the pull mode. Additionally a testbench function is included. In order to avoid to big fuel pressure setpoint gradients a certain gradient limitation is included.

34.9.1 Electrical fuel pump control with fuel pressure sensor for feed pressure

General information:

The electrical fuel pump is controlled by the EFPPWM.

The PI-controller is used to compensate deviations from the nominal fuel pressure after the fuel pump. If no sensor is applied the EFPPWM is only calculated with the help of the precontrol map, which corresponds to the pump data.

In order to control also deviations caused by external influences or aging two adaptation strategies are applied. One adaptation is used in a nominal operating point where the I-part of the controller is taken as an adaptive I-part. The other adaptation gives the minimum EFPPWM for ensuring the correct fuel pressure for the jet pumps without increasing the fuel pressure to the level where the overpressure release valve opens.

Application Condition

Figure 56 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_LIH

Electrical fuel pump off

Calculation of the controller in state "off"

If no fuel delivery is required the ECU has to give a minimum EFPPWM. The only operating point where this rule can not be applied is at request from the independent car heater. At this point the adapted minimum PWM is applied to the pump.

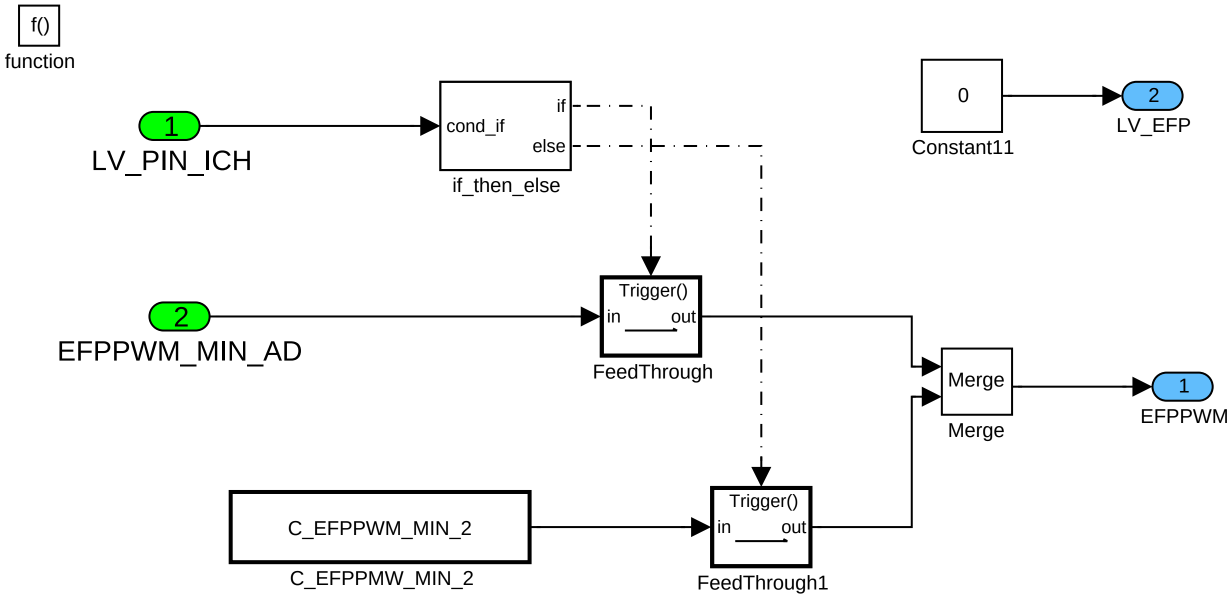

Figure 57 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_OFF

Electrical fuel pump on

Calculation of the Controller in state "on"

The functionality for the electrical fuel pump in status "on" is given here. It is split into a precontrol calculation part, a limitation signal generating part (mainly for PUC), an EFPPWM calculation part and the controller output part.

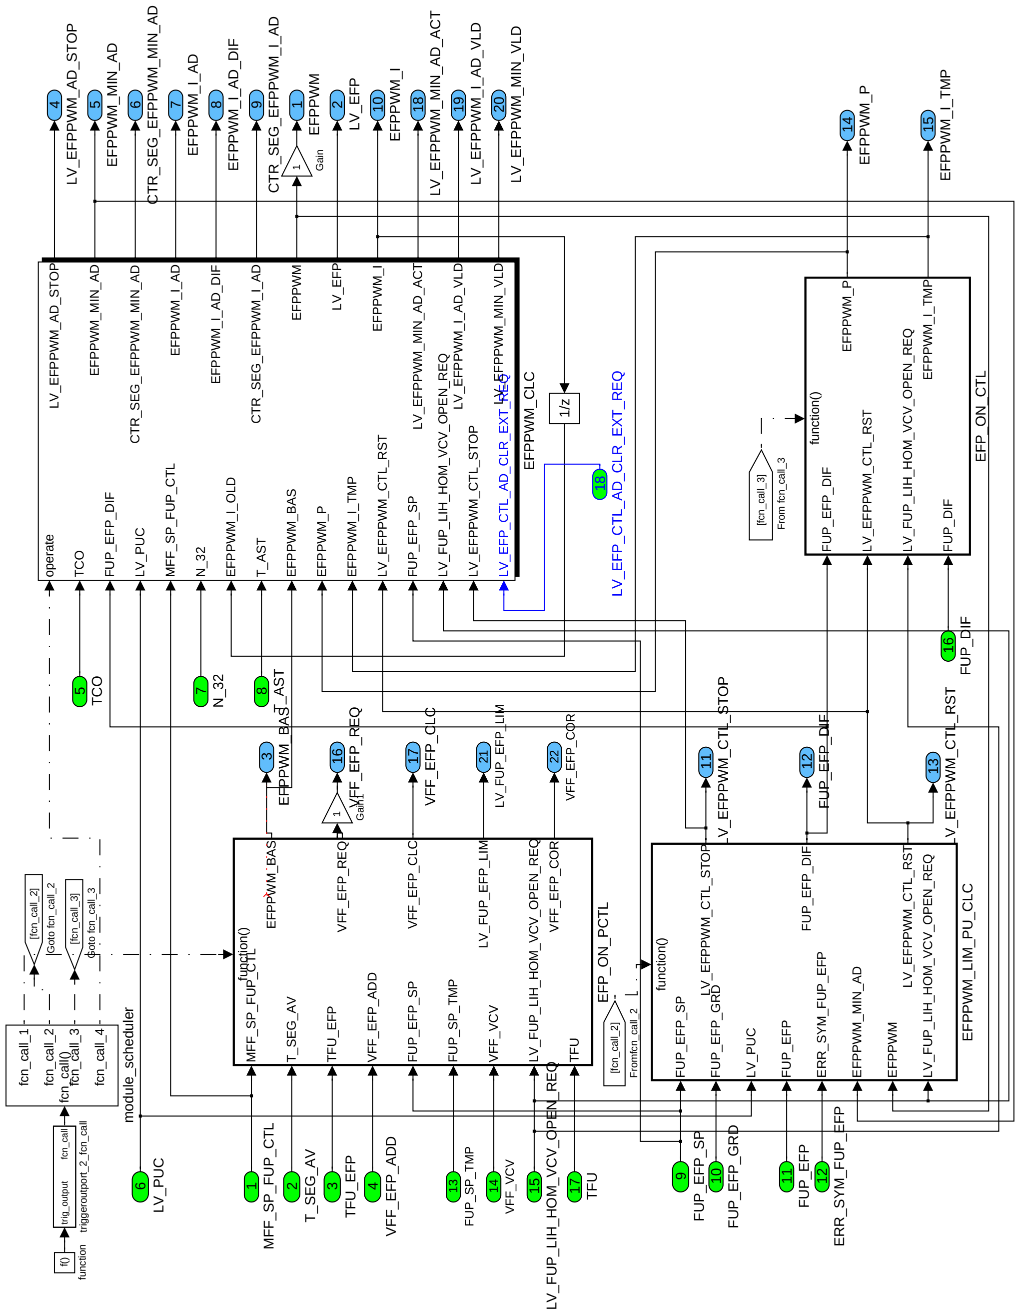

Figure 58 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON

Electrical fuel pump pwm signal calculation

Calculation of the final output signal

The EFPPWM calculation part is split into two parts. One is calculating the adaptation and the other part calculate the final EFPPWM output.

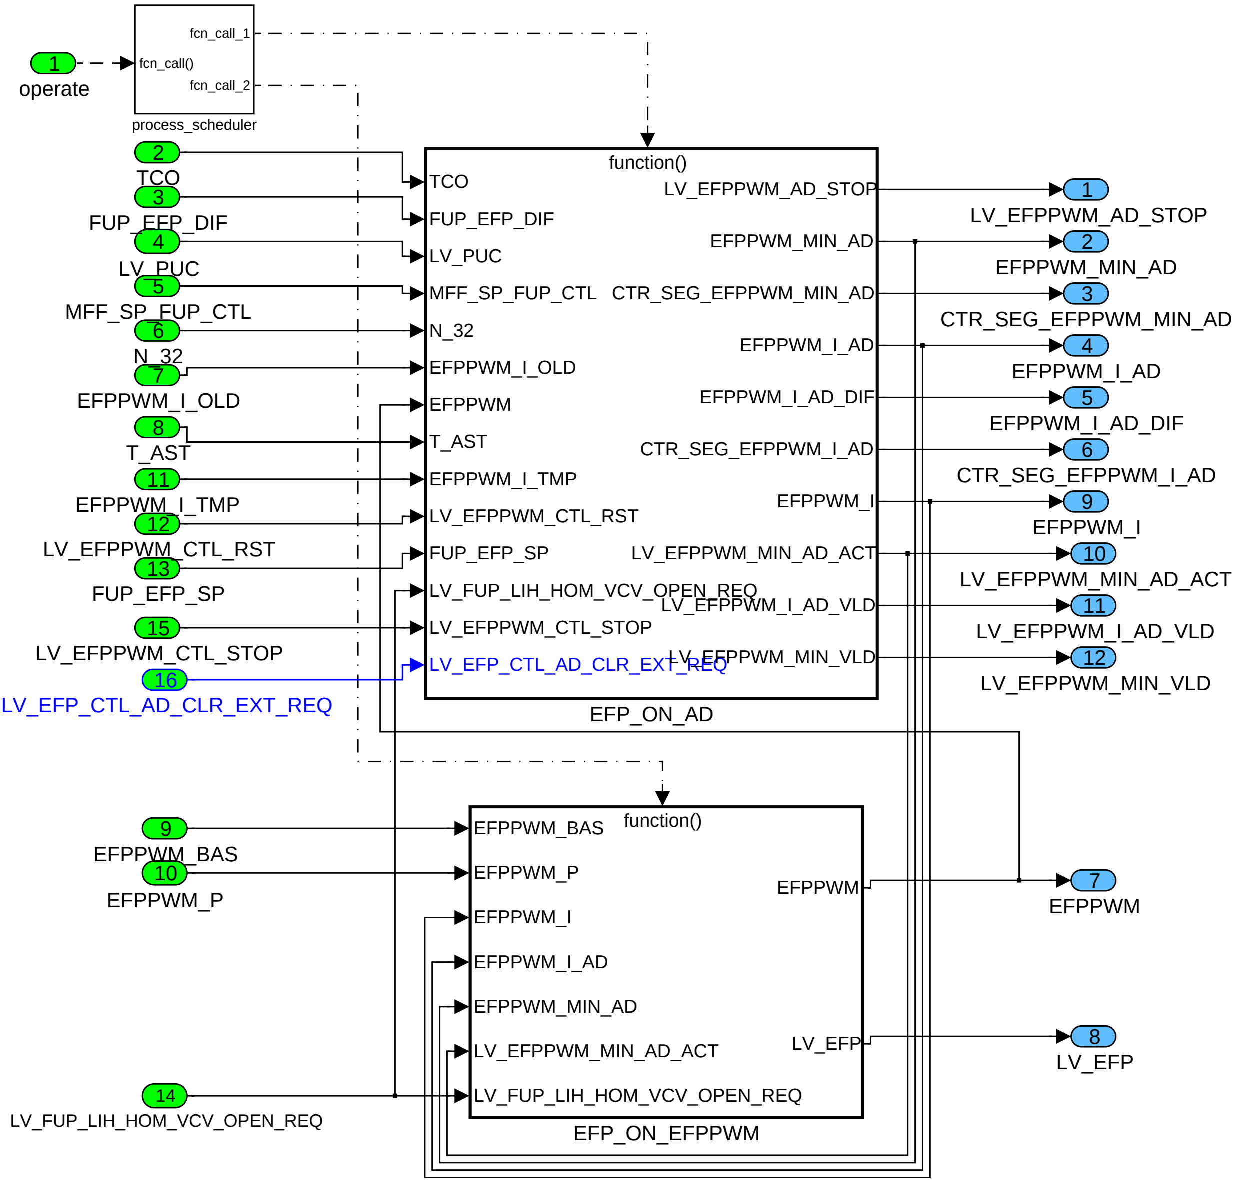

Figure 59 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON/ EFPPWM_CLC

<u>Electrical fuel pump on adaptive</u>

Calculation of the adaptation

The adaptation part is split into the main adaptation inbit flag calculating module, the calculation part for the minimum EFPPWM adaptation part and two modules for the I–part adaptation.

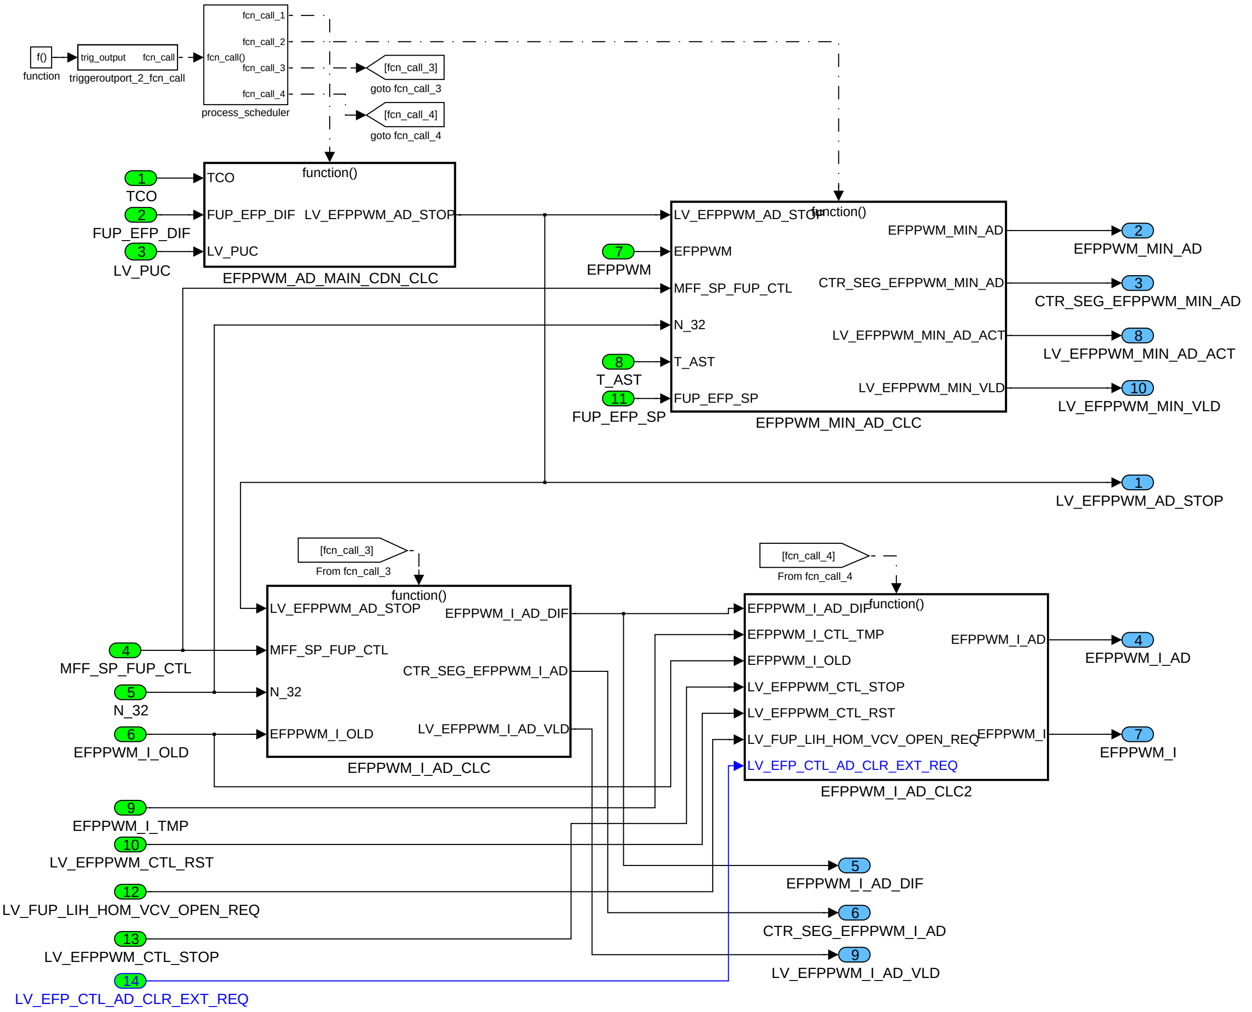

Figure 60 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON/ EFPPWM_CLC/ EFP_ON_AD

Electrical fuel pump pwm signal adaptive main condition calculation

Main conditions for the adaptation

Within this module the inhibition flag for the adaptation is created.

<u>Electrical fuel pump on electrical fuel pump pwm signal</u>

Calculation of the final output for the EFPPWM

In this module the final EFPPWM is calculated.

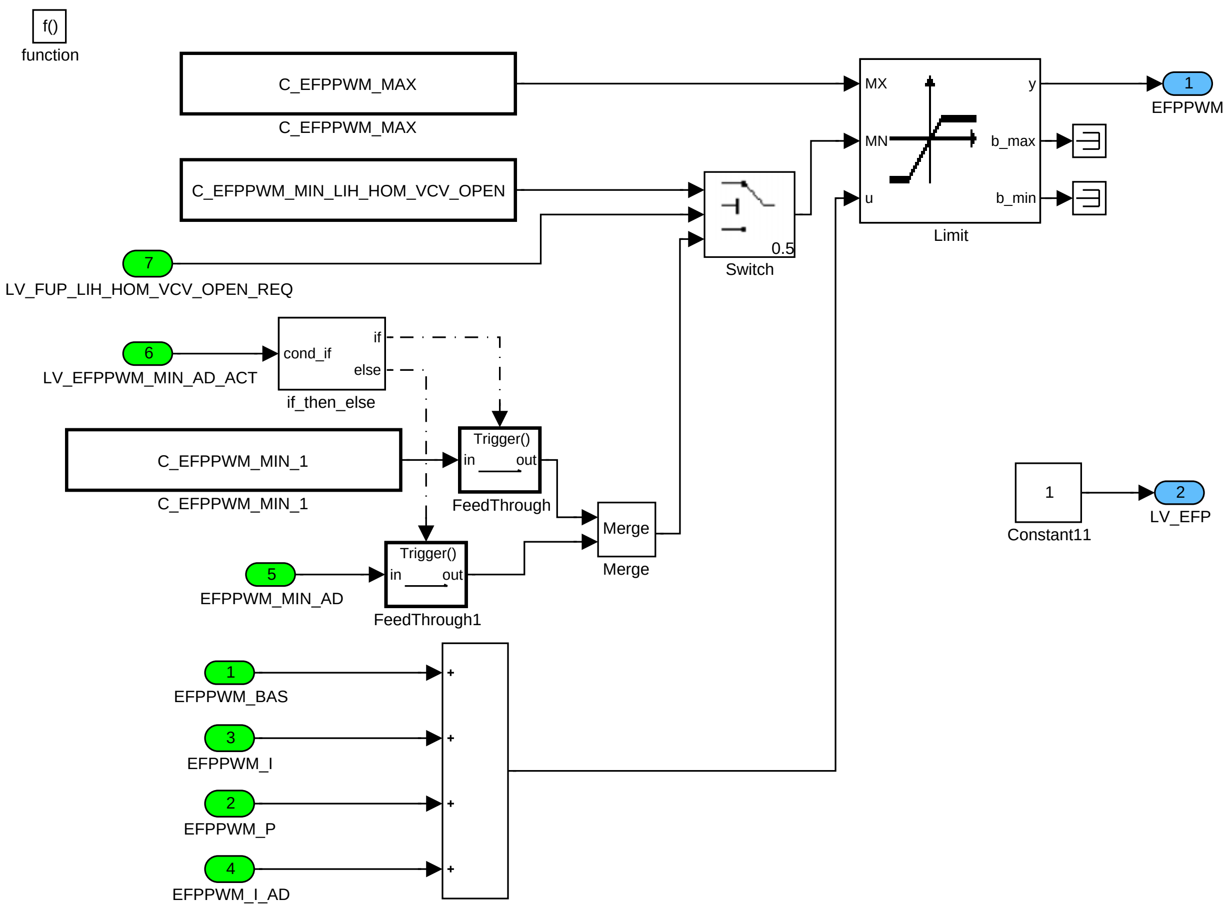

Figure 67 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON/ EFPPWM_CLC/ EFP_ON_EFPPWM

<u>Electrical fuel pump pwm signal limitation pull calculation</u>

Limitation of the controller

Given by special conditions the controller is stopped. This is done within PUC when a too high fuel pressure gradient is measured and the fuel pressure is over the setpoint.

Also the total reset of the controller output can be necessary when there is a sensor error or no sensor is available (given by the flag).

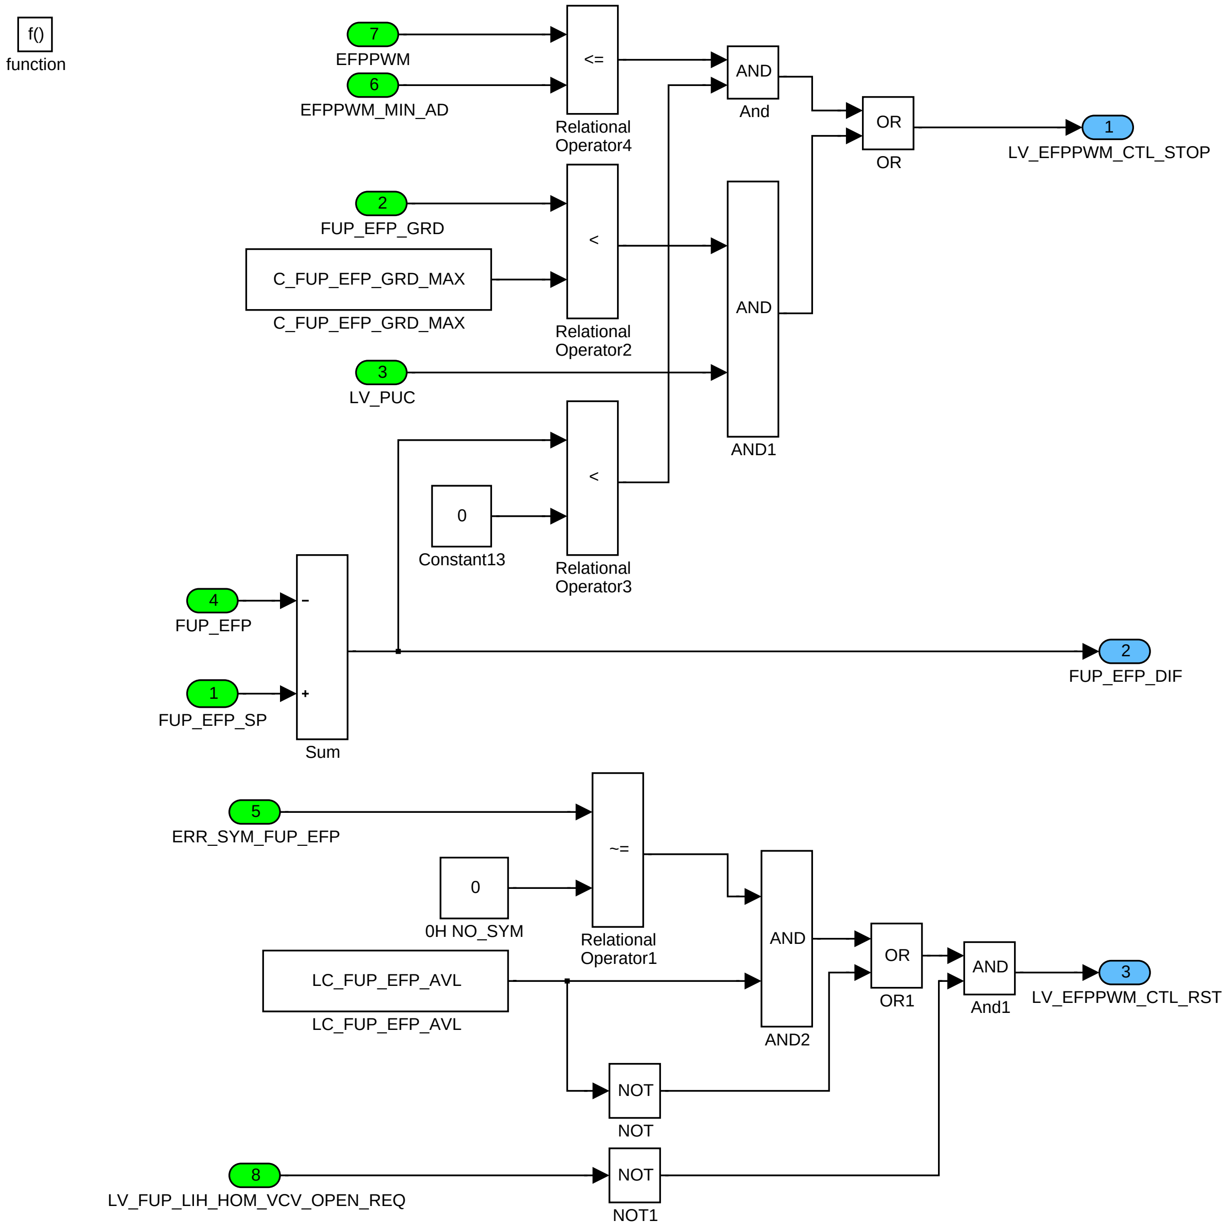

Figure 68 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON/ EFPPWM_LIM_PU_CLC

Electrical fuel pump on control

Calculation of the controller

The controller part gives the output of the controller maps for the I – part. In case of given reset flag the I – part and the P – part are zero.

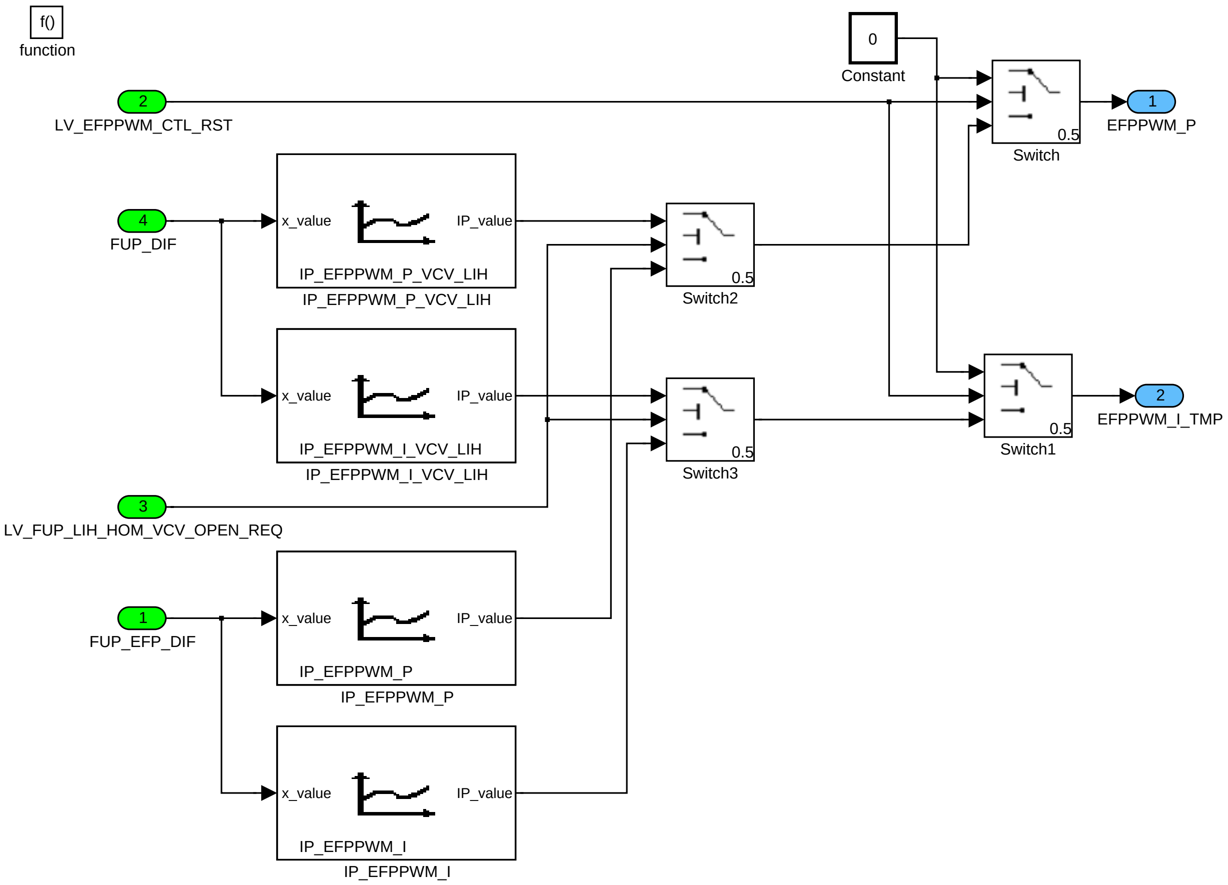

Figure 69 M9014/ EFP_CTL_MAIN/ CLC_EFP_CTL_CLC/ EFP_ON/ EFP_ON_CTL

Electrical fuel pump on pre-control

Calculation of the precontroller

The precontrol part calculated the precontroller value out of the required fuel mass for the injection. Within the given two maps the basic controller output is calculated.

34.10.1 Flow controlled electrical fuel pump

The electrical fuel pump is controlled by the EFPPWM.

The PI-controller is used to compensate deviations from the nominal fuel pressure after the fuel pump.

In this module the switching conditions for the main module are calculated. This includes also limp home and crash reactions. Application Condition

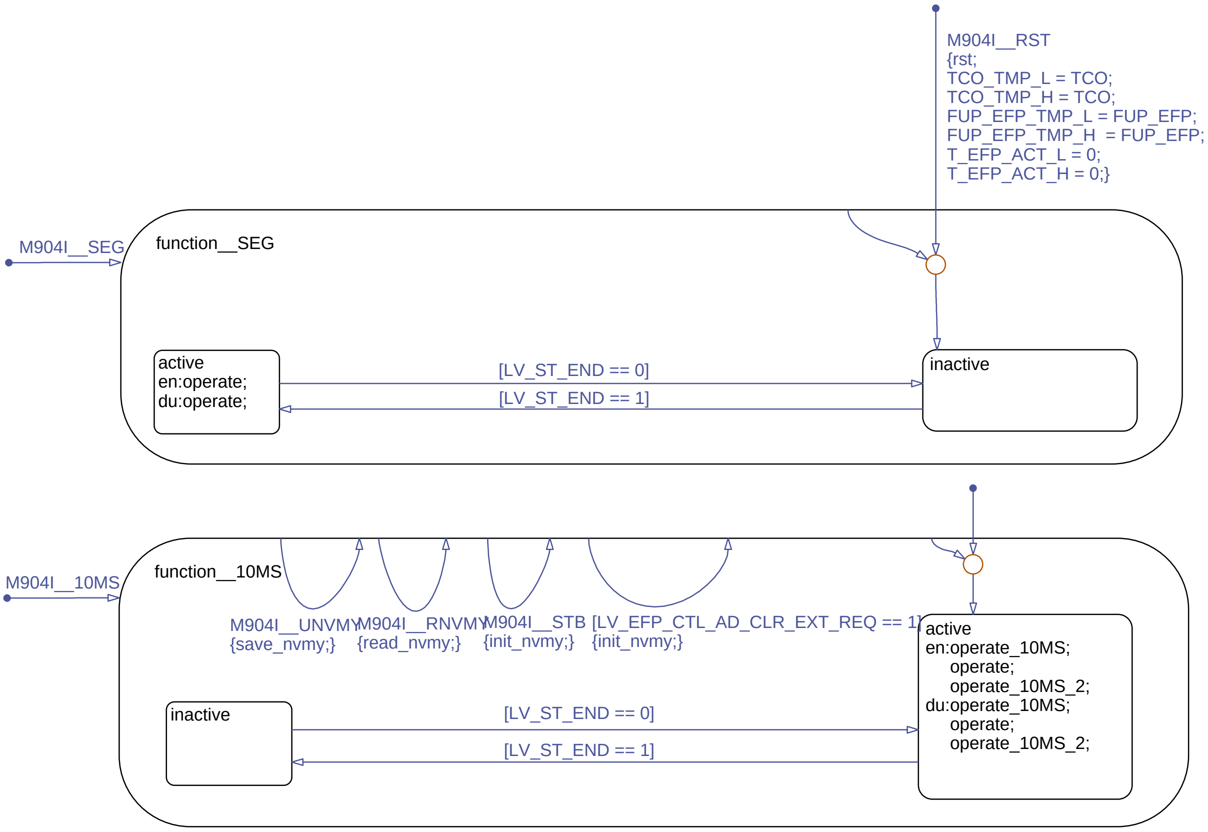

Figure 77 M904I/ APP_CDN/ Chart

Function Description

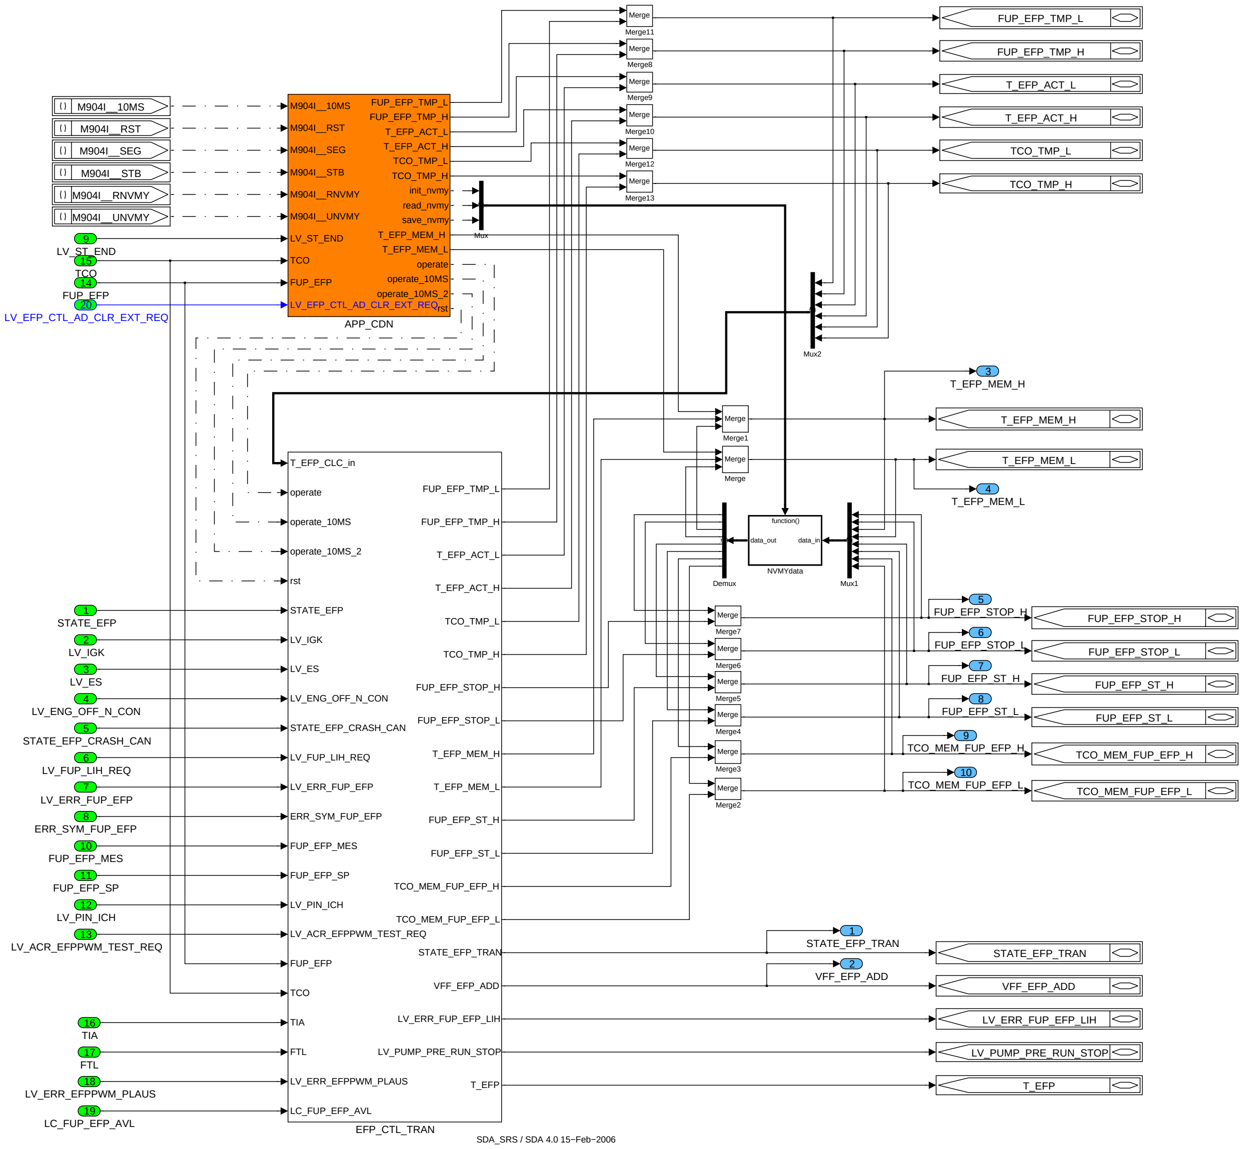

Figure 78 M904I

34.10.1.1 Electrical fuel pump control transition

The function is consisting out of the timer calculation for the EFP and the transition and limp home calculation. Additionally a calculation part for pressure increase and decrease observation is included.

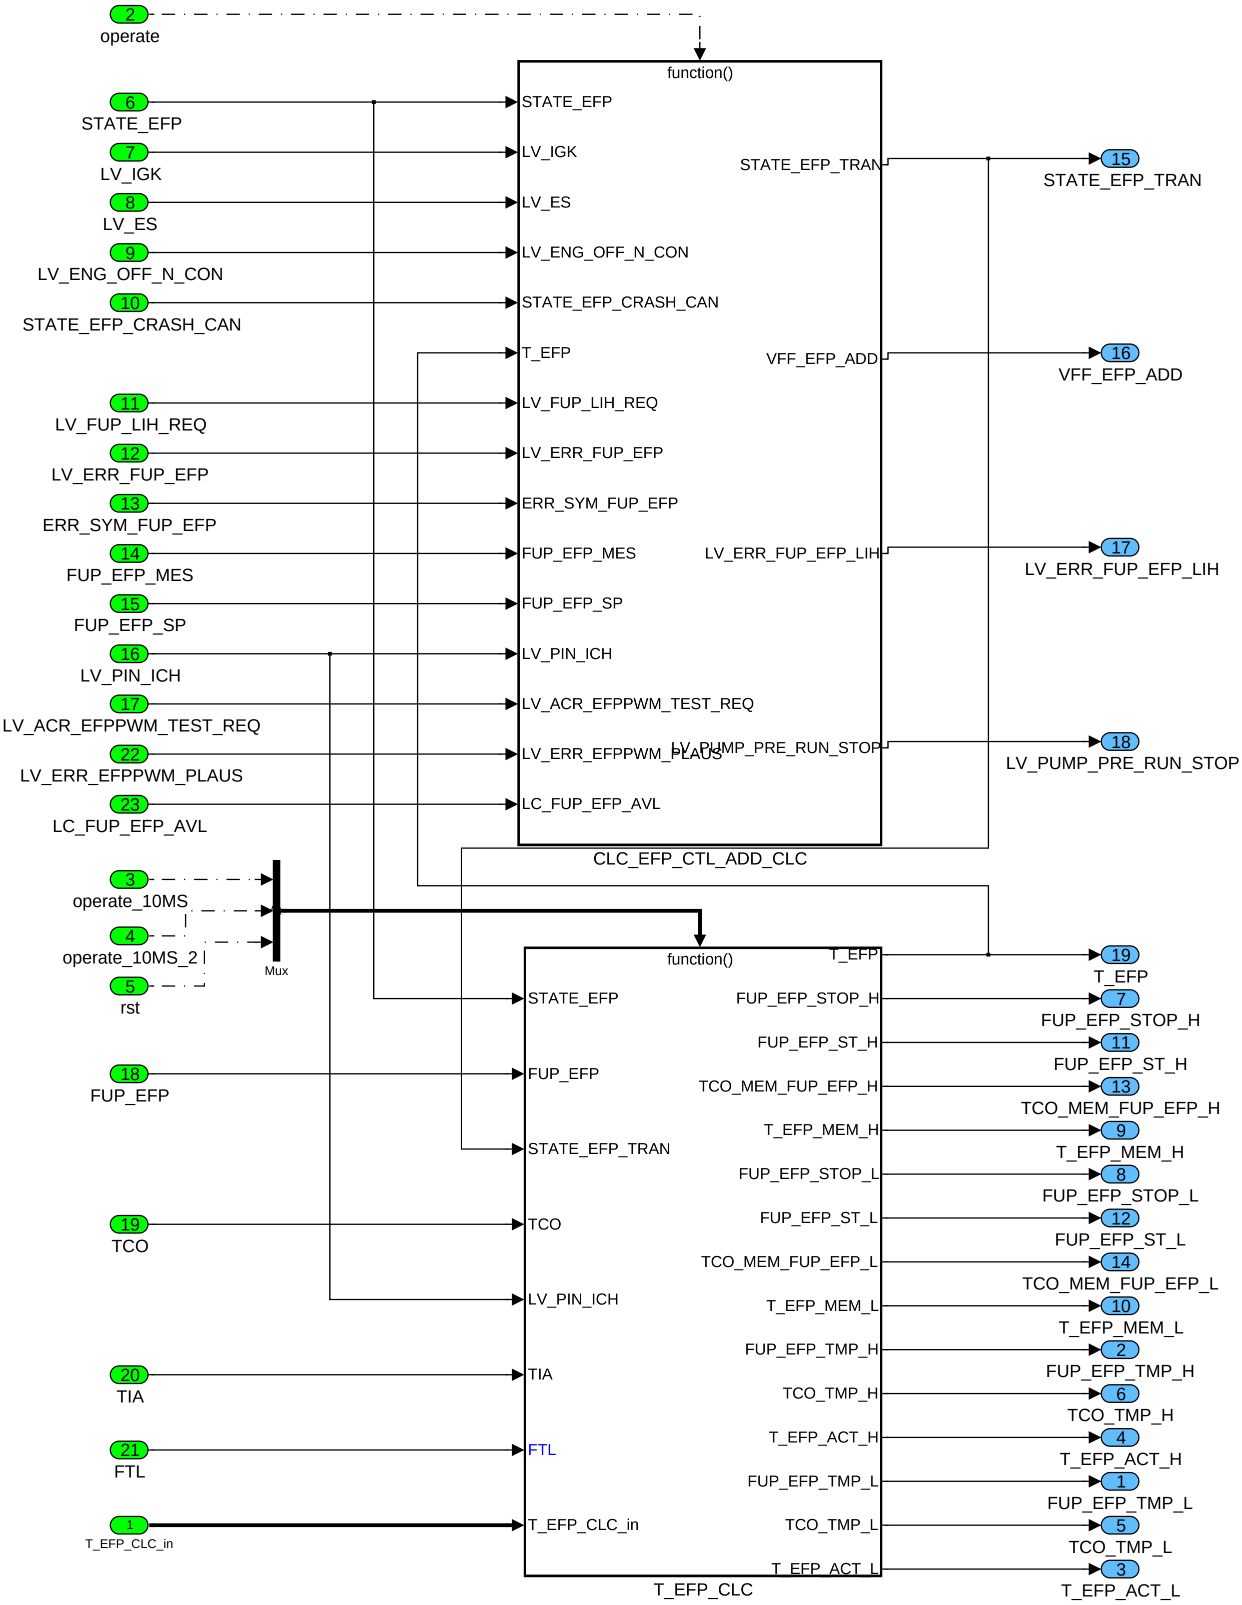

Figure 79 M904I/ EFP_CTL_TRAN

Control additive calculation

This module is consisting out of the transition condition calculation, the addition flow calculation and the limp home determination.

Limp home active

The limp home for the low pressure fuel pump is triggered by different error flags.

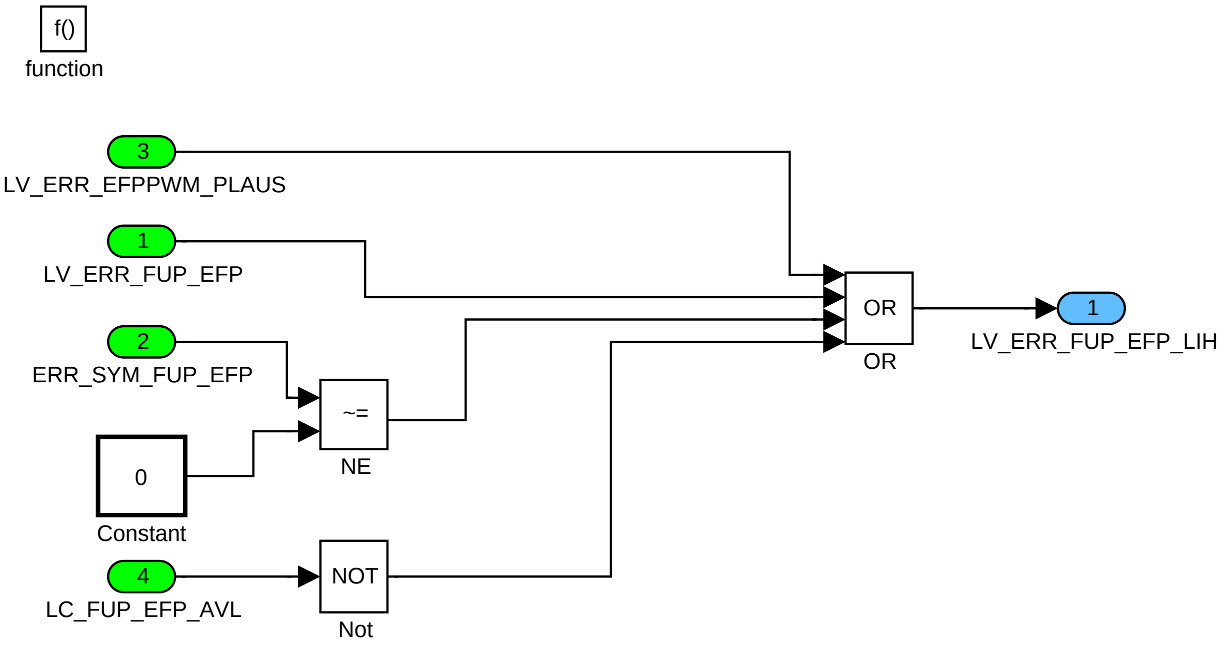

Figure 81 M904I/ EFP_CTL_TRAN/ CLC_EFP_CTL_ADD_CLC/ FUP_EFP_LIH_ACT

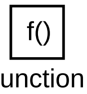
Pump pre-run calculation

The pre-run of the low pressure pump is stopped when the fuel pressure setpoint of the low pressure pump has been reached by the measured fuel pressure (without filtering) or the timer has expired.



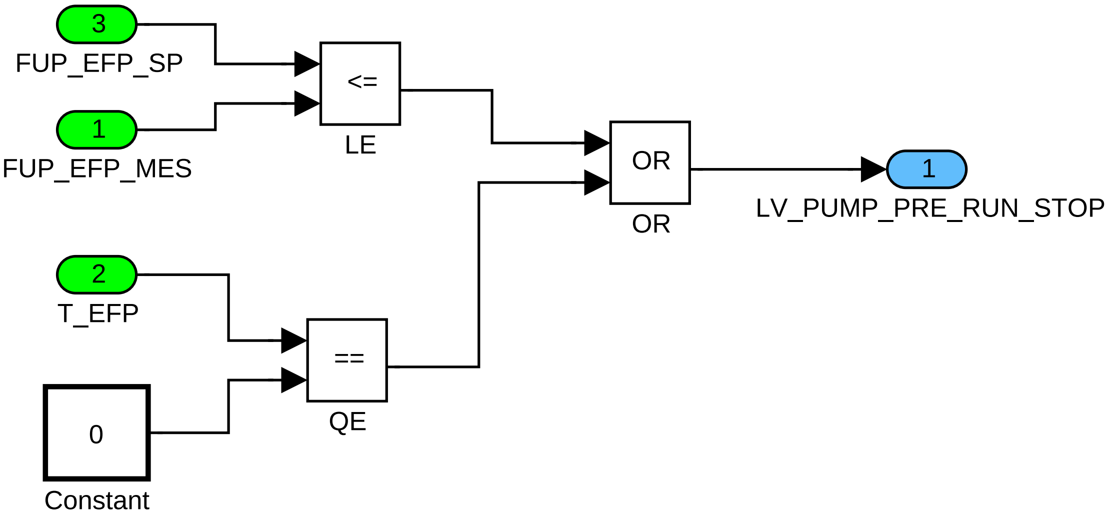


Figure 82 M904I/ EFP_CTL_TRAN/ CLC_EFP_CTL_ADD_CLC/ PUMP_PRE_RUN_CLC

State fuel pressure transition calculation

The transition conditions are split into two parts due to a better overview.

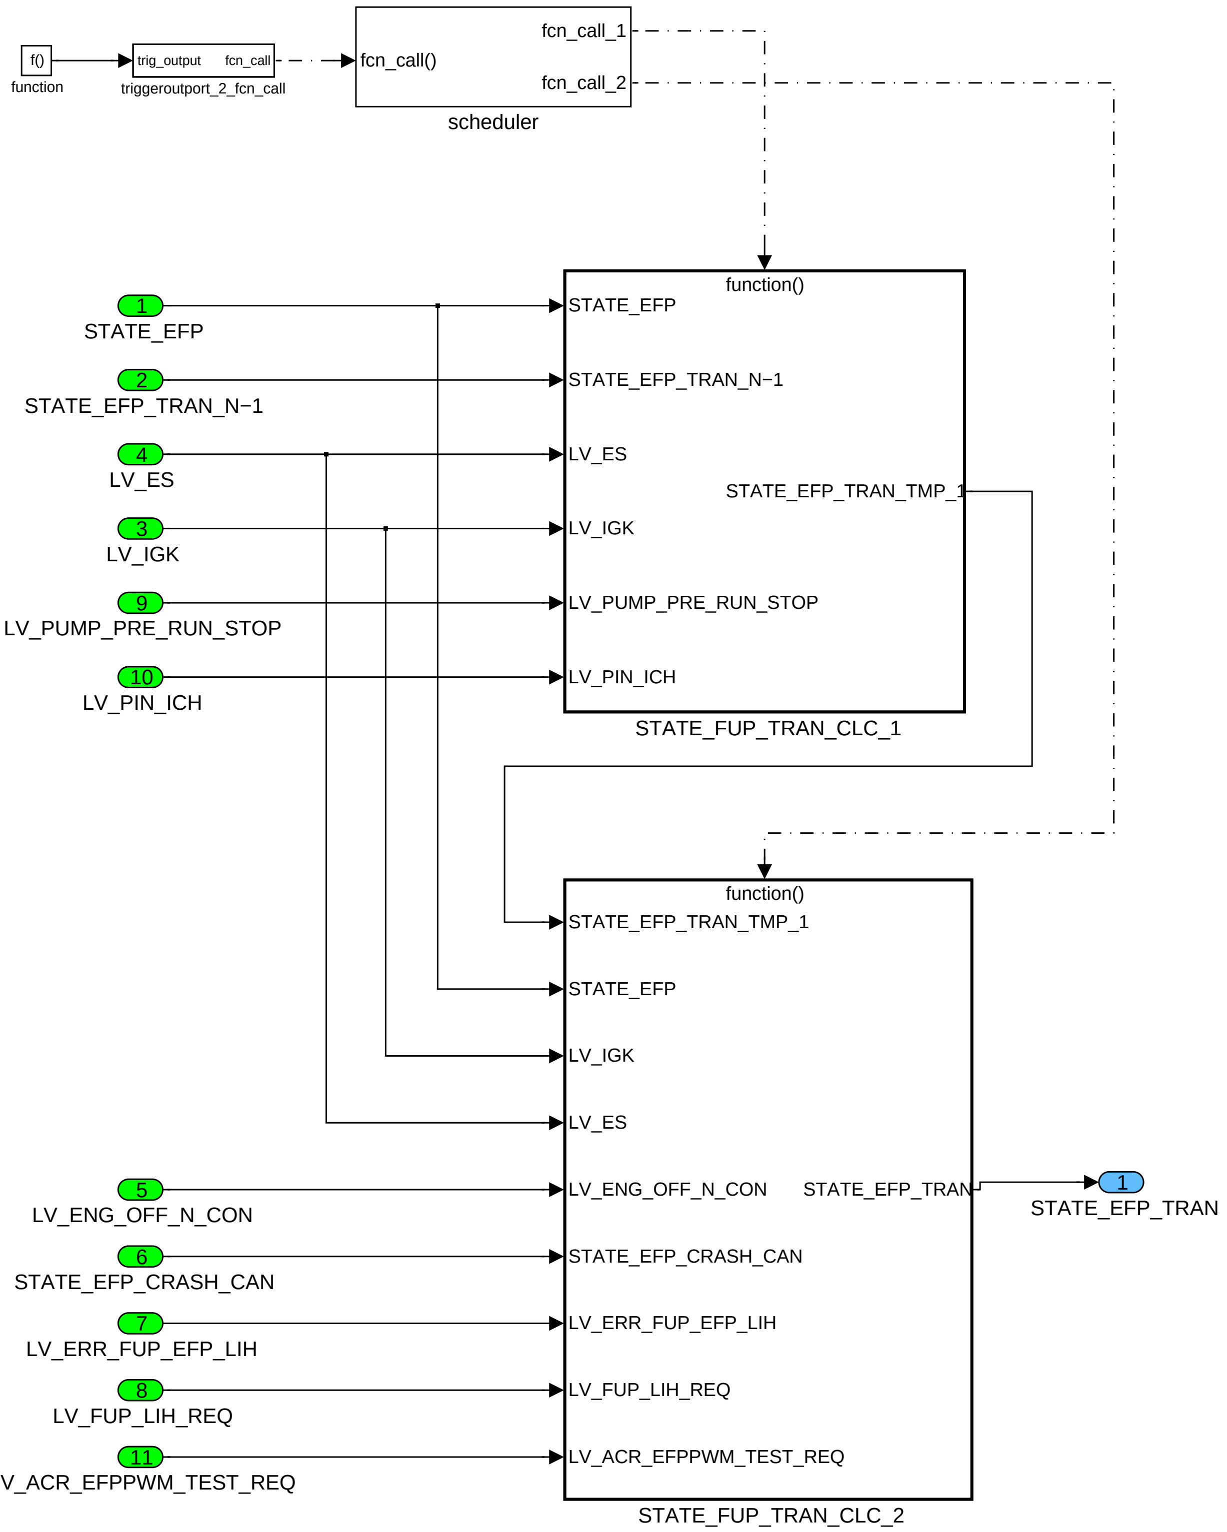

Figure 83 M904I/ EFP_CTL_TRAN/ CLC_EFP_CTL_ADD_CLC/ STATE_FUP_TRAN_CLC

State fuel pressure transition calculation 1

In this part the first part of the transition conditions for the EFP state diagram are calculated.

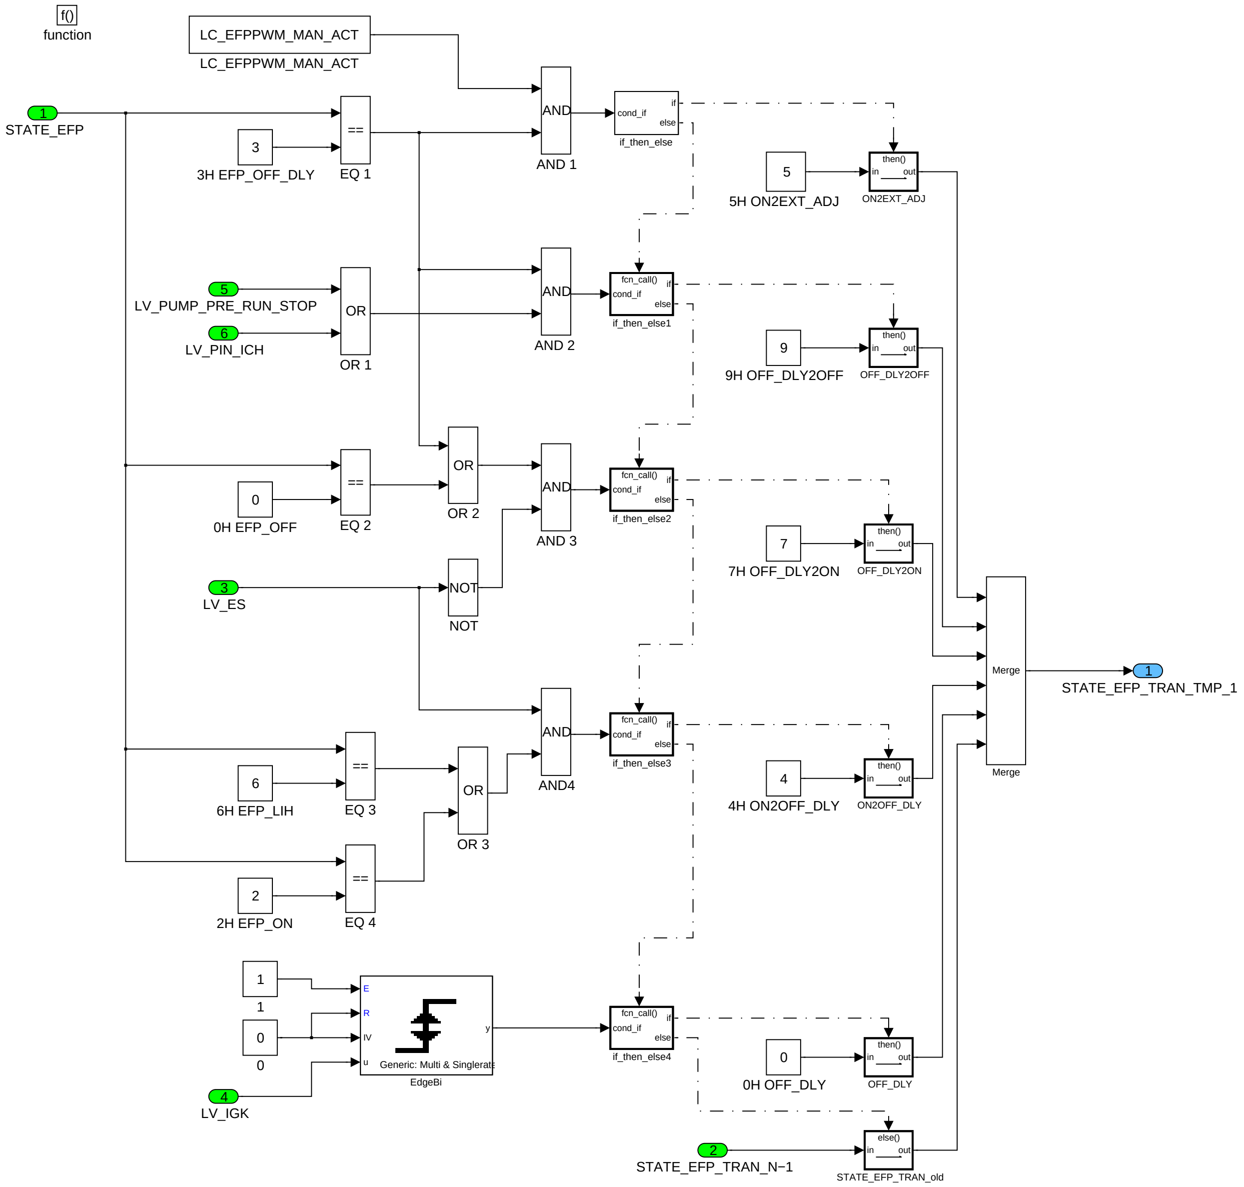

Figure 84 M904I/ EFP_CTL_TRAN/ CLC_EFP_CTL_ADD_CLC/ STATE_FUP_TRAN_CLC/ STATE_FUP_TRAN_CLC_1

State fuel pressure transition calculation 2

In this part the first part of the transition conditions for the EFP state diagram are calculated. Main parts are the limp home conditions and the safety and security reasons.

Volume fuel flow

An additional offset for the requested flow by the low pressure pump can be adjusted with the following constant.

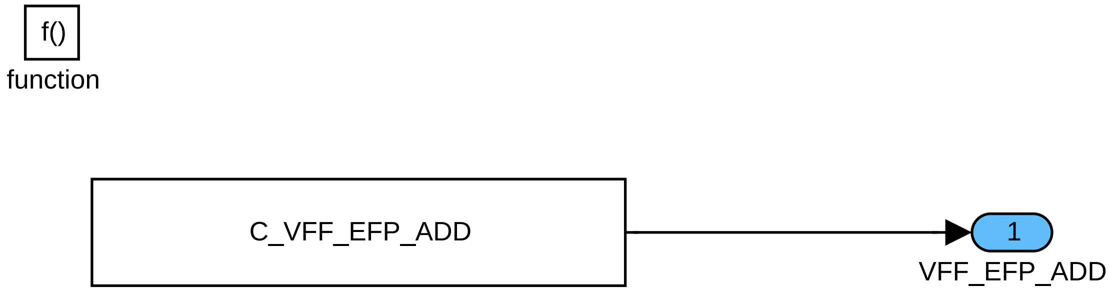

Figure 86 M904I/ EFP_CTL_TRAN/ CLC_EFP_CTL_ADD_CLC/ VFF_EFP_CTL_ADD_CLC

Time calculation

The calculation of the timer for the EFP is done within this module. A reset of this timer is done by the reset or a calculated condition. The calculation part for the pressure increase and decrease is placed within the subblock.

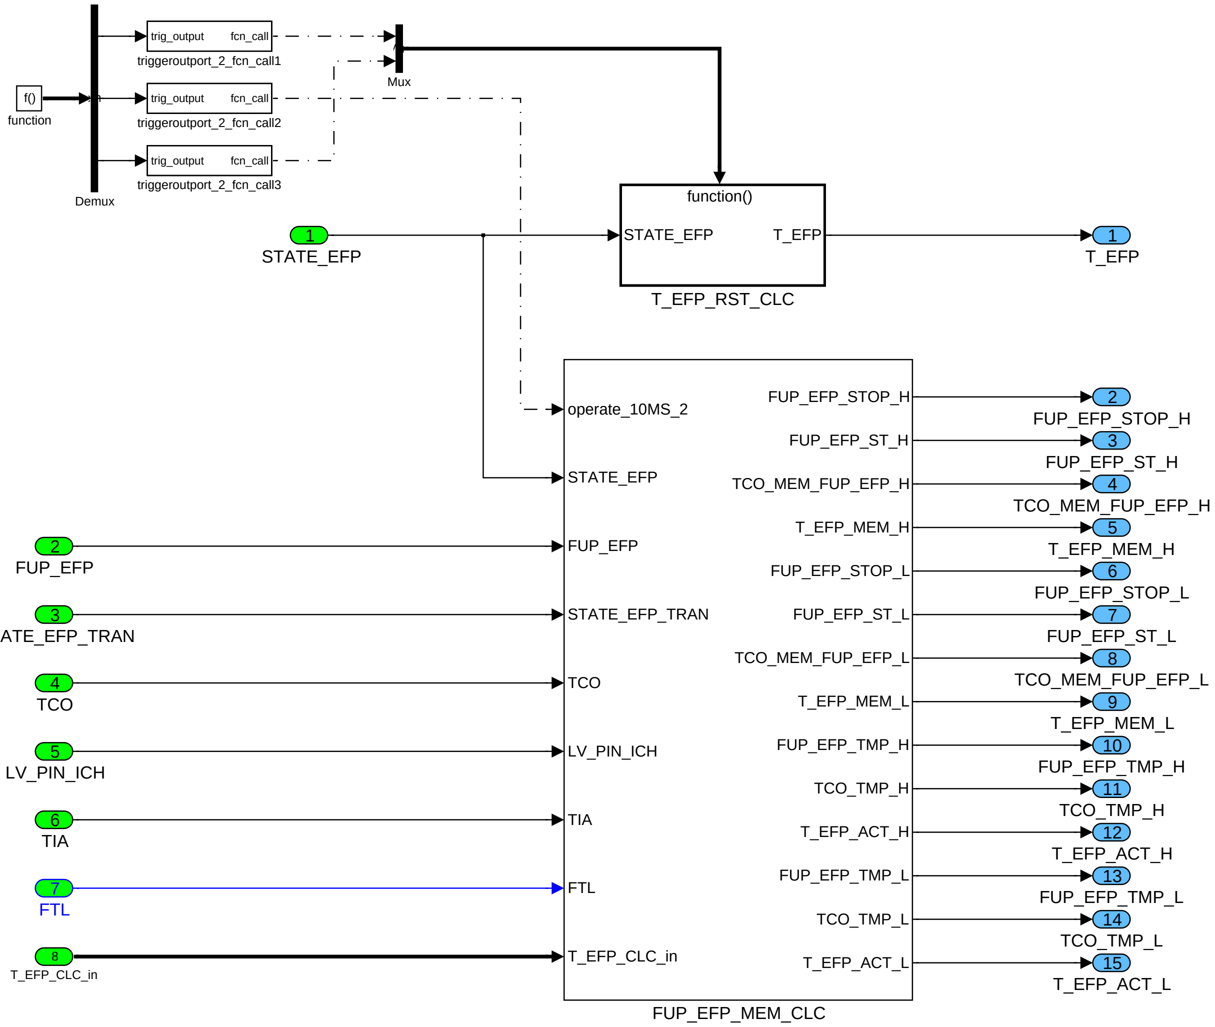

Figure 87 M904I/ EFP_CTL_TRAN/ T_EFP_CLC

Electrical fuel pump memorize calculation

The calculation of the low pressure system observation is split into a calculation for the high part and on calculation for the low part. Each part has an output for the start pressure, stop pressure, coolant temperature and the time for rising/falling pressure.

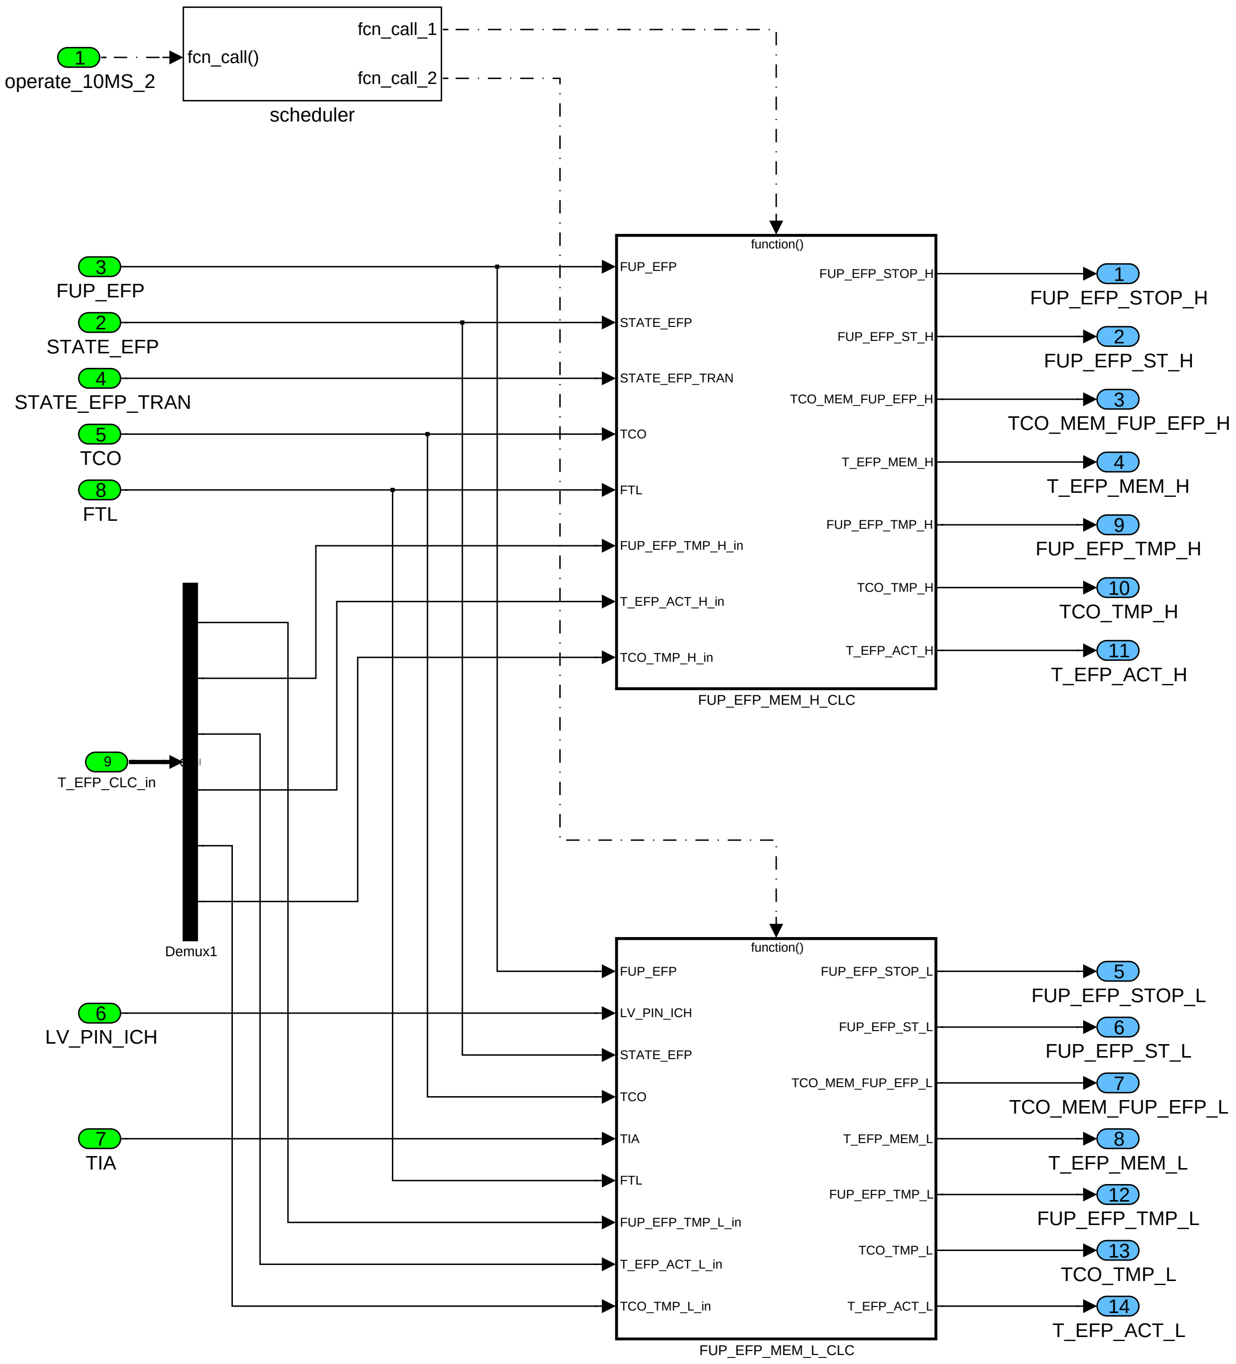

Figure 88 M904I/ EFP_CTL_TRAN/ T_EFP_CLC/ FUP_EFP_MEM_CLC

Electrical fuel pump memorize high calculation

In this part the high signals are calculated.

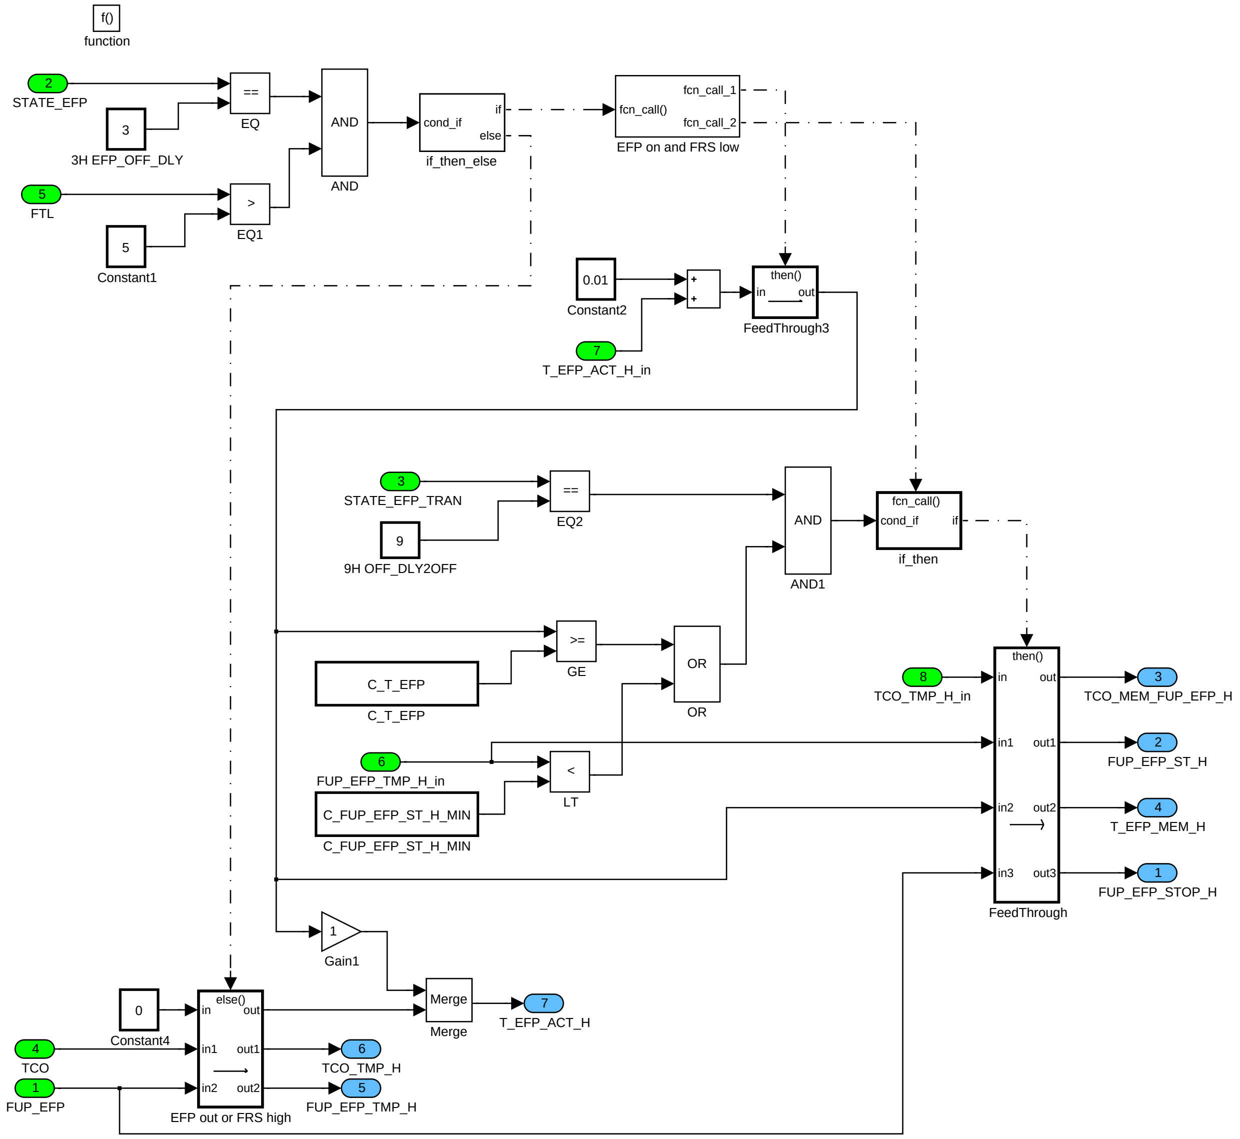

Figure 89 M904I/ EFP_CTL_TRAN/ T_EFP_CLC/ FUP_EFP_MEM_CLC/ FUP_EFP_MEM_H_CLC

Electrical fuel pump memorize low calculation

In this part the low signals are calculated.

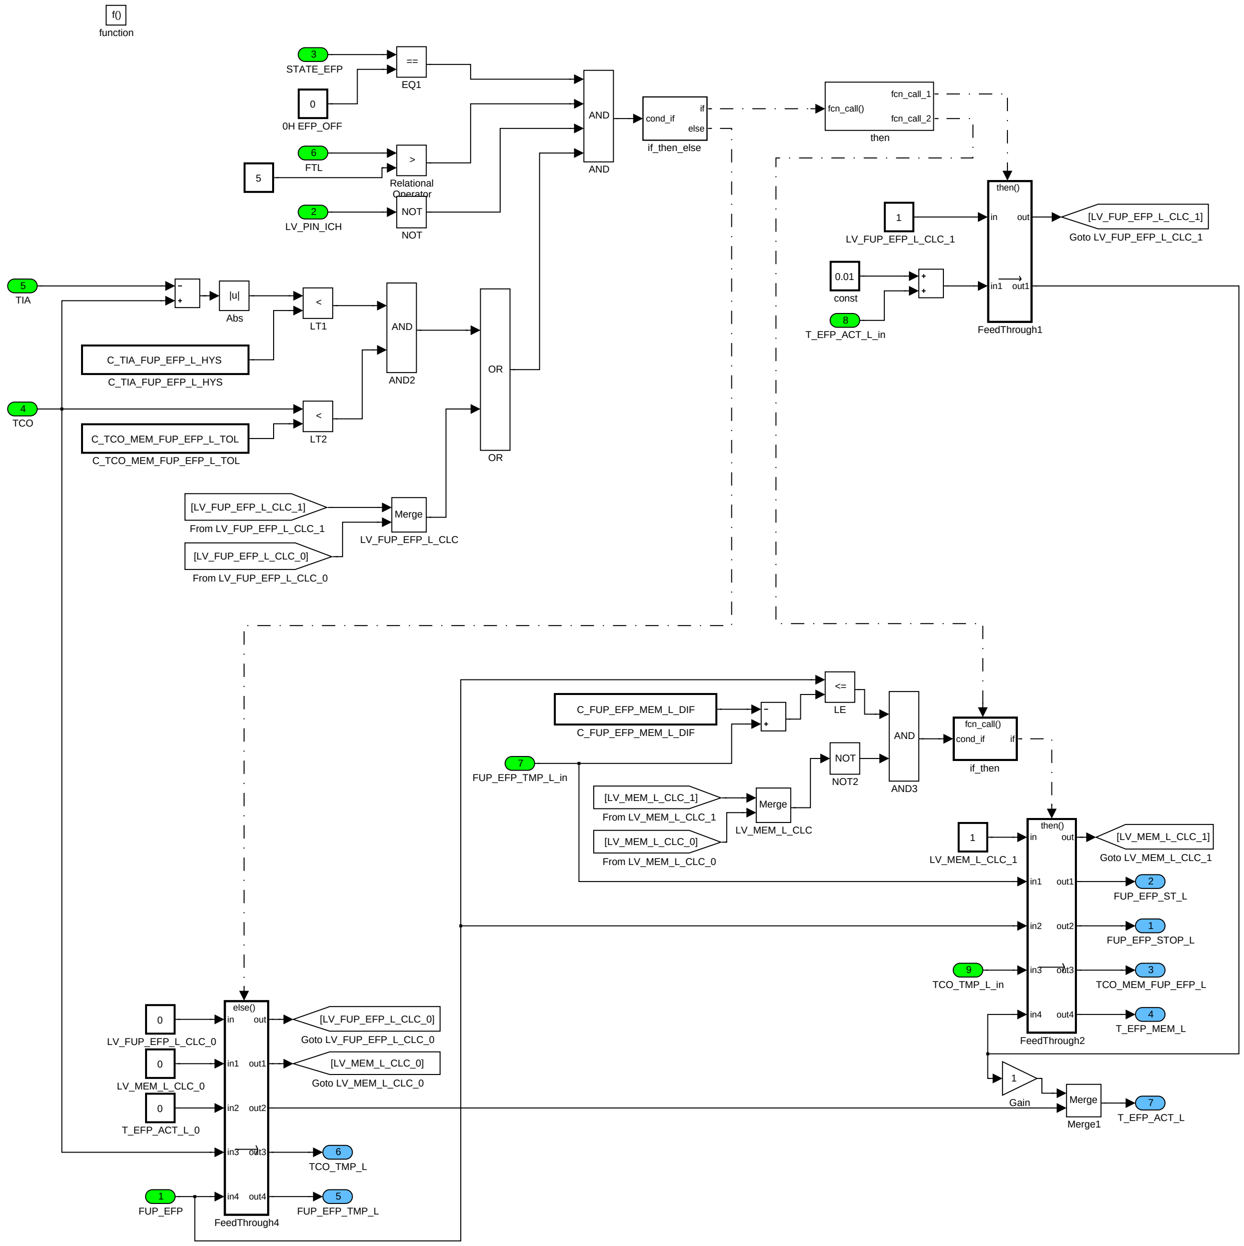

Figure 90 M904I/ EFP_CTL_TRAN/ T_EFP_CLC/ FUP_EFP_MEM_CLC/ FUP_EFP_MEM_L_CLC

Reset of the timer

The reset of the timer is calculated according to the following module.

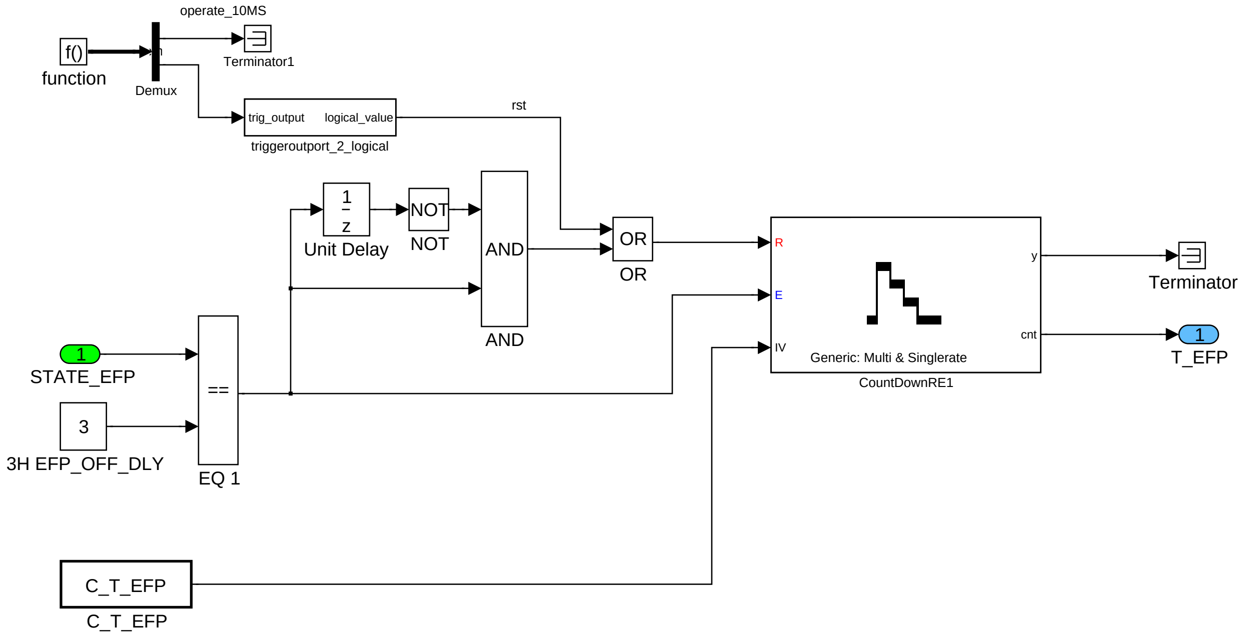

Figure 91 M904I/ EFP_CTL_TRAN/ T_EFP_CLC/ T_EFP_RST_CLC

34.10.1.2 Initialization

In this part outputs are initialised.

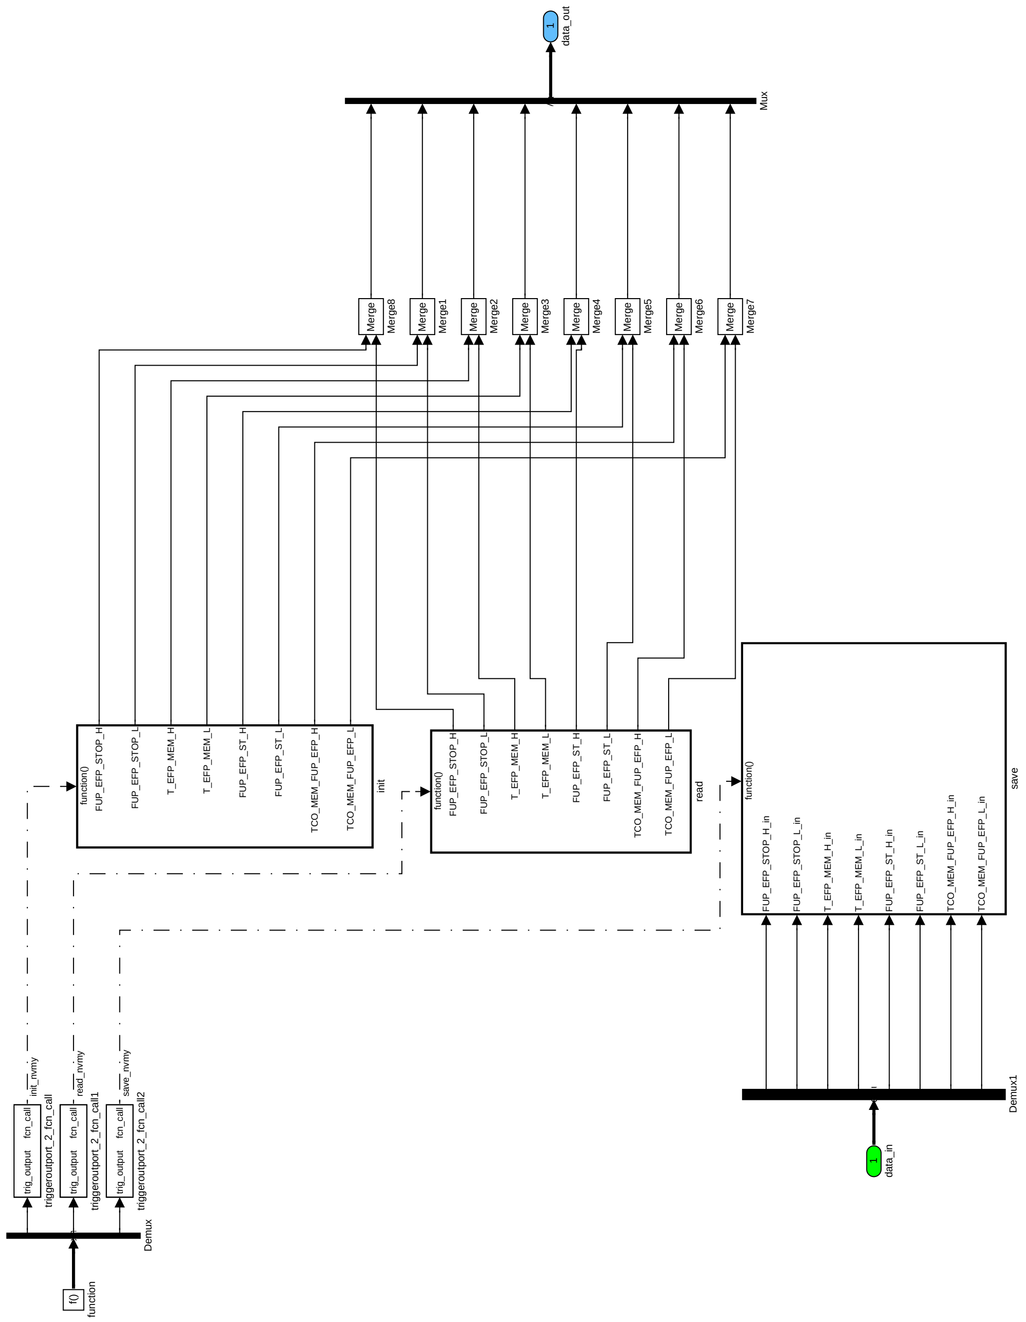

Figure 92 M904I/ NVMYdata

Initialization with FFFFH or FEH

If EEPROM error or ECU brandnew or cleared by service tool then the outputs are initialised with FFFFH or FEH.

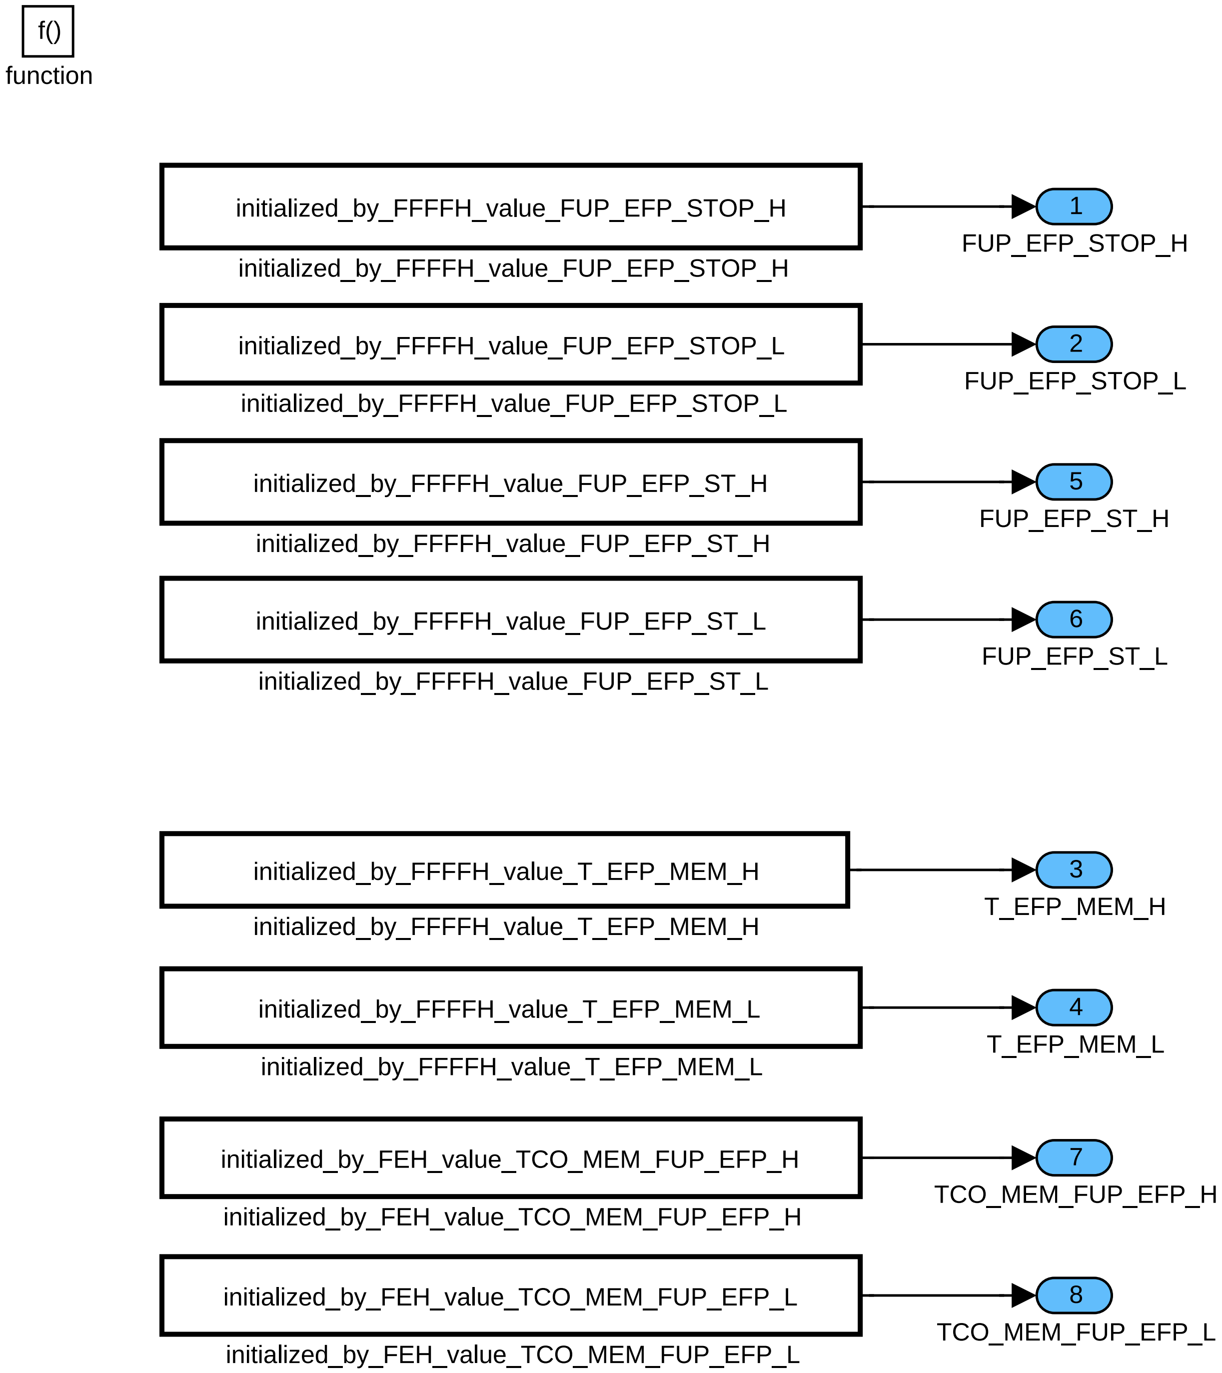

Figure 93 M904I/ NVMYdata/ init

Output read

In this part outputs are initialised by EEPROM value.

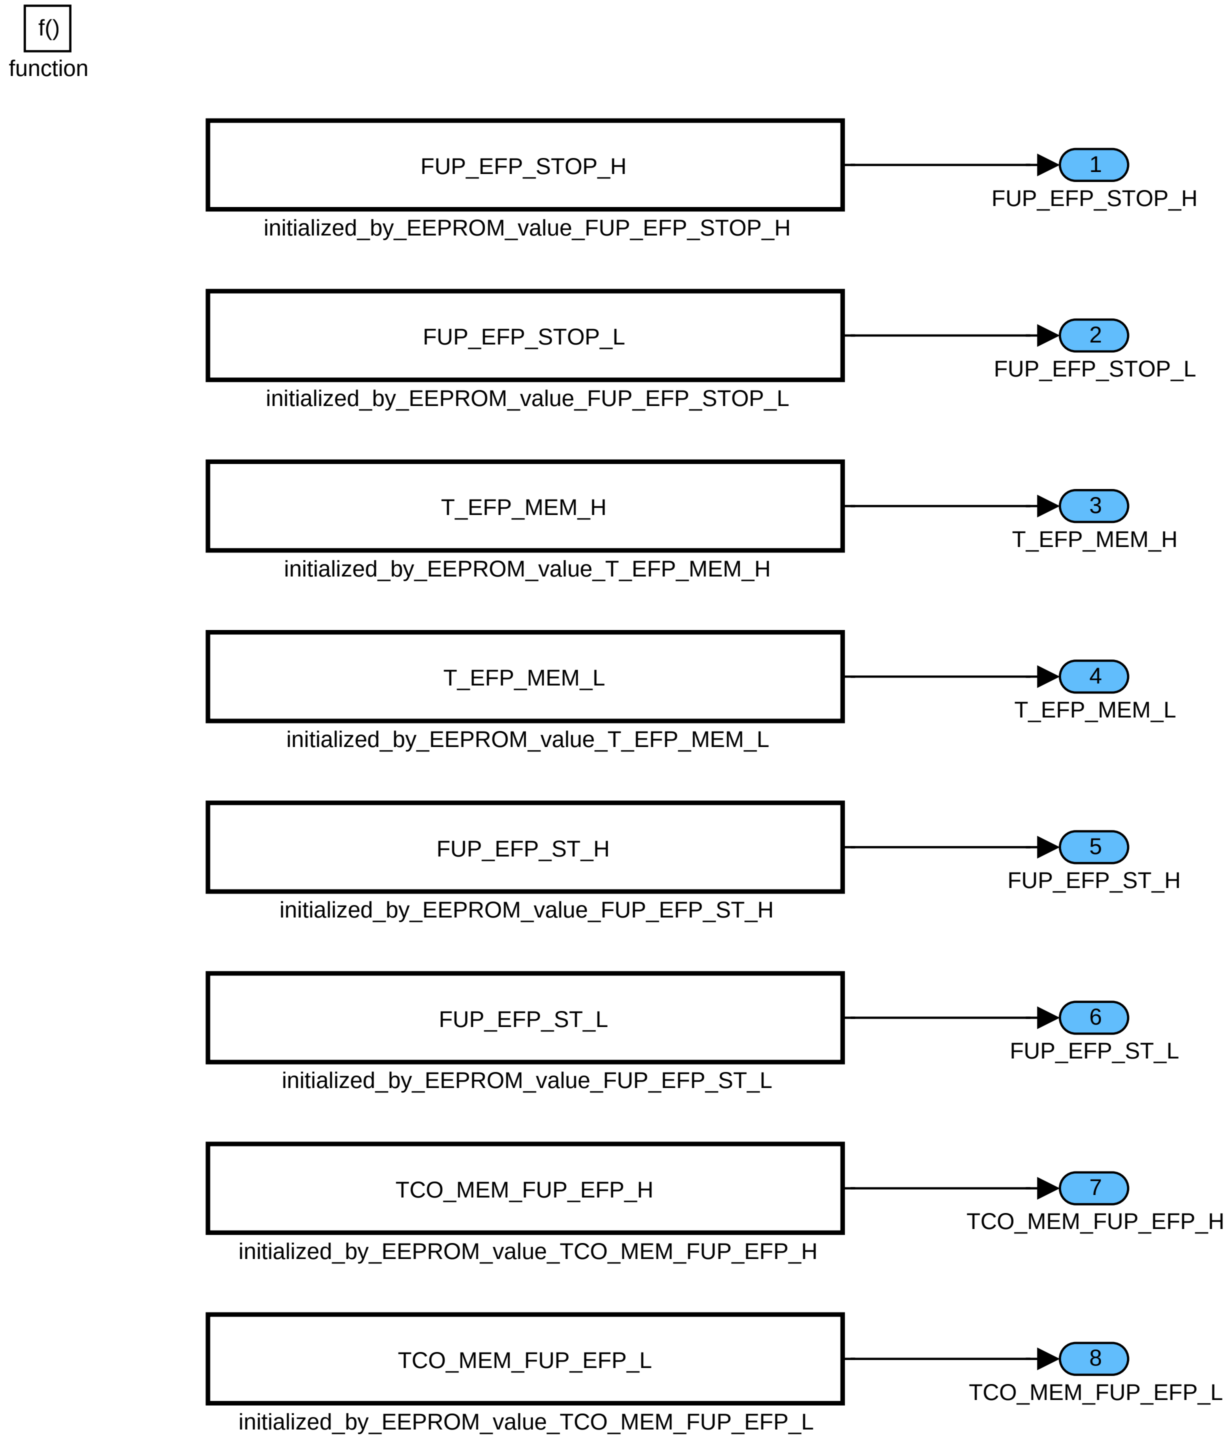

Figure 94 M904I/ NVMYdata/ read

Output save

In this part outputs are saved on the EEPROM.

General Information

There are maps for homogeneous mode and stratified mode according to the variable, which shows the actual engine mode. In PU and PUC a different map for the fuel pressure setpoint is selected.

Additionally a testbench function is also included. In order to avoid too big fuel pressure setpoint gradients a certain gradient limitation is included. That limitation is consisting out of a increment and decrement limitation. For PU and PUC a different limitation for increment and decrement is selected.

Application Conditions

Initialization: RST, ERU2ES
Recurrence: SEG activated if LV_ST_END==1
10MS activated if LV_ST_END==0
Deactivation: !LV_ST_END

34.11.2.1 Fuel pressure setpoint calculation overview

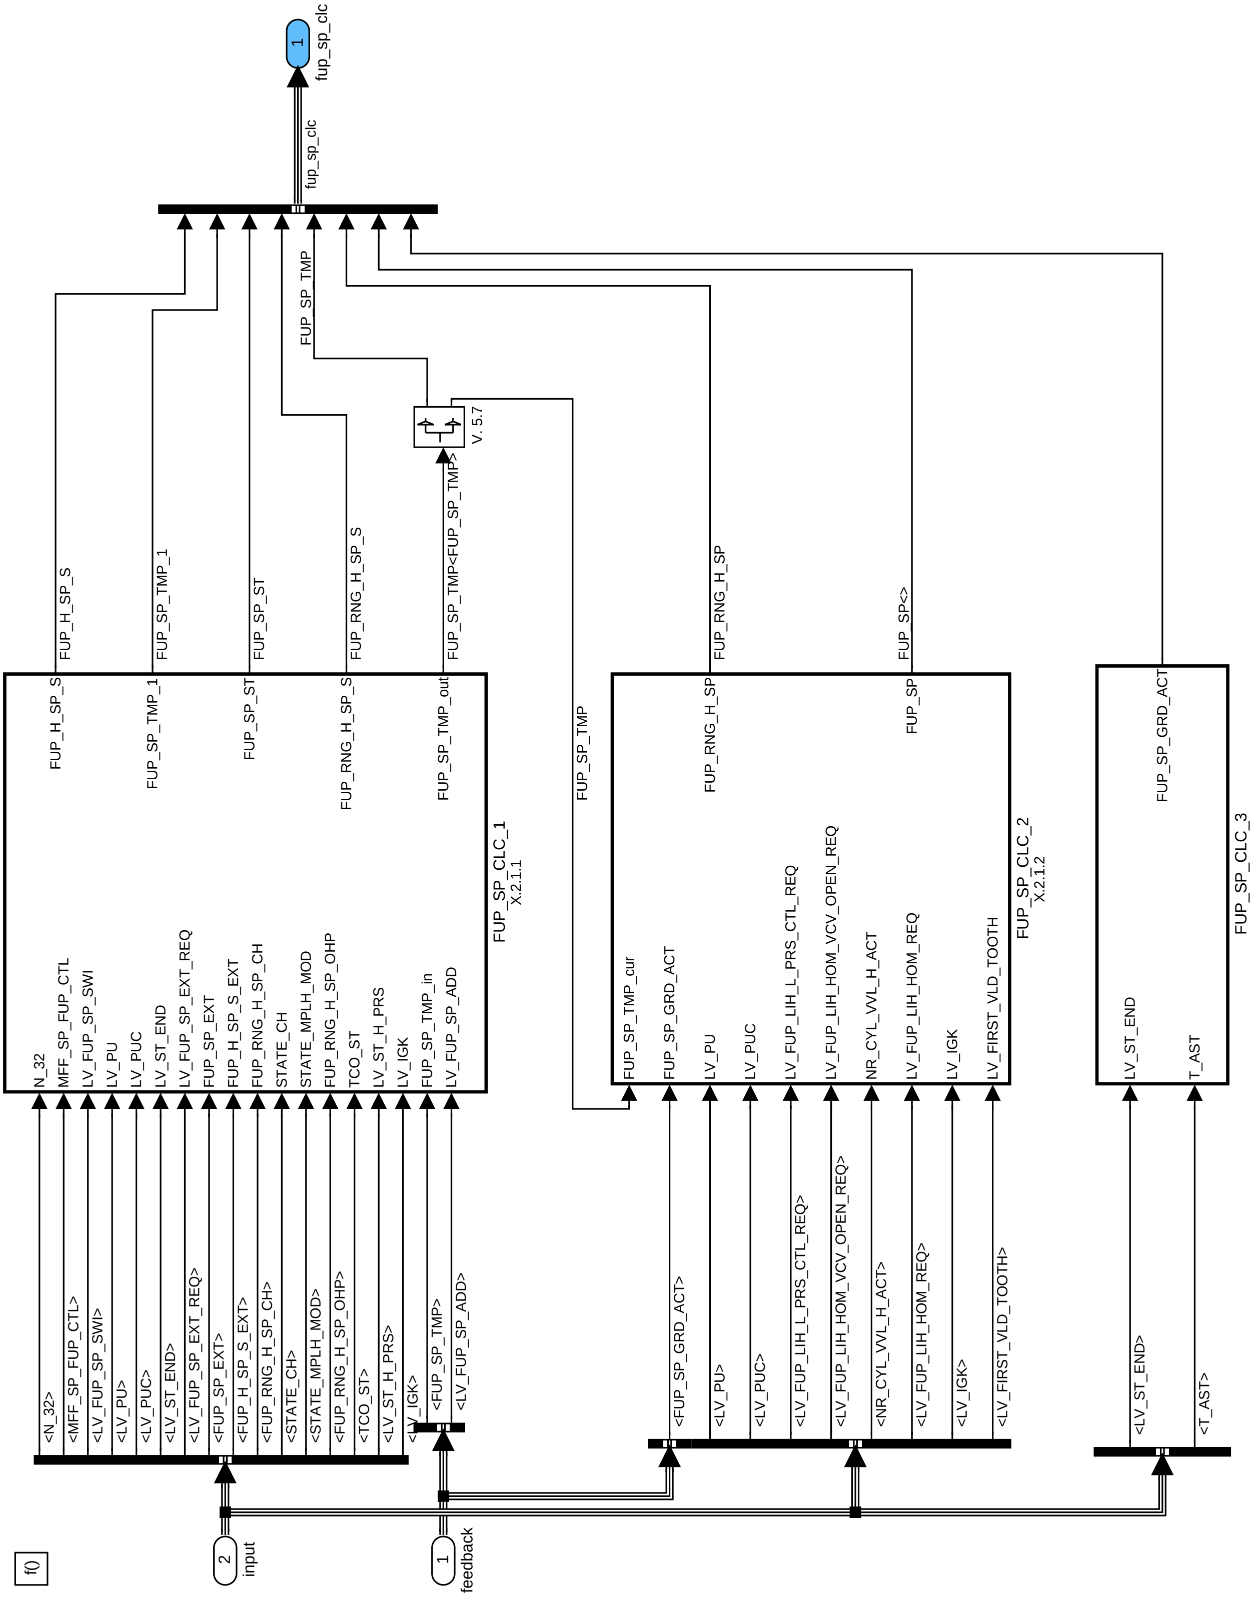

Figure 102:
Path: FUSL_M904A/OPM/FUP_SP_CLC

34.11.2.1.1 Calculation of fuel pressure high setpoint

The actual fuel pressure setpoint is taken out the two maps. Only for PU and PUC mode different fuel pressure setpoints can be selected due to injector requirement.

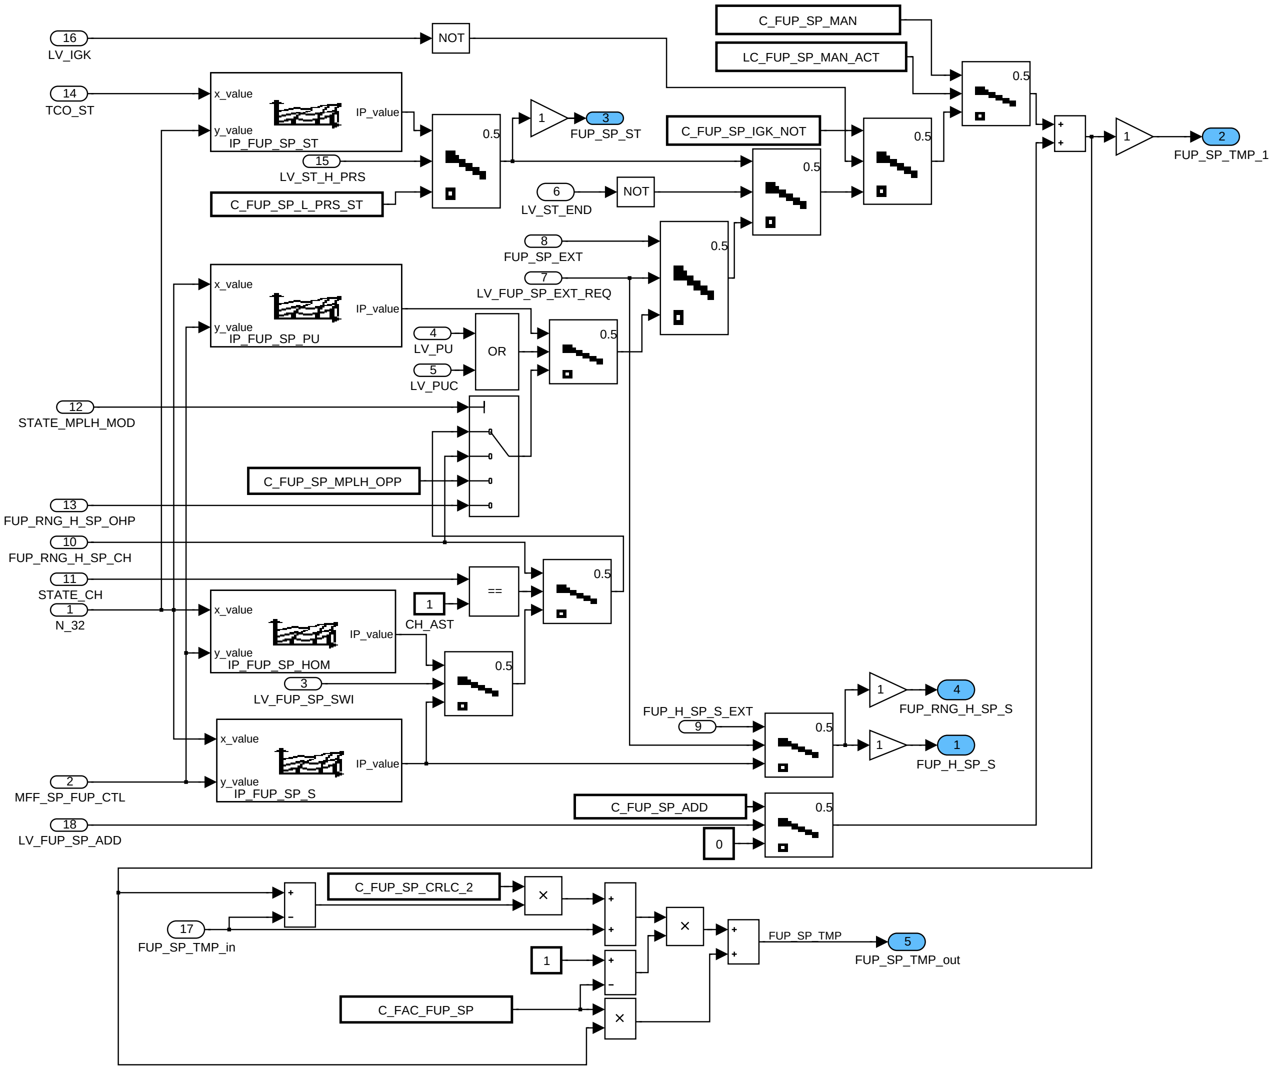

Figure 103:
Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_1

34.11.2.1.2 Calculation of fuel pressure setpoint

For the gradient limitation the calibration should be started with the highest value for all gradient limitations. The values should be lowered by applying jumps the FUP_SP via manual intervention.

The internal value in the difference limiter has to be initialised with FUP_SP_TMP at reset.

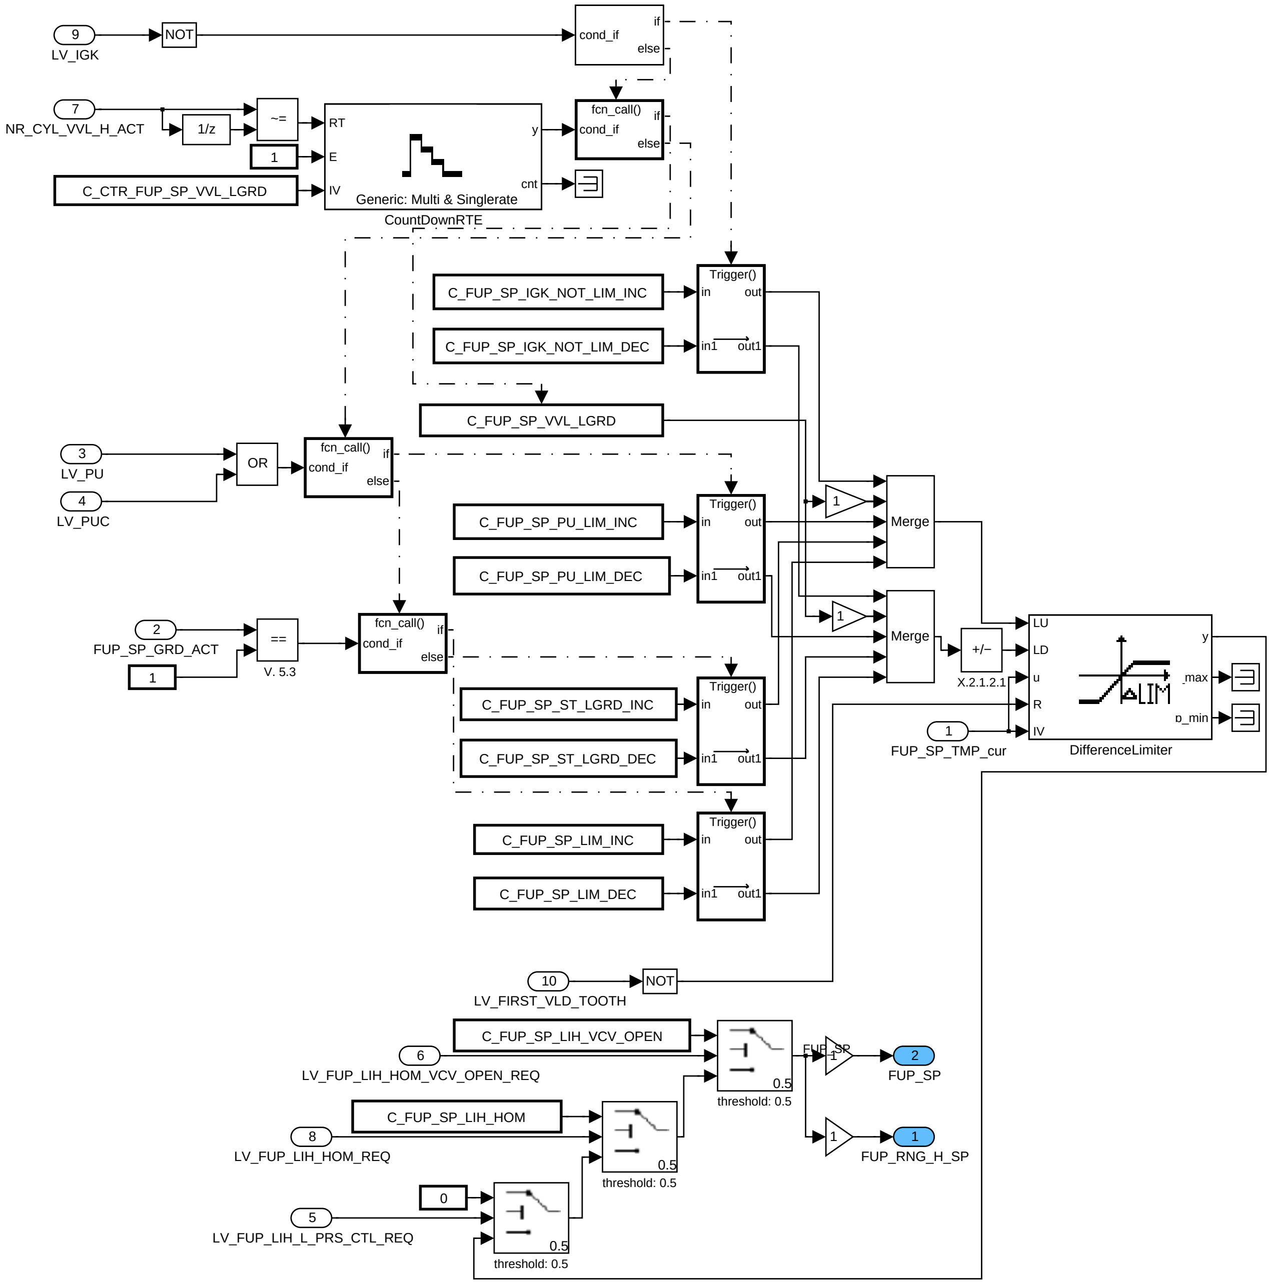

Figure 104:

Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_2

34.11.2.1.3 Fuel pressure setpoint gradient calculation

The gradient limitation out the start phase will be stopped until the FUP_SP is reached.

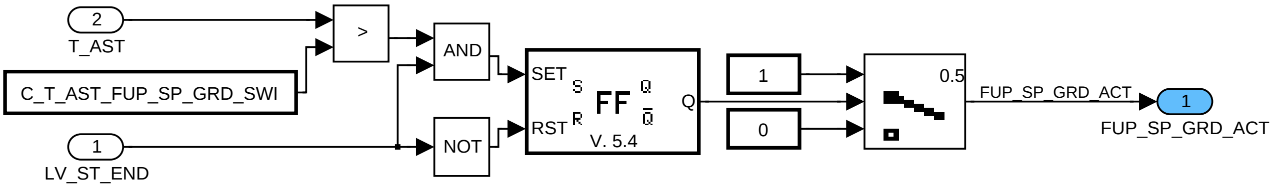

Figure 105:

Path: FUSL_M904A/OPM/FUP_SP_CLC/FUP_SP_CLC_3

34.11.2.2 Calculation of LV_FUP_SP_AD

This block is triggered every time at 10ms without the LV_ST_END == 0 condition.

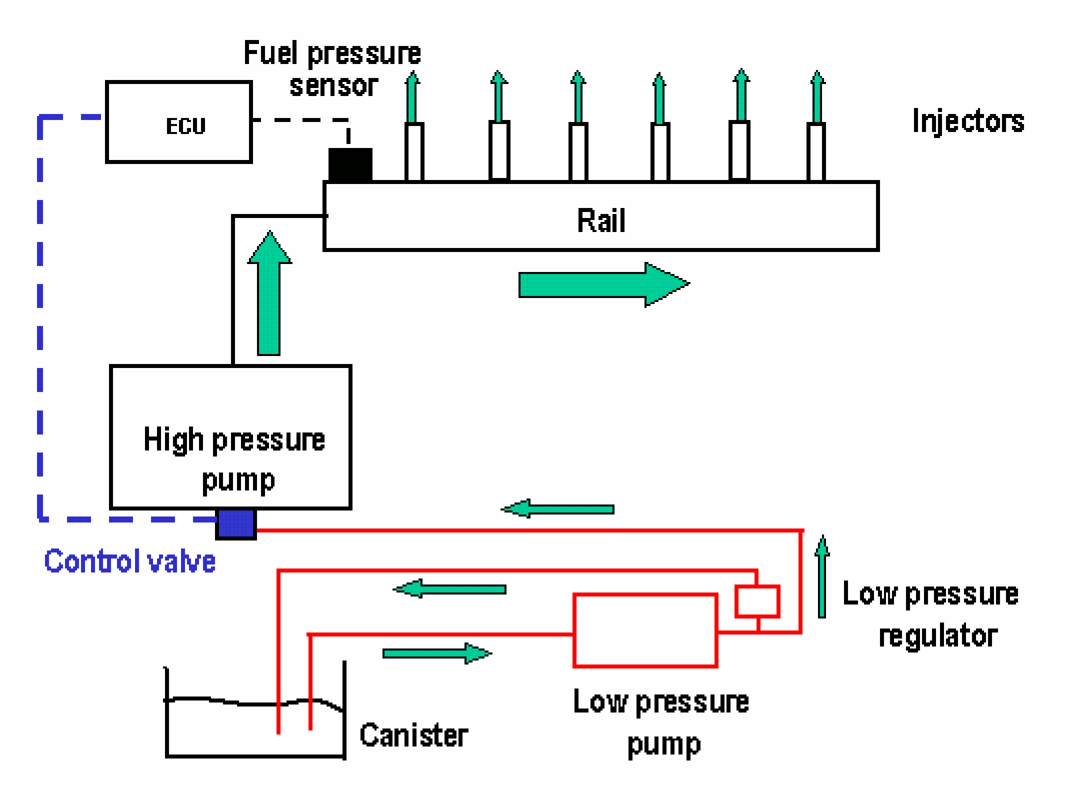
General Information

A variant of the fuel pressure control system is a threewayvalve as a control mode, which combines the volume control valve and the regulator functionality. In that case the regulator is obsolete.



General scheduling

Segment synchronious tasks:

1. Fuel pressure of low pressure pump
2. Fuel pressure
3. {Injection related parts of SW}
4. Electrical fuel pump control (Appl. Inc.)
5. Electrical fuel pump
6. Fuel supply general
7. Fuel pressure setpoint calculation
8. Fuel pressure control
9. High pressure pump control

1 ms tasks:

1. Fuel pressure of low pressure pump

10 ms tasks:

1. Fuel pressure of low pressure pump
2. Fuel pressure
3. {Injection related parts of SW}
4. Electrical fuel pump control (Appl. Inc.)
5. Electrical fuel pump
6. Fuel pressure setpoint calculation
7. Fuel pressure control (Appl. Inc.)
8. Fuel pressure control
9. High pressure pump control (Appl. Inc.)

10. High pressure pump control

20 ms tasks:

1. Fuel system pressure diagnosis for low pressure (Appl. Inc)
2. Fuel system pressure diagnosis for low pressure
3. Fuel system pressure diagnosis (Appl. Inc.)
4. Fuel system pressure diagnosis

40 ms tasks:

1. Fuel pressure sensor diagnosis for low pressure (Appl. Inc.)
2. Fuel pressure sensor diagnosis for low pressure
3. Fuel pressure sensor diagnosis (Appl. Inc.)
4. Fuel pressure sensor diagnosis

100 ms tasks:

1. Electrical diagnosis of fuel pressure actuator (Appl. Inc.)
2. Electrical diagnosis of fuel pressure actuator
3. Fuel pressure setpoint of electrical fuel pump
4. Fuel pressure control (Appl. Inc.)
5. Fuel pressure control
6. High pressure pump control
7. Fuel supply general

1000 ms tasks:
Fuel pressure actuator temperature calculation

Management of the pressure and flow controlers in the intervention mode

Condition VFF_VCV under the C_VFF_SWI_THD

In idle speed:

Reset of the I part of the flow controller
Set of the I part of the pressure controller
No reset of the I part of the pressure controller
No Execution of the adaptations

In PUC:

No reset of the I part of the flow controller
Set of the I part of the pressure controller
Reset of the I part of the pressure controller depending on the reset LC's
Alternative execution of the pressure /leakage adaptations

In PU:

No reset of the I part of the flow controller
Set of the I part of the pressure controller

Reset of the I part of the pressure controller depending on the reset LC's
No Execution of the adaptations.

34.12.1 Function description of 100MS task

Application Conditions

Initialization: RST
Recurrence: 100MS
Activation: always
Deactivation: never

Function description

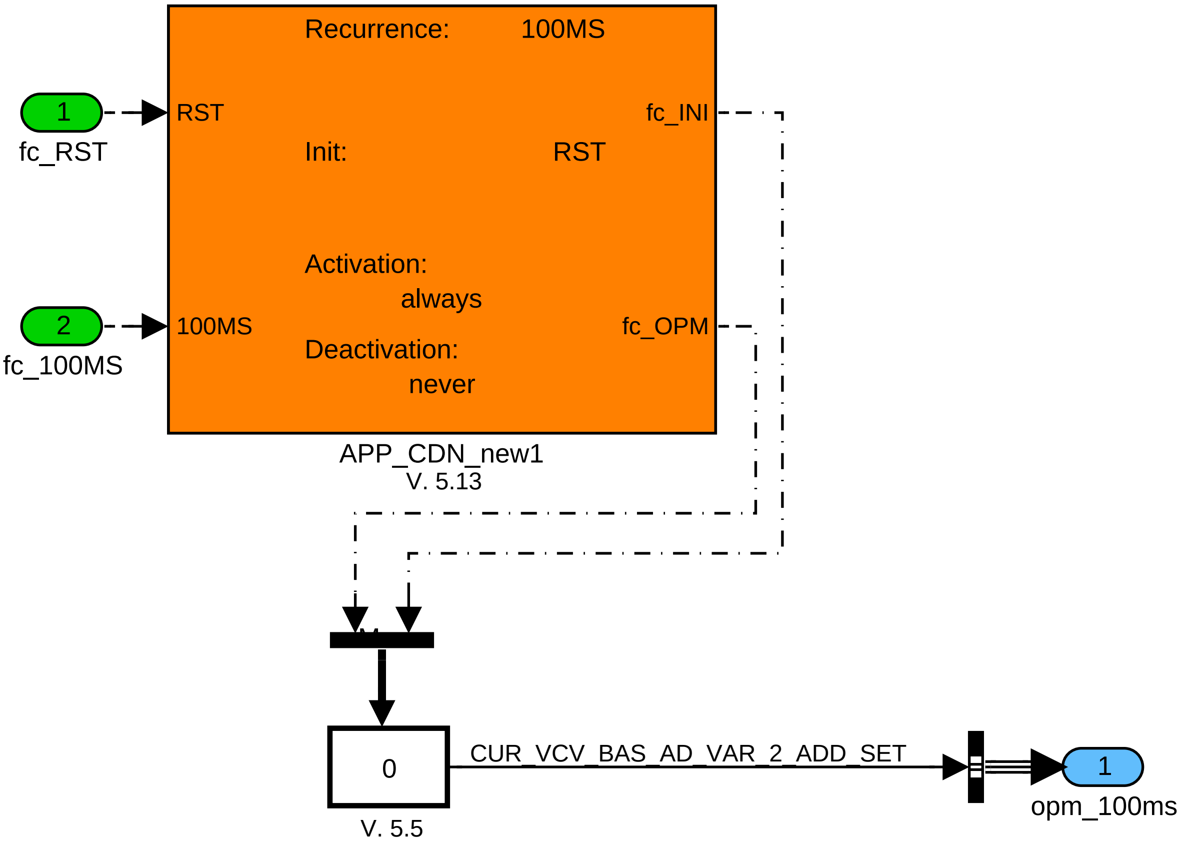


Figure 108:
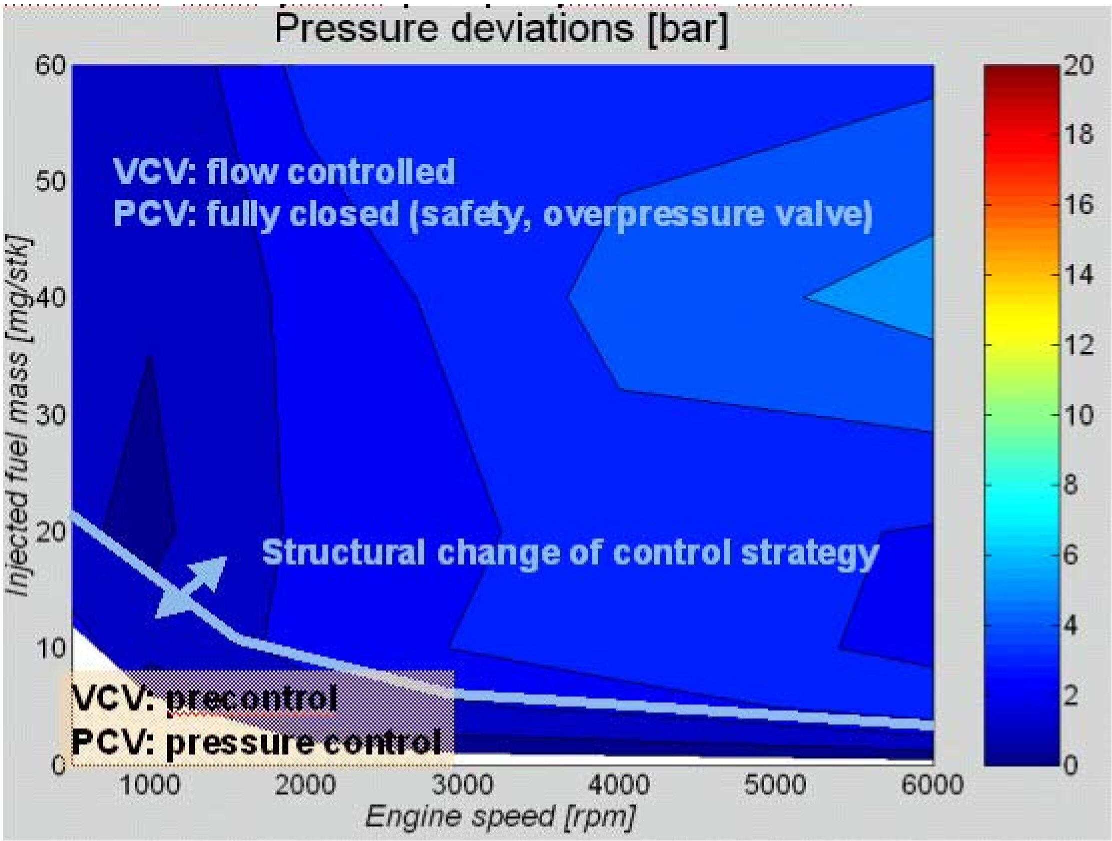
Path: FUSL_M9049/OPM_100MS

34.12.2 Function Description of segment synchronous task

The fuel supply general organizes the different fuel pressure control possiblities. It can be achieved an automatic mode where the flow control and pressure control mode is chosen by the flow through the volume control valve. Also only flow control or pressure control can be selected. The pressure control part can be divided into pressure control with or without flow precontrol and the flow control can be combined with or without pressure control.



Application Conditions

Initialization: RST
Recurrence: SEG
Activation: LV_ES == 0
Deactivation: LV_ES == 1

General Information

The control algorithm can be used for all kind of flow controlled pump. This function is the interface of the fuel pressure acquisition and the fuel pressure setpoint calculation to the fuel pump control.

It calculates basically a requested fuel mass to be delivered into the fuel rail by the HP pump. This calculation is based on the fuel pressure setpoint, measrured fuel pressure, the fuel mass flow setpoint and the feedback of the pump interface, which is the fuel mass delivered by the pump. Additionally there is the input fuel temperature, which is needed to correct the calculation of the fuel mass in the rail.

34.13.1 Function Description of 10MS

The functionality is split into several parts. First part is the precalcualtion of the fuel mass. In this module first the deviation between the fuel pressure setpoint and the measured fuel pressure is calculated. This deviation is the basis for the calculation of the requested fuel mass from the precontroller. This input will be corrected by a weighting factor and a conversion factor, which includes the density of the fuel and the compressibility of the rail and the fuel.

To get a correct input for the mass fuel flow this will be corrected within the module mass fuel flow setpoint for fuel pressure control with the effective fuel cut off ratio.

The controller is split into the fuel mass adaptation and the actual controller. The calculated fuel mass adaptation takes as a basis the old value to the adaptive fuel mass and uses a actual calculated fuel mass adapation deviation. The adaptive fuel mass is min/max limited. The fuel mass adapation deviation is only calculated if the engine speed and the pump fuel mass is within certain limits. Another criteria is a segment counter, which allows the adaptation only after a certain amount of segments with stable conditions. The basis for the adapation is a filtered Ipart of the controller.

The input of the actual controller is also a fuel pressure deviation. This time the deviation is calculated out of the measured fuel pressure fuel pressure setpoint. Out of this deviation the P part and the I part of the controller is calculated out of maps. After that calculation the P part can be reseted by certain conditions. The I part taken out of the map will be added up with the old value. This value can be 'frozen or reseted. Anyway there is limitation to min/max values. The I part and the P part are finally added up to the controller output.

With this controller output, the precalculation and the corrected mass fuel flow setpoint value the requested fuel mass is calculated.

Application Conditions

Initialization: RST, NVMINI, NVMRES, NVMSTO
Activation: SEG: LV_ES == 0 && LV_ST_END == 1
10MS: LV_ES == 0 && LV_ST_END == 0
Deactivation: LV_ES == 1

34.13.1.2 Fuel mass & fuel pressure control

For better visibility of the function the calculation is split into 3 parts.

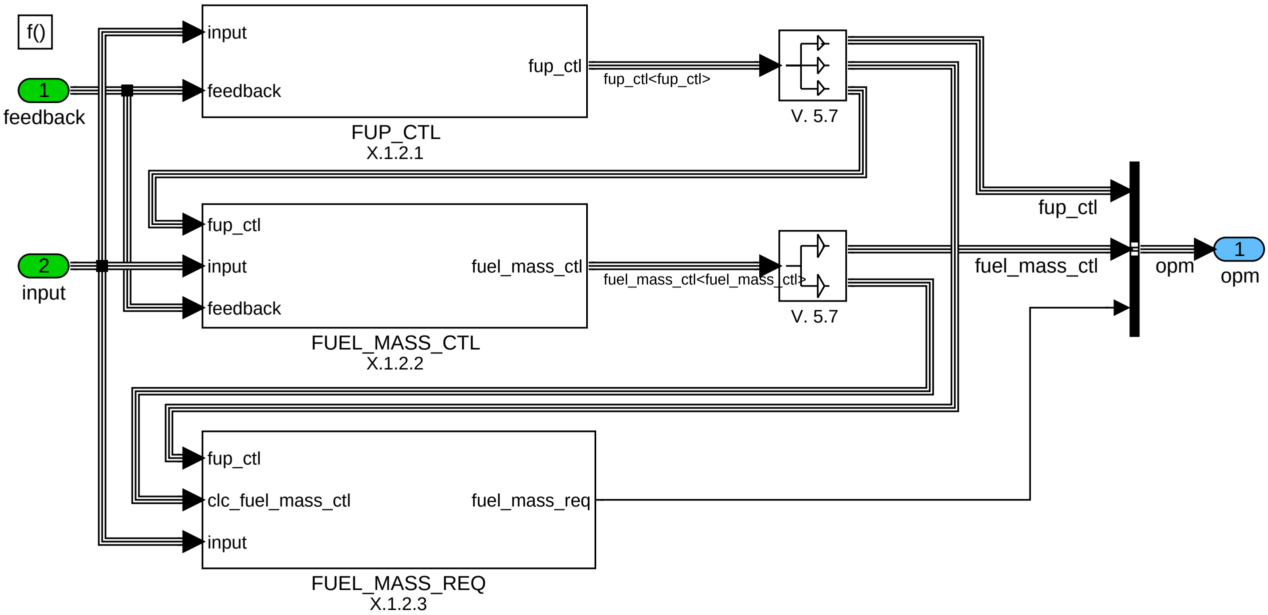

Figure 136:
Path: FUSL_M901Q/OPM_10MS/OPM

34.13.1.2.1 Calculation of Fuel pressure control

This subblock is split into three other blocks in which the precontrol, the adaptive parts and the conditions for a additive fuel mass for the precontrol are calculated

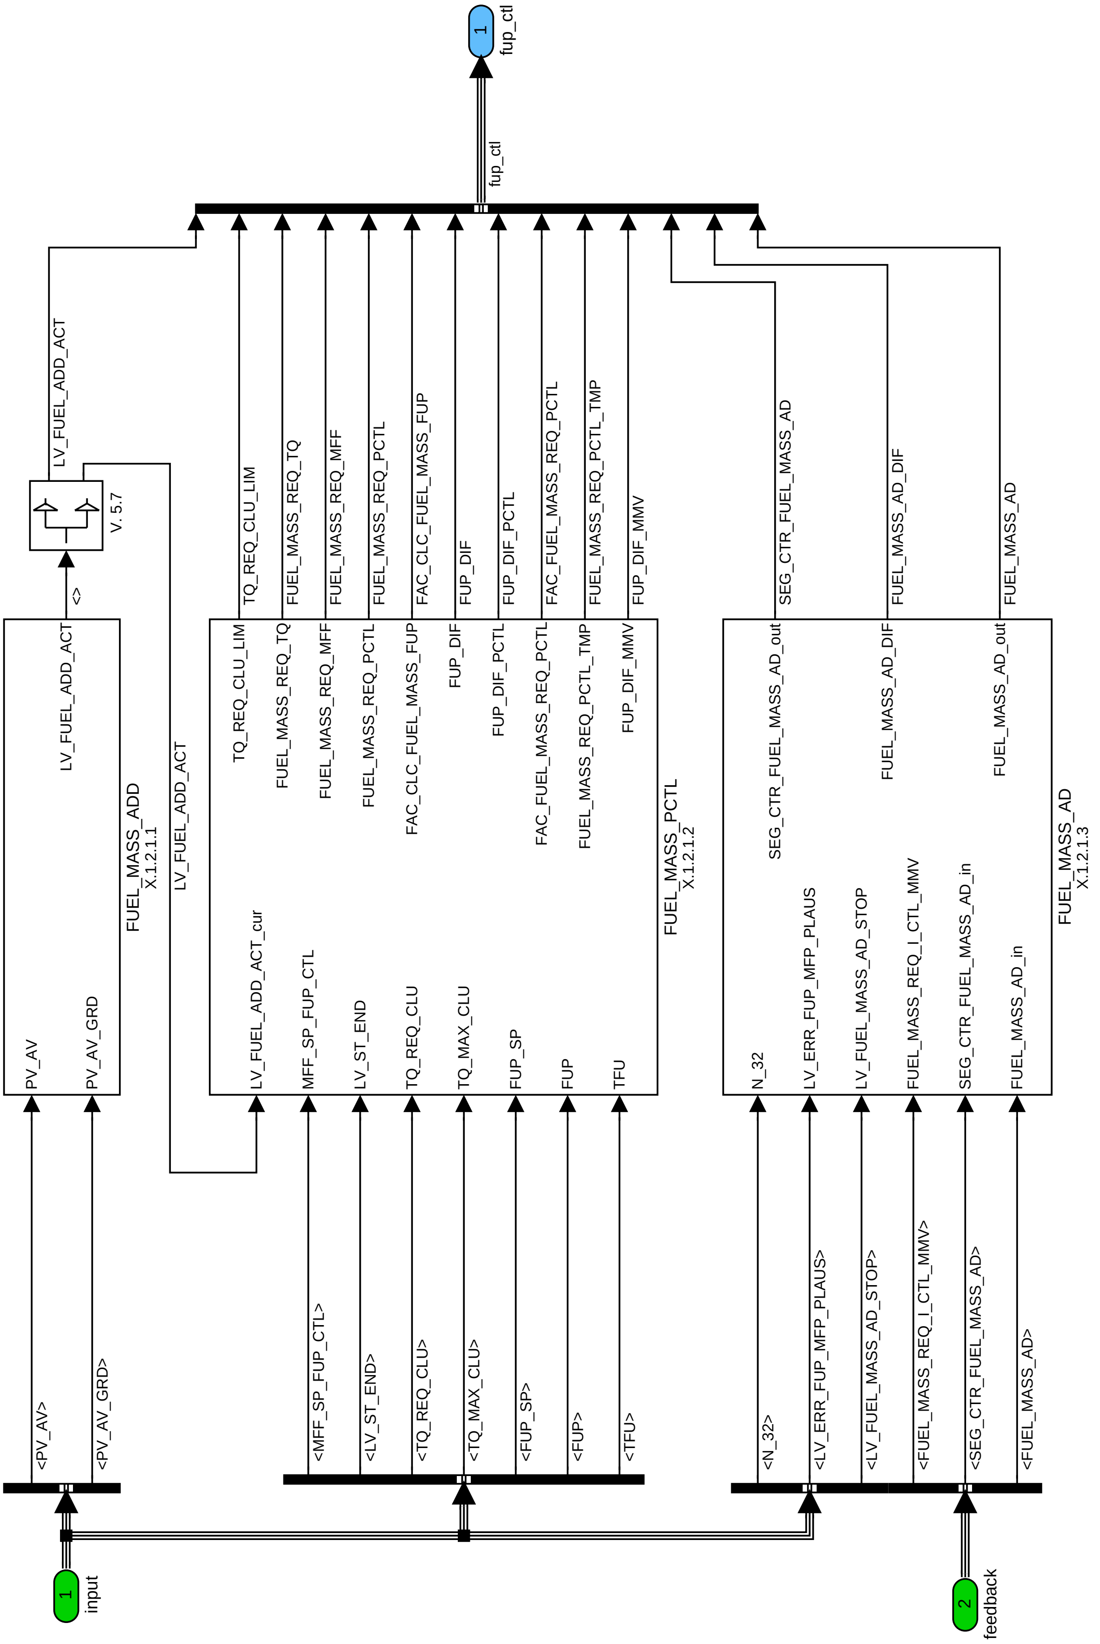

Figure 137:
Path: FUSL_M901Q/OPM_10MS/OPM/FUP_CTL

34.13.1.2.1.1 Additional fuel mass active

Depending on the pedal value and the pedal value gradient a fuel mass is added to the precontroller for a certain amount of cycles. This is indicated by a flag.

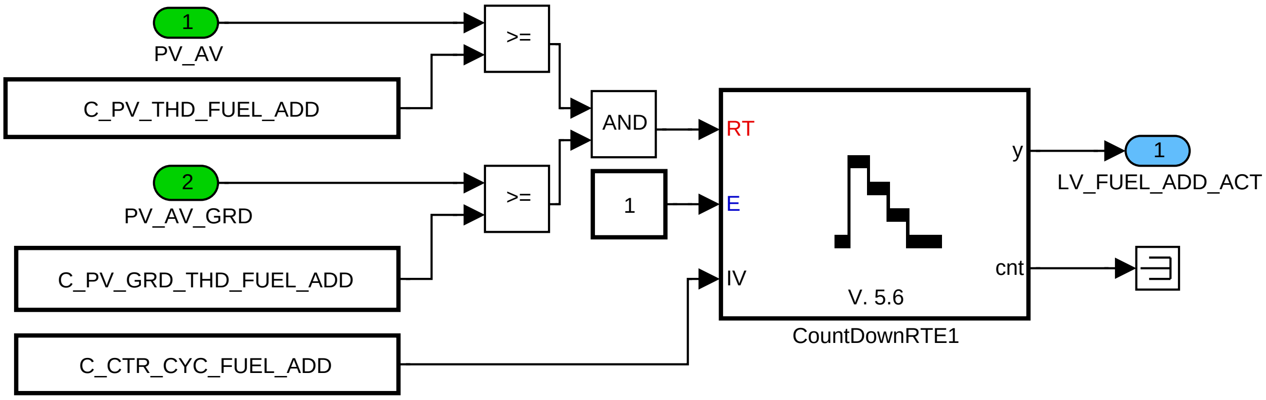

Figure 138:
Path: FUSL_M901Q/OPM_10MS/OPM/FUP_CTL/FUEL_MASS_ADD

34.13.1.2.1.2 Calculation

Out of the fuel pressure deviation related to the used fuel pressure the precontrol value is calculated. This value can be modified by the weighting factor given by the map. Out of this calculated precontrol fuel pressure value a precontrol fuel mass must be chosen. This is done by the second map. Additionally to that a fuel mass can be added to the precontrol.

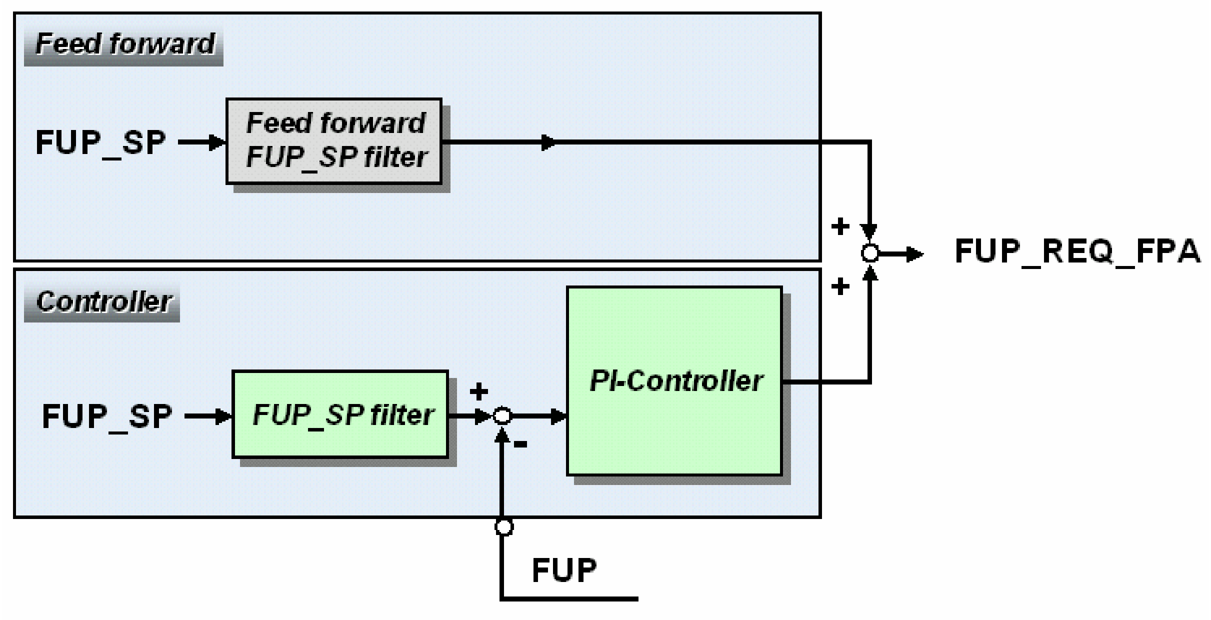
General Information

Application hint: NC_CLC_FUEL_PUMP_CTL = 1 for inlet controlled multi piston pump

The fuel pressure control (Appl. Inc.) provides a fuel pressure demand for the regulator. It is depending on fuel pressure setpoint and the fuel pressure. The structure is constiting out of a feed forward and a controller part.



Application Conditions

Initialization: RST
Recurrence: 10MS
Activation: 1
Deactivation: 0

Function description

34.14.2 Formula Section

The functionality is consiting mainly out of transistion calculation part and a controller part.

The transistion are calculated out of several external inputs and the controller is taken into account this external influences.

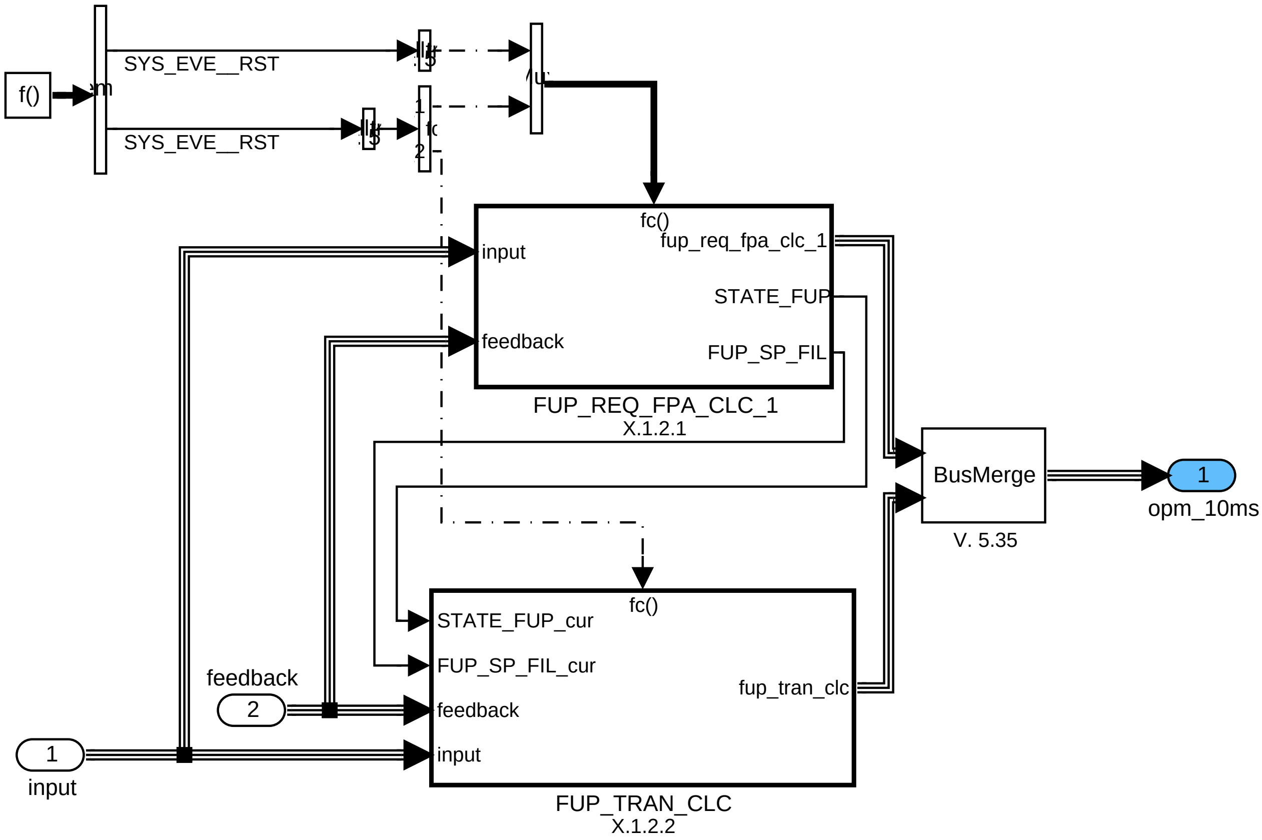

Figure 160:
Path: FUSL_M903W/OPM_10MS

34.14.2.1 Calculation

Out of the result of the state diagram a certain PWM is calculated within that subblocks.

The state diagram is corresponding to the different states of the controller. All the transition conditions are defined in the application incidence of fuel pressure control.

In Low pressure state the FPAPWM signal has minimum value. Also all the initialization is done in this state. Then in order to reach the fuel pressure setpoint the transition is done to Fast pressure increase . In this state the regulator has its maximum FPAPWM value in order to ensure the maximum pressure increase. In the state Pressure control the feed forward controller and the PIcontroller are active. The state Overpressure is selected when the pressure in the rail is too high. Here the FPAPWM signal has minimum value. In the state Limp home the control loop is opened and only the feed forward controller is active.

When a low pressure start is required the controller starts in Low pressure state until STATE_FUP_TRAN = 2. This variable is defined in application incidences. After the start phase the fuel pressure should reach the setpoint in state Fast pressure increase . After fulfilling STATE_FUP_TRAN = 3 (setpoint is reached) the state Pressure control will be entered.

In case of a high pressure start the controller remains in Low pressure state until STATE_FUP_TRAN = 2 (starter relay is activated). This is done for security reasons in order to protect the regulator for overheating. In state Fast pressure increase the fasted pressure increase is performed. After fulfilling STATE_FUP_TRAN = 3 (setpoint is reached) the state Pressure control will be activated.

34.14.2.1.1.2.3 Calculation

Withing that two blocks the adaptation and the fuel pressure request for the FPA are calculated.

The calculation of the I and Ppart is done with the help of the fuel pressure deviation and two maps. The Ipart is not allowed to be outside of certain limits. Out of the precontrol, Ipart and Ppart the final fuel pressure demand for the high pressure pump control is generated.

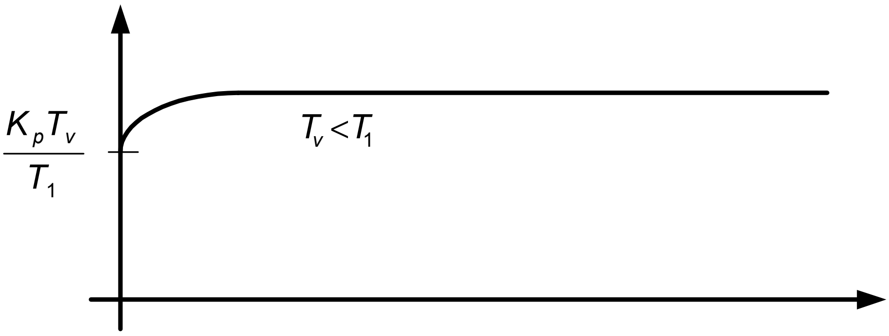
34.14.2.1.2 Set point calculation

Within this subblock the filtered fuel pressure setpoint and the precontroller is calculated.

The aim of the precontroller is to prevent overshoots or undershoots of the fuel pressure at big fuel pressure setpoint slopes. This whole block is basically representing a PPT1block.



Source: PPT1-response.vsd

The factor KpTv/T1 ist represented by FAC_FUP_SP_PCTL. This factor is depending on the FUP_SP change. This factor will be multiplicated with FUP_SP, which is the basis for the FPAPWM value. The FUP_SP value is also filtered with a modified PT1filter.

34.14.2.2.2 Timer Calculation

The different timers for the component protection are calculated within that subblock

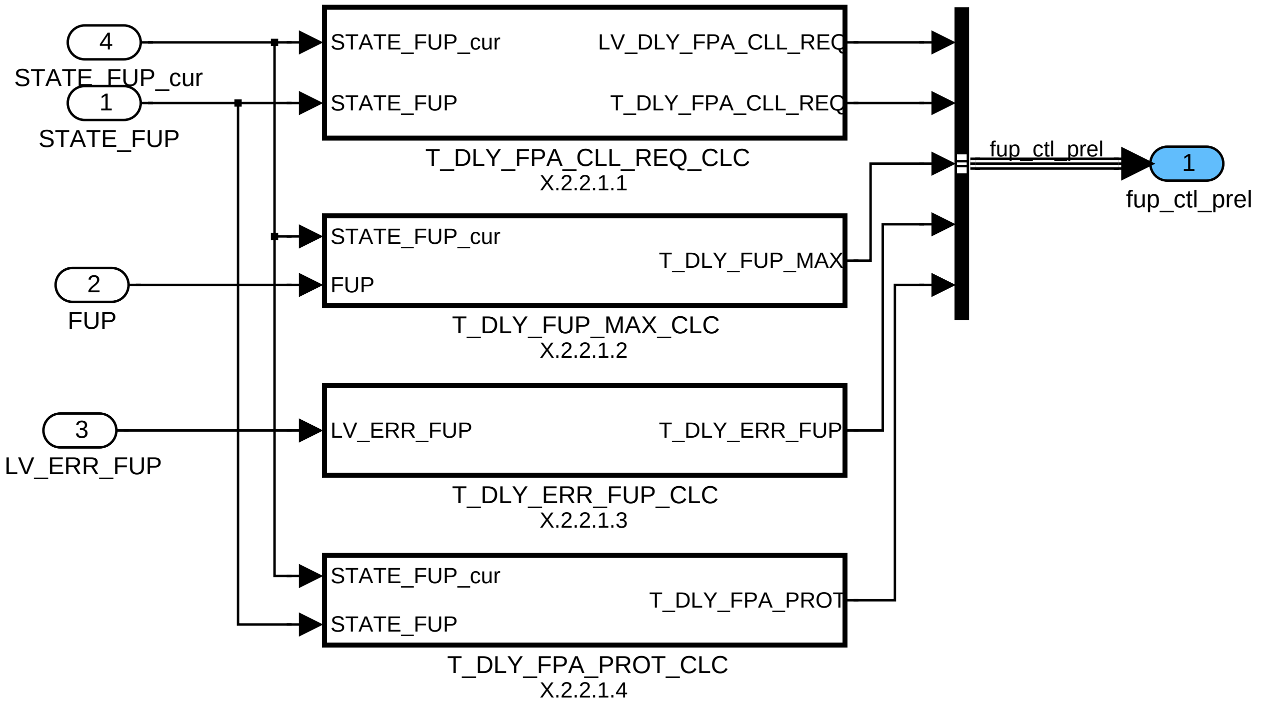

Figure 178:
Path: FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL

34.14.2.2.2.1 Timer Calculation

In case of a fuel pressure error a timer is started

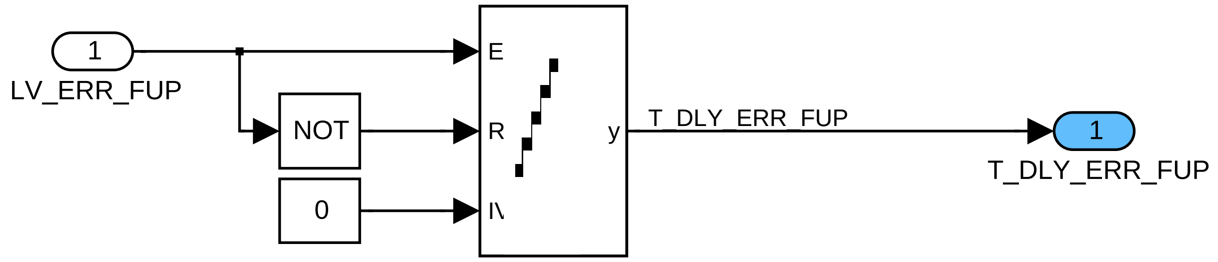

Figure 179:
Path: FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL/T_DLY_ERR_FUP_CLC

34.14.2.2.2.2 Calculation of Timer and LV variales

For the start a higher PWM than allowed can be requested to enable a fast pressure increase. This timer prevents a severe component damage due to overheating
Note: Due to the functionality high pressure pump control the regulator can maybe not respond to that strategy!

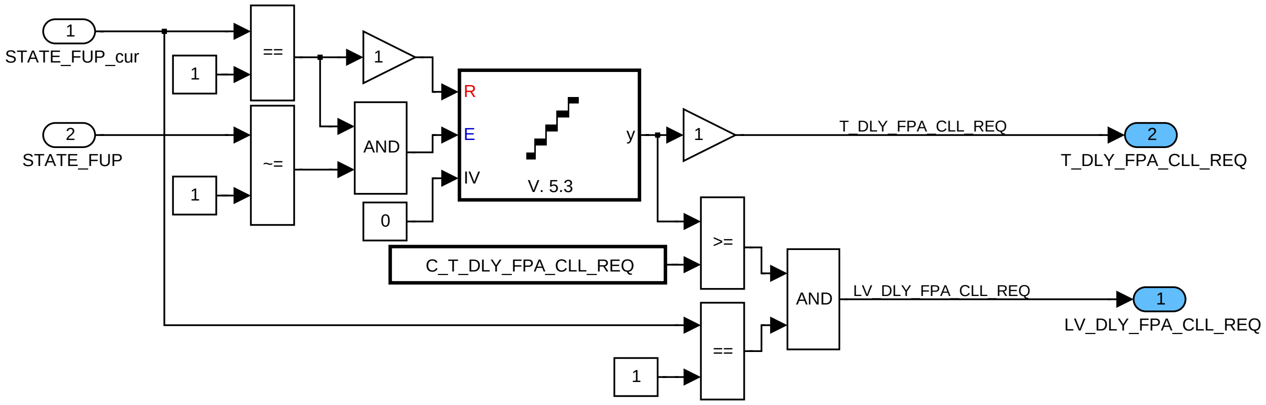

Figure 180:
Path: FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL/T_DLY_FPA_CLL_REQ_CLC

34.14.2.2.2.3 Timer Calculation

Corresponding to the timer before a certain time has to be waited until reaching high PWM again.
Note: Due to the functionality high pressure pump control the regulator can maybe not respond to that strategy!

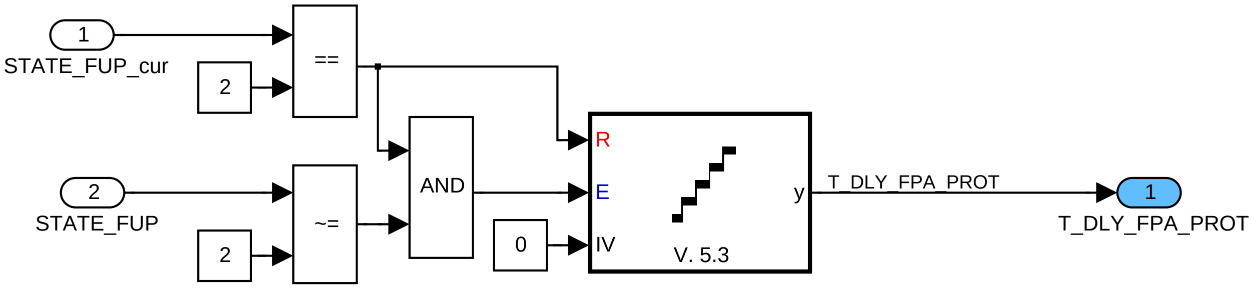

Figure 181:
Path: FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL/T_DLY_FPA_PROT_CLC

34.14.2.2.2.4 Timer Calculation

This timer is observing to overpressure and gives signals to the state diagram.

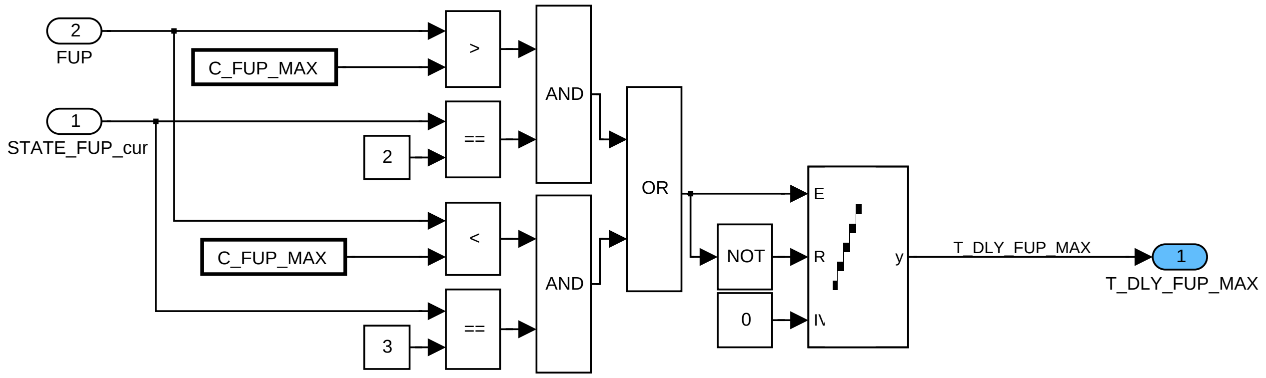

Figure 182:
Path: FUSL_M903W/OPM_10MS/FUP_TRAN_CLC/FUP_CTL_PREL/T_DLY_FUP_MAX_CLC

34.14.2.2.3 Calculation

Due to complexibility of the transition calculation this function part is split into three parts.

In the first part the crash state will be achieved in case of crash event. When the engine stops the low pressure state will be selected. In case of overpressure more than a certain time the overpressure state should be reached. After disappearing of the overpressure more than a certain time this state will be left. In case of fuel pressure sensor failure the open loop state should be selected.

The second part gives possiblities to reach close state. This state might be not valid due to external influences at the actual actuator control done in high pressure pump control.

In the third part mainly start conditions are mentioned. In case of required high pressure start the high request for the FPA control is given as soon as the starter relay has closed. Otherwise a certain engine speed has to be reached.

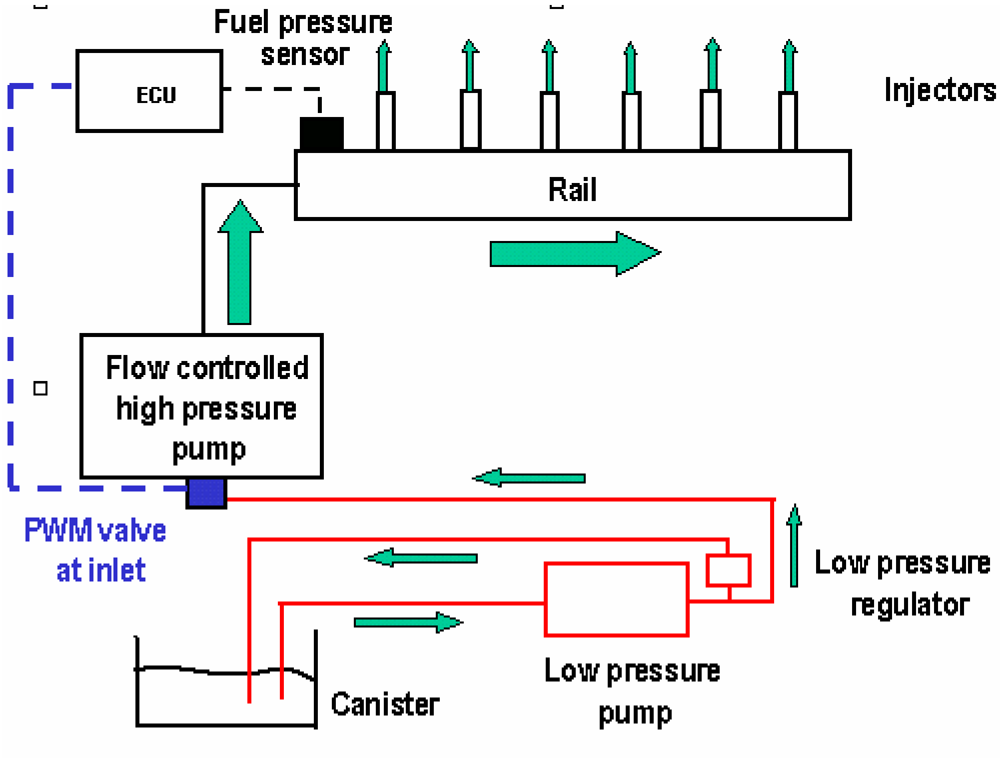
General Information

The fuel pressure in the rail can be controlled by an volume control valve at the inlet side. Depending on the requested fuel mass to be delivered by the fuel pump the inlet valve to the pump has to be controlled.



In case of checksum error or new ECU initial values are taken for the corresponding variables. Otherwise the stored values are taken. All adapted values can be cleared by the variable LC_HPP_CTL_AD_CLR.

```
Use     ACTION_INFR_SetPwmVcv(IN<ducy>)
        ACTION_INFR_SetFrqPwmVcv(IN<frq>)

34.15.2.1.1.1 Additive component calculation

In this block the additive component of the second variant of the VCV_BAS adaptation is calculated.

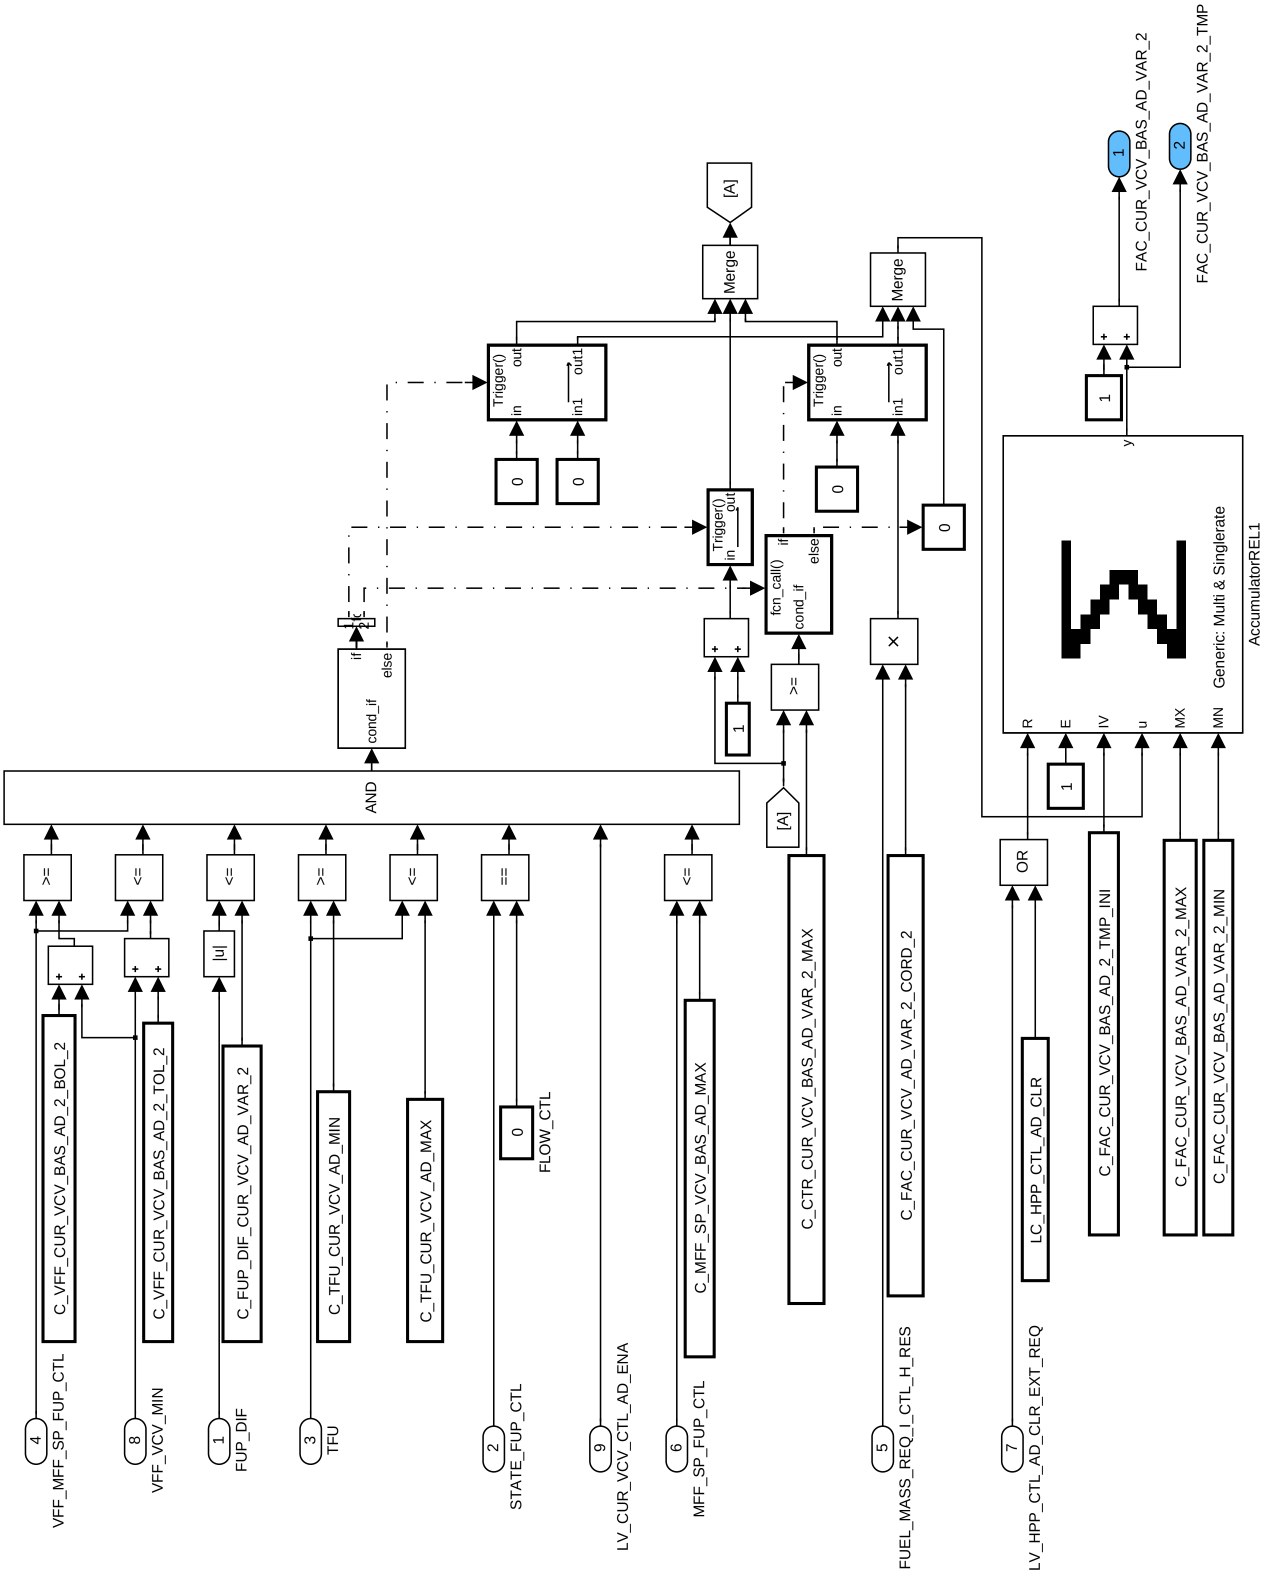

Figure 197:

34.15.2.1.1.2 Factor Calculation

In this block the factor of the second variant of the VCV_BAS adaptation is calculated.

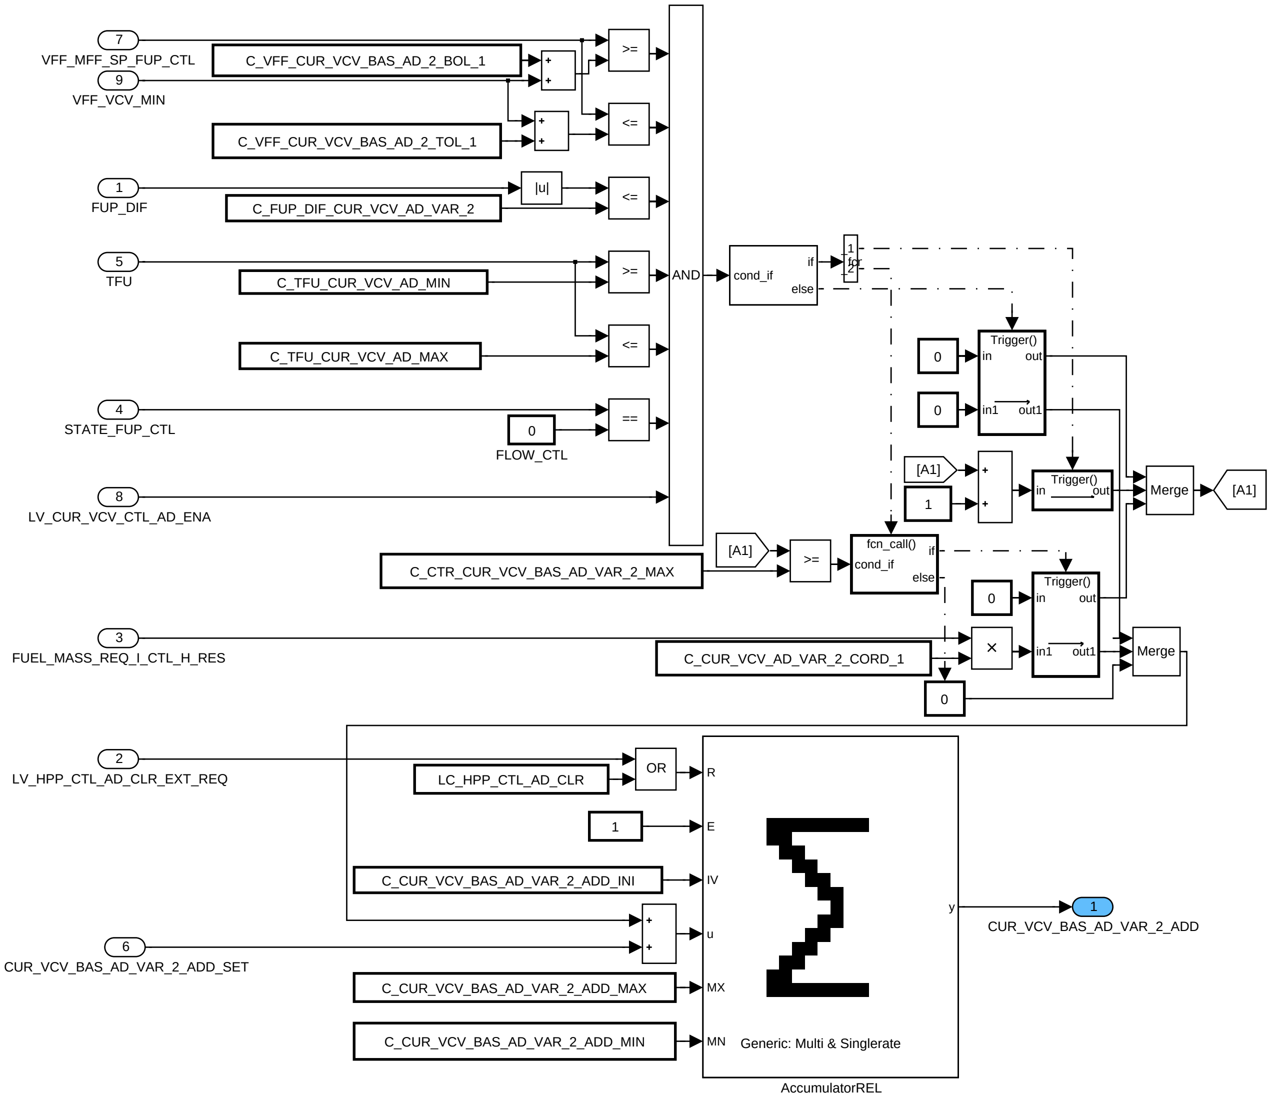

Figure 198:

34.15.2.1.2 Pressure control line adaptation of the VCV valve

This calculation is split into the calculations of the two points, the calculation of a factor and the final calculation of the adaptation value for the pressure control part of the valve.
! CUR_VCV_MIN_AD_CLC has to be calculated at first inside segment synchronous task.

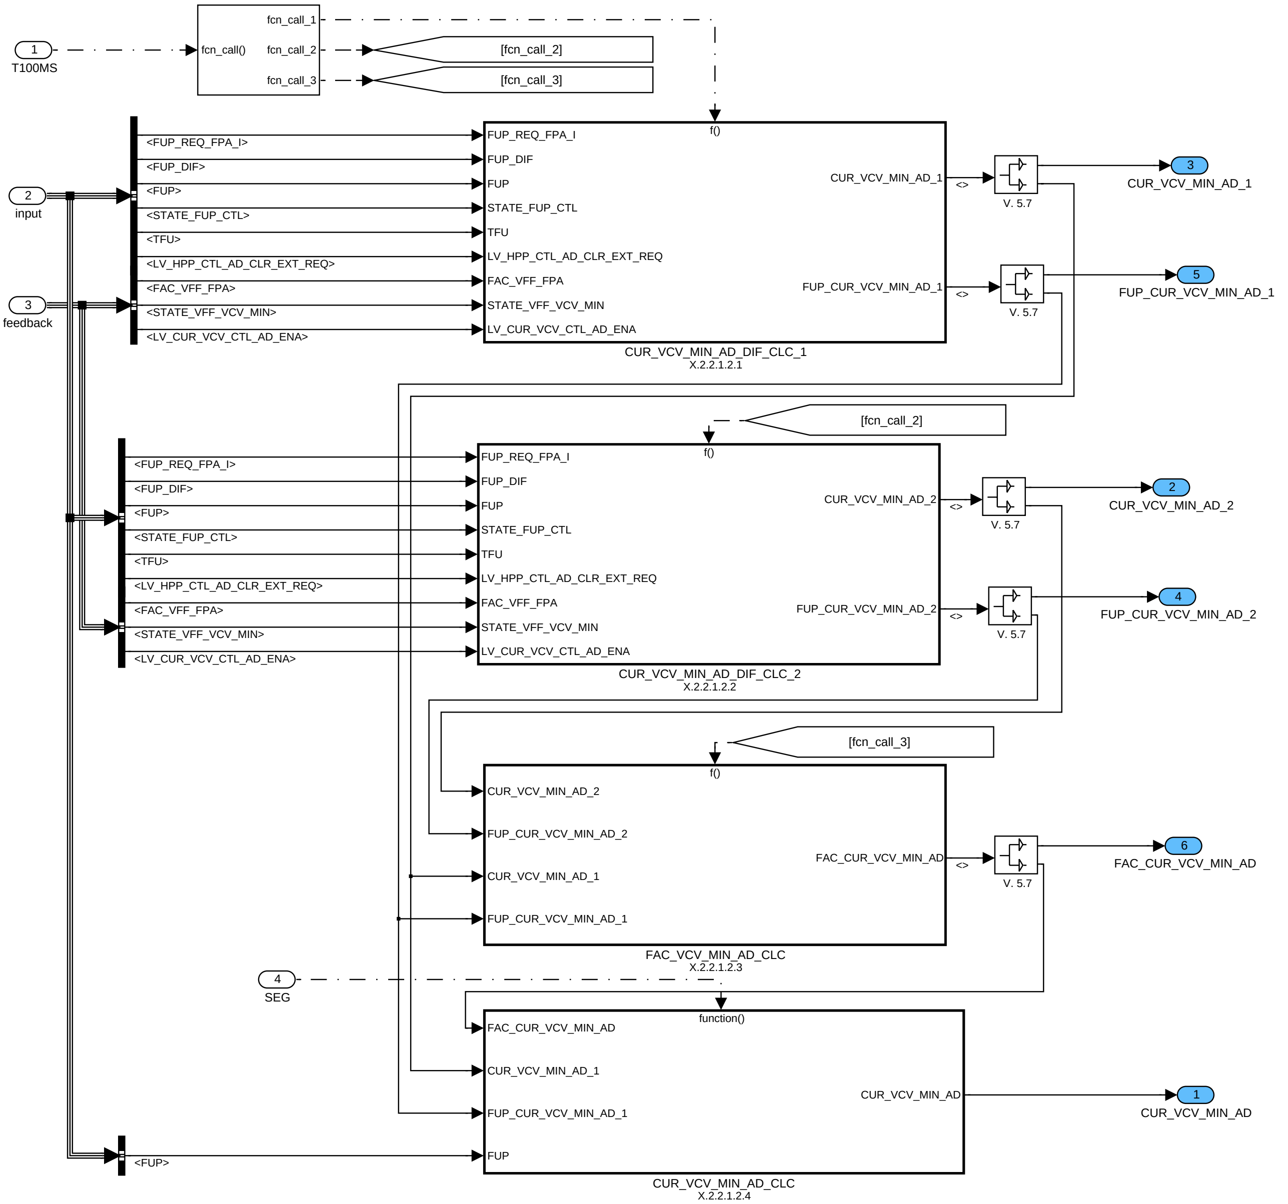

Figure 199:

34.15.2.1.2.1 Calculation of the final pressure control line adaptation value

The final adaptation value for the pressure control part of the valve is calculated in that block.

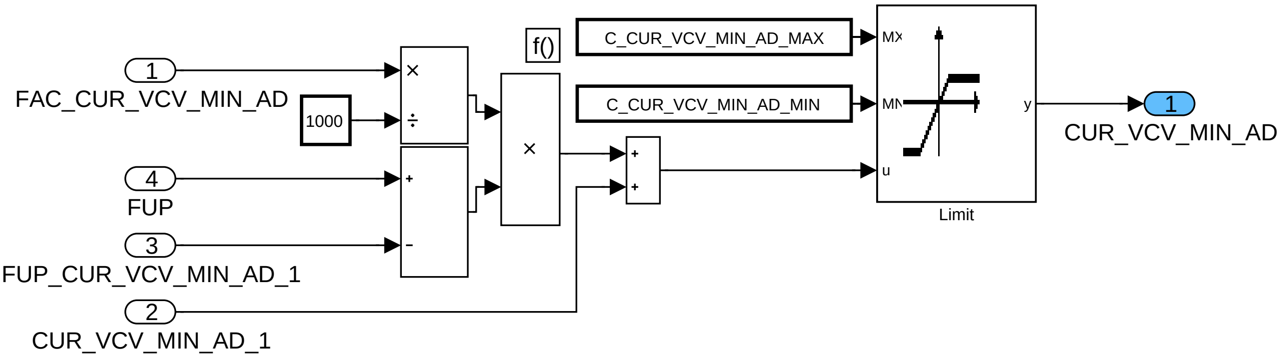

Figure 200:

34.15.2.1.2.2 Adaptation of point 2 of pressure control line

The calculation of the first point of the adaptation of the pressure control line is constisting out of a MMV calculation of the flow and the corresponding state chart

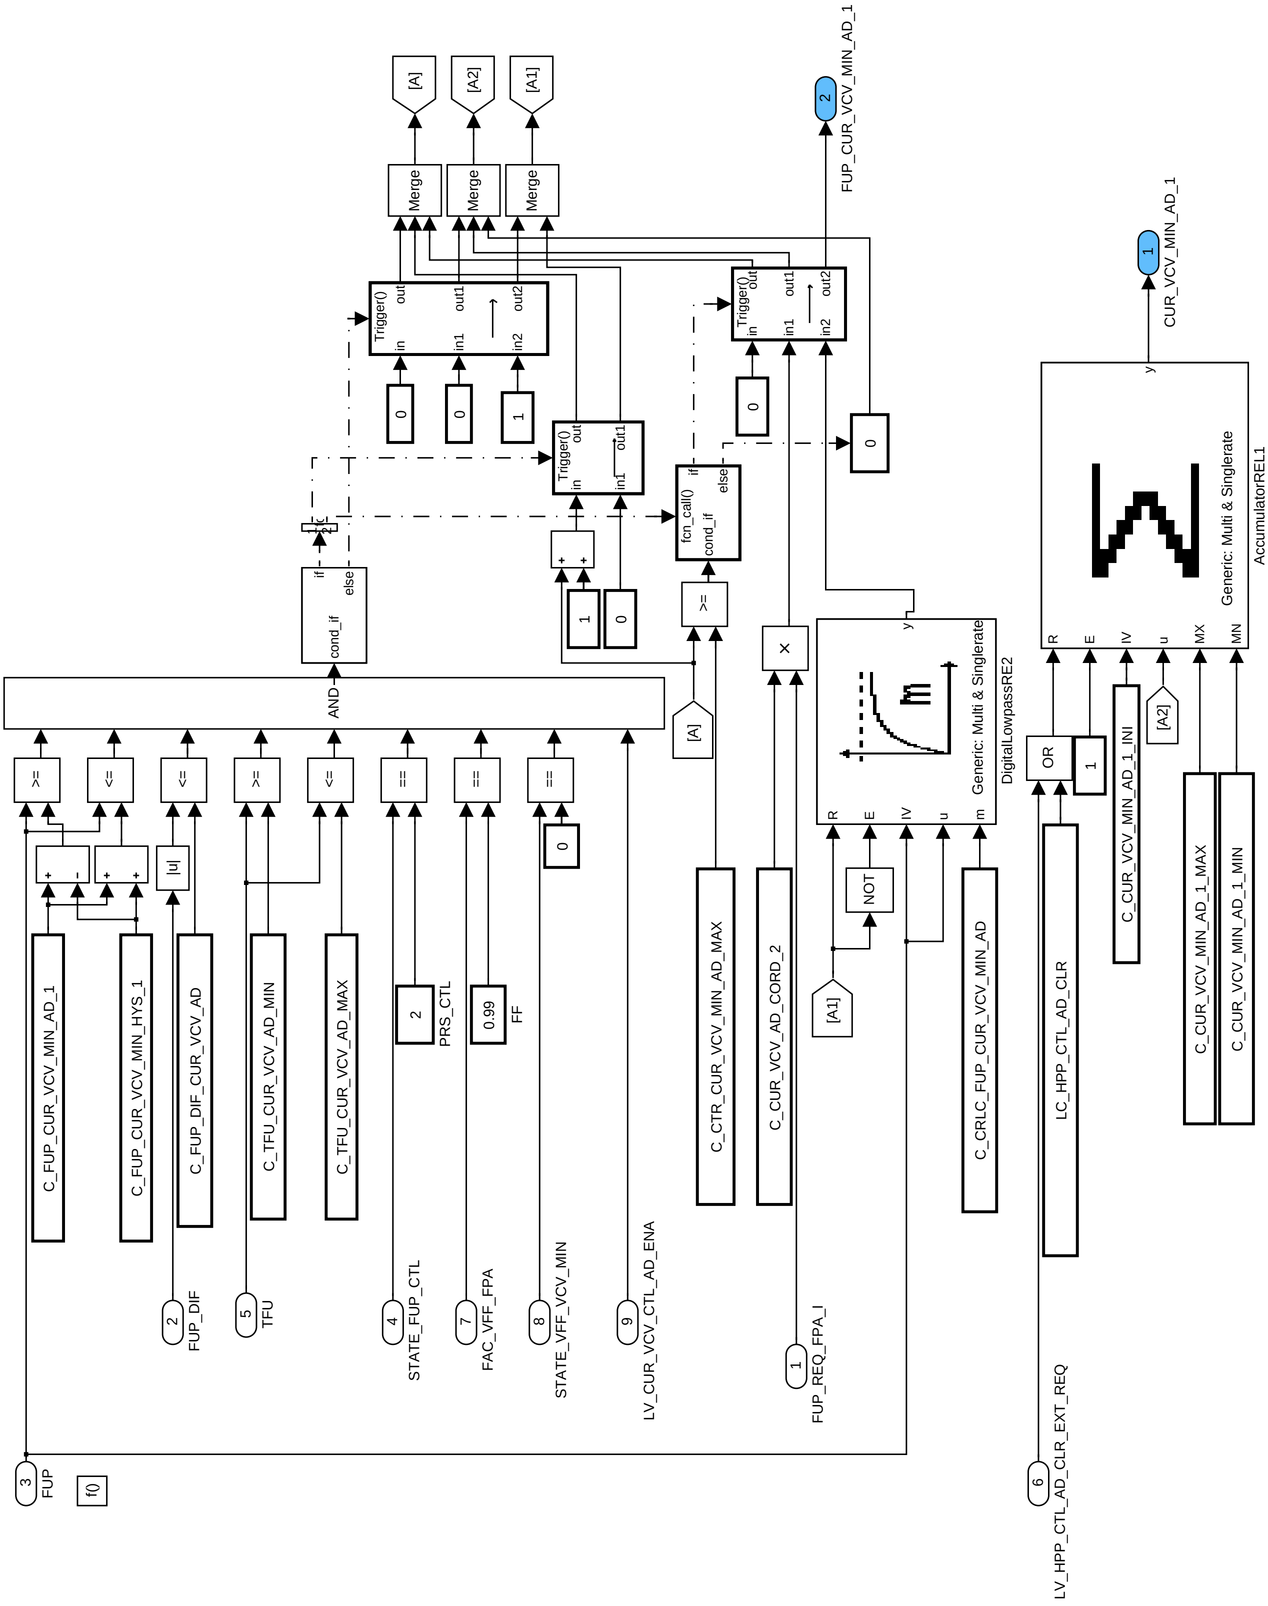

Figure 201:

34.15.2.1.2.3 Calculation of point 1 of pressure control line

The calculation of the second point of the adaptation of the pressure control line is consisting out of a MMV calculation of the flow and the corresponding state chart.

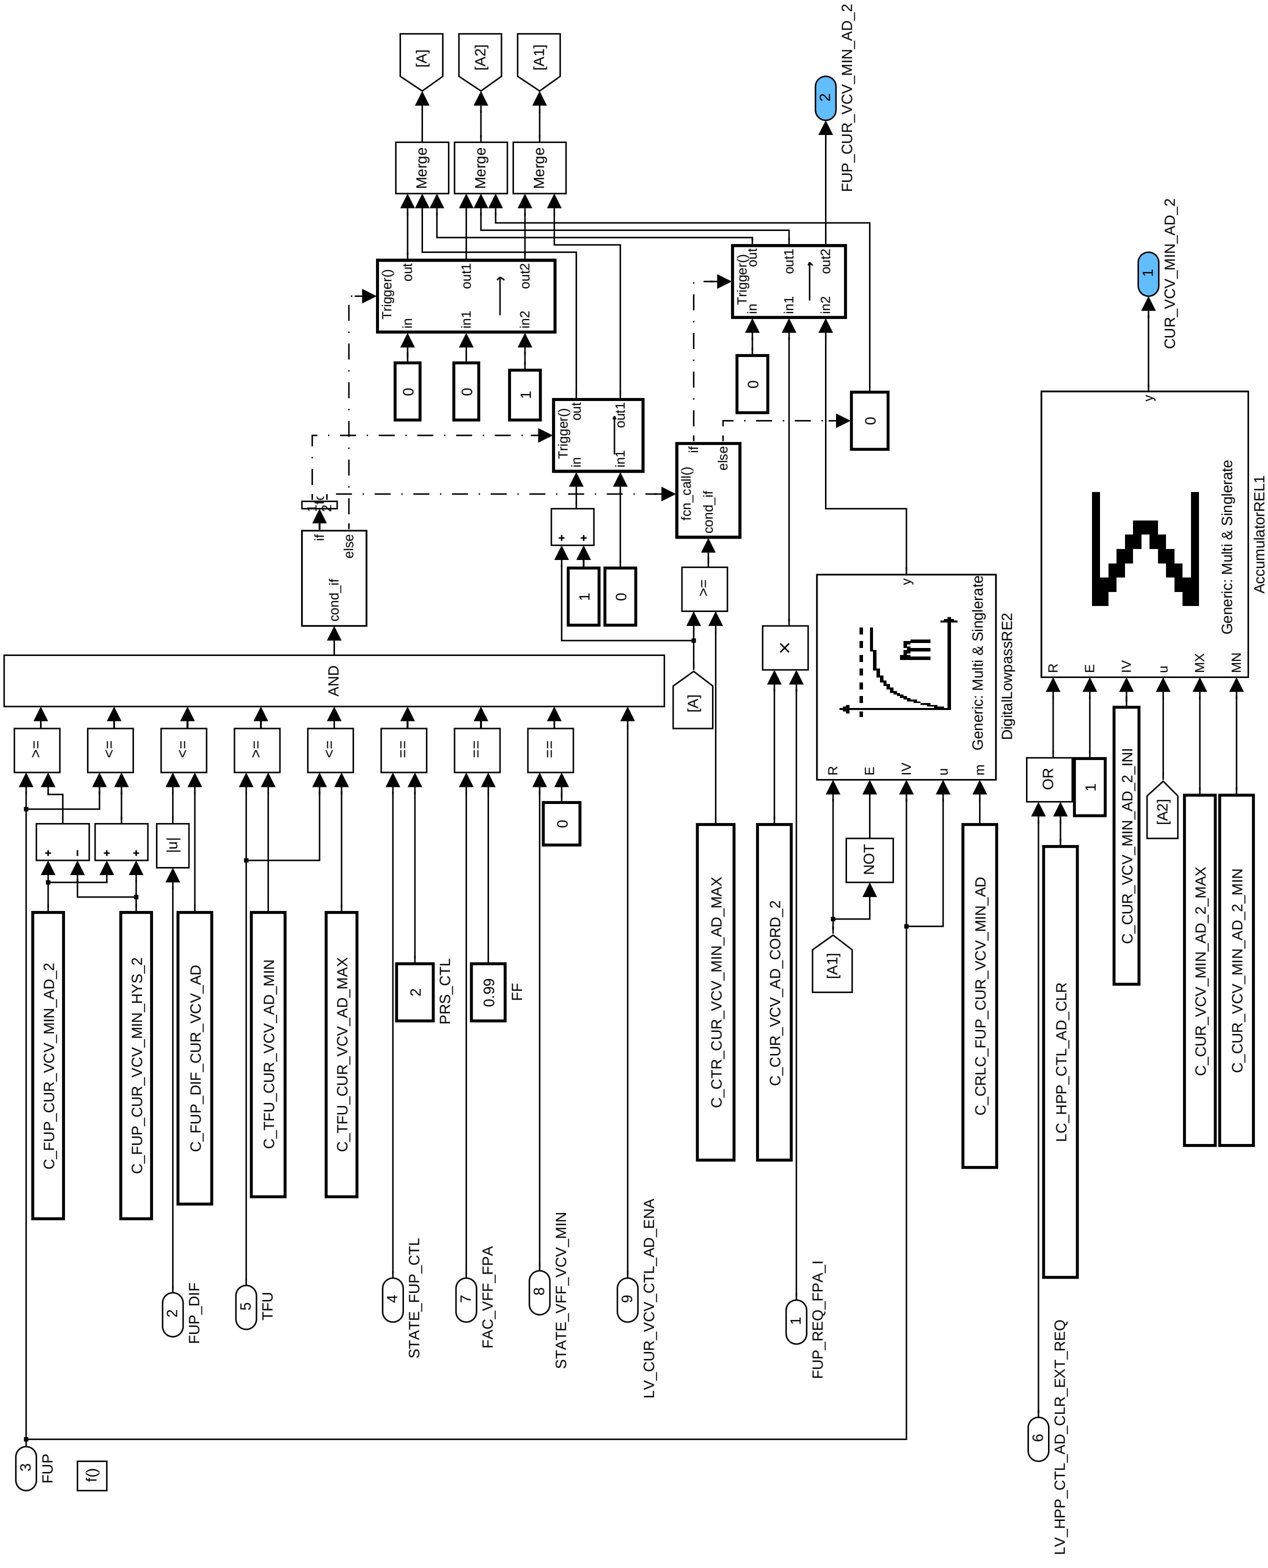

Figure 202:

34.15.2.1.2.4 Calculation of the slope of the pressure control line

In this block the slope for the correction of the pressure control part of the valve is calculated.

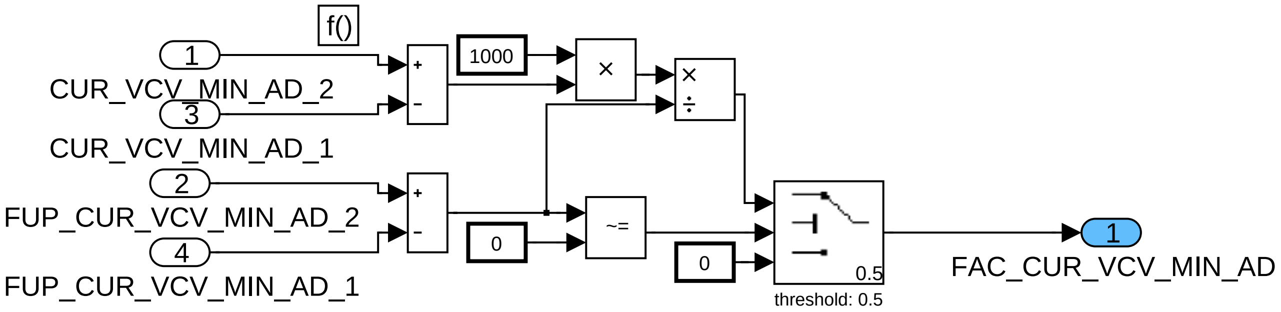

Figure 203:

34.15.2.2 Basic VCV Current Calculation

Overview of basic VCV current calculation. This function part provides the desired VCV current.

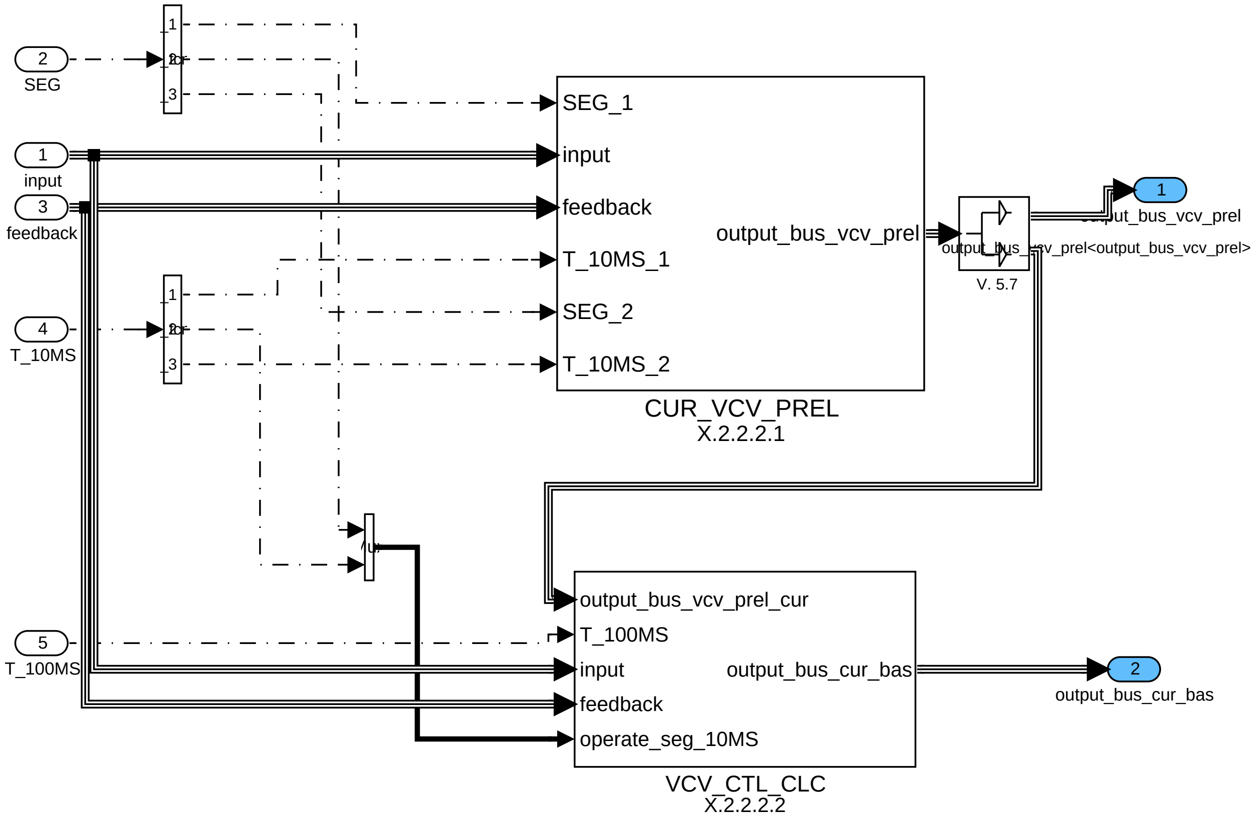

Figure 204:

34.15.2.2.1 Calculation of the basic fuel flows through the valve

The requested volume fuel flow through the volume control valve is calculated by the requested fuel mass and a conversion calculation taken into account the segment time and the density of the fuel. The real pumped fuel flow volume is calculated out of the calculated pump fuel mass.

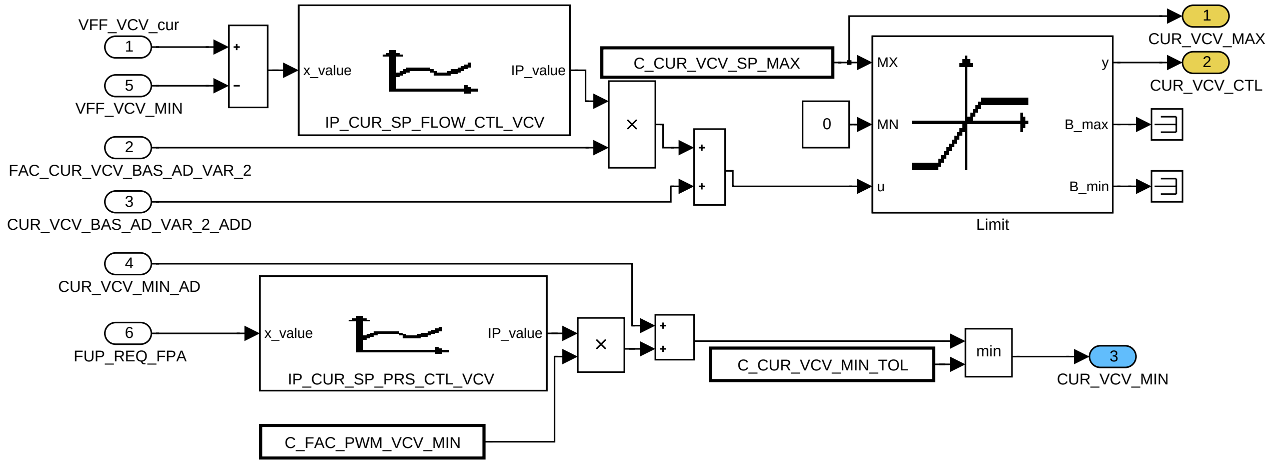

Figure 211:

34.15.2.2.1.2 Calculation of the transition conditions for the different working areas of the volume control valve

In this block the conditions for operating the state diagram are given. At crash event a safe state should be reached. In case of pull the valve should be closed and in case of engine stop the valve should be open. Manual operation can be selected by a flag. If none of the above mentioned cases are valid the normal operation mode can be done.

FUNCTION DESCRIPTION

General information:

In case of EKP on PT-CAN (CONF_SWI_EFP_OUT = 2), the EKP sends diagnosis-information to the DME, the following diagnoses are defined:

- EFP Selfdiagnosis
- EFP switch off in case of vehicle crash

34.18.1 EFP selfdiagnosis

General information:

The state of the self diagnosis of the EFP module is transmitted via PT-CAN. The error handling for the diagnosis results will be done by the ECU.

Description:

Error symptoms are defined for this diagnosis function as:

```
□□□□
 │ │ │ └─> N_high                       (= SYM_0)
 │ │ └───> N_Low                        (= SYM_1)
 │ └─────> LIH                          (= SYM_2)
 └───────> Temp                         (= SYM_3)
```

Application conditions:

Initialisation: *All values are initialized according Filter-type STD_INI*

Recurrence: *1s*

Activation:

```
If      LV_CDN_VB_CAN_DIAG =  1         and
        CONF_SWI_EFP_OUT > 0            and
        {[LV_VAR_BN = 0                 and
        (CONF_SWI_EFP_OUT = 2           and
        LV_ERR_TOUT_EFP_CAN = 0         and
        LV_ERR_CAN_BOFF = 0)]           or
        [LV_VAR_BN = 1                  and
         LV_VAR_BN_EFP = 1              and
        LV_ERR_BN_EFP = 0               and
        LV_ERR_CAN_BOFF = 0]}
Then    LV_CDN_DIAG_EFP = 1
        LV_END_DIAG_EFP = 1
         (Calculated by error management)
Else    LV_CDN_DIAG_EFP =  0
Endif
```

Formula section:

Calculation of detected error

```
If      STATE_DIAG_EFP = 3H
Then    ERR_SYM_EFP = SYM_0        Symptom rpm to high (N_high)
```

```
ElseIf   STATE_DIAG_EFP = 2H
Then     ERR_SYM_EFP = SYM_1          Symptom rpm to low (N_low)
ElseIf   STATE_DIAG_EFP = 5H
Then     ERR_SYM_EFP = SYM_2          Symptom limp home mode (LIH)
ElseIf   STATE_DIAG_EFP = 4H
Then     ERR_SYM_EFP = SYM_3          Symptom high temperature (Temp)
Else     ERR_SYM_EFP = NO_SYM
Endif
```

Calculation of detected error

```
If       ERR_SYM_EFP is not 0
Then     LV_ERR_EFP = 1     set after debounce
Else     LV_ERR_EFP = 0     reset after rebounce
Endif
```

Configuration for diagnostic symptoms :

Diagnostic EFP	Symptom description	Symptom	Filter type
EFP Selfdiagnosis	*Symptom rpm to high (N_high)*	*SYM_0*	*STD_INI*
	Symptom rpm to low (N_low)	*SYM_1*	
	Symptom limp home mode (LIH)	*SYM_2*	
	Symptom high temperature (Temp)	*SYM_3*	

// calculation of end of diagnosis according to ERRM

34.18.2 EFP switch off in case off vehicle crash

General information:

The state of the self diagnosis of the EFP module is transmitted via PT-CAN. The error handling for the diagnosis results will be done by the ECU.

Description:

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                 (= SYM_0)
 │ │ └───> -                 (= SYM_1)
 │ └─────> Crash switch off  (= SYM_2)
 └───────> -                 (= SYM_3)
```

Application conditions:

Initialisation: *All values are initialized according Filter-type STD_INI*

Recurrence: *1s*

Activation:

```
If    LV_CDN_VB_CAN_DIAG =  1         and
      CONF_SWI_EFP_OUT > 0            and
      {[LV_VAR_BN = 0                 and
      (CONF_SWI_EFP_OUT = 2           and
      LV_ERR_TOUT_EFP_CAN = 0         and
      LV_ERR_CAN_BOFF = 0)]           or
      [LV_VAR_BN = 1                  and
       LV_VAR_BN_EFP = 1              and
      LV_ERR_BN_EFP = 0               and
      LV_ERR_CAN_BOFF = 0]}
Then  LV_CDN_DIAG_EFP_CRASH = 1
      LV_END_DIAG_EFP_CRASH = 1
       (Calculated by error management)
Else  LV_CDN_DIAG_EFP_CRASH =  0
Endif
```

Formula section:

Calculation of detected error

```
If      STATE_DIAG_EFP = 1H
Then    ERR_SYM_EFP_CRASH = SYM_2 Symptom switch off due to vehicle crash
        LV_ERR_EFP_CRASH = 1            set after debounce
Else    ERR_SYM_EFP_CRASH = NO_SYM
        LV_ERR_EFP_CRASH = 0            reset after rebounce
Endif
```

// calculation of end of diagnosis according to ERRM

Configuration for diagnostic symptoms :

End of diagnosis for FUP sensor diagnosis					

Input data:

V_FUP_EFP_MV	LV_IGK	LV_INH_DIAG_FUP_EFP	

Import actions:

ACTION_ERRM_FilterSymptom(IN< XX >, IN< LV_CDN_DIAG_XX >, IN< ERR_SYM_XX >,
IN< C_ABC_INC_XX >, IN< C_ABC_DEC_XX >, IN< C_ABC_MAX_XX >, OUT< LV_ERR_XX >)

FUNCTION DESCRIPTION:

General Information:

Analog input signal in the A/D-Input from the Microprocessor.

Description

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> Short circuit in signal wire to VB or wire break      (= SYM_0)
 │  │  └───> Short circuit in signal wire to ground                 (= SYM_1)
 │  └─────> -                                                        (= SYM_2)
 └───────> -                                                         (= SYM_3)
```

Remark: Calculation of LV_END_DIAG_FUP_EFP see generic calculation “End of diagnosis” in anti bounce algorithm.

Application conditions:

Initialization:
LV_CDN_DIAG_FUP_EFP = *Refer to filtering configuration for the initialisation value*
LV_END_DIAG_FUP_EFP = *Refer to filtering configuration for the initialisation value*
LV_ERR_FUP_EFP = *Refer to filtering configuration for the initialisation value*

ERR_SYM_FUP_EFP = *Refer to filtering configuration for the initialisation value*

Recurrence: 40 ms

Activation:

```
if      LV_IGK = 1 AND LV_INH_DIAG_FUP_EFP = 0
Then    LV_CDN_DIAG_FUP_EFP = 1
        (diagnosis is active)
else    LV_CDN_DIAG_FUP_EFP = 0
        (diagnosis is inactive)
endif
```

Deactivation:

When the activation condition is not fulfilled then LV_CDN_DIAG_FUP_EFP = 0.

Formula section:

```
{ SYM_0 : Short circuit in signal wire to VB or wire break }
    If      V_FUP_EFP_MV > C_V_FUP_EFP_MV_MAX_DIAG
    then
            ERR_SYM_ FUP_EFP = SYM_0            { Symptom SCP or OC is active }

    else
        { SYM_1 : Short circuit in signal wire to ground }
        if      V_FUP_EFP_MV      <      C_V_FUP_EFP_MV_MIN_DIAG
                then
                ERR_SYM_FUP_EFP = SYM_1     { Symptom SCG is active }
                else
                ERR_SYM_FUP_EFP = NO_SYM    { No failure has been detected }
                endif
    endif
```

Symptoms are **unchanged** if condition for doing symptopm detection is not fulfilled.

For failure and error management treatment the anti-bounce mechanism is called with the parameters LV_CDN_DIAG_FUP_EFP and ERR_SYM_FUP_EFP.

ACTION_ERRM_FilterSymptom (IN< FUP_EFP >, IN< LV_CDN_DIAG_FUP_EFP >,
IN< ERR_SYM_FUP_EFP >, IN< C_ABC_INC_FUP_EFP >, IN< 1 >,
IN< C_ABC_MAX_FUP_EFP >, OUT< LV_ERR_FUP_EFP >)

This algorithm determines LV_ERR_FUP_EFP and LV_END_DIAG_FUP_EFP and delivers the result to Error Management.

Calibration data:

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>, OUT<LV_ERR_XX>)
ACTION_INFR_GetElDiagVcv(OUT< Cdn_diag_vcv>, OUT< Err_diag_vcv >)

Note :

ACTION_INFR_GetElDia*g*Vcv() is defined in the IRS (Infrastructure requirement specification)

FUNCTION DESCRIPTION:

General information:

The Volume controlled valve (VCV) is driven by the ECU via an output driver. The failure detection is done by ECU Hardware.
The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements.

Description:

After activation conditions are met, the diagnosis activation is delayed for NC_PSD_DLY_VCV executions, to avoid the usage of wrong infrastructure information.

Error-symptoms and conditions: are defined to this diagnosis function as following

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to battery (SCP)      (= SYM_0)
 │ │ └───> Short circuit to ground (SCG)       (= SYM_1)
 │ └─────> Open circuit (OC)                   (= SYM_2)
 └───────> -                                   (= SYM_3)
```

Application conditions:

Initialisation: at transition lv_igk 0->1:
LV_ERR_VCV = 0 and

ERR_SYM_VCV,

LV_END_DIAG_VCV

(according Filter-type)

Set delay counter for NC_PSD_DLY_VCV

at reset:

CDN_DIAG_VCV = 0,

LV_ERR_VCV = 0 and

ERR_SYM_VCV = 0,

LV_CDN_DIAG_VCV = 0,

LV_END_DIAG_VCV = 0,

(according Filter-type)

Set delay counter for NC_PSD_DLY_VCV

Recurrence: 100 ms

Activation: -

Deactivation: When the activation condition is not fulfilled

Formula section:

If LV_IGK = 1
and LV_CDN_VB_OBD1 = 1
and LV_INH_DIAG_VCV = 0

Then

Usage of the diagnosis information (failure symptoms (raw value) ERR_DIAG_VCV and basic diagnosis conditions CDN_DIAG_VCV) received from the infrastructure:

ACTION_INFR_GetElDiagVcv (OUT<Cdn_diag_vcv>, OUT<Err_diag_vcv>)

Basic diagnosis conditions are set according infrastructure information: CDN_DIAG_VCV
Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_VCV

If Activation conditions are met for the NC_PSD_DLY_VCV recurrence of

```
                    the diagnosis
            Then    { Additional diagnosis conditions }
                    If      C_PWM_VCV_MIN_DIAG_SCP > PWM_VCV
                    then  bit 0 of CDN_DIAG_VCV  = 0 {Diagnosis of SCP not possible }
                    Endif
                    If      PWM_VCV > C_PWM_VCV_MAX_DIAG_SCG
                    then  bit 1 of CDN_DIAG_VCV  = 0 { Diagnosis of SCG not possible }
                    Endif
                    If      PWM_VCV < C_PWM_VCV_MIN_DIAG_OC
                    Or      PWM_VCV > C_PWM_VCV_MAX_DIAG_SCG
                    then  bit 2 of CDN_DIAG_VCV  = 0 { Diagnosis of OC not possible }
                    Endif
            Else    CDN_DIAG_VCV = 0
            Endif
Else
            CDN_DIAG_VCV = 0
Endif
```

Failure filtering and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_VCV and ERR_DIAG_VCV.

ACTION_ERRM_FilterMulticondition (IN<*VCV*>, IN<CDN_DIAG_VCV>, IN<ERR_DIAG_VCV>, IN<C_ABC_INC_VCV>, IN<C_ABC_MAX_VCV>, OUT<LV_ERR_VCV>)
This algorithm determines:

ERR_SYM_VCV	(detected error symptom for VCV diagnosis)
LV_ERR_VCV	(Error flag for debounced error of VCV)
LV_CDN_DIAG_VCV	(Diagnosis condition information)
LV_END_DIAG_VCV	(End of diagnosis information)

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

Map to convert CUR_VCV_BAS into VFF_VCV_DIAG_CLC					

Import actions:

ACTION_ERRM_GetLvErr(IN <IDX_DIAG>, OUT <LV_ERR>)
Action that returns the status of the debounced failure
ACTION_ERRM_FilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <ABC_INC>, IN <ABC_DEC>, IN <ABC_MAX>, OUT <LV_ERR>)
This action computes the elementary anti-bounce filter

34.25.1 FUNCTION DESCRIPTION:

The purpose is to diagnose mechanical errors.

Specific diagnosis information to the project are defined in chapters ‘Diagnosis information’ (Freeze frame, DTC, error code number, symptom number, data for MIL management ...).

General information:

After debounce the corresponding error bit LV_ERR... is set to 1 and the corresponding symptom is active. Only if the driving cycle is finished the error bit LV_ERR... and the debounced counter are set to 0 and the corresponding symptom is not active.

The fuel system pressure diagnosis will be executed in dependency on the status of the fuel pressure sensor.

If the diagnosis is not prohibited the MFP plausibility check, the FUP sensor plausibility check and the HP system monitoring can be executed. The MFP plausibility check will be calculated only in state MFP_CTL.

The high-pressure system check indicates mainly an abnormal fuel pressure value in fuel system.

If a plausibility check error or the high-pressure system check error is detected a request for Lambda=1 mode is set to identify the origin of the non-plausibility.

The flags LV_CDN_DIAG_XXX exept the flag for FUP_STOP are ==0 if the function is not active. LV_CDN_DIAG_FUP_STOP == 1 if the function is not active.

General Information

The purpose is to diagnose mechanical errors.
Specific diagnosis information to the project are defined in chapters Diagnosis information (Freeze frame, DTC, error code number, symptom number, data for MIL management ...).

After debounce the correponding error bit LV_ERR... is set to 1 and the corresponding symptom is active. Only if the driving cycle is finished the error bit LV_ERR... and the debounced counter are set to 0 and the corresponding symptom is not active.
The fuel system pressure diagnosis of low pressure will be executed in dependency on the status of the low pressure fuel pressure sensor.

The low-pressure system check indicates mainly an abnormal fuel pressure value in fuel system.

34.27.3 LP system monitoring

General information:
Certain pressure thresholds are observed in order to detect mechanical faults of the components of the fuel circuit. There are two pressure limits to detect overpressure and there is one to detect pressure too low.
FUP_EFP > Tol2 indicates an overpressure with an error in the HP pump pressure relief valve. The pressure is higher than the pressure where the relief valve should open.
Tol1 < FUP_EFP < Tol2 indicates a pressure which is under the critical value of the LP pump pressure relief valve. This could happen when there is a mechanical fault, but the overpressure relief valve is still ok
FUP < Bol1 indicates a excessive loss of pressure. Mechanical failure in the pump, regulator or leakage be detected.

34.27.4 Plausibility check EFPPWM

General information:
The plausibility check for the EFPPWM consists out of three parts. First a check of the I-part of the controller, which indicates mainly rapid changes in the performance of the pump or other low pressure system related topics. The adaptive integral part can be used as an indicator for life time topics of the fuel pump. The adaptive minimum EFPPWM gives the functionality of the fuel pump at zero delivery to the high pressure system.

```

35.1.2 Diagnosis Function

General information:

The intention of this diagnosis is to deteced a fuel level getting empty. An analysis is done based on the two chambers fuel level of the fuel tank.

Application conditions:

Initialisation: **at** reset **and** LV_IGK 0 to 1

LV_ERR_FTL_MIN, RATIO_FTL, RATIO_FTL_INI, LV_CDN_DIAG_FTL_MIN, CTR_FTL_MIN_ACT, ER_FTL_MIN, ERR_SYM_FTL_MIN, LV_LAMB_PLAUS_FTL_MIN_DIAG_TMP, LV_FUP_AVL_DIAG_TMP, LV_FTL_LE_RE_ACT

all with 0 physical

FTL_RI_MMV	*= FTL_RI*
FTL_RI_MMV_H_RES	*= FTL_RI*
FTL_LE_MMV	*= FTL_LE*
FTL_LE_MMV_H_RES	*= FTL_LE*

Recurrence: 100ms

Activation: LV_FTL_MIN_ACT =1 **and** LV_ERR_FTL_MIN = 0

Deactivation: LV_FTL_MIN_ACT = 0 **or** LV_ERR_FTL_MIN = 1

Description:

Error-symptoms are defined to this diagnosis function as following :

```
□□□□
 |  |  |  └─> low pressure intervention in high pressure system      (= SYM_0)
 |  |  └────> low pressure intervention in low pressure system       (= SYM_1)
 |  └───────> -                                                       (= SYM_2)
 └──────────> low fuel level intervention                             (= SYM_3)
```

Formula section:

Reset of variables on FMY_clear:

```
If(1)     failure memory is cleared
THEN(1)        LV_LAMB_PLAUS_FTL_MIN_DIAG_TMP = 0

35.4 Fuel tank level diagnosis (Applic. Inc.)

35.4.1 Interface for Rate – Based – Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_FTL_OBD	V/O	0...7H	0...7	1	[-]
Interface of FTL_OBD monitor with the Rate-Based Monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					

Input data:

LV_DC	LV_END_DIAG_FTL_OBD		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the FTL_OBD monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_FTL_OBD data.

Within STATE_RBM_FTL_OBD, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for FTL_OBD diagnosis)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_FTL_OBD = 0

on failure memory reset :

bit 1 of STATE_RBM_FTL_OBD = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

Bit 0:

```
If    bit 0 of STATE_RBM_FTL_OBD = 0
then
      if      LV_END_DIAG_FTL_OBD = 1
      then    bit 0 of STATE_RBM_FTL_OBD = 1
      endif
endif
```

Bit 1:

bit 1 of STATE_RBM_FTL_OBD = 0

Bit 2:

bit 2 of STATE_RBM_FTL_OBD = 1

36.1 Cylinder numbering

In the software the cylinders are numbered logically with 0...5. The relating physical cylinders are numbered from 1...6. If in the specification a cylinder-specific-variable is mentioned with ..._x or ...[CYL] then always the logic value is ment. The correct firing order of any 6 cylinder engine has to be guaranteed by the wiring harness, see system picture.

The following graphic shows examples of physical cylinder numbers:

M54 / M56 / NG R6
Flywheel
6
5
4
3
2
1

The relation between logical and physical cylinder numbers is as follows:

Logic	Physical M5x / NG R6	bank
0	1	1
1	5	2
2	3	1
3	6	2
4	2	1
5	4	2

36.3 Dataset identification and checksum calculation

FUNCTION DESCRIPTION:

General information:

The INCA application tool doesn’t store a dataset identifier when a dataset is sent to the ECU. Therefore it is not possible to empathise which dataset really is in an ECU. To solve this problem three calibratable variables C_DATA_ID_0, C_DATA_ID_1 and C_DATA_ID_2 are introduced. Every variable can be calibrated with 5 ASCII signs, wich are the identifier of the dataset. The variables are only visible in INCA (SAM doesn't support ascii format).

To activate or deactivate the checksum calculation over the dataset with the help of INCA, the constant C_CHECK_SUM has been introduced. If the value of C_CHECK_SUM is = 0000h, the checksum calculation is deactivated. If the value of C_CHECK_SUM is <> 0000h, the checksum calculation is active.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_DATA_ID_0	1	0...FFH	ASCII	1	[-]
Dataset identifier string 1					
C_DATA_ID_1	1	0...FFH	ASCII	1	[-]
Dataset identifier string 2					
C_DATA_ID_2	1	0...FFH	ASCII	1	[-]
Dataset identifier string 3					
C_CHECK_SUM	1	0...FFFFH	0...65535	1	[-]
Constant to activate the dataset checksum calculation

FIRST	first	zuerst, erst
FL	Full load	Vollast
FLL	flash light	Blinkcode
FLOOD	Flood	Absaufen des Motors
FLOW	flow	Fluß
FLS	Flash	
FLUC	fluctuation	Schwankung
FM	frequency modulation	Frequenzmodulation
FMT	Format	Format
FMY	Failure memory	Fehlerspeicher
FN	front	vorn
FOL	Follower	folgend
FP	Fast pulse	Fast pulse
FPA	Fuel pressure actuator	Kraftstoffdrucksteller
FPAPWM	Fuel pressure PWM	Tastverhältnis Kraftstoffdruck
FPS	fuel pressure sensor	Benzindrucksensor
FPV	Flash programming voltage enable (switch)	Programmierspannungsfreigabe (Schalter)
FRC	frequency counter	Häufigkeitszähler
FRF	freeze frame	OBD II Umweltbedingungen
FRQ	Frequency	Frequenz
FRS	Fuel reserve signal (4-liter-signal)	Füllstandssignal Tank (4-Liter-Signal)
FSD	fuel system diagnosis	Kraftstoffsystem-diagnose
FTL	Fuel tank level	Füllstandsniveau
FUC	fuel cap	Tankdeckel
FUEL	fuel	Kraftstoff
FUP	Fuel pressure	Kraftstoffdruck
FW	freewheeling	Freilaufkreis
GAC	actual gear code	aktueller Gang, kodiert
GAIN	Gain	Verstärkung
GAP	gap	Lücke
GAS	gas	Gas

Keyword	English definition	German definition
GB	gear box	Getriebe
GC	Gear change	Getriebeeingriff
GCB	Gear change begin	Getriebeeingriff-beginn
GCD	Gear change duration	Getriebeeingriffs-dauer
GEAR	gear	Gang
GEN	generator	Generator
GENC	Generator charge connection	Generatorladeleitung
GL	Glow	glühen
GND	Ground	Masse
GP	gear protection	Getriebeschutz
GR	gear ratio	Gang-Verhältnis
GRD	Gradient/slope	Gradient
GS	Gear shift signal	Getriebeschaltsignal
GSC	Gear shift characteristic	Schaltcharakteristik
GSPWM	gear shift signal PWM	Tastverhältnis Getriebeschaltsignal
H	High	high
HAST	Hot after-start	Heißnachstart
HB	high byte	high byte
HC	hydro carbon	Kohlenwasserstoff
HCHPWM	PWM of HC heater	
HD	header	
HDLP	head lamp	Frontscheinwerfer
HEAT	Heat	Beheizen
HFM	Hot film air mass meter	Heißfilmluftmassen-messer
HIV	heater inlet valve	Heizungsvorlaufventil
HLD	Hold	halten
HOM	homogeneous	homogen
HOT	Hot	heiß
HPF	Hight pass filter	Hochpaßfilter
HST	hot start	Heißstart
HTP	heating performance	Heizleistung
HYS	Hysteresis	Hysterese
I	Integral part of PID	Integraler Anteil
I2C	I^2C Bus (similar SPI)	
IC	integrated circuit	integrated circuit
ICL	instrument cluster	Kombiinstrument
ICO	intercooler	Ladeluftkühler
ID	index table with arbitrary many inputs without interpolation	Tabelle mit n-Eingängen ohne Interpolation.
IDM	ID table which is used in different modules with different input data	Tabelle, die in mehreren Modulen mit unterschiedlichen Eingangsgrößen benutzt wird.
IDX	index	Index
IF	Interface	Interface
IGA	Ignition angle	zylinderindividueller Gesamtzündwinkel
IGC	Ignition coil	Zündspule
IGCFB	Ignition current feedback	Zündstromrückmeldung

Keyword	English definition	German definition
IGK	Ignition key	Zündspannung
IGN	ignition	Zündung
IL	interactive layer	
ILSH	Current in the lambda sensor heater	Strom an der Lambda sondenheizung
IM	Intake manifold	Saugrohr
IMOB	Immobilizer	elektronische Wegfahrsperre
IMP	Impulse	Impuls
IN	Intake	Einlaß
INC	Increase	Inkrementierung
IND	Individual	individuell
INDU	inductive	induktiv
INF	intercept function	Abfangfunktion
INFO	information	Information
INH	Inhibition	hemmen
INI	Initialization	Initialisierungswert
INJ	injection	Einspritzung
INP	Input	Eingang
INT	Integral	Integral
INTER	Intermediary	Zwischenwert
INTM	intermittent	diskontinuierlich, sporadisch
INTR	interrupt	Unterbrechung
INTV	intervention	eingreifen
INV	intake valve	Einlaßventil
IP	index table with arbitrary many inputs with interpolation	Tabelle mit n-Engängen mit Interpolation.
IPLSL	pumping current of LSL	Strom an der linearen Lambdasonde
IPLSLPWM	PWM of pumping current of LSL	Tastverhältnis Strom an der linearen LS
IPM	IP table which is used in different modules with different input data	Kennfeld, das in mehreren Modulen mit unterschiedlichen Eingangsgrößen benutzt wird.
IPS	Idle position sensor	Leerlaufstellersensor
IS	Idle Speed	Leerlauf/Leerlauf-regler
ISA	Idle speed actuator	Leerlauffüllungssteller
ISAPWM	Pulse width modulation of idle speed actuator	Tastverhältnis Leerlauffüllungssteller
ISC	idle speed controler	Leerlaufregler
IT	internal	intern
ITC	integration time constant	Integrationszeit-konstante
IV	Injection valve	Einspritzventil
IVS	invers	invers
IVVT	infinitely variable valve timing	Regelvanos
IVVTHPWM	Holding pulse width modulation of infinitely variable valve timing	Haltetastverhältnis Regelvanos
IVVTPWM	Pulse width modulation of infinitely variable valve timing	Tastverhältnis Regelvanos
JAM	jam	klemmen
JERK	Jerk	Ruckeln
JUMP	Jump-start	Jump-start
KD	kick down	Kick down
KGH	Kilogram per hour	Kilogramm / Stunde

Keyword	English definition	German definition
KM	kilometer	
KNK	Knock control	Klopfregelung
KNKS	Knock control signal	Kopfregelungssignal
KNKWB	Beginning of knock control window	Klopfregelungsfenster-Beginnwinkel
KNKWD	Knock control window duration	Klopfregelungsfenster-Dauerwinkel
KNKWE	End of knock window	Klopfregelungs-fenster-Endewinkel
KWP	Keyword protocol 2000	
L	Low	Low
LAM	Lambda controler	Lambda/Lambda-regler
LAMB	Lambda	Lambda
LAT	lateral	
LB	low byte	
LBG	line breakage	Leitungsbruch
LC	logic calibration data	logische Konstante
LD	Loading degree determination	Beladungsgrad-ermittlung
LDC	limited dynamic conditions	begrenzte Dynamik
LDP	list of data points	Stützstellen einer Eingangs-variablen einer Tabelle.
LDPM	repeatedly used list of data points	Stützsellen einer Eingangs-variablen einer Tabelle, die mehrfach verwendet wird
LE	left	links
LEN	Length	Länge
LEVEL	level	Niveau
LFC	Long fuel circulation	großer Kraftstoffkreislauf
LGD	Low gear detection	Low Gang Erkennung
LGRD	Limitating gradient	Änderungs-begrenzung
LGT	longitudinal	
LID	local identifier	
LIH	Limp home	Notlauf
LIM	Limitation	Begrenzung
LINP	logical input	
LOAD	load	Last
LOADPWM	Load output	Tastverhältnis Lastsignal
LOC	local variable	lokale Variable
LOCK	lock	sperren
LOIL	Oil level	Ölniveau
LOILPWM	Oil level PWM	Tastverhältnis Ölniveau
LOSS	loss	Verlust
LOST	lost	verloren
LOUT	logical output	
LPF	Low pass filter	Tiefpaßfilter
LS	Lambda sensor	Lambdasonde
LSCL	Lamda sensor close loop	geschlossener Kreis
LSH	Lambda sensor heater	Lambdasondenheizung
LSHPWM	Pulse width modulation of lambda sensor heater	Tastverhältnis Lambdasondenheizung
LSL	linear lambda sensor	lineare Lambdasonde

Keyword	English definition	German definition
LSOL	Lambda sensor open loop	offener Kreis
LST	last	zuletzt, letzter
LTC	load transient correction	Lastschlagdämpfung
LV	Logic variables data	logische Variable
MAF	Mass air flow	Luftmasse
MAFM	Mass air flow meter	Luftmassenmesser
MAIN	Main	hauptsächlich
MAN	Manual	von Hand
MAP	Manifold air pressure	Saugrohrdruck
MASK	mask	maskieren, verbergen
MASS	mass	Masse
MAT	mathematical	mathematisch
MAX	Maximum	Maximum
MC	main controller	
MCL	missing cap lamp	Diagnoselampe für fehlenden Tankdeckel
MCPS	magnetic crank shaft position sensor	induktiver KW Sensor
MDL	model	Modell
MEC	mechanic	mechanisch
MEM	Memorise	Speicher
MES	measured	gemessen
MF	Fuel mass (diesel)	Einspritzmasse
MFF	mass fuel flow	Kraftstoffmassenstrom
MIL	Malfunction indication light	Diagnose-Fehler, -Lampe
MILM	Malfunction indication light memory	Fehlerspeicher für Anzeigelampe
MIN	Minimum	Minimum
MIS	Misfire	Verbrennungsaussetzer
MISS	missing	fehlen
MMV	Moving mean value	gleitender Mittelwert
MOD	Mode	Modus
MON	monitoring	überwachen
MON2	copy of process monitoring	Kopie der Prozeßüberwachung
MOSE	model series	Baureihe
MOT	motor	Motor
MOVE	movement	Bewegung
MPG	mapping	
MPH	miles per hour	Meilen / Stunde
MPL	Multiple	mehrfach
MSG	message	
MSR	Deceleration slip control	Motorschlepp-momentenregelung
MST	master	Master
MSW	multifunctional steering wheel	Multifunktionslenkrad
MT	Manual shifted transmission	Handschaltgetriebe
MTC	Main throttle control	Motordrosselklappe
MTCPWM	PWM-signal of MTC	Tastverhältnis MDK
MU	monitoring unit	Kontroll Einheit

Keyword	English definition	German definition
MUX	Multiplexer	Multiplexer
MV	Mean value	Mittelwert
MWSS	magnetic wheel speed sensor	induktiver Raddrehzahlsensor
N	Engine speed	Motordrehzahl
NACK	no acknowledge	keine Bestätigung
NAME	name	Name
NAT	Natural	natürlich
NC	no calibrated data	vom Applikationssystem nicht änderbare Daten
NEG	Negative	negativ
NEUT	neutral	neutral
NEW	new	neu
NF	Natural frequency	natural frequency
NL	Noise level	Geräuschwert
NLC	non calibratible logical constant	nicht applizierbare logische Konstante
NOISE	noise	Rauschen
NOT	Not ...	nicht
NOX	NOX	NOX
NR	Number	Nummer
NT	NOX trap	NOX Speicherkat.
NTL	NOX trap loading	NOX Speicherkatbeladung
NTLD	NOX trap loading degree	NOX Speicherkat-beladungsgrad
NULL	null	Null
NVMY	non volatile memory	nichtflüchtiger Speicher
O2	oxygen	Sauerstoff
O2L	oxygen loading	Sauerstoffbeladung
OBD	On board diagnosis	On board diagnosis
OBS	observe	beobachten
OC	Open circuit (hard.)	offener Schaltkreis
OCT	Octal power stage (ATM 39)	
OFF	Off	aus
OFS	Offset	Offset
OIL	oil	Öl
OK	ok	ok (bestanden, erledigt)
OLD	old	alt
ON	On	ein
OP	Opening period (diesel)	Offnungsdauer
OPEN	open	offen
OPL	Open loop	offener Regelkreis
OPM	operating mode	Betriebsart
OPP	operating mode	Betreibspunkt / Arbeitspunkt
OPT	optional	optional
OPTM	optimum	optimal
ORNG	out of range	außerhalb des Bereichs
OS	operating system	
OSC	Oscillate	oszillieren

Keyword	English definition	German definition
OUT	output	Ausgang
OV	output value	
OVB	overboost	
OVER	over	über
OVF	overflow	
OVS	oversteering	übersteuern
P	Proportional part of PID	proportionaler Anteil
PAR	parity	Parität
PARK	park	parken
PAS	Passive	passiv
PAT	Pattern	Muster
PCD	pressure control device	Druckregler
PCTL	pre-control	Vorsteuerung
PCU	Pump control unit (diesel)	Pumpensteuergerät
PCV	high pressure pump pressure control valve	
PEAK	peak	
PER	Period	Periode
PERC	per cent	Prozent
PGAS	gas pressure	Gasdruck
PHA	Phase	Phase
PHY	physical	physikalisch
PIA	parallel interface adapter	
PIN	pin	Pin
PL	Part load	Teillast
PLAUS	plausible	plausibel
PM	Puls modulator	Phasengeber
PN	Park neutral	Park neutral
POIL	Oilpressure	Öldruck
PONCLOFA	Power on to closure offset angle (diesel)	Magnetventil-Anzugswinkel
POP	post operating phase	Rechnernachlauf
PORT	port	Durchgang, Öffnung
PORTPWM	Port PWM	Tastverhältnis Drallklappe
POS	Positive	positiv
POST	Post	nach
POTI	Potentiometer	Potentiometer
POW	power	Leistung
PQ	Pressure quotient	Druckquotient
PR	positive response	
PRED	predicted	prädiziert
PREL	preliminary	vorläufig
PRES	Present	momentan
PREV	Previous	vor, vorab
PRG	progression	Progression
PRI	priority	Vorrang
PRIM	primary	primär
PRJ	project	Projekt

Keyword	English definition	German definition
PROG	programming	programmieren
PROP	Proportional	proportional
PROT	protection	Schutz
PRS	Pressure	Druck
PS	Pump shaft (diesel)	Pumpenwelle
PSI	Flow rate	Durchflußwert
PSN	position	Position
PSTE	Power steering	Servolenkung
PTR	pointer	Zeiger
PU	Pull	Schub
PUB	Pull begin	Schubbeginn
PUC	Pull fuel cutoff	Schubabschaltung
PUE	Pull end	Schubende
PULS	pulsation	Pulsation
PUR	Pull reduction	Schubreduzierung
PV	Pedal value	Pedalwert
PVS	Pedal value sensor (diesel)	Pedalwert
PVSL	permanent vehicle speed limiter	permanenter Geschw.-begrenzer
PWL	power latch	Hauptrelais
PWM	Pulse width modulation	Tastverhältnis
PWR	Power supply	Stromversorgung
QC	quantified charge	normierte Füllung
QF	Fuel quantity (diesel)	Einspritzmenge
QGAS	gas quality	Gasqualität
QOIL	Oil quality	Ölqualität
QOILPWM	Oil quality PWM	Tastverhältnis Ölqualität
QPS	Quad power stage (ATM 36 oder ATM 38)	
QUO	quotient	Quotient
R	Resistance	Widerstand
RA	general gas constant	allg. Gaskonstante
RAA	run away avoidance	Hochlaufunterdrückung
RAE	reactivation acceleration enrichment	Wiedereinsetzen BA
RAF	ratio of air fuel	Luftverhältnis
RAM	RAM	RAM
RAMP	ramp	Rampe
RAS	Radiator shutter	Kühlerjalousie
RATE	rate	Rate
RATIO	Ratio	Verhältnis
RAW	raw value	Rohwert
RCV	receive	erhalten, empfangen
RD	read	lesen
RE	rear	hinten
REAC	reactivation	Wiedereinsetzen
READY	readiness identification	Bereitschaftserkennung
REC	record	aufzeichnen
RED	Reduction	Reduktion

Keyword	English definition	German definition
REF	Reference	Referenz
REFU	refuel	betanken
REINF	reinforce	
REL	Relative	relativ
REQ	Request	Anforderung
RESI	residual	Rest
RESP	response	Antwort
REST	Restart	Wiederholstart
RESU	resume	wiederaufnehmen
REV	Revolution	Umdrehung
RFL	Reactivation Full Load	Wiedereinsetzen Vollast

ROM	read only memory	
RON	research octane number	
RPG	reprogrammation	
RPL	Reactivation Part Load	Wiedereinsetzen Teillast
RPU	Reactivation Pull	Wiedereinsetzen Schub
RR	Rough road	Schlechtwegstrecke
RS	reed switch	Reed switch
RST	Reset	rücksetzen
RT	runtime	Laufzeit
RTD	Retard	spät
RUL	Running losses	running losses
RUN	Runing (working)	laufen
RVL	Reversing light	Rückfahrlicht
RWUP	Rich warm up	fetter Warmlauf
S	stratified	geschichtet
SA	Secondary air	Sekundärluft
SAF	secondary air flow	Sekundärluft-massenstrom
SAM	Siemens Application and Measurement System	

Keyword	English definition	German definition
SAMPLE	sample	Sample
SAMS	SAMS	SAMS
SAP	Secondary air pump	Sekundärluftpumpe
SAPPWM	secondary air pump PWM	
SAS	Safety Cut Off	Sicherheits-schubabschalten
SAV	Secondary air valve	Sekundärluftventil
SAVE	save	speichern
SAVPWM	Secondary air valve PWM	Tastverhältnis Sekundärluftventil
SAWUP	secondary air warm up	
SC	supercharged	aufgeladen
SCA	Scale	Skala
SCAN	scan	
SCB	short circuit brush	Schleiferkurzschluß
SCC	Single cylinder cut off (MSR)	Einzelzylinder-abschaltung
SCG	Short circuit ground	Masseschluß
SCHA	supercharger	mechanischer Lader
SCP	Short circuit plus	auf Betriebsspannung
SDL	scheduler	Verteiler
SDR	status diagnostic result	Status Diagnoseergebnis
SDWN	Shift down	zurückschalten
SECU	Security	Sicherheit
SEED	Seed	Zugangsberechtigung
SEG	Segment	Segment
SEL	selective	selektiv
SEM	successive error management	Folgefehlerbetrachtung
SENS	Sensor	Sensor
SEQ	Sequential	sequentiell
SER	serie	Serie
SERVO	servo	Servo
SET	Set	einstellen
SF	status flag	Status Flag
SFC	Short fuel circulation	kleiner Kraftstoffkreislauf
SFT	sensor frequency time	Sensorfrequenzzeit
SHD	Shield	Schirmung
SHIFT	shift	Verschiebung
SIF	seriel interface	serielle Schnittstelle
SIG	signal	Signal
SIM	Simulation	Simulation
SLAVE	Slave	
SLIP	Slip	Schlupf
SLM	Smoke limitation (diesel)	Rauchdichtebegrenzung
SLOP	slope	Steigung
SLOW	Slow	langsam
SLV	solenoid valve	Magnetventil
SND	send	

Keyword	English definition	German definition
SO2	sulphur dioxide	Schwefeldioxid
SO2P	desulfuration	Entschwefelung
SOA	start of air	Start Lufteinblasung
SOI	Start of injection	Einspritzbeginnwinkel
SOIL	Oil sensor signal	Ölsensorsignal
SOP	Start of pumping (diesel)	Förderbeginnwinkel
SOV	Shut off valve of evap function	Aktivkohlefilterabsperrventil
SP	Setpoint	Sollwert
SPARE	Spare	Reserve
SPI	Serial peripheral interface	
SPR	spring	Feder
SRC	Source	Quelle
ST	Starting	Start
STAB	stability	
STALL	Stalling	Motor abwürgen
STAT	stationary	stationär
STATE	State	Zustand
STB	Standby	Standby
STC	statistic	statistisch
STC	storage capacity	Speicherkapazität
STD	standard deviation	Standardabweichung
STE	Start enable	Startfreigabe
STEP	Step	Stufe
STK	stroke	Hub
STND	Standardization	Normierung
STOP	stop	stop
STP	Stepper motor	Schrittmotor
STR	starter relais	Anlasser Relais
SUB	Substitude	Ersatzgröße
SUBT	Subtractive	subtraktive Korrektur
SUM	Sum	Anzahl
SUP	Shift up	hochschalten
SUPP	suppress	unterdrücken
SUSP	suspicion	Verdacht
SVL	Service vehicle light	Servicelampe
SW	software	Software
SWI	Switch	Schalter
SWT	sensor switching time	Sensorsprungzeit
SYM	Symptom	Symptom
SYN	Synchro	Synchron
SYS	system	System
T	time	Zeit
TAC	After catalyst temperature	Abgastemperatur nach Katalysator
TACE	evaporative temp.air conditioning	
TAM	ambient temperature	Umgebungstemperatur
TAR	target	Ziel

Keyword	English definition	German definition
TBA	Boost air temperature (diesel)	Ladelufttemperatur
TBAT	battery temperature	Batterietemperatur
TBL	table	
TC	throttle control	
TCC	test cycle counter	Prüfintervallzähler
TCI	coolant temperature in	TKW Motoreintritt
TCO	Coolant temperature	Kühlwassertemperatur
TCOPWM	Coolant temperature PWM	Tastverhältnis Kühltemperatur
TCS	traction control system	Traktionskontrolle
TCSPWM	Traction control PWM	Tastverhältnis Traktionskontrolle
TCU	Time control unit	
TCYL	cylinder air temperature	Lufttemp. im Zylinder
TD	Time dwell	Schließzeit
TDC	Top dead center	oberer Totpunkt
TEG	Exhaust gas temperature	Abgastemperatur
TEGR	EGR temperature	Temperatur AGR
TEMP	Temperature	Temperatur
TEST	test	Test
TFU	Fuel temperature	Kraftstofftemperatur
TGAS	gas temperature	Gastemperatur
TGT	tightness	Dichtigkeit
TH	Thermostat	Thermostat
THD	Threshold	Schwellwert
THE	Theoritical	theoretisch
THEAT	heater temperature	Heizlufttemperatur
THERMO	thermo	thermisch
THM	Thermic inertia of the engine	
THR	Throttle	Drosselklappe
TI	Injection time	Einspritzzeit
TIA	Intake air temperature	Ansauglufttemperatur
TIP	tip	getastet
TIPO	Post injection time	Nacheinspritzer-Einspritzzeit
TIPR	Pre injection time	Vorabeinspritzer-Einspritzzeit
TIT	Titanium	Titan
TLDP	Tank leakage detection pump	Tankleckagediagnosepumpe
TLDV	tank leakage detection valve	Leckdiagnoseabschaltventil
TMAG	coil temperature of magnetic valve IVVT	Spulentemperatur VANOS Magnetventil
TMP	temporary	temporär
TNT	temperature Nox trap	
TOG	toggle	toggle
TOIL	Oil-Temperature	Öltemperatur
TOILPWM	Oil temperature PWM	Tastverhältnis Öltemperatur
TOL	Top limit	obere Grenze
TOOTH	Tooth	Zahn
TORS	torsion	Torsion
TOT	Total	gesamt

Keyword	English definition	German definition
TOUT	time out

WG	Waste gate	
WGPWM	Waste gate pulse width modulation	
WHEEL	Wheel speed	Rad
WIN	Window	Fenster
WIND	Windscreen	Windschutzscheibe
WKU	Wake up	wake up
WKUL	Wake up line	Reizleitung-Signal
WORD	word	word
WORK	work	Arbeit
WOUT	without	ohne
WR	write	schreiben
WUP	Warm up	Warmlauf
ZR	Zirconium	Zirkon

The designation of the variables used informs about the type (index table, table, constant), the input and output variables (e.g. TI, TCO etc.), the operating state (e.g. FL, PL, IS) and the dependent parameters, if any (e.g. f (engine speed)).

The designation index table (IP_) means that the index table value is obtained by interpolation in a unidimensional or multidimensional area.

A table (ID_) also can be uni- or multidimensional.
The table value is not obtained by interpolation.

The allocation of the table values to the data points is defined as follows:
A table value i applies if the input value is greater than or equal to the data point i.
Exception: The table value 1 applies in case of input values less than the data point 2.

```
                                                                                     LDP 8
                                                                           LDP 7       | 8
                                                             LDP 6           | 7        |______
                                                   LDP 5       | 6           |______
                                     LDP 4           | 5       |_____
                           LDP 3       | 4           |______
               LDP 2         | 3       |_____
Table            | 2         |_____
value 1          |_____
_______
     |
     |
  LDP 1 (=Input value  <  LDP 2)
```

Unless otherwise specified, the data points are not subject to hysteresis.

Example of nomenclature:

The term "IP_TIB__N__MAF" means that the index table value TIB (basic injection period) is obtained by a two-dimensional interpolation.

The dependence of the index table value is defined by the suffix __N__MAF :
TIB is a function of the engine speed data point and of the air mass data point, i.e. of the general engine speed and air mass data points.

The descriptions of variables and of the free adjustable data points, together with their value ranges and resolutions, are shown in the Annex.

36.5 AT Library - short description

36.5.1 General

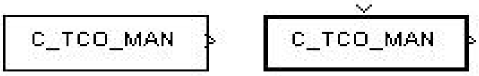
This document is a short reference to all AT Library blocks. It aims to help the reading of SDA based specifications. The complete library reference is available with the current SDA installation.

Optional inputs and outputs: Some blocks can have optional inputs and outputs, which are made available when necessary. These outputs are normally not shown in the example pictures, but described on the explanations.

Maps, curves and axis: Maps and curves are related to their axis definitions. This information can be consulted at the calibration section in the given specification.

Index base: Block inputs for indices can be one-based (standard) or zero-based (special cases). The index base is shown subscripted. For instance R0 stands for "row index, zero-based". Other examples: bit_sel0, x1, y0. See "selector" block example, on this document in chapter 1.8, page 9.

Triggered blocks: Most of the blocks have an optional trigger input. This port accepts function-call connection, which determinate when these blocks shall be calculated. Example:



36.5.2 Block versioning

The block version is shown since SDA 5.0 release. Please note the following:

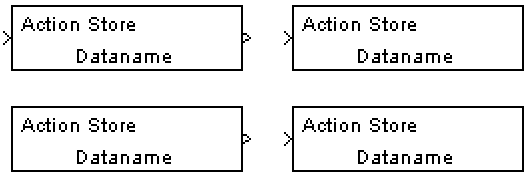
- Blocks from previous SDA versions do not show any version information.
- The version information is shown on the block icon or below it in the format "*V X.Y*".
- Functional change or relevant appearance changes reflects on version information update (only on "X"). A change in "Y" is not functional or appearance relevant. For instance, the versions 5.1, 5.4, 5.13 have all the same appearance and functional behavior.
- The part "X" of the block version number is not coupled to SDA release number. The first block version since SDA 5.0 is "5." for all libraries though.
- All functional changes done to AT Library blocks between SDA releases are shown in this document and in the according library documentation within the SDA installation.
-

36.5.3 Functional behaviour

The blocks of version 6.x have the same functional behaviour than the blocks of version 5.x. The changes in the blocks are only related to code generation and/or to adaptation to the ASAM MBFS standard.

36.5.4 Action Handling

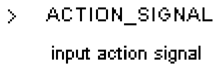
Action_Data_Store (V. 5) **Action_Data_Store_Init (V. 5),**
Read_Action_Data_Store (V. 5) **Write_Action_Data_Store (V. 5)**



These blocks are used to model the initialization and read/write access to an action internal storage that can be accessed by all instances of this action and inside the module defining the action.

If this storage is only used inside the action instance or inside the defining module it is listed as local data on the specification.

Input_Action_Signal (V. 5)



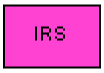
This block is used to model nested Actions (reused Action inside an Action). Here the Action Signal needed for the reused Action is fed in by an Action Input.

Input_To_Action (V. 5) **Output_From_Action (V. 5)**

The Input_To_Action block is used to model an input to an Action that is unique for all action instances and calculated outside of the module that defines the action.

The Output_From_Action block is used to model an output of an action (shared storage) and of the defining module. The value can be set by all instances of the action and inside the module defining the action.

IRS (V. 5)



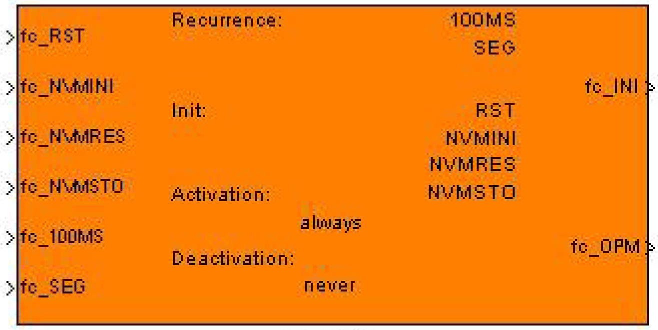
This block indicates that the according subsystem belongs to an Infrastructure Requirement Specification (IRS).

Action Parameters (V. 5.)

The blocks PAR_IN, PAR_OUT and PAR_INOUT are used to model action input, output and input-output parameters.

36.5.5 Application Condition

APP_CDN (V. 5) (V. 6)



APP_CDN

The Application Condition block displays the activation conditions for the according module. It controls when the module is activated or deactivated. All function calls triggering or initializing the functionality of a module are input to the APP_CDN block. Dependent on the activation condition the function calls are fed through the block or not. The Application Conditions are displayed in textual form within the specification.

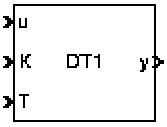
In the above example of the block the according module is always active and never inactive. The initialization is triggered by the Reset (RST) event and the Nonvolatile Memory (NVM...) events. The according function calls are output in bus of function calls fc_INI.

The operate mode is triggered by the 100ms event and the segment synchronous event. The according function calls are output in a bus of function calls fc_OPM.

36.5.6 Basic Algorithms

DT1 Element (V. 5.) (V. 6)

The output signal y is calculated from the input signal u, the amplification factor K and the time constant T according to the following functions:

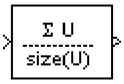


DT1_element

$$z1[n] = (u*K/T);$$
$$z2[n] = z2[n-1]+ (Teff / (T+Teff))*(z1[n] - z2[n-1]);$$
$$y[n] = z1[n] - z2[n];$$

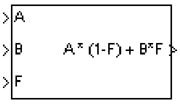
T	Time Constant
u	Input signal
K	Amplification factor

mean value (V. 5.) (V. 6)



This block outputs mean value of elements of a single input vector.

fading (V. 5.) (V. 6)



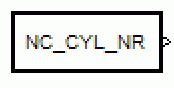
This block implements the fading calculation:

Inputs: A, B, F.

Output: Out=A*(1-F)+B*F.

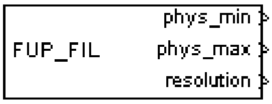
36.5.7 Calibration_Data_Handling

Constant (V. 5.) (V. 6)



Outputs the value specified by a constant or parameter, which can be a scalar or array. The example's output gives the value contained in the constant NC_CYL_NR (a configuration data).

from_data_definition (V. 5.) (V. 6)



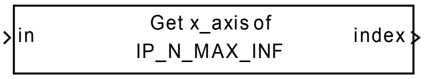
This block reads chosen fields from data definition of specified data (e.g. FUP_FIL) and gives them as outputs. The possible fields to output: minimal physical value, maximal physical value, resolution and states (only for state variables).

Get Curve Index (V. 5.)

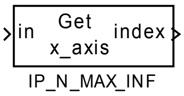
This block outputs the next smallest index from the input axis value. It considers the axis of the selected curve. Indexing starts from zero.

In	Axis value on the axis of the curve
Out	Index of the axis value on the axis of the curve

Get Map Index (V. 5.) (V. 6)

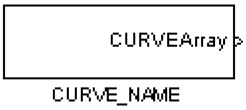


This block outputs the next smallest index of the input axis value on the selected axis (x_axis or y_axis) of the selected map. Indexing starts from zero.



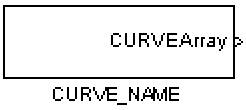
in	Axis value of the specified axis in a map
index	Index of the axis value on the specified axis of the map

getCurveArray (V. 5.)



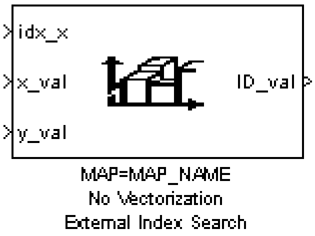
Generates a signal which carries the values from the selected calibration data (an array of curves).

getMapArray (V. 5.) (V. 6)



Generates a signal which carries the values from the selected calibration data (an array of maps).

id_lookup (V. 5.) (V. 6)



This block implements the lookup operation over a non interpolated map or array of maps. A single map has one dimension (calibration curve) or two dimensions (calibration map).

The name of the map is specified by "MAP".

The block supports 3 different modes:

- "local": The map is read from base workspace and only the look up value is exported via the output
- "exported": The map is read from base workspace and the look up value together with the complete map array is exported.
- "imported": The map is read from an inport, as an array signal.

The block outputs the lookup value "ID_val" connected with the next smaller index to the axis values "x_val" and "y_val". There is no interpolation or extrapolation between axis values.

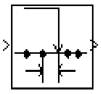
With the option "External Index Search", the search for the axis indices can be done externally (see index_search block). The ports "x_val" and "y_val" are named "x_frac" and "y_frac". In this case, the values on "x_frac" and "y_frac" are directly used as index and fraction values for the map lookup.

The ports "idx_x", "idx_y" and "idx_z" specify the indices selecting a map to be read from the given map array, if an array of maps is used. Their availability as input ports depends on the array dimensions, which can be consulted at the calibration section in the given specification.

For access to an array of maps, the block can be set to:

- "Scalar vectorization" mode: All maps in the array are read with the same inputs for "x_val" and "y_val". The output is a vector carrying the lookup values.
- "Array vectorization" mode: All maps in the array are read with separate values from the inputs "x_val" and "y_val", which are arrays. The output is a vector carrying the lookup values.
- "No vectorization" mode: The lookup operation is calculated for one map which is selected through the inputs "idx_x", "idx_y" and "idx_z". Values for "x_val" and "y_val" are than scalar, as also the output lookup value.

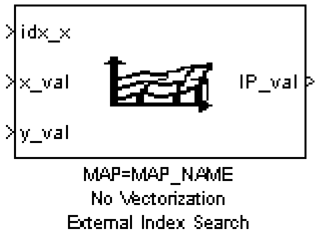
index_search (V. 5.) (V. 6)



The index-search block calculates the zero-based indices and interval fractions for the input value for a selected axis.

The block generates a pair of outputs for each input value by calculating the zero-based index of the breakpoint set element that is less than or equal to the input value and the resulting fractional value (*f* were: 0 <= *f* < 1). This represents the input value's normalized position between the index and the next index value for in-range input.

ip_lookup (V. 5.) (V. 6)



This block is analogous to the id_lookup block. The difference is the output lookup value, which is interpolated.

IP_val is calculated by a linear interpolation through the map values. There is linear interpolation between axis values.

The name of the map is specified by "MAP".

The block supports 3 different modes:

- "local": The map is read from base workspace and only the look up value is exported via the output
- "exported": The map is read from base workspace and the look up value together with the complete map array is exported.
- "imported": The map is read from an inport, as an array signal.

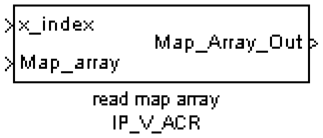
With the option "External Index Search", the search for the axis indices can be done externally (see index_search block). The ports "x_val" and "y_val" are named "x_frac" and "y_frac". In this case, the values on "x_frac" and "y_frac" are directly used as index and fraction values for the map interpolation.

The ports "idx_x", "idx_y" and "idx_z" specify the indices selecting a map to be read from the given map array, if an array of maps is used. Their availability as input ports depends on the array dimensions, which can be consulted at the calibration section in the given specification.

For access to an array of maps, the block can be set to:

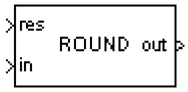
- "Scalar vectorization" mode: All maps in the array are read with the same inputs for "x_val" and "y_val". The output is a vector carrying the lookup values.
- "Array vectorization" mode: All maps in the array are read with separate values from the inputs "x_val" and "y_val", which are arrays. The output is a vector carrying the lookup values.
- "No vectorization" mode: The lookup operation is calculated for one map which is selected through the inputs "idx_x", "idx_y" and "idx_z". Values for "x_val" and "y_val" are than scalar, as also the output lookup value.

read_Map_Array (V. 5.) (V. 6)



This block selects and output the map specified by the input indexes "x_index", "y_index" and "z_index" as a signal. Not shown indexes have standard value "1". The input is an array of maps.

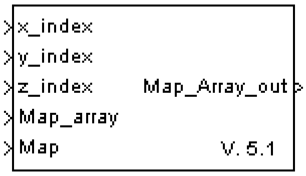
to_resolution (V. 5.) (V. 6)



This block provides the possibility to reduce data with a higher resolution to a lower one. Three types of reduction are possible: truncation (ceils or floor) and round-up to a given resolution. The chosen conversion method is shown in the block icon: ROUND, CEIL or FLOOR. The resolution value can be obtained from the optional input port "res" or given as a block annotation.

write Map Array (V. 5.) (V. 6)

Outputs a map array signal "Map_Array_out" which is a copy from the input array signal "Map_Array", where the single map specified by the input indexes "x_index", "y_index" and "z_index" is substituted by the values of the input "Map". Not shown indexes have standard value "1".

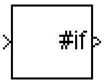


write map array
MAP_NAME

36.5.8 Control_Structures

Compiler switch if (V. 5.) (V. 6) **compiler switch (V. 5.) (V. 6)**

These blocks are used to model compiler switches.



compiler_switch_if : If condition is true then output function call '#if'.

compiler_switch: If condition is true then output function call '#if' else output function call '#else'

do while loop

do while loop (V. 5.) **while loop (V. 5.)**

While-Control Structure and Do-While-Control Structure:

As long as condition is true the function call "while" is cast. The only difference between the blocks is when the condition is checked for the first time. The while_loop block checks the condition before it performs first function call. do_while_loop performs the function call at first and only after that checks the condition. The optional output 'i' indicates the current number of execution.

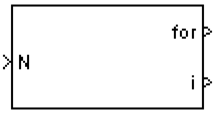
while loop

To omit an endless loop the while is only executed as long as the number of iterations is smaller than the defined maximum (default 500, for model simulation).

for loop (V. 5.)

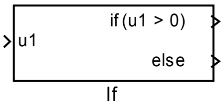
For-Loop-Control Structure:

Executes for-loops function-calls, where the optional output "i" runs from 0 (or 1) to N. The output "for" is a function call signal triggering the according subsystem that contains the functionality within the for loop.



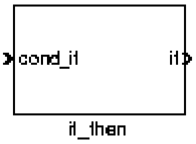
for i = 1 to N

If (V. 6)



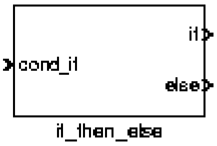
If...Then...Else-Control Structure: If condition 'u1' is true then output action call 'if' else output action call 'else'. In difference to the following if-then-else blocks this block outputs SL action calls instead of function calls.

If...Then (V. 5.) (V. 6)



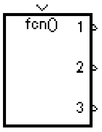
If...Then-control structure: If condition 'cond_if' is true then output function-call 'if'.

If...Then...Else (V. 5.) (V. 6)



If...Then...Else-Control Structure: If condition 'cond_if' is true then output function call 'if' else output function call 'else'.

sequencer (V. 5.) (V. 6)

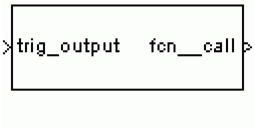


This block generates an ordered sequence of function calls. The number of output ports is variable. The user has a possibility to select in the block mask between three operation variants:

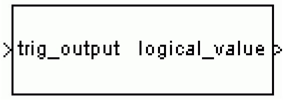
- "not triggered" - the output function calls are generated when the block is calculated;
- "function call triggered" - the output function calls are generated when the block is triggered. In this case block has an extra function call trigger input;
- "logical triggered" - the block has an extra input port "trigg". The output function calls are generated when this input has a value different than zero.

Triggeroutport 2 fcn call (V. 5)

This block generates a function call if the input is different to zero. The block can be used in connection with a trigger block output.



Triggeroutport 2 logical (V. 5)

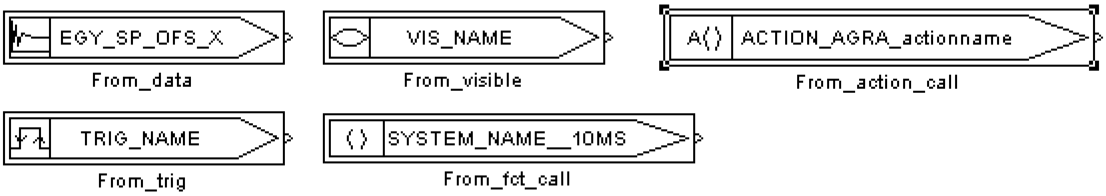


Conversion of a trigger signal into a logical value. This block generates a logical 1 if the input is different to zero. The output is zero otherwise. The block can be used in connection with a trigger block output.

36.5.9 Signal Types

FROM_DATA (V. 5) **FROM_FCT_CALL (V. 5)** **FROM_TRIG (V. 5)**

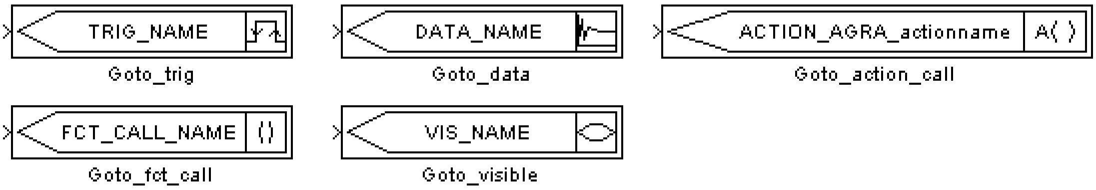
FROM_VISIBLE (V. 5) **FROM_ACTION_CALL (V. 5)**



From_data, From_fct_call, From_trig or From_visible is a From block with scope global for the use with global data, function call, trigger or visible signals only. This From blocks get~~s~~ the signal from a corresponding Goto block.

GOTO_DATA (V. 5.) **GOTO_FCT_CALL (V. 5.)** **GOTO_TRIG (V. 5.)**

GOTO_VISIBLE (V. 5.) **GOTO_ACTION_CALL (V. 5.)**



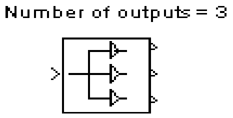
Goto_data, Goto_fct_call, Goto_trig or Goto_visible is a Goto block with scope global for the use with global data, function call, trigger or visible signals only. The signal is sent to a corresponding From block.

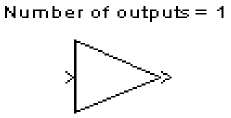
GOTO **FROM**

Goto and From blocks with scope local. The blocks represent a signal line between the Goto and the From block. In the example the signal TCO is submitted between the blocks.

36.5.10 Signals

branch (V. 5.) (V. 6)

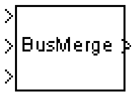




This block creates one or more copies from the input signal, which can than be directly used as input to a merge block.

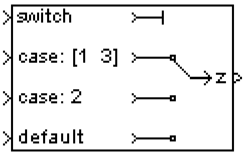
Input signal can be a scalar, a vector or a bus. In case input signal is a bus, every output signal is also a bus with the same bus structure as the input.

BusMerge (V. 5.) (V. 6)



This block constructs a bus output holding the union of all elements of the input busses in a flat bus structure. Flat structure means that the exported bus has only one hierarchy level. Signals that are input on more than one of the input busses are merged separately before being added to the output bus.

case multiport switch (V. 5.) (V. 6)



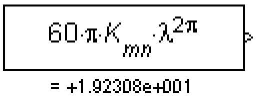
The block connects one of the "case" input ports (or default port) to the output port.

It receives a value on the input port "switch", which is compared to case conditions that determine which of the other input ports is connected to the output port.

If the value on the control port "switch" does not match any case condition, the "default" input is connected to the output.

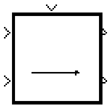
In the example picture, if the value of "switch" is 1 or 3, the port "case: [1 3]" is connected to the output. If its value is 2, than the port "case: 2". Else, the default port is used.

constant value (V. 5.) (V. 6)



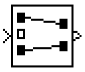
Outputs a constant value with the possibility to show the icon as formula expression. The calculated value is shown on the block annotation.

FeedThrough (V. 5.) (V. 6)



The FeedThrough block outputs the input values if the function-call occurs. The output maintains its last changed value. The number of input and output ports is variable.

Selector (V. 5.) (V. 6)

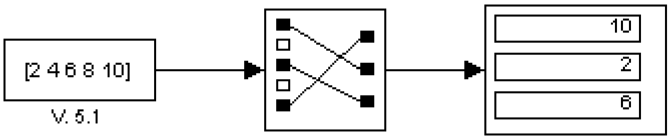


The Selector block generates as output selected elements of an input vector or matrix. It accepts either vector or matrix signals as input. The block icon changes to reflect the type of input used. The way the block determines the elements to select differs slightly, depending on the type of input.

Vector Input

If the input type is vector, a Selector block outputs a vector of selected elements. The block determines the indices of the elements to select either from the block's Elements parameter or from an external signal.

The elements to be selected must be specified as a vector unless only one element is being selected. For example, the following model shows the Selector block icon and the output for an input vector of [2 4 6 8 10] and an Elements parameter value of [5 1 3].



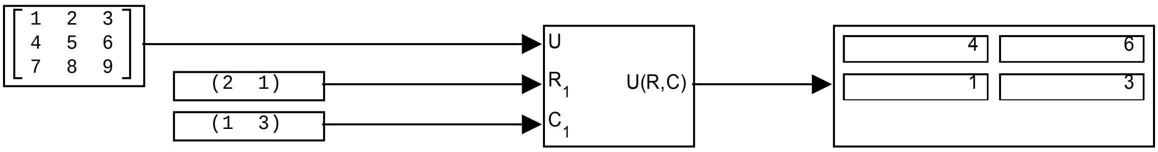
The block icon displays the ordering of input vector elements graphically if the block icon is large enough. If external source for element indices is used, the block adds an input port for the element indices signal.

Matrix Input

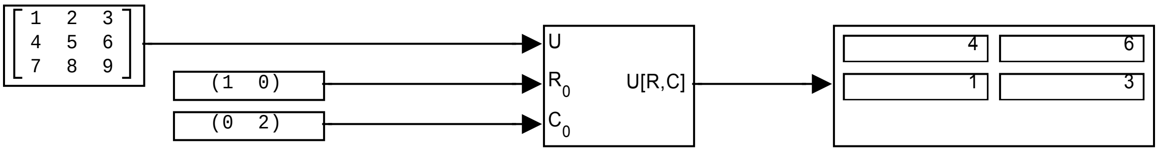
If the input type is matrix, the Selector block outputs a matrix of elements selected from the input matrix. The block determines the row and column indices of the elements to select either from its Rows and Columns parameters or from external signals (input ports "R", for row, and "C" for column selection).

The indices of the row and columns to be selected must be specified as vectors (or a scalar if only one row or column is to be selected). For example, the Rows expression [2 1] and the Columns expression [1 3] specifies output of a 2x2 matrix whose first row contains the first and third elements of the input matrix's second row and whose second row contains the first and third elements of the input matrix's first row.

Using one-based indexing:

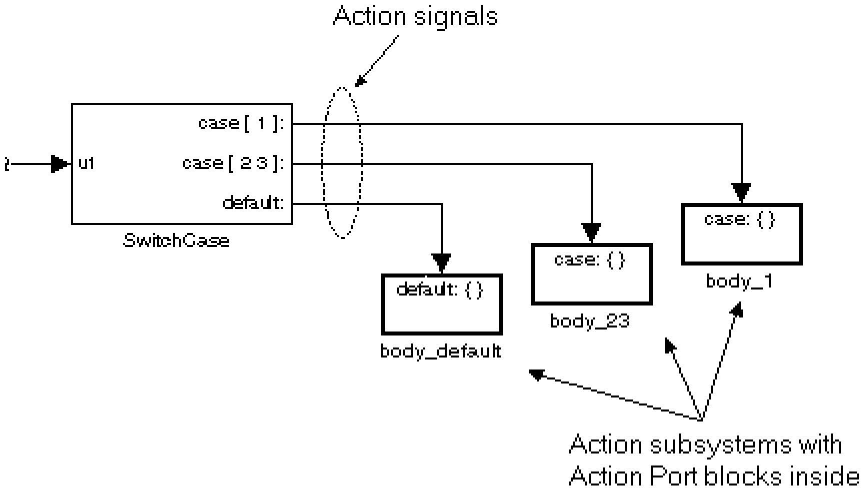


Using zero-based indexing:



Switch Case (V. 5.) (V. 6)

The following shows a completed Simulink C-like switch control flow statement in the subsystem of the SwitchCase block.



As shown in the above example, a Switch_Case block receives a single input, which it uses to form case conditions that determine which Action subsystem to execute. Each output port case condition is attached to an Action subsystem. The cases are evaluated topdown starting with the top case. If a case value (in brackets) corresponds to the actual value of the input, its Action subsystem is executed.

The above switch control flow statement can be represented by the following pseudo code:

```
switch (u1) {
    case [u1=1]:
        body_1;
        break;
    case [u1=2 or u1=3]:
        body_23;
        break;
    default:
        bodydefault;
}
```

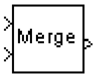
Note: As demonstrated in the pseudo code example above, cases for the SwitchCase block contain an implied break after their Action subsystem is executed. There is no "fall through" behaviour for the Simulink switch control flow statement as found in standard C switch statements.

Note: The naming "Action" in this block is not connected to "Actions" defined in the SV Action concept.

logical value (V. 5.) (V. 6)

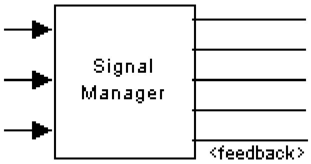
Block outputs logical TRUE or FALSE.

Merge (V. 5.) (V. 6)



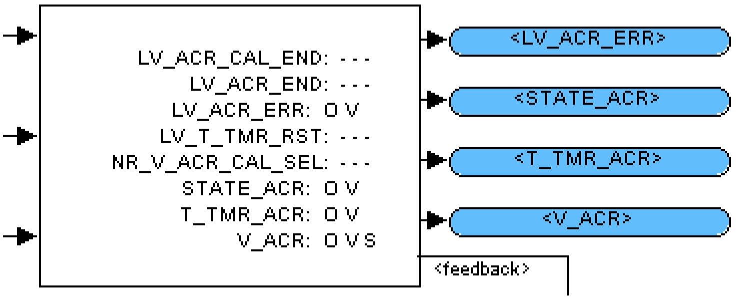
The Merge block combines its inputs into a single output line whose value at any time is equal to the most recently computed output of its driving blocks. The Merge block often is used to merge a calculation signal with a reset signal.

SignalManager (V. 5.) (V. 6)



This block merges signals contained in the input busses. It supports two or more input busses. Optional configurations:

- Output with "feedback" bus, which contains all merged signals. The feedback bus is routed back to the operate subsystem.
- "Show signal names on the mask". Where:



- Outports represent the module outputs;

"O": module output;

"V": visible variable;

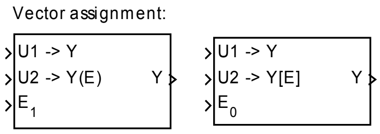
"S": NVMY data;

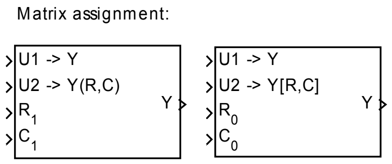
"---": Local variable

Note: Only local signals that are present on one of the input busses to this block are displayed on the block mask

36.5.11 Vectors and Matrices

Assignment (V. 5.) (V. 6)





The Assignment block assigns values from input U2 to selected elements of array input U1, producing the array output Y. Equivalent operation:

Vector assignment:

```
Y = U1;
Y[E] = U2;
```

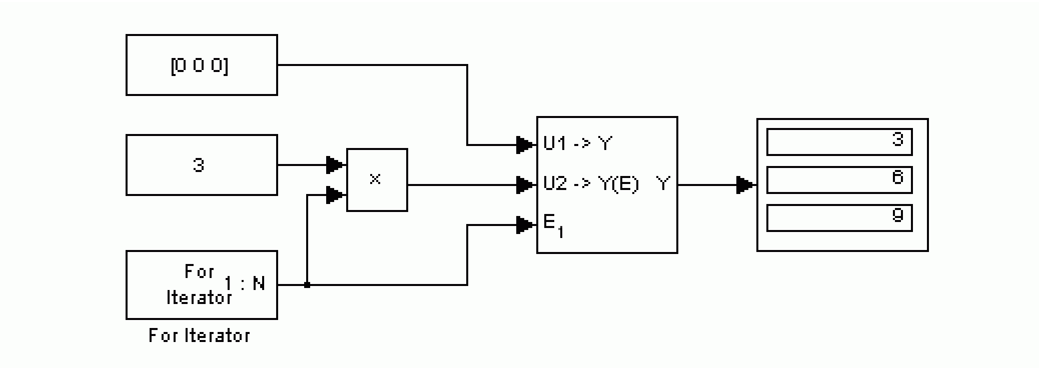
Matrix assignment:

```
Y = U1;
Y[R,C] = U2;
```

On a vector assignment, the input E is used to select the assignment position. On a matrix assignment, the inputs R (row) and C (column) are used to select the assignment position. The assignment position can be a scalar, a vector or a matrix, depending on the dimension of E, or the combined dimensions of R and C.

Example: iterated Assignment

The Assignment block can be used to assign values computed in an iterator (For or While) loop to a vector or matrix signal. The iterator block generates the indices required by the Assignment block. Two iterator blocks are needed to compute row and column indices separately. For example, the following model uses a For block to create a vector signal each of whose elements equals 3*i where i is the index of the assignment element.



Dec2Bin (V. 5.) (V. 6) Bin2Dec (V. 5.) (V. 6)

These blocks convert an integer into a binary number and vice versa. The number of bits can be set to 8, 16, 32 or 64. For decimal numbers the digits after the comma will be cut off. The binary numbers are displayed with leading highest exponent: [2^n, ...,2^1,2^0].

Important: these blocks suffered functional modification from version 3.1 to 4.0. See below.

Pseudo-code since SDA 4.0

```
Dec2Bin:
for ( i=0; i<no_bits; i++) {
    bit_vector[ no_bits - i] =
                      num_dec.i;
}
```

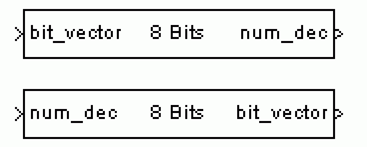
Pseudo-code for SDA 3.1

```
Dec2Bin:
for ( i=0; i<8; i++) {
    8bit_vector[i+1] = num_dec.i;
}

Bin2Dec:
```

Bin2Dec:

```
num_dec = 0;
for ( i=0; i<no_bits; i++) {
    num_dec = num_dec +
              bit_vector[no_bits-i]
              * 2^i;
}
```



First element in bit vector is most significant bit. E.g. **10000000 is equal to 128**

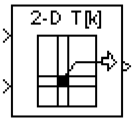
```
num_dec = 0;
for ( i=0; i<8; i++) {
    num_dec = num_dec +
              8bit_vector[i+1]
              * 2^i;
}
```

Dec2Bin

Bin2Dec

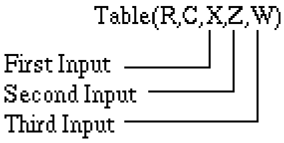
First element in bit vector is less significant bit. E.g. **10000000 is equal to 1**

DirectLookUp (V. 5.) (V. 6)



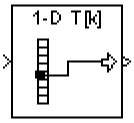
Index into an N-dimensional table to retrieve a scalar, vector or 2-D matrix. The Direct Look-Up Table (n-D) block uses its block inputs as zero-based indices into an n-D table. The number of inputs varies with the shape of the output desired. The output can be a scalar, a vector, or a 2-D matrix. The look-up table uses **zero-based** indexing.

A set of output values can be defined as the Table data parameter. The output can be a scalar, a vector or a 2-D matrix. The first input specifies the zero-based index to the first dimension higher than the number of dimensions in the output, the second input specifies the index to the next table dimension, and so on, as shown by this figure:

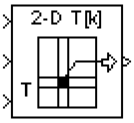


The figure shows a 5-D table with an output shape set to "2-D Matrix"; the output is a 2-D Matrix with R rows and C columns.

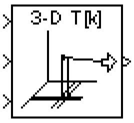
This figure shows the set of all the different icons that the Direct Look-Up Table block shows (depending on which options you choose in the block's dialog box).



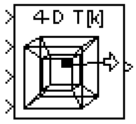
Direct Look-Up Table (n-D)



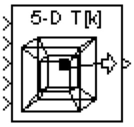
Direct Look-Up Table (n-D)3



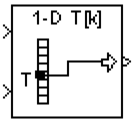
Direct Look-Up Table (n-D)6



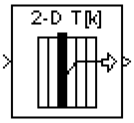
Direct Look-Up Table (n-D)9



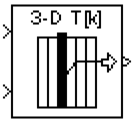
Direct Look-Up Table (n-D)12



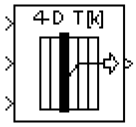
Direct Look-Up Table (n-D)1



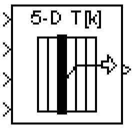
Direct Look-Up Table (n-D)4



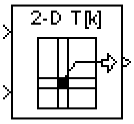
Direct Look-Up Table (n-D)7



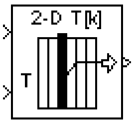
Direct Look-Up Table (n-D)10



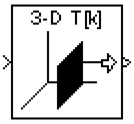
Direct Look-Up Table (n-D)13



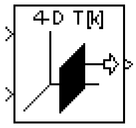
Direct Look-Up Table (n-D)2



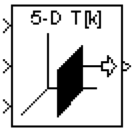
Direct Look-Up Table (n-D)5



Direct Look-Up Table (n-D)8



Direct Look-Up Table (n-D)11



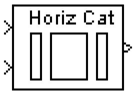
Direct Look-Up Table (n-D)14

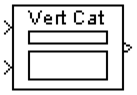
With dimensions higher than 4, the icon matches the 4-D icons, but will show the exact number of dimensions in the top text, e.g., "8-D T[k]." The top row of icons is used when the block output is made from one or more single-element lookups on the table. The blocks labelled "n-D Direct Table Lookup5," 6, 8 and 12 are configured to extract a column from the table and the two blocks ending in 7 and 9 are extracting a plane from the table. Blocks in the figure ending in 10, 11 and 12 are configured to have the table be an input instead of a parameter.

get_bit (V. 5.) (V. 6)

This block gets the values of specific bits of the decimal number obtained from the input port "num_dec". The output can be either single value or vector depending on the input given through "bit_sel" input port. The input "bit_sel" can be a single value or a vector. It selects the bits used in this operation. Bits are selected by its position number from the less significant bit (position 0 or 1) to the most significant bit (7, 15, 31, 63 or 8, 16, 32, 64). The user has possibility to select between zero or one based indexing for "bit_sel".

MatrixConcatenation (V. 5.) (V. 6)





The MatrixConcatenation block concatenates input matrices u_1, u_2, ..., u_n along rows or columns, where n is specified by the number of input ports.

Horizontal Matrix Concatenation

In the horizontal concatenation mode, the block concatenates the input matrices along rows.

y = [u1 u2 u3 ... un] % Equivalent MATLAB code

For horizontal concatenation, inputs must all have the same row dimension, M, but may have different column dimensions. The output matrix has dimension M-by- Ni, where Ni is the number of columns in input ui (i = 1, 2, ..., n). When some of the inputs are length-M 1-D vectors while others are M-by-Ni matrices, the vector inputs are treated as M-by-1 matrices.

Vertical Matrix Concatenation

In the vertical concatenation mode, the block concatenates the input matrices along columns.

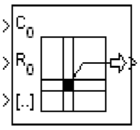
y = [u1;u2;u3;...;un]   % Equivalent MATLAB code

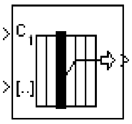
For vertical concatenation, inputs must all have the same column dimension, N, but may have different row dimensions. The output matrix has dimension Mi-by-N, where Mi is the number of rows in input ui (i = 1, 2, ..., n). When some of the inputs are length-Mi 1-D vectors while others are Mi-by-1 matrices, the vector inputs are treated as Mi-by-1 matrices. (1-D vector inputs are not accepted for vertical concatenation when the other inputs have column dimension greater than 1.)

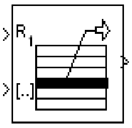
1-D Vector Concatenation

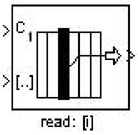
When all inputs to the Matrix Concatenation block are length-Mi 1-D vectors, the output is a Mi-by-1 matrix containing all input elements concatenated in port order: the elements in the vector input to the top port appear as the first elements in the output, and the elements in the vector input to the bottom port appear as the last elements in the output.

read_array (V. 5.) (V. 6)









This block reads elements (values, rows or columns) from input array. There are three possible modes:

- "read single value" - block reads the single value A(R,C) from the input array A at the given positions C (columns) and R (rows).
- "read row(s)" - block reads row(s) A(R) from the input array A at the given position(s) R.
- "read column(s)" - block reads column(s) A(C) from the input array A at the given position(s) C.

In the modes "read row(s)" and "read column(s)" it is possible to give a vector as an input for coordinates R or C. So it is possible to get more than one row or column in the output at once.

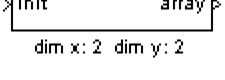
Each coordinate R and C can be obtained from the corresponding input port or as a block parameter. The user has a possibility to select between zero or one based indexing for coordinates R and C, indicated as subscribed 0 or 1 (e.g. C_0 or C_1).

Bus support: The input [..] can be either an array or a bus of arrays. If the input signal is a bus, the output signal is a bus with the same structure as the input. Every element of the bus signal gets the suffix specified below the block (read: [i]). The forth block shows the annotation "read: [i]" which means that every signal name in the output bus gets the suffix [i] to indicate that the i-th element of the array is selected.

set_array (V. 5.) (V. 6)

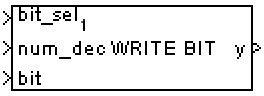
Reduce annotations 'on'

Reduce annotations 'off'



This block outputs the array filled with the given initial value. The initial value can be obtained from the block input ('external source') or can be entered as the block parameter ('internal source'). The size of the output array can be entered directly as the block parameter or can be obtained from the existent data definition.

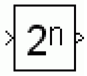
set_bit (V. 5.) (V. 6)



The block sets or resets the bits of decimal number "dec_num" chosen through input port "bit_sel" depending on the value of "bit". User can specify "bit" value either in the parameter "Bit value" or as an input port. The "bit" input port value can be a vector. In this case "bit" vector length should be the same as in "bit_sel" vector.

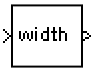
The decimal value can be obtained from the input port "num_dec" or it can be stored in internal memory and initialized by zero. The user has the possibility to select between zero or one based indexing for "bit_sel", indicated as subscribed 0 or 1 (e.g. bit_sel_0 or bit_sel_1).

Two_power_n (V. 5.) (V. 6)



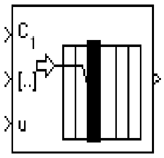
This block calculates 2 to the power of n. The input n has to be an integer. Otherwise the digits after the comma are cut off (floor[n]).

Width (V. 5) (V. 6)



Output the width of the input signal. If an the input is an array of size 3 the output is 3.

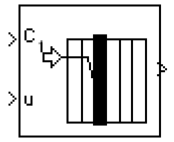
write_array (V. 5.) (V. 6)



This block writes elements (values, rows or columns) into input array. It is possible to select between zero or one based indexing for coordinates.

There are three possible operation modes:

- "write single value" - block writes the single value A(R,C) into the input array A at the given positions R (columns) and C (rows).
- "write row(s)" - block writes row(s) A(R) into the input array A at the given position(s) R.
- "write column(s)" - block writes column(s) A(C) into the input array A at the given position(s) C.



size: [NC_CYL_NR]

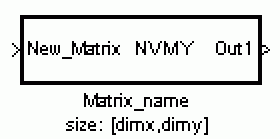
In the modes "write row(s)" and "write column(s)" it is possible to give a vector as an input for coordinates R or C. So it is possible to write more than one row or column in the output array at once.

The input row or column in "write row(s)" or "write column(s)" mode should either be scalar (single value) or have the same length as the according dimension of the input array.

It is possible to obtain the input array A from an input port or from an internal memory. When block uses internal memory to store the array A the size of this array is shown as block annotation like in the second block example. The size of the array in this case is NC_CYL_NR. The dimension can also be obtained from an existent data definition.

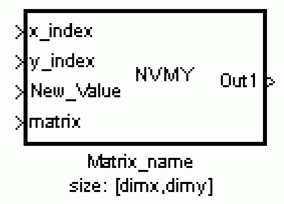
Bus support: The input "[..]" can be either an array or a bus of arrays. When using a bus of arrays, the input "u" can be a single signal or a bus of signals. When both inputs are buses, there is a correspondence between signals with the same names: the signal "X_i" from "u" is used to write on the array "X" from "[..]".

Write Matrix (V. 5.) (V. 6)



The block writes a Matrix 'Matrix_name' directly in the Workspace. This block is used if data in the simulation has to be saved in the nonvolatile memory NVMY (e.g. at PWL_OFF). In the data definition table of the specification the matrix name is set to Mode S. The parameters 'Matrix_name', number of rows 'dimx Rows' and number of columns 'dimy Col' are shown in the block icon.

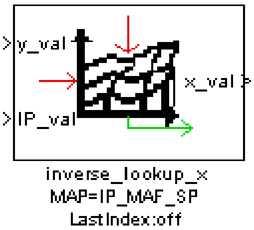
Write To Matrix (V. 5.)



The Block writes a new value to a given position in a 2-dimensional Matrix 'MatrixName' not only in the Simulation but also directly in the Workspace. The new value is given by 'New_Value' and the position in the matrix is given by the indices 'x_index' and 'y_index' (Indexing starts from zero).

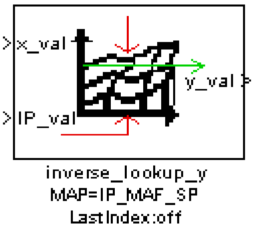
This block can be used if data in the simulation has to be saved in the nonvolatile memory NVMY (e.g. at PWL_OFF). In the specification the matrix name is set to Mode S. The parameters 'Matrix_name', number of rows 'dimx Rows' and number of columns 'dimy Col' are shown in the block icon.

inverse_lookup_x (V. 5.) (V. 6)



This block extracts the value on the x_axis for the map given by Mapname based on the input of the actual map value and the value for the y-axis.

inverse_lookup_y (V. 5.) (V. 6)

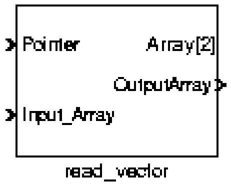


This block extracts the value on the y_axis for the map given by Mapname based on the input of the actual map value and the value for the x-axis.

36.5.12 SDA 4.0 and 3.1 specific blocks

Note: The version information is not available on block icon for blocks from SDA 4.0 and 3.1 releases.

Read Vector

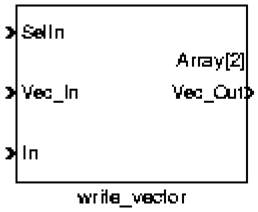


Description

This block returns the value of the array element at the position selected by 'Pointer'. Indexing in this block starts from 1. The size of the array can be directly given in the 'Size of Array' parameter or by a variable set in Workspace.

Pointer	Position of the selected element in the input vector (array index)
Input_Array	input vector
OutputArray	Selected element of the input vector
Array[NC_...]	Size of array

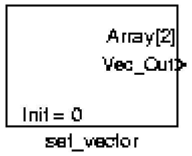
Write Vector



Writes a given value to the selected position in the vector. The block writes a given value to the selected position in the vector. The value is given by 'In' and the position in the vector by 'SelIn' (Indexing starts from 1).The dimension of the array is specified by the 'Size of Array' parameter.

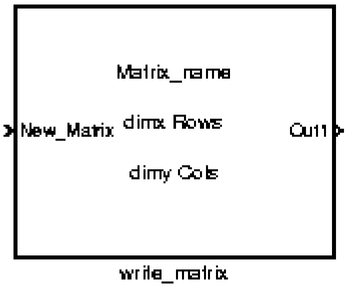
SelIn	Index of the vector position
Vec_In	Input vector
In	Value that is written to vector position 'SelIn'
Vec_Out	Output vector
Array[NC_...]	Size of array

Set Vector



The block initializes all values in a vector with the value 'Init'. The size of the vector can be given directly by the 'Size of Array' parameter or by a variable set in Workspace. 'Vec_Out' outputs the initialized vector.

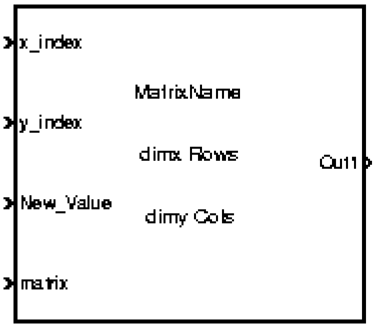
Write Matrix



The block writes a Matrix 'Matrix_name' directly in the Workspace. This block can be used if data in the simulation has to be saved in the nonvolatile memory NVMY (e.g. at PWL_OFF). In the specification the matrix name is set to Mode S. The parameters 'Matrix_name', number of rows 'dimx Rows' and number of columns 'dimy Col' are shown in the block icon.

New_Matrix	Matrix Elements
Out	2-dimensional Matrix, written in the Workspace

Write To Matrix



write_to_matrix

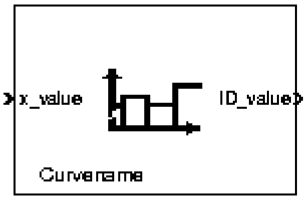
The Block writes a new value to a given position in a 2-dimensional Matrix 'MatrixName' not only in the Simulation but also directly in the Workspace. The new value is given by 'New_Value' and the position in the matrix is given by the indices 'x_index' and 'y_index' (Indexing starts from zero).

This block can be used if data in the simulation has to be saved in the nonvolatile memory NVMY (e.g. at PWL_OFF). In the specification the matrix name is set to Mode S. The parameters 'Matrix_name', number of rows 'dimx Rows' and number of columns 'dimy Col' are shown in the block icon.

x_index	x-index of the matrix position
y_index	y-index of the matrix position
matrix	Input matrix
New_Value	Value that is written to matrix position 'x_index' and 'y_index'
Out	Output matrix

Lookup ID Curve

Looks up an ID_Curve (No interpolation). Outputs the 'ID_value' connected with the next smallest index to the axis value 'x_value'. There is no interpolation between axis values. The names of the axis are given by list_curve in the Workspace. There is also no extrapolation outside the axes values.



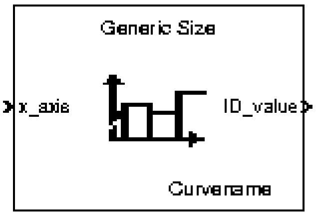
lookup_id_curve

triggered (optional)

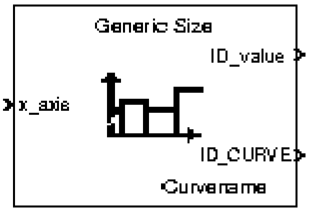
x_value	Input axis value
ID_value	Output curve value connected with the next smallest index to the axis value

Lookup ID Curve Array

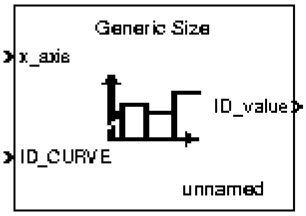
Looks up an ID_Curve_array (No interpolation). [triggered (optional)]



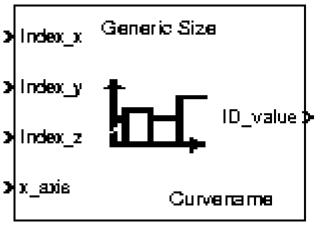
lookup_id_curve_array



lookup_id_curve_array1

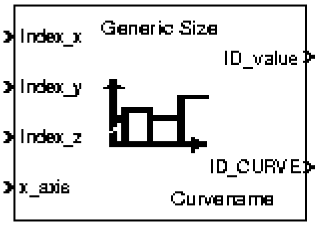


lookup_id_curve_array2



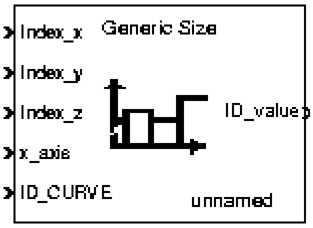
lookup_id_curve_array

local



lookup_id_curve_array

exported



lookup_id_curve_array

imported

Modes

Mode local: 'Curvename' is defined within the block in block parameter 'ID_CURVE'.

Mode exported: 'Curvename' is defined within the block in block parameter 'ID_CURVE' and is exported via an output (if lookup table is input to another specification).

Mode imported: 'Curvename' is imported via an inport (if lookup table is defined in another specification).

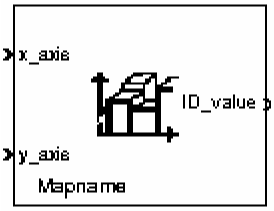
Description

Outputs the 'ID_map' value connected with the next smallest index to the axis value 'x_axis'. There is no interpolation between axis values. Index_x, Index_y and Index_z specify the indices of the ID_Curve in the curve array. The names of the axes and the size of the curve array are given by list_curve in the Workspace. There is no extrapolation outside the axes values.

x_axis	Input x-axis value
ID_map	Output curve value connected with the next smallest index to the x-axis value
Index_x	Input: x-index of the curve in the curve array (optional)
Index_y	Input: y-index of the curve in the curve array (optional)
Index_z	Input: z-index of the curve in the curve array (optional)
ID_CURVE	Input: imports the name of the curve (Mode: imported) (optional)
ID_CURVE	Ouput: exports the name of the curve (Mode: exported) (optional)

Lookup ID Map

Looks up an ID_Map (No interpolation).



lookup_id_map

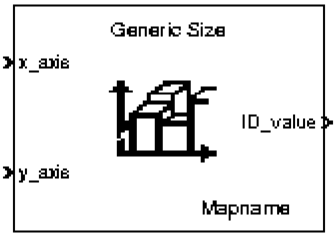
triggered (optional)

Outputs the 'ID_map' value connected with the next smallest index to the axis values 'x_axis' and 'y_axis'. There is no interpolation between axis values. The names of the axes are given by list_map in the Workspace. There is no extrapolation outside the axes values.

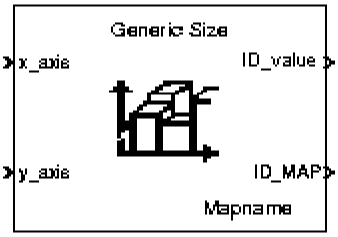
x_axis	Input: x-axis value
y_axis	Input: y-axis value
ID_map	Output: Map value connected with the next smallest index to the x- and y-axis values

Lookup ID Map Array

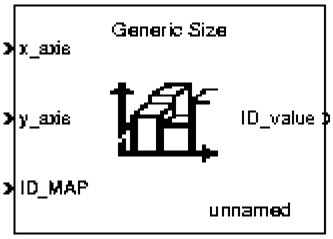
Looks up an ID_Map_array (No interpolation). [triggered (optional)]



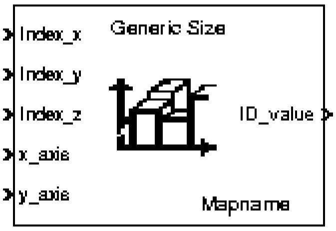
lookup_id_map_array



lookup_id_map_array1

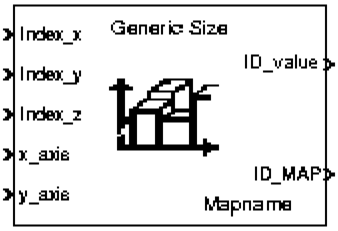


lookup_id_map_array2



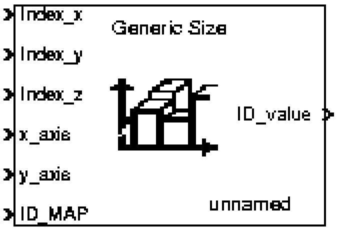
lookup_id_map_array

local



lookup_id_map_array

exported



lookup_id_map_array

imported

Modes

Mode local: 'Mapname' is defined within the block in block parameter 'ID_Map'.

Mode exported: 'Mapname' is defined within the block in block parameter 'ID_Map' and is exported via an outport (if lookup table is input to another specification) .

Mode imported: 'Mapname' is imported via an inport (if lookup table is defined in another specification).

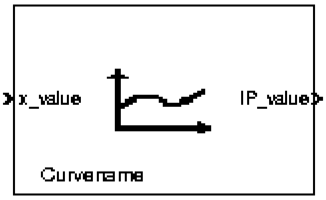
Description

Outputs the 'ID_map' value connected with the next smallest index to the axis values 'x_axis' and 'y_axis'. There is no interpolation between axis values. Index_x, Index_y and Index_z spezify the indices of the ID_Map in the Map array. The names of the axis and the size of the map array are given by list_map in the Workspace. There is no extrapolation outside the axes values.

x_axis	Input x-axis value
y_axis	Input y-axis value
ID_map	Map value connected with the next smallest index to the x-axis and y-axis value
Index_x	x-index of the map in the map array (optional)
Index_y	y-index of the map in the map array (optional)
Index_z	z-index of the map in the map array (optional)
ID_MAP	Imports the name of the map (Mode: imported) (optional)
ID_MAP	Exports the name of the map (Mode: exported) (optional)

Lookup IP Curve

Looks up an IP_Curve (With interpolation).



lookup_ip_curve

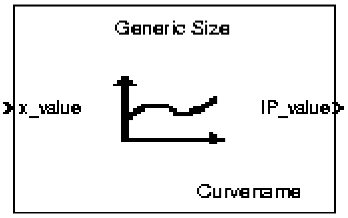
triggered (optional)

Outputs the 'IP_value' connected with the linear interpolated index of the axis value 'x_value'. There is a linear interpolation between axis values. The names of the axes are given by list_curve in the Workspace. There is no extrapolation outside the axes values.

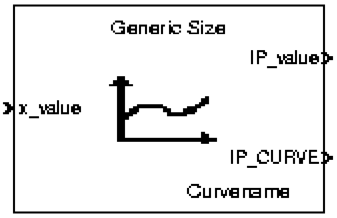
x_axis	Input x-axis value
IP_value	Value obtained interpolating the curve

Lookup IP Curve Array

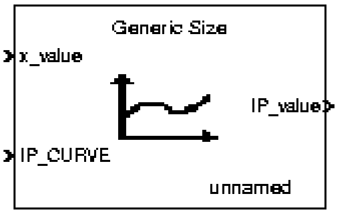
Looks up an IP_Curve_array (With interpolation). [triggered (optional)]



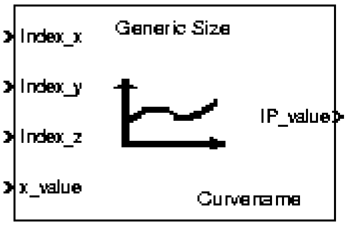
lookup_ip_curve_array



lookup_ip_curve_array1

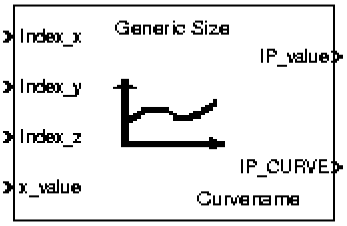


lookup_ip_curve_array2



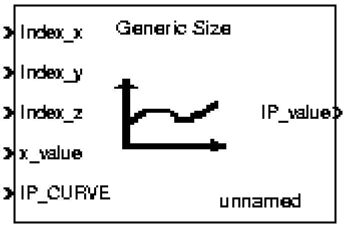
lookup_ip_curve_array

local



lookup_ip_curve_array

exported



lookup_ip_curve_array

imported

Modes

Mode local: 'Curvename' is defined within the block in block parameter 'ID_CURVE'.

Mode exported: 'Curvename' is defined within the block in block parameter 'ID_CURVE and is exported via an outport (if lookup table is input to another specification).

Mode imported: 'Curvename' is imported via an inport (if lookup table is defined in another specification).

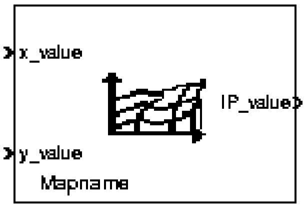
Description

Outputs the 'IP_value' connected with the linear interpolated index to the axis value 'x_value'. There is a linear interpolation between axis values. Index_x, Index_y and Index_z spezify the indices of the IP_Curve in the curve array. The names of the axis and the size of the curve array are given by list_curve in the Workspace. There is no extrapolation outside the axes values.

x_axis	Input x-axis value
IP_value	Value obtained interpolating the curve
Index_x	Input: x-index of the curve in the curve array
Index_y	Input: y-index of the curve in the curve array
Index_z	Input: z-index of the curve in the curve array
IP_CURVE	Imports the name of the curve (Mode: imported)
IP_CURVE	Exports the name of the curve (Mode: exported)

Lookup IP Map

Looks up an IP_Map (With interpolation).



lookup_ip_map

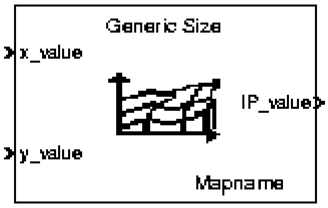
triggered (optional)

Outputs the 'IP_value' connected with the linear interpolated index of the axis values 'x_value' and 'y_value'. There is a linear interpolation between axis values. The names of the axis are given by list_map in the Workspace. There is no extrapolation outside the axes values.

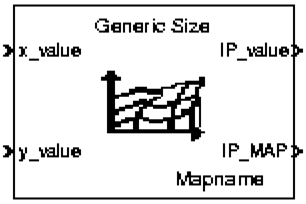
x_value	x-axis value
y_value	y-axis value
IP_value	Map value connected with the linear interpolated indeces to the x- and y-axis values

Lookup IP Map Array

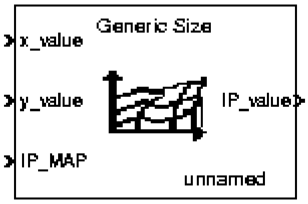
Looks up an IP_Map_array (With interpolation).[triggered (optional)]



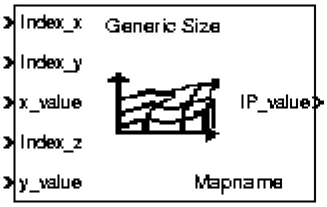
lookup_ip_map_array



lookup_ip_map_array2

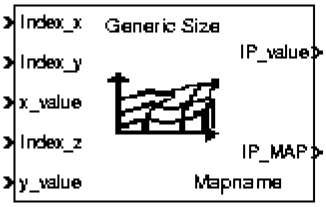


lookup_ip_map_array3



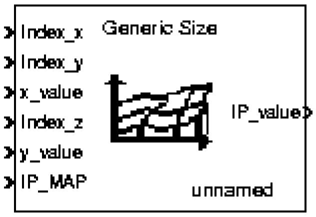
lookup_ip_map_array

local



lookup_ip_map_array

exported



lookup_ip_map_array

imported

Modes

Mode local: 'Mapname' is defined within the block in block parameter 'IP_Map'.

Mode exported: 'Mapname' is defined within the block in block parameter 'IP_Map' and is exported via an outport (if lookup table is input to another specification).

Mode imported: 'Mapname' is imported via an inport (if lookup table is defined in another specification).

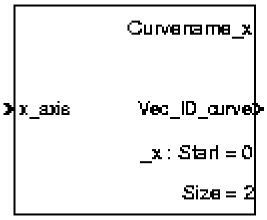
Description

Outputs the 'IP_value' connected with the linear interpolated index to the axis values 'x_value' and 'y_value'. There is linear interpolation between axis values, but there is no extrapolation outside the axes values. 'Index_x',' Index_y' and 'Index_z' specify the indices of the IP_Map in the map array. The names of the axes and the size of the map array are given by list_map in the Workspace.

x_value	x-axis value
y_value	y-axis value
IP_value	Map value connected with the linear interpolated index to the x-axis and y-axis value
Index_x	x-index of the map in the map array
Index_y	y-index of the map in the map array
Index_z	z-index of the map in the map array
IP_MAP	Imports the name of the map (Mode: imported)
IP_MAP	Exports the name of the map (Mode: exported)

Lookup Multiple ID Curve

Looks up multiple ID_Curves (No interpolation).



lookup_multiple_id_curve

triggered (optional)

If the parameter 'Curvename' contains one of the tokens (_x, _i, _j), this is replaced automatically by a given range from 1 to 'Size' or 0 to ('Size'-1). The number of curves accessed is given by 'Size'.

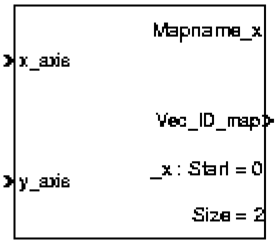
Outputs a vector of length 'Size' of ID_values 'Vec_ID_curve' connected with the next smallest index of the axis values 'x_value' of the different curves.

There is no interpolation between the axis values and no extrapolation outside the axes values. The axis names are given by list_curve in the Workspace.

x_axis	Axis value
Vec_ID_curve	Vector of Curve values with dimension 'Size' connected with the next smallest index of the x-axis value

Lookup Multiple ID Map

Looks up multiple ID_Maps (No interpolation).



lookup_multiple_id_map

triggered (optional)

If the parameter 'Curvename' contains one of the tokens (_x, _i, _j), this is replaced automatically by a given range from 1 to 'Size' or 0 to ('Size'-1). The number of maps accessed is then given by 'Size'.

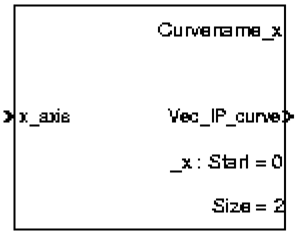
Outputs a vector of length 'Size' of ID_values 'Vec_ID_map' connected with the next smallest indeces to the axis values 'x_axis' and 'y_axis'. There is no interpolation between the axis values.

The axis names are given by list_curve in the Workspace. There is no extrapolation outside the axes values.

x_axis	x-axis value
y_axis	y-axis value
Vec_ID_map	Vector of Curve values connected with the next smallest index of the x-axis and y-axis value

Lookup Multiple IP Curve

Looks up multiple IP_Curves (With interpolation).



lookup_multiple_ip_curve

triggered (optional)

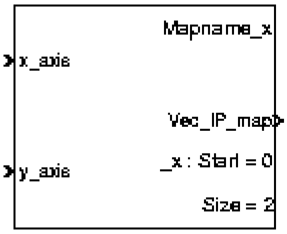
If the parameter 'Curvename' contains one of the tokens (_x, _i, _j), this is replaced automatically by a given range from 1 to 'Size' or 0 to ('Size'-1). The number of curves accessed is then given by 'Size'.

Outputs a vector of length 'Size' of IP_values 'Vec_IP_curve' connected with the linear interpolated index of the axis value 'x_axis'. There is linear interpolation between the axis values and no extrapolation outside the axes values. The axis names are given by list_curve in the Workspace.

x_axis	Axis value
Vec_IP_curve	Vector of Curve values connected with the linear interpolated index to the x-axis value

Lookup Multiple IP Map

Looks up multiple IP_Maps (With interpolation).



lookup_multiple_ip_map

triggered (optional)

If the parameter 'Curvename' contains one of the tokens (_x, _i, _j), this is replaced automatically by a given range from 1 to 'Size' or 0 to ('Size'-1). The number of maps accessed is then given by 'Size'.

Outputs a vector of length 'Size' of IP_values 'Vec_IP_map' connected with the linear interpolated index to the axis values 'x_axis' and 'y_axis'.

There is linear interpolation between the axis values, but there is no extrapolation outside the axes values. The axis names are given by list_map in the Workspace.

x_axis	x-axis value
y_axis	y-axis value
Vec_IP_map	Curve value connected with the linear interpolated index to the x-axis and y-axis value

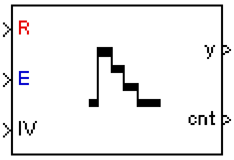
36.6 AT Basic Blocks - short description

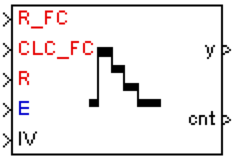
36.6.1 Remarks for block version V 5.x

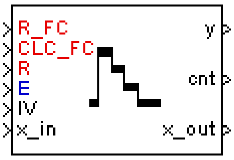
36.6.2 Multi-rate and single-rate block versions

Some blocks have two versions: multi-rate and single-rate. The multi-rate version (with R_FC and CLC_FC inputs) is used in case of system resets have to be simulated. R_FC and CLC_FC are shortcuts for "reset function call" and "calculate function call" respectively.

Various blocks have also optional inputs and outputs, which are chosen according to the model specific needs. The following picture shows an example of a block in its both versions, single-rate and multi-rate. The third picture also shows optional inputs and outputs (internal state):







For each block the functionality is described by an "Init-code" (executed at the start of simulation) and pseudo code (for methods run(), finalize(), pass(), out() and reset()) executed during simulation).

The block functionality, given with the pseudo-code and init-code, remains the same in both versions, multi-rate and single-rate.

In the multi-rate version, the block is only calculated if a function-call triggers the input R_FC or CLC_FC. Triggering the block through the input R_FC simulates a system reset. The calculation done when a R_FC triggers the block is shown in the given pseudo-code "R_FC". The block outputs are not calculated in the R_FC code. Triggering the block through the input CLC_FC runs the execution of this block, calculating a new output value. This calculation is shown in the given pseudo-code for each block.

In the single-rate version, the block calculation is executed every time the subsystem containing the block is triggered. This means, that the block calculation occurs as for every other non triggered block or subsystem. The order of calculation in the single-rate mode is exactly the same as for CLC_FC.

Besides the system reset (R_FC function call) the blocks also implement a logical reset (functional reset). There are two versions of the logical reset which can occur in single-rate mode or in multi-rate mode when CLC_FC triggers the block:

- *State based*: Reset occurs as long as signal R equals 1 (blocks with the suffix _RE)
- *Edge based*: Reset occurs on signal RT rising edge (blocks with the suffix _RTE)

Unlike reset via the R_FC function call, when the logical reset occurs, the block calculates its outputs.

While no logical reset occurs in single-rate mode or while CLC_FC function-call in multi-rate mode, the block computations are defined by the value of the Enable signal E. While E is not equal to zero, the block performs the necessary computation and updates its internal state(s). While E is equal to zero, the internal states are not updated and the output of the block is based on the previously stored value of its internal state.

CLC_FC function uses the following sub-functions:

general specification

- reset() initializes internal state(s) with initial value(s) (IV, IV1, IV2...)
- run() performs general block computations while no logical reset is occurred and the enable signal E is not equal to zero
- finalize() performs general block computations while the logical reset is occurred or the enable signal E is not equal to zero
- pass() performs necessary computations while no logical reset is occurred and enable signal E is equal to zero.
- out() assigns values to output signal

The current implementation of these blocks is described with the following C-pseudo code:

State detecting reset blocks (-RE blocks)

```
function R_FC ( )
{
 reset();
}
```

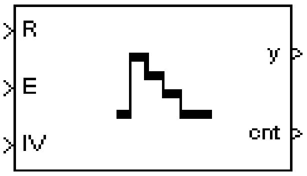
```
function CLC_FC ( )
{
 if (R) {
   reset();
   finalize();
 }
 else if (E) {
   run();
   finalize();
 }
 else {
   pass();
 }
 out();
}
```

Edge detecting reset blocks (-RTE blocks)

```
function R_FC ( )
{
 reset();
 R_1 = 0;
}
```

```
function CLC_FC ( )
{
 if (R & !R_1) {
   reset();
   finalize();
 }
 else if (E) {
   run()
   finalize();
 }
 else {
   pass();
 }
  out();
 R_1 = R;
}
```

In the description later on, for these kinds of blocks, the C-like code for each of these sub-functions is given beside the block icon as shown in the example below:



```
Variables:
  E: logic
  R: logic
  IV: real
  y: logic
  x: int
  cnt: int
```

```
Init-code:
  x = 0;

reset ( )
  x = round(IV);

run ( )
    if (x > 0) {
      x = x - 1;
    }
```

```
finalize( )

pass ( )

out ( )
  y = (x>0);
  cnt = x;
```

The additional inputs and outputs used to set and get internal states have the suffixes "_in" and "_out" after the referred state name respectively. These inputs and outputs are optional.

The following list shows the standard input and output names, with their corresponding descriptions:

Inputs

Port	Description
E	Enable: suppresses the block calculation while 0
R	Resets the block states to their initial values while 1
RT	Resets the block states to their initial values on rising edge 0 -->1
IV	Initial value set upon reset
R_FC	System reset (multirate version)
CLC_FC	System calculation request (multirate version)
dT	Sample time
MX	Upper state limit
MN	Lower state limit
x_in	Direct input of an internal state if the block has one internal state
x1_in	Direct input of an internal state 1 if the block has 2 internal states
x2_in	Direct input of an internal state 2 if the block has 2 internal states

Outputs

Port	Description
B_max	True if the upper limitation active
B_min	True if the lower limitation active
x_out	Direct output of an internal state if the block has one internal state
x1_out	Direct output of a internal state 1 if the block has 2 internal states
x2_out	Direct output of a internal state 2 if the block has 2 internal states
y	Out
cnt	Internal counter state

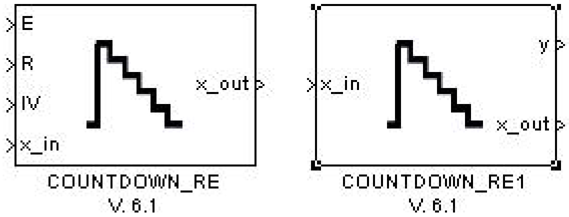
36.6.3 Remarks for block version V 6.x

36.6.4 Functional behaviour

The blocks of version 6.x have the same functional single rate behaviour than the blocks of version 5.x. The changes in the blocks are only related to code generation and to adaptation to the ASAM MBFS standard.

36.6.5 Single-rate block version

Version 6 blocks do not support the multi-rate option. Many blocks have optional inputs and outputs, which are chosen according to the model specific needs. The following picture shows an example for block configuration:



In the single-rate version, the block calculation is executed every time the subsystem containing the block is triggered. This means, that the block calculation occurs as for every other non triggered block or subsystem.

While no logical reset occurs in single-rate mode, the block computations are defined by the value of the Enable signal E. While E is not equal to zero, the block is calculated and updates its internal state(s). While E is equal to zero, the internal states are not updated and the output of the block is based on the previously stored value of its internal state.

x_in and x_out interface

The inputs x_in and outputs x_out are used to export and import the internal state x of the blocks. The internal state is exported in order to be able to initialize the state at system reset via the SignalManager on top module level. This system reset handling replaces the multirate option of the blocks.

36.6.5.1 Input/Output port details for V6 blocks:

Inputs

Port	Description
E	Enable: suppresses the block calculation while 0
R	Resets the block states to their initial values while 1
RT	Resets the block states to their initial values on rising edge 0 -->1
IV	Initial value set upon reset
dT	Sample time
MX	Upper state limit
MN	Lower state limit
x_in	Direct input of an internal state if the block has one internal state
x1_in	Direct input of an internal state 1 if the block has 2 internal states
x2_in	Direct input of an internal state 2 if the block has 2 internal states

Outputs

Port	Description
B_max	True if the upper limitation active
B_min	True if the lower limitation active
x_out	Direct output of an internal state if the block has one internal state

Port	Description
x1_out	Direct output of a internal state 1 if the block has 2 internal states
x2_out	Direct output of a internal state 2 if the block has 2 internal states
y	Output

36.6.6 Directly triggered blocks

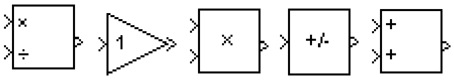
The blocks without internal states (and, as a result, without reset) have the 'Triggered block' parameter. This is a checkbox which can be 'on' or 'off'. When this option is 'off' the calculation for these blocks is executed every time the subsystem, which they are placed in, is triggered. When this option is 'on', the additional control input port is added at the top of these blocks. This port accepts function-call connection (as CLC_FC does) and these blocks are calculated only when a function-call triggers the control port.

36.6.7 Block versioning

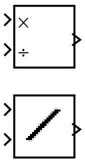
The block version is shown since SDA 5.0 release. Please note the following:

- Blocks from previous SDA versions do not show any version information.
- The version information is shown on the block icon or below it in the format "*V X.Y*".
- Functional change or relevant appearance changes reflects on version information update (only on "X"). A change in "Y" is not functional or appearance relevant. For instance, the versions 5.1, 5.4, 5.13 have all the same appearance and functional behavior.
- The part "X" of the block version number is not coupled to SDA release number. The first block version since SDA 5.0 is "5." for all libraries though.
- All functional changes done to AT Library blocks between SDA releases are shown in this document and in the according library documentation within the SDA installation.

36.6.8 Arithmetic Operators

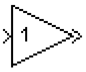


Div **(V. 5) (V. 6)**



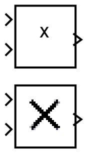
The block divides the elements of the first (upper) input by the elements of the second (lower) input. Case the upper input is a vector or matrix, it performs an element-wise division.

Gain **(simulink block)**



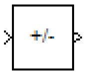
The Gain block generates its output by multiplying its input by a specified gain factor. The input and gain can be a scalar, vector, or matrix. Only unitary gain is allowed in SDA models.

Mul **(V. 5) (V. 6)**



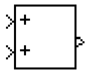
The block multiplies the elements of the first (upper) input by the elements of the second (lower) input (element wise multiplication).

Neg **(V. 5) (V. 6)**



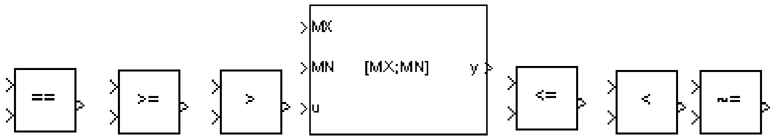
Negates the input signal. The input signal can be a scalar, a vector or a matrix.

Sum **(V. 5) (V. 6)**



The Sum block performs addition ("+" input) or subtraction ("-" input) on its inputs. This block can add or subtract scalar, vector, or matrix inputs. It can also collapse the elements of a single input vector.

36.6.9 Comparison Operators



Interval **(V. 5) (V. 6)**

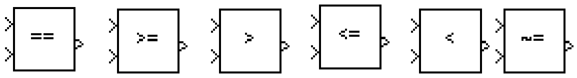
Output y is true if the input signal u lies between MN and MX.

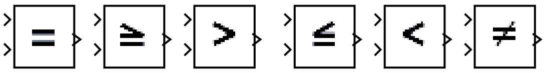
	**Variables:**
	MX: real
	MN: real
	u: real
	y: logic
		run ( )
		if((u < MX) && (u > MN)){
		y = 1;
		}
		else {
		y = 0;
		}

The braces are used to indicate if the interval limits MX and MN are contained ("[MX...", "...MN]") or not ("]MX...", "...MN[") in the interval. The ">" or "<" signs are then changed in ">=" or "<=", accordingly.

Port	I / O	Description
u	IN	Input signal
MX	IN	Maximum value for input signal
MN	IN	Minimum value for input signal
y	OUT	Boolean value, true if u lies in the Interval [MN,MX]

EQ, GE, GT, LE, LT, NE (V. 5) (V. 6)





The blocks EQ, GE, GT, LE, LT and NE performs a relational operation on its two inputs and produces output according to the following table.

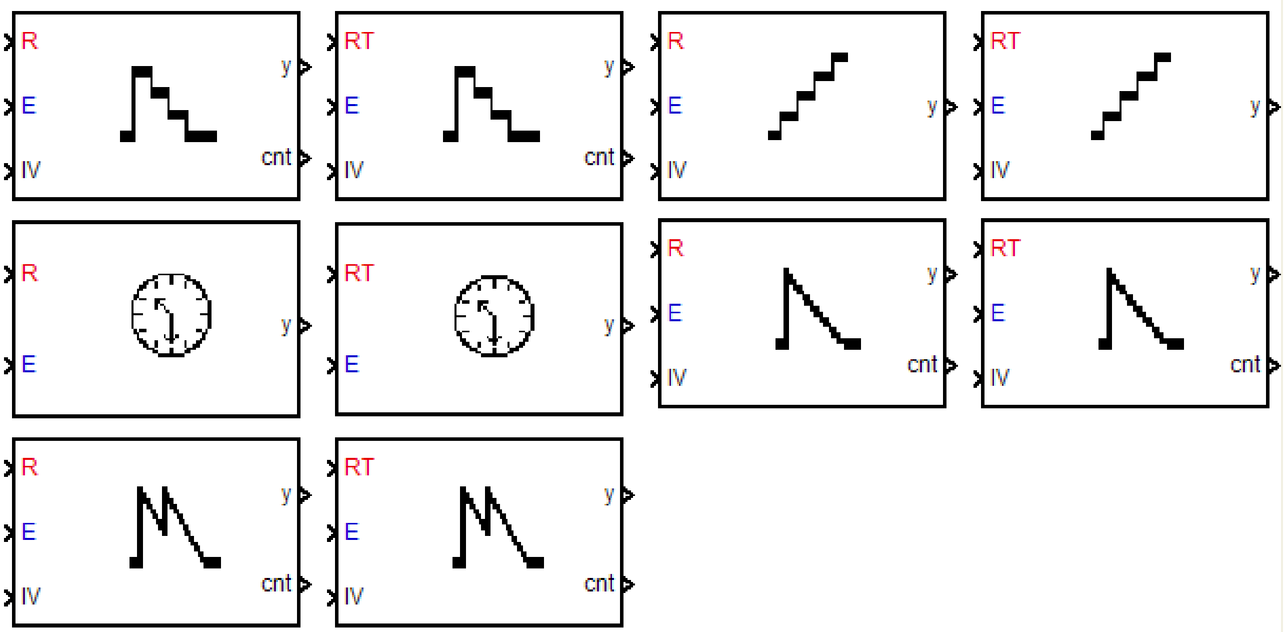
Operator	Output
==	TRUE if the first input is equal to the second input
~=	TRUE if the first input is not equal to the second input
<	TRUE if the first input is less than the second input
<=	TRUE if the first input is less than or equal to the second input
>=	TRUE if the first input is greater than or equal to the second input
>	TRUE if the first input is greater than the second input

If the result is TRUE, the output is 1; if FALSE, it is 0. Inputs can be specified as scalars, arrays, or a combination of a scalar and an array:

- For scalar inputs, the output is a scalar.
- For array inputs, the output is an array of the same dimensions, where each element is the result of an elementwise comparison of the input arrays.
- For mixed scalar/array inputs, the output is an array, where each element is the result of a comparison between the scalar and the corresponding array element.

The block icon displays the selected operator.

36.6.10 Counter and Timer



Optional ports:	R, E, RT, R_FC, CLC_FC, x_in, x_out, dT

CountDownRE (V. 5) (V. 6)

Output y is true, if the number of block evaluations since the last reset is less than the initial number of block evaluations IV. The block has state based reset.

	**Variables:**
	E: logic
	R: logic
	IV: real
	y: logic
	x: int
	cnt: int
		Init-code:
		x = 0;
		
		reset ( )
		x = round(IV);
		
		run ( )
		if (x > 0) {
		x = x - 1;
		}
			finalize( )
			
			pass ( )
			
			out ( )
			y = (x>0);
			cnt = x;

CountDownRTE (V. 5) (V. 6)

Output is true, if the number of block evaluations since the last reset is less than the initial number of block evaluations IV. The block has edge based reset.

general specification

	**Variables:**
	E: logic
	RT: logic
	IV: real
	y: logic
	x: int
	cnt: int
		Init-code:
		x = 0;
		
		reset ( )
		x = round(IV);
		
		run ( )
		if (x1 > 0) {
		x = x - 1;
		}
			finalize( )
			
			pass ( )
			
			out ( )
			y = (x>0);
			cnt = x;

CounterRE (V. 5) (V. 6)

Counts up and gives out the number of block evaluations since the last reset. The block has state based reset.

	**Variables:**
	E: logic
	R: logic
	IV: real
	y: real
	x: int
		Init-code:
		x = 0;
		
		reset ( )
		x = round(IV);
		
		run ( )
		x = x + 1;
			finalize( )
			
			pass ( )
			
			out ( )
			y = x;

CounterRTE (V. 5) (V. 6)

Counts up and gives out the number of block evaluations since last reset. The block has edge based reset.

	**Variables:**
	E: logic
	RT: logic
	IV: real
	y: real
	x: real
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = x + 1;
		pass ( )
			finalize( )
			
			out ( )
			y = x;

StopWatchRE (V. 5) (V. 6)

The block outputs the time since the system init or the last reset. The block has state based reset.

	**Variables:** E: logic R: logic y: real x: real	**Init-code:** x = 0.0; **reset ( )** x = 0.0; **run ( )** x = x + dT	**finalize( )** **pass ( )** **out ( )** y = x;

StopWatchRTE (V. 5) (V. 6)

The block outputs the time since the system init or the last reset. The block has edge based reset.

	**Variables:**
	E: logic
	RT: logic
	y: real
	x: real
		Init-code:
		x = 0.0;
		
		reset ( )
		x =0.0;
		
		run ( )
		x = x + dT;;
			finalize( )
			
			pass ( )
			
			out ( )
			y = x;

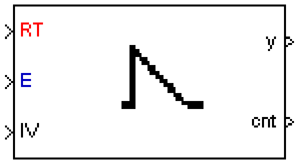
TimerRE (V. 5) (V. 6)

The block indicates true, if the initial time IV has not passed since the last reset of the block. Reset can only be performed, if the counter has run down to zero. The block has state based reset.

	**Variables:**
	E: logic
	R: logic
	IV: real
	y: logic
	x: real
	cnt: real
		Init-code:
		x = 0.0;
		
		reset ( )
		if (x < = 0) {
		x = IV;
		}
		
		run ( )
		x = MAX(x - dT, 0.0);
			finalize( )
			
			pass ( )
			
			out ( )
			cnt = x;
			y = (x>0);

TimerRTE (V. 5) (V. 6)

The block indicates true, if the initial time IV has not passed since the last reset of the block. Reset can only be performed, if the counter has run down to zero. The block has edge based reset.



Variables:
```
E: logic
R: logic
IV: real
y: logic
x: real
cnt: real
```

Init-code:
```
x = 0.0;
```

reset ( )
```
if(x<= 0.0) {
 x = IV;
}
```

run ( )
```
x = x - 1;
```

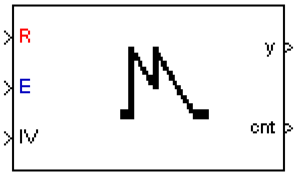
finalize( )

pass ( )

out ( )
```
cnt = x;
y = (x1>0);
```

TimerRetriggerRE (V. 5) (V. 6)

The block indicates true, if the initial time IV has not passed since the last reset of the block. Reset is always possible and independent of the current timer value. The block has state based reset.



Variables:
```
E: logic
R: logic
IV: real
y: logic
x: real
cnt: real
```

Init-code:
```
x = 0.0;
```

reset ( )
```
x = IV;
```

run ( )
```
cnt = x;
x = MAX(x - dT, 0.0);
```

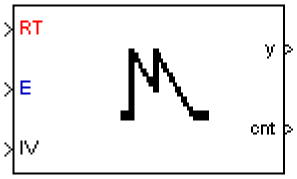
finalize( )

pass ( )

out ( )
```
y = (x>0);
```

TimerRetriggerRTE (V. 5) (V. 6)

The block indicates true, if the initial time IV has not passed since the last reset of the block. Reset is always possible and independent of the current timer value. The block has edge based reset.



Variables:
```
E: logic
RT: logic
IV: real
y: logic
x: real
cnt: real
```

Init-code:
```
x = 0.0;
```

reset ( )
```
x = IV;
```

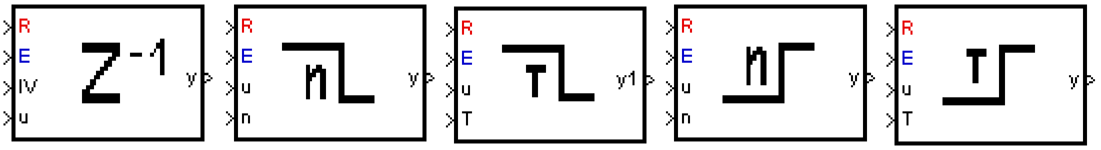
out ( )
```
cnt = x;
y = (x>0);
```

finalize( )

run ( )
```
x = MAX(x - dT, 0.0);
```

pass ( )

36.6.11 Delay Blocks



Optional ports: R, E, R_FC, CLC_FC, x_in, x_out, dT

Delay_RE (V. 5) (V. 6)

Delays the input signal u by one sample time. The reset value IV has direct influence on the output. DelayResetEnabled, Delay_RE and Unit Delay depend on individual simulation purposes.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: real
	x: real
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		y = IV
		
		run ( )
		y = x;
		x = u
			finalize( )
			
			pass ( )
			y = x;
			
			out ( )

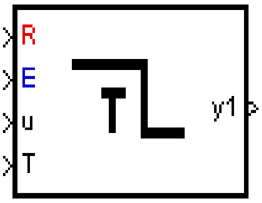
TurnOffDelaySample (V. 5) (V. 6)

A falling edge of the input signal u is delayed by n block evaluations (E).

	**Variables:**
	E: logic
	R: logic
	n: real
	u: logic
	y: logic
	x: int
	temp: int
		Init-code:
		x = 0;
		
		reset ( )
		x = round(n);
		
		pass ( )
		
		out ( )
		y = ((temp>0) || u);
			finalize( )
			temp = x;
			if(u) {
			x = round(n);
			}
			else {
			if(temp > 0) {
			x = x - 1;
			}
			}
			
			run ( )

TurnOffDelayTime (V. 5) (V. 6)

A falling edge of the input signal u is delayed by the time T, if the input remains false for minimum the whole period T.



Variables:
T: real
R: logic
E: logic
y: logic
x: real
temp: real

Init-code:
```
x = 0.0;
```

reset ( )
```
x = T;
```

pass ( )

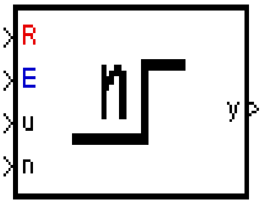
out ( )
```
y = ((temp>0) || u);
```

finalize( )
```
temp = x;
if(u) {
 x = T;
}
else {
 if(temp > 0.0) {
  x = x - dT;
 }
}
```

run ( )

TurnOnDelaySample (V. 5) (V. 6)

A rising edge of the input signal u is delayed by n block evaluations.



Variables:
E: logic
R: logic
n: real
u: logic
y: logic
x: int
temp: int

Init-code:
```
x = 0;
```

reset ( )
```
x = round(n);
```

pass ( )

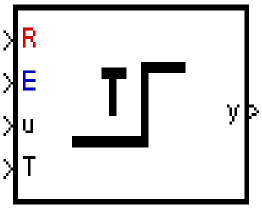
out ( )
```
y =((temp<=0) && u);
```

finalize( )
```
temp = x;
if(u) {
 if(temp > 0) {
  x = x - 1;
 }
}
else {
 x = round(n);
}
```

run ( )

TurnOnDelayTime (V. 5) (V. 6)

A rising edge of the input signal u is delayed by the time T, if the input signal remains high (true) for minimum this period T.



Variables:
E: logic
R: logic
T: real
y: logic
x: real
temp: real

Init-code:
```
x = 0.0;
```

reset ( )
```
x = T;
```

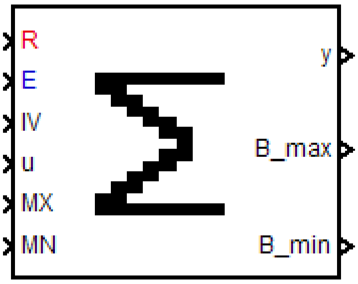
pass ( )

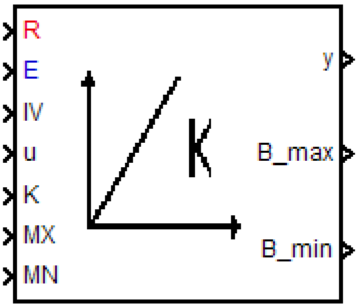
out ( )
```
y = ((temp<=0) && u);
```

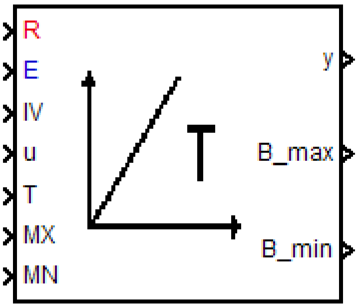
finalize( )
```
temp = x;
if(u) {
 if(temp > 0.0) {
  x = x - dT;
 }
}
else {
 x = T;
}
```

run ( )

36.6.12 Integrators







Optional ports: R, E, R_FC, CLC_FC, x_in, x_out, dT, B_max, B_min

AccumulatorREL (V. 5) (V. 6)

A time discrete integrator. The integrator value y is limited to the maximum MX and the minimum MN.

	**Variables:**
	MX: real
	MN: real
	u: real
	E: logic
	R: logic
	IV: real
	y: real
	B_max: logic
	B_min: logic
	x: real
		Init-code:
		x = 0.0;
		reset ( )
		x = IV;
		run ( )
		x = x+ u;
		pass ( )
		finalize ( )
			out ( )

```
if (x > MX) {
    x = MX;
    B_max = 1;
    B_min = 0;
 }
 else if (x < MN) {
    x = MN;
    B_max = 0;
    B_min = 1;
 }
 else {
   B_max = 0;
   B_min = 0;
 }
 y = x;
```

IntegratorKREL (V. 5) (V. 6)

A time discrete integrator with gain K. The integrated value and therefore the output y are limited by the inputs MX and MN.

	**Variables:**
	MX: real
	MN: real
	K: real
	u: real
	E: logic
	R: logic
	IV: real
	y: real
	B_max: logic
	B_min: logic
	x: real
		Init-code:
		x = 0.0;
		reset ( )
		x = IV;
		run ( )
		x = x + K*u*dT;
		pass ( )
		finalize( )
			out ( )

```
 if (x > MX) {
    x = MX;
    B_max = 1;
    B_min = 0;
 }
 else if (x < MN) {
    x = MN;
    B_max = 0;
    B_min = 1;
 }
 else {
```

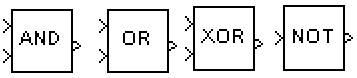
			B_max = 0; B_min = 0; } y = x;

IntegratorTREL **(V. 5) (V. 6)**

A time discrete integrator with gain 1/T. The integrated value and therefore the output y are limited by the inputs MX and MN.

	**Variables:**
	MX: real
	MN: real
	T: real
	u: real
	E: logic
	R: logic
	IV: real
	y: real
	B_max: logic
	B_min: logic
	x: real
		Init-code:
		x = 0.0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = x + u*dT/T;
		
		pass ( )
		
		finalize( )
			out ( )
			if (x > MX) {
			x = MX;
			B_max = 1;
			B_min = 0;
			}
			else if (x < MN) {
			x = MN;
			B_max = 0;
			B_min = 1;
			}
			else {
			B_max = 0;
			B_min = 0;
			}
			y = x;

36.6.13 Logical Operators (V. 5) (V. 6)



Logical Operators

These blocks performs the logical operations on its inputs: AND, OR, XOR, and NOT. The output depends on the number of inputs, and their dimensionality. The output is 1 if TRUE and 0 if FALSE. The block icon shows the corresponding operator.

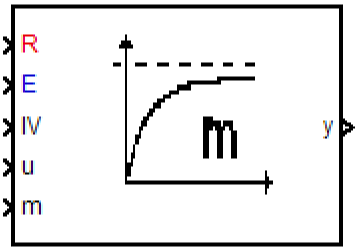
If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the operation is ‘AND’ and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top, left element is the result of applying AND to the top, left elements of the inputs, etc.

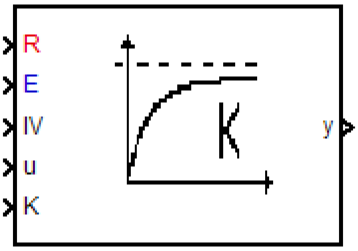
If the block has a single input and the block is not the NOT operator, the input must be vector-like, i.e. a scalar, a 1-D array, or a one-row or one-column 2-D array. The output is a scalar value equal to the result of applying the operation to the elements of the input.

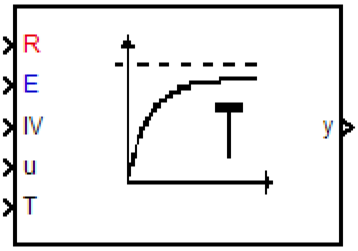
When configured as a multi-input XOR gate, this block performs an addition modulo two operations as mandated by the IEEE standard for logic elements.

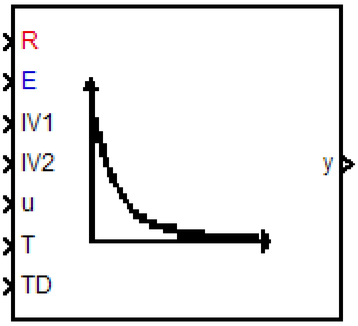
All blocks support **bitwise** operations. In this case, the logical operation is calculated bit by bit between the input ports. The block mode is identified by the annotation "bitwise" under its icon.

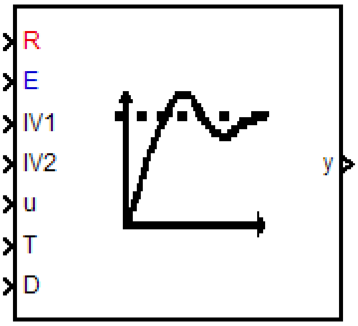
36.6.14 Low and highpass











Optional ports: R, E, RT, R_FC, CLC_FC, x_in, x_in, x1_in, x2_in, x1_out, x2_out, dT

DigitalLowpassRE **(V. 5) (V. 6)**

A discrete time first order lowpass. Value m indicates the percentage of the current approximation of the output value to the aimed input value.

Relationship between the cut-off-frequency (fc) and m:

$$m = 1 - e^{(-f_c \cdot dT \cdot 2 \cdot \pi)} \qquad f_c = -\frac{\ln(1-m)}{2 \cdot \pi \cdot dT}$$

with sample Time dT.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	m: real
	y: real
	x: real
		Init-code:
		x = 0.0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = x + m*(u - x);
			finalize( )
			
			pass ( )
			
			out ( )
			y = x;

HighpassTRE (V. 5) (V. 6)

This block performs a discretized first order high pass filter with the continuous time Laplace notation:

$$G(s) = \frac{TD \cdot s}{1 + T \cdot s}$$

If TD=T the CSD discrete highpass is recovered. In this case the relationship between the highpass cut-off-frequency (fc) and T is :

$$T = \left(1 - e^{(-f_c \cdot dT \cdot 2\pi)}\right) \cdot dT \qquad f_c = -\frac{\ln\left(1 - \frac{T}{dT}\right)}{2 \cdot \pi \cdot dT}$$

with sample Time dT.

	**Variables:**
	E: logic
	R: logic
	IV: real
	y: logic
	x1: real
	x2:real
	T: real
	TD: real
		Init-code:
		x1 = 0.0;
		x2 = 0.0;
		
		pass ( )
		
		out ( )
		y = x1;
			finalize( )
			
			reset ( )
			x1 = IV1;
			x2 = IV2;
			
			run ( )
			x1 = x1 + (TD*(u-x2) - x1*dT)/T;
			x2 = u;

Input IV1	Initial value (for time step n) set upon reset
Input IV2	Initial value (for time step n-1) set upon reset

LowpassKRE (V. 5) (V. 6)

A discrete time first order lowpass filter with time constant 1/K.

Relationship between the cut-off-frequency (f_c) and K:

$$K = \frac{\left(1 - e^{\left(-f_c \cdot dT \cdot 2 \cdot \pi\right)}\right)}{dT} \qquad f_c = -\frac{\ln\left(1 - K \cdot dT\right)}{2 \cdot \pi \cdot dT}$$

with sample Time dT. The input K is the inverse time constant.

	Variables:	**Init-code:**	**finalize( )**

	E: logic
	R: logic
	IV: real
	u: real
	K: real
	y: real
	x: real
		x = 0.0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = x + K*dT*(u-x);
			
			pass ( )
			
			out ( )
			y = x;

<u>**LowpassSecOrdRE**</u> **(V. 5) (V. 6)**

A discrete time second order lowpass filter with time constant T and damping factor D (PT2) with continuous time Laplace notation:

$$G(s) = \frac{1}{s^2 \cdot T^2 + s \cdot 2 \cdot D \cdot T + 1}$$

	Variables:	**Init-code:**	**finalize( )**

	E: logic
	R: logic
	IV1: real
	IV2: real
	u: real
	T: real
	D: real
	y: real
	x1: real
	x2: real
	temp: real
	temp1: real
		x1 = 0.0;
		x2 = 0.0;
		
		reset ( )
		x1 = IV1;
		x2 = IV2;
		
		pass ( )
		
		out ( )
		y = x1;
			
			run ( )
			temp = x2;
			temp1 = pow(T,2) + 2*D*T*dT;
			x2 = x1;
			x1 = x2 + (pow(dT,2)*(u-x2))/temp1 + pow(T,2)*(x2-temp)/temp1;

T	Time constant (real)
D	Damping factor (real)
IV1	Initial value set upon reset
IV2	Initial value set upon reset

LowpassTRE (V. 5) (V. 6)

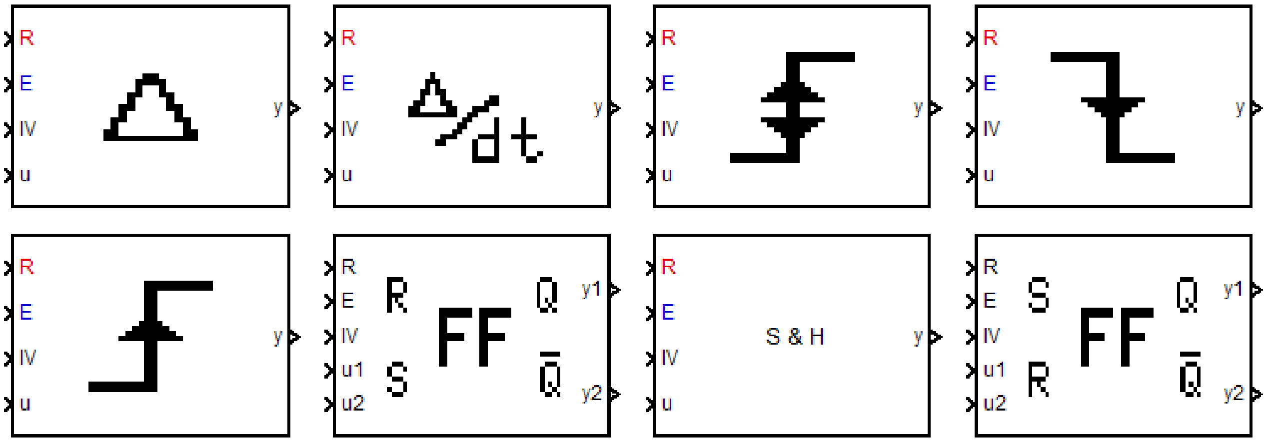
This block performs a first order lowpass filter with T as time constant. Relationship between the cut-off-frequency (fc) and T:

$$K = \frac{\left(1 - e^{(-f_c \cdot dT \cdot 2 \cdot \pi)}\right)}{dT} \qquad f_c = -\frac{\ln\left(1 - K \cdot dT\right)}{2 \cdot \pi \cdot dT}$$

with sample Time dT.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	T: real
	y: real
	x: real
		Init-code:
		x = 0.0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = x + dT*(u-x)/T;
			finalize( )
			
			pass ( )
			
			out ( )
			y = x;

36.6.15 Memory Blocks



Optional ports: R, E, RT, R_FC, CLC_FC, x_in, x_out, dT

DeltaOneStep (V. 5) (V. 6)

Calculates the difference between the current and the last input value.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: real
	x: real
		Init-code:
		x = 0.0;
		reset ( )
		x = IV;
		run ( )
			finalize( )
			y = u - x;
			x = u;
			pass ( )
			out ( )

DifferenceQuotient (V. 5) (V. 6)

Calculates the rate of change of the input signal over time.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: real
	x: real
		Init-code:
		x = 0.0;
		reset ( )
		x = IV;
		run ( )
			finalize( )
			y = (u - x)/dT;
			x = u;
			pass ( )
			out ( )

EdgeBi (V. 5) (V. 6)

The output y indicates true at any change of the logical input value.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: logic
	y: logic
	x: logic
		Init-code:
		x = 0;
		reset ( )
		x = IV;
		run ( )
			finalize( )
			y = (x ! = u);
			x = u;
			pass ( )
			out ( )

EdgeFalling (V. 5) (V. 6)

The output y indicates true if the input value changes from true to false.

	**Variables:**
	E: logic
	R: logic
	IV: logic
	u: logic
	y: logic
	x: logic
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		
		run ( )
			finalize( )
			y = (x && !u);
			x = u;
			
			pass ( )
			
			out ( )

EdgeRising (V. 5) (V. 6)

The output y indicates true if the input value changes from false to true.

	**Variables:**
	E: logic
	R: logic
	IV: logic
	u: logic
	y: logic
	x: logic
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		
		run ( )
			finalize( )
			y = (!x && u);
			x = u;
			
			pass ( )
			
			out ( )

RSFlipFlop (V. 5) (V. 6)

A flip flop. The second input (reset) dominates the first input (set).

	**Variables:**
	SET: logic
	RST: logic
	Q: logic
	~Q: logic
	x: logic
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		
		pass ( )
		
		out ( )
		Q = x;
		~Q = !x;
			finalize( )
			
			run ( )
			if(RST) {
			x = 0;
			}
			else if(SET) {
			x = 1;
			}

SampleAndHoldRE (V. 5) (V. 6)

Sample and Hold or just a simple memory block with enable and reset ports.

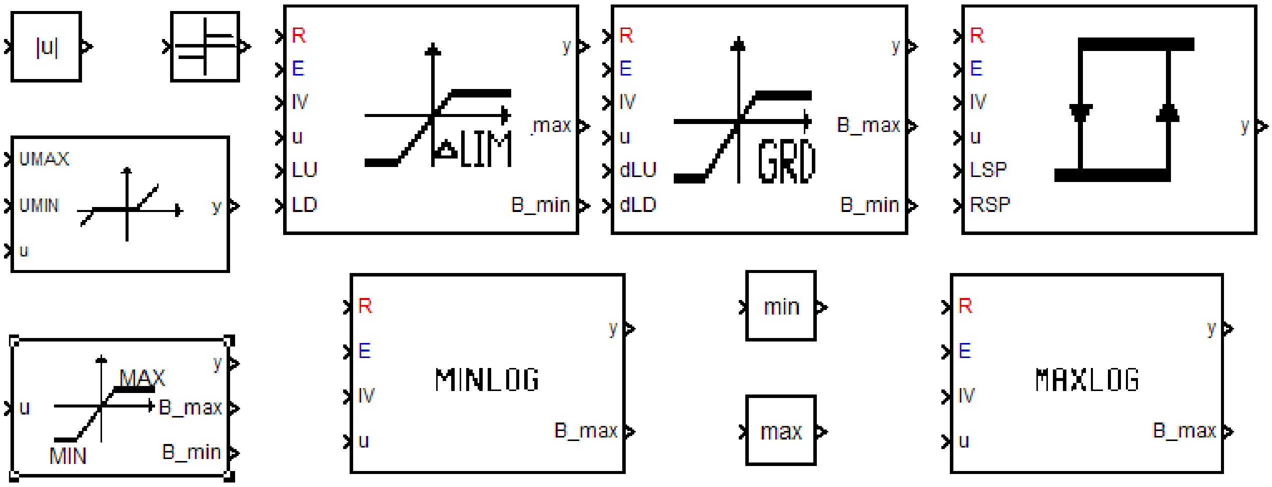
	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: real
	x: real
		Init-code:
		x = 0.0;
		
		reset ( )
		x = IV;
		
		run ( )
		x = u;
			finalize( )
			
			pass ( )
			
			out ( )
			y = x;

SRFlipFlop (V. 5) (V. 6)

A flip flop. The first input (set) dominates the second input (reset).

	**Variables:**
	SET: logic
	RST: logic
	Q: logic
	~Q: logic
	x: logic
		Init-code:
		x = 0;
		
		reset ( )
		x = IV;
		
		pass ( )
		
		out ( )
		Q = x;
		~Q = !x;
			finalize( )
			
			run ( )
			if(SET) {
			x = 1;
			}
			else if(RST) {
			x = 0;
			}

36.6.16 Nonlinear Blocks - automotive blockset

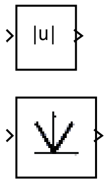


Some blocks have multirate version. The Multirate version of these blocks (with R_FC and CLC_FC inputs) is used if system resets have to be simulated. Other optional inputs and outputs in these blocks are:

Optional ports:	R, E, RT, R_FC, CLC_FC, x_in, x_out, dT, B_max, B_min

Abs **(V. 5) (V. 6)**

The Abs block generates as output the absolute value of the input.



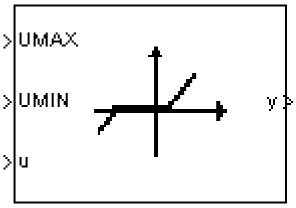
Variables:
u: real
y: real

run ( )

```
if(u >= 0) {
  y = u;
}
else {
  y = -u;
}
```

Dead Band **(V. 5) (V. 6)**

Outputs zero, if the input value is between UMIN and UMAX. Otherwise the output signal is the input signal reduced by the input limits.



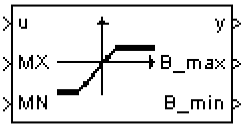
Variables:
UMAX: real
UMIN: real
u: real
y: real

run ( )

```
if(u < UMAX && u > UMIN) {
 y = 0.0;
}
else if(u >= UMAX) {
 y = u - UMAX;
}
else {
 y = u - UMIN;
}
```

Limit **(V. 5) (V. 6)**

The input signal u is limited between maximum value MX and minimum value MN. The boolean output flags B_MAX and B_MIN represent an active limitation in both directions.



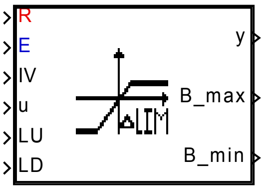
Variables:
MX: real
MN: real
u: real
y: real
B_min: logic
B_max: logic

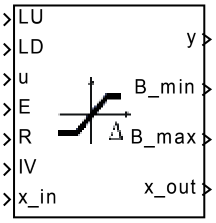
run ( )

```
if(u > MX) {
  y = MX;
  B_max = 1;
  B_min = 0;
}
else if(u < MN) {
  y = MN;
  B_max = 0;
  B_min = 1;
}
else {
  y = u;
  B_max = 0;
  B_min = 0;
}
```

DifferenceLimiter (V. 5) (V. 6)

The output value is limited in its difference to the last input value. The maximum valid difference is LU, the minimum valid difference is LD. Only for a sampling time of 1s this block behaves like a Gradient limiter. For other sampling times this time has to be taken into account in setting the correct values for LU and LD.





Variables:
E: logic
R: logic
IV: real
u: real
LU: real
LD: real
y: logic
B_max: logic
B_min: logic
x: real

run ( )

```
if((u-x)>LU) {
  x = x + LU;
  B_min = 0;
  B_max = 1;
}
else if((u - x)< LD) {
  x = x + LD;
  B_min = 1;
  B_max = 0;
}
else {
  x = u;
  B_min = 0;
  B_max = 0;
}
```

finalize( )

pass ( )

out ( )

```
  y = x;
```

Init-code:

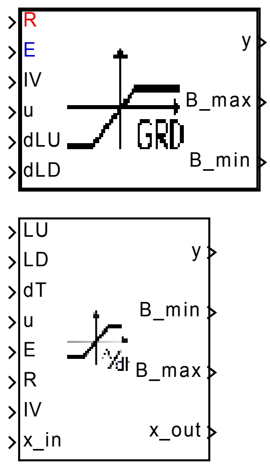
```
  x = 0.0;
```

reset ( )

```
  x = IV;
```

GradientLimiter (V. 5) (V. 6)

The output value is limited in its gradient to the last input value. The maximum valid difference is dLU, the minimum valid difference is dLD. The values of dLD and dLU have to be given per second.



Variables:

```
 E: logic
 R: logic
 IV: real
 u: real
 dLU: real
 dLD: real
 y: real
 B_min: logic
 B_max: logic
 x: real
```

Init-code:

```
 x = 0.0;
```

reset ( )

```
 x = IV;
```

pass ( )

finalize( )

out ( )

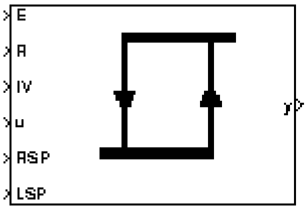
```
 y = x;
```

run ( )

```
if((u - x)/dT > dLU) {
  x = x + dLU*dT;
  B_min = 0;
  B_max = 1;
}
else if((u - x)/dT < dLD) {
  x = x + dLD*dT;
  B_min = 1;
  B_max = 0;
}
else {
  x = u;
  B_min = 0;
  B_max = 0;
}
```

Hysteresis (V. 5) (V. 6)

The Output of this block is a logical 1 if the input value is greater than the RSP and logical 0 if the input is below the LSP.



Variables:

```
 E: logic
 R: logic
 IV: logic
 u: real
 RSP: real
 LSP: real
 y: logic
 x: logic
```

Init-code:

```
 x = 0;
```

reset ( )

```
 x = IV;
```

pass ( )

out ( )

```
 y = x;
```

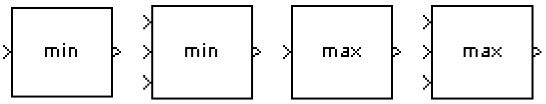
finalize( )

```
 if(u > RSP) {
   x = 1;
 }
 else if(u < LSP) {
   x = 0;
 }
```

run ( )

RSP	Upper threshold value
LSP	Lower threshold value

Min, Max (V. 5) (V. 6)



The MinMax block outputs either the minimum or the maximum element or elements of the input(s).

If the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.

If the block has multiple input ports, the nonscalar inputs must all have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

MaxLogRE (V. 5) (V. 6)

The output value is the maximum value of all input values u between resets, with respect to the initial value IV.

	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: real
	B_max: logic
	x: real
		Init-code:
		x = 0.0;
		B_max = 0;
		
		reset ( )
		x = IV;
		
		out ( )
		y = x;
			finalize( )
			
			run ( )
			B_max = 0;
			if(u > x) {
			x = u;
			B_max = 1;
			}
			
			pass ( )

MinLogRE (V. 5) (V. 6)

The output value y is the minimum value of all input values u between resets, with respect to the initial value IV.

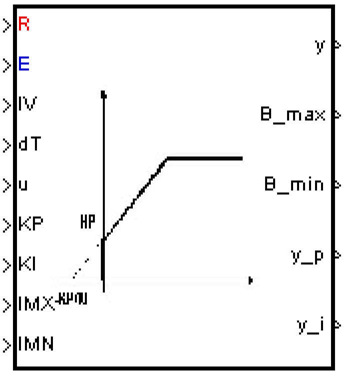
	**Variables:**
	E: logic
	R: logic
	IV: real
	u: real
	y: logic
	B_min: logic
	x: real
		Init-code:
		x = 0.0;
		B_min = 0;
		
		reset ( )
		x = IV;
		
		out ( )
		y = x;
			finalize( )
			
			run ( )
			B_min = 0;
			if(u < x) {
			x = u;
			B_min = 1;
			}
			
			pass ( )

Sign (V. 5) (V. 6)

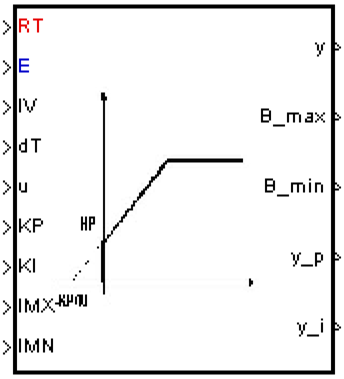
The Sign block indicates the sign of the input:

- The output is 1 when the input is greater than zero.
- The output is 0 when the input is equal to zero.
- The output is -1 when the input is less than zero.

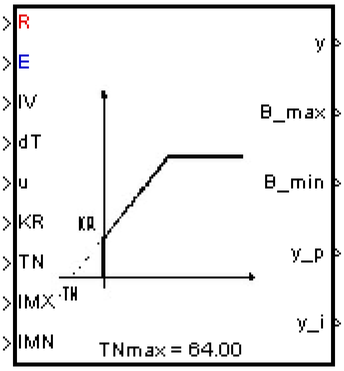
36.6.17 Controller_Blocks (AT_Extended_Lib)



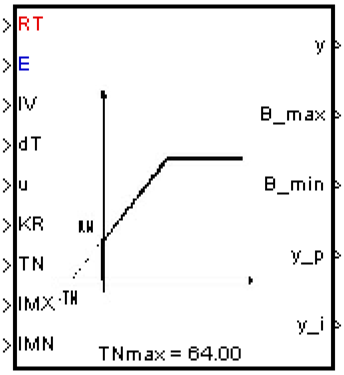
PIControllerK_RE



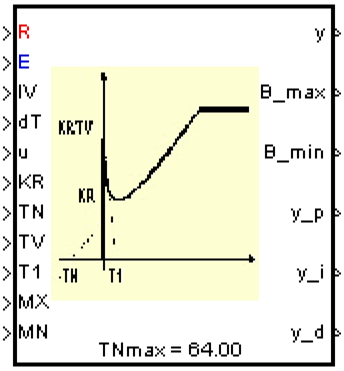
PIControllerK_RTE



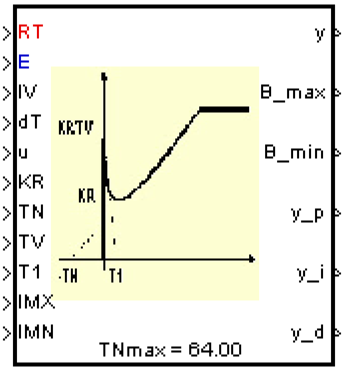
PIControllerT_RE



PIControllerT_RTE



PIDControllerT_RE



PIDControllerT_RTE

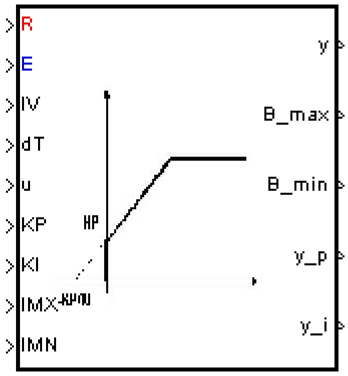
The blocks could be figured for single- and multi-rate version. Multirate version (with inport R_FC and CLC_FC) are used for system reset. Each of PIControllerK, PIControllerT and PIDControllerT has two version with different function reset inport: R (state based) and RT (edge based).

Controller blocks can be configured for single- and multirate mode.

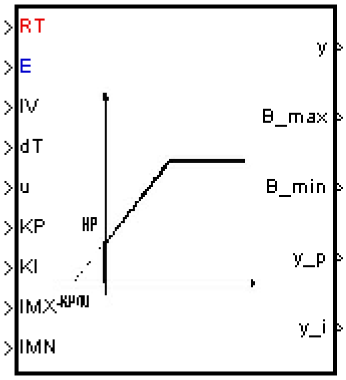
Optional ports:	R, E, RT, R_FC, CLC_FC, IV, xi_in, xd_in, xi_out, xd_out, y_p, y_i, y_d, B_max, B_min

IMX	I-state upper limitation value
IMN	I-state lower limitation value
y_p	Level of proportional part of the controller output
y_i	Level of integral part of the controller output

PIControllerK_RE (V.5) and PIControllerK_RTE (V.5)



PIControllerK_RE



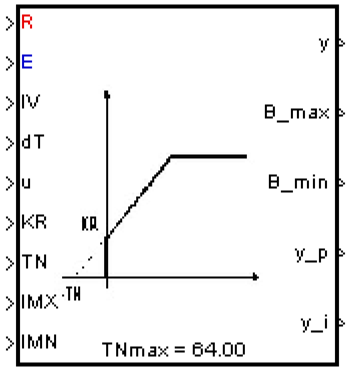
PIControllerK_RTE

This block presents a resetable (integral part) PI controller with variable parameters and state limitation. It is based on the transfer function : G(s) = KP + KI/s, but with full consideration of parameter variability and with the discretization (used method: euler backward) in integrator part.

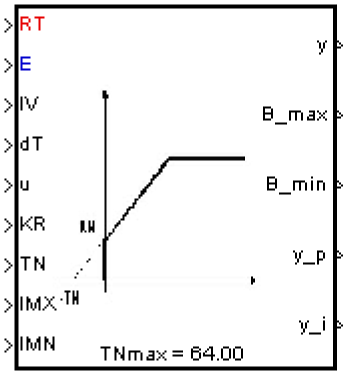
The limits affect the integral state only. The output is the unlimited sum of the unlimited proportional part and the limited integral part.

KP	Proportional gain
KI	Integration gain
y_p	Level of proportional part of the controller output
y_i	Level of integral part of the controller output

PIControllerT_RE (V.5) and PIControllerT_RTE (V.5)



PIControllerT_RE



PIControllerT_RTE

The block represents a resetable (integral part) PI controller with variable parameters and state limitation. It is based on the transfer function :G(s) = KR * (1 + 1/(TN*s)), but with full consideration of parameter variability and with the discretization (used method: euler backward) in integrator part.

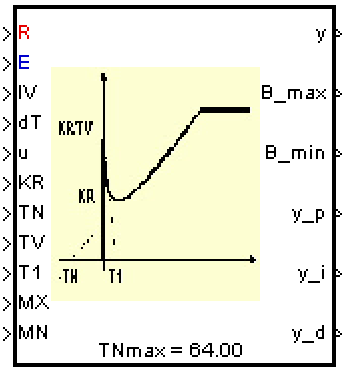
The limits affect the integral state only. The output is the unlimited sum of the unlimited proportional part and the limited integral part.

Setting TN to or below the sample time disables the proportional part (TN <= dt ↔ KR = 0).

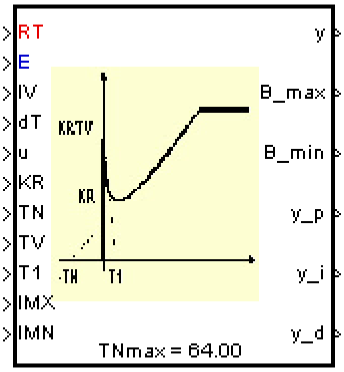
Setting TN to or above the maximum value disables integration (TN >= TNmax ↔ The integrator's part is constant).

KR	Controller amplification
TN	Integrator adjusting time

PIDControllerT_RE (V.5) and PIDControllerT_RTE (V.5)



PIDControllerT_RE



PIDControllerT_RTE

This block represents resetable (integral and derivative part), limitable PID controller with variable parameters. It is based on the transfer function:

G(s) = KR * (1 + 1/(TN*s) + TV*s/(1 + T1*s))

but with full consideration of parameter variability. The discretization (used method: euler backward) is used in integrator part and derivative part (the discretization of each part is separately).

Setting TN to or below the sample time disables the proportional part.

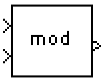
Setting TN to or above the maximum value disables integration.

To disable the derivative part, set TV=0.

KR	Controller amplification
TN	Integrator adjusting time
TV	Derivative adjusting time
T1	Derivative adjusting time
y_d	Level of derivative part of the controller output

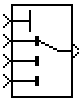
36.6.18 Nonlinear

Modulo (V. 5) (V. 6)



The Modulo block outputs the modulus after division. The inputs must be real arrays of the same size, or real scalars.

Multiport Switch (Simulink block)



The Multiport Switch block chooses between a number of inputs.

The first (top) input is the control input and the other inputs are data inputs. The value of the control input determines which data input to pass through to the output port.

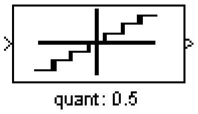
If the control input is not an integer value, the Multiport Switch truncates the value to the nearest integer and issues a warning. If the (truncated) control input is less than one or greater than the number of input ports, the switch issues an out-of-bounds error. Otherwise, the switch passes the data input that corresponds to the (truncated) control input. The following table summarizes the Multiport Switch's behavior.

(Truncated) Control Input	Passes This Data Input
Less than 1	Out of bounds error
1	First input
2	Second input
etc.	etc.
Greater than the number of data inputs	Out of bounds error

Data inputs can be scalar or vector. The control input can be a scalar or a vector. The block output is determined by these rules:

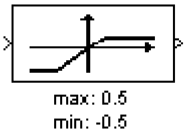
- If inputs are scalar, the output is a scalar.
- If the block has more than one data input, at least one of which is an array, the output is an array. Any scalar inputs are expanded to arrays.
- If the block has only one data input, the input must be a scalar or a vector (1-D array). If the input is a vector, the block output is the element of the vector that corresponds to the truncated value of the control input.

Quantizer **(V. 5)**



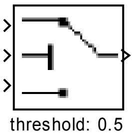
The Quantizer block passes its input signal through a stair-step function so that many neighbouring points on the input axis are mapped to one point on the output axis. The effect is to quantize a smooth signal into a stair-step output. The output is computed using the round-to-nearest method, which produces an output that is symmetric about zero: y = q * round(u/q), where y is the output, u the input, and q the Quantization interval parameter.

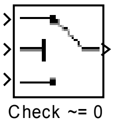
Saturation **(V. 5)**



The Saturation block imposes upper and lower bounds on a signal. When the input signal is within the range specified by the Lower limit and Upper limit parameters, the input signal passes through unchanged. When the input signal is outside these bounds, the signal is clipped to the upper or lower bound. When the parameters are set to the same value, the block outputs that value.

Switch **(V. 5) (V. 6)**



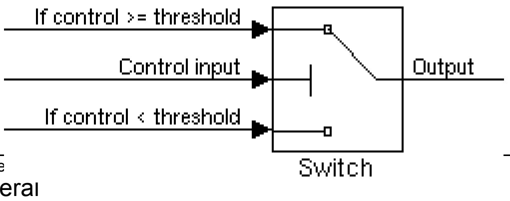


The Switch block propagates one of two inputs to its output depending on the value of a third input, called the control input.

Switch with threshold: If the signal on the control (second) input is greater than or equal to the Threshold parameter, the block propagates the first input; otherwise, it propagates the third input. This figure shows the use of the block ports.

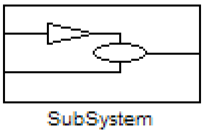
Switch with check unequal 0: If the signal on the control (second) input is unequal to 0, the block propagates the first input; otherwise, it propagates the third input.

This figure shows the use of the block ports:



36.6.19 Signals & Systems

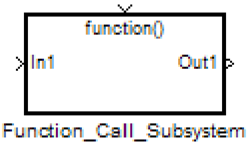
Subsystem



Represent a nested subsystem within another system.

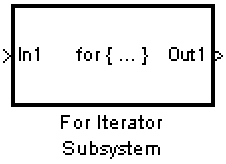
Subsystems can be virtual or atomic, depending on the value of its Treat as Atomic Unit parameter. Simulink ignores virtual subsystem boundaries when determining block update order. By contrast, Simulink executes all blocks within an atomic subsystem before moving on to the next block. Conditionally executed subsystems are atomic. Unconditionally executed subsystems are virtual by default. You can, however, designate an unconditionally executed subsystem as atomic. This is useful if you need to ensure that a subsystem is executed in its entirety before any other block is executed. An atomic subsystem is identified by bold boundaries.

Function Call Subsystem



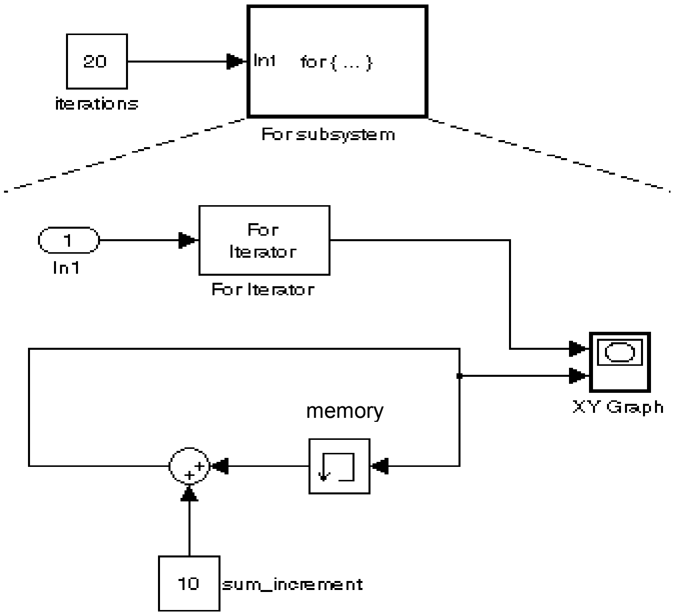
Represent a subsystem that can be invoked as a function by another block. Function-call subsystems are not executed directly by Simulink; rather, the Stateflow charts or other blocks determine when to execute the subsystem. They can be executed repeatedly during the same simulation time step. When the subsystem completes execution, control returns to the caller.

For Iterator Subsystem

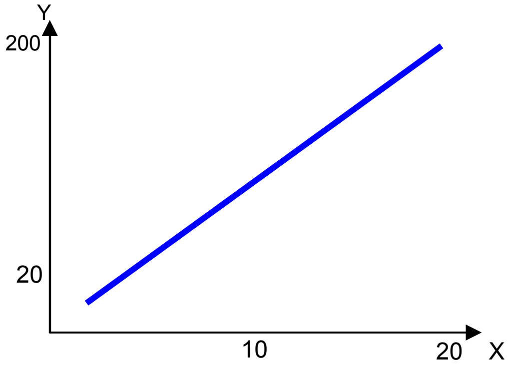


This block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem that executes repeatedly during a simulation time step. It contains the For Iterator block.

The For Iterator block, when placed in a subsystem, implements a C-like for control flow statement in Simulink as a For subsystem. In the For subsystem, the For Iterator block has iterative control over any Simulink blocks present. For each iteration value of the For Iterator block, the accompanying blocks execute. The number of iterations is set internally for the For Iterator block or externally with data input. The following example shows a completed for control flow statement that increments an initial value of zero by 10 over 20 iterations.



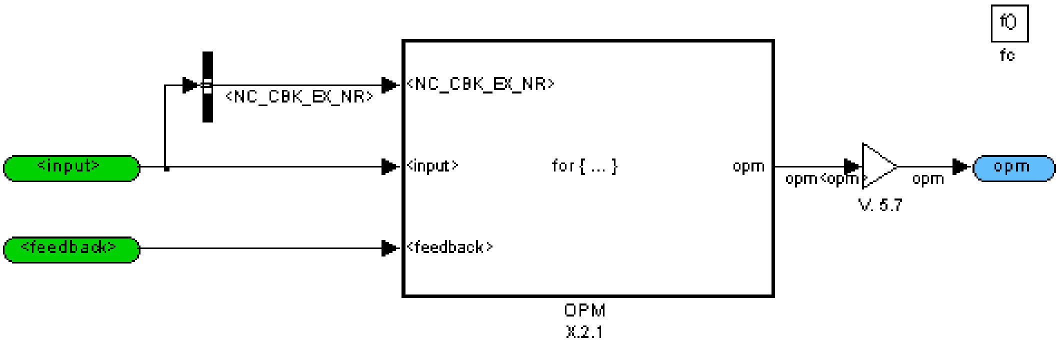
In the example above, a For subsystem receives an input, which it passes to the For Iterator block inside. The For Iterator block uses this input to determine the number of times it executes the blocks of its subsystem, in this case, 20 times. Each time the blocks execute, a value of 10 is added to a sum, which is initially zero. In addition, for each time the blocks of the subsystem execute, the For Iterator block outputs a value equal to the number of times that the blocks have executed, including the current execution. This is referred to as the iterator value. This value, along with the sum value, is sent to an XY Graph block:

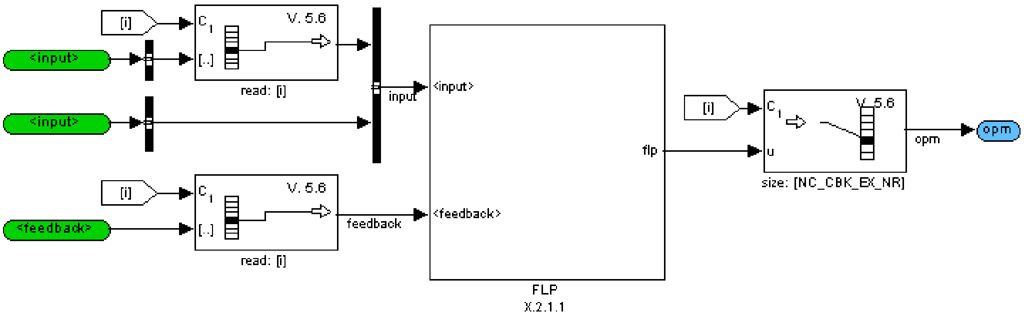


The control flow statement example above can be represented by the following pseudo code.

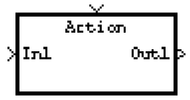
```
sum = 0;
iterations = 20;
sum_increment = 10;
for (i = 0; i < iterations;
i++) {
    sum = sum + sum_increment;
}
```

Example of a For loop:





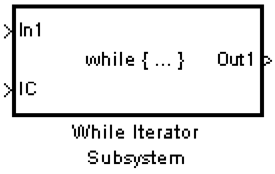
Switch Case Action Subsystem

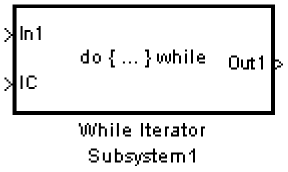


This block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by a Switch Case block. It contains the Action Port that links to a signal from a switch case block:

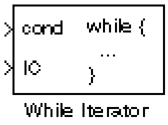
Note: The naming "Action" within this block is different to "Actions" which are connected to the SV Action concept

While Iterator Subsystem



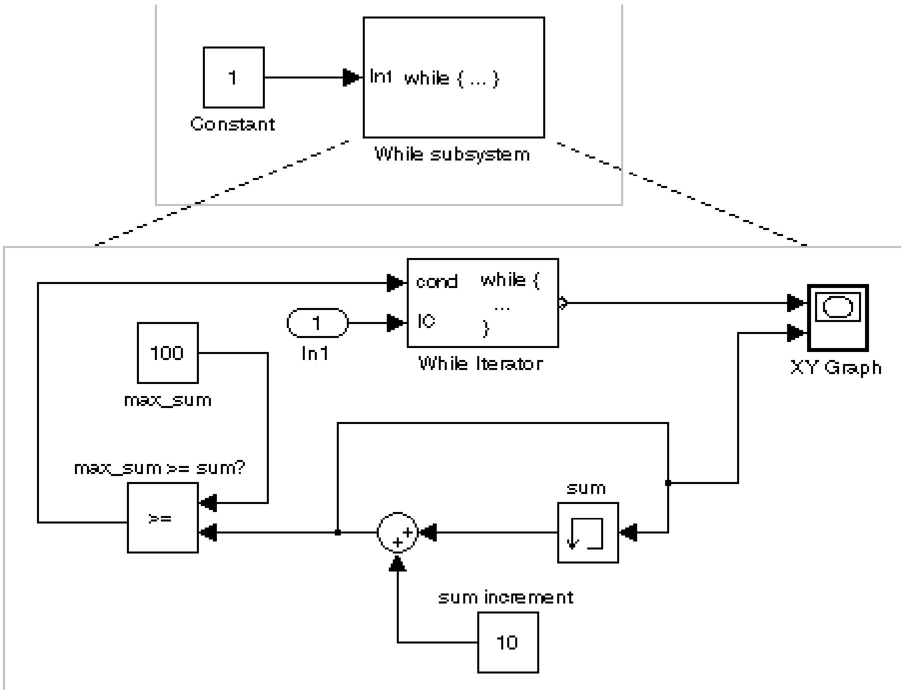


Represent a subsystem that executes repeatedly while a condition is satisfied during a simulation time step. This block is a Subsystem block that is preconfigured to serve as a starting point for creating a subsystem that executes repeatedly while a condition is satisfied during a simulation time step. It contains the While Iterator block.



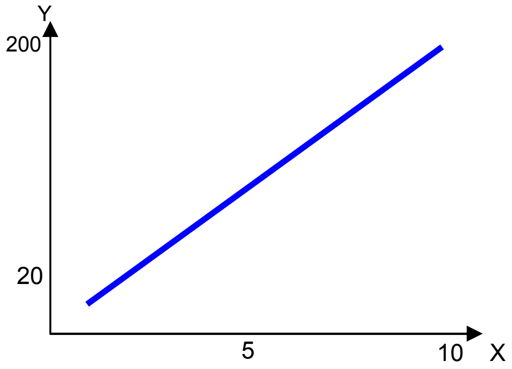
The While Iterator block, when placed in a subsystem, implements a C-like while or do-while control flow statement in Simulink as a While subsystem. It has iterative control over any accompanying Simulink block programming placed in the same subsystem with it.

For each iteration of the While Iterator block, the accompanying blocks perform one execution. Iteration takes place as long as the input conditions are true. This applies to an initial condition for the first execution (input port labeled IC) and a condition for succeeding executions (input port labeled cond). The following While subsystem example increments an initial value of 0 by 10 for every execution.



In the above example, a subsystem with a While block receives an input, which it passes to the IC (initial condition) port of the While block inside. If this value is true, the While block executes the blocks of the subsystem it is in. Since this value is 1 (true), the blocks execute and a value of 10 is added to a sum, which is initially 0. The sum is then compared to a value of 100. If the sum is less than or equal to 100, a value of true is passed to the While block through the cond (condition) port. This causes the blocks to execute again and again until the value passed to the While Iterator block is false and execution ceases.

In addition, for each time the blocks of the subsystem execute, the While block outputs a value equal to the number of times that the blocks have executed, including the current execution. This value, along with the sum value, is sent to the x and y coordinate inputs, respectively, of an XY Graph block with the following result.



The above while control flow statement example can be represented by the following pseudo code.

```
sum = 0;
IC = 1;
iteration_number = 0;
cond = IC;
while (cond != 0) {
    iteration_number = iteration_number + 1;
    sum = sum + sum_increment;
    if (sum >= 100 OR iterations > max_iterations)
        cond = 0;
}
```

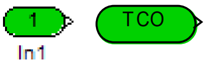
The equivalent pseudo code for a do-while iteration in the example above (minus the IC port) is as follows:

```
sum = 0;

iteration_number = 0;
cond = 1;
do {
    iteration_number = iteration_number + 1;
    sum = sum + sum_increment;
    if (sum >= 100 AND iterations > max_iterations) cond = 0;
} while (cond);
```

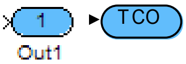
When you change the While Iterator block to do-while operation, the IC (initial condition) input disappears from the While Iterator block. The important distinction between the while and do-while modes of the While Iterator block is that the do-while mode runs the While subsystem at least once. In while mode, the While subsystem may not run its blocks at all depending on the value of the initial condition (IC).

Inport



Inport blocks are the links from outside a system into the system. The signal name (here: TCO) can optionally be displayed on the input

Outport



Outport blocks are the links from a system to a destination outside the system. The signal name (here: TCO) can optionally be displayed on the output.

Bus Creator

The Bus Creator block combines a set of signals into a bus, i.e., a group of signals represented by a single line in a block diagram. The Bus Creator block, when used in conjunction with the Bus Selector block, reduces number of lines required to route signals from one part of a diagram to another.

Bus Selector

Select signals from an incoming bus. The Bus Selector block accepts input from a Bus Creator block or another Bus Selector block. This block has one input port. The number of output ports depends on the state of the Muxed output check box. If you check Muxed output, then the signals are combined at the output port and there is only one output port; otherwise, there is one output port for each selected signal.

Mux

Combine several input signals into a vector or bus output signal. The Mux block combines its inputs into a single output. An input can be a scalar, vector, or matrix signal. Depending on its inputs, the output of a Mux block is a vector or a composite signal, i.e., a signal containing both matrix and vector elements. If all of a Mux block's inputs are vectors or vector-like, the block's output is a vector. A vector-like signal is any signal that is a scalar (one-element vector), a vector, or a single-column or single-row matrix. If any input is a nonvector-like matrix signal, the output of the Mux is a bus signal. Bus signals can drive only virtual blocks, e.g., a Demux, Subsystem, or Go To block.

Demux

Extract and output the elements of a bus or vector signal. The Demux block extracts the components of an input signal and outputs the components as separate signals. The block accepts either vector (1-D array) signals or bus signals.

Ground

The Ground block can be used to connect blocks whose input ports are not connected to other blocks. The Ground block outputs a signal with zero value. The data size of the signal is the same as that of the port to which it is connected.

Terminator

The Terminator block can be used to cap blocks whose output ports are not connected to other blocks.

Enable

Adding an Enable block to a subsystem makes it an enabled subsystem. An enabled subsystem executes while the input received at the Enable port placed at the top of the subsytem is greater than zero.

Trigger and function call

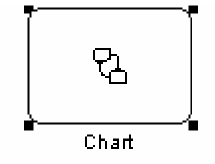
Adding a Trigger block to a subsystem makes it a triggered subsystem. A triggered subsystem executes once on each simulation step when the value of the signal that passes through the trigger port changes in a specifiable way (described below). A subsystem can contain no more than one Trigger block.

The Trigger type parameter allows you to choose the type of event that triggers execution of the subsystem:

- rising triggers execution of the subsystem when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative).
- falling triggers execution of the subsystem when the control signal falls from a positive or a zero value to a negative value (or zero if the initial value is positive).
- either triggers execution of the subsystem when the signal is either rising or falling.
- function-call causes execution of the subsystem to be controlled by logic internal to another block (and the subsystem becomes a Function_Call_Subsystem, see description above).

36.6.20 Stateflow

Stateflow Chart



This block indicates a Stateflow Chart, which is mainly used to model state machines. The chart can be triggered and contain variable number of outputs and inputs.

36.6.21 Functional differences between blocks from SDA 5.0 and blocks from 4.0 and 3.1

Version information

- All SDA 5.0 blocks in Automotive Blockset show version information on the block icon. Every block has own version 5.XX.
- Blocks from SDA 4.0 and 3.1 releases do not show version information on the block icon.

Functional differences

All SDA 5.0 blocks from Automotive Blockset are compatible with the MSR specification (V. 1.12). The previous (4.0 and 3.1) block versions have different functional behavior, which is listed below:

1. Group 1: Blocks which perform reset at the first calculation step after Reset signal (R) becomes zero.
2. Group 2: Blocks which do not perform functional reset (R) correctly if on first step after reset the enable signal E is not zero. In this case, the calculation uses a new state value equal to current input IV instead of stored input IV during the functional reset.
3. Group 3: Blocks which do not assign value to output if enable (E) signal is equal to zero and no logical reset (R or RT) is requested. It can produce mistakes in multi-rate mode after R_FC function call.
4. Group 4: Blocks which have wrong simulation behavior.

Pseudo-code from previous versions

This section lists the pseudo-code for blocks from previous versions (4.0 and 3.1) which have RE or RTE modes.

Standard ports:
- E: Suppresses the block calc.
- R: Resets to init values
- IV: Initial value set upon reset

Optional ports:
- State1_in: Direct input of internal state (x)
- State1_out: Direct output of internal state (x)
- R_FC: System reset request
- CLC_FC: System calculation request

CountDownRE

Port I/O Description
y: if counter state is zero
cnt: Out internal counter state

System-Init-Code
```
x = 0;
R1 = 0;
y = 0;
cnt = 0;
```

Init-Code (R_FC)
```
x = round(IV);
R1 = R;
```

Run-Code (CLC_FC)
```
if (R || R1) {
  x = round(IV);
}
else if (E) {
  if (x > 0){
    x = x - 1;
  }
}
y = (x > 0);
cnt = x;
R1 = R;
```

StopWatchRE

Port I/O Description
y Out Time since last reset
cnt: Out Internal counter state

Optional ports:
dT: Sample Time input

System-Init-Code
```
x = 0.0;
R1 = 0;
cnt = 0.0;
y = 0.0;
```

Init-Code (R_FC)
```
x = 0.0;
R1 = R;
```

Run-Code (CLC_FC)
```

    x = u;
  }
  else {
    y = x;
  }
}
R1 = R;
```

TurnOffDelaySample

Port I/O Description
n: Number of delays
u: Source signal (boolean)
y: Falling edge u, delay by n

System-Init-Code

```
x = 0; /* counter */
y1 = 0; /* y */
y = 0;
R1 = 0;
```

Init-Code (R_FC)

```
x = round(n);
y1 = (u || (x>0));
if (!u && (x>0)) {
  x = x - 1;
}
R1 = R;
```

Run-Code (CLC_FC)

```
if (R || R1) {
  x = round(n);
  y1 = (u || (x>0));
  if (!u && (x>0)) {
    x = x - 1;
  }
}
else if(E) {
  y1 = (u || (x>0));
  if (u) {
    x = round(n);
  }
  else if (x > 0) {
    x = x - 1;
  }
}
y = y1;
R1 = R;
```

TurnOffDelayTime

Port I/O Description
T: Delay time
u: Source signal (boolean)
y: Falling edge u, delay by T

Optional ports:
dT: Sample Time input

System-Init-Code

```
x = 0.0; /* timer */
y1 = 0; /* y */
y = 0;
R1 = 0;
```

Init-Code (R_FC)

```
x = T
```

Run-Code (CLC_FC)

```
if (R || R1) {
  x = T; /* reset */
  y1 =(u || (x>0.0));
  if (!u && (x>0)) {
    x = x - dT;
  }
}
else if (E) {
  y1=(u||(x>0.0));
  if (u) {
    x = T;
  }
  else if (x > 0.0) {
    x = x - dT;
  }
}
y = y1;
R1 = R;
```

TurnOnDelaySample

Port I/O Description
n: Number of delays
u: Source signal (boolean)
y: Rising edge u, delay by n

System-Init-Code
```
x = 0; /* counter */
y1 = 0; /* y */
y = 0;
R1 = 0;
```

Init-Code (R_FC)
```
x = round(n);
y1 = (u && (x<=0));
if (u && (x>0)) {
  x = x - 1;
}
R1 = R;
```

Run-Code (CLC_FC)
```
if (R || R1) {
  x = round(n);
  y1 = (u && (x<=0));
  if (u && (x>0)) {
    x = x - 1;
  }
}

  }
  else if (x > 0) {
    x = x - 1;
  }
}
y = y1;
R1 = R;
```

TurnOnDelayTime

Port I/O Description
T: Delay time
u: Source signal (boolean)
y: Rising edge u, delay by n

System-Init-Code
```
x = 0.0; /* timer */
y1 = 0; /* y */
y = 0;
R1 = 0;
```

Init-Code (R_FC)
```
x = T
```

Run-Code (CLC_FC)
```
if (R || R1) {
  x = T;
  y1=(u&&(x<=0.0));
  if (u&&(x>0.0) {
    x = x - dT;
  }
}
else if (E) {
  y1=(u&&(x<=0.0));
  if (!u) {

R1 = R;
```

36.7 How to read SDA based specifications

36.7.1 Introduction

The aim of this document is to enable the reader to understand the formalism of a SDA-model based specification. It is dedicated to customers or users dealing with the graphical specification.

SDA (System Design Automation) is the Matlab/Simulink/Stateflow[1] based function development environment used at Siemens VDO Automotive AG.

To understand the benefit of this new specification structure and formalism, this document first gives a very brief overview to a SDA model. SDA models are set up as Simulink/Stateflow models and have a clearly defined and unique structure as described in the following sections. Each SDA based specification is based on part of the complete and executable Model.

36.7.2 Matlab/Simulink/Stateflow.

This subchapter describes with a few words the tool used for modeling the behavior of a complete ECU. This tool is called Matlab. Matlab abbreviates "Matrix Laboratory" and has been developed for Technical Computing.

Matlab is:

- an interactive programming environment
- a high performance language
- a developers tool and
- a library of mathematical functions.

There are various software tools featured by Matlab the so-called **Matlab-Toolboxes**. They belong to the Matlab product family and are application-specific libraries of Matlab functions that customize Matlab for solving particular classes of problems. One of these toolboxes is Simulink.

Simulink is a graphical mouse-driven program for:

- the modeling of linear and non-linear dynamic systems,
- the simulation of them
- and of their analysis.

Simulink models are developed and parameterized as block diagrams. Pictures of these block diagrams are used to describe the functionality in the automatic generated specification.

Simulink-Blocksets are application-specific libraries for Simulink models. One of these blocksets is Stateflow.

Stateflow is a special blockset of Simulink for the design of:

- complex control structures,

---

Other product or brand names are trademarks or registered trademarks of their respective holders.

- i.e. for event driven systems,
- for their simulation and
- analysis.

Stateflow models are developed and programmed as state machines. Pictures of these state machines are used to describe the functionality in the automatic generated specification.

36.7.3 SDA model overview

Model

Although the final specification represents only a sub part of a complete SDA model, this section gives a short overview of a complete SDA - model.

A SDA model consists of five main parts:

- Stimuli (STI_PRJ_AGGR)
  The stimuli subsystem provides all signals and data inputs needed for the simulation of the model

- Display (DISP_PRJ_AGGR)
  In the display subsystem all outputs of the models are collected and visualized or saved to the Matlab Workspace.

- Plant (PLA_PRJ_AGGR)
  The plant contains a model of the system that has to be controlled by the Controller Unit. The behavior of the plant can be bypassed with input data in the Stimuli.

- Controller (PRJ_AGGR)
  The Engine Control Unit (ECU) holds the functionality of the controller. It is subdivided into aggregates (see below) which are again subdivided into modules.

For each module a separate specification is generated.

Aggregates

An aggregate holds the functionality of a specific function together with its inputs and outputs. The main part of an aggregate in the SDA environment is the subsystem called "*modules_<AGGR>*", where <AGGR> stands for the aggregate name (see Figure 1). In Simulink a subsystem is a graphical mean to group any portion of a model.
The subsystem "*modules_AGGR*" includes all modules of the aggregate. The modules themselves are once again subsystems. The signal flow between the modules is represented by signal lines and signal buses. Bus selectors are used to select and distribute the appropriate signal to the modules. All data inputs and outputs are defined on this level of the aggregate as shown in the following figure. In future this figure will be used in the specification to give an overview of an aggregate.

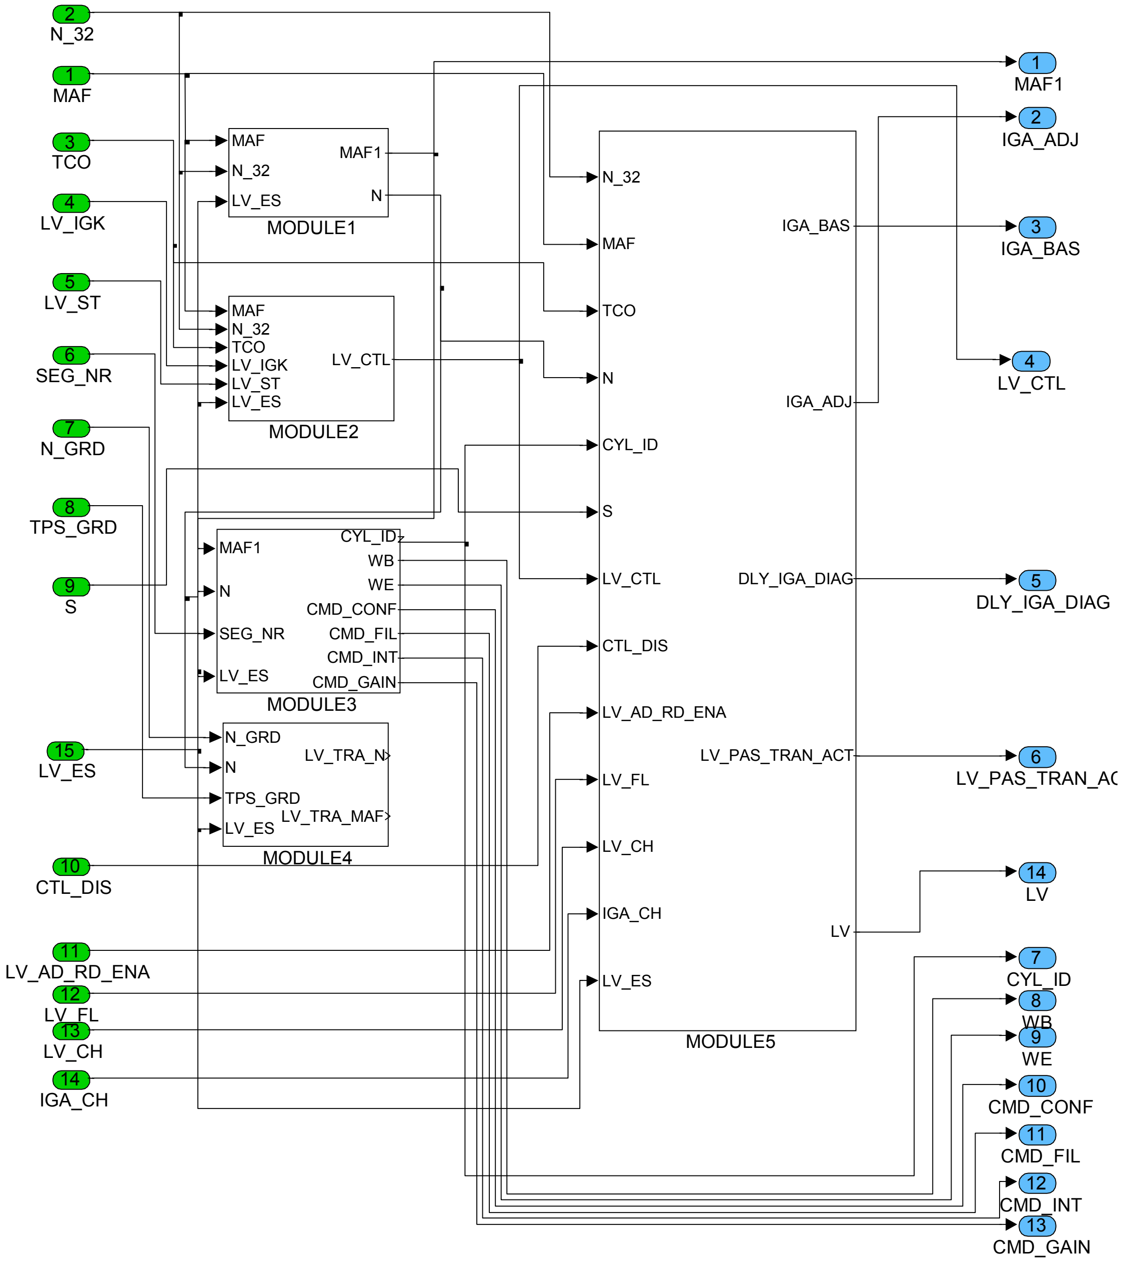

Figure 1 - Schematic picture of the content of an aggregate. This picture shows the subsystem named "modules_<AGGR>" including all the five modules (Module1 to Module5) of the aggregate. For each module a separate specification is generated.

Modules

A module is the lowest level modular component in the model. All modules are included in the subsystem "modules_AGGR". The whole functionality of the model is placed inside triggered subsystems within the modules. There is no restriction to the number of subsystem levels. Content of the subsystems in the modules is shown in the graphical software requirement specification (SDA-SRS). This means that only the part relevant for the calibration is shown in the pictures in the SRS. Beside the pictures there is also some textual description for the separate functionality. These text explanations are directly followed by their respective pictures, as shown in the graphical software requirement specification (SDA-SRS).

36.7.4 SDA specific Simulink notation

The functionality of the modules is build up with Simulink blocks that are placed inside triggered subsystems. The pictograms on the Simulink blocks represent a special functionality.

The blocks that are allowed for modeling within the SDA environment are included in separate libraries:

- the AT_Basic_Blocks ("Automotive Blockset")
- the AT_Lib library

In "Documentation Automotive Blockset" and "Documentation AT_Lib" a short description of the different blocks is given. The blocks are connected by signal lines, which represent the signal flow between them. Moreover the control flow in the model is driven by function calls that trigger the different subsystems, i.e. a function call is a signal that initiates the calculation of a functionality grouped in a subsystem.

SDA generated SRS include some special layout features that are listed here and demonstrated in the example in Figure 2:

- Thin lines mark scalar signals.
- Thick lines mark multidimensional signals e.g. arrays, vectors...
- Threefold lines.

Threefold lines represent bus signals, i.e. different signals that are collected together and represented by one "bus"-signal. This is similar to a data structure in Software. The block "bus creator" is used to collect the data "signal2" from the input "In1" and the data "Signal1" from the block "Constant1".

The block "bus_selector" is used to select dedicated signals from the bus. An example is shown in the figure with "Signal1" and "signal2". This example shows also that:

- Dashed lines represent function calls or triggers. In the example a so-called "Function-call generator" is used to initiate the evaluation of the constant block "Constant1" which write the array [1,2,3] to its output.
- Instead of signal lines local Goto/From blocks can be used to connect two subsystems as a kind of invisible signal line.
- Signal names are written beside the signal line.
- Input ports (e.g. the block "In1") and output ports (the block "Out1" or "Out2") provide the interface of the subsystem to the environment, i.e. they show the input and output data of a subsystem.

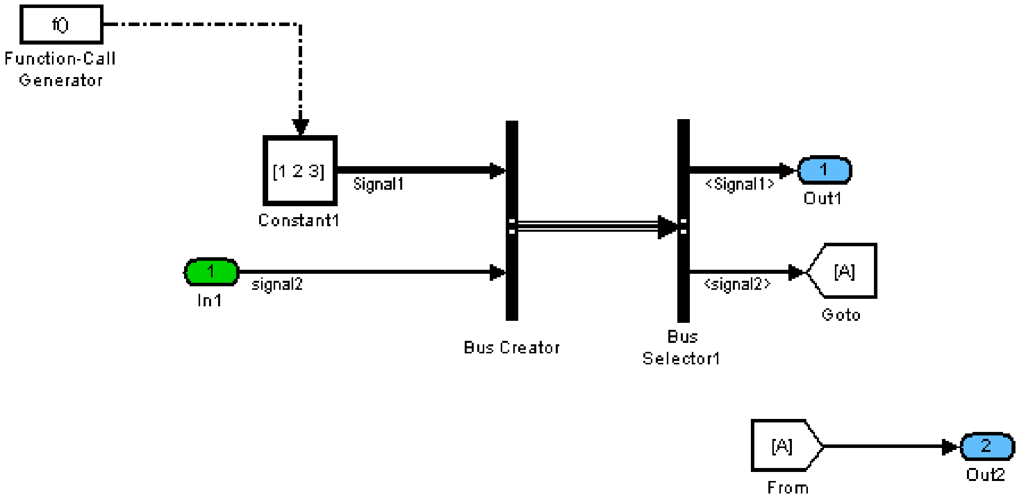

Figure 2 - Example

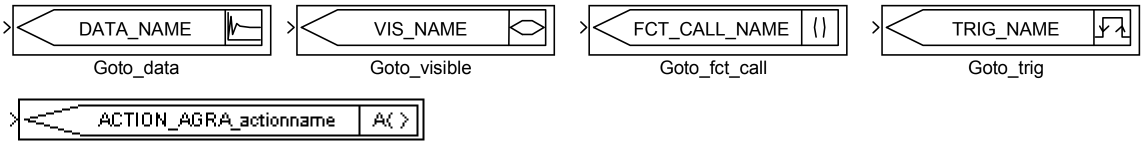
- The port names are shown on the respective subsystem (in this example: "In1", "Out1" and "Out2".
- There exist different **global** Goto/From blocks for data signals, visibles, function calls and triggers. E.g. the Goto blocks:



- All visibles are available via the application system.
- All goto/from data are outputs/inputs of modules.
- If a subsystem has an input signal that is also an output signal of this subsystem, the suffixes "_in" are added to the input port name and "_out" to the output port name.

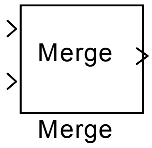
This means for example if the signal "A1" is both, input and output data of a subsystem, the input port is named "A1_in" and the output port "A1_out".

36.7.5 Structure of the SDA-Specification

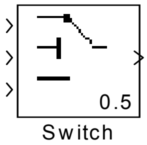
The SDA-SRS layout is based on the layout of the standard WinWord Specifications. The first section includes tables of all output, input, calibration and configuration data. For output data the name, mode, hex. limits, phys. limits, resolution and unit is given in the table, whereas for the calibration and configuration data the dimension is given instead of mode. The input data table only holds the names of the variables.

An optional textual description and an overview picture of the module follow this section. Afterwards the contents of the subsystems with optional textual descriptions are included in hierarchical order. The pictures in a SRS are always shown after their respective text description.

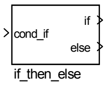
36.7.6 Special Simulink blocks and their usage



The **Merge block** combines its inputs into a single output line. The output value at any time is equal to the most recently computed output of its driving blocks. The Merge block mainly is used to merge a "normal" operate signal with a reset signal. In order to achieve the right performance it has to be taken into account the execution order of its driving blocks.



The **Switch block** propagates one of two inputs to its output, depending on the value of a third input, called the control input. If the signal on the control (second) input is greater than or equal to the Threshold parameter (shown in the block) the first input; otherwise, it propagates the third input.



The **if-then-else block** provides the possibility to implement an if-then-else control structure in Simulink. The input of this block is the condition "cond_if". If the condition is true (= 1) then the function call "if" is sent out. Else the function call "else" is sent out. These function calls can be used to trigger the corresponding subsystems.

36.7.7 How to read SDA conform Stateflow charts

Introduction

The aim of this chapter is to enable the reader of SDA based specifications to understand the Stateflow charts used in SDA models. This document is not a Stateflow reference, it shows only the usage according to the SDA Guidelines.

Stateflow objects overview

Graphical objects

Name	**Description**[2]
State	States are the primary objects of Stateflow. They represent modes of a system.
Transition	A transition is a pathway for a chart or state to change from one mode (state) to another.
Default transition	Default transitions tell Stateflow which of several possible states to enter first for a chart or superstate.
Connective junction	A connective junction represents a decision point between alternative transition paths.
History junction	A history junction records the most recently active state of the chart or superstate in which it is placed.
Function	Functions that are graphically defined by a flow graph. The flow graph is contained inside a box with the function name.
Box	Boxes are used to group parts of a diagram.

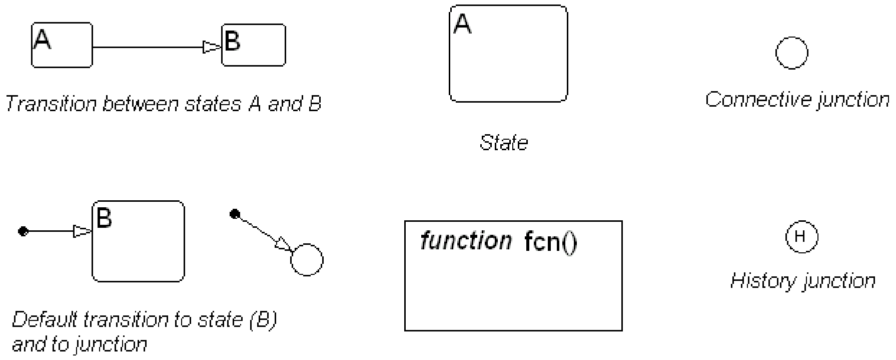


Figure 3 - Symbols used to represent graphical Stateflow objects

Non graphical objects:

Data object: data used in a state chart to control its execution. It can be created in the Stateflow chart itself (local data) or be imported from the Simulink model that calls the chart (input data). Simulink models can also read the Stateflow data, when it is declared as an output from the chart (output data).

Event object: an event can trigger whole Stateflow charts or individual actions in a chart. A Stateflow chart reacts on events and can broadcast events to its internal objects or send events to the Simulink model. Events are triggers or function calls.

Interface to Simulink

Figure 4 shows the interface between a Stateflow chart and the Simulink model. As shown, function calls and triggers can awake the chart. The chart can also send events to the model, use data as inputs and produce data as outputs.

The chart runs only one event input at each time.

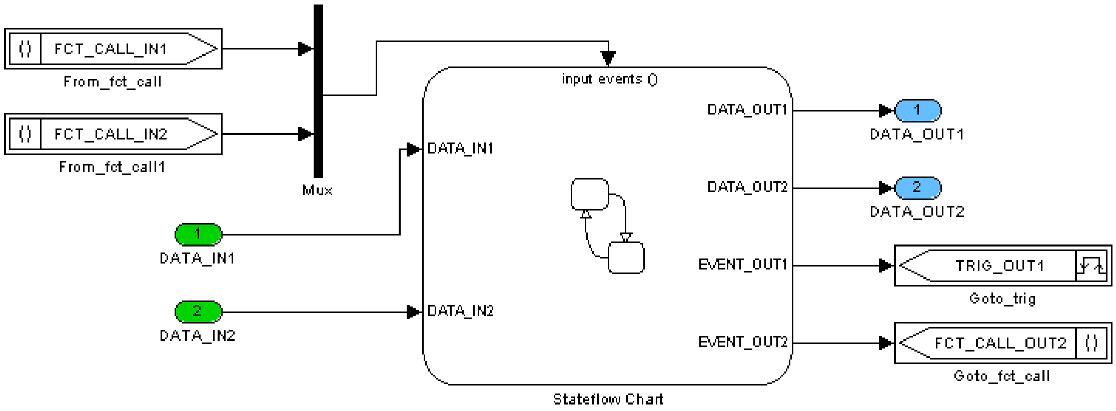

Figure 4 - Interface between a Simulink model and a Stateflow chart

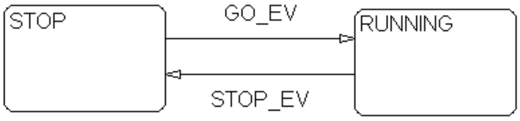
States

A state describes a mode of a reactive Stateflow chart. The chart always has one or more active states. An active state tells that the chart is in this state's mode. Figure 5 shows a chart that can assume two modes: stop and running.



Assume: State "STOP" is at the beginning active.

Chart reaction on certain events:

1. Event "STOP_EV" awakes the chart …nothing happens.
2. Event "GO_EV" awakes the chart.
   "STOP" is deactivated.
   "RUNNING" is activated.
3. Event "STOP_EV" awakes the chart.
   "RUNNING" is deactivated
   "STOP" is activated.

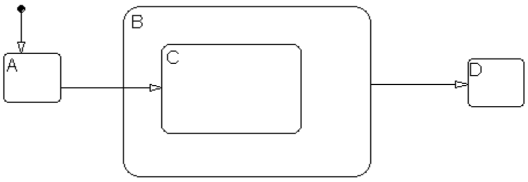
Figure 5 – Transition between two states

Activation

A transition between two states, state A to state B, changes state A to inactive and state B to active. A transition occurs always from an active state to an inactive state. The transitions are driven by events and controlled by conditions. The whole transition path between both active and inactive states must be evaluated and be valid so that the transition can occur.

Hierarchy

Every state is part of a hierarchy. States can be superstates, substates or just states. A state is a superstate if it contains other states, which are called substates. When a superstate turns active, one of its substates - if existent - turns also active. In the same way, when a substate turns active, it makes it superstate also active. See in Figure 6 some examples. The Stateflow chart itself is, in a SDA model, the highest hierarchical element.



The chart is awaken for the first time:
Default transition occurs and state A is activated.

The chart is awaken for the second time:

1. Transition between A and C is valid
2. A is deactivated
3. Transition occurs
4. B is activated
5. C is activated

The chart is awaken for the third time:

1. Transition between B and D is valid
2. C is deactivated
3. B is deactivated
4. Transition occurs
5. D is activated

Figure 6 – Hierarchical relation between states

Decomposition

Each state can be decomposed in substates. There are two kinds of decomposition: AND and EXCLUSIVE OR. See an example on Figure 7.

Parallel AND decomposition: one or more substates can be active at the same time. The substates are drawn with dashed borders.

Parallel EXCLUSIVE OR decomposition: only one substate can be active. The substates are drawn with continuous borders.

Substates of an superstate with parallel AND decomposition are drawn with dashed borders. When such a superstate activates, its substates are then activated in the order they appear - beginning at the top left side and finishing at the bottom right side. Only superstates with AND parallel decomposition can have two or more active substates at the

same time.

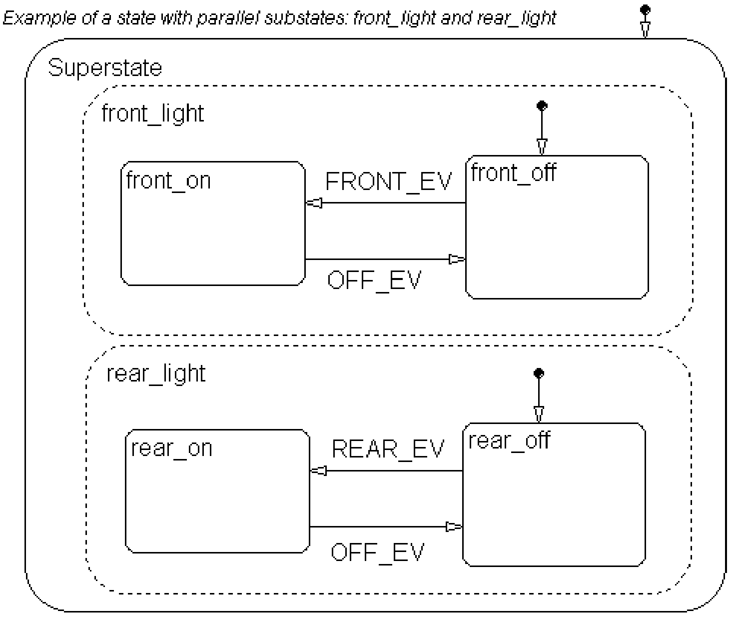


Figure 7 - Example of parallel state decomposition

This example shows a chart with three hierarchy levels:

1. First level: is the chart itself, contains the state "superstate" inside.
2. Second: content from state "superstate".
3. Third: content from the states "front_light" and "rear_light"

Decomposition:

- "superstate" has AND decomposition.
- "front_light","rear_light" and the chart itself have EXCLUSIVE OR decomposition.

Activation order in the AND decomposition:

- "front_light" is activated first ("1") and then "rear_light" ("2"). Both are active during the same time.
- The deactivation of parallelal substates occurs in the inverse order.
- In this example, if "superstate" will be deactivated, first "rear_light" will is deactivated, than "front_light" and finally "superstate".

History

A state also has history that applies to its level of hierarchy in the Stateflow diagram. When a superstate deactivates, it implies that its substates are also turning deactivated. When a history junction is present, activating the superstate again will reactivate the same substate that was activated before the last deactivation.

Stateflow actions

Stateflow action type

Actions are statements with mathematical expressions or event broadcasting. The Figure 8 shows some examples of actions.

In SDA Stateflow charts, actions can be either event broadcasting or value assignment. If a data is an input from Simulink, it can be used only on right hand side operations (is not possible to assign new values to it). If a data is an output to Simulink or a local data, it can be used on both sides. Multiple actions can be ordered in a list, separated with semi-colons to each other. The actions in a list are executed in the order they appear.

State actions

Four action types can be specified for one state: entry:, during:, exit:, or on: <<event_name>>

actions. This actions are specified in the state label, after the state name followed by a slash:
STATE_NAME/
entry: << action list >>; /* Actions are executed right after the state activation. */
during: << action list >>; /* Actions are executed if the state is active and there is no valid transition to another state. */
exit: << action list >> /* Actions are executed right after the state deactivation. */
on <<event_name>>: << action list >> /* Actions are executed when the specified event occurs */

Note: entry: and exit: actions are executed always after a transition has occurred. A during: action is execution as long as no transition has occurred. Entry, during and exit are also referred as en:, du: and ex:.

Transition evaluation

Transition path

A transition path is a sequence of transitions joined by connective junctions. A path doesn't necessary lead to a valid transition between two states.

Evaluating a transition doesn't mean that this transition will occur. A transition (between two states) occurs only if the hole path is valid. Nevertheless, the evaluation of all possible transitions follows always the sequence established by their precedence rules.

*That means, if a transition containing a condition statement is valid, its condition action (if it exists) runs at the evaluation time, without taking care if this transition is in a path that will lead to a transition between states or not. The same is not true for transition actions: they run only if the whole path containing them is true and also only **after** the transition between both states (initial and final) has occurred.*

Transition label

The switching from one state to another may be driven by events (function call, trigger) or conditions that are labeled to the transition arrow. The label notation has the following syntax:

event_name[condition_statement]{condition_ actions;}/transition_ action;

All three parts of the label notation are optional: event_name, transition action, and the set condition expression plus condition action. It is not obligatory to specify a condition action for a condition expression.

*A transition action happens only if the whole path containing the transition is true. The action happens after the transition has occurred. Transition actions are declared after a slash at the end of the transition label. Transition actions are **not** allowed in SDA transition action labels.*

The condition label [condition_statement] is evaluated as an expression with Boolean result. A transition containing a condition statement can only be valid if the condition result is true.

A condition action happens whenever a condition is evaluated and is true. The action *happens right after the condition evaluation. Condition actions are declared inside brackets {<< action list >>} after the condition declaration.*

A condition statement can contain a call to an *In(<<state_name>>)* function, that is evaluated true when the state *"state_name"* is active. See the tables at the end of this documentation for more information about operations precedence and syntax. See in Figures 5, 7 and 8 some transition label examples.

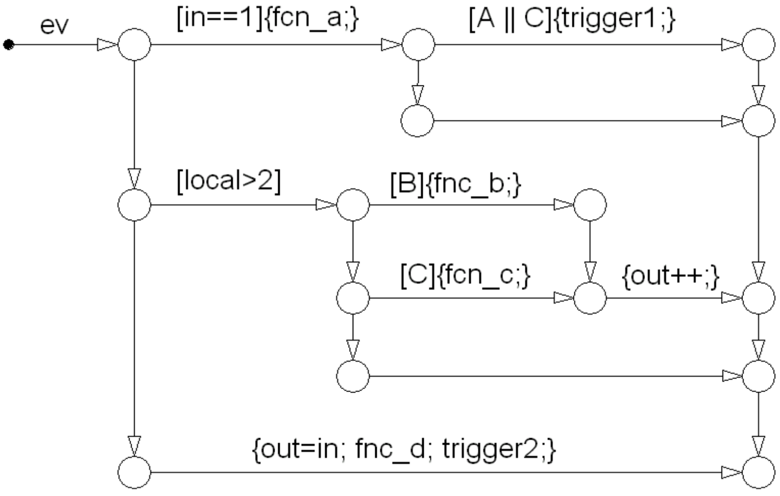
Precedence rules for transition evaluation

The evaluation of transitions coming from a single source obeys the following precedence order:

1. **End point hierarchy:** *transitions whose end points are attached to higher hierarchical levels are evaluated first.*
2. **Label:** *transitions are ordered for evaluation according to the types of action language present in their labels, with precedence as follows:*
   2.1. Labels with events and conditions.
   2.2. Labels with events
   2.3. Labels with conditions
   2.4. No label
3. **Transition angular position in its source:** *evaluation order based on the angular position of the transition on the surface of the originating object:*
   A - Multiple outgoing transitions from states
   Are evaluated in a clockwise progression starting at the upper left corner of the source state.
   B - Multiple outgoing transitions from connective junctions
   Are evaluated in a clockwise progression starting at the twelve o'clock position on the junction.

Figure 8 - Example: if - then - else construction

The following flow chart was made observing the SDA guidelines:



Events:
ev, trigger1, trigger2, fnc_a, fnc_b, fnc_c, fnc_d

Data:
in, out, local, A, B, C, D

Conditions present in the chart:
ev, [in==1], [A||C], [B], [C], [local>2]

Actions present in the chart:
{fnc_a;}, {trigger1;}, {fnc_b;}, {fnc_c}, {out++}, {out=in, fnc_d; trigger2;}

Attempting the precedence rules between transitions, a possible representation of this flow chart in c-like pseudo-code could be (this is not a suggestion!):

```
transition_occurred_flag=0;
if(arriving_event==ev){
      if(in==1){
            fcn_a();
            if(A||C){
                  transition_occurred_flag=1;
                  trigger(trigger1);
            }
            if(1)
                  transition_occurred_flag=1;
      }
      if(!transition_occurred_flag && local>2){
            if(B){
                  transition_occurred_flag=1;
                  fnc_b();
            }
            if(!transition_occurred_flag && C){
                  transition_occurred_flag=1;
                  fnc_c();
            }
            if(transition_occurred_flag)
                  out++;
            }
            if(1)
                  transition_occurred_flag=1;
      }
      if(!transition_occurred_flag){
            out=in;
            fnc_d();
            trigger(trigger2);
            transition_occurred_flag=1;
      }

}
```

Inner transition

An inner transition is a transition that does not exit the source state. It is represented as an internal transition from a superstate to a substate or to the superstate itself. When a inner transition occurs, it has the same result as when the superstate was deactivated and then reactivated, but the state remains active all the time.

The inner transition is part of the state it belongs to. It is evaluated only during this state, like other transitions inside the same state.

That means: when the inner transition occurs, the active substate exits and a new substate is activated. The new active substate is chosen by the inner transition. When it points to the superstate itself, the rules are the same as if the superstate is being activated from an external state. In this case, a default transition inside the superstate or a history junction will take effect. In Figure 9, the transitions 1, 3 and are inner transition of state A. Transition 4 is a inner transitions of state B. Transition 2 is self-loop transition, not a inner transition.

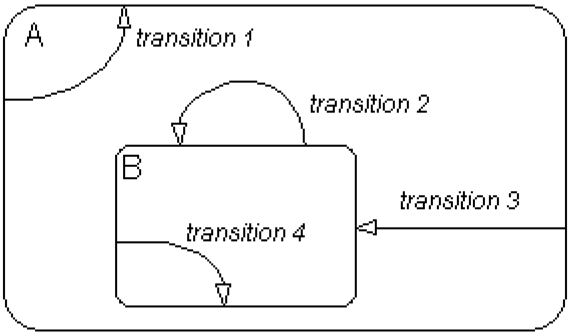


Figure 9 - Inner transition examples: transitions 1, 3 and 4.

Direct event broadcast

It is possible to broadcast an event directly to another state in the same chart (local event) using the action command *send*:

send(event_name,state_name): Broadcasts the event "*event_name*" to the state "*state_name*" and any of its offspring in the hierarchy. "state_name" must be already active in order to receive the sent event.

Notes

1. Matlab, Simulink, and Stateflow are registered trademarks of TheMathworks, Inc. Other product or brand names are trademarks or registered trademarks of their respective holders.
2. From the Matlab, Simulink and Stateflow documentation.

Tables

The following tables show the possible Stateflow operations used to write statements (Stateflow action language) and conditions. The precedence order must be considered.

Assignment operations

Example	Description[2]
`a = expression`	Simple assignment
`a += expression`	Equivalent to `a = a + expression`
`a -= expression`	Equivalent to `a = a - expression`
`a *= expression`	Equivalent to `a = a * expression`
`a /= expression`	Equivalent to `a = a / expression`

In C-like bit operations:

Example	Description[2]
`a |= expression`	Equivalent to `a = a | expression` (bit operation).
`a &= expression`	Equivalent to `a = a & expression` (bit operation).
`a ^= expression`	Equivalent to `a = a ^ expression` (bit operation).

Unary operations

Example	Description[2]
~a	Logical NOT of a
!a	Logical NOT of a
-a	Negative of a

Unary actions

Example	Description[2]
a++	Increment a
a--	Decrement a

Binary and Bitwise operations

Example	Precedence	Description[2]
a * b	10	Multiplication
a / b	10	Division
a %% b	10	Modulus
a + b	9	Addition
a - b	9	Subtraction
a >> b	8	Shift operand a right by b bits. Noninteger operands for this operator are first cast to integers before the bits are shifted.
a << b	8	Shift operand a left by b bits. Noninteger operands for this operator are first cast to integers before the bits are shifted.
a > b	7	Comparison of the first operand greater than the second operand
a < b	7	Comparison of the first operand less than the second operand
a >= b	7	Comparison of the first operand greater than or equal to the second operand
a <= b	7	Comparison of the first operand less than or equal to the second operand
a == b	6	Comparison of equality of two operands
a ~= b	6	Comparison of inequality of two operands
a != b	6	Comparison of inequality of two operands
a <> b	6	Comparison of inequality of two operands
a & b	5	Logical AND of two operands or Bitwise AND of two operands
a ^ b	4	Operand a raised to power b or Bitwise XOR of two operands
a | b	3	Logical OR of two operands or Bitwise OR of two operands
a && b	2	Logical AND of two operands
a || b	1, last precedence	Logical OR of two operands

36.8 Initialization of variables from non implemented functions

All defined LV_ERR_XXX shall not be given ENVD data for the .a2L file (normally automatically defined)

EXCEPT: LV_ERR_TEG_PCAT_DOWN[NC_CBK_EX_NR]

Variable to reset SAG_AD variables due to a EOL request					
SOI_MAX	O	0...780H	0...720	0.375	[°CRK]
Earliest possible SOI					

Input data:

CRK_INJ_BAS[NC_CYL_NR]	INH_IV	LV_CLC_2SEG	LV_CLC_2SEG_ENA
LV_FCUT_IND	SOI_LIM		

FUNCTION DESCRIPTION: ---

Application conditions:

Initialisation: 0

Recurrence : every segment

Activation: every state if LV_CLC_2SEG = 1 **or** LV_CLC_2SEG_ENA = 0

Configuration data: NC_IN_REF = 42 *// one intake bank*

NC_LAMB_REF = 42 *//(101010B)*

Formula section:

EOI_LIM[NC_CYL_NR] = CRK_INJ_BAS[NC_CYL_NR]

INH_CYC_IV = INH_IV

LV_IND_FCUT = LV_FCUT_IND

SOI_MAX = SOI_LIM

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_IN_REF	1	0...FFH	0...255	1	[-]
Pattern for allocation of physical cylinders to intake bank					
NC_LAMB_REF	1	0...FFH	0...255	1	[-]
Pattern for allocation of physical cylinders to exhaust bank					

36.8.6 Adaptation module for non implemented VVL functions

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
ANG_EXC_VVL	O	0...238EH	0...200	0.0219732	[°]
Selected current value in grad after jitter filtration					
MAP_DIP_SP_MMV	O	8000...7FFFH	-1280... 1279.96093	0.0390625	[hPa]
Filtered setpoint of manifold differential pressure					
Mrnn_test_vvt	O	8000...7FFFH	-1...0.99996	0.0305e-3	[-]
Testerwert NN VVT-Adaption					
VLFT_MIN	O/S	0...FFFFH	0...65.535	0.001	[mm]
Result of adaptation of minimal variable valve lift					

FUNCTION DESCRIPTION: ---

Application conditions:

Initialisation: 0, except: ANG_EXC_VVL = 200 °

36.8.7 Adaptation module for non implemented STST (MSA) functions

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_DRIV_BELT_CLOSE	O	0...1H	0...1	1	[-]
Driver seat belt fastened					
LV_STST_DEAC_ACT	O	0...1H	0...1	1	[-]

36.9 Logic outputs

36.9.1 General management of logic outputs

FUNCTION DESCRIPTION:

General information:

Logic outputs are outputs which are piloted by software without PWM or CAPCOM.

Initialization:

At initialization phase, each logical output is set or reset versus function need.
See detail file of each output.

Logic state:

Positive logic means the connector output is "active" or "ON" (current present through the load) when the corresponding boolean is true.

The output is “ON” when the voltage level is low at the ECU connector and is “OFF” when the voltage level is high at the ECU connector.

Update recurrence:

All logical outputs are updated at application recurrence except those piloted by SPI octal link which are updated at 10 ms with jitter < 1ms.

Diagnostic:

Several options are proposed. For detail see chapter on output diagnostic.

36.10 PWM outputs

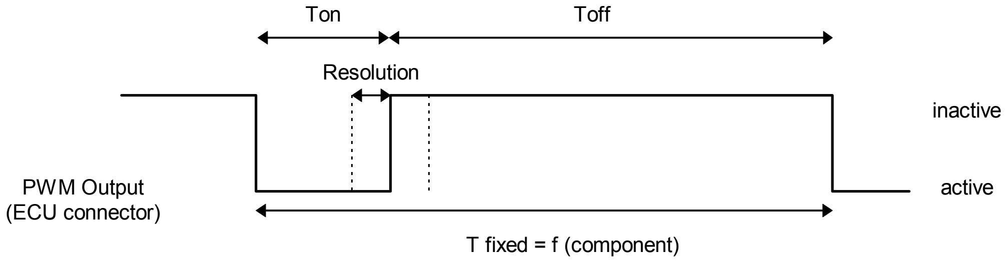
36.10.1 General management of PWM outputs :

FUNCTION DESCRIPTION:

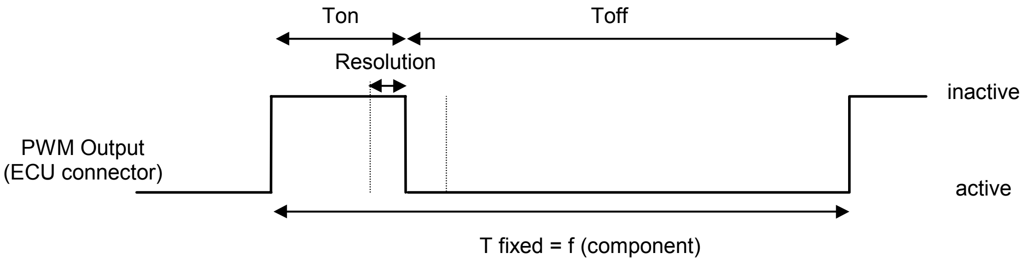
General information:

PWM management principle :

“Positive” PWM :



“Negative” PWM :



Duty cycle = Ton / T

PWM outputs are 2 types :

- True PWM using a POUT µP output. In this case the duty cycle range could be 0 . . 100%
- Pseudo PWM using a CAPCOM µP output. In this case, minimum Ton and minimum Toff are 300 µs with standard priority.

Initalization:

During hard reset and software initalization, all PWM outputs are inactive. As soon as application software start, the PWM outputs are piloted. Inactive output means inactive driver output.

36.11 PWM outputs

36.11.1 List of PWM outputs

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IVVTPWM_0	V/O	0...FFFFH	0...99.99847	1.53E-03	[%]
PWM for inlet VANOS					
IVVTPWM_1	V/O	0...FFFFH	0...99.99847	1.5259e-3	[%]
PWM for outlet VANOS					

Input data:

MTCPWM	CPPWM_CPS	LSHPWM_UP[NC_CBK_EX_NR]	LSHPWM_DOWN[NC_CBK_EX_NR]
ECFPWM_ECF	ECTPWM	VIMPWM_1	VCVPWM
ECRASPWM	VIMPWM_2	WGPWM[NC_CBK_EX_NR]	PWM_ACR
FPAPWM		LV_VAR_TCHA	LC_POIL_CTL_ENA
POIL_PWM			

Data definition:

Name	ECU Pin Name (Output)	Definition / Remark	Frequency (Hz)
MTCPWM	A_T_MDK	Main throttle control	600
LSHPWM_UP_1	A_T_LHV1	LSH bank 1 upstream	See EGCP configuration
LSHPWM_UP_2	A_T_LHV2	LSH bank 2 upstream	
LSHPWM_DOWN_1	A_T_LHH1	LSH bank 1 downstream	
LSHPWM_DOWN_2	A_T_LHH2	LSH bank 2 downstream	
ECTPWM	A_S_KFK	electronically controlled thermostat	1
IVVTPWM_0	A_T_NWE1	VANOS unit 1 (inlet 1 or inlet)	244
IVVTPWM_1	A_T_NWE2	VANOS unit 2 (inlet 2 or outlet)	244
CPPWM_CPS	A_T_TEV	canister purge valve	Def. in EVAC
ECFPWM_ECF	A_T_ELUE1	cooling fan	100 (10 during power latch)
VCVPWM	A_T_MSV	Flow control valve	201
PWM_ACR	A_T_AGR1/2	Exhaust gas recirculation valve	976
ECRASPWM	A_T_LKS	Electronical controlled radiator shutter	200

Switchover between FPAPWM and POIL_PWM

If LC_POIL_CTL_ENA = 0

then

FPAPWM	A_T_DSV	Pressure control valve	1)

else

POIL_PWM	A_T_DSV	Electronically controlled oil pressure actuator	2)

endif

1.) According module ' High pressure pump control (Appl. Inc.)'

2.) According module 'Cus adap module: ENLU'

Additional for LV_VAR_TCHA = 0

Name	ECU Pin Name (Output)	Definition / Remark	Frequency (Hz)
VIMPWM_1	A_T_DISA1	variable intake manifold chanel 1	200
VIMPWM_2	A_T_DISA2	variable intake manifold chanel 2	200

Additional for LV_VAR_TCHA = 1

Name	ECU Pin Name (Output)	Definition / Remark	Frequency (Hz)
WGPWM[2]	A_T_WG2	wastegate chanel 2	300
WGPWM[1]	A_T_WG1	wastegate chanel 1	300

List of corresponding logic values:

Name	Definition
LV_MTC_DIR	direction of MTC
LV_MTC_DIS	disable MTC

36.11.2 Output PWM for inlet and outlet VANOS

The PWM outputs for both VANOS actuators are driven directly by BMW- objects via function call. To know the actual PWM- value in the system, the registers of the PWM-outputs are mirrored into system variables (IVVTPWM_0 and IVVTPWM_1). To reach a permanent micro-movement of the control piston in the valve a variable Frequency-Control is implemented driven directly by BMW- objects via function call: PWM_FRQ_NWA1(), PWM_FRQ_NWE1().

The minimum frequency, which can be adjusted, is 75 Hz

36.11.3 Output for HPDI relay

CH_PWM_DCDC = 80%

36.12 Interface definitions - Outputs from BMW functions to aggregate adaptation modules

Input data:

N	LV_VAR_TCHA		

General information:

This module is a customer request out of the BMW-SV Software Layer, where the scheduling of BMW tasks is defined. For detailled information on the scheduling of BMW tasks please refer to the corresponding layer specification.

To prevent the CPU from overload the scheduling of some BMW tasks may be halved via engine speed thresholds or switched of via LV_VAR_TCHA. In case engine speed exceeds the corresponding threshold only each 2nd function call will be conducted.

Application conditions:

Initialisation: all = 0 at reset

Recurrence: seg and 10ms, 20ms

Activation: always

Deactivation: -

Formula section:

Function call MDBAPRIO_10MS:

36.14 OBJ File Reference List for SW release 80B3800S

FUNCTION DESCRIPTION:

General information:

This document is used to handle the configuration mangement of desired implementation of the customer OBJ files. For each SW release a fitting list of OBJ file references has to be created. The list is sorted in alphabetic order.

Description:

37.1 HVAC - Requirements to Infrastructure interface

Export actions:

ACTION_INFR_SetACCOUT(IN <lv_accout_rly>**)**
This action sets the output pin for the "ACCOUT Switch"
ACTION_INFR_SetCRCVHEAT(IN <lv_rly_crcv_heat>**)**
This action sets the output pin for the "CRCV_HEAT Switch"
ACTION_INFR_GetElDiagACCOUT(OUT < Cdn_diag_rly_accout >, **OUT** < Err_diag_rly_accout >**)**
This action reads the failure and condition information for a symptom of the accout switch.
ACTION_INFR_GetElDiagCRCVHEAT(OUT<Cdn_diag_rly_crcv_heat >, **OUT**<Err_diag_rly_crcv_heat>**)**
This action reads the failure and condition information for a symptom of the crcv_heat switch.

Description for actions:

ACTION_INFR_SetACCOUT(IN < lv_accout_rly >**)**					
This action sets the output pin for the "ACCOUT Switch"					
Name	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
lv_accout_rly	IN	0H 1H	ACC-relay deactivated ACC-relay activated	1	-
Set ACC-relay					

ACTION_INFR_SetCRCVHEAT(IN < lv_rly_crcv_heat >**)**					
This action sets the output pin for the "CRCV_HEAT Switch"					
Name	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
lv_rly_crcv_heat	IN	0H 1H	CRCV-HEAT relay deactivated CRCV-HEAT relay activated	1	-
Set CRCV-HEAT					

ACTION_INFR_GetElDiagACCOUT(OUT <Cdn_diag_rly_accout >, **OUT** < Err_diag_rly_accout >**)**					
This action reads the failure and condition information for a symptom of the accout switch. When calling this action the information inside the infrastructure is reset after returning the OUT parameters.					
Name	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cdn_diag_rly_accout	OUT	0...7H	0...7	1	-
Diagnosis condition for symptoms of ACCOUT: bit 0: Set, if diagnosis condition for symptom SCP (SYM_0) is fulfilled bit 1: Set, if diagnosis condition for symptom SCG (SYM_1) is fulfilled bit 2: Set, if diagnosis condition for symptom OC (SYM_2) is fulfilled (all combinations are possible)					
Err_diag_rly_accout	OUT	0...7H	0...7	1	-
Raw value of error symptom: bit 0: Set, if raw value of error symptom SCP (SYM_0) is set bit 1: Set, if raw value of error symptom SCG (SYM_1) is set bit 2: Set, if raw value of error symptom OC (SYM_2) is set (all combinations are possible)					
Raw value of error symptom. The relevant bit is set, if the error has been detected.

FUNCTION DESCRIPTION:

General information:

ACTION_INFR_GetElDiagACCOUT()

ACTION_INFR_GetElDiagACCOUT() returns the result of the electrical diagnosis of the ACCOUT Switch.
The device readout is performed autonomous by the infrastructure each 10ms.
The error informations of every symptom is gathered in the infrastructure (or-ed symptom) until the application reads out the information by calling ACTION_INFR_GetElDiagACCOUT().
After having read out the information by calling ACTION_INFR_GetElDiagACCOUT(), the data inside the infrastructure is reset. Resetting of Cdn_diag_rly_accout avoids ambiguous results in case of too short calling recurrence of ACTION_INFR_GetElDiagACCOUT(). Reset Cdn_diag_rly_accout indicates that the gathering of the information is not completely finished.

ACTION_INFR_GetElDiagCRCVHEAT()

ACTION_INFR_GetElDiagCRCVHEAT() returns the result of the electrical diagnosis of the CRCV_HEAT Switch.
The device readout is performed autonomous by the infrastructure each 10ms.
The error informations of every symptom is gathered in the infrastructure (or-ed symptom) until the application reads out the information by calling ACTION_INFR_GetElDiagCRCVHEAT ().
After having read out the information by calling ACTION_INFR_GetElDiagCRCVHEAT (), the data inside the infrastructure is reset. Resetting of Cdn_diag_rly_crcv_heat avoids ambiguous results in case of too short calling recurrence of ACTION_INFR_GetElDiagCRCVHEAT (). Reset Cdn_diag_rly_crcv_heat indicates that the gathering of the information is not completely finished.

Requirements for ACTION_INFR_SetACCOUT:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
lv_accout_rly	Not relevant	Not relevant	1	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_SetCRCVHEAT:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
lv_rly_crcv_heat	Not relevant	Not relevant	1	Not relevant	Not relevant

Diagnosis: no electrical diagnosis done here

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_GetElDiagACCOUT:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Cdn_diag_rly_accout	-	-	<bit coded>	Cdn_diag_rly_accout	Diagnosis condition for each symptom bit 0: diagnosis condition for symptom SCP (SYM_0) bit 1: diagnosis condition for symptom SCG (SYM_1) bit 2: diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled
Err_diag_rly_accout	-	-	<bit coded>	Err_diag_rly_accout	Bitcoded result of each symptom bit 0: raw value of error symptom SCP (SYM_0) bit 1: raw value of error symptom SCG (SYM_1) bit 2: raw value of error symptom OC (SYM_2) The relevant bit is set, if the raw error has been detected.

Diagnosis: ACTION_INFR_GetElDiagACCOUT returns the electric diagnosis for the ACCOUT switch.

Coincidence requirements: no coincidence requirements to other events

Requirements for ACTION_INFR_GetElDiagCRCVHEAT:

Data acquisition					
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Cdn_diag_rly_crcv_heat	-	-	<bit coded>	Cdn_diag_rly_crcv_heat	Diagnosis condition for each symptom bit 0: diagnosis condition for symptom SCP (SYM_0) bit 1: diagnosis condition for symptom SCG (SYM_1) bit 2: diagnosis condition for symptom OC (SYM_2) The relevant bit is set, if the condition for a valid diagnosis is fulfilled

Diagnosis: ACTION_INFR_GetElDiagCRCVHEAT returns the electric diagnosis for the CRCV_HEAT switch.

Coincidence requirements: no coincidence requirements to other events

37.2 AGGR HVAC adaptation

37.2.1 Outputs for BMW functions which are defined as HVAC exported data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
Mdi_res_ac	O/V	D8F0...2710H	-1000...1000	0.1	Nm
torque reserve for switching on air conditioning compressor					
Mdi_res_heiz	O/V	D8F0...2710H	-1000...1000	0.1	Nm
Torque reserve for switching on additional heating by ACC					
B_korel	O/V	0...1H	0...1	1	-
condition air compressor					
Md_na_ac	O/V	8000H...7FFFH	-3276.8 ...3276.7	0.1	Nm
torque losses air conditioning compressor					

Input data:

TQ_ADD_ACC	TQ_ADD_HEAT_ACC	LV_ACCIN	ECU_STATE
TQ_LOSS_ACC			

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Application conditions:

Initialisation: 0 at reset

Recurrence : 10 ms

Activation: every engine state

Formula section:

Remark: all formulas are valid in a **physical** meaning

Mdi_res_ac = TQ_ADD_ACC

Mdi_res_heiz = TQ_ADD_HEAT_ACC

```
if      ECU_STATE = 4Hex     "power latch"
then    B_korel = 0
        Md_na_ac  =  0
else    B_korel = LV_ACCIN
        Md_na_ac  =  TQ_LOSS_ACC
endif
```

37.3 Blocking of the air conditioning compressor

37.3.1 Enabling the activation of the ACC-relay

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ACCOUT_RLY_ENA	O/V	0...1H	0...1	1	[-]
LV indicating that the conditions for activating the ACC-relay are fulfilled					

Input data:

LV_ES	LV_ST	VS	PV_AV
LV_ACCIN	T_AST	LV_ERR_BN_ACC	LV_ERR_TOUT_ICL_3
LV_ERR_CAN_BOFF			

FUNCTION DESCRIPTION:

General information:

The activation of the ACC-relay is controlled by the logical value LV_ACCOUT_RLY which is handled by this module. The A/C-ECU requests to switch the ACC-relay by LV_ACCIN. Under certain conditions the activation will be suppressed (LV_ACCOUT_RLY_ENA = 0). These conditions are
- engine stopped or start
- during time after transition from start
- during time after detecting high torque request when vehicle speed is low
- during time after last ACC-relay switch off
- CAN-Timeout (CAN11H) INSTR3-message: LV_ERR_TOUT_ICL_3
- CAN-Timeout (BN2000) IHKA-message: LV_ERR_BN_ACC
- CAN-Busoff

Activation : at every engine operating state

Deactivation : -

Initialization : LV_ACCOUT_RLY_ENA = 0 at reset

Update rate : 10 ms

Formula section:

a) If LV_ES = 1 or LV_ST = 1, then LV_ACCOUT_RLY_ENA = 0

b) If T_AST $\leq$ C_ACCIN_DLY_4 then LV_ACCOUT_RLY_ENA = 0

c) **If** PV_AV becomes $\geq$ C_PVS_FL_ACCIN when VS $\leq$ C_VS_MAX_ACCIN

then LV_ACCOUT_RLY_ENA = 0 for the time C_ACCIN_DLY_1 **and**

a timer (C_ACCIN_DLY_1_LOCK_FL) is started;

a renewed triggering of ACC-suppression due to condition c) is not possible:

- during the time C_ACCIN_DLY_1_LOCK_FL

- if time C_ACCIN_DLY_1_LOCK_FL has passed but the state FL has not been exited since last triggering due to c)

d) If time after last ACC-relay switch off ≤ C_ACCIN_DLY_5
then LV_ACCOUT_RLY_ENA = 0

This condition d) is not valid, if a blocking due to condition c) ends.

h) If LV_ERR_BN_ACC = 1 then LV_ACCOUT_RLY_ENA = 0

i) If LV_ERR_TOUT_ICL_3 = 1 then LV_ACCOUT_RLY_ENA = 0

j) If LV_ERR_CAN_BOFF = 1 then LV_ACCOUT_RLY_ENA = 0

In all other cases : LV_ACCOUT_RLY_ENA = LV_ACCIN

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_VS_MAX_ACCIN	1	0...FFH	0...255	1	[km/h]
Speed condition for ACC suppression at high load					
C_ACCIN_DLY_1	1	1...FFFFH	0.01...655.35	0.01	[s]
Delay for ACC suppression in transition after full load					
C_ACCIN_DLY_1_LOCK_FL	1	1...FFFFH	0.01...655.35	0.01	[s]
Blocking time for renewed triggering of the ACC suppression at high load					
C_ACCIN_DLY_4	1	1...FFFFH	0.1...6553.5	0.1	[s]
Delay in transition from start					
C_PVS_FL_ACCIN	1	0...FFH	0...99.60937	0.390625	[%]
PV-threshold for ACC suppression					
C_ACCIN_DLY_5	1	1...FFFFH	0.01...655.35	0.01	[s]
Delay before renewed reactivation of the ACC					

37.3.2 Turn-On-/Turn-Off-Delay ACC-relay

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ACCOUT_RLY	O/V	0...1H	0...1	1	[-]
Air conditioning compressor clutch signal is enable					
LV_TOUT_ACC	O/V	0...1H	0...1	1	[-]
logical variable to start deactivation of torque reserve and condition for switch off TQ_LOSS_ACC calculation					
T_ACC	O/V	0...FFFFH	0...655.35	0.01	[s]
Timer for duration of transient TQ_LOSS_ACC correction					
T_ACC_DLY	O/V	0...FFH	0...2.55	0.01	[s]
delay time for start of TQ_LOSS_ACC-calculation & de-/activation of the ACC-relay					

Input data:

LV_ACCOUT_RLY_ENA	LV_SUPP_ACCIN_DIAGCPS	LV_ACCOUT_RLY_EXT_ADJ
LV_ACT_ACCOUT_RLY_EXT_ADJ	N_32	LV_VAR_RLY_ACCOUT

Import actions:

ACTION_INFR_SetACCOUT(IN <lv_accout_rly>**)**
This action sets the output pin for the "ACCOUT Switch"

Note: The imported actions are defined in the HVAC – IRS (infrastructure requirement specification).

FUNCTION DESCRIPTION:

General information:

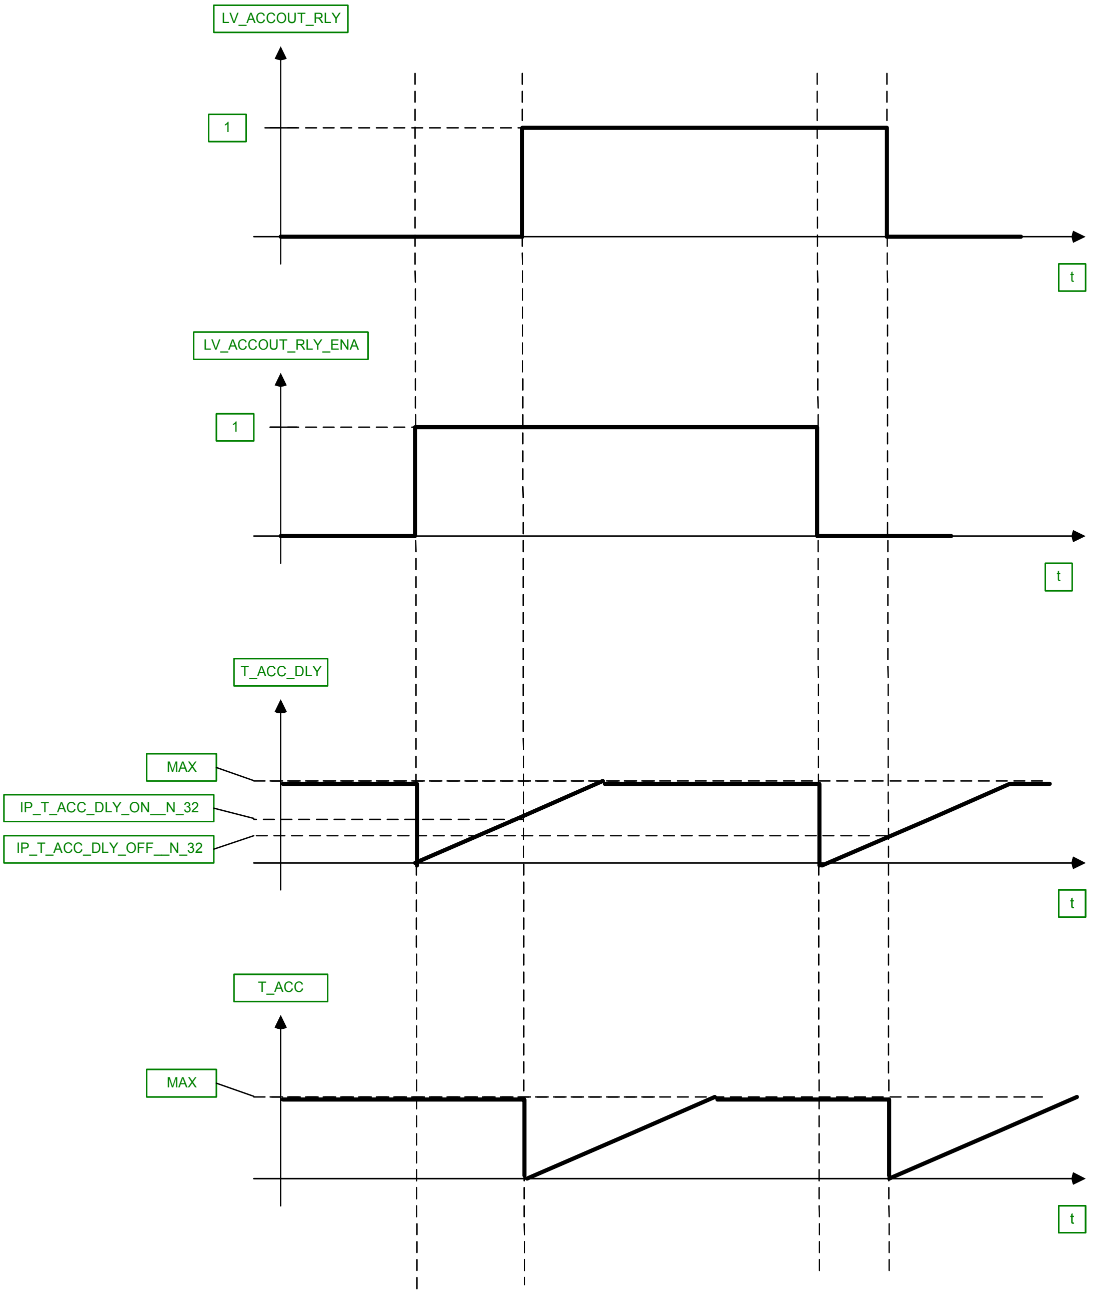
If the enabling conditions for activating the ACC-relay are fulfilled (LV_ACCOUT_RLY_ENA = 0→1) then the ACC-relay is activated (LV_ACCOUT_RLY = 0→1) via a turn-on-delay. The same way the ACC-relay is deactivated (LV_ACCOUT_RLY = 1→0) via a turn-off-delay if LV_ACCOUT_RLY_ENA = 1→0.

If LV_SUPP_ACCIN_DIAGCPS = 1 due to functional check CPS then the state of LV_ACCOUT_RLY is freezed.

For test purpose at assembling line or workshop the ACC-relay can be switched by a serial communication tool, if available (external adjustment). These switchings are done without the turn-on-delay, so the engine speed will show a clear reaction.

Activation :	at every engine operating state
Deactivation :	-
Initialization :	LV_ACCOUT_RLY = 0 at reset LV_TOUT_ACC = 1 T_ACC = FFFFH T_ACC_DLY = FFH
Update rate :	10 ms

Signal flow diagram:



Valid, if external adjustment is not active

Formula section:

Timer T_ACC_DLY :

```
IF        LV_ACCOUT_RLY_ENA $_{N}$ <> LV_ACCOUT_RLY_ENA $_{N-1}$
THEN      T_ACC_DLY = 0
ELSE      IF     T_ACC_DLY < FFH
          THEN   T_ACC_DLY = T_ACC_DLY + 10 ms
          ENDIF
ENDIF
```

Turn-on-delay:

```
IF        LV_ACCOUT_RLY_ENA = 1          AND
          T_ACC_DLY = IP_T_ACC_DLY_ON__N_32
THEN      LV_ACCOUT_RLY = 1
ENDIF
```

Turn-off-delay:

```
IF        LV_ACCOUT_RLY_ENA = 0          AND
          T_ACC_DLY = IP_T_ACC_DLY_OFF__N_32
THEN      LV_ACCOUT_RLY = 0
ENDIF
```

T_ACC for ramping torque loss:

```
IF        LV_ACCOUT_RLY$_{N}$ <> LV_ACCOUT_RLY $_{N-1}$
THEN      T_ACC = 0
          LV_TOUT_ACC =0
ELSE      IF     T_ACC < FFFFH
          THEN   T_ACC = T_ACC + 10ms
          ENDIF
          IF     T_ACC < C_T_TOUT_ACC
          THEN   LV_TOUT_ACC = 0
          ELSE   LV_TOUT_ACC = 1
          ENDIF
ENDIF
```

Freezing the state of LV_ACCOUT_RLY due to activation of DIAGCPS:

```
If        LV_SUPP_ACCIN_DIAGCPS =  1,
  then    the status of   LV_ACCOUT_RLY  is freezed
          until    LV_SUPP_ACCIN_DIAGCPS =  0
```

LV_ACCOUT_RLY during external adjustment:

```
If        LV_ACCOUT_RLY_EXT_ADJ = 1
  then    LV_ACCOUT_RLY  =  LV_ACT_ACCOUT_RLY_EXT_ADJ
  else    LV_ACCOUT_RLY determined as described before   (external adjustment passive)
endif
```

```
If LV_VAR_RLY_ACCOUT = 1
  then
  After LV_ACCOUT_RLY calculation,
  ACTION_INFR_SetACCOUT(IN < LV_ACCOUT_RLY >)
```

Calibration data:

37.4 Crankcase ventilation heater relay control

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_RLY_CRCV_HEAT	V/O	0...1H	0...1	1	[-]
Crankcase ventilation heater relay (1:activated, 0:deactivated)					

Input data:

LV_RLY_CRCV_HEAT_EXT_ADJ	LV_ACT_RLY_CRCV_HEAT_EXT_ADJ	LV_ERR_RLY_CRCV_HEAT	LV_IGK
T_AST	TIA		

Import actions:

ACTION_INFR_SetCRCVHEAT(IN <lv_rly_crcv_heat>**)**
This action sets the output pin for the “CRCV_HEAT Switch”

Note: The imported actions are defined in the HVAC – IRS (infrastructure requirement specification).

General information:

To prevent crankcase ventilation from fouling under cold conditions it is necessary to heat the ventilation rail. For the power stage of this heating an external relay plus heating foil is introduced. The control stage is realised by the engine management system using the below statemachine.

Application conditions:

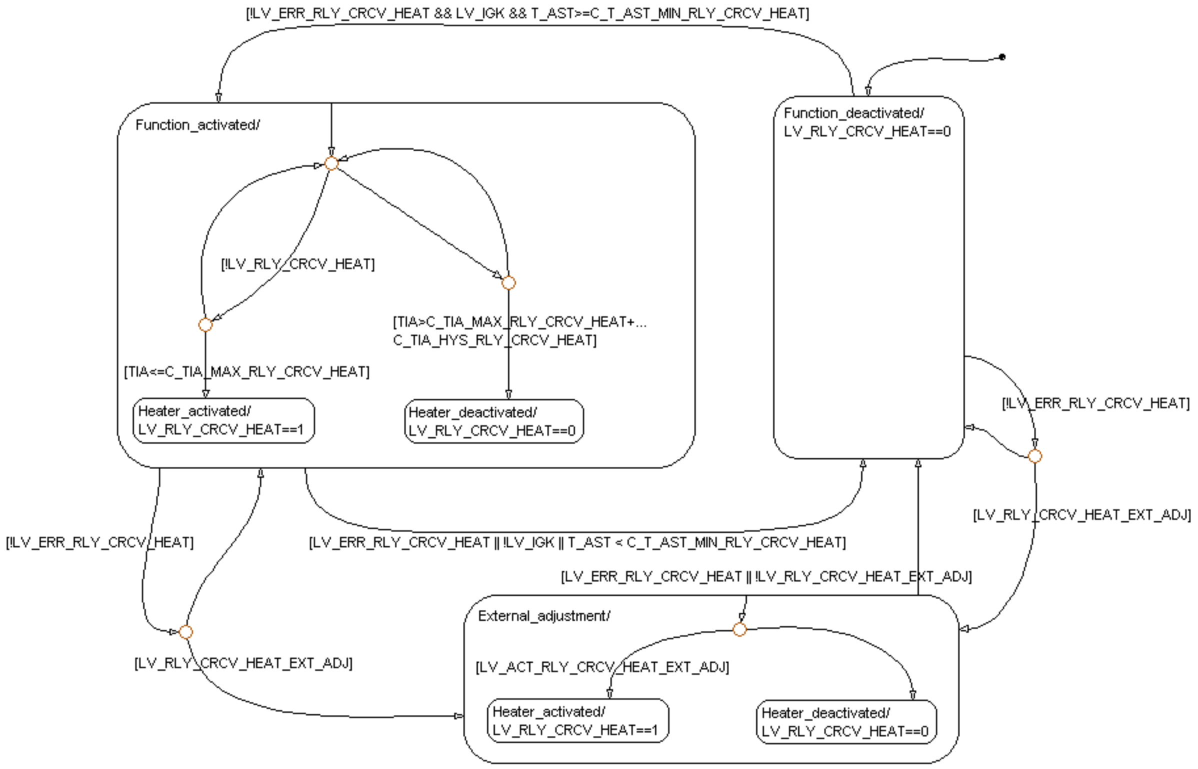
Initialisation: at reset and deactivation all var. are initialised with 0

Recurrence: 1000ms

Activation: *see signal flow diagram*

Deactivation: *see signal flow diagram*

Signal flow diagram:



Formula section:

(redundant information to signal flow diagram – only for a better understanding)

External adjustment:

If(1) LV_ERR_RLY_CRCV_HEAT = 0

Then(1) **If(2)** LV_RLY_CRCV_HEAT_EXT_ADJ = 1

Then(2)

If(3) LV_ACT_RLY_CRCV_HEAT_EXT_ADJ = 1

Then(3) LV_RLY_CRCV_HEAT = 1

Else(3) LV_RLY_CRCV_HEAT = 0

Else(2) either stay in the actual operation mode or (if external adjustment was activated before) firstly deactivate function and check if it has to be reactivated again

Else(1) Function is deactivated

ACTION_INFR_SetCRCVHEAT(IN < LV_RLY_CRCV_HEAT >**)**

"Normal" operation:

```

37.5.2.1 Determination of Torque Loss ACC

FUNCTION DESCRIPTION:

general specification

The calculation of TQ_LOSS_ACC starts already at transition LV_ACCOUT_RLY_ENA = 0 --> 1. The adaptation value TQ_DIF_IS_AD_ACC, determined in the module "idle speed adaptation", is added to the A/C compressor torque TQ_LOSS_ACC_INP which depends on ACC-torque from CAN and on engine speed (N_32).

The A/C-compressor is switched ON and OFF using an electro-magnetic clutch. If the clutch is closing the starting torque overshoots the torque calculated for steady state conditions (basic request) due to the inertia of compressor, which has to be accelerated. This overshoot is taken into account by the weighting factor IP_FAC_TQ_LOSS_ACC_ON depending on time T_ACC and by relative engine speed due to dynamic torque loss depending on target compressor speed (engine speed). The transient correction for clutch switching ON is always active as long as LV_ACCOUT_RLY_ENA = 1. So IP_FAC_TQ_LOSS_ACC_ON has to be 1 at steady state conditions are reached, at latest at T_ACC = 2.55s. At opening clutch the time delay until A/C compressor torque loss has reached 0 Nm is pre-controlled by IP_FAC_TQ_LOSS_ACC_OFF depending on T_ACC. The transient correction for clutch switching OFF is always active as long as LV_ACCOUT_RLY_ENA = 0. So IP_FAC_TQ_LOSS_ACC_OFF has to be 0 at latest at T_ACC = 2.55s.

Torque reserve REQ_HEAT by ACC
FUNCTION DESCRIPTION:
General information:
To guarantee idle quality during additional heating being present (required by INSTR3-message/CAN11H or IHKA/BN2000) a positive torque reserve can be requested.

At transition LV_REQ_HEAT_ACC_ENA = 0 --> 1 the timer T_REQ_HEAT_ACC is set to zero and starts to count until its maximum value is reached. The timer s maximum value is hold until transition LV_REQ_HEAT_ACC_ENA = 1 --> 0. Then the timer is set to zero and and starts again until its maximum value.

38.1.1 Introduction

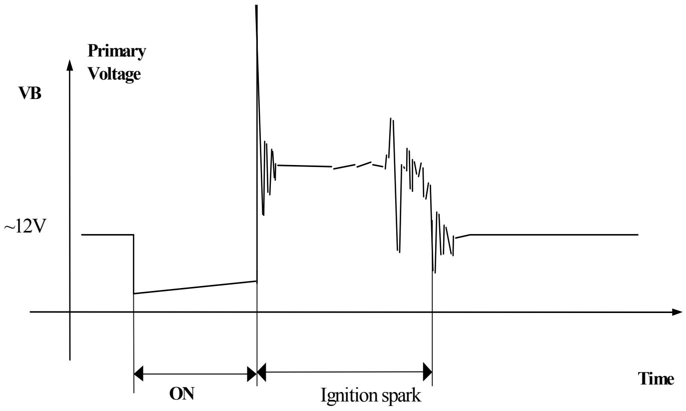
This document is the Aggregate Integration Document of the IGRE Aggregate. Its aim is to describe the integration constraints of this aggregate with the others. It aims with interfaces (imported and exported), architecture, and configuration. This document covers all versions of the IGRE aggregate.

38.1.2 Purpose

The IGRE Aggregate defines the calculation of the dwell time, the ignition realization and the ignition diagnosis functions.

Basically the ignition command function has to fulfill two main tasks; to ensure that there is enough energy in the ignition coil and to start the combustion at the requested ignition angle. Knowing the desired ignition advance, engine speed and several other parameters, this aggregate determines the correct timing for switching ON and OFF the power stage in order to bring the ignition coil to the necessary primary current value. The time during ON state (load phase) of the switch is often improperly called Dwell time (with reference to the dwell ratio in breaker systems).

At the end of this Dwell time the ignition stage is switched OFF and the ignition spark is created. The OFF event corresponds to the advance ignition angle (IGA_IGC).



The ignition command functions and the linked diagnostic functions are regrouped in the ignition realisation aggregate.

38.1.3 Function Description

This function sets the angular position of the dwell time turn on in order to have the time to set up the necessary current in the ignition coil.

The strategy is based on a priority of the ignition angle. If dwell time priority is requested the minimum dwell time is equal to maximum dwell time.

The strategy respects ignition coils with dual and single outputs. This function could be used independently of the number of cylinders (x) and the geometry of the crankshaft target wheel.

All of the functions described in this section operate over the entire engine speed range.

- Realization of minimum 1 ignition spark per cycle
- Realization of a number of multiple spark
- Physical limits of the ignition angle +60°CRK / -35,625°CRK

- In case of an acceleration of ±10 000 RPM/s the ignition spark output tolerance depending on engine speed.

Input data:

NC_IGN_DIAG_TYP	NC_TD_LIM_MIN	NC_TD_LIM_MAX_H	NC_MPL_T_MAX
NC_MAX_IGN_MPL_NR	NC_IGC_DLY	NC_MPL_IGN_H_RNG_CRK_MAX	NC_IGC_CONF
NC_TD_AD_TYP	NC_INI_CTR_DEAC	NC_IGBT_CUT_OFF_T	NC_T_MIN_SCP
NC_CFB_DIAG_SCP_CHN	NC_TD_AD_CHN_L	NC_TD_LIM_MAX_L	NC_TD_AD_CHN_H

General information :

The following describes the general rules for determination of the configuration data

38.1.4 Global configuration data

Data	Value

38.1.5 Local configuration data

Here are listed the configuration data, which are used only in the IGRE aggregate.

Data	Value
NC_IGN_DIAG_TYP	ATM46: Diag with ATM46 or ATIC71 circuit ATIC29: : Diag with ATIC29 circuit SHUNT: Diag with SHUNT (not supported yet)
NC_TD_LIM_MIN	TD_MIN> = NC_TD_LIM_MIN Typical value for debug = 1 ms
NC_TD_LIM_MAX_H	High maximum value for dwell time Typical value for debug = 20 ms
NC_TD_LIM_MAX_L	Low maximal value for dwell time Typical value for debug = 10 ms
NC_MAX_IGN_MPL_NR	Maximum number of multi spark Typical value for debug = 7
NC_IGC_DLY	Number of recurrence after engine start, which had to pass by to activate the diagnosis Typical value =16
NC_MPL_T_MAX	Absolute duration of multispark Typical value 60 ms
NC_MPL_IGN_H_RNG_CRK_MAX	Maximum ignition angle after TDC to start TD_MPL (normal value 12 to 18 °CRK)

Data	Value
NC_IGC_CONF	Ignition mode : half or full static Typical value = Full
NC_TD_AD_TYP	Type of adaptive dwell time control: NONE or FLAG or (CURR not supported today)
NC_INI_CTR_DEAC	Time delay after IGBT response before switching OFF the IGBT – typical value 600µs
NC_IGBT_CUT_OFF_T	Inhibition of "IGBT protection cut off function" (ATM46 ot ATIC71 usage without shunt) – typical value 5ms
NC_T_MIN_SCP	Minimum time to detect SCB with current feedback flag (ATIC71 usage) – typical value 1.5ms
NC_CFB_DIAG_SCP_CHN	Selection of the channel number to be used to do the SCB diagnosis whith current feedback flag
NC_TD_AD_CHN_L	Selection of channel number where current feedback flag is read to do dwell time adaptation
NC_TD_AD_CHN_H	Selection of channel number where current feedback flag is read to do dwell time adaptation in satrt phase

Note: care has to be taken with the setting of NC_TD_LIM_MAX in order to avoid Dwell Time / coil charging recovery:

- For half-static coil configuration, Dwell Time has to be shorter than 360°CRK (= delay time between 2 coil charging request).
  This means, for a maximal engine speed of eg. 7500rpm, Dwell Time < 8ms
- For full-static coil, Dwell Time has to be shorter than 720°CRK
  This means, for a maximal engine speed of eg. 7500rpm, Dwell Time < 16ms

NC_TD_LIM_MAX should be tuned in consequence to respect coil charging time no recovery and coil capacity

Formula Section:

NC_IGN_DIAG_TYP = "ATM46"

NC_TD_LIM_MIN = 1ms

NC_TD_LIM_MAX_L = 10ms

NC_TD_LIM_MAX_H = 20ms

NC_MAX_IGN_MPL_NR = 20

NC_IGC_DLY = 16

NC_MPL_T_MAX = 60ms

NC_MPL_IGN_H_RNG_CRK_MAX = 180°CRK

NC_IGC_CONF = FULL

NC_TD_AD_TYP = "Flag"

NC_INI_CTR_DEAC = 852µs

NC_IGBT_CUT_OFF_T = 5ms

NC_T_MIN_SCP = 1.5ms

NC_CFB_DIAG_SCP_CHN = 1

NC_TD_AD_CHN_L = 0

NC_TD_AD_CHN_H = 1

38.2 Spark Advance and Dwell Output

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TD_FAC_MAX	O/V	1...FFH	1/128...255/128	1/128	-
Maximal dwell time control					
TD_FAC_MIN	O/V	1...FFH	1/128...255/128	1/128	-
Minimal dwell time control					

Input data:

LV_ ERR_CAM	VB	LV_ST	N_32
LDPM_N_32_1_IGRE	NC_CYL_NR		

Import actions:

ACTION_INFR_SetIgnCtl(IN <>)

FUNCTION DESCRIPTION:

This function sets the angular position of the dwell time turn on in order to have the time to set up the necessary current in the ignition coil.

The strategy is based on a priority of the ignition angle. If dwell time priority is requested the minimum dwell time is equal to maximum dwell time.

The strategy respects ignition coils with dual and single outputs. This function could be used independently of the number of cylinders (n) and the geometry of the crankshaft target wheel.

This function could be used for homogeneous combustion mode and for stratified combustion mode. The calculation of the spark advance is in both cases the same.

All of the functions described in this section operate over the entire engine speed range.

This specification includes two mode following the IGRE version: PI or PI + DI

38.2.1 Minimum / Maximum dwell time calculation

FUNCTION DESCRIPTION:

The two values are calculated independently of all environment factors. The aim is to have a larger window at start and low engine speed to obtain a better flexibility to apply the requested ignition angle.

These 2 values are expressed in term of min/max factor to be applied to the nominal dwell time and transferred to the Basic SW

The cylinder individual nominal Dwell Time to be applied requested by ASW function is defined in TD_IGC[x] taking into account the combustion mode switch

Application conditions:

Initialisation: TD_FAC_MIN = TD_FAC_MAX = 1 *at reset*

Recurrence: 10 ms

Formula section:

```
If      LV_ST = 1
Then (Start mode)
    If      VB > C_TD_VB_MAX
    Then    TD_FAC_MAX = 1
            TD_FAC_MIN  = Min[ C_TD_FAC_ST_MIN , 1]
    Else    TD_FAC_MAX  = Max[ C_TD_FAC_ST_MAX , 1]
            TD_FAC_MIN  = Min[ C_TD_FAC_ST_MIN , 1]
Else (run mode)
    If      VB > C_TD_VB_MAX
    Then    TD_FAC_MAX = 1
            TD_FAC_MIN  = Min[ IP_TD_FAC_MIN , 1]
    Else    TD_FAC_MAX  = Max[ IP_TD_FAC_MAX , 1]
            TD_FAC_MIN  = Min[ IP_TD_FAC_MIN , 1]
Endif
```

38.2.2 Half static of full static

Recurrence: engine stop to engine run

Formula section:

Following NC_IGC_CONF = Half or full, the ignition is half static controlled or full static controlled

ACTION_INFR_SetIgnCtl(NC_IGC_CONF)

38.2.3 Limp home without cam signal

Recurrence: engine stop to engine run

Formula section:

In case of CAM failure, the cylinder in combustion cannot be unequivocally identified. Engine phasing might be wrong. In such a case, a limp home mode function on Ignition is provided in order to have the possibility to drive the engine. Nevertheless, in this case, since the right cylinder phasing is not known, Ignition coil have to be driven in Half-Static mode to be sure to execute at least an ignition on the cylinder in combustion.

Decision to use such Limp Home functionality will depend on the setting of LC_IGC_LIH_CONF. If LC_IGC_LIH_CONF = 0, no Limp Home is provided in CAM failure and Ignition is stopped. If LC_IGC_LIH_CONF = 1, then Half-Static Ignition mode is done in case of CAM failure

If LV_ERR_CAM is active, the ignition coil control will be executed in half-static ignition-coil control mode if selected by the settings of LC_IGC_LIH_CONF

In such a case (*half-static mode activation in CAM failure*) the same Ignition and Dwell Time will be applied to the 2 Crank synchronous cylinders (*eg. on a 4 cyl engine, cyl. 1 and 4 and cyl. 2 and 3 will be fed with the same Ignition and Dwell Time*)

The limp home function could be applied only if the number of cylinders is even (2, 4, 6, ...)

```
If      NC_IGC_CONF = full
Then    If     LV_ERR_CAM = 1   And   LC_IGC_LIH_CONF = 1
        Then   ACTION_INFR_SetIgnCtl(HALF_STATIC)
        Else   ACTION_INFR_SetIgnCtl(FULL_STATIC)
        EndIf
Else    ACTION_INFR_SetIgnCtl(HALF_STATIC)
EndIf
```

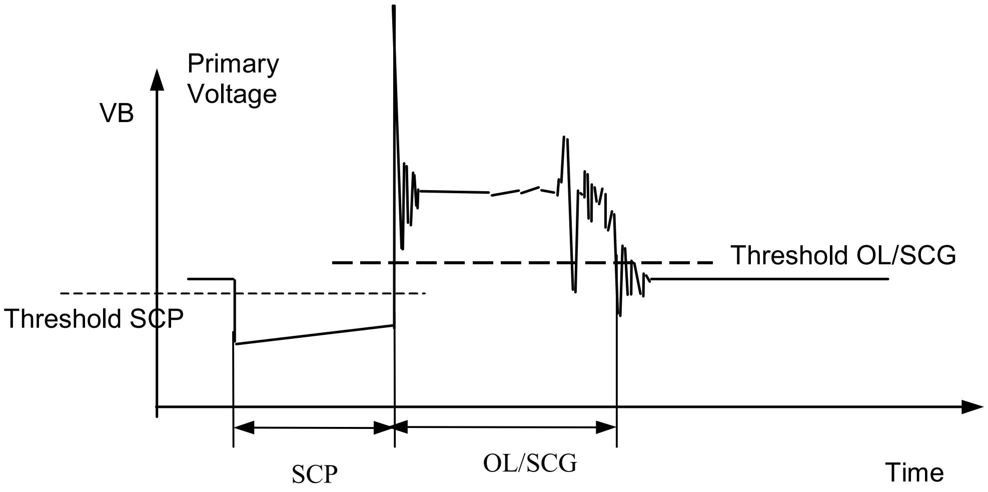
38.3 Ignition output diagnosis (for ATM 46 / Combined “ASIC”)

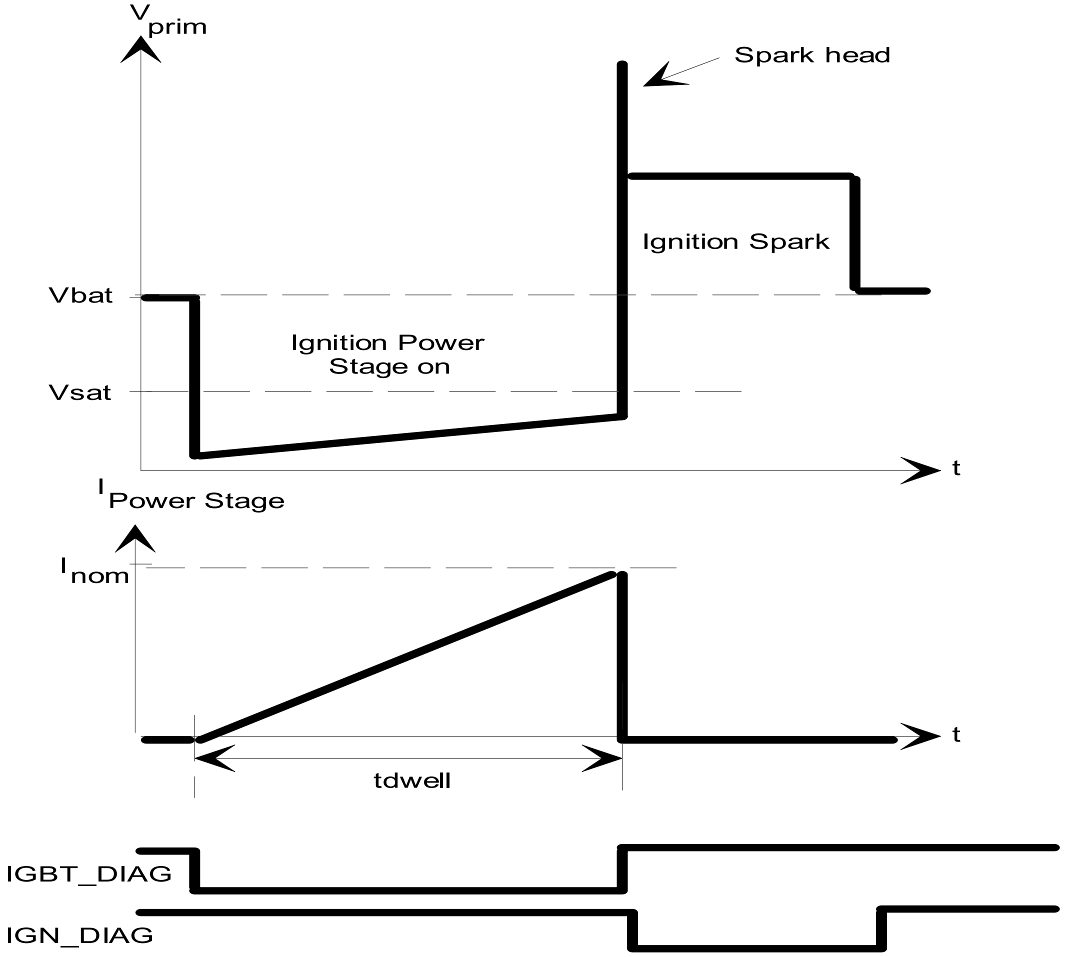
Each ATM46 could analyze 4 ignition coils. If diagnostics for more the than 4 coils are necessary, a parallel ATM46 has to be used.

The diagnosis is based on ignition coil primary over voltage measurement.

The input signal of the ATM 46 is the IGBT collector voltage.

In case of an ignition system with single output coils, the function does not work in camshaft limp home mode.





38.3.1 IGBT Protection (with “ATM46” / Combined “ASIC”)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SCP_IGC[NC_CYL_NR]	O/V	0...1H	0...1	1	-
Diagnostic of primary short circuit to battery (cylinder selected)					

Input data:

LV_SYN_ENG	NC_CYL_NR	SEG_NR	LV_CDN_DIAG_IGC_SCP[NC_CYL_NR]

Import actions:

ACTION_INFR_GetIgnScpDiag(IN<>, OUT<>)

FUNCTION DESCRIPTION:

The aim of the present function is to protect the ignition power stage against short circuit to battery (SCP).

The purpose of ignition power stage diagnostic is to detect a short circuit to battery voltage condition (SCP). At each Dwell Time On event, the ignition power stage is switched on. In normal condition, the current increase in the ignition power stage is limited by the inductance of the ignition coil solenoid.
In case of a short circuit to battery, the coil external device does not limit the current in the ignition power stage. In this situation the current is only limited by the current capability of the ignition power stage. This power dissipation would destroy the power stage. From the Dwell Time ON event in SCP condition, the IGBT’s can withstand this overload current only for a very short time (*750µs for IGBT without shunt*). So, it is necessary to switch off this IGBT transistor for safety and protection reasons by software (*IGBT deactivation by switching off the charging command in SW*) in case of an overload condition and after a certain time delay has elapsed (NC_INI_CTR_DEAC). This time delay is necessary in order to filter parasitic spikes. On the other hand this time delay must not exceed the maximum rating of the IGBT’s.

For ignition power stage diagnostic, the voltage across the ignition power stage is compared to a fixed threshold voltage. This threshold voltage is chosen to be higher than the maximum saturation voltage of the ignition power stage during a dwell time in normal operation. If there is no short to battery voltage condition, the voltage across the ignition power stage drops below this fixed threshold voltage at each dwell time. In case of a short to battery voltage failure, this voltage is not (or only for a short time) passed. A micro controller monitoring the ignition power stage diagnostic output is able to detect this fault.

This ignition power stage diagnostic circuit is designed for an engine management system including four ignition power stages. This four diagnostic information can be evaluated at one output by having a logic OR function of them.

After each deactivation from this protection function, the cut off IGBT will be reactivated again in the next ignition cycle

The function could be used for ignition systems with single-output coils and double-output coils. The IGBT protection function is cylinder selectively deactivated in case of single-output coil and linked dual cylinders for ½ static coils.

Application conditions:

Activation: *LV_SYN_ENG = 1*

Formula section:

Initialization: at reset
LV_SCP_IGC[x] = 0

Update rate: segment

System description:

The ATM46 is used to generate a signal evaluated by the SW for overload condition detection.

To perform the IGBT protection and SCP diagnostic, the BSW provides one functional service (BSW driver – one driver for one ATM46 protection and SCP diagnostic line)

As only one IGBT diagnosis output signal from the “ATM 46” exists (all channels are linked by a wired “OR”) and only one BSW functional service (*this BSW functional service used is described in the following paragraph*) is used in connection to this diagnosis output signal line, the function is limited to non-overlapping dwell time pulses. In case of overlapping Dwell Time, the last TD ON event that occurs will re-trigger the call of this function and thus be considered for diagnosis purpose.

Formula section:

ACTION_INFR_GetIgnScpDiag(SEG_NR -2,LV_SCP_IGC[SEG_NR-2])

38.3.1.1 Ignition Actuator Tests Diagnosis

Formula section:

Initialization: LV_SCP_IGC[x] = 0 at reset

System description:

For ignition coil actuator tests purpose, the SCP diagnostic function has to be enabled and activated upon the tests requests

The same case and comments (see before) apply here also.

Formula section:

```
For     x = 0 to NC_CYL_NR – 1
        If      LV_CDN_DIAG_IGC_SCP[x] = 1
        Then    ACTION_INFR_GetIgnScpDiag(SEG_NR -2,LV_SCP_IGC[SEG_NR-2])

        EndIf
EndFor
```

Input data:

LV_SYN_ENG	N_32	MFF_SP_MV	NC_CYL_NR

Import actions:

ACTION_INFR_GetIgnScgDiag (IN <>,IN<>,OUT<>,OUT<>)

Description:

This ignition diagnosis function evaluates the primary over voltage duration **V_DUR_IGC[x]** provided after the ignition coil cut off.

The aim of this spark burning diagnostic function is to measure the spark duration by detecting the presence of a spark on an ignition plug. The over-voltage at the primary coil of an ignition solenoid is equal to the voltage across the spark gap of the ignition plug divided by the transmission ratio of the ignition solenoid and superimposed on the battery voltage. The time where the voltage at the primary coil of the ignition solenoid is higher than a battery voltage dependent threshold voltage (V_{BD_TH}) gives the spark duration.

In the moment, when the ignition power stage (IGBT) is switched OFF *(ie. at TD OFF event occurrence)*, the voltage V_C at the collector of the IGBT rises, due to self-induction, and ignition occurs. As long as the ignition spark is burning, the voltage is well exceeding the battery voltage.

By means of a hardware defined threshold (V_{BD_TH}; typical value: V_{Bat} + 3V) the burn condition is detected and a matching signal is generated, *eg. Here by the combined ASIC ATM46*. This signal is used to measure the overall burning duration.

The Ignition Burning diagnostic signal IGN_DIAG is generated by this combined ASIC. This time for the burning spark IGN_DIAG is calculated via the duration of the diagnostic signal staying above the threshold of V_{BD_TH}.

This ATM46 ignition diagnostic circuit is designed for an engine management system including up to 4 ignition coils/solenoids. This four diagnostic information are then evaluated on one output by applying a logic NOR function on them. The output signal IGN_DIAG of the ignition diagnostic circuit is processed by the µP.

Due to combustion chamber turbulence the spark of an ignition plug is not stable. The result is an unstable primary voltage at the ignition solenoid. Therefore a filter in the output signal IGN_DIAG is necessary to prevent the µP from high frequency inputs.

The ignition coil primary over voltage on the ignition output is roughly equal to the voltage across the spark gap divided by the ignition coil transformation ratio, superimposed on the battery voltage.

The Burn Time measurement is used today only for Spark / Combustion Diagnosis Purpose. It is a rough measurement of the effective Burn Time.

Please note that the SCG detection is equivalent to the detection of an Open Load.

Application conditions:

Activation: LV_SYN_ENG = 1

Initialisation: LV_SCG_IGC[x] = 0

at reset

V_DUR_IGC[x] = 0

Recurrence: segment

Formula section:

Export actions:

ACTION_IGRE_*GetIgnDwellAdNvmy*(IN <PRM_Cyl>, OUT <PRM_Td_ad_l>, OUT <PRM_Td_ad_h>)
This action allows getting the values of dwell time adaptation stored in NVMY.
ACTION_IGRE_*RstIgnDwellAdNvmy*(IN <PRM_Cyl>)
This action allows resetting the values of dwell time adaptation.

Description for actions:

ACTION_IGRE_*GetIgnDwellAdNvmy*(IN < PRM_Cyl>, OUT < PRM_Td_ad_l>, OUT < PRM_Td_ad_h>)

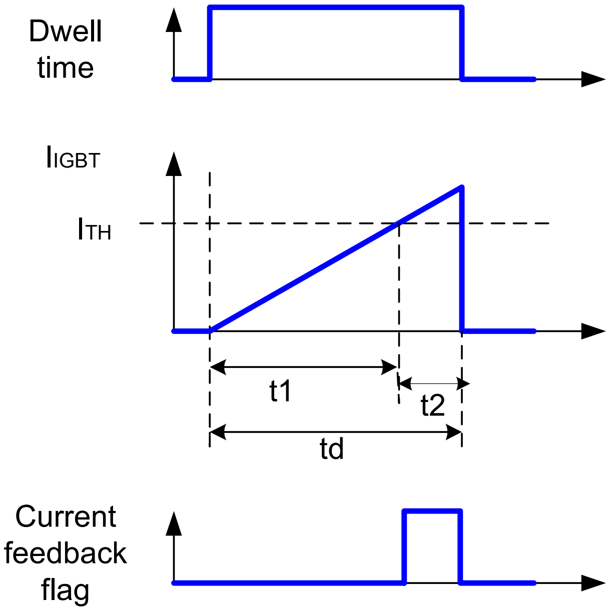
This action allows getting the values of dwell time adaptation stored in NVMY.
For specified cylinder Cyl, the dwell time adaptative values TD_AD_L and TD_AD_H will be read.
If cylinder number received is not in the range of the engine cylinder number, the maximum value will be put in output for TD_AD_L and TD_AD_H.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_Cyl	IN	0...7	0...7	1	-
Cylinder number on which we want to get the dwell time adaptative values					
PRM_Td_ad_l	OUT	8000...7FFFH	-131.072...131.068	0.004	ms
Dwell time adaptative for low current mode					
PRM_Td_ad_h	OUT	8000...7FFFH	-131.072...131.068	0.004	ms
Dwell time adaptative for high current mode					

ACTION_IGRE_*RstIgnDwellAdNvmy* (IN <PRM_Cyl>)					
This action allows resetting the values of dwell time adaptation stored in NVMY. This action will reset for the specified cylinder the adadaptive values TD_AD_L and TD_AD_H to **0 ms**.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
PRM_Cyl	IN	0...7	0...7	1	-
Cylinder number on which we want to reset the dwell time adaptative values					

FUNCTION DESCRIPTION:

This function should be used with ATIC71 component. Through the 2 current feedback flags of the component it is possible to measure the time spent above a given current threshold during the main dwell pulse.



Two different current thresholds can be used depending on which engine condition we are.

The current threshold is fixed by hardware component at the current target the coils have to reach. If the threshold is not reached we increase the dwell time. In the other case we will decrease the dwell time by the time t2(time measured above the current threshold).

Please note that in this whole specification x corresponds to SEG_NR-2.

Application conditions:

Initialisation:

in case of EEPROM fault or new ECU: All TD_AD[x] = 0 ms

At reset :

```
if    LC_TD_AD_CLR = 1
then        for x = 0 to NC_CYL_NR-1
```

```
                            TD_AD_H[x] = 0
                            TD_AD_L[x] = 0
                        Endfor
        Else            TD_AD_H[x] = saved value
                        TD_AD_L[x] = saved value
        endif
```

After power latch : all TD_AD_H[x] and all TD_AD_L[x] are stored into the non-volatile memory

At reset: T_SUM_TD_AD[x] = 0ms

TD_AD[x] = TD_AD_H[x] for all cylinders

Recurrence: segment

```
    if N_32 > C_ N_32_MIN_TD_AD
    Then recurrence = 1 out of NC_CYL_NR-1 segment
    EndIf
```

Activation: at the 3rd segment occurence

Deactivation:

Formula section:

Detection of current threshold switch

```
If          $LV\_TD\_AD\_H_n$ != $LV\_TD\_AD\_H_{n-1}$

Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Inh_igc	1	-	1		0: ignition inhibited 1 : ignition enabled

Coincidence requirements:

The decision to inhibit an ignition stage is taken for each output before the turn on at TD_ON[x]. This means that no Disable / cut off can be set on a coil while charging.

Management of Ignition Cut-Off: Enable / Disable mode of Ignition Power stages

For normal Dwell Time and coil charging management:

a. No Ignition cut is allowed on a currently charging coil, *ie.* no Disable Command of a power stage is considered after the TD_ON event
   Nevertheless, if the Disable request still be present, it will be applied on the next coming to fire cylinder
b. Enable command request coming to a power stage in Disable mode will be only performed if TD_IGC[x] time to IGA_IGC point can be respected/realised.
   In other case, this Enable request will be performed only on the next engine cycle (720°CRK or 360°CRK depending of the Ignition Coil mode - full or half static) if it still be present
c. No Re-Enable command can - neither will - be done on a power stage which is yet already in Enable mode

In Multiple Spark phase:

d. As for the nominal phase, no Ignition-Cut can be allowed on a currently charging coil even in Multiple Spark phase, *ie.* no Disable Command of power stage is considered after during the TD_MPL charge: if one TD_MPL is on the way, no Ignition cut is possible.
   See dwell comments
   The Disable request could be done/happened anywhere but it will only be executed, can only occur and be taken into account only at the end of the charging of this TD_MPL

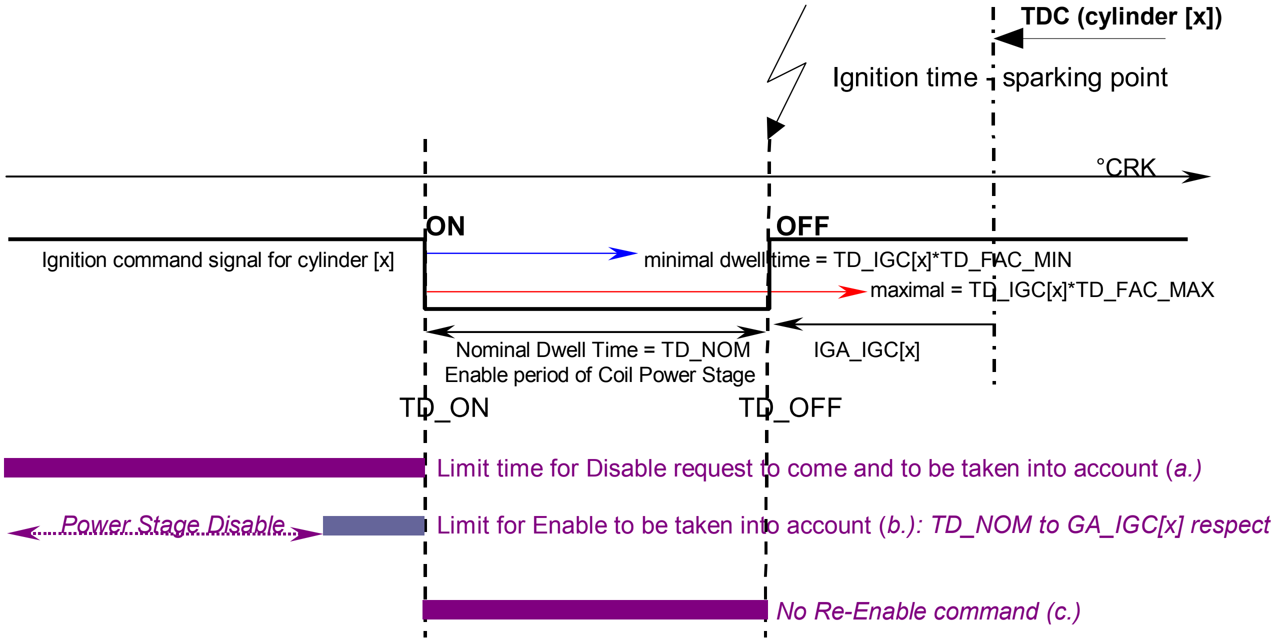
Td_fac_min			1/128		
Td_igc			0.004ms		
Td_fac_max			1/128		

Diagnosis:

Coincidence requirements:

The normal request dwell time to be programmed and applied for charging the ignition coil is and has to be TD_IGC[x]
The coil starts charging with the target of achieving TD_IGC[x] at the IGA_IGC[x] angle. An update occuring for the Ignition Spark Angle will be taken into account as long as TD_MIN is not reached.
This Ignition Spark Angle change obtained when reaching TD_MIN will be taken into account and respected by a corresponding change of the coil charging time (the Dwell Time).
But, such a change of the Dwell Time to be thus and then applied can only be processed within the limits defined by TD MIN and TD MAX limits excursion range (*see drawing here after*)
For the definition and calculation of those TD MIN and TD MAX:



Note: IGA_IGC[x] is a signed value. Negative angles are for sparks generated after TDC; positive angles are for sparks generated before TDC.

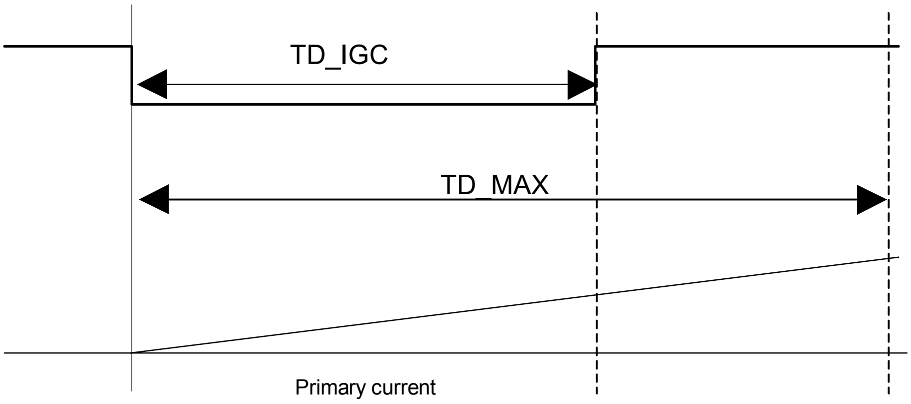
Calculations after starting the dwell time output at TD_ON

For the ignition time there are three main requests for the dwell time output.

1. A minimum dwell time TD_IGC[x] * TD_FAC_MIN has to be guaranteed to ensure ignition.
2. The dwell time has to be limited by a maximum dwell time which is defined as a TD_IGC[x] * TD_FAC_MAX.

   To prevent all cases of big negative engine speed gradients which could destroy the ignition system, by too long conduction between conduction angle calculation and spark, a timer limits the resulting conduction time (ignition power stage protection against high current).

   The ignition output is turned off immediately at TD_IGC[x] * TD_FAC_MAX (IGA_IGC[x] could not be respected).
3. In these limits (TD_IGC[x] * TD_FAC_MIN, TD_IGC[x] * TD_FAC_MAX) we have an absolute ignition angle priority.



Requirements for ACTION_INFR_SetIgcDwellTest:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Td_igc			0.004ms		

Diagnosis:

Coincidence requirements:

The normal request dwell time to be programmed and applied for charging the ignition coil is and has to be TD_IGC[x]
On Actuator test request activation, the coil starts charging with the target of achieving TD_IGC[x]

The coils start charging upon actuator test request pattern with the dwell time defined.

The pulse is generated once and immediately after calling the action. The Dwell time could not be updated during the pulse generation, excepting if it is set to 0. in this case, the current pulse should be stopped immediately.

Detection of SCP failure must be enabled

In case of overlapping dwell time, diagnosis information can be false then in case of dwell time overlap there is a risk to destroy the IGBT.

Requirements for ACTION_INFR_SetIgnCtl:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Td_mpl1			0.004ms		
Td_mpl			0.004ms		
Td_mpl1_dly			0.004ms		
Td_mpl_dly			0.004ms		
Ign_mpl_nr			1		

Diagnosis:

Coincidence requirements:

The parameter Cyl determines the cylinder number on which we set the following attributes.

The values TD_MPL1 and TD_MPL determines the conduction time of the ignition coil: TD_MPL1 for the 1st MPL spark (1st spark after main spark) and TD_MPL for the other sparks (2nd MPL and following sparks)

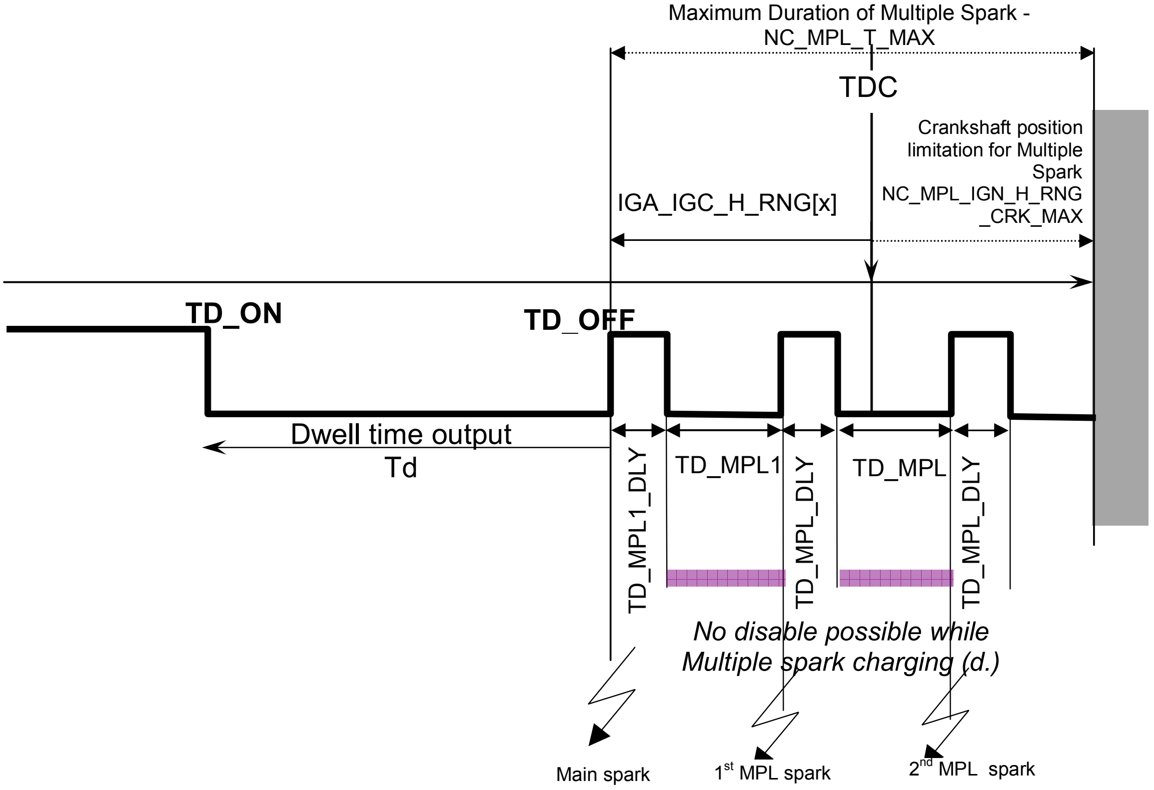
The time delays TD_MPL1_DLY and TD_MPL_DLY specifies a time-out when the ignition coil is turned on for the next spark: TD_MPL1_DLY is the time between main spark and 1st MPL; TD_MPL_DLY is the time between other sparks.

The number of successive sparks is defined as IGN_MPL_NR and checked at every TD_OFF.

The absolute duration of multiple sparks is limited to a maximum time defined as NC_MPL_T_MAX.

The maximum ignition angle to start a TD_MPL is defined as NC_MPL_IGN_H_RNG_CRK_MAX after TDC.

Description:



Requirements description for overlapping prevention in case of multiple spark activation:

Overlapping in between the different cylinders affected to the same HW component could lead to false diagnosis detection.

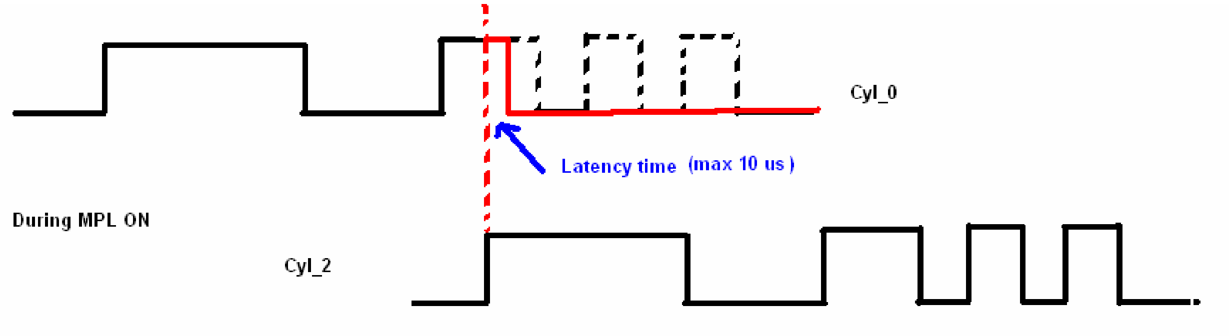
In order to avoid this behavior the following implementation should be made inside the software.

At each dwell ON event, the curent cylinder read the state of the others cylinders in the same IC component.
If the state of others cylinders are in :

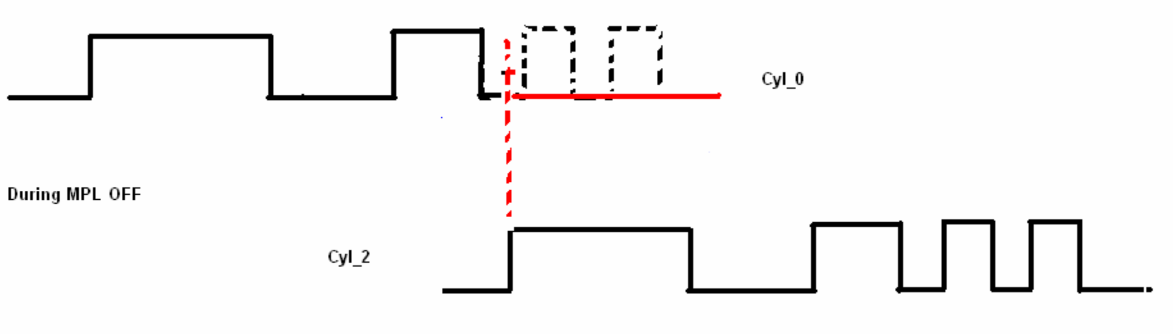
1. **Multiple spark mode** : multiple sparks on these cylinders will be switched off as soon as possible

The 2 following drawings describes the 2 cases which could occur :

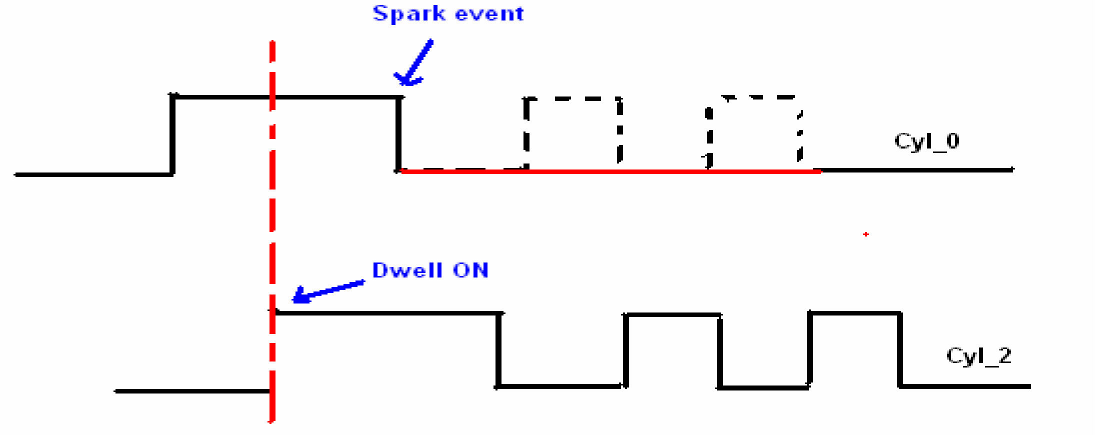
- Cut-off requested during MPL_ON event of cylinder (one multiple spark is currently in charge)
  In this case the latency time to cut-off the MPL in progress will be 10µs in worst case.



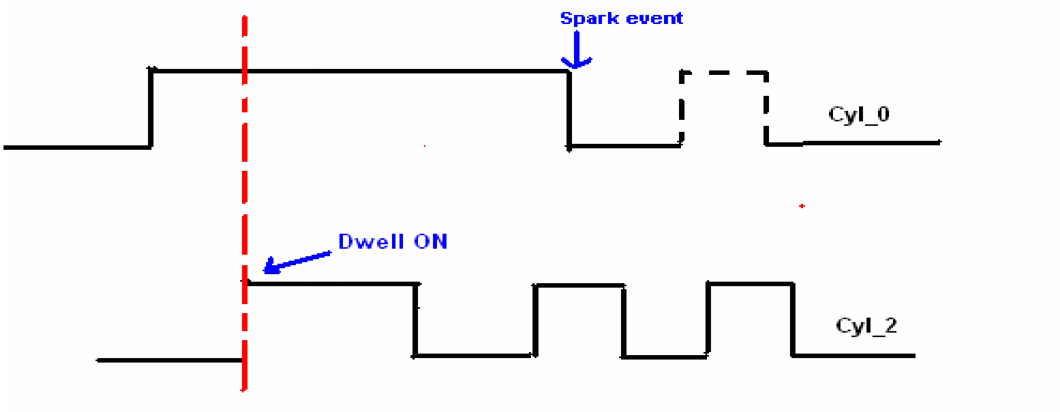
- Cut-off requested during MPL_OFF event of cylinder (in between 2 multiple sparks)
  In this case the following MPL won't be applied at all.



2. Main dwell : the multiple sparks of those cylinders will be cut-off to prevent overlapping.



Note : This implementation only prevents overlapping in between multiple sparks and main spark and in between multiple sparks. Prevention in between main sparks is not addressed because it is not realistic unless at very low battery voltage at high engine speed. (these cases are considered as a limp home mode)
In addition case decribed below could not happen and thus will not be covered by this implementation:



Spark event
Cyl_0
Dwell ON
Cyl_2

38.7 IGRE – Requirements to infrastucture interface

Input data:

NC_INI_CTR_DEAC	NC_T_MIN_SCP		

Detailed input data definition:

Name	Hex. limits	Phys. limits	Resol.	Unit
NC_INI_CTR_DEAC	0...FFFFH	0...262.14	0.004ms	ms
Time delay after IGBT response before switching OFF the IGBT – typical value 600µs				
NC_T_MIN_SCP	0...FFFFH	0...262.14	0.004ms	ms
Minimum time to detect SCB with current feedback flag				

Export actions:

ACTION_INFR_GetIgnDwellAd(IN <Chan>, IN <Cyl>, OUT <T_flag>, OUT <Td>)
Gets the duration of the flag (time in between current threshold and end of the main pulse) and the effective main pulse applied
ACTION_INFR_GetIgnScpDiag(IN <Cyl>, OUT<Diag_scp>)
Gets the diagnosis output for SCP detection with usage of ATM46 or ATIC71
ACTION_INFR_GetIgnScgDiag(IN <Cyl>, IN <Min_burn_time>, OUT <V_dur_igc>, OUT<Diag_scg>)
Gets the diagnosis output for SCG or OL detection and the burn time duration with usage of primary voltage feedback
ACTION_INFR_SetIgnConfigDiag(IN <Chan>)
Sets the channel used for SCP detection

Description for actions:

ACTION_INFR_GetIgnDwellAd(IN <Chan>, IN <Cyl>, OUT <T_flag>, OUT <Td>)					
Gets the duration of the flag (time in between current threshold and end of main pulse) and the effective main pulse applied					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Chan	IN	0 ... 1	0 ... 1	1	-
Channel number on which we want to obtain the time measurement for dwell time control 0: CURR_TH1 1: CURR_TH2					
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which we want to obtain the time measurement for dwell time control					
T_flag	OUT	0 ... FFFF	0 ... 262.14	0.004	-
Integrated time spent above current threshold during the last main dwell pulse (accuracy of 50µs due to SW interrupt latency)					
Td	OUT	0 ... FFFF	0 ... 262.14	0.004	-
Duration of main pulse which has been applied					

ACTION_INFR_GetIgnScpDiag(IN <Cyl>,OUT<Diag_scp>)

Gets the diagnosis output for SCP detection with usage of ATM46 or ATIC71

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the diagnosis for SCP is get					
Diag_scp	OUT	0 ... 1	0 ... 1	1	-
Diagnostic of primary short circuit to battery 0 : no SCP detected from last invocation 1 : SCP detected from last invocation					

ACTION_INFR_GetIgnScgDiag(IN <Cyl>, IN <min_burn_time>, OUT <V_dur_igc>, OUT<Diag_scg>)

Gets the diagnosis output for SCG or OL detection and the burn time duration with usage of primary voltage feedback

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cyl	IN	0 ... 7	0 ... 7	1	-
Cylinder number on which the diagnosis for SCG or OL is get					
Min_burn_time	IN	0 ... FFFF	0 ... 262.14	0.004	ms
Minimum duration for burn time to detect ignition errors					
V_dur_igc	OUT	0 ... FFFF	0 ... 262.14	0.004	ms
Burn time duration for diagnosis validation					
Diag_scg	OUT	0 ... 1	0 ... 1	1	-
Diagnostic for primary short circuit to ground or open load 0 : no SCG detected based on last burntime measured on this cylinder 1 : SCG detected based on last burntime measured on this cylinder					

ACTION_INFR_SetIgnConfigDiag(IN <Chan>)

Sets the channel used for SCP detection

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Chan	IN	0...1	0 ... 1	1	-
Channel number on which the SCP diagnosis will be done 0 : CURR_TH1 1 : CURR_TH2					

FUNCTION DESCRIPTION:

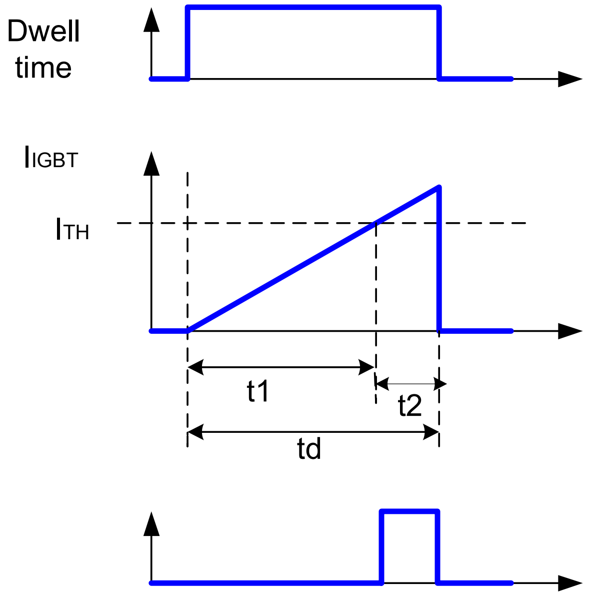
General information:

Requirements for ACTION_INFR_GetIgnDwellAd:

Data acquisition

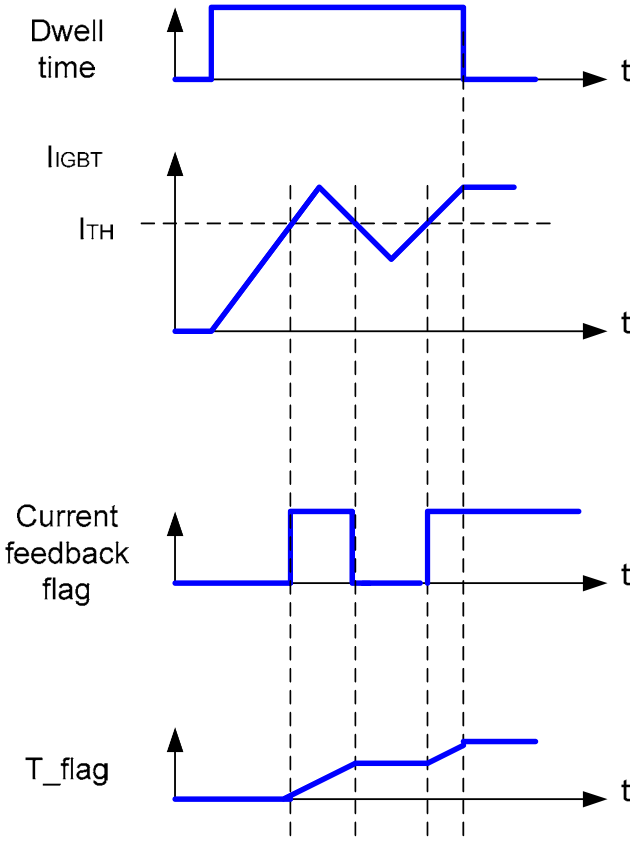
Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Chan	1	-	1		
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
T_flag	1	-	0.004ms		Accuracy of 50µs due to SW interrupt latency
Td	1	-	0.004ms		

Coincidence requirements:



T_flag corresponds to the value t2 of the above graph.
Td corresponds to td.

In case of oscillation of I_{IGBT} around I_{th}, T_flag is the result of the time spent above the threshold I_{th}



Note that: * in case of overlapping of dwell time periods T_flag value cannot be guaranty due to HW design and limitation.

* If Dwell Time periods are overlapping, only the most recent one that has the latest started a coil charging (*last and most recent TD ON event, whatever it is*) will trigger the activation of this integration time function.

With overlapping Dwell Time periods, there is thus a risk to get a wrong T_flag value.

Dwell Times overlapping conditions may occur, in normal running, with too long settings of Dwell time in half and full static ignition modes.

Dwell Times overlapping conditions will occur, in Ignition Limp Home running (*ie. ½ static mode usage for coils charging*).

This interface will return maximum value for T_flag in case :

- SCP has been detected during main pulse
- No dwell has still been performed
- Channel requested is not activated

When Applicative software has read the T_flag value, this value is reseted to maximum value by BSW. This functionning allows safety mode in case applicative software reads two times the same T_flag value without acquisition of new current feedback flag value by BSW.

Requirements for ACTION_INFR_GetIgnScpDiag:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Diag_scp			1		

Diagnosis:

Coincidence requirements:

SCP diagnosis by primary current feedback flag

1. A Dwell Time Pulse is considered as a main or a multiple dwell pulse. Thus there is no distinction in the treatment of “Dwell Time On Events” from main and multiple pulses.
2. Consequently, there is no distinction in the treatment of “Spark Events” from main and/or multiple Dwell Time pulses.
3. A “Dwell Time On Event” defines the start time of coil charging. The resolution and precision of this time is defined by the corresponding ignition channel
4. A “Spark Event” or “Dwell Time Off Event” defines the end time of coil charging. The resolution and precision of this time is defined by the corresponding ignition channel.

Each time a “Dwell Time On Event” occurs, the time during which the IGBT_DIAG Pin indicates a SCP condition has to be integrated within a time window (*defined below*). If this integrated time inside this window exceeds NC_INI_CTR_DEAC, the cylinder that has produced the most recent Dwell Time On event must be switch off as fast as possible for the current ignition cycle. The time window begins at any “Dwell Time On Event” and ends if either one of the following criteria is met:

cr.a) another “Dwell Time On Event” from any Cylinder occurs. This restarts the time window and thus the integration of the time for which IGBT_DIAG indicates SCP conditions

cr.b) a “Spark Event” of the same Cylinder that started charging the coil occurs. “Spark Events” of any other Cylinder are ignored.

cr.c) the integrated time for which the IGBT_DIAG pin indicates a SCP condition exceeds NC_INI_CTR_DEAC

cr.d) the time period back to the most recent “Dwell Time On Event” exceeds NC_IGBT_CUT_OFF_T (primary voltage feedback) or NC_T_MIN_SCP (primary current feedback).

Note that: * in case of overlapping of dwell time periods no short circuit detection can be guaranty due to HW design and limitation.

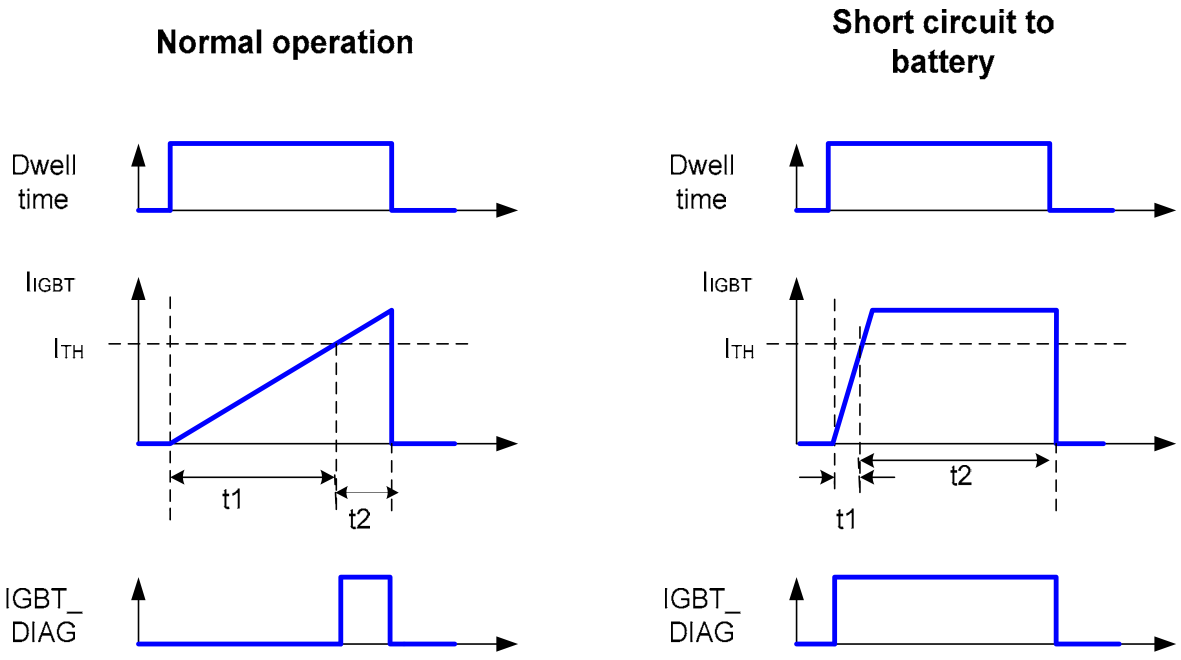
* If Dwell Time periods are overlapping, only the most recent one that has the latest started a coil charging (*last and most recent TD ON event, whatever it is*) will trigger the activation of this protection (BSW service) function. Hence, the last occurring TD ON event will define the coil to be considered by this function and thus diagnosed and protected (cut off if needed, when SCP failure appears)

With overlapping Dwell Time periods, there is thus a risk to do not diagnose (and switch off) the correct IGBT in real failure conditions

Dwell Times overlapping conditions may occur, in normal running, with too long settings of Dwell time in half and full static ignition modes.

Dwell Times overlapping conditions will occur, in Ignition Limp Home running (*ie. ½ static mode usage for coils charging*).

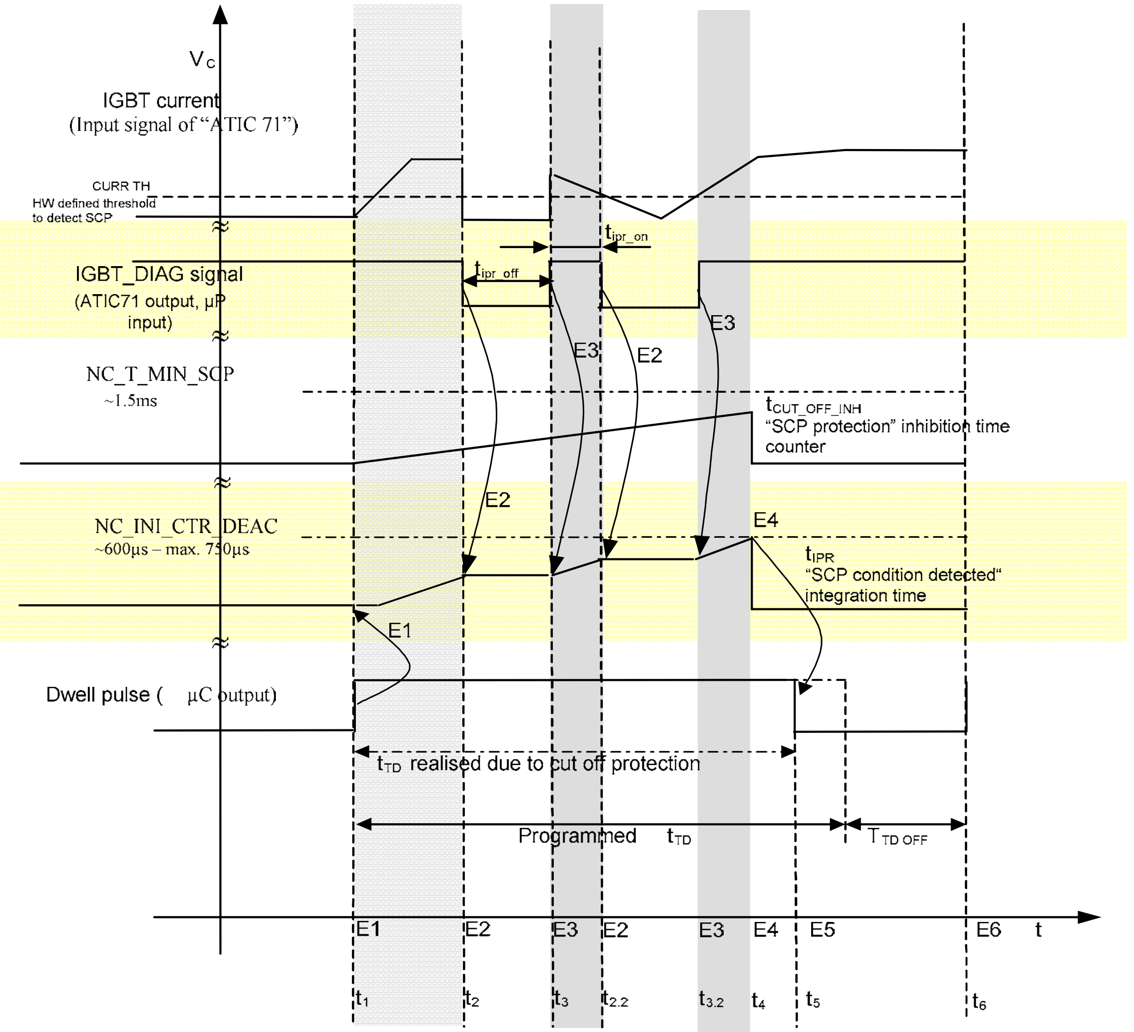
One ATM 46/ATIC71 could handle only 4 ignition coils. If there are more than 4 ignition coils 2 ASIC have to be used. To reduce the possibility of overlapping we have to use them in a crossed order.



Each time a “Dwell Time On Event” occurs, the time during which the IGBT_DIAG(resp. DWELL_DIAG) Pin is high has to be integrated. If this integrated time inside the main dwell pulse exceeds NC_INI_CTR_DEAC, an interruption is generated.

Within this interrupt routine t1+t2 is compared to NC_T_MIN_SCP.

If t1+t2 < NC_T_MIN_SCP the failure is detected and the cylinder that has produced the most recent Dwell Time On event must be switch off as fast as possible for the current ignition cycle.



A dwell pulse is considered as a main or multiple dwell pulse, no distinctions are done as both can be critics in case of SCP failure.

When the IGBT current is higher than the threshold (CURR_TH), it indicates a SCP condition on IGBT. In this case, the IGBT_DIAG signal from the ASIC is high (in SCP level).

a) Events and Actions definition

E1: Dwell Time On Event – Start the charging of the coil
When this event occurs at t_1:
- Clear the SCP pulse periods measured up to now (*ie. the "SCP condition detected" integration time*)
– start / enable to integrate the time for which the IGBT_DIAG Pin indicates a SCP condition

E2: IGBT output without SCP condition (t_2) or transition to No SCP ($t_{2.2}$ - *SCP disappears*)
When E2 occurs, the *"SCP condition detected" integration time* is stopped (*no or no more SCP conditions seen*)

E3: IGBT output in SCP conditions (t_3) or transition to SCP ($t_{3.2}$ - *SCP occurs again*)
When E3 occurs, the *"SCP condition detected" integration time* is started or re-started (*SCP conditions seen or re-seen again*)

E4: Cut Event from the IGBT SCP Protection function
E4 will not occur in normal condition when the coil encounters no SCP conditions (no or too short E3 is met, only E2)

t_{IPR} designates the *“SCP condition detected“ integration time* acquired (*see after*)
t_{IPR} is permanently checked when this protection function is active

IGBT Cut Off in case of SCP detection validated:

If t_{IPR} > NC_INI_CTR_DEAC

And $(t_4 - t_1)$ < NC_T_MIN_SCP

Then Switch off the ignition channel that has produced the most recent Dwell Time On Event (*most recent or latest E1 event*) as fast as possible

Dwell Time applied in this case will be “t_{TD} realized due to cut off protection” function and not the “Programmed t_{TD}”

Else No action on ignition channel

EndIf

E5: Spark Event at the cutting of Ignition Coil charging
E5 occurs at t_5. E5 / t_5 can be either:
- the normal “*Programmed t_{TD}*” if this SCP protection function has not been reached (no E4) or
- the Coil charging Time corresponding to *“t_{TD} realized due to cut off protection”* function if this SCP protection function has been reached (at E4)

When E5 occurs: the *“SCP condition detected“ integration time* (t_{IPR}) is stopped

E6: Identical to Dwell On Event E1 for the next following coil coming to charging mode on the same ASIC diagnostic line

b) Times definition

t_{ipr_on} = time period that indicates a SCP conditions (*ie. I_{IGBT} > CURR_TH, the IGBT_DIAG signal from the ASIC indicates the SCP*). During this time, the *“SCP condition detected” integration time* – t_{IPR} – is enabled.

t_{ipr_off} = time period where no SCP conditions exist (*ie. I_{IGBT} < CURR_TH*). This can happen also in between IGBT SCP diagnosis pulses detection

t_{TD} = time period of any dwell pulse. It correspond normally to the programmed Dwell Time period for charging the Ignition coil. Here, it can be shortened (*cut off of the Coil Charging*) by the IGBT SCP protection function.

$t_{TD\ OFF}$ =time period between any successive dwell pulses

$t_{CUT\_OFF\_INH}$ = For the Ignition Coil under SCP Protection diagnostic, the “Cut Off” functionality is deactivated after a time longer than
$t_{CUT\_OFF\_INH}$ > NC_T_MIN_SCP
If such a time out occurs, the dwell time is not interrupted cause it corresponds to case where IGBT handles over a situation with a high gradient of battery tension and not a short circuit to battery

t_{IPR} = *“SCP condition detected“ integration time* acquired
This Pulse Measurement Method has to be active – which is equivalent to: the IGBT_DIAG input to the µP at SCP level has to be measured – between t_0 and either criteria cr.a), cr.b), cr.c) or cr.d) is met **whichever** comes first.

Warning: due different HW and/or µP architecture and implementation constraint limitations

- Every event E1 to E6 must be processed within a Maximum tolerable time delay smaller than 50µs
- The Dwell Time and Dwell Charging period succession should be limited to:
  100µs ≤ t_{TD} ≤ 60ms and 100µs ≤ $t_{TD\ OFF}$
- Switch off the ignition channel that has produced the most recent Dwell Time On Event should only occur within 50µs after SCP detection confirmation
- IGBT_DIAG pulses shorter than 50µs have a risk of not being processed

Requirements for ACTION_INFR_GetIgnScgDiag:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cyl	1	-	1		Index range: 0 ... NC_CYL_NR-1
Min_burn_time			0.004ms		
V_dur_igc			0.004ms		
Diag_scg			1		

Diagnosis:

Min burn time (V_DUR_IGC) is set to 0 at reset.

So we have open load detection on the first segments until the burn time has been measured and read from applicative software.

The diagnosis is done by comparing V_dur_igc to Min_burn_time. If V_dur_igc < Min_burn_time then the failure is detected.

In case of SCP detection (IGBT cut-off) the burn time measurement must be disabled for the concerned cylinder. The output V_DUR_IGC will be thus in this case the value measured at the previous cycle.

Coincidence requirements:

For the Spark Burn Time Duration measurement, the functionality is:

- To ensure a correct measurement in case of spark blow out, only the Active Level of Burn Time measurement signal from the ATM46 (IGN_DIAG) is integrated in the time window defined by two consecutive main spark events on the same ASIC
- Active Level of Burn Time measurement signal can be “High” or “Low” depending on HW configuration
- Minimum length of Active Level pulses to be detected is 50µs and Minimum inter-space between Active Level pulses to be detected is 50µs. Consequently, IGN_DIAG pulses shorter than 50µs have a risk of not being processed.

Sparking events from multiple spark pulses should not be taken into account for burn time measurement (see timing diagram in case of multiple spark).

At the end of the time measurement window started by cylinder[x], the measured burning duration is read out and written into the variable V_DUR_IGC[x] for the corresponding logical cylinder [x]. The time for Burn Time measurement is then cleared and prepared for the next measurement.

Consider that only one IGN_DIAG signal exists (*this IGN_DIAG signal represents a wired “OR” of all the presents coils channels*) which will limit the measurement range.

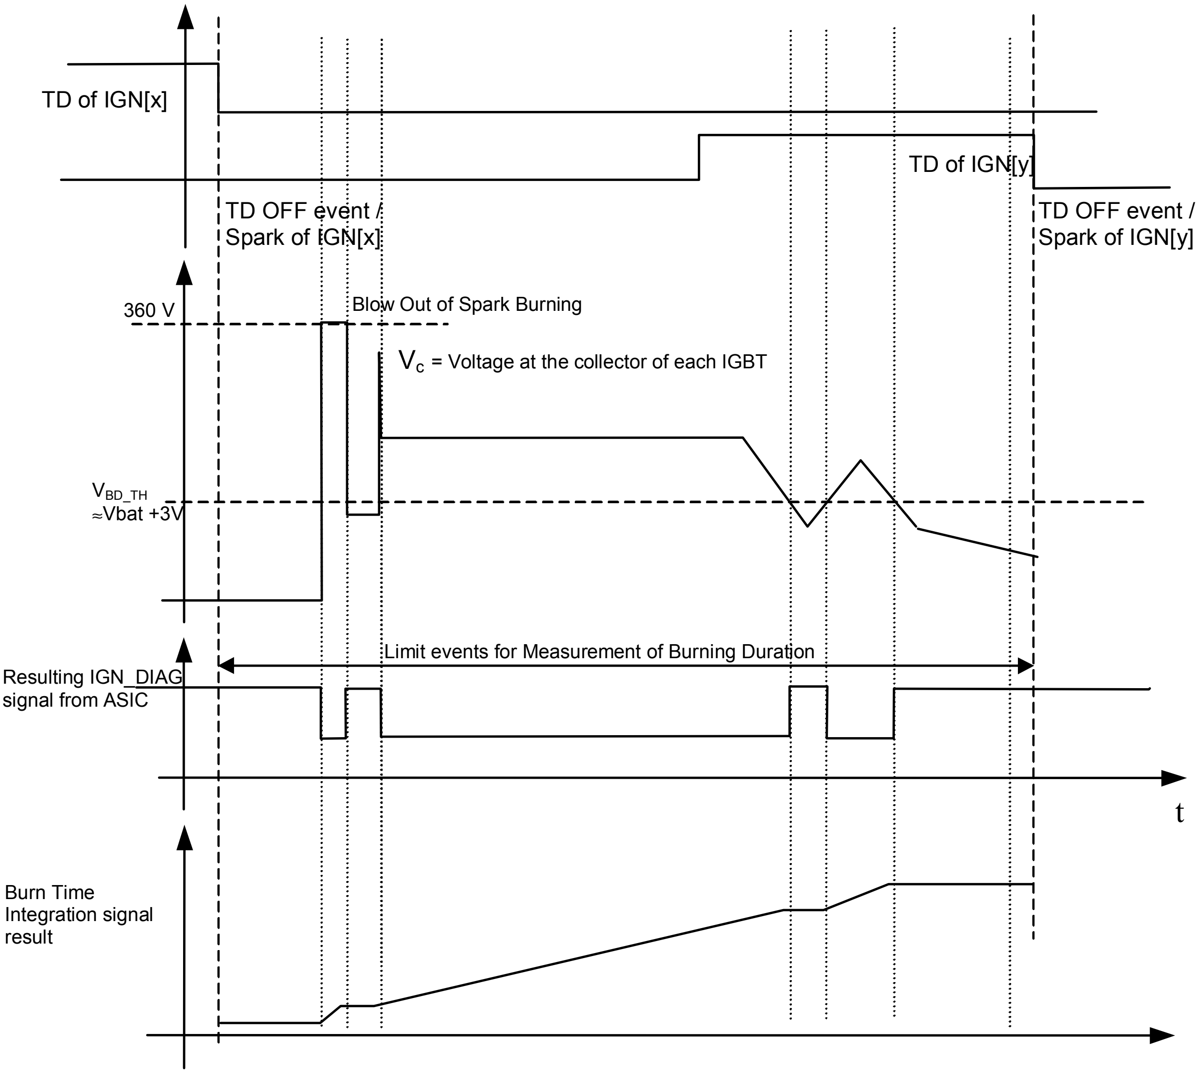
In Limp Home and ½ static modes, 2 main spark events – on one ATM46 diagnostic signal line – occur at the same time. This means that the time windows for measurement of (*at least*) two cylinders overlap. In such cases, due to the “OR” wiring on the signal information,

only the cylinder on which the most recent main spark event (*TD OFF*) is produced will define and will be identified for the time window measurement.
Therefore, the reported burning duration in the interface variable V_DUR_IGC[x] may not correspond to right real burning cylinder [x] in case of Limp Home mode and ½ static coils.

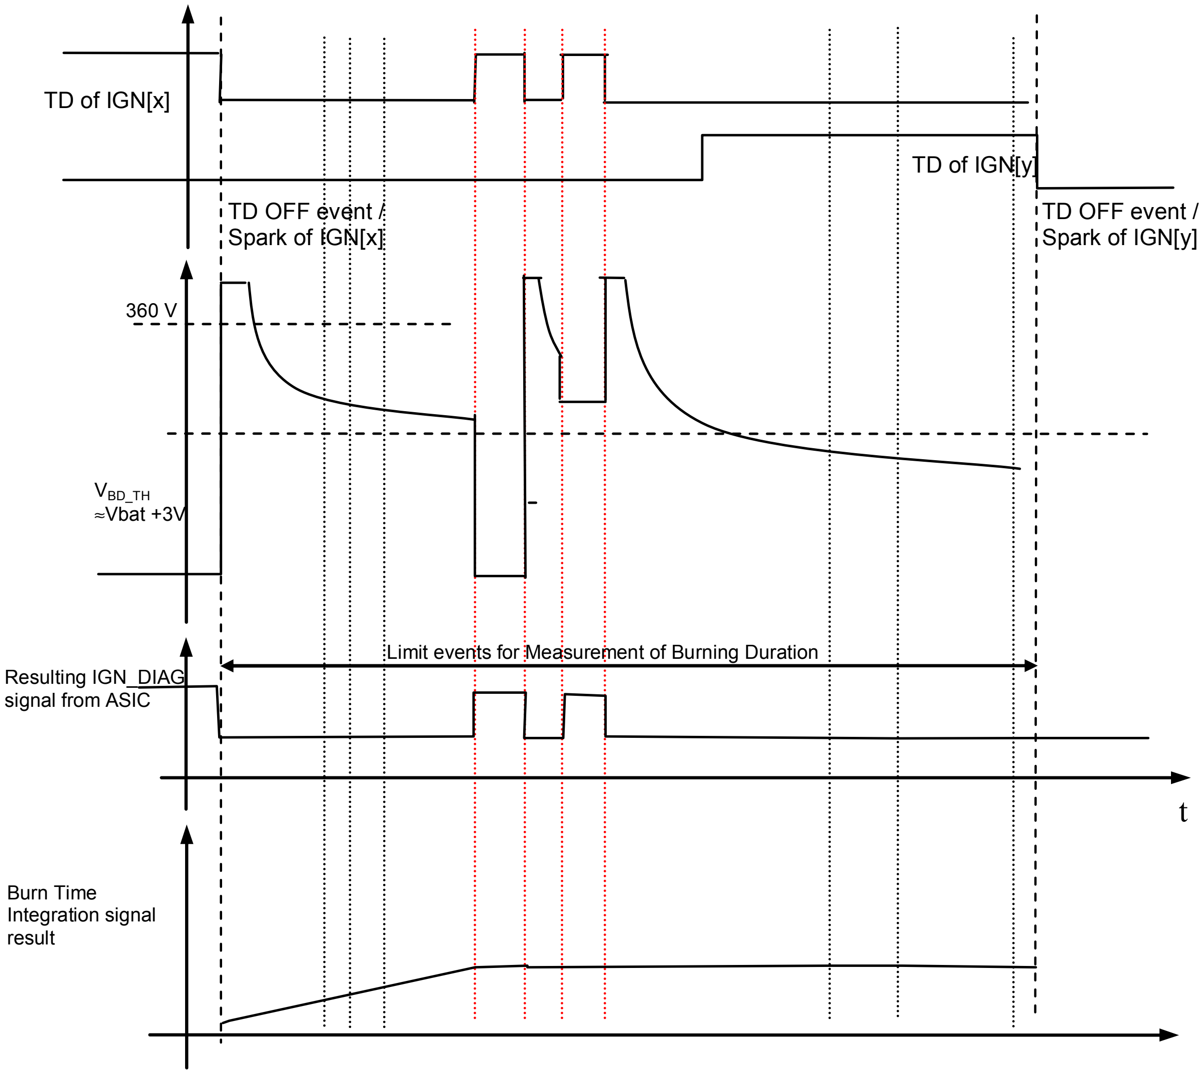
Each ATM46 could analyze 4 ignition coils. If diagnostics for more the than 4 coils are necessary, a parallel ATM46 have to be used.

Timing diagram:

In case of no multiple spark



In case of multiple spark



Requirements for ACTION INFR_SetIgnConfigDiag:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Chan	1	-	1		

Diagnosis:

Coincidence requirements:

This action is sent to configure the channel on which will be done the SCP diagnosis.This action must be sent before the first dwell has occured in order to start the diagnosis on the first dwell generated.

38.8 AGGR IGRE adaptation

38.8.1 Reset of New Ignition Angle Range to old in Integration process

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_AV_MV	O/V	0...FFH	-35.625...60	0.375	°CRK
Mean value of actual ignition angle					
IGA_IGC[NC_CYL_NR]	O/V	0...FFH	-35.625...60	0.375	°CRK
Applied Ignition angle					
IGA_AV[NC_CYL_NR]	O/V	0...FFH	-35.625...60	0.375	°CRK
Ignition Angle Applied on CYL					

Input data:

IGA_IGC_H_RNG[NC_CYL_NR]	IGA_AV_MV_H_RNG	LV_ERR_IGC_SCP[NC_CYL_NR]	LV_ERR_IGC_SCG[NC_CYL_NR]

Information:

Function is applied for Integration of IGRE3.0.0 to keep variables in old ignition angle range. With update to IGRE3.1.0, only new variables will be used. This, except in a few modules that will not be touched due to affection of different projects

Formula section:

IGA_AV_MV = IGA_AV_MV_H_RNG

IGA_IGC[NC_CYL_NR] = IGA_IGC_H_RNG[NC_CYL_NR]

IGA_AV[NC_CYL_NR] = IGA_IGC[NC_CYL_NR]

38.9 Dwell time control (open loop)

38.9.1 Dwell time calculation

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TD	O/V	0...FFFFH	0....262,14	0,004	ms
Dwell time					

Input data:

TD_FAC	VB	N_32	LV_HOM_RUN
LV_TD_AD_H	C_TD_S_AS	IP_TD_S	

FUNCTION DESCRIPTION:

The dwell time raw value calculation is based on the simulation done by the HW-group. At any time an adaptation or correction factor has to be multiplied or added in this chapter.

The dwell time open-loop control value is stored in terms of a battery voltage and engine speed related characteristics.

Application conditions:

Initialisation:	TD = C_TD_INI		*at reset*
Recurrence:	10 ms		
Activation:	*at every engine state*	**if**	LV_HOM_RUN = 1

Formula section

```
If LV_TD_AD_H == 1
Then TD = IP_TD_S(VB, N_32) * TD_FAC + C_TD_S_AS
Else TD = IP_TD(VB, N_32) * TD_FAC + C_TD_AS
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
IP_TD	8*8	0...FFFFH	0...262,14	0,004	ms
LDPM_VB_1_IGRE	8	0…FFH	0….26	0,102	V
LDPM_N_32_1_IGRE	8	0…FFH	0….8160	32	rpm
Dwell time correction versus battery voltage and engine speed					
C_TD_AS	1	F800...7F0H	-8,192..8,128	0,004	ms
Dwell time offset usual value: 0 ms					
C_TD_INI	1	0...FFFFH	0...262,14	0,004	ms
initial value for dwell time control (typ. Value 3ms for standart coils and <2ms for pencil coils)					

38.10 Dwell time factor calculation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
TD_FAC	V/O	0...FFH	0...1.99218	0.0078125	[-]
Basic dwell time factor					
TD_FAC_TCO	V	1...FFH	0.00781... 1.99218	0.0078125	[-]
Adjustment factor with TCO dependence					

Input data:

TCO			

FUNCTION DESCRIPTION:

General information:

The output data could be only TD_FAC. All other factors should be only visible values.

The dwell time factor regroups all adjustment factors as coil temperature factor or a boost factor for start. Here the boost factor is not taken into account as we use for MSD8X project an adaptation of Dwell Time at hight current target at start.

Initialisation : at reset

TD_FAC = 1

TD_FAC_TCO = 1

Recurrence: 10 ms

Formula section:

TD_FAC_TCO = IP_TD_FAC_TCO

TD_FAC = TD_FAC_TCO

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
IP_TD_FAC_TCO	8	1...FFH	0.00781... 1.99218	0.0078125	[-]
LDPM_TCO_TD_FAC	8	0...FEH	-48...142.5	0.75	[°C]
Adjustment Factor for dwell time					

38.11 Dwell time period for stratified mode (open loop)

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
TD_S	O/V	0...FFFFH	0.....262,14	0,004	ms
Dwell time for stratified mode					

Input data:

VB	N_32	LV_S_RUN	TD_FAC
LDPM_VB_1_IGRE	LDPM_N_32_1_IGRE		

FUNCTION DESCRIPTION:

The following function is similar to the dwell time calculation for homogeneous combustion. Only the calibration data should be adapted to stratified combustion.

The dwell time value calculation is based on the simulation done by the HW-group. The dwell time open-loop control value is stored in terms of a battery voltage-related characteristic.

Application conditions:

Initialisation: TD_S = C_TD_S_INI *at reset*

Recurrence: 10 ms

Activation: LV_S_RUN = 1

Deactivation: LV_S_RUN = 0

Formula section:

TD_S = IP_TD_S(VB,N_32) * TD_FAC + C_TD_S_AS

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_TD_S	8*8	0...FFFFH	0...262,14	0,004	ms
LDPM_VB_1_IGRE	8	0…FFH	0….26	0,102	V
LDPM_N_32_1_IGRE	8	0…FFH	0….8160	32	rpm
Dwell time correction versus battery voltage and engine speed for stratified mode					
C_TD_S_INI	2	0...FFFF H	0...262.14	0.004	ms
Init. value for dwell time control (same for homogeneous and stratified mode)					
C_TD_S_AS	2	F800...7F0H	-8.192...8.128	0.004	ms
Application intervention for stratified mode (typ. Value : 0 ms)					

38.12 TD and IGA switches

Output data:

ACTION_INJR_IgnUpdate (IN <>, IN <>)

Exported action:

ACTION_IGRE_SendTrigForIgnUpd (IN <PRM_STATE_IGN_UPD_ENA>)

This action allows INJR to trig IGRE for updating its ignition parameter to its driver according to the designating cylinders specified by action parameter.

Description for action:

ACTION_IGRE_SendTrigForIgnUpd (IN <PRM_STATE_IGN_UPD_ENA>)

This action allows INJR to trig IGRE for updating its ignition parameter to its driver according to the designating cylinders specified by action parameter.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
PRM_STATE_IGN_UPD_ENA	IN	0...FF	0...255	1	-
Bitmap to enable/disable ignition update calculations.					

Formula section For ACTION_IGRE_SendTrigForIgnUpd:

```
TD_IGC_ACT_MAX = 0 ms
TD_IGC_ACT_MIN = 262.14 ms

For x = 0 to NC_CYL_NR - 1
    TD_IGC_ACT_MAX = max (TD_IGC_ACT[x], TD_IGC_ACT_MAX)
    TD_IGC_ACT_MIN = min (TD_IGC_ACT[x], TD_IGC_ACT_MIN)
Endfor

TD_ FAC_MAX_TMP = min (TD_LIM_MAX / TD_IGC_ACT_MAX, TD_FAC_MAX)
TD_ FAC_MIN_TMP = max (NC_TD_LIM_MIN / TD_IGC_ACT_MIN, TD_FAC_MIN)

TD_IGC[x] = TD_IGC_ACT[x]
IGA_IGC_H_RNG[x] = IGA_IGC_H_RNG_ACT[x]

For x = 0 to NC_CYL_NR – 1
    Set ignition parameters if newly calculated:
    If bit x of PRM_STATE_IGN_UPD_ENA == 1
    Then
            ACTION_INFR_SetIgnDwell (x, TD_FAC_MIN_TMP, TD_IGC[x],
                    TD_FAC_MAX_TMP)
            ACTION_INFR_SetIgnAngle (x, IGA_IGC_H_RNG[x])
    EndIf
Endfor
```

FUNCTION DESCRIPTION:

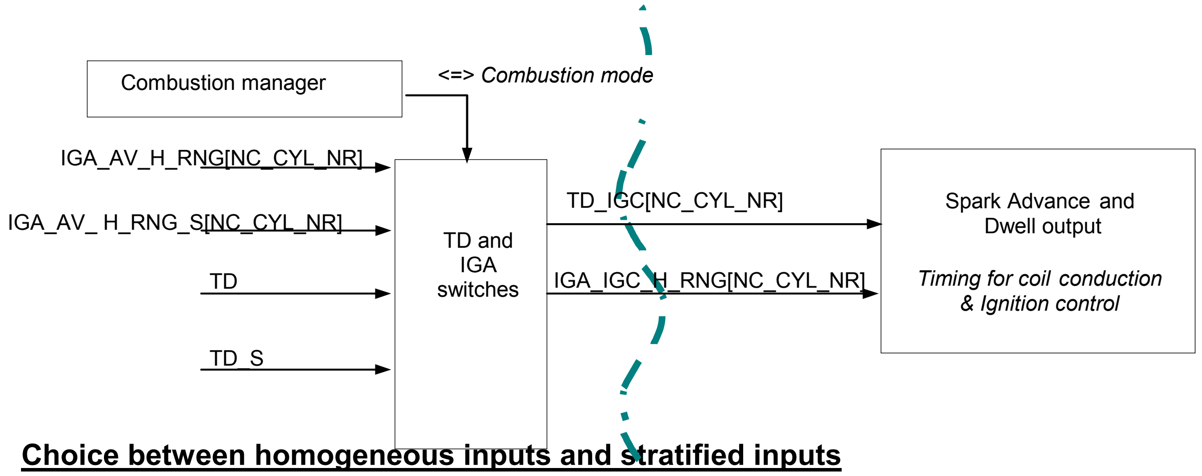
This module should cover all necessary switches between the different dwell times and ignition angles to ensure two outputs, TD_IGC[NC_CYL_NR] and IGA_IGC_H_RNG[NC_CYL_NR].

Initialisation: at reset

```
TD_IGC[NC_CYL_NR] = TD + TD_AD[NC_CYL_NR]
IGA_IGC_H_RNG[NC_CYL_NR] = IGA_AV_H_RNG[NC_CYL_NR]

For x = 0 to NC_CYL_NR - 1
    ACTION_INFR_SetIgnDwell(x,TD_FAC_MIN,TD_IGC[x],TD_FAC_MAX)
    ACTION_INFR_SetIgnAngle(x,IGA_IGC_H_RNG[x])
Endfor
```

Signal flow diagram:



Choice between homogeneous inputs and stratified inputs

The switch between homogeneous and stratified combustion mode could not be realised between TD_ON[NC_CYL_NR] and TD_OFF[NC_CYL_NR].

Switching is only possible if there's no action on the cylinder.

The switch has to be synchronised with the injection switch. The combustion manager managed by INJR does this synchronisation. The switch has to work per cylinder. Some inputs on this signal flow diagram are in fact use by the synchronization module of INJR.

38.12.1 Update of Ignition angle if homogeneous mode is selected

Application conditions:

Activation: LV_ST_END = 1: Engine synchronized

Recurrence: 10ms

Formula section:

```
For x = 0 to NC_CYL_NR - 1
    If    INJ_MOD[x] == 'SNGH' And INJ_MOD_SP[x] == 'SNGH'
          Or    [ INJ_MOD[x] == 'MPLH' And INJ_MOD_SP[x] == 'MPLH' And LV_IGN_INJ_SYN_DEAC = 1 ]
          Or    [ INJ_MOD[x] == 'MPLH+PLS3' And INJ_MOD_SP[x] == 'MPLH+PLS3' And LV_IGN_INJ_SYN_DEAC = 1 ]
    Then  IGA_IGC_H_RNG[x] = IGA_AV_H_RNG[x]
          ACTION_INJR_IgnUpdate (x, IGA_IGC_H_RNG[x])
          ACTION_INFR_SetIgnAngle (x, IGA_IGC_H_RNG_ACT[x])
    Endif
Endfor
```

38.12.2 TD_LIM_MAX calculation

Application conditions:

Activation: Engine synchronized

Recurrence: 10ms

Initialisation: at reset

Formula section:

```
If      VB < C_VB_TD_MAX_LIM_L
Then    TD_LIM_MAX = NC_TD_LIM_MAX_H
Endif

If      VB > C_VB_TD_MAX_LIM_H
Then    TD_LIM_MAX = NC_TD_LIM_MAX_L
Endif
```

In every case: TD_IGC[x] * TD_FAC_MAX <= TD_LIM_MAX

TD_IGC[x] * TD_FAC_MIN >= NC_TD_LIM_MIN

NC_TD_LIM_MIN is defined for dwell time protection in case of advance ignition changes during the dwell time application. If the dwell time is equal to this minimal limit value, the advance ignition could be not guaranteed

NC_TD_LIM_MAX is defined for the maximum dwell time in case of advance ignition changes during the dwell time application. If the dwell time is equal to this maximal limit value, the advance ignition could be not guaranteed

Note: In any case, TD_FAC_MIN has to be smaller than 1 and TD_FAC_MAX greater than one to be sure to respect the requested dwell and avoid inconsistencies
care has to be taken with the setting of NC_TD_LIM_MAX_L and NC_TD_LIM_MAX_H in order to avoid Dwell Time / coil charging recovery:
Dwell time can start at the earliest at 288°CRK before the TDC.
NC_TD_LIM_MAX_L and NC_TD_LIM_MAX_H should be tuned in consequence to respect coil charging time no recovery and coil capacity

*TD MAX = min(TD_IGC[x] * TD_FAC_MAX , TD_LIM_MAX)*

*TD MIN = max(TD_IGC[x] * TD_FAC_MIN, NC_TD_LIM_MIN)*

38.12.3 Dwell time switch Ignition Actuator Tests Diagnosis

Application conditions:

Activation: [LV_ES = 1 *// Actuator tests activation*
and LV_IGK = 1
and LV_FIRST_VLD_TOOTH = 0
and LV_INH_IGC[x] = 0
and at least one LV_IGC _EXT_ADJ[x] = 1]

Deactivation: [LV_ES = 0 *// Actuator tests deactivation*
or LV_IGK = 0
or LV_FIRST_VLD_TOOTH = 1
or LV_INH_IGC[x] = 1
or at least one LV_IGC_EXT_ADJ[x] = 0]

Recurrence: On transition of IGC_EXT_ADJ[x] from 0 to 1

System description:

For ignition coil actuator tests purpose, the Dwell Time has to be applied and transmitted to BSW via action. A specific service is used for those tests purposes.

Formula section:

```
If      (INJ_MOD[x] & NC_INJ_MOD_MASK_1) != NC_INJ_MOD_HOM // Stratified mode for cyl. _x

Then          TD_IGC[x]     = TD_S
Else          TD_IGC[x]     = TD
Endif

For           x = 0 to NC_CYL_NR – 1
              If        LV_IGC _EXT_ADJ[x] = 1
              Then      On transition of IGC _EXT_ADJ[x] from 0 to 1
                                  And LV_FIRST_VLD_TOOTH = 0
                        ACTION_INFR_SetIgcDwellTest(x,TD_IGC[x])
              ElseIf    LV_FIRST_VLD_TOOTH = 1
                        ACTION_INFR_SetIgcDwellTest(x,0)        // immediate cut of tests on engine running
              EndIf
EndFor
```

38.13.1 Calculation of parameters for multiple spark

FUNCTION DESCRIPTION:

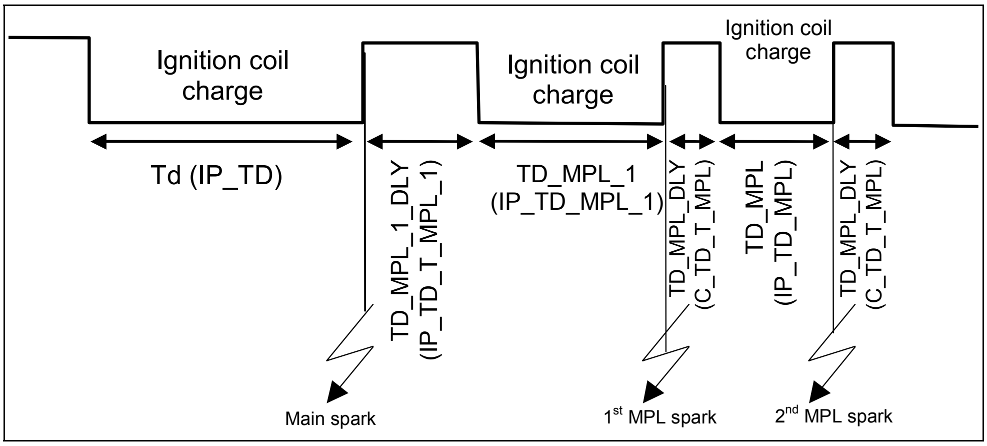
With this function several subsequent sparks could be created. The delay time to create a spark and the time to reload the coil are defined in tables depending on battery voltage and on engine speed.

At start and for the following application conditions, the ignition is controlled by means of multiple sparks.

After an adjustable combustion period, the ignition coil is loaded with a specific dwell time to create successive sparks. The number of successive sparks is defined as IGN_MPL_NR.

The multiple sparks ignition can also be activated by the input flag LV_TD_MPL_SPC_IGN_ACT. In this case, the 1st MPL spark (e.g. the first spark after the main spark) is controlled by specific calibration data IP_TD_MPL_1 and IP_TD_T_MPL_1 (see the picture below for more explanation).

If LV_TD_MPL_SPC_IGN_ACT is inactive, the 1st MPL spark takes the same parameters than the other MPL sparks.



The MPL Sparks are maintained during a time (C_T_CTR_TD_MPL_AST or C_T_CTR_TD_MPL) after the end of the activation condition, before exiting this MPL procedure (*Application Multiple Spark Maintenance for a time before Exit Case*)

We use an estimated coil temperature to limit the number of multiple sparks and then protect ignition coil.

We also increase the number of multiple sparks in case of misfiring.

Priority is given to the protection of ignition coil, according to the estimated temperature coil compared to a maximum value: C_TEMP_MDL_IGC_MAX.

Application conditions:

Initialisation: IGN_MPL_NR = 0
TD_MPL = 0
TD_MPL_1 = 0
TD_MPL_DLY = 0
TD_MPL_1_DLY = 0
T_CTR_TD_MPL = 0 *At reset and in deactivation condition*

Recurrence: 10 ms

Activation: LV_INH_TD_MPL = 0

Deactivation: LV_INH_TD_MPL = 1

38.14.2 Recurrence 100ms

38.14.2.1 Calculation of cooling temperature for temperature model (recurrence 100ms)

The cooling temperature is calculated as the sum of the influence of the ambient temperature and TOIL or TCO. The customer wants the LC to choose between TOIL and TCO because he is not sure which one is correct. In a future version the selection will be removed.

38.14.3.1.1 Calculation overview for Temperature-Model of Ignition-Coils

No Calculation

38.14.3.1.1.1 Energy of ignition-coils in homogeneous and stratified mode

As a fundamental of the ignition-coil model the heat-energy of the ignition-coils is calculated. It can differentiate between the homogenous and stratified mode.

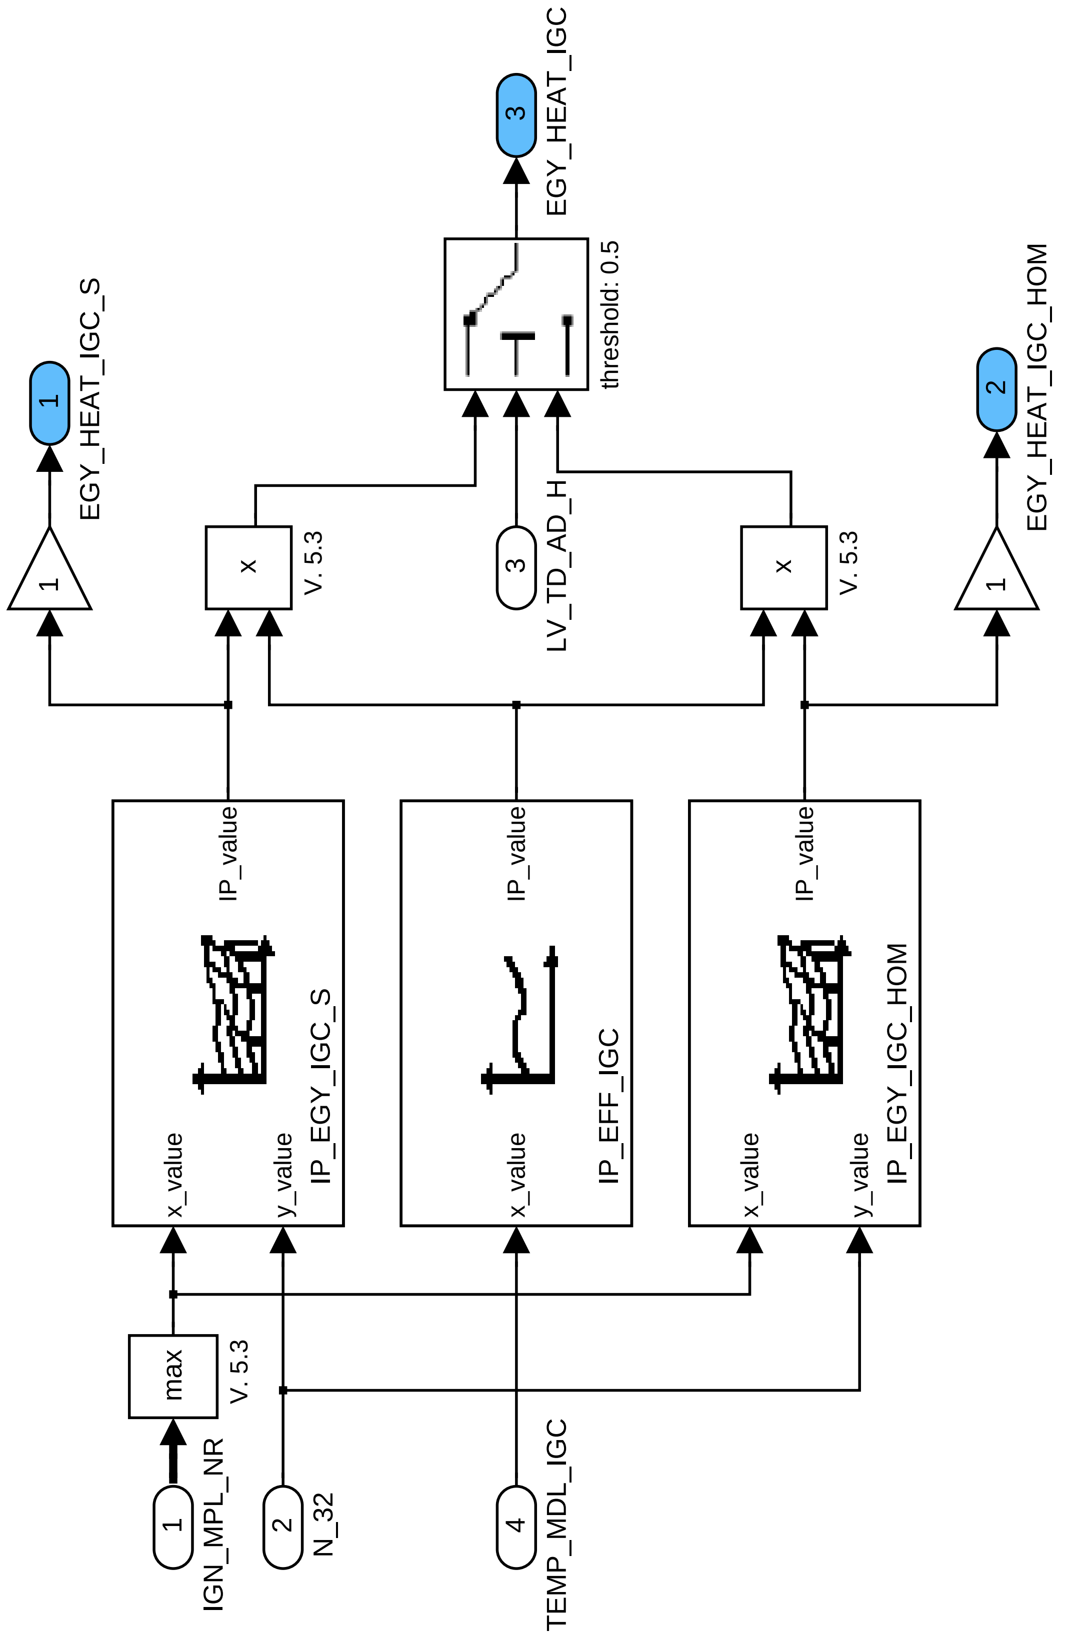

Figure 8:
Path: IGRE_M602J/OPM_10MS/CALC_TEMP_MDL/CALC/EGY_HEAT

38.14.3.1.1.2 Calculation of model-temperature

The model temperature of the ignition coils gets calculated in this function. Based on the heat-energy, the cooling temperature, and the last calculated model temperature the cooling-energy and the new model temperature get calculated. C_ALFA_A_IGC is the product of the heat-transfer-coefficient and the area of the coils and C_CP_M_IGC the product of the heat-capacity and the mass of the coils. The integrator-block generates the temperature.

38.14.3.2 Deactivation of multiple spark on ECU temperature threshold

The purpose of this function is to deactivate the multiple sparks above an ECU temperature threshold in order to decrease heat dissipation due to multiple sparks.

38.14.3.3 Extended Multiple Spark function Activation

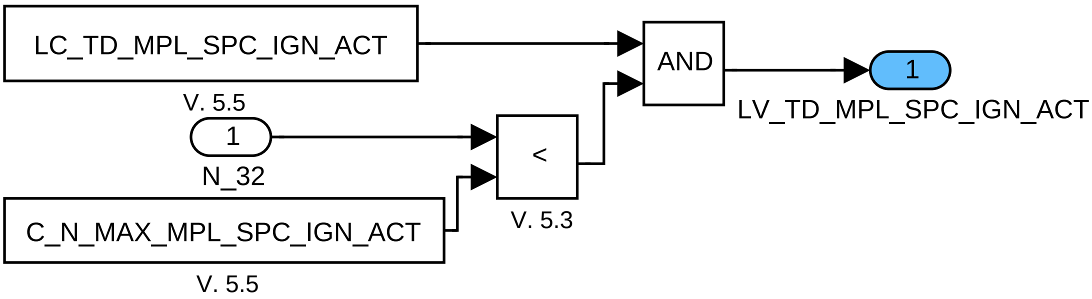

Figure 11:
Path: IGRE_M602J/OPM_10MS/MPL_SPC_IGN_ACT

38.14.3.4 Individual raise of Multiple Spark in case of misfiring

The purpose of this function is to set a calibrated number of multiple spark on a specific cylinder in case of misfiring.
The selection of cylinder is done by a word: STATE_MPL_CYL_IGN. Each bit codes a cylinder, the first cylinder is code by the lowest bit. If the bit is set to 1, there is misfiring and we set the number of MPL for this cylinder to a calibrated value. If it's set to 0, the number of MPL in this specifications will be set to 0 and will be replace in the generic specifications by an appropriate value based on a interpolation table depending on engine speed and battery voltage.

NC_CYL_NR	LV_IGN_INJ_LOCK_REQ	LV_FIRST_VLD_TOOTH	LV_IGK
LV_STST_STOP_REQ	LV_ST_END		

Import actions:

ACTION_INFR_SetIgnEnable(IN <>, IN <>)

38.15.1 Normal Mode Activation

FUNCTION DESCRIPTION:

As there could be different possibilities to deactivate the ignition system an **OR-Junction** is done in this chapter. The output of this or-junction has to be INH_IGC.

The Inputs can come from the ignition diagnosis, from the injection chapter, from the Misfire Generator or from any other function requesting ignition cut-off.

Application conditions:

Initialisation:	at reset

Recurrence:	if LV_ST_END = 1and LV_IGN_INJ_LOCK_REQ = 0:
	segment synchronous (every TDC)
	if LV_ST_END = 0 or LV_IGN_INJ_LOCK_REQ = 1:
	10 ms

Activation:	LV_SYN_ENG = 1
Deactivation:	LV_SYN_ENG = 0

Formula section:

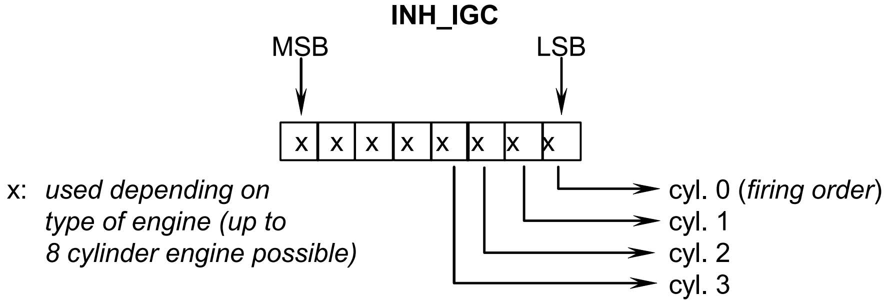
Output driver deactivation

The decision to inhibit an ignition stage is taken for each output before the turn on at TD_ON[x]. This means that no Disable / cut-off can be set on a coil while charging

INH_IGC is the bit wise OR of all inputs requesting an ignition cut-off.

LV_INH_IGC[x] sets the INH_IGC for the corresponding cylinder to 1.

When one bit within INH_IGC is set to 1, the corresponding ignition output is performed as soon as possible. The ignition output remains inhibited while the INH_IGC is unchanged.



- *Calculation of CTR_CYCNR_IGA_ES*

```
IF (LV_IGK$_n$ = 0 and LV_IGK$_{n-1}$ = 1)
   or (LV_STST_STOP_REQ$_n$ = 1 and LV_STST_STOP_REQ$_{n-1}$ = 0)

THEN CTR_CYCNR_IGA_ES$_n$ = C_CYCNR_IGA_ES

ELSE  IF (LV_IGK$_n$ = 0 and LV_IGK$_{n-1}$ = 0)
         or (LV_STST_STOP_REQ$_n$ = 1 and LV_STST_STOP_REQ$_{n-1}$ = 1)

      THEN  CTR_CYCNR_IGA_ES$_n$ = CTR_CYCNR_IGA_ES$_{n-1}$ -1

      ELSE  CTR_CYCNR_IGA_ES$_n$ = CTR_CYCNR_IGA_ES$_{n-1}$

      ENDIF

ENDIF
```

- *Inhibition for ignition system of cylinder x*

```
IF LV_LOCK_IMOB = 1
   or   LV_IGN_INJ_LOCK_REQ = 1
   or   LV_FIRST_VLD_TOOTH = 0
   or   (CTR_CYCNR_IGA_ES = 0 and LV_IGK = 0)
   or   (CTR_CYCNR_IGA_ES = 0 and LV_STST_STOP_REQ = 1)

THEN  INH_IGC = $2^{NC\_CYL\_NR} - 1$   ( ignitions on all the cylinders are inhibited )
ELSE
      FOR x = 0 to NC_CYL_NR-1
            IF LV_INH_IGC[x] = 1
            or bit x of INH_IGC_MIS_GEN = 1
                  THEN the corresponding bit / Cylinder x of INH_IGC is set to 1
                  ELSE  the corresponding bit / Cylinder x of INH_IGC is set to 0
            ENDIF
      ENDFOR
ENDIF

FOR   x = 0 to NC_CYL_NR-1
      ACTION_INFR_SetIgnEnable(x, not(corresponding bit x of INH_IGC))
ENDFOR
```

Note:

1. For DI engine it is strongly recommended to enable Ignition only after Validated synchronisation, *ie.* activation of this function on LV_SYN_VLD = 1 only instead of LV_SYN_ENG
2. No deactivation is possible on a charging coil, *ie.* after TD_ON[x] event: if Dwell Time has started on a stage, this charging will be elapsed to its end
   Refer to module 200X for more details

FUNCTION DESCRIPTION:

General information:

The purpose of this diagnosis function is to detect all major failures, which can happen between ECU output and ignition coils.

This function is adaptable on every engine but the type of spark plugs and ignition coils must be taken into account.

The diagnosis is performed separate for each ignition coil. The feedback signal from the specific ignition coil (following the firing order) is evaluated by the microcontroller.

38.16.1 Short circuit to plus: SCP

Description:

In some hardware driver the ignition power stage is not protected against short circuit to ground and they are not able to withstand an overload current for a long time so it is necessary to switch off the power stage by software.

For ignition coil actuator tests purpose, the SCP diagnostic function has to be enabled, activated and monitored upon the tests requests

The same case and comments (see before) apply here also.

The Ignition output diagnosis function detects short circuit to battery and sets LV_IGC_SCP[x]. It cuts off the ignition driver after a delay time which is defined in the IGBT Protection function. In the ignition diagnosis function the error is debounced.

Application conditions:

1. **Normal Engine Running mode**

Initialization: all ERRM output data according Filter type (see Applic. Inc.), all other output data 0 at reset

Recurrence: **If** NC_IGN_DIAG_TYP =ATM46 every segment

If NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Activation: **If** LV_INH_IGC[x] = 0

And LV_ERR_CAM = 0

And N_32 > C_N_32_MIN_SCP_IGC_DIAG

And LV_INH_DIAG_IGC_SCP = 0

And **if** NC_IGN_DIAG_TYP =ATIC29
Failure information for current cylinder
from ATIC29 is valid

```
                    Endif
        Then        LV_CDN_DIAG_IGC_SCP[x] = 1
        Else        LV_CDN_DIAG_IGC_SCP[x] = 0
        Endif
```

2. **Ignition Actuator Tests mode**

Initialisation: all output variables of the function have to be set to 0 at reset ECU *(except saved error flag)*

Recurrence: **if** NC_IGN_DIAG_TYP =ATM46
On transition of IGC_x_EXT_ADJ from 1 to 0
for reading the SCP failure status

Activation:

```
For         x = 0 to NC_CYL_NR – 1
    If          LV_INH_IGC[x] = 0
        And     LV_ERR_CAM = 0
        [And    LV_ES       = 1          // Actuator tests activation
        And     LV_IGK      = 1
        And     LV_IGC_x_EXT_ADJ = 1]
    Then        LV_CDN_DIAG_IGC_SCP[x] = 1
    Else        LV_CDN_DIAG_IGC_SCP[x] = 0
    Endif
EndFor
```

Formula section:

```
If      LV_CDN_DIAG_IGC_SCP =1
Then    If      LV_SCP_IGC[x] = 1
        Then    ERR_SYM_IGC_SCP[x] = SYM_0
        Else    ERR_SYM_IGC_SCP[x] = NO_SYM
Else    No action on the antibounce counter
Endif
```

Debounce:

Anti - bounce counter increment: according ABC type

Maximum value of anti - bounce counter: according ABC type

```
If      LV_CDN_DIAG_IGC_SCP[x] =1
Then    If      ERR_SYM_IGC_SCP[x] = SYM_0
        Then the antibounce counter is started according ABC type
        Else The antibounce counter is decremented according ABC type
        Endif
Endif
```

Ignition cut off conditions:

If	C_ABC_MAX_IGC_SCP delay is reached
Then	LV_INH_IGC[x] = 1
Endif	

Ignition restart after cut off:

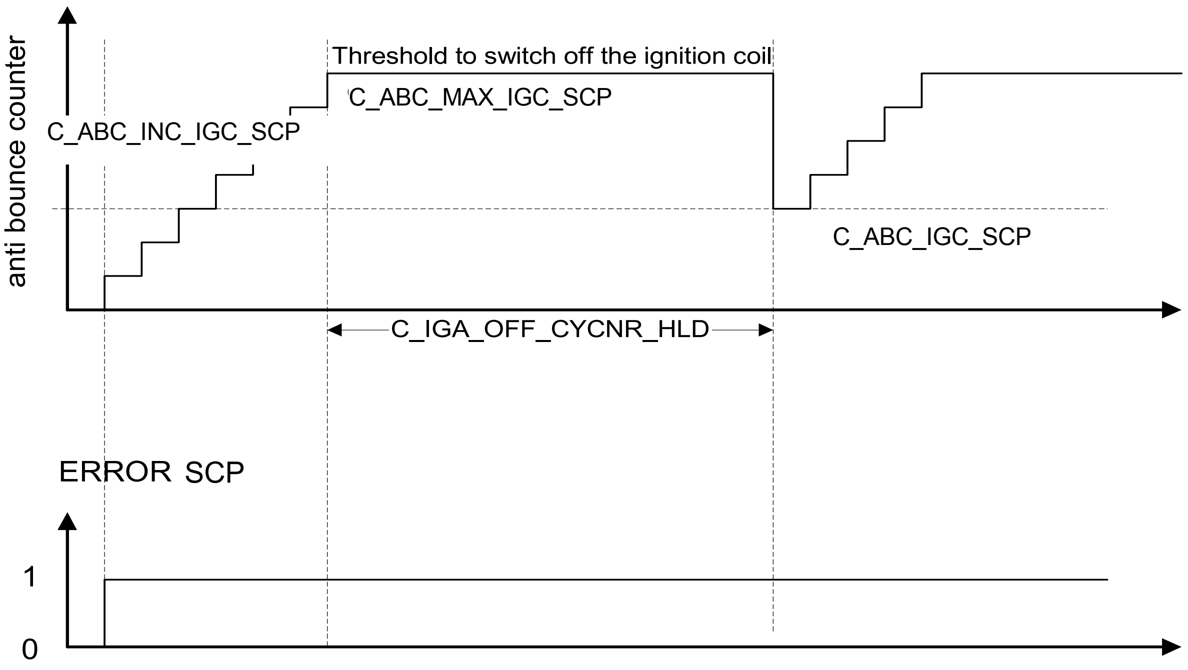
To regenerate the power stage the diagnosis will be switched off (LV_INH_IGC[x] = 1) for C_IGA_OFF_CYCNR_HLD recurrence number (see graphic, failure reaction in case of error).

After the refreshing cycle the debounce counter is set to C_ABC_IGC_SCP (see graphic below) and the ignition will be switched on to test the operating stage again. In case of error it will be debounced again.

This procedure is executed C_SUM_IGC_SCP times before the coil is absolutely switched off, until reset for ATM46 not for ATIC29

In next engine cycle the error is kept present. To take sure that the vehicle is able to restart the ignition will be switched on, till the diagnosis conditions are fulfilled and the diagnosis restarts.

Failure reaction in case of error



Application hint:

Some driver as ATM46 does not cut itself in case of SCP failure. For better Driver protection The counter threshold C_ABC_IGC_SCP mustn’t exceed 4 cycles For the same reason the counter C_ABC_MAX_IGC_SCP must be set below 12 cycles.
The function can be disabled by the ‘enable byte’ C_ESB_IGN_CUT_DIAG.

38.16.2 SCG diagnosis

Description

The diagnosis is based on SCG information from the ignition output diagnosis function.

Please note that this diagnosis is valid also for Open Load detection.

Application conditions:

Initialisation: all ERRM output data according Filter type (see Applic. Inc.), all other output data 0 at reset

Recurrence: *if NC_IGN_DIAG_TYP =ATM46 every segment*

if NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Activation:

```
If      LV_ES = 0
And     LV_ST = 0
And     N_32 > C_N_32_MIN_OL_SCG_IGC_DIAG
And     TCO > C_TCO_MIN_IGC_DIAG
And     LV_INH_IGC[x] = 0
And     LV_ERR_CAM = 0
And     No low voltage battery (LV_CDN_VB_OBD1 = 1)
And     Counter Number of recurrence > NC_IGC_DLY
And     LV_INH_DIAG_IGC_SCG = 0
And     if      NC_IGN_DIAG_TYP =ATIC29
                Failure information for current cylinder
                from ATIC29 is valid
        endif
Then    LV_CDN_DIAG_IGC_SCG[x] =1
Else    LV_CDN_DIAG_IGC_SCG[x] = 0
Endif
```

Formula section:

```
If      LV_CDN_DIAG_IGC_SCG[x] =1
Then    If          LV_SCG_IGC[x] = 1
        Then        ERR_SYM_IGC_SCG[x] = SYM_1
        Else        ERR_SYM_IGC_SCG[x] = NO_SYM
        Endif
Else    No action on the antibounce counter
Endif
```

Debounce:

Anti - bounce counter increment: C_ABC_INC_IGC_SCG

Maximum value of anti - bounce counter: C_ABC_MAX_IGC_SCG

```
If      LV_CDN_DIAG_IGC_SCG[x] =1
  Then  If    ERR_SYM_IGC_SCG[x] = SYM_1
```

```
            Then the antibouce SCG counter is started according ABC type
            Else The antibounce SCG counter is decremented according ABC type
            Endif
 Endif
```

38.16.3 Loss of power supply for all ignition coils

Description:

If all flags V_DUR_IGC[x] are equal to 0 at the same time it is assumed that the power supply for all ignition coils is lost or damaged. in this case LV_ERR_DUR_IGC_MPL is set.

Application conditions:

Initialisation: according ABC type

LV_INH_INJ_DIAG_IGC = 0 at LV_IGK 0 -->1 or reset or clearing FMY

Recurrence: every segment

Activation:

```
    If          LV_ES = 0
          And   LV_ST = 0
          And   LV_IGK = 1
          And   LV_INH_DIAG_DUR_IGC_MPL = 0
    Then        LV_CDN_DIAG_DUR_IGC_MPL = 1
    Else        LV_CDN_DIAG_DUR_IGC_MPL = 0
    Endif
```

Formula section:

```
If      LV_CDN_DIAG_DUR_IGC_MPL =1
Then    If      all V_DUR_IGC[x] = 0 ms                 // for all cylinders

        Then    ERR_SYM_DUR_IGC_MPL =  SYM_3
                If      LV_ERR_DUR_IGC_MPL = 1
                Then    LV_INH_INJ_DIAG_IGC = 1
                Endif
        Else    ERR_SYM_DUR_IGC_MPL = NO_SYM
                LV_INH_INJ_DIAG_IGC = 0
        Endif
Else    No action on the antibounce counter
Endif
```

LV_ERR_DUR_IGC_MPL and LV_END_DIAG_DUR_IGC_MPL are calculated by error management.

38.16.4 Or of ignition failure

Initialisation:	output variable has to be set to "0" at reset
Recurrence:	**If** NC_IGN_DIAG_TYP =ATM46 every segment
	If NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Activation:

Formula section:

LV_ERR_IGC = LV_ERR_IGC_SCP[x] **OR** LV_ERR_IGC_SCG[x]

38.16.5 Unfiltered ignition error information for misfire detection

Application conditions:

Initialisation:	IGC_DIAG_MIS = 0 at reset ECU
Recurrence:	**If** NC_IGN_DIAG_TYP =ATM46 every segment
	If NC_IGN_DIAG_TYP =ATIC29 every 100 ms

Formula section:

```
If      LV_SCP_IGC[x]     = 1
Or      LV_SCG_IGC[x]     = 1
Then    set the bit for the actual cylinder in IGC_DIAG_MIS = 1
Else    reset the bit for the actual cylinder in IGC_DIAG_MIS = 0
Endif
```

Description:

The error information of the ignition system should not be filtered. The different error detections are linked by a wired "OR". As soon as an ignition error is detected the information should be available as output cylinder individually in the byte IGC_DIAG_MIS.

IGC_DIAG_MIS

38.18 Calibration hints for function IGRE – Dwell time period for stratified mode (open loop) - 601L

The same process and tuning as for the Homogenous mode has to / can be followed just considering here the specific needs from the S mode: specific spark energy to be delivered by the coil in order to insure a good burning in S mode.

Consequently, please refer to the module Q018 for this calibration process.

For the stratified mode, it could be interesting to estimate the combustion regularity of the engine, based on an acquisition of the pressure during each cycle, or a bench torquemeter. Compare to homogeneous mode, the energy has to be carefully checked for S needs and also the perfect ignition synchronisation has to be adapted to have a good combustion.

Generally:

IP_TD_S	Dwell time value versus battery voltage and engine speed for stratified mode Normally bigger than in HOM mode ~5 to 4ms decreasing with Engine Speed and Load increase
C_TD_S_INI	Initial value for dwell time control Normally, same value chosen for homogeneous and stratified mode ~5ms
C_TD_S_AS	Application intervention for stratified mode Only for the Calibration phase for testing and validation on engine set to 0 ms

38.19 Calibration hints for function IGRE – Dwell time factor calculation (Template)

To improve Ignition capability of the mixture, especially during Start phase, a specific boost factor will / can be applied to the Dwell Time charging of the coil in order to increase the energy provided in the combustion chamber by the spark.

Care has to be taken when setting such a boost factor on dwell time not to over-stress the coil (*coil internal temperature increase by energy dissipation*) due to the increased dwell time resulting from this boost factor application.

General recommendation from previous experiences and coil / engine test leads to have:

IP_TD_ST_FAC	Factor for dwell time boost at start ~0,5 to 0,25 decreasing when engine speed increase

This file (6025) is a Customer version. For any other boost factor on Dwell Time that could be applied by project choice, please refer to the customer-related file and settings.

38.20 Calibration hints for function IGRE – Dwell time control (open loop)

To ensure the correct ignition of the spark plug on an engine, it is necessary to calibrate different system parameters. This calibration will depend of engine type (direct Injection, homogeneous injection, number of cylinders, capacity).

Specific tests are done, for each application, in order to check if the calibrated dwell times are suitable to the requirements decided by the customer. The tests must consider the conditions for the worst case coil. This also leads to verify if the nominal mapping is coherent when applied on the engine and SOP components, in real running conditions.

Moreover, tests are achieved to show if there is a need of HT or spark duration improvement for transients or cold conditions or stratified mode. One possibility is then to use for example the Multiple Spark Strategy.

The definition and settings of Dwell time control in open loop (6002) is generally performed on a coil test bench in order to simplify the process and to not block an engine or a car for these test cases.

Ignition requirements for the Engine

Depending on the engine (displacement, number of cylinder), injection (classic, direct), combustion (homogeneous or stratified), the ignition requirements for the engine will be specific. Main parameters to ensure the ignition are the secondary performances of the coil: the high tension and energy values necessary for the engine combustion must be inquire by the engine carmaker.

Before calibrate the dwell, although the choice of the coil is not our responsibility, we have to check globally that the coil is adapted to get the performance with correct system condition (primary current not too high).

The customer, responsible of the coil choice and engine design has to provide a target for the spark energy to reach or equivalently for the 1ary current at end of charge time. The Dwell Time setting will then be mapped accordingly to this target taking care to not over-stress the coil (*coil internal temperature increase by energy dissipation*). Description to be given for priority for technical requirements is established, as following, by the customer:

1) high voltage (HT)
2) spark duration
3) spark current: in peak (for a good engine cycles regularity)
4) spark energy...

These data are the base of the primary current definition made by the coil supplier.

Parts

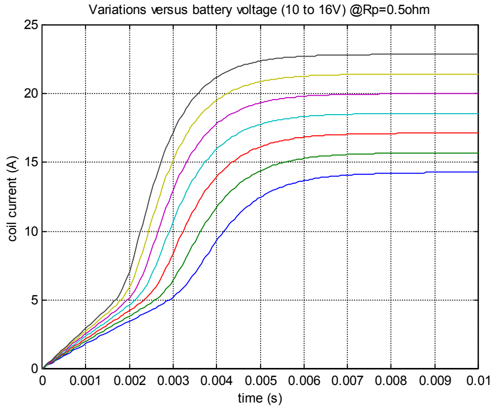
Due to the tolerance of the coils, it is necessary to have several sample coils with different characteristics (Minimum coil, Nominal coil, Maximum coil: in term of inductance).

As the primary current will depend on the coil's dispersion, as far as possible, use nominal coils to do the tests. In other case it is necessary to know the properties of the coil tested (nearest of mini or maxi) to adapt the calibration.

Standard Characterisation

Ignition coil is a transformer where energy stocked during the primary charge is transferred to the secondary and made the high tension necessary for the spark plug. The energy is given by: $E_{tot} = E_{stock} + E_{dis}$ with E_{stock}: stocked energy in the coil

E_{dis}: dispersed energy



- During the primary current charge, energy is stocked. In the “full saturation zone”, stocked energy in the coil is flat because the most influence parameter is the resistance of the coil and inductance L is very low. So in this zone, the energy will be dissipated with heating proportionally to the square of the current. The working energy at the secondary will not increase.
- The saturation’s zone does not allow to stock energy: it is important to check the primary current operating zone not to risk an overheating of coil due to a maximal dissipation (not adapted dwell -> coil damaged), this zone has to be avoided.

The primary current in the coil depends of the voltage supply applied on the +: it will be necessary to compensate the supply (VB) variation in dwell mapping.

A thermocouple is stick on the surface of the coil to control the temperature. For coils with IGBT inside, a thermocouple has to be stick on the radiator.

To simulate the burn time, Zener diode and 1MO load are connected to the secondary of the coil. Only the coil is tested without ECU control: this characterisation is done on the ignition test bench with specifics loads at ambient temperature.

Remarks: it is important to use adapted wire for connecting. For the primary side coil use the appropriate connector with wire with sufficient cross-section (1.5mm² to 2mm²) to limit the electrical leakage. For the secondary side, use specific high-tension wire (no resistive).

if the coil includes the electronic module (IGBT...), tests will be done with it.

Those tests authorise:

- To have an over view of the performance of the coil (linear zone and saturation zone for the primary current, high tension, energy)
- Preliminary analyse for the calibration
- To compare easily the different parameters in same condition with other coils

Endurance Test

The coil is set in a box: 3mm diameter steel balls cover completely the coil. This box is connected to the ground. All external connection with the coil must be isolated of the steel balls. This test is hard to detect a problem of electrical insulation on a coil.

- Power supply: 14V
- Pulse generator: Square signal amplitude 5V
- Frequency 100Hz = 6000 rpm for 4cyl engine in semi-static ignition
- Frequency 50Hz = 6000 rpm for 4cyl engine: full static ignition
- Impulsion width tuned to have 7.5A pick current primary
- No resistive cable for secondary connection

With an X radiation analysis, impacts zone due to the stress are explored to determine the cause (plastic isolation, pick-up...)

Hot Test Sequence

The coil has to be connected to the ignition test bench.

Dwell calibration have to be done with temperature conditions near of heat engine condition (90°C, 100°C to define). For this, before the beginning of the first point, the coil have to be conditioned one hour in the test chamber at the required temperature. For coil with electronic driver inside, short circuit current of the coil (typically at the end of charge) must be conform to the current maximum specified for the driver. Power dissipation and temperature of the driver has to be check.

Depending on the coil type, but especially for double output coil with driver inside, the coil must operate one after one to have similar sequence in comparison with engine operating and to have a warm up more representative. If there is no driver inside the coil, calibration can be done only on one output.

Operating frequency (engine speed) has more impact for the coil temperature that the battery voltage supplier.

So, begin with the lower voltage and frequency and next increase the frequency by 2. The voltage must be measure directly on the + of the coil to have the real voltage and no influence of the electric leakage. After the last speed, increase the voltage by 2 volts steps.

For 24V battery, only test engine speed corresponding to the start-up and idle speed: in fact this calibration point is really important in case of start-up with additional battery.

Check that the primary current is not in full saturation (energy performance at secondary will be not improved and will risk to overheat the coil): the ideal area is in the first zone where the inductance is quasi constant (for a standard coil without hard permanent magnet) and the self has low dispersion. In term of energy the efficiency will be better in the linear area and globally the Energy = g * I. In the linear area, the dissipated temperature is lower. 15 minutes are necessary between each point to stabilise the temperature.

Measurement for each point (VB, N):
- Dwell time tuned (ms)
- Primary current at the end of the dwell (A)
- Burn time (ms)
- Secondary current (mA)
- Secondary voltage (V)
- Energy at secondary (mJ)
- Temperature at the surface of the coil (°C)
- Temperature of the radiator driver if the driver is inside the coil (°C).

Warm up test sequence

With the programmable test chamber, perform a heating sequence representative to the engine warm up (from –30°C to 90°C: ~4°C/min) in driving condition. This test will be done for “cold conditions voltage (11V)” and with an intermediary engine speed of 3000rpm.

Measure the primary current each minute and check it is not in full saturation: a record can be done with oscilloscope to see the current variation pick.

Standard Dwell calibration (VB, Engine speed)

Primary current on the coil is mainly dependants of 3 parameters:
- Battery voltage power source
- Time conduction (dwell)

- Coil’s temperature: this temperature depends on the engine speed (or frequency), ambient temperature of the coil (typically engine temperature) and dwell applied. With the temperature increasing, the primary current decreases (internal resistor increases): so, the performance of the coil will decrease with heating environment. Generally, limit operational temperature for the coil is around 130°C -140°C. As the actual strategies do not yet include compensation for coil's temperature, it is important to not calibrate a dwell for which the temperature on the coil will be too high: it will be a possible cause of failures on the coil. For cold conditions, primary current can be more important but operating point with primary current in fully saturation must be avoid.
  Remark: for the pencils coils or plug top modules which are inside spark-plug recess, the temperature of the coil will be superior compare to a coil only fixed externally.

IP_TD	Dwell time calibration versus battery voltage and engine speed As far as possible, it would be better to begin calibration with precalibrations (coil manufacturer or previous application using similar coil) Care has to be taken regarding the dissipation constraint on the power transistor: short circuit current of the coil (typically at the end of charge) must be conformed to the maximum current specified for the driver. Before the calibration the maximum current supported by the driver has to be know to adapt the dwell and have a short circuit primary current not too high! ~3 to 5 ms decreasing with Engine Speed and Load increase
LDPM_VB_1_IGRE	- 6V: discharged battery - 8V: low voltage - 10V to 11V: cold conditions (winter...) with engine accessories active - 12V: engine accessories active. - 14V: NOMINAL battery voltage in normal driving conditions - 16V: high voltage - 18V or 24V: in case of assistant start-up with 24V truck battery Theses ordinates could be adapted depending on specification. LDPM's have to be reserved for the behaviour in starting phase where jumps to low VB values occur
LDPM_N_32_1_IGRE	The “Volumetric Efficiency” mapping represents the image of the engine torque ramp change and can be use to select engine speed ordinates for the dwell calibration: - Engine start = 400 or 500 rpm - Idle speed (hot conditions) = 700 or 750rpm - Idle Speed (cold conditions) = 1200 or 1300rpm - Engine speed for partial load = 6 points by step (500rpm or 750rpm) until the maximum - Maximum Engine speed Select the most appropriate ordinates (between linear zone) and adapt the number of ordinates for the dimension of the dwell mapping (generally 10 points for the engine speed). Some LDPM's can be reserve for a better mapping of the Start phase. If S mode is also possible a finer grid of specific LDPM can be allocated to this S mode
C_TD_AS	Initial value for dwell time control Normally, same value chosen for homogeneous and stratified mode ~5ms
C_TD_INI	Application intervention in Homogenous mode Only for the Calibration phase for testing and validation on engine set to 0 ms

Engine Change Validation

The dwell calibration will be done normally on chassis dyno and exceptionally precalibration can be done on engine dyno: as the wiring harness for coil connection (battery, command, ground) between the 2 methods is not exactly identical, a complete checking has to be done with the vehicle in case of precalibration on chassis dyno.

Warning: For most of the applications, the customer takes the decision to adapt an ignition coil (and coil supplier) to its engine. This means that any modification of engine design or electrical components leads to a check of the calibrations of the dwell control.

38.21 Calibration hints for function IGRE – Ignition with multiple spark - 6003

In order to improve the combustion capability in some specific phases, it can be useful to use the Multiple Spark Strategy (MPL). MPL will result in:
- Increase of the spark energy provided to the mixture
- Artificial increase of the spark duration in the chamber

Those 2 effect leads to a better ignitability and burn of the air/fuel mixture.

It is recommended to use at least the MPL in:
- Start phase because of the strong variation occurring there
- Idle Speed for more engine stability
- Stratified mode (if applied) to be sure that at least 1 spark event will reach the fuel cloud

Depending on specific engine need and behaviour, those tuning and recommendations can be adapted following engine tests, cold and hot trip, etc…

Generally, from calibration settings, MPL are not dangerous for the coils. Nevertheless, care has to be taken when employing MPL to not over-stress the coil (*coil internal temperature increase by energy dissipation*) due to the increased energy stored in the coil.

The values here proposed have to be refined by measurements on engine, with the target of:
- Engine stability
- burn time increase by 2ary current measurement

C_TCO_MAX_MPL_ST	Max. Coolant Temp. to have MPL at start 142,5°C (full range application in Start)
C_TCO_MAX_MPL_IS	Max. Coolant Temp. to have MPL at Idle speed 142,5°C (full range application in Idle)
C_TCO_MAX_MPL_PL_PU_FL	Max. Coolant Temp. to have MPL at Run -48°C (not used)
C_TCO_MAX_MPL_PUC	Max. Coolant Temp. To have MPL at fuel cut off -48°C (not used)
C_VB_MAX_MPL_ST	Max. Battery voltage to have MPL at start requested value: 16V (full range application in Start)
C_VB_MAX_MPL_IS	Max. Battery voltage to have MPL at idle speed requested value: 16V (full range application in Idle)
C_VB_MAX_MPL_PL_PU_FL	Max. Battery voltage to have MPL at Run 0V (not used)
C_VB_MAX_MPL_PUC	Max. Battery voltage to have MPL at fuel cut off 0V (not used)
C_N_MIN_MPL_ST	Engine speed min for ignition with MPL at Start ~300rpm (electrical starter speed)
C_N_MAX_MPL_ST	Engine speed max for ignition with MPL at Start ~900rpm (max engine speed during flare up)
C_N_MIN_MPL_IS	Engine speed min for ignition with MPL at Idle ~500rpm (cf. setting for minimal engine speed of ISC)
C_N_MAX_MPL_IS	Engine speed max for ignition with MPL at idle ~900rpm (cf. setting for maximal engine speed of ISC)
C_N_MIN_MPL_PL_PU_FL	Engine speed min for ignition with MPL at Run 8160rpm (not used)
C_N_MAX_MPL_PL_PU_FL	Engine speed max for ignition with MPL at Run 0rpm (not used)
C_N_MIN_MPL_PUC	Engine speed min for ignition with MPL at fuel cut off 8160rpm (not used)
C_N_MAX_MPL_PUC	Engine speed max for ignition with MPL at Fuel cut off 0rpm (not used)
IP_TD_T_MPL	Minimum time between two ignition in homogeneous mode decreasing with N increase normal value 110µs - 150µs up to 180µs max.
IP_TD_T_MPL_S	Minimum time between two ignition in stratified mode decreasing with N increase normal value 110µs - 150µs up to 180µs max.

IP_TD_T_MPL_1	Minimum time in between main spark and first MPL decreasing with N increase and increasing with VB increase in H mode ~2 to 10 ms
IP_TD_T_MPL_1_S	Minimum time in between main spark and first MPL decreasing with N increase and increasing with VB increase in S mode ~2 to 10 ms
IP_TD_MPL	Dwell time for MPL in homogeneous mode run ~2 to 0,25ms (~1/10 to 1/15 of nominal TD) decreasing with VB and N increase
IP_TD_MPL_S	Dwell time for MPL in stratified mode run ~2 to 0,25ms (~1/10 to 1/15 of nominal TD) decreasing with VB and N increase
IP_TD_MPL_1	Dwell time for 1st MPL in H mode decreasing with N and VB increase ~10 to 1 ms
IP_TD_MPL_1_S	Dwell time for 1st MPL in S mode decreasing with N and VB increase ~10 to 1 ms
IP_NR_MPL	Number of successive MPL depending on N, MFF_SP_MV in H mode 7 to 3 decreasing with engine speed and TCO increase
IP_NR_MPL_S	Number of successive MPL depending on N, MFF_SP_MV in stratified mode 7 to 3 decreasing with engine speed and TCO increase
IP_FAC_TCO_NR_MPL	TCO factor used in H mode to calculate MPL number
IP_FAC_TCO_NR_MPL_S	TCO factor used in S mode to calculate MPL number
LDP_TCO_IP_NR_MPL	Refer to the setting for Ignition Correction versus temperature in IGSP
C_TD_MPL_MAN	Manual activation of the MPL 0 used only for test and calibration phase
C_T_CTR_TD_MPL_AST	Maintenance Time of MPL activation before Out Case and for the After Start phase only 0ms (not used)
C_T_CTR_TD_MPL	Maintenance Time of MPL activation before Out Case 0ms (not used)

38.22 Calibration hints for function IGRE – Dwell time adaptation – 202C

The primary current slope in fact is not only depending on the battery voltage, but also on many other parameter (e.g. coil inductance, coil and wiring harness resistance, coil temperature, etc.). Most of the parameter cannot be measured on the system, some have manufacturing tolerances and some also vary because of ageing.
This means that the programmed dwell-time table only contains typical values. Therefore the ignition break current can vary in the range of 20..30%. This causes unwanted effects on the system, such as low spark energy or high stress for the ignition power stage.
To solve this, an adaptive dwell-time control can be achieved by using the flag present ion ATIC71 in current controlled mode.

To perform an adaptive dwell-time control, one time is necessary:

- the time **t** during which primary current is above the 100% threshold

For the next ignition a correction can be done.
If **t** = 0 ms => the target threshold has not been reached and the dwell time has to be increased by C_TD_AD_INC

If **t** > C_TD_AD_THD => the target has been reached and we are above the dead zone (C_TD_AD_THD). In this case the dwell time will be reduced at the next ignition by **t** * C_FAC_DEC_TD_AD.

C_TD_AD_MIN	Minimum value learned for dwell time adaptative -3ms
C_TD_AD_MAX	Maximum value learned for dwell time adaptative 3ms
C_TD_AD_INC	Increment on dwell time in case current threshold is not reached 0.052ms
C_TD_AD_THD	Definition of threshold to enable dwell adaptation 0.1ms (defines a dead zone where no action is done)
C_FAC_DEC_TD_AD	Factor applied on T_THD_IGCFB to calculate time to be removed to TD_AD 0.98 (should be near to 1)
C_T_THD_IGCFB_MAX	Maximum measured time for valid sample 3ms
C_T_SUM_TD_AD_MAX	Maximum time allowed to be added in TD_AD without reaching target threshold 3ms
LC_TD_AD_CLR	Logical value enabling reset of variables concerning adaptive values 0 (not used)

38.23 Calibration hints for function IGRE – Dwell time adaptation (Appl.Inc) – 2052

C_TCO_AD_SWI	TCO threshold to enable switch from channel NC_TD_AD_CHN_H to NC_TD_AD_CHN_L -48°C (not used)

38.24 Calibration hints for function IGRE – Spark Advance and Dwell Output

Measurements and tests on an engine define settings of the related calibration values for the Spark Advance management in BSW (200X). The target is to have safe combustion (no misfire) and no coil over-stress with the selected parameters. Here are given normal values applied that should be refined on each engine following tests for combustion stability during transient phases (acceleration and deceleration).

C_TD_ FAC_ST_ MIN	Factor for minimum dwell time in Start phase = 0,5
C_TD_ FAC_ST_ MAX	Factor for maximum dwell time in Start phase = 1,5
C_TD_VB_MAX	Maximum battery voltage to activate MPL = 16V
IP_TD_FAC_MAX	Max dwell time factor in normal running The generic strategy is based on a priority of the ignition angle. If dwell time priority is requested the minimum dwell time has to be equal to the maximum dwell time. The min and Max factor defined here and applied on Dwell Time represent the excursion range window enabled for Ignition Change while the coil is charging To be adapted to coil capability: avoid coil over heating = 1,25 to 1,1 decreasing with engine speed increase
IP_TD_FAC_MIN	Min dwell time factor in normal running To be adapted to coil capability and engine need: avoid misfiring event = 0,7 to 0,8 increasing with engine speed increase
LC_IGC_LIH_CONF	Configuration Choice for Half static Mode in case of CAM limp home (0 = no Limp Home - 1 = Half Static) If CAM LH is enabled on the engine (*cf. ENSD settings: no CAM signal -> engine starting and running on CRK only*) Then the ignition can / have to be turned to 1/2 static mode (=1) to support the case of a false phased engine from start and insure thus at least a spark on the real burning cylinder *Here, this setting can be change to =0 if the engine can only run without CAM and not start without CAM* Else (no CAM LH mode enabled on the project), no LH mode on coil driving is needed (=0) = 1 generic recommendation

38.25 Calibration hints for function IGRE – IGRE Configuration Data

This file (100E) is a Customer version. It has thus to be adapted to the concerned engine configuration (*HW module for coil control and diagnostic + combustion mode + CAM LH settings*) and to project specific needs or recommendations from the customer.

Here are listed the configuration data, which are used only in the IGRE aggregate. Given there are the typical values widely applied and recommended from previous experiences and tests:

NC_IGN_DIAG_TYP	Engine HW dependent: IGRE configuration depending on HW module for coil control and diagnostic used. Please refer to the coil driver mounted on engine 01 = ATM46 02 = ATIC29
NC_TD_LIM_MIN	Minimal value of Dwell Time at least to insure a spark, avoid Misfire = 1 ms
NC_TD_LIM_MAX	Maximal value of Dwell Time. No risk of coil over-stresses. Refer to coil supplier recommendation and information in 100E = 16ms (max)
NC_MAX_IGN_MPL_NR	Maximum number of multiple spark = 7
NC_IGC_DLY	Number of recurrence after engine start, which had to pass by to activate the diagnosis =16
NC_MPL_T_MAX	Absolute maximal duration of multiple spark =60ms
NC_MPL_IGN_CRK_MAX	Maximum ignition angle after TDC where Multiple spark has to be stopped =12 to 18°CRK
NC_IGC_CONF	Engine HW dependant: Ignition mode half or full static. Refer to the coils driver used on the engine and/or engine ECU. 0 = 1/2 Static Coils 1 = Full Static Coils

38.26 Calibration hints for function IGRE

Ignition output diagnosis (for ATM 46)

Settings and Calibration for the Ignition Driver output diagnosis (200Y01) in ATM46 usage

Coil Driver protection

NC_INI_CTR_DEAC	Time delay after IGBT threshold response before switching OFF the IGBT In case of a short circuit to battery, the power dissipation could destroy the power stage = ATM46. From the Dwell Time ON event in Short Circuit to Battery, the IGBT's can withstand this overload current only for a very short time (750µs max. for IGBT without shunt). So, it is necessary to switch off this IGBT transistor for safety and protection reasons after a time delay has elapsed (NC_INI_CTR_DEAC). This time delay is necessary in order to filter parasitic spikes. = 600µs - 750µs max. From ATM46 capability, to not burn the driver
NC_IGBT_CUT_OFF_T	Inhibition of "IGBT protection cut off function" To avoid false diagnostic and cut off, the survey of the power stage has to be limited to ~ the Dwell Time setting ~3 to 5ms

Burn Time measurement

ID_V_DUR_IGC_MIN	Minimum duration of the Burn time to detect sparking failure To be measured on the 2ary wire of the coils on an engine Depend on each combustion chambers burning capability and behaviour (type, geometry, valves, tumble, swirl, etc…) *If measured Burn time is smaller than the map then combustion failure is set. The information is mainly used by Misfire function for cross diagnostic* ~0,5 to 0,1ms decreasing with engine speed increase
LDP_N_32_ID_V_DUR_IGC_MIN LDP_MAF_ID_V_DUR_IGC_MIN	For the LDP settings, refer to the one used for Dwell Time and / or the one from IGSP (volumetric efficiency influence)

Ignition diagnosis - A016

The values of the ABC have to be adapted according to the engine HW (*coil driver device and coils*) capability to withstand a failure.

The Short to Battery failure - most dangerous and damaging one for the driver - has to be set faster than the others

Open Circuit and Short to Ground are only interesting has feedback information to Misfire function for cross diagnosis to alert that spark is no more created (they are generally out of concern regarding coil or coil driver protections). The calibration of the related ABC have thus to be linked also to the Misfire target.

Settings and Calibration for the Ignition diagnosis (A016)

C_ABC_IGC_SCP	Value of anti-bounce counter after regeneration cycle (*cf. after*) = 128 (1/2 of the C_ABC_MAX_IGC_SCP)
C_IGA_OFF_CYCNR_HLD	Number of engine Cycle for the regeneration tentative of the coil = number of engine cycle where the coil is switched off after a confirmed SCP failure, before attempting to set it back to work = 16 (coil cooling time)
C_SUM_IGC_SCP	Number of regeneration cycles (*cf. before*) applied before switching off definitively the coil until next ECU reset = 255 set to max.
C_ABC_INC_IGC_SCP	Anti – bounce counter increment for the ignition system diagnosis SCP = 5 (quicker than OL and SCG)
C_ABC_INC_IGC_OL	Anti – bounce counter increment for the ignition system diagnosis OL = 4
C_ABC_INC_IGC_SCG	Anti – bounce counter increment for the ignition system diagnosis SCG = 4
C_ABC_MAX_IGC_SCP	Maximum value of the ABC for the ignition system diagnosis SCP. Will switch off the coil and launch the regeneration cycle (*cf. before*) = 255
C_ABC_MAX_IGC_OL	Maximum value of the ABC for the ignition system diagnosis OL = 255
C_ABC_MAX_IGC_SCG	Maximum value of the ABC for the ignition system diagnosis SCG = 255
C_ESB_IGN_CUT_DIAG	C_ESB_IGN_CUT_DIAG = 1 will inhibit the Cut Off protection function = 0 (function enabled is recommended)
C_TCO_MIN_IGC_DIAG	Min Temperature for condition diagnosis OL & SCG = 20°C (emission cycle starting)
C_N_32_MIN_SCP_IGC_DIAG	Min engine speed for condition diagnosis SCP = 512rpm = exist of Start phase
C_N_32_MIN_OL_SCG_IGC_DIAG	Min engine speed for condition diagnosis OL/SCG = 512rpm = exist of Start phase

39.1.1 IGSP_M6001

General information:

This module coordinates different ignition angle requests and calculates the ignition angles IGA_AV_H_RNG[x] and IGA_AV_H_RNG_S[x].

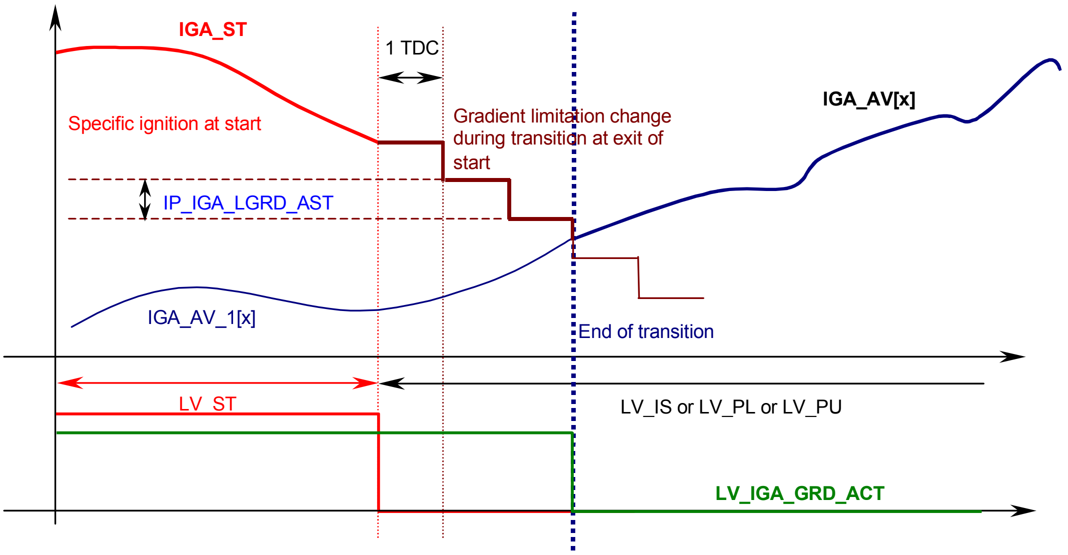
IGA_SP is the output from the torque management functions to realize the torque setpoint. IGA_SP is limited to IGA_MIN the minimum ignition angle which can be applied to the engine.

IGA_BAS_COR is the corrected basic igniton angle which is realized normally if no other requests like knock control or torque requests (via IGA_SP) requires a retarded ignition angle.

The reference ignition angle IGA_REF_COR is a theoretical ignition angle at maximum engine torque. It is the reference value to all ignition angles to calculate the ignition angle differences (IGA_DIF_xxx) for the calculation of EFF_IGA_xxx values.

According to application choice (through logical application incidence flag LC_IGA_ST_ENA) the ignition angle during start phase is not managed through the torque but by the specific value IGA_ST. In this case, the corresponding ignition efficiencies are set to 1. At the end of start phase the transition from IGA_ST to the set point ignition delivered by torque calculation IGA_AV_1[x] is approached through a gradient limitation (the ignition gradient step is calibrateable).

This module delivers the homogeneus ignition angle IGA_AV_H_RNG[x] and the stratified ignition angle IGA_AV_H_RNG_S[x] for the MSD70 project in IGRE. For the MSV70, the stratified ignition angle is a copy of the homogeneus one. Therefore, this HOM / S switch is also visible in MSV70, but effectiv.



Picture: example for transition after start with IGA gradient limitation

Application conditions:

Initialisation:	IGA_AV_H_RNG[x] = C_IGA_INI_H_RNG at reset
	IGA_MIN = -90 °crk at reset
	LV_IGA_GRD_ACT = 0 at engine stalling
Recurrence:	every 10 ms and every TDC
Activation:	at every engine operating state
Deactivation:	-

Correction of the basic ignition angle at start dependen on the start cycle counter at operation mode 2					

39.2.1 IGSP_M6004

FUNCTION DESCRIPTION:

General information:

The ignition angle at start is basically dependent on the engine speed N and coolant temperature TCO determined by the map IP_IGA_ST_BAS. Additionally a map dependent on the ambient pressure AMP corrects this basic ignition angle. To avoid backfiring due to the fast increase of the combustion chamber temperature a second correction dependent on the cycle counter CYC_ST and the coolant temperature is added. A further map consideres influences of the inrake air temperature TIA.

The switch LV_IGA_ST_OPM_SEL is used to determine if either the basic ignition angle at start for operation mode 1 or the basic ignition angle at start for operation mode 2 is calculated.

In case of MSA start (engine start stop automatic) there is an additive correction dependent on the relative engine position PSN_ENG_REL_ST for the first ignition.

Application conditions :

Activation : LV_ST = 1 or (LV_ES = 1 and LV_SYN_ENG = 1)

Deactivation : LV_ST = 0 and (LV_ES = 0 or LV_SYN_ENG = 0)

Update rate : every 10 ms and every TDC

Initialisation: at reset : *IGA_ST = 0*
LV_IGA_ST_PSN_ENG_COR_STST = 0
LV_PSN_ENG_REL_TMP = 0

<u>Remark</u>: if LV_IGA_ST_OPM_SEL = 1 only the upper part has to be executed (ΣIP....OPM_2), else only the lower part has to be executed (ΣIP....OPM_1).

FUNCTION DESCRIPTION:

The minimum ignition angle is the minimum allowable ignition angle which is possible to apply to the engine. The basic minimum ignition angle determined through a calibration map is corrected by a temperature dependent additive term. Furthermore there are additive influences by cat heating and engine operating mode like throttled or unthrottled.In some special engine running states, the minimal ignition angle calibrated in this function can be limited by external request to avoid too strong spark retards during those states.Hence, in all practical cases IGA_DIF_MIN_H_RNG is a negative value which is the maximum allowable spark retard determined by a calibration map. It includes the coolant temperature correction (*for engine protection, pollution condition, etc…*).

39.3.1 IGA_DIF_MIN_H_RNG calculation with extra spark retard for torque intervention and after start management

General information:

In case of a strong fast torque intervention requested (*ie. if IGA_DIF_SP_H_RNG hence requested by torque intervention becomes lower than IGA_DIF_MIN_0_H_RNG*) then a specific over-retard (*IGA_DIF_MIN_DELTA_H_RNG*) is authorised on minimum ignition angle for a while. It permits to manage a strongest response from the engine to a torque reduction request. IGA_DIF_MIN_0_*H_RNG* is just an intermediate variable introduced here for clarification of explanations. IGA_DIF_MIN_0_*H_RNG* is just the result of the interpolation map without other affects. This over-retard is only allowed for a given time (*C_IGA_DIF_MIN_DELTA_TEMP_ENA*). In case of a rising edge of the flag for enabling extra-retard (LV_IGA_DIF_MIN_DELTA_ACT= 0->1) the active counter is reseted to C_IGA_DIF_MIN_DELTA_TEMP_ENA. If torque intervention by spark retard is active as well as homogeneous ignition angle and injection parameters are applied to the engine (LV_TQ_IGA_ACT=1 and LV_HOM_ACT=1) the active counter is decremented to 0, otherwise it is incremented back to C_IGA_DIF_MIN_DELTA_TEMP_ENA. The counter for extra-retard is set to avoid exhaust gas over-heating and thus protect the exhaust branch. At the end of this counter, this over-retard on IGA_DIF_MIN_H_RNG goes back up to 0 with a limited gradient (*C_IGA_DIF_MIN_DELTA_LGRD*_H_RNG) for its come-back law. This limited gradient for come-back is necessary to avoid the changes on ignition angle applied can be felt on-board the car. At the end of this gradient limited come-back, such an other kind of extra retard is inhibited during a while (*C_IGA_DIF_MIN_DELTA_TEMP_ENA*) just to be sure to avoid any problems of exhaust gas over-heating. This functionality aims to deal with thermal exchange effects. So, the timer are in time units (*sec.*) and the calibration map here defined for extra retard is related to LDP of temperature.

Application conditions:

Activation:	LV_HOM_RUN	= 1	
Deactivation:	LV_HOM_RUN	= 0	
Initialisation:	IGA_DIF_MIN_H_RNG	= 0° CRK	at reset
	IGA_DIF_MIN_0_H_RNG	= 0 °CRK	
	IGA_DIF_MIN_AST_H_RNG	= 0 °CRK	
	IGA_DIF_MIN_DELTA_H_RNG	= 0 °CRK	
	IGA_MIN_BAS_x_H_RNG	= -35.625°CRK	
Update Rate:	whole functionality	=> 10 ms	
	IP_IGA_DIF_MIN_TCO_H_RNG	=> 1000 ms	

Formula section:

Condition to enable the extra-spark retard:

If LV_IGA_DIF_MIN_DELTA_ACT = 0
And When IGA_DIF_SP_H_RNG becomes lower than IGA_DIF_MIN_0_*H_RNG*$_{n-1}$
Then LV_IGA_DIF_MIN_DELTA_ACT = 1

```
    And            IGA_DIF_MIN_DELTA_H_RNG = IGA_DIF_MIN_DELTA_1_H_RNG

Elself             LV_IGA_DIF_MIN_DELTA_ACT = 1
    And When       IGA_DIF_SP_H_RNG becomes lower than IGA_DIF_MIN_0_H_RNG$_{n-1}$
Then               IGA_DIF_MIN_DELTA_H_RNG = IGA_DIF_MIN_DELTA_1_H_RNG

Else               if    IGA_DIF_SP_H_RNG is greater than IGA_DIF_MIN_0_H_RNG$_{n-1}$
                   And   LV_IGA_DIF_MIN_DELTA_ACT = 0 or 1
                         (Whatever should be the state of LV_IGA_DIF_MIN_DELTA_ACT)

Then               LV_IGA_DIF_MIN_DELTA_ACT      remains in its previous state
    And            IGA_DIF_MIN_DELTA_H_RNG = 0
EndIf
```

IGA_DIF_MIN_DELTA_1_H_RNG and IGA_DIF_MIN_0_H_RNG are only an intermediate variable just used for calculation and clarification

Management of extra spark retard:

                                 IP_FAC_IGA_DIF_MIN_AMP) *
                                 IP_FAC_IGA_DIF_AST

elseif  LV_AT = 0   and   LV_AST_END = 0   and   NLC_USE_IGA_MIN_AST = 1
then    IGA_DIF_MIN_AST_H_RNG =      (IP_IGA_DIF_MIN_CYC_MT   +
                                  IP_IGA_DIF_MIN_CYC_AMP_MT_H_RNG        *
                                 IP_FAC_IGA_DIF_MIN_AMP) *
                                 IP_FAC_IGA_DIF_AST

ElseIf  IGA_DIF_MIN_AST_H_RNG = 0                 the computation can be
switched off
EndIf
```

39.3.2 Limitation of IGA_DIF_MIN_H_RNG for after start management

General information:

After start phase it is possible to include a specific correction depending on engine cycles after start and engine coolant temperature to the minimum ignition angle calculated from basic maps to improve the efficiency of catalyst heating.

Note: *All this following part is only computed – and integrated in the SW –* ***if NLC_USE_IGA_MIN_AST = 1***

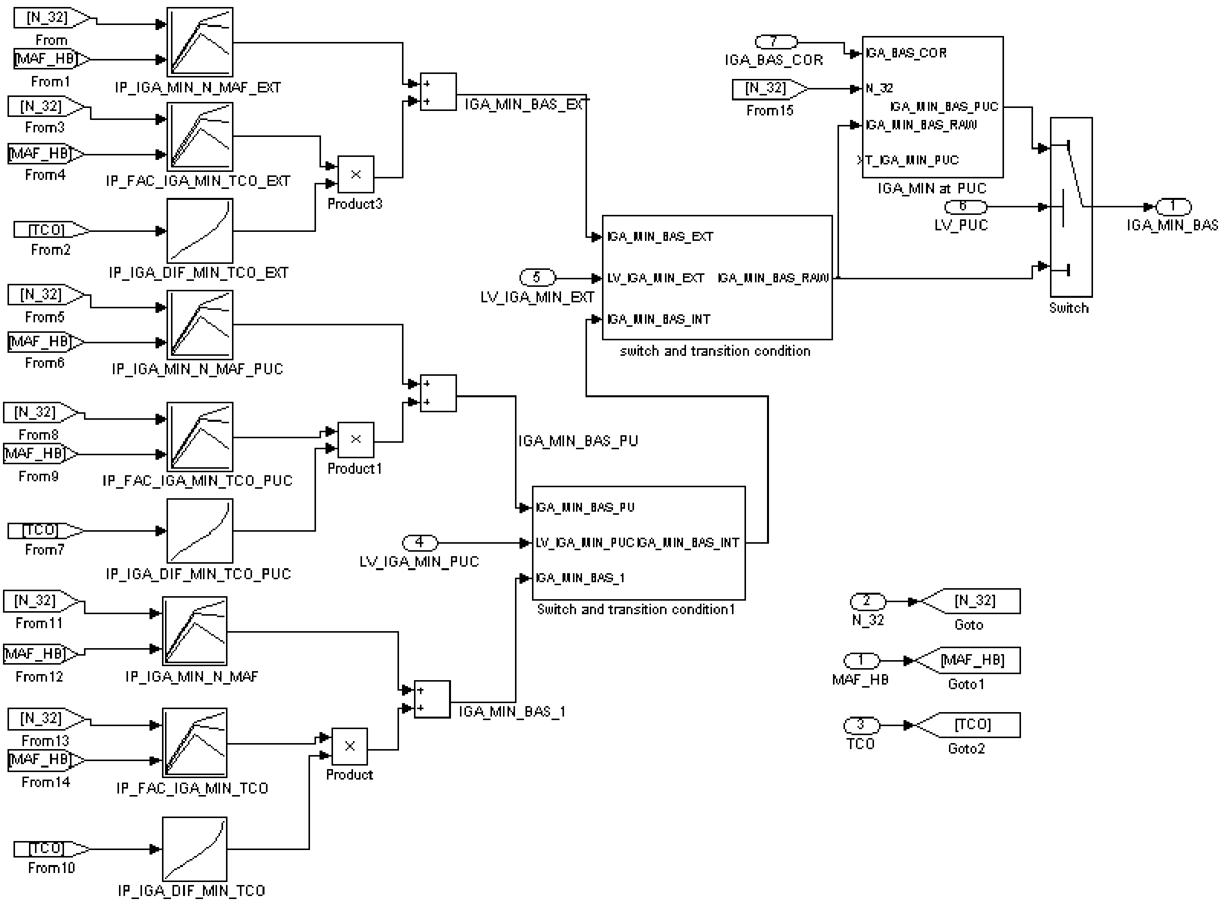
39.3.3 IGA_MIN switch conditions

Signal flow diagram:



Additional maps are introduced to consider the influence of cat heating and throttled engine mode. IP_IGA_MIN_CH_COR and IP_IGA_MIN_OPM_COR are additive corrections on IGA_MIN_BAS_H_RNG. Each one is depending on N_32 and MAF_HB. The combined sum results in IGA_MIN_BAS_OPM.

The fading of IP_IGA_MIN_CH_COR in depence of operation mode is managed by function function OPM_SWI.

Formula description:

IF OPM_REQ_CUS = 66 **or** OPM_REQ_CUS = 82

THEN

IGA_MIN_BAS_2_H_RNG = IGA_MIN_BAS_H_RNG + IP_IGA_MIN_CH_COR_H_RNG

ELSE

IGA_MIN_BAS_2_H_RNG = IGA_MIN_BAS_H_RNG ~~+ IP_IGA_MIN_CH_COR_H_RNG~~

ENDIF

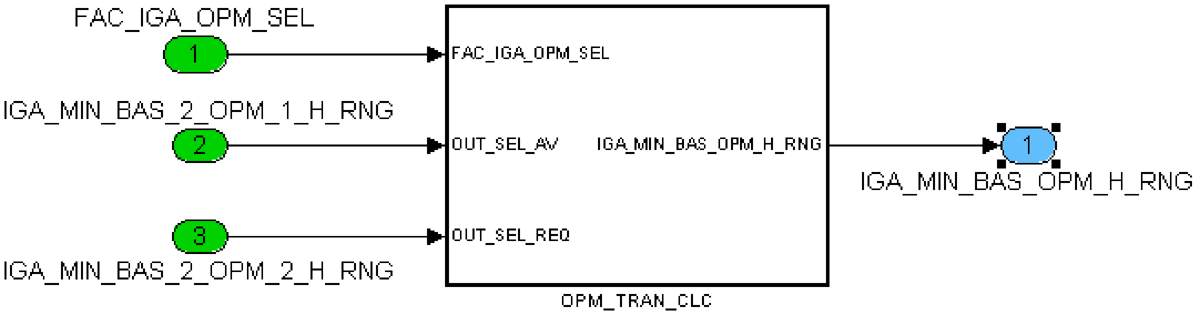
IGA_MIN_BAS_2_OPM_1_H_RNG = IGA_MIN_BAS_2_H_RNG

IGA_MIN_BAS_2_OPM_2_H_RNG = IGA_MIN_BAS_2_H_RNG + IP_IGA_MIN_OPM_COR_H_RNG

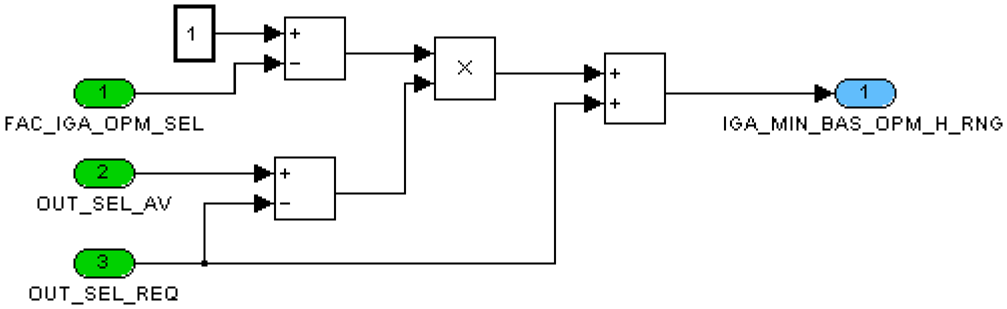
IGA_MIN_BAS_OPM_H_RNG = Function call OPM_SWI (described in chapter 1.5)

39.3.4 Operation mode manager (function OPM_SWI)

There are two input values IGA_MIN_BAS_2_OPM_1_H_RNG, IGA_MIN_BAS_2_OPM_2_H_RNG. Each input value belongs to a special operation mode OPM_1, OPM_2. Moreover the value OPM_SEL_AV indicates the active and OPM_SEL_REQ indicates the requested operation mode. The aim of the operation manager is to create an output value depending on the active operation mode. If there is a switch from one mode to another a smooth changeover from one input value to the other in possible by using the interpolation factor FAC_IGA_OPM_SEL .



Operation mode manager



OPM_TRAN_CLC

To prevent a jump in the IGA_MIN a transition is necessary at switching to an other IGA_MIN_BAS_x_H_RNG with the change limitation of C_IGA_DIF_MIN_BAS_LGRD_H_RNG.

39.4 Customer adaptation module: AGGR IGSP

39.4.1 Outputs for BMW functions which are defined as IGSP exported data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
Zw_ks	V/O	FE0C...258H	-50...60	0.1	[°CRK]
Grundzündwinkel bei KR-Sicherheitsspätverstellung					
Zw_min	V/O	FE0C...258H	-50...60	0.1	[°CRK]
minimum ignition angle					
Zw_ve[NC_CYL_NR]	V/O	FE0C...258H	-50...60	0.1	[°CRK]
basic ignition angle, application correction and knock control included					
Zw_md[NC_CYL_NR]	V/O	FE0C...258H	-50...60	0.1	[°CRK]
ignition angle after torque intervention					
Zw_out_mw	V/O	8000...7FFFH	-3276.8...3276.7	0.1	[°CRK]
Ignition angle applied on the respective cylinder (0 to 5)					

Input data:

IGA_IGC_H_RNG[NC_CYL_NR]	IGA_IGC_0_5_H_RNG	IGA[NC_CYL_NR]	
IGA_MIN_H_RNG	IGA_ADJ_MAX_KNK		

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the outputs are different from the specified values due to the input data attributes.

Application conditions:

Initialisation at reset or at exit power latch phase:

Zw_ks = IGA_ADJ_MAX_KNK
Zw_min = 0°crk
Zw_ve[NC_CYL_NR] = IGA[NC_CYL_NR]
Zw_md[NC_CYL_NR] = 0°crk
Zw_out_mw = IGA_IGC_0_5_H_RNG *`/* IGA_IGC_0_5_H_RNG is initialized with C_IGA_INI_H_RNG */`*

Recurrences: segment: Zw_ks, Zw_min, Zw_ve[NC_CYL_NR], Zw_md[NC_CYL_NR], Zw_out_mw,

Activation: every engine state, except power latch phase

Deactivation: at power latch phase

Values at deactivation: 0, except:

Zw_out_mw = IGA_IGC_0_5_H_RNG

Formula section:

Remark: all formulas are valid in a **physical** meaning

Zw_ks = IGA_ADJ_MAX_KNK
Zw_min = IGA_MIN_H_RNG
Zw_ve[NC_CYL_NR] = IGA[NC_CYL_NR]
Zw_md[NC_CYL_NR] = IGA_IGC_H_RNG[NC_CYL_NR]
Zw_out_mw = IGA_IGC_0_5_H_RNG

39.4.2 Outputs for SV aggregates

Index

40.1 Immobilizer signal diagnosis (EWS4)

General information:

IMOB diagnosis is performed to provide error-symptom-information by setting of LV_ERR_IMOB_i and entry in error memory in case of ECU-blocking/error detection.

Output data:

Name	Mode	Hex. Limits	Phys. limits	Resol.	Unit
LV_ERR_IMOB_0	V/O	0...1H	0...1	1	[-]
Present failure in IMOB manipulation after filtering					
LV_END_DIAG_IMOB_0	V/O	0...1H	0...1	1	[-]
Diagnostic performed at least one time					
LV_CDN_DIAG_IMOB_0	V/O	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_IMOB_0	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					
LV_ERR_IMOB_1	V/O	0...1H	0...1	1	[-]
Present failure in IMOB CAS BUS after filtering					
LV_END_DIAG_IMOB_1	V/O	0...1H	0...1	1	[-]
Diagnostic performed at least one time					
LV_CDN_DIAG_IMOB_1	V/O	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_IMOB_1	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					
LV_ERR_IMOB_2	V/O	0...1H	0...1	1	[-]
Present failure in IMOB data storage after filtering					
LV_END_DIAG_IMOB_2	V/O	0...1H	0...1	1	[-]
Diagnostic performed at least one time					
LV_CDN_DIAG_IMOB_2	V/O	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_IMOB_2	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					
LV_ERR_IMOB_3	V/O	0...1H	0...1	1	[-]
Present failure in IMOB CAN BUS after filtering					
LV_END_DIAG_IMOB_3	V/O	0...1H	0...1	1	[-]
Diagnostic performed at least one time					
LV_CDN_DIAG_IMOB_3	V/O	0...1H	0...1	1	[-]
Diagnostic condition to start symptom detection (set to 1 when condition is fulfilled)					
ERR_SYM_IMOB_3	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
For each symptom : status of failure (set to 1 when failure symptom detected)					
CDN_DIAG_IMOB_1	V/O	0...FFH	0...255	1	[-]
Condition bit coded for each sym					
CDN_DIAG_IMOB_3	V/O	0...FFH	0...255	1	[-]
Condition bit coded for each sym					

Defined in non-public specification:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

LV_LOCK_IMOB	V/O	0...1H	0...1	1	[-]
LV indicates locking of IGN and INJ by IMOB					
INH_IV_IMOB	V/O	0...FFH	0...255	1	[-]
Locking request for INJ by IMOB					

Export actions:

C_ABC_MAX_IMOB_1	1	1...FFH	1...255	1	[-]
Maximum value for antibounce counter					
C_ABC_INC_IMOB_2	1	0...FFH	0...255	1	[-]
Antibounce counter increment					
C_ABC_MAX_IMOB_2	1	1...FFH	1...255	1	[-]
Maximum value for antibounce counter					
C_ABC_INC_IMOB_3	1	0...FFH	0...255	1	[-]
Antibounce counter increment					
C_ABC_MAX_IMOB_3	1	1...FFH	1...255	1	[-]
Maximum value for antibounce counter					
C_ABC_DEC_IMOB_1	1	0...FFH	0...255	1	[-]
Antibounce counter decrement					
C_ABC_DEC_IMOB_3	1	0...FFH	0...255	1	[-]
Antibounce counter decrement					

FUNCTION DESCRIPTION:

This diagnosis calculates the error LV_ERR_IMOB_0

Imob: Manipulation

Application conditions:

Initialisation:

```
LV_CDN_DIAG_IMOB_0  = STD_INI
LV_END_DIAG_IMOB_0  = STD_INI
LV_ERR_IMOB_0       = STD_INI
ERR_SYM_IMOB_0      = STD_INI
```

when LV_IGK changes from 0→1 or at reset:

Recurrence: 100ms

Activation/ Deactivation:

```
IF      LV_IGK = 1 then
THEN    LV_CDN_DIAG_IMOB_0 = 1
ELSE    LV_CDN_DIAG_IMOB_0 = 0
ENDIF
```

Formula section:

Symptoms calculation:

Error state of STATE_IMOB_0_ERR equal to ERR_SYM

Error set after debounce.

End of diag calculation see ERRM

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Configuration for diagnostic symptoms:

Diagnostic IMOB_0	Symptom description	Symptom	Filter type
manipulation	not used	*SYM_0*	STD_INI
	no secrete key	*SYM_1*	
	not used	*SYM_2*	
	response does not match	*SYM_3*	

FUNCTION DESCRIPTION:

This diagnosis calculates the error LV_ERR_IMOB_2

Imob: Data storage

Application conditions:

Initialization:

```
LV_CDN_DIAG_IMOB_2  = STD_INI
LV_END_DIAG_IMOB_2  = STD_INI
LV_ERR_IMOB_2       = STD_INI
ERR_SYM_IMOB_2      = STD_INI
```

when LV_IGK changes from 0→1 or at reset:

Recurrence: 100ms

Activation/ Deactivation:

```
IF      LV_IGK = 1 then
THEN    LV_CDN_DIAG_IMOB_2 = 1
ELSE    LV_CDN_DIAG_IMOB_2 = 0
ENDIF
```

Formula section:

Symptoms calculation:

Error state of STATE_IMOB_2_ERR equal to ERR_SYM

Error set after debounce.

End of diag calculation see ERRM

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Configuration for diagnostic symptoms:

Diagnostic IMOB_2	Symptom description	Symptom	Filter type
Data storage	No storage for secrete key avl.	*SYM_0*	STD_INI
	read/write FSC (nvm error)	*SYM_1*	
	Read error secrete key (2of3)	*SYM_2*	
	Spare for checksum error (later)	*SYM_3*	

Exported Interface: ACTION_IMOB_DIAG_ERR_1(CDN_IMOB, SYM_IMOB)

FUNCTION DESCRIPTION:

This diagnosis calculates the error LV_ERR_IMOB_1

Imob: KBUS Diagnosis

Note: Diagnosis is **not** initialized at KL15 0->1 because diagnosis is already active at ecu_state = wakeup

Application conditions:

Initialization:

all at 0 only at reset:
LV_CDN_DIAG_IMOB_1 = STD = 0
LV_END_DIAG_IMOB_1 = STD = 0
LV_ERR_IMOB_1 = STD = 0
ERR_SYM_IMOB_1 = STD = 0

Activation/ Deactivation:

LV_VAR_BN = 0 **or** (STATE_CAN_DNM_D > 0 and PWL_LOCK_CDN[BN2000] = 1)

Recurrence: at call ACTION_IMOB_DIAG_ERR_1(CDN_IMOB, SYM_IMOB)

Symptoms calculation:

Error state of ERRM: ERR_SYM equal to SYM_IMOB

```
If      SYM_IMOB = END_DIAG
Then    LV_END_DIAG_IMOB_1 = 1 (set immediatly)
Else
    If   SYM_IMOB > 0
    Then     LV_CDN_DIAG_IMOB_1 = 1
         ERR_SYM_IMOB_1= SYM_IMOB
         LV_ERR_IMOB_1 = 1                       (after debounce)
    Else     If    (CDN_IMOB & ERR_SYM_IMOB_1) = true        or
                   ERR_SYM_IMOB_1 = NO_SYM
             Then  LV_CDN_DIAG_IMOB_1 = 1
                   healing only of cdn fits to err_sym once
                   ERR_SYM_IMOB_1= NO_SYM
                   LV_ERR_IMOB_1 = 0                 (after debounce)

Endif

Error state of ERRM: ERR_SYM = SYM_IMOB

CDN_DIAG_IMOB_1 = CDN_IMOB

Error set after debounce.

Symptoms are **unchanged** if condition for doing symptom detection is not fulfilled.

Configuration for diagnostic symptoms:

Diagnostic IMOB_1	Symptom description	Symptom	Filter type
Kbus	Open line	*SYM_0*	STD
	Frame error (type_ews/st_ews)	*SYM_1*	
	Time out data	*SYM_2*	
	CRC error	*SYM_3*	

Exported Interface: ACTION_IMOB_DIAG_ERR_3(CDN_IMOB, SYM_IMOB)

FUNCTION DESCRIPTION:

This diagnosis calculates the error LV_ERR_IMOB_3

Imob: CAN Diagnosis

Note: Diagnosis is **not** initialized at KL15 0->1 because diagnosis is already active at ecu_state = wakeup

Application conditions:

Initialisation:

all at 0 only at reset:
LV_CDN_DIAG_IMOB_3 = STD = 0
LV_END_DIAG_IMOB_3 = STD = 0
LV_ERR_IMOB_3 = STD = 0
ERR_SYM_IMOB_3 = STD = 0

Activation/ Deactivation:

LV_VAR_BN = 0 **or** (STATE_CAN_DNM_D > 0 and PWL_LOCK_CDN[BN2000] = 1)

Recurrence: at call ACTION_IMOB_DIAG_ERR_3(CDN_IMOB, SYM_IMOB)

Formula section:

Symptoms calculation:

Error state of ERRM: ERR_SYM equal to SYM_IMOB

```
If      SYM_IMOB = END_DIAG
Then    LV_END_DIAG_IMOB_3 = 1 (set immediatly)
Else
        If    SYM_IMOB > 0

INJR Configuration Data

The following document describes the general rules for definition of the configuration data for INJR Aggregate.

General information:

The following document describes the general rules for definition of the configuration data for INJR Aggregate

41.1.1 Global configuration data

Here are listed the configuration data, which are not only used in the modules of the INJR aggregate.

Data	Value
NC_INJ_CONF	3
NC_INJ_CONF_GDI	3
NC_NR_SYM_IV	0

41.1.2 Local configuration data

The configuration data are listed here which are used only in the INJR aggregate.

Data	Value
NC_INJ_INH_SWI_IV_SHIFT_NR	6
NC_CRK_INJ_REF_TDC	-360 °CRK
NC_CRK_INJ_BAS_REF	180 °CRK

Number of axis points for MFF axis of MFF TI map.					
NC_NR_IDX_PRS_DEC_INJ	1	0...FFH	0...255	1	[-]
Number of axis points for pressure difference axis of MFF TI map.					
NC_T_DCHA_DLY_MIN	1	0...FFFFH	0...65.535	0.001	[ms]
Minimum applicable time for injector discharge delay that is greater than zero.					

41.2 INJR - Requirements to Infrastructure

Only SV internal

41.3 Final Injection Timing

Overview:

Calculation of the cylinder individual injection times for homogeneous mode:

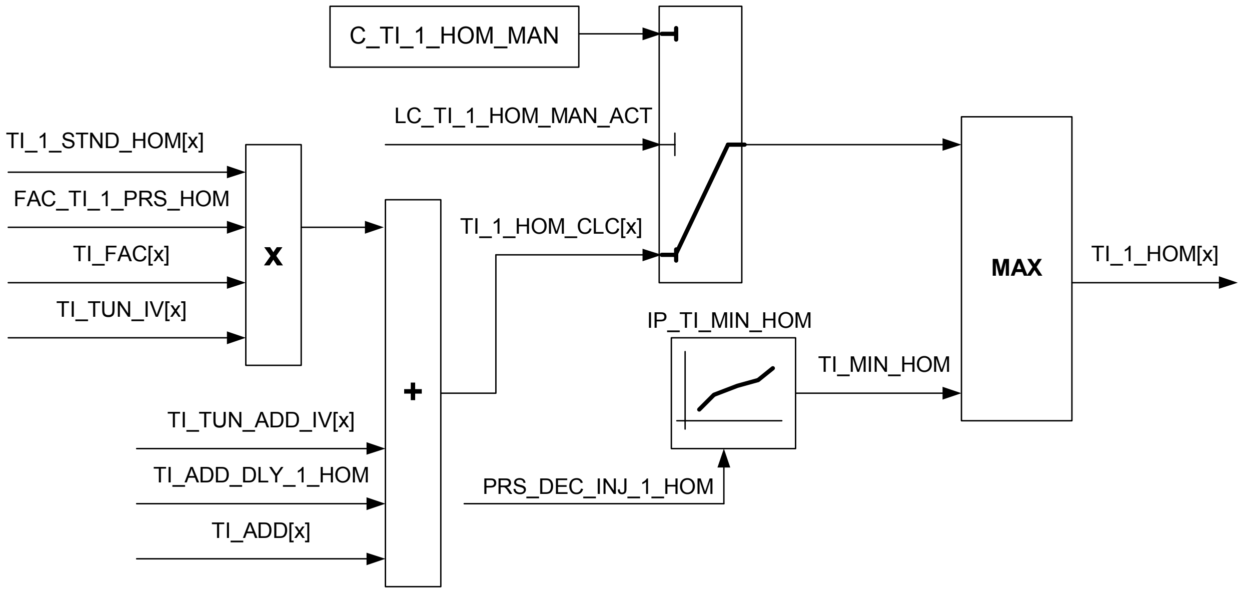
First pulse:

This module calculates the cylinder individual injection times TI_1_HOM[x], which are applied at the injectors.

The injection time can be set manually. If the switch LC_TI_1_HOM_MAN_ACT is set to one, the constant C_TI_1_HOM_MAN is applied.

If homogeneous lean mode is active (STATE_CMB_CTL = HOM_AFL) and TI_1_HOM[x] is smaller than (TI_MIN + C_TI_MIN_OFS), the combustion mode changes to homogeneous mode. This is indicated if the flag LV_AUTH_TI_MIN_AFL is set to zero. Switching back to homogeneous lean mode is allowed at the earliest if the delay time C_T_AUTH_TI_MIN_AFL has elapsed. Then the flag LV_AUTH_TI_MIN_AFL is set back to zero.

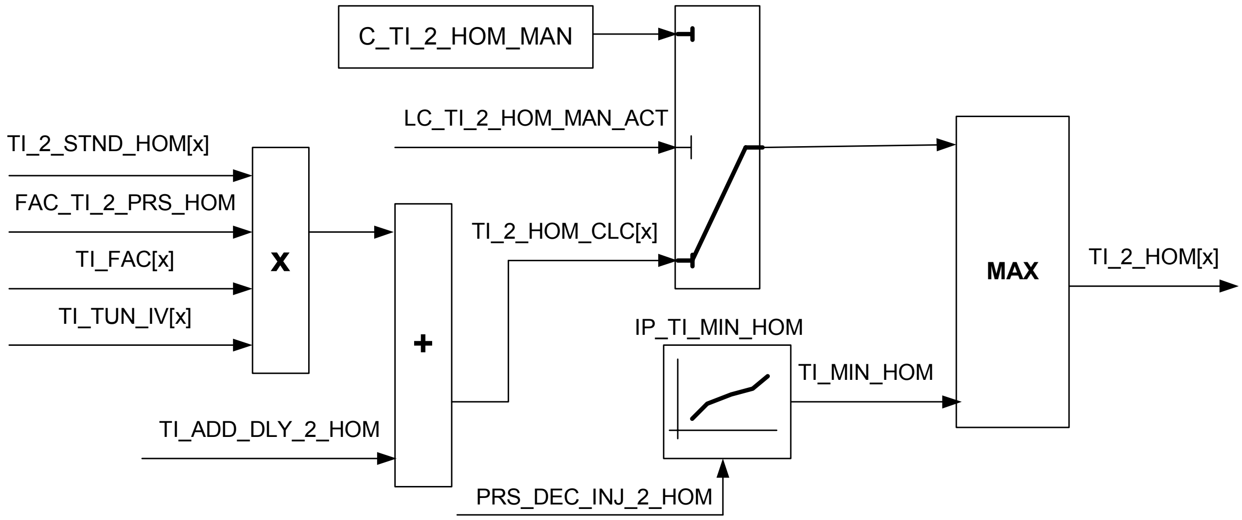
Overview for calculation of the first pulse in homogenous mode:



Second pulse:

If double injection is active (STATE_INJ_MOD_HOM_REQ = MPLH), then TI_2_HOM[x] is calculated. In order to avoid linearity problems, the injection time is limited to TI_MIN_HOM. This is indicated by the flag LV_TI_2_HOM_MIN = 1.

Overview for calculation of the second pulse in homogenous mode:

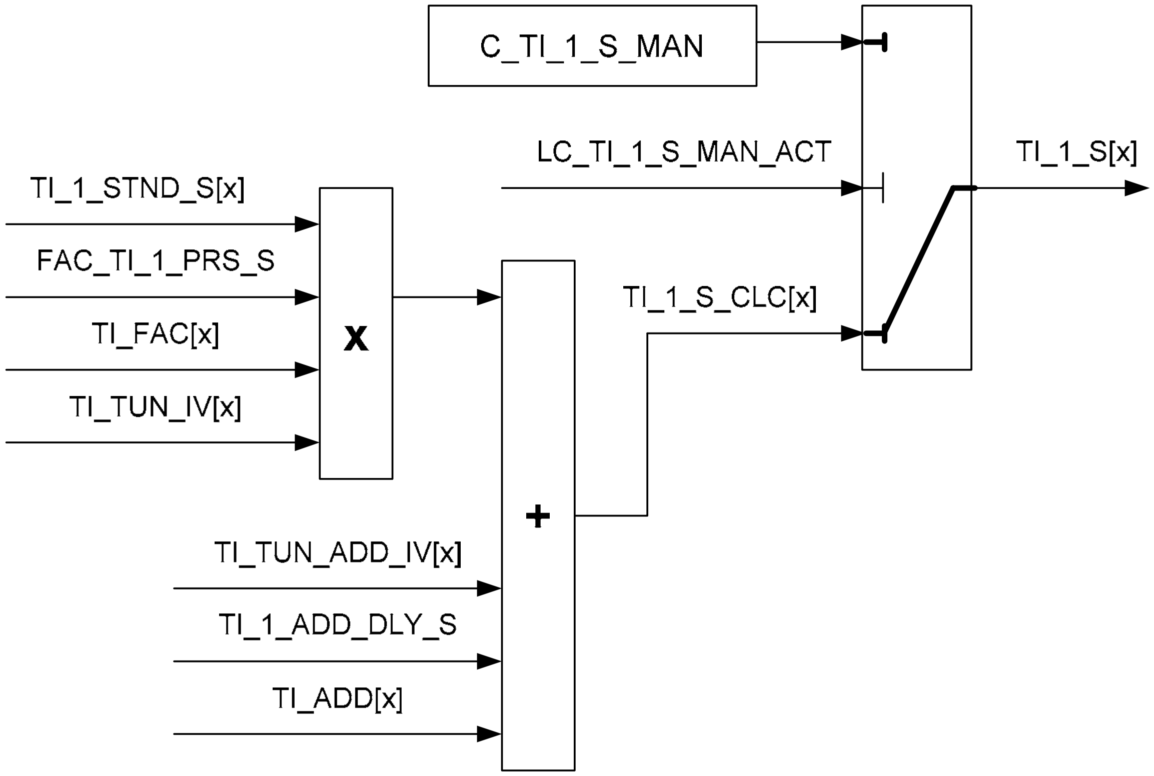


Calculation of the cylinder individual injection times for stratified mode:

First pulse:
The injection time TI_1_S[x] can be set manually. If the switch LC_TI_1_S_MAN_ACT is set to one, the constant C_TI_1_S_MAN is applied.

Then the combustion mode changes to homogeneous mode (indicated by LV_AUTH_TI_MIN_S = 0). The switch back to stratified mode is possible if TI_1_S[x] bigger than (TI_MIN + C_TI_MIN_OFS + C_TI_MIN_HYS_S).

Overview for calculation of the first pulse in stratified mode:

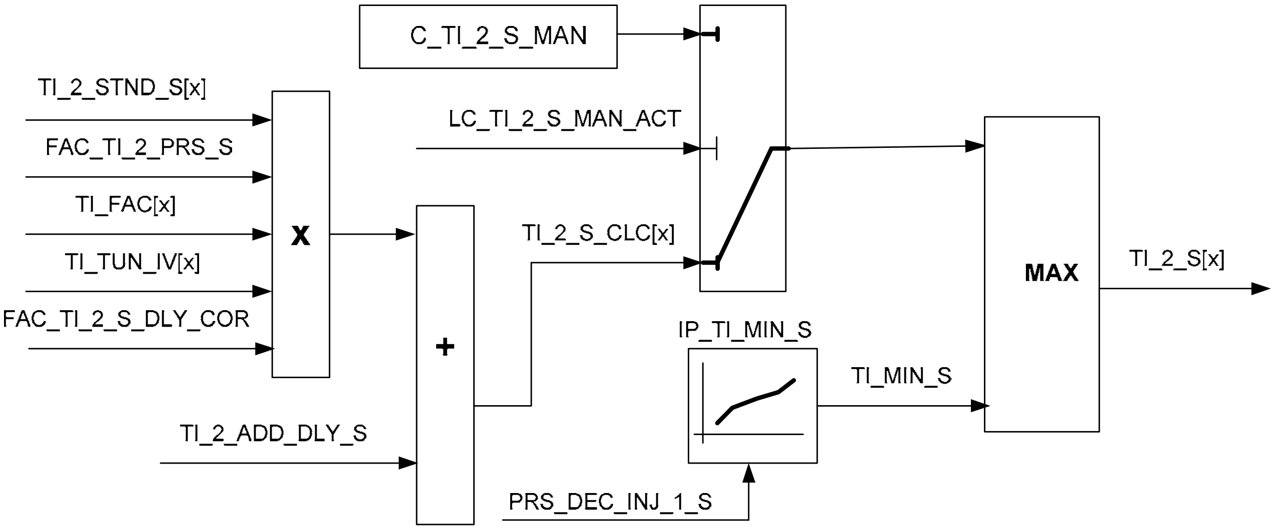


Second pulse:

If double injection is active (STATE_INJ_MOD_S_REQ = MPLS), then TI_2_S[x] is calculated.

The injection time TI_2_S[x] can be set manually. If the switch LC_TI_2_S_MAN_ACT is set to one, the constant C_TI_2_S_MAN is applied.

For stratified multi injection mode the TI_ADD[x] is divided up proportionately.



Output data:

FUNCTION DESCRIPTION:

41.3.1 Segment synchronous tasks

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: at reset: TI_3_HOM_CLC_MIN = 65.535 ms
TI_2_HOM_CLC_MIN = 65.535 ms
TI_1_HOM_CLC_MIN = 65.535 ms

Initialize all NC_CYL_NR elements of following variables:

T_CHA_PER_HOM_1[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]
T_CHA_PER_HOM_2[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]
T_CHA_PER_HOM_3[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]
T_CHA_PER_S_1[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]
T_CHA_PER_S_2[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]
T_CHA_PER_S_3[ ] =
C_T_CHA_PER_H[NC_NR_IDX_TI_PRM_H – 1]

T_DCHA_PER_HOM_1_2[ ] = T_CHA_PER_HOM_1[ ]
T_DCHA_PER_HOM_2_2[ ] = T_CHA_PER_HOM_2[ ]
T_DCHA_PER_HOM_3_2[ ] = T_CHA_PER_HOM_3[ ]
T_DCHA_PER_S_1_2[ ] = T_CHA_PER_S_1[ ]
T_DCHA_PER_S_2_2[ ] = T_CHA_PER_S_2[ ]
T_DCHA_PER_S_3_2[ ] = T_CHA_PER_S_3[ ]

T_DCHA_PER_HOM_1_1[ ] = 0

T_DCHA_PER_HOM_2_1[ ] = 0
T_DCHA_PER_HOM_3_1[ ] = 0
T_DCHA_PER_S_1_1[ ] = 0
T_DCHA_PER_S_2_1[ ] = 0

T_DCHA_DLY_S_3[ ] = 0

Recurrence: LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

<u>Formula section:</u>

For loop for runtime optimization:

In this specification the for loop

```
FOR i = 0, i < NR_CYL_CLC_RED_INJ DO
        x = CTR_CYL_NR_ST_CLC_INJR + i
        (1a)IF x  >= NC_CYL_NR
        (1a)THEN
                x = x – NC_CYL_NR
        (1a)ENDIF
        <loop content>
ENDFOR
```

is substituted by

```
FOR cylinder_start to cylinder_stop DO
    <loop content>
ENDFOR
```

Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

41.3.1.1 Calculation of the cylinder individual injection times for homogeneous mode

41.3.1.1.1 Calculation of the minimal applied injection time

TI_MIN_HOM is used to for deactivation of air fuel lean mode.

```
(1)IF LV_AFL_CLC = 1
(1)THEN
    TI_MIN_HOM = IP_TI_MIN_HOM
    ... (Input data for IP_TI_MIN_HOM is
                PRS_DEC_INJ_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[0]])
(1)ENDIF
```

41.3.1.1.2 First pulse (main pulse)

Correction of fuel pressure pulsations for homogeneous single injection mode:

```
(1)IF STATE_INJ_MOD_HOM_REQ = "SNGH"
     AND LC_PRS_COR_SNGH_ENA = 1
     AND LV_PRS_COR_SNGH_ENA = 1
(1)THEN
     (1a)FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
        (1a)IF Bit m of LF_PRS_COR_HPP_ENA = 1
        (1a)THEN
           Correction due to MFF_SP_1_HOM:
           FAC_PRS_COR_MFF_1_HOM = IP_FAC_PRS_COR_MFF_1_HOM(
             Input: (MFF_SP_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]] +
             MFF_ADD_REAC[IDX_PRS_COR_CYL_CLC_MPLH[m]]) * (1+
             FAC_MFF_DIF_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]]) * FAC_MFF_TFU)
           Correction of damping depending on FUP and delay time between pulses:
           (2)IF LC_PRS_COR_SOI_DLY_ENA = 1
           (2)THEN
             T_DLY_1_1_HOM = (720°/(NC_CYL_NR/NC_CBK_HPP_NR)) / FAC_N
           (2)ELSE
             T_DLY_1_1_HOM = (720°/(NC_CYL_NR/NC_CBK_HPP_NR)) / FAC_N
                             - TI_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]]
                             - T_DCHA_DLY_HOM_1[IDX_PRS_COR_CYL_CLC_MPLH[m]]
             Note: Previous calculated TI_1_HOM is used to calculate delay time between
                   pulses
           (2)ENDIF
           FAC_PRS_COR_DAMP_1_HOM = IP_FAC_PRS_COR_DAMP_1_HOM(
             Inputs: T_DLY_1_1_HOM; FUP_H_INJ[m])
           Calculate period time of pressure waves:
           (3)IF C_PRS_COR_TEMP_SEL = 0
         (3)THEN
           TEMP_PRS_COR_1_HOM = TFU_INJ
         (3)ELSE
           (4) IF C_PRS_COR_TEMP_SEL = 1
           (4)THEN
             TEMP_PRS_COR_1_HOM =
                             TEMP_CAPA_IV_MV
           (4)ELSE
             TEMP_PRS_COR_1_HOM = TCO
           (4)ENDIF
         (3)ENDIF
         T_PER_PRS_COR_1_HOM = IP_T_PER_PRS_COR_1_HOM(
             Inputs: TEMP_PRS_COR_1_HOM; FUP_H_INJ[m])
         Calculate Time offset within one wave:
```

```
        i = 0 // i indicates the number of while loops
        (1)WHILE T_DLY_1_1_HOM > T_PER_PRS_COR_1_HOM DO
            T_DLY_1_1_HOM = T_DLY_1_1_HOM
                - (T_PER_PRS_COR_1_HOM * ID_T_PER_PRS_COR_1_HOM(Input: i))
            Note: In case of i > 9 use 9 as input for ID map to prevent overflow
            i = i + 1
            Note: To prevent an endless loop, break the while-loop if i reaches 50. In that
                case, set T_DLY_1_1_HOM to 0!
        (1)ENDWHILE
        Calculate normalized Time offset within one wave:
        RATIO_T_PER_PRS_COR_1_HOM =
            T_DLY_1_1_HOM/(T_PER_PRS_COR_1_HOM
                                * ID_T_PER_PRS_COR_1_HOM(Input: i))
        RATIO_TI_1_HOM = (TI_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]]
                + T_DCHA_DLY_HOM_1[IDX_PRS_COR_CYL_CLC_MPLH[m]])
            / (T_PER_PRS_COR_1_HOM * ID_T_PER_PRS_COR_1_HOM(Input: i))
        Calculate correction due to wave position and injection time:
        FAC_PRS_COR_OSC_1_HOM = IP_FAC_PRS_COR_OSC_1_HOM(
            Inputs: RATIO_T_PER_PRS_COR_1_HOM; RATIO_TI_1_HOM)
            Note: Previous calculated TI_1_HOM is used to calculate factor
        Calculate final correction factor:
        FAC_TI_PRS_COR_1_HOM[m] = 1 + (FAC_PRS_COR_MFF_1_HOM
                * FAC_PRS_COR_DAMP_1_HOM * FAC_PRS_COR_OSC_1_HOM)
      (1a)ENDIF
    (1a)ENDFOR
(1)ELSE
    (1b)FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
        FAC_TI_PRS_COR_1_HOM[m] = 1
    (1b)ENDFOR
(1)ENDIF
```

Calculation of injection time for homogeneous first pulse:

```
(1)FOR cylinder_start to cylinder_stop DO
MFF_SP_1_HOM_COR_INJ[x] = (MFF_SP_1_HOM[x] + MFF_ADD_REAC[x]) * (1+
        FAC_MFF_DIF_HOM[x]) * FAC_MFF_TFU

41.3.2.1 Subroutines

This chapter describes the sub functions which are called from the main sections.

41.3.2.1.1 Calculate Pulse timing parameters

This section calculates the pulse timing parameter (Charge Time, TI, Discharge Time 1, Discharge Time 2 and Discharge Delay) for the given counting factor index and needle lift.

Input parameters: PRM_LV_EGY_RNG_IV, PRM_IDX_TI_CLC

Output parameters: PRM_T_CHA_PER, PRM_T_DCHA_PER_1, PRM_T_DCHA_PER_2, PRM_T_DCHA_DLY, PRM_TI

Parameter description:

41.3.3 Time synchronous tasks

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: at reset: LV_AUTH_TI_MIN_AFL = 1

Recurrence: 10 ms

Calculation of LV_AUTH_TI_MIN_AFL:

If homogeneous lean mode is active (STATE_CMB_CTL = HOM_AFL) and the electrical injection time is smaller than (TI_MIN_HOM + C_TI_MIN_OFS), the combustion mode changes to homogeneous stochiometric mode. Switching back to homogeneous lean mode is allowed at the earliest if the delay time C_ T_AUTH_TI_MIN_AFL has elapsed.

```
(1) IF
LV_AFL_CLC = 0
(1) THEN
LV_AUTH_TI_MIN_AFL = 1
T_AUTH_TI_MIN_AFL = 0
(1) ELSE
  (2) IF
  LV_AUTH_TI_MIN_AFL = 1
  AND
  STATE_CMB_CTL = 'HOM_AFL'       (homogeneous lean mode)
  AND
  TI_1_HOM_CLC_MIN < (TI_MIN_HOM + C_TI_MIN_OFS)
  (2) THEN
  LV_AUTH_TI_MIN_AFL = 0
  T_AUTH_TI_MIN_AFL = C_ T_AUTH_TI_MIN_AFL
  (2) ELSE
    (3) IF
    T_AUTH_TI_MIN_AFL (n) > 0.01s (0H)
    (3) THEN
    T_AUTH_TI_MIN_AFL (n+1) = T_AUTH_TI_MIN_AFL (n) – 0.01 [s]
    (3) ELSE
    LV_AUTH_TI_MIN_AFL = 1
    (3) ENDIF
```

```
        (2) ENDIF
    (1) ENDIF
```

Output variable for LACO:

```
(4) IF (STATE_INJ_MOD_REQ = 'SNGH') OR (STATE_INJ_MOD_REQ = 'MPLH')
        OR (STATE_INJ_MOD_REQ = 'MPLH+PLS3')
(4) THEN
CRK_DIF_SOI_IGN = CRK_DIF_SOI_IGN_HOM
 (4) ELSE
CRK_DIF_SOI_IGN = CRK_DIF_SOI_IGN_S
(4) ENDIF
```

Application hint:

The input value TI_FAC[x] and TI_ADD[x] are the output value of the module “Coordination of Injection Time Correction Factors for Cylinder Balancing ”. If the Cylinder Balancing Function is not used than TI_FAC[x] and TI_ADD[x] have to be initialized in an “Initialization Module” as follows:

TI_FAC[x] =1

TI_ADD [x] = 0

Imported actions:

ACTION_INFR_**IniInjDriver** ( )
Initialization of the injection driver system.
ACTION_INFR_**SetInjPulseEnable** (IN <Cyl>, IN <Pls_nr>, IN <Lv_pls>)
Enables (Lv_pls=1) or disables (Lv_pls=0) the injection pulse Pls_nr for cylinder Cyl.
ACTION_INFR_**SetInjPulseType**(IN <Cyl>, IN <Pls_nr>, IN <Pls_type>)
Sets the type for the parameterization of the Pulse Pls_nr and Cylinder Cyl by the parameter Pls_type.
ACTION_INFR_**SetInjPulsePosition** (IN <Cyl>, IN <Pls_nr>, IN <Pls_position>)
Sets the position of the Pulse Pls_nr and Cylinder Cyl; value is interpreted according to ACTION_INFR_SetInjPulseType().
ACTION_INFR_**SetInjPulseDuration** (IN <Cyl>, IN <Pls_nr>, IN <Pls_duration>)
Sets the pulse duration for the Pulse Pls_nr and Cylinder Cyl; value is interpreted according to ACTION_INFR_SetInjPulseType().
ACTION_INFR_**SetInjPlsUpdMinPer**(IN <Cyl>, IN <Ti_min>)
Sets the minimum injection time for self-created update pulses of the selected cylinder Cyl.
ACTION_INFR_**SetInjPulseUpdFac**(IN <Cyl>, IN <Pls_nr>, IN <Fac_add_pls>)
In case of an update of the pulse parameters for Cyl and Pls_nr the factor, Fac_add_pls is used.
ACTION_INFR_**ReqInjUpdate** (IN <Cyl>, IN <Mode>, OUT <Acknowledge>)
Update the pulse parameters for cylinder Cyl. Depending on type, a running injection is changed or not. The output parameter Acknowledge reflects if the update mode is fulfilled (=1) or will be fulfilled (=0) later on.
ACTION_INFR_**SetInjPulseUpdMode** (IN <Cyl>, IN <Pls_nr>, IN <Upd_mode>)
Sets the update mode Upd_mode of pulse Pls_nr on cylinder Cyl.
ACTION_INFR_**SetInjPlsUpdOffset**(IN <Cyl>, IN <Upd_offset>)
Sets the injector dead time correction TI_ADD_DLY for self created update pulses of cylinder Cyl.
ACTION_INFR_**SetInjSOILim**(IN <Cyl>, IN <Packet_nr>, IN <Soi_lim>)
ACTION_INFR_SetInjSOILim() and ACTION_INFR_SetInjEOILim() sets the injection window for injection pulse packet Packet_nr and Cylinder Cyl.
ACTION_INFR_**SetInjEOILim**(IN <Cyl>, IN <Packet_nr>, IN <Eoi_lim>)
ACTION_INFR_SetInjSOILim() and ACTION_INFR_SetInjEOILim() sets the injection window for injection pulse packet Packet_nr and Cylinder Cyl.
ACTION_INFR_**ReqInjInhibit** (IN <Cyl>, IN <Lv_inh_inj>)
Enables (Lv_inh_inj=0) or disables (Lv_inh_inj=1) all pulses of the injection for cylinder Cyl.
ACTION_INFR_**SetInjMode** (IN <Injection_mode>)
This action sets the injection mode (DISABLE, SEQUENTIAL, STATIC, PREINJECTION, CRASH).
ACTION_INFR_**GetInjCylAv** (OUT <Cyl_av>)
Returns the actual cylinder Cyl_av of the trigger INJBAS at CRK_INJ_BAS[Cyl_av].
ACTION_INFR_**GetInjPrevState** (IN <Cyl>, OUT <Lv_prev_state_iv>)
Returns the previous state of the injection for cylinder Cyl.
ACTION_INFR_**SetInjBaseAngle** (IN <Crk_inj_bas_ref>)
Sets the crankshaft position, where the Infrastructure generates the trigger INJBAS at the end of the injection of each cylinder. Crk_inj_bas_ref and NC_CRK_INJ_REF_TDC are used to set CRK_INJ_BAS[x].
ACTION_INFR_**SetInjChargeCur** (IN <Cyl>, IN <Ducy>)
Sets the charge current as duty cycle Ducy of Cylinder Cyl
ACTION_INFR_**SetInjDischargeCur** (IN <Cyl>, IN <Ducy>)
Sets the discharge current as duty cycle Ducy of Cylinder Cyl
ACTION_INFR_**SetInjChargePer** (IN <Cyl>, IN <Pls_nr>, IN <Period>)
Sets the charge duration of pulse Pls_nr for cylinder Cyl
ACTION_INFR_SetInjDischargePer2(IN <Cyl>, IN <Pls_nr>, IN <Period>)
Sets the second discharge duration of pulse Pls_nr for cylinder Cyl
ACTION_INFR_SetInjDischargePer1(IN <Cyl>, IN <Pls_nr>, IN <Period>)
Sets the first discharge duration of pulse Pls_nr for cylinder Cyl
ACTION_INFR_SetInjDischargeDly(IN <Cyl>, IN <Pls_nr>, IN <Period>)
Sets the discharge delay time between the first and the second discharge phase of pulse Pls_nr for cylinder Cyl
ACTION_INFR_**GetInjVMesVld** (IN <Cyl>, OUT <Lv_Inj_Mes_Vld>)
Returns a flag that indicates if the measurements for charge and voltage on injector Cyl are valid
ACTION_INFR_**GetInjVCha** (IN <Cyl>, IN <Pls_nr>, IN <Mes_ref>, OUT <Charge>)
Returns the measured charge of a carried out pulse Pls_nr on injector Cyl at reference point Mes_ref

ACTION_INFR_**GetInjVInj** (IN <Cyl>, IN <Pls_nr>, IN <Mes_ref>, OUT <Voltage>)
Returns the measured voltage of a carried out pulse Pls_nr on injector Cyl at reference point Mes_ref
ACTION_INFR_**GetInjVTrim** (IN <Cyl>, OUT <Charge>)
Returns the measured charge of the trim pulse related to cylinder Cyl

ACTION_INFR_**GetInjMesPulsePer** (IN <Cyl>, IN <Pls_nr>, OUT <Period>)
Returns the injection period of a carried out pulse Pls_nr on injector Cyl
ACTION_INFR_**GetInjMesSoi** (IN <Cyl>, IN <Pls_nr>, OUT <Pls_position>)
Returns the start of injection position (SOI) of a carried out pulse Pls_nr on injector Cyl
ACTION_INFR_**GetInjMesEoi** (IN <Cyl>, IN <Pls_nr>, OUT <Pls_position>)
Returns the end of injection position (EOI) of a carried out pulse Pls_nr on injector Cyl
ACTION_INFR_**ReqInjPulse** (IN <Cyl>, IN <Pulse_per>)
Requests static injection test pulses with a period Pulse_per on cylinder Cyl.
ACTION_INFR_**GetElDiagIVCyl** (IN <Cyl>, INOUT <Cdn_diag>, OUT <Err_diag>)
Returns the electrical diagnosis information Err_diag for cylinder Cyl under consideration of diagnosis condition Cdn_diag.
ACTION_INFR_**SetInjDcdc**(IN <Dcdc>, IN <Ducy>)
Sets the duty cycle for the DC/DC converter used by power stages.
ACTION_INFR_**GetInjVDcdc**(IN <Dcdc>, OUT <Voltage_dcdc>)
Returns the output voltage of the DC/DC converter used by power stages.
ACTION_INFR_**GetInjIniErr**(IN <Bank>, OUT <Err_ini>)
Returns error information in Err_ini after startup-check of the selected power stage bank.
ACTION_INFR_**GetInjOnlineErr** (IN <Bank>, OUT <Err_online>)
Returns error information in Err_online about the online state of the selected power stage Bank.
ACTION_INJR_**SetStateInjUpdEna**(IN <Cyl>, IN <Value>)
This action sets the bit x of the variable STATE_INJ_UPD_ENA to the input Value
ACTION_IGRE_**SendTrigForIgnUpd**(IN <PRM_STATE_IGN_UPD_ENA>)
Trig IGRE to update ignition parameter on designated cylinders which are specified by the parameter.

Exported actions:

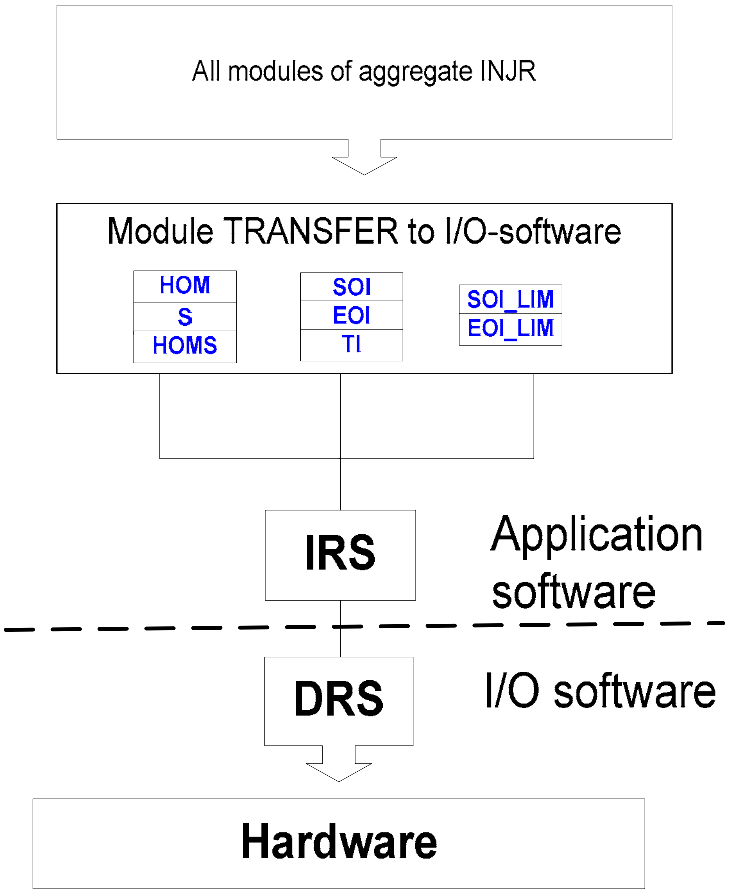
ACTION_INJR_IgnUpdate(IN <Cyl>, IN <Iga_Igc_H_Rng>)
This action sets the cylinder individual ignition angle for mode switch and data update of <Cyl> to <Iga_Igc_H_Rng>..

FUNCTION DESCRIPTION:

Overview:

The purpose of this module is the transfer of injection related data to IO-Software under real time conditions. The most important thing is to maintain the data consistency. The figure shows the general flow of data:

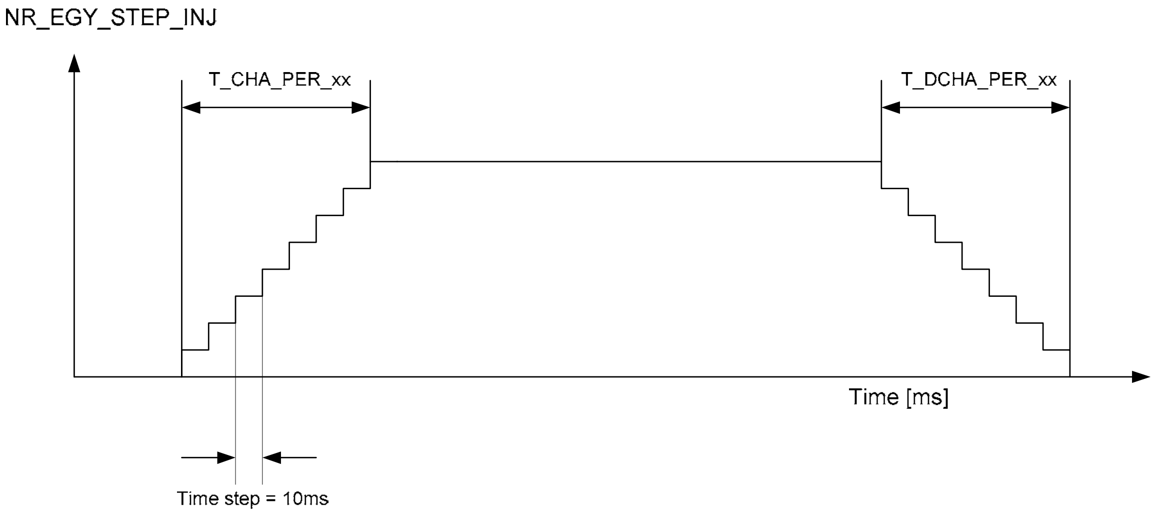
Overview: Interface ASW to I/O-software



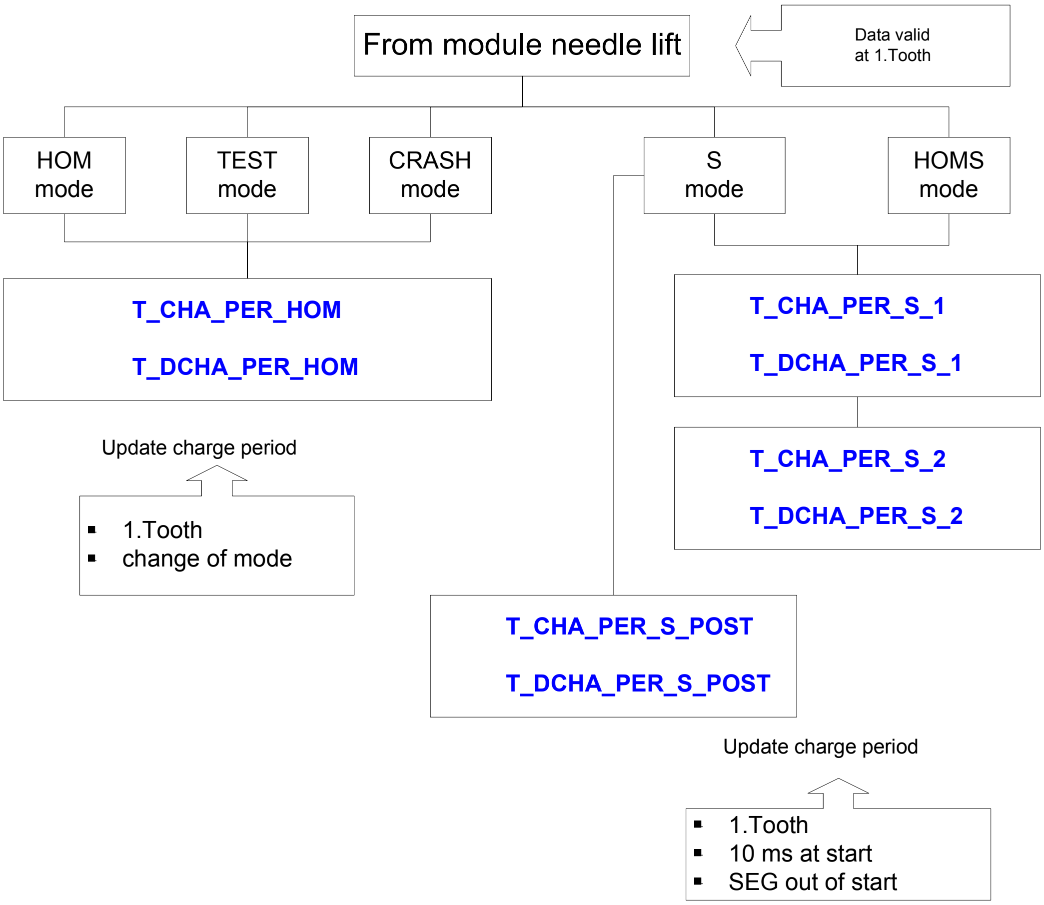
Control of piezo injector needle lift

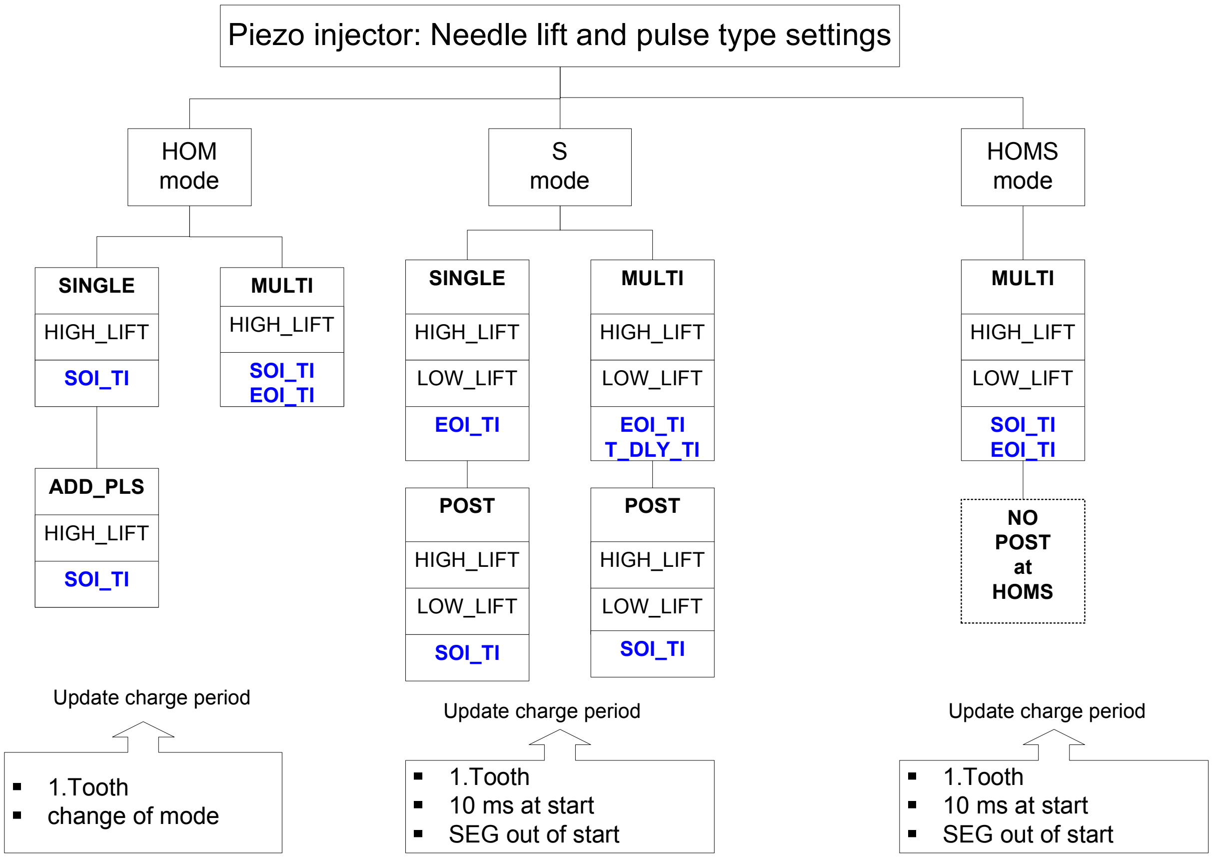
To control the needle lift of the piezo injector the energy loaded into the actuator is set by the number of energy packets. In the actual version are two possible setting: High lift and low lift. The data is an input data from module needle lift. The variables are T_CHA_PER_xxx and T_DCHA_PER_xxx, which describe the charge and discharge time.

Setting of energy packets for piezo injector



For different injection modes, the energy packets can be different. The following picture shows the overview of the different setting and the update timing conditions.



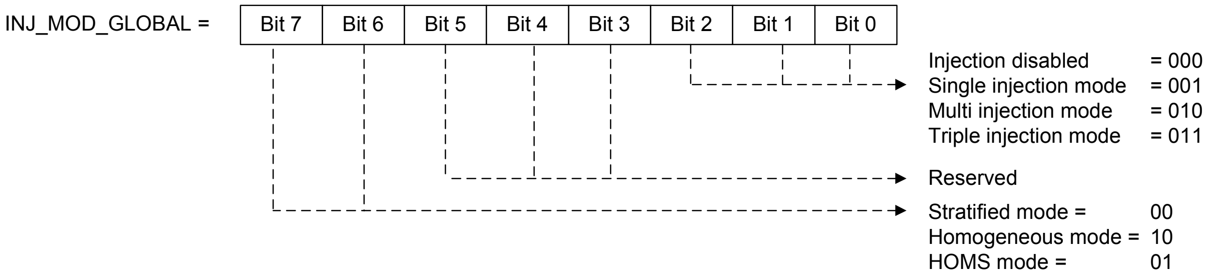


Formula section

41.4.1 Definitions bit masks for injection mode

Byte definition

INJ_MOD[x], INJ_MOD_SP[x]



Example: homogenous multi injection mode (MPLH)

INJ_MOD_GLOBAL =								
	1	0	0	0	0	0	1	0

Definition of NC constants

NC_INJ_MOD_DI = 0x00H
NC_INJ_MOD_S = 0x00H
NC_INJ_MOD_HOM = 0x80H
NC_INJ_MOD_HOMS = 0x40H
NC_INJ_MOD_SINGLE = 0x01H

NC_INJ_MOD_MULTI = 0x02H
NC_INJ_MOD_MULTI_PLS3 = 0x03H
NC_INJ_MOD_TEST_PLS = 0x07H
NC_INJ_MOD_MASK_1 = 0xC0H
NC_INJ_MOD_MASK_2 = 0x07H

41.4.2 Reset tasks

This chapter describes the procedures required at reset for an accurate engine start.

Application conditions:

Activation: at reset
Deactivation: -
Initialization: -
Recurrence: once at reset

Note! This task has to be called first in calculation order of reset tasks.

Formula Section:

Set the crankshaft position where the Infrastructure generates the trigger INJBAS at the end of the injection of each cylinder.

```
ACTION_INFR_SetInjBaseAngle (IN Crk_inj_bas_ref = NC_CRK_INJ_BAS_REF)
(1) FOR d = 0 TO (NC_NR_DCDC_INJ - 1) DO
41.4.2.1    ACTION_INFR_SetInjDcdc(IN d, IN Ducy = C_DUCY_SP_BOOST_PBK_IV)
(1) ENDFOR

CTR_INJ_SWI_ACK_ERR = 0
STATE_INJ_UPD_TRM = 0
LV_INJ_UPD_CLC_ENA = 1

(1) FOR x = 0 TO (NC_CYL_NR –1) DO:
      INJ_MOD[x] = "DISABLE"
      SOI_1_MES[x] = 720° CRK
      SOI_2_MES[x] = 720° CRK
      SOI_POST_MES[x] = 720° CRK
(1) ENDFOR
```

Do not start injection before first valid tooth event was reached. Injection driver is locked

```
LV_ST_INJ = 1
STATE_INJ_DR = "DISABLED"
STATE_PBK_IV_INI = "INIT_PENDING"
LV_INJ_REST_ENA = 0
LV_STATE_PBK_IV_INI_ACT = 0
```

41.4.3 Power stage initialization

This chapter describes the procedures to initialize the power stage driver.

Application conditions:

Activation: at every engine state

Deactivation: -

Initialization: -

Recurrence: every 10ms

Formula Section:

Initialization of injection IO-driver

```
(1)IF (STATE_PBK_IV_INI = "INIT_PENDING")
    AND
    (LV_MC_SOPC_INH_DI = 0)
    AND
    (LV_ERR_TMP_MU_MC = 0)
    AND
    (LV_DIAG_END_RLY_MAIN_DLY = 1)
    AND
    (LV_RLY_MAIN_DLY_ERR = 0)
    AND
    (LV_INJ_OFF_TMR_INJ_ENA = 1)
    AND
    (LV_STATE_PBK_IV_INI_ACT = 0)
(1)THEN
    STATE_PBK_IV_INI = "INIT_ACTIVE"
    NR_PBK_IV_INI = 0
    LV_STATE_PBK_IV_INI_ACT = 1
    ACTION_INFR_IniInjDriver ()
(1)ENDIF
```

Re-initialization of injection IO-driver

```
(2)IF (STATE_PBK_IV_INI = "REINIT_PENDING")
    AND
    (LV_IGK = 1)
    AND
    (LV_INJ_OFF_TMR_INJ_ENA= 1)
    AND
    (LV_STATE_PBK_IV_INI_ACT = 0)
(2)THEN
    STATE_PBK_IV_INI = "INIT_ACTIVE"
    NR_PBK_IV_INI = 0
    LV_STATE_PBK_IV_INI_ACT = 1
    ACTION_INFR_IniInjDriver ()
```

```
(2)ENDIF
```

Set flag to indicate that a proper start was performed

```
(3)IF LV_ST_END = 1
(3)THEN
        LV_INJ_REST_ENA = 1
(3)ENDIF
```

41.4.4 End of injection driver initialization

Application conditions:

Activation:	every INJEOD-event (EndOfDriverInitialization)
Deactivation:	-
Initialization:	-
Recurrence:	INJEOD-event (EndOfDriverInitialization)

Formula Section:

Note! p represents the power-stage bank which reached the INJEOD-event.

```
NR_PBK_IV_INI = NR_PBK_IV_INI + 1
ACTION_INFR_GetInjIniErr (IN p, OUT STATE_ERR_PBK_IV_ST_RAW[p] = Err_ini)

(1)IF NR_PBK_IV_INI >= NC_PBK_IV_NR
(1)THEN – every injection valve powerbank was initialized
  LV_STATE_PBK_IV_INI_ACT = 0
  (1a)IF STATE_PBK_IV_INI = "INIT_ACTIVE"
  (1a)THEN
      STATE_PBK_IV_INI = "INIT_FINISHED"
        (2)IF STATE_INJ_DR = "DISABLED" AND LV_INJ_REST_ENA = 1
        (2)THEN
             Calculate section 41.4.6 (Start initialization)
        (2)ENDIF
  (1a)ENDIF
(1)ENDIF
```

41.4.5 First valid tooth tasks

Application conditions:

Activation: at first valid tooth

Deactivation: -

Initialization: -

Recurrence: once at first valid tooth

This chapter describes the procedures required at first valid tooth for an accurate engine start.

Formula Section:

Calculate section 41.4.6 (Start initialization)

LV_ST_INJ = 0

41.4.6 Start initialization

Note: calculate this section only if called by another section

41.4.6.1 Mode independent

```
(1) FOR d = 0 TO (NC_NR_DCDC_INJ - 1) DO
41.4.6.2    ACTION_INFR_SetInjDcdc(IN d, IN Ducy = C_DUCY_SP_BOOST_PBK_IV)
(1) ENDFOR
INH_IV_DYN = 0
NR_CYL_OFS_INH_IV_DYN = C_NR_CYL_OFS_INH_IV_DYN
STATE_INJ_UPD_TRM = 0 (all bits)
LV_INJ_UPD_CLC_ENA = 1
INH_IV_MIS_GEN_ACK = 0
Do the following calculations for all cylinders
(2) FOR x = 0 TO (NC_CYL_NR –1) DO:
    ACTION_INJR_SetStateInjUpdEna(IN Cyl = x, State_Inj_Upd_Ena = 0)
    CTR_INH_IV_MIS_GEN[x] = 0

(2) ENDFOR (all cylinders)
NR_CYL_INJ_BAS = 0
NR_CYL_INJ_BAS_PREV = NC_CYL_NR -1
```

41.4.7 Crank synchronous tasks

Application conditions:

Activation: every engine state
Deactivation: -
Initialization: -
Recurrence: LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Formula Section:

```
(1)IF LV_INJ_UPD_CLC_ENA = 1
(1)THEN
    STATE_IGN_UPD_ENA = 0 (all bits)
```

Minimum injection time for additional pulse:
In case of single injection and homogeneous mode, a second injection pulse can be applied by the I/O-software at transient engine operation (as a result of an injection update). For this pulse, a minimum injection time TI_ADD_PULSE_MIN is defined. Each of the applied IP_TI_ADD_PULSE_MIN data should be greater than the smallest calculated TI_MIN.

```
    TI_ADD_PULSE_MIN = 0
    FOR m = 0 TO NC_CBK_HPP_NR - 1 DO
        TI_ADD_PULSE_MIN = MAX(TI_ADD_PULSE_MIN;
            IP_TI_ADD_PULSE_MIN (Input:
            PRS_DEC_INJ_1_HOM[IDX_PRS_COR_CLY_CLC_MPLH[m]]) )
    ENDFOR
    FAC_ADD_PULSE = IP_FAC_ADD_PULSE (Input: N_32, TCO)

(1)FOR x = 0 TO (NC_CYL_NR-1) DO
```

Note: In this specification the LSB of a bit field (e. g. STATE_INJ_UPD_ENA) is revered to as Bit 0! That means that the first loop of the for loop (x = 0) reveres to the LSBs, the next (x = 1) to the next and so on.

Cylinder shut off transfer data:

```
    Disable_task_interruption
    LV_INH_INJ[x] = ((Bit x of INH_INJ) OR (Bit x of INH_IV_MIS_GEN_ACK)    )    … logical
    ACTION_INFR_ReqInjInhibit (IN Cyl = x, IN Lv_inh_inj = LV_INH_INJ[x])
    Enable_task_interruption
```

Set injection mode set-point:

```
    (2)IF Bit x of STATE_INJ_UPD_TRM = 0
    (2)THEN – no valid data set within I/O software
```

```
        (3)IF Bit x of STATE_INJ_UPD_ENA = 1
        (3)THEN
                INJ_MOD[x] = INJ_MOD_SP[x]

41.4.10 ECU-state-transition from synchronous to asynchronous state

Application conditions:

Activation: at ECU-state-transition from SYN_ENG_IGK_ON to ENG_RUN (SYN_ON to ASYN_ON)

Deactivation: -

Initialization: -

Recurrence: every ECU-state-transition from SYN_ENG_IGK_ON to ENG_RUN

(SYN_ON to ASYN_ON)

Formula Section:

```
LV_INJ_DEAC_BACK_ENG = 1
ACTION_INFR_SetInjMode (IN Injection_mode= DISABLE)
STATE_INJ_DR = "DISABLED"
```

41.4.11 ECU-state-transition from asynchronous to synchronous state

Application conditions:

Activation: at ECU-state-transition from ENG_RUN to SYN_ENG_IGK_ON (ASYN_ON to SYN_ON)

Deactivation: -

Initialization: -

Recurrence: every ECU-state-transition from ENG_RUN to SYN_ENG_IGK_ON (ASYN_ON to SYN_ON)

Formula Section:

```
IF LV_INJ_DEAC_BACK_ENG = 1
THEN
        Calculate section 41.4.6 (Start initialization)
    LV_ST_INJ = 0
    LV_INJ_DEAC_BACK_ENG = 0
ENDIF
# ENDIF
```

41.4.12 Ignition key OFF

Application conditions:

Activation: at transition of LV_IGK from 1 -> 0

Deactivation: -

Initialization: -

Recurrence: every transition of LV_IGK from 1 -> 0

Formula Section:

STATE_PBK_IV_INI = "REINIT_PENDING"

LV_INJ_DEAC_BACK_ENG = 0

41.4.13 Ignition key on

Application conditions:

Activation: at ignition key on event (LV_IGK = 0 -> 1)

Deactivation: -

Initialization: -

Recurrence: once at every ignition key on event

This chapter describes the procedures required at ignition key on to ensure an accurate engine restart at running engine.

Note: This section has to be calculated before all other time and segment synchronous sections which are dependent on LV_IGK!

Formula Section:

```
(1)IF (STATE_PBK_IV_INI = "REINIT_PENDING")
(1)THEN
        Calculate section 41.4.15 (Disable injection driver functionality)
(1)ENDIF
```

41.4.14 Engine stop

Application conditions:

Activation: at transition of LV_ES from 0 -> 1

Deactivation: -

Initialization: -

Recurrence: every transition of LV_ES from 0 -> 1

Formula Section:

Calculate section 41.4.15 (Disable injection driver functionality)

```
LV_INJ_REST_ENA = 0
LV_INJ_DEAC_BACK_ENG = 0
```

41.4.15 Disable injection driver functionality

Note: Calculate this section only if called by another section

Formula Section:

This chapter describes the engine stop procedure as required for this specification.
It is called either at engine run to engine stop event or at ignition key off event

```
(1) FOR x = 0 TO (NC_CYL_NR –1) DO:

41.4.18 Crash signal reaction of injection driver

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: at reset: T_INJ_CRASH_ACT = 0
STATE_INJ_CRASH_ACT = 00H

Recurrence: 10 ms

This chapter describes the behavior of the injection driver during vehicle crash. Under crash conditions, all selected injectors (NC_IV_CRASH) are open for a predefined period, to drain off the fuel from the rail into the cylinder. This will reduce the danger of fire or explosion, if the rail will be damaged.

Definition of STATE_INJ_CRASH_ACT:

00H = no request received;
The injection driver works under normal conditions.

01H = vehicle crash reaction request received by LV_INJ_CRASH_ACT = 1;
The injection driver will be shut down.

02H = injection driver crash reaction acknowledged;
The selected injectors are opened for NC_TI_CRASH period.

03H = injection driver crash reaction finished;
All working injectors are closed. The driver is under hold conditions.

Formula Section:

```
(1) IF (STATE_INJ_CRASH_ACT = 01H) AND (STATE_PBK_IV_INI = "INIT_FINISHED")
(1) THEN
    ACTION_INFR_SetInjMode (IN Injection_mode= STATIC)

41.4.19 Description of exported ACTIONS

41.4.19.1 Description of ACTION_INJR_IgnUpdate

ACTION_INJR_IgnUpdate(IN <Cyl>, IN <Iga_Igc_H_Rng>)					
This action sets the cylinder individual ignition angle for mode switch and data update of <Cyl> to <Iga_Igc_H_Rng>..					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0 ... 7	0 ... 7	1	1
This action affects the injection mode of cylinder Cyl.					
Iga_Igc_H_Rng	IN	FA60 ... 5A0H	-90 ... 90	0.0625	[°CRK]
This parameter defines the new ignition angle for homogeneous single injection mode.					

Formula Section:

IGA_IGC_H_RNG_ACT[Cyl] = Iga_Igc_H_Rng

STATE_UPD_IGN[Cyl] = "TRIG_EXT"

41.4.20 Subroutines

This section defines the subroutines. The following chapters are only calculated if called by another section like a function call. The input parameters are mentioned at the function calls.

41.4.20.1 Configure Injection

Note: Calculate this section only if called by another section.

FUNCTION DESCRIPTION:

This function reads the ECU end of line trimming values for piezo injector energy measurement. A check against the complementary values is done as well as a plausibility check.

General information:

The pizo injector energy measurement consists of a voltage measurement and a charge measurement. Both kinds of measurement have to be calibrated at the end of production line (EOL trimming) to improve measurement accuracy. The results of the EOL trimming are one correction factor for voltage measurement and one correciton factor for charge measurement for each injection driver ATIC.

Signal flow diagram:

-

Description:

If the functionality is activated by LC, each values are checked against their complementary values which are also stored within the ECU at end of produciton line. After that, a plausibility check is done by using an upper and a lower threshold. If the complementary check or the plausibility check fails or if the functionality is deactivated by LC, the trimming factors are set to 1.

Application conditions:

Initialisation: -

Recurrence: only once at reset

Activation: every engine state

Deactivation: -

FUNCTION DESCRIPTION:

41.6.1 Definition of the injection range

Application conditions:

Activation:	at reset
Deactivation:	-
Initialization:	-
Recurrence:	once at reset

The fuel can be injected over a range of 720 °CRK. The cylinder individual zero position of this range is defined via the constants NC_CRK_INJ_REF_TDC and NC_CRK_INJ_BAS_REF with reference to the ignition TDC of cylinder 0, see figure below.

Formula section:

Related to tdc cylinder 0:

```
FOR x = 0 TO (NC_CYL_NR-1) DO:

Definition of the non calibrateable constants:

NC_CRK_INJ_REF_TDC = -360°CRK

NC_CRK_INJ_BAS = 180 °CRK

For loop for runtime optimization:

In this specification the for loop

```
FOR i = 0, i < NR_CYL_CLC_RED_INJ DO
            x = CTR_CYL_NR_ST_CLC_INJR + i
            (1a)IF x  >= NC_CYL_NR
            (1a)THEN
                    x = x – NC_CYL_NR
            (1a)ENDIF
            <loop content>
ENDFOR
```

is substituted by

```
FOR cylinder_start to cylinder_stop DO
     <loop content>
ENDFOR
```

Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

41.6.2 Injection phasing at start

Application conditions:

Activation: LV_ST_END = 0

Deactivation: -

Initialization: -

Recurrence: 10ms

Formula section:

All calculations are related to CRK_INJ_BAS[NC_CYL_NR].

```
EOI_LIM_HOM = 0
(1) IF (single injection)
INJ_MOD_HOM_REQ = NC_INJ_MOD_SINGLE (if single injection is requested)
(1) THEN
    FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
            EOI_LIM_HOM = MAX(EOI_LIM_HOM;
                   C_EOI_LIM_HOM_ST + IP_EOI_LIM_HOM_FUP_COR (Input: FUP_H_INJ[m]) )
    ENDFOR
(1) ELSE (multiple injection)
    For double injection the minimum injection angle will be limited by the following calculation:
    FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
            EOI_LIM_HOM = MAX(EOI_LIM_HOM;
                   C_EOI_LIM_HOM_ST + IP_EOI_LIM_HOM_FUP_COR (Input: FUP_H_INJ[m])
                   + C_EOI_LIM_HOM_MULTI_COR )
    ENDFOR
(1) ENDIF
```

```
SOI_LIM = C_SOI_LIM + CAM_SHIFT_EX
```

Check if the difference between SOI and EOI is beyond the maximum.

```
(2) IF
    (TI_1_HOM_CLC_MAX * FAC_N + EOI_LIM_HOM) > SOI_LIM
(2) THEN
    LV_CRK_DIF_SOI_EOI_LIM = 1          (TI is beyond the maximum)
(2) ELSE
    LV_CRK_DIF_SOI_EOI_LIM = 0          (TI is below the maximum)
(2) ENDIF
```

Calculation of SOI:

```
(3) IF
LC_SOI_1_HOM_ST_MAN = 1
(3) THEN
   (1) FOR x = 0 TO (NC_CYL_NR -1) DO:
      SOI_1_HOM_CLC[x] = C_SOI_1_HOM_ST_MAN
   (1) ENDFOR
(3) ELSE

FUNCTION DESCRIPTION:

In this part, the conversion of injection phasing from customer nomenclature to SV nomenclature is done.

For calculation order purposes, the specification is divided in two parts. The part that calculates the delay times for stratified combustion mode must be calculated before the task "Final injection timing", the part that calculates the rest of the phasing must be calculated after.

For loop for runtime optimization:

In this specification the for loop

```
FOR i = 0, i < NR_CYL_CLC_RED_INJ DO
        x = CTR_CYL_NR_ST_CLC_INJR + i
        (1a)IF x  >= NC_CYL_NR
        (1a)THEN
             x = x – NC_CYL_NR
        (1a)ENDIF
        <loop content>
ENDFOR
```

is substituted by

```
FOR cylinder_start to cylinder_stop DO
   <loop content>
ENDFOR
```

Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

41.13.1 Calculation of pulse delay times for stratified combustion mode

Note: This task must be calculated **before** the task "Final injection timing"!

FUP_H_INJ[NC_CBK_HPP_NR]	NC_CBK_HPP_NR	NC_CYL_NR	NC_IDX_CYL_HPP_REF[NC_CYL_NR]

FUNCTION DESCRIPTION:

General information:

The module calculates a correction factor to compensate the influence of the cylinder counter pressure at the injector (here: MAP) and the influence of the fuel temperature on the injected fuel mass. Also, the pressure difference at the injector is calculated.

Application conditions:

Activation: every engine state

Deactivation: -

Initialisation: at reset: FAC_TI_1_PRS_CYL_HOM[ ] = 1 // all NC_CYL_NR elements

Update rate: LV_ST_END = 0: 10 ms

LV_ST_END = 1: segment synchronous

Formula section:

```
FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
    The pressure difference at the injector is calculated from fuel rail pressure and the manifold pressure.

    PRS_DEC_INJ_1_HOM_TMP = FUP_H_INJ[m] – MAP_INJ[m]

    The correction factor FAC_TI_1_PRS_CYL_HOM is used to compensate the influence of the cylinder counter pressure and the fuel tempreature on the injector needle lift. In case of the first pulse in homogeneous mode, the cylinder couter pressure equals MAP.
    A separate map is used for low energy pulses.

    IF LV_EGY_RNG_IV_PLS_1_HOM[IDX_PRS_COR_CYL_CLC_MPLH[m]] = 1
    THEN
        FAC_TI_1_PRS_CYL_HOM_TMP = IP_FAC_TI_PRS_CYL(MAP_INJ[m])
    ELSE

Overview

The module calculates a correction factor to compensate the influence of the cylinder counter pressure and the influence of the fuel temperature on the injected fuel mass.

Note for Software: IDX_TI_TMP_PRS is a temporary calculation value with same resolution and range as IDX_TI_2_PRS_HOM_SP_TMP.

Application Condition

(3)ENDIF
```

A rough injection duration angle CRK_INJ_1_S is estimated from TI_1_PRS_S_SP_TMP, FAC_TI_1_PRS_CYL_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1) and engine speed:

From the manifold pressure MAP_INJ[m], the end of injection EOI_1_S[IDX_PRS_COR_CYL_CLC_S[m]] and the rough injection angle a mean counter pressure within the cylinder during the injection is calculated.

CRK_INJ_1_S = TI_1_PRS_S_SP_TMP * FAC_N
~~* FAC_TI_1_PRS_CYL_S[IDX_PRS_COR_CYL_CLC_S[m]](n-1)~~

PRS_INJ_MV_1_S = MAP_INJ[m] * IP_PRS_INC_CMP_S
(EOI_1_S[IDX_PRS_COR_CYL_CLC_S[m]]; CRK_INJ_1_S)

The pressure difference at the injector is calculated from fuel rail pressure and the mean counter pressure.

If the engine is not running in stratified mode (LV_IGA_AND_INJ_SWI = 1), for a correct calculation of the pressure correction the FUP_H_SP_S_INJ[m] has to be used instead of the actual FUP_H_INJ[m], because the actual FUP_H_INJ[m] is tuned for a different combustion mode than stratified.

```
(4)IF LV_IGA_AND_INJ_SWI = 1
(4)THEN
    FUP_PRS_COR[m] = FUP_H_SP_S_INJ[m]
(4)ELSE
    FUP_PRS_COR[m] = FUP_H_INJ[m]
(4)ENDIF
PRS_DEC_INJ_1_S_TMP = FUP_PRS_COR[m] - PRS_INJ_MV_1_S
```

The total correction factor results from the map IP_FAC_TI_PRS_CYL.
For low injector needle lift, a separate map IP_FAC_TI_PRS_CYL_L is used.

```
    (4a)IF LV_EGY_RNG_IV_PLS_1_S[IDX_PRS_COR_CYL_CLC_S[m]] = 1

FUNCTION DESCRIPTION:

General information:

The module calculates a correction factor to compensate the influence of the cylinder counter pressure and the influence of the fuel temperature on the injected fuel mass.

Note for Software: IDX_TI_TMP_PRS is a temporary calculation value with same resolution and range as IDX_TI_3_PRS_S_SP_TMP.

Application conditions:

Activation: every engine state

Deactivation: -

Initialisation: -

Update rate: LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Formula section:

```
(1)FOR m = 0 TO NC_CBK_HPP_NR – 1 DO

Nominal temperature-capacity relationship of the piezo injector depending on fuel pressure					

41.25.1 General information

The large signal capacity of the piezo stack rises with temperature. This dependency can be used to determine the piezo temperature out of its capacity. Since the capacity is also influenced by forces acting on the piezo stack the fuel pressure has to be taken into account. This dependency is described by the map IP_TEMP_CAPA_IV_NOM supplying a temperature for a certain nominal (mean) capacity and fuel pressure level. The map IP_CAPA_IV_NOM describes the inverse relationship supplying a capacity for a given temperature and fuel pressure. The look-up curve IP_CAPA_COR_EGY_IV accounts for the dependency of the capacity on the energy stored in the piezo stack and provides an additive correction for the capacity value.

The capacity value deviates from one stack to another due to manufacturing variations, aging effects etc.. Therefore the offset of each injector to the nominal capacity has to be determined at a reference temperature.(Fig. 1)

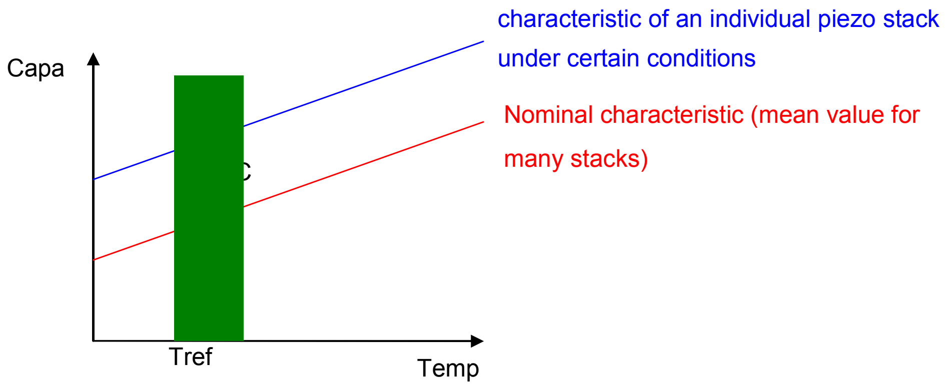

Fig. 1: capacity-temperature relationship for piezo stacks

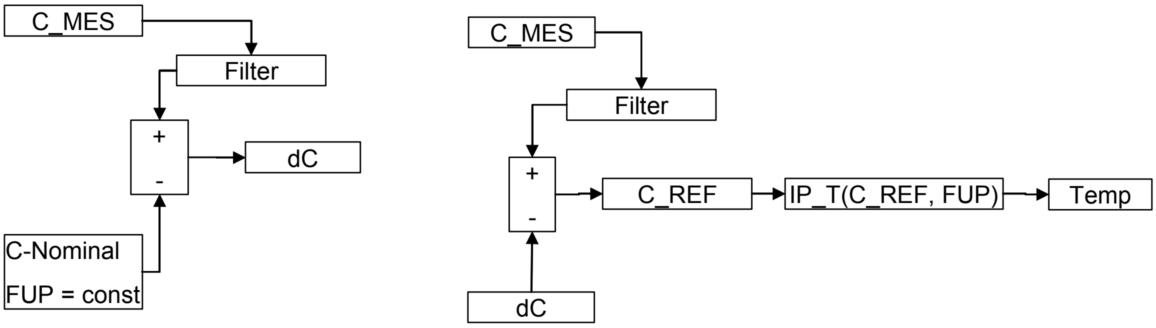
The capacity offset of each injector is stored in the nonvolatile memory (NVMY). Once the capacity offset is available the individual capacity can be shifted to the nominal characteristic allowing for a determination of the piezo temperature (Fig. 2).



Determination of capacity offset at T_{ref} Determination of piezo stack temperature

Fig. 2: Functional overview

Application Condition

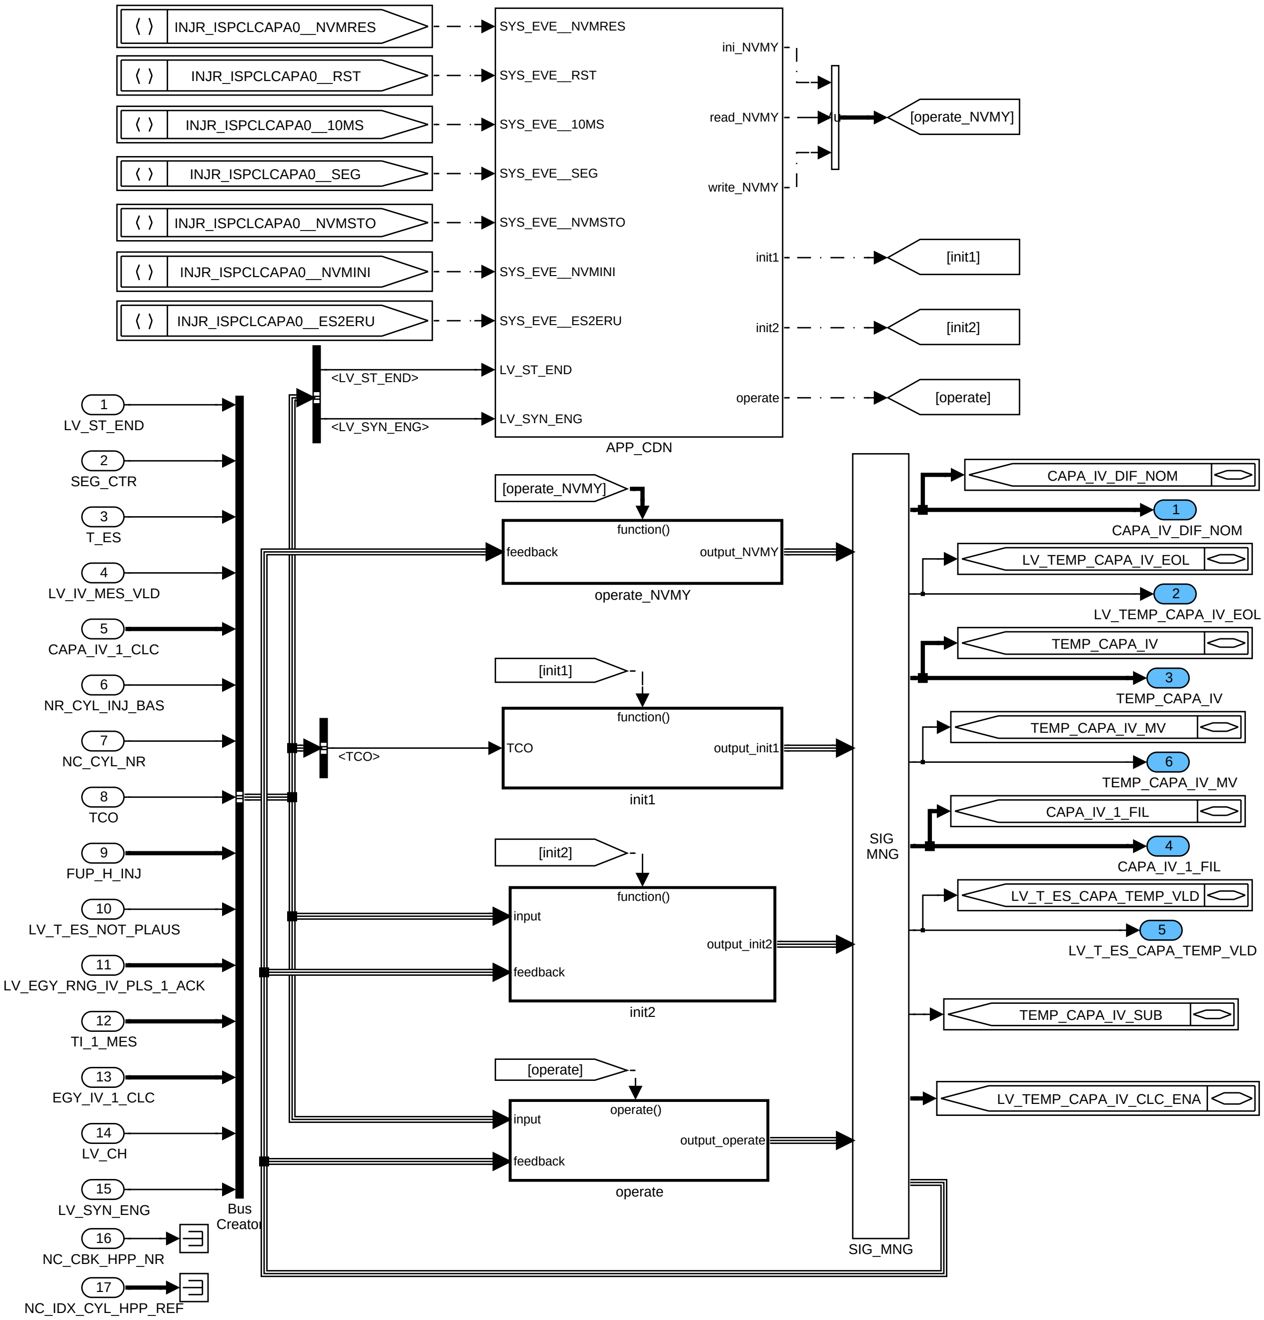
Function Description



SDA_SRS / SDA 4.0 24−Oct−2006

Figure 13 INJR_ISPCLCAPA0

41.25.1.1 Handling of nonvolatile memory

The capacity offset of each injector is stored. It is read and written to the NVMY before/after each complete driving cycle.

Initialization of nonvolatile memory

Reading of nonvolatile memory

Writing of nonvolatile memory

41.25.1.2 Initialization

The piezo stack temperature is initialized with the coolant temperature at ECU-reset.

41.25.1.3 Plausibility check of engine off time and calculation of substitute value for TEMP_CAPA_IV

A new adaptation value of the capacity offset is calculated if the engine offtime is plausible and greater than a calibratable constant. If both conditions are true the bit LV_T_ES_CAPA_TEMP_VLD is set. For the first engine start at end-of-line the capacity offset adaptation is always done. At the first engine start LV_TEMP_CAPA_IV_EOL is zero. It is set to one if the capacity offset is adapted and will be stored in the nonvolatile memory. Furthermore an substitute value for the piezo-capacity temperature is determined via engine off-time, coolant-temperature and the mean value of the piezo-temperatures of the last driving cycle.

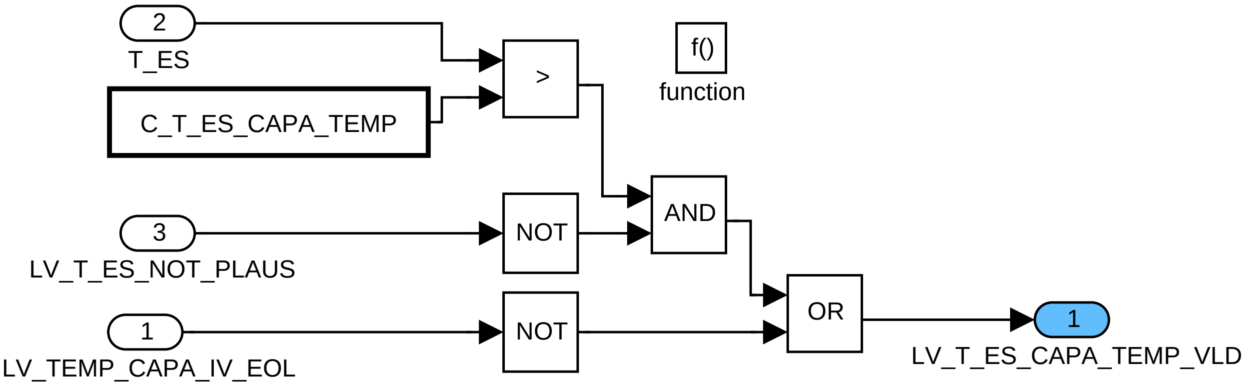


Figure 14 INJR_ISPCLCAPA0/ init2/ Plausiblity_Check

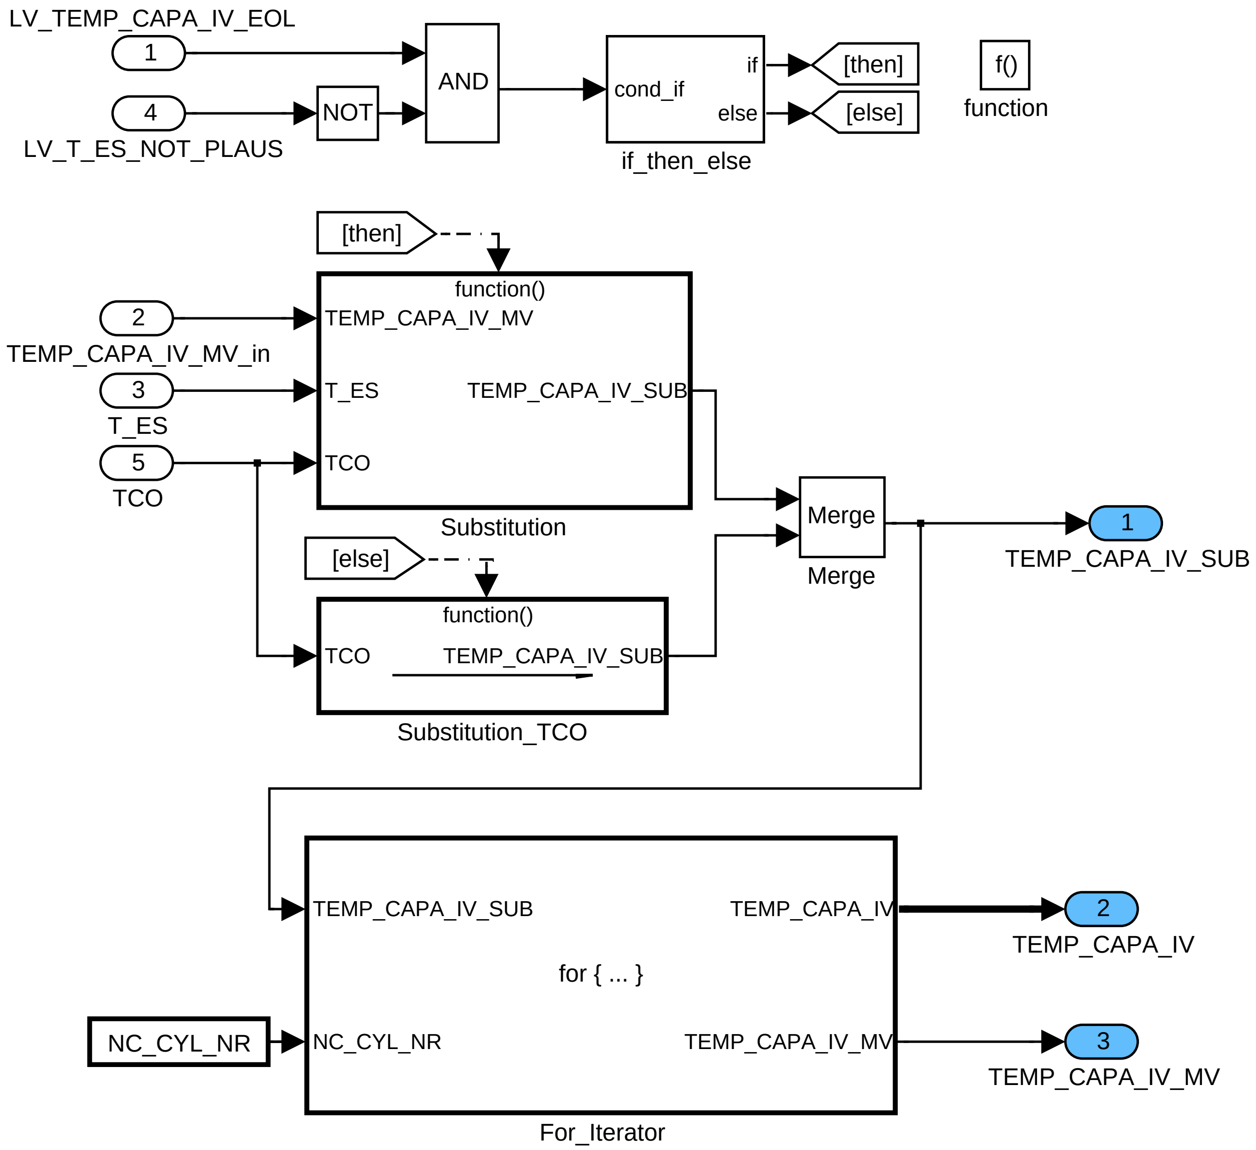

Figure 15 INJR_ISPCLCAPA0/ init2/ TEMP_CAPA_Sunstitution

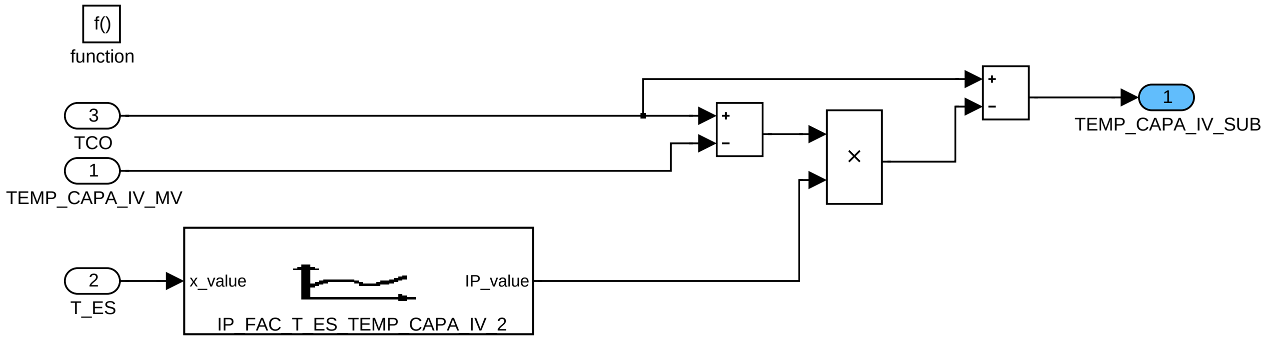

Figure 16 INJR_ISPCLCAPA0/ init2/ TEMP_CAPA_Sunstitution/ Substitution

41.25.1.4 Calculation of filtered capacity, capacity offset and stack temperature

Filtering of piezo capacity

The large signal capacity is calculated out of measured charge and voltage value. Since the signal is noisy it has to be low pass filtered. The filter constant can be applied via C_FAC_FIL_CAPA_IV. The filtered capacity is used for the further calculations. At first entry the filtered capacity is set to the measured capacity value via reset (R) and intial value (IV) input ports. The filter is enabled if the measured voltage and charge values are valid (LV_IV_MES_VLD), if the measured injection time is greater than a calibratable constant and if high energy range is used (LV_EGY_RNG_IV_PLS_1_ACT).

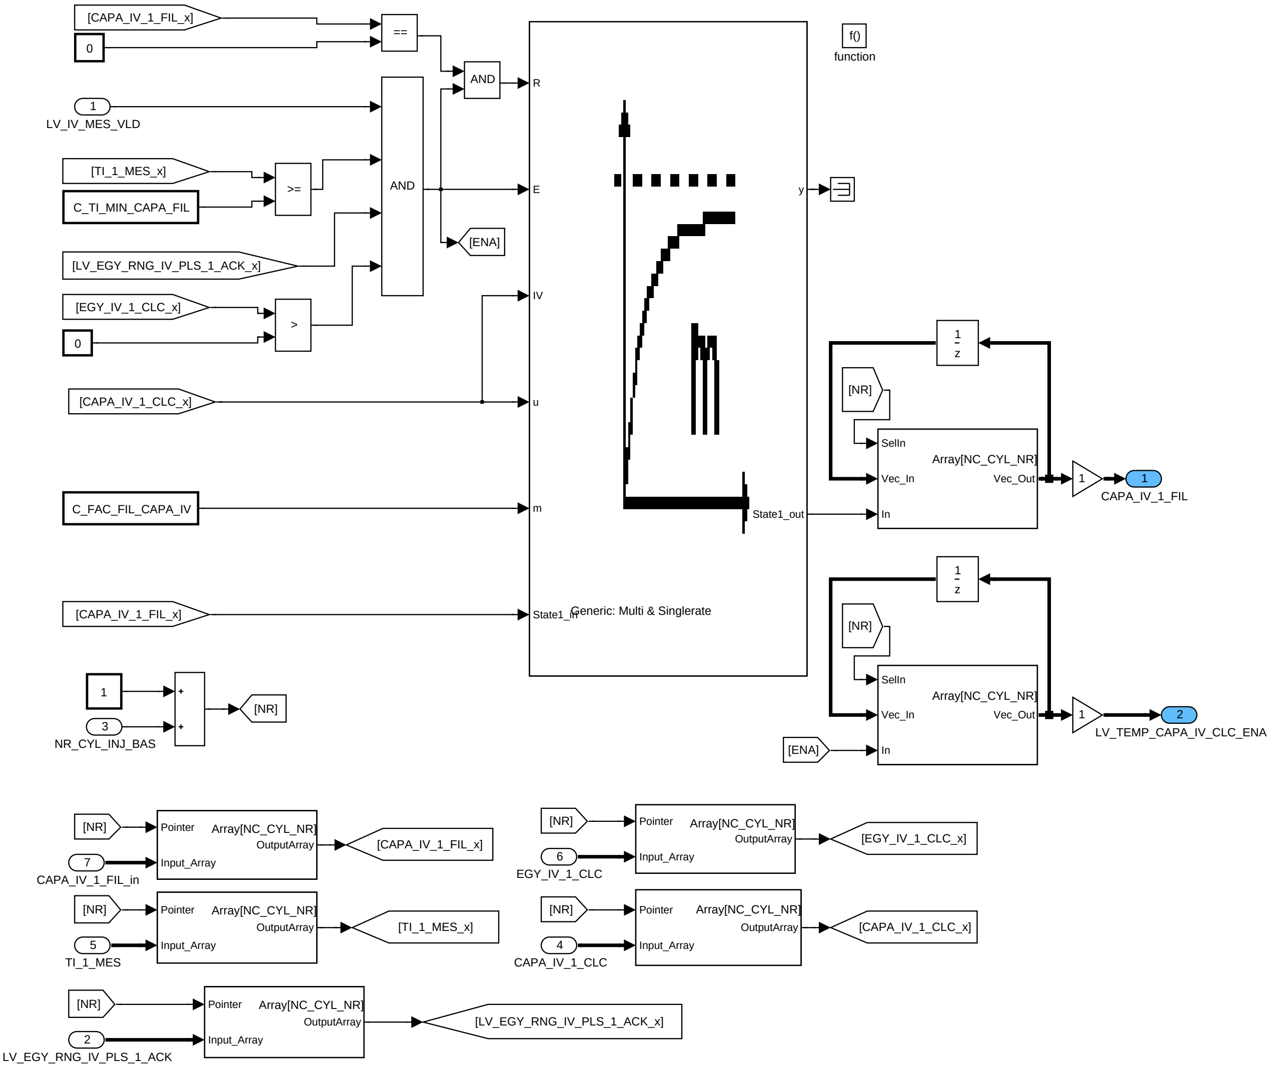

Figure 17 INJR_ISPCLCAPA0/ operate/ Capa_Filter

Calculation of capacity offset

The capacity offset of each injector is stored in the nonvolatile memory. A new adaptation value is calculated if the engine offtime T_ES is plausible and greater than a calibratable constant (LV_T_ES_CAPA_TEMP_VLD = TRUE). Then the coolant temperature TCO is used as the reference temperature. The calculation of the offset value is triggered as soon as the segment counter exceeds a calibratable level. The capacity offset is limited to C_CAPA_IV_DIF_NOM_LIM. The calculation of capacity offset can be inhibited if catalyst heating is active. For the first engine start the end-of-line flag LV_TEMP_CAPA_IV_EOL is set if adaptation was done.

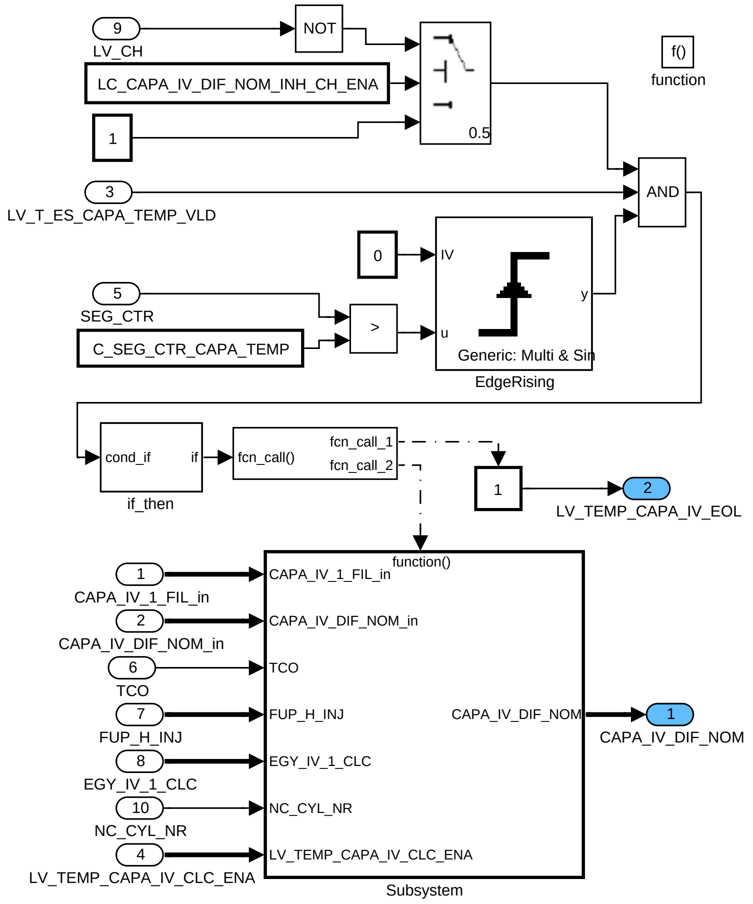

Figure 18 INJR_ISPCLCAPA0/ operate/ Capacity_Offset

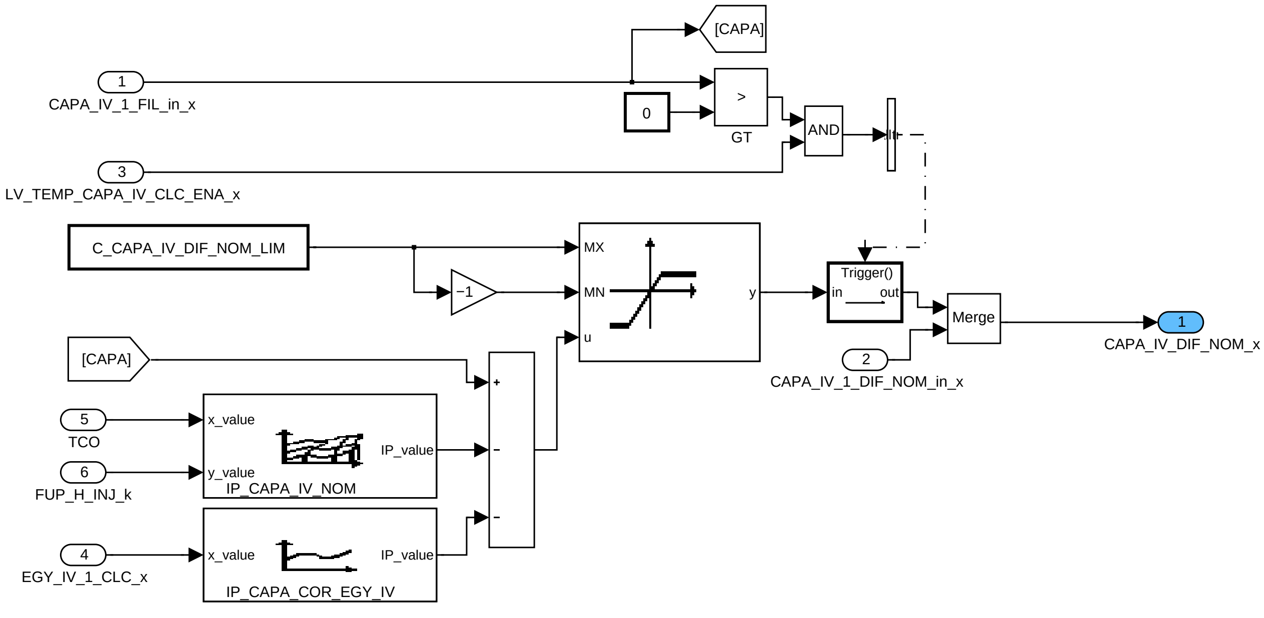

Figure 19 INJR_ISPCLCAPA0/ operate/ Capacity_Offset/ Subsystem/ For_Iterator/ Sub_System

Calculation of piezo stack temperature

While the segment counter is lower than a calibratable constant the temperature of the piezo stacks is set to the substitute value TEMP_CAPA_IV_SUB. When the SEG_CTR exceed this threshold the temperature is extracted from the map IP_TEMP_CAPA_IV_NOM accounting for each stack's individual capacity offset to the nominal value.

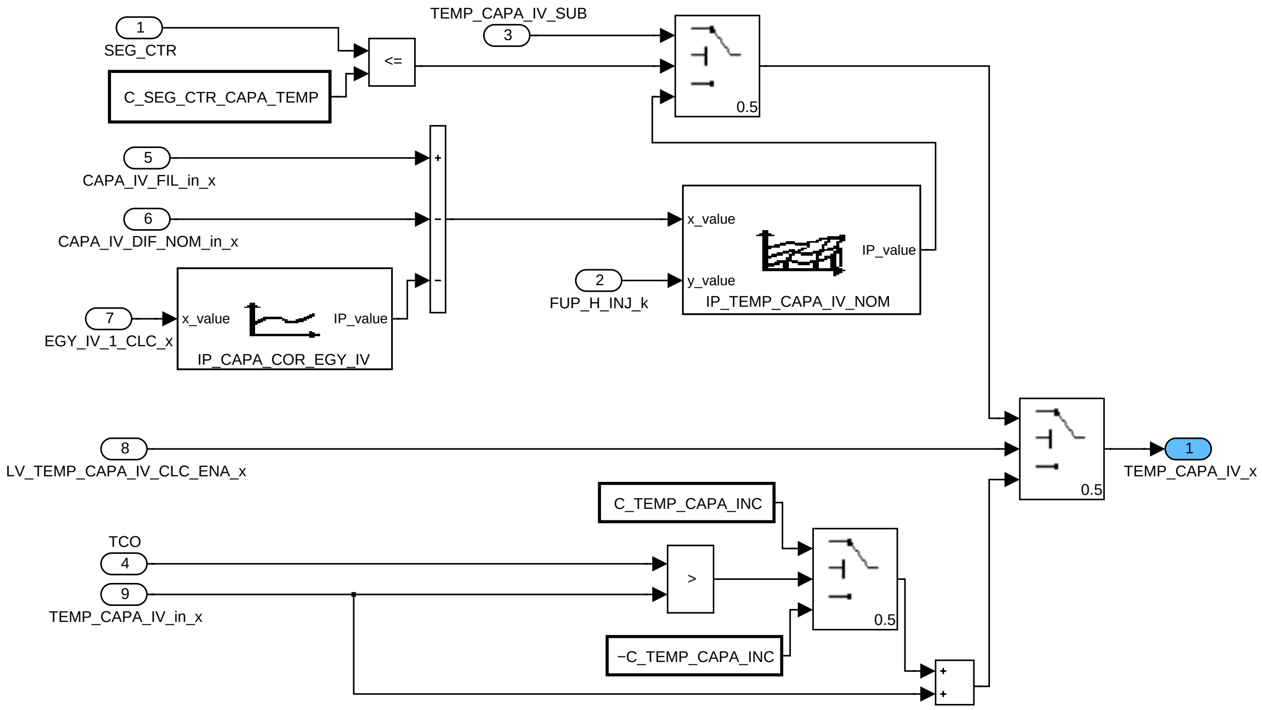

Figure 20 INJR_ISPCLCAPA0/ operate/ Calc_of_Temp/ For_Iterator2/ Subsystem

Manual setting for end of line flag

The end-of-line fag LV_TEMP_CAPA_IV_EOL can be set manually via LC_TEMP_CAPA_IV_EOL_MAN and C_TEMP_CAPA_IV_EOL.

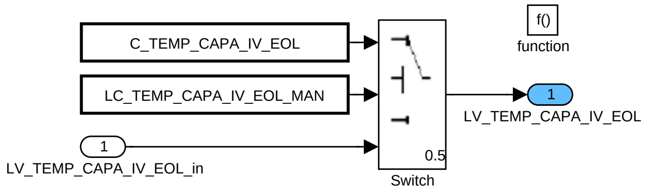

Figure 21 INJR_ISPCLCAPA0/ operate/ Manual_setting_for_EOL

DESCRIPTION:

General information:

This functionality switches between two different base energy ranges for PIEZO injectors. Starting with these base ranges, specific energy levels are calculated for each cylinder depending on the cylinder balancing injection valve energy level.

Application Conditions:

Initialization: at reset and at first valid tooth:

```
LF_EGY_RNG_IV_1_HOM_REQ = (2^NC_CYL_NR) - 1
LF_EGY_RNG_IV_2_HOM_REQ = (2^NC_CYL_NR) - 1

LV_ST_END = 1: segment synchronous

Activation: every engine state

Deactivation: -

Formula section:

For loop for runtime optimization:

In this specification the for loop

```
FOR i = 0, i < NR_CYL_CLC_RED_INJ DO
            x = CTR_CYL_NR_ST_CLC_INJR + i
            (1a)IF x  >= NC_CYL_NR
            (1a)THEN
                    x = x – NC_CYL_NR
            (1a)ENDIF
            <loop content>
ENDFOR
```

is substituted by

```
FOR cylinder_start to cylinder_stop DO
     <loop content>
ENDFOR
```

Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

41.26.1 Cylinder individual adjustment of the energy level

This function calculates cylinder individual charge and discharge gradients depending on the cylinder balancing injection valve energy level. Should the unlimited gradient value run out of the lower/upper limits, the gradient variable shall be limited to the maximum or minimum threshold – dependently on engine operation mode (homogenous or stratified) - and the energy-level-difference factor shall be converted in the MFF-difference factor.

41.26.2 Selection of injector energy range

41.26.2.1 Basis calculations

The minimum fuel mass setpoint for stratified mode is determined from the pulses with a fuel mass setpoint greater than zero. The corresponding minimum injection time is calculated and if the injection time is greater than a threshold or homogeneous mode is selected, high energy range will be selected for the injector, pulse individual.

The energy range can also be clipped to low range by dynamic injector needle lift selection (bit field LFT_L_IV_S_REQ).

Important note: For better readability of the specification, the LSB of the bit field LFT_L_IV_S_REQ, which corresponds to the physically first injection pulse, is referred to as bit 1 (**not** bit 0 as it would be in SW). The next bit would be bit 2 etc.

41.26.2.2 Main calculations for stratified combustion mode:

```
FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
    FAC_TI_COR_IV_EGY_RNG_L[m] =
                IP_FAC_TI_COR_IV_EGY_RNG_L (Input: FUP_H_INJ[m])

endif(2)
```

end of section 41.26.2.5

41.26.2.6 Energy range calculations for multiple homogeneous mode (Main calculations)

If multiple homogenous injection mode is selected, the second/third fuel mass setpoint will be checked against a threshold. If the fuel mass is below the threshold, the second/third injection pulse will be executed with low energy range.

The energy range can also be clipped to low range by dynamic injector needle lift selection (bit field LFT_L_IV_HOM_REQ).

Important note: For better readability of the specification, the LSB of the bit field LFT_L_IV_HOM_REQ, which corresponds to the physically first injection pulse, is referred to as bit 1 (**not** bit 0 as it would be in SW). The next bit would be bit 2 etc.

Note: For improvement of runtime, calculate the map IP_MFF_THD_IV_EGY_RNG only once per recurrence for every fuel pressure value!

```
FOR m = 0 TO NC_CBK_HPP_NR – 1 DO
    MFF_THD_EGY_RNG_IV[m] = IP_MFF_THD_IV_EGY_RNG(Input: FUP_H_INJ[m])

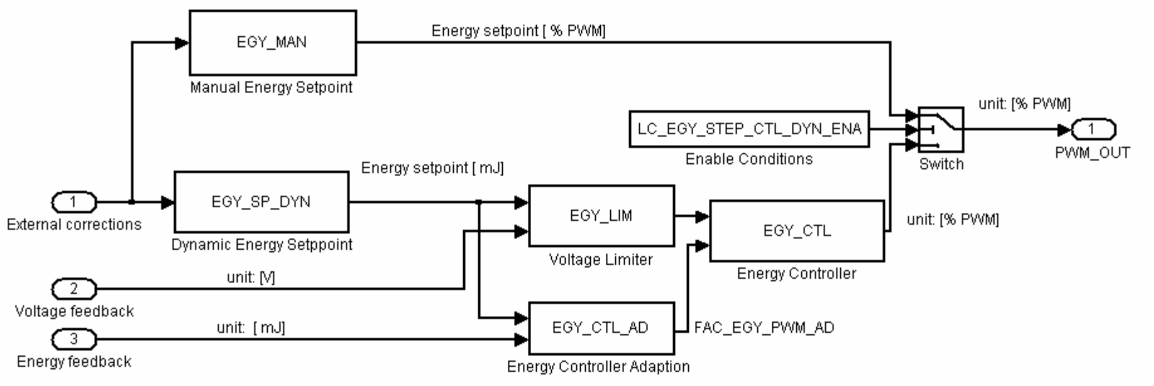
Exported actions:

ACTION_INJR_**SetFacEgyPwmAd** (IN <Cyl>, IN <Fac>)
Sets the cylinder individual conversion factor FAC_EGY_PWM_AD of cylinder <Cyl> to value <Fac>.

41.27.1 Controller concept overview



There are several modes to operate the piezo energy controller unit.

If **LC_EGY_STEP_CTL_DYN_ENA** is FALSE, the manual set point calculation with direct feed through to the PWM output is active.

Otherwise the dynamic set point calculation and voltage limiter are activated.

For the voltage limiter are proper feedback conditions necessary.

The adaption of the conversion factor FAC_EGY_PWM_AD is calculated, if switched ON only, and if proper feedback is granted.

Value of NC_EGY_RNG_H = 1.

41.27.1.1 Description for ACTION_INJR_SetFacEgyPwmAd

ACTION_INJR_SetFacEgyPwmAd (IN <Cyl>, IN <Fac>)					
Sets the cylinder individual conversion factor FAC_EGY_PWM_AD of cylinder <Cyl> to value <Fac>.					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
Cyl	IN	0...7 H	0...7	1	1
This action affects the conversion factor FAC_EGY_PWM_AD of cylinder Cyl.					
Fac	IN	0...FFFFH	0...1.99996948	3.05176 E-5	%/mJ
This parameter defines the new value of FAC_EGY_PWM_AD.					

Formula Section for ACTION_INJR_SetFacEgyPwmAd:

FAC_EGY_PWM_AD[Cyl] = Fac

Application Condition

41.28.1 General information

This module generates an external cylinder individual set point for the piezo energy controller. EGY_SP_IV_EXT. Furthermore an additive piezo energy correction is supplied. It is taken into account for the energy set point calculation.

Application Condition

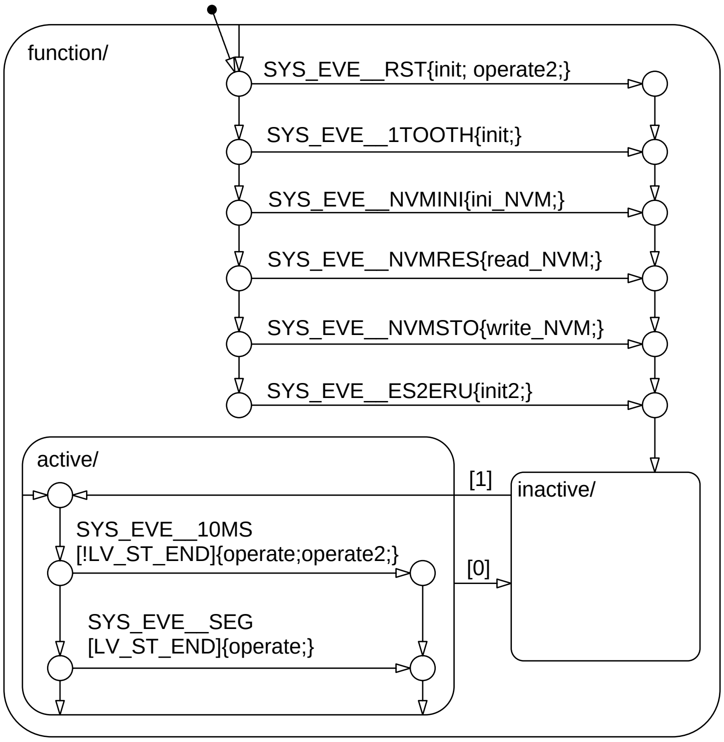

Figure 31 INJR_ISPCLEGYAI0/ APP_CDN/ Chart

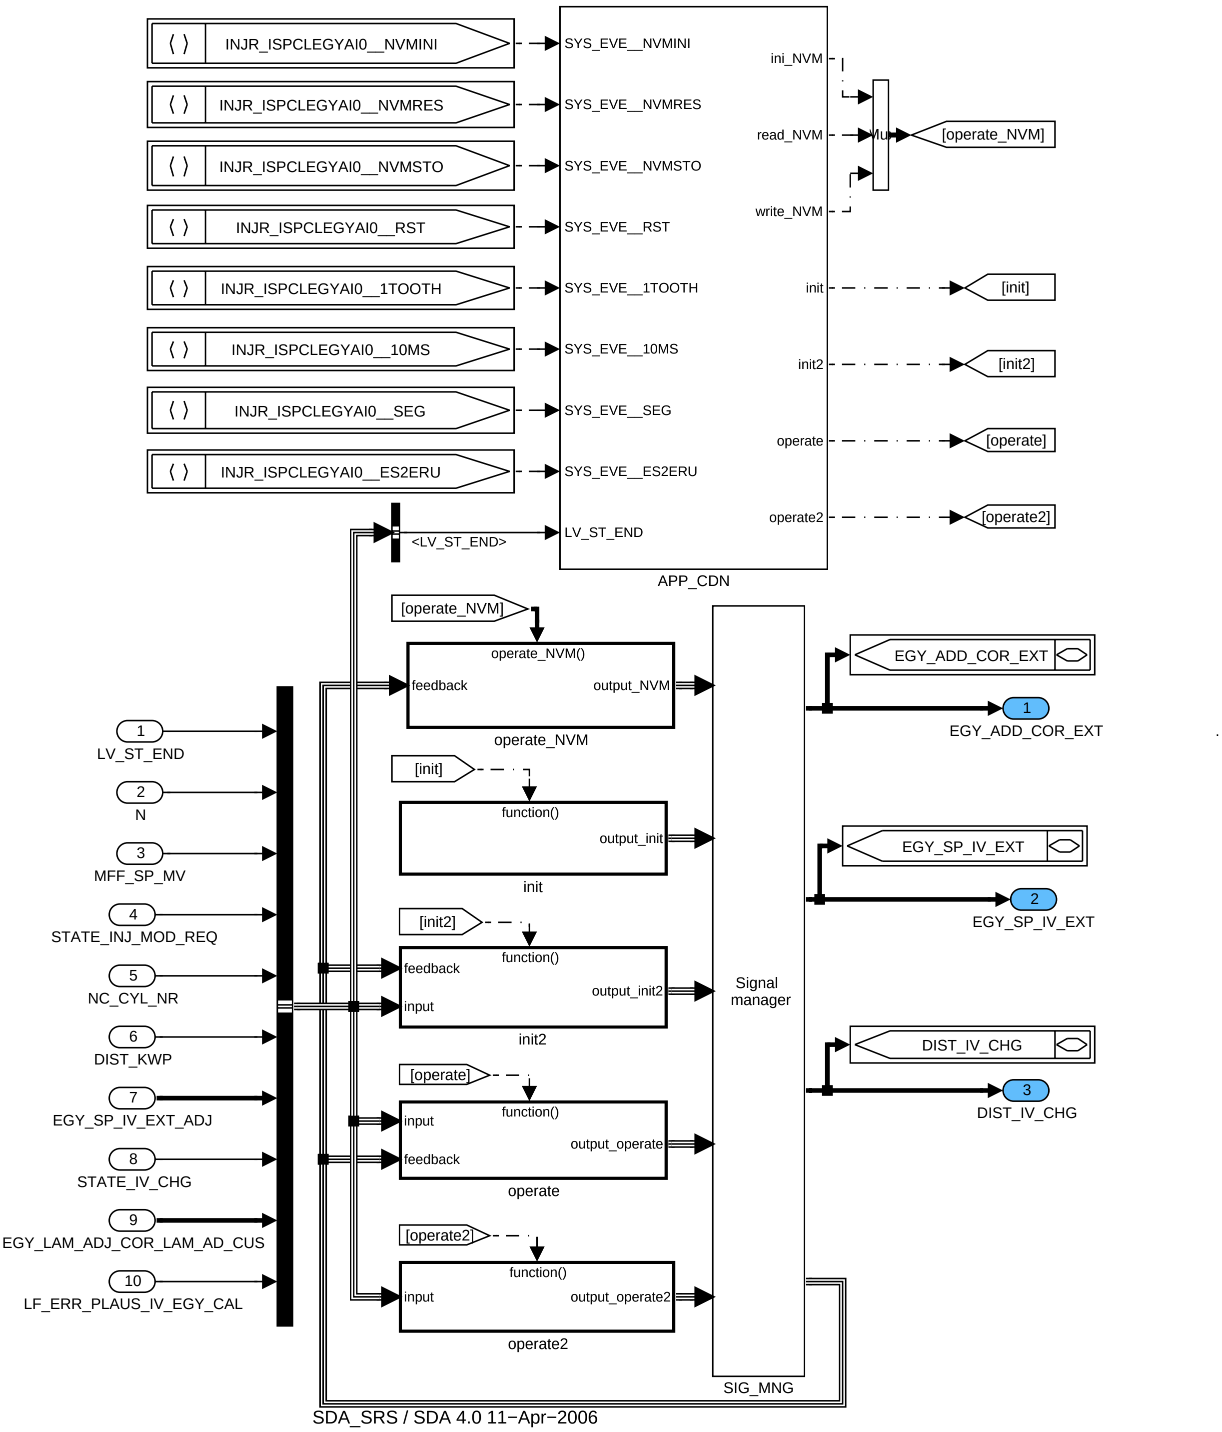

Figure 32 INJR_ISPCLEGYAI0

41.28.1.1 Nonvolatile memory operations

The accumulated driving distance at injector change DIST_IV_CHG is stored in the nonvolatile memory (NVM). It is read from and written to the NVM before/after each complete driving cycle.

Please note: DIST_IV_CHG has to be allocated in that part of the NVM-RAM which is not erased during reflashing of ECU.

41.28.1.2 Initialization at reset and first valid tooth

At reset and fist valid tooth the additive energy correction is set to 0.

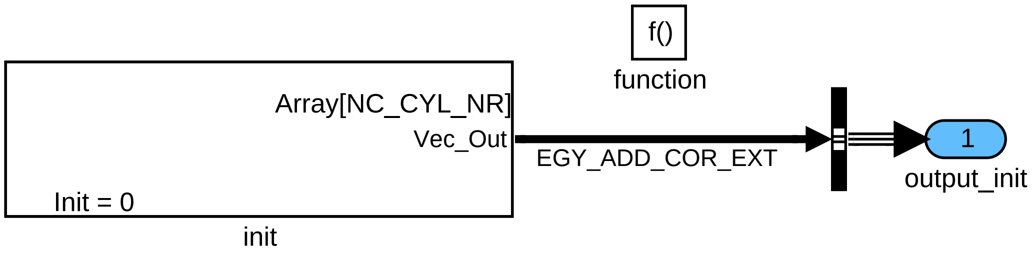

Figure 33 INJR_ISPCLEGYAI0/ init

41.28.1.3 Calculation at engine stop to engine run

At ES2RUN it is determined whether an injection valve was changed: STATE_IV_CHG is provided by the keyword-protocol KWP and supplies a bit coded information: If the bit on position x is set the injector was changed. DIST_IV_CHG is the cylinder individual driving distance when the injector was changed. It is stored in the nonvolatile memory.

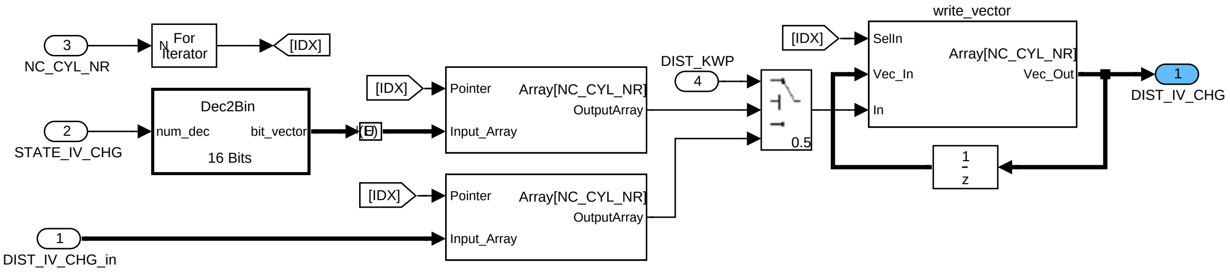

Figure 34 INJR_ISPCLEGYAI0/ init2/ ForIterator

41.28.1.4 Calculation of additive energy correction

An additive piezo energy correction depending on engine speed and load is supplied. Depending on the requested combustion modes (homogeneous, homogeneous-stratified and stratified) different maps are used. Furthermore an additive correction accounting for aging effects of the piezo injection valve is supplied cylinder individually. The accumulated driving distance is used as an indicator for aging. It is given by the difference of the actual driving distance and the driving distance at the last injector change. EGY_LAM_ADJ_COR_LAM_AD_CUS accounts for the long term lambda adaptation.

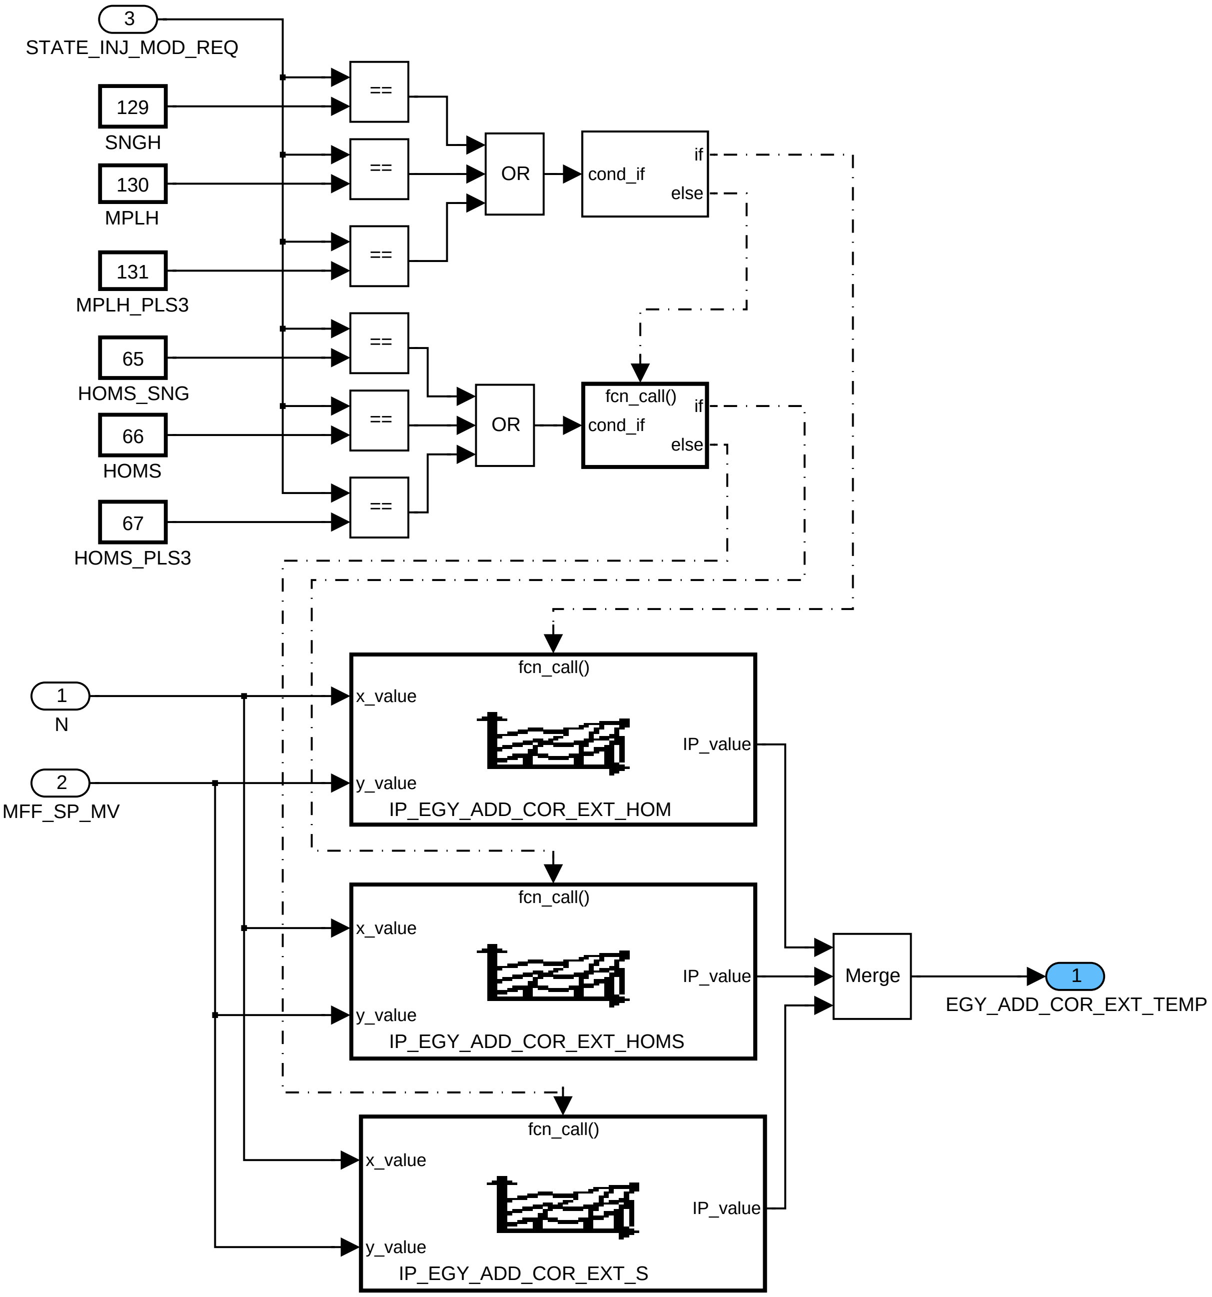

Figure 35 INJR_ISPCLEGYAI0/ operate/ CLC_EGY_ADD_COR_EXT

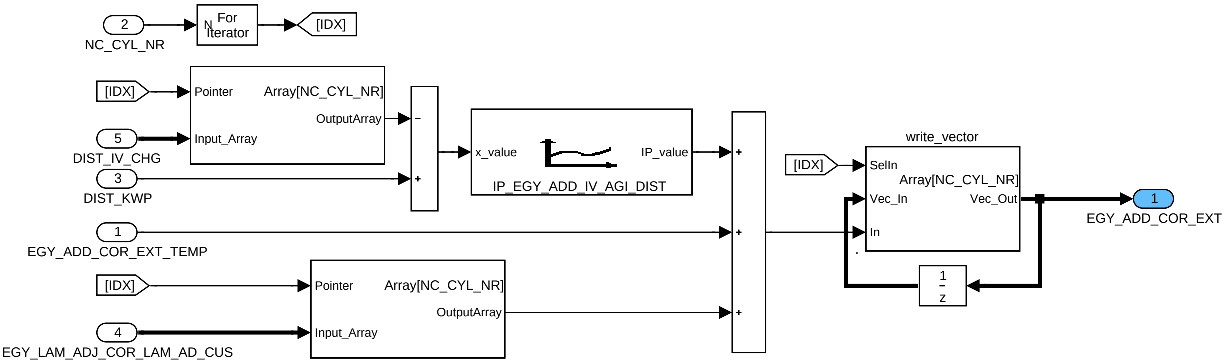

Figure 36 INJR_ISPCLEGYAI0/ operate/ ForIterator

41.28.1.5 External energy setpoint for energy controller

This functionality supplies a cylinder individual injection valve energy set point for the energy controller. It is set to EGY_SP_IV_EXT_ADJ given by the KWP if the cylinder individual values are plausible (bit x is zero in bit-mask LF_ERR_PLAUS_IV_EGY_CAL for logical cylinder x) and if LC_EGY_SP_IV_EXT_ADJ_ENA is set. Otherwise cylinder individual values can be supplied manually via the calibration constant C_EGY_SP_IV_EXT_ADJ.

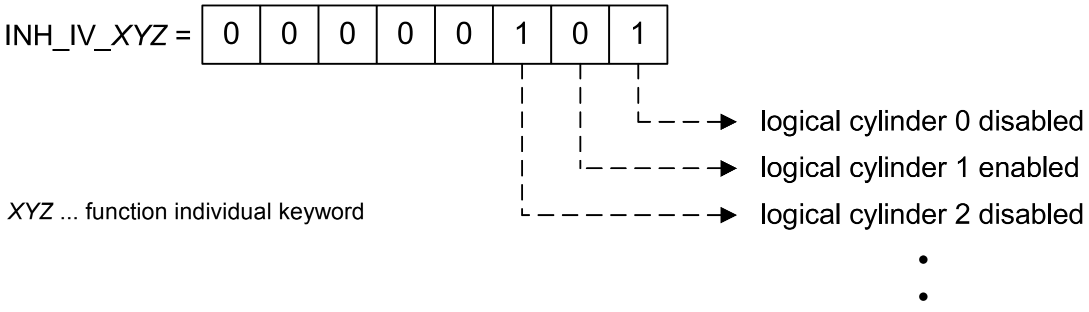
41.29.1 General information

Static fuel shut off:
In several engine operating- and system states and in case of malfunctions of the injection or ignition system the fuel injection must be disabled at individual cylinders. All the shut off requirements are coordinated, hence these requirements have to have the same structure as described below:



Dynamic fuel shut off:
The information which cylinder has to be shut off static, is coded within a byte (with the length of 8 bit) at the cylinder corresponding position.
In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.
Injections, which are already started, will not be stopped.

FUNCTION DESCRIPTION:

Application conditions:

Activation:	every engine state
Deactivation:	-
Initialization:	-
Reccurence:	if LV_ST_END = 0: 10 ms if LV_ST_END = 1: segment synchronous

INH_IV_MIS (Input pattern)

41.29.2.5 Pull Fuel Cut Off

To guarantee a moderate transition from trailing throttle PU to trailing throttle fuel cut off, the transition is handled by the module “Sequential fuel cut off and restart fuel feed”, see chapter Cylinder Individual Fuel Shut Off with Pattern. After the transition is finished (indicated by the flag LV_SEL_CYL) all cylinders are shut off by INH_IV_PUC.

```
IF      LV_PUC = 1
        AND
        LV_SEL_CYL = 0

THEN
        IF LV_INJ_PUC_ENA = 1
        THEN
                INH_IV_PUC = LF_IV_INH_PUC_EXT
        ELSE

                all cylinders are shut off
                INH_IV_PUC = | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
        ENDIF

ELSE    no cylinder is shut off
        INH_IV_PUC = | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
ENDIF
```

41.29.2.6 Engine speed limitation

```
IF      LV_N_MAX_REQ_FCUT = 1

THEN    all cylinders are shut off
        INH_IV_N_MAX_REQ_FCUT = | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

ELSE    no cylinder is shut off
        INH_IV_N_MAX_REQ_FCUT = | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
ENDIF
```

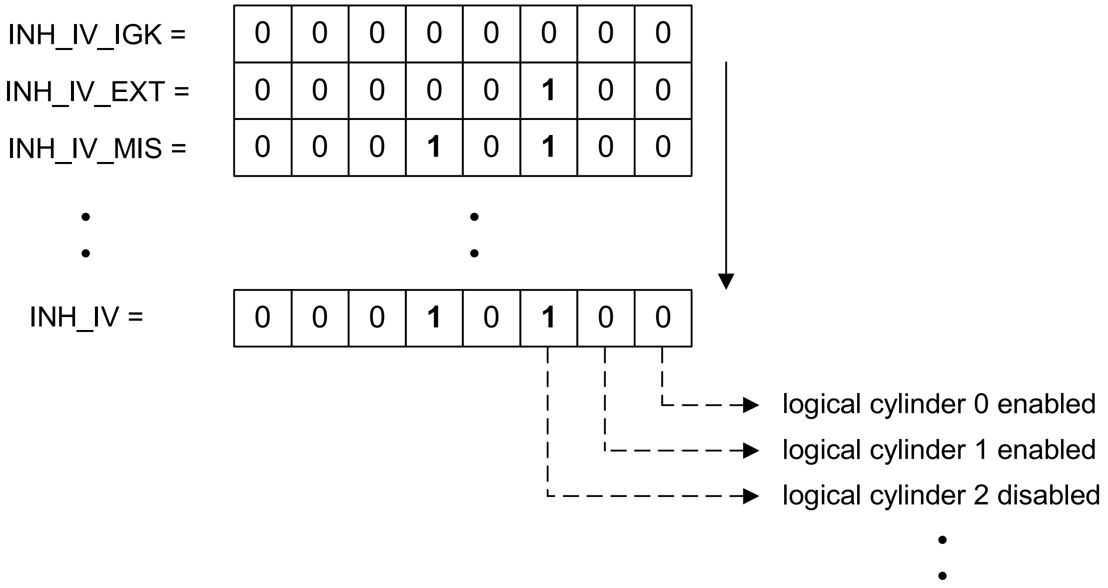
41.29.2.7 Shut Off Pattern from Application Incidences

INH_IV_EXT (Input pattern)

Additional shut off requirements are coordinated within the module “Cylinder Shut Off (Application Incidences)”.

41.29.2.8 Coordination of the Static Fuel Shut Off Requirements

The output pattern INH_IV is the bitwise OR of all pattern, linked with a mask $((2^{NC\_CYL\_NR})-1)$. As an example see below:



41.29.3 Dynamic fuel shut off

In some engine operating states, e. g. fast torque reduction, restart fuel feed or pull fuel cut off, the injection has to be disabled for a certain subsequent numbers of injections. The fuel cut off starts immediately at the next cylinder following an order defined in a pattern. That means, different to the cylinder individual static fuel shut off, there is no predefined and fixed association between cylinders and the shut off sequence.

Injections, which are already started, are not stopped.

The map ID_INH_SWI_IV contains (2 * NC_CYL_NR + 1) different pattern with calibrate able shut off sequences. Every pattern is allocated to an index NR_PAT (mapping points).

There are two requirements for “Dynamic fuel shut off” to this module:

NR_PAT_SEL_CYL is an index defined by the module “Sequential fuel cut off and restart fuel feed”.

NR_PAT_SCC is an index defined by the module “Torque based pattern calculation”.

NR_PAT is the index corresponding to the highest shut off level (number of cylinders disabled) of these both requirements. A certain pattern is repeated until this index changes.

NR_PAT_OLD = NR_PAT

NR_PAT = MAX (NR_PAT_SEL_CYL, NR_PAT_SCC)

INH_SWI_IV = ID_INH_SWI_IV

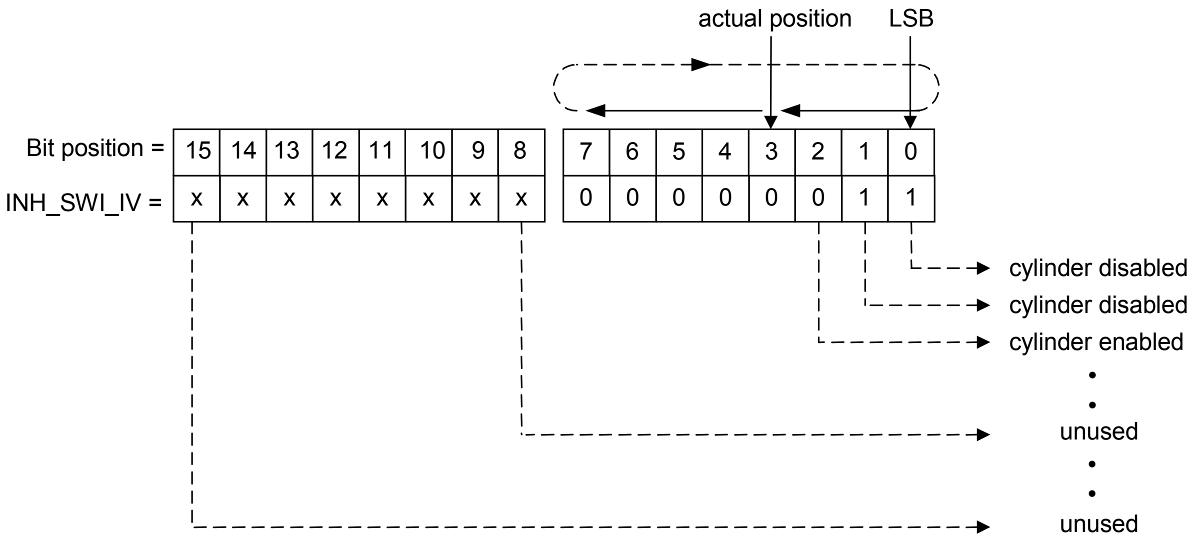
For example a map ID_INH_SWI_IV for an 8-cylinder engine with different shut off sequences (8 next injections):

NR_PAT (Index)	Shut off sequence
0	xxxxxxxx 00000000
1	xxxxxxxx 00000001
2	xxxxxxxx 00000011
3	xxxxxxxx 00000111
4	xxxxxxxx 00001111
5	xxxxxxxx 00011111
6	xxxxxxxx 00111111
7	xxxxxxxx 01111111
8	xxxxxxxx 11111111
The following sequences can be used for reactivation of cylinders	
9	xxxxxxxx 11111111
10	xxxxxxxx 01111111
11	xxxxxxxx 00111111
12	xxxxxxxx 00011111
13	xxxxxxxx 00001111
14	Xxxxxxxx 00000111
15	xxxxxxxx 00000011
16	xxxxxxxx 00000001

Note:

To guarantee that the algorithm works correct, the table ID_INH_SWI_IV has to be applied as follows: The higher the index NR_PAT, the higher the number of cylinders deactivated.

INH_SWI_IV is defined as follows:



(e.g. NC_INJ_INH_SWI_IV_SHIFT_NR = 8, actual bit position = 4):

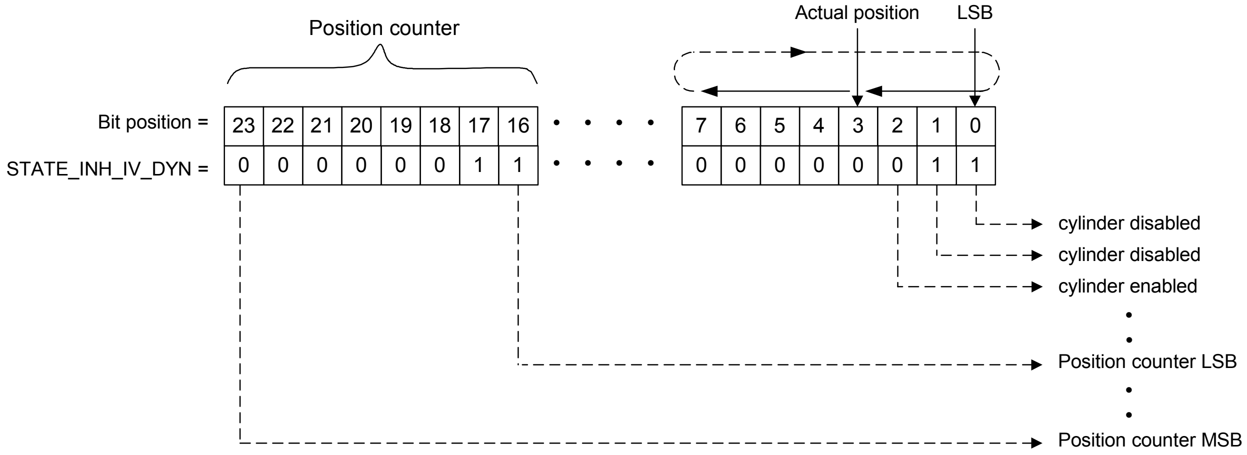
If the bit at a bit position = 1 → cylinder disabled
If the bit at a bit position = 0 → cylinder enabled

The length of the pattern is 16 bit. NC_INJ_INH_SWI_IV_SHIFT_NR defines how many bits are used for the shut off sequence.

NC_CYL_NR < = NC_INJ_INH_SWI_IV_SHIFT_NR < = 16

Calculation of STATE_INH_IV_DYN:

Definition of STATE_INH_IV_DYN:



**Note! The position counter data field inside STATE_INH_IV_DYN will be updated at TRIG_EOI_LIM[x].
It contains the 'Actual position' inside the shut off pattern sequence.**

Select between two different algorithm for STATE_INH_IV_DYN calculation:

(1) IF LC_SWI_MOD_INH_IV_DYN = 0

(1) THEN Classic mode: If NR_PAT increases, then STATE_INH_IV_DYN starts always with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the ‘Actual position’ stays unchanged and a new shut off pattern – or the old one – is used based on INH_SWI_IV – see picture above.

(2) IF NR_PAT > NR_PAT_OLD

(2) THEN

Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(2) ELSE

Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:

```
STATE_INH_IV_DYN = STATE_INH_IV_DYN AND 0xFFFF0000        ...bitwise
                   OR                                     ...bitwise
                   INH_SWI_IV AND 0x0000FFFF              ...bitwise
```

Note! Pay attention of data consistency of STATE_INH_IV_DYN.

(2) ENDIF

(1) ELSE Modern mode: Only if NR_PAT was zero and increases, then STATE_INH_IV_DYN starts with a new fuel cut off sequence and 'Actual position' will be set to zero. Otherwise the ‘Actual position’ stays unchanged and a new shut off pattern – or the old one – is used based on INH_SWI_IV – see picture above.

(3) IF (NR_PAT_OLD = 0) **AND** (NR_PAT > NR_PAT_OLD)

(3) THEN

Start with a new fuel cut off sequence at the first bit position (LSB). Use as sequence the current content of INH_SWI_IV.
STATE_INH_IV_DYN = INH_SWI_IV

(3) ELSE

Continue with the fuel cut off sequence at 'Actual position' and change the shut off pattern depending on INH_SWI_IV:

```
STATE_INH_IV_DYN = STATE_INH_IV_DYN AND 0xFFFF0000        ...bitwise
                   OR                                     ...bitwise
                   INH_SWI_IV AND 0x0000FFFF              ...bitwise
```

Note! Pay attention of data consistency of STATE_INH_IV_DYN.

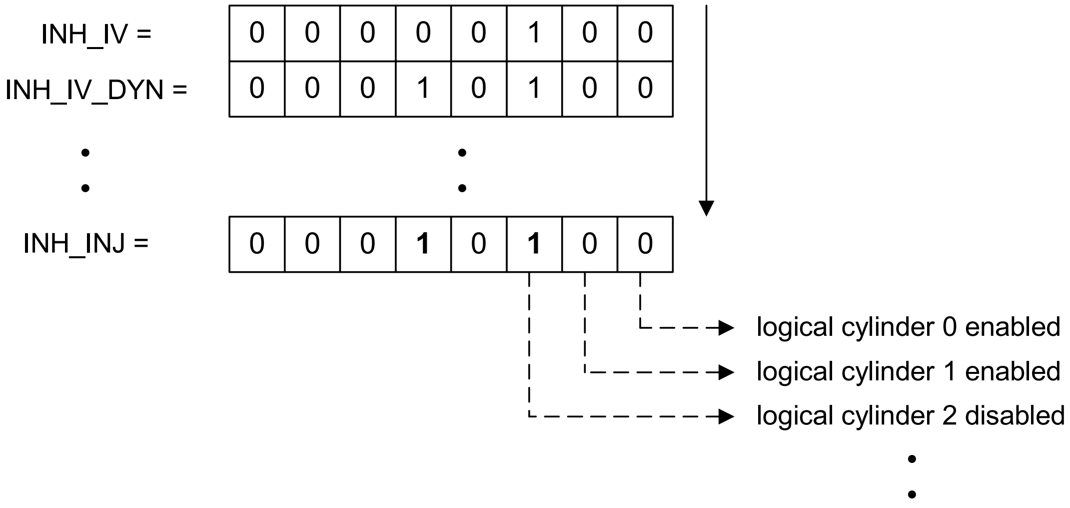
(3) ENDIF

(1) ENDIF

41.29.4 Coordination of shut off information for basic software (INH_INJ)

The output pattern INH_INJ is the bitwise OR of the pattern INH_IV and INH_IV_DYN, linked with a mask $((2^{NC\_CYL\_NR}) -1)$.

As an example see below:



Note! Pay attention of data consistency of INH_IV.

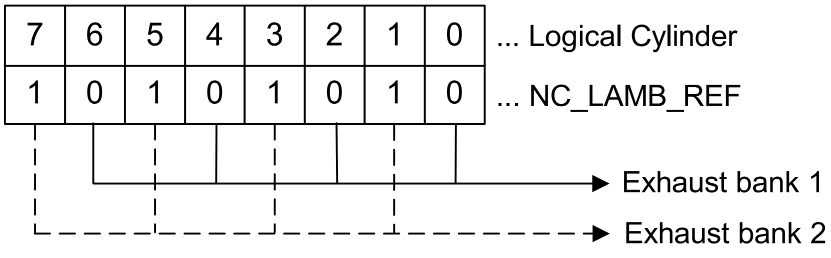
41.29.5 Shut Off Status Information

SUM_INH_IV	.... sum of INH_IV
SUM_INH_IV_CBK_i	.... sum of those bits within INH_IV which are allocated to exhaust cylinderbank i, with i = 1 for exhaust cylinderbank 1 and i = 2 for exhaust cylinderbank 2.
SUM_INH_IV_DYN	..... sum of INH_IV_DYN
SUM_INH_INJ	..... sum of INH_INJ

Note! Pay attention on data consistency of SUM_INH_INJ and SUM_INH_IV_DYN

Note:

The allocation between physical cylinders and exhaust cylinderbank 1 and 2 is defined by the pattern NC_LAMB_REF. For example an 8 cylinder engine:



```
(1) IF   SUM_INH_INJ ≠ 0
(1) THEN
        LV_FCUT_IND = 1            (at least one cylinder is shut off)
    (2) IF      SUM_INH_INJ ≥ NC_CYL_NR
    (2) THEN                       (all cylinders are shut off)
            LV_INJ_CUT = 1
            (3) FOR i = 1 TO NC_CBK_EX_NR DO:
                LV_SCC[i] = 1        (i = 1 and 2, for exhaust cylinder bank 1 and 2)
            (3) ENDFOR
    (2) ELSE
            LV_INJ_CUT = 0
            (4) FOR i = 1 TO NC_CBK_EX_NR DO:
                (5) IF SUM_INH_IV_CBK[i] ≠ 0
                (5) THEN
                LV_SCC[i] = 1
                (5) ELSE
                LV_SCC[i] = 0
                (5) ENDIF
            (4) ENDFOR
    (2) ENDIF
(1) ELSE
        LV_FCUT_IND = 0
        LV_INJ_CUT = 0
        (6) FOR i = 1 TO NC_CBK_EX_NR DO:
            LV_SCC[i] = 0
        (6) ENDFOR
(1) ENDIF
```

41.30 Cylinder Shut Off (Application Incidences)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Application constant for manual shut off request					
LC_INH_IV_DIAG_ERR_IMDT_ENA	1	0...1H	0...1	1	[-]
Manual switch to activate cylinder shut off immediate after debouncing of an IV error without accordance to MISF					

41.30.1 Cylinder Individual Static Fuel Shut Off

Application conditions:

Activation:	every engine state
Deactivation:	-
Initialization:	at reset all 0

```
# IF NC_STATE_STST_ENA = 1
# THEN
at ECU_STATE transition SYN_ENG_IGK_ON to RUN_ENG
LV_INJ_LOCK_REQ_TMP = 1
at ECU_STATE transition RUN_ENG to ENG_STOP
LV_INJ_LOCK_REQ_TMP = 0
# ENDIF
```

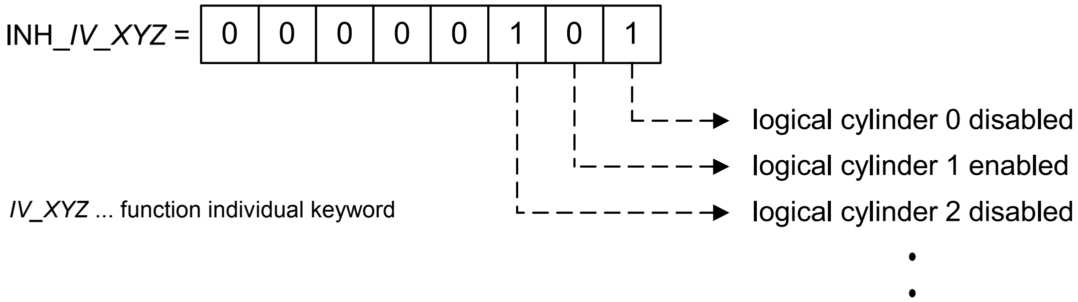
Reccurence: if LV_ST_END = 0: 10 ms

if LV_ST_END = 1: segment synchronous

Note: The module has to be calculated before the module “Cylinder Shut Off”.

Formula section:

41.30.1.1 General



In several engine operating- and system states and in case of malfunctions the fuel injection must be disabled at individual cylinders. All the shut off requirements are coordinated, hence these requirements have to have the same structure as described below:

The information which cylinder has to be shut off static, is coded within a byte (with the length of 8 bit) at the cylinder corresponding position.

41.30.1.2 Static Fuel Shut Off Requirements

41.30.1.2.1 Inhibit by manual switch

INH_IV_SWI_MAN (Input pattern) = C_INH_IV_SWI_MAN

41.30.1.2.2 INH_IV_IMOB

41.30.1.2.3 Shut off request from immobilizer (cylinder allocated):

41.30.1.2.4 INH_IV_IMOB (Input pattern)

41.30.1.2.5 Inhibition of the injection by ENSD

```
IF      LV_IGN_INJ_LOCK_REQ = 1          or
        (LC_INJ_LOCK_REQ_TMP = 1         and
        LV_INJ_LOCK_REQ_TMP = 1)

THEN
    INH_IV_IGN_INJ_LOCK_REQ = $2^{NC\_CYL\_NR} - 1$ (Input pattern)
ELSE
    INH_IV_IGN_INJ_LOCK_REQ = 0x00 (Input pattern)
ENDIF
```

41.30.1.2.6 Inhibition of the injection by injection valve diagnosis error

```
IF (LC_INH_IV_DIAG_ERR_IMDT_ENA = 1)
   OR                                                   ... logical
   ((INH_IV_DIAG_ERR AND INH_IV_MIS) ≠ 0)               ... bitwise
THEN
     INH_IV_DIAG_ERR (Input pattern)
ELSE
     0x00 (Input pattern)
ENDIF
```

41.30.1.2.7 Inhibition of the injection by pre-ignition knock control

Cylinder individual shut off in case of knock pre-ignition	INH_IV_KNK (Input pattern)

41.30.1.2.8 FTL_MIN diagnosis

Cylinder individual shut off in case of less fuel	INH_IV_FTL_MIN

41.30.1.2.9 Inhibition of the injection by customer

Cylinder individual shut off by customer request	INH_IV_CUS

41.30.1.2.10 Workshop tester

Cylinder individual shut off by KWP-job, sent from tester:	INH_IV_KWP

41.30.1.2.11 Inhibition due to Clock Drift in ATIC88 or over voltage in injector

```
For i = 0 to NC_CYL_NR - 1
{
Bit i of INH_IV_CLK_DRIFT = LV_ERR_CLK_DRIFT_PBK_IV[i]
}
```

41.30.1.2.12 Inhibition of the injection for engine shut down due to stop request

INH_IV_STST (Input pattern)

41.30.1.2.13 Inhibition of the injection due to injector power bank errors

Cylinder individual shut off in case of injector power bank errors

INH_PBK_IV_DIAG_ERR

41.30.1.3 Coordination of the Static Fuel Shut Off Requirements

The output pattern INH_IV_EXT is the bitwise OR of all patterns INH_IV_XYZ (and INH_PBK_IV_DIAG_ERR). As an example see below:

INH_IV_XYZ =	0	0	0	0	0	0	0	0
INH_IV_XYZ =	0	0	0	0	0	**1**	0	0
INH_IV_XYZ =	0	0	0	**1**	0	**1**	0	0
:					:			
INH_IV_EXT =	0	0	0	**1**	0	**1**	0	0

Calibration data:

FUNCTION DESCRIPTION:

General information:

This specification is for project specific adaptations.

41.31.1 Runtime reduction

Description:

This chapter describes runtime reduction steps. First step is to reduce cylinder dependent calculations from all cylinders to one cylinder, dependent on the engine speed. An additional step is to reduce bank dependent calculations to that intake or exhaust bank, which is allocated to the related cylinder by NC_IN_REF and NC_LAMB_REF. The control variables for cylinder and bank dependent calculations will be imported via CTR_CYL_NR_xxx and CTR_CBK_xxx data.

Application conditions :

Activation :	every engine state
Deactivation :	-
Initialization:	-
Recurrence :	LV_ST_END = 0: 10 ms LV_ST_END = 1: segment sychronous

Formula Section :

For loop for runtime optimization:

In this specification the for loop

```
FOR i = 0, i < NR_CYL_CLC_RED_INJ DO
        x = CTR_CYL_NR_ST_CLC_INJR + i
        (1a)IF x  >= NC_CYL_NR
        (1a)THEN
              x = x – NC_CYL_NR
        (1a)ENDIF
        <loop content>
ENDFOR
```

is substituted by

```
FOR cylinder_start to cylinder_stop DO
    <loop content>
ENDFOR
```

Note: In the for loops, x will be used as loop variable to indicate the cylinder x!

Determine cylinder and bank numbers for follow up calculations

```
CTR_CYL_NR_ST_CLC_INJR          = CTR_CYL_NR_ST_CLC
CTR_CYL_NR_STOP_CLC_INJR        = CTR_CYL_NR_STOP_CLC
CTR_CBK_IN_NR_ST_CLC_INJR       = CTR_CBK_IN_NR_ST_CLC
CTR_CBK_IN_NR_STOP_CLC_INJR     = CTR_CBK_IN_NR_STOP_CLC
CTR_CBK_EX_NR_ST_CLC_INJR       = CTR_CBK_EX_NR_ST_CLC
CTR_CBK_EX_NR_STOP_CLC_INJR     = CTR_CBK_EX_NR_STOP_CLC
```

Note: NR_CYL_CLC_RED_INJ has to be greater than zero and less or equal than NC_CYL_NR;

```
(1)IF LC_LOAD_CPU_RED_INJ = 0
    OR CTR_CYL_NR_ST_CLC_INJR ≠ 0
    OR CTR_CYL_NR_STOP_CLC_INJR ≠ (NC_CYL_NR – 1)
    OR LV_ST_END = 0
    OR SUM(LV_LAM_AD_INJ_CUS_ACK[ ]) ≠ 0     // sum over all elements; at least one
                                               exhaust-bank requests MFMA
(1)THEN
    NR_CYL_CLC_RED_INJ = CTR_CYL_NR_STOP_CLC_INJR
                                  - CTR_CYL_NR_ST_CLC_INJR + 1
(1)ELSE
  (2)IF SEG_NR < C_NR_CYL_OFS_CLC_RED_INJ
  (2)THEN
    CTR_CYL_NR_STOP_CLC_INJR = NC_CYL_NR + SEG_NR
        - C_NR_CYL_OFS_CLC_RED_INJ
  (2)ELSE
    CTR_CYL_NR_STOP_CLC_INJR = SEG_NR - C_NR_CYL_OFS_CLC_RED_INJ
  (2)ENDIF
  NR_CYL_CLC_RED_INJ = ID_NR_CYL_CLC_RED_INJ(Input: N)
  (3)IF CTR_CYL_NR_STOP_CLC_INJR < (NR_CYL_CLC_RED_INJ – 1)
  (3)THEN
          CTR_CYL_NR_ST_CLC_INJR = NC_CYL_NR
              + CTR_CYL_NR_STOP_CLC_INJR - NR_CYL_CLC_RED_INJ + 1
    (3)ELSE
```

```
    CTR_CYL_NR_ST_CLC_INJR = CTR_CYL_NR_STOP_CLC_INJR
        - NR_CYL_CLC_RED_INJ + 1
  (3)ENDIF
(1)ENDIF
```

41.31.2 General tasks

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset : FAC_TI_EXT_ADJ = 1
LV_TI_EXT_ADJ[NC_CYL_NR] = 0
TI_EXT_ADJ[NC_CYL_NR] = 0

Recurrence : LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Formula Section :

To prevent N_FAST_INJ from signal jittering a hysteresis for the calculation is introduced:

```
(1) IF (N > = C_N_TOOTH_END)
(1) THEN
    LV_N_TOOTH_END_ACT = 1
(1) ELSE
    (2) IF (N <  C_N_TOOTH_END - 100)
    (2) THEN
            LV_N_TOOTH_END_ACT = 0
    (2) ENDIF
(1) ENDIF
(3) IF (LV_N_TOOTH_END_ACT = 1)
(3) THEN
    N_FAST_INJ = N
(3) ELSE
    N_FAST_INJ = N_TOOTH_CUS
(3) ENDIF

(4) IF (LV_ST_INJ = 0)
(4) THEN
   LV_MFF_SP_HOM_VLD = 0
   (1) FOR x = 0 TO (NC_CYL_NR -1)
            (2) IF ((Mk_soll_h[x][0] > 0) OR (Mk_soll_h[x][1] > 0) OR (Mk_soll_h[x][2] > 0))
            (2) THEN
                    LV_MFF_SP_HOM_VLD = 1
            (2) ENDIF
   (1) END FOR
   (5) IF (LV_MFF_SP_HOM_VLD = 1) AND (LV_ST_INJ_AUTH = 1)
   (5) THEN
            LV_ST_INJ_REQ = 1
   (5) ELSE
            LV_ST_INJ_REQ = 0
   (5) ENDIF
(4) ELSE
            LV_ST_INJ_REQ = 0
```

```
(4) ENDIF

TFU_INJ = TFU_IV
FAC_N = N_FAST_INJ  * 360 / (1000 * 60)
LV_FAC_TI_EXT_ADJ = 0
FAC_TI_EXT_ADJ = 1
LV_PRS_COR_SNGH_ENA = LV_PRS_COR_SNGH_ENA_CUS
LV_PRS_COR_MPLH_ENA = LV_PRS_COR_MPLH_ENA_CUS
(2)FOR cylinder_start to cylinder_stop DO
    LV_TI_EXT_ADJ[x] = 0
    TI_EXT_ADJ[x]= 0
(2) END FOR
FUP_H_INJ[0] = FUP_H
FUP_H_SP_S_INJ[0] = FUP_H

(6)IF LC_MAP_PHY_CLC_ENA = 1
(6)THEN – physical calculation of cylinder pressure at inlet closing
    The cylinder pressure is calculated by use of the ideal gas law:
            $p = m * T * R_S/V$
    $R_S/V$ as well as the unit conversions (1hPa = 100N/m² and 1rpm = 30stk/h) is included in
    C_FAC_MAP_TCYL_MDL (C_FAC_MAP_TCYL_MDL = $R_S/(V*3000)$).
    MAP_INJ[0] = MAF_CYL * TCYL_MDL_CUS * C_FAC_MAP_TCYL_MDL / N
(6)ELSE
    MAP_INJ[0] = MAP

(6)ENDIF

LV_INJ_PUC_ENA = 0
LF_IV_INH_PUC_EXT = 255 // all bits must be set to 1
```

41.31.3 Compensation of missing residual-gas amount after PUC

Description:

This chapter describes the compensation of missing residual-gas amount at restart of fuel feed. This is caused by a inhibit of injection in the past. At restart of fuel feed for the first combustion residual-gas amount is missing. Therfore the calculated fuel amount is wrong. This functionality should compensate this effect.

Application conditions :

Activation :	LV_ST_END = 0
Deactivation :	-
Initialization:	-
Recurrence :	10 ms

Formula Section :

```
FOR x = 0 TO NC_CYL_NR-1
    MFF_ADD_REAC[x] = 0
END FOR
```

Application conditions :

Activation :	LV_ST_END = 1
Deactivation :	-
Initialization:	-
Recurrence :	segment sychronous

Formula Section :

```
(1)IF LC_MFF_ADD_REAC_ENA = 1
(1)THEN
    FOR cylinder_start to cylinder_stop DO
        IF (Bit-Nr x of PREV_STATE_IV = 0)
        THEN
            MFF_ADD_REAC[x] = IP_MFF_ADD_REAC
            Input for IP_MFF_ADD_REAC is (MFF_SP_1_HOM[x], N)
        ELSE
            MFF_ADD_REAC[x] = 0
        ENDIF
    END FOR
(1)ENDIF
```

41.31.4 Injector test mode

Application conditions:

Activation: LV_ES = 1

Deactivation: -

Initialization: -

Recurrence: 1 s

This chapter describes the necessary interfaces to the procedure for actuator tests by diagnostic tester.

41.31.4.1 Formula Section:

```
LV_IV_TEST_MOD_AUTH = 0
NR_CYL_IV_TEST_MOD = 0
(1) FOR x = 0 TO (NC_CYL_NR -1)
    CTR_TEST_MOD_IV_EXT[x] = CTR_TEST_MOD_IV[x]
(1) END FOR
```

Please note! This for-loop should be realized in SW with a #define. CTR_TEST_MOD_IV_EXT[NC_CYL_NR] has to be realized also as a #define for CTR_TEST_MOD_IV to preserve resources.

41.31.5 Crash signal reaction of injection driver

Application conditions:

Activation: every engine state

Deactivation: -

Initialization: -

Recurrence: 10 ms

This chapter describes the necessary interfaces to customer signals to react on a vehicle crash.

41.31.5.1 Formula Section:

```
(1) IF STATE_EFP_CRASH_CAN = 2H
(1) THEN
    LV_INJ_CRASH_ACT = 1
(1) ELSE
    LV_INJ_CRASH_ACT = 0
(1) ENDIF
```

41.31.6 Select injection mode STATE_INJ_MOD_REQ and copy information of dynamic needle lift selection from customer nomenclature to SV nomenclature

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset : STATE_INJ_MOD_REQ = 'DISABLE'
STATE_INJ_MOD_HOM_REQ = 'SNGH'
STATE_INJ_MOD_S_REQ = 'SNGS'
STATE_INJ_MOD_HOMS_REQ = 'HOMS-SNG'
LFT_L_IV_HOM_REQ = 0
LFT_L_IV_S_REQ = 0
INJ_MOD_GLOBAL = "DISABLE"
STATE_INJ_MOD_SWI_ACT = 0

at engine run to engine stop event: INJ_MOD_GLOBAL = "DISABLE"
STATE_INJ_MOD_SWI_ACT = 0

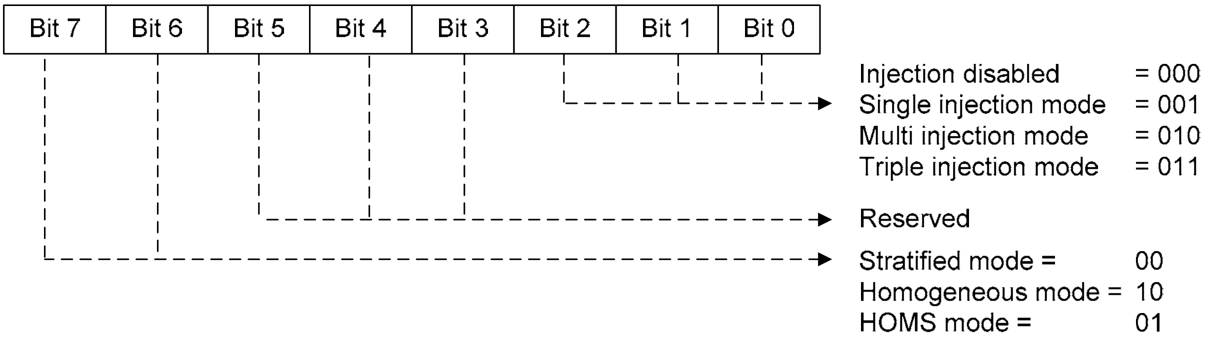
Recurrence : LV_ST_END = 0: 10 ms
LV_ST_END = 1: segment synchronous

Description:

This section determines the actual set injection mode request.

Byte definition

Definitions bit masks for injection modes: STATE_INJ_MOD_REQ, STATE_INJ_MOD_HOM_REQ, STATE_INJ_MOD_S_REQ and STATE_INJ_MOD_HOMS_REQ



Example: homogenous multi injection mode (MPLH)

1	0	0	0	0	0	1	0

The mapping of the information about injector needle lift selection is done from a bit field as input to bit field as output. Here, the conversion from customer pulse numeration to SV numeration is done.

Important note: For better readability of the specification, the LSB of each bit field, which corresponds to the physically first injection pulse, is referred to as bit 1 (**not** bit 0 as it would be in SW). The next bit would be bit 2 etc.

Definition of NC constants

NC_INJ_MOD_SINGLE = 0x01H

Formula Section :

    (1)ENDIF
(1)ENDFOR
```

41.31.7 Calculation of injection fixed update window and ignition update window

Application conditions :

Activation : every engine state

Deactivation : -

Initialization: at reset : **calculate Formula Section**

Recurrence : 1s

Description:

This section calculates the crank windows for ignition and injection update. The initialization routine at reset is the same as the time synchronous routine (1s)!

Formula Section :

```
CRK_PSN_STAT_WIN_ST = C_CRK_PSN_STAT_WIN_ST
(1)IF CRK_PSN_STAT_WIN_ST >= ((720°/NC_CYL_NR)*1.1)
(1)THEN
    CRK_PSN_STAT_WIN_ST = ((720°/NC_CYL_NR)*1.1)
    CRK_PSN_STAT_WIN_END = 720°
(1)ELSE
    CRK_PSN_STAT_WIN_END = 720° - ((720°/NC_CYL_NR)*1.1
                                            - CRK_PSN_STAT_WIN_ST)
(1)ENDIF
CRK_PSN_STAT_IGN_UPD_ST = C_CRK_PSN_STAT_IGN_UPD_ST
CRK_PSN_STAT_IGN_UPD_END = C_CRK_PSN_STAT_IGN_UPD_END
```

41.31.8 Description of exported actions

41.31.8.1 Description of ACTION_INJR_SetStateInjUpdEna

ACTION_INJR_SetStateInjUpdEna(IN <Cyl>, IN <State_Inj_Upd_Ena>)

This action sets the cylinder individual bit <Cyl> of STATE_INJ_UPD_ENA to <State_Inj_Upd_Ena>.

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
Cyl	IN	0 ... 7	0 ... 7	1	-
Number of logical cylinder.					
State_Inj_Upd_Ena	IN	0 ... 1	0 ... 1	1	-
Logical value for setting or resetting the corresponding cylinder value.					

Formula Section:

Bit Cyl of STATE_INJ_UPD_ENA = State_Inj_Upd_Ena

Note: The LSB of STATE_INJ_UPD_ENA is referred to as Bit 0 (zero based indication)!

41.31.9 Detection of locked injection driver, fault reaction and diagnosis

This function detects a locked injection driver and generates a resync to restart the driver. Additionally, a failure memory entry is done.

41.31.9.1 Detection of locked injection driver – segment synchronous task

Application conditions :

Activation: every engine state

Deactivation: -

Initialization: at reset: CTR_SEG_EOC_INJ[ ] = 0 // all NC_PBK_IV_NR elements
CTR_SEG_EOC_INJ_ERR[ ] = 0
// all NC_PBK_IV_NR elements
ACTION_ERRM_NoFilterReset(
IN<NC_IDX_DIAG_SEG_EOC_INJ>,
OUT<LV_ERR_SEG_EOC_INJ>)

at engine stop to engine run and at clearing of error memory:
CTR_SEG_EOC_INJ[ ] = 0 // all NC_PBK_IV_NR elements
CTR_SEG_EOC_INJ_ERR[ ] = 0
// all NC_PBK_IV_NR elements

Recurrence: segment synchronous

Description:

This function shall detect a locked injection driver on one or more injection banks indiviually. The detection criteria are missing end of cycle (EOC) events. Theoretically, only a limited number of segments may occure between two EOC events on one injection bank. If more than this amount of segments occure before the next EOC event, the conclusion is that EOC events are missing. To get the injection drivers alive again, it is set to mode DISABLED and then to SEQUENTIAL again to trigger a resynchronization. Also, a failure memory entry is done.

Configuration for diagnostic symptoms:

Diagnostic SEG_EOC_INJ	Symptom description	Symptom	Filter type
Injection dirver lock detection diagnosis	Injection driver lock detection on injection bank 0 (physical bank 1)	*SYM_0*	NO
	Injection driver lock detection on injection bank 1 (physical bank 2)	*SYM_1*	
	not used	*SYM_2*	
	not used	*SYM_3*	

Formula Section:

Reset condition flag and error symptom flag for diagnosis function:

LV_CDN_DIAG_SEG_EOC_INJ = 0
ERR_SYM_SEG_EOC_INJ = NO_SYM

```
(0)IF C_CTR_SEG_EOC_INJ_MAX_PLAUS > 0
      // Function is disabled in case of C_CTR_SEG_EOC_INJ_MAX_PLAUS = 0
(0)THEN
  Segment counter since last EOC event:
  (1)FOR i = 0 TO NC_PBK_IV_NR – 1 DO
    (2)IF STATE_PBK_IV_INI = "INIT_FINISHED"    // injection banks initialized ...
      AND (STATE_ERR_PBK_IV_ST_RAW[i] = 0       // ... without errors or ...
             OR STATE_ERR_PBK_IV_ST_RAW[i] = 10hex)
                                                // ...  only with trim pulse error
      AND STATE_INJ_DR = "RUN"                  // injection driver is not in disable mode
      AND STATE_INJ_CRASH_ACT = 00hex           // injection driver is not in static mode
                                                           due to crash reaction
      // injection driver is not in static mode due to test mode
                 (LV_IV_TEST_MOD_AUTH is always zero => test mode is nerver active)
    (2)THEN
      Increment CTR_SEG_EOC_INJ[i] by 1
      Set diagnosis condition flag to indicate that diagnosis is active:

            IN<lv_end_diag = 1>, OUT<LV_ERR_SEG_EOC_INJ> )
(0)ENDIF
```

41.31.9.2 Detection of locked injection driver – end of cycle synchronous task

Application conditions :

Activation:	every engine state
Deactivation:	-
Initialization:	-
Recurrence:	INJ EOC synchronous (every end of cycle trigger)

Description:

At an EOC event, the segment counter for the bank that reached the EOC shall be reset to zero to indicate that the driver bank is still alive.

Formula Section:

Note: x represents the cylinder number that reached its EOC. The EOC trigger provides the cylinder number x that reached its EOC.

Reset segment counter for the injection bank that reached an EOC event:

CTR_SEG_EOC_INJ[NC_IDX_CYL_PBK_IV_REF[x]] = 0

41.32 Injection valves diagnosis

Overview

The purpose of the diagnosis is to detect electrical faults as defined by OBD I requirements. STATE_ERR_IV is the general error state after de-bouncing for limp-home reactions.

All symptoms of the current error code are handled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

The error detection is effected via the ECU hardware.

Please Note:
A valid diagnosis of all failures can only be detected when the injector was operated at least one time since the last changes and the filter times are observed.

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_DIAG_IV	V/O	0...FFH	0...255	1	[-]
Error pattern without debouncing for all injectors

41.32.1 Electrical Injection Valve Diagnosis – selection of the current cylinder number

Determine the previous cylinder:

NR_CYL_INJ_BAS_PREV_DIAG_IV_TMP = NR_CYL_INJ_BAS_PREV

Determine the current cylinder:

NR_CYL_INJ_BAS_DIAG_IV_TMP = NR_CYL_INJ_BAS

Check cylinder numbers under consideration of re-entrance capability:

```
(1) IF NR_CYL_INJ_BAS_ PREV_DIAG_IV_TMP ≠ NR_CYL_INJ_BAS_PREV
(1) THEN
    NR_CYL_INJ_BAS_PREV_DIAG_IV_TMP = NR_CYL_INJ_BAS_PREV
    NR_CYL_INJ_BAS_DIAG_IV_TMP = NR_CYL_INJ_BAS
(1) ENDIF
```

41.32.2 Electrical Injection Valve Diagnosis – diagnosis routine call

```
(1) IF NR_CYL_DIAG_IV = NR_CYL_INJ_BAS_DIAG_IV_TMP
(1) THEN
    Nothing to do! The last diagnosis cycle is equal to the current.
(1) ELSE
    Diagnosis Cycle has to be done:
    (1) IF NR_CYL_DIAG_IV ≠ NR_CYL_INJ_BAS_PREV_DIAG_IV_TMP
    (1) THEN
        Diagnosis Cycle has to be done for the previous cylinder, because its missing:
        EXECUTE "41.32.3 Common Diagnosis Operations" for cylinder x =
                                      NR_CYL_INJ_BAS_PREV_DIAG_IV_TMP
    (1) ENDIF
    Diagnosis Cycle has to be done for the current cylinder:
    EXECUTE "41.32.3 Common Diagnosis Operations" for cylinder x =
                                      NR_CYL_INJ_BAS_DIAG_IV_TMP
    Update cylinder number of the done diagnosis cycle:
    NR_CYL_DIAG_IV = NR_CYL_INJ_BAS_DIAG_IV_TMP
(1) ENDIF
```

41.32.3 Common Diagnosis Operations

This section works like a subroutine call in C-code programs
Note! x represents the current assigned active cylinder number from calling section.

```
(1) IF   (LV_INH_DIAG_IV = 0)
         AND
         (LV_CDN_VB_OBD1 = 1)
         AND
         (LV_ES = 0)
         AND
         (LV_FL = 0)
         AND
         (TI_1_MES[x] >= C_TI_THD_INH_DIAG_IV)
         AND

```

ACTION_ERRM_FilterMulticondition (IV[x], CDN_DIAG_IV[x], ERR_DIAG_IV[x], LV_END_DIAG_IV[x], LV_ERR_IV[x], LV_CDN_DIAG_IV[x], ERR_SYM_IV[x])

Note: For failure debouncing and error management treatment the multicondition debounce algorithm (part of Error Management AGGR) is used with the parameters CDN_DIAG_IV[x] and ERR_DIAG_IV[x].

This algorithm determines:

ERR_SYM_IV [x] (= raw value ERR_DIAG_IV [x] filtered with CDN_DIAG_IV [x])

and

LV_ERR_IV [x] (Error flag for debounced error of Injector [x])

and

LV_CDN_DIAG_IV [x]

and

LV_END_DIAG_IV [x]

Calculation of STATE_DIAG_IV:

```
(11) IF      ERR_SYM_IV [x] <> 0
(11) THEN    Bit x of STATE_DIAG_IV = 1
(11) ELSE    Bit x of STATE_DIAG_IV = 0
(11) ENDIF
```

Calculation of STATE_ERR_IV:

Bit x of STATE_ERR_IV = LV_ERR_IV [x]

Calculation of detailed SC error information:

```
(12) IF LV_ERR_IV[x] 0 → 1
(12) THEN
    (13) IF Bit HG of STATE_ERR_IV_CYL[x] is set
    (13) THEN
        ERR_SYM_IV_SC_TMP = SYM_0 (HG-Error detected)
    (13) ELSE
        (14) IF Bit LB of STATE_ERR_IV_CYL[x] is set
        (14) THEN
            ERR_SYM_IV_SC_TMP = SYM_1 (LB-Error detected)
        (14) ELSE
            (15) IF Bit HB of STATE_ERR_IV_CYL[x] is set
            (15) THEN
                ERR_SYM_IV_SC_TMP = SYM_2 (HB-Error detected)
            (15) ELSE
                (16) IF Bit LG of STATE_ERR_IV_CYL[x] is set
                (16) THEN
                    ERR_SYM_IV_SC_TMP = SYM_3 (LG-Error detected)
                (16) ELSE
                    ERR_SYM_IV_SC_TMP = NO_SYM (Not a detailed SC-Error was detected
                                                or HL-Error was detected)
                (16) ENDIF
            (15) ENDIF
        (14) ENDIF
    (13) ENDIF
    ERR_SYM_IV_SC[x] = ERR_SYM_IV_SC_TMP

(18) THEN
        STATE_ERR_IV_CYL[x] = 0
(18) ENDIF
```

Please Note! Synchronization of LV_CDN_DIAG_IV_SC[x] with LV_CDN_DIAG_IV[x] and LV_END_DIAG_IV_SC[x] with LV_END_DIAG_IV[x] by parameter passing to ACTION_ERRM_NoFilterSymptom.

41.33 Injection valve diagnosis for ATIC 63 PIEZO injection driver (Application Incidences)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_IV	V/O	0...1H	0...1	1	[-]
Inhibition condition for the IV diagnostic					
LV_ERR_IV_LST_CYC	V/O/S	0...1H	0...1	1	[-]
Flag that indicates if a debounced injector error is present at the end of the driving cycle					
INH_IV_DIAG_ERR	V/O	0...FFH	0...255	1	[-]
Cylinder shut off request from injection valve diagnosis (cylinder allocated)					
INJ_DR_CYL_REF[NC_CYL_NR]	O/V	0...FFH	0...255	1	[-]
Assignment between logical cylinders and injector drivers					

Input data:

STATE_ERR_IV	LV_IGK	TCO	ERR_SYM_IV[NC_CYL_NR]
NC_CYL_NR	NC_IDX_CYL_PBK_IV_REF[NC_CYL_NR]		

Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
C_TCO_THD_INH_DIAG_IV	1	0...FEH	-48...142.5	0.75	[°C]
TCO threshold below which the injector diagnosis is inhibited					
LC_INH_IV_DIAG_ERR_ENA	1	0...1H	0...1	1	[-]
Manual switch for activation of INH_IV_DIAG_ERR					

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_IV deactivates (freezes) the power stage diagnostic of all injection valves.

The injector diagnosis has to be deactivated in case of:

- TCO is below the threshold C_TCO_THD_INH_DIAG_IV

If a de-bounced injector error is present at the end of the driving cycle (LV_ERR_IV = 1), the flag LV_ERR_IV_LST_CYC is set and is stored in the permanent RAM.

41.33.1 Calculation of INJ_DR_CYL_REF[NC_CYL_NR]

Application conditions:

Activation:	every engine state
Deactivation:	-
Initialisation:	-

Recurrence: only once at reset

Formula section:

The variable INJ_DR_CYL_REF[x] represents an inhibit pattern where all cylinders on the same bank as cylinder x are inhibited (corresponding bits are set to 1) due to injection valve errors.

Calculation of INJ_DR_CYL_REF[NC_CYL_NR]:
Note: m reveres to the injection power stage bank within this loop

```
FOR x = 0 TO NC_CYL_NR – 1 DO
    INJ_DR_CYL_REF[x] = 0
    m = NC_IDX_CYL_PBK_IV_REF[x]
    FOR y = 0 TO NC_CYL_NR – 1 DO
        IF NC_IDX_CYL_PBK_IV_REF[y] = m  // cylinder y is on bank m
        THEN
            Bit y of INJ_DR_CYL_REF[x] = 1
        ENDIF
    ENDFOR
ENDFOR
```

41.33.2 Calculation of LV_INH_DIAG_IV

Application conditions:

Activation: every engine state

Deactivation: -

Initialisation: at reset: LV_INH_DIAG_IV = 1

Recurrence: 100 ms and 'at first valid tooth'

Formula section:

```
(1) IF
TCO < C_TCO_THD_INH_DIAG_IV
(1) THEN
LV_INH_DIAG_IV = 1
(1) ELSE
LV_INH_DIAG_IV = 0
(1) ENDIF
```

41.33.3 Calculation of LV_ERR_IV_LST_CYC

Application conditions:

Activation: LV_IGK = 1 → 0

Deactivation: -

Initialisation: -

Recurrence: only once at LV_IGK = 1 → 0

Formula section:

(1) IF

STATE_ERR_IV ≠ 0

(1) THEN

LV_ERR_IV_LST_CYC = 1

(1) ELSE

LV_ERR_IV_LST_CYC = 0

(1) ENDIF

Note: In case of "checksum error" after power latch or reset the flag LV_ERR_IV_LST_CYC has to be set to zero.

41.33.4 Shut off request from injection valve diagnosis

General information:

In this chapter the diagnosis information for ATIC 63 PIEZO driver will be analysed. In the case of a short circuit error (SC) except the case of a high side to low side short circuit error (HL) all the injectors, which are connected to the same injection driver have to be switched off to prevent wrong fuel mass on not affected injection valves. In the case of an OC or HL error only the injector with a diagnosed error has to be switched off.

Application conditions:

Activation: LV_IGK = 1

Deactivation: -

Initialisation: at reset, at transition of LV_IGK 0 -> 1 and at global clearing of failure memory DO:
INH_IV_DIAG_ERR = 0

Recurrence: segment synchronous

Note: The chapter 41.33.4 Shut off request from injection valve diagnosis has to be calculated after the module "Injection valve diagnosis".

Formula section:

```
(1) IF (STATE_ERR_IV ≠ 0) AND (LC_INH_IV_DIAG_ERR_ENA = 1)
(1) THEN
      INH_IV_DIAG_ERR = STATE_ERR_IV
      (Switch off all injectors with an error symptom)
      (1) FOR x = 0 TO (NC_CYL_NR –1 ) DO:
        (2) IF (Bit x of STATE_ERR_IV = 1) AND (ERR_SYM_IV[x] = 'SC-Error')
              (Check if a short circuit error (without HL-error) was detected)
        (2) THEN
              (Switch off all the injectors which are connected to the same driver additionally)
              INH_IV_DIAG_ERR =          INH_IV_DIAG_ERR
                                    OR                                    ...bitwise
                                         INJ_DR_CYL_REF[x]
        (2) END IF
      (1) END FOR
(1) ELSE
      INH_IV_DIAG_ERR = 0
(1) ENDIF
```

41.34 Injection valves power stage diagnosis

Overview

The purpose of the injection valve power stage diagnosis is to detect electrical faults of used ATIC drivers. STATE_ERR_PBK_IV is the general error state after de-bouncing for limp-home reactions.

All symptoms of the current error code are handled by anti-bouncing.
We assume that only one symptom of an error code can be active at the same time.

The error detection is effected via the ECU hardware.

Please Note:
A valid diagnosis of all failures can only be detected when the injector was operated at least one time since the last changes and the filter times are observed.

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_DIAG_PBK_IV	V/O	0...FFH	0...255	1	[-]
Error pattern without debouncing for all injection valve power stages					
LV_ERR_PBK_IV[NC_PBK_IV_NR]	V	0...1H	0...1	1	[-]
Error flag for injection valve power stage bank errors derived from STATE_ERR_PBK_IV (only for display)					
STATE_ERR_PBK_IV	V/O	0...FFH	0...255	1	[-]
Error pattern after debouncing for all injection valve power stages					
LV_CDN_DIAG_PBK_IV[NC_PBK_IV_NR]	V	0...1H	0...1	1	[-]
Diagnosis condition for injection valve power stage bank					
LV_END_DIAG_PBK_IV[NC_PBK_IV_NR]	V	0...1H	0...1	1	[-]
End of diagnosis for injection valve power stage bank					
ERR_DIAG_PBK_IV[NC_PBK_IV_NR]	-	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]

Error symptom for injection valve power stage bank filtered with CDN_DIAG_PBK_IV					
CDN_DIAG_PBK_IV[NC_PBK_IV_NR]	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Diagnosis condition for each error symptom of injection valve power stage bank					
STATE_ERR_SYM_PBK_IV[NC_PBK_IV_NR]	V/O	0...FFH	0...255	1	[-]
Detailed error symptom information of injection valve power stages, ATIC bank individual					
STATE_ERR_SYM_PBK_IV_ST[NC_PBK_IV_NR]	V/O	0...FFH	0...255	1	[-]
Detailed error symptom information of injection valve power stages during startup phase, ATIC bank individual					

Input data:

LV_ES	STATE_ERR_PBK_IV_RAW[NC_PBK_IV_NR]	CDN_DIAG_PBK_IV_RAW[NC_PBK_IV_NR]	STATE_ERR_PBK_IV_ST_RAW[NC_PBK_IV_NR]
STATE_PBK_IV_INI	LV_INH_DIAG_PBK_IV	NC_PBK_IV_NR	LV_IGK
SEG_NR			

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_PBK_IV	1	0...FFH	0...255	1	[-]
Anti-bounce increment value for injection valve power stage diagnosis					
C_ABC_MAX_PBK_IV	1	1...FFH	1...255	1	[-]
Anti-bounce maximum value for injection valve power stage diagnosis					
C_STATE_ERR_SYM_PBK_IV_INH	1	0...FFH	0...255	1	[-]
Manual inhibition pattern for injection valve power stage online diagnosis symptom (bit x = 1, diagnosis symptom will be inhibited)					
C_STATE_ERR_SYM_PBK_IV_ST_INH	1	0...FFH	0...255	1	[-]
Manual inhibition pattern for injection valve power stage startup diagnosis symptom (bit x = 1, diagnosis symptom will be inhibited)					

Import actions:

ACTION_ERRM_FilterMulticondition(IN< *XX* >, IN< CDN_DIAG_XX >, IN< ERR_DIAG_XX >, IN<C_ABC_INC_XX>, IN<C_ABC_MAX_XX>,OUT<LV_ERR_XX>)
This action compute the elementary antibounce filter for one failure treatment and return filter result

Configuration for diagnostic symptoms:

Diagnosis	Symptom	Nr	ABC type
Injection valves power stage diagnosis	*Power stage startup error*	*0*	MPL_STD_INI
	Power stage online error	*1*	
	Power stage discharge error	*2*	
PBK_IV[p]			

FUNCTION DESCRIPTION:

Application conditions:

Activation : (LV_IGK = 1) **AND** (STATE_PBK_IV_INI = "INIT_FINISHED")

Deactivation: at transition of LV_IGK 1 -> 0 DO:
LV_CDN_DIAG_PBK_IV[NC_PBK_IV_NR] = 0
CDN_DIAG_PBK_IV[NC_PBK_IV_NR] = NO_SYM

Initialization: at reset , at transition of LV_IGK 0 -> 1 and at global clearing of failure memory DO:
STATE_DIAG_PBK_IV = 0
STATE_ERR_PBK_IV = 0
STATE_ERR_SYM_PBK_IV[NC_PBK_IV_NR] = 0
STATE_ERR_SYM_PBK_IV_ST[NC_PBK_IV_NR] = 0
all other output data according filter type by ERRM

Recurrence: LV_ES = 0: segment synchronous
LV_ES = 1: 10 ms

Formula section:

LC_DIAG_INH_PBK_IV_ERR_ENA	1	0...1H	0...1	1	[-]
Flag to enable inhibition of cylinders due to injection power bank errors					
LC_DIAG_INH_PBK_IV_ERR_ST_ENA	1	0...1H	0...1	1	[-]
Flag to enable inhibition of cylinders due to injection power bank start up errors					

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_PBK_IV deactivates (freezes) the power stage online diagnostic of all injection valve drivers.

If a de-bounced injector error is present at the end of the driving cycle (LV_ERR_PBK_IV = 1), the flag LV_ERR_PBK_IV_LST_CYC is set and is stored in the non-volatile memory.

The variable INJ_DR_PBK_IV_REF[NC_PBK_IV_NR] represents an inhibit pattern, which inhibits all cylinders assigned to the injection power bank revered to by the array index.

41.35.1 Calculation of INJ_DR_PBK_IV_REF[NC_PBK_IV_NR]

Application conditions:

Activation:	every engine state
Deactivation:	-
Initialisation:	-

Recurrence: only once at reset

Formula section:

The variable INJ_DR_PBK_IV_REF[p] represents an inhibit pattern where all cylinders on bank m are inhibited (corresponding bits are set to 1) due to injection power bank errors.

Initial value:

```
FOR p = 0 TO NC_PBK_IV_NR – 1 DO
    INJ_DR_PBK_IV_REF[p] = 0
ENDFOR
```

Calculation of INJ_DR_PBK_IV_REF[NC_PBK_IV_NR]:

```
FOR x = 0 TO NC_CYL_NR – 1 DO
    Bit x of INJ_DR_PBK_IV_REF[NC_IDX_CYL_PBK_IV_REF[x]] = 1
ENDFOR
```

41.35.2 Calculation of LV_INH_DIAG_PBK_IV

Application conditions:

Activation: (LV_IGK = 1) AND (STATE_PBK_IV_INI = "INIT_FINISHED")

Deactivation: -

Initialisation: at reset, at transition of LV_IGK 0 -> 1 DO:
LV_INH_DIAG_PBK_IV = 1
INH_PBK_IV_DIAG_ERR = 0

Recurrence: segment synchronous

Formula section:

```
LV_INH_DIAG_PBK_IV = 0

(1)IF STATE_ERR_PBK_IV ≠ 0
(1)THEN
    (1)FOR p = 0 TO NC_PBK_IV_NR – 1 DO
          (2)IF (Bit p of STATE_ERR_PBK_IV = 1)
             AND (ERR_SYM_PBK_IV[p] BitwiseAND SYM_0 = SYM_0)
             AND (STATE_ERR_SYM_PBK_IV_ST[p] ≠ 0x10) // no trim pulse error
             AND (LC_DIAG_INH_PBK_IV_ERR_ST_ENA = 1)
          (2)THEN
```

```
                INH_PBK_IV_DIAG_ERR = INH_PBK_IV_DIAG_ERR BitwiseOR
                                      INJ_DR_PBK_IV_REF[p]
            (2)ENDIF
            (3)IF (Bit p of STATE_ERR_PBK_IV = 1)
               AND (ERR_SYM_PBK_IV[p] ≠ SYM_0)
               AND (LC_DIAG_INH_PBK_IV_ERR_ENA = 1)
            (3)THEN
                INH_PBK_IV_DIAG_ERR = INH_PBK_IV_DIAG_ERR BitwiseOR
                                      INJ_DR_PBK_IV_REF[p]
            (3)ENDIF
        (1)ENDFOR
    (1)ELSE
        INH_PBK_IV_DIAG_ERR = 0
    (1)ENDIF
```

41.35.3 Calculation of LV_ERR_PBK_IV_LST_CYC

Application conditions:

Activation:	LV_IGK = 1 → 0
Deactivation:	-
Initialisation:	-
Recurrence:	only once at LV_IGK = 1 → 0

Formula section:

```
(1) IF
STATE_ERR_PBK_IV ≠ 0
(1) THEN
LV_ERR_PBK_IV_LST_CYC = 1
(1) ELSE
LV_ERR_PBK_IV_LST_CYC = 0
(1) ENDIF
```

Note: In case of “checksum error” after power latch or reset the flag LV_ERR_PBK_IV_LST_CYC has to be set to zero.

Action that returns the status of the debounced failure
ACTION_ERRM_FilterSymptom(IN<IDX_DIAG>, IN<LV_CDN_DIAG>, IN<ERR_SYM>, IN<ABC_INC>, IN<ABC_DEC>, IN<ABC_MAX>, OUT<LV_ERR>)
This action computes the elementary anti-bounce filter

41.36.1 Checking plausiblity of injector programming value "Kleinmenge"

FUNCTION DESCRIPTION:

General information:

Goal of this chapter is to check the plausiblity of injector programming value "Kleinmenge".

Application conditions:

Initialisation at reset:	first calculation
Recurrence:	1 s

Activation: at every engine operating state

Deactivation: -

Formula section:

```
For i = 0 to (NC_CYL_NR -1)
do
        if MFF_ABSV_IV_EXT_ADJ[i] < C_MFF_ABS_IV_CAL_MIN
          or
          MFF_ABSV_IV_EXT_ADJ[i] > C_MFF_ABS_IV_CAL_MAX
        then
                set bit i of LF_ERR_PLAUS_IV_MFF_CAL to "1"
        else
                reset bit i of LF_ERR_PLAUS_IV_MFF_CAL to "0"
        endif
endfor
```

41.36.2 Checking plausiblity of injector programming value "Energie"

FUNCTION DESCRIPTION:

General information:

Goal of this chapter is to check the plausiblity of injector programming value "Energie".

Application conditions:

Initialisation at reset: first calculation

Recurrence: 1 s

Activation: at every engine operating state

Deactivation: -

Formula section:

```
For i = 0 to (NC_CYL_NR -1)
do
        if  EGY_SP_IV_EXT_ADJ[i] < C_EGY_SP_IV_CAL_MIN
           or
           EGY_SP_IV_EXT_ADJ[i] > C_EGY_SP_IV_CAL_MAX
        then
                set bit i of LF_ERR_PLAUS_IV_EGY_CAL to "1"
        else
                reset bit i of LF_ERR_PLAUS_IV_EGY_CAL to "0"
        endif
endfor
```

41.36.3 Error detection for injector programming plausibility

FUNCTION DESCRIPTION:

General information:

The flag LV_ERR_PLAUS_IV_CAL indicates an at least one not plausible injector programming values. That occurs if injector programming was not done by testerservice or at least one written value by testerservice is out of allowed range.

Description:

Error-symptoms are defined to this diagnosis function as following :

```
┌──┬──┬──┬──┐
└──┴──┴──┴──┘
 |  |  |  └─>-                                    (= SYM_0)
 |  |  └────>-                                    (= SYM_1)
 |  └────────> unplausible Energie                (= SYM_2)
 └───────────> unplausible Kleinmenge             (= SYM_3)
```

Application conditions:

Initialisation: all output data according ABC configuration "**STD_INI**"

// LV_IGK 0->1 ***or*** *reset* ***or*** *at clearing error memory*

This action initialized the diagnostic result according the filtering configuration :

ACTION_ERRM_GetLvErr(IN<NC_IDX_DIAG_GS>, OUT<LV_ERR_GS>)

```
Activation:      if      LV_IGK = 1 and LV_ST_END = 0
                 then    LV_CDN_DIAG_PLAUS_IV_CAL = 1
                 endif
Deactivation:    if      LV_IGK = 0  or  LV_ST_END = 1
                 then    LV_CDN_DIAG_PLAUS_IV_CAL = 0
                 endif
Recurrence:      10ms
```

Formula section:

```
if(1)       LF_ERR_PLAUS_IV_EGY_CAL =  0
      and   LF_ERR_PLAUS_IV_MFF_CAL  = 0
then(1)     ERR_SYM_PLAUS_IV_CAL =  NO_SYM
 else(1)
      if(2) N  >=  C_N_MIN_PLAUS_IV_VAL
            if(3)   LF_ERR_PLAUS_IV_EGY_CAL <> 0
            then(3) ERR_SYM_PLAUS_IV_CAL =  SYM_2
            endif(3)
            if(3)   LF_ERR_PLAUS_IV_MFF_CAL <> 0
```

```
            then(3) ERR_SYM_PLAUS_IV_CAL =  SYM_3
            endif(3)
      endif(2)
endif(1)
```

For failure and error management treatment the anti-bounce mechanism is called with the parameters LV_CDN_DIAG_PLAUS_IV_CAL and ERR_SYM_PLAUS_IV_CAL.

```
ACTION_ERRM_FilterSymptom
    ( IN< GS >,
      IN< LV_CDN_DIAG_GS >,
      IN< ERR_SYM_GS >,
      IN< C_ABC_INC_GS >,
      IN< 1 >,
      IN< C_ABC_MAX_GS >,
      OUT< LV_ERR_GS >
    )
```

This algorithm determines LV_ERR_PLAUS_IV_CAL and LV_END_DIAG_PLAUS_IV_CAL and delivers the result to Error Management.

Configuration for diagnostic symptoms:

Mass air flow sensor raw acquisition.					

Input data:

LV_VAR_MAF	LV_VAR_TCHA		

Import action:

ACTION_INFR_GetVmafSensor(OUT <V_maf**>)**
This action returns the digitized voltage values from the analog MAF sensor

Note: The imported action is defined in 'INSY - Requirements to infrastructure interface'

FUNCTION DESCRIPTION:

General information:

After having read out one buffer - MAF_SUM or MAF_SUM_1 - the application software has to clear this buffer as well as the corresponding counter - MAF_CTR or MAF_CTR_1.

Application conditions:

Initialisation:

After HW reset, the buffers - MAF_SUM and MAF_SUM_1 - and the corresponding counters - MAF_CTR and MAF_CTR_1 - have to be cleared and the pointer ID_MAF_PTR has to be initialized with the address of ID_MAF_TAB.

Recurrence: 1ms

Activation: LV_VAR_MAF = 1 **and** LV_VAR_TCHA = 1

Deactivation: LV_VAR_MAF = 0 **or** LV_VAR_TCHA = 0

Description:

The raw value for MAF is measured by continous conversion every 1 ms. The raw values (8 bit) are converted by a table ID_MAF_TAB (size: 256 bytes) into values with the unit [kg/h] and summed up in one of the two buffers, MAF_SUM and MAF_SUM_1. The number of values is counted in MAF_CTR or MAF_CTR_1.

A two-buffer-system is used to avoid incorrect MAF calculation. The buffers alternate with each change of segment, i. e. LV_MAF_SEG is toggled each segment from the BSW always on fixed tooth event before setting crankshaft trigger.

The conversion of the mass air flow voltage V_MAF into the physical meanig of a mass air flow with the unit kg/h is done by using the map ID_MAF_TAB. Basicly the table represents a one dimensional map with the dependency V_MAF. V_MAF is splitted into 256 steps with the resolution of 0.0195. That mean, if V_MAP=0.468V (=24 steps) the corresponding mass air flow will be find in ID_MAF_TAB at the break point number 24. The indexing of this map has to be understood in the following way:

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	32	33	...	...												
													...	...	...	

...

...

Formula section:

ACTION_INFR_GetVmafSensor(OUT <V_maf**>)**

$$\mathrm{MAF\_SUM} = \sum_{i=1}^{\mathrm{MAF\_CTR}} maf_i,\ maf_i\text{: MAF acquis., converted by the table ID\_MAF\_TAB in kg/h}$$

Import actions:

ACTION_INFR_GetResultTimeStamp (OUT <CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]>, OUT <T_PER_MAF_FRQ_SUM[NC_MAF_NR]>)

FUNCTION DESCRIPTION:

General information:

Calculation of basic air mass flow for a frequency MAF sensor

The determination of basic air mass flow from the input signal to the ECU in general is done in 3 steps.

First step:

Using these informations the mean value of time periods between falling edges during the last sampling time is calculated:

T_PER_MAF_FRQ[NC_MAF_NR] = T_PER_MAF_FRQ_SUM[NC_MAF_NR] / CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]

Second step:

The mean value of time periods (T_PER_MAF_FRQ[NC_MAF_NR]) is converted into air mass flows (MAF_FRQ_KGH_BAS[NC_MAF_NR]) with help of a map (ID_MAF_FRQ_TAB[NC_MAF_NR]).

Third step:

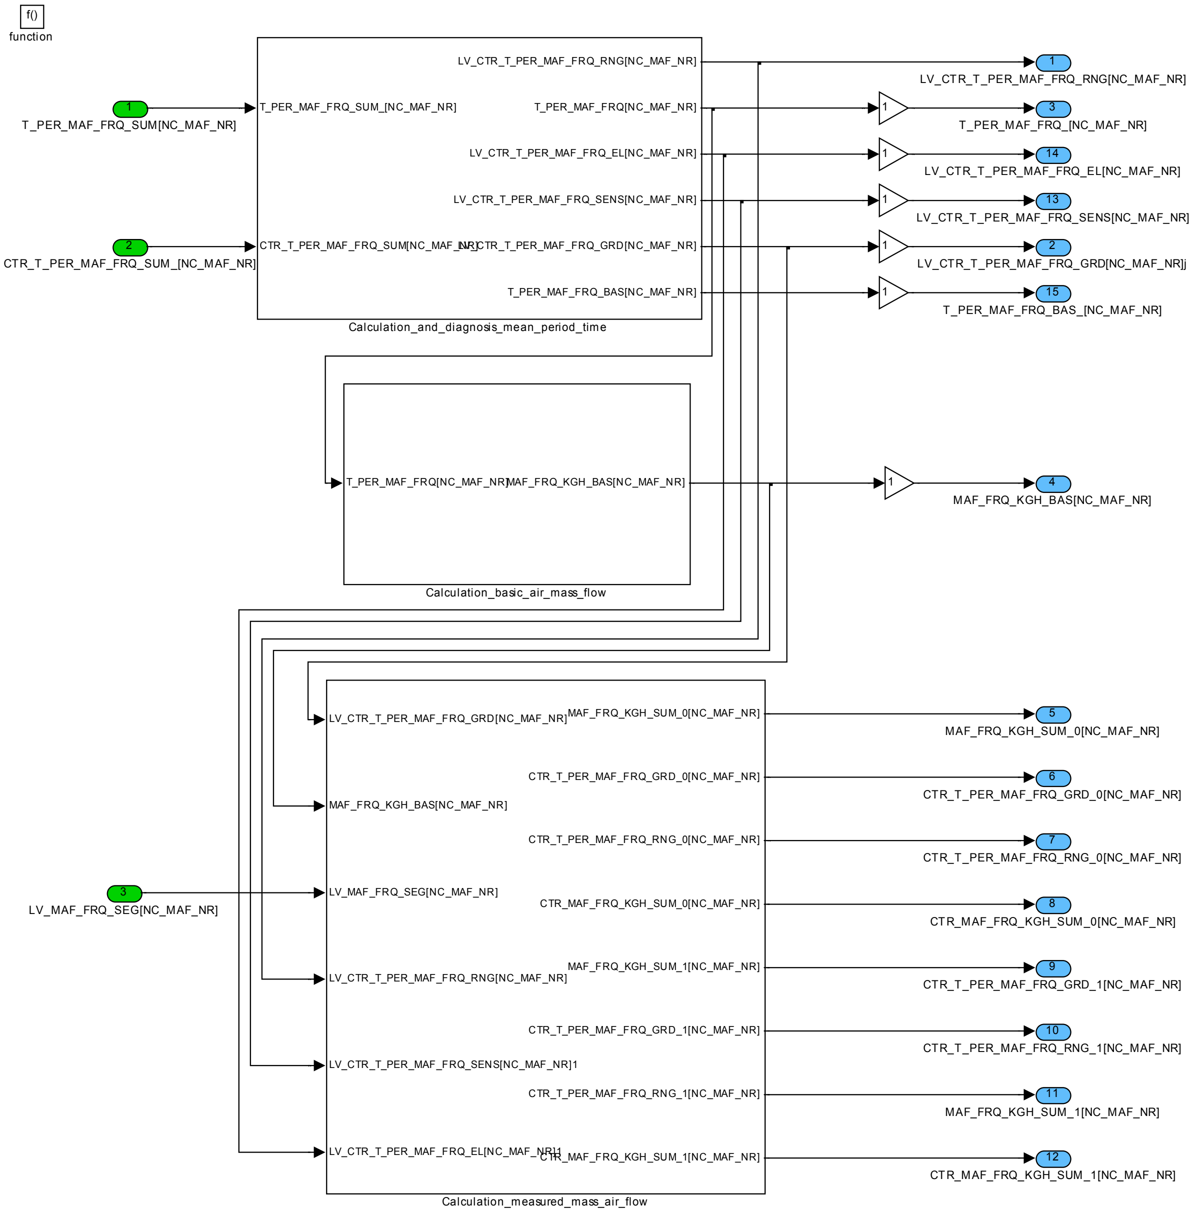
During a segment time the air mass flows of each millisecond (MAF_FRQ_KGH_BAS[NC_MAF_NR]) are summed up (MAF_FRQ_KGH_SUM[NC_MAF_NR]) in order to calculate the mean value of air mass flow:

MAF_FRQ_KGH_MES[NC_MAF_NR] = MAF_FRQ_KGH_SUM[NC_MAF_NR] / CTR_MAF_FRQ_KGH_SUM[NC_MAF_NR]

Description:

This is a global overview about all input and output signals of this function. Details are shown in the following chapters.

42.2.1 Overview



The function to do all calculations is splitted into three parts:

- calculation of mean period time
- calculation of basic mass air flow
- calculation of mean mass air flow during one segment

Besides the number of MAF sensors is fixed.

42.2.1.1 Calculation and Diagnosis of the mean period time

Application conditions:

Initialisation: -

Recurrence: 1 ms

Activation: **If** (LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 0) **or**
(LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 1) **or**
(LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 1)

Deactivation: **If** (LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 0)

FUNCTION DESCRIPTION:

The logical value LV_CTR_T_PER_MAF_FRQ_RNG[NC_MAF_NR] will be set, if the mean period time is not within a maximum and minimum threshold.

Additionally the logical value LV_CTR_T_PER_MAF_FRQ_GRD[NC_MAF_NR] will be set, if the gradient of the mean period time is higher than C_T_PER_MAF_FRQ_GRD_DIAG.

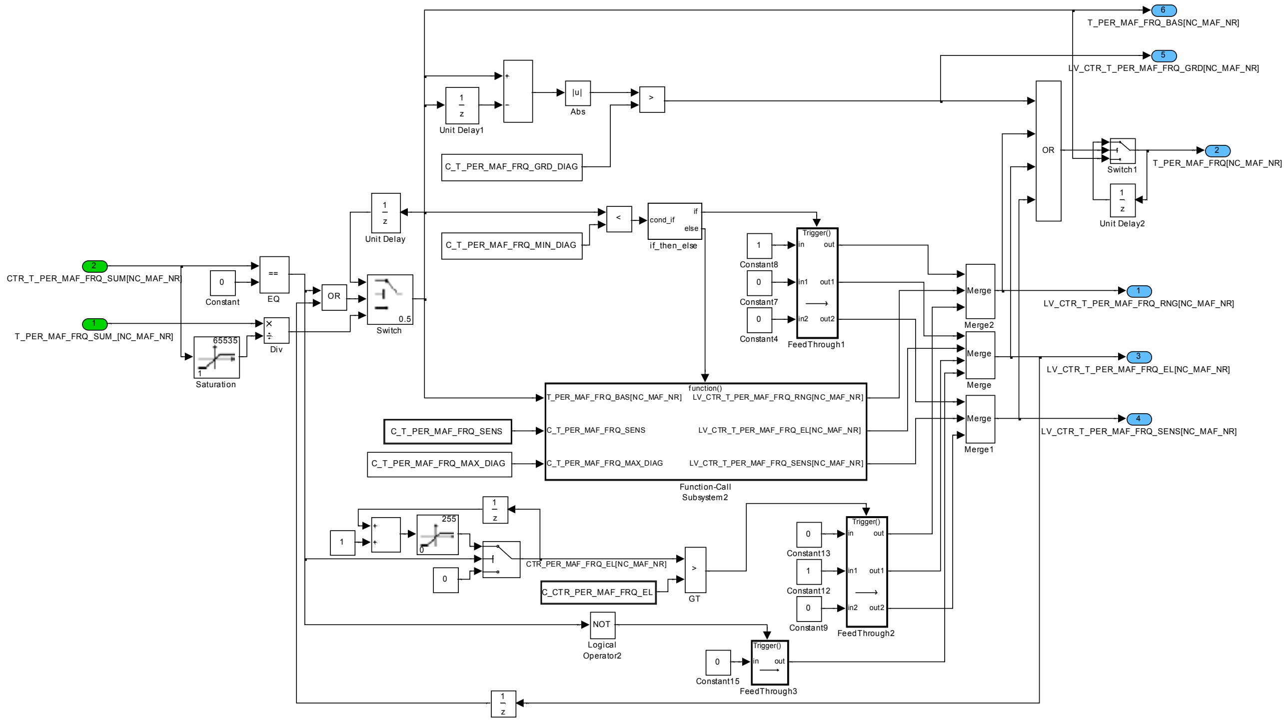
If one of the error bits LV_CTR_T_PER_MAF_FRQ_EL/SENS/RNG/GRD[NC_MAF_NR] is set, the old period time is used.

If one of the error bits LV_CTR_T_PER_MAF_FRQ_EL/SENS/RNG is set, then the other error bits has to be set to zero.

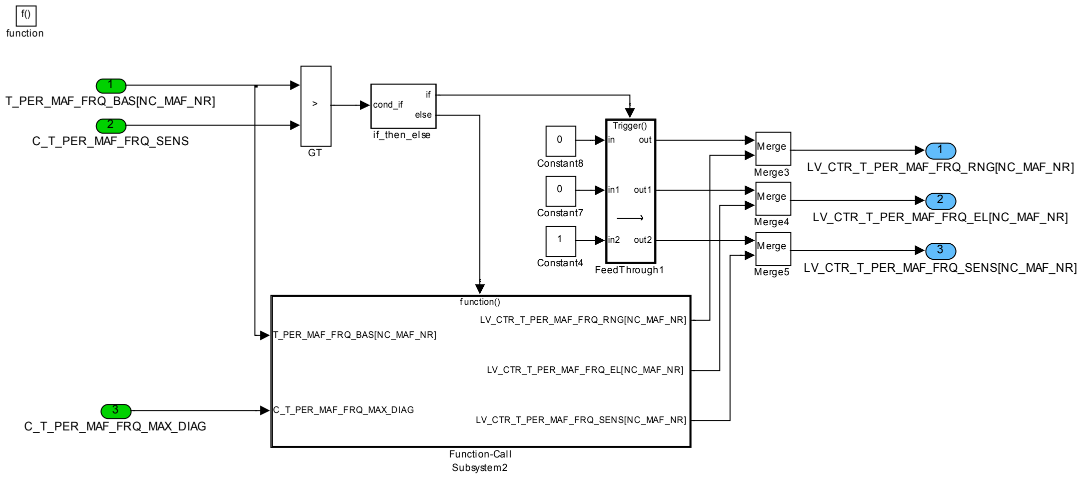
For setting of LV_CTR_T_PER_MAF_FRQ_EL[NC_MAF_NR] a counter is started everytime CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR] = 0, if the counter is over a calibratable threshold LV_CTR_T_PER_MAF_FRQ_EL[NC_MAF_NR] is set.

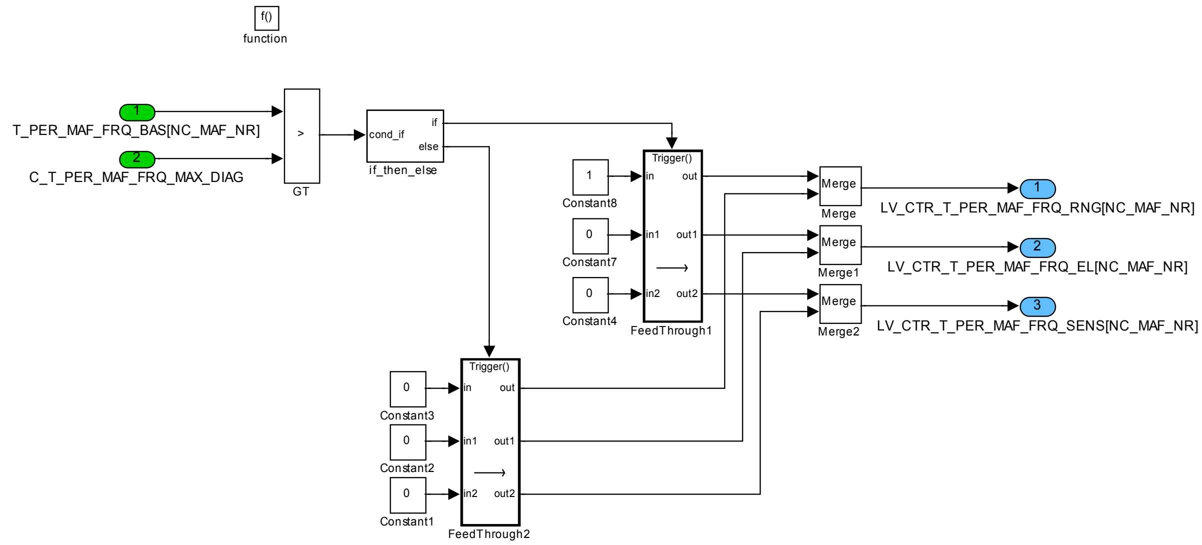
If LV_CTR_T_PER_MAF_FRQ_EL[NC_MAF_NR] = 1 the first value T_PER_MAF_FRQ_SUM[NC_MAF_NR] != 0 delievered by infrastructure is not used.

Signal flow diagram:



In the following 2 signal flow diagrams, the function call function call subsystem2 is shown:





42.2.1.2 Basic air mass flow calculation for frequency MAF sensor

Application conditions:

Initialisation: -

Recurrence: 1 ms

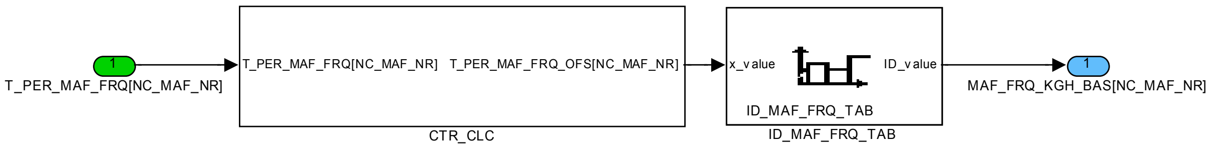
Activation: **If** (LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 0) **or**
(LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 1) **or**
(LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 1)

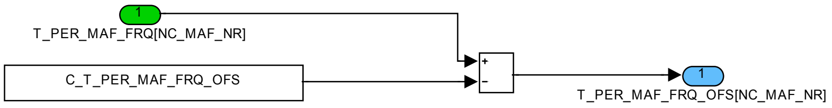
Deactivation: **If** (LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 0)

FUNCTION DESCRIPTION:

The limited mean value of the period time T_PER_MAF_FRQ[NC_MAF_NR] are converted by a table ID_MAF_FRQ_TAB[NC_MAF_NR] into values with the unit [kg/h].

Signal flow diagram:





42.2.1.3 Calculation of measured air mass flow buffer

Application conditions:

Initialisation: -

Recurrence: 1 ms

Activation: **If** (LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 0) **or**
(LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 1) **or**
(LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 1)

Deactivation: **If** (LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 0)

FUNCTION DESCRIPTION:

The calculation of measured air mass flow consists of two different parts.

Accumulation of air mass flow during one segment:

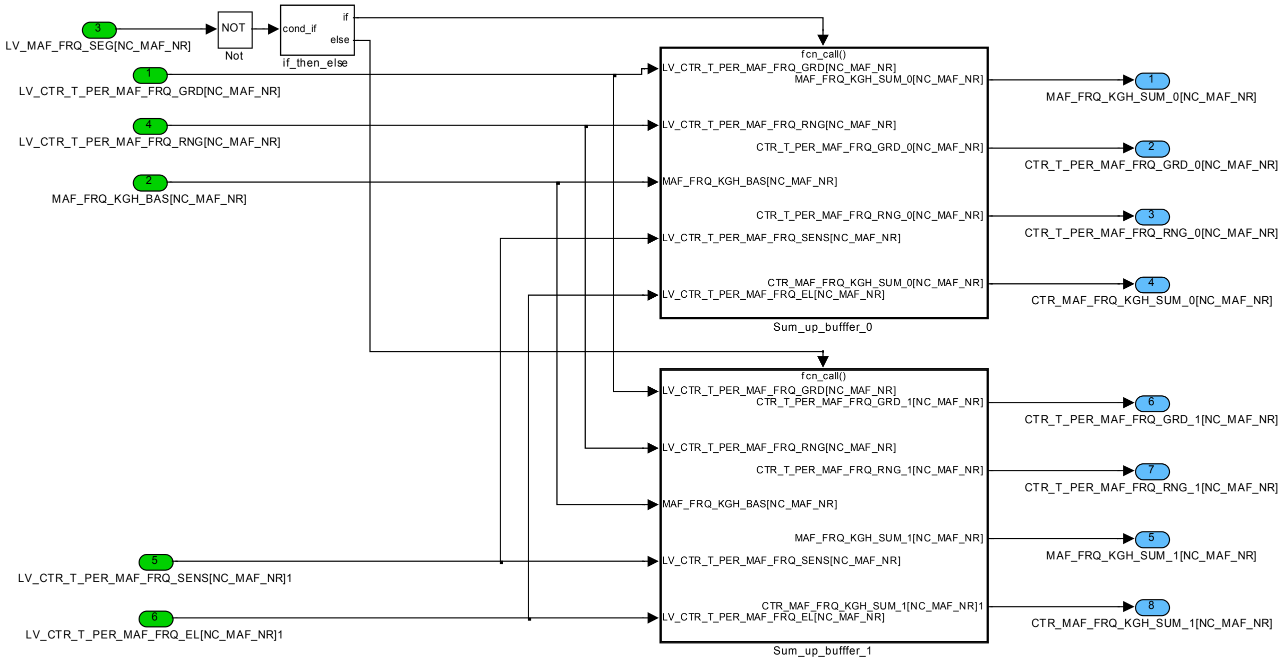
The air mass flows MAF_FRQ_KGH_BAS[NC_MAF_NR] are summed up in alternating buffers, if there is no failure. The number of summed up values is counted in

CTR_MAF_FRQ_KGH_SUM_0[NC_MAF_NR] or CTR_MAF_FRQ_KGH_SUM_1[NC_MAF_NR].

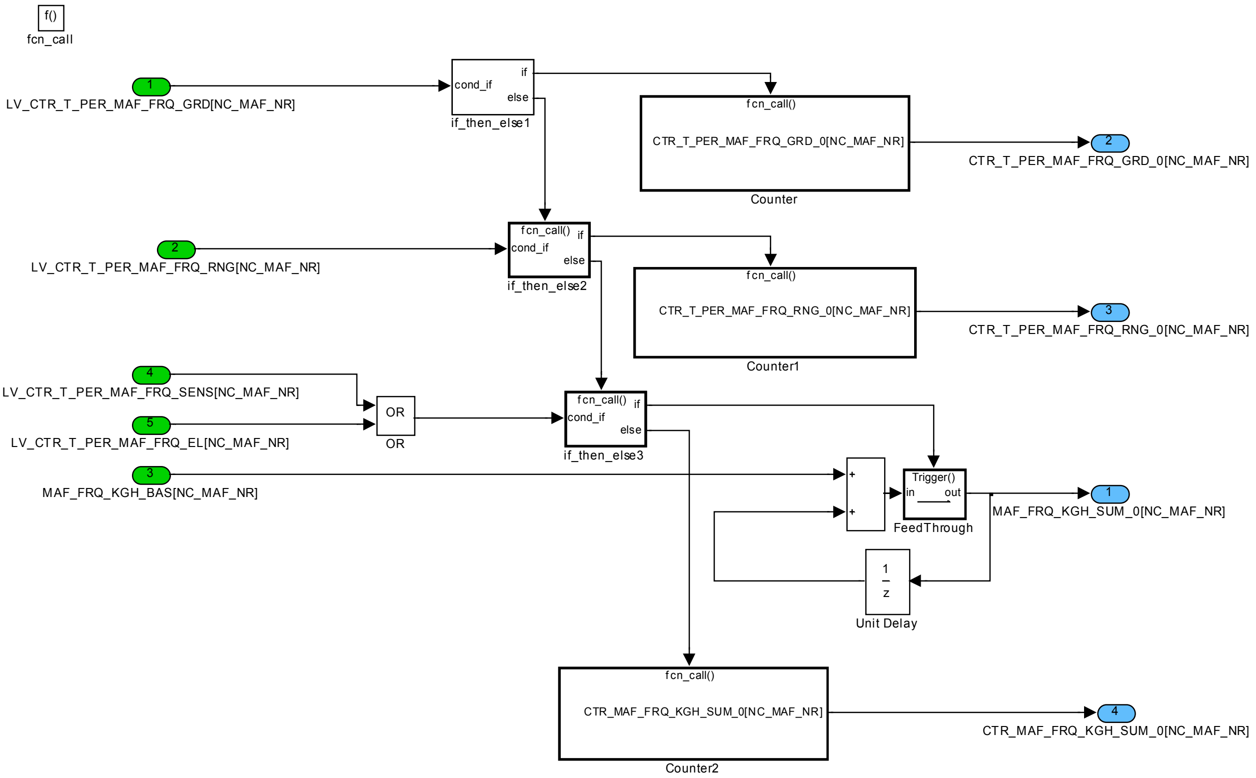
Depending on the logical value LV_MAF_FRQ_SEG one of the two buffers and counters is selected for writing whereas the content of the other buffer and counter is used for calculation.

After having read out one buffer, it needs to be cleared as well as the corresponding counter. Such a two-buffer-system is used to avoid incorrect mass air flow calculation. The buffer alternate at each change of segment.

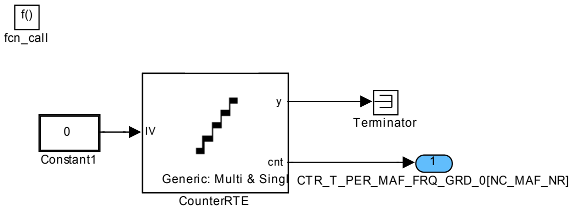
Signal flow diagram:

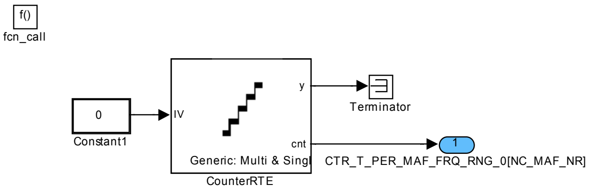


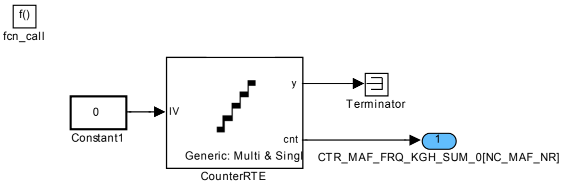
Sum up buffer:



Description of the defined counter:







The calculation above is defined only for the buffer 0, the calculation of the necessary variables for buffer 1 has to be done analogous.

42.2.1.4 Calculation of measured mean value of air mass flow

Application conditions:

Initialisation: at LV_ES 0->1, *set MAF_FRQ_KGH_MES[NC_MAF_NR] = 0*

Recurrence: every segment

Activation: **If** LV_ES = 0 **and**
(LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 0) **or**
(LV_VAR_MAF_LEARNT = 0 **and** LV_VAR_MAF = 1) **or**
(LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 1)

Deactivation: **If** (LV_VAR_MAF_LEARNT = 1 **and** LV_VAR_MAF = 0)

FUNCTION DESCRIPTION:

Selection of the sum up buffer:

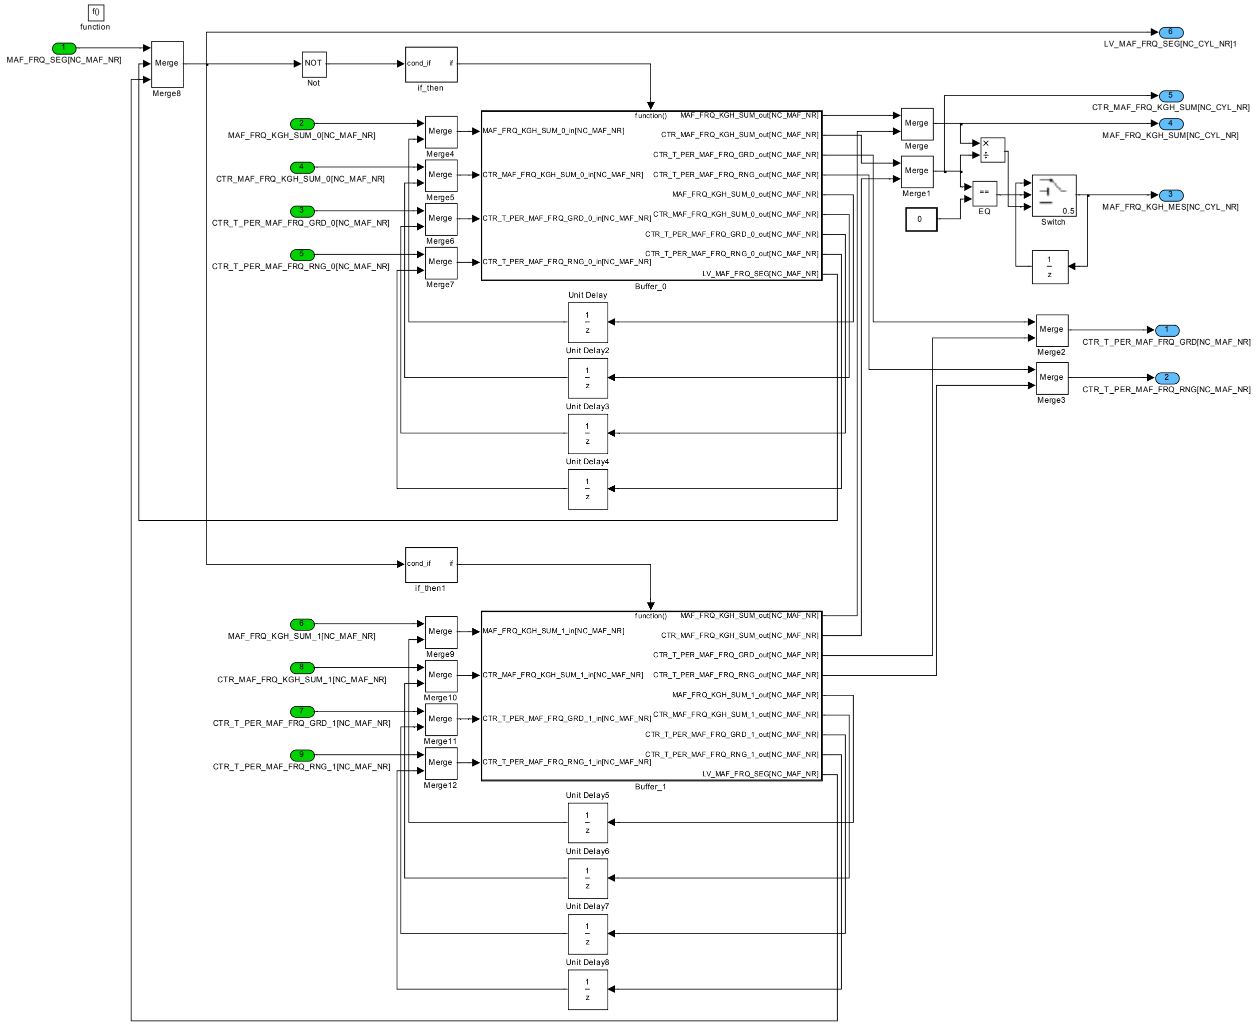
LV_MAF_FRQ_SEG[NC_MAF_NR] = 1 - LV_MAF_FRQ_SEG[NC_MAF_NR]

switching LV_MAF_FRQ_SEG[NC_MAF_NR] once per segment

mean value of the mass air flow during a segment:

MAF_FRQ_KGH_MES[NC_MAF_NR] = MAF_FRQ_KGH_SUM[NC_MAF_NR] / CTR_ MAF_FRQ_KGH_SUM[NC_MAF_NR]

Signal flow diagram:



The calculation above is defined only for the buffer 0, the calculation of the necessary variables for buffer 1 has to be done analogous.

42.3 Acquisition of manifold air pressure (MAP_MES)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAP_SUM	V/O	0...FFFFFFFFH	0...4294967295	1	[-]
Acquisition sum, buffer					
MAP_SUM_1	V/O	0...FFFFFFFFH	0...4294967295	1	[-]
Acquisition sum, buffer1					
MAP_CTR	V/O	0...FFFFH	0...65535	1	[-]
Number of MAP samples in buffer					
MAP_CTR_1	V/O	0...FFFFH	0...65535	1	[-]
Number of MAP samples in buffer1					
PUT_SUM	V/O	0...FFFFFFFFH	0...4294967295	1	[-]
Acquisition sum pressure up throttle, buffer					
PUT_SUM_1	V/O	0...FFFFFFFFH	0...4294967295	1	[-]
Acquisition sum pressure up throttle, buffer1					
PUT_CTR	V/O	0...FFFFH	0...65535	1	[-]
Number of PUT samples in buffer					
PUT_CTR_1	V/O	0...FFFFH	0...65535	1	[-]
Number of PUT samples in buffer1					

Input data:

MAP_BAS	PUT_BAS	LV_VAR_TCHA	LV_MAP_SEG

FUNCTION DESCRIPTION:

The raw value (voltage) for MAP_BAS (PUT_BAS) is measured every 1 ms. The values (10 bit) are summed up in one of the two buffers, MAP_SUM or MAP_SUM_1 (PUT_SUM or PUT_SUM_1). The number of values is counted in MAP_CTR or MAP_CTR_1 (PUT_CTR or PUT_CTR_1).

A two-buffer-system is used to avoid incorrect MAP_MES_BAS calculation.

Calculation Description:

If (LV_MAP_SEG == 0) then

$$\text{MAP\_SUM} = \sum_{i=1}^{\text{MAP\_CTR}} \text{MAP\_BAS}_i$$

and in case the alternate buffer is active for writing (LV_MAP_SEG == 1)

$$\text{MAP\_SUM\_1} = \sum_{i=1}^{\text{MAP\_CTR\_1}} \text{MAP\_BAS}_i$$

MAP_BAS_i: MAP acquisition, raw values from the ad_buffer

additional variables for LV_VAR_TCHA = 1 (turbo)

If (LV_MAP_SEG == 0) then

$$\text{PUT\_SUM} = \sum_{i=1}^{\text{PUT\_CTR}} \text{PUT\_BAS}_i$$

and in case the alternate buffer is active for writing (LV_MAP_SEG == 1)

$$\text{PUT\_SUM\_1} = \sum_{i=1}^{\text{PUT\_CTR\_1}} \text{PUT\_BAS}_i$$

PUT_BAS_i: PUT acquisition, raw values from the ad_buffer

42.4 INSY - Requirements Infrastructure Interface

Export actions:

ACTION_INFR_GetResultTimeStampMaf(OUT <CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]>, OUT <T_PER_MAF_FRQ_SUM[NC_MAF_NR]>)
This action returns the number of falling edges during one sampling time (1 ms) and the time over all detected signal periods of mass air flow data acquisition
ACTION_INFR_GetVmafSensor(OUT <v_maf**>)**
This action returns the digitized voltage values from the analog MAF sensor

Description for actions:

ACTION_INFR_GetResultTimeStampMaf(OUT <CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]>, OUT <T_PER_MAF_FRQ_SUM[NC_MAF_NR]>)					
This action returns the number of falling edges during one sampling time (1 ms) and the time over all detected signal periods of mass air flow data acquisition. The counting is done autonoumous by the Infrastructure. Default SYNCHRONIZATION option is ASYNCHRONOUS					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]	OUT	0 ... FFFFH	0 ... 65535	1	-
This parameter returns number of falling edges during one sampling time (1 ms)					
T_PER_MAF_FRQ_SUM[NC_MAF_NR]	OUT	0 ... FFFFH	0 ... 65535	1	us
This parameter returns the time over all detected signal periods					

ACTION_INFR_GetVmafSensor(OUT <v_maf**>)**					
This action returns the digitized voltage values from the analog MAF sensor					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
v_maf	OUT	0 ... FFH	0 ... 4.98046	0.0195313	V
This parameter returns voltage values from the analog MAF sensor					

FUNCTION DESCRIPTION:

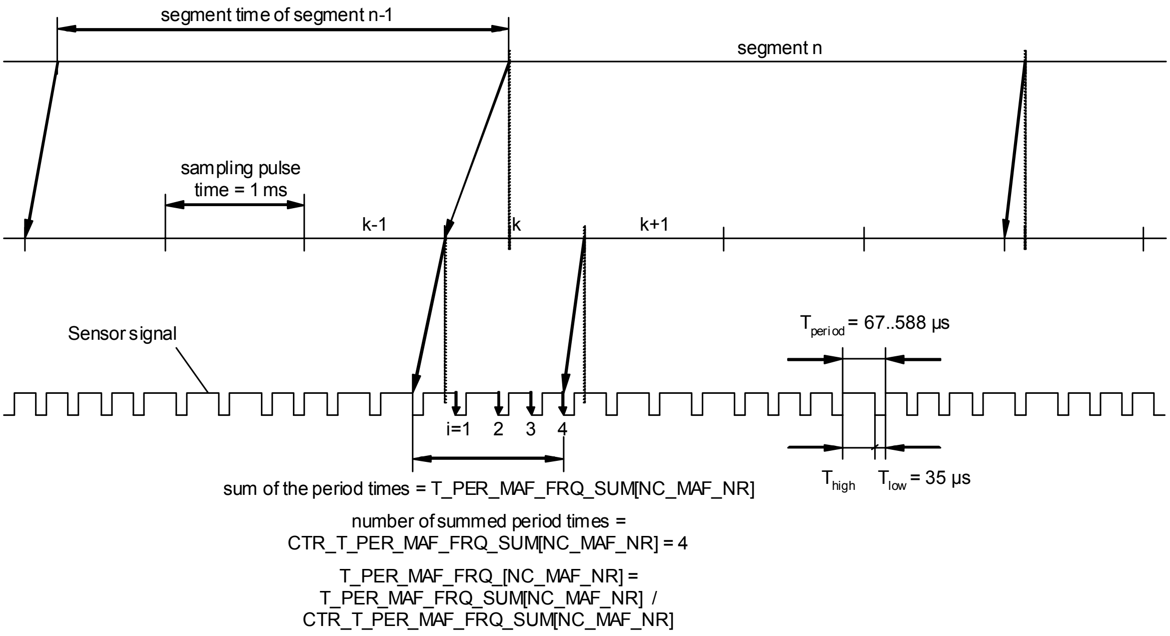
General information:

Those Actions reads out the dedicated information about the measured pulse input of the air mass flow sensor.

ACTION_INFR_GetResultTimeStampMaf

A BIOS driver called detects falling edges of the input signal. During one sampling time (1ms)

- the number of falling edges is counted (variable CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR] for further calculations in this specification)
- and the time over all detected signal periods is measured (variable T_PER_MAF_FRQ_SUM[NC_MAF_NR])



ACTION_INFR_GetVmafSensor

This action is used for the acquisition of the digitized voltage values from the analog MAF sensor connected on ECU pin 1-25 (N54 only). The content of the standard AD converter queue is transfered to the application software.

- The AD conversion is performed autonomously by the infrastructure, the returned values have not be older than 1 ms.
- The voltage values are gathered in the infrastructure until the application SW reads out the information by calling the action, old values are replaced by new ones.

Requirements for ACTION_INFR_GetResultTimeStampMaf:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR]			1	Not relevant	the number of falling edges is counted
T_PER_MAF_FRQ_SUM[NC_MAF_NR]			1us	Not relevant	time over all detected signal periods.

Diagnosis: A diagnosis is performed based on the returned signal elsewhere

Coincidence requirements: When calling the Action, the returned voltage is not older than 1ms.

further requirement due to timeout behaviour:

In case of that no falling edges are detected the parameter are delieverd as follows:
CTR_T_PER_MAF_FRQ_SUM[NC_MAF_NR] = 0

T_PER_MAF_FRQ_SUM[NC_MAF_NR] = 0

Hint for use in Application SW:
If this state is active during a sufficient long time this can be used to diagose a timeout. Due to overrun problems which can occur after a long time without any flank the first new delivered signals after a timeout should not be considered for further evaluations in the application SW.

Requirements for ACTION_INFR_GetVmafSensor:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
v_maf	-	-	0.0195313 V	not relevant	-

Diagnosis: No electrical diagnosis is done here.

Coincidence requirements:

42.5 AGGR INSY adaptation

42.5.1 Outputs for SV aggregates

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Input data:

AMP_MES	MAF_INT_PUC_ACT	MAF_INT_PUC_NOT_ACT	LV_ERR_MAP_DIP_SENS
LV_ERR_MAP_DIP_PLAUS			

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: AMP = AMP_AD = AMP_MDL = AMP_MES
MAF_INT_PUC_ACT, MAF_INT_PUC_NOT_ACT 0 g at reset
Recurrence: AMP, AMP_AD, AMP_MDL 100ms
MAF_INT_PUC ; MAF_INT_PUE 20 ms, as input data (sequencing: input before output)
LV_ERR_RATIO_CHK, LV_ERR_MAP: 10ms

Activation: at every engine state

Deactivation: -

Formula section:

AMP = AMP_MES

AMP_AD = AMP_MES

AMP_MDL = AMP_MES

MAF_INT_PUC = MAF_INT_PUC_ACT

MAF_INT_PUE = MAF_INT_PUC_NOT_ACT

LV_ERR_RATIO_CHK = 0

```
IF      LV_ERR_MAP_DIP_SENS = 1     OR    LV_ERR_MAP_DIP_PLAUS = 1
THEN    LV_ERR_MAP = 1
ELSE    LV_ERR_MAP = 0
ENDIF
```

42.6 Common Air-Mass Flow Variables

Input data:

LV_MAF_CTL	LV_MAP_CTL	LV_MAF_CONF	LV_MAP_CONF
MAF_MDL_MV	MAF_KGH_MES	MAF_KGH_FG_PRED	MAF
LV_CLC_2SEG	LV_CLC_2SEG_ENA		

Application conditions:

Initialisation: all outputs phys. 0 at reset

Recurrence: segment synchronous

Activation: LV_CLC_2SEG = 0

Deactivation: LV_CLC_2SEG = 1

42.6.1 Air-mass flow MAF_KGH

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_KGH	V/O	0...FFFFH	0...2047.96875	0.03125	[kg/h]
Air-mass flow per segment in kg/h					

FUNCTION DESCRIPTION:

General information:

Depending on system configuration the air-mass flow MAF_KGH is calculated. If no air-mass sensor is available or if the sensor diagnosis rejects the measured value (e.g. due to pulsation), a substitution value is assigned to MAF_KGH.

Formula section:

```
if ( LV_MAF_CONF = 1 )    then
    if ( LV_MAF_CTL = 1 )   then
        MAF_KGH = MAF_KGH_MES
    else
        if ( LV_MAP_CONF = 1 )then
            if ( LV_MAP_CTL = 1 )   then
                MAF_KGH =  MAF_KGH_FG_PRED
            else
                MAF_KGH = MAF_MDL_MV
            endif
        else
            MAF_KGH = MAF_MDL_MV
        endif
    endif
else
    MAF_KGH =  MAF_KGH_FG_PRED
endif
```

42.6.2 Air-mass flow difference between two segments

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_DIF	V/O	8000...7FFFH	-694.51059... 694.48940	2.12E-02	[mg/stk]
Mass air flow difference per segment					

FUNCTION DESCRIPTION:

General information:

This function calculates the difference air-mass flow between two consecutive segments MAF_DIF.

Formula section:

```
if  LV_CLC_2SEG_ENA = 0
 then    MAF_DIF  =  $MAF_n - MAF_{n-1}$
 else    MAF_DIF  =  $\frac{1}{2} * (MAF_n - MAF_{n-1})$
endif
```

42.6.3 Air mass difference for rapidly falling load (MAF_MMV)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_MMV	V/O	0...FFFFH	0...1389	2.12E-02	[mg/stk]
MAF moving mean value					

FUNCTION DESCRIPTION:

General information:

In the case of rapidly falling load, the transition to (LV_PUC) can be accelerated in order to avoid an engine speed run-up, which is undesirable.

To trigger this function (see the following chapters: ignition, ignition angle correction for trailing throttle) some load conditions have to be fulfilled. For this reason, the value MAF_MMV is calculated every segment from the corrected air mass MAF.

Formula section:

```
if  MAF_DIF > C_MAF_MMV_HYS          ( MAF_MMV for increasing air mass )
  then    MAF_MMV = MAF
  else                               ( MAF_MMV for decreasing air mass )
    if      LV_CLC_2SEG_ENA = 0
      then  MAF_MMV =  MAF_MMV + (MAF - MAF_MMV) * C_MAF_MMV_DIF_CRLC
      else  MAF_MMV =  MAF_MMV + (MAF - MAF_MMV) * C_MAF_MMV_DIF_CRLC * 2
    endif
endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_MAF_MMV_DIF_CRLC	1	0...FFH	0...0.99609	3.91E-03	[-]
MAF moving mean value filtering factor					
C_MAF_MMV_HYS	1	0...7FFFH	0...694.47880	2.12E-02	[mg/stk]
Threshold for detecting raising MAF_MMV					

42.7 Pressure Variables (MAP-Sensor, PUT-Sensor)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAP_DIP_MES_BAS	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure per segment measured (differential pressure)					
MAP_DIP_MES_BAS_2SEG	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure per second segment measured (differential pressure)					
MAP_DIP_MES_2SEG	O/V	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold differential pressure mean value over two segments, model value in case of sensor error					
V_MAP	V/O	0...400H	0...5	4.8828e-3	[V]
Voltage of the intake manifold pressure sensor (for diagnosis)					
PUT_MES_BAS	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure up throttle per segment measured					
PUT_MES_BAS_2SEG	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure up throttle per second segment measured					
V_PUT	V/O	0...400H	0...5	4.8828e-3	[V]
Voltage of the intake manifold pressure sensor up throttle					
LV_MAP_SEG	V/O	0...1H	0...1	1	[-]
Event segment, used to switch buffer					
MAP_MES	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure per segment measured					
MAP_MES_BAS	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure per segment measured (raw value)					
MAP_MES_BAS_2SEG	V	0...FFFFH	0...5434	0.0829175	[hPa]
Intake manifold pressure per second segment measured					
MAP_SAE	O/V	0...FFH	0...255	1	[kPA]
Intake manifold pressure raw value for OBD					

Input data:

MAP	MAP_SUM_1	MAP_CTR	MAP_CTR_1
PUT_CTR	LV_ERR_MAP_DIP_SENS	LV_ES	N_32
LV_VAR_TCHA	AMP	PUT_SUM	PUT_SUM_1
	PUT_CTR_1	PUT	LV_ERR_PUT_EL

FUNCTION DESCRIPTION:

General information:

The raw value (voltage) MAP_BAS (PUT_BAS) is measured every 1 ms. The values (10 bit) are summed up in two alternating buffers, MAP_SUM or MAP_SUM_1 (PUT_SUM or PUT_SUM_1). The number of the values are counted in comparable buffers MAP_CTR or MAP_CTR_1 (PUT_CTR or PUT_CTR_1). This mechanism is necessary to synchronize the measurement and the calculation of MAP_DIP_MES_BAS resp. PUT_MES_BAS (build mean value with a standardized range)

Depending on the logical variable LV_MAP_SEG one of the two buffers — MAP_SUM or MAP_SUM_1 (PUT_SUM or PUT_SUM_1) — and the respective counter — MAP_CTR or MAP_CTR_1 (PUT_CTR or PUT_CTR_1) — are selected for writing, the contents of the other buffer (counter) is used for calculations and diagnosis (after this buffer and the corresponding counter have been read they are cleared).

To avoid pressure sensor diagnosis errors during initialization of the ECU, the first measured value is mirrored from buffer MAP_SUM into MAP_SUM_1 resp. PUT_SUM into PUT_SUM_1 (also the counters). This ensures, that the sensor diagnosis gets reasonable values and doesn’t detect a bad sensor due to zero values in the buffer.

*MAP_DIP/PUT*_MES_BAS_2SEG is introduced to get a smooth signal of MAP_DIP_MES_BAS (filtering of possibly occurring pulsation of pressure).

Signal flow diagram:

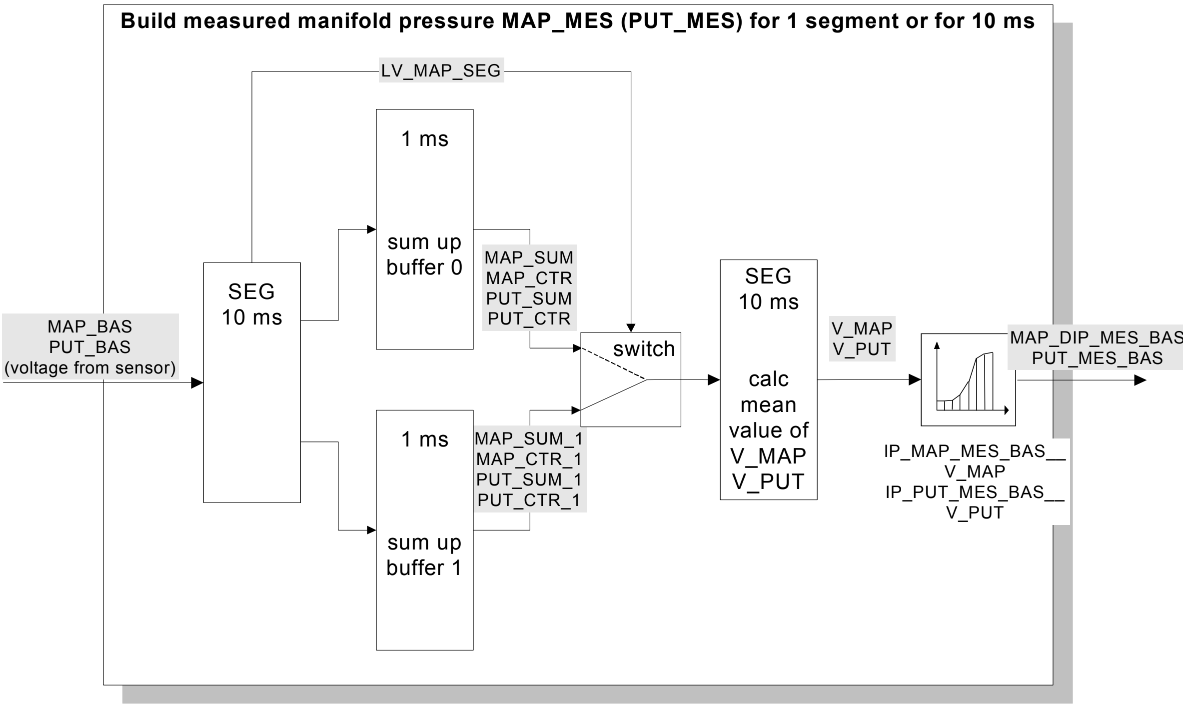

Figure 1: Signal flow during acquisition of manifold pressure MAP_DIP_MES_BAS, PUT_MES_BAS

Description:

The application SW toggles LV_MAP_SEG either at a period of 10 ms (N_32 < C_N_MAP_PUT_CLC_SWI) or at each segment (N_32 >= C_N_MAP_PUT_CLC_SWI).

Because there are used two different MAP-sensors for pressure acquisition (relativ and absolute sensors) it is necessary to calculate the absolute value as input variable for the intake manifold modell.

Application conditions:

Initialisation: all: 0
except:
MAP_MES_BAS = AMP *// AMP must be initialized before*
MAP_MES_BAS_2SEG = AMP *// AMP must be initialized before*
MAP_MES = AMP *// AMP must be initialized before*

Recurrence: at N_32 < C_N_MAP_PUT_CLC_SWI all: 10ms
at N_32 >= C_N_MAP_PUT_CLC_SWI all: segment

Activation: at every engine state

Deactivation: -

Formula section:

Calculation of V_MAP:

```
If      LV_MAP_SEG = 1          and
        MAP_CTR > 0
Then    $V\_MAP = \frac{MAP\_SUM}{MAP\_CTR}$ - V_MAP_AD
Else
        If      LV_MAP_SEG = 0          and
                MAP_CTR_1 > 0
        Then    $V\_MAP = \frac{MAP\_SUM\_1}{MAP\_CTR\_1}$ - V_MAP_AD
        Endif
Endif
```

Calculation of V_MAP_1:

```
If      MAP_CTR = 0             and
        MAP_CTR_1 = 0
Then    $V\_MAP\_1_n = V\_MAP\_1_{n-1}$
Else
    If          V_MAP > 0
    Then        $V\_MAP\_1 = \frac{(MAP\_SUM + MAP\_SUM\_1)}{(MAP\_CTR + MAP\_CTR\_1)}$ - V_MAP_AD
    Else        V_MAP_1 = 0
    Endif
Endif
```

If the selected counter is zero V_MAP(_1) and MAP(_DIP)_MES_BAS(_2SEG) remain unchanged.

Calculation of MAP_MES_BAS(_2SEG) and MAP_DIP_MES_BAS(_2SEG):

V_MAP (unit: V) has to be converted in MAP(_DIP)_MES_BAS(_2SEG) (unit: hPa)

```
If LC_MAP_ABSV_REL_SWI = 1
then    (N54)
        MAP_MES_BAS = IP_MAP_MES_BAS(V_MAP)
        MAP_MES_BAS_2SEG = IP_MAP_MES_BAS(V_MAP_1)
        MAP_DIP_MES_BAS = AMP - MAP_MES_BAS
```

```
                MAP_DIP_MES_BAS_2SEG = AMP - MAP_MES_BAS_2SEG
else            (N53)
                MAP_DIP_MES_BAS = IP_MAP_MES_BAS(V_MAP)
                MAP_DIP_MES_BAS_2SEG = IP_MAP_MES_BAS(V_MAP_1)
                MAP_MES_BAS = AMP - MAP_DIP_MES_BAS
                MAP_MES_BAS_2SEG = AMP - MAP_DIP_MES_BAS_2SEG
endif
If              LV_ERR_MAP_DIP_SENS = 0
then            MAP_MES = MAP_MES_BAS
                MAP_DIP_MES_2SEG = MAP_DIP_MES_BAS_2SEG
else            MAP_MES = MAP     (model value)
                MAP_DIP_MES_2SEG = AMP – MAP (model value)
endif
```

<u>Calculation of OBD relevant MAP_SAE:</u>

```
MAP_SAE = IP_MAP_MES_BAS(V_MAP)          //Convertion must be done in physical way
```

Additional variables for LV_VAR_TCHA = 1 (turbo)

<u>Calculation of V_PUT:</u>

```
If              LV_MAP_SEG = 1            and
                PUT_CTR > 0
Then            $V\_PUT = \frac{PUT\_SUM}{PUT\_CTR}$
Else
                If      LV_MAP_SEG = 0            and
                        PUT_CTR_1 > 0
                Then    $V\_PUT = \frac{PUT\_SUM\_1}{PUT\_CTR\_1}$
                Endif
Endif
```

If the selected counter is zero V_PUT and PUT_MES_BAS stay unchanged.

Calculation of PUT_MES_BAS:

V_PUT (unit: V) has to be converted in PUT_MES_BAS (unit: hPa)

```
If      LV_ERR_PUT_EL = 0
Then            if      LC_PUT_ABSV_REL_SWI =1
                then    PUT_MES_BAS = IP_PUT_MES_BAS
                else    PUT_MES_BAS = AMP - IP_PUT_MES_BAS
                endif

Else    PUT_MES_BAS = PUT               (calculated from Model)
Endif
```

Calculation of V_PUT_1:

```
If      PUT_CTR = 0             and
        PUT_CTR_1 = 0
Then    $V\_PUT\_1_n = V\_PUT\_1_{n-1}$
Else
    If      V_PUT > 0
    Then    $V\_PUT\_1 = \frac{(PUT\_SUM + PUT\_SUM\_1)}{(PUT\_CTR + PUT\_CTR\_1)}$
    Else    V_PUT_1 = 0
    Endif
Endif
```

Calculation of PUT_MES_BAS_2SEG:

V_PUT_1 (unit: V) has to be converted into PUT_MES_BAS_2SEG (unit: hPa)

```
If      LV_ERR_PUT_EL = 0
Then    if      LC_PUT_ABSV_REL_SWI = 1
        then    PUT_MES_BAS_2SEG = IP_PUT_MES_BAS
        else    PUT_MES_BAS_2SEG = AMP - IP_PUT_MES_BAS
        endif

Else    PUT_MES_BAS_2SEG = PUT          (calc. from Model)
Endif
```

Hysteresis for PQ-threshold for LV_MAF_PULS					

FUNCTION DESCRIPTION:

General information:

For non turbo variant (N53) a frequency MAF sensor is used. For turbo variant (N54) a frequency MAF sensor (index [0]) and an analog MAF sensor (index [1]) is used.

Analog sensor: Depending on the logical value LV_MAF_SEG one of the two buffers MAF_SUM or MAF_SUM_1 and the respective counter MAF_CTR or MAF_CTR_1 is selected for writing, the contents of the other buffer (counter) is used for diagnosis and calculations. After having read out one buffer MAF_SUM or MAF_SUM_1 the buffer has to be cleared as well as the corresponding counter MAF_CTR or MAF_CTR_1.

Analog and frequency sensor: A correction is possible in order to take into consideration deviations of the measured mass air flow due to different installations of the air mass meter. This correction factor is dependant from MAF_KGH_MES_BAS itself and of the air temperature.

Application conditions:

Initialisation: all 0 at reset **or** LV_IGK 0->1

Recurrence: at STATE_ENG: ST, IS, PL, PU and PUC segment synchronous

at STATE_ENG: ES 1s

Activation: at all STATE_ENG

Deactivation: -

Formula section:

```
If      LV_VAR_TCHA = 0
then    // evaluation of frequency MAF sensor (N53)
        MAF_KGH_MES_BAS = MAF_FRQ_KGH_MES[0]
        MAF_KGH_MES = MAF_KGH_MES_BAS *
                IP_FAC_MAF_KGH_COR(MAF_KGH_MES_BAS, TIA)
else    // evaluation of frequency and analog MAF sensor  (N54)
        MAF_KGH_MES_BAS = (MAF * N) / NC_MAF_FAC_CYL
        MAF_KGH_MES = MAF_KGH_MES_BAS
        MAF_KGH_MES_BAS_TCHA[0] = MAF_FRQ_KGH_MES[0]
        MAF_KGH_MES_TCHA[0] = MAF_KGH_MES_BAS_TCHA[0] *

endif
```

42.8.2 Air-mass Flow Acquisition MAF_MES

FUNCTION DESCRIPTION:

General information:

The air-mass MAF_MES in mg/stroke is calculated from the measured air-mass flow MAF_KGH_MES and the engine speed N. The non calibratable constant NC_MAF_FAC_CYL is inversly proportional to the number of cylinders, so the output MAF_MES depends on the number of cylinders.

Application conditions:

Initialisation: all 0 at reset **or** LV_IGK 0->1

Recurrence: at STATE_ENG: ST, IS, PL, PU and PUC segment synchronous

at STATE_ENG: ES 1s

Activation: at all STATE_ENG

Deactivation: -

Formula section:

```
If      N = 0
Then    MAF_MES = 0
Else    $MAF\_MES = \frac{MAF\_KGH\_MES}{N} * NC\_MAF\_FAC\_CYL$
Endif
```

42.8.3 Fade out of Mass Airflow Sensor

FUNCTION DESCRIPTION:

General information:

It is possible, that in some operating points of an engine the MAF sensor is unable to deliver the correct MAF value. Those operating points are displayed by LV_MAF_PULS = 1. This state will result in switching off the MAF feedback loop of the intake manifold model, so the load determination will be done like "α-/N-control".

Application conditions:

Initialisation: all 0 at reset **or** LV_IGK 0->1

Recurrence: at STATE_ENG: ST, IS, PL, PU and PUC segment synchronous

at STATE_ENG: ES 1s

Activation: at all STATE_ENG

Deactivation: -

Formula section:

```
If      PQ_SP > IP_PQ_SP_PULS
Then    LV_MAF_PULS = 1
Else    If      PQ_SP < IP_PQ_SP_PULS - C_PQ_SP_HYS_PULS
        Then    LV_MAF_PULS = 0
        Else    LV_MAF_PULS remains unchanged
        Endif
Endif
```

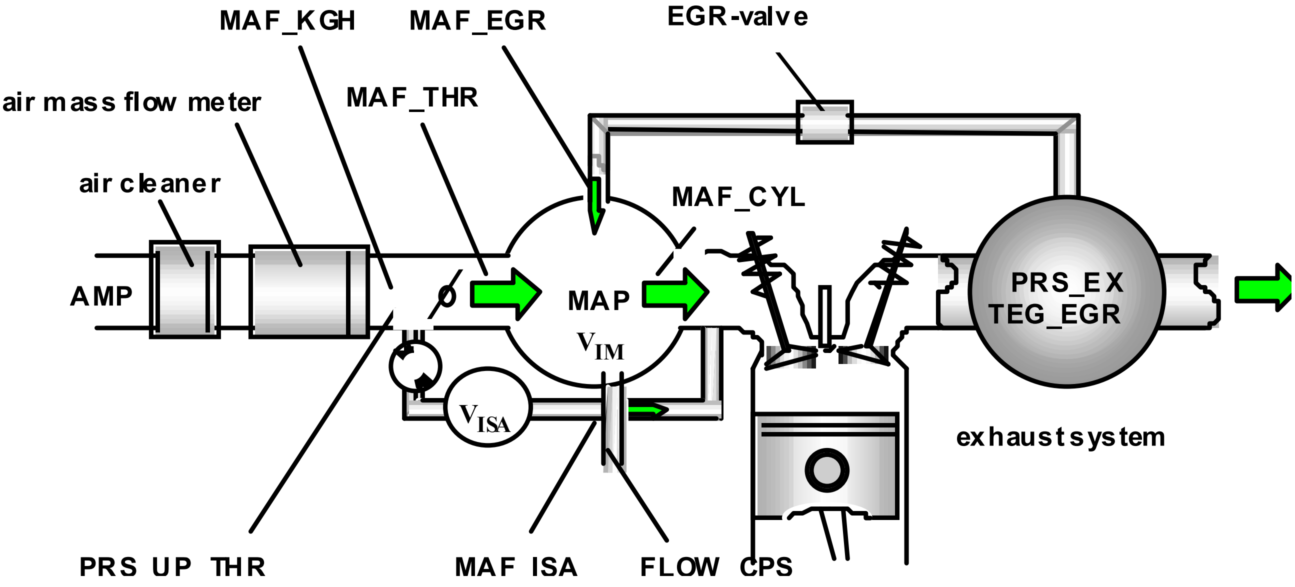
42.10 Intake Manifold Model with Turbulence System and EGR

General information:

The intake manifold model calculates the air mass flow at throttle, at idle speed actuator valve, the air mass flow into the cylinder and the pressure in the intake manifold. In case of exhaust gas recirculation in addition the residual gas partial pressure and the fresh gas partial pressure are calculated. The calculation is done every segment due to charge determination for injection and ignition. Therefore it is necessary to scan the throttle- and idle speed actuator valve position also every segment.



Signal flow diagram:

Application conditions:

Recurrence:	segment synchronous
Activation:	at LV_IGK = 1
Deactivation:	-

42.10.1 Calculation of the manifold pressure MAP

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PQ_EGR	V/O	0000...FFFFH	0...0.999985	1.52e-5	-
pressure quotient at the EGR - valve					

Input data:

MAP	PRS_EX_EGR		

Application conditions:

Initialisation: PQ_EGR =0

Formula section:

$PQ\_EGR_N = MAP_N / PRS\_EX\_EGR_N$

42.10.2 Calculation of MAP_FG

42.12 Pressure decrease in the air cleaner

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
PUT	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Pressure upstream throttle					
PUT_MAX	V/O	0...FFFFH	0...5434	0.0829175	[hPa]
Maximum possible pressure upstream throttle					

Input data:

AMP_MDL	AMP_AD	MAF_CYL	LV_CLC_2SEG
AMP_MES	PUT_MES_BAS]	LV_VAR_TCHA	LV_ERR_PUT_EL
LV_ES		LV_ERR_PUT_PLAUS	

FUNCTION DESCRIPTION:

General information:

With increasing air mass flow through the air cleaner there is a drop of pressure in the air cleaner in comparison to the ambient pressure.

Application conditions:

Initialisation: PUT = AMP_MES

PUT_MAX = AMP_MES at ECU reset

Activation: LV_CLC_2SEG = 0

Deactivation: LV_CLC_2SEG = 1

No pressure decrease will be calculated, if all elements of IP_AMP_DEC are 0.

Recurrence: LV_ES = 10 ms

LV_ES = 0 segment synchronous

Formula section:

```
If      LV_VAR_TCHA = 0
Then    PUT = AMP_MDL - IP_AMP_DEC
        PUT_MAX = AMP_AD - IP_AMP_DEC
Else    If      LV_ERR_PUT_EL = 1  or
              ( LV_ERR_PUT_PLAUS = 1 and
                LC_ENA_ PUT_SUB_PLAUS_ERR = 1 )

        Then    PUT = AMP_MDL - IP_AMP_DEC
                PUT_MAX = AMP_AD - IP_AMP_DEC
```

```
        Else    PUT = PUT_MES_BAS
                PUT_MAX = AMP_AD - IP_AMP_DEC
        Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
IP_AMP_DEC	4	0...FFFFH	0...5434	8.29E-02	[hPa]

Switch to enable PUT substitution during PUT_PLAUS_ERR					

42.13 Temperature correction of Volumetric Efficiency

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
EFF_VOL_TEMP_COR	V	0...FFFFH	0...1.99996	3.05E-05	[-]
Volumetric efficiency correction factor due to temperature effects					
EFF_VOL_TEMP_COR_MMV	V/O	0...FFFFH	0...1.99996	3.05E-05	[-]
Filtered volumetric efficiency correction factor due to temperature effects					

Input data:

MAF	N_32	TCO	TIA_IM
	LV_CLC_2SEG	LV_CLC_2SEG_ENA	

General information:

Target of the temperature correction function is, to compensate the temperature influences onto the volumetric efficiency calculation. The air-mass flow into the cylinder is the product of the volume flow and the density of the air $\dot{m} = A \cdot w \cdot \rho(T) = \dot{V} \cdot \rho(T)$, where the density depends on the air-temperature. At low temperatures the air-density is much higher than at standard temperatures, therefore the air flowing into the cylinder at the same manifold pressure will increase. The basic volumetric efficiency usually is calibrated at standard temperatures of about 25 °C for intake air and about 90 °C for coolant temperature. To take into account the different density at operating points with other temperatures, the volumetric efficiency then has to be corrected.

Especially at speed-density systems, this temperature correction is essential, because the density of the air and therefore the air-mass flow strongly depend on the air temperature. This means all deviations from the temperatures at which the volumetric efficiency was calibrated will lead to a wrong air-mass flow value into the cylinder (e.g. wrong MAF value at cold starts without temperature corrections for a MAP system).

At systems equipped with an HFM sensor, the temperature correction is not as essential as for speed-density systems. Nevertheless, it is used to consider the heating of the air due to heat transfer from the warm intake duct to the air.

The compensation function is capable of taking into account deviations of coolant temperature and intake air temperature separately.

$$EFF\_VOL\_COR = \frac{273 + C\_TCYL\_STND}{273 + C\_TCYL\_STND + IP\_EFF\_TCO\_FAC \cdot (TCO\_C\_TCO\_STND) + IP\_EFF\_TIA\_IM\_FAC \cdot (TIA\_IM - C\_TIA\_STND)}$$

Signal flow diagram:

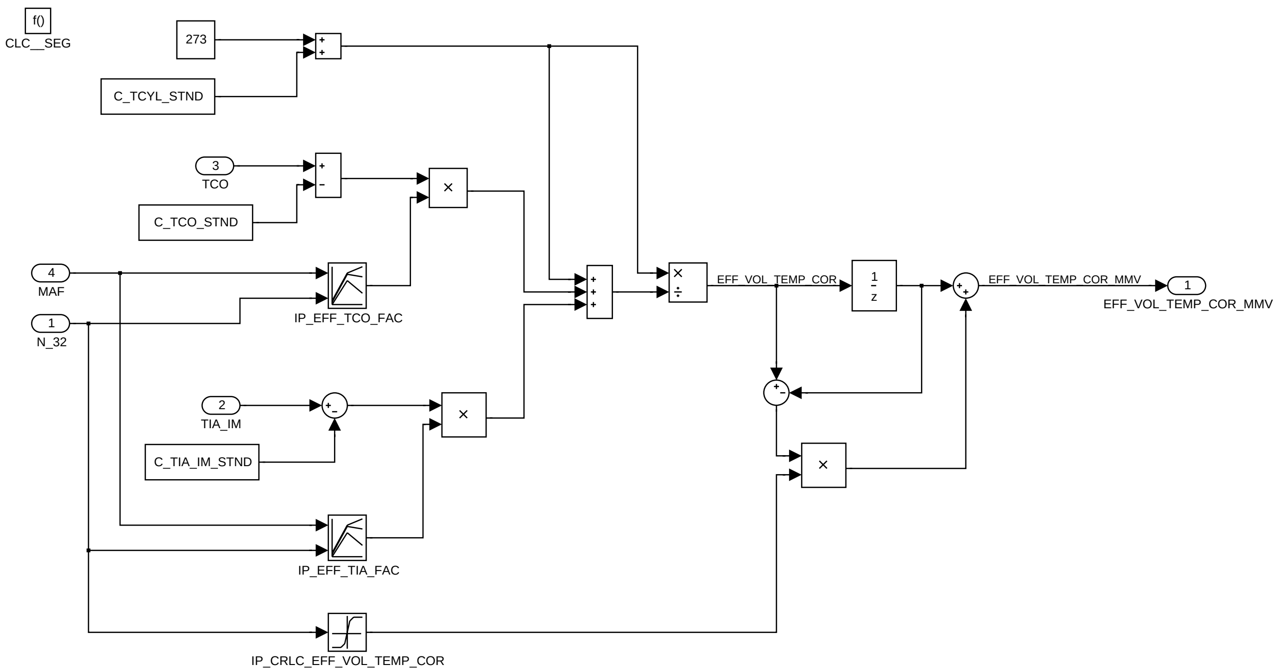

Figure 1: Calculation algorithm for temperature correction

Description:

The temperature correction factor EFF_VOL_TEMP_COR is the ratio between air temperature in the cylinder for standard conditions TCYL compared to air temperature in the cylinder for current TCO, TIA_IM and operating point. TCO and TIA_IM are compared to standard conditions and weighted by operating point.

Application conditions:

Initialisation: *at reset and engine running to stopped engine*

EFF_VOL_TEMP_COR = 1

Remark: The typical range of EFF_VOL_TEMP_COR is 0,8 to 1,5.

Activation: LV_CLC_2SEG = 0

Deactivation: LV_CLC_2SEG = 1

Recurrence: segment synchronous

Formula section:

$$\mathrm{EFF\_VOL\_TEMP\_COR} = [\,273 + \mathrm{C\_TCYL\_STND}\,] \;/\; [\,273 + \mathrm{C\_TCYL\_STND} + \mathrm{IP\_EFF\_TCO\_FAC} * (\mathrm{TCO} - \mathrm{C\_TCO\_STND}) + \mathrm{IP\_EFF\_TIA\_IM\_FAC} * (\mathrm{TIA\_IM} - \mathrm{C\_TIA\_IM\_STND})\,]$$

Changes in the operating point cause thermal inertia effects, which have to be taken into account. Filtering EFF_VOL_TEMP_COR does this.

At first calculation EFF_VOL_TEMP_COR_MMV is = EFF_VOL_TEMP_COR.

```
if LV_CLC_2SEG_ENA = 0
    then  $\mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_n = \mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_{n-1} + (\mathrm{EFF\_VOL\_TEMP\_COR} - \mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_{n-1}) * \mathrm{IP\_CRLC\_EFF\_VOL\_TEMP\_COR}$
    else  $\mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_n = \mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_{n-1} + (\mathrm{EFF\_VOL\_TEMP\_COR} - \mathrm{EFF\_VOL\_TEMP\_COR\_MMV}_{n-1}) * 2 * \mathrm{IP\_CRLC\_EFF\_VOL\_TEMP\_COR}$
endif
```

End of Diagnosis AMP					

Input data:

V_AMP	LV_IGK	LV_ES	LV_ST

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect electrical faults as defined by OBD I requirements.
The signal of the altitude pressure sensor on the A/D-input of the microcontroller is checked.

Description:

Error-symtoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Signal Line Short to Battery Voltage or Open load   (= SYM_0)
 │ │ └───> Signal Line Short to Ground                         (= SYM_1)
 │ └─────> -                                                   (= SYM_2)
 └───────> -                                                   (= SYM_3)
```

Application conditions:

Initialization: all 0 at LV_IGK 0->1 **or** reset

Recurrence: 100ms

```
Activation  If    LV_IGK = 1           and
                  LV_ES = 0            and
                  LV_ST = 0
            Then  LV_CDN_DIAG_AMP = 1
            Else  LV_CDN_DIAG_AMP = 0
            Endif
```

Formula section:

Short circuit to VBatt or open load

```
If      V_AMP  >  C_V_AMP_MAX_DIAG
Then    ERR_SYM_AMP = SYM_0
```

Input data:

V_MAP	LV_IGK	LV_ES	LV_ST

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect electrical faults as defined by OBD I requirements.
The signal of the manifold differential pressure sensor on the A/D-input of the microcontroller is checked.

Description:

Error-symtoms are defined to this diagnosis function as following :

```
|_|_|_|_|
 | | | └─→ Signal Line Short to Battery Voltage or Open load    (= SYM_0)
 | | └───→ Signal Line Short to Ground                         (= SYM_1)
 | └─────→ -                                                   (= SYM_2)
 └───────→ -                                                   (= SYM_3)
```

Application conditions:

Initialization: according ABC type **STD_INI** (all 0 at LV_IGK 0→1 or at reset)

Recurrence: 100ms

```
Activation    If     LV_IGK = 1    and
                     LV_ES = 0     and
                     LV_ST = 0
              Then   LV_CDN_DIAG_MAP_DIP_SENS = 1
              Else   LV_CDN_DIAG_MAP_DIP_SENS = 0
              Endif
```

Formula section:

Short circuit to VBatt or open load

```
If        V_MAP  >  C_V_MAP_BAS_MAX_DIAG
Then      ERR_SYM_MAP_DIP_SENS  =  SYM_0
```

Short circuit to ground

```
Elself    V_MAP  <  C_V_MAP_BAS_MIN_DIAG
Then      ERR_SYM_MAP_DIP_SENS  =  SYM_1
Else      ERR_SYM_MAP_DIP_SENS  =  NO_SYM
Endif
```

Calculation of present error and end of diagnosis:

LV_ERR_MAP_DIP_SENS and LV_END_DIAG_MAP_DIP_SENS is calculated by error management.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

LV_ERR_TPS_ST_CHK_2	LV_ERR_LOAD_TPS_PLAUS	LV_ERR_MAP_TPS_PLAUS	

FUNCTION DESCRIPTION:

General information:

The purpose of the diagnosis shall be to detect an unplausible shift of the sensor characteristic. The deviation and the maximum allowed deviation from the nominal curve are determined by the module "Pressure Variables (MAP-Sensor) / Adaptation of sensor characteristic".

Description:

Error-symtoms are defined to this diagnosis function as following :

```
□□□□
 | | | └→ -                                       (= SYM_0)

Input data:

ANG_EXC_VVL	LV_ST_END	LV_INH_DIAG_MAF	LV_VAR_MAF
LV_PUC	V_MAF	N_32	LV_VAR_TCHA
LV_IGK	TPS_AV		

FUNCTION DESCRIPTION:

General information:

Diagnosis of analog input signal in the A/D-Input from the Microprocessor. The diagnosis is only performed if the variant is learnt.

Description

To avoid the readiness before the diagnosis is able to detect a symptom the diagnosis is delayed until V_MAF_DIAG_L / H are reaching the thresholds for SCP / SCG_OC detection.
In some engine operating states the measured air flow is under the threshold for SCG / OC detection, thus the diagnosis result SCG / OC is only validated if the engine conditions can ensure a minimum air flow.

The following error symptoms can be detected:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Vbatt SCP                (= SYM_0)
 │ │ └───> Short circuit to Ground or Open load      (= SYM_1)
 │ └─────> -                                         (= SYM_2)
 └───────> -                                         (= SYM_3)
```

Application conditions:

Initialisation: According the ABC configuration **STD_INI**

(0 at LV_IGK 0->1 or reset)

[V_MAF_DIAG / _L / _H = C_V_MAF_DIAG_INI ;

LV_MAF_READY_L / H = 0

at clearing error management **or** LV_IGK 0->1 **or** reset]

Recurrence: 20ms

Activation: LV_VAR_MAF = 1 **and** LV_VAR_TCHA = 1

Deactivation:

```
If      (LV_VAR_MAF = 0 or LV_VAR_TCHA = 0)        and
        LV_ST_END = 1
Then    LV_END_DIAG_MAF_AN = 1                 // set for readiness
Endif
```

Formula section:

Calculation of V_MAF_DIAG:

```
If      LV_ST_END = 1
Then    V_MAF_DIAG = V_MAF_DIAG + ID_CRLC_V_MAF_DIAG__N_32 *
                                          (V_MAF – V_MAF_DIAG)
Else    V_MAF_DIAG = V_MAF_DIAG      //freeze
Endif
```

Calculation of delay to activate the diagnosis:

```
If      LV_MAF_READY_L = 0      or
        LV_MAF_READY_H = 0
Then
    If          LV_ST_END = 1
    Then        V_MAF_DIAG_L = V_MAF_DIAG_L + ID_CRLC_V_MAF_DIAG__N_32 *
                                          (0h – V_MAF_DIAG_L)
                V_MAF_DIAG_H = V_MAF_DIAG_H + ID_CRLC_V_MAF_DIAG__N_32 *
                                          (FFh – V_MAF_DIAG_H)
    Else        V_MAF_DIAG_H / L = V_MAF_DIAG_H / L        // freeze
```

```
        If              V_MAF_DIAG_L < C_V_MAF_MIN_DIAG
        Then            LV_MAF_READY_L = 1
        If              V_MAF_DIAG_H > C_V_MAF_MAX_DIAG
        Then            LV_MAF_READY_H = 1
        Endif
    Else        V_MAF_DIAG_H / L = V_MAF_DIAG_H / L        // freeze
    Endif
```

Calculation of error symptoms:

```
    If(1)       LV_IGK              = 1         and

FUNCTION DESCRIPTION:

The whole electrical diagnostic feature for frequential MAF sensor consists of four parts:

The error detection itself is done within the signal acquisition. Every 1 ms the mean period time per ms of mass air flow sensor (T_PER_MAF_FRQ_BAS[NC_MAF_NR]) is evaluated. Whenever an error is detected (per ms) the corresponding counter (CTR_T_PER_MAF_FRQ_RNG[NC_MAF_NR] or CTR_T_PER_MAF_FRQ_GRD[NC_MAF_NR]) gets incremented and this value itself is neglected.

Here in the diagnostic function these summed up error counters as well as the summed up counter for valid values per segment (CTR_MAF_FRQ_KGH_SUM[NC_MAF_NR]) are evaluated at the end of each segment.

42.17.1 Frequential MAF Sensor: Period Range Check per ms

General information:

The diagnosis described in this section is performed for each MAF sensor separately [NC_MAF_NR].

The purpose is to check the range of the mean period time per ms of mass air flow sensor (T_PER_MAF_FRQ_BAS[NC_MAF_NR]). The diagnostic instance consists of the following symptom:

- SYM_0: ‘MAF-sensor-[NC_MAF_NR]: mean period time per ms exceeding limit’

  MAF_FRQ_RNG[NC_MAF_NR]

Description:

Activation

```
If     LV_VAR_MAF = 1
then if     LV_IGK = 1                                   and
            LV_CDN_VB_OBD1 = 1                           and

    endif
endif
```

Calculation end of diagnosis

LV_END_DIAG_MAF_FRQ_RNG[NC_MAF_NR] is calculated by error management if diagnosis is active.

42.17.2 Frequential MAF Sensor: Gradient Check per ms

General information:

The diagnosis described in this section is performed for each MAF sensor separately (j = 0 ... NC_MAF_NR – 1).

Purpose is to check the gradient of consecutively measured mean period times per ms (absolute value) of mass air flow sensor (T_PER_MAF_FRQ_BAS[NC_MAF_NR]). This allows to detect a completely unplausible increase or decrease of it caused by a loose contact. The diagnostic instance consists of the following error symptom:

- SYM_0: ‘MAF-sensor-[NC_MAF_NR]: unplausible gradient of mean period time per ms’

MAF_FRQ_GRD[NC_MAF_NR]

Description:

```
Activation  If      LV_VAR_MAF = 1
            then    if      LV_IGK = 1                  and
                            LV_CDN_VB_OBD1 = 1          and
                            LV_ST_END = 1
                    Then    LV_CDN_DIAG_MAF_FRQ_GRD[NC_MAF_NR] = 1
                    Else    LV_CDN_DIAG_MAF_FRQ_GRD[NC_MAF_NR] = 0
                    endif
            else    LV_END_DIAG_MAF_FRQ_GRD[NC_MAF_NR] = 1
                    LV_CDN_DIAG_MAF_FRQ_GRD[NC_MAF_NR] = 0
            Endif
```

Initialization: STD_INI

Recurrence: every segment

Formula section:

```
If    LV_CDN_DIAG_MAF_FRQ_GRD[NC_MAF_NR] = 1

then if
      [CTR_T_PER_MAF_FRQ_GRD[NC_MAF_NR] /
 (CTR_MAF_FRQ_KGH_SUM[NC_MAF_NR] + CTR_T_PER_MAF_FRQ_RNG[NC_MAF_NR] +
      CTR_T_PER_MAF_FRQ_GRD[NC_MAF_NR])]
      > C_RATIO_T_PER_MAF_FRQ_GRD_DIAG                    AND
      LV_CTR_T_PER_MAF_FRQ_SENS[NC_MAF_NR] = 0            AND
      LV_CTR_T_PER_MAF_FRQ_EL[NC_MAF_NR] = 0
      then   ERR_SYM_MAF_FRQ_GRD[NC_MAF_NR] = SYM_0
      else   ERR_SYM_MAF_FRQ_GRD[NC_MAF_NR] = NO_SYM
      endif
endif
```

Calculation end of diagnosis

LV_END_DIAG_MAF_FRQ_GRD[NC_MAF_NR] is calculated by error management if diagnosis is active.

42.17.3 MAF electrical diagnosis

General information:

The diagnosis described in this section is performed for each MAF sensor separately (j = 0 ... NC_MAF_NR – 1).

Purpose is to recognize a problem due to an electrical error (SCG, SCB of open line) of the mass air flow sensor (within the sensor on the wiring harness) or a self diagnosis problem is recognized. The diagnostic instance consists of the following error symptom:

- SYM_0: ‘MAF-sensor-[NC_MAF_NR]: electrical fault
- SYM_1: 'MAF-sensor-[NC_MAF_NR]: sensor error recognized

```
Activation   If      LV_VAR_MAF = 1
             then    if     LV_IGK = 1               and
                            LV_CDN_VB_OBD1 = 1       and
                            LV_ST_END = 1
                     Then   LV_CDN_DIAG_MAF_FRQ_EL[NC_MAF_NR] = 1
                     Else   LV_CDN_DIAG_MAF_FRQ_EL[NC_MAF_NR] = 0
                     endif
             else    LV_END_DIAG_MAF_FRQ_EL[NC_MAF_NR] = 1
```

```
                    LV_CDN_DIAG_MAF_FRQ_EL[NC_MAF_NR] = 0
          Endif
```

Initialization: STD_INI

Recurrence: every segment

Formula section:

```
If      LV_CDN_DIAG_MAF_FRQ_EL[NC_MAF_NR] = 1
then if     LV_CTR_T_PER_MAF_FRQ_EL[NC_MAF_NR] = 1
    then    CTR_TCC_T_PER_MAF_FRQ_EL[NC_MAF_NR] ++
    Else    CTR_TCC_T_PER_MAF_FRQ_EL[NC_MAF_NR] = 0
    Endif
    If      CTR_TCC_T_PER_MAF_FRQ_EL[NC_MAF_NR] >

        Endif
Endif
```

Calculation end of diagnosis

LV_END_DIAG_MAF is calculated by error management if diagnosis is active.

42.18 Mass air flow diagnosis (Applic. Inc.)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MAF_BLS_DIAG	O/V	0...1H	0...1	1	-
MAF error and brake is active					
LV_INH_DIAG_MAF	V/O	0...1H	0...1	1	[-]
Inhibition of MAF diagnosis					

Input data:

LV_ERR_MAF	LV_BRAKE_DET	LV_ERR_BLS_PLAUS	LV_VAR_MAF

General information:

LV_MAF_BLS_DIAG is used by engine speed limit coordination and torque request at clutch.

Application conditions:

Initialisation: 0 at reset

Recurrence: 10ms

Activation: LV_VAR_MAF = 1

Deactivation: LV_VAR_MAF = 0

Formula section:

```
LV_INH_DIAG_MAF = 0

If      LV_ERR_MAF = 1              and
        [ LV_BRAKE_DET = 1          or
        LV_ERR_BLS_PLAUS = 1]
Then    LV_MAF_BLS_DIAG = 1
Else    LV_MAF_BLS_DIAG = 0
Endif
```

42.18.1 Interface for Rate – Based – Monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_MAF	V/O	0...7H	0...7	1	[-]
Interface of MAF monitor with the Rate-Based Monitoring statistics Bit 0: conditions for monitoring are met long enough to detect malfunction (bit 0 = 1) Bit 1: inhibition of the monitor because of system failure(s) (bit 1 = 1) Bit 2: individual RBM conditions of the monitor were encountered within this DC (bit 2 = 1)					

Input data:

LV_DC	LV_END_DIAG_MAF		

FUNCTION DESCRIPTION:

General information:

With this module the interface between the MAF monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_MAF data.

Within STATE_RBM_MAF, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for MAF diagnosis)

Application conditions:

Initialisation :

at LV_DC 0 → 1 transition :

bit 0, bit 1 and bit 2 of STATE_RBM_MAF = 0

on failure memory reset :

bit 1 of STATE_RBM_MAF = 0

Recurrence: 1 s

Activation: LV_DC 0 → 1 transition **and** LV_DC = 1

Formula section:

Bit 0:

```
If    bit 0 of STATE_RBM_MAF = 0
then
      if      LV_END_DIAG_MAF = 1
      then    bit 0 of STATE_RBM_MAF = 1
      endif
endif
```

Bit 1:

bit 1 of STATE_RBM_MAF = 0

Bit 2:

bit 2 of STATE_RBM_MAF = 1

42.19 Ambient pressure plausibility diagnosis (LV_ERR_AMP_PLAUS)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_AMP_PLAUS	V/O	0...1H	0...1	1	[-]
Boolean for detected error Ambient pressure plausibility diagnosis					
LV_CDN_DIAG_AMP_PLAUS	V	0...1H	0...1	1	[-]
Status of diagnosis flag for Ambient pressure plausibility					
ERR_SYM_AMP_PLAUS	V	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected symptom Ambient pressure plausibility					
LV_END_DIAG_AMP_PLAUS	V	0...1H	0...1	1	[-]
End of diagnosis flag for Ambient pressure plausibility diagnosis					
AMP_MMV_PLAUS	V	0...FFFFH	0...5434	0.0829175	[hPa]
Mean moving value of AMP_MES					

Input data:

LV_IGK	AMP_MES	LV_INH_DIAG_AMP_PLAUS	VS

FUNCTION DESCRIPTION:

General information:

Due to CARB requirements the diagnosis detects unplausible ambient pressures which cannot be detected by electrical diagnosis.

The diagnosis is based gradient monitoring of AMP_MES.

Description:

AMP_MMV_PLAUS is the mean-moving value of AMP_MES and represents the maximum possible change of AMP if the car is driving uphill or downhill.

If AMP_MES is below or upper AMP_MMV_PLAUS -/+ calibratable offset C_AMP_PLAUS_DIF_ERR the sensor is detected as not plausible and ERR_SYM_AMP_PLAUS is set.

Application conditions:

Initialisation: according ABC – type "**MEM**" *(all 0 at LV_IGK 0->1, error is set irreversible)*

AMP_MMV_PLAUS = AMP_MES at LV_IGK 0->1 **or** Reset

Recurrence: 1s

Activation: LV_IGK = 1 **and** LV_INH_DIAG_AMP_PLAUS = 0

Deactivation: LV_IGK = 0 **or** LV_INH_DIAG_AMP_PLAUS = 1
(set LV_CDN_DIAG_AMP_PLAUS = 0 at deactivation)

Formula section:

Continuous gradient monitoring:

```
LV_CDN_DIAG_AMP_PLAUS = 1
AMP_MMV_PLAUS(n) = AMP_MMV_PLAUS(n-1)
                   + IP_CLRC_AMP_PLAUS * (AMP_MES – AMP_MMV_PLAUS(n-1))
If      AMP_MES > AMP_MMV_PLAUS + C_AMP_PLAUS_DIF_ERR
Then    ERR_SYM_AMP_PLAUS = SYM_0
Elseif  AMP_MES < AMP_MMV_PLAUS - C_AMP_PLAUS_DIF_ERR
Then    ERR_SYM_AMP_PLAUS = SYM_1
Else    ERR_SYM_AMP_PLAUS = NO_SYM
Endif
```

LV_ERR_AMP_PLAUS, LV_END_DIAG_AMP_PLAUS is calculated by error management.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_AMP_PLAUS	1	0...FFH	0...255	1	[-]
Anti bounce increment AMP_PLAUS					
C_ABC_MAX_AMP_PLAUS	1	1...FFH	1...255	1	[-]
Anti bounce maximum AMP_PLAUS					
C_AMP_PLAUS_DIF_ERR	1	0...FFFFH	0...5434	0.0829175	[hPa]
Maximum allowed offset to detect a unplausible AMP_MES					
IP_CLRC_AMP_PLAUS	4	0...FFFFH	0...0.99998	0.0153e-3	[-]
LDP_VS_IP_CLRC_AMP_PLAUS	4	0...FFH	0...255	1	[km/h]
Filter constant for mean moving calculation of AMP_MES					

42.20 Application incidences for ambient plausibility diagnosis

42.20.1 Inhibition of diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_AMP_PLAUS	V/O	0...1H	0...1	1	[-]
Inhibition of AMP_PLAUS diagnosis					

Input data:

LV_ERR_AMP	LV_ERR_VS	LV_IGK	

Description:

LV_INH_DIAG_AMP_PLAUS is set to 1 if AMP_PLAUS diagnosis is inhibited due to a present OBD1 error.

Application conditions:

Initialisation: 0 at reset

Recurrence: 1s

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Formula section:

```
If      LV_ERR_VS = 1     or
        LV_ERR_AMP = 1
Then    LV_INH_DIAG_AMP_PLAUS = 1
Else    LV_INH_DIAG_AMP_PLAUS = 0
Endif
```

42.20.2 Interface for Rate-based-monitoring

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
STATE_RBM_AMP_PLAUS	V/O	0...7H	0...7	1	[-]
Interface of AMP_PLAUS monitor with the Rate-Based Monitoring statistics					

Input data:

LV_DC	CTR_ERR_DYN_NR	LV_END_DIAG_AMP_PLAUS	LV_INH_DIAG_AMP_PLAUS

Import actions:

ACTION_ERRM_CheckPendingStatus (IN <XX>, OUT<PendingStatus>)

General information:

With this module the interface between the AMP_PLAUS plausibility monitor and the Rate-Based Monitoring statistics is defined with STATE_RBM_AMP_PLAUS data.

Within STATE_RBM_AMP_PLAUS, three different information are defined:

- Conditions for monitoring are met long enough to detect malfunction (bit 0)
  (no intrusive operation, no short trip)
- Monitor disabled because of system malfunction (bit 1)
  (depending on failure status: pending)
- Monitor individual RBM conditions encountered within this DC (bit 2)
  (not valid for AMP_PLAUS diagnosis)

Application conditions:

Initialisation :

at ECU reset :

bit 0, bit 1 and bit 2 of STATE_RBM_AMP_PLAUS = 0

at LV_DC 0 → 1 transition :

bit 0 and bit 1of STATE_RBM_AMP_PLAUS = 0

bit 2 of STATE_RBM_AMP_PLAUS = 1

on failure memory reset :

bit 1 of STATE_RBM_AMP_PLAUS = 0

Recurrence: 1 s

Activation: LV_DC = 1

Formula section:

At LV_DC 0 → 1 transition

The pending status of the following failures has to be checked only once :

LV_ERR_AMP	LV_ERR_VS		

```
If(1)       { CPU optimization at LV_DC 0 → 1 transition }
            CTR_ERR_DYN_NR <> 0    { the dynamic failure memory isn't empty }
Then(1)
            While bit 1 of STATE_RBM_AMP_PLAUS = 0 do
                  with each XX failure of the above list :
                  ACTION_ERRM_CheckPendingStatus(IN<XX>, OUT<PendingStatus>,
                  SYNCHRONIZATION<CALL>)
                  If(2)         XX has a pending status
                  Then(2)
                                bit 1 of STATE_RBM_AMP_PLAUS = 1
                  Endif(2)
            Endwhile
Else(1)
            { the dynamic failure memory is empty }
            No action
Endif(1)
```

Every 1 s :

```
If   bit 0 of STATE_RBM_AMP_PLAUS = 0
Then
          If     LV_END_DIAG_AMP_PLAUS = 1
          Then   bit 0 of STATE_RBM_AMP_PLAUS = 1
          Endif
Endif

If   bit 1 of STATE_RBM_AMP_PLAUS = 0
Then
          If     LV_INH_DIAG_AMP_PLAUS = 1
          Then   bit 1 of STATE_RBM_AMP_PLAUS = 1
          Endif
Endif
```
