General information:

The basis of this CAN communication is the specification for "BN 2000" integration revision 6.3.0 (E65) and 4.1.0 (E60). All messages are transmitted as a complete frame, that means every label which is not defined will be transmitted with its "invalid" value (not initialization value!!).
The network management is done by the standard core, so it isn´t described in that document.

The allocation of the messages to the two CAN- controller follows the BMW- Excel- Sheet “Verteilung_CAN_Kanäle_2CANController.xls” from 25-06-2003. The messages which are according to this sheet transmitted in channel 0 ... 13, Basic 1 and Basic 2 are sent via CAN-controller 1. The messages in channel 14 ... 27, Basic 3 and Basic 4 are sent via CAN-controller 2.

43.1.3 Enable conditions for BN 2000 diagnosis

General information:

The CAN diagnosis for BN input messages is only to be enabled if the variant has been recognized. In case of a modul (e.g. TCS) which is not a variant but implemented in every vehicle the diagnosis is always enabled.

If BN diagnosis for message XXX is enabled (conditions see table below) then the conditions for activating the BN diagnosis have to be checked: only if LV_CDN_DIAG_BN_XXX =1 then the BN diagnosis is to be activated. For activation conditions see Chapter "BN2000 diagnosis".

In the following the input messages, their keywords, the symptoms which have to be dectected (timeout, alive, checksum) and the enable conditions for each diagnosis are described.

The XXX in the Chapter "BN2000 diagnosis" have to be replaced by the respective keyword in the table below.

As soon as an TOUT/CKS/TCC-symptom is detected the last CAN-signals of the corresponding message are freezed until the LV_ERR_BN_xxx is debounced, no more new values are taken over. After the LV_ERR_BN_xxx is debounced the signals are set to default-values.

The diagnosis of the symptoms TOUT/CKS/TCC can be inhibited by setting the
corresponding calibration constant C_CTR_DIAG_TOUT/CKS/TCC_CAN_MAX_xxx to 0.
In this case the CAN-signals will be taken over.

43.1.4 Input messages

General information:

The handling of default-values in case of a CAN-error is as follows: if one of the symptoms (timeout, alive or checksum) is detected the last received value should be freezed until the error is debounced. After debounce the respective default-value should be used until rebounce.

43.1.4.1 ACC-Modul

Formula section:

Endif
```

NOTE : Bit LV_OBD_SCAN_REQ is supplied via network layer. Purpose of this part is to make sure that Kl15 will be deactivated only by pressing START/STOP button once OBD scan tool has been connected to vehicle and one of the messages in table below was sent. Switching off KL15 by power managment is not possible in this state.

Requirements for LV_OBD_SCAN_REQ :

- is initialised with "0" at reset

- after disconnecting OBD scan tool Kl15 can be switched off by pressing START/STOP button.

- is set when OBD scan tool is connected to vehicle can and one of the messages listed in table has been sent successfully once.

CAN identifier (hex)	Description
7DF	CAN identifier for functionally addressed request messages sent by the external test equipment.

CAN identifier (hex)	Description
7E0	Physical request CAN identifier from the external test equipment to ECU #1
7E1	Physical request CAN identifier from the external test equipment to ECU #2
7E2	Physical request CAN identifier from the external test equipment to ECU #3
7E3	Physical request CAN identifier from the external test equipment to ECU #4
7E4	Physical request CAN identifier from the external test equipment to ECU #5
7E5	Physical request CAN identifier from the external test equipment to ECU #6
7E6	Physical request CAN identifier from the external test equipment to ECU #7
7E7	Physical request CAN identifier from the external test equipment to ECU #8

Condition for sending DISP_RPM_ENG on CAN (0...message not sent, 1...=N_DISP_DYN, 2...=N_CAN)					

43.2.2.24 Dienste - Anforderung Bus/Teilnetz (ID2 = 12/Ch)

General information:

This message is sent to guarantee a defined PWL time for DMTL-diagnosis. The maximum power latch time is requested only once per driving cycle. This Function is only necessary for vehicle platforms which have a switched Klemme 30 by CAS. Message Layout:

	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
Byte7								
Byte6								
Byte5	DUR_FLLUPT							
Byte4	ST_LAW_RQ				ST_RQ_BUS			
Byte3	ID_RQ_BUS							
Byte2	ID_FN_RQ_BUS							
Byte1	ID_FN_RQ_BUS							
Byte0	12-Anforderung Bus/Teilnetz							

Application conditions:

Initialisation: LV_REQ_PWL_DMTL_SND = 0 at reset or LV_IGK 0->1

Recurrence: event triggered (tmin=100ms, sent 3 times with recurrence 160ms) -> see formula section

Activation: LC_ENA_REQ_PWL_DMTL_CAN = 1

Formula section:

```
If      LV_REQ_PWL_DMTL = 0 -> 1  and  LV_REQ_PWL_DMTL_SND = 0
Then    send message 3 times with recurrence 160ms (as described below)
        //ID_function_request_bus : tank leakage diagnosis:
        ID_FN_RQ_BUS      =  110h
        //request bus  "Klemme 30g":
        ID_RQ_BUS         =  50
```

```
        // status of request bus : activation:
        ST_RQ_BUS          =  0
        // request due to law:
        ST_LAW_RQ          =  1
        // requested powerledge time (converted and limited):
        DUR_FLLUPT         =  C_T_DMTL_MAX
        (DUR_FLLPT = 0 ... 254 min,  (PH) = (HEX)  [min])
        If      sending finished
        Then    LV_REQ_PWL_DMTL_SND = 1
        Endif
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_ENA_REQ_PWL_DMTL_CAN	1	0...1H	0...1	1	[-]
Switch to enable requests to get additional powerledge time for DMTL via CAN (only relevant for E70)

43.2.4 Check Sum Calculation

FUNCTION DESCRIPTION:

The check sum calculation is additional to the "alive counter" a further possibility to supervise the data transmitted via CAN. From all safety relevant controllers, the ECU included, a check sum over all sent data including his own CAN-ID (11 bit) is calculated and sent together with the data frame. The receiver of the data frame can calculate the check sum over the received data and compare it with the received check sum. If both check sums are not the same a transmission error occured. For check sum calculation see newest BN 2000 specification.
The check sums CKS_CLC_TQ_DCC, CKS_CLC_CAS, CKS_CLC_TQ_TCS, CKS_CLC_TQ_ETCU, CKS_CLC_TQ_AMT, CKS_CLC_MSW, CKS_CLC_LDM, CKS_CLC_TQ_PSTE_3, CKS_CLC_PBR, CKS_CLC_ETCU, CKS_CLC_TQ_TCT CKS_CLC_TQ_PBR are calculated with received data (see description below).

CKS_CLC_ECU1, CKS_CLC_ECU2 and CKS_CLC_ECU3, CKS_CLC_TQ_WHEEL_1, CKS_CLC_TQ_WHEEL_2, CKS_CLC_GS_IDC are calculated with sent data from ECU.

Formula section:

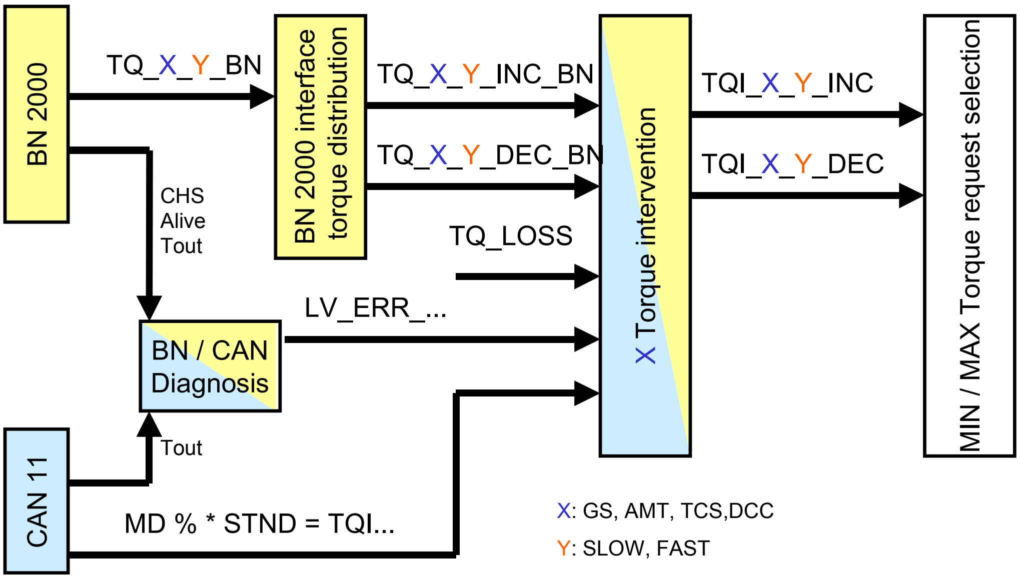
FUNCTION DESCRIPTION:

General information:

Some functions of BN 2000 contain a torque request. For the torque structure interfaces it's necessary to define the direction of torque request as increased or decreased. The BN delivers just one torque request and an additional direction information bit. This module combines the direction information bit of BN with the torque request and supported the torque structure interfaces.

Signal flow diagram:



Application conditions:

Initialisation: *TQ_**X**_FAST_DEC_BN = 1023.97Nm*

*TQ_**X**_SLOW_DEC_BN = 1023.97Nm*

*TQ_**X**_FAST_INC_BN = -1024 Nm*

*TQ_**X**_SLOW_INC_BN = -1024 Nm*

TQ_WHEEL_LDM_INC_DEC_BN = -32000 Nm

LV_RST_T_TQ_DCC_CS = 1

T_TQ_DCC_CS = 0

LV_ERR_SYM_TQ_DCC_CS = 0

Recurrence: 10ms

Activation: LV_VAR_BN = 1 and LV_IGK = 1

Description:

INDEX	Functionality				
Customer	EGS	DSC	SSG	ACC	LDM
Y	ETCU	TCS	AMT	DCC	LDM
X_INC	GS_INC	MSR	AMT_INC	DCC_INC	LDM_INC_ DEC
X_DEC	GS_DEC	ASR	AMT_DEC	-	-
Z	GS	TCS	AMT	DCC	LDM

(The DCC function delivers only an increased Torque request. By using this template the initialisation of LV_TQ_DCC_DEC_REQ with 0 is necessary.) Beside of this, it is necessary that under defined conditions the torque request of the DCC is controlled by the ECU.

43.4 11hex – Diagnosis Gateway

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_STMIN_ECU	1	0...FFH	0...255	1	[ms]
STMIN for gateway from EGS to tester					

Description:

ECU is in case of 11hex gateway between EGS on PT-CAN and Tester on Lo-CAN (e.g reprogramming via tester). The table below describes the way of routing the named diagnosis messages. Routing by hardware means that the controller is used (no application software involved). Routing by software means that the related message is received and if necessary modified and than sent to designated receiver (e.g. tester).

Messages	ID	Routing by ..	Sent from..	Sent to..
Diagnosis-Messages	6F0-6FF	Hardware	Tester	EGS
Diagnosis-Messages	618	Software	EGS	Tester

Formula section:

Rule for software routing:

```
receive message (buffer byte 0-7)
If      byte 1 of received message == 30hex              (FlowControl)
Then    if      byte 3 of received message <  C_STMIN_ECU  (STMIN)
        Then    byte 3 = C_STMIN_ECU
        Endif
Endif
send message (buffer byte 0-7)
```

43.5 CAN Calibration Protocol (CCP)

The Software contains a CAN calibration protocol in accordance with the Spec

CAN-Calibration Protocol
Draft Version 2.1, 03-june-98

Remark: Online Data acquisition with CCP is also possible with connected ETK, but calibration with these ECUs is only possible via ETK.

43.6 Component Driver for BSD-components

43.6.1 BSD-Drivers

43.6.1.1 Device–detection algorithm

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_SENS_BAT_SMT_DET	V/O/S	0...1H	0...1	1	[-]
IBS has been detected					
LF_BSD_CPT_AVL	V/O	0...FFH	0...255	1	[-]
Logical data field displaying the learnt and configured BSD devices					

Input data:

LV_IGK			

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_CTR_BSD_CPT_DET	1	0...FFH	0...255	1	[-]
Number of required consecutive positive acknowledges to get a component learnt					
C_STATE_BSD_CPT_AVL	1	0...FFH	0...255	1	[-]
Actual used BSD devices (bit coded! 1 = used)					
C_STATE_BSD_CPT_DET	1	0...FFH	0...255	1	[-]
BSD devices, which are set by default (bit coded! 1 = not to be learnt)					

FUNCTION DESCRIPTION:

General information:

There is an algorithm installed to detect the single component devices connected to the ECU via BSD. At every ECU reset the learning algorithm is started and for each possible device it is checked whether the device is available or not. In case the consecutive positive acknowledges of the device reach the calibratabel threshold C_CTR_BSD_CPT_DET the corresponding device has been learnt. Once a device has been detected it is assumed that it is installed for ever and for this specific device the learning algorithm is deactivated. To realise this the flag indicating whether a device is learnt or not is stored in the NVMY. The learnt devices can solely be deleted via tester tool. They can be read via KWP job. Alternator, QLT and electronically controlled water pump are assumed to be there in every case, resulting in a fulltime activation of the corresponding device drivers. In addition each device can be set by a SW constant as to be available (C_STATE_BSD_CPT_AVL) and if the available devices should be leart or not (C_STATE_BSD_CPT_DET) (set as loc. True!)

Description:

The following bit-coding is applied to the calibration constants C_STATE_BSD_CPT_AVL, C_STATE_BSD_CPT_DET and the status byte LF_BSD_CPT_AVL (set as loc. True!)
The logical data field LF_BSD_CPT_AVL displays the configured and learnt BSD components. In case there is a mismatch between C_STATE_BSD_CPT_AVL and LF_BSD_CPT_AVL obviously a problem occurred in the BSD components learning session. The by the constant C_STATE_BSD_CPT_DET configured BSD components are directly set in the logical data field LF_BSD_CPT_AVL. The BSD components which have to be learnt are set after the learning process has been finished. In case the BSD component has been successfully learnt the corresponding bit is set to 1 in the logical data field LF_BSD_CPT_AVL. Otherwise the corresponding device bit stays 0.
.

Bit position	BSD device
0	SENS_BAT_SMT -- Intelligent battery sensor (IBS)
1	-- O3 Sensor
2	-- el. waterpump electronics
3	CWP -- electrical coolant water pump
4	QOIL – oil quality sensor (QLT)
5	-- alternator 2
6	ALTER – alternator
7	-- glow plug control unit

Application conditions:

Initialisation: all variables are initialised out of NVMY

Recurrence: once after LV_IGK = 1

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

Formula section:

```
If      KT_IBS_VAR = 1 (ASW, BSW Interface)
Then    LV_SENS_BAT_SMT_DET = 1
Else    LV_SENS_BAT_SMT_DET = 0
Endif

If      LV_SENS_BAT_SMT_DET = 0
Then    Device–detection algorithm for IBS is activated
Else    Device–detection algorithm for IBS is deactivated
Endif

If      LV_SENS_BAT_SMT_DET = 1            /*IBS learnt in this or in any former driving cycle*/
Then    Component driver for IBS is activated
Else    Component driver for IBS is deactivated
Endif
```

Import actions:

ACTION_COMS_*SetBsdGlobalCom* (IN <CTR_BSD_CPT_COM_OK>)

ACTION_COMS_*SetBsdSingleCom (*IN <STATE_BSD_CPT>, IN <STATE_BSD_COM>)

Description for actions:

ACTION_COMS_*SetBsdGlobalCom* (<CTR_BSD_CPT_COM_OK>)					
Action which delivers at the end of the BSD timing table the status of the communication of all BSD devices of the list; number of successful communications for one scheduling timing list cycle					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
CTR_BSD_CPT_COM_OK	IN	0...FFH	0...255	1	-
Number of the 'ok' communications per total scheduling timing list cycle of the BSD devices					
ACTION_COMS_*SetBsdSingleCom* (<STATE_BSD_CPT>,<STATE_BSD_COM>)					
Action which delivers at the end of the BSD timing slot the status of the communication of the actual BSD device of the scheduling list					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
STATE_BSD_CPT	IN	0...FFH	0...255	1	-
BSD device, which communicates actually with the ECU via BSD					
STATE_BSD_COM	IN	0...FFH	0...255	1	-
Status of the communication to the BSD devices (faulty /o.k.)					

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
ID_STATE_BSD_SDL_TBL	32	0...FFH	0...255	1	[-]
LDP_IDX_BSD_SDL_TBL	32	0...FFH	0...255	1	[-]
BSD component device scheduling timing table					

FUNCTION DESCRIPTION:

General information:

The BSD timing coordinator handles the scheduling of the device drivers. The 8 possible component devices (bit 0...3) can be configured in the table ID_STATE_BSD_SDL_TBL. In addition the configuration can be configered for 3 different states (Engine running (bit 4), power latch (bit 5), wake up (bit3)). The table configures the scheduling of the BSD devices. The end of the scheduling table is marked by FFH.

For each BSD device the status of the communication is checked. In case of no acknowledge of the device the flags LV_CWP_COM_ACT, LV_ALTER_COM_ACT, LV_QOIL_COM_ACT, LV_SENS_BAT_SMT_COM_ACT are set at the end of the timing slot and the action ACTION_COMS_*SetBsdSingleCom (*IN <STATE_BSD_CPT>, IN <STATE_BSD_COM>) is called.
The action feeds the diagnosis of the individual BSD devices in term of the detection of a communication error.

After the detection of faulty communication in a certain timing slot the next corresponding timing slot is served with a '22 synchronisation pulse phase' followed by a none acknoledge!

Unter certain circumstances the communication to a device can be stopped (LV_MSG_xxx_COM_STOP) although the time slot is still reserved for this device. The staus byte STATE_BSD_MSG_COM_STOP communicates the information via to the BSD timing coordinator to which BSD component a timout is applied. Background: it is assumed that after a disturbed communication to a device has been detected a 'break' in the communication could cure the problem.

Before the BSD device scheduling timing table is started again (IDX_BSD_SDL_TBL =0) the flags LV_xxx_COM_ACT have to be reset to 0. In case no acknowledge is set through the whole BSD timing table, the flags LV_xxx_COM_ACT are still =0 at the end of the timing table, so therefore the global BSD error can be fed with this information. For each positive acknowledge per timing slot the counter CTR_BSD_CPT_COM_OK is incremented by 1. CTR_BSD_CPT_COM_OK equal to 0 indicates a global BSD communication error. At the end of the list IDX_BSD_SDL_TBL(ID_STATE_BSD_SDL_TBL = FFH) the action ACTION_COMS_*SetBsdGlobalCom*(<CTR_BSD_CPT_COM_OK>) is called and the global BSD error can be debounced by the ERRM.

The communication to the devices is monitored by the BSW.

The error symptom detection is made out of basic software information BIOS_BSD_xx.
If a problem is detected the corresponding malfunction of the communication between the ECU and the BSD device is indicated by the corresponding flag LV_xxx_COM_ACT.

With xxx:

ALTER	– alternator
CWP	– electrical coolant water pump
QOIL	– oil quality sensor (QLT)
SENS_BAT_SMT	– intelligent battery sensor (IBS)

Description:

The driver of a certain device is only called if the device has been learnt. Some BSD device drivers are not called (writing only!) if the message to be written has not changed. So if it is not necessary for the device driver to send (e.g. if the values did not change), this is reported to the timing coordinator. The timing coordinator can then pass on this time slot to the next BSD device in the scheduling timing table.

Design of the scheduling timing table of the BSD devices:

ID_STATE_BSD_SDL_TBL

IDX_BSD_SDL_TBL	Bit 7 not used	Bit 6 not used	Bit 5 'wake up' ECU_STATE = 6H	Bit 4 'engine running' ECU_STATE = 0H v	Bit 3 'power latch' ECU_STATE = 4H	Bit 2	Bit 1	Bit 0	
0	0	0	0	1	0	1	1	0	e.g. Alternator ***SetBsdSingleCom***

30	0	0	0	0	0	0	0	0	
31	0	0	0	0	0	0	0	0	

The BSD device is coded in Bit 0...2.

Application conditions:

Initialisation:	0 at WakeUp	
	Recurrence:	20ms (optional 25ms in MS45)
Activation:	WakeUp	
Deactivation:	Sleeping	

Formula section:

Handling of the single /global BSD com error /counter CTR_BSD_CPT_COM_OK:

```
If      IDX_BSD_SDL_TBL < IDX_BSD_SDL_TBL(ID_STATE_BSD_SDL_TBL = FFH)
        //Pointer of the BSD timing coordinator is between the starting point of the scheduling timing table
          and the end of the Scheduling timing table//

Then
   If      LV_MSG_xxx_COM_STOP = 0 (STATE_BSD_MSG_COM_STOP)
   Then  If      ECU receives no positive acknowledge from slave device
         Then    LV_xxx_COM_ACT = 0                    and
                 Send a 22 sychronisation pulse phase
                 in next corresponding time slot followed by
                 LV_xxx_COM_ACT == 0
         Else    LV_xxx_COM_ACT = 1
         Endif
             If      LV_xxx_COM_ACT = 1
                     With: xxx – corresponding to the actual time slot device
             Then    CTR_BSD_CPT_COM_OK ++
             Endif
         // the end of the timing table is not reached-transmit single message error status//
         Call ACTION_COMS_SetBsdSingleCom (IN <STATE_BSD_CPT>, IN <STATE_BSD_COM>)
         IDX_BSD_SDL_TBL++
   Else  stop communication to device xxx in the corresponding time slot
         STATE_BSD_COM = FFH
         Call ACTION_COMS_SetBsdSingleCom (IN <STATE_BSD_CPT>, IN <STATE_BSD_COM>)
         IDX_BSD_SDL_TBL++

   Endif

        //Counter is reset to 0 at the end of the Scheduling timing table after the action has been called//
        // the end of the timing table is reached-transmit global BSD error status//
Else    Call        ACTION_COMS_SetBsdGlobalCom(IN          <CTR_BSD_CPT_COM_ACT>)
        CTR_BSD_CPT_COM_OK = 0          // reset communication counter//*
        IDX_BSD_SDL_TBL = 0             // re-started BSD timing table//*
        LV_CWP_COM_ACT = 0              // Table is re-started ; reset communication flags//*
        LV_ALTER_COM_ACT = 0
        LV_QOIL_COM_ACT = 0
        LV_SENS_BAT_SMT_COM_ACT = 0
Endif
```

Control of the communication after an communication error has been detected:

```
If      C_CTR_MAX_xxx_COM_STOP <> FFFFH             and
        LV_ERR_xxx_COM = 1
Then    stop communication with this device for this DC (LV_IGK 1-->0)
Else    communication with the corresponding device to be continued
```

With:
STATE_BSD_CPT = STATE_BSD_SDL_TBL(bit0...2)
STATE_BSD_COM = LV_xxx_COM_ACT
STATE_BSD_MSG_COM_STOP = LV_MSG_xxx_COM_STOP

6H -- ALTER – alternator	40H = LV_MSG_ALTER_COM_STOP = 1

43.6.1.3 Component driver

FUNCTION DESCRIPTION:

General information:

Basics that should be implemented in a device driver:

Description:

To be translated:

- Wenn Werte geschrieben werden sollen, soll abgeprüft werden ob der Wert gleich dem zuletzt gesendeten Wert ist. Ist dieses der Fall, kann die Funktion für diesen Buszyklus wieder verlassen werden.
  Diese Funktionalität dient dazu, die Busbelastung niedrig zu halten.
  Der nächste Teilnehmer laut Timing-Liste kann dann diesen Zeitslot nutzen.

  Nach dem Lernprozess wird das angeschlossene Gerät vom BSD-Timing-Koordinator als vorhanden markiert. Jetzt wird die eigentliche BSD-Kommunikation mit dem ausgewähltem Gerät gestartet. Dabei läuft innerhalb des Komponententreibers wiederum ein Schreib-Lese-Koordinator, welcher in seiner Abfolge frei definiert werden kann. Getaktet wird dieser Vorgang durch den Aufruf des BSD-Timing-Koordinators.

Application conditions:

Recurrence:	wird durch BSD-Timingcoordinator generiert
Activation:	WakeUp
Deactivation:	Sleeping

43.6.2 Component Driver for BSD-alternator

43.6.2.1 Identification of the controller type

FUNCTION DESCRIPTION:

This function allows to identify the controller type of the alternator that is installed and to choose the communication protocol via code word. Possible controller types:

General information:

BSD-controller II measures and limits the exciting current. Additional a detection of the chip temperature. It provides information about the actual alternator torque for a torque model. The communication of the BSD-controller type I is different to the BSD-controller type II. In the first phase BSD-controller type I or type II can be installed. At init., register 7 provides information about controller- and chip version and the nominal voltage. Address 6 communicates with type I and type II. Later on a mix of type I and type II assembly is impossible.

Description:

Detection of the controller type (Register 7, Bit 6/7):

Type	ALTER_COD_2
BSD-controller I	00
BSD-controller II	01

Choosing the communication protocol via code word:

Type	LC_ALTER_BSD_PROT_2
BSD-controller I	0
BSD-controller II	1

Combinations and possible BSD protocol:

ALTER_COD_2	LC_ALTER_BSD_PROT_2	LV_ALTER_BSD_PROT_2
00	0	0
00	1	0
01	0	0
01	1	1

Conditions to be choose by software switch:

sw-switch / codeword	condition	meaning	BMW naming
LC_ALTER_BSD_PROT_2	LV_ALTER_BSD_PTOT_2	BSD-prot 1 or 2	CW_GENPROT

43.6.2.2 BSD controller I

Id. for address 0x06 (BSD component driver controller typ I)

Part: electr. alternator, electronic: address: 6

Remark: address 6 must communicate with type I and type II (depending of the detection what type is installed).

Specification only for BSD-controller type I !!

logical constant: software swich to choose BSD protocol					

FUNCTION DESCRIPTION:

General information:

V_ALTER_SP will be limited to the upper threshold 16.0 V. After that it will be provided to the BSW for the BSD interface.
T_LOAD_RESP_ALTER will be converted to 3 s resolution, limited between 0 and 9 seconds and provided to the BSW for the BSD interface as well.
ALTER_COD_1 delivers the type of alternator
ALTER_COD_0 delivers the manufactory of alternator
This both information is necessary to identify the alternator. Depending on this information the power management is able to switch different calibrations.

Application conditions:

Activation: at every engine operating state

Deactivation: -

Initialization: all outputs 0 (LV_GEN_xx = FALSE)

ALTER_COD_1 = 1F H /*initalisation to max value*/
ALTER_COD_0 = 7 H /*initalisation to max value*/

Update-Rate: 50 ms

Formula section:

if no valid message was received during a timeout : T_LOAD_RESP_ALTER = 3 s
V_ALTER = 14.3 V

else : POW_REL_ALTER_CLC, T_LOAD_RESP_ALTER and V_ALTER are received via BSD interface.

The failure-bits LV_GEN_xx are received via BSD interface.

FUNCTION DESCRIPTION:

General information:

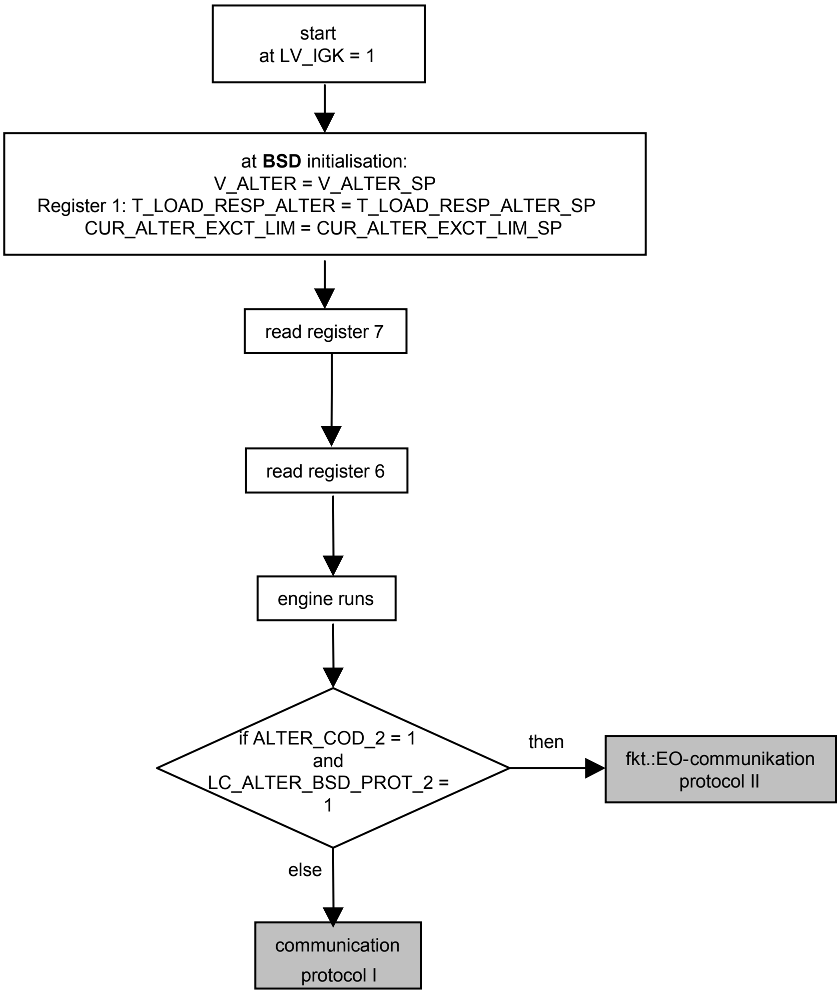
LF_ALTER_EVE_WR is a status flag, which is generated by comparison of the variables CUR_ALTER_EXCT_LIM, T_LOAD_RESP_ALTER, V_ALTER and the corresponding setpoints.
NR_ALTER_EVE_WR is the output of the map **ID_NR_ALTER_EVE_WR** and describes the number of the eo-write event. In case of equality of LF_ALTER_EVE_WR and the datapoint of ID_NR_ALTER_EVE_WR one of 8 possible write events is selected, otherwise the output of ID_NR_ALTER_EVE_WR is 0.
CTR_ALTER_EVE_WR is the counter for the eo-write event process.
STATE_ALTER_VALUE_WR is the output of the map **ID_STATE_ALTER_VALUE_WR** and selects dependant on CTR_ALTER_EVE_WR and NR_ALTER_EVE_WR the next value to write on the bus.

43.6.2.3.1 Additional information for the BSD controller II protocol.

Writing only after a value has changed (after events) therefore comparison of value and reference value (for example Tlrgen -> Tlrfgen).

register 1:
Tlrgen (LR-value) should be round down to the next value of tn. For more details see 1.2.3.5 table writing reg 1. When writing the LR-value then the bit B_lrreg1ak = 1.
Writing of the set points to the alternator register 0 only in a defined time schedule (depending on C_T_WR_PER_ALTER_TBL_0)
register 2:
Reading of the values only in a defined time schedule (depending on C_T_RD_PER_ALTER_TBL_2).
register 3:
Read of register 3 “as often as possible” without eo-communication (defined in the flow chart 1.2.3.2). Minimum every second time slot = read register 3. At successfully communication the variable lerrfgrenz is written.
register 5:
Reading of the values only in a defined time schedule (depending on C_T_RD_PER_ALTER_TBL_5)
register 6:
Reading once at start communication BSD
register 7:
Reading once at start communication BSD

General flowchart KT_Gen BSD controller II



43.6.2.3.2 Flow chart for function EO-communication BSD controller II

Superior function KT_Sched (time scheduler)

only for example, content of time slots not describe the software !!!

20 ms	20 ms	20 ms	20 ms	20 ms	20 ms	20 ms	20 ms	20 ms	20 ms	20 ms
alter- nator	battery sensor	electr. cwp	QLT	alter- nator	battery sensor	electr. cwp	QLT	alter- nator	battery sensor	....

By a time scheduler every 20 ms a new communication is triggered. During this time one register can be in progress (sending a protocol and call a driver). If KT_Gen is triggered, then the progress shown below is started.

Subordinated function EO communication KT_GEN

Application conditions:

Initialisation: only if LV_ALTER_BSD_PROT_2 = 1

Recurrence: 40 ms

Activation: at every engine state

Deactivation: -

Following flow charts are only a functional description of EO-communication BSD controller II. Due to the fact, that it is not possible to do action on BSD immediately for the requested device (for e.g. Generator), the requested jobs has to be stored in circular buffer (FIFO).

In case of GEN slot is carry out the jobs in the buffer will be executed according the FIFO principle.

In case of "V_ALTER_SP (U_gen)" goes to 10,6V, immediately write of REG 0 and delete all other Jobs in the queue.

In case of "wrablauf > 0", immediately execute function "ablaufwr" and delete all other Jobs in the queue. New entries can be done after the last requested job from "ablaufwr" was executed.

Was a deleting of the queue performed and there are still jobs for reading Reg. 2 or Reg. 5 in the buffer, the jobs are lost.
Due to the fact, there is no positive response for reading Reg.2 or Reg.5, therefore set the timers for Reg.2 and Reg.5 again.

The recurrence of calculation "Generator BSD Controller II function" (40ms) could be higher than the BSD-Driver execute the Generator components (best case 20ms, worst case more than 40ms).
To avoid multiple entries for the same job in the buffer (because there was no update yet), the job entry in the buffer is locked till this job was performed by the BSD Driver.

The locking of the Register will be indicated with following flags:

- LV_REQ_GEN_WR_REG0
- LV_REQ_GEN_WR_REG 1
- LV_REQ_GEN_WR_REG 3
- LV_REQ_GEN_RD_REG 2
- LV_REQ_GEN_RD_REG 5
- LV_STEP_BSD_ALTER

the corresponding flags will be set to "0" after job has been perfomed.

Following locks in the buffer could be possible:

wrablauf = 0
Lock requested writing Reg. 0, 1, 3 till this job is done.
wrablauf > 0
Immediately execute function "ablaufwr", writing all jobs that are defined in ID_STATE_ALTER_VALUE_WR and lock new entry in the queue.

Lock reading Reg. 2 or Reg. 5 till reading was successfully executed.

In case of C_T_WR_PER_ALTER_TBL_0 / 1 are set to "0" not time triggert write to REG 0 / 1 will be executed, only event triggert action can be perfomed.

43.6.2.4 State machine Component Driver for BSD-alternator Type I

FUNCTION DESCRIPTION:

General information:

Der Komponententreiber wird durch einen Zustandsautomaten der im Aufrufraster des BSD-Timing-Koordinator läuft dargestellt. Wie der **Error! Reference source not found.** zu entnehmen ist besteht der KT aus mehreren Zuständen die im folgenden näher beschrieben werden.

Signal flow diagram:

Abbildung 43.6-1: Statemachine KT-Treiber Generator

Description:

A) Allgemeiner Zustand:

In jedem Zustand des KT werden folgende Fehler geprüft:

Überschreitet der ***timeout counter for valid message*** die Schwelle **KT_GEN_VALID_MESSAGE_TIMEOUT** so wird die Größe **V_ALTER** auf den Applikationswert **UGENTYP** (13.8V entspricht den Notlaufwert des Generators) bzw. die Größe **T_LOAD_RESP_ALTER** auf den Applikatonswert **TLRDEFAULT** (0x1E entspricht den Notlaufwert des Generators) gesetzt ansonsten wird der ***timeout counter for valid message*** inkrementiert (bei gültigen Daten wird dieser durch die Call_Back-Function zurückgesetzt).

Anschließend wird geprüft ob das Generatorinterface aktiv ist d.h. Bedingung ***B_genactiv*** = True, wenn ja wird der ***timeout send counter*** und der ***timeout read counter*** inkrementiert (bei gültigen Daten wird dieser durch die jeweilige Call_Back-Function zurückgesetzt).

Desweiteren wird im jedem Zustand geprüft ob der ***timeout send counter*** die Schwelle **KT_GEN_SEND_TIMEOUT** bzw. der ***timeout read counter*** die Schwelle **KT_GEN_SEND_TIMEOUT** überschritten hat. Wurde einer dieser Schwellen überschritten geht der KT in den Zustand *kt_GenStatus = KT_GEN_ST_INI* über .

B) Zustand KT_GEN_ST_INI:

Zu Beginn wird der KT initialisiert d.h.
V_ALTER = 0;
T_LOAD_RESP_ALTER = 0;
LV_GEN_ERR_EL = FALSE;
LV_GEN_ERR_TEMP = FALSE;
LV_GEN_ERR_MEC = FALSE;
LV_GEN_IF_OFF = FALSE;
POW_REL_ALTER_CLC = 0;

und andere diverse Größen wie Fehlerzähler usw..

Nach der Initialisierung befindet sich der KT im Zustand *kt_GenStatus = KT_GEN_ST_INI*. In diesem Zustand wird zyklisch ein ***initialization timeout counter*** hochgezählt und dem Hardwaretreiber (HWT) Initialisierungsdaten übergeben und anschließend der HWT gestartet. Als Initialisierungsdaten werden dem HWT folgende Größen übergeben:

period length
low_time Sync pulse
low_time of sended LOW Bit
low_time of sended HIGH Bit
pointer to callback function for read register when result is ready
pointer to callback function for send register when quit from peripherie is OK
pointer to error handler

Wie oben zu sehen ist, werden dem HWT unter anderem zwei Pointer für die Call-Back-Funktion übergeben genaueres hierzu folgt etwas später.

Nun wird der ***initialization timeout counter*** inkrementiert. Anschließend wird geprüft ob der ***initialization timeout counter*** die Initialisierungsschwelle **KT_GEN_INI_TIMEOUT** überschritten hat, wenn ja geht der KT in dem Zustand *kt_GenStatus = KT_GEN_ST_IDLE* über und der ***initialization timeout counter*** wird zurückgesetzt.

Nachdem der HWT gestartet worden ist, geht der KT in dem Zustand *kt_GenStatus = KT_GEN_ST_WAIT* über.

C) Zustand KT_GEN_ST_WAIT:

In diesem Zustand wird gewartet bis der HWT den Status „work“ mitteilt. Hier muß durch den BSD-Timing-Koordinator angezeigt werden ob sich der Treiber noch im Lernmodus befindet . Ist dieser Lernprozess abgeschlossen wird der ***initialization timeout counter*** , ***timeout counter send message*** und der ***timeout counter read message*** zurückgesetzt und die Bedingung ***B_genactiv*** auf True gesetzt (generator interface is active). Anschließend geht der KT in den Status über welcher vom internen Schreib-Lese-Koordinator vorgegeben wird.

D) Zustand KT_GEN_ST_IDLE:

Befindet sich der KT im Zustand *kt_GenStatus = KT_GEN_ST_IDLE* wird dem HWT ein „ausschalten“ des generator interface mitgeteilt, d.h. die Kommunikation auf der BSD-Schnittstelle bzgl. Generator wird eingestellt. Anschließend wird gewartet bis der HWT ein generator interface off mitteilt.

Nachdem vom HWT ein generator interface off mitgeteilt wurde wird die Bedingung ***B_genactiv*** auf False gesetzt, die Bedingung ***LV_GEN_IF_OFF*** auf True gesetzt und in diesem Zustand verharrt. Die Bedingung ***LV_GEN_IF_OFF*** wird nur oberhalb einer Batterie Spannungsschwelle VB >=C_VB_MIN_POW_DIAG aktiviert.

E) Zustand KT_GEN_ST_WRITE_REG0:

Die Generatorsollspannung ***V_ALTER_SP*** zwischen den beiden Applikationswerten **UGMN** und **UGMX** begrenzt. Ist ***V_ALTER_SP*** kleiner gleich **UGMN** wird als Generatorsollspannung der Applikationswert **OUINIGEN** verwendet.

Nach einer Umquantisierung des Sollwerts Load- Response- Zeit Generator ***T_LOAD_RESP_ALTER_SP*** wird diese zwischen den beiden Applikationswerten **TLRMN** und **TLRMX** begrenzt.

Anschließend wird dem HWT über einen Funktionsaufruf die Generatorsollspannung ***V_ALTER_SP*** und der Sollwert der Load-Response-Zeit ***T_LOAD_RESP_ALTER_SP*** mitgeteilt. Wurden diese Werte vom HWT über die BSD-Schnittstelle gesendet, wird die Call-Back-Funktion *KT_gen_sendErgHandler* über einen Pointer aufgerufen.

Nachdem die Werte dem HWT übergeben worden sind, geht der KT in den nächsten angeforderten Zustand *kt_GenStatus* über.

F) Zustand KT_GEN_ST_READ_REG0:

Es werden HWT Daten von der BSD-Schnittstelle bzw. vom Generator durch einen Funktionsaufruf des HWT mit gültiger Generatoradressse angefordert.

Liegen Daten vom BSD-Generator dem HWT vor, so ruft der HWT durch einen Pointer die Call-Back-Funktion *KT_gen_readErgHandler* auf.
Nachdem die Werte durch den HWT übernommen worden sind, geht der KT in den nächsten angeforderten Zustand *kt_GenStatus* über.

G) Zustand KT_GEN_ST_READ_REG2:

Es werden HWT Daten von der BSD-Schnittstelle bzw. vom Generator durch einen Funktionsaufruf des HWT mit gültiger Generatoradressse angefordert.

Liegen Daten vom BSD-Generator dem HWT vor, so ruft der HWT durch einen Pointer die Call-Back-Funktion *KT_gen_readErgHandler* auf.

Nachdem die Werte durch den HWT übernommen worden sind, geht der KT in den nächsten angeforderten Zustand *kt_GenStatus* über.

H) Call-Back-Funktion KT_gen_sendErgHandler:

Wie bereits im Kapitel erwähnt, wird bei einer erfolgreichen Übertragung der Generatorsollspannung ***V_ALTER_SP*** bzw. des Sollwerts Load- Response- Zeit ***T_LOAD_RESP_ALTER_SP*** durch den HWT die Call-Back-Funktion *KT_gen_sendErgHandler* über einen Pointer durch den HWT aufgerufen.

In dieser Call-Back-Funktion wird der ***timeout counter for valid message*** sowie der ***timeout send counter*** zurückgesetzt.

I) Call-Back-Funktion KT_gen_readErgHandler:

Liegen Daten vom BSD-Generator dem HWT vor, so ruft der HWT durch einen Pointer die Call-Back-Funktion *KT_gen_readErgHandler* and the flag LV_ALTER_ERR_IF is reset.

In dieser Call-Back-Funktion wird zunächst der ***timeout counter for valid message*** sowie der ***timeout read counter*** zurückgesetzt. Anschließend werden die vom HWT übergebenen Daten ausgewertet bzw. nach einer entsprechenden Umquantisierung abgespeichert.

J) Fehler-Handler-Funktion KT_gen_errHandler:
Erkennt der HWT Fehler auf der BSD-Schnitstelle, geht der KT in den Zustand *kt_GenStatus = KT_GEN_ST_INI* über and the flag LV_ALTER_ERR_IF is set.

FUNCTION DESCRIPTION:

Beschreibung der Schnittstelle HW-Treiber – Komponententreiber für die Verbindung IBS – DME

General information:

Der intelligente Batteriesensor bietet eine Reihe unterschiedlicher Einsatzmöglichkeiten und wird darum auf längere Sicht Gegenstand der Entwicklung sein. Dabei ist abzusehen, dass bei den unterschiedlichen Nutzungen auch wechselnde Variablen, Parameter und sonstige Datenstrukturen von und zum Sensor übertragen werden müssen. Es ist daher sinnvoll, in der Kommunikation zwischen Host und Sensor eine invariante Schnittstelle zu definieren, die die variablen Schichten des Komponententreibers und der Anwendersoftware vom Hardwaretreiber trennt, der nur einmal implementiert wird.

Description:

A) Realisierung Schnittstelle

Zum Datenaustausch in beiden Richtungen werden 3 Variable vom Typ unsigned char verwendet.:
BSD_SENS_BAT_SMT_INFO, BSD_SENS_BAT_SMT_ADR und LF_BSD_SENS_BAT_SMT_CTL. Sie sind im Modul des Hardwaretreibers global vereinbart.

BSD_SENS_BAT_SMT_INFO überträgt den Inhalt eines der acht BSD Register.

BSD_SENS_BAT_SMT_ADR (0 .. 7) adressiert das gewünschte Register.

LF_BSD_SENS_BAT_SMT_CTL enthält 7 Flags, die als Anforderung, Quittung, Fehlermeldung etc. die Kommunikation zwischen Komponententreiber (KT) und Hardwaretreiber (HT) koordinieren.

Um eine möglichst schnelle Übertragung zu erreichen, müssen der KT und der HT nacheinander in dieser Reihenfolge von der gleichen zyklischen Task aufgerufen werden.

B) Flags zur Kommunikation Hardware-/ Komponententreiber, in LF_BSD_SENS_BAT_SMT_CTL

Name	***Bit***	***gesetzt durch***	***gelöscht durch***	***Bedeutung***
BSDHTOK LV_SENS_BAT_SMT_BSD_DR_OK	0	HT	HT	Hardware Treiber ist bereit zur Übertragung; Flag bleibt an solange kein Fehlerzustand
BSDWRITE **LV_SENS_BAT_SMT_BSD_WR**	1	KT	KT	Richtung, hi: Register im Sensor schreiben
BSDDO **LV_SENS_BAT_SMT_BSD_RUN**	2	KT	HT	Anforderung von Komponenten- an Hardwaretreiber zum Start einer Übertragung
BSDBSY LV_SENS_BAT_SMT_BSD_WORK	3	HT	HT	Übertragung aktiv, Hardwaretreiber busy; Flag wird z.Zt. vom KT nicht benutzt
BSDRXRDY **LV_SENS_BAT_SMT_BSD_TRM_END_AVL**	4	HT	KT	Übertragung beendet, eingelesenes Byte ist verfügbar; Flag von Handler () im HT gesetzt
BSDTXOK **LV_SENS_BAT_SMT_BSD_TRM_END_OK**	5	HT	KT	Übertragung beendet, Byte wurde erfolgreich gesendet; Flag von Handler () im HT gesetzt
BSDERR LV_SENS_BAT_SMT_BSD_ERR_IT	7	HT	HT	BSD Fehler

Nur die fett gedruckten Flags werden für die laufende Kommunikation zwischen Komponenten- und Hardwaretreiber benötigt.

C) Ablauf der Übertragung eines BSD Telegramms

1. Nach „KL15 an“ löscht die Hardwaretreiber- Initialisierung alle Flags in LF_BSD_SENS_BAT_SMT_CTL.

2. Der Hardwaretreiber baut die Verbindung zur Schnittstellen- Hardware auf. Nach erfolgreicher Verbindung und bei Funktionsbereitschaft setzt der HT das Flag LV_SENS_BAT_SMT_BSD_DR_OK.

3. Ist ausschließlich das Bit LV_SENS_BAT_SMT_BSD_DR_OK in LF_BSD_SENS_BAT_SMT_CTL gesetzt, interpretiert der KT dies als Startbedingung und setzt seine zyklische Kommunikation zum Sensor auf.

4. Der Komponententreiber prüft LV_SENS_BAT_SMT_BSD_DR_OK vor jeder Aktion. Ist der HT bereit, wird das gewünschte Register in BsdReg adressiert. Bei Schreiboperationen wird das Bit LV_SENS_BAT_SMT_BSD_WR und das Datenbyte BSD_SENS_BAT_SMT_INFO belegt. Der KT setzt das Bit LV_SENS_BAT_SMT_BSD_RUN.

5. Der Hardwaretreiber erkennt an LV_SENS_BAT_SMT_BSD_RUN die Anforderung zur Übertragung. Soll gesendet werden, übermittelt er das Datenbyte an die Hardware und startet die Sendung zum gewünschten Register, andernfalls veranlasst er den Empfang eines Bytes aus dem Sensor. Der HT löscht dann die Anforderung LV_SENS_BAT_SMT_BSD_RUN und setzt statt dessen das Flag LV_SENS_BAT_SMT_BSD_WORK.

6. Das Ende einer Übertragung wird je nach Implementierung durch schnelles Polling oder per Interrupt festgestellt, der HT enthält eine entsprechende Handler Routine. Diese löscht LV_SENS_BAT_SMT_BSD_WORK, kopiert nach einem Lesevorgang das eingelesene Byte nach BSD_SENS_BAT_SMT_INFO und setzt das Flag LV_SENS_BAT_SMT_BSD_TRM_END_AVL zum Zeichen, dass der Komponententreiber ein empfangenes Byte auslesen kann. Nach einem erfolgreichen Schreibvorgang wird nur das Flag LV_SENS_BAT_SMT_BSD_TRM_END_OK gesetzt.

7. Der Komponententreiber liest LV_SENS_BAT_SMT_BSD_TRM_END_AVL bzw. LV_SENS_BAT_SMT_BSD_TRM_END_OK und löscht diese Flags, nachdem er ggf. das eingelesene Byte übernommen hat. Nach einem erneuten Test auf LV_SENS_BAT_SMT_BSD_DR_OK kann die nächste Übertragung durch Setzen von LV_SENS_BAT_SMT_BSD_RUN gestartet werden, s. 4).

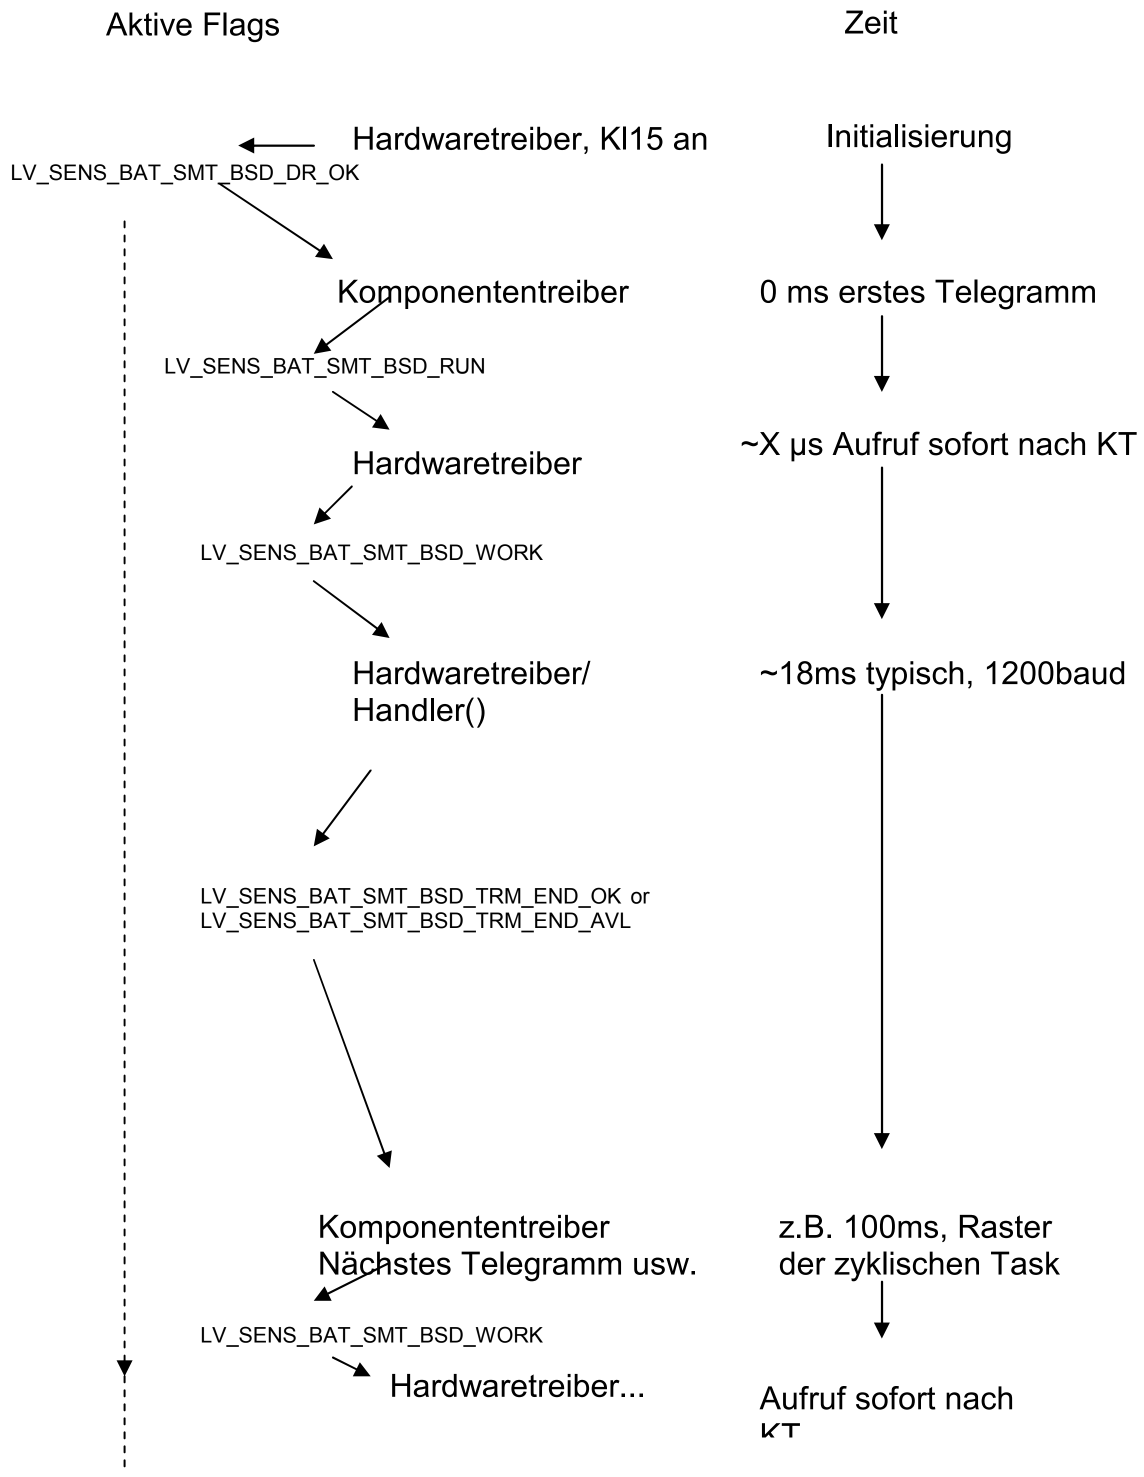
Bemerkungen:
Das Flag LV_SENS_BAT_SMT_BSD_WORK wird z.Zt. nur HT- intern verwendet, der KT greift nicht darauf zurück.
Bei interruptgesteuerten Handler Routinen muss die Möglichkeit einer Unterbrechung von HT oder KT durch den Interrupt berücksichtigt werden. Im Komponententreiber wird darum eine lokale Kopie von LF_BSD_SENS_BAT_SMT_CTL verwendet.

D) Fehlerbehandlung durch den HT

Wenn der Hardwaretreiber initial die Verbindung nicht herstellen kann oder wenn zwischenzeitlich die Verbindung abreisst, wird das Flag LV_SENS_BAT_SMT_BSD_DR_OK nicht gesetzt bzw. gelöscht.
In der Folge werden laufend neue Versuche zur Verbindung unternommen. Ist nach Ablauf einer entsprechenden Wartezeit Ibs_Ht_TimeOut keine Verbindung zustande gekommen, wird das Flag LV_SENS_BAT_SMT_BSD_ERR_IT gesetzt und alle anderen Flags gelöscht.
Der HT nimmt anschliessend einen Idle- Zustand ein, aus dem er nach der Zeit Ibs_Ht_IdleTime erwacht und wieder für Ibs_Ht_TimeOut weitere Initialisierungen versucht. Bei Erfolg kann wieder LV_SENS_BAT_SMT_BSD_DR_OK gesetzt und alle anderen Flags gelöscht werden, andernfalls bleibt die Fehlermeldung stehen.

Ibs_Ht_TimeOut:	20 Lese/ Schreibversuche
Ibs_Ht_IdleTime:	applizierbar, vorbelegt 100s

E) Schema Flagaustausch zwischen Komponenten- und Hardwaretreiber



Application conditions:

```
Activation:    if LC_POW_CORD_INH = 0   and
                  LV_VAR_BN = 1         and
                  LV_VAR_VEH = 0
Deactivation:     -
Update rate:      100ms
```

Formula section:

Setting of LV_SENS_BAT_SMT_ACT:

```
if      ReadyStatus from BSD-interface
then    LV_SENS_BAT_SMT_ACT = 1
endif
```

Re-setting of LV_SENS_BAT_SMT_ACT:

```
if      BSD-control-flag IBS_BSD = 1
then    LV_SENS_BAT_SMT_ACT = 0
endif
```

Control of error interface across the BMW Layer for the PWSL OBJ file

As soon as a certain number of communications between the IBS and the ECU were not succesful the bit LV_SENS_BAT_SMT_ERR_IT is set. This bit is part of the logical field LF_BSD_SENS_BAT_SMT_CTL (bit 7). This logical field is then copied across the BMW Layer and used in the PWSL functionality. In case of a global BSD error the bit is set as well. Due to the fact that the single BSD error is de-bounced with a anti bounce counter and the counter CTR_MSG_SENS_BAT_SMT_COM_DIAG is reset to 0 after each increment of the anti bounce counter the anti bounce counter has to be taken into account as well.

```
IF      LV_SENS_BAT_SMT_DET = 1                         and
        [ CTR_MSG_SENS_BAT_SMT_COM_DIAG ≥ 1        or
          CTR_ABC_SENS_BAT_SMT_COM ≥ 1             or
          LV_ERR_BSD = 1                              ]
THEN    LV_SENS_BAT_SMT_BSD_ERR_IT = 1
EISE    LV_SENS_BAT_SMT_BSD_ERR_IT = 0
```

FUNCTION DESCRIPTION:

General information:

The oil sensor (QLT = Quality Level Temperature) delivers information about the oil temperature, the oil level and the oil quality. This sensor is located in oil pan. The communication between this oil sensor and the engine management systen (ECU) is done via BSD-interface.

Description:

A) Describtion of communication of the BSD-Interface

On the SW-side in the ECU the recieved BSD-messages are treated with a "component driver".
5 Registers are relevant:
0 Oiltemperatur
1 Oilniveau
2,3 Permittivity
6 Status / Variant
this values are updated every 200ms

In case of a BSD-communication error the bit B_ozfbsd is set

B) Describtion of the registers

Ident	Parameter	LS Bit	Bit Anz.	w(rite) r(ead)	Ein-heit	Function
0	OZ_TEMP	0	8	-/r	°C	Öltemperatur (8Bit)

Signal Öltemperatur:

Label : OZ_TEMP
Skalierungsbereich: -55,2 bis +175,4 = 01 h bis FE h [°C]
Plausibler Bereich: -40°C bis +160°C ⇒ Messwertebereich = 200 K
Messbereichsverletzung: 00 h ⇒ Messbereichsunterschreitung
FF h ⇒ Messbereichsüberschreitung
Fehlerkennzeichnung: DATA2 = 4 h ⇒ Sensorfehler Öltemperaturmessung
Auflösung: 8 bit

Signal Ölstand:

Label :	OZ_NIV	
Skalierungsbereich:	0.bis 75 = 01 h .bis.FE h [mm]	
Plausibler Bereich:0 bis	75 mm	⇒ Messwertebereich = 75 mm
Messbereichsverletzung:	00 h	⇒ Messbereichsunterschreitung
	FF h	⇒ Messbereichsüberschreitung
Fehlerkennzeichnung:	DATA2 = 2 h	⇒ Sensorfehler Ölstandsmessung
Auflösung:	8 bit	

Signal Ölzustand (Permittivitätszahl ε_r):

Label :	OZ_PERMM / OZ_PERML	
Skalierungsbereich:	1 bis 6 = 0001 h bis 03FE h	
Plausibler Bereich:	1 bis 6	⇒ Messwertebereich = 5
Messbereichsverletzung:	0000 h	⇒ Messbereichsunterschreitung
	03FF h	⇒ Messbereichsüberschreitung
Fehlerkennzeichnung:	DATA2 = 1 h	⇒ Sensorfehler Permittivitätsmessung
Auflösung:	10 bit	

Application conditions:

Initialisation: *all 0 at reset*

Recurrence: *200ms*

Activation: *at every engine state*

43.7 CAN (11H) diagnosis

FUNCTION DESCRIPTION

General information:

The following CAN diagnosis are defined:

- Timeout diagnosis of CAN message **ASC1**
- Timeout diagnosis of CAN message **ASC3**
- Timeout diagnosis of CAN message **ASC4**
- Timeout diagnosis of CAN message **EGS1**
- Timeout/Alive/Checksum diagnosis of CAN message **EGS2**
- Timeout diagnosis of CAN message **INSTR2**
- Timeout diagnosis of CAN message **INSTR3**
- Timeout diagnosis of CAN message **INSTR7**
- Timeout diagnosis of CAN message **LWS1**
- Timeout diagnosis of CAN message **EKP**

- Timeout/Alive/Complement diagnosis of CAN message **SSG1**

For calculation of LV_END_DIAG_xxx, see “Calculation end of diagnosis” in chapter “Anti-bounce algorithm.

43.7.1 Timeout diagnosis of CAN message ASC1

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TOUT_ASR_1	V/O	0...1H	0...1	1	[-]
logical variable timeout error CAN message ASC1					
CYC_CTR_ASR_1_DIAG	V	0...FFH	0...255	1	[-]
Counter of not received ASC1 messages					
LV_CDN_DIAG_TOUT_ASR_1	V/O	0...1H	0...1	1	[-]
Diagnosis condition ASC1 messages					
ERR_SYM_TOUT_ASR_1	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected error symptom ASC1 messages					
LV_END_DIAG_TOUT_ASR_1	V/O	0...1H	0...1	1	[-]
End of diagnosis ASC1 messages					

Input data:

LV_CDN_VB_CAN_DIAG	LV_VAR_ASR	LV_ERR_CAN_BOFF	LV_IGK

Description:

The counter CYC_CTR_ASR_1_DIAG is always incremented If the CAN message ASC1 has not been received. The counter is set to 0 If a CAN message ASC1 has been received or If the counter has reached his maximum value C_ASR_1_CYCNR_MAX.
If this counter has reached the calibratable threshold C_ASR_1_CYCNR_MAX and there is no CAN message ASC1 then the error symptom is set and the anti bounce counter is incremented by C_ABC_INC_TOUT_ASR_1. If a CAN message ASC1 is received, the anti bounce counter is decremented.
If the anti bounce counter has reached his maximum value C_ABC_MAX_TOUT_ASR_1 the timeout error CAN message ASC1 (LV_ERR_TOUT_ASR_1) is set.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                            (= SYM_0)
 │  │  └────> -                            (= SYM_1)
 │  └───────> Timeout signal ASC1          (= SYM_2)
 └──────────> -                            (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** reset **or** at clearing error memory

Recurrence: 10 ms

Activation: **If** LV_CDN_VB_CAN_DIAG = 1 **and**
LV_VAR_ASR = 1 **and**
LV_ERR_CAN_BOFF = 0
Then LV_CDN_DIAG_TOUT_ASR_1 = 1
Else LV_CDN_DIAG_TOUT_ASR_1 = 0

```
            Endif
```

Formula section:

Calculation of time-out counter

```
If          no CAN message ASC1 received
Then        $CYC\_CTR\_ASR\_1\_DIAG_{N} = CYC\_CTR\_ASR\_1\_DIAG_{N-1} + 1$
Else        CYC_CTR_ASR_1_DIAG   = 0     (reset)
EndIf
```

Detection of error symptom:

```
If(1)       CYC_CTR_ASR_1_DIAG = C_ASR_1_CYCNR_MAX
Then(1)     CYC_CTR_ASR_1_DIAG   = 0     (reset)
    If(2)       no CAN message ASC1 is received
    Then(2)     ERR_SYM_TOUT_ASR_1 = SYM_2
                Error symptom is detected, ABC counter starts to increment
                LV_ERR_TOUT_ASR_1     = 1     (after debounce)
    Else(2)     ERR_SYM_TOUT_ASR_1 = NO_SYM
                on Error symptom is detected, ABC counter starts to decrement
                LV_ERR_TOUT_ASR_1     = 0     (after rebounce)
    EndIf(2)
EndIf(1)
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ASR_1_CYCNR_MAX	1	1...FFH	1...255	1	[-]
Maximum number of missing ASC1 messages for error debounce counter increment					
C_ABC_INC_TOUT_ASR_1	1	0...FFH	0...255	1	[-]
Anti bounce counter increment - diagnosis of timeout CAN message ASC1					
C_ABC_MAX_TOUT_ASR_1	1	1...FFH	1...255	1	[-]
Anti bounce counter maximum value - diagnosis of timeout CAN message ASC1					

43.7.2 Timeout CAN message ASC3

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TOUT_ASR_3	V/O	0...1H	0...1	1	[-]
Logical variable timeout error CAN message ASC3					
CYC_CTR_ASR_3_DIAG	V	0...FFH	0...255	1	[-]
Counter of not received ASC3messages					
LV_CDN_DIAG_TOUT_ASR_3	V/O	0...1H	0...1	1	[-]
Diagnosis condition ASC3messages

Input data:

LV_CDN_VB_CAN_DIAG	LV_VAR_ICL	LV_ERR_CAN_BOFF	LV_IGK

Description:

The counter CYC_CTR_ICL_2_DIAG is always incremented If the CAN message INSTR2 has not been received. The counter is set to 0 If a CAN message INSTR2 has been received or If the counter has reached his maximum value C_ICL_2_CYCNR_MAX.
If this counter has reached the calibratable threshold C_ICL_2_CYCNR_MAX and there is no CAN message ASC1 then the error symptom is set and the anti bounce counter is incremented by C_ABC_INC_TOUT_ICL_2. If a CAN message INSTR2 is received, the anti bounce counter is decremented. If the anti bounce counter has reached his maximum value C_ABC_MAX_TOUT_ICL_2 the timeout error CAN message INSTR2 (LV_ERR_TOUT_ICL_2) is set.

43.8 BN2000 diagnosis

43.8.1 Table of BN2000 diagnosis

FUNCTION DESCRIPTION:

General information:

This chapter is for the definition of all ERRM relevant output – data using the general BN2000 diagnosis algoritm.

The CAN diagnosis for BN input messages are only enabled if the variant has been recognized. In case of a modul (e.g. Kombi) which is not a variant but implemented in every vehicle the diagnosis is always enabled.

43.8.1.1 Diagnosis ACC module (Distance cruise control)

43.8.1.1.1 DREHMOMENT_ANF_ACC (LV_ERR_BN_TQ_DCC)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_BN_TQ_DCC	V/O	0...1H	0...1	1	[-]
Present error BN2000					
LV_CDN_DIAG_BN_TQ_DCC	V/O	0...1H	0...1	1	[-]
Diagnosis condition BN2000 diagnosis					
ERR_SYM_BN_TQ_DCC	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected symptom BN2000 diagnosis					
LV_END_DIAG_BN_TQ_DCC	V/O	0...1H	0...1	1	[-]
End of diagnosis BN2000 diagnosis					
CTR_DIAG_TCC_CAN_TQ_DCC	V	0...FFH	0...255	1	[-]
Diagnosis counter for alive-counter error symptom detection					
CTR_DIAG_CKS_TQ_DCC	V	0...FFH	0...255	1	[-]
Diagnosis counter for checksum counter error symptom detection					
CTR_DIAG_TOUT_TQ_DCC	V	0...FFH	0...255	1	[-]
Diagnosis counter for timeout counter error symptom detection					

Input data:

LV_VAR_DCC			

General information:

See general BN2000 diagnosis algorithm

Application conditions:

Activation: LV_VAR_DCC = 1

Description:

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │  │  │  └─> -                                       (= SYM_0)
 │  │  └────> Alive counter did not count             (= SYM_1)
 │  └───────> Timeout                                 (= SYM_2)
 └──────────> Sent checksum ≠ calculated checksum     (= SYM_3)
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_BN_TQ_DCC	1	0...FFH	0...255	1	[-]

D

43.8.2 BN2000 diagnosis algorithm

FUNCTION DESCRIPTION:

General information:

All diagnosis are only activated if the variant BN2000 is valid (LV_VAR_BN = 1).
For the diagnosis each message is monitored.

XXX is the variable for each different input message (see “CAN messages BN2000, Enable condition for BN2000 diagnosis).

Description:

The following symptoms can be detected:

- Alive counter did not count
- Timeout of the message
- Sent checksum is not equal to the calculated checksum of the message

For detailed information of Alive-counter, checksum calculation and timeout see (see “CAN messages BN2000).

If symptom “Timeout” is detected (counter CTR_DIAG_TOUT_XXX ≠ 0), the remaining symptom detection is inhibited.

If C_CTR_DIAG_TOUT/CKS/TCC_CAN_MAX_XXX are calibrated to 0 then the diagnosis of the symptom TOUT/CKS/TCC_CAN is inhibited.

Error symptoms are defined for this diagnosis function as:

```
□□□□
 │ │ │ └─> -                                   (= SYM_0)
 │ │ └───> Alive counter did not count         (= SYM_1)
 │ └─────> Timeout                             (= SYM_2)
 └───────> Sent checksum ≠ calculated checksum (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** reset **or** at clearing error memory

Recurrence: each message is diagnosed

Activation:

```
If        Diagnosis is enabled       (learnt/calibrated etc..., see "CAN messages
                                     BN2000, enable condition for BN2000 diagnosis).
Then If          LV_WAKE_UP                = 1          and
                 LV_CDN_VB_BN_DIAG         = 1          and
                 LV_ERR_CAN_BOFF           = 0          and
                 LV_VAR_BN                 = 1          and
     Then        LV_CDN_DIAG_BN_XXX        = 1
     Else        LV_CDN_DIAG_BN_XXX        = 0
     Endif
Else      LV_CDN_DIAG_BN_XXX    = 0
Endif
```

Deactivation:

```
If   XXX = TQ_DCC                    (Diagnosis of TQ_DCC message)
Then      If     LV_ERR_BN_XXX             = 1          and
                 ERR_SYM_BN_XXX            = SYM_1/SYM_3
          Then   LV_CDN_DIAG_BN_XXX        = 0    (for this DC!)
          Endif

Endif
```

Formula section:

Error detection alive counter:

```
If(1)       CTR_DIAG_TOUT_XXX = 0              and
            CTR_DIAG_CKS_xxx = 0               and
            C_CTR_DIAG_TCC_CAN_MAX_XXX ≠ 0
Then If(2)  $TCC\_CAN\_XXX_{n} = TCC\_CAN\_XXX_{n-1}$        or
                TCC_CAN_XXX = FH
    Then(2)     $CTR\_DIAG\_TCC\_CAN\_XXX_{n} = CTR\_DIAG\_TCC\_CAN\_XXX_{n-1} + 1$
        If(3)   CTR_DIAG_TCC_CAN_XXX >= C_CTR_DIAG_TCC_CAN_MAX_XXX
        Then(3)     Error symptom “Alive-counter” is active
                    ERR_SYM_BN_XXX = SYM_1
                    anti-bounce increment per C_ABC_INC_BN_XXX
                    LV_ERR_BN_XXX = 1          after debounce
        Endif(3)
    Else(2)     CTR_DIAG_TCC_CAN_XXX = 0
                Error symptom “Alive-counter” is passive
                ERR_SYM_BN_XXX = NO_SYM
                anti-bounce decrement per C_ABC_DEC_BN_XXX
                LV_ERR_BN_XXX = 0          after rebounce
    Endif(2)
Else(1)     No error detection
Endif(1)
```

Error detection “Checksum is wrong”:

```
If(1)       CTR_DIAG_TOUT_XXX = 0              and
            C_CTR_DIAG_CKS_MAX_XXX ≠ 0
Then  If(2)     CKS_CAN_XXX ≠ CKS_CLC_XXX  (sent ≠ calculated)
    Then(2)     $CTR\_DIAG\_CKS\_XXX_{n} = CTR\_DIAG\_CKS\_XXX_{n-1} + 1$
        If(3)       CTR_DIAG_CKS_XXX >= C_CTR_DIAG_CKS_MAX_XXX
        Then(3)     Error symptom “Calculated checksum ≠ sent checksum” is active
                    ERR_SYM_BN_XXX = SYM_3
                    anti-bounce increment per C_ABC_INC_BN_XXX
                    LV_ERR_BN_XXX = 1          after debounce
        Endif(3)
    Else(2)     CTR_DIAG_CKS_XXX = 0
                Error symptom “Calculated checksum ≠ sent checksum” is passive,
                ERR_SYM_BN_XXX = NO_SYM
```

```
                    anti-bounce decrement per C_ABC_DEC_BN_XXX
                    LV_ERR_BN_XXX = 0       after rebounce
        Endif(2)
Else(1)     No error detection
Endif(1)
```

Error detection “Timeout”:

```
If(1)       C_CTR_DIAG_TOUT_MAX_XXX ≠ 0
ThenIf(2)           no BN2000 message XXX is received
    Then(2)         CTR_DIAG_TOUT_XXX $_n$ = CTR_DIAG_TOUT_XXX $_{n-1}$ + 1
        If(3)           CTR_DIAG_TOUT_XXX >= C_CTR_DIAG_TOUT_MAX_XXX
        Then(3)         Error symptom “Timeout” is active
                        ERR_SYM_BN_XXX = SYM_2
                        anti-bounce increment per C_ABC_INC_BN_XXX
                        LV_ERR_BN_XXX = 1       after debounce
                        Else(3)
        Endif(3)
    Else(2)         CTR_DIAG_TOUT_XXX = 0
                    Error symptom “Timeout” is passive,
                    ERR_SYM_BN_XXX = NO_SYM
                    anti-bounce decrement per C_ABC_DEC_BN_XXX
                    LV_ERR_BN_XXX = 0       after rebounce
    Endif(2)
Else(1)     No error detection
Endif(1)
```

Calculation of the end of diagnosis:

For calculation of LV_END_DIAG_BN_XXX see “Anti-bounce algorithm, calculation of the end of diagnosis

Configuration of Anti-bounce

NC_ABC_CONF_FCT_DIAG_XX = 19H (Not saved, INI at LV_IGK, CTR_ABC_.. = 0 at INI, Calibratable decrement)

43.9 CAN diagnosis for NOX control (local CAN)

FUNCTION DESCRIPTION

General information:

The following CAN diagnosis are defined:

- Timeout CAN messages NOX

43.9.1 Timeout CAN messages NOX

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_TOUT_NOX_SENS_i	V/O	0 ... 1H	0 ... 1	1	-
logical variable timeout error CAN message NOX_SENS_i (NOX_SENS – sensor bank i)					
LV_CDN_DIAG_TOUT_ NOX_SENS_i	V/O	0 ... 1H	0 ... 1	1	-
Diagnosis condition NOX_SENS_i					
ERR_SYM_TOUT_ NOX_SENS_i	V/O	0H 4H	NO_SYM SYM_3	1	-
Detected Symptom NOX_SENS_i					
LV_END_DIAG_TOUT_ NOX_SENS_i	V/O	0 ... 1H	0 ... 1	1	-
End of diagnosis NOX_SENS_i					
CYC_CTR_NOX_SENS_i_DIAG	V	0 ... FFH	0 ... 255	1	-
counter of not received NOX_SENS_i messages					

Input data:

LV_CDN_VB_CAN_DIAG	LV_IGK	LV_ERR_LOCAN_BOFF	

Description:

The counter CYC_CTR_NOX_SENS_i_DIAG are always incremented if the CAN messages NOX_SENS_i have not been received. The counter are set to 0 if a CAN message NOX_SENS_i has been received or if the counter has reached his maximum value C_NOX_SENS_CYCNR_MAX.
If these counters have reached the calibratable threshold C_NOX_SENS_CYCNR_MAX and there is no CAN message NOX_SENS_i then the error symptom is set and the anti bounce counter is incremented by C_ABC_INC_TOUT_NOX_SENS. If a CAN message NOX_SENS_i is received, the anti bounce counter is decremented. If the anti bounce counter has reached his maximum value C_ABC_MAX_TOUT_NOX_SENS the timeout error CAN message NOX_SENS (LV_ERR_TOUT_NOX_SENS_i) is set.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                         (= SYM_0)
 │ │ └───> -                         (= SYM_1)
 │ └─────> Timeout signal NOX_SENS_i (= SYM_2)
 └───────> -                         (= SYM_3)
```

Application conditions:

Initialisation: all 0 at Transition LV_IGK 0->1 or reset or at clearing error memory

Recurrence: 10 ms

Activation:

```
If      LV_CDN_VB_CAN_DIAG = 1        and
NOX-message has been received via LoCAN at least for once     and
LV_ERR_LOCAN_BOFF = 0
Then    LV_CDN_DIAG_TOUT_NOX_SENS_i = 1
Else    LV_CDN_DIAG_TOUT_NOX_SENS_i = 0
Endif
```

Formula section:

Calculation of time-out counter

```
If      no CAN message NOX_SENS_i received
Then    $CYC\_CTR\_NOX\_SENS\_i\_DIAG_{N} = CYC\_CTR\_NOX\_SENS\_i\_DIAG_{N-1} + 1$
Else    CYC_CTR_NOX_SENS_i_DIAG = 0     (reset)
EndIf
```

Detection of error symptom

```
If(1)       CYC_CTR_NOX_SENS_i_DIAG = C_NOX_SENS_CYCNR_MAX
Then(1)     CYC_CTR_NOX_SENS_i_DIAG = 0     (reset)
    If(2)       no CAN message NOX_SENS_i is received
    Then(2)     ERR_SYM_TOUT_NOX_SENS_i = SYM_2          Timeout is detected
                ABC counter starts to increment
                LV_ERR_TOUT_NOX_SENS_i = 1               (after debounce)
    Else(2)     ERR_SYM_TOUT_NOX_SENS_i = NO_SYM
                ABC counter starts to decrement
                LV_ERR_TOUT_NOX_SENS_i = 0               (after rebounce)
    EndIf(2)
EndIf(1)
```

Calculation end of diagnosis

LV_END_DIAG_TOUT_NOX_SENS_i is calculated by error management

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_NOX_SENS_CYCNR_MAX	1	1 ... FFH	1 ... 255	1	-
maximum number of missing NOX_SENS messages for error debounce counter increment					
C_ABC_INC_TOUT_NOX_SENS	1	0 ... FFH	0 ... 255	1	-
anti bounce counter increment - diagnosis of timeout CAN message NOX_SENS					
C_ABC_MAX_TOUT_NOX_SENS	1	1 ... FFH	1 ... 255	1	-
anti bounce counter maximum value - diagnosis of timeout CAN message NOX_SENS					

43.10 CAN bus off diagnosis

43.10.1 PT-CAN bus off diagnosis

FUNCTION DESCRIPTION

General information:

This diagnosis is working for BN2000 and CAN11H.

Description:

From CPU- CAN- controller a message is sent if CAN bus is on or off (internal). This diagnosis takes place every 10 ms at all engine operating states with ignition key on.
If CAN bus off is active the anti bounce counter is incremented by C_ABC_INC_CAN_BOFF.
If the anti bounce counter reaches the calibratable threshold C_ABC_MAX_CAN_BOFF then the error bit LV_ERR_CAN_BOFF is set to 1.

Error symptoms are defined for this diagnosis function as:

```
|_|_|_|_|
 |  |  |  └─> -                                     (= SYM_0)
 |  |  └───> -                                      (= SYM_1)
 |  └─────> CAN bus off          controller                (= SYM_2)
 └───────> -                                        (= SYM_3)
```

Application conditions:

Initialisation: STD_INI

Recurrence: 10 ms

```
Activation:   If     LV_CDN_VB_CAN_DIAG = 1
              Then   LV_CDN_DIAG_CAN_BOFF = 1
              Else   LV_CDN_DIAG_CAN_BOFF = 0
              Endif
```

Formula section:

Detection of error symptom

```
If      CAN bus off = active
Then    ERR_SYM_CAN_BOFF = SYM_2
        LV_ERR_CAN_BOFF = 1     (after debounce)
Else    ERR_SYM_ CAN_BOFF = NO_SYM
        LV_ERR_CAN_BOFF = 0     (after rebounce)
Endif
```

Calculation end of diagnosis

LV_END_DIAG_CAN_BOFF is calculated by error management

43.10.2 LOCAN bus off diagnosis

FUNCTION DESCRIPTION

General information:

This diagnosis is working for LOCAN applications like EFP – control or NOX - sensors.

Description:

From CPU hardware a message is sent if CAN bus is on or off (internal). This diagnosis takes place every 10 ms at all engine operating states with ignition key on.
If CAN bus off is active the anti bounce counter is incremented by C_ABC_INC_LOCAN_BOFF. If the anti bounce counter reaches the calibratable threshold C_ABC_MAX_LOCAN_BOFF then the error bit LV_ERR_LOCAN_BOFF is set to 1.

Error symptoms are defined for this diagnosis function as:

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                        (= SYM_0)
 │ │ └───> -                        (= SYM_1)
 │ └─────> LOCAN bus off            (= SYM_2)
 └───────> LOCAN TxWARN or RxWARN   (= SYM_3)
```

Application conditions:

Initialisation: STD_INI

Recurrence: 10 ms

Activation:

```
If    LV_CDN_VB_CAN_DIAG = 1
Then  LV_CDN_DIAG_LOCAN_BOFF = 1
Else  LV_CDN_DIAG_LOCAN_BOFF = 0
Endif
```

Formula section:

Detection of error symptom

```
If      LOCAN bus off = active
Then    ERR_SYM_LOCAN_BOFF = SYM_2
        LV_ERR_LOCAN_BOFF = 1          (after debounce)
Else    ERR_SYM_ LOCAN_BOFF = NO_SYM
        LV_ERR_LOCAN_BOFF = 0          (after rebounce)
EndIf
```

Calculation end of diagnosis

LV_END_DIAG_LOCAN_BOFF is calculated by error management

43.11 BSD diagnosis

43.11.1 Global BSD Error – No communication to any of the BSD components

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_BSD	V/O	0...1H	0...1	1	[-]
logical variable for BSD error					
LV_CDN_DIAG_BSD	V/O	0...1H	0...1	1	[-]
Diagnosis condition BSD diagnosis					
ERR_SYM_BSD	V/O	0H 1H 2H 4H 8H	NO_SYM SYM_0 SYM_1 SYM_2 SYM_3	1	[-]
Detected symptom BSD					
LV_END_DIAG_BSD	V/O	0...1H	0...1	1	[-]
End of BSD - Diagnosis					

Input data:

LV_CDN_VB_MIN_DIAG	LV_IGK		

Export actions:

ACTION_AGGR_*SetBsdGlobalCom* (IN <CTR_BSD_CPT_COM_OK>)
Action which delivers at the end of the BSD scheduling timing table the status of the communication of all BSD components of the list (counter = 0 ; no communication occured at all)

Description for actions:

ACTION_COMS_*SetBsdGlobalCom _COM* (<CTR_BSD_CPT_COM_OK>)

Action which delivers at the end of the BSD timing table the status of the communication of all BSD devices of the list; number of successful communications for one scheduling timing list cycle

Parameter	Type	Hex. Limits	Phys. Limits	Resol.	Unit
CTR_BSD_CPT_COM_OK	IN	0...FFH	0...255	1	-
Number of the ‘ok’ communications per total scheduling timing list cycle of the BSD devices					

FUNCTION DESCRIPTION:

General information:

This diagnosis is to detect a malfunction in the BSD-line (**B**it-**S**erial-**D**ata transfer). There could be several components be connected to the BSD bus (alternator, intelligent battery sensor, oil quality sensor, electrical coolant water pump).
The diagnosis works with the help of basic software information. To detect an error symptom it is necessary to have a data tranfer before, thus the information is stored until the next recurreny of the diagnosis. The error symptoms are set exclusive per data transfer.
There is a certain scheduling defined to serve the several components via BSD bus. In total for one complete cycle (defined in the BSD scheduling timing table) several time slots have to be passed after a decision can be made wether the communication to at least one BSD component has successfully been passed. Is there no positve acknowegde from none of the BSD components, the counter CTR_BSD_CPT_COM_OK = 0 is indicating a global communication.
Each component is linked to certain time slots.
In general each component can be either configered by a calibration switch (‘must’ component; e.g. alternater, electrical coolant water pump, oil quality sensor) or can be learnt (intelligent battery sensor).

Description:

As soon as the communication via BSD has been started the ECU expects in all time slots correct messages (positive acknowledge). In case none of the messages have been received the global BSD error is set after debounce followed by inhibiting of the individual BSD communication errors.
After the error has been detected, the BSD timing coordinator is still serving the BSD components in the hope that the problem which disturbed the global communication disapears.

The error symptom detection is made out of basic software information BIOS_BSD_xx:
If one of the following error symptoms are detected:

- To less Bits were received (*BIOS_BSD_TOO_FEW_BITS_ERR* is set)
- To many Bits were received (*BIOS_BSD_TOO_MANY_BITS_ERR* is set)
- At least one data-bit was not inside the puls (*BIOS_BSD_BIT_LVL_ERR* is set)
- Receiver send “NAK” (*BIOS_BSD_ACK_ERR* is set)
- Receiver does not respond (*BIOS_BSD_SLAVE_TO_ERR* is set)
- One of the parity-bits in the data frame is wrong (*BIOS_BSD_PARITY_ERR* is set)
- Period of last measured bit was not o.k. (*BIOS_BSD_PER_ERR* is set)

then the error symptom “BSD signal error” is set” to active.

For error symptom calculation (*ERR_SYM_BSD*) the symptom position is:

```
☐☐☐☐
 | | | └─> -                       (= SYM_0)
 | | └───> -                       (= SYM_1)
 | └─────> BSD signal error        (= SYM_2)
```

```
└────────> -                              (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** at reset

Recurrence: Function called after each communication block (see BSD timing table)

Activation:

```
If      LV_CDN_VB_MIN_DIAG = 1 and
        Communication on BSD started
Then    LV_CDN_DIAG_BSD = 1
Else    LV_CDN_DIAG_BSD = 0
Endif
```

Error management:

```
If      LV_CDN_DIAG_BSD = 1
Then If     CTR_BSD_CPT_COM_OK = 0      //no BSD com occured at all conf. CPT
     Then   ERR_SYM_BSD = SYM_2         //Error symptom detected, ABC increments
     Else   ERR_SYM_BSD = NO_SYM        //No error symptom detected, ABC decrements
     Endif
Endif
```

Remark: LV_ERR_BSD and LV_END_DIAG_BSD are calculated by error management if diagnosis is active.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_ABC_INC_BSD	1	0...FFH	0...255	1	[-]
anti bounce counter increment - diagnosis BSD					
C_ABC_MAX_BSD	1	1...FFH	1...255	1	[-]

Input data:

LV_CDN_VB_MIN_DIAG	LV_IGK		

Export actions:

ACTION_AGGR_*SetBsdSingleCom* (IN<STATE_BSD_CPT>,IN<STATE_BSD_COM>)
Action which delivers at the end of the BSD timing slot the status of the communication of the actual BSD device of the scheduling list

Description for actions:

ACTION_COMS_*SetBsdSingleCom* (<STATE_BSD_CPT>,<STATE_BSD_COM>)					
Action which delivers at the end of the BSD timing slot the status of the communication of the actual BSD device of the scheduling list					
Parameter	**Type**	**Hex. Limits**	**Phys. Limits**	**Resol.**	**Unit**
STATE_BSD_CPT	IN	0...FFH	0...255	1	-
BSD device, which communicates actually with the ECU via BSD					
STATE_BSD_COM	IN	0...FFH	0...255	1	-
Status of the communication to the BSD devices (faulty /o.k.)					

FUNCTION DESCRIPTION:

General information:

In addition to the global diagnosis of the BSD communication a selective diagnosis for each individual BSD component (alternator, intelligent battery sensor, oil quality sensor, electrical coolant water pump) is performed. There are several counters introduced to control the diagnosis. A counter (CTR_MSG_xxx_COM_DIAG) which monitors the transmitting slot of each individual component is incremented as soon as a faulty transmitting slot has been detected by the BSW (symptoms of the error please see 'Global BSD Error – No communication to any of the BSD components'). In case of a faulty transmitting slot (no positive acknowledge) has been detected the next corresponding transmitting slot is served by a '22 synchronisation pulse phase' and an incrementation of the counter CTR_MSG_xxx_COM_DIAG by 1+1 (1 for the missing acknowledge and 1 for the 22 synchronisation pulses).

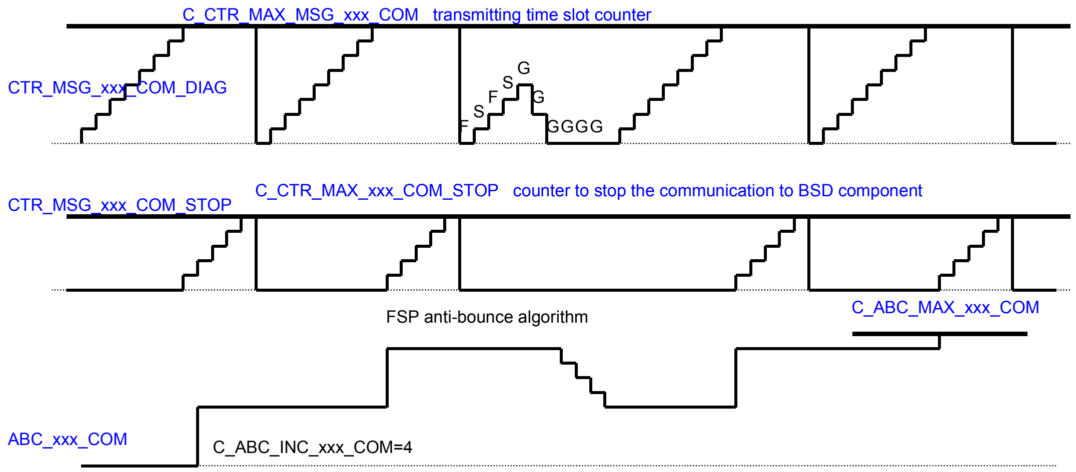
The '22 synchronisation pulse phase' is followed by new communication trial in the transmitting slot of the corresponding component determined by the timing coordinator. In case of a positive acknowledge the counter CTR_MSG_xxx_COM_DIAG is decremted by 2, otherwise it is proceeded as decribed above.

As soon as the counter CTR_MSG_xxx_COM_DIAG exceeds the threshold C_CTR_MAX_MSG_xxx_COM, a break for certain transmitting time slots can be applied by starting the counter CTR_MSG_xxx_COM_STOP (displayed in the flags LV_MSG_xxx_COM_STOP) in combination with the call of the anti-bounce algorithm of the error management and resetting the counter CTR_MSG_xxx_COM_DIAG after the counter CTR_MSG_xxx_COM_STOP has reached the threshold C_CTR_MAX_xxx_COM_STOP. The counter CTR_MSG_xxx_COM_STOP is incremented in each corresponding transmitting time slot until the threshold C_CTR_MAX_xxx_COM_STOP has been reached. During this period the timing coordinator does not serve the corresponding component. After the 'break' in the communication to the corresponding component has elapsed (C_CTR_MAX_xxx_COM_STOP reached) the next test cycle is started as described above. This occurs until the error has been debounced by the anti-bounce algorithm. After the debounce of the error the component is no longer served in this driving cycle by the timing coordinator.

If the counter threshold C_CTR_MAX_xxx_COM_STOP to stop the communication to the corresponding BSD component is calibrated to = 0, no 'break' of the communication occurs. Special treatment if the counter threshold is calibrated to C_CTR_MAX_xxx_COM_STOP = FFFFH. In that case no 'break' of the communication occurs and the component is served although the error has been detected.

With xxx:	ALTER	– alternator
	CWP	– electrical coolant water pump
	QOIL	– oil quality sensor (QLT)
	SENS_BAT_SMT	– intelligent battery sensor (IBS)

Description:



F -- faulty
G -- good
S -- 22 sync. pulse

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** at reset

Recurrence: Function called after each communication time slot (see BSD timing table)

Activation:

If LV_CDN_VB_MIN_DIAG = 1 **and**
Communication on BSD started **and**
LV_ERR_BSD = 0
Then LV_CDN_DIAG_xxx_COM = 1
Else LV_CDN_DIAG_xxx_COM = 0
Endif

STATE_TQ_ARS_PLAUS	STATE_TQ_PSTE_2_PLAUS	ECU_STATE	LV_ERR_SYM_TQ_DCC_CS
LV_CDN_VB_BN_DIAG	STATE_TQ_PSTE_3_PLAUS		

FUNCTION DESCRIPTION:

General information:

The torque functionality detects if the torque requests via CAN are not plausible.
As a consequence of that further torque requests of the respective control unit are rejected. The purpose of this diagnosis is to provide the information when a ECU is rejected by error-entry in the FMY. Through environmental data (STATE_TQ_CAN_PLAUS) the information is given which ECU has been rejected.
Additional there is the possibility to calibrate via LC_TQ_CAN_PLAUS which failure of the respective ECU lead to the error entry.

If a torque-plausibility-error is detected by the torque calculation (STATE_TQ_xxx_PLAUS =) the error symptom is set and the anti bounce counter is incremented by C_ABC_INC_TQ_REQ_CAN. If the plausibility error is not present any longer, the anti bounce counter is decremented.

Application conditions:

Initialisation: according ERRM initialization type **"STD_INI"**

//reset at LV_IGK 0->1 or reset

Recurrence: 10 ms

Activation:

```
If    LV_CDN_VB_BN_DIAG = 1          and
      LV_ES  = 0
Then  LV_CDN_DIAG_TQ_REQ_CAN = 1
```

Deactivation:

```
If    LV_CDN_VB_BN_DIAG = 0          or
      LV_ES  = 1                     or
      ECU_STATE = PWL
Then  LV_CDN_DIAG_TQ_REQ_CAN = 0
Endif
```

FUNCTION DESCRIPTION:

General information:

At implausible LDM messages, e.g. timeout errors, or ECU internal errors a reversible or irreversible error is detected and reflect to the LDM Unit.

Description:

The following symptoms can be detected:

```
|_|_|_|_|
 | | | └─> LDM Brake plausibility error     (= SYM_0)
 | | └───> -                               (= SYM_1)
 | └─────> -                               (= SYM_2)
 └───────> LDM plausibility error          (= SYM_3)
```

Application conditions:

Initialisation: all 0 at LV_IGK 0->1 **or** reset **or** at clearing error memory

Recurrence: 10 ms

Activation:

```
If      LV_VAR_BN_LDM = 1          and
        LV_IGK= 1                  and

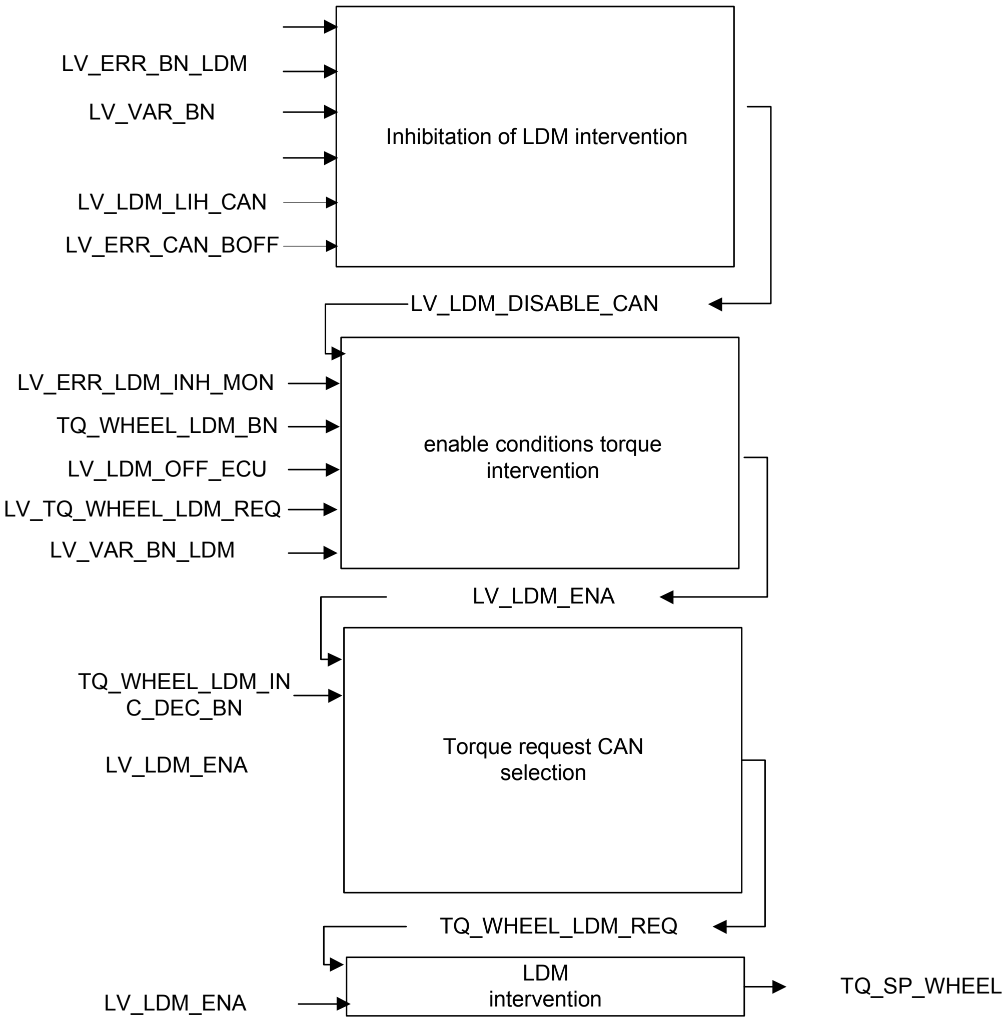
General information:

The LDM unit delivers a torque request via BN. This module serves the enable conditions and the torque request which will be used in the torque request selection.

Signal flow diagram:



44.2.1 Enable conditions

44.2.1.1 Inhibitation LDM intervention

FUNCTION DESCRIPTION:

If the EMS detects an error on the CAN messages, the logical variable LV_LDM_DISABLE_CAN is set to 1.

Application conditions:

Initialisation: LV_LDM_DISABLE_CAN = 0 **at reset**

Recurrence: 10 ms

Activation: LV_IGK = 1 and LV_VAR_BN_LDM = 1

Deactivation: -

Formula section:

CAN enviroment LDM inhibition:

```
if      LV_ERR_BN_LDM            = 1        or
        LV_ERR_CAN_BOFF          = 1        or
        LV_LDM_LIH_CAN           = 1        or
        LV_CDN_VB_CAN_TQ_DIAG = 0

then        LV_LDM_DISABLE_CAN   = 1
else        LV_LDM_DISABLE_CAN   = 0
endif
```

44.2.1.2 enable conditions torque intervention

FUNCTION DESCRIPTION:

Depending on the configuration and plausible torque interfaces an increaced torque intervention is possible.

Application conditions:

Initialisation: LV_LDM_ENA = 0 **at reset**

Recurrence: 10 ms

Activation: LV_IGK = 1 and LV_VAR_BN_LDM =1

Formula section:

Torque increase intervention:

```
if      LV_LDM_OFF_ECU = 0                       and
        LV_TQ_WHEEL_LDM_REQ = 1                  and
        LV_LDM_DISABLE_CAN =  0                  and
        LV_TQ_WHEEL_LDM_BN_ERR = 0               and
        LV_ERR_LDM_INH_MON = 0                   and
        (STATE_ENGG_POS != 2H  or  LC_LDM_OFF_CLU = 0)
then    LV_LDM_ENA        = 1
else    LV_LDM_ENA        = 0
endif
```

STATE_TQ_LDM_PLAUS

```
if    LV_LDM_BRAKE_PLAUS_ERR = 1                              BIT [00] set
If    LV_LDM_ENA_PLAUS_ERR = 1                                BIT [01] set
if    LV_LDM_OFF_ECU = 1                                      BIT [03] set
if    LV_TQ_WHEEL_LDM_REQ = 1     and
      LV_TQ_WHEEL_LDM_BN_ERR = 1                              BIT [05] set
else                                                          BIT [04] set
endif
```

44.2.2 Torque request CAN selection

FUNCTION DESCRIPTION:

If the LDM intervention is enabled (LV_LDM_ENA = 1), the torque request is received from CAN and copied into TQ_SP_WHEEL.
After LV_LDM_ACT changes back to 0, TQ_SP_WHEEL becomes its minimum value again.

Application conditions:

Initialisation: at reset and LV_IGK off --> on

TQ_WHEEL_LDM_REQ = -32000 Nm

Recurrence: 10 ms

Activation: at LV_IGK = 1 and LV_VAR_BN_LDM = 1

Deactivation: -

Formula section:

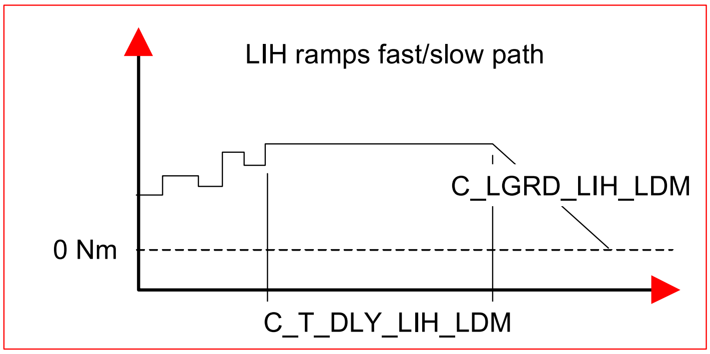
```
IF      LV_LDM_ENA = 1
Then    TQ_WHEEL_LDM_REQ = TQ_WHEEL_LDM_INC_DEC_BN
Else    TQ_WHEEL_LDM_REQ = -32000 Nm
Endif
```

44.2.2.1 LDM increased intervention and emergency operation

FUNCTION DESCRIPTION:

If during an active LDM intervention an LDM or an EMS error occurs, the current torque offset is continued for the time C_T_DLY_LIH_LDM and then subsequently decreased to TQ_SP_WHEEL = -32000 Nm using C_LGRD_LIH_LDM. The LDM unit itself controls the torque leading during active LV_TQ_WHEEL_LDM_REQ therefore you won't have a plausible Torque request without LV_LDM_ENA.

Signal flow diagram:



Application conditions:

Initialisation: at reset or at transition LV_IGK off -> on

LV_LDM_LIH = 0

LV_LDM_ACT = 0

TQ_SP_WHEEL = -32000 Nm

T_LDM_LIH_CTR = C_T_DLY_LIH_LDM

Recurrence: 10 ms

Activation: LV_IGK = 1 **and** LV_VAR_BN_LDM = 1

Formula section:

General information:

Activation : at ENG_STOP to SYN_ENG_IGK_ON
or RUN_ENG to SYN_ENG_IGK_ON
T_KNK_ENABLE

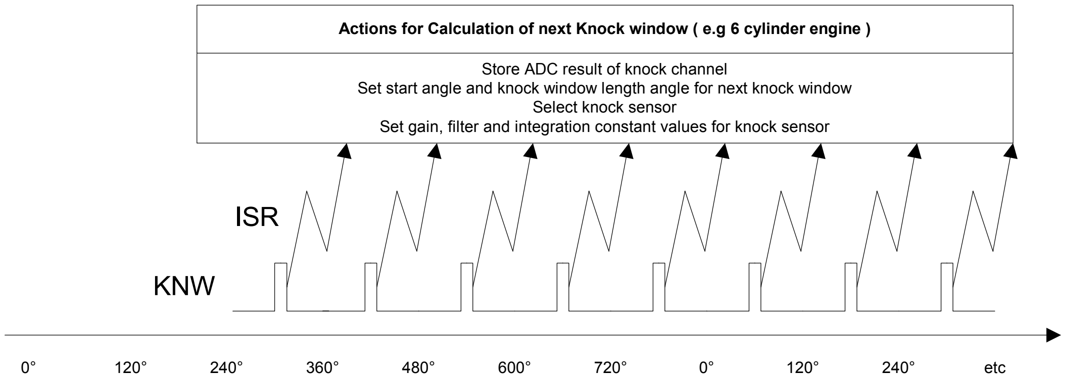
Deactivation : at SYN_ENG_IGK_ON to RUN_ENG (if supported by ECOP)
or SYN_ENG_IGK_ON to ENG_STOP
or SYN_ENG_IGK_OFF to PWL
T_KNK_DISABLE

Initialization : at reset or engine running to engine stop
KNKS_REL_NL[x] = C_KNKS_REL_INI (T_KNK_INIT)

The knock detection is performed for cylinder-individually defined measurement windows since knock-typical oscillations only occur for certain crankshaft angles. For the time of the knock window the knock signal is integrated. At the end of the knock window the integrated signal is sampled and converted to the digital value KNKSx.

KNKS_REL_NL[NC_CYL_NR] is the relative knocking value, it is the quotient of KNKS[NC_CYL_NR] and NL[NC_CYL_NR].

The knock window for cylinder x+1 is reprogrammed at the end of the knock window for cylinder x. The parameters KNKS_CMD_FIL[NC_CYL_NR], KNKS_CMD_FIL_PRE[NC_CYL_NR], KNKS_CMD_INT[NC_CYL_NR], KNKS_CMD_INT_PRE[NC_CYL_NR], KNKS_CMD_GAIN[NC_CYL_NR], KNKS_GAIN_PRE[NC_CYL_NR], KNKS_CMD_CONF[NC_CYL_NR], KNKWB KNKWB_PRE[NC_CYL_NR], KNKWE_PRE[NC_CYL_NR] and KNKWE have to be stable at this time. The knock channel adc is configured for triggering on the end of the knock window. The end of conversion generates an interrupt in which the parameters for the next knock window are set. The following picture illustrates this.



The knock function may be activated by T_KNK_INIT or T_KNK_ENABLE and deactivated by T_KNK_DISABLE.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

45.2 KNCK - Requirements to infrastructure

Input data:

NC_KNKS_CYL_CONF_1	NC_KNKS_CYL_CONF_2	C_KNKS_CYL_CONF	

Export actions:

ACTION_INFR_*SetKnkWindow*(IN <Knkwb>, IN <Knkwd>, IN <Cyl>, IN <Win>)
Sets knock window for cylinder *cyl*
ACTION_INFR_*SetKnkCfg*(IN <Cmd_fil>, IN <Cmd_gain>, IN <Cmd_int>, IN <Cyl>, IN <Win>)
Sets knock pre-processor window, filter, gain and integrator factors for cylinder *cyl*
ACTION_INFR_*GetKnkDiag*(OUT <Diag>)
Gets the diagnosis information of knock pre-processor settings transfer
ACTION_INFR_*GetVKnks*(OUT <V_knks>, IN <Cyl>, IN <Win>)
Gets the formatted knock noise raw signal
ACTION_INFR_EnaKnks(IN <Enable>)
Enables the knock functionnality
ACTION_INFR_*InitKnKSensConf*()
This action Initialize theI/O driver configuration for different KNK Sensor to Cylinder configuration

Description for actions:

ACTION_INFR_*InitKnKSensConf*()

```
If      C_KNKS_CYL_CONF = 0
        Initialization of I/O driver configuration for configuration 1 fitting with NC_KNKS_CYL_CONF_1
Else
        Initialization of I/O driver configuration for configuration 2 fitting with NC_KNKS_CYL_CONF_2
EndIf
```

This action Initialize the I/O driver configuration at I/O driver initialisation depending on different "KNK Sensor to Cylinder configuration". This enables a dynamic run time configuration of KNCK.

This ACTION and implementation is not compatible to IRS guideline and aggregate implementation guideline. This solution is a temporary solution that will be managed in specific SW AGGR implementation file to isolate this solution.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit

ACTION_INFR_*SetKnkWindow*((IN <Knkwb>, IN <Knkwd>, IN <Cyl>, IN <Win>)

This action sets the knock window for cylinder *Cyl*. The *Cyl* parameter is introduced to stay flexible regarding which cylinder to set. The knock window is defined by selected window, beginning (*Knkwb*) and duration (*Knkwd*) in degree crankshaft.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
Knkwb	IN	0...BBH	0...70.125	0.375	[°CRK]
Parameter for formatting of the knock window beginning					
Knkwd	IN	0...A0H	0...60	0.375	[°CRK]
Parameter for formatting of the knock window duration					
Cyl	IN	0...7H	0...7	1	[-]
Cylinder for which the knock window settings will apply					
Win	IN	0...1H	0...1	1	[-]
Window for which the knock window settings will apply					

ACTION_INFR_*SetKnkCfg*(IN <Cmd_fil>, IN <Cmd_gain>, IN <Cmd_int>, IN <Cyl>, IN <Win>)

This action passes the settings of the knock pre-processor for cylinder *Cyl*. The *Cyl* parameter is introduced to stay flexible regarding which cylinder to set. Physical values are mapped in the pre-processor and will be choosen corresponding to the transmitted hex. values. The correlation is given below in the action requirements. Since there is no linear dependency between the hex. values and the physical values of *Cmd_fil*, *Cmd_gain* and *Cmd_int*, no resolution is declared.
To check possible transmission errors ACTION_INFR_GetKnkDiag is introduced.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
Cmd_fil	IN	0...3FH	-	-	[-]
Filter centre frequency factor of the knock pre-processor					
Cmd_gain	IN	0...3FH	-	-	[-]
Gain of the knock pre-processor					
Cmd_int	IN	0...1FH	-	-	[-]
Integrator time constant of the knock pre-processor					
Cyl	IN	0...7H	0...7	1	[-]
Cylinder for which the transmitted factors will apply					
Win	IN	0...1H	0...1	1	[-]
Selected knock window					

ACTION_INFR_*GetKnkDiag*(OUT <Diag>)

This action checks if ACTION_INFR_SetKnockCfg was carried out successfully. In case of error, the parameter *Diag* is set to 1.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
Diag	OUT	0...1H	0 ... 1	1	[-]
Error flag for configuration settings of knock pre-processor					

ACTION_INFR_*GetVKnks*(OUT <V_knks>, IN <Cyl>, IN <Win>)

Gives back the formatted knock noise raw signal.

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
V_knks	OUT	0...3FFH	0...4.995	5/1024	[V]
Formatted knock noise signal					
Cyl	OUT	0...7H	0...7	1	[-]
Cylinder for which the value was taken					
Win	IN	0...1H	0...1	1	[-]
Selected knock window					

ACTION_INFR_EnaKnks(IN <Enable>)

This action enables the knock strategie if Enable =1

Parameter	Type	Hex. limits	Phys. limits	Resol.	Unit
Enable	IN	0...1H	0 ... 1	1	[-]
Enable flag for knock strategie					

FUNCTION DESCRIPTION:

General information:

This strategy uses a knock signal pre-processor, which formats the knock sensor raw signal according the anti-knock strategy necessities. Figure 2 describes the functionality of this device.

The infrastructure is responsible for transmitting the programmable settings of the pre-processor calculated inside the knock aggregate and for synchronizing the internal tasks.

There are 2 configurations SENSORS-CYLINDERS possible: NC_KNKS_CYL_CONF_1 or_2 and the configuration of the engine is determined by the value C_KNKS_CYL_CONF.

Remark:

Two knock windows are created for each cylinder. The first of the two windows (Win=0) starts at least at the cylinder's TDC.
The 2nd window (Win=1) starts at least 2° after the TDC and ends at least 62° after the TDC.

The first window's length may exceed the 2° threshold, however it must not overlap the 2nd window. It has to be guaranteed by calibration that the gap between knock windows has a sufficient length.

If the beginning angle and length of the first window (Win=0) is set to 0,0, no window shall be generated and no parametrisation of the pre-processing device shall be performed.

Task synchronisation:

The task synchronisation of the anti knock strategy over °CRK is the following:

At each segment:
1. Ensure no error has occured for last transmission of the knock parameters
2. Get value of knock noise energy V_KNKS
3. Transmission of the knock window parameters for cylinder *cyl*
4. Transmission of the knock pre-processor parameters for cylinder *cyl*

At each window beginning:
5. Reset integrated noise signal

At each window end::
6. Store the value of the formatted (filtered end integrated) raw noise signal

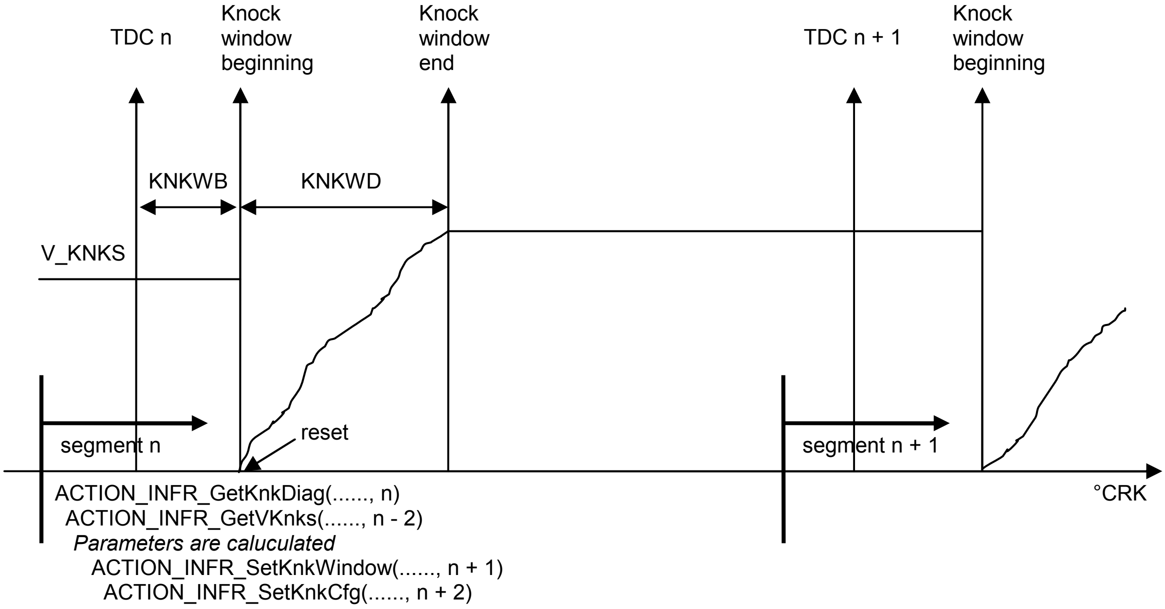

Figure 1: Synchronization of infrastructure internal tasks over °CRK

Pre-processor algorithm:

The knock pre-processor is used to provide a formatted representative of the knock sensor raw signal (see figure 2).

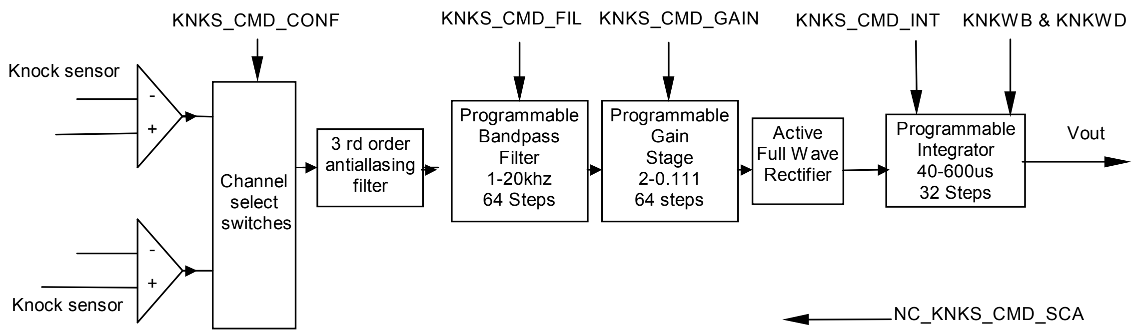

Figure 2: Simplified block of the pre-processor device

- For multi-sensor configuration: the pre-processor selects the sensors whose signal should be processed.
- A programmable band-pass filter processes the raw signal.
- A programmable gain adjusts stage is applied on the frequency band of knock
- An active full wave rectifier rectifies the signal
- After reset at window beginning, a programmable integrator integrates the signal during an angular window

The result is an analogue voltage whose output level is proportional to the engine noise. This value is called by ACTION_INFR_GetKnks.

Requirements for ACTION_INFR_SetKnkWindow:

Data acquisition

Parameter	Absolute precision	Relative precision	Resolution	Coincidence with parameter	Comment
Knkwb	+-0.375 °CRK		0.375 °CRK		TDC must be detected precisely enough
Knkwd	+-0.375 °CRK		0.375 °CRK		Gives duration of knock window with an absolute precision of 0.750°CRK
Cyl	1		1		
Win	1		1		Selected knock window, pre or normal one.

Diagnosis:	No diagnosis needed
Coincidence requirements:	It must be guaranteed, that the window configuration is transferred in time to the pre-processor for the given cylinder. For details see Figure 1.

Requirements for ACTION_INFR_SetKnkCfg:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Cmd_fil		<4%	Relative resolution 1.04 to next value		**Parameter to set band pass filtering of knock raw noise** The relation between frequency freq(i) and the hexadecimal value i given by: freq(i) = freq(1) * 1.04 ^ (i-1) frequency range 1 ... 20kHz hex. range 0 ... 3FH
Cmd_gain		<9.5%	Relative resolution 0.948 to next value		**Programmable gain stage** The relation between gain and the hexadecimal value i given by: gain(i) = gain(1) * 0.948 ^ (i-1) gain range 2.00 ... 0.111 hex. range 0 ... 3FH
Cmd_int		<9%	6bit		**Programmable integrator** The relation between integration time ITC and the hexadecimal value i given by: ITC(i) = ITC(1) * 1.091 ^ (i-1) ITC range 40 ... 600µs hex. range 0 ... 3FH
Cyl	1		1		
Win	1		1		Selected knock window

Diagnosis: When setting the parameters of the pre-processor the received parameters are returned and compared with the originally send value. In case of error, ACTION_INFR_GetKnkDiag raises an error flag.

Coincidence requirements: see Figure 1.

Requirements for ACTION_INFR_GetKnkDiag:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Diag			1bit		

Diagnosis: no diagnosis done here

Coincidence requirements: When setting the pre-processor parameters using ACTION_INFR_SetKnockCfg the diagnosis result is stored. The diagnosis result of the last configuration setting is read out with this action.

Requirements for ACTION_INFR_GetVKnks:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
V_knks	50mV		10bit		
Cyl	1		1		
Win	1		1		Selected knock window

Diagnosis: no diagnosis done here

Coincidence requirements: The integrated signal value of the pre-processor must be read out and copied in time, see figure 1.

Requirements for ACTION_INFR_EnaKnks:

Data acquisition					
Parameter	**Absolute precision**	**Relative precision**	**Resolution**	**Coincidence with parameter**	**Comment**
Enable	1		1		

Diagnosis: no diagnosis done here

Coincidence requirements: this action should be called to enable knock acquisition when engine is synchronised

45.3 Application incidences for knock control and measurement CAN-interface

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNK_CTL_DIS	V/O	0...1H	0...1	1	[-]
knock control disabled due to malfunctions					

Input data:

Freeze frame for knocking cylinder identification when excursion limit event occurs					

Input data:

NC_CYL_NR	LC_AD_CLR_RON	LV_IGA_DIF_MAX_KNK	CYL_ID_KNK
N_32	MAF_HB	TCO	TIA

FUNCTION DESCRIPTION:

General information:

'Control Excursion Limit' in the 'Knock Control' module is used to limit the difference of the ignition adjustment angle through knock control of the single cylinders to a certain value.
When a limitation on one cylinder is done, LV_IGA_DIF_MAX_KNK is set in order to give this information to the 'Excursion Limit Analysis' functionality.
Here the values for the concerning cylinder and actual operation point are stored.

Graphical interpretation:

- Cylinder individual counter CTR_IGA_DIF_MAX_KNK[NC_CYL_NR]

```
input  |_CTR_|
   --> |______|  (for CYL_ID_KNK = 0)
   --> |______|  (for CYL_ID_KNK = 1)
   --> |______|  (for CYL_ID_KNK = 2)
   --> |______|  (for CYL_ID_KNK = 3)
   --> |______|  (for CYL_ID_KNK = 4)
   --> |______|  (for CYL_ID_KNK = 5)
         :
       NC_CYL_NR rows for counting excursion limit events on each cylinder individually
```

- Freezed operation point data and id of concerning cylinder
  (shifting register with newest values on top position)

       :
       NC_NR_FRF_KNK_RTD rows for data freeze at events on all cylinders
```

Application conditions:

Initialisation: CTR_IGA_DIF_MAX_KNK[0 to NC_CYL_NR - 1],
N_IGA_DIF_MAX_KNK[0 to NC_NR_FRF_KNK_RTD - 1],
MAF_IGA_DIF_MAX_KNK[0 to NC_NR_FRF_KNK_RTD - 1],
TCO_IGA_DIF_MAX_KNK[0 to NC_NR_FRF_KNK_RTD - 1],
TIA_IGA_DIF_MAX_KNK[0 to NC_NR_FRF_KNK_RTD - 1],
CYL_ID_IGA_DIF_MAX_KNK[0 to NC_NR_FRF_KNK_RTD - 1]
get values from E2PROM at reset

Recurrence: every segment

Activation: at every engine state except engine stop

Deactivation: at engine stop

Formula section:

Module has to be executed
- after calculation of 'Control Excursion Limit' module
- within the same SEG_NR.

fix number of 'freeze frames' with respect to storage space:
NC_NR_FRF_KNK_RTD = 60

cylinder individual counter for recognition of reaching excursion limit:

```
If    LV_IGA_DIF_MAX_KNK = 1 And $CTR\_IGA\_DIF\_MAX\_KNK[CYL\_ID\_KNK]_n < 255$
Then  $CTR\_IGA\_DIF\_MAX\_KNK[CYL\_ID\_KNK]_n = CTR\_IGA\_DIF\_MAX\_KNK[CYL\_ID\_KNK]_{n-1} + 1$
Endif
```

overwriting old values in 'freeze frames': data are shifted, latest values are stored

```
If      LV_IGA_DIF_MAX_KNK = 1
Then    For   i = NC_NR_FRF_KNK_RTD - 1 To 1 Step -1
                N_IGA_DIF_MAX_KNK[i] = N_IGA_DIF_MAX_KNK[i-1]
                MAF_IGA_DIF_MAX_KNK[i] = MAF_IGA_DIF_MAX_KNK[i-1]
                TCO_IGA_DIF_MAX_KNK[i] = TCO_IGA_DIF_MAX_KNK[i-1]
                TIA_IGA_DIF_MAX_KNK[i] = TIA_IGA_DIF_MAX_KNK[i-1]
                CYL_ID_IGA_DIF_MAX_KNK[i] = CYL_ID_IGA_DIF_MAX_KNK[i-1]
        Next i
        N_IGA_DIF_MAX_KNK[0] = N_32
        MAF_IGA_DIF_MAX_KNK[0] = MAF_HB
        TCO_IGA_DIF_MAX_KNK[0] = TCO
        TIA_IGA_DIF_MAX_KNK[0] = TIA
        CYL_ID_IGA_DIF_MAX_KNK[0] = CYL_ID_KNK
Endif
```

N.B.: i represents identification index of stored info data set
(shifting in 'For' loop has not to be executed, if NC_NR_FRF_KNK_RTD = 1)
(efficiency of CPU load could be optimized, if only 'filled' freeze frames are shifted)

Configuration data:

Number of freeze frame datasets for storing operation point and cylinder number for excursion limit analysis					

45.3.3 Knock Control Measurement CAN-Interface

General information:

This chapter is used as interface between the variables on the local CAN bus of the knock control measurement with CAN-interface and the system variables.

The process is as followed:

a.) start the output of systemvalues

b.) output of the systemvalue

c.) stop the output of systemvalues

45.3.3.1 CAN Protocol

Description:

The following control units participate to CAN-communication:
DME: Engine management system
IAV: Measurement equipment from BMW

Baudrate: 500 kBaud

The IAV sends for starting its measurement values on CAN Messages the ID = **700H.**

The DME sends its measurement concerning the IAV interface on CAN Messages with the ID = **701H and 702H.**

The IAV sends for stopping its measurement values on CAN Messages the ID = **70AH.**

45.3.3.2 Send messages by DME ID 701H and ID702H

ID 701H

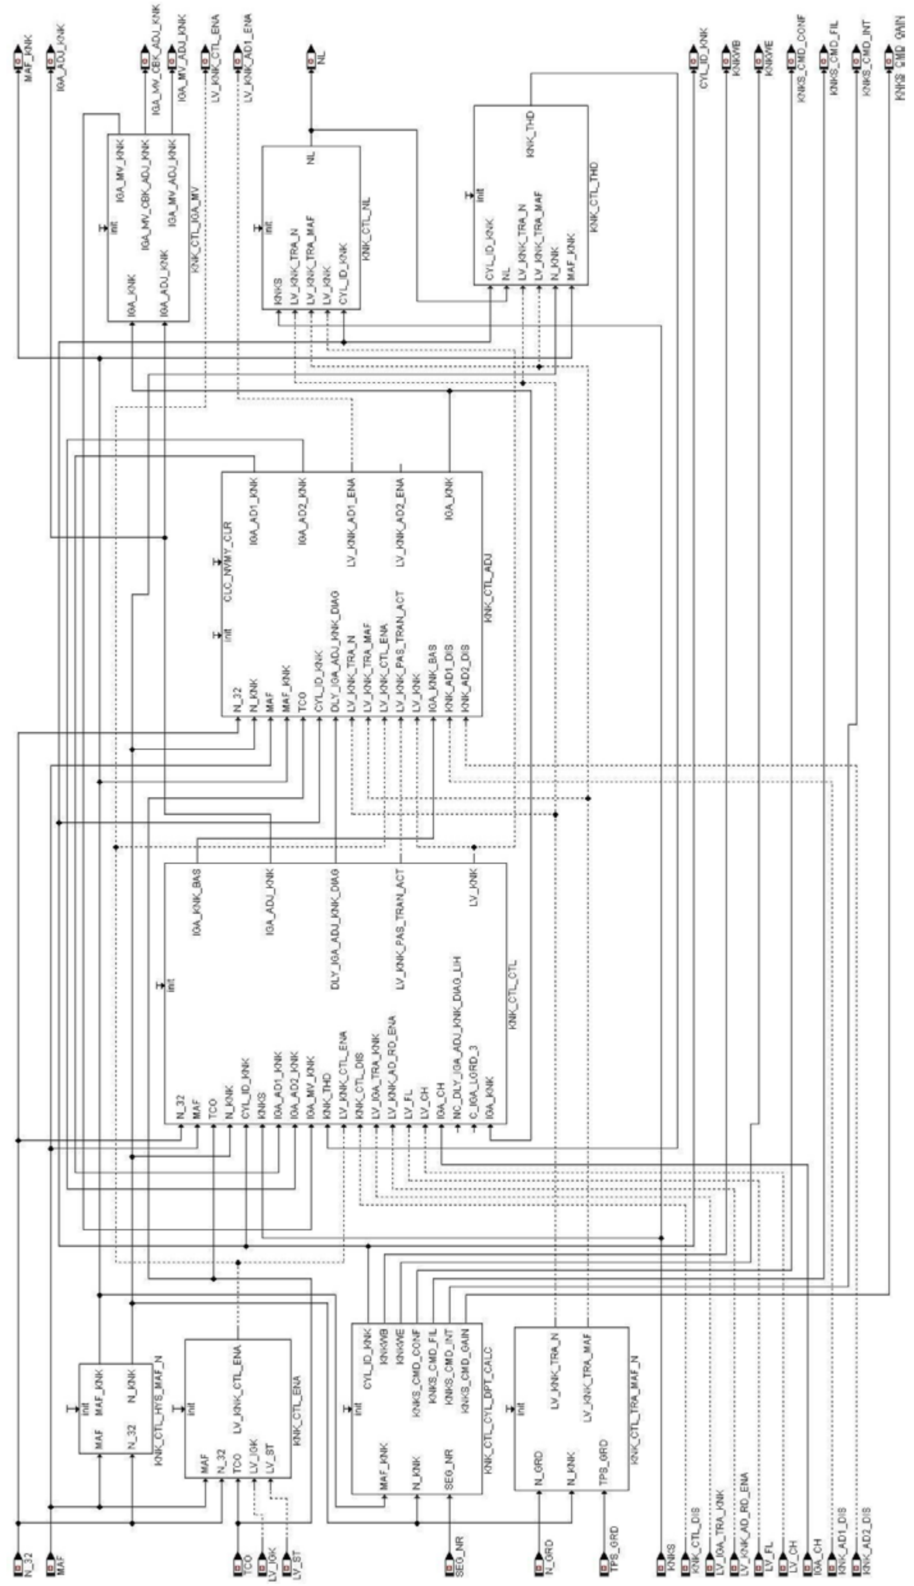
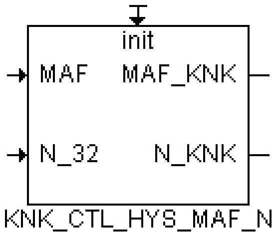
45.4.1 Overview



45.4.2 Pre-processing

45.4.2.1 Hysteresis Function for MAF and N_32



General information:

Hysteresis functions for engine speed and air-mass changes are defined for the tables relevant for the knock control in order to avoid steps recognisable for the driver due to small changes of the operation point.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialization:	MAF_KNK = N_KNK = 0 at reset and engine running to engine stop
Update Rate:	every segment

Formula section:

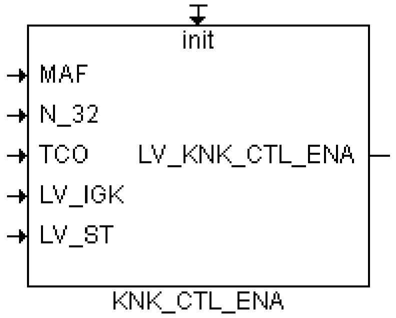
```
if    |(N_32 - N_KNK)|    >=    C_N_IGA_HYS_KNK
      N_KNK = N_32
else
      N_KNK remains unchanged
end if

if    |(MAF - MAF_KNK)|  >=    C_MAF_IGA_HYS_KNK
      MAF_KNK = MAF
else
      MAF_KNK remains unchanged
end if
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_IGA_HYS_KNK	1	0...FFH	0...8160	32	[rpm]
Speed Hysteresis for Knock Control					
C_MAF_IGA_HYS_KNK	1	0...FFH	0...1389	5.45E+00	[mg/stk]
Air-Mass Hysteresis for Knock Control					

45.4.2.2 Knock Control Enable



Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialization:	LV_KNK_CTL_ENA = 0 at reset and engine running to engine stop LV_KNK_CTL_PRE_ENA = 0 at reset and engine running to engine stop LV_CTR_KNK_CMB = 0 reset and engine running to engine stop CTR_KNK_CMB = 0 reset and engine running to engine stop
Update Rate:	every segment

Formula section:

knock control enable:

```
if        (LV_ST = 1  or  LV_IGK = 0)
then      LV_KNK_CTL_ENA = 0
else
    if    (MAF_KNK  >= IP_MAF_MIN_KNK__N__TCO)
          LV_KNK_CTL_ENA = 1
    else
          LV_KNK_CTL_ENA = 0
    end if
end if
```

knock control pre-ignition enable:

```
if        LV_KNK_CTL_ENA = 1 and MAF_KNK >= IP_MAF_MIN_KNK_PRE
then      LV_KNK_CTL_PRE_ENA = 1
else      LV_KNK_CTL_PRE_ENA = 0
end if
```

inhibit knock control pre-ignition:

```
if        N_32 > C_N_KNK_CTL_PRE_INH
then      LV_KNK_CTL_PRE_INH = 1
else      LV_KNK_CTL_PRE_INH = 0
end if
```

If the relevant air-mass is below the air-mass threshold (LV_KNK_CTL_ENA = 0), only the noise value calculation is executed.
An additional air-mass threshold exists for enabling cylinder cut off algorithm (LV_KNK_CTL_PRE_ENA).

A complete inhibition of pre-window calculation and consideration is forced (LV_KNK_CTL_PRE_INH = 1), when pre-window is initialized with 0 (see IRS); especially when engine speed is above a calibratable threshold.

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit

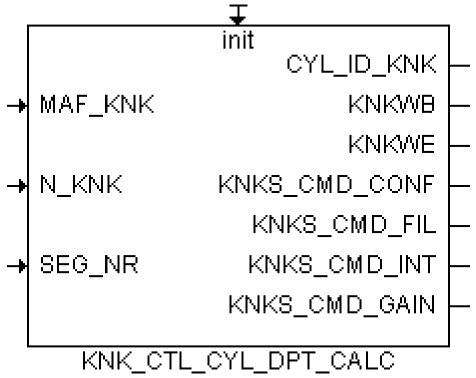
Engine speed threshold for complete inhibition of knock control pre-ignition					

45.4.2.3 Cylinder Dependent Calculations



45.4.2.3.1 Cylinder Number for Knock Control

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

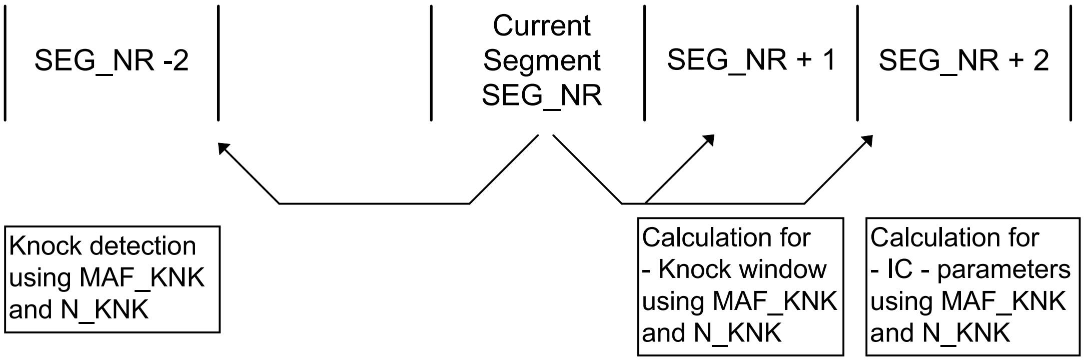
Initialization: CYL_ID_KNK = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

CYL_ID_KNK = SEG_NR - 2

Description:



45.4.2.3.2 Knock Measurement Window

General information:

The knock detection is performed for cylinder-individually defined measurement windows since knock-typical oscillations only occur for certain crankshaft angles. The measurement windows (crank angle of beginning and end) are specified as function of the engine speed and load.
If the estimated ‘End of the Knock Measurement Window’ is lower or equal compared to the ‘Beginning of the Knock measurement Window’, both values are initialized.

The crank angle for the beginning of the knock measurement window is taken for each cylinder from the respective table IP_KNKWB[x] according to the firing order.
The crank angle for the end of the knock measurement window is taken for each cylinder from the respective table IP_KNKWE[x] according to the firing order.

Apart from window settings for AFS (stoichiometric) separate windows are existing in operation mode AFL (lean) and S (stratified).

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialization:	at reset and engine running to engine stop
	KNKWB[0 to NC_CYL_NR] = NC_KNKWB_INI
	KNKWE[0 to NC_CYL_NR] = NC_KNKWE_INI
	KNKWB_PRE[0 to NC_CYL_NR] = NC_KNKWB_PRE_INI
	KNKWE_PRE[0 to NC_CYL_NR] = NC_KNKWE_PRE_INI
Update Rate:	every segment

Formula section:

Definition of cylinder dependent knock window ranges:

RNG_WB = (720° / NC_CYL_NR) - 12°
RNG_WB_HEX = HEX(RNG_WB / 0.375°)
RNG_WE = (720° / NC_CYL_NR) - 6°

call action interface for pre and normal window

ACTION_INFR_*SetKnkWindow*(IN <Knkwb>, IN <Knkwd>, IN <Cyl>, IN <Win>)
Sets knock window for cylinder *cyl*

N.B.: x represents current SEG_NR + 1

Important information for calibration:

In order to have the possibility of two windows (pre- and main) in one segment, BSW is calculating with double number of segments with half of the original length. Every window begin (pre- or main) must lie within one of such doubled segments. The beginning of a segment for the main window is fixed in BSW to 2°CRK after TDC. Due to that the main knock window KNKWB[x] must be calibrated not before 2°CRK.

IP_KNKWE_PRE_GAP calibration must be done before KNKS_PRE signal parameter calibration (window, gain, filter frequency, integration time constant), in order to assure right calculated and transferred values from the knock IC and not to have different values because of new window length after changing this restriction. The duration of the gap between KNKWE_PRE and KNKWB is determined by the SPI bus communication. During the gap the integrator value of the pre-window has to be read and the ATIC62 device has to be programmed with the main window parameters (window, gain, filter frequency, integration time constant). The required duration has to be determined system individually by the BSW SW department.
Special restrictions must be considered, if distance between 0°CRK (minimum possible value for pre-window begin and end; also when set inactive a activation peak is remaining) and main window begin should be smaller than this determined gap or a smaller gap in general should be used. Then especially the same parametrisation for pre- and main window is required and no inhibition for pre-window calculation is allowed. Thus in BSW right parameters for main window are already set during pre-window parametrisation.

To have low CPU load, the knock pre-ignition window can be set to 0 by LV_KNK_CTL_PRE_INH = 1. This is done either above a calibratable engine speed threshold or at implausibility, when pre-window end is earlier than pre-window begin. KNKWB_PRE and KNKWE_PRE values are initialized with the NC values 0. Then no parametrisation and knock IC processing is executed (see IRS). Also the detection algorithm and KNK_THR_PRE aren't executed any longer.

Description:

45.4.2.3.3 Assignment of cylinder number to Knock sensor diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
KNKS_1_DIAG	O	0...FFH	0...255	1	[-]
Assignment of cylinder number to knock sensor 1 (diagnosis only)					
KNKS_2_DIAG	O	0...FFH	0...255	1	[-]
Assignment of cylinder number to knock sensor 2 (diagnosis only)					

Input data:

LV_ES	NC_KNKS_CONF		

FUNCTION DESCRIPTION:

The physically defined cylinder number is defined in firing oder 1 5 3 6 2 4 for a in-line 6 cyl. engine. There is the possibility to define especially for the knock sensor diagnosis which cylinder should be used for the knock sensor diagnosis via the help of the calibration constants C_KNKS_1/_2_DIAG. Only 'loud' cylinders should be used to detect a malfunktion of the Knock sensor signal.

The maximum possible number of cylinders is defined with NC_KNKS_CONF. Only cylinders can be used which are assigned for the knock detection of the individual knock sensor.

e.g. in-line 6 cyl. engine:

logically:	0	1	2	3	4	5	
physically:	1	5	3	6	2	4	
assignment KR	0	1	0	1	0	1	NC_KNKS_CONF = 2A hex
assignment KNKS1	1	0	1	0	1	0	C_KNK_1_DIAG = 15 hex
assignment KNKS2	0	1	0	1	0	1	C_KNK_2_DIAG = 2A hex

Application conditions:

Initialisation: all = 0 at reset and engine running to engine stop

Recurrence: segment synchronous

Activation: all engine states except LV_ES

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_KNKS_1_DIAG	1	0...FFH	0...255	1	[-]
Assignment of cylinder number to knock sensor 1 (diagnosis only)					
C_KNKS_2_DIAG	1	0...FFH	0...255	1	[-]
Assignment of cylinder number to knock sensor 2 (diagnosis only)					

45.4.2.3.4 Calibration of ATIC62 device

FUNCTION DESCRIPTION:

General information:

The knock control in the engine management works with the ATIC62 device. The output value of the integrator after the end of the measurement window is fed as Knock Value KNKS through an analogue channel to the control algorithm.
(Further information may be obtained in "Applications Guide to ATIC62 ".)

Apart from parameters for AFS (stoichiometric) separate sets of parameters are existing in operation mode AFL (lean) and S (stratified).

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization:
KNKS_CMD_INT[0 to NC_CYL_NR] = 0
KNKS_CMD_FIL[0 to NC_CYL_NR] = 0
KNKS_CMD_GAIN[0 to NC_CYL_NR] = 0

KNKS_CMD_INT_PRE[0 to NC_CYL_NR] = 0
KNKS_CMD_FIL_PRE[0 to NC_CYL_NR] = 0
KNKS_CMD_GAIN_PRE[0 to NC_CYL_NR] = 0

KNKS_CMD_CONF[0 to NC_CYL_NR] = value of configuration bit at position x in NC_KNKS_CONF

at reset and engine running to engine stop

Update Rate: every segment

Formula section:

If OPM_AV = "AFS"

Then KNKS_CMD_INT[x] = ID_ITC_KNK[x]
KNKS_CMD_FIL[x] = ID_FIL_FRQ_KNK[x]
KNKS_CMD_GAIN[x] = IP_GAIN_KNK[x]

KNKS_CMD_INT_PRE[x] = ID_ITC_KNK_PRE[x]
KNKS_CMD_FIL_PRE[x] = ID_FIL_FRQ_KNK_PRE[x]
KNKS_CMD_GAIN_PRE[x] = IP_GAIN_KNK_PRE[x]

```
Else KNKS_CMD_INT[x]          =    C_ITC_KNK_AFL[x]
     KNKS_CMD_FIL[x]          =    C_FIL_FRQ_KNK_AFL[x]
     KNKS_CMD_GAIN[x]         =    IP_GAIN_KNK_AFL[x]

     KNKS_CMD_INT_PRE[x]      =    C_ITC_KNK_AFL[x]
     KNKS_CMD_FIL_PRE[x]      =    C_FIL_FRQ_KNK_AFL[x]
     KNKS_CMD_GAIN_PRE[x]     =    IP_GAIN_KNK_AFL[x]

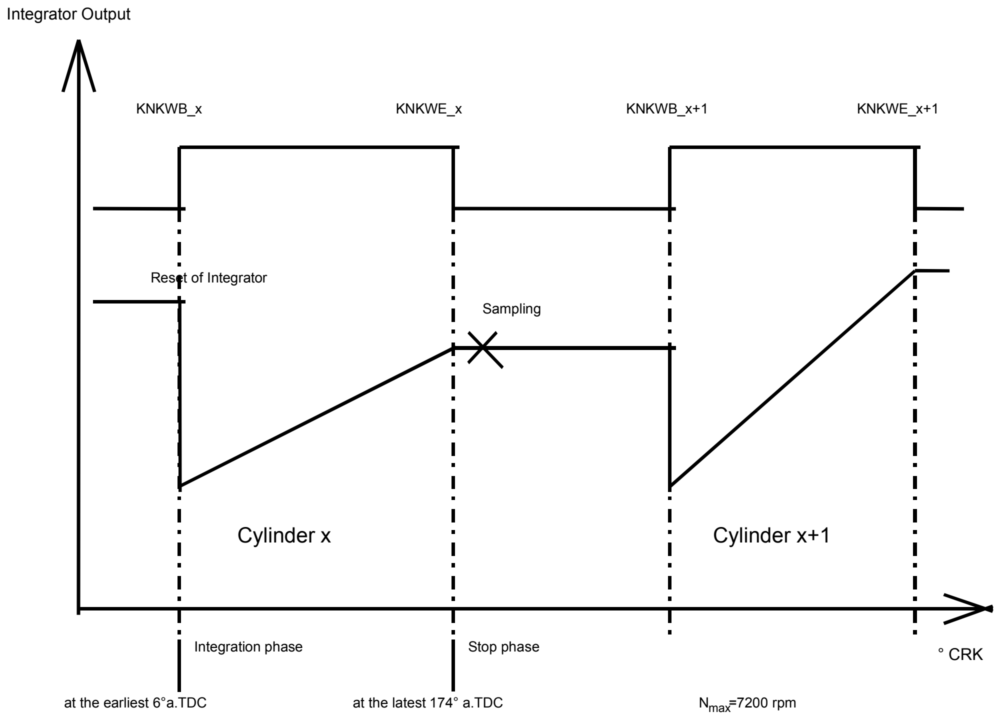
Endif
```

call action interface for pre and normal window parameters

ACTION_INFR_*SetKnkCfg*(IN <Cmd_fil>, IN <Cmd_gain>, IN <Cmd_int>, IN <Cyl>, IN <Win>)
Sets knock pre-processor window, filter, gain and integrator factors for cylinder *cyl*

N.B.: x represents current SEG_NR + 2

Description (example for 4 cylinder engine):



Note: These calibration data have to be adjusted if the processor sampling rate is changed.

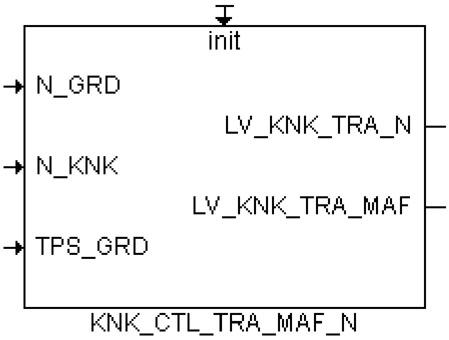
45.4.2.4 Load and Speed Dynamics



45.4.2.4.1 Speed Dynamics Function

FUNCTION DESCRIPTION:

General information:

In order to keep track with the noise values for large engine speed gradients (LV_KNK_TRA_N = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA.
Care needs to be given to the absolute function evaluation, so that there is no difference in the treatment of positive and negative speed gradients.
Furthermore the values of Knock -Adaptation-circuits 1 + 2 are only read at active speed dynamics.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: LV_KNK_TRA_N = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

```
if    (|N_GRD| >= ID_N_GRD_MAX_KNK__N)

          LV_KNK_TRA_N = 1
else
          LV_KNK_TRA_N = 0
end if
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
ID_N_GRD_MAX_KNK__N	8	0...7FH	0...4064	32	[rpm/s]
LDPM_N_IGA_AD	8	0...FFH	0...8160	32	[rpm]
Speed Gradient for dynamic identification					

45.4.2.4.2 Load Dynamics Function

FUNCTION DESCRIPTION:

General information:

In order to keep track with the noise values for large (positive) load gradients (LV_KNK_TRA_MAF = 1), the standard filtering constant is exchanged by a faster averaging constant C_NL_CRLC_TRA. After the triggering of the load dynamics the special filtering constant C_NL_CRLC_TRA is applied for the number of ID_CYCNR_FAC_TRA_KNK__N cycles. In addition, at active load dynamics function, the knock detection (KNK_THD[x]) is made less sensitive with the help of the factor C_FAC_TRA_KNK.
The values from the knock adaptation-circuits 1 + 2 are only read.

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: LV_KNK_TRA_MAF = 0 at reset and engine running to engine stop

Update Rate: every segment

Formula section:

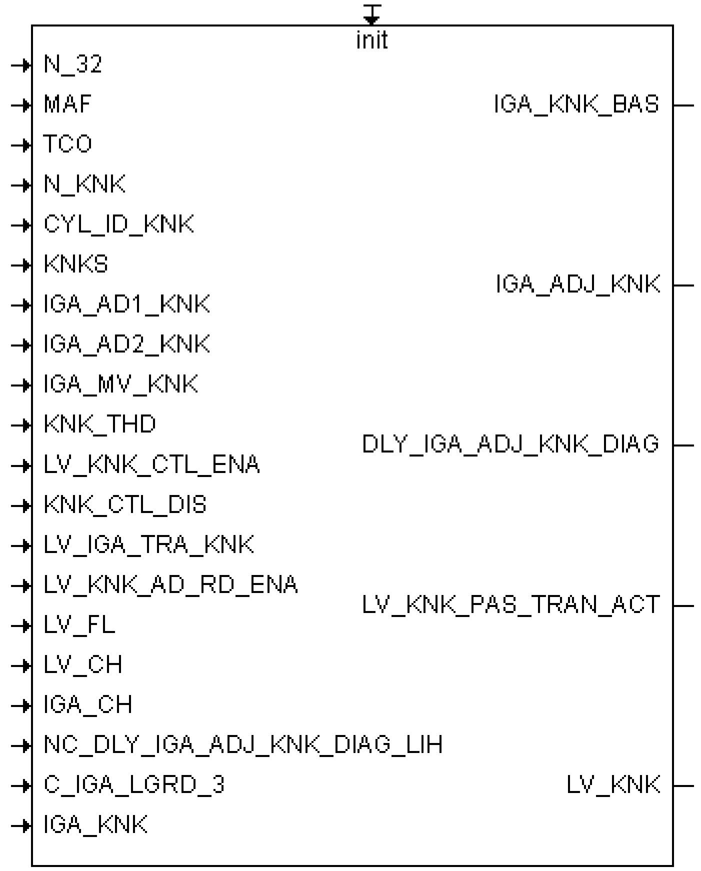
```
if      LV_IGA_TRA_KNK 0 -> 1

        LV_KNK_TRA_MAF = 1 for ID_CYCNR_FAC_TRA_KNK__N  cycles
else
            if      (ID_CYCNR_FAC_TRA_KNK__N has elapsed)
                    LV_KNK_TRA_MAF = 0
            end if
end if
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
ID_CYCNR_FAC_TRA_KNK__N	4	0...FFH	0...255	1	[seg]
LDPM_N_6_4	4	0...FFH	0...8160	32	[rpm]
Cycle counter during which the Load Dynamic Function stays active after triggering					

45.4.3 Knock Control

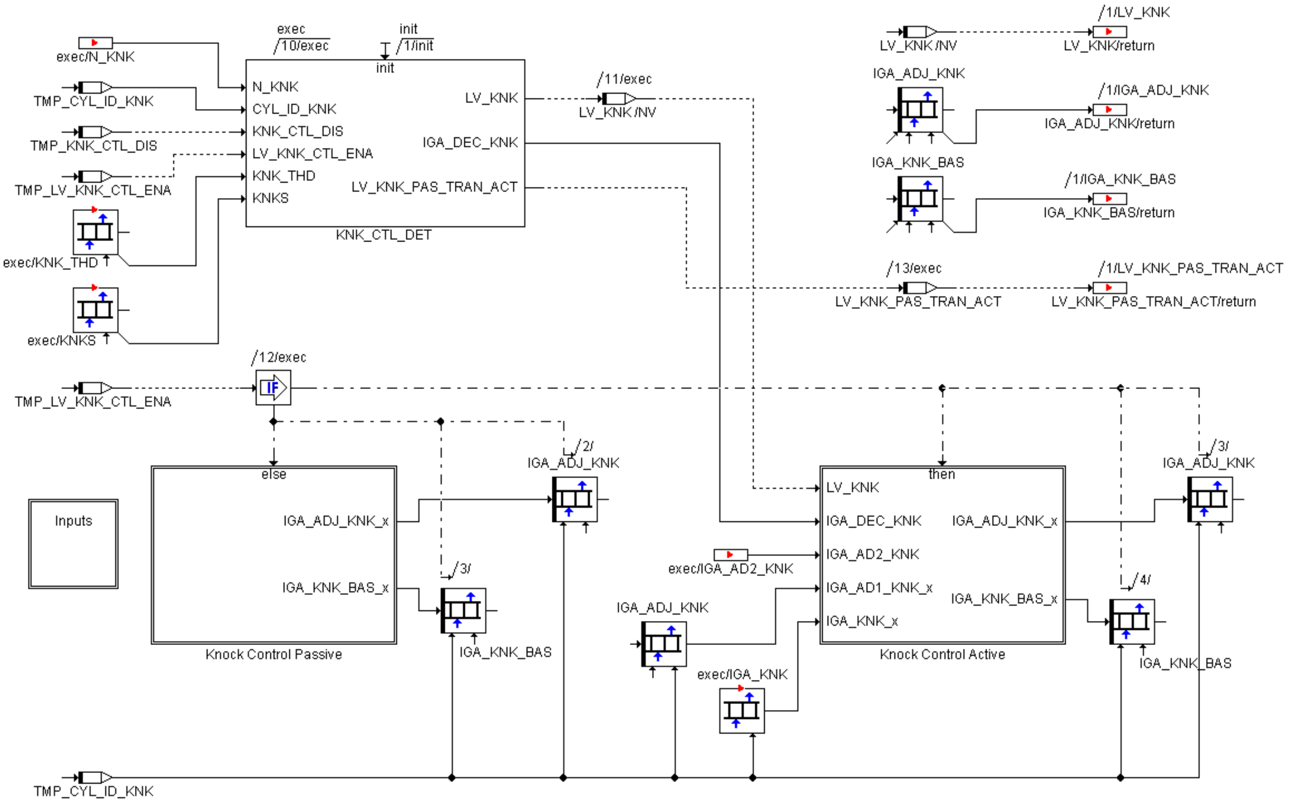


KNK_CTL_CTL

Overview:

```
→ Knock Control at change of operation mode
→ Knock Detection in separate window
→ Knock Detection
if    (LV_KNK_CTL_ENA = 1)
      → Knock Control active
            if    Combustion mode  = 'stratified'
                  → Calculation 'knock control in stratified mode'
            else
                  if
                  → Calculation of Maximum Retard Adjustment
                        if    (KNK_CTL_DIS = 1)
                              → Limp Home operation
                        else
                              if    (LV_KNK_CTL_PRE_ENA = 1)
                                    → Normal Operation Pre-Ignition
                              end if
                              → Normal operation
                              → Control excursion limit
                        end if
                  → Limitation of total ignition retard
                  else
```

```
                → Reset of Knock control
            end if
        endif
else
    → Knock control passive (Reset after abandoning the Knock-Operating-Limit)
end if
```



Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialisation:	at reset and engine running to engine stop
	IGA_ADJ_KNK[NC_CYL_NR] = 0
	STATE_CMB_CTL_KNK = 0
Update Rate:	every segment

45.4.3.1 Knock Control at change of operation mode

Changing the operation mode causes some additional noise. To avoid faulty detection of knock, the knock control is cut off for a calibratable time. The noise level has to be shifted with a own correlation constant. This calculation has to be done before IGA_DEC_KNK is calculated.

Definition of temp variable for change between combustion states:

```
if          OPM_AV(n) != OPM_AV(n-1) // operation mode has changed
then
            if          OPM_AV = "AFS" to "AFL"
            then        STATE_CMB_CTL _TMP = "AFS_TO_AFL"       (1H)

            elseif      OPM_AV = "AFS" to "S"
            then        STATE_CMB_CTL _TMP = " HOM_TO_S "       (4H)

            elseif      OPM_AV = "S" to "AFL"
            then        STATE_CMB_CTL _TMP = "BACKHOM"          (8H)

            elseif      OPM_AV = "S" to "AFS"
            then        STATE_CMB_CTL _TMP = " S_TO_HOM "       (7H)

            elseif      OPM_AV = "AFL" to "AFS"
            then        STATE_CMB_CTL _TMP = "AFL_TO_AFS"       (3H)

            elseif      OPM_AV = "'AFL"  to "S"
            then        STATE_CMB_CTL _TMP = "BACKS"            (5H)
else
            if          OPM_AV = "AFS"
            then        STATE_CMB_CTL _TMP = "HOM_AFS"          (0H)

            elseif      OPM_AV = "AFL"
            then        STATE_CMB_CTL _TMP = "HOM_AFL"          (2H)

            elseif      OPM_AV = "S"
            then        STATE_CMB_CTL _TMP = "S"                           (6H)
endif

if          OPM_AV(n) != OPM_AV(n-1) // operation mode has changed
      then
            LV_CTR_KNK_CMB = 1
            CTR_KNK_CMB = 0
            STATE_CMB_CTL_KNK = STATE_CMB_CTL_TMP
endif

if    LV_CTR_KNK_CMB = 1 and CTR_KNK_CMB < ID_CTR_KNK_CMB
      then
            CTR_KNK_CMB ++
      else
            CTR_KNK_CMB = 0
            LV_CTR_KNK_CMB = 0
endif
```

ID_CTR_KNK_CMB is to be used in dividers of six (six segments equal one working cycle)

45.4.3.2 Knock Detection in separate window

FUNCTION DESCRIPTION:

General information:

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialisation:	at reset and engine running to engine stop LV_KNK_PRE=0 CYCNR_KNK_PRE_DET = 0 CTR_KNK_PRE_DET[0 to NC_CYL_NR] = 0 CYCNR_INH_IV_KNK_PRE_DET[0 to NC_CYL_NR] = 0 set all bits in INH_IV_KNK = 0
Update Rate:	every segment

Formula section:

```
if    (LV_KNK_CTL_PRE_ENA = 1)
      Knock Control Pre-Ignition Active:
      if     (KNK_CTL_DIS = 0)
             if     (NC_CYL_NR cycles has elapsed after Passive or Limp-Home)
                    LV_KNK_PAS_TRAN_ACT = 1

        LV_KNK_PAS_TRAN_ACT = 0
        LV_KNK = 0
    end if
else
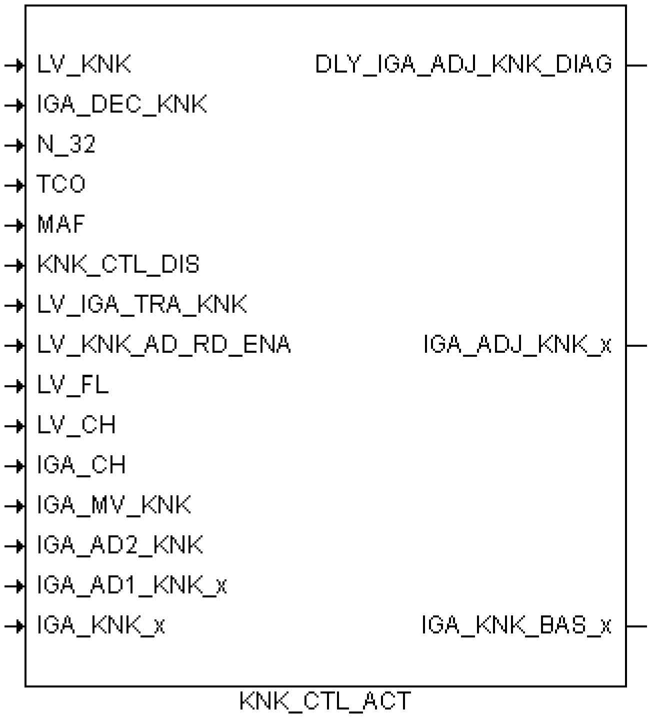
    Knock Control Passive:
    LV_KNK_PAS_TRAN_ACT = 0
    LV_KNK = 0
end if
```

N.B.: x represents current CYL_ID_KNK

Different adjustment decrements are also produced due to the different knock intensities. Then it is possible to react to hard knock-strikes with a greater ignition - timing retardation.

45.4.3.4 Knock control active



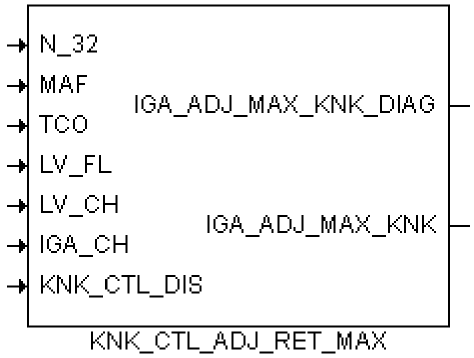
General information:

The spark retard is calculated cylinder-individual at every firing event. The spark retard due to the knock control system is determined by the spark retard due to knocking combustion (IGA_KNK[x]). The sum of these retard components is limited to a maximum spark retard.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	LV_ES = 1
Initialisation:	-
Update Rate:	every segment

45.4.3.4.1 Calculation of Maximum Retard Adjustment



FUNCTION DESCRIPTION:

General information:

This ignition angle is also executed if a knock control related malfunction is detected (KNK_CTL_DIS = 1).

Please note that this maximum spark retard is an absolute ignition angle referring to TDC.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	-
Initialisation:	-
Update Rate:	every segment

Formula section:

```
IGA_OFS_MAX_KNK      = IP_IGA_OFS_MAX_KNK(N_32, MAF)
FAC_IGA_MAX_KNK      = IP_FAC_IGA_MAX_KNK(TCO, TIA)
IF      LV_ERR_KNKS[NC_NR_SENS_KNK]  = 1   (or condition)
Then
        IGA_BAS_MAX_KNK      = IP_IGA_BAS_MAX_KNK_ERR(N_32, MAF)
Else
        IGA_BAS_MAX_KNK      = IP_IGA_BAS_MAX_KNK(N_32, MAF)
EndIf
IGA_ADJ_MAX_KNK = IGA_BAS_MAX_KNK + (IGA_OFS_MAX_KNK * FAC_IGA_MAX_KNK)
```

45.4.3.4.2 Normal Operation Pre-Ignition

FUNCTION DESCRIPTION:

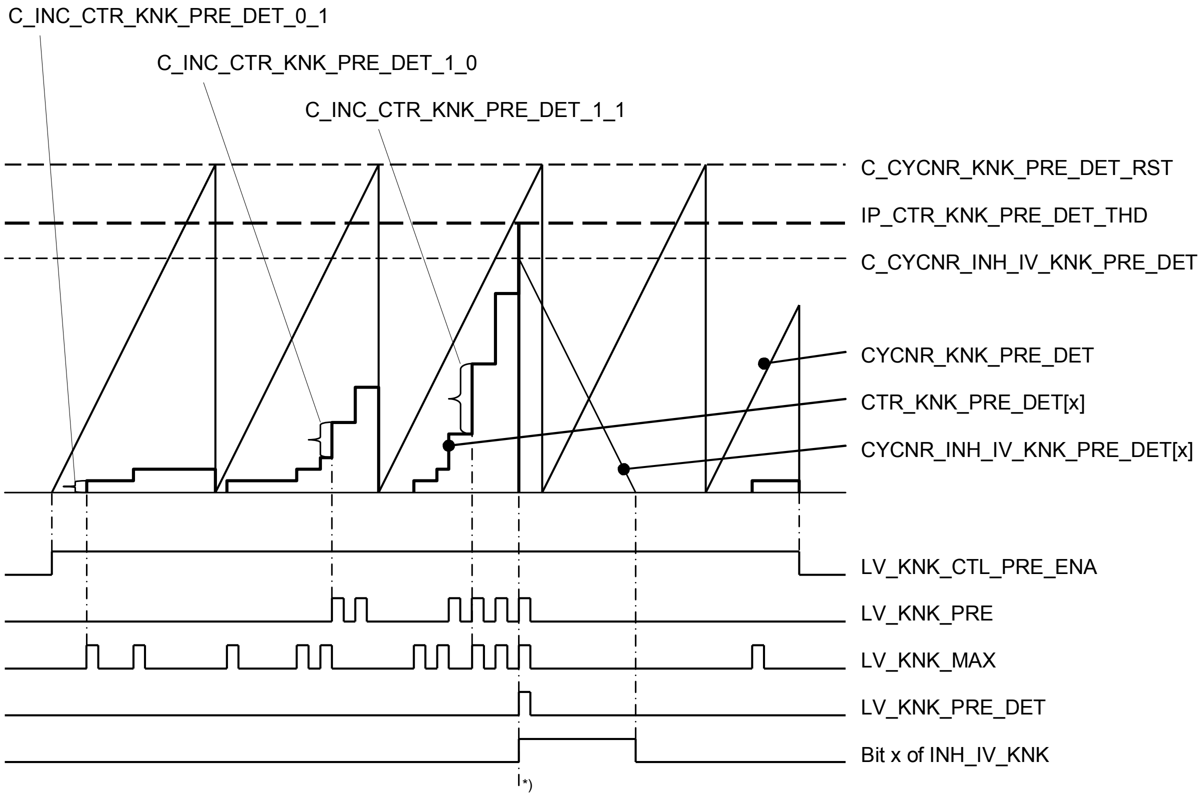
General information:

Surface ignition, before the regular ignition is triggered, is called pre-ignition. This kind of autoignition is caused by a hot spot, generated by prolonged, heavy spark knock. It is known as knock-induced pre-ignition. This is the most damaging side effect of spark knock.

Knock-induced pre-ignition is detected by following algorithm, that is observing normal knocking (normal knock window) and pre-ignition (pre-knock window). Both windows are evaluated to detect occuring pre-ignition events. If either many knock events are detected in the normal knock window or in the pre-knock window or in the normal knock window plus the pre-knock window during a certain number of firing events, autoignition is detected and the protection function of the engine is activated. Then the injection of the concerned cylinder is shut off for a calibratable number of firing events to prevent engine damage.

(No execution, if not (LV_KNK_CTL_PRE_ENA = 1))

Detection algorithm:



*) counter exceeds threshold within observation period --> cycle counter for injection inhibition starts

LV_KNK_PRE refers to ID_KNK_THD_MAX_PRE threshold,
LV_KNK_MAX refers to IP_KNK_THD_MAX threshold!

Formula section:

cycle counter for observation period
(update rate: every 720°)

```
CYCNR_KNK_PRE_DET = CYCNR_KNK_PRE_DET$_{n-1}$ + 1
```

cycle counter and detection counter reset when reaching cycle counter threshold
(update rate: every 720°)

Endif
```

```
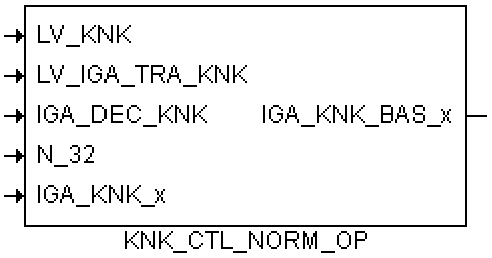
If      CYCNR_INH_IV_KNK_PRE_DET[x] > 0
Then    CYCNR_INH_IV_KNK_PRE_DET[x] = CYCNR_INH_IV_KNK_PRE_DET[x]$_{n-1}$ - 1
        set bit x for corresponding cylinder in INH_IV_KNK = 1
Else    set bit x for corresponding cylinder in INH_IV_KNK = 0
Endif
```

this calculation has to be done before 'Cylinder Shut Off (Application Incidences)'

N.B.: x represents current CYL_ID_KNK

45.4.3.4.3 Normal Operation



FUNCTION DESCRIPTION:

General information:

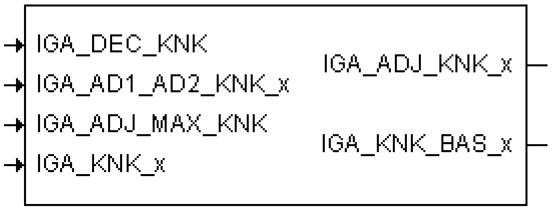
The spark retard is calculated cylinder-individual at every firing event. The spark retard due to the knock control system is determined by the spark retard due to knocking combustion (IGA_KNK[NC_CYL_NR]). The sum of these retard components is limited to a maximum spark retard.
In case of knock free operation (LV_KNK=0) and LV_KNK_CTL_ENA = 1 the Ignition retard due to knock control is re-set to zero (Controlled reset at Knock-free operation).
The controlled ignition-timing reset remains active until either the map ignition timing (IGA_KNK_BAS[x] = 0) is reached or until knocking occurs.

Formula section:

```
if        (LV_KNK = 1)
then      IGA_KNK_BAS[x] = IGA_KNK[x] - IGA_DEC_KNK
else      Controlled reset at Knock-free operation
    if    (LV_IGA_TRA_KNK = 0)
    then  IGA_KNK_BAS[x] = IGA_KNK[x] + IP_IGA_INC_KNK__N
    else  IGA_KNK_BAS[x] = IGA_KNK[x]
    end if
end if
```

N.B.: x represents current CYL_ID_KNK

45.4.3.4.4 Limp Home Operation



KNK_CTL_LIH

FUNCTION DESCRIPTION:

General information:

After an diagnosis error on the knock control system is detected (KNK_CTL_DIS = 1) the limp home spark retard level is achieved via spark retard Intensity 1 (IGA_DEC_KNK).

Formula section:

```
Check if limphome spark retard level is already reached
if    IGA_KNK[x] - IGA_DEC_KNK < IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard
then
      IGA_KNK_BAS[x] = IGA_ADJ_MAX_KNK  – IGA_WOUT_KNK
Limphome spark retard level not yet reached
else
      IGA_KNK_BAS[x] = IGA_KNK[x] - IGA_DEC_KNK
end if
```

45.4.3.4.5 Control Exursion limit

FUNCTION DESCRIPTION:

General information:

The control excursion limit is used to limit the difference of the ignition adjustment angle through knock- control of the single cylinders to a certain value. All 720 °CRK the arithmetic mean value of the cylinder ignition adjustment angles IGA_KNK_BAS[NC_CYL_NR] is calculated:
All 720/Cyl. °CRK a test will be done, to see whether the ignition adjustment angle of the just calculated cylinder is more retarded or advanced than
$|$IGA_MV_KNK - C_IGA_ DIF_MIN_MAX_KNK$|$. In this case the knock control adjustment angle is limited to the control excursion limit.
In case that ignition angle retard reaches the maximum limit, LV_IGA_DIF_MAX_KNK is set in order to give this information to the 'Excursion Limit Analysis' functionality, where the values for concerning cylinder and actual operation point are stored.

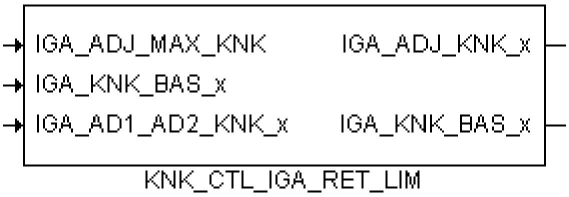
Formula section:

Case Differentiation:

```
Analysis trigger reset:
LV_IGA_DIF_MAX_KNK = 0
if          IGA_KNK_BAS[x]  >  IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK
advance limitation:
then        IGA_KNK_BAS[x]  = IGA_MV_KNK + C_IGA_DIF_MIN_MAX_KNK
else
    if      IGA_KNK_BAS[x] < IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK
    retard limitation:
    then    IGA_KNK_BAS[x] = IGA_MV_KNK - C_IGA_DIF_MIN_MAX_KNK
            Analysis trigger for cylinder individual counter, freeze of Cyl_ID_KNK and operation point:
            LV_IGA_DIF_MAX_KNK = 1
    endif
end if
```

N.B.: x represents current CYL_ID_KNK

45.4.3.4.6 Limitation of total ignition retard

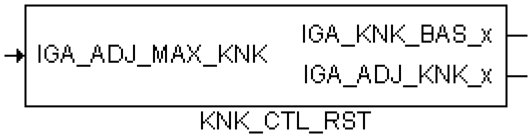


Formula section:

```
if    LV_HOM_ACT = 1
then
      check if limphome spark retard level is already reached
      if        IGA_KNK_BAS[x]  <  IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
      limphome spark retard level reached: Limitation to max. absolute (refering to TDC) possible ignition retard
      then
                IGA_KNK_BAS[x] = IGA_ADJ_MAX_KNK – IGA_WOUT_KNK
      endif
endif
IGA_KNK[x] = IGA_KNK_BAS[x]
IGA_ADJ_KNK[x] = IGA_KNK_BAS[x]
```

N.B.: x represents current CYL_ID_KNK

45.4.3.4.7 Reset of Knock control

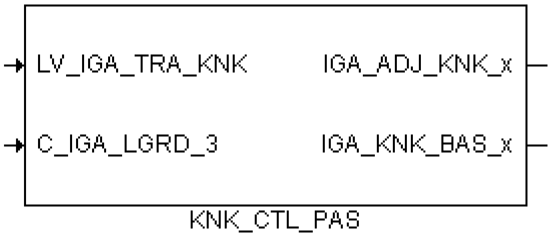


Formula section:

```
IGA_KNK_BAS[x]          = 0°CRK
IGA_ADJ_KNK[x]          = IGA_ADJ_MAX_KNK - IGA_WOUT_KNK
```

N.B.: x represents current CYL_ID_KNK

45.4.3.5 Knock control passiv (Reset after abandoning the Knock-Operating-Limit)



FUNCTION DESCRIPTION:

General information:

If the operating limit falls below (LV_KNK_CTL_ENA = 0), then the ignition adjustment angle IGA_KNK_BAS[x] is re-set to 0, with the change limitation C_IGA_LGRD_3 - however referring to 720° CRK -, in order to reach the map ignition timing.

Formula section:

```
if    (LV_IGA_TRA_KNK = 0)
then
      $IGA\_ADJ\_KNK[x] = IGA\_ADJ\_KNK[x]_{(N-1)} + C\_IGA\_LGRD\_3$
      $IGA\_KNK\_BAS[x] = 0$
else
      $IGA\_ADJ\_KNK[x] = IGA\_ADJ\_KNK[x]_{N-1)}$ (remains unchanged)
      $IGA\_KNK\_BAS[x] = 0$
end if
```

45.4.3.6 Knock Control in Stratified Mode

FUNCTION DESCRIPTION:

General information:

Knock detection and knock control is also active in stratified combustion mode. As ignition retard is not usable in stratified mode and may lead to problems at combustion mode changes, the spark retard variables IGA_ADJ_KNK and IGA_KNK_BAS are set to zero during stratifed. If stratified mode is left, the spark retard has to start at 0 °CRK when knock is recognized.

Formula section:

```
if    OPM_AV = 'S'        (stratified combustion, 1H)
then
```

call action interface for acquisition of knks signal for pre and normal window

ACTION_INFR_*GetVKnks*(OUT <V_knks>, IN <Cyl>, IN <Win>)
Gets the formatted knock noise raw signal

```
    IGA_ADJ_KNK[x]  = 0 °CRK
    IGA_KNK_BAS[x] = 0 °CRK
    if      (KNKSx >= KNK_THD[x])
    then    LV_KNK = 1
    else    LV_KNK = 0
    endif
    if      (KNKS_PRE[x] ≥ KNK_THD_PRE)
    then    LV_KNK_PRE = 1
    else    LV_KNK_PRE = 0
    end if
    CYCNR_KNK_PRE_DET = 0 (reset of counter for observation period)
    CTR_KNK_PRE_DET[x] = 0 (reset of detection counter)
    CYCNR_INH_IV_KNK_PRE_DET[x] = 0 (reset of injection shut off counter)
    set all bits in INH_IV_KNK = 0 (reset of pre-ignition inhibit bits)
else
    IGA_ADJ_KNK[x]  is calculated as described in the previous chapters
    IGA_KNK_BAS[x]  is calculated as described in the previous chapters
end if
```

Hints:

Due to former changes IGA_KNK[x] is now identical to IGA_KNK_BAS[x].

At transition from stratified combustion mode to normal operation mode of knock control, NC_CYL_NR cycles have to be elapsed for spark retard.

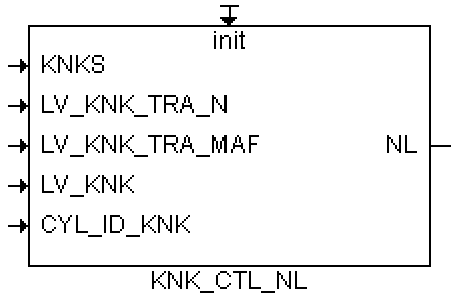
        IGA_MV_CBK_ADJ_KNK[1] = IGA_MV_CBK_ADJ_KNK[1] / NC_CYL_NR
ENDIF
```

45.4.4.2 Noise Value



FUNCTION DESCRIPTION:

The noise value is cylinder-individually calculated as sliding average from the knock values. The averaging constant is either taken from ID_NL_CRLC, if no knock control transient function is active (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0) or C_NL_CRLC_TRA, when a knock control transient function is active (LV_KNK_TRA_N = 1 or LV_KNK_TRA_MAF = 1).

Application conditions:

Activation: at every engine state except engine stop

Deactivation: at engine stop

Initialization: NL[0 to NC_CYL_NR] = C_KNK_THD_MAX

at reset or engine running to engine stop

Update Rate: every segment

Formula section:

```
if        (LV_KNK_TRA_N or LV_KNK_TRA_MAF)
 then     if      OPM_AV = "AFS"
          then    NL[x] =  NL[x] + (KNKS[x] – NL[x]) * C_NL_CRLC_TRA
          else    NL[x] = NL[x] + (KNKS[x] – NL[x]) * C_NL_CRLC_TRA_AFL
          end if

 elseif   LV_CTR_KNK_CMB = 1
 then     NL[x] = NL[x] + (KNKS[x] – NL[x]) * C_NL_CRLC_CMB

else      NL[x] =  NL[x] + (KNKS[x] – NL[x]) * ID_NL_CRLC
end if
```

NL[NC_CYL_NR] shows always the measured noise value from the ATIC62 device. The noise value is calculated always (independant from detection of knocking combustion).

In transient condition, if knocking combustions are detected (LV_KNK = 1) after knock-free operation, the first noise value is used weighted ((KNKS[x] / IP_FAC_THD_KNK) * C_FAC_KNK_TRA instead of simply use of KNKS[x]) to calculate the noise level, the second and the following are taken into consideration for normal transient calculation of noise level again.
Else, if KNKS[x] ≥ IP_FAC_NL_UPD_DEAC * KNK_THD[x] (signal near threshold) AND LV_KNK_PAS_TRAN_ACT = 1 (delay cycles elapsed after passive or limp-home) AND LV_CTR_KNK_CMB = 0 (delay counter elapsed after combustion mode switch), the first and the second noise value isn`t used to calculate the noise level (NL[NC_CYL_NR] remains unchanged), the third and the following are taken into consideration for calculation of noise level. NL[NC_CYL_NR] remains unchanged for this time.

N.B.: x represents current CYL_ID_KNK

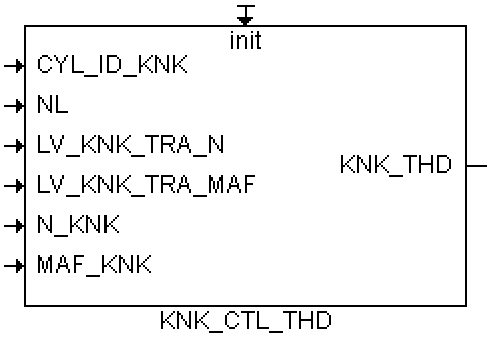
45.4.4.3 Relative and Absolute Knock Threshold



FUNCTION DESCRIPTION:

General information:

The knock threshold (KNK_THD[NC_CYL_NR]) is the limit for the knock values (KNKSx), which are used for knock decision. If the knock values are greater or equal to the knock threshold, then knocking is recognised (LV_KNK = 1) and an ignition timing retardation follows. If the knock values are smaller, knocking is not detected (LV_KNK = 0) and the relevant KNK-ignition-angle is reset (→ Knock-free Operation after Knocking).

The knock threshold is calculated for each cylinder separately and depends on the cylinder-individual noise value. Calculation of the knock threshold occurs with help from the cylinder-individual knock factors IP_FAC_THD_KNK[NC_CYL_NR] and knock summand IP_ADD_KNK__N.

If the noise value is above the minimum threshold C_NL_MIN, the knock threshold is calculated on the basis of the cylinder-individually noise value NL[NC_CYL_NR]. If the noise value is below C_NL_MIN this value is used as noise value for calculation of the knock threshold. If the knock threshold is above ID_THD_MAX_KNK this value is used as knock threshold (Limitation). C_THD_MAX_KNK stays preserved as initialisation value for NL and NL_0_5 (in multiplexer specification).

N.B.: The actual knock value KNKS[x]$_n$ is not used in the calculation of the actual knock threshold KNK_THD[x]$_n$ but in the calculation of the next threshold KNK_THD[x]$_{n+1}$. So the decision knocking combustion yes/no is done with using the knock threshold KNKS[x]$_{n-1}$.

Application conditions:

Activation:	at every engine state except engine stop
Deactivation:	at engine stop
Initialization:	KNK_THD[0 to NC_CYL_NR] = KNK_THD_PRE = 5V at reset and engine running to engine stop
Update Rate:	every segment

Formula section:

The lower absolute threshold is one value for all cylinders and is represented by the constant C_NL_MIN.

```
If   NL[x] < C_NL_MIN
     NL_LIM = C_NL_MIN
else
     NL_LIM = NL[x]
end if

if   OPM_AV = "AFS"
     if      (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0)
             KNK_THD[x] = ( NL_LIM + IP_KNK_THD_ADD_N ) * IP_FAC_THD_KNK[x]
     else
             KNK_THD[x] = ( NL_LIM + IP_KNK_THD_ADD_N ) * IP_FAC_THD_KNK[x] *
                                  C_FAC_TRA_KNK
     end if
else
     if      (LV_KNK_TRA_N = 0 and LV_KNK_TRA_MAF = 0)
             KNK_THD)[x] = ( NL_LIM + IP_KNK_THD_ADD_N_AFL ) *
                                  IP_FAC_THD_KNK_AFL[x]
     else
             KNK_THD)[x] = ( NL_LIM + IP_KNK_THD_ADD_N_AFL ) *
                                  IP_FAC_THD_KNK_AFL[x] * C_FAC_TRA_KNK
     end if
end if
```

The knock threshold is generally limited to KNK_THD_MAX

```
KNK_THD_MAX = IP_KNK_THD_MAX
If  (KNK_THD[x] > KNK_THD_MAX)
    KNK_THD[x] = KNK_THD_MAX
end if

If  LV_KNK_CTL_PRE_INH = 0
    KNK_THD_PRE = ID_KNK_THD_MAX_PRE
end if
```

N.B.: x represents current CYL_ID_KNK

(*) The correction factor **C_FAC_TRA_KNK** is part of the KNK-load dynamics function and is effective after recognised load dynamics **ID_CYCNR_FAC_TRA_KNK__N** cycles.

The knock factor is the multiplicative part used for calculation of the knock threshold from the noise value.
The knock summand is an additive correction of the knock noise value. Thereby the knock threshold can be moved, dependent on the speed, in a positive or negative direction.

KNK_THD_MAX with respect to **IP_KNK_THD_MAX** is used as absolute threshold for detection algorithm in main window.
KNK_THD_PRE with respect to **ID_KNK_THD_MAX_PRE** is used as absolute threshold for detection algorithm in pre-window.

MAF	N_32	LV_INH_DIAG_KNKS	LV_KNK_CTL_ENA
KNKS_1_DIAG	KNKS_2_DIAG	NC_KNKS_CONF	NC_NR_SENS_KNK
LV_DC	USE_SW_VER	MFF_SP_MV	

FUNCTION DESCRIPTION:

The array NC_CBK_EX_NR refers to sensor number (0 is KNKS_1; 1 is KNKS_2).

General information:

The task of the function "knock sensor diagnosis" lies in the input signal monitoring of the respective knock sensor.

The sensor signal is checked continuously regarding plausibility. This is done by observation of the signal noise value NL[NC_CYL_NR] ('Range Check') and with two algorithms (‘Master’- and ‘Slave’-Algorithm). The bandwidth (DYW_KNKS_DIAG) of the signal will be observed with these two algorithms. Both algorithms have to indicate the same system condition before the debounce counter is started.

The debounce counter will be called up every 720 °KW. The three test algorithms will be called up segment synchronously which will be done under consideration of the configuration values NC_KNKS_CONF (which knock sensor "hears" which cylinder), KNKS_1_DIAG and KNKS_2_DIAG (which cylinder will be taken for which knock sensor regarding diagnosis).

Range Check

In the range check a test will be done to find out if the output signal of the knock-IC is in the allowed working range between the calibratable minimum fault detection threshold and maximum fault detection threshold. A fault case is given if the minimum threshold is fallen-below or the maximum limit is exceeded. The ERR_SYM_KNKS is set when one (or more) of the monitored signals infringe a fault threshold.

‘Master’-Algorithm

In the master-algorithm the bandwidth of the signal (DYW_KNKS_DIAG = | NL[NC_CYL_NR] – KNKS[NC_CYL_NR] will be calculated for the concerned cylinder which is allocated to the concerned knock sensor regarding diagnosis purposes. The calculated bandwidth will be compared to the calibrated threshold value C_DYW_MIN_KNKS_DIAG.

At short circuit against ground or VB as well as a broken signal line the bandwidth of the signal does not exceed the threshold value. In this case the counter CYCNR_DYW_KNKS_DIAG will be incremented in each monitored segment.

As soon as the bandwidth of the sensor signal exceeds the value C_DYW_MIN_KNKS_DIAG again and LV_ERR_KNKS is not set the value will be reset again. In the case of LV_ERR_KNKS already set the value CYCNR_DYW_KNKS_DIAG will be decremented by 5 units.

If the counter reaches the value C_CYCNR_KNKS_DIAG a failure of the knock sensor will be set if the 'slave'-algorithm confirms this failure. When a failure has already debounced the SYM_3 is set as long as the counter of the master-algorithm is above 5. This is to delay the failure recovery.

The counter will be reset at transition LV_CDN_DIAG_KNKS = 0=>1.

‘Slave’-Algorithm

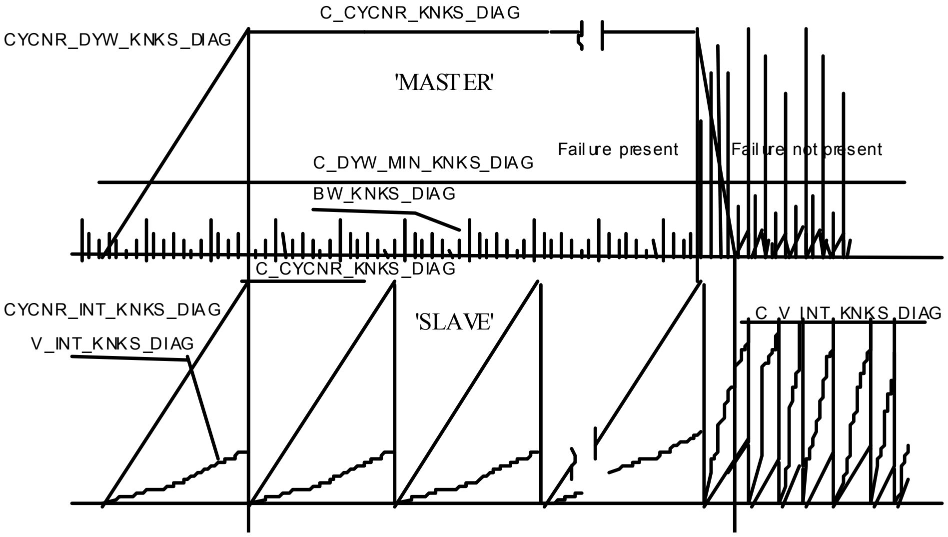
In the slave-algorithm the bandwidth of the sensor signal will also be used as an input signal. It will be recorded in its chronological process and will be integrated by means of an appropriate integration method. The calculated integral value V_INT_KNKS_DIAG will be compared to the threshold value C_V_INT_KNKS _DIAG.

As soon as the threshold value is reached or exceeded the counter CYCNR_INT_KNKS_DIAG will be reset. Otherwise it will be incremented by '1' in each monitored segment. When the counter reaches the value C_CYCNR_KNKS_DIAG the sensor failure will be confirmed through the slave-algorithm and value CYCNR_INT_KNKS_DIAG and value V_INT_KNKS_DIAG reset to 0.

The counter will be reset at transition LV_CDN_DIAG_KNKS = 0=>1.

If a sensor failure is recognized by both algorithms the debounce will get started.

Description:



Application conditions:

Initialisation: at reset **or** LV_IGK = 0->1 **or** clearing FMY:

all = 0, except:

LV_ERR_KNKS[NC_NR_SENS_KNK] **and**

CTR_ABC_KNKS[NC_NR_SENS_KNK] are initialised from FMY

(according STD filter type)

Recurrence: Signal range check and Master- Slave- Algorithm: segment

Error management: each 720 °KW

Activation:

If LV_KNK_CTL_ENA = 1 **and**
LV_PU = 0 **and**
LV_PUC = 0 **and**

Input data:

SEG_NR	INH_IV_KNK	LV_KNK_CTL_PRE_ENA	

FUNCTION DESCRIPTION:

General information:

Workshops must be able to get information about cylinder shut off caused by pre-ignition detection e.g. in case of engine damages.

Description:

For error management failures on single cylinders should be set in case of cylinder shut off by pre-ignition detection algorithm within knock control.
An ABC counter starts incrementing segment synchronous. In case if a calibrataible number of counted segments is reached, a fault is detected by the error management.

Application conditions:

Initialisation: according filter type 'STD_INI'

Recurrence: segment synchronous (analogous knock control)
every 720° CRK for the individual cylinder – update for cylinder x
only in the corresponding segement, where injection shut off bit could change

Activation: **If** LV_KNK_CTL_PRE_ENA = 1
Then LV_CDN_DIAG_KNK_PRE[x] = 1

Deactivation: **If** LV_KNK_CTL_PRE_ENA = 0
Then LV_CDN_DIAG_KNK_PRE[x] = 0

Formula section:

```
If      bit x for corresponding cylinder in INH_IV_KNK = 1
Then    ERR_SYM_KNK_PRE[x]  = SYM_3
Else    ERR_SYM_KNK_PRE[x]  = NO_SYM
Endif
```

The bits LV_ERR_xx and LV_END_DIAG_xx are set by the error management after debounce.

N.B.: x represents the SEG_NR, where the corresponding cylinder can have a change in position x of INH_IV_KNK

Failure reaction:

handled by INH_IV_KNK

Configuration for diagnostic symptoms:

For each cylinder a separate fault location is used

symptoms for cylinder[NC_CYL_NR]

45.8.2 Outputs for SV aggregates

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Application conditions:

Recurrence: 10 ms
Activation: every engine state

Formula section:

LV_IGA_TRA_KNK = B_zwdyn

IGA_IS_TQ_KNK = Dzw_krkorll

IGA_MV_ADJ_KNK_CUS = Dzw_annm

46 Lambda control

Table of Contents

Index

46.1 LACO General

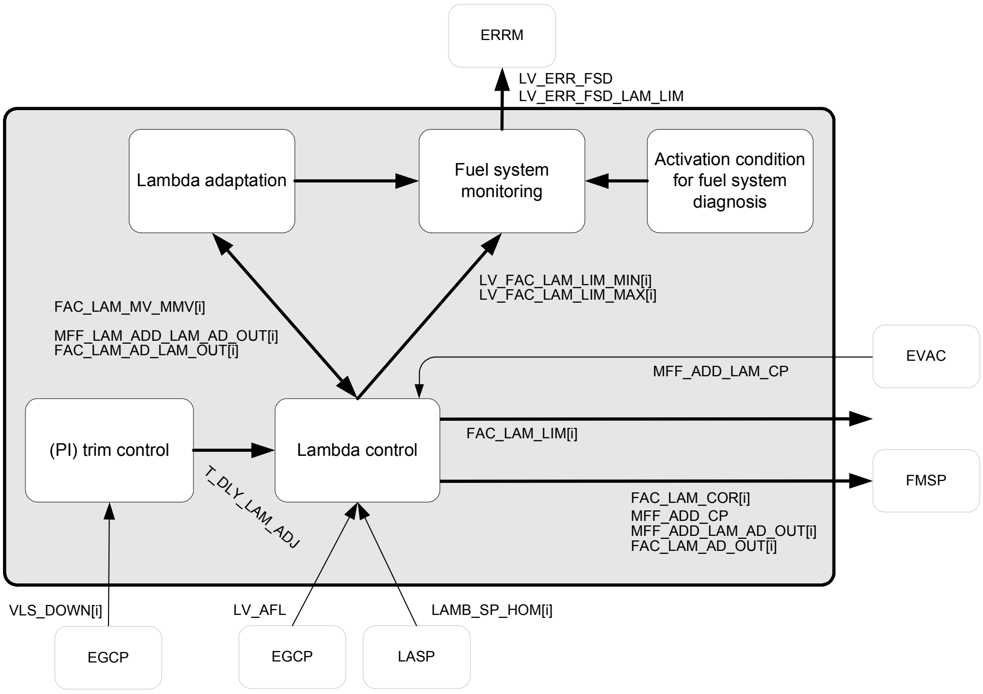
General information:

The Aggregate LACO fulfils the following tasks:
- Lambda control based von upstream oxygen sensor signal
- Trim control based on downstream oxygen sensor signal
- Lambda adaptation
- Fuel system monitoring

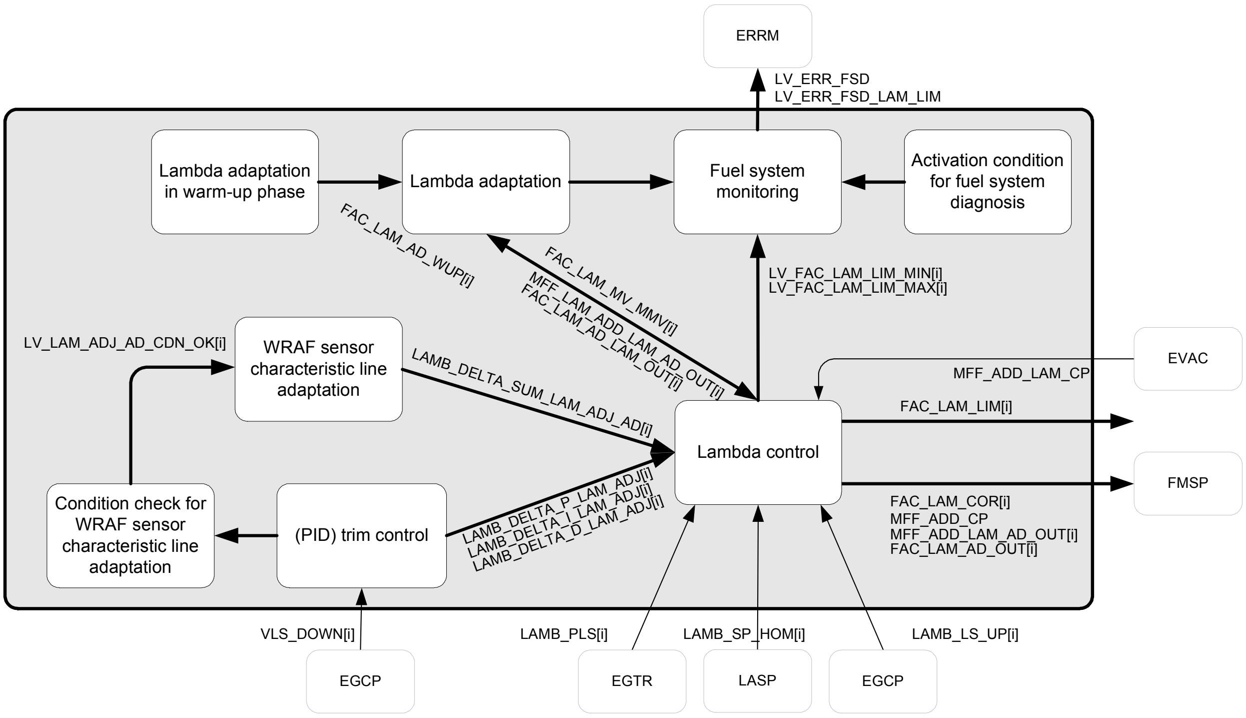
The aggregate is available in 2 variants:
- Variant 1 : bin/bin
- Variant 2 : lin/bin

Architecture Overview:

Variant 1:



Variant 2:



Functional Overview:

46.1.1 Lambda control

The Lambda Control Correction adjusts the fuel-air mixture to the desired ratio. It controls the factor FAC_LAM_COR which is adjusted to produce a leaner or a richer mixture according to the oxygen sensor information. The FAC_LAM_COR forms a multiplicative factor in the fuel mass set point calculation thus exerting direct influence on the injected quantity.

46.1.2 Lambda control conditions (Variant 2: Lin/Bin only)

This function manages the stop modes of the linear lambda controller, defines non stationary conditions, calculates the crankshaft difference between start of fuel injection and the position where the sensor detects the exhaust gas, detects whether lambda closed loop control was active at least once during the actual driving cycle and evaluates the fuel system status.

46.1.3 Lambda adaptation

In order to compensate serial production tolerances of components, an adaptive correction is calculated (one additive and two multiplicative) based on the filtered lambda controller output. Depending on load and engine speed three different adaptation fields (one offset and two factor areas) are observed. The additive and multiplicative adaptation corrections are used for calculating the injection time for all engine operating states, except at ‘engine stop’ and ‘engine start’. Lambda adaptation learning, for precision reason, needs to be performed at lambda equal 1 conditions. The function itself is activated by the corresponding LV_LAM_AD_ACT[i].

46.1.4 Lambda adaptation in warm-up phase (Variant 2: Lin/Bin only)

The Lambda adaptation in warm-up phase enhances the Lambda adaptation functionality to obtain a more precise correction at low temperatures (< 50°C). The adaptive correction is applied to compensate serial production tolerances of components at low.

TCO dependent correction factors (%) are learned in five temperature ranges. The correction factors are derived from the Lambda controller output. They are learned in an adaptation field specified by MFF_SP[i] and N_32. They are, however, to correct the injection time for all engine states. Learning of these factors requires that the Lambda controller is in the state 'ON'.

46.1.5 Dynamic fuel trim

The trim-controller causes a better observance of the catalyst window during all the life of the vehicle. The control value is determined depending on the trim control sensor signal (downstream binary signal). The difference of the sensor voltage from set point value is the basic characteristic. The set point value can be applied depending on the operating point, so that the dynamic lambda can be adjusted according to the operating range. For Variant 1 : bin/bin a PI controller is used while for Variant 2 : lin/bin an additional D share increases the control dynamics (PID controller). Variant 1 : bin/bin furthermore includes an adaptation functionality at the end of a driving cycle in order to compensate ageing effects of the upstream O2-sensor. This functionality is covered for Variant 2 : lin/bin by the module "*WRAF sensor characteristic line adaptation with trim control*" described hereafter.

46.1.6 WRAF sensor characteristic line adaptation with trim control (Variant 2: Lin/Bin only)

This function adapts the WRAF sensor characterisic line by observing the I share of the trim control function. A basic (load depending) lambda shift of the WRAF sensor can be corrected by means of an additional offset. This offset can change due to ageing of the sensor.

46.1.7 Valid cond. check for WRAF sensor char. line adap. with trim control (Variant 2: Lin/Bin only)

This function checks several conditions that must be fulfilled in order to start the WRAF sensor characteristic line adaption. These conditions shall define a stable state of the downstream sensor signal used by trim control.

46.1.8 Mean value calculation for limited dynamics

This function calculates only differences between base values and their moving means values. These differences or deltas are to be used within the function that needs limited dynamic conditions. The evaluation of the limited dynamic bit is part of the function that need this flag. So the mean value calculation is concentrated in this function.

46.1.9 Fuel system monitoring

The objective of the fuel system diagnosis is to monitor the lambda control output and the lambda adaptation values in various areas. It should also cover the PCV monitoring where the lambda control output is considered in the idle range.

Breaking the adaptation and lambda controller limits for a long time, which may have been caused by failures in the fuel or intake system will involve emission rise and therefore shall be diagnosed by fuel system diagnosis.

46.1.10 Activation of fuel system monitoring

This function checks all necessary activation conditions in order to activate fuel system diagnosis. High rate of evaporated fuel during rich warm-up phase under cold start conditions could lead to wrong failure detection and therefore a special inhibition flag for that case is generated.

46.2 LACO Configuration Data

General information :

The following describes the general rules for determination of the configuration data

46.2.1 Local configuration data

Here are listed the configuration data, which are used only in the EGCP aggregate.

Data	Value
NC_ERR_SYM_FSD_CONF	1

To be defined by project with information from customer.

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_ERR_SYM_FSD_CONF	1	1...2H	1...2	1	[-]
Number of failure locations in FSD					

46.3 AGGR LACO adaptation

46.3.1 Outputs for SV aggregates, SV internally

Output data:

46.4.1 General information

This function

- manages the stop modes of the linear lambda controller,
- defines non stationary conditions,
- calculates the crankshaft difference between start of fuel injection and the position where the sensor detects the exhaust gas,
- detects whether lambda closed loop control was active at least once during the actual driving cycle and
- evaluates the fuel system status.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Application Condition

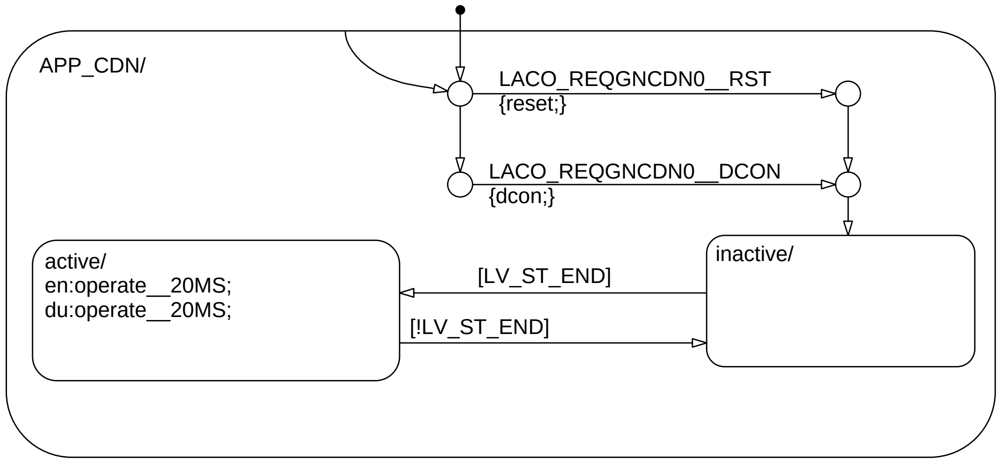

Figure 1 LACO_REQGNCDN0/ APP_CDN/ Chart

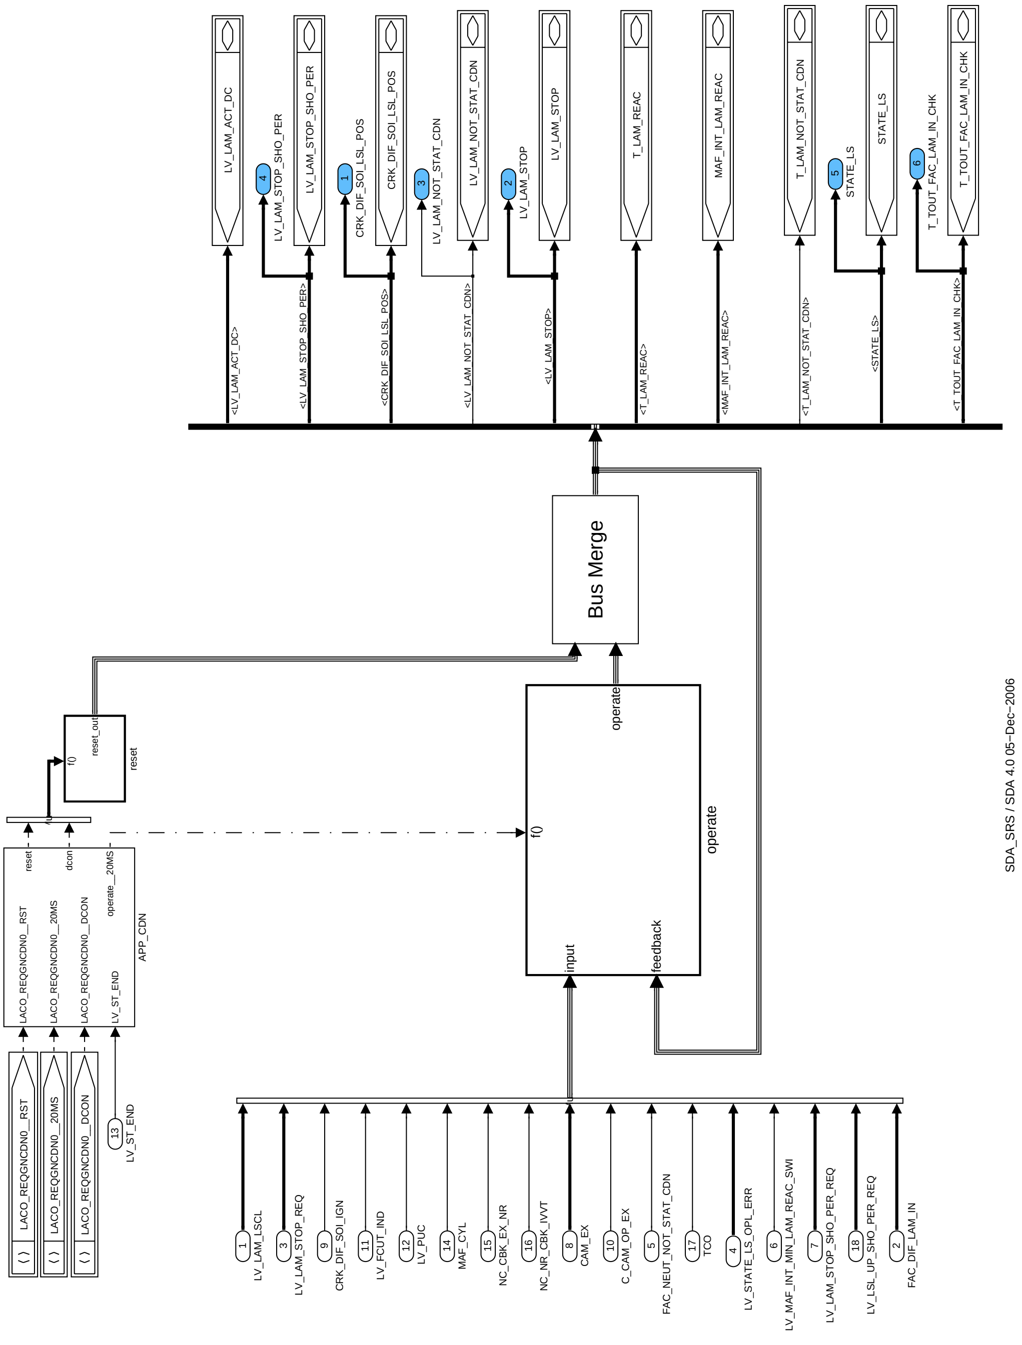

Figure 2 LACO_REQGNCDN0

46.4.1.1 Formula section

Exhaust bank specific functionality

Calculation of LV_LAM_STOP[i], LV_LAM_STOP_SHO_PER[i], CRK_DIF_SOI_LSL_POS[i], LV_LAM_LSCL[i], LV_LAM_ACT_DC[i], STATE_LS[i] and CTR_RAF_CHG[i]

Calculation of LV_LAM_STOP[i] and LV_LAM_STOP_SHO_PER[i]

The lambda-controller is in the stop-mode (LV_LAM_STOP[i] = 1) if one of the conditions

a) the offset-adjustment of the lambda-sensor is active

(LV_LSL_OFS_ADJ_ACT[i] = 1)

b) Switching of the pump current measurement range (gain-switching) of the lambda-sensor is currently taking place (LV_VLS_UP_INIT[i] = 1)

c) Ip gain-switch of the lambda-sensor is not yet confirmed by the hardware (LV_SWI_GAIN_LSL_IF[i] ≠ STATE_LSL_IF_SPI_RD[i] (*bit* SWI_GAIN))

d) OBDI signal failed (LV_LSL_DEAC[i] = 1)

e) one cylinder at least is cut off (LV_FCUT_IND = 1)

f) the engine state LV_PUC is active

g) lambda controller stop mode request (LV_LAM_STOP_REQ[i] = 1)

is fulfilled.

Additionally LV_LAM_STOP_SHO_PER[i] is set to 1 in case that condition a), b), c) or d) is true (short period stop mode).

LV_LAM_STOP_SHO_PER[i] is set to 0 if condition e), f) or g) is true (nominal stop mode). These latter conditions have the higher priority if a) or b) are fulfilled too.

If condition a) and b) are not fulfilled anymore the timer T_LAM_REAC[i] is to start. If this timer exceeds a calibration threshold, LV_LAM_STOP[i] and LV_LAM_STOP_SHO_PER[i] are set both to 0.

If condition e), f) and g) are not fulfilled anymore the integral MAF_INT_LAM_REAC[i] is calculated. If this integral exceeds a calibration threshold and the controller difference FAC_DIF_LAM_IN[i] is below a threshold while a time out threshold is not exceeded, LV_LAM_STOP[i] is set to 0.

For the calcuation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

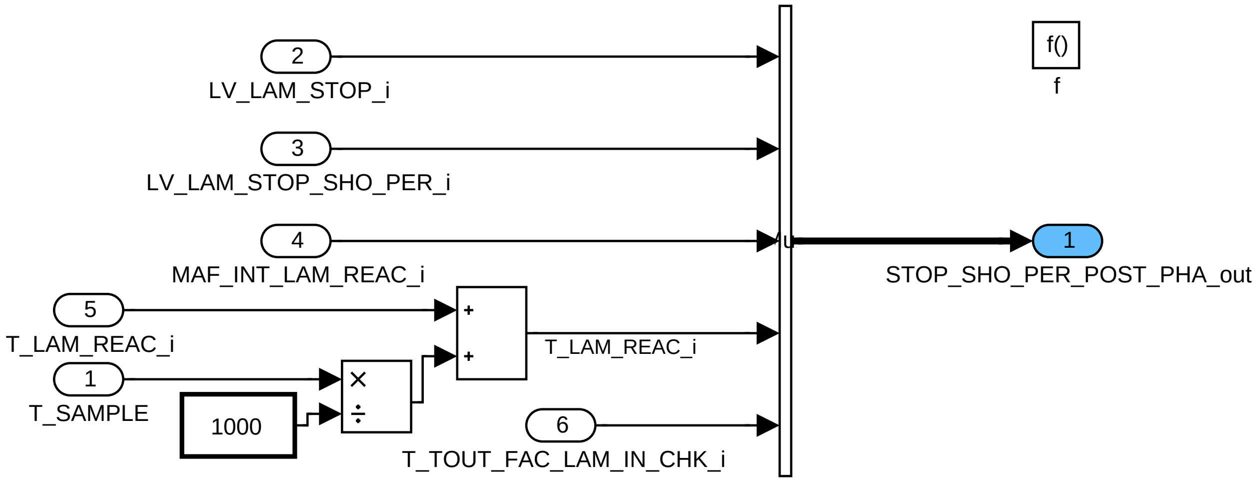

Figure 8 LACO_REQGNCDN0/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ MNG_LAM_STOP/ STOP_SHO_PER_POST_PHA

Calculation of CRK_DIF_SOI_LSL_POS[i]

The value of CRK_DIF_SOI_LSL_POS[i] corresponds to the crankshaft angle difference between the start of injection and the end of the exhaust cycle of the engine. This value is required for the calculation of the gas delay needed for the linear lambda controller. The distance between start of injection and top dead center where the injected fuel is ignited is defined by CRK_DIF_SOI_IGN (see injection phase for homogeneous and stratified mode). The distance from the mentioned top dead center to the point where the exhaust valves close is defined by 360°CRK plus current position of exhaust camshaft (CAM_EX[i]; is always negative) minus half of the opening period. So the opening timing edge of the exhaust valve is met.

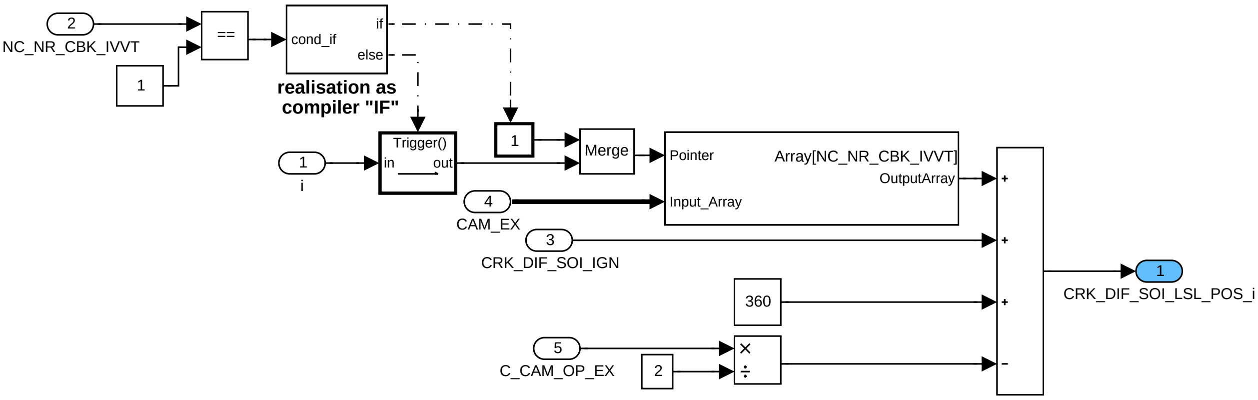

Figure 9 LACO_REQGNCDN0/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ CLC_CRK_DIF_SOI_LSL_POS

Calculation of LV_LAM_ACT_DC[i]

The flag LV_LAM_ACT_DC[i] shows that lambda closed loop control was active at least once during the actual driving cycle.

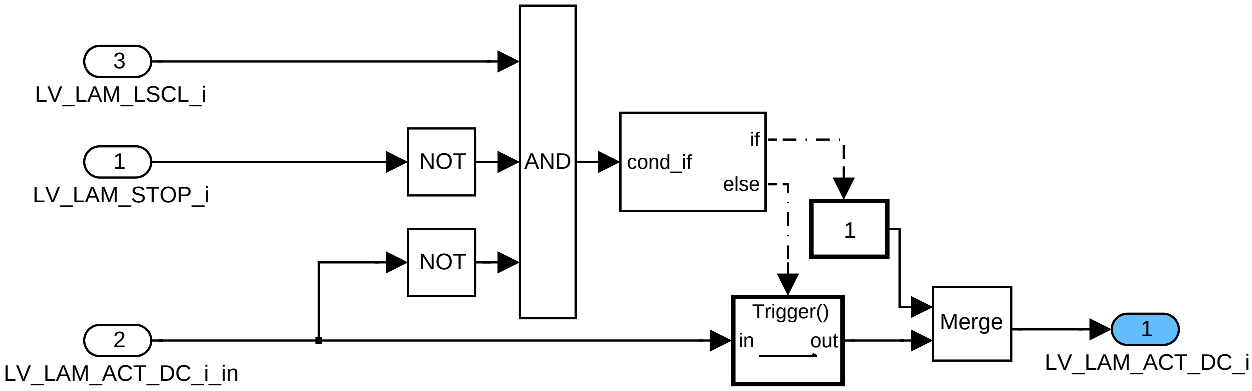

Figure 10 LACO_REQGNCDN0/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ DET_LAM_ACT_DC

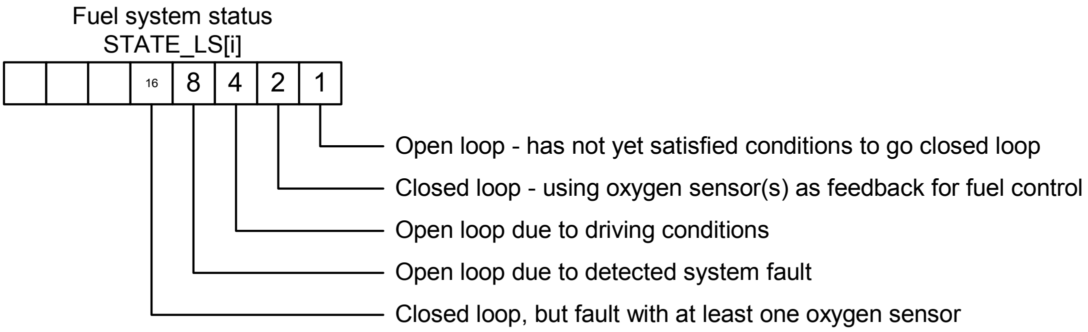
Evaluation of fuel system status STATE_LS[i]

The fuel system status byte indicated the status (open / closed loop) of the cylinder bank. It belongs to the freeze frame requested by law SAE J1979. State 16 is not supported.



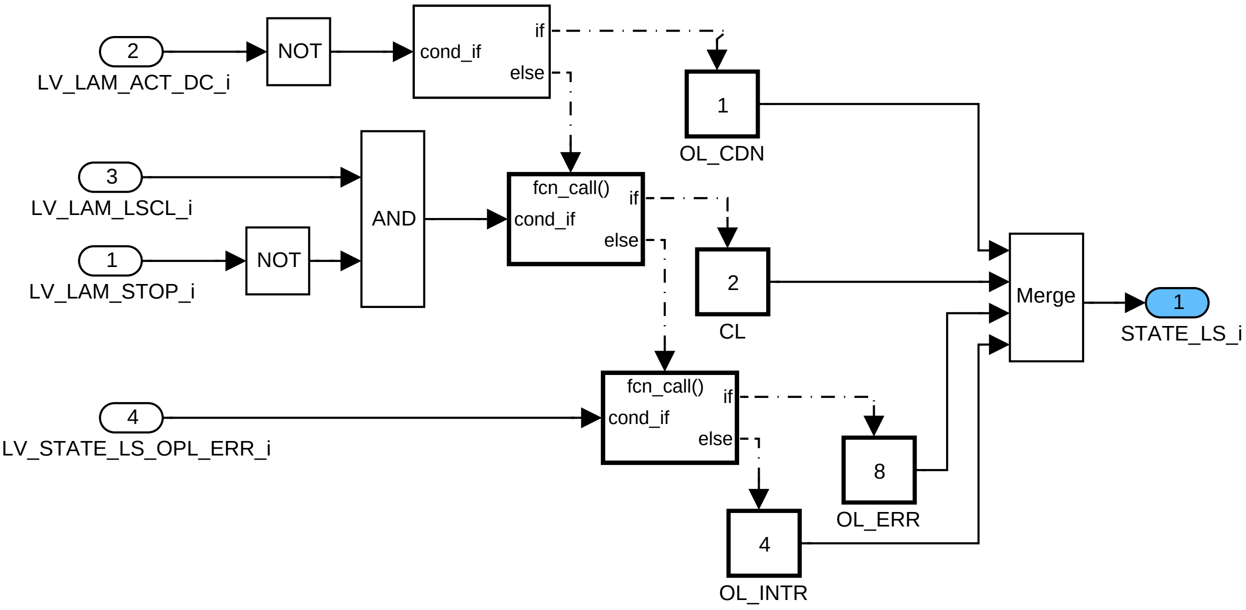


Figure 11 LACO_REQGNCDN0/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ CLC_STATE_LS

Definition of non stationary conditions

To avoid big controller excursion under non stationary conditions like wall film the output limitation of the lambda controller can be restricted. Therefore the flag LV_LAM_NOT_STAT_CDN is set if the neutral value FAC_NEUT_NOT_STAT_CDN exceeds the calibration minimum or maximum. The limitation itself (reaction on this flag) is executed in the module linear lambda control.

If the sum of the wall film is lower than this calibration threshold a counter is decreased. If the counter is 0 then the lambda-controller works without the limitation again.

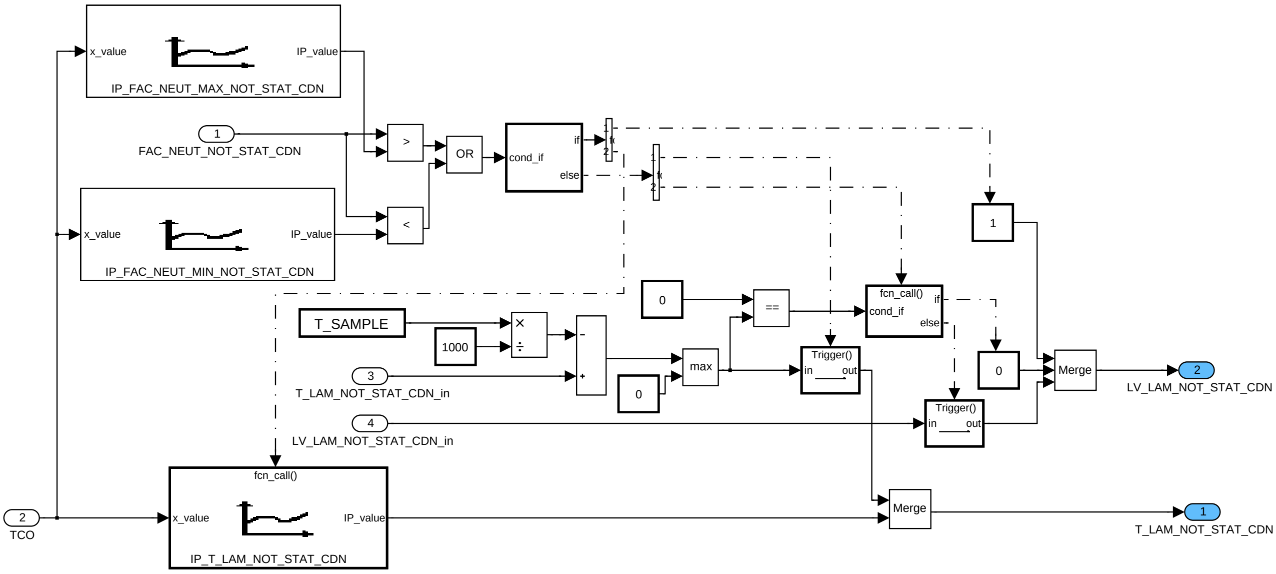

Figure 12 LACO_REQGNCDN0/ operate/ CLC_LAM_NOT_STAT_CDN/ LAM_NOT_STAT_CDN

46.4.1.2 Initialization

STATE_LS[i] is set to "OL_CDN".

T_LAM_REAC[i] is set to C_T_MIN_LAM_REAC.

MAF_INT_LAM_REAC[i] is set to C_MAF_INT_MIN_LAM_REAC.

T_TOUT_FAC_LAM_IN_CHK[i is set to C_T_MIN_TOUT_FAC_LAM_IN_CHK.]

All other output variables are set to 0.

46.5 Lambda control for WRAF sensor

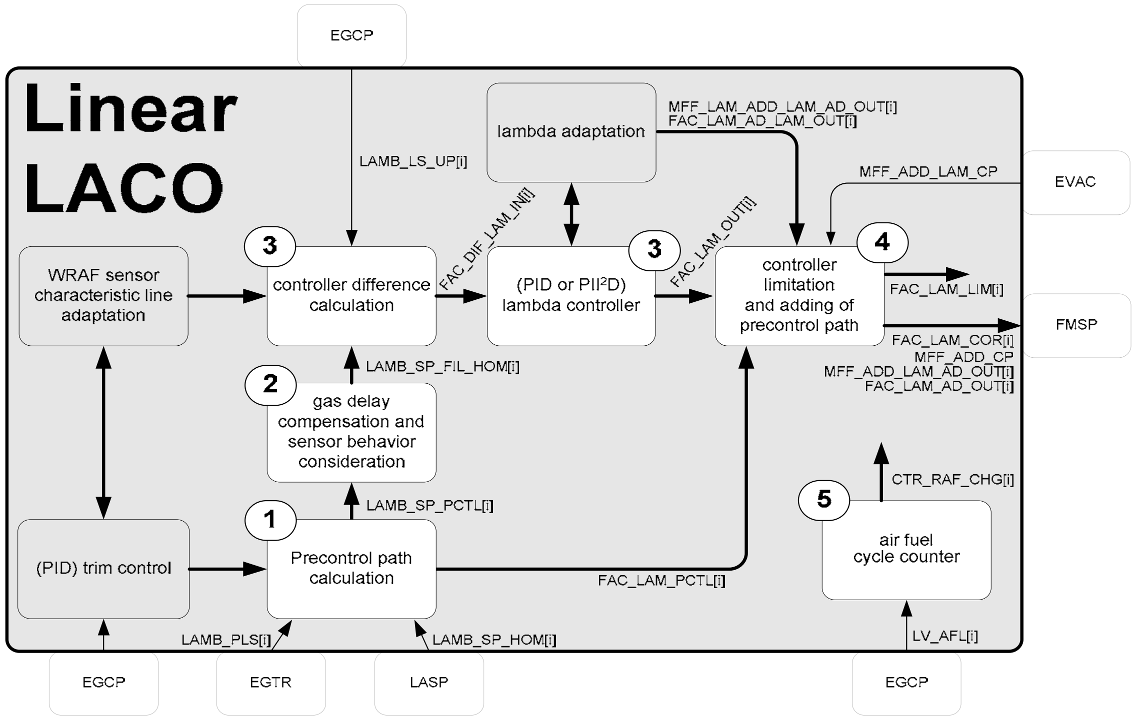
Overview

The linear lambda controller adjusts the air fuel ratio depending on the engine operating state. The controller is designed as a 4th order controller containing P, I, I^2 and D share. Beyond this also a PID controller can be calibrated. The measuring signal of the air fuel ratio is generated by a continuous (WRAF) O_2 sensor. An interface to lambda adaptation, canister purge function and evaporative system monitoring function permits the adjustment of the lambda controller output signal and internal state variables. Furthermore mean values of the output signal are calculated and provided to other functions.

This module consists of 5 sub-functionalities:

1. Precontrol path calculation (including set point determination)
2. Exhaust gas delay compensation and sensor behavior consideration
3. Closed loop control; PII^2D or PID controller including controller difference calculation (main functionality)
4. Controller output limitation and precontrol path correction consideration
5. Calculation of air fuel ratio changes counter (auxiliary function used by other modules)

The figure below gives an overview about the single sub-functions of this module.



Lambda control functions in the LACO context.

LACO_REQGNLACO0 used as model name defines unambiguously this whole module.

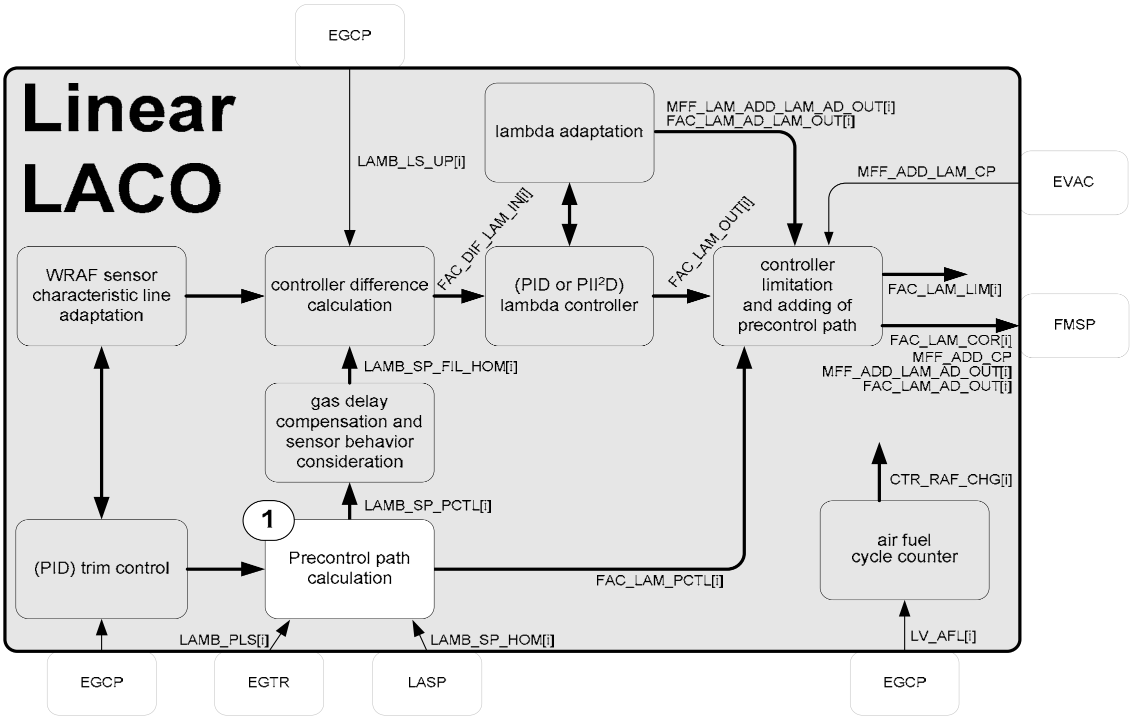
46.5.1 Precontrol path calculation

For fast reaction on lambda set point changes a feed forward control (precontrol path) is included. Therefore in a first step the precontrol lambda set point LAMB_SP_PCTL[i] also used by the controller is determined.



Sub-function in the whole module context

Additional remark:

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

LAMB_SP_PCTL[i] is set to 1.

46.5.1.2 Formula section

Exhaust bank specific functionality

Calculation of LAMB_SP_PCTL[i] and FAC_LAM_PCTL[i]

In case of homogeneous mode the precontrol lambda set point is the static set point LAMB_SP_HOM[i] added up by the forced stimulation output LAMB_PLS[i]. LAMB_SP_DELTA_LAM[i] is subtracted to consider trim control lambda intervention. This latter variable is assigned in the application incidences.

The precontrol correction FAC_LAM_PCTL[i] is calculated by inverting LAMB_SP_PCTL[i].

In case of stratified mode (LV_HOM_ACT[i] = 0) both outputs are initialized.

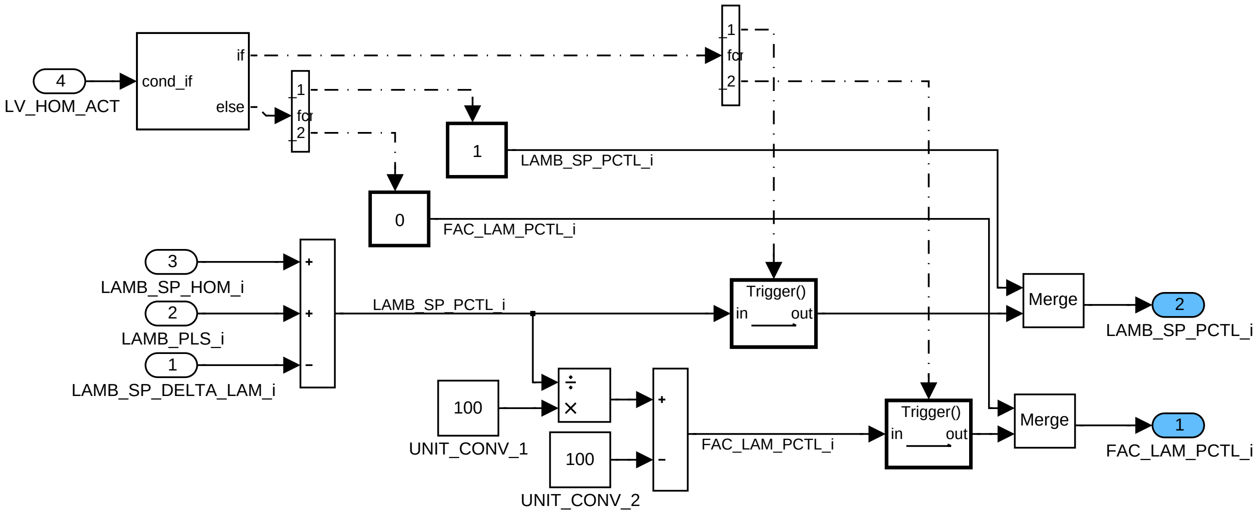

Figure 16 LACO_REQGNLACO0/ CLC_PCTL/ operate/ CBK_EX_MNG/ CBK_EX_SPC

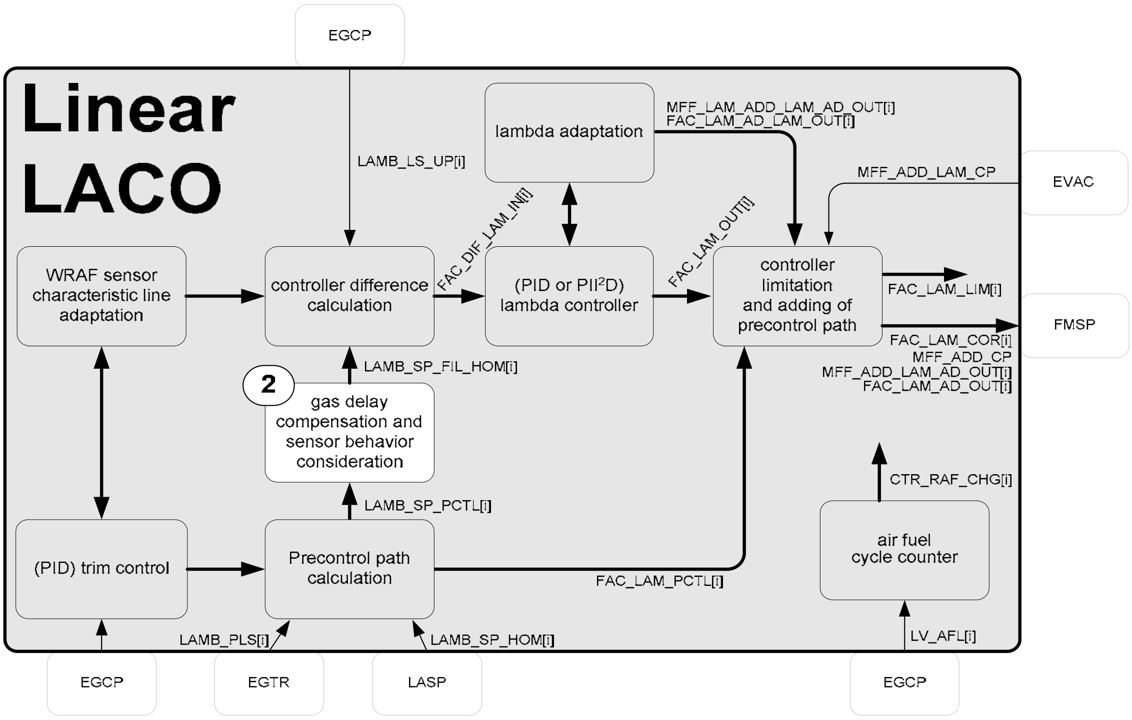
46.5.2 Exhaust gas delay compensation and sensor behavior consideration

The lambda set point for homogeneous mode includes the signal of the forced lambda stimulation, the trim control intervention and eventually an influence of secondary air. In stratified mode the lambda set point is calculated out of the fuel mass flow set point. Both set points are corrected taking into account the exhaust gas delay and the sensor behavior. When changing the injected fuel mass the result of the air fuel ratio due to this change is "seen" by the WRAF sensor some time later. The consideration of this delay and the WRAF sensor rise time is the main content of this function.

The result is a filtered lambda set point for homogeneous mode LAMB_SP_FIL_HOM[i] and for stratified mode LAMB_SP_FIL_S[i]. This latter variable is calculated for other functions like canister purge; it is not used by LACO.



Sub-function in the whole module context

Additional remark:

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

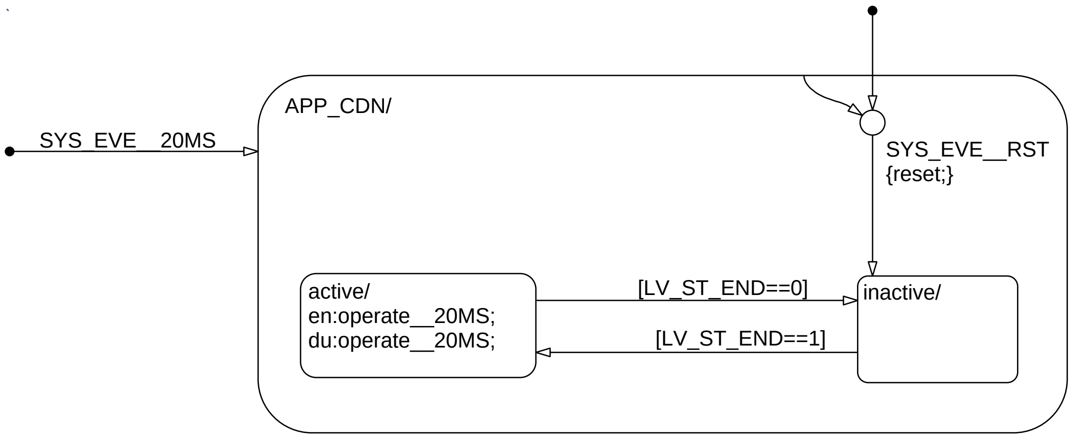


Figure 17 LACO_REQGNLACO0/ SENS_MDL/ APP_CDN/ Chart

Function Description

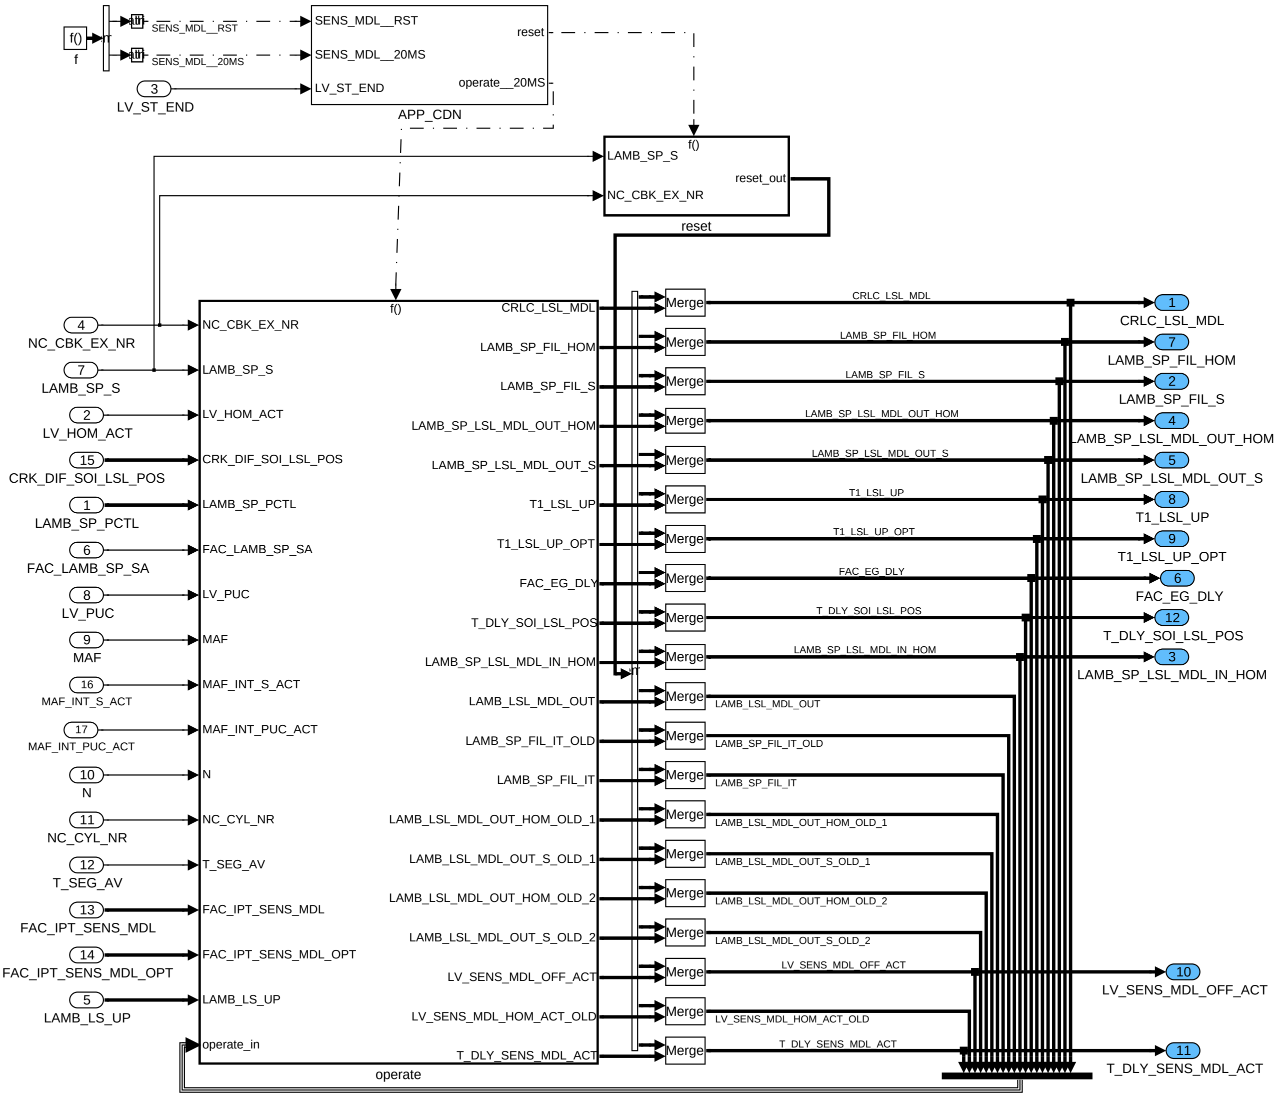

Figure 18 LACO_REQGNLACO0/ SENS_MDL

46.5.2.1 Initialization

All lambda variables are set to 1 except LAMB_SP_FIL_S[i] which is set to LAMB_SP_S.

All other output variables are set to 0.

46.5.2.2 Formula section

Exhaust bank specific functionality

Lambda set point; T1 determination; sensor and exhaust gas delay model

Lambda set point as model input (LAMB_SP_LSL_MDL_IN_HOM[i])

In case of homogeneous mode the input to the model LAMB_LSL_MDL_INP[i] (internal variable) is given by the variable LAMB_SP_LSL_MDL_IN_HOM[i] and in case of stratified mode by LAMB_SP_S.

The lambda set point LAMB_SP_LSL_MDL_IN_HOM[i] in homogeneous mode is being based on the precontrol lambda set point LAMB_SP_PCTL[i] and the secondary air factor

FAC_LAMB_SP_SA. If the secondary air function is not active or no secondary air function is included this factor is set to 1.

When lambda sensor signal LAMB_LS_UP exceeds during PUC the threshold C_LAMB_SENS_MDL_OFF_PUC or when LV_HOM_ACT switches from 0 to 1, the flag LV_SENS_MDL_OFF_ACT[i] is set in order to deactivate and initialize the sensor model.

Based on LV_SENS_MDL_OFF_ACT[i]=1 the 1st order filter and Padé filter are initialized either with IP_LAMB_SP_THE_PUC or IP_LAMB_SP_THE_S_HOM depending on LV_HOM_ACT.

Once set to 1 the flag LV_SENS_MDL_OFF_ACT is set to 0 after a tunable time delay outside PUC. The time delay is given by C_T_DLY_SENS_MDL_ACT[i] and should be >=40ms (= 2 sample steps) in order to initialize the Padé filter well. In order to avoid double initialization when LV_HOM_ACT switches just after exit from PUC the delay time threshold can be used with increased values (e.g. 200ms).

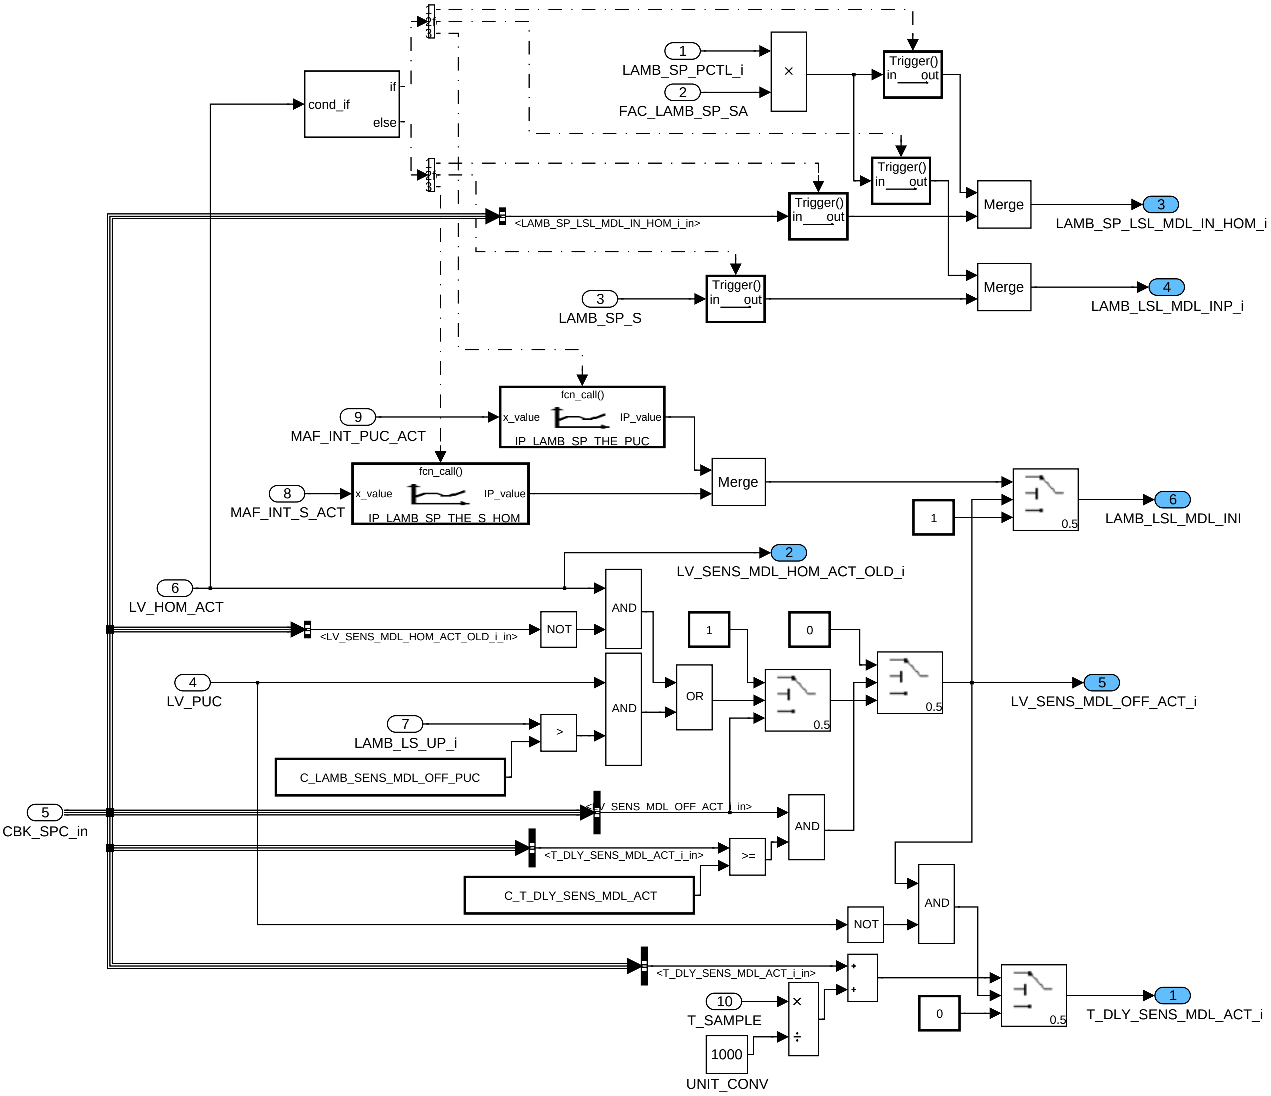

Figure 19 LACO_REQGNLACO0/ SENS_MDL/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ CLC__LSL_MDL_INP

Consideration of dynamic sensor behavior; T1 determination (T1_LSL_UP[i])

The dynamic behavior of the WRAF sensor is approximated by a first order lag system (low pass filter). The time lag (T1_LSL_UP[i]) of the lambda sensor model is calibrated N and MAF dependent. FAC_IPT_SENS_MDL[i] interpolates between the map IP_T1_LSL_UP[i] and the map IP_T1_LSL_UP_FAC_IPT[i] to take into account difference in the sensor behavior.

Furthermore the correlation constant CRLC_LSL_MDL[i] is calculated from T1_LSL_UP[i] taking into account the sample rate of the function.

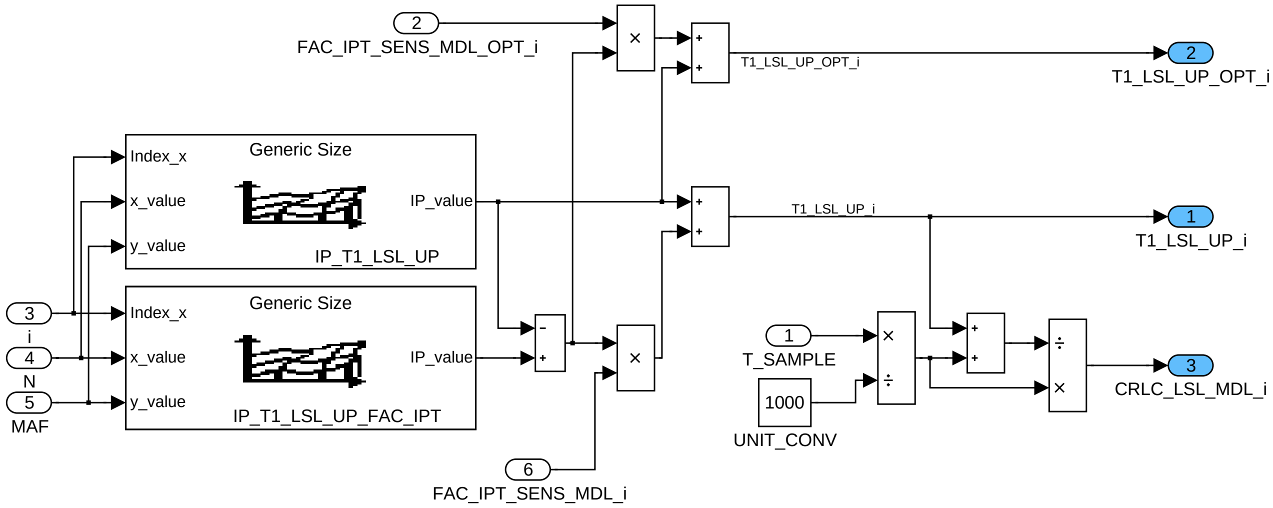

Figure 20 LACO_REQGNLACO0/ SENS_MDL/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ CLC__T1_LSL_UP

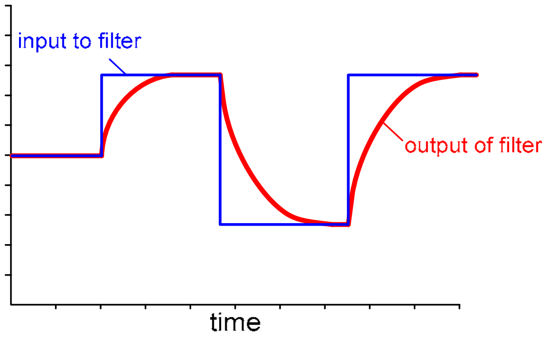
Filtering of lambda set point model input (LAMB_SP_LSL_MDL_OUT_HOM/S[i])

LAMB_LSL_MDL_INP[i] is low pass filtered (moving mean value) by means of the correlation constant CRLC_LSL_MDL[i]. The result is written to the variables LAMB_LSL_MDL_OUT[i] (internal variable), LAMB_SP_LSL_MDL_OUT_S[i] and LAMB_SP_LSL_MDL_OUT_HOM[i] with the corresponding resolution and physical range.

Based on LV_SENS_MDL_OFF_ACT[i] = 1 the 1st order filter is initialized with LAMB_LSL_MDL_INI.

The output LAMB_LSL_MDL_OUT[i] is copied to both variables LAMB_SP_LSL_MDL_OUT_HOM[i] and LAMB_SP_LSL_MDL_OUT_S[i]. If the range of LAMB_SP_LSL_MDL_OUT_HOM[i] is exceeded then the output is limited to the upper range. The defined range is sufficient for homogeneous mode. LAMB_SP_LSL_MDL_OUT_S[i] always covers the whole range but with a lower resolution. Both variables are calculated in stratified as well as in homogeneous mode.

The principle is shown here below.



Sensor behavior consideration (1^{st} order time lag)

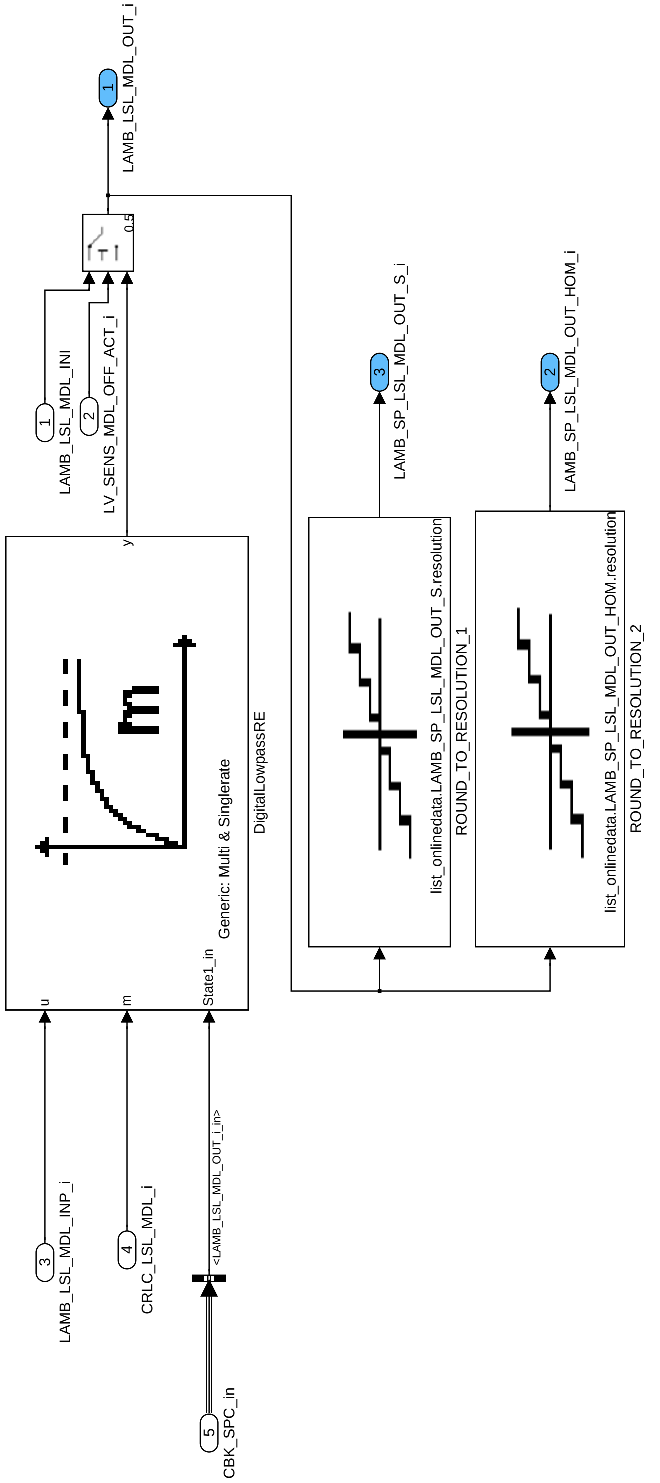


Figure 21 LACO_REQGNLACO0/ SENS_MDL/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ FIL__LAMB_LSL_MDL_INP

Calculation of gas delay time (T_DLY_SOI_LSL_POS[i])

The gas delay T_DLY_SOI_LSL_POS[i] corresponds to the time from fuel injection up to the measurement of the air fuel ratio by the WRAF sensor. IP_FAC_EG_DLY[i] is a tuning factor for the sensor position and is determined together with the T1 maps by means of a system identification. FAC_IPT_SENS_MDL[i] interpolates between the map IP_FAC_EG_DLY[i] and the map IP_FAC_EG_DLY_FAC_IPT[i] to take into account difference in the gas delay time.

The gas delay is calculated with the following formula:

$$\text{T\_DLY\_SOI\_LSL\_POS[i]} = \left[\frac{\text{CRK\_DIF\_SOI\_LSL\_POS[i]}}{180°\text{CRK}} \bullet \frac{\text{NC\_CYL\_NR}}{4} + \text{FAC\_EG\_DLY[i]}\right] \bullet \text{T\_SEG\_AV}.$$

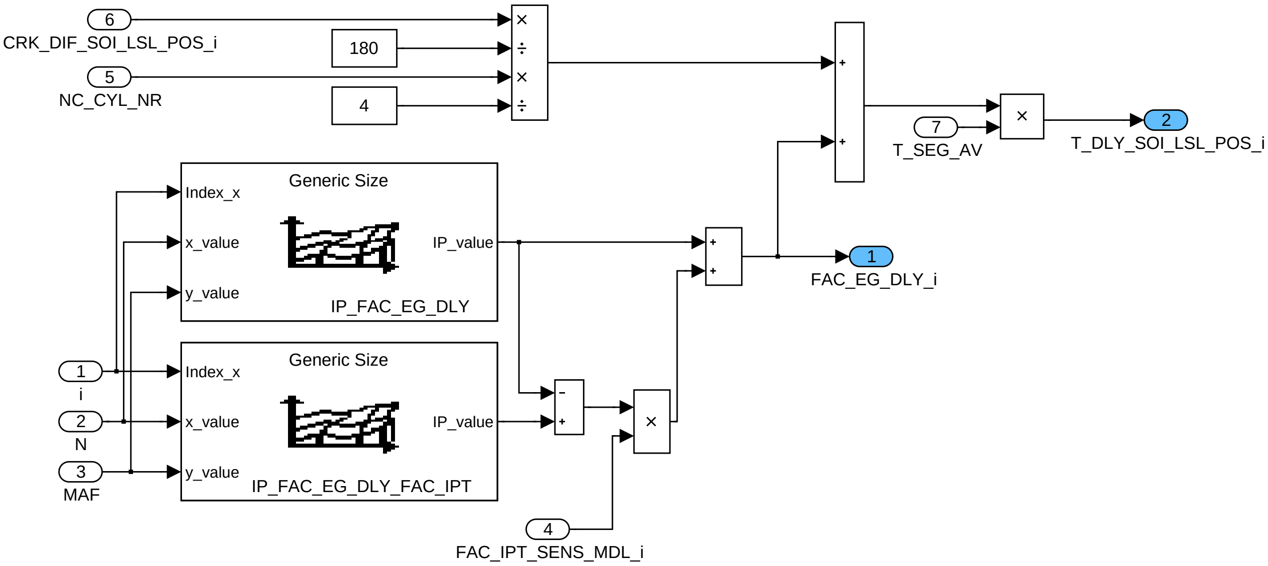

Figure 22 LACO_REQGNLACO0/ SENS_MDL/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ CLC__T_DLY_SOI_LSL_POS

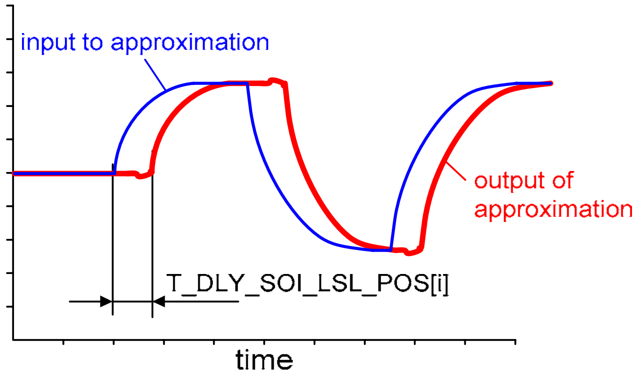
Consideration of the gas delay

By means of a Padé approximation the delayed lambda set point LAMB_SP_FIL_HOM[i] (for homogeneous mode) and LAMB_SP_FIL_S[i] (for stratified mode) is calculated. All other variables which are output of these sub-systems are only necessary to realize the functionality with the desired accuracy.

The behavior of the delay is described by an all-pass filter (Padé approximation of 2nd order). Its principle is shown here below.



Gas delay approximation (2nd order Padé approximation)

The following formula describes the Padé approximation in its mathematical representation:

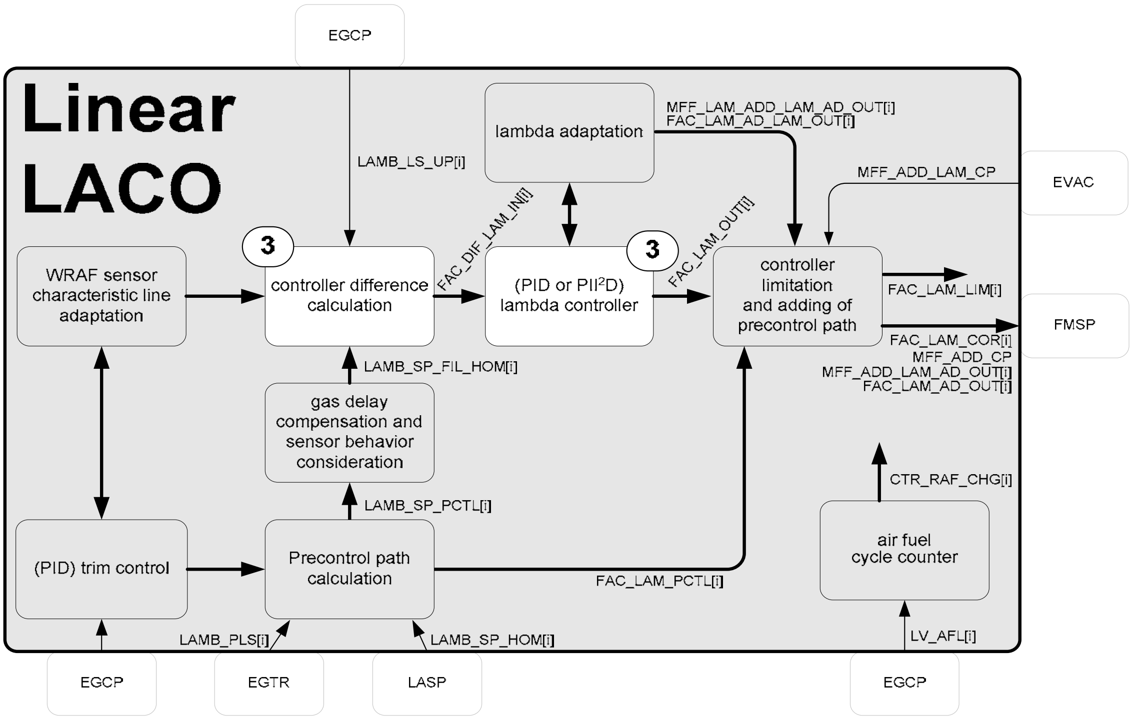
$$f_1 = \frac{\text{T\_DLY\_SOI\_LSL\_POS[i]}}{\text{T\_SAMPLE}},$$

$$f_2 = \frac{f_1^2}{3},$$

$$out_N = \frac{\left(1 - f_1 + f_2\right) \bullet \left(in_N - out_{N-2}\right) + 2 \bullet \left(1 - f_2\right) \bullet \left(in_{N-1} - out_{N-1}\right)}{1 + f_1 + f_2} + in_{N-2}.$$

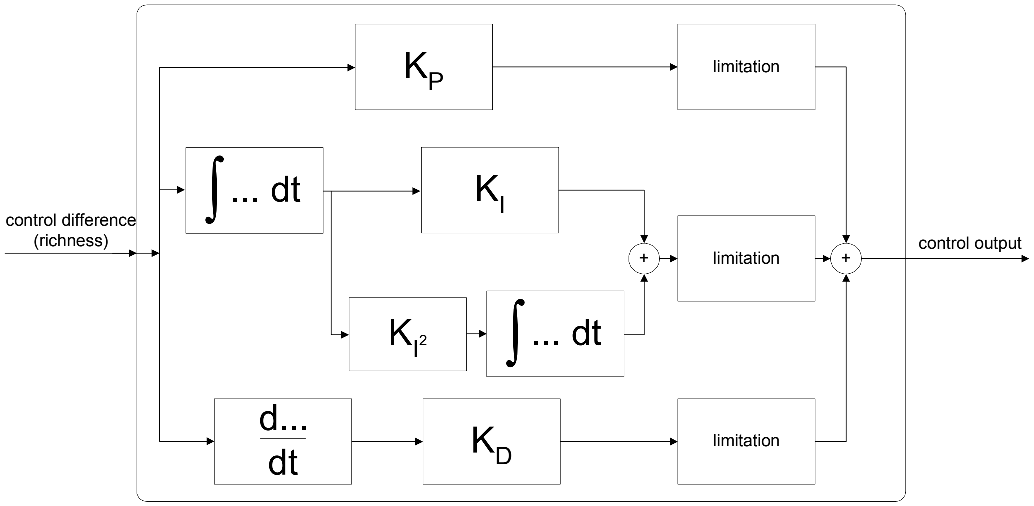
46.5.3 Linear lambda controller

The linear lambda controller can be used as PII^2D or PID controller. By means of the calibration flag LC_LAM_I2_ACT can be switched between both.

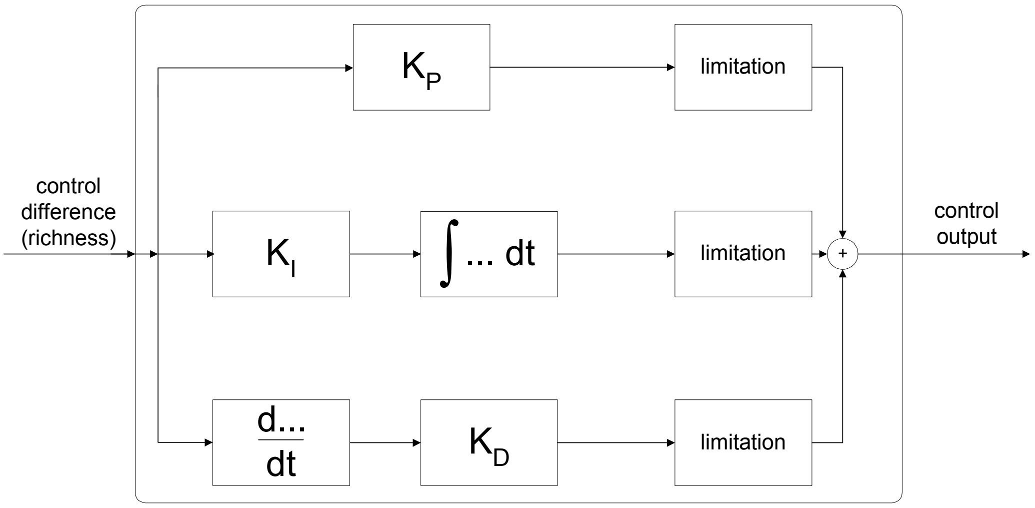


Sub-function in the whole module context

The structure of both controller (PII^2D and PID) is shown hereafter:



Structure of PII^2D controller



Structure of PID controller

Additional remark:

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

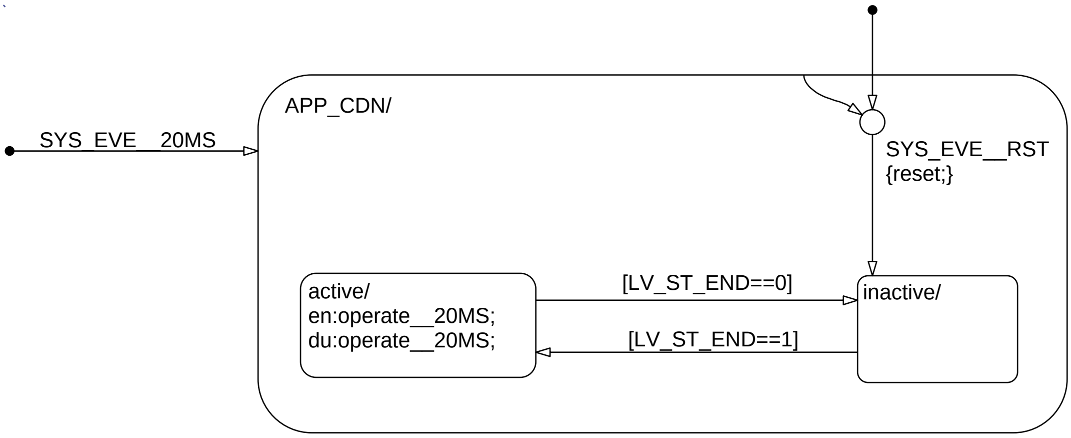


Figure 23 LACO_REQGNLACO0/ LAM/ APP_CDN/ Chart

Function Description

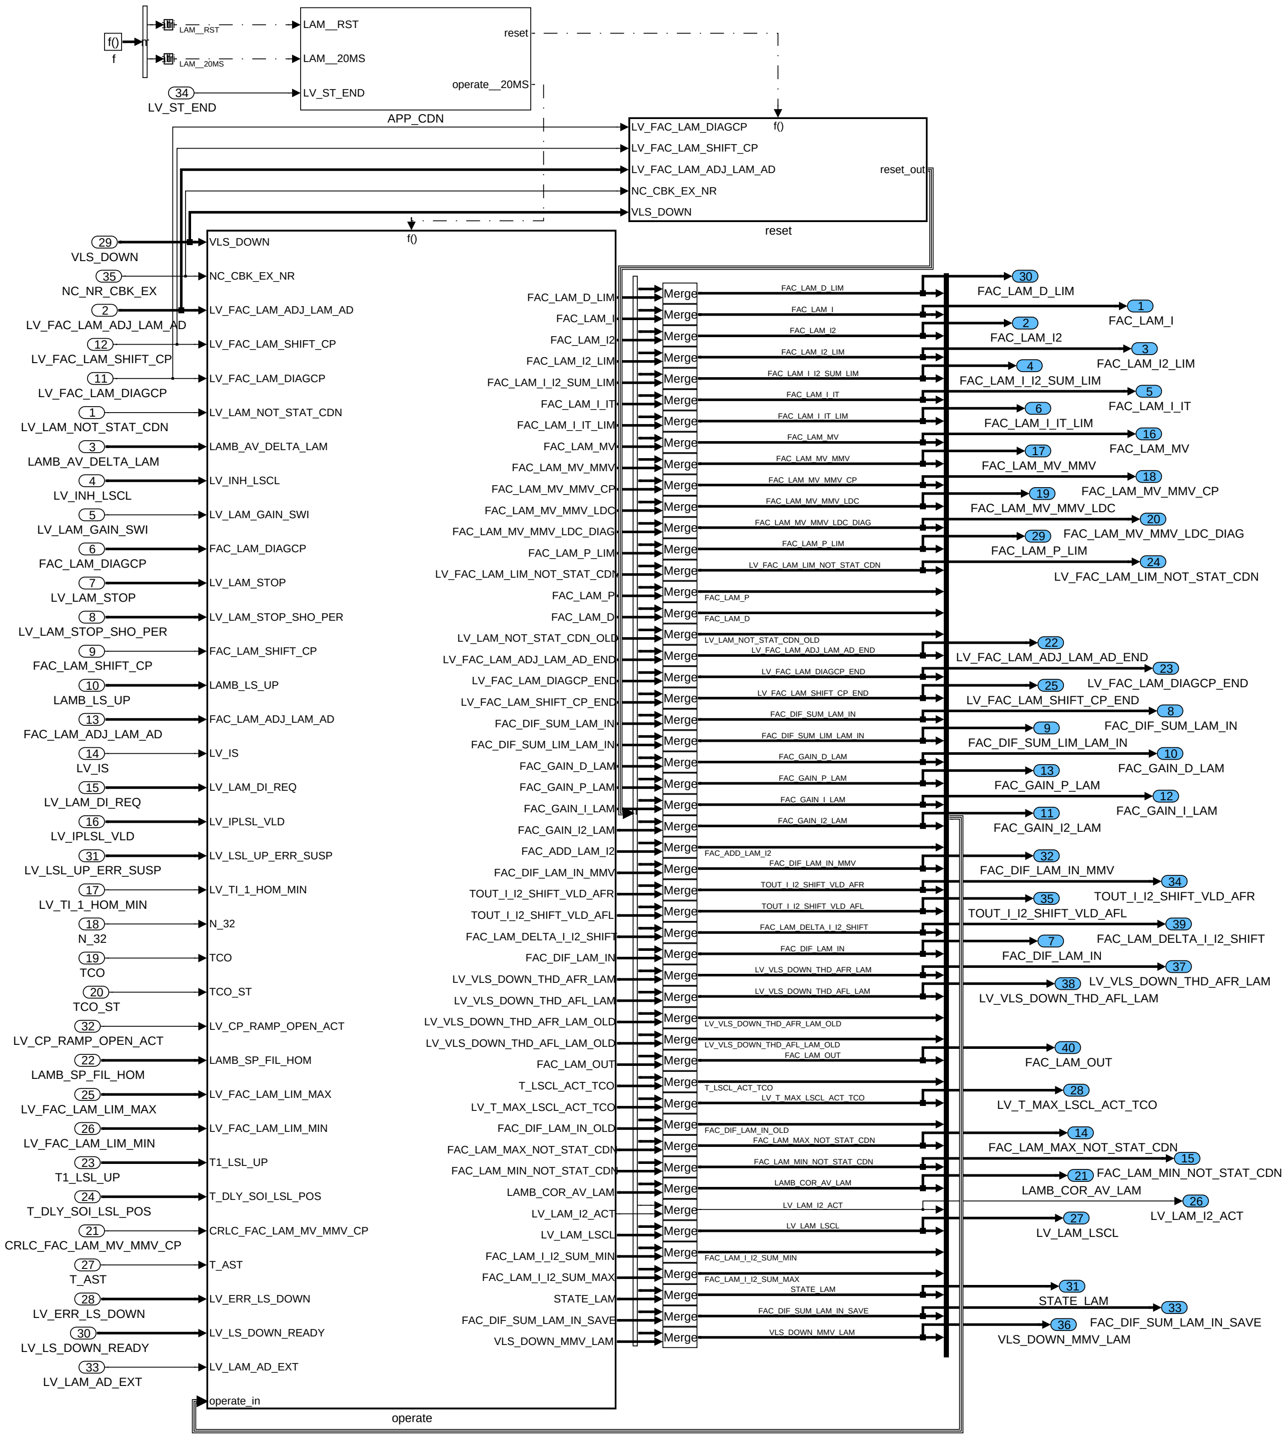

Figure 24 LACO_REQGNLACO0/ LAM

46.5.3.1 Initialization

LAMB_COR_AV_LAM[i] is set to 1.

FAC_LAM_MAX_NOT_STAT_CDN[i] and FAC_LAM_I_I2_SUM_MAX[i] are both set to their physical maximum.

FAC_LAM_MIN_NOT_STAT_CDN[i] and FAC_LAM_I_I2_SUM_MIN[i] are both set to their physical minimum.

LV_LAM_I2_ACT is set to LC_LAM_I2_ACT.

VLS_DOWN_MMV_LAM[i] is set to VLS_DOWN[i].

LV_FAC_LAM_ADJ_LAM_AD_END[i] is set to LV_FAC_LAM_ADJ_LAM_AD[i].

LV_FAC_LAM_SHIFT_CP_END[i] is set to LV_FAC_LAM_SHIFT_CP.

LV_FAC_LAM_DIAGCP_END[i] is set to LV_FAC_LAM_DIAGCP.

All other output variables are set to 0.

46.5.3.2 Formula section

Exhaust bank specific functionality

State machine of lambda controller (STATE_LAM[i])

The state machine of lambda controller distinguishes between 4 different states:

0:OFF

1:ON

2:STOP_SHO_PER

3:STOP

If LV_LAM_LSCL[i] is 0 then state "0:OFF" is applied. Otherwise three different states are to distinguish.

State "1:ON" is applied when the controller is not stopped by the flag LV_LAM_STOP[i]. In that case the controller is in normal operation mode.

If LV_LAM_STOP[i] is set to 1 either state "2:STOP_SHO_PER" or state "3:STOP" is applied depending on LV_LAM_STOP_SHO_PER[i].

If a transition to state "0:OFF" from any other state occurs the variable FAC_LAM_OUT[i] is set to FAC_LAM_I_I2_SUM_LIM[i]. Otherwise FAC_LAM_OUT[i] remains unchanged.

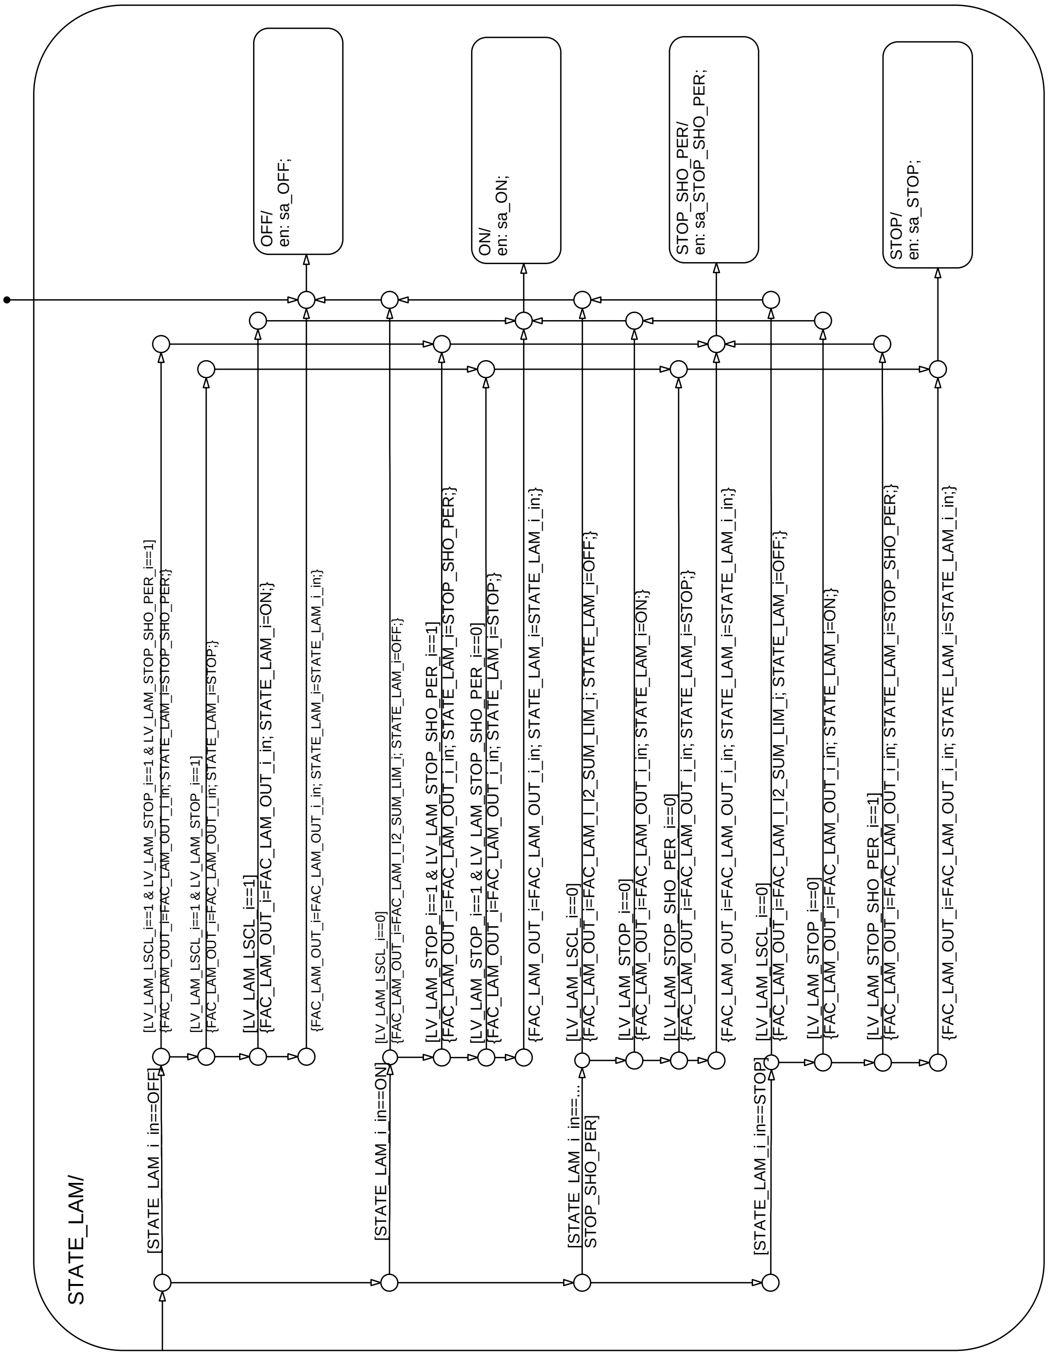

Figure 25 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM

Controller activation / deactivation (LV_LAM_LSCL[i])

Independent of the lambda controller state (STATE_LAM[i]) the evaluation of controller activation / deactivation is calculated.

The controller is activated by the flag LV_LAM_LSCL[i] = 1. This flag is set if the following conditions are fulfilled:

- inhibit flag not set (LV_INH_LSCL[i] = 0)
- no request from OBD function to inhibit lambda controller (LV_LAM_DI_REQ[i] = 0)

- WRAF sensor operability recognised (LV_IPLSL_VLD[i] = 1). In case the operability is removed due to an suspicion of an oxygen sensor error, the Lambda controller shall remain closed loop until the error is confirmed.

- engine speed above threshold (N_32 > C_N_MIN_LAM_LSCL)

- time after start threshold expired (T_AST > ID_T_AST_MIN_LSCL_ACT)

- coolant temperature exceeds threshold
  (in idle speed TCO > ID_TCO_MIN_LAM_LSCL_IS
  otherwise TCO > ID_TCO_MIN_LAM_LSCL)
  or the time ID_T_MAX_LSCL_ACT_TCO is expired

LV_T_MAX_LSCL_ACT_TCO[i] is permanently set to 1 if the controller was activated by the time condition instead of activation by the corresponding TCO condition. Otherwise LV_T_MAX_LSCL_ACT_TCO[i] is set to 0.

If one of the conditions above is not fulfilled the flag LV_LAM_LSCL[i] is set to 0 and the controller is not activated.

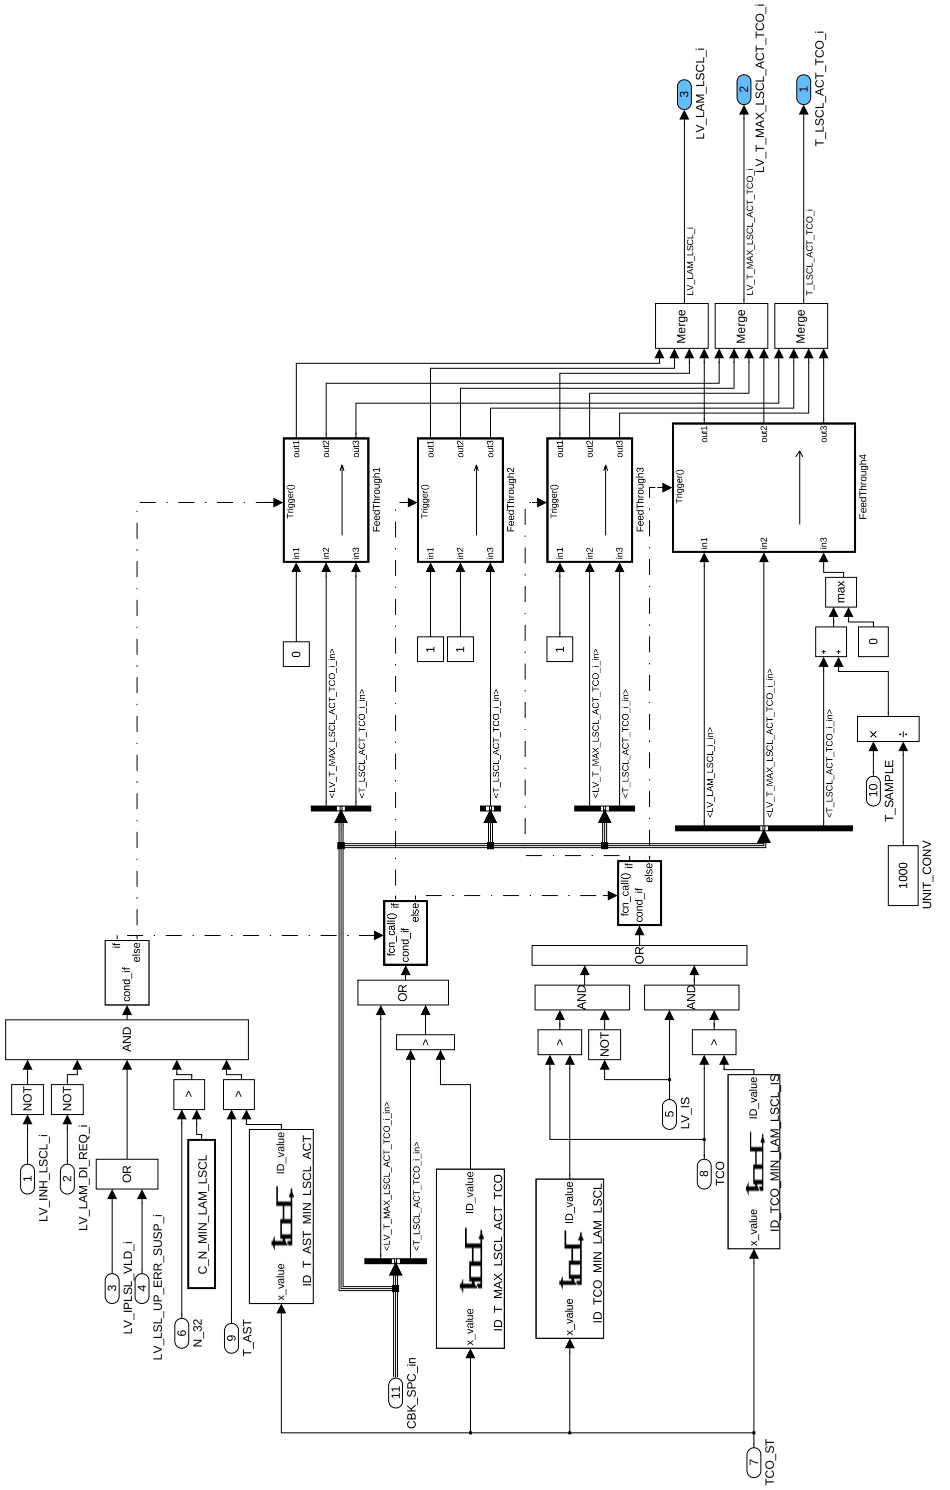

Figure 26 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ ACT_LAM

STATE_LAM: “0:OFF”

FAC_LAM_OUT[i] is set to the current offset (I + I^2 share) when entering this state and then ramped down to zero (for realization see state machine).

Reset of all internal state variables and output values

LV_FAC_LAM_ADJ_LAM_AD_END[i] is set to LV_FAC_LAM_ADJ_LAM_AD[i].

LV_FAC_LAM_SHIFT_CP_END[i] is set to LV_FAC_LAM_SHIFT_CP.

LV_FAC_LAM_DIAGCP_END[i] is set to LV_FAC_LAM_DIAGCP.

Most of all other internal state variables and output values are set to 0 except the ones which are output of the sub-systems described hereafter.

Ramping down of lambda controller output signal (FAC_LAM_OUT[i])

Depending on the sign of the lambda controller output signal FAC_LAM_OUT[i] this latter variable is increased or decreased by C_FAC_LAM_DELTA_LSCL_OFF in order to reach zero (no controller intervention).

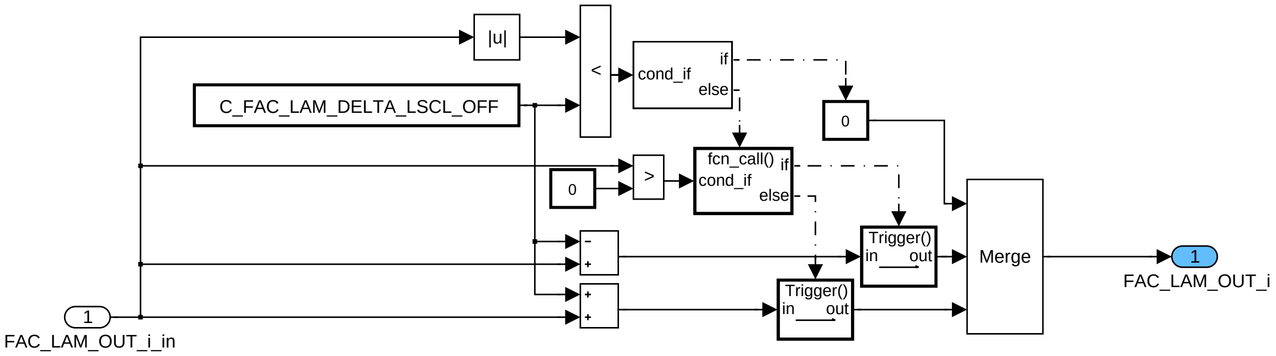

Figure 27 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__OFF/ RAMP_DOWN__FAC_LAM_OUT

Switch between PID or PII2D controller (LV_LAM_I2_ACT)

Depending on LC_LAM_I2_ACT it can be chosen whether I2 share calculation is active (LC_LAM_I2_ACT = 1 -> PII^2D) or not (LC_LAM_I2_ACT = 0 -> PID). This calibration flag is only taken into account in state "OFF".

Figure 28 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__OFF/ SET__LV_LAM_I2_ACT

Calculation of controller difference as richness (FAC_DIF_LAM_IN[i])

The controller difference FAC_DIF_LAM_IN[i] is calculated as difference of the inverted lambda set point

1 / LAMB_SP_FIL_HOM[i]

and the inverted measured lambda signal corrected by the trim control influence

1 / (LAMB_LS_UP[i] + LAMB_AV_DELTA_LAM[i]).

Therefore FAC_DIF_LAM_IN[i] represents a richness. LAMB_AV_DELTA_LAM[i] is assigned in the application incidences.

A moving mean value of the controller difference FAC_DIF_LAM_IN_MMV[i] is calculated in order to realise a shift of I and I^2 share based on downstream signal evaluation. This is described later on.

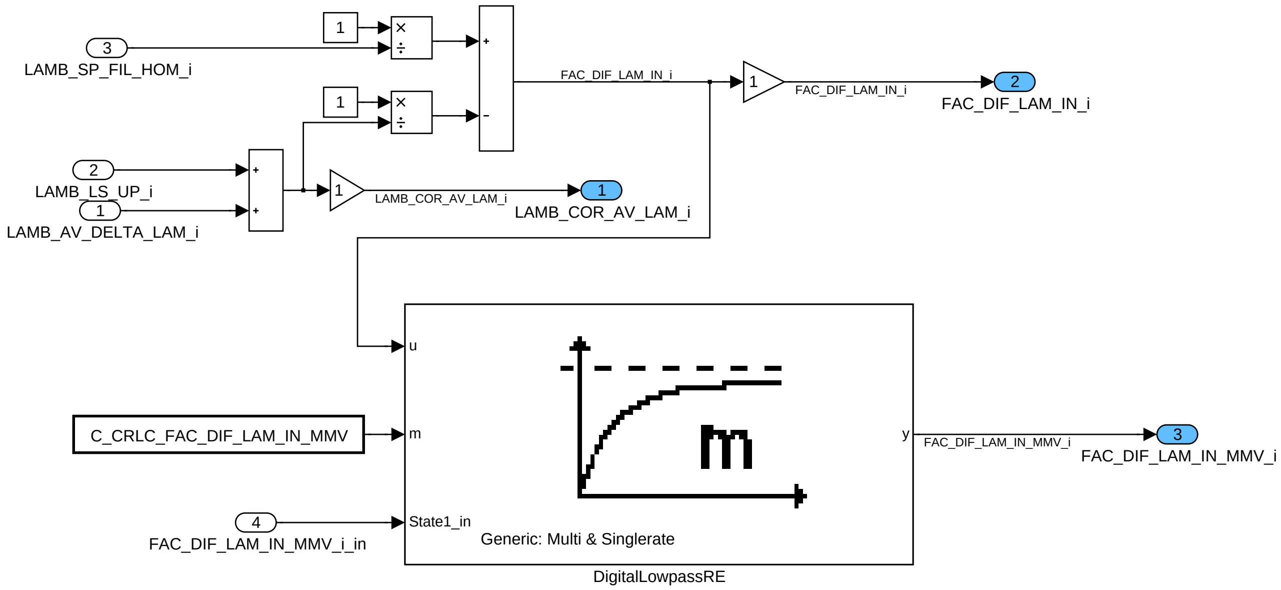

Figure 29 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__OFF/ CLC__FAC_DIF_LAM

Evaluation of downstream sensor voltage (LV_VLS_DOWN_THD_AFL/AFR_LAM[i])

A moving mean value of the downstream sensor signal voltage VLS_DOWN_LAM_MMV[i] is calculated. Based on this moving mean value a lean mixture (100% O_2 loading of the catalyst) or rich mixture (0% O_2 loading of the catalyst) is detected.

The respective flags LV_VLS_DOWN_THD_AFL_LAM[i] or LV_VLS_DOWN_THD_AFR_LAM[i] are set to 1.

The "OLD" flags LV_VLS_DOWN_THD_AFL_LAM_OLD[i] and LV_VLS_DOWN_THD_AFR_LAM_OLD[i] are representing the information of the before mentioned flags one sample step afore. In case of downstream sensor error LV_ERR_DOWN[i] or when the sensor is not operable (LV_LS_DOWN_READY[i] = 0) the "OLD" flags are set to the information of the flags of the current sample step.

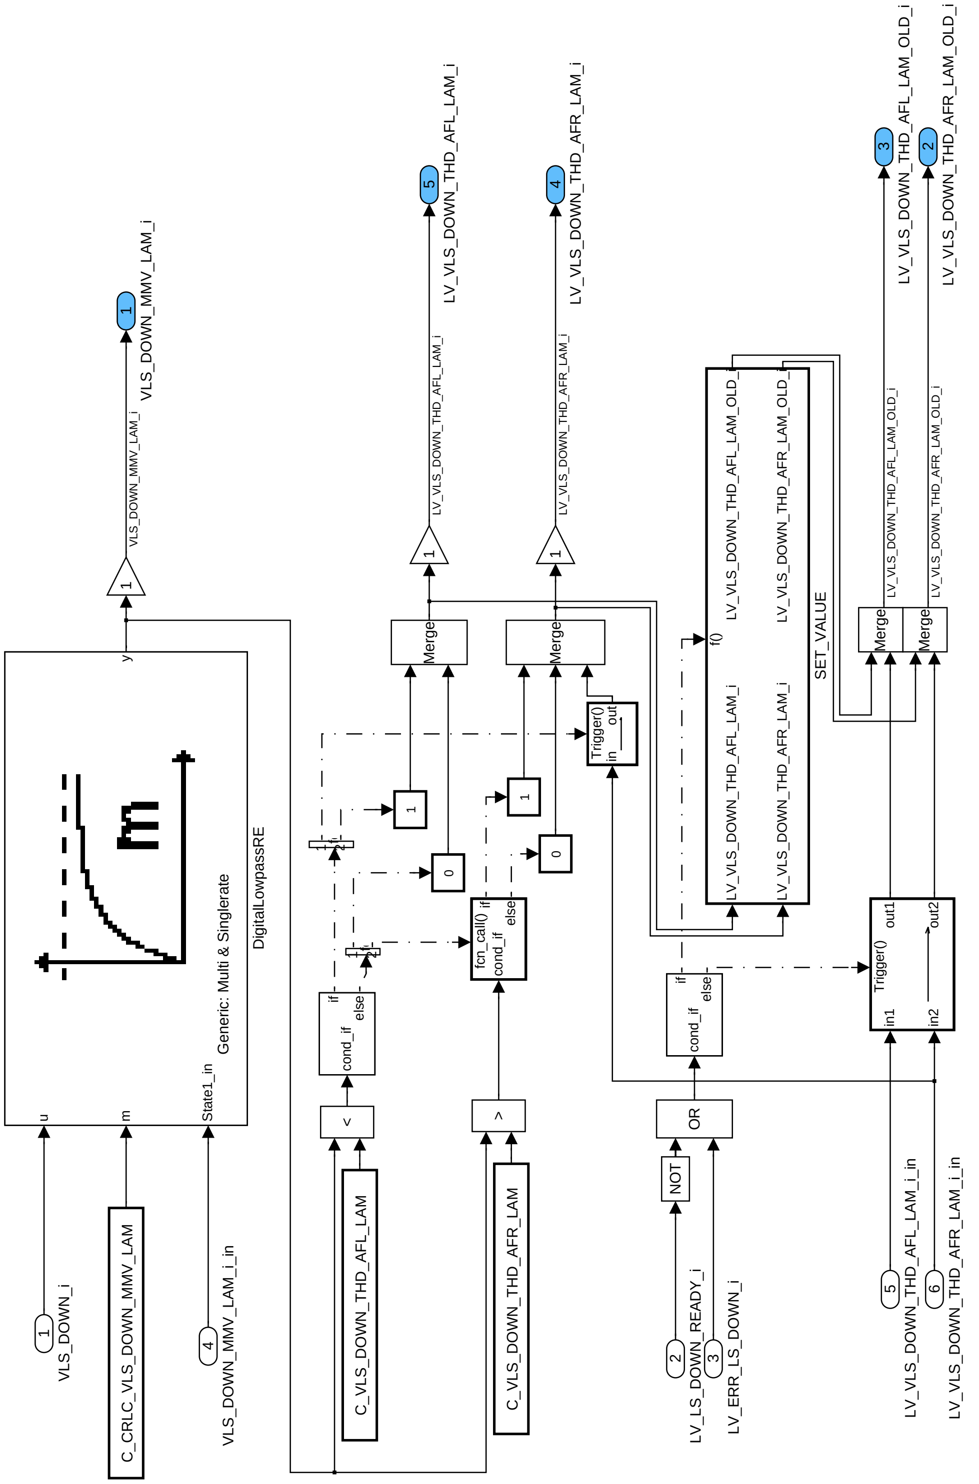

Figure 30 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__OFF/ DET__VLS_DOWN_AFL_AFR

STATE_LAM: "1:ON"

This is the normal operating mode of the lambda controller.

Calculation of controller difference as richness (FAC_DIF_LAM_IN[i])

For details see state "0:OFF".

Evaluation of downstream sensor voltage (LV_VLS_DOWN_THD_AFL/AFR_LAM[i])

For details see state "0:OFF".

Shift and initialization of lambda controller

Output shift of the lambda controller by lambda adaptation

A step change in the output signal of the lambda adaptation requires an inverse step change in the lambda controller output. The control of the output shift takes place in the lambda adaptation function and is indicated by the flags LV_FAC_LAM_ADJ_LAM_AD[i]. The shift of the controller output effects additionally a change of the initial values of the I and I^2 share and in the moving mean values of the lambda controller output.

In case the flag LV_LAM_AD_EXT is set this shift is suppressed.

The lambda controller is shifted if the condition LV_FAC_LAM_ADJ_LAM_AD[i] = 1 is valid. This variable is to be reset if the lambda controller shift was carried out. That requires a confirmation of the executed controller shift. The confirmation is done by setting the variable LV_FAC_LAM_ADJ_LAM_AD_END[i] to 1.

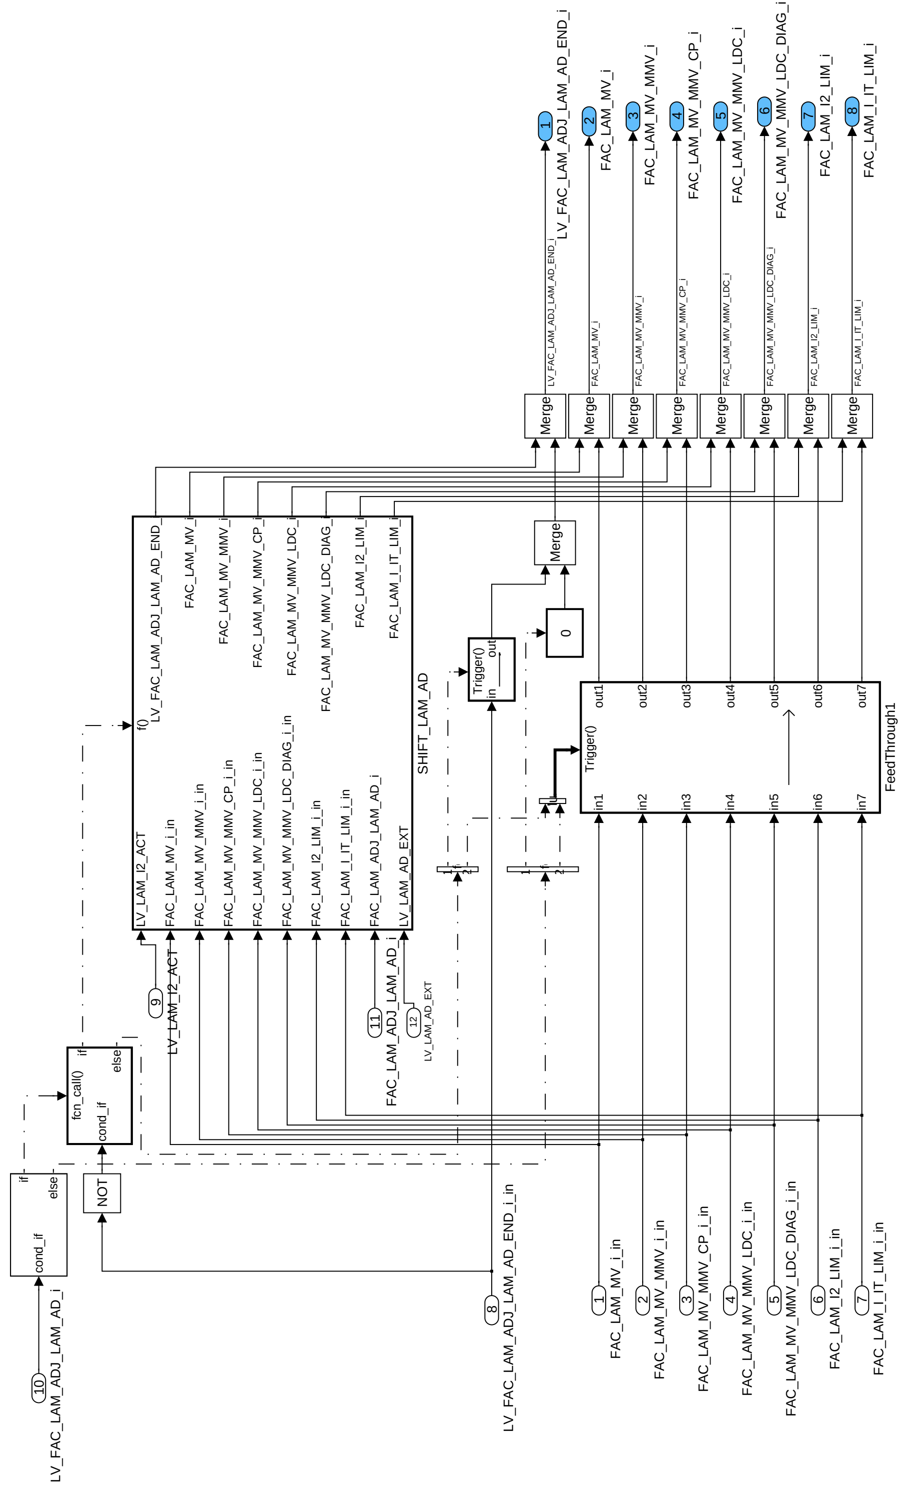

Figure 31 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__FAC_LAM__SHIFT/ MNG__SHIFT_LAM_AD

Execution of shift (SHIFT_LAM_AD)

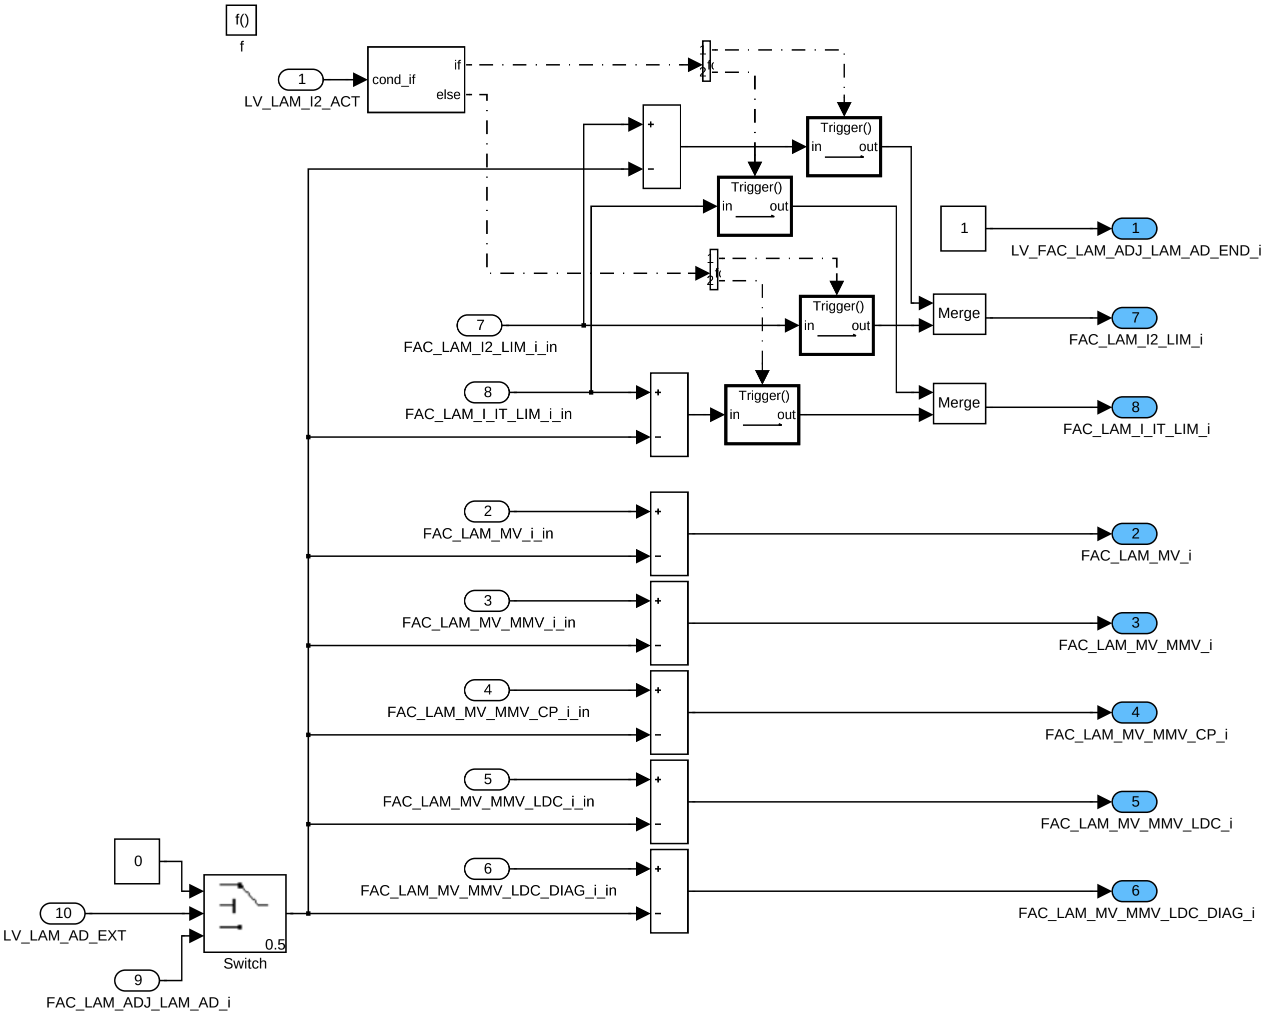

Figure 32 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__FAC_LAM__SHIFT/ MNG__SHIFT_LAM_AD/ SHIFT_LAM_AD

Output shift of lambda controller by canister purge function

A step change in the output signal of the canister purge function requires an stepped change in the lambda controller output. The control of the output shift takes place in the corresponding function and is indicated by the flag LV_FAC_LAM_SHIFT_CP. The shift of the controller output effects additionally a change of the initial values of the I and I^2 share and in the moving mean values of the lambda controller output.

If LV_FAC_LAM_SHIFT_CP is set to 1 the output shift must be carried out for both banks. This variable is to be reset if the lambda controller shift was carried out. That requires a confirmation of the executed controller shift. The confirmation is done by setting the variable LV_FAC_LAM_SHIFT_CP_END[i] to 1.

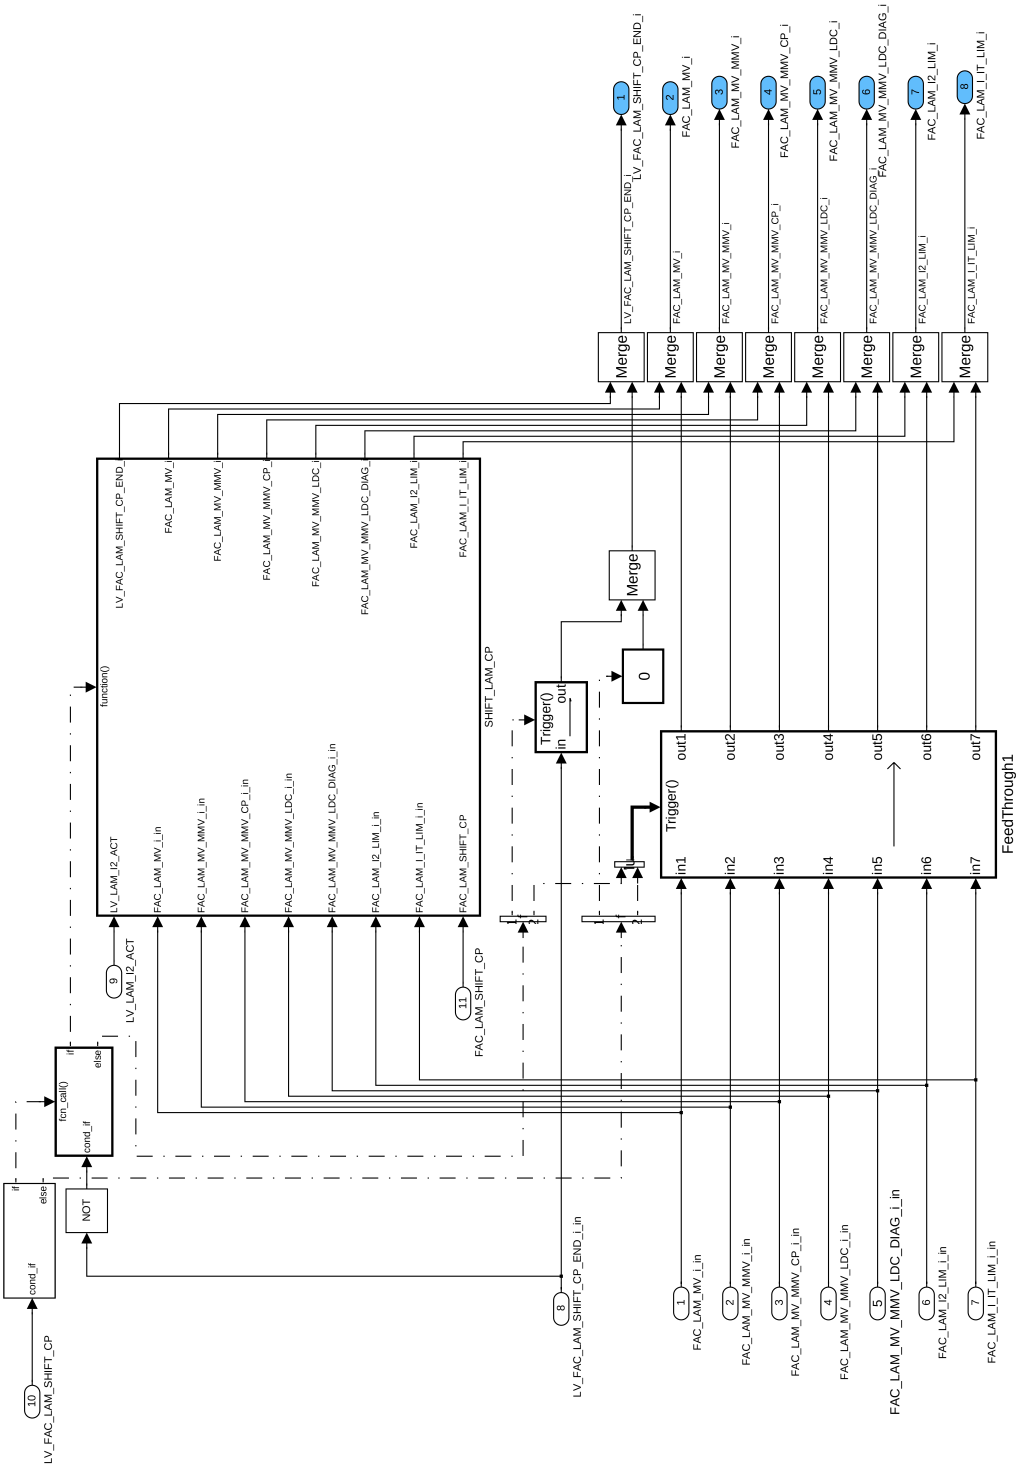

Figure 33 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__FAC_LAM__SHIFT/ MNG__SHIFT_LAM_CP

Execution of shift (SHIFT_LAM_CP)

Output initialization of lambda controller by evaporative system monitoring function

The EVAP system monitoring function can require an initialization of the lambda controller output. The control of the output initialization takes place in the corresponding function and is indicated by the flag LV_FAC_LAM_DIAGCP. The initialization of the controller output effects additionally a change of the initial values of I and I^2 share and in the moving mean values of the lambda controller output.

If LV_FAC_LAM_DIAGCP is set to 1 the output initialization is carried out for both banks. This variable is to be reset if the lambda controller initialization was carried out. That requires a confirmation of the executed initialization. The confirmation is done by setting the variable LV_FAC_LAM_DIAGCP_END[i] to 1.

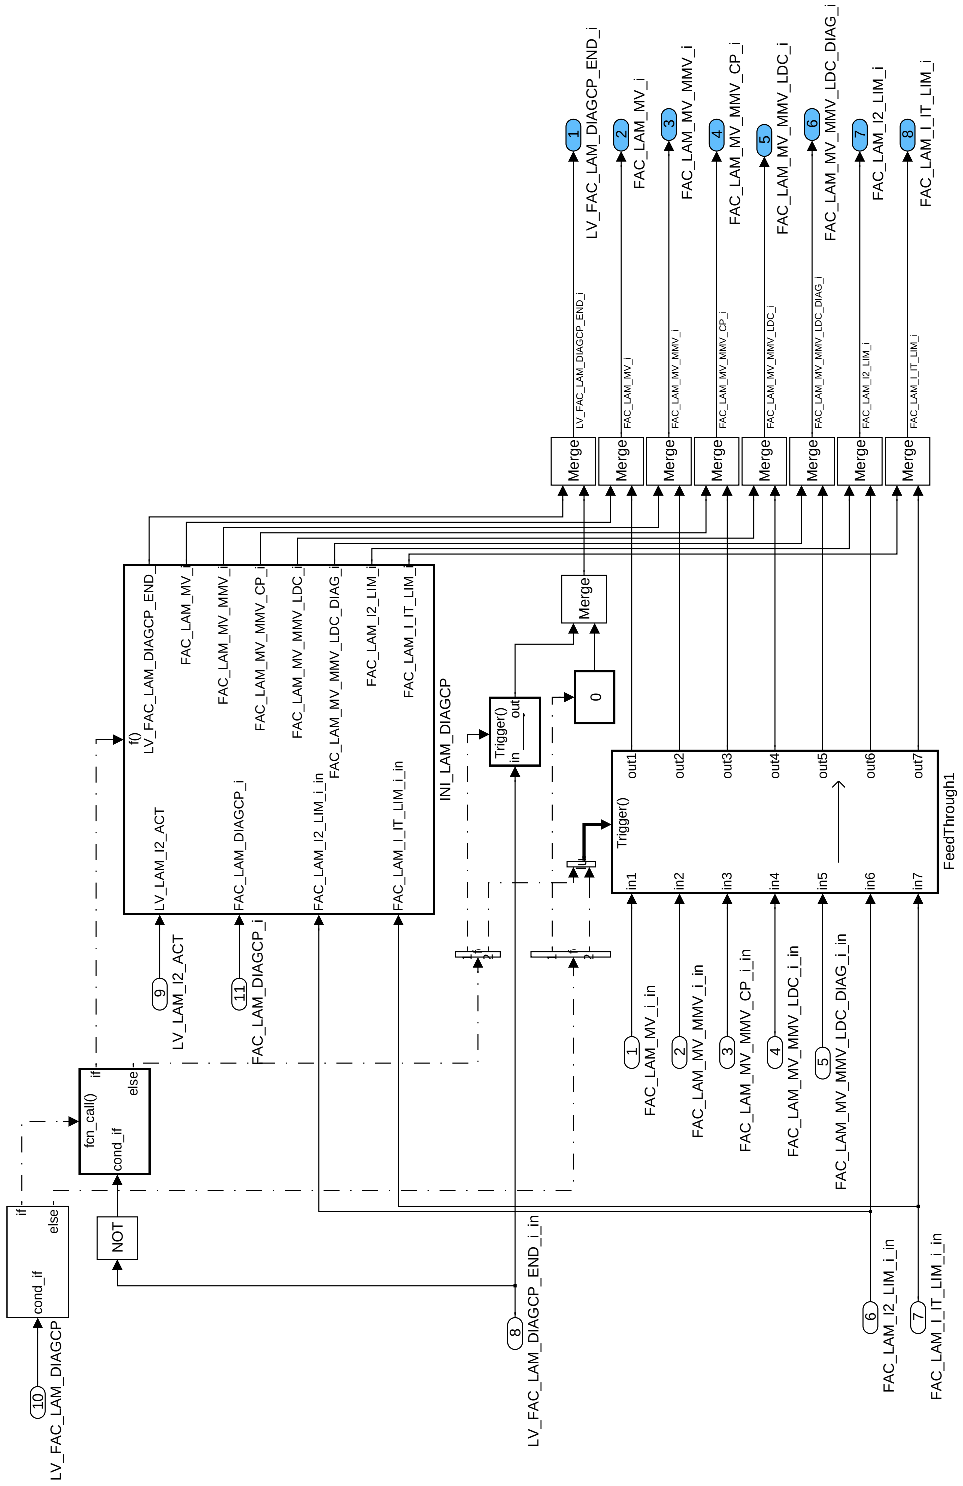

Figure 35 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__FAC_LAM__SHIFT/ MNG__INI_LAM_DIAGCP

Execution of initialization (INI_LAM_DIAGCP)

Determination of controller parameters (FAC_GAIN_P/I/I2/D_LAM[i])

Switching of controller parameters depending on specific engine operating states e.g. idle speed (to be defined in the application incidences) is controlled by the value of LV_LAM_GAIN_SWI. If this flag is set to 1 a special parameter set is applied.

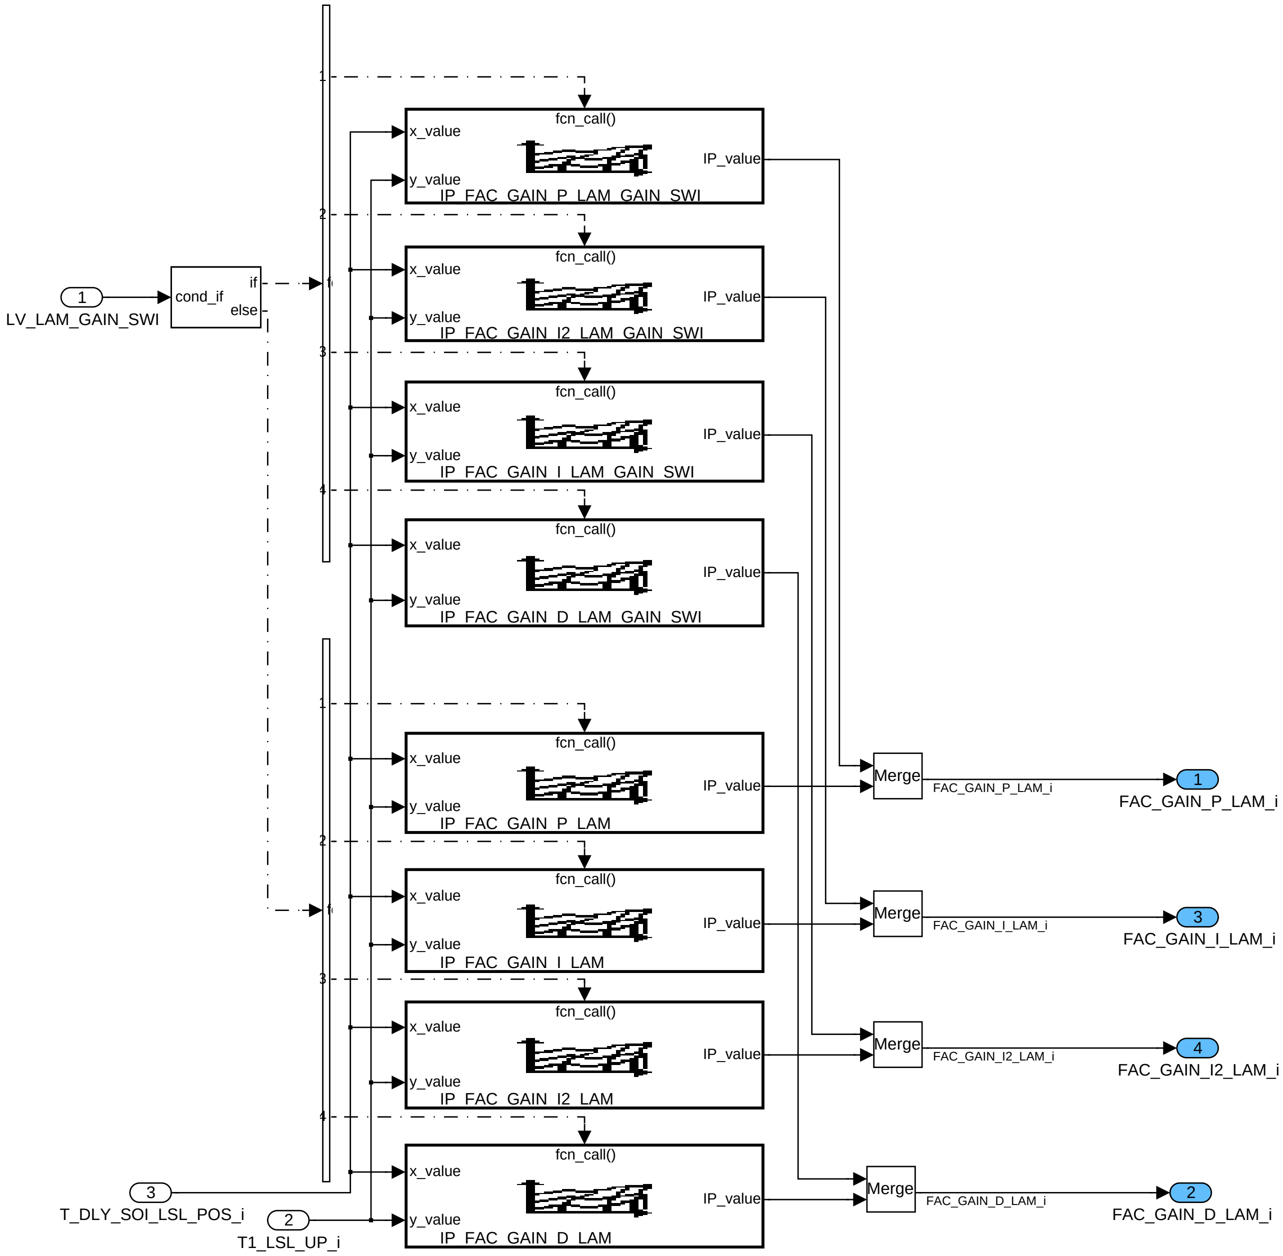

Figure 37 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ DET__CTL_GAIN

P share calculation (FAC_LAM_P_LIM[i])

The P share is calculated by multiplying the controller difference FAC_DIF_LAM_IN[i] with the P share gain FAC_GAIN_P_LAM[i]. Then limitation depending on active ramp open of canister purge is applied. The limited P share is given by the variable FAC_LAM_P_LIM[i].

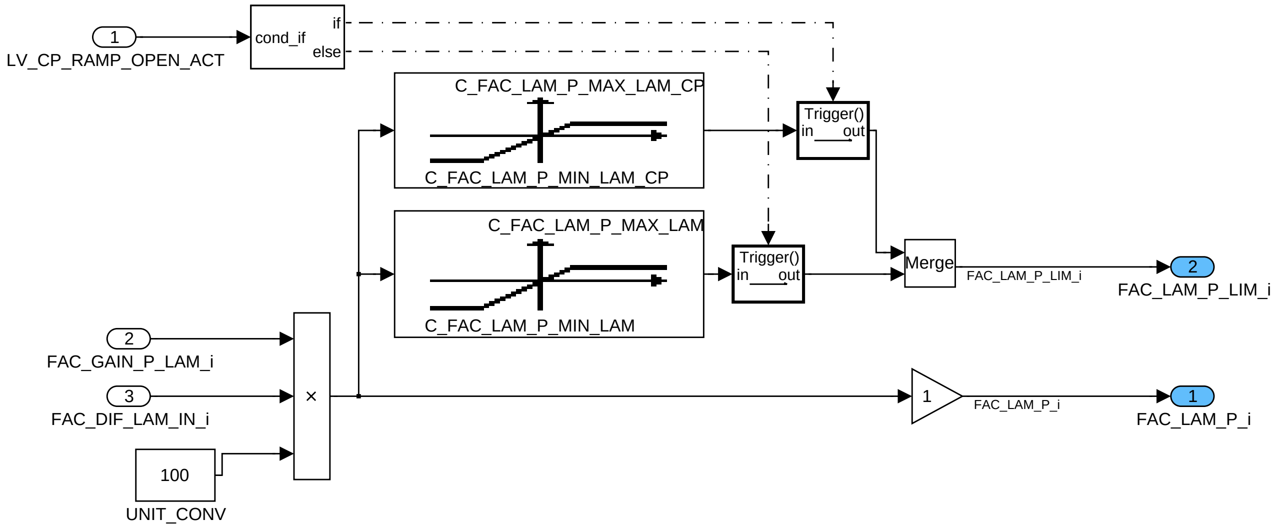

Figure 38 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ CLC__FAC_LAM_P

I share calculation

Depending on the flag LV_LAM_I2_ACT the lambda controller is calculated as PII^{2}D controller or PID controller.

I shares calculation with active I2 share

Summation of controller differences; only with active I2 share calculation (FAC_DIF_SUM_LAM_IN[i])

The controller differences FAC_DIF_LAM_IN[i] are summed up with the variable FAC_DIF_LAM_IN[i]. The summation is not applied in case of:

- controller limitation on positive side (LV_FAC_LAM_LIM_MAX[i] = 1) and positive FAC_DIF_LAM_IN[i],
- controller limitation on negative side (LV_FAC_LAM_LIM_MIN[i] = 1) and negative FAC_DIF_LAM_IN[i] or
- injected fuel mass is at its minimum value (LV_TI_1_HOM_MIN = 1) and negative FAC_DIF_LAM_IN[i].

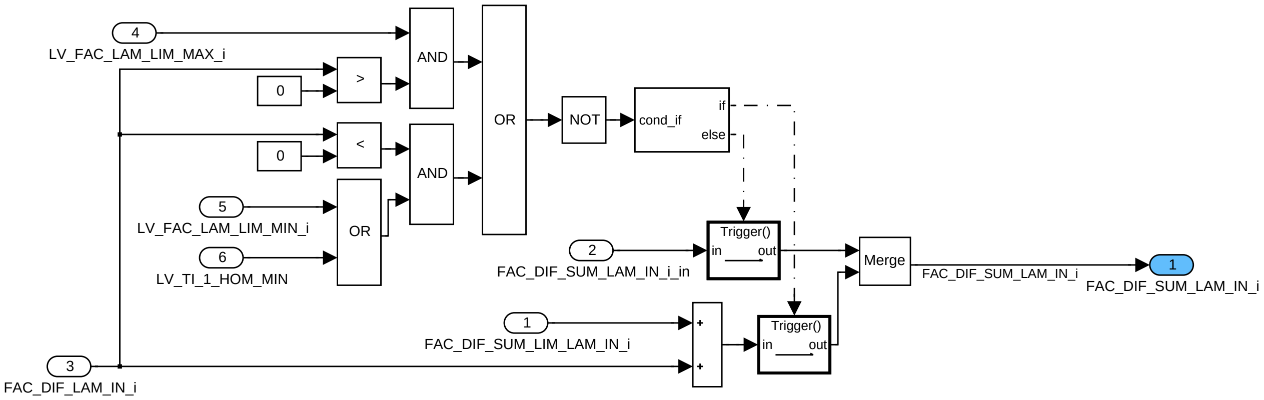

Figure 39 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_DIF_SUM_LAM_IN

Determination of I and I2 share shift based on downstream signal evaluation (only with active I2 share)

By means of the lambda controller I^2 share an oxygen balancing for the catalyst is applied. This balancing is only valid if the oxygen storage capacity (OSC) of the catalyst is between 0 and 100%. By observing the downstream signal these conditions can be evaluated. When catalyst OSC reaches its limits the integration of the control differences should be stopped. In order to influence the control behavior as less as possible the control differences sum is stored when OSC reaches the limits and applied later on when the disturbance is rejected. As this "manipulation" of the control differences sum leads to a shift of the I share the I^2 share is shifted by the same amount in the opposite direction. So the controller output is neutral.

Shift due to lean mixture detection (FAC_LAM_DELTA_I_I2_SHIFT[i])

In case of rising edge of LV_VLS_DOWN_THD_AFL_LAM[i] (OSC reaches 100%) the summarized controller differences FAC_DIF_SUM_LAM_IN[i] are stored in the variable FAC_DIF_SUM_LAM_IN_SAVE[i]. Furthermore the time out counter TOUT_I_I2_SHIFT_VLD_AFL[i] is initialized by the calibration value C_TOUT_I_I2_SHIFT_VLD.

If the controller compensates a disturbance (when FAC_DIF_LAM_IN_MMV[i] becomes 0) before the timer reaches zero, both, I share and I^2 share are shifted in opposite directions by the same amount. The shift of the I share is realized by setting the summarized controller differences to the saved value. The amount of the shift for the I^2 share FAC_LAM_DELTA_I_I2_SHIFT[i] is calculated from the difference between saved value and current summarized controller differences (of course before setting this latter variable to the saved value) multiplied with the I share gain and the sample time. The shift of the I^2 share itself is realized where the I^2 share is calculated by adding always FAC_LAM_DELTA_I_I2_SHIFT[i] which normally is 0 when no shift should be applied.

When the timer TOUT_I_I2_SHIFT_VLD_AFL[i] reaches 0 before the disturbance is compensated no shift is applied anymore because a later zero crossing of FAC_DIF_LAM_IN_MMV[i] cannot be surely assigned to the disturbance.

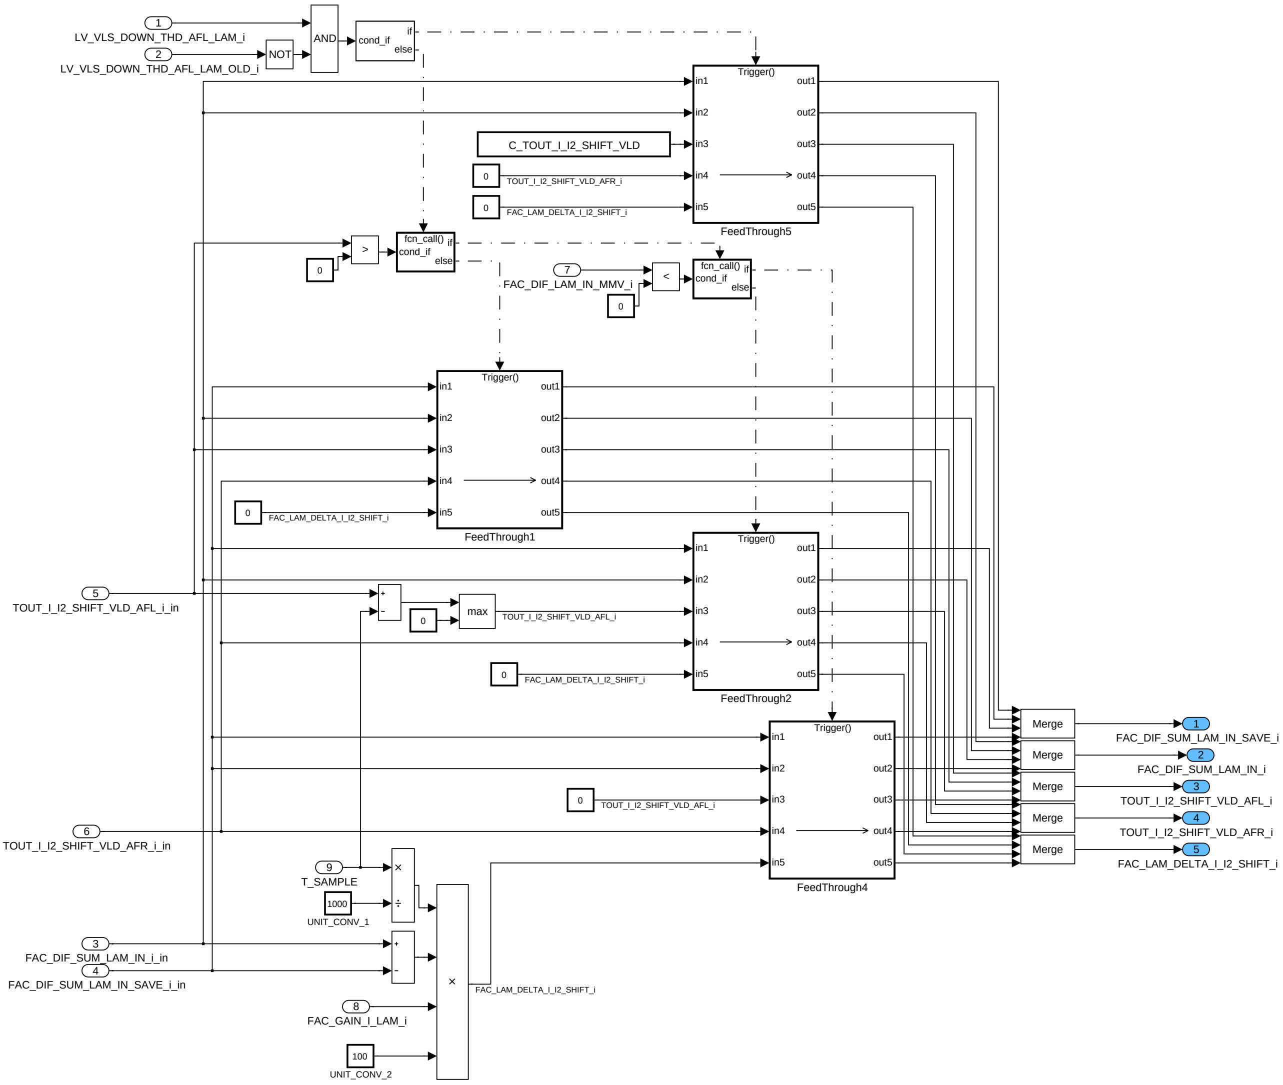

Figure 40 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ DET__FAC_LAM_I_FAC_LAM_I2_SHIFT/ FAC_LAM_I_FAC_LAM_I2_SHIFT_AFL

Shift due to rich mixture detection (FAC_LAM_DELTA_I_I2_SHIFT[i])

The realization for the opposite case (OSC reaches 0% abd rich mixture detection) is exactly the same as for the shift due to lean mixture detection. The summarized controller differences are stored in case of rising edge of LV_VLS_DOWN_THD_AFR_LAM[i] and the timer TOUT_I_I2_SHIFT_VLD_AFR[i] is used instead. The resulting shift of I and I^2 share is inverted.

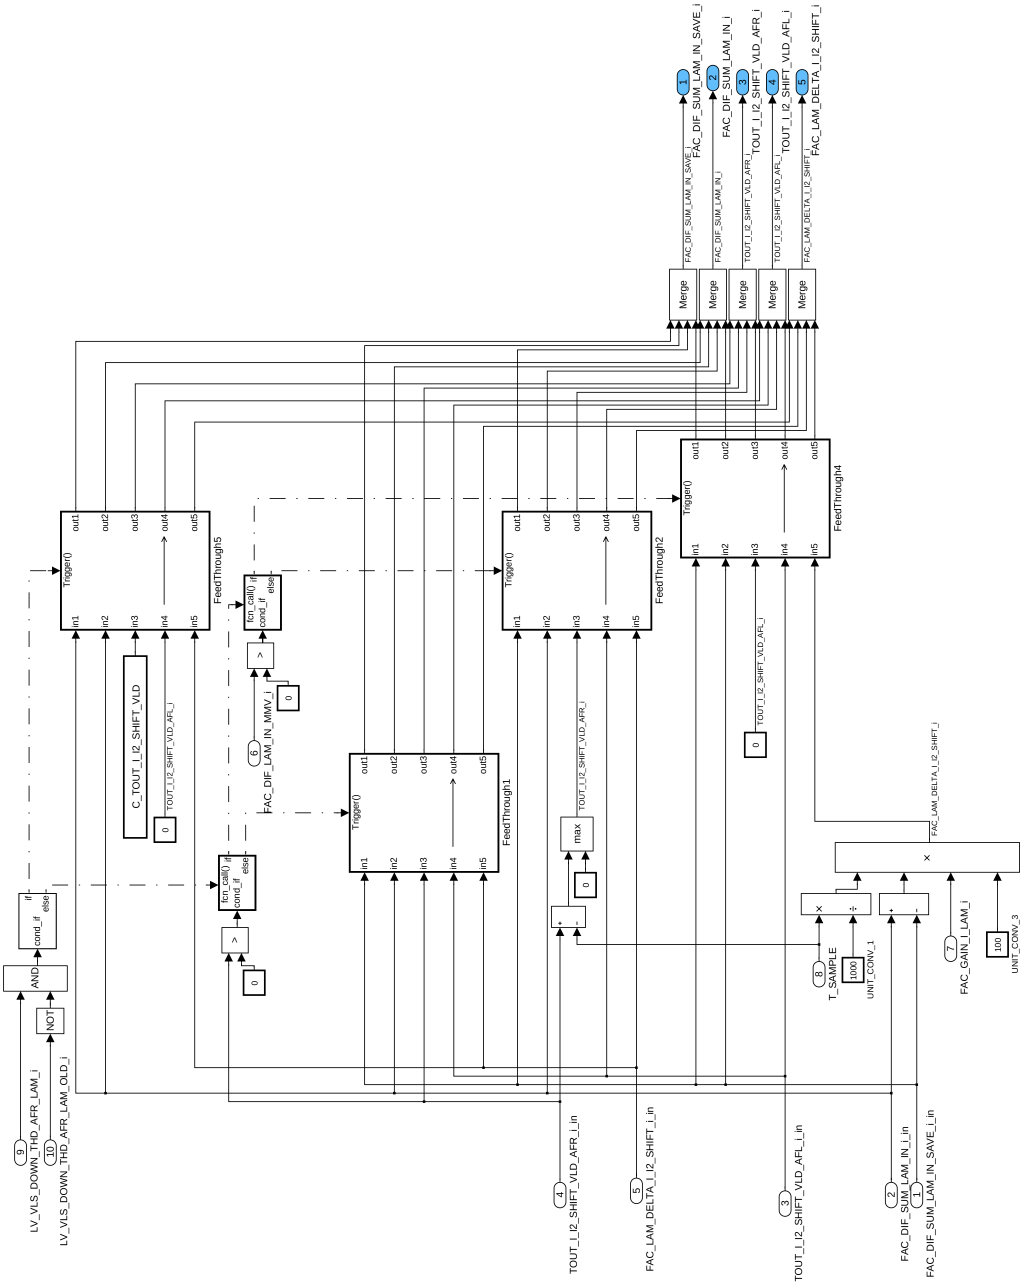

Figure 41 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ DET__FAC_LAM_I_FAC_LAM_I2_SHIFT/ FAC_LAM_I_FAC_LAM_I2_SHIFT_AFR

<u>I share calculation and anti wind up limitation (only with active I2 share calculation)</u>

The I share FAC_LAM_I[i] is calculated by multiplying the summarized controller differences with the I share gain and with the sample time. If FAC_LAM_I[i] reaches its physical limits it will be automatically limited but the summarized controller differences must be adapted to this limitation (anti wind up limitation).

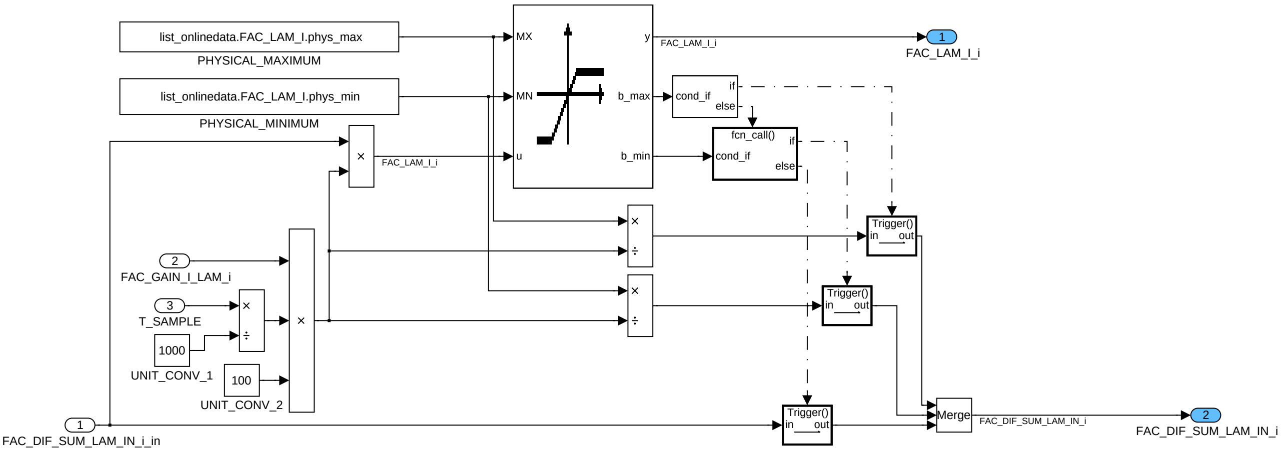

Figure 42 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ LIM__FAC_DIF_SUM_LAM_IN

I2 share calculation (FAC_LAM_I2[i])

The I^2 share calculation is not executed in case of:

- controller limitation on positive side (LV_FAC_LAM_LIM_MAX[i] = 1) and positive FAC_DIF_SUM_LAM_IN[i],
- controller limitation on negative side (LV_FAC_LAM_LIM_MIN[i] = 1) and negative FAC_DIF_SUM_LAM_IN[i] or
- injected fuel mass is at its minimum value (LV_TI_1_HOM_MIN = 1) and negative FAC_DIF_SUM_LAM_IN[i].

FAC_LAM_I2[i] remain unchanged in that case. Otherwise the calculation is active.

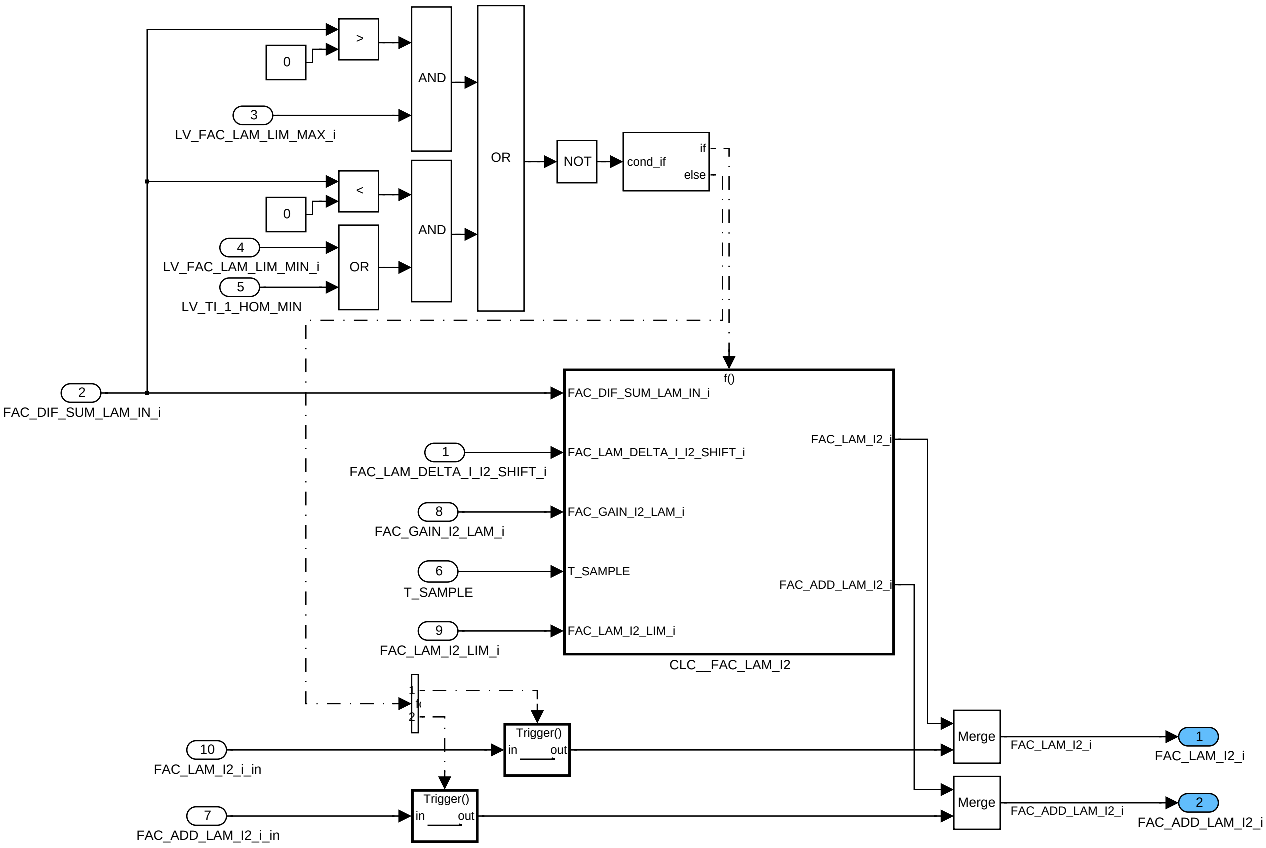

Figure 43 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ MNG__CLC__FAC_LAM_I2

Calculation of FAC_LAM_I2[i]

FAC_LAM_I2[i] is calculated by integrating the summarized controller differences FAC_DIF_SUM_LAM_IN[i] using the gain for the I^2 share FAC_GAIN_I2_LAM[i]. The sample time is considered twice (T_SAMPLE^2) as for the summarized controller differences no sample time was considered yet.

If FAC_DIF_SUM_LAM_IN[i] is not equal to 0 but the numerical result for FAC_ADD_LAM_I2[i] is 0 the resolution of this variable is added or subtracted depending on the sign of FAC_DIF_SUM_LAM_IN[i]. This prevents the I^2 share from being stopped although FAC_DIF_SUM_LAM_IN[i] is not 0 and is only needed because of fixed point arithmetic realization. FAC_ADD_LAM_I2[i] represents the amount that is added each sample step to the I^2 share. Furthermore a shift (if FAC_LAM_DELTA_I_I2_SHIFT[i] is not 0) is applied.

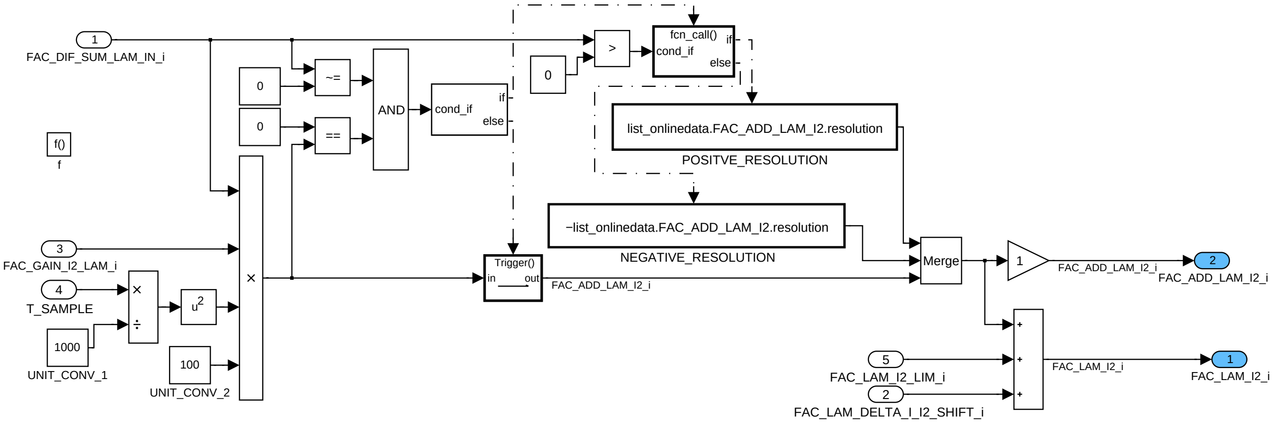

Figure 44 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I__FAC_LAM_I2/ MNG__CLC__FAC_LAM_I2/ CLC__FAC_LAM_I2

<u>I share calculation without active I2 share (FAC_LAM_I[i])</u>

The I share is not calculated in case of:

- controller limitation on positive side (LV_FAC_LAM_LIM_MAX[i] = 1) and positive FAC_DIF_LAM_IN[i],
- controller limitation on negative side (LV_FAC_LAM_LIM_MIN[i] = 1) and negative FAC_DIF_LAM_IN[i] or
- injected fuel mass is at its minimum value (LV_TI_1_HOM_MIN = 1) and negative FAC_DIF_LAM_IN[i].

Otherwise FAC_LAM_I[i] is calculated.

The I^2 share FAC_LAM_I2[i] is always set to 0.

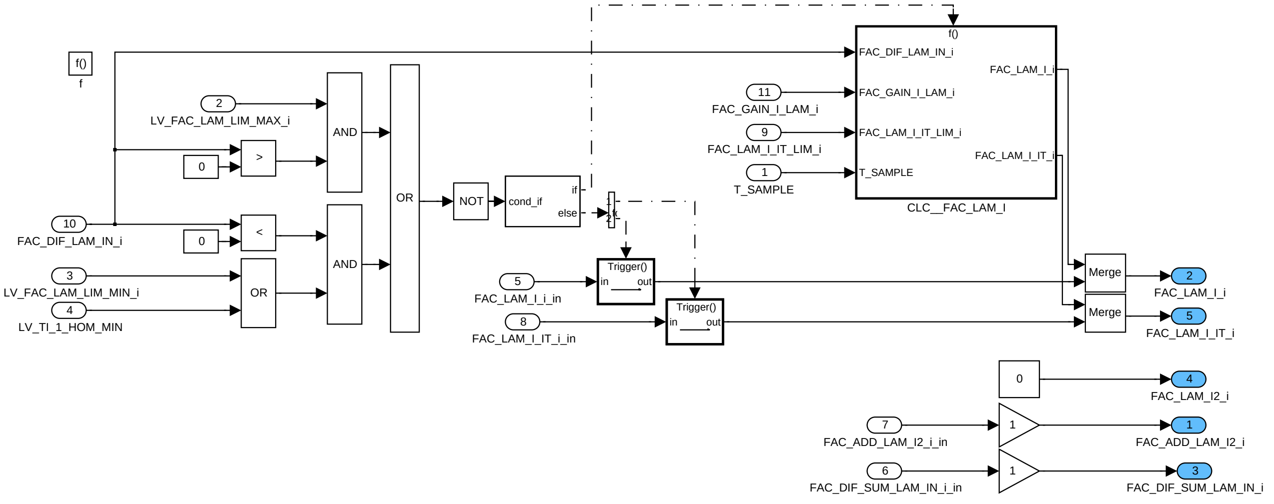

Figure 45 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I_WOUT_I2

<u>Calculation of FAC_LAM_I[i]</u>

The I share is calculated with an internal variable FAC_LAM_I_IT[i] that has a higher resolution. FAC_LAM_I[i] is calculated by rounding FAC_LAM_I_IT[i] off to the resolution of FAC_LAM_I[i].

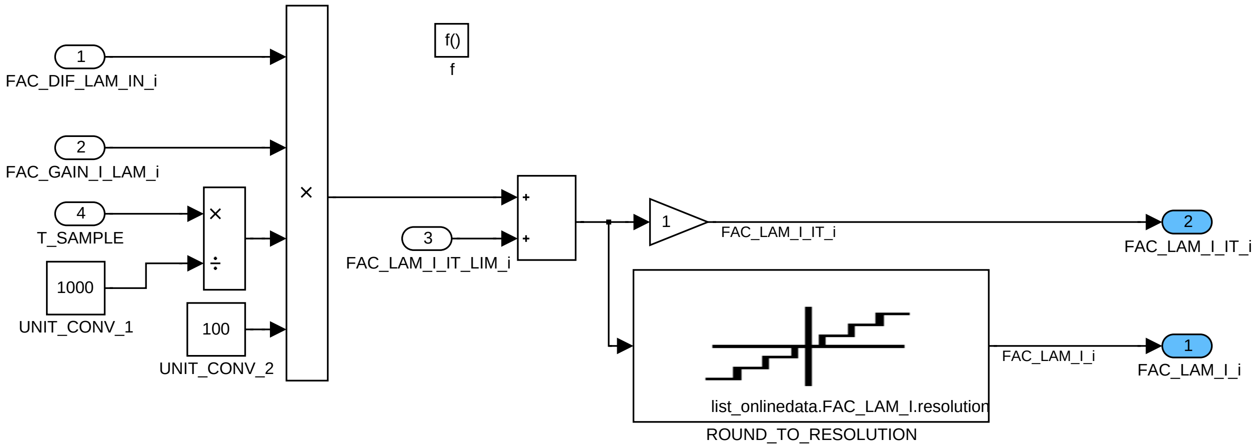

Figure 46 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ CLC__FAC_LAM_I_WOUT_I2/ CLC__FAC_LAM_I

Summation and limitation of I and I2 share (FAC_LAM_I_I2_SUM_LIM[i])

The I share and I^2 share are summarised in the variable FAC_LAM_I_I2_SUM_LIM[i]. Furthermore the sum of both can be limited (during canister purge ramp open with different thresholds).

In case of limitation 2 cases must be distinguished:

1. LV_LAM_I2_ACT = 1:

-> FAC_DIF_SUM_LIM_LAM_IN[i] = 0

-> FAC_LAM_I2_LIM[i] = FAC_LAM_I_I2_SUM_LIM[i]

2. LV_LAM_I2_ACT = 0:

-> FAC_LAM_I_IT_LIM_LIM[i] = FAC_LAM_I_I2_SUM_LIM[i]

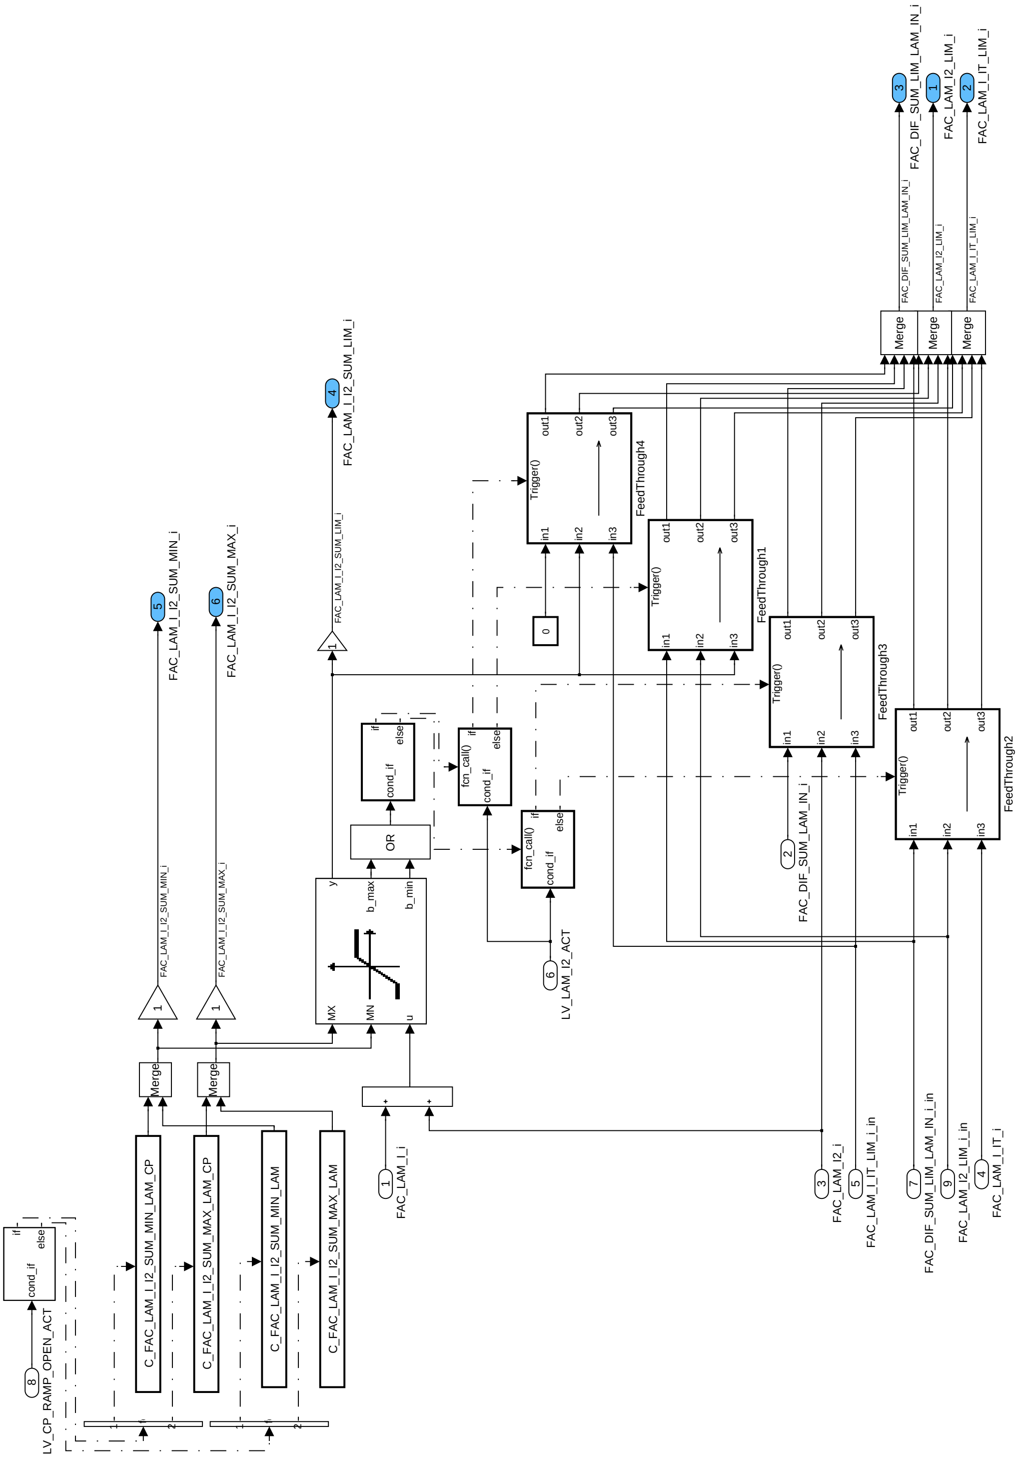

Figure 47 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__CLC__FAC_LAM_I__FAC_LAM_I2/ SUM__FAC_LAM_I__FAC_LAM_I2

D share calculation (FAC_LAM_D_LIM[i])

The D share is calculated by dividing the difference of FAC_DIF_LAM_IN[i]$_N$ and FAC_DIF_LAM_IN[i]$_{N-1}$ by T_SAMPLE and multiplying the result with the gain for the D share (FAC_GAIN_D_LAM[i]). Then limitation is applied and the limited D share is stored in the variable FAC_LAM_D_LIM[i].

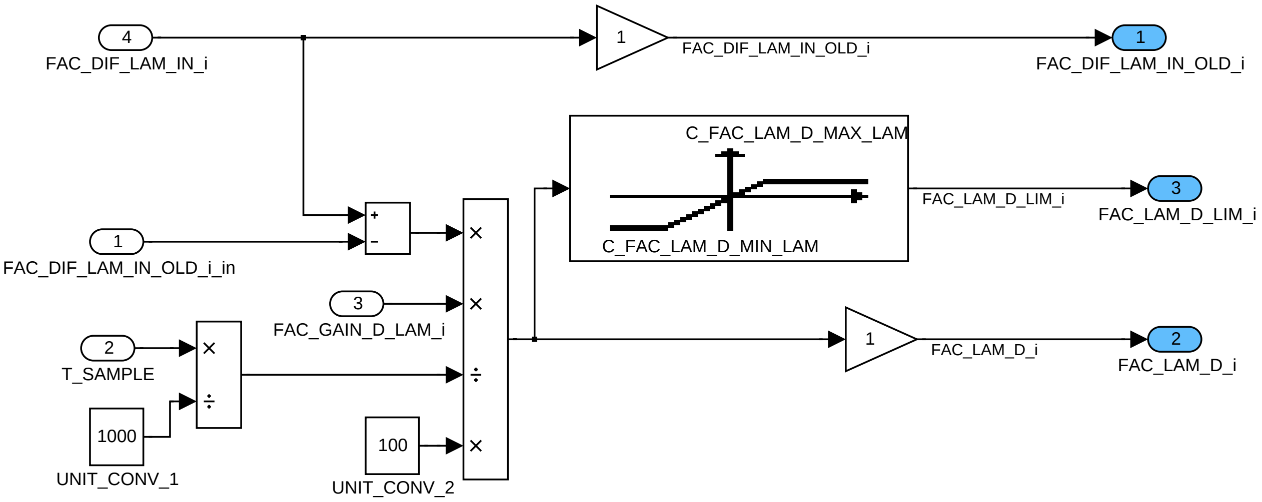

Figure 48 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ CLC__FAC_LAM_D

Calculation of controller output signal (FAC_LAM_OUT[i])

The limited sum output of the I and I^2 share FAC_LAM_I_I2_SUM_LIM[i] together with the limited P and D share (FAC_LAM_P_LIM[i] and FAC_LAM_D_LIM[i]) are summarised in the variable FAC_LAM_OUT[i].

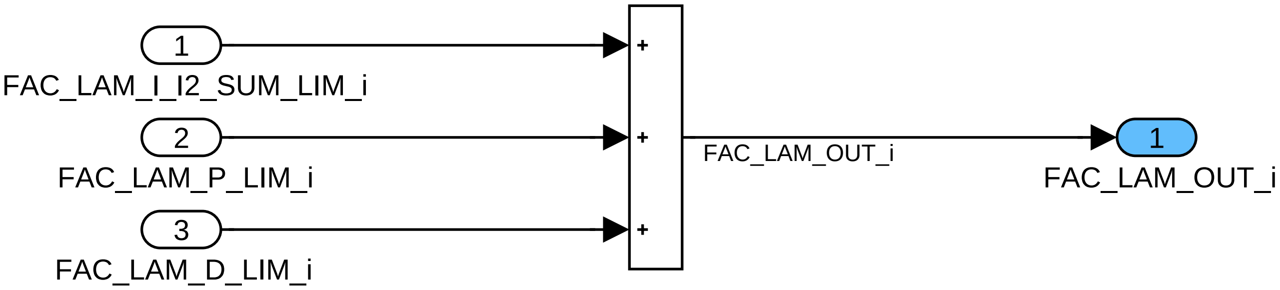

Figure 49 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ CLC__FAC_LAM_OUT

Calculation of moving mean values (FAC_LAM_MV[i] et al.)

For other functions like lambda adaptation, catalyst efficiency diagnosis and canister purge moving mean values of the remaining controller offset need to be calculated.

First FAC_LAM_MV[i] is calculated as filtered I (+I^2) share FAC_LAM_I_I2_SUM_LIM. Then FAC_LAM_MV[i] is input to all other moving mean value calculations.

The moving mean values can be shifted, initialized or limited by other functionalities as described before in "shift and initialization of lambda controller" and afterwards in "limitation under non stationary conditions".

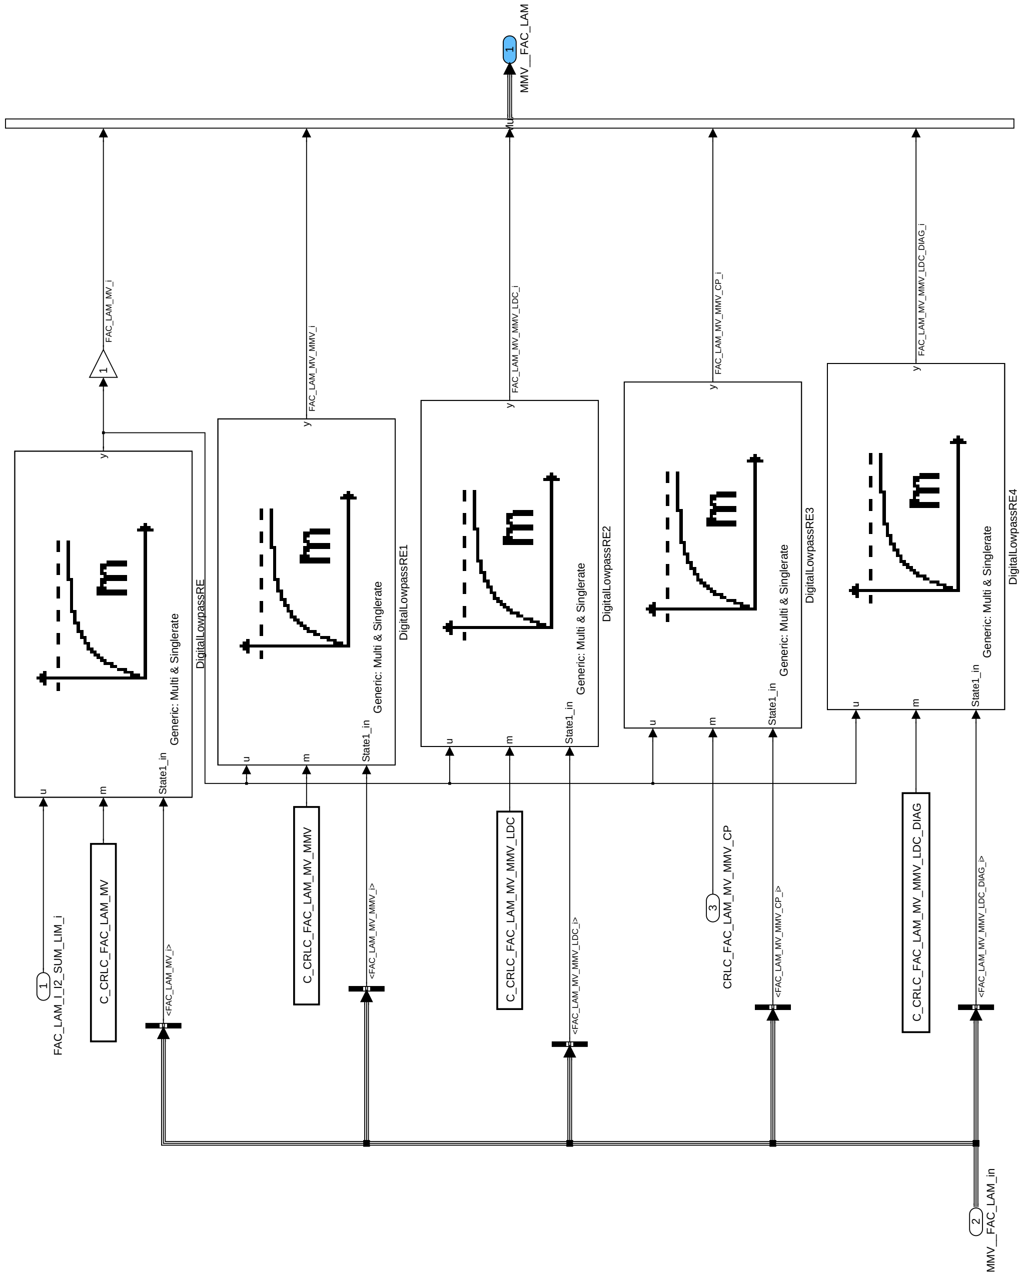

Figure 50 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ CLC__FAC_LAM_MV

<u>Limitation under non stationary conditions</u>

Under non stationary operating conditions (LV_LAM_NOT_STAT_CDN is set to 1), the value of the controller output shall be kept inside a tolerable area. In case of exceeding the calibrated threshold the lambda controller output FAC_LAM_OUT[i] must be limited and the initial values for integrators and low pass filters must be set to the limited output.

If the controller was stopped by LV_LAM_STOP[i] and released later while non stationary conditions are still valid the following cases must be distinguished:

a) LV_LAM_STOP_SHO_PER[i] = 1, then

- no reset of LV_FAC_LAM_LIM_NOT_STAT_CDN[i]
- no renewed determination of thresholds

b) LV_LAM_STOP_SHO_PER[i] = 0, then

- reset of LV_FAC_LAM_LIM_NOT_STAT_CDN[i]
- new determination of thresholds

If the lambda controller had been deactivated (LV_LAM_LSCL[i] = 0) and was activated later while non stationary conditions are still valid then the thresholds must be re-calculated.

Storage of limitation values for non stationary conditions (FAC_LAM_MIN/MAX_NOT_STAT_CDN[i])

The threshold values are given by the maps IP_FAC_LAM_MIN_NOT_STAT_CDN and IP_FAC_LAM_MAX_NOT_STAT_CDN and are evaluated when LV_LAM_NOT_STAT_CDN switches from 0 to 1.

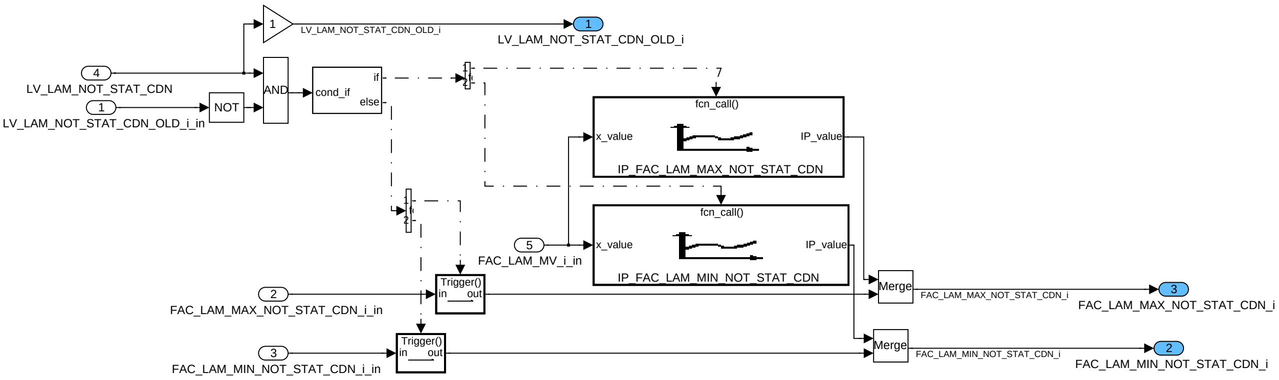

Figure 51 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__LIM_NOT_STAT_CDN/ CLC__LIM_NOT_STAT_CDN

Limitation of controller output FAC_LAM_OUT[i] and moving mean values; indicated by LV_FAC_LAM_LIM_NOT_STAT_CDN[i]

In case of exceeding the thresholds while non stationary conditions are valid the flag LV_FAC_LAM_LIM_NOT_STAT_CDN[i] is set to 1. This flag is reset if the non stationary conditions are not fulfilled anymore or the limitation is not valid anymore.

FAC_LAM_OUT[i] is limited to the threshold values. If the I share FAC_LAM_I_I2_SUM_LAM[i] exceeds the thresholds too all moving mean values are set to the limitation value.

In case LV_LAM_I2_ACT is set FAC_LAM_I2_LIM[i] is set to the limitation value and FAC_DIF_SUM_LIM_LAM_IN[i] is set to 0 (in order to reset the I share and apply the threshold value to the I^2 share).

In case LV_LAM_I2_ACT is not set FAC_LAM_I_IT_LIM[i] is limited.

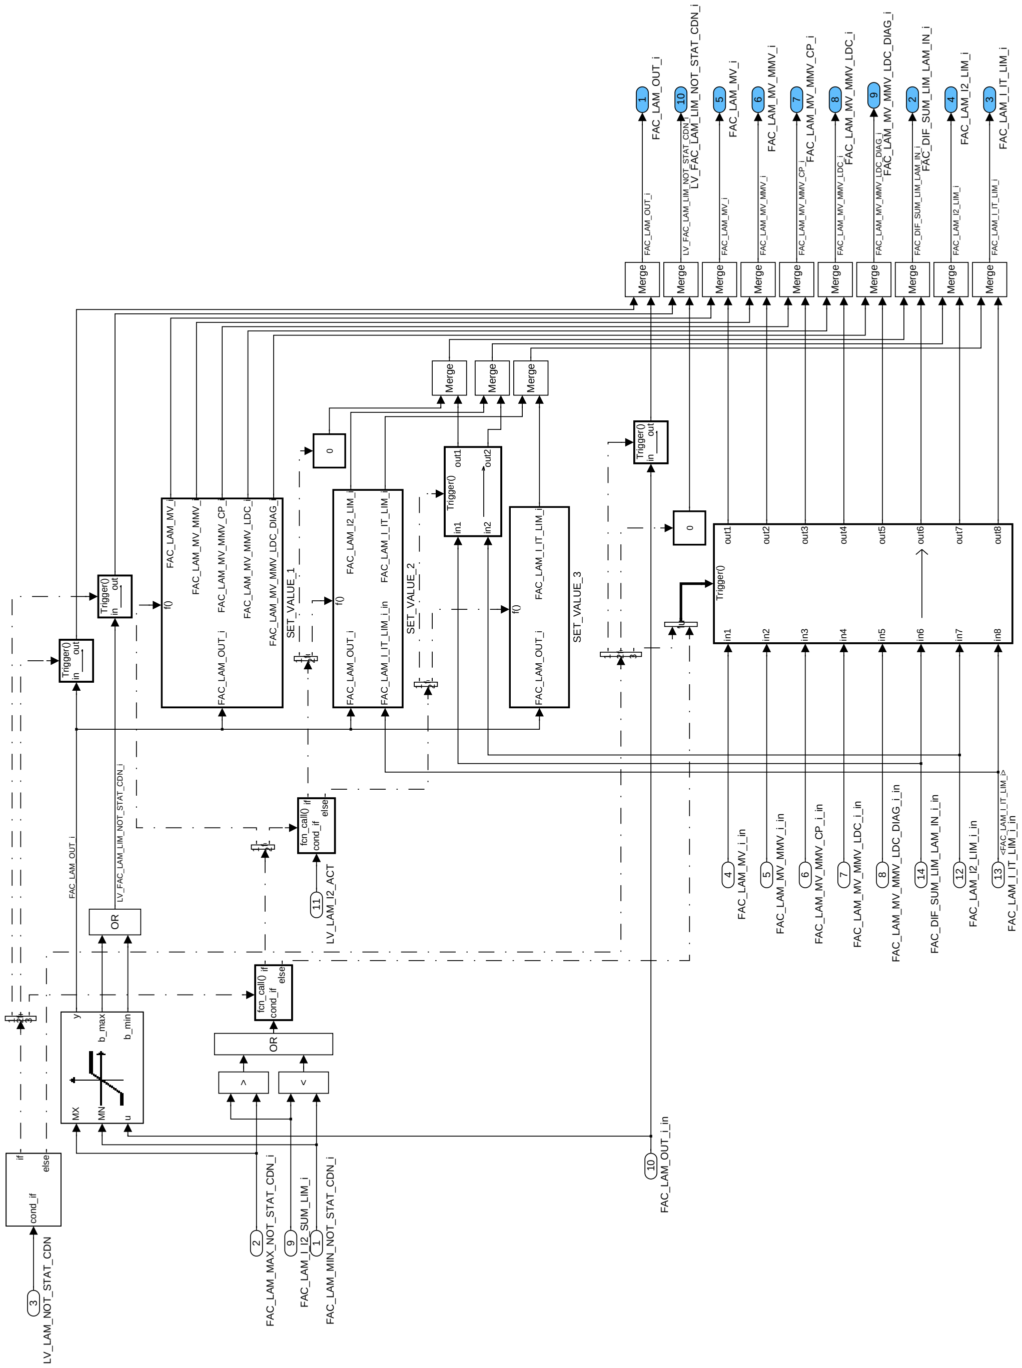

Figure 52 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__ON/ MNG__LIM_NOT_STAT_CDN/ LIM__FAC_LAM_OUT__NOT_STAT_CDN

STATE_LAM: “2:STOP_SHO_PER”

In state "2:STOP_SHO_PER " the D share is set to 0 and P, I and I^2 share are frozen. This state is for very short term controller stops.

Calculation of controller difference as richness (FAC_DIF_LAM_IN[i])

For details see state "0:OFF".

Evaluation of downstream sensor voltage (LV_VLS_DOWN_THD_AFL/AFR_LAM[i])

For details see state "0:OFF".

Reset D share (FAC_LAM_D_LIM[i])

The D share and its limited value are both set to 0.

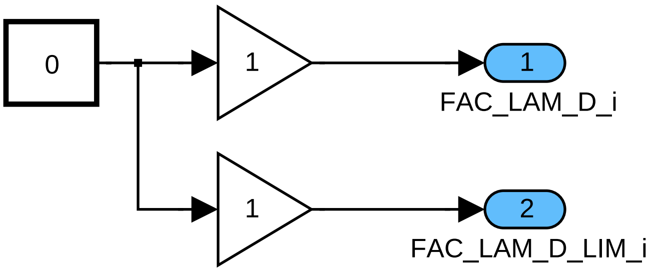

Figure 53 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__STOP_SHO_PER/ SET__FAC_LAM_D

Reset limitation flag for non-stationary conditions

If during short term controller stops the non-stationary conditions are no longer fulfilled (LV_LAM_NOT_STAT_CDN switches to 0) the flag indicating the limitation LV_FAC_LAM_LIM_NOT_STAT_CDN[i] is reset.

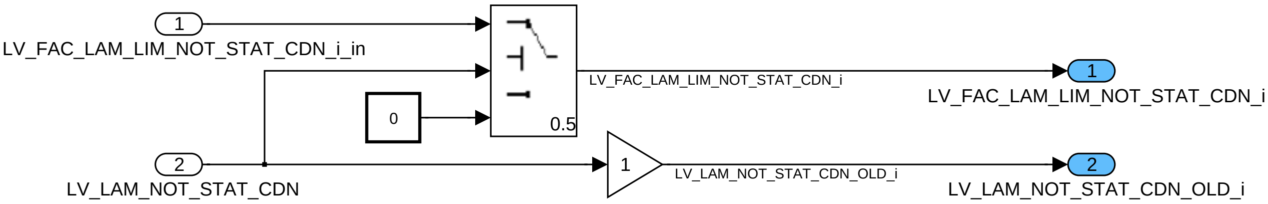

Figure 54 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__STOP_SHO_PER/ RST__LIM_NOT_STAT_CDN

Calculation of controller output signal (FAC_LAM_OUT[i])

FAC_LAM_OUT[i] is the sum of a frozen P and I share. In order to ensure limitation under non stationary conditions (which might be set in state “1:ON”) the flag indicating this limitation LV_FAC_LAM_LIM_NOT_STAT_CDN[i] is evaluated and – if set – the limitation is applied.

In case the request for limitation under non stationary conditions (LV_LAM_NOT_STAT_CDN) is reset and set again during state "2:STOP_SHO_PER" no new limitation is applied.

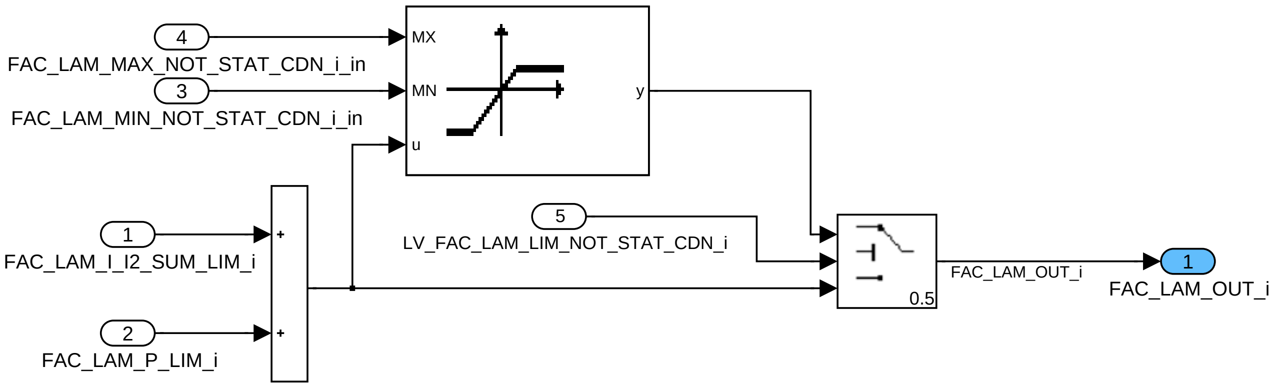

Figure 55 LACO_REQGNLACO0/ LAM/ operate/ CBK_EX_MNG/ CBK_EX_SPC/ STATE_LAM__STOP_SHO_PER/ CLC__FAC_LAM_OUT

STATE_LAM: “3:_STOP”

FAC_LAM_OUT[i] is set to 0.

Reset of all internal state variables and output values

For details see state "0:OFF".

Calculation of controller difference as richness (FAC_DIF_LAM_IN[i])

For details see state "0:OFF".

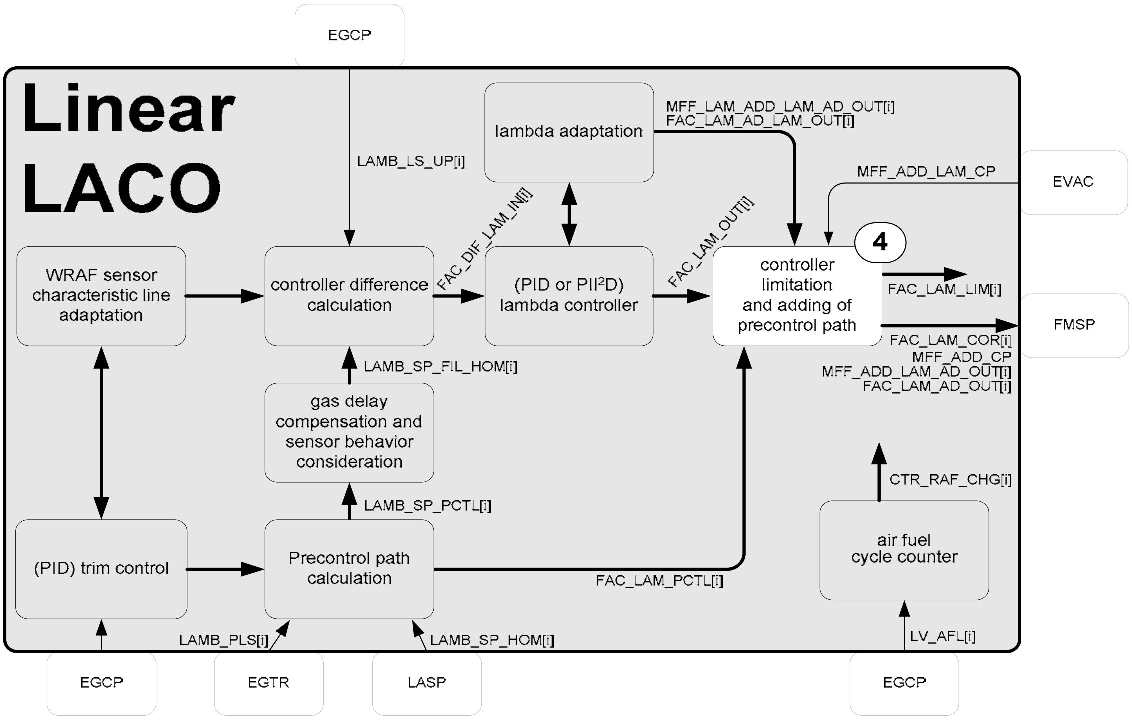
Evaluation of downstream sensor voltage (LV_VLS_DOWN_THD_AFL/AFR_LAM[i])

For details see state "0:OFF".

46.5.4 Controller output limitation and precontrol path correction consideration

The overall lambda control output FAC_LAM_COR[i] is computed taking into account also the precontrol intervention. This value is the correction for the fuel mass flow set point.

In order to synchronize output values of lambda controller, lambda adaptation and canister purge function some variables are fed through inside this function.



Sub-function in the whole module context

Additional remark:

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

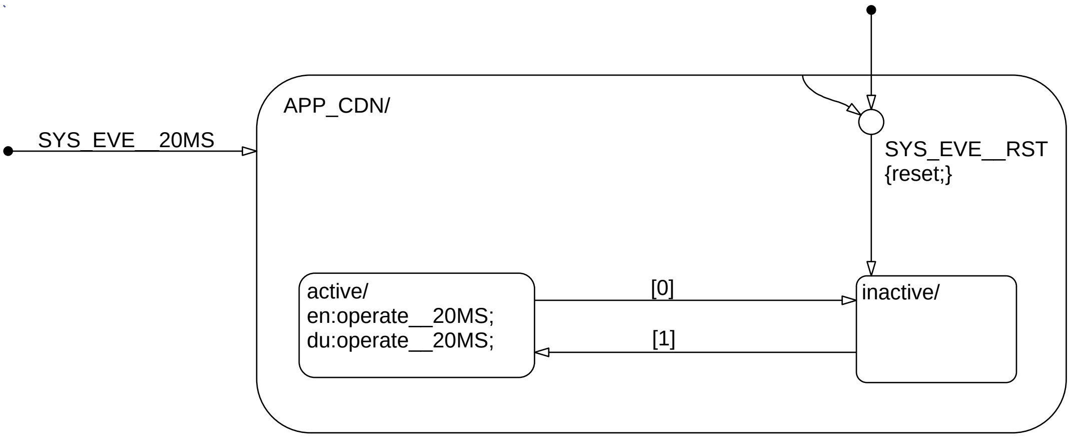


Figure 56 LACO_REQGNLACO0/ LAM_OUT/ APP_CDN/ Chart

Function Description

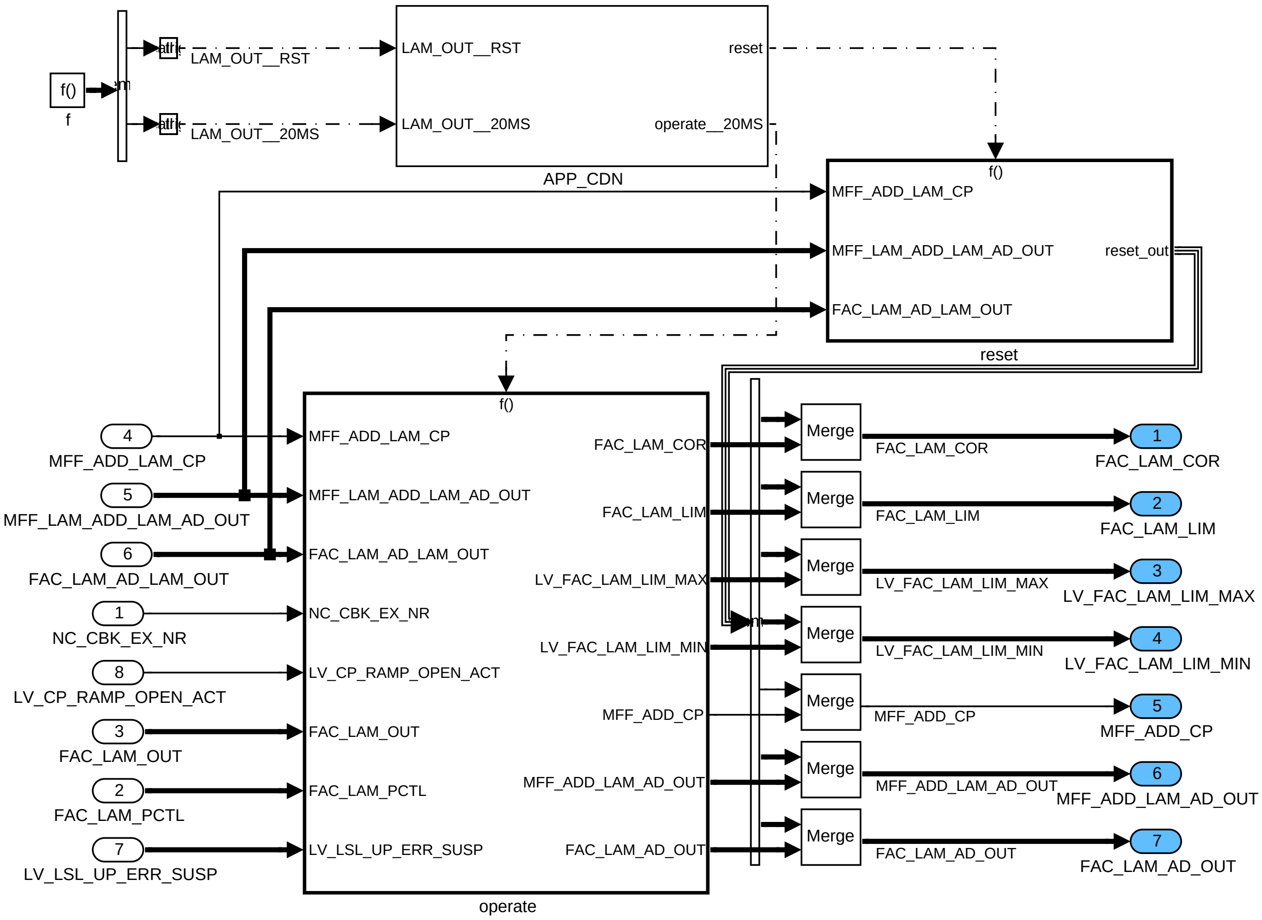

Figure 57 LACO_REQGNLACO0/ LAM_OUT

46.5.4.1 Initialization

MFF_ADD_CP is set to MFF_LAM_ADD_CP.

MFF_ADD_LAM_AD_OUT[i] is set to MFF_LAM_ADD_LAM_AD_OUT[i].

FAC_LAM_AD_OUT[i] is set to FAC_LAM_AD_LAM_OUT[i].

All other output variables are set to 0.

46.5.4.2 Formula section

Feed through of canister purge ouput varaible (MFF_ADD_CP)

The canister purge output variables (additive fuel mass flow) is written to the variable that is finally influencing the fuel mass set point.

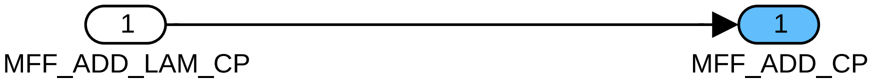

Figure 58 LACO_REQGNLACO0/ LAM_OUT/ operate/ CLC_MFF_ADD_CP

Exhaust bank specific functionality

Calculation of output variables (FAC_LAM_COR[i], MFF_ADD_LAM_AD_OUT[i], FAC_LAM_AD_OUT[i])

FAC_LAM_LIM[i] includes the limited output signal of the lambda controller. The limitation thresholds depend on whether the ramp open mode during canister purge is active or whether there is a suspicion of an oxygen sensor error. The limited output and the precontrol path correction together are summarised in the variable FAC_LAM_COR[i].

The lambda adaptation output variables (additive fuel mass flow and corrective factor) are written to the variables that are finally influencing the fuel mass set point.

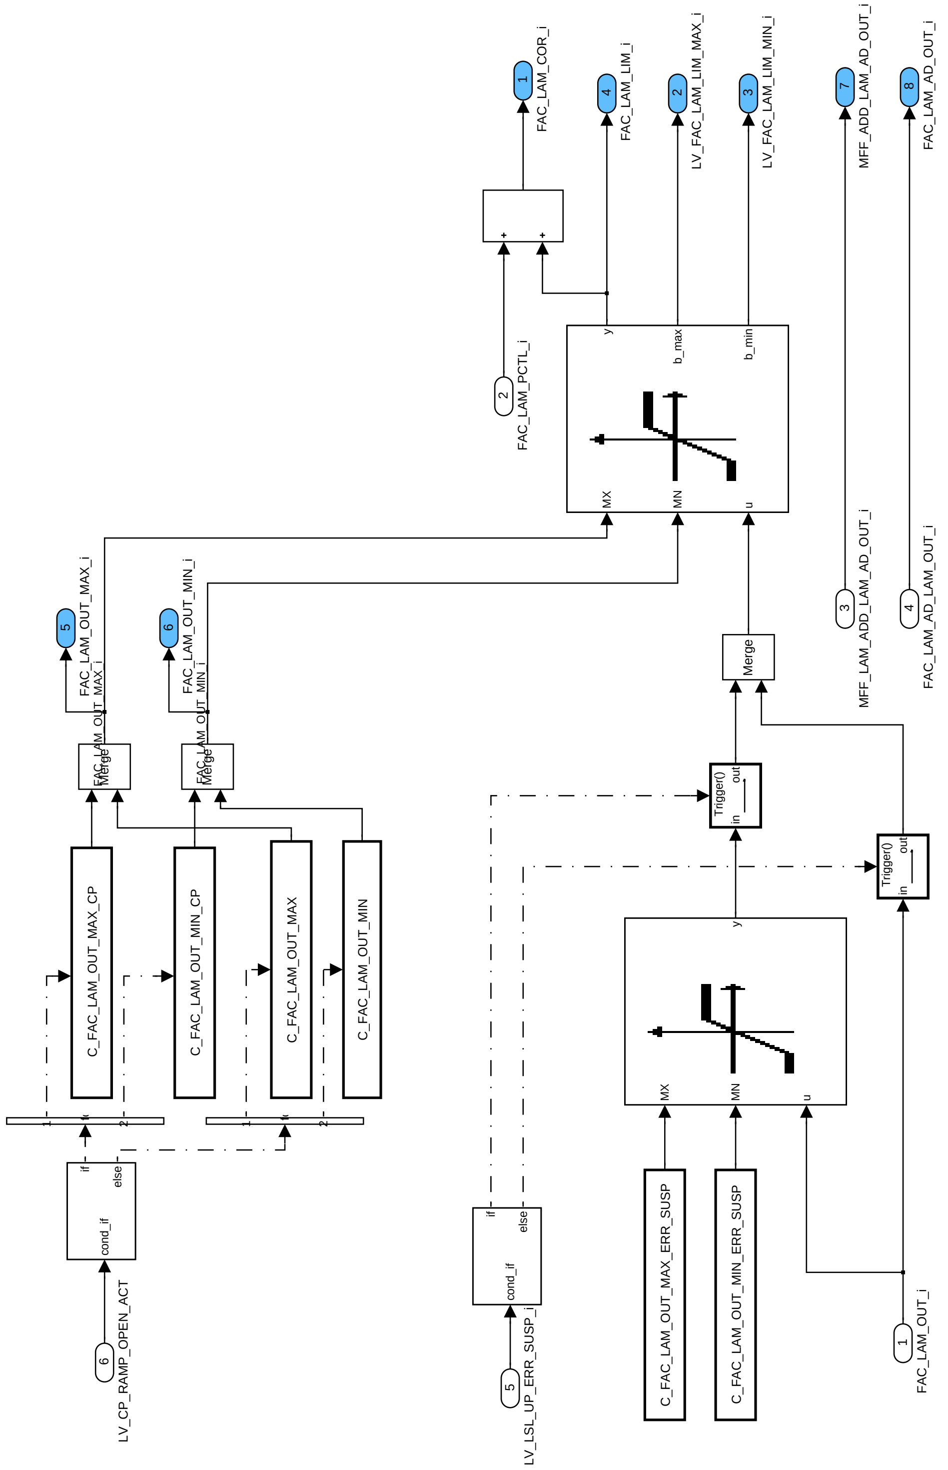

Figure 59 LACO_REQGNLACO0/ LAM_OUT/ operate/ CBK_EX_MNG/ CBK_EX_SPC

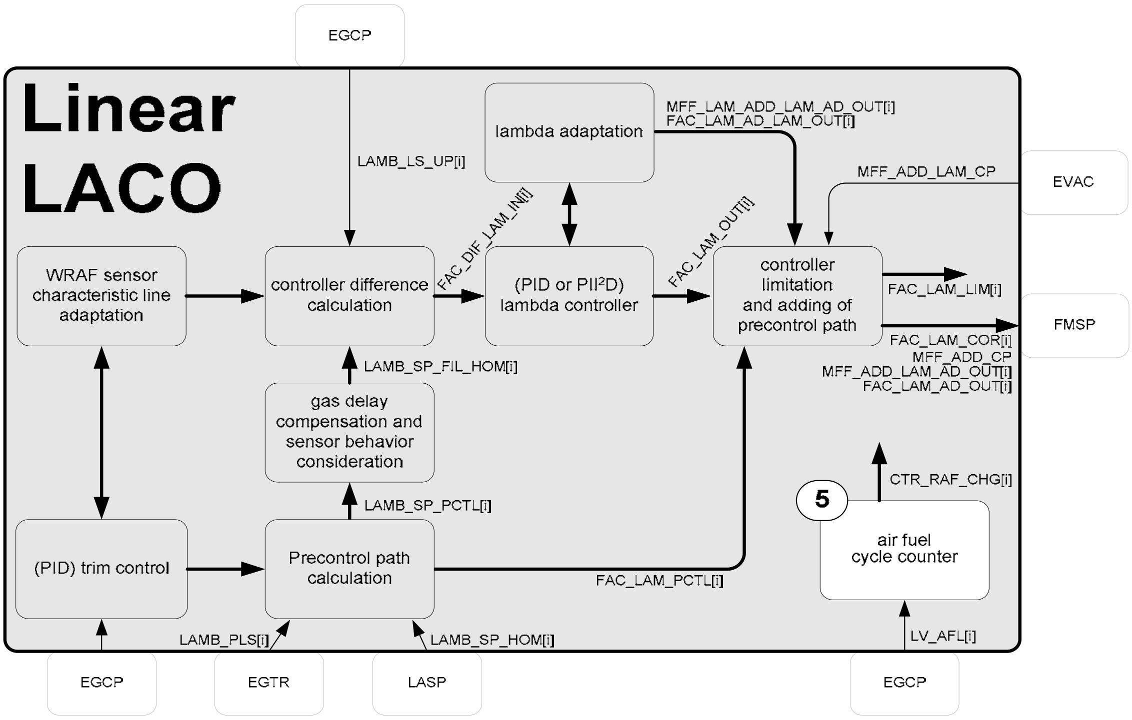
46.5.5 Calculation of air fuel ratio changes counter

In order to detect air fuel ratio changes in other functions a counter is provided that is incremented each time the air fuel ratio changes from lean to rich or vice versa.



Sub-function in the whole module context

Additional remark:

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

FUNCTION DESCRIPTION:

General information:

This module defines the project specific activation conditions and necessary output variables for the linear lambda controller.
The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: at ECU reset:

LV_INH_LSCL[i] = 1
LV_LAM_GAIN_SWI = LC_LAM_GAIN_SWI
LAMB_SP_DELTA_LAM[i] = 0
LAMB_AV_DELTA_LAM[i] = 0
LV_LAM_STOP_REQ[i] = 0
LV_STATE_LS_OPL_ERR[i] = 0
LV_LAMB_SP_AFR_THD[i] = 0
LV_LAMB_SP_AFL_THD[i] = 0
LV_LAM_MAF_MIN = 0

MFF_ADD_WF = 0

MAF_INT_S_ACT = 0

At LV_IGK = 0 -> 1

LAMB_DIF_AV_CTL_ST_OUT[i] = 0
LV_CLC_LAMB_DIF_AV_ST = 1
LV_MAF_INT_MIN_LAM_REAC_SWI = 0

Recurrence: T_SAMPLE = 20 ms

Activation: LV_ST_END = 1

Deactivation: -

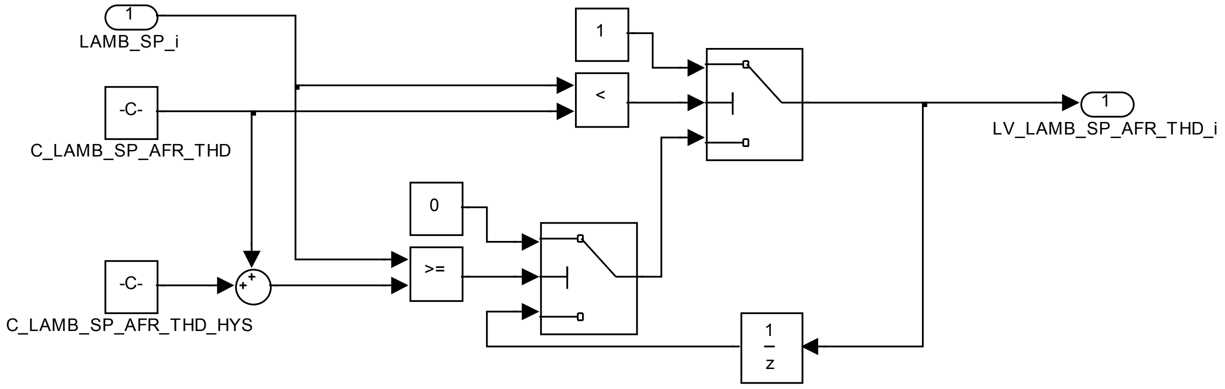
Formula section:

46.6.1 Calculation of LV_INH_LSCL[i]

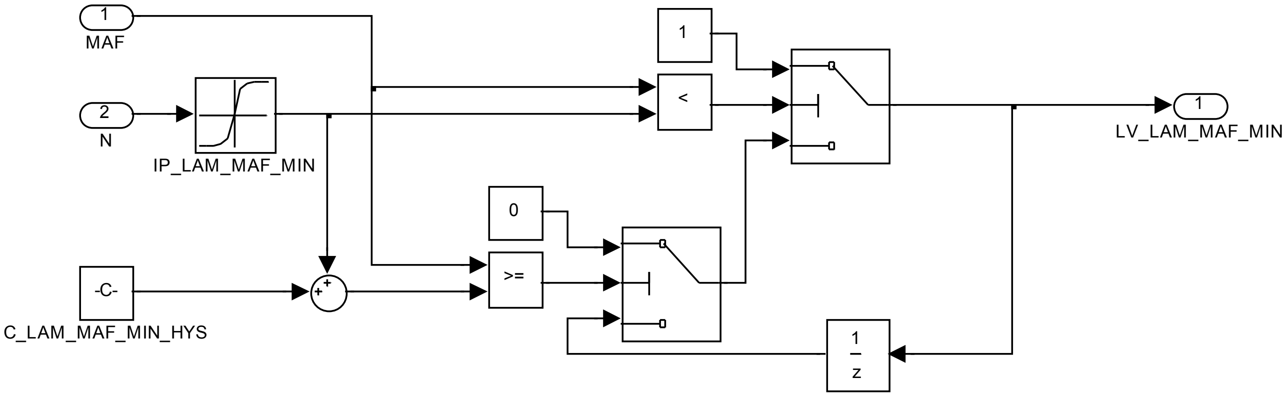
46.6.1.1 Inhibition of the lambda feedback control circuit

```
If(1)          LAMB_SP[i] < C_LAMB_SP_AFR_THD
        % lambda setpoint value is less than the rich air-fuel mixture threshold
Then(1)        LV_LAMB_SP_AFR_THD[i] = 1
Else(1)
        If(2)    LAMB_SP[i] ≥ C_LAMB_SP_AFR_THD + C_LAMB_SP_AFR_THD_HYS
        Then(2)  LV_LAMB_SP_AFR_THD[i]= 0
        Endif(2)
Endif(1)
If(1)          LAMB_SP[i] > C_LAMB_SP_AFL_THD  lambda setpoint value is greater than
                                               the lean air-fuel mixture threshold
Then(1)        LV_LAMB_SP_AFL_THD[i]  =  1
Else(1)
        If(2)    LAMB_SP[i] ≤ C_LAMB_SP_AFL_THD - C_LAMB_SP_AFL_THD_HYS
        Then(2)  LV_LAMB_SP_AFL_THD[i]  =  0
        Endif(2)
Endif(1)
```

(signal flow is analogous LV_LAMB_SP_AFR_THD[i] , see above)



```
If(1)       MAF < IP_LAM_MAF_MIN
Then(1)     LV_LAM_MAF_MIN = 1
Else(1)
    If(2)   MAF ≥ IP_LAM_MAF_MIN + C_LAM_MAF_MIN_HYS
    Then(2) LV_LAM_MAF_MIN = 0
    Endif(2)
Endif(1)
```



46.6.1.2 Inhibition due to present error

```
If      LV_ERR_IGC              = 1   or
        LV_ERR_LSL_UP_IF[i]     = 1   or
        LV_ERR_OFS_LSL_UP[i]    = 1   or
        LV_ERR_CTL_LSL_UP[i]    = 1   or
        LV_ERR_LS_UP[i]         = 1   or
        LV_ERR_CHG_LS_UP        = 1   or
        LV_MIS_STATE_A          = 1   or
Then    LV_STATE_LS_OPL_ERR[i]  = 1
Else    LV_STATE_LS_OPL_ERR[i]  = 0
Endif
```

46.6.1.3 Summary of all inhibition conditions for activation of lambda controller

```
If      LV_STATE_LS_OPL_ERR[i]        = 1   or    (present error)
        LV_LAMB_SP_AFR_THD[i]         = 1   or    (lambda setpoint to rich)
        LV_LAMB_SP_AFL_THD[i]         = 1         or    (lambda setpoint to lean)
        LV_LAM_MAF_MIN                = 1   or    (minimum maf not fulfilled)
        ( LC_LAMB_COP_OFF             = 1   and
        LV_LAMB_COP[i]                = 1)  or    (catalyst overheat prevention)
        LV_ACT_SA_EOL                 = 1   or    (EOL test SA is active)
        (LC_LAM_OFF_SAWUP=1and
        LV_SA_END                     = 0)  or    (secondary air is active)
        LV_INH_LAM_KWP                = 1         (disable Controller via Tester)
Then    LV_INH_LSCL[i] =  1
Else    LV_INH_LSCL[i] =  0
Endif
```

46.6.2 Calculation of LV_LAM_STOP_REQ[i]

The request to stop the lambda-controller (LV_LAM_STOP_REQ[i] = 1), if one of the conditions

a) stratified charge mode (LV_HOM_ACT=0) **and** LC_HOM_ACT_COMP = 0 **or**

b) secondary air is active (LV_SA_END = 0) **and** LC_LAM_OFF_SAWUP = 1

is fulfilled.

```
If      (LV_HOM_ACT            = 0     and
        LC_HOM_ACT_COMP        = 0)    or
        LV_INH_LSCL_CUS[i]     = 1     or
        LV_MIS_STATE_A         = 1     or
        (LV_SA_END             = 0     and
        LC_LAM_OFF_SAWUP       = 1)
Then    LV_LAM_STOP_REQ[i] = 1
Else    LV_LAM_STOP_REQ[i]= 0
Endif
```

46.6.3 Setting of LV_LAM_GAIN_SWI

The gain of the lambda controller is different between idle speed and part load. Therefore, the gain is switched in case of active idle speed controller.

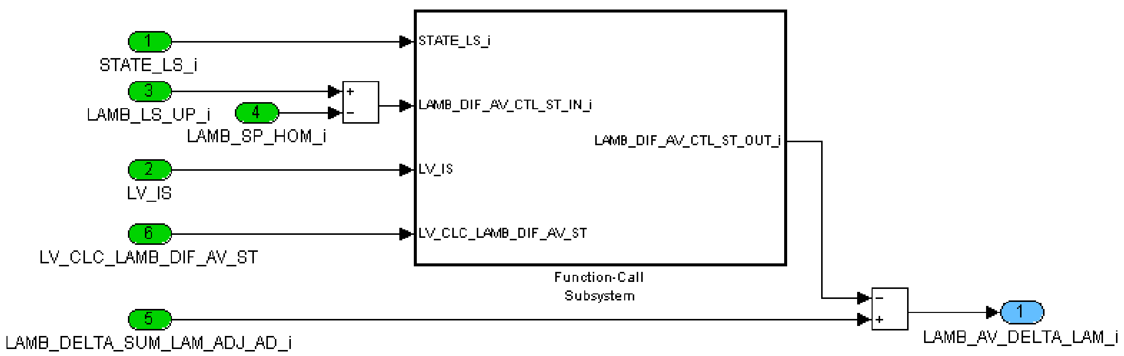
```
If      (LV_REQ_ISC = 1 and LC_LAM_GAIN_SWI = 1)
        or (LV_LAM_AD_INJ_ACT = 1 and LC_LAM_GAIN_SWI_LAM_AD_INJ = 1)
Then    LV_LAM_GAIN_SWI = 1
Else    LV_LAM_GAIN_SWI = 0
Endif
```

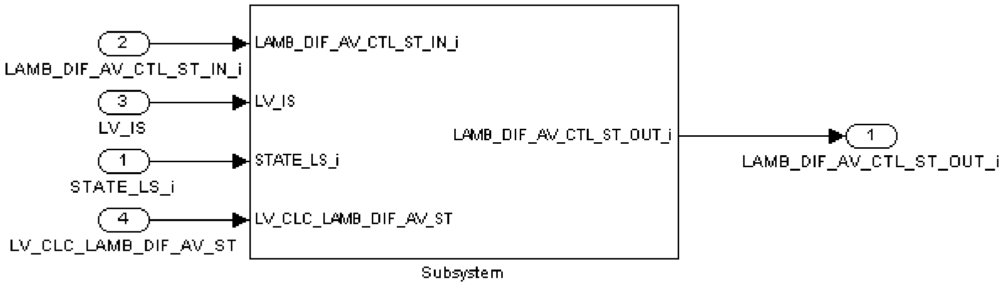
46.6.4 Assignment of LAMB_SP_DELTA_LAM[i]

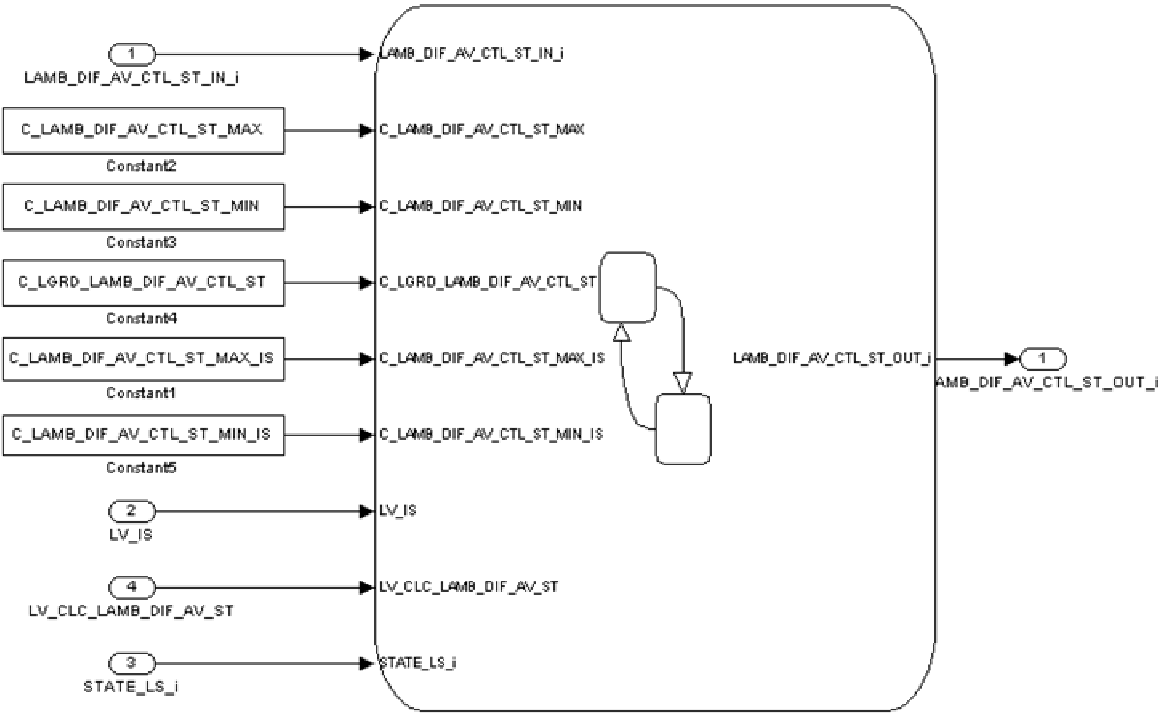
The output of the trim controller (P and I share) is distributed as follows as corrective intervention on the lambda set point and on the measured lambda signal:

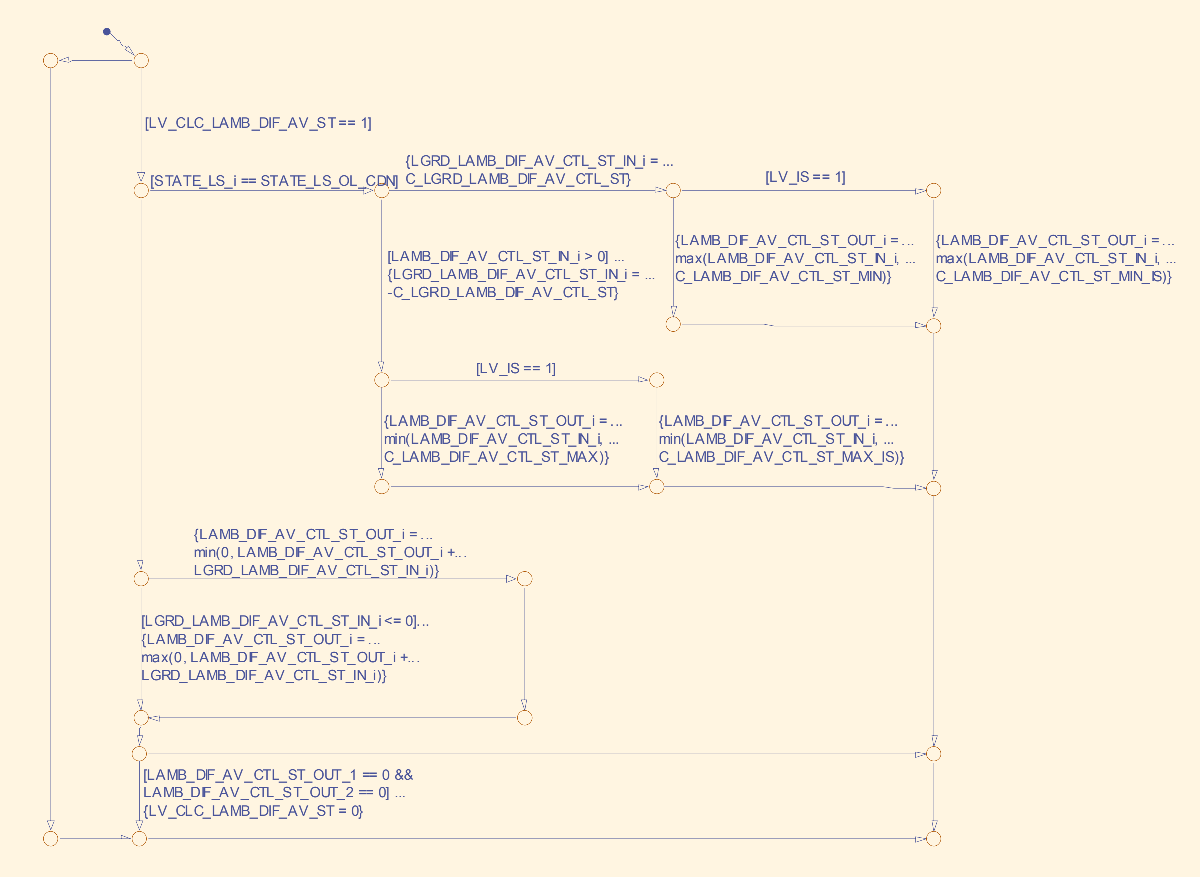
LAMB_SP_DELTA_LAM[i] = LAMB_DELTA_LAM_ADJ[i]
+ DELTA_LAMB_SP_O2L_MDL[i]

46.6.5 Assignement of LAMB_AV_DELTA_LAM[i]









46.6.6 Detection of non-stationary condition

A limited dynamic condition based on N, MAF and PV_AV is detected when the variation of those variables exceed the calibrateable threshold.

```
IF (ABS(N_DELTA_LDC) > C_N_DYW_LAM_NOT_STAT)
THEN
   IF (ABS(N_DELTA_LDC - N_OFS_LAM_NOT_STAT) > C_N_DYW_LAM_NOT_STAT)
   THEN
      N_OFS_LAM_NOT_STAT = N_DELTA_LDC
      MAF_INT_LAM_NOT_STAT = 0
   ENDIF
ELSE
   N_OFS_LAM_NOT_STAT = 0
ENDIF

IF (ABS(MAF_DELTA_LDC) > C_MAF_DYW_LAM_NOT_STAT)
THEN
   IF (ABS(MAF_DELTA_LDC - MAF_OFS_LAM_NOT_STAT) >
       C_MAF_DYW_LAM_NOT_STAT)
   THEN
      MAF_OFS_LAM_NOT_STAT = MAF_DELTA_LDC
      MAF_INT_LAM_NOT_STAT = 0
   ENDIF
ELSE
   MAF_OFS_LAM_NOT_STAT = 0
ENDIF

IF (ABS(FAC_TQ_REQ_DELTA_LDC) > C_FAC_TQ_REQ_DYW_LAM_NOT_STAT)
THEN
   IF (ABS(FAC_TQ_REQ_DELTA_LDC - FAC_TQ_REQ_OFS_LAM_NOT_STAT) >
       C_FAC_TQ_REQ_DYW_LAM_NOT_STAT)
   THEN
      FAC_TQ_REQ_OFS_LAM_NOT_STAT = FAC_TQ_REQ_DELTA_LDC
      MAF_INT_LAM_NOT_STAT = 0
   ENDIF
ELSE
   FAC_TQ_REQ_OFS_LAM_NOT_STAT = 0
ENDIF

IF (MAF_INT_LAM_NOT_STAT < C_MAF_INT_LAM_NOT_STAT)
THEN  % non stationary condition detected
   MAF_INT_LAM_NOT_STAT [g] = MAF_INT_LAM_NOT_STAT [g] +
                              MAF_CYL [kg/h] * T_SAMPLE [ms] * 1/3600 [(g*h) / (kg*ms)]
   FAC_NEUT_NOT_STAT_CDN= 7FFFh
ELSE  % stationary condition
   FAC_NEUT_NOT_STAT_CDN= 0h
ENDIF
```

46.6.7 Assignment of interpolation factor

```
If LC_FAC_IPT_SENS_MDL_OPT_ACT = 1
then
        FAC_IPT_SENS_MDL[i] = 0
        FAC_IPT_SENS_MDL_OPT[i] = IP_FAC_IPT_SENS_MDL_OPT(FAC_DIAG_DYN_LSL_UP[i])
else
        FAC_IPT_SENS_MDL[i] = ID_FAC_IPT_SENS_MDL(WGPWM[i])
        FAC_IPT_SENS_MDL_OPT[i] = 0
endif
```

46.6.8 Calculation of air massflow integral during S/HOMS operation mode

```
If LV_HOM_ACT = 1 -> 0
Then  MAF_INT_S_ACT = 0
Elseif  LV_HOM_ACT = 0
Then MAF_INT_S_ACT = MAF_INT_S_ACT + MAF_CYL [kg/h] * T_SAMPLE [ms] * 1/3600
        [(g*h) / (kg*ms)]
Elseif LV_HOM_ACT = 1
Then  hold MAF_INT_S_ACT
Endif
```

sensor voltage set point for trim control					

46.7.1 LACO_REQGNTRIM0

The trim controller causes a shift of the WRAF sensor signal (upstream of the catalyst) or/and a shift of the lambda set point (in opposite direction). The output components (P share, I share, the sum of both or the adaptation value) of the trim controller can be linked in the application incidence for the lambda controller to corresponding inputs of the lambda controller. A compensation of ageing effects of the WRAF sensor as well as a better observance of the catalyst window is reached because of these shifts.

The control value is composed of P, I and D shares. All are determined depending on the trim control sensor signal (binary signal). The difference of the sensor voltage from set point value is the basic characteristic. The set point value can be applied depending on the operating point, so that the dynamic lambda can be adjusted according to the operating range.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

Function Description

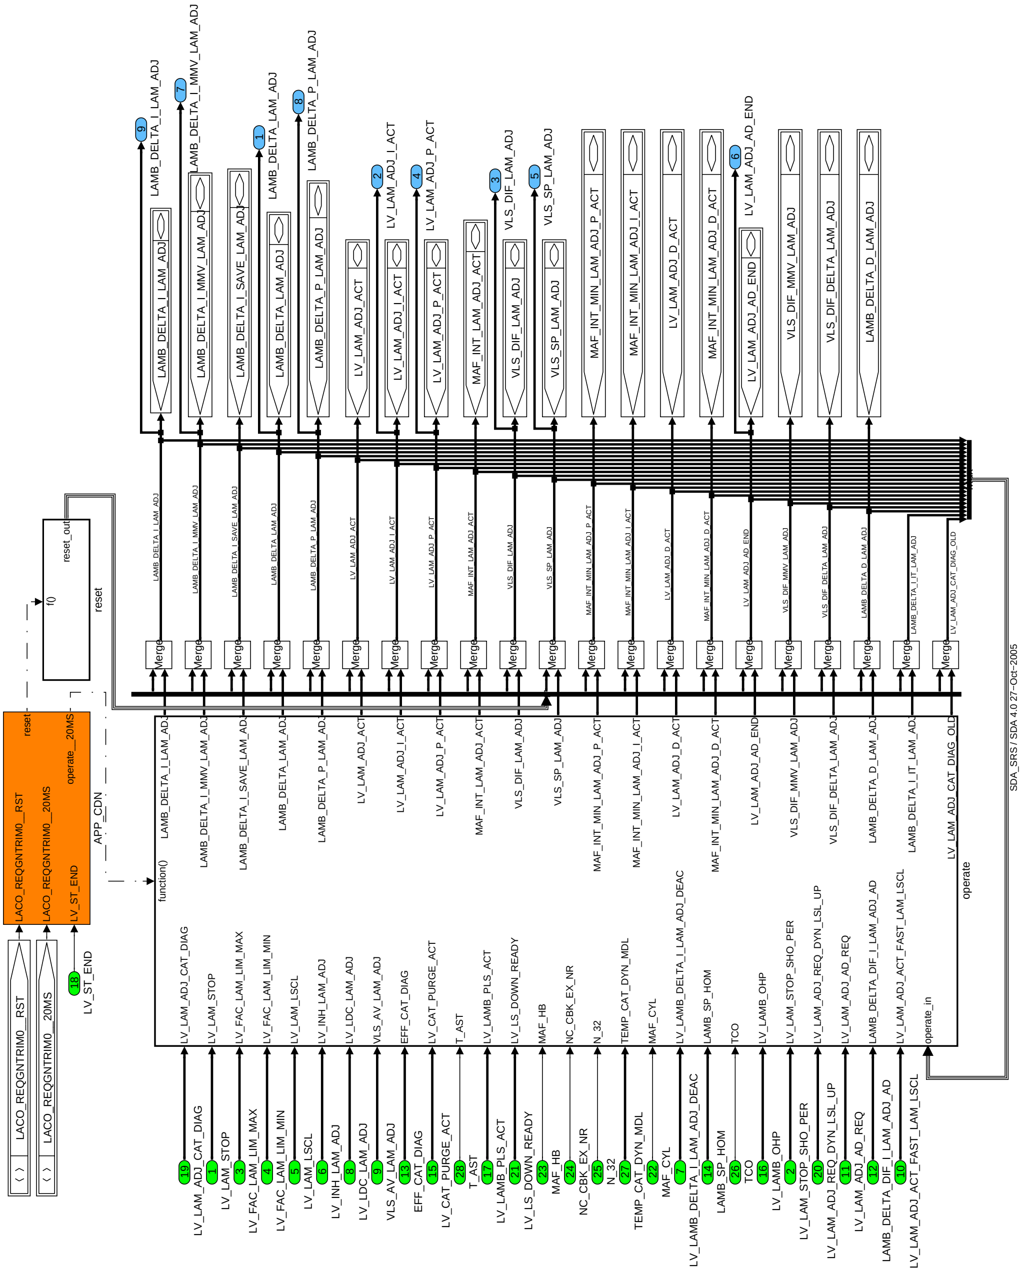

Figure 64 LACO_REQGNTRIM0

46.7.1.1 SUBFUNCTION: operate

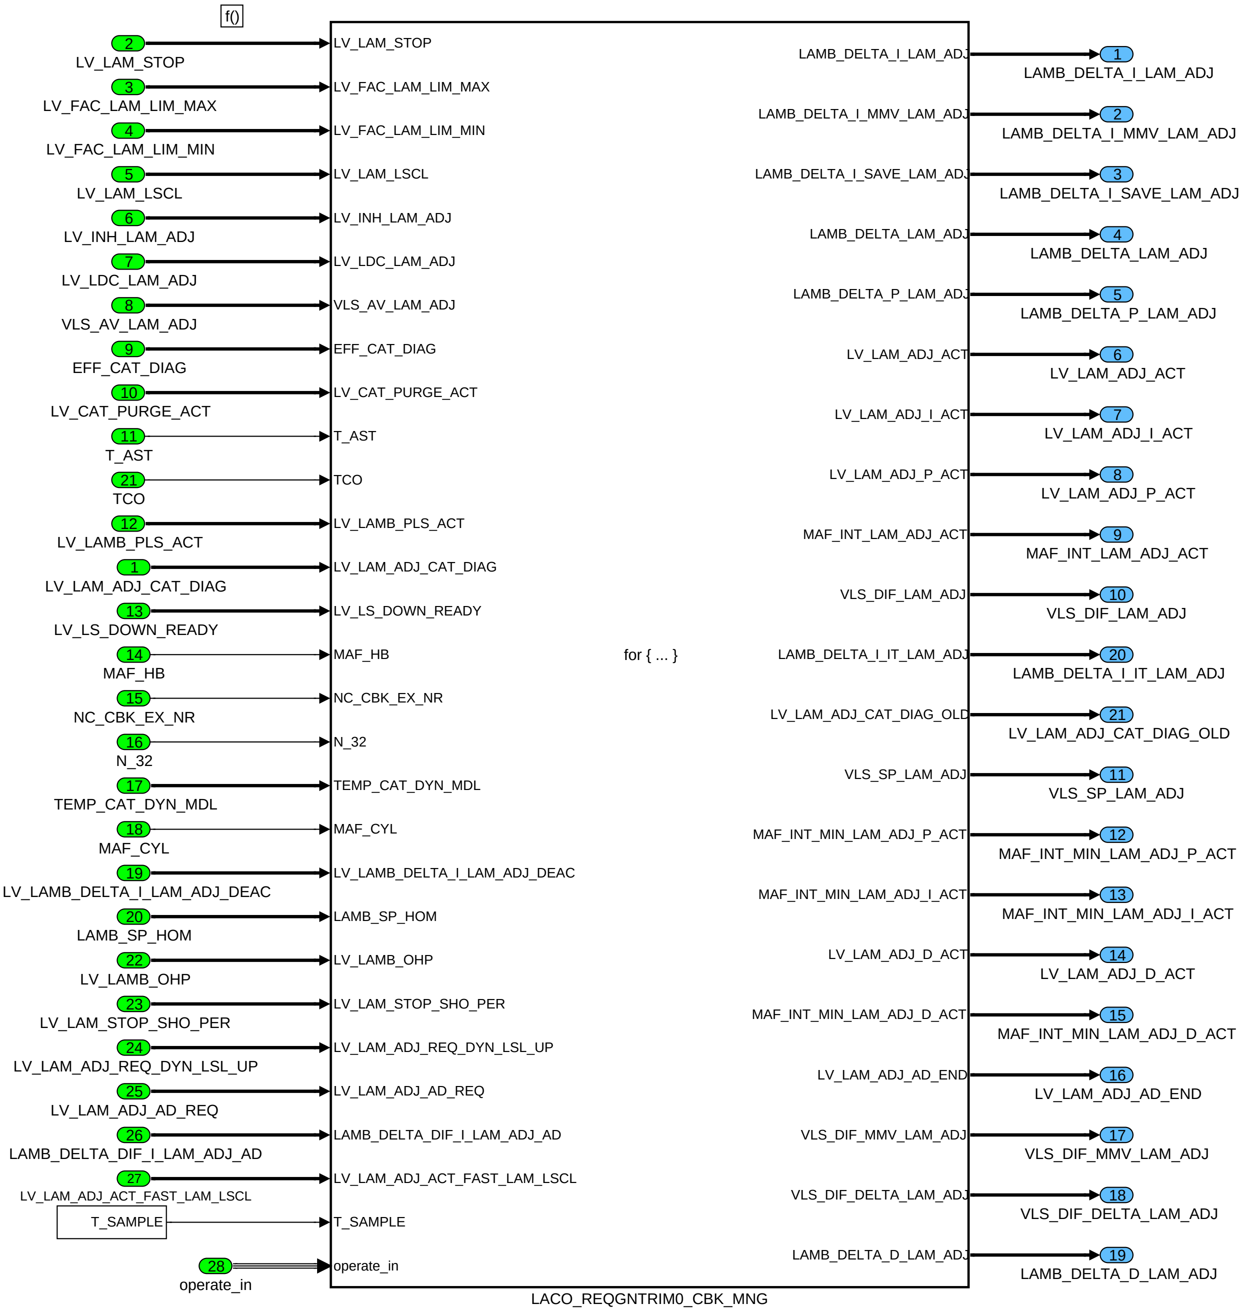

Figure 65 LACO_REQGNTRIM0/ operate

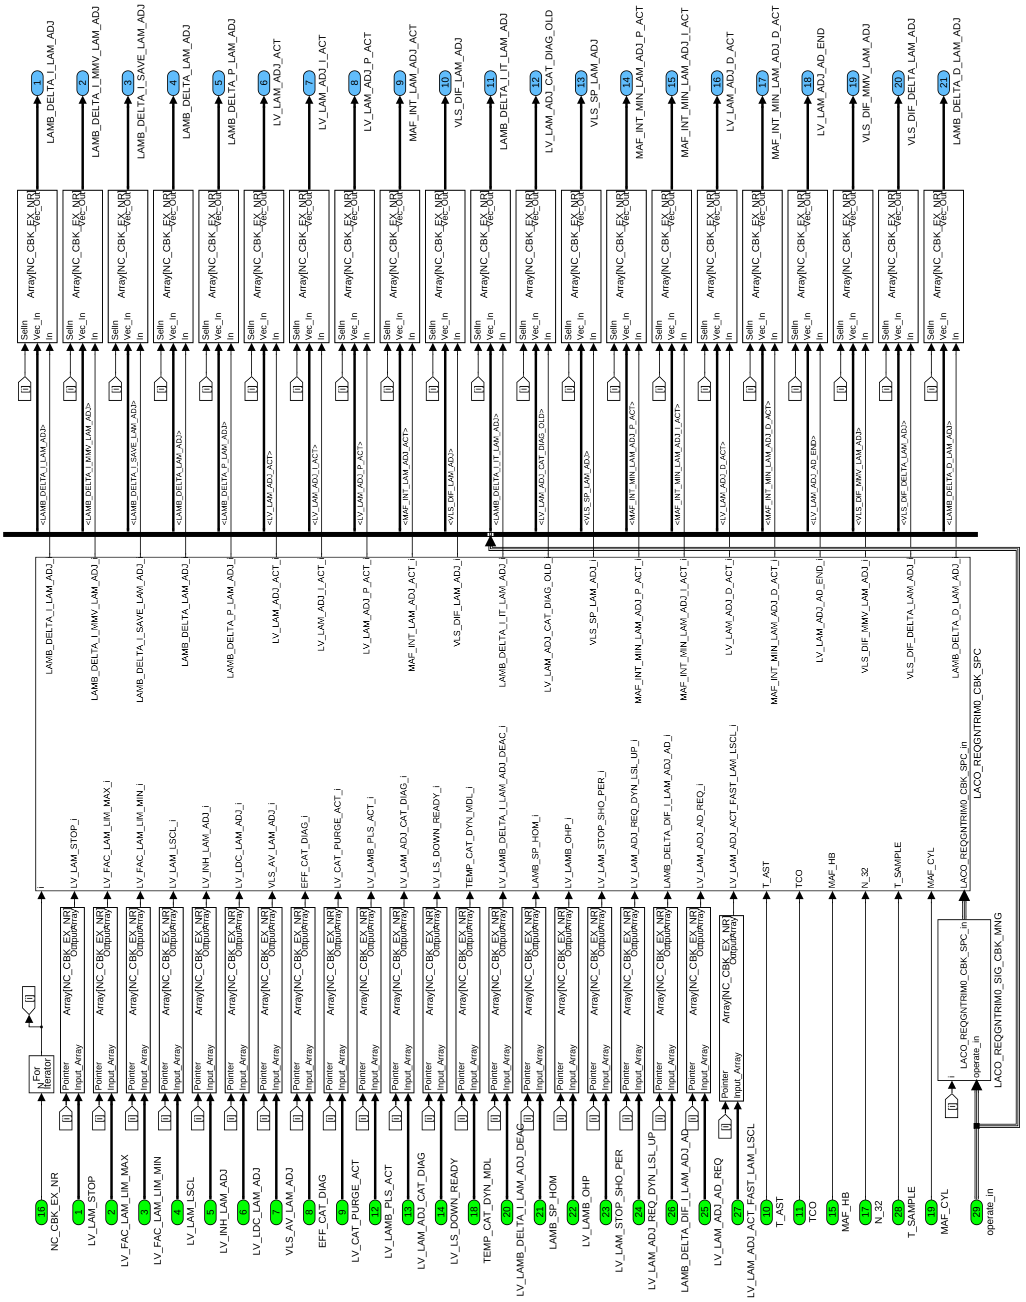

Figure 66 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG

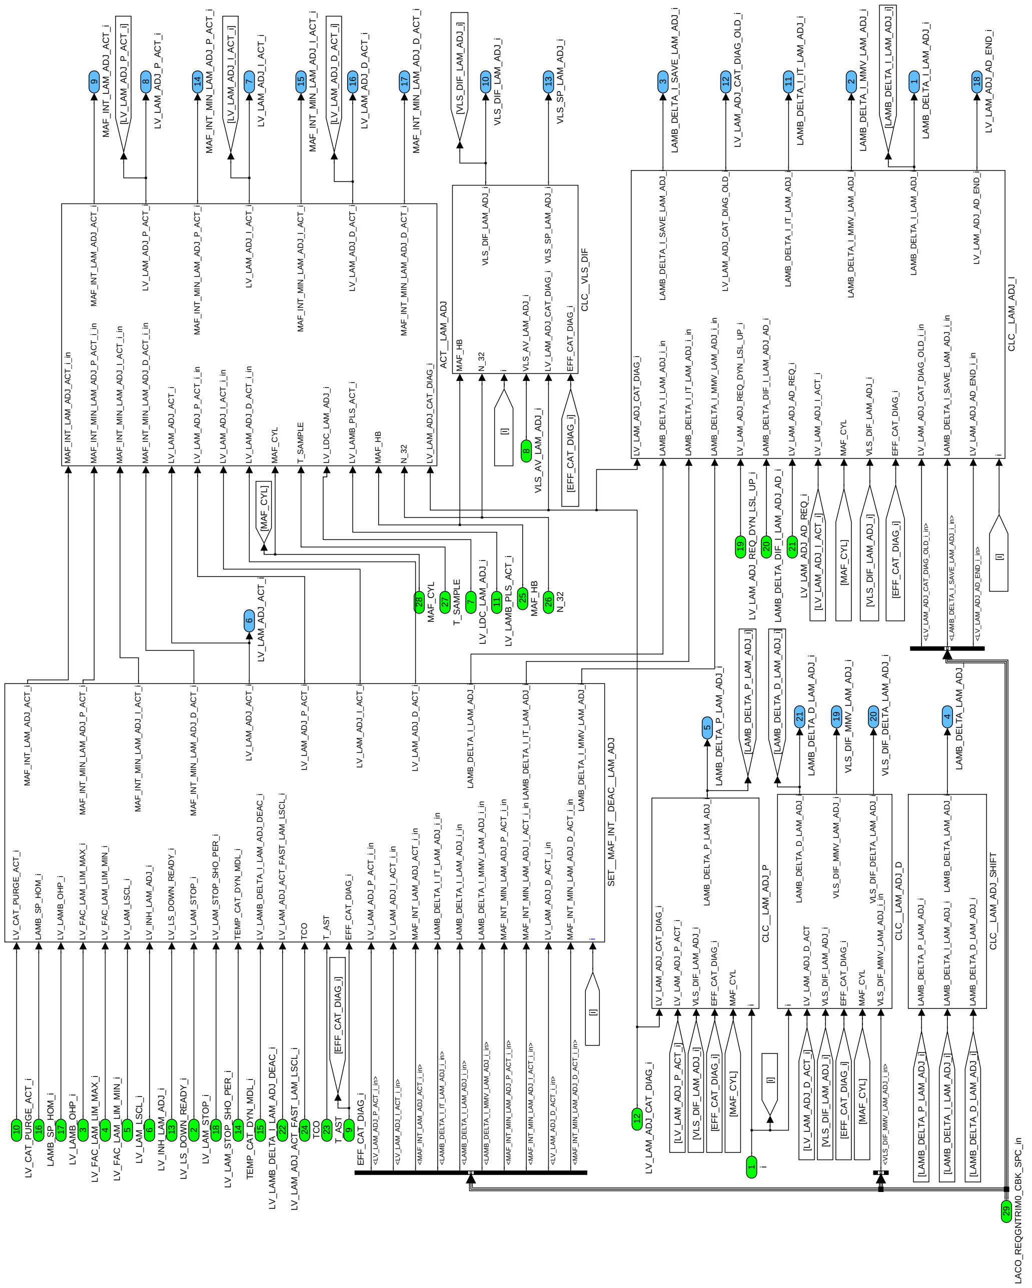

Figure 67 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC

Activation / deactivation of trim control (part I)

The trim controller is activated when the following conditions are fulfilled:

- no general inhibition
- the trim sensor is ready for operation
- the catalyst enrichment function is not active
- the lambda controller must be active
- the lambda controller must not be in short term in stop mode
- no output limitation of the lambda controller is active

- the catalyst is at operating temperature
- the catalyst efficiency is in the valid area
- the lambda set point must lie within calibration range
- no overheating protection with rich lambda is active

Before verifying the condition for P, I and/or D share activation, an air mass flow integral must exceed the threshold applied thresholds. These thresholds can be calibrated independently for P share, I share and D share activation. Depending on the deactivation reason different air mass flow integral thresholds can be applied. In case of hot start indicated by T_AST below limit and TCO above threshold the P share can be activated immediately if no other above mentioned activation condition is not fulfilled. The activation is realised by setting the MAF integral threshold for the P share to 0.

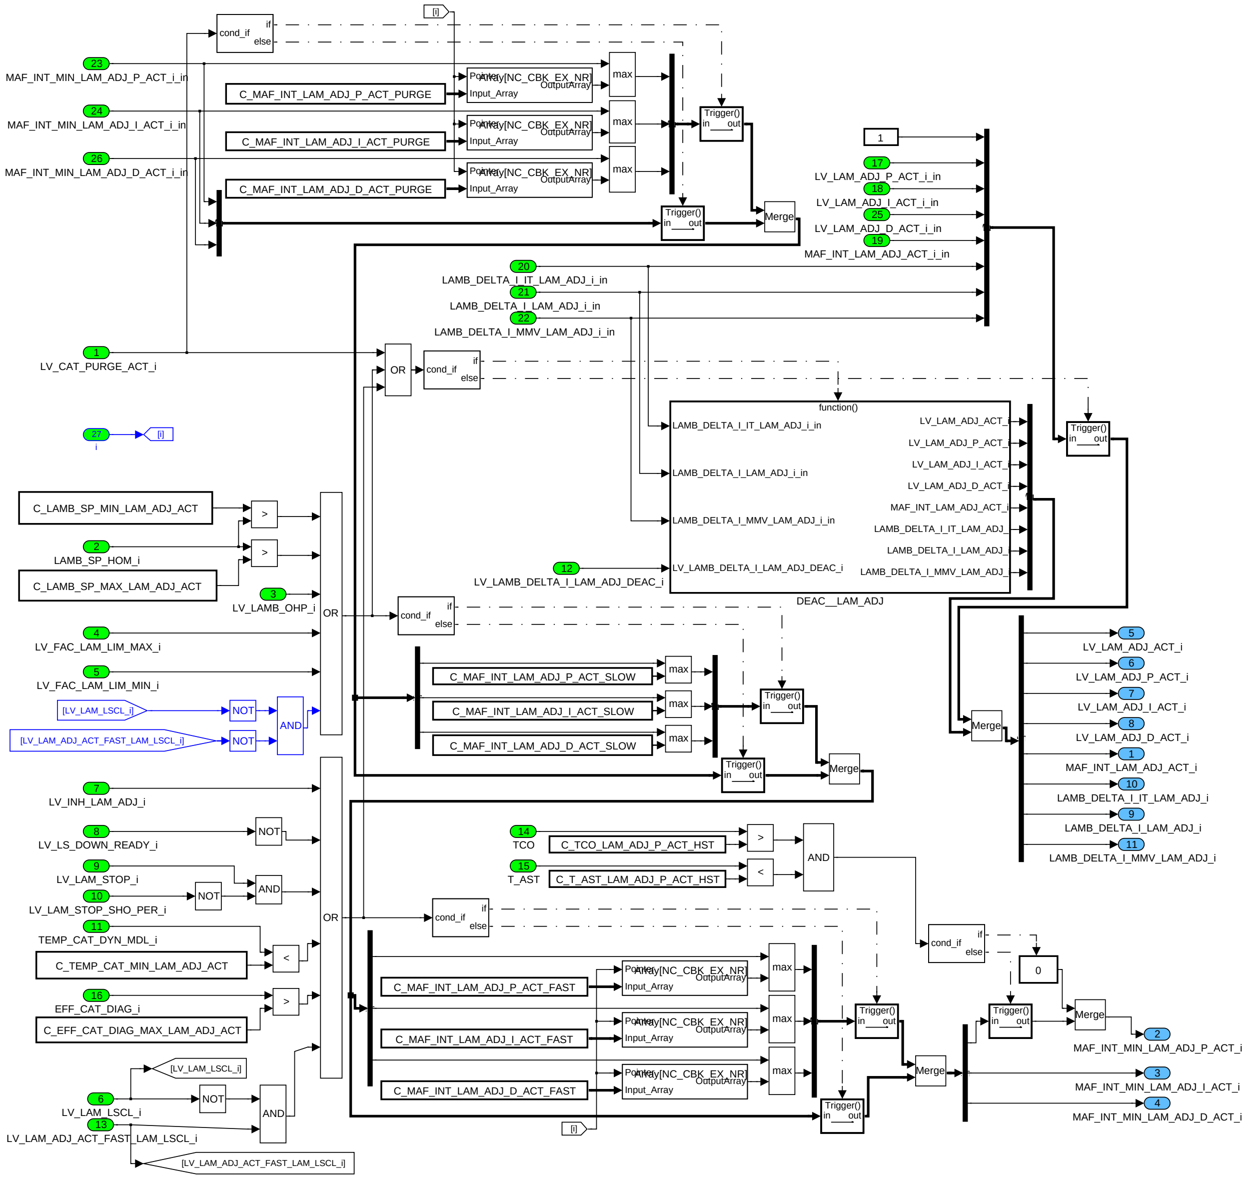

Figure 68 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ SET__MAF_INT__DEAC__LAM_ADJ

Deactivate trim controller

When deactivating the trim controller the P share and D share will get 0 and the I share remain fix (by deactivating the calualtion). If LV_LAMB_DELTA_I_LAM_ADJ_DEAC[i] was set to 0 (in the application incidences) then the I share is set to 0.

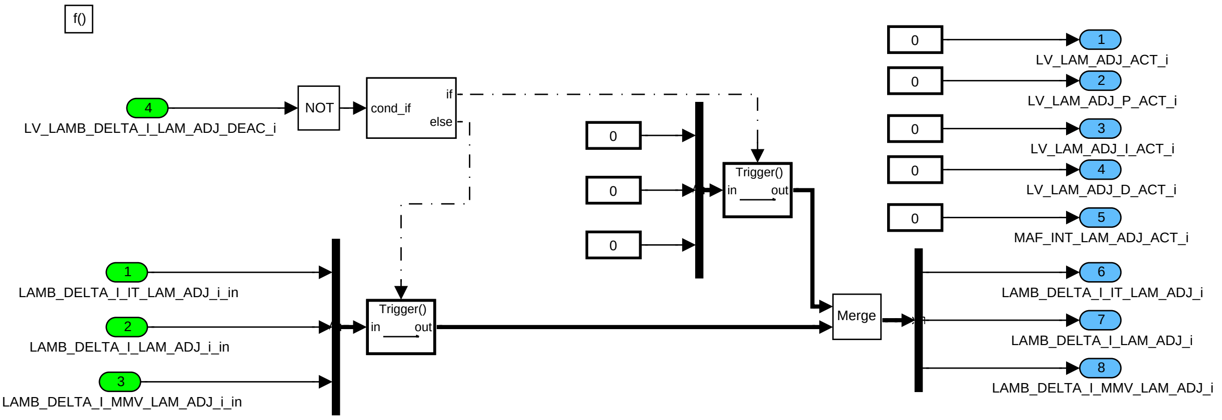

Figure 69 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ SET__MAF_INT__DEAC__LAM_ADJ/ DEAC__LAM_ADJ

Activation / deactivation of trim control (part II)

When all conditions to activate the trim controller are fulfilled an air mass integral is started and the conditions for P, I and D share are checked separately.

For the calcuation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

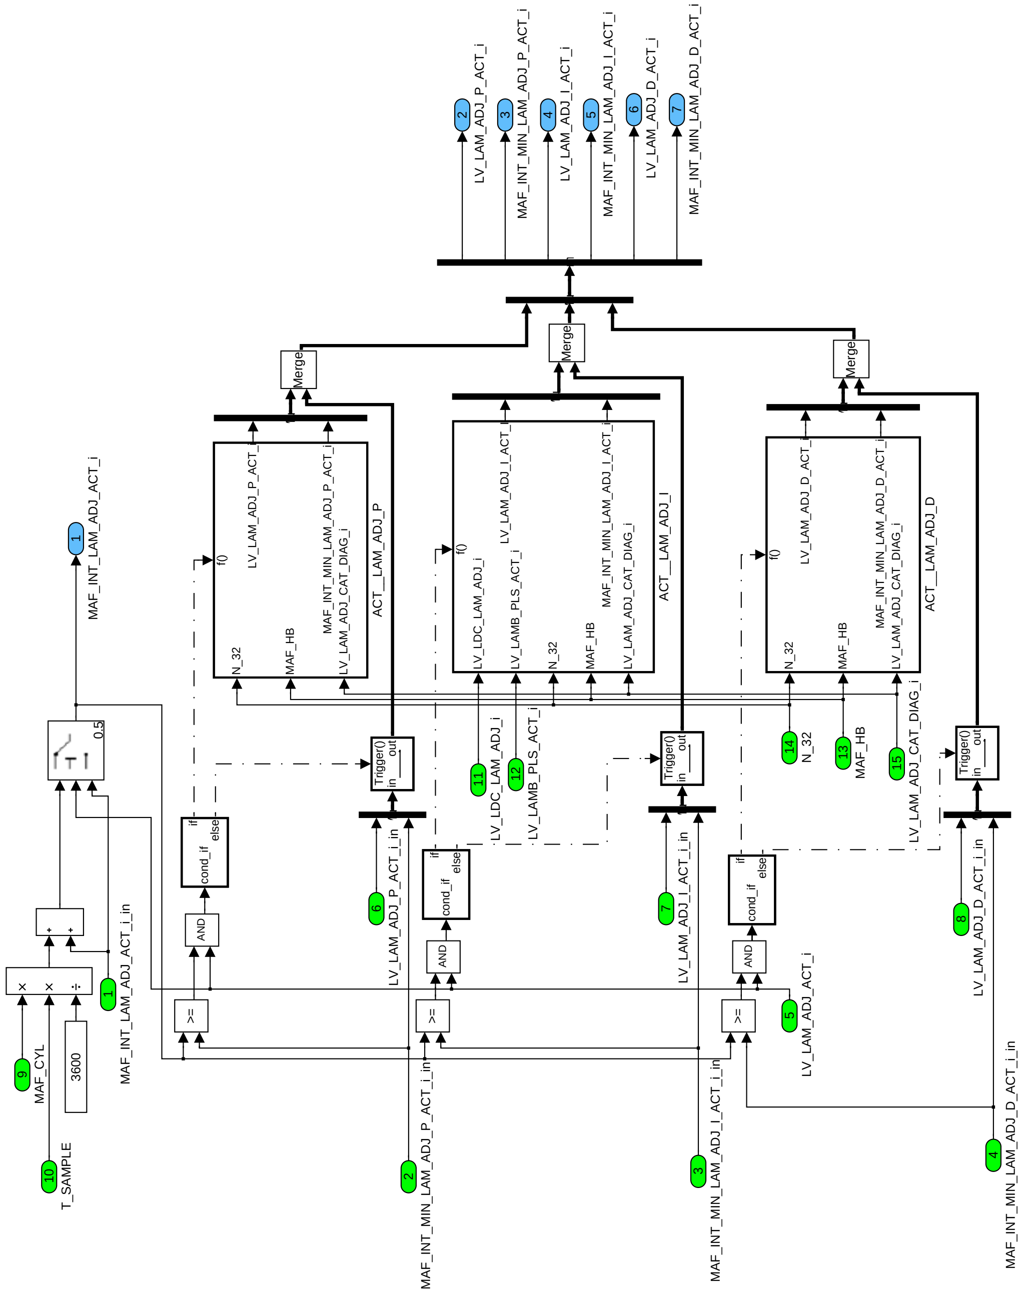

Figure 70 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ ACT__LAM_ADJ

Check D share activation conditions

The D share calculation gets active (indicated by LV_LAM_ADJ_D_ACT[i] – after the D share MAF integral threshold is exceeded - only in applied N and MAF areas and when the catalyst efficiency diagnosis is not active.

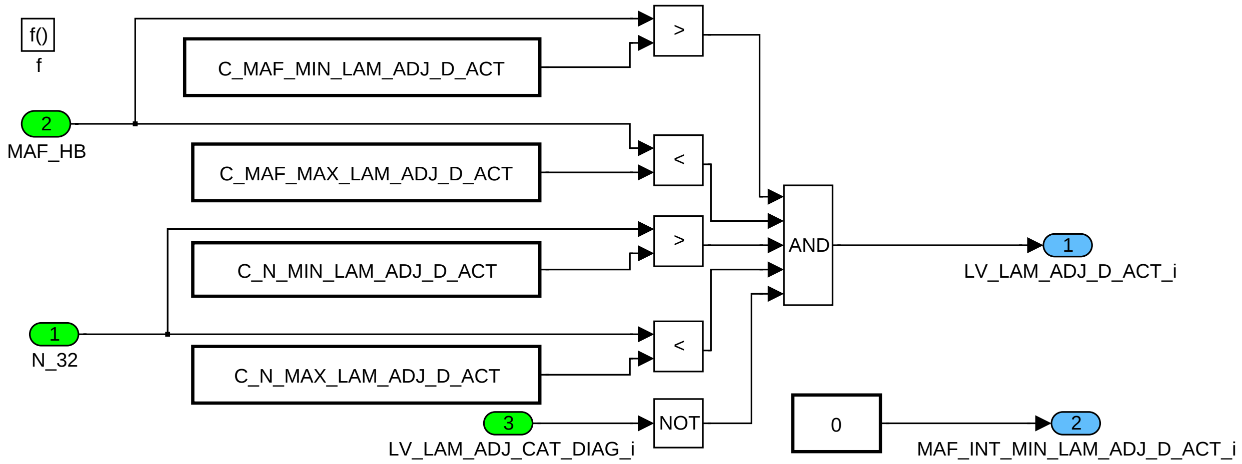

Figure 71 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ ACT__LAM_ADJ/ ACT__LAM_ADJ_D

Check I share activation conditions

The I share calculation gets active (indicated by LV_LAM_ADJ_I_ACT[i]) – after the I share MAF integral threshold is exceeded - in applied MAF areas when the limited dynamics conditions are fulfilled and when the forced lambda stimulation is active. Both latter conditions can be inhibited by means of calibration flags. During active cat efficiency diagnosis the I share is always active after exceeding the MAF integral threshold.

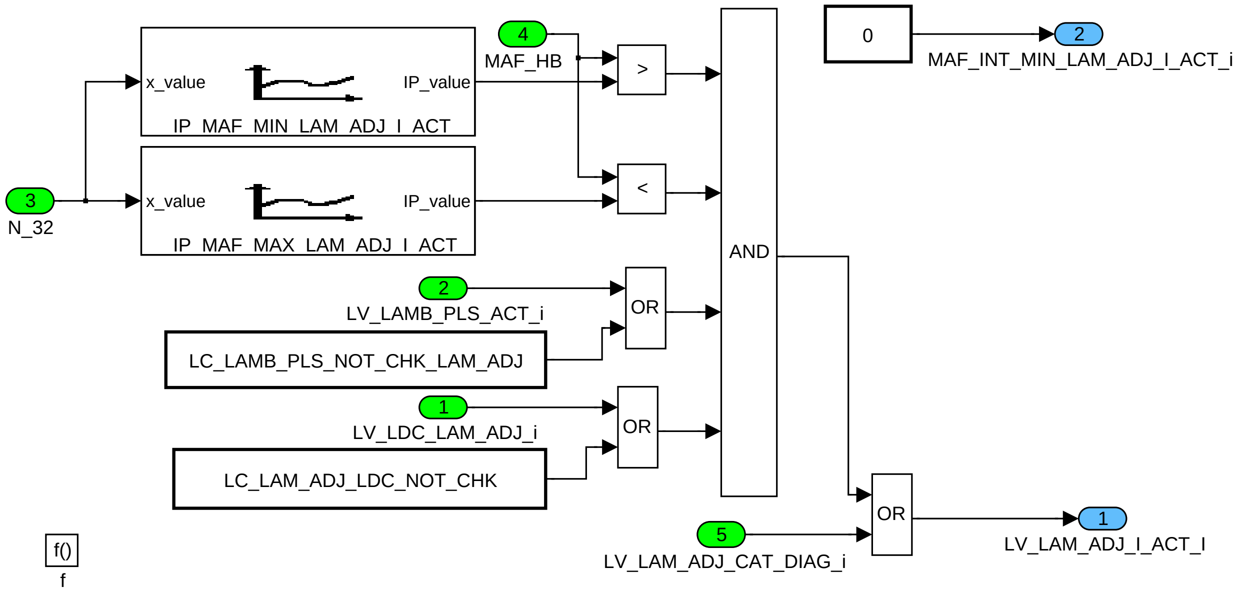

Figure 72 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ ACT__LAM_ADJ/ ACT__LAM_ADJ_I

Check P share activation conditions

The P share calculation gets active (indicated by LV_LAM_ADJ_P_ACT[i] – after the P share MAF integral threshold is exceeded - only in applied N and MAF areas or when catalyst efficiency diagnosis is active.

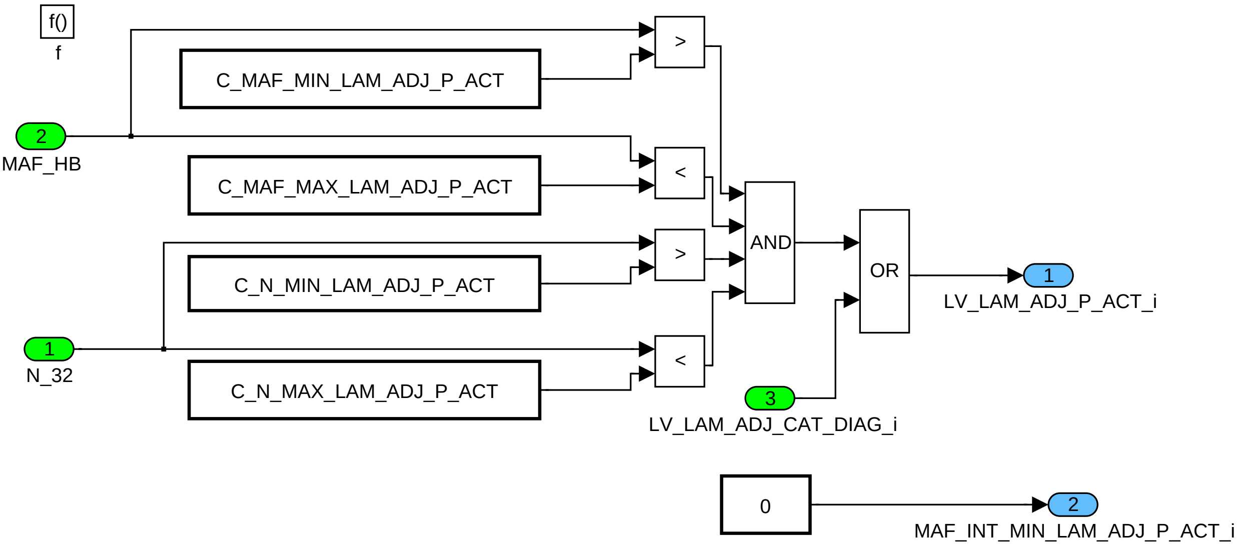

Figure 73 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ ACT__LAM_ADJ/ ACT__LAM_ADJ_P

Calculation of controller difference

The controller deviation is defined by the difference of the set point of the sensor output voltage IP_VLS_SP_LAM_ADJ[i] and the actual value VLS_AV_LAM_ADJ[i]. The setpoint can be shifted by IP_VLS_SP_DELTA_LAM_ADJ depending on catalyst ageing to take into account stringent NOx increase with catalyst ageing.

VLS_AV_LAM_ADJ[i] is calculated in the application incidences and can be directly the measured trim sensor signal or the filtered and shifted signal in case of Catalyst diagnosis (depending on project requirements). The actual value can also inlude an external adjustment.

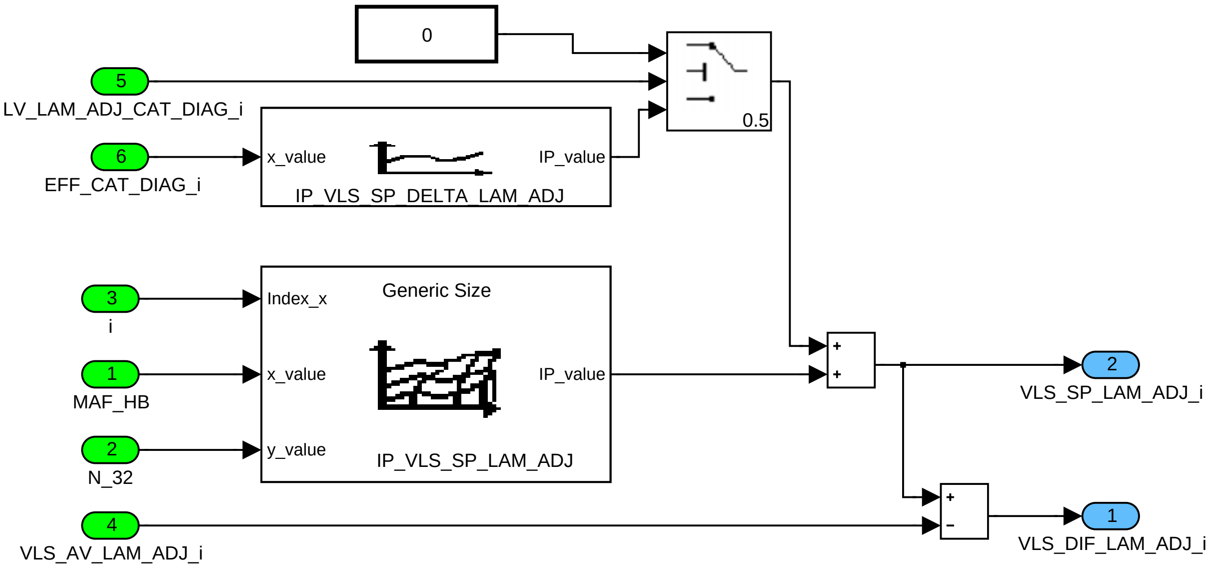

Figure 74 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__VLS_DIF

D share calculation

The D share is calculated when LV_LAM_ADJ_D_ACT[i] is 1. The D share is calculated by evaluating the voltage difference between the control difference and its moving mean value. The filter parameter for moving mean value is MAF_CYL and EFF_CAT_DIAG depending to take into account longer needed duration of D-share at low MAF_CYL and shorter due to OSC deterioring due to catalyst ageing This voltage difference is then input to a characteristic line IP_LAMB_DELTA_D_LAM_ADJ that is weighted by MAF_CYL and EFF_CAT_DIAG[i].

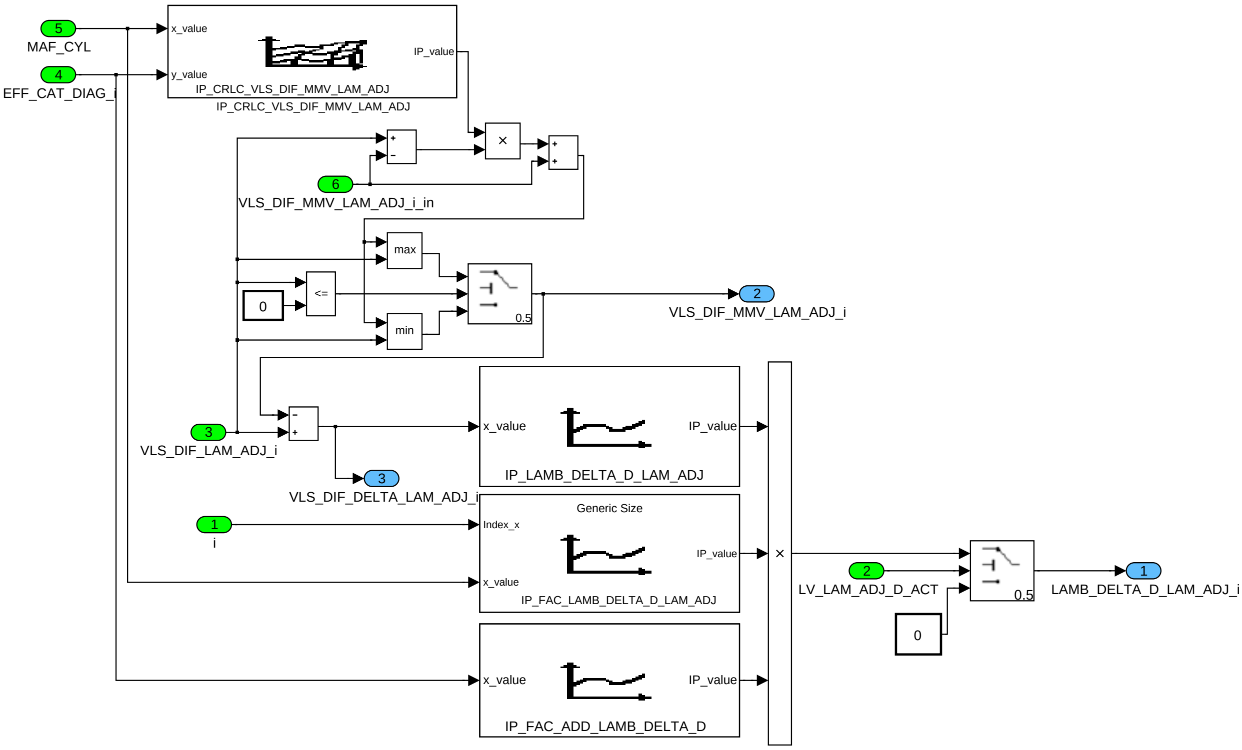

Figure 75 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_D

I share calculation management

The I share itself is calculated internally with a higher resolution than the output variable LAMB_DELTA_I_LAM_ADJ[i]. The variable LAMB_DELTA_I_IT_LAM_ADJ[i] is used. A limitation of calibration thresholds (C_LAMB_DELTA_I_MIN_LAM_ADJ and C_LAMB_DELTA_I_MAX_LAM_ADJ) is applied at the end of the calculation. Both variables are initialised with the adaptation value LAMB_DELTA_AD_LAM_ADJ[i].

The I share is only calculated when LV_LAM_ADJ_I_ACT[i] is 1. The calculation is the summation of IP_LAMB_DELTA_I_LAM_ADJ * IP_CRLC_LAMB_DELTA_I_LAM_ADJ. This latter map is for MAF_CYL weighting. If the I share is not calculated it remains fix.

A moving mean value of the I share LAMB_DELTA_I_MMV_LAM_ADJ[i] (needed for WRAF sensor characterisitc line adaptation) is calculated.

In case of active catalyst diagnosis and sensor dynamic diagnosis own parameters are applied (IP_LAMB_DELTA_I_LAM_ADJ_DIAG multiplied by IP_CRLC_LAMB_DELTA_I_LAM_ADJ) and the moving mean value of the I share is not calculated. When cat diagnosis gets active the I share is stored. It is written back to the corresponding variable at the end of the diagnosis only in case that LC_LAM_ADJ_I_SAVE_CAT_DIAG is set to 1.

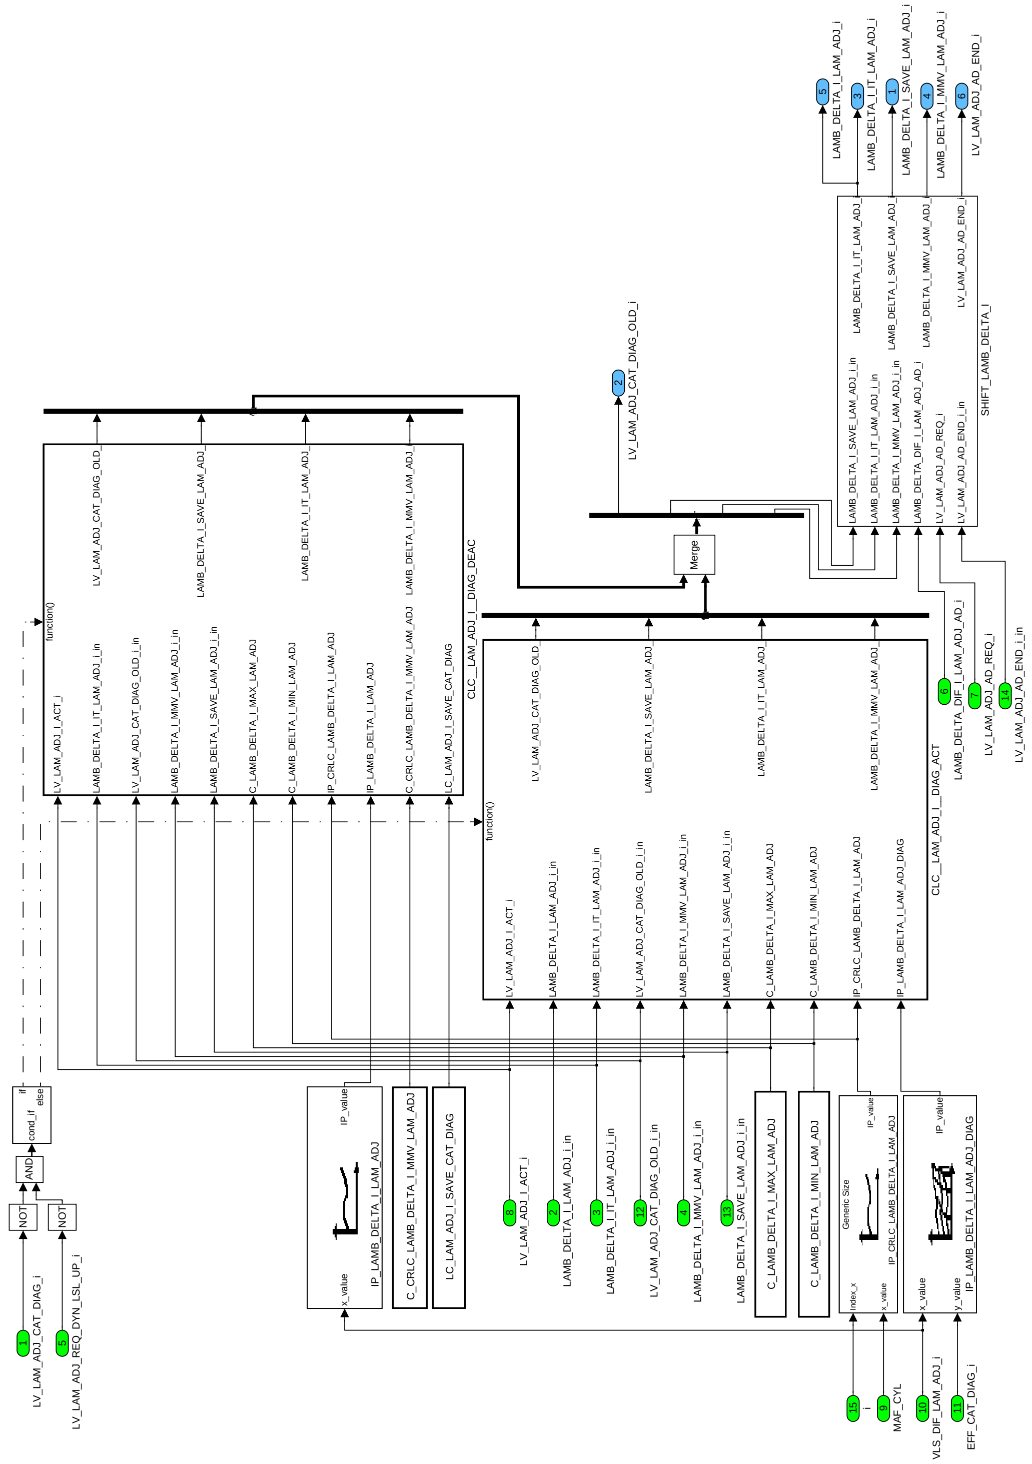

Figure 76 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_I

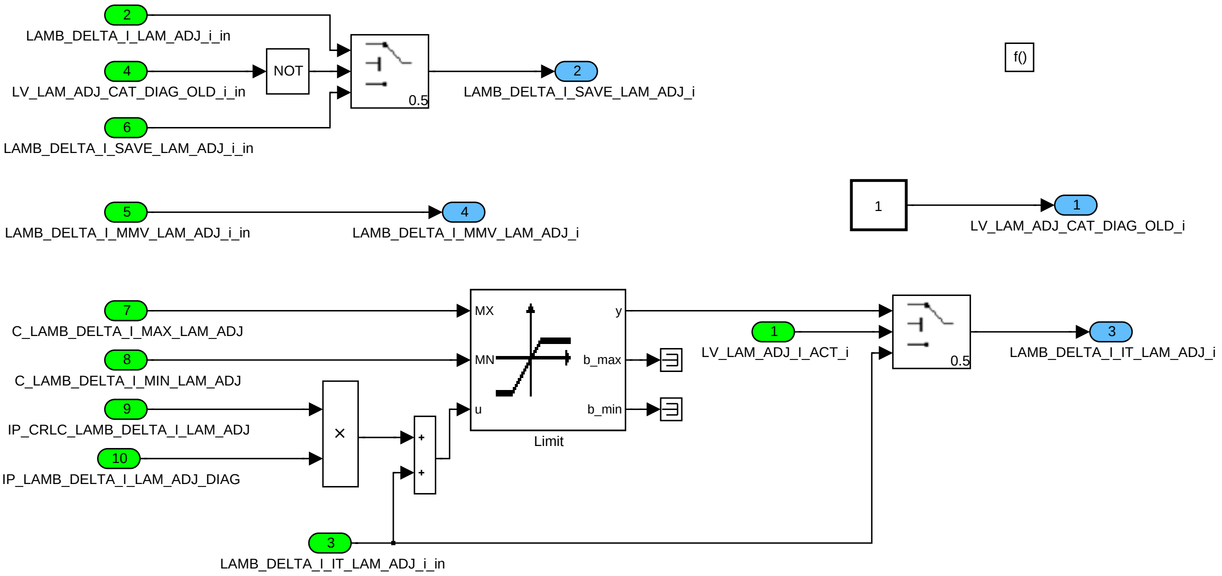

Figure 77 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_I/ CLC__LAM_ADJ_I__DIAG_ACT

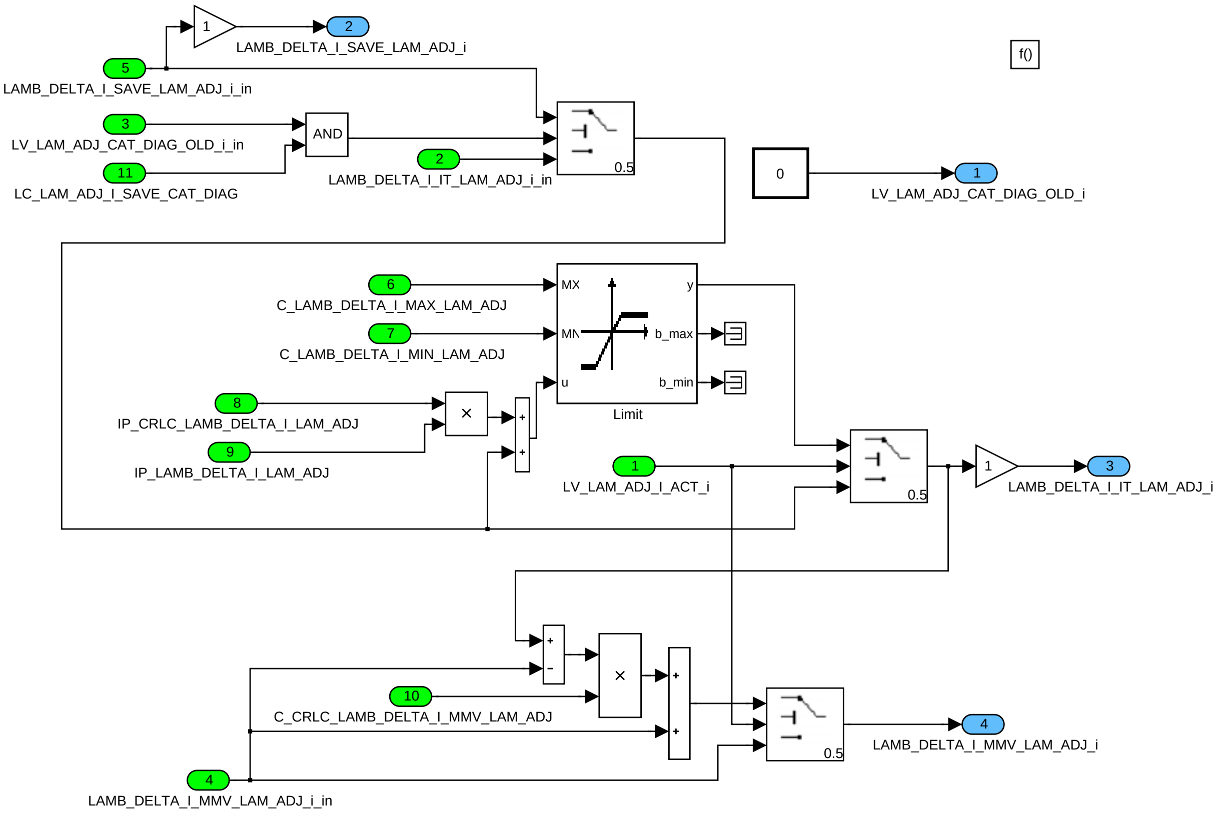

Figure 78 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_I/ CLC__LAM_ADJ_I__DIAG_DEAC

Shift of I share

When requested by the function “WRAF sensor characterisitc line adaptation” a shift of all I share components is applied. The adaptation value in the mentioned function executes an opposite shift.

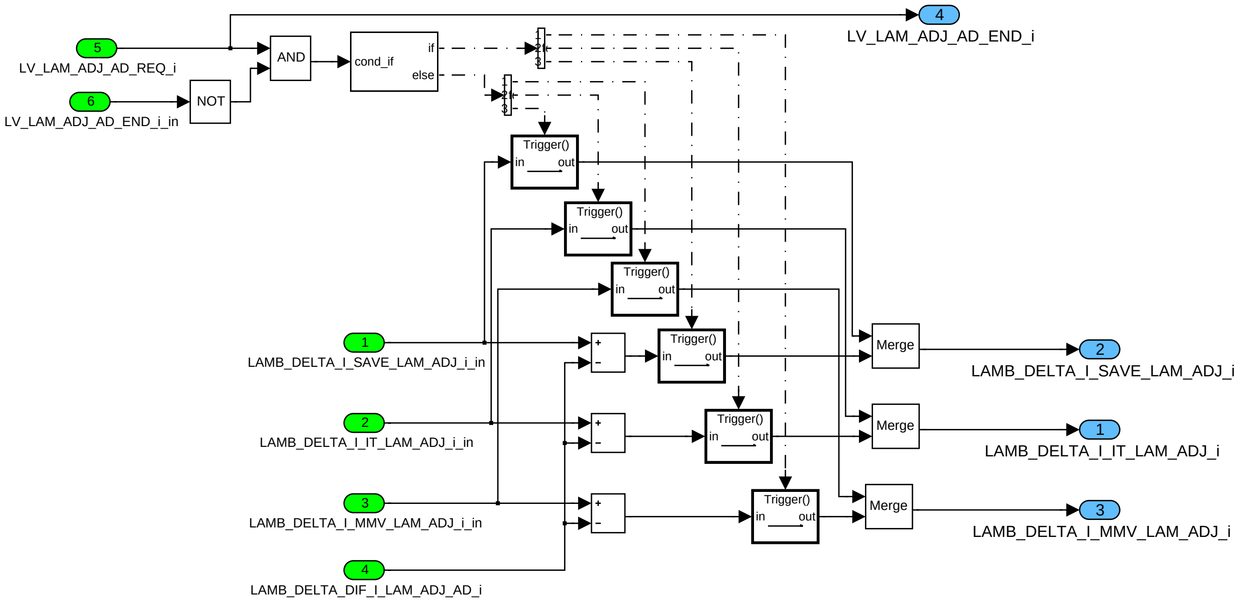

Figure 79 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_I/ SHIFT_LAMB_DELTA_I

P share calculation

The P share is calculated when LV_LAM_ADJ_P_ACT[i] is 1. Otherwise the P share is 0. In case of active catalyst diagnosis an own P share gain characteristic line is used.

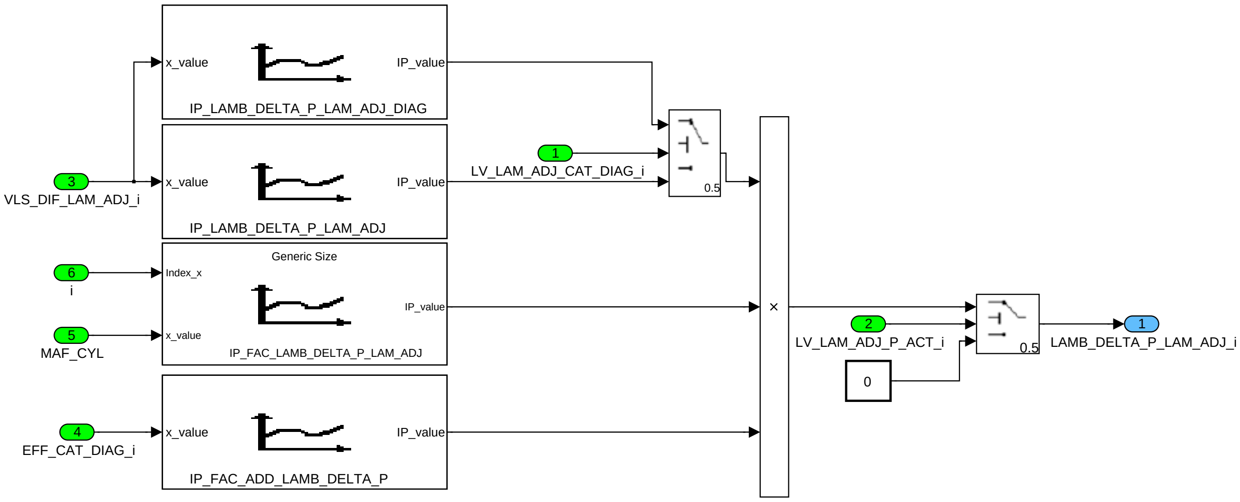

Figure 80 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_P

Calculation of total lambda shift

The total lambda shift LAMB_DELTA_LAM_ADJ[i] is calculated by adding P share, I share and D share.

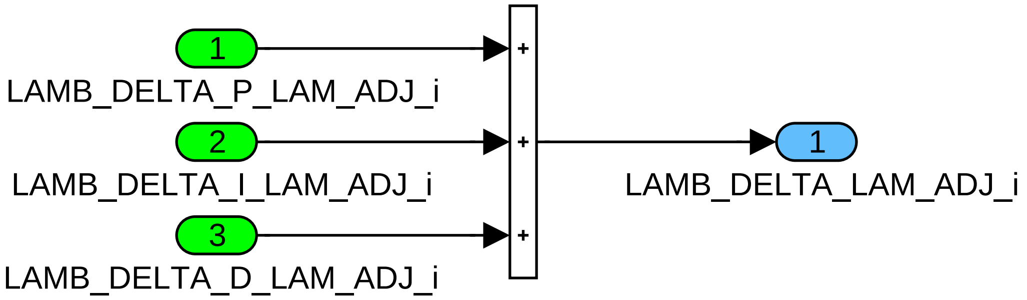

Figure 81 LACO_REQGNTRIM0/ operate/ LACO_REQGNTRIM0_CBK_MNG/ LACO_REQGNTRIM0_CBK_SPC/ CLC__LAM_ADJ_SHIFT

46.8.1 LACO_REQGNTRMAD0: General information

This function adapts the WRAF sensor characterisic line by observing the I share of the trim control function. A basic (load depending) lambda shift of the WRAF sensor can be corrected by means of an additional offset. This offset can change due to ageing of the sensor.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

46.8.1.1 SUBFUNCTION: OPERATE

Basic WRAF sensor characteristic line shift

By means of IP_LAMB_DELTA_BAS_LAM_ADJ[i] the basic sensor characteristic line shift is defined MAF and N dependent. In idle speed the calibration data C_LAMB_DELTA_BAS_LAM_ADJ_IS[i] is applied. Together with the adaptive correction LAMB_DELTA_AD_LAM_ADJ[i] (stored as non volatile data) the total shift LAMB_DELTA_SUM_LAM_ADJ_AD[i] is defined.

When the conditions for activating the adaptation are fulfilled the sub-system “AD_CDN_OK” is executed. Otherwise the sub-system “AD_CDN_NOT_OK” is called where no action is executed.

LACO_REQGNTRMAD0/operate/LACO_REQGNTRMAD0_CBK_MNG/LACO_REQGNTRMAD0_CBK_SPC

Adaptation of WRAF sensor characteristic line offset

The function waits a certain number of lean – rich air fuel ratio changes (C_NR_RAF_CHG_WAIT_LAM_ADJ) between 2 adaptation cycles. Then the current I share of the trim controller is shifted step by step into the adaptation value. Furthermore this latter value is limited on a calibration maximum and minimum.

46.9.1 LACO_REQGNTRCDN0

This function checks several conditions that must be fulfilled in order to start the WRAF sensor characteristic line adaption. These conditions shall define a stable state of the downstream sensor signal used by trim control.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Function Description

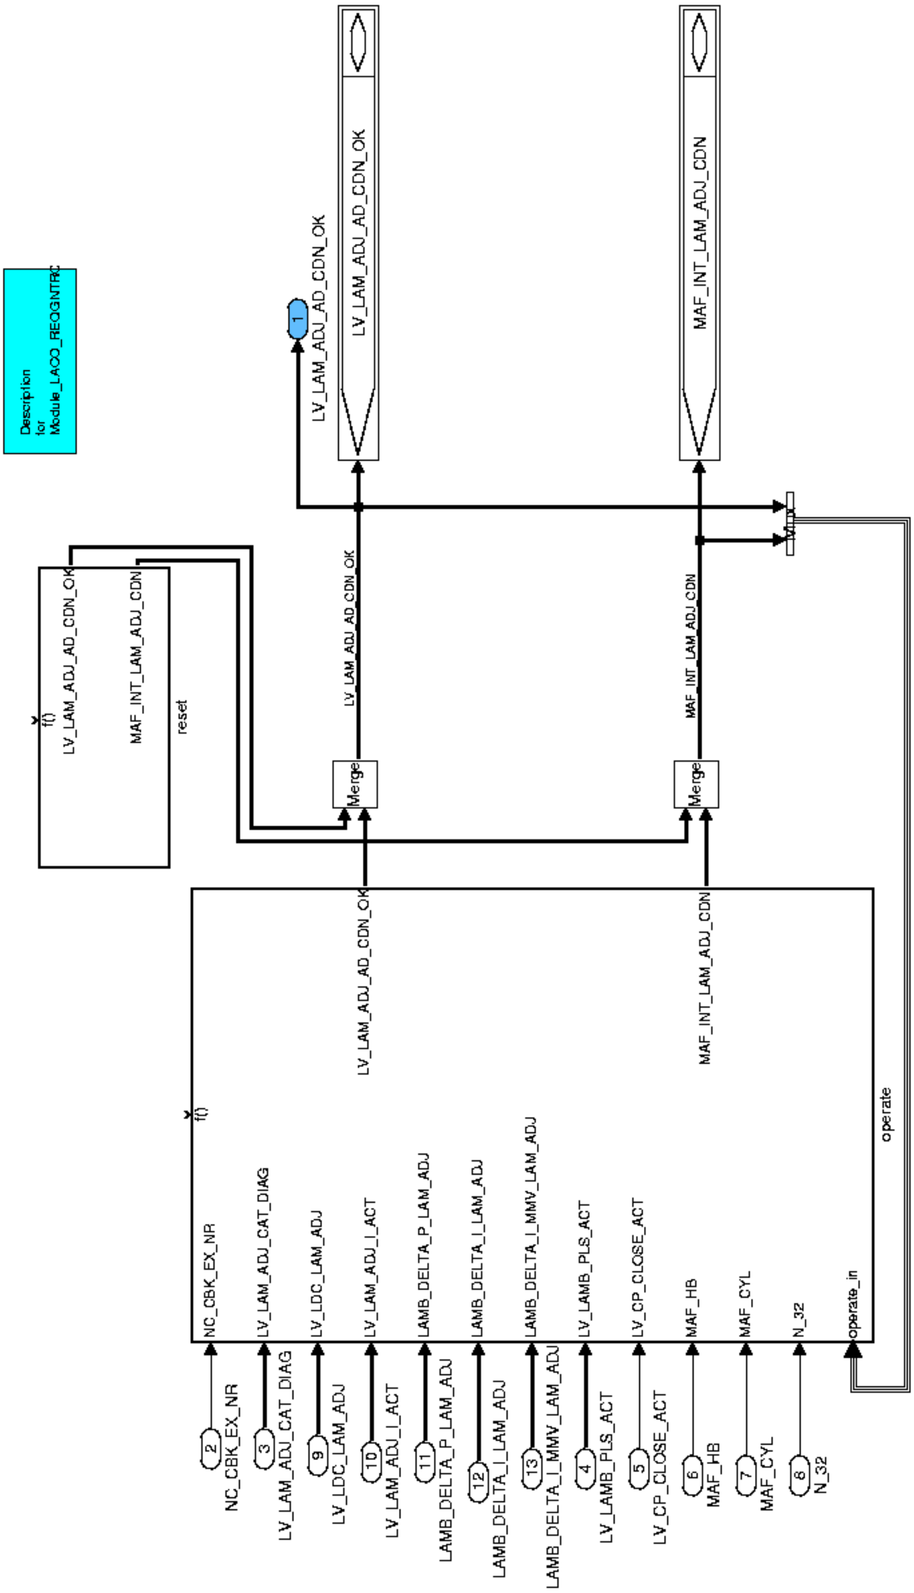

Figure 83 LACO_REQGNTRCDN0

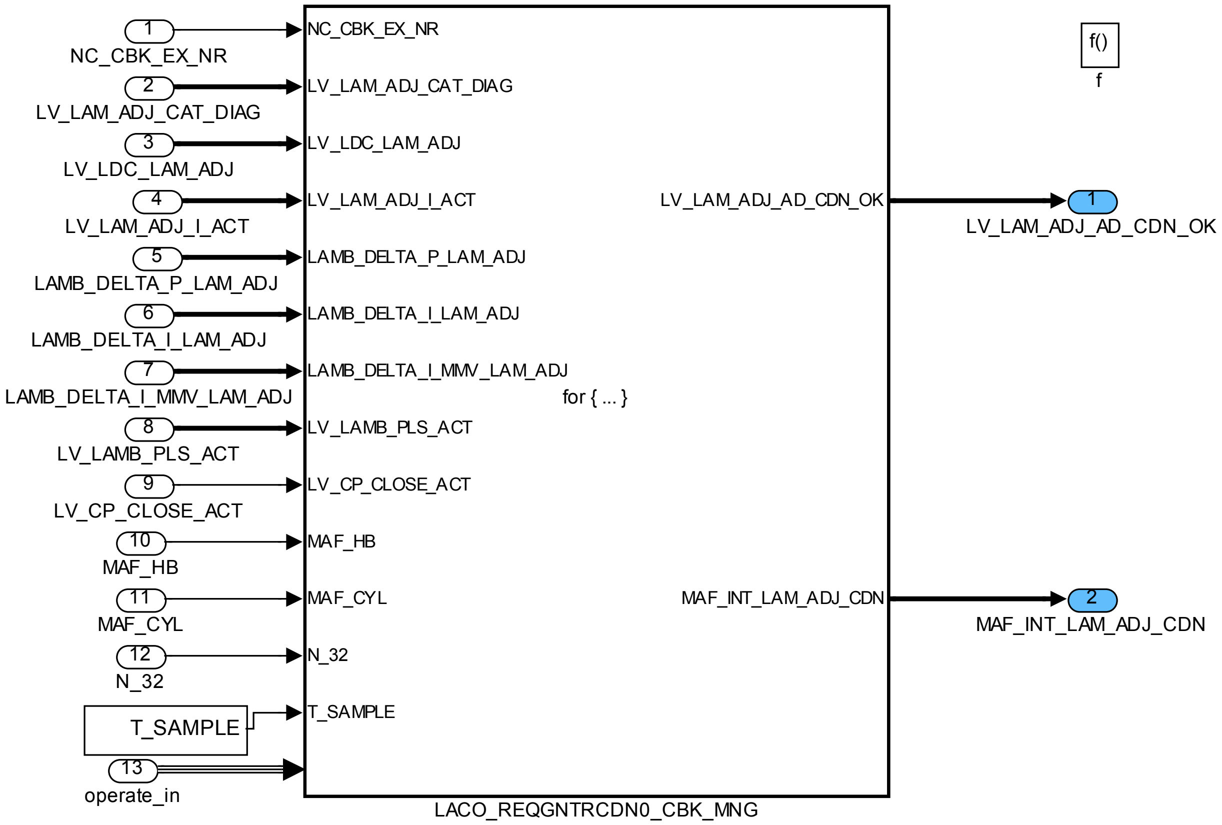

Figure 84 LACO_REQGNTRCDN0/ operate

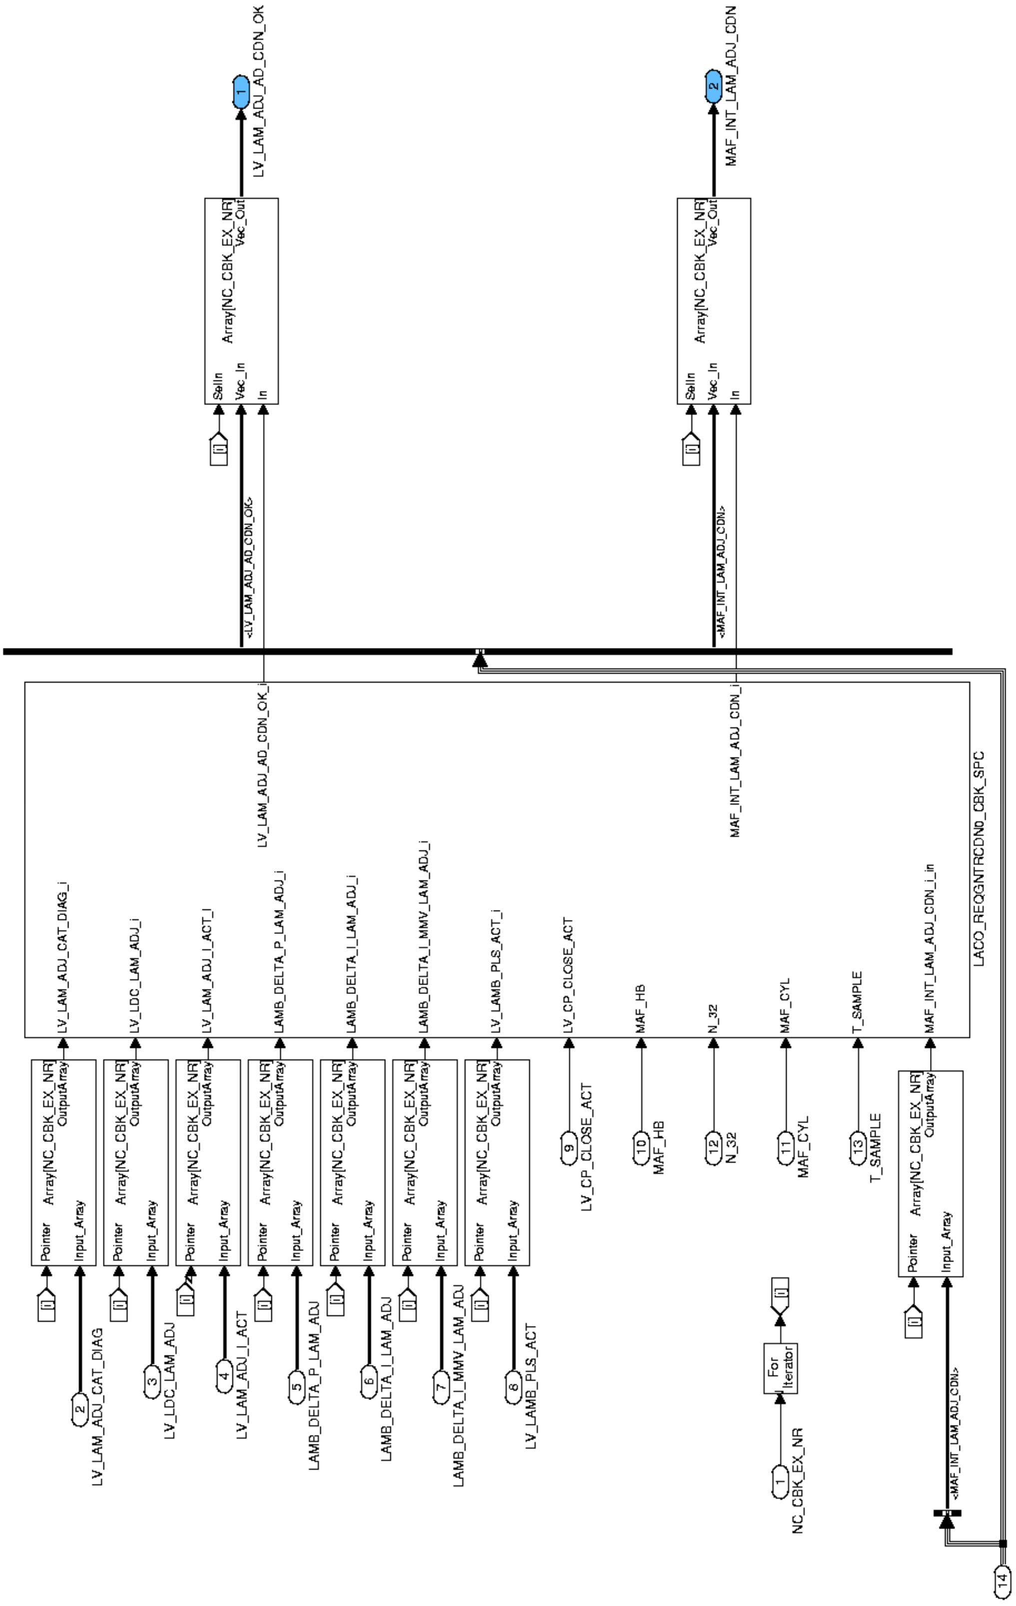

Figure 85 LACO_REQGNTRCDN0/ operate/ LACO_REQGNTRCDN0_CBK_MNG

Check conditions

If all the following conditions are fulfilled an air mass flow integral is calulated:

- Catalyst efficiency diangnosis not active

- limited dynamics (LV_LDC_LAM_ADJ[i]) are fulfilled
- I share of trim control is active
- forced lambda stimulation is active
- canister purge valve is closed
- air mass flow is in a valid range
- engine speed is in a valid range
- P share of trim contol must be very low (absolute value)
- I share of trim control must be stable
  (difference between I share and moving mean value must be small)

When the air mass flow integral exceeds a calibration threshold the flag LV_LAM_ADJ_AD_CDN_OK[i] indicating that the adaptation can be started is set.

For the calcuation of the air mass flow integral the unit conversion:

[g] = [kg/h] * [ms] * [(g*h) / (kg*ms)] / 3600

has to be considered.

FUNCTION DESCRIPTION:

General information:

There are many errors which make it necessary to stop the trim control when they occure.
The calculation shall be done for all exhaust cylinder banks.

For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then
i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,

otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Application conditions:

Initialisation: at ECU reset:

LV_INH_LAM_ADJ[i] = 1
LV_LAMB_DELTA_AD_LAM_ADJ_CLC[i] = 1
LV_LAMB_DELTA_I_LAM_ADJ_DEAC[i] = 1
VLS_AV_LAM_ADJ[i] = 0.649414 V
LV_LDC_LAM_ADJ[i] = 0
LV_LAMB_DELTA_AD_LAM_ADJ_EXT = 0

Recurrence: T_SAMPLE = 20 ms

Activation: in all engine operating states

Deactivation: -

FUNCTION DESCRIPTION:

General information:

For a two bank exhaust gas configuration the calculation of the limited dynamic condition LV_LDC_DLY[i] is calculated for each bank separately. To differentiate variables and calibration data the index i is used.

i = 1, for cylinder bank 1
i = 2, for cylinder bank 2

The limited dynamic conditions LV_LDC_DLY[i] for dynamic fuel trim is detected if engine speed, mass air flow, FAC_LAM_MV[i] and the factor torque request gradient are within the correspondent dynamic window. Once this condition is met, an integral of the air flow is incremented until the calibrated threshold exceeds. After this point the flag LV_LDC_DLY[i] is set to indicate the trim controller, that the engine is running under limited dynamic conditions.

Application conditions:

Initialisation: *at reset:*
LV_LDC_DLY[i] = 0
MAF_INT_LDC_DLY[i] = 0

Recurrence: 20ms

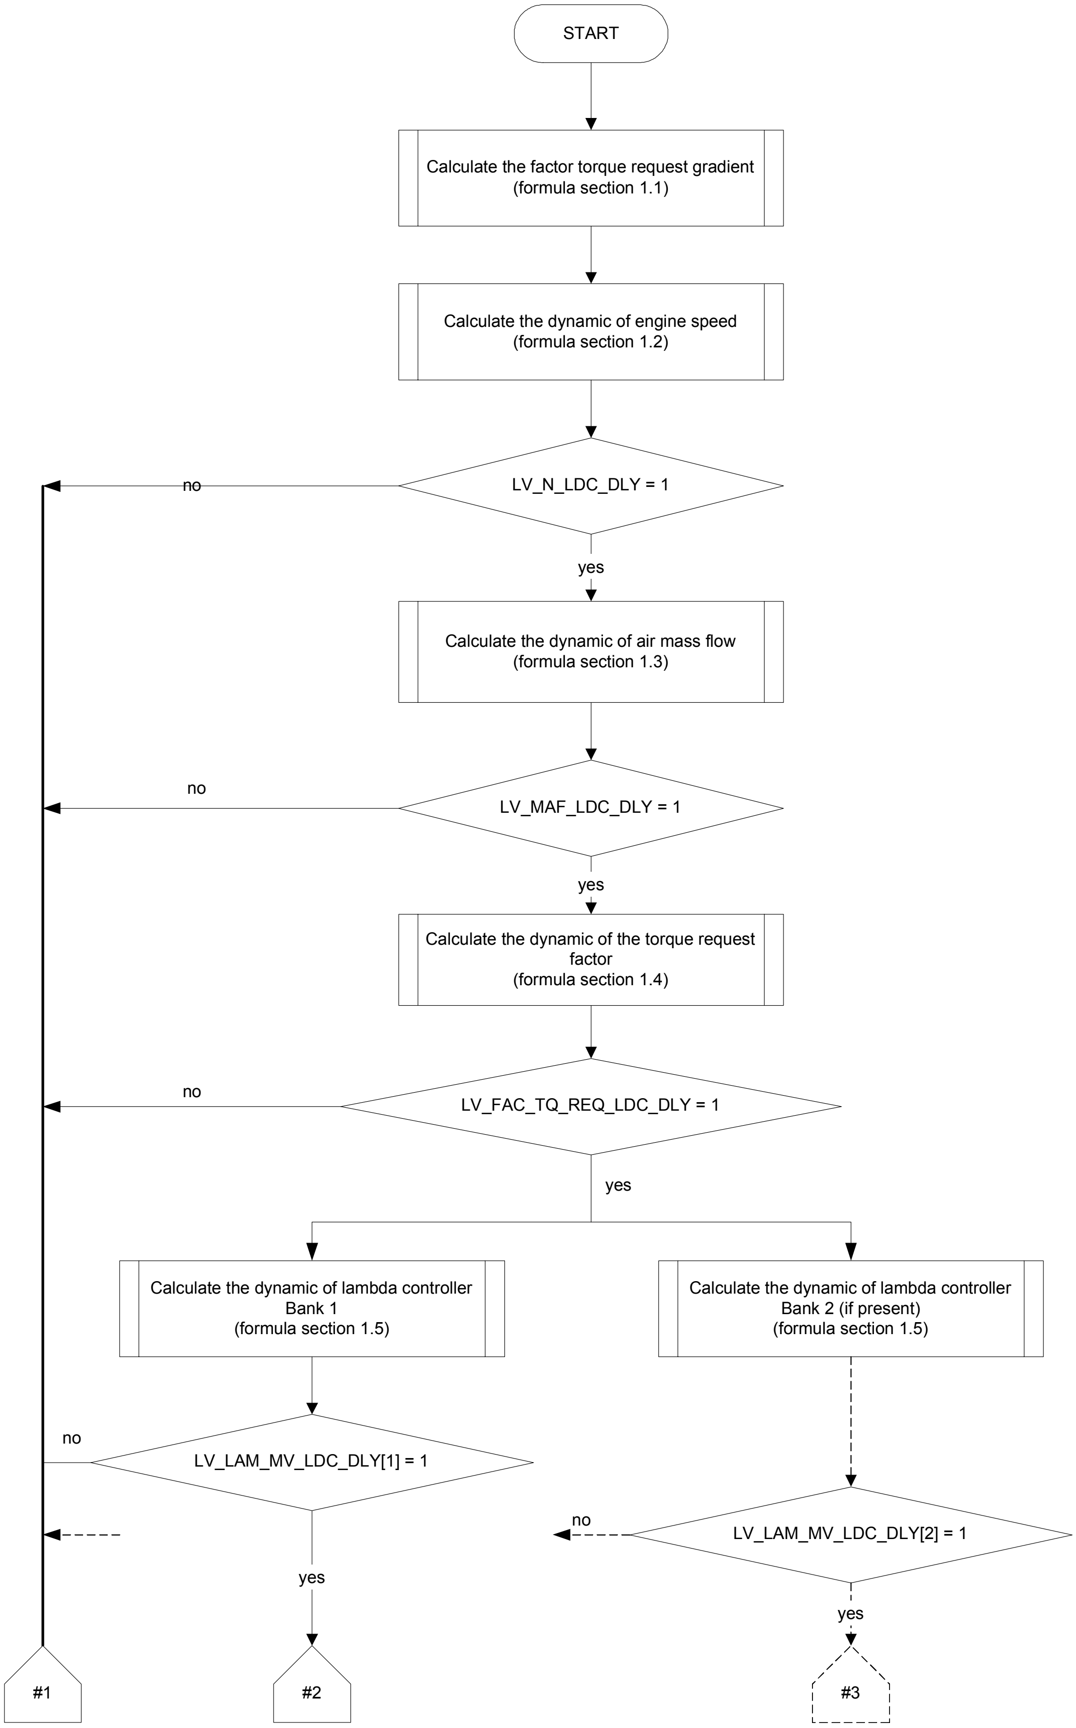
Activation: LV_VAR_LSH_UP = 1 **and** LV_ST_END = 1 **and** LV_IGK = 1

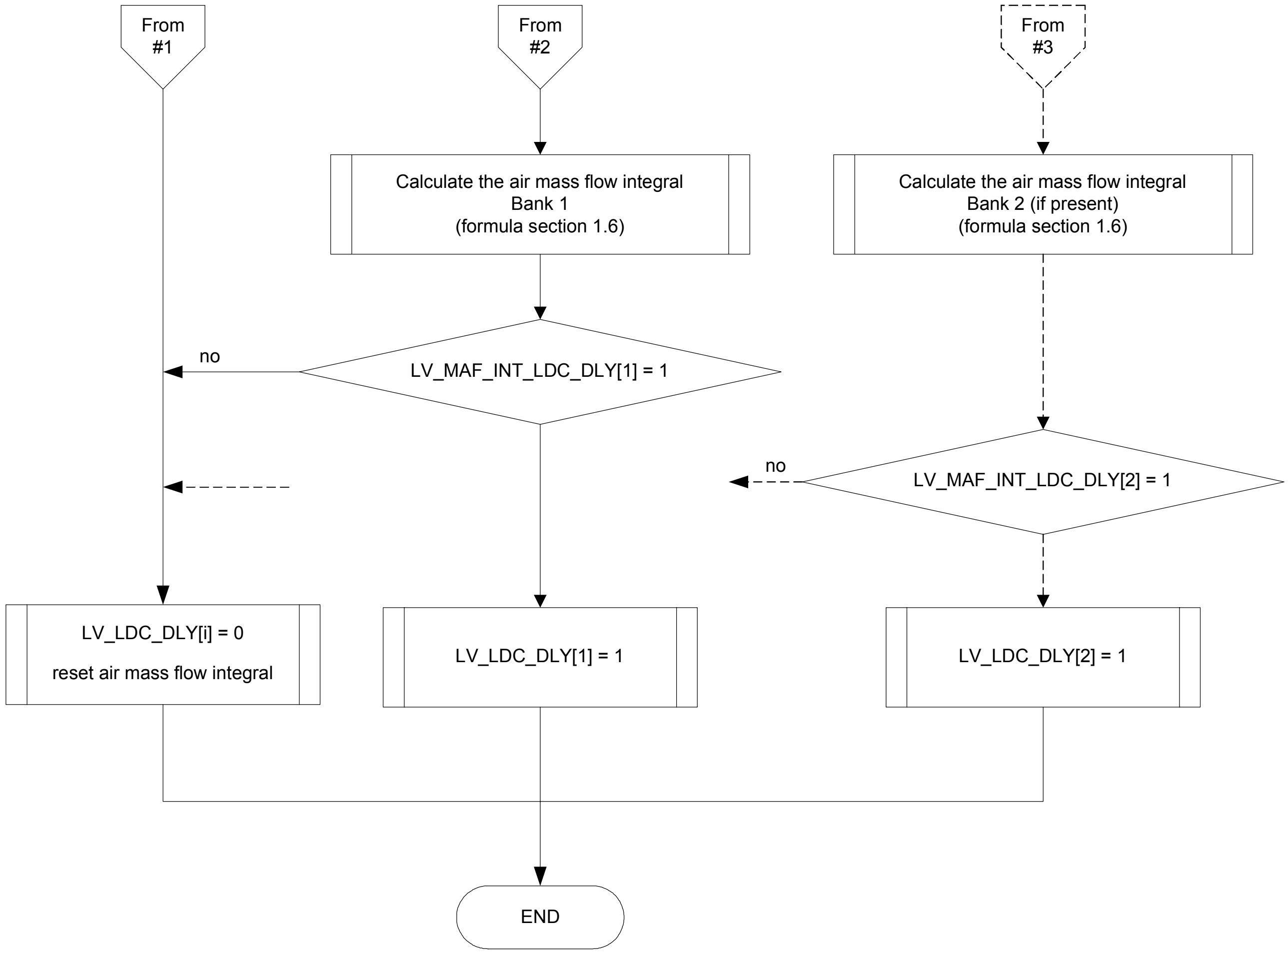
Deactivation: LV_VAR_LSH_UP = 0 **or** LV_ST_END = 0 **or** LV_IGK = 0

Initialisation at deactivation:
LV_LDC_DLY[i] = 0
LV_N_LDC_DLY = 0
LV_MAF_LDC_DLY = 0
MAF_INT_LDC_DLY[i] = 0
N_MMV_DLY = N
MAF_MMV_DLY = MAF
FAC_LAM_MV_MMV_DLY[i] = FAC_LAM_MV[i]
FAC_TQ_REQ_GRD_SUM_DLY = 0

All ring buffer registers shall be initialized with the same value, namely the value of FAC_TQ_REQ at the moment of activation.

Signal flow diagram:





Formula section:

46.11.1 Calculation of the factor torque request gradient FAC_TQ_REQ_GRD

At every recurrence the variable FAC_TQ_REQ shall be written into a ring buffer containing the last four FAC_TQ_REQ values. The gradient of FAC_TQ_REQ (FAC_TQ_REQ_GRD) is calculated based on the FAC_TQ_REQ difference between the values contained in the first and last position of the ring buffer.

46.11.2 Limited engine speed (N) dynamics

The floating mean value N_MMV_DLY is computed using the averaging constant C_N_CRLC_DLY. The limited dynamics condition only exist while the engine speed N lies within the dynamics window around N_MMV_DLY.
If the above limited dynamics condition is violated, the floating mean value N_MMV_DLY is set to the current engine speed in order to reach the limited dynamics condition faster:

N_MMV_DLY = N_MMV_DLY * (1 - C_N_CRLC_DLY) + C_N_CRLC_DLY * N

```
IF | N - N_MMV_DLY | < C_N_DYW_DLY
  THEN    LV_N_LDC_DLY = 1
  ELSE    LV_N_LDC_DLY = 0
```

```
        N_MMV_DLY = N
ENDIF
```

46.11.3 Limited mass air flow (MAF) dynamics

The floating mean value MAF_MMV_DLY is computed using the averaging constant C_MAF_CRLC_DLY. The limited dynamics condition only exist while the air mass MAF stays within the dynamics window around MAF_MMV_DLY.
If the above limited dynamics condition is violated, the floating mean value MAF_MMV_DLY is set to the current air-mass value in order to reach the limited dynamics condition faster:

```
IF LV_N_LDC_DLY = 1
THEN
    MAF_MMV_DLY = MAF_MMV_DLY * (1 - C_MAF_CRLC_DLY) +
                            C_MAF_CRLC_DLY * MAF

    IF | MAF - MAF_MMV_DLY | < C_MAF_DYW_DLY
      THEN        LV_MAF_LDC_DLY = 1
      ELSE        LV_MAF_LDC_DLY = 0
                  MAF_MMV_DLY = MAF
    ENDIF
ELSE
    MAF_MMV_DLY = MAF
    LV_MAF_LDC_DLY = 0
    LV_LDC_DLY[i] = 0
    MAF_INT_LDC_DLY[i] =  0
ENDIF
```

46.11.4 Limited requested torque factor gradient (FAC_TQ_REQ_GRD) dynamics

The FAC_TQ_REQ_GRD reflects the dynamic of the actual driver's demand prior to the corrections and is calculated with the recurence T_SAMPLE in [ms].

If C_FAC_TQ_REQ_GRD_SUM_MIN is larger than C_FAC_TQ_REQ_GRD_SUM_MAX the FAC_TQ_REQ gradient summation FAC_TQ_REQ_GRD_SUM_LDC_DLY will be no condition to determine the limited dynamic bit LV_LDC_DLY[i].

```
IF(3) LV_MAF_LDC_DLY = 1

THEN(3)

    IF(3a)   |FAC_TQ_REQ_GRD| ≥ C_FAC_TQ_REQ_GRD_MIN_LDC_DLY
    THEN(3a)       FAC_TQ_REQ_GRD_SUM_DLY$_{n+1}$ = FAC_TQ_REQ_GRD_SUM_DLY$_{n}$
                                                   +  |FAC_TQ_REQ_GRD|
                % Incrementation of FAC_TQ_REQ_GRD_SUM_DLY if FAC_TQ_REQ_GRD exceeds a threshold
    ENDIF(3a)

    T_FAC_TQ_REQ_GRD_SUM_DLY$_{n}$  =
                                T_FAC_TQ_REQ_GRD_SUM_DLY$_{n-1}$ + 1

    IF(3b)  T_FAC_TQ_REQ_GRD_SUM_DLY ≥
                            C_T_FAC_TQ_REQ_GRD_SUM_DLY
    THEN(3b)
```

```
            FAC_TQ_REQ_GRD_SUM_DLY$_n$   =   FAC_TQ_REQ_GRD_SUM_DLY$_{n-1}$ –
                                                 C_FAC_TQ_REQ_GRD_DEC_DLY
              % The decrementation by C_FAC_TQ_REQ_GRD_DEC_DLY is done every
              % C_T_FAC_TQ_REQ_GRD_SUM_DLY intervalls

```

46.11.5 Limited mean lambda controller output (FAC_LAM_MV[i]) dynamics

The floating mean value of the mean lambda controller output FAC_LAM_MV_MMV_DLY[i] is computed by using the averaging constant C_FAC_LAM_MV_CRLC_DLY. The limited dynamics condition is present while FAC_LAM_MV[i] stays within the dynamics window around FAC_LAM_MV_MMV_DLY[i]. If this condition violated, the correspondent flag is reset indicating a dynamic condition is present and the floating mean value FAC_LAM_MV_MMV_DLY[i] is set to the current value in order to reach the limited dynamics condition faster.

```
IF LV_FAC_TQ_REQ_LDC_DLY   =   1
THEN
    FAC_LAM_MV_MMV_DLY[i]  =
        FAC_LAM_MV_MMV_DLY[i] * (1 - C_LAM_MV_CRLC_DLY) +
                                  C_LAM_MV_CRLC_DLY * FAC_LAM_MV[i]

    IF | FAC_LAM_MV[i] - FAC_LAM_MV_MMV_DLY[i] | < C_LAM_MV_DYW_DLY

    THEN  LV_LAM_MV_LDC_DLY[i] = 1
```

```
        ELSE   LV_LAM_MV_LDC_DLY[i] = 0
               FAC_LAM_MV_MMV_DLY[i]  = FAC_LAM_MV[i]
        ENDIF
    ELSE
        FAC_LAM_MV_MMV_DLY[i]  = FAC_LAM_MV[i]
        LV_LAM_MV_LDC_DLY[i] = 0
        LV_LDC_DLY[i] = 0
        MAF_INT_LDC_DLY[i] =  0
    ENDIF
```

46.11.6 Calculation of mass air flow integral

```
    IF LV_LAM_MV_LDC_DLY[i] = 1

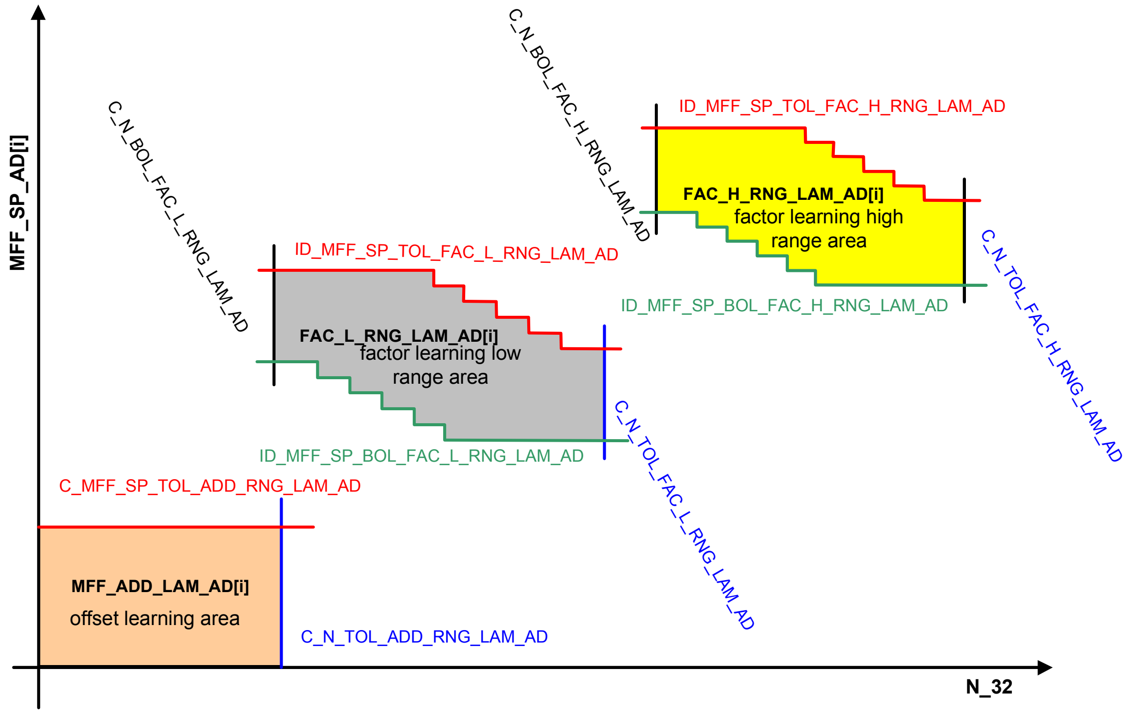
46.12.1 General Information

In order to compensate serial production tolerances of components, an adaptive correction is calculated (one additive and two multiplicative) based on the filtered lambda controller output.

The additive and multiplicative adaptation corrections are used for calculating the injection time for all engine operating states, except at ‘engine stop’ and ‘engine start’.

Lambda adaptation, for precision reason, needs to be performed at lambda equal 1 conditions. The function itself is activated by the corresponding LV_LAM_AD_ACT[i].

Depending on load and engine speed three different adaptation fields (one offset and two factor areas) are observed.



Adaptation field diagram

According to project philosophy homogeneous mode and suitable conditions can be forced by setting:

- LC_MFF_ADD_RNG_AFS_REQ_LAM_AD,
- LC_FAC_L_RNG_AFS_REQ_LAM_AD and / or
- LC_FAC_H_RNG_AFS_REQ_LAM_AD.

Furthermore this function is used by the lambda adaptation in warm-up phase to provide an unique interface to lambda controller and fuel mass set point calculation.

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Non-Volatile Memory Data

MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i], FAC_H_RNG_LAM_AD[i] and FAC_MFF_ADD_FAC_LAM_AD[i] are stored in the NVMY (at the end of PWL phase) and read out at ECU reset.

If the ECU is brand new or in case of EEPROM error these data are set to the default value 0.

Furthermore the variables MFF_ADD_LAM_AD_TMP[i], FAC_L_RNG_LAM_AD_TMP[i] and FAC_H_RNG_LAM_AD_TMP[i] are used to store the initial values of MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i] and FAC_H_RNG_LAM_AD[i] during the whole driving cycle for potential use.

If the low range or the high adaptation value is zero indicating that the adaptation value was not yet learned since the last reset of the NVMY data, LV_FAC_L_RNG_LAM_AD_INI[i] respectively LV_FAC_H_RNG_LAM_AD_INI[i] are set to one.

46.12.1.2 Formula Section

The main functionality is executed by means of a FOR loop over the number of exhaust banks. Only the determination of the priority information for the priority manager between canister purge and lambda adaptation is independent of the number of exhaust banks and executed after the FOR loop.

For Loop over Number of Exhaust Banks

Initialization of FOR Loop

Set Variables

Before executing the for loop variables are initialized.

State Machine Management and State Independent Calculations

Manage Lambda Adaptation State Machine

Determine Calibration Values Used inside State Machine

The calibration data used to determine the current adaptation field are evaluated.

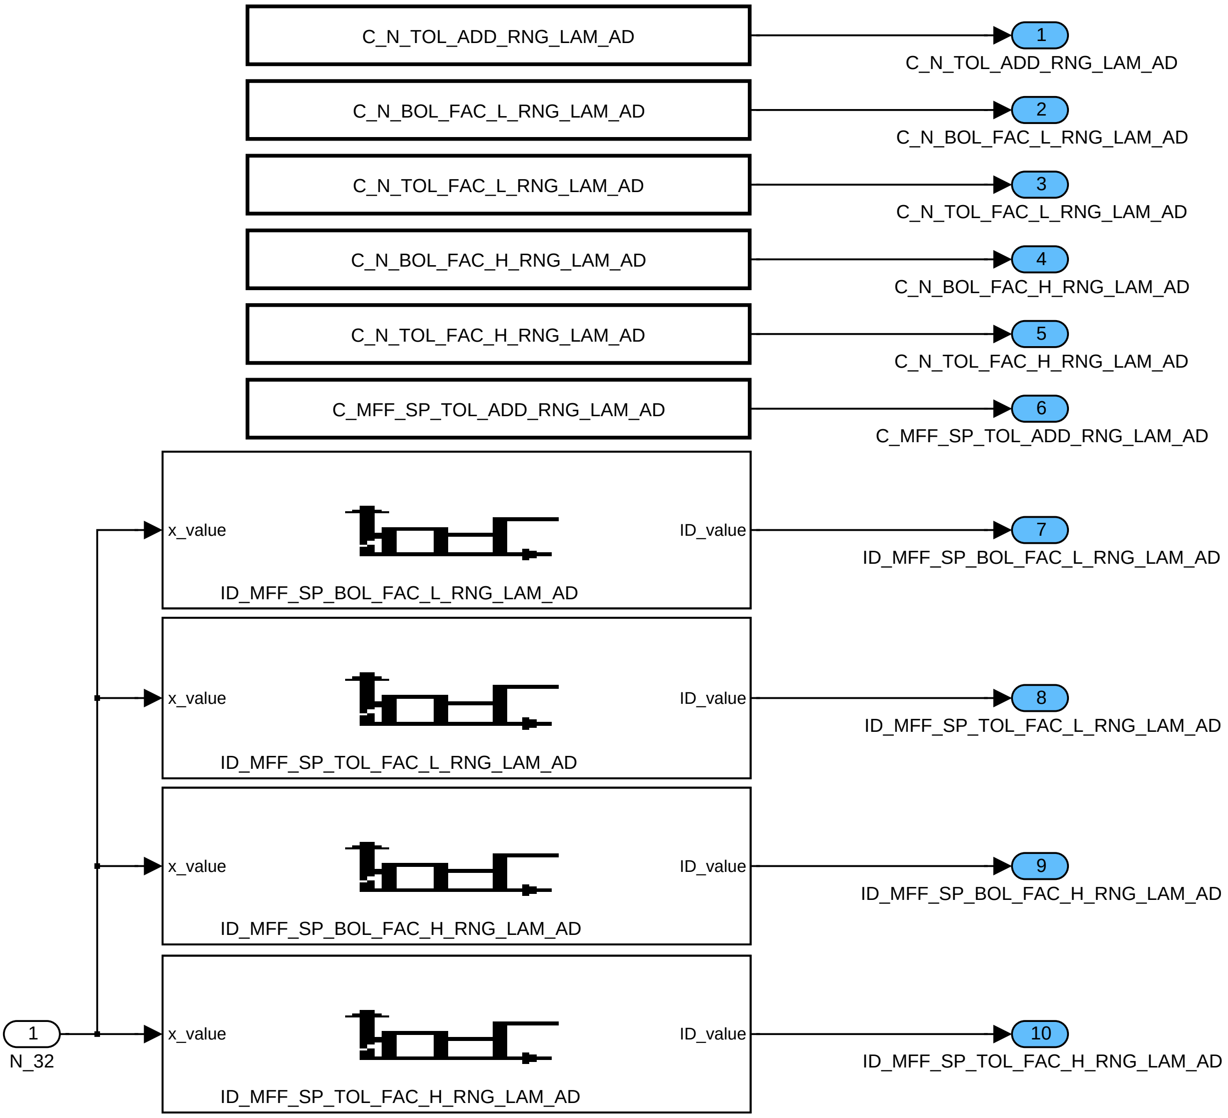

Figure 91 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ DET_STATE_LAM_AD/ SET_CAL_VALUE

State Machine

If the lambda adaptation is not active the state INIT is applied.

If the engine is not running in one of the adaptation fields the state WAIT is applied.

Depending on fuel mass flow and engine speed limits the respective states are entered.

If the respective condition bit LV_LAM_AD_CDN_ADD; LV_LAM_AD_CDN_L_RNG or LV_LAM_AD_CDN_H_RNG is set, the adaptation state ADAPT_ADD, ADAPT_FAC_L or ADAPT_FAC_H is applied. Otherwise one of the condition states is applied (CDN_ADD, CDN_FAC_L or CDN_FAC_H).

Furthermore at each transition to one of the adaptation sates the counter CTR_RAF_CHG_LAM_AD[i] is set to 0.

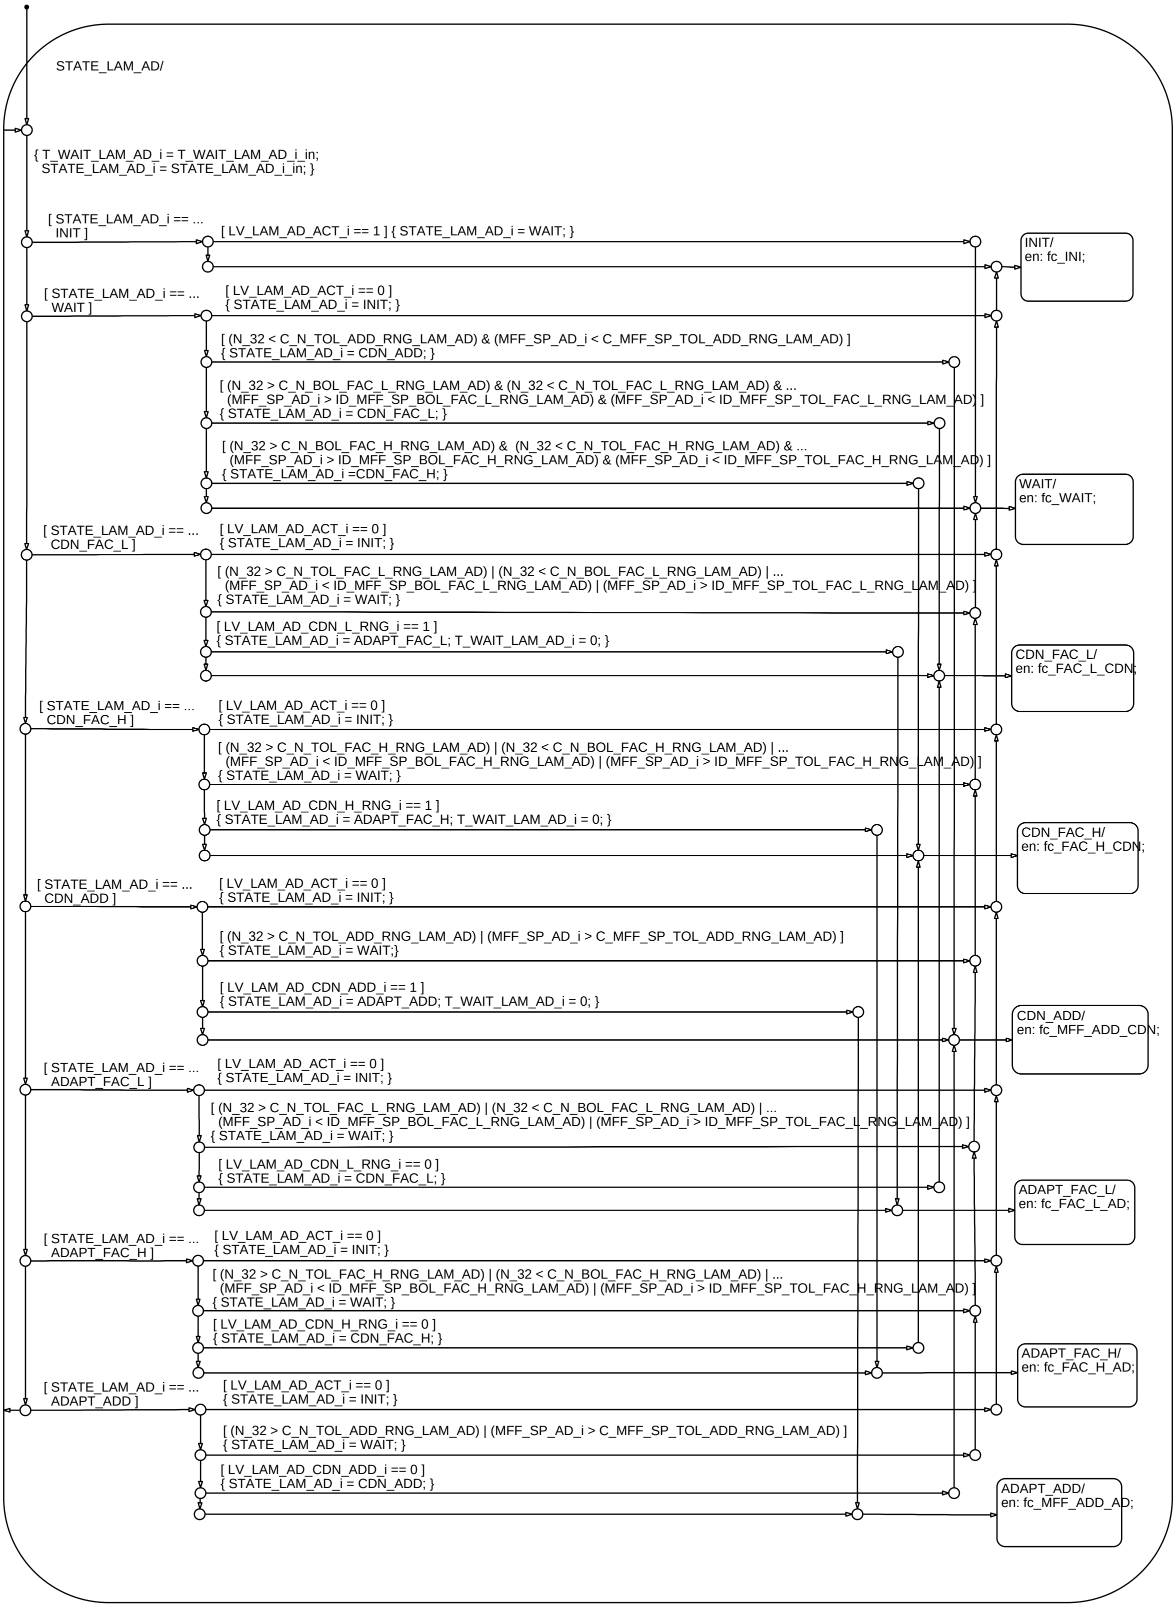

Figure 92 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ DET_STATE_LAM_AD/ STATE_LAM_AD/ STATE_LAM_AD

State Actions

The following flags are set in any state.

LV_LAM_AD_CDN is indicating that the conditions for adaptation are fulfilled (used by priority manager between canister purge and lambda adaptation).

LV_LAM_AD_END sets the temporary end of lambda adaptation (to indicate to the priority manager that the priority for lambda adaptation is low).

LV_LAM_AD_AFS_REQ (if set to 1) requests stoichiometric mixture.

LV_MFF_ADD_RNG_LAM_AD[i], LV_FAC_L_RNG_LAM_AD[i] and LV_FAC_H_RNG_LAM_AD[i] are indicating that the lambda adaptation is active and running in the respective adaptation field.

State “INIT”

Set Variables

The general flags are set to 0. All other variables remain unchanged.

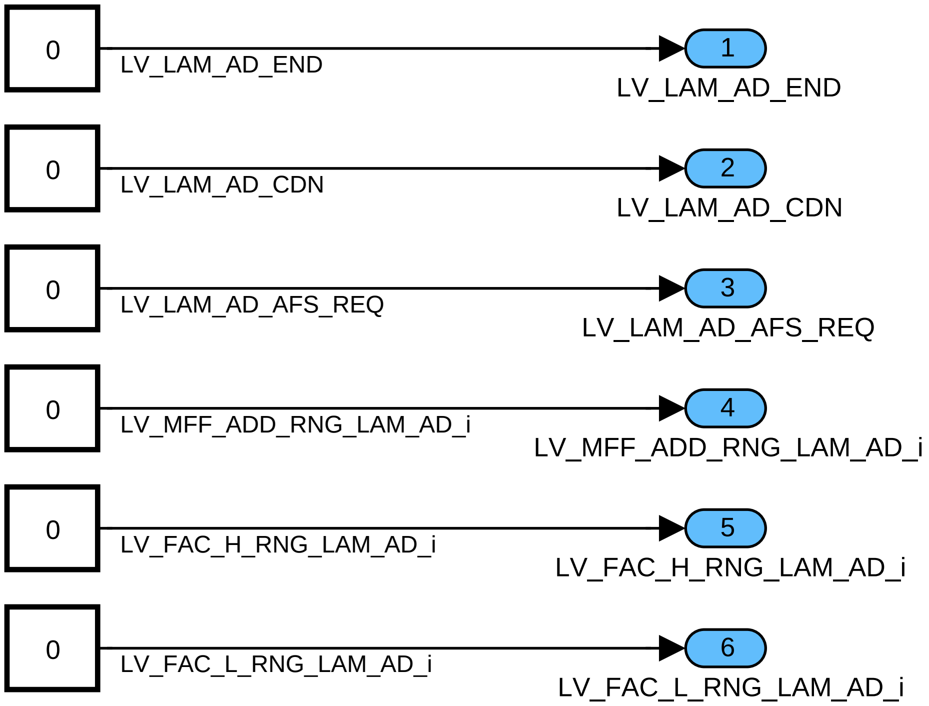

Figure 93 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ STATE_ACTION/ INI/ SET_VALUE

State “WAIT”

Set Variables

The general flags are set to 0. The time T_PRI_LAM_AD[i] is set to the maximum value of the 3 adaptation fields. All other variables remain unchanged.

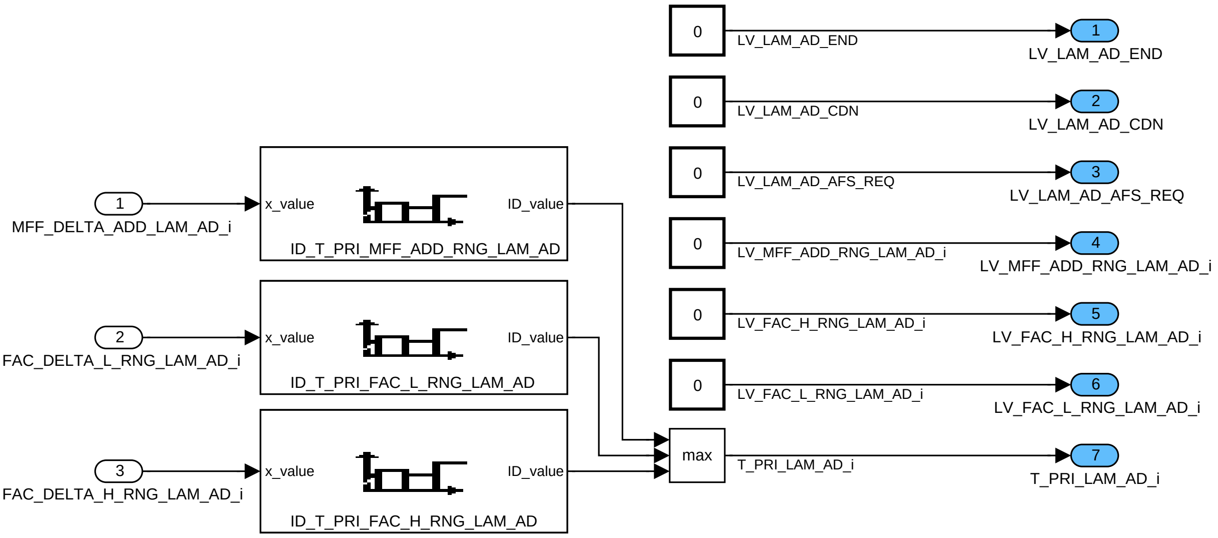

Figure 94 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ STATE_ACTION/ WAIT/ SET_VALUE

State “CDN_ADD”

Set Variables

LV_LAM_AD_CDN is set to 1 as the load conditions for adaptation are fulfilled.

If LV_LAM_AD_ENA is set by the priority manager and stoichiometry request is allowed for offset adaptation by means of the respective calibration flag LV_LAM_AD_AFS_REQ is set to 1.

T_PRI_LAM_AD[i] is set depending on the last learned value in this adaptation field.

The other general flags are set to 0 and all other variables remain unchanged.

Calculation of lambda controller shift

In order to apply the lambda controller shift with the same amount as the lambda adaptation shift FAC_LAM_ADJ_LAM_AD[i] is calculated based on the lambda controller output and a correlation constant (defined in application incidences) The respective lambda adaptation shift is calculated (with high resolution by the internal variable MFF_DELTA_ADD_LAM_AD_H_RES[i]) by multiplying FAC_LAM_ADJ_LAM_AD[i] with the fuel mass flow set point. The result is assigned to MFF_DELTA_ADD_LAM_AD[i] which is the lambda adaptation shift that is finally applied.

The variable MFF_DELTA_ADD_LAM_AD[i] will be 0 as long as the absolute value of MFF_DELTA_ADD_LAM_AD_H_RES[i] is below the resolution of MFF_DELTA_ADD_LAM_AD[i]

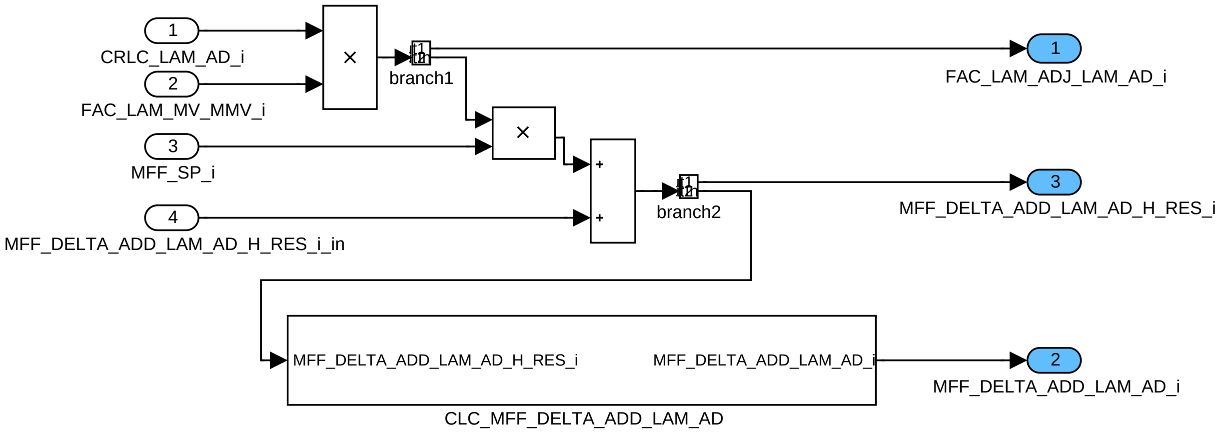

Figure 100 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ STATE_ACTION/ MFF_ADD_AD/ AD/ MNG_AD/ WAIT_CTR_THD/ CTR_THD/ CLC_LAM_SHIFT

Wait for determination of new adaptation value

As long as MFF_DELTA_ADD_LAM_AD[i] is 0 no new adaptation value is taken into account.

State Machine Independent Calculations

Re-Writing of Adaptation Correction at transition of ignition key

Re-writing of the adaptation values if required if not both adaptation factors were learned in the past.

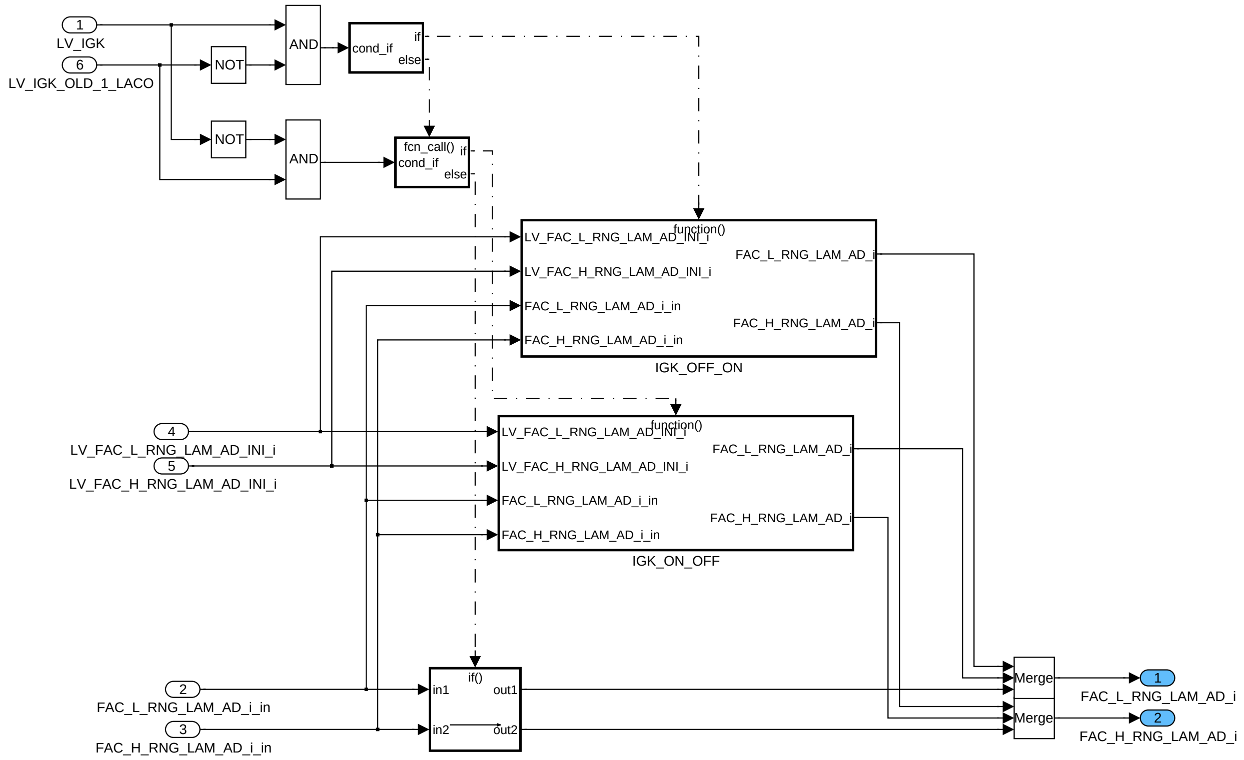

Figure 117 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ IGK_LAM_AD

Ignition key transition off to on

If only one of the initialization flags is set, then the respective adaptation value is reinitialized with the adaptation value of the other adaptation range.

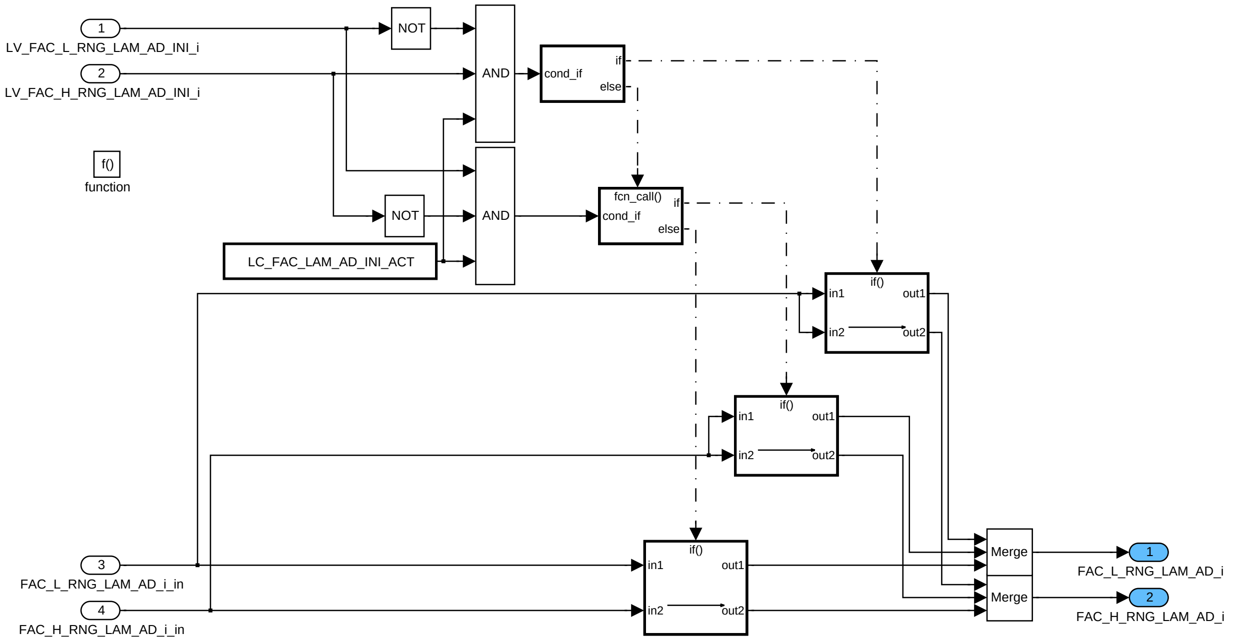

Figure 118 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ IGK_LAM_AD/ IGK_OFF_ON

Ignition key transition on to off

If the flag indicating that no adaptation was done in the relevant adaptation range, the adaptation values shall be reset to zero. This is required to set LV_FAC_L_RNG_LAM_AD_INI[i] respectively LV_FAC_H_RNG_LAM_AD_INI[i] in the next driving cycle.

If by any chance a adaptation of excately zero was learned, a adaptation value of 1 hex shall be written to the NVMY in order to avoid any false setting of LV_FAC_L_RNG_LAM_AD_INI[i] respectively LV_FAC_H_RNG_LAM_AD_INI[i] in the next driving cycle.

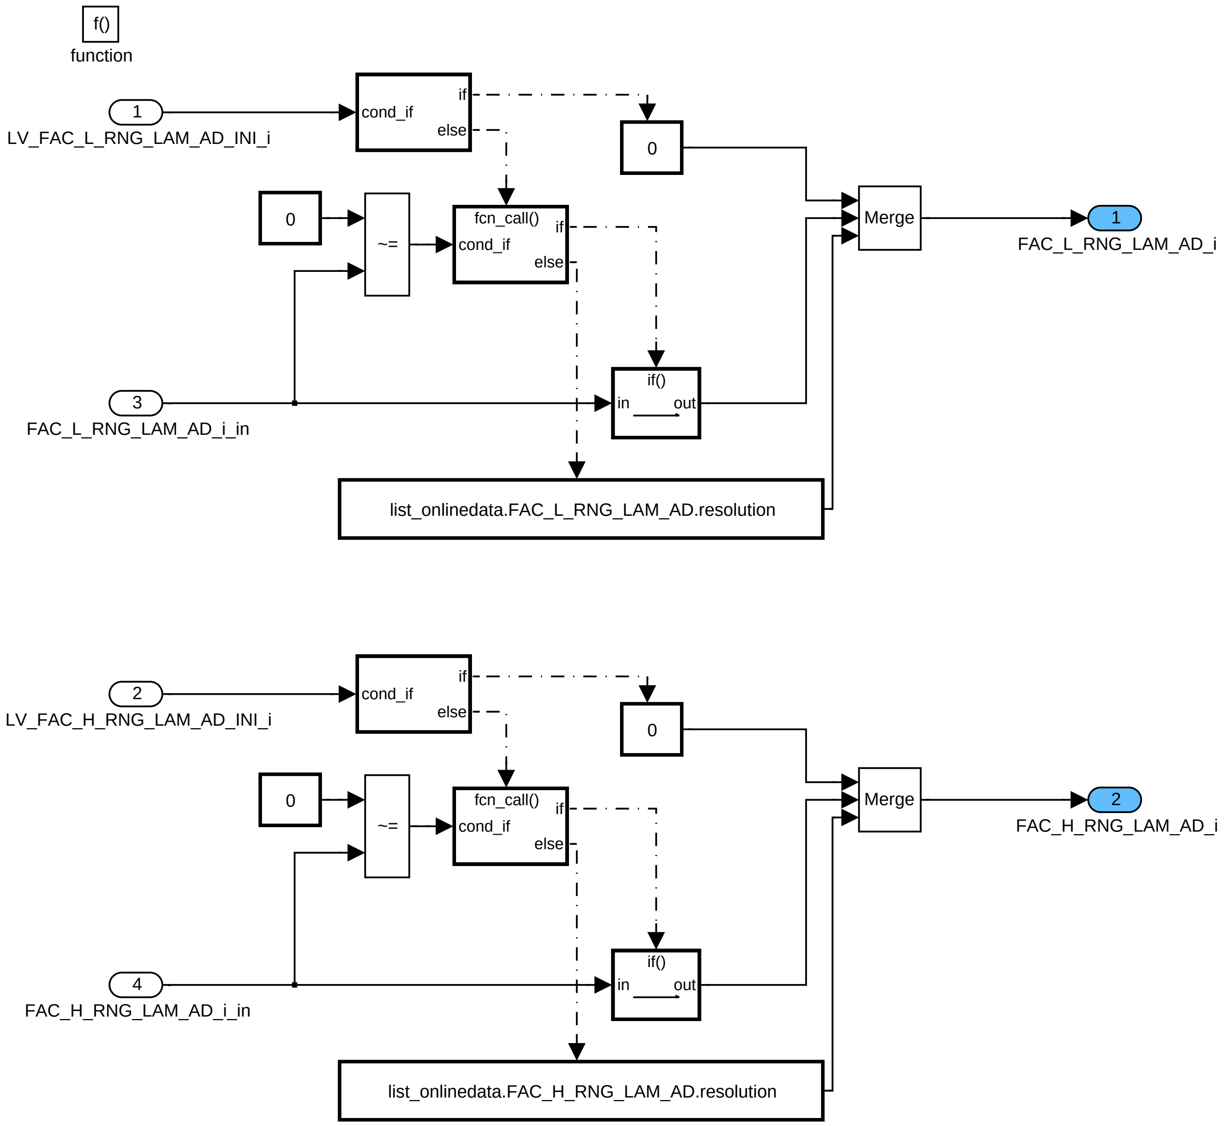

Figure 119 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ IGK_LAM_AD/ IGK_ON_OFF

Re-Writing of Adaptation Correction with Non Volatile Stored Values

In case of lambda adaptation relevant errors (see application incidences) the adaptation correction values MFF_ADD_LAM_AD[i], FAC_L_RNG_LAM_AD[i] and FAC_H_RNG_LAM_AD[i] must be rewritten with the values stored at the end of the last driving cycle. These values are available with the variables MFF_ADD_LAM_AD_TMP[i], FAC_L_RNG_LAM_AD_TMP[i] and FAC_H_RNG_LAM_AD_TMP[i] written to at the beginning of the driving cycle with the stored values of the last driving cycle.

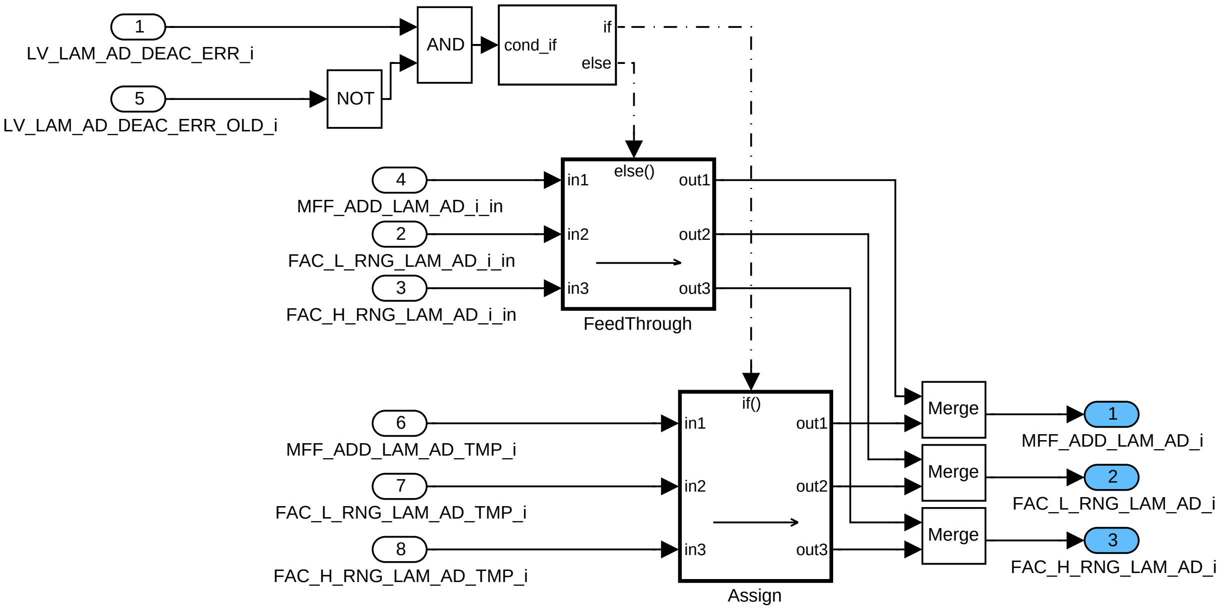

Figure 120 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ ERR_LAM_AD

Shift of adaptation values by external function

External functions might require an inverse step change in the Lambda adaptation value. The control of the value shift takes place in the external function and is indicated by the flags LV_FAC_LAM_AD_SHIFT[i].

The Lambda adaptation is shifted if the condition LV_FAC_LAM_AD_SHIFT[i] = 1 is valid. This variable is to be reset if the Lambda adaptation shift was carried out. That requires a confirmation of the executed controller shift. The confirmation is done by setting the variable LV_FAC_LAM_AD_SHIFT_END[i] to 1.

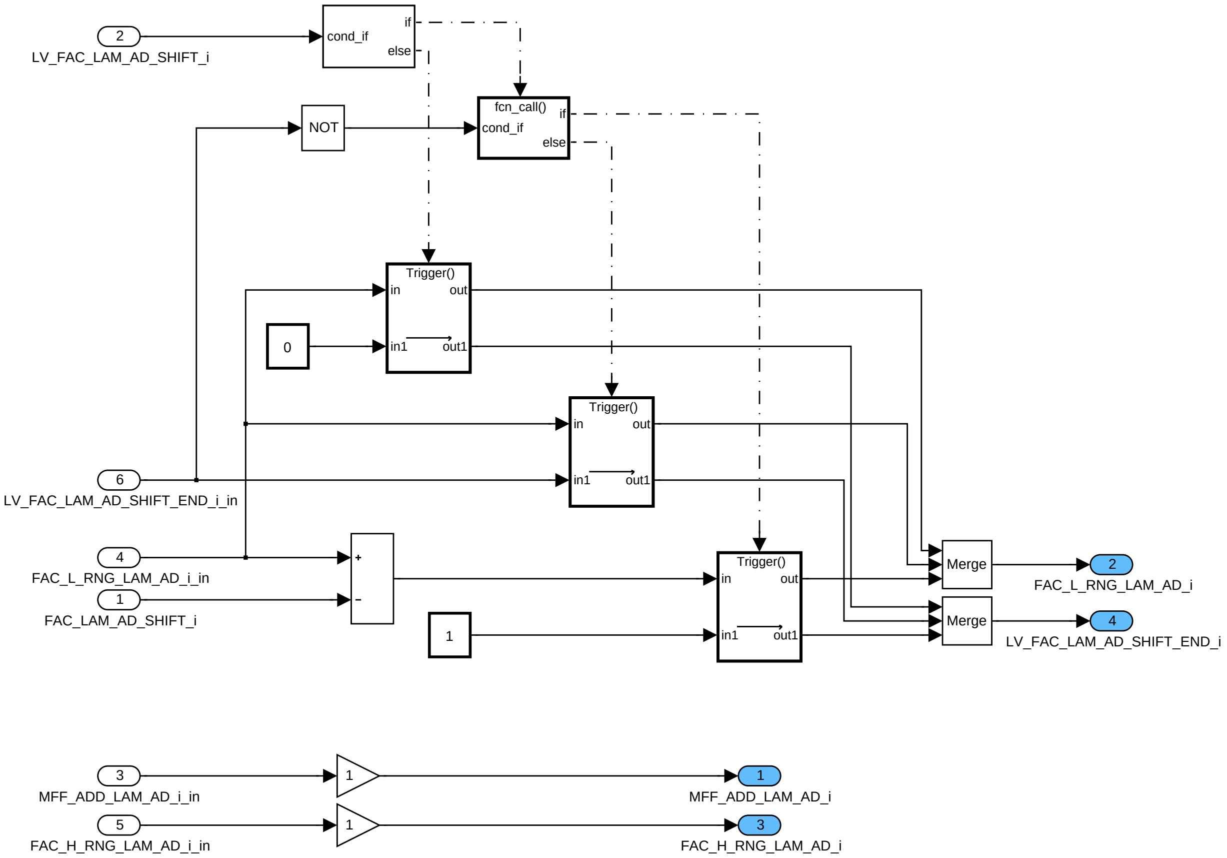

Figure 121 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ SHIFT_LAM_AD

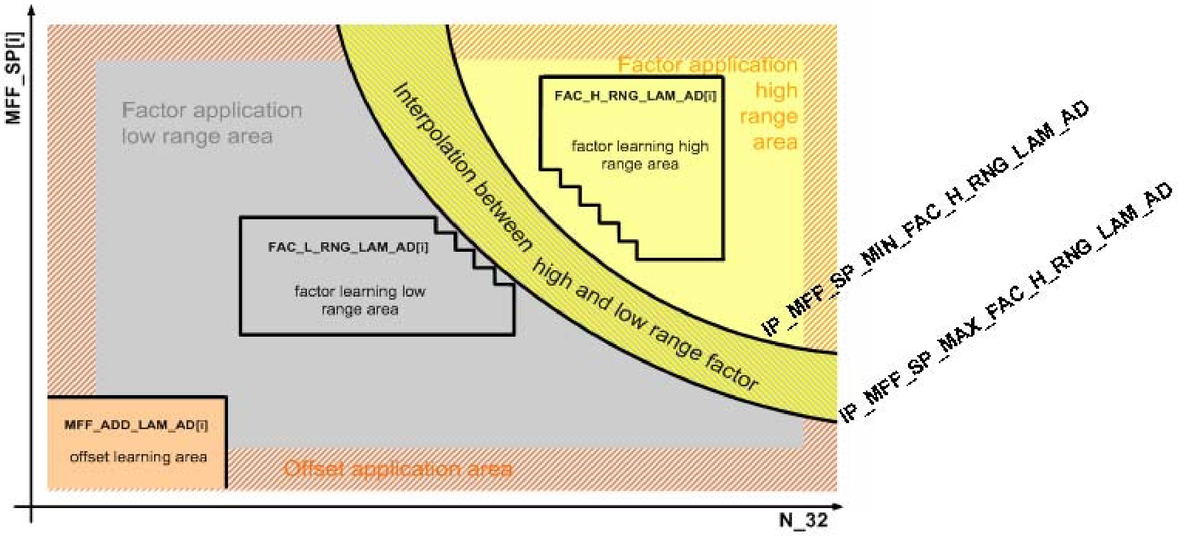
Determination of Interpolated Lambda Adaptation Factor

In order to meet the physical behaviour of engine components (especially the air mass flow sensor), the actual multiplicative factor is calculated out of the two determined factors by interpolation at every state. Interpolation is applied between the borders

- IP_MFF_SP_MAX_FAC_H_RNG_LAM_AD (lower border) and
- IP_MFF_SP_MIN_FAC_H_RNG_LAM_AD (upper border)

as shown in the figure.



Interpolation of adaptation factors

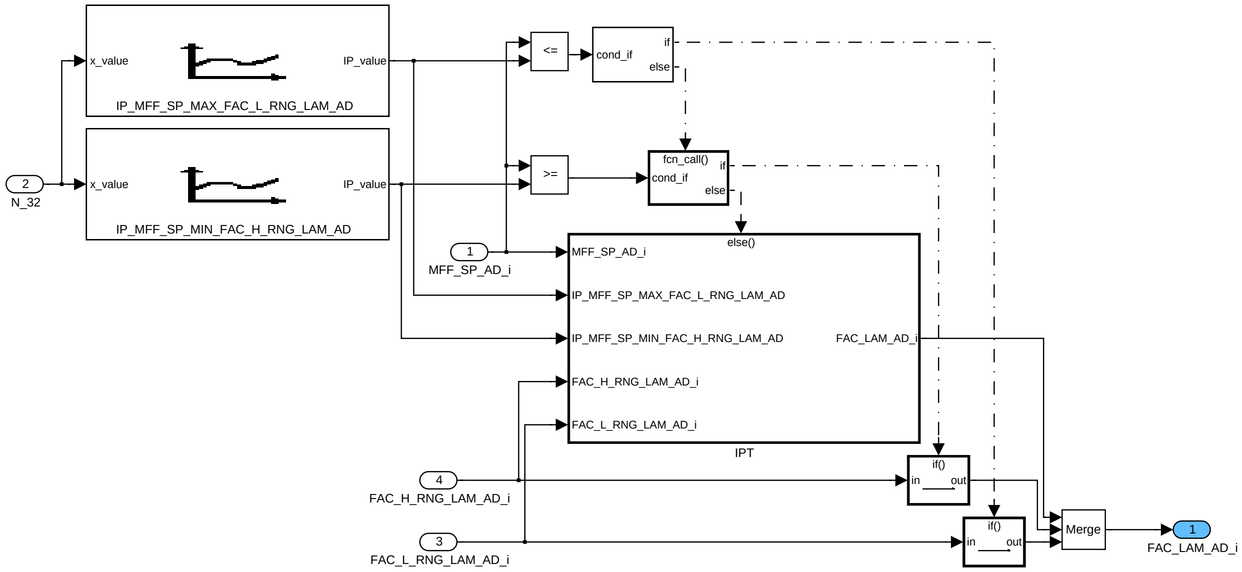


Figure 122 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ CLC_FAC_LAM_AD

Calculation of Output Signals for Fuel Mass Flow Set Point Correction

In order to avoid mixture problems when the engine has not reached its service temperature (warm up), lambda adaptation factors and their corresponding relative intermediate results can be decreased versus TCO and their own value (which is applied when the engine has its service temperature).

This is performed by weighting the adaptive factors as long as the lambda adaptation is disabled due to TCO ≤ C_TCO_MIN_LAM_AD (see: "application incidences").

The quotient of the additive relative factor is determined. The values MFF_LAM_ADD_LAM_AD_OUT[i] and MFF_SP[i] should be conditioned so, that FAC_MFF_ADD_LAM_AD_OUT[i] does not exceed the physical range of +/-100 %!

The relative lambda adaptation FAC_MFF_ADD_FAC_LAM_AD[i] as long term adaptation is calculated out of both adaptation factors.

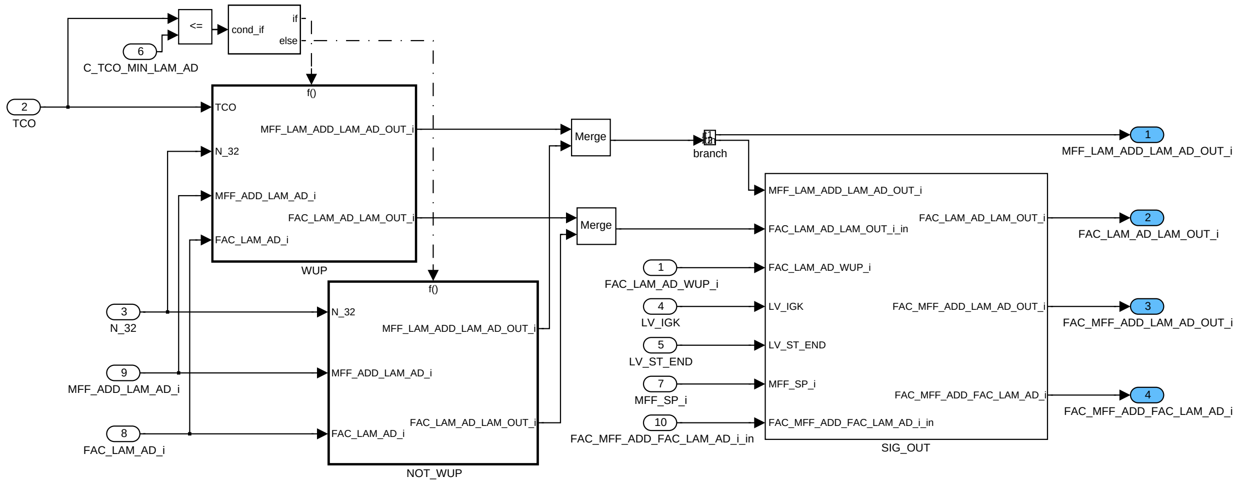

Figure 123 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ CLC_SIG_OUT

Apply Weighting Factors

A factor depending on engine speed can be applied if the lambda adaptation correction must not be applied by 100% in the whole engine speed range.

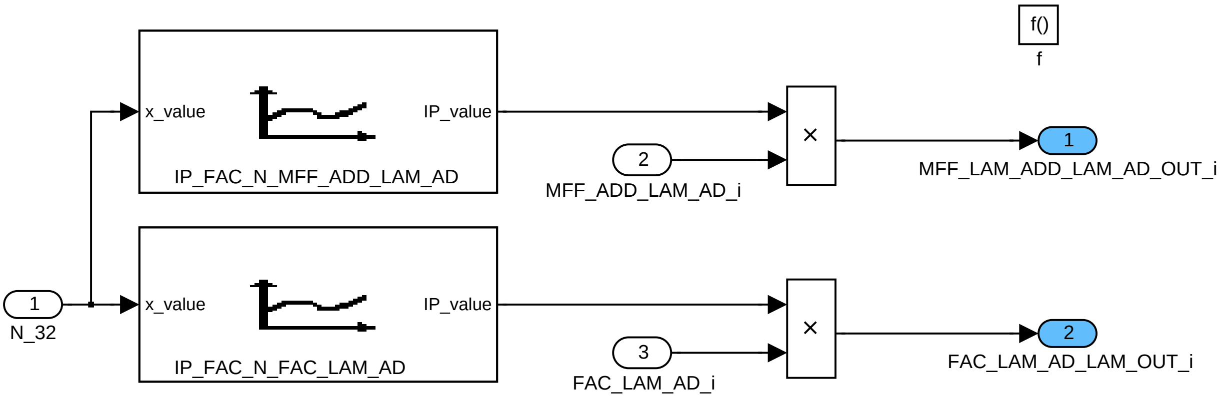

Figure 124 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ CLC_SIG_OUT/ NOT_WUP

Apply Weighting Factors during Warm Up Phase

During warm-up an additional factor depending on TCO and the lambda adaptation correction itself is applied.

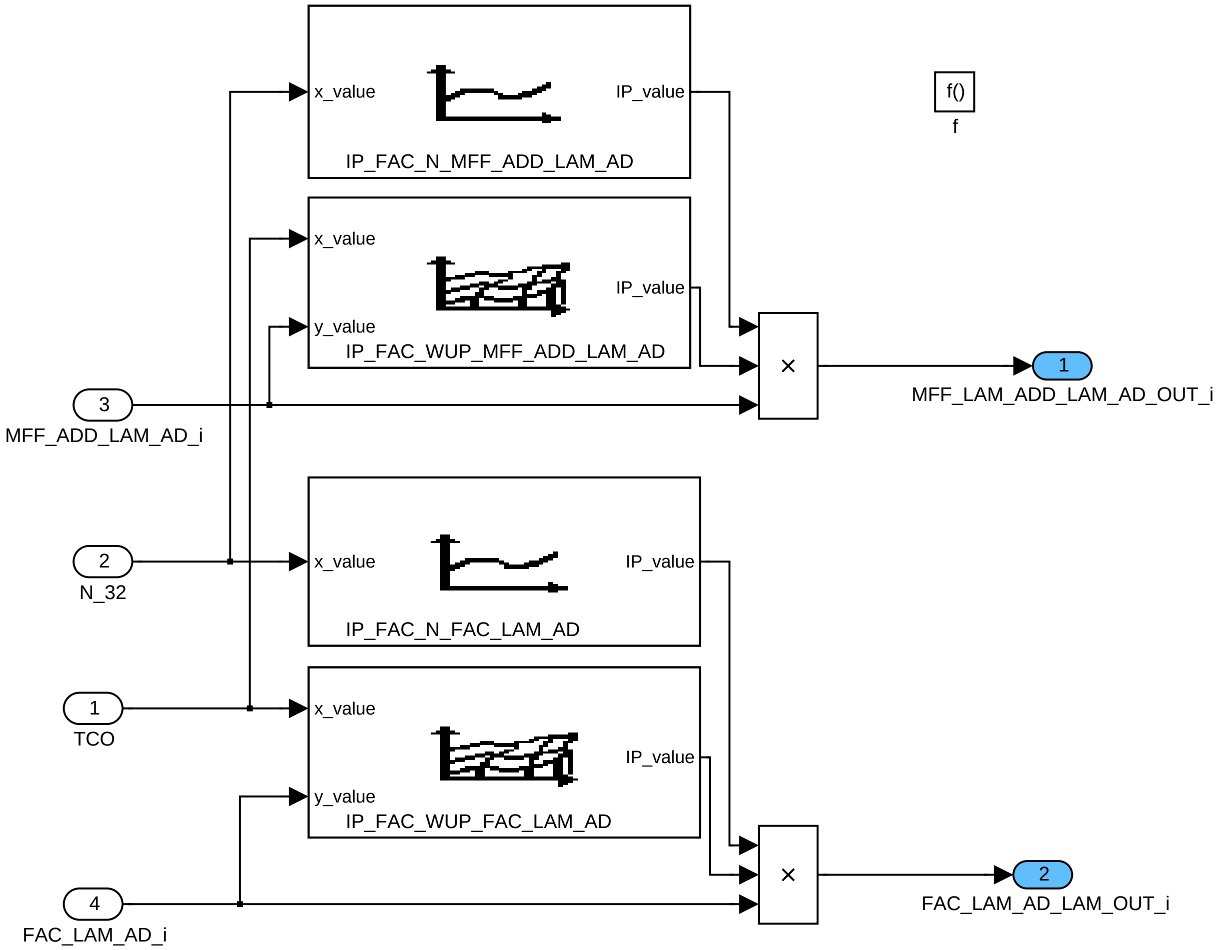

Figure 125 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ CLC_SIG_OUT/ WUP

Final Output

FAC_MFF_ADD_LAM_AD_OUT[i] is the additive correction related to the fuel mass flow set point in order to have the same definition as for the multiplicative correction. When the engine is running this value is added to the multiplicative correction; so with the variable FAC_MFF_ADD_FAC_LAM_AD[i] the whole lambda adaptation correction is expressed.

If the lambda adaptation in warm-up phase (external module) is active the respective output of this function FAC_LAM_AD_WUP[i] is not zero and added here to the over all lambda adaptation multiplicative correction.

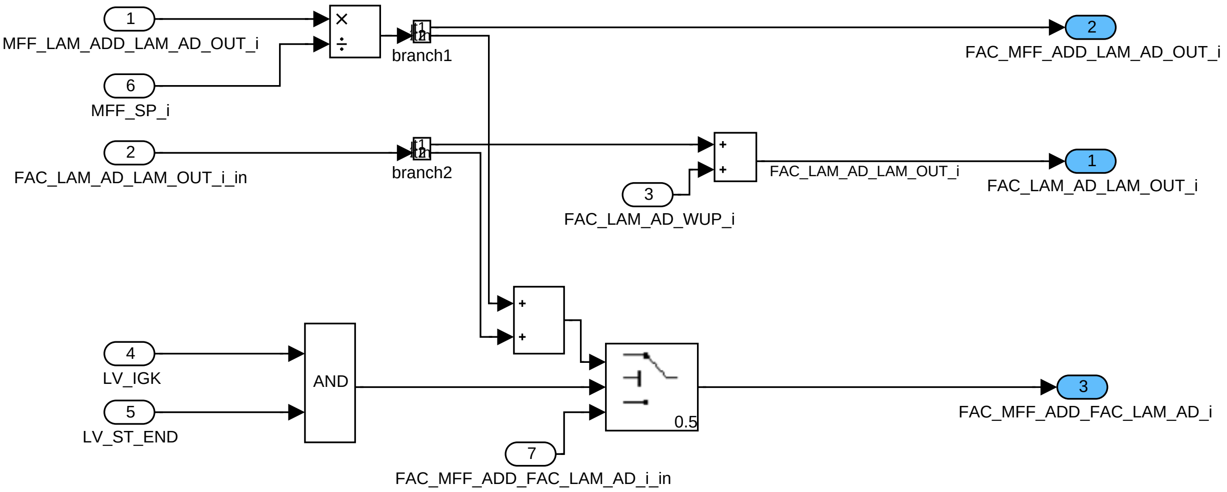

Figure 126 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ CLC_SIG_OUT/ SIG_OUT

Interface to Lambda Controller

Interfacing Lambda Adaptation (this function)

A shift of the lambda controller output after the calculation of a valid adaptation value by FAC_LAM_ADJ_LAM_AD[i] is required in order to avoid rapid changes in the air fuel ratio caused by the lambda adaptation. FAC_LAM_ADJ_LAM_AD[i] is calculated in the states "ADAPT_ADD", "ADAPT_FAC_L" and "ADAPT_FAC_H".

The shift of the lambda controller output is not carried out, if the lambda controller is stopped. To avoid a loss of adaptation values in that case, the lambda controller shall confirm the successful lambda controller shift.

If the lambda controller does not confirm the controller shift by FAC_LAM_ADJ_LAM_AD[i] by setting LV_FAC_LAM_ADJ_LAM_AD_END[i] to 1, the lambda adaptation stops further calculations (LV_LAM_AD_STOP[i] is set to 1) until the controller shift is confirmed. FAC_LAM_ADJ_LAM_AD[i] shall be set to 0 and LV_FAC_LAM_ADJ_LAM_AD[i] and LV_LAM_AD_STOP[i] are reset, if at a stopped lambda adaptation the deactivating conditions are fulfilled.

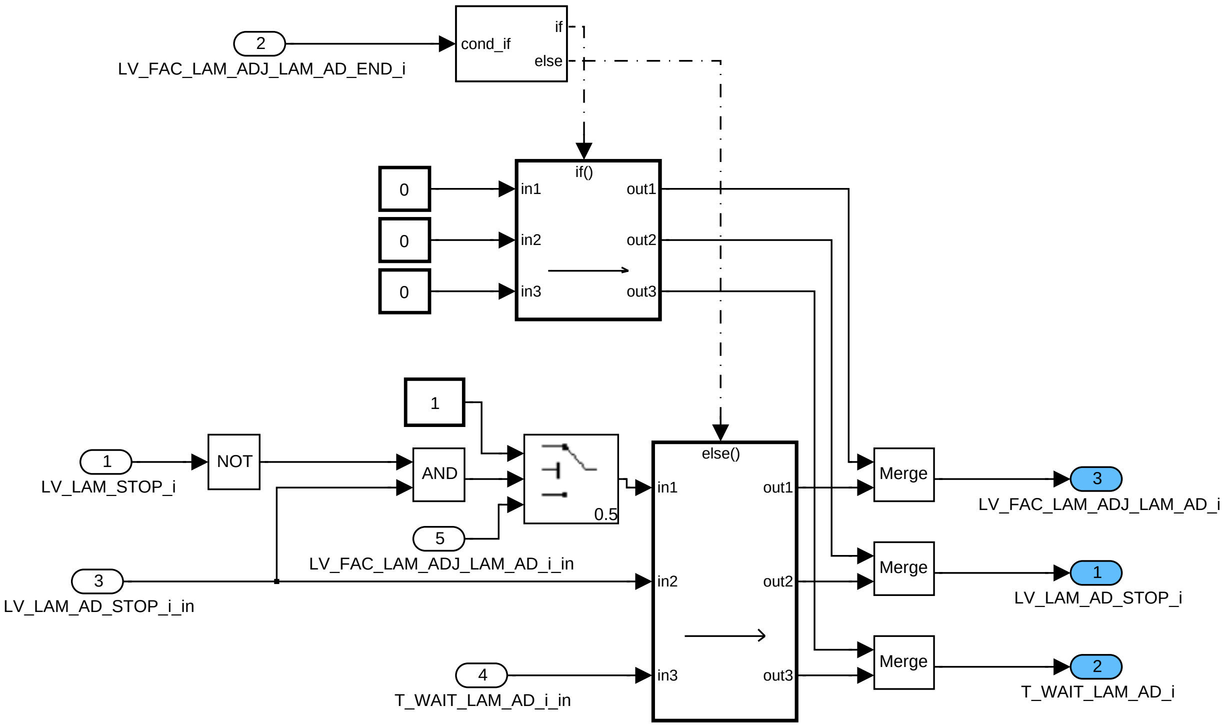

Figure 127 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ LAM_IF/ LAM_AD

Interfacing Lambda Adaptation in Warm-up phase (external module)

If TCO is below C_TCO_MIN_LAM_AD, any required shift by the warm-up lambda adaptation is taken into account. Above this threshold lambda adaptation is active and any shift of this function is taken into account. As both adaptation function cannot be active at the same time the request flag LV_FAC_LAM_ADJ_LAM_AD[i] is used for both.

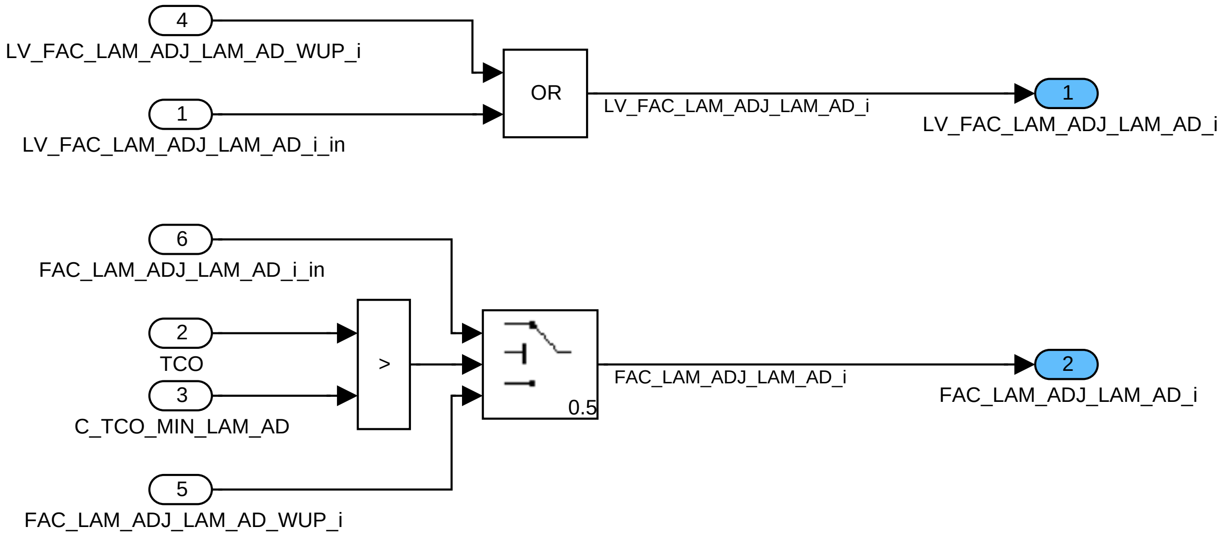

Figure 128 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ LAM_IF/ LAM_AD_WUP

Check of Requirements for Time Scheduler

In order to observe the priority of further lambda adaptations, the differences between the old and the new adapted factors are observed. According to the observed deviations the new maximum time for next adaptation is calculated regarding the present conditions.

The output value for the time scheduler T_PRI_TOT_LAM_AD is not bank selective and represents the minimum time of all cylinder banks. In case of single exhaust cylinder bank T_PRI_TOT_LAM_AD is equal to T_PRI_LAM_AD[i] of this single bank.

If at least for one exhaust bank LV_LAM_AD_STOP[i] is set then the auxiliary flag LV_LAM_AD_STOP_CBK_EX is set to 1.

If the Lambda adaptation priority of any bank is below a limit (that means that the priority time is above a calibration threshold), the bank selective temporary Lambda adaptation end flag is set. When T_PRI_LAM_AD[i] exceeds C_T_PRI_MAX_LAM_AD the flag LV_LAM_AD_END_CBK[i] is set.

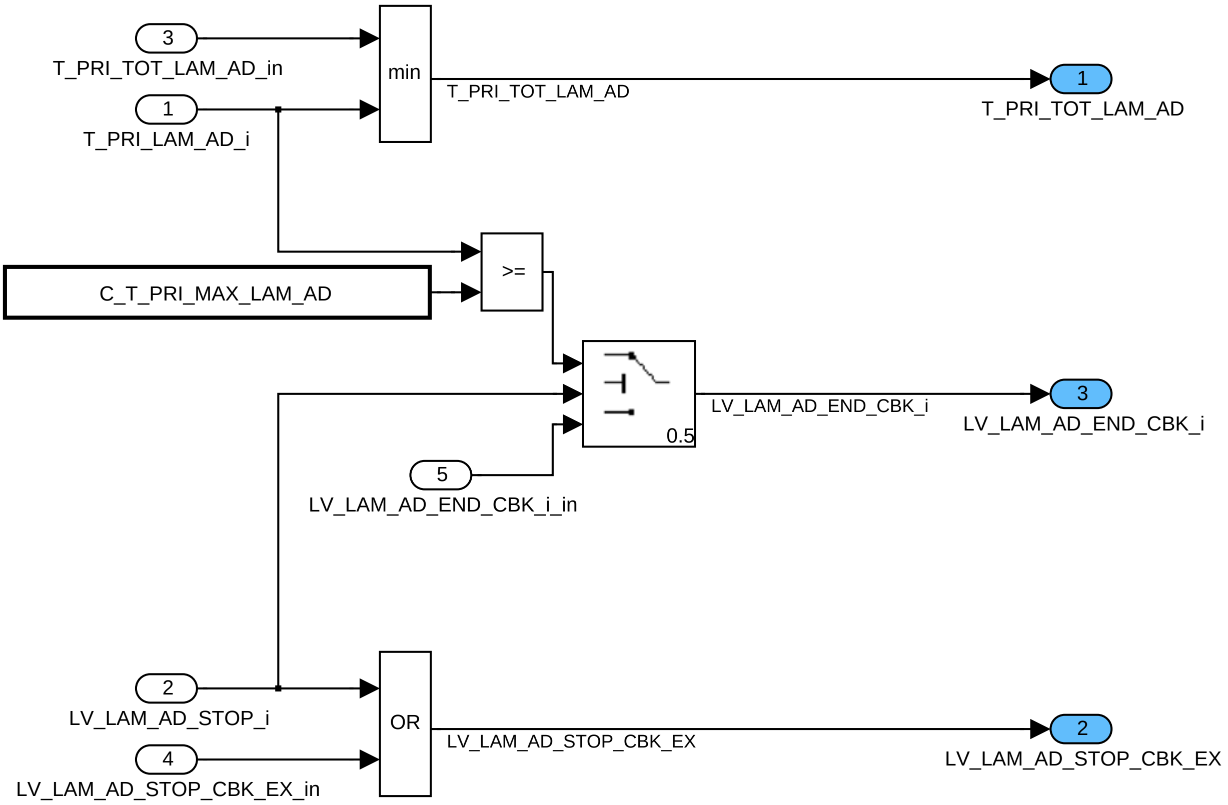

Figure 129 LACO_ISPCLADA0/ OPM_20MS/ CBK_MNG/ CBK_FLP/ CLC_CMN/ T_PRI_MNG

Not exhaust bank specific calculations

Set Lambda Adaptation End Flag

If the total lambda adaptation priority of both exhaust banks is below a limit (that means that the priority time is above a calibration threshold), the temporary lambda adaptation end flag is set. When T_PRI_TOT_LAM_AD exceeds C_T_PRI_MAX_LAM_AD the flag LV_LAM_AD_END is set.

46.13.1 LACO_ISPCLADAW0

The Lambda adaptation in warm-up phase enhances the Lambda adaptation functionality to obtain a more precise correction at low temperatures (< 50°C). The adaptive correction is applied to compensate serial production tolerances of components at low.

TCO dependent correction factors (%/°C) are learned in five temperature ranges. The correction factors are derived from the Lambda controller output. They are learned in an adaptation field specified by MFF_SP[i] and N_32. They are, however, to correct the injection time for all engine states. Learning of these factors requires that the Lambda controller is in the state 'ON'.

The recurrence time is defined by T_SAMPLE in [ms].

NC_CBK_EX_NR defines the number of exhaust banks. For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

Function Description

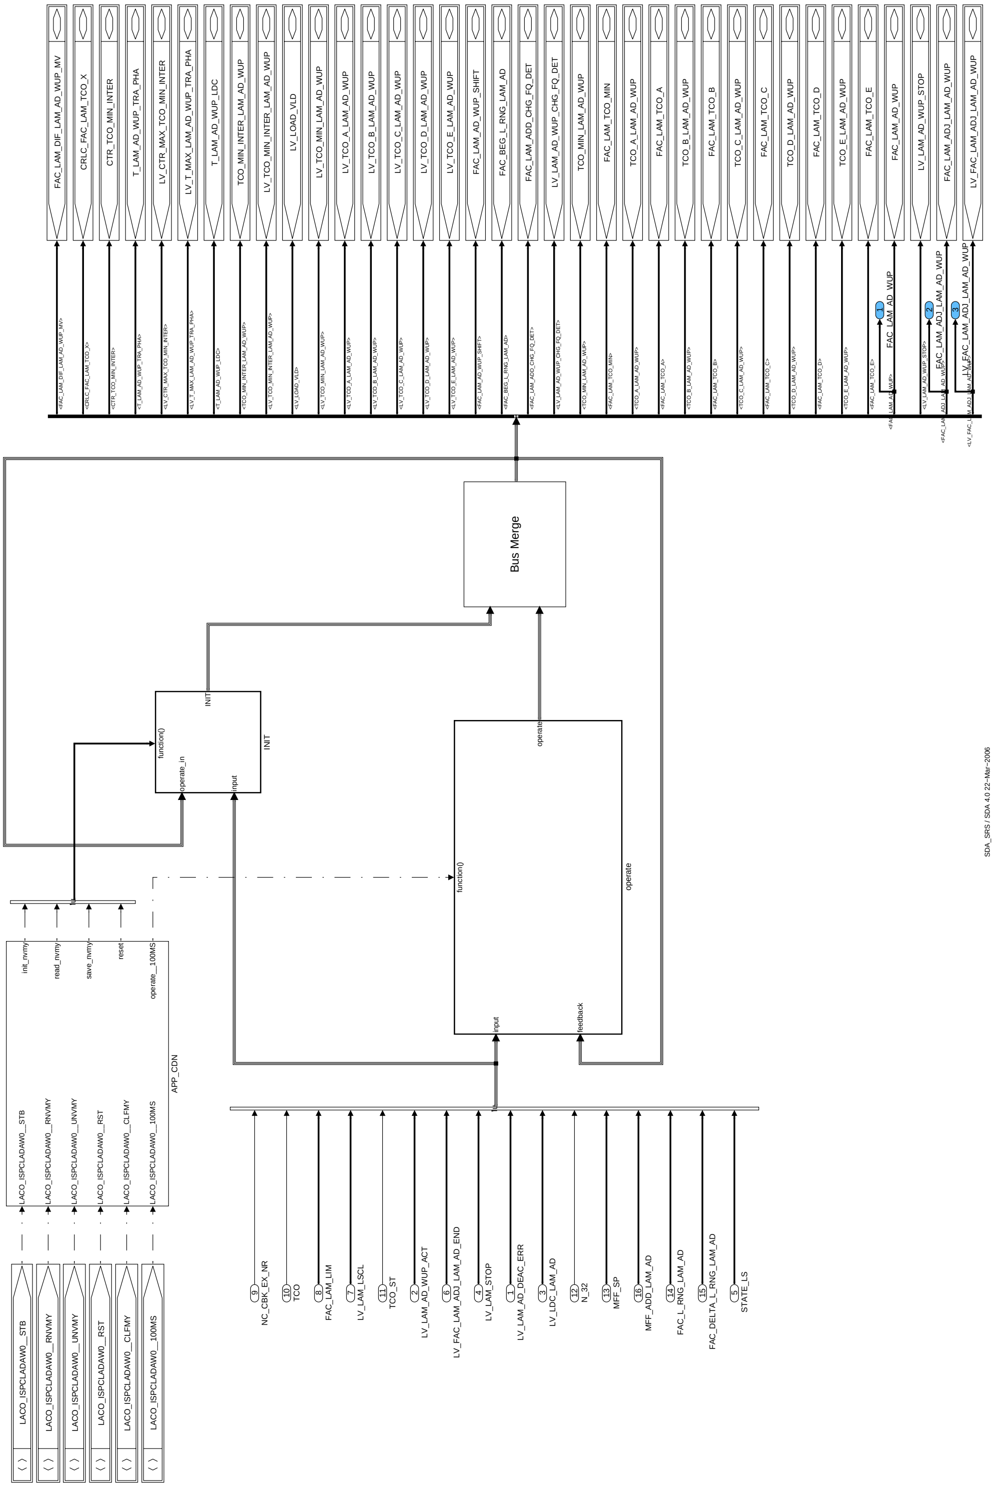

Figure 132 LACO_ISPCLADAW0

46.13.1.1 SUBFUNCTION: operate

Calculation of the uncorrected Lambda controller output

To obtain the actual load on the Lambda controller, the controller output without adaptation is calculated. This is the sum of FAC_LAM_LIM[i] and applied adaptive correction in the warm-up phase. The actual load is then filtered to have a smoother signal. In case of a not yet activated Lambda controller the value is set to zero. This is necessary in order to facilitate the detection of end of the transient phase after the start of the Lambda controller.

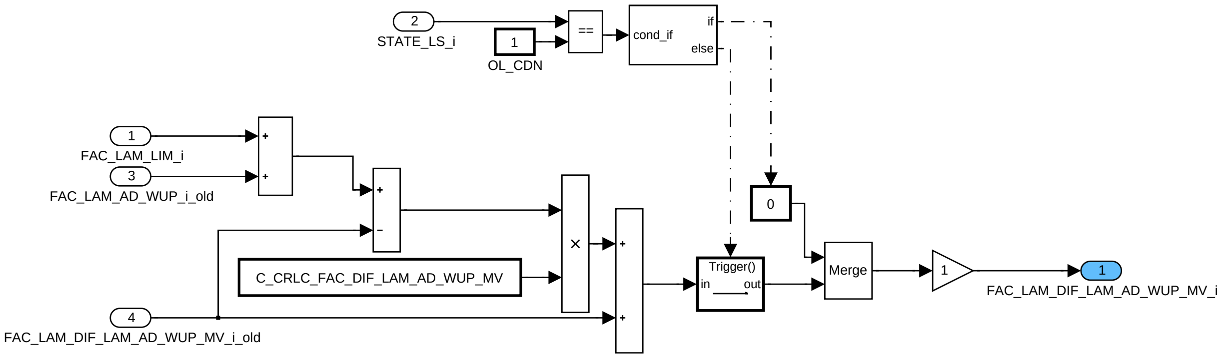

Figure 133 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ FAC_LAM_DIF_LAM_AD_WUP_MV

Correlation constant for updating of adaptation factors

In the update process of the adaptation factor a correlation constant is taken into account. Typically this value will be less then one to reduce the impact of outlier.

In case of a brand new ECU the cold adaptation values need to be shifted, if they are learned before the warm adaptation values are learned. The shift value amounts to the adaptation factor in the low range area. During this shift process no correlation constant is considered. Hence, in case of a brand new ECU the correlation constant is set to 1. Otherwise the auto shift value will not correspond to the corresponding value learned in the cold adaptation.

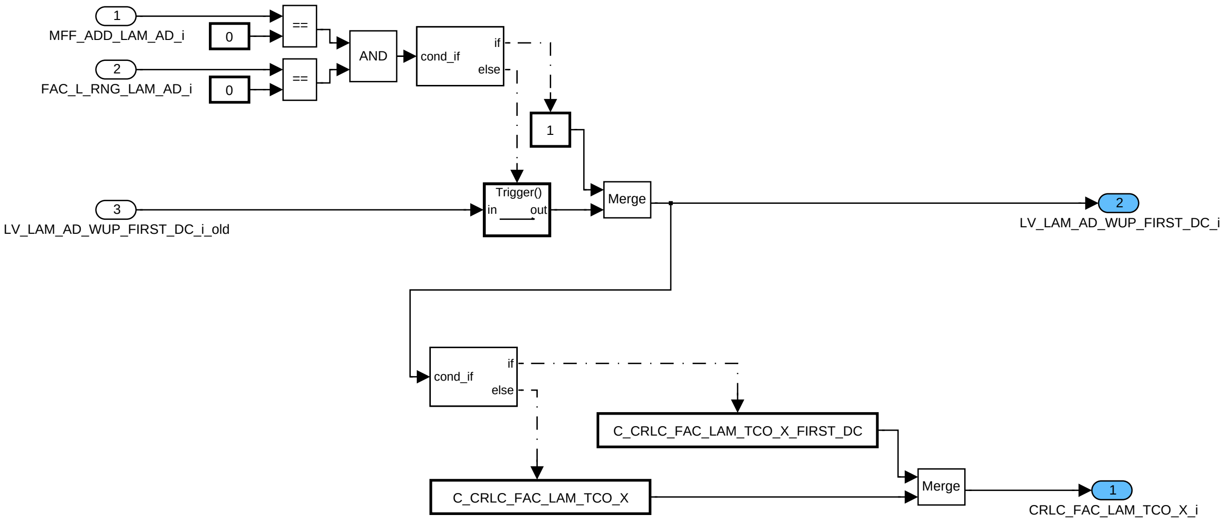

Figure 134 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_CRLC_LAM_TCO_X

Determination of valid partial load phase

To enable learning of the adaptation factor the conditions for valid learning have be fulfilled for at least the calibratable time C_T_MAX_LAM_AD_WUP_LDC.

The conditions are:

- Limited dynamics of the Lambda adaptation are fulfilled.
- Lambda controller is active.
- Lambda controller is not in the stop mode.
- N_32 is below a threshold, but above another threshold.
- MFF_SP[i] is below a threshold, but above another threshold.

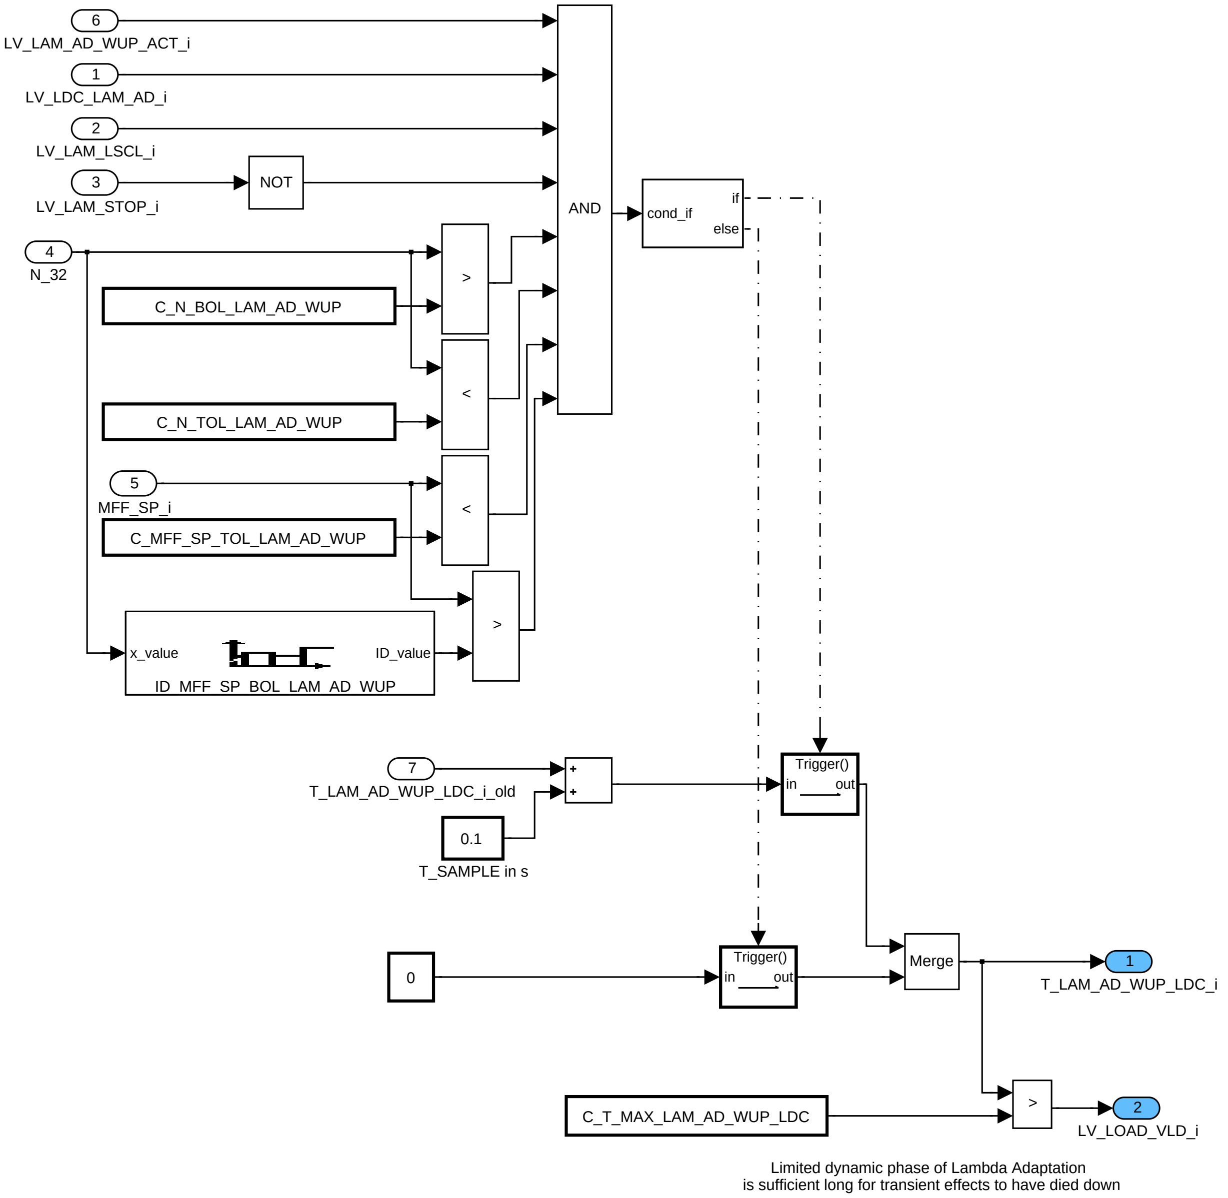

Figure 135 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_INTER_LAM_AD_WUP/ CLC_T_LAM_AD_WUP_LDC

Determination of minimum temperature valid for learning in current driving cycle

To enable learning in the current driving cycle for the first time the following conditions must be satisfied:

- The counter as well as the timer criteria are fulfilled, thus is transient phase is over.

- The global activation conditions are fulfilled.

- Limited dynamics are given, the Lambda controller is in state on and engine operating point is within the required mass air flow and speed range (see also definition of LV_LOAD_VLD[i]).

- The coolant temperature is within the temperature range of the lowest and highest interpolation points.

If above conditions are fulfilled, then the flag indicating the detection of TCO_MIN_INTER is set.

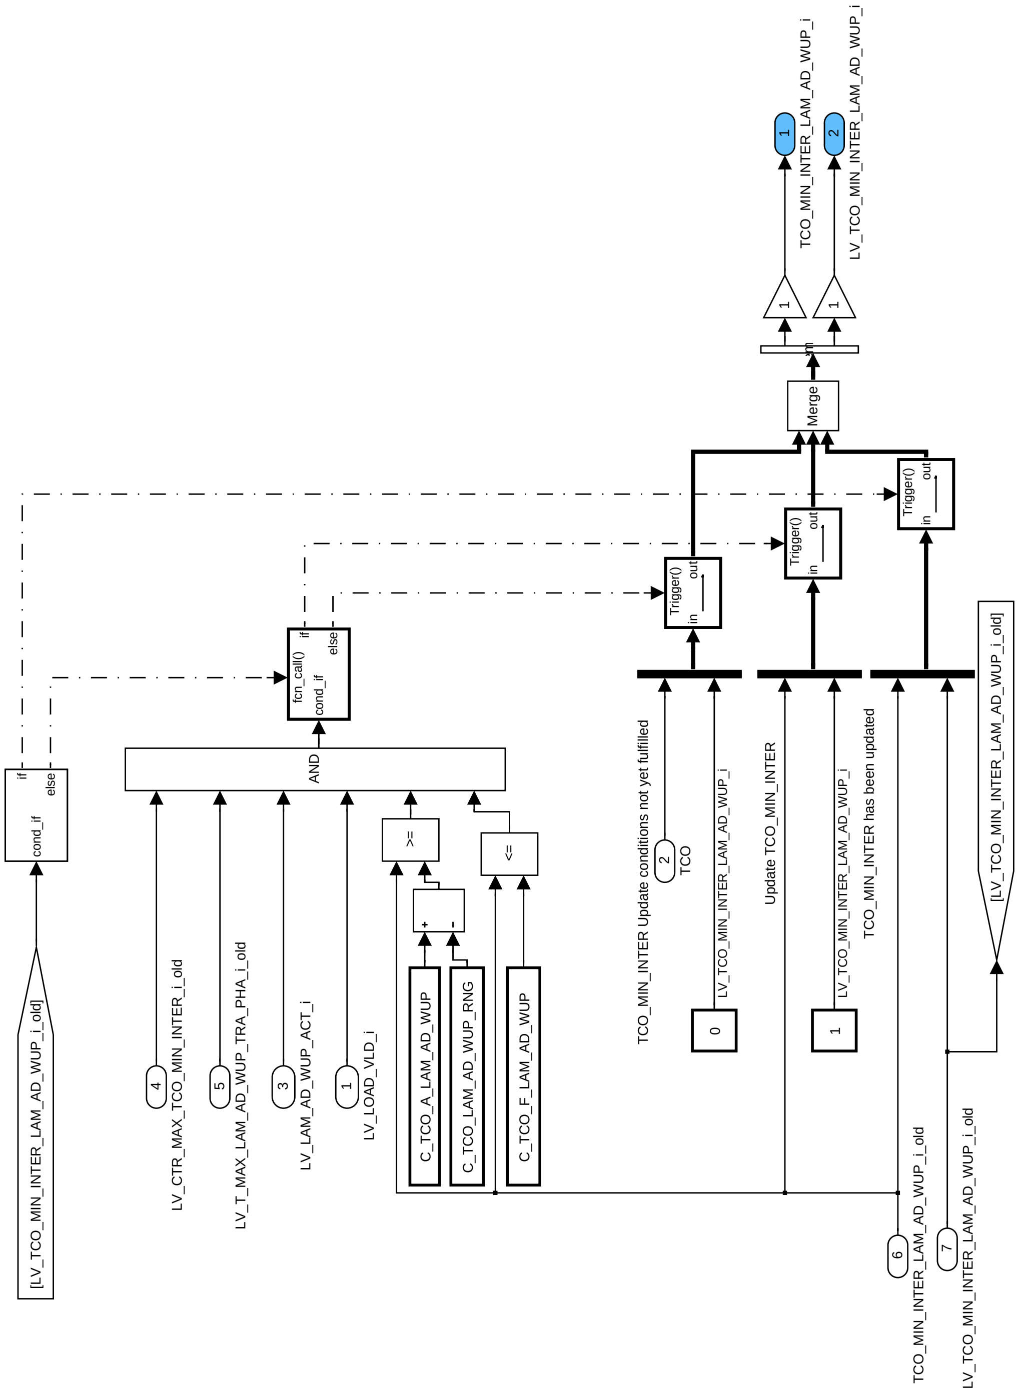

Figure 136 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_INTER_LAM_AD_WUP/ CLC_TCO_MIN_INTER_LAM_AD_WUP

Determination of end of transient phase

Two different criteria can be used to determine the end of the transient phase:

Timer criteria:

When the Lambda controller enters the state ON a timer is incremented. If this timer exceeds a threshold, it is assumed that the transient is over. This criterion is very simple, but not very accurate.

Counter criteria:

The counter is incremented when the uncorrected Lambda controller moves towards the zero percent line or stays unchanged. In case it moves away from the zero percent line, the counter is decremented. The counter cannot be decremented below zero. If the counter exceeds a certain threshold, the end of the transient phase is detected. This criterion was found to be very accurate.

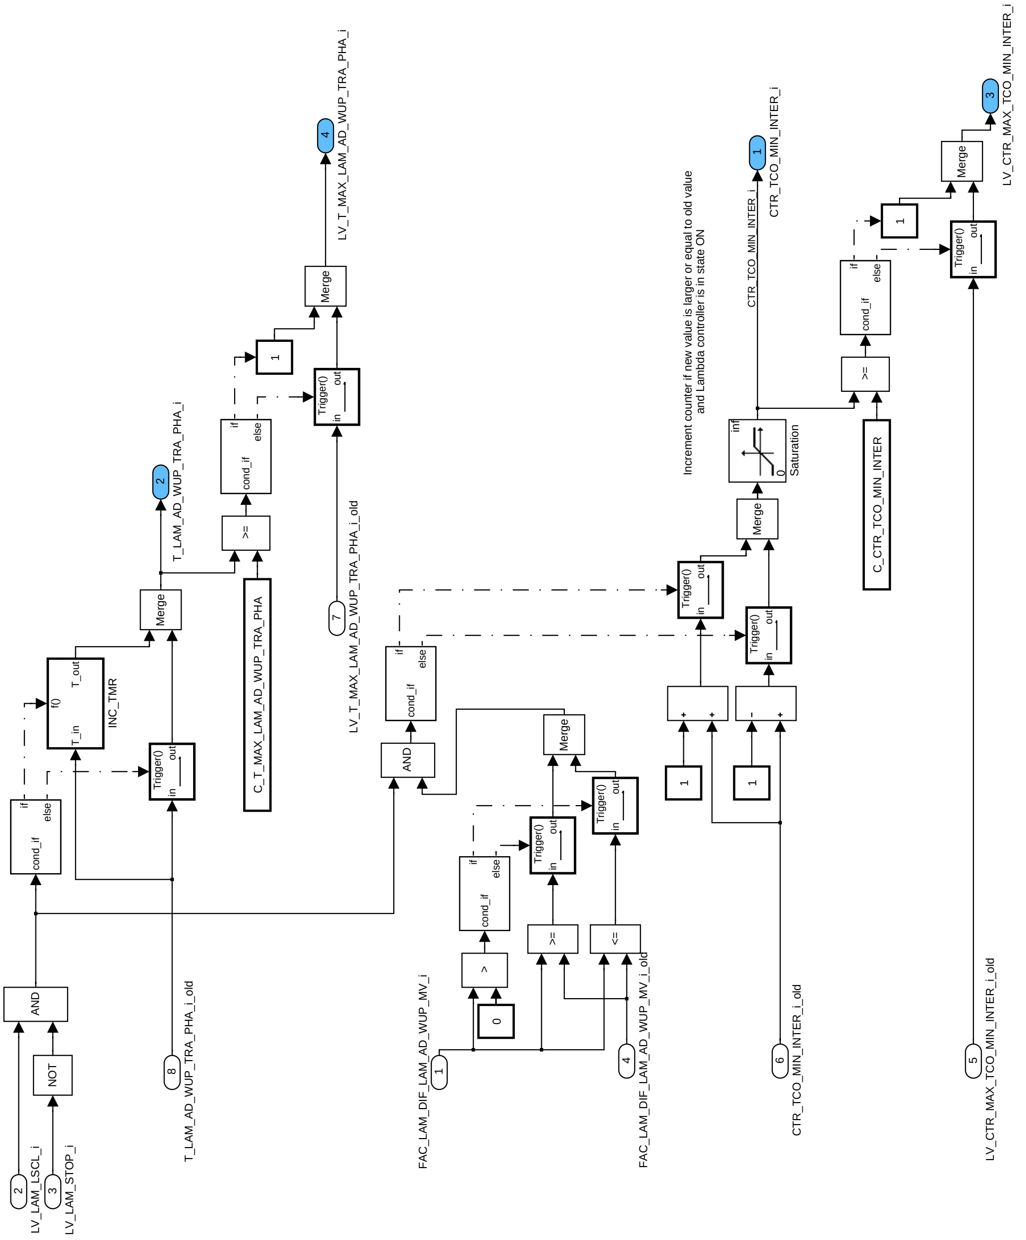

Figure 137 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_INTER_LAM_AD_WUP/ CLC_CTR_TCO_MIN_INTER

Auto shift functionality – correction of adaptation value with warm adaptation value

In each driving cycle it is checked whether the fuel quality has changed to the worse. This check is done once per driving cycle at the time when the conditions for learning are fulfilled for the first time. A change of fuel quality is detected if the uncorrected Lambda controller output has shifted by at least a calibratable threshold towards lean. The threshold is specified in a map with TCO as an input. This allows taking into account the TCO dependent deterioration effect of poor fuel quality.

Once fuel of low quality is detected, a flag indicating that detection was done in the current driving cycle is set to one. Furthermore, the difference in the uncorrected Lambda controller output (which led to this detection) is normalized. The normalization is done using a TCO dependent map. The same map is used later on to shift all adaptation values. Therefore, the map has to represent the qualitative course of the additional enrichment demand caused by the poor fuel quality.

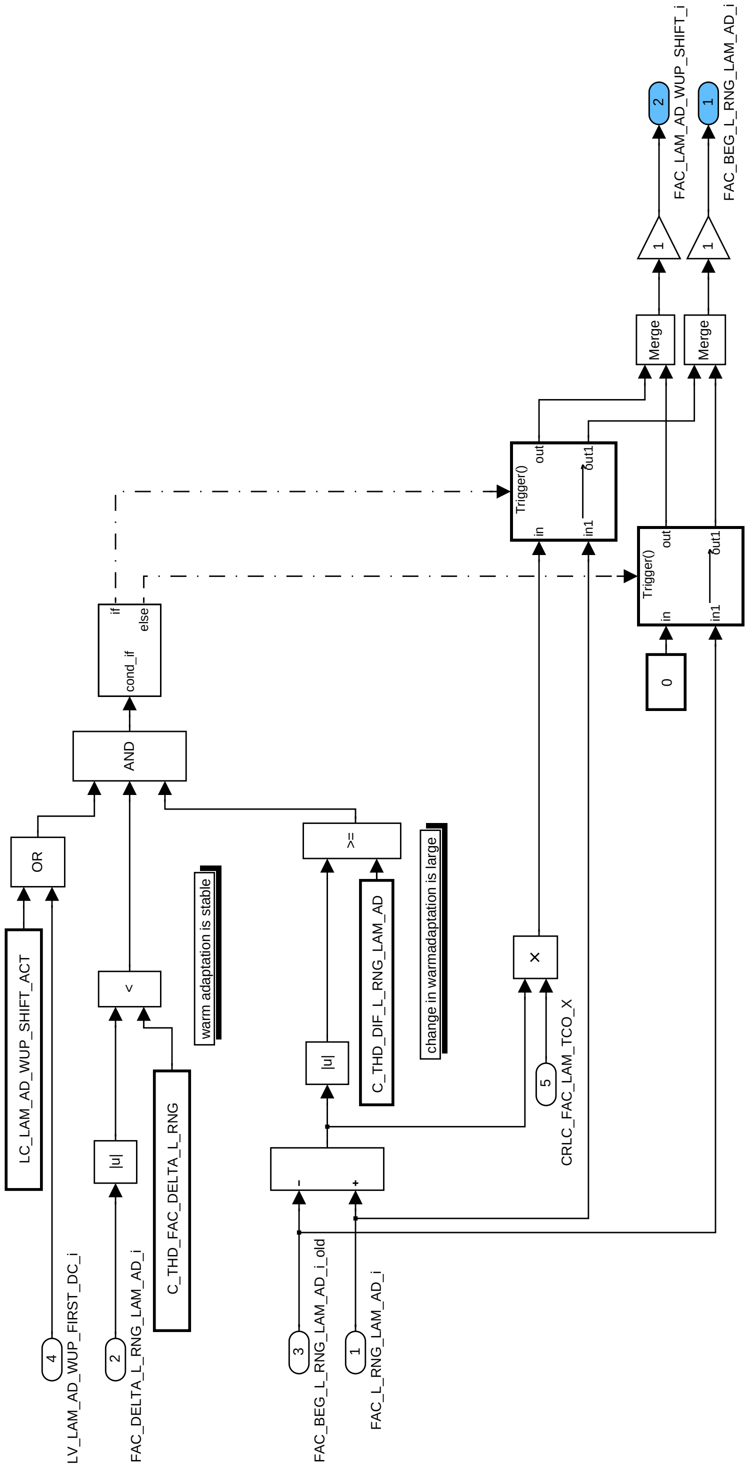

Figure 138 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_FAC_LAM_AD_WUP_SHIFT

Detection of change in fuel quality

In each driving cycle it is checked whether the fuel quality has changed to the worse. This check is done once per driving cycle at the time when the conditions for learning are fulfilled for the first time. A change of fuel quality is detected if the uncorrected Lambda controller output has shifted by at least a calibratable threshold towards lean. The threshold is specified in a map with TCO as an input. This allows taking into account the TCO dependent deterioration effect of poor fuel quality.

Once fuel of low quality is detected, a flag indicating that detection was done in the current driving cycle is set to one. Furthermore, the difference in the uncorrected Lambda controller output (which led to this detection) is normalized. The normalization is done using a TCO dependent map. The same map is used later on to shift all adaptation values. Therefore, the map has to represent the qualitative course of the additional enrichment demand caused by the poor fuel quality.

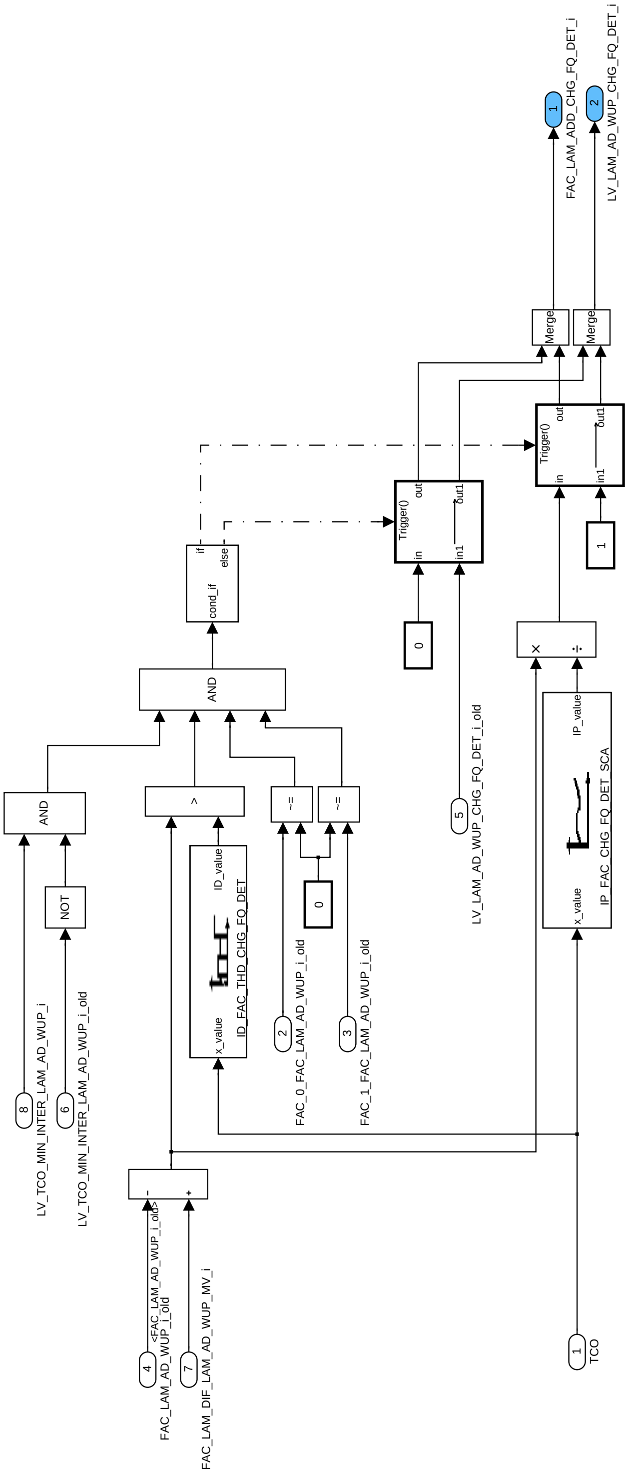

Figure 139 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_CHG_FQ_DET

<u>Adaptive factor at lowest temperature over all driving cycles</u>

Beside the interpolation points A to F with fixed temperature ranges, a moving interplation point is used. This interpolation point also represents the lowest temperature over all driving cycles at which the learning conditions were fulfilled.

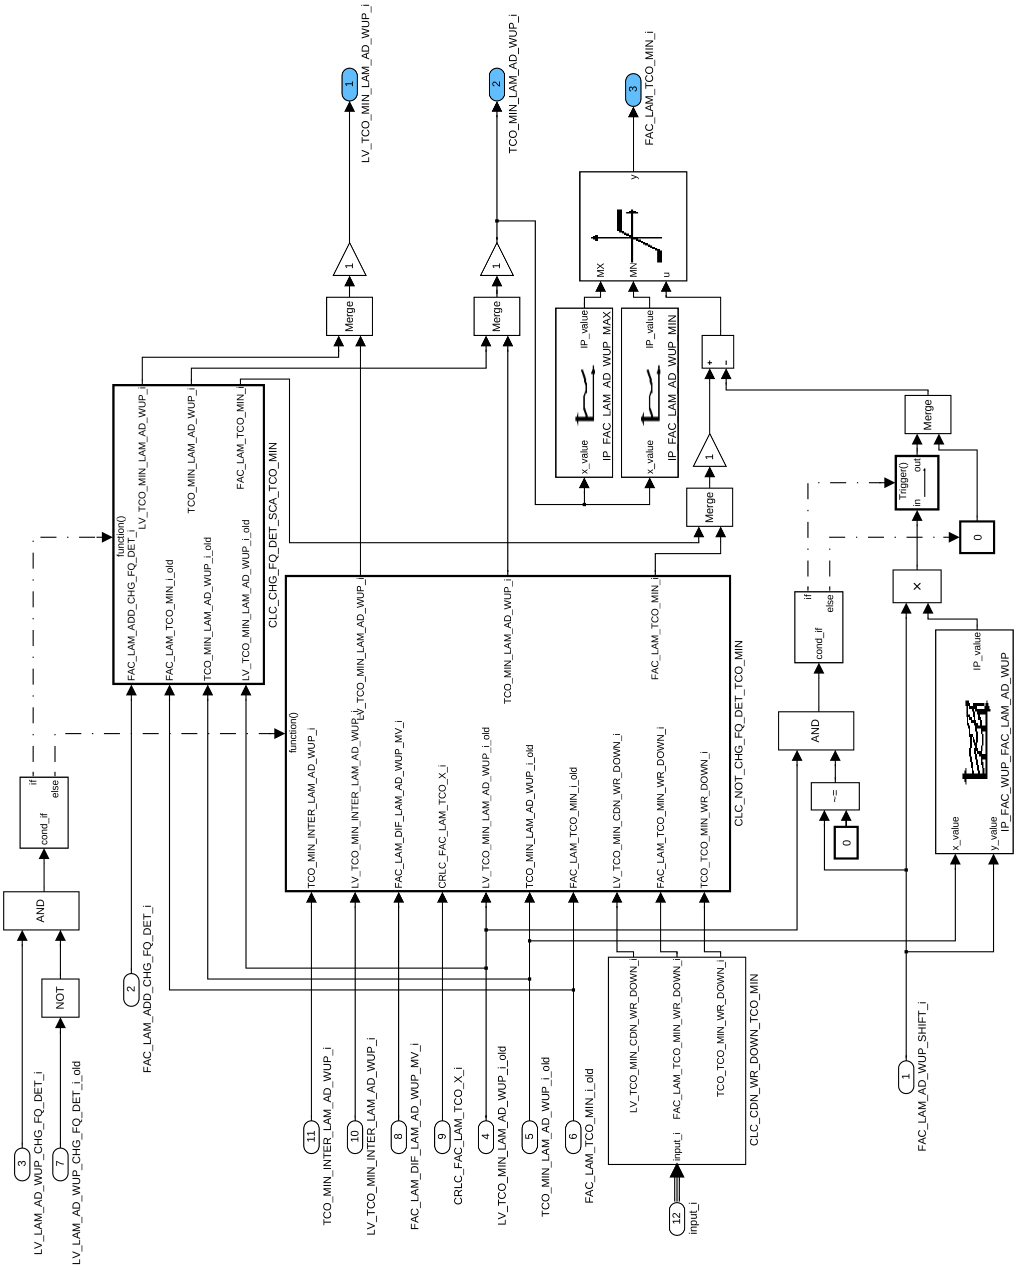

Figure 140 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_LAM_AD_WUP

Determination of adaptation value during detection of change in fuel quality

First it is checked whether the adaptation factor is different from zero to confirm, that it has been updated at some point in the past. If this is not the case no shift is realized at this particular interpolation point.

For shifting the normalized shift value is multiplied by a TCO dependent weighting factor and then added to the old adaptation factor. The weighting factor takes into account that the negative effects of the low quality fuel disappear with rising temperature. Hence, the weighting factor should be around 1 for the lowest interpolation point and at around zero for the highest temperature.

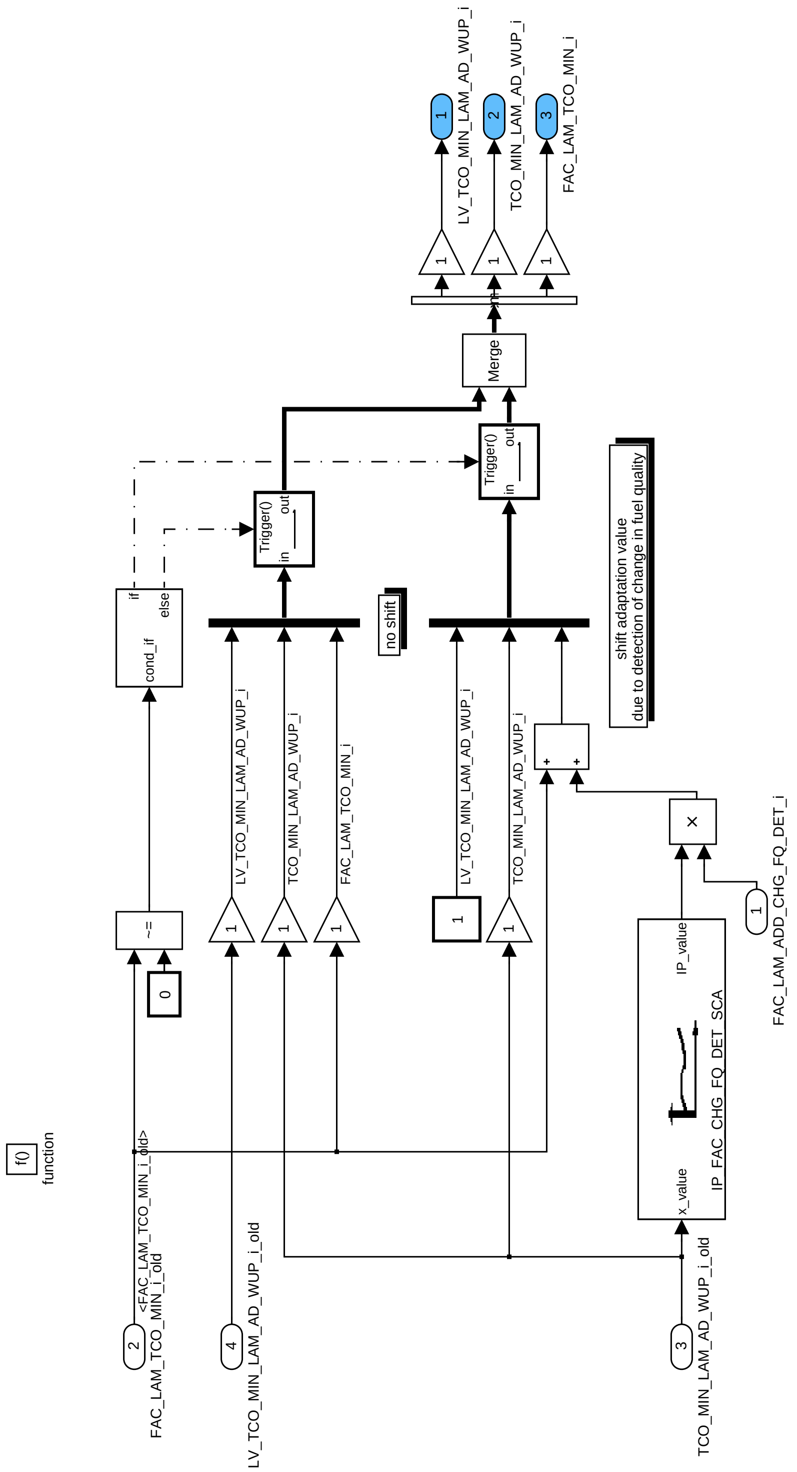

Figure 141 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_LAM_AD_WUP/ CLC_CHG_FQ_DET_SCA_TCO_MIN

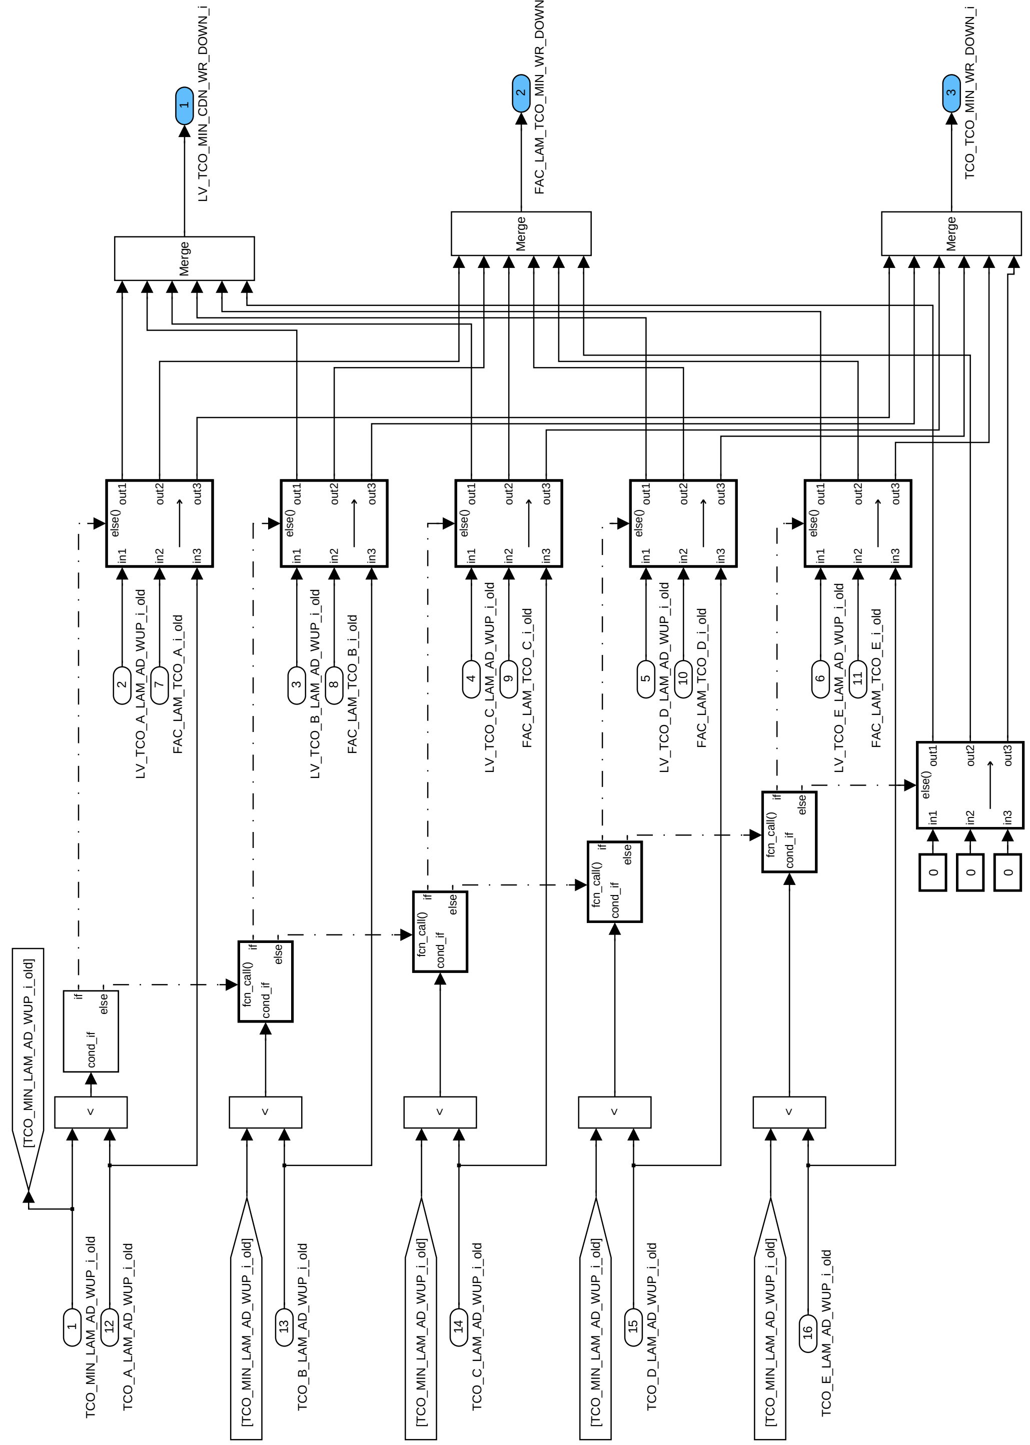

Figure 142 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_LAM_AD_WUP/ CLC_CDN_WR_DOWN_TCO_MIN/ CLC

<u>Determination of minimum temperature valid for learning of all driving cycles</u>

TCO_MIN is updated with TCO_MIN_INTER if the value for the current driving cycle (TCO_MIN_INTER) is smaller than the previously stored value of TCO_MIN. During update the correlation constant is considered.

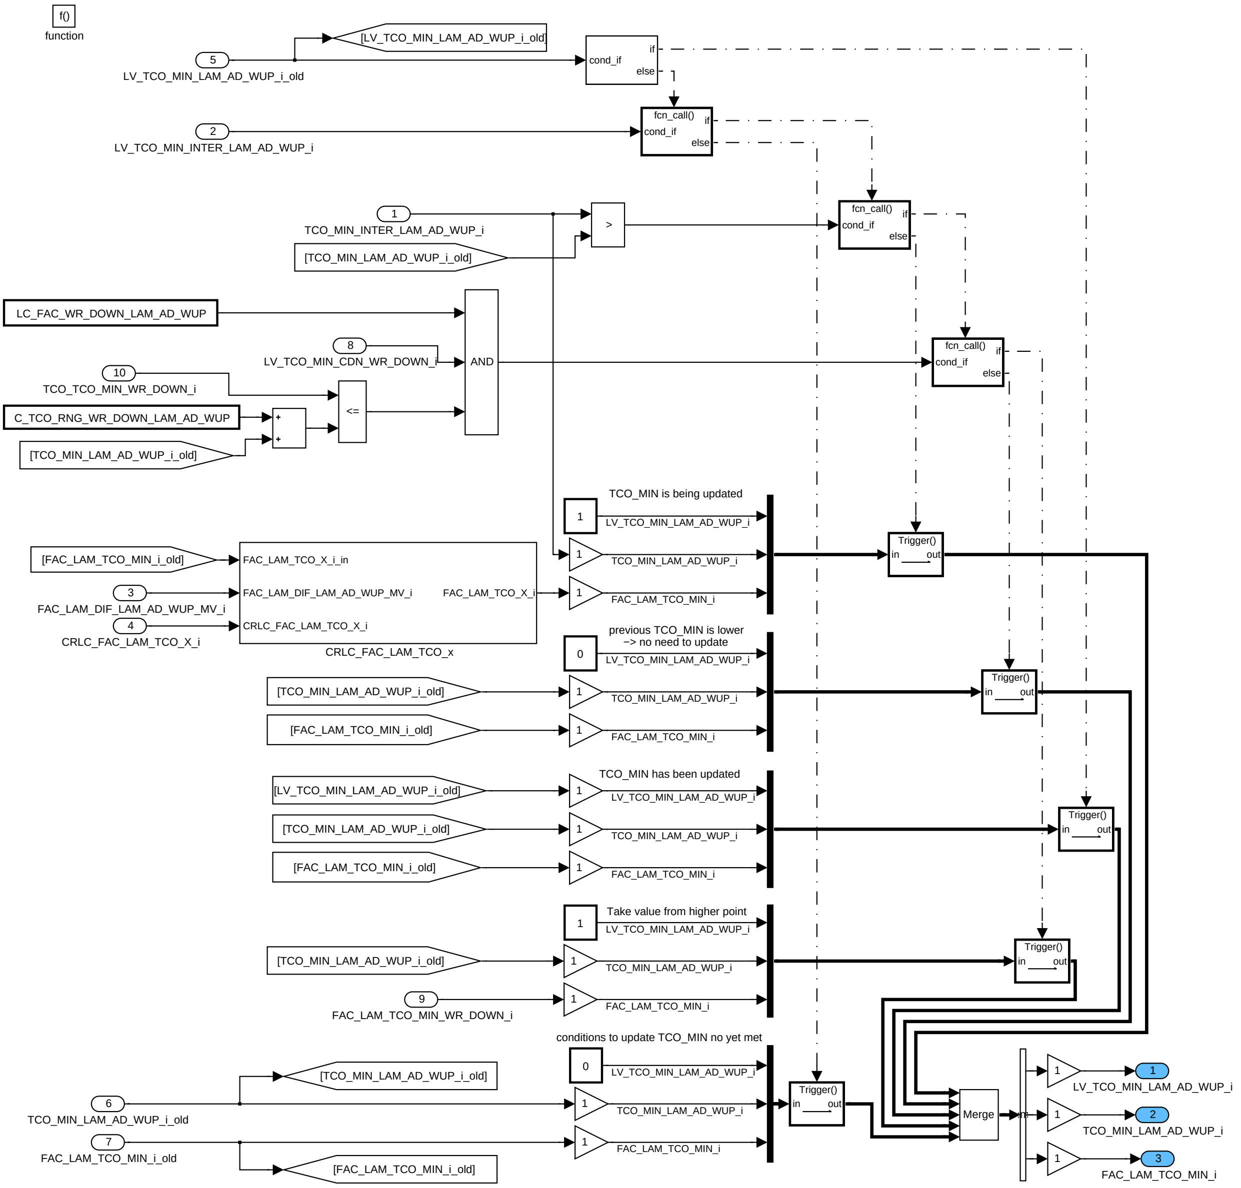

Figure 143 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_LAM_AD_WUP/ CLC_NOT_CHG_FQ_DET_TCO_MIN

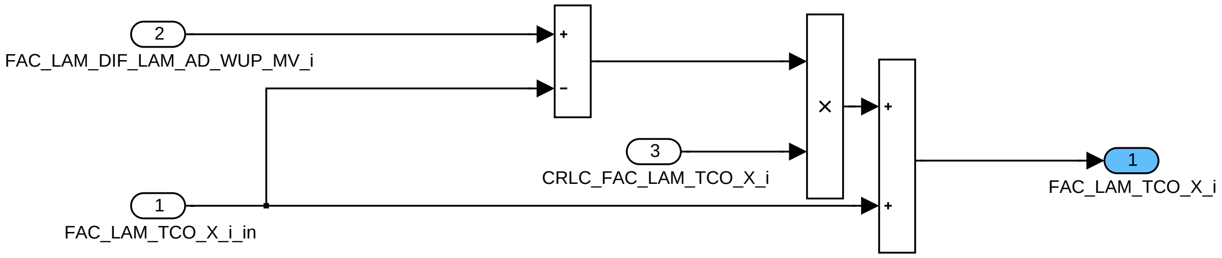

Figure 144 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_MIN_LAM_AD_WUP/ CLC_NOT_CHG_FQ_DET_TCO_MIN/ CRLC_FAC_LAM_TCO_x

Determination of new adaptation value at point A to E

If a change in fuel quality is detected the normal update process of the adaptation factor is inhibited. The auto shift value is always zero with the exception of the calculation recurrence during which the shift is executed. Furthermore, if the adaptation factor was not updated in this driving cycle (LV_TCO_X_LAM_AD_WUP[i]), then the auto shift correction is not applied.

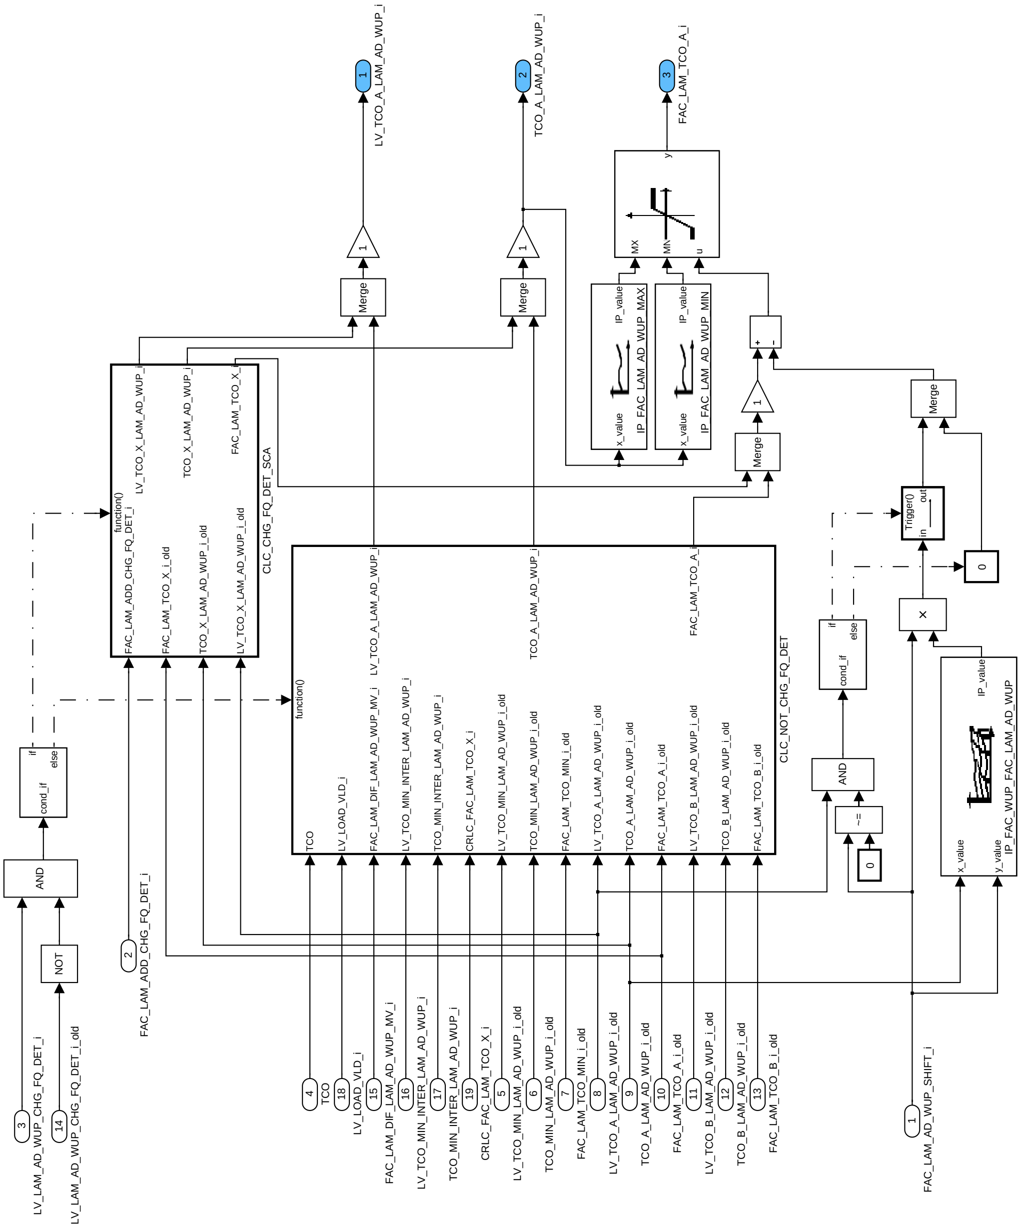

Figure 145 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_LAM_AD_WUP/ CLC_FAC_LAM_TCO_A

Determination of adaptation value during detection of change in fuel quality

First it is checked whether the adaptation factor is different from zero to confirm, that it has been updated at some point in the past. If this is not the case no shift is realized at this particular interpolation point.

For shifting the normalized shift value is multiplied by a TCO dependent weighting factor and then added to the old adaptation factor. The weighting factor takes into account that the negative effects of the low quality fuel disappear with rising temperature. Hence, the weighting factor should be around 1 for the lowest interpolation point and at around zero for the highest temperature.

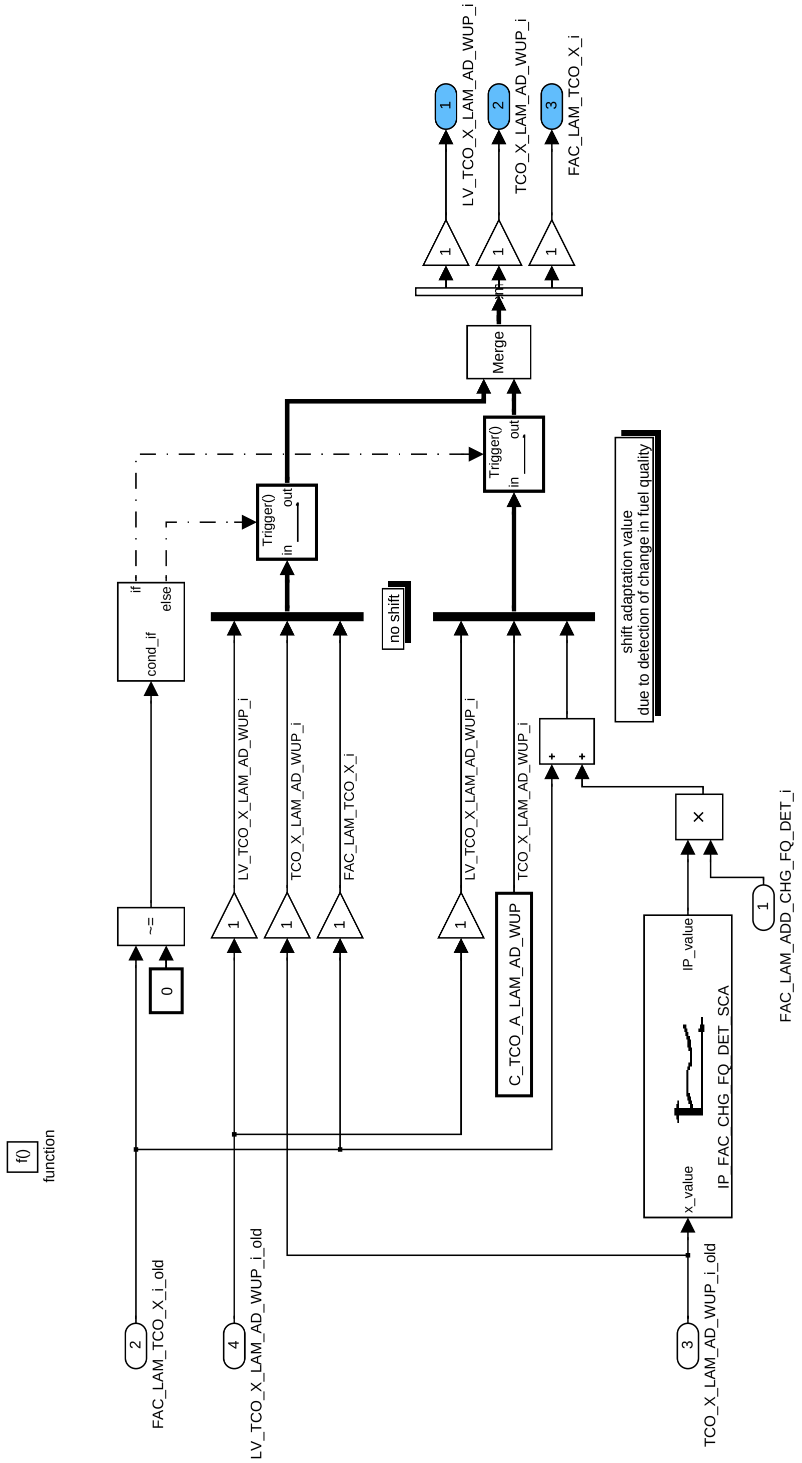

Figure 146 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ TCO_LAM_AD_WUP/ CLC_FAC_LAM_TCO_A/ CLC_CHG_FQ_DET_SCA

Determination of adaptation value during normal operation

Four different states shall be distinguished:

1.) Conditions to update are not yet fulfilled. Indicator flag remains zero and the factor and the temperature at the interpolation point are not updated.

2.) The adaptation factor the corresponding temperature are updated once the following conditions are met:
- TCO is within the temperature window
- End of transient phase has been detected, thus TCO_MIN_INTER[i] is set
- The conditions for valid learning are fulfilled sufficiently long (LV_LOAD_VLD[i])
- The difference to the previously stored value is sufficiently large

If all above conditions are met, the adaptation factor is updated with the uncorrected Lambda controller output (in this process a correlation factor is considered) and the corresponding temperature is updated with the current TCO. Additionally the indicator flag is set to one.

3.) If TCO_MIN[i] is updated (the lowest ever learnt temperature is reduced) and it is larger than the temperature of the interpolation point, then the adaptation value is updated with factor belonging to TCO_MIN[i]. The corresponding temperature is not updated in this state. This update procedure can be restricted in such that TCO_MIN[i] needs to be within temperature of point of A and point B plus size of the temperature window.

4.) Update was already done in this driving cycle: No actions are undertaken.

The calculation at point B to E proceed analogous. At interpolation point F the correction factor is fixed at zero, in order to fade out the correction smoothly.

Parameters for slope equation

Here the parameters which are required to solve the slope equation are arranged.

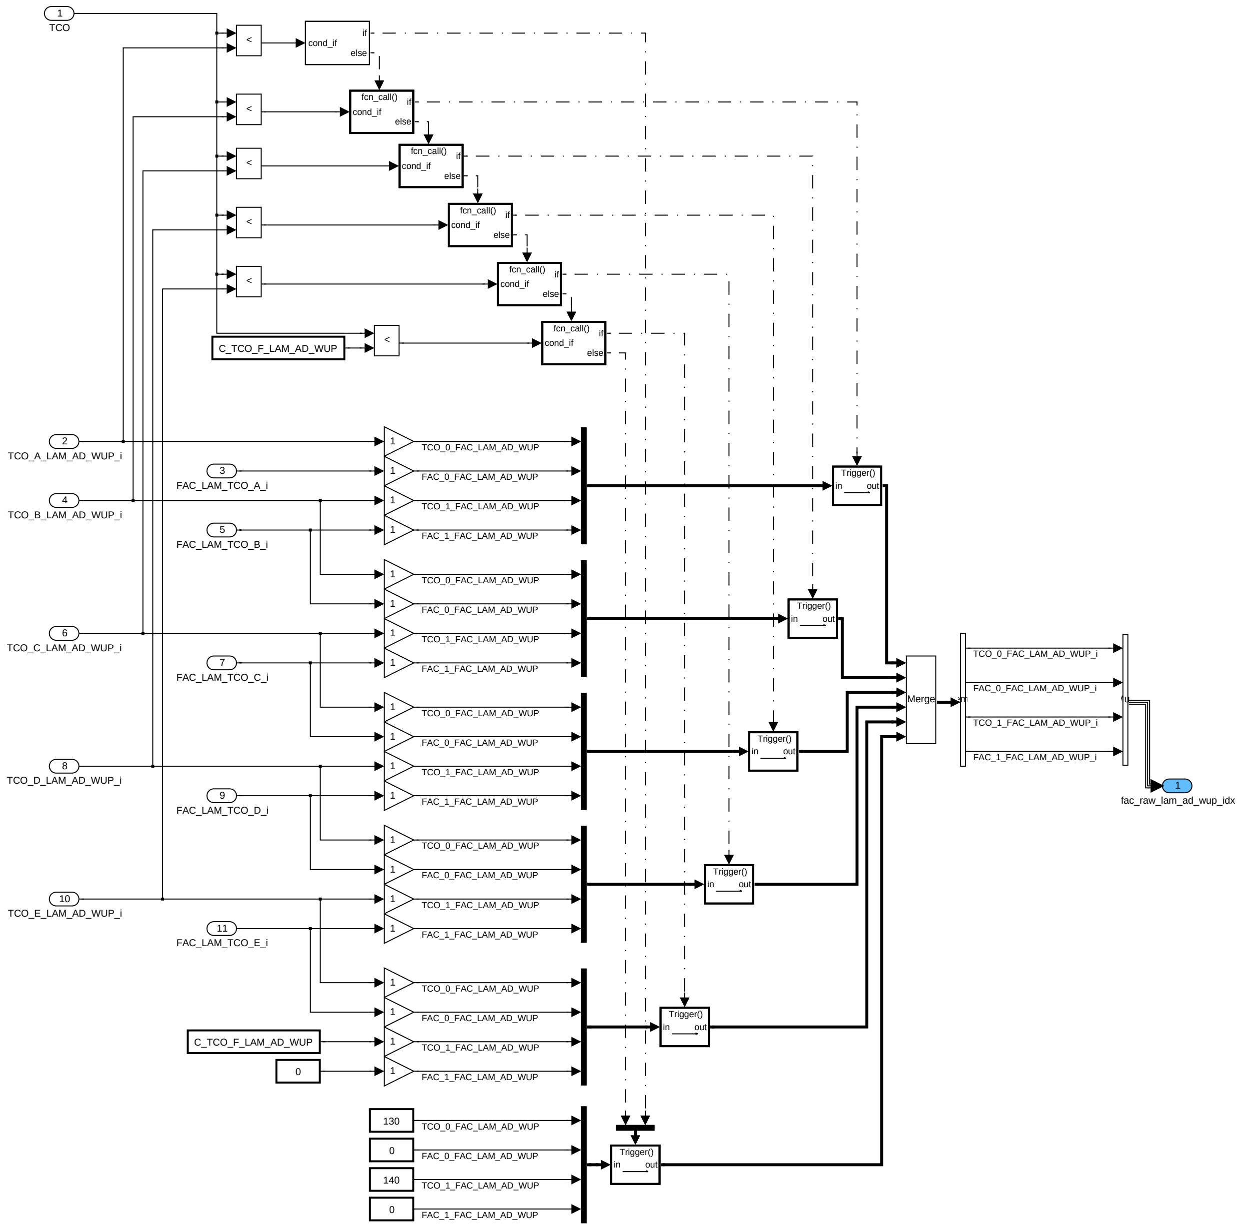

Figure 161 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_FAC_LAM_AD_WUP/ FAC_RAW_LAM_AD_WUP_IDX

Calculation of the Lambda adaptation factor in the warm-up phase

The respective adaptation factor in warm-up phase is derived from slope equation with TCO as an input. Five different cases for the calculation of FAC_RAW_LAM_AD_WUP must be distinguished:

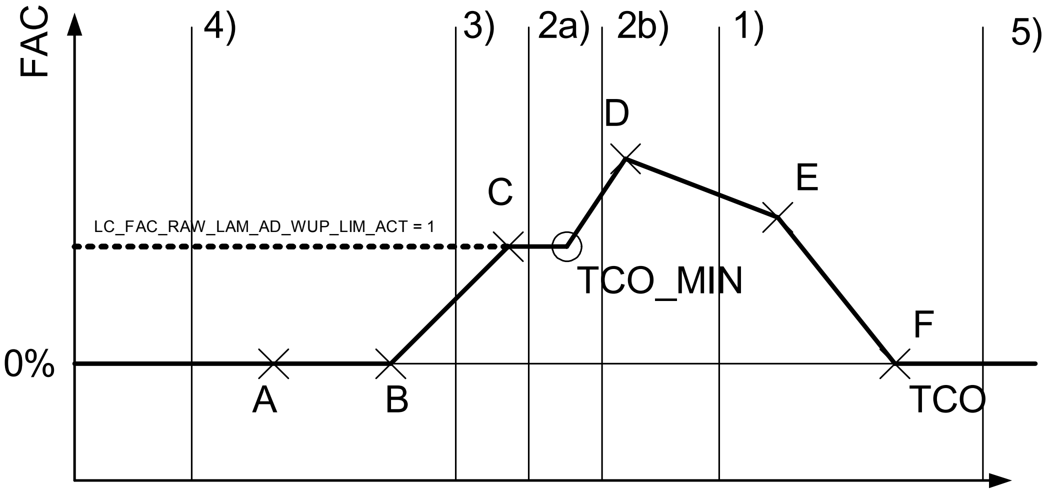
1.) The momentary TCO is between two interpolation points with TCO_MIN *smaller* than the lower interpolation point: Solving the slope equation with the two interpolation points and TCO as an input will yield FAC_RAW_LAM_AD_WUP.

2.) The momentary TCO is between two interpolation points with TCO_MIN *larger* than the lower interpolation point: Between the lower interpolation point and TCO_MIN, the output is fixed to FAC_LAM_TCO_MIN. Between TCO_MIN and the upper interpolation point, the slope equation made up from TCO_MIN and the upper interpolation point shall be used to calculate FAC_RAW_LAM_AD_WUP.

3.) TCO is smaller than TCO_MIN and TCO_MIN is larger than the next higher interpolation point. If LC_FAC_RAW_LAM_AD_WUP_LIM_ACT is set to one, the output value is fixed to FAC_LAM_TCO_MIN; otherwise it shall be obtained by solving the slope equation.

4.) TCO is smaller than temperature at point A:
If LC_FAC_RAW_LAM_AD_WUP_LIM_ACT is set to one, the output value is fixed to FAC_LAM_TCO_MIN, otherwise it is zero.

5.) TCO is larger than temperature of point F: the output is zero.



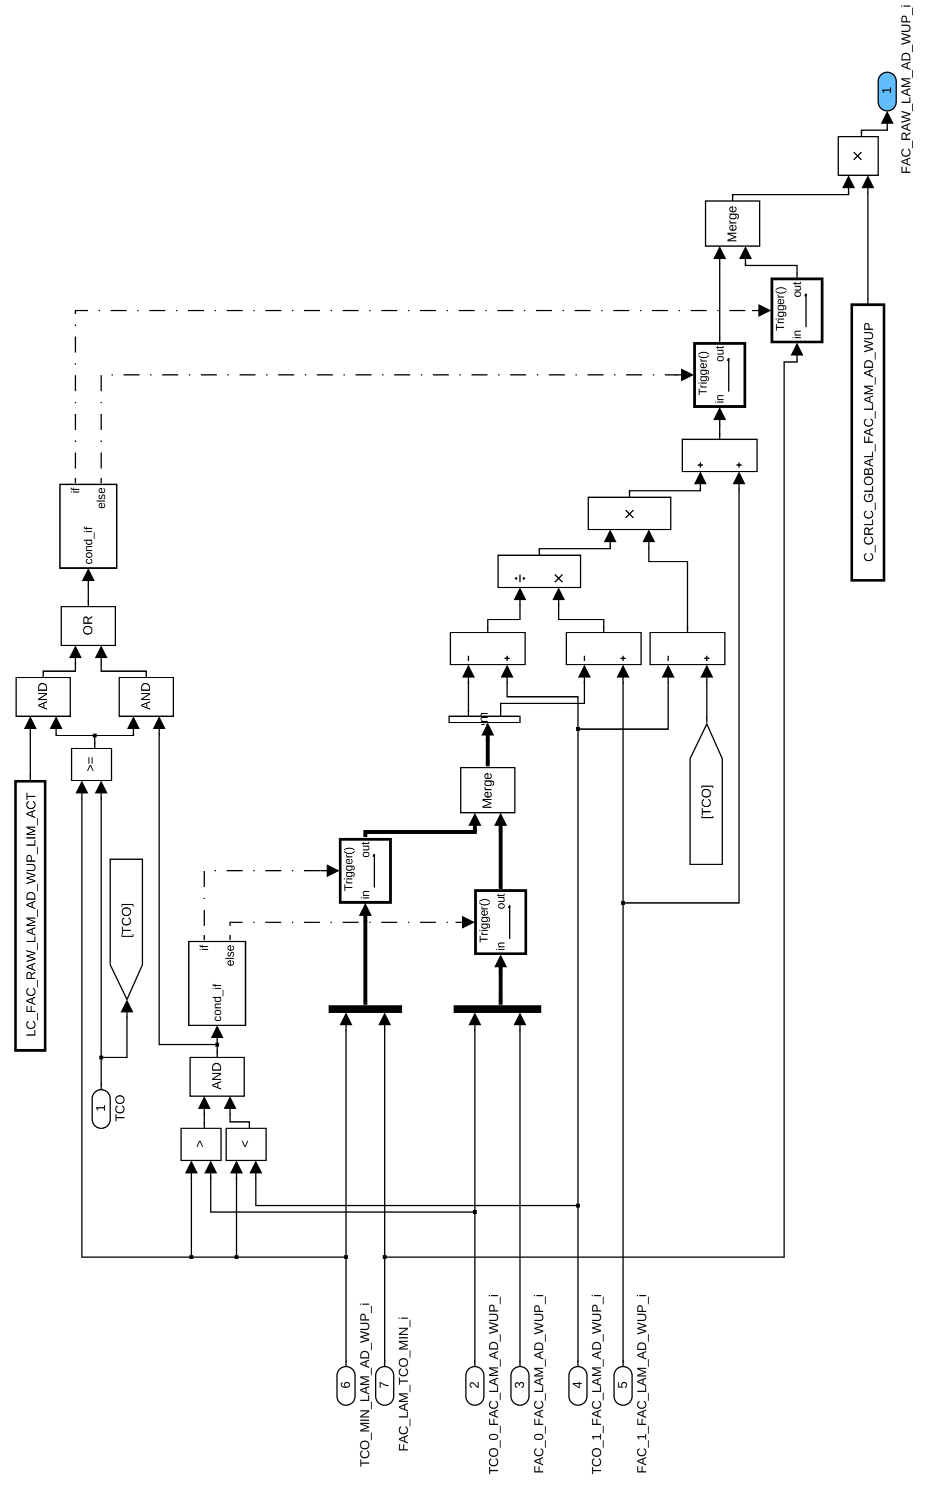


Figure 162 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_FAC_LAM_AD_WUP/ FAC_RAW_LAM_AD_WUP

Limitation of adaptation factor

Three different limitations of the Lambda adaptation factor in warm-up phase can be applied. If the conditions to go closed loop Lambda control are not yet fulfilled (STATE_LS == 0) C_FAC_LAM_AD_WUP_MAX/MIN_LSCL_OFF is applied. In the transient phase until TCO_MIN_INTER is detected C_FAC_LAM_AD_WUP_MAX/MIN_INTER is the relevant limitation. After detection of TCO_MIN_INTER the limitation are specified by IP_FAC_LAM_AD_WUP_MAX/MIN.

With C_FAC_LAM_AD_WUP_DELTA the shifts in the Lambda adaptation factor in warm-up phase can be smoothed by specifying the maximum step value. It has been observed that for large changes in the adaptation value that Lambda controller output is not reduced as fast as the adaptation value increases (due to transient effects). This causes unwanted deviation of the Lambda value, which can be avoided by specifying a smooth transition between different values of the adaptation factor.

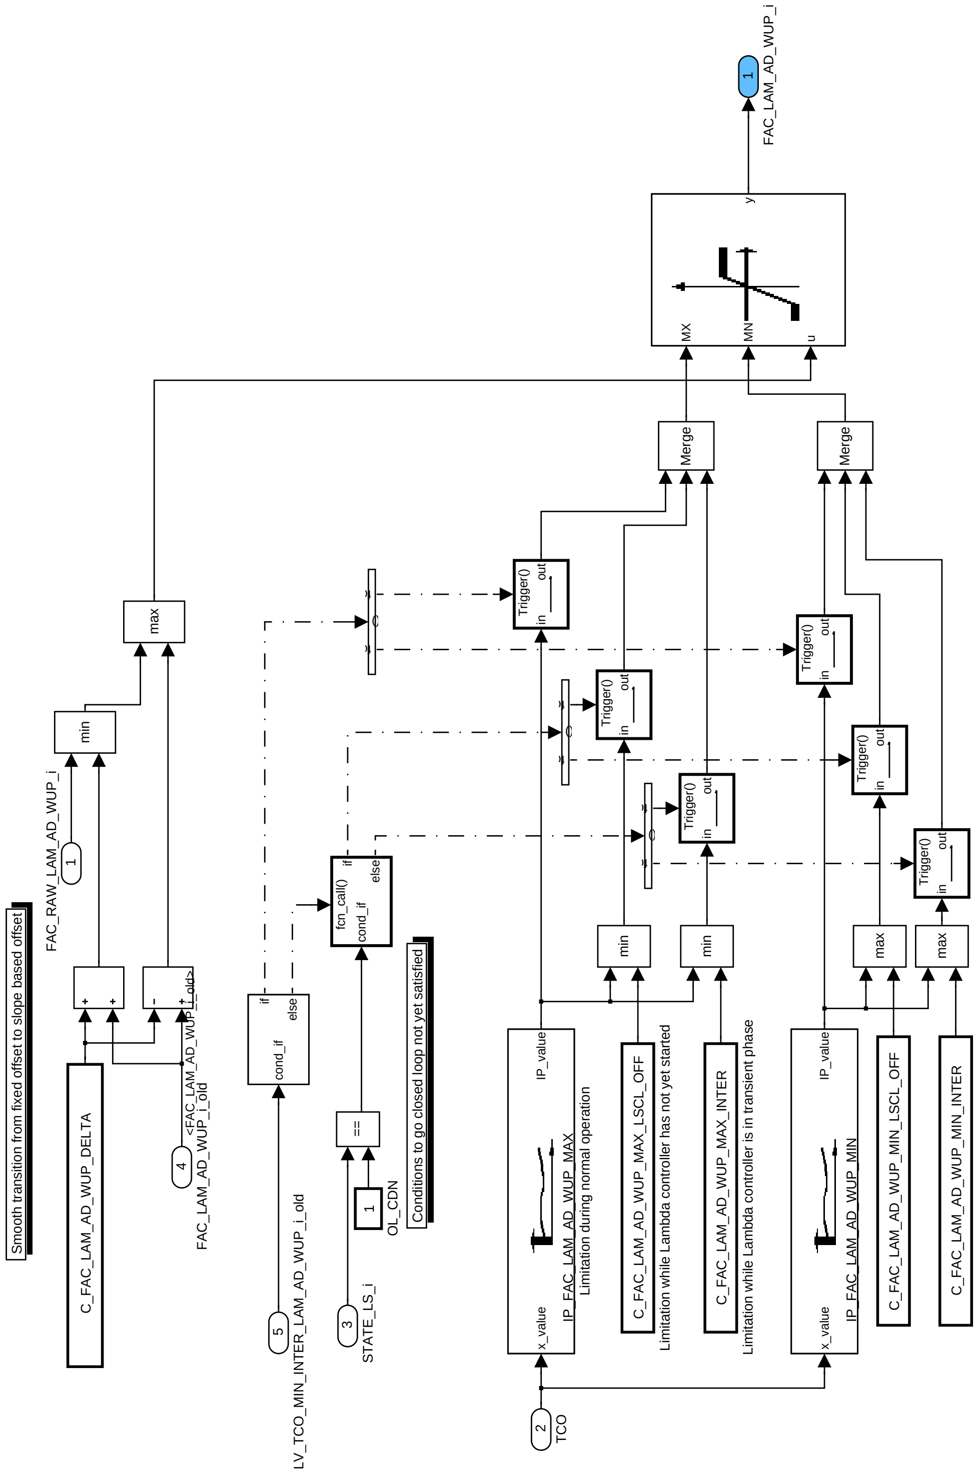

Figure 163 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_FAC_LAM_AD_WUP/ FAC_LAM_AD_WUP_LIM

Shift of the Lambda controller

A shift of the Lambda controller output is required if the value of FAC_LAM_AD_WUP[i] has changed since the last calculation recurrence in order to avoid large Lambda controller excursions.

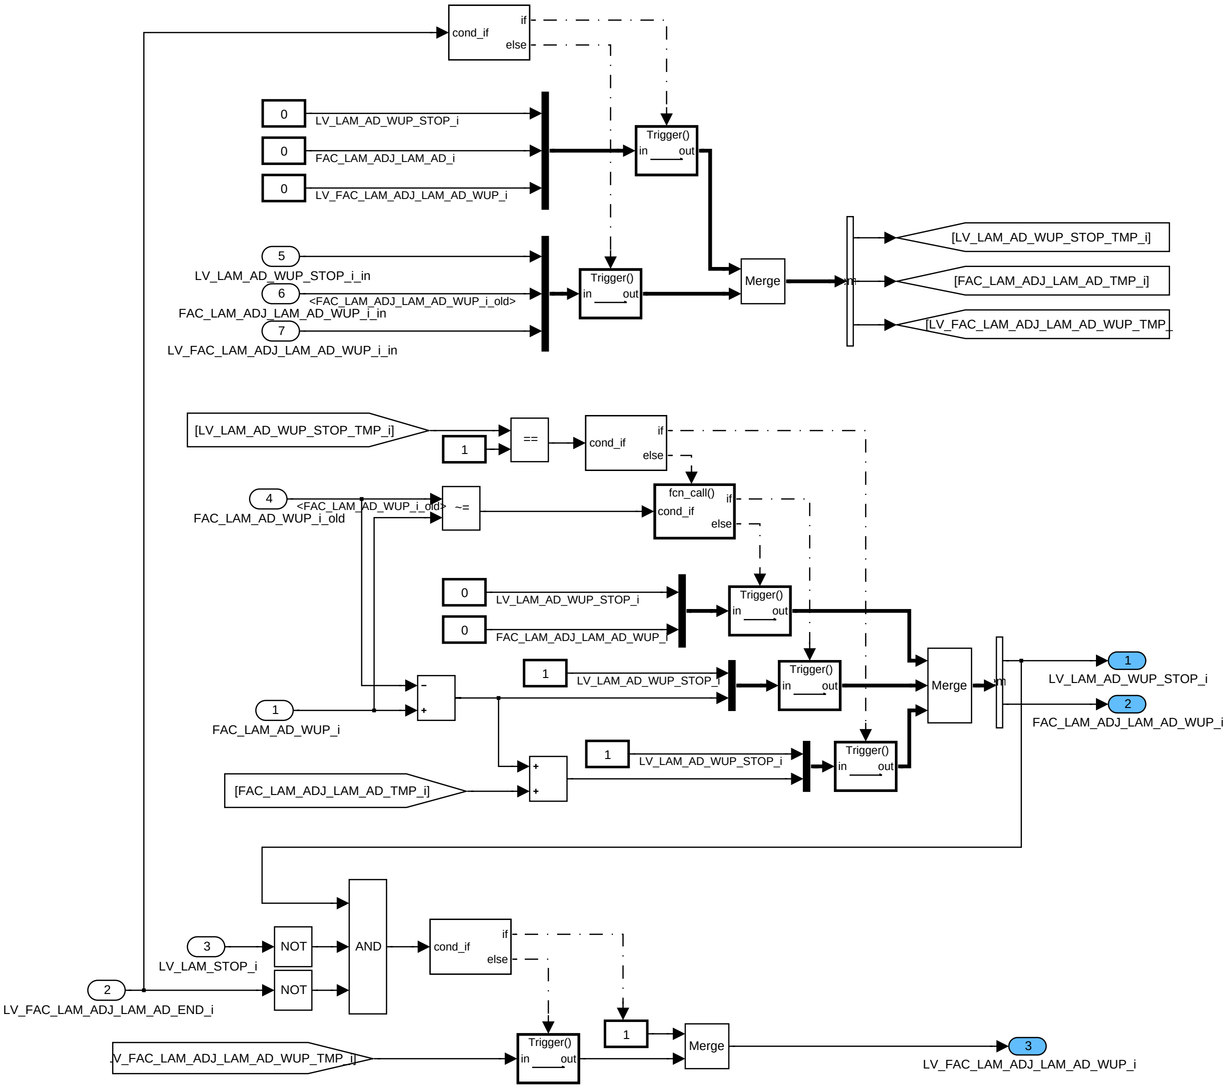

Figure 164 LACO_ISPCLADAW0/ operate/ FAC_LAM_AD_WUP_CBK_MNG/ FAC_LAM_AD_WUP_CBK_SPC/ CLC_FAC_LAM_AD_WUP/ CLC_FAC_LAM_ADJ_LAM_AD_WUP

<u>Rewriting of adaptation correction in warm-up phase with non volatile stored values</u>

In case of Lambda adaptation relevant errors (see application incidences) the values of the data to be stored in the non-volatile memory must be rewritten with the values stored at the end of the last driving cycle.

46.14.1 LACO_ISPCLMVLDC0

This function calculates only differences between base values and their moving means values. These differences or deltas are to be used within the function that needs limited dynamic conditions. The evaluation of the limited dynamic bit is part of the function that need this flag. So the mean value calculation is concentrated in this function.

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension "_i" is used in the model instead of "[i]" as found in the textual description.

Application Condition

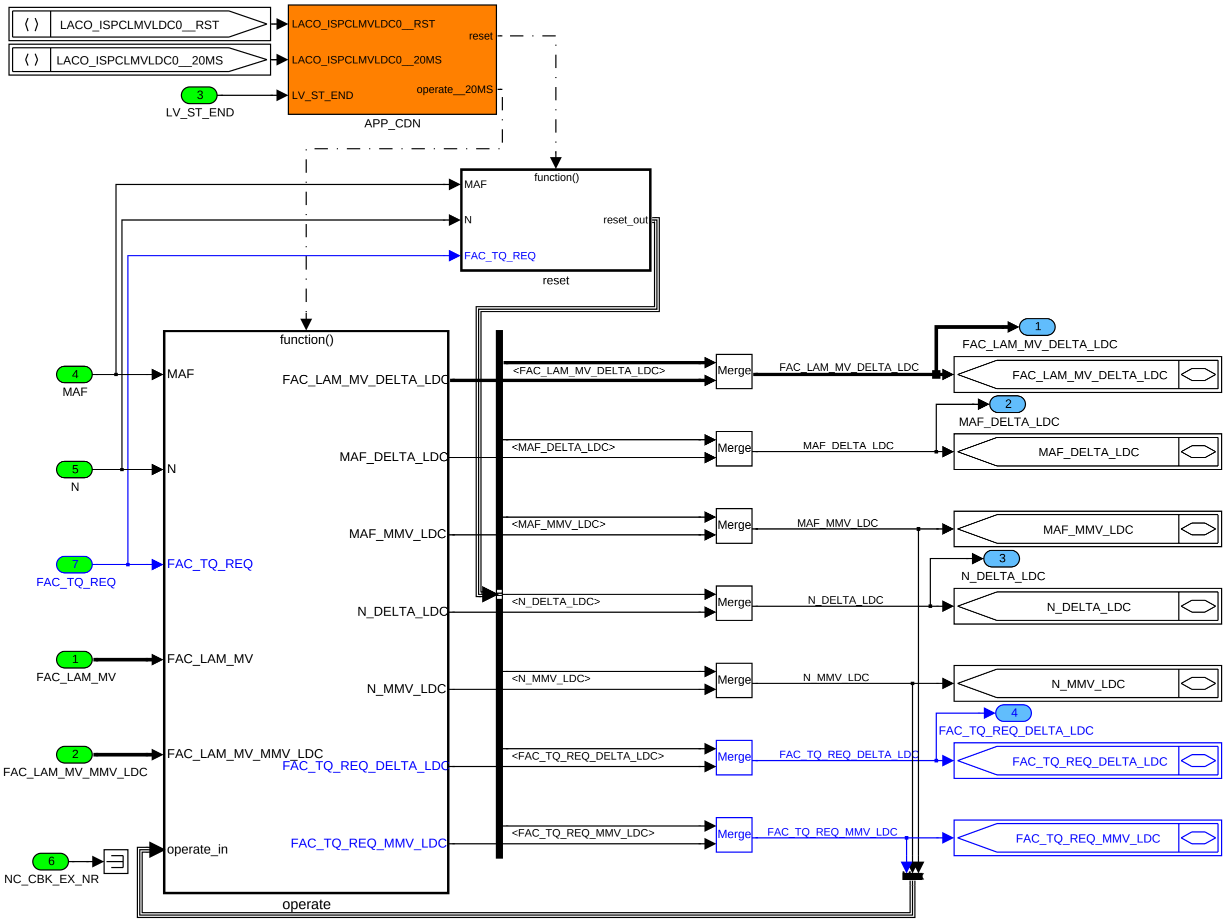
Function Description



SDA_SRS / SDA 4.0 20−May−2005

Figure 172 LACO_ISPCLMVLDC0

46.14.1.1 SUBFUNCTION: reset

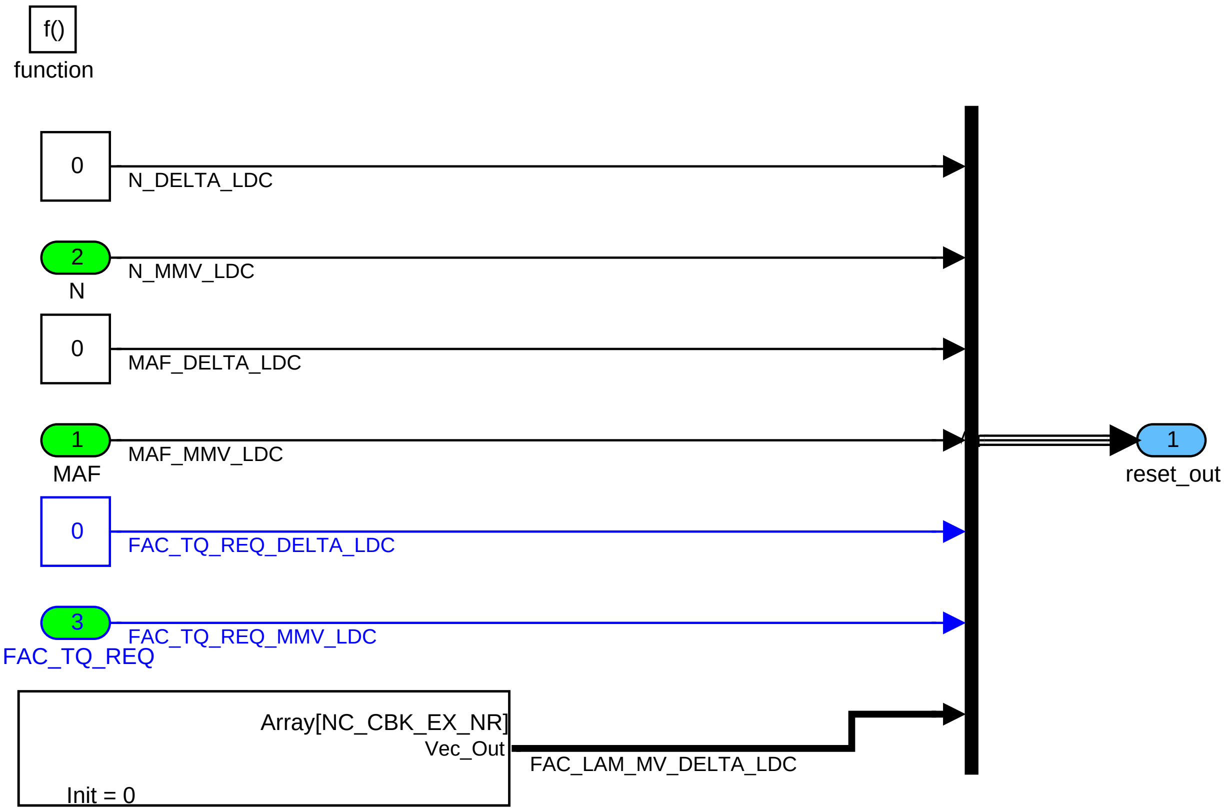


Figure 173 LACO_ISPCLMVLDC0/ reset

46.14.1.2 operate

This function calculates for the detection of the limited dynamics the moving mean values of engine speed (N and N_MMV_LDC), air mass flow (MAF and MAF_MMV_LDC) and degree of activation of the accelerator pedal (PV and PV_AV_MMV_LDC). Furthermore the difference between these input values and the moving mean values is calculated.

For the lambda control output only the difference is evaluated because the moving mean value calculation is located in the lambda control module itself because of easier realisation of shift operations of the moving mean value (FAC_LAM_MV_MMV_LDC[i]).

Remark: The difference calculation of lambda control output is a vector operation.

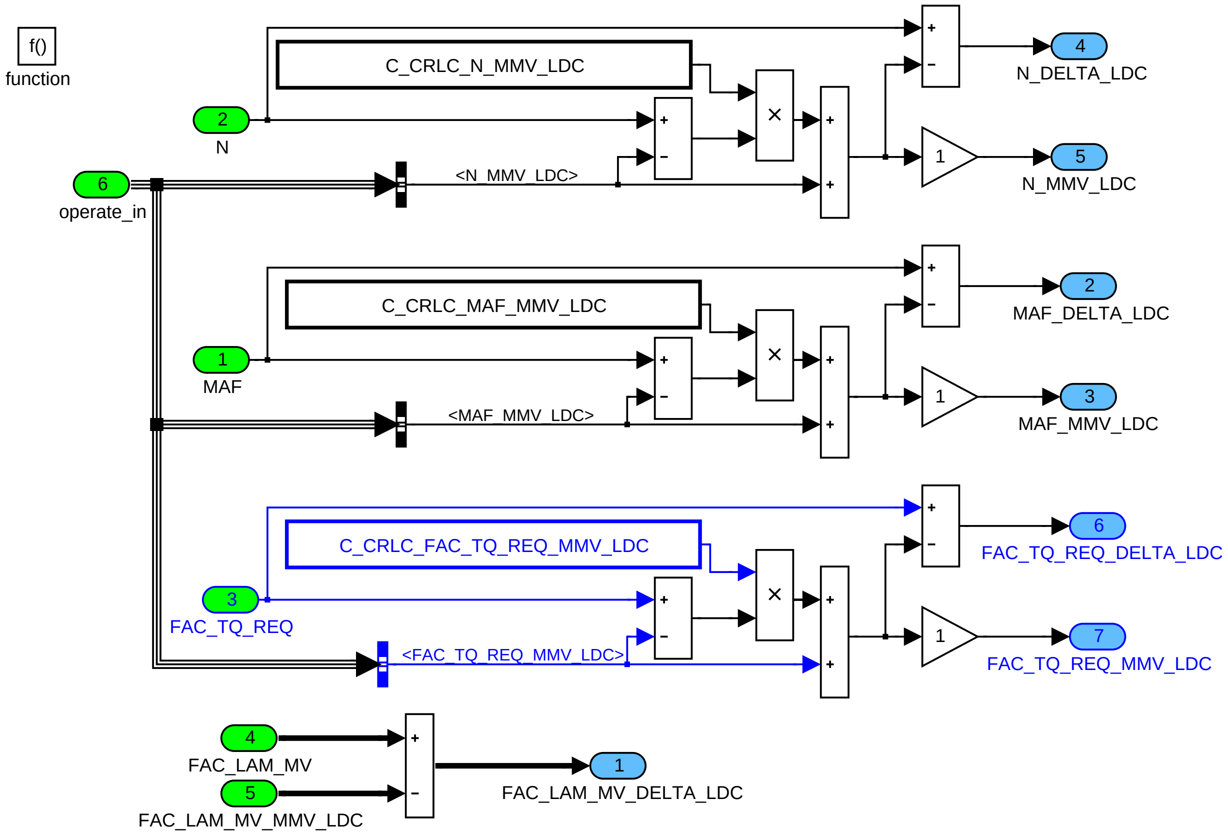

Figure 174 LACO_ISPCLMVLDC0/ operate

FUNCTION DESCRIPTION:

General information:

The calculation shall be done for all exhaust cylinder banks. For instance, if two separate catalyst systems are concerned (NC_CBK_EX_NR = 2) then

i = 1, for exhaust cylinder bank 1
i = 2, for exhaust cylinder bank 2,
otherwise (NC_CBK_EX_NR = 1)
i = 1, for single exhaust cylinder bank.

Description:

The activation conditions of the lambda adaptation depends on:

- coolant temperature thresholds,
- temperature of intake air into manifold threshold,
- air mass flow threshold,
- secondary air function including diagnosis finished
- lambda setpoint thresholds
- and several error flags that must be zero

If all activation conditions are fulfilled, during the warm-up phase LV_LAM_AD_WUP_ACT[i] is set and during normal warm conditions LV_LAM_AD_ACT[i] is set to 1. That means that the lambda adaptation can get active if no other inhibition defined in the lambda adaptation module is set.

The detection of the limited dynamics is calculated based on the current engine speed, air mass flow and filtered lambda control output. The input to this function is the difference between each of the mentioned base values and its moving mean values. If one of those differences exceeds a calibrated threshold, an air mass flow integral is started to be calculated until a calibrated MAF threshold is reached. During the calculation the limited dynamics are defined to be not fulfilled (LV_LDC_LAM_AD[i] = 0). In order to reset the difference between base value and moving mean value after each threshold exceeding, an offset variable is introduced (see formula section).

Furthermore the correlation constant for calculation of adaptive values and the distance between two adaptations are determined dependent on the different adaptation ranges.

Application conditions:

Initialisation: *at ECU reset:*

LV_LAM_AD_ACT[i]	*= 0*

46.16.1 General information

This function checks all necessary activation conditions in order to activate fuel system diagnosis. High rate of evaporated fuel during rich warm-up phase under cold start conditions could lead to wrong failure detection and therefore a special inhibition flag for that case is generated.

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

Application Condition

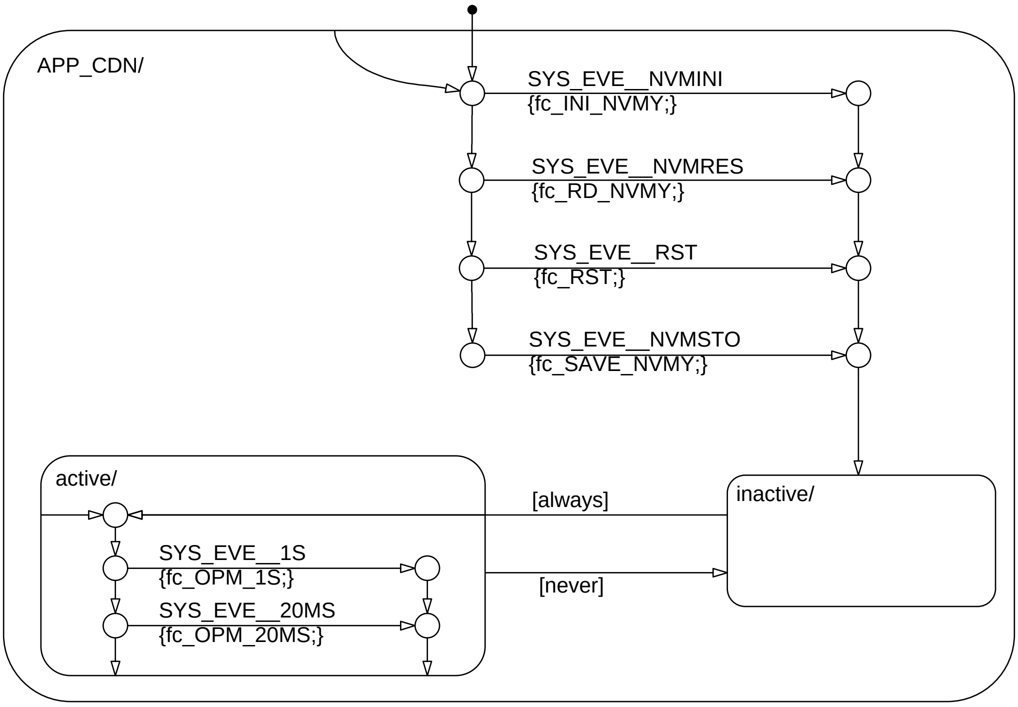

Figure 175 LACO_FCTDGFSDA0/ APP_CDN/ Chart

Function Description

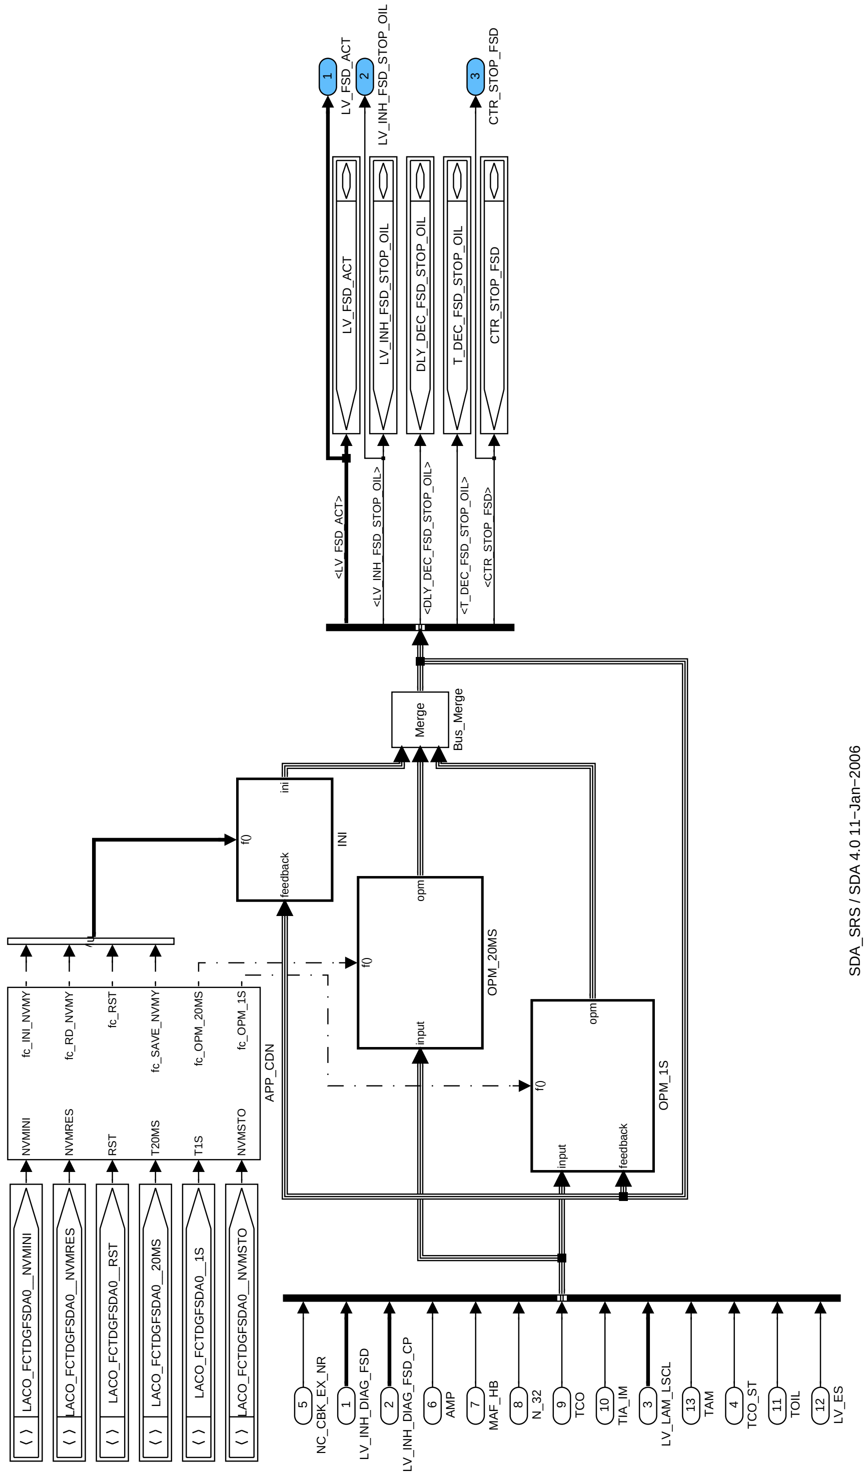

Figure 176 LACO_FCTDGFSDA0

46.16.1.1 Initialization

Initialization at ECU reset

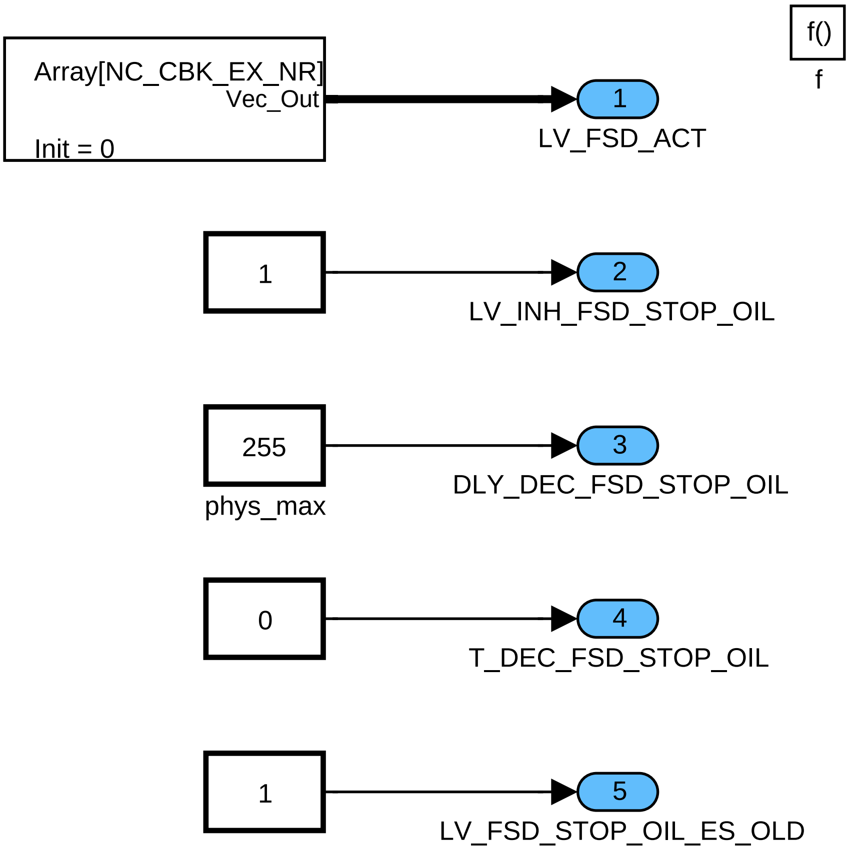

Figure 177 LACO_FCTDGFSDA0/ INI/ RST

Initialize NVMY data

CTR_STOP_FSD is set to 0 in case of failure in the non-volatile memory data storage.

Read NVMY data

CTR_STOP_FSD is restored from the non-volatile memory data storage after reset.

Store NVMY data

CTR_STOP_FSD is saved in the non-volatile memory data storage during PWL phase.

46.16.1.2 Formula section for 20ms task

Exhaust bank specific functionality

Activation of fuel system diagnosis

Calculation of LV_FSD_ACT[i]

In order to activate fuel system diagnosis no inhibition must be present, lambda controller must be active and ambient pressure, air mass flow, engine speed, coolant temperature and intake air temperature must be above their thresholds.

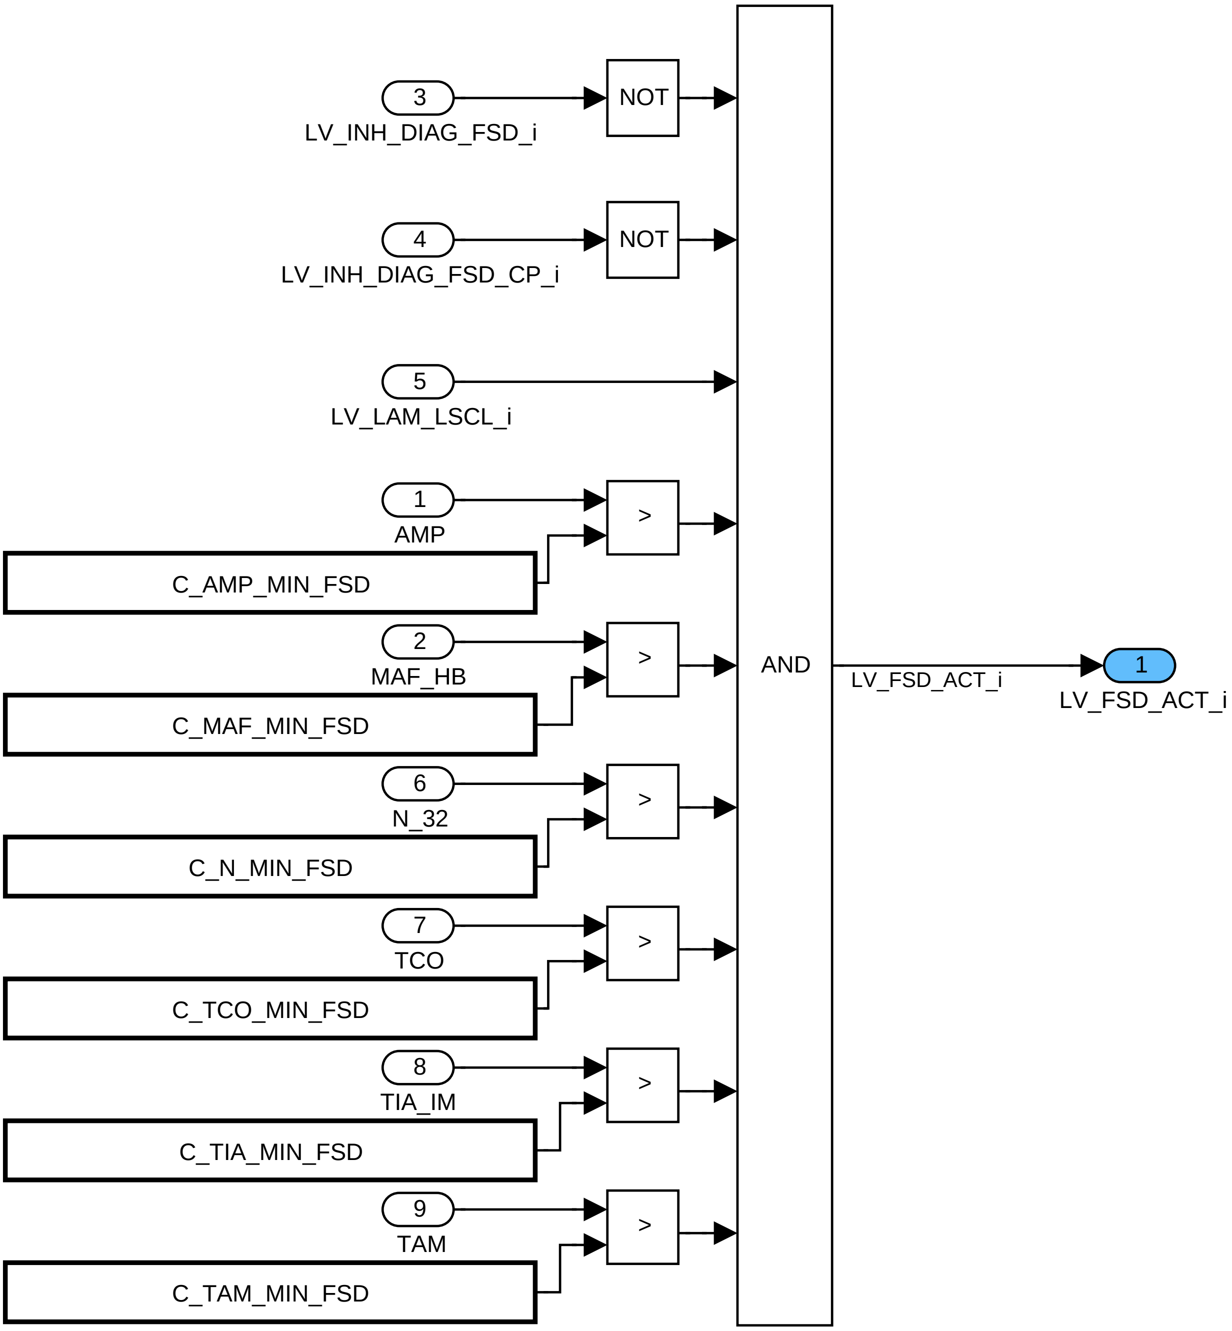

Figure 178 LACO_FCTDGFSDA0/ OPM_20MS/ OPM/ FSD_ACT/ FSD_ACT

46.16.1.3 Formula section for 1s task

For high rate of evaporated fuel (diluted in the engine oil) during rich warm-up phase under cold start conditions lambda controller and adaptation may reach the negative limits relevant for FSD (MIN limits). In order to prevent an error detection in that case the flag LV_INH_FSD_STOP_OIL used by FSD is set. The counter CTR_STOP_FSD is a measure for the amount of diluted fuel in the engine oil.

Increment of CTR_STOP_FSD

At each transition from engine stop to engine run (LV_ES switches from 1 to 0) the counter CTR_CTOP_FSD is incremented by the TCO_ST depending map value ID_CTR_INC_FSD_STOP_OIL.

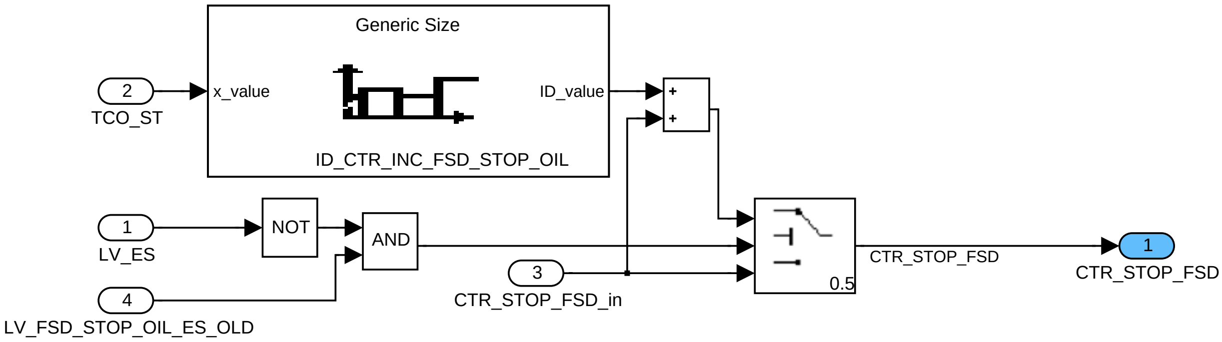

Figure 179 LACO_FCTDGFSDA0/ OPM_1S/ INC_CTR

Decrement CTR_STOP_FSD

ID_DLY_DEC_FSD_STOP_OIL defines the time to elapse at a certain TOIL range for decrementing CTR_STOP_FSD by 1. The TOIL range is defined by 2 adjacent map break points. At engine stop and as long as the oil temperature is below a threshold this timer is set to 0 in order to not run the increment functionality. The timer is reset to 0 as soon the threshold is reached.

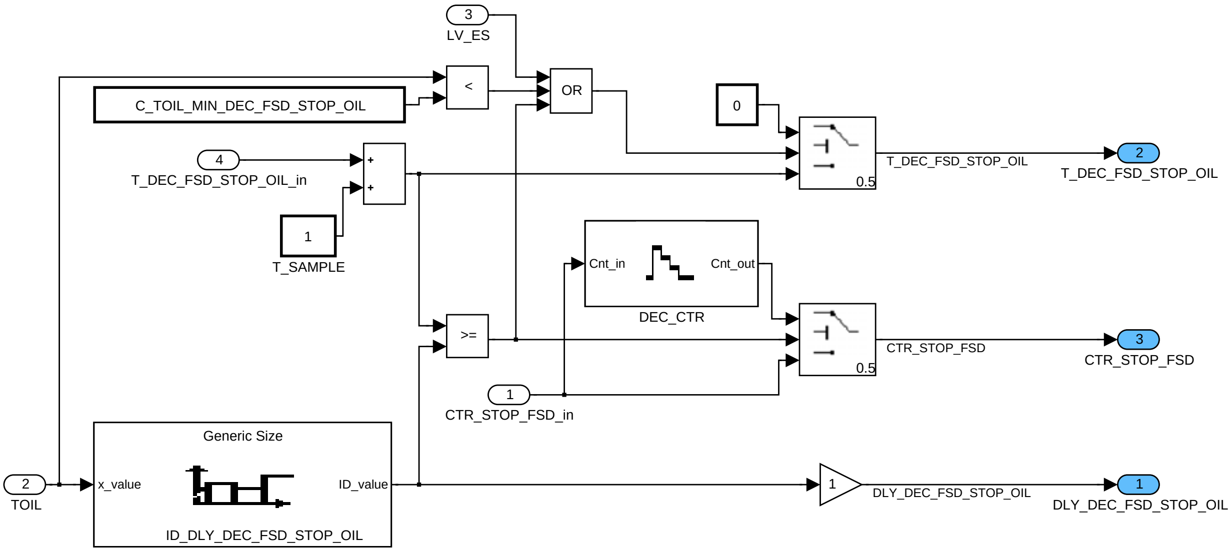

Figure 180 LACO_FCTDGFSDA0/ OPM_1S/ DEC_CTR

Inhibition of fuel system diagnosis

The flag LV_INH_FSD_STOP_OIL is set if the counter CTR_STOP_FSD reaches a calibration threshold.

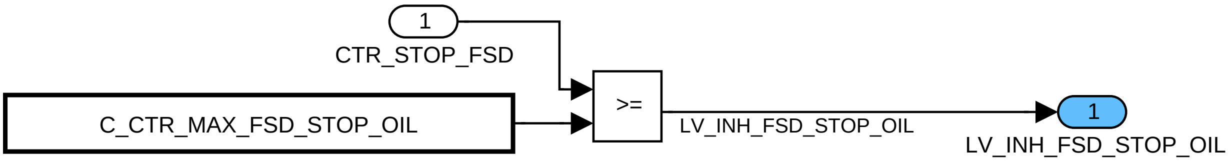

Figure 181 LACO_FCTDGFSDA0/ OPM_1S/ INH_FSD

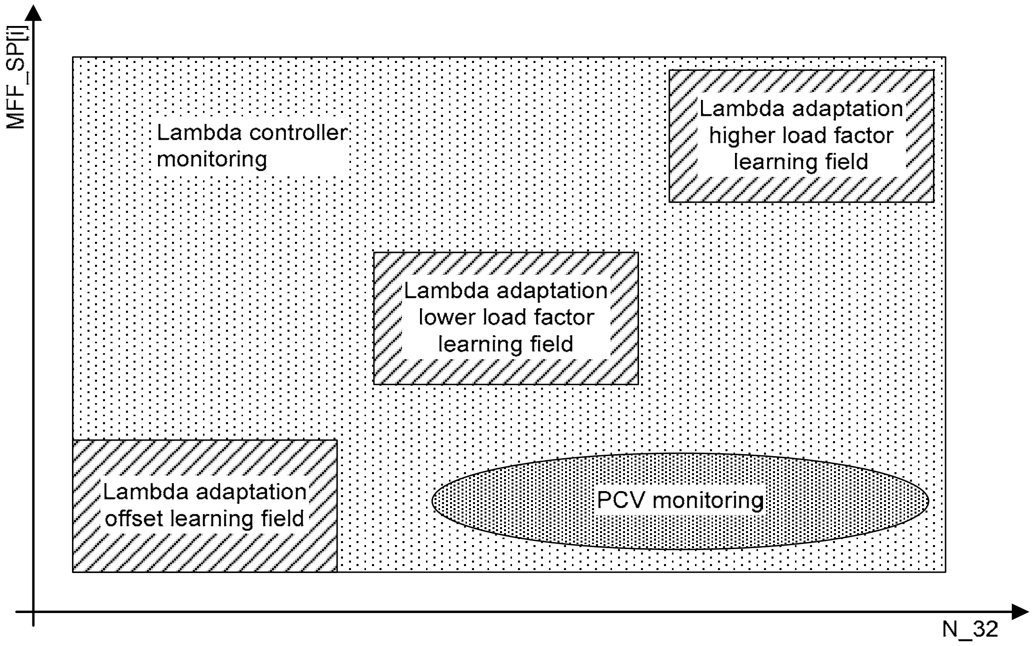
Import actions:

ACTION_ERRM_NoFilterReset(IN <IDX_DIAG>, OUT <LV_ERR>)
This action resets data filter in case of no filter usage
ACTION_ERRM_GetLvErr(IN <IDX_DIAG>, OUT <LV_ERR>)
Action that returns the status of the debounced failure
ACTION_ERRM_NoFilterSymptom(IN <IDX_DIAG>, IN <LV_CDN_DIAG>, IN <ERR_SYM>, IN <LV_ERR_SET>, IN <LV_ERR_RST>, IN <LV_END_DIAG>, OUT <LV_ERR>)
This action returns the result on symptoms detected at each diagnostic recurrence, when no filter is used

46.17.1 General information

The objective of the fuel system diagnosis is to monitor the lambda control output and the lambda adaptation values in various areas. It should also cover the PCV monitoring where the lambda control output is considered in the idle range.



Monitoring area of fuel system diagnosis

Breaking the adaptation and lambda controller limits for a long time, which may have been caused by failures in the fuel or intake system will involve emission rise and therefore shall be diagnosed by fuel system diagnosis.

FSD errors are located in three failure memories with two and four symptoms each:

ERR_SYM_FSD[i]:

NO_SYM: no symptom
SYM_0: maximum limit of additive adaptation value reached
SYM_1: minimum limit of additive adaptation value reached
SYM_2: maximum limit of multiplicative adaptation value (lower area) reached
SYM_3: minimum limit of multiplicative adaptation value (lower area) reached

ERR_SYM_FSD_H_RNG[i]:

NO_SYM: no symptom
SYM_0: maximum limit of multiplicative adaptation value (upper area) reached
SYM_1: minimum limit of multiplicative adaptation value (upper area) reached

ERR_SYM_FSD_LAM_LIM[i]:

NO_SYM: no symptom
SYM_0: lambda control in dead stop (upper limit)
SYM_1: lambda control in dead stop (lower limit)

NC_CBK_EX_NR defines the number of exhaust banks.

For vector elements the variable extension “_i” is used in the model instead of “[i]” as found in the textual description.

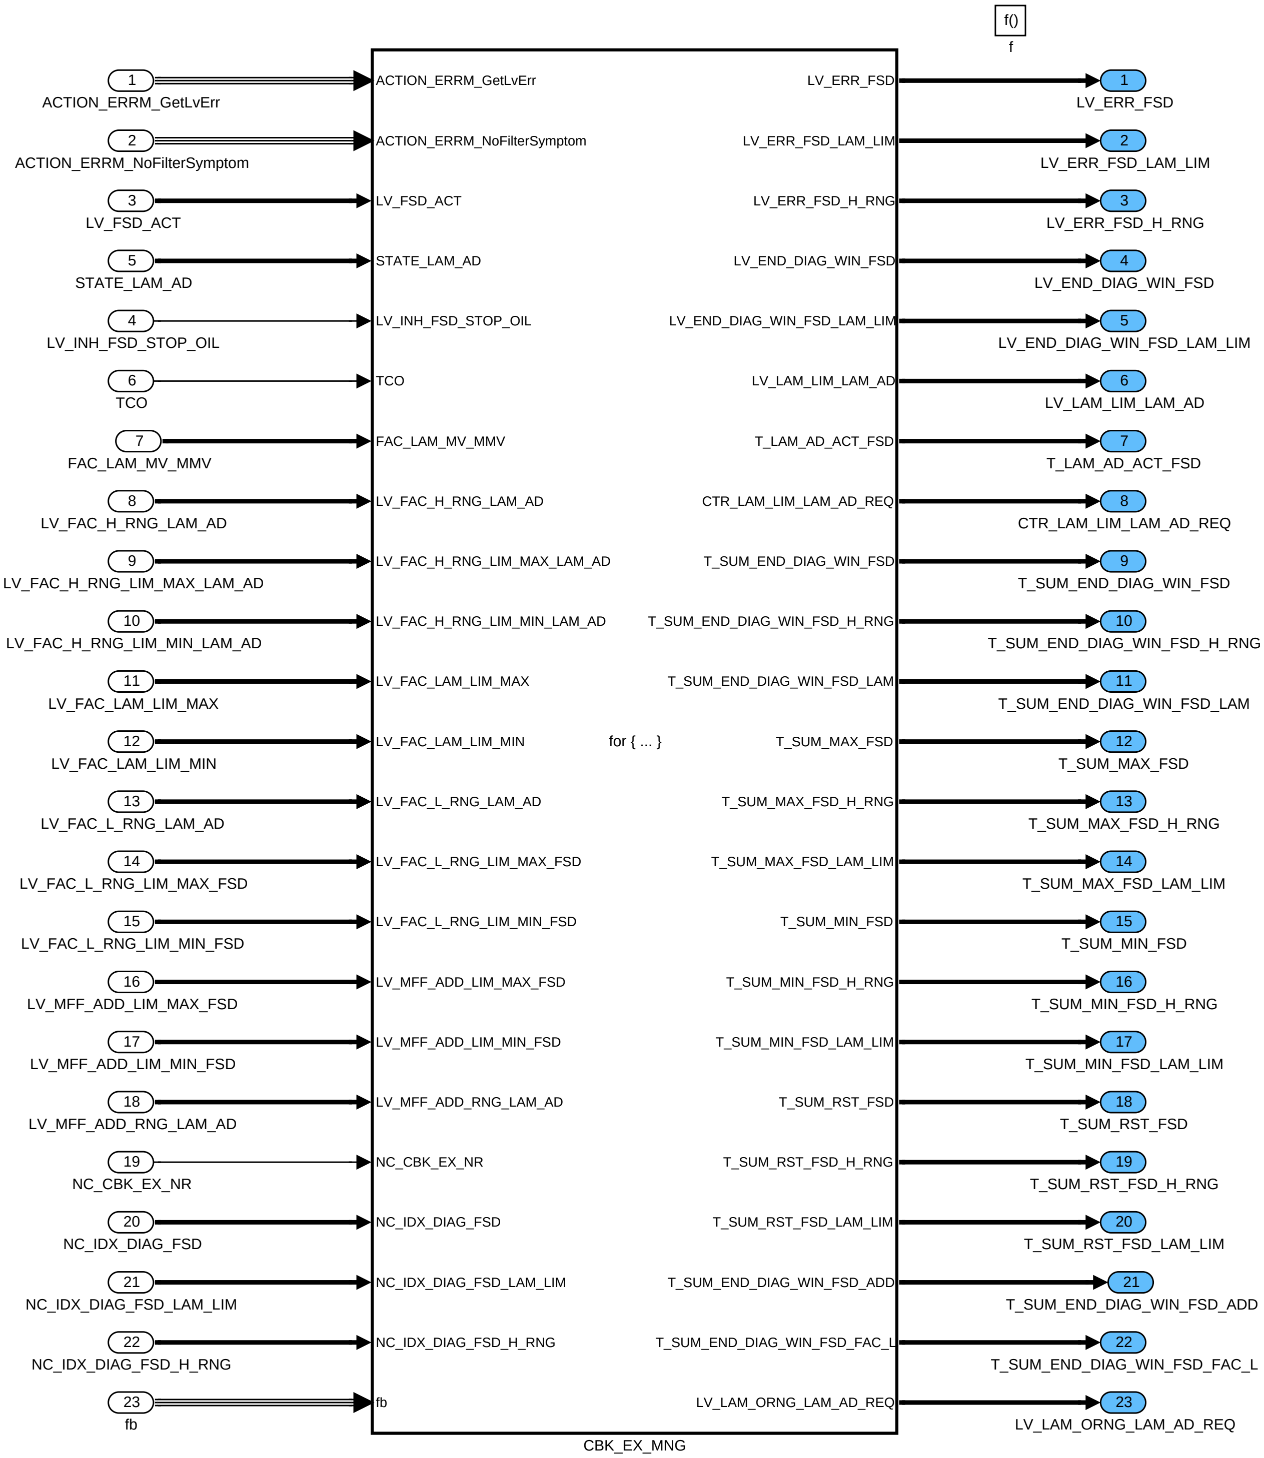

Figure 186 LACO_FCTDGFSD0/ operate_20MS

Exhaust bank specific functionality

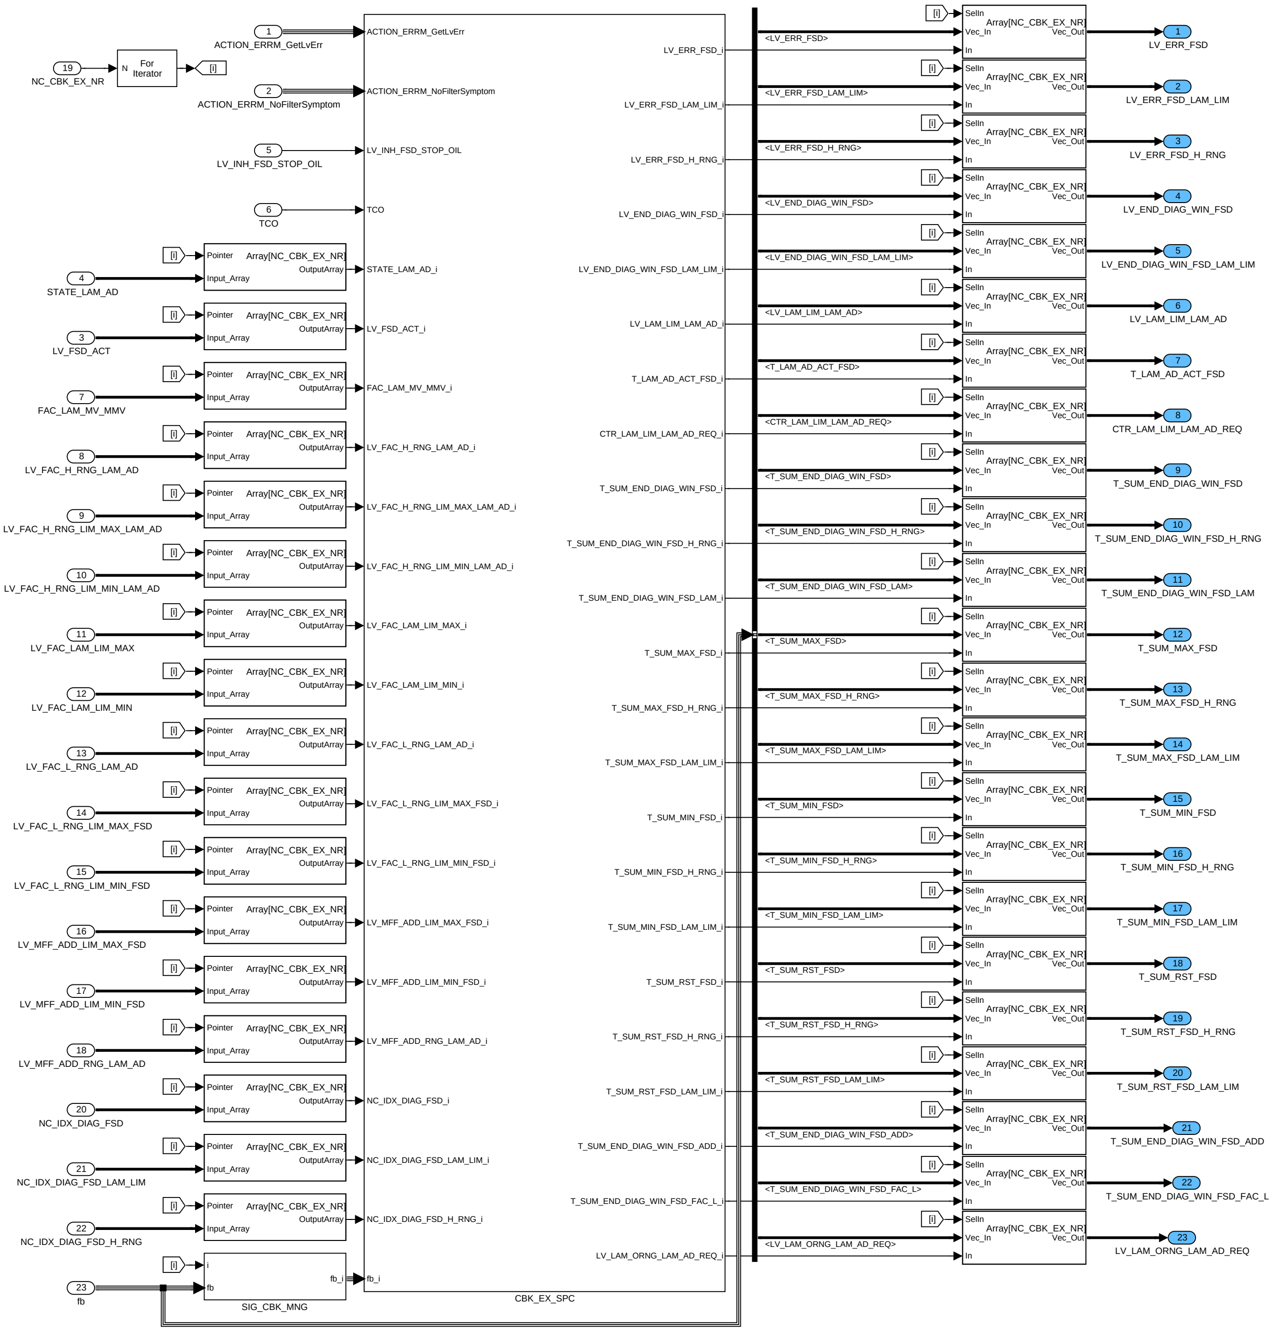

Figure 187 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG

Overview about the diagnostics

The diagnosis function is split into 4 blocks.

1. By means of an interface functionality to the lambda adaptation the forced lambda adaptation can be requested by the FSD. This functionality runs independent of the rest.

2. The diagnosis conditions for all failure location are evaluated separately from each other.

3. The main block is the evaluation of the error symptom and the management of the end of diagnosis information. The decision about present errors is also part of this block.

4. The interface to the error management ERRM is handled in this block. My means of ACTION calls the relevant information is transmitted to the ERRM.

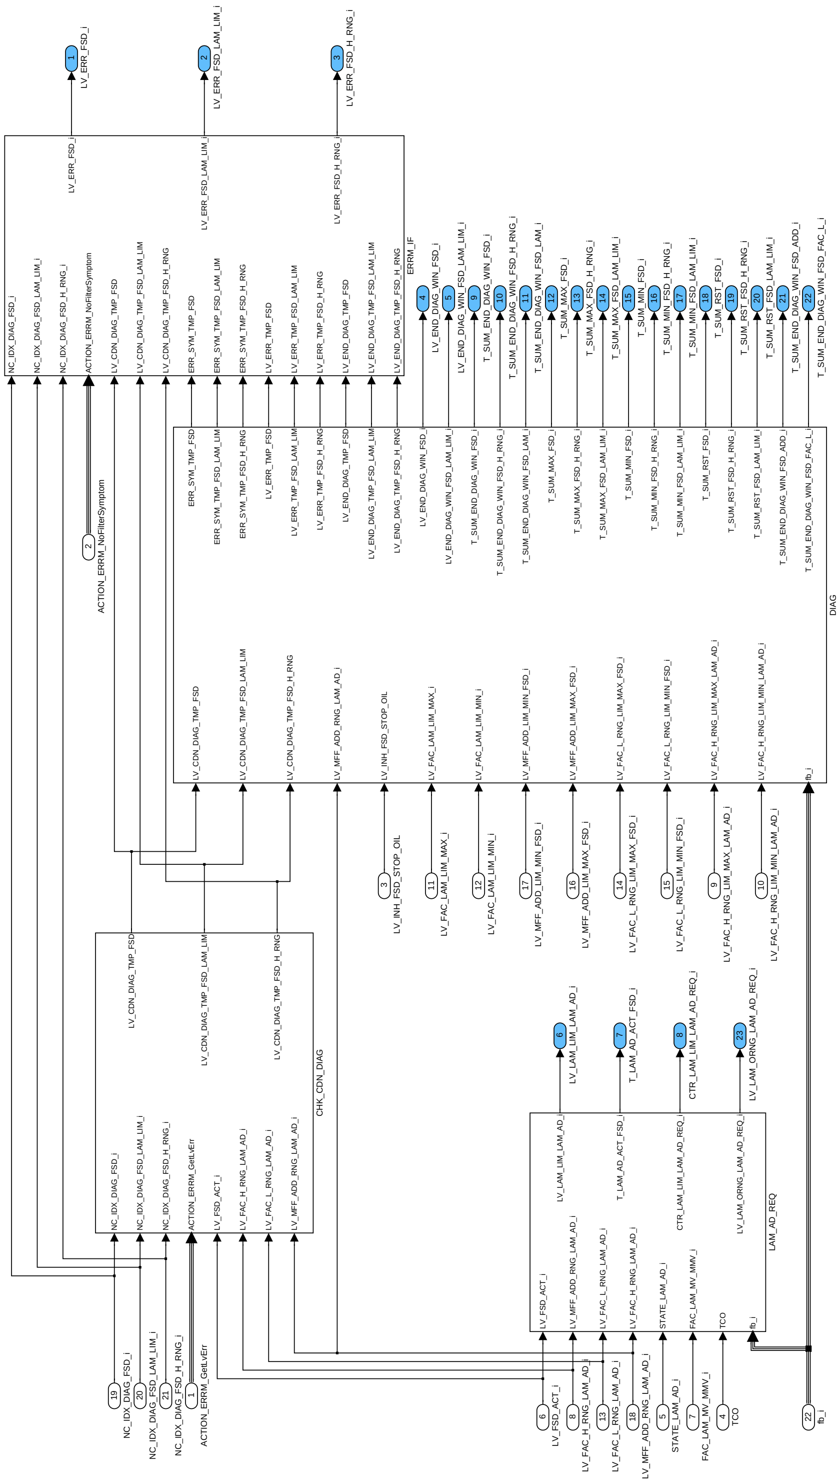

Figure 188 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC

Interface to lambda adaptation

When the low-pass filtered lambda controller output exceeds a minimum or maximum calibration threshold the lambda adaptation shall be forced by the FSD to get active and adapt the lambda controller deviation in order to confirm to lambda excursion. The request for this forced lambda adaptation is controlled by an anti-bounce mechanism.

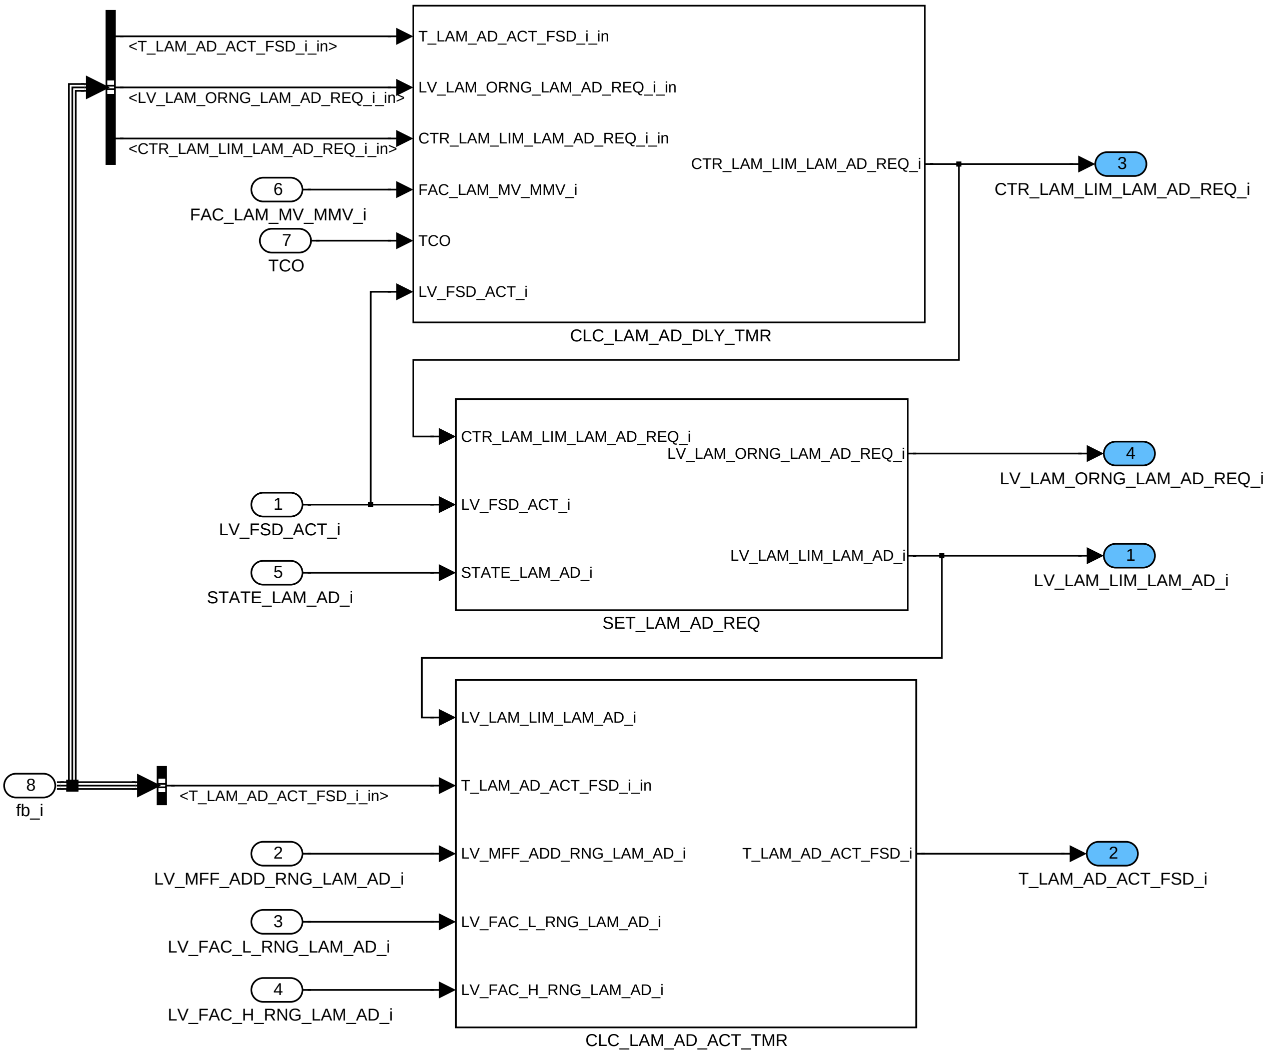

Figure 189 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ LAM_AD_REQ

Request counter

The request counter CTR_LAM_LIM_LAM_AD_REQ[i] is reset to 0 as soon as the activation timer T_LAM_AD_ACT_FSD[i] expires.

As long as

- the request counter is not yet expired (indicated by the flag LV_LAM_ORNG_LAM_AD_REQ[i]),
- fuel system diagnosis is active (LV_FSD_ACT[i] = 1) and
- lambda controller output is not zero

the counter is either incremented or decremented depending on whether lambda controller output is inside or outside the permitted range. The incrementation / decrementation speed is tunable.

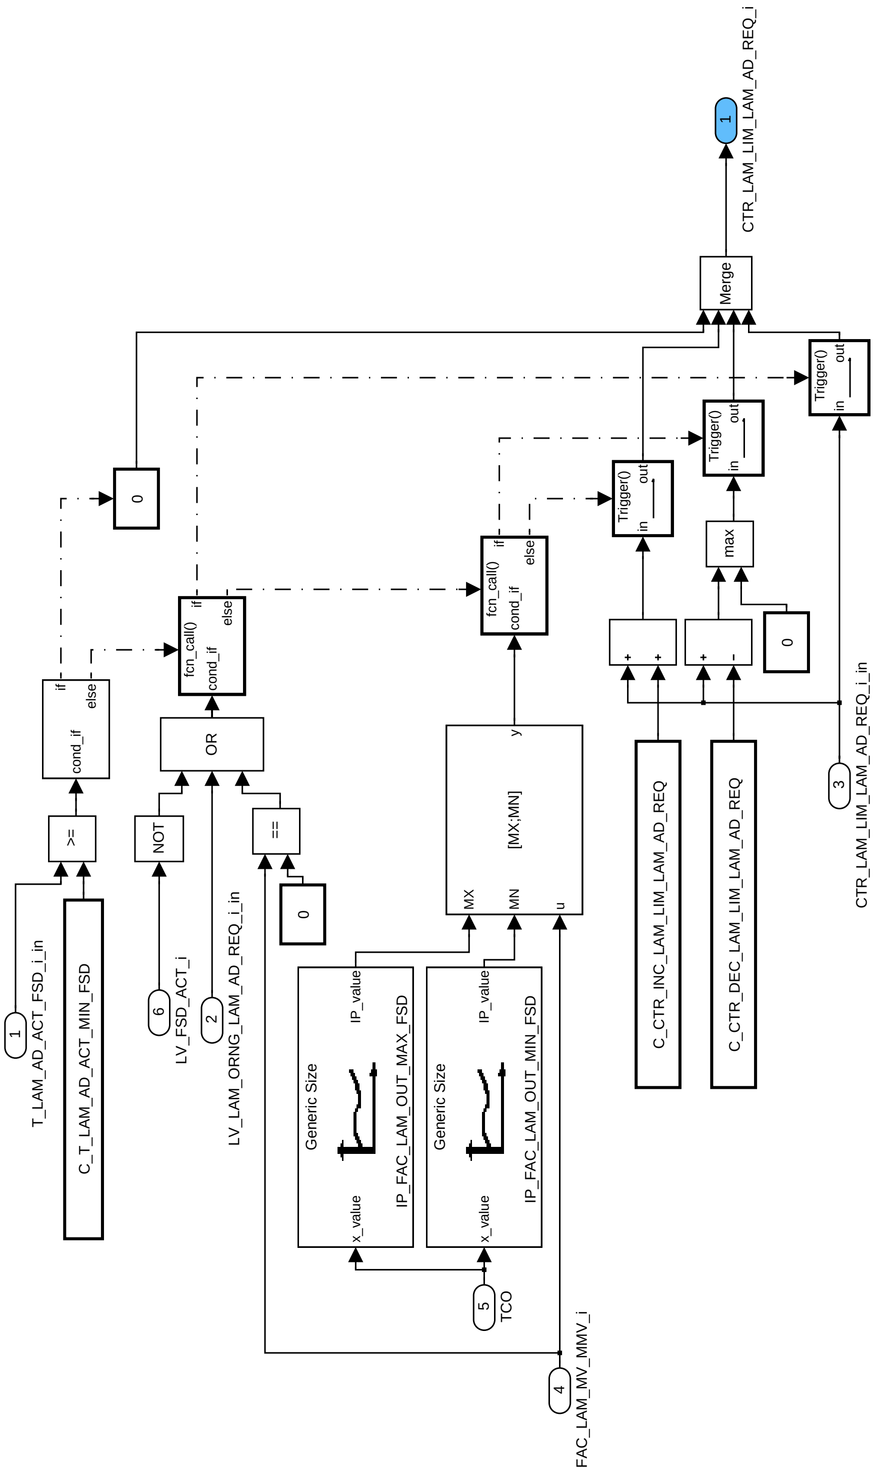

Figure 190 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ LAM_AD_REQ/ CLC_LAM_AD_DLY_TMR

Request flag / Lamda controller out of range flag

If the request counter is expired, fuel system diagnosis is active and the lambda adaptation is inside one of its learning fields (either state CDN_FAC_L, CDN_FAC_H, CDN_ADD, ADAPT_FAC_L, ADAPT_FAC_H or ADAPT_ADD indicated by STATE_LAM_AD[i] >= CDN_FAC_L), the flag LV_LAM_LIM_LAM_AD[i] that requests the forced lambda adaptation is set to 1.

As soon as request counter reaches the calibration threshold the flag LV_LAM_ORNG_LAM_AD_REQ[i] indicating that the request timer expired is set.

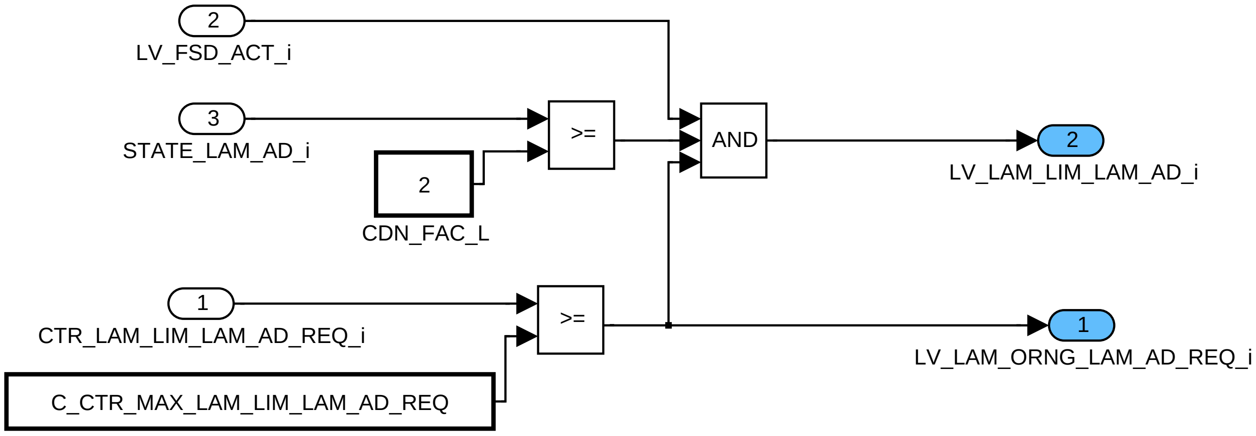

Figure 191 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ LAM_AD_REQ/ SET_LAM_AD_REQ

Activation timer

The activation timer T_LAM_AD_ACT_FSD[i] is incremented as long as the request flag for forced lambda adaptation is set and lambda adaptation is active. As soon as the activation timer expires it is reset to 0.

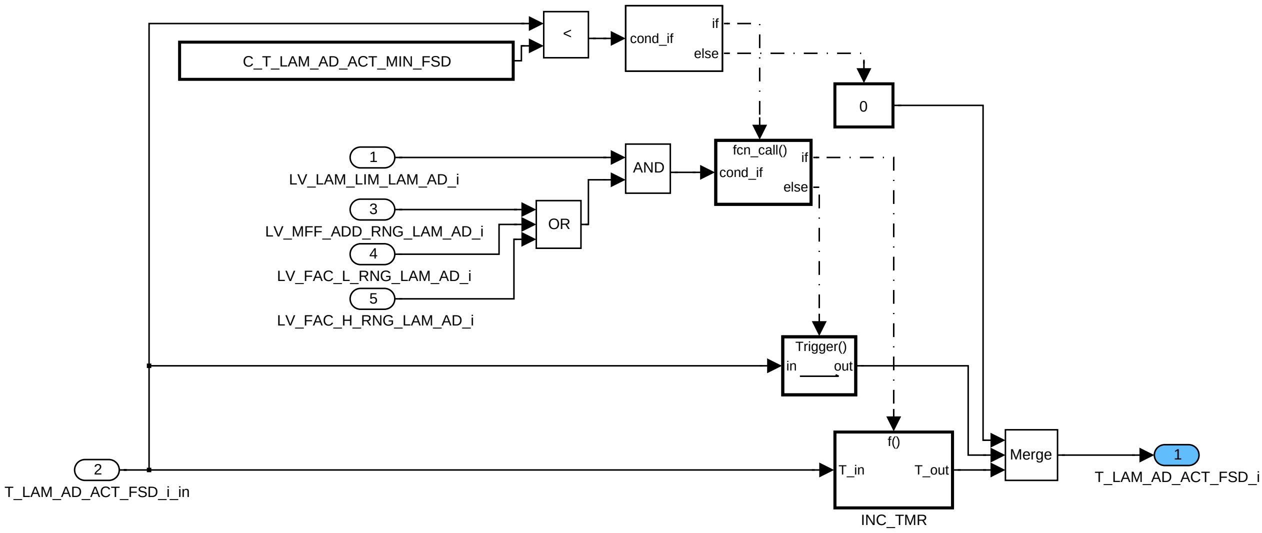

Figure 192 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ LAM_AD_REQ/ CLC_LAM_AD_ACT_TMR

Increment timer

Error detection and end of diagnosis management

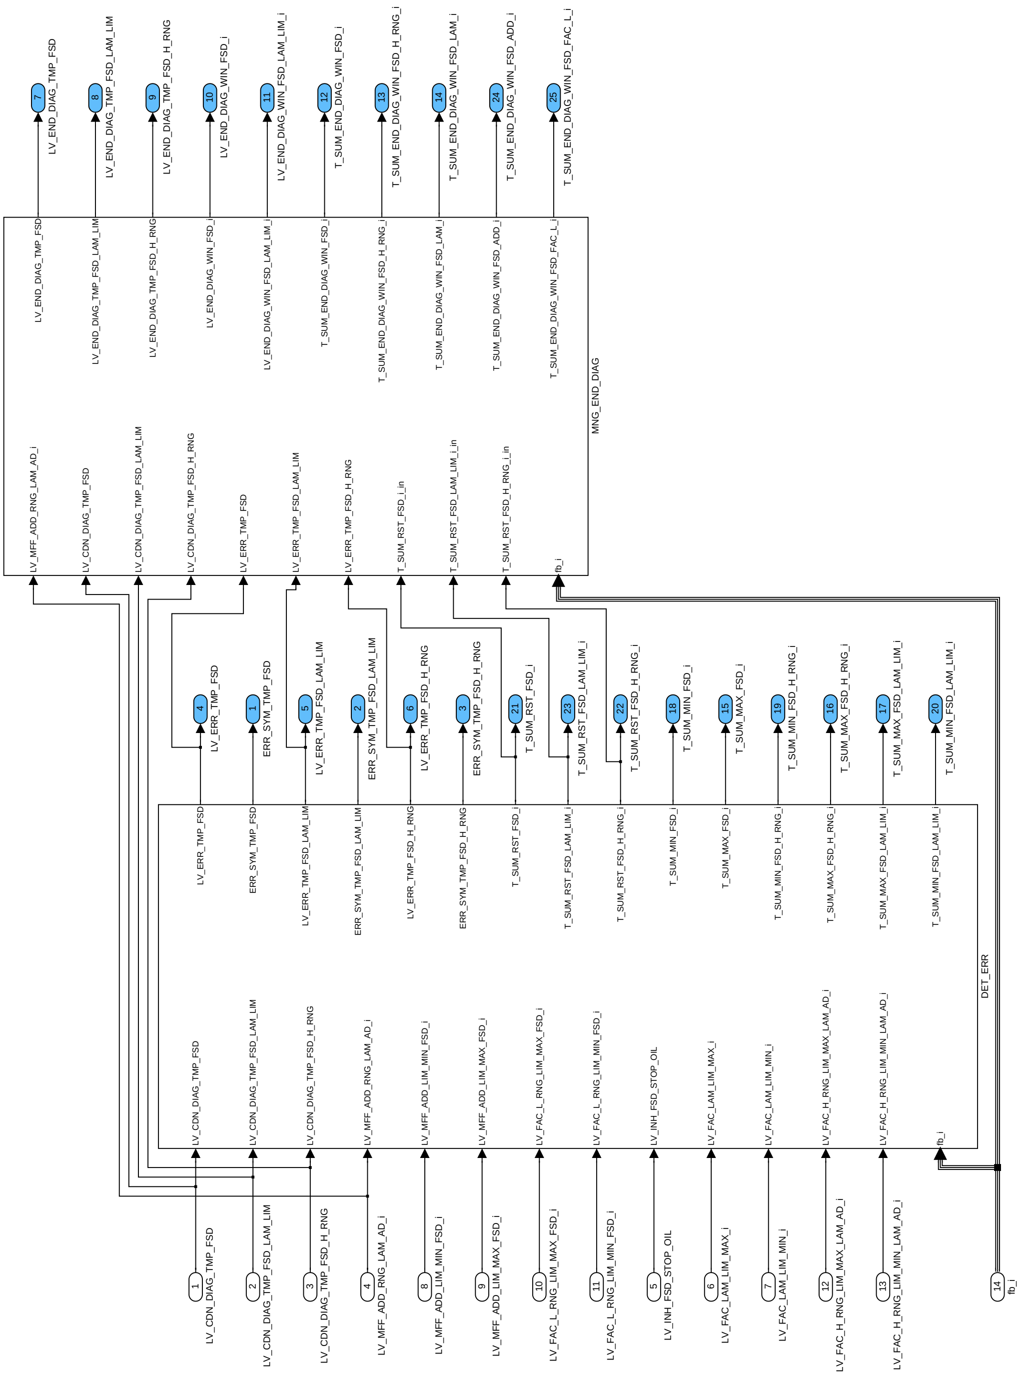

Figure 198 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG

Error symptom detection

For each failure location the symptom detection is executed separately.

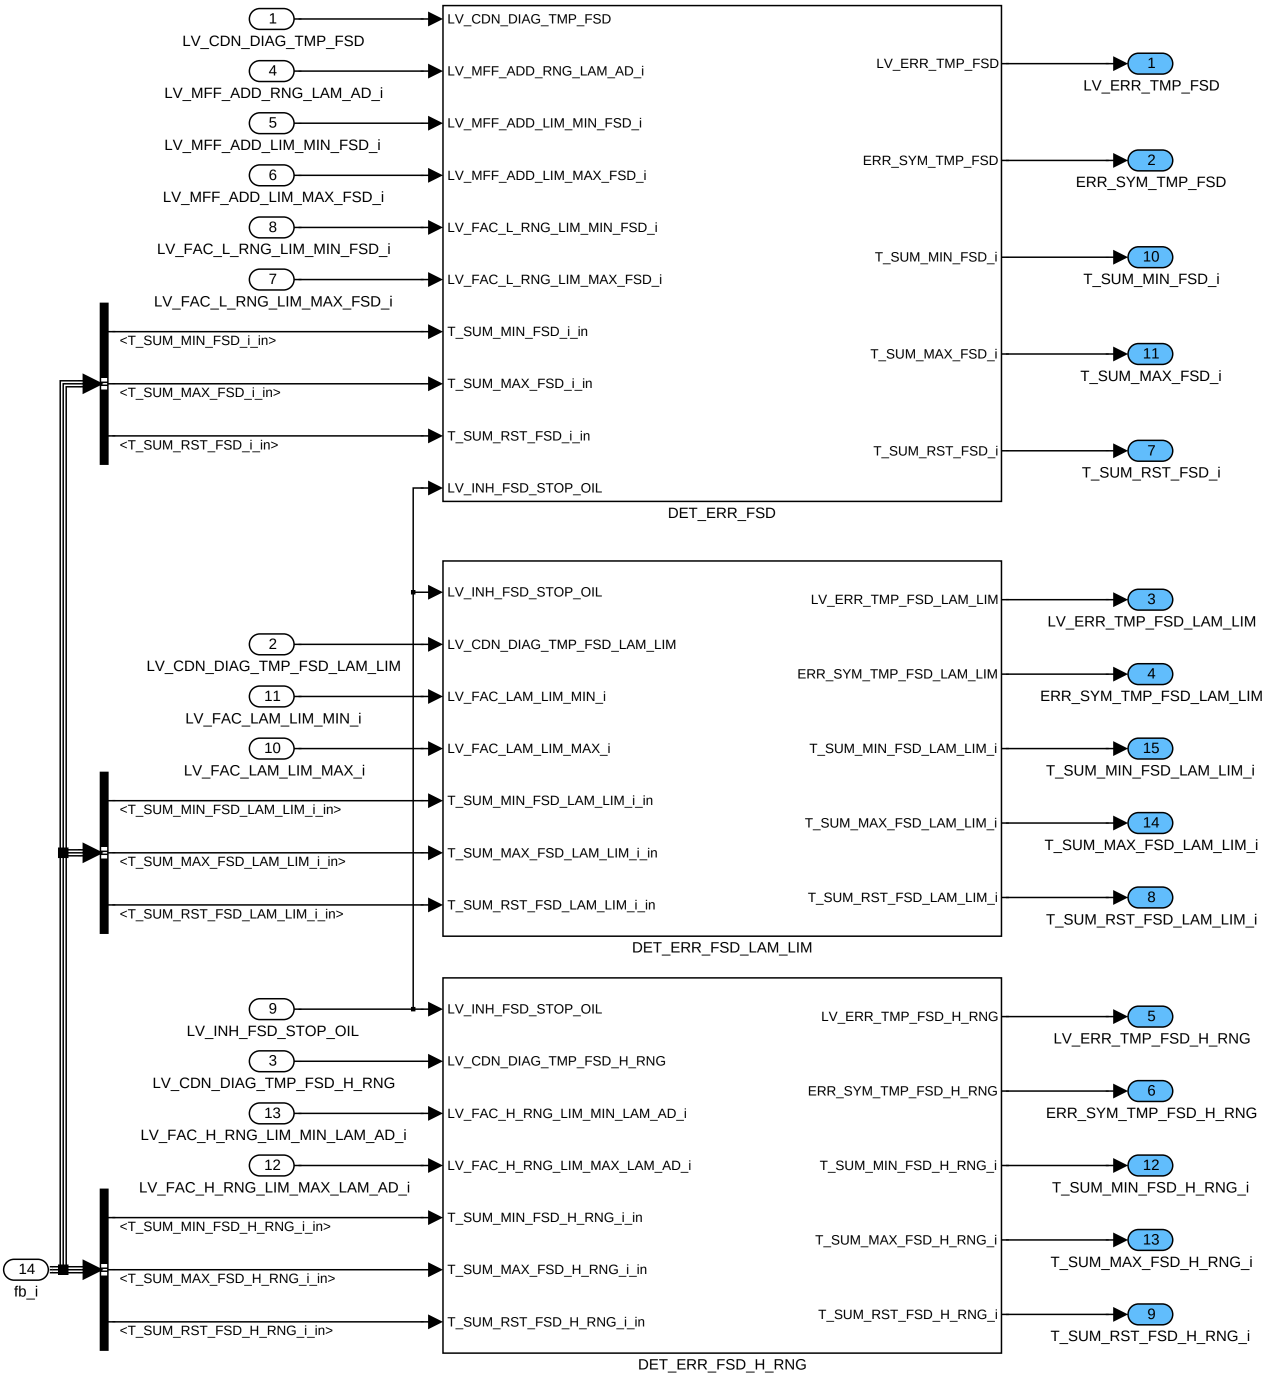

Figure 199 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ DET_ERR

Error symptom detection for lambda adaptation monitoring

In case the conditions are not fulfilled all timers remain unchanged and the temporary error flag and symptom have no relevance.

Depending on whether lambda adaptation is in the offset or lower load factor learning field different but similar functionalities are executed.

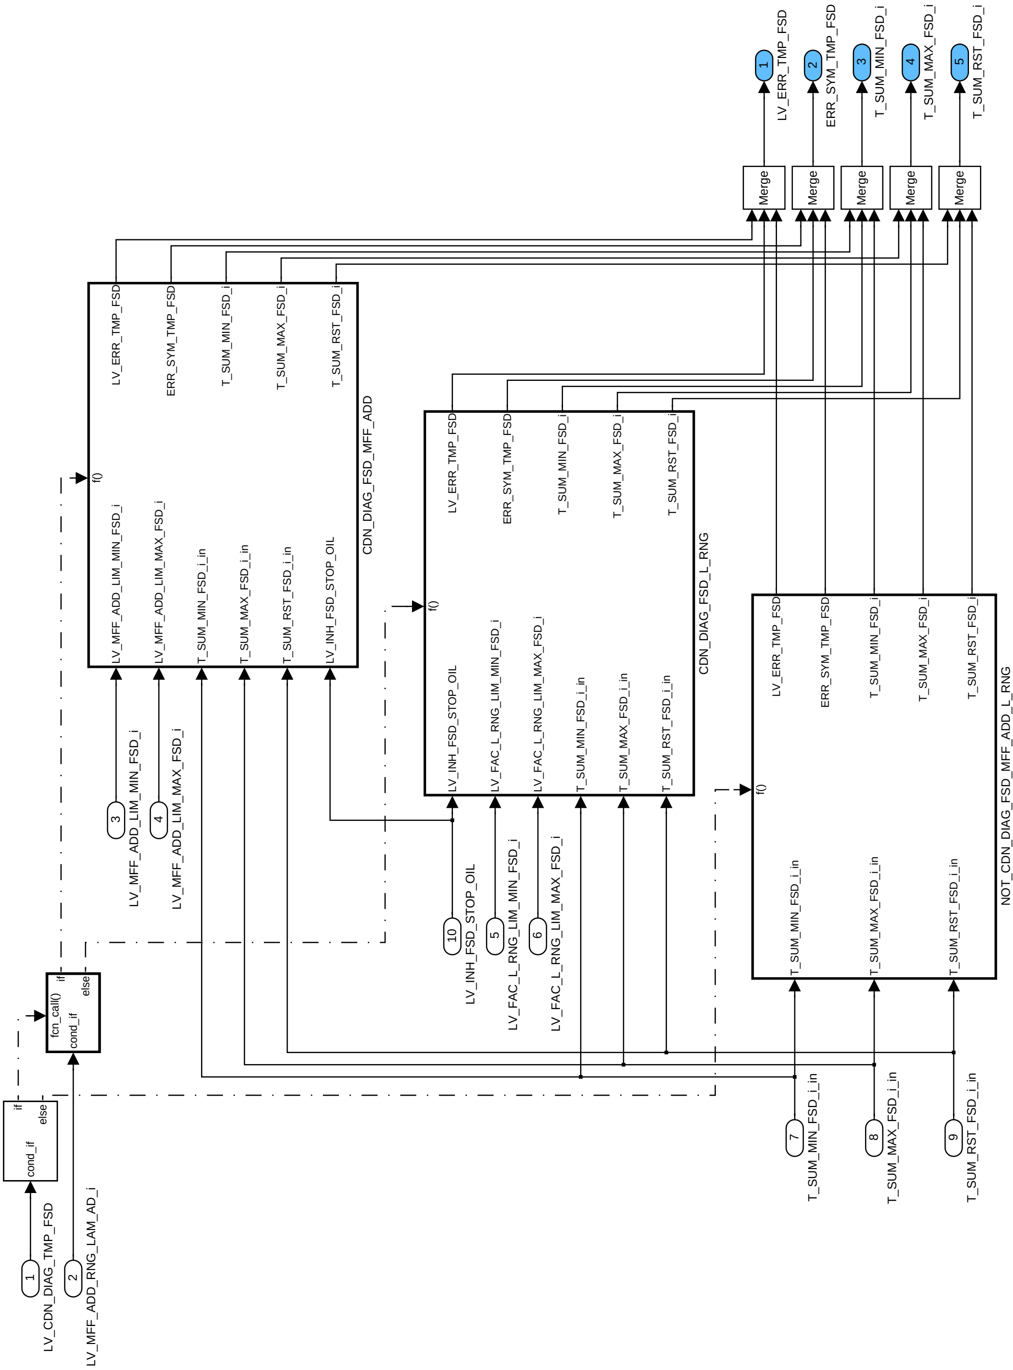

Figure 200 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ DET_ERR/ DET_ERR_FSD

Conditions for lambda adaptation offset monitoring fulfilled

Between 3 different cases must be distinguished:

1. Lambda adaptation factor for lower load is at its minimum threshold (indicated by the flag LV_ MFF_ADD _LIM_MIN_LAM_AD[i]) and no inhibition due to oil dilution under cold start conditions.

2. Lambda adaptation factor for lower load is at its maximum threshold (indicated by the flag LV_MFF_ADD_LIM_MAX_LAM_AD[i]).

3. No limitation of the lambda adaptation factor for lower load.

Independent of these cases the anti-bounce timers used to finally set the error are evaluated afterwards.

Error symptom detection for lambda adaptation high range monitoring

In case the conditions are not fulfilled all timers remain unchanged and the temporary error flag and symptom have no relevance.

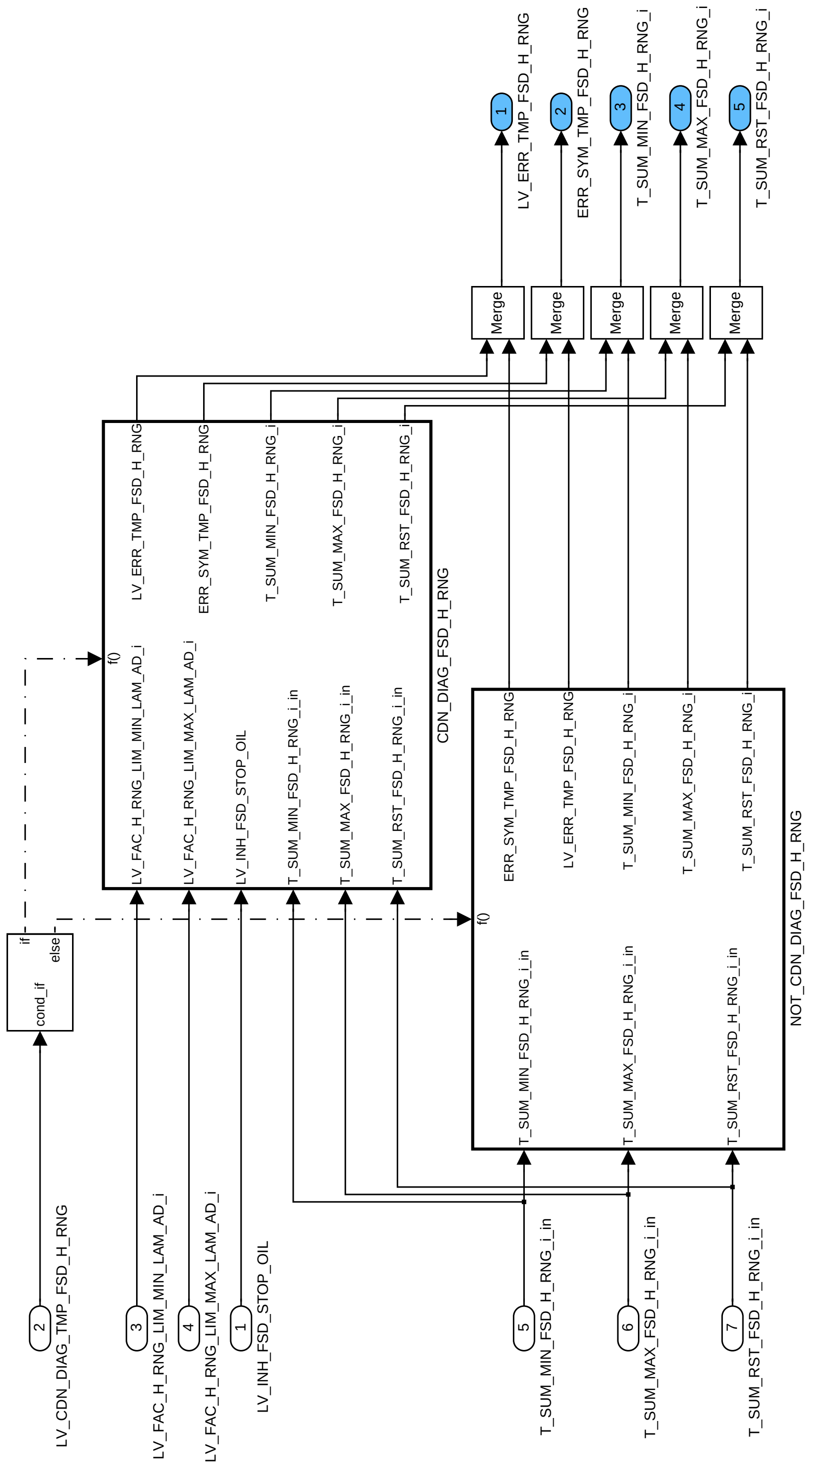

Figure 234 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ DET_ERR/ DET_ERR_FSD_H_RNG

Conditions for lambda adaptation high range monitoring fulfilled

Between 3 different cases must be distinguished:

1. Lambda adaptation factor for higher load is at its minimum threshold (indicated by the flag LV_FAC_H_RNG_LIM_MIN_LAM_AD[i]) and no inhibition due to oil dilution under cold start conditions.

2. Lambda adaptation factor for higher load is at its maximum threshold (indicated by the flag LV_FAC_H_RNG_LIM_MAX_LAM_AD[i]).

3. No limitation of the lambda adaptation factor for higher load.

Independent of these cases the anti-bounce timers used to finally set the error are evaluated afterwards.

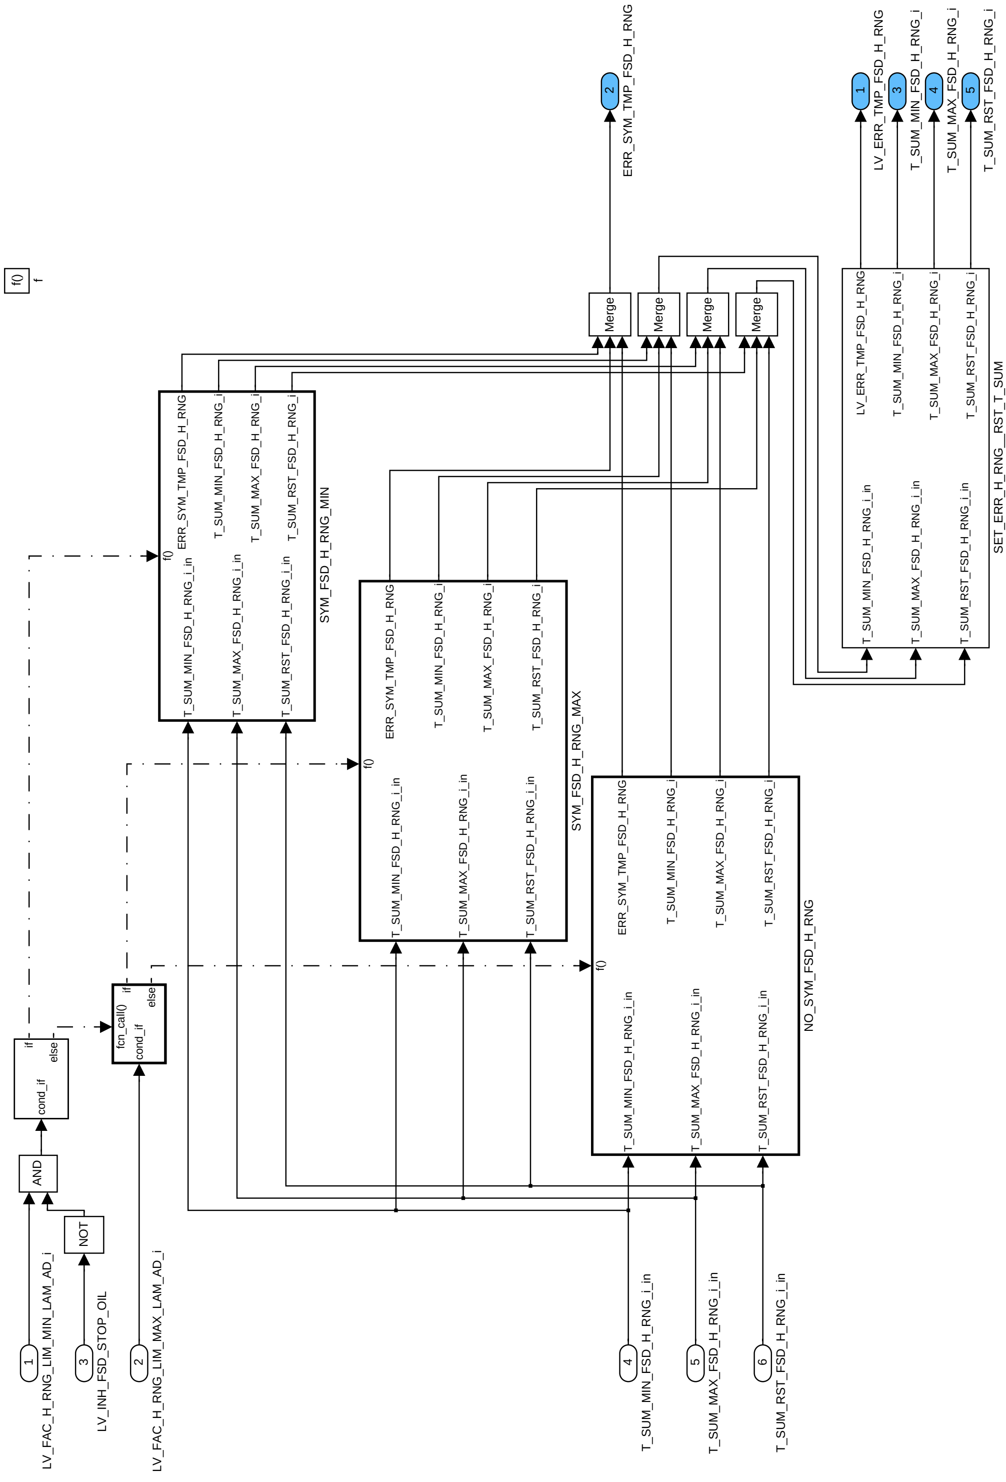

Figure 235 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ DET_ERR/ DET_ERR_FSD_H_RNG/ CDN_DIAG_FSD_H_RNG

Set error symptom for lambda adaptation high range at the minimum

The error symptom is set to the respective value (SYM_1). The timer indicating that the minimum threshold is reached and the reset timer are both increased.

Set end of diagnosis for lambda adaptation monitoring

The condition to set the temporary end flag LV_END_DIAG_TMP_FSD are: Diagnostic condition must be fulfilled and either an error was detected (temporary end flag LV_ERR_TMP_FSD is 1) or the timer T_SUM_END_DIAG_WIN_FSD[i] has reached the calibration threshold.

If LV_END_DIAG_TMP_FSD is set once, the corresponding error flag of the error management remain set for the rest of the driving cycle.

In order to set the end flag for similar conditions LV_END_DIAG_WIN_FSD[i] the diagnostic conditions must be fulfilled too and either the temporary error flag was set or the timer T_SUM_END_DIAG_WIN_FSD[i] has reached the calibration threshold and both timers T_SUM_END_DIAG_WIN_FSD_ADD[i] and T_SUM_END_DIAG_WIN_FAC_L[i] were above the threshold defined by C_T_SUM_RST_FSD and C_CRLC_T_SUM_WIN_FSD_RST.

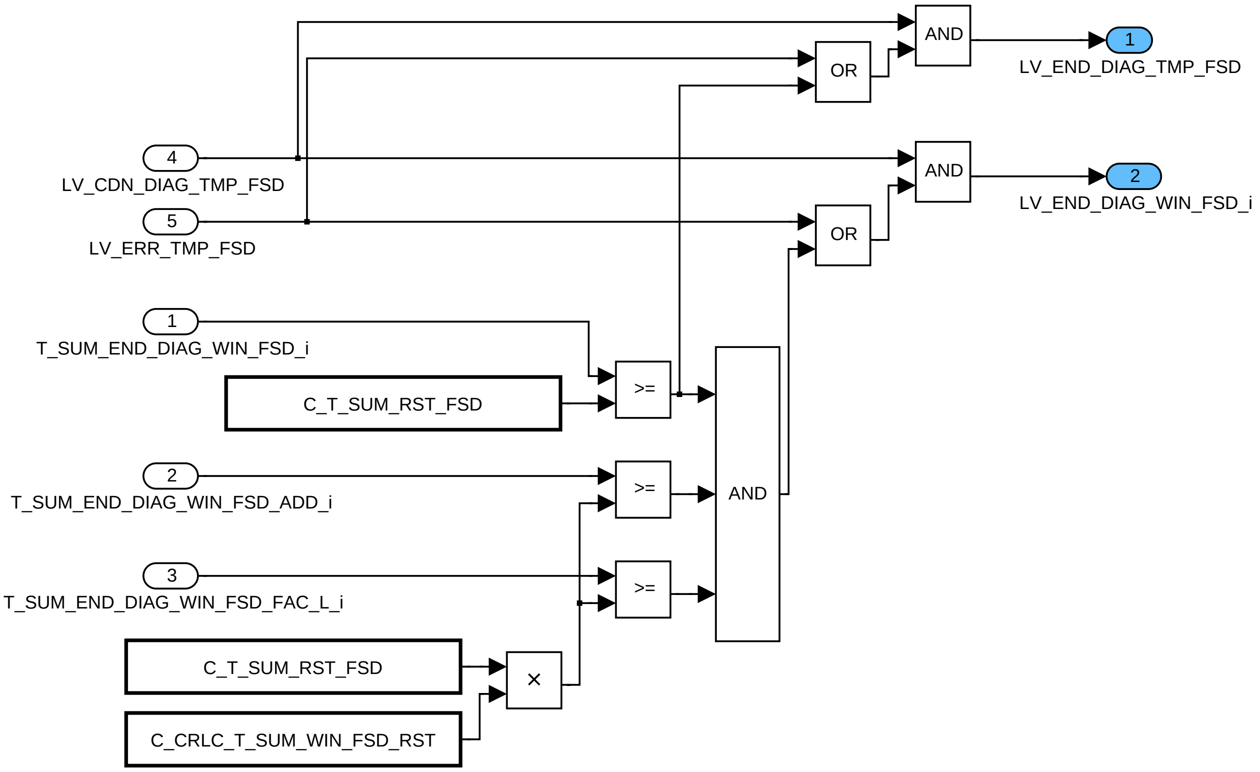

Figure 254 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ MNG_END_DIAG/ MNG_END_DIAG_FSD/ SET_END_DIAG

Manage end flags for lambda controller monitoring

First the end flag timers are calculated and then the conditions to set the end flags are evaluated.

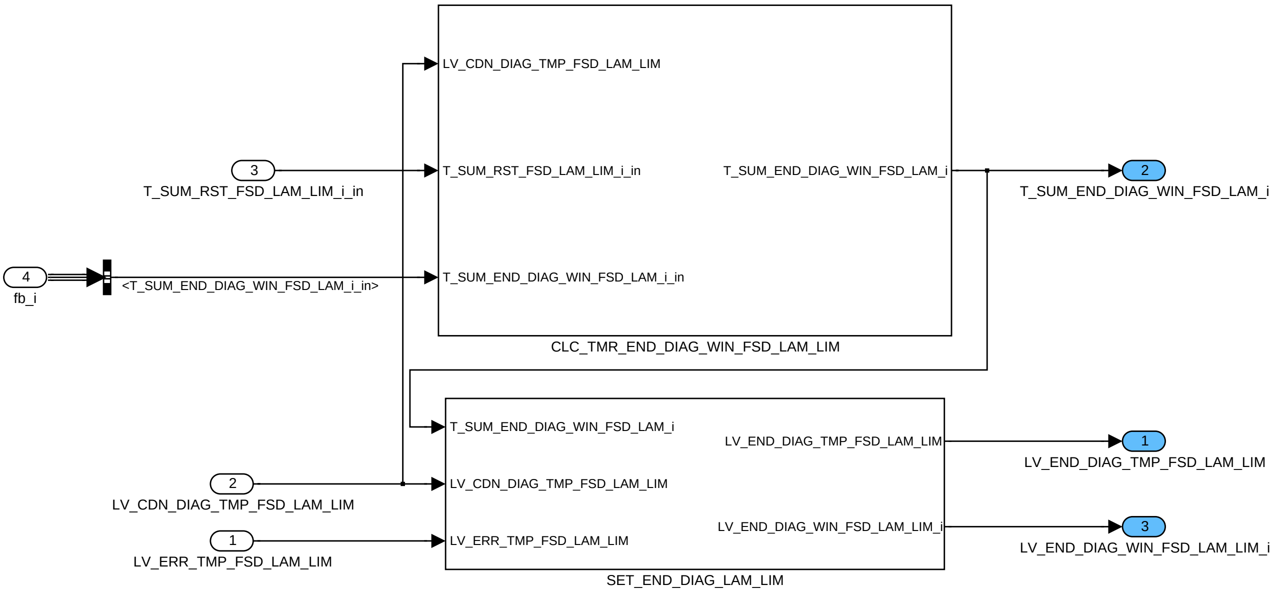

Figure 255 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ MNG_END_DIAG/ MNG_END_DIAG_FSD_LAM_LIM

Calculate end of diagnosis timers for lambda controller monitoring

If the conditions are not fulfilled the timer T_SUM_END_DIAG_WIN_FSD_LAM_LIM[i] remains unchanged.

The end timer is reset (to one sample step) either if the calibration threshold is reached or when the reset timer was started to be incremented.

In all other cases the timer is incremented.

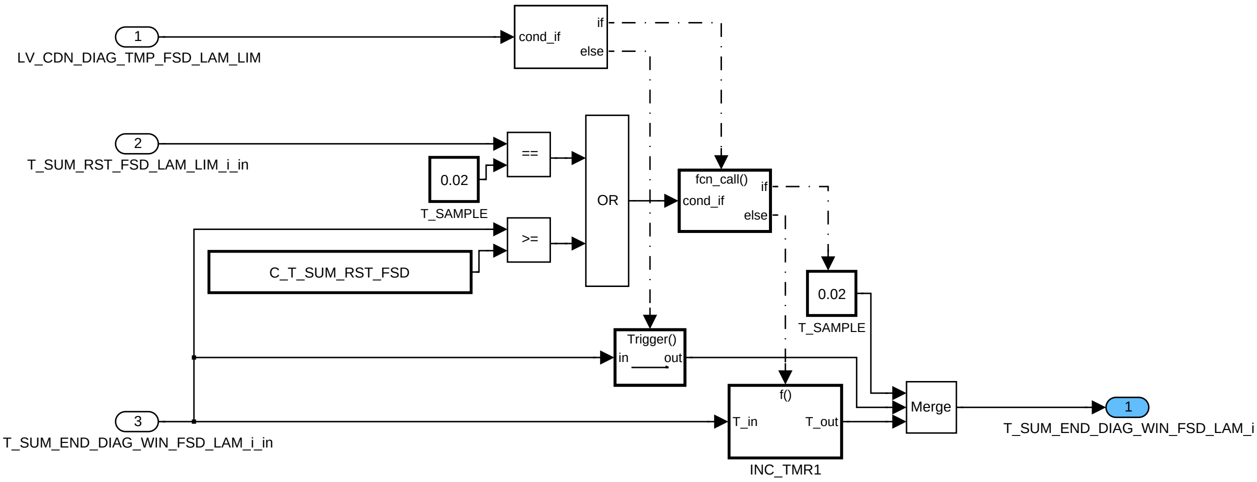

Figure 256 LACO_FCTDGFSD0/ operate_20MS/ CBK_EX_MNG/ CBK_EX_SPC/ DIAG/ MNG_END_DIAG/ MNG_END_DIAG_FSD_LAM_LIM/ CLC_TMR_END_DIAG_WIN_FSD_LAM_LIM

Increment timer

General Information

This function manages the inhibition of the fuel system diagnosis (FSD) due to system errors and canister purge states.

NC_CBK_EX_NR defines the number of exhaust banks.
For vector elements the variable extension _i is used in the model instead of [i] as found in the textual description.
Configuration for diagnostic symptoms:

Diagnostic FSD[i]	Symptom description	Symptom	Filter type
Fuel System Diagnosis for lambda adaptation monitoring – relevant to malfunction indication light	*maximum limit of additive adaptation value reached*	*SYM_0*	*NO*
	minimum limit of additive adaptation value reached	*SYM_1*	
	maximum limit of multiplicative adaptation value (lower area) reached	*SYM_2*	
	minimum limit of multiplicative adaptation value (lower area) reached	*SYM_3*	

Diagnostic FSD_LAM_LIM[i]	Symptom description	Symptom	Filter type
Fuel System Diagnosis in area where lambda controller output is concerned - relevant to malfunction indication light	*lambda control in dead stop (upper limit)*	*SYM_0*	*NO*
	lambda control in dead stop (lower limit)	*SYM_1*	

Diagnostic FSD_H_RNG[i]	**Symptom description**	**Symptom**	**Filter type**
Fuel System Diagnosis in upper multiplicative adaptation learning area	*maximum limit of multiplicative adaptation value (upper area) reached*	*SYM_0*	*NO*
	minimum limit of multiplicative adaptation value (upper area) reached	*SYM_1*	

Application Conditions

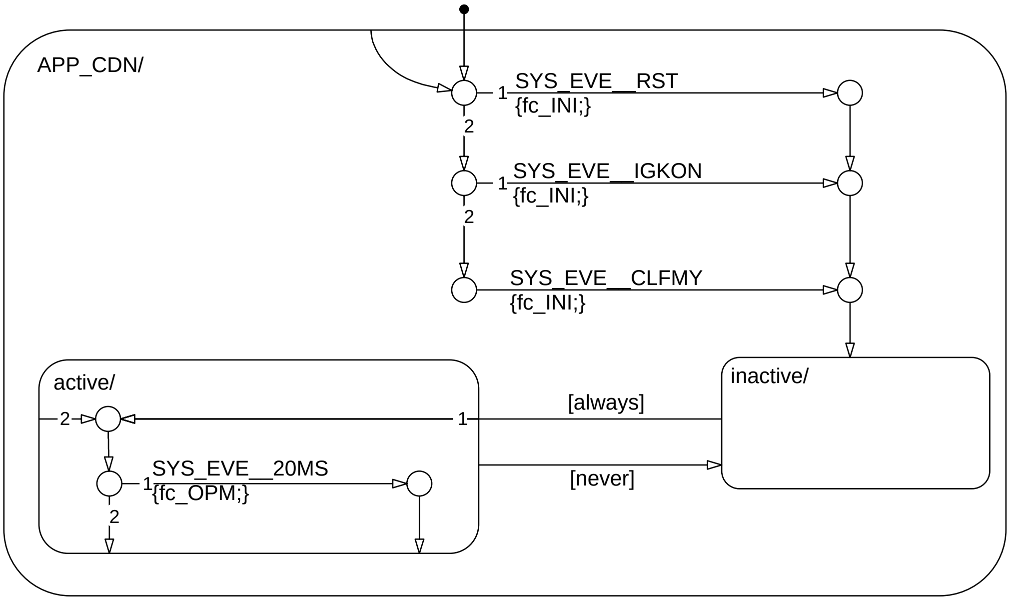

Figure 267:

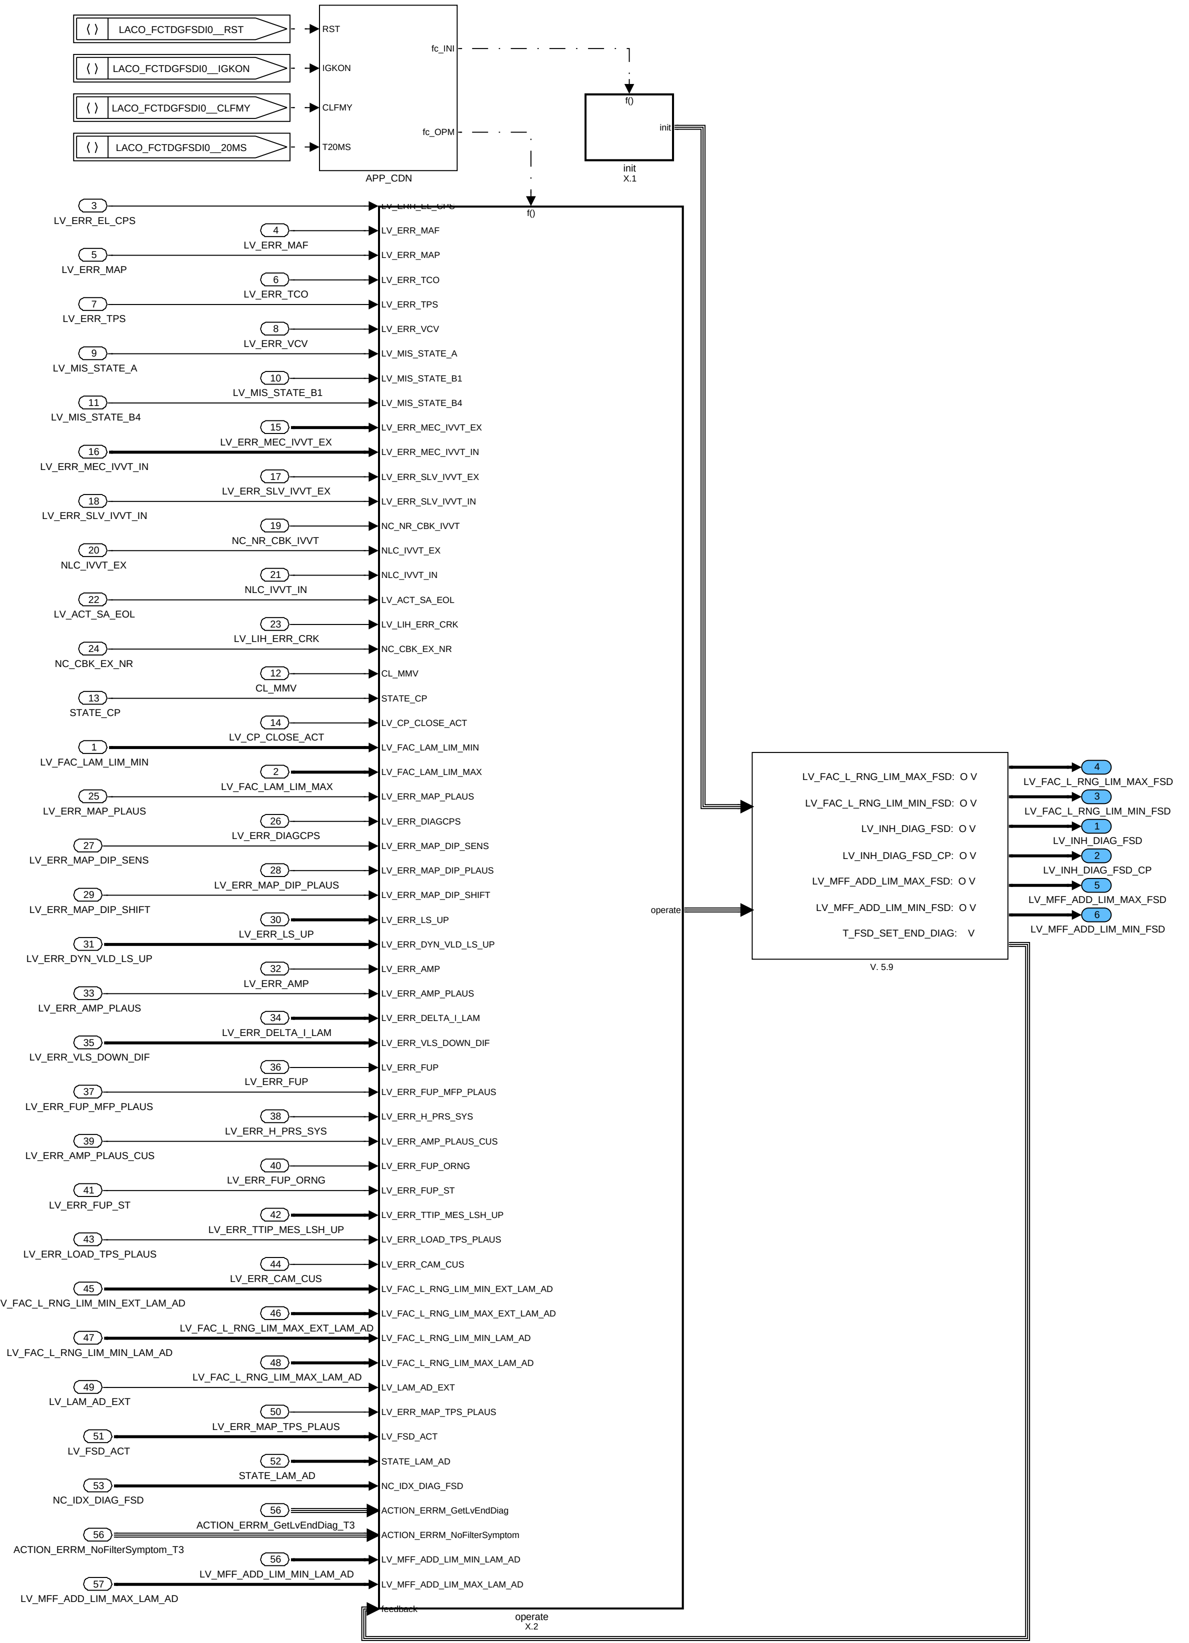

SDA_SRS / SDA V 5.2.5 18−May−2007

Figure 268:

46.18.1 Initialization

The inhibition flags LV_INH_DIAG_FSD[i] and LV_INH_DIAG_FSD_CP[i] are both set to 1. All other variables are initialzed with 0.

46.18.1.1 Calculation of initialization

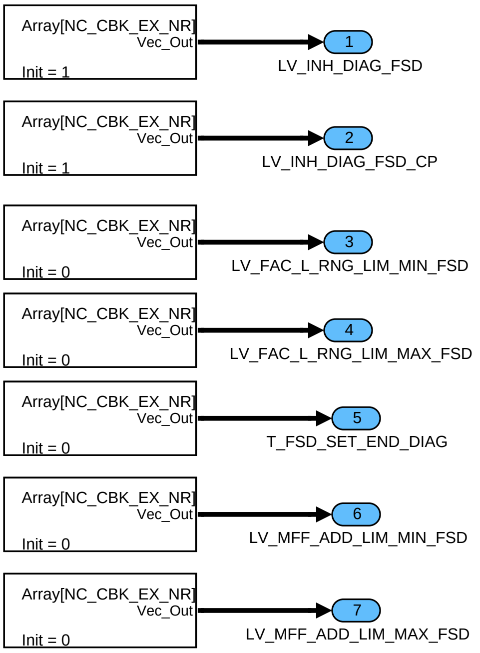

Figure 269:

46.18.2 Formula section

46.18.2.1 Inhibition of fuel system diagnosis

LV_INH_DIAG_FSD[i] represents the influence of errors deactivating the fuel system diagnosis. All exhaust bank independent errors are summarized in the temporary and not visible variable LV_INH_DIAG_FSD_NOT_CBK_SPC.
The temporary and not visible inhibition flag LV_INH_DIAG_FSD_IVVT_TMP is set if an IVVT error (intake or exhaust) affects the relevant exhaust bank for FSD.
If LC_INH_FSD_MAN_DEAC is set to 1 fuel system diagnosis is not inhibited by a present error.

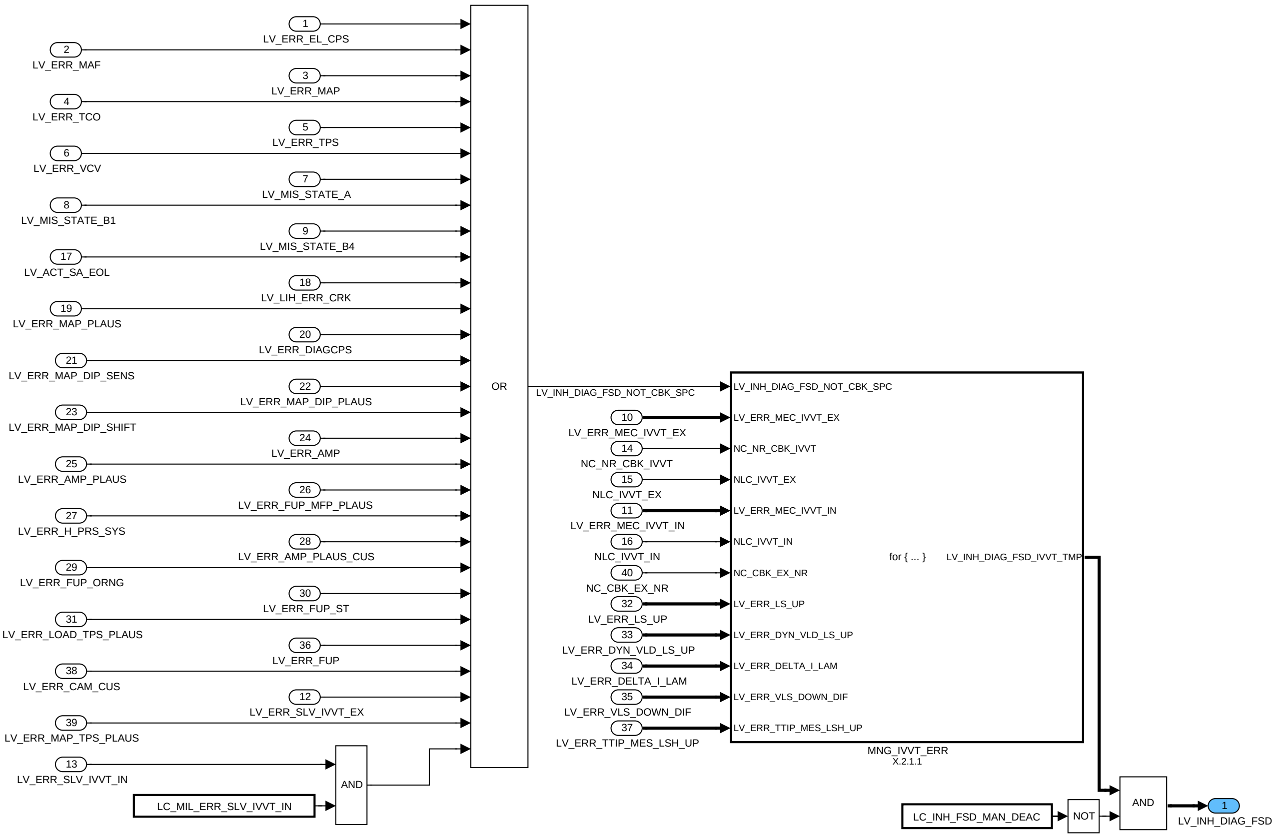

Figure 270:

46.18.2.1.1 Exhaust bank specific inhibition due to IVVT errors

The temporary and not visible inhibition flags LV_INH_DIAG_FSD_IVVT_IN/EX_TMP are set bank specifically depending on whether IVVT for exhaust and/or intake bank is present or not. If not present these flags are 0. If the IVVT banks and the FSD exhaust banks are identical then bank specific inhibition is possible.

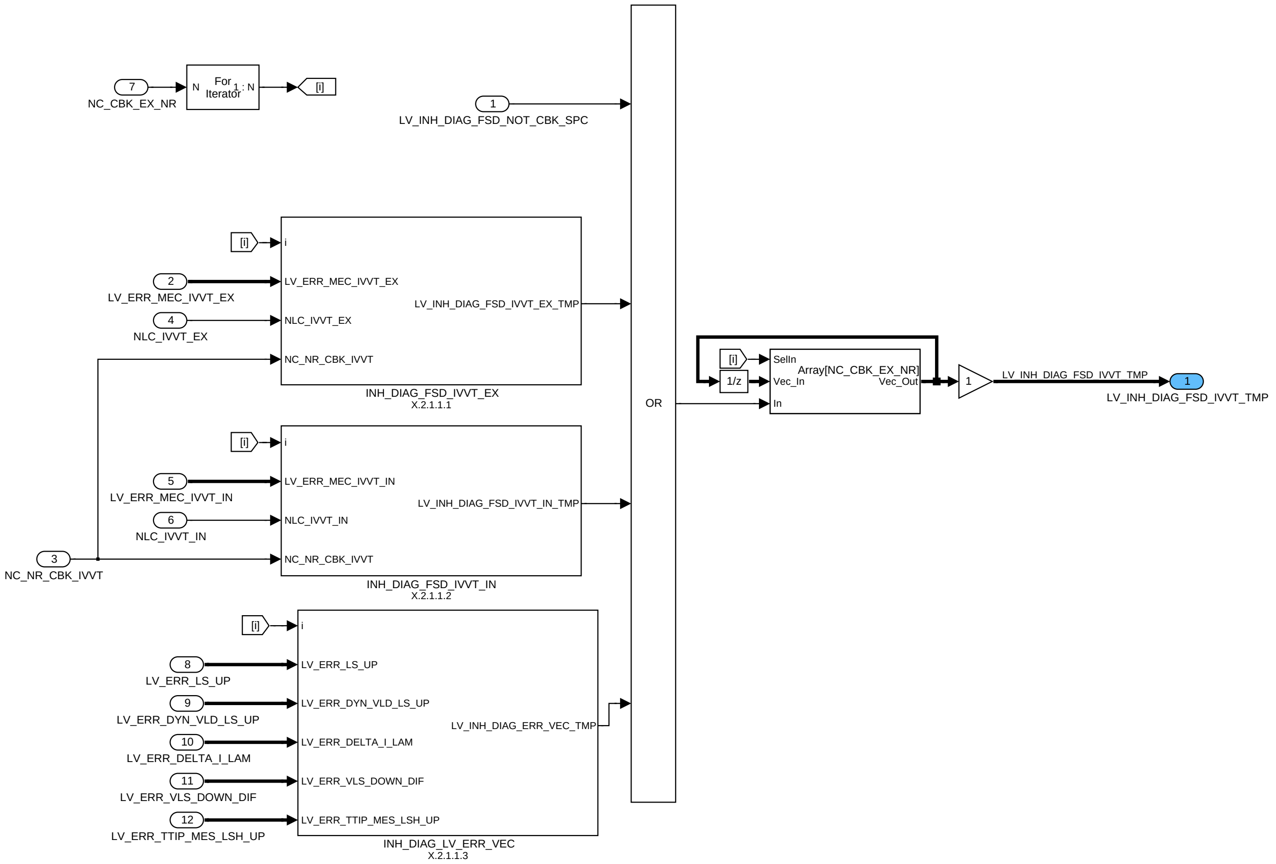

Figure 271:

46.18.2.1.1.1 Manage IVVT errors for exhaust bank

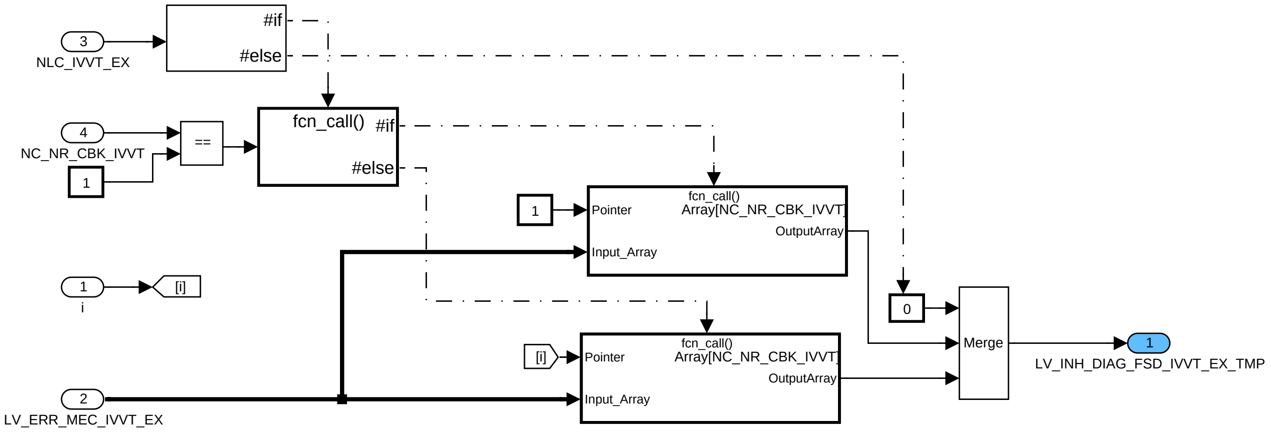

Figure 272:

46.18.2.1.1.2 Manage IVVT errors for intake bank

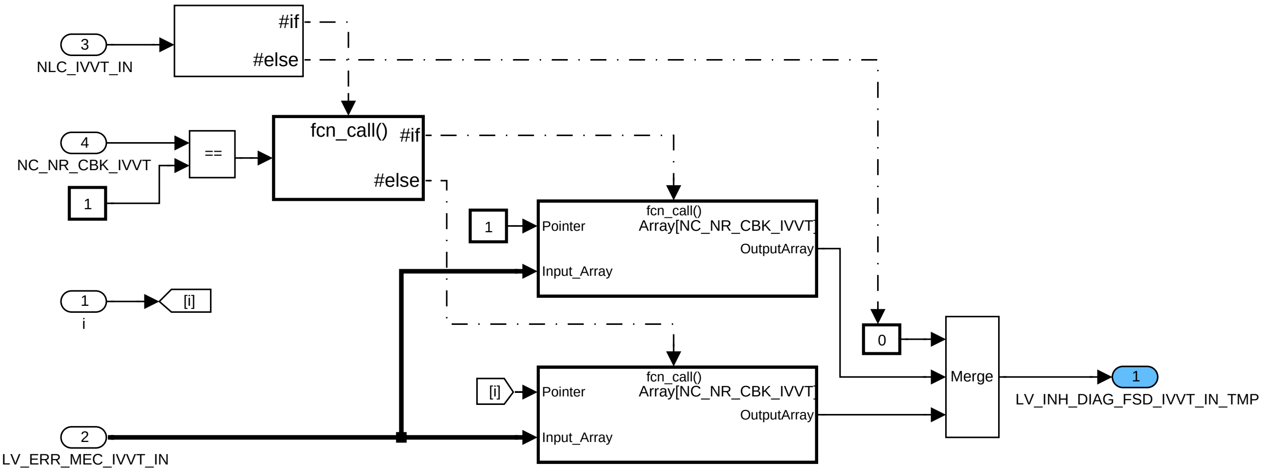

Figure 273:

46.18.2.1.1.3 Exhaust bank specific inhibition due to error vectors

LV_INH_DIAG_FSD_IVVT_TMP is set bank specific according to the error vectors.

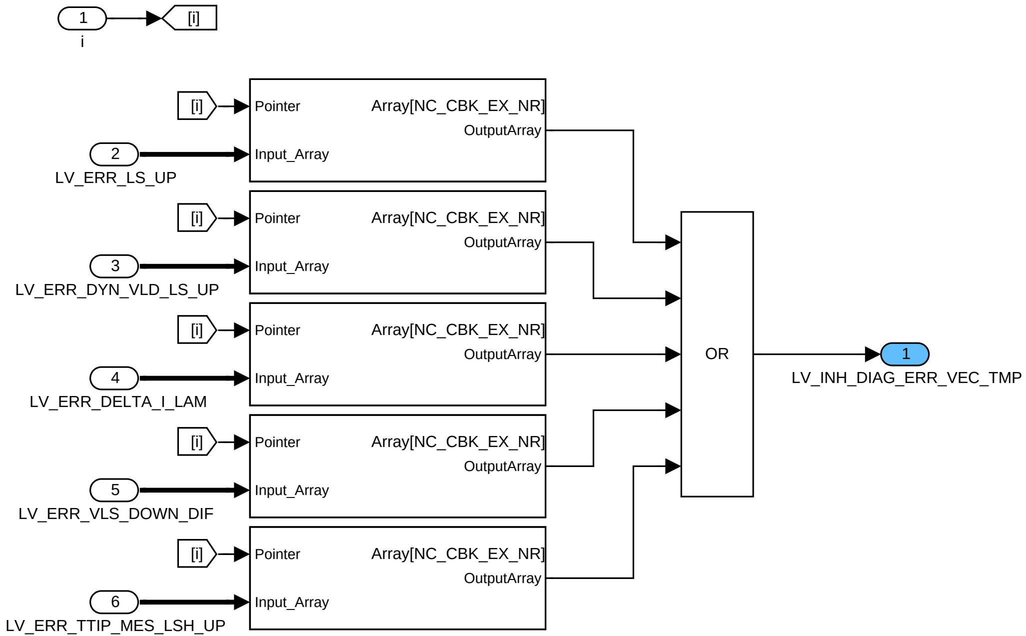

Figure 274:

46.18.2.2 Inhibition of fuel system diagnosis due to canister purge

46.18.2.2.1 Exhaust bank specific functionality

LV_INH_DIAG_FSD_CP[i] respects the influence of canister purge on FSD. The inhibition flag is not set when the canister purge valve is closed, in MAX PURGE at low charcoal canister load and in MIN_PURGE when the lambda controller is at one of its limits.

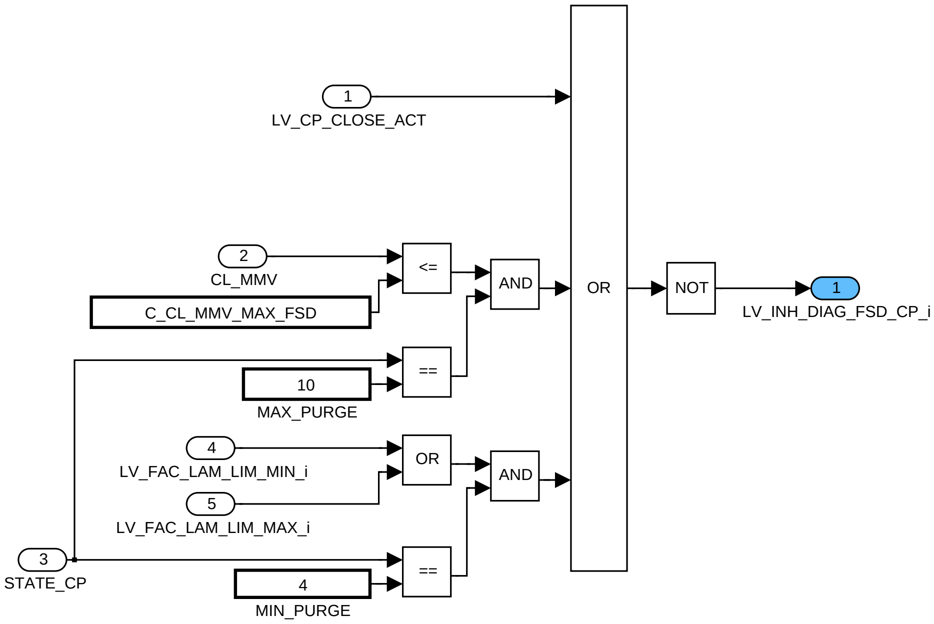

Figure 275:

46.18.2.3 Determination of limitation flags for lambda adaption (in- / outside LACO)

Determination if indicator flag for minimum and maximum limitation of lambda adaptation used by fuel system diagnosis is calculated inside of outside of LACO, according to LV_LAM_AD_EXT.

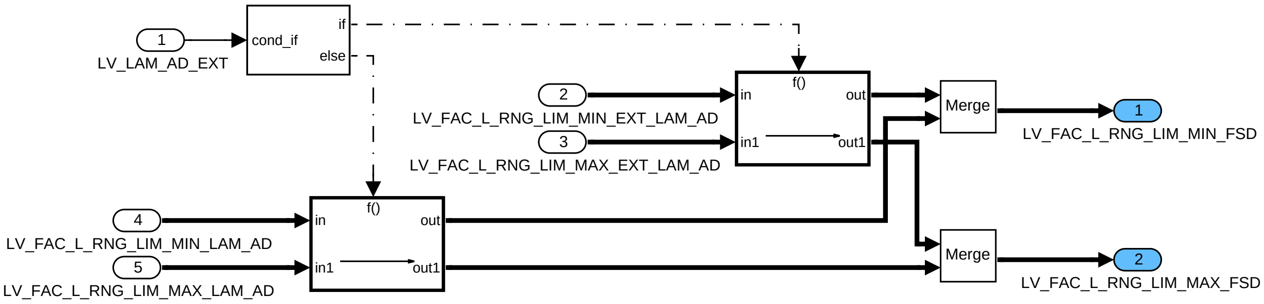

Figure 276:

46.18.2.4 Force FSD end diag flag to 1

46.18.2.4.1 Exhaust bank specific functionality

46.18.2.4.1.1 Increment timer

The timer T_SET_END_DIAG_FSD[i] that forces FSD end of diagnostic flag to 1 is incremented if general FSD activation conditions are fulfilled and engine is running in one of the lambda adaptation fields independent whether adaptation is active or not.

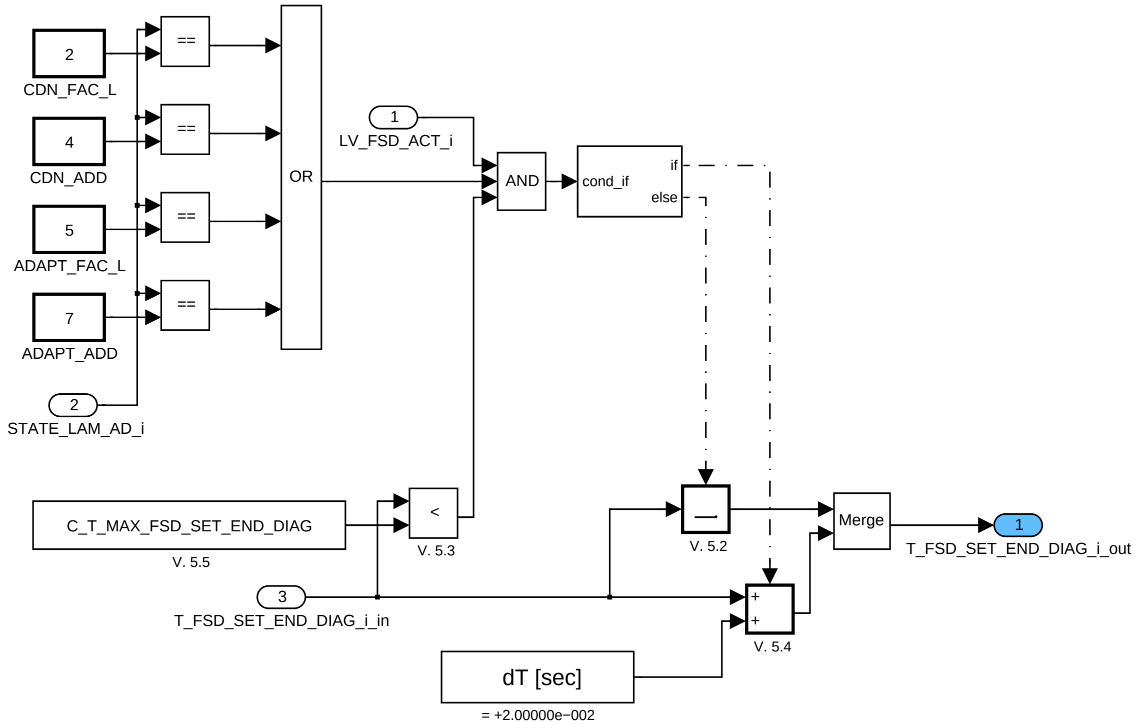

Figure 277:

46.18.2.4.1.2 Timer elapsed

As soon as the timer T_SET_END_DIAG_FSD[i] reaches a calibration threshold the error management is called to set the end of diagnosis information (if not yet set).
This feature can be disabled by the calibration flag LC_FSD_SET_END_DIAG_ENA.

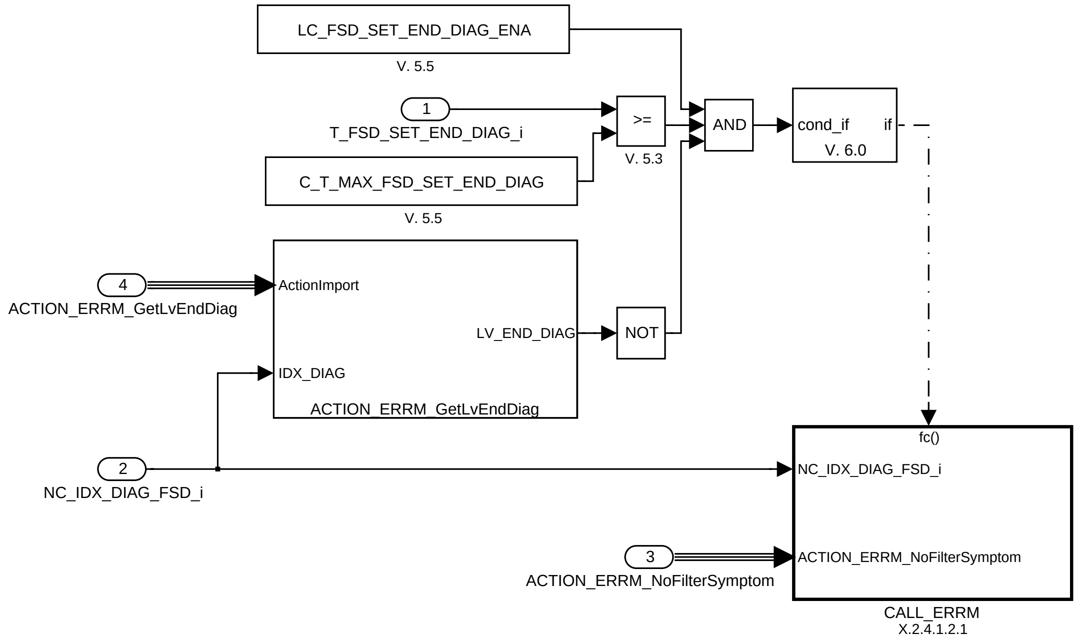

Figure 278:

46.18.2.4.1.2.1 Call Error Management

Error management is called with action NoFilterSymptom in order to set end of FSD diagnostic information.

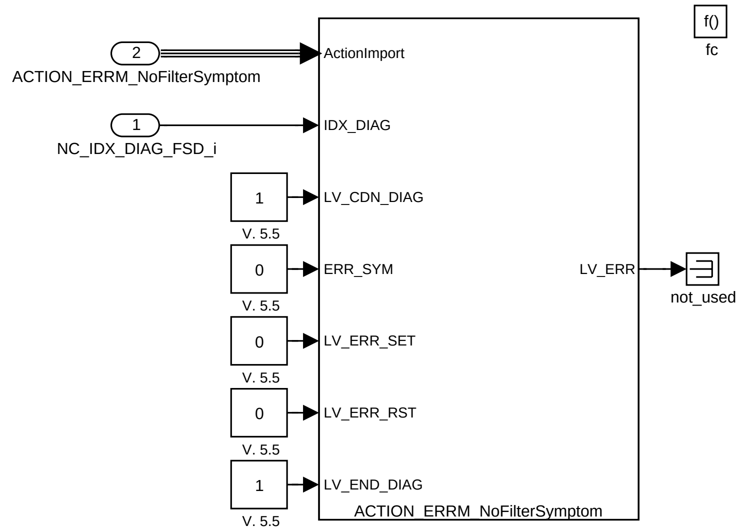

Figure 279:

46.18.2.5 Calculation of LV_MFF_ADD_LIM_MIN_FSD and LV_MFF_ADD_LIM_MAX_FSD

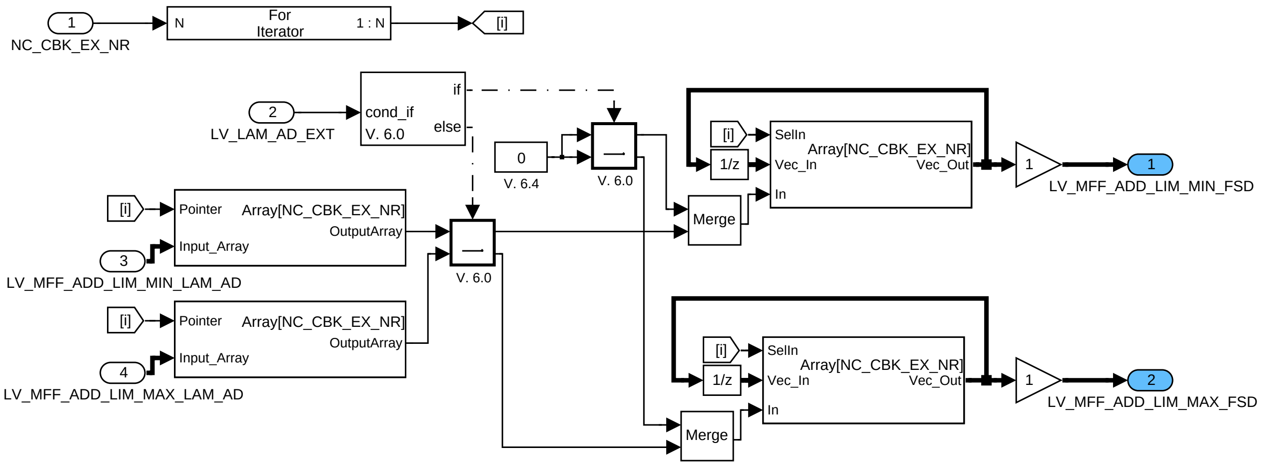

Figure 280:

46.19 Dynamic Fuel Trim

The trim controller causes a shift of the WRAF sensor signal (upstream of the catalyst) or/and a shift of the lambda set point (in opposite direction). The output components (P share, I share, D-share, the sum of all or the adaptation value) of the trim controller can be linked in the application incidence for the lambda controller to corresponding inputs of the lambda controller. A compensation of ageing effects of the WRAF sensor as well as a better observance of the catalyst window is reached because of these shifts.

The control value is composed of P, I and D shares. All are determined depending on the trim control sensor signal (binary signal). The difference of the sensor voltage from set point value is the basic characteristic. The set point value can be applied depending on the operating point, so that the dynamic lambda can be adjusted according to the operating range.

46.19.1 Calibration interfering functions

- Fuel path (injection realisation) and air path (intake manifold model)
- Heater functions of upstream and downstream sensors
- Linear Lambda Control
- Forced Lambda stimulation
- Catalyst Diagnosis

46.19.2 Calibration flowchart

The sequence is also described by the order in Calibration method.

46.19.3 Calibration method

The binary sensor signal (VLS_DOWN[i]) should be measured during emission tests. If the cycle show emission problems with NOx, and a correlation with VLS_DOWN[i] can be observed (VLS_DOWN[i] < 450 mV when NOx ↑) , then the P share intervention for VLS_DIF_LAM_ADJ[i] > 0 can be increased. When HC ↑ and/or CO ↑ during emission test, then the P share intervention for VLS_DIF_LAM_ADJ[i] > 0 can be decreased.

The set point for the sensor signal voltage should be evaluated by measuring the catalyst efficiency in all operational areas. The downstream sensor signal voltage showing the best catalyst efficiency should be used as set point in that operational point.

46.19.3.1 Common Activation Conditions

C_TEMP_CAT_MIN_LAM_ADJ_ACT	The constant represents the minimum threshold for of the Catalyst temperature for activation of the trim controller. **(e.g. 300 °C)**
C_EFF_CAT_DIAG_MAX_LAM_ADJ_ACT	The constant is the threshold for the EFF_CAT_DIAG above which the trim controller will be deactivated. **(e.g. 1)**
C_MAF_INT_LAM_P_ADJ_ACT_FAST[NC_CBK_EX_NR]	The constant is the integral threshold for MAF for reactivation of the trim controller (P-share) from inactive state. **(e.g. 3 g)**

C_MAF_INT_LAM_P_ADJ_ACT_SLOW	The constant is the integral threshold for MAF for reactivation of the trim controller (P-share) after Lambda set point violation, Lambda controller at hard limit or open-loop operation of Lambda controller. **(e.g. 5 g)**
C_MAF_INT_LAM_ADJ_P_ACT_PURGE	The constant is the integral threshold for MAF for reactivation of the trim controller (P-share) after PUC. **(e.g. 10 g)**
C_MAF_INT_LAM_I_ADJ_ACT_FAST[NC_CBK_EX_NR]	The constant is the integral threshold for MAF for reactivation of the trim controller (I-share) from inactive state. **(e.g. 15 g)**
C_MAF_INT_LAM_I_ADJ_ACT_SLOW	The constant is the integral threshold for MAF for reactivation of the trim controller (I-share) after Lambda set point violation, Lambda controller at hard limit or open-loop operation of Lambda controller. **(e.g. 35 g)**
C_MAF_INT_LAM_ADJ_I_ACT_PURGE	The constant is the integral threshold for MAF for reactivation of the trim controller (I-share) after PUC. **(e.g. 50 g)**
C_MAF_INT_LAM_D_ADJ_ACT_FAST[NC_CBK_EX_NR]	The constant is the integral threshold for MAF for reactivation of the trim controller (D-share) from inactive state. **(e.g. 10 g)**
C_MAF_INT_LAM_D_ADJ_ACT_SLOW	The constant is the integral threshold for MAF for reactivation of the trim controller (D-share) after Lambda set point violation, Lambda controller at hard limit or open-loop operation of Lambda controller. **(e.g. 15 g)**
C_MAF_INT_LAM_ADJ_D_ACT_PURGE	The constant is the integral threshold for MAF for reactivation of the trim controller (D-share) after PUC. **(e.g. 25 g)**
C_TCO_LAM_ADJ_P_ACT_HST	Fast activation of trim controller P-share in case of hot start. If TCO is above this threshold and T_AST below limit (and all other conditions are fulfilled) the P-share is activated immediately. (**e.g. 75 °C**)
C_T_AST_LAM_ADJ_P_ACT_HST	Fast activation of trim controller P-share in case of hot start. If TCO is above threshold and T_AST below this limit (and all other conditions are fulfilled) the P-share is activated immediately. (**e.g. 20 s**)
C_LAMB_SP_MIN_LAM_ADJ_ACT	Minimum Lambda setpoint for overall trim controller activation. Defines setpoint range valid for Lambda eq. 1 operation. (**min. value of IP_LAMB_BAS**) Full load enrichment setpoints in IP_LAMB_BAS may no be used as minimal thresholds for trim controller activation.
C_LAMB_SP_MAX_LAM_ADJ_ACT	Maximum Lambda setpoint for overall trim controller activation. Defines setpoint range valid for Lambda eq. 1 operation. (**max. value of IP_LAMB_BAS**)

46.19.3.2 *Lambda Voltage Setpoint*

IP_VLS_SP_LAM_ADJ[NC_CBK_EX_NR]	The setpoint of the sensor signal voltage should be evaluated measuring the Catalyst Efficiency for the whole operating range. At each operating point the sensor signal voltage with the best catalyst efficiency should be chosen as the setpoint. IP_VLS_SP_LAM_ADJ[i] is an N-MAF-dependent map. **(e.g. 650 mV for all points)**

IP_VLS_SP_DELTA_LAM_ADJ	Shift of the downstream signal setpoint based on EFF_CAT_DIAG to take into account stringent NOx increase with catalyst ageing. **(e.g. 0 for all points)**
IP_VLS_DELTA_LAM_ADJ_CAT_DIAG	Map is defined in Appl. Inc. Offset of VLS_DOWN_MV because of non-linearity of the binary sensor in case of break through **(e.g. 0 for all points)**
IP_CRLC_VLS_LAM_ADJ_CAT_DIAG	Map is defined in Appl. Inc. Aim of calculation is, to filter the oscillations of the VLS_DOWN signal to remain in the plateau of P-share resp. I-share during catalyst diagnosis (filtered amplitude is 10% of VLS_DOWN) (see Figure 1) **(IP_CRLC_VLS_LAM_ADJ_CAT_DIAG = 2*π*T_SAMPLE/(10*T_SUM_AFL_AFR_LAM+2*π*T_SAMPLE))**

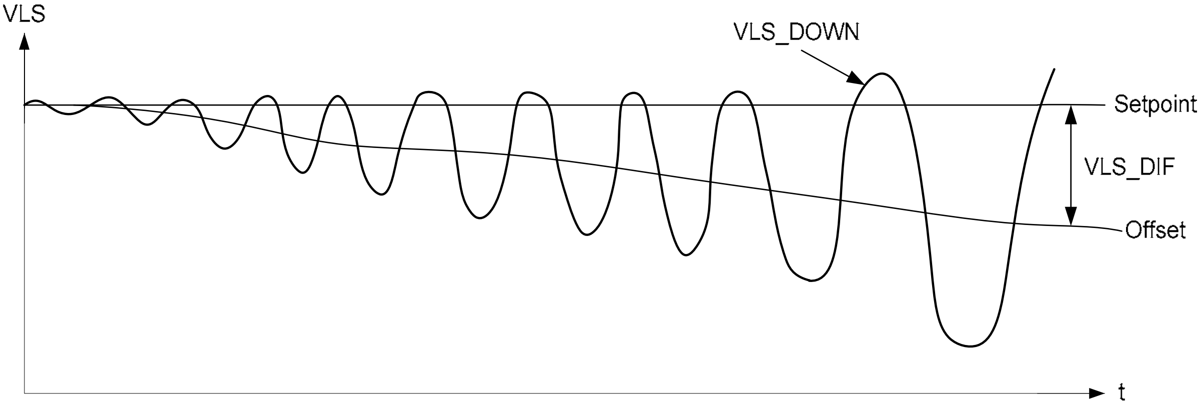

Figure 1: mean value shift

46.19.3.3 *P-share Specific Activation and Calculation*

C_MAF_MIN_LAM_ADJ_P_ACT	This constant forms the minimum MAF threshold for the activation of the Proportional component of the trim controller. **(e.g. 65 mg/stk)**
C_MAF_MAX_LAM_ADJ_P_ACT	This constant forms the maximum MAF threshold for the activation of the Proportional component of the trim controller. **(e.g. 501 mg/stk)**
C_N_MIN_LAM_ADJ_P_ACT	This constant forms the minimum Engine Speed threshold for the activation of the Proportional component of the trim controller. **(e.g. 544 rpm)**
C_N_MAX_LAM_ADJ_P_ACT	This constant forms the maximum Engine Speed threshold for the activation of the Proportional component of the trim controller. **(e.g. 4224 rpm)**
IP_LAMB_DELTA_P_LAM_ADJ	This forms the Trim Proportional Correction based on the voltage error of the Downstream sensor from the Setpoint. The benefit of the P component is rejection of transient disturbance to reduce NOx emission. The dependency is only on VLS_DIF_LAM_ADJ. **(e.g. see table below)**
IP_FAC_LAMB_DELTA_P_LAM_ADJ [NC_CBK_EX_NR]	This is a weighting factor for the P component based on MAF. **(e.g. see table below)**

IP_FAC_ADD_LAMB_DELTA_P	This is a weighting factor for the P component based on EFF_CAT_DIAG. So the normal P operation can be fine tuned with the aging of the Catalyst. **(e.g. see table below)**
IP_LAMB_DELTA_P_LAM_ADJ_DIAG	This forms the Trim Proportional Correction based on the voltage error of the Downstream sensor from the Setpoint in the Cat Diagnosis phase. **(e.g. same as for IP_LAMB_DELTA_P_LAM_ADJ)**

46.19.3.4 I-share Specific Activation and Calculation

IP_MAF_MIN_LAM_ADJ_I_ACT	This constant forms the minimum MAF threshold for the activation of the Integral component of the trim controller. **(e.g. see table below)**
IP_MAF_MAX_LAM_ADJ_I_ACT	This constant forms the maximum MAF threshold for the activation of the Integral component of the trim controller. **(e.g. see table below)**
LC_LAMB_PLS_NOT_CHK_LAM_ADJ	Disable active forced Lambda stimulation as condition for trim controller I-share activation. (**e.g. 0**)
LC_LAM_ADJ_LDC_NOT_CHK	Disable limited dynamics as condition for activation of trim controller I-share activation. (**e.g. 0**)

Calibration of IP_MAF_MIN_LAM_ADJ_I_ACT and IP_MAF_MAX_LAM_ADJ_I_ACT:

The calculation of I component should be carried out in part load. Therefore, the minimum engine speed should be chosen over the nominal idle speed. A low load leads to a long response time of lambda sensor; therefore in the calibration low values of mass air flow should be avoided. The maximum value of allowed engine speed for calculation of I component should be less than the maximum occurred engine speed during the emission test cycles.

In order to define the range of MAF_CYL with constant adaptation value, drive several operating points. The calibration should be performed using a system with a 100K aged catalyst, which has a low oxygen storage capacity, and a slowed-down sensor (high lambda amplitude). For the whole range of allowed MAF_CYL the downstream lambda sensor signal should be stable.

Calibration of I-share calculation parameters:

The integral term of dynamic fuel trim shall be stable after the three first pre-conditioning cycles. For the chosen operating point the controller output shall decrease if the deviation is negative (rich side) and increase if the deviation is positive (lean side).

Overshoots shall be avoided. For the chosen operating point set first IP_CRLC_LAMB_DELTA_I_LAM_ADJ[i] = 1 and then adjust the value of IP_LAMB_DELTA_I_LAM_ADJ.

IP_CRLC_LAMB_DELTA_I_LAM_ADJ[i] has influence on the adaptation speed.

C_LAMB_DELTA_I_MIN_LAM_ADJ	This forms the minimum value possible for the Integral component of the trim controller. (**e.g. -0.035…-0.025**)
C_LAMB_DELTA_I_MAX_LAM_ADJ	This forms the maximum value possible for the Integral component of the trim controller. (**e.g. +0.025…+0.035**)
LC_LAM_ADJ_I_SAVE_CAT_DIAG	With this parameter set to 1 the I-share calculated during the catalyst diagnosis is discarded afterwards. (**e.g. 1**)

46.19.3.5 Integral Component Mean Value

C_CRLC_LAMB_DELTA_I_MMV_LAM_ADJ	This forms the correlation constant for the Integral Share mean value calculation during the normal trim control phase. **(e.g. 0.001)**

46.19.3.6 D-share Specific Activation and Calculation

C_MAF_MIN_LAM_ADJ_D_ACT	This constant forms the minimum MAF threshold for the activation of the D-share of the trim controller. **(e.g. same as for P-share)**
C_MAF_MAX_LAM_ADJ_D_ACT	This constant forms the maximum MAF threshold for the activation of the D-share of the trim controller. **(e.g. same as for P-share)**
C_N_MIN_LAM_ADJ_D_ACT	This constant forms the minimum Engine Speed threshold for the activation of the D-share of the trim controller. **(e.g. same as for P-share)**
C_N_MAX_LAM_ADJ_D_ACT	This constant forms the maximum Engine Speed threshold for the activation of the D-share of the trim controller. **(e.g. same as for P-share)**

IP_LAMB_DELTA_D_LAM_ADJ	This forms the Trim D-share Correction based on the voltage error of the Downstream sensor from the Setpoint. The benefit of the D-share is rejection of transient disturbance to reduce NOx emission. The dependency is only on VLS_DIF_LAM_ADJ. **(e.g. see table below)**
IP_FAC_LAMB_DELTA_D_LAM_ADJ[NC_CBK_EX_NR]	This is a weighting factor for the D-share based on MAF. **(e.g. see table below)**
IP_FAC_ADD_LAMB_DELTA_D	This is a weighting factor for the D-share based on EFF_CAT_DIAG. So the normal D operation can be fine tuned with the aging of the Catalyst. **(e.g. see table below)**

IP_CRLC_VLS_DIF_MMV_LAM_ADJ	Filter parameter for calculation of the moving mean value of the voltage difference. The parameter is MAF_CYL and EFF_CAT_DIAG dependent in order to consider longer durations of the D-share at low air mass flows and shorter due to OSC deterioration with an aged catalyst. **(e.g. see table below)**

46.20 Lambda adaptation (LACO_ISPCLADA0)

The Lambda Adaptation is compensating air/fuel ratio variations based on vehicle to vehicle differences caused by air path and/or fuel path errors via an additive and a multiplicative correction in the injection set point calculation (component variations for injector pressure regulator / injection valves / small air leakage's / bypass air for throttle plate / MAF or Map sensor / intake system, ...). Furthermore long term variations of air/fuel metering are covered (component ageing for e.g. injector pressure regulator / injection valves / throttle plate and throttle body deposit. / MAF or Map sensor, ...).

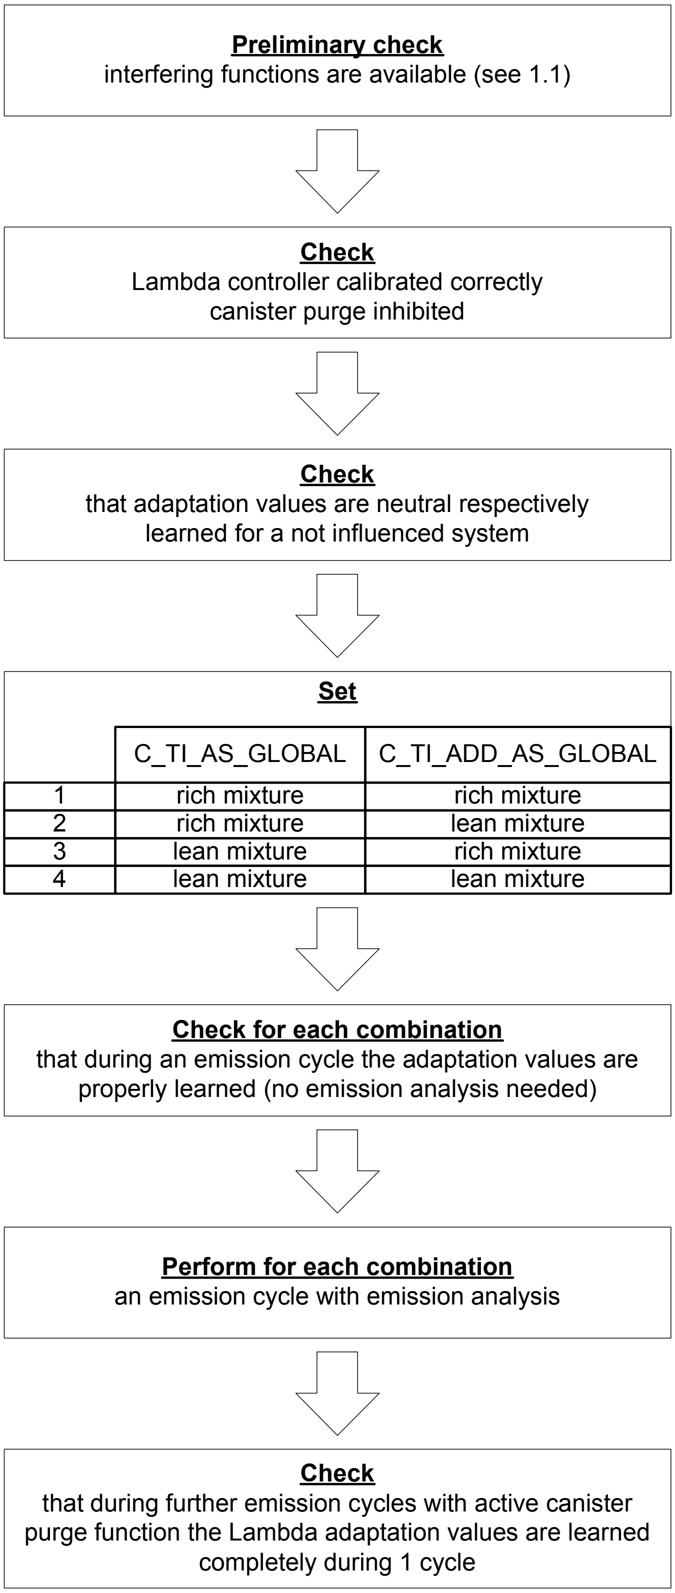
A typical example for an additive correction is the variation of air leakage's as they are constant in idle speed and negligible for higher charges. A typical example for a multiplicative correction is the variation of pressure regulator, which has to be applied for all charges.

In an early development phase for a new engine/car large variations of the lambda adaptive values may give you a hint (like the lambda control itself) for a principle problem / error in the field mentioned above (wrong component used) but also on the intake system general (e.g. mismatch between CAM-shaft and CRK-shaft) and also on the outlet system (change of exhaust line which provides a different exhaust back pressure).

46.20.1 Calibration interfering functions

- Lambda control (LACO_REQGNLACO0)
- Fuel System Diagnosis (LACO_FCTDGFSD0)
- Evaporative system control (EVAC_REQCOTIME0)
- Fuel mass setpoint calculation (FMSP_REGGNMFFSP0)

46.20.2 Calibration flowchart



Preliminary check
interfering functions are available (see 1.1)

Check
Lambda controller calibrated correctly
canister purge inhibited

Check
that adaptation values are neutral respectively
learned for a not influenced system

Set

	C_TI_AS_GLOBAL	C_TI_ADD_AS_GLOBAL
1	rich mixture	rich mixture
2	rich mixture	lean mixture
3	lean mixture	rich mixture
4	lean mixture	lean mixture

Check for each combination
that during an emission cycle the adaptation values are
properly learned (no emission analysis needed)

Perform for each combination
an emission cycle with emission analysis

Check
that during further emission cycles with active canister
purge function the Lambda adaptation values are learned
completely during 1 cycle

The following values are to be recorded with application system during emission cycle every (sample rate of at least 20 ms is recommended):

LACO_REQGNLACO0 – "Lambda Control (fuel mass)":

FAC_LAM_MV_MMV[i]
FAC_LAM_LIM[i]
LV_LAM_LSCL[i]
LV_LAM_STOP[i]

EVAC_MDLAD0 – "Evaporative emission control":

STATE_CP
LV_CP_CLOSE_ACT

EVAC_REQCOTIME0 – "Time control between EVAP and Lambda adaptation":

STATE_T_SDL_CP

LACO_ISPCLADA0 – "Lambda adaptation":

STATE_LAM_AD[i]
MFF_ADD_LAM_AD_OUT[i]
MFF_ADD_LAM_AD[i]
MFF_DELTA_ADD_LAM_AD[i]
FAC_LAM_AD_OUT[i]
FAC_LAM_AD[i]
FAC_L_RNG_LAM_AD[i]
FAC_DELTA_L_RNG_LAM_AD[i]
FAC_H_RNG_LAM_AD[i]
FAC_DELTA_H_RNG_LAM_AD[i]
LV_LAM_AD_END
T_PRI_TOT_LAM_AD

LACO_ISPCLADAPI0 – " Application Incidences for Lambda adaptation":

LV_LAM_AD_ACT[i]

46.20.3 Calibration method

The normal range for the lambda controller may have ±5% in steady state which would represent a good calibration. This range may increase up to ±15% during transient conditions. As the lambda adaptation has to cover long term drifts and/ or vehicle to vehicle deviations one has to face to a value resulting out of this for example (rough estimation):

Tolerances of Injectors + MAF/MAP + Fuel Pressure + ... = ±5% ± 5% ± 5% = ±15%

Taking both into account the working range for the lambda sensor has to be at least ±30%. On the other hand a wider range should not be chosen to guarantee a driveability at all in case of a completely wrong lambda sensor signal; eg. due to exhaust line leakage. The range for the lambda adaptation has to be smaller than the one for the lambda control to avoid a “blocked” system which cannot correct wrongly learned values (for example during low fuel tank level).

Weighting factors

IP_FAC_N_MFF_ADD_LAM_AD	Engine speed weighting of additive adaptation factor (offset). (**e.g. 1 for all points**)
IP_FAC_N_FAC_LAM_AD	Engine speed weighting of multiplicative adaptation factor. (**e.g. 1 for all points**)

IP_FAC_WUP_MFF_ADD_LAM_AD	Warm-up weighting of additive adaptation factor (offset). (**e.g. 1 for all points**) *For the warm-up phase (in case TCO <= C_TCO_MIN_LAM_AD) additional weighting factors can be applied to lower the adaptive influence if needed.*
IP_FAC_WUP_FAC_LAM_AD	Warm-up weighting of multiplicative adaptation factor. (**e.g. 1 for all points**) *see remark at IP_FAC_WUP_MFF_ADD_LAM_AD*

For each of the outputs MFF_ADD_LAM_AD[i] and FAC_LAM_AD[i] the respective weighting factor depending on engine speed can be applied. They should be normally calibrated to 1 to have both outputs applied over the whole engine speed range. Another calibration strategy would be a weighting factor for the additive adaptive value decreasing from 1 to 0 for 1300 to 1500 rpm while the factor for the multiplicative adaptive value is working in the opposite direction to avoid any influence on each other.

Priority management between Lambda adaptation and canister purge

ID_T_PRI_MFF_ADD_RNG_LAM_AD	Priority management between lambda adaptation and canister purge. Priority time according to offset difference. (**e.g. see Table 1**) *The right calibration depends on engine displacement and engine auxiliaries and on the overall strategy of "Time control between EVAP and Lambda adaptation".*
ID_T_PRI_FAC_L_RNG_LAM_AD	Priority management between lambda adaptation and canister purge. Priority time according to factor difference in lower learning area. (**e.g. see Table 1**)
ID_T_PRI_FAC_H_RNG_LAM_AD	Priority management between lambda adaptation and canister purge. Priority time according to factor difference in upper learning area. (**e.g. see Table 1**)
C_T_TRI_MAX_LAM_AD	Maximum priority time to set temporary end of adaptation flag. (**e.g. 88 s**) Must below maximum of map values (ID_T_PRI…).

ID_T_PRI_MFF_ADD_RNG_LAM_AD	30	40	60	90	50	30	20	15	s

Table 1: Example for priority management between lambda adaptation and canister purge

Definition of learning areas

C_N_TOL_ADD_RNG_LAM_AD	Maximum engine speed for offset Lambda adaptation field definition. (**e.g. 1000 rpm**)
C_MFF_SP_TOL_ADD_RNG_LAM_AD	Maximum fuel mass setpoint for offset Lambda adaptation field definition. (**e.g. 14 mg/stk**)
C_N_BOL_FAC_L_RNG_LAM_AD	Minimum speed for lower multiplicative Lambda adaptation field definition. (**e.g. 1400 rpm**)
C_N_TOL_FAC_L_RNG_LAM_AD	Maximum speed for lower multiplicative Lambda adaptation field definition. (**e.g. 3000 rpm**)

ID_MFF_SP_BOL_FAC_L_RNG_LAM_AD	Minimum fuel mass setpoint for lower multiplicative Lambda adaptation field definition. (**e.g. see Table 2**)
ID_MFF_SP_TOL_FAC_L_RNG_LAM_AD	Maximum fuel mass setpoint for lower multiplicative Lambda adaptation field definition. (**e.g. see Table 2**)
C_N_BOL_FAC_H_RNG_LAM_AD	Minimum speed for upper multiplicative Lambda adaptation field definition. (**e.g. 2500 rpm**)
C_N_TOL_FAC_H_RNG_LAM_AD	Maximum speed for upper multiplicative Lambda adaptation field definition. (**e.g. 4200 rpm**)
ID_MFF_SP_BOL_FAC_H_RNG_LAM_AD	Minimum fuel mass setpoint for upper multiplicative Lambda adaptation field definition. (**e.g. see Table 2**)
ID_MFF_SP_TOL_FAC_H_RNG_LAM_AD	Maximum fuel mass setpoint for upper multiplicative Lambda adaptation field definition. (**e.g. see Table 2**)

Three learning field have to be specified. In one field a fuel mass flow offset for MFF_SP[i] is learned and in two fields a factor that is multiplied with MFF_SP[i] is learned. The 3 learned values are stored in the non-volatile memory. The following points must be considered when calibrating the field borders:

- the three defined learning areas must not overlap each other.
- the additive value should cover the idle speed area.
- operating points in part load covered in the emission cycle should lie within the learning area of the lower multiplicative factor.
- operating points in higher part load covered in the emission cycle may lie within the learning area of the lower multiplicative factor.

LDPM_N_32_5_LACO	0	1120	3008	3360	4512	5632	6752	8000	rpm

Table 3: Example for interpolation range of mulitplicative adaptation factor

Limitation of adaptation values

C_MFF_MIN_ADD_RNG_LAM_AD	Minimum limitation of offset adaptation. (**e.g. -2.5 mg/stk**) *The range for the lambda adaptation has to be smaller than the one for the lambda control to avoid a “blocked” system which cannot correct wrongly learned values (for example during low fuel tank level).*
C_MFF_MAX_ADD_RNG_LAM_AD	Maximum limitation of offset adaptation. (**e.g. +2.5 mg/stk**) *see remark at C_MFF_MIN_ADD_RNG_LAM_AD*
C_FAC_MIN_L_RNG_LAM_AD	Minimum limitation of lower multiplicative adaptation factor (**e.g. -20%**) *see remark at C_MFF_MIN_ADD_RNG_LAM_AD*
C_FAC_MAX_L_RNG_LAM_AD	Maximum limitation of lower multiplicative adaptation factor (**e.g. +20%**) *see remark at C_MFF_MIN_ADD_RNG_LAM_AD*
C_FAC_MIN_H_RNG_LAM_AD	Minimum limitation of upper multiplicative adaptation factor (**e.g. -20%**) *see remark at C_MFF_MIN_ADD_RNG_LAM_AD*
C_FAC_MAX_H_RNG_LAM_AD	Maximum limitation of upper multiplicative adaptation factor (**e.g. +20%**) *see remark at C_MFF_MIN_ADD_RNG_LAM_AD*

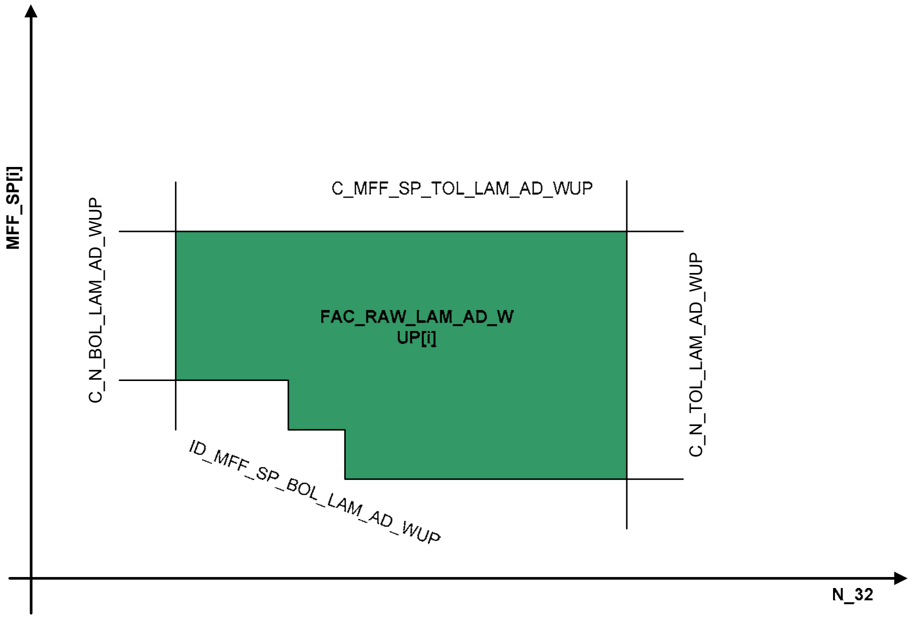
Force Lambda eq. 1 conditions

LC_MFF_ADD_RNG_AFS_REQ_LAM_AD	Enable request flag to for combustion manager to force Lambda eq. 1 conditions for Lambda adaptation in additive learning area (**0** for MPI, 1 for HPDI depending on project philosophy)
LC_FAC_L_RNG_AFS_REQ_LAM_AD	Enable request flag to for combustion manager to force Lambda eq. 1 conditions for Lambda adaptation in lower multiplicative learning area (**0** for MPI, 1 for HPDI depending on project philosophy)
LC_FAC_H_RNG_AFS_REQ_LAM_AD	Enable request flag to for combustion manager to force Lambda eq. 1 conditions for Lambda adaptation in upper multiplicative learning area (**0** for MPI, 1 for HPDI depending on project philosophy)

46.21 Lambda adaptation in warm-up phase (LACO_ISPCLADW0)

An adaptive corrections applied to compensate serial production tolerances of components at low temperatures and reduce thereby the Lambda controller excursions. The correction factors (%) are learned in five temperature ranges. They are derived from the Lambda controller output and are learned in a calibratable speed/load range. They are, however, used for calculating the injection time for all engine states. Learning of these factors requires that the Lambda controller is in the state 'ON'.

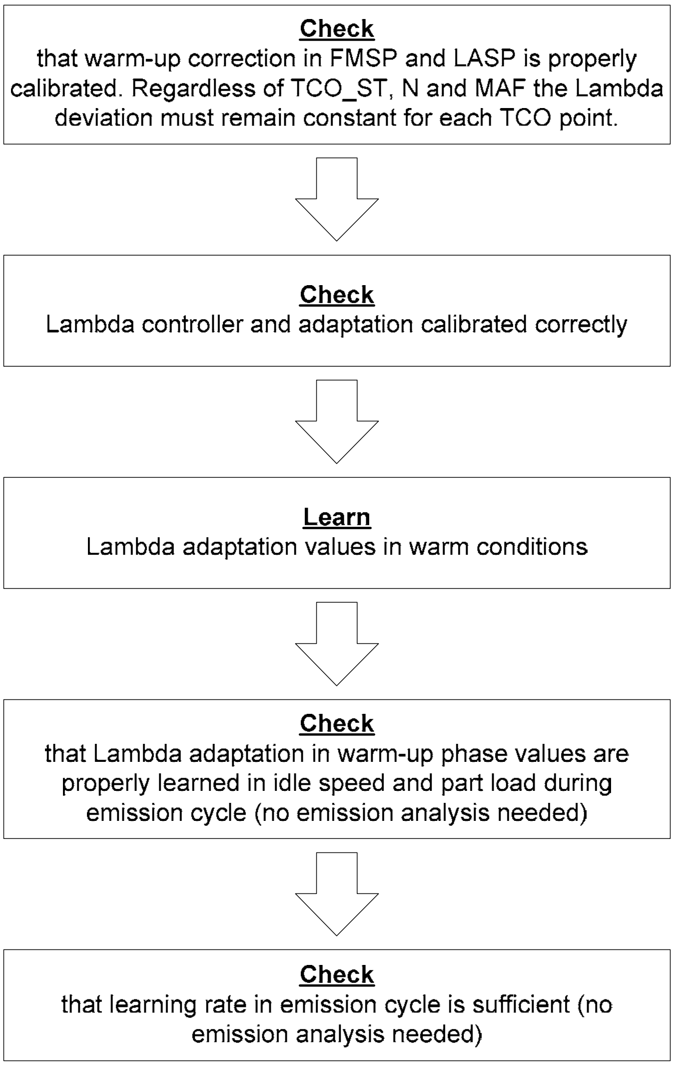
Depending on MFF_SP[i] and N_32 the adaptation fields is defined as follows:.



46.21.1 Calibration interfering functions

- Lambda control (LACO_REQGNLACO0)
- Lambda adaptation (LACO_ISPCLADA0)
- Fuel System Diagnosis (LACO_FCTDGFSD0)
- Fuel mass setpoint calculation (FMSP_REGGNMFFSP0)
- Warm-up correction (FMSP – 700A)
- Basic Lambda Setpoint including Homogeneous Lean Mode (LASP – 702P)
-

46.21.2 Calibration flowchart



Check
that warm-up correction in FMSP and LASP is properly calibrated. Regardless of TCO_ST, N and MAF the Lambda deviation must remain constant for each TCO point.

Check
Lambda controller and adaptation calibrated correctly

Learn
Lambda adaptation values in warm conditions

Check
that Lambda adaptation in warm-up phase values are properly learned in idle speed and part load during emission cycle (no emission analysis needed)

Check
that learning rate in emission cycle is sufficient (no emission analysis needed)

46.21.3 Calibration method

Learning of adaptation factors

C_CRLC_FAC_DIF_LAM_AD_WUP_MV	Correlation constant for Lambda controller output without Lambda adaptation in warm-up phase correction (**e.g. 0.05**) *Chose value in such way, that no major noise influence is seen, but still the shape should be similar to that of the controller output, especially with regard to the bumps and dents. The location of the largest deviation from the 0%-line should be similar for the filtered and not filtered Lambda controller out. The difference should be less than 10s and not more than one resolution step of TCO.*
C_CTR_TCO_MIN_INTER	Threshold above which counter has to rise to detect the lowest temperature valid for learning. (**e.g. 10**) *The threshold should not be exceeded by a dithering counter prior to the largest deviation of the controller output. However, the detection should not be delayed unnecessary once the largest deviation is passed.*
C_T_MAX_LAM_AD_WUP_LDC	Minimum time for which the conditions required for learning have to be fulfilled. (**e.g. 5 s**)

C_T_MAX_LAM_AD_WUP_TRA_PHA	Minimum time after first activation of Lambda controller to enable learning of adaptation values. (**e.g. 10 s**) *The time criteria has to be satisfied in parallel to the counter criteria to enable learning.*
C_FAC_LAM_AD_WUP_MIN_GAP	Minimum (absolute) difference to previously learned adaptation factors to update adaptation factor. (**e.g. 0%**)
C_CRLC_FAC_LAM_TCO_X	Correlation constant for updating adaptation factor. (**e.g. 0.7**)
C_CRLC_FAC_LAM_TCO_FIRST_DC	Correlation constant for updating adaptation factor in first driving cycle after initialisation of ECU or clearing of adaptation values. This factor enables a faster learning in case no previous adaptation values are available. (**e.g. 1**)

Limitation of adaptation value

IP_FAC_LAM_AD_WUP_MIN	Minimum limitation of adaptation factor in warm-up phase. (**e.g. -15% for all points**) *The range for the lambda adaptation has to be smaller than the one for the lambda control.*
IP_FAC_LAM_AD_WUP_MAX	Maximum limitation of adaptation factor in warm-up phase (**e.g. +20% for all points**) *see remark at IP_FAC_LAM_AD_WUP_MIN*
C_FAC_LAM_AD_WUP_MIN_LSCL_OFF	Minimum limitation of adaptation factor in warm-up phase while Lambda controller is off. (**e.g. -15%**) *see remark at IP_FAC_LAM_AD_WUP_MIN*
C_FAC_LAM_AD_WUP_MAX_LSCL_OFF	Maxmum limitation of adaptation factor in warm-up phase while Lambda controller is off. (**e.g. +20%**) *see remark at IP_FAC_LAM_AD_WUP_MIN*
C_FAC_LAM_AD_WUP_MIN_INTER	Minimum limitation of adaptation factor in warm-up phase after activation of Lambda controller but before detection of minimum temperature valid for learning. (**e.g. -15%**) *see remark at IP_FAC_LAM_AD_WUP_MIN*
C_FAC_LAM_AD_WUP_MAX_INTER	Maximum limitation of adaptation factor in warm-up phase after activation of Lambda controller but before detection of minimum temperature valid for learning. (**e.g. +20%**) *see remark at IP_FAC_LAM_AD_WUP_MIN*
C_CRLC_GLOBAL_FAC_LAM_AD_WUP	Factor to limit the adaptive influence, if needed. (**e.g. 1**)

Definition of learning areas

C_N_BOL_LAM_AD_WUP	Minimum speed for adaptation field definition. (**e.g. 750 rpm**)
C_N_TOL_LAM_AD_WUP	Maximum speed for adaptation field definition. (**e.g. 4000 rpm**)
ID_MFF_SP_BOL_LAM_AD_WUP	Minimum fuel mass setpoint for adaptation field definition. (**e.g. 7 mg/stk for all points**)
C_MFF_SP_TOL_LAM_AD_WUP	Maximum fuel mass setpoint for adaptation field definition. (**e.g. 23 mg/stk**)

Temperature sampling point definition

C_TCO_A_LAM_AD_WUP	Coolant temperature of sampling point A to learn adaptation value. (**e.g. -10 °C**)
C_TCO_B_LAM_AD_WUP	Coolant temperature of sampling point B to learn adaptation value. (**e.g. 0 °C**)
C_TCO_C_LAM_AD_WUP	Coolant temperature of sampling point C to learn adaptation value. (**e.g. +10 °C**)

C_TCO_D_LAM_AD_WUP	Coolant temperature of sampling point D to learn adaptation value. (**e.g. +20 °C**)
C_TCO_E_LAM_AD_WUP	Coolant temperature of sampling point E to learn adaptation value. (**e.g. +30 °C**)
C_TCO_F_LAM_AD_WUP	Coolant temperature at which adaptation in warm-up phase value is faded out. (**e.g. 40 °C**) *This must be lower than C_TCO_MIN_LAM_AD to differentiate between Lambda adaptation in warm conditions and Lambda adaptation in cold conditions (warm-up phase).*
C_TCO_LAM_AD_WUP_RNG	Coolant temperature range above and below TCO sampling point A to E in which the respective controller ouput can be learned. (**e.g. 2 °C**) *Parameter has diametrical effect on learning rate and on accuracy. On the one hand, larger values assist the learning as the temperature window in which learning is possible is increased. On the other hand, the accuracy decreases since the distance between two interpolation points may increase. Therefore, the less monoton the curve is the larger the possible error will be.*

Application of adaptation factor

C_FAC_LAM_AD_WUP_DELTA	Maximum step size to ramp adaptation factor to new value. (**e.g. 1 %**) *Ramp should not be steeper than system reaction.*
LC_FAC_RAW_LAM_AD_WUP_LIM_ACT	Logical variable to force application of adaptation value learnt at lowest temperature to all interpolation points below this sampling point. (**e.g. 1**)
LC_LAM_AD_WUP_CLR_INH	Logical variable to exclude all data of this fuction which is stored in the non-volatile memory from initialization. This variable offers the opportunity to prevent the loss of adaptattion data in case of failure memory clearing (**e.g. 0**) *For application purposes only!*

Detection of change in fuel quality

ID_FAC_THD_CHG_FQ_DET	Threshold of difference in adaptation value compared to previously learnt values to trigger change in fuel quality detection and execute shift of all adaptation values. (**e.g. 5% for all values**)
IP_FAC_CHG_FQ_DET_SCA	Scaling factor by which all adaptation values are shifted in case of change in fuel quality detection. (**e.g. 1 for all values**)

Auto shift functionality

C_THD_DIF_L_RNG_LAM_AD	Threshold of change in adaptation value compared to previous shift that must be exceeded to execute the auto shift of adaptation values in warm-up phase. (**e.g. 0**) *Set to maximum to deactivate functionality.*
C_THD_FAC_DELTA_L_RNG	Threshold below which the change in adaptation values in low range FAC_DELTA_L_RNG_LAM_AD[i] must fall to all shift of adaptation values in warm-up phase. (**e.g. 0.05**)
IP_FAC_WUP_FAC_LAM_AD_WUP	Copy of map defined in Lambda adaptation. (**values must be identical to IP_FAC_WUP_FAC_LAM_AD!**)

LC_LAM_AD_WUP_SHIFT_ACT	Logical variable to allow auto shift in all driving cycle (and not only in first driving cycle after clearing of adaptation values. (**e.g. 1**)

Write down of adaption value to next lower value

C_TCO_RNG_WR_DOWN_LAM_AD_WUP	Maximum temperature difference between two adaptation values to enable (if all other conditions are fulfilled) write down of adaptation value to next lower interpolation point. (**e.g. 0 °C**) *Functionality is not recommended and shall therefore be deactivated.*
LC_FAC_WR_DOWN_LAM_AD_WUP	Logical variable to enable write down to next lower adaptation value. (**e.g. 0**) *Functionality is not recommended and shall therefore be deactivated.*

46.22 Lambda control for WRAF sensor

46.22.1 Calibration interfering function:

- Forced lambda stimulation (linear control) (EGTR_DEFSPFSTI0): Lambda stimulation is used for system identification as "lambda set point step generator".
- Lambda Adaptation (LACO_ISPCLADA0): Can be used to adjust lambda = 1 condition before start system identification; must be inactive during system identification.
- Dynamic fuel trim (LACO_REQGNTRIM0): Trim control should be deactivated to not generate a set point shift with the P share output (eg. set C_TEMP_CAT_MIN_LAM_ADJ_ACT to maximum value).
- Evaporative emission control (EVAC_MDLAD0): Canister purge must be switched off during system identification (eg. set LC_CP_ACT to 0 or C_TCO_MIN_CP to maximum; LC_CP_ACT is only available in AGGR version of EVAC).
- Activation conditions and in cylinders EGR ratio setpoints calculation (EGRC_ISPCL0): EGR must not be active during system identification (eg. set C_N_32_MIN_ACT_EGR to maximum value).
- Catalyst efficiency diagnosis (EGTR_FCTDGCEF0): Catalyst efficiency diagnosis must be deactivated during system identification by setting C_N_32_CAT_DIAG_DEAC_THD to 0.
- Offset adjustment of oxygen sensor (linear control) (EGCP_ADCPRLSL1): The offset can be learned once immediately after engine start. Then the function must be deactivated to not disturb the system identification (offset adjustment would lead to interruption of forced lambda stimulation). The function can be deactivated by setting C_LAMB_LS_UP_MIN_OFS_ADJ and C_LAMB_LS_UP_MAX_OFS_ADJ both to the same value eg. to 0.
- Linear Oxygen sensor diagnosis (EGCP_SIGDGLSL2): The WRAF Sensor Dynamic Diagnosis is part of this diagnosis function and needs the calibration of the time for the WRAF sensor model for the aged limit sensor.

46.22.2 Calibration Flowchart:

46.22.3 Calibration method:

	First order time lag of the WRAF sensor model **(result of the system identification; calculated with the PT1-Tool out of measurements)**
IP_T1_LSL_UP_AGI_LIM	First order time lag of the WRAF sensor model of the aged sensor **(result of the system identification; calculated with the PT1-Tool out of measurements)**
IP_FAC_EG_DLY	Weighting factor for the calculation of the exhaust gas delay **(result of the system identification; calculated with the PT1-Tool out of measurements)**
IP_LAMB_SP_THE_PUC	Theoretical lambda-setpoint during PUC **(e.g. see table below)**

LDP_MAF_INT_PUC_IP_LAMB_SP_THE	0	607	1213	1820	g
IP_LAMB_SP_THE_PUC	2.5	2.5	2.5	2.5	-

Calibration data for controller parameter:

The IP-maps for determination of the controller parameter can be calculated with the **LAM_CTL_Tool** (SPT).

IP_FAC_GAIN_P_LAM	Gain of lambda controller P share **(calculated with the LAM_CTL_Tool based on the result of the identification of the plant)**
IP_FAC_GAIN_I_LAM	Gain of lambda controller I share **(calculated with the LAM_CTL_Tool based on the result of the identification of the plant)**
IP_FAC_GAIN_I2_LAM	Gain of lambda controller I^2 share **(calculated with the LAM_CTL_Tool based on the result of the identification of the plant)**
IP_FAC_GAIN_D_LAM	Gain of lambda controller D share **(calculated with the LAM_CTL_Tool based on the result of the identification of the plant)**

Calibration data for controller parameter in case of LV_LAM_GAIN_SWI = 1:

Calibration Data for extended O_2 balancing based on down stream signal evaluation

IP_FAC_GAIN_P_LAM_GAIN_SWI	Gain of lambda controller P share in case of LV_LAM_GAIN_SWI is set **(calculated with the LAM_CTL_Tool based on the results of the identification of the plant)**
IP_FAC_GAIN_I_LAM_GAIN_SWI	Gain of lambda controller I share in case of LV_LAM_GAIN_SWI is set **(calculated with the LAM_CTL_Tool based on the results of the identification of the plant)**
IP_FAC_GAIN_I2_LAM_GAIN_SWI	Gain of lambda controller I^2 share in case of LV_LAM_GAIN_SWI is set **(calculated with the LAM_CTL_Tool based on the results of the identification of the plant)**
IP_FAC_GAIN_D_LAM_GAIN_SWI	Gain of lambda controller D share in case of LV_LAM_GAIN_SWI is set **(calculated with the LAM_CTL_Tool based on the results of the identification of the plant)**

Calibration Data for controller activation:

ID_TCO_MIN_LAM_LSCL_IS	Minimum TCO for lambda controller activation at idle speed **(e.g. see table below)**
ID_TCO_MIN_LAM_LSCL	Minimum TCO for lambda controller activation **(e.g. see table below)**
ID_T_MAX_LSCL_ACT_TCO	Maximum time value up to that the controller can be activated by TCO condition **(e.g. see table below)** *Depends on legal requirements: time after that lambda controller must get active.*
C_N_MIN_LAM_LSCL	Minimum engine speed for lambda controller activation **(e.g. 416 rpm)**
ID_T_AST_MIN_LSCL_ACT	Minimum time after start that must be elapsed before activating the lambda controller **(e.g. see table below)** *Depends on wether it's necessary to have a reproduceable time to switch on the lamba controller after start. Serial dispersion can be taken into account.*

LDPM_TCO_ST_1_LACO	-30.0	-9.0	0.0	20.0	50.0	90.0	°C

ID_T_AST_MIN_LSCL_ACT	tbd.	tbd.	tbd.	tbd.	tbd.	tbd.	s

Calibration data for correlation constants:

Phys. limits for correlation constants are 0...1

High values mean a weak filtering of the signal (1 : no filtering), low values mean a strong filtering of the signal.

C_CRLC_FAC_LAM_MV	Correlation constant for calculation of the controller output mean value FAC_LAM_MV **(e.g. 0.1)**
C_CRLC_FAC_LAM_MV_MMV	Correlation constant for the calculation of the filtered controller output mean value FAC_LAM_MV **(e.g. 0.05)** *Depending on lambda adaption strategy speed.*
C_CRLC_FAC_LAM_MV_MMV_LDC	Correlation constant for the calculation of moving mean value for limited dynamics detection **(e.g. 0.1)**
C_CRLC_FAC_DIF_LAM_IN_MMV	Correlation constant for the calculation of FAC_DIF_LAM_IN_MMV **(e.g. 0.2)**
C_CRLC_VLS_DOWN_MMV_LAM	Correlation constant for the calculation of VLS_DOWN_MMV_LAM **(e.g. 0.082)**
C_CRLC_FAC_LAM_MV_MMV_LDC_DIAG	Correlation constant for the calculation of the moving mean value of lambda controller output, used by limited dynamics for cat efficiency diagnosis **(e.g. 0.08)**

Calibration data for controller limits:

C_FAC_LAM_OUT_MIN	Bottom limitation of the lambda controller output **(e.g. -25.0 %)**
C_FAC_LAM_OUT_MAX	Upper limitation of the lambda controller output **(e.g. +25.0 %)**
C_FAC_LAM_OUT_MIN_CP	Bottom limitation of the lambda controller output during canister purge ramp open phase **(e.g. -35.0 %)**
C_FAC_LAM_OUT_MAX_CP	Upper limitation of the lambda controller output during canister purge ramp open phase **(e.g. +35.0 %)**
C_FAC_LAM_P_MIN_LAM	Bottom limitation of lambda controller P share **(e.g. -25 %)**
C_FAC_LAM_P_MAX_LAM	Upper limitation of lambda controller P share **(e.g. +25 %)**
C_FAC_LAM_P_MIN_LAM_CP	Bottom limitation of lambda controller P share during active canister purge **(e.g. -35 %)**
C_FAC_LAM_P_MAX_LAM_CP	Upper limitation of lambda controller P share during active canister purge **(e.g. +35 %)**
C_FAC_LAM_I_I2_SUM_MIN_LAM	Bottom limitation of lambda controller I share + I^2 share **(e.g. -25 %)**
C_FAC_LAM_I_I2_SUM_MAX_LAM	Upper limitation of lambda controller I share + I^2 share **(e.g. +25 %)**
C_FAC_LAM_I_I2_SUM_MIN_LAM_CP	Bottom limitation of lambda controller I share + I^2 share during active canister purge **(e.g. -35 %)**
C_FAC_LAM_I_I2_SUM_MAX_LAM_CP	Upper limitation of lambda controller I share + I^2 share during active canister purge **(e.g. +35 %)**
C_FAC_LAM_D_MIN_LAM	Bottom limitation of the lambda controller D share **(e.g. -10 %)**
C_FAC_LAM_D_MAX_LAM	Upper limitation of the lambda controller D share **(e.g. +10 %)**
IP_FAC_LAM_MIN_NOT_STAT_CDN	Bottom limit of lambda controller output under non stationary operating conditions **(e.g. see table below)**
IP_FAC_LAM_MAX_NOT_STAT_CDN	Upper limit of lambda controller output under non stationary operating conditions **(e.g. see table below)**
C_FAC_LAM_DELTA_LSCL_OFF	Output signal delta to ramp the output signal to zero in case of deactivated lambda controller **(e.g. 0.999 %)**
LC_LAM_I2_ACT	Calibration flag to switch between PII^2D and PID lambda controller **(e.g. 1 for PII^2D)**

46.23.3 Calibration

Define and verify

Lambda adaptation thresholds (see 30701F)

C_MFF_MIN_ADD_RNG_LAM_AD
C_MFF_MAX_ADD_RNG_LAM_AD
C_FAC_MIN_L_RNG_LAM_AD
C_FAC_MAX_L_RNG_LAM_AD

⇩

Define and verify

Lambda controller thresholds (see 30701E)

C_FAC_LAM_OUT_MAX
C_FAC_LAM_OUT_MAX

⇩

Define and verify

Lambda adaptation thresholds; to be checked whether the FAC_H range and therefore these thresholds are used in the project (see 30701F)

C_FAC_MIN_H_RNG_LAM_AD
C_FAC_MAX_H_RNG_LAM_AD

If FAC_H adaptation range is not used C_T_SUM_MIN_WIN_FSD_H_RNG must be set to 0.

⇩

Verify

Time control between CP and Lamdba Adaptation (see 30903P)

⇩

Apply

Upper and lower limit of lambda controller ouput to request forced lambda adaptation

IP_FAC_LAM_OUT_MIN/MAX_FSD =
approx. 70…80% of lambda controller limitation

⇩

Apply

Counter threshold and increment / decrement for forced activation of lambda adaptation

C_CTR_MAX_LAM_LIM_LAM_AD_REQ
C_CTR_INC_LAM_LIM_LAM_AD_REQ
C_CTR_DEC_LAM_LIM_LAM_AD_REQ

⇩

Apply

Timer threshold to reset forced activation of lambda adaptation

C_T_LAM_AD_ACT_MIN_FSD

⇩

_AMP_MIN_FSD
_MAF_MIN_FSD
_N_MIN_FSD
_TAM_MIN_FSD
_TCO_MIN_FSD
_TIA_MIN_FSD

_TOIL_MIN_DEC_FSD_STOP_OIL
_CTR_MAX_FSD_STOP_OIL
)_CTR_INC_FSD_STOP_OIL
)_DLY_DEC_FSD_STOP_OIL

as soon as the general activation conditions are fulfilled and
ed. That means the function monitors the lambda controller
the lambda adaptation is activated. As soon as the lambda
after an applicable time) the request for lambda adaptation will
[i] = 1). Figure 1 shows the monitoring area of fuel system
area of lambda adaptation is subset of lambda controller

30B075:

C_N_MIN_FSD	Engine speed threshold for fuel system diagnosis (**e.g. 608rpm**)
C_MAF_MIN_FSD	Mass air flow threshold for fuel system diagnosis (**e.g. 71mg/stk**)
C_TCO_MIN_FSD	Minimum threshold of TCO for fuel system diagnosis (**e.g. 65°C**)
C_AMP_MIN_FSD	Minimum ambient pressure threshold for fuel system diagnosis (**e.g. 699.99hPa**)
C_TIA_MIN_FSD	Minimum intake air temperature threshold for fuel system diagnosis (**e.g. -10.5 °C**)
C_TAM_MIN_FSD	Minimum ambient temperature threshold for fuel system diagnosis (**e.g. -10.50°C**)
C_CTR_MAX_FSD_STOP_OIL	Maximum value for the debounce counter CTR_STOP_FSD for oil dilution detection in fuel system diagnosis (**e.g. 30**)
C_TOIL_MIN_DEC_FSD_STOP_OIL	Minimum oil temperature threshold to activate timer to debounce oil dilution detection in fuel system diagnosis (**e.g. 0°C**).
ID_CTR_INC_FSD_STOP_OIL	Increasing value for the debounce counter CTR_STOP_FSD for oil dilution detection in fuel system diagnosis (**e.g. see Table 1**)
ID_DLY_DEC_FSD_STOP_OIL	Time delay for decreasing the debounce counter CTR_STOP_FSD for oil dilution detection in fuel system diagnosis (**e.g. see Table 1**)

30B006:

C_CTR_MAX_LAM_LIM_LAM_AD_REQ	Counter threshold for forced activation of lambda adaptation (**e.g. 150**)
C_CTR_INC_LAM_LIM_LAM_AD_REQ	Counter decrement for activation of forced lambda adaptation (**e.g. 1**)

C_CTR_DEC_LAM_LIM_LAM_AD_REQ	Counter increment for activation of forced lambda adaptation (**e.g. 1**)
C_T_LAM_AD_ACT_MIN_FSD	Minimum time during which forced Lambda adaptation shall be active. This value depends on the adaptation rate. (**e.g. 30s**)
IP_FAC_LAM_OUT_MIN_FSD	The lower limit of lambda controller output to request forced lambda adaptation (**e.g. 70…80% of lambda controller minimum limitation; see 30701E; e.g. see Table 2)**
IP_FAC_LAM_OUT_MAX_FSD	The upper limit of lambda controller output to request forced lambda adaptation (**e.g. 70…80% of lambda controller maximum limitation; see 30701E; e.g. see Table 2)**
C_T_SUM_MIN_THD_FSD	Fuel system diagnosis timer threshold for lambda adaptation monitoring - minimum limit (**e.g. 35s**)
C_T_SUM_MAX_THD_FSD	Fuel system diagnosis timer threshold for lambda adaptation monitoring - maximum limit (**e.g. 35s**).
C_T_SUM_MIN_THD_FSD_LAM_LIM	Fuel system diagnosis timer threshold for lambda controller monitoring - minimum limit (**e.g. 60 s**)
C_T_SUM_MAX_THD_FSD_LAM_LIM	Fuel system diagnosis timer threshold for lambda controller monitoring - maximum limit (**e.g. 60 s**)
C_T_SUM_RST_FSD	Fuel system diagnosis reset threshold (**e.g. 120 s**)
C_CRLC_T_SUM_WIN_FSD_RST	Minimal fraction of counter threshold that must be spent in ADD as well as L_RNG for error healing (**e.g. 0.2**)

46.24.1 Outputs for BMW functions which are defined as LACO exported data

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the outputs are different from the specified values due to the input data attributes.

Application conditions (for BMW variables):

Initialisation at reset or at exit power latch phase: 0

Recurrence :	10ms:	B_zwgemad_1, B_zwgemad_2
	20ms:	F_lakor[NC_CBK_EX_NR]
	100ms:	F_lrad_in1/2, St_lam_ad_1/2, B_lrad_akt1/2, B_lrad_deak1/2

Activation: every engine state, except power latch phase

Decativation: at power latch phase

Values at deactivation: 0

Formula section:

Remark: all formulas except the two 1st are valid in a **physical** meaning

```
B_zwgemad_1 =LV_LAM_LIM_LAM_AD[1]
B_zwgemad_2 = LV_LAM_LIM_LAM_AD[2]
F_lrad_in1 = FAC_LAM_MV_MMV[1]
F_lrad_in2 = FAC_LAM_MV_MMV[2]
B_lrad_deak1 = LV_LAM_AD_DEAC_ERR[0]
B_lrad_deak2 = LV_LAM_AD_DEAC_ERR[1]

If STATE_LAM_AD[1] == "ADAPT_FAC_L"
or STATE_LAM_AD[1] == " ADAPT_ADD"
Then B_lrad_akt1 = 1
Else   B_lrad_akt1 = 0
Endif

```

46.24.2 Outputs of customer to SV functions

Input data:

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Remark: the really possible resolution and limits of the outputs are different from the specified values due to the input data attributes.

Application conditions:

Initialisation at reset:

FAC_LAM_CYL_SEL_LAM_AD_CUS[x], CTR_KM_LAM_ADJ_LAM_AD_CUS CTR_KM_DELTA_LAM_ADJ_LAM_AD_CUS and CTR_LAM_ADJ_LAM_AD_CUS shall be initialised with their stored values in NVMY.

```
// The sum below shall be done for each exhaust gas bank over the cylinders belonging
//   to it.
FAC_LAM_ADJ_LAM_AD_CUS[i] =
  {ΣFAC_LAM_CYL_SEL_LAM_AD_CUS[x]} / (NC_CYL_NR / NC_CBK_EX_NR)
//
```

All others variables shall be initialised with 0.

Recurrence : 10 ms,

except the Long Term Adaptation which some parts shall have a 1s recurrence

Activation: at every engine state

Formula section:

Remark: all formulas are valid in a **physical** meaning

```
LV_INH_LSCL_CUS[1]   =    B_la_stopp1

Relative knock value					

Input data:

IGA_IGC_H_RNG[NC_CYL_NR]	IGA_KNK[NC_CYL_NR]	NL[NC_CYL_NR]	KNK_THD[NC_CYL_NR]
KNKS[NC_CYL_NR]	C_IGA_INI_H_RNG	C_KNK_THD_MAX	KNKS_REL_NL[NC_CYL_NR]
TI_1_HOM[NC_CYL_NR]	TI_2_HOM[NC_CYL_NR]	TI_1_S[NC_CYL_NR]	TI_2_S[NC_CYL_NR]

FUNCTION DESCRIPTION:

General information:

The purpose of introducing multiplexed segment-synchronous variables is to be able to “watch” several online-values (segment-synchronous) via only one variable during calibration. This way the number of used online-variables can be reduced during measurements while still having the possibility to measure the data of all cylinders.

Description:

E.g.: The variable IGA_0_5 shows the ignition angle of the currently firing cylinder as online-output-data by writing the different succeeding IGA-values (firing order) into the respective segments of the variable.

Application conditions:

Initialisation: IGA_IGC_0_5_H_RNG = C_IGA_INI _H_RNG

KNK_THD_0_5 = 5V at reset and engine running to engine stop
IGA_KNK_0_5 initialised as IGA_KNK_x
KNKS_0_5 initialised as KNKS_x
NL_0_5 = C_KNK_THD_MAX at reset or engine running to engine stop
TI_1/2_HOM/S_0_5 = 0 ms
KNKS_REL_NL_0_5 = initialised as KNKS_REL_NL_x

Recurrence: (update rate) every segment

Activation: every engine operating state

Deactivation: ------

Formula section:

IGA_IGC_0_5_H_RNG:	IGA_IGCH_RNG of cylinder x = value segment x
IGA_KNK_0_5:	IGA_KNK of cylinder x = value segment x
KNK_THD_0_5:	KNK_THD of cylinder x = value segment x
KNKS_0_5:	KNKS of cylinder x = value segment x
NL_0_5:	NL of cylinder x = segment x
TI_1_HOM_0_5:	calculated out of TI_1_HOM[NC_CLY_NR]
TI_2_HOM_0_5:	calculated out of TI_2_HOM[NC_CLY_NR]
TI_1_S_0_5:	calculated out of TI_1_S[NC_CLY_NR]
TI_2_S_0_5:	calculated out of TI_2_S[NC_CLY_NR]
KNKS_REL_NL_0_5:	KNKS_REL_NL x = segment x

Enable of the lambda adaptation via injection mode
ACTION_MFMA_SetEnableCondition(**IN** <PRM_FLAG_PAR_IN>)
Activates lambda adaption via tester

Description for Actions

ACTION_MFMA_GetEnableCondition(**OUT** <PRM_LV_LAM_AD_INJ_EXT_ENA>)					
Enable of the lambda adaptation via injection mode					
Parameter	**Type**	**Hex.Limits**	**Phys.Limits**	**Resol.**	**Unit**
PRM_LV_LAM_AD_INJ_EXT_ENA	OUT	0... 1H	0... 1	1	[-]
Set the external enable the lambda adaption via injection mode with a test device					

ACTION_MFMA_SetEnableCondition(**IN** <PRM_FLAG_PAR_IN>)					
Activates lambda adaption via tester					
Parameter	**Type**	**Hex.Limits**	**Phys.Limits**	**Resol.**	**Unit**
PRM_FLAG_PAR_IN	IN	0... 1H	0... 1	1	[-]
Set the flag FLAG_PAR_IN to 1 if a tester device activate thbe lambda adaptation via injection mode					

General Information

This module handles the activation for the upper and lower temperature range for the lambda adaptation via injection mode and the engine speed controller, the lambda controller and the misfire detection are monitored during the adaptation.

Application Conditions

Initialization: RST, IGKON, NVMINI, NVMRES, NVMSTO
Activation: 20MS: always
SEG: always
ES2ERU: always
Deactivation: never

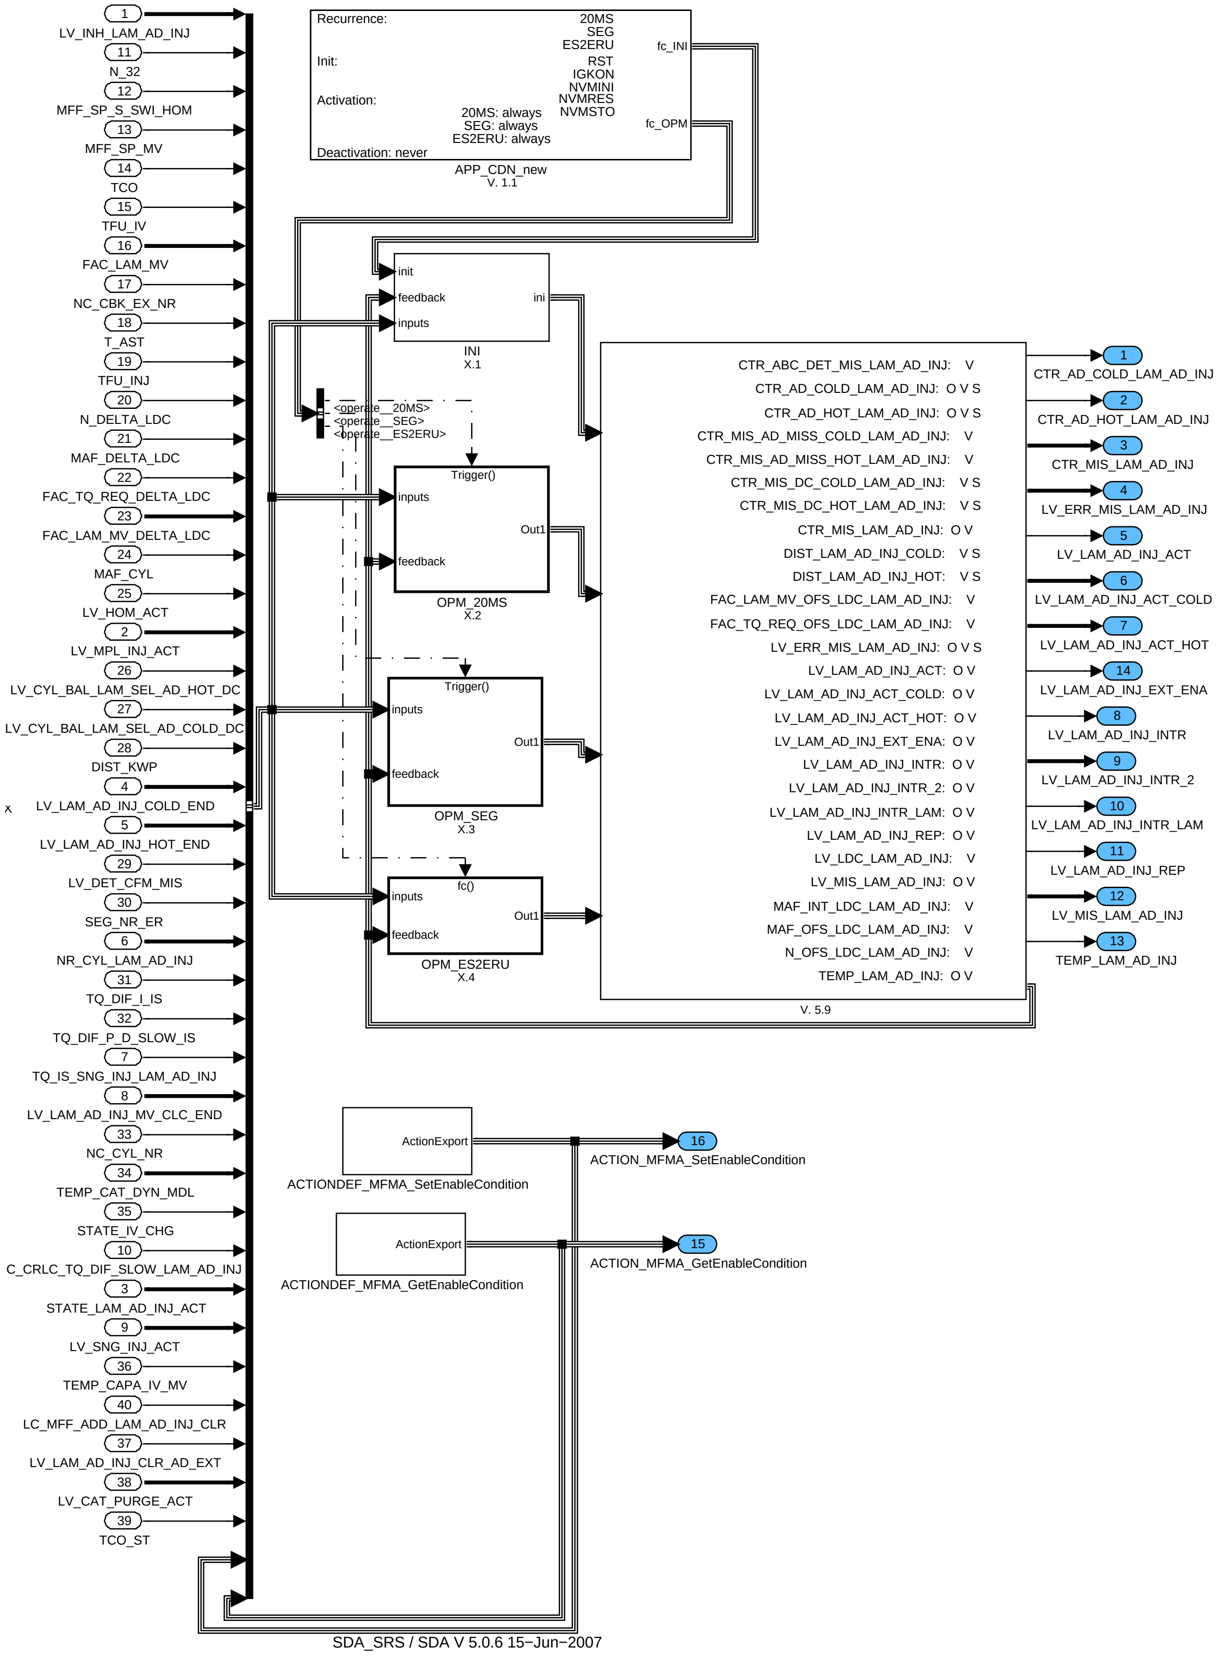

Figure 1:
Path: MFMA_ISPCLAIMA0

49.2.1 Initialization

Initialization of the variables at ignition on and reading and writing of the variables stored in the non volatile memory.

49.2.1.1 Initialization of the online variables at reset

All variables are initialized with 0 at reset.

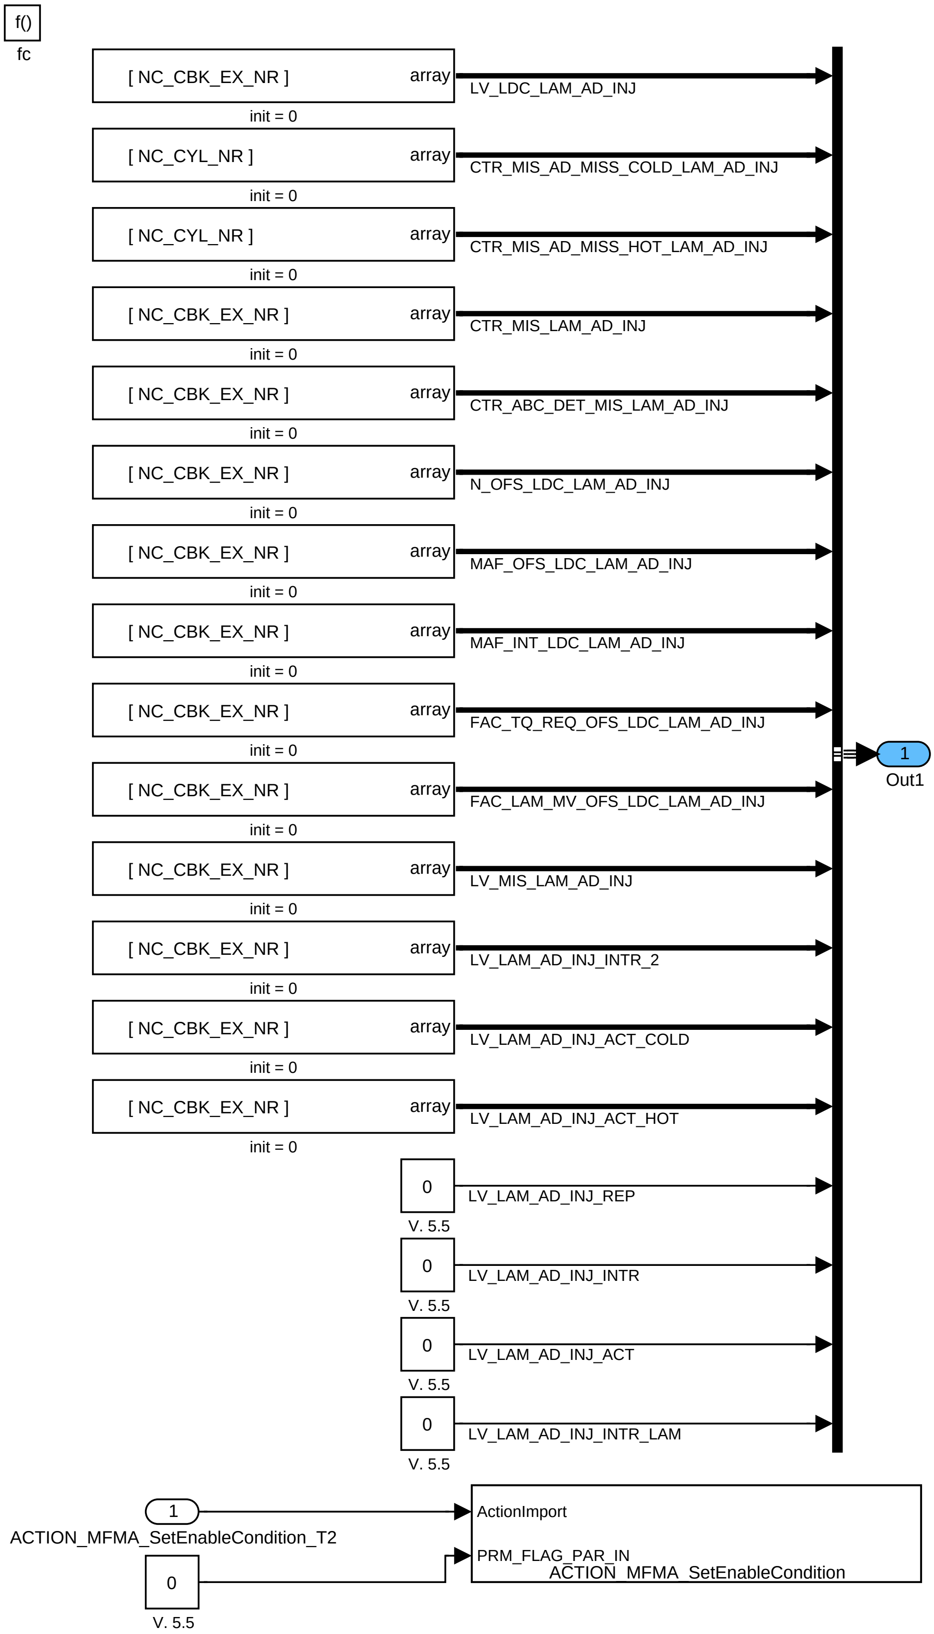

Figure 2:
Path: MFMA_ISPCLAIMA0/INI/RST

49.2.1.2 Initialization of the online variables at IGK on

All values, except CTR_MIS_AD_MISS_COLD/HOT_LAM_AD_INJ, are initialized with 0 at IGKON.

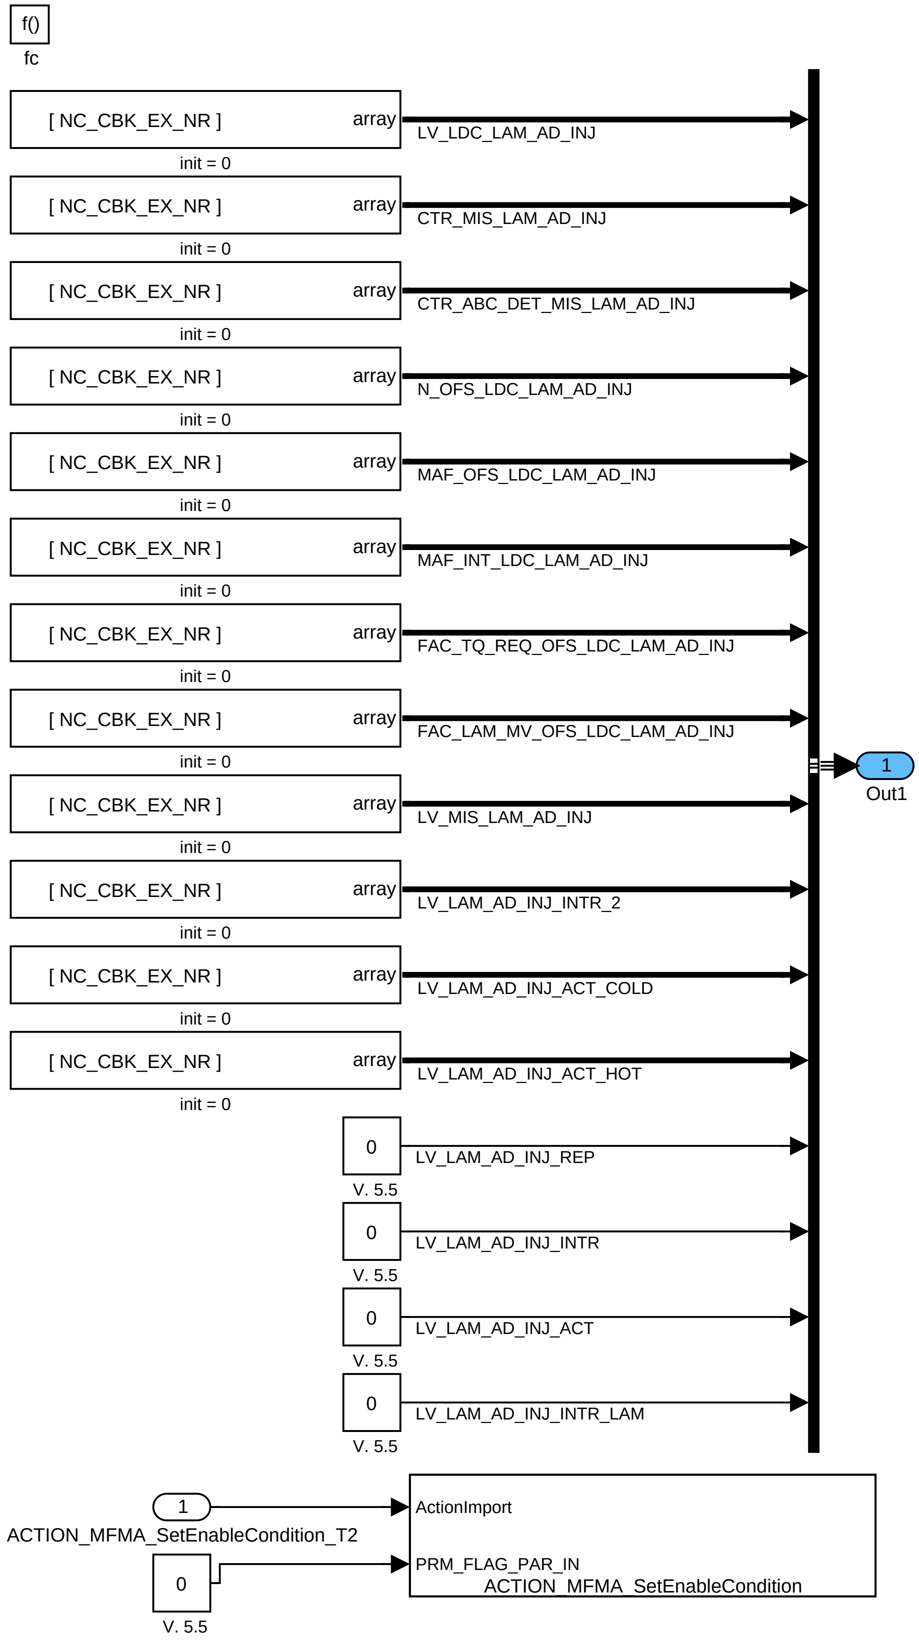

Figure 3:
Path: MFMA_ISPCLAIMA0/INI/IGKON

49.2.1.3 Initialization and reading of non volatile memory variables

The values are read from the NVMY memory. The first initialization of the values is done in an other subsystem, DIST_LAM_AD_INJ_COLD/HOT are not initialized with zero.

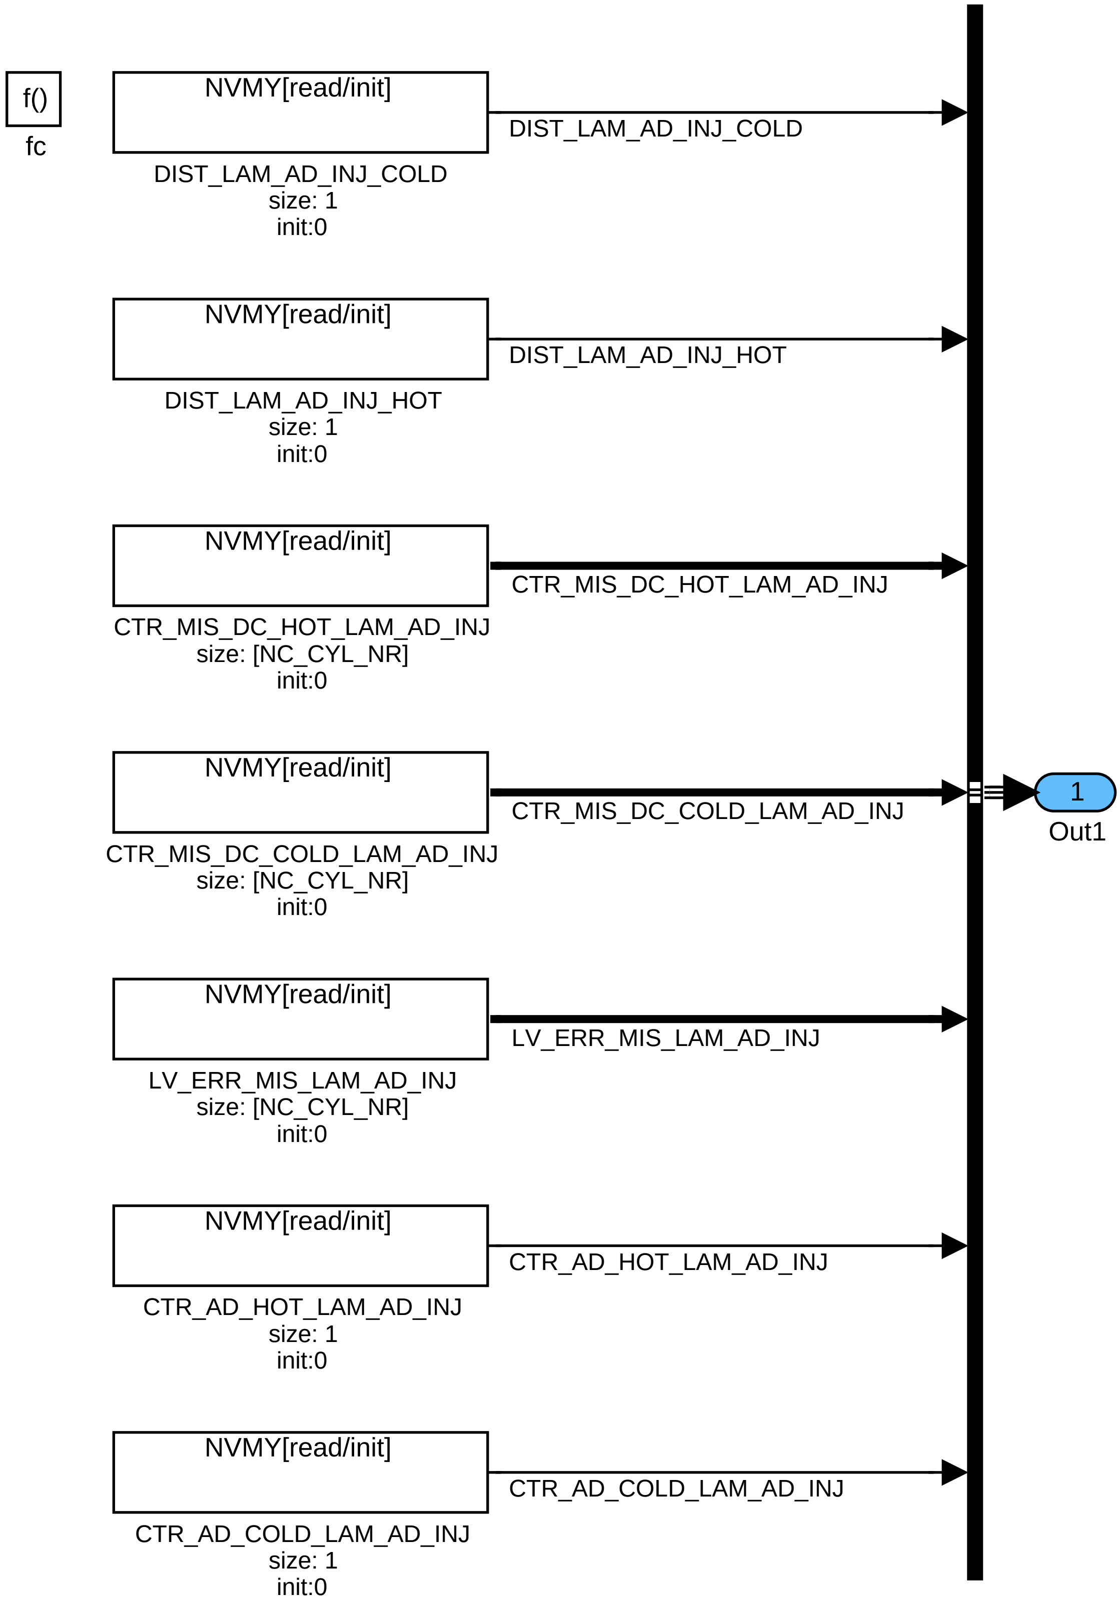

Figure 4:
Path: MFMA_ISPCLAIMA0/INI/NVMINI_NVMRES

49.2.1.4 Writing of non volatile memory variables

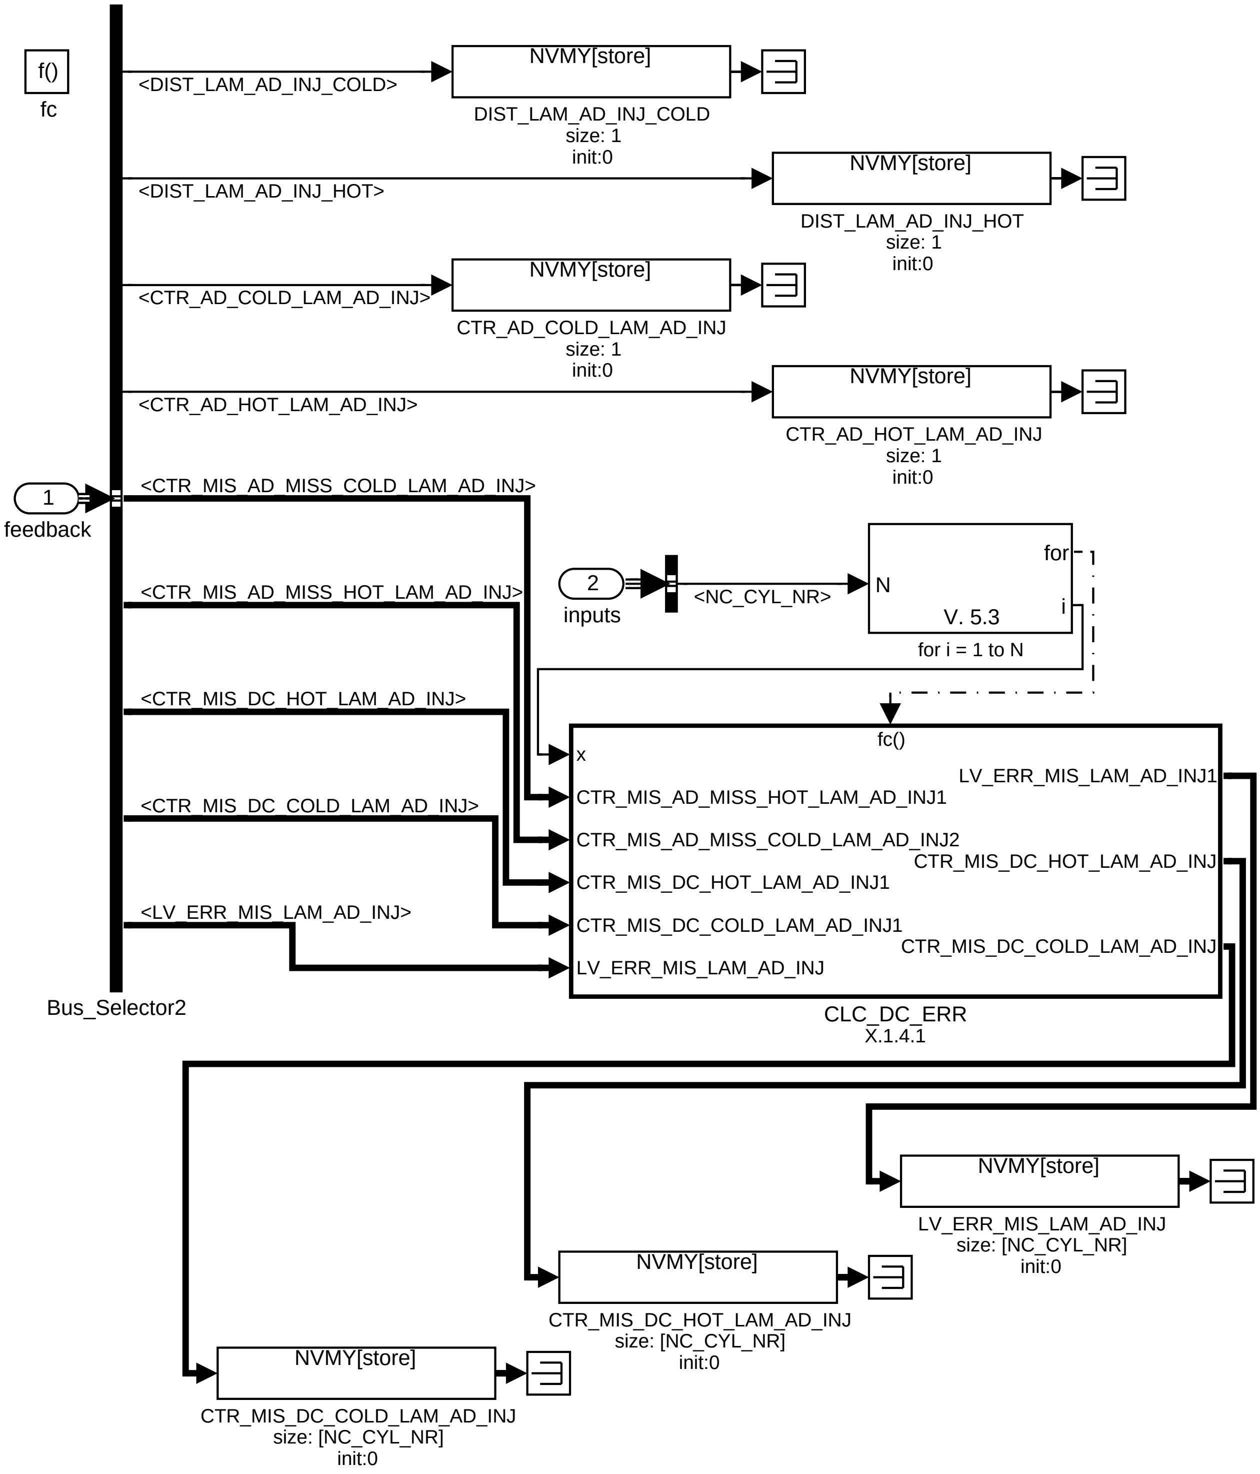

Figure 5:
Path: MFMA_ISPCLAIMA0/INI/NVMSTO

49.2.1.4.1 Calculation of driving cycle counter and creation of error flags

For each cylinder the number of driving cycles with missed adaptation due to misfire are counted. If the counter exceeds a threshold, the error flag will be set at the end of a driving cycle.

49.2.1.4.1.1 Calculation of driving cycle counter and error flags

If the number of missed adaptation cycles due to misfire in a driving cycle exceeds the threshold C_CTR_MIS_LAM_DC_MIN_LAM_AD_INJ, the counter for driving cycles with missed adaptation is increased. If the number of driving cycles with failed adaptations reaches the threshold C_CTR_MAX_DC_LAM_AD_INJ, the error flag for the depending cylinder is set.

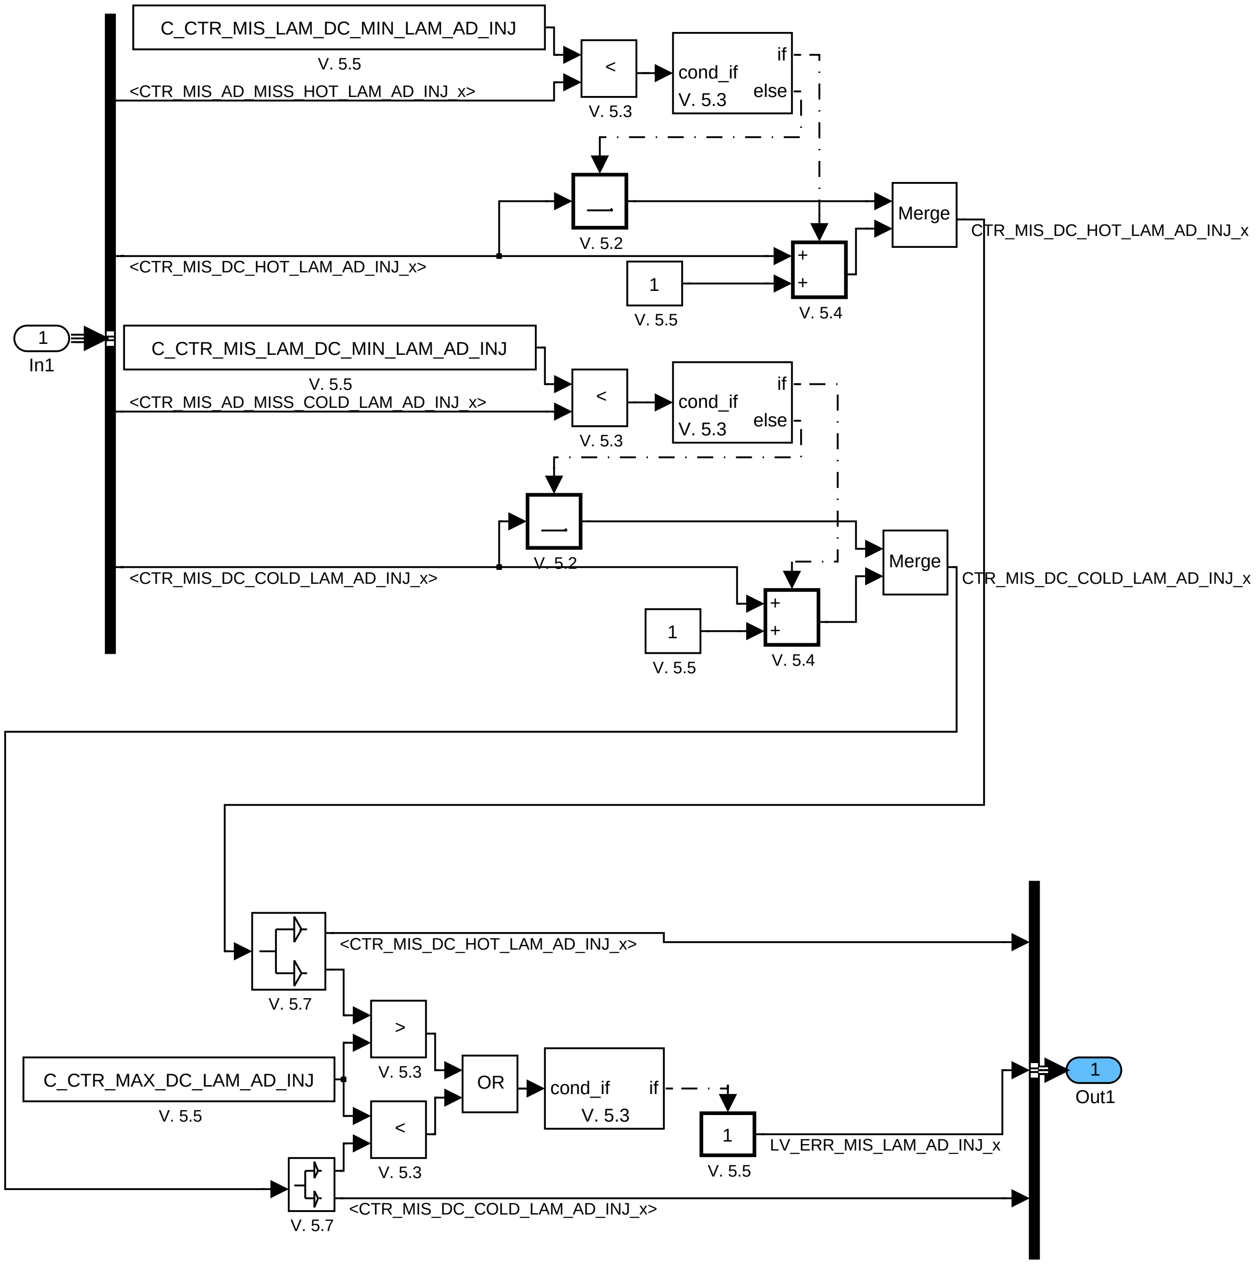

Figure 6:
Path: MFMA_ISPCLAIMA0/INI/NVMSTO/CLC_DC_ERR/CLC_CTR_MIS_DC

49.2.1.5 NVMY initialization

The distance counter is initialized at non volatile memory initialization with the sum of the mileage counter and the output of the map IP_DIST_LAM_AD_INJ_HOT/COLD. With this calculation the first adaptation after NVMY initialization will start after a mileage distance defined in the map. All other values are initialized with zero.

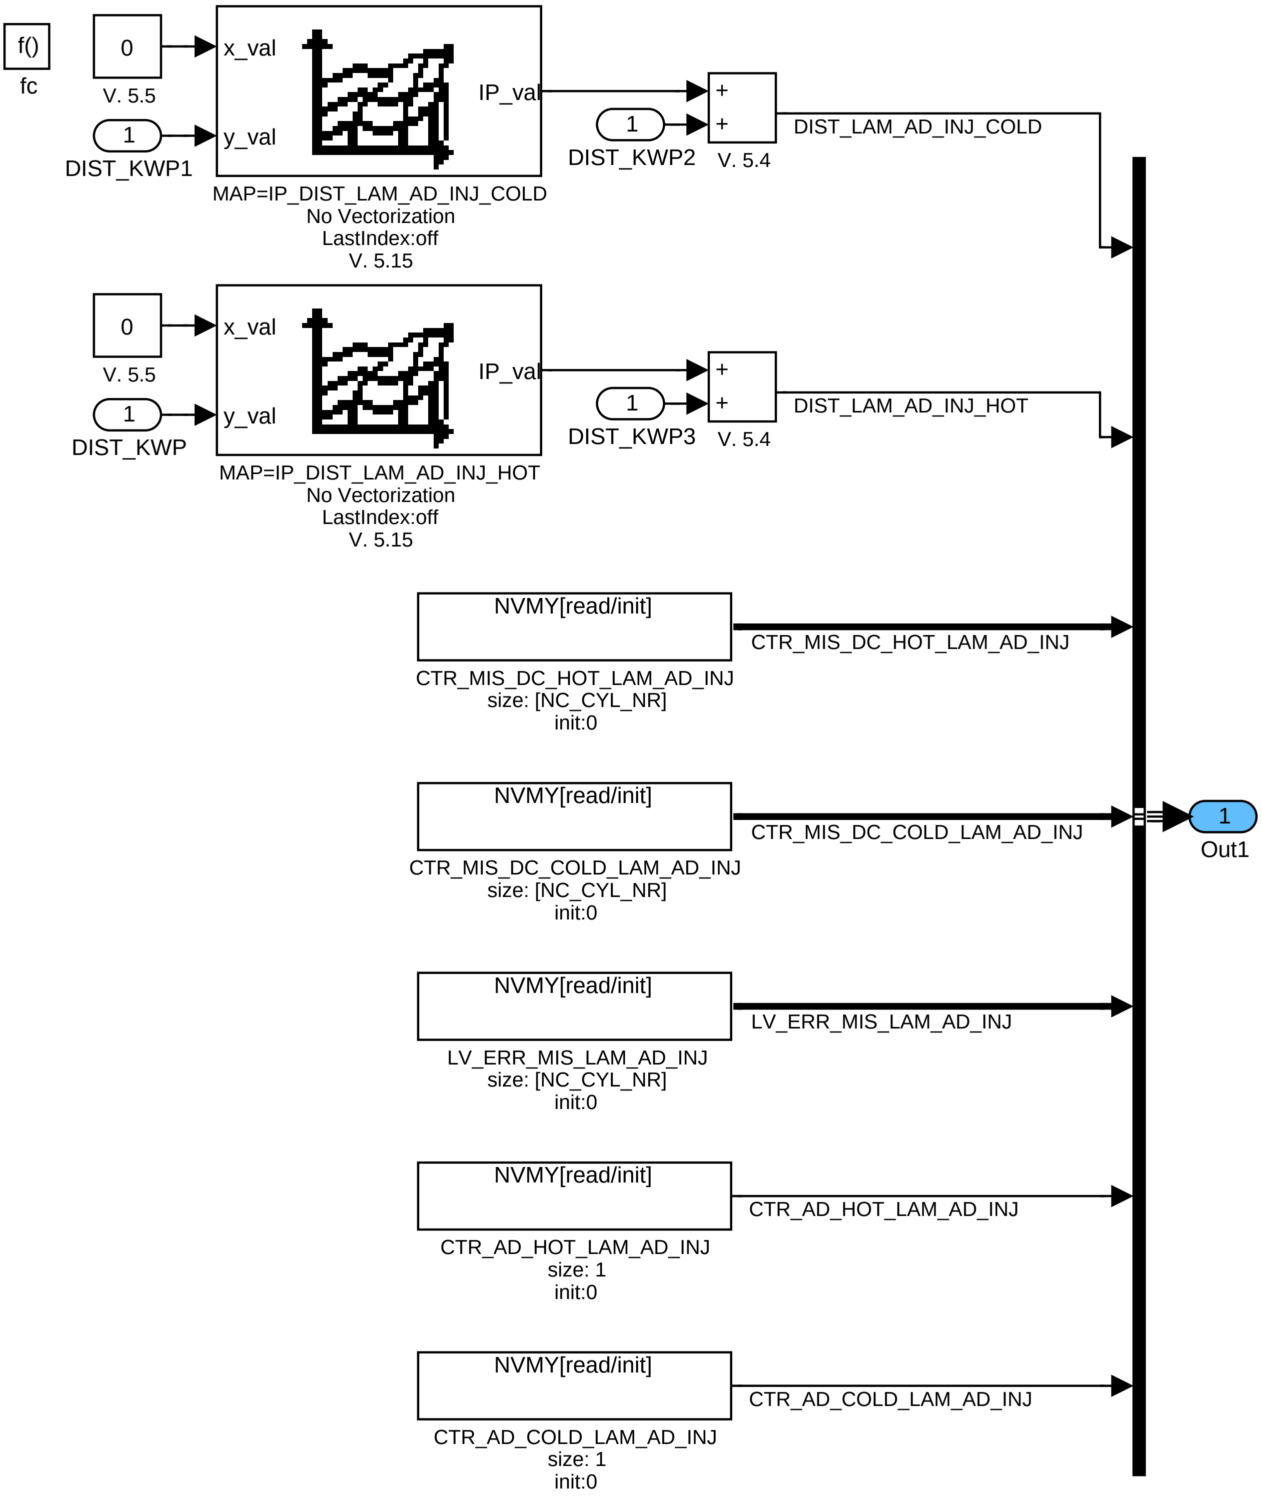

Figure 7:
Path: MFMA_ISPCLAIMA0/INI/NVMINI_NVMINI

49.2.2 Determination of the adaptation conditions

The determination of adaptation conditions is divided into bank specific and bank independent calculations.

49.2.2.1 Bank independent calculations

The bank independent calculations are divided in general calculations, temperature calculations and the clearance of interruption and repeat flags.

49.2.2.1.1 General activation conditions

For activation of the adaptation the fuel mass flow and the engine speed has to be inside limitations. Also a certain time after engine start has to be passed.

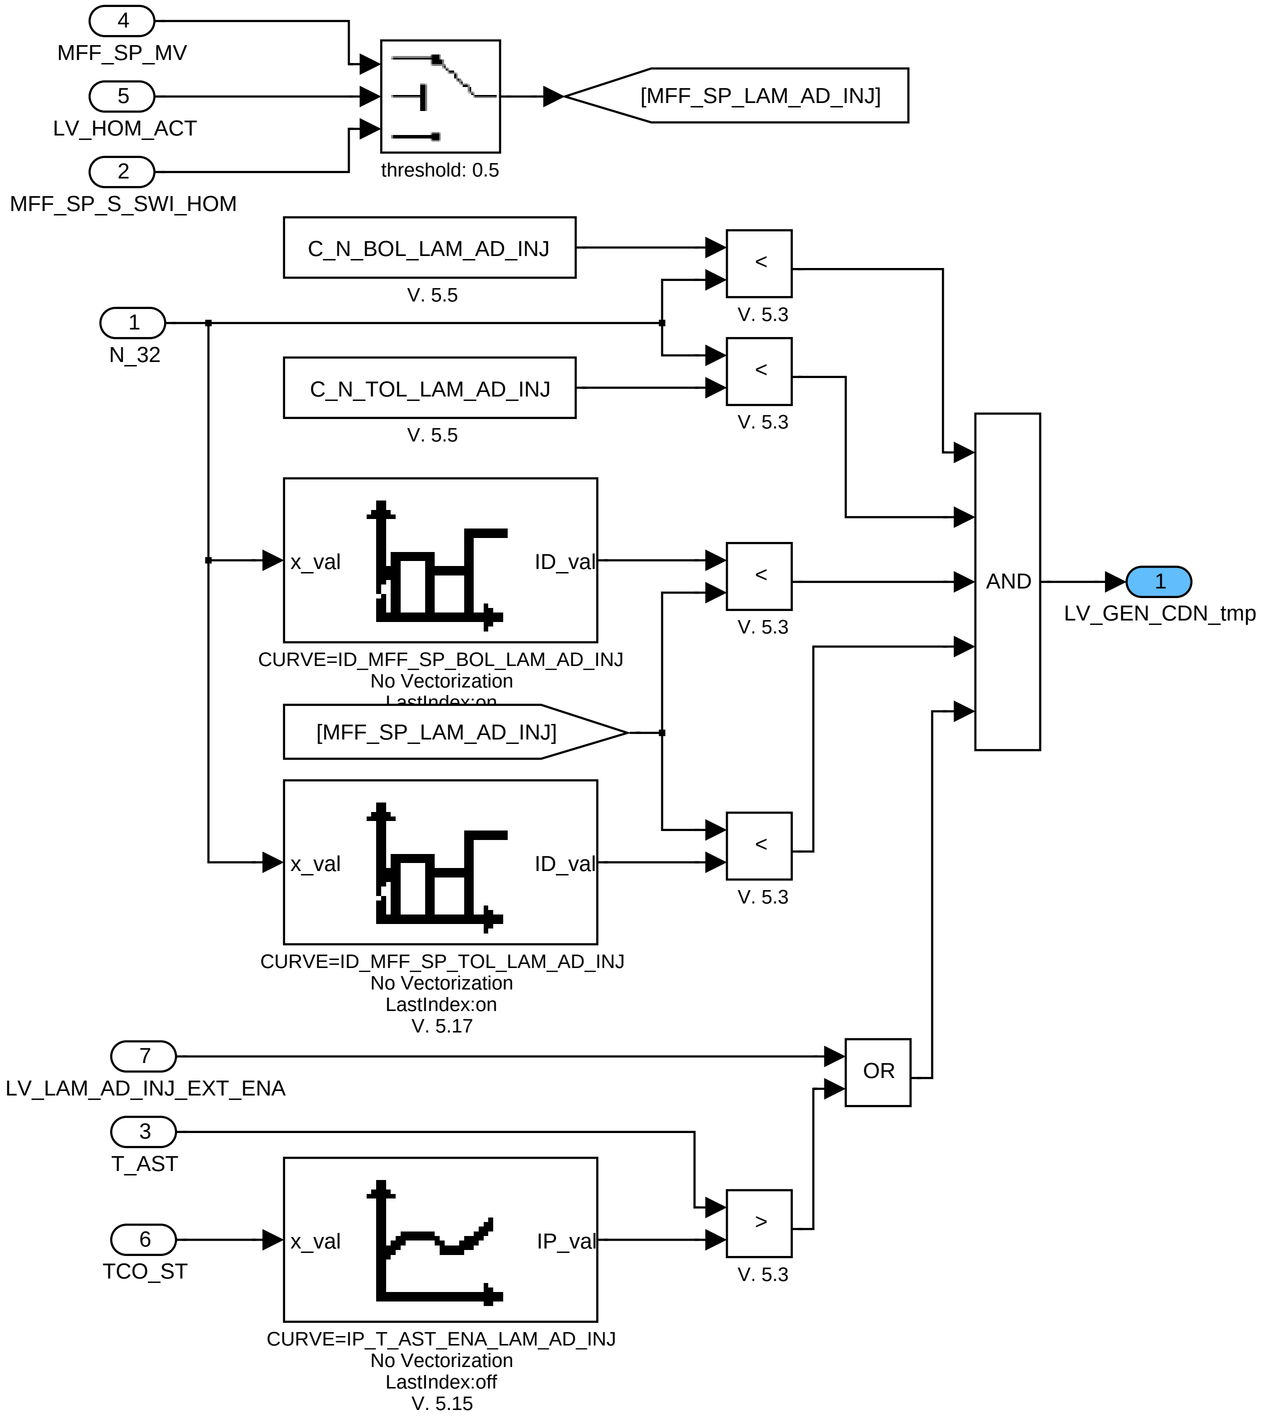

Figure 8:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/GEN_CDN

49.2.2.1.2 Temperature range activation conditions

To activate the adaptation for cold and hot adaptation range the depending temperature can bee chosen between coolant temperature and fuel temperature. For activation the temperature has to be inside limitations, the general conditions has to be fulfilled, the cylinder individual lambda controller has to be ready and the condition for the mileage counter has to be fulfilled. Also the maximum number of adaptation cycles in the driving cycle has not to be reached.

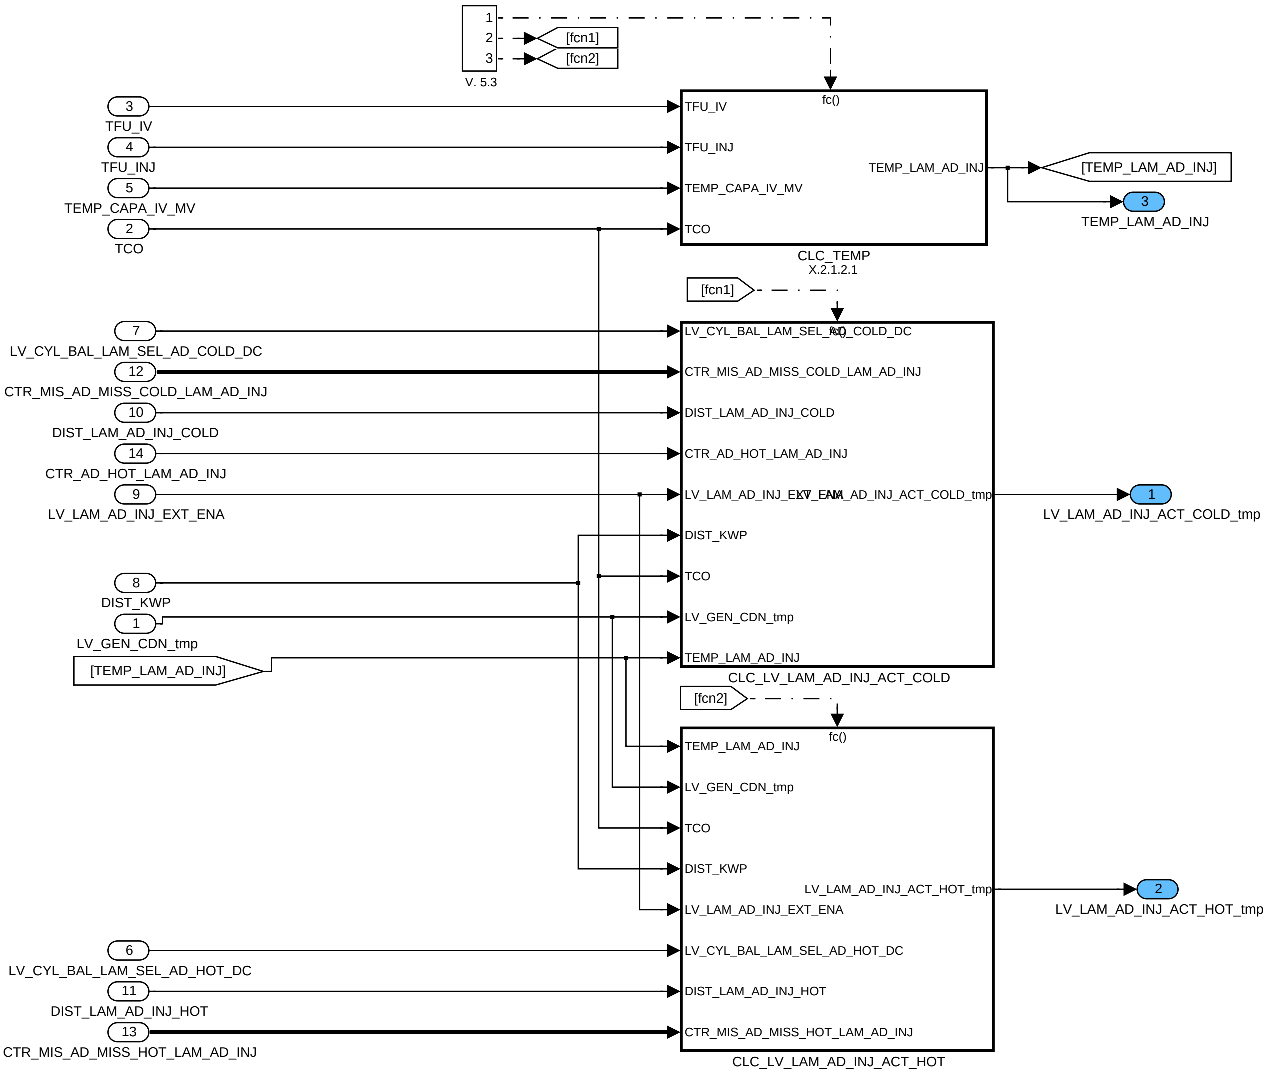

Figure 9:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/TEMP_CDN

49.2.2.1.2.1 Selection of temperature value

Using the calibration C_TEMP_LAM_AD_INJ_ENA the temperature for use within the lambda adaptation via injection mode can be chosen.

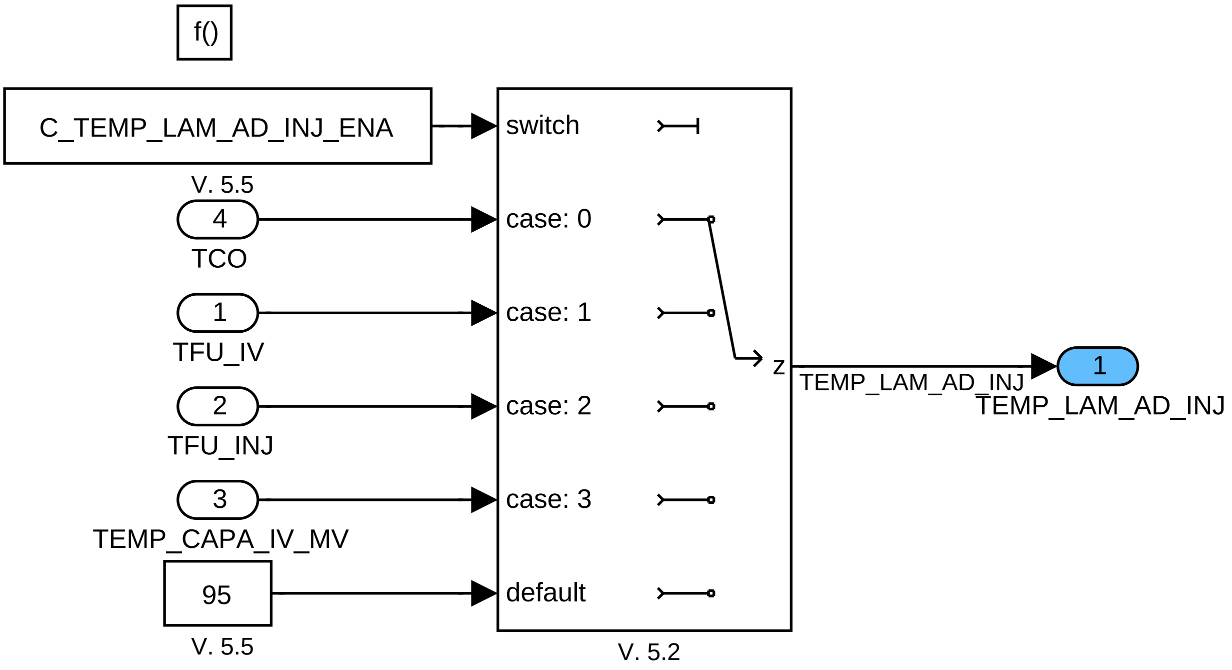

Figure 10:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/TEMP_CDN/CLC_TEMP

49.2.2.1.2.2 Condition for the lower adaptation range

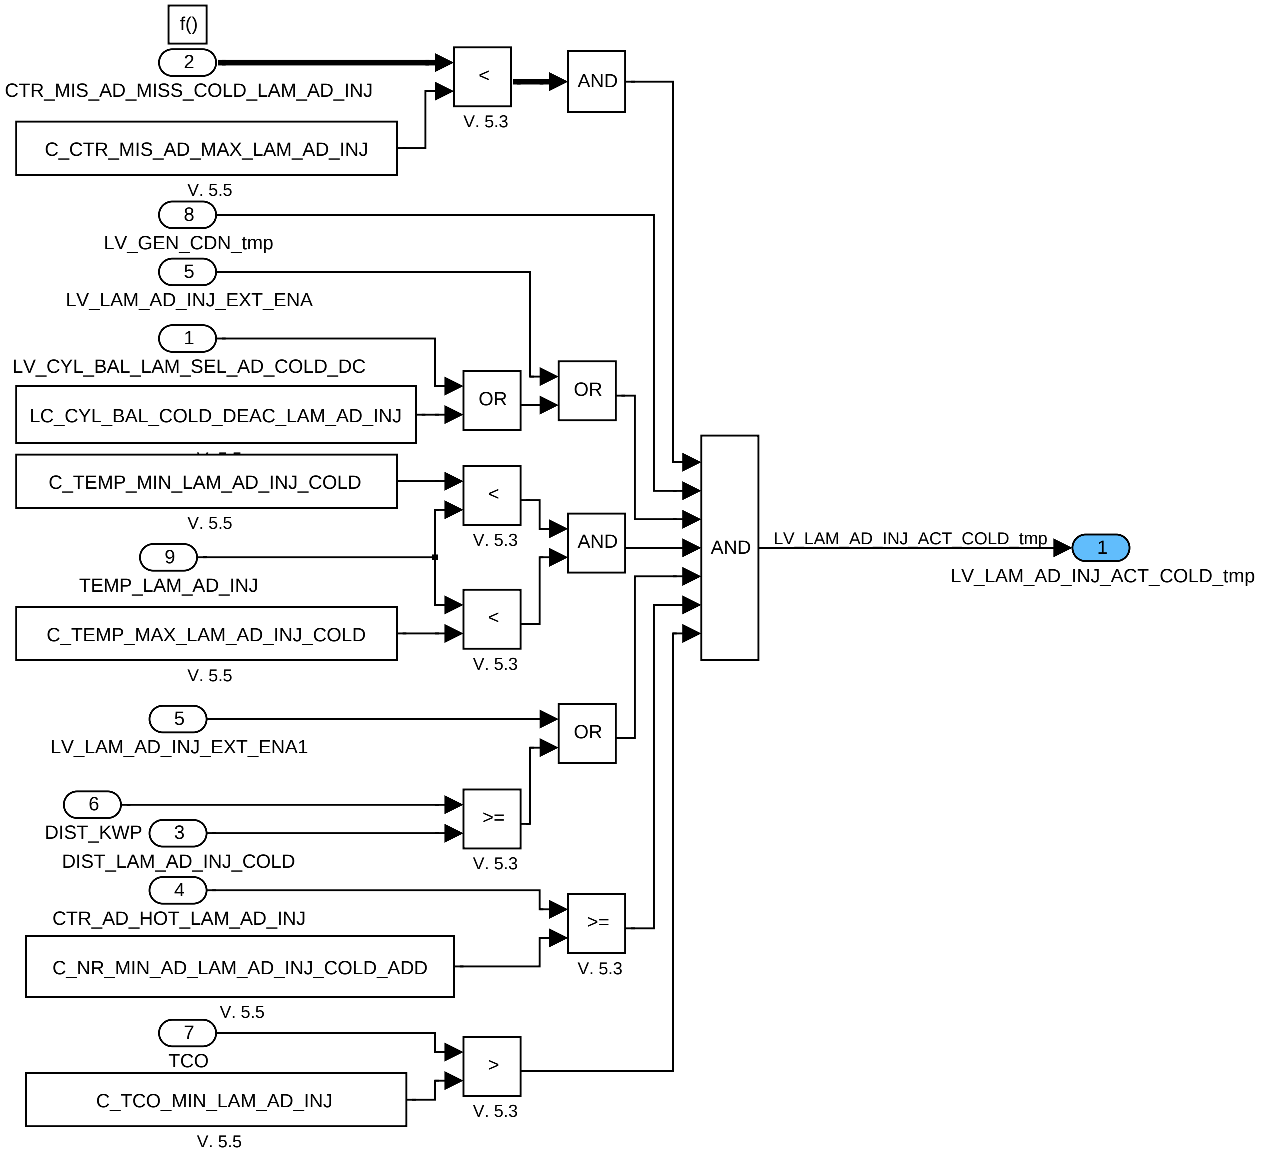

Figure 11:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/TEMP_CDN/CLC_LV_LAM_AD_INJ_ACT_COLD

49.2.2.1.2.3 Condition for the upper adaptation range

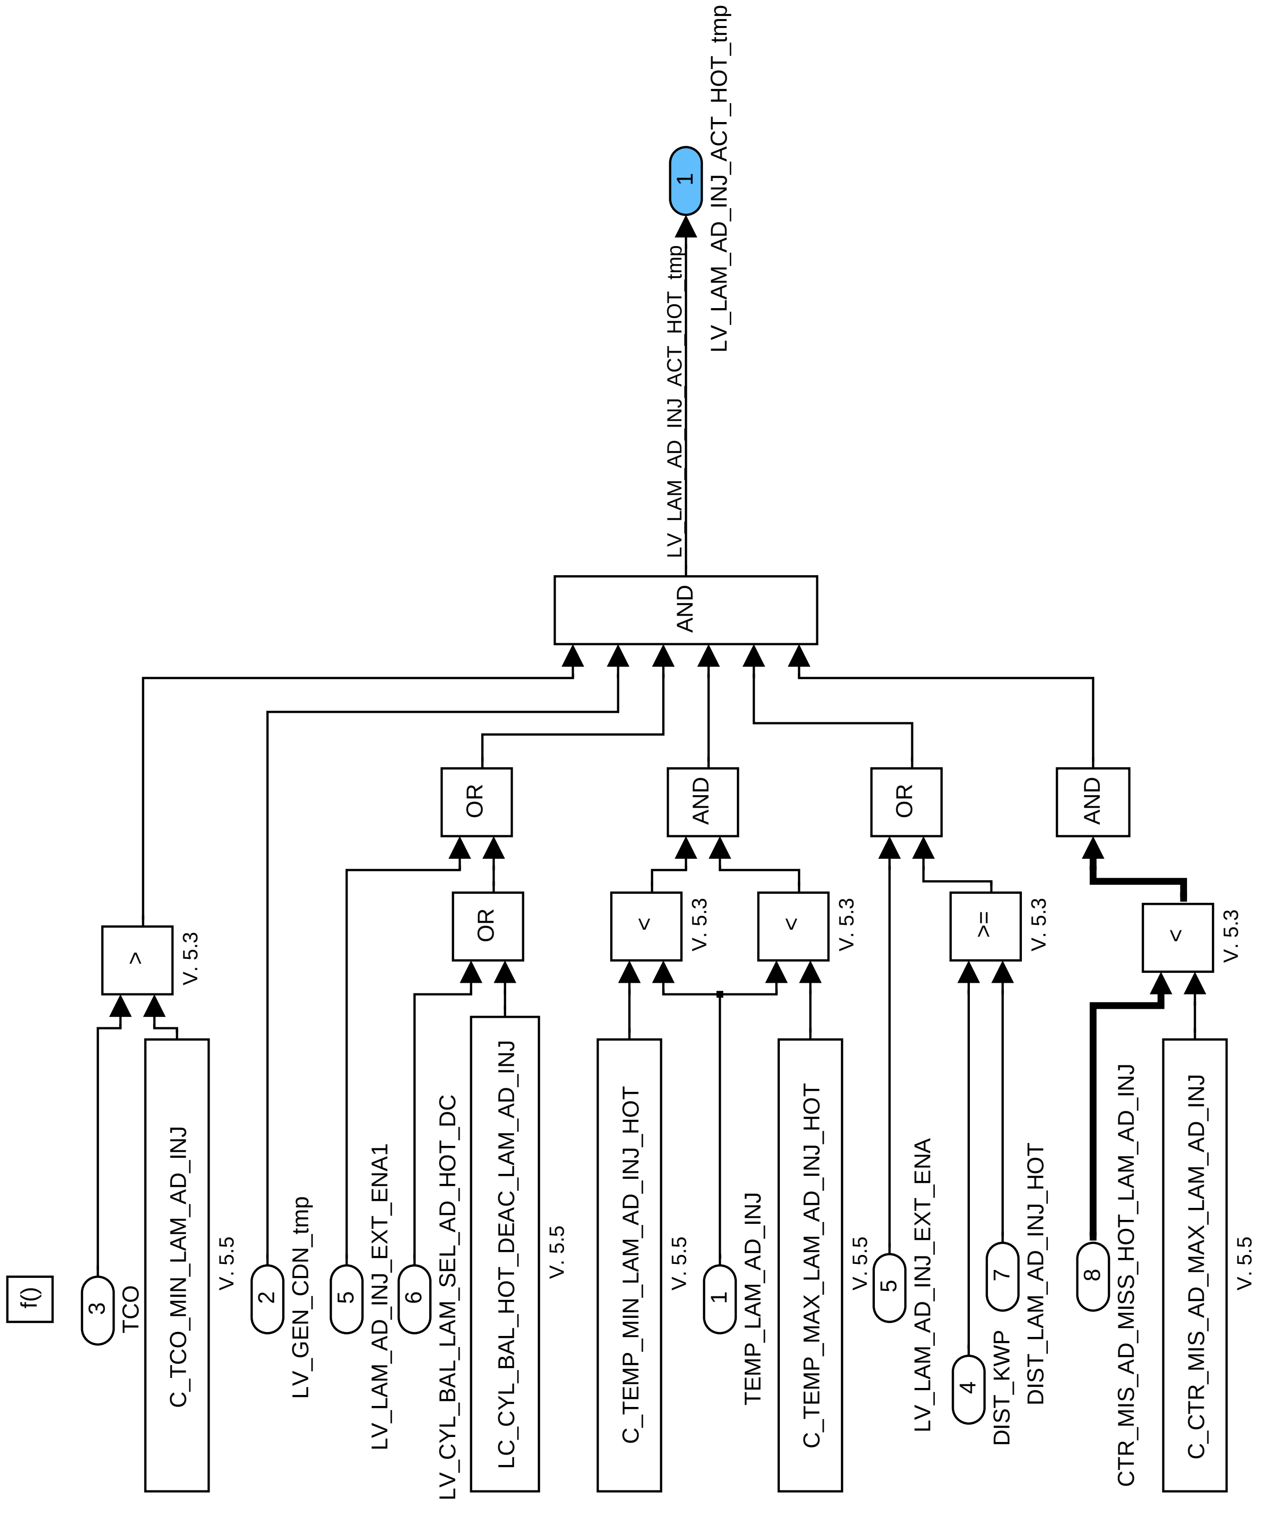

Figure 12:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/TEMP_CDN/CLC_LV_LAM_AD_INJ_ACT_HOT

49.2.2.1.3 Clear the values for interruption and repeat

If all banks are not in multiple and not in single injections, the flags to interrupt and repeat the adaptation are reset. In single injection for all banks the flags and counter for misfire are reset.

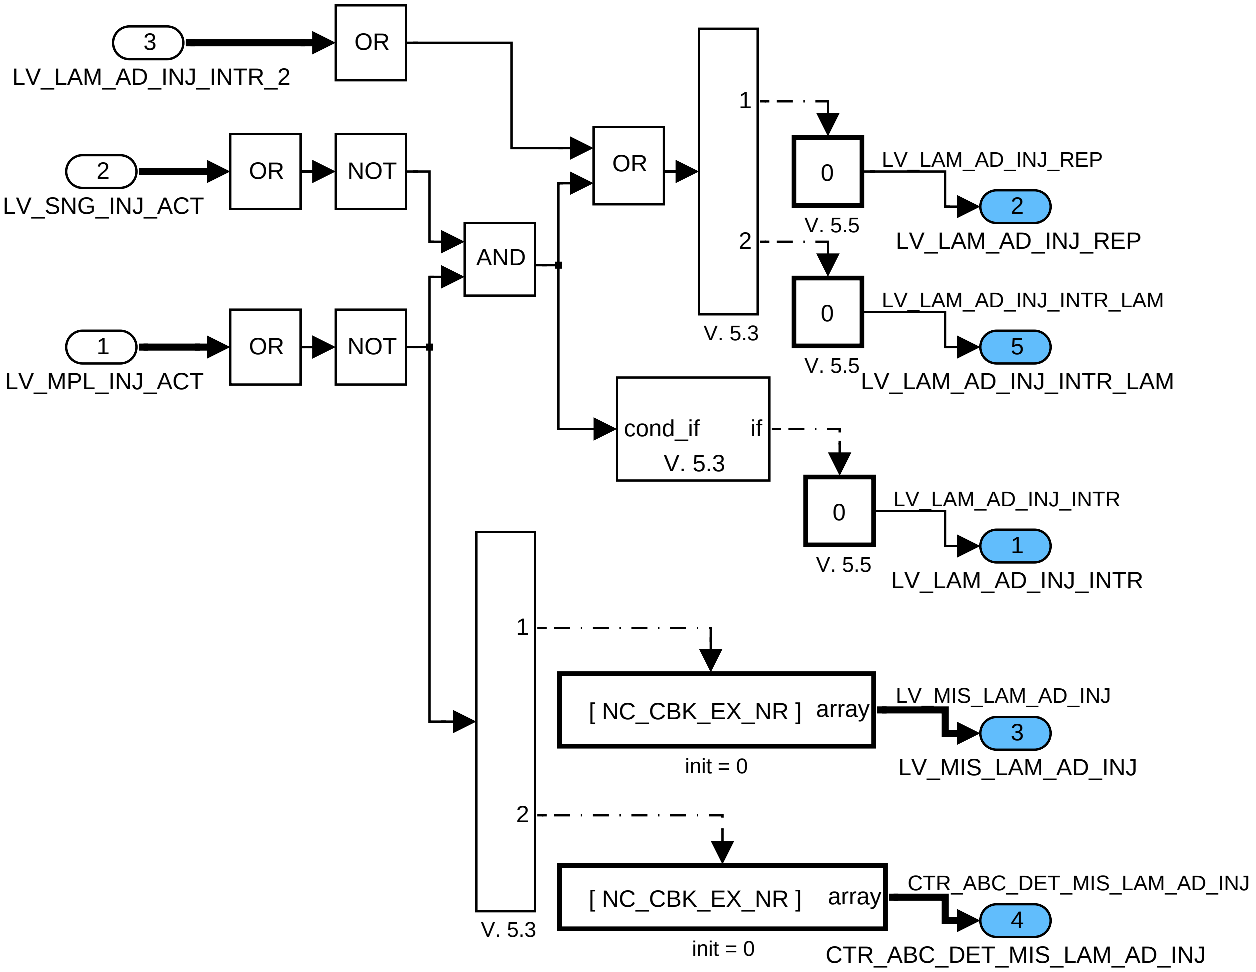

Figure 13:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/CLR_LV_INTR_REP

49.2.2.1.4 Reset of LV_LAM_AD_INJ_EXT_ENA

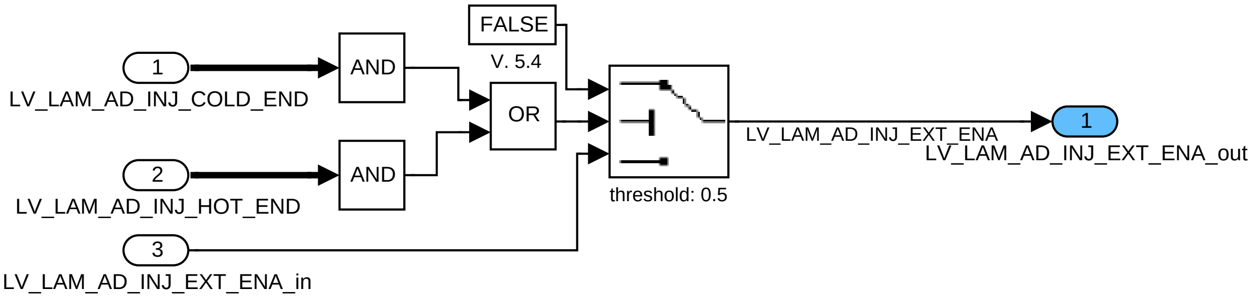

Figure 14:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_INDEP_CLC/CLR_LV_EXT_ENA

49.2.2.2 Bank specific calculations

The following calculations are done for all cylinder banks. Inside the model the bank specific values are denoted with the suffix _i whereas in the textual description they are referenced via [i].

49.2.2.2.1 Limited dynamics determination

The flag LV_LDC_LAM_AD_INJ[i] is calculated using N, MAF; FAQ_TQ_REQ and FAC_LAM_MV conditions. During multiple injections the monitoring of FAC_LAM_MV can be changed by using different thresholds.

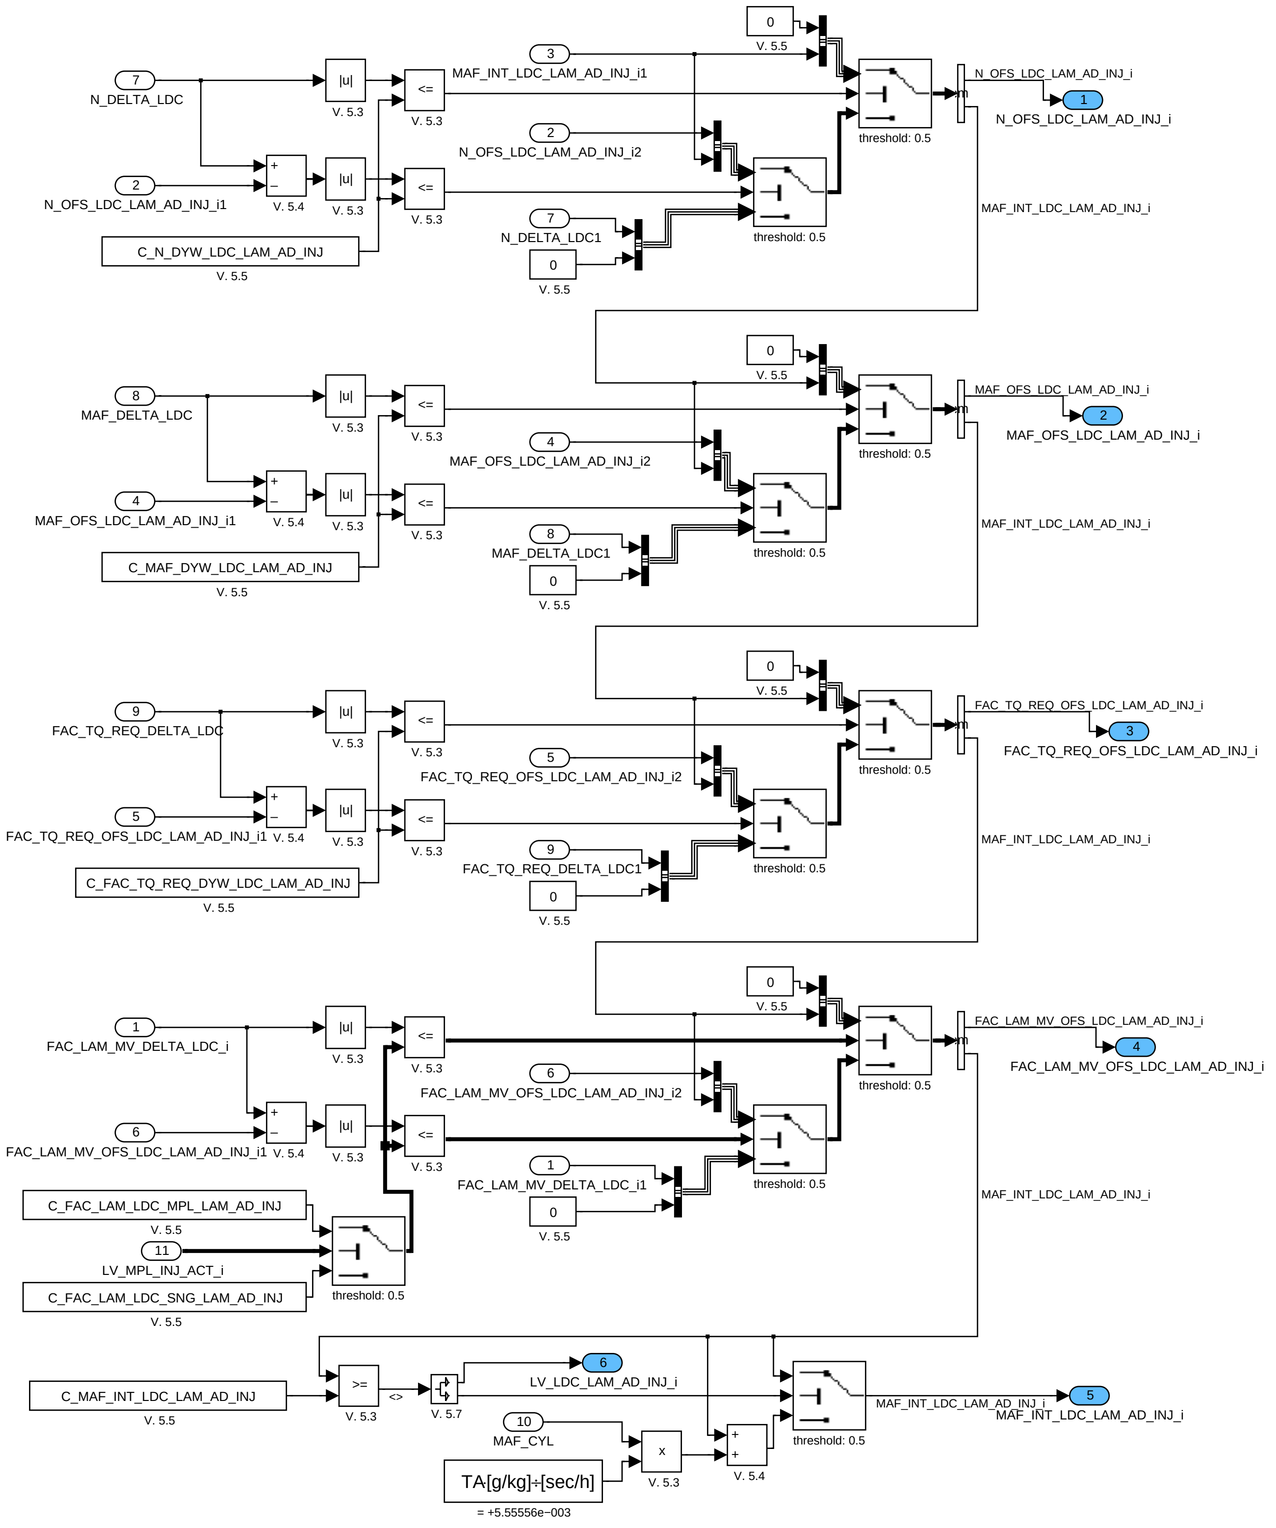

Figure 15:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/LDC_CLC

49.2.2.2.2 Determination of adaptation conditions for upper or lower temperature range

If the limited dynamics are given and the lambda controller operates within defined limits, depending on the temperature conditions the adaptation for the upper or lower temperature range is enabled, if all banks fulfil these conditions and the catalyst temperature has to be below a threshold. Or the adaptation can be activated manually via calibration value.

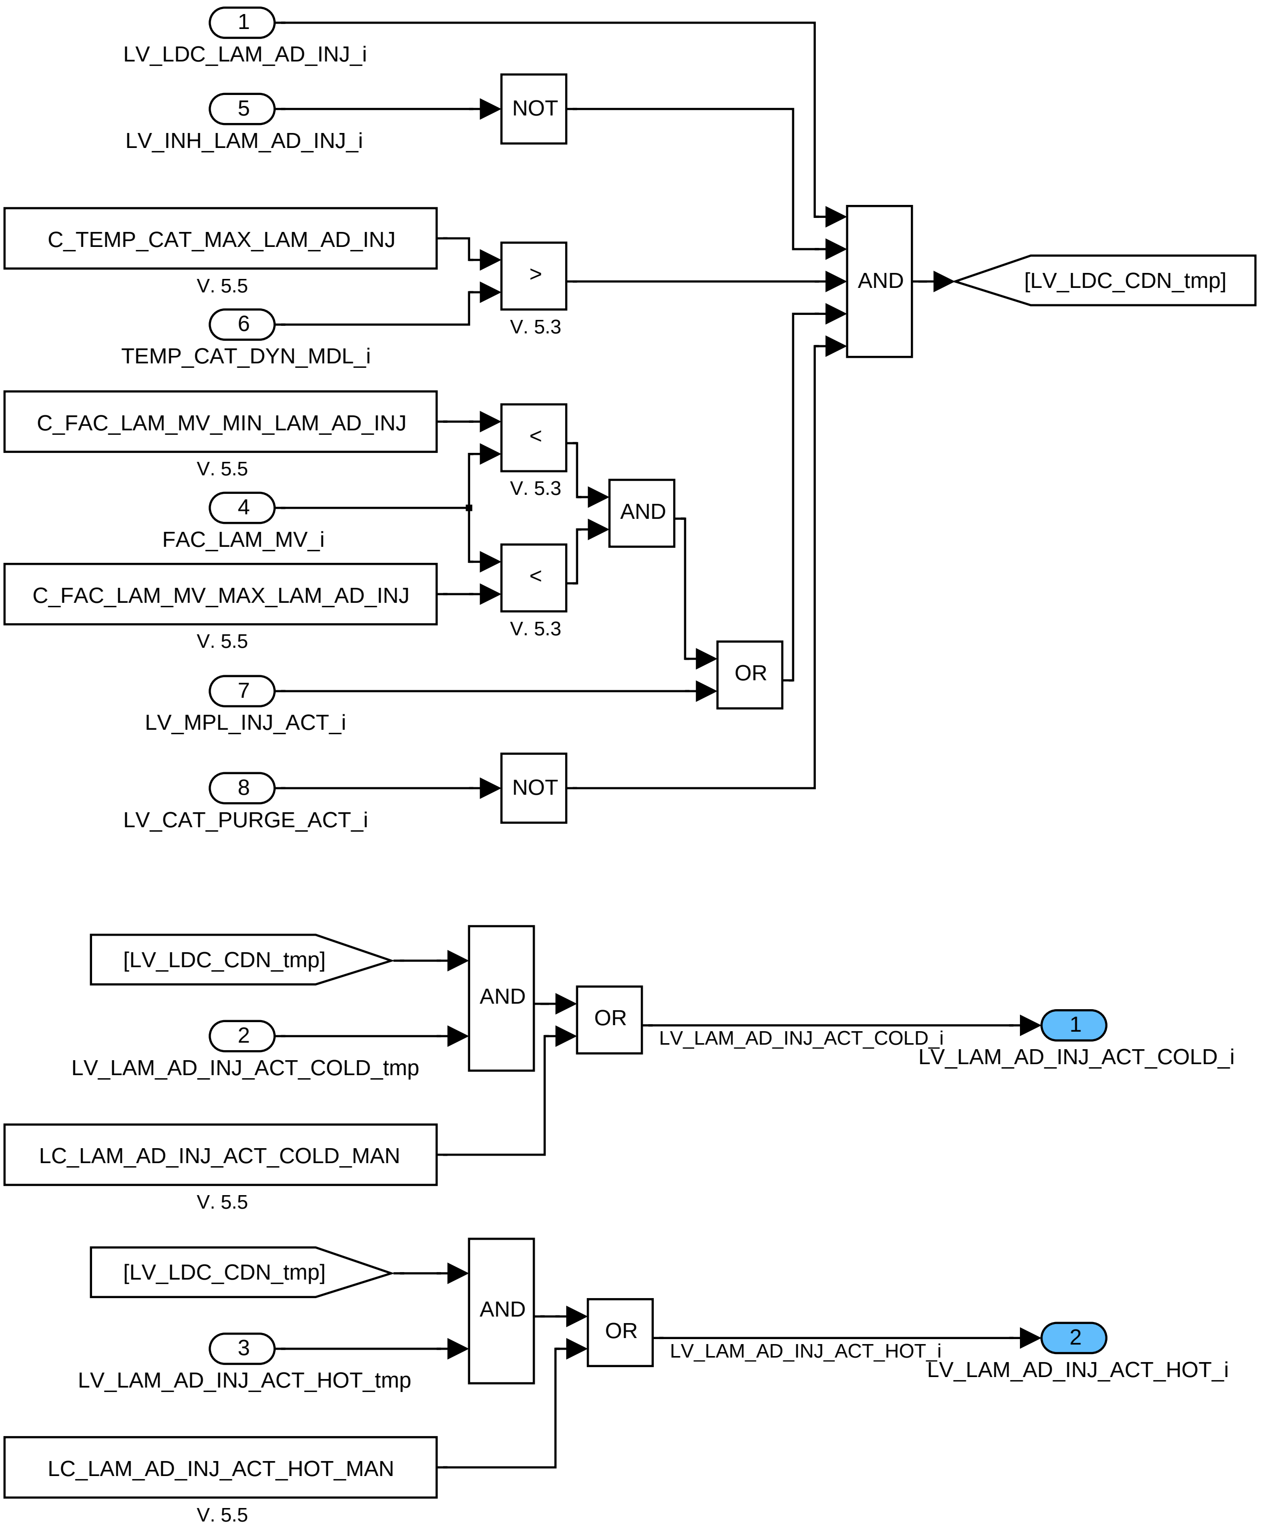

Figure 16:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_HOT_COLD_CDN

49.2.2.2.3 Monitoring of ENSC, LACO and MISF

During the multiple injection phase the output of the engine speed controller, the lambda controller and the misfire detection are monitored.At a certain number of misfire events or at a certain deviation in the lambda controller output the adaptation is interrupted immediately and the adaptation is repeated.For a deviation in the engine speed controller, the adaptation is at first finished and then repeated.

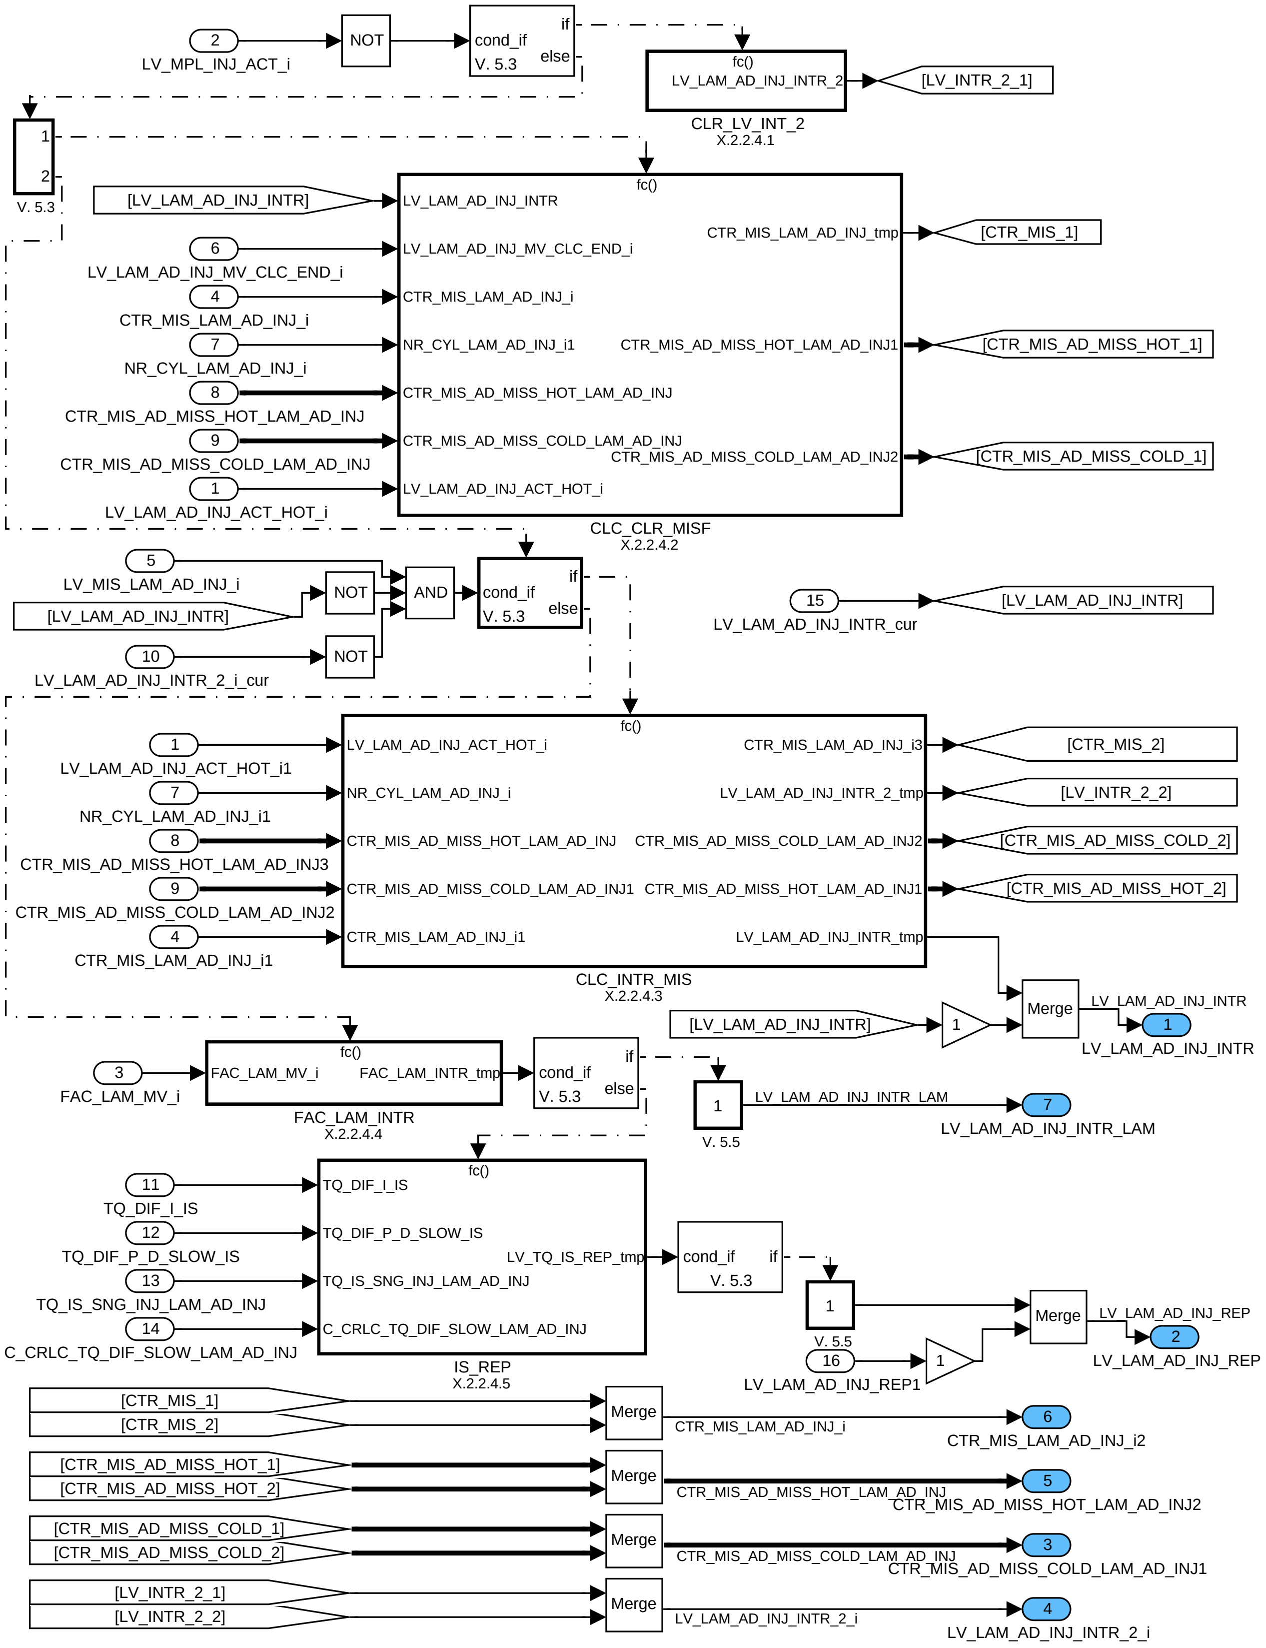

Figure 17:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP

49.2.2.2.3.1 Clear interruption flag

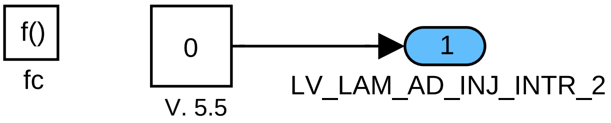

Figure 18:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLR_LV_INT_2

49.2.2.2.3.2 Clear the counter for misfire handling

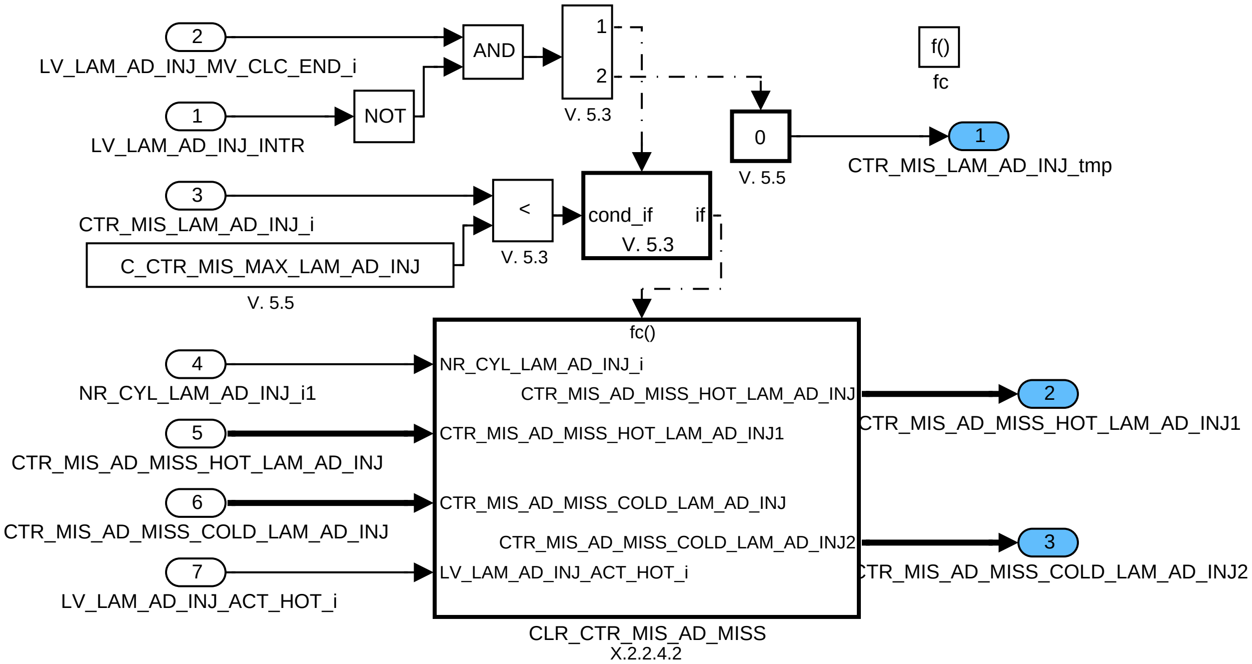

Figure 19:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLC_CLR_MISF

49.2.2.2.3.2.1 Clear temperature depending counters for misfire handling

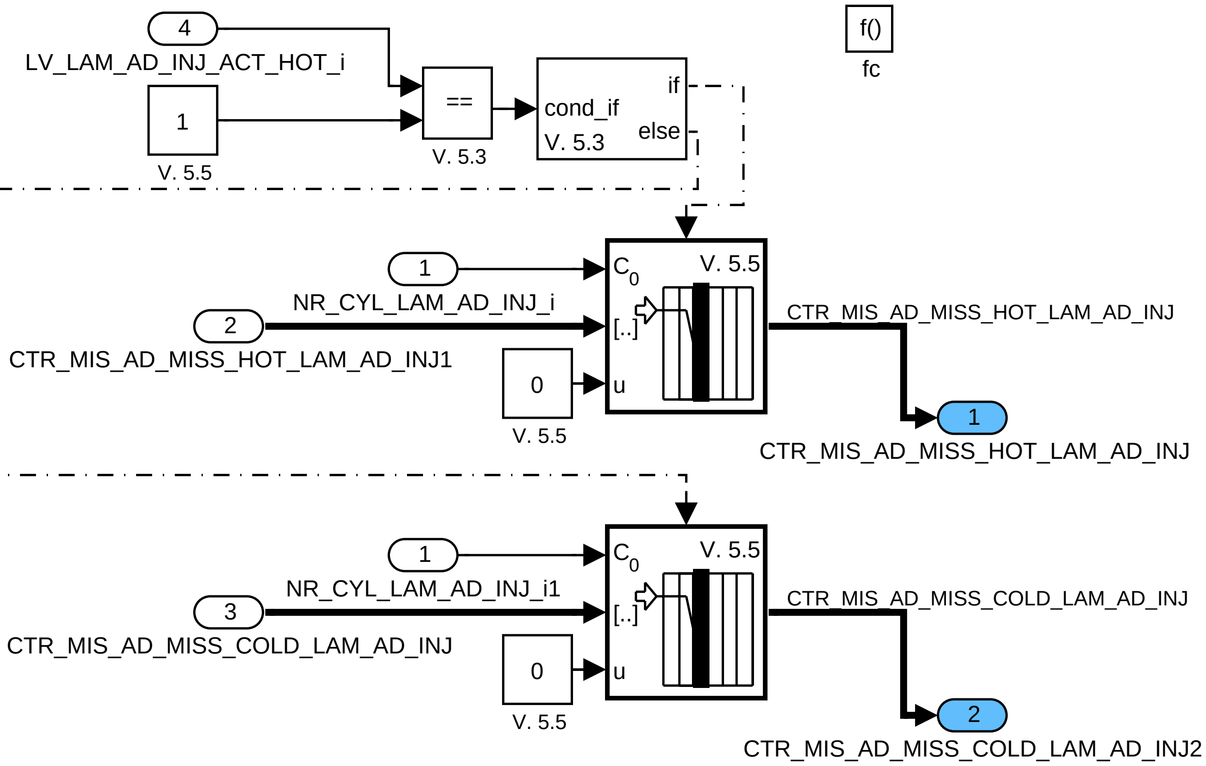

Figure 20:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLC_CLR_MISF/CLR_CTR_MIS_AD_MISS

49.2.2.2.3.3 Calculate counter for misfire handling

This calculation are done, if a misfire during multiple injection is detected. At misfire the misfire counter is incremented an the interruption flag is set, which leads to a repeat of the adaptation. If the maximum number of repeated adaptation due to misfire are reached, a second interruption flag is set, a counter is incremented and the adaptation is continued with all left cylinders.

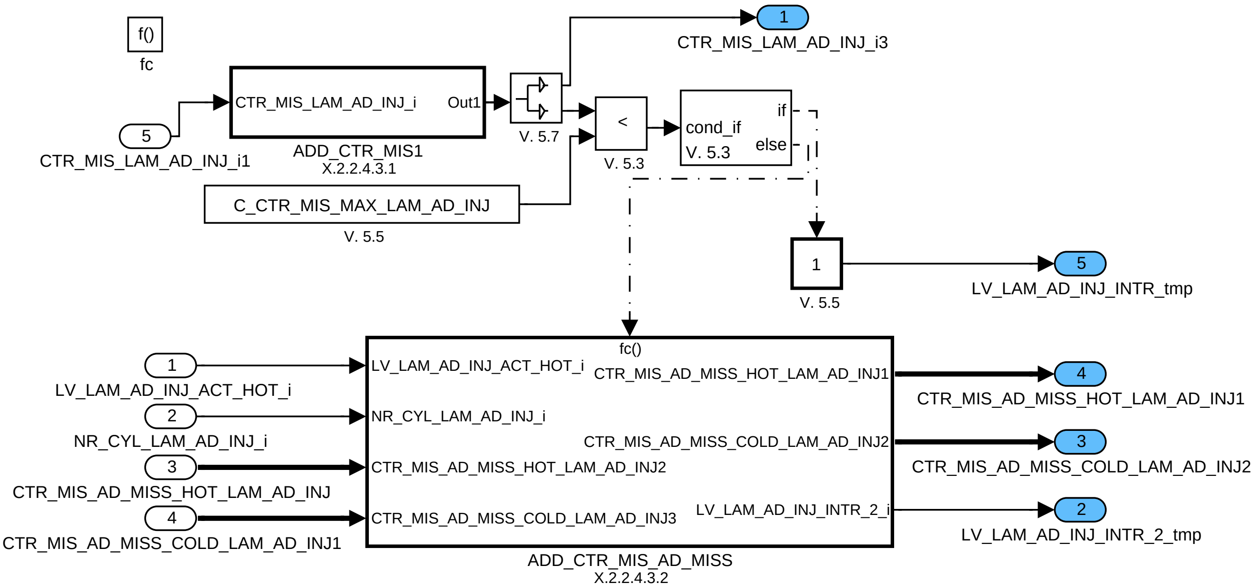

Figure 21:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLC_INTR_MIS

49.2.2.2.3.3.1 Incrementation of CTR_MIS_LAM_AD_INJ

The counter is incremented and limited.

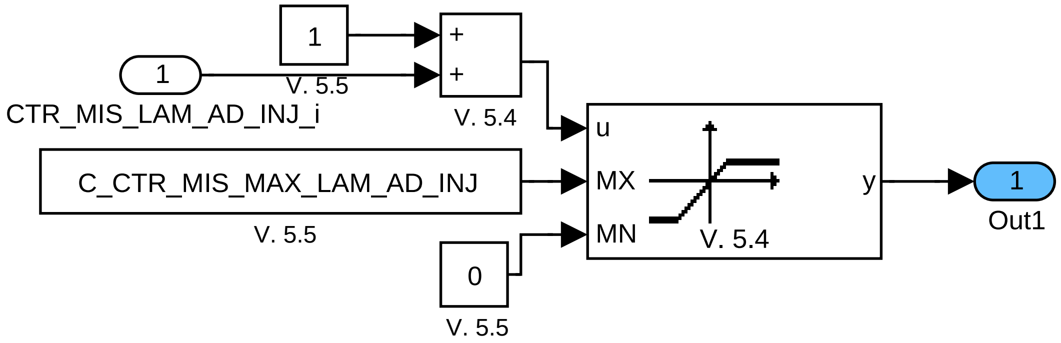

Figure 22:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLC_INTR_MIS/ADD_CTR_MIS1

49.2.2.2.3.3.2 Incrementation of of CTR_MIS_AD_MISS_COLD/HOT_LAM_AD_INJ

Depending on the temperature range the counters are incremented.

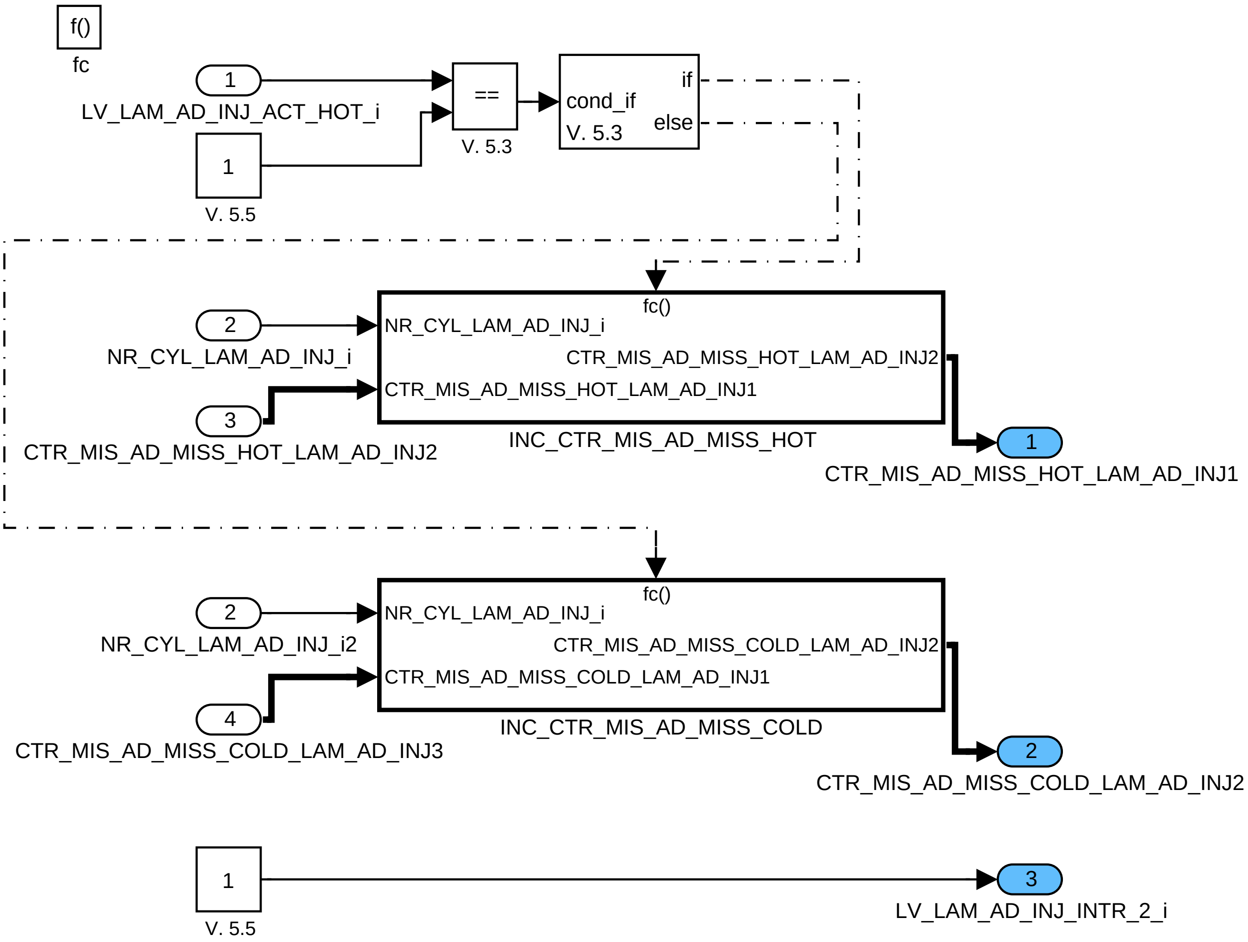

Figure 23:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/CLC_INTR_MIS/ADD_CTR_MIS_AD_MISS

49.2.2.2.3.4 Conditions for interruption due to lambda conditions

If the lambda controller output exceeds the limitations, the adaptation is interrupted.

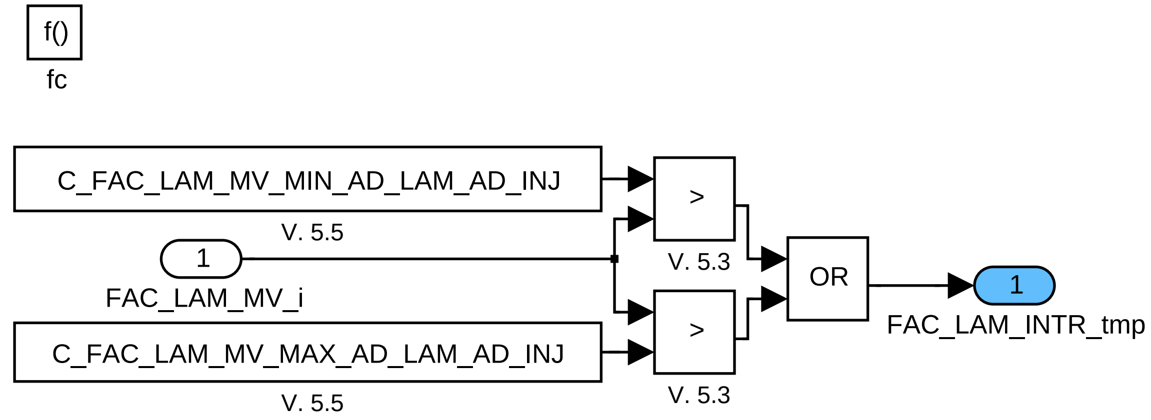

Figure 24:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/FAC_LAM_INTR

49.2.2.2.3.5 Conditions for interruptions due to ENSC controller output deviation

For a big difference in the idle speed controller in single and multiple injection, the adaptation will be finished and repeted.

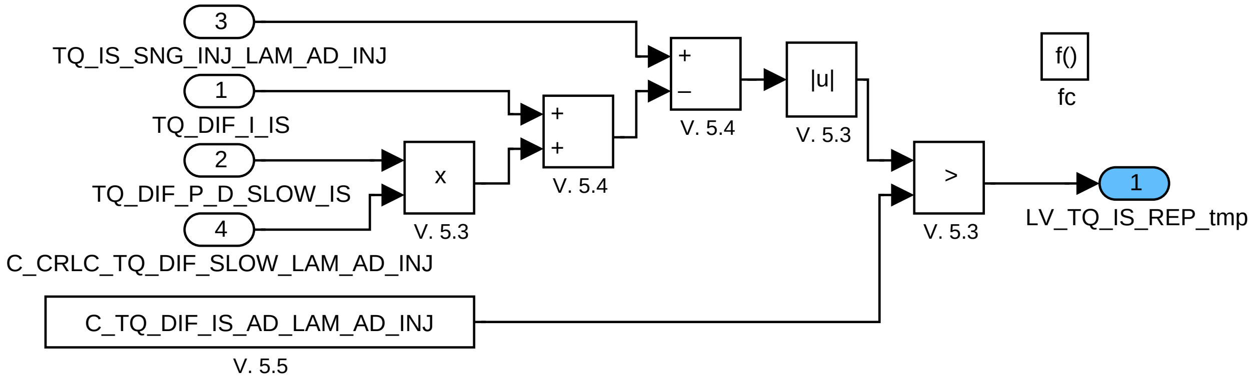

Figure 25:
Path: MFMA_ISPCLAIMA0/OPM_20MS/BANK_SPECIFIC_CLC/CLC_INTR_REP/IS_REP

49.2.2.3 Calculation of general activation flag and update of the distance counter

The general activation flag is set if the bank specific condition for hot or cold conditions are given. Also the update of the mileage threshold is updated.

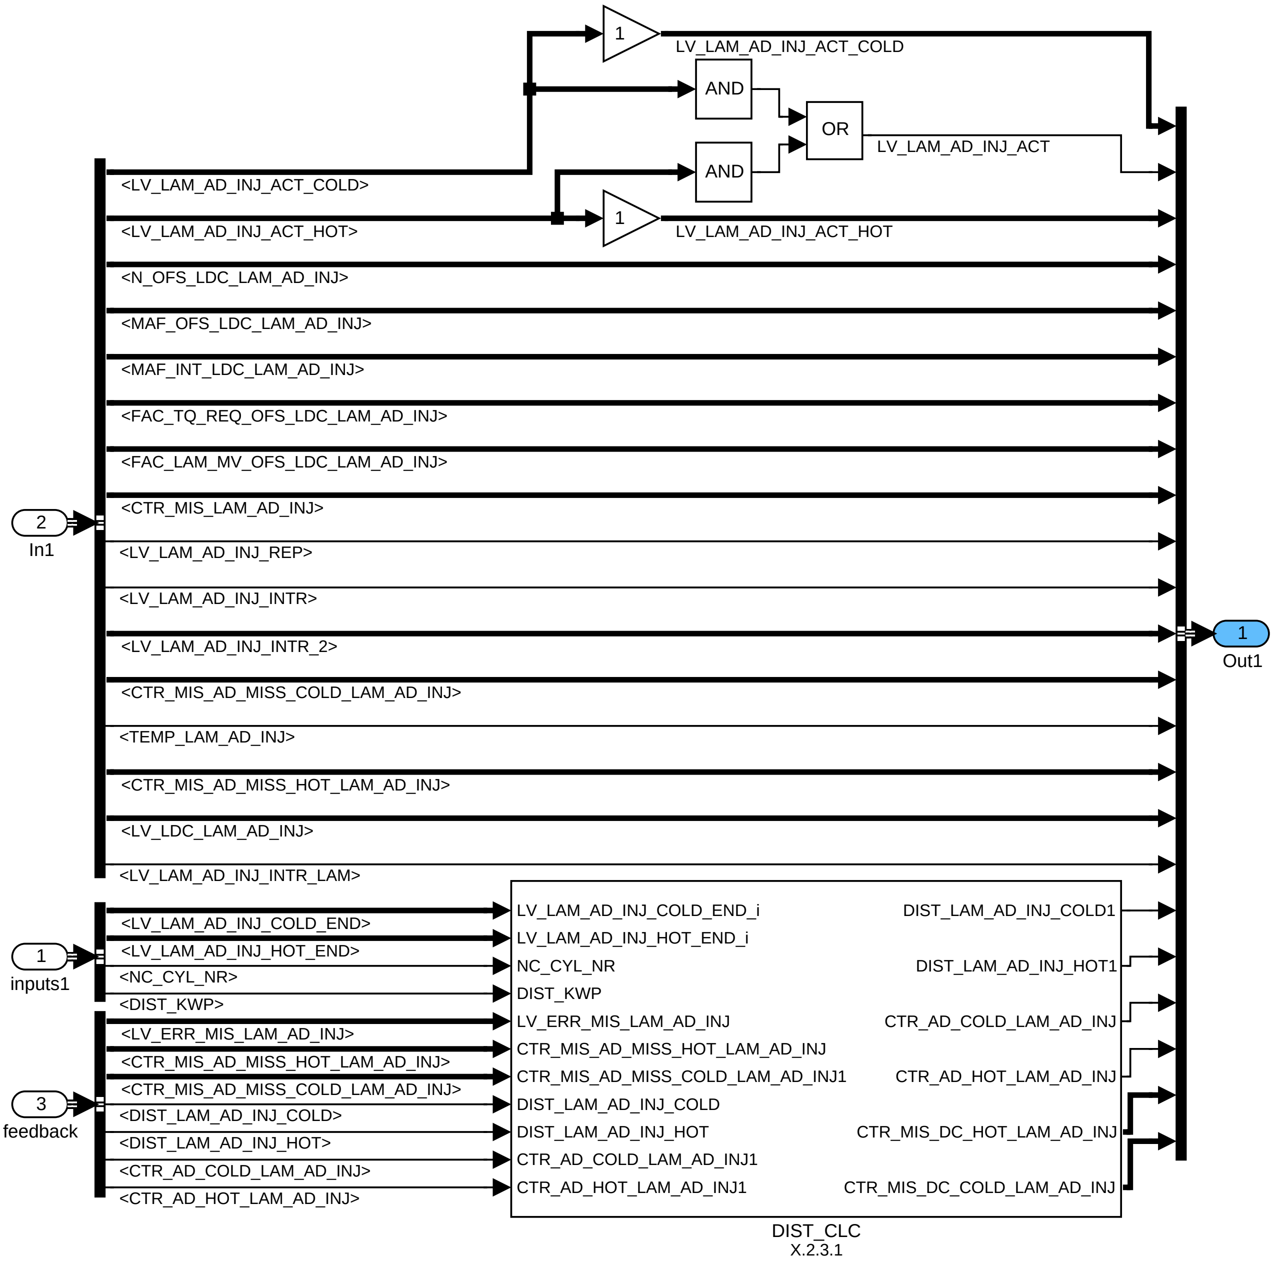

Figure 26:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT

49.2.2.3.1 Update of the mileage threshold

The mileage threshold is separately updated for hot and cold adaptation if the adaptation is finished successfully for all cylinders and no repeat of adaptation due to misfire is necessary.

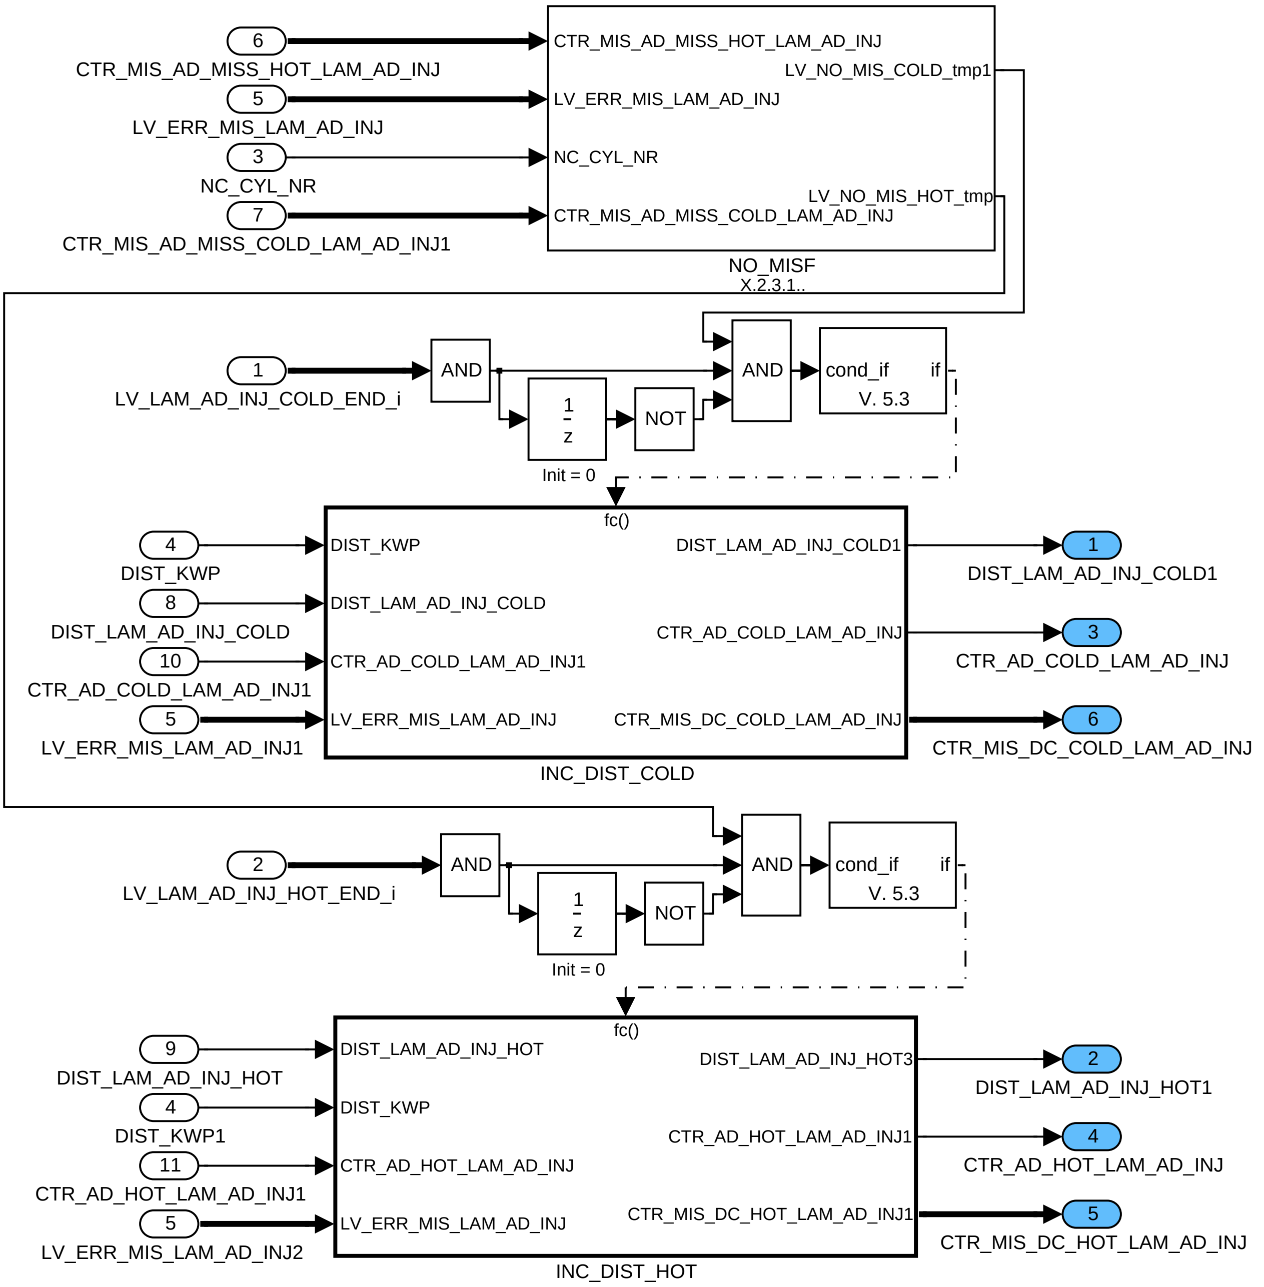

Figure 27:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT/DIST_CLC

49.2.2.3.1.1 Distance threshold incrementation for cold adaptation

At successful adaptation the distance counter will be incremented; the CTR_AD_COLD_LAM_AD_INJ will be incremented and if no error is present and the LC_CTR_MIS_DC_LAM_AD_INJ_CLR is set the CTR_MIS_DC_COLD_LAM_AD_INJ is cleared.

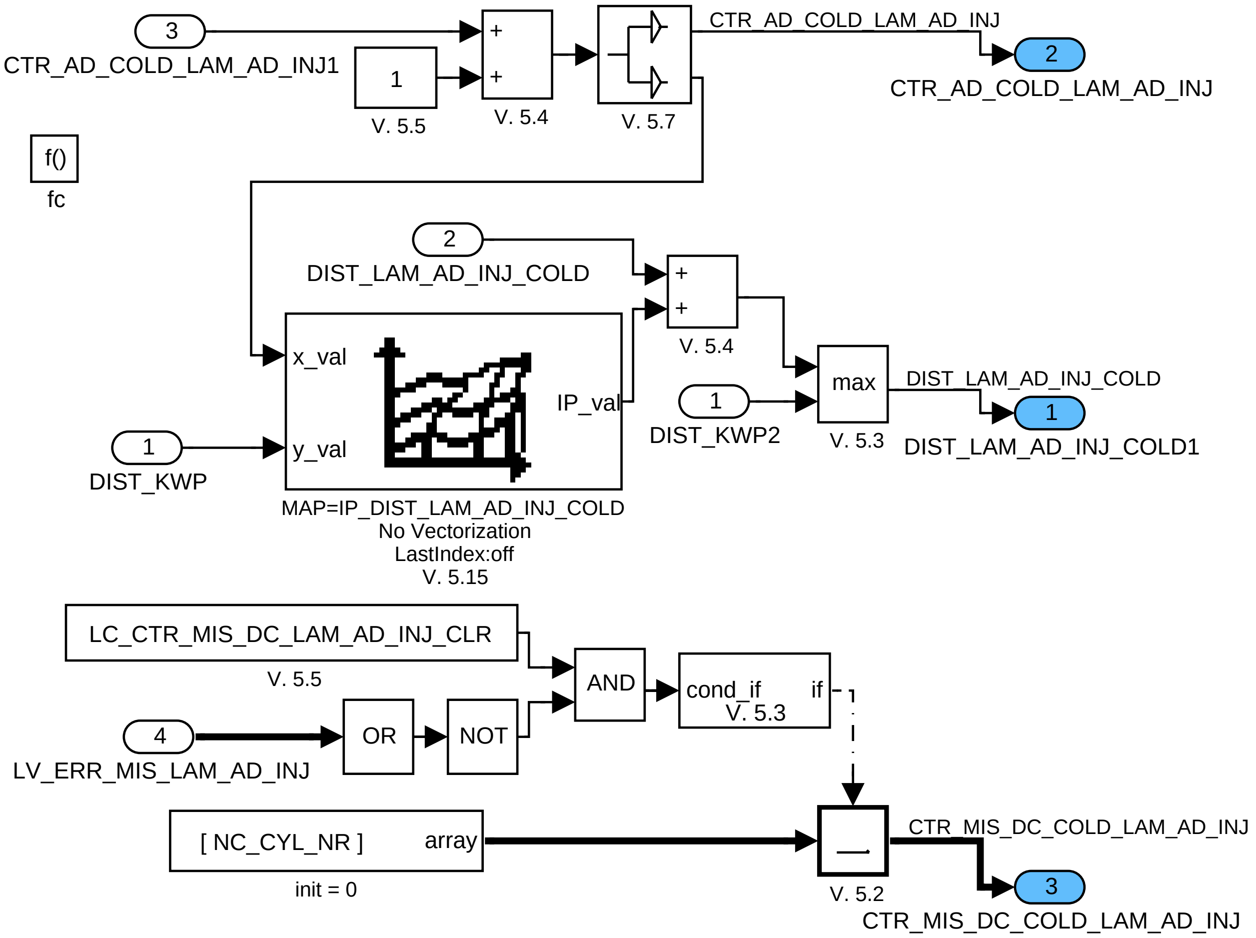

Figure 28:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT/DIST_CLC/INC_DIST_COLD

49.2.2.3.1.2 Distance threshold incrementation for hot adaptation

At successful adaptation the distance counter will be incremented; the CTR_AD_HOT_LAM_AD_INJ will be incremented and if no error is present and the LC_CTR_MIS_DC_LAM_AD_INJ_CLR is set the CTR_MIS_DC_HOT_LAM_AD_INJ is cleared.

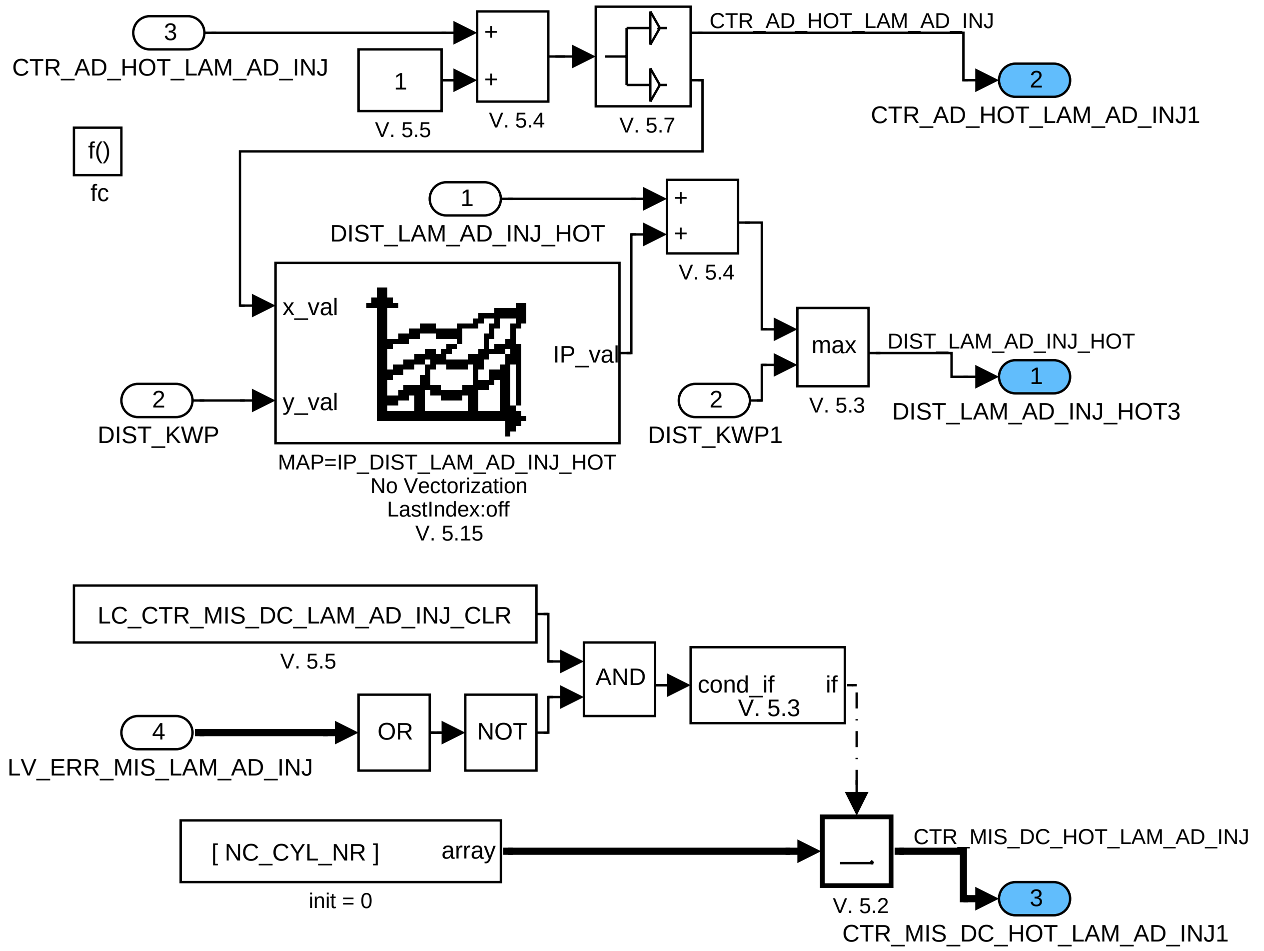

Figure 29:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT/DIST_CLC/INC_DIST_HOT

49.2.2.3.1.3 No misfire condition for mileage threshold update

The mileage threshold can be updated, if the condition "no misfire" is present for all cylinders.

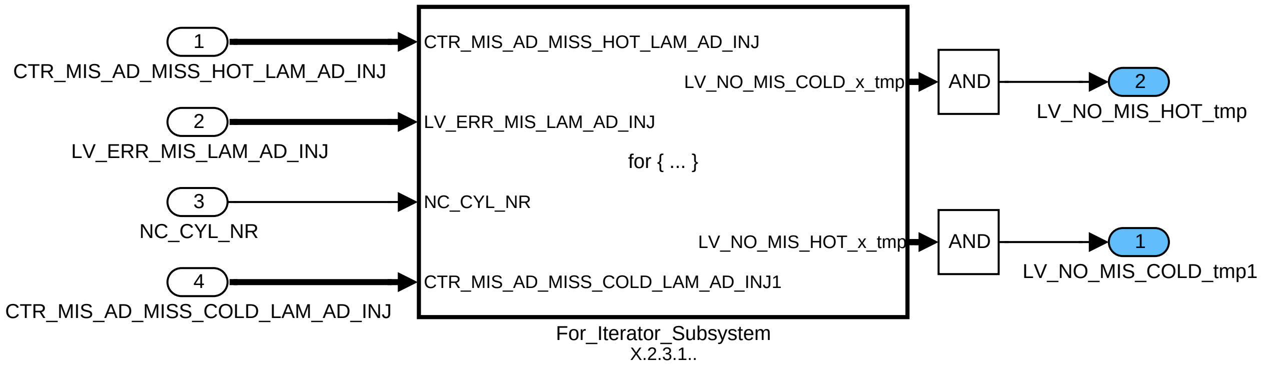

Figure 30:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT/DIST_CLC/NO_MISF

49.2.2.3.1.3.1 No misfire condition

For each cylinder it tested, if no misfire was present or the error for misfire is already present.

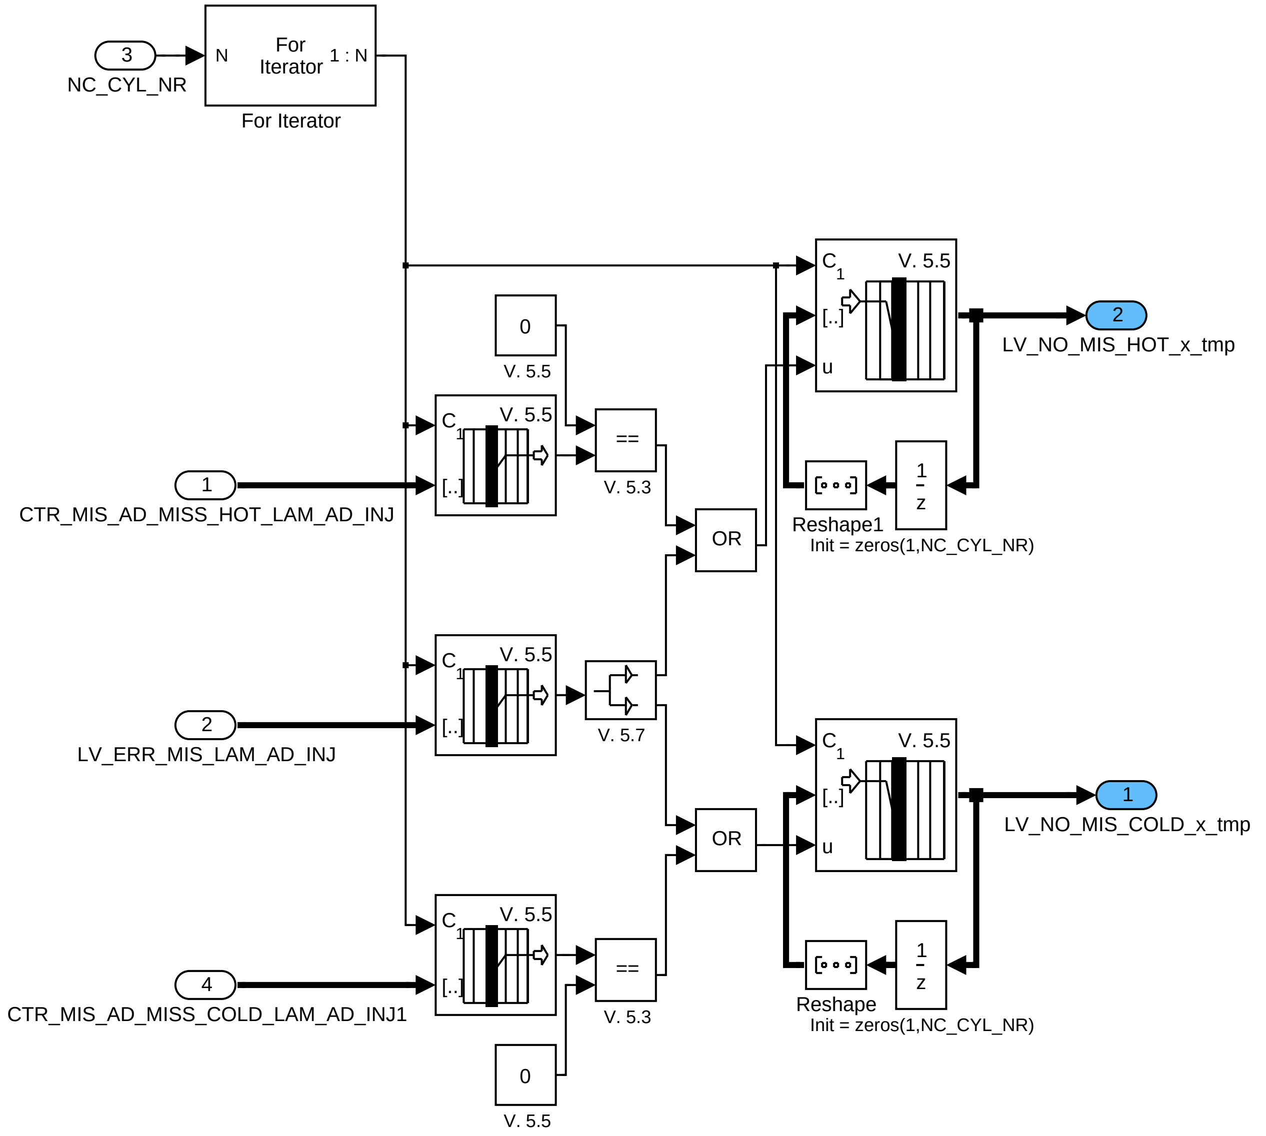

Figure 31:
Path: MFMA_ISPCLAIMA0/OPM_20MS/CLC_ACT/DIST_CLC/NO_MISF/For_Iterator_Subsystem

49.2.3 Segment synchronous calculations to detect misfire

Calculations to detect misfire with the same recurrence as the misfire calculations. Misfire will be detected only at multiple injection phase, represented by STATE_LAM_AD_INJ_ACT > 2 (single injection)

49.2.3.1 Detection of misfire

If misfire is detected for the cylinder with multiple injections, a misfire counter is incremented. The flag indicating misfire is set, if the counter reach a threshold.

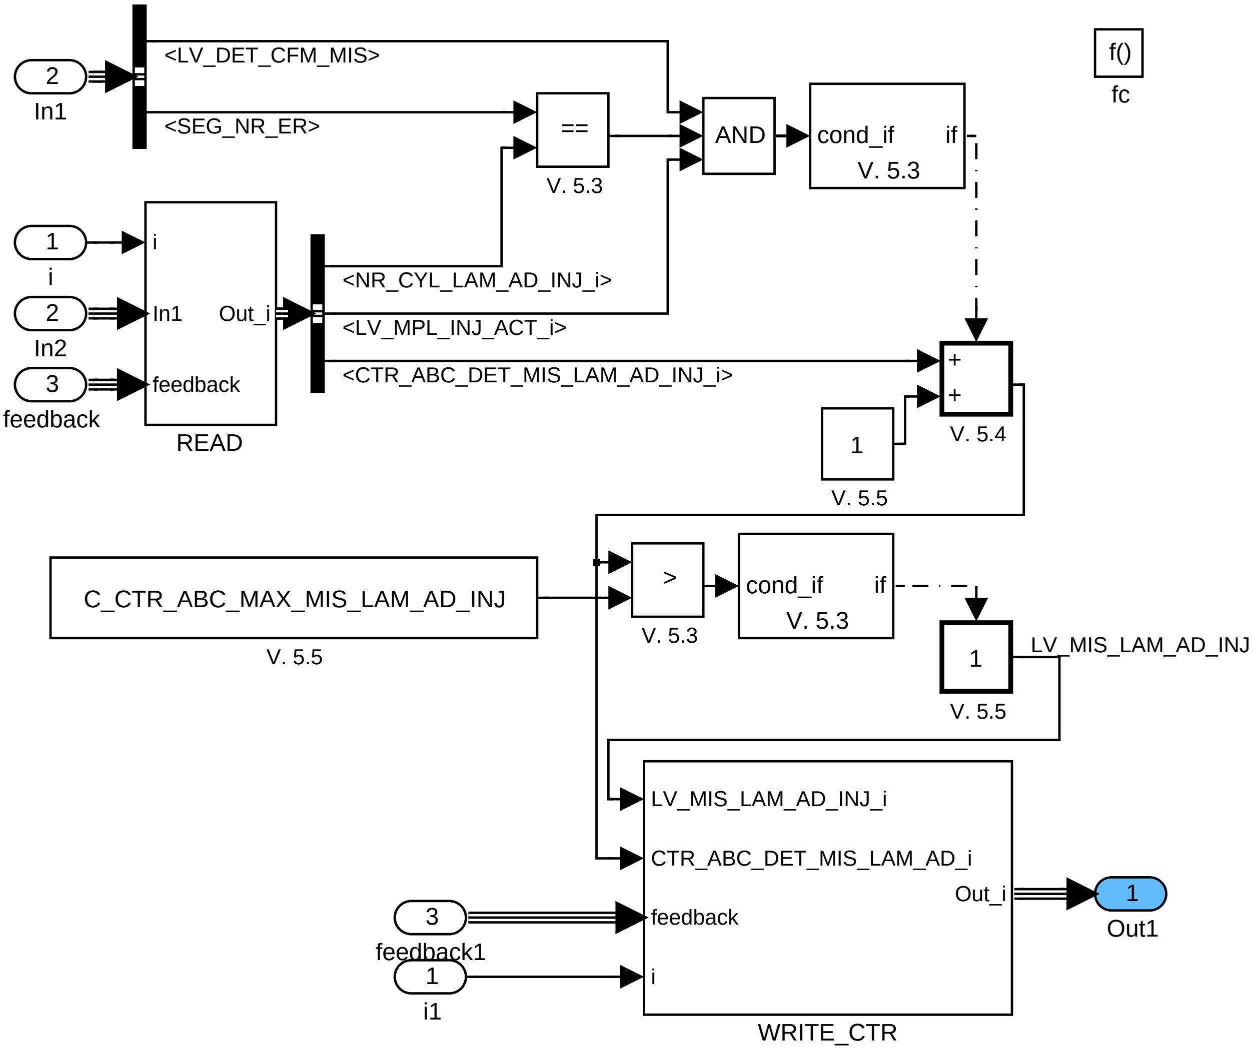

Figure 32:
Path: MFMA_ISPCLAIMA0/OPM_SEG/CLC_MIS

49.2.4 Calculations at event engine stop to engine run

Cylinder individual calculations to clear the error flags.

49.2.4.1 Clear error flags, distance threshold and counters

At a change of an injector, the CTR_AD_HOT/COLD_LAM_AD_INJ and the error flags and counter are cleared. The distance threshold and the error can also be cleared by calibration data. If a resetting of the NVMY data via service tester is requested with the flag LV_LAM_AD_INJ_CLR_AD_EXT, the counters and the distance thresholds are cleared.

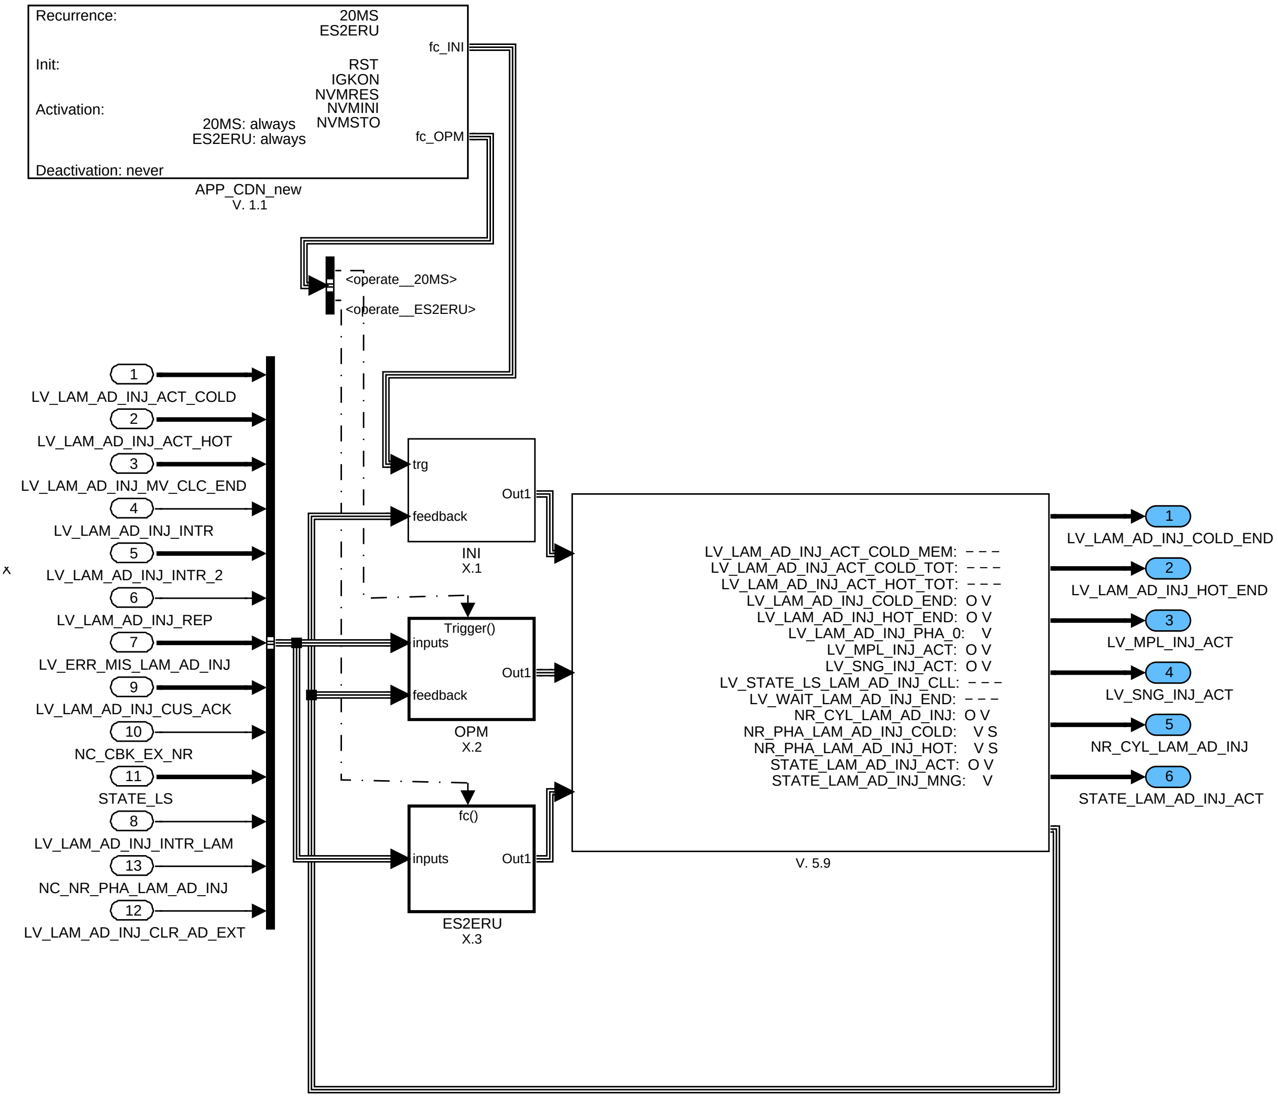
General Information

This module coordinates the usage of single and multiple injections for lambda adaptation via injection mode.

Application Conditions

Initialization: RST, IGKON, NVMRES, NVMINI, NVMSTO
Activation: 20MS: always
ES2ERU: always
Deactivation: never

Function description



SDA_SRS / SDA V 5.0.4 29−Aug−2006

Figure 38:
Path: MFMA_REQCOAIMM0

49.3.1 Initialization and NVMY management

49.3.1.1 Reading from non-volatile memory

The phase number NR_PHA_LAM_AD_INJ_COLD/HOT are initialized from the non-volatile memory.

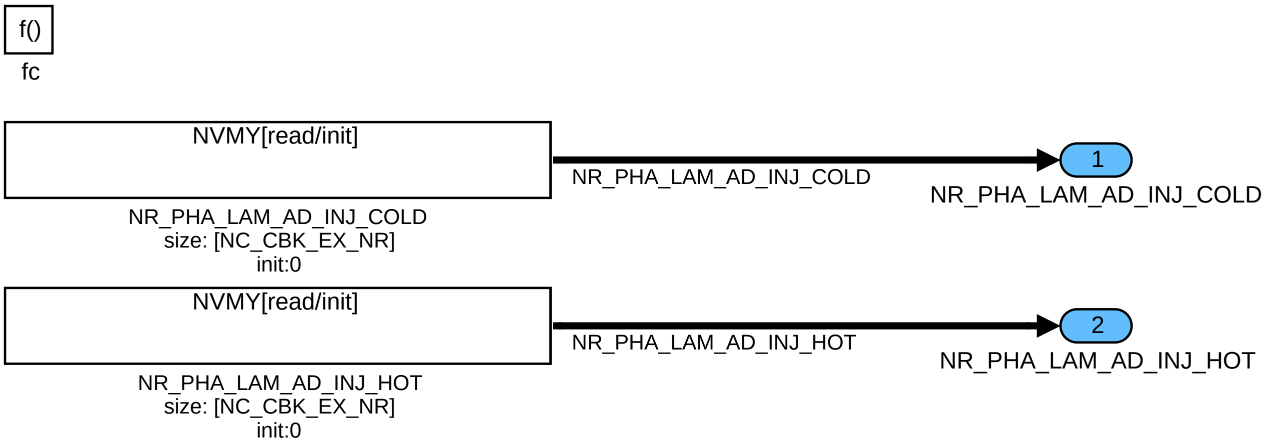


Figure 39:
Path: MFMA_REQCOAIMM0/INI/NVMY_RD

49.3.1.2 Writing to the non-volatile memory

After powerlatch the values of NR_PHA_LAM_AD_INJ_COLD/HOT are written to the non-volatile memory.

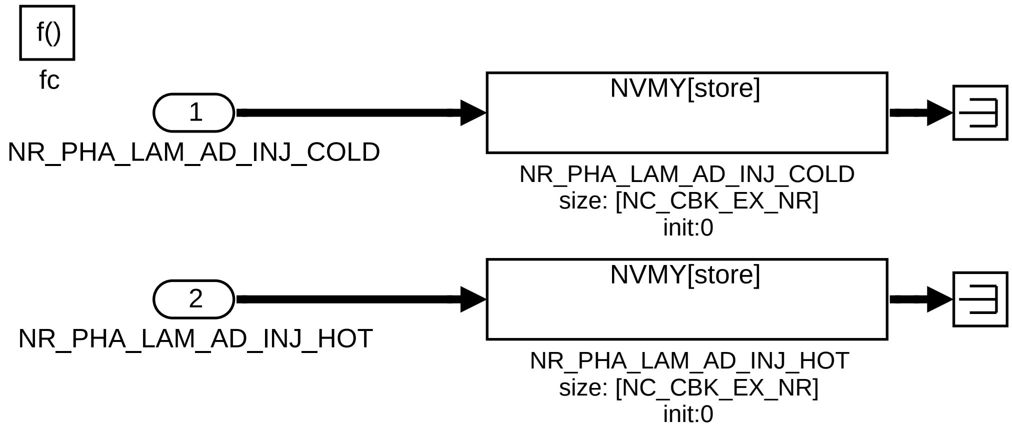

Figure 40:
Path: MFMA_REQCOAIMM0/INI/NVMY_WR

49.3.1.3 Initialization

All variables are initialized with 0 at reset or IGKON.

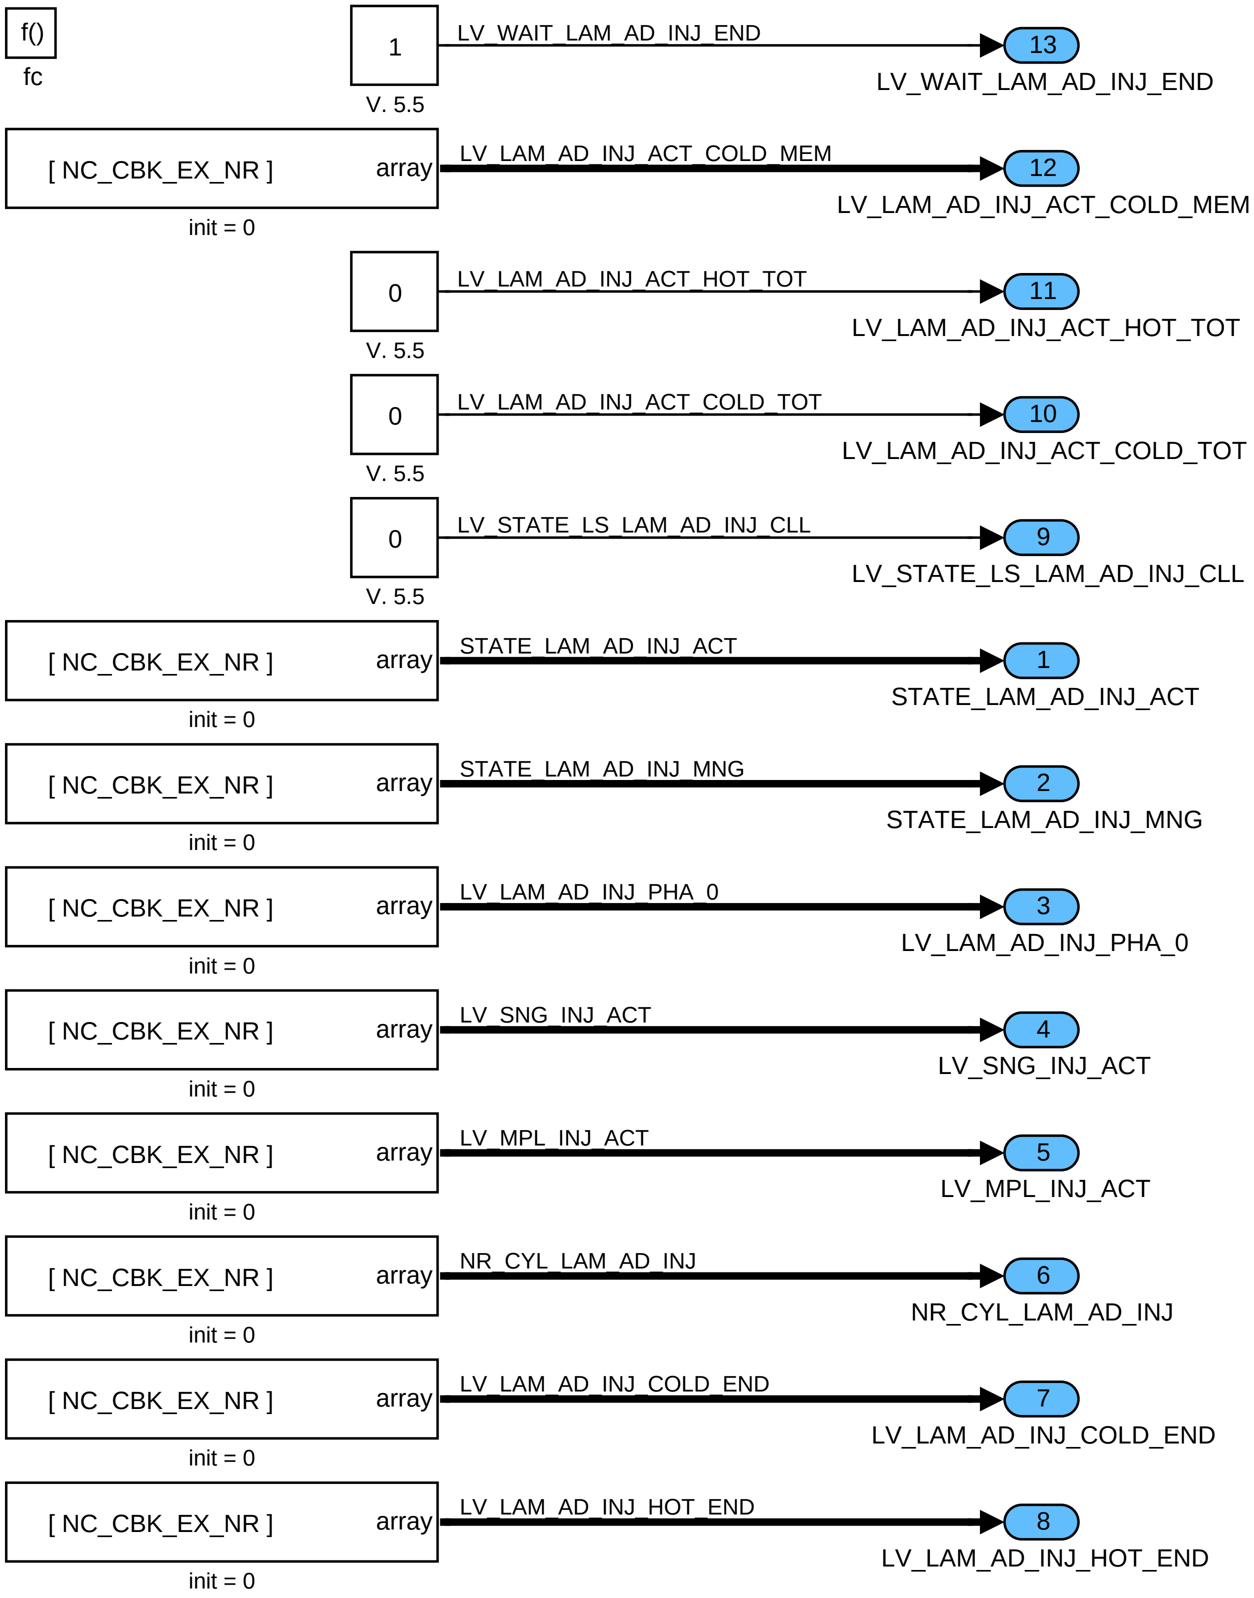

Figure 41:
Path: MFMA_REQCOAIMM0/INI/INI

49.3.2 Bank specific calculations

All calculations are done for every bank. The value for the specific bank is denoted in the graphical model with the suffix _i whereas in the textual description the bank specific values are referred to with [i].

49.3.2.1 Preliminary calculations

49.3.2.1.1 Calculation of LV_LAM_AD_INJ_ACT_COLD_MEM, LV_WAIT_LAM_AD_INJ_END and LV_STATE_LS_LAM_AD_INJ_CLL

The flag LV_WAIT_LAM_AD_INJ_END is set if the adaptation signals the end of the mean value calculation for both banks. The values of LV_LAM_AD_INJ_ACT_COLD are memorized in LV_LAM_AD_INJ_ACT_COLD_MEM as this is used for determination of the phase numbers NR_PHA_LAM_AD_INJ_COLD/HOT. To get a bank synchronous switching of the state machine, the activation conditions for the lambda controller are checked for all banks and stored in LV_STATE_LS_LAM_AD_INJ_CLL.

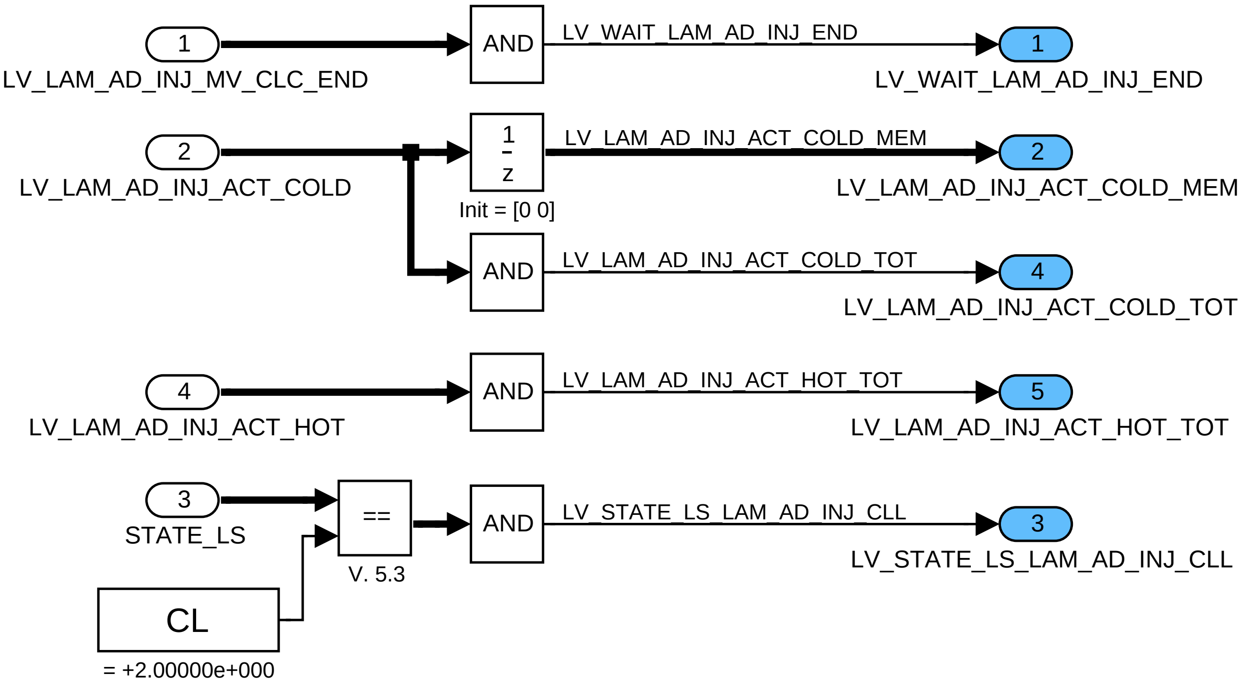

Figure 42:
Path: MFMA_REQCOAIMM0/OPM/CLC_MEM/CLC

49.3.2.2 Adaptation manager

The adaptation manager consists of three states STATE_LAM_AD_INJ[i]:
NOT_ACT: inactive state
CLC_CYL_STATE: intermediate state to determine single/multiple injection-mode for the next adaptation phase
WAIT_LAM_AD_INJ: the adaptation enabled for the injection-mode defined in the previous state

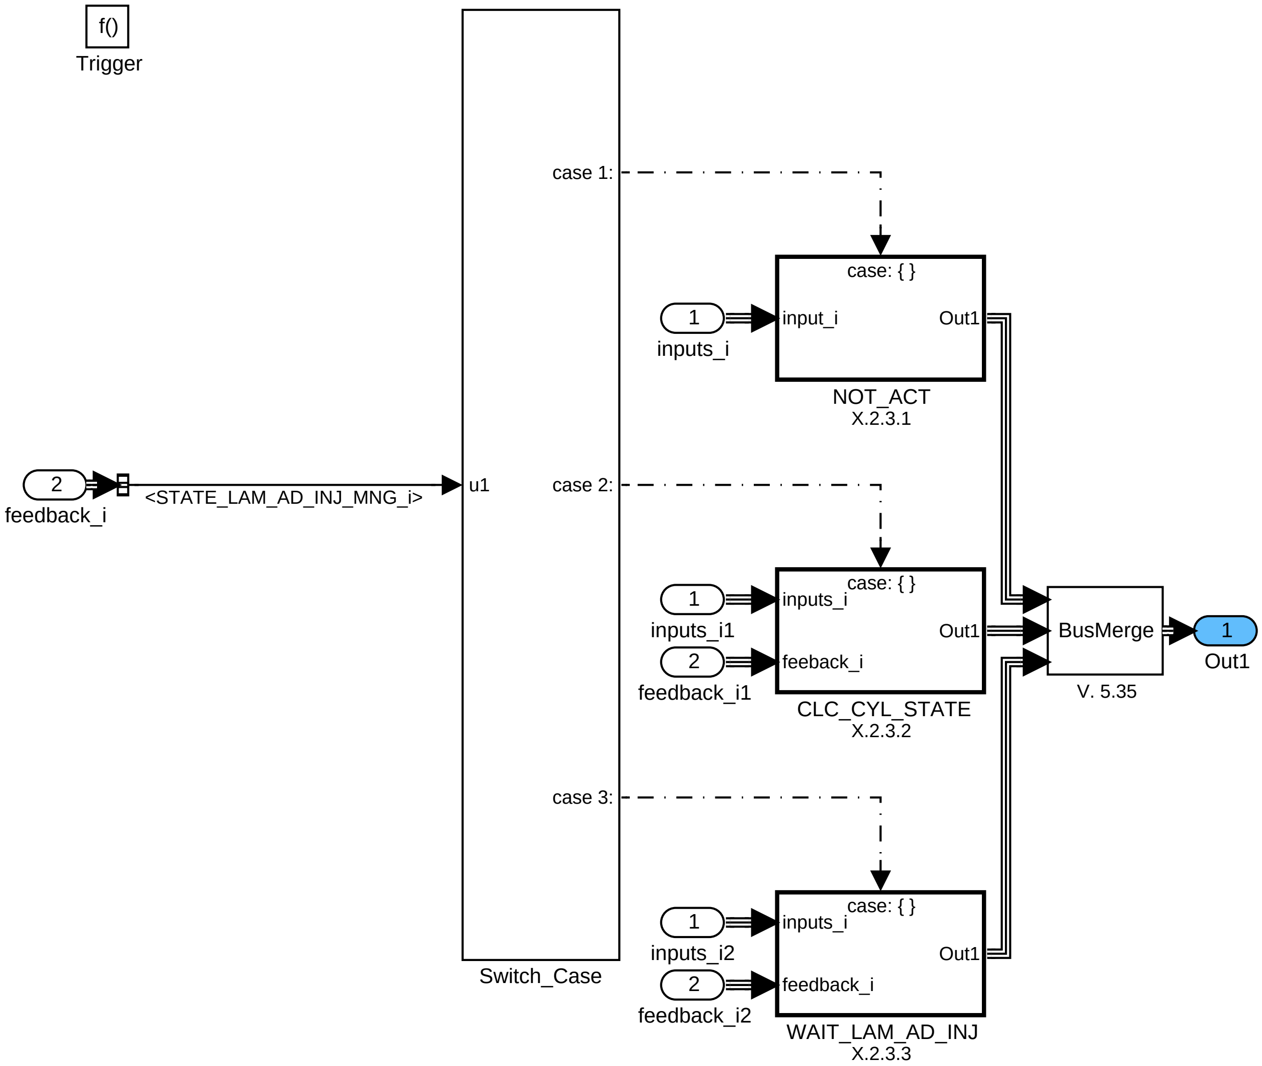

Figure 43:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG

49.3.2.2.1 NOT_ACT

In this state the adaptation is inactive. If the conditions for the adaptation in the upper or lower temperature range apply, the injection mode control is requested by setting the state STATE_LAM_AD_INJ_ACT[i] different from zero.

49.3.2.2.1.1 Transition conditions

If the adaptation conditions apply the injection mode control is requested and the state is left if it is granted (LV_LAM_AD_INJ_CUS_ACK = 1).

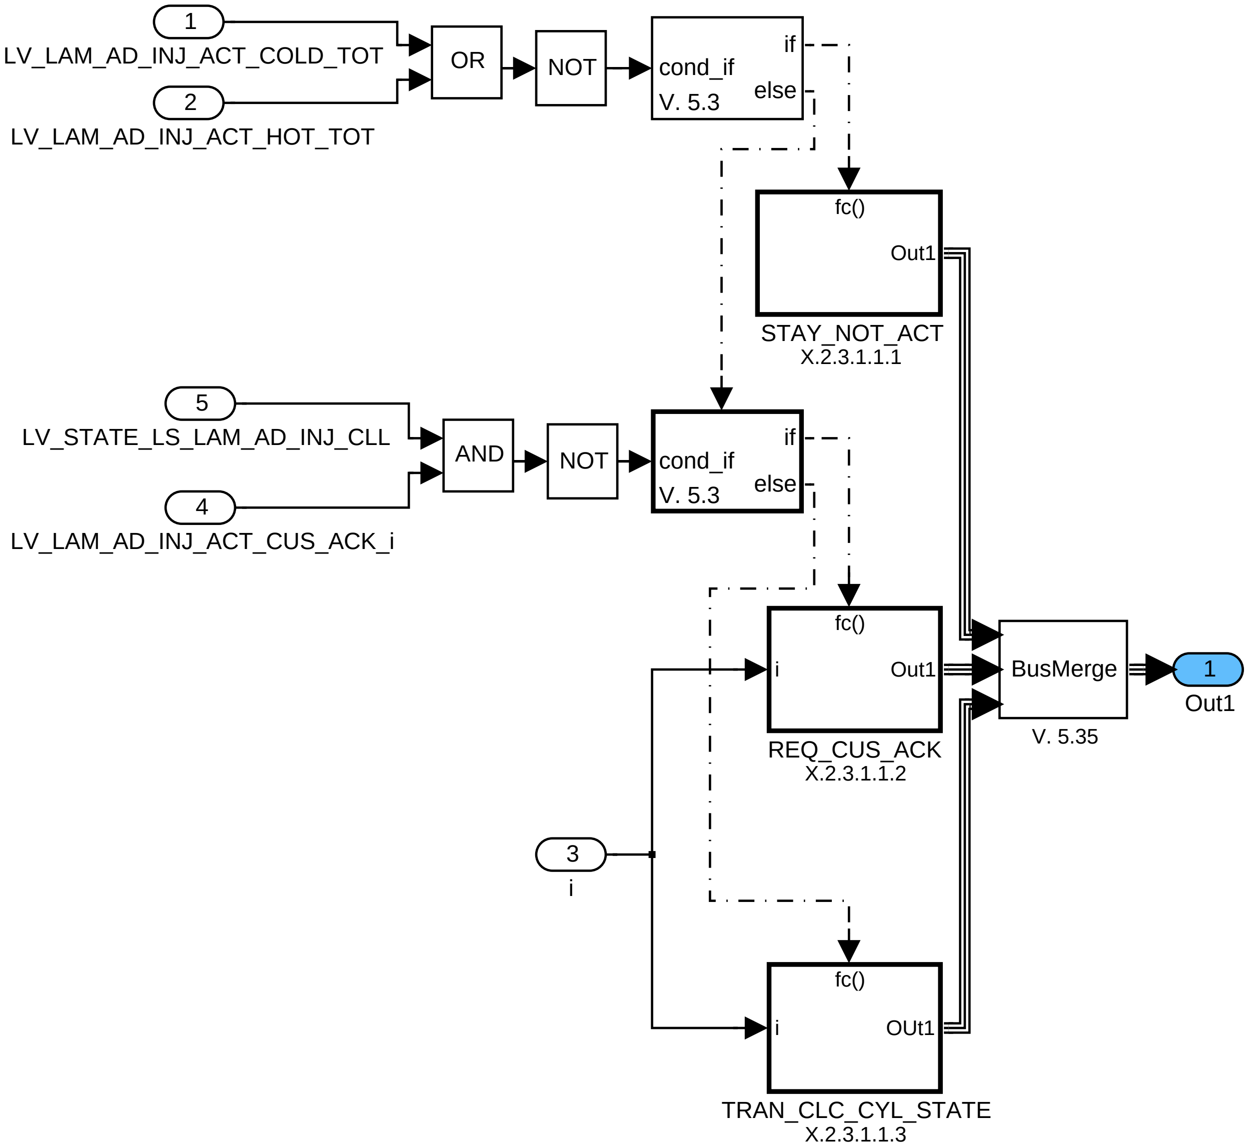

Figure 44:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC

49.3.2.2.1.1.1 Remaining in NOT_ACT

49.3.2.2.1.1.1.1 Reset of the request for the injection mode control

The request is reset if the conditions are no more fulfilled.

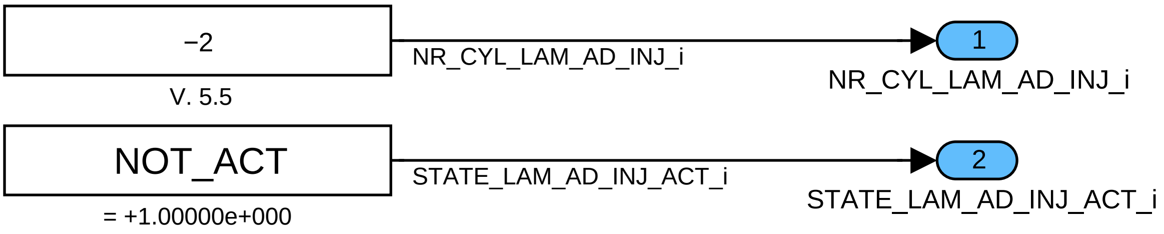

Figure 45:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/STAY_NOT_ACT/CLC

49.3.2.2.1.1.2 Start of injection mode control handshake

The injection mode for the bank is requested.

49.3.2.2.1.1.2.1 Request for injection mode control

The control of the injection mode is requested by setting the STATE_LAM_AD_INJ_ACT[i] to the first element of ID_NR_CYL_LAM_AD_INJ[i], which should be set to one or two to request single injections.

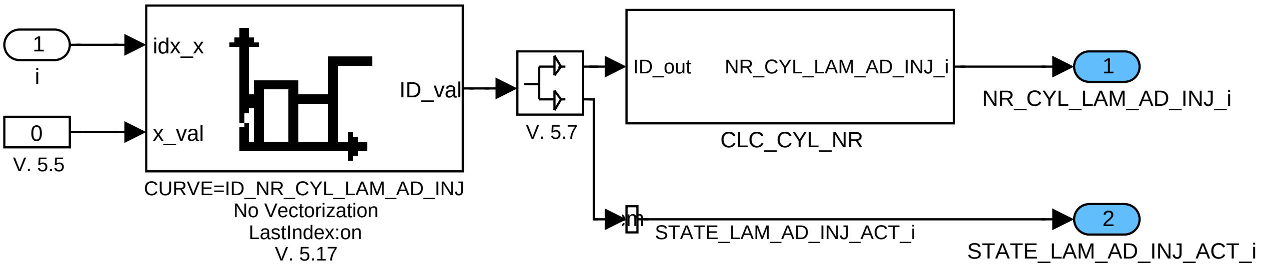

Figure 46:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/REQ_CUS_ACK/CLC

49.3.2.2.1.1.3 Injection mode control granted

49.3.2.2.1.1.3.1 Transition to CLC_CYL_STATE

If the acknowledge bit for injection mode control LV _LAM_AD_INJ_CUS_ACK is set, the state is left towards CLC_CYL_STATE.

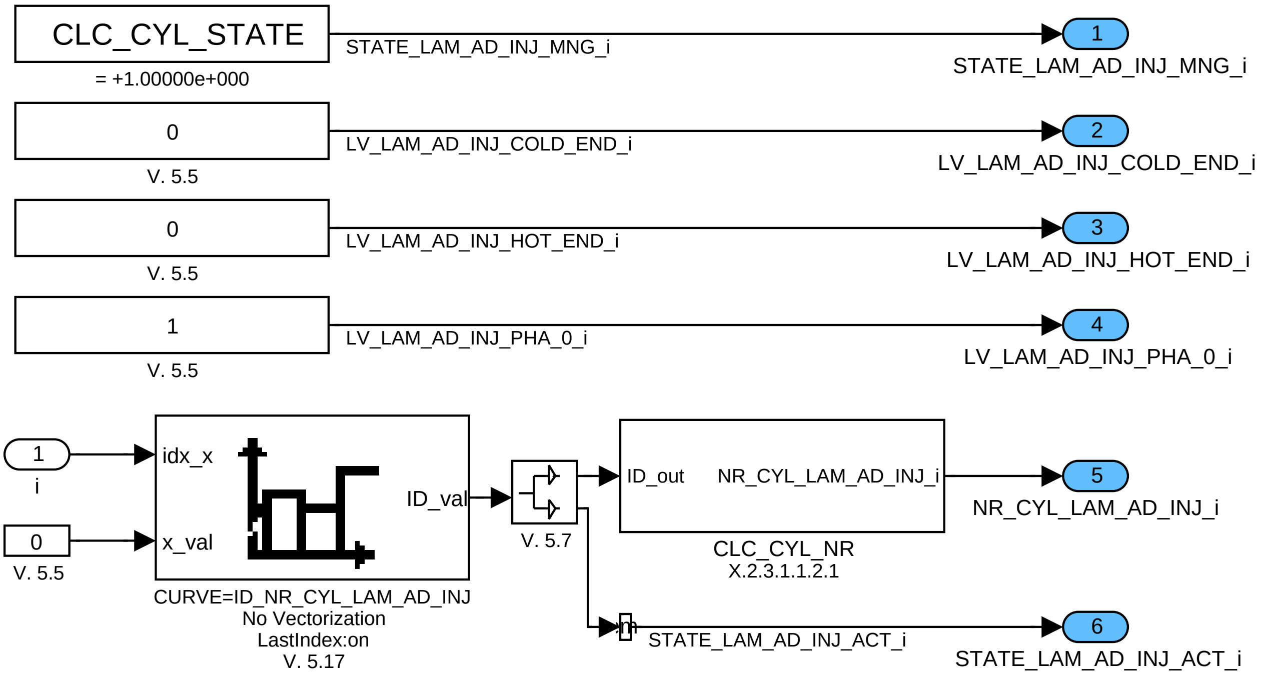

Figure 47:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/TRAN_CLC_CYL_STATE/CLC

49.3.2.2.1.1.3.1.1 Calculation of the cylinder number from STATE_LAM_AD_INJ_ACR

The conversion from ID_out[i] to NR_CYL_LAM_AD_INJ[i] can be done in the code as follows:
NR_CYL_LAM_AD_INJ[i] = (signed)((ID_out+1) >> 1) - 2;
Therewith the conversion should be done as follows:

ID_OUT	NR_CYL_LAM_AD_INJ
0	-2
1	-1
2	-1
3	0
4	0
...	...
18	7

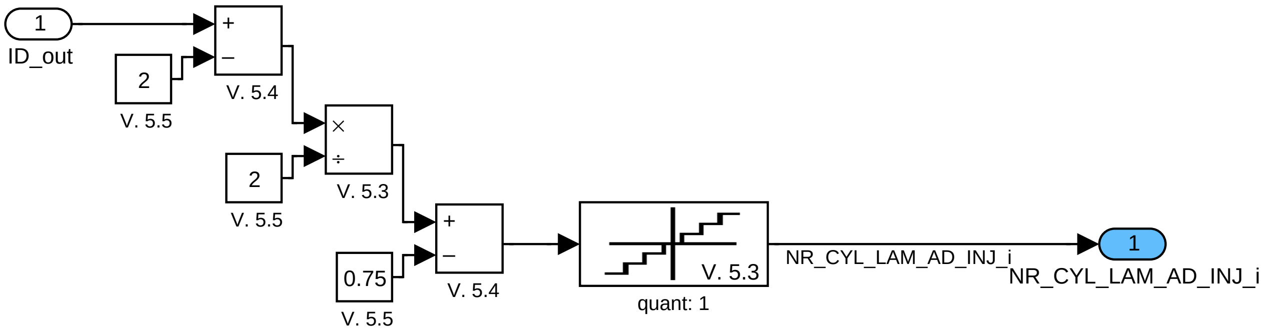

Figure 48:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/NOT_ACT/CLC/TRAN_CLC_CYL_STATE/CLC/CLC_CYL_NR

49.3.2.2.2 CLC_CYL_STATE

This state is used for determination of the injection mode for the next adaptation phase.

49.3.2.2.2.1 Transition conditions

If the cylinder number of the current bank NR_CYL_LAM_AD_INJ[i] is equal to -2, the current adaptation is assumed to be finished and the state is left to NOT_ACT. If the adaptation is interrupted due to the lack of the necessary conditions, a transition to NOT_ACT is performed, too. Otherwise the state changes to WAIT_LAM_AD_INJ.

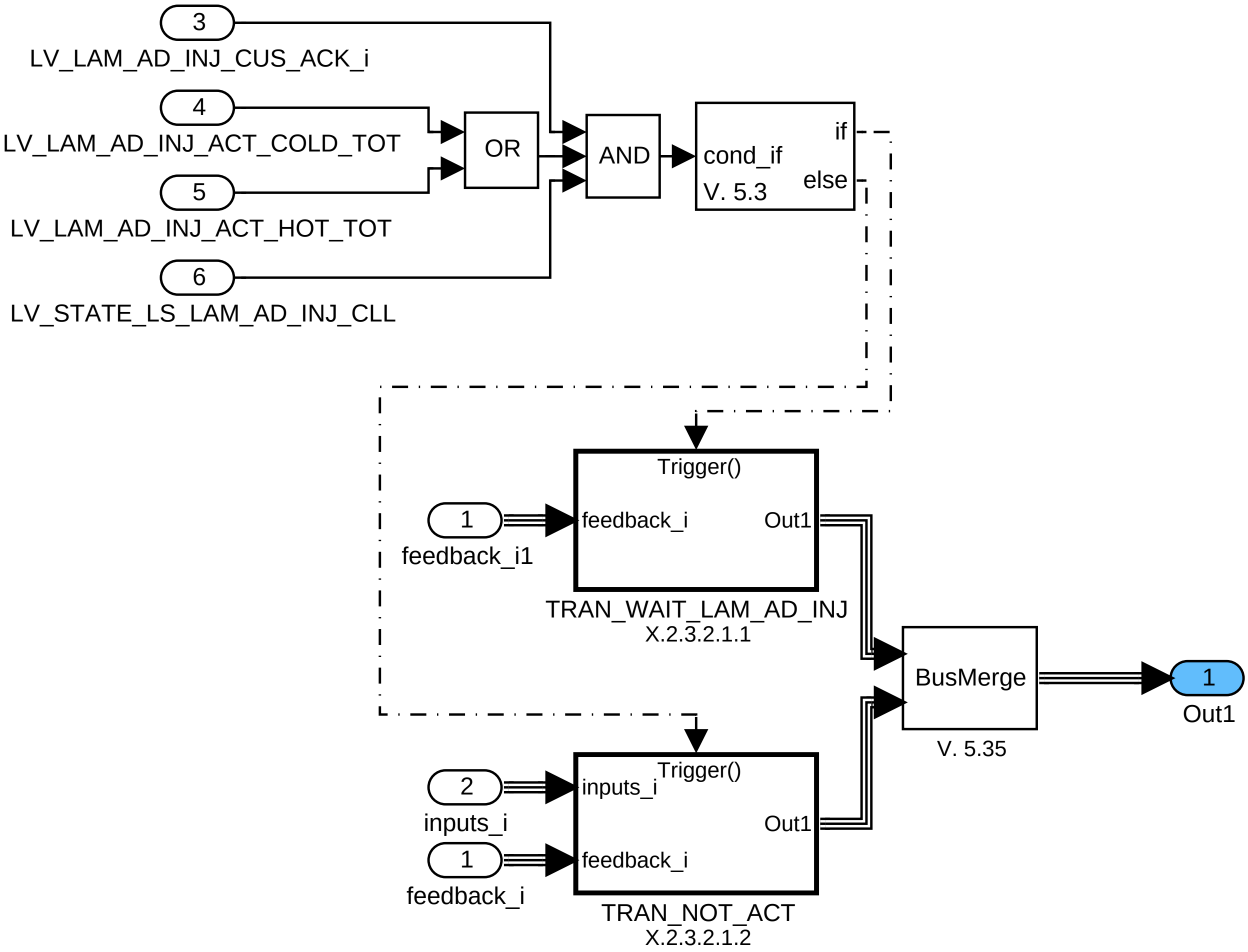

Figure 49:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC

49.3.2.2.2.1.1 Transition to WAIT_LAM_AD_INJ

49.3.2.2.2.1.1.1 Setting of LV_SNG/MPL_ACT

If the STATE_LAM_AD_INJ_ACT[i] is bigger than 2, multiple injections for this cylinder number are requested and therefore LV_MPL_INJ_ACT[i] is set. Otherwise LV_SNG_INJ_ACT[i] is set to enable the corresponding adaptation.

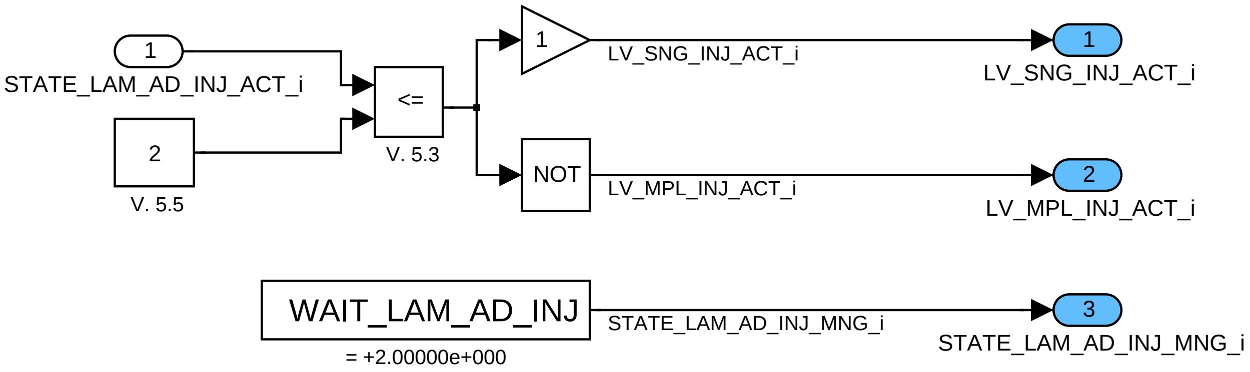

Figure 50:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC/TRAN_WAIT_LAM_AD_INJ/CLC

49.3.2.2.2.1.2 Transition to NOT_ACT due to interruption

49.3.2.2.2.1.2.1 Saving of the last completed phase number

If the adaptation is interrupted, the last completed adaptation phase number is stored in NR_PHA_LAM_AD_INJ_COLD/HOT[i], to make sure the adaptation is continued with the correct phase number if the conditions apply again and therefore all cylinders are adapted.

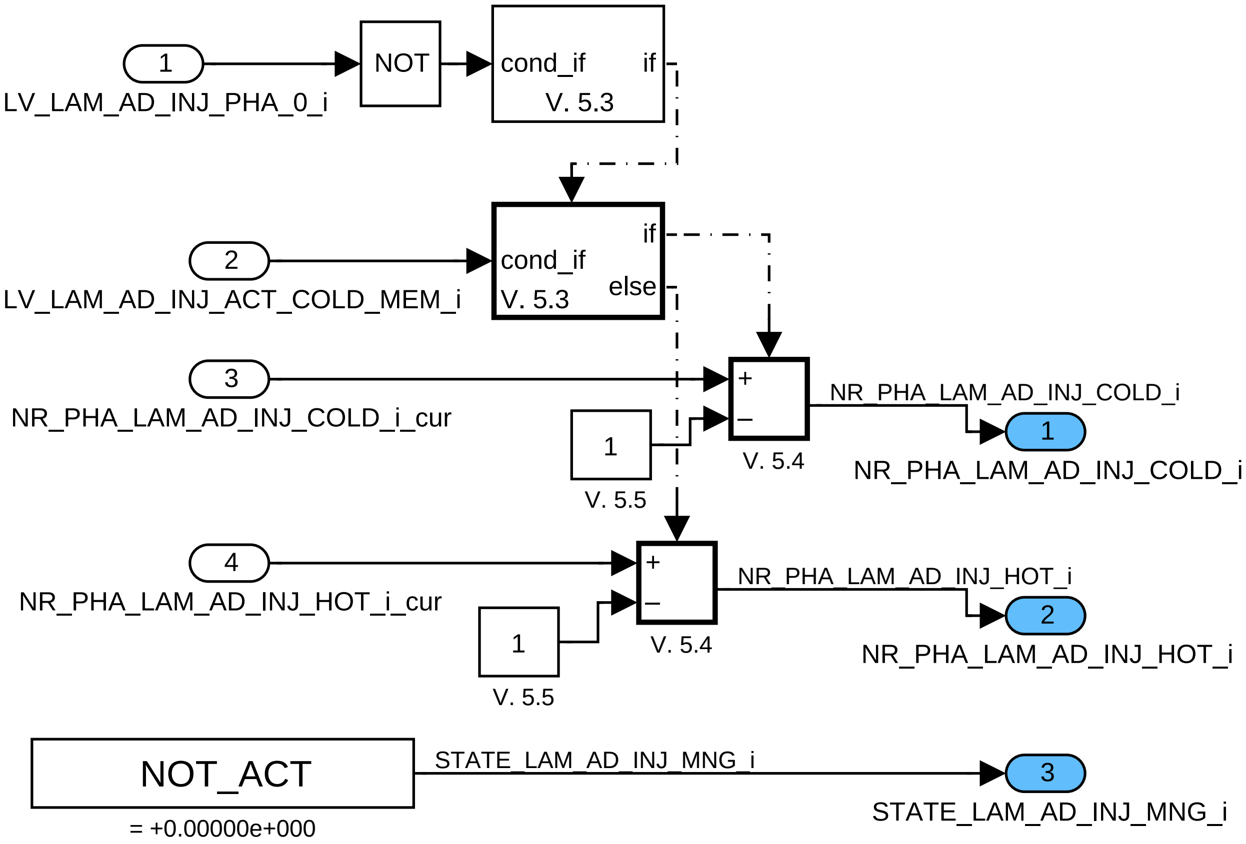

Figure 51:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/CLC_CYL_STATE/CLC/TRAN_NOT_ACT/CLC

49.3.2.2.3 WAIT_LAM_AD_INJ

This state waits for the current adaptation phase to be completed or the adaptation conditions to be stopped.

49.3.2.2.3.1 Transitions conditions

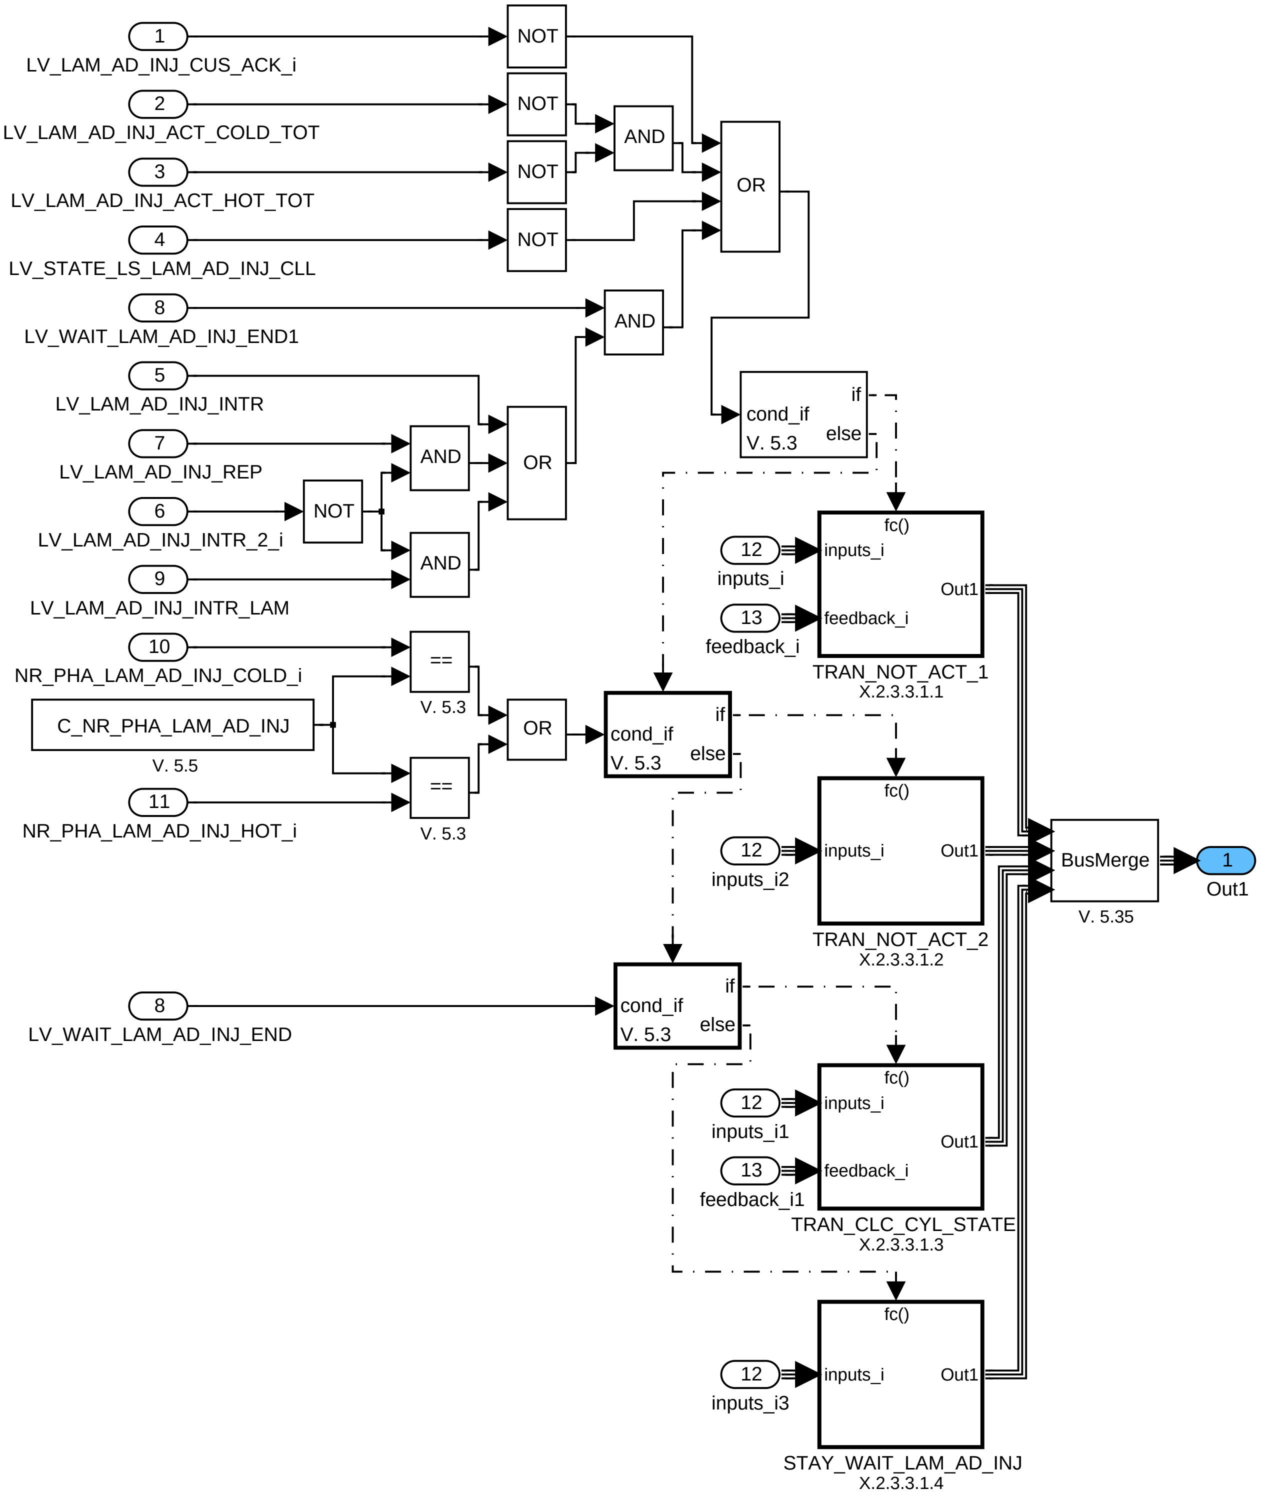

Figure 52:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC

49.3.2.2.3.1.1 Transition to NOT_ACT due to interruption

49.3.2.2.3.1.1.1 Saving of the last completed phase number

If the adaptation is interrupted, the last completed adaptation phase number is stored in NR_PHA_LAM_AD_INJ_COLD/HOT[i], to make sure the adaptation is continued with the correct phase number if the conditions apply again and therefore all cylinders are adapted. Furthermore the activation flags LV_SNG/MPL_ACT[i] are reset, to ensure that the current adaptation phase is stopped.

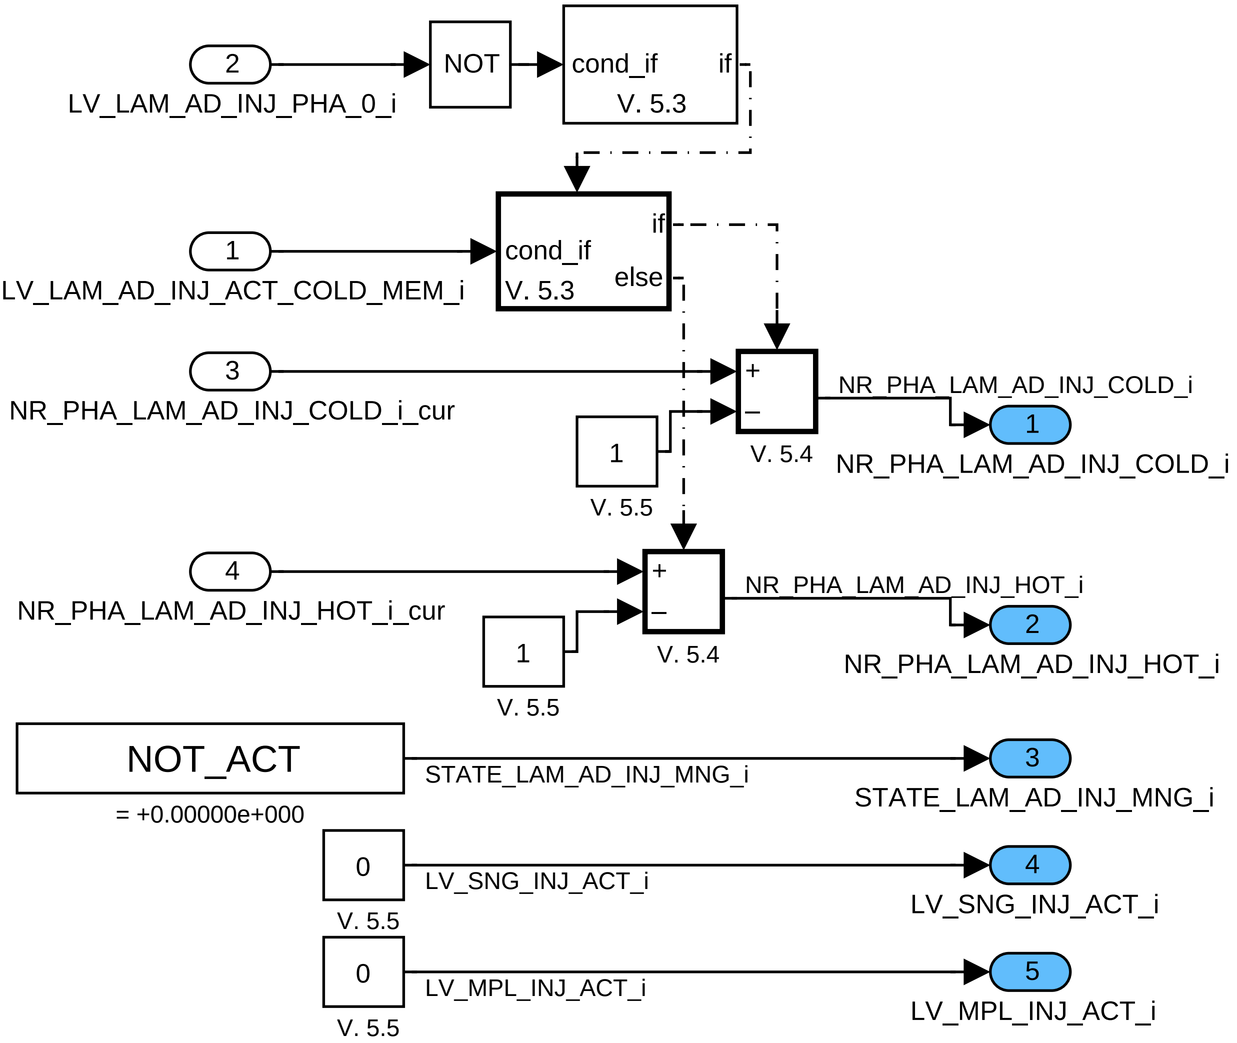

Figure 53:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_NOT_ACT_1/CLC

49.3.2.2.3.1.2 Transition to NOT_ACT due to finished adaptation

49.3.2.2.3.1.2.1 Setting of LV_LAM_AD_INJ_COLD/HOT_END

As the adaptation for the current temperature range is finished, the corresponding end-flag is set and the corresponding phase number NR_PHA_LAM_AD_INJ_COLD/HOT[i] is reset to 0. Therefore the adaptation starts from the beginning if the conditions apply for the next time.

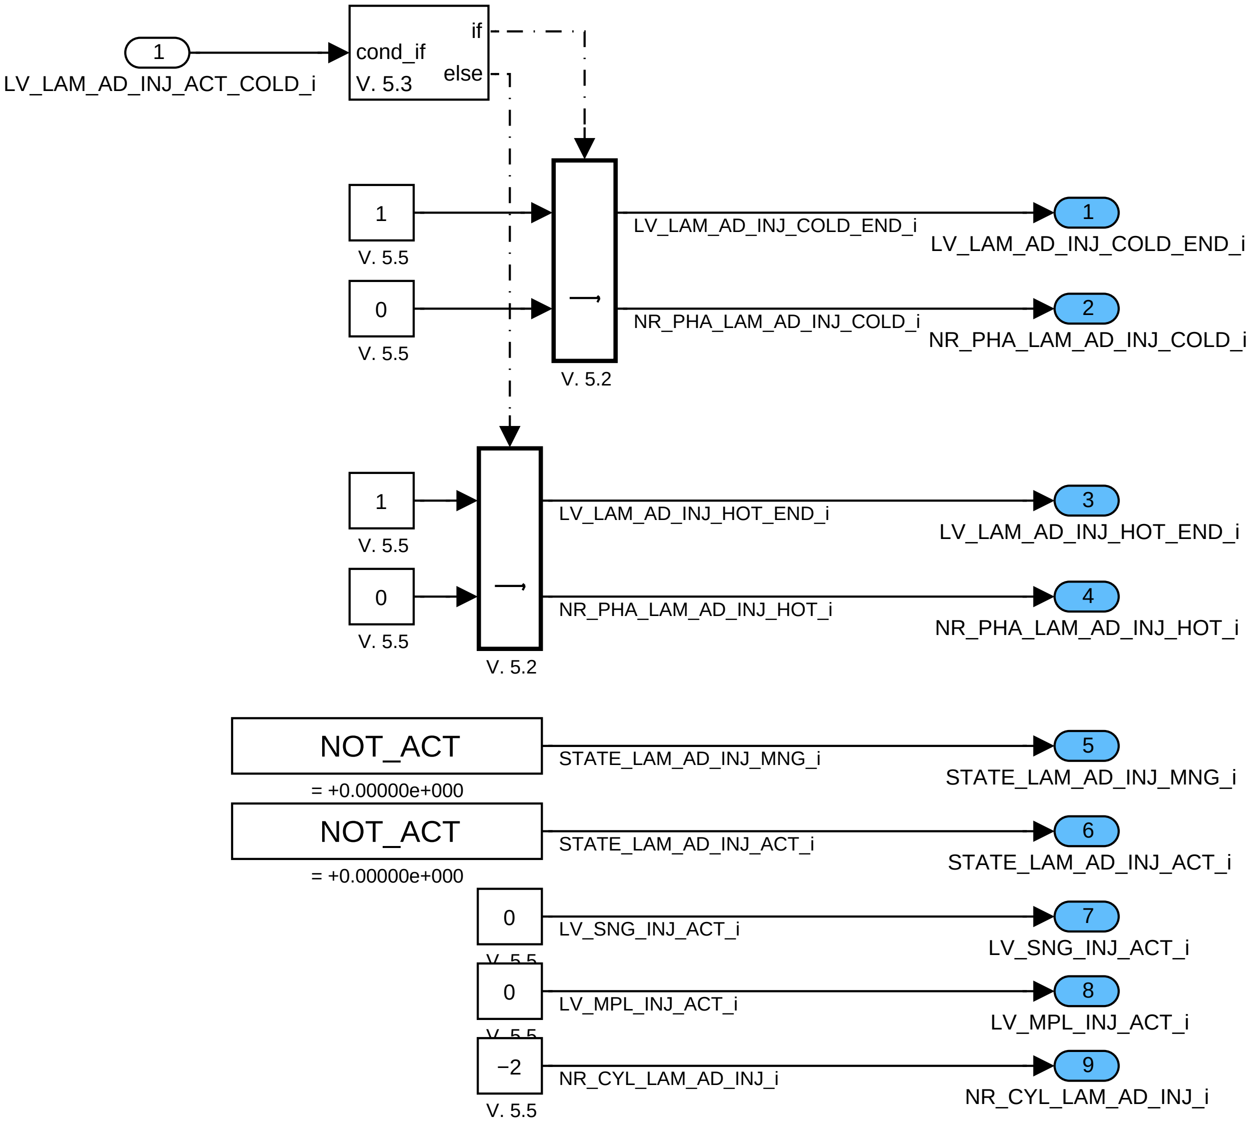

Figure 54:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_NOT_ACT_2/CLC

49.3.2.2.3.1.3 Transition to CLC_CYL_STATE

49.3.2.2.3.1.3.1 Determination of the injection mode for the next adaptation phase

The injection mode for the next adaptation phase is determined from the map ID_NR_CYL_LAM_AD_INJ[i] and requested via STATE_LAM_AD_INJ_ACT[i]. If multiple injections for one cylinder of the current bank is requested, the corresponding cylinder number is stored in NR_CYL_LAM_AD_INJ[i]. Otherwise -1 (single injection) or -2(end of adaptation) is used.

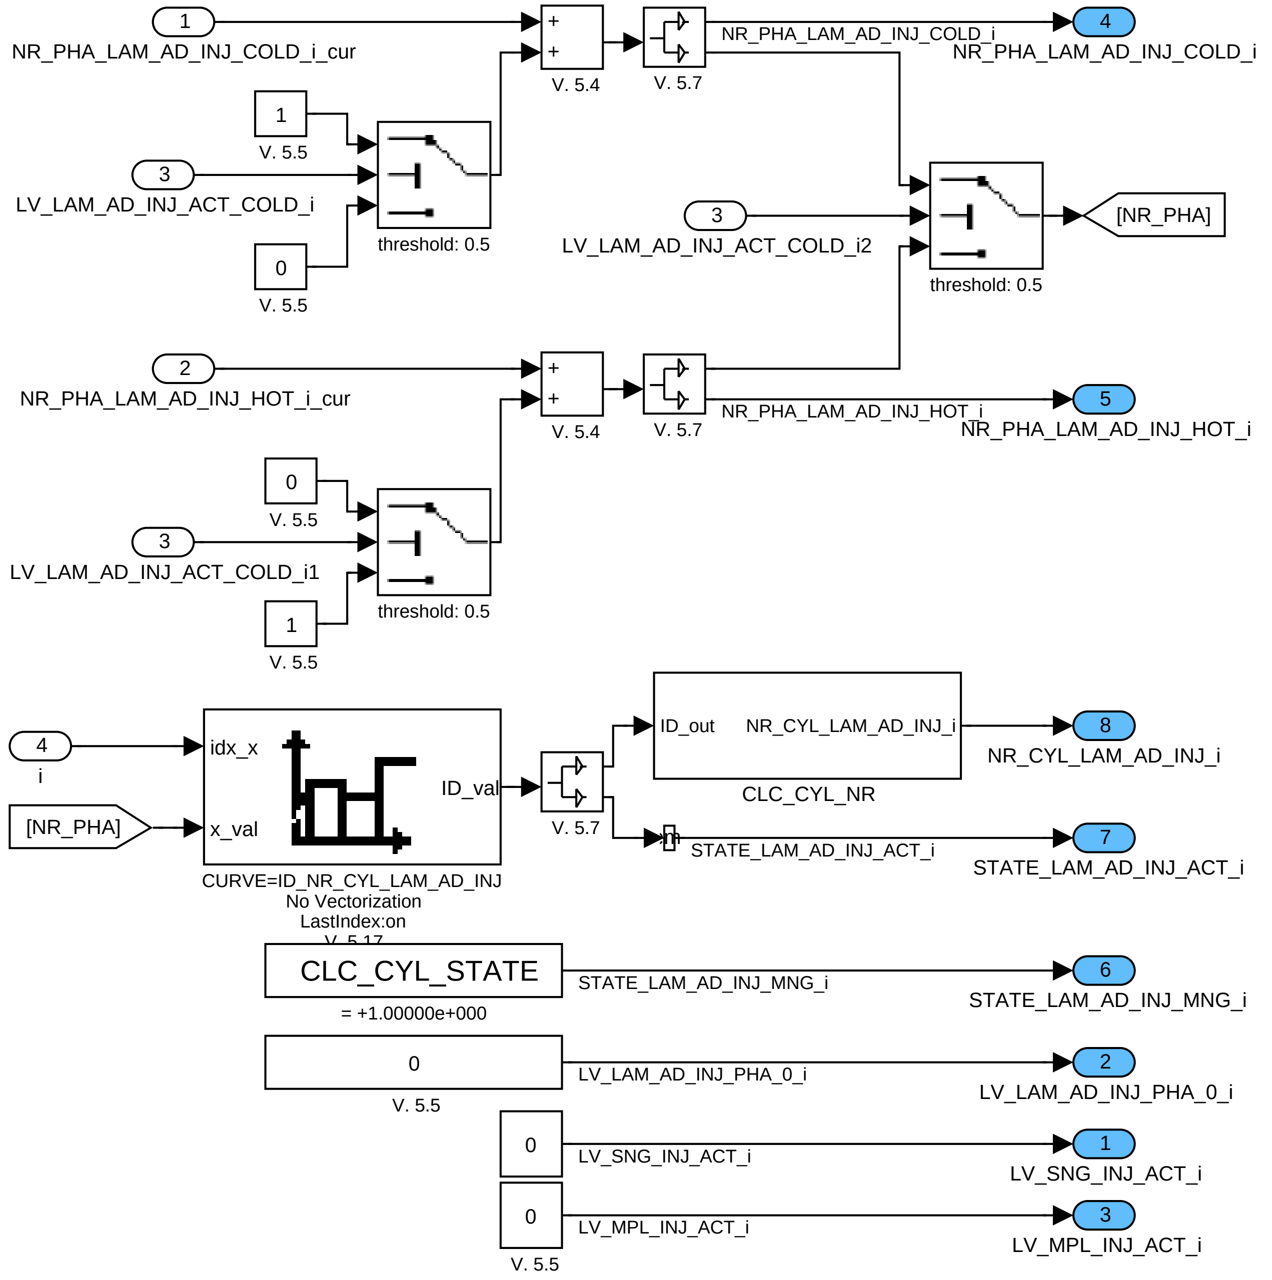

Figure 55:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_CLC_CYL_STATE/CLC_1

49.3.2.2.3.1.3.2 Cancelling of multiple injection due to misfire error

If the flag LV_ERR_MIS_LAM_AD_INJ[x] (where x denotes the current cylinder number) is set, i.e. a repeated misfire error is detected, the request for multiple injections is cancelled and another single injection phase will be started to continue with the adaptation of the other cylinders.

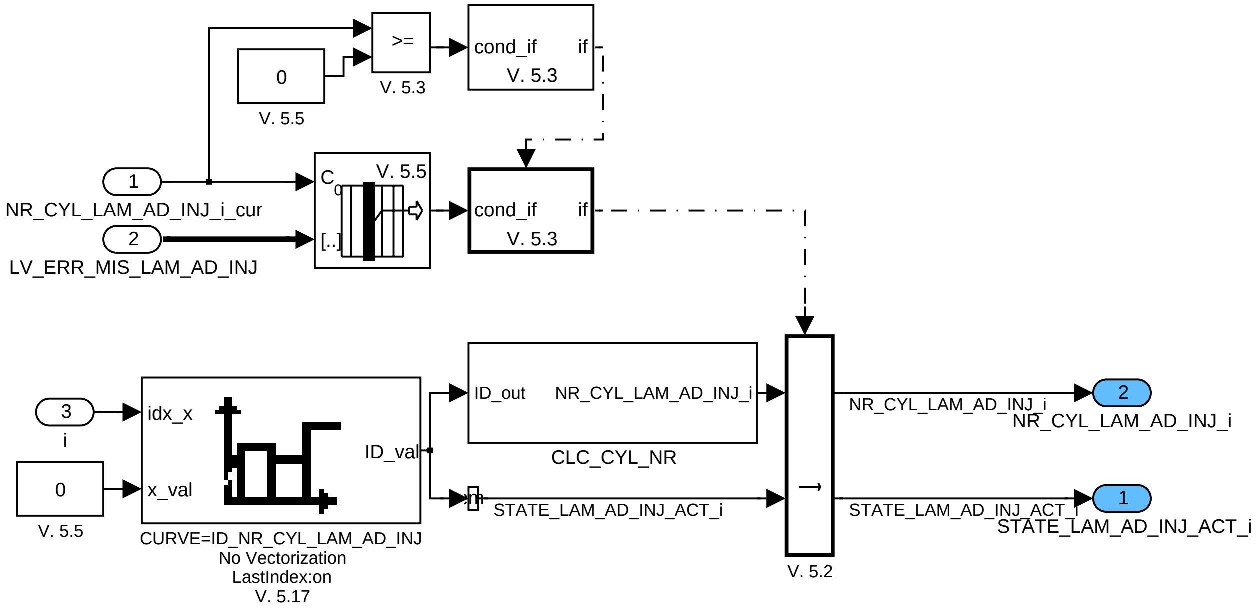

Figure 56:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/TRAN_CLC_CYL_STATE/CLC_2

49.3.2.2.3.1.4 Waiting for the end of the current adaptation cycle

49.3.2.2.3.1.4.1 Resetting of LV_SNG/MPL_INJ_ACT

If one bank signals the end of its adaptation phase (LV_LAM_AD_INJ_MV_CLC_END[i]), the corresponding activation flags LV_SNG/MPL_INJ_ACT[i] are reset. If the flag LV_LAM_AD_INJ_INTR_2[i] is set, repeated misfire is detected on the current cylinder and therefore single injection is requested.

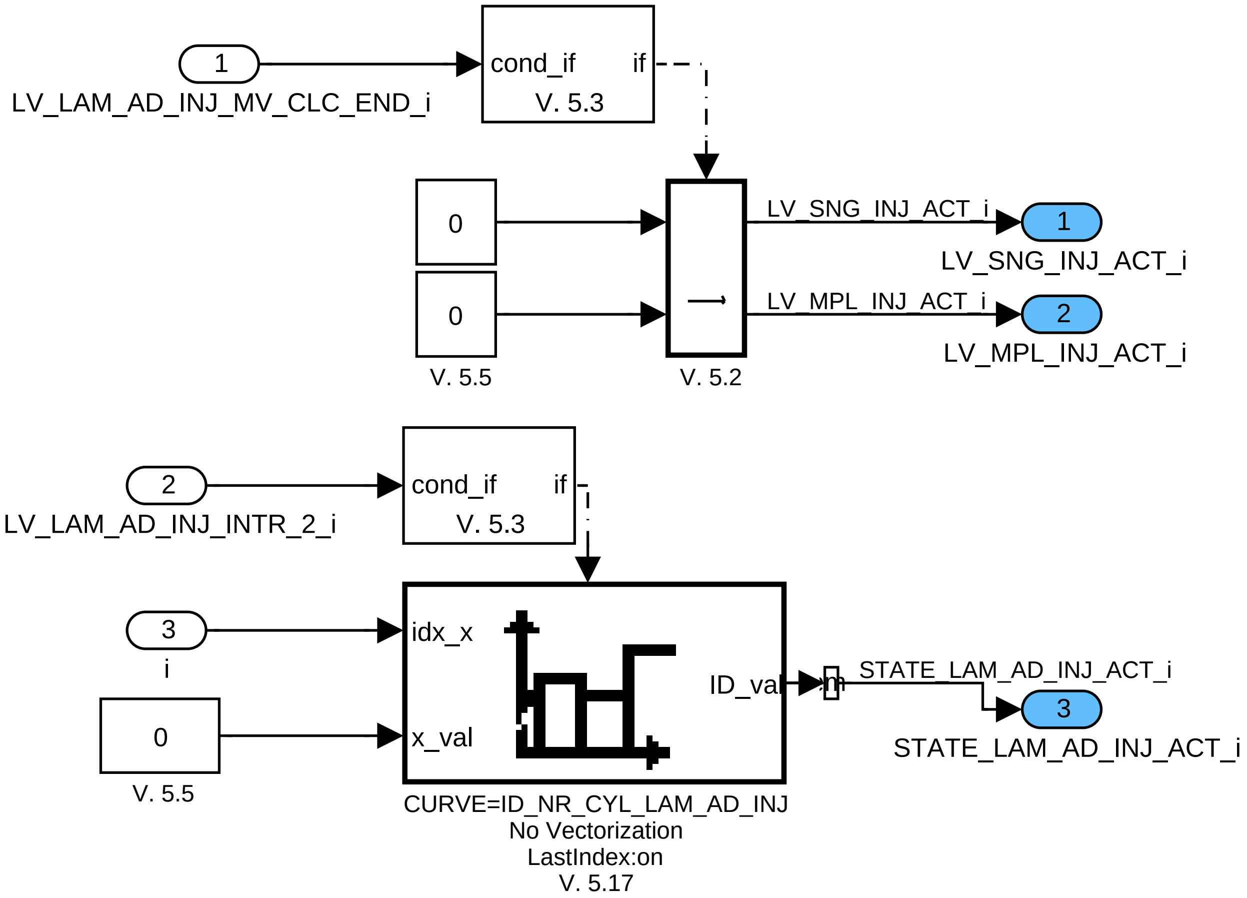

Figure 57:
Path: MFMA_REQCOAIMM0/OPM/STATE_MNG/WAIT_LAM_AD_INJ/CLC/STAY_WAIT_LAM_AD_INJ/CLC

49.3.3 Operations at transition engine stop to engine run

49.3.3.1 Resetting of the phase numbers

If a resetting of the NVMY data via service tester is requested with the flag LV_LAM_AD_INJ_CLR_AD_EXT, the phase numbers of both banks for the upper and lower temperature range are reset to 0.

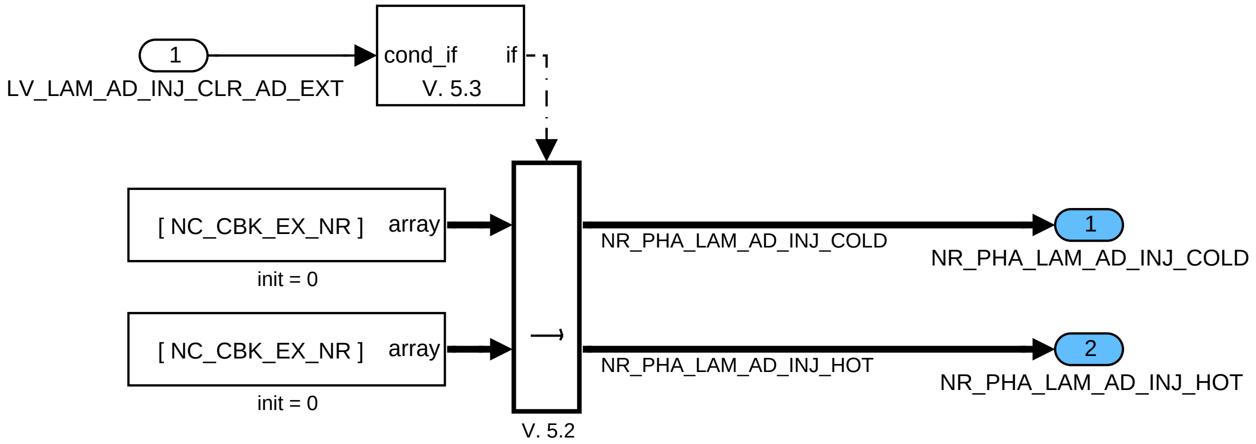

Figure 58:
Path: MFMA_REQCOAIMM0/ES2ERU/CLC

Figure 59:
Path: MFMA_ISPCLAIMI0

49.4.1 Initialization

The inhibition flag is initialized at reset and at ignition key on.

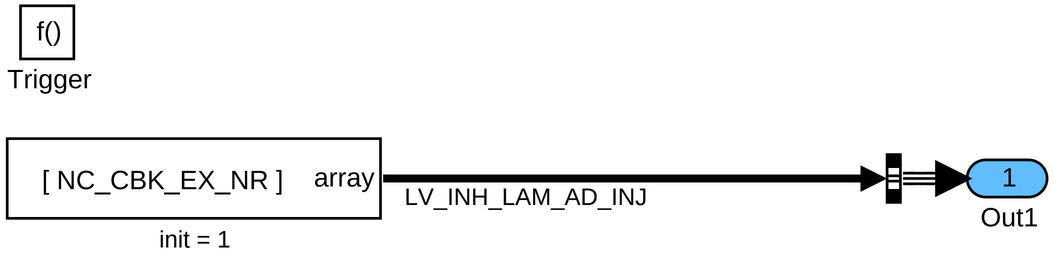

Figure 60:
Path: MFMA_ISPCLAIMI0/INI

49.4.2 Inhibition conditions calculation

The inhibition conditions calculation is divided into two parts. The first part consists of conditions, which do not depend on a specific exhaust cylinder bank, and therefore any of the conditions will inhibit the adaptation of all banks. The second part consists only of conditions, which depend on a specific bank and will inhibit only the adaptation on the corresponding bank.

49.4.2.1 Bank independent conditions

The bank independent conditions are also split in two parts, where the first part uses all scalar conditions/error flags and the second part uses the non-scalar (array) conditions.

49.4.2.1.1 Scalar conditions

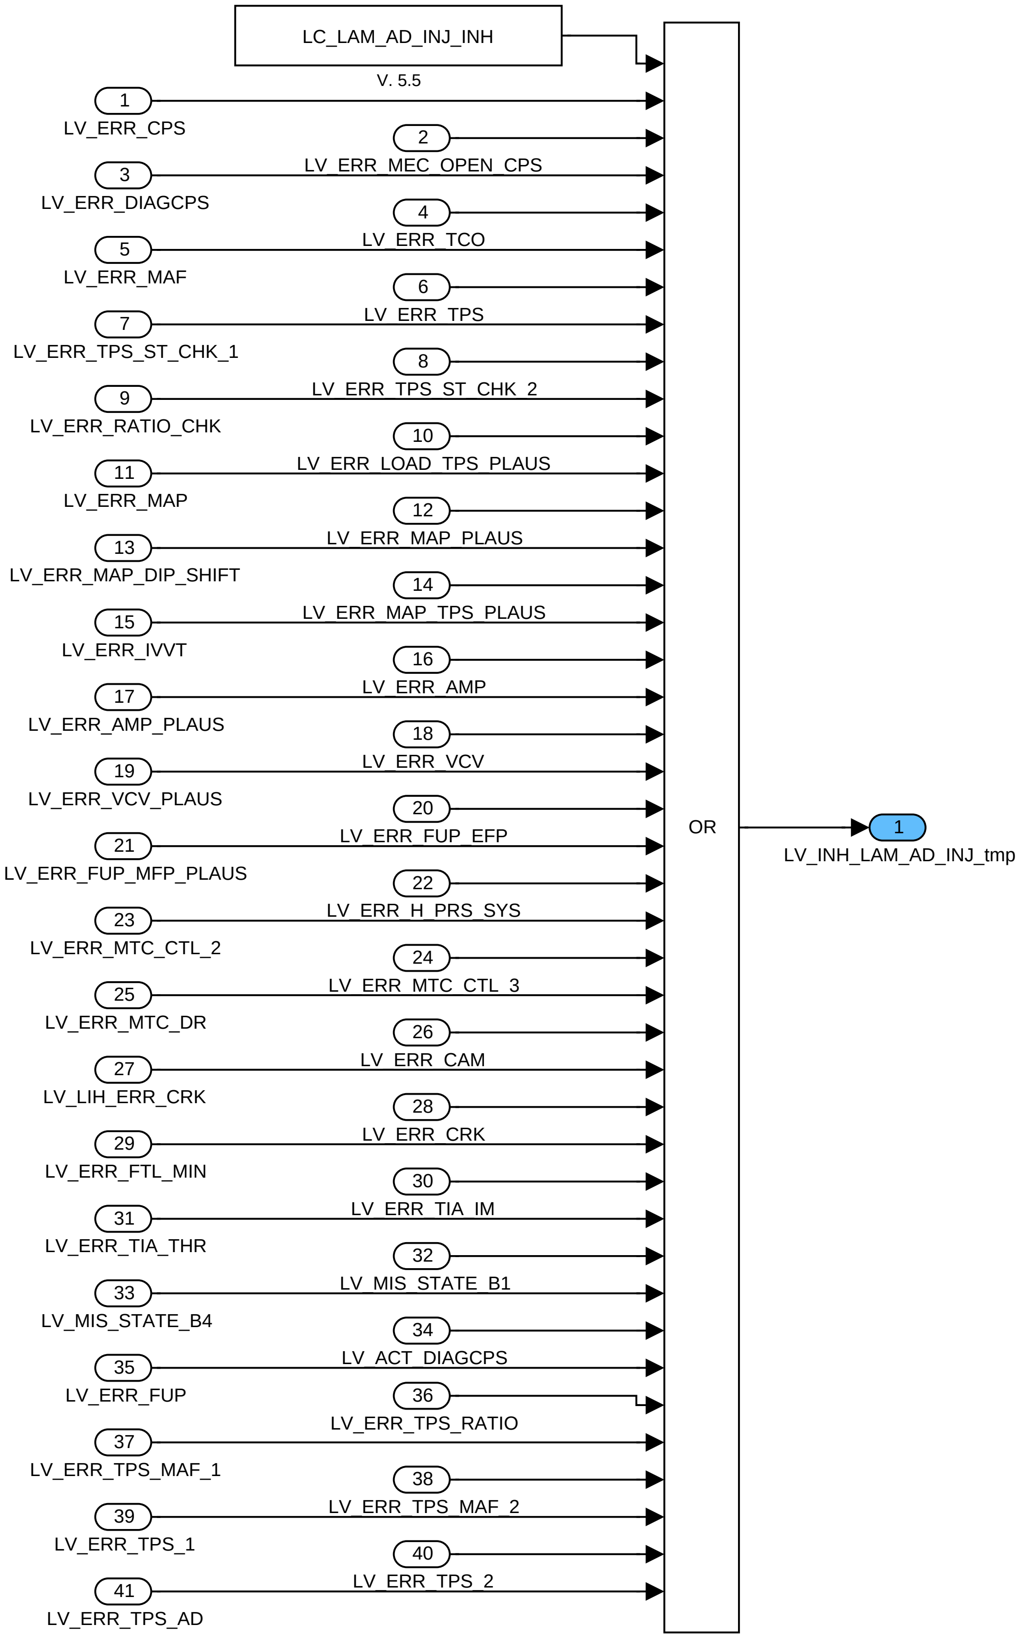

Figure 61:
Path: MFMA_ISPCLAIMI0/OPM_20MS/BANK_INDEP_CLC/CLC_1

49.4.2.1.2 Non-scalar conditions

In this block the all conditions whose dimension can be bigger than 1 are used for the calculation of the inhibition flag. The OR-blocks with only one input return true of at least one index of the array is set to 1.

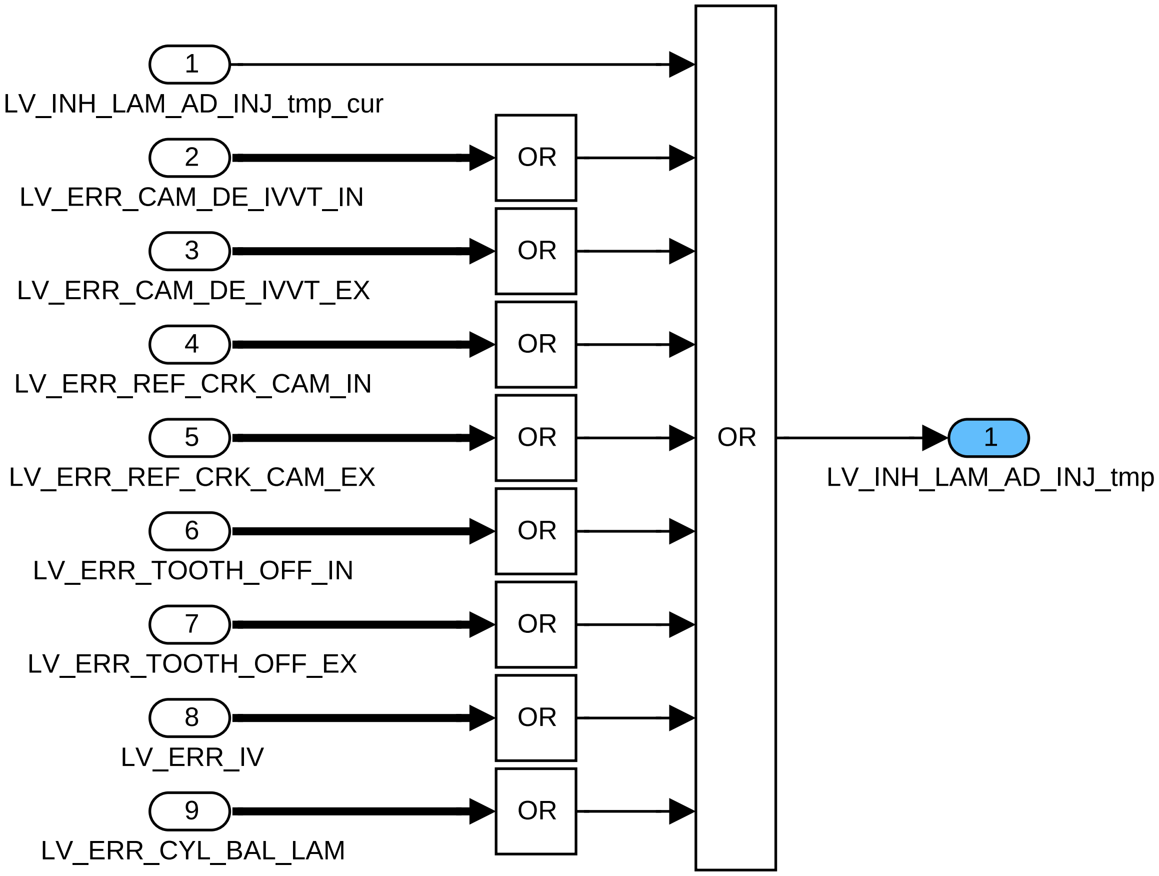

Figure 62:
Path: MFMA_ISPCLAIMI0/OPM_20MS/BANK_INDEP_CLC/CLC_2

49.4.2.2 Bank specific calculations

The bank specific calculations are done for every exhaust cylinder bank (1...NC_CBK_EX_NR). The index of the current cylinder bank is denoted with the suffix _i in the model whereas in the text square brackets are used (e.g. LV_INH_LAM_AD_INJ[i]).

49.4.2.2.1 Bank selective inhibition conditions

If one of the bank selective conditions applies, only the adaptation of the corresponding bank is inhibited. If LV_INH_LAM_AD_INJ_tmp (bank independent condition) is set, both banks will be inhibited.

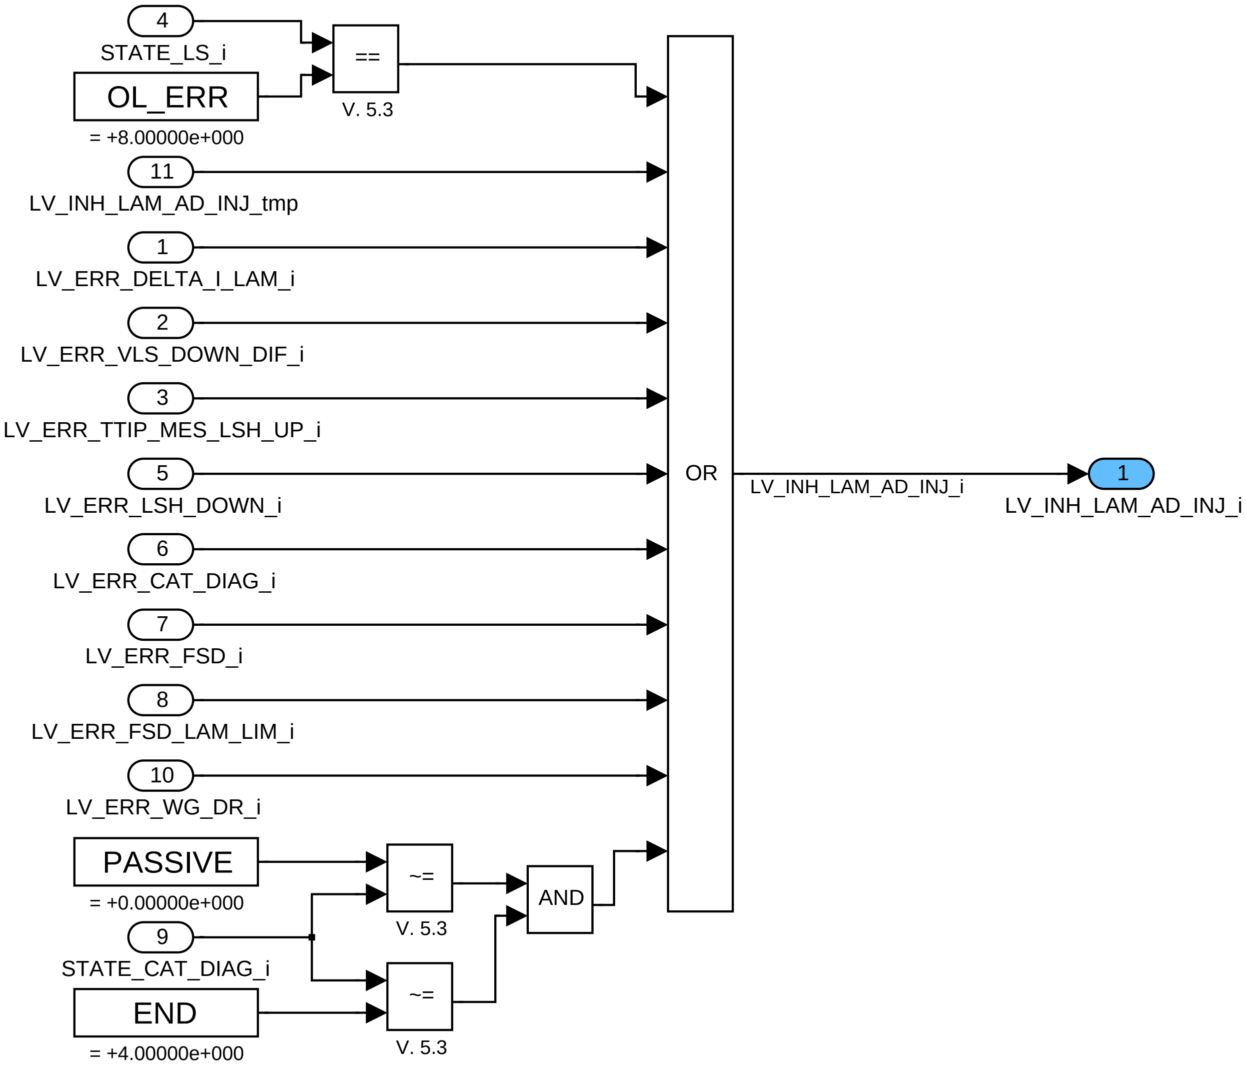

Figure 63:
Path: MFMA_ISPCLAIMI0/OPM_20MS/BANK_SPECIFIC_CLC/CLC

49.5 Lambda adaptation via injection mode

Output Data:

ACTION_MFMA_GetEnableCondition(**OUT** <PRM_LV_LAM_AD_INJ_EXT_ENA>)

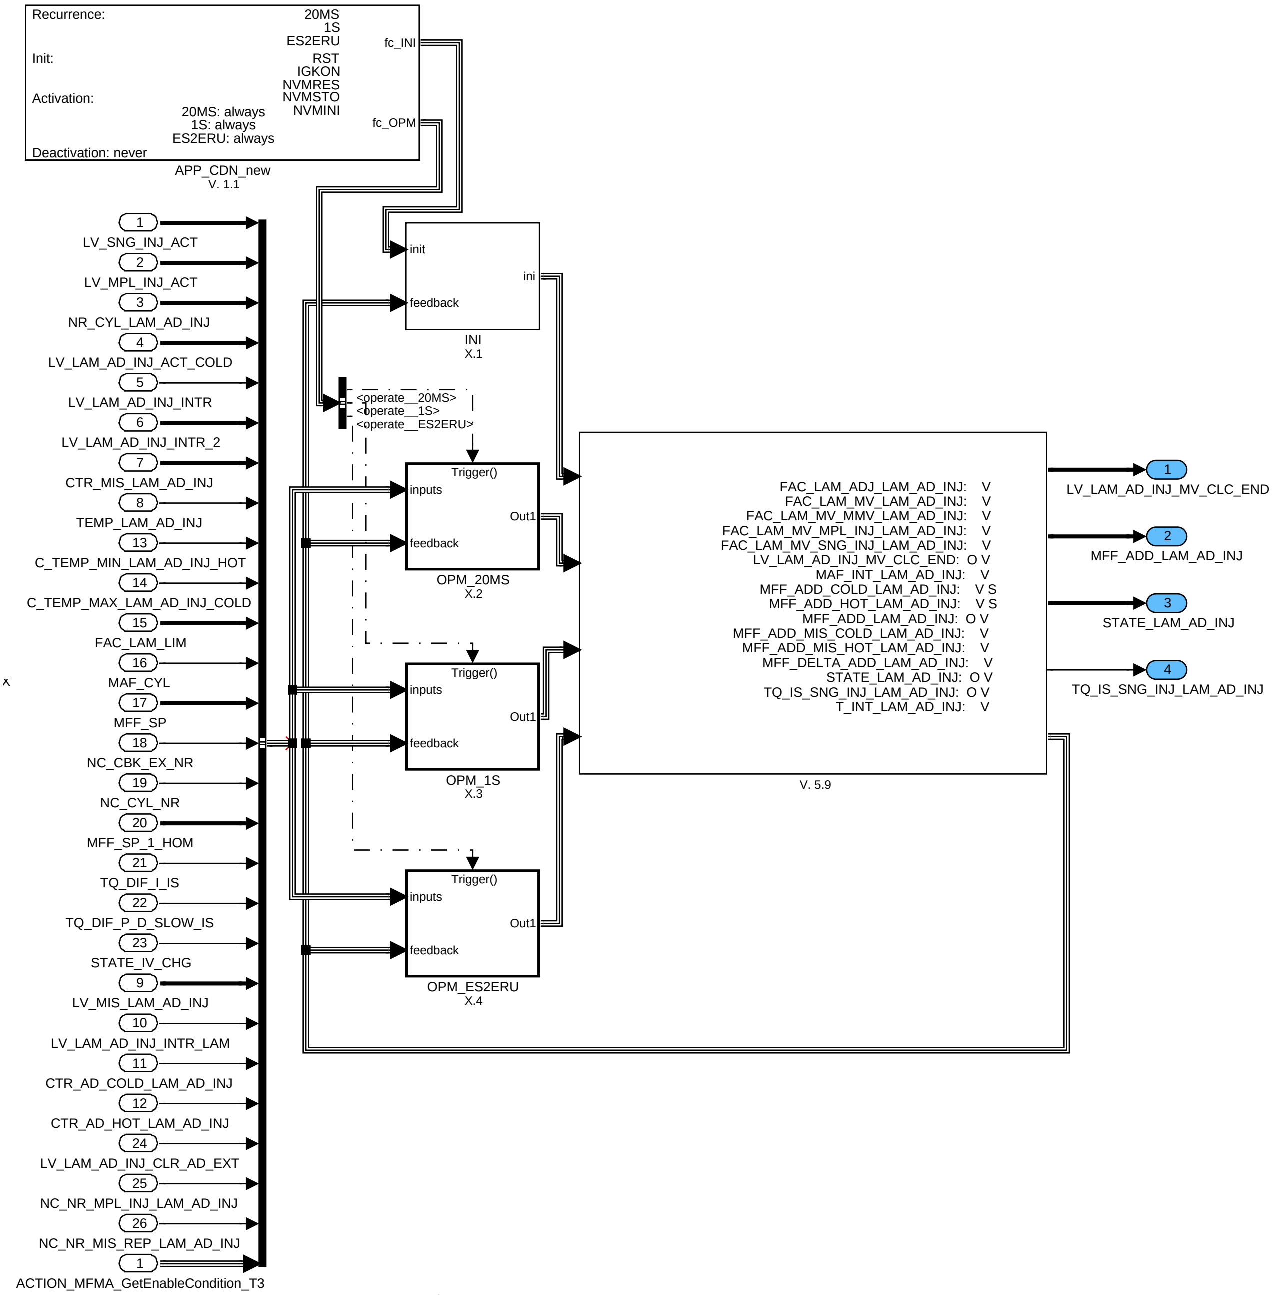
General Information

The adaptation of the additional fuel mass at minimum fuel mass injection is divided in a time slice with single injection and with multiple injections. At the beginning of each phase a certain time is waited in a transient phase for system stabilization. In a second phase the lambda mean value is calculated. At the end of the phase with multiple injections, the additional fuel at minimum injection is calculated from the lambda controller output difference of the single and multiple injection phase.

Application Conditions

Initialization: RST, IGKON, NVMRES, NVMSTO, NVMINI
Activation: 20MS: always
1S: always
ES2ERU: always
Deactivation: never

Function description



SDA_SRS / SDA V 5.0.4 30−Oct−2006

Figure 64:
Path: MFMA_ISPCLAIM0

49.5.1 Initialization and NVMY management

49.5.1.1 Initialization at RST and IGKON

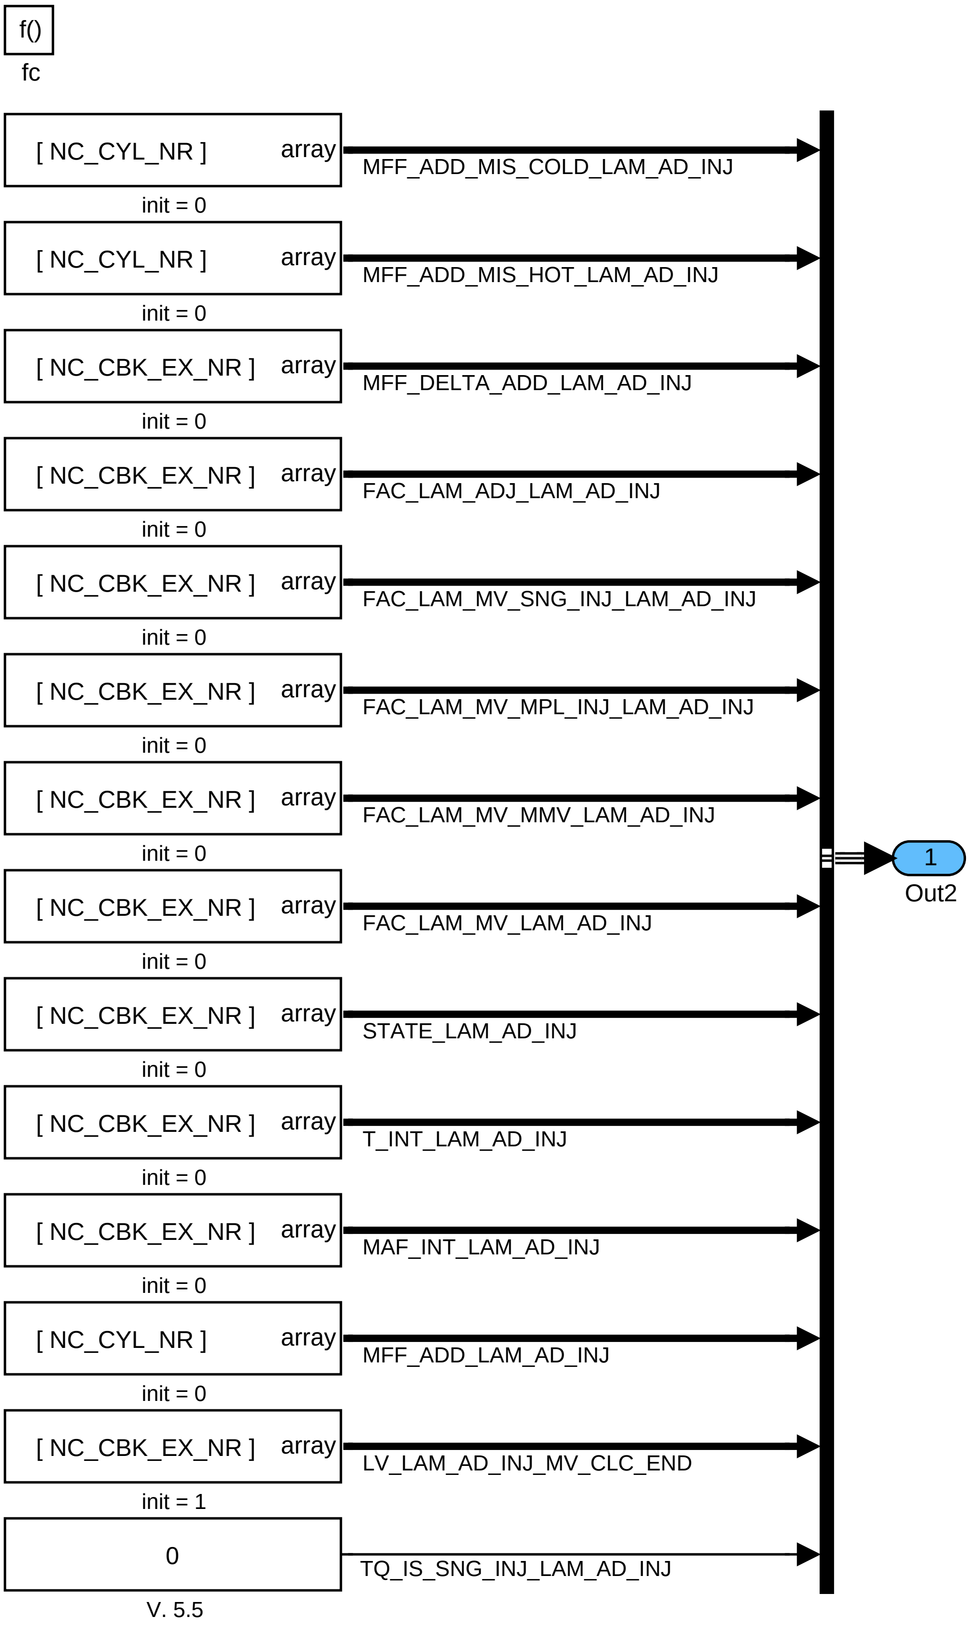


Figure 65:
Path: MFMA_ISPCLAIM0/INI/RST_IGKON

49.5.1.2 Initialization and reading of NVMY values

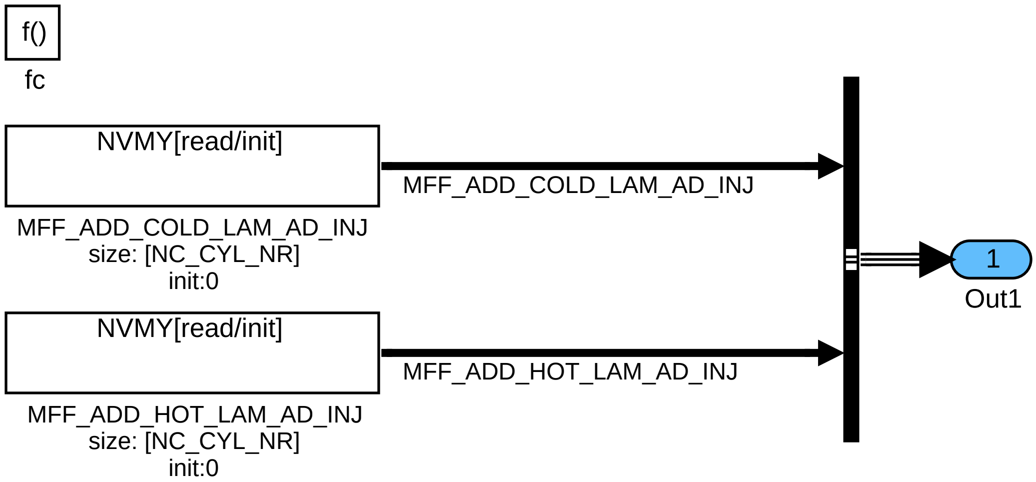

Figure 66:
Path: MFMA_ISPCLAIM0/INI/NVMINI_NVMRES

49.5.1.3 Writing of the NVMY values

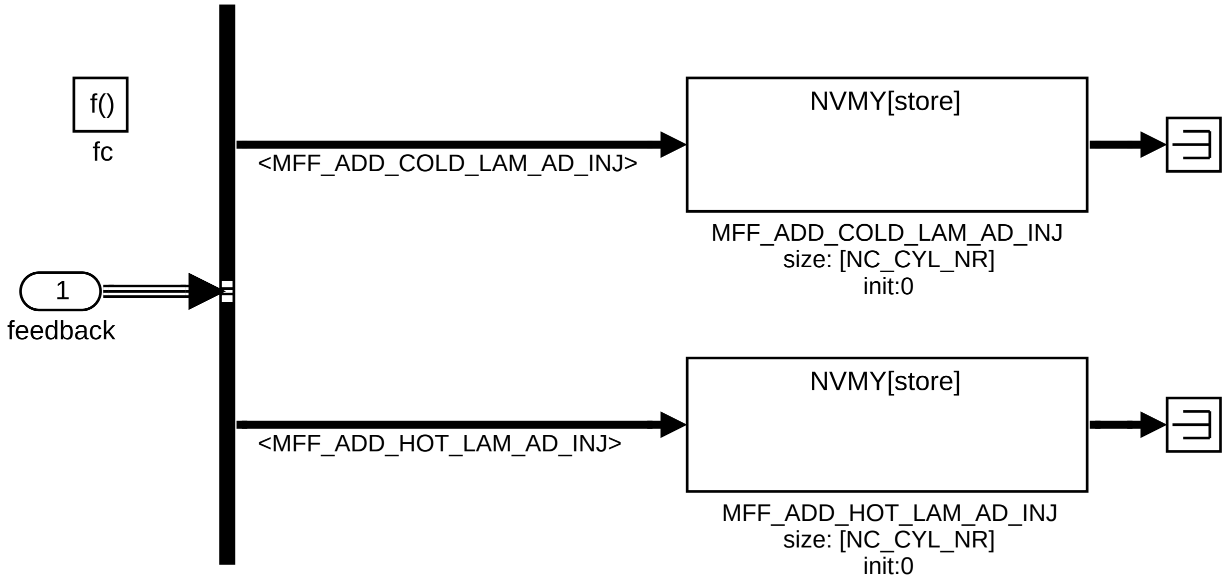

Figure 67:
Path: MFMA_ISPCLAIM0/INI/NVMSTO

49.5.2 20ms operations

All calculations are done for each exhaust cylinder bank, where the bank specific values are denoted within the graphical model with the suffix _i, in the textual description they are referenced via [i].

49.5.2.1 State machine and general calculations

Calculation of state transitions, state actions and general calculations.

49.5.2.1.1 State transitions

49.5.2.1.1.1 State selection

49.5.2.1.1.1.1 NOT_ACT

If the next adaptation cycle starts (either with single or multiple injections), the state is left towards TRA_PHA.

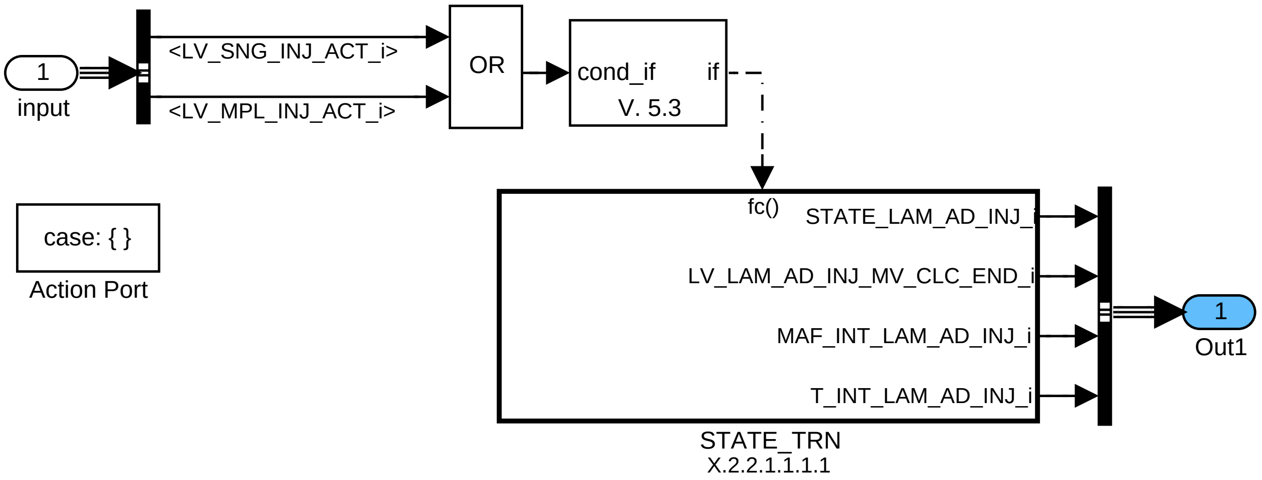

Figure 68:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/NOT_ACT

49.5.2.1.1.1.1.1 Transition to TRA_PHA

On the transition to TRA_PHA the MAF and time integrals are set to 0 and furthermore the end flag used in the manager module is reset.

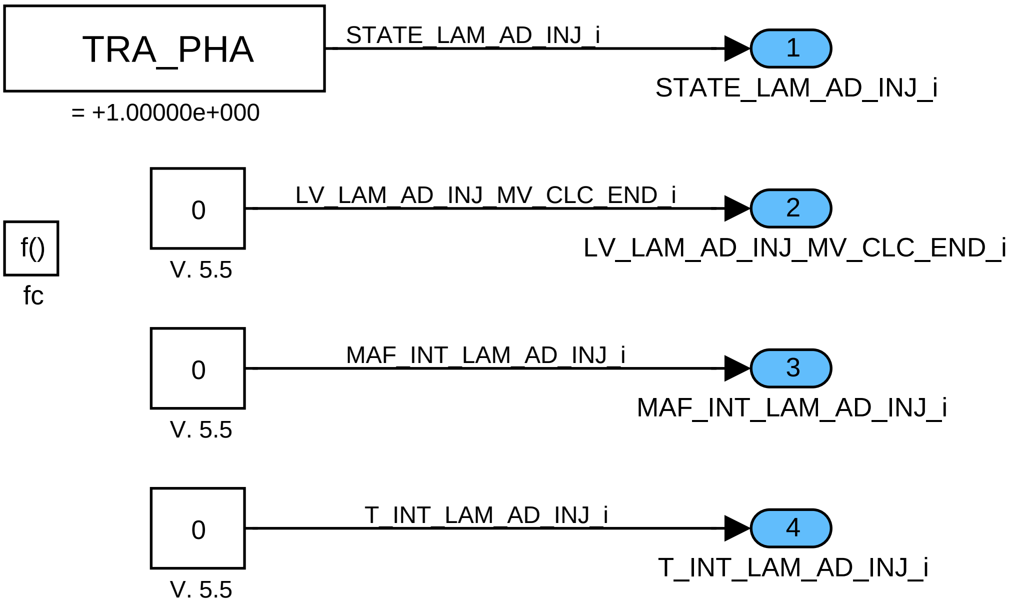

Figure 69:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/NOT_ACT/STATE_TRN

49.5.2.1.1.1.2 TRA_PHA

The state TRA_PHA is usually left towards MV_CLC, but if the adaptation is interrupted, the state will change back to NOT_ACT.

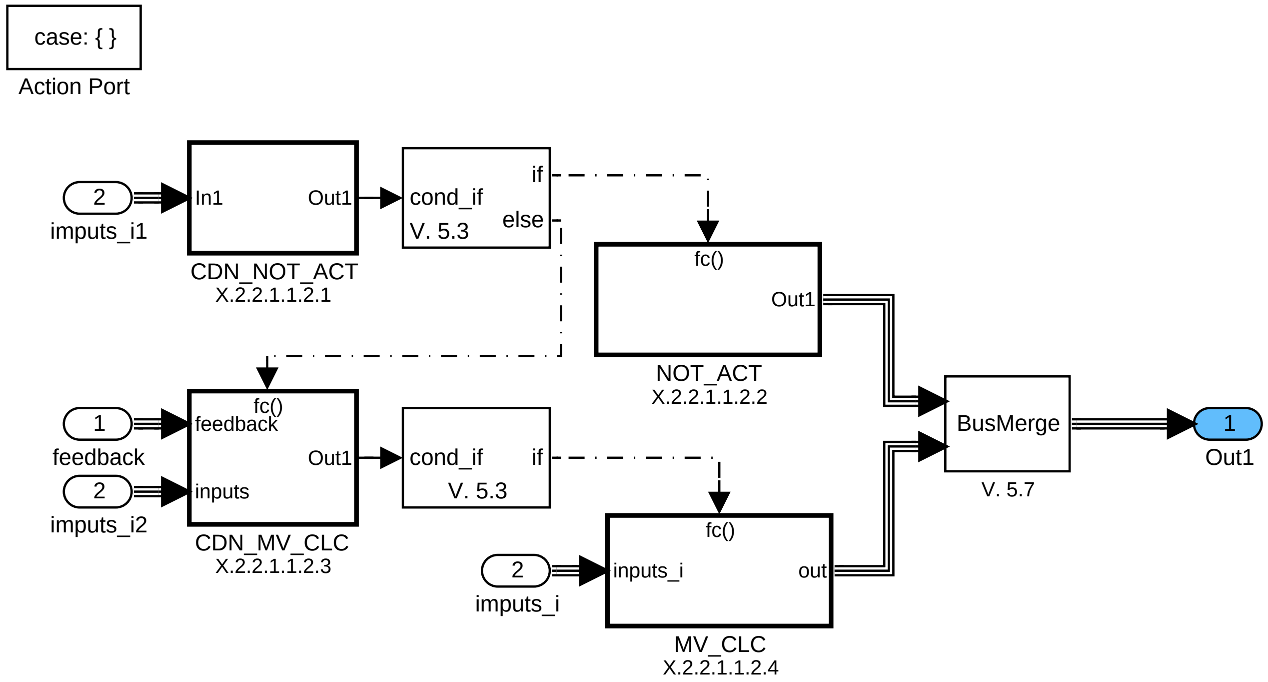

Figure 70:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA

49.5.2.1.1.1.2.1 Conditions for NOT_ACT

If none of the flags LV_SNG/MPL_INJ_ACT is set, the state is left towards NOT_ACT.

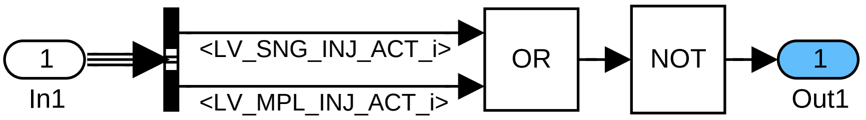

Figure 71:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/CDN_NOT_ACT

49.5.2.1.1.1.2.2 Transition to NOT_ACT

Figure 72:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/NOT_ACT

49.5.2.1.1.1.2.3 Conditions for MV_CLC

If the MAF and time integrals have reached a threshold and if the lambda controller output has stabilized, the state is left towards MV_CLC. Furthermore this transition is done if misfire is detected or the lambda controller had reached its limitations.

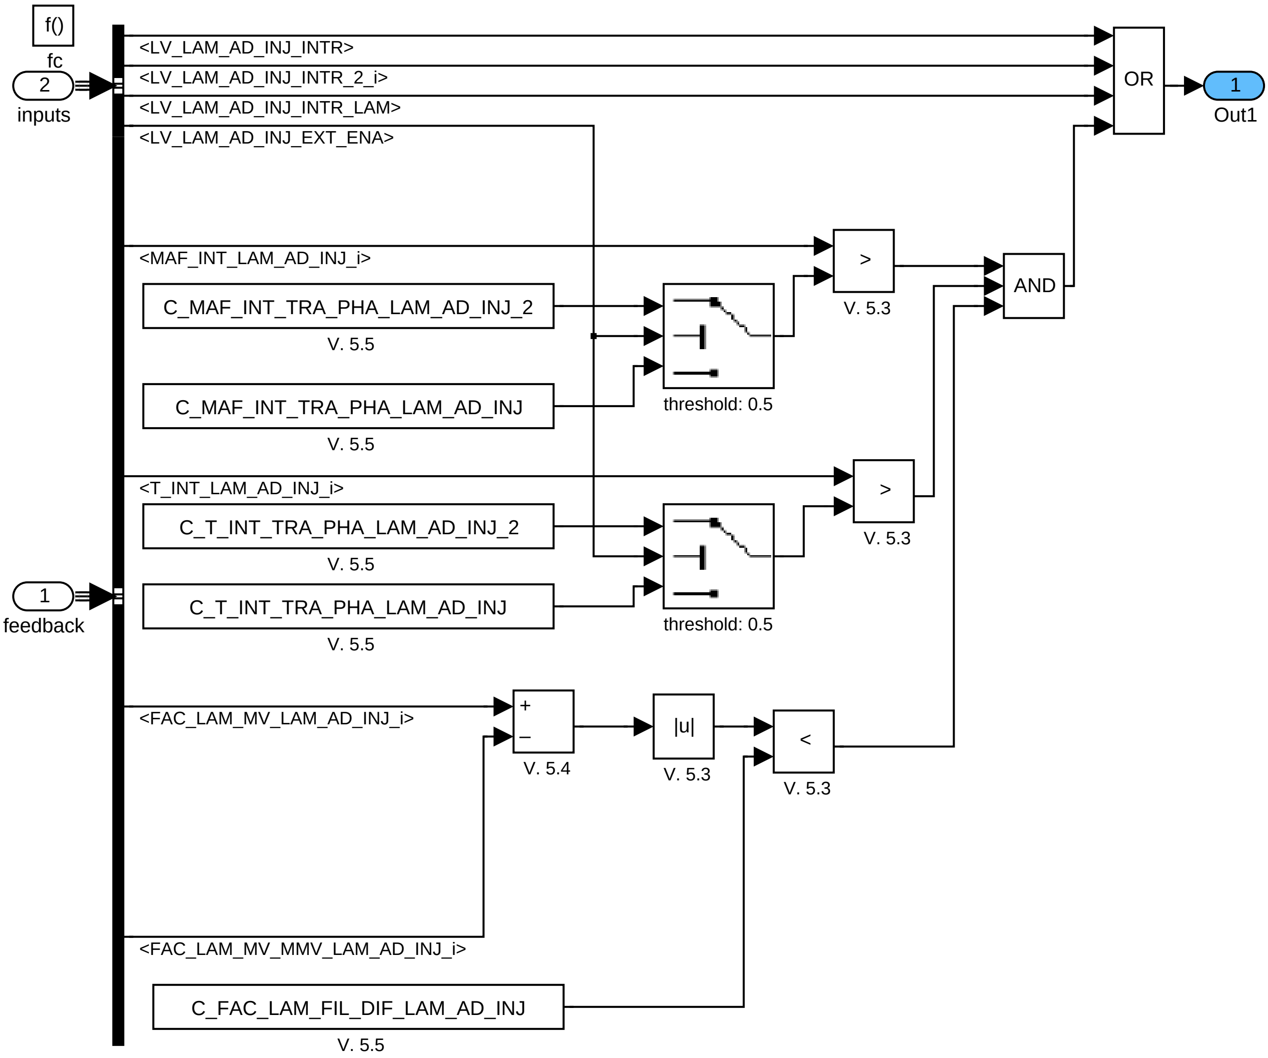

Figure 73:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/CDN_MV_CLC

49.5.2.1.1.1.2.4 Transition to MV_CLC

On transition to MV_CLC the MAF and time integrals are reset.

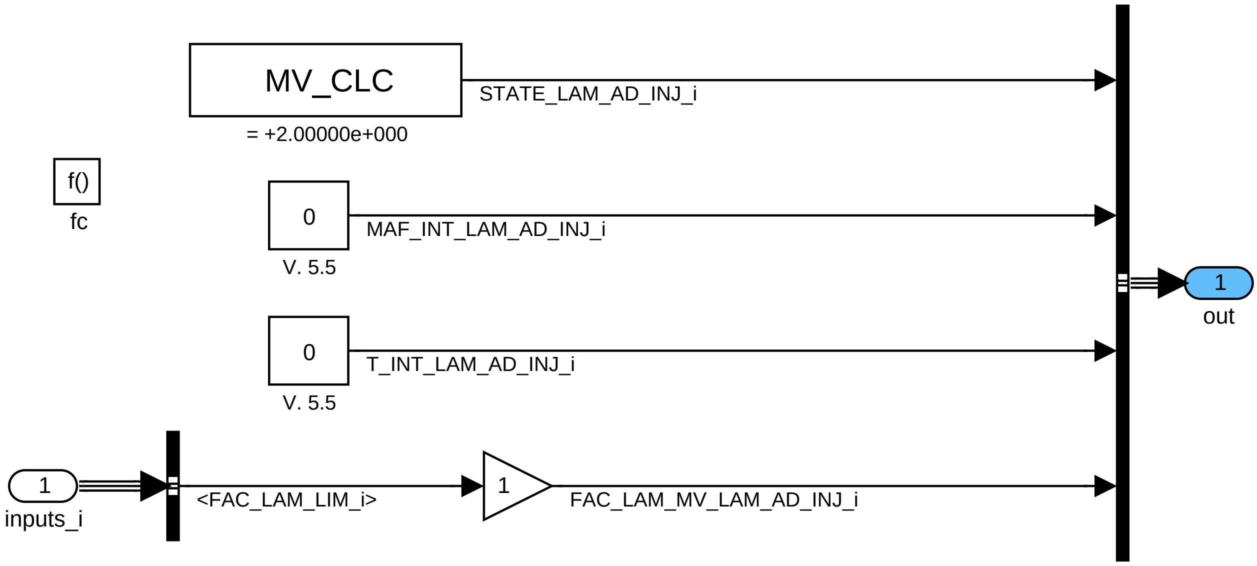

Figure 74:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/TRA_PHA/MV_CLC

49.5.2.1.1.1.3 MV_CLC

The state MV_CLC is usually left towards NOT_ACT after a single injection adaptation phase or due to interruption, and towards LAM_AD after a multiple injection adaptation phase.

49.5.2.1.1.1.3.1 Interruption of the mean-value calculation

If neither single nor multiple injection adaptation is allowed anymore, the state is left towards NOT_ACT.

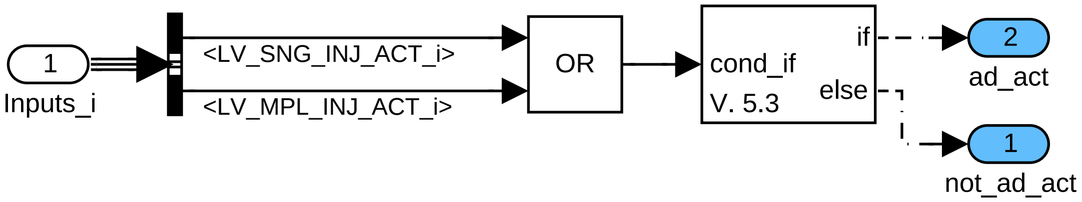

Figure 75:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/CDN_AD_ACT

49.5.2.1.1.1.3.2 Conditions for normal end of MV_CLC

If the MAF and time integrals reach a threshold, the state is left to NOT_ACT after single injections and to LAM_AD after multiple injections. If misfire is detected or the lambda controller had reached its limitations, the state is also left immediately.

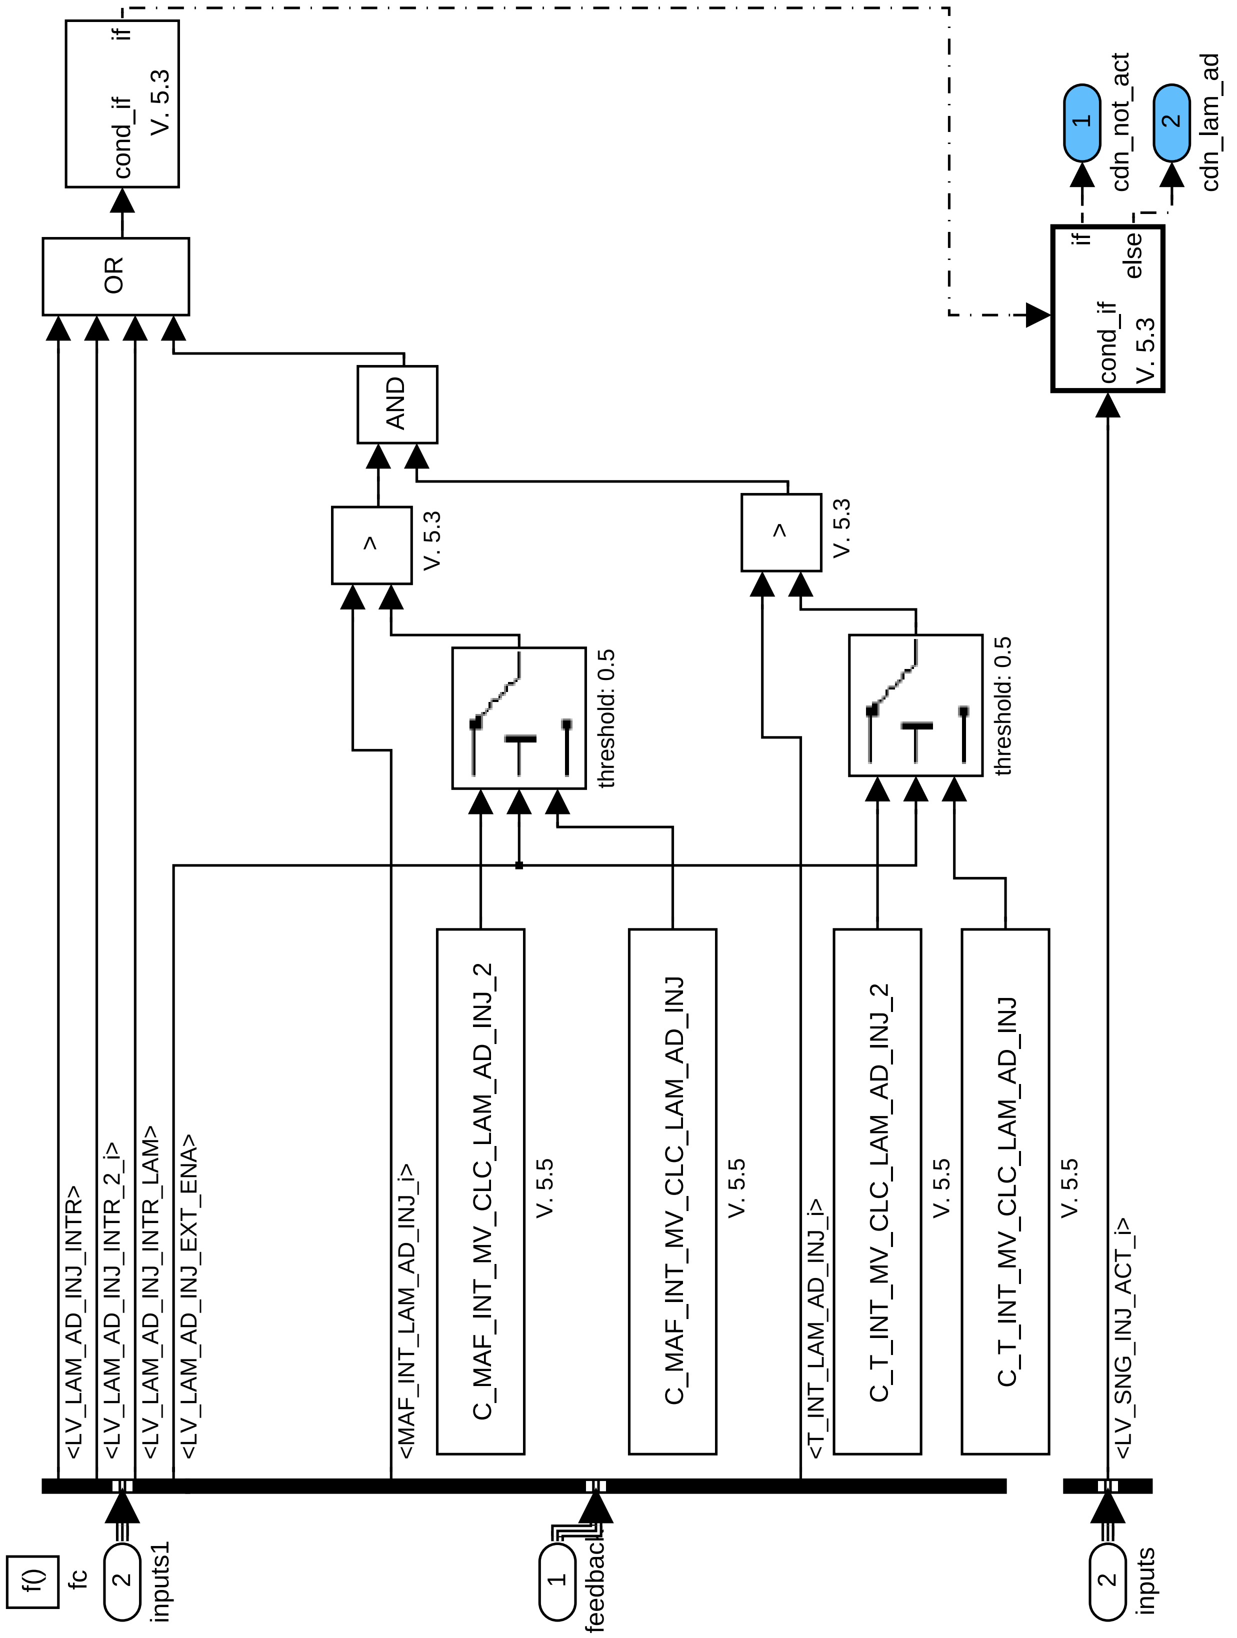

Figure 76:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/CDN_INT_MAX

49.5.2.1.1.1.3.3 Transition to NOT_ACT due to interruption

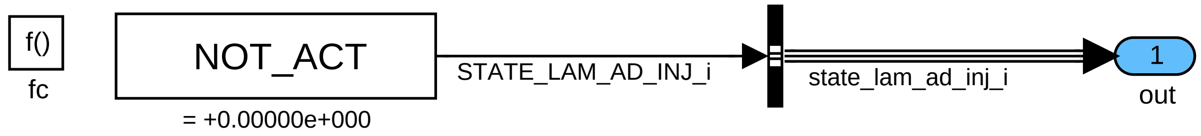

Figure 77:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/NOT_ACT_1

49.5.2.1.1.1.3.4 Transition to NOT_ACT due to normal ending

49.5.2.1.1.1.3.4.1 Memorization of lambda and engine speed controller outputs

The lambda and engine speed controller outputs are memorized for comparison after/in the multiple injection adaptation phases.

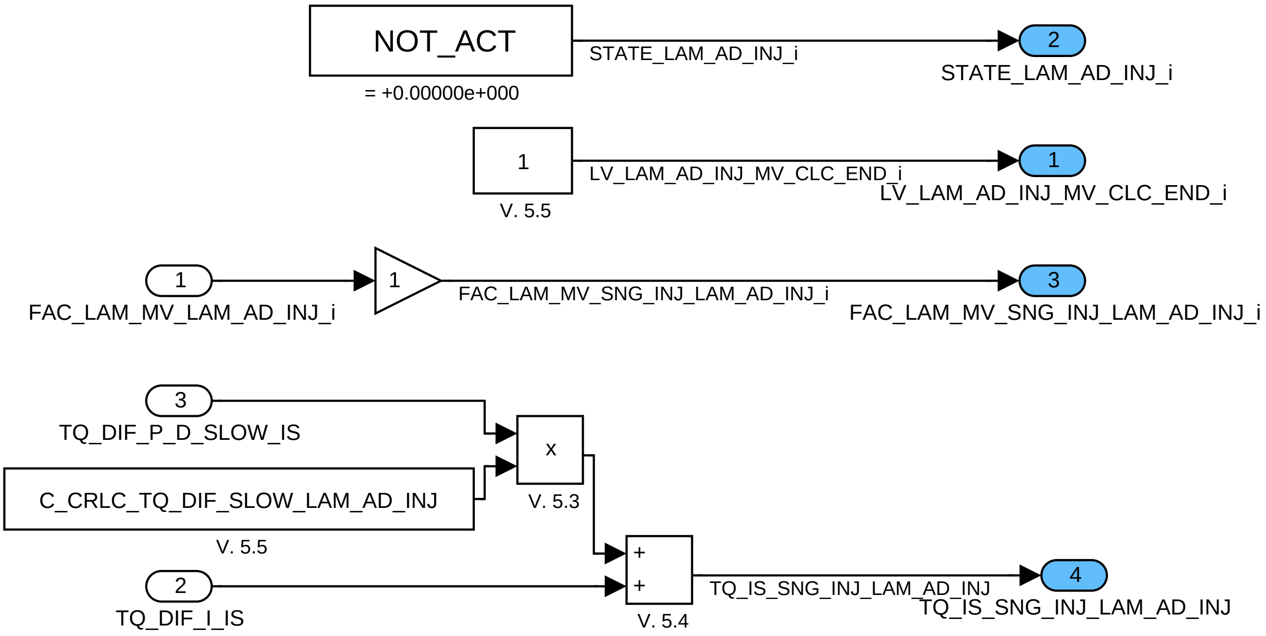

Figure 78:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/NOT_ACT_2/CLC

49.5.2.1.1.1.3.5 Transition to LAM_AD

49.5.2.1.1.1.3.5.1 Calculation of FAC_LAM_MV_MPL_INJ_LAM_AD_INJ[i]

The lambda controller output (mean value) of the multiple injection phase is stored.

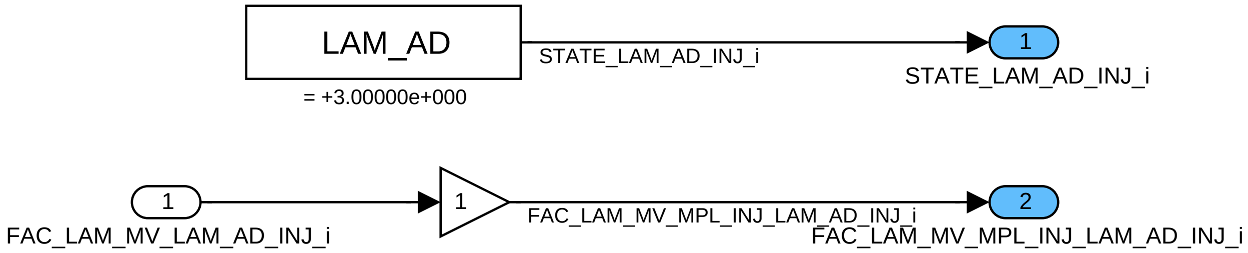

Figure 79:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/MV_CLC/LAM_AD/CLC

49.5.2.1.1.4 LAM_AD

The state LAM_AD is left immediately towards NO_ACT after the adaptation value has be calculated.

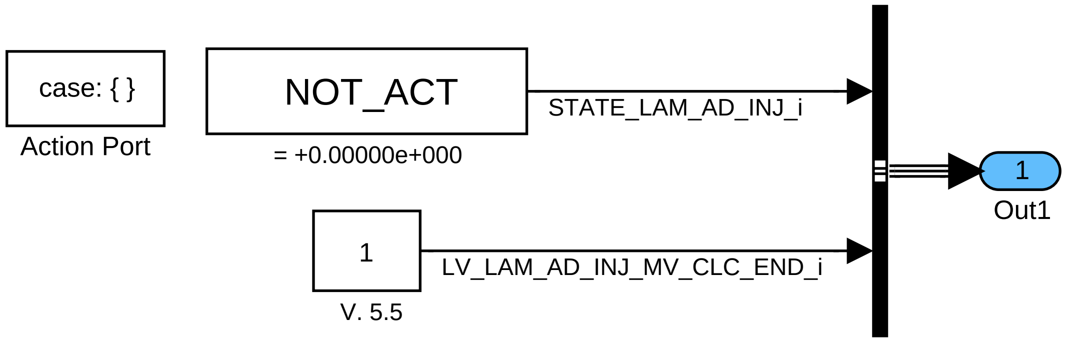

Figure 80:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_TRANSITION/CLC/LAM_AD

49.5.2.1.2 State actions

49.5.2.1.2.1 State selection

49.5.2.1.2.1.1 TRA_PHA

49.5.2.1.2.1.1.1 MAF and time integral calculation

During the state TRA_PHA the MAF and time integrals are calculated.

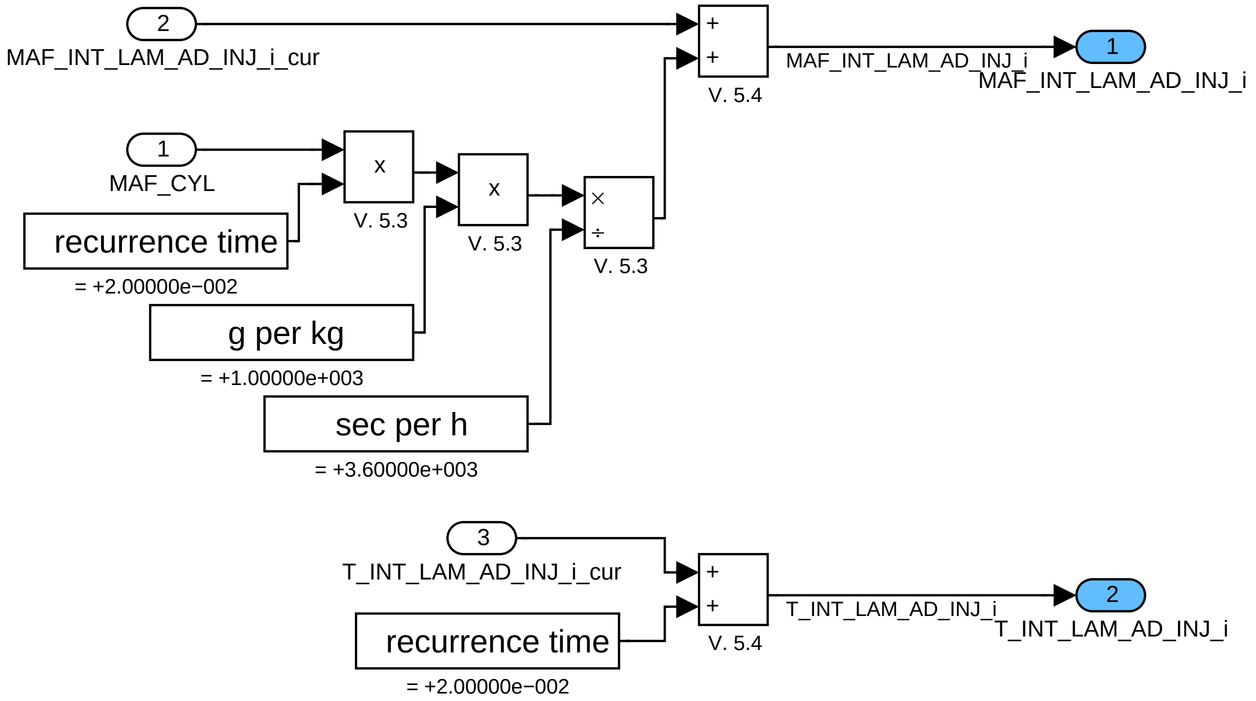

Figure 81:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/TRA_PHA/CLC

49.5.2.1.2.1.2 MV_CLC

49.5.2.1.2.1.2.1 MAF and time integral calculation

During the state MV_CLC the MAF and time integrals are calculated.

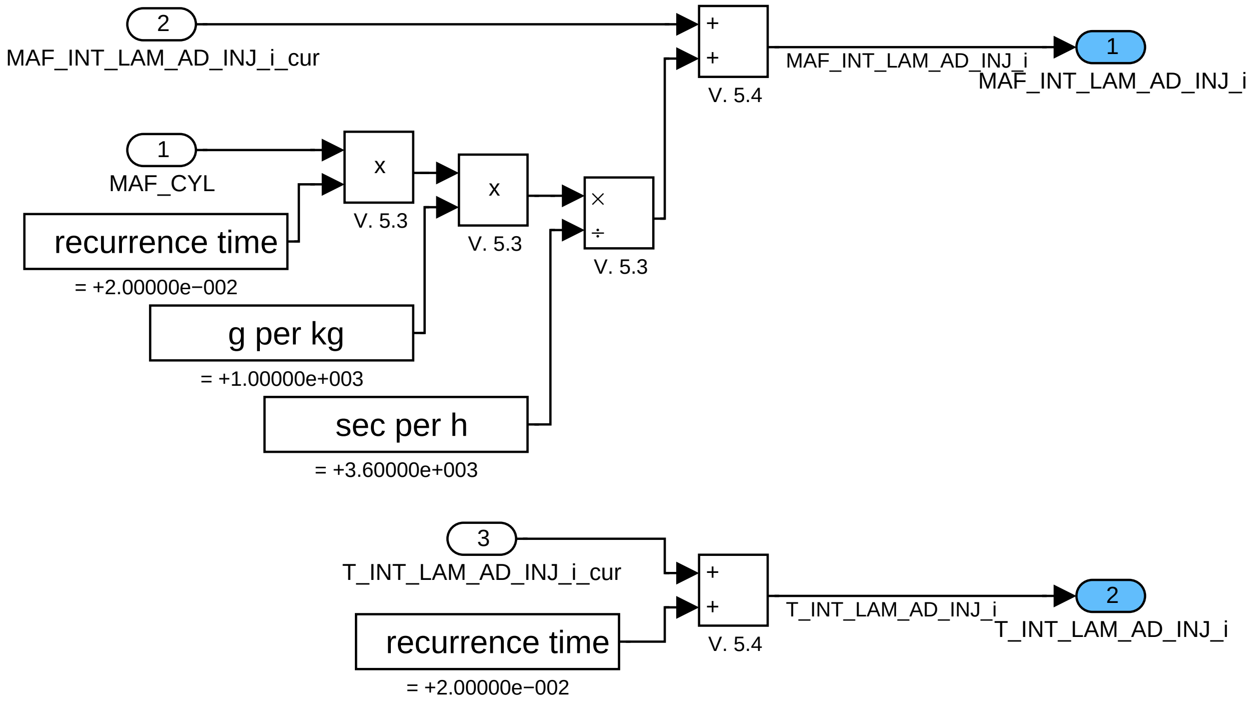

Figure 82:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/MV_CLC/CLC

49.5.2.1.2.1.3 LAM_AD

During the state LAM_AD the lambda controller output difference and the corresponding fuel mass caused by multiple injections are calculated and then stored in the adaptation values of the active temperature range.

49.5.2.1.2.1.3.1 Lambda controller difference and fuel mass calculation

49.5.2.1.2.1.3.1.1 Calculation of FAC_LAM and MFF_DELTA

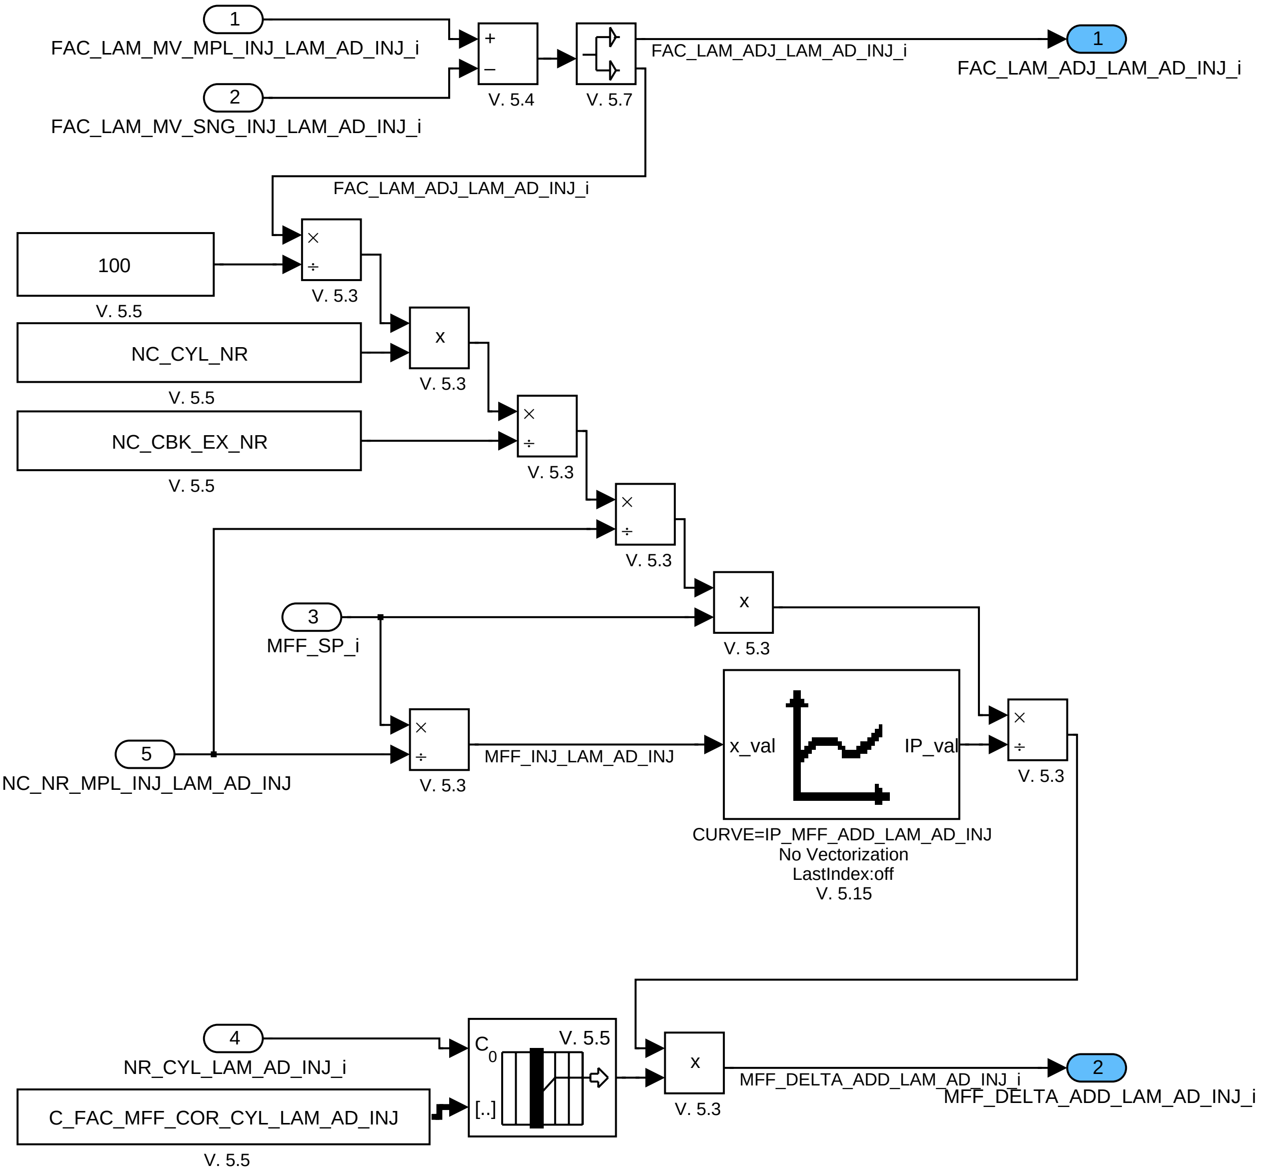

Figure 83:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_MFF_DELTA/CLC

49.5.2.1.2.1.3.2 Lower temperature range

If the lower temperature range is active, the adaptation values are written to the corresponding variables.

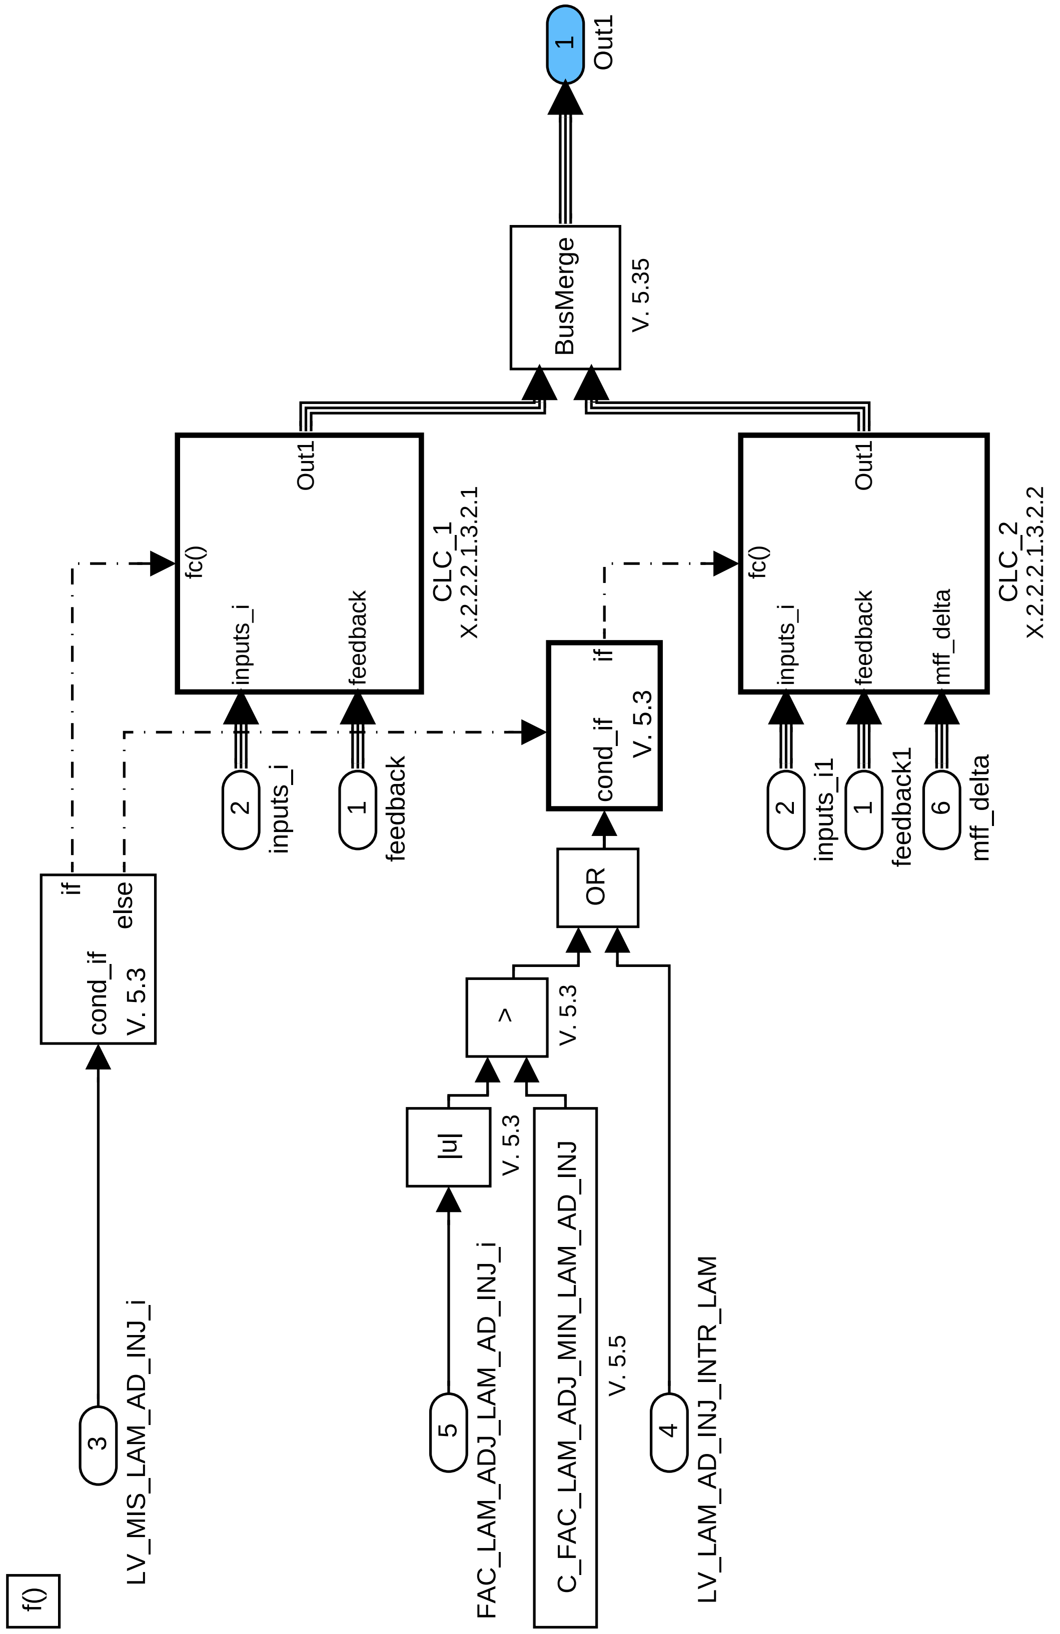

Figure 84:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_COLD

49.5.2.1.2.1.3.2.1 Correction of adaptation values in case of misfire

49.5.2.1.2.1.3.2.1.1 Determination of corrective fuel mass for misfire

In case misfire was detected on the active cylinder during multiple injections, an additional fuel mass is determined from the map ID_MFF_DELTA_MIS_LAM_AD_INJ.

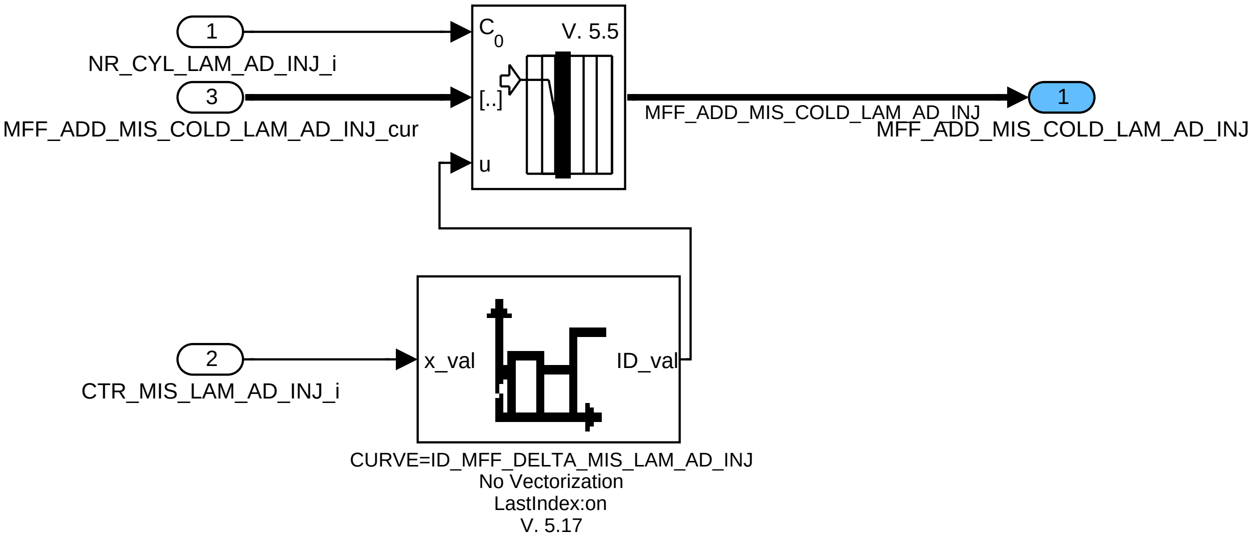

Figure 85:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_COLD/CLC_1/CLC

49.5.2.1.2.1.3.2.2 Calculation of the adaptation value

49.5.2.1.2.1.3.2.2.1 Calculation of MFF_ADD_COLD_LAM_AD_INJ

The adaptation value is determined from its old value and the actual calculated difference using the correlation factor C_CRLC_MFF_ADD_COLD_LAM_AD_INJ. Afterwards the additional misfire fuel mass is reset to 0.

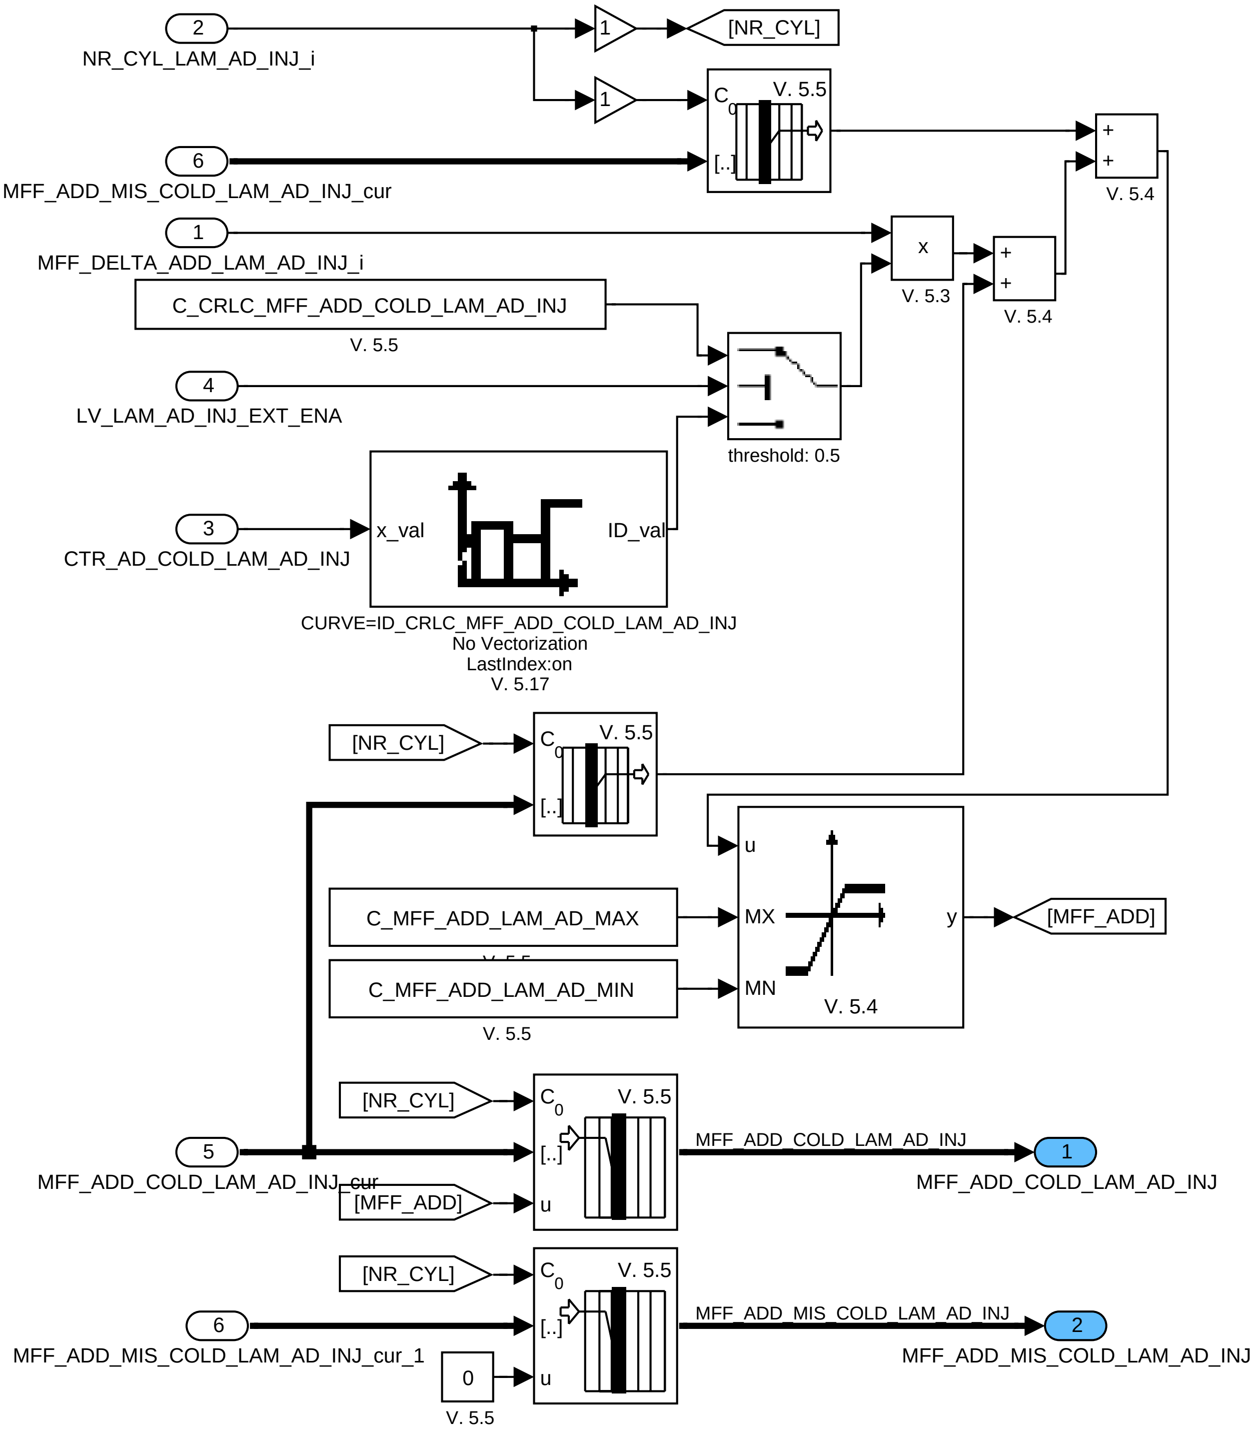

Figure 86:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_COLD/CLC_2/CLC

49.5.2.1.2.1.3.3 Upper temperature range

If the upper temperature range is active, the adaptation values are written to the corresponding variables.

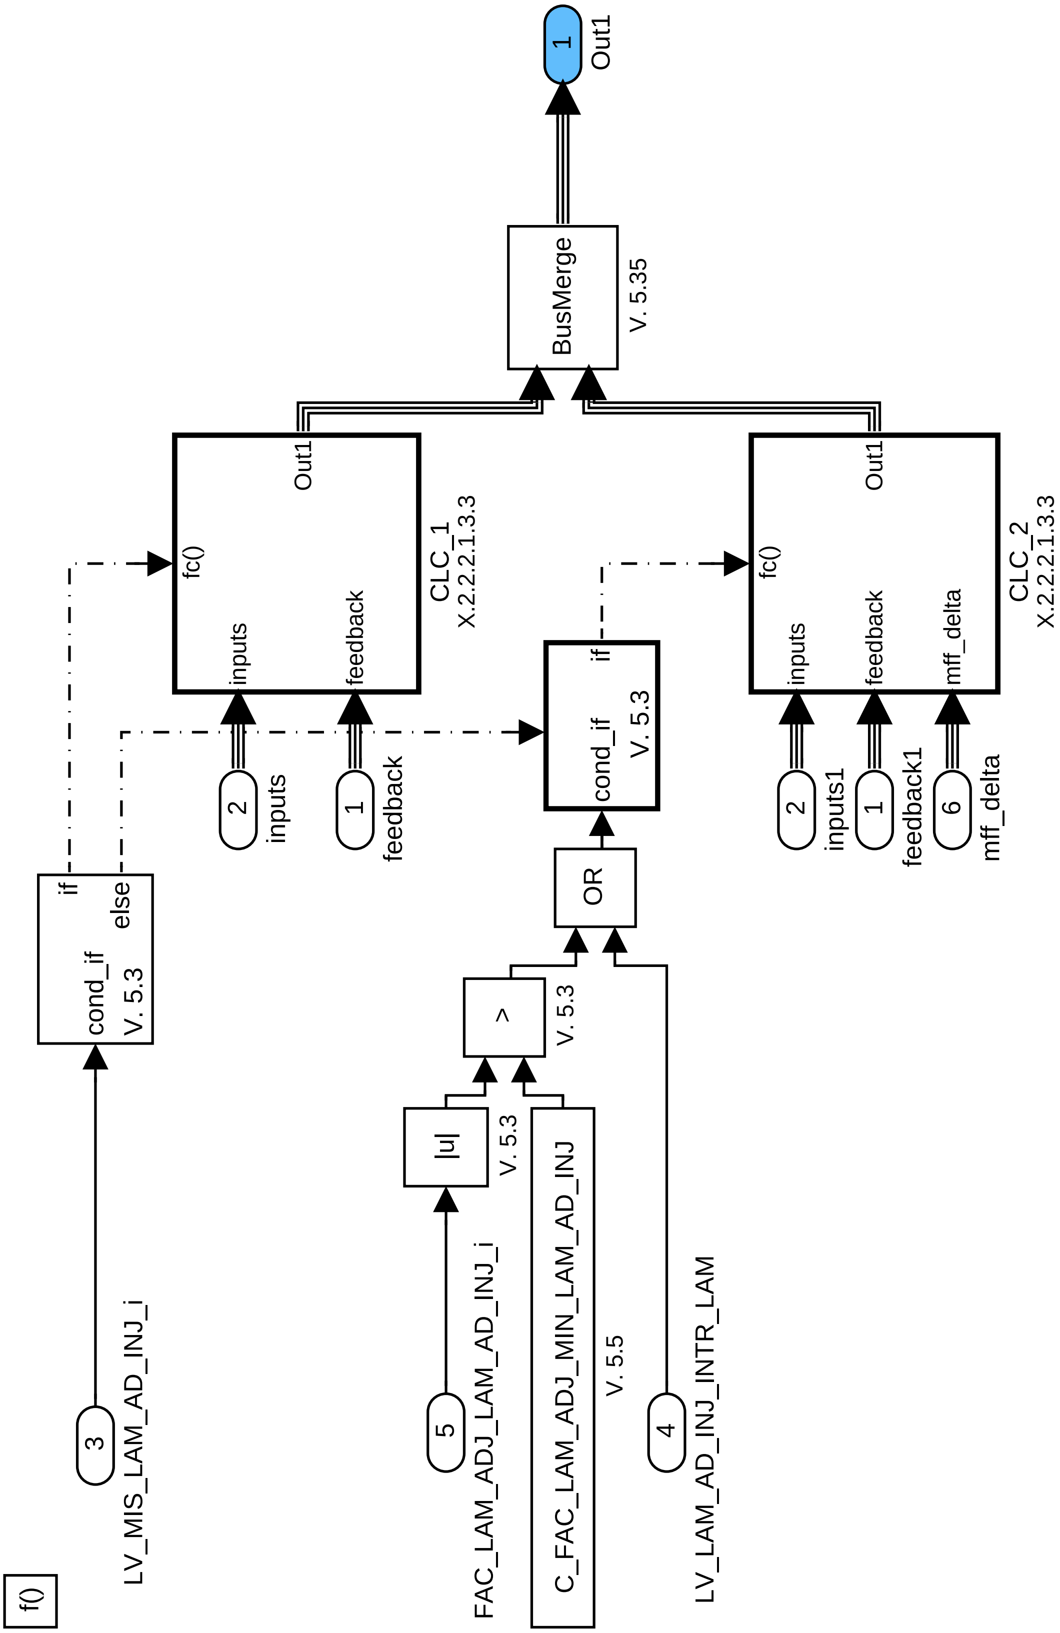

Figure 87:

Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_HOT

49.5.2.1.2.1.3.3.1 Correction of adaptation values in case of misfire

49.5.2.1.2.1.3.3.1.1 Determination of corrective fuel mass for misfire

In case misfire was detected on the active cylinder during multiple injections, an additional fuel mass is determined from the map ID_MFF_DELTA_MIS_LAM_AD_INJ.

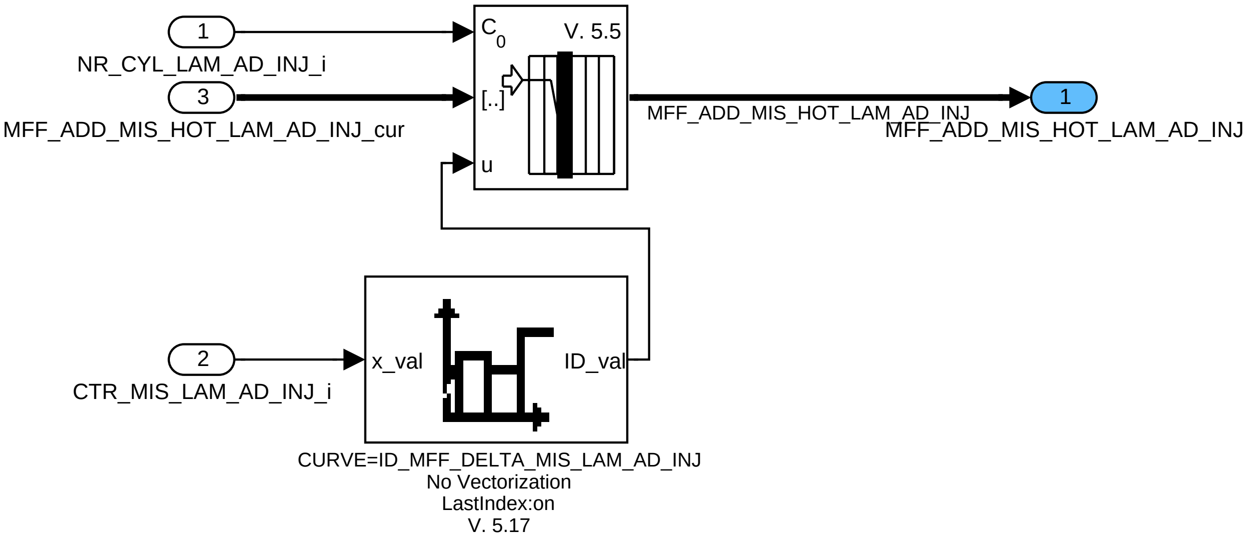

Figure 88:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_HOT/CLC_1/CLC

49.5.2.1.2.1.3.3.2 Calculation of the adaptation value

49.5.2.1.2.1.3.3.2.1 Calculation of MFF_ADD_HOT_LAM_AD_INJ

The adaptation value is determined from its old value and the actual calculated difference using the correlation factor C_CRLC_MFF_ADD_HOT_LAM_AD_INJ. Afterwards the additional misfire fuel mass is reset to 0.

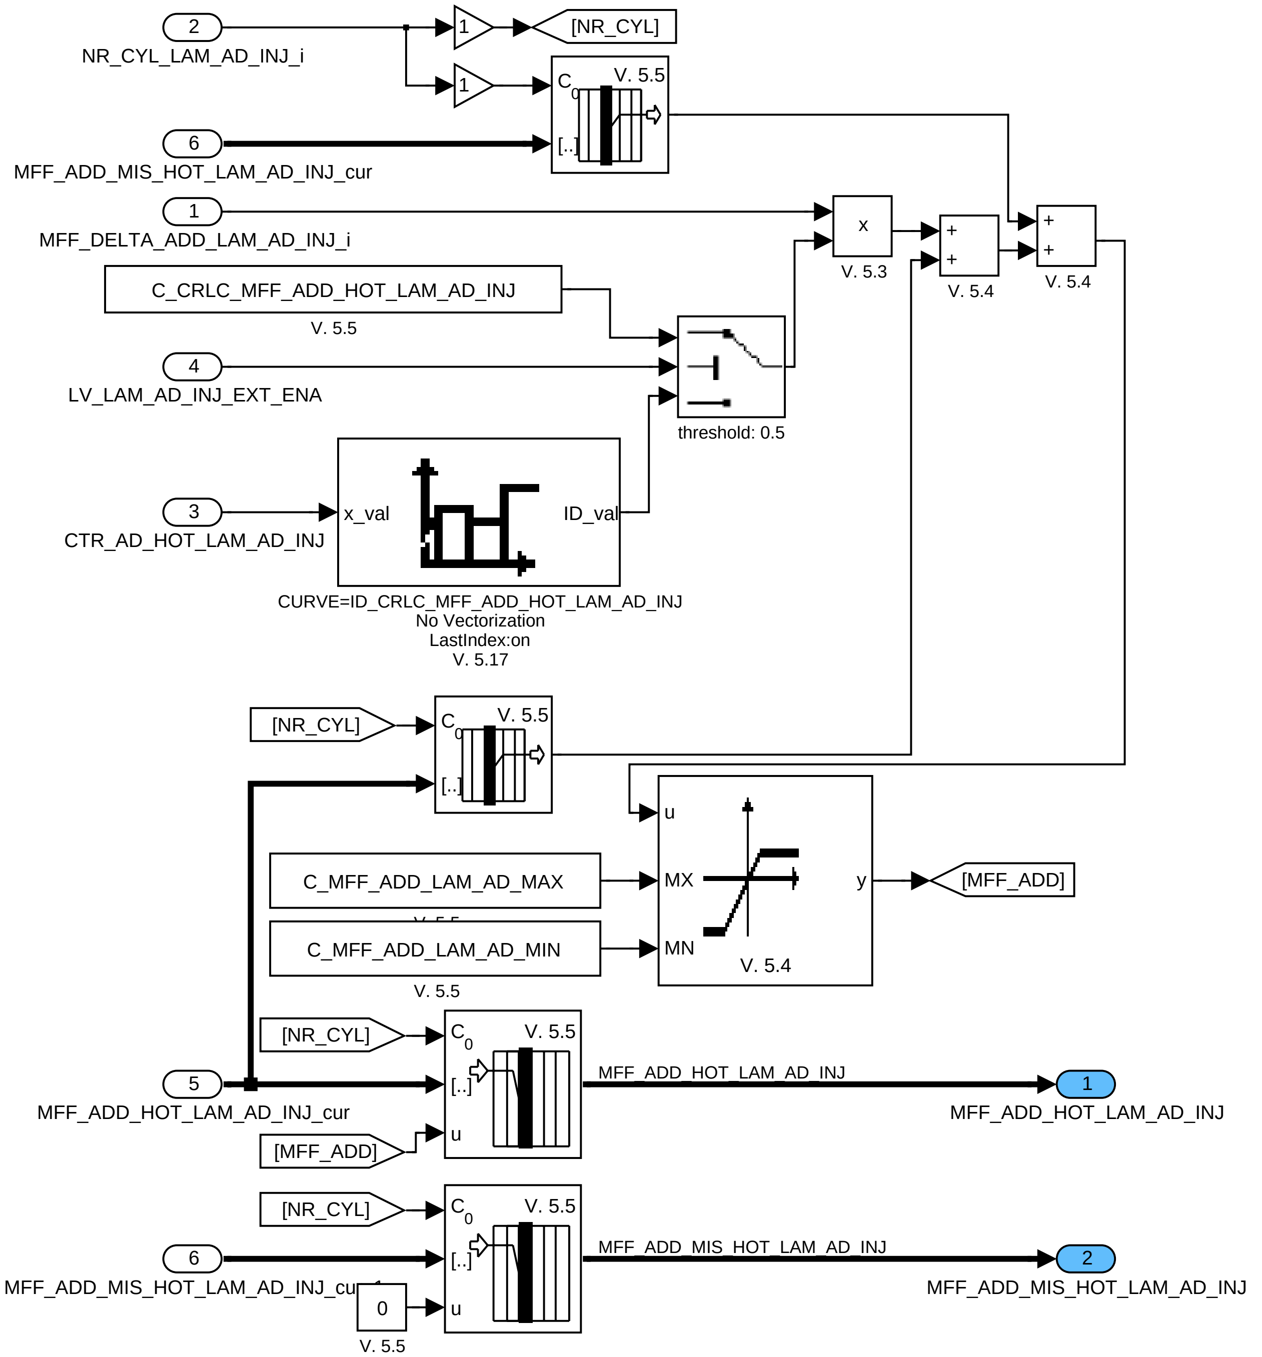

Figure 89:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/STATE_ACTION/CLC/LAM_AD/CLC_HOT/CLC_2/CLC

49.5.2.1.3 General calculations

The mean value calculations are done for the current active bank(s).

49.5.2.1.3.1 Mean value calculation

The mean value calculations are done for the current active bank(s).

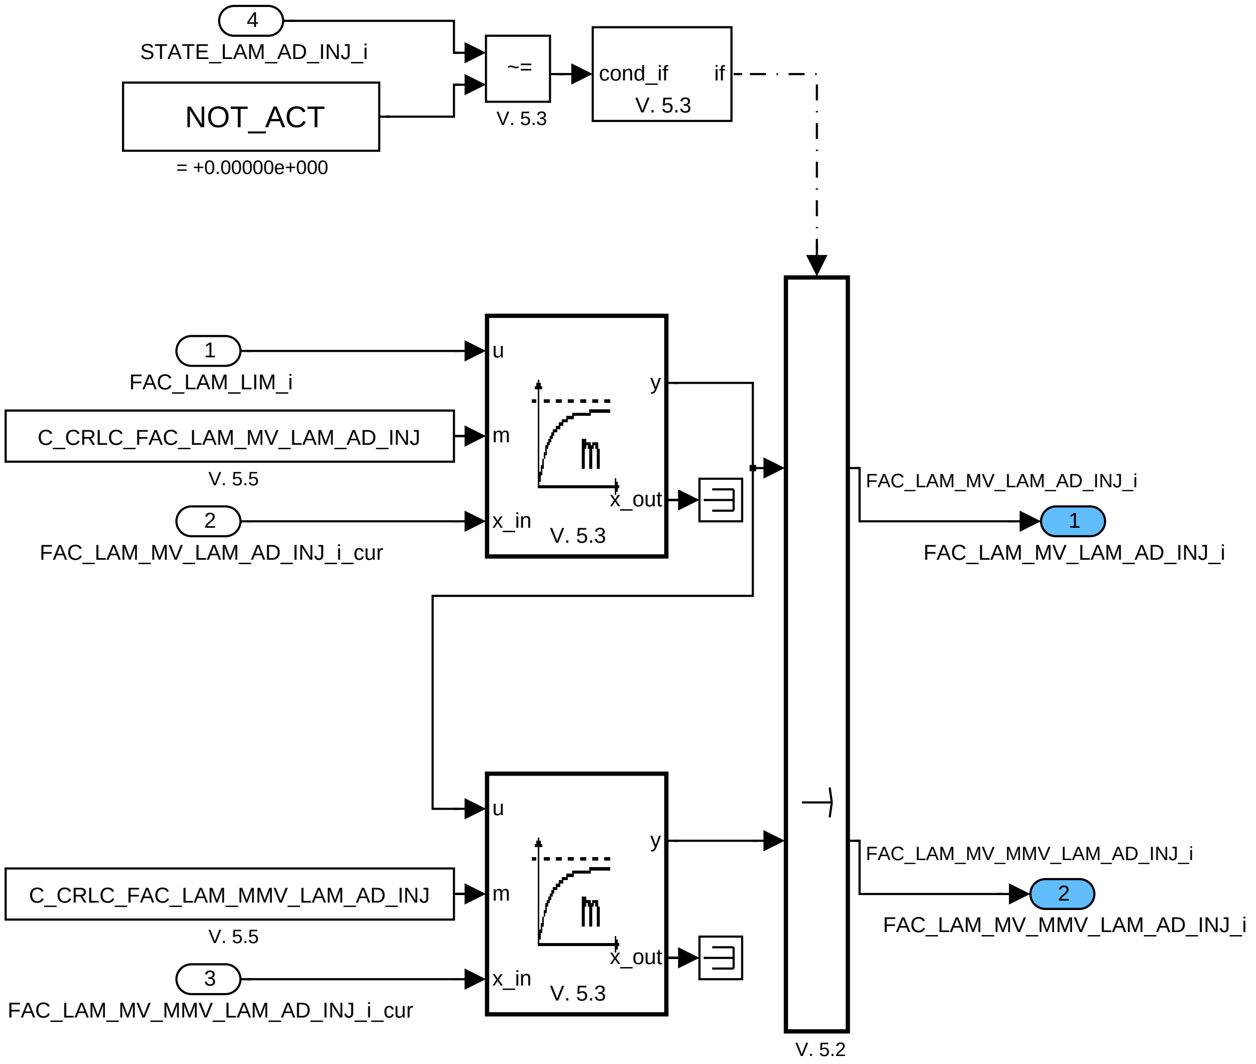

Figure 90:
Path: MFMA_ISPCLAIM0/OPM_20MS/CLC/GEN_CALC/CLC

49.5.3 1s operations

All calculations are done for each cylinder, where the cylinder specific values are denoted within the graphical model with the suffix _x, in the textual description they are referenced via [x].

49.5.3.1 Calculation of the adaptation value

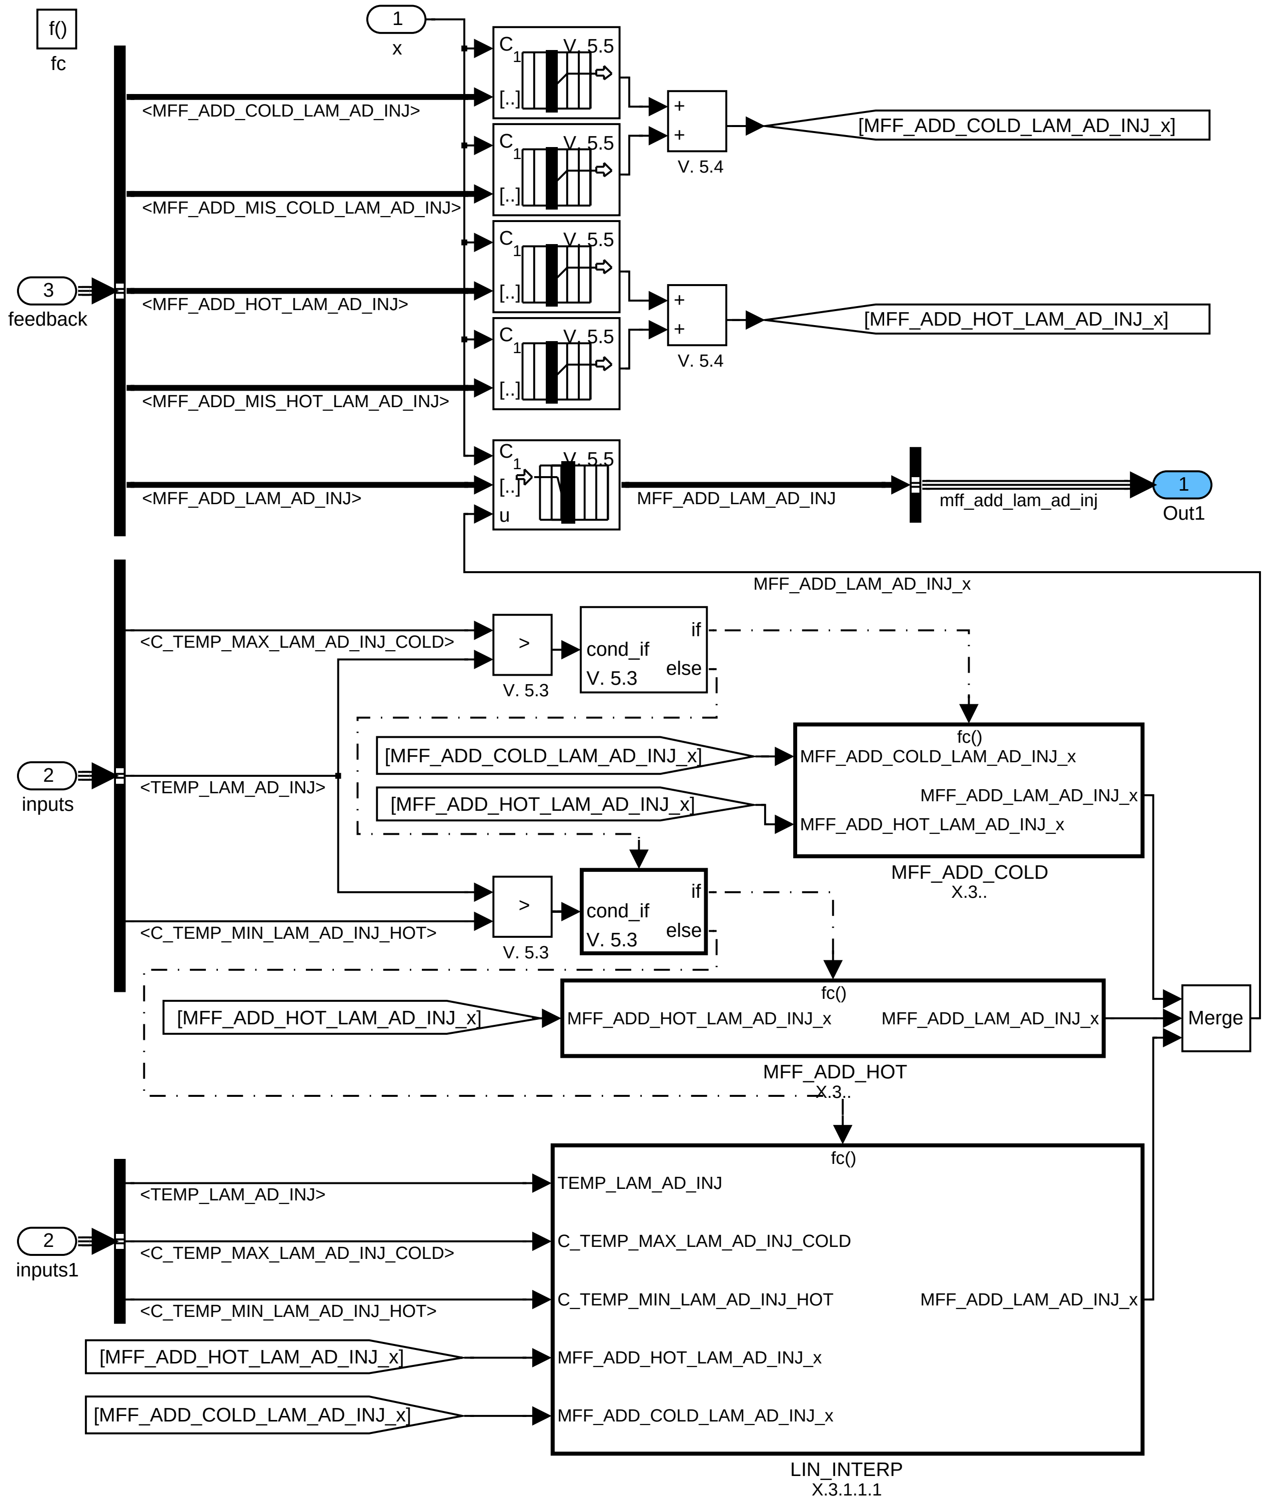

Figure 91:
Path: MFMA_ISPCLAIM0/OPM_1S/CLC_AD_VALUE

49.5.3.1.1 Linear interpolation

Depending on the calibration data LC_MFF_CLC_ADD_LAM_COLD_ADD two different ways of calculation for the adaptation value can be chosen. For setting the calibration to zero here is a linear interpolation between the upper and lower temperature range. For one the cold adaptation value is added as an offset to the hot adaptation value. The offset is faded out between the upper temperature threshold for the cold area and the lower threshold for the hot area.

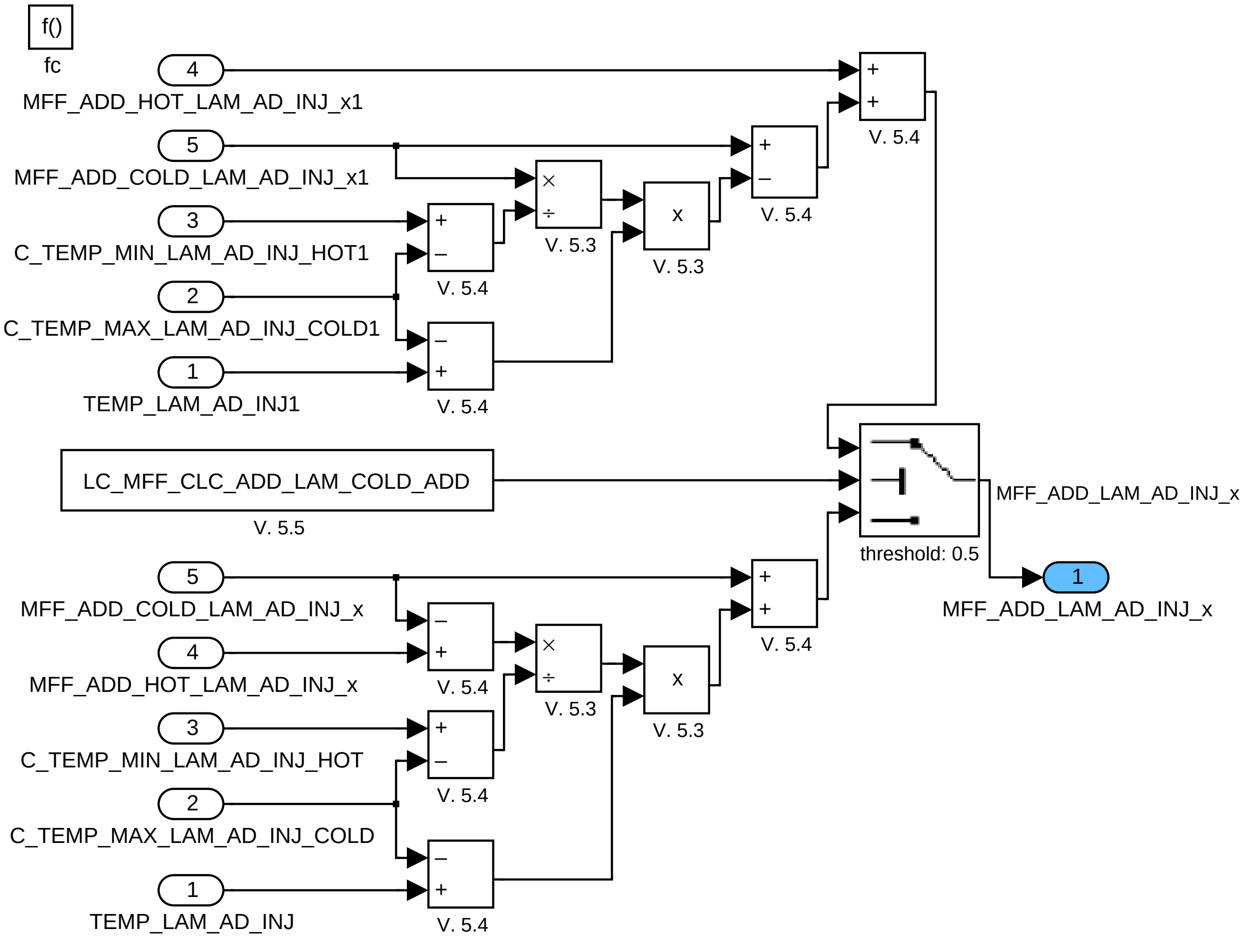

Figure 92:
Path: MFMA_ISPCLAIM0/OPM_1S/CLC_AD_VALUE/LIN_INTERP

49.5.3.1.2 Cold adaptation value

Depending on the calibration value LC_MFF_CLC_ADD_LAM_COLD_ADD the adaptation value for the cold range can be used alone or the adaptation of the cold range can be used as an offset for the hot range adaptation value.

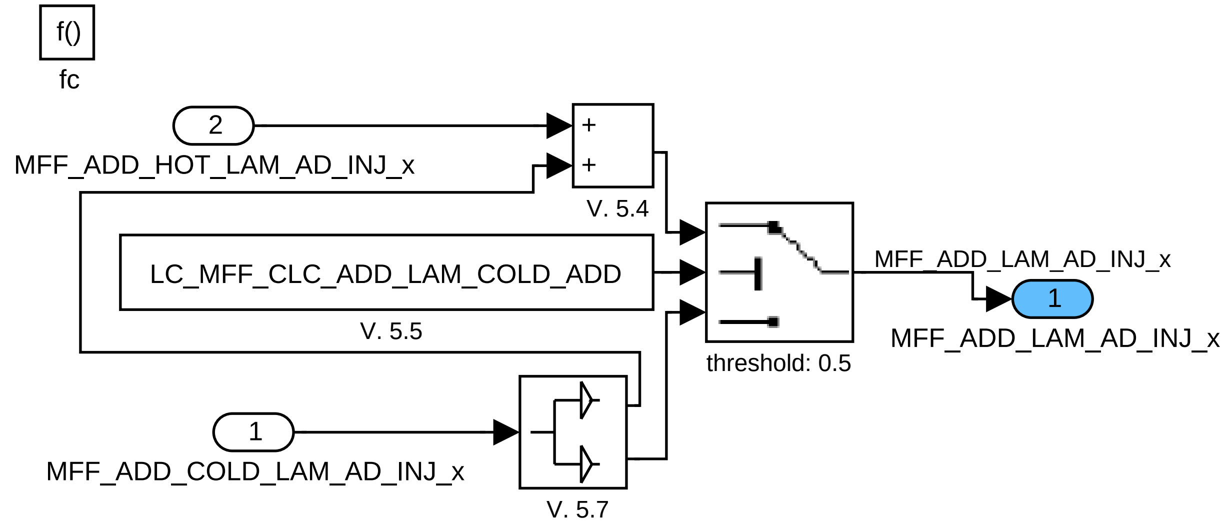

Figure 93:
Path: MFMA_ISPCLAIM0/OPM_1S/CLC_AD_VALUE/MFF_ADD_COLD

49.5.3.1.3 Hot adaptation value

At hot temperature range, the hot adaptation value is valid.

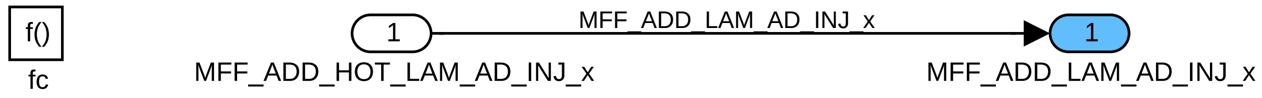

Figure 94:
Path: MFMA_ISPCLAIM0/OPM_1S/CLC_AD_VALUE/MFF_ADD_HOT

49.5.4 Resetting of adaptation values

The need to reset the adaptation values is checked every time at the transition engine off to engine on. The condition is checked for each cylinder, where the cylinder specific values are denoted within the graphical model with the suffix _x, in the textual description they are referenced via [x].

49.5.4.1 Reset due to manual request or injector change

If an injector was changed (i.e. the corresponding STATE_IV_CHG is set to one), the corresponding adaptation value is reset. If a manual reset is requested via LC_MFF_ADD_LAM_AD_INJ_CLR, all adaptation values are set to 0.
If a resetting of the NVMY data via service tester is requested with the flag LV_LAM_AD_INJ_CLR_AD_EXT, the adaptation values are also reset to 0.

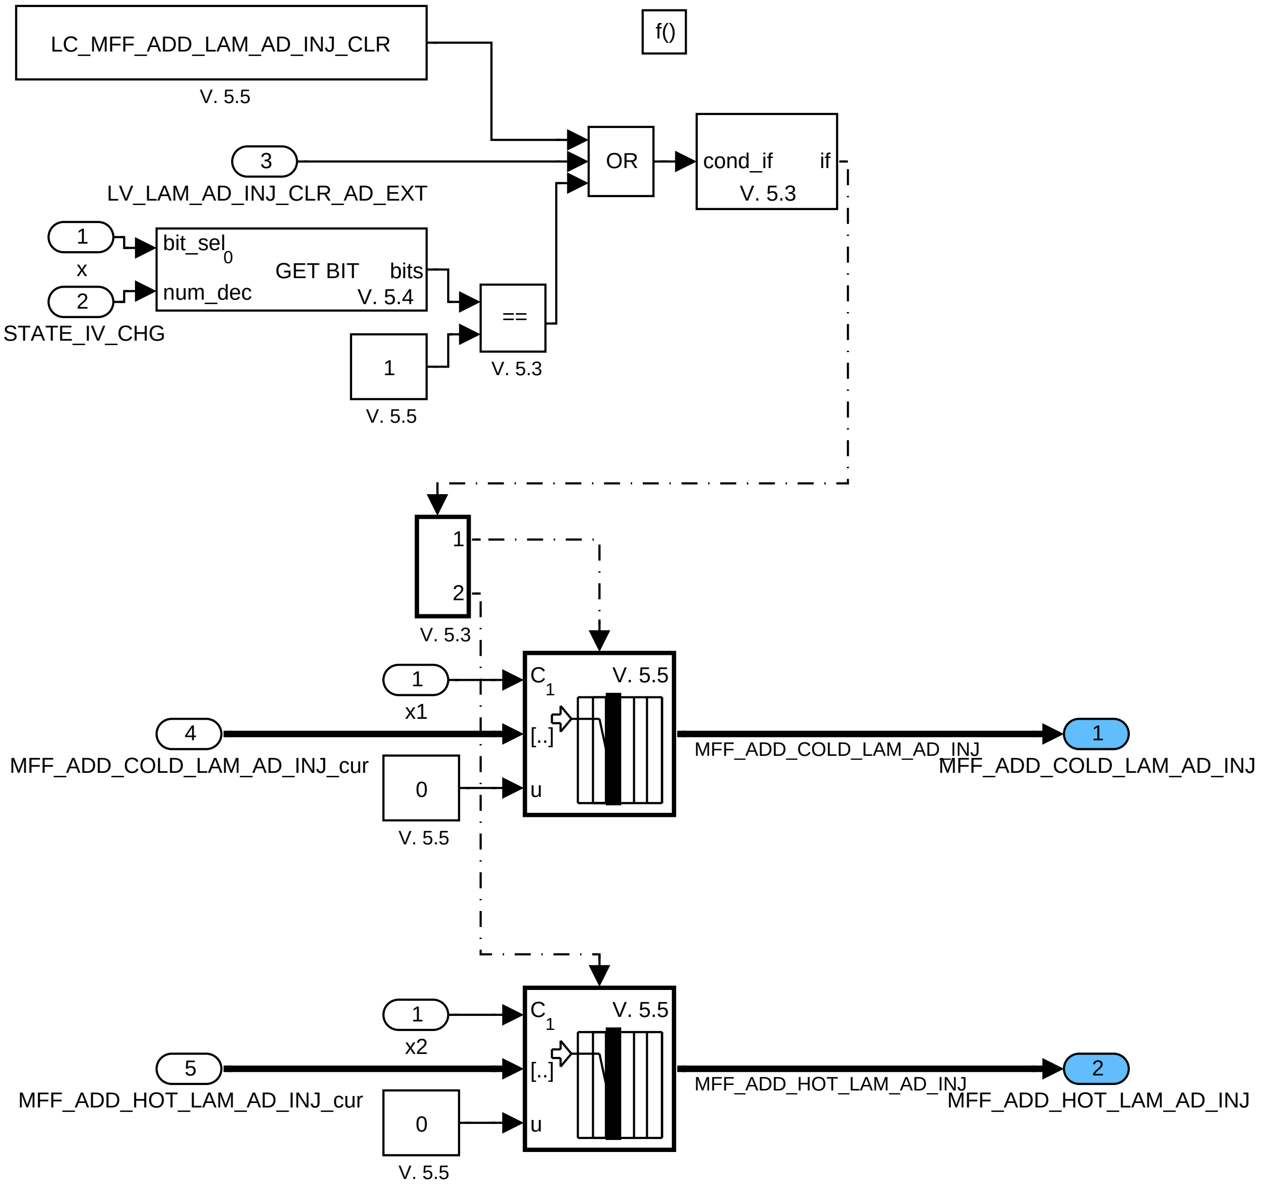

Figure 95:
Path: MFMA_ISPCLAIM0/OPM_ES2ERU/CLC

49.6 Calibration hints for function MFMA- LAM_AD_INJ Minimum fuel mass adaptation- Lambda adaptation via injection mode

Calibration interfering function:

- calibrate lambda controller before
- calibrate engine speed controller before

Calibration flowchart:

The sequence of calibration is described by the order in Calibration process

Calibration process:

49.6.1 Non calibrated data

NC_NR_PHA_LAM_AD_INJ	For maximum flexibility use "number cylinder per bank" * 2 + 1; After final calibration the number can be reduced for RAM optimization.
NC_NR_MIS_REP_LAM_AD_INJ	Number of tries to adapt a single cylinder that shows continuous misfire.
NC_NR_MPL_INJ_LAM_AD_INJ	Number of injection pulses for multiple injection mode. The value is only used for calculation of the adaptation value and has no influence on the injection itself.

49.6.2 Lambda adaptation via injection mode (Appl. Inc.)

LC_LAM_AD_INJ_INH	Manual inhibition of the adaptation. Only the manual activation conditions have a higher priority.

49.6.3 Activation of Lambda adaptation via injection mode

C_CTR_ABC_MAX_MIS_LAM_AD_INJ	Maximum number of misfire events for one cylinder at multiple injections to detect misfire.
C_CTR_MAX_DC_LAM_AD_INJ	Maximum number of driving cycles with a non successful adaptation for at least one cylinder. If the threshold is reached, an error flag is set and the cylinder will not be adapted anymore.
C_CTR_MIS_AD_MAX_LAM_AD_INJ	Maximum number of repeated adaptations for all cylinders due to misfire for at least one cylinder in a driving cycle. The value has to be equal or bigger then C_CTR_MIS_LAM_DC_MIN_LAM_AD_INJ
C_CTR_MIS_LAM_DC_MIN_LAM_AD_INJ	Threshold for number of repeated adaptations for all cylinders due to misfire for at least one cylinder in a driving cycle. If the threshold is at least reached, the counter for driving cycles with missed adaptations due to misfire is incremented.
C_CTR_MIS_MAX_LAM_AD_INJ	Maximum number of following tries for one cylinder due to misfire. The value has to be smaller or equal to NC_NR_MIS_REP_LAM_AD_INJ.
C_FAC_LAM_LDC_MPL_LAM_AD_INJ	Limited dynamic threshold for lambda controller during multiple injection. The threshold has to be set as high as the influence of multiple injections has no impact on the limited dynamic condition.
C_FAC_LAM_LDC_SNG_LAM_AD_INJ	Limited dynamic threshold for lambda controller during single injection.
C_FAC_LAM_MV_MAX_AD_LAM_AD_INJ	Maximum threshold during multiple injections to stop and repeat the adaptation. The activation condition C_FAC_LAM_MV_MAX_LAM_AD_INJ has to be taken in account.
C_FAC_LAM_MV_MIN_AD_LAM_AD_INJ	Minimum threshold during multiple injections to stop and repeat the adaptation. The activation condition C_FAC_LAM_MV_MAX_LAM_AD_INJ has to be taken in account.
C_FAC_LAM_MV_MAX_LAM_AD_INJ	Lambda controller output threshold for activation. Be sure that the distance to C_FAC_LAM_MV_MAX_AD_LAM_AD_INJ is as high as an adaptation can be calculated.
C_FAC_LAM_MV_MIN_LAM_AD_INJ	Lambda controller output threshold for activation. Be sure that the distance to C_FAC_LAM_MV_MIN_AD_LAM_AD_INJ is as high as an adaptation can be calculated.
C_FAC_TQ_REQ_DYW_LDC_LAM_AD_INJ	Limited dynamic threshold for torque.
C_MAF_DYW_LDC_LAM_AD_INJ	Limited dynamic threshold for mass air flow.
C_MAF_INT_LDC_LAM_AD_INJ	Max threshold for mass air flow integration for limited dynamics calculation.
C_N_BOL_LAM_AD_INJ	Engine speed threshold for activation.
C_N_TOL_LAM_AD_INJ	Engine speed threshold for activation.
C_N_DYW_LDC_LAM_AD_INJ	Limited dynamic threshold for engine speed.
C_NR_MIN_AD_LAM_AD_INJ_COLD_ADD	Number of hot adaptations to be performed before a cold adaptation can start.
C_T_AST_MIN_LAM_AD_INJ_MOD	Minimum time after start to be waited before the

	adaptation start.
C_TCO_MIN_LAM_AD_INJ	Minimum coolant temperature to be waited before the adaptation start.
C_TEMP_CAT_MAX_LAM_AD_INJ	Catalyst threshold for catalyst protection.
C_TEMP_LAM_AD_INJ_ENA	Selection for temperature input. The cold and hot areas are calculated with these input values.
C_TEMP_MIN_LAM_AD_INJ_COLD	Minimum threshold for cold area.
C_TEMP_MAX_LAM_AD_INJ_COLD	Maximum threshold for cold area.
C_TEMP_MIN_LAM_AD_INJ_HOT	Minimum threshold for hot area.
C_TEMP_MAX_LAM_AD_INJ_HOT	Maximum threshold for hot area.
ID_MFF_SP_BOL_LAM_AD_INJ	Minimum fuel mass to activate the adaptation
ID_MFF_SP_TOL_LAM_AD_INJ	Maximum fuel mass to activate the adaptation
IP_DIST_LAM_AD_INJ_COLD	Additive vale for distance threshold at successful adaptation. A calibration with zero at the fist element for both axes can be used to define a threshold for first initialization and an initialization after injector change.
IP_DIST_LAM_AD_INJ_HOT	Additive vale for distance threshold at successful adaptation. A calibration with zero at the fist element for both axes can be used to define a threshold for first initialization and an initialization after injector change.
LC_LAM_AD_INJ_ACT_COLD_MAN	Manual activation for cold adaptation range. Be sure that the lambda controller is able to operate in closed loop.
LC_LAM_AD_INJ_ACT_HOT_MAN	Manual activation for hot adaptation range. Be sure that the lambda controller is able to operate in closed loop.
LC_CTR_MIS_DC_LAM_AD_INJ_CLR	The driving cycle counter for adaptations with misfire is cleared after a successful adaptation if the flag is set.

49.6.4 Coordination of Lambda adaptation via injection mode

C_NR_PHA_LAM_AD_INJ	Maximum number of filled elements (single or multiple injections) in the ID_NR_CYL_LAM_AD_INJ +1.
ID_NR_CYL_LAM_AD_INJ	The sequence of multiple and single injection for each cylinder is defined. The first element has to be filled with SINGLE_ALL. Fill all unused elements (> C_NR_PHA_LAM_AD_INJ) with NOT_ACT.

49.6.5 Lambda adaptation via injection mode

C_CRLC_FAC_LAM_MMV_LAM_AD_INJ	Filter constant for lambda controller moving mean value.
C_CRLC_FAC_LAM_MV_LAM_AD_INJ	Filter constant for lambda controller mean value.
C_CRLC_TQ_DIF_SLOW_LAM_AD_INJ	Filter constant to weight the influence of the P- and D-Path of the idle speed controller.
C_FAC_LAM_ADJ_MIN_LAM_AD_INJ	Minimum lambda controller deviation of single and multiple injections to update the adaptation values.
C_FAC_LAM_FIL_DIF_LAM_AD_INJ	Threshold for difference of lambda controller mean value and moving mean value to allow transition to MV_CLC. With this value a stable lambda controller can be detected.
C_FAC_MFF_COR_CYL_LAM_AD_INJ	Cylinder individual factor to weight the adaptation result.
C_MAF_INT_MV_CLC_LAM_AD_INJ	Minimum mass air flow integration to reach a stable lambda controller at mean value calculation phase.
C_MAF_INT_TRA_PHA_LAM_AD_INJ	Minimum mass air flow integration to reach a stable lambda controller at transient phase.
C_MFF_ADD_LAM_AD_MAX	Maximum limitation of adaptation value.
C_MFF_ADD_LAM_AD_MIN	Minimum limitation of adaptation value.
C_T_INT_MV_CLC_LAM_AD_INJ	Minimum time integration to reach a stable lambda controller at mean value calculation phase.
C_T_INT_TRA_PHA_LAM_AD_INJ	Minimum time integration to reach a stable lambda controller at transient phase.
ID_CRLC_MFF_ADD_COLD_LAM_AD_INJ	Correlation constant for wighting the adaptaiton result.
ID_CRLC_MFF_ADD_HOT_LAM_AD_INJ	Correlation constant for wighting the adaptaiton result.
ID_MFF_DELTA_MIS_LAM_AD_INJ	Corrective fuel mass at detected misfire. The last element can be calculated to zero, so that after a failed adaptation due to misfire no more correction are done.
IP_MFF_ADD_LAM_AD_INJ	Normalization to reference fuell mall. This has to be calculated together with the incection module.
LC_MFF_ADD_LAM_AD_INJ_CLR	The adaptaiton values will be deleted at transition engine off to on.
LC_MFF_CLC_ADD_LAM_COLD_ADD	Two strategies can be choosen: - the hot and cold range are calculated seperately - the hot adaptation is valid for the whole temperatue range. The cold adaptation is valid for the cold range as an offset.

50.1 Bios H-Bridge Diagnosis Function for DISA

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
BIOS_HBR_FAULT_STATUS_VIM	O	0H 1H	NO_ERROR ETC_HBR_ERROR	0	[-]
STATUS OF H-BRIDGE DISA					

FUNCTION DESCRIPTION:

General information:

The function Bios H-Bridge Diagnosis manages detection of H-Bridge faults witch deactivate the DISA H-Bridge.

Description:

The following error conditions can be distinguished:

- Undervoltage
- Overcurrent
- Overtemperature

Application conditions:

Initialisation: 0
Recurrence: 10 ms

Formula section:

```
if      one error condition is fulfilled
then    BIOS_HBR_FAULT_STATUS_VIM = 1
else    BIOS_HBR_FAULT_STATUS_VIM = 0
endif
```

50.2 Exhaust flap actuation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_EF_NR	1	1...4H	1...4	1	[-]
Number of the exhaust flaps in system					

Import actions:

ACTION_INFR_SetEf(IN<ef_nr>, IN <Lv_ef>)

General information:

To optimize the vehicle noise behaviour, an exhaust flap can be activated depending on the engine speed (N_EF) and the load (FAC_TQ_REQ). The exhaust flap is closed below a FAC_TQ_REQ value threshold, it is opened above the threshold.
The exhaust flap activation is only activated after the time C_T_EF_AST after the transition from Start.

The switching threshold (FAC_TQ_EF_THD) is depending on enginespeed (N_EF), the selected gear (GEAR_EF), the transmission (manuell or automatic) and the convertible top (LV_CTOP = 0 closed, or LV_CTOP = 1 open).

To prevent the exhaust flap from switching continuously during constant driving at the switching threshold, two hysteresises (C_N_EF_HYS and C_FAC_TQ_EF_THD_HYS) are introduced for the switching process.
The closing of the exhaust flap is delayed depending on the enginespeed (N_32).

During catalyst heating with increased idle speed setpoint, the state of the exhaust flap is adjustable by C_STATE_CH_EF.

At low vehicle speeds the state of the exhaust flap is adjustable by C_STATE_VS_MIN_EF_xx, but C_STATE_CH_EF has higher priority as C_STATE_VS_MIN_EF_xx (xx = MT/AT).
For MSD85 is NC_EF_NR=2 and for all other projects is NC_EF_NR=1.

Application conditions:

Initialisation: all variables are initialised with 0 at deactivation

Recurrence: 100 ms

Activation: LV_IGK = 1 and (LV_VAR_EF = 1 **or** LV_EF_EXT_ADJ = 1)

Deactivation: LV_IGK = 0;

at Deactivation LV_EF = LC_EF_CONF // is still calculated during PWL;

Formula section:

- Control of sound exhaust flap by external adjustment

```
If      LV_EF_EXT_ADJ = 1
Then    LV_EF = LV_ACT_EF_EXT_ADJ
Else    external adjustment passive/standard function active
```

- Flap during start and engine stopped

```
    If LV_ST = 1 or LV_ES = 1
    Then LV_EF = LC_EF_CONF      \\ flap opened; in case of LC_EF_CONF = 1 flap closed
    Endif
```

- Highest priority is ‘time after start’, P1

```
If      VS > C_VS_MIN_EF_AC_2
Then    LV_CDN_AC_VS = 1        *** initialised at deactivation***
Endif;
```

```
If   T_AST ≤ C_T_EF_AST    AND   LV_CDN_AC_VS = 0

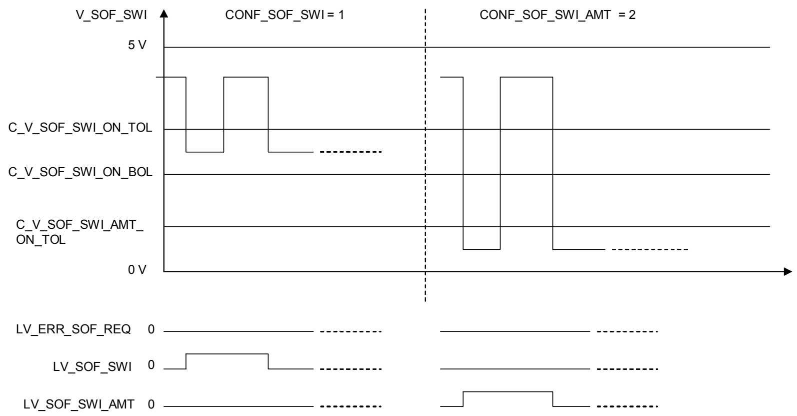
50.3.1 Acquisition of sport-mode-switch

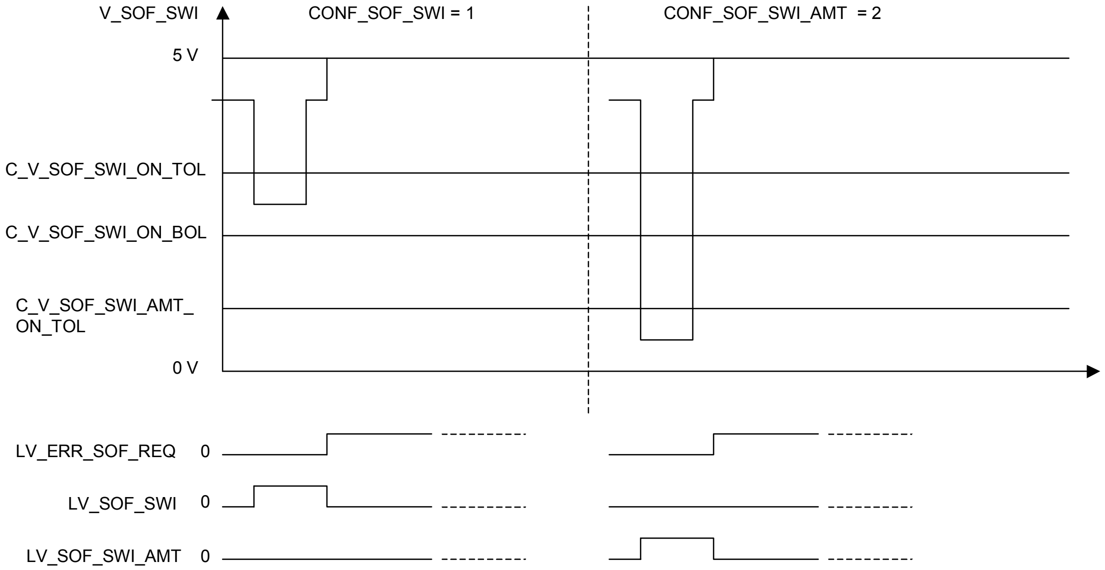
General information:

Calculation of the sport-mode request by taking the voltage of the sport-mode-switch.
The request acts according to the rising egde of the voltage signal.
There must be for 3 cyles the same result of LV_SOF_SWI(_AMT) to accept the level.

Signal flow diagram:



In case of failure LV_ERR_SOF_REQ =1 inhibitation of LV_SOF_SWI(_AMT):



Application conditions:

Initialisation:	all variables are initialised with 0 at:
	reset or LV_ES = 0-->1
Recurrence:	10ms
Activation:	every engine state

Formula section:

If (1) LV_VAR_BN = 0
Then (1)

If(2) LV_ERR_SOF_REQ = 0
Then(2)

If(3) (V_SOF_SWI > C_V_SOF_SWI_ON_TOL) changes to

Else        LV_SOF_SWI_AMT_REQ   = 0
Endif
```

50.3.2 Acquisition of sound-flap

General information:

To optimize the vehicle noise behaviour, an sound flap can be activated depending on the engine speed (N_SOF) and the load (FAC_TQ_REQ). The sound flap is closed below a FAC_TQ_REQ threshold, it is opened above the threshold.
The sound flap is only activ after the time C_T_SOF_AST after the transition from Start.

The switching threshold (FAC_TQ_SOF_THD) is depending on enginespeed (N_SOF), the selected gear (GEAR_EF), the transmission (manuell or automatic) and the convertible top (LV_CTOP = 0 closed, or LV_CTOP = 1 open).

To prevent the sound flap from switching continuously during constant driving at the switching threshold, two hysteresises (C_N_SOF_HYS and C_FAC_TQ_SOF_THD_HYS) are introduced for the switching process.
The closing of the sound flap is delayed depending on the enginespeed (N_32).

At low vehicle speeds the state of the sound flap is adjustable by C_STATE_VS_MIN_SOF_xx (xx = MT/AT).

The sound flap can be tested via KWP protocol at EOL or at service station by setting LV_SOF_EXT_ADJ = 1.

Application conditions:

Initialisation:	all variables are initialised with 0 at deactivation
Recurrence:	100ms
Activation:	LV_VAR_SOF = 1 **or** LV_SOF_EXT_ADJ = 1
Deactivation:	LV_IGK = 0

Formula section:

Control of sound-flap by external adjustment:

```
IF          LV_SOF_EXT_ADJ = 1
THEN        LV_SOF = LV_ACT_SOF_EXT_ADJ
Endif
```

Control of sound-flap

- **SOF during start and engine stopped**

```
    If LV_ST = 1 or LV_ES = 1
    Then LV_SOF = 0                                  \\ flap closed
```

```
    Endif
```

- Highest priority is ‘time after start’,   P1

```

End of Diagnosis					

Input data:

V_SOF_SWI	LV_IGK	CONF_SOF_SWI	LV_VAR_BN

FUNCTION DESCRIPTION:

General information:

This diagnosis is for checking the range of input signal voltage from the sport-mode-switch.

Description:

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> Short circuit to Ubatt or line break   (= SYM_0)
 │ │ └───> Short circuit to ground                (= SYM_1)
 │ └─────> -                                      (= SYM_2)
 └───────> -                                      (= SYM_3)
```

Application conditions:

Initialisation: at reset or LV_IGK = 0 → 1 all 0

Recurrence: 10 ms

Activation:

If LV_VAR_BN = 0 **and**

LV_IGK = 1 **and**

CONF_SOF_SWI > 0 **and**

LV_ERR_SOF_REQ = 0

Then LV_CDN_DIAG_SOF_REQ = 1

Else LV_CDN_DIAG_SOF_REQ = 0

```
        Endif
```

Formula section:

Short circuit to ground:

```
If      V_SOF_SWI < C_V_SOF_SWI_MIN    AND
        CONF_SOF_SWI = 1
Then    ERR_SYM_SOF_REQ = SYM_1
        LV_ERR_SOF_REQ = 1     (after debounce)
Endif
```

Short circuit to Ubatt or open line:

```
If      V_SOF_SWI > C_V_SOF_SWI_MAX
Then    ERR_SYM_SOF_REQ = SYM_0
        LV_ERR_SOF_REQ = 1     (after debounce)
Endif
```

Calculation of end of diagnosis:

For calculation of LV_END_DIAG_SOF_REQ see “Anti-bounce – algorithmus, calculation of the end of diagnosis”.

```

Application conditions:

Initialisation: according Filter-type **MPL_STD_INI**

(reset of variables at LV_IGK = 0 → 1 or ECU reset)

Recurrence: 100ms

Activation: LV_VAR_SOF = 1

Formula section:

If diagnosis is not inhibited (LV_INH_DIAG_SOF = 1) the diagnosis conditions are set according infrastructure information: CDN_DIAG_SOF.

Failure symptoms (raw value) are set according infrastructure information: ERR_DIAG_SOF.

Failure debouncing and error management treatment:

For failure and error management treatment the anti-bounce mechanism is called with the parameters CDN_DIAG_SOF and ERR_DIAG_SOF

This algorithm determines:

ERR_SYM_SOF	(Detected error symptom)
LV_ERR_SOF	(Error flag for debounced error)
LV_CDN_DIAG_SOF	(Diagnosis condition information)
LV_END_DIAG_SOF	(End of diagnosis information)

Diagnosis inhibition:

```
IF      LV_IGK = 1                      AND
        LV_CDN_VB_MIN_DIAG = 1                AND
        LV_ERR_SPI_MPS = 0
THEN    LV_INH_DIAG_SOF = 0
ELSE    LV_INH_DIAG_SOF = 1
ENDIF
```

Calibration data:

51 Misfire monitoring

Table of Contents

Index

51.1 MISF General

51.1.1 General description

The goal of the MISF is execute a misfire monitoring according legal requirements (conditions, engine area, errors & symptoms handling...) and provide to the ERRM aggregate following CARB misfire legal informations to manage the MIL and corresponding error Pcodes

- **CARB A misfire failure criterion:**

  Risk of catalyst damage, monitoring interval over 200 crankshaft during the driving cycle.

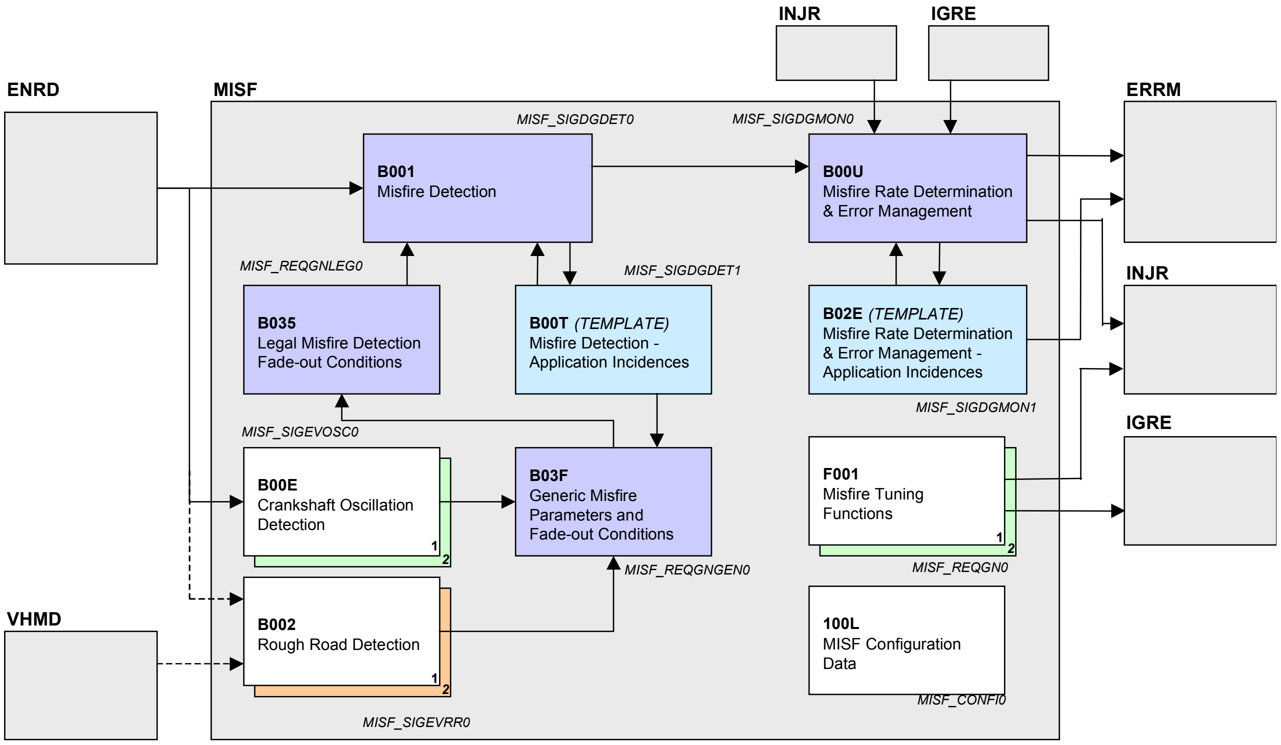
- **CARB B1 misfire failure criterion:**

  Emission increase, monitoring interval over the first 1000 crankshaft revolutions of the driving cycle.

- **CARB B4 misfire failure criterion:**

  Emission increase, monitoring interval over 1000 crankshaft revolutions. For error detection, misfire must be take place for 4 monitoring intervals (consecutive or not).

51.1.2 Architecture Overview



51.1.3 Description of the containing functions

51.1.3.1.1 B00E - Crankshaft oscillation detection

The crankshaft oscillation detection module uses engine roughness components to identify drivetrain oscillations than could cause wrong misfire detections in a defined engine operating area. If such oscillation occurs, this module triggers a fade-out.

51.1.3.1.2 B002 - Rough road detection

The rough road detection module uses informations coming from wheel speed sensor(s) or from ABS module (via harness or CAN) to identify transmission oscillations than could cause wrong misfire detections in a defined engine operating area. If such oscillation occurs, this module triggers a fade-out.

51.1.3.1.3 B03F - Generic misfire parameters & fade-out conditions

This module provides parameters needed for the misfire detection process (data delayed, data stacks, and zero load line...). It also managed all generic misfire fade-out conditions linked to the misfire detection method.

51.1.3.1.4 B035 - Legal misfire detection fade-out conditions

This module manages all legal misfire fade-out conditions defined in legal texts (US & EC).

51.1.3.1.5 B00T - Misfire detection - Application incidences

This module defines specific corrections for detection thresholds, application specific fade-out with standardised outputs to the generic modules.

51.1.3.1.6 B001 - Misfire detection

Detection core function based on engine roughness index provided by ENRD.

51.1.3.1.7 B00T - Misfire detection - Application incidences

Some functionality for calibration ease can be launched after detection.

51.1.3.1.8 B02E - Misfire rate determination & error management - Application Incidences

This module defines application specific fade-out & informations with standardised outputs to the generic misfire rate determination module. Diagnosis conditions are defined in this module.

Must be executed before B00U module.

51.1.3.1.9 B00U - Misfire rate determination & error management

This module defines the Misfire criterions according legal texts description *(MIS_A = misfire damage catalyst criterion, MIS_B1 = misfire emission criterion at engine warm-up & MIS_B4 = misfire emission criterion)* and identify the cylinders in failures

51.1.3.1.10 B02E - Misfire rate determination & error management - Application Incidences

This module defines misfire errors according the type chosen by NC_TREAT_DIAG_MIS: errors defined per misfire criterions or errors defined per cylinder.

Failures like Misfire with low fuel tank level, Multiple cylinder misfire, Random cylinder misfire are also managed in this module.

Must be executed after B00U module.

51.1.3.1.11 F001 - Misfire Tuning Functions

This module allows to generate misfire patterns (continuous or pseudo random) via injection and/or ignition shut-off interfaces.

This module is optionnal and can be integrated during validation and calibration stages. It is strongly recommended to remove this functionally on serial product software (integration choice via NC_USE_MIS_GEN compilation switch).

51.2 MISF Configuration Data

Input data:

NLC_TREAT_DIAG_MIS	NLC_USE_ER_STND_MIS	NLC_USE_MIS_GEN	NC_CONF_RR_MIS
NLC_USE_CRK_OSC_MIS	NC_SIZE_THD_ER_BUF	NC_CBK_EX_NR_MISF[NC_CYL_NR]	NC_CYL_NR
SEG_NR_ER			

General information:

The following describes the general rules for determination of the configuration data

51.2.1 Global configuration data

Here are listed the configuration data, which can be used in other aggregates :

Data	Value
NLC_TREAT_DIAG_MIS	**1**

51.2.2 Local configuration data

Here are listed the configuration data, which are used only in the MISF aggregate.

Data	Value
NC_MISF_VERS	**1**
NLC_USE_ER_STND_MIS	**0**
NC_SIZE_THD_ER_BUF	**4**
NC_CONF_RR_MIS	**OTHER**
NLC_USE_CRK_OSC_MIS	**1**
NLC_USE_MIS_GEN	**1**
NC_CBK_EX_NR_MISF[NC_CYL_NR]	*see table below*

LV_HOM_AFL_ACT	LC_MIS_INH	LV_DRI	LV_CVT
LV_VAR_4WD	THD_ER_CLC		

Function description:

ER strategy misfire detection is based on a comparison between a cylinder specific ER value (nominal or normalised) and a threshold who is relative to the engine parameters when this same cylinder was in intake phase (threshold relative to combustion conditions image).

The engine roughness value ER depends strongly on the current operating point, both in its spread during undisturbed engine operation, and in the signal amplitude in case of an actual misfire.

ER misfire detection thresholds are defined according basic threshold maps and threshold corrections:

- *A basic threshold map:*

This map is function of engine load and speed which are calibrated for engine at operating temperature as well as for adapted transmitter gear. One map is assigned through the vehicle transmission type, idle speed condition & the combustion mode.

- *A threshold temperature correction:*

A temperature correction is applied to compensate larger signal amplitudes arise of ER values at lower engine temperatures. This correction is relative to TCO value.

- *A threshold correction during active injection valve cut-off:*

If one or several injection valves are cut off selectively by the engine management system (IV diagnoses ...), then the cylinder or cylinders are excluded from the misfire check. Due to the system, the signal amplitude of the ER value is reduced with a misfire at another cylinder. To improve the detection for this period, the absolute amount of the threshold can be reduced multiplicatively with the factor IP_FAC_THD_IV_ER(N_32) or IP_FAC_THD_IV_S_ER(N_32) *(in stratifed mode)*. *FAC_THD_IV_ER is a temporary data.*

- *A threshold correction defined in application incidences:*

FAC_THD_APP_ER is a threshold multiplicative correction who is defined in the misfire detection application incidences file.

51.3.2.1 Multiplicative correction for misfire thresholds

Application conditions:

Initialisation: *FAC_THD_IV_ER = 1*
Recurrence: every ENRD segment task
Activation: *LV_ENA_SEG_T_MES = 1*
And *LC_MIS_INH = 0*
Deactivation: *LV_ENA_SEG_T_MES = 0*
Or *LC_MIS_INH = 1*

Formula section:

```
#IF NC_CMB_CONF = AFS_S Or AFS_AFL_S
    If      INH_INJ = 0
    Then    FAC_THD_IV_ER = 1
    Elself  LV_S_ACT = 1
    Then    FAC_THD_IV_ER = IP_FAC_THD_IV_S_ER(N_32)
    Else    FAC_THD_IV_ER = IP_FAC_THD_IV_ER(N_32)
    EndIf
```

```
#ELSE
    If      INH_INJ = 0
    Then    FAC_THD_IV_ER = 1
    Else    FAC_THD_IV_ER = IP_FAC_THD_IV_ER(N_32)
    EndIf
#ENDIF
FAC_THD_ER = IP_FAC_THD_TCO_ER(TCO) * FAC_THD_IV_ER * FAC_THD_APP_ER
```

51.3.2.2 Misfire detection threshold buffers management

To manage the delay between cylinder intake phase and cylinder ER values, buffers are used to store threshold values before using for detection.

THD_ER_BUF[NC_SIZE_THD_ER_BUF] buffer is managed as a FIFO stack.

THD_ER_BUF[0] threshold value is the one obtained at current segment.

THD_ER is threshold value delayed and who will be used for detection with current segment ER value. This delay between ER value and cylinder corresponding threshold depends on engine cylinder number (NC_CYL_NR).

51.3.2.3 Misfire detection threshold based on engine roughness value (THD_ER)

By using the ER value for misfire detection, the engine speed has the greatest influence on basic thresholds definition. On the other hand, by using the ER_STND values for misfire detection, the engine load has the greatest influence on basic thresholds definition.

The influence of the engine load on the detection thresholds can change rapidly during instationary operation, it is urgently necessary to determine and to temporarily store the threshold values already at the time of the actual combustion before the calculatory check.

note: at each ER segment occurence, THD_ER_BUF is shifted with one memory unit (FIFO management) before determination process.

Application conditions:

Initialisation: at ECU reset **Or** engine stop

```
    THD_ER = -32768
    //  ER Threshold buffer init on ER buffer reinitialisation
    For k = 0 : NC_SIZE_THD_ER_BUF-1
            THD_ER_BUF[k] = -32768    // For all buffer cells
    EndFor
    For x = 0 : NC_CYL_NR-1
            THD_ER_CYL[x] = -32768    // For all cylinders
    EndFor
```

Recurrence: every ENRD segment task

Activation: *LV_ENA_SEG_T_MES = 1*

***And** LC_MIS_INH = 0*

```
Deactivation:  LV_ENA_SEG_T_MES = 0
               Or LC_MIS_INH = 1
Actions on Deactivation event:
    THD_ER = -32768
    // ER Threshold buffer init on ER buffer reinitialisation
    For k = 0 : NC_SIZE_THD_ER_BUF-1
        THD_ER_BUF[k] = -32768    // For all buffer cells
    EndFor
    For x = 0 : NC_CYL_NR-1
        THD_ER_CYL[x] = -32768    // For all cylinders
    EndFor
```

Formula section:

THD_ER_BUF[0] = THD_ER_CLC * FAC_THD_ER

THD_ER = THD_ER_BUF[NC_SIZE_THD_ER_BUF-1]   // Last cell of THD_ER buffer

THD_ER_CYL[SEG_NR_ER] = THD_ER

Input data:

LV_REQ_INH_MIS	LV_ENA_ER	ER	ER_STND
THD_ER	LC_MIS_INH	LV_ZDLY_DIAG_MIS	SEG_NR_ER
LV_DIAG_MIS	NC_CYL_NR	LV_ER_CLC_MIS_DET_CUS_SPC	MIS_STATE_CUS_SPC

General information:

The system identifies misfiring by monitoring engine roughness index. Misfiring causes the angular velocity of the crankshaft to drop in an angular range specific to the cylinder in question.

Misfire detection is based on nominal engine roughness (ER) by using THD_ER detection threshold.

The identification of the cylinder(s) detected in misfire is realised according SEG_NR_ER segment reference (see definition and scheme in ENRD aggregate) *(Chapter system variables)*.

THD_ER is already phased according ER delay *(see detection thresholds management)*.

Application conditions:

*Initialisation: at ECU reset, at Engine Stop **Or** at Deactivation Event*

LV_DET_MIS = 0

LV_DET_THD_MIS = 0

LV_INH_DET_MIS = 1

MIS_STATE_ER = 0

MIS_DET_CYL_INH = $2^{NC\_CYL\_NR} - 1$

Recurrence: every segment task

Activation: *LV_ENA_ER = 1*

***And** LC_MIS_INH = 0*

Deactivation: *LV_ENA_ER = 0*

***Or** LC_MIS_INH = 1*

Update rate:

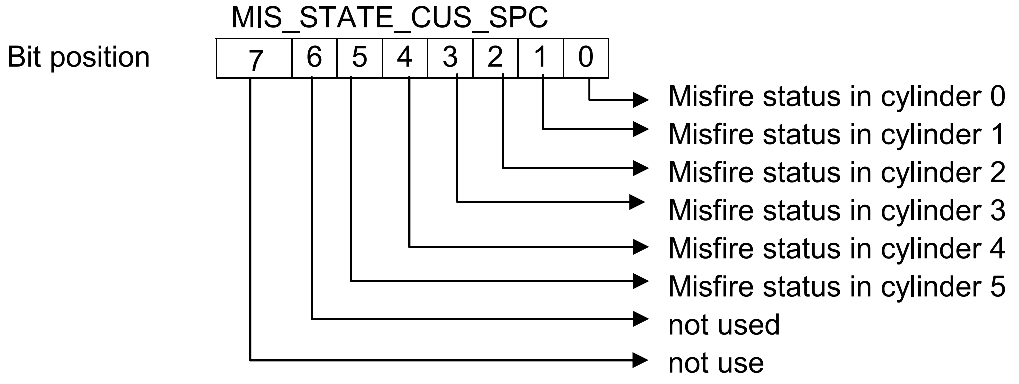
ENRD segment task

Forumla section:

Misfire detection criterion

```
#IF NLC_USE_ER_STND_MIS = 0         // ER based detection
    If      ( ER < THD_ER )
            OR
            {
             LC_MIS_INH_CUS_SPC = 0                 AND
             LV_ER_CLC_MIS_DET_CUS_SPC =1    AND
            (Bit (SEG_NR_ER)  of  MIS_STATE_CUS_SPC = 1 )
            }
                                         // Read bit position of MIS_STATE_CUS_SPC
    Then    LV_DET_THD_MIS = 1          // basic detection before fade-out
    Else    LV_DET_THD_MIS = 0
    EndIf
#ELSE                                   // ER_STND based detection
    If      ( ER_STND < THD_ER )
            OR
            {
             LC_MIS_INH_CUS_SPC = 0                 AND
             LV_ER_CLC_MIS_DET_CUS_SPC  =1  AND
            (Bit (SEG_NR_ER)  of  MIS_STATE_CUS_SPC = 1 )
            }
                                        // Read bit position of MIS_STATE_CUS_SPC
    Then    LV_DET_THD_MIS = 1          // basic detection before fade-out
    Else    LV_DET_THD_MIS = 0
    EndIf
#ENDIF
```

// Customer specific misfire detection algorithm, has been introduced in this release, If there is catalyst heating and all related conditions are met, then LV_ER_CLC_MIS_DET_CUS_SPC is set to 1. This enables customer specific algorithm. MIS_STATE_CUS_SPC is a status byte, and the information from the misfiring cylinder are stored in it.



Value in Bit position = 0, No misfire detected.
Value in Bit position = 1, Misfire detected on respective cylinder.

General fade-out management

```
If    LV_REQ_INH_MIS = 0         // no fade-out request on going (legal and generic)
      And   ( LV_ZDLY_DIAG_MIS = 1 Or LV_DIAG_MIS = 1 )  // diagnosis phase started
Then        LV_INH_DET_MIS = 0
            MIS_DET_CYL_INH[SEG_NR_ER] = 0
            (corresponding cylinder bit in MIS_DET_CYL_INH structure is set to 0,
            misfire detection will be enabled on this cylinder
Else        LV_INH_DET_MIS = 1

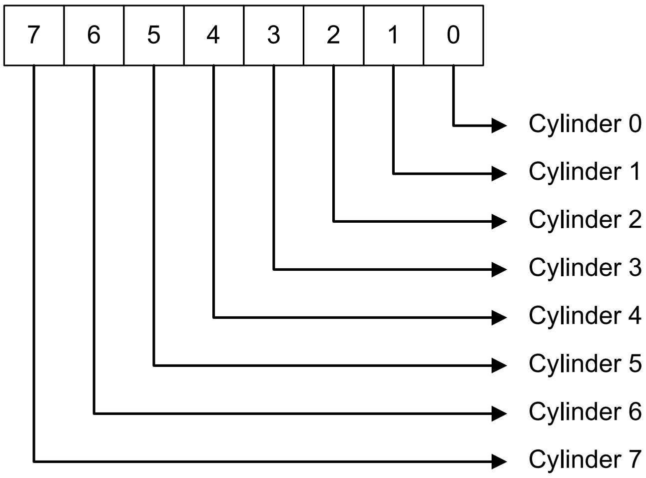
Else            LV_DET_MIS = 0
                MIS_STATE_ER[SEG_NR_ER] = 0
                Cylinder specific bit in MIS_STATE_ER carrier structure is set to 0 according SEG_NR_ER
                segment reference.
EndIf
```

Misfire cylinder fade out carrier definition:

MIS_DET_CYL_INH : Carrier used for cylinder fade-out reference
Shows the cylinders that will be in fade-out during the detection phase

MIS_STATE_ER *:* Carrier used for identification of the cylinder detected in misfire
Shows the cylinders that will be detected in misfire

Carrier stucture valid for
MIS_STATE_ER
and
MIS_DET_CYL_INH



Calibration data:

51.4 Misfire detection - Application incidences

51.4.1 Global fade out condition (N_32 threshold)

Input data:

N_32			

FUNCTION DESCRIPTION:

General information:

There is one global condition N_32 > C_N_THD_MIS_INH which can be used for inhibition (deactivation) of the following modules:

- Appl. Inc. for engine roughness calc.	: chapter System variables
- Engine roughness calculation	: chapter System variables
- Appl. Inc. for misfire detection	: chapter OBDII
- Misfire detection	: chapter OBDII
- Misfire rate detection and error handling	: chapter OBDII

Formula section:

```
If      N_32 > C_N_THD_MIS_INH
Then    Engine roughness/Misfire detection is inhibited
Else    no inhibition due to this condition
Endif
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_N_THD_MIS_INH	1	0...FFH	0...8160	32	[rpm]
Global condition for inhibiting (deactivation) of all misfire modules					

51.4.2 Misfire detection threshold correction gain specific to application

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_THD_APP_ER	V/O	0...1FFH	0...1.99609	3.9063e-3	[-]
Misfire detection threshold correction gain specific to application					

Input data:

TQ_ADD_CH	LV_IS	LV_S_ACT	LC_MIS_INH
LV_ENA_SEG_T_MES			

Description:

To ensure misfire detection during active catalyst heating in IS (in homogenous mode only), the threshold is multiplied with a factor depending on the torque reserve at catalyst heating TQ_ADD_CH.

Application conditions:

Initialization: all 1 at reset and at each activation and deactivation

Recurrency: segment

Activation: LV_ENA_SEG_T_MES = 1 **and** LC_MIS_INH = 0

Deactivation: LV_ENA_SEG_T_MES = 0 **or** LC_MIS_INH = 1

Formula section:

```
If      LV_IS = 1           and
        LV_S_ACT = 0
Then    FAC_THD_APP_ER = IP_FAC_THD_ER_CH(TQ_ADD_CH)
Else    FAC_THD_APP_ER = 1
EndIf
```

51.4.3 Misfire detection inhibition related to OBDI diagnosis

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_OBD_DET_MIS	V/O	0...1H	0...1	1	[-]
OBD I misfire detection process inhibition flag					

Input data:

LV_ERR_SEG_AD_ER	LV_ERR_MAF	LC_MIS_INH	LV_ERR_IVVT
LV_ENA_ER	LV_ERR_TPS		

Description:

Misfire detection process is inhibited when one of the following OBD I errors occurs.

Depending on calibration, IVVT diagnosis is considered for inhibition or not.

Application conditions:

Initialization: all 0 at reset and at each activation and deactivation

Recurrency: updated every segment before misfire detection function

Activation: LV_ENA_ER = 1 **and** LC_MIS_INH = 0

Deactivation: LV_ENA_ER = 0 **or** LC_MIS_ INH = 1

Formula section:

```
If      LV_ERR_MAF = 1                 // mass air flow signal error detected
   or   LV_ERR_TPS = 1                 // throttle error
   or   [ LV_ERR_IVVT = 1 and LC_USE_IVVT_INH_MIS = 1]   // VANOS error
   or   LV_ERR_SEG_AD_ER = 1   // Segment adaptation error

Then    LV_INH_OBD_DET_MIS  = 1
Else    LV_INH_OBD_DET_MIS  = 0
EndIf
```

Calibration data:

Enable IVVT diagnosis for Inhibition of misfire detection					

51.4.4 Misfire detection inhibition related to AMT gearshift intervention

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_MIS_INH_IV_KNK	V	0...1H	0...1	1	[-]
Misfire detection process inhibition due to injection shut of from knock control					
LV_MIS_INH_CS	V	0...1H	0...1	1	[-]
Misfire detection process inhibition during clutch transition.					
LV_INH_APP_DET_MIS	O/V	0...1H	0...1	1	[-]
Misfire detection process inhibition flag (application specific).					

Input data:

LC_MIS_INH	LV_ENA_ER	LV_GS	INH_IV_KNK
LV_CS_CUS			

FUNCTION DESCRIPTION:

General information:

LV_INH_APP_DET_MIS is used for project-specific inhibition of Misfire detection, e.g.:

- AMT gearshift intervention

Description:

When AMT gearshift intervention is detected (LV_GS = 1) misfire detection can be suppresed because this load jump can cause a segment period jump and crankshaft vibration, depending on the engine operating state and load request.

If AMT gearshift intervention has been detected (LV_GS changes from 1 to 0 or 0 to 1), Misfire detection can be suppressed for the applicable constant period C_T_AMT_GS_DLY_MIS starting at transition LV_GS 1->0.

Application conditions:

Initialization:	all 0 at reset and at each activation and deactivation		
Recurrence:	updated every segment before misfire detection function		
Activation:	LV_ENA_ER = 1	**and**	LC_MIS_INH = 0
Deactivation:	LV_ENA_ER = 0	**or**	LC_MIS_ INH = 1

Formula section:

Cylinder fuel shut-off:

// if any one cylinder is switched off from Knock control fuinction, then misfire is deactivated. This can be activated using the switch LC_MIS_INH_IV_KNK.

NOTE: The Activation by LC_MIS_INH_IV_KNK has to be checked with CARB

```
If(1)  INH_IV_KNK > 0       // indexed by cylinder bit position
Then(1)     LV_MIS_INH_IV_KNK = 1 after a  delay of C_NR_TDC_IV_OFF_DET_MIS_KNK

            TDC,s

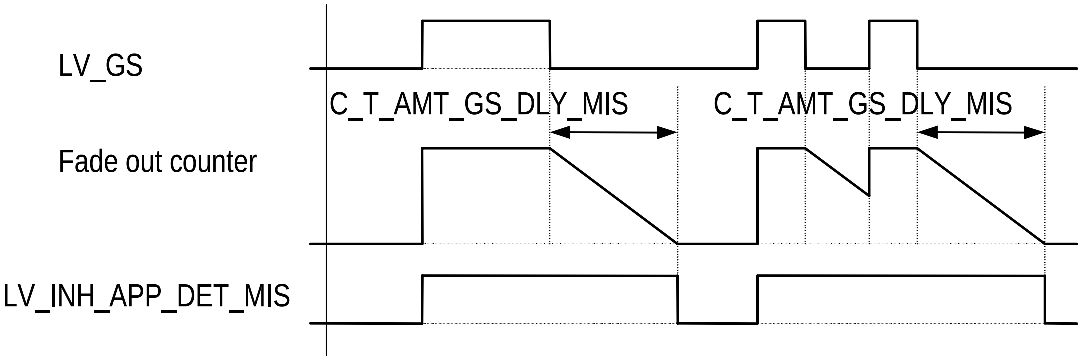
                                                                        TDC,s
EndIf(1)

If(2) (  ( LV_CS_CUS 1->0  or  LV_CS_CUS 0->1)  AND  LC_MIS_INH_CS=1  )
Then(2)  LV_MIS_INH_CS = 1 for C_T_CS_DLY_MIS    TDC,s
Else(2)  LV_MIS_INH_CS = 0
Endif(2)
```

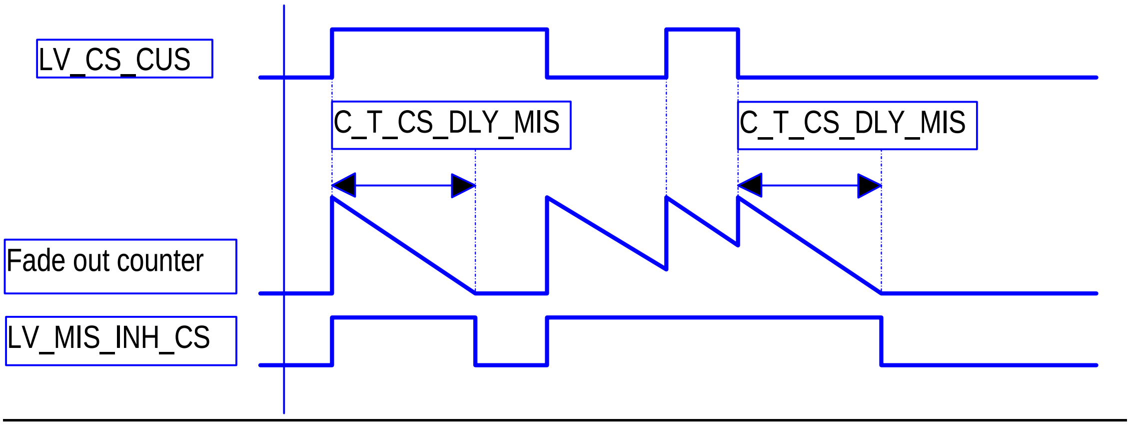
// inhibition of misfire function during gear change, is not allowed for CARB applications.

```
If(3)       LV_GS = 1
     Or     LV_GS 1->0 and Time C_T_AMT_GS_DLY_MIS is active
     Or     LV_MIS_INH_IV_KNK =1     AND    LC_MIS_INH_IV_KNK = 1
     Or     LV_MIS_INH_CS = 1
Then(3)     LV_INH_APP_DET_MIS = 1
Else(3)     LV_INH_APP_DET_MIS = 0
EndIf(3)
```

Fade out behaviour summary for AMT gear shift :



Fade out behaviour summary for MT – Change in clutch signal



Calibration data:

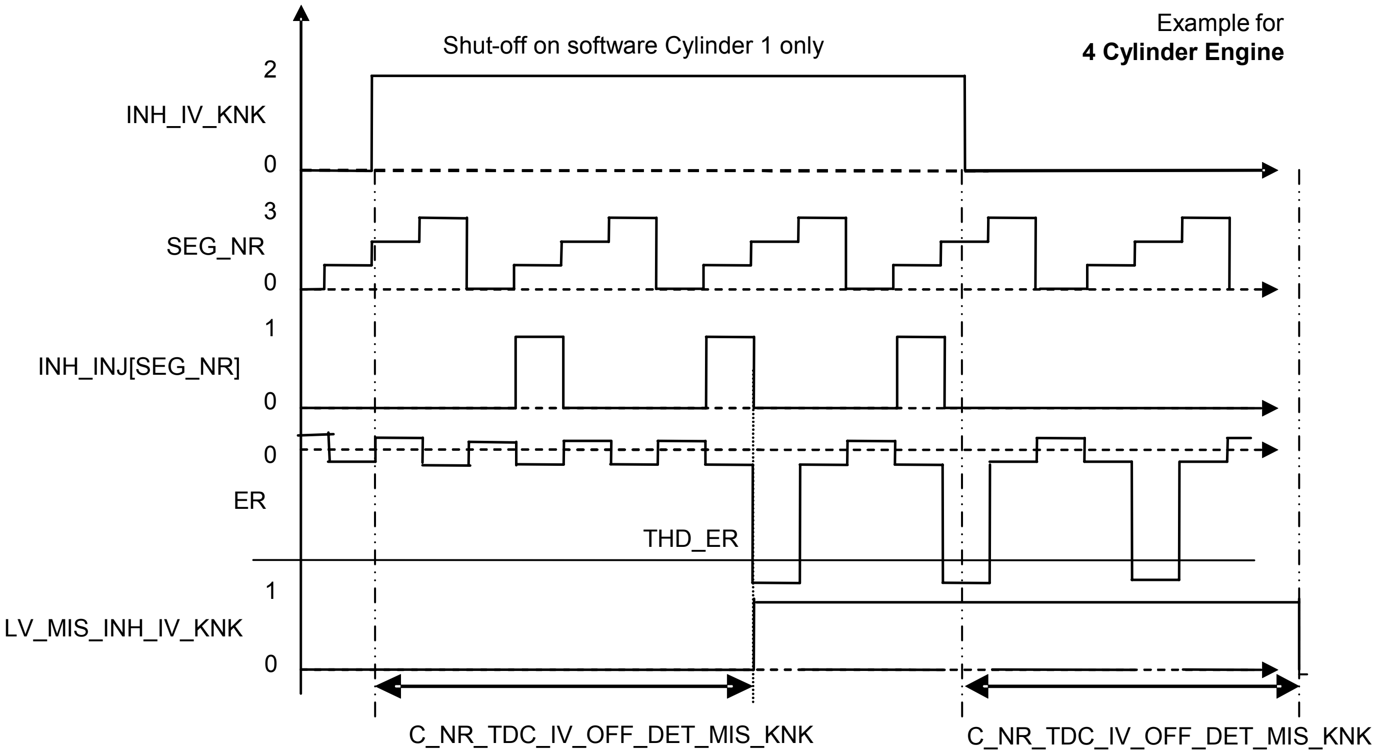
Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
C_NR_TDC_IV_OFF_DET_MIS_KNK	1	0...FFH	0...255	1	[-]
TDC delay to synchronise cylinder shut-off (from Knock control) information with the misfire detection index					
LC_MIS_INH_IV_KNK	1	0...1H	0...1	1	[-]
Switch to enable misfire deactivation due to injection switch off from knock control					
LC_MIS_INH_CS	1	0...1H	0...1	1	[-]
Switch to enable misfire deactivation during Clutch transition					
C_T_CS_DLY_MIS	1	0...FFH	0...255	1	[-]
No. of TDC,s for which misfire is deactivated during clutch transition.					
C_T_AMT_GS_DLY_MIS	1	0...FFFFH	0...655.35	0.01	[s]
Fade out duration when gearshift of AMT has been detected					

// Initial appliation value for C_NR_TDC_IV_OFF_DET_MIS_KNK, should be taken from C_NR_TDC_IV_OFF_DET_MIS + *NC_CYL_NR-2*

There is a delay of 2 segments for calculation of INH_IV_KNK, hence delay of

NC_CYL_NR-2 segments to shut off the injector. Injection switch off only in the next segment calculation.

Further there is a delay of C_NR_TDC_IV_OFF_DET_MIS TDC,s for ER calculation. Hence total delay is C_NR_TDC_IV_OFF_DET_MIS + *NC_CYL_NR-2*



51.4.5 Rough road detection fade out condition

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_INH_APP_RR	V/O	0...1H	0...1	1	[-]
Rough road detection appl. Inc. fade out					

Input data:

LC_MIS_INH	LV_ERR_VS		

Description:

Rough road detection is inhibited if no VS signal is available (LV_ERR_VS = 1).

Application conditions:

Initialisation: all 0 at reset and at each activation and deactivation

Recurrence: same as rough road detection update rate

Activation: LC_MIS_INH = 0

Deactivation: LC_MIS_ INH = 1

Formula section:

```
If      LV_ERR_VS = 1
Then    LV_INH_APP_RR = 1
Else    LV_INH_APP_RR = 0
Endif
```

51.4.6 Misfire low fuel tank level informations

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_FTL_L_DET_MIS	V/O	0...1H	0...1	1	[-]
Misfire detection inhibition flag in case of low fuel tank level					
LV_FTL_L_DIAG_MIS	V/O	0...1H	0...1	1	[-]
Request to allow error management of misfire occurence with low fuel tank level					

Input data:

LV_FTL_OBD_INH_L	LC_MIS_INH		

Description:

- Misfire detection can be supressed if low fuel is detected (LV_INH_FTL_L_DET_MIS).
- Low fuel signal can be used to calculate P-Code “Misfire with low fuel” P313.

Application conditions:

Initialisation: all 0 at reset and at each activation and deactivation

Recurrence: 200ms *//same as fuel tank level information*

Activation: LC_MIS_INH = 0

Deactivation: LC_MIS_INH = 1

Formula section:

Low fuel tank level information for misfire detection inhibition

```
If    LV_FTL_OBD_INH_L = 1
      And   LC_FTL_L_DET_MIS = 1
Then        LV_INH_FTL_L_DET_MIS = 1
Else        LV_INH_FTL_L_DET_MIS = 0
EndIf
```

Low fuel tank level information for error management of symptom "misfire with low fuel tank level".

Then        LV_FTL_L_DIAG_MIS = 1
Else        LV_FTL_L_DIAG_MIS = 0
EndIf
```

Calibration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
LC_FTL_L_DET_MIS	1	0...1H	0...1	1	[-]
Inhibition of misfire detection in case of low fuel tank level					
LC_FTL_L_DIAG_MIS	1	0...1H	0...1	1	[-]
Enable error management of misfire with low fuel tank level					

51.4.7 Total counter misfire detection

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
CTR_TOT_MIS	V/S	0...FFFFFFFFH	0...4294967295	1	[-]
Overall misfire detection counter					

Input data:

LV_DET_MIS	LC_MIS_INH		

FUNCTION DESCRIPTION:

General information:

This counter is incremented at each misfire detection based on misfire index evaluation *(before crossed diagnosis with IGC & IV OBDI diags evaluation)*. Thus, it's possible to determine the total number of misfire detected during engine lifetime.

Application conditions:

Initialisation: restored from NVMY

Recurrence: updated every segment after LV_DET_MIS calculation

Activation: LC_MIS_INH = 0

Deactivation: LC_MIS_INH = 1

Formula section:

On NV memory formatting or on NV memory corruption detection :

CTR_TOT_MIS = 0

Processing :

at each transition LV_DET_MIS 0 -> 1

CTR_TOT_MIS = CTR_TOT_MIS + 1

51.4.8 Crankshaft oscillation detection fade-out

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
LV_INH_CRK_OSC_DET	V/O	0...1H	0...1	1	[-]
Crankshaft oscillation detection fade out					

Input data:

LV_ERR_VS	LC_MIS_INH		

FUNCTION DESCRIPTION:

Crankshaft oscillation detection process can be inhibited when one function and/or error requires an inhibition.

Note : This bit is necessary only if the crankshaft oscillation detection module is used in the project (NLC_USE_CRK_OSC_MIS = 1)

Application conditions:

Initialisation:	all 0 at reset and at each activation and deactivation
Recurrence:	Segment, before Crankshaft oscillation detection
Activation:	LC_MIS_INH = 0
Deactivation:	LC_MIS_ INH = 1

Formula section:

```
If      LV_ERR_VS = 1
Then    LV_INH_CRK_OSC_DET = 1
Else    LV_INH_CRK_OSC_DET = 0
EndIf
```

51.4.9 Mean value of the corrected basic ignition angles

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
IGA_BAS_COR_MV	V/O	0...FFH	-35.625...60	0.375	[°CRK]
Mean value of the corrected basic ignition angles					

Input data:

IGA_BAS_COR			

Application conditions:

Initialisation: IGA_BAS_COR_MV = 0 at reset

Recurrence: 10 ms

Activation: LV_IGK = 1

Formula section:

IGA_BAS_COR_MV = IGA_BAS_COR

51.4.10 Correction gain for engine load specific to application

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
FAC_GAIN_LOAD_MIS	V/O	0...1FFH	0...1.99609	3.9063e-3	[-]
Correction gain of the normalised engine load for misfire, specific to application					

Input data:

LV_ENA_SEG_T_MES	LC_MIS_INH		

Description:

Here can be defined a gain who can change the normalised engine load dedicated to misfire monitoring according specific load corrections.

This correction can be applied during torque reduction sequences specific to project.

Application conditions:

Activation: *LV_ENA_SEG_T_MES = 1*

And *LC_MIS_INH = 0*

Deactivation: *LV_ENA_SEG_T_MES= 0*

Or *LC_MIS_INH = 1*

Initialisation: FAC_GAIN_LOAD_MIS = 1

Recurrency: -

51.4.11 Current Misfire Detection Threshold

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
THD_ER_CLC	V/O	8000...7FFFH	-32768...32767	1	[-]
Value of the table used for Misfire detection threshold at current segment					
THD_ER_CLC_PREV	V	8000...7FFFH	-32768...32767	1	[-]
Previous value of the table used for misfire detection threshold at current segment					
LV_ER_CLC_PREV_INI	-	0...1H	0...1	1	[-]
Boolean for initialisation of THD_ER_CLC_PREV at start of gradient limitation					

Input data:

N	LV_AT	OPM_AV	LV_IS
LOAD_MIS	LC_MIS_INH	LV_ENA_SEG_T_MES	NC_CMB_CONF
LV_VAR_TCT			

General information:

THD_ER_CLC represents the current value used for determination of the misfire detection threshold. This data must be calculated before THD_ER calculation and after LOAD_MIS calculation.

Description:

Keyword configuration table:

NC_CMB_CONF	OPM_AV	xx
AFS	2	AFS
AFS_AFL	2	AFS
AFS_AFL	3	HOM_S
AFS_S	1	S
AFS_S	2	AFS
AFS_AFL_S	1	S
AFS_AFL_S	2	AFS
AFS_AFL_S	3	HOM_S

Application conditions:

Initialisation: at ECU reset **Or** engine stop
THD_ER_CLC = -32768
THD_ER_CLC_PREV = -32768
LV_ER_CLC_PREV_INI = 1

Recurrence: every ENRD segment task

Activation: *LV_ENA_SEG_T_MES = 1*
***And** LC_MIS_INH = 0*

Deactivation: *LV_ENA_SEG_T_MES = 0*
***Or** LC_MIS_INH = 1*

Actions on Deactivation event:

```
        THD_ER_CLC = -32768
        LV_ER_CLC_PREV_INI = 1
```

Formula section:

Convention for combustion mode determination:

```
#If  NC_CMB_CONF = AFS_AFL Or AFS_AFL_S
    If      OPM_AV = 3          (homogeneous-stratified)
    Then    xx = "HOM_S"
    EndIf

51.4.12 Zero Load Line for Misfire detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LOAD_MIN_MIS	V/O	0...7FFFH	0...99.99694	3.0518e-3	[%]
Normalised engine "zero" load for misfire detection					

Input data:

N	TCO	LV_AT	NC_CMB_CONF
LC_MIS_INH	AMP	OPM_AV	LV_VAR_TCT

FUNCTION DESCRIPTION:

The zero load line is a function of the engine speed and depends on the engine combustion mode (for GDI application), coolant temperature and atmospheric pressure.

Application conditions:

Initialisation: Variable is initialised to 0 at reset, at engine stop **Or** at LC_MIS_INH 0 to 1 transition

Recurrence: every segment task

Activation: LV_ENA_SEG_T_MES = 1

And LC_MIS_INH = 0

Deactivation: LV_ENA_SEG_T_MES = 0

Or LC_MIS_INH = 1

Formula section:

Minimum engine load and zero load lines

Convention for combustion mode determination:

```
#If NC_CMB_CONF = AFS_AFL Or AFS_AFL_S
    If      OPM_AV = 3          (homogeneous-stratified)
    Then    xx = "HOM_S"
    EndIf
#EndIf
#If NC_CMB_CONF = AFS_S Or AFS_AFL_S
    If      OPM_AV = 1          (stratified)
    Then    xx = "S"
    EndIf
#EndIf

If          OPM_AV <> 1  and  OPM_AV <> 3 (homogeneous)
```

```
Then        xx = "AFS"
EndIf
```

Convention for transmission type determination:

```
If(1) LV_AT = 1
Then(1)
            yy= AT
ElseIf(2)   LV_VAR_TCT = 1
    Then(2)
            yy= TCT
    Else(2)
            yy= MT
    Endif(2)
Endif(1)
```

```
LOAD_MIN_MIS = IP_LOAD_MIN_MIS_xx_yy(N, TCO)
                    + IP_LOAD_MIN_OFS_AMP_MIS_xx_yy(N, AMP)
```

51.4.13 Misfire Combustion mode transients informations

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_CMB_TRA_MIS	V/O	0...1H	0...1	1	[-]
Misfire detection fade out request flag due to combustion mode transients					

Input data:

OPM_AV	NC_CMB_CONF		

Application conditions:

While the combustion manager is in transient state, the misfire detection can be disabled to have a proper base for evaluation of the ER-misfire detection thresholds, which are defined for the stationary modes (AFS, AFL & S).

This function must be called before the generic specification named "Generic fade out conditions for misfire detection"

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_CMB_TRA_MIS = 1

Formula section:

```
#If  NC_CMB_CONF = AFS_S Or AFS_AFL_S
     If     OPM_AV = x -> 1      (x is different of 1)
     Then   LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_S_MIS tdc's
     EndIf
#EndIf

#If  NC_CMB_CONF = AFS_AFL Or AFS_AFL_S
     If     OPM_AV = x -> 3      (x is different of 3)
     Then   LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_AFL_MIS tdc's
     EndIf
#EndIf
     If     OPM_AV = x -> 2      (x is different of 2)
     Then   LV_INH_CMB_TRA_MIS is set to 1 during C_NR_TDC_CMB_TRA_HOM_MIS tdc's
     EndIf
```

LOAD_GRD_MIS	V/O	0...7FFFH	0...99.99694	3.0518e-3	[%]
Normalised engine load gradient for misfire detection					

Input data:

LC_MIS_INH	TCO	MAP	LV_ENA_SEG_T_MES
TQI_AV	AMP	MAF	FAC_GAIN_LOAD_MIS

FUNCTION DESCRIPTION:

In order to cover all the combustion states of an engine (Hom. AFS, AFL & Strat.) in torque based engine control, a general variable LOAD_MIS that represents the ratio of engine load – whatever should be the load definition depending on engine combustion state (*eg. MAF in Hom. and TQI_AV in Strat.*) – is defined for the purpose of the Misfire function and the calculation of the ER-misfire detection thresholds.

Depending on the project choice configuration (*with C_CONF_LOAD_MIS*), in Homogenous combustion mode this Misfire load variable should be either MAF, MAP or TQI_AV. In the other hand this Misfire load variable is always TQI_AV in Stratified combustion mode.

Legally, the presence of engine misfire in the engine operating region is bounded by the positive torque line (i.e. engine load with the transmission in neutral) and an engine speed value.

The zero load line is a function of the engine speed and depends on the engine combustion mode (for GDI application), coolant temperature and atmospheric pressure.

Application conditions:

Initialisation: All variables are initialised to 0 at reset, at engine stop **Or** at LC_MIS_INH 0 to 1 transition

LOAD_GRD_MIS is first time calculated when LOAD_MIS stack have been fill in (4 segments).

Recurrence: every segment task

Activation: LV_ENA_SEG_T_MES = 1
And LC_MIS_INH = 0

Deactivation: LV_ENA_SEG_T_MES = 0
Or LC_MIS_INH = 1

Formula section:

Normalised engine load dedicated to misfire detection

For each misfire segment, the following stack is serviced:

```
LOAD_MIS_3 =LOAD_MIS_2
LOAD_MIS_2 =LOAD_MIS_1
LOAD_MIS_1 = LOAD_MIS
If        C_CONF_LOAD_MIS = 0
    Or    LV_S_ACT = 1
Then      LOAD_MIS_Temp = TQI_AV / IP_TQI_AV_MAX_MIS(N_32)      // TQI_AV based
ElseIf    C_CONF_LOAD_MIS = 1
Then      LOAD_MIS_Temp = MAF / IP_MAF_MAX_MIS(N32)             // MAF based
Else      LOAD_MIS_Temp = MAP / C_MAP_MAX_MIS                   // MAP based
EndIf
LOAD_MIS = FAC_GAIN_LOAD_MIS * LOAD_Temp        // Application incidence correction
LOAD_GRD_MIS = | LOAD_MIS - LOAD_MIS_3 |
```

Note : LOAD_MIS calculation steps are checked against division by zero
LOAD_MIS_Temp is a non visible, temporary value

Calibration data:

LC_MIS_INH	LV_IS	N	MAP

General information:

Generic fade out (LV_REQ_APP_INH_MIS) is based on all conditions who could create unreliable conditions for misfire detection :

- Engine gradients (engine load, throttle, combustion mode & ignition angle transients).
- Crankshaft jolt effects who can distrub detection process (rough road, drivetrain oscillations, air conditionner & accessoiries activation/deactivation).
- OBDI errors on one of the sensors used by the misfire monitoring process.

All these different conditions are merge into a carrier (MIS_DET_CDN_APP_INH).

Application conditions:

Initialisation: at ECU reset, at Engine Stop **Or** at LC_MIS_INH 0 to 1 transition

LV_REQ_APP_INH_MIS = 1
MIS_DET_CDN_APP_INH = 2047
MIS_DET_CDN_APP_INH_NR = 11
MAP_DIF_MIS = 0
IGA_DIF_MIS = 0
IGA_BAS_DIF_MIS = 0
IGA_MIS_2 = 0
IGA_MIS_1 = 0
IGA_MIS = 0

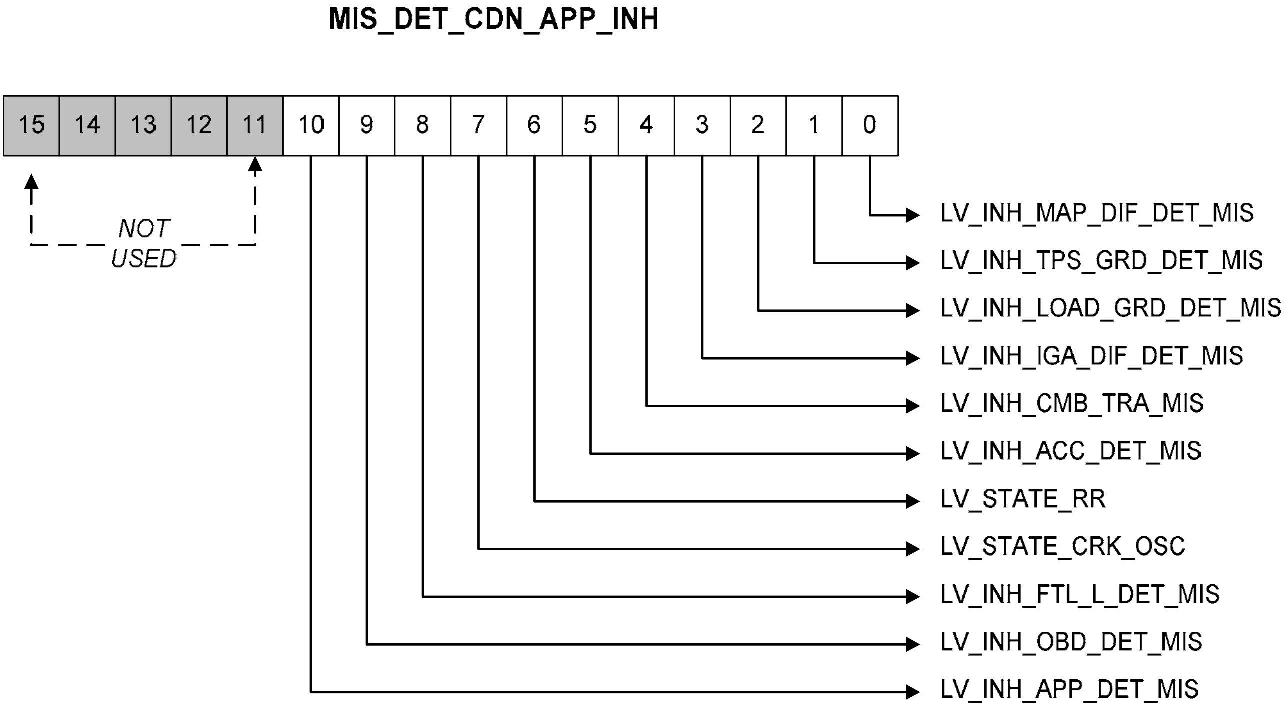
Recurrence: segment task for data process
10 ms for free running timers

Activation: LV_ENA_ER = 1
And LC_MIS_INH = 0

Deactivation: LV_ENA_ER = 0
Or LC_MIS_INH = 1

Remark : Timers used for delay are 10 ms free running decounters, they are not linked to activation/deactivation conditions described above.

51.5.2.1 Generic fade out condition carrier definition



<u>remark</u> : MIS_DET_CDN_APP_INH is updated at current misfire task

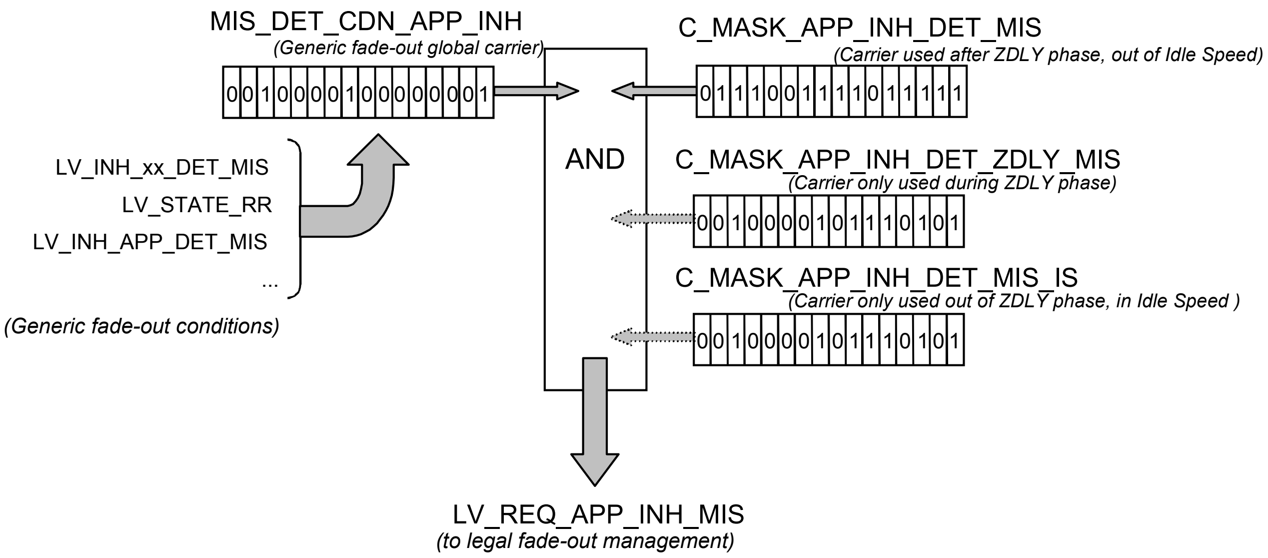
51.5.2.2 Configurable generic fade-out management

Generic fade out management during zero delay phase, nominal phase & idle speed engine state can be configurated via 3 bitfield masks that allow to take in account or not some conditions in a phase and not in the other.

If the corresponding bit in the MIS_DET_CDN_APP_INH carrier structure is set to 0 in C_MASK_APP_INH_DET_ZDLY_MIS, C_MASK_APP_INH_DET_MIS or C_MASK_APP_INH_DET_MIS_IS calibration, then the corresponding condition will not fade-out misfire detection.

For the definition of C_MASK_APP_INH_DET_ZDLY_MIS, C_MASK_APP_INH_DET_MIS & C_MASK_APP_INH_DET_MIS_IS masks please refer to the legal requirements & customer recommendations.

<u>Overview:</u>



<u>Formula section:</u>

```
If(1) CTR_T_ZDLY_MIS != 0
Then(1)    // ZDLY phase
    MIS_DET_CDN_APP_INH_NR =
            sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_ZDLY_MIS)
    (bitfield operations)
Else(1)
    If(2)    LV_IS = 1
    Then(2)        // Idle Speed engine state
            MIS_DET_CDN_APP_INH_NR =
                    sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_MIS_IS)
            (bitfield operations)
    Else(2)        // Out of idle speed engine state
            MIS_DET_CDN_APP_INH_NR =
```

```
            sum(MIS_DET_CDN_APP_INH & C_MASK_APP_INH_DET_MIS)
        (bitfield operations)
    EndIf(2)
EndIf(1)

If    MIS_DET_CDN_APP_INH_NR != 0
Then        LV_REQ_APP_INH_MIS = 1
Else        LV_REQ_APP_INH_MIS = 0
EndIf
```

51.5.2.3 Maximum manifold air-pressure gradient

Due to trailing throttle / acceleration transition problems, it could be necessary to disable misfire detection for a short period when the manifold air-pressure gradient exceeds an applicable value.

Application conditions:

In all homogeneous combustion mode, Misfire detection is disabled when the amount of the MAP gradient exceeds IP_MAP_DIF_MAX_MIS(MAP)

Initialisation: *at ECU reset, at Engine Stop **Or** at LC_MIS_INH 0 to 1 transition*

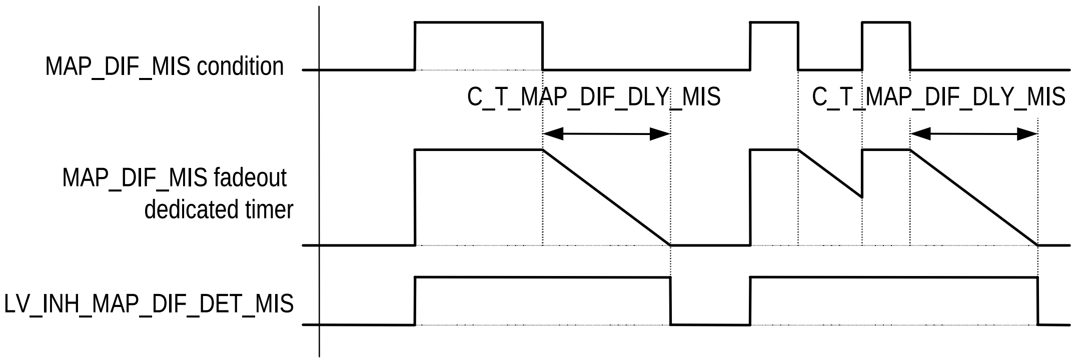
LV_INH_MAP_DIF_DET_MIS = 1

Formula section:

$MAP\_DIF\_MIS = | MAP_{(n)} - MAP_{(n-2)} |$

```
If    LV_S_ACT = 0
      And MAP_DIF_MIS > IP_MAP_DIF_MAX_MIS(MAP)
Then
      After condition rising edge triggering, LV_INH_MAP_DIF_DET_MIS flag is set to 1 as long as condition is true.
      After condition falling edge triggering, LV_INH_MAP_DIF_DET_MIS flag is hold to 1 for a period of C_T_MAP_DIF_DLY_MIS.
EndIf
```

Fade out behaviour summary:



51.5.2.4 Maximum throttle gradient

Due to trailing throttle / acceleration transient problems at low load, it is necessary to disable misfire detection for a short period when the throttle gradient exceeds an applicable value.

Application conditions:

Misfire detection can be disabled when the amount of the throttle gradient exceeds the applicable value hereunder mentioned. But during the 0-delay activation of the misfire monitoring, driver-induced fade-out is allowed:

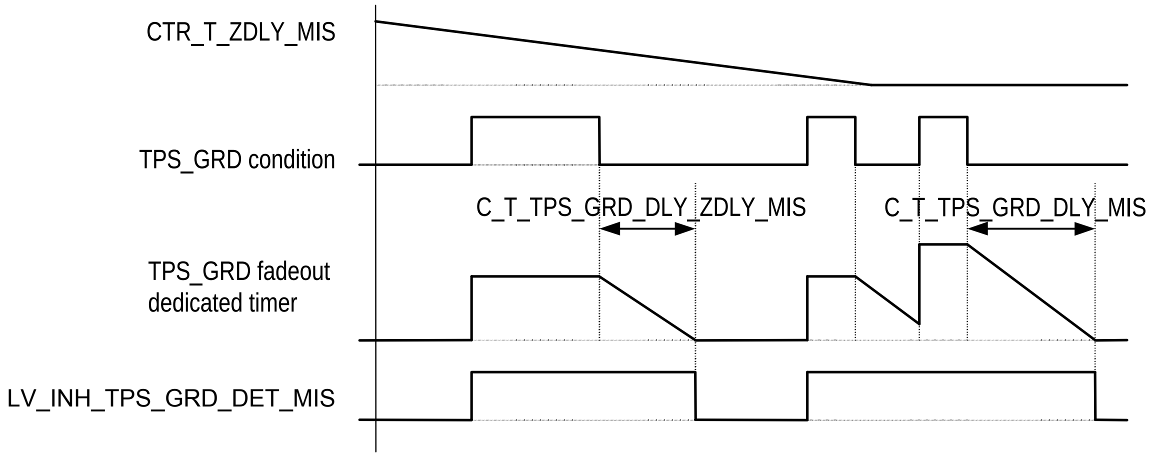
Initialisation: *at ECU reset, at Engine Stop **Or** at LC_MIS_INH 0 to 1 transition*

LV_INH_TPS_GRD_DET_MIS = 1

Formula section:

```
If(1) CTR_T_ZDLY_MIS = 0
Then(1)
    If(2)   TPS_GRD > IP_TPS_GRD_MAX_MIS(TPS_AV)
    Then(2)
            After condition rising edge triggering, LV_INH_TPS_GRD_DET_MIS flag is set to 1 as long as condition is true.
            After condition falling edge triggering, LV_INH_TPS_GRD_DET_MIS flag is hold to 1 for a period of C_T_TPS_GRD_DLY_MIS.
    EndIf(2)
Else(1)
    If(2)   TPS_GRD > IP_TPS_GRD_ZDLY_MIS(TPS_AV)
    Then(2)
            After condition rising edge triggering, LV_INH_TPS_GRD_DET_MIS flag is set to 1 as long as condition is true.
            After condition falling edge triggering, LV_INH_TPS_GRD_DET_MIS flag is hold to 1 for a period of C_T_TPS_GRD_DLY_ZDLY_MIS.
    EndIf(2)
EndIf(1)
```

Fade out behaviour summary:



51.5.2.5 Maximum engine load gradient

Due to trailing throttle / acceleration transient problems at low load, it could be necessary to disable misfire detection for a short period when the engine load exceeds an applicable value.

Application conditions:

Misfire detection can be disabled when the amount of engine load gradient exceeds a calibration value, this value is switched according combustion mode. Fade out delay is also specific to combustion mode.

Initialisation: *at ECU reset, at Engine Stop **Or** at LC_MIS_INH 0 to 1 transition*

LV_INH_LOAD_GRD_DET_MIS = 1

Formula section:

```
If(1) LV_S_ACT = 0
Then(1)
    If(2)   LOAD_GRD_MIS > IP_LOAD_GRD_MIS(LOAD_MIS)
    Then(2)
            After condition rising edge triggering, LV_INH_LOAD_GRD_DET_MIS flag is set to 1 as long as condition is true.
            After condition falling edge triggering, LV_INH_LOAD_GRD_DET_MIS flag is hold to 1 for a period of C_T_LOAD_GRD_HOM_DLY_MIS.
    EndIf(2)
EndIf(1)
#If  NC_CMB_CONF = AFS_S Or AFS_AFL_S

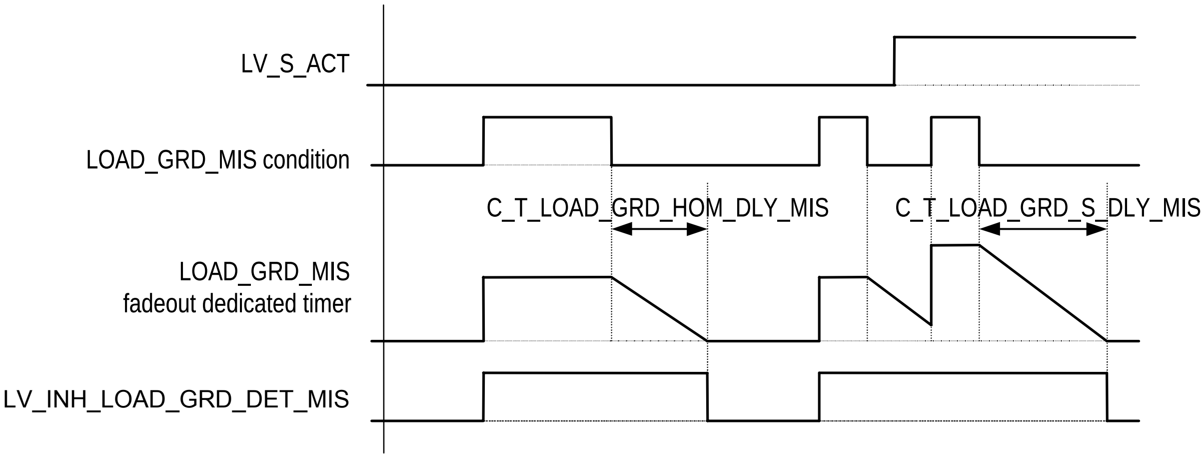
            Then(2)
                    After condition rising edge triggering, LV_INH_LOAD_GRD_DET_MIS flag is set to 1 as long as condition is true.
                    After condition falling edge triggering, LV_INH_LOAD_GRD_DET_MIS flag is hold to 1 for a period of C_T_LOAD_GRD_S_DLY_MIS.
            EndIf(2)
    EndIf(1)
#EndIf
```

Fade out behaviour summary:



51.5.2.6 Ignition retardation without change limitation

Various functions or CAN requests (e.g.. gear-shift signal. torque reduction. etc...) cause an ignition - timing retardation, without change limitation. Misfire detection can be disabled when the amount of the ignition timing retardation is too important.

Several criterion are available to disable the misfire monitoring according the ignition angle behaviour. Two relative criterions dedicated to focus on IGA transients, one in idle speed and one in part load, plus one absolute criterion dedicated to focus on too important IGA values compared to the

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_IGA_DIF_DET_MIS = 1

Formula section:

For each TDC, the following stacks are serviced after having calculated IGA_AV_x.

IGA_DIF_MIS = | IGA_MIS_2 - IGA_MIS |

IGA_BAS_DIF_MIS = IGA_BAS_COR_MV - IGA_MIS

IGA_MIS_2 = IGA_MIS_1

IGA_MIS_1 = IGA_MIS

                        LV_INH_IGA_DIF_DET_MIS flag is hold to 1 for a period of
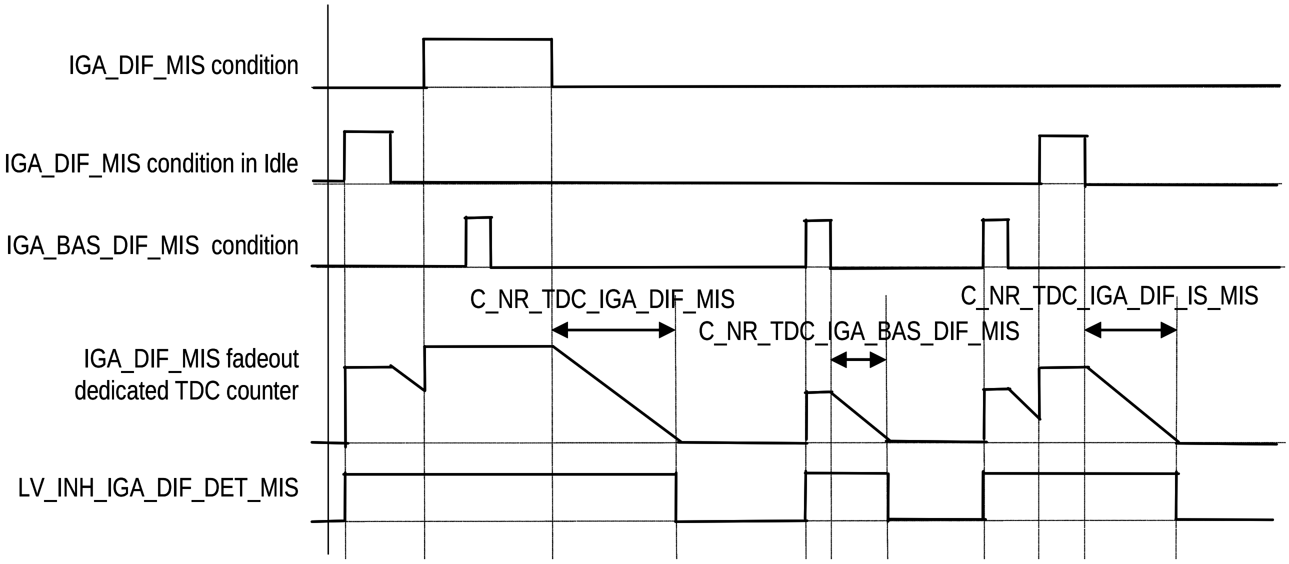
                        C_NR_TDC_IGA_DIF_MIS.
                        When this period is exceeded without retriggering,
                        LV_INH_IGA_DIF_DET_MIS releases to 0.
            EndIf(3)
        EndIf(2)
        If(2)   LV_IGA_GRD_ACT = 0      // out of IGA engine start calculation phase
            And IGA_BAS_DIF_MIS > IP_DELTA_IGA_BAS_MIS(N_MIS,LOAD_MIS)
        Then(2)     After condition rising edge triggering, LV_INH_IGA_DIF_DET_MIS flag is
                    set to 1 as long as condition is true.
        Else(2)     After condition falling edge triggering, LV_INH_IGA_DIF_DET_MIS flag is
                    hold to 1 for a period of C_NR_TDC_IGA_BAS_DIF_MIS.
                    When this period is exceeded without retriggering,
                    LV_INH_IGA_DIF_DET_MIS releases to 0.
        EndIf (2)
    EndIf(1)
```

// note: the TDC decounter is retriggered only if the considered preload calibration is greater than the decounter actual value.

Fade out behaviour summary:



51.5.2.7 Combustion mode transients

Application conditions:

While the combustion manager is in transient state, the misfire detection can be disabled to have a proper base for evaluation of the ER-misfire detection thresholds, which are defined for the stationary modes (AFS, AFL & S). See definiton in Application Incidences file. (LV_INH_CMB_TRA_MIS = 1).

51.5.2.8 Air - conditioning compressor activation

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine.
This load jump can cause a segment period jump and crankshaft vibration, depending on the engine operating state and load request.

Application conditions:

Misfire detection can be suppressed for the applicable constant period C_T_ACCOUT_DLY_MIS, starting if the air - conditioning compressor is switched on or off (LV_ACCOUT_RLY changes from 0 to 1 or from 1 to 0), during this period LV_INH_ACC_DET_MIS is set to 1.

Initialisation: *at ECU reset, at Engine Stop* ***Or*** *at LC_MIS_INH 0 to 1 transition*

LV_INH_ACC_DET_MIS = 1

Formula section:

```
If    LV_ACCOUT_RLY = 0 -> 1
      Or     LV_ACCOUT_RLY = 1 -> 0
Then         LV_INH_ACC_DET_MIS is set to 1 during C_T_ACCOUT_DLY_MIS
EndIf
```

51.5.2.9 Rough road detection

Application conditions:

Misfire detection can be suppressed when the status of the *rough road detection* is active (LV_STATE_RR = 1).

51.5.2.10 Crankshaft oscillation detection

Application conditions:

Misfire detection can be suppressed when the status of the *crankshaft oscillation detection* is active (LV_STATE_CRK_OSC = 1).

51.5.2.11 Low fuel level

Application conditions:

Misfire detection can be suppressed when the low fuel level is detected (LV_INH_FTL_L_DET_MIS=1).

51.5.2.12 OBDI diagnosis fade-out

Application conditions:

LV_INH_OBD_DET_MIS combines all OBD project specific error bits to generate an input for the generic misfire detection fade-out conditions. *See definition in Misfire detection - Application Incidences file.* Misfiring detection can be suppressed if LV_INH_OBD_DET_MIS = 1

51.5.2.13 Application incidences fade-out

Application conditions:

LV_INH_APP_DET_MIS combines all project specific special conditions to generate an input for the generic misfire detection fade-out conditions. *See definition in Misfire detection - Application Incidences file*. Misfiring detection can be suppressed if LV_INH_APP_DET_MIS = 1

51.6 Legal Misfire Detection Fade-Out Conditions

51.6.1 General information

This chapter is relative to misfire detection fade out management as defined by legal texts linked to functionnal OBD diagnosis (OBDII, EOBD...).

Continuous misfire monitoring from engine starting instant:

- ***<u>Engine start instant</u>*** *: the point when the engine reaches a speed 150 rpm below the normal, warmed-up idle speed (as determined in the drive position for vehicles equipped with an automatic transmission) (CARB definition).*
  - *<u>One engine cycle (2 crankshaft revolutions) is allowed to initialise misfire detection process</u> (see CTR_TDC_ZDLY_MIS using).*

Fade out conditions may disable misfire monitoring with the following conditions:

- **Minimum engine speed** : N_IS_SP - 150 rpm *(US)*
- **Maximum engine speed** : Redline engine speed *(US)* or 4500 rpm *(EC)*
- **Minimum engine load** :

  Zero load line (engine positive torque line)

  A line joining the point (3000 rpm, zero load) and a point (6000 rpm, 135 hPa *(or 4 inches Hg)* above the zero load line)

- **Minimum coolant or ambiant temperature**

  Below 20°F (US) or -7°C (EC) *(equivalent),*

  Or If Engine start coolant temperature is below 20°F, until current temperature reaches warm up engine temperature 70°F.

- **Minimum atmospheric pressure**

  Elevations above 8000 feet above sea level (US) or 2 500 meters (EC)

- **Time after start**

  A 5s time after start fade-out can be allowed for EC market

  Such kind of fade out is prohibited for US market (see CARB requirement for zero delay misfire monitoring activation)

- **Cylinder shut-off**

  During fuel cut-off phase, on a specific cylinder shut-off or the number of cylinder in shut-off is too important, misfire diagnosis may be fade out *(no injection/combustion occurs)*

51.6.2 Misfire detection fade out management

Misfire Detection Phase State Machine					

Input data:

N	LV_RUN_ENG	LV_ES	

FUNCTION DESCRIPTION:

CARB requests an activation of the misfire monitoring and diagnosis as off engine start. Particular fade-out conditions are required during the first 5 seconds since engine running. In this section the flag representing the request is defined, and is used in several other modules that are concerned with this requirement *(LC_REQ_ZDLY_MIS = 1).*

For non-CARB applications, this special monitoring is not required and has to be de-activated *(LC_REQ_ZDLY_MIS = 0).*

A state-based approach is taken for the activation of the misfire detection algorithms, distinguishing the separate monitoring during the first 5 seconds and the 'nominal' monitoring afterwards, and preparatory phases. During the monitoring phases, the normal fade-out mechanisms are used, corrected for some fade-outs that are not allowed during the first 5 seconds.

Application conditions:

Activation:

Engine Start LV_RUN_ENG = 1

Deactivation:

Engine Stop LV_RUN_ENG = 0 **Or** ECU reset

Remark: At deactivation, ALL internal and external variables related to the legal fade out misfire detection conditions must be reset to 0.
In nominal mode (after engine start and zero delay period), the state machine executes no operations.

Formula section:

At engine start-up (LV_RUN_ENG switches from 0 to 1) the system starts in STATE_DIAG_MIS = 0 (initialisation phase).

In the case of a CARB-application, special monitoring takes placed during C_T_ZDLY_MIS seconds. The timer is started at detection of engine running:

```
If        LC_REQ_ZDLY_MIS = 1
    And   STATE_DIAG_MIS = 0
Then      CTR_T_ZDLY_MIS = C_T_ZDLY_MIS
EndIf
```

Transition initialisation state to preparation states for 0-delay OR to nominal monitoring

```
If        LC_REQ_ZDLY_MIS = 1
    And   STATE_DIAG_MIS = 0
    And   N > C_N_MIN_ZDLY_MIS
Then      Zero-Delay Activation of Misfire Detection
          STATE_DIAG_MIS = 1
          CTR_TDC_ZDLY_MIS = C_NR_TDC_ZDLY_MIS
ElseIf    LC_REQ_ZDLY_MIS = 0
    And   STATE_DIAG_MIS = 0
    And   N > C_N_MIN_ZDLY_MIS
Then      Standard Activation of Misfire Detection
          STATE_DIAG_MIS = 3
          CTR_TDC_ZDLY_MIS = C_NR_TDC_ZDLY_MIS
Else      Initialisation Phase
          LV_DIAG_MIS = 0
          LV_ZDLY_DIAG_MIS = 0
EndIf
```

Transition back to the initialisation phase

```
If        LV_ES = 1
    And   STATE_DIAG_MIS <> 0
Then      In case of engine stop, return to initialisation phase
          STATE_DIAG_MIS = 0
EndIf
```

Transition preparation state 0-delay monitoring to 0-delay monitoring state

```
If          LC_REQ_ZDLY_MIS = 1           CARB application
    And     STATE_DIAG_MIS = 1            0-delay preparation state
    And     N > C_N_MIN_ZDLY_MIS          engine speed over threshold
    And     CTR_TDC_ZDLY_MIS = 0          1 engine cycle passed
Then        STATE_DIAG_MIS = 2
            LV_ZDLY_DIAG_MIS = 1
EndIf
```

Transition preparation nominal state to nominal monitoring state

```
If          LC_REQ_ZDLY_MIS = 0           standard application
    And     STATE_DIAG_MIS = 3            preparation monitoring state
    And     N > C_N_MIN_ZDLY_MIS          engine speed over threshold
    And     CTR_TDC_ZDLY_MIS = 0          1 engine cycle passed
Then        STATE_DIAG_MIS = 4
            LV_DIAG_MIS = 1
EndIf
```

Transition 0-delay monitoring state to nominal monitoring state

```
If  LC_REQ_ZDLY_MIS = 1                   CARB application
    And     STATE_DIAG_MIS = 2            0-delay monitoring state
    And     N > C_N_MIN_ZDLY_MIS          engine speed over threshold
    And     CTR_TDC_ZDLY_MIS = 0          1 engine cycle passed
    And     CTR_T_ZDLY_MIS = 0            timer finished (typically 5 seconds)
Then        STATE_DIAG_MIS = 4
            LV_DIAG_MIS = 1
            LV_ZDLY_DIAG_MIS = 0
EndIf
```

The counter CTR_T_ZDLY_MIS is decremented at every time instance of 10 ms when STATE_DIAG_MIS != 0.

The counter CTR_TDC_ZDLY_MIS is decremented with 1 at every TDC.

(both counters are saturated to 0)

Rermark: During the 0-delay misfire detection, no fade-outs are allowed for crankshaft oscillation, rough road detection and zero-load line conditions (see appropriate sections). However, it is allowed to have so-called driver-induced fade-outs (e.g. gradient on pedal value). This latter section has been added.

At hot resets, the system starts again in the initialisation phase.

FUNCTION DESCRIPTION:

General information:

Legal fade out (LV_REQ_INH_MIS) is based on all fade out conditions allowed by the legal texts for continuous misfire monitoring.

All these different fade-out conditions are merge into a global carrier (MIS_DET_CDN_INH).

Timers used for fade-out conditions delays are free running timers who are not deactivated according following conditions.

Application conditions: *(global to Misfire detection legal fade out conditions chapter)*

Initialisation: at Reset, Engine Stop, **Or** on Deactivation event

LV_PUC_DET_MIS = 0

LV_IV_OFF_DET_MIS = 1

LV_REQ_INH_MIS = 1

MIS_DET_CDN_INH = 127

MIS_DET_CDN_INH_NR = 7

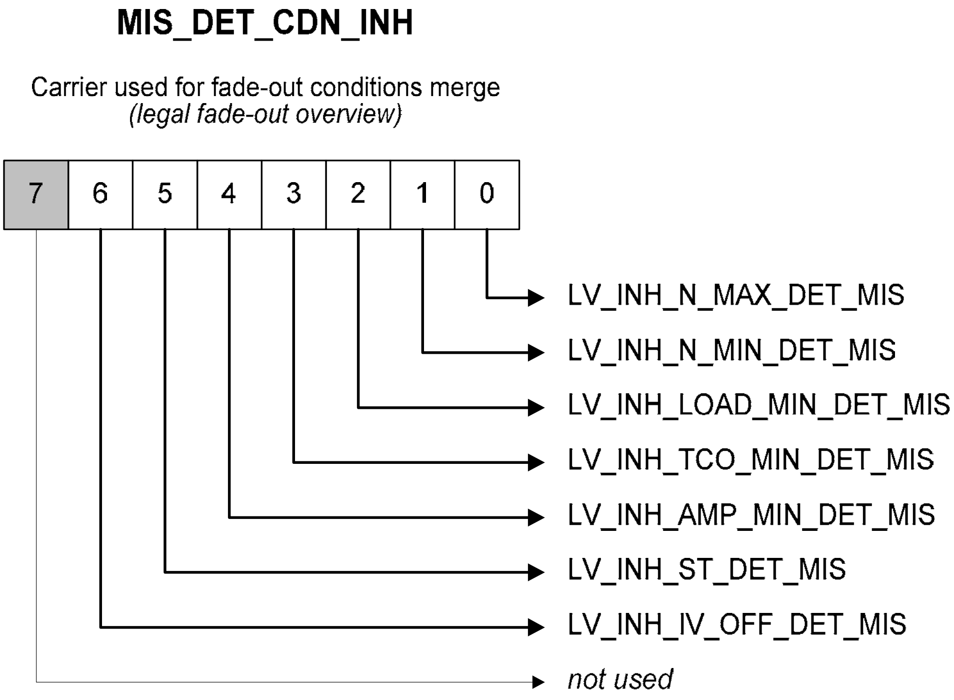
Recurrence: every segment task

Activation: *LC_MIS_INH = 0*

Deactivation: *LC_MIS_INH = 1*

51.6.3.1 Fade out carrier definition

Misfire fade out conditions carrier:



51.6.3.2 Configurable Fade-out Management

Application conditions:

Fade out management during zero delay phase & nominal phase can be configurated via 2 bitfield masks that allow to take in account or not some conditions in a phase and not in the other.

If the corresponding bit in the MIS_DET_CDN_INH carrier structure is set to 0 in C_MASK_INH_DET_ZDLY_MIS or C_MASK_INH_DET_MIS calibration, then the corresponding condition will not fade-out misfire detection.

For the definition of C_MASK_INH_DET_ZDLY_MIS & C_MASK_INH_DET_MIS masks please refer to the legal requirements & customer recommendations.

Formula section:

```
If    CTR_T_ZDLY_MIS ≠ 0
Then
      MIS_DET_CDN_INH_NR = sum(MIS_DET_CDN_INH & C_MASK_INH_DET_ZDLY_MIS)
      (bitfield operations)
Else
      MIS_DET_CDN_INH_NR = sum(MIS_DET_CDN_INH & C_MASK_INH_DET_MIS)
      (bitfield operations)
EndIf
If    MIS_DET_CDN_INH_NR ≠ 0
      Or      LV_REQ_APP_INH_MIS = 1      // Fade out request linked to misfire detection method
Then          LV_REQ_INH_MIS = 1          // General fade out request
Else          LV_REQ_INH_MIS = 0
EndIf
```

51.6.3.3 Maximum engine speed fade-out

Application conditions:

The misfire monitoring can be inhibated when the engine speed reachs the maximum engine speed imposed by the market target : Redline engine speed for US applications or 4500 rpm for EC applications.

Moreover this information is use to stop misfire monitoring process for high speed if not required (limitation of cpu load especially for european application).

Formula section:

```
If    ( LV_AT = 1   And   N > C_N_MAX_MIS_AT )
      Or      ( LV_AT = 0   And   N > C_N_MAX_MIS_MT )
Then          LV_INH_N_MAX_DET_MIS = 1
Else          LV_INH_N_MAX_DET_MIS = 0
EndIf
```

51.6.3.4 Minimum engine speed fade-out

The irregular engine operation test is performed as soon as the above-mentioned condition is disabled.

Important:

- C_N_MIN_MIS is defined by the current configuration of the index used for misfire detection in the current application. C_N_MIN_MIS should be lower than C_N_MIN_ZDLY_MIS.
- C_N_MIN_ZDLY_MIS is defined as the engine speed set-point for a warm engine minus 150 rpm. After passing below the C_N_MIN_ZDLY_MIS threshold, one is allowed one engine cycle (meaning for example for a 4-cylinder engine 4 tdc's) before reactivating the output of the misfire detection algorithm. Misfire detection is suppressed for a period of C_NR_TDC_INH_MIS tdc's.
- It should be checked in each application that within the allowed number of TDC's proper misfire detection index values have been re-obtained. Typically, it should be possible to restart misfire detection earlier.

Application conditions:

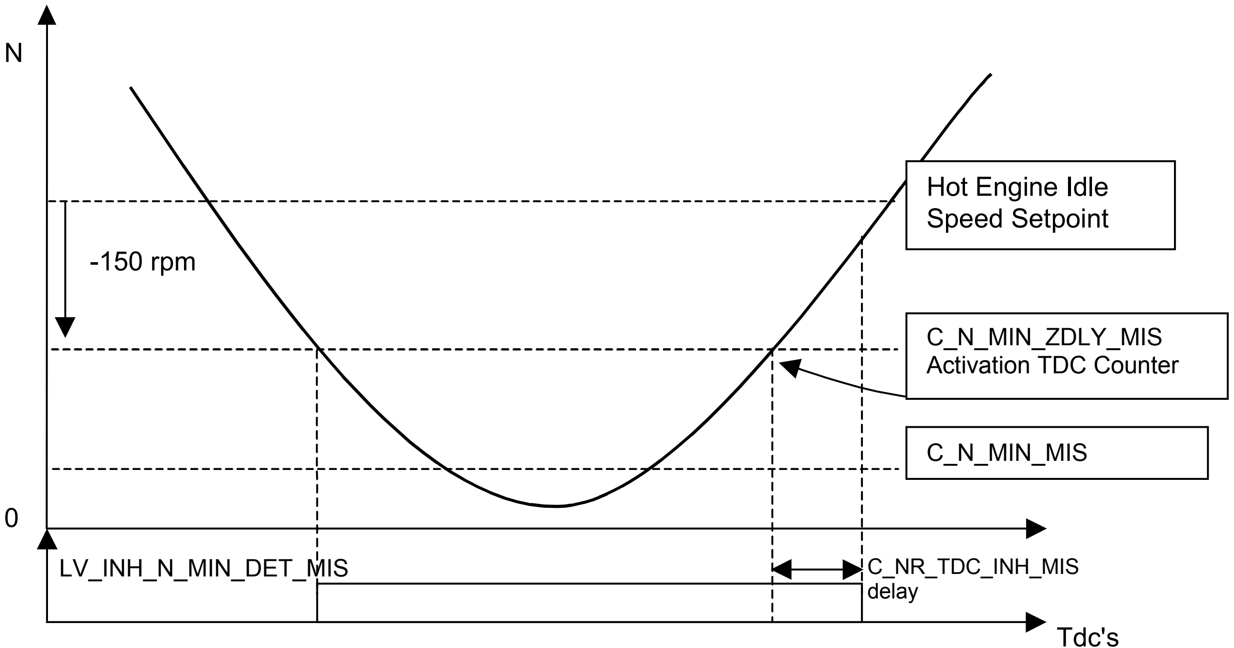
N < C_N_MIN_ZDLY_MIS

Engine speed below CARB requirements *(used for US applications)*.

Typically, once N < C_N_MIN_ZDLY_MIS, the output of the misfire detection is inhibited, allthough the calculation is still valid. C_NR_TDC_ZDLY_MIS tdc's decounter is started at passing engine speed C_N_MIN_ZDLY_MIS again. Once the decounter is at 0, misfire detection index output is allowed.

N < C_N_MIN_MIS

Engine speed below misfire detection index resolution *(used for CE applications)*. If the engine speed falls below C_N_MIN_MIS.



Explanation on the mechanism to re-activate the misfire detection after an engine speed drop

As the misfiring test is not mandatory and risky over a certain engine speed threshold, a fade out condition is tested on engine rpm (not allowed for US market).

Activation: *LV_INH_N_MAX_DET_MIS = 0*

Deactivation: *LV_INH_N_MAX_DET_MIS = 1*

Action on deactivation event: *LV_INH_N_MIN_DET_MIS = 1*

Formula section:

```
If    N < C_N_MIN_ZDLY_MIS
      Or    N < C_N_MIN_MIS
Then        LV_INH_N_MIN_DET_MIS = 1
Else        LV_INH_N_MIN_DET_MIS = 0
                caution : see specific reactivation conditions above  when
                N > C_N_MIN_ZDLY_MIS, C_NR_TDC_INH_MIS delay used
EndIf
```

51.6.3.5 Minimum engine load

Application conditions:

Below a specific load (zero load), fluctuations in engine speed cannot be detected, even in the event of misfire. In this case, the misfire detection is disabled.

Activation: *LV_INH_N_MAX_DET_MIS = 0*

Deactivation: *LV_INH_N_MAX_DET_MIS = 1*

Action on deactivation event: *LV_INH_LOAD_MIN_DET_MIS = 1*

Formula section:

```
    If      LOAD_MIS < LOAD_MIN_MIS
    Then    LV_INH_LOAD_MIN_DET_MIS = 1
    Else    LV_INH_LOAD_MIN_DET_MIS = 0
    EndIf
```

51.6.3.6 Minimum coolant temperature

Application conditions:

Misfire detection can be disabled when the coolant temperature is below a threshold (20°F / -7°C). Additionally when the coolant temperature at engine start is below this threshold, the misfire monitoring can be disable on that driving cycle until the current engine temperature reaches a warm up temperature threshold (70°F / 21°C):

Activation: *LV_INH_N_MAX_DET_MIS = 0*

Deactivation: *LV_INH_N_MAX_DET_MIS = 1*

Action on deactivation event: *LV_INH_TCO_MIN_DET_MIS = 1*

Formula section:

LV_TEMP : temporary bit used to check only one occurence per engine start

Initialisation : *LV_TEMP = 0 at ECU reset* ***Or*** *LV_DC 0 -> 1*

```
    If      TCO < C_TCO_MIN_MIS
```

```
            Or     ( TCO_ST < C_TCO_MIN_MIS
                   And    TCO < C_TCO_WUP_MIN_MIS
                   And    LV_TEMP = 0 )
      Then  LV_INH_TCO_MIN_DET_MIS = 1
      Else  LV_INH_TCO_MIN_DET_MIS = 0
            LV_TEMP = 1
      EndIf
```

51.6.3.7 Minimum atmospheric pressure

Application conditions:

Misfire detection can be disabled when the atmospheric pressure is below a threshold:

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_AMP_MIN_DET_MIS = 1

Formula section:

```
If     AMP < C_AMP_MIN_MIS
Then   LV_INH_AMP_MIN_DET_MIS = 1
Else   LV_INH_AMP_MIN_DET_MIS = 0
EndIf
```

51.6.3.8 After start

Application conditions:

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_ST_DET_MIS = 1

Misfire detection can be suppressed (see legal requirements - forbidden for CARB zero delay requirements) for a C_T_DLY_ST_MIS duration after the engine exits the operating state start (LV_ST), during this period LV_INH_ST_DET_MIS is set to 1, even if C_T_DLY_ST_MIS = 0.

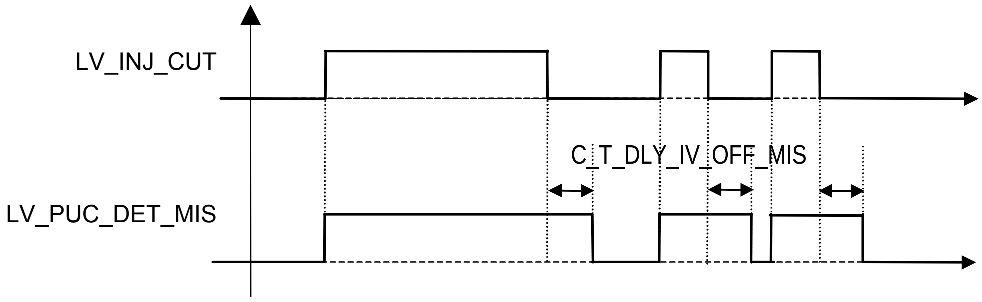
51.6.3.9 Injection shut-off

Application conditions:

Misfire detection can be suppressed for the cylinder(s), for which injection has been shut-off.

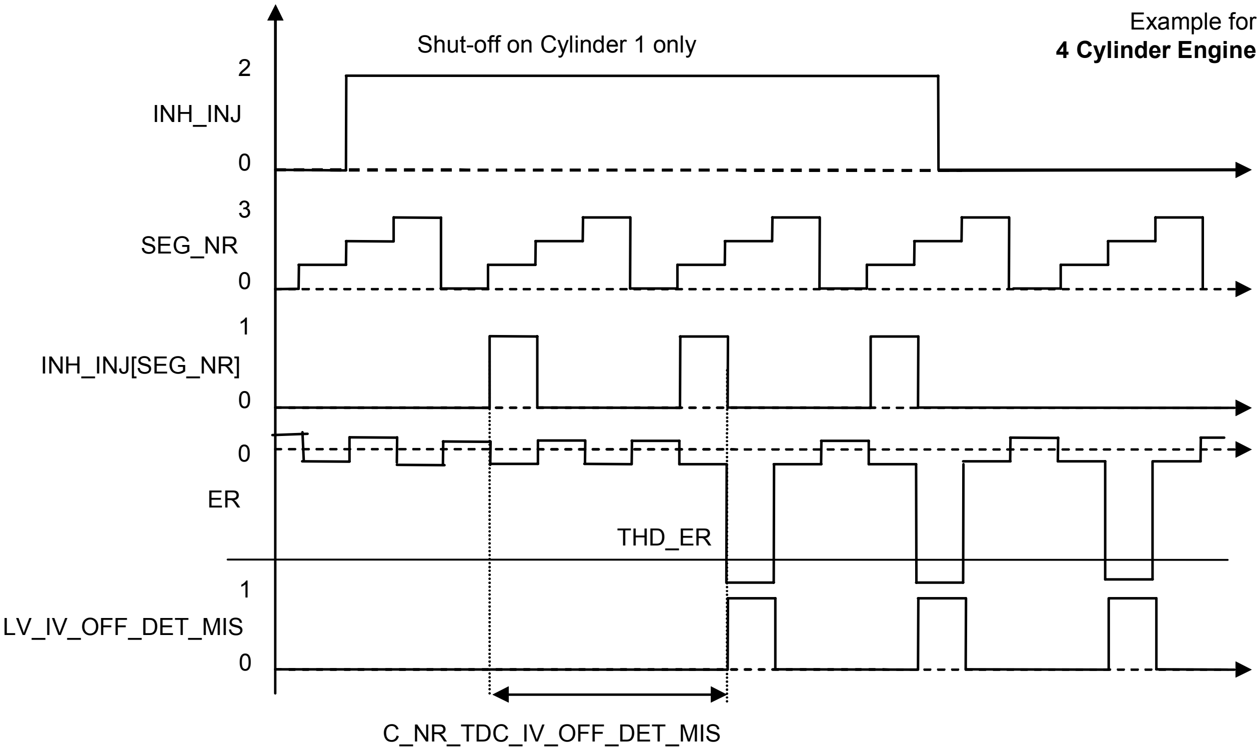
General fuel shut-off:

LV_INJ_CUT indicates a general fuel shut-off. LV_PUC_DET_MIS bit includes a calibration delay time (C_T_DLY_IV_OFF_MIS) triggered at fuel cut-off condition falling edge, in a way to start the misfire detection only after crankshaft oscillations due to fuel reactivation.



Cylinder specific shut-off:

If the current cylinder checked by misfire detection is shut-off by any EMS function even MISF limp home functionnality), a fade-out can be apply for the misfire detection of this cylinder. Due to the delay between the misfire index and the injection current informations, a calibration delay (C_NR_TDC_IV_OFF_DET_MIS) has been introduced on LV_IV_OFF_DET_MIS. This delay synchronises MISF & INJR informations in a way to apply correctly the fade-out on the proper cylinder during individual cylinder shut-off operations, and to be able the perform the misfire monitoring on the other cylinders who are not in shut-off mode.



Limit number of cylinders shut-off:

If the number of shut-off cylinders reaches a calibration data (C_SUM_INH_IV_MAX_DET_MIS), reliable misfire detection is impossible. In such case is preferable to inhibate misfire detection.

Formula section:

General fuel shut-off:

If LV_INJ_CUT = 1 *// All cylinders are shut off*

Then LV_PUC_DET_MIS = 1

Else LV_PUC_DET_MIS = 0 after C_T_DLY_IV_OFF_MIS delay time

```
EndIf
```

Cylinder fuel shut-off:

```
If    INH_INJ[SEG_NR] = 1          // indexed by cylinder bit position
Then      LV_IV_OFF_DET_MIS = 1 after a C_NR_TDC_IV_OFF_DET_MIS delay
Else      LV_IV_OFF_DET_MIS = 0 after a C_NR_TDC_IV_OFF_DET_MIS delay
EndIf
```

Activation: LV_INH_N_MAX_DET_MIS = 0

Deactivation: LV_INH_N_MAX_DET_MIS = 1

Action on deactivation event: LV_INH_IV_OFF_DET_MIS = 1

Formula section:

General definition:

```
If    LV_PUC_DET_MIS = 1
      Or  LV_IV_OFF_DET_MIS = 1
      Or  SUM_INH_INJ >= C_SUM_INH_IV_MAX_MIS
Then      LV_INH_IV_OFF_DET_MIS = 1
Else      LV_INH_IV_OFF_DET_MIS = 0
EndIf
```

51.7 Misfire rate determination and error management

General information:

The misfire rate determination and misfire specific error management are applied to the following CARB misfire legal definitions:

- **CARB A misfire failure criterion** *(LV_MIS_STATE_A)*:

Risk of catalyst damage, monitoring interval over 200 crankshaft revolutions (= 200 * NC_CYL_NR / 2 TDCs) during the driving cycle.

- **CARB B1 misfire failure criterion** *(LV_MIS_STATE_B1):*

Emission increase, monitoring interval over the first 1000 crankshaft revolutions (= 1000 * NC_CYL_NR / 2 TDCs) of the driving cycle.

- **CARB B4 misfire failure criterion** *(LV_MIS_STATE_B4):*

Emission increase, monitoring interval over 1000 crankshaft revolutions (= 1000 * NC_CYL_NR / 2 TDCs). For criterion confirmation, misfire must be take place for 4 monitoring intervals (consecutive or not).

MIS_A, MIS_B1 & MIS_B4 Handling Flowchart diagram:

N_32	LV_INH_IGC_DIAG_MIS	SEG_NR_ER	FAC_ER_DIAG_MIS
LV_INH_IV_DIAG_MIS	LV_DET_MIS		

FUNCTION DESCRIPTION:

General information:

Due to their physical principle, the individual diagnostic functions have a different diagnostic relevance depending on the operating point.

To achieve the best possible detection of misfires, the individual diagnostic methods are combined. Here with an assumed misfire of a part function, an operating point dependent weighting factor, which reflects the reliability of this part function in the current operating point, is taken from a map. If the sum of these three values now exceeds a threshold for one combustion, then misfire is detected.

The value which is not debounced is used as input value of the IV and IGCFB diagnoses. The injection for a cylinder is cut off exclusively by the CARB error mechanism and not by the IV and IGCFB diagnostic functions.

Application conditions:

Misfire segment after detection, before CARB diagnosis

Application conditions:

Update rate: every segment

Activation:

LC_MIS_INH = 0

Deactivation:

LC_MIS_INH = 1

Initialisation on ECU reset, on LV_DC 0 to 1 transition and on LC_MIS_INH 0 to 1 transition:

SUM_FAC_DIAG_MIS = 0

FAC_IGC_DIAG_MIS = 0

FAC_IV_DIAG_MIS = 0

LV_DET_CFM_MIS = 0

Formula section:

The output from the misfire detection, injection and ignition diagnosis functions is influenced by weighting interpolated table, giving the reliability of the individual functions.

- A weighting value of **0** means that detection is not possible for this engine operating point.

- A value equal to or greater than **1** indicates reliable detection.

- The values in between represent the corresponding levels of reliability.

- Irregular engine operation weighting (LV_DET_MIS = 1):

If misfiring is suspected by the irregular engine operation test, a weighting factor for the corresponding engine operating point is applied. This factor is derived from tables according combustion mode and determine in application incidence. The corresponding result is in FAC_ER_DIAG_MIS data.

- Ignition diagnosis weighting (IGC_DIAG_MIS):

IGC_DIAG_MIS is the not debounced carrier from Ignition diagnosis, which has to be delayed due to misfire detection *(according segment reference SEG_NR_ER-1, cylinder x compression phase)*. If misfiring is suspected by the ignition diagnosis function, a weighting factor for the corresponding engine operating point is applied.

This factor is derived from IP_FAC_IGC_DIAG_MIS table.

For the time the number of cylinders shut off due to misfire detection limp home reaches or exceeds the applicable number of C_MIS_NR_OFF_IV_IGCFB, FAC_IGC_DIAG factor is forced to ''1'' *(test based on INH_IV_MIS carrier)*.

```
If(1) IGC_DIAG_MIS[SEG_NR_ER] = 1
    And LV_INH_IGC_DIAG_MIS = 0
Then(1)
  If(2)     number of bits set to "1" in INH_IV_MIS carrier structure >=
            C_MIS_NR_OFF_IV_IGCFB
  Then(2)   FAC_IGC_DIAG_MIS = 1
  Else(2)   FAC_IGC_DIAG_MIS = IP_FAC_IGC_DIAG_MIS(N_32, LOAD_MIS)
  EndIf(2)
Else(1)     FAC_IGC_DIAG_MIS = 0
EndIf(1)
```

- Injection diagnosis weighting (STATE_DIAG_IV) :

STATE_DIAG_IV is a not debounced carrier from Injection valves diagnosis.

Injection valve in default is identifed according segment reference SEG_NR_ER within the bitfield structure STATE_DIAG_IV.

If misfiring is suspected by the injection valve diagnosis function, a weighting factor for the corresponding engine combustion mode is applied.

```
If    STATE_DIAG_IV[SEG_NR_ER] = 1
```

```
    And   LV_INH_IV_DIAG_MIS = 0
Then      FAC_IV_DIAG_MIS = IP_FAC_IV_DIAG_MIS(N_32, LOAD_MIS)
Else      FAC_IV_DIAG_MIS = 0
EndIf
```

- Formation of a cylinder - specific diagnosis weighting sum :

The sum of the three weighting values SUM_FAC_DIAG_MIS is performed for the individual cylinder. as soon as one of the three diagnosis function suspects misfiring.

```
SUM_FAC_DIAG_MIS = FAC_ER_DIAG_MIS
                   + FAC_IGC_DIAG_MIS
                   + FAC_IV_DIAG_FAC
If    SUM_FAC_DIAG_MIS >= 1
Then      LV_DET_CFM_MIS = 1      misfire status is confirmed
Else      LV_DET_CFM_MIS = 0      no misfire
EndIf
```

51.7.2 Misfire detection counters (ISO 15031 Data)

Output data:

Name	Mode	Hex. limits	Phys. Limits	Resol.	Unit
CTR_MIS_TOT_NVMY	V/S	0...FFFFFFFFH	0...4294967295	1	[-]
Overall misfire detection counter					
CTR_MIS_TOT_DC	V/S	0...FFFFH	0...65535	1	[-]
Former / current driving cycle overall misfire detection counter					
CTR_MIS_DC_CYL[NC_CYL_NR]	V/S	0...FFFFH	0...65535	1	[-]
Former / current driving cycle misfire detection cylinder counters (ISO15031 Data $0C)					
CTR_MIS_DC_MMV_CYL[NC_CYL_NR]	V/S	0...FFFFH	0...65535	1	[-]
Exponential weighted moving average (EWMA) misfire counters (ISO15031 Data $0B)					

Input data:

LV_DC	LV_ENA_ER	LC_MIS_INH	SEG_NR_ER

FUNCTION DESCRIPTION:

General information:

These counters are incremented at each misfire detection based on misfire index evaluation *(after crossed diagnosis with IGC & IV OBDI diags evaluation)*. Thus, it's possible to determine the total number of misfire detected during engine lifetime and during current driving cycle.

Moreover, cylinder misfire counters have been introduced for Mode 6 communication service, as described in last ISO specification available (ISO/DIS 15031-5.8).

Note: CTR_MIS_TOT_DC & CTR_MIS_DC_CYL[NC_CYL_NR] are initialised only at engine running to keep the information after engine stop.

51.7.2.1 NVMY Data Formating

On non volatile memory formatting or on NV memory corruption detection:

```
CTR_MIS_TOT_NVMY = 0
CTR_MIS_TOT_DC = 0
For(1) x = 0 : NC_CYL_NR-1
    CTR_MIS_DC_CYL[x] = 0
    CTR_MIS_DC_MMV_CYL[x] = 0
EndFor(1)
```

51.7.2.2 Initialisation of former / current driving cycle counters

Initialisations:

- at ECU reset

  NVMY data loading
- at LV_DC 0 -> 1 transition event

  CTR_MIS_TOT_DC = 0

```
For(1) x = 0 : NC_CYL_NR-1
    CTR_MIS_DC_CYL[x] = 0
EndFor(1)
```

51.7.2.3 Increment of misfire counters during current driving cycle

Application conditions:

Activation: *LV_ENA_ER = 1*

And *LC_MIS_INH = 0*

Deactivation: *LV_ENA_ER = 0*

Or *LC_MIS_INH = 1*

Update rate: Segment task

Formula section:

```
If    LV_DET_CFM_MIS = 1
Then      CTR_MIS_TOT_DC = CTR_MIS_TOT_DC + 1                  // with saturation
          CTR_MIS_TOT_NVMY = CTR_MIS_TOT_NVMY + 1              // with saturation
          CTR_MIS_DC_CYL[SEG_NR_ER] = CTR_MIS_DC_CYL[SEG_NR_ER] + 1
                                                                // with saturation
EndIf
```

51.7.2.4 Update of the EWMA misfire counters

Exponential weighted moving average (EWMA) misfire counters are updated at the beginning of the driving cycle based on former driving cycle values.

Update rate: at LV_DC 0 -> 1 transition event *before CTR_MIS_DC_CYL[x] reset*

```
For x = 0 : NC_CYL_NR-1
    CTR_MIS_DC_MMV_CYL[x] =
        0.9 * CTR_MIS_DC_MMV_CYL[x] + 0.1 * CTR_MIS_DC_CYL[x]
EndFor
```

51.7.3 Exhaust cylinder bank reference for misfire detection

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
SEG_NR_CBK_ER	V	0...FFH	0...255	1	[-]
Exhaust cylinder bank reference for misfire monitoring					

Input data:

SEG_NR_ER	LV_SYN_ENG	NC_CBK_EX_NR	NC_CYL_NR

FUNCTION DESCRIPTION:

For catalyst damage and/or emission criterion, misfire diagnosis functions can be set via calibration data in a way to be able to detect criterions according exhaust cylinder bank phasing instead of a global criterion detection.

Exhaust cylinder bank reference for misfire detection allows to increase these criterions on the dedicated cylinder bank weighting factor if the misfire detected has effect on the impacted cylinder bank and not on the other (if multiple exhaust cylinder bank design).

Description:

The exhaust cylinder bank reference SEG_NR_CBK_ER is determinate according the segment reference SEG_NR_ER. It already includes the delay introduced by the misfire index chosen.

Application conditions:

Update rate: Segment task

Activation: *LV_SYN_ENG = 1*

Deactivation: *LV_SYN_ENG = 0*

Initialisation on Deactivation condition:

SEG_NR_CBK_ER = 0

Initialisation: at ECU reset

SEG_NR_CBK_ER = 0

Formula section:

SEG_NR_CBK_ER = NC_CBK_EX_NR_MISF[SEG_NR_ER]

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_CBK_EX_NR_MISF[NC_CYL_NR]	-	0...FFH	0...255	1	[-]
Exhaust cylinder bank allocation according misfire segment phasing

LC_MIS_INH	FAC_MIS_A_APP	N	FAC_MIS_SUM_A_THD_APP
FAC_MIS_A_THD_IND_APP			

Description:

With a CARB A misfire rate criterion, the emissions are increased and there is a risk of catalyst damage if the cylinder causing the failure criterion can not be shut off.

Detection:

The check for misfire rate violation **CARB A** comprises 200 crankshaft revolutions *(100 * NC_CYL_NR tdc's)* for statistic misfiring and cyclewise monitoring for best possible catalyst protection.

If a confirmed misfiring is detected on ER current TDC (LV_DET_CFM_MIS=1), a weighting factor (MIS_A_FAC) is added to the cylinder-specific counter MIS_CTR_A[SEG_NR_ER], extracted from an interpolated table *(see APP. INC.)* who depends on engine combustion mode and current operating point. The increment represents the severity of catalyst damage.

Statistic:

The monitoring for Misfire **CARB A** is performed continuously in intervals of 200 crankshaft revolutions.

Monitoring during CARB A window:

To guarantee best possible catalyst protection, the cylinder-specific counters are monitored each cycle. For that purpose, MIS_CTR_A[SEG_NR_ER] is compared to the applicable value C_MIS_A_IND_THD representing the critical threshold for single cylinder misfiring.

If the threshold is reached outside of the FTP cycle, the concerning cylinder is shut off immediately. CARB A misfire criterion is confirmed, else the criterion will be evaluated at the end of the 200 crankshaft revolution window.

Monitoring at the end of 200 crankshaft revolutions:

At the end of each monitoring interval the cylinder-specific sums MIS_CTR_A[NC_CYL_NR] and the global sum (MIS_SUM_A) are available.

If the sum MIS_SUM_A is greater than the threshold C_MIS_SUM_A_THD, the cylinder with the highest misfire rate is determined (by comparing the different MIS_CTR_A[NC_CYL_NR] values).

Then operation inside/outside of the FTP-area is checked by comparison of the counter CTR_FTP_CDN_MIS_A / MIS_NR_TDC_A with the threshold C_RATIO_FTP_CDN_MIS_A. If the FTP tdc's ratio is lower than the threshold, not enough operating points have been inside the FTP-window and therefore operation outside FTP-area is detected (LV_FTP_MIS_A=0). This is done in order to fulfil the CARB-regulations, which require MIL-illumination at first threshold exceeding outside the FTP-area and at third exceeding inside the FTP-area.

Therefore the counter CTR_DET_MIS_A is incremented inside the FTP-area at each threshold exceeding. That means it reaches the maximum of C_NR_DET_MAX_MIS_A = 3 only if the threshold is exceeded in 3 succeeding monitoring intervals.

Outside the FTP-area the failure CARB A is validated immediately. The counter is reset only after an ECU-reset.

Even if we are inside the FTP-area, a specific application request (according catalyst temperature or else) LV_REQ_APP_CTR_MIS_A can force to validate immediately the failure CARB A *(see legal requirements & customer wishes).* This request is defined in associated Application Incidences file.

Note: cylinder and Exhaut cylinder bank specific counters are respectively indexed with SEG_NR_ER and SEG_NR_CBK_ER phase reference counters to take in account ERND delay in misfire monitoring process

Application conditions:

Initialisation: *at ECU reset, at LV_DC 0 - > 1 transition, at LC_MIS_INH 0 to 1 transition & at MIS_A or MIS_[NC_CYL_NR] errors clearing*

```

    MIS_SUM_A_CBK[i] = 0       // All Exhaut cylinder bank specific counters
EndFor
```

Update rate: segment task

Activation:

```
LV_DC = 1
And LC_MIS_INH = 0
```

Deactivation:

```
LV_DC = 0
Or LC_MIS_INH = 1
```

51.7.4.1 Determination of catalyst damage weighting factor

Catalyst damage weighting factor is determinated according engine combustion mode & buffered to take in account admission phase (SEG_NR_ER - 2).

MIS_A_FAC_BUF is managed as a rotary buffer, MIS_A_FAC_BUF[0] is the weighting factor for the actual segment value.

At each ER segment recurrence:

FAC_MIS_A_APP depends on the combustion mode and determine in application incidence (must be calculated first)

MIS_A_FAC_BUF is managed as a rotary buffer

```
MIS_A_FAC_BUF[current_position] = FAC_MIS_A_APP
MIS_A_FAC = MIS_A_FAC_BUF          [oldest_position]       // points on the oldest value of the buffer
```

51.7.4.2 CARB A window management (main process)

```
If(1)   LV_CDN_MIS_A = 1                  // MIS_A monitoring active (see App Inc file)

 └────────────────────────────────────> -
```

51.7.4.9 Misfire Cylinder Limp Home process:

Cylinder shut off is limited by a C_MIS_MAX_NR_OFF_IV maximum number of cylinders that can be shut-off simultaneously

Each time, the misfire cylinder limp home process on one (or more) cylinder(s) is triggered, the corresponding cylinder counter(s) CTR_MIS_A_LIH_CYL[NC_CYL_NR] is(are) unitary incremented.

The location of switched off Cylinder(s) x is set to 1 in INH_IV_MIS, other cylinder bits are set to 0.

<u>On the same driving cycle</u>, if after a cylinder shut-off cancellation, a new cylinder MIS_A criterion occurs during CARB A window, the sytem must shut-off this cylinder once more.

<u>Carrier structure :</u>

```

```

51.7.4.10 Conditions for Cylinder switch back on

Update rate: *every 100ms, independently of MIS_A window process & conditions*

Cylinder(s) x can be switched on according two different methods:

1. Cylinder(s) x can be switched back on at the end of the driving cycle

   LC_CONF_INH_IV_MIS = 0

2. Cylinder(s) x can be switched back on after a defined number of fuel cut-off phases **and** at the end of the driving cycle

   LC_CONF_INH_IV_MIS = 1

   For this purpose, the system performs a test for the applicable number C_MIS_MIN_NR_PUC of trailing throttle fuel cut-off LV_PUC cycles, since the last cylinder(s) shutoff.

   Therefore, the trailing throttle fuel cut-off LV_PUC flag must have been active for the applicable minimum period C_T_MIS_MIN_PUC.

   If the condition concerning the minimum number of trailing throttle fuel cut-off events is met. Cylinder shut-off is cancelled at the end of the last trailing throttle fuel cut-off phase only for cylinders who answer to the conditions CTR_MIS_A_LIH_CYL[x] < C_NR_MAX_MIS_A_LIH_CYL *(check for all cylinders),* all other cylinders stay in fuel cut-off up to end of the driving cycle.

Cylinder shut-off is also cancelled after engine stopped LV_ES.

51.7.4.11 Process on cylinder shut-off cancellation

Update rate: *every TDC, independently of MIS_A window process & conditions*

```
If    Any 1 -> 0 cylinder bit(s) transition within INH_IV_MIS
      And LC_CONF_MIS_A_LIH = 1

FAC_MIS_SUM_B1_THD_APP	NC_CYL_NR	LV_MIS_B_DIAG_REQ_APP	LV_DC

Description:

The purpose is to detect a misfire rate causing an emission increase. The failure criterion entry is performed by direct statistical evaluation.

Detection:

The check for misfire rate violation CARB comprises 1.000 crankshaft revolutions (500*NC_CYL_NR tdc's).

Each combustion during these 1.000 crankshaft revolutions is monitored for misfiring.

If a confirmed misfiring is detected on ER current TDC (LV_DET_CFM_MIS=1), the cylinder-specific misfire counter MIS_CTR_B[SEG_NR_ER] is incremented by one.

In every driving cycle a distinction is made between misfires detected during the first 1000 crankshaft revs after engine start (**CARB B1**) and misfires detected in later observing intervals. In the second case, a misfire rate violation must take place during four monitoring intervals to recognise misfire (**CARB B4**).

Statistic:

At the end of the first 1.000 crankshaft revolutions, the added cylinder-specific sums are evaluated. If the sum exceeds the applicable value C_THD_MIS_B1_AT/MT, **CARB B1** misfire criterion is detected.

At the end of each following 1.000 crankshaft revolutions interval, the added cylinder-specific sums are evaluated. If the sum exceeds the applicable value C_THD_MIS_B1_AT/MT the anti-bounce counter CTR_DET_MIS_B4 will be incremented till its maximum C_NR_DET_MAX_MIS_B4 (typical = 3) is reached. If the sum does not exceed C_THD_MIS_B1_AT/MT, CTR_DET_MIS_B4 remains unchanged.

To filter out those cylinders with low misfire rates, the cylinder-specific counters MIS_CTR_B[NC_CYL_NR] shall be compared to the applicable value C_THD_MIS_B_MIN before storage takes place.

If none of the cylinder-specific counters is higher than C_THD_MIS_B_MIN, a maximum choice is done and the cylinder with the highest misfire rate is entered into failure memory.

Application conditions:

Initialisation: *at ECU reset, at LV_DC 0 -> 1 transition, at LC_MIS_INH 0 to 1 transition & at MIS_B1/B4 or MIS_[NC_CYL_NR] errors clearing*

```

51.7.5.4 Monitoring process during CARB B1/B4 window

This part is realized during CARB B1/B4 window when NLC_ENA_SCDN_NEW=1.

In this case, we do exactly the same operations that those done in "**'Monitoring process at CARB B1/B4 window end'.**"

51.7.5.5 CARB B1 criterion determination process:

// Global CARB B1 default

As soon as an error occurs during B1 window, we set the error.

But if the error enters again, we do not want to store it again. This is realized by lv_err_in_win_mis_b1 flag.

```
 if(1) (LV_ERR_IN_WIN_MIS_B1 = 0)
Then(1)
    LV_MIS_STATE_B1 = 1
    LV_ERR_IN_WIN_MIS_B1 = 1
    // CARB B1 cylinder identification
    For   x = 0 to NC_CYL_NR - 1                  // Check for each cylinder x
        If(2)       MIS_CTR_B[x] > C_MIS_B1_MIN_NR * MIS_SUM_B
        Then(2)     Set in SYM_CYL_MIS_B1 the cylinder x concerned bit to 1
        EndIf(2)
    EndFor
    // CARB B1 random cylinder pattern
    If  No specific cylinder counters comply with C_MIS_B1_MIN_NR * MIS_SUM_B
        criterion
    Then
        If(3)      LC_CONF_RND_DET_MIS_B = 0
        Then(3)  Evaluate Cylinder with the highest  MIS_CTR_B[x]  value
```

```
                    Set concerned cylinder bit to 1 in SYM_CYL_MIS_B1 carrier
                    Set RDN bit (random) to 0 in SYM_CYL_MIS_B1 carrier
                Else(3)   Set RDN bit (random) to 1 in SYM_CYL_MIS_B1 carrier
                Endif(3)
            Else  Set RDN bit (random) to 0 in SYM_CYL_MIS_B1 carrier
            EndIf
            // CARB B1 multiple cylinder identification
            If  LC_CONF_MPL_DET_MIS_B = 1
            And  number of cylinder(s) set to 1 in SYM_CYL_MIS_B1 is equal or over
                C_NR_CYL_MPL_MIS_B
            Then      Set MPL bit (multiple) to 1 in SYM_CYL_MIS_B1 carrier
            Else      Set MPL bit (multiple) to 0 in SYM_CYL_MIS_B1 carrier
            End
        Endif(1)
```

51.7.5.6 CARB B4 criterion determination process

```
If(1)   (LV_ERR_IN_WIN_MIS_B4 = 0)
Then(1)
    CTR_DET_MIS_B4 = CTR_DET_MIS_B4 + 1
    LV_DET_MIS_B4 = 1
    LV_ERR_IN_WIN_MIS_B4 = 1
```

As soon as the misfire criterion detected counter reached his threshold, we directly set the error. To avoid to stored it in the same window a second time, we used *lv_err_in_win_mis_b4 flag.*

```
    If(2)   (CTR_DET_MIS_B4 ≥ C_NR_DET_MAX_MIS_B4)
    Then(2)
        // Global CARB B4 default
        LV_MIS_STATE_B4 = 1
        // CARB B4 cylinder identification
        For(3) x = 0 to NC_CYL_NR-1          // Check for each cylinder x
            If(4)   MIS_CTR_B[x] > C_MIS_B4_MIN_NR * MIS_SUM_B
            Then(4)      Set in SYM_CYL_MIS_B4 the cylinder x concerned bit to 1
             EndIf(4)
        EndFor(3)
        // CARB B4 random cylinder pattern
```

```
        If(3)   No specific cylinder counters comply with C_MIS_B4_MIN_NR *
                MIS_SUM_B criterion
        Then (3)
            If(4)     LC_CONF_RND_DET_MIS_B = 0
            Then(4)   Evaluate Cylinder with the highest  MIS_CTR_B[x]  value
                      Set concerned cylinder bit to 1 in SYM_CYL_MIS_B4 carrier
                      Set RDN bit (random) to 0 in SYM_CYL_MIS_B4 carrier
            Else(4)   Set RDN bit (random) to 1 in SYM_CYL_MIS_B4 carrier
            Endif(4)
        Else(3)     Set RDN bit (random) to 0 in SYM_CYL_MIS_B4 carrier
        EndIf(3)
        // CARB B4 multiple cylinder identification
        If(3)   LC_CONF_MPL_DET_MIS_B = 1
            And    number of cylinder(s) set to 1 in SYM_CYL_MIS_B4 is equal or over
            C_NR_CYL_MPL_MIS_B
        Then(3)     Set MPL bit (multiple) to 1 in SYM_CYL_MIS_B4 carrier
        Else(3)     Set MPL bit (multiple) to 0 in SYM_CYL_MIS_B4 carrier
        End(3)
    Else(2)
        SYM_CYL_MIS_B4 = 0
        LV_MIS_STATE_B4 = 0
    EndIf(2)
EndIf(1)
```

51.7.5.7 CARB B1/B4 ends detection process

```
If(1) LV_END_MIS_B1 = 0
Then(1)     LV_END_MIS_B1 = 1
            LV_END_WIN_MIS_B1 = 1 (set for one segment)
Else(1)
    LV_END_WIN_MIS_B4 = 1 (set for one segment)
    If(2)   CTR_DET_MIS_B4 ≥ C_NR_DET_MAX_MIS_B4
            Or CTR_CHK_MIS_B4 ≥ C_NR_DET_MAX_MIS_B4
    Then(2)         LV_END_MIS_B4 = 1
    EndIf(2)
EndIf(1)
```

51.7.5.8 CARB B1/B4 window reset process

```
MIS_NR_TDC_B = 0
MIS_SUM_B = 0
LV_ERR_IN_WIN_MIS_B1 = 0

EndFor
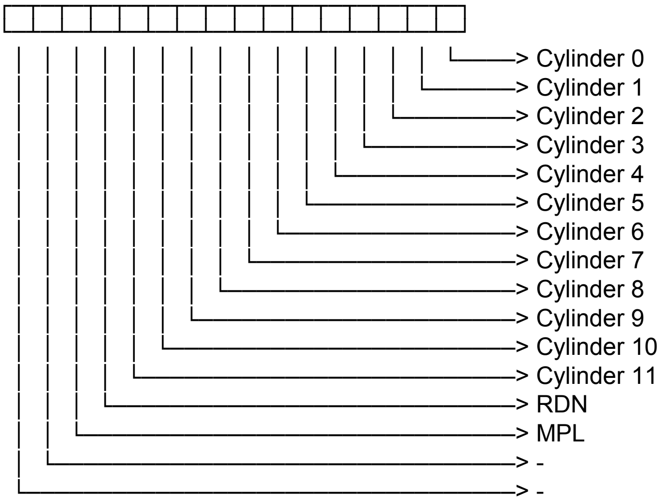
```

51.7.5.9 SYM_CYL_MIS_B1 and SYM_CYL_MIS_B4 carriers definition

The location of detected cylinders with misfire status CARB B is coded in two carrier bytes:

SYM_CYL_MIS_B1, SYM_CYL_MIS_B4



Calibration data:

Name	Dim	Hex. limits	Phys. Limits	Resol.	Unit
C_MIS_SUM_B1_THD_MT	1	0...FFFFH	0...65535	1	[-]
Global threshold for CARB B1 misfire criterion detection, LV_AT = 0					
C_MIS_SUM_B1_THD_AT	1	0...FFFFH	0...65535	1	[-]
Global threshold for CARB B1 misfire criterion detection, LV_AT = 1					
C_MIS_SUM_B4_THD_MT	1	0...FFFFH	0...65535	1	[-]
Global threshold for CARB B4 misfire criterion detection, LV_AT = 0					
C_MIS_SUM_B4_THD_AT	1	0...FFFFH	0...65535	1	[-]
Global threshold for CARB B4 misfire criterion detection, LV_AT = 1					
C_MIS_B1_MIN_NR	1	0...FFH	0...99.60937	0.390625	[%]
Cylinder identification ratio for CARB B1 criterion detection					
C_MIS_B4_MIN_NR	1	0...FFH	0...99.60937	0.390625	[%]
Cylinder identification ratio for CARB B4 criterion detection					
C_MIS_SUM_B1_CBK_THD	1	0...FFFFH	0...65535	1	[-]
Exhaut cylinder bank threshold for CARB B1 misfire criterion detection					
C_MIS_SUM_B4_CBK_THD	1	0...FFFFH	0...65535	1	[-]
Exhaut cylinder bank threshold for CARB B4 misfire criterion detection					
C_NR_CYL_MPL_MIS_B	1	0...FFH	0...255	1	[-]
Number of cylinder in MIS_Bx to set the multiple misfire CARB Bx status (typical: 2)					
C_NR_DET_MAX_MIS_B4	1	0...FFH	0...255	1	[-]
Maximum value of CTR_DET_MIS_B4 for misfire CARB B4 status detection (typical: 4)					
LC_CONF_MIS_STATE_B	1	0...1H	0...1	1	[-]
Configuration for LV_MIS_STATE_B setting (=0, setting by MIS_B1 only when end of MIS_B4 isn't reached, then only set by MIS_B4) (=1, setting by MIS_B1 or MIS_B4 in any case)					
LC_CONF_MPL_DET_MIS_B	1	0...1H	0...1	1	[-]
Configuration for multiple cylinder status set in SYM_CYL_MIS_Bx (multiple misfire pattern Pcode saved) (=1)					
LC_CONF_RND_DET_MIS_B	1	0...1H	0...1	1	[-]
Configuration for random cylinder detection when no specific cylinder identified,: (=0) Cyl. with the highest value is identified in SYM_CYL_MIS_B1 or SYM_CYL_MIS_B4 or (=1) No identification is realised and RDN bit is set to 1 in SYM_CYL_MIS_B1/B4

51.8.1 Application Incidences data for diagnosis

Description:

LV_REQ_APP_CTR_MIS_A is used for Misfire A calculation considering the load for the catalyst due to exhaust temperature.

Application conditions:

Initialisation: 0 at reset

Recurrence: ENRD segment synchronous,
After misfire detection, Before misfire diagnosis

Activation: LC_MIS_INH = 0 **and** LV_DC = 1

Deactivation: LC_MIS_INH = 1 **or** LV_DC = 0

Formula section:

LV_INH_IV_DIAG_MIS = LV_INH_DET_MIS

LV_INH_IGC_DIAG_MIS = LV_INH_DET_MIS

Calculation of LV_REQ_APP_CTR_MIS_A

If TEG_CAT_UP_MDL_MAX > C_TEG_CAT_UP_MIS_A_MAX

Then LV_REQ_APP_CTR_MIS_A = 1

```
Else      LV_REQ_APP_CTR_MIS_A = 0
EndIf
```

Request to evaluate CARB A criterion with project specific calibration set

```
LV_MIS_A_DIAG_REQ_APP  = 0
FAC_MIS_A_THD_IND_APP = 0
FAC_MIS_SUM_A_THD_APP = 0
```

Request to evaluate CARB B1 & B4 criterions with project specific calibration set

```
LV_MIS_B_DIAG_REQ_APP  = 0
FAC_MIS_SUM_B1_THD_APP = 0
FAC_MIS_SUM_B4_THD_APP = 0
```

51.8.2 Combustion mode influence on the catalyst damage weigthing factor

At each ER segment recurrence:

FAC_MIS_A_APP must be calculated before "Determination of catalyst damage weighting factor" in the generic specification named **Misfire rate and error management**

Convention for combustion mode determination:

```
#If  NC_CMB_CONF = AFS_AFL Or AFS_AFL_S
    If     OPM_AV = 3          (homogeneous-stratified)
    Then   xx = "HOM_S"
    EndIf
#EndIf
#If  NC_CMB_CONF = AFS_S Or AFS_AFL_S
    If     OPM_AV = 1          (stratified)
    Then   xx = "S"
    EndIf
#EndIf
If         OPM_AV <> 1 and OPM_AV <> 3   (homogeneous)
Then       xx = "AFS"
EndIf

    FAC_MIS_A_APP= IP_MIS_A_FAC_xx(N, LOAD_MIS)
```

51.8.3 Combustion mode gestion for combination of different diagnosis relability level

FUNCTION DESCRIPTION:

General information:

FAC_ER_DIAG_MIS must be calculated before the determination of SUM_FAC_DIAG_MIS (in the generic specification named Misfire rate determination and error mamagement)

Application conditions:

Misfire segment after detection, before CARB diagnosis

Update rate: every segment

Activation:

LC_MIS_INH = 0

Deactivation:

LC_MIS_INH = 1

Formula section:

Initialisation on ECU reset, on LV_DC 0 to 1 transition and on LC_MIS_INH 0 to 1 transition:

FAC_ER_DIAG_MIS = 0

Irregular engine operation weighting (LV_DET_MIS = 1):

If misfiring is suspected by the irregular engine operation test, a weighting factor for the corresponding engine operating point is applied. This factor is derived from tables according combustion mode.

Convention for combustion mode determination:

```
#If  NC_CMB_CONF = AFS_AFL Or AFS_AFL_S
     If     OPM_AV = 3          (homogeneous-stratified)
     Then   xx = "HOM_S"
     EndIf
#EndIf
#If  NC_CMB_CONF = AFS_S Or AFS_AFL_S
     If     OPM_AV = 1          (stratified)
     Then   xx = "S"
     EndIf
#EndIf
If          OPM_AV <> 1 and OPM_AV <> 3   (homogeneous)
Then        xx = "AFS"
```

```
EndIf

If LV_DET_MIS = 1
Then     FAC_ER_DIAG_MIS = IP_FAC_ER_xx_DIAG_MIS(N_32, LOAD_MIS)
Else     FAC_ER_DIAG_MIS = 0
EndIf
```

51.8.4 Determination of CARB misfire criterion monitoring conditions *(ER algorithm integration, NC_MISF_VERS = 1)*

Description:

Depending on customers & legal requirements reached, two Tdc's counting modes are available :

- counting each Tdc's even if some aren't diagnosed *(LC_CTR_CONF_DIAG_MIS = 0)*
- counting only diagnosed Tdc's *(LC_CTR_CONF_DIAG_MIS = 1)*

LV_DC	LC_CTR_CONF_DIAG_MIS	LV_INH_DET_MIS	LC_CTR_CONF_OSC_MIS	LV_STATE_CRK_OSC	LV_CDN_MIS_A LV_CDN_MIS_B1 LV_CDN_MIS_B4	MIS_A, MIS_B1 & MIS_B4 Monitoring Modes
0	x	x	x	x	0	Out of Driving Cycle
1	0	x	x	x	1	All TDC's Counting Mode
1	1	1	x	x	0	Diagnosed TDC's Counting Mode / Classical Fade Out

          LV_CDN_MIS_B1 = 0           // Carb B1 diagnosis inactive
          LV_CDN_MIS_B4 = 0           // Carb B4 diagnosis inactive
    EndIf(1)
```

51.8.5 Specific cylinder misfire errors

FUNCTION DESCRIPTION:

General information:

There is one LV_ERR_MIS[x] for each cyllinder (x = 0, 1, 2, 3, 4, 5), thus a seperate calibration of P-codes for each symptom is possible.

Description:

If Misfire criterion is detected on one cylinder with at least one of the CARB_A, CARB_B1 or CARB4 default criterions, the corresponding cylinder error is set (error is set directly without debounce). The symptom is always corresponding to the last error occurence, and the error is reseted only when all misfire criterions on this cylinder have disappeared.

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> - Cylinder in misfire, Criterion default : MIS_A        (= SYM_0)
 │ │ └───> - Cylinder in misfire, Criterion default : MIS_B1       (= SYM_1)
 │ └─────> - Cylinder in misfire, Criterion default : MIS_B4       (= SYM_2)
 └───────> -                                                       (= SYM_3)
```

Formula section:

Initialisation: at ECU reset **or** LV_DC 0 -> 1 **or** LC_MIS_INH 0 -> 1 for all cylinders

LV_CDN_DIAG_MIS[x] = 0

LV_END_DIAG_MIS[x] = 0

LV_ERR_MIS[x] = 0

ERR_SYM_MIS[x] = 0

Recurrence: The application recurrence is **ENRD segment**

After misfire detection, after misfire diagnosis !

Activation:

```
If(1)       LV_DC = 1
      And   LC_MIS_INH = 0
      And   ( LV_CDN_MIS_A = 1
            Or    LV_CDN_MIS_B4 = 1
            Or    LV_CDN_MIS_B1 = 1 )
Then(1)     For(2) x = 0 ... NC_CYL_NR-1
            LV_CDN_DIAG_MIS[x] = 1          // Diagnosis is active for all cylinders
                  If(3) NLC_ENA_SCDN_NEW = 1
                  Then(3) ACTION_ERRM_CdnDiagScdn (MIS[x])
```

```
                        EndIf(3)
                    EndFor(2)
    Else(1)         For(2)  x = 0 ... NC_CYL_NR-1
                    LV_CDN_DIAG_MIS[x] = 0          // Diagnosis is passive for all cylinders
                    EndFor(2)
    EndIf(1)
```

Formula section:

Remark:

Note : CARRIER*[x]* = 1, stands for bit dedicated to cylinder x inside CARRIER structure is set to 1

ERR_SYM[x]*[0]* = 1, stands for symptom 0 inside ERR_SYM[x] structure is set to 1

[x] (italic) stands for bit assignement within a data, [x] stands for data assignement within an array

Individual cylinder errors set in case of MIS_A failure

```

EndIf
```

51.8.6 Multiple cylinder misfire

Description:

If at the end of the concerned checking range (LV_END_WIN_MIS_A), misfire is detected on two or more cylinders, then the “Multiple cylinder misfire” is detected.
Depending if only MIS_A, MIS_B1, MIS_B4 or a combination is active, the concerned bits are set. The error is set directly without debounce.

Error-symptoms are defined to this diagnosis function as following :

```
☐☐☐☐
 │ │ │ └─> Multiple cylinder MIS_A detected      (= SYM_0)
 │ │ └───> Multiple cylinder MIS_B1 detected     (= SYM_1)
 │ └─────> Multiple cylinder MIS_B4 detected     (= SYM_2)
 └───────> Multiple cylinder misfire detected    (= SYM_3)
```

Application conditions:

Initialisation: all outputs with 0 at LV_DC 0->1 **or** reset

Recurrence: The application recurrence is **ENRD segment,**
After misfire detection, After misfire diagnosis

Activation:

```
If      LV_DC = 1
        And     LV_CDN_MIS_A = 1
        And     LC_MIS_INH = 0
        And     ( LC_CONF_MPL_DET_MIS_A = 1          or
                LC_CONF_MPL_DET_MIS_B = 1 )
        And     LV_END_WIN_MIS_A = 1
```

```
    Then    LV_CDN_DIAG_MIS_MPL = 1     // diagnosis is active
    Else    LV_CDN_DIAG_MIS_MPL = 0     // diagnosis is passive
    Endif
```

Formula section:

Error detection Muliple misfire without symptom detection

```
If      LV_CDN_DIAG_MIS_MPL = 1
Then    If      at least two Multiple Misfire Bits are active (Bits MPL are set in
                SYM_CYL_MIS_A, SYM_CYL_MIS_B1, SYM_CYL_MIS_B4)
        Then            ERR_SYM_MIS_MPL = SYM_3
                        LV_ERR_MIS_MPL = 1
        Error detection Muliple misfire MIS_A
        Else If  only MPL Misfire MIS_A is active (Bit MPL is set in SYM_CYL_MIS_A)

51.8.7 Misfire with low fuel signal active

Description:

If Misfire is detected (CARB_A / CARB_B1/4) with low fuel signal active then a error bit is set in order to supply a own P-code requested by CARB (error is set directly without debounce)

Error-symptoms are defined to this diagnosis function as following :

```
┌─┬─┬─┬─┐
└─┴─┴─┴─┘
 │ │ │ └─> -                                   (= SYM_0)
 │ │ └───> Misfire with active fuel-tank reserve (= SYM_1)
 │ └─────> -                                   (= SYM_2)
 └───────> -                                   (= SYM_3)
```

Application conditions:

Initialisation: all outputs with 0 at LV_DC 0->1 **or** reset

Recurrence: The application recurrence is ***ENRD segment***,

After misfire detection, After misfire diagnosis

Activation:

```
If          LV_DC = 1
      And   LV_CDN_MIS_A = 1
      And   LC_MIS_INH = 0
Then        LV_CDN_DIAG_MIS_FTL_L = 1    (diagnosis is active)
Else        LV_CDN_DIAG_MIS_FTL_L = 0    (diagnosis is passive)
Endif
```

Formula section:

Error detection

```
If          ( LV_MIS_STATE_A  = 1          or
              LV_MIS_STATE_B1  = 1         or
              LV_MIS_STATE_B4  = 1 )
      and
              LV_FTL_L_DIAG_MIS = 1        fuel reseve active and calibrated

Then          ERR_SYM_MIS_FTL_L = SYM_1
              LV_ERR_MIS_FTL_L = 1               set directly
Else          ERR_SYM_MIS_FTL_L = NO_SYM
              LV_ERR_MIS_FTL_L = 0               reset
Endif
```

End of Diagnosis

```
If      LV_ERR_MIS_FTL_L = 1      or
        LV_END_MIS_B4      = 1
Then    LV_END_DIAG_MIS_FTL_L = 1
Endif
```

51.8.8 Misfire event counters

Description:

The counters should be used for reading out diagnosis data in the workshop. All Data are stored in NVMY. The DC – related counters (CTR_SEG_MIS_ACT and CTR_MIS_DET) are initialized if engine is started or if NVMY is cleared.

Application conditions:

Initialisation: CTR_SEG_MIS_ACT and CTR_MIS_DET are initialized from MVMY and set to 0 at LV_RUN_ENG 0->1 **or** at clearing misfire NVMY variables.

CTR_MIS_DET_CYL[i] are initialized from MVMY and only set to 0 at clearing misfire NVMY variables

Recurrence: ER segment task, after ER determination process & Misfire detection

Activation:	LV_REQ_INH_MIS = 0	increment counters
Deactivation:	LV_REQ_INH_MIS = 1	counters are unchanged

Formula section:

Calculation of CTR_SEG_MIS_ACT

$CTR\_SEG\_MIS\_ACT_{n} = CTR\_SEG\_MIS\_ACT_{n-1} + 1$

//counting every segment if MSF detetion is active

Calculation of CTR_MIS_DET

```
If      LV_DET_MIS = 1
Then    $CTR\_MIS\_DET_{n} = CTR\_MIS\_DET_{n-1} + 1$
        $CTR\_MIS\_DET\_CYL[SEG\_NR\_ER]_{n} =$
        $CTR\_MIS\_DET\_CYL[SEG\_NR\_ER]_{n-1} + 1$

Endif
```

Remark for all counters:

If the counters reaches the end of Hex-limit, then the inrementing process is stopped and value remain on max value.

51.9 Crankshaft oscillation detection

N	LOAD_MIS	LV_ENA_ER	LC_MIS_INH
LV_INH_CRK_OSC_DET			

51.9.1 General information

The misfire detection based on engine roughness index (ER) may be disturbed by crankshaft oscillations when single misfire (random) occurs, especially for front drive vehicles crankshaft in the low engine speed / high engine load area (in combination with a 3rd, 4th or 5th gear ratio). A single misfire acts as a drivetrain / crankshaft oscillations trigger, in this case the ER index is distrubed by these oscillations, in some conditions it is practically not possible to distinguish on ER index, real misfire towards speed drop caused through crankshaft speed oscillations.

The trigger for such oscillations can be a single misfire, an obstacle, a big torque change or others instantaneous conditions.

The principle of this crankshaft / drivetrain oscillation detection is to detect such an oscillation and then to fade-out the misfire detection for a short period to avoid over-detection.

Initialisation: *on ECU reset, on LC_MIS_INH 0 to 1 transition*

SEG_SUM_FRQ_CRK_OSC = 0

DRV0_ER_SUM_OSC = 0

LV_STATE_CRK_OSC = 0

Application conditions:

Activation/Deactivation:

```
RATIO_VS_N_CRK_OSC  = VS / N
If    LV_DET_CFM_MIS = 1
Then        CTR_TDC_CRK_OSC_ACT = C_NR_TDC_MAX_CRK_OSC
ElseIf      CTR_TDC_CRK_OSC_ACT ≠ 0
Then        CTR_TDC_CRK_OSC_ACT = CTR_TDC_CRK_OSC_ACT - 1
EndIf

      And   N_32 < C_N_MAX_CRK_OSC
      And   RATIO_VS_N_CRK_OSC > C_RATIO_VS_N_MIN_CRK_OSC
      And   CTR_TDC_CRK_OSC_ACT ≠ 0
Then        LV_CRK_OSC_DET_ACT = 1        // Crankshaft oscillation detection active
Else        LV_CRK_OSC_DET_ACT = 0        // Crankshaft oscillation detection inactive
            SEG_SUM_FRQ_CRK_OSC = 0
            DRV0_ER_SUM_OSC = 0
EndIf
```

Update rate: Segment

51.9.2 Detection description

The final decision about crankshaft oscillation consists of two parts:

- The detection of a critical engine roughness oscillation frequency.
- The detection of a critical engine roughness oscillation amplitude.

If both parts fulfilled at the same time their own detection criterion, a crankshaft oscillation is detected. The reason therefore is, that even at constant speed due to normal little speed variations a high frequency or at a normal acceleration phase a big amplitude is possible.

51.9.2.1 Determination of a critical engine roughness frequency

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

```
If    Bit sign between $DRV0\_ER_{(n-1)}$ and $DRV0\_ER_{(n)}$ changes
Then        SEG_SUM_FRQ_CRK_OSC = IP_SEG_MIN_FRQ_CRK_OSC(N_32)
ElseIf      SEG_SUM_FRQ_CRK_OSC ≠ 0
Then        SEG_SUM_FRQ_CRK_OSC = SEG_SUM_FRQ_CRK_OSC - 1
```

```
EndIf
If    SEG_SUM_FRQ_CRK_OSC ≠ 0
Then        LV_FRQ_CRIT_CRK_OSC = 1        // Critical crankshaft frequency status is active
Else        LV_FRQ_CRIT_CRK_OSC = 0
EndIf
```

51.9.2.2 Determination of a critical engine roughness oscillation amplitude

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

```
If    Bit sign between DRV0_ER$_{(n-1)}$ and DRV0_ER$_{(n)}$ changes
Then        DRV0_ER_SUM_OSC$_{(n)}$ = |DRV0_ER$_{(n)}$|
Else        DRV0_ER_SUM_OSC$_{(n)}$ = DRV0_ER_SUM_OSC$_{(n-1)}$ + |DRV0_ER$_{(n)}$|
            // with saturation
EndIf
DRV0_ER_SUM_THD_OSC = IP_DRV0_ER_THD_OSC(N_32, LOAD_MIS)
If    DRV0_ER_SUM_OSC > DRV0_ER_SUM_THD_OSC
Then        LV_AMPL_CRIT_CRK_OSC = 1        // Critical crankshaft amplitude status is active
Else        LV_AMPL_CRIT_CRK_OSC = 0
EndIf
```

51.9.2.3 Determination of crankshaft oscillation final status

Application conditions:

Activation: LV_CRK_OSC_DET_ACT = 1

Deactivation: LV_CRK_OSC_DET_ACT = 0

Formula section:

If in the same time, both conditions are active, a crankshaft oscillation status is triggered :

```
If    LV_FRQ_CRIT_CRK_OSC = 1
      And   LV_AMPL_CRIT_CRK_OSC = 1
Then  After condition rising edge triggering, LV_STATE_CRK_OSC flag is set to 1 as long
      as condition is true.
      After condition falling edge triggering, LV_STATE_CRK_OSC flag is hold to 1 for a
      period of C_DLY_TDC_CRK_OSC tdc's, even if LV_CRK_OSC_DET_ACT is then
      set to 0.
EndIf
```

VS	LV_ERR_VS	LV_AT	

Import Actions:

ACTION_INFR_GetVsRrPulsStamp(**OUT**< vs_rr_edge_ctr_av >, **OUT**<vs_rr_edge_t_av>, **OUT**<vs_rr_edge_t_av_max)
Reading of information about vehicle speed on rough road

The above imported action is defined in the VHMD – IRS (Infrastructure Requirement Specification)

FUNCTION DESCRIPTION:

General information:

Rough road conditions must be detected to prevent erroneous misfire detection because of the influence jolty tracks have on the crankshaft as a result of transmission via the drive train.
The speed disturbance of one wheel can be used to calculate the road conditions. Therefore, the control unit uses the signal from the driven wheel on the right side (ABS sensor or an additive sensor for the version without ABS) because the probability of the presence of a jolty track is greater than left.

However, transmission from the left to the right side has also been observed depending on the chassis and other circumstances, so that a limited detection of unilateral rough-road conditions on the left side is also possible.
The minimum number of integrated teeth for one segment depends on the number of teeth per revolution of the wheel speed. An angle of about 30 ° is preferable (e.g. an integration of 4 teeth is used for a wheel with 48 teeth). This number is determined by the non calibrateable constant NC_SEG_TOOTH_RR.
At higher speed ranges the number of integrated teeth for one segment is determined by the recurrence time of 10 ms.

Application conditions:

Initialisation:	SUM_RR = 0 at ECU-reset	
	LV_RR_PREV_INI = 1 at ECU-reset and at function deactivation	
	all other outputs = 0 at ECU-reset and at function deactivation	
Recurrence:	10 ms	
Activation:	LV_ERR_VS = 0	**and**
	VS $\geq$ C_VS_MIN_RR	**and**
	VS $\leq$ C_VS_MAX_RR	
Deactivation:	LV_ERR_VS = 1	**or**
	VS $<$ C_VS_MIN_RR	**or**
	VS $>$ C_VS_MAX_RR	

Remark: to avoid unnecessary burden of the micro controler it is recommended to calibrate C_VS_MAX_RR according the needs. At vehicle speeds above approximately 100 km/h there is no more feed back from wheels to crankshaft.

Formula section:

ACTION_INFR_GetVsRrPulsStamp(VS_RR_EDGE_CTR_AV, VS_RR_EDGE_T_AV, VS_RR_EDGE_T_AV_MAX)

Initialisation of VS_RR_EDGE_T_AV/CTR(n-1) and new_rr_clc:

```
If      LV_RR_PREV_INI = 1
then    VS_RR_EDGE_T_AV(n-1) = VS_RR_EDGE_T_AV(n)
        VS_RR_EDGE_CTR_AV(n-1) = VS_RR_EDGE_CTR_AV(n)
        new_rr_clc = 2
        LV_RR_PREV_INI = 0
endif
```

a) Segment period acquisition

The function uses consecutive segment times for calculation of a wheel speed gradient. The segments are built with a minimum number of NC_SEG_TOOTH_RR edges and afterwards normalized to a length of 8 teeth.

If VS_RR_EDGE_CTR_AV $_n$ – VS_RR_EDGE_CTR_AV $_{n-1}$ >= NC_SEG_TOOTH_RR
then

$$\mathrm{SEG\_T\_MES\_0\_RR} = \left| \frac{(\mathrm{VS\_RR\_EDGE\_T\_AV}_n - \mathrm{VS\_RR\_EDGE\_T\_AV}_{n-1}) * 8}{\mathrm{VS\_RR\_EDGE\_CTR\_AV}_n - \mathrm{VS\_RR\_EDGE\_CTR\_AV}_{n-1}} \right|$$

SEG_T_MES_1_RR is the segment period preceding SEG_T_MES_0_RR.

endif

b) Calculation of rough road value

$$WHEEL\_GRD = \left| \frac{SEG\_T\_MES\_1\_RR - SEG\_T\_MES\_0\_RR}{SEG\_T\_MES\_1\_RR} \right| * 1000[‰]$$

The raw values WHEEL_GRD are used in a floating averaging, to restrict suppression to actual rough road conditions.

$$\mathrm{WHEEL\_GRD\_MMV}_n = \mathrm{WHEEL\_GRD\_MMV}_{n-1} + \mathrm{C\_WHEEL\_GRD\_CRLC\_RR} * (\mathrm{WHEEL\_GRD}_n - \mathrm{WHEEL\_GRD\_MMV}_{n-1})$$

When the calculation of the wheel speed segment duration is stopped due to the vehicle speed condition (see above), the calculation of WHEEL_GRD and WHEEL_GRD_MMV is stopped as well until again 2 consecutive segment durations could be determined (realised by the internal SW counter new_rr_clc).

Set of VS_RR_EDGE_T_AV/CTR(n-1) after each calculation of WHEEL_GRD(_MMV):
VS_RR_EDGE_T_AV(n-1) = VS_RR_EDGE_T_AV(n)
VS_RR_EDGE_CTR_AV(n-1) = VS_RR_EDGE_CTR_AV(n)

c) Detection of rough road status

WHEEL_GRD_MMV_THD = IP_WHEEL_GRD_MMV_THD_XX__VS

(XX = AT for automatic transmission, LV_AT = 1 ; XX = MT for manual transmission, LV_AT = 0)

```
If   WHEEL_GRD_MMV ≥ WHEEL_GRD_MMV_THD
     then   LV_STATE_RR = 1    and  timer DLY_ER_RR becomes started    and
            increment SUM_RR by one
     elseif timer DLY_ER_RR > 0
            then LV_STATE_RR = 1   and  decrement timer DLY_ER_RR
            else LV_STATE_RR = 0
     endif
endif
```

The start value of the timer DLY_ER_RR is C_DLY_ER_RR.

Input data:

SEG_NR	N	TD_IGC[NC_CYL_NR]	IGA_AV[NC_CYL_NR]
EOI_LIM[NC_CYL_NR]	SOI_MAX		

FUNCTION DESCRIPTION:

According the project SI integration plan and/or customer requirements/wishes, a software misfire generator can be included on EMS softwares and used during integration validation and calibration stages. It is strongly recommended to remove this functionally on serial product software: integration choice via NLC_USE_MIS_GEN compilation switch.

Application conditions:

Initialisation: at reset & engine stalling

LV_MIS_GEN = 0

LV_MIS_GEN_DET = 0

INH_IV_MIS_GEN = 0

INH_IGC_MIS_GEN = 0

No function calls to INJR & IGRE

Recurrence: Segment

Activation:

The regular or random misfiring generation is applied on ignition and/or injection sequences.

```
If      LC_IGN_OFF_MIS_GEN = 1
Then    Ignition cut-off mode
        (using INH_IGC_MIS_GEN carrier, see § Ignition misfire realisation)
        LV_MIS_GEN is set to 1 according misfiring generation mode selected
        (pseudo random or regular mode, see dedicated chapters below)
EndIf
If      LC_INJ_OFF_MIS_GEN = 1
```

```
Then    Injection cut-off mode
        (using INH_IV_MIS_GEN carrier, see § Injection misfire realisation)
        LV_MIS_GEN is set to 1 according misfiring generation mode selected
        (pseudo random or regular mode, see dedicated chapters below)
EndIf
If      LC_IGN_OFF_MIS_GEN = 1
        And LC_INJ_OFF_MIS_GEN = 1
Then    Ignition and injection off modes (for the same TDC)
        (using INH_IGC_MIS_GEN & INH_IV_MIS_GEN carrier)
        LV_MIS_GEN is set to 1 according misfiring generation mode selected
        (pseudo random or regular mode, see dedicated chapters below)
EndIf
If      LC_IGN_OFF_MIS_GEN = 0
        And LC_INJ_OFF_MIS_GEN = 0
Then    No misfire generation allowed
        LV_MIS_GEN = 0
        INH_IV_MIS_GEN = 0
        INH_IGC_MIS_GEN = 0
        No function calls to INJR & IGRE
EndIf
LV_MIS_GEN_DET = LV_MIS_GEN delayed with C_NR_TDC_DLY_MIS_GEN tdc's
```

51.11.1.1 Pseudo random misfiring generation mode

Application conditions:

The misfiring generation mode is authorised when the misfiring tuning function and the pseudo random misfiring tuning function are active.

This misfiring generation mode is global to all cylinders.

Recurrence: Segment

Activation:

```
If      LC_REQ_MIS_GEN = 1
    And C_MOD_MIS_GEN = 0
    And SEG_NR = C_SEG_ST_MIS_GEN
Then    Pseudo random misfiring generation is triggered
EndIf
```

Deactivation:

```
If      LC_REQ_MIS_GEN = 0
    Or  C_MOD_MIS_GEN ≠ 0
Then    Pseudo random misfiring generation mode is disabled
EndIf
```

Formula section:

A random ignition and/or injection is missing following the bitfield sequence ID_RND_PAT_MIS_GEN, where each bit corresponds to a TDC.

If the current bit value is 0 then the ignition and/or injection are missing; else ignition and injection are realised.

During the TDC where the ignition and/or injection are missing **And** if at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 **Or** LC_INJ_OFF_MIS_GEN = 1), the flag LV_MIS_GEN is set to 1 else the flag LV_MIS_GEN is set to 0.

51.11.1.2 Regular misfiring generation mode

Application conditions:

This generation mode is authorised when the misfiring tuning function and the regular misfiring tuning function are active.

This misfiring generation mode is global to all cylinders.

Recurrence: Segment

Activation:

```
If      LC_REQ_MIS_GEN = 1
    And C_MOD_MIS_GEN = 1
    And SEG_NR = C_SEG_ST_MIS_GEN
Then    Regular misfiring generation mode is triggered
EndIf
```

Deactivation:

```
If      LC_REQ_MIS_GEN = 0
    Or  C_MOD_MIS_GEN ≠ 1
Then    Regular misfiring generation mode is disabled
EndIf
```

Formula section:

Regular ignition and/or injection are missing every C_MIS_RATE tdc.

During the TDC where the ignition and/or injection are missing **And** if at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 **Or** LC_INJ_OFF_MIS_GEN = 1), the flag LV_MIS_GEN is set to 1 else the flag LV_MIS_GEN is set to 0.

51.11.1.3 Cylinder regular misfiring generation mode

Application conditions:

This generation mode is authorised when the misfiring tuning function and the regular misfiring tuning function are active.

This misfiring mode is dedicated to specific cylinder generation.

Recurrence: Segment

Activation:

```
If    LC_REQ_MIS_GEN = 1
      And    C_MOD_MIS_GEN = 2
      And    SEG_NR = C_SEG_ST_MIS_GEN
Then         Cylilnder regular misfiring generation mode is triggered
EndIf
```

Deactivation:

```
If    LC_REQ_MIS_GEN = 0
      Or     C_MOD_MIS_GEN ≠ 2
Then         Cylinder regular misfiring generation mode is disabled
EndIf
```

Formula section:

```
If(1)    LC_MIS_RATE_ENA_CYL[SEG_NR] = 1
Then(1)  Ignition and/or injection are missing on cylinder SEG_NR every
         C_RATE_MIS_CYL[SEG_NR] tdc's.
      If(2)    During the TDC where the ignition And/Or injection are missing
               And at least one of the cut-off mode is allowed (LC_IGN_OFF_MIS_GEN = 1 Or
               LC_INJ_OFF_MIS_GEN = 1),
      Then(2)        LV_MIS_GEN = 1
      Else(2)        LV_MIS_GEN = 0
      EndIf(2)
Else(1)  No Ignition and/or injection are missing on cylinder SEG_NR
         LV_MIS_GEN is set to 0
EndIf(1)
```

51.11.1.4 Injection misfire realisation

Recurrence: Every engine cycle, phased with required cylinder injection

Formula section:

The injection misfire realisation is realised via the INH_IV_MIS_GEN carrier. This is an input for the Injection Cylinder Shut-Off Application Incidences file.

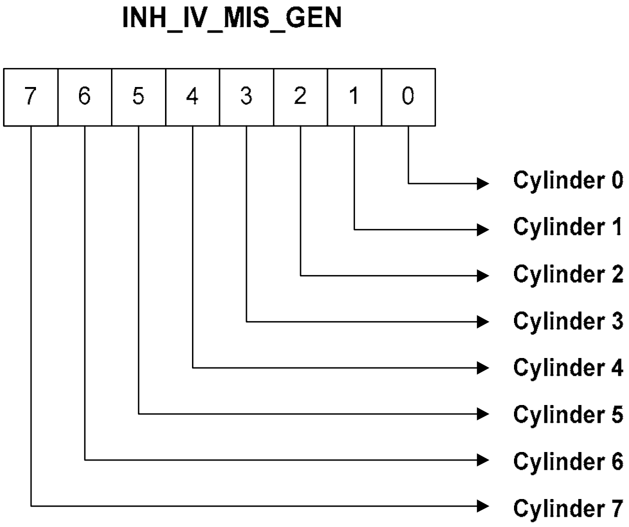
Cylinder switched off by injection software misfire generator is set to 1 within INH_IV_MIS_GEN carrier.

All others cylinder bits are reset to 0 only if not set by the misfire pattern defined for the current engine cycle

Important note on injection shut-off triggering:

To be effective, the injection shut-off on Cylinder x must be triggered before the injection time starts on this cylinder. To evaluate the correct phasing for the injection shut-off, the maximum SOI *(start of injection angle)* is evaluated.

INH_IV_MIS_GEN carrier must be updated at the segment just before the maximum start of injection (SOI_MAX + EOI_LIM[0]) to be strictly taken in account on this injection phase.



51.11.1.5 Ignition misfire realisation

Recurrence: Every engine cycle, phased with required cylinder /coil ignition

Formula section:

The ignition misfire realisation is realised via the INH_IGC_MIS_GEN carrier. This is an input for the Ignition Cylinder Shut-Off Application Incidences file.

Cylinder switched off by ignition software misfire generator is set to 1 within INH_IGC_MIS_GEN carrier.

All others cylinder bits are reset to 0 only if not set by the misfire pattern defined for the current engine cycle

Important note on ignition shut-off triggering:

To be effective, the ignition shut-off on cylinder x must be triggered on the segment before the dwell time on the coil y starts for this cylinder x.

To evaluate the correct phasing for the ignition shut-off, the period TD_IGC[x] must be converted in angle and added to the IGA_AV[x] angle to defined the correct segment for triggering.

INH_IGC_MIS_GEN

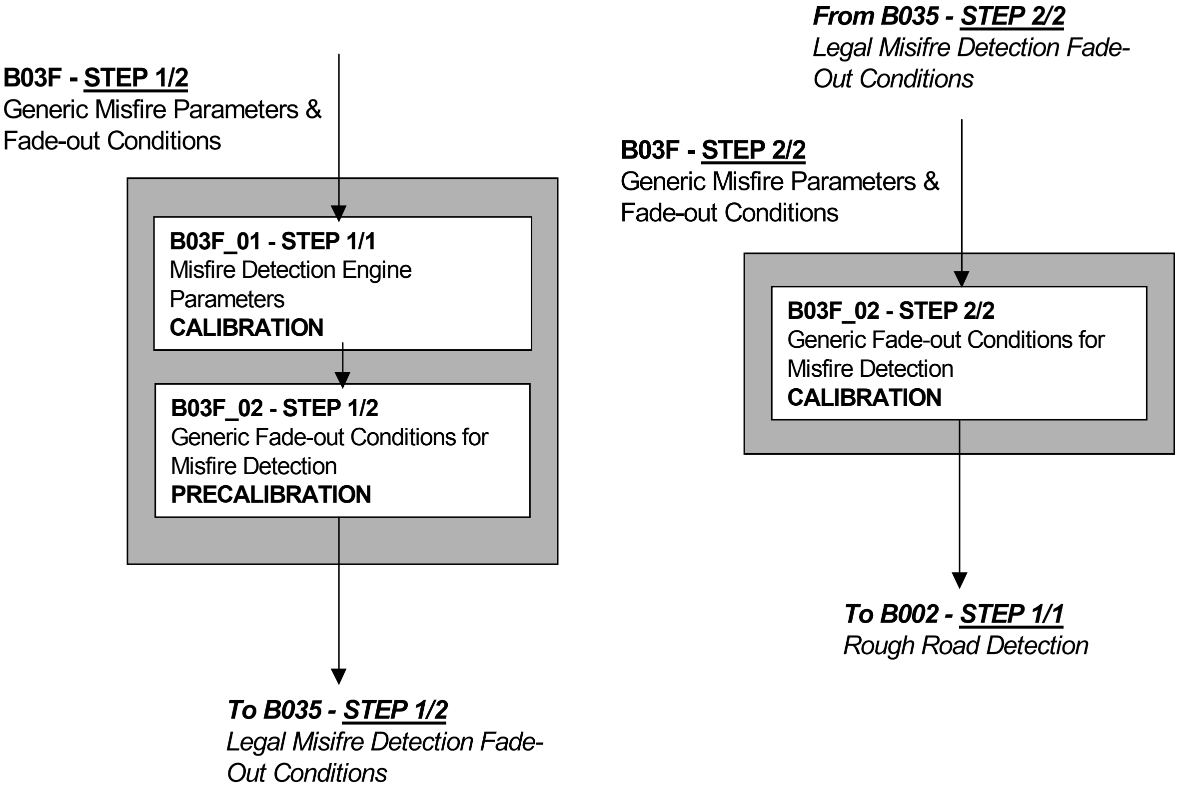
51.12 Misfire fade out (gen)

51.12.1 Tuning hints for Generic Misfire Parameters & Fade-out Conditions (Module B03F)

51.12.1.1 Module calibration flowchart



.

51.12.1.2 B03F_01 : Misfire detection engine parameters

51.12.1.2.1 General Information

In this chapter, LOAD_MIS is defined as a "transparent" engine load independently of the EMS structure type (based on MAP, MAF, TQI or else...). This variable is strictly dedicated to the misfire monitoring process. It allows commuting from one reference to another depending on different conditions (engine combustion mode, engine states or others).

This engine load is essentially used for:

- Zero load line definition
- Engine load breakpoint definition for misfire detection thresholds, gradient detections, catalyst destruction threshold ...

Today, engine load LOAD_MIS is defined as a ratio between the current system variable used for system control (see application system definition) and its maximum value.

MPI in MAP structure: LOAD_MIS = MAP / C_MAP_MAX_MIS

MPI in MAF structure: LOAD_MIS = MAF / IP_MAF_MAX_MIS(N_32)

MPI in Torque structure: LOAD_MIS = TQI_AV / IP_TQI_AV_MAX_MIS(N_32)

For MAF and TQI_AV, the maximum reached values partly depend on engine speed. The normalisations according IP_MAF_MAX_MIS & IP_TQI_AV_MAX_MIS allow reaching 100% of the engine load independently of the engine speed.

Hint: LOAD_MIS can be based on TQI_AV (actual indicated torque value). But with torque structure, TQI_AV quick torque requests can induce noise on detection threshold determination; so on some applications it's better to use MAF or MAP and multiply LOAD_MIS by ignition efficiency to correct torque reductions *(SI choice, introduction of an application multiplicative correction planned from MISF_2.1.x version)*.

GDI structure: one or two engine load references can be used MAP/MAF & TQI_AV.

MAP or MAF system variables can be used for homogeneous combustion modes (AFS and AFL) and TQI_AV or MFF for stratified combustion (engine torque mainly proportional to fuel mass).

TQI_AV can also be used for homogenous and stratified combustion modes (but take care on noise ratio).

Remark: MAF information has a slower response regarding to MAP for dynamic behaviour of the strategy *(could depend on applications)*.

51.12.1.2.2 Module calibration prerequisites

Airpath calibrated

Legal target known (for zero load line definition)

Engine speed redline known, engine capable to reach this engine speed (for US applications)

51.12.1.2.3 Calibration Step B03F_01 – Step 1 / 1

51.12.1.2.3.1 Calibration of engine load reference LOAD_MIS

C_MAP_MAX_MIS is often set to MAP maximum value obtain on your application (LOAD_MIS = 100%), but can be minimised next to have the best full-scale ratio for mean weather/altitude conditions (~1014hPa). No correction for atmospheric pressure is included due to the large ER signal noise ratio at high engine load.

IP_MAF_MAX_MIS is often set to MAF maximum value observed on the application *(see air path calibration step and intake architecture)* for each engine speed, but can also be minimised next to have the best full scale ratio for mean intake conditions.

IP_TQI_AV_MAX_MIS, is an image of the maximum torque setpoint reached in the engine torque reference map for each engine speed breakpoint.

According maximum MAF and/or TQI_AV characterization vs. engine speed that can be reached by our engine, define these calibrations in a way to reach LOAD_MIS = 100% for each engine speed when in wide open throttle.

51.12.1.2.3.2 Calibration of the engine zero load line

LOAD_MIN_MIS, the engine zero load line is based on a basic shape (zero torque line plus legal inhibition triangle defined according legal target), a coolant temperature correction and an atmospheric pressure correction.

51.12.1.2.3.2.1 Basic zero load line definition

Basic zero load line are determinated according, the transmission type (MT, AT) & the combustion mode (AFS, AFL or S)

Conditions: hot engines, low friction, no consumers, low altitude

Determination:

First with hot engine, drive the engine forced in desired combustion mode; with no gear engaged for manual transmission or in neutral for automatic transmission in all speed points (idle speed, 1000 rpm to max. engine speed for OBDII applications by step of 500 rpm) and note the load (LOAD_MIS[%], and/or MAP and TQI_AV engine parameter).

Test has to be evaluated on several engines/transmissions to take in account engine/car fluctuations.

Calibrate the values of IP_LOAD_MIN_MIS_xx_yy 5% below these values in the speed area up to 3000 rpm in a way to be able to detect misfire in idle speed & close to the zero load line.

This basic calibration will be firstly evaluated with constant TCO value, as a consequence IP_LOAD_MIN_MIS_xx_yy will be defined as an unique row.

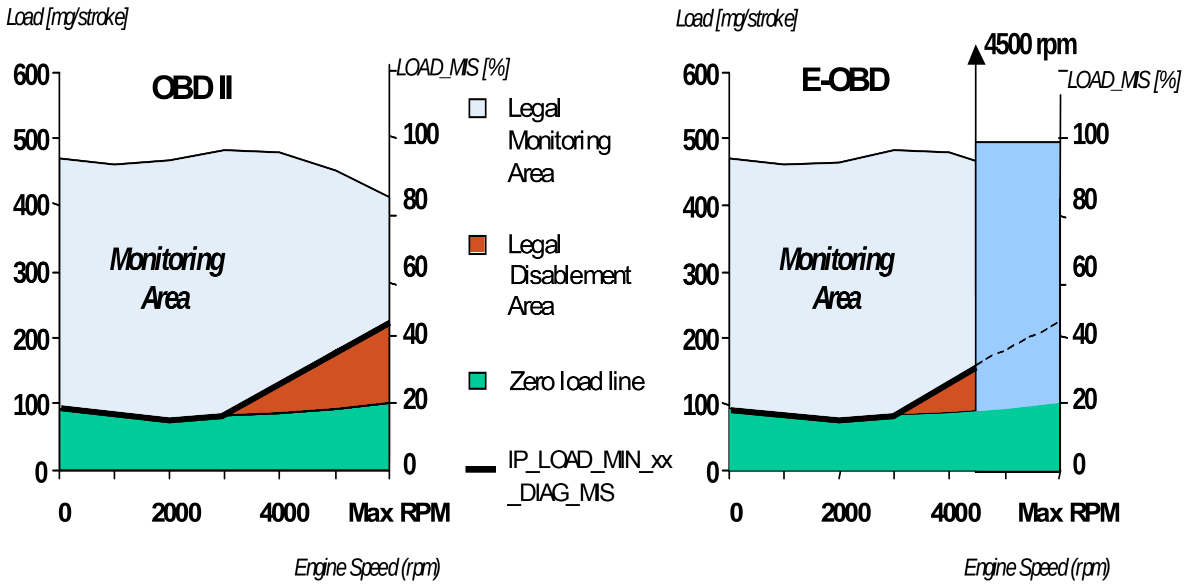
51.12.1.2.3.2.2 OBD II triangular offset

In the CARB mail-out #96-34, the disablement region from 3000 rpm to 6000 rpm is described with a line from 3000 rpm to 6000 rpm and the load increased with 4 inch Hg at 6000 rpm (i.e. ≈ 135 hPa). In this region, an offset has to be added. For that, a correspondence between 135 hPa offset and a LOAD_MIS offset has to be evaluated.

This offset can be applied by the calibrations IP_LOAD_MIN_OFS_AMP_MIS_xx_yy, evaluated at sea level.

51.12.1.2.3.2.3 E-OBD triangular offset

TThe disablement region from 3000 rpm to the max. speed (i.e.: minimum between 4500 or 1000 greater the highest speed occurring in ECE + EUDC cycle) is described with a line from 3000 rpm to the max. speed and the load increased with 133 hPa at this maximum speed. For that, a correspondence between 135 hPa offset and a LOAD_MIS offset has to be evaluated (if LOAD_MIS not based on MAP).



As for US application, the EC offset can be applied by the calibrations IP_LOAD_MIN_OFS_AMP_MIS_xx_yy, evaluated at sea level.

Remark: Today for GDI engines who are able to be in stratified combustion mode above 3000 rpm, no specific E-OBD law articles are related to GDI for equivalencies between 135hPa offset and a value in torque or mass fuel. A triangular offset between 3000 and 4500-rpm can be applied with a final value at 4500 rpm included between 15 and 20% of the maximum torque that this engine can provide in stratified combustion mode.

51.12.1.2.3.2.4 Engine coolant temperature correction

TCO correction for cold engine start.

Evaluate zero load line influence with cold starts and engine warm-up (global offset versus TCO) for each combustion mode used, this offset correction will be relative to engine friction effects versus engine coolant temperature.

Note: very often AFL and S combustion modes are not used under cold engine conditions. Moreover is really hard to evaluate the zero load line high engine speed and TCO low.

This TCO variations allow to complete the determination of the IP_LOAD_MIN_MIS_xx_yy calibrations.

51.12.1.2.3.2.5 Atmospheric pressure correction

AMP correction for zero load line altitude compensation (to be executed in altitude mission).

Evaluate zero load line variation versus different altitudes and different combustion mode. This correction can be applied in a relative way to the basic triangular offset formely defined, it completes the definition of IP_LOAD_MIN_OFS_AMP_MIS_xx_yy calibration .

51.12.2 Tuning hints for generic fade out conditions for misfire detection (B03F_02)

51.12.2.1 General Information

Generic fade out flag (LV_REQ_APP_INH_MIS) is based on all conditions that could create unreliable conditions for misfire detection :

- Engine gradients (engine load, engine speed, throttle, combustion mode & ignition angle transients).
- Crankshaft jolt effects that can disturb detection process (rough road, drivetrain oscillations, and air conditioner & accessories activation/deactivation).
- OBDI errors on one of the sensors used by the misfire monitoring process.

All these different conditions are merge into a carrier (MIS_DET_CDN_APP_INH).

51.12.2.2 Calibration advice for US applications

For OBD-II, take care that on a complete reference cycle this fade-out occurs to often, in the course of time the CARB reduce more and more the possibilities to use fade out based on IGA, TPS, MAF transients. In any case see with the executive officer the possibility to keep this functionality if you can provide an engineering evaluation to prove that you aren't able to detect misfire in such case in reliable conditions.

51.12.2.3 Module calibration prerequisites

Good vehicle driveability (at least 80% of the driveability calibration reached)

51.12.2.4 Calibration Step B03F_02 - Step 1 / 2

<u>Module precalibration</u>

A short way to disable all the generic fade-out described in this chapter is to set carrier masks to zero (all fade-out disabled).

C_MASK_APP_INH_DET_ZDLY_MIS = 0

C_MASK_APP_INH_DET_MIS = 0

C_MASK_APP_INH_DET_MIS_IS = 0

Thus MIS_DET_CDN_APP_INH_NR & LV_REQ_APP_INH_MIS will be always set to 0.

51.12.2.5 Calibration Step B03F_02 - Step 2 / 2

51.12.2.5.1 Configurable generic fade-outs management

A maskable fade-out management has been introduced to answer to the incertitude of the final 2002 CARB mail-out contents (always a draft up to now), especially for the fade-out management during and out of the "zero delay" phase. Moreover, as quite all fade-out must be discussed and justified to the executive officer, depending on results some fade-out could be cancelled in last minutes.

This maskable fade-out management can be very useful during calibration steps to remove non-tuneable fade-outs like OBDI errors and/or external function requests.

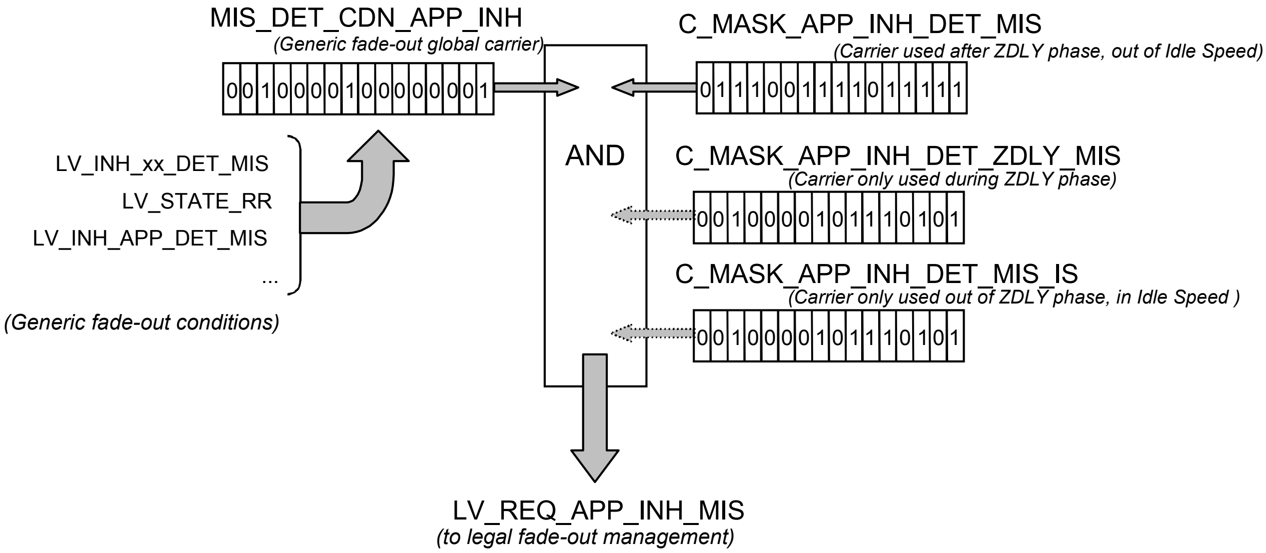
The maskable fade-out management can totally configure the fade-outs required or not for the legal target you require.

All generic fade-out conditions (LV_INH_xxx flags) are merged within a carrier structure MIS_DET_CDN_APP_INH (see definition below).

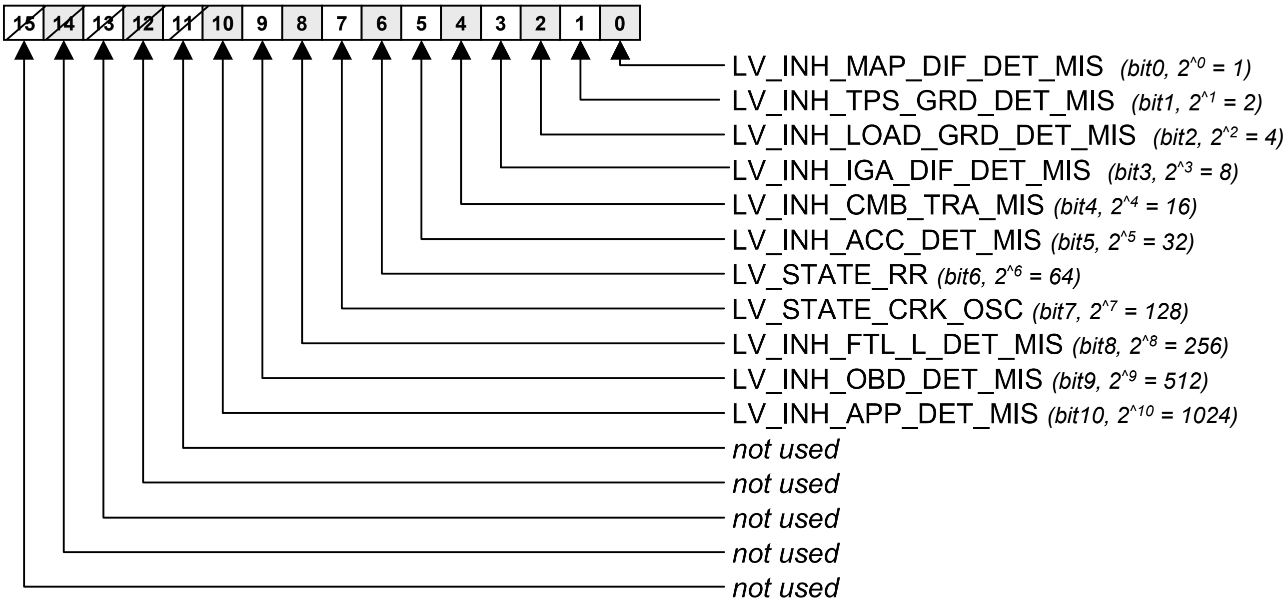
Three different mask calibrations (C_MASK_APP_INH_DET_ZDLY_MIS during & C_MASK_APP_INH_DET_MIS / C_MASK_APP_INH_DET_MIS_IS out of ZDLY period) are applied on this carrier to evaluate the number of fade-out flags set to 1 and validated by the masking.

Example: C_MASK_APP_INH_DET_ZDLY_MIS = 0x00 will disable all generic fade-outs during the ZDLY & C_MASK_APP_INH_DET_MIS = 0x7FF will enable all generic fade-outs out of the ZDLY period in part load & C_MASK_APP_INH_DET_MIS_IS = 0x7FF will enable all generic fade-outs out of the ZDLY period in idle speed.

Note: Bits 11 to 15 of calibrations C_MASK_APP_INH_DET_ZDLY_MIS, C_MASK_APP_INH_DET_MIS & C_MASK_APP_INH_DET_MIS_IS have no effects.



MIS_DET_CDN_APP_INH Carrier Structure



51.12.2.5.2 Maximum manifold air-pressure gradient

Due to trailing throttle / acceleration transition problems (especially for engines with dual mass flywheels), it could be necessary to disable misfire detection for a short period when the manifold air-pressure gradient exceeds an applicable value.

To evaluate the fade-out necessary in such conditions, please check at the transitions from fuel cut off to part load and vice versa as well as all transitions from low load to high load, if some speed fluctuations are critical for misdetection of misfire.

Measure in parallel the different engine load like informations available (TPS, MAP, MAF, TQI_AV & LOAD_MIS) who will be necessary for others fade-out calibrations *(LV_INH_LOAD_GRD_DET_MIS, LV_INH_TPS_GRD_DET_MIS)*.

For LV_INH_MAP_DIF_DET_MIS determination, look at which load difference the engine speed fluctuation is sufficiently forced to increase the risk of wrong misfire detection *(to be evaluated regarding ER, THD_ER & N_GRD values, use of ER_THD_RATIO would be appreciated if integrated, see misfire detection App. Inc. file)*.

Test Profiles:

- At low engine load (close to the zero load line LOAD_MIN_MIS): small values for the MAP difference could be necessary to fade out the detection. The risk of wrong detection is high in such conditions due to low Signal Noise Ratio on ER index.
- At high load, very big values can be calibrated, as there is less danger for such crankshaft fluctuations (larger ER signal noise ratio).

Evaluate in such conditions MAP_DIF_MIS versus MAP to calibrate the IP_MAP_DIF_MAX_MIS calibration map.

C_T_MAP_DIF_DLY_MIS must be set from 1.5 to 2 times the longest disturbance on ER index due to MAP_DIF_MIS you've observed during these tests.

Note for US applications

Not necessary and/or unjustified fade out at normal load conditions should be avoided according CARB requirements for US applications *(no fade-out based on TPS, Loads, MAP gradients should occur on FTP cycles).*

Fade out allowed for US: *" ... engine speed, load, or torque transients due to throttle movements more rapid than occurs over the US06 cycle for the worst case vehicle within each test group...".*

Note for stratified combustion: as in stratified combustion, the MAP information isn't relative to the engine load, LV_INH_MAP_DIF_MIS is always set to 0 in such mode. The engine load gradient in stratified is managed by LOAD_MIS gradient that is relative to torque information is this case.

51.12.2.6 Maximum throttle gradient

Due to trailing throttle / acceleration transient problems at low load, it is necessary to disable misfire detection for a short period when the throttle gradient exceeds an applicable value

Re-use the files obtained for LV_INH_MAP_DIF_DET_MIS calibration and look at which throttle gradient the engine speed fluctuation is sufficiently forced to increase the risk of wrong misfire detection *(to be evaluated regarding ER, THD_ER & N_GRD values)*.

The fade out through throttle gradient normally works at the transition from part load to fuel-cut-off. The air mass gradient is in this case too slow (LOAD_MIS based on MAF) and TPS_GRD is more accurate than MAP in such conditions.

Remark: The most critical point is a short time before undershoot the zero load line.

Evaluate in such conditions TPS_GRD versus TPS_AV to calibrate the IP_TPS_GRD_MAX_MIS calibration map.

C_T_TPS_GRD_DLY_MIS must be set from 1.5 to 2 times the longest disturbance on ER index due to TPS_GRD you've observed during these same tests.

Note for US: after discussion with our internal OBD Program Coordinator, it has been decided to introduce a specific TPS_GRD based fade-out during Zero Delay phase. This fade-out is dedicated to engine cranking misfire monitoring. IP_TPS_GRD_ZDLY_MIS must be greater than IP_TPS_GRD_MAX_MIS in a way to not trigger fade-out during nominal engine cranking, except when TPS is highly driver induced.

C_T_TPS_GRD_DLY_ZDLY_MIS must be set from 1.5 to 2 times the longest disturbance on ER index due to TPS_GRD you've observed during the 'Zero Delay Period' *(5s after engine start)*.

51.12.2.7 Maximum engine load gradient

Misfire detection can be disabled when the amount of engine load gradient exceeds a calibration value, this value is switched according the engine combustion mode. Fade out delay is also specific to combustion mode.

Re-use the former files obtained for LV_INH_MAP_DIF_DET_MIS calibration and look at which LOAD_GRD_MIS the engine speed fluctuation is sufficiently forced to increase the risk of wrong misfire detection *(to be evaluated regarding ER, THD_ER & N_GRD values, use of ER_THD_RATIO would be appreciated if integrated)*.

Note: If LOAD_MIS is based on MAP value, the fade-out flags LV_INH_LOAD_GRD_DET_MIS & LV_INH_MAP_DIF_DET_MIS will be equivalent if calibrated in the same way.

LV_INH_LOAD_GRD_DET_MIS is better used when LOAD_MIS defined according TQI_AV and MAF system variables *(C_CONF_LOAD_MIS = 0 or 1)*.

Test Profiles are equivalent to those used for LV_INH_MAP_DIF_DET_MIS

Evaluate in such conditions LOAD_GRD_MIS versus LOAD_MIS to calibrate the IP_LOAD_GRD_MIS calibration map.

C_T_LOAD_GRD_HOM_DLY_MIS must be set from 1.5 to 2 times the longest disturbance on ER index due to LOAD_GRD_MIS you've observed during these tests *(also AFL if necessary).*

Note for GDI Applications:

In stratified combustion mode, LV_INH_LOAD_GRD_DET_MIS is the main engine load gradient fade-out. An accurate calibration is required in such mode especially in idle speed and at low engine load (close to stratified LOAD_MIN_MIS values).

Test profiles required for calibration in stratified are mainly low engine and part-load up to the highest engine speed where stratified combustion is active.

In the same way C_T_LOAD_GRD_S_DLY_MIS must be set from 1.5 to 2 times the longest disturbance on ER index due to LOAD_GRD_MIS you've observed during stratified combustion tests.

51.12.2.8 Ignition retardation without change limitation

Various functions and/or CAN requests (e.g.. gearshift signal, traction control, torque structure reduction. etc...) could cause an ignition angle retardation.

Misfire detection can be disabled when the amount of the ignition timing retardation changes is too important OR/AND when the global ignition timing retardation is too important.

The fade-out conditions are split in 2 modes:

- 2 calibrations maps focus on the IGA transients (cylinder to cylinder)

  IP_DELTA_IGA_IS_MIS is used to detect unreliable conditions for detection according a certain amount of ignition angle transients. only used in idle speed.

  IP_DELTA_IGA_MIS is used to detect unreliable conditions for detection according a certain amount of ignition angle transients. only used in part load.

- 1 calibration map focus on the difference between the basic ignition angle and the current one.

  IP_DELTA_IGA_BAS_MIS is used to detect unreliable conditions for detection due to an important ignition angle retardation (rough combustions).

The experience has often shown that an advance reduction of 10°Crk could cause a torque fluctuation that can be critical for the misfire detection in lowest engine load conditions (lowest signal noise ratio on ER index).

Critical points : focus on low engine load with strong IGA corrections, idle speed & any torque reduction request case

Therefore, check at low and medium load and speed conditions at such advance (torque) reductions, if any problem occurs with misfire detection (ER decreases) and how long the disturbance last.

If there is any problem, calibrate the table to fade out for the duration of the disturbance; otherwise calibrate 20°Crk and a minimum duration of 10 tdc's.

Note for stratified combustion: as in stratified combustion, IGA corrections (if they exist) have minimum influence on engine load, LV_INH_IGA_DIF_DET_MIS is always set to 0 in such mode. The torque reduction in stratified is managed by LOAD_MIS gradient that is directly relative to torque information is such case.

51.12.2.9 Combustion mode transients

While the combustion manager is in transient state (change from a torque reference to another), the misfire detection must be disabled to have a proper base for the evaluation of the ER-misfire detection thresholds, which are defined for the stationary modes (AFS, AFL & S).

When combustion mode transients occur, during a certain number of Tdc's due to ER delay, LOAD_MIS and threshold maps switch, the misfire detection could be disturbed.

The experience has shown that a fade out of 8 tdc's for C_NR_TDC_CMB_TRA_S_MIS and C_NR_TDC_CMB_TRA_AFL_MIS is a minimum number. To be evaluated on each application according the driveability calibration target applied for the whole combustion structure.

51.12.2.10 Air - conditioning compressor activation

When the air - conditioning compressor is switched on, an additional load is briefly applied to the engine. This load jump can cause a segment period jump and crankshaft vibration, depending on the engine operating state and load request.

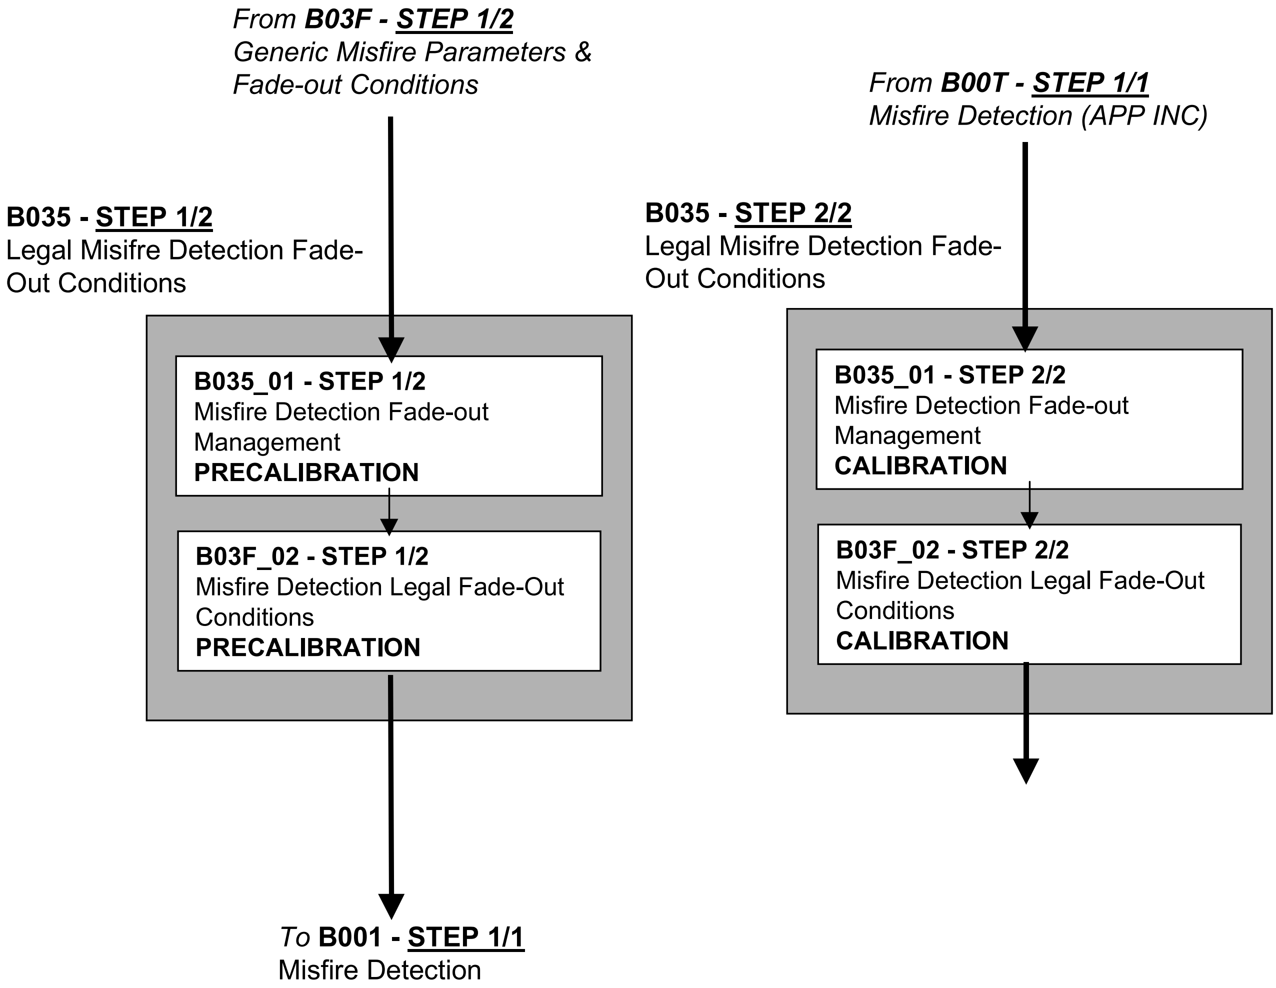
For C_T_ACCOUT_DLY_MIS calibration, check at different engine speed and load points, if the engine roughness ER could produce wrong misfire detection at the turn-on and off of the air conditioning compressor and the duration of the disturbance that could occur.

Calibrate this delay 2 times the longest disturbance you've observed.

Note for US application: This fade-out is no longer allowed for US

51.12.3 Tuning hints for Legal Misfire Detection Fade-out Conditions (Module B035)

51.12.3.1 Module calibration flowchart



51.12.3.2 B035_1 : Misfire detection fade out management

51.12.3.2.1 General information

For US applications, CARB requests an activation of the misfire monitoring and diagnosis as off engine start. Particular fade-out conditions are required during the first 5 seconds since engine running.

For non-CARB applications, this special monitoring is not required and has to be de-activated *(LC_REQ_ZDLY_MIS = 0).*

A state machine has been introduced for the activation of the misfire detection algorithms, distinguishing the separate monitoring during the first 5 seconds, called 'Zero Delay Phase' and the 'Nominal' monitoring afterwards, and preparatory phases.

During the monitoring phases, the nominal fade-out mechanisms are used, corrected for some fade-outs that could be not allowed during the first 5 seconds *(to be confirmed with official mail-out)*.

"... (3.3) Monitoring Conditions:
(3.3.1) Manufacturers shall continuously monitor for misfire under the following conditions:
(A) From no later <u>than the end of the second crankshaft revolution</u> after engine start,
(B) During the rise time and settling time for engine speed to reach the desired idle engine speed at engine start-up (i.e., "flare-up" and "flare-down"), ... "

51.12.3.2.2 B035_1, Step 1/2, Example of calibration

LC_REQ_ZDLY_MIS = 0, *// no specific Zero Delay Phase management*

C_N_MIN_ZDLY_MIS = 0

C_T_ZDLY_MIS = 0

C_NR_TDC_ZDLY_MIS = 0

51.12.3.2.3 B035_1, Step 2/2, Calibration

For Non US applications, no specific Zero Delay Phase management is required up to now. Please contact your E-OBD coordinator to confirm this information.

In such case, LV_ZDLY_DIAG_MIS, CTR_TDC_ZDLY_MIS & CTR_T_ZDLY_MIS will be set always set to 0.

LC_REQ_ZDLY_MIS = 0

C_N_MIN_ZDLY_MIS = 0, minimum engine speed will be managed in module B035_2.

C_T_ZDLY_MIS = 0, fade-out during engine start period will be managed in module B035_2.

C_NR_TDC_ZDLY_MIS = 0

For US applications,

CTR_T_ZDLY_MIS, the zero delay period is fixed by law to 5s (to be confirmed by OBD coordinator) after legal definition of engine start

C_NR_TDC_ZDLY_MIS = NC_CYL_NR tdc's, it's maximum value corresponding to "...*no later than the end of the second crankshaft revolution after engine start...*"

C_N_MIN_ZDLY_MIS corresponds to the engine speed that is the legal definition of engine start : "... “Engine start” is defined as the point when the engine reaches a speed 150 rpm below the normal, warmed-up idle speed (as determined in the drive position for vehicles equipped with an automatic transmission)..."

51.12.3.3 B035_2 : Misfire detection legal fade out conditions

51.12.3.3.1 General information:

Legal fade out (LV_REQ_INH_MIS) is based on all fade out conditions allowed by the legal texts on going and known for continuous misfire monitoring.

All these different fade-out conditions are merge into a global carrier (MIS_DET_CDN_INH).

51.12.3.3.2 B035_2, Step 1/2, example of calibration

Module precalibration

A short way to disable all the legal fade-out described in this chapter is to set carrier masks to zero (all fade-out disabled).

C_MASK_INH_DET_ZDLY_MIS = 0

C_MASK_INH_DET_MIS = 0

Thus MIS_DET_CDN_INH_NR & LV_REQ_INH_MIS will be always set to 0.

51.12.3.3.3 B035_2, Step 2/2, Calibration

51.12.3.3.3.1 Configurable legal fade-outs management

In the same way that for generic fade-outs, a maskable fade-out management has been introduced to answer to the incertitude of the final 2002 CARB mail-out contents (always a draft up to now), especially for the fade-out management during and out of the "zero delay" phase.

Moreover this maskable fade-out management can be very useful during calibration steps to quickly enable the misfire detection without detune other legal fade-outs.

The maskable fade-out management can totally configure the fade-outs required or not for the legal target you require.

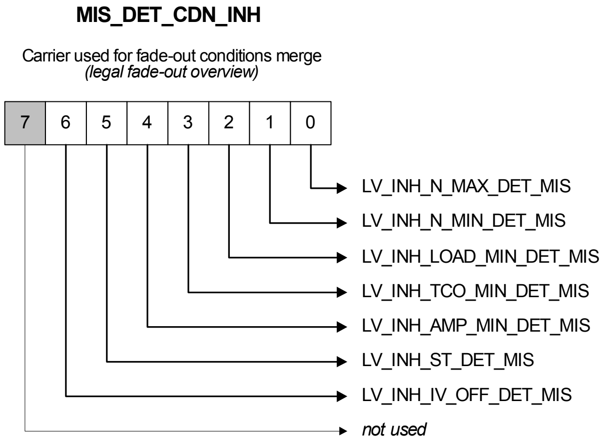
All generic fade-out conditions (LV_INH_xxx flags) are merged within a carrier structure MIS_DET_CDN_INH (see definition below).

Two different mask calibrations (C_MASK_INH_DET_ZDLY_MIS during & C_MASK_INH_DET_MIS out of ZDLY period) are applied on this carrier to evaluate the number of fade-out flags set to 1 <u>and</u> validated by the masking.

<u>Example:</u> C_MASK_INH_DET_ZDLY_MIS = 0x00 will disable all legal fade-outs during the ZDLY & C_MASK_INH_DET_MIS = 0x7F will enable all legal fade-outs out of the ZDLY period.

<u>Note:</u> Bit 7 of calibrations C_MASK_INH_DET_ZDLY_MIS & C_MASK_INH_DET_MIS has no effects on carrier.

MIS_DET_CDN_INH : Carrier used for fade-out conditions merge *(legal fade-out overview)*



For US applications, its recommended to set to 0 the LV_INH_ST_DET_MIS corresponding bit within C_MASK_INH_DET_MIS and C_MASK_INH_DET_ZDLY_MIS mask calibration to avoid any fade-out during engine start *(who is forbidden for US applications)*.

51.12.3.3.3.2 Engine speed range fade-out

The misfire monitoring can be inhibited when the engine speed reaches the maximum engine speed imposed by the market target : Redline engine speed for US applications or 4500 rpm for EC applications.

Moreover this information is used to stop the misfire monitoring process for high speed if not required (limitation of CPU load especially for European application).

The misfire monitoring can be inhibited when the engine speed is below the engine speed corresponding to engine start speed.

<u>for US applications:</u>

C_N_MIN_MIS must below C_N_MIN_ZDLY_MIS, set to the lowest engine speed where the engine roughness index is still declared valid (LV_ENA_ER = 1)

C_N_MAX_MIS_xT = Engine speed red line, fuel cut-off limiter

"... “Redline engine speed” shall be defined by the manufacturer as either the recommended maximum engine speed as normally displayed on instrument panel tachometers or the engine speed at which fuel shutoff occurs... "

for non US applications:

C_N_MIN_MIS, same calibration than C_N_MIN_ZDLY_MIS for US is recommended *(hot engine idle speed - 150rpm)*

C_N_MAX_MIS is 4500 rpm, can be higher if customer still want to diagnosis catalyst overheating criterion. In such case be sure that your input hardware stage is conform to execute such functionality (crankshaft input signal sensitivity & filtering).

51.12.3.3.3.3 Minimum engine load (zero load line)

Below a specific load (zero torque line), fluctuations in engine speed cannot be detected, even in the event of misfire. In this case, the misfire detection is disabled.

Difference between US and Non-US applications stands in the LOAD_MIN_MIS zero load line definition. See the dedicated LOAD_MIN_MIS calibration chapter.

LOAD_MIN_MIS is compared to actual engine load LOAD_MIS, both are determinated in module 'Misfire detection engine parameters'.

A fade-out is applied as soon as actual engine load is below the zero load line (out of legal monitoring area).

51.12.3.3.3.4 Minimum coolant temperature

Misfire detection can be disabled when the coolant temperature is below a threshold (20°F / -7°C). Additionally when the coolant temperature at engine start is below this threshold, the misfire monitoring can be disabled on that driving cycle until the current engine temperature reaches a warm up temperature threshold (70°F / 21°C):

C_TCO_MIN_MIS : 20°F (-6.75°C) under executive officer approval for OBD-II

C_TCO_WUP_MIN_MIS : 70°F (21°C)

Equivalent calibrations can be applied to non US calibrations.

51.12.3.3.3.5 Minimum atmospheric pressure

Misfire detection can be disabled when the atmospheric pressure is below a threshold:

C_AMP_MIN_MIS : 8000 feet above sea level under executive officer approval for OBD-II (see average correspondence to atmospheric pressure), 2500 m for E-OBD.

Correspondence in atmospehric pressure : 750 hPa frequently used.

51.12.3.3.3.6 Inhibition delay after start

Non US applications

Check at cold start conditions, how long the engine needs to get a stabilised condition after leaving start. The expected value must be less than 5s. This value is the maximum value allowed by the E-OBD.

US applications

Today for US applications, such fade out are now **forbidden**. Misfire monitoring has to be active at least at legal engine start definition + one engine cycle.

To disable LV_INH_ST_DET_MIS at engine start, set corresponding bit to 0 in C_MASK_INH_DET_ZDLY_MIS carrier calibration.

51.12.3.3.3.7 Injection shut-off

Misfire detection can be suppressed for the cylinder(s), for which injection has been shut-off.

General cylinder shut-off (all cylinders off)

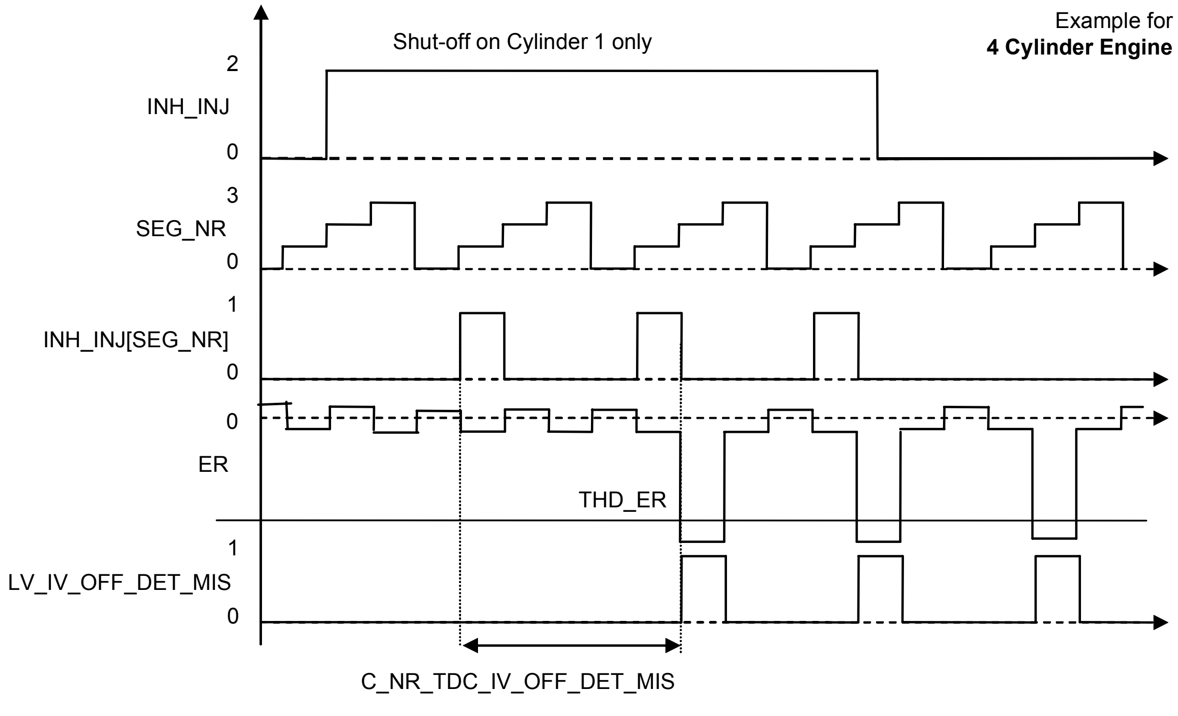
The flag LV_PUC_DET_MIS includes a calibration delay C_T_DLY_IV_OFF_MIS retriggered at each fuel cut-off condition falling edge, in a way to start the misfire detection only after crankshaft oscillations due to fuel reactivation.

To calibrate C_T_DLY_IV_OFF_MIS, execute several road tests with gear ratios allowing general fuel cut-off sequences. Observe at fuel reactivation instant, the disturbances on ENRD index that could generate misfire wrong detection (in positive torque). Set C_T_DLY_IV_OFF_MIS from 1.5 to 2 times the longest disturbances you've observed during these tests.

Cylinder specific shut-off:

If the current cylinder checked by misfire detection is shut-off by any EMS function (even MISF limp home), a fade-out can be apply for the misfire detection of this cylinder.

As it exists a delay between the instant where the cylinder is in shut-off and the backwash on ER index to detect the misfire, a tdc delay (C_NR_TDC_IV_OFF_DET_MIS) has been introduced on LV_IV_OFF_DET_MS flag to properly phase the fade-out information LV_IV_OFF_DET_MIS and the ER signal.



As example for a 4 cylinder engine, C_NR_TDC_IV_OFF_DET_MIS = 5 tdc's.

Check process:

To check quickly and simply this synchronisation, we will use the individual cylinder shut-off fade-out, check its action on ER, THD_ER, LV_INH_DET_MIS, LV_DET_THD_MIS & LV_DET_MIS.

Prerequisite: LV_INH_IV_OFF_DET_MIS must be taken in account in legal fade-out structure to be able to set the fade-out merge bit LV_REQ_INH_MIS. For that, please set the bit 6 to 1 (see MIS_DET_CDN_INH structure definition) in calibrations C_MASK_INH_DET_MIS & C_MASK_INH_DET_ZDLY_MIS (ex: 64).

The goal is to:

- Apply a single fuel shut-off on a cylinder (here via the misfire generator with injection), LV_MIS_GEN = 1.
- Observe LV_INH_IV_OFF_DET_MIS = 1, when this cylinder shut-off is effective.
- Observe next the ER value in misfire (no fuel), at this instant LV_INH_DET_MIS must be set to 1, LV_DET_THD_MIS must be set to 1 (if detection calibrated on this engine operating point) but LV_DET_MIS must stay to 0 due to this fade-out.

Limit number of cylinders shut-off:

If the number of shut-off cylinders reaches a calibration data (C_SUM_INH_IV_MAX_DET_MIS), reliable misfire detection could be impossible. In such case is preferable to inhibit misfire detection to avoid wrong misfire detections.

This number of cylinders in shut-off to disable the misfire detection depends on NC_CYL_NR, the number of engine cylinders.

The experience has shown that

C_SUM_INH_IV_MAX_MIS = 1 for NC_CYL_NR = 3

C_SUM_INH_IV_MAX_MIS = 2 for NC_CYL_NR = 4 and 5

C_SUM_INH_IV_MAX_MIS = 3 for NC_CYL_NR = 6 and 8

Limitation of this functionality: misfire detection could be unreliable also depending on the position of the cylinders in shut-off regarding to the crankshaft (mechanical balance). To evaluate that effect, during misfire diagnosis create MIS_A with different cylinder positions and numbers with C_SUM_INH_IV_MAX_MIS = NC_CYL_NR to see the detection efficiency & the number of wrong detections in such conditions. Apply finally the minimum number of cylinder in shut-off, to be sure of a reliable misfire detection in any case.

51.12.4 Tuning hints for Rough road detection (Module B002)

VHMD version (NC_CONF_RR_MIS = VHMD)

51.12.4.1 General information

Rough road conditions must be detected to prevent erroneous misfire detection that could be caused by jollity tracks influence on crankshaft via the drive train.

The speed disturbance of vehicle wheels is used to evaluate the rough road conditions.

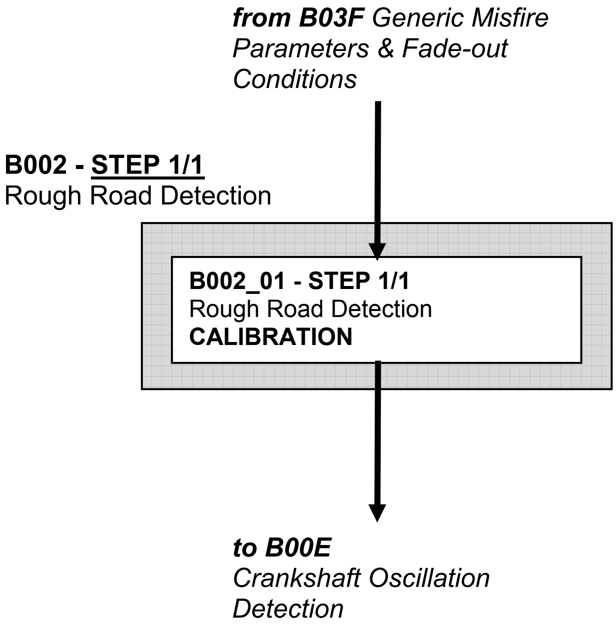
The EMS control unit can use two kinds of signal coming from wheel speed sensors:

WSS : EMS uses directly a wheel speed sensor as an input and acquires wheel segment times by its own timer.

CAN : EMS uses indirectly a wheel speed information coming from a CAN chassis module like ABS or TCS.

The VHMD (vehicle motion determination) aggregate manage in a transparent manner the configuration (one or several wheel speed sensors and TCS/ABS units communication through CAN...) and dataflow to provide a unique input to the rough road detection module (VS_DRV0_STD) plus a control flag (LV_VS_DRV0_STD_NOT_ENA) who inform that this information is valid or not.

51.12.4.2 Module calibration flowchart



51.12.4.3 B002_2: Rough road indexes determination

Filter coefficients for rough road index:

C_CRLC_VS_DRV0_STD_INC & C_CRLC_VS_DRV0_STD_DEC

Precals: C_CRLC_VS_DRV0_STD_INC = 0.3 & C_CRLC_VS_DRV0_STD_DEC = 0.1

Wheel gradient filtering constant

The filtering constant is responsible to avoid a rough road triggering at short disturbances on the one hand and on the other to ensure a detection fast enough this means before an oscillation is induced on the crankshaft.

The coefficient C_CRLC_VS_DRV0_STD_INC is used for rising rough road values, and C_CRLC_VS_DRV0_STD_DEC is for the decay of these rough road values. This differentiation allows to have a fast rise of the rough road values and a smooth decay.

The proposed constant C_CRLC_VS_DRV0_STD_DEC = 0.1 should be a suitable compromise between both demands.

If at the validation phase many erroneous rough road detection due to short disturbances are observed, a smaller filtering constant e.g. 0.05 should be tested *(stronger filtering to avoid high frequency noises).*

On the other hand, If rough road shocks and disturbances are not detected due to a too important filtering, this means a too slow reaction of the detection is observed, a bigger value e.g. 0.3 should be tested *(lighter filtering to take in account medium frequencies)*.

51.12.4.4 B002_3: Detection of rough road status

Precalibrations:

Following values have to be calibrated at the begin to enable the rough-road detection process.

- C_VS_MAX_RR: 120 km/h
- C_VS_MIN_RR: 4 km/h

Following measurements have to be made:

Sampling rate = 10ms

Basic data, for rough road calibration: VS, SUM_RR, VS_DRV0_STD and VS_DRV0_STD_MMV.

Data to evaluate rough road effects on misfire detection: ER *(or ER_STND)* & THD_ER.

Data to evaluate rough road fade-out sequencing toward misfire detection: LV_INH_DET_MIS, MIS_DET_CDN_APP_INH & MIS_DET_CDN_INH

Data to evaluate misfire wrong detection: LV_DET_MIS & CTR_TOT_DC_MIS

Process:

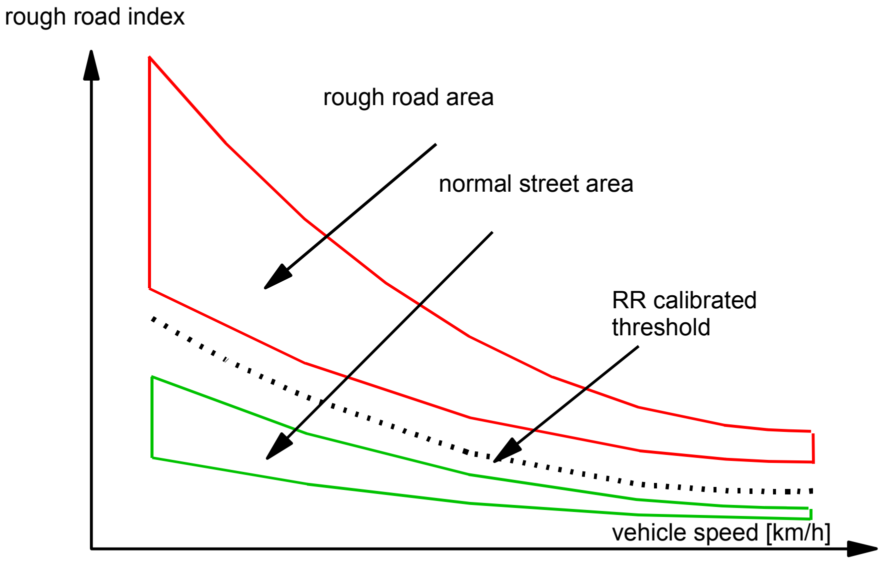
The vehicle has to be driven on normal roads (asphalt road, concrete street) to get the nominal noise (upper limit for threshold) at different vehicle speeds.

Therefore drive the vehicle with different gears and small acceleration from low to high engine rpm. A maximum velocity of 120 km/h should be sufficient.

Second step, same measurements have to be made on rough road (as described above) to get the amplitude under such conditions. If the rough road distance is not long enough, more measurements with constant speed are also possible. The thresholds IP_VS_DRV0_STD_MMV_THD_AT or IP_VS_DRV0_STD_MMV_THD_MT have to be calibrated in the middle between normal street and rough road (see following graphic).

(Remark: some restrictions for the vehicle speed due to driveability of the vehicle must be accepted)

Due to the high dynamic, the breakpoints should be calibrated nearer at low vehicle velocity in comparison to higher velocity.



Rough road fade out delay: C_T_DLY_RR

The fade out time for misfire detection **:** C_T_DLY_RR should be about two times longer than the worst case time between disappearance of rough road influence and the complete disappearance of the crankshaft oscillation on engine roughness index.

For the disappearance of the rough road influence, the non-filtered wheel speed gradient and the engine roughness index should be observed in parallel to the rough road value *(fastest signals)*.

51.12.4.5 B002_4: Vehicle speed range for rough road calculation & detection:

Minimum vehicle speed: C_VS_MIN_RR

The absolute minimum is the specified minimum vehicle speed from the wheel speed sensor. As at normal driving condition a speed below 5 km/h with gear engaged is impossible, this value is suggested.

Moreover, according new regulations for US legal target, it is recommended to adapt this value to avoid wrong rough road detections at vehicle start (high wheel speed gradient in such case). Take care that no rough road detections occur during US emission cycles.

Maximum vehicle speed: C_VS_MAX_RR

Depending on the drivetrain and car body design, crankshaft speed disturbances are only possible up to a certain vehicle speed. The upper critical speed should be known from the former tests for the misfire detection.

A maximum vehicle speed higher than 120 km/h should be avoided because of ECU runtime and high accuracy decreasing on wheel speed gradient.

51.12.4.6 B002_5: Limp-home state

According legal requirements / customers wishes, a limp-home calibration is available.

Recommended for US: LC_STATE_RR_LIH = 0.

In case of WSS error and or ABS/TPS module error and/or CAN channel error, the misfire monitoring must not be faded-out. LV_STATE_RR = LC_STATE_RR_LIH = 0.

For such case, you can apply a specific error who inform that one of the misfire criterions has been reached but with the rough road module in limp-home (LV_ERR_MIS_RR). Please consult for this point, the dedicated chapter in the tuning guide for misfire diagnosis part.

Up to now for CE, a fade-out of the misfire monitoring can be applied in case of rough road module error. Please contact our OBD expert to be informed of any change on this status.

51.12.4.7 Vehicle Validation

A separated vehicle validation plan has to be fixed based on the experience of the experts, (different wheel pressure, driving with trailer, ABS influence, traction control,...) and generally on customer "rough road" track profiles & requirements.

Focus on worst cases of rough road influence for the misfire monitoring:

- lowest signal/noise ratio on engine roughness index (close to zero load line & medium/high engine speed)
- washboard rough roads (medium frequencies) where there's a clear overlap between road oscillations and engine firing events.

Check misfire detection counter CTR_TOT_DC_MIS during rough road tests to evaluate wrong misfire detections and rough road fade-out efficiency.

51.12.4.8 Fleet Validation

A special driving program has to be performed to get a wide range of different environmental conditions for the fleet, especially that bad road conditions are included. Nevertheless it is useful to drive some cars without any program.

The counter SUM_RR can be used for determine non-typical behaviour of a vehicle

51.12.5 Tuning hints for Crankshaft oscillation detection (Module B00E)

Used only if NLC_USE_CRK_OSC_MIS = 1

51.12.5.1 General information

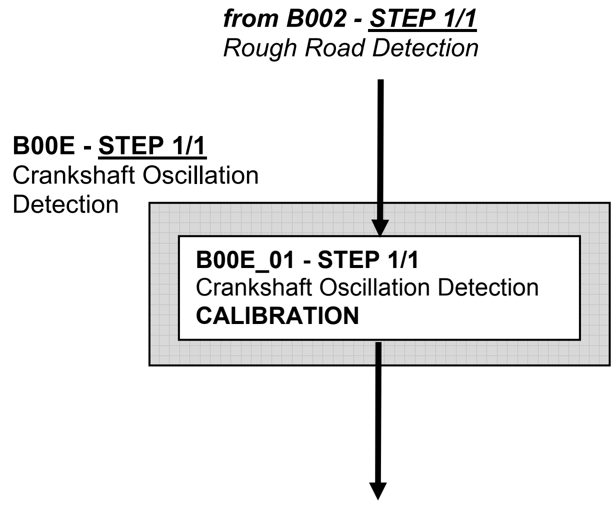
In case of a single misfire detected at low engine speed / high engine load, in combination with a high gear (e.g. 3rd, 4th, 5th gear), drivetrain & crankshaft oscillations can occurs, it would not be possible to ensure a proper misfire calculation due to oscillations amplitude. The trigger of such an oscillation may be a single misfire, an obstacle, a big torque change or other instantaneous conditions.

A fade-out can be applied according your legal target to disable misfire detection during these oscillations *(please consult your OBD specialist / customer to ensure the possibility to use such a functionality, if no please set NLC_USE_CRK_OSC_MIS = 0 on your application)*.

The crankshaft oscillation detection is based on two criterions during a fixed tdc's window after a detected misfire: detection of a critical frequency & detection of a critical amplitude.

If both parts fulfilled at the same time their own detection criterion, a crankshaft oscillation is detected. The reason therefore is that even at constant speed due to normal little speed variations a ER high frequency, or during a normal acceleration phase, a big ER amplitude are possible.

51.12.5.2 Module calibration flowchart



51.12.5.3 Determination of critical conditions for misfire detection

Basis for the calibration of the crankshaft oscillation is knowledge of the critical areas (speed, load, and gear) for the misfire detections.

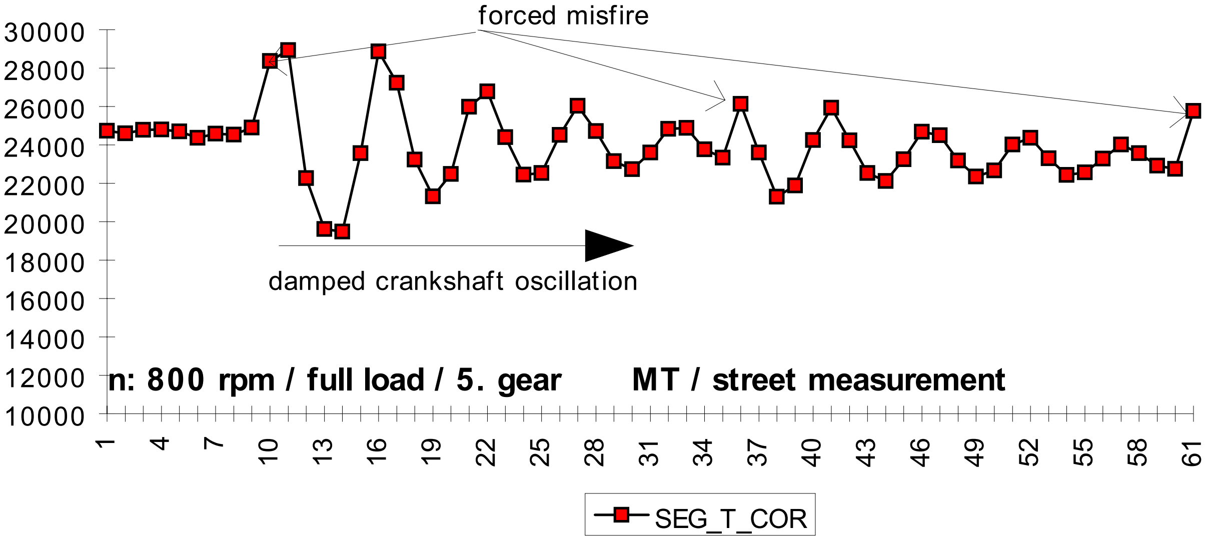
Therefore, tests on the street have to be carried out for the misfire detection in order to determine such conditions.

Engine Speed:	800 / 1000 / 1200 / 1400 / 1600 / 1800
Engine Load:	idle / 3 steps / full load
Gear:	1 / 2 / 3 / 4 / 5
Misfire Pattern:	without misfire / 1cyl. In misfiring / Misfire rate 1/33 (pseudo-random)

An analysis of the data must be made for the check, under which conditions false misfire is detected.

Observe ER indexes toward detection thresholds to evaluate the risk of wrong detection.

Example for critical oscillation after 1/33 misfire.



51.12.5.4 B00E_1: Maximum engine speed for Crankshaft oscillation detection

Set C_N_MAX_CRK_OSC to the maximum engine speed that you've observed oscillations phenomenon that could produce wrong misfire detections. *Typical: 2000 rpm*

51.12.5.5 B00E_2: Minimum VS / N ratio to activate crankshaft oscillation detection

Set C_RATIO_VS_N_MIN_CRK_OSC to the minimum engine speed / vehicle speed ratio where you've observed oscillations phenomenon that could produce wrong misfire detections. *Typical: corresponding to 3rd gear. The value C_RATIO_VS_N_MIN_CRK_OSC should be calibrated in the middle between the critical gear (e.g. 4th gear) and the gear below (3rd gear) to ensure the detection (e.g. 0.030).*

Maximum TDC after detected misfire to activate crankshaft oscillation detection process

The monitoring process to analyse crankshaft detection will be limited to a window of C_NR_TDC_MAX_CRK_OSC tdc's after LV_DET_CFM_MIS is set.

Set C_NR_TDC_MAX_CRK_OSC to the high number tdc's corresponding to the longer oscillations that you've observed induced by a generated misfire. *Depends mainly on drivetrain design.*

51.12.5.6 B00E_3: Determination of a critical engine roughness oscillation frequency

It allows retriggering the detection criterion for a defined number of tdc's after each DRV0_ER sign change. Equivalent to a restart of oscillation detection. In case of crankshaft oscillation, it must be checked how many subsequent DRV0_ER values are needed to distinguish clear from DRV0_ER single value at misfire and crankshaft oscillation.

Hint: IP_SEG_MIN_FRQ_CRK_OSC values in the complete engine speed range are = 2, this seems to be the best compromise (No critical frequency will be detected at 1cyl. misfiring). *To be checked on your application.*

51.12.5.7 B00E_4: Determination of a critical engine roughness oscillation amplitude

Each time DRV0_ER changes its sign, the process to evaluate the amplitude of the oscillation is retriggered. If this oscillation exceeds the amplitude DRV0_ER_SUM_THD_OSC defined versus N_32 and LOAD_MIS, thus a critical engine roughness oscillation amplitude is declared (*LV_AMPL_CRIT_CRK_OSC = 1).*

Remark: The threshold is linked to the value SEG_SUM_FRQ_CRK_OSC. In case of a 2 for calibration, the threshold must be calibrated for the sum of two subsequent DRV0_ER values after sign change of DRV0_ER. There must be a clear difference between one DRV0_ER value at misfire and two values at crankshaft oscillation.

IP_DRV0_ER_THD_OSC(N_32, LOAD_MIS) must be lower than basic misfire detection thresholds in a way to avoid any wrong misfire detection.

51.12.5.8 B00E_5: Determination of crankshaft oscillation final status

A crankshaft oscillation is detected *(LV_STATE_CRK_OSC=1)* when in the same time, application conditions are active *(LV_CRK_OSC_DET_ACT=1),* a crankshaft oscillation has reach critical frequency *(LV_FRQ_CRIT_CRK_OSC=1)* and amplitude criterions (*LV_AMPL_CRIT_CRK_OSC=1).*

LV_STATE_CRK_OSC is hold to 1 for C_DLY_TDC_CRK_OSC tdc's. This delay must be set according the maximum impact time of the longer oscillation that could induce wrong misfire detection. *Practically C_DLY_TDC_CRK_OSC is very close to C_NR_TDC_MAX_CRK_OSC.*

51.13 Misfire OBDII (gen)

51.13.1 Calibration hints for function Misfire Detection (module B001)

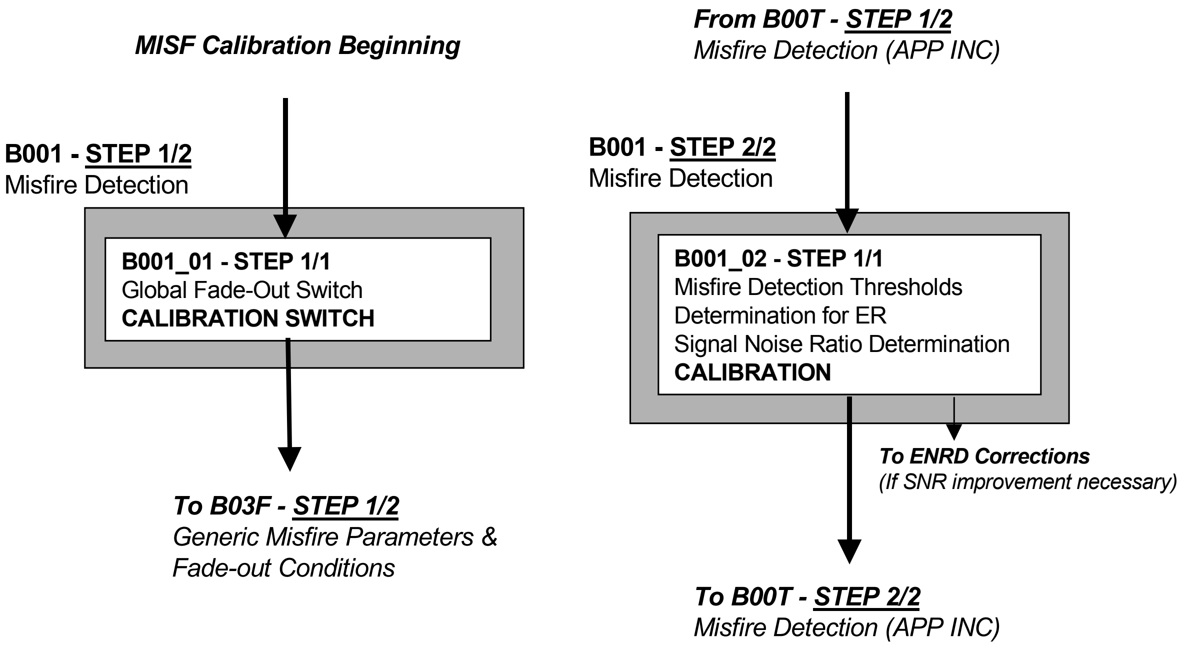
For NC_MISF_VERS = 1, the detection can be evaluated according two different indexes:

NLC_USE_ER_STND = 0 use ER nominal index

NLC_USE_ER_STND = 1 use ER normalized index (ER_STND)

Calibration methods for both configurations are strictly identical, only the data behavior & range are different.

51.13.1.1 Module calibration flowchart



51.13.1.2 B001_01: Misfire Monitoring Global Fade-Out Switch

Calibration data:

LC_MIS_INH	1	0 ... 1H	0 ... 1	1	-
Global switch to disable all misfire monitoring related modules (Inhibition with = 1)					

51.13.1.2.1 General information

There is one global switch that is used to inhibit quickly all the MISF aggregate modules

It's the highest priority fade-out for MISF aggregate.

51.13.1.2.2 Calibration Step B001_01 – Step 1 / 1

Before to start any MISF aggregate calibration, please check that LC_MIS_INH is correctly set to 0, to enable each aggregate modules call and activate each nominal process.

Otherwise, processes are totally frozen and data initialized.

51.13.1.3 B001_02: Misfire detection thresholds determination for engine roughness index

51.13.1.3.1 General information

ER misfire detection method is based on a comparison between an engine roughness index (ER or ER_STND) value and a threshold that is relative to the engine parameters when the monitored cylinder was in intake phase *(threshold relative to combustion conditions image, memory effect managed by a buffer)*.

The ER engine roughness value depends strongly on the current operating point, both in its spread during undisturbed engine operation, and in the signal amplitude in case of an actual misfire.

ER misfire detection thresholds are defined according basic threshold maps and threshold corrections:

- *A basic threshold map:* IP_THD_y_ER_x

Basic threshold maps are singular for Transmission Type, ER index type and combustion mode.

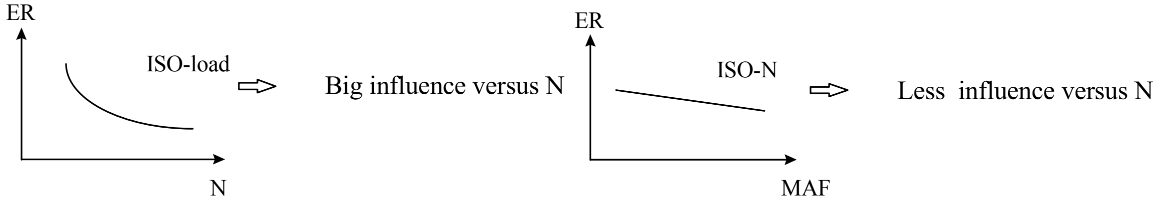
_x: stands for _MT or _AT

_y: stands for _AFS, _AFL or _S

Theses maps are function of engine load and speed, which are calibrated for engine at operating temperature as well as for, adapted transmitter gear.

IP_THD_y_ER_x maps are switched according the vehicle transmission type, idle speed condition & the combustion mode.

The nominal engine roughness threshold THD_ER is influenced mainly by the engine speed. Nevertheless, the air mass has to be taken into account (if NLC_USE_ER_STND = 0)

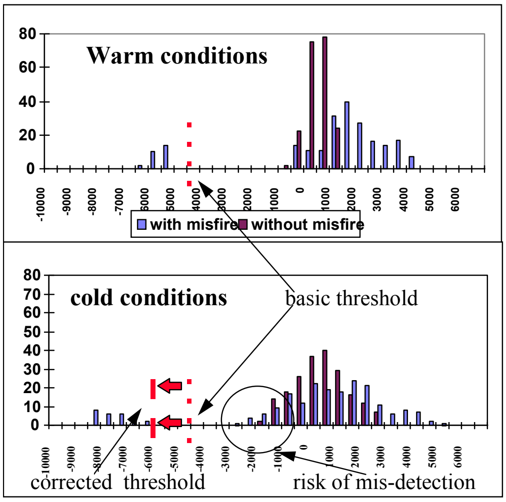


Otherwise, the normalized engine roughness threshold using ER_STND index is influenced essentially by the engine load (if NLC_USE_ER_STND = 1)

- *A threshold temperature correction:*

At cold conditions, the engine friction resistance is more important as well as the combustion is irregular, therefore it exists a possibility of misfire misdetection if the same threshold as warm conditions is kept.

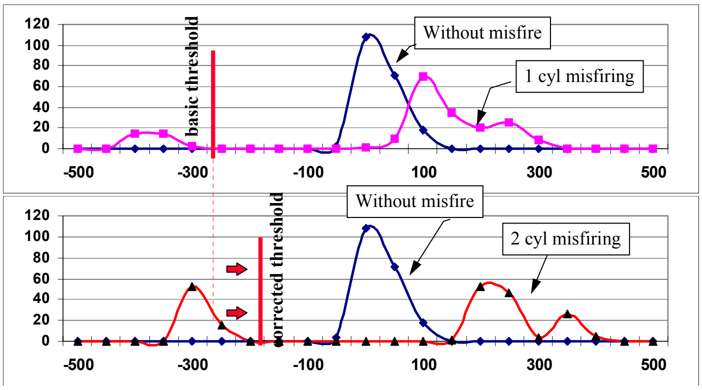
A temperature correction is applied to compensate larger signal amplitudes arise of ER values at lower engine temperatures. This correction is relative to TCO value.



- *A threshold correction during active injection valve cut-off:*

If one or several injection valves are cut off selectively by the engine management system (IV diagnosis...), then the cylinder or cylinders are excluded from the misfire check.

Due to the system, the signal amplitude of the ER value is reduced with a misfire at another cylinder. To improve the detection for this period, the absolute amount of the threshold can be reduced with the factor IP_FAC_THD_IV_ER(N_32) or IP_FAC_THD_IV_S_ER(N_32) *(in stratified mode)*.



- *A threshold correction defined in application incidences:*

FAC_THD_APP_ER is a threshold multiplicative correction who is defined in the misfire detection application incidences file.

51.13.1.3.2 Equipment

Chassis dyno in engine speed control

Remark:

It is better to perform the calibration of the basic threshold on a single roll chassis dyno than on a twin-rolls chassis-dyno. The experience has shown that a single roll chassis-dyno is more representative of the street than the twin-rolls chassis-dyno.

Car with dummy catalyst

One car per transmission type (AT, MT, else)

Engine warm

One misfire generator (software or external).

Remark:

If external misfire generator used please inhibited the IV and/or IGC diagnosis for no limp-home feedback.

51.13.1.3.3 Calibration Prerequisites

ENRD calibration frozen,

ENRD adaptive process executed and locked

ENRD calculation running & LC_MIS_INH = 0

LOAD_MIN_MIS (legal zero load line, *inhibition triangle included*) already calibrated

51.13.1.3.4 Calibration Step B001_02 – Step 1 / 1

51.13.1.3.4.1 SNR evaluation of ER index and basic detection threshold determination

Note: This calibration step is fundamental to evaluate if the ER index can answer to legal requirements, in the same time the acquisition files obtained during this analysis step will be used to determinate the basic detection threshold.

For SNR criterion definition see definition chapter §3.3.6.

The signal / noise ratio is observed statistically with histogram figures as presented. In case of misfire, ER indexes will drop of a certain gap. This gap is proportional to engine load & speed; as a consequence the SNR is also proportional to engine load & speed.

Under certain conditions (correct adaptive process achieved, no important cylinder unbalancing, no quick dyno rolls control...) ER values that are image of engine "good" combustions & "misfire" can be considered as two normal distributions.

Each distribution has its own average value and standard deviation

Population 1 *(misfire population)*

ER_M1 = mean(ER samples in misfire)

ER_STD1 = std(ER samples in misfire)

Population 2 *(combustion population)*:

ER_M2 = mean(ER samples in combustion)

ER_STD2 = std(ER samples in combustion)

ER SNR criterion: 2 * | ER_M2 - ER_M1 | / [ER_STD1 + ER_STD2]

For each ER histogram a basic misfire detection threshold will be determinate as:

ER Basic Threshold: | ER_M2 - ER_M1 | - 2 * (ER_STD1 + ER_STD2)

51.13.1.3.4.2 Measurement files

Measurement type:

Crankshaft synchronous *(for example SAM2000 flight recorder with Tdc's update rate, oscilloscope tool can't perform TDC acquisition files),* *Chassis dyno in engine speed control mode,*

Engine stabilized.

Channels:

SEG_NR_ER, ER or ER_STND

Basic software inputs *(T_SEG_ER & SEG_T_COR if post computation needed due to new ENRD calibration)*

Engine speed, Engine load *(LOAD_MIS, MAP, MAF, TQI_AV...)*

LV_MIS_GEN_DET if software misfire generator integrated (NLC_USE_MIS_GEN = 1)

Sample numbers: 3000 tdc's recommended for a representative statistical analysis.

One file is acquired per typical misfire generator ratios *(1/2, 1/4 and 1/33 misfire patterns, example for a 4cyl engine)*, per engine operating points & per combustion modes available.

1/2 means one misfire for 2 tdc's (50%): simulation of coil driver trouble for half-static ignition systems on 4cyl engine. *1/3 for 6cyl engine.*

1/4 means one misfire for 4 tdc's (25%): simulation of coil driver trouble for full static ignition systems or injector trouble on 4cyl engine. *1/6 for 6cyl engine.*

1/33, means one misfire for 33 tdc's (3%): 'random pattern', simulation of MIS_Bx emission criterion, increase close to 1.5 times EURO IV target for a 4cyl engine (to be confirmed on your application, less on 5,6 & 8cyl engines). Important note: the 'random' pattern must be an odd ratio in a way to generate a misfire on all cylinders (worst case).

Engine operating points considered:

Proposal *(see also according your legal requirements, calibration timing and engine load references and combustion mode area)*

N [rpm]	N_IS_SP	800	1250	1500	1750	2000	2500	3000	3500	4000	4500	5000*	5500*	Redline*

US applications

LOAD_MIS [%]	LOAD_MIN_MIS (ZLL)	30	35	40	50	60	70	80	90

Measurement recommendations:

Operate one acquisition per misfire pattern.

If you try to link 1/2, 1/4 and 1/33 misfire patterns on only one acquisition file, engine system variables like engine load will fluctuate. As a consequence ER indexes will change also, so statistical analysis will be wrong due to histograms highly disturbed.

Recommended operating mode: In order to avoid ER indexes gradients, switch on the misfire generator with the required ratio, checked engine speed, reach engine load setpoint and finally trigger the acquisition file when operating point is stabilized.

Input files *(theoretical):*

MPI, CE applications MT: 3 misfire patterns * 11 * 9 ~= 300 acquisition files

MPI, CE applications AT/MT: 2 * 3 misfire patterns * 11 * 9 ~= 600 acquisition files

MPI, US applications AT: 3 misfire patterns * 13 * 9 ~= 350 acquisition files

GDI, CE applications MT: 3 misfire patterns * 11 * 9 ~= 300 acquisition files (AFS)

3 misfire patterns * 9 * 6 ~= 160 acquisition files, (S mode)

Total (460 files)

Note: for some combinations between engine operating points and misfire pattern, acquisitions are impossible (engine stalling, engine behavior, stabilization impossible...) especially for low engine speed/load. But in any case, please control that you've executed an acquisition with as least the misfire "random" pattern (1/33 for 4cyl engine).

51.13.1.3.4.3 Acquisition file analysis & calibration

Manual analysis with MS Excel (or else)

For each acquisition files, calculate mean and standard deviation values of ER indexes (combustions and misfires population).

To separate combustions and misfire populations, you can apply a threshold/criterion at 3/4 of the difference between max and min ER values *(criterion to be checked with low engine load files)*

Calculate for each acquisition file the SNR & corresponding basic detection threshold

For each engine operating point, you have to compare the Signal Noise Ratio of the three different misfire patterns and keep the worst one and its associated basic detection threshold, in order to be sure to have at least this SNR ratio for any kind of misfire pattern observed at this engine operating point.

This method is direct but laborious and very long.

51.13.1.3.5 Misfire signal noise target

To be compatible with legal requirements, you have to check that for each monitored operating point, the corresponding SNR has to be at least > 5.

For the misfire monitoring strategy, if for one operating point ER index has a signal noise ratio below 5, it means that an overlap between misfire and combustion populations is possible: risk of wrong detection

If during this calibration step, you remark such a trouble on any acquisition file, please inform SI team and/or Domain 7 to evaluate crankshaft segment drifts, crankshaft torsion or else who could be the trouble source (see dedicated chapter in ENRD tuning guide).

In such case, Torsion and/or adaptive value corrections could be applied to ENRD to increase its signal/noise ratio.

For applications who have large crankshaft oscillations at low engine speed who could strongly decrease the signal noise ratio in this area, a local fade-out is recommended by using the module B00E 'Crankshaft Oscillation Detection' with MISF configuration NLC_USE_CRK_OSC_MIS = 1

51.13.1.3.6 Coolant temperature correction for misfire detection.

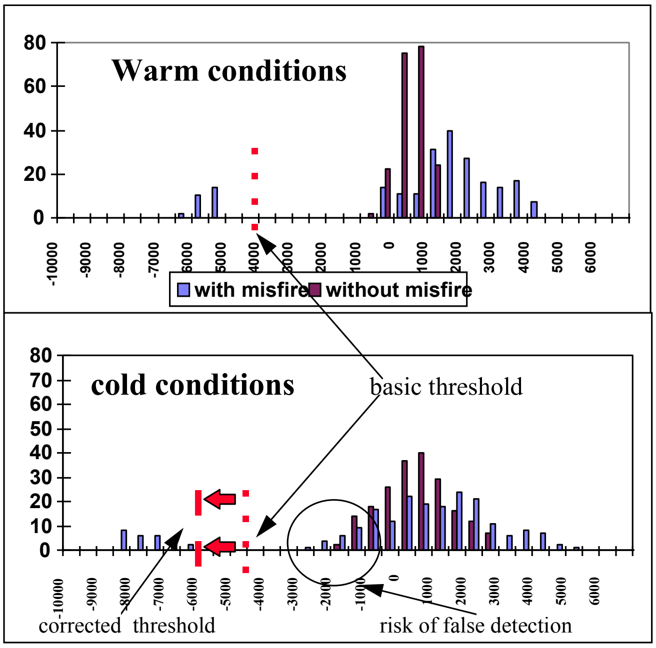
When the engine is in cold conditions, it is more resistant to rotation and the combustion process is more irregular. Therefore it can be necessary to increase the detection threshold in order to avoid misdetections.

The noise of the engine roughness values has to be checked at low temperature conditions and compared to the values with a warm engine.

The calibration value of IP_FAC_THD_TCO_ER at warm condition should be 1, and with an increased value at lower temperature. E.g.: the noise amount on ER index is about 1,2 times bigger at 0°C than at 90°C.

Perform several engine crankings with different coolant temperatures (-20°C ... 20°C...) and apply different misfire ratio. Correct IP_FAC_THD_TCO_ER map in order to be able to detect each misfire pattern on different coolant temperature.

Classic Target: more than 75% of misfire detection efficiency at minimum monitoring coolant temperature (TCO > -7.5°C)



51.13.1.3.7 Cylinder shut-off correction for misfire detection.

The ER value is bigger for one cylinder misfiring than in the case of two cylinders misfiring:

If cylinders in misfire are non-successive, it's very often due to DRV2_MMV_ER correction that increases global ER values.

If cylinders in misfire are successive, the DRV2_MMV_ER effect is present but moreover it's also due to lowest deceleration on second cylinder.

Therefore, when the injector is shut-off on one cylinder, the threshold can be modified for the remaining cylinders.

Make at several engine speeds and load points, measurements with one cylinder misfiring and two cylinders misfiring and calculate at every operating point the ratio of ER between both cases.

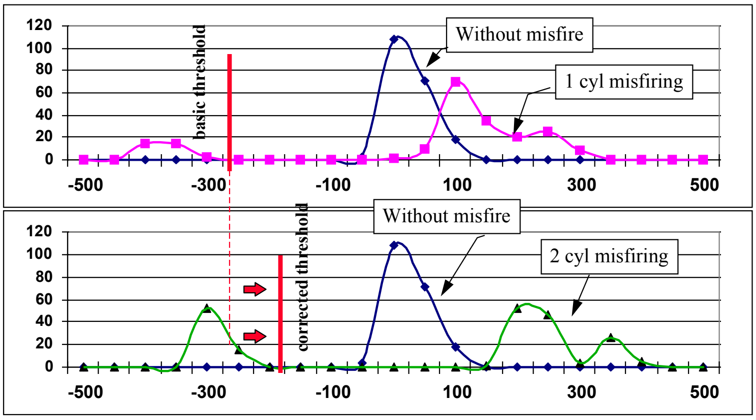
The biggest ER ratio hence measured can than be used for the calibration of the IV correction.

E.g. one cylinder misfiring ER = -400 µs

two cylinders misfiring ER = -300 µs

-300 / -400 = 0.75; if this is the biggest value then calibrate 0.75

If there is at other operating points a ratio of 0.8, then calibrate 0.8.



51.13.1.4 B001_03: Management of general misfire detection fade out according engine roughness index phasing

51.13.1.4.1 NC_SIZE_THD_ER_BUF Integration Check

NC_SIZE_THD_ER_BUF defines the misfire detection threshold buffer size.

We have a correct value of NC_SIZE_THD_ER_BUF when the detection threshold THD_ER is delayed in a way to be synchronized by the correct ER value during accelerations and decelerations.

51.13.1.5 Misfire detection based on engine roughness evaluation B001_04

51.13.1.5.1 Calibration Step

No Calibration Step specific to this section.

Remark on LV_DET_THD_MIS & LV_INH_DET_MIS for calibration validation:

LV_DET_THD_MIS has been introduced to observe the validity of the detection threshold even if the misfire detection is in fade-out due to any reason.

It can be helpful to limit for instance the fade-out occurrence during FTP cycle and to see exactly in which conditions fade-out of the detection is really necessary.

51.13.2 Calibration hints for misfire software generator (Module F001)

51.13.2.1 General Information

According the project SI integration plan and/or customer requirements/wishes, a software misfire generator can be included on EMS software and used during integration validation and calibration stages.

It is strongly recommended to remove this functionally on serial product software: NLC_USE_MIS_GEN = 0

The software misfire generator is integrated if NLC_USE_MIS_GEN = 1

Moreover, for a correct integration of the generator and a full functionality, the inhibit carriers (INH_IV_MIS_GEN & INH_IGC_MIS_GEN) must be integrated:

- Combine INH_IGC_MIS_GEN (bitwise or logical operation with other carriers) with INH_IGC in Ignition Activation Module (6024 - Hook Module) see IGRE definition.
- No specific integration work is necessary for INH_IV_MIS_GEN, as there is a specific link between this carrier and the INJR aggregate

The misfire generator is useful for the following calibration items:

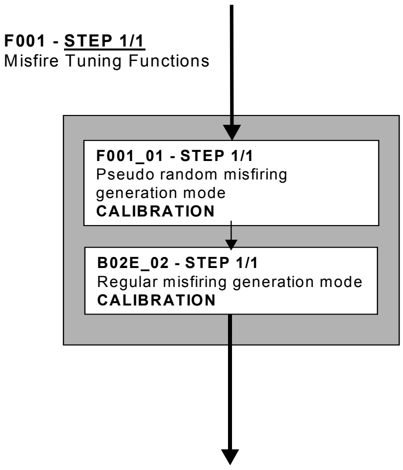
- Misfire Detection: Detection threshold determination, Detection efficiency validation ...
- Misfire Diagnosis: Determination of the MIS_A catalyst destruction criterion & MIS_B emission criterion

Two different generation modes are available:

- Pseudo-random misfiring generation mode mainly used for robustness test of the misfire detection efficiency.
- Regular misfiring generation mode, used to simulate the main misfire patterns (one/two coils off, one cylinder off, emission pattern)

LC_REQ_MIS_GEN is the main calibration switch to enable (=1) or disable (=0) the misfire generator.

51.13.2.2 Module calibration flowchart



51.13.2.3 F001_01: Pseudo random misfiring generation mode

Pseudo random pattern:

The generation mode "Pseudo random misfiring" is based on LC_RND_PAT_MIS_GEN, an index table of 256 cells; each cell corresponds to a TDC scanned by the generator, providing a 256 tdc's sequence.

If a cell is set to "0", it means that this TDC will be set in misfire by ignition (if LC_IGN_OFF_MIS_GEN = 1) and/or by injection (LC_INJ_OFF_MIS_GEN = 1). Otherwise, this TDC will be in firing.

Fill the table LC_RND_PAT_MIS_GEN according the misfire patterns you want to apply.

For a correct scanning of the table, please set the index breakpoints as following:

ldp_x_id_rnd_pat_mis_gen																
-	0	16	32	48	64	80	96	112	128	144	160	176	192	208	224	240

ldp_y_id_rnd_pat_mis_gen																
-	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Generator Activation:

To activate this misfire generation mode, it is recommended to activate the generator by the following sequence:

1. Check that the table LC_RND_PAT_MIS_GEN is mainly filled with "1" data, to avoid immediate stalling.
2. Select the reference segment cylinder C_SEG_ST_MIS_GEN *(first cylinder affected by the first misfire generator cell)*
3. Chose the way to generate the misfires, LC_IGN_OFF_MIS_GEN = 1 and/or LC_INJ_OFF_MIS_GEN = 1
4. Select the misfire generation mode C_MOD_MIS_GEN = 0
5. Switch on the generator LC_REQ_MIS_GEN = 1

If no misfire occurs, please check that at least one of LC_IGN_OFF_MIS_GEN or LC_INJ_OFF_MIS_GEN calibration is set to 1.

To stop the misfire generator, set LC_REQ_MIS_GEN = 0.

51.13.2.4 F001_02: Regular misfiring generation mode

Regular pattern:

The generation mode "Regular misfiring" is based on C_MIS_RATE calibration. The generator will produce a misfiring every C_MIS_RATE tdc's.

Examples:

To perform a 1/2 misfire pattern on a 4 cylinder engine, set C_MIS_RATE = 2

To perform a cylinder off misfire pattern on a 6 cylinder engine, set C_MIS_RATE = 6

To apply a cylinder "roll-over" misfire pattern (misfire generated each time on a different cylinder), set C_MIS_RATE to an odd value *(example: C_MIS_RATE = 33 is often used for misfire detection efficiency tests)*

Generator Activation:

To activate this misfire generation mode, it is recommended to activate the generator by the following sequence:

1. Check that the calibration C_MIS_RATE is not 0 or 1, to avoid immediate stalling.
2. Select the reference segment cylinder C_SEG_ST_MIS_GEN *(first cylinder affected by the regular ratio)*
3. Select the misfire generation mode C_MOD_MIS_GEN = 1
4. Chose the way to generate the misfires, LC_IGN_OFF_MIS_GEN = 1 and/or LC_INJ_OFF_MIS_GEN = 1
5. Switch on the generator LC_REQ_MIS_GEN = 1

If no misfire occurs, please check that at least one of LC_IGN_OFF_MIS_GEN or LC_INJ_OFF_MIS_GEN calibration is set to 1.

To stop the misfire generator, set LC_REQ_MIS_GEN = 0.

51.13.2.5 F001_03: Cylinder regular misfiring generation mode

Cylinder regular pattern:

The generation mode "cylinder regular misfiring" is similar to the 'regular misfiring' mode, but act like a unique misfire generator per cylinder. In this way different misfire ratios can be applied to different cylinders.

The generator will produce a misfiring on cylinder x every NC_CYL_NR * C_MIS_RATE_CYL_x tdc's.

Example:

With a 4 cylinder engine, to perform a 1/2 misfire pattern on a cylinder 3, set C_MIS_RATE_CYL_3 = 2 and LC_MIS_RATE_ENA_CYL_2 = 1.

As a result, we will have a misfire rate of 50% on cylinder 3, but will be a 12.5% ratio as global ratio for the engine if only this cylinder is set in misfire.

Generator Activation:

To activate this misfire generation mode, it is recommended to activate the generator by the following sequence:

1. Select the cylinder(s) x who will be impacted by the misfire generator with LC_MIS_RATE_ENA_CYL_x = 1
2. Check that the calibration C_MIS_RATE_CYL[NC_CYL_NR] is not 0 or 1, to avoid immediate stalling.
3. Select the ratios you want to apply to the different cylinders C_MIS_RATE_CYL[NC_CYL_NR]
4. Select the misfire generation mode C_MOD_MIS_GEN = 2
5. Chose the way to generate the misfires, LC_IGN_OFF_MIS_GEN = 1 and/or LC_INJ_OFF_MIS_GEN = 1
6. Switch on the generator LC_REQ_MIS_GEN = 1

If no misfire occurs, please check that at least one of LC_IGN_OFF_MIS_GEN or LC_INJ_OFF_MIS_GEN calibration is set to 1.

To stop the misfire generator, set LC_REQ_MIS_GEN = 0.

51.13.2.6 F001_04: Misfire generator informations

Two informations are available from the misfire generator.

LV_MIS_GEN is an internal data used for synchronization between request and exchange with INJR (injection realization) and IGRE (ignition realization) aggregates. Mainly useful during validation & integration process. This flag is set to 1 as soon as the misfire generator has requested a cylinder shut-off (segment synchronous).

LV_MIS_GEN_DET is identical to LV_MIS_GEN, but delayed with C_NR_TDC_DLY_MIS_GEN tdc's. This flag is useful to synchronize misfire generator request and result on the ER signal for the misfire detection, and evaluate if the misfire generated has been properly detected. Afterwards, by using this information and LV_DET_MIS, we can after evaluate the wrong detection ratio and/or the non detection ratio with post processing tools or/and by visualization.

Calibration evaluation:

To find the proper phasing of LV_MIS_GEN_DET, please increment C_NR_TDC_DLY_MIS_GEN up to have the proper phasing between this bit and the ER value in misfire.

For this, apply a low misfire ratio, like C_MIS_RATE = 33 and observe on a segment synchronous measurement when LV_MIS_GEN_DET = 1 and the misfire on ER will be present.

As example: for a 4 cylinder engine C_NR_TDC_DLY_MIS_GEN = 9.

51.14 Misfire OBDII (cus)

51.14.1 Calibration hints for Misfire Detection (APP INC) (Module B00T)

For the module B00T who is application specific, no specific calibration method is recommended in this tuning guide.

Please contact your project SI Team and Domain for calibration recommendations if specific algorithm has been integrated

51.14.1.1 B00T_01: Detection threshold correction – Application specific gain

FAC_THD_APP_ER is a gain specified between 0 and 2 that correct the basic detection threshold defined in the generic core function.

This gain can be modified between 0.5 and 1 in case of specific conditions when the detection is difficult (catalyst heating period...).

Otherwise, when the risk of wrong detection becomes too important, this gain can be set between 1 and 2, in a way to minimize the detection sensitivity in very noisy conditions on the ER index (case of important knock events, limp-home...).

Can be also used in case of specific end of line process.

FAC_THD_APP_ER = 1 has no effect.

51.14.1.2 B00T_02: Misfire engine load – Application specific gain

The gain FAC_GAIN_LOAD_MIS allows to modify the engine load information used in ENRD and MISF in case of torque reduction according the system variable chosen as reference by calibration.

FAC_GAIN_LOAD_MIS = 1 has no effect.

51.14.1.3 B00T_03: Inhibition based on OBI diagnosis

LV_INH_OBD_DET_MIS has to be set to 1 when at least one of the most important sensors providing input system variables for MISF is declared in failure.

Typical: CRK, CAM, TPS, MAF, MAP ...

LV_INH_OBD_DET_MIS = 0 has no effect.

51.14.1.4 B00T_04: Inhibition based on application functions

LV_INH_APP_DET_MIS has to be set to 1 when at least one of the functions that could corrupt the misfire detection is declared active.

Typical: ESP, canister purge on going...

LV_INH_APP_DET_MIS = 0 has no effect.

51.14.1.5 B00T_05: Inhibition of the crankshaft oscillation detection function

LV_INH_CRK_OSC_DET has to be set to 1 when conditions to detect crankshaft oscillations are unreliable, or not necessary.

LV_INH_CRK_OSC_DET = 0 has no effect.

51.14.1.6 B00T_06: Misfire low fuel tank level informations

Two different low fuel tank level informations have been introduced in MISF answering to two different methods generally used by customers.

LV_INH_FTL_L_DET_MIS, who is a low fuel inhibition bit dedicated to misfire detection. This bit is used and located on bit 8 of MIS_DET_CDN_APP_INH the generic fade out condition carrier.

If LC_FTL_L_DET_MIS is set to 1, a misfire detection fade-out coming from low fuel tank level information is possible.

Take care of your legal "Low Fuel Tank Level" definition:

- for US you can declare a low fuel level when level is **15 percent** or less of the nominal capacity of the fuel tank.
- for Europe you can declare a low fuel level when level is **20 percent** or less of the nominal capacity of the fuel tank.

Note: with the maskable fade-out management, even if LC_FTL_L_DET_MIS = 1, if the bit 8 of MIS_DET_CDN_APP_INH is masked to 0, by C_MASK_APP_INH_DET_MIS and/or C_MASK_APP_INH_DET_ZDLY_MIS, the low fuel tank level fade-out will be cancelled. Check that this fade-out is allowed on both side (LC_FTL_L_DET_MIS and by C_MASK_APP_INH_DET_MIS and/or C_MASK_APP_INH_DET_ZDLY_MIS).

LV_FTL_L_DIAG_MIS is a low fuel information, which will allow the error management to save a specific misfire error called 'MIS_FTL' and a specific Pcode 'P313'.

Note: If LC_FTL_DET_MIS = 1 and corresponding bits 6 inside calibrations C_MASK_APP_INH_DET_MIS & C_MASK_APP_INH_DET_ZDLY_MIS are set to 1, in such case LC_FTL_L_DIAG_MIS = 1 has not effect (misfire errors not possible in low fuel, because the detection is fade-out).

Combination LC_FTL_DET_MIS = 0 & LC_FTL_L_DIAG_MIS = 0, will process low fuel tank level as a nominal condition for misfire monitoring.

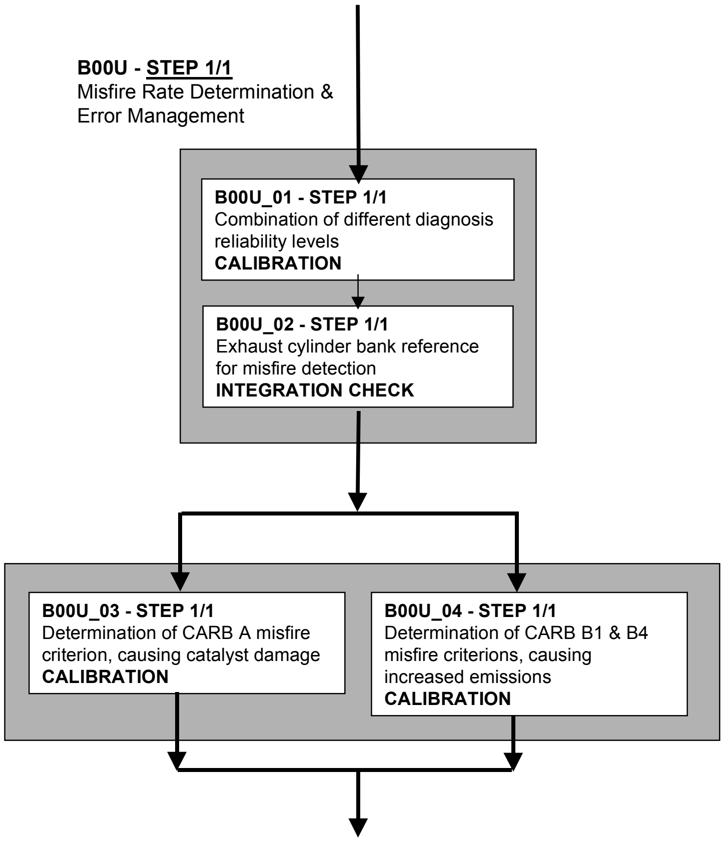
51.14.1.7 B00T_07: Misfire detection calibration ease

This ratio between ER index and detection threshold is clipped by the C_ER_THD_RATIO_MAX calibration.

To be suitable, ER_THD_RATIO must be clipped at least at 100% (misfire occurence).

51.15 Misfire rate determ. (gen)

51.15.1 Module calibration flowchart



51.15.2 B00U_01: Combination of different diagnosis reliability levels

51.15.2.1 General information

Due to their physical principle & design, the individual diagnostic functions have a different reliability depending on the current operating point.

To perform best possible confirmation of misfire detection, the function combines the ENRD+MISF method results with non debounced informations of ignition and injector diagnosis.

This functionality can be useful on some specific operating points where the misfire detection efficiency could be affected by: low load, engine combustion mode, number of cylinders in fuel shut-off...

Moreover, to use of ignition and injection diagnosis informations for misfire detection imply that correlation between non-debounced electric diagnosis and misfire are always true, if not the combination with IV or IGC diagnosis must be avoid in concerned area.

LV_INH_IGC_DIAG_MIS & LV_INH_IV_DIAG_MIS must be set in module B02E according OBDI IGC & IV diagnosis conditions to avoid wrong detections & misfire monitoring conditions *(crossed diagnosis is not necessary when out of monitoring area)*.

51.15.2.2 Calibration Prerequisites & Precalibrations

IGC & IV diagnosis calibrated.

IGC & IV diagnosis efficiencies are known on every engine operating points *(please contact your HW pilot and diagnosis tuning team to have these informations).*

Misfire detection efficiency results according engine operating points, combustion modes and misfire patterns.

Note: If the misfire detection efficiency is 100% on every operating points every combustion modes and with every misfire patterns; the non-debounced diagnosis information from Ignition coils & Injection valves are not necessary.

In such case, please set IP_FAC_IV_DIAG_MIS = 0, IP_FAC_IGC_DIAG_MIS = 0 and IP_FAC_ER_x_DIAG_MIS = 1.

These calibrations can be used as precalibration as long as IGC & IV diagnosis efficiencies are unknown.

51.15.2.3 Calibration Step B00U_01 – Step 1 / 1

The principle of the combination is that in every point optimised reliability for the misfire detection is reached even if the single diagnostic is not so strong in some points.

Calibration of IP_FAC_ER_y_DIAG_MIS

If misfiring is suspected by ENRD & MISF result (LV_DET_MIS=1), a weighting factor IP_FAC_ER_y_DIAG_MIS is applied to FAC_ER_DIAG_MIS for the corresponding operating point according the current engine combustion mode.

- A weighting value of **0** means that the detection is not possible for this engine operating point & combustion mode.
- A value equal to or greater than **1** indicates that the detection is reliable for this engine operating point & combustion mode.

Nominal case: IP_FAC_ER_y_DIAG_MIS = 1

Calibration of IP_FAC_IGC_DIAG_MIS

If misfire is suspected by the ignition diagnosis (no ignition spark, firing period too short) a weighting factor FAC_IGC_DIAG_MIS is applied for the corresponding operating point.

Moreover, this weighting factor can be forced to 1, when the number of cylinders in shut-off due to MIS_A criterion reaches C_MIS_NR_OFF_IV_IGCFB cylinders.

Recommended value: C_MIS_NR_OFF_IV_IGCFB = 1

Remark: if C_MIS_NR_OFF_IV_IGCFB >= C_SUM_INH_IV_MAX_MIS (see MISF tuning guide part 1), FAC_IGC_DIAG_MIS will have no effect as the misfire diagnosis will be disable by the flag LV_INH_IV_OFF_DET_MIS.

Nominal case: IP_FAC_IGC_DIAG_MIS = 0

Calibration of IP_FAC_IV_DIAG_MIS

If misfire is suspected by the injection valve diagnosis (wide-open injector, injection period too short) a weighting factor FAC_IV_DIAG_MIS is applied for the corresponding operating point.

Nominal case: IP_FAC_IV_DIAG_MIS = 0

51.15.3 B00U_02: Exhaust cylinder bank reference for misfire detection

51.15.3.1 General information

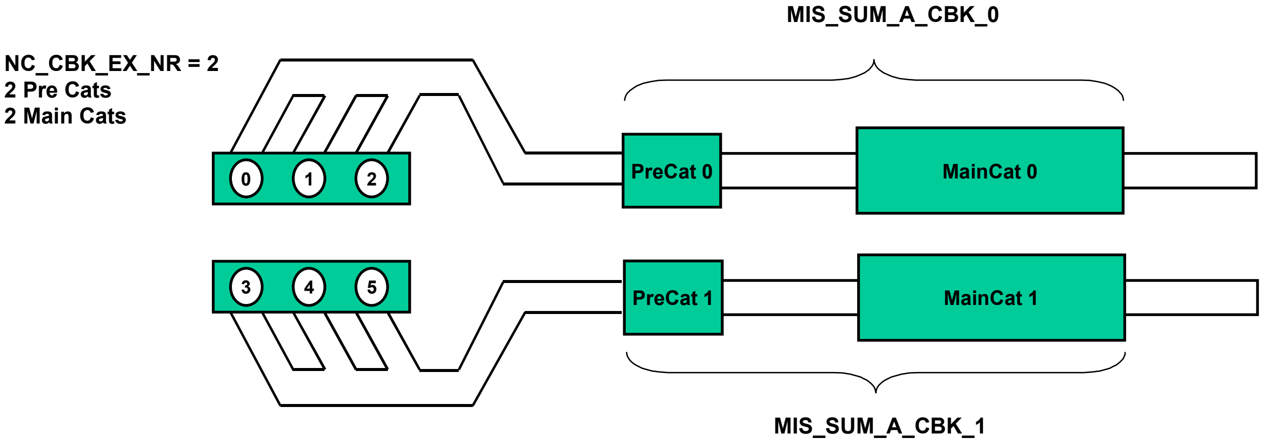
Exhaust cylinder bank reference for misfire detection allows to increase MIS_A & MIS_Bx criterions on the dedicated cylinder bank weighting factor if the misfire detected has effect on the impacted cylinder bank and not on the other (if multiple exhaust cylinder bank design).

general specification

NC_CBK_EX_NR_MISF is a configuration table that takes in account the number of cylinder banks & the number of cylinders.

In case of a project with multiple exhaust cylinder banks, it allows to switch on the correct cylinder bank according the cylinder detected in misfire with the correct ER phasing.

Example:



SEG_NR	0	1	2	3	4	5
NC_CBK_EX_NR_MISF	0	0	0	1	1	1

51.15.3.2 Integration Check

Please check that SEG_NR_CBK_ER is correctly set according SEG_NR_ER values and your configuration data set in module 100L (MISF Configuration Data).

51.15.4 B00U_03: Determination of CARB A misfire criterion, causing catalyst damage

51.15.4.1 General information

LV_STATE_MIS_A is one of two malfunction criterions of CARB OBDII misfire monitoring requirements.

It's the malfunction criterion related to misfire ratio causing catalyst damage. CARB A criterion is evaluated each 200-crankshaft revolutions (long term diagnosis); moreover a short-term diagnosis is available in case of very strong misfire rate detected (short-term diagnosis).

51.15.4.2 Calibration Prerequisites

INJR, IGRE, torque & enrichment calibration frozen

Exhaust line design frozen

No specific misfire detection and diagnosis prerequisite (can be perform with no ENRD & MISF calibration set)

51.15.4.3 Equipment

Exhaust line with temperature sensor on each Pre and Main catalyst.

Misfire generator (software or hardware) in ignition shut-off & regular mode. *(See software misfire generator user manual in following chapters)*

51.15.4.4 Calibration Advises

Do not perform this calibration step on chassis dyno; the risk of fire is important on vehicle.

Better to execute it on engine bench, but please note that the cooling of the exhaust line(s) on engine bench is not representative of the nominal cooling process on vehicle.

Check several time during this calibration step, that each catalyst is still active *(no melting):* use catalyst diagnosis if calibrated.

51.15.4.5 Calibration Step B00U_03 – Step 1 / 1

51.15.4.5.1 Catalyst critical overheating tests

This calibration step concerns IP_MIS_A_FAC_AFS, IP_MIS_A_FAC_AFL & IP_MIS_A_FAC_S maps.

IP_MIS_A_FAC_AFS is the map of a weighting factor depending on engine load and engine speed proportional to the misfire destructive effect on the catalyst(s) due to a misfire for AFS combustion mode.

Calibration Process:

In AFS mode, for each operating point (N, LOAD_MIS) that you need to monitor *(check if US or Europe legal target)*, the minimum misfiring rate that enables to reach the catalyst(s) temperature limit(s) is searched.
Start from 0% misfire rate then increase by 2% steps for each engine operating points and notice the misfire rate obtained as soon as you've reached the critical temperature on one of the different sensors of the different catalysts used on the engine.
Note for each point, C_MIS_RATE & C_SEG_ST_MIS_GEN *(useful if even misfire rate is applied to know which cylinder bank is impacted)* used and which catalyst reaches the first the critical temperature.
Between two different operating points, cut the engine misfire generator to cool down the catalyst.
For example:
N: 1000 to Nmax [rpm] (4500 rpm for Europe, Redline for US) with a N step of 1000 rpm
LOAD_MIS: Zero load line to maximum LOAD_MIS with a LOAD_MIS step of 10%

51.15.4.5.1.1 Calibration of MIS_A long term catalyst diagnosis

Calibration step concerning C_MIS_SUM_A_THD, C_MIS_SUM_A_CBK_THD, C_MIS_A_MIN_ER, IP_MIS_A_FAC_y

As it is obvious that the 5% misfiring at (6000 rpm, 600 mg/stk) is more dangerous for catalyst damage than the 20% misfire at (1000 rpm, 300 mg/stk). That's why in order to give a better representation to the weighting factor; the value 100 is attributed to the minimum misfiring rate over all operating points *(MIS_RATE_MIN, not a system data)*. That enables to have a factor MIS_A_FAC between 0...100.

C_MIS_SUM_A_THD = 100 * NC_CYL_NR * *MIS_RATE_MIN*

MIS_A_FAC = 100 will correspond to these 5% *(as an example)* and therefore C_MIS_A_THD = 3000 in case of a 6 cylinder engine and C_MIS_A_THD = 2000 in case of a 4 cylinder engine.

The factor IP_MIS_A_FAC_y has to be calculated for each operating point as follow:

MIS_A_FAC = C_MIS_SUM_A_THD / (*Misfiring Rate obtained on current operating point* * NC_CYL_NR)

Example: 4 cylinder engine, AFS combustion mode

*(MIS_RATE_MIN = 4% @ LOAD_MIS = 100% and N = 4500 rpm), ratio are used in formula as entire numbers; MIS_RATE_MIN = 4 => **C_MIS_SUM_A_THD = 1600***

AFS_MODE LOAD_MIS

Proceed in the same way for all other combustion modes available on your application.

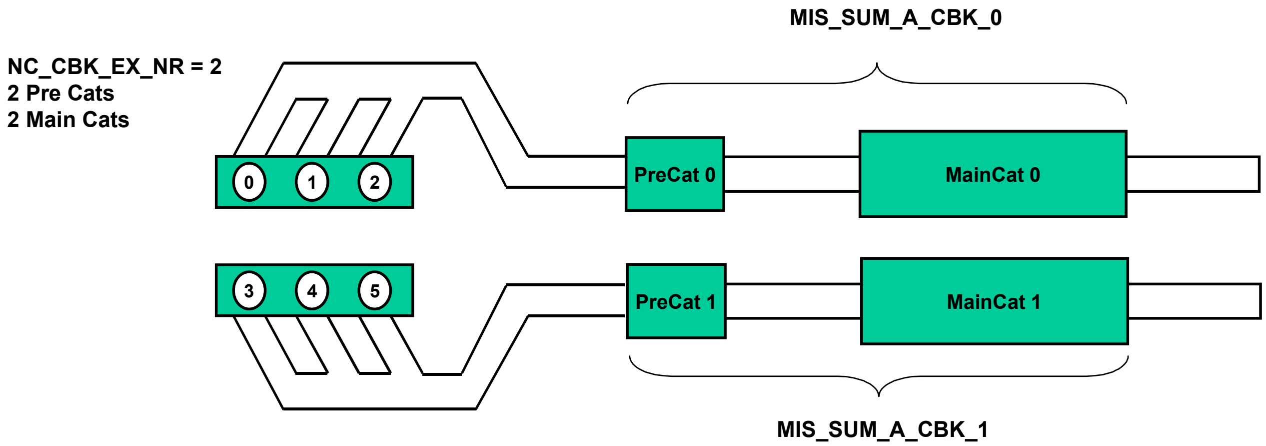
<u>Note for engines with multiple exhaust branches:</u>

For engine with multiple exhaust branches, specifics weighting factor sums MIS_SUM_A_CBK[NC_CBK_EX_NR] have been introduced for dedicated catalyst monitoring, in a way to only diagnose the catalyst impacted by the misfire detected. MIS_A is detected as soon as a MIS_SUM_A_CBK[i] counter exceeds the threshold C_MIS_SUM_A_CBK_THD.

If global catalyst detection preferred, set C_MIS_SUM_A_CBK_THD *= 65535*

If cylinder bank detection preferred, set C_MIS_SUM_A_THD *= 65535*

<u>Example 1:</u>

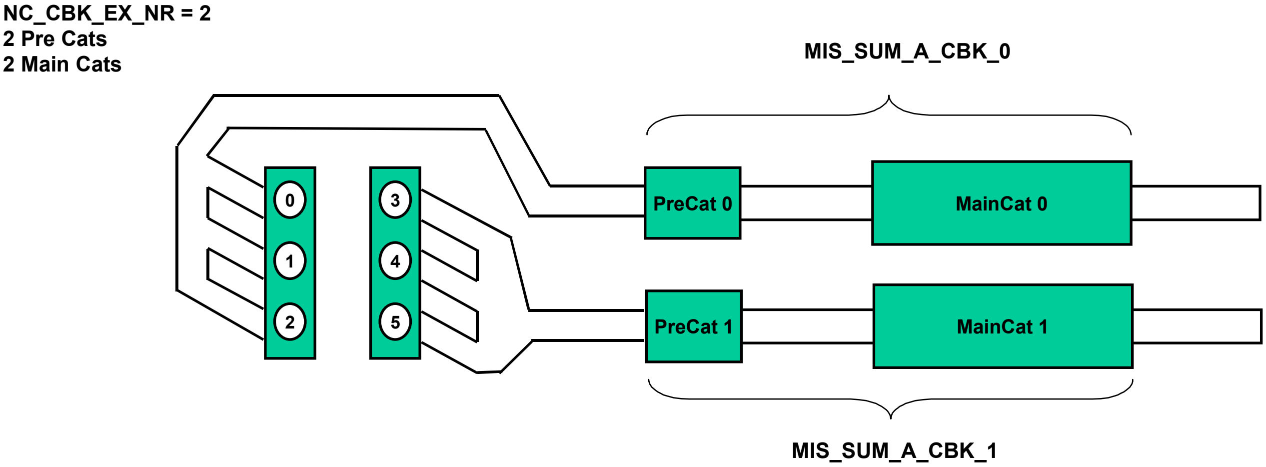


With this exhaust design; **C_MIS_SUM_A_THD** (global threshold) can't be applied, as there are no common catalyst parts between cylinder banks, so the use of MIS_SUM_A_CBK[0] & MIS_SUM_A_CBK[1] is recommended for MIS_A detection with C_MIS_A_CBK_THD threshold.

To know the misfire MIS_A criterion on only one exhaust line during MIS_A criterion calibration, apply each time a C_MIS_RATE (misfire ratio) that could be divided by NC_CYL_NR = 6 (to generate misfire always on the same exhaust), and chose C_SEG_ST_MIS_GEN to select CBK_0 (segments 0, 1 or 2) or CBK_1 (segments 3, 4 or 5).

Example 2:

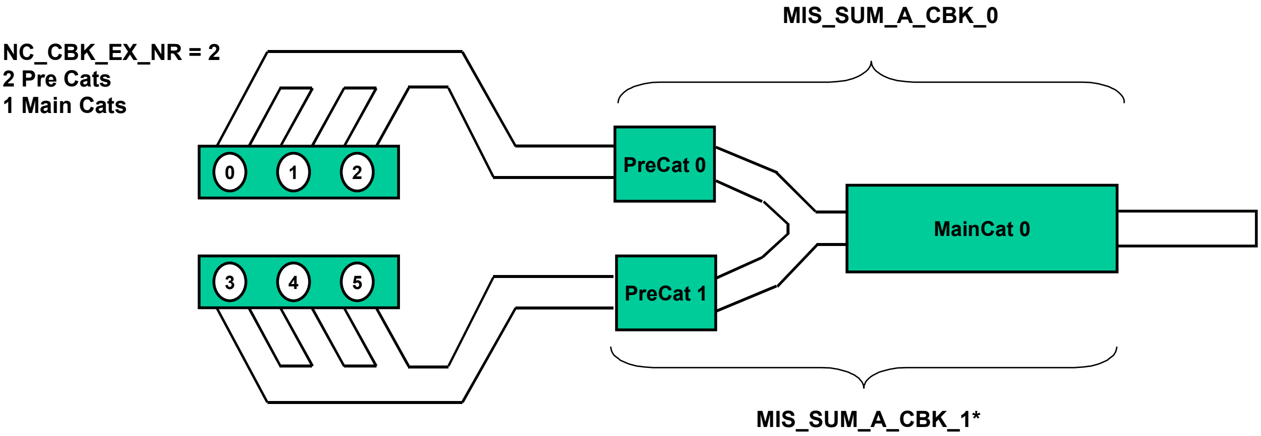
Same configuration than example 1 but with asymmetric exhaust lines *(can occurs on transversal mounted 6 cylinder engines)*



With asymmetric exhaust lines, the misfire MIS_A criterion has to be evaluated separately on the two exhaust lines during MIS_A criterion calibration, apply each time a C_MIS_RATE (misfire ratio) that could be divided by NC_CYL_NR = 6 (to generate misfire always on the same exhaust), and chose C_SEG_ST_MIS_GEN to select CBK_0 (segments 0, 1 or 2) or CBK_1 (segments 3, 4 or 5).

Next apply to the system the calibration set, corresponding to the worst case: exhaust line who will reach the critical temperature on its precatalyst or main catalyst with the lowest misfire ratio.

Example 3:



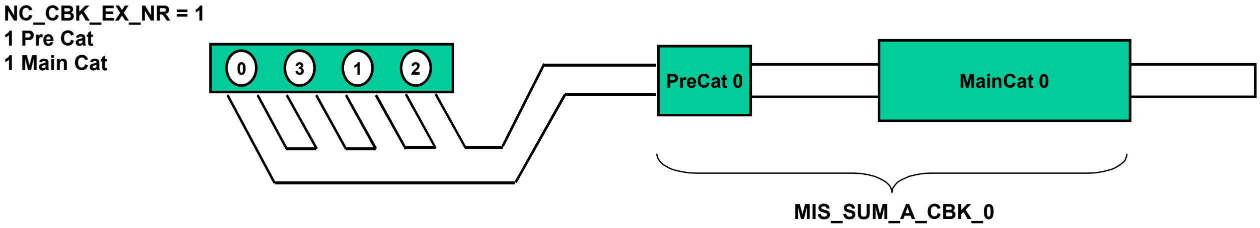
(used only if Pre CATs reach always critical temperature before Main Cat)

With this exhaust design, the choice between C_MIS_SUM_A_THD (global threshold) & C_MIS_SUM_A_CBK_THD (cylinder bank dedicated threshold), depends on the results obtained.

If the precatalysts (it's very often the case) reaches every time the critical temperature with least misfire rate than for main catalyst, the method using C_MIS_SUM_A_CBK_THD (cylinder bank) is recommended.

Otherwise, if the main catalyst reaches every time the critical temperature with least misfire rate than for precatalysts, the method using C_MIS_SUM_A_THD (global) is recommended.

Example 4:



With this exhaust design, C_MIS_SUM_A_THD & C_MIS_SUM_A_CBK_THD act exactly in the same way on the criterion detection *(MIS_SUM_A = MIS_SUM_A_CBK[0]).*

51.15.4.5.1.2 Calibration of MIS_A short term catalyst diagnosis

Nominal legal diagnosis requires a 200 crankshaft revolutions to evaluate MIS_A criterion (long term MIS_A diagnosis) with 3 occurrences if within FTP cycle, or with only 1 occurrence if out of FTP cycle.

In case of every strong misfire rate, this wait of 3 occurrences could be enough to damage one of the catalysts before to apply the cylinder shut-off limp-home.

A MIS_A misfire criterion is set within the 200 crankshaft revolutions window as soon as one of the MIS_CTR_A[NC_CYL_NR] cylinder dedicated counters exceeds the cylinder individual C_MIS_A_IND_THD threshold.

Recommendation for C_MIS_A_IND_THD calibration.

C_MIS_A_IND_THD = [1.5 * C_MIS_SUM_A_THD] / NC_CYL_NR

The 1.5 coefficient can be modified according your safety target for risk of overdetection.

51.15.4.5.1.3 MIS_A Auxiliary calibrations

FTP conditions for MIS_A default criterion.

C_LOAD_MIS_FTP correspond to the maximum load reached on an FTP cycle.

C_N_MIS_FTP corresponds to the maximum engine speed reached on an FTP cycle.

To identify if the current MIS_A window was executed in FTP cycle conditions, at each tdc CTR_FTP_CDN_MIS_A is unitary incremented.

Process during the MIS_A window when a short term is possible due to MIS_CTR_A > C_MIS_A_IND_THD_xT:

In such case, if CTR_FTP_CDN_MIS_A / MIS_NR_TDC_A < C_RATIO_FTP_CDN_IND_MIS_xT, the short term part of the MIS_A window will be declared as 'out of the FTP window', and the LV_MIS_STATE_A default will be set and the limp-home can be triggered.

(_xT stands for _AT if LV_AT=1, stands for _MT otherwise)

Process at the end of the MIS_A window:

If CTR_FTP_CDN_MIS_A / MIS_NR_TDC_A > C_RATIO_FTP_CDN_MIS_x tdc's, then LV_FTP_MIS_A is set to 1.

To declare that a window is within a FTP cycle, you must set 80% < C_CTR_FTP_CDN_MIS_A < 100% of MIS_A window tdc's number *(100 * NC_CYL_NR)*.

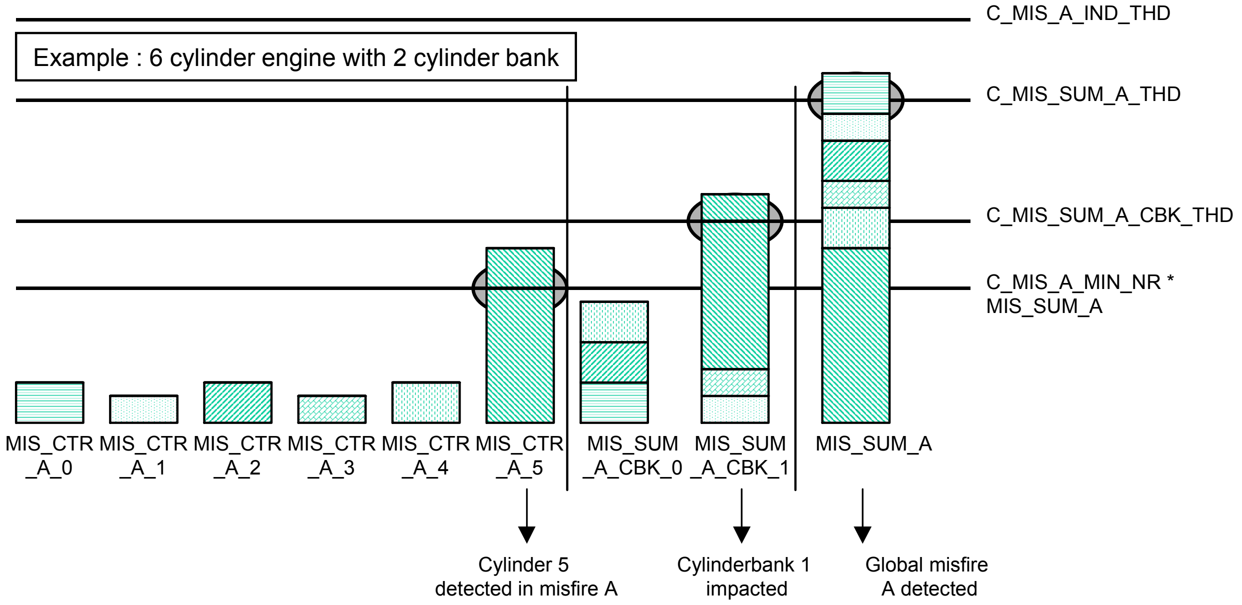
C_RATIO_FTP_CDN_IND_MIS_xT is recommended identical as C_RATIO_FTP_CDN_MIS_xT.

MIS_A default present.

If no MIS_A, MIS_B1 or MIS_B4 error have been already detected, if we are outside the FTP area or if there's no specific request (LV_REQ_APP_CTR_MIS_A=1), LV_STATE_MIS_A needs C_NR_DET_MAX_MIS_A occurrences *(consecutive or not)* within a driving cycle to be set *(at most* C_NR_DET_MAX_MIS_A = *3 according regulations).*

Cylinder identification

The cylinder identification is based on an analysis of each misfire cylinder specific counters; the one(s) identified with a number of misfire at least greater than global misfire sum MIS_SUM_A multiplied with a gain C_MIS_A_MIN_NR (defined between 0 and 100%). This ratio depends of maximum number of Pcode you wish to provide on one MIS_A failure and / or to detect half-static ignition modules default.



If no specific cylinder is identified with the C_MIS_A_MIN_NR * MIS_SUM_A criterion, LC_CONF_RND_DET_MIS_A will select the way to manage such situation.

If LC_CONF_RND_DET_MIS_A = 0, the diagnosis evaluate the cylinder with the highest weighting factor. No random misfire is stored

Random misfire identification

If LC_CONF_RND_DET_MIS_A = 1, the diagnosis will store in the MIS_A symptom a dedicated RDN information. This information will produce next in the error management, the Misfire random information (Pcode 0x300).

Multiple misfire identification

If LC_CONF_MPL_DET_MIS_A = 1 and the number of cylinders set to 1 within SYM_CYL_MIS_A is equal or over C_NR_CYL_MPL_MIS_A, an additional information in MIS_A symptom (MPL). This information will produce next in the error management, the Misfire multiple information (Pcode 0x300, equals to RND).

MIL management in case of MIS_A limp-home

If LC_CONF_MIS_A_LIH = 1 and at least a cylinder is in shut-off due to a misfire MIS_A limp home, even if no misfire is currently detected, LV_MIS_STATE_A will be forced to 1 to allow a MIL blinking during MIS_A limp-home.

Cylinder shut-off on MIS_A default criterion.

In case of short term catalyst protection (monitoring process during CARB A window) or if in long term catalyst protection (monitoring process at the end of CARB A window) and if at least a cylinder in misfire has been identified, a cylinder shut-off limp-home can be triggered to stop fuel injection in the exhaust line.

Moreover, this cylinder shut-off limp-home is allowed for short-term diagnosis only if LC_ENA_MIS_A_LIH = 1 and CTR_DET_MIS_A > ID_NR_ENA_MIS_A_LIH_xT. The table ID_NR_ENA_MIS_A_LIH_xT allows to delay the cylinder shut-off even if the LV_MIS_STATE_A is present. The limp-home will be applied only if the default is still present after ID_NR_ENA_MIS_A_LIH_xT MIS_A occurrences.

For no specific effect with the tables ID_NR_ENA_MIS_A_LIH_xT, set all cells equals to 3 and/or like C_NR_DET_MAX_MIS_A.

The cylinder identified in misfire for such cases can be shut-off by using the carrier INH_IV_MIS to inform the fuel system which cylinder is impacted by this limp-home.

C_MIS_MAX_NR_OFF_IV indicates how many cylinders can be shut-off by this limp home maximally.

Preferred: 1 for a 4-cyl engine, 2 for a 6 cylinder engine *(see customer requirements).*

If C_MIS_MAX_NR_OFF_IV = 0, this limp-home mode will be disable.

Conditions for Cylinder switch back on:

Cylinder(s) x can be switch on according two different methods:

3. Cylinder(s) x can be switched back on at the end of the driving cycle

   LC_CONF_INH_IV_MIS = 0

4. Cylinder(s) x can be switched back on after a defined number of fuel cut-off phases

   LC_CONF_INH_IV_MIS = 1

With C_MIS_MIN_NR_PUC is the minimum number fuel cut-off phases *(LV_PUC)* before cancelling cylinder(s) shut-off, each one with a minimum duration of C_T_MIS_MIN_PUC *[s]*.

Moreover, to avoid infinite cylinder switch back on when there's a really important trouble on one cylinder, when LC_CONF_INH_IV_MIS = 1, the reactivation on one cylinder is limited to C_NR_MAX_MIS_A_LIH_CYL on the current driving cycle.

This limitation is per cylinder and not global.

By using C_NR_MAX_MIS_A_LIH_CYL = 3, each time you will have a cylinder shut-off due to MIS_A diagnosis on cylinder x, the counter CTR_MIS_A_LIH_CYL_x will be limited incremented by one. After 2 occurrences of limp-home > fuel reactivation after PUC phase, at the next fuel shut-off request on this cylinder x, the fuel reactivation will be impossible on this cylinder for the current driving cycle. Reactivation is possible on the others cylinders up to reach C_NR_MAX_MIS_A_LIH_CYL.

At the next driving cycle, this control process restarts from 0.

Project specific request to modulate MIS_A default criterions.

The project can define in their application incidences file, different parameters that can bypass or modulate the generic thresholds for MIS_A detection criterion.

- LV_REQ_APP_CTR_MIS_A, if set to 1 during diagnosis, acts as an accelerator of the diagnosis (equivalent to LV_FTP = 0).
- LV_MIS_A_DIAG_REQ_APP, if set to 1 during diagnosis, changes all the generic thresholds with the following gains (between 0 and 2):
    - FAC_MIS_A_APP & FAC_MIS_SUM_A_THD_APP for the MIS_A criterions at the end of the window
    - FAC_MIS_A_THD_IND_APP for the MIS_A criterion during the window.

51.15.5 B00U_04: Determination of CARB B1 & B4 misfire criterions, causing increased emissions

51.15.5.1 General information

LV_STATE_MIS_B1 & LV_STATE_MIS_B4 are the emission malfunction criterions of CARB OBDII misfire monitoring requirements.

CARB B1 criterion is evaluated at the end of the first 1000 crankshaft revolutions of the driving cycle. CARB B4 is based on all other 1000 crankshaft revolutions windows of the driving cycle.

51.15.5.2 Calibration Prerequisites

Emission calibration frozen *(for each transmission type)*

No specific misfire detection and diagnosis prerequisite (can be perform with no ENRD & MISF calibration set)

51.15.5.3 Calibration Step B00U_04 – Step 1 / 1

CARB B1 and B4 are based on the same conception than MIS_A, but with a unitary increment step (independent to engine operating point).

51.15.5.4 Calibration of C_MIS_SUM_B1/4_THD_xT (detection thresholds)

Calibration should be done once all emissions calibrations enable to reach at least 90 % of the emission target.

Use always the same calibration data set for each cycle performed during this calibration step.

Perform emission cycles with an 80K catalyst while generating misfiring

Goal: Execute for each transmission type several FTP (or MVEG) test cycles with an increasing number of misfires to show the correlation between misfire rate and emission increase. (See graphic below)

Adjust the value of the misfiring rate in order to obtain 1,5 times the emission standard level of one pollutant (ex: often HC reaches its limit in first).

C_MIS_B_THD stands for C_MIS_SUM_B1_THD_AT, C_MIS_SUM_B4_THD_AT, C_MIS_SUM_B1_THD_MT, C_MIS_SUM_B4_THD_MT

Start with a reference cycle (no misfire generation), and then increase the misfire rate by 1% step. As soon as you reach 1,5 times one of emission criterions of your vehicle standard, note the corresponding misfire rate *(MIS_RATE_Emissions)*.

To calculate C_MIS_B_THD = (*MIS_RATE_Emissions* / 100) * NC_CYL_NR * 500

Example: *MIS_RATE_Emissions* is 2,5% for a 4-cyl engine, then C_MIS_B_THD = (2.5/100)* 2000 = 50

The effective threshold C_MIS_B_THD should be close to this value, but nevertheless modulated by your misfire detection efficiency on cycle.

Finally, an emission test has to be run afterwards with the same misfire rate successfully. Perform this calibration step for each transmission type vehicles.

Note for Europe application: C_MIS_SUM_B1_THD_xT can be set differently of C_MIS_SUM_B4_THD_xT, to avoid overdetection at engine start. Contact your OBD co-ordinator for legals update on this topic.

Note for US application: today it's no more allowed to apply a specific emission threshold for MIS_B1 regarding to MIS_B4 nominal threshold, C_MIS_B_THD = C_MIS_SUM_B1_THD_AT/MT = C_MIS_SUM_B4_THD_AT/MT.

Example:

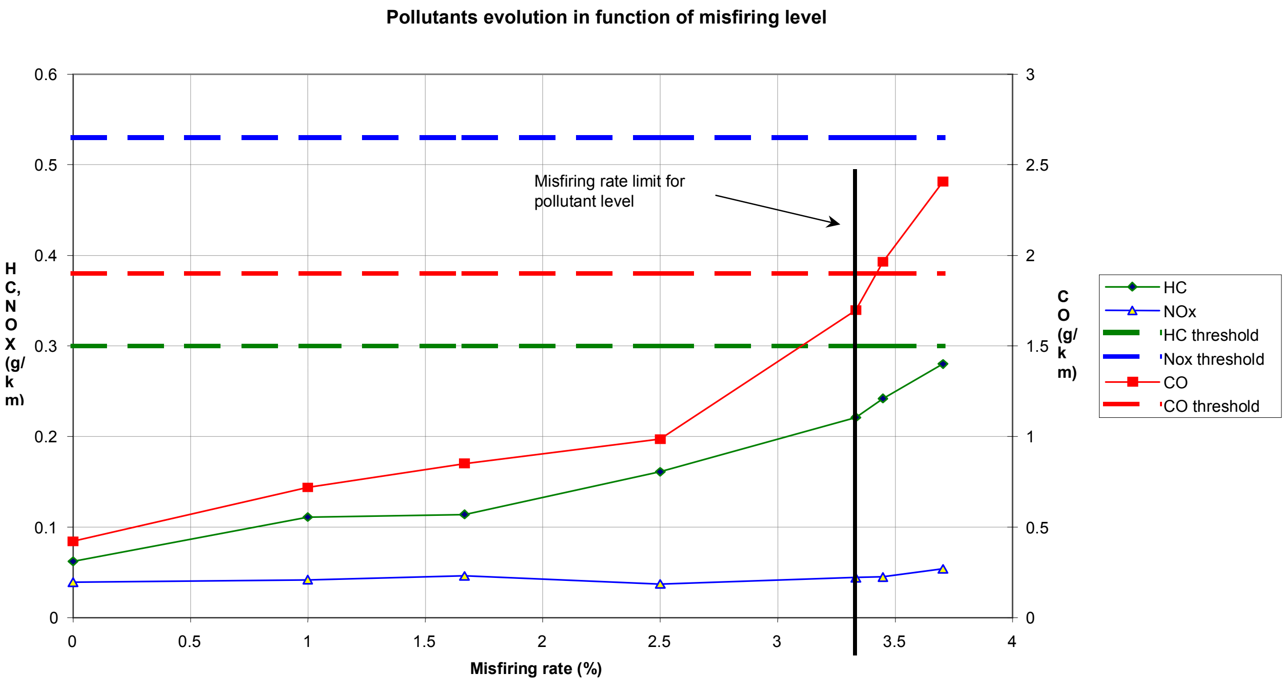
The 1.5 times the level of emission given by the customer (HC : 0.3 g/km ; CO : 1.9 g/km ; Nox : 0.53 g/km on an ECE+EUDC cycle, Europe application, *customer specific emission level, don't use it as a reference, use your application emission standards*).

To calibrate the threshold, several pollutant cycles (7) were made with increasing misfire rate.

On this application the CO target is reached first

CO > 1.9 g/km, C_MIS_RATE = 29, Misfire rate = 3.44%, NC_CYL_NR = 4

C_MIS_SUM_Bx_THD_MT = 68



<u>Note for engines with multiple exhaust branches:</u>

For engine with multiple exhaust branches, specifics sums MIS_SUM_B_CBK[NC_CBK_EX_NR] have been introduced for dedicated emission monitoring per catalyst branch, in a way to only diagnose the catalyst emission impacted by the misfire detected. MIS_B1 / MIS_B4 are detected as soon as a MIS_SUM_B_CBK_i counter exceeds the thresholds C_MIS_SUM_B1/4_CBK_THD*.*

If global catalyst detection preferred, set C_MIS_SUM_B1/B4_CBK_THD = *65535*

If cylinder bank detection preferred, set C_MIS_SUM_B1/B4_THD = *65535*

The MIS_B1/B4 detection per cylinder bank is mainly dedicated for projects that use asymmetric exhaust design (see example 2, in MIS_A chapter)

With asymmetric exhaust lines, the misfire MIS_Bx criterions have to be evaluated <u>separately on the two exhausts lines</u> during MIS_B criterion calibration.

Apply each time a C_MIS_RATE (misfire ratio) that could be divided by NC_CYL_NR = 6 (to generate misfire always on the exhaust), and chose C_SEG_ST_MIS_GEN to select CBK_0 (segments 0, 1 or 2) or CBK_1 (segments 3, 4 or 5).

51.15.5.5 Auxiliary calibrations

<u>MIS_B1 default present.</u>

As there's only one MIS_B1 window per driving cycle, if it occurs, the MIS_B1 default is immediately defined as present at the end this window.

<u>MIS_B4 default present.</u>

To be declared present, LV_STATE_MIS_B4 needs C_NR_DET_MAX_MIS_B4 occurrences *(consecutive or not)* within a driving cycle to be set *(at most C_NR_DET_MAX_MIS_A = 4).*

<u>Cylinder identification</u>

The cylinder identification is identical to principle applied on MIS_A default criterion.

There're specific gains for MIS_B1 and MIS_B4, respectively C_MIS_B1_MIN_NR & C_MIS_B4_MIN_NR.

If no specific cylinder is identified with the C_MIS_B1_MIN_NR (or C_MIS_B4_MIN_NR) * MIS_SUM_B criterion, LC_CONF_RND_DET_MIS_B will select the way to manage such situation.

<u>Random misfire identification</u>

If LC_CONF_RND_DET_MIS_B = 1, the diagnosis will store in the MIS_B1 and/or MIS_B4 symptoms a dedicated RDN information. These informations will produce next in the error management, the Misfire random information (Pcode 0x300).

<u>Multiple misfire identification</u>

If LC_CONF_MPL_DET_MIS_B = 1 and the number of cylinders set to 1 within SYM_CYL_MIS_B1 and/or SYM_CYL_MIS_B4 is equal or over C_NR_CYL_MPL_MIS_B, an additional information in MIS_B1 and/or MIS_B4 symptom (MPL). These informations will produce next in the error management, the Misfire multiple information (Pcode 0x300, equals to RND).

<u>Project specific request to modulate MIS_Bx default criterions.</u>

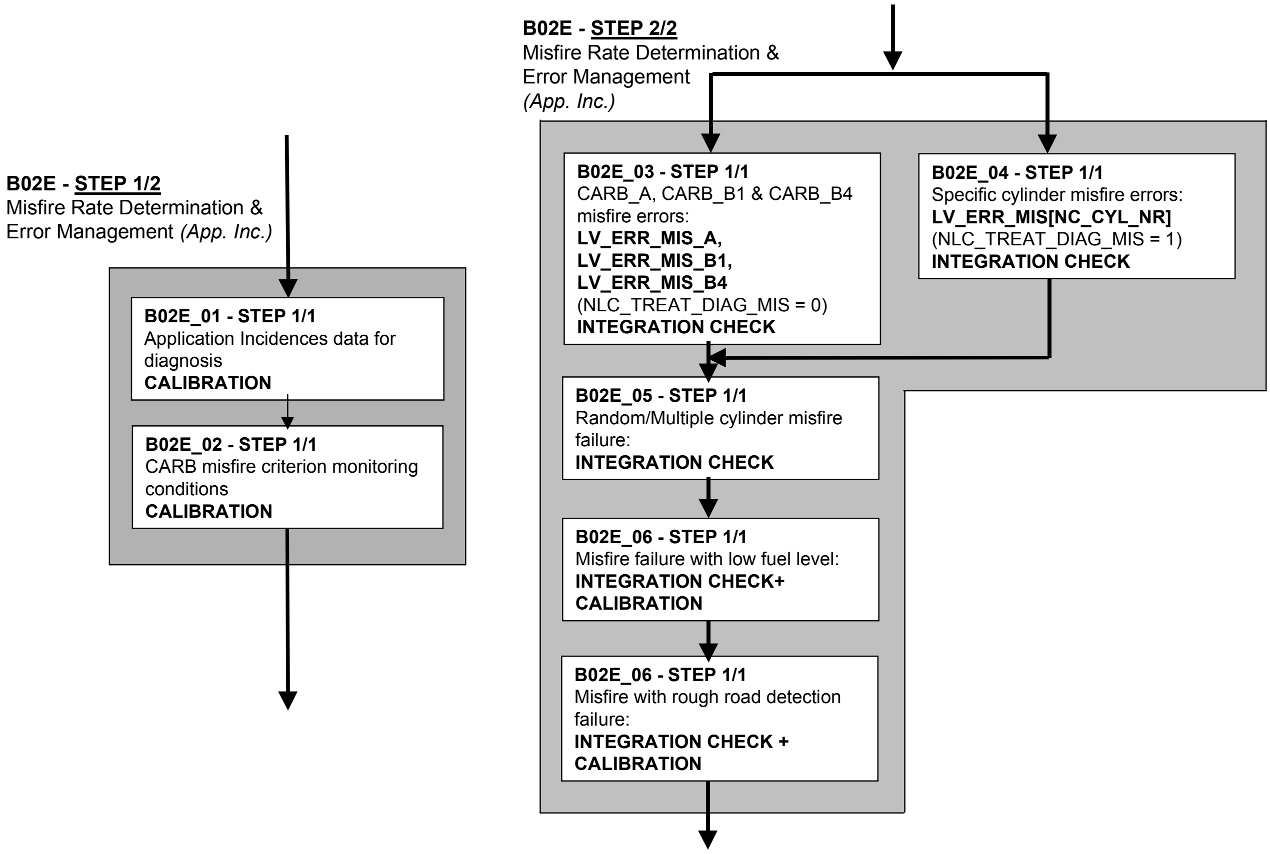
The project can define in their application incidences file, different parameters that can bypass or modulate the generic thresholds for MIS_B1 and/or MIS_B4 detection criterions.

LV_MIS_B_DIAG_REQ_APP, if set to 1 during diagnosis, changes all the generic thresholds with the following gains (between 0 and 2):

- FAC_MIS_SUM_B1_THD_APP at the end of the MIS_B1 window
- FAC_MIS_SUM_B4_THD_APP at the end of the MIS_B4 windows

51.16 Misfire rate determ. (cus)

51.16.1 Module calibration flowchart



51.16.2 B02E_01 : Application Incidences data for diagnosis

51.16.2.1 General information

This module will specify the definition of LV_REQ_APP_CTR_MIS_A : an application specific request to force the out of FTP counting mode (MIS_A long term diagnosis confirmed with one occurrence) even if we are within FTP area.

51.16.3 B02E_02 : Determination of CARB misfire criterion monitoring conditions

LV_DC	LC_CTR_CONF_DIAG_MIS	LV_INH_DET_MIS	LC_CTR_CONF_OSC_MIS	LV_STATE_CRK_OSC	LV_CDN_MIS_A LV_CDN_MIS_B1 LV_CDN_MIS_B4	MIS_A, MIS_B1 & MIS_B4 Monitoring Modes
0	x	x	x	x	0	Out of Driving Cycle
1	0	x	x	x	1	All TDC's Counting Mode
1	1	1	x	x	0	Diagnosed TDC's Counting Mode / Classical Fade Out
1	1	0	0	0	1	Diagnosed TDC's Counting Mode / No Fade Out
1	1	0	0	1	0	Classical Fade Out **with** CRK_OSC / Diagnosed TDC's Counting Mode
1	1	0	1	0	1	Diagnosed TDC's Counting Mode / No Fade Out
1	1	0	1	1	1	Classical Fade Out **without** CRK_OSC / Diagnosed TDC's Counting Mode

51.16.3.1 General information

Depending on customers & legal requirements reached, two Tdc's counting modes are available:

- Counting each Tdc's even if some aren't diagnosed *(LC_CTR_CONF_DIAG_MIS = 0)*
- Counting only diagnosed Tdc's *(LC_CTR_CONF_DIAG_MIS = 1)*

51.16.3.2 Calibration Step B02E_01 – Step 1 / 1

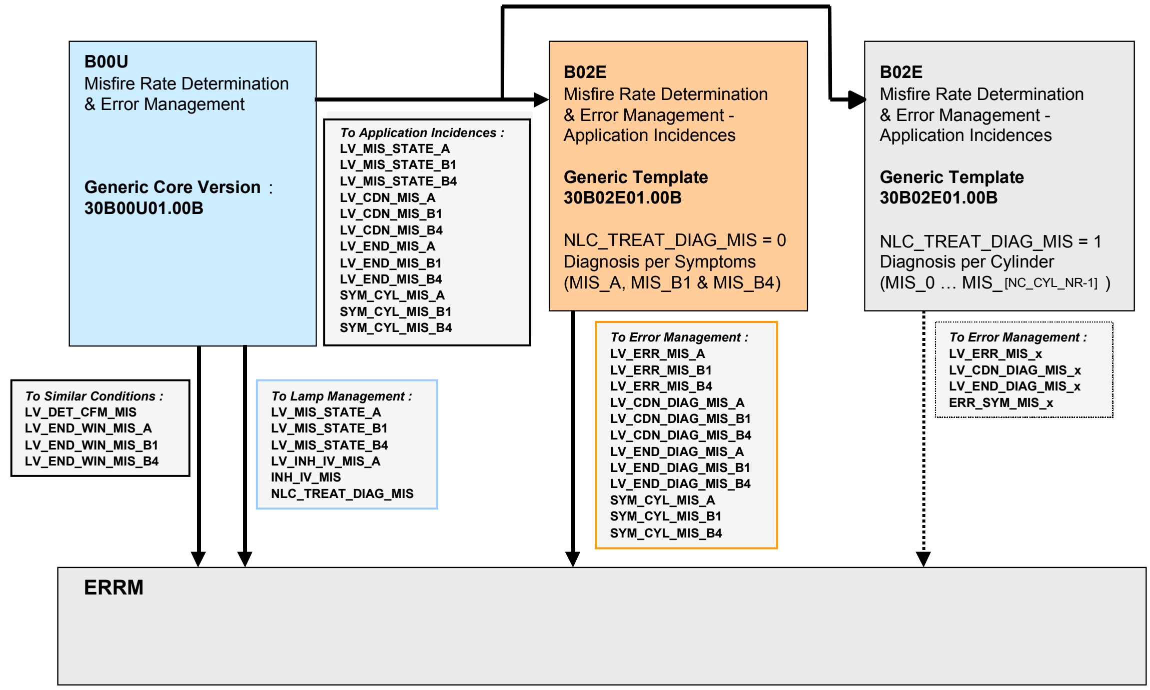
LC_CTR_CONF_DIAG_MIS = 0, is not recommended as the results in term of misfire ratio are always reduced in such case: number of misfire detection / number of TDC diagnosed (LV_CDN_MIS_x = 1). As a result it could produce MIS_A and/or MIS_Bx non-detections according the MISF detection fade-out calibration.

Please note that LC_CTR_CONF_OSC_MIS has not effect on diagnosis conditions, when NLC_USE_CRK_OSC_MIS = 0 (crankshaft oscillation detection not integrated).

51.16.4 B02E_03 : CARB_A, CARB_B1 & CARB_B4 misfire errors (NLC_TREAT_DIAG_MIS = 0)

NLC_TREAT_DIAG_MIS = 0,
Errors *= misfire criterions (MIS_A, MIS_B1 & MIS_B4),*
Symptoms *= Cylinders identified in misfire*

NLC_TREAT_DIAG_MIS = 1,
Errors *= cylinders (MIS_x wit x = 0 … NC_CYL_NR-1),*
Symptoms *= misfire criterions (MIS_A, MIS_B1 & MIS_B4)*



Diagnosis failure class

MIS_B4	MPL	14		P0300	

There's two different ways to transmit to the Error Management (ERRM) the misfire monitoring diagnosis informations.

NLC_TREAT_DIAG_MIS = 0, Three misfire errors are defined (LV_ERR_MIS_A, LV_ERR_MIS_B1 & LV_ERR_MIS_B4) per misfire legal criterion; attached symptoms are defined per cylinders.

This case is the nominal one, described by US & Europe legal texts.

The DTC's generated provide only Cylinder identification informations (P300...P313), no informations allowing to know the criterion of the errors stored in FMY (MIS_A, MIS_B1 & MIS_B4).

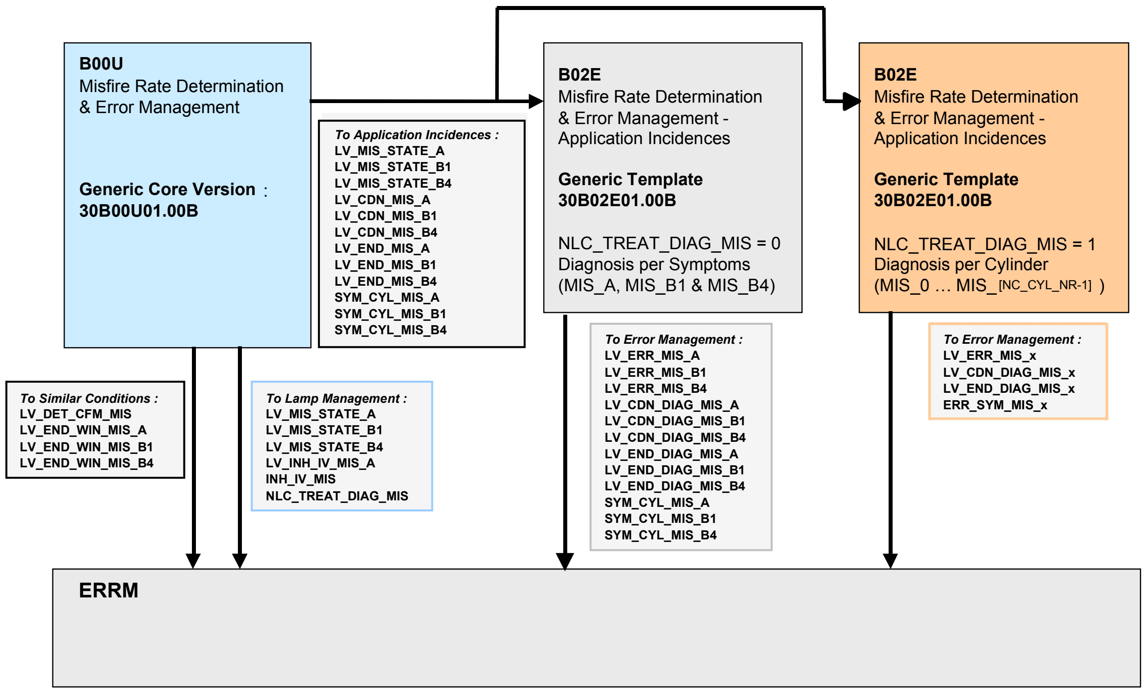
Default calibrations for DTC's of this solution *(see diagnosis failure class table above)* are exactly the codes coming from document SAE J2012 Revised March 1999 in appendix C, called Powertrain System Diagnostic Trouble Codes.

Contact our OBD co-ordinator/Customer to know if modifications occur on these Codes since 1999.

51.16.5 B02E_03 : Specific cylinder misfire errors (NLC_TREAT_DIAG_MIS = 1)

NLC_TREAT_DIAG_MIS = 0,
Errors *= misfire criterions (MIS_A, MIS_B1 & MIS_B4),*
Symptoms *= Cylinders identified in misfire*

NLC_TREAT_DIAG_MIS = 1,
Errors *= cylinders (MIS_x wit x = 0 … NC_CYL_NR-1),*
Symptoms *= misfire criterions (MIS_A, MIS_B1 & MIS_B4)*



Diagnosis failure class *(example for a 6-cylinder engine)*

Diagnosis	Symptom	Nr	P-Code/ Failure	P-Code/ Symptom	Failure class A/B
#IF NLC_TREAT_DIAG_MIS = 1					
Misfire Cylinder 1	MIS_A	1	-	P301	MIL_ON_FLL / CARB_H
	MIS_B1	2		P321	MIL_ON / CARB_H
MIS_1	MIS_B4	3		P331	MIL_ON / CARB_H
Misfire Cylinder 2	MIS_A	1	-	P302	MIL_ON_FLL / CARB_H
	MIS_B1	2		P322	MIL_ON / CARB_H
MIS_2	MIS_B4	3		P332	MIL_ON / CARB_H
Misfire Cylinder 3	MIS_A	1	-	P303	MIL_ON_FLL / CARB_H
	MIS_B1	2		P323	MIL_ON / CARB_H
MIS_3	MIS_B4	3		P333	MIL_ON / CARB_H
Misfire Cylinder 4	MIS_A	1	-	P304	MIL_ON_FLL / CARB_H
	MIS_B1	2		P324	MIL_ON / CARB_H
MIS_4	MIS_B4	3		P334	MIL_ON / CARB_H
Misfire Cylinder 5	MIS_A	1	-	P305	MIL_ON_FLL / CARB_H
	MIS_B1	2		P325	MIL_ON / CARB_H

MIS_5	MIS_B4	3		P335	MIL_ON / CARB_H
Misfire Cylinder 6	MIS_A	1	-	P306	MIL_ON_FLL / CARB_H
	MIS_B1	2		P326	MIL_ON / CARB_H
MIS_6	MIS_B4	3		P336	MIL_ON / CARB_H

The second way to transmit the misfire monitoring diagnosis informations to the Error Management (ERRM) is NLC_TREAT_DIAG_MIS = 1,

One misfire errors is produced per cylinder (LV_ERR_MIS_0 ... LV_ERR_MIS_[NC_CYL_NR-1]); attached symptoms are defined per misfire legal criterions.

This case is a customers group solution.

The DTC's generated provide cylinder identification informations & the misfire criterion of the errors stored in FMY.

DTC's codes set in the diagnosis failure class table above, are only example; please see with your customer the extended codes that could be used of additional symptoms.

51.16.6 B02E_04 : Random/Multiple cylinder misfire failure

		3			
MIS_MPL					

For the solution using NLC_TREAT_DIAG_MIS = 1, the definition of a specific Random/Multiple cylinder misfire error is required, to be able to generate the DTC P300, when no cylinder could be identified.

51.16.7 B02E_05 : Misfire with low fuel signal active

Diagnosis failure class

Diagnosis	Symptom	Nr	P-Code/ Failure	P-Code/ Symptom	Failure class A/B
MIS_FTL_L					
lisfire Detected with low fuel	FTL_L	1	P313	P313	NO_LAMP / NO_CARB_H
		2			
		3			
MIS_FTL_L					

A specific error can be set when a Misfire Criterion is detected (LV_MIS_STATE_x = 1) and a low fuel tank level is detected at the same time.

To allow this error, please set LC_CONF_ERR_MIS_FTL_L = 1.

Note: if LC_FTL_L_DET_MIS = 1 and a low fuel status occurs, the misfire detection is out of diagnosis (LV_CDN_DIAG_MIS_x = 0), so it will be impossible to detect misfire errors while low fuel tank level. In such case, the integration of LV_ERR_MIS_FTL_L is not necessary.

51.16.8 B02E_06 : Misfire with rough road detection failure

Diagnosis failure class

Diagnosis	Symptom	Nr	P-Code/ Failure	P-Code/ Symptom	Failure class A/B
MIS_RR					
Misfire with RR failure	MIS_RR	1	P314	P314	NO_LAMP / NO_CARB_H
		2			
		3			
MIS_RR					

A specific error can be set when a Misfire Criterion is detected (LV_MIS_STATE_x = 1) and when the Rough Road detection module is in limp-home.

This error will be set only for US applications who don't allow a misfire detection fade-out when the rough road detection function is in limp-home. So, in such case, the misfire errors will be stored but with an additional error LV_ERR_MIS_RR who informs that the misfire error could be due to a rough road module limp-home.

This error could occurs only is LC_STATE_RR_LIH = 0 in the rough road detection module (B002) *(LV_STATE_RR = 0 in limp-home)*.

51.17 Customer adaptation module: MISF (Misfire detection)

51.17.1 Outputs for BMW functions

Output data:

51.17.2 Outputs for SV MISF Aggregate

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ER_CLC_MIS_DET_CUS_SPC	O/V	0...1H	0...1	1	[-]
Enable engine roughness and misfire detection based on customer specific algorithm					
MIS_STATE_CUS_SPC	O/V	0...FFH	0...255	1	[-]
Status carrier byte of actual detected misfire through customer specific algorithm					
MIS_DET_ENA_CUS_SPC	O/V	0...FFH	0...255	1	[-]
Misfire detection enabling condition based on customer specific algorithm, Carrier structure					

Input data:

St_aekh	St_aekh_ae	B_aekh_akt	

FUNCTION DESCRIPTION:

Adaptation to BMW environment

Application conditions:

Initialisation: at reset or at exit powerlatch: *0*

Recurrence: Segment

Activation: every engine state

Formula section:

LV_ER_CLC_MIS_DET_CUS_SPC = B_aekh_akt

MIS_STATE_CUS_SPC = St_aekh_ae

MIS_DET_ENA_CUS_SPC = St_aekh

Important Note for the calling sequence :

51.17.3 The following calling sequence should be maintained only for the segment task which

51.17.4 calculates outputs for SV MISF Aggregate. That is the segment task for this function

51.17.5 should be called only after the following calculation

1) Misfire calculation functions from SV.
2) VRAMO – Misfire calcuation from BMW

   After VRAMO, copying BMW variables to SV variables is done, and hence used in next segment raster of SV misfire functions.

52.1 NOXD Configuration Data

FUNCTION DESCRIPTION:

General information:

The following describes the general rules for determination of the configuration data:

- All configuration data shall be defined by project with information from customer.

Formula section:

Global configuration data

Here are listed the configuration data, which can be used in other aggregates:

Data	Value
NC_NOX_SENS_CONF	1

Local configuration data

Here are listed the configuration data, which are used only in the NOXD aggregate:

Data	Value
-	

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NOX_SENS_CONF	-	0...2H	0...2	1	[-]
Number of NOx sensors within the exhaust system					

52.2 AGGR adaptation: NOXD

FUNCTION DESCRIPTION:

General information:

This module handles all variable interfaces of aggregate NOXD. It adapts inputs to aggregate NOXD and outputs from aggregate NOXD on project specific requirements or aggregate structure requirements.

52.2.1 Inputs to aggregate NOXD – 10ms (fast variable assignments)

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_ERR_NOX_SENS_CAN_BOFF	V/O	0...1H	0...1	1	[-]
CAN bus, at which the NOx sensor is connected, has the state "busoff"

52.3 NOx sensor Interface

Input data:

LV_IGK			

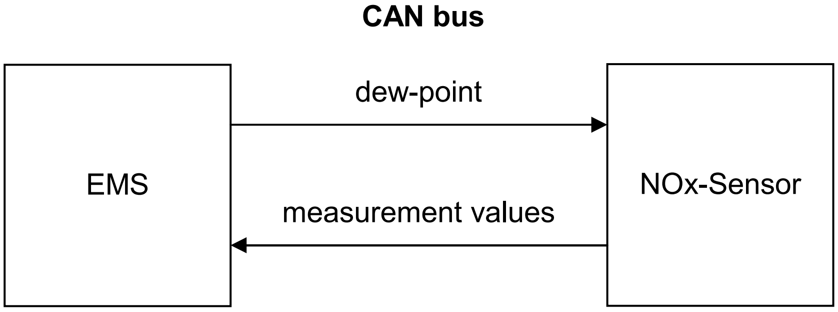
FUNCTION DESCRIPTION:

General information:

The number of NOx sensors in the system is defined by NC_NOX_SENS_CONF. The value of NC_NOX_SENS_CONF is to set within the project specific module ‘List of Configuration Data’.

```
if    NC_NOX_SENS_CONF = 0
then  the system contains no NOx sensor
      nothing is to calculate, no NOx sensor variables are declared
else  if    NC_NOX_SENS_CONF = 1
      then  the system contains 1 NOx sensor
            all NOx sensor variables are xxx_1 (i = 1)
      else  if    NC_NOX_SENS_CONF = 2
            then  the system contains 2 NOx sensors
                  all NOx sensor variables for exhaust line 1 are xxx_1 (i = 1)
                  all NOx sensor variables for exhaust line 2 are xxx_2 (i = 2)
            endif
      endif
endif
```

The NOx sensor Interface handles the variables and CAN messages for the use of NOx sensor into the EMS.



The EMS sends the dew point to the NOx sensor and receives measurement values and sensor status information from the NOx sensor via CAN bus. The CAN message structure and the CAN message ID’s are defined project specific, e.g. at module ‘NOx sensor Interface (Application Incidences)’.
The dew point handling is also performed in a project specific module, e.g. at module ‘NOx sensor Interface (Application Incidences)’.

Description:

The NOx sensor sends messages with actual measurement values, sensor status and a failure byte to the EMS.

The information from the NOx sensor status byte are combined with the CAN bus failure information's to the signal valid indicators. These CAN bus failures are lost message from the NOx sensor and the state CAN busoff.

Application conditions:

Recurrence: 10 ms

Activation: LV_IGK = 1

Deactivation: LV_IGK = 0

FUNCTION DESCRIPTION:

General information:

The EMS receives the NOx concentration signal from the NOx sensor by CAN. After that the NOx concentration signal is evaluated by NOx sensor status information and filtered within the EMS.

Description:

The NOx output signal NOX_NOX_SENS_DIAG_i is used for the NOx sensor diagnosis functions. It is generated by filter of CAN_NOX_NOX_SENS_i, which is received from the NOx sensor.

The NOx output signal NOX_NOX_SENS_i is used for the NOx catalyst control functions. It is generated by filter of CAN_NOX_NOX_SENS_i after an analysis of sensor status information CAN_STATE_NOX_SENS_i. A new NOX_NOX_SENS_i value is calculated if no CAN bus error is occurred and CAN_STATE_NOX_SENS_i indicates full sensor readiness by CAN_STATE_NOX_SENS_i = 1EH. All other bits of CAN_STATE_NOX_SENS_i have no relevance for full readiness. So the system is authorised to use the NOx signal.

The bit LV_NOX_SENS_NOX_AUTH_i is set to 1 after the NOx sensor was uninterrupted full ready for at least C_T_NOX_SENS_NOX_AUTH. LV_NOX_SENS_NOX_AUTH_i is reset to 0 when the temperature of NOx sensor element is out of control range and the power supply of NOx sensor is out of specified range (bit PWR_OK of NOX_SENS_TEMP_i = 0) or when the engine is stopped or when the NOx sensor dew point is reset. This is necessary in order to deactivate the NOx sensor OBD II diagnosis functions.

The variable LV_NOX_SENS_NOX_DIAG_VLD_i is reset to 0 every time when the sensor loses the full readiness. So the diagnosis functions are informed in order to exclude a wrong diagnosis. At the same time starts the timer T_NOX_SENS_NOX_HLD_i. It runs up to the maximum value. An overflow is not allowed. The timer is stopped and reset, when the sensor reaches its full readiness.

The variable LV_NOX_SENS_NOX_MDL_VLD_i is used in the module ‘NOx catalyst model controller’. The variable LV_NOX_SENS_NOX_MDL_VLD_i informs this module about the NOx signal state. It is reset to 0 every time when the sensor loses the full readiness. It is set to 1 after the NOx signal was valid for the time C_T_NOX_SENS_NOX_MDL.

Note! The timer T_NOX_SENS_NOX_MDL_i runs up to the maximum value. An overflow is not allowed.

If the permanently authorisation of NOx signal is activated by LC_NOX_SENS_NOX_VLD_i = 1 and LV_NOX_SENS_NOX_AUTH_i = 1 then it is allowed to calculate a new NOX_NOX_SENS_i value without full sensor readiness. The variable LV_NOX_SENS_NOX_VLD_i is set to 1 so that the system is authorised to use the NOx signal. After the engine start the permanently authorisation of NOx signal is blocked up to the use of sensor signals is allowed by LV_NOX_SENS_NOX_AUTH_i = 1. Then the calculation of NOX_NOX_SENS_i values is started.

When the sensor loses its full readiness the last valid NOx signal value NOX_NOX_SENS_i and LV_NOX_SENS_NOX_VLD_i are held up to the time C_T_NOX_SENS_NOX_HLD is passed. After that the NOx signal NOX_NOX_SENS_i is set to C_NOX_NOX_SENS_i and LV_NOX_SENS_NOX_VLD_i is reset.

If the manual setting of NOx values is active LC_NOX_SENS_NOX_MAN_i = 1 then NOX_NOX_SENS_DIAG_i and NOX_NOX_SENS_i are set to C_NOX_NOX_SENS_i, LV_NOX_SENS_NOX_VLD_i is set to 1 and LV_NOX_SENS_NOX_DIAG_VLD_i is reset.

The calculation of NOX_NOX_SENS_i and NOX_NOX_SENS_DIAG_i shall be done with an internal resolution of 32 bit.

Application conditions:

FUNCTION DESCRIPTION:

General information:

The EMS receives the Lambda signal from the NOx sensor by CAN. The Lambda signal is issued in the kind of 1000/ λ. The 1000/ λ value was chosen for an easy data transmission by CAN.

Description:

The Lambda signal CAN_LAMB_NOX_SENS_i, which is received from the NOx sensor, is converted from 1000/ λ value to λ and then it is stored at LAMB_NOX_SENS_DIAG_i. After that the Lambda signal is evaluated by the sensor status CAN_STATE_NOX_SENS_i.

The value of LAMB_NOX_SENS_DIAG_i is copied to LAMB_NOX_SENS_i if no CAN bus error is occurred and CAN_STATE_NOX_SENS_i indicates at least level 2 sensor readiness by CAN_STATE_NOX_SENS_i = 0EH. For level 2 sensor readiness must be checked the bits B1, B2, B3 and B6 of CAN_STATE_NOX_SENS_i. All other bits of CAN_STATE_NOX_SENS_i have no relevance for level 2 readiness. At the same time the variables LV_NOX_SENS_LAMB_VLD_i and LV_NOX_SENS_LAMB_DIAG_VLD_i are set to 1. So the system is authorised to use the Lambda signal.

The variable LV_NOX_SENS_LAMB_DIAG_VLD_i is reset to 0 every time when the sensor loses the level 2 readiness. So the diagnosis functions are informed in order to exclude a wrong diagnosis. At the same time starts the timer T_NOX_SENS_LAMB_HLD_i. It runs up to the maximum value. An overflow is not allowed. The timer is stopped and reset, when the sensor reaches the level 2 readiness.

If the permanently authorisation of Lambda signal is activated by LC_NOX_SENS_LAMB_VLD_i = 1 and LV_NOX_SENS_NOX_AUTH_i = 1 then it is allowed to pass the Lambda signal to LAMB_NOX_SENS_i without level 2 sensor readiness. The variable LV_NOX_SENS_LAMB_VLD_i is set to 1 so that the system is authorised to use the Lambda signal. After the engine start the permanently authorisation of Lambda signal is blocked up to LV_NOX_SENS_LAMB_AUTH_i = 1. Then the Lambda signal values are passed to LAMB_NOX_SENS_i.

When the sensor loses the level 2 readiness the last valid Lambda signal value LAMB_NOX_SENS_i and LV_NOX_SENS_LAMB_VLD_i are held up to the time C_T_NOX_SENS_LAMB_HLD is passed. After that the Lambda signal LAMB_NOX_SENS_i is set to C_LAMB_NOX_SENS_i and LV_NOX_SENS_LAMB_VLD_i is reset.

If the manual setting of Lambda values is active (LC_NOX_SENS_LAMB_MAN_i = 1) then LAMB_NOX_SENS_DIAG_i and LAMB_NOX_SENS_i are set to C_LAMB_NOX_SENS_i, LV_NOX_SENS_LAMB_VLD_i is set to 1 and LV_NOX_SENS_LAMB_DIAG_VLD_i is reset.

FUNCTION DESCRIPTION:

General information:

The EMS receives the binary O2 signal from the NOx sensor by CAN. The principle characteristic of the NOx sensor’s binary signal is the same as of a binary O2 sensor.

Description:

The binary O2 signal CAN_VLS_NOX_SENS_i, which is received from the NOx sensor, is copied to VLS_NOX_SENS_DIAG_i. After that the binary O2 signal is evaluated by the sensor status CAN_STATE_NOX_SENS_i.

The value of CAN_VLS_NOX_SENS_i is copied to VLS_NOX_SENS_i if no CAN bus error is occurred and CAN_STATE_NOX_SENS_i indicates at least level 2 sensor readiness by CAN_STATE_NOX_SENS_i = 0EH. For level 2 sensor readiness must be checked the bits B1, B2, B3 and B6 of CAN_STATE_NOX_SENS_i. All other bits of CAN_STATE_NOX_SENS_i have no relevance for level 2 readiness. At the same time the variables LV_NOX_SENS_VLS_VLD_i and LV_NOX_SENS_VLS_DIAG_VLD_i are set to 1. So the system is authorised to use the binary O2 signal.

The variable LV_NOX_SENS_VLS_DIAG_VLD_i is reset to 0 every time when the sensor loses the level 2 readiness. So the diagnosis functions are informed in order to exclude a wrong diagnosis. At the same time starts the timer T_NOX_SENS_VLS_HLD_i. It runs up to the maximum value. An overflow is not allowed. The timer is stopped and reset, when the sensor reaches the level 2 readiness.

If the permanently authorisation of binary O2 signal is activated by LC_NOX_SENS_VLS_VLD_i = 1 and LV_NOX_SENS_NOX_AUTH_i = 1 then it is allowed to pass the binary O2 signal to VLS_NOX_SENS_i without level 2 sensor readiness. The variable LV_NOX_SENS_VLS_VLD_i is set to 1 so that the system is authorised to use the binary O2 signal. After the engine start the permanently authorisation of binary O2 signal is blocked up to LV_NOX_SENS_VLS_AUTH_i = 1. Then the binary O2 signal values are passed to VLS_NOX_SENS_i.

When the sensor loses the level 2 readiness the last valid binary O2 signal value VLS_NOX_SENS_i and LV_NOX_SENS_VLS_VLD_i are held up to the time C_T_NOX_SENS_VLS_HLD is passed. After that the binary O2 signal VLS_NOX_SENS_i is set to C_VLS_NOX_SENS_i and LV_NOX_SENS_VLS_VLD_i is reset.

If the manual setting of binary O2 values is active LC_NOX_SENS_VLS_MAN_i = 1 then VLS_NOX_SENS_DIAG_i and VLS_NOX_SENS_i are set to C_VLS_NOX_SENS_i, LV_NOX_SENS_VLS_VLD_i is set to 1 and LV_NOX_SENS_VLS_DIAG_VLD_i is reset.

Application conditions:

Initialisation: at reset, at LV_IGK = 1 -> 0:

Input data:

CAN_ERR_NOX_SENS[NC_NOX_SENS_CONF]	LV_ERR_NS_CAN_MSG_LOST[NC_NOX_SENS_CONF]	LV_ERR_NS_CAN_BOFF	LV_IGK
NC_NOX_SENS_CONF			

FUNCTION DESCRIPTION:

General information:

The NOx sensor monitors the connection between the NOx sensor interface unit and the sensor element. The sensor interface is able to detect open wires and short circuits between the sensor connection wires.

The NOx sensor sends the monitoring result together with the measurement data as failure byte to the EMS. The EMS uses this failure byte for the NOx sensor diagnosis.

Description:

The NOx sensor's failure byte is valid, if no CAN bus error is occurred. In this case the failure byte CAN_ERR_NOX_SENS_i is copied to the variable ERR_NS[i], so that it can be evaluated by the NOx sensor diagnosis function. Otherwise the variable ERR_NS[i] is reset.

If the manual setting of error byte is active LC_NOX_SENS_ERR_MAN_i = 1 then ERR_NS[i] is set to C_ERR_NOX_SENS_i.

Application conditions:

Initialisation: at reset, at LV_IGK = 1 -> 0: ERR_NS[i] = 0

Formula section:

```
if    LC_NOX_SENS_ERR_MAN_i = 0
then
      if    LV_ERR_NS_CAN_MSG_LOST[i] = 0        AND

Input data:

CAN_STATE_NOX_SENS[NC_NOX_SENS_CONF]	LV_ERR_NS_CAN_MSG_LOST[NC_NOX_SENS_CONF]	LV_ERR_NS_CAN_BOFF	NC_NOX_SENS_CONF

FUNCTION DESCRIPTION:

General information:

The NOx sensor interface unit controls the temperature of the sensor element. The state of the temperature control is transmitted to the EMS by the status byte.

The NOx sensor observes its power supply voltage. If the power supply voltage is in the range MIN < voltage < MAX then the bit B0 of CAN_STATE_NOX_SENS_i is 0.

In the case of voltage < MIN (specification value of sensor) it is possible that the sensor can not control the correct sensor element temperature. Because of this the sensor loses the readiness. The possible reasons of undervoltage are a to low battery voltage or a high voltage drop over the power supply wire (e.g. connector problem).

In the case of voltage > MAX (specification value of sensor) the sensor is shut down up to the power supply voltage is again in the allowed range (self-protection mode).

At both cases the NOx sensor diagnosis functions must be deactivated in order to prevent wrong diagnoses.

Description:

The state of sensor temperature control and the state of sensor power supply voltage are indicated by bits of NOX_SENS_TEMP_i. The meaning of each bit of NOX_SENS_TEMP_i is described at the table below.

NOX_SENS_TEMP_i	Description
Bit B0 ... TEMP_OK	Sensor temperature is ok.
Bit B1 ... PWR_OK	Sensor power supply is ok.
Bit B2	not used
Bit B3	not used
Bit B4	not used
Bit B5	not used
Bit B6	not used
Bit B7	not used

The sensor temperature is valid if no CAN bus error is occurred and the status byte CAN_STATE_NOX_SENS_i indicates level 1 readiness.

The level 1 readiness is indicated by CAN_STATE_NOX_SENS_i = 02H. For the level 1 readiness must be checked the bits B1 and B6 of CAN_STATE_NOX_SENS_i. All other bits of CAN_STATE_NOX_SENS_i have no relevance for level 1 readiness.

If the level 1 readiness is ok then bit TEMP_OK of NOX_SENS_TEMP_i is set. Otherwise bit TEMP_OK of NOX_SENS_TEMP_i is reset.

With bit B0 of CAN_STATE_NOX_SENS_i = 0 indicates the sensor that the power supply is in the correct range. Then bit PWR_OK of NOX_SENS_TEMP_i is set to 1.

At undervoltage or at overvoltage the sensor sets bit B0 of CAN_STATE_NOX_SENS_i = 1. This information is combined with the temperature information from the sensor and the timer T_NOX_SENS_PWR_i in order to debounce short power supply peaks, which are reported by sensor.

Application conditions:

Initialisation: at reset: NOX_SENS_TEMP_i = 0
T_NOX_SENS_PWR_i = 0

Formula section:

```
if    LV_ERR_NS_CAN_MSG_LOST[i] = 0                                AND

STATE_NS_VERS[NC_NOX_SENS_CONF]	T_AST_SAE	CAN_HW_NS[NC_NOX_SENS_CONF]	

FUNCTION DESCRIPTION:

General information:

This chapter is used as interface between the variables on the CAN bus and the system variables.

The NOx sensor needs from the EMS the information, that the dew point is passed. This information is necessary for the heater management of the NOx sensor. It protects the NOx sensor in order to avoid damages by water splash of condense water in the exhaust system. The dew point recognition is performed in the ‘NOx catalyst monolith temperature model’.

If the NOx sensor has been received the dew point from the EMS, then the heater management warms up the sensor on the normal operating temperature.

Description:

The dew point flag for the NOx sensor LV_CAN_TEMP_MIN_THD_i is set, if the dew point, which is calculated by the NOx catalyst monolith temperature model, is reached or if the NOx sensor's ceramic (sensor element) was sufficiently heated up by exhaust gas. The detection of sufficient sensor element heating uses a temperature dependent resistance ratio signal, which is sent by the NOx sensor while the NOx sensor is waiting for the dew point.

The resistance ratio signal is sent instead of the NOx signal. This resistance ratio signal represents the momentary temperature of sensor element. It is defined as:

$$\mathrm{CAN\_R\_RATIO\_NOX\_SENS\_i} = \frac{R}{R_{25}} = 911 \cdot \left(1 + \alpha \cdot T + \beta \cdot T^2\right)$$

α ... material constant, $\alpha = 3.92 \cdot 10^{-3}\ K^{-1}$

β ... material constant, $\beta = -0.6 \cdot 10^{-6}\ K^{-2}$

T ... temperature of sensor element [°C]

The scope of dew point detection by sensor element temperature is an earlier set of dew point in comparison with the dew point set by NOx catalyst monolith temperature model.

The dew point is detected by sensor element temperature when the resistance ratio signal from the NOx sensor exceeds the threshold C_R_RATIO_NOX_SENS_MIN. The set of dew point by sensor element temperature is allowed only 1x after engine start. A reset of dew point is possible by the NOx catalyst temperature model within a driving cycle (e.g. very long pull fuel cutoff phase). In this case the sensor temperature condition has not the right to set the dew point again. Hence the resistance ratio signal is set to maximum value after the dew point was reached the 1st time within a driving cycle and is reset to "0" at every engine start.

Calibration hints:

A typical sensor element temperature threshold for set of dew point is:

T ≈ 300°C => C_R_RATIO_NOX_SENS_MIN = 1936

Other values for C_R_RATIO_NOX_SENS_MIN can be calculated by use of definition equation (see above).

This function can be switched off by calibration

C_R_RATIO_NOX_SENS_MIN = maximum value (7FFFH or 32767)

Application conditions:

Initialisation: at reset:

LV_CAN_TEMP_MIN_THD_i = 0
LV_MDL_TEMP_MIN_THD_i = 0
CAN_STATE_NS_DIAG_REQ[i] = 0
LV_NS_VERS_REQ_1[i] = 0
LV_NS_VERS_REQ_2[i] = 0

Recurrence: corresponding to EMS send message with CAN-ID = 140H

Activation: after reset, at every engine state

Deactivation: -

Formula section:

```
if    LV_IGK = 1

52.4.2 CAN Protocol

General information:

The following control units participate to CAN-communication:

EMS:	Engine management system
NOX1:	NOx sensor on exhaust line 1
NOX2:	NOx sensor on exhaust line 2

CAN communication is based on messages. A message is defined at the identifier number. Valid identifier numbers are numbers from 1 to 1023 (short identifier). Messages with lower identifier number have higher priority. The length of a message can vary from 1 to 8 bytes.

Baudrate: 500 kBaud
Data format: Motorola

The NOx sensor in exhaust line 1 sends its measurement values on CAN Messages with the ID = 130H. The NOx sensor in exhaust line 2 sends its measurement values on CAN Messages with the ID = 135H.

The NOx sensors in all exhaust lines receive the dew point on the CAN Message with the ID = 140H.

52.4.2.1 Send messages by EMS

52.4.2.1.1 ID = 140H - NOx sensor dew point

Input data:

LV_CAN_TEMP_MIN_THD[NC_NOX_SENS_CONF]	LV_NS_VERS_REQ_1[NC_NOX_SENS_CONF]	LV_NS_VERS_REQ_2[NC_NOX_SENS_CONF]	CAN_STATE_NS_DIAG_REQ[NC_NOX_SENS_CONF]

General information:

ATTENTION!!!

The CAN message description in this function specification is **for information only!** It is not included within NOx sensor component change management!

This message transfers the dew point and special operation mode requests from the EMS to all NOx sensors within the system. The sending of this message is permanently active.

Description:

The calibration value NOx sensor self diagnosis run-in time C_T_RUN_DIAG_NS_SHIFT allows to overwrite the NOx sensor internal default value of this parameter. For a explanation of NOx sensor self diagnosis, its parameters and effects contact the NOx sensor supplier or see NOx sensor component specification.

Calibration hint:

It is strongly recommended to use the NOx sensor internal default value of this parameter. Hence use the According to the definitions into the NOx sensor component specification for project MSD80, the following calibration is recommended:

1. activation of functionality:

   C_T_RUN_DIAG_NS_SHIFT > 0.0 s

2. deactivation of functionality (use of NOx sensor internal default value):

   C_T_RUN_DIAG_NS_SHIFT = 0.0 s

Application conditions:

Initialisation: -

Recurrence: 100ms

Activation: *after reset*

Deactivation: -

Formula section:

Temporary signal from CAN message buffer - byte 8

Input data:

LV_IGK			

General information:

For all received messages are applicable:

```
if    LV_IGK = 0                                          OR
      lost message error of a particular message is detected
then
          if    default values for this message are defined
          then  the default values are used
          else  the previous values of this message are used
          endif
else      the received message values are used
endif
```

Description:

The NOx sensor transmits different signals, which can identified by the "Sensor status" signal. Detailed information are included into the next section with the CAN message description.

ATTENTION!!!

The CAN message description in this function specification is **for information only!** It is not included within NOx sensor component change management!

Calibration hint:

According to the definitions into the NOx sensor component specification for project MSD80, the following calibration is recommended:

C_CAN_STATE_NS_TMP_MASK = 1110 0000b = E0H = 224 (decimal)
C_STATE_NS_MASK_MODE_1 = 0100 0000b = 40H = 64 (decimal)
C_STATE_NS_MASK_MODE_2 = 0000 0000b = 00H = 0 (decimal)
C_STATE_NS_MASK_MODE_3_A = 1000 0000b = 80H = 128 (decimal)
C_STATE_NS_MASK_MODE_3_B = 1100 0000b = C0H = 192 (decimal)
C_STATE_NS_MASK_MODE_4_A = 1010 0000b = A0H = 160 (decimal)
C_STATE_NS_MASK_MODE_4_B = 1110 0000b = E0H = 224 (decimal)
C_STATE_NS_MASK_MODE_5 = 0010 0000b = 20H = 32 (decimal)

A functionality can be deactivated by mode mask calibration of 0FH.

Application conditions:

Initialisation: at reset:

CAN_R_RATIO_NOX_SENS[i] = 0
CAN_STATE_NS_TMP[i] = 0

CAN_SW_NS[i] = 0
CAN_HW_NS[i] = 0
CAN_STATE_DIAG_NS[i] = 0
CAN_NOX_REF_NS[i] = 0
CAN_NOX_DIAG_NS[i] = 0

Recurrence: 10ms

Activation: after reset, at every engine state

Deactivation: -

Formula section:

Signals, which are to copy from CAN message buffer without any condition

52.4.2.3 ID = 130H – NOx sensor 1 data and ID = 135H – NOx sensor 2 data

General information:

ATTENTION!!!

The CAN message description in this function specification is **for information only!** It is not included within NOx sensor component change management!

This messages transfers the measurement data, diagnosis data and sensor identification data from the NOx sensor 1 and NOx sensor 2 to the EMS.

The message content depends on sensor operation mode. It exists following sensor operation modes:

- Mode 1 – Wait on dew point
- Mode 2 – Measuring
- Mode 3 – Sensor identification data, part 1
- Mode 4 – Sensor identification data, part 2
- Mode 5 – Sensor self diagnosis

The sensor indicates its operation mode by the signal "Sensor status" which is included within each transmitted message.

Formula section:

[1] The following table describes the meaning of byte "Sensor status":

Byte: "Sensor status"								
B7	B6	B5	B4	B3	B2	B1	B0	Function
							X	Power supply bit. 0 ... 11.5V <= VB <= 15.5V 1 ... VB < 11.5V or VB > 15.5V) VB...battery voltage measured by NOx sensor ECU inside of NOx sensor ECU
						X		Sensor temperature indication bit. 0 ... Sensor temperature is not ok (out of operating range) 1 ... Sensor temperature is ok (within operating range)
					X			Ip1 ready indication bit. 0 ... not ok (out of operating range) 1 ... ok (within operating range)
				X				Ip0 ready indication bit. 0 ... not ok (out of operating range) 1 ... ok (within operating range)
			X					Ip2 ready indication bit. 0 ... not ok (out of operating range) 1 ... ok (within operating range)
		X						Mode switch for read out of sensor identification data and sensor self diagnosis mode For details see NOx sensor specification. Bit B7 = 0: 0 ... Normal sensor operation mode 1 ... Sensor self diagnosis mode Bit B7 = 1 (sensor identification data read out mode): 0 ... Sensor transmits sensor identification data part 1 1 ... Sensor transmits sensor identification data part 2
	X							Dew point bit. 0 ... Sensor has received dew point Byte 1 and 2 contains NOx signal. 1 ... Sensor is waiting for dew point

								Byte 1 and 2 contains resistance ratio.
X								Mode switch for read out of sensor identification data. For details see NOx sensor specification. 0 = normal sensor operation or sensor self diagnosis mode 1 = sensor identification data read out mode
								Important combinations:
0	0	0	0	0	0	0	0	0 (00H): NOx sensor is not yet active.
0	1	0	0	0	0	0	0	64 (40H): NOx sensor is waiting for dew point.
0	0	0	0	0	0	0	1	1 (01H): NOx sensor can not reach any readiness level because of power supply problem
0	0	0	0	0	0	1	0	2 (02H): NOx sensor readiness is level 1. Temperature is ok.
0	0	0	0	1	1	1	0	14 (0EH): NOx sensor readiness is level 2. Lambda and binary O2 signal are valid.
0	0	0	1	1	1	1	0	30 (1EH): NOx sensor has full readiness. NOx, Lambda and binary O2 signals are valid.
0	0	0	1	1	1	1	1	31 (1FH): NOx sensor has full readiness. All signals are valid. But a power supply problem is present.

[2] The following table describes the meaning of byte "Error status":

Byte: "Error status"								
B7	B6	B5	B4	B3	B2	B1	B0	Function
0	0	0	0	0	0	0	0	NOx sensor no failure
							X	NOx sensor error 1, Open wire at heater
						X		NOx sensor error 2, Open wire at NOx function
					X			NOx sensor error 3, Open wire at Lambda function
				X				NOx sensor error 4, Open wire at binary O2 function
			X					NOx sensor error 5, Short circuit at heater
		X						NOx sensor error 6, Short circuit at NOx function
	X							NOx sensor error 7, Short circuit at Lambda function
X								NOx sensor error 8, Short circuit at binary O2 function

[3] The following table describes the meaning of byte "Diagnosis status":

Byte: "Diagnosis status"	
Value	Function
0 (00H)	Sensor self diagnosis is running
1 (01H)	Sensor self diagnosis was aborted. Sensor is returning to normal operation mode.
2 (02H)	Sensor self diagnosis was completed. Result: "Sensor is ok". Sensor is returning to normal operation mode.
3 (03H)	Sensor self diagnosis was completed. Result: "Sensor is faulty". Sensor is returning to normal operation mode.
other values	Other values are not defined yet.

[4] The following table describes the meaning of byte "Diagnosis signal":

Byte: "Diagnosis status"		Byte: "Diagnosis signal"	
Value	Function	Signal	ECU signal variable name
0 (00H)	Diagnosis runs	Diagnosis reference value	CAN_NOX_REF_NS[i]
1 (01H)	Diagnosis aborted	Diagnosis reference value	CAN_NOX_REF_NS[i]
2 (02H)	Diagnosis completed	Diagnosis value	CAN_NOX_DIAG_NS[i]
3 (03H)	Diagnosis completed	Diagnosis value	CAN_NOX_DIAG_NS[i]
other values	not defined	not defined	not defined

52.4.2.3.1 Selection of NOx sensor configuration

General information:

The EMS system MSD80 is designed for various exhaust gas system configurations (e.g. N43UL – 1 branch system, N43OL – Y system with 1 NOx catalyst, N53 – Y system with 2 NOx catalysts, N53 development samples – full 2 branch system). Hence the adjusted value of NC_NOX_SENS_CONF (number of NOx sensors within the system) does not correspond always correctly with the number of really necessary or really used NOx sensors. Therefore NC_NOX_SENS_CONF is adjusted mostly on 2 NOx sensors even if only 1 NOx sensor is really necessary or really used.

example: MSD80 – N53

1. full 2 branch system with 2 NOx sensors:
   NC_NOX_SENS_CONF has to be adjusted to 2.
2. Y system with 2 NOx catalysts and 1 NOx sensor:
   NC_NOX_SENS_CONF should be adjusted to 1 but is adjusted to 2 because it is the same software like as for full 2 branch system.

So that these different exhaust system configurations can be handled with 1 ECU software it was implemented a functionality for copying of NOx sensor signals from line i = 1 to line i = 2.

Application conditions:

Initialisation: -

Recurrence: 10ms

Activation: after reset

Deactivation: -

Formula section:

```
if    NC_NOX_SENS_CONF = 2
then
        if    LC_NOX_SENS_2 = 0
        then
              CAN_NOX_NOX_SENS_2 = CAN_NOX_NOX_SENS_1
              CAN_LAMB_NOX_SENS_2 = CAN_LAMB_NOX_SENS_1
              CAN_VLS_NOX_SENS_2 = CAN_VLS_NOX_SENS_1
              CAN_STATE_NOX_SENS_2 = CAN_STATE_NOX_SENS_1
              CAN_ERR_NOX_SENS_2 = CAN_ERR_NOX_SENS_1
        else
              CAN_NOX_NOX_SENS_2 = CAN message data from ID=135H
              CAN_LAMB_NOX_SENS_2 = CAN message data from ID=135H
              CAN_VLS_NOX_SENS_2 = CAN message data from ID=135H
              CAN_STATE_NOX_SENS_2 = CAN message data from ID=135H
              CAN_ERR_NOX_SENS_2 = CAN message data from ID=135H
        endif
endif
```

52.7.1 NOx signal offset adaptation

NOx signal offset adaptation can be done at PUC phase. At PUC phase NOx signal is influenced by the humidity cross-sensitivity of NOx-Sensor. The NOx signal is a combination out of signal offset and humidity cross-sensitivity.

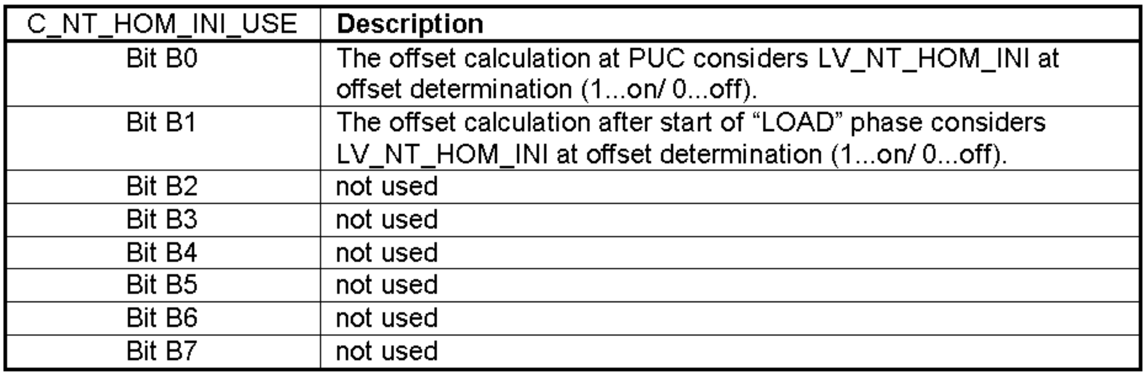
Another possibility for NOx signal offset adaptation is after the start of a new NOx catalyst “LOAD” phase. At this time the NOx catalyst stores the NOx so that the NOx emissions are nearly to 0 [ppm]. Hence the NOx signal is dominated by signal offset. Attention! After an incompletely NOx regeneration or when the NOx catalyst has got a high sulphur load this offset adaptation must be inhibited.

This NOx signal offset adaptation calculates all offset values. Which offset value is used for the NOx signal offset adaptation, is possible to calibrate.

The NOx signal NOX_NS_i is compared with C_NOX_OFS_PUC_MAX before a new adaptation value (NOX_OFS_PUC_i) is calculated. This check is for prevention of adaptation failures.

C_NOX_OFS_PUC_MAX is the sum of the maximum humidity cross-sensitivity and the maximum positive NOx signal offset according to the sensor specification.

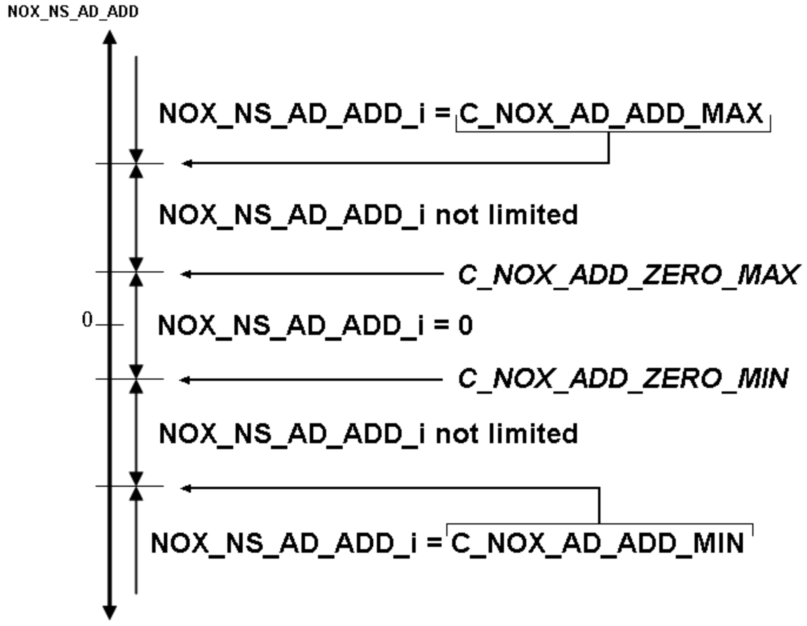
The calibration constant C_NT_HOM_INI_USE is used for independent configuration of “offset calculation at PUC” and of “offset calculation after start of LOAD phase”.



C_NT_HOM_INI_USE	**Description**
Bit B0	The offset calculation at PUC considers LV_NT_HOM_INI at offset determination (1...on/ 0...off).
Bit B1	The offset calculation after start of “LOAD” phase considers LV_NT_HOM_INI at offset determination (1...on/ 0...off).
Bit B2	not used
Bit B3	not used
Bit B4	not used
Bit B5	not used
Bit B6	not used
Bit B7	not used

The final NOx signal offset adaptation value NOX_NS_AD_ADD _i arises out of PUC offset value (NOX_OFS_PUC_i), LOAD offset value (NOX_OFS_LOAD_i) or manual offset value (C_ NOX_NS_AD_ADD_i). The used value is selected by C_NOX_OFS_SEL.

After the calculation of NOX_NS_AD_ADD_i it is limited (see below).



Setting NOX_NS_AD_ADD_i to 0 within the gap C_NOX_ADD_ZERO_MIN < NOX_NS_AD_ADD_i < C_NOX_ADD_ZERO _MAX was implemented in order to switch off the NOx signal offset adaptation if the calculated offset value is within the specified NOx signal tolerance (see NOx-Sensor specification).

NOX_NS_AD_i is the measured signal which is corrected by the signal offset NOX_NS_AD_ADD_i.

The calculation of NOX_NS_AD_i is done with a recurrence, which is in accordance with the NOx catalyst regeneration request calculation.

Additional information:

Suffix "_cur" is an abbreviation of current and means that the value is calculated in the same recurrence not first time.

Suffix "_old" means that this value is calculated last time in previous recurrence.

52.7.2 NOx sensor valid flag after regeneration

After regeneration it is prohibited to generate a new regeneration request by the NOx sensor (LV_RGN_REQ_NOX_SENS_i = 1) if the signal is not valid. This can be triggered by observation of the signal gradient or the time C_T_NOX_SENS_VLD. The gradient has to be permanently within a certain range for a continuous time. The time C_T_NOX_SENS_VLD is controlled by the timer T_AFL. T_AFL has to exceed C_T_NOX_SENS_VLD before regeneration can be requested by the NOx sensor.

FUNCTION DESCRIPTION:

General information:

The NOx sensor has an own Electronic Control Unit (ECU), which monitors the cable connection between sensor element and sensor ECU on electrical faults like open circuits or short circuits. The actual monitoring result/ the actual diagnosis result is cyclic transmitted to the EMS by the CAN messages, which include the sensor measurement signals.

The purpose of this diagnosis is to evaluate the cyclic received sensor ECU diagnosis result. If the sensor ECU reports an electrical fault (OBDI error between sensor element and sensor ECU) then this error is debounced and stored within error memory by use of standard error memory algorithm.

At ERR_SYM_NS_OBD_1_HTP, ERR_SYM_NS_OBD_1_NOX, ERR_SYM_NS_OBD_1_LAMB and ERR_SYM_NS_OBD_1_VLS combinations of error symptoms are possible (0...0x0F).

The following table describes the meaning of NOx sensor status byte:

Remark: The meaning of NOx sensor error byte was copied from NOx sensor specification of sensor manufacturer. If the sensor manufacturer makes a change at sensor error byte meaning, then this specification will not be updated!

NOx sensor error byte: ERR_NS[i]								
B7	B6	B5	B4	B3	B2	B1	B0	Function
0	0	0	0	0	0	0	0	no failure detected
							1	open wire at heater circuit
						1		open wire at NOx circuit

        IN<C_ABC_MAX_NS_OBD_1_LAMB>, OUT<LV_ERR_NS_OBD_1_LAMB[i]>)
```

Binary Lambda circuit failures:

```
if      Bit B3 of ERR_NS[i] = 1
then    ERR_SYM_NS_OBD_1_VLS[i] = set bit SYM_2 of ERR_SYM_NS_OBD_1_VLS[i]
else    ERR_SYM_NS_OBD_1_VLS[i] = reset bit SYM_2 of ERR_SYM_NS_OBD_1_VLS[i]
endif
if      Bit B7 of ERR_NS[i] = 1
then    ERR_SYM_NS_OBD_1_VLS[i] = set bit SYM_3 of ERR_SYM_NS_OBD_1_VLS[i]
else    ERR_SYM_NS_OBD_1_VLS[i] = reset bit SYM_3 of ERR_SYM_NS_OBD_1_VLS[i]
endif
```

For failure and error management treatment the anti-bounce mechanism is called:

```
ACTION_ERRM_FilterSymptom(                              IN<NS_OBD_1_VLS[i]>,
        IN<LV_CDN_DIAG_NS_OBD_1[i]>,         IN<ERR_SYM_NS_OBD_1_VLS[i]>,
        IN<C_ABC_INC_NS_OBD_1_VLS>,                                   IN<1>,
        IN<C_ABC_MAX_NS_OBD_1_VLS>, OUT<LV_ERR_NS_OBD_1_VLS[i]>)
```

Summarise of failures:

```
if    LV_ERR_NS_OBD_1_HTP[i] = 1             OR
      LV_ERR_NS_OBD_1_NOX[i] = 1             OR
      LV_ERR_NS_OBD_1_LAMB[i] = 1            OR
      LV_ERR_NS_OBD_1_VLS[i] = 1
then  LV_ERR_NS_OBD_1[i] = 1
else  LV_ERR_NS_OBD_1[i] = 0
endif
```

52.9 NOx sensor OBDI diagnosis (Application Incidences)

52.9.1 Inhibition of NOx sensor error byte evaluation

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_DIAG_NS_OBD_1[NC_NOX_SENS_CONF]	V/O	0...1H	0...1	1	[-]
Inhibition of NOx sensor OBD I diagnosis					

Input data:

NC_NOX_SENS_CONF	LV_ST_END	LV_CDN_VB_CAN_DIAG	LV_VAR_NOX

FUNCTION DESCRIPTION:

General information:

The flag LV_INH_DIAG_NS_OBD_1[i] allows to inhibit the NOx sensor OBDI diagnosis, which evaluates the NOx sensor error byte.

Application conditions:

Initialisation: at reset, at deactivation:

LV_INH_DIAG_NS_OBD_1[i] = 1

Recurrence: 100ms

Activation: LV_ST_END = 1

Deactivation: LV_ST_END = 0

Formula section:

```
if    (NOx message has not been received via LOCAN at least for once - LV_VAR_NOX)
      LV_VAR_NOX = 0                                    OR
      ~~LV_ERR_NS_CAN_BOFF = 1                            OR~~
      LV_CDN_VB_CAN_DIAG = 0
then  LV_INH_DIAG_NS_OBD_1[i] = 1
else  LV_INH_DIAG_NS_OBD_1[i] = 0
endif
```

Shift diagnosis will be inhibited if cat diagnosis is active					

General information:

Each type of OBDII diagnosis will be inhibited, if any used input signal is not valid. Additionally, each diagnosis may be enabled or disabled without any cross dependencies.

The calculation have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

Application conditions:

Initialisation: at reset:

FAC_PV_GRD_ABSV_INT = 0
PV_AV_OLD_AVL = 0
T_LAMB_LS_UP_NOT_VLD[k] = 0 *k = 1...NC_CBK_EX_NR*

Recurrence: 10 ms

Activation:

Deactivation:

Formula section:

FAC_PV_GRD_ABSV_INT = FAC_PV_GRD_ABSV_INT
+ 16 * ABS(PV_AV - PV_AV_OLD_AVL)
- C_FAC_PV_GRD_ABSV_INT_DEC

PV_AV_OLD_AVL = PV_AV

The values PV_AV and PV_AV_OLD_AVL should be normalized to the resolution, which results in an easy addition of the hex values.

For each lambda sensor: k **= 1...NC_CBK_EX_NR**

```
If      LV_LAMB_LS_UP_VLD[k]
Then    T_LAMB_LS_UP_NOT_VLD[k] = 0
Else    increment T_LAMB_LS_UP_NOT_VLD[k]          10ms
Endif
```

52.11.1 General information

This module consists a limited dynamics evaluation for the NOx sensor and the global NOx sensor OBD II error flag.

The reset strategy of this error bit LV_ERR_NS_OBD_2_i can be selected by C_ERR_RST_NS_OBD_2_i. It can be chosen between following possibilities for error bit reset:

- reset only at clear of error memory
- reset at every start of new driving cycle
- manual reset, permanent reset.

Application Condition

52.11.1.2 Management of non volatile memory

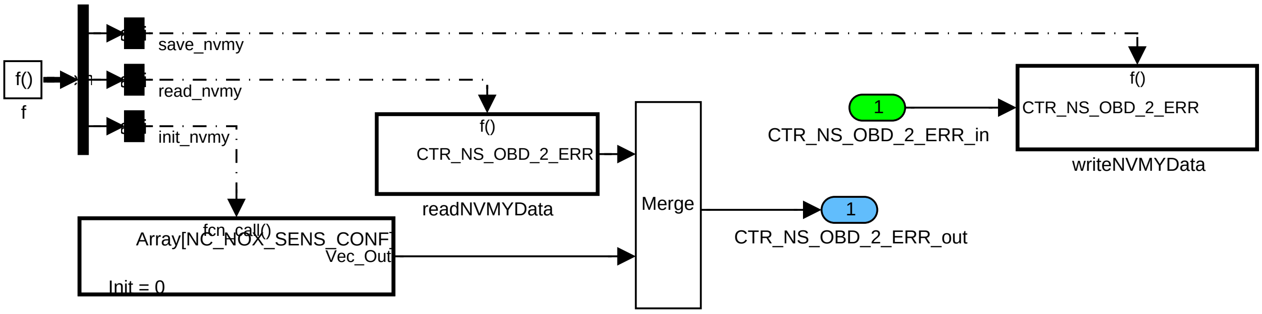

Figure 46 NOXD_MODULB07G/ NVMY

52.11.1.3 Loop control 100 ms

The calculation inside FOR_LOOP_LS have to be done for each upstream lambda sensor, controlled by configuration data NC_CBK_EX_NR.

If NC_CBK_EX_NR = 1, then calculation for i = 1.

If NC_CBK_EX_NR = 2, then calculation for i = 1 and 2.

The calculation inside NO_LOOP have to be done only once.

The calculation inside FOR_LOOP_NS have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

NC_NOX_SENS_CONF cannot be greater than NC_CBK_EX_NR.

Calculation for each NOx sensor

Evaluation of limited dynamics

The dynamic is limited if several conditions are valid for a longer time, controlled by the MAF integral.

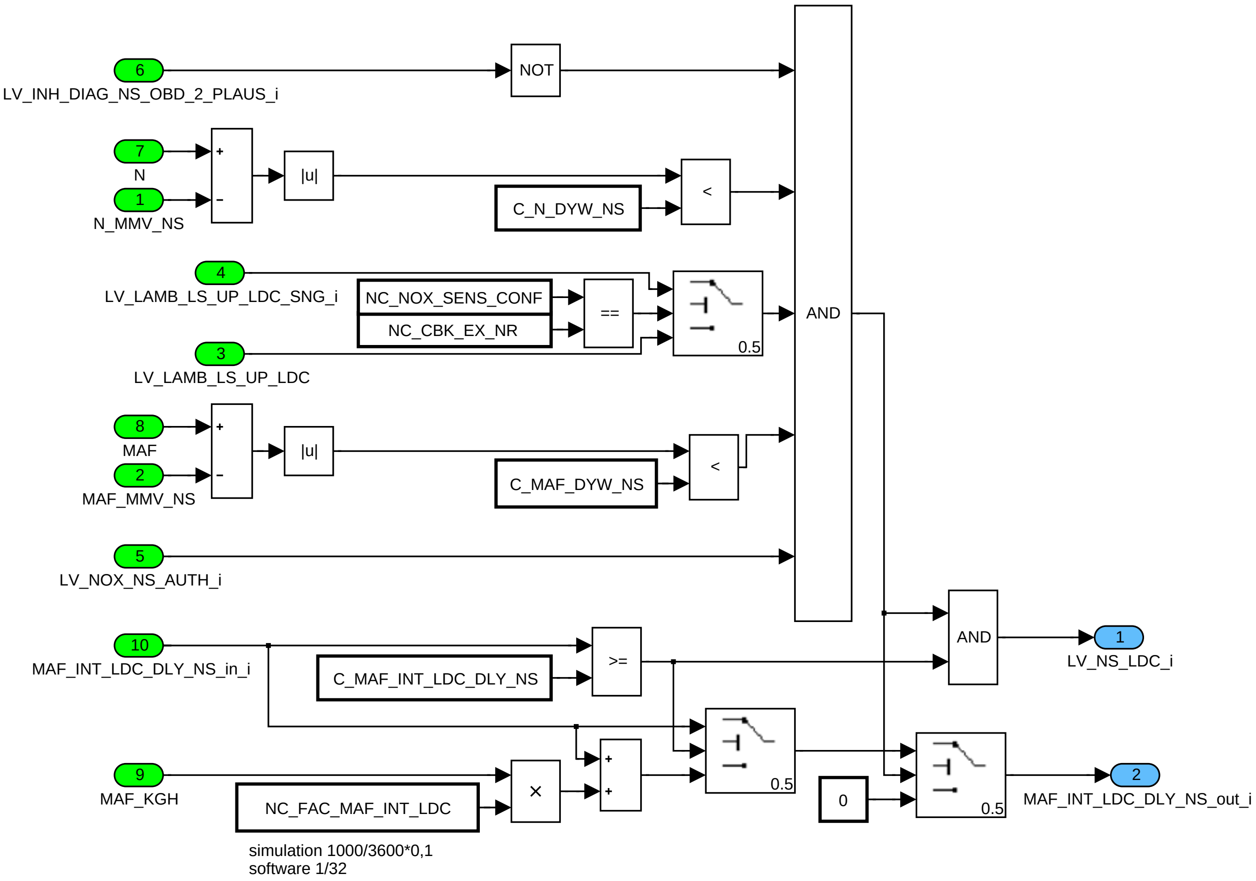

Figure 53 NOXD_MODULB07G/ OPM_100MS/ FOR_LOOP_NS/ CLC1

Collection of error information of all OBD II diagnosis types

The results of all diagnosis types will be collected in two status variables.

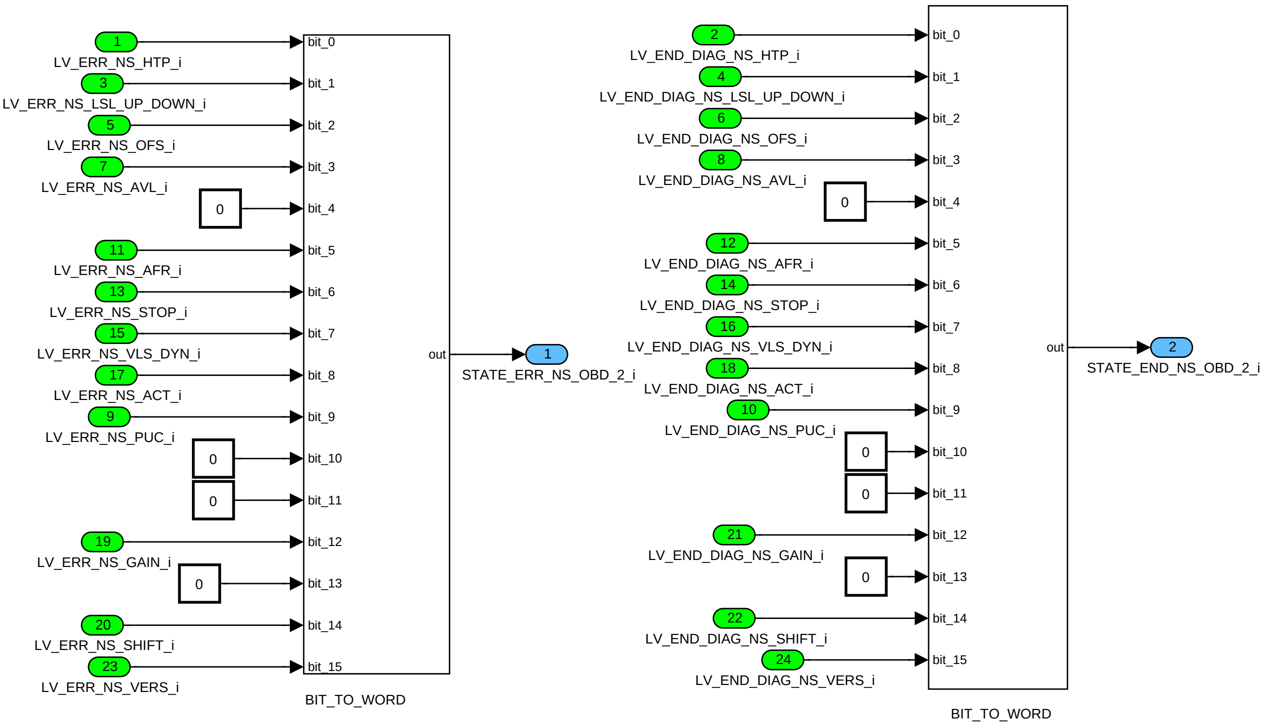

Figure 54 NOXD_MODULB07G/ OPM_100MS/ FOR_LOOP_NS/ CLC2

Global OBD II error bit

If any diagnosis detects an error, then the global error bit will be set.

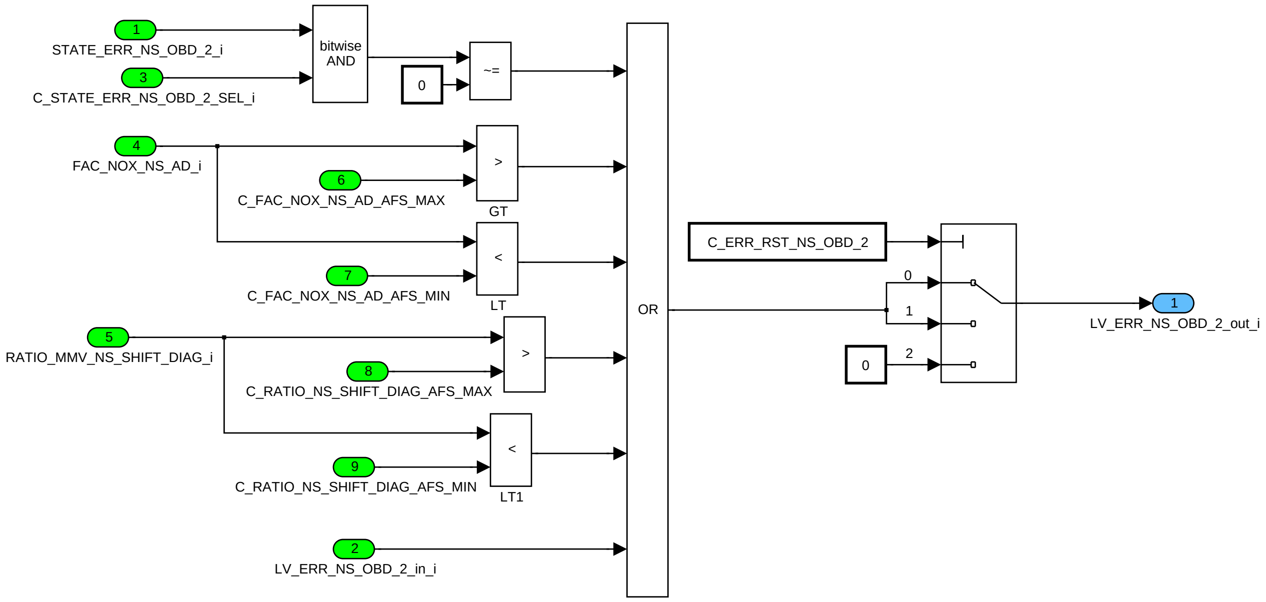

Figure 55 NOXD_MODULB07G/ OPM_100MS/ FOR_LOOP_NS/ CLC3

52.11.1.4 Loop control at engine run to engine stop

The calculation inside FOR_LOOP_NS have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

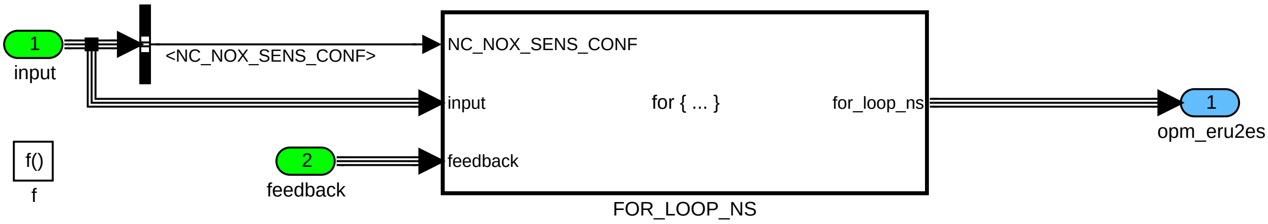

Figure 56 NOXD_MODULB07G/ OPM_ERU2ES

Error counter

For each NOx sensor a counter will be incremented if any OBD II error was detected or decremented if all selected end of OBD II diagnosis signals are valid. This is only done once at the end of the driving cycle. This selection will be done with the bit mask C_ERR_NS_OBD_2_BIT_SEL_i.

This action computes the elementary anti-bounce filter
ACTION_ERRM_GetLvEndDiag(IN <IDX_DIAG>, OUT <LV_END_DIAG>)
Action that returns the diagnosis end information
ACTION_ERRM_GetLvErr(IN <IDX_DIAG>, OUT <LV_ERR>)
Action that returns the status of the debounced failure

52.12.1 General information

If the sensor is OK, then the diagnosis state machine is in the state PASSIVE, see next picture. If the temperature of the sensor is not OK, then a diagnosis will be made inside state ACTIVE. If the power supply is not OK, then a diagnosis will be made inside state POWER.

Additionally, at start-up a diagnosis of the sensor temperature behaviour will be made inside state START.

Action that returns the status of the debounced failure

52.13.1 General information

This diagnosis observes the availability of NOx signal after the start and during the “LOAD” phases of NOx catalyst. This function shall detect when the NOx sensor is not able to transmit valid signals because of controller problems such as oscillations.

In normal operation mode the diagnosis is in state ACTIVE if suitable lean conditions are reached, otherwise the state PASSIVE is set. Inside ACTIVE the signal LV_NOX_NS_DIAG_VLD_i will be observed by a statistical method.

At the start-up the diagnosis observes the time which the sensor needs in order to reach the full readiness. This is necessary in order to detect NOx sensors with instable control loops. It will be done inside the state START.

52.14.1 General information

This signal plausibility check compares the upstream oxygen signal (WRAF sensor) with the WRAF signal of NOx-Sensor, which is downstream of NOx catalyst. The result of this check can indicate a strong discrepancy between the two sensors, which can be caused by reference air contamination.

Application Condition

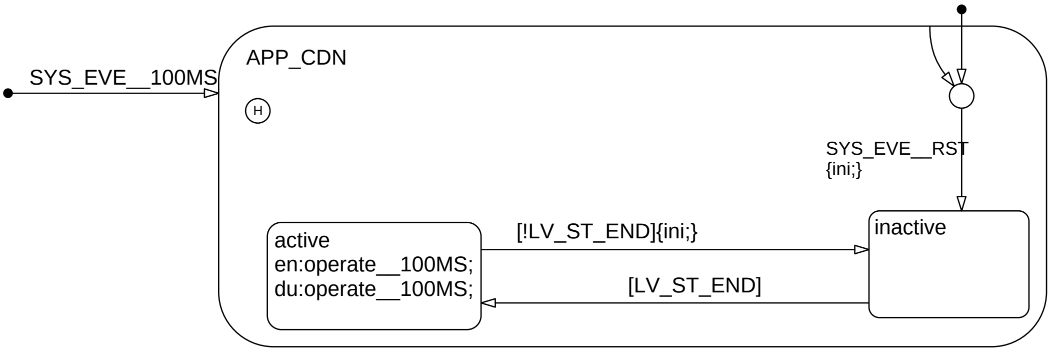

Figure 89 NOXD_MODULB07X/ APP_CDN/ Chart

Calculation for each upstream lambda sensor

Lambda sensor lean check

Linear as well as binary lambda sensors of a bank will be checked if PUC is active.

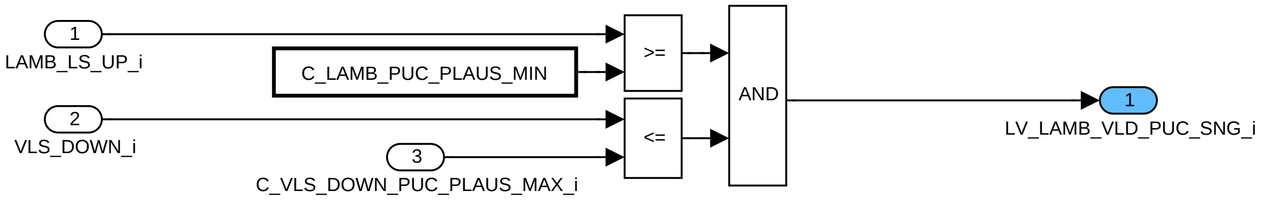

Figure 106 NOXD_MODULB07Y/ OPM_100MS/ FOR_LOOP_LS/ CLC

Bank independent calculation

The signal shows that all lambda sensors of all banks measures lean exhaust gas due to PUC.

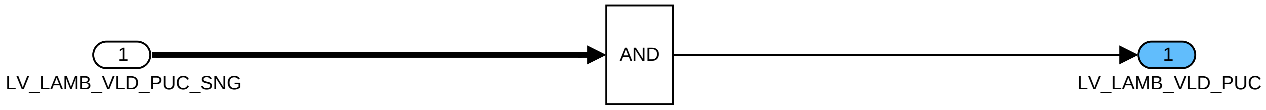

Figure 107 NOXD_MODULB07Y/ OPM_100MS/ NO_LOOP/ CLC

Calculation for each NOx sensor

Activation of diagnosis

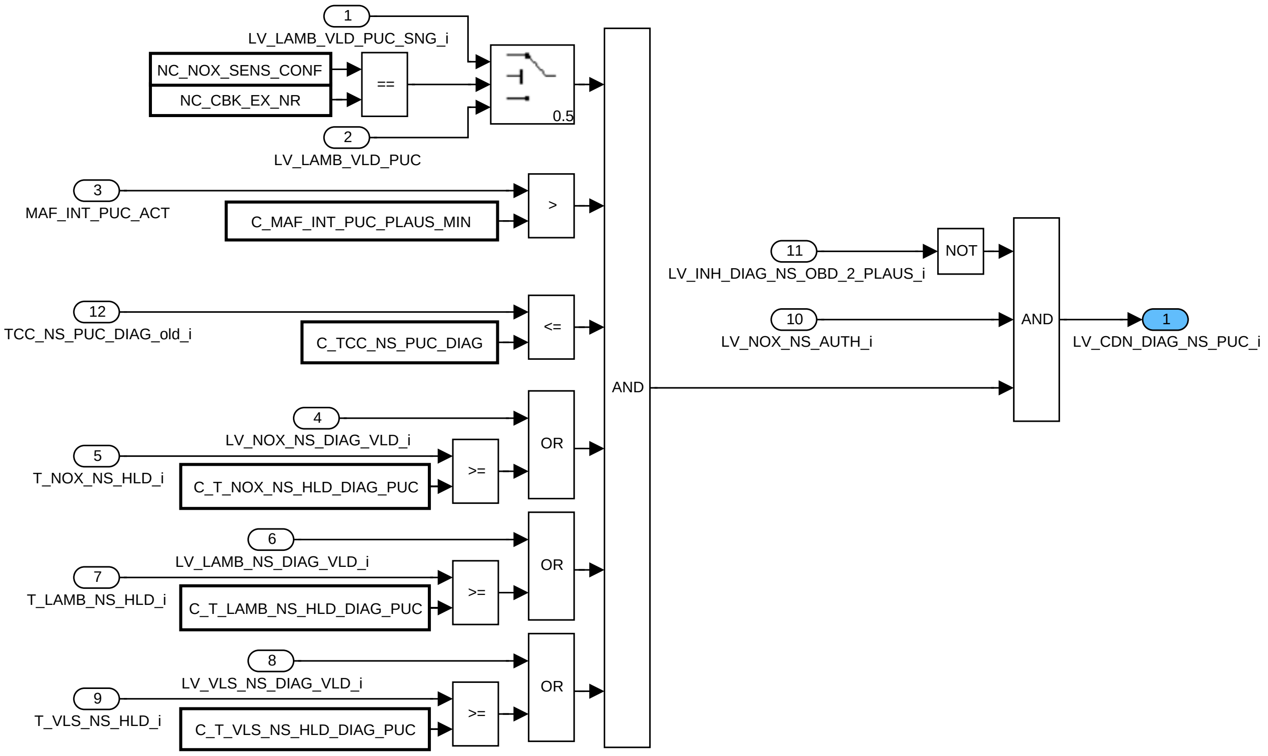

Figure 108 NOXD_MODULB07Y/ OPM_100MS/ FOR_LOOP_NS/ CLC1

Plausibility check counter

At every PUC phase the number of plausibility checks is counted with this counter and limited with C_TCC_NS_PUC_DIAG.

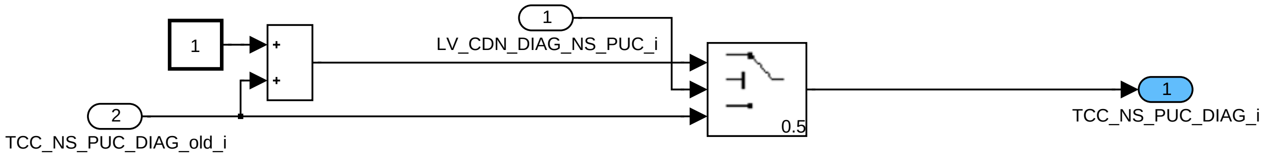

Figure 109 NOXD_MODULB07Y/ OPM_100MS/ FOR_LOOP_NS/ CLC2

Signal diagnosis

Both lambda signals of the NOx sensor will be compared with a threshould.

The NOx signal will be checked with a range.

If the signal is higher than the top limit, then a special check have to be done. The reason is a NOx loading of NOx storage catalyst at start of 'pull fuel cut-off' phase and the fact that the NOx catalyst loses a part of its stored NOx at 'pull fuel cut-off'. Hence a NOx signal, which is higher than the diagnosis threshold at 'pull fuel cut-off' diagnosis time, shall be interpreted as sensor failure only if the NOx loading of NOx catalyst is low at start of 'pull fuel cut-off' diagnosis time.

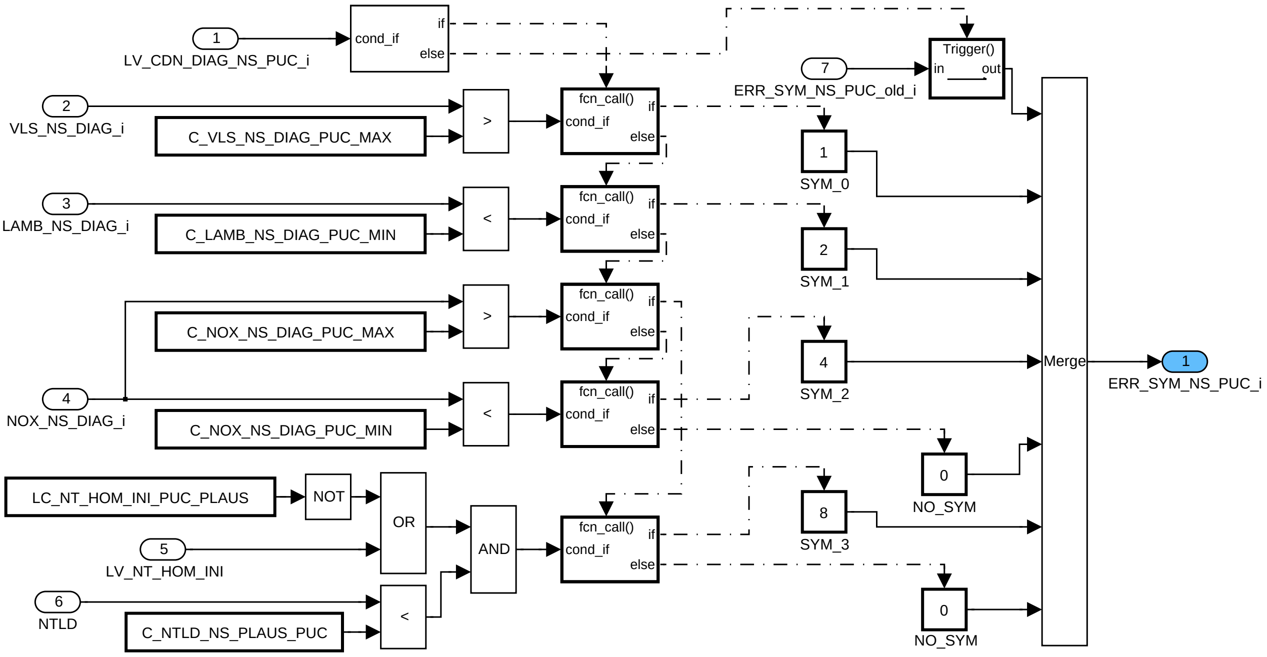

Figure 110 NOXD_MODULB07Y/ OPM_100MS/ FOR_LOOP_NS/ CLC3

Error management

52.16.1.2 Loop control

The calculation inside FOR_LOOP_LS have to be done for each upstream lambda sensor, controlled by configuration data NC_CBK_EX_NR.

If NC_CBK_EX_NR = 1, then calculation for i = 1.

If NC_CBK_EX_NR = 2, then calculation for i = 1 and 2.

The calculation inside both NO_LOOP subsystems have to be done only once.

The calculation inside FOR_LOOP_NS have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

NC_NOX_SENS_CONF cannot be greater than NC_CBK_EX_NR.

Calculation for each NOx sensor

MAF integral and plausibility check counter

At every rich phase the number of plausibility checks will be counted with this counter and limited with C_MAF_INT_AFR_DIAG_MIN.

The MAF integral will start if the upstream lambda becomes higher than the rich threshould due to identify, when the rich exhaust gas should be arrived at the NOx sensor.

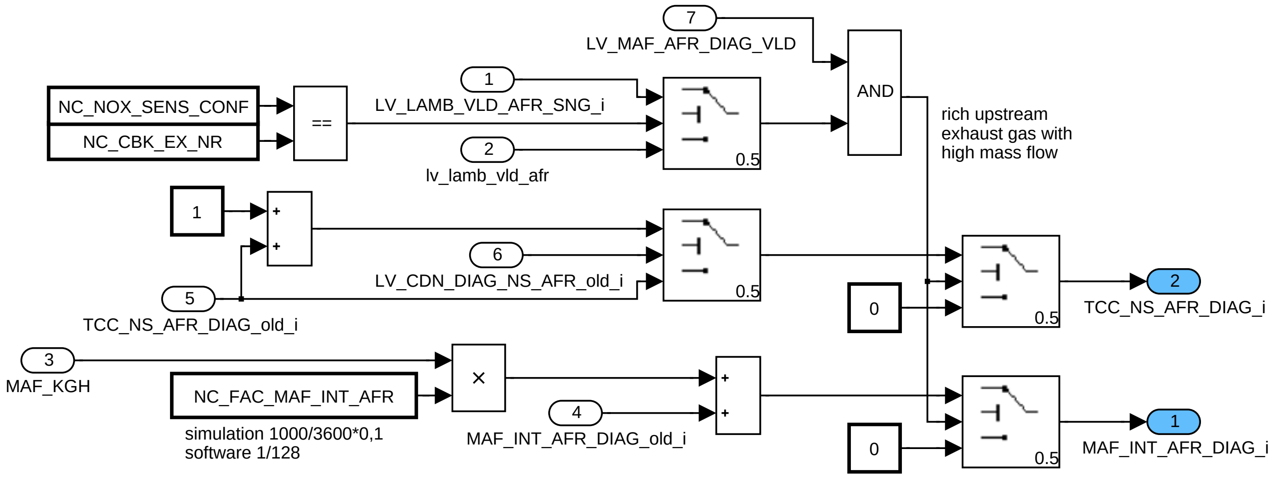

Figure 120 NOXD_MODULB07Z/ OPM_100MS/ FOR_LOOP_NS/ CLC1

Diagnosis evaluation

The NOx sensor may only be identified as defect if the lambda control adaptation is inside the desired range. Outside this range the sensor may only be identified as OK.

The check of the NOx threshould C_NOX_NS_DIAG_AFR_MIN uses the NOx sensor cross sensitivity on NH3, which is originate in the catalyst at rich exhaust gas conditions.

Application hint: The constant C_MAF_INT_AFR_DIAG_MIN shall be calibrated so that this diagnosis is not activated during a NOx catalyst regeneration.

52.17.1 General description

This diagnosis observes the Lambda signal of NOx sensor, which was selected to stop a NOx catalyst regeneration. The signal is checked on its capability to stop a NOx catalyst regeneration. It is possible that the signal can not exceed the NOx catalyst regeneration stop threshold because of sensor aging or a defect. In this case the regeneration is stopped by a time limit. If this problem is present then it is not possible to fulfil the emission regulations. Then it is necessary to inhibit the engine lean burn operation mode and to mark the NOx sensor as “defect”.

Main part of diagnosis

Start of regeneration stop observation

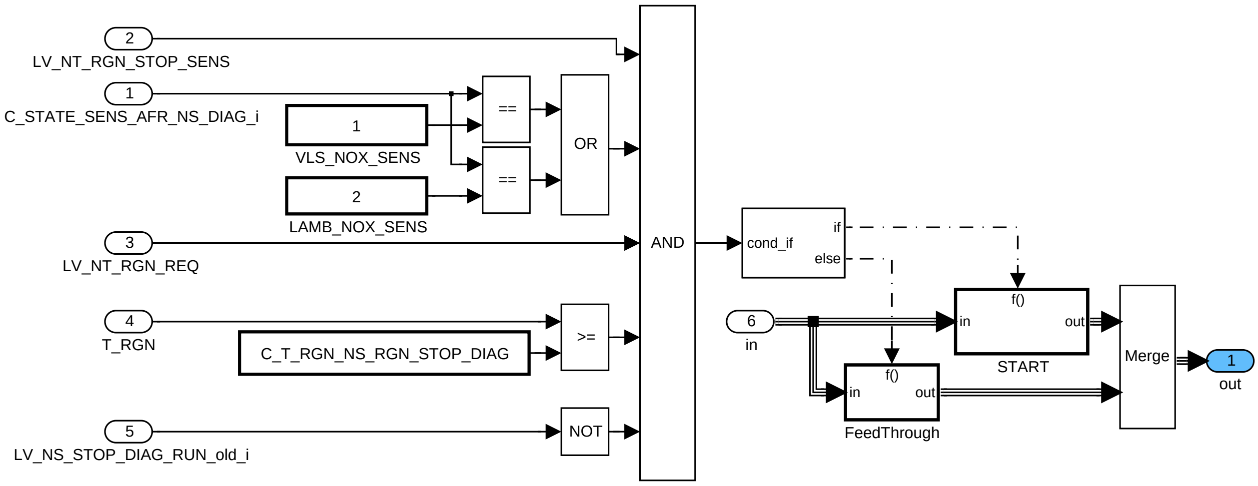

Figure 130 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC1

The diagnosis threshold (maximum necessary amount of regeneration agent) NTL_DEC_INT_THD_i is calculated by the absolute NOx and O2 loading of NOx catalyst at start of regeneration NTL_RGN_ST and a safety factor. The safety factor depends on the mean NOx catalyst monolith temperature in order to consider the NOx storage capability of catalyst.

Additionally the temperature difference between first and second NOx catalyst monolith is determined at the start of regeneration. If this temperature threshold is higher than the threshold C_TNT_MDL_DIF_MAX then regeneration agent diagnosis is inhibited because the NOx catalyst regeneration behaviour is not exactly predictable.

At the first regeneration (after warm up of catalyst) NTL_RGN_ST is about 0. Then the default diagnosis threshold C_NTL_DEC_INT_DFT_THD is used.

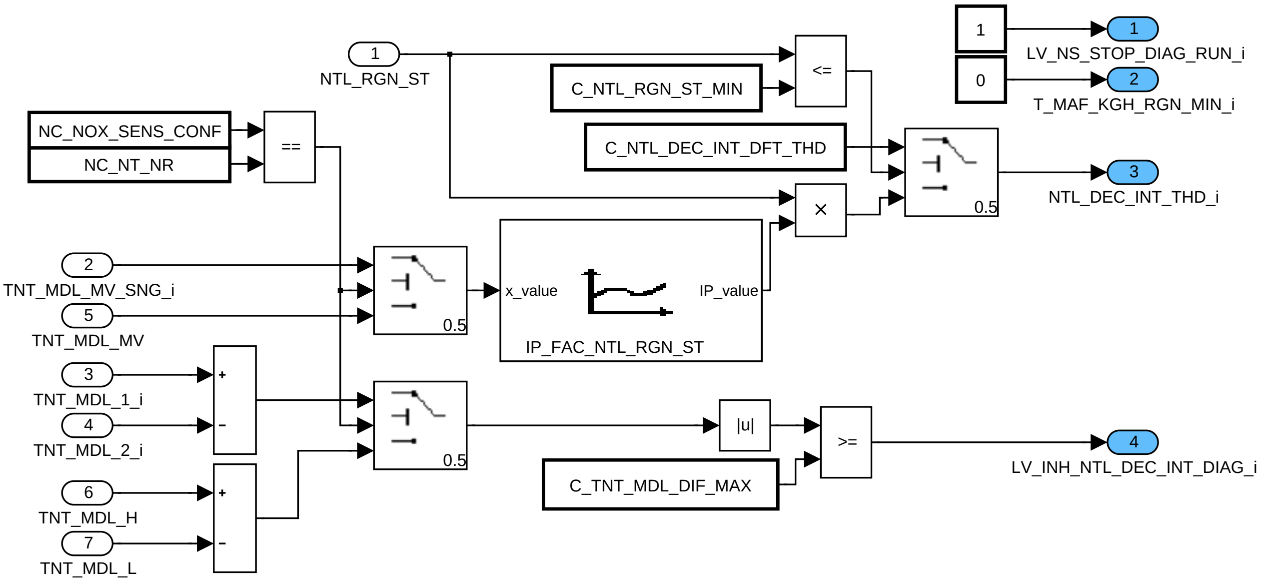

Figure 131 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC1/ START/ CLC

Observation of regeneration agent integral during regeneration

The system knows the absolute loading of NOx catalyst with NOx and O2. On this base it is possible to determine the necessary amount of regeneration agent. When this amount of regeneration agent was transferred to the NOx catalyst then the NOx catalyst shall be cleared from NOx and O2. Now the sensor signal must stop the NOx regeneration by exceeding of regeneration stop threshold. Otherwise the sensor signal is wrong.

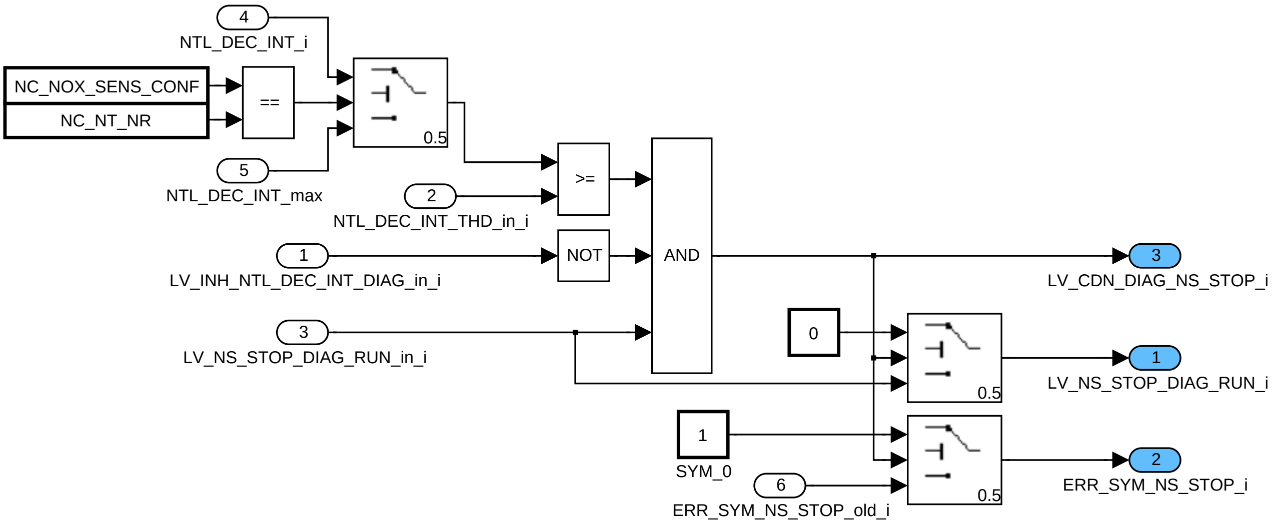

Figure 132 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC2

Observation of air flow and lambda during regeneration

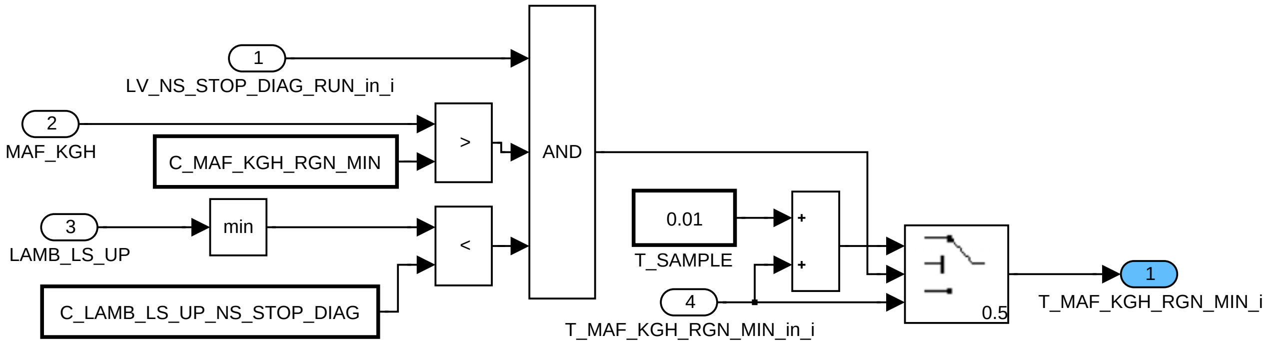

Figure 133 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC3

Detection of regeneration stop

The NOx catalyst regeneration stop can be caused by

- rich exhaust gas, which is detected by a sensor based lambda signal
- NOx catalyst model
- maximum regeneration duration (time out).

The NOx catalyst management indicates the regeneration stop method by the bits LV_SENS_AFR_i (sensor stop), LV_NT_MDL_AFR (catalyst model) and LV_T_OUT_AFR (time out). This bits are used to observe the lambda signals of NOx sensor on its capability to stop a NOx catalyst regeneration.

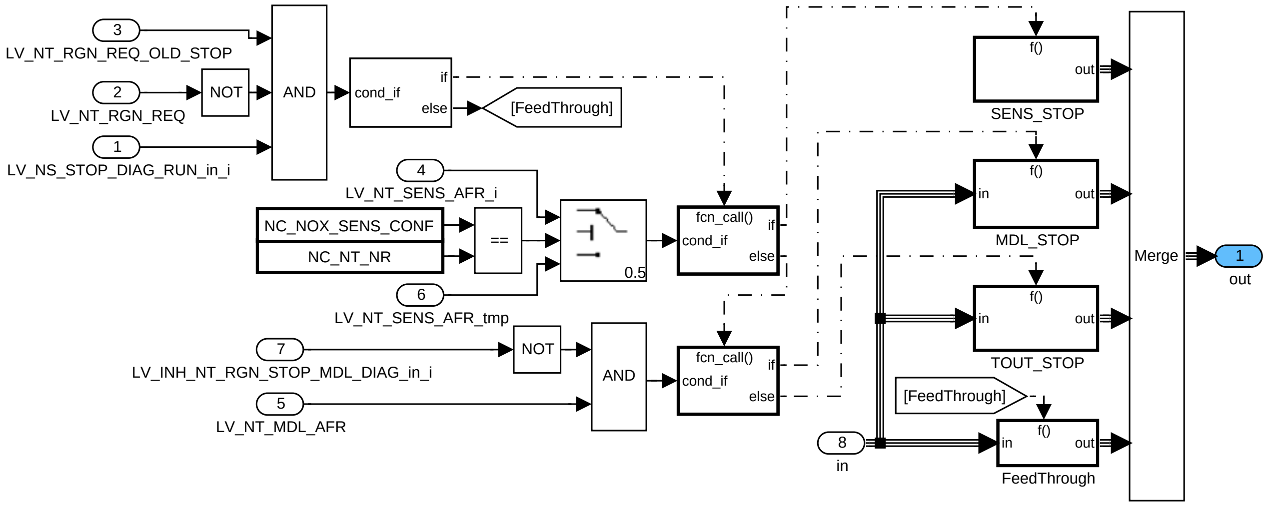

Figure 134 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC4

Regeneration stop by sensor

Normally the NOx catalyst regeneration is stopped by a sensor signal. Then the sensor is classified as OK.

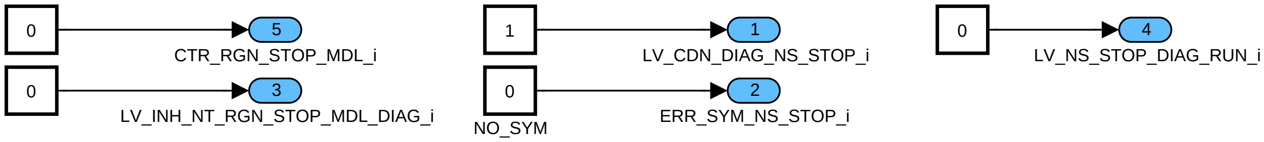

Figure 135 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC4/ SENS_STOP/ CLC

Regeneration stop by model

If the regeneration was stopped by the NOx catalyst model, then it is not possible to classify the sensor as OK or defect. Hence the number of successive regenerations, which are stopped by model, is determined by CTR_RGN_STOP_MDL_i. If CTR_RGN_STOP_MDL_i exceeds a threshold then the regeneration stop by model is inhibited by set of LV_INH_NT_RGN_STOP_MDL_DIAG_i. Now the next regeneration can be stopped only by sensor (LV_SENS_AFR_i) or by time out (LV_T_OUT_AFR). If the next regeneration is stopped by sensor then the sensor is OK. Remark: In this case the calibration values and/ or adaptation values of model should be checked.

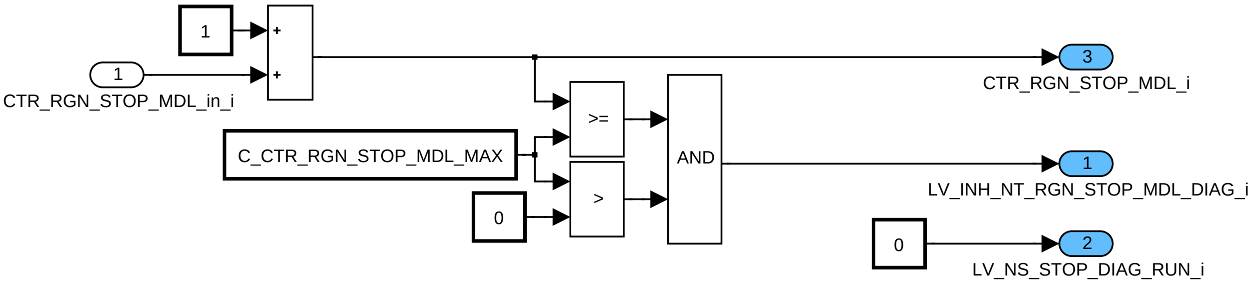

Figure 136 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC4/ MDL_STOP/ CLC

Regeneration stop by time out

If the regeneration is stopped by time out then the sensor is not able to stop the regeneration (sensor is defect) or the calibration of maximum regeneration duration is to short. Especially regenerations with a low air flow (idle speed) are critical. Hence the mass air flow is observed during the regenerations. The observation measures the time at which the mass air flow is higher than the threshold C_MAF_KGH_RGN_MIN. If a regeneration time out is reached now then it is checked the duration at which the mass air flow was higher than the threshold C_MAF_KGH_RGN_MIN. When the regeneration duration with a sufficient mass air flow is lower than C_T_MAF_KGH_MIN then this signal diagnosis is inhibited, the failure counter is not incremented. When the regeneration duration with a sufficient mass air flow is higher than C_T_MAF_KGH_MIN then the sensor is classified as defect and the failure counter is incremented.

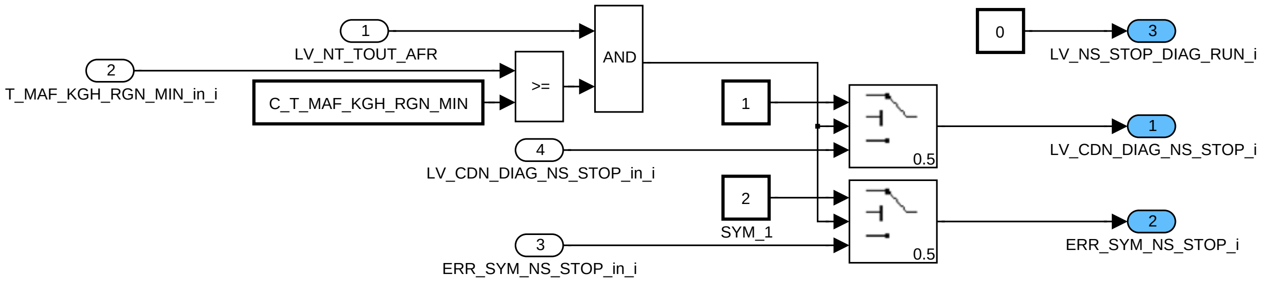

Figure 137 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC4/ TOUT_STOP/ CLC

Lambda 1 operation

It is possible that the Lambda signals of NOx-Sensor exceeds the regeneration stop threshold at homogeneous Lambda = 1.0 engine operation. This fact is used to classify the sensor as OK.

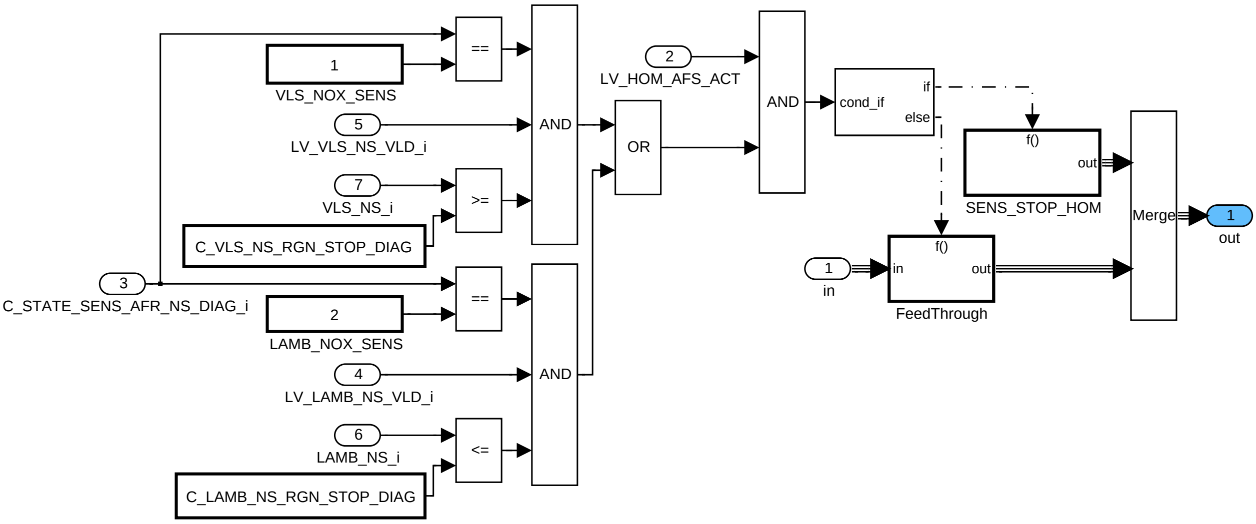

Figure 138 NOXD_MODULB080/ OPM_10MS/ FOR_LOOP_NS/ CLC/ MAIN/ CLC5

Description for Actions

ACTION_NOXD_CleanNSShiftAdapt()
Initialization of NOx signal shift diagnosis values

ACTION_NOXD_EndNNShiftDiag()
Manual end of the NOx signal Shift Diagnosis

ACTION_NOXD_StartNNShiftDiag()
Manual initialization of the NOx signal Shift Diagnosis

ACTION_NOXD_WriteNSShiftDiagExtAdj()
Write external adjust values for NOx Sensor shift diagnosis

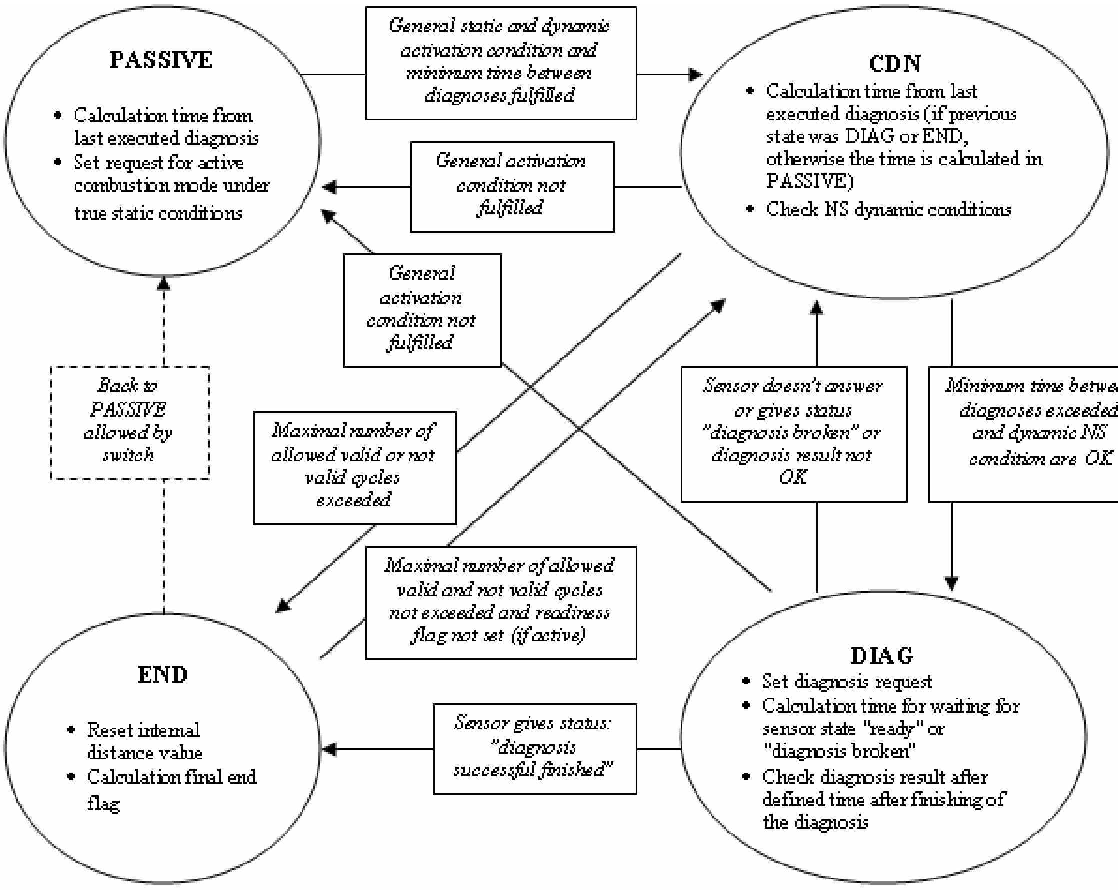
General Information

Introduction of NOx signal internal setpoint shift diagnosis.
When activation conditions are fulfilled, then a request for the NOx signal shift is generated. In this case, via modification of NOx sensor internal signals the diagnosis is executed. After the NOx sensor delivered it status, the diagnosis is either finished or paused, depending on allowed length.

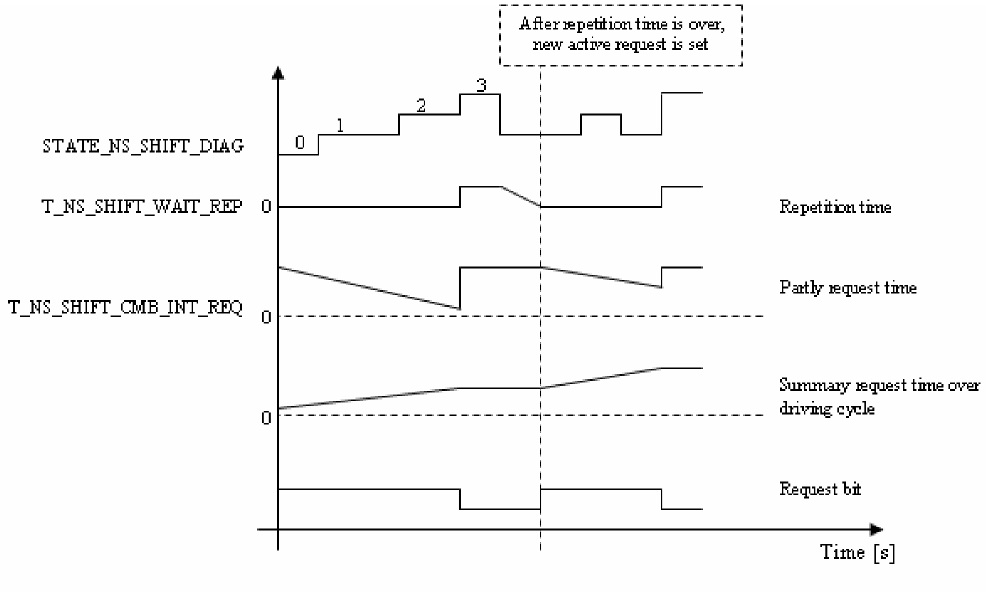
Description of the STATE_NS_SHIFT_DIAG actions:
PASSIVE: check of activation condition, especially combustion state
CDN: if the combustion conditions are fulfilled, switch to DIAG state is done after minimum time between two diagnoses. In case of executed maximum of valid or not valid diagnoses, switch to END state is done.
DIAG: if the combustion conditions are fulfilled, request for the diagnosis is sent to the NOx sensor. If the sensor doesn't confirm it readiness, transition to the CDN is performed and counter for not valid cycle calculated. In case of valid diagnosis cycle, transition to the END state is done

END: if maximum number of not valid or valid diagnoses is not exceeded, transition to the CDN state is done. In all other cases (except manual switch), no any transition is done and the diagnosis is finally finished

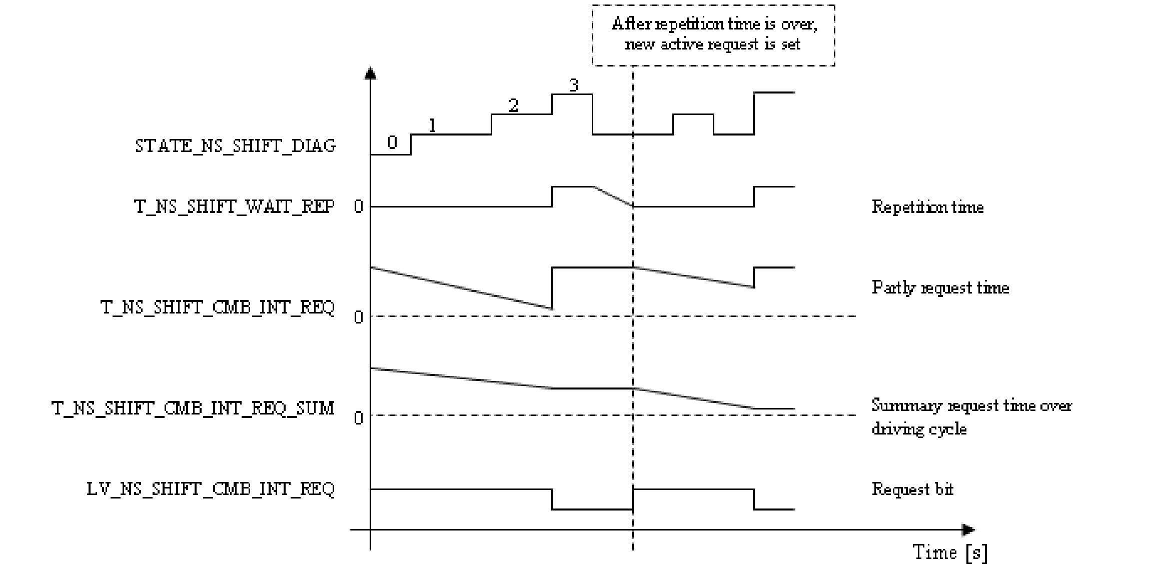
Short overview of states:



Short overview of valid and not valid counters:



Short overview of timers:



Application Conditions

Initialization: RST, NVMINI, NVMRES, NVMSTO
Recurrence: 100MS
Activation: always
Deactivation: never

Description for Actions

ACTION_NOXD_CleanMMVNSAdapt()
Initialization of NOx signal shift MMV diagnosis values

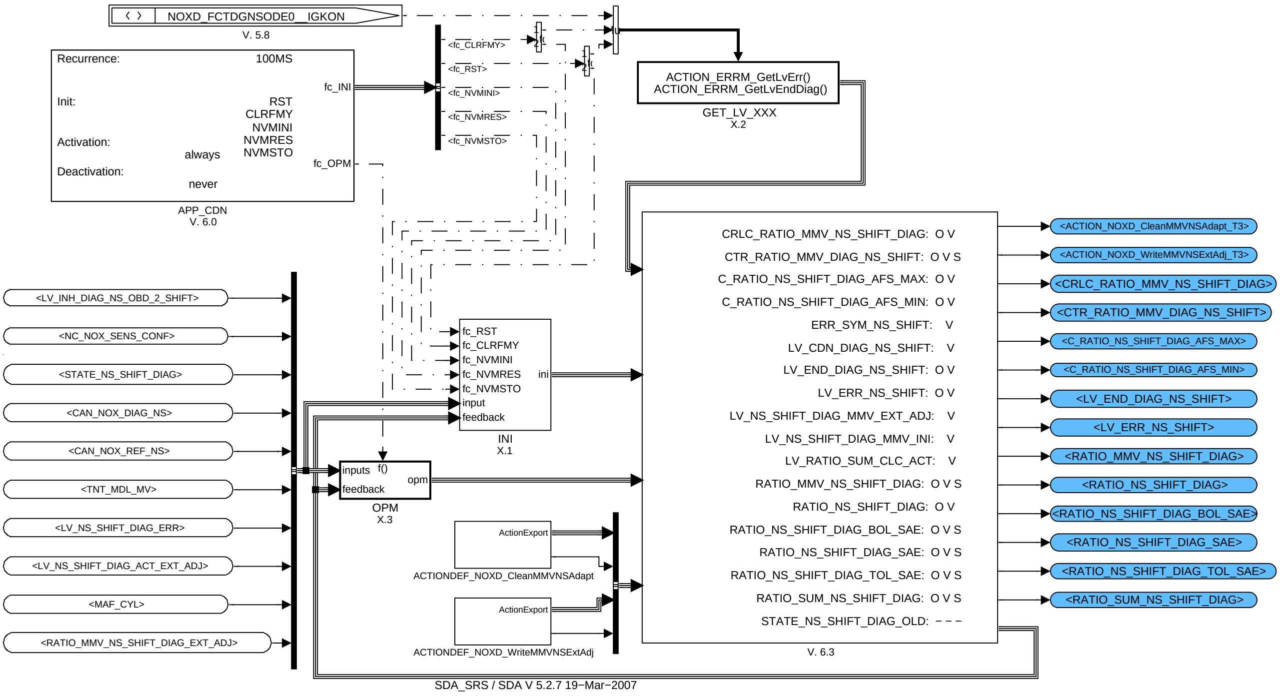
ACTION_NOXD_WriteMMVNSExtAdj()
Write external adjustment values to NOx signal shift MMV diagnosis values

General Information

Application Conditions

Initialization: RST, CLRFMY, NVMINI, NVMRES, NVMSTO
Recurrence: 100MS
Activation: always
Deactivation: never

Function description



SDA_SRS / SDA V 5.2.7 19−Mar−2007

Figure 199:

52.20.1 Initialization and Management of nonvolatile memory

52.20.1.1 Initialization at Reset

The old values will be initialized with the regarding inputs, due to avoid an edge detection after reset.

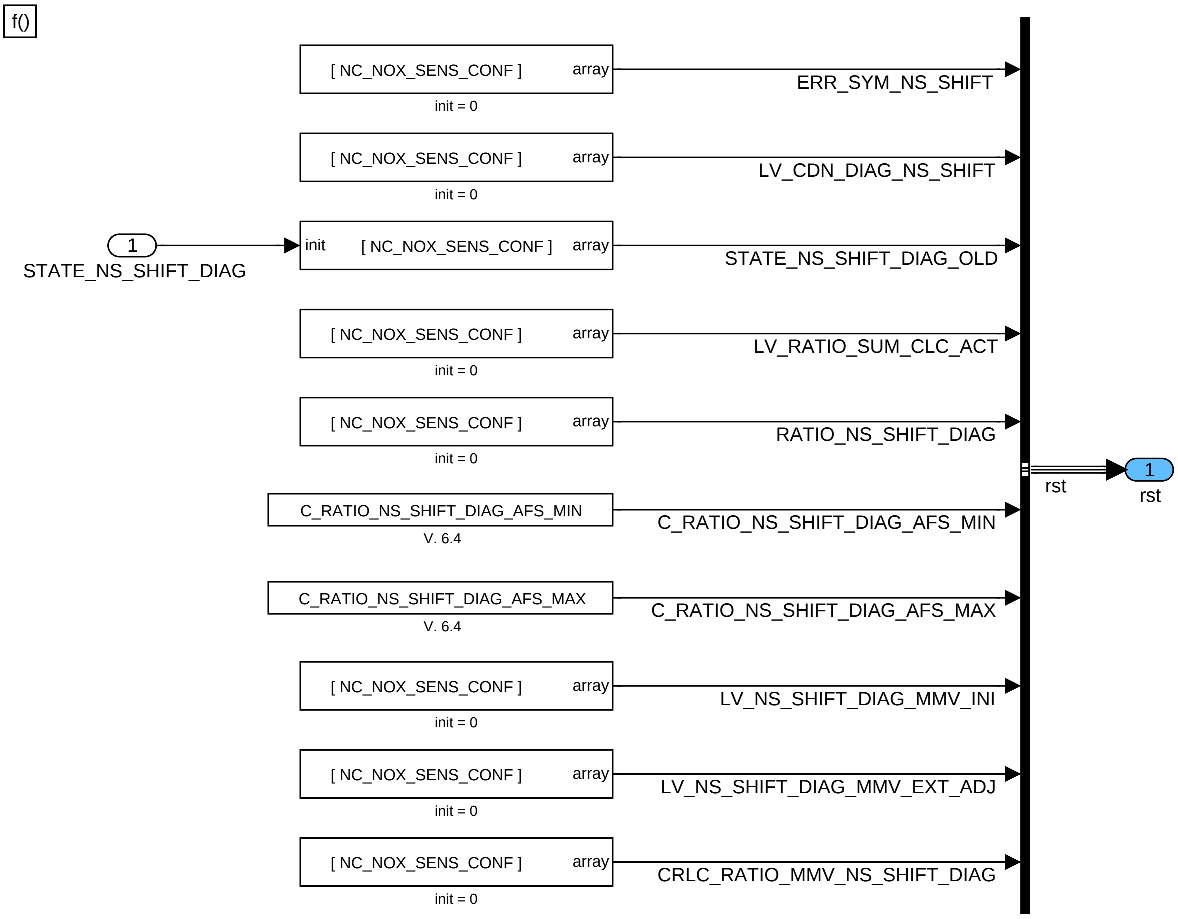


Figure 200:

52.20.1.2 Initialization of NVMY variables

All Mode 6 values will be stored in the nonvolatile memory. The values will be reset to zero, if failure memory will be cleared.

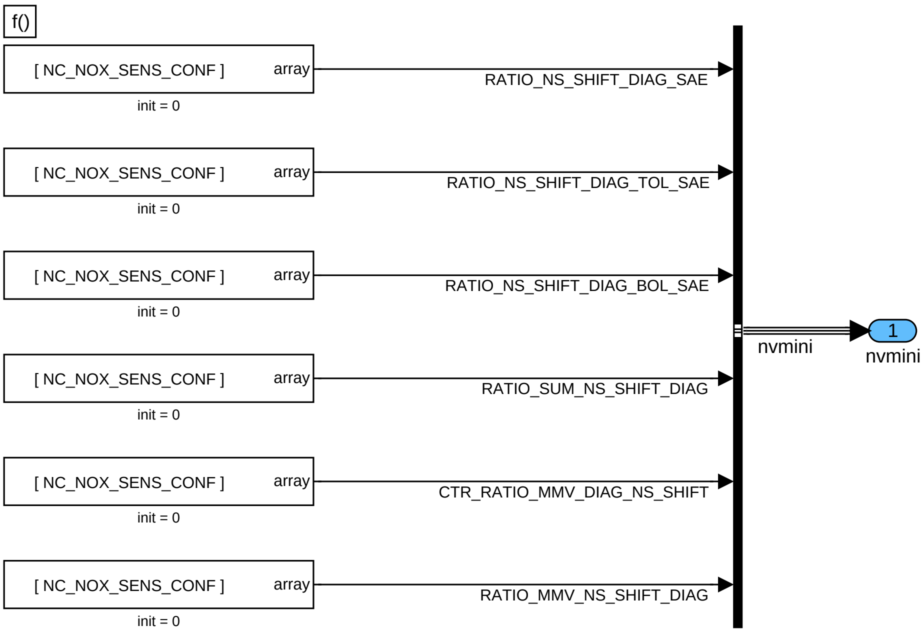

Figure 201:

52.20.1.3 Actions at clear fault memory

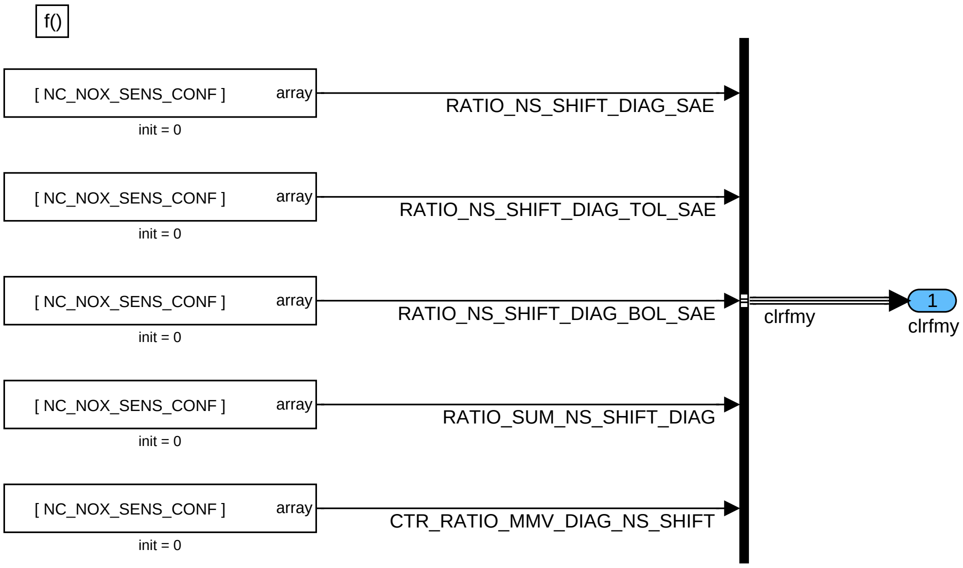

Figure 202:

52.20.2 Synchronization of the LV_ERR_NS_SHIFT and LV_END_DIAG_NS_SHIFT

Synchronisation between LV_ERR_NS_SHIFT and its result from ERRM is done using action ACTION_ERRM_GetLvErr() similarly synchronisation between LV_END_DIAG_NS_SHIFT and its result from ERRM is done using action ACTION_ERRM_GetLvEndDiag()at RESET ,IGKON and CLRFMY events.

52.20.3 Operation at 100MS

switch for request of NOx Sensor version check diagnosis value					

General Information

This is evaluation of NOx sensor software version. In case of too less version, an error shall be generated.
Meaning of states:

PAS passive state, no actions are executed
REQ request for NOx sensor software version
CHK check of the NOx sensor software version and calculation of diagnosis values
END diagnosis finished

Application Conditions

Initialization: RST, CLRFMY, NVMINI, NVMRES, NVMSTO
Recurrence: 100MS
Activation: LV_DC==1
Deactivation: LV_DC==0

52.22.1 General information

This diagnosis checks the NOx signal behaviour after the start of a NOx catalyst “LOAD” phase. The use of NOx signal for generation of a NOx catalyst regeneration request is blocked for a limited time after the start of a NOx catalyst “LOAD” phase. This is necessary because of NH3 cross sensitivity of sensor. This cross sensitivity pushes up the NOx signal up to the upper limit at the end of a NOx catalyst regeneration. Hence the sensor needs a recovery time after the start of next NOx catalyst “LOAD” phase. During this recovery time the NOx signal must go to a level which is lower than the threshold for start of a new regeneration. Otherwise it is a sensor failure present.

Application Condition

52.22.1.2 Initialization

These actions initialized the diagnostic data according filtering configuration :

ACTION_ERRM_GetLvErr(IN<NC_IDX_DIAG_XX>, OUT< LV_ERR_XX >)

ACTION_ERRM_GetLvEndDiag(IN<NC_IDX_DIAG_XX>, OUT< LV_END_DIAG_XX >)

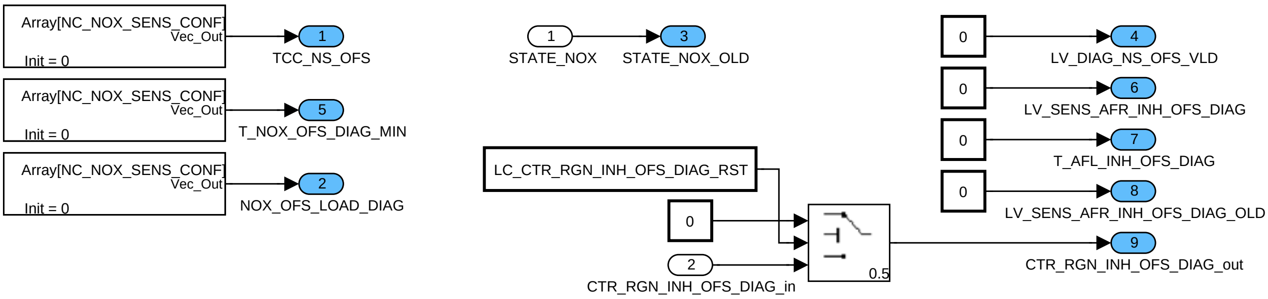

Figure 230 NOXD_MODULB07D/ INI/ CLC

52.22.1.3 Loop control

The calculation inside FOR_LOOP_NS have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

The calculation inside NO_LOOP have to be done only once.

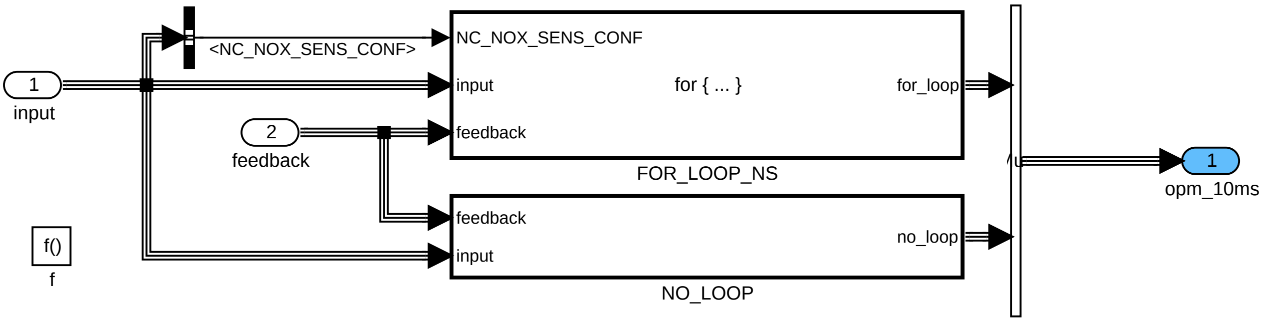

Figure 231 NOXD_MODULB07D/ OPM_10MS

Calculation for each NOx sensor

Minimum search

The minimum of the selected NOx signal during the load phase will be calculated.

NOX_NS_AD:

The signal NOX_NS_AD_i is a 'strong' filtered and offset adapted NOx signal. The lower limit of NOX_NS_AD_i value range is 0 ppm. Hence this selection does not allow to diagnose a negative NOx signal offset.

NOX_NS:

The signal NOX_NS_i is a 'strong' filtered NOx signal. This selection allows to diagnose a negative NOx signal offset.

NOX_NS_DIAG:

The signal NOX_NS_DIAG_i is a 'light' filtered NOx signal. This selection allows to diagnose a negative NOx signal offset.

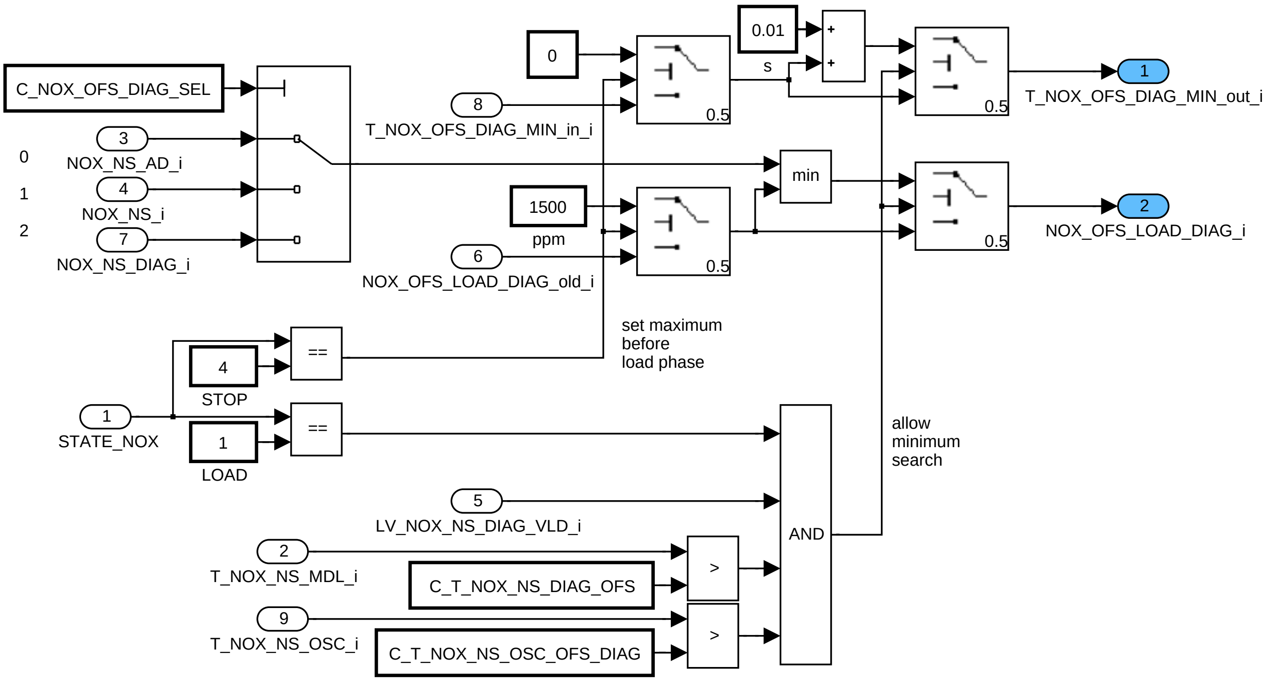

Figure 232 NOXD_MODULB07D/ OPM_10MS/ FOR_LOOP_NS/ CLC1

Condition for evaluation of the diagnosis result

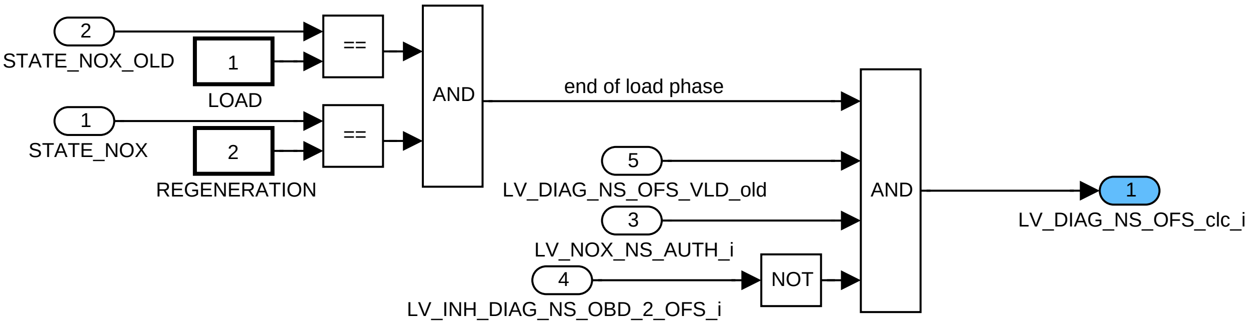

Figure 233 NOXD_MODULB07D/ OPM_10MS/ FOR_LOOP_NS/ CLC2

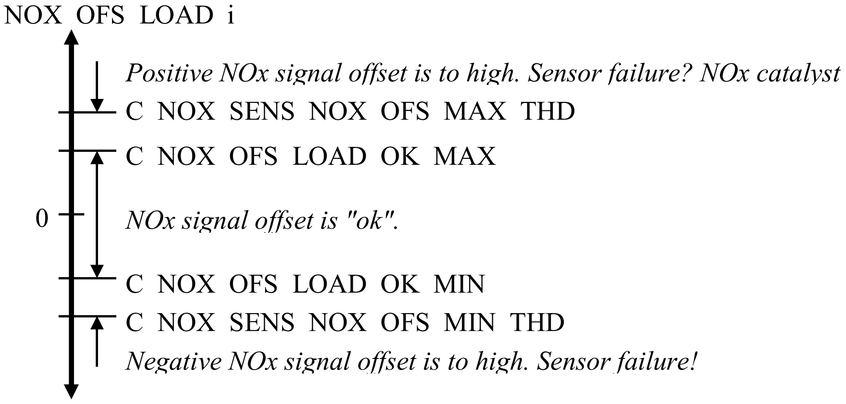
Minimum validation

At the end of the load phase the minimum of the NOx signal will be evaluated to get the result if the sensor is OK.



Application hint: The constant C_NOX_NS_OFS_MIN_THD shall be set to a negative value. So it is possible to detect a high negative NOx signal offset.

Application hint: The constant C_SYM_NS_OFS has to be set to the symptom as described in NOx sensor OBDII (Appl. Inc.).

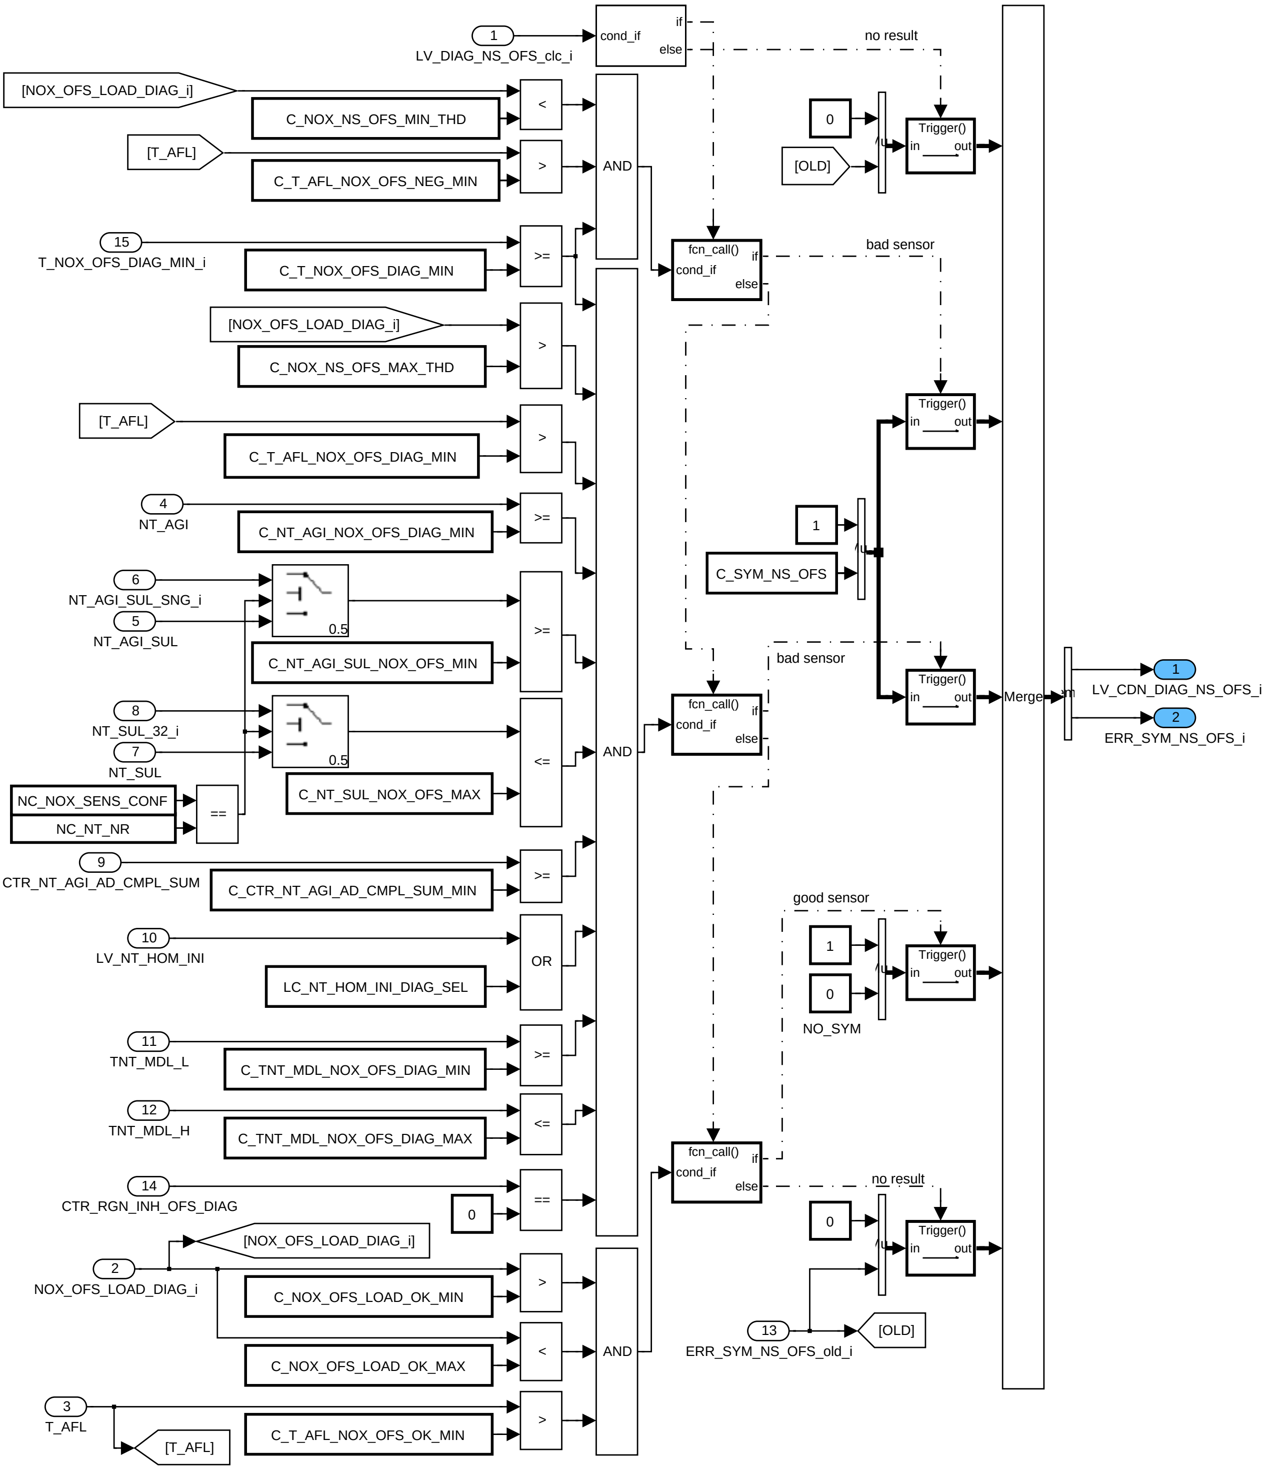


Figure 234 NOXD_MODULB07D/ OPM_10MS/ FOR_LOOP_NS/ CLC3

Test cycle counter

The test cycle counter TCC_NS_OFS_i counts the number of completed offset diagnoses. This information is needed for detection of diagnosis readiness and decrementation of counter for consecutive driving cycles with or without a NOx sensor failure.

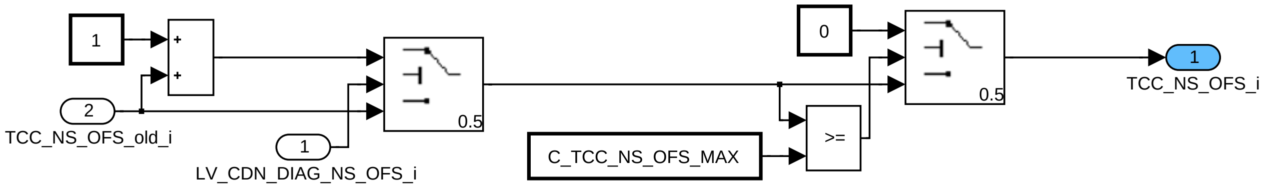

Figure 235 NOXD_MODULB07D/ OPM_10MS/ FOR_LOOP_NS/ CLC4

Error management

LV_ERR_NS_OFS will be get by ACTION_ERRM_GetLvErr and LV_END_DIAG_NS_OFS will be get by ACTION_ERRM_GetLvEndDiag.

Inhibition of diagnosis for one sensor

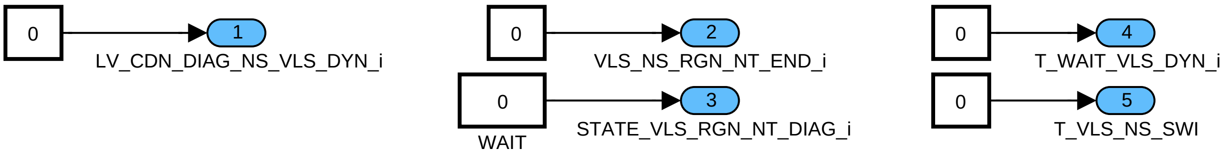

Figure 248 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ INH/ CLC

State machine

This diagnosis is divided into 3 states:

- WAIT: waiting for the end of a regeneration phase of NOx catalyst

- INIT: regeneration phase left, initial conditions for diagnosis present
- DIAG: Diagnosis runs

The default case is is case 0 (WAIT).

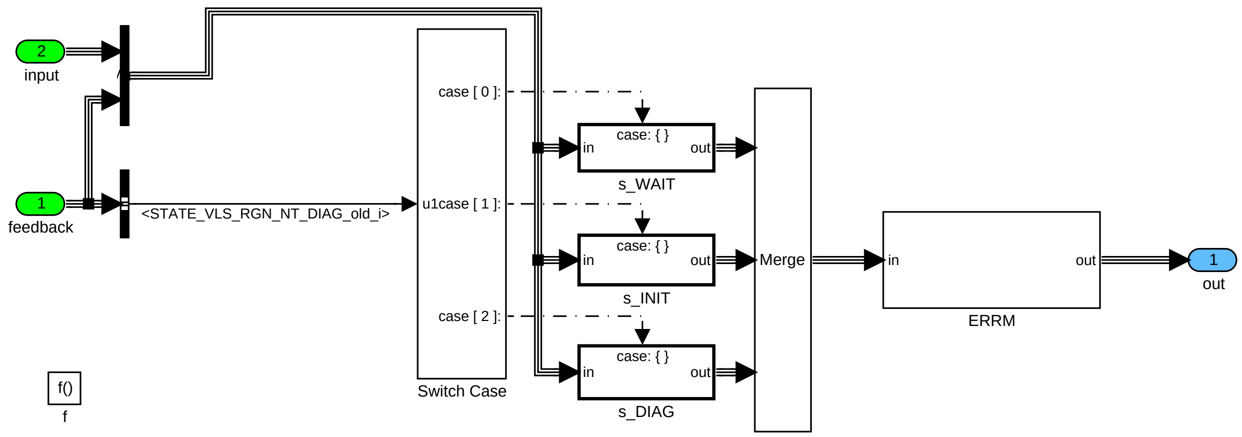

Figure 249 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN

STATE_VLS_RGN_NT_DIAG_i = 0 (WAIT)

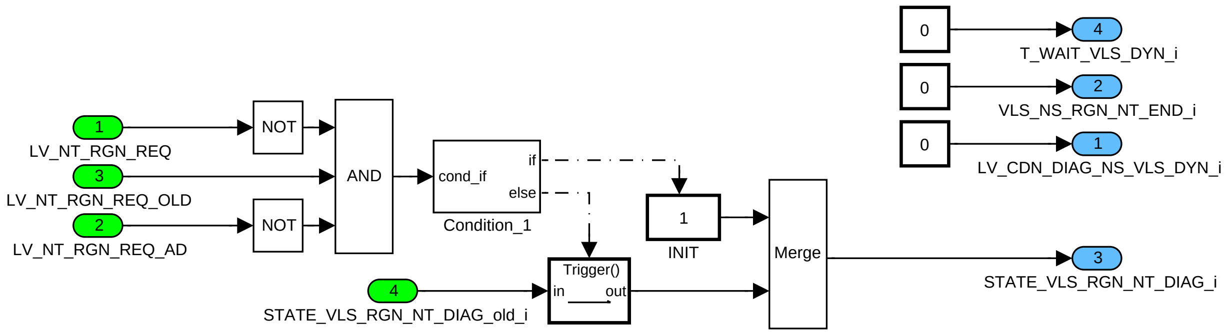

Figure 250 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN/ s_WAIT/ CLC

STATE_VLS_RGN_NT_DIAG_i = 1 (INIT)

This timer limits the phase INIT. If no diagnosis will be started in this time, then the state machine switches back to WAIT.

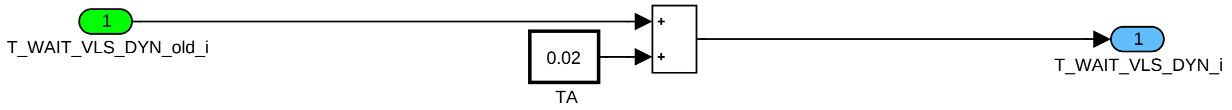

Figure 251 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN/ s_INIT/ CLC1

During the waiting the binary O2 signal voltage is checked on their validity. If the signal is valid or if a special condition is fulfilled then the last binary O2 signal value is stored.

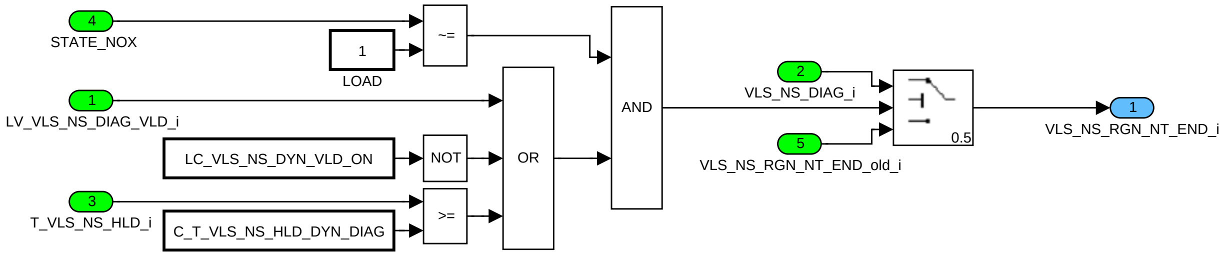

Figure 252 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN/ s_INIT/ CLC2

The diagnosis will be started if the binary signal has a suitable behaviour. The threshould C_VLS_NS_DIAG_SWI_ST defines the start of the gradient check.

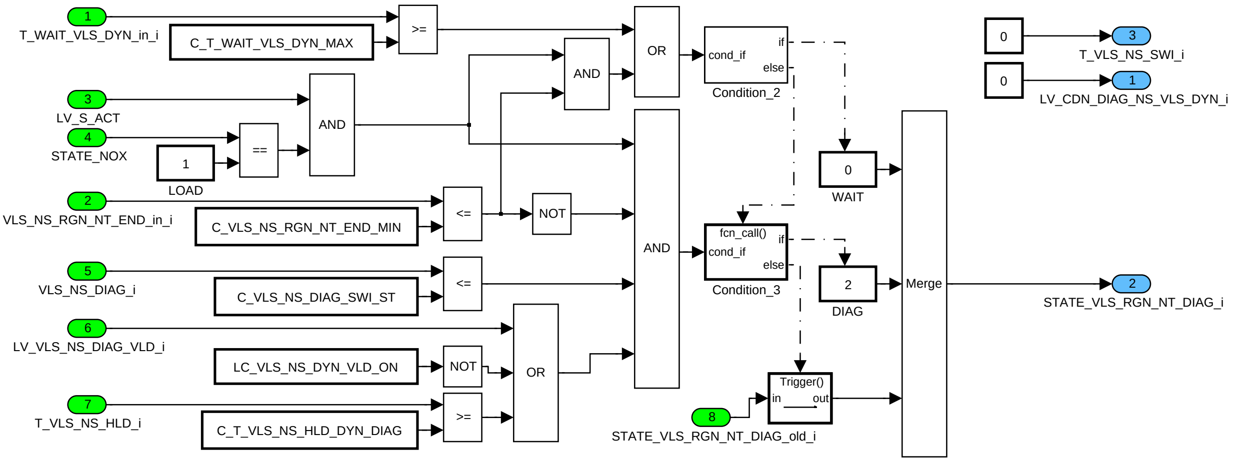

Figure 253 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN/ s_INIT/ CLC3

STATE_VLS_RGN_NT_DIAG_i = 2 (DIAG)

The time of the gradient of the binary signal will be measured.

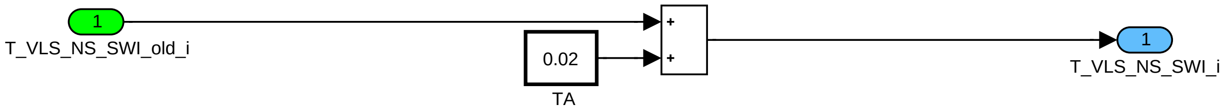

Figure 254 NOXD_MODULB07E/ OPM_20MS/ FOR_LOOP_NS/ CLC/ MAIN/ s_DIAG/ CLC1

The threshould C_VLS_NS_DIAG_SWI_END defines the end of the gradient check. The elapsed time for the gradient will be evaluated to decide whether the sensor dynamic is OK or not.

NOx sensor diagnosis is running

The maximum detection will be divided into two periods. The first period is a calibrated time of part load. The second period is a calibrated number of suitable regenerations. A NOx sensor activity error will be set if during both periods the maxima have not reached the diagnosis threshoulds.

Time of part load is measured

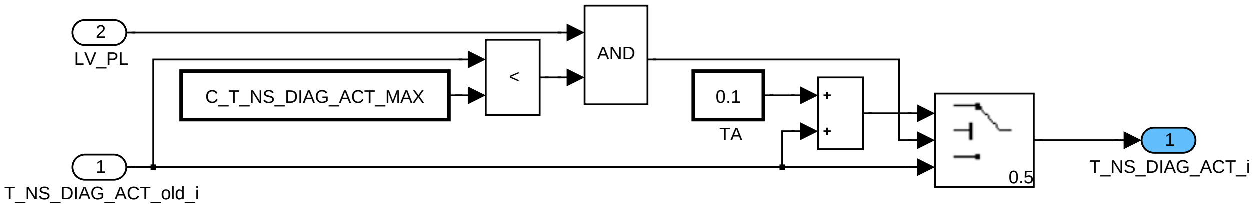

Figure 270 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC4/ DIAG/ CLC1

NOx sensor error decision

After the calibrated number of regenerations the error will be set.

Figure 271 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC4/ DIAG/ CLC2

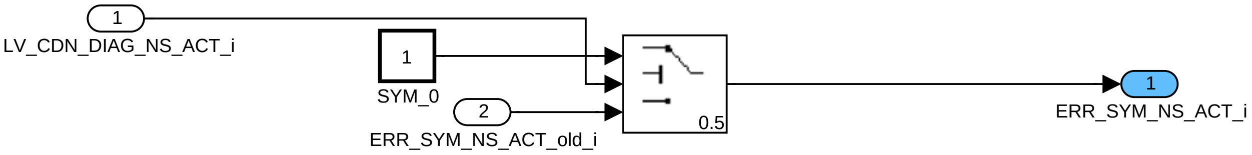

Figure 272 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC4/ DIAG/ CLC3

Control of stratified mode

If an error after the second period will be detected, then the stratified mode will be inhibited.

Otherwise, if the first period is over, then the stratified mode will be allowed, although no activity was detected during the first period. In this period activity of the NOx signal should be monitored due to the stimulation by regeneration.

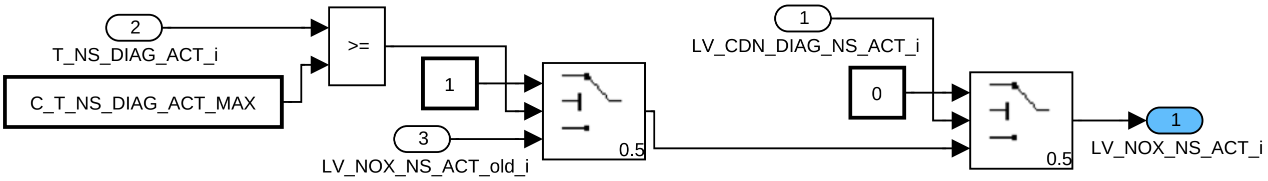

Figure 273 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC4/ DIAG/ CLC4

Regeneration counter

During the second period the number of suitable regenerations will be counted.

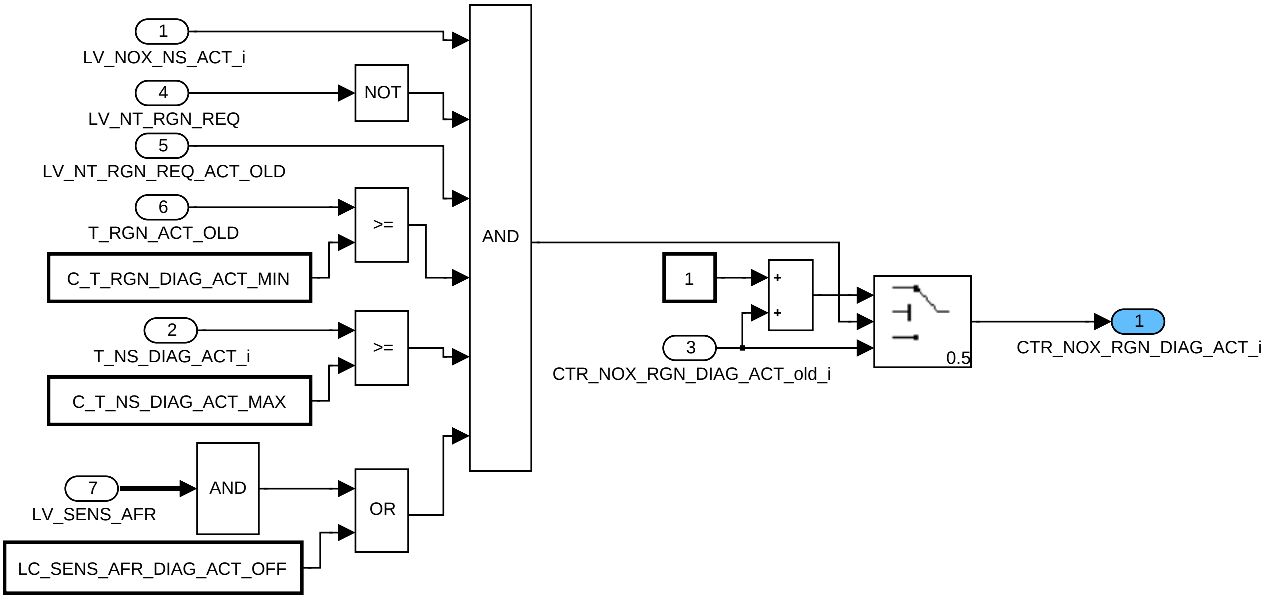

Figure 274 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC4/ DIAG/ CLC5

Error management

LV_ERR_NS_ACT will be get by ACTION_ERRM_GetLvErr and LV_END_DIAG_NS_ACT will be get by ACTION_ERRM_GetLvEndDiag.

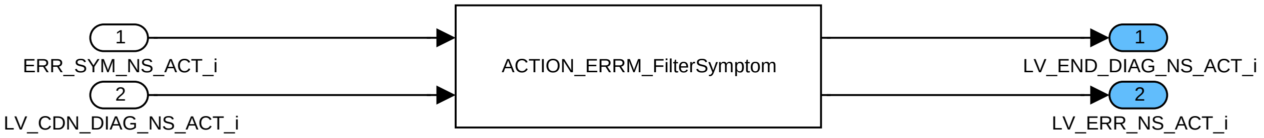

Figure 275 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC5

Old value for gradient calculation

Figure 276 NOXD_MODULB07F/ OPM_100MS/ FLP_NS/ CLC/ MAIN/ CLC6

Bank independent calculation

The old values of the inputs will be stored for edge detection and because the regeneration time before the edge is needed.

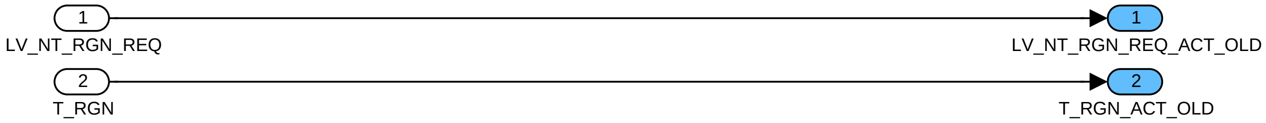

Figure 277 NOXD_MODULB07F/ OPM_100MS/ NOT_FLP/ CLC

52.24.1.4 Loop control at engine run to engine stop

The calculation inside FLP_NS have to be done for each NOx sensor, controlled by configuration data NC_NOX_SENS_CONF.

If NC_NOX_SENS_CONF = 1, then calculation for i = 1.

If NC_NOX_SENS_CONF = 2, then calculation for i = 1 and 2.

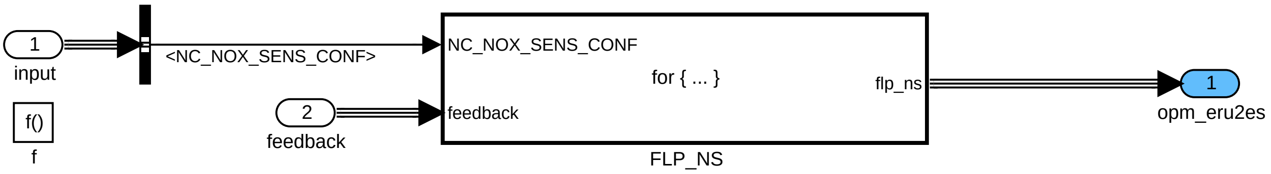

Figure 278 NOXD_MODULB07F/ OPM_ERU2ES

Decision about storage of diagnosis result

The new activity result will be stored in the non-volatile memory if the diagnosis was finished. Otherwise the stored value from the last driving cycle will be kept.

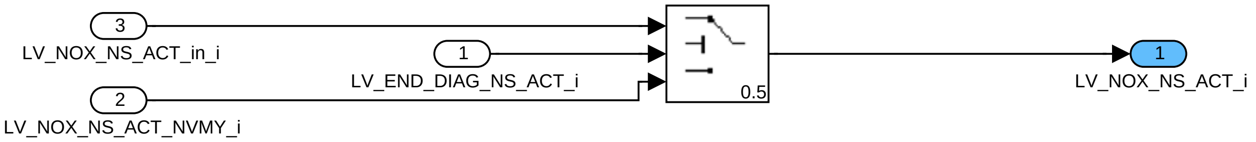

Figure 279 NOXD_MODULB07F/ OPM_ERU2ES/ FLP_NS/ CLC

52.25 Customer adaptation module: AGGR NOXD

52.25.1 Outputs for BMW functions which are not defined as NOXD exported data

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
B_fi_nsobd1	O/V	0...1H	0...1	1	[-]
Summenfehler Nox Sensor OBD1					
B_fi_nsobd2	O/V	0...1H	0...1	1	[-]
Summenfehler Nox Sensor OBD2					
B_nsadap_anf	O/V	0...1H	0...1	1	[-]
Status Anforderung Noxsensoradaption					
B_nsdiag_anf	O/V	0...1H	0...1	1	[-]
Status Anforderung Noxsensordiagnose					
Baw_nsadap	O/V	0...FFFFH	0...65535	1	[-]
Betriebsarten-Anforderung Noxsensoradaption					
Baw_nsdiag	O/V	0...FFFFH	0...65535	1	[-]
Betriebsarten-Anforderung Noxsensordiagnose					

Input data:

ECU_STATE	LV_ERR_NS_OBD_1[NC_NOX_SENS_CONF]	LV_ERR_NS_OBD_2[NC_NOX_SENS_CONF]	LV_NS_AD_REQ
LV_NS_SHIFT_CMB_INT_REQ	NC_NOX_SENS_CONF	STATE_NS_SHIFT_CMB_REQ	STATE_OPM_REQ_NS_AD

FUNCTION DESCRIPTION:

Adaptation to BMW environment.

Application conditions:

Initialisation at reset and at exit "PWL": 0

Recurrence : 10 ms

Activation: every engine state

Formula section:

```
B_fi_nsobd1       =  LV_ERR_NS_OBD_1[1]
B_fi_nsobd2       =  LV_ERR_NS_OBD_2[1]
If    ECU_STAT = "PWL"
Then         B_nsadap_anf  = 0
             B_nsdiag_anf = 0
             Baw_nsadap = 0
             Baw_nsdiag = 0

53.1 NOXM Configuration Data

FUNCTION DESCRIPTION:

General information:

The following describes the general rules for determination of the configuration data:

- All configuration data shall be defined by project with information from customer.

Formula section:

Global configuration data

Here are listed the configuration data, which can be used in other aggregates:

Data	Value
NC_NT_NR	2

Local configuration data

Here are listed the configuration data, which are used only in the NOXM aggregate:

Data	Value
NC_NT_CONF	1

Configuration data:

Name	Dim	Hex. limits	Phys. limits	Resol.	Unit
NC_NT_NR	-	1...4H	1...4	1	[-]
Number of NOx catalysts					
NC_NT_CONF	-	0...1H	0...1	1	[-]
configuration data for single/twin branched exhaust line (0: one NOx trap, 1: two NOx traps)					

53.2 AGGR adaptation: NOXM

FUNCTION DESCRIPTION:

General information:

This module handles all variable interfaces of aggregate NOXM. It adapts inputs to aggregate NOXM and outputs from aggregate NOXM on project specific requirements or aggregate structure requirements.

53.2.1 Inputs to aggregate NOXM – 20ms

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_CLU_SWI	O/V	0...1H	0...1	1	[-]
Boolean for clutch switch detection					

Input data:

LV_AT	LV_IM_CS_PN	LV_VAR_TCT	

Application conditions:

Initialisation: at reset:

LV_CLU_SWI = 0

Recurrence: 20ms

Activation: after reset

Deactivation: -

Formula section:

LV_CLU_SWI = (LV_IM_CS_PN = 1) **AND** (LV_AT = 0) **AND** (LV_VAR_TCT = 0)

53.2.2 Outputs of aggregate NOXM – 20ms

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_NT_RGN_REQ	V/O	0...1H	0...1	1	[-]
flag inhibiting the request of a NOx catalyst regeneration					
LV_NT_MDL_AFR	V/O	0...1H	0...1	1	[-]
Model rich exhaust gas (stop of regeneration)					
LV_NT_RGN_STOP_SENS	V/O	0...1H	0...1	1	[-]
Flag indicating: Stop of Rgn by sensor enabled					
LV_NT_SENS_AFR[NC_NT_NR]	V/O	0...1H	0...1	1	[-]
downstream sensor measures rich exhaust gas (stop of regeneration)					
LV_NT_TOUT_AFR	V/O	0...1H	0...1	1	[-]
rich exhaust gas after timeout (stop of regeneration)					
LV_NT_RGN_REQ	V/O	0...1H	0...1	1	[-]
Logical value for regeneration phase request					
LV_RGN_REQ_AD	V/O	0...1H	0...1	1	[-]
Request for a full regeneration for adaptation or elongated stratified mode					

Input data:

NC_NT_NR	LV_INH_RGN_REQ	LV_NT_RGN_REQ_AD	LV_MDL_AFR
LV_RGN_STOP_SENS	LV_SENS_AFR[NC_NT_NR]	LV_TOUT_AFR	LV_RGN_NT_REQ

Application conditions:

Initialisation: at reset:

LV_INH_NT_RGN_REQ = 0

LV_RGN_REQ_AD = 0

LV_NT_MDL_AFR = 0

LV_NT_RGN_STOP_SENS = 0

LV_NT_SENS_AFR[i] = 0

LV_NT_TOUT_AFR = 0

LV_NT_RGN_REQ = 0

~~NOX_PPM_RGN_ST[i] = 0~~

Recurrence: 20ms

Activation: after reset

Deactivation: -

Formula section:

LV_INH_NT_RGN_REQ = LV_INH_RGN_REQ

LV_RGN_REQ_AD = LV_NT_RGN_REQ_AD

LV_NT_MDL_AFR = LV_MDL_AFR

LV_NT_RGN_STOP_SENS = LV_RGN_STOP_SENS

LV_NT_SENS_AFR[i] = LV_SENS_AFR[i]

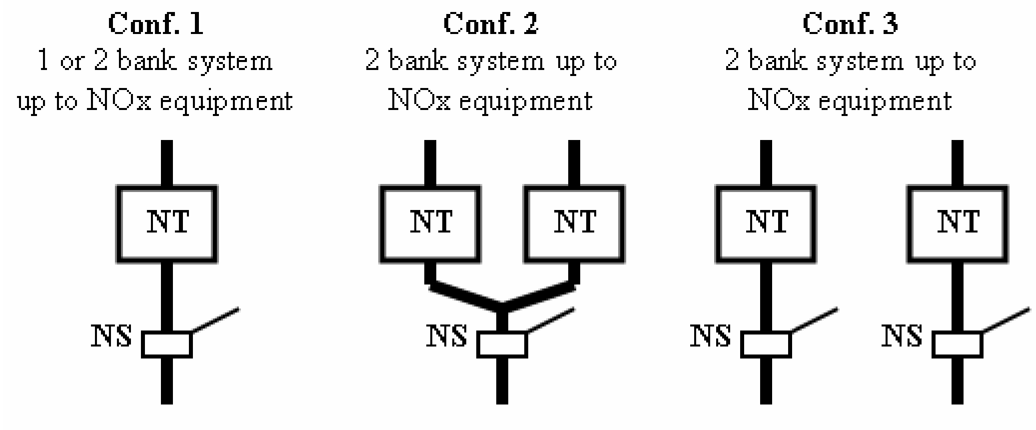
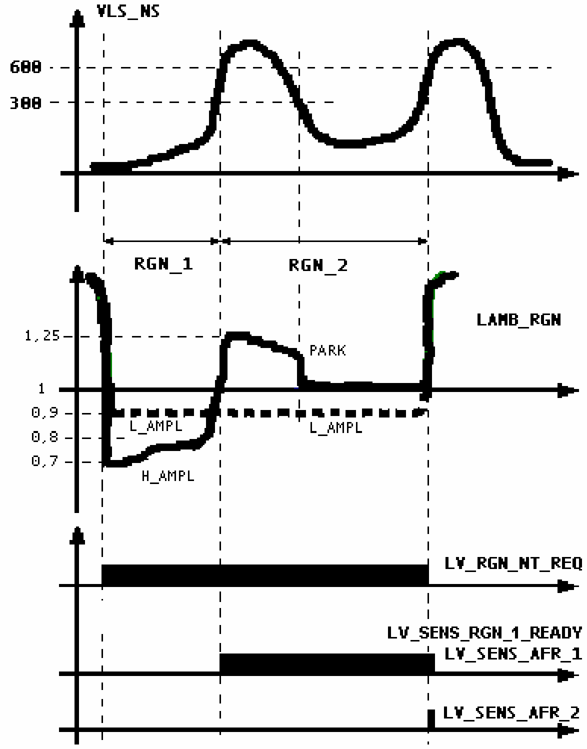
conversion factor between MAF					

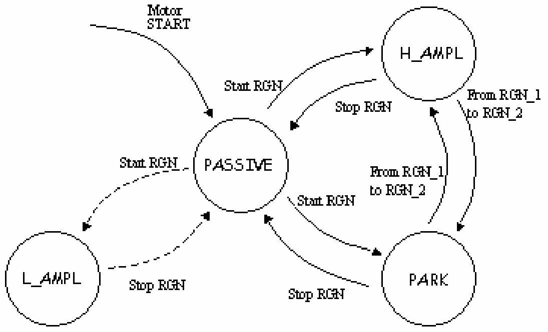
General Information

The requirement of NOxstorage catalyst regeneration is the engine is operated with a rich mixture. This is the lambda setpoint for catalyst regeneration edition for single- and twin-branched exhaust lines, also for the Y configuration with two NOx-Traps (NT) and one NOx-Sensor (Conf 2). In this case the lambda setpoint of the already regenerated NT is set to the park value C_LAMB_PARK_BAS. The covered exhaust gas configurations are shown in the picture below:



The regeneration curves, state flow and correction options for example configuration shows the picture:





Options of correction factor calculation for RGN_1:

	PURGE	VLS	T_RGN	VLS/MAF	NONE
L_AMPL	✓	–	✓	✓	✓
H_AMPL	✓	✓	–	–	✓
PARK	–	✓	✓	–	✓

Options of correction factor calculation for RGN_2:

	PURGE	VLS	T_RGN_2	VLS/MAF	NONE
PARK	–	–	✓	–	✓
L_AMPL	–	✓	✓	–	✓
H_AMPL	–	✓	–	–	✓

NC_CBK_EX_NR is the number of exhaust gas lines. Therefore
i = 1, for cylinder bank 1
i = 2, for cylinder bank 2.
NC_NOX_SENS_CONF is the number of NOx-Sensors. Therefore
NC_NOX_SENS_CONF = 0, for no NOx-Sensor
NC_NOX_SENS_CONF = 1 (n = 1), for one NOx-Sensor
NC_NOX_SENS_CONF = 2 (n = i), for two NOx-Sensors
NC_NT_NR is the number of NOx Catalysts. Therefore
NC_NT_NR = 1 (k = 1), for one NOx Catalyst
NC_NT_NR = 2 (k = i), for two NOx Catalysts

Application Conditions

Function description

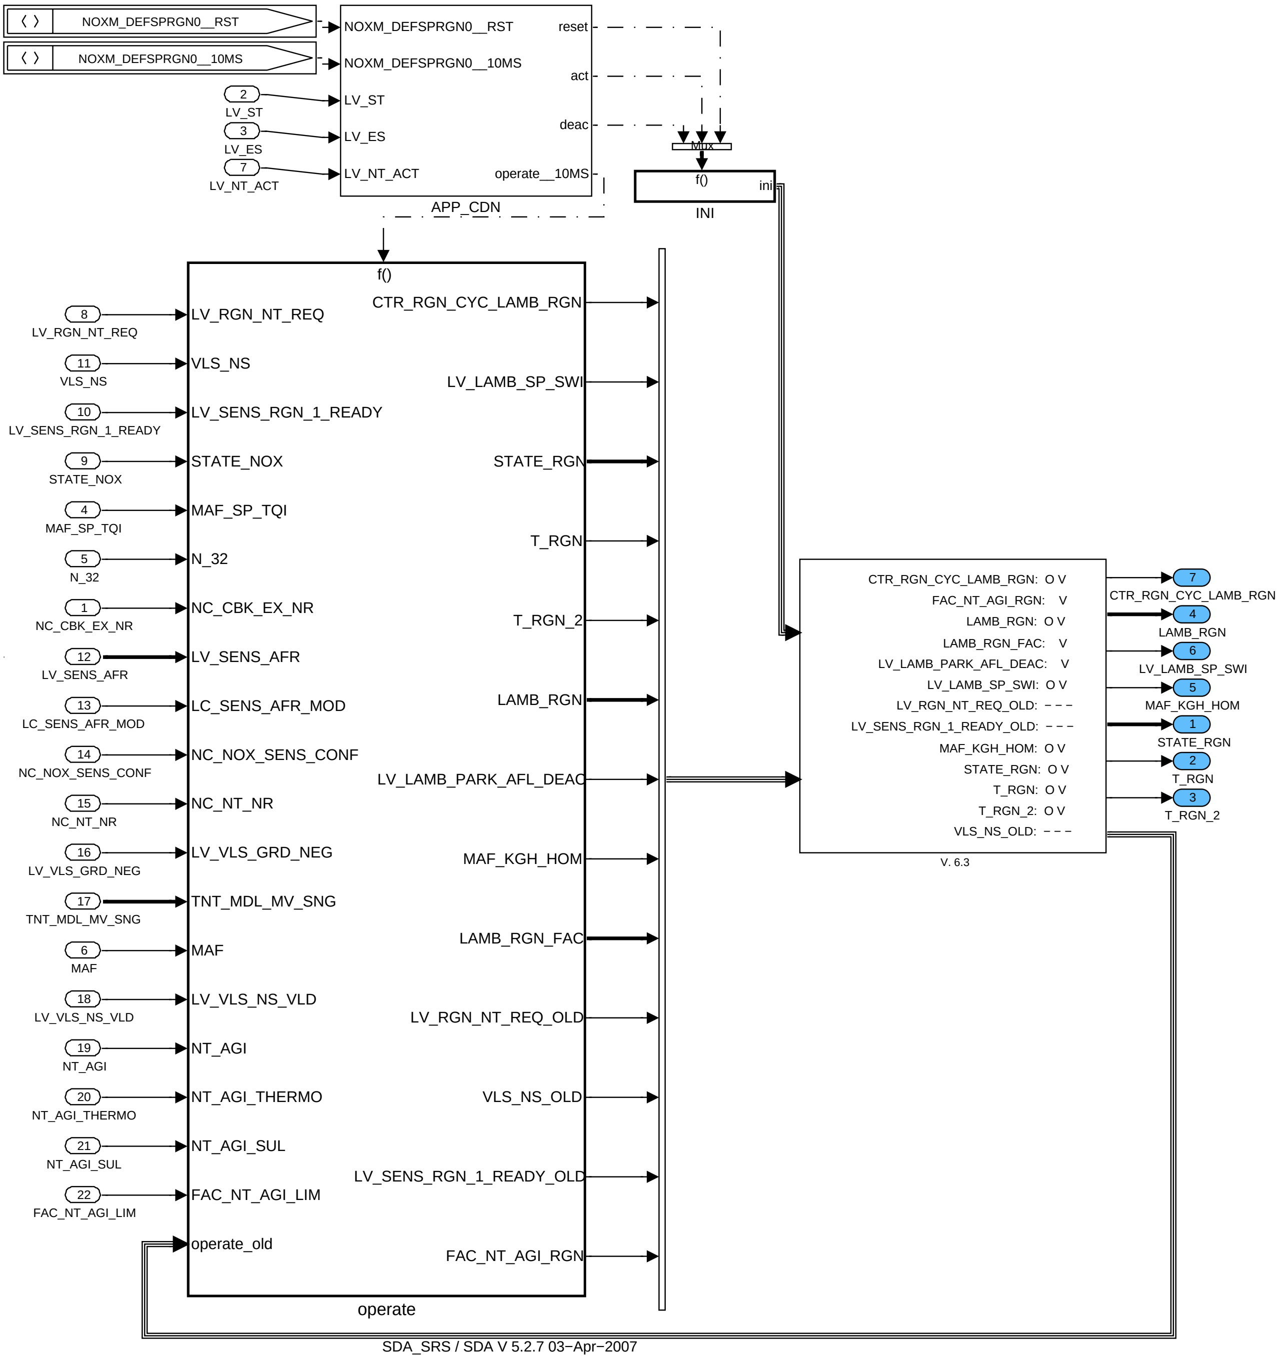

Figure 2:

53.3.1 INITIALIZATION AT RESET, ACTIVATION AND DEACTIVATION

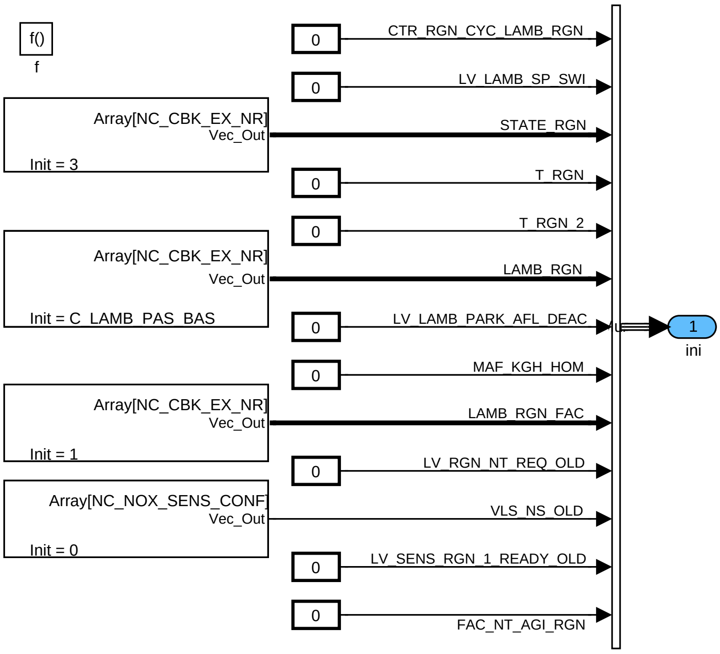

Figure 3:

53.3.2 FORMULA SECTION

The function consists of two main sections:
SECTION 1: Initialization of the Regeneration State at start of the regeneration, calculation of the regeneration time and of the lambda basis for the low amplitude regeneration
SECTION 2: Calculation of the Regeneration State and the Regeneration Lambda Setpoint

Figure 4:

53.3.2.1 SECTION 1: Initialization of Regeneration State at start of the regeneration, calculation of regeneration time and lambda basis for the low amplitude regeneration

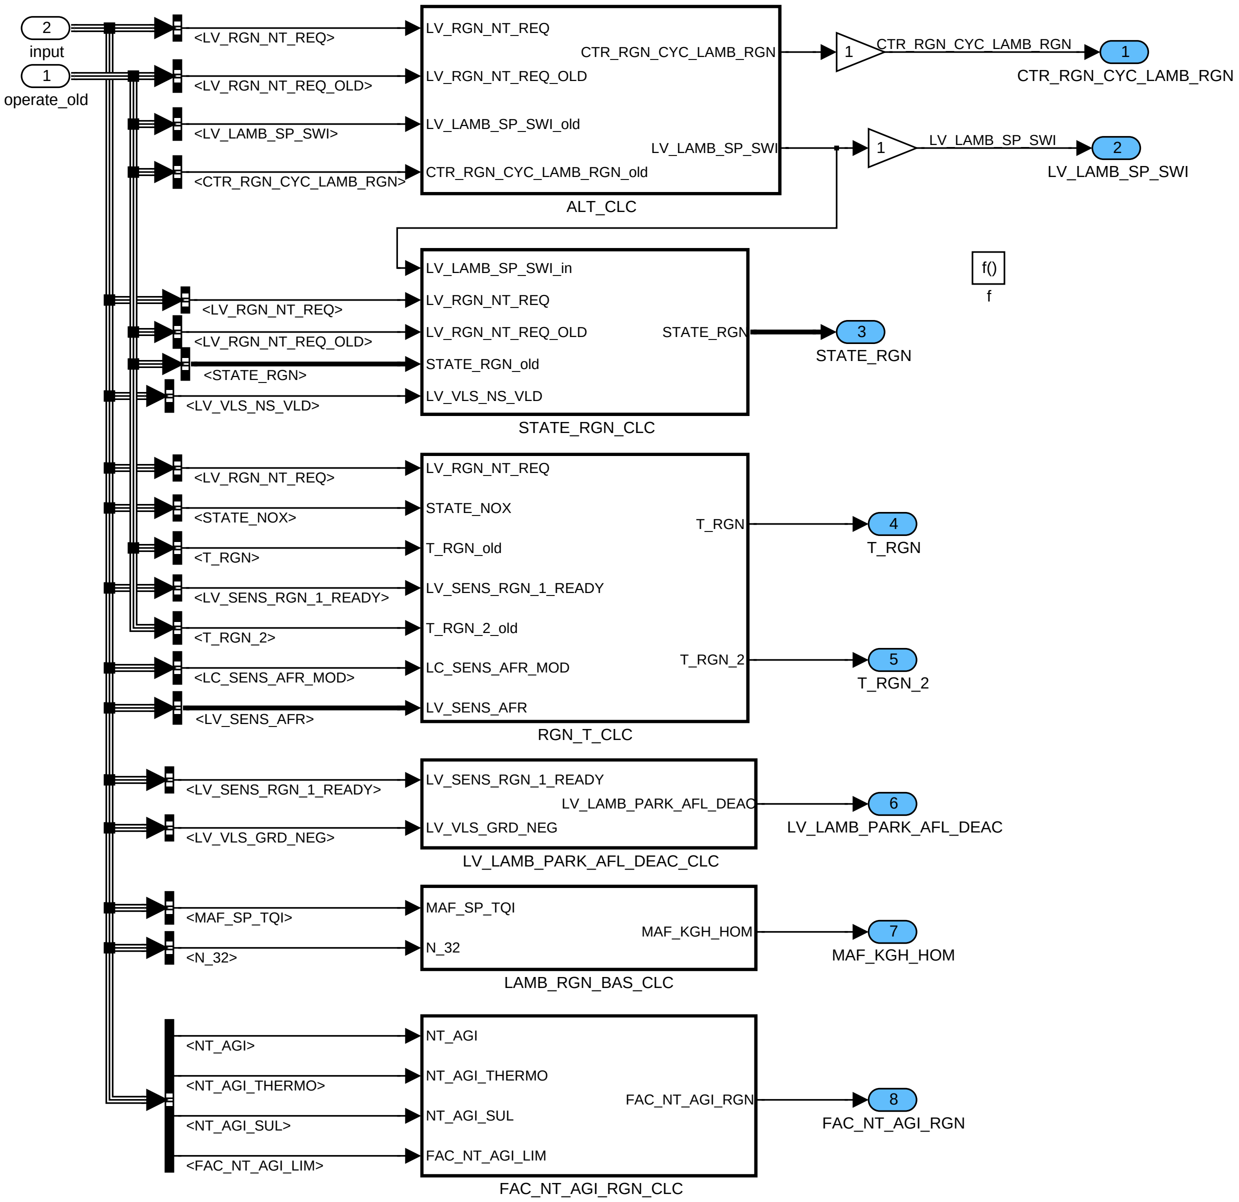

Figure 5:

53.3.2.1.1 Calculation of regeneration counter and alternate flag

The regeneration counter is incremented at entering in regeneration. The alternate flag is used for switching of initialization values for the STATE_RGN between both banks. The interval between switching is set by the C_CTR_RGN_SWI_DEAC (alternate flag is not active) and by the C_CTR_RGN_SWI_ACT (alternate flag is active).

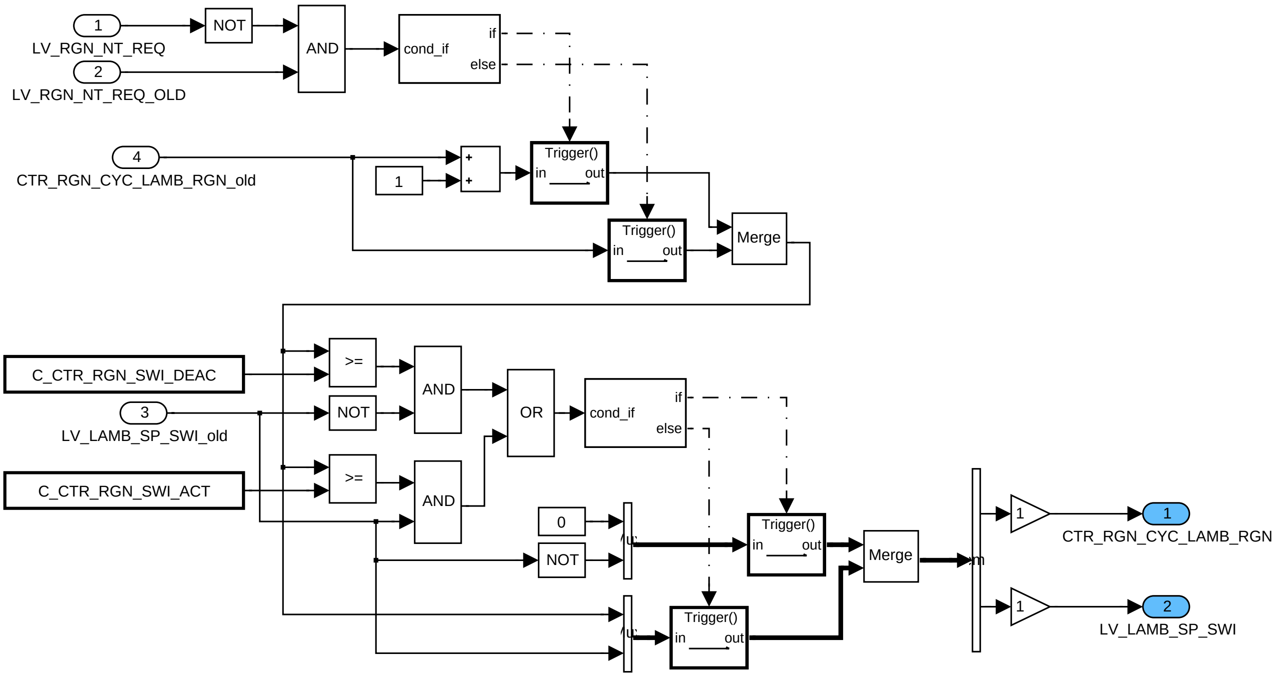

Figure 6:

53.3.2.1.2 Initialization of regeneration state

The regeneration strategy for all banks is set at start of regeneration. The regeneration state is initialized depending on alternate flag.

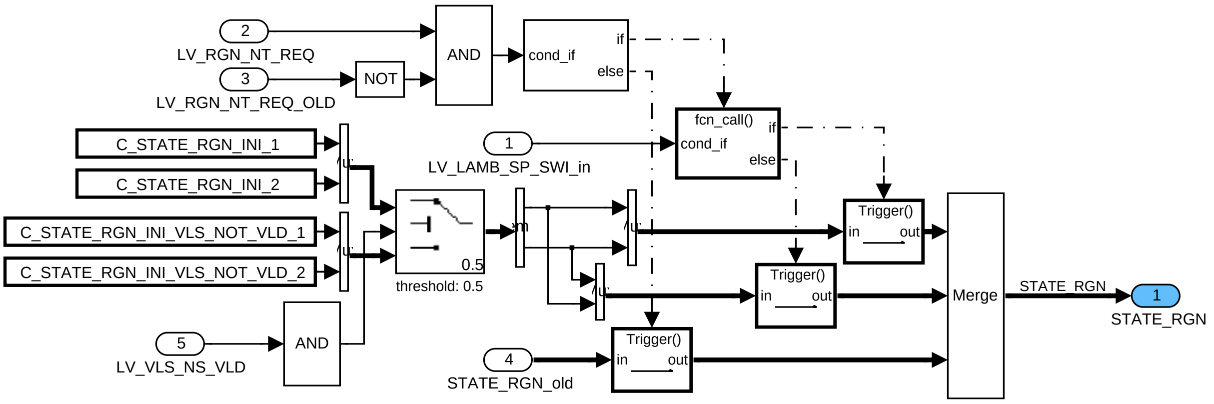

Figure 7:

53.3.2.1.3 Calculation of time for the first and the second regeneration

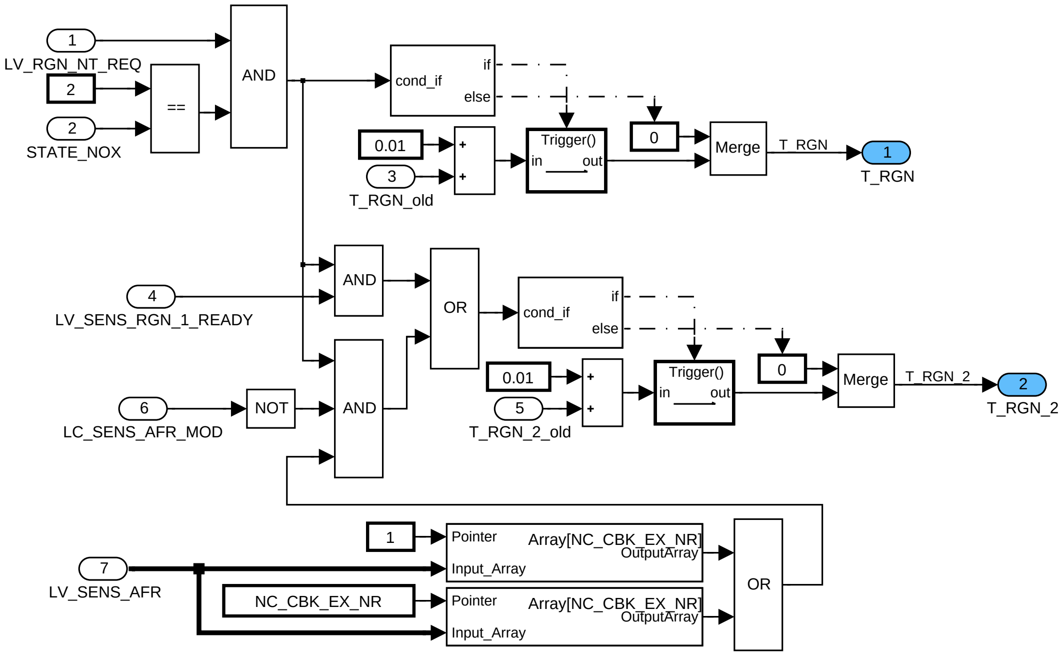

Figure 8:

53.3.2.1.4 Deactivation of lean lambda setpoint after switch to the state "PARK".

To ensure the binary signal of the NOx Sensor can fall down after first regeneration, the deactivation of the lean lambda setpoint take place only when defined negative gradient has been reached.

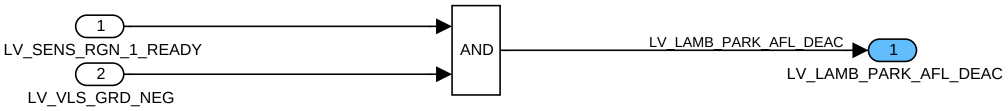

Figure 9:

General Information

This module calculates the NOx engine out emission mass flow at homogeneous-stratified mode. This module guesses also a predicted value, if the homogeneous-stratified mode would become active at the actual conditions.
The calculations consist of an basis calibration, depending on fuel mass, motor speed and ambient temperature. This value will be corrected by several factors, which depend from the deviation of state variables compared to the basis calibration.

General Information

This module calculates the NOx engine out emission mass flow at stratified mode. This module guesses also a predicted value, if the stratified mode would become active at the actual conditions.
The calculations consist of an basis calibration, depending on fuel mass, motor speed and ambient temperature. This value will be corrected by several factors, which depend from the deviation of state variables compared to the basis calibration.

Application Conditions

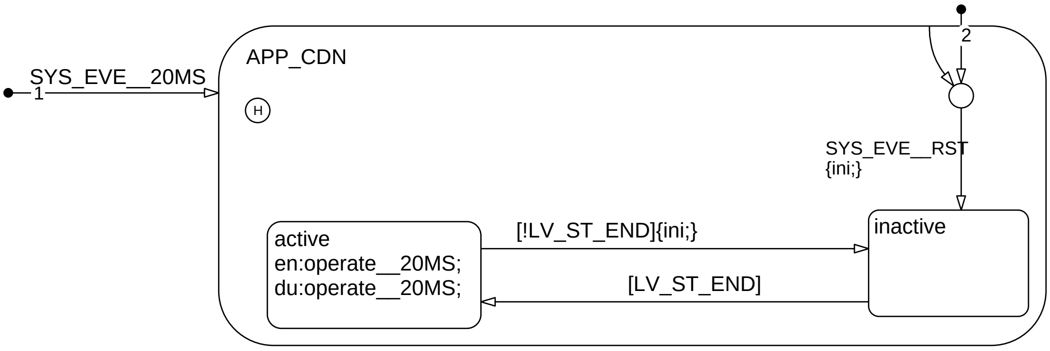

Figure 50:

Function description

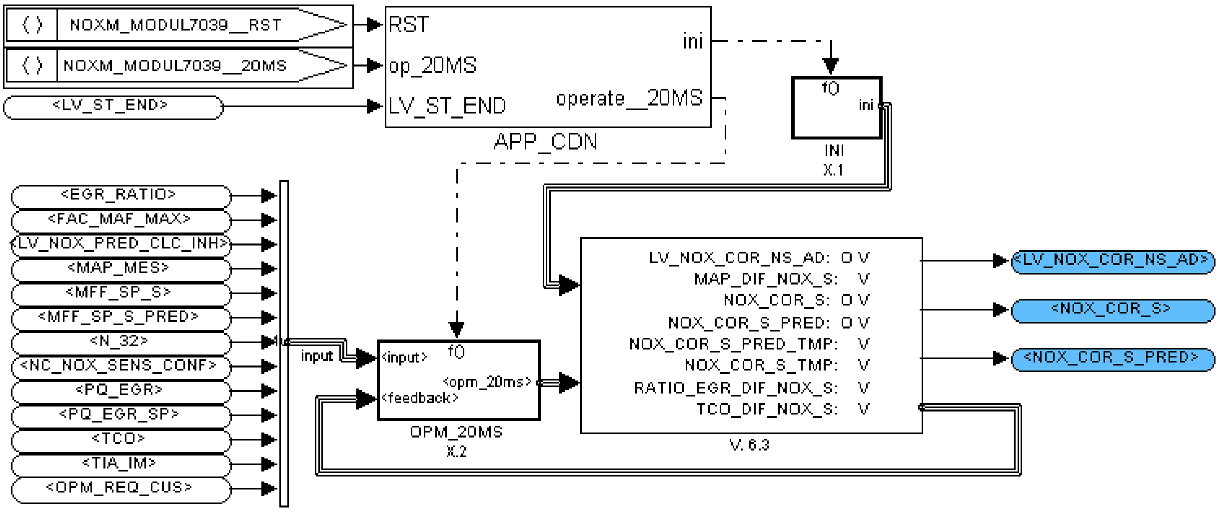

Figure 51:

53.5.1 Initialization at reset and deactivation

53.5.2 Calculation at 20 ms

53.5.2.1 Deviation of air pressure

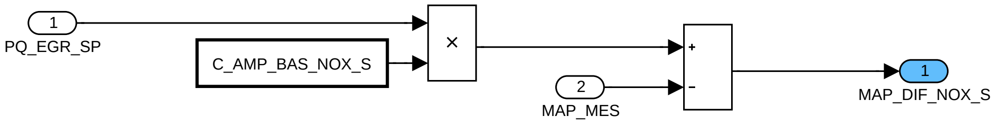

Figure 52:

53.5.2.2 Deviation of cooling water temperature

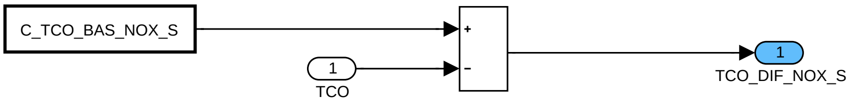

Figure 53:

53.5.2.3 Deviation of exhaust gas recirculation

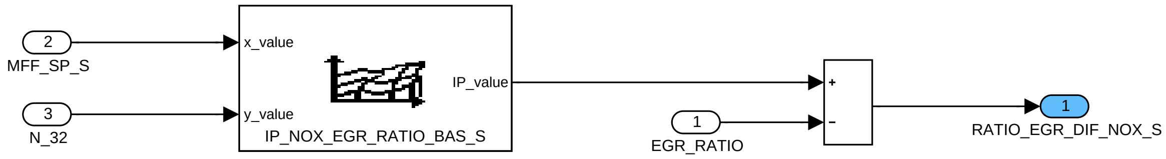

Figure 54:

53.5.2.4 Detection of NOx signal gain adaptation

If the NOx signal gain adaptation for any NOx sensor is in required combustion mode, then a special basis calibration matrix is used.

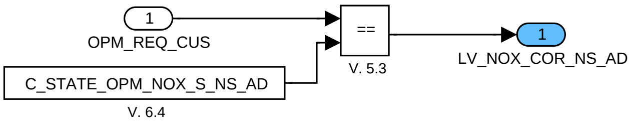

Figure 55:

53.5.2.5 Basis calibration of NOx engine out emissions

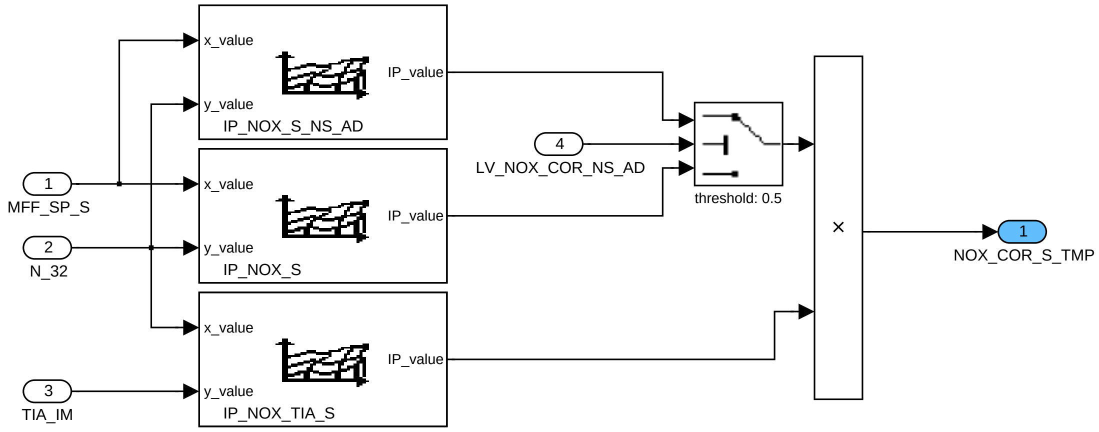

Figure 56:

53.5.2.6 Corrected engine out NOx emissions

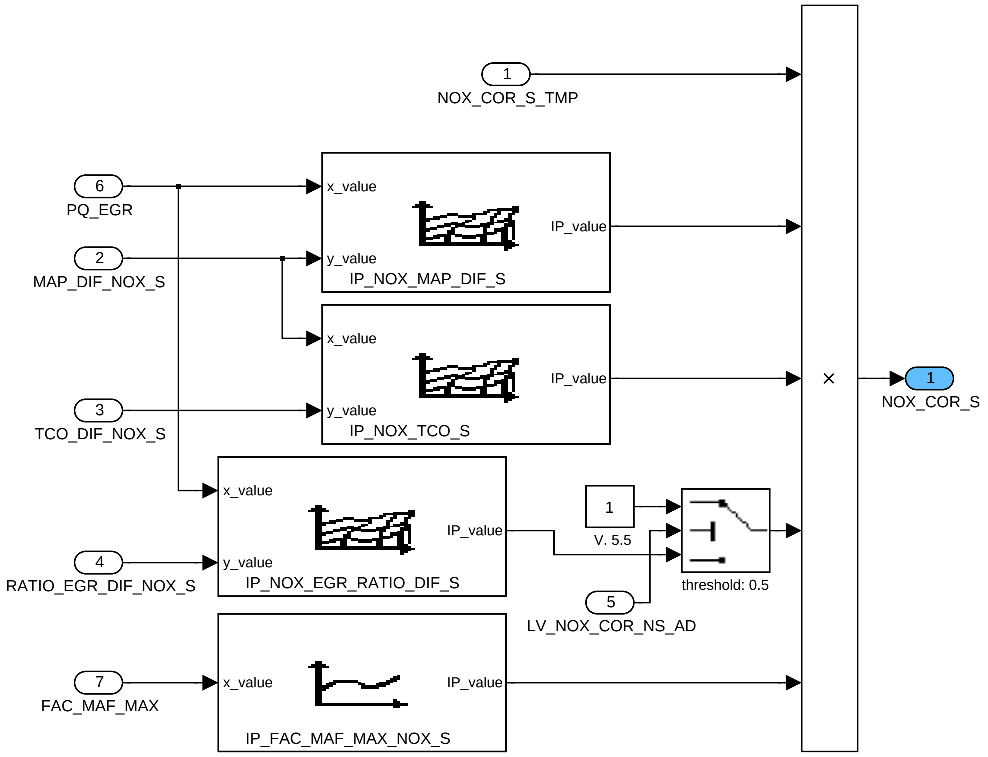

Figure 57:

53.5.2.7 Basis for predicted NOx emissions

The calibration maps are the same as for actual emissions. They deliver the predicted emissions, because the predicted fuel mass MFF_SP_S_PRED may be used here.

FUNCTION DESCRIPTION:

General information:

The NOx catalyst management can handle single branch and twin branch exhaust gas lines with the configuration data NC_NT_NR.

If NC_NT_NR = 1, just one NOx catalyst is taken into account, if NC_NT_NR = 2, the software calculates the twin branch version concerning NOx catalysts.

with i = 1 ... NC_NT_NR

typical values of NC_NT_NR = 1; 2

If two or more separate cylinder banks are concerned, then

m = 1, for cylinder bank 1

m = 2, for cylinder bank 2

with m = 1 ... NC_CBK_EX_NR

typical values of NC_CBK_EX_NR = 1;2

NC_NOX_SENS_CONF considers the number of NOx sensors in the system

with k = 1 ... NC_NOX_SENS_CONF

typical values of NC_NOX_SENS_CONF = 1;2

In some passages logical expressions are calculated using information of different branches (example: A_1 and A_2). If this module is compiled for single branched exhaust lines, only the first expression (here: A_1) should be taken into consideration.

In case of LV_NT_STST = 1 all calculations of this module shall be inhibited. That's valid for all used recurrences (10ms, 20ms, 100ms, 1000ms).

Application conditions:

Initialisation: --

Recurrence: defined at each subchapter of this module,
basic recurrence of this module is 10 ms

Activation: LV_NT_STST = 0

Deactivation: LV_NT_STST = 1

53.6.1 NOx catalyst management - catalyst states

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: --

Recurrence: 10 ms

Activation: --

Deactivation: --

53.6.1.1 State transition manager

FUNCTION DESCRIPTION:

General information:

The NOx catalyst state manager should be initialized with the STATE_NOX = PASSIVE.

In order to keep the state manager as simple as possible without loss of functionality, the state STOP contains all engine states based on stoichiometric operation except the regeneration. Such possible states are besides the „ordinary“ lambda=1 operation the desulfation, the catalyst heating (see lambda=1-request chapter). Due to lambda oscillations in lambda=1 operation, the consideration of LV_NT_AFS_REQ is necessary in order to prevent an undesired leave of STOP.

The flag LV_RGN_AGI_i is set to 1 when the regeneration just starts (STATE_NOX switches from LOAD to REGENERATION) and the starting regeneration was requested by the modelled loading degree (LV_RGN_REQ_NTLD=1). It is reset, when the regeneration is stopped by a downstream sensor signal (see Sub-chapter: STATE_NOX = STOP).

STATE_NOX has to be initialised with PASSIVE

The states of the NOx Trap function are:

- ***PASSIVE*** : Initialisation of NOx catalyst management
- ***WARMUP***: Sensors ready, waiting for suitable catalyst temperature
- ***LOAD*** : storage of NOx (and oxygen) during lean burn phases
- ***REGENERATION*** : NOx-regeneration of the catalyst during a rich burn phase
- ***STOP*** : Lambda=1 operation
- ***WAIT***: During Fuel Cut Off, only oxygen crosses the catalyst

Signal flow diagram:

Notes:

- For the detection of a regeneration in catalyst purge the calibration data C_LAMB_RGN has to be calibrated always more lean than the calibrated lambda for catalyst purge.

  The following table gives an overview, how variables are calculated depending on the NOx catalyst management state.

state-depending actions

	Passive/ Warmup	RGN	Load	Wait	Stop
NOX_COR_xx	0	0	C	0	0
NOX_CONC_xx	0	0	C	-	-

0	set to zero
C	calculate
-	freeze value (no changes)
/	action forbidden

53.6.1.2 STATE_NOX = PASSIVE

FUNCTION DESCRIPTION:

General information:

The state PASSIVE is active during engine stop, engine start, after start, warming up and inactivated NOx catalyst function.

The values of the variables listed below are their initialisation values.

If regeneration stop mode is “model”, NTL has to be initialised with a suitable high value in order to prevent the state manager to leave first regeneration (after function start) due to low model load.

Application conditions:

Initialisation: at reset:

```
if (139)    LC_NTL_INI_ST = 1
then (139)    NTL = C_NTL_INI_ST
else (139)    NTL = max(NTL(from NVMY) * C_FAC_NTL_INI_ST,
                            C_NTL_INI_ST)
endif (139)
NTL_H = NTL
```

NOX_COR_RED_MMV$_n$ = NOX_COR_RED * C_CRLC_NOX_COR_RED

+ NOX_COR_RED_MMV$_{n-1}$ * (1 - C_CRLC_NOX_COR_RED)
NOX_FLOW = NOX_COR_RED * NT_EFF

NOX_CONC_RAW = (NOX_COR_TMP / MAF_FG_CYL) * C_NOX_CONC_COR
NOX_CONC = NOX_CONC_RAW * NOX_AD_FAC
NOX_CONC_RED = NOX_CONC * IP_NOX_RED_FAC (TNT_MDL_MV)
NOX_CONC_MMV$_n$ = NOX_CONC * C_CRLC_NOX_CONC_RED
+ NOX_CONC_MMV$_{n-1}$ * (1 - C_CRLC_NOX_CONC_RED)
NOX_CONC_RED_MMV$_n$ = NOX_CONC_RED * C_CRLC_NOX_CONC_RED
+ NOX_CONC_RED_MMV$_{n-1}$ * (1 - C_CRLC_NOX_CONC_RED)

NOX_OUT_MDL = NOX_COR_RED * (1- NT_EFF)
NOX_CONC_OUT_MDL = NOX_CONC_RED * (1- NT_EFF)
NOX_CONC_OUT_MDL_MMV$_n$ = NOX_CONC_OUT_MDL *
C_CRLC_NOX_CONC_OUT_MDL + NOX_CONC_OUT_MDL_MMV$_{n-1}$ *
(1 - C_CRLC_NOX_CONC_OUT_MDL)
NOX_OUT_MDL_INT= NOX_OUT_MDL_INT$_{n-1}$ + NOX_OUT_MDL
% NOX_OUT_MDL_INT has to be internally treated as a longint.

The factor C_NOX_CONC_COR consists of the following chemical constants:

C_NOX_CONC_COR = molmass air / molmass NO2 * (1/factor for transformation “kg/h--> kg/s”) = 29 /46 * 3600 = 2269.565

This value should be the initialization value of the calibration data.

Due to possible small values of NOX_OUT_MDL, NOX_OUT_MDL_INT has to be internally treated as a longint.

53.6.1.4.2 NOx trap storage capacity and loading degree

General information:

The basic catalyst storage capacity is worked out by a map depending on the raw NOx concentration NOX_CONC and on the modelled NOx-trap temperature mean value. The aging factor NT_AGI_NTLD is delivered from the module NOx catalyst aging and reduces the basic storage capacity with the present aging state depending on catalyst temperature.

The current load of the NOx storage catalyst is worked out by the NOx mass flow actually available to be stored in the catalyst NOX_FLOW and the NOx trap efficiency NT_EFF.

The NOx trap loading degree is the ratio of the NOx trap absolute loading and the NOx storage capacity. The increase of NTLD is limited to C_NTLD_LGRD per time step.

Signal flow diagram:

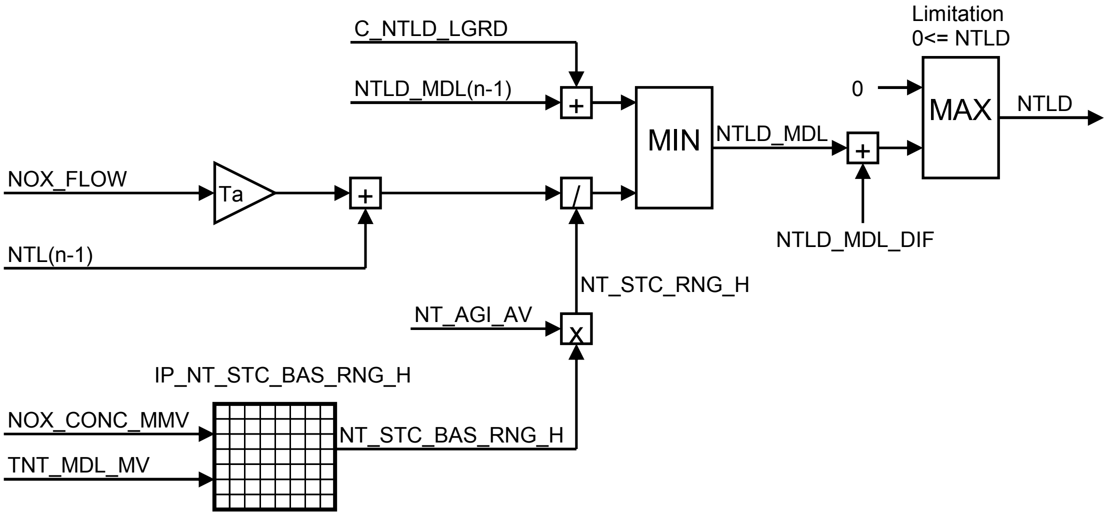

Figure 62: NOx catalyst storage capacity, absolute loading and loading degree

Formula section:

NT_STC_BAS_RNG_H = IP_NT_STC_BAS_RNG_H (NOX_CONC_MMV, TNT_MDL_MV))

NT_AGI_AV = IP_NT_AGI_RGN_FRQ (NT_AGI_NTLD, TNT_MDL_MV)

NT_STC_RNG_H = NT_STC_BAS_RNG_H * NT_AGI_AV

$NTL_n = NTL_{n-1} + NOX\_FLOW * Ta$

```
if (164)    TNT_MDL_MV >= (C_TNT_MDL_MV_NTL_H_RST_MIN +
                               C_TNT_MDL_MV_NTL_H_RST_HYS)        AND
            TNT_MDL_MV <= (C_TNT_MDL_MV_NTL_H_RST_MAX -
                               C_TNT_MDL_MV_NTL_H_RST_HYS)
then (164)    $NTL\_H_n = NTL\_H_{n-1} + NOX\_FLOW * Ta$
else (164)
        if (165)   LC_NTL_H_RST_LOAD_TNT = 1
        then (165)   NTL_H is reset
                     $NTL\_H_n = NTL\_MIN$
        else (165)   NTL_H is frozen
                     $NTL\_H_n = NTL\_H_{n-1}$
        endif (165)
endif (164)
```

Attention!
- Observe different resolutions and value ranges of NTL, NTL_H and NTL_MIN.
- NTL and NTL_H should be internally calculated as longint.

$NTLD\_MDL = \min(NTL / NT\_STC\_RNG\_H, NTLD\_MDL_{(n-1)} + C\_NTLD\_LGRD)$

NTLD = **max** (0, NTLD_MDL + NTLD_MDL_DIF)

53.6.1.4.3 NOx trap efficiency

General information:

The base NOx trap efficiency is given by a map depending on NOx trap loading degree and the modelled NOx trap temperature. The base value is corrected depending on the raw NOx mass flow NOX_COR.

Note: The value NT_EFF is limited to 1 in the program.

Signal flow diagram:

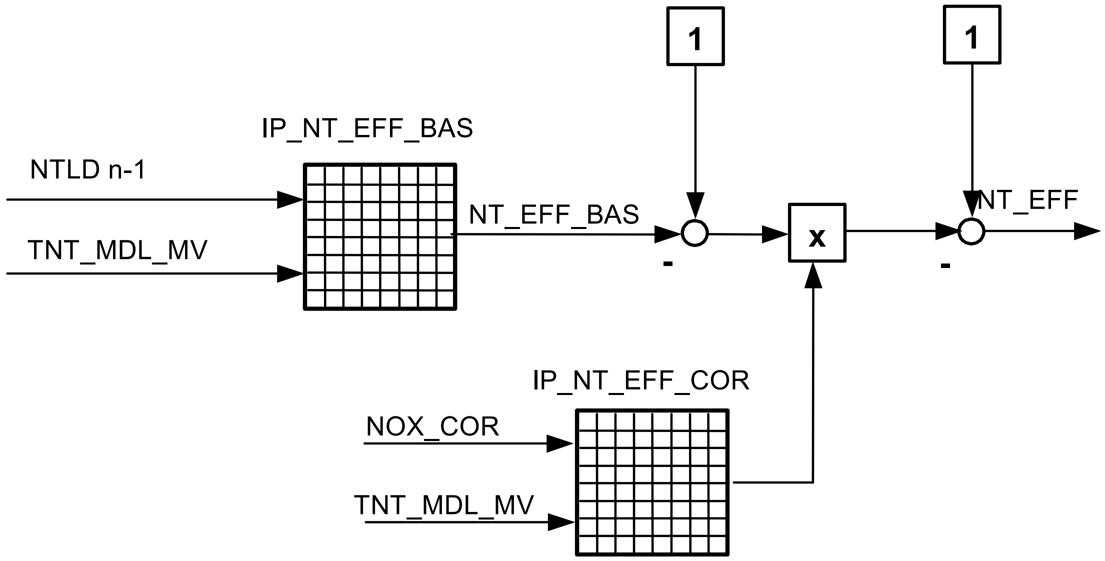

Figure 63: NOx trap efficiency (simplified)

Formula section:

if (30) LV_EF = 0

then (30) NT_EFF_BAS = IP_NT_EFF_BAS (NTLD, TNT_MDL_MV)

else (30) NT_EFF_BAS = IP_NT_EFF_BAS_EF_CLOSE (NTLD, TNT_MDL_MV)

% not shown in the figure

NT_EFF_COR = IP_NT_EFF_COR (NOX_COR, TNT_MDL_MV)

NT_EFF = 1 - ((1 - NT_EFF_BAS) * NT_EFF_COR)

53.6.1.4.4 Oxygen storage

General information:

During lean operation the NOx trap stores Oxygen. The current load of stored Oxygen in the NOx trap, O2L is worked out by a formula.

Signal flow diagram:

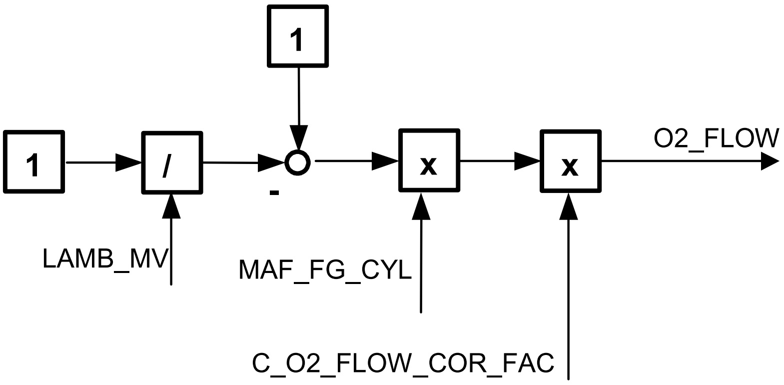

Figure 64: Oxygen mass flow

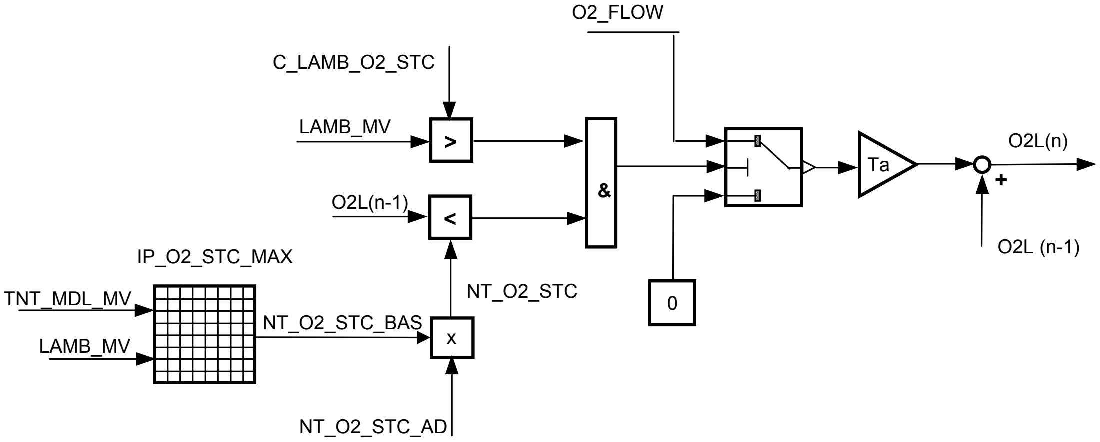

Figure 65: Oxygen storage

Formula section:

NT_O2_STC_BAS= IP_O2_STC_MAX (LAMB_LS_UP_MV, TNT_MDL_MV)

NT_O2_STC = NT_O2_STC_BAS * NT_O2_STC_AD

if (32) (LAMB_LS_UP_MV > C_LAMB_O2_STC)

and LAMB_LS_UP_MV > 1

and (O2L < NT_O2_STC)

then (32) O2_FLOW = (1 - (1/ LAMB_LS_UP_MV)) * MAF_FG_CYL * C_O2_FLOW_COR_FAC

O2L $_{(n)}$ = O2L (n-1) + O2_FLOW * Ta

else (32) O2L $_{(n)}$ = O2L (n-1)

endif (32)

The factor C_O2_FLOW_COR_FAC consists of the following constants:

C_O2_FLOW_COR_FAC = (0.21* molmass(O2)) / molmass(air) * factor for transformation of MAF_FG_CYL (kg/h) to (mg/s)) = 0.21 * 32 / 29 * 10^6 / 3600 = 64.37

This value should be the initialization value of the calibration data.

53.6.1.5 STATE_NOX = WAIT

FUNCTION DESCRIPTION:

53.6.1.5.1 General, NOx storage

General information:

When the engine state LV_PUC is active (-> STATE_NOX = WAIT), the NOx trap loading calculation is frozen.

Formula section:

NOX_COR = 0
NOX_COR_RED = 0
NOX_COR_RED_MMV = 0
NOX_CONC_RAW = 0
NOX_CONC = 0
NOX_CONC_RED = 0
NOX_CONC_MMV = NOX_CONC_MMV $_{n-1}$
NOX_CONC_RED_MMV = NOX_CONC_RED_MMV $_{n-1}$

NOX_CONC_OUT_MDL_MMV = NOX_CONC_OUT_MDL_MMV $_{n-1}$

NOX_OUT_MDL = 0

NT_STC_RNG_H = NT_STC_RNG_H(n-1)

NTLD = NTLD (n-1)

NTLD_MDL = NTLD_MDL (n-1)

NT_EFF = 0

T_AFL = T_AFL (n-1)

T_AFL_PUC = 0

NTL_DEC_INT_i = 0

T_NT_HOM = T_NT_HOM (n-1)

LV_CAT_PURGE_REQ_POST_AFL[i] = 0

NTL = NTL$_{n-1}$

```
if (161)    ( MAF_INT_PUC_ACT(n-1) < MAF_INT_PUC_ACT(n)     AND
              MAF_INT_PUC_ACT(n) > C_MAF_INT_PUC_NTL_H_RST )          OR
            TNT_MDL_MV < C_TNT_MDL_MV_NTL_H_RST_MIN                   OR
            TNT_MDL_MV > C_TNT_MDL_MV_NTL_H_RST_MAX
then (161)  NTL_H is reset
            NTL_H = NTL_MIN
else (161)  NTL_H is frozen
            NTL_H = NTL_H$_{n-1}$
endif (161)
```

LV_ACT_INT_PUC_AFL_i = 0

Evaluation of slope of MAF_INT_PUC_ACT moved from 20ms to 10ms.

53.6.1.5.2 Oxygen mass flow and oxygen storage

General information:

During the engine state LV_PUC the NOx catalyst stores oxygen. The current load of stored oxygen in the NOx trap is worked out by a formula.

The calculation of the following quantities is done in the same way as in STATE_NOX = LOAD.

(see subchapter “STATE_NOX = LOAD”, passage “oxygen storage”) (3 pages above)

Formula section:

call "Oxygen storage"

53.6.1.6 STATE_NOX = REGENERATION

FUNCTION DESCRIPTION:

General information:

For the regeneration of the NOx trap a rich mixture is required.

Application conditions:

Initialisation: --

```

53.6.1.6.3 Calculation of NTL_DEC and NTL_DEC_INT

General information:

For the regeneration of the NOx trap a rich mixture is required.

NTL_DEC_i represents the „lack of oxygen“ during regeneration. This lack of oxygen corresponds to the reducing agent mass. The unit of NTL_DEC therefore is [mg O2 / time step].

NTL_DEC_INT_i represents the integral of the NTL_DEC_i during regeneration. It is calculated during the regeneration phase.

NTL_DEC_INT_SWI represents the NTL_DEC_INT up to the moment the downstream sensor switches from lean to rich. This value may be used for several adaptation purposes.

Due to possible small values of NTL_DEC (defined as a longint), NTL_DEC_INT has to be internally treated as a longint.

Formula section:

```
if (155)   NC_NT_NR = 2
then (155) Twin branch system with 2 TWC and 2 NOx catalysts NC_CBK_EX_NR =
           NC_NT_NR = 2  =>  i = m = 2

        then (154)   NTL_DEC_INT_SWI[1] = NTL_DEC_INT_1

        endif (154)

        NTL_DEC_SUM = NTL_DEC[1]

    endif (155)
```

The factor C_O2_FLOW_COR_FAC consists of the following constants:

C_O2_FLOW_COR_FAC = (0.21* molmass(O2)) / molmass(air) * factor for transformation of MAF_FG_CYL (kg/h) to (mg/s)) = 0.21 * 32 / 29 * 10^6 / 3600 = 64.37

This value should be the initialization value of the calibration data.

NTL_DEC_INT has to be internally treated as a longint.

53.6.1.6.4 Decrementation of the NOx trap absolute loading of NOx and O2

General information:

During the regeneration phase the reducing agent is used for both, the reduction of the stored NOx and the stored O2. This is taken into account by using a share factor FAC_RGN_DEC_SHAR for the decrement of the NTL and the O2L. This share factor is calculated using the ratio of stored O2 to the sum of stored O2 and NOx.

C_FAC_O2_EQU and C_FAC_COR_O2L are based on the chemical equation of the regeneration phase.

- C_FAC_O2_EQU should be calibrated with 1.25 to be neutral.
- C_FAC_COR_O2L should be calibrated with 1 to be neutral.

The constant C_O2_FLOW_COR_FAC and is also defined in „oxygen storage“ subchapter of STATE_NOX=LOAD chapter.

Signal flow diagram:

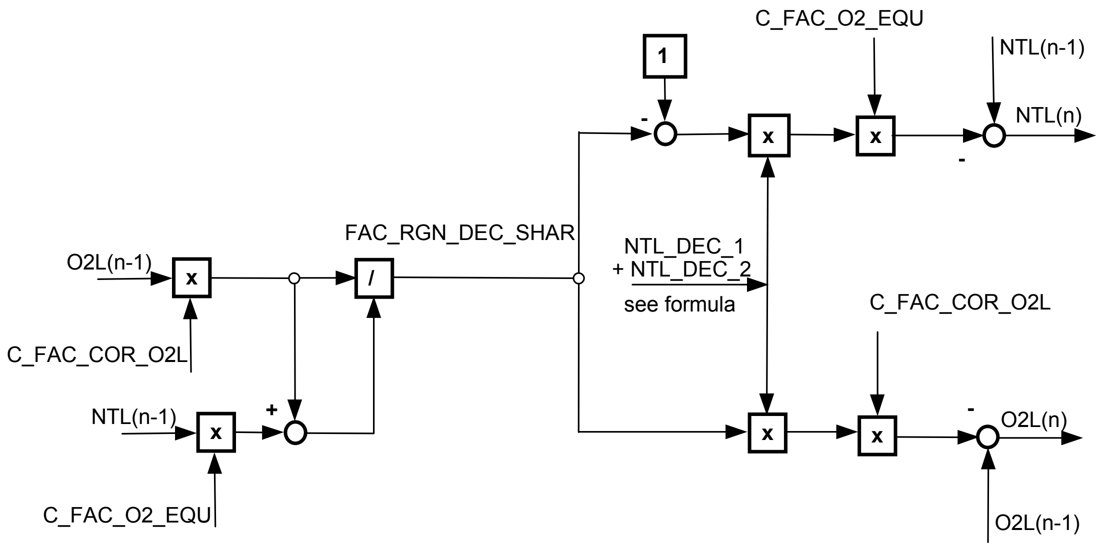

Figure 66: NOx trap loading decrement during regeneration phase

Formula section:

$$FAC\_RGN\_DEC\_SHAR = O2L_{(n-1)} * C\_FAC\_COR\_O2L / (O2L_{(n-1)} * C\_FAC\_COR\_O2L + NTL_{(n-1)} * C\_FAC\_O2\_EQU)$$

$$NTL_n = \mathbf{max}\ [NTL\_MIN, NTL_{n-1} - (1\text{-}FAC\_RGN\_DEC\_SHAR) * NTL\_DEC\_SUM * C\_FAC\_O2\_EQU]$$

$$NTL\_H_n = \mathbf{max}\ [NTL\_MIN, NTL\_H_{n-1} - (1\text{-}FAC\_RGN\_DEC\_SHAR) * NTL\_DEC\_SUM * C\_FAC\_O2\_EQU]$$

Attention!
- Observe different resolutions and value ranges of NTL, NTL_H and NTL_MIN.
- NTL and NTL_H should be internally calculated as longint.

$$O2L_{(n)} = \mathbf{max}\ (0, O2L_{(n-1)} - FAC\_RGN\_DEC\_SHAR * NTL\_DEC\_SUM * C\_FAC\_COR\_O2L)$$

$$NTLD\_MDL = NTL / NT\_STC\_RNG\_H$$

$$NTLD = max (0, NTLD\_MDL + NTLD\_MDL\_DIF)$$

53.6.1.7 STATE_NOX = STOP

FUNCTION DESCRIPTION:

General information:

When STATE_NOX remains in STOP (e.g. due to Lambda=1-engine operation), NTL_MIN can change due to trap temperature changes.

When the system remains in STATE_NOX = STOP for a longer time after a lean operation phase then the catalyst purge functionality is activated. The catalyst purge functionality is controlled by an own state machine.

Signal flow diagram:

Notes:

- For detection of a regeneration in catalyst purge the calibration data C_LAMB_RGN has to be calibrated always more lean than the calibrated lambda for catalyst purge.

- C_NT_STC_BAS_MAX_RNG_H should represent the maximum value of the base NOx trap storage capacity map IP_NT_STC_BAS_RNG_H. If any changes occur to IP_NT_STC_BAS_RNG_H, this constant must be updated manually.

53.6.2 NOx catalyst management - request coordination

53.6.2.1 Called blocks

FUNCTION DESCRIPTION:

These blocks are executed when called

53.6.2.1.1 Filtered exhaust gas flow

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: FLOW_NT_MMV = 0

Recurrence: 20 ms

Activation: --

Deactivation: --

Formula section:

$$FLOW\_NT\_MMV = FLOW\_NT\_MMV_{(n-1)} * (1-C\_CRLC\_FLOW\_NT) + MAF\_KGH * C\_CRLC\_FLOW\_NT$$

53.6.2.1.2 Homogeneous time counter handling

FUNCTION DESCRIPTION:

Application conditions:

Initialisation: T_NT_HOM_DELTA = 0

Recurrence: --

Activation: --

Deactivation: --

Formula section:

% decrement per 10ms

if (46) LV_HOM_AFS_ACT = 1

then (46)

```
    if (47)       LV_SENS_AFR_TRIM = 1
    then (47)     T_NT_HOM_DELTA = - IP_T_NT_HOM_DEC (MAF_KGH, LAMB_AV_COR)
    else (47)     T_NT_HOM_DELTA = IP_T_NT_HOM_INC (MAF_KGH, LAMB_AV_COR)
    endif (47)
else (46)   T_NT_HOM_DELTA = 0
endif (46)
```

53.6.2.2 General, definition of slow flags

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX

The switch LC_NOX_SENS and the logical variable LV_NOX_SENS indicate the existence of a NOx-Sensor in the exhaust system.

The regeneration of the NOx catalyst can be started by the NOx-Sensor signal or by the NOx trap loading degree model. With LV_NOX_SENS_RGN, generated by the code word LC_NOX_SENS_RGN, it is possible to decide whether only the NOx sensor should be able to request a regeneration or both, model and sensor are able to request:

- LV_NOX_SENS_RGN = 1: The regeneration is started exclusively by the NOx sensor signal. The loading degree model is blocked (the regeneration request before switching to lambda 1 is not affected).
- LV_NOX_SENS_RGN = 0: The regeneration starts when the NOx catalyst loading degree exceeds a threshold or by the signal of the NOx-Sensor (which comes first)

If the system is not equipped with a NOx-Sensor, LV_RGN_REQ_NOX_SENS is permanently set to zero.

Application conditions:

Initialisation: --

Recurrence: 1000 ms

Activation: --

Deactivation: --

Formula section:

```
LV_NOX_SENS = LC_NOX_SENS
LV_NOX_SENS_RGN =
    (LV_NOX_SENS= 1               and
    LC_NOX_SENS_RGN = 1           and
    LV_INH_NOX_SENS_RGN = 0       and
    LV_ADJ_NOX_SENS_RGN = 0)
```

53.6.2.3 General, definition of medium flags

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX except PASSIVE.

Application conditions:

Initialisation: --

Recurrence: 100ms

Activation: --

Deactivation: --

Formula section:

```
% definition of flag indicating initialised catalyst state
if (48)      T_NT_HOM = 0
then (48)    LV_NT_HOM_INI = 1
endif (48)
```

53.6.2.4 General, definition of fast flags

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX except PASSIVE.

At the beginning of a regeneration phase LV_TRIG_AFR_AFL must be 0. In order to trigger the transition from rich to lean operation the logical value LV_TRIG_AFR_AFL is set to 1 if the NTL becomes lower than C_NTL_TRIG_AFR_AFL.

Every time when a regeneration phase is finished the value SUM_NTL_CYC is incremented by 1. SUM_NTL_CYC has to be stored in the nonvolatile memory. SUM_NTL_CYC can be set to the specific value C_SUM_NTL_CYC_SP using the logical constant LC_SUM_NTL_CYC_NEW.

When either the binary lambda sensor or the NOx sensor indicates a rich exhaust gas downstream NOx trap, the logical variable LV_SENS_AFR_i is set to 1.

The mode of stopping a regeneration can be controlled by C_STATE_RGN_CTL. Thereby, it is possible to stop the regeneration only by the model, only by the sensor signal (LV_SENS_AFR) or by either model or sensor. In addition, a stop of regeneration after a constant regeneration time is possible. If a special regeneration (e.g. for adaptation purposes) was requested by LV_RGN_REQ_AD, the stop of the regeneration is forbidden until the adapting module re-enables it.

Application conditions:

Initialisation: --

Recurrence: 10ms

Activation: --

Deactivation: --

Formula section:

```
% definition of regeneration stop mode
LV_RGN_STOP_SENS =  ( LV_RGN_REQ_AD = 0 )                              and
                    ( C_STATE_RGN_CTL = SENSOR                  or
                      C_STATE_RGN_CTL = SENSOR_MODEL )

LV_RGN_STOP_MDL =   ( LV_RGN_REQ_AD = 0 )                              and
                    ( LV_INH_NT_RGN_STOP_MDL_DIAG[k] = 0
                        % valid if all [k] = 0
                        % condition should be removed at special
                        % case NC_NOX_SENS_CONF = 0
                    )                                                  and
                    ( C_STATE_RGN_CTL = MODEL                   or

53.6.2.4.1 Rich mode calculation of binary NOx-Senor signal

FUNCTION DESCRIPTION:

General information:

53.6.3 Rich mode calculation of binary NOx Sensor signal (named NOXY_VLSAFCLC110 in Figure 69)

The function sets the status flag LV_SENS_AFR_1 to rich mode and parallel sets the end of first regeneration flag LV_SENS_RGN_1_READY when the binary NOx-Sensor signal goes up for the first time over a threshold and sets the status flag LV_SENS_AFR_2 to rich mode in three ways (see Figure 68 below):

a) when the same binary signal goes up for the second time over a threshold (see Figure 68a).

b) when the binary NOx-Sensor signal goes for the first time over the threshold, then it goes not down enough and finally goes up (see Figure 68b).

c) when the binary NOx-Sensor signal goes for the first time over the threshold and then goes not down and the maximal time is over (see Figure 68c).

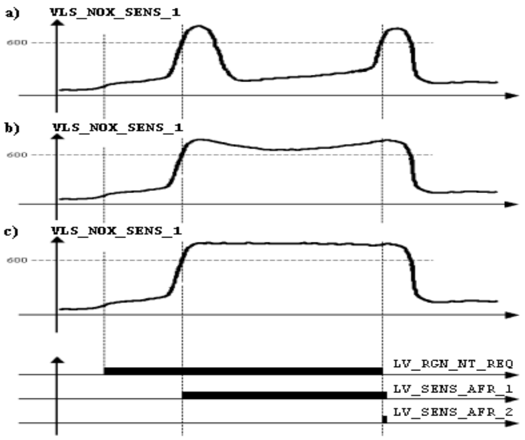

Figure 68: Signals during a NOx regeneration

This specification is special designed for systems with two banks (including two NOx-Traps) and Y-configuration of the exhaust gas system.

53.6.3.1 Request of a regeneration phase

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = LOAD

A request of a regeneration of the NOx catalyst can be made by the following conditions:

• from the model by a high loading degree	LV_RGN_REQ_NTLD
• by the signal of the post-trap NOx-Sensor	LV_RGN_REQ_NOX_SENS
• before switching to lambda=1 or richer operation	LV_RGN_REQ_AFS
• by the diagnosis / adaptation module	LV_RGN_REQ_AD

In order to guarantee a minimum duration of the lean phase the value IP_T_AFL_MIN has to be exceeded by the counter T_AFL before any regeneration request can be set.

In order to limit the regeneration frequency, T_AFL has to exceed C_T_AFL_RGN_REQ_NTLD before a regeneration request can be made by the loading degree model.

After a regeneration it is prohibited to generate a new regeneration request by the NOx sensor (LV_RGN_REQ_NOX_SENS_TMP_i = 1) for the time C_T_NOX_SENS_VLD. The time C_T_NOX_SENS_VLD is controlled by the timer T_AFL. T_AFL has to exceed C_T_NOX_SENS_VLD before a regeneration can be requested by the NOx sensor.

In case of active auxiliary functionalities module, a regeneration request by the loading degree model or by the NOx sensor may be inhibited by the flag LV_INH_RGN_AD.

When switching from lean conditions to lambda=1 or richer operation a regeneration can be required. The request of this regeneration phase depends on the maximum NOx-trap loading degree for stoichiometric operation IP_NTLD_MAX_AFS_MT / IP_NTLD_MAX_AFS_AT. The check for this maximum loading degree for stoichiometric operation is carried out ever when switching to homogeneous Lambda=1 or richer engine operation which should indicated by LV_AFL_NOT=1.

A regeneration can only be requested if various conditions for allowing a regeneration are fulfilled. In this case, the logical variable LV_RGN_CDN is set to 1.

53.6.3.1.2 NOx sensor based regeneration request

This block is executed when called

General information:

If the system has only 1 cylinder bank then the variable LV_RGN_REQ_NOX_SENS_TMP_1 generates directly the value of the logical variable LV_RGN_REQ_NOX_SENS. If the system is equipped with 2 cylinder banks, a regeneration request is set LV_RGN_REQ_NOX_SENS = 1, if at least one cylinder bank requests a regeneration LV_RGN_REQ_NOX_SENS_TMP_i = 1.

With LV_NOX_SENS_NOX_VLD_k is indicated that the signal NOX_NS_AD[k] is valid. In this case NOX_NS_AD[k] can be used for the generation of a regeneration request. Otherwise the regeneration request can not be generated by using NOX_NS_AD[k].

A NOx regeneration request can be generated by different methods. These are:

- the NOx concentration, which is measured downstream of NOx catalyst, exceeds a threshold
- the downstream measured NOx integral exceeds a threshold
- the ratio of downstream measured NOx integral to mileage exceeds a threshold
- the ratio of downstream measured NOx integral to upstream modelled NOx integral exceeds a threshold

Recurrence: called by superior chapter

53.6.3.2 Request of a NOx catalyst purge

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = LOAD

If there is no request for a regeneration before switching from lean burn condition to lambda=1 or richer mixture a NOx catalyst purge request is set dependent on the amount of stored NOx and O2 (NTL + O2L). The request is reset under the same conditions a regeneration is reset **or** when lambda exceeds C_LAMB_RGN.

The check for setting the request is only to be carried out if the request is yet unset.

LV_ACT_INT_PUC_AFL is passed to the *“catalyst enrichment function (cat-purge function for continuous lambda control)”* where a displacement of the lambda-controller setpoint will be done.

Signal flow diagram:

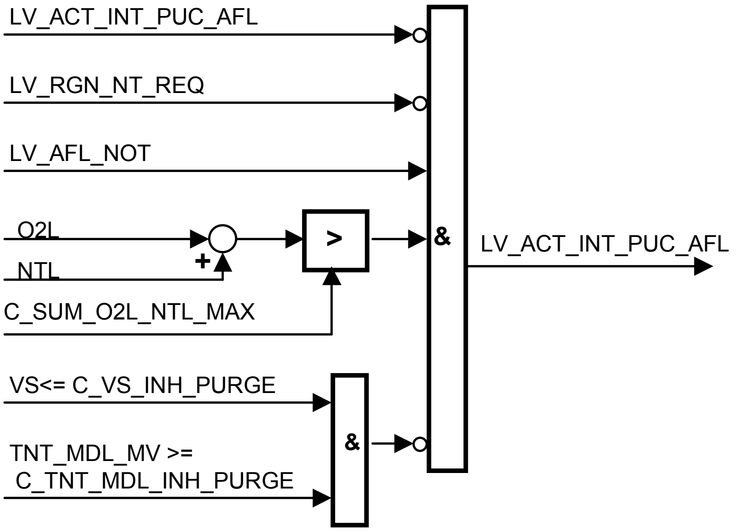

Figure 86: request of a catalyst purge

    endif (74)
```

53.6.3.3 Reset of regeneration and purge requests

FUNCTION DESCRIPTION:

General information:

This block is executed in STATE_NOX = REGENERATION

A regeneration phase is stopped under the following conditions:

- The modelled loadings of NOx and O2L both fall below a threshold
- All downstream sensors detect a rich mixture LV_SENS_AFR
- A constant time period is exceeded
- an engine state with higher priority is activated. These higher prior engine states can be fuel cut-off (PUC) or full load (FL).

The regeneration stopping conditions are valid under the following circumstances:

- A stop out of the model is possible if LV_RGN_STOP_MDL is set to 1.
- A stop by the sensor signal is possible if LV_RGN_STOP_SENS is set to 1.
- A stop by the time counter is possible if LV_RGN_STOP_TOUT is set to 1.
- Also a combination of sensor stop and model stop is possible.

The priority of the engine states fuel cut-off (PUC) and full load (FL) in relation to a running NOx regeneration are selectable by C_NT_RGN_STOP_PUC_SEL and C_NT_RGN_STOP_FL_SEL. It can be chosen:

C_NT_RGN_STOP_PUC_SEL =

0 ... the NOx catalyst control functionality does not react on the engine state fuel cut-off (PUC)

1 ... a running NOx regeneration is broken, when the air mass flow at PUC exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by
IP_T_AFL_MIN_NT_RGN_STOP

2 ... a running NOx regeneration is broken, when the air mass flow at PUC exceeds a threshold and the clutch is closed;
the minimum duration of next "LOAD" phase is defined by
IP_T_AFL_MIN_NT_RGN_STOP

C_NT_RGN_STOP_FL_SEL =

0 ... the NOx catalyst control functionality does not react on the engine state full load or a high engine load near full load.

1 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is broken, when the air mass flow at full load exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN

2 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is broken, when the air mass flow at full load exceeds a threshold;
the minimum duration of next "LOAD" phase is defined by IP_T_AFL_MIN_NT_RGN_STOP

3 ... new NOx regeneration requests are inhibited up to the end of full load phase or high engine load phase;
a running NOx regeneration is not broken

FUNCTION DESCRIPTION:

General information:

This block is executed in any STATE_NOX except PASSIVE.

Depending on various conditions the lean operation of the engine can be forbidden using LV_NT_AFS_REQ. This flag is an input to the combustion manager. There, it forces the combustion manager to switch to lambda=1 homogeneous mode.

All conditions leading to stoichiometric homogeneous operation of all modules of the NOx trap functions (including NOx catalyst aging and NOx catalyst desulfation) are handled by this subroutine in order to get only one flag as interface to the combustion manager. These conditions are:

- catalyst temperature too high
- catalyst temperature too low
- aging state too bad
- desulfation introduced
- other reasons considered in the corresponding application incidences module

Application conditions:

Initialisation: at reset:

TNT_MDL_MAX = 0
TNT_MDL_MIN = 0
LV_NT_AFS_REQ_PRED = 0
T_NT_AFS_REQ_PRED = 0
TQI_MMV_NOX = 0
VS_MMV_NOX = 0
VS_DIF_NOX = 0
VS_DIF_THD = 0
VS_DIF_HYS = 0

Recurrence: 100 ms

Activation: --

Deactivation: --

53.7 NOx catalyst management (Application Incidences)

53.7.1 Inhibiting the NOx catalyst management

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_NT_ACT	O/V	0...1H	0...1	1	[-]
flag inhibiting the NOx catalyst management					
T_IPLSL_VLD_DLY	V	0...FFH	0...25.5	0.1	[s]
Timer for hiding of short LV_IPLSL_VLD[i] = 0 phases at a MSA start					

Input data:

	LV_ERR_CAM	LV_ERR_MAF	LV_ERR_TCO
	NC_CBK_EX_NR	NC_NOX_SENS_CONF	LV_IPLSL_VLD[NC_CBK_EX_NR]

FUNCTION DESCRIPTION:

Number of NOx sensors:	NC_NOX_SENS_CONF	k = 1...NC_NOX_SENS_CONF
Number of lambda sensors:	NC_CBK_EX_NR	i = 1...NC_CBK_EX_NR

Typical configurations:
[NC_CBK_EX_NR:NC_NOX_SENS_CONF] =[1:1], [2:2], [2:1]

Description:

The timer T_IPLSL_VLD_DLY is limited to its maximum value. An overflow is not allowed.

Application conditions:

Initialisation: at reset

LV_INH_NT_ACT = 0
T_IPLSL_VLD_DLY = 0

Recurrence: 100 ms

Activation: at every engine state

Deactivation: -

Formula section:

```
if      LV_IPLSL_VLD[i] = 0                          % valid if at least one [i] = 0
then    T_IPLSL_VLD_DLY(n) = T_IPLSL_VLD_DLY(n-1) + Recurrence
else    T_IPLSL_VLD_DLY = 0
endif
```

53.7.3 Inhibiting the regeneration request due to modeled loading degree

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
LV_INH_RGN_REQ_NTLD	O/V	0...1H	0...1	1	[-]
flag inhibiting the request of a NOx catalyst regeneration due to high loading degree					

Input data:

LV_NT_ACT	LV_NOX_NS_AUTH[NC_NOX_SENS_CONF]	LV_NOX_NS_VLD[NC_NOX_SENS_CONF]	
LV_AT	NT_AGI	DIST_NT	

FUNCTION DESCRIPTION:

This is a dummy file provided for project-specific reasons to disable regeneration request due to high loading degree. Contrary to the previous subchapter, this new inhibition flag does not inhibit a regeneration due to a switch to homogeneous operation due to torque request by driver.

Application conditions:

Initialisation: at reset

LV_INH_RGN_REQ_NTLD = 0

Recurrence: 100 ms

Activation: LV_NT_ACT = 1

Deactivation: LV_NT_ACT = 0

Formula section:

Input data:

LV_NOX_NS_VLD[NC_NOX_SENS_CONF]	LV_T_NS_VLD	STATE_NOX	NTLD
T_NOX_NS_HLD[NC_NOX_SENS_CONF]	LV_NOX_NS_ACT[NC_NOX_SENS_CONF]	STATE_ERR_NS_OBD_2[NC_NOX_SENS_CONF]	STATE_END_NS_OBD_2[NC_NOX_SENS_CONF]
LV_NOX_NS_AUTH[NC_NOX_SENS_CONF]	LV_ERR_NS_OBD_1[NC_NOX_SENS_CONF]		

FUNCTION DESCRIPTION:

If the function is active (LC_INH_REQ_NOX_SENS_OFF = 0) and the NOx signal is not valid during the NOx catalyst loading phase the mode of the NOx regeneration request is switched from "SENSOR" to "MODEL". The NOx regeneration request by NOx sensor is as long as forbidden until the NOx sensor OBDII diagnosis is carried out and no error is appeared.

Application conditions:

Initialisation: at reset, at deactivation:

LV_INH_RGN_REQ_NOX_SENS = 0
LV_INH_NOX_SENS_RGN = 0
LV_NTLD_ADJ = 0
STATE_RGN_REQ = SENSOR

Recurrence: 100ms.

Activation: LC_INH_REQ_NOX_SENS_OFF = 0

Deactivation: LC_INH_REQ_NOX_SENS_OFF = 1

Formula section:

Default State:

STATE_RGN_REQ = SENSOR

Transitions:

STATE_RGN_REQ: **SENSOR to MODEL**

```
if    STATE_NOX = LOAD

53.7.8 Calculation of full load air mass flow integral

Output data:

Name	Mode	Hex. limits	Phys. limits	Resol.	Unit
MAF_INT_FL_ACT	O/V	0...FFFFH	0...6553.5	0.1	[g]
Air mass flow since activation of full load (LV_FL = 0->1)					
LV_LOAD_H	O/V	0...1H	0...1	1	[-]
High engine load detected					

Input data:

LV_NT_ACT	LV_FL	MAF_KGH	TQI_SP_MAF
N_32			

General information:

The air mass flow integral MAF_INT_FL_ACT is used for detection of short and long full load phases or high engine load phases inside of NOx catalyst management functionality. This classification of full load phases or high engine load phases is required for the decision whether a running NOx regeneration is terminated because of higher full load priority or not.

Description:

The constant NC_FAC_MAF_INT_FL includes the recurrence and converts the physical unit of MAF_KGH from [kg/h] to [g/ms].

NC_FAC_MAF_INT_FL = Recurrence/ 3.6

Note! The calculation of MAF_INT_FL_ACT shall be stopped if the maximum value of value range is reached. An overflow is not allowed.

Application conditions:

Initialisation: at reset, at deactivation:

MAF_INT_FL_ACT = 0
LV_LOAD_H = 0

Recurrence: 100ms

Activation: LV_NT_ACT = 1

Deactivation: LV_NT_ACT = 0

Formula section:

```
if      TQI_SP_MAF > IP_TQI_SP_MAF_LOAD_H(N_32)
then        LV_LOAD_H = 1
else
        if      TQI_SP_MAF < IP_TQI_SP_MAF_LOAD_H(N_32) - C_TQI_SP_MAF_LOAD_H_HYS
```

```
        then    LV_LOAD_H = 0
        else    LV_LOAD_H remains unchanged
        endif
endif

if      LV_FL = 1 OR LV_LOAD_H = 1
then    MAF_INT_FL_ACT(n) = MAF_INT_FL_ACT(n-1) + MAF_KGH * NC_FAC_MAF_INT_FL
else    MAF_INT_FL_ACT = 0

LV_ERR_NS_CAN_MSG_LOST[NC_NOX_SENS_CONF]	LV_T_NS_VLD	NC_NOX_SENS_CONF	STATE_ERR_NS_OBD_2[NC_NOX_SENS_CONF]

FUNCTION DESCRIPTION:

LV_ERR_NS_OBD_2[NC_NOX_SENS_CONF]

General information

The NOx signal of the NOx sensor is used to calculate the NOx tailpipe emission during lean operation mode.

The NOx concentration measured behind the NOx catalyst is converted into a mass flow. This NOx mass flow is integrated up to the absolute NOx tailpipe emission during a lean phase.

NC_NOX_SENS_CONF is the number of NOx sensors within the system. Therefore the index i represents:

i = 1 ... signals based on NOx sensor 1, which is mounted at cylinder bank 1 or at a summary tailpipe section of a Y exhaust line configuration

i = 2 ... signals based on NOx sensor 2, which is mounted at cylinder bank 2

Application conditions:

Initialisation: at reset

NOX_OUT_MES_INT[i] = 0
NOX_OUT_MES[i] = 0

Recurrence: *20 ms*

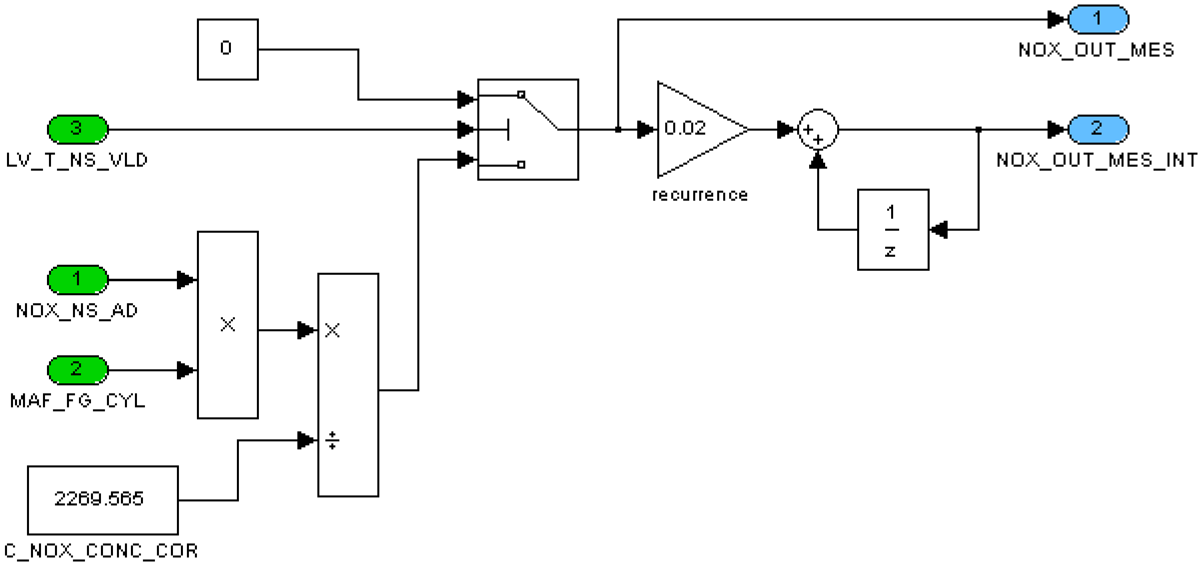
Activation: **if** NC_NOX_SENS_CONF > 0

then every time

```
        endif

Deactivation:  NC_NOX_SENS_CONF = 0
```

Signal flow diagram:



This signal flow diagram shows the calculation principle. For details see the "Formula section" below.

Formula section:

```
if (1)   STATE_NOX(n-1) = STOP                                AND

FUNCTION DESCRIPTION:

Number of NOx sensors NC_NOX_SENS_CONF i = 1...NC_NOX_SENS_CONF

General information:

The NOx catalyst model (NOx catalyst management) provides the modelled NOx emission flow downstream the NOx Catalyst, NOX_OUT_MDL, which corresponds to NOX_OUT_MES, the measured NOx emission flow downstream the NOx Catalyst. The deviations between modelled and measured values are minimised with a PI-controller influencing NTLD used in the NOx catalyst model.

If the system is equipped with 2 cylinder banks, a regeneration request is set if at least one cylinder bank requests a regeneration. Due to the NOx catalyst model ist calibrated with the NOx-Sensor measuring the higher value.

Application conditions:

Initialisation:	at engine stop -> start: *LV_INH_NOX_MDL_CTRL_RGN_SNG[i] = LC_INH_NOX_MDL_CTRL_INI*
Recurrence:	20 ms
Activation:	LC_NOX_MDL_CTRL_ACT = 1
Deactivation:	**if** LC_NOX_MDL_CTRL_ACT = 0

```
if    LC_NOX_MDL_CTRL_ACT = 0
then  NTLD_MDL_DIF = 0,
      T_NOX_MDL_CTRL_ENA[i] = 0
      T_NOX_MDL_CTRL_ACT[i] = 0
      NTLD_MDL_DIF_I = 0
      NTLD_MDL_DIF_I_SNG[i] = 0
      NOX_OUT_MES_MMV[i] = NOX_OUT_MES[i]

FUNCTION DESCRIPTION:

General information:

Number of NOx catalyst:	NC_NT_NR	i = 1...NC_NT_NR
Number of NOx sensors:	NC_NOX_SENS_CONF	k = 1...NC_NOX_SENS_CONF
Number of lambda sensors:	NC_CBK_EX_NR	m = 1...NC_CBK_EX_NR

Typical configurations:
[NC_CBK_EX_NR:NC_NT_NR:NC_NOX_SENS_CONF] =[1:1:1], [2:2:2], [2:2:1], [2:1:1]

53.10.1 Limited Dynamics

Initialisation: -

Recurrence: 20 ms

Activation: at any state

Formula section:

```
if (1)      STATE_NOX = STOP --> !STOP          % initialisation of LV_NOX_AD_DYW
then(1)     LV_NOX_AD_DYW = 1
            NOX_COR_S_MMV (n) = NOX_COR_S
endif(1)

MAF_FG_CYL_MMV (n) = MAF_FG_CYL_MMV (n-1) * (1 - C_CRLC_MAF_FG_CYL) +
 C_CRLC_MAF_FG_CYL * MAF_FG_CYL

Limited dynamics for stratified operation:

if(1) STATE_NOX = LOAD and LV_HOM_AFS_REQ = 0
                        %monitoring limited dynamics during stratified
                mode
then(1)
NOX_COR_S_MMV (n) = NOX_COR_S_MMV (n-1) * (1 - C_CRLC_NOX_AD) +
                    C_CRLC_NOX_AD * NOX_COR_S
    if(2) |NOX_COR_S - NOX_COR_S_MMV| > C_NOX_AD_DYW or
            (LV_NOX_NS_VLD[k] = 0 and LV_T_NS_VLD = 1)
                                % valid if any condition for [k] is true
            or     LAMB_LS_UP[m] < C_LAMB_NOX_AD_DYW
                                % valid if any condition for [m] is true
    or      N_32 <= C_N_32_NT_AGI_MIN
            or     N_32 >= C_N_32_NT_AGI_MAX
            or     MFF_SP_S <= C_MFF_SP_S_NT_AGI_MIN
            or     MFF_SP_S >= C_MFF_SP_S_NT_AGI_MAX
    then(2)        LV_NOX_AD_DYW = 0
    else(2)        LV_NOX_AD_DYW remains unchanged
    endif(2)
else(1) LV_NOX_AD_DYW remains unchanged
```

```
endif(1)
```

Limited dynamics for regeneration:

```
if(1) STATE_NOX = REGENERATION %monitoring limited dynamics during stratified mode
then(1)
    if(2) | MAF_FG_CYL - MAF_FG_CYL_MMV | > C_MAF_FG_CYL_DYW
    or      VS ≤ C_VS_MIN_RGN_NOX_AD
    or      N_32 < C_N_32_MIN_RGN_NOX_AD
    or      MAF_FG_CYL < C_MAF_MIN_RGN_NOX_AD
    or      LV_PUC = 1
     then(2)        LV_NOX_AD_DYW = 0
    else(2)         LV_NOX_AD_DYW remains unchanged
    endif(2)
else(1) LV_NOX_AD_DYW remains unchanged
endif(1)
```

53.10.2 Emission Adaptation

Application conditions:

Initialisation: *At flashing: NOX_AD_FAC_SNG[i] = 1*

At reset: LV_NOX_AD_CMPL = 0
At reset: NOX_AD_FAC = (NOX_AD_FAC_SNG[1] + NOX_AD_FAC_SNG[2]) /NC_NT_NR

Recurrence: 100 ms

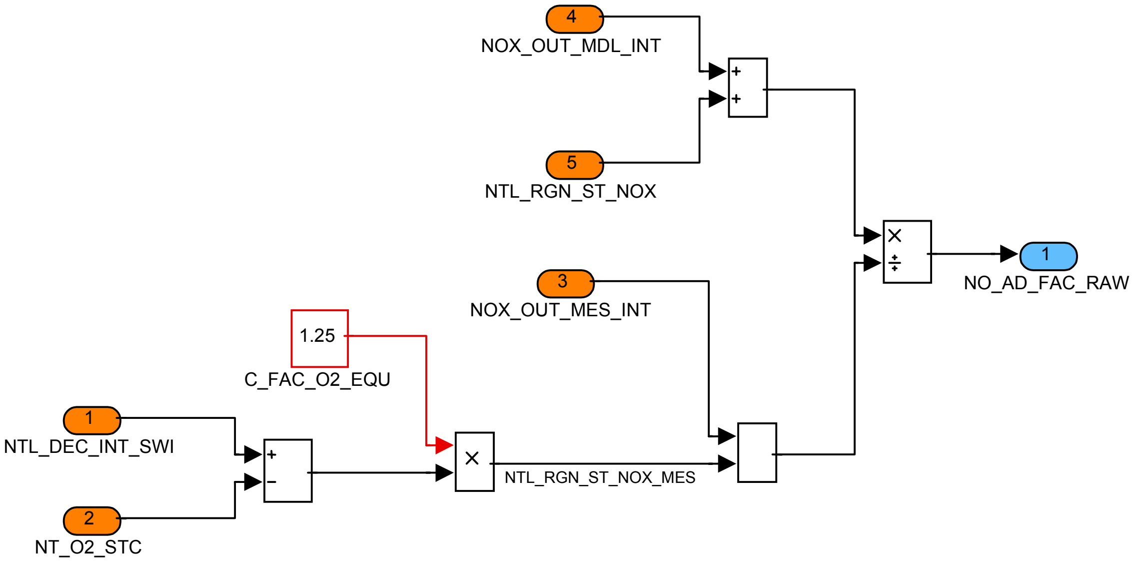
Activation: LC_NOX_AD_ACT = 1

Deactivation: **if** LC_NOX_AD_ACT = 0

then Initialisation*:* LV_NOX_AD_CMPL = 1

NOX_AD_FAC = (NOX_AD_FAC_SNG[1] +
NOX_AD_FAC_SNG[2])/ NC_NT_NR

Signal flow diagram:



Formula section:

53.12.1 General information

The NOx catalyst aging function can handle single branched and twin branched exhaust gas lines with the configuration data NC_NT_NR defined in the NOx catalyst management module.

If NC_NT_NR=1, just one exhaust line is taken into account, if NC_NT_NR=2, the software calculates the twin branch version.

i characterises the variable of branches which can be counted up

The NOx storage catalyst looses its storage capacity due to thermal aging and sulfur poisoning.

The aging is determined by the NOx-signal of a NOx-sensor, mounted downstream the NOx catalyst. The information, which kind of sensor is installed is included in LV_NOX_SENS.

The aging state of the catalyst is evaluated by an aging factor NT_AGI_SNG_i. The value of this factor is 1 in the case of a fresh catalyst, a value near zero indicates a destroyed catalyst. The resulting aging factor NT_AGI is the minimum of all existing NT_AGI_SNG_i.

The aging factors NT_AGI_SNG_i mainly will be decreased by the aging determination in this routine. Due to desulfation, the aging state of the catalyst can be improved (storage capacity increases). This increase is calculated by the desulfation function and passed to the aging function by NT_AGI_INC_SO2P. This value is set to 0 if no desulfation is active, otherwise it includes the incremetation of the aging factor per time step. This increment is added to the aging factor at every call of the aging function.

Handling of the aging states

When the resulting aging factor NT_AGI falls below the threshold C_NT_AGI_1 the desulfation request bit LV_SO2P_REQ_1 is set.

When the aging factor falls below the threshold C_NT_AGI_2 the desulfation request bit LV_SO2P_REQ_2 is set, this means an active catalyst heating is required.

When the aging factor falls below the threshold C_NT_AGI_3 a desulfation is requested. If this desulfation is not successful lean operation has to be forbidden, the request bit LV_NT_AFS_REQ_AGI for lambda=1 operation due to aging state is set.

The request for a desulfation or for operation in lambda=1 mode can be manually reseted by LC_NT_AGI_INI_MAN, in this case NT_AGI_SNG_i is initialized with C_NT_AGI_INI_i.

The values NT_AGI, NT_AGI_i have to be stored in the non-volatile memory.

Calculation of the base aging factor

The basis aging factor is determined by the NOx-signal of the NOx-Sensor NOX_PPM_i and the calculated reduced NOx raw emissions NOX_CONC_RED. In the moment the first NOx-Sensor detects an inadmissible high NOx concentration downstrem the NOx catalyst and as a consequence LV_RGN_REQ_NOX_SENS is switched from 0 to 1, the actual storage capacity is calculated and compared with the base storage capacity of a fresh catalyst. The aging factor is calculated using the ratio of the actual storage capacity and the base storage capacity NT_STC. The calculation is carried out once when the regeneration starts.

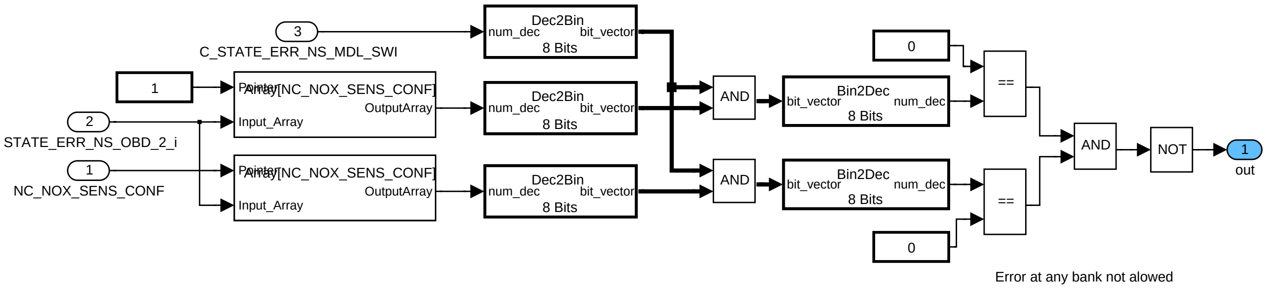

Figure 103 NOXM_MODUL703P/ operate/ MAIN/ CBK/ CLC_LV_SWI/ BITWISE_AND

MAIN (for each NOx trap)

The following calculation will be done for each NOx trap, controlled by NC_NT_NR.

Aging calculation will only be done if a rising edge of the trigger signal LV_AGI_AD_TRIG occurs and the NOx sensor reaches a threshold at start of regeneration.

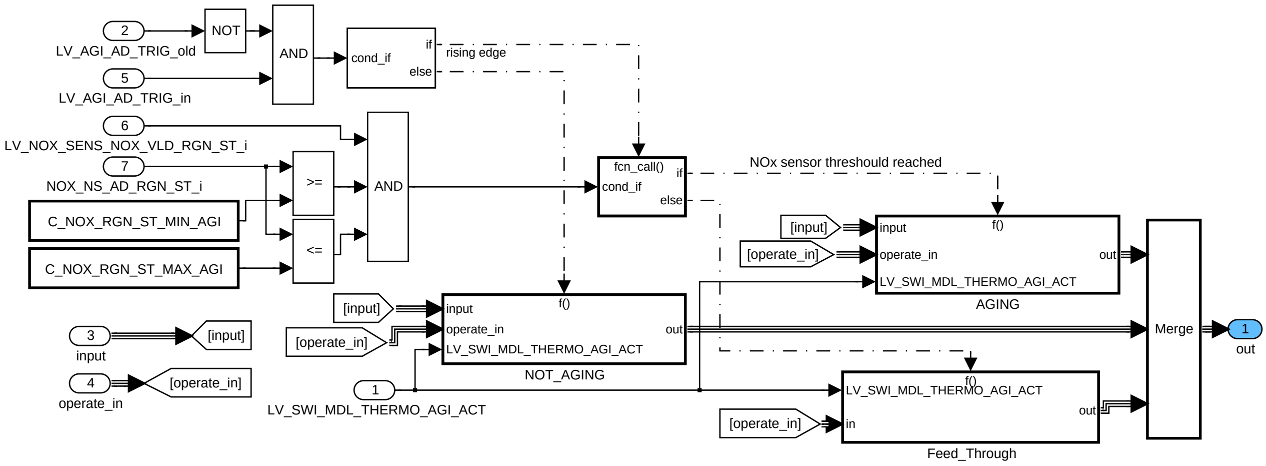

Figure 104 NOXM_MODUL703P/ operate/ MAIN/ CBK/ SELECT

Calculation of the new base aging factor

Update of sulphur aging factor during desulfation (during desulfation, the sulphur load is decreased and the sulphur load aging factor is incremented).

Initialisation of quick aging monitoring factors

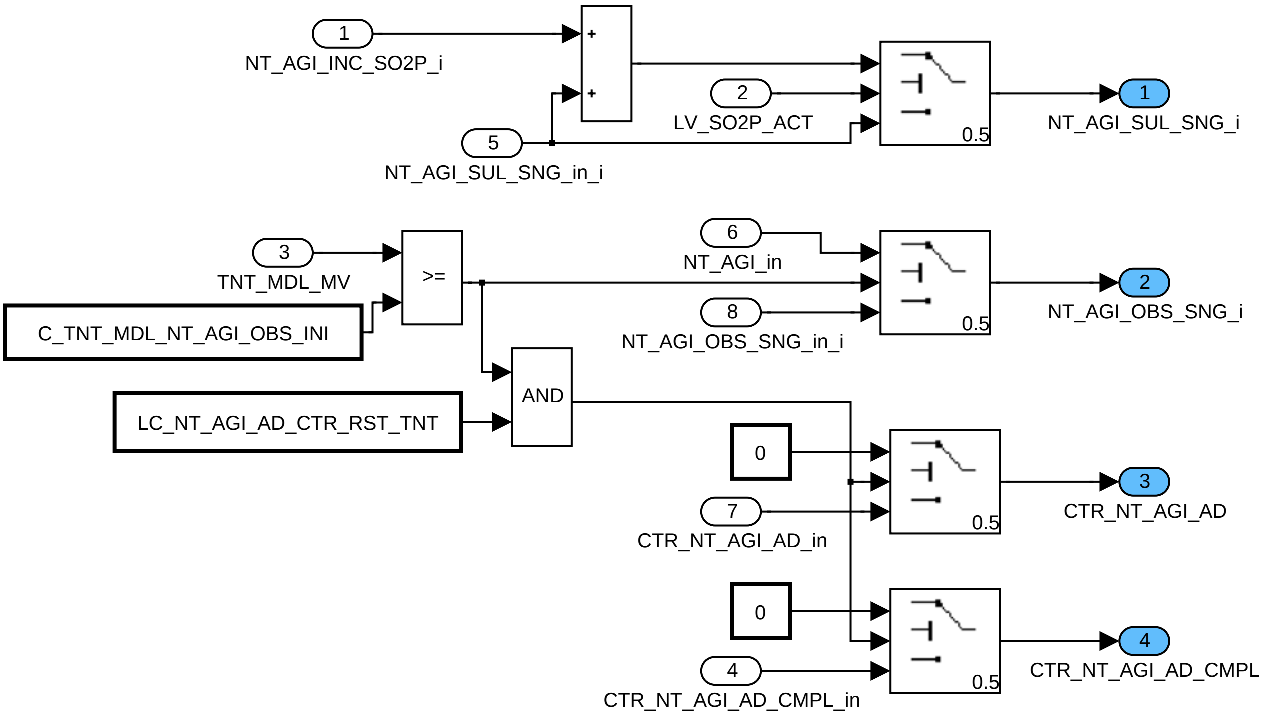

Figure 110 NOXM_MODUL703P/ operate/ MAIN/ CBK/ SELECT/ NOT_AGING/ CLC

MAIN (after calculations for each NOx trap)

The incrementation of the counters and the integral for the fuel quality calculation have to be calculated once if the condition is true for one bank or both banks.

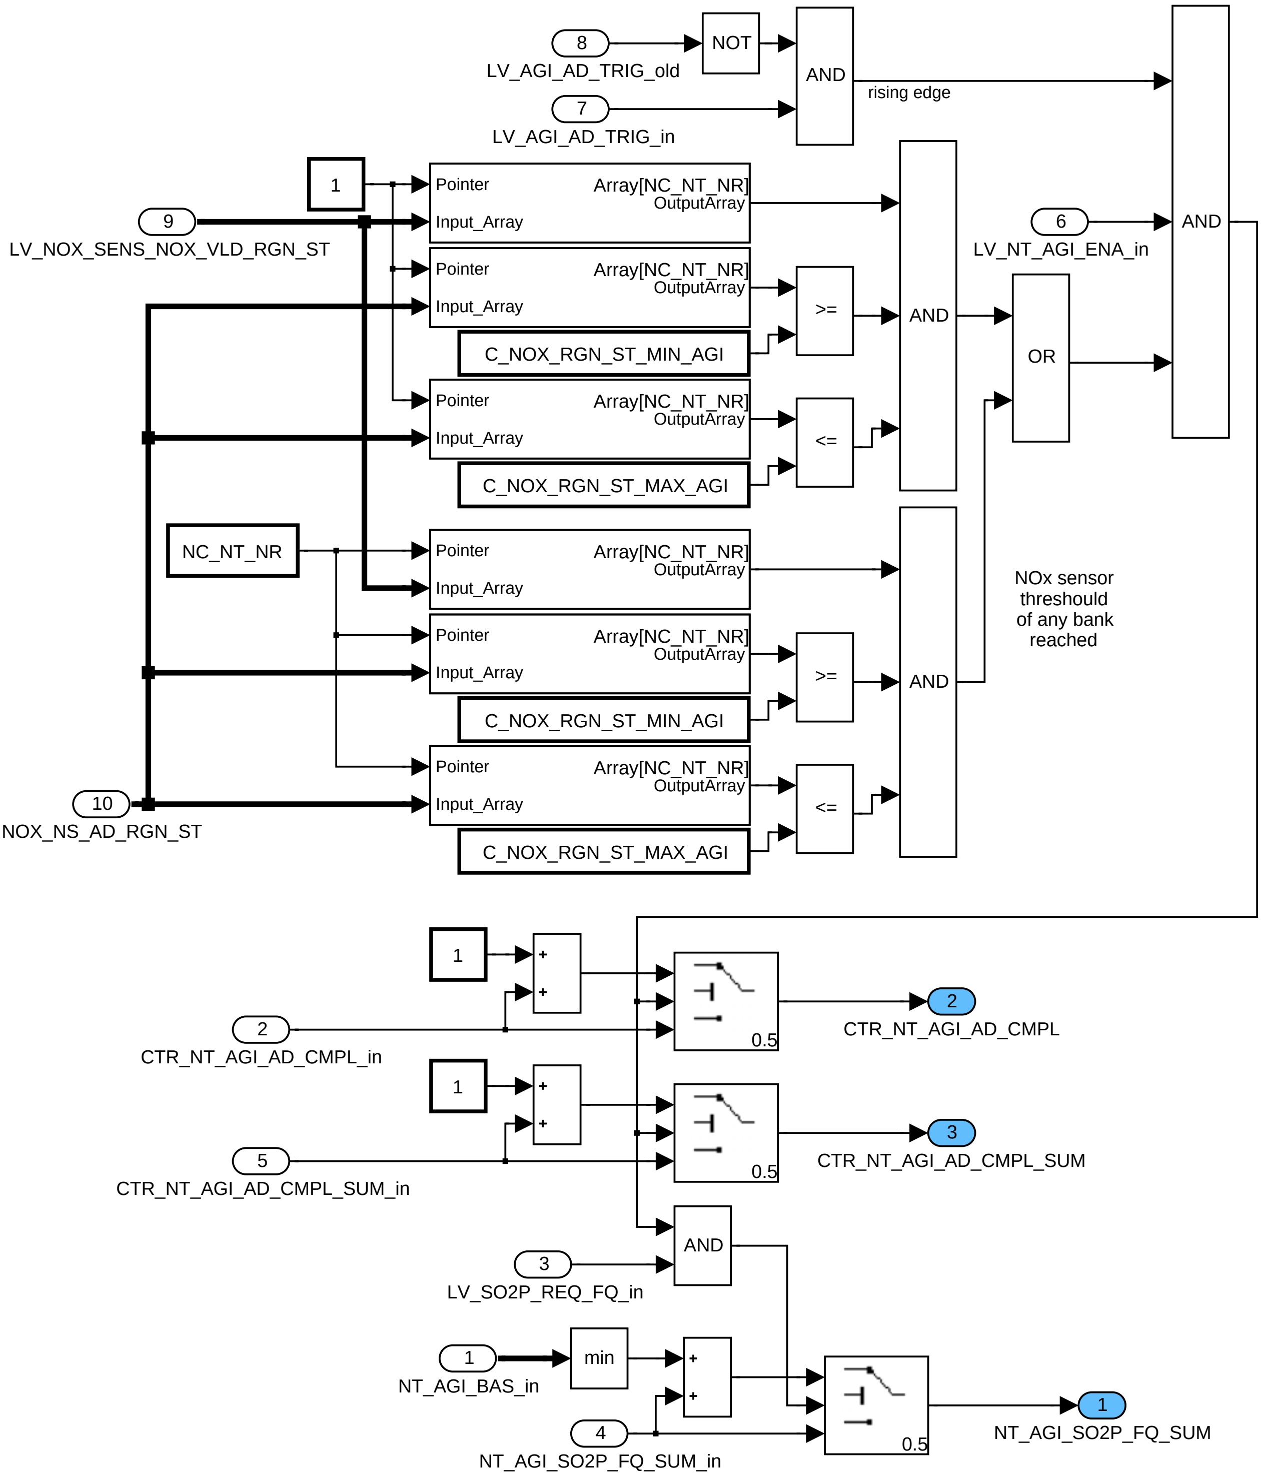

Figure 111 NOXM_MODUL703P/ operate/ MAIN/ CTR

ENABLING_FLAGS

The calculation of the aging enabling flags is done after the aging calculation, thereby it's possible to reset LV_NT_AGI_ENA in regeneration, the aging calculation is done at the first calculation of the main loop in regeneration.

Conditions to enable base aging fctor calculation/quick monitoring

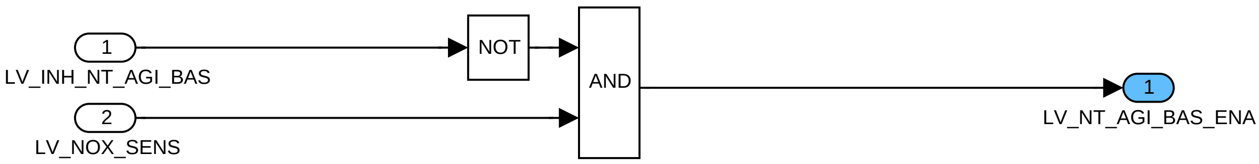

Figure 112 NOXM_MODUL703P/ operate/ ENABLING_FLAGS/ CLC1

Condition to enable aging factor calculation

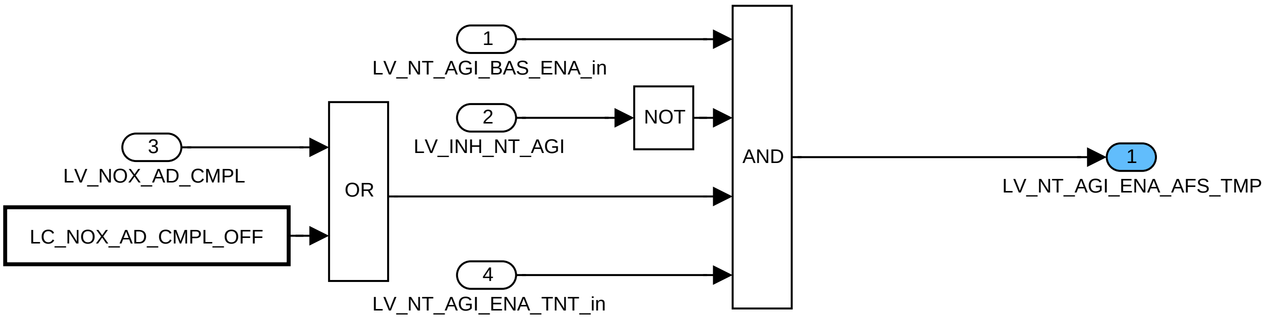

Figure 113 NOXM_MODUL703P/ operate/ ENABLING_FLAGS/ CLC2

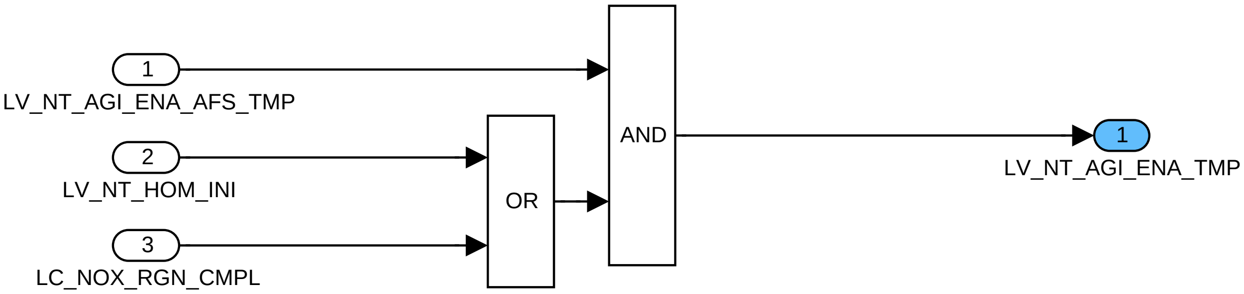

Figure 114 NOXM_MODUL703P/ operate/ ENABLING_FLAGS/ CLC3

The T_AFL condition uses only lean phases whith LV_NT_AGI_ENA given at the beginning of the lean phase; aim is to prevent a closing of the EGR valve in the “middle” of a lean phase due to aging adaptation conditions given starting there as well as performing an adaptation after a lean phase with adaptation condition given only temporary.

CTR_NT_AGI_AD and CTR_NT_AGI_AD_CMPL have physical limits from 0 to 254 whereas the corresponing threshold constants C_CTR_NT_AGI_AD_MAX & C_CTR_NT_AGI_AD_CMPL_MAX have physical limits from 0 to 255. Thus by setting the constants to their maximum value the condition CTR < thd is always true and no limitation of the adaptation attemps / adaptation cycles will occur

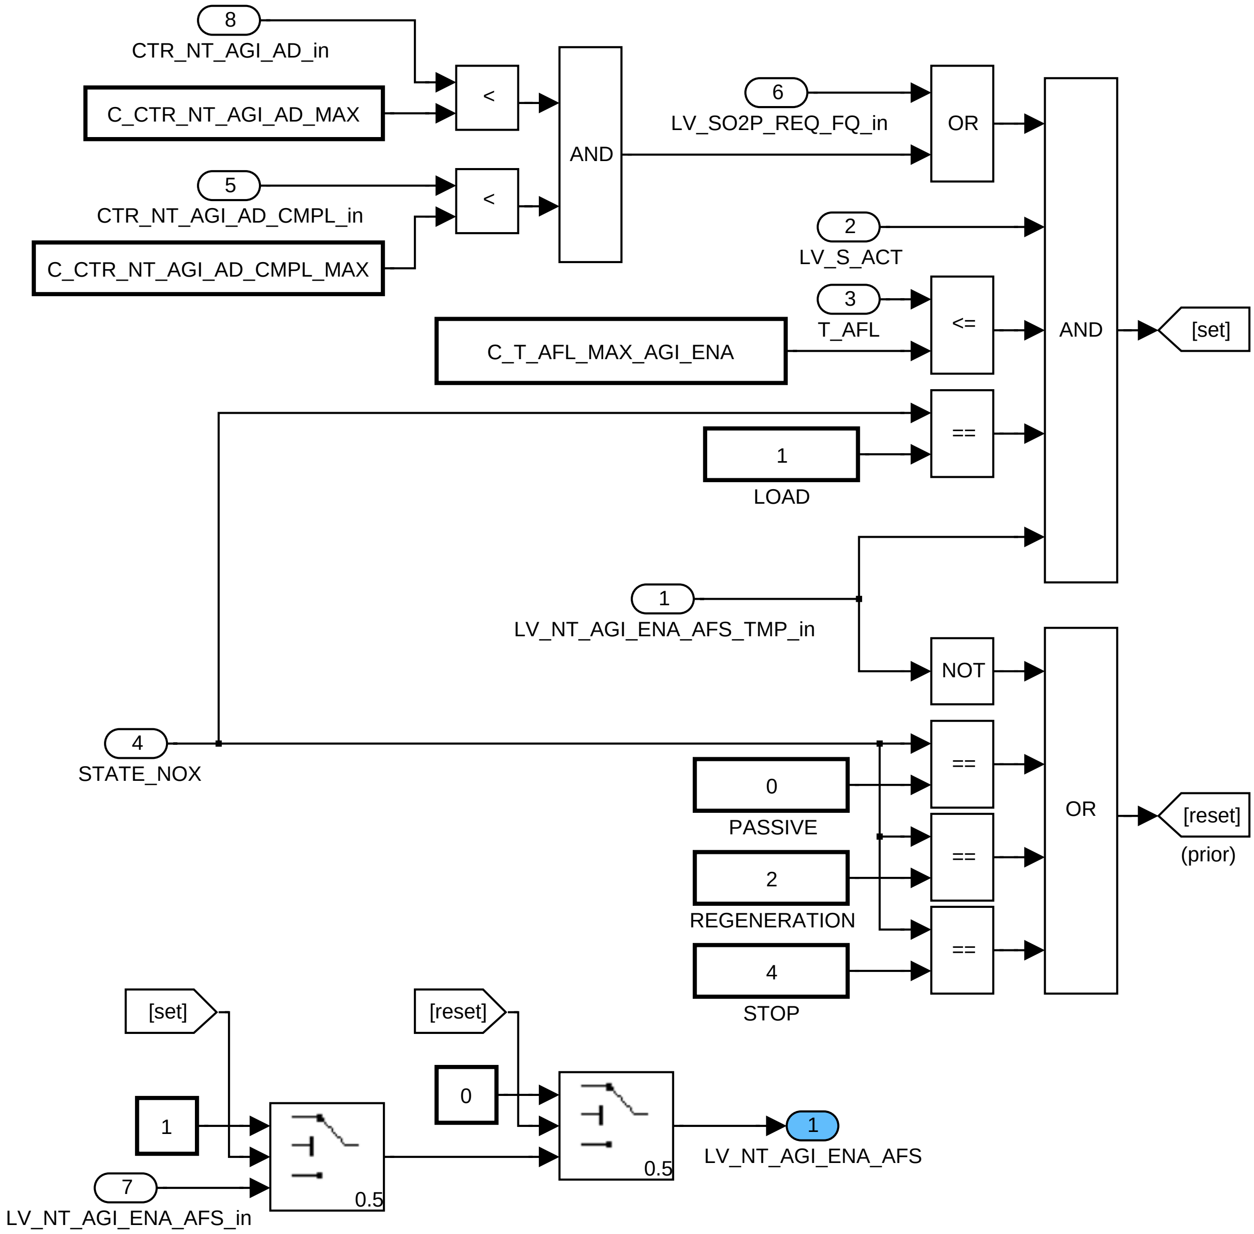

Figure 115 NOXM_MODUL703P/ operate/ ENABLING_FLAGS/ CLC4

Conditions to close EGR valve during aging adaptation

The attemps counter is only calculated if EGR was closed; if the function is calibrated “passive” (i.e. without closing EGR) the number of attempts is not limited.

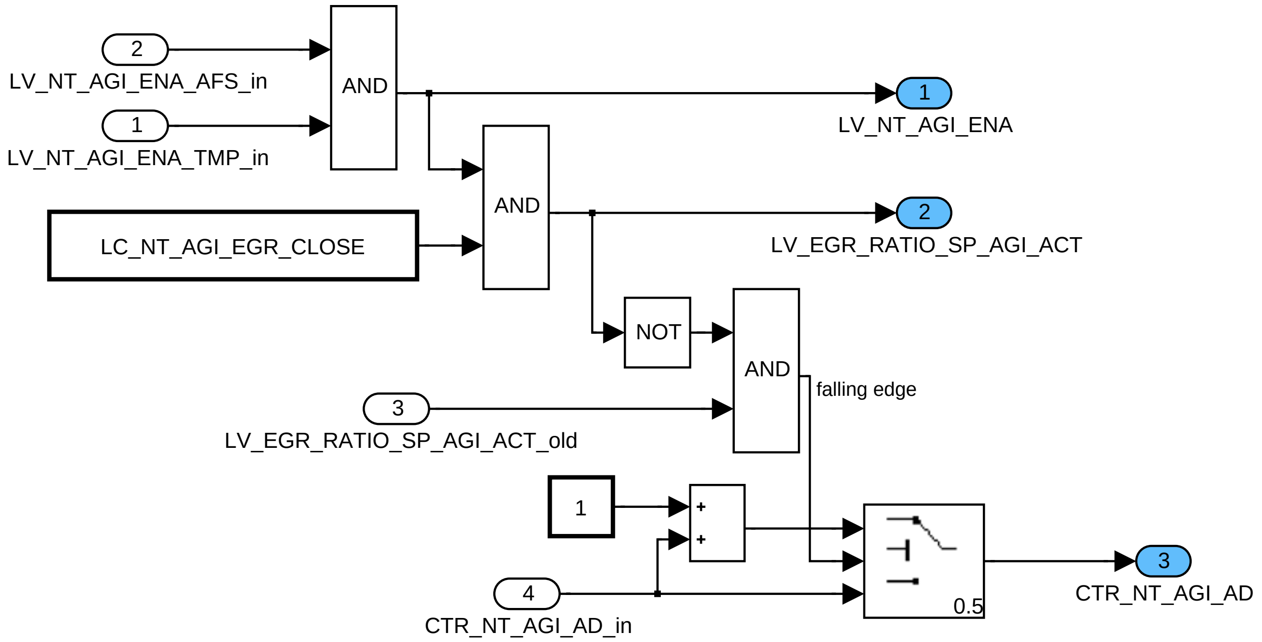

Figure 116 NOXM_MODUL703P/ operate/ ENABLING_FLAGS/ CLC5

AGING_FACTOR: Aging factor handling

NT_SUL_AGI_SNG will be calculated from the aging factor due to sulphur load for each bank, defined by NC_NT_NR.

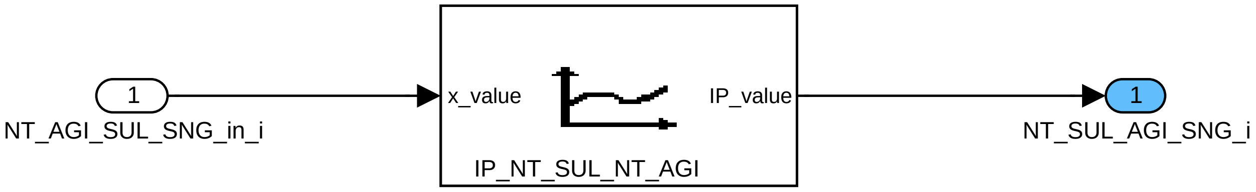

Figure 117 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CBK/ CLC1

Bank selective values will be combined: minimum of aging factors and maximum of sulphur load.

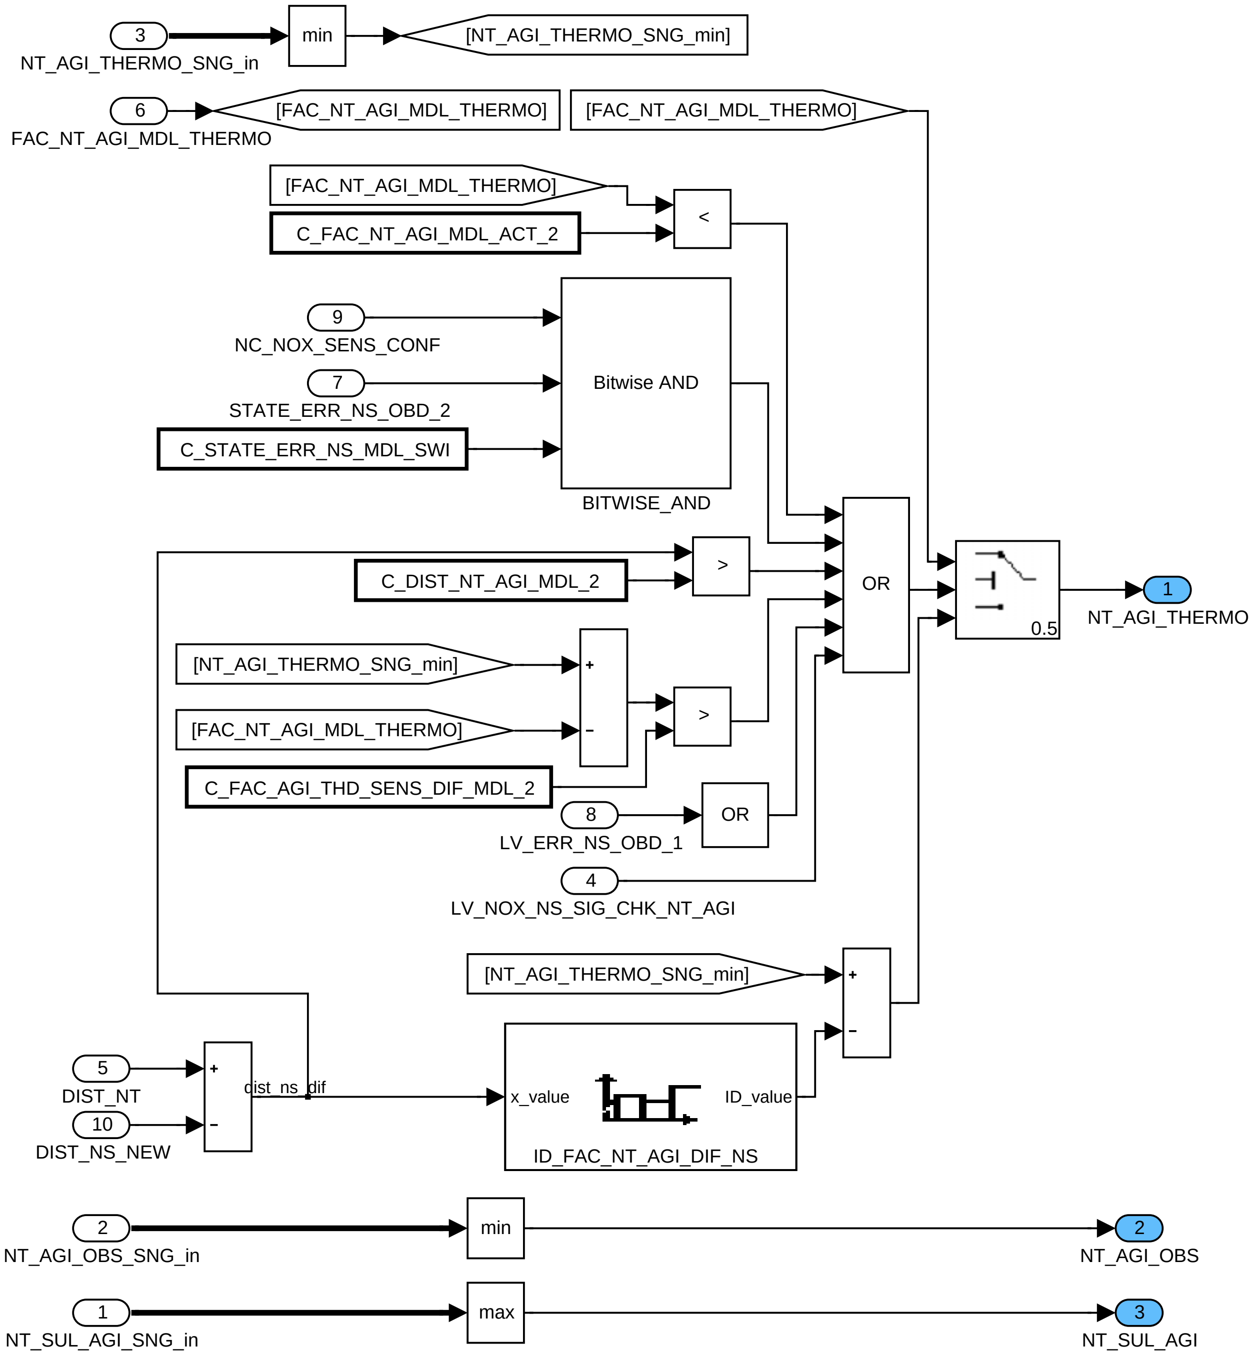

Figure 118 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC2

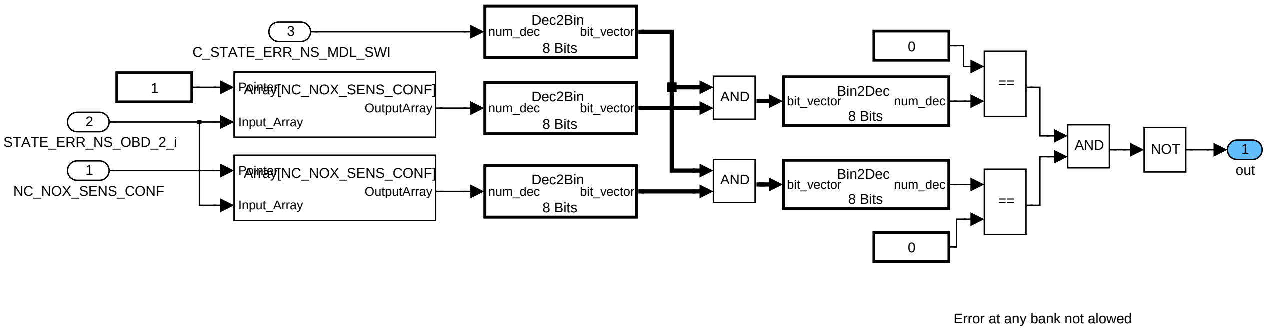

Figure 119 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC2/ BITWISE_AND

The NOx trap aging factor may be updated from updated from sulphur model (this picture) or vice versa (next picture)

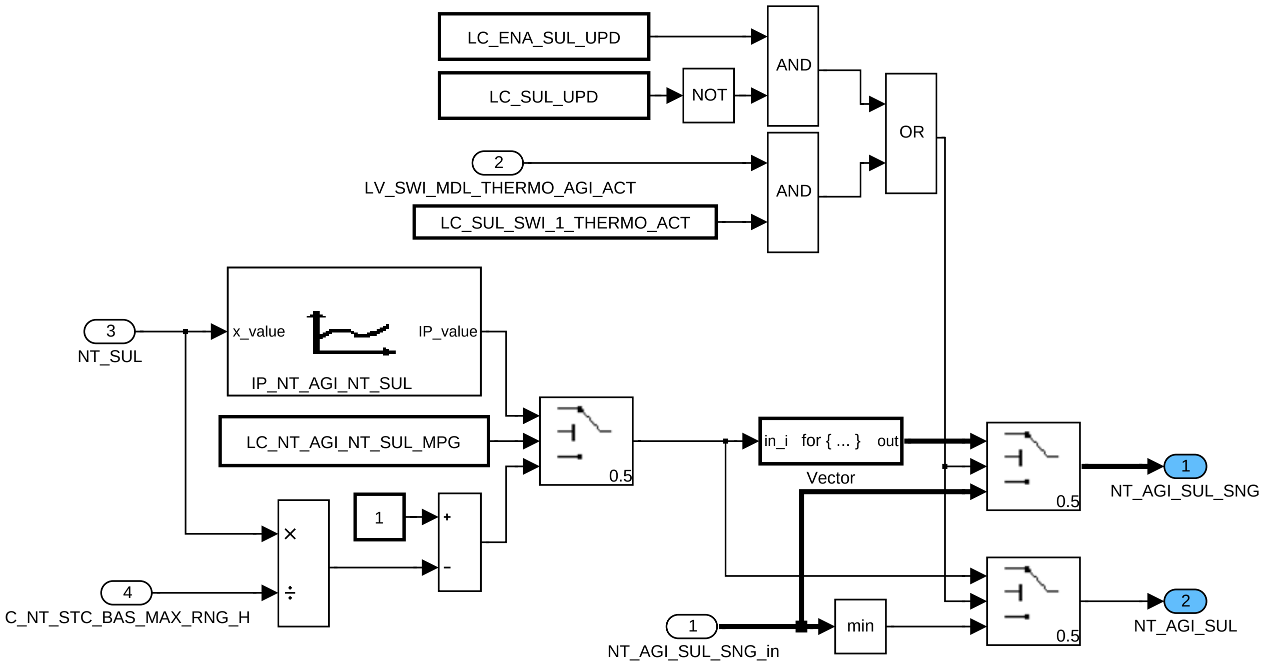

Figure 120 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC3

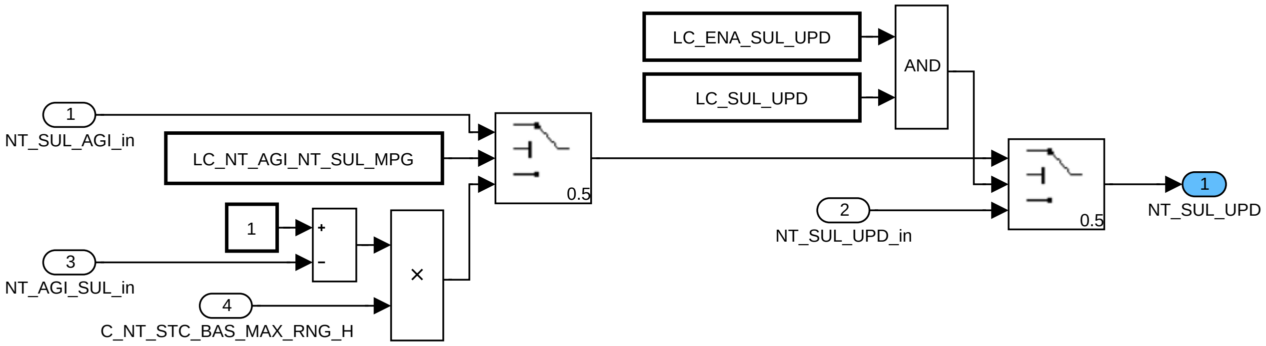

Figure 121 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC4

The following pictures show that NOx trap aging factors may be selected from different sources.

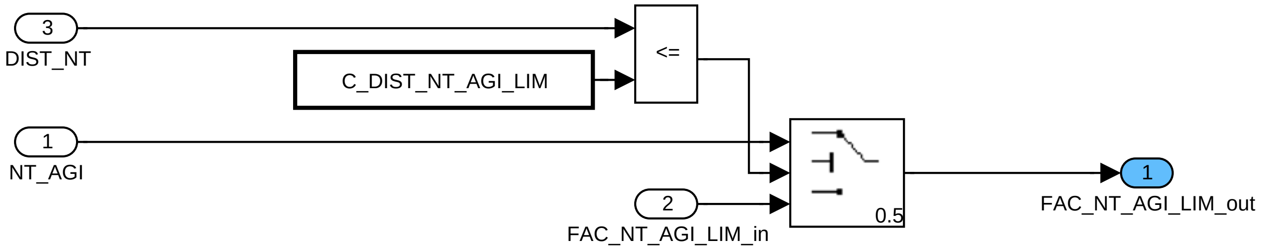

Figure 123 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC6

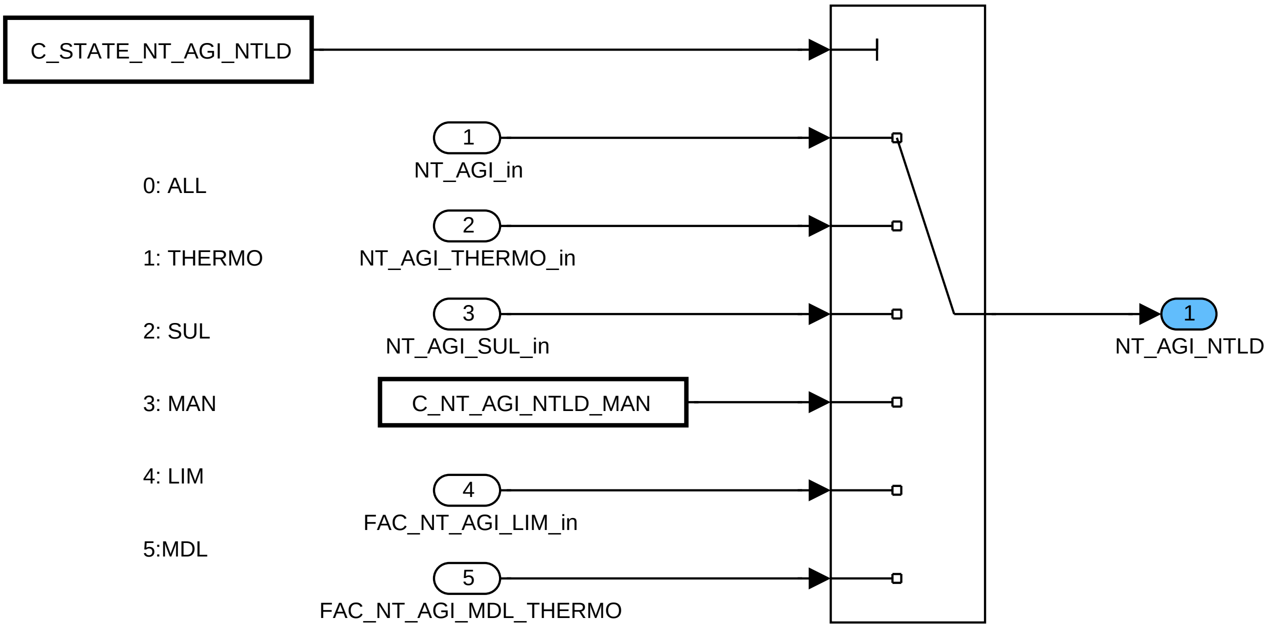

Figure 124 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC7

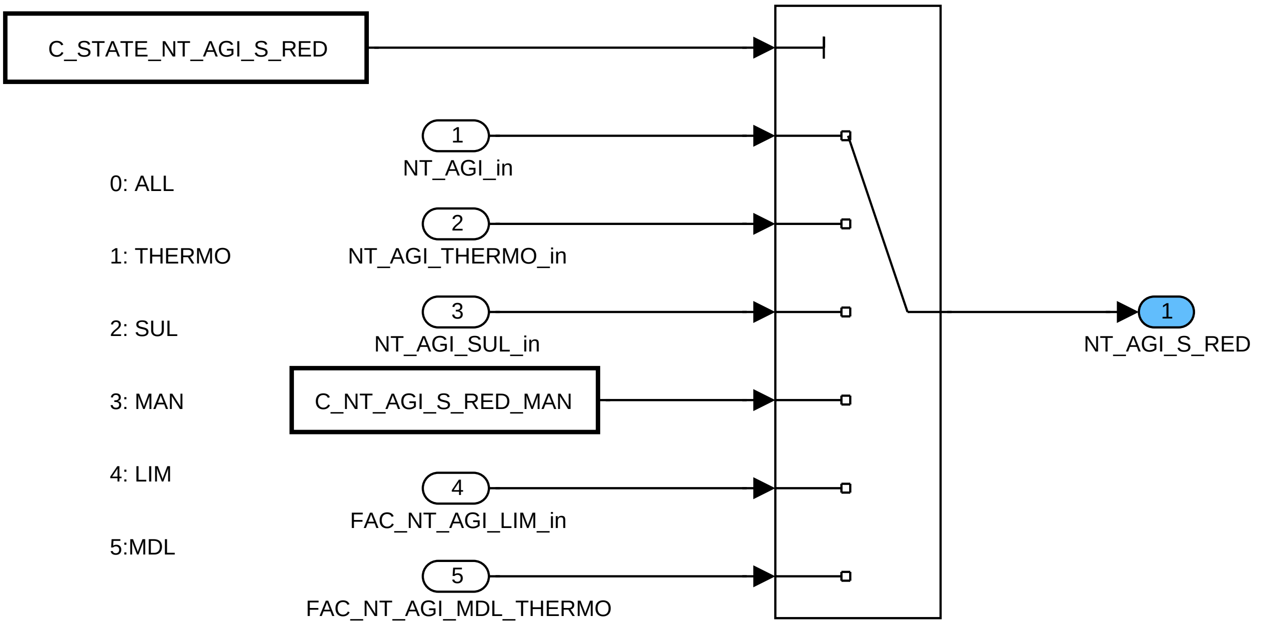

Figure 125 NOXM_MODUL703P/ operate/ AGING_FACTOR/ CLC8

MANUAL_RESET: Manual reset of desulfation requests

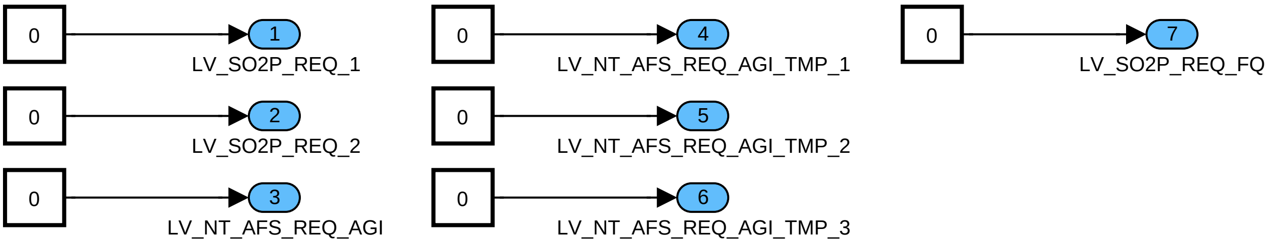

Figure 126 NOXM_MODUL703P/ operate/ MANUAL_RESET/ CLC

DESULFATION

If aging factor or sulphur load reaches the first threshold, then the first desulfation request will be set.

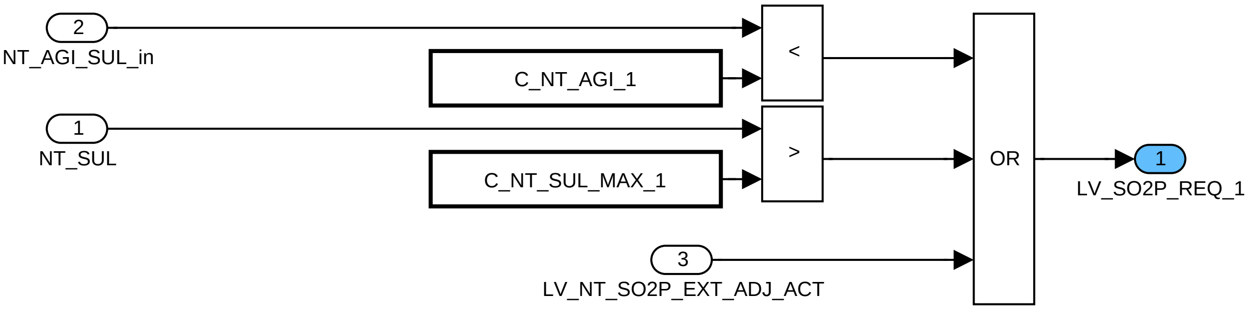

Figure 127 NOXM_MODUL703P/ operate/ DESULFATION/ CLC1

If the values become worse and reach the second threshold, then the second desulfation request will be set. In standard cases with no need of separate reset conditions for

LV_SO2P_REQ_2, IP_NT_SUL_MAX_2_DEAC and IP_NT_SUL_MAX_2 have to be calibrated identically

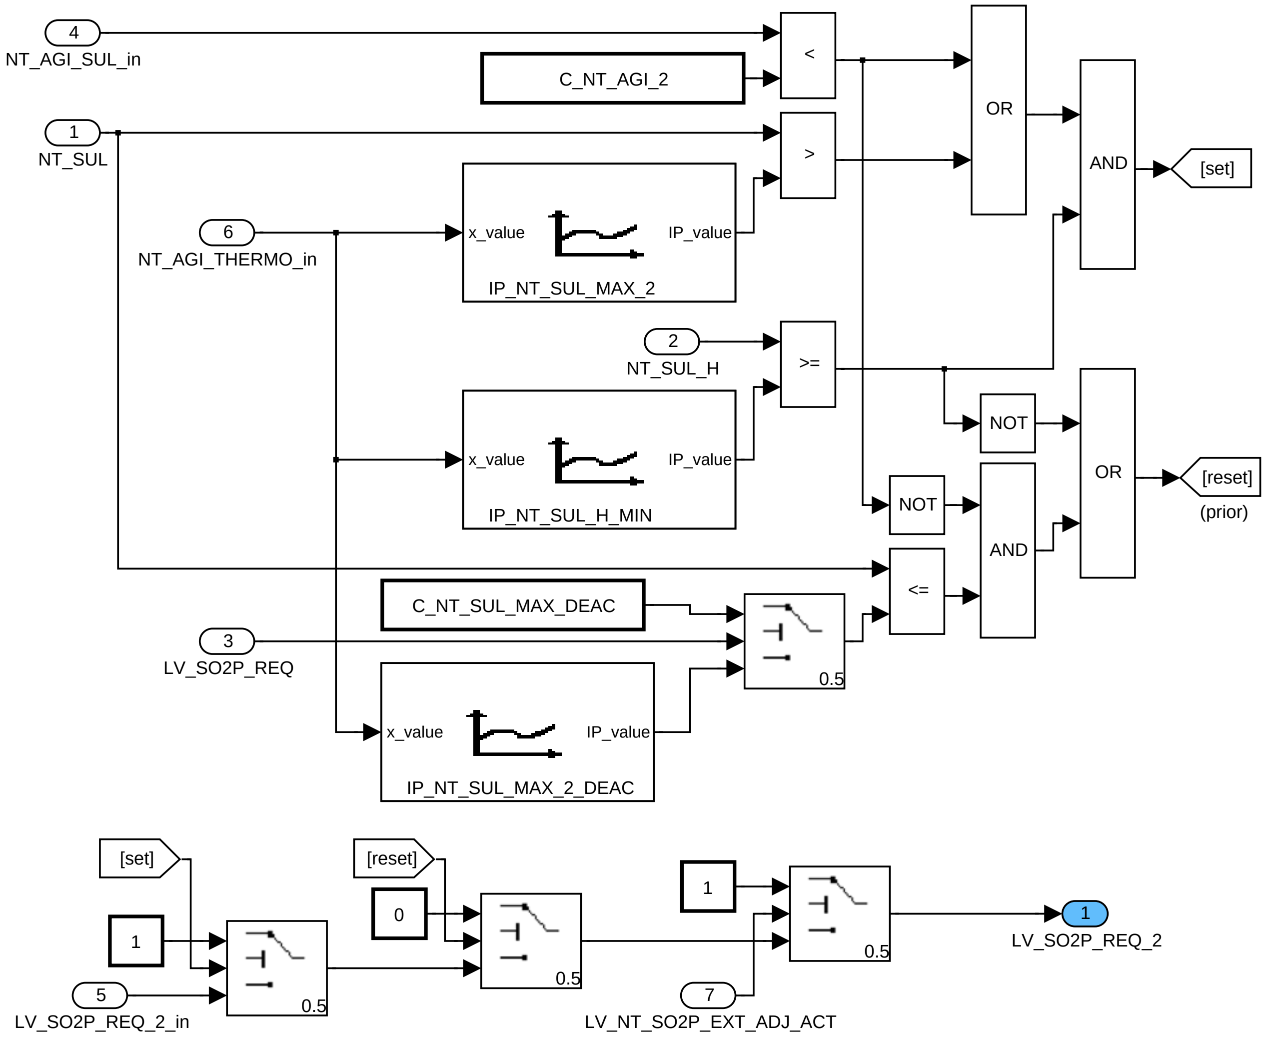

Figure 128 NOXM_MODUL703P/ operate/ DESULFATION/ CLC2

Condition for lambda=1 request

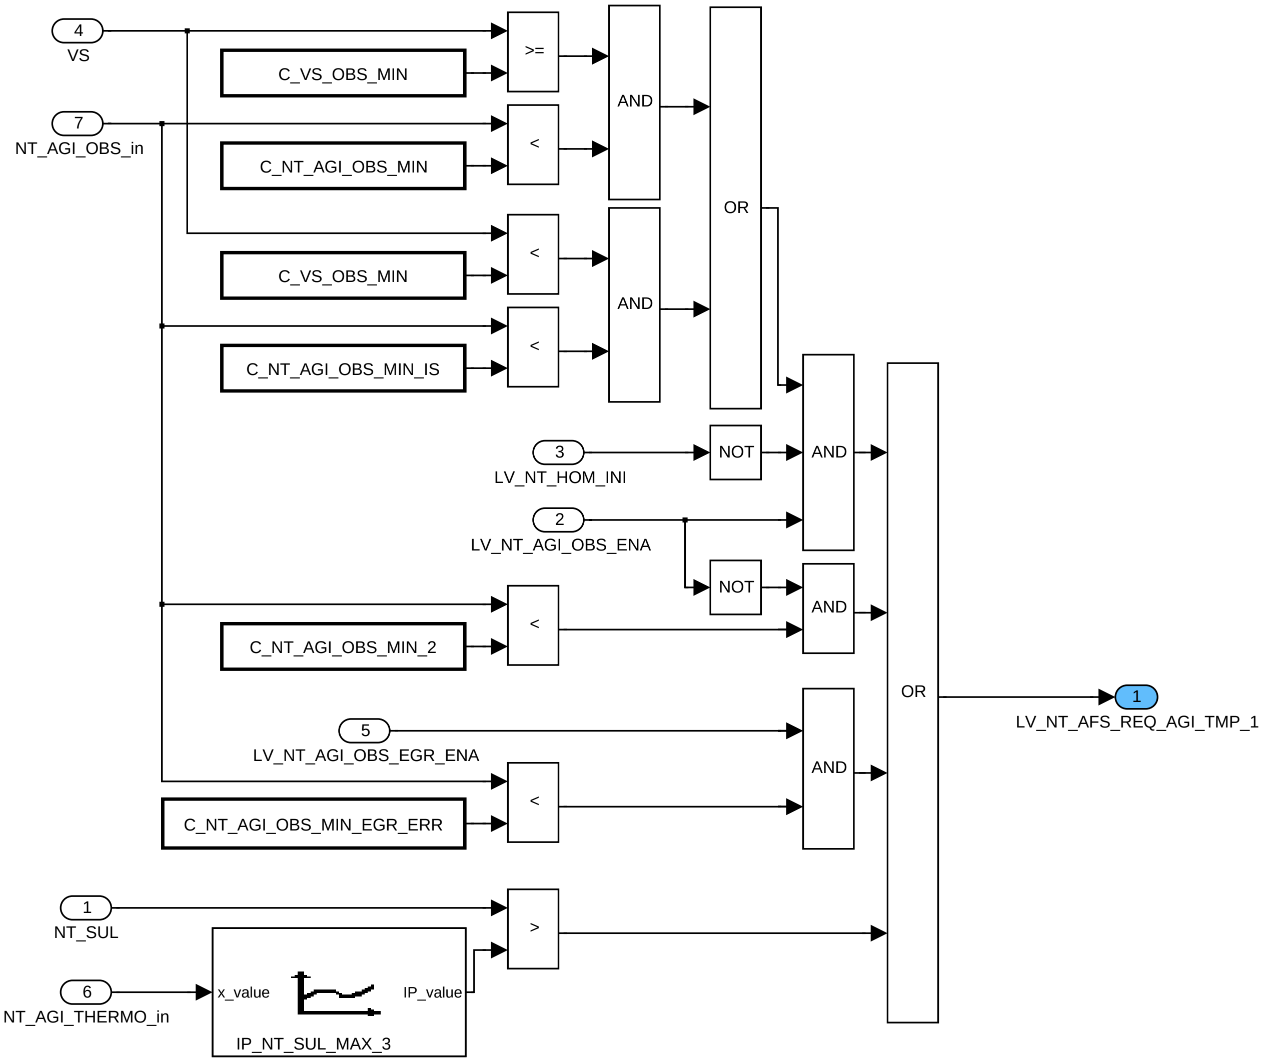

Figure 129 NOXM_MODUL703P/ operate/ DESULFATION/ CLC3

Structure of fuel quality check

If the thermal aging factor reaches the third threshold, then the fuel quality check will be started. In that case a desulfation will be requested and the sulfur model will be calculated with higher sulfur ratio, controlled by FAC_SU_CONC_FUEL.

After desulfation (LV_SO2P_REQ_1=0) the prohibition of stratified mode (LV_NT_AFS_REQ_AGI_TMP_2) will be canceled.

Either the aging factor is OK and the fuel check will be finished immediately (sub-system OK) or after a calibratable number of cycles a decicion will be made (sub-system END) whether the NOx trap is OK or not. If OK the fuel quality check will be finished, if not the lambda=1 mode will be forced (LV_NT_AFS_REQ_AGI_TMP_3=1) because the trap is defect.

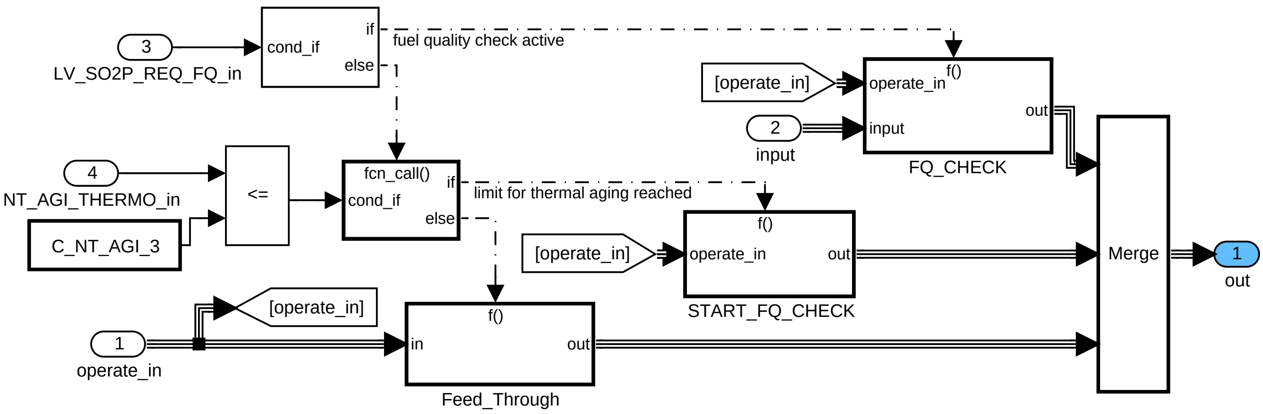

Figure 130 NOXM_MODUL703P/ operate/ DESULFATION/ CLC4

Collection of all lambda=1 requests.

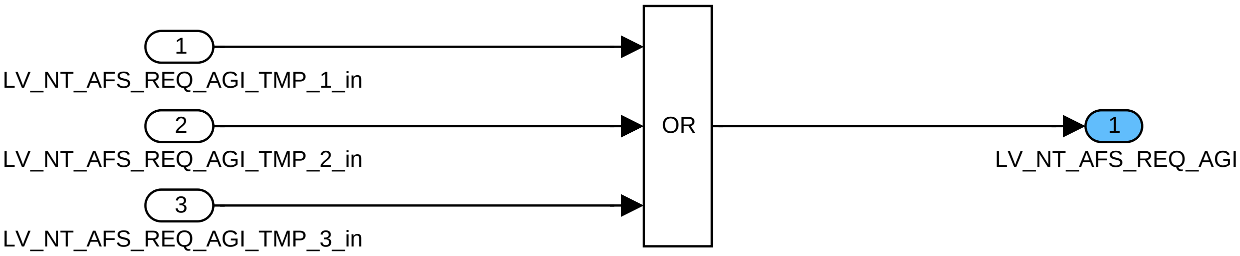

Figure 136 NOXM_MODUL703P/ operate/ DESULFATION/ CLC5

NEW_DEVICE: Initialisation by scan tool

If a new NOx trap is built in, then a initialization via a scan tool have to be made.

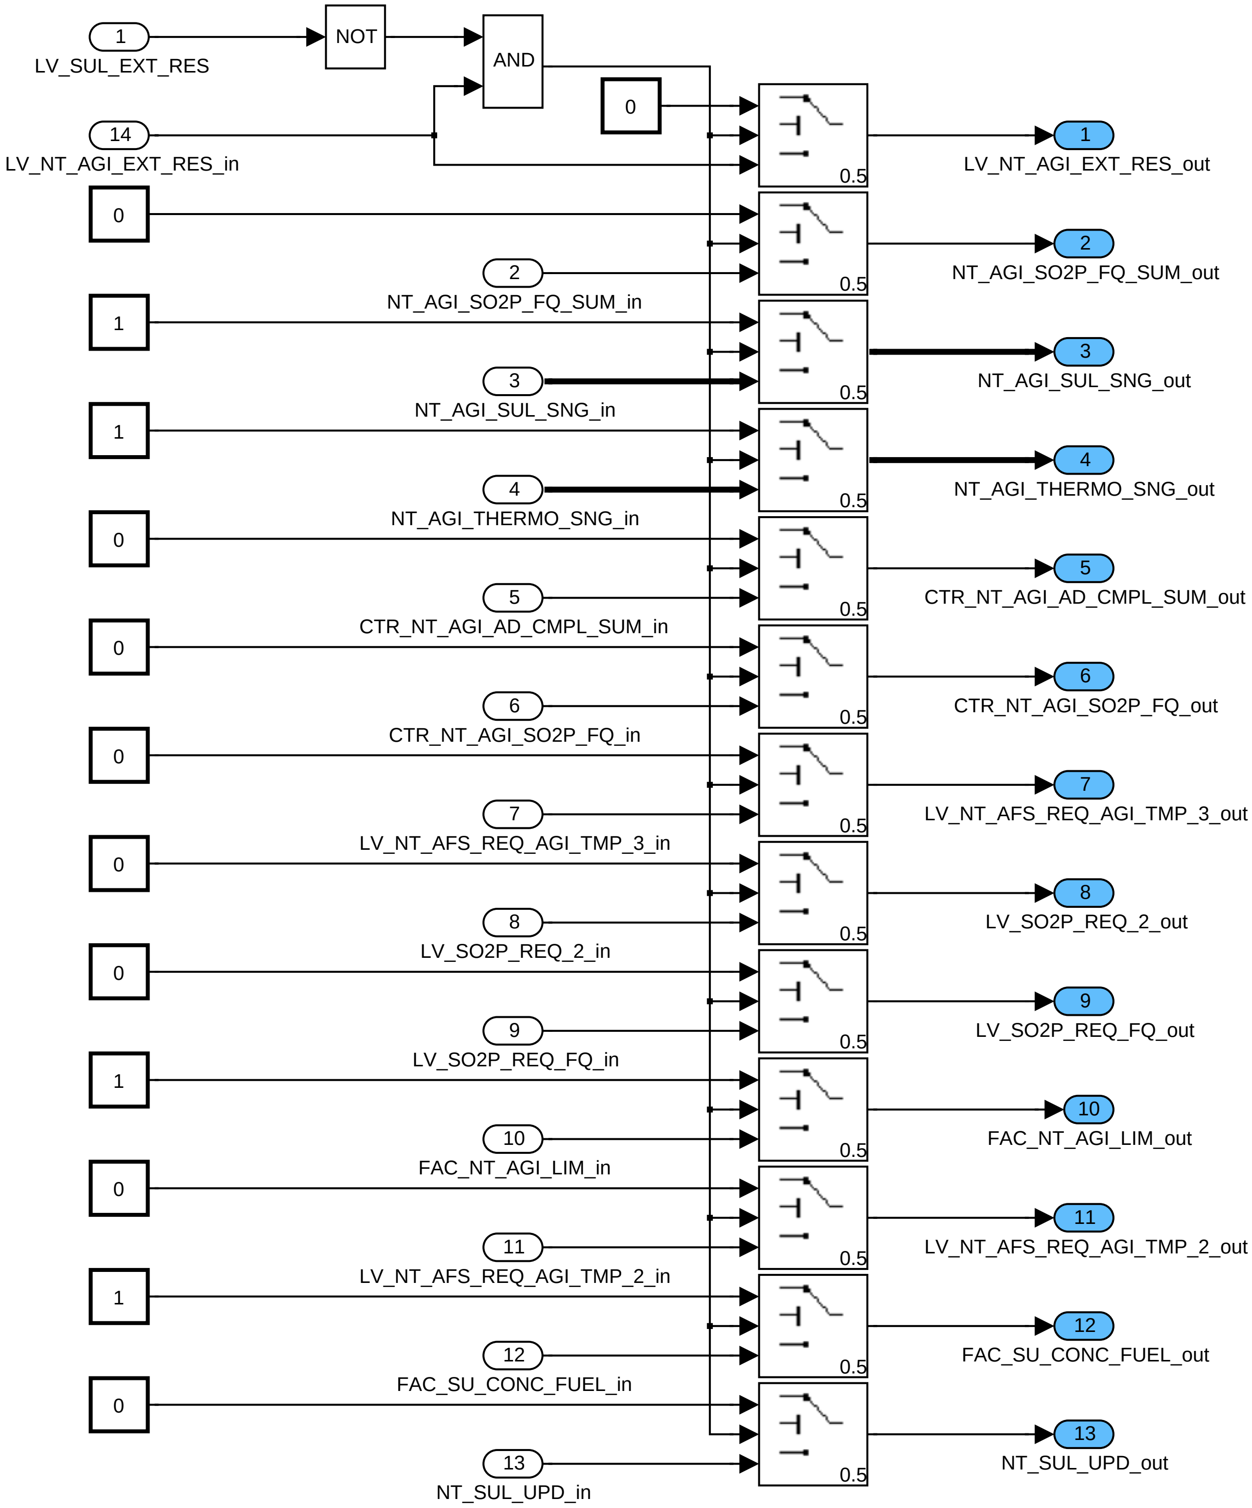

Figure 137 NOXM_MODUL703P/ operate/ NEW_DEVICE/ CLC1

Update of external adjustment values

If the flag LV_NT_AGI_EXT_ADJ was set by action ACTION_NOXM_WriteAgingExtAdj and the external sulfur model values are already written, then the external values will be used and the flag will be reset.

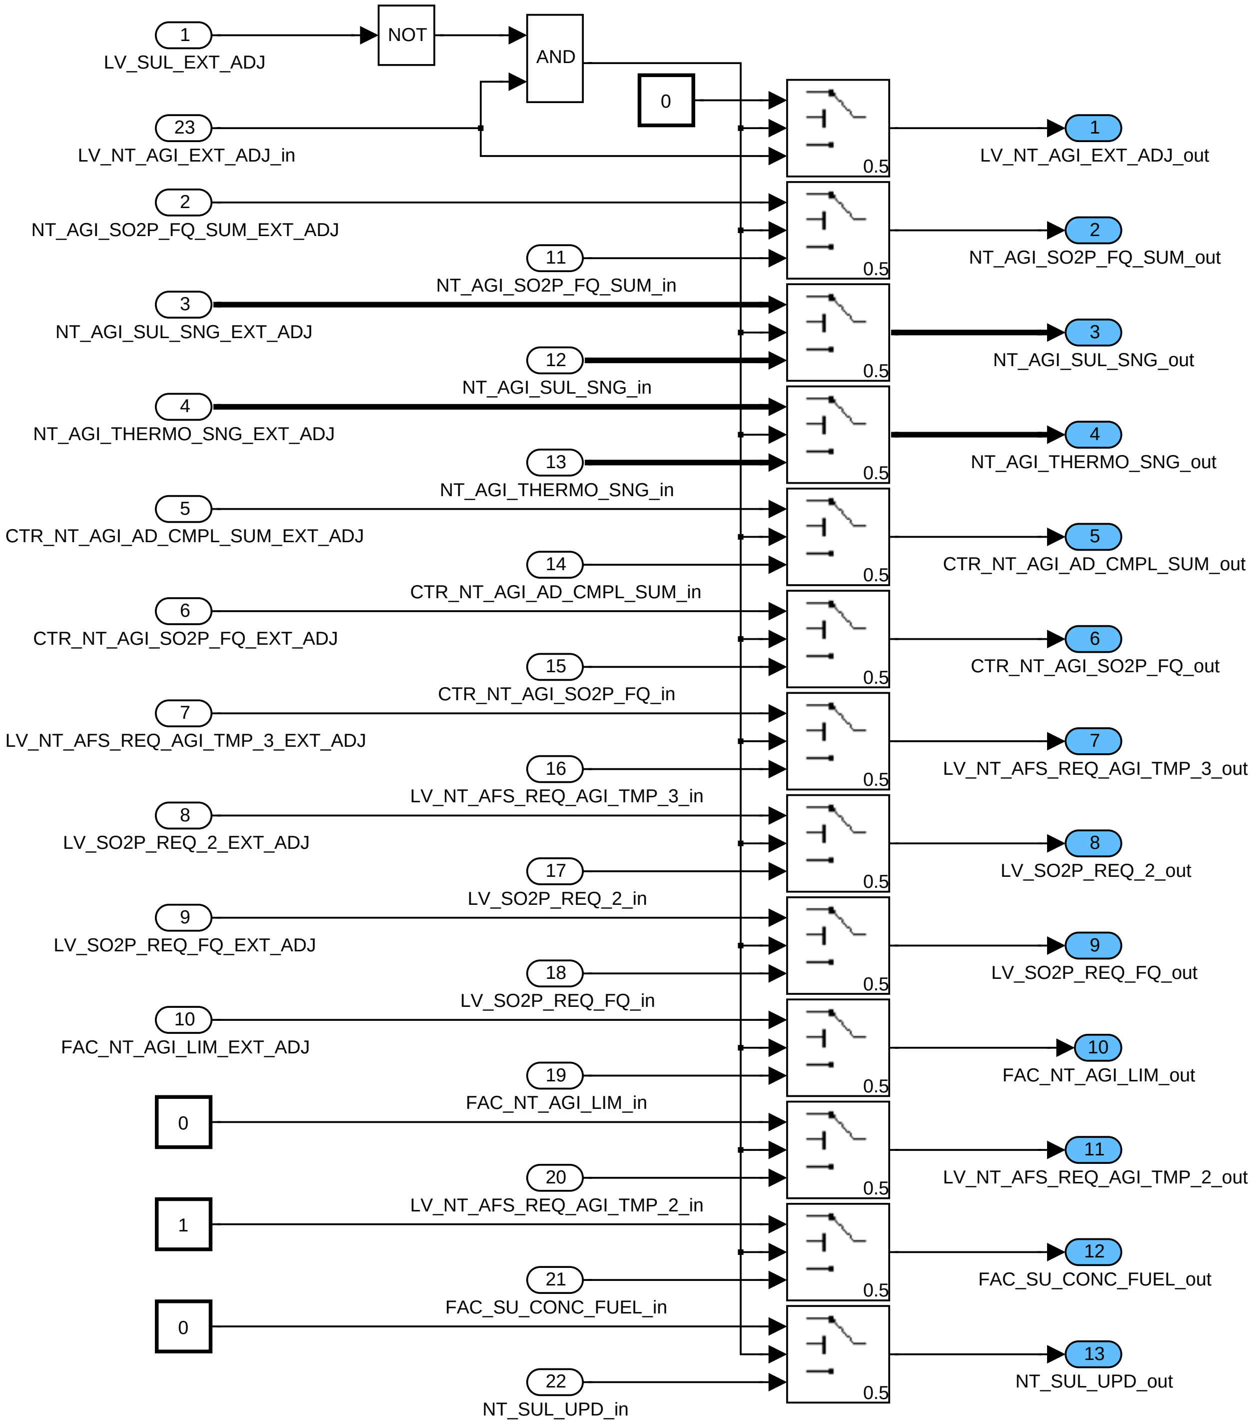

Figure 138 NOXM_MODUL703P/ operate/ NEW_DEVICE/ CLC2

53.12.1.4 RESET

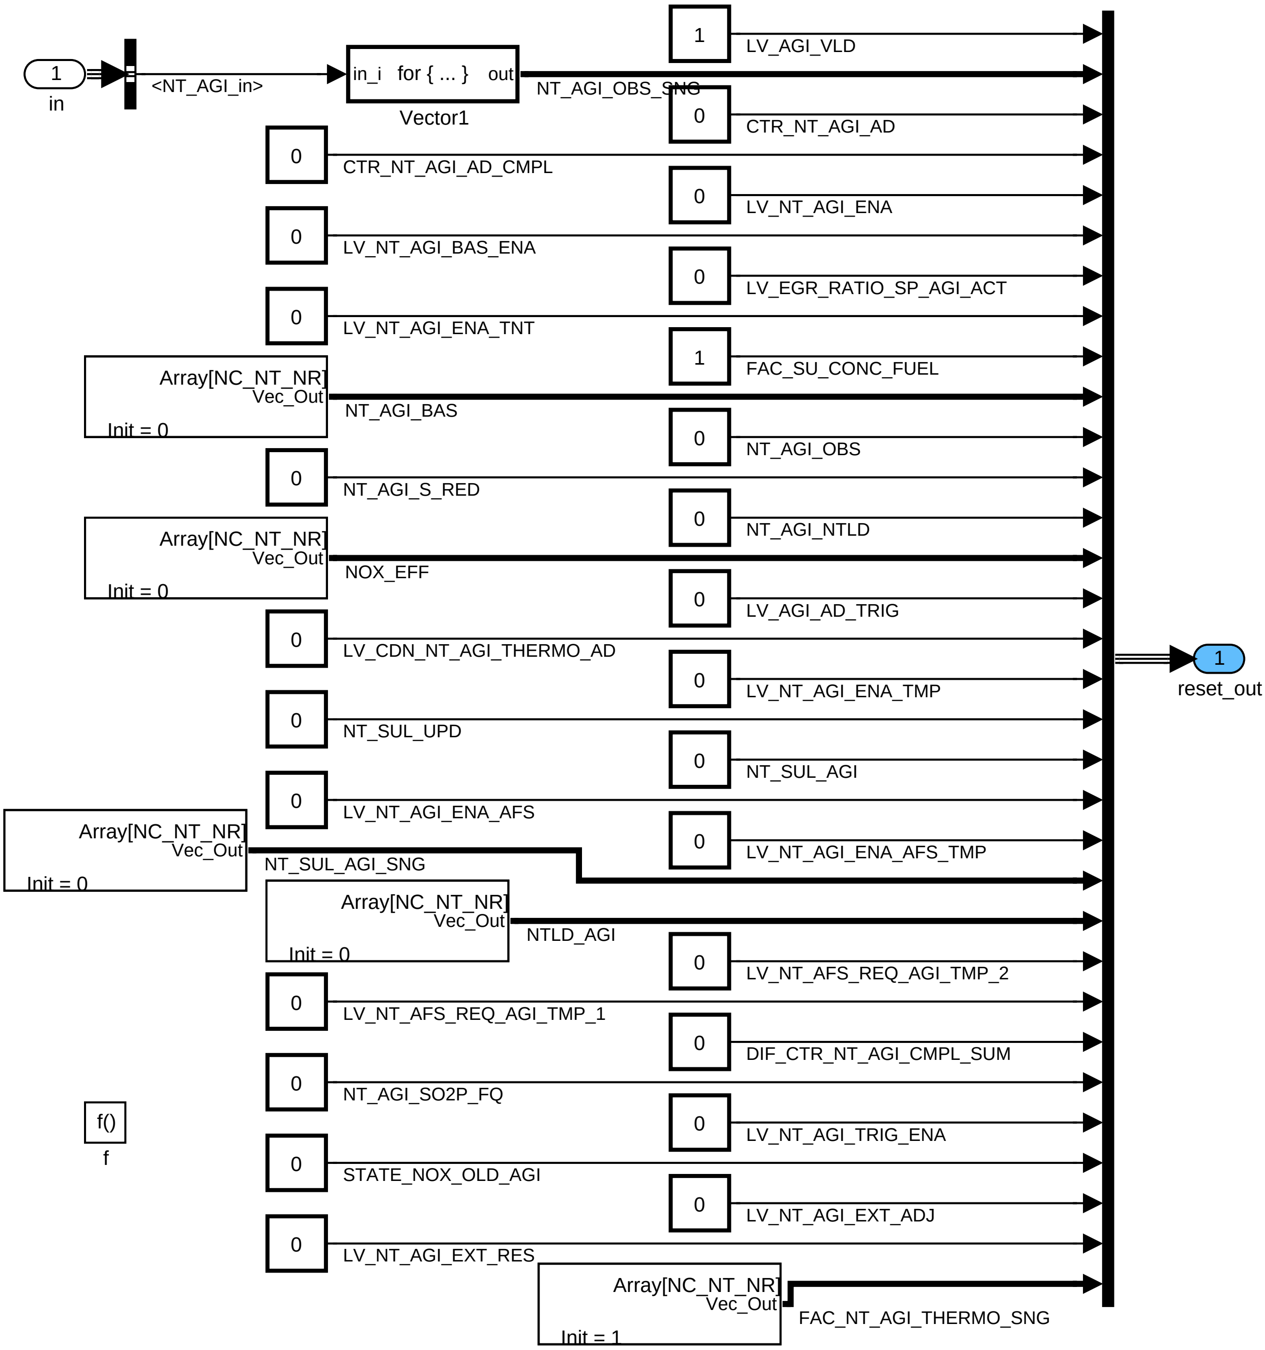

Figure 139 NOXM_MODUL703P/ reset

53.12.1.5 Handling of non volatile memory

The non-volatile data will be read out of the memory at the after power-on and stored in the memory before power-off. The initialization of the non-volatile memory is shown in the next picture.

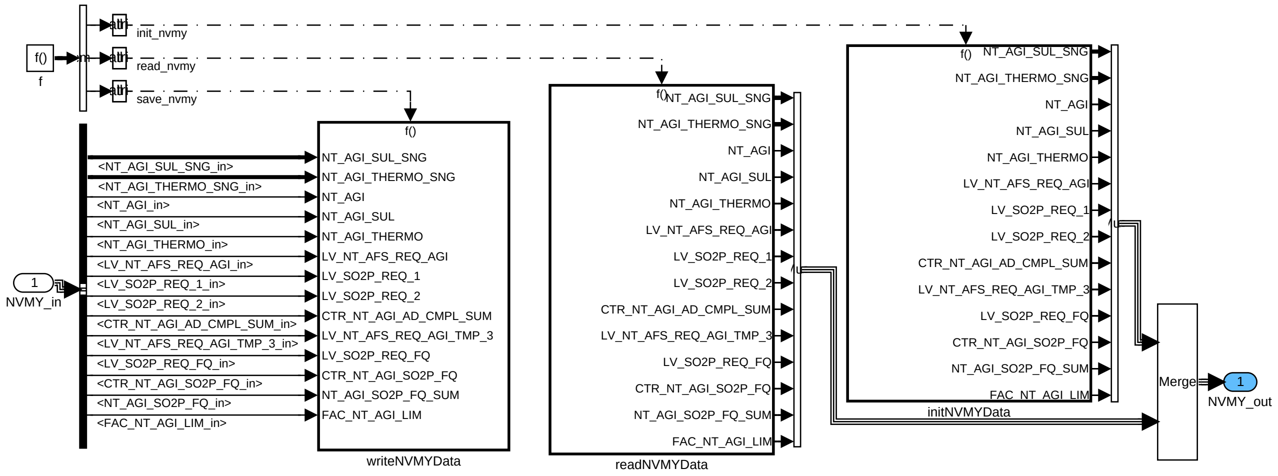

Figure 140 NOXM_MODUL703P/ NVMYdata

Initialization of non-volatile memory

The aging factors will be set to one, that means fresh catalyst. All other values will be initialized to its inactive value.

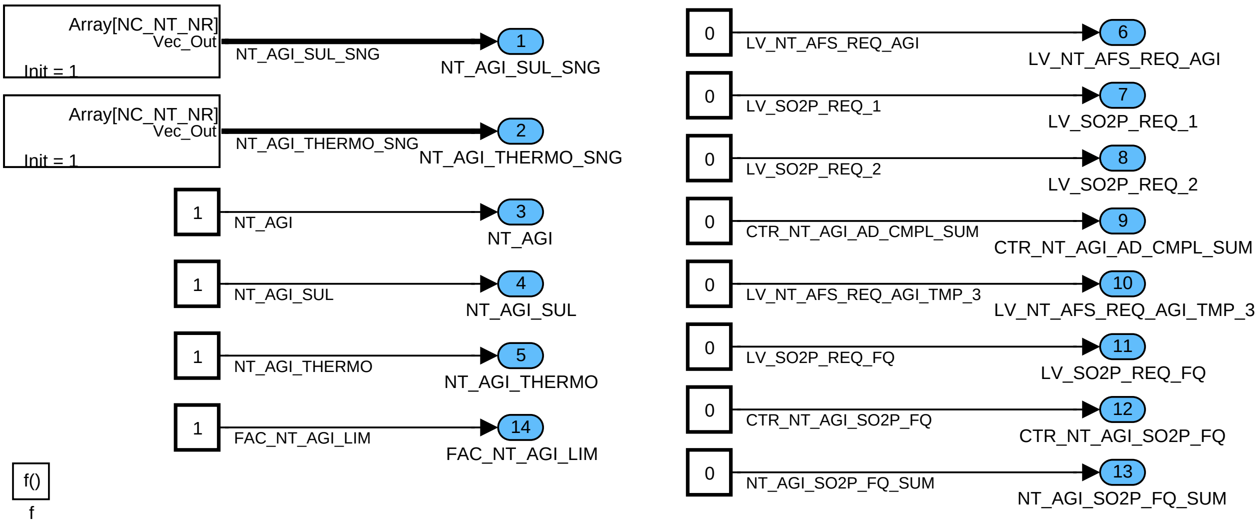

Figure 141 NOXM_MODUL703P/ NVMYdata/ initNVMYData
